Many signals are digitally generated or transmitted as square waves. It is often desirable to convert these signals into sine waves. For example, the 350Hz, 440Hz, 480Hz, and 620Hz telephone supervisory tones transmitted over fiber-optics may appear at curb-side as square waves. To be used in telephone equipment it is desirable to convert the square waves into low-distortion sine waves. This can be done with a simple filter.

According to its Fourier series, a 50% duty-cycle square wave consists of odd order harmonic sine waves with the fundamental at the same frequency as the square wave.

\[
\frac{4k}{\pi} \left( \sin x + \frac{1}{3} \sin 3x + \frac{1}{5} \sin 5x + \cdots \right)
\]

where \( k \) = peak amplitude of the square wave

A sine wave with the same frequency as the square wave can be gleaned by filtering out the harmonics above the fundamental. A “tuned-circuit” bandpass filter with a Q of 10 attenuates signals at three times the bandpass frequency by 28.4dB. Since the amplitude of the third harmonic is 1/3 that of the fundamental, the total attenuation of the third harmonic compared to the fundamental is nearly 40dB. The result is a low distortion sine wave as shown in Figure 1A. Notice that although the filter has unity gain, the amplitude of the sine wave output signal is greater than that of the square wave. This is because the fundamental has an amplitude of \( 4/\pi \) times that of the square wave as shown by the Fourier series. The bandpass filter will also filter out any DC component of the square wave input as shown in Figure 1B.

The circuit for a “tuned-circuit” bandpass filter using a Burr-Brown UAF42 universal active filter chip is shown in Figure 2. The UAF42 contains op amps, gain-set resistors, and on-chip precision (0.5%) 1000pF capacitors to form a time continuous filter, free from the anomalies and switching noise associated with switched-capacitor filters. The only external components required are three 1% resistors to set center frequency and Q. In this example, resistors are selected to produce a “tuned-circuit” bandpass filter simulating a tuned-circuit response with 350Hz center frequency and Q = 10. A computer-aided design program, FilterPro, is available free of charge from Burr-Brown to make it easy to design all kinds of active filters using the UAF42.

To design a “tuned-circuit” bandpass filter with Q = 10: load FilterPro FILTER42, select Bandpass filter response, select Order \( n = 2 \), set the desired center frequency (\( f_{\text{CENTER}} \)), and set the bandwidth to 1/10 the center frequency. You can plot the filter response and print out component values.

A fourth, auxiliary, op amp in the UAF42 is available for use in other circuitry. If the auxiliary op amp is not used, connect it as a unity-gain follower with the input to ground (connect –IN to VOUT and +IN to ground).

**FIGURE 1. Low Distortion Sine Wave.**
Mismatches between the frequency of the input square wave and the center frequency of the bandpass filter will affect the sine wave output. Figure 3 shows measured sine wave output total harmonic distortion (THD) and gain variation for mismatches from 0 to ±5%. A typical mismatch of 1% gives less than 1.5% THD and less than 2% gain deviation.

Variations of the square-wave duty cycle from 50% will also increase distortion due to second-order harmonic content. In applications with a pulse train or other non-50% duty cycle square wave, it may be desirable to place an inexpensive divide by two digital flip-flop ahead of the filter to assure a 50% duty cycle square-wave input.
