Design Description

This circuit performs a ±12-V isolated voltage sensing measurement utilizing the ISO224 isolated amplifier, TLV9002 operational amplifier, and the ADS7142 SAR ADC. The ISO224 can measure single-ended signals of ±12V with a fixed gain of ½V/V and produces a ±4-V isolated differential output voltage with an output common-mode voltage of VDD2 / 2. Channel 1 of the TLV9002 conditions the output of the ISO224 to fit the input range of the ADS7142, while Channel 2 monitors the ISO224 fail-safe output. The ADS7142 is a dual-channel ADC with a full-scale input and reference voltage of AVDD which can range from 1.65V to 3.6V. For this cookbook circuit, the ADS7142 dual-channel input will be used in a pseudo-differential configuration which allows for both positive and negative signals to be measured by the ISO224. This circuit is applicable to many high Voltage industrial applications such as Train Control & Management Systems, Analog Input Modules, and Inverter & Motor Control. The equations and explanation of component selection in this design can be customized based on system specifications and needs.

Design Notes
1. The ISO224 was selected due to its wide input range, flexible power configuration, and high accuracy.
2. The ADS7142 was selected due to its very low power, high level of integration, flexible power configurations, and small size.
3. The TLV9002 operational amplifier was selected for its cost optimization, configuration options, and small size.
4. Select low impedance, low noise sources for AVDD, V_CM, and the pseudo-differential input to AINN which sets the common-mode voltage of the ADC.
5. Find the ADC full-scale range and common-mode specifications. This is covered in component selection.
6. Select a COG capacitor for C_FILT to minimize distortion.
7. For best performance, consider using a 0.1% 20ppm/°C film resistor for R_FILT1,2 or better, to minimize distortion.
8. Understanding and Calibrating the Offset and Gain for ADC Systems covers methods for error analysis. Review the link for methods to minimize gain, offset, drift, and noise errors.
9. The TI Precision Labs - ADCs training video series covers methods for selecting the charge bucket circuit R_FILT and C_FILT. These component values are dependent on the amplifier bandwidth, data converter sampling rate, and data converter design. The values shown here will give good settling and AC performance for the amplifier and data converter in this example. If the design is modified, a different RC filter must be selected. Refer to Introduction to SAR ADC Front-End Component Selection for an explanation of how to select the RC filter for best settling and AC performance.
Component Selection

1. Select an isolated amplifier based on the input voltage range and determine the output common-mode voltage and output voltage range:

   The **ISO224** power supplies can be 4.5V to 18V for the high-side power supply, and 4.5V to 5.5V for the low-side power supply. The ISO224 has a ±12V single-ended input range with a fixed gain of \(\frac{1}{3}V/V\), yielding ±4V differential output at a common-mode voltage of \(VDD2 / 2\), +2.5V for this example:

   \[
   \frac{\pm 12 \text{V}_{\text{IN, Single-Ended}}}{3} = \pm 4 \text{V}_{\text{OUT, Differential}} @ 2.5 \text{V} \left(\frac{VDD2}{2}\right) \text{ common-mode}
   \]

2. Select an ADC with small size and low power:

   The **ADS7142** is a small sized, low power, dual channel ADC that can be used in a pseudo-differential configuration. The max input range is set by the reference voltage and is equal to AVDD, 3.3V for this example:

   \[
   \text{ADC}_{\text{Full-Scale Range}} = V_{\text{REF}} = AVDD = 3.3 \text{V}
   \]

   Find the required ADC common-mode voltage for pseudo-differential measurements:

   \[
   V_{CM} = \frac{V_{\text{REF}}}{2} = 1.65 \text{V}
   \]

3. Select an operational amplifier that can convert the ±4V differential, +2.5-V common-mode output of the ISO224 to the 3.3-V pseudo-differential, 1.65-V common-mode input of the ADS7142. Additionally, selecting an operational amplifier with a second channel that can monitor the fail-safe output feature of the ISO224 is preferred:

   The **TLV9002** is a 2 channel, rail-to-rail input and output amplifier optimized for cost sensitive and small size applications.

   Channel 1 is used to convert the ±4-V differential, +2.5-V common-mode output of the ISO224 to a 3.3-V peak pseudo-differential output with a common-mode voltage of 1.65 V. When \(R1 = R4\) and \(R2 = R3\), the transfer function is set by the following equation:

   \[
   V_{OUT} = V_{OUTP} \left(\frac{R4}{R3}\right) + V_{OUTN} \left(\frac{R1}{R2}\right) + V_{CM}
   \]

   The signal must be converted from ±4V to 3.3V, this means that the signal must be reduced by a factor of 3.3V/±4V = 3.3V/8V. Substituting \(V_{CM}\) with the previously calculated value of 1.65V and setting \(R2\) and \(R3\) to an easy to work with 10 k\(\Omega\) yields the following equations:

   \[
   3.3V = 4V \left(\frac{R4}{10k\Omega}\right) + 1.65V \quad 0V = -4V \left(\frac{1}{10k\Omega}\right) + 1.65V
   \]

   Solving for \(R1\) and \(R4\) yields values of 4.125 k\(\Omega\).

   Additional information on this topic can be seen in the Interfacing a Differential-Output (Isolated) Amplifier to a Single-Ended Input ADC tech note.

   Channel 2 of the TLV9002 is used to monitor the fail-safe output feature of the ISO224. The ISO224 fail-safe output feature becomes active whenever the high-side power supply, \(VDD1\), is missing independent of the input signal on the \(V_{IN}\) pin. The TLV9002 channel 2 output, VCOMP, is fed to a GPIO port on the system controller and goes high whenever the Fail-Safe output feature is active. For additional details please see the Fail-Safe Output Feature application note.

4. Select \(R_{\text{1FILT}}, R_{\text{2FILT}},\) and \(C_{\text{FILT}}\) for settling of the input signal and sample rate of 140kSPS:

   Refine the \(R_{\text{FILT}}\) and \(C_{\text{FILT}}\) Values is a TI Precision Labs video showing the methodology for selecting \(R_{\text{FILT}}\) and \(C_{\text{FILT}}\). The final value of 1.1 k\(\Omega\) and 330pF proved to settle to well below \(\frac{1}{2}\) of a least significant bit (LSB) within the acquisition window.
**DC Transfer Characteristics**

The following graphs show the simulated inputs of the TLV9002 and the ADS7142 from a ±15-V input signal to the ISO224. The ISO224 has a linear output of ±VIN/3 and the input to the TLV9002 can be seen in the first graph. The second graph shows that the TLV9002 further reduces the gain by VIN / 2.43 and shifts the common mode to 1.65V. This results in the full-range ±12-V input signal utilizing the 0V–3.3V full-scale range (FSR) of the ADC with AVDD = VREF = 3.3V.

The following transfer function shows that the gain of the ISO224 and TLV9002 is 1/7.28 V/V.

\[
\frac{1}{3} \cdot \frac{1}{2.43} \cdot 12V = \frac{1}{7.28} \cdot 12V = 1.65V
\]
AC Transfer Characteristics

The simulated bandwidth of the signal chain is approximately 145kHz and the gain is –17.25dB which is a linear gain of approximately 0.137V/V (attenuation ratio 1/7.28V/V). This matches the expected gain of the system.

![AC Transfer Characteristics Graph]

Transients ADC Input Settling Simulation

The following simulation shows the transient settling results with an acquisition time of 5.3μs. The 88μV of noise is well within the 0.5 · LSB limit of 403μV. See Refine the Rfilt and Cfilt Values for detailed theory on this subject.

![Transient ADC Input Settling Simulation Graph]
Noise Simulation

The simulated noise seen at the input of the ADC is greater than the expected calculated noise. This difference is due to noise peaking in the simulation model which is not included in the calculation. The following equations show that the ISO224 noise dominates the signal chain, and that the noise from the TLV9002 is negligible. Refer to Calculating the Total Noise for ADC Systems for detailed theory on this subject.

\[
E_n = \text{Gain}(e_n) \sqrt{(1.57 \cdot BW)}
\]

\[
E_{n_{\text{ISO224A}}} = \frac{1}{3} \cdot \frac{1}{2.43} \cdot (4 \mu V / \sqrt{\text{Hz}}) \cdot \sqrt{1.57 \cdot 1.45 \text{kHz}} = 262 \mu V_{\text{RMS}}
\]

\[
E_{n_{\text{TLV9002}}} = \frac{1}{2.43} \cdot (27 \mu V / \sqrt{\text{Hz}}) \cdot \sqrt{1.57 \cdot 1.45 \text{kHz}} = 5 \mu V_{\text{RMS}}
\]

\[
E_{n_{\text{ISO224A+TLV9002}}} = E_{n_{\text{ISO224A}}} + E_{n_{\text{TLV9002}}} = \sqrt{262^2 \mu V_{\text{RMS}} + 5^2 \mu V_{\text{RMS}}} = 262 \mu V_{\text{RMS}}
\]

Total Noise = 526 \mu V_{\text{RMS}}
