1 Features
- Up to 97% Efficiency and 93% Duty Cycle
- Wide Input Voltage Range of 3 V to 20 V
- Switching Frequency From 200 kHz to 1.2 MHz
- Inductor-DCR-Based Overcurrent Protection With Thermal Compensation
- 0.6-V Reference With 1% Feedback Accuracy
- 30-ns Min On-Time for Low VOUT
- Integrated High-Current MOSFET Drivers
  - Adaptive Deadtime Control
- Ultrafast Line and Load Transient Response
  - High GBW Error Amplifier
  - PWM Line Feedforward
- Integrated VDD Bias Supply LDO Subregulator
- Programmable System-Level OTP
- Precision Enable With Hysteresis
- Frequency Synchronization
- Monotonic Prebiased Start-up
- Programmable Soft-Start With Tracking
- Output Remote Sense
- Open-Drain Power Good Indicator
- 4-mm x 4-mm WQFN-24 PowerPAD™ Package

2 Applications
- DC-DC Converters and POL Modules
- Telecommunications Infrastructure
- Embedded Computing, Servers, Storage

3 Description
The LM27403 is a feature-rich, easy-to-use, synchronous buck controller offering exceptional levels of integration and performance for superior efficiency in high power density, point-of-load (POL) DC-DC regulator solutions. The resistor-programmable switching frequency from 200 kHz to 1.2 MHz and integrated, high-current MOSFET gate drivers with adaptive deadtime offer flexibility to optimize solution size and maximize conversion efficiency.

High precision and low output voltage are easily obtained with a 0.6-V, 1% accurate voltage reference together with a 30-ns high-side MOSFET minimum controllable on-time. Using lossless inductor dc resistance (DCR) current sensing and an inexpensive 2N3904 BJT to sense temperature remotely at the inductor, the LM27403 supports accurate and thermally compensated overcurrent protection (OCP).

Changes from Revision A (September 2013) to Revision B

- Added Pin Configuration and Functions section, Handling Rating table, Feature Description section, Device Functional Modes, Application and Implementation section, Power Supply Recommendations section, Layout section, Device and Documentation Support section, and Mechanical, Packaging, and Orderable Information section ................................................................. 1
5 Description (Continued)
The LM27403 has a conventional voltage-mode control loop with high gain-bandwidth error amplifier and PWM input voltage feedforward to simplify compensation design and enable excellent transient response throughout the full line voltage and load current ranges. Forced-PWM (FPWM) operation eliminates frequency variation to minimize EMI in sensitive applications. An open-drain Power Good circuit provides power-rail sequencing and fault reporting. Other features include programmable system-level thermal shutdown with automatic recovery, output voltage remote sense, configurable soft-start, monotonic start-up into prebiased loads, an integrated bias supply low-dropout (LDO) regulator, external power supply tracking, precision enable with customizable hysteresis for programmable line undervoltage lockout (UVLO), and synchronization capability for beat frequency sensitive and multiregulator applications. The LM27403 is offered in a 4-mm x 4-mm thermally enhanced WQFN-24 package with 0.5-mm pitch.

### Pin Functions (continued)

<table>
<thead>
<tr>
<th>PIN</th>
<th>I/O/P(1)</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>D–</td>
<td>10 I</td>
<td>External temperature sense return. This pin is the return current path for the external NPN transistor configured as a thermal diode. This trace should be routed as a differential pair with the D+ trace back to the LM27403 to avoid excessive coupling from external noise sources. Connect D– to GND.</td>
</tr>
<tr>
<td>D+</td>
<td>9 I</td>
<td>External temperature sense. A 2N3904-type NPN transistor configured as a remote thermal diode with the base and collector shorted should be connected to this pin to sense the inductor temperature. The sensed temperature is used to compensate for the inductor DCR drift over temperature and to implement system-level thermal shutdown protection.</td>
</tr>
<tr>
<td>UVLO/EN</td>
<td>7 I</td>
<td>Precision UVLO/enable input. To implement a VIN UVLO function, connect UVLO/EN to the tap of a voltage divider between VIN and GND. UVLO/EN is initially pulled up by an internal 1.8-µA pullup current source. UVLO/EN has both a 165-mV voltage hysteresis and an 8.7-µA pullup current hysteresis. Thus, when a rising UVLO/EN voltage exceeds the 1.15-V enable threshold, the internal pullup current becomes 10.5 µA and the falling threshold voltage is 0.985 V. Therefore, the effective total hysteresis can be customized to suit the specific application.</td>
</tr>
<tr>
<td>EP</td>
<td>— P</td>
<td>Exposed die attach pad. Connect this pad to the printed circuit board (PCB) ground plane using multiple thermal vias.</td>
</tr>
<tr>
<td>FADJ</td>
<td>5 I</td>
<td>Frequency adjust input. The switching frequency is programmable between 200 kHz and 1.2 MHz by virtue of the size of resistor connected to this pin and GND.</td>
</tr>
<tr>
<td>FB</td>
<td>3 I</td>
<td>Feedback input. This pin is a voltage-mode control-loop error amplifier inverting input to set the output voltage. In closed-loop (output in regulation) operation, FB is at 0.6 V ±1%.</td>
</tr>
<tr>
<td>GND</td>
<td>13 G</td>
<td>Common ground connection. This pin provides the power and signal return connections for analog functions, including low-side MOSFET gate return, soft-start capacitor, OTP resistor, and frequency adjust resistor.</td>
</tr>
<tr>
<td>HG</td>
<td>17 O</td>
<td>High-side MOSFET gate drive output. This pin is the high-side N-FET gate connection.</td>
</tr>
<tr>
<td>LG</td>
<td>15 O</td>
<td>Low-side MOSFET gate drive output. This pin is the low-side N-FET gate connection.</td>
</tr>
<tr>
<td>NC</td>
<td>19-22 G</td>
<td>No connection. Connect directly to GND.</td>
</tr>
<tr>
<td>OTP</td>
<td>8 I</td>
<td>Overtemperature protection (OTP) output. A resistor and 0.1-µF capacitor from this pin to GND sets the overtemperature protection setpoint for the DC-DC power supply solution using the temperature sensed at a remotely connected thermal diode. Connect this pin to GND if the system level OTP function is not required.</td>
</tr>
<tr>
<td>PGOOD</td>
<td>11 O</td>
<td>Power Good monitor output. This open-drain output goes low during overcurrent, short-circuit, UVLO, output overvoltage and undervoltage, overtemperature, or when the output is not regulated (such as an output prebias). An external pullup resistor to VDD or to an external rail is required. Included is a 20-µs deglitch filter. The PGOOD voltage should not exceed 5.5 V.</td>
</tr>
<tr>
<td>RS</td>
<td>2 I</td>
<td>Negative remote sense input. This pin eliminates the voltage drop between GND and the local ground adjacent to the load. In particularly noisy environments, connect an RC filter between RS and GND. Connect RS to GND at the IC if not used.</td>
</tr>
<tr>
<td>SS/TRACK</td>
<td>1 I/O</td>
<td>Soft-start or tracking input. This pin allows a predetermined startup rate to be defined with the use of a capacitor to GND. A 3-µA current source charges the capacitor until the reference reaches 0.6 V. SS/TRACK can also be controlled with an external voltage source for tracking applications.</td>
</tr>
<tr>
<td>SW</td>
<td>16 P</td>
<td>Power stage switch-node connection. This pin is the high-side N-FET gate driver return.</td>
</tr>
<tr>
<td>SYNC</td>
<td>6 I</td>
<td>Synchronization input. This pin enables PLL synchronization to an external clock frequency. If a SYNC signal is not present, the switching frequency defaults to the frequency set by the FADJ pin. This pin should be tied to GND if not used.</td>
</tr>
<tr>
<td>VDD</td>
<td>14 P</td>
<td>Bias supply rail. This pin is a subregulated 4.7-V internal and gate drive bias supply rail. VDD also supplies the current to CBOOT to facilitate high-side switching. Decouple VDD to GND locally with a 10-µF ceramic capacitor. VDD should not be used to drive auxiliary system loads because of gate drive loading possibility.</td>
</tr>
<tr>
<td>VIN</td>
<td>12 P</td>
<td>Input voltage rail. This input is used to provide the feedforward modulation for output voltage control and for generating the internal bias supply voltage. Decouple VIN to GND locally with a 1-µF ceramic capacitor. For better noise rejection, connect to the power stage input rail with an RC filter.</td>
</tr>

</table>

\(^{(1)}\) Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other condition beyond those included under Recommended Operating Conditions is not implied. Exposure to absolute-maximum-rated conditions for extended periods of time may affect device reliability.

\(^{(2)}\) All voltages are with respect to the network ground pin unless otherwise noted.

\(^{(3)}\) The SW pin can tolerate negative voltage spikes as low as −10 V and as high as 30 V for a duration up to 10 ns.

\(^{(4)}\) Body diode of the low-side MOSFET notwithstanding, parasitic inductance in a real application may result in the SW voltage ringing negative.

\(^{(5)}\) The CBOOT pin can tolerate positive voltage spikes as high as 35 V for a duration up to 10 ns.

<td></td>
<td></td>
</tr>
<tr>
<td>VDD</td>
<td>2.6</td>
<td>4.7</td>
<td>5.5</td>
<td>V</td>
<td></td>
</tr>
</tbody>
</table>

| SW SW pin voltage | VIN tied to VDD | −0.3 | 20 | V |
| VDD VDD pin voltage | 2.6 | 4.7 | 5.5 | V |
| PGOOD PGOOD pin voltage | 0 | 5.5 | V |
| UVLO/EN UVLO/EN pin voltage | 0 | min (\(V_{\text{VIN}}\), 5.5) | V |
| SS/TRACK SS/TRACK pin voltage | 0 | \(V_{\text{DD}}\) | V |
| SYNC SYNC pin voltage | 0 | 5.5 | V |
| RS RS pin voltage | −0.1 | 0.1 | V |
| \(T_{\text{j}}\) Operating junction temperature | −40 | +125 | °C |
| \(T_{\text{A}}\) Operating free-air temperature | −40 | +125 | °C |

\(^{(1)}\) Recommended Operating Conditions are conditions under which operation of the device is intended to be functional but does not guarantee performance limits.

\(^{(2)}\) VDD is the output of the internal linear regulator bias supply. Under normal operating conditions, where VIN is greater than 5.5 V, VDD must not be tied to any external voltage source. In an application where VIN is between 3.0 V and 5.5 V, connecting VIN to VDD maximizes the bias supply rail voltage.

8 Detailed Description

8.1 Overview

The distributed power supply architecture, pervasive in myriad applications including communications infrastructure equipment and computing systems, uses an intermediate bus and multiple downstream DC-DC regulators dedicated and proximate to each “point-of-load.” The ASICs, FPGAs, and microprocessors that comprise these loads have supply voltage requirements whose levels are decreasing on an absolute basis and whose tolerance bands are decreasing on a percentage basis. The hallmarks of point-of-load (POL) DC-DC regulators are efficiency, size, load transient response, and cost.

To this end, the LM27403 is a feature-rich, easy-to-use, synchronous PWM DC-DC step-down controller capable of providing an ultrahigh current output for demanding, high power density POL applications. An input voltage range of 3 V to 20 V is compatible with a wide range of intermediate bus system rails and battery chemistries; especially 3.3-V, 5-V, and 12-V inputs. The output voltage is adjustable from 0.6 V to as high as 93% of the input voltage, with better than ±1% feedback system regulation accuracy over the full junction temperature range. With an accurate, adjustable and thermally compensated inductor DCR based current limit setpoint, ferrite and composite core inductors with low DCR and small footprint can be specified to maximize efficiency and reduce power loss. High-current gate drivers with adaptive deadtime are used for the high-side and low-side MOSFETs to provide further efficiency gains.

The LM27403 employs a voltage-mode control loop with output voltage remote sense, input voltage feedforward modulation, and a high gain-bandwidth error amplifier to accurately regulate the output voltage over substantial load, line, and temperature ranges. The switching frequency is programmable between 200 kHz and 1.2 MHz through a resistor or an external synchronization signal. The LM27403 is available in a 4-mm × 4-mm, thermally enhanced, 24-lead WQFN PowerPad package. This device offers high levels of integration by including MOSFET gate drivers, a low dropout (LDO) bias supply linear regulator, and comprehensive fault protection features to enable highly flexible, reliable, energy-efficient, and high power density regulator solutions.

Multiple fault conditions are accommodated, including overvoltage, undervoltage, overcurrent, and overtemperature. To improve overcurrent setpoint accuracy and enable easier filter inductor selection, the LM27403 thermally compensates for the temperature coefficient (TC) of the inductor’s winding resistance by sensing the inductor temperature with an external NPN transistor configured as a thermal diode. The same thermal diode also monitors the PCB temperature to initiate a thermal shutdown in the event that the sensed temperature exceeds the programmed thermal shutdown setpoint.
8.3 Feature Description

8.3.1 Input Range: VIN

The LM27403 operational input voltage range is from 3 V to 20 V. The device is intended for POL conversions from 3.3-V, 5-V, and 12-V unregulated, semiregulated and fully regulated supply rails. It is also suitable for connection to intermediate bus converters with output rails centered at 12 V and 9.6 V (derived from 4:1 and 5:1 primary-secondary transformer step-downs in nonregulated full-bridge converter topologies) and voltage levels intrinsic to a wide variety of battery chemistries.
Feature Description (continued)

The LM27403 uses an internal LDO subregulator to provide a 4.7-V bias rail for the gate drive and control circuits (assuming the input voltage is higher than 4.7 V plus the necessary subregulator dropout specification). Naturally, it can be more favorable to connect VDD directly to the input during low input voltage operation ($V_{\text{VIN}} < 5.5$ V). In summary, connecting VDD to VIN during low input voltage operation provides a greater gate drive voltage level and thus an inherent efficiency benefit. However, by virtue of the low subregulator dropout voltage, this VDD to VIN connection is not mandatory, thus enabling input ranges from 3 V up to 20 V. The application circuits shown below detail LM27403 configuration options suitable for several input rails.

Figure 23. Schematic Diagram for VIN Operating Range of 3 V to 20 V

Figure 23 shows the schematic diagram for an input voltage ranging from 3 V to 20 V. Note that a finite subregulator dropout voltage exists and is manifested to a larger extent when driving high gate charge ($Q_G$) power MOSFETs at elevated switching frequencies. For example, at $V_{\text{VIN}} = 3$ V, the VDD rail voltage is 2.8 V with a dc operating current, $I_{\text{VDD}}$, of 40 mA. Such a low gate drive rail may be insufficient to fully enhance the power MOSFET gates. At the very least, MOSFET on-state resistance, $R_{\text{DS(ON)}}$, increases at such low gate drive levels. Here are the main concerns when operating at a low input voltage:

- Increase of conduction losses (higher $R_{\text{DS(ON)}}$ at lower $V_{\text{GS}}$).
- Increase of switching losses associated with sluggish switching times when operating at low $V_{\text{GS}}$ levels.
- Deadtime may be larger as a result of the lower gate drive level and associated slower gate voltage slew rate. This may become evident, for example, when using two high-side MOSFETs in a 3.3-V to 2.5-V converter design.
- Dramatic reduction in the range of suitable MOSFETs that a designer can choose from (MOSFETs with $R_{\text{DS(ON)}}$ rated at $V_{\text{GS}} = 2.5$ V become mandatory).

Note that the increased on-state resistance is compounded by an increase in MOSFET junction temperature, bearing in mind the negative temperature coefficient of the MOSFET threshold voltage.
Feature Description (continued)

In general, the subregulator is rated to drive the two internal gate driver stages in addition to the quiescent current associated with LM27403 operation. Figure 24 shows the schematic diagram for lower input voltages such as 3.0 V to 5.5 V. The LM27403’s VDD and VIN pins can be tied together if the input voltage is guaranteed not to exceed 5.5 V (absolute maximum 6 V). This short bypasses the internal LDO bias regulator and eliminates the LDO dropout voltage and power dissipation. An RC filter from the input rail to the VIN pin, for example 2.2 \( \Omega \) and 1 \( \mu \)F, presents supplementary filtering at the VIN pin. Low gate threshold voltage MOSFETs are recommended for this configuration.

![Figure 24. Schematic Diagram for VIN Operating Range of 3.0 V to 5.5 V](image)

8.3.2 Output Voltage: FB Voltage and Accuracy

The reference voltage seen at the FB pin is set at 0.6 V, and a feedback system accuracy of \( \pm 1\% \) over the full junction temperature range is met. Junction temperature range for the device is –40°C to +125°C. While somewhat dependent on frequency and load current levels, the LM27403 is generally capable of providing output voltages in the range of 0.6 V to a maximum of greater than 90% VIN. The dc output voltage during normal operation is set by the feedback resistor network, \( R_{FB1} \) and \( R_{FB2} \), connected to VOUT.

8.3.3 Input and Bias Rail Voltages: VIN and VDD

The LM27403 internal UVLOs ensure that the input rail (VIN) and bias supply rail (VDD) are charged and stable at 2.7 V before switching begins. VDD and VIN have independent UVLO comparators, each with 250 mV of hysteresis. There is a definite delay between UVLO power-on and switching power-on. This delay is related to the fact that the LM27403 does not begin switching until the internal temperature sense circuitry is ready and stabilized. The delay is four measurement cycles on D+, equivalent to 512 clock cycles.

The VDD bias supply LDO has a nominal current limit of 106 mA during normal operation. However, a lower current limit is engaged at startup to control the rate of rise of the VDD voltage. Figure 25 shows the typical scope waveforms of VDD and VOUT when the input voltage is instantaneously applied. Here, the VDD voltage ramps in approximately 1.4 ms based on a 10-\( \mu \)F VDD decoupling capacitor and current-limited VDD feature. For more details, please see the LM27403 EVM User's Guide, SNVU233.
Feature Description (continued)

8.3.4 Precision Enable: UVLO/EN

The UVLO/EN pin represents a precision analog enable function for user-defined UVLO power-on input voltage levels and to toggle the output on and off. The UVLO/EN pin is essentially a comparator-based input referenced to a flat bandgap voltage with a fixed hysteresis of 165 mV.

The UVLO/EN pin has an internal pullup current of 1.8 µA, as shown in Figure 26. There is also a low I_Q shutdown mode when UVLO/EN is effectively pulled below a base-emitter voltage drop (approximately 0.7 V at room temperature). This mode shuts down the bias currents of the LM27403, but the UVLO/EN pullup current source is still available. If UVLO/EN is pulled below this hard shutdown threshold, the internal LDO regulator powers off and the VDD rail collapses.

When the precision enable threshold of 1.15 V is exceeded, the UVLO/EN pullup current source increases from 1.8 µA to 10.5 µA (that is, an 8.7-µA hysteresis current). Use this feature to create a customizable UVLO hysteresis (above the standard 165-mV fixed voltage hysteresis) based on the resistor divider from VIN to turn on and off the LM27403 at the required input voltage levels. Also, use a capacitor from the UVLO/EN pin to GND to implement a fixed time delay in power systems with timed sequencing requirements.

Figure 25. Typical Startup Waveforms of VDD and VOUT With Controlled Ramp Rates

Figure 26. Precision UVLO/Enable Circuit with Hysteretic Comparator and Pullup Current Sources
Feature Description (continued)

Figure 27 shows an example using the circuit in Figure 23 where the input voltage is ramping from 0 V to 10 V in 100 ms. Here, the UVLO resistors, \( R_{\text{UV1}} \) and \( R_{\text{UV2}} \), are respectively set to 47.5 k\( \Omega \) and 10 k\( \Omega \). Given these resistances, the typical input UVLO turn-on and turn-off levels are 6.5 V and 5.2 V, respectively. The UVLO/EN pin voltage steps at the rising and falling thresholds are defined by the UVLO/EN pin current hysteresis.

![Figure 27. Typical Input Voltage UVLO Turn On and Off Behavior](image)

Given \( V_{\text{IN(on)}} \) and \( V_{\text{IN(off)}} \) as the input voltage turn-on and turn-off thresholds, respectively, select the UVLO resistors using the following expressions:

\[
R_{\text{UV1}} = \frac{V_{\text{UVLO1}} - V_{\text{IN(off)}}}{I_{\text{UVLO2}} - I_{\text{UVLO1}}} \]

\[
R_{\text{UV2}} = R_{\text{UV1}} \frac{V_{\text{UVLO2}}}{V_{\text{IN(on)}} - V_{\text{UVLO2}} + R_{\text{UV1}} V_{\text{UVLO1}}} \]

(1) (2)

The UVLO/EN pin has a maximum operating voltage rating equal to the input voltage or 5.5 V, whichever is lower. Do not exceed this rating. If the input UVLO level is set at low input voltage, it is possible that this maximum UVLO/EN pin voltage could be exceeded at the higher end of the input voltage operating range. In this case, use a small 4.7-V zener diode clamp, designated \( D_{\text{EN}} \) in Figure 23, from UVLO/EN to GND, such that the maximum operating level is never exceeded.

8.3.5 Switching Frequency

There are two options for setting the switching frequency of the LM27403, thus providing a power supply designer a level of flexibility when choosing external components for multiple applications. To adjust the frequency, use a resistor from the FADJ pin to GND, or synchronize the LM27403 to an external clock signal through the SYNC pin.

8.3.5.1 Frequency Adjust: FADJ

Adjust the LM27403 free-running switching frequency by using a resistor from the FADJ pin to GND. The switching frequency range of the device is from 200 kHz to 1.2 MHz. An open circuit at the FADJ pin forces the frequency to the minimum value. FADJ shorted moves the frequency to its maximum value. The frequency set resistance, \( R_{\text{FADJ}} \), is governed by Equation 3.

\[
R_{\text{FADJ}} [\text{k}\Omega] = \frac{10000}{F_{\text{sw}} [\text{kHz}]^{0.99}} - 7
\]

(3)

E96 resistors for common switching frequencies are given in Table 1.
### 8.3.5.2 Clock Synchronization: SYNC

Apply an external clock synchronization signal to the LM27403 to synchronize switching in both frequency and phase. Requirements for the clock SYNC signal are:

- Clock SYNC range: 200 kHz to 1.2 MHz
- SYNC frequency range from the FADJ frequency: up to 400 kHz (up only)

In applications where the external clock is not applied to the LM27403, use the external FADJ resistor to set the minimum switching frequency. When the external clock is applied, it takes precedence only if the switching frequency is greater than that set by the FADJ resistor. When the external clock is disconnected, the LM27403 switching frequency does not decrease below the minimum frequency set by the resistor. Setting a minimum frequency in this way prevents the inductor ripple current from increasing dramatically. Externally tie SYNC to GND if synchronization functionality is not required. The SYNC logic thresholds are based on an NMOS threshold referenced to GND and, as such, are effectively independent of the VDD operating voltage.

Figure 28 shows a SYNC TTL signal at 600 kHz and the corresponding SW node waveform ($V_{IN} = 12\, V$, $V_{OUT} = 1.2\, V$, free-running frequency = 250 kHz). The synchronization is with respect to the rising edge of SYNC. The rising edge of the SW voltage is phase delayed relative to SYNC by approximately 250 ns.

![Figure 28. Typical 600-kHz SYNC Waveform](image)

### 8.3.6 Temperature Sensing: D+ and D–

The LM27403 PWM controller offers low-cost programmable thermal protection by using remote thermal diode temperature measurements based on the change in forward bias voltage of a diode when operated at two different currents. The thermal diode is a discrete small-signal 2N3904 type silicon NPN BJT located (in good thermal contact) adjacent the filter inductor.
The ideality factor is a parameter in the diode I-V relationship that approaches 1.0 or 2.0 as carrier diffusion or recombination current dominate current flow, respectively. The ideality factor for 2N3904 type diode-connected BJTs available from several manufacturers is typically 1.004. Note that 3-terminal BJTs such as the 2N3904 are vastly preferred over true 2-terminal diodes in this application. Discrete 2-terminal diodes with current largely dictated by recombination have a much higher ideality factor (\(\eta = 1.2\) to 1.5) than BJTs and, to such an extent, would cause unacceptable temperature measurement error.

Switched capacitor technology is integrated in the LM27403 to sample and measure the base-emitter voltages created by respective 10-µA and 100-µA bias currents flowing from the D+ to D− pins. The difference in these voltages, termed \(\Delta V_{BE}\), is readily extracted and the sensed temperature is calculated noting that \(\Delta V_{BE}\) is directly proportional to temperature as follows:

\[
V_{BE(\text{high})} - V_{BE(\text{low})} = \frac{\eta k T}{q} \ln\left(\frac{i_{\text{high}}}{i_{\text{low}}}\right)
\]

where
- \(k = \) Boltzmann’s constant, \(1.3806488 \times 10^{-23}\) J/K (Joules/Kelvin)
- \(T = \) absolute temperature in Kelvin (K)
- \(q = \) electron charge = \(1.602176 \times 10^{-19}\) C (Coulombs)
- \(\eta = \) diode ideality factor = 1.004
- \(i_{\text{low}} = \) bias current in state 1 = 10 µA
- \(i_{\text{high}} = \) bias current in state 2 = 100 µA

The source currents from the D+ pin during state 1 and state 2 are 10 µA and 100 µA, respectively. The sensed temperature in Kelvin becomes:

\[
T = \frac{q \Delta V_{BE}}{\eta k \ln(10)}
\]

(5)

Figure 29 shows the 2N3904 \(V_{BE}\) voltage at ambient temperatures of −40°C, 25°C and 125°C. The low and high states in \(V_{BE}\) voltage correspond to the 10-µA and 100-µA currents sourced from D+, each of 64 clock cycle duration. The voltage level is sampled at the end of each state. While the dc level of the \(V_{BE}\) voltage decreases logarithmically with increasing temperature, the \(\Delta V_{BE}\) amplitude increases with and is directly proportional to temperature according to Equation 5.

![Figure 29. Typical 2N3904 Base-Emitter Voltage at –40°C, 25°C and 125°C](image)

Note that D− is essentially a kelvin connection to the remote thermal diode. As such, the D− pin needs to be tied to GND at the LM27403; the D− trace should not connect to any of the PCBs current-carrying ground planes.
8.3.7 Thermal Shutdown: OTP

A current proportional to the sensed temperature is sourced from the OTP pin. The resultant voltage at the OTP pin (set by a resistor connected from OTP to GND) is compared to an internal shutdown threshold of 1.15 V with 80-mV hysteresis. When the threshold is exceeded, the device stops switching until the sensed temperature drops to a level where the OTP pin voltage falls to the restart threshold. The external thermal protection is disabled by grounding the OTP pin. The thermal shutdown setpoint is governed by Equation 6:

\[
R_{\text{OTP}} = \frac{R_{\text{OTP}(125^\circ \text{C})} \times 398}{T_{\text{OTP}}(\text{C}) + 273}
\]

where

- \( R_{\text{OTP}} \) is the required resistance at the OTP pin for the desired thermal shutdown temperature
- \( R_{\text{OTP}(125^\circ \text{C})} \) is the nominal resistance at the OTP pin, 80.7 k\( \Omega \), for 125°C thermal shutdown, and
- \( T_{\text{OTP}} \) is the desired thermal shutdown temperature. (6)

For example, the OTP resistor required for a thermal shutdown setpoint of 105°C is calculated as shown in Equation 7:

\[
R_{\text{OTP}} = \frac{80.7 \text{ k}\Omega \times 398}{105 + 273} = 85 \text{ k}\Omega
\]

A 100-nF capacitor connected in parallel with \( R_{\text{OTP}} \) is required. When the IC detects an overtemperature event, it responds with the normal hiccup-mode sequence of events when going into shutdown. More specifically, the following steps occur when an internal or external OTP event is detected:

1. The high-side MOSFET immediately turns off.
2. An internal zero-cross circuit is enabled to detect whether the inductor current is positive or negative:
   (a) If the current is negative, the low-side MOSFET immediately turns off.
   (b) If the current is positive, the low-side MOSFET turns off when the inductor current ramps down to zero.

Note that it is important to prevent water-soluble flux residues from contaminating the PCB during the manufacturing process. Contaminants such as these can result in unexpected leakage currents and consequent temperature-measurement errors.

8.3.8 Inductor-DCR-Based Overcurrent Protection

The LM27403 exploits the filter inductor DCR to detect overcurrent events. This technique enables lossless and continuous monitoring of the output current using an RC sense network in parallel with the inductor. DCR current sensing allows the system designer to use inductors specified with low tolerance DCRs to improve the current limit setpoint accuracy. A dc current limit setpoint accuracy within the range of 10% to 15% is easily achieved using inductors with low DCR tolerances.

8.3.9 Current Sensing: CS+ and CS–

As mentioned, the LM27403 implements an inductor DCR lossless current sense scheme designed to provide both accurate overload (current limit) and short-circuit protection. Figure 30 shows the popular inductor DCR current sense method. Figure 31 shows an implementation with current shunt resistor, \( R_{\text{ISNS}} \).

Components \( R_S \) and \( C_S \) in Figure 30 create a low-pass filter across the inductor to enable differential sensing of the inductor DCR voltage drop. When \( R_S C_S \) is equal to \( L/R_{\text{dcr}} \), the voltage developed across the sense capacitor, \( C_S \), is a replica of the inductor DCR's voltage waveform. Choose the capacitance of \( C_S \) greater than 0.1 \( \mu \text{F} \) to maintain low impedance of the sense network, thus reducing the susceptibility of noise pickup from the switch node.
The current limit circuit arrangement is portrayed in Figure 32. The current limit setpoint is set by a single external resistor, $R_{ISET}$, connected from the CS– pin to the output voltage terminal. The current sourced from CS– in combination with this series resistance sets the reference voltage to the current limit comparator, as governed by Equation 8.

$$R_{ISET} = \frac{R_{dcr} \left( I_{OCP} + \frac{\Delta I_L}{2} \right)}{I_{CS}}$$

where

- $I_{CS}$ is the CS– pin current, 9.9 µA typically at 25°C
- $I_{OCP}$ is the dc overcurrent protection setpoint, and
- $\Delta I_L$ is the peak-to-peak inductor ripple current. (8)

Inductor DCR temperature compensation is automatically provided using the remote-diode sensed temperature. The temperature coefficient (TC) of the inductor winding resistance is typically 3720 ppm/°C. The current-limit setpoint is maintained essentially constant over temperature by the slope of CS– pin current over temperature. An increase in sensed DCR voltage associated with an increase of inductor winding temperature is matched by a concomitant increase in current limit comparator reference voltage. The inductor temperature is measured by placing an external diode-connected 2N3904 discrete NPN transistor, designated $Q_T$ in Figure 32, in close proximity to the inductor (see the Temperature Sensing: D+ and D– section for more details).

Figure 32. Current-Limit Setpoint Defined by Current Source $I_{CS}$ and Resistor $R_{ISET}$
Note that the inductor DCR is shown schematically as a discrete element in Figure 30 and Figure 32. The current-sense comparator inputs operate at common mode up to the input rail voltage. The comparator incorporates a very low input-referred offset to reduce the SNR of the voltage detected across the inductor DCR. The CS– pin current is specified down to a headroom compliance voltage of less than 0.8 V (that is, $V_{\text{VIN}} - V_{\text{CS-}}$) and over the full operating temperature range (see the Electrical Characteristics Table and Figure 13). The current source is powered from the input to allow the current limit circuit to work in high duty cycle applications.

With power inductors selected to provide lowest possible DCR to minimize power losses, the typical DCR ranges from 0.4 m$\Omega$ to 4 m$\Omega$. Then, given a load current of 25 A, the voltage presented across the CS+ and CS– pins ranges between 10 mV and 100 mV. Note that this small differential signal is superimposed on a large common-mode signal that is the dc output voltage, which makes the current sense signal challenging to process. To aid in rejection of high frequency common-mode noise, a series resistor, $R_{\text{CS}}$, of same resistance as $R_{\text{ISET}}$, is added to the CS+ signal path as shown in Figure 32. A small capacitor, $C_{\text{CS}}$, added across CS+ and CS– provides differential filtering.

A current sense (or current shunt) resistor in series with the inductor can also be implemented at lower output current levels to provide accurate overcurrent protection, see Figure 31. Burdened by the unavoidable efficiency penalty and/or additional cost implications, this configuration is not usually implemented in high-current applications (except where OCP setpoint accuracy and stability over the operating temperature range are critical specifications). However, if a shunt resistor is used, temperature compensation is not required. In this case, short the D+ to D– pins to disable this function. The current sourced from CS– in this case becomes 5 µA (typical) and is independent of temperature.

In the PCB layout, component pads are recommended to install a small capacitor, designated $C_{d}$ in Figure 32, between the D+ and D– pins as close to the LM27403 as possible. This capacitor should not exceed 1 nF for 2N3904-type devices. Locate an additional capacitor, typically 100 pF, at the BJT, when operating in noisy environments (for example, where leakage flux from the airgap of a ferrite inductor may couple into the adjacent circuit board traces).

### 8.3.10 Current Limit Handling

The LM27403 implements a **hiccup** mode to allow the device to cool down during overcurrent events. If five overcurrent events are detected during any 32 clock cycle interval, the LM27403 shuts down and stops switching for a period of 5 ms. During this time, negative inductor current is not allowed, and the output cannot swing negative. After 5 ms, the LM27403 starts up in the normal startup routine at an output voltage ramp rate determined by the internal soft-start function or the external soft-start capacitor (if one is used). With each detected current limit event, the high-side MOSFET is turned off and the low-side MOSFET is turned on.

### 8.3.11 Soft-Start: SS/TRACK

After the UVLO/EN pin exceeds the rising threshold of 1.15 V, the LM27403 begins charging the output to the dc level dictated by the feedback resistor network. The LM27403 features an adjustable soft-start (set by a capacitor from the SS/TRACK pin to GND) that determines the charging time of the output. A 3-µA current source charges this soft-start capacitor. Soft-start limits inrush current as a result of high output capacitance and avoids an overcurrent condition. Stress on the input supply rail is also reduced. The soft-start time, $t_{\text{SS}}$, for the output voltage to ramp to its nominal level is set by Equation 9:

$$t_{\text{SS}} = \frac{C_{\text{SS}} V_{\text{REF}}}{I_{\text{SS}}}$$

where

- $C_{\text{SS}}$ is the soft-start capacitance
- $V_{\text{REF}}$ is the 0.6-V reference, and
- $I_{\text{SS}}$ is the 3-µA current sourced from the SS/TRACK pin.

If a soft-start capacitor is not used, then the LM27403 defaults to a minimum internal soft-start time of 1.28 ms and provides a resolution of 128 steps. Thus, the internal soft-start dictates the fastest startup time for the circuit.

When the SS/TRACK voltage exceeds 91% of the reference voltage, the Power Good flag transitions high. Conversely, the Power Good flag goes low when the SS/TRACK voltage goes below 87% of the reference.
8.3.11.1 Tracking

The SS/TRACK pin also doubles as a tracking pin when master-slave power-supply tracking is required. This tracking is achieved by simply dividing down the master's output voltage with a simple resistor network. Coincident, ratiometric, and offset tracking modes are possible.

If an external voltage source is connected to the SS/TRACK pin, the external soft-start capability of the LM27403 is effectively disabled (the internal soft-start is still enabled). The regulated output voltage level is reached when the SS/TRACK pin reaches the 0.6-V reference voltage level. It is the responsibility of the system designer to determine if an external soft-start capacitor is required to keep the device from entering current limit during a startup event. Likewise, the system designer must also be aware of how fast the input supply ramps if the tracking feature is enabled.

Figure 33 shows a triangular voltage signal directly driving SS/TRACK and the corresponding output voltage tracking response. Nominal output voltage here is 1.2 V, with channel scales chosen such that the waveforms overlap during tracking. As expected, the PGOOD flag transitions at thresholds of 91% (rising) and 87% (falling) of the nominal output voltage setpoint.

![Figure 33. Typical Output Voltage Tracking Waveforms and PGOOD Flag](image)

Two practical tracking configurations, ratiometric and coincident, are shown in Figure 34. The most common application is coincident tracking, used in core vs. I/O voltage tracking in DSP and FPGA implementations. Coincident tracking forces the master and slave channels to have the same output voltage ramp rate until the slave output reaches its regulated setpoint. Conversely, ratiometric tracking sets the slave's output voltage to a fraction of the master's output voltage during startup.

![Figure 34. Tracking Implementation With Master, Ratiometric Slave and Coincident Slave Rails](image)
For coincident tracking, connect the slave regulator’s SS/TRACK input to a resistor divider from the master’s output voltage that is the same as the divider used on the slave’s FB pin. In other words, simply select $R_{\text{TRACK1}} = R_{\text{FB1}}$ and $R_{\text{TRACK2}} = R_{\text{FB2}}$ as shown in Figure 34. As the master voltage rises, the slave voltage rises identically. Eventually, the slave voltage reaches its regulation voltage, at which point the internal reference takes over the regulation while the SS/TRACK input continues to increase, thus removing itself from changing the output voltage.

In all cases, to ensure that the output voltage accuracy is not compromised by the SS/TRACK voltage being too close to the 0.6-V reference voltage, the final value of the slave’s SS/TRACK voltage should be at least 20 mV above FB.

8.3.12 Monotonic Startup

The LM27403 has monotonic startup capability with no dips or flat spots in the output voltage waveform during startup (including prebiased startup) and fault recovery. During the soft-start interval, FB follows SS/TRACK, and the output voltage linearly increases to the nominal output setpoint. Figure 35 illustrates the output voltage behavior during a monotonic startup to a nominal level of 1.2V. The UVLO/EN pin is driven high by a TTL logic signal. As mentioned previously, the startup time is determined by the use of an external soft-start capacitor at the SS/TRACK pin charged by an internally generated 3-µA constant current source. If a soft-start capacitor is not used, the device automatically enables the internal 7-bit (128 step) digital soft-start. The PGOOD flag transitions high when FB reaches its 91% threshold. As described previously, there is a calibration interval based on four cycles on the D+ pin (that is, 512 clock cycles) that creates a delay from UVLO/EN crossing its precision threshold to SS/TRACK being released.

![Figure 35. Typical Monotonic Output Voltage Startup Waveforms, 1.2-V Output](image)

8.3.13 Prebias Startup

In certain applications, the output voltage may have an initial voltage prebias before the LM27403 is powered on or enabled. The LM27403 is able to startup into a prebiased load while maintaining a monotonic output voltage startup characteristic.

The LM27403 does not allow switching until the SS/TRACK pin voltage has reached the feedback (FB) voltage level. Once this level is reached, the controller begins to regulate and switch synchronously, allowing a certain amount of negative current during PWM switching operation. Thereafter, the feedback voltage follows the soft-start voltage up to 0.6 V. This is illustrated in Figure 36 where nominal output voltage is 1.2 V and the output voltage waveform represents twice the FB level. The output is not pulled low during a prebiased startup condition. Note that if the output is prebiased to a higher voltage than the nominal level (as set by the feedback resistor divider), the LM27403 does not pull the output low, hence eliminating current flow through parasitic paths in the system.
The LM27403 automatically pulls down the SS/TRACK pin to GND before the onset of switching and during a restart from a fault condition. When SS/TRACK is initially released, subsequent to the temperature sense calibration delay, the COMP voltage is released to the lower COMP clamp level and no switching occurs. Both the LG and HG pins are held low while the SS/TRACK voltage stays below the FB voltage level. This action ensures that a prebiased load is not pulled down by a negative dc output current component. When the SS/TRACK pin voltage crosses above either FB or VREF, the COMP voltage slews up to the valley of the PWM ramp and switching begins.

**8.3.14 Voltage-Mode Control**

The LM27403 incorporates a voltage-mode control loop implementation with input voltage feedforward to eliminate the input voltage dependence of the PWM modulator gain. This configuration allows the controller to maintain stability throughout the entire input voltage operating range and provides for optimal response to input voltage transient disturbances. The constant gain provided by the controller greatly simplifies feedback loop design because loop characteristics remain constant as the input voltage changes, unlike a buck converter without voltage feedforward. An increase in input voltage is matched by a concomitant increase in ramp voltage amplitude to maintain constant modulator gain. The input voltage feedforward gain, $k_{FF}$, is 1/9, equivalent to the ramp amplitude divided by the input voltage, $V_{RAMP}/V_{IN}$. See the Control Loop Compensation section for more detail.

**8.3.15 Output Voltage Remote Sense: RS**

High-current switching power supplies typically use output voltage remote sensing to achieve the greatest accuracy at the point of load. There are usually some finite bus structure resistances between the power supply and load, denoted by lumped elements $R_{BUS+}$ and $R_{BUS-}$ in Figure 37, that cause unwanted voltage drops or load regulation errors, particularly at high output currents.
Remote ground sensing is implemented in the LM27403 by bringing another amplifier input, designated RS, outside of the device package to act as a kelvin ground sense. This circuit is created by replacing the standard error amplifier used in the PWM loop with a new amplifier that has two pairs of differential inputs. One of the differential input pairs is used to sense the internal reference voltage relative to the IC ground potential. The other differential input is used to remotely sense the feedback (FB) voltage relative to RS connected to the negative load terminal (at the output point of load). The output of the new error amplifier is the difference between the two pairs of inputs multiplied by some gain factor, and in all other respects works the same as the classic op-amp type error amplifier.

For accurate remote sensing of the output at the load, make sure to tie upper feedback resistor $R_{FB1}$ directly to the load at the point where output regulation is required. However, in order to minimize injected noise into the high-impedance FB node, connect the RC lead network, $R_{C2}$ and $C_{C3}$, typically found across $R_{FB1}$ in voltage-mode control loop compensation networks, to the local VOUT connection, as shown in Figure 37. Similarly, connect the negative sense line locally at the negative load terminal and route both sense lines as a differential pair to minimize pickup and injected noise. Sense resistors, $R_{SENSE+}$ and $R_{SENSE-}$, typically 10 $\Omega$ each, are used to maintain regulation when the remote sense lines are not connected or as a fail-safe measure if the lines become disconnected. In particularly noisy environments, capacitor $C_{RS}$ shown in Figure 37 (typically 0.1 $\mu$F) is supplemented by a series resistor (for example, 10 $\Omega$). If remote sense is not required, RS is simply shorted to GND.

The configuration in Figure 37 avoids the use of a separate unity-gain differential amplifier, a solution commonly used to perform remote sensing. The offset and gain error of this differential amplifier configuration compound any inaccuracy associated with the reference and error amplifier input offset voltage. The accuracy of the feedback system is not compromised when using the method shown in Figure 37. The LM27403 specified feedback accuracy of ±1% is preserved over the full operating temperature range.

### 8.3.16 Power Good: PGOOD

To implement an open-drain power-good function for sequencing and fault detection, use the PGOOD pin of the LM27403. The PGOOD open-drain MOSFET is pulled low during current limit, UVLO, output undervoltage and overvoltage, or if the output is not regulated.

More specifically, this function can be triggered by multiple events, including the output voltage either exceeding the overvoltage threshold (117% VREF) or decreasing below the undervoltage threshold (91% VREF), heavy overcurrent, soft-start voltage (both internal and external) below 91% VREF, UVLO, thermal shutdown, enable delay, or disabled state.
To prevent momentary glitches to the PGOOD pin, a 20-µs de-glitch filter is built into the LM27403 to prevent multiple triggerings of the flag. Note that the primary objective of PGOOD is to signal to the system that the soft-start period has expired and the output voltage is in regulation for loads within the rated limit. This can be used for sequencing downstream regulators, an example of which is shown schematically in Figure 48.

During soft-start operation, the PGOOD flag is effectively a logic AND of two signals:

1. The internal soft-start counter (signals the internal soft-start-done flag when the count reaches 128).
2. The UVT comparator output. Note that the UVT comparator monitors SS/TRACK voltage until the first PWM pulse, and then monitors the FB voltage.

The reason for multiplexing the UVT comparator is to support prebias loads and tracking. The PGOOD voltage waveform is shown in Figure 33 with a 100-kΩ pullup resistor to VDD. As described previously, VDD disappears when UVLO/EN is pulled lower than an effective diode drop (~0.7 V). This does not represent a system-level issue because PGOOD is already pulled low in that scenario.

8.3.17 Gate Drivers: LG and HG

The LM27403 gate driver impedances are low enough to perform effectively in high output current applications where large die-size or paralleled MOSFETs with correspondingly large gate charge, \( Q_G \), are used. Measured at \( V_{DD} = 4.5 \) V, the LM27403's low-side driver has a low impedance pull-down path of 0.9 \( \Omega \) to minimize the effect of \( dv/dt \) induced turn-on, particularly with low gate-threshold voltage MOSFETs. Similarly, the high-side driver has 1.5-\( \Omega \) and 1.0-\( \Omega \) pull-up and pull-down impedances, respectively, for faster switching transition times, lower switching loss, and greater efficiency.

Furthermore, there is a proprietary adaptive deadtime control on both switching edges to prevent shoot-through and cross-conduction, minimize body diode conduction time, and reduce body diode reverse recovery related losses. The LM27403 is fully compatible with discrete and Power Block NexFET™ MOSFETs from TI.

8.3.18 Sink and Source Capability

Even though an LM27403-based DC/DC regulator is capable of sinking and sourcing current (as it operates in CCM), the inductor DCR-based overcurrent protection operates only with positive currents. Negative currents are detected through the low-side MOSFET only when the device is in an overvoltage condition (refer to Zero Cross and Negative Current Limit sections). Note that prebias startup still operates normally (refer to Prebias Startup section).

8.4 Device Functional Modes

8.4.1 Fault Conditions

Overcurrent, overtemperature, output undervoltage and overvoltage protection features are included in the LM27403.

8.4.1.1 Thermal Shutdown

The LM27403 includes an internal junction temperature monitor. If the temperature exceeds 150°C (typ), thermal shutdown occurs. When entering thermal shutdown, the device:

1. turns off the low-side and high-side MOSFETs;
2. flushes the external soft-start capacitor;
3. initiates a soft-start sequence when the die temperature decreases by the OTP hysteresis, 20°C (typ).

This is a nonlatching protection, and, as such, the device will cycle into and out of thermal shutdown if the fault persists.

8.4.1.2 Current Limit and Short Circuit Operation (Positive Overcurrent)

When detecting a current-limit (CL) event, one of the following actions occur:

1. Light CL: When a current limit event is detected, the high-side on-pulse is immediately terminated (HG off, LG on) and the system continues regulating on the next system clock event;
2. Heavy CL: If five current limit events occur in any 32 clock cycles, the pulse is terminated (HG off, LG off) and hiccup mode is entered.
Device Functional Modes (continued)

The following actions occur in hiccup mode:

1. HG off, LG off;
2. Re-enable soft-start clock to count 5-ms timeout for hiccup delay;
3. At the end of the hiccup delay, re-enter the startup sequence, including the internal enable delay.

Every time a current limit event is detected, the current limit event counter is incremented on the next clock edge. If the current limit event counter reaches its threshold of five, then the hiccup mode is entered.

8.4.1.3 Negative Current Limit

Negative current limit detection is in effect only after an overvoltage (OV) condition is met. The OV flag is deglitched by 10 µs. By the time OV is signaled, the loop has most likely moved into a low- or zero-percent duty cycle that poses the threat of excessive negative current. Thus, the negative current limit is in effect as soon as the OV condition is detected rather than waiting for the deglitched version. If the negative current limit is exceeded, the low-side MOSFET gate (LG pin) is pulled low and the LM27403 enters Negative Current Limit hiccup mode for 5 ms.

Negative Current Limit hiccup mode (subsequent to OVP) is different from Current Limit hiccup mode in that zero-cross current detection is active in the latter and the LG output is high. However, as with Current Limit hiccup mode, the system attempts to restart after the 5-ms timeout, as described in the Current Limit Handling section. The LM27403 detects a negative current limit by monitoring the switch-node (SW) voltage while the low-side MOSFET is on. If the switch-node voltage (that is, the low-side MOSFET drain-source voltage) rises 100 mV above ground during the low-side MOSFET conduction interval, the comparator trips, signaling that the negative current limit threshold has been reached. The low-side MOSFET is turned off, thus protecting it from excess current.

The negative current comparator is valid only when the LG is high. Blanking time lasts 20 ns to 50 ns after LG has been asserted. Blanking recurs as soon as PWM goes high.

8.4.1.4 Undervoltage Threshold (UVT)

The FB pin is also monitored for an output voltage excursion below the nominal level. However, if the UVT comparator is tripped, no action occurs on the normal switching cycles. The UVT signal is used solely as a valid condition for the Power Good flag to transition low. When the FB voltage exceeds 91% of the reference voltage, the Power Good flag transitions high. Conversely, when the FB voltage is less than 87% of the reference.

8.4.1.5 Overvoltage Threshold (OVT)

When the FB voltage exceeds 116.5% of the reference voltage, the Power Good flag transitions low after a 10-µs deglitch. The control loop attempts to bring the output voltage back to the nominal setpoint. Conversely, when the FB voltage goes below 113% of the reference, the Power Good flag is allowed to transition high. Negative current-limit detection is activated when the regulator is in an OV condition. See the Negative Current Limit section for more details.
9 Application and Implementation

NOTE
Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information

9.1.1 Design and Implementation
To expedite the process of designing a LM27403-based regulator for a given application, please use the LM27403 Quick-start Design Tool available as a free download. As well as numerous LM27403 reference designs populated in TI Designs™ reference design library, five designs are provided in the Typical Applications section of this datasheet. The LM27403 is also WEBENCH® Designer enabled.

9.1.2 Power Train Components
Comprehensive knowledge and understanding of the power train components are key to successfully completing a buck regulator design. The LM27403 Design Tool and WEBENCH are available to assist the designer with selection of these components for a given application.

9.1.2.1 Filter Inductor
For most applications, choose an inductance such that the inductor ripple current, \( \Delta I_L \), is between 20% and 40% of the maximum dc output current. Choose the inductance using Equation 10:

\[
L = \frac{V_{OUT}}{V_{IN}} \left( \frac{V_{IN} - V_{OUT}}{\Delta I_L F_{SW}} \right)
\]

Check the inductor datasheet to ensure that the inductor's saturation current is well above the peak inductor current of a particular design. Ferrite designs have very low core loss and are preferred at high switching frequencies, so design goals can then concentrate on copper loss and preventing saturation. Low inductor core loss is evidenced by reduced no-load input current and higher light-load efficiency. However, ferrite core materials exhibit a hard saturation characteristic — the inductance collapses abruptly when the saturation current is exceeded. This results in an abrupt increase in inductor ripple current, higher output voltage ripple, not to mention reduced efficiency and compromised reliability. Note that an inductor's saturation current generally decreases as its core temperature increases. Of course, accurate overcurrent protection is key to avoiding inductor saturation.

9.1.2.2 Output Capacitors
Ordinarily, the regulator’s output capacitor energy store combined with the control loop response are prescribed to maintain the integrity of the output voltage within both the static and dynamic (transient) tolerance specifications. The usual boundaries restricting the output capacitor in power management applications are driven by finite available PCB area, component footprint and profile, and cost. The capacitor parasitics – equivalent series resistance (ESR) and equivalent series inductance (ESL) – take increasing precedence in shaping the regulator’s load transient response as the output current ramp amplitude and slew rate increase.

So, the output capacitor, \( C_{OUT} \), exists to filter the inductor ripple current and provide a reservoir of charge for step load transient events. Typically, ceramic capacitors provide extremely low ESR to reduce the output voltage ripple and noise spikes, while tantalum and electrolytic capacitors provide a large bulk capacitance in a relatively compact footprint for transient loading events.

Based on the static specification of peak-to-peak output voltage ripple denoted by \( \Delta V_O \), choose an output capacitance that is larger than

\[
C_{OUT} \geq \frac{\Delta I_L}{8F_{SW} \sqrt{\Delta V_O^2 - (R_{ESR} \Delta I_L)^2}}
\]
Application Information (continued)

Figure 38 conceptually illustrates the relevant current waveforms during both load step-up and step-down transitions. As shown, the large-signal slew rate of the inductor current is limited as the inductor current ramps to match the new load-current level following a load transient. This slew-rate limiting exacerbates the deficit of charge in the output capacitor, which must be replenished as rapidly as possible during and after the load-on transient. Similarly, during and after a load-off transient, the slew rate limiting of the inductor current adds to the surplus of charge in the output capacitor that needs to be depleted as quickly as possible.

Figure 38. Load Transient Response Representation Showing C_{OUT} Charge Surplus Or Deficit.

In a typical regulator application of 12-V input to low output voltage (say 1.2 V), it should be recognized that the load-off transient represents worst-case. In that case, the steady-state duty cycle is approximately 10% and the large-signal inductor current slew rate when the duty cycle collapses to zero is approximately \(-V_{OUT}/L\). Compared to a load-on transient, the inductor current takes much longer to transition to the required level. The surplus of charge in the output capacitor causes the output voltage to significantly overshoot. In fact, to deplete this excess charge from the output capacitor as quickly as possible, the inductor current must ramp below its nominal level following the load step. In this scenario, a large output capacitance can be advantageously employed to absorb the excess charge and rein in the voltage overshoot.

To meet the dynamic specification of output voltage overshoot during such a load-off transient (denoted as \(\Delta V_{overshoot}\) with step reduction in output current given by \(\Delta I_o\)), the output capacitance should be larger than

\[
C_{OUT} \geq \frac{\Delta I_o^2 L}{(V_{OUT} + \Delta V_{overshoot})^2 - V_{OUT}^2}
\]  

(12)

The ESR of a capacitor is provided in the manufacturer’s datasheet either explicitly as a specification or implicitly in the impedance vs. frequency curve. Depending on type, size and construction, electrolytic capacitors have significant ESR, 5 mΩ and above, and relatively large ESL, 5 nH to 20 nH. PCB traces contribute some ESR and ESL as well. Ceramic output capacitors, on the other hand, are such that the impedances related to the ESR and ESL are small at the switching frequency, and the capacitive impedance dominates. However, depending on package and voltage rating of the ceramic capacitor, the effective capacitance can drop quite significantly with applied voltage and operating temperature.

Ignoring the ESR term in Equation 11 gives a quick estimation of the minimum ceramic capacitance necessary to meet the output ripple specification. One to four 100-µF, 6.3-V, X5R capacitors in 1206 or 1210 footprint is a common choice. Use Equation 12 to quantify if additional capacitance is necessary to meet the load-off transient overshoot specification.
Application Information (continued)

A composite implementation of ceramic and electrolytic capacitors highlights the rationale of paralleling capacitors of dissimilar chemistries yet complementary performance. The frequency response of each capacitor is accretive in that each capacitor provides desirable performance over a certain portion of the frequency range of interest. While the ceramic provides excellent mid- and high-frequency decoupling characteristics with its low ESR and ESL to minimize the switching frequency output ripple, the electrolytic device with its large bulk capacitance provides low-frequency energy storage to cope with load-transient demands.

9.1.2.3 Input Capacitors

Input capacitors are necessary to limit the input ripple voltage while switching-frequency ac current to the buck power stage. It is generally recommended to use X5R or X7R dielectric ceramic capacitors, thus providing low impedance and high RMS current rating over a wide temperature range. To minimize the parasitic inductance in the switching loop, position the input capacitors as close as possible to the drain of the high-side MOSFET and the source of the low-side MOSFET.

The input capacitors’ RMS current is given by Equation 13.

\[ I_{\text{cin rms}} = \sqrt{D \left( \frac{\Delta V^2}{12} (1 - D) + \frac{\Delta V^2}{12} \right)} \]  \hspace{1cm} (13)

The highest requirement for input capacitor RMS current rating occurs at \( D = 0.5 \), at which point the RMS current rating should be greater than half the output current.

Ideally, the dc component of input current is provided by the input voltage source and the ac component by the input filter capacitors. Neglecting inductor ripple current, the input capacitors source current of amplitude \( I_{\text{cin}} \) during the \( D \) interval and sinks \( I_{\text{cin}} \) during the \( 1 - D \) interval. Thus, the input capacitors conduct a square-wave current of peak-to-peak amplitude equal to the output current. It follows that the resultant capacitive component of ac ripple voltage is a triangular waveform. Together with the ESR-related ripple component, the peak-to-peak ripple voltage amplitude is given by Equation 14.

\[ \Delta V_{\text{IN}} = I_{\text{IN}} D (1 - D) + \frac{\Delta V_{\text{IN}}}{I_{\text{IN}}} R_{\text{ESR}} \]  \hspace{1cm} (14)

The input capacitance required for a particular load current, based on an input voltage ripple specification of \( \Delta V_{\text{IN}} \), is given by Equation 15.

\[ C_{\text{IN}} \geq \frac{D (1 - D) I_{\text{IN}}}{\Delta V_{\text{IN}} \left(1 + \frac{1}{R_{\text{ESR}} I_{\text{IN}}}\right)} \]  \hspace{1cm} (15)

Low ESR ceramic capacitors can be placed in parallel with higher valued bulk capacitance to provide optimized input filtering for the regulator and damping to mitigate the effects of input parasitic inductance resonating with high-Q ceramics. One bulk capacitor of sufficiently high current rating and one or two 10-\( \mu \)F 25-V X7R ceramic decoupling capacitors are usually sufficient. Select the input bulk capacitor based on its ripple current rating and operating temperature.

9.1.2.4 Power MOSFETs

The choice of MOSFET has significant impact on DC-DC regulator performance. A MOSFET with low on-state resistance, \( R_{\text{DS(on)}} \), reduces conduction loss, whereas low parasitic capacitances enable faster transition times and reduced switching loss. Normally, the lower the \( R_{\text{DS(on)}} \) of a MOSFET, the higher the gate charge, \( Q_G \), and vice versa. As a result, the product \( R_{\text{DS(on)}} \cdot Q_G \) is commonly specified as a MOSFET figure-of-merit. Low thermal resistance ensures that the MOSFET power dissipation does not result in excessive MOSFET die temperature.

The main parameters affecting MOSFET selection in an LM27403 application are as follows:

- \( R_{\text{DS(on)}} \) at \( V_{\text{GS}} = 4.5 \) V;
- Drain-source voltage rating, \( BV_{\text{DSS}} \), typically 25 V or 30 V;
- Gate charge parameters at \( V_{\text{GS}} = 4.5 \) V;
- Body diode reverse recovery charge, \( Q_{RR} \);
- Gate threshold voltage, \( V_{\text{GS(th)}} \) derived from the plateau in the \( Q_G \) vs. \( V_{\text{GS}} \) curve in the MOSFET’s datasheet. \( V_{\text{GS(th)}} \) should be in the range 2 V to 3 V such that the MOSFET is adequately enhanced when on and margin
Application Information (continued)

against Cdv/dt shoot-through exists when off.

The MOSFET-related power losses are summarized by the equations presented in Table 2. While the influence of inductor ripple current is considered, second-order loss modes, such as those related to parasitic inductances, are not discussed. Consult the LM27403 Quick-start Design Tool to assist with power loss calculations.

(1) MOSFET $R_{DS(on)}$ has a positive temperature coefficient of approximately 4000 ppm/°C. The MOSFET junction temperature, $T_J$, and its rise over ambient temperature is dependent upon the device total power dissipation and its thermal impedance.

(2) $D' = 1–D$ is the duty cycle complement.

(3) Gate drive loss is not dissipated in the MOSFET but rather in the LM27403's integrated drivers.

The high-side (control) MOSFET carries the inductor current during the PWM on time (or D interval) and typically incurs most of the switching losses. It is therefore imperative to choose a high-side MOSFET that balances conduction and switching loss contributions. The total power dissipation in the high-side MOSFET is the sum of the losses due to conduction, switching and typically two-thirds of the net loss attributed to body diode reverse recovery.

The low-side (synchronous) MOSFET carries the inductor current when the high-side MOSFET is off (or 1–D interval). The low-side MOSFET switching loss is negligible as it is switched at zero voltage – current just commutates from the channel to the body diode or vice versa during the deadtime. The LM27403, with its adaptive gate drive timing, minimizes body diode conduction losses when both MOSFETs are off. Such losses scale directly with switching frequency.

In high input voltage and low output voltage applications, the low-side MOSFET carries the current for a large portion of the switching period. Therefore, to attain high efficiency, it is critical to optimize the low-side MOSFET for low $R_{DS(on)}$. In cases where the conduction loss is too high or the target $R_{DS(on)}$ is lower than available in a single MOSFET, connect two low-side MOSFETs in parallel. The total power dissipation of the low-side MOSFET is the sum of the losses due to channel conduction, body diode conduction, and typically one-third of the net loss attributed to body diode reverse recovery.

The LM27403 is well matched to TI's comprehensive portfolio of 25-V and 30-V NexFET™ family of power MOSFETs. In fact, the LM27403 is ideally suited to driving the Power Block NexFET™ modules with integrated high-side and low-side MOSFETs. Excellent efficiency is obtained by virtue of reduced parasitics and exemplary thermal performance of the Power Block MOSFET implementation. See the Typical Applications section for more details.

9.1.3 Control Loop Compensation

The poles and zeros inherent to the power stage and compensator are respectively illustrated by red and blue dashed rings in the schematic embedded in Table 3.
The compensation network typically employed with voltage-mode control is a type-III circuit with three poles and two zeros. One compensator pole is located at the origin to realize high DC gain. The normal compensation strategy then is to use two compensator zeros to counteract the LC double pole, one compensator pole located to nullify the output capacitor ESR zero, with the remaining compensator pole located at one-half switching frequency to attenuate high frequency noise. Finally, a resistor divider network to FB determines the desired output voltage. Note that the lower feedback resistor, \( R_{FB2} \), has no impact on the control loop from an ac standpoint since the FB node is the input to an error amplifier and is effectively at ac ground. Hence, the control loop is designed irrespectively of output voltage level. The proviso here is the necessary output capacitance derating with bias voltage and temperature.

### Table 3. Regulator Poles and Zeros

<table>
<thead>
<tr>
<th>Power Stage Poles</th>

<td>( \omega_{z2} = \frac{1}{(R_{FB2} + R_{C2}) C_{C3}} )</td>
</tr>
</tbody>
</table>

\(^{(1)}\) \( R_{ESR} \) represents the ESR of output capacitor \( C_o \).
\(^{(2)}\) \( R_{DAMP} = D^*R_{DS(on)\text{high-side}} + (1-D)^*R_{DS(on)\text{low-side}} + R_{dc} \), shown as a lumped element in the schematic, represents the effective series damping resistance.

The small-signal open-loop response of a buck regulator is the product of modulator, power train and compensator transfer functions. The power stage transfer function can be represented as a complex pole pair associated with the output LC filter and a zero related to the output capacitor’s ESR. The dc (and low frequency) gain of the modulator and power stage is \( V_{IN}/V_{RAMP} \). Representing the gain from COMP to the average voltage at the input of the LC filter, this is held essentially constant by the LM27403’s PWM line feedforward feature at 9 V/V or 19 dB.

Complete expressions for small-signal frequency analysis are presented in Table 4. The transfer functions are denoted in normalized form. While the loop gain is of primary importance, a regulator is not specified directly by its loop gain but by its performance related characteristics, namely closed-loop output impedance and audio susceptibility.
Table 4. Buck Regulator Small-Signal Analysis

<table>
<thead>
<tr>
<th>PARAMETER</th>
<th>EXPRESSION</th>
</tr>

<tr>
<td>Open-loop transfer function</td>
<td>( T_v(s) = \frac{\hat{v}_{\text{comp}}(s)}{\hat{v}<em>o(s)} \cdot \hat{v}<em>o(s) \cdot \frac{d(s)}{\hat{v}</em>{\text{comp}}(s)} = G_c(s)G</em>{vd}(s)F_M )</td>
</tr>
<tr>
<td>Duty-cycle-to-output transfer function</td>
<td>( G_{vd}(s) = \left. \frac{\hat{v}_o(s)}{d(s)} \right</td>
</tr>
<tr>
<td>Compensator transfer function(^{(1)})</td>
<td>( G_c(s) = \frac{\hat{v}<em>{\text{comp}}(s)}{\hat{v}<em>o(s)} = K</em>{\text{mid}} \left( 1 + \frac{\omega</em>{Z1}}{s} \right) \left( 1 + \frac{s}{\omega_{Z2}} \right) )</td>
</tr>
<tr>
<td>Modulator transfer function</td>
<td>( F_M = \frac{d(s)}{\hat{v}<em>{\text{comp}}(s)} = \frac{1}{V</em>{\text{RAMP}}} )</td>
</tr>
</tbody>
</table>

\(^{(1)}\) \( K_{\text{mid}} = \frac{R_{C1}}{R_{FB1}} \) is the compensator's mid-band gain. By expressing one of the compensator zeros in inverted zero format, the mid-band gain is denoted explicitly.

An illustration of the open-loop response gain and phase is given in Figure 39. The poles and zeros of the system are marked with x and o symbols, respectively, and a + symbol indicates the crossover frequency. When plotted on a log (dB) scale, the open-loop gain is effectively the sum of the individual gain components from the modulator, power stage and compensator – this is clear from Figure 40. The open-loop response of the system is measured experimentally by breaking the loop, injecting a variable-frequency oscillator signal and recording the ensuing frequency response using a network analyzer setup.

If the pole located at \( \omega_{p1} \) cancels the zero located at \( \omega_{ESR} \) and the pole at \( \omega_{p2} \) is located well above crossover, the expression for the loop gain, \( T_v(s) \) in Table 4, can be manipulated to yield the simplified expression given in Equation 16.

\[
T_v(s) = \frac{R_{C1}C_{C3}}{s} \frac{V_{IN}^2}{V_{\text{RAMP}}} 
\]

(16)
Essentially, a multi-order system is reduced to a single order approximation by judicious choice of compensator components. A simple solution for the crossover frequency, denoted as \( f_c \) in Figure 39, with type-III voltage-mode control is derived as in Equation 17.

\[
\omega_c = 2 \pi f_c = K_{\text{mid}} \frac{V_{\text{IN}}}{V_{\text{RAMP}}} \omega_o
\]

(17)

Figure 40. Buck Regulator Constituent Gain Components

The loop crossover frequency is usually selected between one-tenth to one-fifth of switching frequency. Inserting an appropriate crossover frequency into Equation 17 gives a target for the compensator's mid-band gain, \( K_{\text{mid}} \). Given an initial value for \( R_{FB1} \), \( R_{FB2} \) is then selected based on the desired output voltage. Values for \( R_{C1}, R_{C2}, \) \( C_{C1}, C_{C2} \) and \( C_{C3} \) are calculated from the design-oriented expressions listed in Table 5, with the premise that the compensator poles and zeros are set as follows: \( \omega_{z1} = 0.5 \omega_o, \omega_{z2} = \omega_o, \omega_{p1} = \omega_{\text{ESR}}, \omega_{p2} = \omega_{sw}/2. \)

<table>

<td>( R_{C1} = K_{\text{mid}} R_{FB1} )</td>
</tr>
<tr>
<td>( R_{C2} = \frac{1}{\omega_{p1}C_{C3}} )</td>
</tr>
</tbody>
</table>

Referring to the bode plot in Figure 39, the phase margin, indicated as \( \phi_{\text{PM}} \), is the difference between the loop phase and \(-180^\circ\) at crossover. A target of 50° to 70° for this parameter is considered ideal. Additional phase boost is dialed in by locating the compensator zeros at a frequency lower than the LC double pole (hence why \( C_{C1} \) is scaled by a factor of 2 above). This helps to mitigate the phase dip associated with the LC filter, particularly at light loads when the Q-factor is higher and the phase dip becomes especially prominent. The ramification of low phase in the frequency domain is an under-damped transient response in the time domain.

The power supply designer now has all the tools at his/her disposal to optimally position the loop crossover frequency while maintaining adequate phase margin over the power supply's required line, load and temperature operating ranges.
9.2 Typical Applications

9.2.1 Design 1 - High-Efficiency Synchronous Buck Regulator for Telecom Power

Figure 41. Application Circuit 1 with $V_{IN} = 6.5$ V to 20 V ($V_{IN(nom)} = 12$ V), $V_{OUT} = 0.6$ V to 5.3 V, $I_{OUT(max)} = 25$ A, $F_{SW} = 300$ kHz (Using External Synchronization Signal)

9.2.1.1 Design Requirements

The schematic diagram of a 25-A regulator is given in Figure 41. In this example, the target full-load efficiencies are 91% and 97% at 1.2-V and 5.3-V output voltages, respectively, based on a nominal input voltage of 12 V that ranges from 6.5 V to 20 V. Output voltage is adjusted simply by changing $R_{FB2}$. The switching frequency is set by means of a synchronization signal at 300 kHz, and free-running switching frequency (in the event that the synchronization signal is removed) is set to 250 kHz by resistor $R_{FADJ}$. In terms of control loop performance, the target loop crossover frequency is 45 kHz with a phase margin in excess of 50°. The output voltage soft-start time is 8 ms.

9.2.1.2 Detailed Design Procedure

The design procedure for an LM27403-based converter for a given application is streamlined by using the LM27403 Quick-Start Design Tool available as a free download, or by availing of TI's WEBENCH® Designer online software. Such tools are complemented by the availability of two LM27403 evaluation module (EVM) designs as well as numerous LM27403 reference designs populated in TI Designs™ reference design library.

The current limit setpoint in this design is set at 28.5 A, based on resistor $R_{ISET}$ and the inductor DCR (1.1 mΩ typ at 25°C). Of course, the current limit setpoint should always be selected such that the operating current level does not exceed the saturation current specification of the chosen inductor. The component values for the DCR sense network ($R_S$ and $C_S$ in Figure 41) are chosen based on making the $R_S C_S$ product approximately equal to $L/R_{dcr}$, as recommended in the Current Sensing: CS+ and CS– section.

The selected buck converter powertrain components are cited in Table 6, and many of the components are available from multiple vendors. The MOSFETs in particular are chosen for both lowest conduction and switching power loss, as discussed in detail in the Power MOSFETs section.

### 9.2.2.2 Detailed Design Procedure

A high power density, high efficiency solution is feasible by using TI NexFET™ Power Block module CSD87350Q5D (dual asymmetric MOSFETs in a SON 5-mm x 6-mm package) together with and low-DCR ferrite inductor and all-ceramic capacitor design. The design occupies 20 mm x 15 mm on a single-sided PCB. Knowing the cumulative resistance of the inductor DCR and Power Block MOSFET SW clip (approximately 1 m\(\Omega\) at 25°C), resistor \(R_{ISET}\) positions the current limit setpoint at 28A. The output voltage is adjusted by choosing the resistance of \(R_{FB2}\) appropriately. Resistors \(R_{TRK1}\) and \(R_{TRK2}\) connected to the SS/TRACK pin define a coincidental tracking startup sequence from a master power supply, \(V_{TRACK}\).
Additional input and/or output capacitance can be added if needed, but adjust the compensation if $C_{OUT}$ changes. The $T_{GR}$ pin of the Power Block MOSFET serves as a kelvin connection to the source of the high-side MOSFET and represents the return path for the high-side gate drive. Along with bootstrap capacitor, $C_{BOOT}$, $T_{GR}$ is connected to the LM27403’s SW pin.

### 9.2.2.3 Application Curves

**Figure 47. Efficiency vs. Output Current at $V_{IN} = 12$ V**
9.2.3 Design 3 - Powering Multicore DSPs

The schematic diagram of a 450-kHz, 12-V nominal input, 15-A regulator powering a KeyStone™ DSP is given in Figure 48. The important components are listed in Table 8. The regulator output current requirements are dependent upon the baseline and activity power consumptions of the DSP in a real-use case. While baseline power is highly dependent on voltage, temperature and DSP frequency, activity power relates to dynamic core utilization, DDR3 memory access, peripherals, and so on. To this end, the IDAC_OUT pin of the LM10011 connects to the LM27403 FB pin to allow continuous optimization of the core voltage. The SmartReflex-enabled DSP provides 6-bit information using the VCNTL open-drain IOs (1) to command the output voltage setpoint with 6.4-mV step resolution. This design uses a TI NexFET™ Power Block module CSD87330Q3D (dual asymmetric MOSFETs in SON 3.3-mm x 3.3-mm package) together with low-DCR, metal-powder inductor and composite ceramic–polymer electrolytic output capacitor implementation.

Figure 48. Application Circuit 3 with \( V_{IN} = 3 \) V to 20 V, \( V_{OUT} = 0.9 \) V to 1.1 V, \( I_{OUT(max)} = 15 \) A, \( F_{SW} = 450 \) kHz

9.2.4 Design 4 - Regulated 12-V Rail with LDO Low-Noise Auxiliary Output for RF Power

![Application Circuit Diagram]

Figure 49. Application Circuit 4 with $V_{IN} = 13$ V to 20 V ($V_{IN(nom)} = 18$ V), $V_{OUT1} = 12$ V, $I_{OUT1(max)} = 10$ A, $F_{SW} = 280$ kHz, $V_{OUT2} = 10$ V, $I_{OUT2(max)} = 0.8$ A.

The schematic diagram of a 280-kHz, 12-V output, 10-A buck regulator for RF power applications is given in Figure 49(1). A 10-Ω resistor in series with $C_{BOOT}$ is used to slow the turn-on transition of the high-side MOSFET, reducing the spike amplitude and ringing of the SW node waveform and minimizing the possibility of $C_{dv/dt}$-induced shoot-through of the low-side MOSFET. If needed, place an RC snubber (for example, 2.2 kΩ and 1 nF) close to the SW node and GND(2). An auxiliary 10-V, 800-mA rail to power noise-sensitive circuits is available using the LP38798 ultra-low noise LDO as a post-regulator. The internal pullup of the LP38798’s EN pin facilitates direct connection to the LM27403’s PGGOOD for sequential startup control.

9.2.5 Design 5 - High Power Density Implementation From 3.3-V or 5-V Supply Rail

The schematic diagram of a 250-kHz, 25-A regulator is given in Figure 50. A high power density, ultra-high efficiency solution is possible using two paralleled TI CSD87353Q5D NexFET™ Power Block modules (dual MOSFETs in a SON 5-mm x 6-mm package) and low-DCR ferrite inductor. The design occupies 25 mm x 15 mm on a two-sided PCB. Knowing the cumulative resistance of the inductor DCR and Power Block MOSFET SW clip (approximately 0.8 mΩ at 25°C), resistor $R_{ISET}$ positions the current limit setpoint at 30A. VDD is tied to VIN to maximize the gate drive voltage for the MOSFETs. Capacitor $C_{DLY}$ defines a 3-ms startup delay based on the current sourced from the UVLO/EN pin.

The powertrain components are listed in Table 10, and the filter components are available from multiple vendors. The TG pin of the Power Block MOSFET serves as a kelvin connection to the source of the high-side MOSFET and represents the return path for the high-side gate drive. Along with bootstrap capacitor, $C_{BOOT}$, TG is connected to the LM27403’s SW pin.

10 Power Supply Recommendations

The LM27403 PWM controller is designed to operate from an input voltage supply range between 3 V and 20 V. If the input supply is located more than a few inches from the LM27403-based converter, additional bulk capacitance may be required in addition to ceramic bypass capacitance. Given the negative incremental input impedance of a buck converter, a bulk electrolytic component provides damping to reduce effects of input parasitic inductance resonating with high-Q ceramics.

11 Layout

11.1 Layout Guidelines

Proper PCB design and layout is important in a high current, fast switching circuit (with high current and voltage slew rates) to assure appropriate device operation and design robustness. As expected, certain issues must be considered before designing a PCB layout using the LM27403. The main switching loop of the power stage is denoted by #1 in Figure 51. The topological architecture of a buck converter means that particularly high di/dt current will flow in loop #1, and it becomes mandatory to reduce the parasitic inductance of this loop by minimizing its effective loop area. For loop #2 however, the di/dt through inductor L1 and capacitor COUT is naturally limited by the inductor. Keeping the area of loop #2 small is not nearly as important as that of loop #1. Also important are the gate drive loops of the low-side and high-side MOSFETs, denoted by #3 and #4, respectively, in Figure 51.

![Figure 51. DC-DC Regulator Ground System With Power Stage and Gate Drive Circuit Switching Loops](image)

11.1.1 Power Stage Layout

1. Input capacitor(s), output capacitor(s) and MOSFETs are the constituent components in the power stage of a buck regulator and are typically placed on the top side of the PCB (solder side). Leveraging any system-level airflow, the benefits of convective heat transfer are thus maximized. In a two-sided PCB layout, small-signal components are typically placed on the bottom side (component side). At least one inner plane should be inserted, connected to ground, in order to shield and isolate the small-signal traces from noisy power traces and lines.

2. The DC-DC converter has several high-current loops. Minimize the area of these loops in order to suppress generated switching noise and parasitic loop inductance and optimize switching performance.
   - Loop #1: The most important loop to minimize the area of is the path from the input capacitor(s) through the high- and low-side MOSFETs, and back to the capacitor(s) through the ground connection. Connect the input capacitor(s) negative terminal close to the source of the low-side MOSFET (at ground). Similarly, connect the input capacitor(s) positive terminal close to the drain of the high-side MOSFET (at...
Layout Guidelines (continued)

VIN). Refer to loop #1 of Figure 51.

Loop #2. The second important loop is the path from the low-side MOSFET through inductor and output capacitor(s), and back to source of the low-side MOSFET through ground. Connect source of the low-side MOSFET and negative terminal of the output capacitor(s) at ground as close as possible. Refer to loop #2 of Figure 51.

3. The PCB trace defined as SW node, which connects to the source of the high-side (control) MOSFET, the drain of the low-side (synchronous) MOSFET and the high-voltage side of the inductor, should be short and wide. However, the SW connection is a source of injected EMI and thus should not be too large.

4. Follow any layout considerations of the MOSFETs as recommended by the MOSFET manufacturer, including pad geometry and solder paste stencil design.

5. The SW pin connects to the switch node of the power conversion stage, and it acts as the return path for the high-side gate driver. The parasitic inductance inherent to loop #1 in Figure 51 and the output capacitance (C\text{OSS}) of both power MOSFETs form a resonant circuit that induces high frequency (>100 MHz) ringing on the SW node. The voltage peak of this ringing, if not controlled, can be significantly higher than the input voltage. Ensure that the peak ringing amplitude does not exceed the absolute maximum rating limit for the SW pin. In many cases, a series resistor and capacitor snubber network connected from the SW node to GND damps the ringing and decreases the peak amplitude. Provide provisions for snubber network components in the printed circuit board layout. If testing reveals that the ringing amplitude at the SW pin is excessive, then include snubber components.

11.1.2 Gate Drive Layout

The LM27403 high- and low-side gate drivers incorporate short propagation delays, adaptive deadtime control and low-impedance output stages capable of delivering large peak currents with very fast rise and fall times to facilitate rapid turn-on and turn-off transitions of the power MOSFETs. Very high di/dt can cause unacceptable ringing if the trace lengths and impedances are not well controlled.

Minimization of stray/parasitic loop inductance is key to optimizing gate drive switching performance, whether it be series gate inductance that resonates with MOSFET gate capacitance or common source inductance (common to gate and power loops) that provides a negative feedback component opposing the gate drive command, thereby increasing MOSFET switching times. The following loops are important:

• Loop #3: high-side MOSFET, Q\textsubscript{1}. During the high-side MOSFET turn on, high current flows from the boot capacitor through the gate driver and high-side MOSFET, and back to negative terminal of the boot capacitor through the SW connection. Conversely, to turn off the high-side MOSFET, high current flows from gate of the high-side MOSFET through the gate driver and SW, and back to source of the high-side MOSFET through the SW trace. Refer to loop #3 of Figure 51.

• Loop #4: low-side MOSFET, Q\textsubscript{2}. During the low-side MOSFET turn on, high current flows from VDD decoupling capacitor through the gate driver and low-side MOSFET, and back to negative terminal of the capacitor through ground. Conversely, to turn off the low-side MOSFET, high current flows from gate of the low-side MOSFET through the gate driver and GND, and back to source of the low-side MOSFET through ground. Refer to loop #4 of Figure 51.

The following circuit layout guidelines are strongly recommended when designing with high-speed MOSFET gate drive circuits.

1. Connections from gate driver outputs, HG and LG, to the respective gate of the high-side or low-side MOSFET should be as short as possible to reduce series parasitic inductance. Use 0.65 mm (25 mils) or wider traces. Use via(s), if necessary, of at least 0.5 mm (20 mils) diameter along these traces. Route HG and SW gate traces as a differential pair from the LM27403 to the high-side MOSFET, taking advantage of flux cancellation.

2. Minimize the current loop path from the VDD and CBOOT pins through their respective capacitors as these provide the high instantaneous current to charge the MOSFET gate capacitances. Specifically, locate the bootstrap capacitor, C\textsubscript{BOOT}, close to the LM27403’s CBOOT and SW pins to minimize the area of loop #3 associated with the high-side driver. Similarly, locate the VDD capacitor, C\textsubscript{VDD}, close to the LM27403’s VDD and GND pins to minimize the area of loop #4 associated with the low-side driver.

3. Placing a 2-Ω to 10-Ω BOOT resistor in series with the BOOT capacitor, as shown in Figure 49, slows down the high-side MOSFET turn-on transition, serving to reduce the voltage ringing and peak amplitude at the SW node at the expense of increased MOSFET turn-on power loss.
Layout Guidelines (continued)

11.1.3 Controller Layout

Components related to the analog and feedback signals, current limit setting and temperature sense are considered in the following:

1. In general, separate power and signal traces, and use a ground plane to provide noise shielding.
2. Place all sensitive analog traces and components such as COMP, FB, RS, FADJ, OTP, D+ and SS/TRACK away from high-voltage switching nodes such as SW, HG, LG or CBOOT avoid coupling. Use internal layer(s) as ground plane(s). Pay particular attention to shielding the feedback (FB) trace from power traces and components.
3. The upper feedback resistor can be connected directly to the output voltage sense point at the load device or the bulk capacitor at the converter side. Connect RS to the ground return point at the load device or the general ground plane/layer. These connections can be used for the purpose of remote sensing across the downstream load; however, care must be taken to minimize the routing trace to prevent noise injection into the sense lines. The remote sense lines (SENSE+ and SENSE- in Figure 37) are typically routed as a differential pair, either side-by-side on the same PCB layer or overlapping each other on adjacent layers.
4. Connect the OCP setting resistor from CS+ pin to VOUT and make the connections as close as possible to the LM27403. The trace from the CS+ pin to the resistor should avoid coupling to a high-voltage switching node. Similar precautions apply if a resistor is tied to the CS– pin (as shown in Figure 32).
5. Minimize the current loop from the VDD and VIN pins through their respective decoupling capacitors to the GND pin. In other words, locate these capacitors as close as possible to the LM27403.
6. The layout of the temperature sense circuit is particularly important. Locate the thermal diode (2N3904-type BJT) adjacent the inductor on the same side of the PCB if possible. Close thermal coupling to the inductor is imperative to match the inductor winding's temperature coefficient.
   (a) Keep D+ and D– traces close together to minimize pickup. 10-mil trace width with 10-mil spacing is adequate. Keep D+ and D– traces short and surround with ground guard copper in especially noisy environments.
   (b) Route traces away from inductor, particularly with ferrite cores that have wide airgap and large fringing/leakage flux fields. Run a separate trace from the 2N3904 emitter back to LM27403 D– pin. Then connect D– to GND at the LM27403's DAP. Do not use a ground plane that carries high currents to make a return connection.

11.1.4 Thermal Design and Layout

The useful operating temperature range of a PWM controller with integrated gate drivers and bias supply LDO regulator is greatly affected by:
- average gate drive current requirements of the power MOSFETs;
- switching frequency;
- operating input voltage (affecting LDO voltage drop and hence its power dissipation);
- thermal characteristics of the package and operating environment.

In order for a PWM controller to be useful over a particular temperature range, the package must allow for the efficient removal of the heat produced while keeping the junction temperature within rated limits. The LM27403 controller is available in a small 4-mm x 4-mm WQFN-24 (RSW) PowerPAD™ package to cover a range of application requirements. The thermal metrics of this package are summarized in the Thermal Information section of this datasheet. For detailed information regarding the thermal information table, please refer to IC Package Thermal Metrics, SPRA953, application report.

The WQFN-24 package offers a means of removing heat from the semiconductor die through the exposed thermal pad at the base of the package. While the exposed pad of the LM27403's package is not directly connected to any leads of the package, it is thermally connected to the substrate of the device (ground). This allows a significant improvement in heat-sinking, and it becomes imperative that the PCB is designed with thermal lands, thermal vias, and a ground plane to complete the heat removal subsystem. The LM27403's exposed pad is soldered to the ground-connected copper land on the PCB directly underneath the device package, reducing the thermal resistance to a very low value. Wide traces of the copper tying in the LM27403's no-connect pins (pins 19–23) and connection to this thermal land helps to dissipate heat.
Layout Guidelines (continued)

Numerous vias with a 0.3-mm diameter connected from the thermal land to the internal/solder-side ground plane(s) are vital to help dissipation. In a multi-layer PCB design, a solid ground plane is typically placed on the PCB layer below the power components. Not only does this provide a plane for the power stage currents to flow but it also represents a thermally conductive path away from the heat generating devices.

The thermal characteristics of the MOSFETs also are significant. The high-side MOSFET's drain pad is normally connected to a VIN plane for heat-sinking. The low-side MOSFET's drain pad is tied to the SW plane, but the SW plane area is purposely kept relatively small to mitigate EMI concerns.

11.2 Layout Example

Figure 52 shows an example PCB layout based on the LM27403 25A EVM design. For more details, please see the LM27403 EVM User's Guide, SNVU233.

(1) The marketing status values are defined as follows:
- **ACTIVE**: Product device recommended for new designs.
- **LIFEBUY**: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
- **NRND**: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
- **PREVIEW**: Device has been announced but is not in production. Samples may or may not be available.
- **OBsolete**: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check [http://www.ti.com/productcontent](http://www.ti.com/productcontent) for the latest availability information and additional product content details.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a “~” will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.
