OPA858 5.5GHzゲイン帯域幅積、7V/Vゲイン安定、FET入力アンプ

特長
- 高いゲイン帯域幅積: 5.5GHz
- 不完全補償型、ゲイン7V/V以上 (安定)
- 超低バイアス電流MOSFET入力: 10pA
- 低入力電圧ノイズ: 2.5nV/√Hz
- スルーレート: 2000V/µs
- 低い入力容量
  - 同相: 0.6pF
  - 差動: 0.2pF
- 広い入力同相範囲
  - 正電源から1.4V
  - 負電源を含む
- TIA構成で2.5Vppの出力スイング
- 電源電圧範囲: 3.3V〜5.25V
- 静止電流: 20.5mA
- 8ピンのWSONパッケージで供給
- 温度範囲: -40〜+125℃

アプリケーション
- 高速トランスインピーダンス・アンプ
- レーザーによる距離測定
- LIDARレシーバ
- レベル・トランスミッタ(光学)
- 光学時間領域反射率測定(OTDR)
- 分散温度センシング
- 3Dスキャナ
- タイム・オブ・フライト(ToF)システム
- 自動運転システム

オペアンプ

概要
OPA858は、広帯域トランスインピーダンスおよび電圧アンプ・アプリケーション用の、広帯域、低ノイズのCMOS入力オペアンプです。デバイスがトランスインピーダンス・アンプ(TIA)として構成されているとき、5.5GHzのゲイン帯域幅積、数十〜数百kHzの範囲のトランスインピーダンス・ゲインで高い閉ループ帯域幅を必要とするアプリケーションに使用できます。

下のグラフは、アンプがTIAとして構成されているときのOPA858の帯域幅およびノイズ特性を、フォトダイオード容量の関数として示したものです。合計ノイズは、左側のスケールでDCから、計算されるf_{3dB}周波数までの帯域幅にわたって計算されます。OPA858のパッケージにはフィードバック・ピン(FB)が搭載されているため、入力と出力の間の帰還回路接続が簡単になります。

OPA858は、下の図に示すような光学的タイム・オブ・フライト(ToF)システムでの使用に最適化されており、この場合にOPA858はTDC7201時間/デジタル・コンバータとともに使用されます。OPA858は、高速のアナログ/デジタル・コンバータ(ADC)、およびADCを駆動するためのTHS4541やLMH5401などの差動出力アンプとともに、高分解能LIDARシステムにも使用できます。

(1) Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under Recommended Operating Conditions. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

(2) Long-term continuous output current for electromigration limits.

7.2 ESD Ratings

<table>

8 Parameter Measurement Information

8.1 Parameter Measurement Information

The various test setup configurations for the OPA858 are shown below.

**図 43. Noninverting Configuration**

**図 44. Inverting Configuration (Gain = –7 V/V)**

**図 45. Capacitive Load Driver Configuration**
9 Detailed Description

9.1 Overview

The ultra-wide, 5.5-GHz gain bandwidth product (GBWP) of the OPA858, combined with the broadband voltage noise of 2.5 nV/√Hz, produces a viable amplifier for wideband transimpedance applications, high-speed data acquisition systems, and applications with weak signal inputs that require low-noise and high-gain front ends. The OPA858 combines multiple features to optimize dynamic performance. In addition to the wide, small-signal bandwidth, the OPA858 has 600 MHz of large signal bandwidth ($V_{OUT} = 2 V_{PP}$) and a slew rate of 2000 V/µs.

The OPA858 is offered in a 2-mm × 2-mm, 8-pin WSON package that features a feedback (FB) pin for a simple feedback network connection between the amplifiers output and inverting input. Excess capacitance on an amplifiers input pin can reduce phase margin causing instability. This problem is exacerbated in the case of very wideband amplifiers like the OPA858. To reduce the effects of stray capacitance on the input node, the OPA858 pinout features an isolation pin (NC) between the feedback and inverting input pins that increases the physical spacing between them thereby reducing parasitic coupling at high frequencies. The OPA858 also features a very low capacitance input stage with only 0.8-pF of total input capacitance.

9.2 Functional Block Diagram

The OPA858 is a classic, voltage feedback operational amplifier (op amp) with two high-impedance inputs and a low-impedance output. Standard application circuits are supported, like the two basic options shown in 图 46 and 图 47. The DC operating point for each configuration is level-shifted by the reference voltage ($V_{REF}$), which is typically set to midsupply in single-supply operation. $V_{REF}$ is typically connected to ground in split-supply applications.
9.3 Feature Description

9.3.1 Input and ESD Protection

The OPA858 is fabricated on a low-voltage, high-speed, BiCMOS process. The internal, junction breakdown voltages are low for these small geometry devices, and as a result, all device pins are protected with internal ESD protection diodes to the power supplies as 图 48 shows. There are two antiparallel diodes between the inputs of the amplifier that clamp the inputs during an overrange or fault condition.

![Internal ESD Structure](image)

图 48. Internal ESD Structure

9.3.2 Feedback Pin

The OPA858 pin layout is optimized to minimize parasitic inductance and capacitance, which is critical in high-speed analog design. The FB pin (pin 1) is internally connected to the output of the amplifier. The FB pin is separated from the inverting input of the amplifier (pin 3) by a no connect (NC) pin (pin 2). The NC pin must be left floating. There are two advantages to this pin layout:

1. A feedback resistor (R_F) can connect between the FB and IN– pin on the same side of the package (see 图 49) rather than going around the package.
2. The isolation created by the NC pin minimizes the capacitive coupling between the FB and IN– pins by increasing the physical separation between the pins.

![RF Connection Between FB and IN– Pins](image)

图 49. R_F Connection Between FB and IN– Pins
Feature Description (continued)

9.3.3 Wide Gain-Bandwidth Product

図 10 shows the open-loop magnitude and phase response of the OPA858. Calculate the gain bandwidth product of any op amp by determining the frequency at which the $A_{OL}$ is 60 dB and multiplying that frequency by a factor of 1000. The second pole in the $A_{OL}$ response occurs before the magnitude crosses 0 dB, and the resultant phase margin is less than 0°. This indicates instability at a gain of 0 dB (1 V/V). Amplifiers that are not unity-gain stable are known as decompensated amplifiers. Decompensated amplifiers typically have higher gain-bandwidth product, higher slew rate, and lower voltage noise, compared to a unity-gain stable amplifier with the same amount of quiescent power consumption.

図 50 shows the open-loop magnitude ($A_{OL}$) of the OPA858 as a function of temperature. The results show minimal variation over temperature. The phase margin of the OPA858 configured in a noise gain of 7 V/V (16.9 dB) is close to 55° across temperature. Similarly 図 51 shows the $A_{OL}$ magnitude of the OPA858 as a function of process variation. The results show the $A_{OL}$ curve for the nominal process corner and the variation one standard deviation from the nominal. The simulated results suggest less than 1° of phase margin difference within a standard deviation of process variation when the amplifier is configured in a gain of 7 V/V.

One of the primary applications for the OPA858 is as a high-speed transimpedance amplifier (TIA), as 図 59 shows. The low-frequency noise gain of a TIA is 0 dB (1 V/V). At high frequencies the ratio of the total input capacitance and the feedback capacitance set the noise gain. To maximize the TIA closed-loop bandwidth, the feedback capacitance is typically smaller than the input capacitance, which implies that the high-frequency noise gain is greater than 0 dB. As a result, op amps configured as TIAs are not required to be unity-gain stable, which makes a decompensated amplifier a viable option for a TIA. What You Need To Know About Transimpedance Amplifiers – Part 1 and What You Need To Know About Transimpedance Amplifiers – Part 2 describe transimpedance amplifier compensation in greater detail.

9.3.4 Slew Rate and Output Stage

In addition to wide bandwidth, the OPA858 features a high slew rate of 2000 V/µs. The slew rate is a critical parameter in high-speed pulse applications with narrow sub 10-ns pulses such as Optical Time-Domain Reflectometry (OTDR) and LIDAR. The high slew rate of the OPA858 implies that the device accurately reproduces a 2-V, sub-ns pulse edge as seen in 図 20. The wide bandwidth and slew rate of the OPA858 make it an ideal amplifier for high-speed, signal-chain front ends.

図 52 shows the open-loop output impedance of the OPA858 as a function of frequency. To achieve high slew rates and low output impedance across frequency, the output swing of the OPA858 is limited to approximately 3 V. The OPA858 is typically used in conjunction with high-speed pipeline ADCs and flash ADCs that have limited input ranges. Therefore, the OPA858 output swing range coupled with the class-leading voltage noise specification maximizes the overall dynamic range of the signal chain.
9.3.5 Current Noise

The input impedance of CMOS and JFET input amplifiers at low frequencies exceed several GΩs. However, at higher frequencies, the transistors parasitic capacitance to the drain, source, and substrate reduces the impedance. The high impedance at low frequencies eliminates any bias current and the associated shot noise. At higher frequencies, the input current noise increases (see 图53) as a result of capacitive coupling between the CMOS gate oxide and the underlying transistor channel. This phenomenon is a natural artifact of the construction of the transistor and is unavoidable.
9.4 Device Functional Modes

9.4.1 Split-Supply and Single-Supply Operation

The OPA858 can be configured with single-sided supplies or split-supplies as shown in 图 63. Split-supply operation using balanced supplies with the input common-mode set to ground eases lab testing because most signal generators, network analyzers, spectrum analyzers, and other lab equipment typically reference inputs and outputs to ground. Split-supply operation is preferred in systems where the signals swing around ground. However, the system requires two supply rails. In split-supply operation, the thermal pad must be connected to the negative supply.

Newer systems use a single power supply to improve efficiency and reduce the cost of the extra power supply. The OPA858 can be used with a single positive supply (negative supply at ground) with no change in performance if the input common-mode and output swing are biased within the linear operation of the device. To change the circuit from a split-supply to a single-supply configuration, level shift all the voltages by half the difference between the power supply rails. In this case, the thermal pad must be connected to ground.

9.4.2 Power-Down Mode

The OPA858 features a power-down mode to reduce the quiescent current to conserve power. 图 23 and 图 24 show the transient response of the OPA858 as the PD pin toggles between the disabled and enabled states.

The PD disable and enable threshold voltages are with reference to the negative supply. If the amplifier is configured with the positive supply at 3.3 V and the negative supply at ground, then the disable and enable threshold voltages are 0.65 V and 1.8 V, respectively. If the amplifier is configured with ±1.65-V supplies, then the disable and enable threshold voltages are at −1 V and 0.15 V, respectively. If the amplifier is configured with ±2.5-V supplies, then the threshold voltages are at −1.85 V and −0.7 V.

图 54 shows the switching behavior of a typical amplifier as the PD pin is swept down from the enabled state to the disabled state. Similarly 图 55 shows the switching behavior of a typical amplifier as the PD pin is swept up from the disabled state to the enabled state. The small difference in the switching thresholds between the down sweep and the up sweep is due to the hysteresis designed into the amplifier to increase its immunity to noise on the PD pin.

Connecting the PD pin low disables the amplifier and places the output in a high-impedance state. When the amplifier is configured as a noninverting amplifier, the feedback (RF) and gain (RG) resistor network form a parallel load to the output of the amplifier. To protect the input stage of the amplifier, the OPA858 uses internal, back-to-back protection diodes between the inverting and noninverting input pins as 图 48 shows. When the differential voltage between the input pins of the amplifier exceeds a diode voltage drop, an additional low-impedance path is created between the inputs.
10 Application and Implementation

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI’s customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

10.1 Application Information

10.1.1 Using the OPA858 as a Transimpedance Amplifier

The OPA858 design has been optimized to meet the industry’s growing demand for wideband, low-noise photodiode amplifiers. The closed-loop bandwidth of a transimpedance amplifier is a function of the following:

1. The total input capacitance. This includes the photodiode capacitance, input capacitance of the amplifier (common-mode and differential capacitance) and any stray capacitance from the PCB.
2. The op amp gain bandwidth product (GBWP), and,
3. The transimpedance gain \( R_F \).

![Transimpedance Amplifier Circuit](image)

**図56. Transimpedance Amplifier Circuit**

**図56** shows the OPA858 configured as a TIA with the avalanche photodiode (APD) reverse biased such that its cathode is tied to a large positive bias voltage. In this configuration the APD sources current into the op amp feedback loop so that the output swings in a negative direction relative to the input common-mode voltage. To maximize the output swing in the negative direction, the OPA858 common-mode is set close to the positive limit, 1.6 V from the positive supply rail.

The feedback resistance \( R_F \) and the input capacitance form a zero in the noise gain that results in instability if left unchecked. To counteract the effect of the zero, a pole is inserted by adding the feedback capacitor (\( C_F \)) into the noise gain transfer function. The Transimpedance Considerations for High-Speed Amplifiers application report discusses theories and equations that show how to compensate a transimpedance amplifier for a particular gain and input capacitance. The bandwidth and compensation equations from the application report are available in a Microsoft Excel™ calculator. What You Need To Know About Transimpedance Amplifiers – Part 1 provides a link to the calculator.
Application Information (continued)

The equations and calculators in the application report and blog posts referenced above are used to model the bandwidth ($f_{3dB}$) and noise ($I_{RN}$) performance of the OPA858 configured as a TIA. The resultant performance is shown in 图 57 and 图 58. The left side Y-axis shows the closed-loop bandwidth performance, while the right side of the graph shows the integrated input referred noise. The noise bandwidth to calculate $I_{RN}$, for a fixed $R_F$ and $C_{PD}$ is set equal to the $f_{-3dB}$ frequency.

图 57 shows the amplifier performance as a function of photodiode capacitance ($C_{PD}$) for $R_F = 10 \, \text{k}\Omega$ and $20 \, \text{k}\Omega$. Increasing $C_{PD}$ decreases the closed-loop bandwidth. It is vital to reduce any stray parasitic capacitance from the PCB to maximize bandwidth. The OPA858 is designed with 0.8 pF of total input capacitance to minimize the effect on system performance.

图 58 shows the amplifier performance as a function of $R_F$ for $C_{PD} = 1 \, \text{pF}$ and $2 \, \text{pF}$. Increasing $R_F$ results in lower bandwidth. To maximize the signal-to-noise ratio (SNR) in an optical front-end system, maximize the gain in the TIA stage. Increasing $R_F$ by a factor of "X" increases the signal level by "X", but only increases the resistor noise contribution by "$\sqrt{X}$", thereby improving SNR.
10.2 Typical Application

The high GBWP, low input voltage noise and high slew rate of the OPA858 makes the device a viable wideband, high input impedance voltage amplifier.

![Diagram](attachment:image.png)

**図 59. OPA858 in a Gain of –2V/V (No Noise Gain Shaping)**

**図 60. OPA858 in a Gain of –2V/V (With Noise Gain Shaping)**

10.2.1 Design Requirements

Design a high-bandwidth, high-gain, voltage amplifier with the design requirements listed in 表 1. An inverting amplifier configuration is chosen here; however, the theory is applicable to a noninverting configuration as well. In an inverting configuration the signal gain and noise gain transfer functions are not equal, unlike the noninverting configuration.

10.2.2 Detailed Design Procedure

The OPA858 is compensated to have less than 1 dB of peaking in a gain of 7 V/V. Using the device in lower gains results in increased peaking and potential instability. 図 59 shows the OPA858 configured in a signal gain of –2 V/V. The DC noise gain ($1/β$) of the amplifier is affected by the 62-Ω termination resistor and the 50-Ω source resistor and is given by 式 1. At higher frequencies the noise gain is affected by reactive elements such as inductors and capacitors. These include both discrete board components as well as printed circuit board (PCB) parasitics.

\[
\text{Noise Gain} = \frac{1}{\beta} = \frac{453 \, \Omega}{226 \, \Omega + (62 \, \Omega \parallel 50 \, \Omega)} = 2.79 \, \text{V/V} = 5.04 \, \text{dB}
\] (1)
The stability and phase margin of the amplifier depend on the loop gain of the amplifier, which is the product of the $A_{OL}$ and the feedback factor ($\beta$) of the amplifier. The $\beta$ of a negative-feedback loop system is the portion of the output signal that is fed back to the input, and in the case of an amplifier is the inverse of the noise gain. The noise gain of the amplifier at high frequencies can be increased by adding an input capacitor and a feedback capacitor as 图 60 shows. If done carefully, increasing $1/\beta$ improves the phase margin just as any amplifier is more stable in a high gain configuration versus a unity-gain buffer configuration. The modified network with the added capacitors alters the high-frequency noise gain, but does not alter the signal gain. The AN-1604 *Decompensated Operational Amplifiers* application report provides a detailed analysis of noise gain-shaping techniques for decompensated amplifiers and shows how to choose external resistors and capacitor values.

图 61 shows the uncompensated frequency response of the OPA858 configured as shown in 图 59. Without any added noise gain shaping components, the OPA858 shows approximately 13 dB of peaking.

图 62 shows the noise gain compensated frequency response of the OPA858 configured as shown in 图 60. The noise gain shaping elements reduce the peaking to less than 1.5 dB. The 2.7-pF input capacitor, the input capacitance of the amplifier, the gain resistor, and the feedback resistor create a zero in the noise gain at a frequency $f$, as 式 2 shows.

$$f = \frac{1}{2\pi (R_F || R_G) C_{IN}}$$

where

- $R_F$ is the feedback resistor
- $R_G$ is the input or gain resistor (includes the effect of the source and termination resistor)
- $C_{IN}$ is the total input capacitance, which includes the external 2.7-pF capacitor, the amplifier input capacitance, and any parasitic PCB capacitance.

The zero in 式 2 increases the noise gain at higher frequencies, which is important when compensating a decompensated amplifier. However, the noise gain zero reduces the loop gain phase which results in a lower phase margin. To counteract the phase reduction due to the noise gain zero, add a pole to the noise gain curve by inserting the 0.5-pF feedback capacitor. The pole occurs at a frequency shown in 式 3. The noise gain pole and zero locations must be selected so that the rate-of-closure between the magnitude curves of $A_{OL}$ and $1/\beta$ is approximately 20 dB. To ensure this, the noise gain pole must occur before the $1/\beta$ magnitude curve intersects the $A_{OL}$ magnitude curve. In other words, the noise gain pole must occur before $|A_{OL}| = |1/\beta|$. The point at which the two curves intersect is known as the loop gain crossover frequency.

$$f = \frac{1}{2\pi R_F C_F}$$

where

- $C_F$ is the feedback capacitor (includes any added PCB parasitic)

For more information on op amp stability, watch the *TI Precision Lab series on stability* video.

### 10.2.3 Application Curves
11 Power Supply Recommendations

The OPA858 operates on supplies from 3.3 V to 5.25 V. The OPA858 operates on single-sided supplies, split and balanced bipolar supplies, and unbalanced bipolar supplies. Because the OPA858 does not feature rail-to-rail inputs or outputs, the input common-mode and output swing ranges are limited at 3.3-V supplies.

---

**a) Single supply configuration**

---

**b) Split supply configuration**

---

![Split and Single Supply Circuit Configuration](image_url)
12 Layout

12.1 Layout Guidelines
Achieving optimum performance with a high-frequency amplifier like the OPA858 requires careful attention to board layout parasitics and external component types. Recommendations that optimize performance include:

1. Minimize parasitic capacitance from the signal I/O pins to AC ground. Parasitic capacitance on the output and inverting input pins can cause instability. To reduce unwanted capacitance, TI recommends cutting out the power and ground traces underneath the signal input and output pins. Otherwise, ground and power planes must be unbroken elsewhere on the board. When configuring the amplifier as a TIA, if the required feedback capacitor is under 0.15 pF, consider using two series resistors, each of half the value of a single resistor in the feedback loop to minimize the parasitic capacitance from the resistor.

2. Minimize the distance (less than 0.25") from the power-supply pins to high-frequency bypass capacitors. Use high quality, 100-pF to 0.1-µF, C0G and NPO-type decoupling capacitors with voltage ratings at least three times greater than the amplifiers maximum power supplies to ensure that there is a low-impedance path to the amplifiers power-supply pins across the amplifiers gain bandwidth specification. At the device pins, do not allow the ground and power plane layout to be in close proximity to the signal I/O pins. Avoid narrow power and ground traces to minimize inductance between the pins and the decoupling capacitors. The power-supply connections must always be decoupled with these capacitors. Larger (2.2-µF to 6.8-µF) decoupling capacitors, effective at lower frequency, must be used on the supply pins. These are placed further from the device and are shared among several devices in the same area of the PC board.

3. Careful selection and placement of external components preserves the high-frequency performance of the OPA858. Use low-reactance resistors. Surface-mount resistors work best and allow a tighter overall layout. Never use wirewound resistors in a high-frequency application. Because the output pin and inverting input pin are the most sensitive to parasitic capacitance, always position the feedback and series output resistor, if any, as close to the output pin as possible. Place other network components (such as noninverting input termination resistors) close to the package. Even with a low parasitic capacitance shunting the external resistors, high resistor values create significant time constants that can degrade performance. When configuring the OPA858 as a voltage amplifier, keep resistor values as low as possible and consistent with load driving considerations. Decreasing the resistor values keeps the resistor noise terms low and minimizes the effect of the parasitic capacitance. However, lower resistor values increase the dynamic power consumption because $R_F$ and $R_G$ become part of the output load network of the amplifier.

12.2 Layout Example

[Representative schematic]

Connect $R_F$ to VS+ to enable the amplifier

NC (Pin 2) isolates the IN- and FB pins thereby reducing capacitive coupling

Place gain and feedback resistors close to pins to minimize stray capacitance

Connect the thermal pad to the negative supply pin

Place bypass capacitor close to power pins

図 64. Layout Recommendation
Layout Example (continued)

When configuring the OPA858 as a transimpedance amplifier additional care must be taken to minimize the inductance between the avalanche photodiode (APD) and the amplifier. Always place the photodiode on the same side of the PCB as the amplifier. Placing the amplifier and the APD on opposite sides of the PCB increases the parasitic effects due to via inductance. APD packaging can be quite large which often requires the APD to be placed further away from the amplifier than ideal. The added distance between the two device results in increased inductance between the APD and op amp feedback network as shown in 图65. The added inductance is detrimental to a decompensated amplifiers stability since it isolates the APD capacitance from the noise gain transfer function. The noise gain is given by 式4. The added PCB trace inductance between the feedback network increases the denominator in 式4 thereby reducing the noise gain and the phase margin. In cases where a leaded APD in a TO can is used inductance should be further minimized by cutting the leads of the TO can as short as possible.

The layout shown in 图65 can be improved by following some of the guidelines shown in 图66. The two key rules to follow are:

- Add an isolation resistor $R_{ISO}$ as close as possible to the inverting input of the amplifier. Select the value of $R_{ISO}$ to be between 10 $\Omega$ and 20 $\Omega$. The resistor dampens the potential resonance caused by the trace inductance and the amplifiers internal capacitance.
- Close the loop between the feedback elements ($R_F$ and $C_F$) and $R_{ISO}$ as close to the APD pins as possible. This ensures a more balanced layout and reduces the inductive isolation between the APD and the feedback network.

\[
\text{Noise Gain} = \left(1 + \frac{Z_F}{Z_IN}\right)
\]

where
- $Z_F$ is the total impedance of the feedback network.
- $Z_{IN}$ is the total impedance of the input network.

(1) The marketing status values are defined as follows:
ACTIVE: Product device recommended for new designs.
LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
PREVIEW: Device has been announced but is not in production. Samples may or may not be available.
OBSOLETE: TI has discontinued the production of the device.

(2) RoHS: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".
RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.
Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.
TAPE AND REEL INFORMATION

### TAPE DIMENSIONS

- **A0**: Dimension designed to accommodate the component width
- **B0**: Dimension designed to accommodate the component length
- **K0**: Dimension designed to accommodate the component thickness
- **W**: Overall width of the carrier tape
- **P1**: Pitch between successive cavity centers

This image is a representation of the package family, actual package may vary. Refer to the product data sheet for package details.
NOTES:

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. The package thermal pad must be soldered to the printed circuit board for thermal and mechanical performance.
NOTES: (continued)

4. This package is designed to be soldered to a thermal pad on the board. For more information, see Texas Instruments literature number SLUA271 (www.ti.com/lit/slua271).

5. Vias are optional depending on application, refer to device data sheet. If any vias are implemented, refer to their locations shown on this view. It is recommended that vias under paste be filled, plugged or tented.
6. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.
important notice and disclaimer

TI is, technical data and reliability data (data sheets included), design resources (reference designs included), application advice, various Web tools, safety information, and other resources provided "as is" without any warranty, including any implied warranty of merchantability and fitness for a particular purpose, and no warranty against infringement of third-party intellectual property rights.
