ABSTRACT

Digital power controller UCD3138 filter is a PID filter, which includes proportion branch, integral branch and differential branch. A register at the output of integrator, named KI_YN, supports write and read operations. In application, writing this register could make the DPWM change rapidly, which is convenient for some designs. The KI_STALL register in the integrator stalls its elements at the current value. It is useful for suppressing response to transients when such response is not desirable. This application note provides the guidance of applying the integrator, as well as several real experimental tests.

1 UCD3138 PID Filter and Integral Branch

1.1 UCD3138 PID Filter

Figure 1 shows a block diagram of the first part of the filter, PID architecture. The UCD3138 PID filter includes proportional branch, integral branch, and differential branch. All values shown in the filter are signed numbers. The main input to the filter is a 9-bit signed value from an Error ADC. The main input is shown as XN at the upper-left of Figure 1. The sum of the output of these branches determines the DPWM duty, which is implemented at the cascaded parts of PID filter.

The XN value, or the XN + XN-1 sum is multiplied by the KI coefficient. The output of this multiplication always fits within 24 bits. This value is then added to the existing KI_YN value. The hardware automatically clamps KI_YN value at a 24-bit signed number, and high and low clamp registers (KI_CLAMP_HIGH and KI_CLAMP_LOW) are available which can be used to clamp KI_YN value to lower values. If the value of KI_YN is between KI_CLAMP_HIGH and KI_CLAMP_LOW, the output value of the integrator is exactly the value in KI_YN.

1.2 Integrator Branch

The XN value, or the XN + XN-1 sum is multiplied by the KI coefficient. The output of this multiplication always fits within 24 bits. This value is then added to the existing KI_YN value. The hardware automatically clamps KI_YN value at a 24-bit signed number, and high and low clamp registers (KI_CLAMP_HIGH and KI_CLAMP_LOW) are available which can be used to clamp KI_YN value to lower values. If the value of KI_YN is between KI_CLAMP_HIGH and KI_CLAMP_LOW, the output value of the integrator is exactly the value in KI_YN.
2 The Application of Writing KI_YN

2.1 Change DPWM Duty by Modifying XN

When the power supply is in regulation, the XN is relatively small, hence the output of proportional branch and differential branch are both closed to 0. But, the output of integrator is extremely large. When the XN is modified, the integrator performs calculation and refreshes the output. After a certain period of time, the output is stable with the new value. According to this, the DPWM duty needs a certain time to finish its change. This certain period of time is determined by the coefficients of PID.

Design an experiment to demonstrate. Run open-loop firmware, and change XN from initial 100 to -30. Meanwhile, measure the time that DPWM duty finishes its change. The firmware design follows. Send the PMBus command to trigger the change of XN. DPWM3A is configured to GPIO, used to indicate when the XN is rewritten.

```c
Uint8 pmus_write_iode_config(void)
{
    int i,j,k;
    Filter0Regs.CPUXN.bit.CPU_SAMPLE = -30;
    Dpmw3Regs.DPWMCTRL1.bit.GPIO_A_VAL = 0;
    for (i=0;i<5000;i++)
    {
        for (j=0;j<40;j++)
        {
            Dpmw3Regs.DPWMCTRL1.bit.GPIO_B_VAL = 0;
            Dpmw3Regs.DPWMCTRL1.bit.GPIO_B_VAL = 1;
            Dpmw3Regs.DPWMCTRL1.bit.GPIO_B_VAL = 0;
            Dpmw3Regs.DPWMCTRL1.bit.GPIO_B_VAL = 1;
            Dpmw3Regs.DPWMCTRL1.bit.GPIO_B_VAL = 0;
            Dpmw3Regs.DPWMCTRL1.bit.GPIO_B_VAL = 1;
            Dpmw3Regs.DPWMCTRL1.bit.GPIO_B_VAL = 0;
            Dpmw3Regs.DPWMCTRL1.bit.GPIO_B_VAL = 1;
        }
    }
    Dpmw3Regs.DPWMCTRL1.bit.GPIO_A_VAL = 1;
    return PMBUS_SUCCESS;
}
```

Figure 2 shows the waveform. CH1 indicates the DPWM1A, which is controlled by Filter0; CH2 indicates the DPWM3A. After 3.5 ms of XN being written when DPWM3A turns low, the DPWM1A duty finishes its change. This experiment indicates that, using the way of modifying XN, DPWM needs a certain amount of time to complete its change.
2.2 Change DPWM Duty by Modifying KI_YN

Modifying KI_YN can rapidly change the DPWM duty.
Design an experiment to demonstrate. Run open-loop firmware, and write KI_YN directly. The firmware
design follows. The value of 0xd99039 is the corresponding value when XN is -30.

```c
UInt8 pmbus_write_i2e_config(void)
{
    Filter0Regs.CPU3YN.bit.CPU_SAMPLE = -30;
    Dpwm3Regs.DPWMCTRL1.bit.GPI0_A_VAL = 0;

    LoopMaxRegs.SAMPTRIGCTRL.bit.FE0_TRIG_DPWM0_EN = 0;
    Filter0Regs.FILTERPRESET.all = (1 << 27) + (1 << 24) + 0xd99039;
    LoopMaxRegs.SAMPTRIGCTRL.bit.FE0_TRIG_DPWM0_EN = 1;

    Dpwm3Regs.DPWMCTRL1.bit.GPI0_A_VAL = 1;

    return PMBUS_SUCCESS;
}
```

Figure 3 shows the waveform. CH1 indicates the DPWM1A, which is controlled by Filter0; CH2
indicates the DPWM3A. After KI_YN is written when DPWM3A turns low, the DPWM1A duty finishes its
change rapidly. This experiment indicates that, using the way of modifying KI_YN, DPWM duty can
rapidly complete its change.
2.3 Pre-bias Design

If the output voltage is not 0 V when the power supply with synchronous rectification restarts, the pre-bias is essential. In the power supply based on UCD3138, the pre-bias can design by step and step as below:

1. Acquire the current input voltage and output voltage.
2. Calculate the reference voltage, and then write this value to DAC_VALUE.
3. Calculate the integrator output value with DPWM duty, and then write it into KI_YN.

In the third step, we use the approach described in Section 2.2. The firmware design of the pre-bias function follows.

```c
vout = adc_values.Vout;
vdc_prebias = vout * 6.15; // 6.15 is scaler from ADC to DAC
Ferr10Regs.EADC0AC.bit.DAC_VALUE = vdc_prebias;

vout = adc_values.Vout * 6; // output scaler's voltage
vin = (vin_wadc_sns * 30); // input scaler's voltage
duty_prebias = (unsigned int)(((Uint64) vout) << 22) / (Uint64)vin;

LoopMuxRegs.SAMPTRICCTRL.bit.FEO_TRIG_DPWMO_EN = 0; // Stop triggering EADC2/Filter2
Filter0Regs.FILTER0PRES.set(1 << 77); // Write preset value;
LoopMuxRegs.SAMPTRICCTRL.bit.FEO_TRIG_DPWMO_EN = 1; // Resume triggering EADC2/Filter2
Ferr10Regs.RAMPCTRL.bit.FIRMWARE_START = 1;
```

Figure 4 shows the waveform. When the power supply restarts, the output voltage is 2.4 V. After soft-start, the output arrives to its target value, 12 V. During this phase, there is no sharp dip at the output voltage, which indicates the pre-bias works well.
3 Stall Calculation of Integral Branch

3.1 Introduction

Stall calculation of integral branch means to freeze the integrator. Therefore, the value in KI_YN is preserved. By setting KI_STALL to 1, this function is enabled, and disabled when KI_STALL is 0. Once disable this function, the integral branch restarts its calculation with the preserved KI_YN value.

3.2 Demonstration

Design an experiment to demonstrate. Run open-loop firmware, and change XN from initial 100 to -30. Before this change, enable the stall by writing 1 into KI_STALL.

```c
Uint8 pmos_write_iode_config(void)
{
    int i;
    filter0Regs.FILTERCTRL.bit.KI_STALL = 1;
    filter0Regs.CROSS.bit.CROSS_SAMPLE = -30;
    ipmsReg0.DPWMCTRL1.bit.OP10_A_VAL = 0;
    for (i=0; i<500; i++)
    {
        ipmsReg0.DPWMCTRL1.bit.OP10_B_VAL = 0;
        ipmsReg0.DPWMCTRL1.bit.OP10_B_VAL = 1;
        ipmsReg0.DPWMCTRL1.bit.OP10_B_VAL = 0;
        ipmsReg0.DPWMCTRL1.bit.OP10_B_VAL = 1;
        ipmsReg0.DPWMCTRL1.bit.OP10_B_VAL = 0;
        ipmsReg0.DPWMCTRL1.bit.OP10_B_VAL = 1;
    }
    ipmsReg0.DPWMCTRL1.bit.OP10_A_VAL = 1;
    return PWM_SUCCESS;
}
```

Figure 5 shows the waveform. CH1 indicates the DPWM1A, which is controlled by Filter0; CH2 indicates the DPWM3A. After about 40 ms of XN being changed, the DPWM1A duty is still mainained. Meanwhile, reading the KI_YN value with Memory Debugger, it shows this value does not change. This unchanged value indicates that after enabling KI_STALL, the KI_YN is, indeed, preserved.
Redesign the firmware, and add the code of setting KI_STALL to 0. This effort intends to check whether or not the integral branch restarts its calculation value with the preserved value before.

```c
}

Filter0Regs.FILTERCTRL.bit.KI_STALL = 0;
Dpwm0Regs.DPWMCTRL.bit.GPIO_A VAL = 1;

return PAMBUS_SUCCESS;
}
```

Figure 6 shows the waveform. After approximately 3.5 ms of KI_STALL being set 0, when DPWM3A turns high, the duty of DPWM1A changes. This indicates that the integrator restarts its calculation.
4 Conclusion

Writing KI_YN directly, the DPWM duty can be changed rapidly. In some scenarios, this makes the design more convenient, such as the pre-bias mentioned in this document.
Stall calculation of integral branch is a flexibility feature. This feature can be of great assistance to designs which must preserve the KI_YN.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as “components”) are sold subject to TI’s terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or “enhanced plastic” are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have not been so designated is solely at the Buyer’s risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
