Wideband, Low-Noise, Voltage-Feedback OPERATIONAL AMPLIFIER

FEATURES
- HIGH BANDWIDTH: 400MHz (G = +10)
- LOW INPUT VOLTAGE NOISE: 1.2nV/√Hz
- VERY LOW DISTORTION: –100dBc (5MHz)
- HIGH SLEW RATE: 625V/µs
- HIGH DC ACCURACY: $V_{IO} \pm 150\mu V$
- LOW SUPPLY CURRENT: 12.6mA
- HIGH GAIN BANDWIDTH PRODUCT: 1750MHz
- STABLE FOR GAINS $\geq 7$

DESCRIPTION
The OPA846 combines very high gain bandwidth and large signal performance with very low input voltage noise, while dissipating a low 12.6mA supply current. The classical differential input stage, along with two stages of forward gain and a high power output stage, combine to make the OPA846 an exceptionally low distortion amplifier with excellent DC accuracy and output drive. The voltage-feedback architecture allows all standard op amp applications to be implemented with very high performance.

The combination of low input voltage and current noise, along with a 1.75GHz gain bandwidth product, make the OPA846 an ideal amplifier for wideband transimpedance stages. As a voltage gain stage, the OPA846 is optimized for a flat response at a gain of +10 and is stable down to a gain of +7.

APPLICATIONS
- HIGH DYNAMIC RANGE ADC PREAMPS
- LOW-NOISE, WIDEBAND, TRANSIMPEDEANCE AMPLIFIERS
- WIDEBAND, HIGH GAIN AMPLIFIERS
- LOW-NOISE DIFFERENTIAL RECEIVERS
- VDSL LINE RECEIVERS
- ULTRASOUND CHANNEL AMPLIFIERS
- SECURITY SENSOR FRONT ENDS
- UPGRADE FOR THE OPA686, CLC425, AND LMH6624

A new external compensation technique can be used to give a very flat frequency response below the minimum stable gain for the OPA846, further improving its already exceptional distortion performance. Using this compensation makes the OPA846 one of the premier 12- to 16-bit Analog-to-Digital (A/D) converter input drivers. The supply current for the OPA846 is precisely trimmed to 12.6mA at +25°C. This, along with carefully defined supply current tempco in the input and output stages, combine to provide exceptional performance over the full specified temperature range.

NOTE: (1) Stresses above these ratings may cause permanent damage. Exposure to absolute maximum conditions for extended periods may degrade device reliability. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those specified is not implied.

ELECTROSTATIC DISCHARGE SENSITIVITY

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

TYPICAL CHARACTERISTICS: \( V_S = \pm 5V \)

\[ T_A = 25^\circ C, \ G_D = 20, \ R_D = 50\Omega, \text{ and } R_L = 400\Omega, \text{ unless otherwise noted.} \]
APPLICATIONS INFORMATION

WIDEBAND, NONINVERTING OPERATION

The OPA846 provides a unique combination of features. Low input voltage noise, along with a very low distortion output stage, gives one of the highest dynamic range op amps available. The very high Gain Bandwidth Product (GBP) can be used either to deliver high signal bandwidths at high gain, or to deliver very low distortion signals at moderate frequencies and lower gains. To achieve the full performance of the OPA846, careful attention to PCB board layout and component selection is required, as discussed in the following sections of this data sheet.

Figure 1 shows the noninverting gain of a 10V/V circuit used as the basis of the Electrical Characteristics and most of the Typical Characteristic curves. Most of the curves are characterized using signal sources with a 50Ω driving impedance, and with a 50Ω load impedance presented by the measurement equipment. In Figure 1, the 50Ω resistor at the VIN terminal matches the source impedance of the test generator, while the 50Ω series resistor at the VO terminal provides a matching resistor for the measurement equipment load. Generally, the data sheet voltage swing specifications are at the output pin (VO in Figure 1), while the output power (dBm) specifications are at the matched 50Ω load. The total 100Ω load at the output, combined with the 503Ω total feedback network load, presents the OPA846 with an effective output load of 83Ω for the circuit of Figure 1.

Voltage-feedback op amps (unlike current-feedback designs) can use a wide range of resistor values to set the gain, although these resistors usually have low values to maintain a low total output noise. The circuit of Figure 1, and the specifications at other gains, use the constraint that RG be set to 50Ω and RF adjusted to get the desired gain. Using this guideline ensures that the noise added at the output due to the Johnson noise of the resistors does not significantly increase the total noise over that due to the 1.2nV/√Hz input voltage noise for the op amp. Higher resistor values can certainly be used where the application requires it, but can start to add significantly to the output noise power as described in the Setting Resistor Values to Minimize Noise section.

WIDEBAND INVERTING GAIN OPERATION

Operating the OPA846 as an inverting amplifier has several benefits and is particularly appropriate when a matched input impedance is required. Figure 2 shows the inverting gain circuit used as the basis of the inverting mode of the Typical Characteristic curves.

Driving this circuit from a 50Ω source, and constraining the gain resistor (RG) to equal 50Ω, gives both a signal bandwidth and noise advantage. RG acts as both the input termination resistor and the gain setting resistor for the circuit. Although the signal gain (VO/VI) for the circuit of Figure 2 is double that for Figure 1, the noise gains are in fact equal when the 50Ω source resistor is included. This has the interesting effect of doubling the equivalent GBP of the amplifier. This can be seen by observing the 200MHz bandwidth for the inverting gain of ~20. This implies a GBP of 4GHz, when in fact this extended bandwidth is given by the reduced noise gain when the matched source resistor is included. If the signal source is actually the low impedance output of another amplifier, RG is increased to the minimum load resistance value allowed for that amplifier and RF is then adjusted to achieve the desired gain. For stable operation of the OPA846, it is critical that this driving amplifier show very low output impedance at frequencies beyond the expected closed-loop bandwidth for the OPA846.
WIDEBAND, HIGH-SENSITIVITY TRANSIMPEDANCE DESIGN

The high GBP and low input voltage and current noise for the OPA846 make it an ideal wideband transimpedance amplifier. Very high transimpedance gains (> 100kΩ) benefit from the low input noise current of a JFET-input op amp, such as the OPA657. Unity-gain stability in the op amp is not required for application as a transimpedance amplifier. One transimpedance design example is shown on the front page of this data sheet. Designs that require high bandwidths from a large area (high capacitance) detector with relatively low transimpedance gain will benefit from the low input voltage noise offered by the OPA846. This input voltage noise is peaked up over frequency at the output by the diode source capacitance, and can, in many cases, become the limiting factor to input sensitivity. The key elements of the design are the expected diode capacitance (C_D) with the reverse bias voltage (−V_B) applied, the desired transimpedance gain (R_F), and the GBP of the OPA846 (1750MHz). Figure 3 shows a design using a 50pF detector diode capacitance and a 10kΩ transimpedance gain. With these three variables set (including the parasitic input capacitance for the OPA846 added to C_D) the feedback capacitor (C_F) value can be set to control the frequency response. To achieve a maximally flat 2nd-order Butterworth frequency response, set the feedback pole as shown in Equation 1.

\[
\frac{1}{2\pi R_F C_F} = \frac{\text{GBP}}{\sqrt{4\pi R_F C_D}}
\]

(1)

Adding the common-mode and differential-mode input capacitance (1.8 + 2.0)pF to the 50pF diode source capacitance of Figure 3, with a 10kΩ transimpedance gain using the 1750MHz GBP for the OPA846, requires a feedback pole set to 16.1MHz. This requires a 1pF total feedback capacitance. Typical surface-mount resistors have 0.2pF parasitic capacitance leaving a required extrinsic 0.8pF value, as shown in Figure 3. Equation 2 gives the approximate −3dB bandwidth, if C_F is set using Equation 1.

\[
f_{-3dB} = \frac{\text{GBP}}{2\pi R_F C_D} \text{(Hz)}
\]

(2)

The example of Figure 3 gives approximately 23MHz flat bandwidth using the 0.8pF feedback compensation. If the total output noise is bandlimited to a frequency less than the feedback pole frequency, a simple expression for the equivalent input noise current is given as Equation 3.

\[
I_{E0} = \sqrt{\frac{4kT}{R_F}} + \left(\frac{E_N}{R_F}\right)^2 + \left(\frac{E_N 2\pi F C_D}{3}\right)
\]

(3)

Where:
- \(I_{E0}\) = equivalent input noise current if the output noise is bandlimited to \(F < 1/(2\pi R_F C_F)\)
- \(I_N\) = input current noise for the op amp inverting input
- \(E_N\) = input voltage noise for the op amp
- \(C_D\) = diode capacitance
- \(F\) = bandlimiting frequency in Hz (usually a post filter prior to further signal processing)
- \(4kT = 1.6E - 20J\) at \(T = 290K\)

Evaluating this expression up to the feedback pole frequency at 16.1MHz for the circuit of Figure 3 gives an equivalent input noise current of 4.9pA/√Hz. This is much higher than the 2.8pA/√Hz for just the op amp. This result is dominated by the last term in the equivalent input noise current calculation from Equation 3. It is essential in this case to use a low-voltage noise op amp. For example, if a slightly higher input noise voltage, but otherwise identical op amp, was used instead of the OPA846 amplifier in this application noise amplifier (say 2.0nV/√Hz), the total input-referred current noise would increase to 7.0pA/√Hz.

The output DC error for the circuit of Figure 3 is minimized by including the 10kΩ to ground on the noninverting input. This reduces the impact at the output of input bias current errors to the offset current times the feedback resistor. To minimize the output noise contribution of this resistor, a 0.01µF capacitor is included in parallel. Worst-case output DC error for the circuit of Figure 3 at 25°C is:

- \(V_{OS} = \pm 0.6mV\) (input offset voltage) ± 0.35µA (input offset current) • 10kΩ = ±4.1mV

Worst-case output offset DC drift is over the 0°C to 70°C span is \(dV_{OS}/dT = \pm 1.5µV/^\circ C\) (input offset drift) ± 2nA/^\circ C (input offset current drift) • 10kΩ = ±21.5µV/^\circ C

Improved output DC precision and drift is possible, particularly at higher transimpedance gains, using the JFET input of the OPA657. The JFET input removes the input bias current from the error equation (eliminating the need for the resistor to ground on the noninverting input), leaving only the input offset voltage and drift as an output error term.

Included in the characteristic curves are transimpedance frequency response curves for a fixed 10kΩ gain over various detector diode capacitance settings. These curves, along with the test circuit, are repeated in Figure 4. As the photo-
diode capacitance changes, the feedback capacitor must change to maintain a stable and flat frequency response. Using Equation 1, \( C_F \) is adjusted to give the Butterworth frequency responses presented in Figure 4.

**LOW-GAIN COMPENSATION FOR IMPROVED SFDR**

Where a low gain is desired, and inverting operation is acceptable, a new external compensation technique may be used to retain the full slew rate and noise benefits of the OPA846, while giving increased loop gain and the associated improvement in distortion offered by the decompensated architecture. This technique shapes the loop gain for good stability, while giving an easily controlled 2nd-order low-pass frequency response. Considering only the noise gain (noninverting signal gain) for the circuit of Figure 5, the low-frequency noise gain (NG1) is set by the resistor ratios, while the high-frequency noise gain (NG2) is set by the capacitor ratios. The capacitor values set both the transition frequencies and the high-frequency noise gain. If this noise gain (determined by NG2 = 1 + CS/CF) is set to a value greater than the minimum stable gain for the OPA846, the key desired low-frequency signal gain \( NG_1 \) = 3 in this example. Then, using only these two gains and the GBP for the OPA846 (1750MHz), the key frequency in the compensation can be determined as:

\[
Z_O = \frac{GBP}{NG_1} \left[ \left( 1 - \frac{NG_1}{NG_2} \right) - \sqrt{1 - \frac{2NG_1}{NG_2}} \right]
\]

and is the frequency at which the rising portion of the noise gain would intersect the unity gain if projected back to a 0dB gain. The actual zero in the noise gain occurs at \( NG_1 \cdot Z_O \), and the pole in the noise gain occurs at \( NG_2 \cdot Z_O \). Since GBP is expressed in Hz, multiply \( Z_O \) by 2\( \pi \), and use this to get \( C_F \) by solving:

\[
C_F = \frac{1}{2\pi R_F Z_O NG_2} = 2.86pF
\]

Finally, since \( C_S \) and \( C_F \) set the high-frequency noise gain, determine \( C_S \) by using \( NG_2 = 10.5 \):

\[
C_S = (NG_2 - 1)C_F, \text{ which gives } C_S = 24.9pF
\]

The resulting closed-loop bandwidth is approximately equal to:

\[
f_{-3dB} \approx \sqrt{Z_O \cdot \text{GBP}}
\]

For the values of Figure 5, \( f_{-3dB} \) is approximately 142MHz. This is less than that predicted by dividing the GBP product by \( NG_1 \). The compensation network controls the bandwidth to a lower value, while providing the full slew rate at the output and an exceptional distortion performance due to increased loop gain at frequencies below \( NG_1 \cdot Z_O \). The capacitor values shown in Figure 5 are calculated for \( NG_1 = 3 \) and \( NG_2 = 10.5 \) with no adjustment for parasitic components.

See Figure 6 for the measured frequency response for the circuit of Figure 5. This shows the expected gain of −2 (6dB) with exceptional flatness through 70MHz and a −3dB bandwidth of 170MHz. Repeating the swept frequency distortion measurement for a 2\( V_{pp} \) output into a 200\( \Omega \) load and comparing to the gain of +10 data shown in the Typical Characteristic curves illustrates the improved distortion for this low-gain compensation circuit.

Figure 7 compares the distortion at a gain of +10 for the circuit of Figure 1 to the distortion at a gain of −2 for the circuit of Figure 5.
The low input noise voltage of the OPA846, and its high 2-tone, 3rd-order intercept, can be used to good advantage as a fixed-gain IF amplifier. While input noise figures in the 10dB range (for a matched 50Ω input) are easily achieved with just the OPA846 alone, Figure 8 shows a technique that reduces the noise figure even further, while providing a broadband, moderate-gain IF amplifier stage using the OPA846.

Bringing the signal in through a step-up transformer to the inverting input gain resistor has several advantages for the OPA846. First, grounding the noninverting input eliminates the contribution of the noninverting input current noise to the output noise. Second, the noninverting input voltage noise of the op amp is actually attenuated if reflected to the input side of R_G. Using the 1:2 (turns ratio) step-up transformer reflects the 50Ω source impedance at the primary through to the secondary as a 200Ω source impedance. The 200Ω R_G resistor is reflected through to the transformer primary as a 50Ω input matching impedance. The noninverting signal gain (noise gain, NG) to the amplifier output is then 1 + 1000/400 = 3.5V/V. Taking the input voltage noise (1.2nV/√Hz) for the OPA846 times this noise gain to the output, then reflecting this noise term to the input side of the R_G resistor, divides it by 5. This gives a net gain of 0.7 for the noninverting input voltage noise when reflected to the input point for the op amp circuit. This term is further reduced when referred back to the transformer input.

The 14dB gain to the matched load, for the circuit of Figure 8, is precisely controlled (±0.2dB) and gives a 6dB noise figure at the input of the transformer. The DC noise gain for this circuit (3.5) is below the specified minimum stable gain. The amplifier portion of the circuit uses the low-gain inverting compensation described in the previous section. Measured results show 140MHz small-signal bandwidth for the circuit of Figure 8 with ±0.1dB flatness through 50MHz. The OPA846 easily delivers a 2Vpp A/D converter full-scale input at the matched 50Ω load. 2-tone testing at 20MHz for the circuit of Figure 8 (1Vpp for each test tone) shows that the 2-tone intermodulation intercept has improved to 40dBm versus the 34dBm shown in the Typical Characteristic curves, giving a 72dBc SFDR for the two 4dBm test tones at the load. This high SFDR comes with relatively low total power dissipation versus fixed-gain IF amplifier alternatives. Significantly higher SFDR is delivered at lower frequencies and/or for the lighter loads driving A/D converter inputs directly.

The low input noise voltage of the OPA846, and its high 2-tone, 3rd-order intercept, can be used to good advantage as a fixed-gain IF amplifier. While input noise figures in the 10dB range (for a matched 50Ω input) are easily achieved with just the OPA846 alone, Figure 8 shows a technique that reduces the noise figure even further, while providing a broadband, moderate-gain IF amplifier stage using the OPA846.

Significantly higher SFDR is delivered at lower frequencies and/or for the lighter loads driving A/D converter inputs directly.
result. However, operation at low gains may be desirable to take advantage of the higher slew rate and exceptional DC precision of the OPA846. Numerous external compensation techniques are suggested for operating a high-gain op amp at low gains. Most of these give zero/pole pairs in the closed-loop response that cause long term settling tails in the pulse response and/or phase nonlinearity in the frequency response. Figure 9 shows an external compensation method for a noninverting configuration that does not suffer from these drawbacks.

**Differential Operation**

Operating two OPA846 amplifiers in a differential inverting configuration can further suppress even-order harmonic terms. The Typical Characteristic curves show measured performance for this condition. For the distortion data, the output swing is increased to $4V_{pp}$ into $400\Omega$ to allow direct comparison to the $2V_{pp}$ into $200\Omega$ data for single-channel operation. Figure 11 shows the swept frequency 2nd- and 3rd-harmonic distortion for an inverting differential configuration, where each channel is set up for a gain of 20.

Comparing this to the single-channel distortion (at 10MHz for instance), about the same 3rd-harmonic and about a 5dB improvement in the 2nd-harmonic is shown.

**Single-Supply Operation**

The OPA846 may be operated from a single power supply if system constraints require it. Operation from a single +5V to +12V supply is possible with minimal change in AC performance. The Typical Characteristics show the input and output voltage ranges for a bipolar supply range from $\pm2.5V$ to $\pm6V$. The Common-Mode Input Range and Output Swing vs Supply Voltage plot shows that the required headroom on both the input and output nodes remains at approximately 1.5V over this entire range. On a single +5V supply for instance, this means the noninverting input should remain centered at $2.5V \pm 1V$, as should the output pin. See Figure 12 for an example application biasing the noninverting input at mid-supply and running an AC-coupled input to the inverting gain path. Since the gain resistor is blocked off for DC, the bias point on the noninverting input appears at the output, centering up that node, as well on the power supply. The OPA846 can support this mode of operation down to a single +5V supply and up to a single +12V supply.
**DESIGN-IN TOOLS**

**DEMONSTRATION FIXTURES**

Two printed circuit boards (PCBs) are available to assist in the initial evaluation of circuit performance using the OPA846 in its two package options. Both of these are offered free of charge as unpopulated PCBs, delivered with a user’s guide. The summary information for these fixtures is shown in Table I.

The demonstration fixtures can be requested at the Texas Instruments web site (www.ti.com) through the OPA846 product folder.

**MACROMODELS AND APPLICATIONS SUPPORT**

Computer simulation of circuit performance using SPICE is often a quick way to analyze the performance of the OPA846 and its circuit designs. This is particularly true for video and RF amplifier circuits where parasitic capacitance and inductance can play a major role on circuit performance. A SPICE model for the OPA846 is available through the TI web page (www.ti.com). These models predict typical small-signal AC, transient steps, and DC performance under a wide variety of operating conditions. The models include the noise terms found in the electrical specification of this data sheet. These models do not attempt to distinguish between the package types in small-signal AC performance.

**OPERATING SUGGESTIONS**

**SETTING RESISTOR VALUES TO MINIMIZE NOISE**

The OPA846 provides a very low input noise voltage while requiring a low 12.6mA quiescent current. To take full advantage of this low input noise, careful attention to the other possible noise contributors is required. Figure 13 shows the op amp noise analysis model with all the noise terms included. In this model, all the terms are taken to be noise voltage or current density terms in either nV/√Hz or pA/√Hz.

![FIGURE 12. Single-Supply Inverting Amplifier.](image-url)

![FIGURE 13. Op Amp Noise Analysis Model.](image-url)
FREQUENCY RESPONSE CONTROL

Voltage-feedback op amps exhibit decreasing closed-loop bandwidth as the signal gain is increased. In theory, this relationship is described by the GBP shown in the Electrical Characteristics. Ideally, dividing GBP by the noninverting signal gain (also called the noise gain, or NG) predicts the closed-loop bandwidth. In practice, this only holds true when the phase margin approaches 90°, as it does in high-gain configurations. At low gains (increased feedback factor), most high-speed amplifiers exhibit a more complex response with lower phase margin. The OPA846 is compensated to give a maximally flat 2nd-order Butterworth closed-loop response at a noninverting gain of +10 (see Figure 1). This results in a typical gain of +10 bandwidth of 400MHz, far exceeding that predicted by dividing the 1750MHz GBP by 10. Increasing the gain causes the phase margin to approach 90° and the bandwidth to more closely approach the predicted value of (GBP/NG). At a gain of +50, the OPA846 shows the 35MHz bandwidth predicted using the simple formula \( F_{3db} = \frac{GBP}{NG} \).

Inverting operation offers some interesting opportunities to increase the available GBP. When the source impedance is matched by the gain resistor (see Figure 2), the signal gain is \( -\frac{R_S}{R_G} \), while the noise gain for bandwidth purposes is \( 1 + \frac{R_F}{2R_G} \). This cuts the noise gain almost in half, increasing the minimum stable gain for inverting operation under these conditions to \(-12V/V\) and increases the equivalent GBP to > 3.5GHz.

DRIVING CAPACITIVE LOADS

One of the most demanding and yet very common load conditions for an op amp is capacitive loading. Often the capacitive load is the input of an A/D converter, including additional external capacitance that may be recommended to improve A/D linearity. A high-speed, high open-loop gain amplifier like the OPA846 is susceptible to decreasing stability with capacitive loads and results in closed-loop response peaking when a capacitive load is placed directly on the amplifier output pin. If the primary considerations are frequency response flatness, pulse fidelity, and/or distortion, the simplest and most effective solution is to isolate the capacitive load from the feedback loop by inserting a series isolation resistor between the amplifier output and the capacitive load. This does not eliminate the pole from the loop response, but rather shifts it and adds a zero at a higher frequency. The additional zero acts to cancel the phase lag from the capacitive load pole, thus increasing the phase margin and improving stability.

The Typical Characteristic curves help the designer pick a recommended \( R_S \) versus Capacitive Load. The resulting frequency response curves show the flat response for a given capacitive load. Parasitic capacitive loads greater than 2pF can begin to degrade the performance of the OPA846. Long PC board traces, unmatched cables, and connections to multiple devices can easily add additional capacitance to the existing circuit. Always consider these effects carefully and add the recommended series resistor as close to the output pin of the OPA846 as possible (see the Board Layout section). The criterion for setting the \( R_S \) resistor for maximum bandwidth, flat frequency response at the load is a simple procedure. For the OPA846 operating in a gain of +10V/V, the frequency response at the output pin is very flat to begin with, allowing relatively small values of \( R_S \) to be used for low capacitive loads. As the signal gain increases, the unloaded phase margin also increases. Driving capacitive loads at higher gain settings require lower \( R_S \) values than those shown for a gain of +10V/V.

DISTORTION PERFORMANCE

The OPA846 is capable of delivering an exceptionally low distortion signal at high frequencies over a wide range of gains. The distortion plots found in the Typical Characteristic curves show the typical distortion under a wide variety of conditions. Most of these plots are limited to 110dB dynamic range. The OPA846 distortion, while driving a 500Ω load, does not rise above –90dB until either the signal level exceeds 2.0Vpp and/or the fundamental frequency exceeds 5MHz. Distortion in the audio band is < –120dBc.

Generally, until the fundamental signal reaches very high frequencies or power, the 2nd-harmonic dominates the distortion with negligible 3rd-harmonic component. Focusing then on the 2nd-harmonic, increasing the load impedance improves distortion directly. Remember that the total load includes the feedback network: in the noninverting configuration, this is the sum of \( R_F + R_G \), while in the inverting configuration it is just \( R_F \). Increasing output voltage swing increases harmonic distortion directly. A 6dB increase in output swing generally increases the 2nd-harmonic to 12dB and the 3rd-harmonic to 18dB. Increasing the signal gain also increases the 2nd-harmonic distortion. Again, a 6dB increase in gain increases the 2nd- and 3rd-harmonic by approximately 6dB, even with constant output power and frequency. Finally, the distortion increases as the fundamental frequency increases, due to the rolloff in the loop gain with frequency. Conversely, the distortion improves going to lower frequencies down to the dominant open-loop pole at approximately 100kHz. Starting from the –86dBc 2nd-harmonic for a 5MHz, 2Vpp fundamental into a 200Ω load at a gain +10V/V (from the Typical Characteristic curves), the 2nd-harmonic distortion for frequencies lower than 100kHz is approximately –86dBc – 20 log(5MHz/100kHz) = –120dBc. The OPA846 has extremely low 3rd-order distortion. This also gives a high 2-tone, 3rd-order intermodulation intercept, as shown in the Typical Characteristic curves. This intercept curve is defined at the 50Ω load when driven through a 50Ω-matching resistor to allow direct comparisons to \( R_S \) devices. This matching network attenuates the voltage swing from the output pin to the load by 6dB. If the OPA846 drives directly into the input of a high-impedance device, such as an A/D converter, the 6dB attenuation is not present. Under these conditions, the intercept increases by a minimum of 6dBm. The intercept is used to predict the intermodulation spurious for two closely-spaced frequencies. If the two test frequencies \( f_1 \) and \( f_2 \) are specified in terms of average and delta frequency, \( f_{02} = \frac{(f_1 + f_2)}{2} \) and \( \Delta f = |f_2 - f_1|/2 \), the two 3rd-order, close-in spurious tones appear at \( f_0 \pm 3 \times \Delta f \).
difference between the two equal test-tone power levels and these intermodulation spurious power levels is given by \( \Delta \text{dBc} = 2 \cdot (\text{IM3} - P_O) \) where IM3 is the intercept taken from the typical characteristic curve and \( P_O \) is the power level in dBm at the 50\( \Omega \) load for one of the two closely-spaced test frequencies. At 5MHz for instance, the OPA846 at a gain of +10V/V has an intercept of 48dBm at a matched 50\( \Omega \) load. If the full envelope of the two frequencies needs to be 2V \( \text{pp} \), this requires each tone to be 4dBm. The 3rd-order intermodulation spurious tones are \( 2 \cdot (48 - 4) = 88\text{dBc} \) below the test-tone power level \((-84\text{dBm})\). If this same 2V \( \text{pp} \), 2-tone envelope were delivered directly into the input of an A/D converter—without the matching loss or the loading of the 50\( \Omega \) network—the intercept would increase to at least 54dBm. With the same signal and gain conditions, but now driving directly into a light load, the spurious tones will then be at least \( 2 \cdot (54 - 4) = 100\text{dBc} \) below the 4dBm test-tone power levels centered on 5MHz.

**DC ACCURACY AND OFFSET CONTROL**

The OPA846 can provide excellent DC signal accuracy due to its high open-loop gain, high common-mode rejection, high power-supply rejection, and low input offset voltage and bias current offset errors. To take full advantage of its low \( \pm 0.6\text{mV} \) maximum (25°C) input offset voltage, careful attention to input bias current cancellation is also required. The low-noise input stage for the OPA846 has a relatively high input bias current (10\( \mu \text{A} \) typical into the pins), but with a very close match between the two input currents—typically \( \pm 100\text{nA} \) input offset current. Figures 14 and 15 show typical distributions of input offset voltage and current for the OPA846. The total output offset voltage can be considerably reduced by matching the source impedances looking out of the two pins.

For example, one way to add bias current cancellation to the circuit of Figure 1 would be to insert a 20\( \Omega \) series resistor into the noninverting input from the 50\( \Omega \) terminating resistor. When the 50\( \Omega \) source resistor is DC-coupled, this increases the source resistances for the noninverting input bias current to 45\( \Omega \). Since this is now equal to the resistance looking out of the inverting input \( (R_F || R_G) \), the circuit cancels the gains for the bias currents to the output, leaving only the offset current times the feedback resistor as a residual DC error term at the output. Using the 453\( \Omega \) feedback resistor, this output error is now less than \( \pm 600\text{nA} \cdot 453\Omega = \pm 272\text{\mu V} \) over the full temperature range.

A fine-scale output offset null, or DC operating point adjustment, is often required. Numerous techniques are available for introducing a DC offset control into an op amp circuit. Most of these techniques eventually reduce to setting up a DC current through the feedback resistor. One key consideration to selecting a technique is to ensure that it has minimal impact on the desired signal path frequency response. If the signal path is intended to be noninverting, the offset control is best applied as an inverting summing signal to avoid interaction with the signal source. If the signal path uses the inverting mode, applying an offset control to the noninverting input can be considered. For a DC-coupled inverting input signal, this DC offset signal sets up a DC current back into the source that must be considered. An offset adjustment placed on the inverting op amp input can also change the noise gain and frequency response flatness. See Figure 16 for one example of an offset adjustment for a DC-coupled signal path that has minimum impact on the signal frequency response. In this case, the input is brought into an inverting gain resistor with the DC adjustment as an additional current summed into the inverting node. The resistor values for setting this offset adjustment are chosen to be much larger than the signal path resistors. This ensures that the adjustment has minimal impact on the loop gain and hence, the frequency response.
FIGURE 16. DC-Coupled, Inverting Gain of −20V/V with Output Offset Adjustment.

THERMAL ANALYSIS

The OPA846 does not require heat sinking or airflow in most applications. Maximum desired junction temperature sets the maximum allowed internal power dissipation as described following. In no case should the maximum junction temperature be allowed to exceed +150°C.

Operating junction temperature (T_J) is given by T_A + P_D · θ_JA. The total internal power dissipation (P_D) is the sum of quiescent power (P_DQ) and additional power dissipated in the output stage (P_DL) to deliver load power. Quiescent power is the specified no-load supply current times the total supply voltage across the part. P_DL depends on the required output signal and load but would, for a grounded resistive load, be at a maximum when the output is fixed at a voltage equal to 1/2 either supply voltage (for equal bipolar supplies). Under this worst-case condition, P_DL = V_S^2/(4 · R_L), where R_L includes the feedback network loading.

Note that it is the power in the output stage and not in the load that determines internal power dissipation.

As a worst-case example, compute the maximum T_J using an OPA846IDBV (SOT23-5 package) in the circuit of Figure 1 operating at the maximum specified ambient temperature of +85°C and driving a grounded 100Ω load at +2.5VDC.

P_D = 10V(13.9mA) + 5V/(4 · (100Ω || 500Ω)) = 214mW

Maximum T_J = +85°C + (0.21W · 150°C/W) = 117°C

All actual applications will operate at a lower junction temperature than the 117°C computed above. Compute the actual stage power to get an accurate estimate of maximum junction temperature, or use the results shown here as an absolute maximum.

BOARD LAYOUT

Achieving optimum performance with a high-frequency amplifier such as the OPA846 requires careful attention to board layout parasitics and external component types. Recommendations that optimize performance include:

a) Minimize parasitic capacitance to any AC ground for all of the signal I/O pins. Parasitic capacitance on the output and inverting input pins can cause instability: on the noninverting input, it can react with the source impedance to cause unintentional bandlimiting. To reduce unwanted capacitance, create a window around the signal I/O pins. Avoid narrow power and ground traces to minimize inductance between the pins and the decoupling capacitors. The power-supply connections should always be decoupled with these capacitors. Larger (2.2µF to 6.8µF) decoupling capacitors are effective at lower frequencies, and are recommended on the main supply pins. These may be placed somewhat further from the device and shared among several devices in the same area of the PC board.

b) Minimize the distance (< 0.25") from the power-supply pins to high-frequency 0.1µF decoupling capacitors. At the device pins, the ground and power plane layout should not be in close proximity to the signal I/O pins. Avoid narrow power and ground traces to minimize inductance between the pins and the decoupling capacitors. The power-supply connections should always be decoupled with these capacitors. Larger (2.2µF to 6.8µF) decoupling capacitors are effective at lower frequencies, and are recommended on the main supply pins. These may be placed somewhat further from the device and shared among several devices in the same area of the PC board.

c) Careful selection and placement of external components preserves the high-frequency performance of the OPA846. Use resistors that have low reactance at high frequencies. Surface-mount resistors work best and allow a tighter overall layout. Metal-film and carbon composition, axially leaded resistors can also provide good high-frequency performance. Again, keep their leads and PC board trace length as short as possible. Never use wire wound type resistors in a high-frequency application. Since the output pin and inverting input pin are the most sensitive to parasitic capacitance, always position the feedback and series output resistor, if any, as close as possible to the output pin. Other network components, such as noninverting input termination resistors, should also be placed close to the package. Where double-feedback side component mounting is allowed, place the feedback resistor directly under the package on the other side of the board between the output and inverting input pins. Even with a low parasitic capacitance shunting the external resistors, excessively high resistor values can create significant time constants that can degrade performance. Good axial metal-film or surface-mount resistors have approximately 0.2ΩF in shunt with the resistor. For resistor values > 1.5kΩ, this parasitic capacitance can add a pole and/or a zero below 500MHz that can effect circuit operation. Keep resistor values as low as possible consistent with load driving considerations. It has been suggested here that a good starting point for design would be set the R_D be set to 50Ω. Doing this automatically keeps the resistor noise terms low, and minimizes the effect of parasitic capacitance. Transimpedance applications can use much higher resistor values. The compensation techniques described in this data sheet allow excellent frequency response control, even with very high feedback resistor values.
d) Connections to other wideband devices on the board may be made with short direct traces or through onboard transmission lines. For short connections, consider the trace and the input to the next device as a lumped capacitive load. Relatively wide traces (50mils to 100mils) should be used, preferably with ground and power planes opened up around them. Estimate the total capacitive load and set $R_S$ from the plot of Recommended $R_S$ vs Capacitive Load. Low parasitic capacitive loads (< 5pF) may not need an $R_S$, since the OPA846 is nominally compensated to operate with a 2pF parasitic load. Higher parasitic capacitive loads without an $R_S$ are allowed, as the signal gain increases (increasing the unloaded phase margin). If a long trace is required, and the 6dB signal loss intrinsic to a doubly-terminated transmission line is acceptable, implement a matched impedance transmission line using microstrip or stripline techniques (consult an ECL design handbook for microstrip and stripline layout techniques). A 50Ω environment is normally not necessary onboard and, in fact, a higher impedance environment improves distortion, as shown in the distortion versus load plots. With a characteristic board trace impedance defined based on board material and trace dimensions, a matching series resistor into the trace from the output of the OPA846 is used, as well as a terminating shunt resistor at the input of the destination device. Remember also that the terminating impedance is the parallel combination of the shunt resistor and input impedance of the destination device; this total effective impedance should be set to match the trace impedance. If the 6dB attenuation of a doubly-terminated transmission line is unacceptable, a long trace can be series-terminated at the source end only. Treat the trace as a capacitive load in this case and set the series resistor value as shown in the plot of Recommended $R_S$ vs Capacitive Load. This does not preserve signal integrity as well as a doubly-terminated line. If the input impedance of the destination device is low, there will be some signal attenuation due to the voltage divider formed by the series output into the terminating impedance.

e) Socketing a high-speed part like the OPA846 is not recommended. The additional lead length and pin-to-pin capacitance introduced by the socket can create an extremely troublesome parasitic network, which can make it almost impossible to achieve a smooth, stable frequency response. Best results are obtained by soldering the OPA846 onto the board.

**INPUT AND ESD PROTECTION**

The OPA846 is built using a very high-speed complementary bipolar process. The internal junction breakdown voltages are relatively low for these very small geometry devices. These breakdowns are reflected in the Absolute Maximum Ratings table. All device pins are protected with internal ESD protection diodes to the power supplies, as shown in Figure 17.

![Figure 17](image.png)

**FIGURE 17. Internal ESD Protection.**

These diodes provide moderate protection to input overdrive voltages above the supplies as well. The protection diodes can typically support 30mA continuous current. Where higher currents are possible (e.g., in systems with ±15V supply parts driving into the OPA846), current-limiting series resistors should be added into the two inputs. Keep these resistor values as low as possible, since high values degrade both noise performance and frequency response.

(1) The marketing status values are defined as follows:
- **ACTIVE:** Product device recommended for new designs.
- **LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
- **NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
- **PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.
- **OBSOLETE:** TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substances do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".
- **RoHS Exempt:** TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.
- **Green:** TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) **MSL, Peak Temp.** - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) **Lead/Ball Finish** - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

C. Publication IPC–7351 is recommended for alternate designs.  
D. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Refer to IPC–7525 for other stencil recommendations.  
E. Customers should contact their board fabrication site for solder mask tolerances between and around signal pads.
Texas Instruments Incorporated (TI) reserves the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete.

TI's published terms of sale for semiconductor products (http://www.ti.com/sc/docs/stdterms.htm) apply to the sale of packaged integrated circuit products that TI has qualified and released to market. Additional terms may apply to the use or sale of other types of TI products and services.

Reproduction of significant portions of TI information in TI data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such reproduced documentation. Information of third parties may be subject to additional restrictions. Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and/or implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyers and others who are developing systems that incorporate TI products (collectively, “Designers”) understand and agree that Designers remain responsible for using their independent analysis, evaluation and judgment in designing their applications and that Designers have full and exclusive responsibility to assure the safety of Designers’ applications and compliance of their applications (and of all TI products used in or for Designers’ applications) with all applicable regulations, laws and other applicable requirements. Designer represents that, with respect to their applications, Designer has all the necessary expertise to create and implement safeguards that (1) anticipate dangerous consequences of failures, (2) monitor failures and their consequences, and (3) lessen the likelihood of failures that might cause harm and take appropriate actions. Designer agrees that prior to using or distributing any applications that include TI products, Designer will thoroughly test such applications and the functionality of such TI products as used in such applications.

TI's provision of technical, application or other design advice, quality characterization, reliability data or other services or information, including, but not limited to, reference designs and materials relating to evaluation modules, (collectively, “TI Resources”) are intended to assist designers who are developing applications that incorporate TI products; by downloading, accessing or using TI Resources in any way, Designer (individually or, if Designer is acting on behalf of a company, Designer's company) agrees to use any particular TI Resource solely for this purpose and subject to the terms of this Notice.

TI's provision of TI Resources does not expand or otherwise alter TI’s applicable published warranties or warranty disclaimers for TI products, and no additional obligations or liabilities arise from TI providing such TI Resources. TI reserves the right to make corrections, enhancements, improvements and other changes to its TI Resources. TI has not conducted any testing other than that specifically described in the published documentation for a particular TI Resource.

Designer is authorized to use, copy and modify any individual TI Resource only in connection with the development of applications that include the TI product(s) identified in such TI Resource. NO OTHER LICENSE, EXPRESS OR IMPLIED, BY ESTOPPEL OR OTHERWISE TO ANY TECHNOLOGY, PATENT, COPYRIGHT, TRADE SECRET, TRADE SECRET LAW, TRADEMARK, TRADE NAME, TRADE PRACTICE, TRADE CUSTOM, PROPERTY RIGHT OR ANY THIRD PARTY IS GRANTED HEREIN, including but not limited to any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information regarding or referencing third-party products or services does not constitute a license to use such products or services, or a warranty or endorsement thereof. Use of TI Resources may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

TI RESOURCES ARE PROVIDED “AS IS” AND WITH ALL FAULTS. TI DISCLAIMS ALL OTHER WARRANTIES OR REPRESENTATIONS, EXPRESS OR IMPLIED, REGARDING RESOURCES OR USE THEREOF, INCLUDING BUT NOT LIMITED TO ACCURACY OR COMPLETENESS, TITLE, ANY EPIDEMIC FAILURE WARRANTY AND ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, AND NON-INFRINGEMENT OF ANY THIRD PARTY INTELLECTUAL PROPERTY RIGHTS. TI SHALL NOT BE LIABLE FOR AND SHALL NOT DEFEND OR INDEMNIFY DESIGNER AGAINST ANY CLAIM, INCLUDING BUT NOT LIMITED TO ANY INFRINGEMENT CLAIM THAT RELATES TO OR IS BASED ON ANY COMBINATION OF PRODUCTS EVEN IF DESCRIBED IN TI RESOURCES OR OTHERWISE. IN NO EVENT SHALL TI BE LIABLE FOR ANY ACTUAL, DIRECT, SPECIAL, COLLATERAL, INDIRECT, PUNITIVE, INCIDENTAL, CONSEQUENTIAL OR EXEMPLARY DAMAGES IN CONNECTION WITH OR ARISING OUT OF TI RESOURCES OR USE THEREOF, AND REGARDLESS OF WHETHER TI HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

Unless TI has explicitly designated an individual product as meeting the requirements of a particular industry standard (e.g., ISO/TS 16949 and ISO 26262), TI is not responsible for any failure to meet such industry standard requirements.

Where TI specifically promotes products as facilitating functional safety or as compliant with industry functional safety standards, such products are intended to help enable customers to design and create their own applications that meet applicable functional safety standards and requirements. Using products in an application does not by itself establish any safety features in the application. Designers must ensure compliance with safety-related requirements and standards applicable to their applications. Designer may not use any TI products in life-critical medical equipment unless authorized officers of the parties have executed a special contract specifically governing such use. Life-critical medical equipment is medical equipment where failure of such equipment would cause serious bodily injury or death (e.g., life support, pacemakers, defibrillators, heart pumps, neurostimulators, and implantables). Such equipment includes, without limitation, all medical devices identified by the U.S. Food and Drug Administration as Class III devices and equivalent classifications outside the U.S.

TI may expressly designate certain products as completing a particular qualification (e.g., Q100, Military Grade, or Enhanced Product). Designers agree that it has the necessary expertise to select the product with the appropriate qualification designation for their applications and that proper product selection is at Designers’ own risk. Designers are solely responsible for compliance with all legal and regulatory requirements in connection with such selection.

Designer will fully indemnify TI and its representatives against any damages, costs, losses, and/or liabilities arising out of Designer's non-compliance with the terms and provisions of this Notice.
