QUAD, 12-BIT, LOW-POWER, VOLTAGE OUTPUT, I^2C INTERFACE DIGITAL-TO-ANALOG CONVERTER

FEATURES
- Micropower Operation: 600 µA at 5 V \( V_{DD} \)
- Power-On Reset to Zero
- +2.7 V to +5.5 V Analog Power Supply
- 12-Bit Monotonic
- \( I^2C \)™ Interface Up to 3.4 Mbps
- Data Transmit Capability
- On-Chip Output Buffer Amplifier, Rail-to-Rail Operation
- Double-Buffered Input Register
- Address Support for up to Four DAC7574s
- Synchronous Update Support for up to 16 Channels
- Operation From -40°C to 105°C
- Small 10 Lead MSOP Package

DESCRIPTION
The DAC7574 is a low-power, quad channel, 12-bit buffered voltage output DAC. Its on-chip precision output amplifier allows rail-to-rail output swing to be achieved. The DAC7574 utilizes an \( I^2C \) compatible two wire serial interface supporting high-speed interface mode with address support of up to four DAC7574s for a total of 16 channels on the bus.

The DAC7574 uses \( V_{DD} \) and GND to set the output range of the DAC. The DAC7574 incorporates a power-on-reset circuit that ensures that the DAC output powers up at zero volts and remains there until a valid write takes place to the device. The DAC7574 contains a power-down feature, accessed via the internal control register, that reduces the current consumption of the device to 200 nA at 5 V.

The low power consumption of this part in normal operation makes it ideally suited to portable battery operated equipment. The power consumption is less than 3mW at \( V_{DD} = 5 \) V reducing to 1 µW in power-down mode.

The DAC7574 is available in a 10-lead MSOP package.

APPLICATIONS
- Process Control
- Data Acquisition Systems
- Closed-Loop Servo Control
- PC Peripherals
- Portable Instrumentation

I^2C is a trademark of Philips Corporation.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.
This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

THEORY OF OPERATION

D/A SECTION

The architecture of the DAC7574 consists of a string DAC followed by an output buffer amplifier. Figure 29 shows a generalized block diagram of the DAC architecture.

\[ V_{\text{OUT}} = V_{\text{DD}} \times \frac{D}{4096} \]  

(1)

Where D = decimal equivalent of the binary code that is loaded to the DAC register; it can range from 0 to 4095.

RESISTOR STRING

The resistor string section is shown in Figure 30. It is basically a divide-by-2 resistor, followed by a string of resistors, each of value R. The code loaded into the DAC register determines at which node on the string the voltage is tapped off to be fed into the output amplifier by closing one of the switches connecting the string to the amplifier. Because the architecture consists of a string of resistors, it is specified monotonic.

Output Amplifier

The output buffer is a gain-of-2 noninverting amplifiers, capable of generating rail-to-rail voltages on its output, which gives an output range of 0V to \( V_{\text{DD}} \). It is capable of driving a load of 2 k\( \Omega \) in parallel with 1000 pF to GND. The source and sink capabilities of the output amplifier can be seen in the typical curves. The slew rate is 1 V/\( \mu \)s with a half-scale settling time of 8 \( \mu \)s with the output unloaded.

I\(^2\)C Interface

I\(^2\)C is a 2-wire serial interface developed by Philips Semiconductor (see I\(^2\)C-Bus Specification, Version 2.1, January 2000). The bus consists of a data line (SDA) and a clock line (SCL) with pullup structures. When the bus is idle, both SDA and SCL lines are pulled high. All the I\(^2\)C compatible devices connect to the I\(^2\)C bus through open drain I/O pins, SDA and SCL. A master device, usually a microcontroller or a digital signal processor, controls the bus. The master is responsible for generating the SCL signal and device addresses. The master also generates specific conditions that indicate the START and STOP of data transfer. A slave device receives and/or transmits data on the bus under control of the master device.
THEORY OF OPERATION (continued)

The DAC7574 works as a slave and supports the following data transfer modes, as defined in the I²C-Bus Specification: standard mode (100 kbps), fast mode (400 kbps), and high-speed mode (3.4 Mbps). The data transfer protocol for standard and fast modes is exactly the same, therefore they are referred to as F/S-mode in this document. The protocol for high-speed mode is different from the F/S-mode, and it is referred to as H/S-mode. The DAC7574 supports 7-bit addressing; 10-bit addressing and general call address are not supported.

F/S-Mode Protocol

- The master initiates data transfer by generating a start condition. The start condition is when a high-to-low transition occurs on the SDA line while SCL is high, as shown in Figure 31. All I²C-compatible devices should recognize a start condition.

- The master then generates the SCL pulses, and transmits the 7-bit address and the read/write direction bit R/W on the SDA line. During all transmissions, the master ensures that data is valid. A valid data condition requires the SDA line to be stable during the entire high period of the clock pulse (see Figure 32). All devices recognize the address sent by the master and compare it to their internal fixed addresses. Only the slave device with a matching address generates an acknowledge (see Figure 33) by pulling the SDA line low during the entire high period of the 9th SCL cycle. Upon detecting this acknowledge, the master knows that communication link with a slave has been established.

- The master generates further SCL cycles to either transmit data to the slave (R/W bit 1) or receive data from the slave (R/W bit 0). In either case, the receiver needs to acknowledge the data sent by the transmitter. So acknowledge signal can either be generated by the master or by the slave, depending on which one is the receiver. 9-bit valid data sequences consisting of 8-bit data and 1-bit acknowledge can continue as long as necessary.

- To signal the end of the data transfer, the master generates a stop condition by pulling the SDA line from low to high while the SCL line is high (see Figure 31). This releases the bus and stops the communication link with the addressed slave. All I²C compatible devices must recognize the stop condition. Upon the receipt of a stop condition, all devices know that the bus is released, and they wait for a start condition followed by a matching address.

H/S-Mode Protocol

- When the bus is idle, both SDA and SCL lines are pulled high by the pullup devices.

- The master generates a start condition followed by a valid serial byte containing H/S master code 00001XXX. This transmission is made in F/S-mode at no more than 400 Kbps. No device is allowed to acknowledge the H/S master code, but all devices must recognize it and switch their internal setting to support 3.4 Mbps operation.

- The master then generates a repeated start condition (a repeated start condition has the same timing as the start condition). After this repeated start condition, the protocol is the same as F/S-mode, except that transmission speeds up to 3.4 Mbps are allowed. A stop condition ends the H/S-mode and switches all the internal settings of the slave devices to support the F/S-mode. Instead of using a stop condition, repeated start conditions should be used to secure the bus in H/S-mode.
THEORY OF OPERATION (continued)

Figure 31. START and STOP Conditions

Figure 32. Bit Transfer on the I^2C Bus

Figure 33. Acknowledge on the I^2C Bus
DAC7574 requires a start condition, a valid I²C address, a control byte, an MSB byte, and an LSB byte for a single update. After the receipt of each byte, DAC7574 acknowledges by pulling the SDA line low during the high period of a single clock pulse. A valid I²C address selects the DAC7574. The control byte sets the operational mode of the selected DAC7574. Once the operational mode is selected by the control byte, DAC7574 expects an MSB byte followed by an LSB byte for data update to occur. DAC7574 performs an update on the falling edge of the acknowledge signal that follows the LSB byte.

Control byte needs not to be resent until a change in operational mode is required. The bits of the control byte continuously determine the type of update performed. Thus, for the first update, DAC7574 requires a start condition, a valid I²C address, a control byte, an MSB byte and an LSB byte. For all consecutive updates, DAC7574 needs an MSB byte and an LSB byte as long as the control command remains the same.

Using the I²C high-speed mode \( f_{\text{scl}} = 3.4 \text{ MHz} \), the clock running at 3.4 MHz, each 12-bit DAC update other than the first update can be done within 18 clock cycles (MSB byte, acknowledge signal, LSB byte, acknowledge signal), at 188.88 KSPS. Using the fast mode \( f_{\text{scl}} = 400 \text{ kHz} \), clock running at 400 kHz, maximum DAC update rate is limited to 22.22 KSPS. Once a stop condition is received DAC7574 releases the I²C bus and awaits a new start condition.

**Address Byte**

<table>
<thead>
<tr>
<th>MSB</th>
<th>1</th>
<th>0</th>
<th>0</th>
<th>1</th>
<th>1</th>
<th>A1</th>
<th>A0</th>
<th>R/W</th>
</tr>
</thead>
</table>

The address byte is the first byte received following the START condition from the master device. The first five bits (MSBs) of the address are factory preset to 10011. The next two bits of the address are the device select bits A1 and A0. The A1, A0 address inputs can be connected to \( V_{DD} \) or digital GND, or can be actively driven by TTL/CMOS logic levels. The device address is set by the state of these pins during the power-up sequence of the DAC7574. Up to 4 devices (DAC7574) can still be connected to the same I²C-Bus.
Broadcast addressing is also supported by DAC7574. Broadcast addressing can be used for synchronously updating or powering down multiple DAC7574 devices. DAC7574 is designed to work with other members of the DAC857x and DAC757x families to support multichannel synchronous update. Using the broadcast address, DAC7574 responds regardless of the states of the address pins. Broadcast is supported only in write mode (Master writes to DAC7574).

**Broadcast Modes (controls up to 4 devices on a single serial bus)**

| X | X | 1 | 1 | X | 0 | X | X | X | X | Update all DACs, all devices with previously stored TRx data |
| X | X | 1 | 1 | X | 1 | X | 0 | Data | Update all DACs, all devices with MSB[7:0] and LSB[7:0] data |
| X | X | 1 | 1 | X | 1 | X | 1 | see Table 8 | 0 | Power-down all DACs, all devices |

**Most Significant Byte**

Most Significant Byte MSB[7:0] consists of eight most significant bits of 12-bit unsigned binary D/A conversion data. C0=1, MSB[7], MSB[6] indicate a powerdown operation as shown in Table 8.

**Least Significant Byte**

Least Significant Byte LSB[7:0] consists of the 4 least significant bits of the 12-bit unsigned binary D/A conversion data, followed by 4 don’t care bits. DAC7574 updates at the falling edge of the acknowledge signal that follows the LSB[0] bit.

**Default Readback Condition**

If the user initiates a readback of a specified channel without first writing data to that specified channel, the default readback is all zeros, since the readback register is initialized to 0 during the power on reset phase.
LDAC Functionality

Depending on the control byte, DACs are synchronously updated on the falling edge of the acknowledge signal that follows LS byte. The LDAC pin is required only when an external timing signal is used to update all the channels of the DAC asynchronously. LDAC is a positive edge triggered asynchronous input that allows four DAC output voltages to be updated simultaneously with temporary register data. The LDAC trigger should only be used after the buffers temporary registers are properly updated through software.

DAC7574 as a Slave Receiver - Standard and Fast Mode

Figure 35 shows the standard and fast mode master transmitter addressing a DAC7574 Slave Receiver with a 7-bit address.

Figure 35. Standard and Fast Mode: Slave Receiver
Figure 36 shows the high-speed mode master transmitter addressing a DAC7574 Slave Receiver with a 7-bit address.

**Figure 36. High-Speed Mode: Slave Receiver**
Master Transmitter Writing to a Slave Receiver (DAC7574) in Standard/Fast Modes

All write access sequences begin with the device address (with R/W = 0) followed by the control byte. This control byte specifies the operation mode of DAC7574 and determines which channel of DAC7574 is being accessed in the subsequent read/write operation. The LSB of the control byte (PD0-Bit) determines if the following data is power-down data or regular data.

With (PD0-Bit = 0) the DAC7574 expects to receive data in the following sequence HIGH-BYTE – LOW-BYTE – HIGH-BYTE – LOW-BYTE..., until a STOP Condition or REPEATED START Condition on the I²C-Bus is recognized (refer to the DATA INPUT MODE section of Table 4).

With (PD0-Bit = 1) the DAC7574 expects to receive 2 Bytes of power-down data (refer to the POWER DOWN MODE section of Table 4).

(1) Use repeated START to secure bus operation and loop back to the stage of write addressing for next Write.
(2) Once DAC7574 is properly addressed and control byte is sent, HIGH–BYTE–LOW–BYTE sequences can repeat until a STOP condition or repeated START condition is received.
Master Transmitter Writing to a Slave Receiver (DAC7574) in HS Mode

When writing data to the DAC7574 in HS-mode, the master begins to transmit what is called the HS-Master Code (0000 1XXX) in F/S-mode. No device is allowed to acknowledge the HS-Master Code, so the HS-Master Code is followed by a NOT acknowledge.

The master then switches to HS-mode and issues a repeated start condition, followed by the address byte (with R/W = 0) after which the DAC7574 acknowledges by pulling SDA low. This address byte is usually followed by the control byte, which is also acknowledged by the DAC7574. The LSB of the control byte (PD0-Bit) determines if the following data is power-down data or regular data.

With (PD0-Bit = 0) the DAC7574 expects to receive data in the following sequence HIGH-BYTE – LOW-BYTE – HIGH-BYTE – LOW-BYTE..., until a STOP condition or repeated start condition on the I²C-Bus is recognized (refer to Table 5 HS-MODE WRITE SEQUENCE - DATA).

With (PD0-Bit = 1) the DAC7574 expects to receive 2 bytes of power-down data (refer to Table 5 HS-MODE WRITE SEQUENCE - POWER DOWN).

\[\text{Figure 38. High-Speed Mode: Slave Transmitter}\]
Master Receiver Reading From a Slave Transmitter (DAC7574) in Standard/Fast Modes

When reading data back from the DAC7574, the user begins with an address byte (with R/W = 0) after which the DAC7574 will acknowledge by pulling SDA low. This address byte is usually followed by the Control Byte, which is also acknowledged by the DAC7574. Following this there is a REPEATED START condition by the Master and the address is resent with (R/W = 1). This is acknowledged by the DAC7574, indicating that it is prepared to transmit data. Two or three bytes of data are then read back from the DAC7574, depending on the (PD0-Bit). The value of Buff-Sel1 and Buff-Sel0 determines, which channel data is read back. A STOP Condition follows.

With the (PD0-Bit = 0) the DAC7574 transmits 2 bytes of data, HIGH-BYTE followed by the LOW-BYTE (refer to Table 2. Data Readback Mode - 2 bytes).

With the (PD0-Bit = 1) the DAC7574 transmits 3 bytes of data, POWER-DOWN-BYTE followed by the HIGH-BYTE followed by the LOW-BYTE (refer to Table 2. Data Readback Mode - 3 bytes).

(1) Use repeated start to secure bus operation and loop back to the stage of write addressing for next Write.
Master Receiver Reading From a Slave Transmitter (DAC7574) in HS-Mode

When reading data to the DAC7574 in HS-MODE, the master begins to transmit, what is called the HS-Master Code (0000 1XXX) in F/S-mode. No device is allowed to acknowledge the HS-Master Code, so the HS-Master Code is followed by a NOT acknowledge.

The Master then switches to HS-mode and issues a REPEATED START condition, followed by the address byte (with R/W = 0) after which the DAC7574 acknowledges by pulling SDA low. This address byte is usually followed by the control byte, which is also acknowledged by the DAC7574.

Then there is a REPEATED START condition initiated by the master and the address is resent with (R/W = 1). This is acknowledged by the DAC7574, indicating that it is prepared to transmit data. Two or Three bytes of data are then read back from the DAC7574, depending on the (PD0-Bit). The value of Buff-Sel1 and Buff-Sel0 determines, which channel data is read back. A STOP condition follows.

With the (PD0-Bit = 0) the DAC7574 transmits 2 bytes of data, HIGH-BYTE followed by LOW-BYTE (refer to Table 7 HS-Mode Readback Sequence).

With the (PD0-Bit = 1) the DAC7574 transmits 3 bytes of data, POWER-DOWN-BYTE followed by the HIGH-BYTE followed by the LOW-BYTE (refer to Table 7 HS-Mode Readback Sequence).

Power-On Reset

The DAC7574 contains a power-on-reset circuit that controls the output voltage during power up. On power up, the DAC register is filled with zeros and the output voltage is 0 V; it remains there until a valid write sequence is made to the DAC. This is useful in applications where it is important to know the state of the output of the DAC while it is in the process of powering up. No device pin should be brought high before supply is applied.
Power-Down Modes

The DAC7574 contains four separate power-down modes of operation. The modes are programmable via two most significant bits of the MSB byte, while (CTRL[0] = PD0 = 1). Table 8 shows how the state of these bits correspond to the mode of operation of the device.

Table 8. Power-Down Modes of Operation for the DAC7574

When (CTRL[0] = PD0 = 0), the device works normally with its normal power consumption of 150 µA at 5 V per channel. However, for the three power-down modes, the supply current falls to 200 nA at 5 V (50 nA at 3 V). Not only does the supply current fall but also the output stage is also internally switched from the output of the amplifier to a resistor network of known values. This has the advantage that the output impedance of the device is known while in power-down mode. There are three different options: the output is connected internally to GND through a 1 kΩ resistor, a 100 kΩ resistor or left open-circuit (high impedance). The output stage is illustrated in Figure 39.

Figure 39. Output Stage During Power Down

All linear circuitry is shut down when the power-down mode is activated. However, the contents of the DAC register are unaffected when in power-down. The time to exit power down is typically 2.5 µs for \( V_{\text{DD}} = 5 \text{ V} \) and 5 µs for \( V_{\text{DD}} = 3 \text{ V} \). (See the Typical Curves section for additional information.)

The DAC7574 offers a flexible power-down interface based on channel register operation. A channel consists of a single 12 bit DAC with power-down circuitry, a temporary storage register (TR) and a DAC register (DR). TR and DR are both 14 bits wide. Two MSBs represent the power-down condition and the 12 LSBs represent data for TR and DR. By using bits 13 and 14 of TR and DR, a power-down condition can be temporarily stored and used just like data. Internal circuits ensure that MSB[7] and MSB[6] get transferred to TR[13] and TR[12] (DR[13] and DR[12]) when the power-down flag (CTRL[0] = PD0) is set. Therefore, DAC7574 treats power-down conditions like data and all the operational modes are still valid for power down. It is possible to broadcast a power-down condition to all the DAC7574s in the system, or it is possible to simultaneously power down a channel while updating data on other channels.

CURRENT CONSUMPTION

The DAC7574 typically consumes 150µA at \( V_{\text{DD}} = 5 \text{ V} \) and 125µA at \( V_{\text{DD}} = 3 \text{ V} \) for each active channel, including reference current consumption. Additional current consumption can occur at the digital inputs if \( V_{\text{IH}} << V_{\text{DD}} \). For most efficient power operation, CMOS logic levels are recommended at the digital inputs to the DAC. In power-down mode, typical current consumption is 200 nA. A delay time of 10 to 20 ms after a power-down command is issued to the DAC is typically sufficient for the power-down current to drop below 10 µA.
DRIVING RESISTIVE AND CAPACITIVE LOADS

The DAC7574 output stage is capable of driving loads of up to 1000 pF while remaining stable. Within the offset and gain error margins, the DAC7574 can operate rail-to-rail when driving a capacitive load. Resistive loads of 2 kΩ can be driven by the DAC7574 while achieving a typical load regulation of 1%. As the load resistance drops below 2 kΩ, the load regulation error increases. When the outputs of the DAC are driven to the positive rail under resistive loading, the PMOS transistor of each Class-AB output stage can enter into the linear region. When this occurs, the added IR voltage drop deteriorates the linearity performance of the DAC. This only occurs within approximately the top 20 mV of the DAC’s digital input-to-voltage output transfer characteristic. The reference voltage applied to the DAC7574 may be reduced below the supply voltage applied to VDD in order to eliminate this condition if good linearity is a requirement at full scale (under resistive loading conditions).

CROSSTALK

The DAC7574 architecture uses separate resistor strings for each DAC channel in order to achieve ultra-low crosstalk performance. DC crosstalk seen at one channel during a full-scale change on the neighboring channel is typically less than 0.5 LSBs. The ac crosstalk measured (for a full-scale, 1 kHz sine wave output generated at one channel, and measured at the remaining output channel) is typically under -100 dB.

OUTPUT VOLTAGE STABILITY

The DAC7574 exhibits excellent temperature stability of ±3 ppm/°C typical output voltage drift over the specified temperature range of the device. This enables the output voltage of each channel to stay within a ±25 µV window for a ±1°C ambient temperature change. Combined with good dc noise performance and true 12-bit differential linearity, the DAC7574 becomes a perfect choice for closed-loop control applications.

SETTLING TIME AND OUTPUT GLITCH PERFORMANCE

Settling time to within the 12-bit accurate range of the DAC7574 is achievable within 10 µs for a full-scale code change at the input. Worst case settling times between consecutive code changes is typically less than 2 µs. The high-speed serial interface of the DAC7574 is designed in order to support up to 188ksps update rate. For full-scale output swings, the output stage of each DAC7574 channel typically exhibits less than 100 mV of overshoot and undershoot when driving a 200 pF capacitive load. Code-to-code change glitches are extremely low (~10 µV) given that the code-to-code transition does not cross an Nx256 code boundary. Due to internal segmentation of the DAC7574, code-to-code glitches occur at each crossing of an Nx256 code boundary. These glitches can approach 100 mVs for N = 15, but settle out within ~2 µs. Sufficient bypass capacitance is required to ensure 10 µs settling under capacitive loading. To observe the settling performance under resistive load conditions, the power supply (hence DAC7574 reference supply) must settle quicker than the DAC7574.
APPLICATION INFORMATION

The following sections give example circuits and tips for using the DAC7574 in various applications. For more information, contact your local TI representative, or visit the Texas Instruments website at http://www.ti.com.

BASIC CONNECTIONS

For many applications, connecting the DAC7574 is extremely simple. A basic connection diagram for the DAC7574 is shown in Figure 40. The 0.1 µF bypass capacitors help provide the momentary bursts of extra current needed from the supplies.

![Figure 40. Typical DAC7574 Connections](image)

**NOTE:** DAC7574 power and input/output connections are omitted for clarity, except I²C Inputs.

The DAC7574 interfaces directly to standard mode, fast mode and high-speed mode I²C controllers. Any microcontroller’s I²C peripheral, including master-only and non-multiple-master I²C peripherals, work with the DAC7574. The DAC7574 does not perform clock-stretching (i.e., it never pulls the clock line low), so it is not necessary to provide for this unless other devices are on the same I²C bus.

Pullup resistors are necessary on both the SDA and SCL lines because I²C bus drivers are open-drain. The size of these resistors depend on the bus operating speed and capacitance on the bus lines. Higher-value resistors consume less power, but increase the transition times on the bus, limiting the bus speed. Lower-value resistors allow higher speed at the expense of higher power consumption. Long bus lines have higher capacitance and require smaller pullup resistors to compensate. If the pullup resistors are too small the bus drivers may not be able to pull the bus line low.

USING GPIO PORTS FOR I²C

Most microcontrollers have programmable input/output pins that can be set in software to act as inputs or outputs. If an I²C controller is not available, the DAC7574 can be connected to GPIO pins, and the I²C bus protocol simulated, or bit-banged, in software. An example of this for a single DAC7574 is shown in Figure 41.
APPLICATION INFORMATION (continued)

Figure 41. Using GPIO With a Single DAC7574

Bit-banging I^2C with GPIO pins can be done by setting the GPIO line to zero and toggling it between input and output modes to apply the proper bus states. To drive the line low, the pin is set to output a zero; to let the line go high, the pin is set to input. When the pin is set to input, the state of the pin can be read; if another device is pulling the line low, this reads as a zero in the port's input register.

Note that no pullup resistor is shown on the SCL line. In this simple case the resistor is not needed. The microcontroller can simply leave the line on output, and set it to one or zero as appropriate. It can do this because the DAC7574 never drives its clock line low. This technique can also be used with multiple devices, and has the advantage of lower current consumption due to the absence of a resistive pullup.

If there are any devices on the bus that may drive their clock lines low, the above method should not be used. The SCL line should be high-Z or zero, and a pullup resistor provided as usual. Note also that this cannot be done on the SDA line in any case, because the DAC7574 drives the SDA line low from time to time, as all I^2C devices do.

Some microcontrollers have selectable strong pullup circuits built in to their GPIO ports. In some cases, these can be switched on and used in place of an external pullup resistor. Weak pullups are also provided on some microcontrollers, but usually these are too weak for I^2C communication. Test any circuit before committing it to production.
APPLICATION INFORMATION (continued)

POWER SUPPLY REJECTION

The positive reference voltage input of DAC7574 is internally tied to the power supply pin of the device. This increases I2C system flexibility, creating room for an extra I2C address pin in a low pin-count package. To eliminate the supply noise appearing at the DAC output, the user must pay close attention to how DAC7574 is powered. The supply to DAC7574 must be clean and well regulated. For best performance, use of a precision voltage reference is recommended to supply power to DAC7574. This is equivalent to providing a precision external reference to the device. Due to low power consumption of DAC7574, load regulation errors are negligible. In order to avoid excess power consumption at the Schmitt-triggered inputs of DAC7574, the precision reference voltage should be close to the I2C bus pullup voltage. For 3-V, 3.3-V and 5-V I2C bus pullup voltages, REF2930, REF2933 and REF02 precision voltage references are recommended respectively. These precision voltage references can be used to supply power for multiple devices on a system.

USING REF02 AS A POWER SUPPLY FOR DAC7574

Due to the extremely low supply current required by the DAC7574, a possible configuration is to use a REF02 +5 V precision voltage reference to supply the required voltage to the DAC7574’s supply input as well as the reference input, as shown in Figure 42. This is especially useful if the power supply is quite noisy or if the system supply voltages are at some value other than 5 V. The REF02 outputs a steady supply voltage for the DAC7574. If the REF02 is used, the current it needs to supply to the DAC7574 is 600 µA typical and 900 µA max for VDD = 5 V. When a DAC output is loaded, the REF02 also needs to supply the current to the load. The total typical current required (with a 5-kΩ load on a single DAC output) is:

600 µA + (5 V / 5 kΩ) = 1.6 mA

The load regulation of the REF02 is typically 0.005%/mA, which results in an error of 400µV for 1.6-mA of current drawn from it. This corresponds to a 0.33 LSB error for a 0 V to 5 V output range.

![Figure 42. REF02 Power Supply](image)

LAYOUT

A precision analog component requires careful layout, adequate bypassing, and clean, well-regulated power supplies.

The power applied to VDD should be well-regulated and low noise. Switching power supplies and dc/dc converters often have high-frequency glitches or spikes riding on the output voltage. In addition, digital components can create similar high-frequency spikes as their internal logic switches states. This noise can easily couple into the DAC output voltage through various paths between the power connections and analog output.
As with the GND connection, V_{DD} should be connected to a positive power-supply plane or trace that is separate from the connection for digital logic until they are connected at the power-entry point. In addition, a 1 \mu F to 10 \mu F capacitor in parallel with a 0.1 \mu F bypass capacitor is strongly recommended. In some situations, additional bypassing may be required, such as a 100 \mu F electrolytic capacitor or even a Pi filter made up of inductors and capacitors—all designed to essentially low-pass filter the –5 V supply, removing the high-frequency noise.

(1) The marketing status values are defined as follows:

**ACTIVE**: Product device recommended for new designs.

**LIFEBUY**: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND**: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW**: Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE**: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check [http://www.ti.com/productcontent](http://www.ti.com/productcontent) for the latest availability information and additional product content details.

**TBD**: The Pb-Free/Green conversion plan has not been defined.

**Pb-Free (RoHS)**: TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

**Pb-Free (RoHS Exempt)**: This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

**Green (RoHS & no Sb/Br)**: TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. – The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) Multiple Top-Side Markings will be inside parentheses. Only one Top-Side Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Top-Side Marking for that device.

TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

*All dimensions are nominal.*

**TAPE DIMENSIONS**

- **A0**: Dimension designed to accommodate the component width
- **B0**: Dimension designed to accommodate the component length
- **K0**: Dimension designed to accommodate the component thickness
- **W**: Overall width of the carrier tape
- **P1**: Pitch between successive cavity centers

**REEL DIMENSIONS**

- **Reel Diameter**: Diameter of the reel
- **Reel Width (W1)**: Width of the reel

**QUADRANT ASSIGNMENTS FOR PIN 1 ORIENTATION IN TAPE**

- **Q1**: Quadrant 1
- **Q2**: Quadrant 2
- **Q3**: Quadrant 3
- **Q4**: Quadrant 4

**User Direction of Feed**

NOTES:

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. This dimension does not include mold flash, protrusions, or gate burrs. Mold flash, protrusions, or gate burrs shall not exceed 0.15 mm per side.
4. This dimension does not include interlead flash. Interlead flash shall not exceed 0.25 mm per side.
5. Reference JEDEC registration MO-187, variation BA.
NOTES: (continued)

6. Publication IPC-7351 may have alternate designs.
7. Solder mask tolerances between and around signal pads can vary based on board fabrication site.
8. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.
9. Board assembly site may have different recommendations for stencil design.
