Low-cost current-shunt monitor IC revives moving-coil meter design

By Thomas Kugelstadt (Email: tk@ti.com)
Senior Systems Engineer, Industrial Systems

Despite their lack of resolution and accuracy in comparison to digital meters, analog moving-coil meters remain the display of choice when it comes to tracking a reading’s trend or drawing information upon a measurement’s rate of change. For low-level current measurements, however, the meter current for a full-scale deflection usually exceeds the current to be measured, and a separate supply driving the meter is required. Analog meters of the past, such as the Multavi-10 from Hartmann & Braun, solved this problem by implementing a rechargeable accumulator as the meter supply. Manually selectable shunt resistors in combination with a high-precision chopper amplifier allowed the user to choose from thirteen different current ranges between 1 µA and 1 A.

With the introduction of modern current-shunt monitor ICs such as the INA19x family, the amplifier design of moving-coil meters has been drastically simplified. Figure 1 shows the drive circuit of an 8-inch moving-coil meter measuring a current range from 0 to 100 mA. The meter current for a full-scale deflection is 15 mA. The current-shunt monitor, INA193, senses the voltage drop across the 1-Ω shunt resistor, \( R_{S1} \). At a maximum current of 100 mA, the voltage across \( R_{S1} \) is 100 mV.

The value chosen for \( R_{S1} \) depends on the application and is a compromise between small-signal accuracy and maximum permissible voltage drop in the measurement line. High values of \( R_{S1} \) provide better accuracy at lower currents by minimizing the effects of offset, while low values of \( R_{S1} \) minimize voltage loss in the supply line. For most applications, the best performance is attained with an \( R_{S1} \) value that provides a full-scale shunt voltage range of 50 to 100 mV. The maximum input voltage for accurate measurements is 500 mV.

In this example, the INA193 amplifies the 100-mV full-scale input by a gain factor of 20 V/V, thus providing a full-scale output of 2 V. The succeeding operational amplifier, OPA344, possesses rail-to-rail inputs and outputs; it operates in conjunction with the N-channel MOSFET, BSN254, as a voltage-controlled current source.

Note that the entire meter circuit, including the INA193, operates from a single 5-V supply, which also limits the maximum output voltage swing of the OPA344 to 5 V. It therefore is necessary to choose a MOSFET with a low gate-source threshold voltage, \( V_{GS} \), since this voltage subtracts from the amplifier output swing. The BSN254 has a maximum threshold voltage of 2 V, which satisfies the
low-$V_{GS}$ requirement. Because the voltage at the non-inverting OPA344 input equals the one at the inverting input, the full-scale output of 2 V lies across $R_{S2}$. To allow for the maximum deflection current to flow, $R_{S2}$ is calculated via

$$R_{S2} = \frac{V_{OUT(FS)}}{I_{Meter(FS)}} = \frac{2 \text{ V}}{15 \text{ mA}} = 133 \Omega.$$

$R_{S2}$ can be adjusted to calibrate the meter or to change its full-scale current range. $R_{S1}$ can be adjusted to increase low-current measurement accuracy or to extend the measurement range to higher current values. Another benefit of the circuit is that the meter can be separated from the point of measurement. Because moving-coil meters are not intended for high-precision measurements, the designer can use relaxed-accuracy resistors. Bypassing the instrument supply with decoupling capacitors is necessary to avoid stray pickup from the electrical-noise environment.

**About the INA19x current-shunt monitor**

The INA193 is just one member of a family of current-shunt monitors. The INA194 and INA195 are members that have the same pinout but provide different gains of 50 V/V and 100 V/V, respectively. Three other current-shunt monitors, the INA196, INA197, and INA198, are functionally identical but come in a different pinout.

The INA19x family uses a new, unique internal circuit topology that provides a common-mode range extending from $-16 \text{ V}$ to $+80 \text{ V}$ while operating from a single power supply. The common-mode rejection in a classic instrumentation amplifier approach is limited by the requirement for accurate resistor matching. By converting the induced input voltage to a current, the INA19x provides common-mode rejection that is no longer a function of closely matched resistor values, providing the enhanced performance necessary for such a wide common-mode range.

The simplified diagram in Figure 2 shows the basic circuit function. When the common-mode voltage is positive, amplifier $A2$ is active. The differential input voltage, $V_{IN+} - V_{IN-}$, applied across $R_S$, creates the voltage potentials $V_N$ and $V_P$ at $A2$'s inputs:

$$V_N = V_{IN+} - I_S R_S$$
$$V_P = V_{IN+}.$$

To make $V_P = V_N$, $A2$ must drive the transistor so that its collector current, $I_C$, causes a voltage drop across the 5-kΩ resistor that equals the differential input voltage:

$$V_P = V_N$$
$$V_{IN+} - I_C \times 5 \text{ kΩ} = V_{IN+} - I_S R_S$$
$$I_C \times 5 \text{ kΩ} = I_S R_S.$$

![Figure 2. INA19x simplified circuit diagram](image-url)
Expressing $I_C$ through the ratio of output voltage to load resistor,

$$I_C = \frac{V_{OUT}}{R_L},$$

defines the output voltage as

$$V_{OUT} = l_3 R_3 R_L \frac{5 k \Omega}{5 k \Omega}.$$  

When the common-mode voltage is negative, amplifier A1 is active. The differential input voltage, $V_{IN+} - V_{IN-}$, dropped across $R_S$, is converted to a current through a 5-kΩ resistor. A1 then drives a precision current mirror whose output through $R_L$ provides the signal voltage to the output buffer amplifier. Patent-pending circuit architecture ensures smooth device operation, even during the transition period when both amplifiers A1 and A2 are active.

The input pins, $V_{IN+}$ and $V_{IN-}$, should be connected as closely as possible to the shunt resistor to minimize any resistance in series with the shunt resistance. Power-supply bypass capacitors are required for stability. Applications with noisy or high-impedance power supplies may require additional decoupling capacitors to reject power-supply noise. Bypass capacitors should be connected close to the device pins.

The input circuitry of the INA19x can accurately measure beyond its power-supply voltage, $V_+$. For example, the $V_+$ power supply can be 5 V, whereas the load power-supply voltage is up to 80 V. The output voltage range of the OUT terminal, however, is limited by the voltages on the power-supply pin.

The output of the INA19x is accurate within the output-voltage-swing range set by the power-supply pin, $V_+$. This is best illustrated by the INA195 or INA198 (both of which use a gain of 100), where a 100-mV full-scale input from the shunt resistor requires an output voltage swing of $+10$ V and a power-supply voltage sufficient to achieve $+10$ V on the output.

An obvious and straightforward location for filtering is at the output of the INA19x series; however, this location negates the advantage of the internal buffer’s low output impedance. The only other option for filtering is at the input pins of the INA19x, which is complicated by the internal input impedance of 5 kΩ + 30% (see Figure 3). Using the lowest possible resistor values minimizes both the initial shift in gain and the effects of tolerance. The effect on initial gain is given by

$$\text{Gain Error \%} = 100 \left( 100 \times \frac{5 \Omega}{5 \Omega + R_{\text{Filter}}} \right).$$

Total effect on gain error can be calculated by replacing the 5-kΩ term with 5 kΩ – 30% (or 3.5 kΩ) or 5 kΩ + 30% (or 6.5 kΩ). The tolerance extremes of $R_{\text{Filter}}$ can also be inserted into the equation. If a pair of 100-Ω 1% resistors is used on the inputs, the initial gain error will be 1.96%. Worst-case tolerance conditions will always occur at the lower excursion of the internal 5-kΩ (3.5-kΩ) resistor, and at the higher excursion of $R_{\text{Filter}}$ – 3% in this case.

Note that the specified accuracy of the INA19x must then be combined in addition to these tolerances. While this discussion has handled accuracy worst-case conditions by combining the extremes of the resistor values, it is appropriate to use geometric mean or root-sum-square calculations to total the effects of accuracy variations.
