OPA862 High Input Impedance, Single-Ended to Differential ADC Driver

### 1 Features
- Wide supply range: 3 V to 12.6 V
- High input impedance: 325 MΩ
- Voltage noise:
  - Input-referred (f ≥ 5 kHz): 2.3 nV/√Hz
  - Output-referred (f ≥ 10 kHz): 8.3 nV/√Hz
- Differential output offset: ±700 µV (maximum)
- Output offset drift: ±1.5 µV/°C (typical)
- A2 bias current cancellation, I_B: ±5 nA (typical)
- Gain-bandwidth product: 400 MHz
- Small-signal bandwidth: 44 MHz (G = 2 V/V)
- Slew rate: 140 V/µs
- HD2, HD3 (V_{OD} = 10 V_{PP}, 50 kHz):
  -122 dBc, –140 dBc
- Rail-to-rail output:
  - High linear output current: 60 mA (typ)
- Quiescent current: 3.1 mA
- Disable mode: 12-µA quiescent current
- Extended temperature operation:
  -40°C to +125°C

### 2 Applications
- 16-bit and 18-bit ADC drivers
- Memory and LCD testers
- Data acquisition (DAQ)
- Test and measurement
- Transimpedance amplifiers (TIA)
- Class-D audio amplifier drivers
- Piezoelectric sensor interface
- Medical instrumentation

### 3 Description
The OPA862 is a single-ended to differential analog-to-digital converter (ADC) driver with high input impedance for directly interfacing with sensors. The device only consumes 3.1-mA quiescent current for an output-referred noise density of 8.3 nV/√Hz in a gain of 2-V/V configuration. A fully differential amplifier configured in a gain of 1 V/V with 1-kΩ resistors must be less than 1 nV/√Hz to achieve the OPA862 equivalent output-referred noise density of 8.3 nV/√Hz. The OPA862 can be configured for other gains using external resistors. The device has a large gain-bandwidth product of 400 MHz and a slew rate of 140 V/µs. This yields exceptional linearity and fast-settling, 18-bit performance over comparable single-ended-to-differential ADC drivers. The device includes a reference input pin for setting the output common-mode voltage.

The OPA862 is fully characterized to operate over a wide supply range of 3 V to 12.6 V, and features a rail-to-rail output stage. The device is fabricated using Texas Instruments’ proprietary, high-speed, silicon-germanium (SiGe) process and achieves exceptional distortion performance for 18-bit systems. The device includes a disable mode that consumes only 12-µA quiescent current in power-down state.

The OPA862 is rated to work over the extended industrial temperature range of −40°C to +125°C.

(1) Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under Recommended Operating Conditions. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

(2) Stay below this \(±\) supply turn-on edge rate to make sure that the edge-triggered ESD absorption device across the supply pins remains off.

(3) Continuous input current limit for both the ESD diodes to supply pins and amplifier differential input clamp diode. The differential input clamp diode limits the voltage across it to 0.7 V with this continuous input current flowing through it.

(4) Long-term continuous current for electromigration limits.

6.2 ESD Ratings

7 Detailed Description

7.1 Overview

The OPA862 is a 44-MHz, single-ended-to-differential amplifier suitable for use in high-input impedance analog front-ends. This device offers a gain-bandwidth product (GBWP) of 400 MHz with a low output-referred voltage noise of 8.3 nV/√Hz while consuming only 3.1 mA of quiescent current. The OPA862 includes a REF pin for output common-mode voltage control using amplifier 2 and a shutdown pin for low-power mode operation that consumes only 12 µA of quiescent current.

The OPA862 can be configured for a single-ended-to-differential gain of 2 V/V without using any external resistors. The device can be configured in gains other than 2 V/V by using only two external resistors in the feedback loop of amplifier 1 (A1) and requires fewer external gain-setting resistors compared to a fully differential amplifier (FDA). The noninverting input of A1 offers high input impedance (325 MΩ typical) for interfacing single-ended sensors that often have a non-zero output impedance to differential input analog-to-digital converters (ADCs). A combination of large 140-V/µs slew rate, 400-MHz GBWP, and nonlinearity cancellation in the output stages of the two amplifiers results in exceptional distortion and settling performance for 18-bit systems.

The OPA862 includes an internal capacitor CFILT in the feedback circuit of amplifier 2 (A2) that limits the device bandwidth to approximately 44 MHz. Although the individual amplifiers have a GBWP of 200 MHz, because of the architecture of the OPA862, the input and output signal bandwidth must not exceed approximately 44 MHz to achieve good linearity. High GBWP amplifiers generally have high linearity because they can maintain high loop gain. The simple architecture of the OPA862 (as compared to an FDA) has an inherent delay between the outputs VOUT+ and VOUT− that primarily limits the linearity performance versus the high GBWP of the individual amplifiers. The benefit of the CFILT capacitor is that the CFILT filters and minimizes the noise at the output beyond the usable frequency of the OPA862.

The VREF pin can be used to set the output common-mode to a desired value. The Device Functional Modes section describes various configurations that the OPA862 can be used in.

7.2 Functional Block Diagram
7.3 Feature Description

7.3.1 Input and ESD Protection

The OPA862 is built using a high-speed complementary bipolar process. The internal junction breakdown voltages are relatively low for these very small geometry devices. These breakdowns are reflected in the Absolute Maximum Ratings table. As shown in Figure 53 all device pins are protected with internal ESD protection diodes to the power supplies.

These diodes provide moderate protection to input overdrive voltages beyond the supplies as well. The protection diodes can typically support 10-mA continuous current. Where higher currents are possible (for example, in systems with ±12-V supply parts driving into the OPA862), add current limiting series resistors in series with the inputs to limit the current. Keep these resistor values as low as possible because high values can degrade both noise performance and frequency response. The OPA862 has back-to-back ESD diodes between the VIN and VFB pins. As a result, the differential input voltage between the VIN and VFB pins must be limited to 0.7 V or less to keep from forward biasing these back-to-back ESD diodes. The diodes are robust enough to survive transient conditions such as those common during slew conditions. In the event the differential input voltage exceeds 0.7 V, these back-to-back diodes forward bias and protect the amplifier but the current must be limited per the specifications in the Absolute Maximum Ratings table to avoid permanent damage to these diodes or the amplifier.

Figure 53. Internal ESD Protection
Feature Description (continued)

7.3.2 Anti-Phase Reversal Protection

When the input common-mode voltage approaches or exceeds V\textsubscript{S–}, the base-collector junction of the input transistors forward biases. This condition creates an output path parallel to the normal g\textsubscript{m} path of the transistors that is opposite in phase to the g\textsubscript{m} path. When this parallel path starts to dominate, phase inversion occurs. To protect against phase inversion, the OPA862 features anti-phase reversal (APR) protection Schottky diodes on the input transistors. The Schottky diodes turn on at a voltage lower than the forward bias voltage of the base-collector junction, thus preventing the forward bias and the phase-inversion at the base-collector junction of the input transistors. Figure 54 shows a diagram of APR protection within the OPA862.

![Figure 54. Anti-Phase Reversal Protection](image)

7.3.3 Precision and Low Noise

The OPA862 is laser trimmed for high DC precision. An important factor that reduces the DC precision of the system that uses the OPA862 is the errors introduced by the bias currents of A2 flowing through the internal feedback resistors, R\textsubscript{INT}; see the Functional Block Diagram section. To minimize the error contribution from I\textsubscript{B}, the A2 amplifier of the OPA862 features a unique I\textsubscript{B} cancellation mechanism. This I\textsubscript{B} cancellation mechanism is the reason why the I\textsubscript{B} of A2 is orders of magnitude lower than the I\textsubscript{B} of A1. The DC errors are negligible for most applications because of the nanoamperes of I\textsubscript{B} and very low I\textsubscript{B} drift of A2. However, despite being very low, if the I\textsubscript{B} errors of A2 are significant for an application, a 348-Ω R\textsubscript{REF} resistor can be used on the VREF input to cancel out the I\textsubscript{B} errors. The tradeoff of using the R\textsubscript{REF} is that this resistor introduces noise that is amplified by a factor of two at VOUT– because of the noise gain of two of A2. The C\textsubscript{FILT} capacitor (the Functional Block Diagram section) also helps filter out the flat band noise contribution of R\textsubscript{REF}. The 700-Ω internal resistors were carefully chosen to balance low noise while keeping the total power dissipation low by taking advantage of the low 3.1-mA quiescent current of the OPA862. As shown in Figure 55, to get the equivalent 8.3-nV/√Hz noise of the OPA862 with a typical FDA configuration, the FDA must be less than 1 nV/√Hz; such FDAs are often difficult to find or expensive. When R\textsubscript{REF} equals 0 Ω, the typical error resulting from the I\textsubscript{B} of A2 appears as an input-referred offset of 3.5 µV at the VREF input, and when R\textsubscript{REF} is 348 Ω, the differential output-referred noise increases from 8.3 nV/√Hz to 9.6 nV/√Hz.

![Figure 55. Equivalent Voltage Noise FDA to OPA862](image)
7.4 Device Functional Modes

7.4.1 Split-Supply Operation (±1.5 V to ±6.3 V)

To facilitate testing with common lab equipment, the OPA862 can be configured to allow for split-supply operation. This configuration eases lab testing because the mid-point between the power rails is ground, and most signal generators, network analyzers, oscilloscopes, spectrum analyzers, and other lab equipment reference the inputs and outputs to ground. For split-supply operation referenced to ground, the power supplies $V_{S+}$ and $V_{S-}$ are symmetrical around ground and generally $V_{\text{REF}}$ is also set equal to ground. Split-supply operation is preferred in systems where the signals swing around ground because of the ease-of-use; however, the system requires two supply rails.

7.4.2 Single-Supply Operation (3 V to 12.6 V)

Many newer systems use a single power supply to improve efficiency and reduce the cost of the extra power supply. The OPA862 can be used with a single supply (negative supply set to ground), as shown in Figure 56, with no change in performance if the input and output are biased within the linear operation of the device. To change the circuit from split supply to a single-supply configuration, level shift all the voltages by half the difference between the power-supply rails. In the single-supply configuration, a voltage must be set on the VREF pin, typically midsupply, such that VREF does not violate the common-mode input range (CMIR) specification or the output voltage range of $A_2$. An additional advantage of configuring an amplifier for single-supply operation is that the effects of PSRR are minimized because the low-supply rail is grounded. See the Single-Supply Op Amp Design Techniques application report for examples of single-supply designs.

![Figure 56. Typical Single-Supply Configuration](image-url)
8 Application and Implementation

NOTE
Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI’s customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

8.1.1 Single-Ended-to-Differential Gain of 4 V/V

Figure 57 shows the configuration that can be used for a single-ended-to-differential gain of 4 V/V. Amplifier A1 follows all the conventional equations of a regular voltage-feedback amplifier for inverting and noninverting gains. With the fixed inverting gain of –1 V/V for the configuration of A2, the primary role of A2 is to invert the output of A1 so that a differential signal is available at the output pins, VOUT+ and VOUT–. In the configuration shown in Figure 57, VOUT+ is always in phase with VIN and equal to VIN times two. VOUT– has the same swing as VOUT+ but 180° out of phase. The common-mode voltage at A1 is equal to VIN and the common-mode voltage at A2 is equal to the voltage on the VREF pin, which in the case of Figure 57 is GND.

Equation 1 through Equation 4 can be derived from the configuration in Figure 57. The output common-mode voltage, VOCM, is the average of VOUT+ and VOUT– and is equal to the voltage on the VREF pin as given by Equation 4.

\[ V_{OUT+} = V_{IN} \left(1 + \frac{R_F}{R_G}\right) \]  
\[ V_{OUT-} = -V_{OUT+} + 2 \times V_{REF} = -V_{IN} \left(1 + \frac{R_F}{R_G}\right) + 2 \times V_{REF} \]  
\[ V_{OD} = V_{OUT+} - V_{OUT-} = 2 \times V_{IN} \left(1 + \frac{R_F}{R_G}\right) - 2 \times V_{REF} \]  
\[ V_{OCM} = \frac{V_{OUT+} + V_{OUT-}}{2} = V_{REF} \]
8.2 Typical Applications

8.2.1 Single-Ended to Differential with 2.5-V Output Common-Mode Voltage

Most real-world signals are single ended. Often, fully differential amplifiers (FDAs) are used for single-ended-to-differential conversions but the low-impedance input of the FDA configuration can be a challenge for digital acquisition systems (DAQs). The high input impedance input of the OPA862, coupled with its ability to convert single-ended inputs to differential outputs, makes the device an excellent choice for DAQs.

8.2.1.2 Detailed Design Procedure

For \( R_F = 0 \ \Omega \), with the VFB pin shorted to VOUT+, use Equation 3 to determine that the OPA862 is in a differential gain of 2 V/V configuration. Equation 4 describes how setting \( V_{REF} \) equal to 2.5 V results in a \( V_{OCM} \) of 2.5 V, as required per the design criteria. When designing a front-end stage with the OPA862, the input common-mode voltage and the output voltage range of the input and output pins, respectively, must be considered carefully. Choose the supplies such that none of these voltage ranges are violated and that the single-ended output voltages at each output do not exceed the maximum allowed voltages of the subsequent stage that the OPA862 is driving. Simulate the transfer characteristics of this circuit to ensure the output voltages are within the desired operation limits. Figure 59 illustrates the transfer characteristics for the OPA862 configuration in Figure 58. The output waveforms of the circuit in Figure 58 are described in Figure 60 and meets the design requirements of Table 1.
8.2.1.3 Application Curves

- Figure 59. DC Transfer Characteristics
- Figure 60. Transient Output Response

8.2.2 Transimpedance Amplifier Configuration

With recent advancements in light-sensing technology, transimpedance (TIA) applications are becoming popular, ranging in signal bandwidth needs from tens of kHz to hundreds of MHz. Because the current output of the photodiode in these TIA applications is unipolar, a key challenge in interfacing with the fully differential input analog-to-digital converters (ADCs) is maximizing the differential signal to the ADC in order to maximize the signal-to-noise ratio (SNR).

As illustrated in the output waveform of Figure 62, only half the differential output signal swing of the FDA is available. On the contrary, by using the OPA862 as the TIA stage, a single-device interface to the ADC can be designed that also allows the full differential swing to the ADC and set the desired output common-mode as shown in Figure 61. $V_{\text{REF}}$ is used to set the output common-mode voltage and $V_{\text{DC}}$ is used to DC shift the outputs such that for a zero photodiode current, $V_{\text{OD}}$ (equal to $V_{\text{OUT+}} - V_{\text{OUT-}}$) is at one of the peaks of the desired differential peak-to-peak swing. Whether the $V_{\text{OD}}$ peak at the zero photodiode current is at a high or low peak is determined by the direction of current through $R_F$ in the presence of the photodiode signal current.

8.2.2.2 Detailed Design Procedure

In most TIA designs, selecting the right photodiode for the application is the most important decision because the photodiode determines the $I_{IN}$ and $C_D$ parameters that in turn determine the bandwidth required from the amplifier, the realizable TIA gain, and the signal bandwidth. Signal bandwidth also determines the rise time of the pulses. Choosing the photodiode with as low a capacitance as possible maximizes the TIA signal bandwidth for a given amplifier. Similarly, choosing a low TIA gain ($R_F$) allows for higher signal bandwidth but having a $R_F$ as high as possible maximizes the SNR of the signal chain.

In order to take advantage of the increased SNR by using the OPA862 as described in Figure 61, the amplifier is already chosen. Using the design methodology explained at What You Need To Know About Transimpedance Amplifiers – Part 1 and the design parameters in Table 2, $R_F$ can be determined to be 1 kΩ and the required feedback capacitor, $C_F$, is 22 pF. Because the range of $I_{IN}$ is 0 mA to 5 mA and $R_F$ is 1 kΩ, the range of a single-ended output voltage at $V_{OUT+}$ is 0 V to 5 V ($I_{IN} \times R_F$). In the cathode bias configuration of the photodiode condition in Figure 63, when the photodiode is excited the current flows towards $V_{OUT+}$ through $R_F$, resulting in a voltage pulse that goes lower from the zero current value. Thus, setting $V_{OUT+} = 5$ V and $V_{OUT-} = 0$ V ($V_{OD} = +5$ V) is desirable when the current is zero so that when the maximum current pulse of 5 mA occurs, $V_{OUT+}$ goes to 0 V and $V_{OUT-}$ reaches 5 V ($V_{OD} = -5$ V). The $V_{OCM}$ target of 2.5 V, which is a typical mid-reference voltage for differential input ADCs, can be set by choosing $V_{REF} = V_{OCM}$. The values of $V_{DC}$ and $V_{REF}$ can be determined by setting the values of $V_{OUT+}$ and $V_{OUT-}$ to appropriate values at the zero photo-current in the following equations:

- $V_{DC} = V_{OUT+}$
- $V_{REF} = (V_{OUT-} + V_{DC}) / 2 = V_{OCM}$
Figure 64 and Figure 65 show the small-signal bandwidth and large-signal step response TINA simulation results of the circuit in Figure 63.

8.2.2.3 Application Curves

![Figure 64. Small-Signal Bandwidth](image1.png)

![Figure 65. Large-Signal Transient Response](image2.png)
8.2.3 DC Level-Shifting

Often, applications must level-shift a ground-referenced signal to a non-ground voltage. Configurations in Figure 66 and Figure 67 show two different ways of level-shifting a signal by using the OPA862 without having to use external resistors, saving board cost and space. These configurations leverage the fixed noninverting gain-of-2 configuration of A2 and the summing configuration of A1 to level-shift the signal at VOUT–. The internal resistors of the OPA862 are extremely well-matched to maintain the gain-of-2 accuracy of A2. Similarly matched external resistors can add significant cost to the system and often are more expensive than the amplifier itself.

Apart from the polarity of the $V_{DC}$-shift at the output, a key difference between the configurations of Figure 66 and Figure 67 is that in the case of Figure 66, $V_{DC}$ only must be capable of driving the $I_{B}$ of A1 but in the case of Figure 67, $V_{DC}$ must be capable of driving higher currents, as given by $I = V_{DC} / R_{G}$ when a noninverting input of A1 is grounded.

![Figure 66. Level-Shifting With a DC Source of Polarity Opposite to the Desired DC Shift](image)

![Figure 67. Level-Shifting With a DC Source of Polarity Same as the Desired DC Shift](image)
9 Power Supply Recommendations

The OPA862 is intended to work in a supply range of 3 V to 12.6 V. The OPA862 can be used in single-supply operation, or in a balanced or unbalanced split-supply operation. Good power-supply bypassing is recommended for best AC performance and distortion in particular. Minimize the distance (less than 0.1 inch) from the power-supply pins to high-frequency, 0.1-µF decoupling capacitors. A larger capacitor (2.2 µF or 10 µF is typical) is used with a high-frequency, 0.1-µF supply decoupling capacitor at the device supply pins. For single-supply operation, only the positive supply has these capacitors. When a split-supply is used, use these capacitors for each supply to ground. If necessary, place the larger capacitors further from the device and share these capacitors among several devices in the same area of the printed circuit board (PCB). Avoid narrow power and ground traces to minimize inductance between the pins and the decoupling capacitors. An optional 0.1-µF supply decoupling capacitor across the two power supplies (for bipolar operation) reduces second-order harmonic distortion.

10 Layout

10.1 Layout Guidelines

Achieving optimum AC performance with a fast amplifier such as the OPA862 requires careful attention to board layout parasitics and external component types. The OPA862EVM can be used as a reference when designing the circuit board. Recommendations that optimize performance include:

1. **Minimize parasitic capacitance** to any AC ground for all of the signal I/O pins. Parasitic capacitance on the output and input pins can cause instability. On the noninverting input, VІН, the device can react with the source impedance to cause unintentional band limiting. To reduce unwanted capacitance, open a plane cutout around the signal I/O pins in the ground and power planes below those pins. Otherwise, ground and power planes must be unbroken elsewhere on the board.

2. **Minimize the distance** (< 0.1") from the power-supply pins to high-frequency, 0.01-µF or 0.1-µF decoupling capacitors. At the device pins, do not allow the ground and power plane layout to be in close proximity to the signal I/O pins. Avoid narrow power and ground traces to minimize inductance between the pins and the decoupling capacitors. The power-supply connections must always be decoupled with these capacitors. Larger (2.2-µF to 10-µF) decoupling capacitors, effective at lower frequencies, must also be used on the supply pins. These capacitors can be placed somewhat farther from the device and shared among several devices in the same area of the PCB.

3. **Careful selection and placement of external components** preserve the AC performance of the OPA862. Resistors must be a low reactance type. Surface-mount resistors work best and allow a tighter overall layout. Metal film and carbon composition axially leaded resistors can also provide good high-frequency performance. Again, keep their leads and PCB trace length as short as possible. Because the VOUT+ pin and the VFB pin are the most sensitive to parasitic capacitance, always position the feedback and series output resistor, if any, as close as possible to the VFB and VOUT+ pins, respectively.

4. **Connections to other wideband devices** on the board can be made with short direct traces or through onboard transmission lines. For short connections, consider the trace and the input to the next device as a lumped capacitive load. Relatively wide traces (50 mils to 100 mils) must be used, preferably with ground and power planes opened up around them.

5. **Socketing a high-speed part such as the OPA862 is not recommended.** The additional lead length and pin-to-pin capacitance introduced by the socket can create troublesome parasitic network that can make achieving a smooth, stable frequency response difficult. Best results are obtained by soldering the OPA862 to the board.

This glossary lists and explains terms, acronyms, and definitions.

12 Mechanical, Packaging, and Orderable Information
The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.
NOTES:

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. For more information, see Texas Instruments literature number SLUA271 (www.ti.com/lit/slua271).
4. Solder mask tolerances between and around signal pads can vary based on board fabrication site.
NOTES: (continued)

5. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.

(1) The marketing status values are defined as follows:
- **ACTIVE**: Product device recommended for new designs.
- **LIFEBUY**: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
- **NRND**: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
- **PREVIEW**: Device has been announced but is not in production. Samples may or may not be available.
- **OBSOLETE**: TI has discontinued the production of the device.

(2) **RoHS**: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".
- **RoHS Exempt**: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.
- **Green**: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) **MSL, Peak Temp.**: The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) **Lead/Ball Finish**: Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

*All dimensions are nominal*
NOTES:

1. Linear dimensions are in inches [millimeters]. Dimensions in parenthesis are for reference only. Controlling dimensions are in inches. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. This dimension does not include mold flash, protrusions, or gate burrs. Mold flash, protrusions, or gate burrs shall not exceed .006 [0.15] per side.
4. This dimension does not include interlead flash.
5. Reference JEDEC registration MS-012, variation AA.
NOTES: (continued)

6. Publication IPC-7351 may have alternate designs.
7. Solder mask tolerances between and around signal pads can vary based on board fabrication site.
8. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.

9. Board assembly site may have different recommendations for stencil design.
IMPORTANT NOTICE AND DISCLAIMER

TI PROVIDES TECHNICAL AND RELIABILITY DATA (INCLUDING DATASHEETS), DESIGN RESOURCES (INCLUDING REFERENCE DESIGNS), APPLICATION OR OTHER DESIGN ADVICE, WEB TOOLS, SAFETY INFORMATION, AND OTHER RESOURCES “AS IS” AND WITH ALL FAULTS, AND DISCLAIMS ALL WARRANTIES, EXPRESS AND IMPLIED, INCLUDING WITHOUT LIMITATION ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT OF THIRD PARTY INTELLECTUAL PROPERTY RIGHTS.

These resources are intended for skilled developers designing with TI products. You are solely responsible for (1) selecting the appropriate TI products for your application, (2) designing, validating and testing your application, and (3) ensuring your application meets applicable standards, and any other safety, security, or other requirements. These resources are subject to change without notice. TI grants you permission to use these resources only for development of an application that uses the TI products described in the resource. Other reproduction and display of these resources is prohibited. No license is granted to any other TI intellectual property right or to any third party intellectual property right. TI disclaims responsibility for, and you will fully indemnify TI and its representatives against, any claims, damages, costs, losses, and liabilities arising out of your use of these resources.

TI's products are provided subject to TI's Terms of Sale (www.ti.com/legal/termsofsale.html) or other applicable terms available either on ti.com or provided in conjunction with such TI products. TI's provision of these resources does not expand or otherwise alter TI's applicable warranties or warranty disclaimers for TI products.
