ABSTRACT
Many modern data acquisition systems consist of high-speed, high-resolution ADCs. CMOS-switched, capacitor-based ADCs are often chosen for such designs due to their low cost and low power dissipation. These ADCs use an unbuffered front end directly coupled to the sampling network. To effectively minimize noise and signal distortion, it is necessary to drive the ADC with a high-speed, low-noise, low-distortion operational amplifier. To achieve minimal distortion it is important for the op amp output to settle to the desired accuracy within the acquisition time of the ADC. Normally the op amp settling time is either calculated from the frequency response specified in the datasheet or measured by probing the output with an oscilloscope that has a limitation on resolution. Sometimes the difference between the op amp input and output is amplified to achieve better accuracy. These methods are limited by the oscilloscope resolution or circuit parasitic. Moreover, the settling time of the op amp is affected by the parasitic capacitance and inductance introduced by the oscilloscope probe. In another method, the difference between output and input is amplified to increase the resolution of the measurement. None of these methods includes the parasitic capacitance and inductance present in the ADC sampling circuit and package.

1  **Definition of Settling Time**

*Settling time* is the time elapsed from the application of an ideal instantaneous step input to the time at which the closed-loop amplifier output has entered and remained within a specified symmetrical error band. Settling time includes a very brief propagation delay, plus the time required for the output to slew to the vicinity of the final value, recover from the overload condition associated with slewing, and finally settle to within the specified error. For high-resolution ADCs, the specified error band is usually one fourth of one least significant bit (LSB) of the ADC.

2  **Basic Setup**

The ADC used here is the Texas Instruments (TI) ADS8411, which is a 16-bit, 2-MSPS successive approximation register (SAR) ADC. The driver op amp is the TI THS4031. Figure 1 shows the evaluation setup.

The instantaneous step input is generated with an analog multiplexer (MUX) (the TI TS5A3159) by switching its two channels. A dc voltage, V, is applied to channel 2, and channel 1 is connected to ground; so this setup can produce a step input rising to V from 0 or falling to 0 from V. Alternatively, the step input can be generated from any step generator. The step generator should settle much faster than the op amp settling time.

2.1  **Explanation**

**Step 1**

ADC samples channel 1 (connected to ground) first. A long sampling time is provided to make sure that the input capacitor of the ADC is fully discharged.

**Step 2**

The analog MUX is switched to channel 2 from channel 1 at instant A in Figure 2. This diagram shows the voltage at point S (Figure 1) when the MUX switches over to channel 2 from channel 1. The settling time of the MUX is denoted by ts. It is assumed that ts is much shorter than the op amp settling time.

![Figure 1. Settling Time Evaluation Setup](image1)

![Figure 2. Settling Time for MUX Channel Change](image2)
Step 3

Once the analog MUX is switched at instant A, the input of the op amp starts changing. The output of the op amp starts changing after a very brief propagation delay after instant A. The op amp settling time ($t_{\text{ideal}}$) is approximately calculated from the slew rate and bandwidth specified in the op amp datasheet. The method proposed here plots the op amp output from instant A to instant B (Figure 3). The time difference between instant B and instant A is $2t_{\text{ideal}}$.

![Diagram showing sampling and op amp output](image)

**Figure 3. Averaging n Samples from B to A Increases Accuracy**

Step 4

The first ADC sampling edge appears at instant B, and $n$ number of readings (digital outputs from the ADC) are taken. The $n$ number of readings are averaged for better accuracy (discussed later). Next the sampling edge is shifted to the left by 1 ns (Figure 3) with the help of a pattern generator and an adjustable-delay generator (Figure 1), and again $n$ number of readings are taken. This way the sampling edge is shifted toward the left from instant B to instant A in 1-ns steps. At each sampling edge the average is stored in an element of an array. The array is plotted against the time to get the true picture of the op amp output settling (Figure 3).

2.2 Averaging to Achieve Better Resolution

Input of an $n$-bit ADC should settle to at least $n+2$ bits, but measured output is an $n$-bit digital code from the ADC. The resolution can be increased by repeatedly sampling the same input and taking multiple ($n$) readings from the ADC. Finally an average is taken on the $n$ digital output codes. It can be shown that for each additional bit of resolution, the number of readings should be 4, so $w$ extra bits of resolution require $4^w$ readings.

For each additional bit, the signal-to-noise ratio (SNR) increases by 6.02 dB. In this case the 16-bit ADC should settle with at least 18-bit accuracy.

$$\text{SNR} = 6.02 \times N + 1.76,$$

where $N$ is the ADC resolution. SNR is 110.08 dB for 18-bit accuracy, so an extra bit ($w$) of resolution required is:

$$110.08 - 86^* / 6.02 = 4$$

* Typical SNR specification of ADS8411

The number of samples ($n$) needed for each reading is $4^w = 256$. 

2.3 Results

An RC filter is used at the output of the op amp to filter the external noise. An ADC sampling circuit always consists of another RC (R', C'), as shown in Figure 4.

Figure 5 shows the settling behavior when three different values of an external capacitor are used for RC filtering.

![Figure 4. Typical Noise Filter](image1)

![Figure 5. Input Settling Time With an External Capacitor](image2)

Figure 6 is a zoomed-in version of Figure 5 to show the settling more accurately. While the output code is based on 16-bit sampling, the resolution of the measurement is more than 16-bit because 65536 samples were captured and averaged for each reading. The result shows significant ringing and underdamping of the system when no capacitor was used. Also note that use of a bigger (1000-pF) capacitor significantly increases the settling time.

![Figure 6. Expanded Scale Magnifies Settling-Time Behavior Shown in Figure 5](image3)
A summary of these results is shown in Table 1. Averaging the output data can improve the resolution of the result beyond 16-bit.

**Figure 7. Effects of Changing Feedback Resistors**

### 3 Measurement of Bias Current

Figure 7 shows op amp settling behavior with different values of feedback resistors. The difference between the settled voltages indicates the offset voltage shift caused by bias current. From this the bias current can be calculated as 3 μA, which matches the typical specification of the THS4031. This experiment validates the correctness of this setup.
4 Bias Current Calculation

The settled value with 0 Ω in the feedback is 59595. The settled value with 301 Ω in the feedback is 59610.

\[
\text{Delta (Offset Voltage)} = \text{bias current} \times \text{resistor}
\]

(used in the feedback).

\[
\text{Delta (Offset Voltage)} = \frac{(59610 \times 59595) \times 4.096}{65536} = 938 \mu V
\]

\[
\text{Bias Current} = \frac{938}{301} = 3.12 \mu A
\]

(compared to the datasheet typical specification of 3 μA).

5 Conclusion

This is a practical and simple method to accurately measure the settling time of an ADC driving circuit. The settling behavior is unaffected by the measurement, because no additional component is used for the setup. This method can be implemented as a built-in self-test (BIST) in the future. The averaging of multiple readings improves the accuracy of the result.

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as “components”) are sold subject to TI’s terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI’s terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers’ products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers’ products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI’s goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or “enhanced plastic” are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have not been so designated is solely at the Buyer’s risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
