**1 特長**
- 2チャンネル独立にSPI™制御されるDVGA
- 5V単一電源
- -3dB帯域幅: 1.1GHz (最大ゲイン)
- フラット帯域幅応答: 300MHz
- チャンネル間ゲイン・マッチング: ±0.05dB
- チャンネル間位相マッチング: ±0.1°
- ゲイン
  - 30dB〜-9dB
  - 1dBステップ、±0.2dB
- 出力の3次インターセプト・ポイント (OIP3)
  - 300MHzで43dBm
  - 200MHzで51dBm
- ノイズ値 (NF)
  - 300MHzで6.5dB (最大ゲイン)、Z_in = 150Ω
- 可変消費電力
  - チャンネルごとに90mA〜108mA
- パワーバービングおよびパワーダウン機能
  - チャンネルごとにIQ < 4.5 mA
  - パワーダウン・ピンとSPIでプログラム可能
- 300MHzでの入力リターン・ロス
  - 17dB (R_s = 150Ω)

**2 アプリケーション**
- DOCSIS 3.1 CMTSアップストリーム直接サンプリング受信機
- CATVモデル信号スケーリング
- プログラマブル・ゲインのIFアンプ
- 汎用RF、IFゲイン・ステージ
- ADCドライバ

**3 概要**
LMH2832は直線性が高い2チャネルのデジタル可変ゲイン・アンプ (DVGA)で、高速信号チェーンおよびデータ収集システム用です。LMH2832は高い帯域幅、低い歪み、低いノイズを実現するように最適化されているため、2チャネル、14ビットのA/Dコンバータ (ADC)ドライバに理想的です。このデバイスは、1つ固定ゲインブロックと、1つの可変アッテネータで構成され、合計ゲインは30dB、最大減衰は39dBです。平均価は30dB〜9dBで、1dBステップで設定でき、ゲイン精度は±0.2dBです。入力インピーダンスは1:3または1:2の比率のバランスを使用して、それぞれ50Ωまたは75Ωに簡単にマッチングできます。LMH2832は汎用ADCを駆動するよう設計されており、ケーブル上データ・サービス・インタフェース仕様 (DOCSIS) 3.0の32直交振幅変調 (QAM)キャリア、およびDOCSIS 3.1の広帯域直交周波数分割多重化 (OFDM)システムの両方の要件も満たしています。LMH2832は非常に良好なNF (6.5dB)と直線性を持ち、DOCSISの仕様内で動作するよう設計されています。パワーダウン状態での静止電流はチャネルごとに5mA未満で、動作時の標準消費電流はチャネルごとに105mAです。

**出力の3次インターセプト・ポイント (OIP3)特性**

\(^{(1)}\) Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under Recommended Operating Conditions. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

7.2 ESD Ratings

<table>
<thead>
<tr>

<td>±1000</td>
<td>V</td>
</tr>
</tbody>
</table>

\(^{(1)}\) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
\(^{(2)}\) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

8.2 ATE Testing and DC Measurements

All production testing and dc parameters are measured on automated test equipment (ATE) capable of dc measurements only. Some measurements (such as voltage gain) are referenced to the output of the internal amplifier and do not include losses attributed to the on-chip output resistors. The Electrical Characteristics values specify these conditions. When the measurement is referred to the amplifier output, the output resistors are not included in the measurement. If the measurement is referred to the device pins, then the output resistor loss is included in the measurement.

8.3 Frequency Response

This test is done by running an S-parameter sweep on a 4-port differential network analyzer using the standard EVM with no baluns; see Figure 41. The inputs and outputs of the EVM are connected to the network analyzer using 75-Ω coaxial cables with the input ports set to a characteristic impedance of 75 Ω, and the output ports set to a characteristic impedance of 50 Ω.

The frequency response test with capacitive load is done by soldering the capacitor across the LMH2832 output pins. In this configuration, the on-chip, 10-Ω resistors on each output leg isolate the capacitive load from the amplifier output pins.

8.4 Distortion

The standard EVM is used for measuring both the single-tone harmonic distortion and two-tone intermodulation distortion; see Figure 42 and Figure 43, respectively. The distortion is measured with differential input signals to the LMH2832. In order to interface with 50-Ω, single-ended test equipment, 50-Ω to 75-Ω impedance matching pads followed by external baluns (1:2, \( z_o = 75 \) Ω) are required between the EVM output ports and the test equipment. These baluns are used to combine two single tones in the two-tone test plots as well as to convert the single-ended input to differential output for harmonic distortion tests. The use of 6-dB attenuator pads on both the inputs and outputs is recommended to provide a balanced match between the external balun and the EVM.

8.5 Noise Figure

This test is done by matching the input of the LMH2832 to a 50-Ω noise source using a 50-Ω to 75-Ω impedance transformation pad followed by a 1:2 balun (Figure 44), with the noise figure being referred to the input impedance (\( R_S = 150 \) Ω). As noted in Figure 44, a Keysight Technologies™ E4443A with NF features is used for the testing.
8.6 Pulse Response, Slew Rate, and Overdrive Recovery

For time-domain measurements, the standard EVM is driven through an impedance transformation pad and a balun again to convert a single-ended output from the test equipment to the differential inputs of the LMH2832. The differential outputs are directly connected to the oscilloscope inputs, with the differential signal response calculated using trace math from the two separate oscilloscope inputs.

8.7 Power-Down

The standard EVM is used for this test by completely removing the shorting block on jumper JPD. A high-speed, 50-Ω pulse generator is used to drive the PDx pin that toggles the output signal on or off depending upon the PDx pin voltage.

8.8 Crosstalk, Gain Matching, and Phase Matching

The standard EVM is used for these tests with both channels enabled. For gain and phase matching, the responses of both channels are measured on a network analyzer and the gain and phase values are compared. For crosstalk, a single channel is driven with a signal on the network analyzer when the other channel is measured.

8.9 Output Measurement Reference Points

The LMH2832 has two on-chip, 10-Ω output resistors on each channel. When matching the output to a 100-Ω load, the evaluation module (EVM) uses an external 40-Ω resistor on each output leg to complete the output matching. The inclusion of on-chip output resistors creates two potential reference points for measuring the output voltage. The first reference point is at the internal amplifier output (OUT_AMP), and the second reference point is at the externally-matched 100-Ω load (OUT_LOAD). The measurements in the Electrical Characteristics table and in the Typical Characteristics section are referred to the (OUT_AMP) reference point unless otherwise specified. The conversion between reference points is a straightforward correction of 3 dB for power and 6 dB for voltage, as shown in Equation 1 and Equation 2. The measurements are referenced to OUT_AMP when not specified.

\[ V_{OUT\_LOAD} = (V_{OUT\_AMP} - 6 \text{ dB}) \]  
\[ P_{OUT\_LOAD} = (P_{OUT\_AMP} - 3 \text{ dB}) \]
9 Detailed Description

9.1 Overview
Each channel of the LMH2832 consists of an input attenuator block followed by a fully differential amplifier that has a gain of 30 dB. The attenuator has a range of 0 dB to –39 dB in 1-dB steps that is controlled by an SPI interface. The two channels can be controlled independently using the digital interface including power-down and bias settings. A separate analog power-down pin (PDA, PDB) is also included for each channel so that the device can be set to a low-power state without waiting for a serial write to a register. The internal registers also include a power-on-reset (POR) that ensures the device starts in a known state after the power is reset.

9.2 Functional Block Diagram

9.3 Feature Description

9.3.1 Analog Input Characteristics
The LMH2832 is a dual-channel device with two identical channels (A and B) that each have differential input pins (INP and INM) that denote the positive and negative inputs, respectively. The inputs are expected to be ac-coupled only, typically through a transformer or capacitor. The amplifier self-biases the input common-mode to mid-supply for the maximum input voltage range. The inputs of the LMH2832 can only be driven differentially. For single-ended input source applications, use a balun or fully differential amplifier (such as the LMH3401 or LMH5401) that can convert single-ended to differential signals before the LMH2832.
Feature Description (continued)

At maximum gain, the digital attenuator is set to 0 dB of attenuation, causing the input signal to be much larger than the output signal and forcing the maximum output voltage swing to be limited by the outputs of the device. However, at minimum gain, the maximum voltage swing is limited by the inputs of the device because the attenuator causes the output voltage to be 9 dB lower than the input voltage. In minimum gain, the input voltage limits against the electrostatic discharge (ESD) devices before the output reaches the maximum swing limits. For linear operation, the input voltage must be kept within the maximum input voltage ratings described in the Electrical Characteristics table.

The input impedance of the LMH2832 is set by internal termination resistors to a nominal value of 150 \( \Omega \), differential. Process variations result in a range of values, as described in the Electrical Characteristics table. The input impedance is also affected by device parasitic effects at higher frequencies that cause the impedance to shift away from the nominal value.

9.3.2 Analog Output Characteristics

The LMH2832 has series, 10-\( \Omega \), on-chip resistors on each output to provide isolation from board parasitics that can cause instability. When designing a filter following the LMH2832, the filter source impedance calculation must include the two 10-\( \Omega \), on-chip resistors. Table 2 shows the calculated external source impedance values required for various matched filter loads.

9.3.3 Driving Low Insertion-Loss Filters

When driving high-speed ADCs, a filter is commonly driven with a matched impedance to the ADC. This impedance is matched by the amplifier by setting the combination of the output resistors to the same impedance as the ADC inputs. Impedance matching is often done to minimize any transmission reflections caused by the physical signal path. The drawback to using a matched impedance is that a voltage swing is required from the amplifier outputs that is twice the desired ADC input voltage swing, which can cause output voltage limitation issues.

To avoid using a matched impedance, a low insertion loss filter can be driven where there is little to no resistance added at the amplifier outputs. The amplifier outputs then only must swing to the value of the ADC full-scale input voltage, thus eliminating most of the potential amplifier output headroom issues. The requirements of this technique are that the amplifier must be able to provide enough current to the load of the ADC and that the path between the amplifier outputs and ADC inputs must be minimized to prevent any reflections.

9.3.4 Input Impedance Matching

The LMH2832 has a differential input impedance of 150 \( \Omega \) that can be easily matched to single-ended, 50-\( \Omega \) or 75-\( \Omega \) systems using baluns. For a single-ended, 50-\( \Omega \) input, a 1.3-\( \Omega \) ratio balun can be used to create a 150-\( \Omega \) differential source impedance to the device with a balun gain of 4.8 dB. For a single-ended, 75-\( \Omega \) input, a 1.2-\( \Omega \) ratio balun creates a 150-\( \Omega \) differential source impedance to the device with a voltage gain of 3 dB.

9.3.5 Power-On Reset (POR)

The LMH2832 has a built-in, power-on-reset (POR) that sets the device registers to their default state (see the Register Maps section) on power-up. Note that the LMH2832 register information is lost when power is removed. When power is reapplied, the POR ensures that the device enters a default state. Power glitches (of sufficient duration) can also initiate the POR and return the device to a default state.
9.4 Device Functional Modes

9.4.1 Power-Down (PD)

The device supports power-down control using an external power-down (PDx) pin or by writing a logic high to bit 6 of SPI register 2h (see the Register Maps section). The external PDx pins are active high; when left floating, the device defaults to an on condition resulting from the internal pulldown resistors that cause a logic low on the PDx pins. The device PDx thresholds are noted in the Electrical Characteristics table. The device consumes approximately 7 mA in power-down mode. Note that the SPI register contents are preserved in power-down mode.

9.4.2 Gain Control

The LMH2832 gain can be controlled from 30-dB gain (0-dB attenuation) to –9-dB gain in 1-dB steps by digitally programming the SPI register 2h; see the Register Maps section for more details.

9.5 Programming

9.5.1 Details of the Serial Interface

The LMH2832 has a set of internal registers that can be accessed by the serial interface formed by the CS (serial interface enable), SCLK (serial interface clock), SDI (serial interface input data), and SDO (serial interface read-back data) pins. Serially shifting bits into the device is enabled when CS is low. SDI serial data are latched at every SCLK rising edge when CS is active (low). The serial data are loaded into the register at every 16th SCLK rising edge when CS is low. When the word length exceeds a multiple of 16 bits, the excess bits are ignored. Data can be loaded in multiples of 16-bit words within a single active CS pulse. The first eight bits form the register address and the remaining eight bits are the register data. The interface can function with SCLK frequencies from 25 MHz down to very low speeds (of a few hertz) and also with a non-50% SCLK duty cycle. A summary of the LMH2832 SPI protocol is:

1. SPI-1.1 interface
2. Independent channel A, B attenuation programming (6-bit gain control)
3. SPI register contents are preserved in power-down mode
4. SPI-controlled power modes (3-bit control for eight options to step down the power)
5. Powered for the main 5-V power supply
6. 1.8-V logic
Programming (continued)

9.5.2 Timing Diagrams

Figure 45 and Figure 46 show timing diagrams for the SPI write and read bus cycles, respectively. Figure 47 shows an example timing diagram for a streaming write cycle and Figure 48 shows an example timing diagram for a streaming read cycle. Figure 49, Figure 50, Figure 51, and Figure 52 illustrate timing diagrams and requirements for the clock, data input, data output, and chip select, respectively. See the Timing Requirements: SPI table for SPI timing requirements.

10 Application and Implementation

NOTE
Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI’s customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

10.1 Application Information

The LMH2832 is designed as a general-purpose, analog-to-digital converter (ADC) driver that also meets the performance requirements for DOCSIS 3.X upstream CMTS solutions. This section describes various requirements and considerations for using the LMH2832 and also some design examples.

10.1.1 Driving ADCs

When the amplifier is driving an ADC, the key points to consider for implementation are the signal-to-noise ratio (SNR), spurious-free dynamic range (SFDR), and ADC input considerations, as described in this section.

A typical application of the LMH2832 involves driving a wideband, 14-bit ADC (such as the ADS54J40), as shown in Figure 59. The LMH2832 can drive the full Nyquist bandwidth of ADCs with sampling rates up to 900 MSPS. If the front-end bandwidth of the ADC is more than 450 MHz, then use a simple noise filter to improve SNR. Otherwise, the ADC can be connected directly to the amplifier output pins with appropriate matching resistors to limit the full-scale input of the ADC. Note that the LMH2832 inputs must be driven differentially using a balun or fully differential amplifiers (FDAs). For dc-coupled applications, an FDA (such as the LMH3401 or LMH5401) that can convert a single-ended input to a differential output with low distortion is preferred.

Figure 59. ADC Driver with a 50-Ω Source
10.1.1 SNR Considerations

When using the LMH2832 with a filter, the signal-to-noise ratio (SNR) of the amplifier and filter can be calculated from the amplitude of the signal and the bandwidth of the filter. The noise from the amplifier is band-limited by the filter with the equivalent brick-wall filter bandwidth. The amplifier and filter noise can be calculated using Equation 3:

\[
\text{SNR}_{\text{AMP+FILTER}} = 10 \cdot \log \left( \frac{V_o^2}{e_{\text{FILTEROUT}}^2} \right) = 20 \cdot \log \left( \frac{V_o}{e_{\text{FILTEROUT}}} \right)
\]

where:
- \(e_{\text{FILTEROUT}} = e_{\text{NAMPOUT}} \cdot \sqrt{\text{ENB}}\)
- \(e_{\text{NAMPOUT}}\) is the output noise density of the LMH2832 (50.4 nV/√Hz) at \(A_V = 30\ \text{dB}\)
- ENB is the brick-wall equivalent noise bandwidth of the filter
- \(V_o\) is the amplifier output signal

For example, with a first-order (\(N = 1\)) band-pass or low-pass filter with a 1000-MHz cutoff, ENB is \(1.57 \cdot f_{-3dB} = 1.57 \cdot 1000\ \text{MHz} = 1570\ \text{MHz}\). For second-order (\(N = 2\)) filters, ENB is \(1.22 \cdot f_{-3dB}\). When the filter order increases, ENB approaches \(f_{-3dB}\) (\(N = 3\ → \ ENB = 1.15 \cdot f_{-3dB}; N = 4 \ → \ ENB = 1.13 \cdot f_{-3dB}\)). Both \(V_o\) and \(e_{\text{FILTEROUT}}\) are in RMS voltages. For example, with a 2-VPP (0.707 V RMS) output signal and a 300-MHz, first-order, low-pass filter, the SNR of the amplifier and filter is 56 dB with \(e_{\text{FILTEROUT}} = 50.4\ \text{nV/√Hz} \cdot \sqrt{471\ \text{MHz}} = 1.09\ \text{mV RMS}\).

The SNR of the amplifier, filter, and ADC sum in RMS fashion, as shown in Equation 4 (SNR values in dB):

\[
\text{SNR}_\text{SYSTEM} = -20 \cdot \log \left[ \sqrt{\frac{\text{SNR}_{\text{AMP+FILTER}}}{10}} + \frac{\text{SNR}_{\text{ADC}}}{10} \right]
\]

This formula shows that if the SNR of the amplifier and filter equals the SNR of the ADC, then the combined SNR is 3 dB lower (worse). Thus, for minimal degradation (< 1 dB) on the ADC SNR, the SNR of the amplifier and filter must be 10 dB greater than the ADC SNR. The combined SNR calculated in this manner is usually accurate to within ±1 dB of the actual implementation.

10.1.1.2 SFDR Considerations

The SFDR of the amplifier is usually set by the second- or third-order harmonic distortion for single-tone inputs, and by the second-order or third-order intermodulation distortion for two-tone inputs. Harmonics and second-order intermodulation distortion can be filtered to some degree, but third-order intermodulation spurs cannot be filtered. The ADC generates the same distortion products as the amplifier, but also generates additional spurs (not harmonically related to the input signal) as a result of sampling and clock feed through.

When the spurs from the amplifier and filter are known, each individual spur can be directly added to the same spur from the ADC, as shown in Equation 5, to estimate the combined spur (spur amplitudes in dBC):

\[
\text{HDx}_{\text{SYSTEM}} = -20 \cdot \log \left[ \frac{\text{HDx}_{\text{AMP+FILTER}}}{10} + \frac{\text{HDx}_{\text{ADC}}}{10} \right]
\]

This calculation assumes that the spurs are in phase, but usually provides a good estimate of the final combined distortion.

For example, if the spur of the amplifier and filter equals the spur of the ADC, then the combined spur is 6 dB higher. To minimize the amplifier contribution (< 1 dB) to the overall system distortion, the spur from the amplifier and filter must be approximately 15 dB lower in amplitude than that of the converter. The combined spur calculated in this manner is usually accurate to within ±6 dB of the actual implementation; however, higher variations can be detected as a result of phase shift in the filter, especially in second-order harmonic performance.
Application Information (continued)

This worst-case spur calculation assumes that the amplifier and filter spur of interest is in phase with the corresponding spur in the ADC, such that the two spur amplitudes can be added linearly. There are two phase-shift mechanisms that cause the measured distortion performance of the amplifier-ADC chain to deviate from the expected performance calculated using Equation 5; one mechanism is the common-mode phase shift and the other is the differential phase shift.

Common-mode phase shift is the phase shift detected equally in both branches of the differential signal path including the filter. Common-mode phase shift nullifies the basic assumption that the amplifier, filter, and ADC spur sources are in phase. This phase shift can lead to better performance than predicted when the spurs become phase shifted, and there is the potential for cancellation when the phase shift reaches 180°. However, there is a significant challenge in designing an amplifier-ADC interface circuit to take advantage of a common-mode phase shift for cancellation: the phase characteristics of the ADC spur sources are unknown, thus the necessary phase shift in the filter and signal path for cancellation is also unknown.

Differential phase shift is the difference in the phase response between the two branches of the differential filter signal path. Differential phase shift in the filter is a result of mismatched components caused by nominal tolerances and can severely degrade the even harmonic distortion of the amplifier-ADC chain. This effect has the same result as mismatched path lengths for the two differential traces, and causes more phase shift in one path than the other. Ideally, the phase responses over frequency through the two sides of a differential signal path are identical, such that even harmonics remain optimally out of phase and cancel when the signal is taken differentially. However, if one side has more phase shift than the other, then the even harmonic cancellation is not as effective.

Single-order, resistor-capacitor (RC) filters cause very little differential phase shift with nominal tolerances of 5% or less, but higher-order, inductor-capacitor (LC) filters are very sensitive to component mismatch. For instance, a third-order Butterworth band-pass filter with a 100-MHz center frequency and a 20-MHz bandwidth displays as much as 20° of differential phase imbalance in a SPICE Monte Carlo analysis with 2% component tolerances. Therefore, although a prototype may work, production variance is unacceptable. For ac-coupled or dc-coupled applications where a transformer or balun cannot be used, using first- or second-order filters is recommended to minimize the effect of differential phase shift.

10.1.1.3 ADC Input Common-Mode Voltage Considerations (AC-Coupled Input)

When interfacing to an ADC, the input common-mode voltage range of the ADC must be taken into account for proper operation. In an ac-coupled application between the amplifier and the ADC, the input common-mode voltage bias of the ADC can be accomplished in different ways. Some ADCs use internal bias networks such that the analog inputs are automatically biased to the required input common-mode voltage if the inputs are ac-coupled with capacitors (or if the filter between the amplifier and ADC is a band-pass filter). Other ADCs supply the required input common-mode voltage from a reference voltage output pin (often termed CM or V\(_{\text{CM}}\)). With these ADCs, the ac-coupled input signal can be re-biased to the input common-mode voltage by connecting resistors from each input to the CM output of the ADC, as shown in Figure 60. AC coupling provides dc common-mode isolation between the amplifier and the ADC; thus, the output common-mode voltage of the amplifier is a don’t care for the ADC.

Figure 60. Biasing AC-Coupled ADC Inputs Using the ADC CM Output
Application Information (continued)

10.1.1.4 ADC Input Common-Mode Voltage Considerations (DC-Coupled Input)

The LMH2832 is designed to primarily be used in ac-coupled applications only. However, the LMH2832 can be dc-coupled if certain strict conditions are met. The LMH2832 has an internal common-mode bias equal to the mid-supply voltage, so any dc coupling on the input or output must have a common-mode voltage that is also set to mid-supply. To dc couple to an ADC input, the mid-supply voltage of the LMH2832 must be centered around the ADC input common-mode. This common-mode matching can be accomplished by shifting the supplies to center the mid-supply voltage around the ADC input common-mode voltage. However, shifting the supplies also changes the ground reference for the digital inputs, which then likely requires a voltage-shifted interface as well. The LMH2832 is not recommended to be operated as dc-coupled unless absolutely necessary.

10.2 Typical Applications

10.2.1 DOCSIS 3.X Driver

The LMH2832 is designed to perform best when driving differential input ADCs in high-speed applications. Figure 61 shows an example diagram of the LMH2832 driving an ADC with a fifth-order, low-pass filter for a 75-Ω impedance, data over cable service interface specification (DOCSIS) 3.X upstream receiver return path application. The primary interface between the amplifier and the ADC is usually an antialiasing filter to suppress high-frequency harmonics that otherwise alias back into the ADC FFT spectrum. Filters range from single-order real RC poles to higher-order, resistor-inductor-capacitor (RLC) filters, depending on the application requirements. Series output resistors (R_O) help isolate the amplifier from any capacitive load presented by the filter, and can also be used to create a matched impedance to drive transmission lines.

![Figure 61. DOCSIS 3.X Driver with the ADS54J40 and a 300-MHz, 4th-Order, Butterworth, Low-Pass Filter](image)

10.2.1.2 Detailed Design Procedure

To begin the design process, make sure that none of the following design parameters exceed the limits listed in the Electrical Characteristics table, such as:

- Supply voltage
- Temperature range
- Input voltage range across gain
- Output current requirements
- Digital I/O voltages and currents

10.2.1.2.1 Source Resistance Matching

Standard DOCSIS systems use a characteristic single-ended impedance of 75 Ω that must be properly matched to the 150-Ω differential impedance of the LMH2832. The circuit in Figure 61 uses a transformer with a 1:2-Ω ratio to convert the signal from single-ended to differential, and also to match the differential impedance. The transformer also adds a signal gain of approximately 3 dB to the system with some insertion loss depending on the chosen transformer.

10.2.1.2.2 Output Impedance Matching

For the circuit in Figure 61, the output impedance is matched to a 150-Ω characteristic impedance filter to maximize the performance of the LMH2832. On the amplifier output side, the output impedance is matched to 150 Ω by including a 65-Ω series resistor on each output. Combined with the internal 10-Ω resistors on each output, the total differential impedance becomes 150 Ω. The ADS54J40 has an input impedance of approximately 600 Ω that is reduced to 150 Ω by using two 5-Ω series input resistors in parallel with two 100-Ω series resistors. The 5-Ω series resistors are included to isolate the input capacitance of the ADC so that the response of the filter is not affected. With both the amplifier and ADC impedances matched, any transmission line effects of the connection are minimized.

If the ADC is physically located close enough to the amplifier, a matched impedance may not be needed; see Driving Low Insertion-Loss Filters section for more information on driving non-matched filters.

10.2.1.2.3 Voltage Headroom Considerations

Because of the series resistors included on both the amplifier outputs and ADC inputs, the amplifier must drive a voltage that is significantly higher than the ADC full-scale input. For the circuit in Figure 61, the ADS54J40 full-scale input voltage is 1.9 VPP, so the required voltage at the amplifier output pins is 3.6 VPP. This voltage is less than the specified output voltage of 5 VPP for the LMH2832, thus system performance is not limited. If the required output voltage is higher than what the amplifier can support, then the matched resistance value can be reduced. However, this reduction can have performance implications because more current output is required from the amplifier.

The input voltage swing can be larger than the output voltage swing because the LMH2832 can operate as an attenuator. To maintain the full-scale voltage of the ADS54J40 input in this application, the amplifier cannot attenuate more than 1 dB from input to output; otherwise, the maximum input voltage swing is exceeded. If the amplifier must be operated with more attenuation, then the output voltage must be reduced.
10.2.1.3 Application Curve

Figure 62. Amplifier Dual Channel Isolation Presented to ADC Interface

10.2.2 IQ Receiver

The LMH2832 is a dual-channel device; therefore, the device has excellent gain and phase matching between channels A and B. This matching makes the LMH2832 an excellent choice for systems that require two matched channels (such as an IQ demodulation receiver), as shown in Figure 63. For an IQ system, both the gain and phase must match for the real and imaginary channel. When using two single-channel amplifiers, the matching characteristics are subject to process lot and packaging variations for two individual devices, and there is often no way to make sure that the amplifiers match without testing each amplifier. However, the dual-channel architecture of the LMH2832 allows for much tighter gain and phase matching with minimal crosstalk effects. For more matching information, see the Electrical Characteristics table.

Figure 63. IQ Receiver Block Diagram
10.3 Do’s and Don’ts

10.3.1 Do:
- Include a thermal analysis at the beginning of the project
- Use well-terminated transmission lines for all signals
- Maintain symmetrical input and output trace layouts
- Use solid metal layers for the power supplies
- Keep signal lines as straight as possible

10.3.2 Don’t:
- Use a lower power-supply voltage than necessary
- Forget about the common-mode response of filters and transmission lines
- Rout digital line traces close to the analog signals and supply line traces

11 Power Supply Recommendations

The LMH2832 is designed to be used with a single supply with a range of 4.75 V to 5.25 V. The ideal supply voltage is a 5.0-V total single-ended supply. If the supply is reduced to the minimum voltage, then the maximum input and output voltage range is reduced by 0.25 V.

11.1 Split Supplies

Ideally, the LMH2832 uses a single-ended, 5-V supply, but the device can be operated on a split supply if necessary. However, the digital logic is referenced to the GND pins, meaning that the logic reference shifts with the GND supply if connected to a negative voltage and must be accounted for in the logic connections. In general, the LMH2832 is not suggested to be operated with a split-supply configuration.

11.2 Supply Decoupling

Power-supply decoupling is critical to high-frequency performance. Onboard bypass capacitors are used on the LMH2832EVM; however, the most important component of the supply bypassing is provided by the printed circuit board (PCB). As illustrated in Figure 64, there are multiple vias connecting the LMH2832 power planes to the power-supply traces. These vias connect the internal power planes to the LMH2832. Both V_{CC} and GND must be connected to the internal power planes with several square centimeters of continuous plane in the immediate vicinity of the amplifier. The capacitance between these power planes provides the bulk of the high-frequency bypassing for the LMH2832.
12 Layout

12.1 Layout Guidelines

With a small bandwidth greater than 1 GHz, layout for the LMH2832 is critical and nothing can be neglected. In order to simplify board design, the LMH2832 has on-chip resistors that reduce the affect of off-chip capacitance. For this reason, make sure that the ground layer below the LMH2832 is not cut. The recommendation to not cut the ground plane under the amplifier input and output pins is different than many other high-speed amplifiers, but the reason is that parasitic inductance is more harmful to the LMH2832 performance than parasitic capacitance. By leaving the ground layer under the device intact, parasitic inductance of the output and power traces is minimized. The DUT portion of the evaluation board layout is shown in Figure 64.

The EVM uses long-edge capacitors for the decoupling capacitors, which reduces series resistance and increases the resonant frequency. Vias are also placed to the power planes before the bypass capacitors. Although not evident in the top layer, two vias are used at the capacitor in addition to the two vias underneath the device.

The output-matching resistors are 0402 size and are placed very close to the amplifier output pins, which reduces both parasitic inductance and capacitance. The use of 0603 output-matching resistors produces a measurable decrease in bandwidth.

When the signal is on a 50-Ω or 75-Ω controlled impedance transmission line, the layout then becomes much less critical. The transition from the 50-Ω or 75-Ω transmission line to the amplifier pins is the most critical area.

(1) The marketing status values are defined as follows:
**ACTIVE:** Product device recommended for new designs.
**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.
**OBSELETE:** TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check [http://www.ti.com/productcontent](http://www.ti.com/productcontent) for the latest availability information and additional product content details.
**TBD:** The Pb-Free/Green conversion plan has not been defined.
**Pb-Free (RoHS):** TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.
**Pb-Free (RoHS Exempt):** This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.
**Green (RoHS & no Sb/Br):** TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.
In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

*All dimensions are nominal*
NOTES:
A. All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5M–1994.
B. This drawing is subject to change without notice.
C. QFN (Quad Flatpack No-Lead) Package configuration.
D. The package thermal pad must be soldered to the board for thermal and mechanical performance.
E. See the additional figure in the Product Data Sheet for details regarding the exposed thermal pad features and dimensions.
F. Package complies to JEDEC MO−220 variation VJD−2.
THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.
NOTES:
A. All linear dimensions are in millimeters.
B. This drawing is subject to change without notice.
C. Publication IPC-7351 is recommended for alternate designs.
D. This package is designed to be soldered to a thermal pad on the board. Refer to Application Note, Quad Flat-Pack Packages, Texas Instruments Literature No. SLUA271, and also the Product Data Sheets for specific thermal information, via requirements, and recommended board layout. These documents are available at www.ti.com (http://www.ti.com).
E. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Refer to IPC 7525 for stencil design considerations.
F. Customers should contact their board fabrication site for recommended solder mask tolerances and via tenting recommendations for vias placed in the thermal pad.
ご注意

Texas Instruments Incorporated 及びその関連会社（以下総称して TI とないます）は、最新の®JEStdsに従いその半導体製品及びサービスを最善、改善、改良、その他の変更をし、又は、最新の®JEStdsに従い製品の製造中止またはサー ビスの提供を中止する権利を保有します。お客様は、発注された後に、製造する最 新の情報を取得を頂き、その情報を現在有効かつ完全なものであるかどうかを確認下さい。全ての半導体製品は、ご注文の受注の際に提示される TI の標準販 売契約条項に従って販売されます。

TI は、その製品が、半導体製品に関する TI の標準販売契約条項に記載された 保証条件に従い、販売時に仕様に対応した性能を有していることを保証します。検査及びその他の品質管理技術は、TI が当該保証を支払うのに必要とみなす範囲で行なわれております。各デバイスの全てのパラメーターに関する固有の 検査は、適用される法令によってそれ等の実行が義務づけられている場合を除 き、必ずしも行なわれておりません。

TI は、その製品が、半導体製品に関する TI の標準販売契約条項に記載された 保証条件に従い、販売時に仕様に対応した性能を有していることを保証します。検査及びその他の品質管理技術は、TI が当該保証を支払うのに必要とみなす範囲で行なわれております。各デバイスの全てのパラメーターに関する固有の 検査は、適用される法令によってそれ等の実行が義務づけられている場合を除 き、必ずしも行なわれておりません。

TI は、製品のアプリケーションに関する支援又はお客様の製品の設計についての 責任を負うことはありません。TI 製品は使用するお客様の製品及びそのアプリケーションに関する責任はお客様にあります。製品を使用したお客様の製品及びアプリケーションに関する危険は最小ものとするため、適切な設計及び操作上の安全性対策は、お客様にてお取扱いください。

TI のデータ・ブック又はデバイス中にある情報の重要な部分の複製は、その情報に一切の変更を加えることなく、且つその情報を関連する全ての保証、条件、制限及び通知と共に成る限りにおいてのみ許可されるものとします。TI は、変更を加えられて文書化されたものについては一切責任を負いません。第三者の情報については、追加的な制約に屈する可能性があります。

TI の製品又はサービスについて TI が提示したパラメーターと異なる、又は、それ を超えた使用を含むで当該 TI 製品又はサービスを再販することは、関連する TI 製品又はサービスに対する全ての明示的保証、及び何れかの暗示的保証を無 効に、且つ不公正で誤解を生じさせる行為です。TI は、そのような説明について は何の義務も負いません。

TI からのアプリケーションに関する情報提供又は支援の一切に拘らず、お客様 は、ご自身の製品及びお客様のアプリケーションにおける TI 製品の使用に関する法 的責任、規制及び安全に関する要求事項の全てに従い、これからご自身で遵守する 表現があることを目安としておりません。お客様、は、想定される不具合がも たらされる結果に対する安全対策を立案し実施し、不具合及びその回復を監視し、否及可能性のある不具合の可能性を低減し、及び、適切な治療措置を講 じるために必要な専門家知識的一切を自ら負担することを表明し、保証します。お客様 は、TI 製品を安全でないことが致命的となるアプリケーションに使用したことか生じる損害の一切につき、TI 及びその代表者にその全額の補償をするものとします。

TI 製品につき、安全に関するアプリケーションを促進するために特に宣伝される 場合があります。そのような製品については、TI が選択の際は、適用される 機関の安全標準及び要求事項を満たしたお客様の最終製品につき、お客様が 設計及び製造ができるよう手順をすることにあつて、何も拘らず、当該 TI 製品については、前段のパラグラフに記載の条件の適用を受けるものとします。

FDAクラスIII（又は同様に安全でないことが致命的となるような医薬機器）への TI 製品の使用の場合は、TI およびお客様及びその使用に起因する一切の責任を負うことは、一切認められません。

TI が軍需対応グレード製品又は「強化プラスチック製品」製品として特定に指定した製品 のみが軍事用又は宇宙航空用アプリケーション、若し、軍用環境又は航空宇宙環境にて使用されるように設計され、かつ使用されることを期待しています。お客様、は、このように指定されて 要求される全ての法的規制及び規則上要求する事項についてご自身の管理に お托しすることを認め、法令上同様の制約を負うこととします。

TI は、主に自動車用に使用されるものを目的として、ISO/TIS16949の要求事項 を満たしていると特別に指定した製品があります。当該指定を受けている製品 については、自動車用に使われる上は設計されていません。使用されることを意識しております。従いまして、各指定品目以外の TI 製品は当該要求事項 を満たしていないかった場合には、TI はかかる責任を負いません。

弊社半導体製品の取り扱い、保管について

半導体製品は、取り扱い、保管-搬送環境、基板実装条件によっては、お客様で の実装前後に破損/劣化、または故障を起こすことがあります。
弊社半導体製品のお取り扱い、保管を図る上にあたっては下記の点を必ず遵守してください。

1. 静電気
   - パッケージがショートして、静電気による破損を防ぐため、パッケージを確実に静電気防止用の袋に密封してください。
   - 使用する際にも、静電気防止用のエアーツールを使用して、パッケージを開封してから使用してください。

2. 溶液環境
   - 温度：0～40℃、相対湿度：40～85％で保管、搬送及び取り扱いを行うこと。（但し、結露しないこと。）
