Design Description

Instrumentation amplifiers are a common way of translating low level sensor outputs to high level signals to drive an ADC. Typically, instrumentation amplifiers are optimized for low noise, low offset, and low drift. Unfortunately, the bandwidth of many instrumentation amplifiers may not be sufficient to achieve good settling to ADC charge kickback at maximum sampling rates. This document shows how sampling rate can be adjusted to achieve good settling. Furthermore, many instrumentation amplifiers are optimized for high-voltage supplies and it may be required to interface the high-voltage output (that is, ±15V) to a lower voltage ADC (for example, 5V). This design shows how to use Schottky diodes and a series resistor to protect the ADC input from an overvoltage condition. Note that the following circuit shows a bridge sensor, but this method could be used for a wide range of different sensors. A modified version of this circuit, Driving a Switched-Capacitor SAR With a Buffered Instrumentation Amplifier shows how a wide bandwidth buffer can be used to achieve higher sampling rate.

This circuit implementation is applicable to all Bridge Transducers in PLC’s and Analog Input Modules that require Precision Signal-Processing and Data-Conversion.

Design Notes

1. Select the gain to achieve an input swing that matches the input range of the ADC. Use the instrumentation amplifier reference pin to shift the signal offset to match the input range. This is covered in the component selection section.

2. The input Schottky diode configuration is used to prevent driving the input voltage outside of the absolute maximum specifications. The BAT54S Schottky is a good option for design as this device integrates both diodes into one package and the diodes are low leakage and have a low forward voltage. This is covered in the component selection section.

3. The buffer amplifier following the voltage divider is required for driving the reference input of most instrumentation amplifiers. Choose precision resistors and a precision low-offset amplifier as the buffer. Refer to Selecting the right op amp for more details on this subject.

4. Check the common-mode range of the amplifier using the Common-Mode Input Range Calculator for Instrumentation Amplifiers software tool.

5. Select C0G capacitors for C_{CM1}, C_{CM2}, C_{DF}, and C_{filt} to minimize distortion.

6. Use 0.1% 20ppm/°C film resistors or better for the gain set resistor R_g. The error and drift of this resistor will directly translate into gain error and gain drift.

7. The TI Precision Labs – ADCs training video series covers methods for selecting the charge bucket circuit R_{filt} and C_{filt}. Although this method was designed for op amps, it can be modified for instrumentation amplifiers. Refer to Introduction to SAR ADC Front-End Component Selection for details on this subject.
Component Selection

1. Find the gain set resistor for the instrumentation amplifier to set the output swing to 0.2V to 4.8V.

\[ \text{Gain} = \frac{V_{\text{out\_max}} - V_{\text{out\_min}}}{V_{\text{in\_max}} - V_{\text{in\_min}}} = \frac{4.9V - 0.2V}{5mV - (-10mV)} = 306.7 \]

\[ \text{Gain} = 1 + \frac{49.4k\Omega}{R_g} \]

\[ R_g = \frac{49.4k\Omega}{\text{Gain} - 1.0} = \frac{49.4k\Omega}{306.7 - 1.0} = 151.6\Omega \text{ or } 162\Omega \text{ for standard 0.1% resistor} \]

2. Find the INA826 reference voltage \((V_{\text{ref}})\) to shift the output swing to the proper voltage level.

\[ V_{\text{out}} = \text{Gain} \cdot V_{\text{in}} + V_{\text{ref\_INA}} \]

\[ V_{\text{ref\_INA}} = V_{\text{out}} - \text{Gain} \cdot V_{\text{in}} - 4.8V - \left(1 + \frac{49.4k\Omega}{162\Omega}\right) (5mV) = 3.27V \]

3. Select standard value resistors to set the INA826 reference voltage \((V_{\text{ref}} = 3.27V)\). Use Analog Engineer's Calculator ("Passive\: Find Voltage Divider" section) to find standard values for the voltage divider.

\[ V_{\text{ref\_INA}} = \frac{R_2}{R_1 + R_2} V_{\text{in\_div}} = \frac{21.5k\Omega}{11.3k\Omega + 21.5k\Omega} (5V) = 3.277V \]

4. Use the Common-Mode Input Range Calculator for Instrumentation Amplifiers to determine if the INA826 is violating the common-mode range.
DC Transfer Characteristics

The following graph shows a linear output response for inputs from –5mV to +15mV. Refer to Determining a SAR ADC’s Linear Range when using Instrumentation Amplifiers for detailed theory on this subject. Note that the output range is intentionally limited to –0.12V to 5.12V using Schottky diodes to protect the ADS8860. Note that Schottky diodes are used because the low forward voltage drop (typically less than 0.3V) keeps the output limit very near the ADC supply voltages. The absolute maximum rating for the ADS8860 is –0.3V < Vin < REF +0.3V.

![DC Transfer Characteristic Graph]

AC Transfer Characteristics

The bandwidth is simulated to be 20.1kHz, and the gain is 49.7dB which is a linear gain of 305.8. See the video series on Op Amps: Bandwidth 1 for more details on this subject.

![AC Transfer Characteristic Graph]
Transient ADC Input Settling Simulation

The following simulation shows settling to a +15mV dc input signal. This type of simulation shows that the sample and hold kickback circuit is properly selected. Refer to Introduction to SAR ADC Front-End Component Selection for detailed theory on this subject.

Noise Simulation

The following simplified noise calculation is provided for a rough estimate. We neglect noise from the OPA192 as the instrumentation amplifier is in high gain, so its noise is dominant.

\[
E_n = \text{Gain} \sqrt{\sum \frac{E_{NO}^2}{\text{Gain}}} \sqrt{\frac{1}{f}}
\]

\[
E_n = (305.8) \sqrt{\left(18 \text{HV} / \sqrt{\frac{1}{f}}\right)^2 + \left(\frac{110 \text{nV} / \sqrt{\text{Hz}}}{305.8}\right)^2} \sqrt{1.57(20.3 \text{kHz})} = 978 \text{uV} / \sqrt{\text{Hz}}
\]

Note that calculated and simulated match well. Refer to TI Precision Labs - Op Amps: Noise 4 for detailed theory on amplifier noise calculations, and Calculating the Total Noise for ADC Systems for data converter noise.
Optional Input Filter

The following figure shows a commonly used instrumentation amplifier input filter. The differential noise is filtered with $C_{\text{dif}}$, and the common-mode noise is filtered with $C_{\text{cm1}}$ and $C_{\text{cm2}}$. Note that it is recommended that $C_{\text{dif}} \geq 10C_{\text{cm}}$. This prevents conversion of common-mode noise to differential noise due to component tolerances. The following filter was designed for a differential cutoff frequency of 15kHz.

Let $C_{\text{dif}} = 1\, \text{nF}$ and $f_{\text{dif}} = 15\, \text{kHz}$

$$R_{\text{in}} \leq \frac{1}{4 \cdot \pi \cdot f_{\text{dif}} \cdot C_{\text{dif}}} = \frac{1}{4 \cdot \pi \cdot (15\, \text{kHz}) \cdot (1\, \text{nF})} = 5.305\, \text{k}\Omega \text{ or } 5.23\, \text{k}\Omega \text{ for } 1\% \text{ standard value}$$

$$C_{\text{cm}} = \frac{1}{10} \cdot C_{\text{dif}} = 100\, \text{pF}$$

$$f_{\text{cm}} = \frac{1}{2 \cdot \pi \cdot R_{\text{in}} \cdot C_{\text{cm}}} = \frac{1}{2 \cdot \pi \cdot (5.23\, \text{k}\Omega) \cdot (100\, \text{pF})} = 304\, \text{kHz}$$

$$f_{\text{dif}} = \frac{1}{4 \cdot \pi \cdot R_{\text{in}} \left( C_{\text{dif}} + \frac{1}{2} C_{\text{cm}} \right)} = \frac{1}{4 \cdot \pi \cdot (5.23\, \text{k}\Omega) \left( 1\, \text{nF} + \frac{1}{2} \cdot 100\, \text{pF} \right)} = 14.5\, \text{kHz}$$
