INA828 50-µV Offset, 7-nV/√Hz Noise, Low-Power, Precision Instrumentation Amplifier

1 Features

- Precision Instrumentation Amplifier Evolution:
  - Second Generation: INA828
  - First Generation: INA128
- Low Offset Voltage: 50 µV, MAX
- Gain Drift: 5 ppm/°C (G = 1), 50 ppm/°C (G > 1)
- Noise: 7 nV/√Hz
- Bandwidth: 2 MHz (G = 1), 260 kHz (G = 100)
- Stable with 1-nF Capacitive Loads
- Inputs Protected Up to ±40 V
- Common-Mode Rejection:
  - 110 dB, MIN (G = 10)
- Power-Supply Rejection: 100 dB, MIN (G = 1)
- Supply Current: 650 µA, MAX
- Supply Range:
  - Single Supply: 4.5 V to 36 V
  - Dual Supply: ±2.25 V to ±18 V
- Specified Temperature Range: −40°C to +125°C
- Package: 8-Pin SOIC

2 Applications

- Industrial Process Controls
- Circuit Breakers
- Battery Testers
- ECG Amplifiers
- Power Automation
- Medical Instrumentation
- Portable Instrumentation

3 Description

The INA828 is a high-precision instrumentation amplifier that offers low power consumption and operates over a very wide single- or dual-supply range. A single external resistor sets any gain from 1 to 1000. The device offers excellent precision due to the use of new super-beta input transistors which provide exceptionally low input offset voltage, offset voltage drift, input bias current, and input voltage and current noise. Additional circuitry protects the inputs against overvoltage up to ±40 V.

The INA828 is optimized to provide excellent common-mode rejection ratio. At G = 1, the common-mode rejection ratio exceeds 90 dB across the full input common-mode range. The device is well-suited for low-voltage operation from a 5-V single supply as well as dual supplies up to ±18 V. Finally, INA828 is available in an 8-pin SOIC package and specified over the −40°C to +125°C temperature range.

(1) Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under Recommended Operating Conditions. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

(2) Short-circuit to \(V_S\) / 2.

(1) Total offset, referred-to-input (RTI): $V_{OS} = (V_{OSI}) + (V_{OSO} / G)$.
(2) Offset drifts are uncorrelated. Input-referred offset drift is calculated using: $\Delta V_{OS(RTI)} = \sqrt{\Delta V_{OS}^2 + (\Delta V_{OSO} / G)^2}$
(3) Specified by characterization.
(4) Input voltage range of the INA828 input stage. The input range depends on the common-mode voltage, differential voltage, gain, and reference voltage. See Typical Characteristic curves Figure 48 through Figure 51 for more information.
(5) Total RTI voltage noise is equal to: $e_{N(RTI)} = \sqrt{e_{NI}^2 + (e_{NO} / G)^2}$
(6) The values specified for $G > 1$ do not include the effects of the external gain-setting resistor, $R_G$.

7 Detailed Description

7.1 Overview

The INA828 is a monolithic precision instrumentation amplifier incorporating a current-feedback input stage and a 4-resistor difference amplifier output stage. The differential input voltage is buffered by Q₁ and Q₂ and is forced across R_G, which causes a signal current to flow through R_G, R₁, and R₂. The output difference amplifier, A₃, removes the common-mode component of the input signal and refers the output signal to the REF terminal. The V_BE and voltage drop across R₁ and R₂ produce output voltages on A₁ and A₂ that are approximately 0.8 V lower than the input voltages.

Each input is protected by two field-effect transistors (FETs) that provide a low series resistance under normal signal conditions, and preserve excellent noise performance. When excessive voltage is applied, these transistors limit input current to approximately 8 mA.

7.2 Functional Block Diagram
7.3 Feature Description

7.3.1 Setting the Gain

Figure 52 shows that the gain of the INA828 is set by a single external resistor, $R_G$, connected between the RG pins (pins 1 and 8).

The value of $R_G$ is selected according to:

$$ G = 1 + \frac{50 \text{k} \Omega}{R_G} $$

(1)

Table 1 lists several commonly-used gains and resistor values. The 50-kΩ term in Equation 1 comes from the sum of the two internal 25-kΩ feedback resistors. These on-chip resistors are laser-trimmed to accurate absolute values. The accuracy and temperature coefficients of these resistors are included in the gain accuracy and drift specifications of the INA828.

7.3.1.1 Gain Drift

The stability and temperature drift of the external gain setting resistor, $R_G$, also affects gain. The contribution of $R_G$ to gain accuracy and drift can be determined from Equation 1.

The best gain drift of 5 ppm/°C (maximum) can be achieved when the INA828 uses $G = 1$ without $R_G$ connected. In this case, gain drift is limited only by the slight mismatch of the temperature coefficient of the integrated 40-kΩ resistors in the differential amplifier ($A_3$). At gains greater than 1, gain drift increases as a result of the individual drift of the 25-kΩ resistors in the feedback of $A_1$ and $A_2$, relative to the drift of the external gain resistor $R_G$. The low temperature coefficient of the internal feedback resistors significantly improves the overall temperature stability of applications using gains greater than 1 V/V over alternate solutions.

Low resistor values required for high gain can make wiring resistance important. Sockets add to the wiring resistance and contribute additional gain error (such as a possible unstable gain error) at gains of approximately 100 or greater. To assure stability, avoid parasitic capacitance of more than a few picofarads at $R_G$ connections. Careful matching of any parasitics on both $R_G$ pins maintains optimal CMRR over frequency; see Typical Characteristics, Figure 17.

7.3.2 EMI Rejection

Texas Instruments developed a method to accurately measure the immunity of an amplifier over a broad frequency spectrum, extending from 10 MHz to 6 GHz. This method uses an EMI rejection ratio (EMIRR) to quantify the ability of the INA828 to reject EMI. The offset resulting from an input EMI signal can be calculated using Equation 2:

$$\Delta V_{OS} = \left( \frac{V_{RF\_PEAK}^2}{100 \text{ mV}_P} \right) \cdot 10^{\left( \frac{\text{EMIRR (dB)}}{20} \right)}$$

where

- $V_{RF\_PEAK}$ is the peak amplitude of the input EMI signal.

Figure 53 and Figure 54 show the INA828 EMIRR graph for both differential and common-mode EMI rejection across this frequency range. Table 2 shows the EMIRR values for the INA828 at frequencies commonly encountered in real-world applications. Applications listed in Table 2 can be centered on or operated near the particular frequency shown. Depending on the end-system requirements, additional EMI filters may be required near the signal inputs of the system, as well as incorporating known good practices such as using short traces, low-pass filters, and damping resistors combined with parallel and shielded signal routing.

7.3.3 Input Common-Mode Range

The linear input voltage range of the INA828 input circuitry extends within 2 Volts of both power supplies and maintains excellent common-mode rejection throughout this range. The common-mode range for the most common operating conditions are shown in Figure 55, Figure 50, and Figure 51. The common-mode range for other operating conditions is best calculated using the INA common-mode range calculating tool. The INA828 device can operate over a wide range of power supplies and VREF configurations, thus providing a comprehensive guide to common-mode range limits for all possible conditions is impractical.

![Figure 57. Input Common-Mode Voltage vs Output Voltage](image)

![Figure 58. Input Common-Mode Voltage vs Output Voltage](image)
7.3.4 Input Protection

The inputs of the INA828 device are individually protected for voltages up to ±40 V. For example, a condition of –40 V on one input and 40 V on the other input does not cause damage. Internal circuitry on each input provides low series impedance under normal signal conditions. If the input is overloaded, the protection circuitry limits the input current to a value of approximately 8 mA.

![Input Current Path During an Overvoltage Condition](image)

**Figure 59. Input Current Path During an Overvoltage Condition**

During an input overvoltage condition, current flows through the input protection diodes into the power supplies, see Figure 59. If the power supplies are unable to sink current, then Zener diode clamps (ZD1 and ZD2 in Figure 59) must be placed on the power supplies to provide a current pathway to ground. Figure 60 illustrates the input current for input voltages from –40 V to +40 V when the INA828 is powered by ±15-V supplies.

7.4 Device Functional Modes

The INA828 has a single functional mode and is operational when the power-supply voltage is greater than 4.5 V (±2.25 V). The maximum power-supply voltage for the INA828 is 36 V (±18 V).
8 Application and Implementation

NOTE
Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI’s customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Reference Terminal

The output voltage of the INA828 is developed with respect to the voltage on the reference terminal, REF. Often, in dual-supply operation, the reference pin (pin 6) is connected to the low-impedance system ground. In single-supply operation, offsetting the output signal to a precise mid-supply level is useful (for example, 2.5 V in a 5-V supply environment). To accomplish this level shift, a voltage source must be connected to the REF pin to level-shift the output so that the INA828 can drive a single-supply ADC.

The voltage source applied to the reference terminal must have a low output impedance. As illustrated in Figure 61, any resistance at the reference terminal (shown as $R_{REF}$ in Figure 61) is in series with one of the internal 40-kΩ resistors.

![Figure 61. Parasitic Resistance Shown at the Reference Terminal](image)

The parasitic resistance at the reference terminal, $R_{REF}$, creates an imbalance in the 4 resistors of the internal difference amplifier, resulting in degraded common-mode rejection ratio (CMRR). Figure 62 shows the degradation in CMRR of the INA828 for increasing resistance at the reference terminal. For the best performance, keep the source impedance to the REF terminal, $R_{REF}$, below 5 Ω.
Reference Terminal (continued)

Figure 62. The Effect of Increasing Resistance at the Reference Terminal

Voltage reference ICs are an excellent option for providing a low-impedance voltage source for the reference terminal. However, if a resistor voltage divider is used to generate a reference voltage, it must be buffered by an op amp as shown in Figure 63 to avoid CMRR degradation.

Figure 63. Using an Op Amp to Buffer Reference Voltages
8.2 Input Bias Current Return Path

The input impedance of the INA828 is extremely high—approximately 100 GΩ. However, a path must be provided for the input bias current of both inputs. This input bias current is typically 150 pA. High input impedance means that this input bias current changes very little with varying input voltage.

Input circuitry must provide a path for this input bias current for proper operation. Figure 64 shows various provisions for an input bias current path. Without a bias current path, the inputs float to a potential that exceeds the common-mode range of the INA828, and the input amplifiers saturate. If the differential source resistance is low, the bias current return path can be connected to one input (as shown in the thermocouple example in Figure 64). With a higher source impedance, using two equal resistors provides a balanced input with possible advantages of a lower input offset voltage as a result of bias current and better high-frequency common-mode rejection.

Figure 64. Providing an Input Common-Mode Current Path
8.3 PCB Assembly Effects on Precision

The printed-circuit board (PCB) assembly process, including reflow soldering, imparts thermal stresses on the INA828 which can degrade the precision of the device and must be considered in the development of very-high-precision systems. Baking the PCBs after the assembly process can restore the precision of the device to pre-assembly values. Figure 65, Figure 66, and Figure 67 illustrate the effect of reflow soldering on the typical distribution of input offset voltage of the INA828. Figure 65 shows the distribution of input offset voltage for a set of INA828 devices prior to the PCB assembly process. Exposing the INA828 to a JEDEC-standard thermal profile for reflow soldering produces the histogram shown in Figure 66 on another set of INA828 devices. The standard deviation of input offset voltage has almost doubled due to the thermal stress imparted to the INA828 from the reflow process. However, baking INA828 units for 30 minutes at 125°C after the reflow soldering process produced the distribution given in Figure 67. The post-reflow bake restored the standard deviation of the input offset voltage to pre-assembly levels.

Figure 65. Typical Distribution of INA828 Input Offset Voltage Prior to Reflow Soldering

8.4 Typical Application

Figure 68 shows a three-terminal programmable-logic controller (PLC) design for the INA828. This PLC reference design accepts inputs of ±10 V or ±20 mA. The output is a single-ended voltage of 2.5 V ±2.3 V (or 200 mV to 4.8 V). Many PLCs typically have these input and output ranges.

![Typical Application Diagram](image)

8.4.1 Design Requirements

For this application, the design requirements are:

- 4-mA to 20-mA input with less than 20-Ω burden
- ±20-mA input with less than 20-Ω burden
- ±10-V input with impedance of approximately 100 kΩ
- Maximum 4-mA to 20-mA or ±20-mA burden voltage equal to ±0.4 V
- Output range within 0 V to 5 V

8.4.2 Detailed Design Procedure

There are two modes of operation for the circuit shown in Figure 68: current input and voltage input. This design requires \( R_1 >> R_2 >> R_3 \). Given this relationship, Equation 3 calculates the current input mode transfer function.

\[
V_{OUT-I} = V_D \times G + V_{REF} = -(I_{IN} \times R_3) \times G + V_{REF}
\]

where

- \( G \) represents the gain of the instrumentation amplifier
- \( V_D \) represents the differential voltage at the INA828 inputs
- \( V_{REF} \) is the voltage at the INA828 REF pin
- \( I_{IN} \) is the input current

Equation 4 shows the transfer function for the voltage input mode.

\[
V_{OUT-V} = V_D \times G + V_{REF} = -\left(\frac{V_{IN} \times R_3}{R_1 + R_2}\right) \times G + V_{REF}
\]

where

- \( V_{IN} \) is the input voltage

\( R_1 \) sets the input impedance of the voltage input mode. The minimum typical input impedance is 100 kΩ. 100 kΩ is selected for \( R_1 \) because increasing the \( R_1 \) value also increases noise. The value of \( R_3 \) must be extremely small compared to \( R_1 \) and \( R_2 \). 20 Ω for \( R_3 \) is selected because that resistance value is much smaller than \( R_1 \), and yields an input voltage of ±400 mV when operated in current mode (±20 mA).
Typical Application (continued)

Use Equation 5 to calculate \( R_2 \) given \( V_D = \pm 400 \text{ mV} \), \( V_{IN} = \pm 10 \text{ V} \), and \( R_1 = 100 \text{ k}\Omega \).

\[
V_D = V_{IN} \times \frac{R_2}{R_1 + R_2} \quad \Rightarrow \quad R_2 = \frac{R_1 \times V_D}{V_{IN} - V_D} = 4.17 \text{ k}\Omega
\]  

(5)

The value obtained from Equation 5 is not a standard 0.1% value, so 4.17 k\( \Omega \) is selected. \( R_1 \) and \( R_2 \) also use 0.1% tolerance resistors to minimize error.

Use Equation 6 to calculate the ideal gain of the instrumentation amplifier.

\[
G = \frac{V_{OUT} - V_{REF}}{V_D} = \frac{4.8 \text{ V} - 2.5 \text{ V}}{400 \text{ mV}} = 5.75 \frac{V}{V}
\]  

(6)

Equation 7 calculates the gain-setting resistor value using the INA828 gain equation, Equation 1.

\[
R_G = \frac{50 \text{ k}\Omega}{G - 1} = \frac{50 \text{ k}\Omega}{5.75 - 1} = 10.5 \text{ k}\Omega
\]  

(7)

10.5 k\( \Omega \) is a standard 0.1% resistor value that can be used in this design.

8.4.3 Application Curves

9 Power Supply Recommendations

The nominal performance of the INA828 is specified with a supply voltage of ±15 V and mid-supply reference voltage. The device can also be operated using power supplies from ±1.5 V (3 V) to ±18 V (36 V) and non mid-supply reference voltages with excellent performance. Parameters that can vary significantly with operating voltage and reference voltage are illustrated in the *Typical Characteristics* section.

10 Layout

10.1 Layout Guidelines

Attention to good layout practices is always recommended. For best operational performance of the device, use good PCB layout practices, including:

- Care must be taken to assure that both input paths are well-matched for source impedance and capacitance to avoid converting common-mode signals into differential signals. In addition, parasitic capacitance at the gain-setting pins can also affect CMRR over frequency. For example, in applications that implement gain switching using switches or PhotoMOS® relays to change the value of RG, select the component so that the switch capacitance is as small as possible.
- Noise can propagate into analog circuitry through the power pins of the circuit as a whole and of the device itself. Bypass capacitors are used to reduce the coupled noise by providing low-impedance power sources local to the analog circuitry.
  - Connect low-ESR, 0.1-µF ceramic bypass capacitors between each supply pin and ground, placed as close to the device as possible. A single bypass capacitor from V+ to ground is applicable for single-supply applications.
- To reduce parasitic coupling, run the input traces as far away from the supply or output traces as possible. If these traces cannot be kept separate, crossing the sensitive trace perpendicular is much better than in parallel with the noisy trace.
- Place the external components as close to the device as possible. As illustrated in Figure 74, keeping RG close to the pins minimizes parasitic capacitance.
- Keep the traces as short as possible.
10.2 Layout Example

Use ground pours for shielding the input signal pairs.

- Use ground pours for shielding the input signal pairs.
- Ground plane removed at gain resistor to minimize parasitic capacitance.
- Input traces routed adjacent to each other.
- Low-impedance connection for reference terminal.
- Place bypass capacitors as close to IC as possible.

*All dimensions are nominal*
NOTES:

1. Linear dimensions are in inches [millimeters]. Dimensions in parenthesis are for reference only. Controlling dimensions are in inches. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. This dimension does not include mold flash, protrusions, or gate burrs. Mold flash, protrusions, or gate burrs shall not exceed .006 [0.15] per side.
4. This dimension does not include interlead flash.
5. Reference JEDEC registration MS-012, variation AA.
NOTES: (continued)

6. Publication IPC-7351 may have alternate designs.
7. Solder mask tolerances between and around signal pads can vary based on board fabrication site.
8. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.
9. Board assembly site may have different recommendations for stencil design.
