TPS61253A 3.8-MHz, 5-V / 4-A Boost Converter in 1.2-mm x 1.3-mm WCSP

1 Features

- Wide Input Voltage Range from 2.3 V to 5.5 V
- Fixed Output Voltage: 4.5 / 4.7 / 5.0 / 5.2 V
- Two FETs Integrated: 35-mΩ LS-FET, 60-mΩ HS-FET
- $I_{OUT} \geq 1500\text{mA}$ continuously at $V_{OUT} = 5 \text{ V}$ and $V_{IN} \geq 3 \text{ V}$
- 42-µA Quiescent Current from Input
- 4-A Switching Valley Current Limit
- 3.8-MHz Switching Frequency
- Selectable Auto PFM, Forced PWM and Ultrasonic Mode
- Support Pass-Through Mode
- ±2% Output Voltage Accuracy
- 600-µs Soft-Start Time
- Hiccup-Mode Short Protection
- Load Disconnection during Shutdown
- Thermal Shutdown
- Total Solution Size < 25 mm²
- Create a Custom Design Using the TPS61253A With the WEBENCH® Power Designer

2 Applications

- Smart Phones
- Portable Speaker
- USB Charging Ports
- NFC PA Supply
- Li Battery to 5-V Power Conversion

3 Description

The TPS6125xA device provides a power supply solution for battery-powered portable applications. With the input voltage ranging from 2.3 V to 5.5 V, the device supports the applications powered by the Li-ion batteries with the extended voltage range. Different fixed output voltage versions are available of 4.5 V, 4.7 V, 5 V and 5.2 V. The TPS6125xA supports up to 1500-mA load current from a battery discharged as low as 3 V.

The TPS6125xA operates at typical 3.8-MHz switching frequency. The TPS6125xA could be flexibly configured at the Auto PFM mode, forced PWM mode or ultrasonic mode. The Auto PFM mode could benefit with the high efficiency at the light load. The forced PWM operation can make the switching frequency be constant crossing the whole load range. The ultrasonic mode keeps the switching frequency always larger than 25 kHz at any load condition to avoid the acoustic noise.

TPS6125xA has a built-in 600-µs soft start to avoid the inrush current at startup. When the output is shorted, the device enters into the hiccup mode and recovers automatically after the short releases. During the shutdown, the load is completely disconnected from the input end with maximum 1.3-uA current being consumed.

The TPS6125xA comes in a 9-ball 1.2-mm x 1.3-mm WCSP package and offers a very small solution size with the minimum amount of external components.

8 Detailed Description

8.1 Overview

The TPS6125xA synchronous step-up converter typically operates at a quasi-constant 3.8-MHz frequency pulse width modulation (PWM) from the moderate to heavy load currents. During the PWM operation, the converter uses a quasi-constant on-time valley current mode control scheme to achieve the excellent line / load regulation and allows the use of a small inductor and ceramic capacitors. Based on the $V_{IN}$ / $V_{OUT}$ ratio, a simple circuit predicts the required on-time. At the beginning of the switching cycle, the low-side N-MOS switch is turned on and the inductor current ramps up to a peak current that is defined by the on-time and the inductance. In the second phase, once the on-timer has expired, the rectifier FET is turned on and the inductor current decays to a preset valley current threshold. Then, the switching cycle repeats by setting the on timer again and activating the low-side N-MOS switch.

At the light load current conditions, the TPS6125xA could be flexibly configured at the Auto PFM mode, the forced PWM or the ultrasonic mode. At the Auto PFM mode, the TPS6125xA converter operates in Power Save Mode with pulse frequency modulation (PFM) and improves the efficiency. For the forced PWM mode, the switching frequency is the same at the light load as that of heavy load. The ultrasonic mode is a unique control feature that keeps the switching frequency above 25 kHz to avoid the acoustic audible frequencies toward virtually no load condition.

In general, a dc/dc step-up converter can only operate in "true" boost mode, i.e. the output “boosted” by a certain amount above the input voltage. The TPS6125xA device operates differently as it can smoothly transition in and out of pass-through operation ($V_{IN}$ exceeds the preset out of Boost). Therefore the output can be kept as close as possible to its regulation limits even though the converter is subject to an input voltage that tends to be excessive.

Internal soft-start and loop compensation simplify the design process while minimizing the number of external components.

8.2 Functional Block Diagram
8.3 Feature Description

8.3.1 Startup
The TPS6125xA integrates an internal circuit that controls the ramp up of the output voltage during start-up and prevents the converter from the large inrush current. When the device is enabled, the high-side rectifying switch turns on to charge the output capacitor linearly which is called the pre-charge phase. During the pre-charge phase, the output current is limited to the pre-charge current limit $I_{\text{LIM,DC}}$. The pre-charge phase terminates until the output voltage getting close to the input voltage.

Once the output capacitor has been biased close to the input voltage, the device starts switching which is called the soft start phase. During the soft start phase, there is a soft start voltage controlling the FB pin voltage, and the output voltage rising slope follows the soft start voltage slope. The device finishes the soft start phase and operates normally when the nominal output voltage is reached.

### Table 1. Start-up Mode Description

<table>
<thead>
<tr>
<th>MODE</th>
<th>DESCRIPTION</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pre-charge</td>

</tr>
<tr>
<td>Boost Soft Start</td>
<td>$V_{\text{OUT}}$ starts up with switching phase</td>
<td>$V_{\text{OUT,BOOST}} \geq V_{\text{OUT}} \geq V_{\text{IN}} - 300 \text{ mV}$</td>
</tr>
</tbody>
</table>

8.3.2 Enable and Disable
The device is enabled by setting EN pin to a voltage above 1.2 V and $V_{\text{IN}}$ above UVLO threshold. At first, the internal reference is activated and the internal analog circuits are settled. Afterwards, the startup is activated and the output voltage ramps up. With the EN pin pulled to ground, the device enters into the shutdown mode. In the shutdown mode, the TPS6125xA stops switching and the internal control circuitry is turned off.

8.3.3 Under-Voltage Lockout (UVLO)
The under voltage lockout circuit prevents the device from malfunctioning at the low input voltage of the battery from the excessive discharge. The device starts operation once the rising $V_{\text{IN}}$ trips the under-voltage lockout (UVLO) threshold and it disables the output stage of the converter once the $V_{\text{IN}}$ is below UVLO falling threshold.

8.3.4 Current Limit Operation
During the startup phase, the output current is limited to the pre-charge current limit which is specified as the $I_{\text{LIM,DC}}$ in the Electrical Characteristic Table.

The TPS6125xA employs a valley current sensing scheme at the normal boost switching phase. When the output load is increased, the cycle-by-cycle valley current limit will be triggered. As shown in Figure 18, the maximum continuous output current, prior to entering the current limit operation, can be defined by Equation 1:

$$I_{\text{OUT, LIM}} = (1-D) \times (I_{\text{VALLEY, LIM}} + \frac{1}{2} \Delta I_L)$$

$$D = 1 - \frac{V_{\text{IN}} \times \eta}{V_{\text{OUT}}}$$

$$\Delta I_L = \frac{V_{\text{IN}} \times D}{L \times f}$$

where
- $I_{\text{OUT, LIM}}$ is the output current limit, $I_{\text{VALLEY, LIM}}$ is switching valley current limit
- $\Delta I_L$ is the peak-peak inductor current ripple
- $D$ is the duty cycle, $f$ is the switching frequency, $\eta$ is the efficiency, $L$ is the inductor
- $V_{\text{OUT}}$ is the output voltage, $V_{\text{IN}}$ is the input voltage

Copyright © 2017, Texas Instruments Incorporated

Product Folder Links: TPS61253A
If the output current is further increased and trigger the short protection threshold (typical 6A of inductor current), the TPS6125xA enters into the hiccup mode. Once the hiccup is triggered, the device turns on the high-side FET for around 1 ms with the pre-charge current limit and stops for around 20 ms. The hiccup on / off cycle repeats again and again if the short condition is present. Figure 19 illustrates the TPS6125xA’s working scheme of the hiccup mode. The average current and thermal will be much lowered at the hiccup steady state and the device could recover automatically as long as the short releases.

8.3.5 Load Disconnection

The advantage of TPS6125xA is that this converter disconnects the output from the input of the power supply when it is disabled. In case of a connected battery it prevents it from being discharged during shutdown of the converter.

8.3.6 Thermal Shutdown

The TPS6125xA has a built-in temperature sensor which monitors the internal junction temperature, $T_J$. If the junction temperature exceeds the threshold (typical 150 °C), the device goes into the thermal shutdown, and the high-side and low-side FETs are turned off. When the junction temperature falls below the thermal shutdown falling threshold (typical 130 °C), the device resumes the operation.
8.4 Device Functional Modes

8.4.1 Auto PFM Mode
The device integrates the Power Save Mode with pulse frequency modulation (Auto PFM) to improve the efficiency at the light load. At the light load operation, when the valley current of the inductor triggers the Auto PFM threshold, the device enters into the Auto PFM mode operation. During the Auto PFM operation, the output voltage is regulated at typically 100.8% of voltage of the heavy load with the off time extended to lower the switching frequency. The Auto PFM operation exists when valley current exceeds the Auto PFM threshold. Figure 20 shows the output voltage behavior of Auto PFM operation.

8.4.2 Forced PWM Mode
In the forced PWM mode, the TPS6125xA keeps the switching frequency being constant for the whole load range. When the load current decreases, the output of the internal error amplifier decreases as well to lower the inductor peak current and delivers less power from input to output. The high-side FET is not turned off even if the current through the FET goes negative to keep the switching frequency being the same as that of the heavy load.

8.4.3 Ultrasonic Mode
The ultrasonic mode is an unique control feature that keeps the switching frequency above the acoustic audible frequency toward no load condition. The ultrasonic mode control circuit monitors the switching frequency and keeps the switching frequency above 25 kHz to avoid the acoustic band. The output voltage becomes typically 1.6% higher than PWM operation. Figure 21 illustrates the details of ultrasonic mode operation.

8.4.4 Mode Configuration
There is a mode pin to configure the TPS6125xA into different operation modes. Table 2 describes the conditions of each mode operation.

---

#### 8.4.5 Pass-Through Mode

When the input voltage is higher than $V_{\text{OUT}} + 0.1$ V and $V_{\text{OUT}}$ is higher than the nominal output voltage, the device automatically enters to the Pass-Through mode. In the Pass-Through mode, the high-side FET is fully turned on and the low side switch is turned off. The output voltage follows the input with the drop caused by the inductor resistance and the high-side FET resistance.
9 Application and Implementation

NOTE
Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI’s customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information

With a wide input voltage range of 2.3 V to 5.5 V, the TPS6125xA supports applications powered by Li-ion batteries with extended voltage range. Intended for the low-power applications, it supports up to 1500-mA load current from a battery discharged as low as 3 V and allows the use of low cost chip inductor and capacitors. Different fixed voltage output versions are available from 4.5 V to 5.2 V. The TPS6125xA offers a very small solution size due to minimum amount of external components. It allows the use of small inductors and input capacitors to achieve a small solution size. During the pass-through mode, the output voltage is biased to the input voltage.

9.2 Typical Application

Figure 22. Typical Application Circuit

9.2.1 Design Requirements

In this example, TPS6125xA is used to design a 5-V output Boost converter. The TPS6125xA can be powered by one-cell Li-ion battery. It supports up to 1500-mA output current from the input voltage as low as 3.0 V. During shutdown, the load is completely disconnected from the battery.

9.2.2 Detailed Design Procedure

9.2.2.1 Custom Design With WEBENCH® Tools

Click here to create a custom design using the TPS61253A device with the WEBENCH® Power Designer.

1. Start by entering the input voltage (V\text{IN}), output voltage (V\text{OUT}), and output current (I\text{OUT}) requirements.
2. Optimize the design for key parameters such as efficiency, footprint, and cost using the optimizer dial.
3. Compare the generated design with other possible solutions from Texas Instruments.

The WEBENCH Power Designer provides a customized schematic along with a list of materials with real-time pricing and component availability.

In most cases, these actions are available:
- Run electrical simulations to see important waveforms and circuit performance
- Run thermal simulations to understand board thermal performance
Typical Application (continued)

- Export customized schematic and layout into popular CAD formats
- Print PDF reports for the design, and share the design with colleagues

Get more information about WEBENCH tools at www.ti.com/WEBENCH.

9.2.3 Inductor Selection

A boost converter normally requires two main passive components for storing energy during the conversion, an inductor and an output capacitor. It is advisable to select an inductor with a saturation current rating higher than the possible peak current flowing through the power switches.

The inductor peak current varies as a function of the load, the input and output voltages. It can be estimated using Equation 4.

\[
I_{\text{PEAK}} = \frac{V_{\text{IN}} \cdot D}{2 \cdot f \cdot L} + \frac{I_{\text{OUT}}}{(1-D)} \quad \text{with} \quad D = 1 - \frac{V_{\text{IN}} \cdot \eta}{V_{\text{OUT}}}
\]

Selecting an inductor with insufficient saturation current can lead to excessive peak current in the converter. This could eventually harm the device and reduce its reliability.

When selecting the inductor, as well as the inductance, parameters of importance are: the maximum current rating, series resistance, and operating temperature. The inductor DC current rating should be greater (by some margin) than the maximum input average current, refer to Equation 5 for more details.

\[
I_{\text{(DC)}} = \frac{V_{\text{OUT}}}{V_{\text{IN}}} \cdot \frac{1}{\eta} \cdot I_{\text{OUT}}
\]

The TPS6125xA series of step-up converters could support operating with an effective inductance in the range of 0.33 μH to 1.3 μH and with effective output capacitance in the range of 3.5 μF to 30 μF. The internal compensation is optimized for an output filter of the inductance between 0.56 μH and 1 μH and output capacitance from 5 μF to 10 μF. Larger or smaller inductor and capacitor values can be used to optimize the performance of the device for specific operating conditions. For more details, see the Checking Loop Stability section.

In high-frequency converter applications, the efficiency is essentially affected by the inductor AC resistance (i.e. quality factor) and to a smaller extent by the inductor DCR value. To achieve high efficiency operation, care should be taken in selecting inductors featuring a quality factor above 25 at the switching frequency. Increasing the inductor value produces lower RMS current, but degrades transient response. For a given physical inductor size, increased inductance usually results in an inductor with lower saturation current.

The total losses of the coil consist of both the losses in the DC resistance, \(R_{\text{(DC)}}\), and the following frequency-dependent components:

- The losses in the core material (magnetic hysteresis loss, especially at high switching frequencies)
- Additional losses in the conductor from the skin effect (current displacement at high frequencies)
- Magnetic field losses of the neighboring windings (proximity effect)
- Radiation losses

The following inductor series from different suppliers have been used with the TPS6125xA converters.

9.2.4 Output Capacitor

For the output capacitor, it is recommended to use small ceramic capacitors placed as close as possible to the VOUT and GND pins of the IC. If, for any reason, the application requires the use of large capacitors which cannot be placed close to the IC, using a smaller ceramic capacitor in parallel to the large one is highly recommended. This small capacitor should be placed as close as possible to the VOUT and GND pins of the IC. To get an estimate of the recommended minimum output capacitance, Equation 6 can be used.

\[
C_{\text{MIN}} = \frac{I_{\text{OUT}} \cdot (V_{\text{OUT}} - V_{\text{IN}})}{f \cdot \Delta V \cdot V_{\text{OUT}}}
\]  

(6)

Where f is the switching frequency which is 3.8 MHz (typ.) and \(\Delta V\) is the maximum allowed output ripple.

With a chosen ripple voltage of 25mV, a minimum effective capacitance of 7 µF is needed for maximum 1500mA load. The capacitor could be smaller if the load is lower or the ripple can be larger. The total ripple is larger due to the ESR of the output capacitor. This additional component of the ripple can be calculated using Equation 7

\[
V_{\text{ESR}} = I_{\text{OUT}} \cdot R_{\text{ESR}}
\]  

(7)

An MLCC capacitor with twice the value of the calculated minimum should be used due to DC bias effects. This is required to maintain control loop stability. The output capacitor requires either an X7R or X5R dielectric. Y5V and Z5U dielectric capacitors, aside from their wide variation in capacitance over temperature, become resistive at high frequencies. There are no additional requirements regarding minimum ESR. Larger capacitors cause lower output voltage ripple as well as lower output voltage drop during load transients but the total effective output capacitance value should not exceed ca. 30µF.

DC bias effect: high cap. ceramic capacitors exhibit DC bias effects, which have a strong influence on the device’s effective capacitance. Therefore the right capacitor value has to be chosen very carefully. Package size and voltage rating in combination with material are responsible for differences between the rated capacitor value and effective capacitance. For instance, a 10-µF X5R 6.3-V 0603 MLCC capacitor would typically show an effective capacitance of less than 4 µF under 5 V bias condition.

9.2.5 Input Capacitor

Multilayer ceramic capacitors are an excellent choice for input decoupling of the step-up converter as they have extremely low ESR and are available in small footprints. Input capacitors should be located as close as possible to the device. While a 4.7-µF input capacitor is sufficient for most applications, larger values may be used to reduce input current ripple without limitations.

Take care when using only ceramic input capacitors. When a ceramic capacitor is used at the input and the power is being supplied through long wires, such as from a wall adapter, a load step at the output can induce ringing at the VIN pin. This ringing can couple to the output and be mistaken as loop instability or could even damage the part. Additional “bulk” capacitance (electrolytic or tantalum) should in this circumstance be placed between C_IN and the power source lead to reduce ringing that can occur between the inductance of the power source leads and C_IN.

9.2.6 Checking Loop Stability

The first step of circuit and stability evaluation is to look from a steady-state perspective at the following signals:

- Switching node, SW
- Inductor current, I_L
- Output ripple voltage, V_{OUT(AC)}

These are the basic signals that need to be measured when evaluating a switching converter. When the switching waveform shows large duty cycle jitter or the oscillation happens for the output voltage or inductor current, the regulation loop may be unstable. This is often a result of board layout and/or L-C combination.
As a next step in the evaluation of the regulation loop, the load transient response is tested. The time between the application of the load transient and the turn on of the high-side FET, the output capacitor must supply all of the current required by the load. \( V_{OUT} \) immediately shifts by an amount equal to \( \Delta I_{LOAD} \times ESR \), where ESR is the effective series resistance of \( C_{OUT} \). \( \Delta I_{LOAD} \) begins to charge or discharge \( C_{OUT} \) generating a feedback error signal used by the regulator to return \( V_{OUT} \) to its steady-state value. The results are most easily interpreted when the device operates in PWM mode.

During this recovery time, \( V_{OUT} \) can be monitored for settling time, overshoot or ringing that helps judge the converter’s stability. Without any ringing, the loop has usually more than 45° of phase margin. Because the damping factor of the circuitry is directly related to several resistive parameters (e.g., MOSFET \( r_{DS(on)} \)) that are temperature dependant, the loop stability analysis has to be done over the input voltage range, load current range, and temperature range.

9.3 System Examples

For the < 1000 mA output current application, the output capacitors could be less. Figure 31 shows the typical application circuit for the lower current applications.

**Figure 31. Typical Application with Minimum Output Capacitance**

10 Power Supply Recommendations

The power supply can be three-cell alkaline, NiCd or NiMH, or one-cell Li-Ion or Li-Polymer battery. The input supply should be well regulated with the rating of TPS6125xA. If the input supply is located more than a few inches from the device, additional bulk capacitance may be required in addition to the ceramic bypass capacitors. An electrolytic or tantalum capacitor with a value of 47 µF is a typical choice.
11 Layout

11.1 Layout Guidelines

For all switching power supplies, the layout is an important step in the design, especially at high peak currents and high switching frequencies. If the layout is not carefully done, the regulator could show stability problems as well as EMI problems. Therefore, use wide and short traces for the main current path and for the power ground tracks. The input capacitor, output capacitor, and the inductor should be placed as close as possible to the IC. Use a common ground node for power ground and a different one for control ground to minimize the effects of ground noise. Connect these ground nodes at any place close to the ground pins of the IC.

11.2 Layout Example

![Recommended Layout Diagram]

Figure 32. Recommended Layout

11.3 Thermal Considerations

Implementation of integrated circuits in low-profile and fine-pitch surface-mount packages typically requires special attention to power dissipation. Many system-dependent issues such as thermal coupling, airflow, added heat sinks and convection surfaces, and the presence of other heat-generating components affect the power-dissipation limits of a given component.

Three basic approaches for enhancing thermal performance are listed below:

- Improving the power dissipation capability of the PCB design
- Improving the thermal coupling of the component to the PCB
- Introducing airflow in the system

As power demand in portable designs is more and more important, designers must figure the best trade-off between efficiency, power dissipation and solution size. Due to integration and miniaturization, junction temperature can increase significantly which could lead to bad application behaviors (i.e. premature thermal shutdown or worst case reduce device reliability).

Junction-to-ambient thermal resistance is highly application and board-layout dependent. In applications where high maximum power dissipation exists, special care must be paid to thermal dissipation issues in board design. The device operating junction temperature \((T_J)\) should be kept below 125°C.
12 Device and Documentation Support

12.1 Device Support

12.1.1 Development Support

12.1.1.1 Custom Design With WEBENCH® Tools

Click here to create a custom design using the TPS61253A device with the WEBENCH® Power Designer.

1. Start by entering the input voltage \(V_{\text{IN}}\), output voltage \(V_{\text{OUT}}\), and output current \(I_{\text{OUT}}\) requirements.
2. Optimize the design for key parameters such as efficiency, footprint, and cost using the optimizer dial.
3. Compare the generated design with other possible solutions from Texas Instruments.

The WEBENCH Power Designer provides a customized schematic along with a list of materials with real-time pricing and component availability.

In most cases, these actions are available:
- Run electrical simulations to see important waveforms and circuit performance
- Run thermal simulations to understand board thermal performance
- Export customized schematic and layout into popular CAD formats
- Print PDF reports for the design, and share the design with colleagues

Get more information about WEBENCH tools at www.ti.com/WEBENCH.

(1) The marketing status values are defined as follows:
- **ACTIVE**: Product device recommended for new designs.
- **LIFEBUY**: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
- **NRND**: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
- **PREVIEW**: Device has been announced but is not in production. Samples may or may not be available.
- ** OBSOLETE**: TI has discontinued the production of the device.

(2) **RoHS**: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".
- **RoHS Exempt**: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.
- **Green**: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) **MSL, Peak Temp.** - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "--" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

TI RESOURCES ARE PROVIDED “AS IS” AND WITH ALL FAULTS. TI DISCLAIMS ALL OTHER WARRANTIES OR REPRESENTATIONS, EXPRESS OR IMPLIED, REGARDING RESOURCES OR USE THEREOF, INCLUDING BUT NOT LIMITED TO ACCURACY OR COMPLETENESS, TITLE, ANY EPIDEMIC FAILURE WARRANTY AND ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, AND NON-INFRINGEMENT OF ANY THIRD PARTY INTELLECTUAL PROPERTY RIGHTS. TI SHALL NOT BE LIABLE FOR AND SHALL NOT DEFEND OR INDEMNIFY DESIGNER AGAINST ANY CLAIM, INCLUDING BUT NOT LIMITED TO ANY INFRINGEMENT CLAIM THAT RELATES TO OR IS BASED ON ANY COMBINATION OF PRODUCTS EVEN IF DESCRIBED IN TI RESOURCES OR OTHERWISE. IN NO EVENT SHALL TI BE LIABLE FOR ANY ACTUAL, DIRECT, SPECIAL, COLLATERAL, INDIRECT, PUNITIVE, INCIDENTAL, CONSEQUENTIAL OR EXEMPLARY DAMAGES IN CONNECTION WITH OR ARISING OUT OF TI RESOURCES OR USE THEREOF, AND REGARDLESS OF WHETHER TI HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

Unless TI has explicitly designated an individual product as meeting the requirements of a particular industry standard (e.g., ISO/TS 16949 and ISO 26262), TI is not responsible for any failure to meet such industry standard requirements.

Where TI specifically promotes products as facilitating functional safety or as compliant with industry functional safety standards, such products are intended to help enable customers to design and create their own applications that meet applicable functional safety standards and requirements. Using products in an application does not by itself establish any safety features in the application. Designers must ensure compliance with safety-related requirements and standards applicable to their applications. Designer may not use any TI products in life-critical medical equipment unless authorized officers of the parties have executed a special contract specifically governing such use. Life-critical medical equipment is medical equipment where failure of such equipment would cause serious bodily injury or death (e.g., life support, pacemakers, defibrillators, heart pumps, neurostimulators, and implantables). Such equipment includes, without limitation, all medical devices identified by the U.S. Food and Drug Administration as Class III devices and equivalent classifications outside the U.S.

TI may expressly designate certain products as completing a particular qualification (e.g., Q100, Military Grade, or Enhanced Product). Designers agree that it has the necessary expertise to select the product with the appropriate qualification designation for their applications and that proper product selection is at Designers’ own risk. Designers are solely responsible for compliance with all legal and regulatory requirements in connection with such selection.

Designer will fully indemnify TI and its representatives against any damages, costs, losses, and/or liabilities arising out of Designer’s non-compliance with the terms and provisions of this Notice.
