LM74700-Q1 Low \( I_0 \) reverse battery protection ideal diode controller

1 Features

- AEC-Q100 Qualified with the following results
  - Device temperature grade 1: –40°C to +125°C Ambient operating temperature range
  - Device HBM ESD classification level 2
  - Device CDM ESD classification level C4B
- 3.2-V to 65-V Input range (3.9-V start up)
- –65-V Reverse voltage rating
- Charge pump for external N-Channel MOSFET
- 20-mV ANODE to CATHODE forward voltage drop regulation
- Enable pin feature
- 1-\( \mu \)A Shutdown current (EN=Low)
- 80-\( \mu \)A Operating quiescent current (EN=High)
- 2.3-A Peak gate turnoff current
- Fast response to reverse current blocking: < 0.75 \( \mu \)s
- Meets automotive ISO7637 transient requirements with a suitable TVS Diode
- 6-Pin SOT-23 Package 2.90 mm × 1.60 mm

2 Applications

- Automotive ADAS systems - camera
- Automotive infotainment systems - digital cluster, head unit
- Industrial factory automation - PLC
- Enterprise power supplies
- Active ORing for redundant power

3 Description

The LM74700-Q1 is an automotive AEC Q100 qualified ideal diode controller which operates in conjunction with an external N-channel MOSFET as an ideal diode rectifier for low loss reverse polarity protection with a 20-mV forward voltage drop. The wide supply input range of 3.2 V to 65 V allows control of many popular DC bus voltages such as 12-V, 24-V and 48-V automotive battery systems. The 3.2-V input voltage support is particularly well suited for severe cold crank requirements in automotive systems. The device can withstand and protect the loads from negative supply voltages down to –65 V.

The device controls the GATE of the MOSFET to regulate the forward voltage drop at 20-mV. The regulation scheme enables graceful turn off of the MOSFET during a reverse current event and ensures zero DC reverse current flow. Fast response (< 0.75 \( \mu \)s) to Reverse Current Blocking makes the device suitable for systems with output voltage holdup requirements during ISO7637 pulse testing as well as power fail and input micro-short conditions.

The LM74700-Q1 controller provides a charge pump gate drive for an external N-channel MOSFET. The high voltage rating of LM74700-Q1 helps to simplify the system designs for automotive ISO7637 protection. With the enable pin low, the controller is off and draws approximately 1-\( \mu \)A of current.

(1) Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under Recommended Operating Conditions. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

(2) High junction temperatures degrade operating lifetimes. Operating lifetime is de-rated for junction temperatures greater than 125°C.

9 Detailed Description

9.1 Overview

The LM74700-Q1 ideal diode controller has all the features necessary to implement an efficient and fast reverse polarity protection circuit or be used in an ORing configuration while minimizing the number of external components. This easy to use ideal diode controller is paired with an external N-channel MOSFET to replace other reverse polarity schemes such as a P-channel MOSFET or a Schottky diode. An internal charge pump is used to drive the external N-Channel MOSFET to a maximum gate drive voltage of approximately 15 V. The voltage drop across the MOSFET is continuously monitored between the ANODE and CATHODE pins, and the GATE to ANODE voltage is adjusted as needed to regulate the forward voltage drop at 20 mV. This closed loop regulation scheme enables graceful turn off of the MOSFET during a reverse current event and ensures zero DC reverse current flow. A fast reverse current condition is detected when the voltage across ANODE and CATHODE pins reduces below −11 mV, resulting in the GATE pin being internally connected to the ANODE pin turning off the external N-channel MOSFET, and using the body diode to block any of the reverse current. An enable pin, EN is available to place the LM74700-Q1 in shutdown mode disabling the N-Channel MOSFET and minimizing the quiescent current.

9.2 Functional Block Diagram

![Functional Block Diagram](image-url)
9.3 Feature Description

9.3.1 Input Voltage

The ANODE pin is used to power the LM74700-Q1's internal circuitry, typically drawing 80 µA when enabled and 1 µA when disabled. If the ANODE pin voltage is greater than the POR Rising threshold, then LM74700-Q1 operates in either shutdown mode or conduction mode in accordance with the EN pin voltage. The voltage from ANODE to GND is designed to vary from 65 V to –65 V, allowing the LM74700-Q1 to withstand negative voltage transients.

9.3.2 Charge Pump

The charge pump supplies the voltage necessary to drive the external N-channel MOSFET. An external charge pump capacitor is placed between VCAP and ANODE pins to provide energy to turn on the external MOSFET. In order for the charge pump to supply current to the external capacitor the EN pin voltage must be above the specified input high threshold, \( V_{(EN_{IH})} \). When enabled the charge pump sources a charging current of 300 µA typical. If EN pins is pulled low, then the charge pump remains disabled. To ensure that the external MOSFET can be driven above its specified threshold voltage, the VCAP to ANODE voltage must be above the undervoltage lockout threshold, typically 6.6 V, before the internal gate driver is enabled. Use Equation 1 to calculate the initial gate driver enable delay.

\[
T_{(DRV\_EN)} = 75\mu s + C_{(VCAP)} \times \frac{V_{(VCAP\_UVLOR)}}{300\mu A}
\]

where

- \( C_{(VCAP)} \) is the charge pump capacitance connected across ANODE and VCAP pins
- \( V_{(VCAP\_UVLOR)} = 6.6V \) (typical)

To remove any chatter on the gate drive approximately 900 mV of hysteresis is added to the VCAP undervoltage lockout. The charge pump remains enabled until the VCAP to ANODE voltage reaches 13 V, typically, at which point the charge pump is disabled decreasing the current draw on the ANODE pin. The charge pump remains disabled until the VCAP to ANODE voltage is below 12.1 V typically at which point the charge pump is enabled. The voltage between VCAP and ANODE continue to charge and discharge between 12.1 V and 13 V as shown in Figure 17. By enabling and disabling the charge pump, the operating quiescent current of the LM74700-Q1 is reduced. When the charge pump is disabled it sinks 5 µA typical.

![Figure 17. Charge Pump Operation](image)
Feature Description (continued)

9.3.3 Gate Driver

The gate driver is used to control the external N-Channel MOSFET by setting the GATE to ANODE voltage to the corresponding mode of operation. There are three defined modes of operation that the gate driver operates under forward regulation, full conduction mode and reverse current protection, according to the ANODE to CATHODE voltage. Forward regulation mode, full conduction mode and reverse current protection mode are described in more detail in the *Regulated Conduction Mode*, *Full Conduction Mode* and *Reverse Current Protection Mode* sections. Figure 18 depicts how the modes of operation vary according to the ANODE to CATHODE voltage of the LM74700-Q1. The threshold between forward regulation mode and conduction mode is when the ANODE to CATHODE voltage is 50 mV. The threshold between forward regulation mode and reverse current protection mode is when the ANODE to CATHODE voltage is –11 mV.

![Figure 18. Gate Driver Mode Transitions](image)

Before the gate driver is enabled following three conditions must be achieved:

- The EN pin voltage must be greater than the specified input high voltage.
- The VCAP to ANODE voltage must be greater than the undervoltage lockout voltage.
- The ANODE voltage must be greater than VANODE POR Rising threshold.

If the above conditions are not achieved, then the GATE pin is internally connected to the ANODE pin, assuring that the external MOSFET is disabled. Once these conditions are achieved the gate driver operates in the correct mode depending on the ANODE to CATHODE voltage.

9.3.4 Enable

The LM74700-Q1 has an enable pin, EN. The enable pin allows for the gate driver to be either enabled or disabled by an external signal. If the EN pin voltage is greater than the rising threshold, the gate driver and charge pump operates as described in *Gate Driver* and *Charge Pump* sections. If the enable pin voltage is less than the input low threshold, the charge pump and gate driver are disabled placing the LM74700-Q1 in shutdown mode. The EN pin can withstand a voltage as large as 65 V and as low at –65 V. This allows for the EN pin to be connected directly to the ANODE pin if enable functionality is not needed. In conditions where EN is left floating, the internal sink current of 3uA pulls EN pin low and disables the device.

9.4 Device Functional Modes

9.4.1 Shutdown Mode

The LM74700-Q1 enters shutdown mode when the EN pin voltage is below the specified input low threshold $V_{EN\ IL}$. Both the gate driver and the charge pump are disabled in shutdown mode. During shutdown mode the LM74700-Q1 enters low $I_D$ operation with the ANODE pin only sinking 1 µA. When the LM74700-Q1 is in shutdown mode, forward current flow through the external MOSFET is not interrupted but is conducted through the MOSFET's body diode.
Device Functional Modes (continued)

9.4.2 Conduction Mode

Conduction mode occurs when the gate driver is enabled. There are three regions of operating during conduction mode based on the ANODE to CATHODE voltage of the LM74700-Q1. Each of the three modes is described in the Regulated Conduction Mode, Full Conduction Mode and Reverse Current Protection Mode sections.

9.4.2.1 Regulated Conduction Mode

For the LM74700-Q1 to operate in regulated conduction mode, the gate driver must be enabled as described in the Gate Driver section and the current from source to drain of the external MOSFET must be within the range to result in an ANODE to CATHODE voltage drop of –11 mV to 50 mV. During forward regulation mode the ANODE to CATHODE voltage is regulated to 20 mV by adjusting the GATE to ANODE voltage. This closed loop regulation scheme enables graceful turn off of the MOSFET at very light loads and ensures zero DC reverse current flow.

9.4.2.2 Full Conduction Mode

For the LM74700-Q1 to operate in full conduction mode the gate driver must be enabled as described in the Gate Driver section and the current from source to drain of the external MOSFET must be large enough to result in an ANODE to CATHODE voltage drop of greater than 50 mV typical. If these conditions are achieved the GATE pin is internally connected to the VCAP pin resulting in the GATE to ANODE voltage being approximately the same as the VCAP to ANODE voltage. By connecting VCAP to GATE the external MOSFET's $R_{DS(ON)}$ is minimized reducing the power loss of the external MOSFET when forward currents are large.

9.4.2.3 Reverse Current Protection Mode

For the LM74700-Q1 to operate in reverse current protection mode, the gate driver must be enabled as described in the Gate Driver section and the current of the external MOSFET must be flowing from the drain to the source. When the ANODE to CATHODE voltage is typically less than –11 mV reverse current protection mode is entered and the GATE pin is internally connected to the ANODE pin. The connection of the GATE to ANODE pin disables the external MOSFET. The body diode of the MOSFET blocks any reverse current from flowing from the drain to source.
10 Application and Implementation

NOTE
Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

10.1 Application Information

The LM74700-Q1 is used with N-Channel MOSFET controller in a typical reverse polarity protection application. The schematic for the 12V battery protection application is shown in Figure 19 where the LM74700-Q1 is used in series with a battery to drive the MOSFET Q1. The TVS is not required for the LM74700-Q1 to operate, but they are used to clamp the positive and negative voltage surges. The output capacitor C_{OUT} is recommended to protect the immediate output voltage collapse as a result of line disturbance.

10.1.1 Typical Application

10.1.1.2 Detailed Design Procedure

To begin the design process, the system designer must determine the following:

10.1.1.2.1 Design Considerations

- Input operating voltage range, including cold crank and load dump conditions
- Nominal load current and maximum load current
10.1.1.2.2 MOSFET Selection

The important MOSFET electrical parameters are the maximum continuous drain current $I_D$, the maximum drain-to-source voltage $V_{DS(MAX)}$, the maximum source current through body diode and the drain-to-source On resistance $R_{DS(ON)}$. The maximum continuous drain current, $I_D$, rating must exceed the maximum continuous load current. The maximum drain-to-source voltage, $V_{DS(MAX)}$, must be high enough to withstand the highest differential voltage seen in the application. This would include any anticipated fault conditions. It is recommended to use MOSFETs with voltage rating up to 60 V maximum with the LM74700-Q1 because anode-cathode maximum voltage is 65V. The maximum $V_{GS}$ LM74700-Q1 can drive is 13-V, so a MOSFET with 15-V minimum $V_{GS}$ should be selected. If a MOSFET with <15-V $V_{GS}$ rating is selected, a zener diode can be used to clamp $V_{GS}$ to safe level. During startup, inrush current flows through the body diode to charge the bulk hold-up capacitors at the output. The maximum source current through the body diode must be higher than the inrush current that can be seen in the application.

To reduce the MOSFET conduction losses, lowest possible $R_{DS(ON)}$ is preferred, but selecting a MOSFET based on low $R_{DS(ON)}$ may not be beneficial always. Higher $R_{DS(ON)}$ will provide increased voltage information to LM74700-Q1’s reverse comparator at a lower reverse current. Reverse current detection is better with increased $R_{DS(ON)}$. It is recommended to operate the MOSFET in regulated conduction mode during nominal load conditions and select $R_{DS(ON)}$ such that at nominal operating current, forward voltage drop $V_{DS}$ is close to 20 mV regulation point and not more than 50 mV.

As a guideline, it is suggested to choose \[ (20 \text{ mV} / I_{Load(Nominal)}) \leq R_{DS(ON)} \leq (50 \text{ mV} / I_{Load(Nominal)}) \].

MOSFET manufacturers usually specify $R_{DS(ON)}$ at 4.5-V $V_{GS}$ and 10-V $V_{GS}$. $R_{DS(ON)}$ increases drastically below 4.5-V $V_{GS}$ and $R_{DS(ON)}$ is highest when $V_{GS}$ is close to MOSFET $V_{th}$. For stable regulation at light load conditions, it is recommended to operate the MOSFET close to 4.5V $V_{GS}$, i.e., much higher than MOSFET gate threshold voltage. It is recommended to choose MOSFET gate threshold voltage $V_{th}$ of 2-V to 2.5V maximum. Choosing a lower $V_{th}$ MOSFET also reduces the turn ON time.

Based on the design requirements, preferred MOSFET ratings are:

- 60-V $V_{DS(MAX)}$ and ±20-V $V_{GS(MAX)}$
- $R_{DS(ON)}$ at 3A nominal current: \[ (20 \text{ mV} / 3A) \leq R_{DS(ON)} \leq (50 \text{ mV} / 3A) = 6.67 \text{ m}\Omega \leq R_{DS(ON)} \leq 16.67 \text{ m}\Omega \].
- MOSFET gate threshold voltage $V_{th}$: 2V maximum

DMT6007LFG MOSFET from Diodes Inc. is selected to meet this 12V reverse battery protection design requirements and it is rated at:

- 60-V $V_{DS(MAX)}$ and ±20-V $V_{GS(MAX)}$
- $R_{DS(ON)}$: 6.5 m\Omega typical and 8.5 m\Omega maximum rated at 4.5V $V_{GS}$
- MOSFET $V_{th}$: 2V maximum

Thermal resistance of the MOSFET should be considered against the expected maximum power dissipation in the MOSFET to ensure that the junction temperature ($T_J$) is well controlled.

10.1.1.2.3 Charge Pump VCAP, input and output capacitance

Minimum required capacitance for charge pump VCAP and input/output capacitance are:

- VCAP: Minimum 0.1 µF is required; recommended value of VCAP (µF) $\geq 10 \times C_{ISS(MOSFET)}$ (µF)
- $C_{IN}$: minimum 22 nF of input capacitance
- $C_{OUT}$: minimum 100 nF of output capacitance.

10.1.1.3 Selection of TVS Diodes for 12V Battery Protection Applications

TVS diodes are used in automotive systems for protection against transients. In the 12V battery protection application circuit shown in Figure 20, a bi-directional TVS diode is used to protect from positive and negative transient voltages that occur during normal operation of the car and these transient voltage levels and pulses are specified in ISO 7637-2 and ISO 16750-2 standards.
There are two important specifications are breakdown voltage and clamping voltage of the TVS. Breakdown voltage is the voltage at which the TVS diode goes into avalanche similar to a zener diode and is specified at a low current value typical 1 mA and the breakdown voltage should be higher than worst case steady state voltages seen in the system. The breakdown voltage of the TVS+ should be higher than 24-V jump start voltage and 35-V suppressed load dump voltage and less than the maximum ratings of LM74700-Q1 (65V). The breakdown voltage of TVS- should be beyond than maximum reverse battery voltage -16-V, so that the TVS- is not damaged due to long time exposure to reverse connected battery.

Clamping voltage is the voltage the TVS diode clamps in high current pulse situations and this voltage is much higher than the breakdown voltage. TVS diodes are meant to clamp transient pulses and should not interfere with steady state operation. In the case of an ISO 7637-2 pulse 1, the input voltage goes up to –150 V with a generator impedance of 10 Ω. This translates to 15 A flowing through the TVS - and the voltage across the TVS would be close to its clamping voltage.

Figure 20. Typical 12V Battery Protection with single bi-directional TVS

The next criterion is that the absolute maximum rating of Anode to Cathode reverse voltage of the LM74700-Q1 (-75V) and the maximum V_DS rating MOSFET are not exceeded. In the design example, 60V rated MOSFET is chosen and maximum limit on the cathode to anode voltage is 60V.

In case of ISO 7637-2 pulse 1, the anode of LM74700-Q1 is pulled down by the ISO pulse and clamped by TVS-. The MOSFET is turned off quickly to prevent reverse current from discharging the bulk output capacitors. When the MOSFET turns off, the cathode to anode voltage seen is equal to (TVS Clamping voltage + Output capacitor voltage). If the maximum voltage on output capacitor is 16 V (maximum battery voltage), then the clamping voltage of the TVS- should not exceed, (60 V – 16) V = -44 V.

SMBJ33CA TVS diode can be used for 12V battery protection application. The breakdown voltage of 36.7 V meets the jump start, load dump requirements on the positive side and 16V reverse battery connection on the negative side. During ISO 7637-2 pulse 1 test, SMBJ33CA clamps at -44V with 15A of peak surge current as shown in Figure 23 and it meets the clamping voltage ≤ 44V.

SMBJ series of TVS' are rated up to 600 W peak pulse power levels. This is sufficient for ISO 7637-2 pulses and suppressed load dump (ISO-16750-2 pulse B).

10.1.1.4 Selection of TVS Diodes and MOSFET for 24V Battery Protection Applications

Typical 24V battery protection application circuit shown in Figure 21 uses two uni-directional TVS diodes to protect from positive and negative transient voltages.
The breakdown voltage of the TVS+ should be higher than 48-V jump start voltage, less than the absolute maximum ratings of anode and enable pin of LM74700-Q1 (65V) and should withstand 65-V suppressed load dump. The breakdown voltage of TVS- should be lower than maximum reverse battery voltage -32-V, so that the TVS- is not damaged due to long time exposure to reverse connected battery.

During ISO 7637-2 pulse 1, the input voltage goes up to ~600 V with a generator impedance of 50 Ω. This translates to 12A flowing through the TVS-. The clamping voltage of the TVS- cannot be the same as that of 12V battery protection circuit. Because during the ISO 7637-2 pulse, the Anode to Cathode voltage seen is equal to (-TVS Clamping voltage + Output capacitor voltage). For 24V battery application, the maximum battery voltage is 32-V, then the clamping voltage of the TVS- should not exceed, 75 V – 32 V = 43V.

Single bi-directional TVS cannot be used for 24V battery protection because breakdown voltage for TVS+ ≥ 65V, maximum clamping voltage is ≤ 43V and the clamping voltage cannot be less than the breakdown voltage. Two un-directional TVS connected back-back needs to be used at the input. For positive side TVS+, SMBJ58A with the breakdown voltage of 64.4V (minimum), 67.8 (typical) is recommended. For the negative side TVS-, SMBJ26A with breakdown voltage close to 32V (to withstand maximum reverse battery voltage -32V) and maximum clamping voltage of 42.1V is recommended.

For 24V battery protection, a 75V rated MOSFET recommended to be used along with SMBJ26A and SMBJ58A connected back-back at the input.

10.2 OR-ing Application Configuration

Basic redundant power architecture comprises of two or more voltage or power supply sources driving a single load. In its simplest form, the OR-ing solution for redundant power supplies consists of Schottky OR-ing diodes that protect the system against an input power supply fault condition. A diode OR-ing device provides effective and low cost solution with few components. However, the diodes forward voltage drops affects the efficiency of the system permanently, since each diode in an OR-ing application spends most of its time in forward conduction mode. These power losses increase the requirements for thermal management and allocated board space.

The LM74700-Q1 ICs combined with external N-Channel MOSFETs can be used in OR-ing Solution as shown in Figure 36. The forward diode drop is reduced as the external N-Channel MOSFET is turned ON during normal operation. LM74700-Q1 quickly detects the reverse current, pulls down the MOSFET gate fast, leaving the body diode of the MOSFET to block the reverse current flow. An effective OR-ing solution needs to be extremely fast to limit the reverse current amount and duration. The LM74700-Q1 devices in OR-ing configuration constantly
OR-ing Application Configuration (continued)

sense the voltage difference between Anode and Cathode pins, which are the voltage levels at the power sources ($V_{IN1}$, $V_{IN2}$) and the common load point respectively. The source to drain voltage $V_{DS}$ for each MOSFET is monitored by the Anode and Cathode pins of the LM74700-Q1. A fast comparator shuts down the Gate Drive through a fast Pull-Down within 0.45 $\mu$s (typical) as soon as $V_{(IN)} - V_{(OUT)}$ falls below $-11$ mV. It turns on the Gate with $11$ mA gate charge current once the differential forward voltage $V_{(IN)} - V_{(OUT)}$ exceeds $50$ mV.

![OR-ing Application Configuration Diagram](image)

Figure 36. Typical OR-ing Application

Figure 30 to Figure 33 show the smooth switch over between two power supply rails $V_{IN1}$ at 12V and $V_{IN2}$ at 15V. Figure 34 and Figure 35 illustrate the performance when $V_{IN2}$ fails. LM74700-Q1 controlling $V_{IN2}$ power rail turns off quickly, so that the output remains uninterrupted and $V_{IN1}$ is protected from $V_{IN2}$ failure.

11 Power Supply Recommendations

The LM74700-Q1 Ideal Diode Controller designed for the supply voltage range of $3.2 \leq V_{ANODE} \leq 65$ V. If the input supply is located more than a few inches from the device, an input ceramic bypass capacitor higher than $22$ nF is recommended. To prevent LM74700-Q1 and surrounding components from damage under the conditions of a direct output short circuit, it is necessary to use a power supply having over load and short circuit protection.

12 Layout

12.1 Layout Guidelines

• Connect ANODE, GATE and CATHODE pins of LM74700-Q1 close to the MOSFET’s SOURCE, GATE and DRAIN pins.
• The high current path of for this solution is through the MOSFET, therefore it is important to use thick traces for source and drain of the MOSFET to minimize resistive losses.
• The charge pump capacitor across VCAP and ANODE pins must be kept away from the MOSFET to lower the thermal effects on the capacitance value.
Layout Guidelines (continued)

- The Gate pin of the LM74700-Q1 must be connected to the MOSFET gate without using vias. Avoid excessively thin traces to the Gate Drive.
- Obtaining acceptable performance with alternate layout schemes is possible, however the layout shown in the Layout Example is intended as a guideline and to produce good results.
- Keep the GATE pin close to the MOSFET to avoid increase in MOSFET turn-off delay due to trace resistance.

12.2 Layout Example
13 Device and Documentation Support

13.1 Receiving Notification of Documentation Updates
To receive notification of documentation updates, navigate to the device product folder on ti.com. In the upper right corner, click on Alert me to register and receive a weekly digest of any product information that has changed. For change details, review the revision history included in any revised document.

13.2 Community Resources
The following links connect to TI community resources. Linked contents are provided “AS IS” by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI’s views; see TI’s Terms of Use.

**TI E2E™ Online Community** *TI's Engineer-to-Engineer (E2E) Community.* Created to foster collaboration among engineers. At e2e.ti.com, you can ask questions, share knowledge, explore ideas and help solve problems with fellow engineers.

**Design Support** *TI's Design Support* Quickly find helpful E2E forums along with design support tools and contact information for technical support.

13.3 Trademarks
E2E is a trademark of Texas Instruments.

13.4 Electrostatic Discharge Caution
These devices have limited built-in ESD protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

13.5 Glossary
**SLYZ022 — TI Glossary.**
This glossary lists and explains terms, acronyms, and definitions.

14 Mechanical, Packaging, and Orderable Information
The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. (1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

(2) RoHS: TI defines “RoHS” to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, “RoHS” products are suitable for use in specified lead-free processes. TI may reference these types of products as “Pb-Free”.

**RoHS Exempt:** TI defines “RoHS Exempt” to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

**Green:** TI defines “Green” to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a “~” will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.
