FEATURES

- Speed and Resolution Grades:
  - ADS5281: 12-bit, 50MSPS
  - ADS5282: 12-bit, 65MSPS
- Power Dissipation:
  - 48mW/Channel at 30MSPS
  - 55mW/Channel at 40MSPS
  - 64mW/Channel at 50MSPS
  - 77mW/Channel at 65MSPS
- 70dBFS SNR at 10MHz IF
- Analog Input Full-Scale Range: 2Vpp
- Low-Frequency Noise Suppression Mode
- 6dB Overload Recovery In One Clock
- External and Internal (Trimmed) Reference
- 3.3V Analog Supply, 1.8V Digital Supply
- Single-Ended or Differential Clock:
  - Clock Duty Cycle Correction Circuit (DCC)
- Programmable Digital Gain: 0dB to 12dB
- Serialized DDR LVDS Output
- Programmable LVDS Current Drive, Internal Termination
- Test Patterns for Enabling Output Capture
- Straight Offset Binary or Two’s Complement Output
- Package Options:
  - 9mm × 9mm QFN-64
  - HTQFP-80 PowerPAD™ Compatible with ADS527x Family

APPLICATIONS

- Medical Imaging
- Wireless Base-Station Infrastructure
- Test and Measurement Instrumentation

DESCRIPTION

The ADS528x is a family of high-performance, low-power, octal channel analog-to-digital converters (ADCs). Available in either a 9mm × 9mm QFN package or an HTQFP-80 package, with serialized low-voltage differential signaling (LVDS) outputs and a wide variety of programmable features, the ADS528x is highly customizable for a diversity of applications and offers an unprecedented level of system integration. An application note, XAPP774 (available at www.xilinx.com), describes how to interface the serial LVDS outputs of TI’s ADCs to Xilinx® field-programmable gate arrays (FPGAs). The ADS528x family is specified over the industrial temperature range of –40°C to +85°C.
This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

## INITIALIZATION REGISTERS

After the device has been powered up, the following registers must be written to (in the exact order listed below) through the serial interface as part of an initialization sequence. (1)

<table>
<thead>
<tr>
<th>ADDRESS (hex)</th>
<th>DATA (hex)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Initialization Register 1 (1)</td>
<td>03</td>
</tr>
<tr>
<td>Initialization Register 2 (1)</td>
<td>01</td>
</tr>
<tr>
<td>Initialization Register 3 (1)</td>
<td>C7</td>
</tr>
<tr>
<td>Initialization Register 4 (1)</td>
<td>DE</td>
</tr>
</tbody>
</table>

(1) It is no longer necessary to write these initialization registers. However, customers who have already included them in their software can continue to use them. Programming these registers does not affect device performance.

If the analog input is ac-coupled, the following registers must be written to in the order listed below.

<table>
<thead>
<tr>
<th>ADDRESS (hex)</th>
<th>DATA (hex)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Initialization Register 1</td>
<td>01</td>
</tr>
<tr>
<td>Initialization Register 5</td>
<td>E2</td>
</tr>
</tbody>
</table>

To disable the PLL configuration switching (especially useful in systems where a system-level timing calibration is done once after power-up), the following registers must be written to in the order listed below. Also, see section PLL Operation Across Sampling Frequency.

<table>
<thead>
<tr>
<th>ADDRESS (hex)</th>
<th>DATA (hex)</th>
</tr>
</thead>
<tbody>
<tr>
<td>For 10 ≤ $F_s$ ≤ 25 (1)</td>
<td>E3</td>
</tr>
<tr>
<td>For 15 ≤ $F_s$ ≤ 45 (1)</td>
<td>E3</td>
</tr>
</tbody>
</table>

(1) where $F_s = $ sampling clock frequency
DIGITAL CHARACTERISTICS

DC specifications refer to the condition where the digital outputs are not switching, but are permanently at a valid logic level '0' or '1'. At $C_{LOAD} = 5\text{pF}^{(1)}$, $I_{OUT} = 3.5\text{mA}^{(2)}$, $R_{LOAD} = 100\Omega^{(2)}$, and no internal termination, unless otherwise noted.

</tbody>
</table>

(1) $C_{LOAD}$ is the effective external single-ended load capacitance between each output pin and ground.
(2) $I_{OUT}$ refers to the LVDS buffer current setting; $R_{LOAD}$ is the differential load resistance between the LVDS output pair.
## ELECTRICAL CHARACTERISTICS

Typical values at +25°C. Minimum and maximum values are measured across the specified temperature range of \( T_{\text{MIN}} = -40^\circ \text{C} \) to \( T_{\text{MAX}} = +85^\circ \text{C} \), AVDD = 3.3V, LVDD = 1.8V, clock frequency = 10MSPS to 65MSPS, 50% clock duty cycle, –1dBFS differential analog input, internal reference mode, \( I_{\text{SET}} \) resistor = 56.2kΩ, and LVDS buffer current setting = 3.5mA, unless otherwise noted.

---

1. All characteristics are common for the ADS528x family.
2. The offset temperature coefficient in ppm/°C is defined as \( (O_1 - O_2) \times 10^6/(T_1 - T_2)/4096 \), where \( O_1 \) and \( O_2 \) are the offset codes in LSB at the two extreme temperatures, \( T_1 \) and \( T_2 \).
3. The internal reference temperature coefficient is defined as \( (\text{REF}1 - \text{REF}2) \times 10^6/(T_1 - T_2)/2 \), where \( \text{REF}1 \) and \( \text{REF}2 \) are the internal reference voltages (\( V_{\text{REFT}} - V_{\text{REFB}} \)) at the two extreme temperatures, \( T_1 \) and \( T_2 \).
4. DC PSRR is defined as the ratio of the change in the ADC output (expressed in mV) to the change in supply voltage (in volts).

(1) Timing characteristics are common to the ADS528x family.
(2) Timing parameters are ensured by design and characterization; not production tested.
LVDS OUTPUT TIMING CHARACTERISTICS

Typical values are at +25°C, minimum and maximum values are measured across the specified temperature range of $T_{\text{MIN}} = -40°C$ to $T_{\text{MAX}} = +85°C$, sampling frequency = as specified, $C_{\text{LOAD}} = 5\text{pF}^{(3)}$, $I_{\text{OUT}} = 3.5\text{mA}$, $R_{\text{LOAD}} = 100\Omega^{(4)}$, and no internal termination, unless otherwise noted.

<td>0.09</td>
</tr>
</tbody>
</table>

(1) All characteristics are at the maximum rated speed for each speed grade.
(2) Timing parameters are ensured by design and characterization; not production tested.
(3) $C_{\text{LOAD}}$ is the effective external single-ended load capacitance between each output pin and ground.
(4) $I_{\text{OUT}}$ refers to the LVDS buffer current setting; $R_{\text{LOAD}}$ is the differential load resistance between the LVDS output pair.
(5) Measurements are done with a transmission line of 100Ω characteristic impedance between the device and the load.
(6) Setup and hold time specifications take into account the effect of jitter on the output data and clock. These specifications also assume that data and clock paths are perfectly matched within the receiver. Any mismatch in these paths within the receiver would appear as reduced timing margin.
(7) Data valid refers to a logic high of +100mV and a logic low of –100mV.

<td>8</td>
</tr>
</tbody>
</table>

(1) Only the setup time, hold time and clock propagation delay parameters are affected. Rest of the parameters are same as given in previous two tables.

(2) Only timing specifications for 40MSPS are affected when using register 0xE3 (as specified in the recommended operating table section). The timing specifications for other clock frequencies are same as given in previous two tables.

(3) Data valid refers to logic high of +100mV and logic low of –100mV.

RECOMMENDED POWER-UP SEQUENCING AND RESET TIMING

10μs < t₁ < 50ms, 10μs < t₂ < 50ms, –10ms < t₃ < 10ms, t₄ > 10ms, t₅ > 100ns, t₆ > 100ns, t₇ > 10ms, and t₈ > 100μs.

(1) The AVDD and LVDD power on sequence does not matter as long as –10ms < t₃ < 10ms. Similar considerations apply while shutting down the device.

(2) Write initialization registers listed in the Initialization Registers table.
Power-down time shown is based on 1μF bypass capacitors on the reference pins. $t_{\text{WAKE}}$ is the time it takes for the device to wake up completely from power-down mode. The ADS528x has two power-down modes: complete power-down mode and partial power-down mode. The device can be configured in partial power-down mode through a register setting.

$t_{\text{WAKE}} < 50\mu s$ for complete power-down mode.

$t_{\text{WAKE}} < 2\mu s$ for partial power-down mode (provided the clock is not shut off during power-down).
SERIAL INTERFACE

The ADS528x has a set of internal registers that can be accessed through the serial interface formed by pins CS (chip select, active low), SCLK (serial interface clock), and SDATA (serial interface data). When CS is low, the following actions occur:
- Serial shift of bits into the device is enabled
- SDATA (serial data) is latched at every rising edge of SCLK
- SDATA is loaded into the register at every 24th SCLK rising edge

If the word length exceeds a multiple of 24 bits, the excess bits are ignored. Data can be loaded in multiples of 24-bit words within a single active CS pulse. The first eight bits form the register address and the remaining 16 bits form the register data. The interface can work with SCLK frequencies from 20MHz down to very low speeds (a few hertz) and also with a non-50% SCLK duty cycle.

Register Initialization

After power-up, the internal registers must be initialized to the respective default values. Initialization can be done in one of two ways:
1. Through a hardware reset, by applying a low-going pulse on the RESET pin; or
2. Through a software reset; using the serial interface, set the RST bit high. Setting this bit initializes the internal registers to the respective default values and then self-resets the RST bit low. In this case, the RESET pin stays high (inactive).

After all registers have been initialized to their default values through a RESET operation, the registers detailed in the Initialization Registers table must be written into. This process must be done after every hardware or software RESET operation in order to reconfigure the device for the best mode of operation.

</table>

(1) The unused bits in each register (identified as blank table cells) must be programmed as ‘0’.
(2) X = Register bit referenced by the corresponding name and description (default is 0).
(3) Bits marked as ‘0’ should be forced to 0, and bits marked as ‘1’ should be forced to 1 when the particular register is programmed.
(4) Multiple functions in a register should be programmed in a single write operation.

SOFTWARE RESET

Software reset is applied when the RST bit is set to ‘1’; setting this bit resets all internal registers and self-clears to ‘0’.

POWER-DOWN MODES

Each of the eight channels can be individually powered down. PDN_CH<N> controls the power-down mode for the ADC channel <N>.

In addition to channel-specific power-down, the ADS528x also has two global power-down modes—partial power-down mode and complete power-down mode. Partial power-down mode partially powers down the chip; recovery from this mode is much quicker, provided that the clock has been running for at least 50μs before exiting this mode. Complete power-down mode, on the other hand, completely powers down the chip, and involves a much longer recovery time.

In addition to programming the device for either of these two power-down modes (through either the PDN_PARTIAL or PDN_COMPLETE bits, respectively), the PD pin itself can be configured as either a partial power-down pin or a complete power-down pin control. For example, if PDN_PIN_CFG = 0 (default), when the PD pin is high, the device enters complete power-down mode. However, if PDN_PIN_CFG = 1, when the PD pin is high, the device enters partial power-down mode.

LVDS DRIVE PROGRAMMABILITY

The LVDS drive strength of the bit clock (LCLKP or LCLKN) and the frame clock (ADCLKP or ADCLKN) can be individually programmed. The LVDS drive strengths of all the data outputs OUTP and OUTN can also be programmed to the same value.
All three drive strengths (bit clock, frame clock, and data) are programmed using sets of three bits. Table 5 shows an example of how the drive strength of the bit clock is programmed (the method is similar for the frame clock and data drive strengths).

</tbody>
</table>

(1) Current settings lower than 1.5mA are not recommended.

The LVDS buffers have high-impedance current sources driving the outputs. When driving traces whose characteristic impedance is not perfectly matched with the termination impedance on the receiver side, there may be reflections back to the LVDS output pins of the ADS528x that cause degraded signal integrity. By enabling an internal termination (between the positive and negative outputs) for the LVDS buffers, the signal integrity can be significantly improved in such scenarios. To set the internal termination mode, the EN_LVDS_TERM bit should be set to '1'. Once this bit is set, the internal termination values for the bit clock, frame clock, and data buffers can be independently programmed using sets of three bits. Table 6 shows an example of how the internal termination of the LVDS buffer driving the bit clock is programmed (the method is similar for the frame clock and data buffers). These termination values are only typical values and can vary by up to ±20% across temperature and from device to device.

</table>
LOW-FREQUENCY NOISE SUPPRESSION MODE

The low-frequency noise suppression mode is specifically useful in applications where good noise performance is desired in the frequency band of 0MHz to 1MHz (around dc). Setting this mode shifts the low-frequency noise of the ADS528x to approximately f_S/2, thereby moving the noise floor around dc to a much lower value. LFNS_CH<8:1> enables this mode individually for each channel.

ANALOG INPUT INVERT

Normally, the IN_P pin represents the positive analog input pin, and IN_N represents the complementary negative input. Setting the bits marked INVERT_CH<8:1> (individual control for each channel) causes the inputs to be swapped. IN_N now represents the positive input, and IN_P the negative input.

LVDS TEST PATTERNS

The ADS528x can output a variety of test patterns on the LVDS outputs. These test patterns replace the normal ADC data output. Setting EN_RAMP to ‘1’ causes all the channels to output a repeating full-scale ramp pattern. The ramp increments from zero code to full-scale code in steps of 1LSB every clock cycle. After hitting the full-scale code, it returns back to zero code and ramps again.

The device can also be programmed to output a constant code by setting SINGLE_CUSTOM_PAT to ‘1’, and programming the desired code in BITS_CUSTOM1<11:0>. In this mode, BITS_CUSTOM1<11:0> take the place of the 12-bit ADC data at the output, and are controlled by LSB-first and MSB-first modes in the same way as normal ADC data are.

The device may also be made to toggle between two consecutive codes by programming DUAL_CUSTOM_PAT to ‘1’. The two codes are represented by the contents of BITS_CUSTOM1<11:0> and BITS_CUSTOM2<11:0>.

In addition to custom patterns, the device may also be made to output two preset patterns:

1. Deskew pattern: Set using PAT_DESKEW, this mode replaces the 12-bit ADC output D<11:0> with the 010101010101 word.
2. Sync pattern: Set using PAT_SYNC, the normal ADC word is replaced by a fixed 111111000000 word.

Note that only one of the above patterns should be active at any given instant.
PROGRAMMABLE GAIN

In applications where the full-scale swing of the analog input signal is much less than the 2V_{PP} range supported by the ADS528x, a programmable gain can be set to achieve the full-scale output code even with a lower analog input swing. The programmable gain not only fills the output code range of the ADC, but also enhances the SNR of the device by utilizing quantization information from some extra internal bits. The programmable gain for each channel can be individually set using a set of four bits, indicated as GAIN_CHN<3:0> for Channel N. The gain setting is coded in binary from 0dB to 12dB, as shown in Table 7.

| ADDRESS IN HEX | D15 | D14 | D13 | D12 | D11 | D10 | D9 | D8 | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 | NAME |

#### INPUT CLOCK

The ADS528x is configured by default to operate with a single-ended input clock—CLK_p is driven by a CMOS clock and CLK_n is tied to '0'. However, by programming DIFF_CLK to '1', the device can be made to work with a differential input clock on CLK_p and CLK_n. Operating with a low-jitter differential clock usually gives better SNR performance, especially at input frequencies greater than 30MHz.

In cases where the duty cycle of the input clock falls outside the 45% to 55% range, it is recommended to enable an internal duty cycle correction circuit. This enabling is done by setting the EN_DCC bit to ‘1’.

#### EXTERNAL REFERENCE

The ADS528x can be made to operate in external reference mode by pulling the INT/EXT pin to '0'. In this mode, the REF_T and REF_B pins should be driven with voltage levels of 2.5V and 0.5V, respectively, and must have enough drive strength to drive the switched capacitance loading of the reference voltages by each ADC. The advantage of using the external reference mode is that multiple ADS528x units can be made to operate with the same external reference, thereby improving parameters such as gain matching across devices. However, in applications that do not have an available high drive, differential external reference, the ADS528x can still be driven with a single external reference voltage on the V_CM pin. When EXT_REF_VCM is set as '1' (and the INT/EXT pin is set to '0'), the V_CM pin is configured as an input pin, and the voltages on REF_T and REF_B are generated as shown in Equation 1 and Equation 2.

\[
V_{REF_T} = 1.5V + \frac{V_{CM}}{1.5V} \tag{1}
\]

\[
V_{REF_B} = 1.5V - \frac{V_{CM}}{1.5V} \tag{2}
\]
BIT CLOCK PROGRAMMABILITY

The output interface of the ADS528x is normally a DDR interface, with the LCLK rising edge and falling edge transitions in the middle of alternate data windows. This default phase is shown in Figure 1.

![Figure 1. Default Phase of LCLK](image1)

The phase of LCLK can be programmed relative to the output frame clock and data using bits PHASE_DDR<1:0>. The LCLK phase modes are shown in Figure 2.

![Figure 2. Phase Programmability Modes for LCLK](image2)
In addition to programming the phase of LCLK in the DDR mode, the device can also be made to operate in SDR mode by setting the EN_SDR bit to ‘1’. In this mode, the bit clock (LCLK) is output at 12x times the input clock, or twice the rate as in DDR mode. Depending on the state of FALL_SDR, LCLK may be output in either of the two manners shown in Figure 3. As can be seen in Figure 3, only the LCLK rising (or falling) edge is used to capture the output data in SDR mode.

The SDR mode does not work well beyond 40MSPS because the LCLK frequency becomes very high.

**DATA OUTPUT FORMAT MODES**

The ADC output, by default, is in straight offset binary mode. Programming the BTC_MODE bit to ‘1’ inverts the MSB, and the output becomes binary two’s complement mode.

Also by default, the first bit of the frame (following the rising edge of ADCLK_p) is the LSB of the ADC output. Programming the MSB_FIRST mode inverts the bit order in the word, and the MSB is output as the first bit following the ADCLK_p rising edge.
TYPICAL CHARACTERISTICS

3. Standard deviation of every set of first and second points after overload are analyzed over the 16 groups.
4. Worst case of all such standard deviations are plotted in the graphs.
APPLICATION INFORMATION

THEORY OF OPERATION

The ADS528x devices are a family of 8-channel, high-speed, CMOS ADCs. The 12 bits given out by each channel are serialized and sent out on a single pair of pins in LVDS format. All eight channels of the ADS528x operate from a single clock (ADCLK). The sampling clocks for each of the eight channels are generated from the input clock using a carefully matched clock buffer tree. The 12x clock required for the serializer is generated internally from ADCLK using a phase-locked loop (PLL). A 6x and a 1x clock are also output in LVDS format, along with the data, to enable easy data capture. The ADS528x operates from internally-generated reference voltages that are trimmed to improve to a high level of accuracy. Trimmer references improve the gain matching across devices, and provide the option to operate the devices without having to externally drive and route reference lines. The nominal values of REF_T and REF_B are 2.5V and 0.5V, respectively. The references are internally scaled down differentially by a factor of 2. This scaling results in a differential input of –1V to correspond to the zero code of the ADC, and a differential input of +1V to correspond to the full-scale code (4095 LSB). V_CM (the common-mode voltage of REF_T and REF_B) is also made available externally through a pin, and is nominally 1.5V.

The ADC employs a pipelined converter architecture that consists of a combination of multi-bit and single-bit internal stages. Each stage feeds its data into the digital error correction logic, ensuring excellent differential linearity and no missing codes at the 12-bit level.

The ADC output goes to a serializer that operates from a 12x clock generated by the PLL. The 12 data bits from each channel are serialized and sent LSB first. In addition to serializing the data, the serializer also generates a 1x clock and a 6x clock. These clocks are generated in the same way the serialized data are generated, so these clocks maintain perfect synchronization with the data. The data and clock outputs of the serializer are buffered externally using LVDS buffers. Using LVDS buffers to transmit data externally has multiple advantages, such as a reduced number of output pins (saving routing space on the board), reduced power consumption, and reduced effects of digital noise coupling to the analog circuit inside the ADS528x.

The ADS528x operates from two sets of supplies and grounds. The analog supply and ground set is identified as AVDD and AVSS, while the digital set is identified by LVDD and LVSS.

ANALOG INPUT

The analog input consists of a switched-capacitor based, differential sample-and-hold architecture. This differential topology results in very good ac performance even for high input frequencies at high sampling rates. The IN_N and IN_P pins must be externally biased around a common-mode voltage of 1.5V, available on V_CM. For a full-scale differential input, each input pin (IN_N and IN_P) must swing symmetrically between V_CM + 0.5V and V_CM – 0.5V, resulting in a 2V_PP differential input swing. The maximum input peak-to-peak differential swing is determined to be the difference between the internal reference voltages REF_T (2.5V nominal) and REF_B (0.5V nominal). Figure 34 illustrates the model of the input driving circuit.
Input Common-Mode Current

The input stage of all eight ADCs together sinks a common-mode current on the order of 2mA at 50MSPS. Equation 3 describes the dependency of the common-mode current and the sampling frequency.

\[
\text{(2mA)} \times \frac{f_s}{50\text{MSPS}}
\]  

(3)

If the driving stage is dc-coupled to the inputs, then Equation 3 can be used to determine its common-mode drive capability and impedance. The inputs can also be ac-coupled to the IN\textsubscript{N} and IN\textsubscript{P} pins. In that case, the input common-mode is set by two internal 1.2kΩ resistors connecting the input pins to \(V_{CM}\). This architecture is shown in Figure 35.

When the inputs are ac-coupled, there is a drop in the voltages at IN\textsubscript{P} and IN\textsubscript{N} relative to \(V_{CM}\). This can be computed from Equation 3. At 50MSPS, for example, the drop at each of the 16 input pins is 150mV, which is not optimal for ADC operation. Initialization Registers 1 and 5, described in the Initialization Registers table, can be used to partially reduce the effect of this input common-mode drop during ac-coupling by increasing \(V_{CM}\) by roughly 75mV. When operating above 50MSPS, it is recommended that additional parallel resistors be added externally to restore the input common-mode to at least 1.4V, if the inputs are to be ac-coupled.

Dashed area denotes one of eight channels.

Figure 34. Analog Input Circuit Model

Figure 35. Common-Mode Biasing of Input Pins
Driving Circuit

For optimum performance, the analog inputs must be driven differentially. This approach improves the common-mode noise immunity and even-order harmonic rejection. Input configurations using RF transformers suitable for low and high input frequencies are shown in Figure 36 and Figure 37, respectively. The single-ended signal is fed to the primary winding of the RF transformer. The transformer is terminated by 50Ω resistor on the secondary side. Placing the termination on the secondary side helps to shield the kicks caused by the input sampling capacitors from the RF transformer leakage inductances. The termination is accomplished by two 25Ω resistors, connected in series, with the center point connected to the 1.5V common-mode. The 4.7Ω resistor in series with each input pin is required to damp the ringing caused by the device package parasitics.

At high input frequencies, the mismatch in the transformer parasitic capacitance (between the windings) results in degraded even-order harmonic performance. Connecting two identical RF transformers back-to-back helps to minimize this mismatch, and good performance is obtained for high-frequency input signals. An additional termination resistor pair is required between the two transformers, as shown in Figure 37. The center point of this termination is connected to ground to improve the balance between the positive and negative sides. The values of the terminations between the transformers and on the secondary side must be chosen to achieve an overall 50Ω (in the case of 50Ω source impedance).

![Figure 36. Drive Circuit at Low Input Frequencies](image)

![Figure 37. Drive Circuit at High Input Frequencies](image)
CLOCK INPUT

The eight channels on the device operate from a single ADCLK input. To ensure that the aperture delay and jitter are the same for all channels, a clock tree network is used to generate individual sampling clocks to each channel. The clock paths for all the channels are matched from the source point to the sampling circuit. This architecture ensures that the performance and timing for all channels are identical.

The use of the clock tree for matching introduces an aperture delay that is defined as the delay between the rising edge of ADCLK and the actual instant of sampling. The aperture delays for all the channels are matched to the best possible extent. A mismatch of ±20ps (±3σ) could exist between the aperture instants of the eight ADCs within the same chip. However, the aperture delays of ADCs across two different chips can be several hundred picoseconds apart.

The ADS528x can be made to operate either in CMOS single-ended clock mode (default is DIFF_CLK = 0) or differential clock mode (SINE, LVPECL, or LVDS). When operating in the single-ended clock mode, CLK_N must be forced to 0V DC, and the single-ended CMOS applied on the CLK_P pin. This operation is shown in Figure 38.

When configured to operate in the differential clock mode (register bit DIFF_CLK = 1) the ADS528x clock inputs can be driven differentially (SINE, LVPECL, or LVDS) with little or no difference in performance between them, or with a single-ended (LVCMOS).

For best performance, the clock inputs must be driven differentially in order to reduce susceptibility to common-mode noise. For high input frequency sampling, it is recommended to use a clock source with very low jitter. Bandpass filtering of the clock source can help reduce the effect of jitter. If the duty cycle deviates from 50% by more than 2% or 3%, it is recommended to enable the DCC through register bit EN_DCC.
PLL OPERATION ACROSS SAMPLING FREQUENCY

The ADS528X uses a PLL for generating the high speed bit clock (LCLK), the frame clock (ADCLK) & internal clocks for the serializer operation.

To enable operation across the entire frequency range, the PLL is automatically configured to one of four states, depending on the sampling clock frequency range. The frequency range detection is automatic and each time the sampling frequency crosses a threshold, the PLL changes its configuration to a new state. To prevent unwanted toggling of PLL state around a threshold, the circuit has an inbuilt hysteresis. The ADS528x has three thresholds – taking into account the hysteresis range of each threshold, variation across devices and temperature, the thresholds can span the sampling clock frequency range from 10MHz to 45MHz.

Based on actual system clock frequency, there are two scenarios:

1. For sampling clock frequency ≤ 45MSPS

   After system power up, depending on the frequency of operation and the frequency threshold for the given device, the frequency range detection circuit may change state once. In some applications where a timing calibration might be done at the system level once after power up, this subsequent change of the PLL state might be undesirable as it can cause a loss of alignment in the received data. A software fix for eliminating this one-time change of PLL state exists using the serial register interface:
   - Disable the automatic switch of the PLL configuration based on frequency detected.
   - In addition to disabling the switching, it is also required to set the PLL to the correct configuration, depending on the sample clock frequency used in the system.

   The following sequence of register writes must be followed:

   Step 1: Write Address = 0x01, Data = 0x0010

2. For sampling clock frequency ≥ 45MSPS

   As there are no PLL thresholds beyond 45MHz, no change in PLL configuration can occur as the temperature in the system stabilizes. The ADS528x can be used in the system without using the above software fix.

INPUT OVER-VOLTAGE RECOVERY

The differential peak-to-peak full-scale range supported by the ADS528x is nominally 2.0V. The ADS528x is specially designed to handle an over-voltage condition where the differential peak-to-peak voltage can be up to twice the ADC full-scale range. If the input common-mode is not considerably off from \( V_{CM} \) during overload (less than 300mV around the nominal value of 1.5V), recovery from an over-voltage pulse input of twice the amplitude of a full-scale pulse is expected to be within one clock cycle when the input switches from overload to zero signal.

REFERENCE CIRCUIT

The digital beam-forming algorithm in an ultrasound system relies on gain matching across all receiver channels. A typical system would have about 12 octal ADCs on the board. In such a case, it is critical to ensure that the gain is matched, essentially requiring the reference voltages seen by all the ADCs to be the same. Matching references within the eight channels of a chip is done by using a single internal reference voltage buffer. Trimming the reference voltages on each chip during production ensures that the reference voltages are well-matched across different chips.

All bias currents required for the internal operation of the device are set using an external resistor to ground at the \( I_{SET} \) pin. Using a 56.2kΩ resistor on \( I_{SET} \) generates an internal reference current of 20μA. This current is mirrored internally to generate the bias current for the internal blocks. Using a larger external
resistor at \( I_{\text{SET}} \) reduces the reference bias current and thereby scales down the device operating power. However, it is recommended that the external resistor be within 10% of the specified value of 56.2k\( \Omega \) so that the internal bias margins for the various blocks are proper.

Buffering the internal bandgap voltage also generates the common-mode voltage \( V_{CM} \), which is set to the midlevel of \( R_{\text{EF}_T} \) and \( R_{\text{EB}} \), and is accessible on a pin (pin 65 in TQFP-80 package, pin 53 in QFN-64 package). It is meant as a reference voltage to derive the input common-mode if the input is directly coupled. It can also be used to derive the reference common-mode voltage in the external reference mode. The suggested decoupling for the reference pins is shown in Figure 43.

The device also supports the use of external reference voltages. There are two methods to force the references externally. The first method involves pulling INT/EXT low and forcing externally \( R_{\text{EF}_T} \) and \( R_{\text{EB}} \) to 2.5V and 0.5V nominally, respectively. In this mode, the internal reference buffer goes to a 3-state output. The external reference driving circuit should be designed to provide the required switching current for the eight ADCs inside the chip. It should be noted that in this mode, \( V_{CM} \) and \( I_{\text{SET}} \) continue to be forceable from the internal bandgap voltage, as in the internal reference mode. It is therefore important to ensure that the common-mode voltage of the externally-forced reference voltages matches to within 50mV of \( V_{CM} \).

The second method of forcing the reference voltages externally can be accessed by pulling INT/EXT low, and programming the serial interface to drive the external reference mode through the \( V_{CM} \) pin (register bit called EXT_REF_VCM). In this mode, \( V_{CM} \) becomes configured as an input pin that can be driven from external circuitry. The internal reference buffers driving \( R_{\text{EF}_T} \) and \( R_{\text{EB}} \) are active in this mode. Forcing 1.5V on the \( V_{CM} \) pin in the mode results in \( R_{\text{EF}_T} \) and \( R_{\text{EB}} \) coming to 2.5V and 0.5V, respectively. In general, the voltages on \( R_{\text{EF}_T} \) and \( R_{\text{EB}} \) in this mode are given by:

\[
V_{\text{EF}_T} = 1.5V + \frac{V_{CM}}{1.5V} \\
V_{\text{EB}} = 1.5V - \frac{V_{CM}}{1.5V}
\]

The state of the reference voltage internal buffers during various combinations of the PD, INT/EXT, and EXT_REF_VCM register bits is described in Table 8.

The state of the reference voltage internal buffers during various combinations of the PD, INT/EXT, and EXT_REF_VCM register bits is described in Table 8.

**NOISE COUPLING ISSUES**

High-speed mixed signals are sensitive to various types of noise coupling. One primary source of noise is the switching noise from the serializer and the output buffers. Maximum care is taken to isolate these noise sources from the sensitive analog blocks. As a starting point, the analog and digital domains of the device are clearly demarcated. AVDD and AVSS are used to denote the supplies for the analog sections, while LVDD and LVSS are used to denote the digital supplies. Care is taken to ensure that there is minimal interaction between the supply sets within the device. The extent of noise coupled and transmitted from the digital to the analog sections depends on:

1. The effective inductances of each of the supply and ground sets.
2. The isolation between the digital and analog supply and ground sets.

Copyright © 2006–2012, Texas Instruments Incorporated
Smaller effective inductance of the supply and ground pins leads to better noise suppression. For this reason, multiple pins are used to drive each supply and ground. It is also critical to ensure that the impedances of the supply and ground lines on the board are kept to the minimum possible values. Use of ground planes in the printed circuit board (PCB) as well as large decoupling capacitors between the supply and ground lines are necessary to obtain the best possible SNR performance from the device.

It is recommended that the isolation be maintained on the board by using separate supplies to drive AVDD and LVDD, as well as separate ground planes for AVSS and LVSS. The use of LVDS buffers reduces the injected noise considerably, compared to CMOS buffers. The current in the LVDS buffer is independent of the direction of switching. Also, the low output swing as well as the differential nature of the LVDS buffer results in low-noise coupling.
# REVISION HISTORY

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBsolete:** TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check [http://www.ti.com/productcontent](http://www.ti.com/productcontent) for the latest availability information and additional product content details.

**TBD:** The Pb-Free/Green conversion plan has not been defined.

**Pb-Free (RoHS):** TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

**Pb-Free (RoHS Exempt):** This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

**Green (RoHS & no Sb/Br):** TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.
(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

*All dimensions are nominal*
Images above are just a representation of the package family, actual package may vary. Refer to the product data sheet for package details.
NOTES:

A. All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5–1994.
B. This drawing is subject to change without notice.
C. Quad Flatpack, No-Leads (QFN) package configuration.
D. The package thermal pad must be soldered to the board for thermal and mechanical performance.
E. See the additional figure in the Product Data Sheet for details regarding the exposed thermal pad features and dimensions.
THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

NOTE: A. All linear dimensions are in millimeters
NOTES:
A. All linear dimensions are in millimeters.
B. This drawing is subject to change without notice.
C. Publication IPC-7351 is recommended for alternate designs.
D. This package is designed to be soldered to a thermal pad on the board. Refer to Application Note, Quad Flat-Pack Packages, Texas Instruments Literature No. SLUA271, and also the Product Data Sheets for specific thermal information, via requirements, and recommended board layout. These documents are available at www.ti.com <http://www.ti.com>.
E. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Refer to IPC 7529 for stencil design considerations.
F. Customers should contact their board fabrication site for recommended solder mask tolerances and via tenting recommendations for via placed in thermal pad.
MECHANICAL DATA

PFP (S-PQFP-G80)  PowerPAD™ PLASTIC QUAD FLATPACK

NOTES:
A. All linear dimensions are in millimeters.
B. This drawing is subject to change without notice.
C. Body dimensions do not include mold flash or protrusion.
D. This package is designed to be soldered to a thermal pad on the board. Refer to Technical Brief, PowerPad Thermally Enhanced Package, Texas Instruments Literature No. SLMA002 for information regarding recommended board layout. This document is available at www.ti.com.<http://www.ti.com>.
E. See the additional figure in the Product Data Sheet for details regarding the exposed thermal pad features and dimensions.
F. Falls within JEDEC MS-026

THERMAL INFORMATION

This PowerPAD™ package incorporates an exposed thermal pad that is designed to be attached to a printed circuit board (PCB). The thermal pad must be soldered directly to the PCB. After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For additional information on the PowerPAD package and how to take advantage of its heat dissipating abilities, refer to Technical Brief, PowerPAD Thermally Enhanced Package, Texas Instruments Literature No. SLMA002 and Application Brief, PowerPAD Made Easy, Texas Instruments Literature No. SLMA004. Both documents are available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

NOTE: A. All linear dimensions are in millimeters

NOTES:
A. All linear dimensions are in millimeters.
B. This drawing is subject to change without notice.
C. Customers should place a note on the circuit board fabrication drawing not to alter the center solder mask defined pad.
D. This package is designed to be soldered to a thermal pad on the board. Refer to Technical Brief, PowerPad Thermally Enhanced Package, Texas Instruments Literature No. SMB004, and also the Product Data Sheets for specific thermal information, via requirements, and recommended board layout. These documents are available at www.ti.com. Publication IPC-7351 is recommended for alternate designs.
E. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Example stencil design based on a 50% volumetric metal load solder paste. Refer to IPC-7525 for other stencil recommendations.
F. Customers should contact their board fabrication site for solder mask tolerances between and around signal pads.
