AN-1737 Managing EMI in Class D Audio Applications

ABSTRACT
Electromagnetic interference (EMI) is an unwanted disturbance caused in an electrical circuit by electromagnetic radiation emitted from an external source. The disturbance may interrupt, obstruct, or otherwise degrade the effective performance of the circuit.

EMI - The Basics

In today’s portable and consumer applications, space has become a premium, and engineers are often required to eliminate enclosures and shielding, and suppress EMI and noise through other means such as better segregation at the circuit level. Smaller space and higher functionality require high-density PCBs, and the use of wafer-scale packaging with tiny PCB design rules makes EMI more of a concern.

EMI encompasses two aspects. Emissions refer to the scope to which equipment generates radiated noise. Susceptibility is the scope to which equipment is affected by emissions generated from other electromagnetic waves. The degree to which a designer controls unintended emissions may make the task of susceptibility easier. Emissions are generally classified as radiated and conducted emissions. Radiated emissions leave a circuit board, trace, or wire, and propagate through the air in the form of electromagnetic waves to interfere with a nearby receiver. It is important to note that a “receiver” refers to any circuit whose operation can be affected adversely by the reception of electromagnetic energy - such as a PCB trace or even the lead of an IC. Conducted emissions refer to energy which escapes, or is conducted, out of a circuit through wires or cables. Conducted emissions may cause problems directly or manifest themselves as radiated emissions.

In order to understand emissions, it is important to understand antennas. In Figure 1, the well-known physical relationship between wavelength and frequency is shown:

\[
\lambda = \frac{\text{Velocity of Light}}{\text{Frequency} \times \sqrt{\varepsilon_r}} = \frac{300}{f \text{ (MHz)} \times \sqrt{\varepsilon_r}}
\]

\(\varepsilon_r\) is the relative permittivity

**Figure 1. Wavelength as a Function of Frequency**

The shortest length required to be an efficient antenna is \(\lambda/4\). In the case of air, permittivity is 1, but in the case of FR4 or glass-epoxy PCBs, permittivity is reduced to approximately 4.8. The effect causes a signal traveling a trace to slow once it reaches the dielectric gradient created by the FR4 material, causing essentially, a "wavelength- shortening" effect. For example, a 200 MHz signal has a quarter wavelength in air of 16.7 cm.

In an inner-layer PCB trace, it is: 16.7/4.8\(^{1/2}\) = 7.6 cm.

A PCB trace can act as an unintentional antenna even at lengths shorter than \(\lambda/4\), increasing both emissions and susceptibility. Surface traces also exhibit this wavelength shortening effect, as one side of the dielectric serves to change the overall permittivity of the transmission.

Unintended antennas, such as PCB traces, are the key culprit behind radiated noise in digital systems. As you will see, the Class D audio amplifier is, in essence, a digital system from the perspective of radiated emissions. One key principle underlying electromagnetism is that of reciprocity. A flow of current can create an electric field, and a change in electric flux can induce a current to flow. Likewise, an antenna that is good for receiving is also good for transmitting. If any of the dimensions of an unintentional antenna approach quarter wavelength at the frequency at which that antenna is excited by noise current, radiated emissions can be expected.

**Figure 2. Common Antennas**
These are two common antenna designs: the simple dipole and whip shown in Figure 2. An interesting observation is that the whip is essentially one half of a dipole with the horizontal ground essentially being induced to act as the other half of a dipole.

Antennas are intended to transmit and receive signals through the radiation of electric energy. But, as illustrated in Figure 3, unintended antennas in circuit boards can include:

- Long traces
- Vias
- Component leads and pins
- Unpopulated PCB board connectors and headers

![Figure 3. Unintended Antennas in PCBs](image)

An unterminated surface trace or an unterminated buried trace can become an unintended whip antenna. Segments of traces at different RF potential due to poor layout can become unintentional dipole antennas. Also, the conductive layers of the PCB can act as the other leg of a dipole antenna with the plane itself being coupled into the electric field.

## 2 The Class D Audio Amplifier

The Class D audio amplifier has emerged as a popular topology for the consumer market due to its high efficiency. It modulates a high-frequency square wave by the incoming analog signal. The square wave itself could be fixed frequency, variable frequency, or simply random pulses with no fixed frequency. A low-pass filter, typically a 2-pole Butterworth, is used to filter the high-frequency content and recover the original audio signal. In "filterless" topologies, the inductance of the speaker itself is incorporated as part of the filter. One common Class D topology, pulse width modulation (PWM), uses a fixed-frequency waveform and changes the duty cycle to create a moving average of the signal after a low-pass filter as seen in Figure 4.

![Figure 4. Class D Audio Amplifier](image)

The benefits of a switching topology are apparent: high efficiency, low power consumption, and small thermal designs. But increased efficiency is not without cost. In order to drive efficiencies up, a sharp, rapidly switching square wave is required. This can lead to the same undesirable artifacts that are present in digital systems as the spectral energy is highly concentrated on the edges of the square wave. Also, there will be some overshoot, causing the waveform to go beyond the maximum and minimum voltages for a short time. Overshoot creates additional high-frequency content in the output spectrum and is undesirable for EMI and audio performance.
Countering EMI

To counter EMI, it is essential to include PCB floor planning as part of the circuit design with the electrical engineer, PCB layout engineer, and manufacturing engineer. General PCB guidelines for dealing with EMI include:

- Placement of decoupling capacitors between power and ground where voltage fluctuations are determined to exist. Haphazard placement of caps can exacerbate the EMI problem. References for the use of decoupling capacitors are included at the end of this application report.
- Power planes should be backed off from the edges of the PCB.
- Avoidance of traces cut within ground or power planes, which can create an unintended aperture.
- Adequate termination of all high-frequency clock lines.
- Proper filtering of PCB connectors.
- Good PCB design will avoid loop antennas. Loop antennas encompass any route in which both forward and return currents are on a well-defined conducting path.

Optimally, you will stop radiation by suppressing the source of current that is feeding the antenna.

For the audio designer, it is important to consider the following:

- Keep traces from the audio amplifier to the speaker as short as possible. PCB traces and wires act as antennas with significant radiation occurring once the trace length reaches $\lambda/4$.
- For filterless Class D systems, the trace and cable length connecting the amplifier’s output to the speakers will likely be the largest source of RF emissions.

The practice of placing ferrite beads in series with the loudspeakers close to the amplifier can be effective. In order to better understand the suppression mechanism of ferrite beads, it is useful to break the ferrite bead down into frequency-dependent resistive and inductive elements - $R(f)$ and $L(f)$ - as shown in Figure 5.

Regarding EMI suppression purposes, ferrite beads act as resistors, but because $R_{DC} = 0$, there is no DC voltage drop. This makes them useful in cases where frequencies of interest are significantly below 1 MHz. Also, as shown in Figure 5, it is important to understand that the ferrite bead is effective when considered part of a two-element voltage divider. Both $Z_1$ and $Z_2$ are frequency dependent. To achieve the desired function of a low-pass filter, the following relationships should be present: $Z_2 > Z_1$ at desired frequencies and $Z_1 > Z_2$ at noise frequencies.
Figure 5. Resistance and Inductance as a Function of Frequency

The ferrite usually serves as the series element, and the shunt element is a capacitance - either a physical capacitance or a lumped capacitance. The transfer function indicates that $Z_1$ increases and $Z_2$ decreases with frequency ($1/j\omega C$) and that the system is damped to the extent that resonance effects are significantly diminished. The primary difficulty with periodic square waves inherent in Class D is the concentration of energy at the harmonic intervals.

In the push to create a "quiet" low-EMI class D amplifier, one approach is to dither that frequency back and forth or spread the spectrum of the switching so the energy at any one point in the spectrum is reduced. Compared to traditional Class D amplifiers, the spread-spectrum-modulation scheme has some key advantages. Efficiency and low THD+N are maintained, but radiated noise and EMI can be significantly reduced, as seen in Figure 6.

Figure 6. Comparison of Fixed-Frequency and Spread-Spectrum Modulation

The LM48511 is a spread-spectrum-modulated class D audio amplifier. It also includes a built-in boost regulator that drives the supply voltage to 7 V, increasing amplifier output power and the audio-sound pressure level compared to an unboosted amplifier. The boost regulator allows the amplifier to maintain a constant output level, even when powered from a decaying voltage source such as a battery.

The LM48511 amplifier features a logic-selectable, spread-spectrum modulator that reduces EMI, eliminating the need for output filters or chokes. As shown in Figure 7, the spread-spectrum modulator feeds a standard H-bridge that drives the bridgetied-load speaker. In spread-spectrum mode, the switching frequency varies randomly by 10% around a 330 kHz center frequency, decreasing EMI emissions radiated by the speaker and associated cables and traces. Where a fixed-frequency Class D exhibits large amounts of spectral energy at multiples of the switching frequency, the spread-spectrum architecture of the LM48511 amplifier spreads that energy over a larger bandwidth, reducing peak noise power in the circuit.

Electromagnetic interference is a system-level concern, and it is essential for today's audio engineer to design with EMI in mind, including the best possible design practices and judicious choice of components and materials.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as “components”) are sold subject to TI’s terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI’s terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers’ products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers’ products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI’s goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or “enhanced plastic” are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have not been so designated is solely at the Buyer’s risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
