

DAC7811 12ビット、シリアル入力、乗算型デジタル/アナログ・コンバータ

1 特長

- 2.7V~5.5V電源での動作
- 50MHzのシリアル・インターフェイス
- 10MHzの乗算帯域幅
- $\pm 15V$ の基準入力
- 低いグリッチ電力: 5nV-s
- 拡張温度範囲:
-40°C~+125°C
- 10ピンのVSSOPパッケージ
- 12ビット単調
- 4象限の乗算
- パワーオン・リセットとブラウンアウト検出
- デイジー・チェーン・モード
- リードバック機能
- 業界標準のピン配置

2 アプリケーション

- 携帯型のバッテリー駆動計測機器
- 波形生成器
- アナログ処理
- プログラム可能なアンプおよびアッテネータ
- デジタル制御較正
- プログラム可能なフィルタおよび発振器
- コンポジット・ビデオ
- 超音波

3 概要

DAC7811はCMOS、12ビットの電流出力デジタル/アナログ・コンバータ(DAC)です。このデバイスは2.7V~5.5Vの電源で動作するため、バッテリー駆動および他の多くのアプリケーションに適しています。

このDACは、ダブル・バッファされた3線式シリアル・インターフェイスを使用しており、SPI、QSPI™、MICROWIRE、およびほとんどのDSPインターフェイス標準と互換性があります。さらに、複数のデバイスを使用するときは、シリアルデータ出力ピン(SDO)によりデイジー・チェーン接続が可能です。データのリードバック機能により、ユーザーはSDOピンからDACレジスタの内容を読み出すことができます。電源オン時には、内部のシフト・レジスタとラッチに0が書き込まれ、DAC出力はゼロスケールに設定されます。

DAC7811は非常に優れた4象限乗算特性を持ち、10MHzの信号乗算帯域幅があります。フルスケール出力電流は、印加される外部基準入力電圧(V_{REF})により決定されます。内蔵の帰還抵抗(R_{FB})を外部の高精度電流電圧変換アンプと組み合わせると、温度トラッキングおよびフルスケール電圧出力が可能になります。

DAC7811は10リードのVSSOPパッケージで供給されます。

5 Pin Configuration and Functions

Pin Functions

PIN		TYPE	DESCRIPTION
NO.	NAME		
1	I _{OUT1}	O	DAC Current Output
2	I _{OUT2}	O	DAC Analog Ground. This pin is normally tied to the analog ground of the system.
3	GND	G	Ground pin.
4	SCLK	I	Serial Clock Input. By default, data is clocked into the input shift register on the falling edge of the serial clock input. Alternatively, by means of the serial control bits, the device may be configured such that data is clocked into the shift register on the rising edge of SCLK.
5	SDIN	I	Serial Data Input. Data is clocked into the 16-bit input register on the active edge of the serial clock input. By default, on power-up, data is clocked into the shift register on the falling edge of SCLK. The control bits allow the user to change the active edge to the rising edge.
6	$\overline{\text{SYNC}}$	I	Active Low Control Input. This is the frame synchronization signal for the input data. When $\overline{\text{SYNC}}$ goes low, it powers on the SCLK and DIN buffers, and the input shift register is enabled. Data is loaded to the shift register on the active edge of the following clocks (power-on default is falling clock edge). In stand-alone mode, the serial interface counts the clocks and data is latched to the shift register on the 16th active clock edge.
7	SDO	O	Serial Data Output. This allows a number of parts to be daisy-chained. By default, data is clocked into the shift register on the falling edge and out via SDO on the rising edge of SCLK. Data will always be clocked out on the alternate edge to loading data to the shift register. Writing the Readback control word to the shift register makes the DAC register contents available for readback on the SDO pin, clocked out on the opposite edges to the active clock edge.
8	V _{DD}	I	Positive Power Supply Input. These parts can be operated from a supply of 2.7 V to 5.5 V.
9	V _{REF}	I	DAC Reference Voltage Input
10	R _{FB}	O	DAC Feedback Resistor pin. Establish voltage output for the DAC by connecting to external amplifier output.

6 Specifications

6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

	MIN	MAX	UNIT
V _{DD} to GND	-0.3	7	V
Digital input voltage to GND	-0.3	V _{DD} + 0.3	V
I _{OUT1} , I _{OUT2} to GND	-0.3	V _{DD} + 0.3	V
Operating temperature	-40	125	°C
Junction temperature, (T _J max)		150	°C
Storage temperature, T _{stg}	-65	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

6.2 ESD Ratings

		VALUE	UNIT
V _(ESD) Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2000	V
	Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±1000	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.

- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
V _{DD}	Supply voltage to GND	2.7		5.5	V
V _{REF}	Reference voltage	-15		15	V
V _{IL}	Input low voltage	V _{DD} = 2.7 V		0.6	V
		V _{DD} = 5 V		0.8	V
V _{IH}	Input high voltage	V _{DD} = 2.7 V	2.1		V
		V _{DD} = 5 V	2.4		V
T _A	Operating ambient temperature	-40		125	°C

6.4 Thermal Information

THERMAL METRIC ⁽¹⁾		DAC7811	UNIT

7 Detailed Description

7.1 Overview

The DAC7811 is a CMOS, 12-bit, current output digital-to-analog converter (DAC). This device operates from a 2.7-V to 5.5-V power supply, making it suitable for battery-powered and many other applications. This DAC uses a double-buffered 3-wire serial interface that is compatible with SPI, QSPI™, MICROWIRE, and most DSP interface standards. In addition, a serial data out pin (SDO) allows for daisy-chaining when multiple devices are used. Data readback allows the user to read the contents of the DAC register via the SDO pin. On power-up, the internal shift register and latches are filled with zeroes and the DAC outputs are at zero scale.

7.2 Functional Block Diagram

Copyright © 2016, Texas Instruments Incorporated

7.3 Feature Description

The DAC7811 is a single channel, current output, 12-bit digital-to-analog converter (DAC). The architecture, illustrated in Figure 25, is an R-2R ladder configuration with the three MSBs segmented. Each 2R leg of the ladder is either switched to I_{OUT1} or the I_{OUT2} terminal. The I_{OUT1} terminal of the DAC is held at a virtual GND potential by the use of an external I/V converter op amp. The R-2R ladder is connected to an external reference input V_{REF} that determines the DAC full-scale current. The R-2R ladder presents a code independent load impedance to the external reference of $10k\Omega \pm 20\%$. The external reference voltage can vary over a range of $-15V$ to $+15V$, thus providing bipolar I_{OUT} current operation. By using an external I/V converter and the DAC7811 R_{FB} resistor, output voltage ranges of $-V_{REF}$ to V_{REF} can be generated.

Figure 25. Equivalent R-2R DAC Circuit

Feature Description (continued)

When using an external I/V converter and the DAC7811 R_{FB} resistor, the DAC output voltage is given by [Equation 1](#):

$$V_{OUT} = -V_{REF} \times \left(\frac{CODE}{4096} \right) \quad (1)$$

Each DAC code determines the 2R leg switch position to either GND or I_{OUT} . Because the DAC output impedance as seen looking into the I_{OUT1} terminal changes versus code, the external I/V converter noise gain will also change. Because of this, the external I/V converter op amp must have a sufficiently low offset voltage such that the amplifier offset is not modulated by the DAC I_{OUT1} terminal impedance change. External op amps with large offset voltages can produce INL errors in the transfer function of the DAC7811 due to offset modulation versus DAC code.

For best linearity performance of the DAC7811, a low offset voltage op amp (such as the [OPA277](#)) is recommended (see [Figure 26](#)). This circuit allows V_{REF} swinging from -10 V to 10 V .

Figure 26. Voltage Output Configuration

7.4 Device Functional Modes

7.4.1 Serial Interface

The DAC7811 has a 3-wire serial interface (\overline{SYNC} , SCLK, and SDIN), which is compatible with SPI, QSPI, and MICROWIRE interface standards as well as most Digital Signal Processor (DSP) devices. See the Serial Write Operation timing diagram ([Figure 28](#)) for an example of a typical write sequence. The write sequence begins by bringing the \overline{SYNC} line low. Data from the DIN line are clocked into the 16-bit shift register on the falling edge of SCLK. The serial clock frequency can be as high as 50MHz, making the DAC7811 compatible with high-speed DSPs. The SDIN and SCLK input buffers are gated off while \overline{SYNC} is high which minimizes the power dissipation of the digital interface. After \overline{SYNC} goes low, the digital interface will respond to the SDIN and SCLK input signals and data can now be shifted into the device. If an inactive clock edge occurs after \overline{SYNC} goes low, but before the first active clock edge, it will be ignored. If the SDO pin is being used then \overline{SYNC} must remain low until after the inactive clock edge that follows the 16th active clock edge.

7.4.2 Input Shift Register

The input shift register is 16 bits wide, as shown in [Figure 27](#). The four MSBs are the control bits C3–C0; these bits determine which function will be executed at the rising edge of \overline{SYNC} in daisy-chain mode or the 16th active clock edge in stand-alone mode. The remaining 12 bits are the data bits. On a load and update command (C3–C0 = 0001) these 12 data bits will be transferred to the DAC register; otherwise, they have no effect. [Table 1](#) shows serial shift register and DAC register operation with CLK and \overline{SYNC} pin settings.

Device Functional Modes (continued)

4 CONTROL BITS				12 DATA BITS											
B15 (MSB)	B14	B13	B12	B11	B10	B9	B8	B7	B6	B5	B4	B3	B2	B1	B0 (LSB)
C3	C2	C1	C0	DB11											DB0

Figure 27. Contents of the 16-Bit Input Shift Register

Table 1. Control Logic Truth Table⁽¹⁾

CLK	$\overline{\text{SYNC}}$	SERIAL SHIFT REGISTER	DAC REGISTER
X	H	No effect	Latched
↓−	L	Shift register data advanced one bit	Latched
X	↑+	In daisy-chain mode, the function as determined by C3-C0 is executed.	In daisy-chain mode, the contents may change as determined by C3-C0.

(1) ↓− Negative logic transition, default CLK mode; ↑+ Positive logic transition; X = Do not care.

7.4.3 $\overline{\text{SYNC}}$ Interrupt (Stand-Alone Mode)

In a normal write sequence, the $\overline{\text{SYNC}}$ line is kept low for at least 16 falling edges of SCLK and the DAC is updated on the 16th falling edge. However, if $\overline{\text{SYNC}}$ is brought high before the 16th falling edge, this acts as an interrupt to the write sequence. The shift register is reset and the write sequence is seen as invalid. Neither an update of the DAC register contents nor a change in the operating mode occurs.

7.4.4 Daisy-Chain

The DAC7811 powers up in the daisy-chain mode which must be used when two or more devices are connected in tandem. The SCLK and $\overline{\text{SYNC}}$ signals are shared across all devices while the SDO output of the first device connects to the SDIN input of the following device, and so forth. In this configuration 16 SCLK cycles for each DAC7811 in the chain are required. Please refer to the timing diagram of [Figure 28](#).

For n devices in a daisy-chain configuration, $16n$ SCLK cycles are required to shift in the entire input data stream. After $16n$ active SCLK edges are received following a falling $\overline{\text{SYNC}}$, the data stream becomes complete, and $\overline{\text{SYNC}}$ can be brought high to update n devices simultaneously.

When $\overline{\text{SYNC}}$ is brought high, each device will execute the function defined by the four DAC control bits C3-C0 in its input shift register. For example, C3-C0 must be **0001** for each DAC in the chain that is to be updated with new data, and C3-C0 must be **0000** for each DAC in the chain whose contents are to remain unchanged.

A continuous stream containing the exact number of SCLK cycles may be sent first while the $\overline{\text{SYNC}}$ signal is held low, and then raise $\overline{\text{SYNC}}$ at a later time. Nothing happens until the rising edge of $\overline{\text{SYNC}}$, and then each DAC7811 in the chain will execute the function defined by the four DAC control bits C3-C0 in its input shift register.

Figure 28. DAC7811 Timing Diagram

7.4.5 Control Bits C3 to C0

Control Bits C3 to C0 allow control of various functions of the DAC; see [Table 2](#). Default settings of the DAC on powering up are as follows: Data clocked into shift register on falling clock edges; daisy-chain mode is enabled. The device powers on with zero-scale loaded into the DAC register and I_{OUT} lines. The DAC control bits allow the user to adjust certain features as part of an initialization sequence; for example, daisy-chaining may be disabled if not in use, active clock edge may be changed to rising edge, and DAC output may be cleared to either zero or midscale. The user may also initiate a readback of the DAC register contents for verification purposes.

Table 2. Serial Input Register Data Format, Data Loaded MSB First

C3	C2	C1	C0	FUNCTION IMPLEMENTED
0	0	0	0	No operation (power-on default)

8 Application and Implementation

NOTE

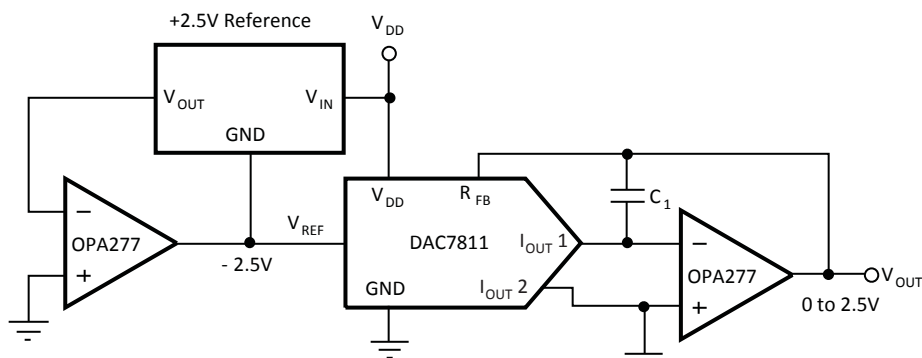

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

The 2.7-V to 5.5-V supply operation makes the DAC7811 a viable candidate for battery operated applications, such as waveform generators, programmable amplifiers, and any mobile platforms that may require analog outputs and processing. Additionally, the large signal multiplying bandwidth of the DAC7811 makes it an excellent choice for programmable filters and oscillators.

8.1.1 Unipolar Operation Using DAC7811

To generate a positive voltage output, a negative reference is input to the DAC7811. This design is suggested instead of using an inverting amp to invert the output as a result of resistor tolerance errors. For a negative reference, V_{OUT} and GND of the reference are level-shifted to a virtual ground and a -2.5-V input to the DAC7811 with an op amp.

Copyright © 2016, Texas Instruments Incorporated

Figure 29. Positive Voltage Output Circuit

8.1.2 Bipolar Operation Using the DAC7811

The DAC7811, as a 2-quadrant multiplying DAC, can be used to generate a unipolar output. The polarity of the full-scale output I_{OUT} is the inverse of the input reference voltage at V_{REF} .

Some applications require full 4-quadrant multiplying capabilities or bipolar output swing. As shown in Figure 30, external op amp U3 is added as a summing amp and has a gain of 2X that widens the output span to 5 V. A 4-quadrant multiplying circuit is implemented by using a 2.5-V offset of the reference voltage to bias U3. According to the circuit transfer equation given in Equation 2, input data (D) from code 0 to full-scale produces output voltages of $V_{OUT} = -2.5\text{ V}$ to $V_{OUT} = +2.5\text{ V}$

$$V_{OUT} = \left[\left(\frac{D}{2^{11}} \right) - 1 \right] \times V_{REF} \quad (2)$$

External resistance mismatching is the significant error in Figure 30.

Application Information (continued)

Copyright © 2016, Texas Instruments Incorporated

Figure 30. Bipolar Output Circuit
8.1.3 Stability Circuit

For a current-to-voltage design (see [Figure 31](#)), the DAC7811 current output (I_{OUT}) and the connection with the inverting node of the op amp should be as short as possible and according to correct printed circuit board (PCB) layout design practices. For each code change, there is a step function. If the gain bandwidth product (GBP) of the op amp is limited and parasitic capacitance is excessive at the inverting node, then gain peaking is possible. Therefore, for circuit stability, a compensation capacitor C_1 (1pF to 5pF typ) can be added to the design, as shown in [Figure 31](#).

Copyright © 2016, Texas Instruments Incorporated

Figure 31. Gain Peaking Prevention Circuit With Compensation Capacitor
8.1.4 Amplifier Selection

There are many choices and many differences in selecting the proper operational amplifier for a multiplying DAC (MDAC). Making the analog signal out of the MDAC is one critical aspect. However, there are also other issues to take into account such as amplifier noise, input bias current, and offset voltage, as well as MDAC resolution and glitch energy. [Table 3](#) and [Table 4](#) suggest some suitable operational amplifiers for low power, fast settling, and high-speed applications. A greater selection of operational amplifiers can be found at www.ti.com/amplifier.

8.1.5 Programmable Current Source Circuit

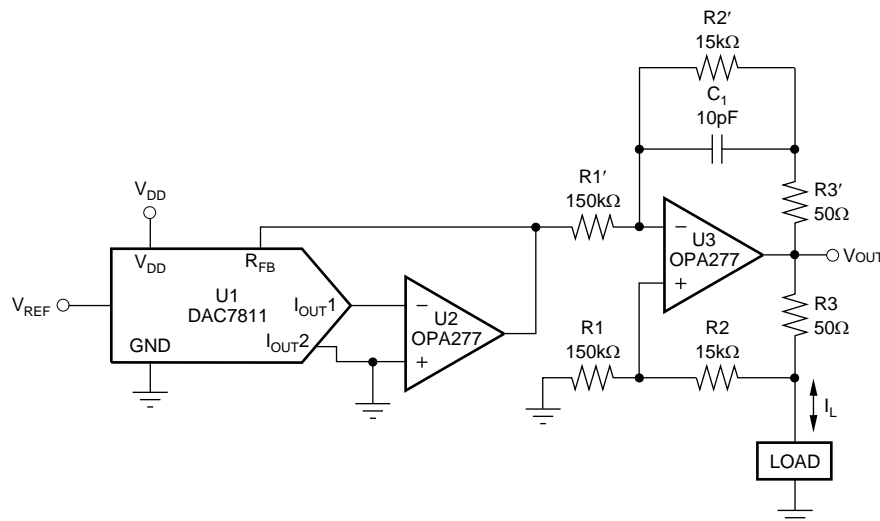

A DAC7811 can be integrated into the circuit in [Figure 32](#) to implement an improved Howland current pump for precise voltage to current conversions. Bidirectional current flow and high voltage compliance are two features of the circuit. With a matched resistor network, the load current of the circuit is shown by [Equation 3](#):

$$I_L = \frac{(R_2 + R_3) / R_1}{R_3} \times V_{REF} \times \frac{D}{4096} \quad (3)$$

The value of R_3 in [Equation 3](#) can be reduced to increase the output current drive of U_3 . U_3 can drive $\pm 20\text{mA}$ in both directions with voltage compliance limited up to 15V by the U_3 voltage supply. Elimination of the circuit compensation capacitor C_1 in the circuit is not suggested as a result of the change in the output impedance Z_O , according to [Equation 4](#):

$$Z_O = \frac{R_1' R_3 (R_1 + R_2)}{R_1 (R_2' + R_3') - R_1' (R_2 + R_3)} \quad (4)$$

As shown in [Equation 4](#), with matched resistors, Z_O is infinite and the circuit is optimum for use as a current source. However, if unmatched resistors are used, Z_O is positive or negative with negative output impedance being a potential cause of oscillation. Therefore, by incorporating C_1 into the circuit, possible oscillation problems are eliminated. The value of C_1 can be determined for critical applications; for most applications, however, a value of several pF is suggested.

8.2 Typical Application

8.2.1 Single Supply Unipolar Multiplying DAC

Copyright © 2016, Texas Instruments Incorporated

Figure 33. Complete Circuit Schematic

8.2.1.1 Design Requirements

This multiplying DAC (MDAC) circuit outputs unipolar voltages from 0 V to 2.5 V. This design does not require dual supplies to realize a unipolar, positive output voltage. This design removes the need for a negative supply rail by applying a bias voltage the output transimpedance stage.

8.2.1.2 Detailed Design Procedure

The DAC7811 output current is converted into a voltage by including an op-amp in a transimpedance configuration at the DAC7811 current output terminal. The transimpedance stage creates an output voltage with opposite polarity to that of VREF and subsequently requires dual supplies. This circuit removes the need of dual power supplies and uses a single supply to power the circuit.

The transfer function from digital code to output voltage is shown in Equation 5.

$$V_{OUT}(Code) = V_{BIAS} - \frac{(V_{REF} - V_{BIAS})}{2^{bits}} \times Code \quad (5)$$

More information regarding this design can be found in [Single-Supply Unipolar Multiplying DAC Reference Design \(TIDU300\)](#).

8.2.1.3 Application Curve

The Absolute error (TUE) in %FSR is shown the following graph, [Figure 34](#). The plot below represents data ranging from code 30 to 4050. The figure shows the absolute error (TUE) has a maximum value of about 0.05% FSR.

Typical Application (continued)

Figure 34. Absolute Error (TUE) in %FSR

9 Power Supply Recommendations

The DAC7811 can operate within the specified supply voltage range of 2.7 V to 5.5 V. The power applied to VDD should be well regulated and low noise. Switching power supplies and DC-DC converters often have high frequency glitches or spikes riding on the output voltage. In addition, digital components can create similar high-frequency spikes. This noise can easily couple into the DAC output voltage through various paths between the power connections and analog output. To further minimize noise from the power supply, a strong recommendation is to include a 1- μ F to 10- μ F capacitor and 0.1- μ F bypass capacitor. The required supply current vs Logic Input voltage or temperature is displayed in [Typical Characteristics](#). The power supply must meet the aforementioned current requirements.

10 Layout

10.1 Layout Guidelines

A precision analog component requires careful layout, the list below provides some insight into good layout practices.

- All Power Supply pins should be bypassed to ground with a low ESR ceramic bypass capacitor. The typical recommended bypass capacitance is 0.1 to 0.22- μ F ceramic with a X7R or NP0 dielectric.
- Power supplies and VREF bypass capacitors should be placed close to terminals or planes to minimize inductance and optimize performance.
- A high-quality ceramic type NP0 or X7R is recommended for its optimal performance across temperature, and very low dissipation factor.
- The digital and analog sections should have proper placement with respect to the digital pins and analog pins of the DAC7811 device. The separation of analog and digital blocks will allow for better design and practice as it will ensure less coupling into neighboring blocks, and will minimize the interaction between analog and digital return currents.

10.2 Layout Example

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSELETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
