THS6072
LOW-POWER ADSL DIFFERENTIAL RECEIVER

- ADSL Differential Receiver
  - Ideal for Central Office or Remote Terminal Applications
- Low 3.4 mA Per Channel Quiescent Current
- 10 nV/√Hz Voltage Noise
- Very Low Distortion
  - THD = –79 dBc (f = 1 MHz, R_L = 1 kΩ)
- High Speed
  - 175 MHz Bandwidth (–3 dB, G = 1)
  - 230 V/µs Slew Rate
- High Output Drive, I_O = 85 mA (typ)
- Wide Range of Power Supplies
  - V_CC = ±5 V to ±15 V
- Available in Standard SOIC or MSOP PowerPAD™ Package
- Evaluation Module Available

description

The THS6072 is a high-speed, low-power differential receiver designed for ADSL communication systems. Its low 3.4-mA per channel quiescent current reduces power to half that of other ADSL receivers making it ideal for low power ADSL applications. This receiver operates with a very low distortion of –79 dBc (f = 1 MHz, R_L = 1 kΩ). The THS6072 is a voltage feedback amplifier offering a high 175-MHz bandwidth and 230-V/µs slew rate and is unity gain stable. It operates over a wide range of power supply voltages including ±4.5 V to ±15 V. This device is available in a standard SOIC or MSOP PowerPAD™ package.

APPLICATION INFORMATION

ADSL line noise

Per ANSI T1.413, the noise power spectral density for an ADSL line is \(-140\) dBm/\(\sqrt{\text{Hz}}\). This results in a voltage noise requirement of less than 31.6 nV/\(\sqrt{\text{Hz}}\) for the receiver in an ADSL system with a 1:1 transformer ratio.

\[
\text{Noise Power Spectral Density} = -140 \text{ dBm}/\sqrt{\text{Hz}}
\]
\[
\text{Power} = 1 \times 10^{-17} \times 1 \text{ Hz} = 0.01 \text{ fW}
\]
Assume: \(R_L = 100 \ \Omega\)

\[
V_{\text{noise}} = \sqrt{\left(\text{Power} \times R_L\right)} = \sqrt{0.01 \text{ fW} \times 100 \ \Omega} = 31.6 \text{ nV}/\sqrt{\text{Hz}}
\]

For ADSL systems that use a 1:2 transformer ratio, such as central office line cards, the voltage noise requirement for the receiver is lowered to 15.8 nV/\(\sqrt{\text{Hz}}\).

<table>
<thead>
<tr>
<th>TRANSFORMER RATIO</th>
<th>V_{\text{noise}} ON LINE</th>
</tr>
</thead>
<tbody>
<tr>
<td>1:1</td>
<td>31.6 nV/\sqrt{\text{Hz}}</td>
</tr>
<tr>
<td>1:2</td>
<td>15.8 nV/\sqrt{\text{Hz}}</td>
</tr>
</tbody>
</table>

The THS6072 was designed to operate with 10 nV/\(\sqrt{\text{Hz}}\) voltage noise, exceeding the noise requirements for an ADSL system operating with 1:1 or 1:2 transformer ratios. For systems where a voltage noise of less than 10 nV/\(\sqrt{\text{Hz}}\) voltage noise is required, see the THS6062 low noise ADSL receiver which operates with a voltage noise level of 1.6 nV/\(\sqrt{\text{Hz}}\).

minimizing distortion

One way to minimize distortion is to increase the load impedance seen by the amplifier, thereby reducing the currents in the output stage. This will help keep the output transistors in their linear amplification range and will also reduce the heating effects. This can be seen in Figure 10 through Figure 13, which show a 1-k\(\Omega\) load distortion is much better than a 150-\(\Omega\) load.
APPLICATION INFORMATION

Figure 37. Typical ADSL Central Office Application

Figure 38. Typical ADSL Remote Terminal Application
theory of operation

The THS6072 is a high-speed, operational amplifier configured in a voltage feedback architecture. It is built using a 30-V, dielectrically isolated, complementary bipolar process with NPN and PNP transistors possessing $f_T$ of several GHz. This results in an exceptionally high performance amplifier that has a wide bandwidth, high slew rate, fast settling time, and low distortion. A simplified schematic is shown in Figure 39.

\begin{figure}
\centering
\includegraphics[width=\textwidth]{figure39.png}
\caption{THS6072 Simplified Schematic}
\end{figure}

noise calculations and noise figure

Noise can cause errors on very small signals. This is especially true when amplifying small signals, where signal-to-noise ratio (SNR) is very important. The noise model for the THS6072 is shown in Figure 40. This model includes all of the noise sources as follows:

- $e_n =$ Amplifier internal voltage noise (nV/\sqrt{Hz})
- $IN+ =$ Noninverting current noise (pA/\sqrt{Hz})
- $IN− =$ Inverting current noise (pA/\sqrt{Hz})
- $e_{Rx} =$ Thermal voltage noise associated with each resistor ($e_{Rx} = 4 kT R_x$)
APPLICATION INFORMATION

noise calculations and noise figure (continued)

The total equivalent input noise density ($e_{ni}$) is calculated by using the following equation:

$$e_{ni} = \sqrt{\left(e_n\right)^2 + \left(IN + \times R_S\right)^2 + \left(IN- \times \left(R_F || R_G\right)\right)^2 + 4kT R_S + 4kT \left(R_F || R_G\right)}$$

Where:

- $k = \text{Boltzmann’s constant} = 1.380658 \times 10^{-23}$
- $T = \text{Temperature in degrees Kelvin (273 } ^\circ\text{C)}$
- $R_F || R_G = \text{Parallel resistance of } R_F \text{ and } R_G$

To get the equivalent output noise of the amplifier, just multiply the equivalent input noise density ($e_{ni}$) by the overall amplifier gain ($A_V$).

$$e_{no} = e_{ni} A_V = e_{ni} \left(1 + \frac{R_F}{R_G}\right) \text{ (noninverting case)}$$

As the previous equations show, to keep noise at a minimum, small value resistors should be used. As the closed-loop gain is increased (by reducing $R_G$), the input noise is reduced considerably because of the parallel resistance term. This leads to the general conclusion that the most dominant noise sources are the source resistor ($R_S$) and the internal amplifier noise voltage ($e_n$). Because noise is summed in a root-mean-squares method, noise sources smaller than 25% of the largest noise source can be effectively ignored. This can greatly simplify the formula and make noise calculations much easier to calculate.

For more information on noise analysis, please refer to the Noise Analysis section in Operational Amplifier Circuits Applications Report (literature number SLVA043).
APPLICATION INFORMATION

noise calculations and noise figure (continued)

This brings up another noise measurement usually preferred in RF applications, the noise figure (NF). Noise figure is a measure of noise degradation caused by the amplifier. The value of the source resistance must be defined and is typically 50 Ω in RF applications.

\[ NF = 10 \log \left[ \frac{e_{n_i}^2}{(e_{Rs})^2} \right] \]

Because the dominant noise components are generally the source resistance and the internal amplifier noise voltage, we can approximate the noise figure as:

\[ NF = 10 \log \left[ 1 + \frac{\left( e_n \right)^2 + (IN + R_S)^2}{4kT_R} \right] \]

Figure 41 shows the noise figure graph for the THS6072.

![Noise Figure vs Source Resistance](image-url)
APPLICATION INFORMATION

driving a capacitive load

Driving capacitive loads with high performance amplifiers is not a problem as long as certain precautions are taken. The first is to realize that the THS6072 has been internally compensated to maximize its bandwidth and slew rate performance. When the amplifier is compensated in this manner, capacitive loading directly on the output will decrease the device’s phase margin leading to high frequency ringing or oscillations. Therefore, for capacitive loads of greater than 10 pF, it is recommended that a resistor be placed in series with the output of the amplifier, as shown in Figure 42. A minimum value of 20 Ω should work well for most applications. For example, in 75-Ω transmission systems, setting the series resistor value to 75 Ω both isolates any capacitance loading and provides the proper line impedance matching at the source end.

![Figure 42. Driving a Capacitive Load](image)

offset voltage

The output offset voltage, \( V_{OO} \), is the sum of the input offset voltage \( V_{IO} \) and both input bias currents \( I_{IB} \) times the corresponding gains. The following schematic and formula can be used to calculate the output offset voltage:

\[
V_{OO} = V_{IO} \left( 1 + \frac{R_F}{R_G} \right) \pm I_{IB+} R_S \left( 1 + \frac{R_F}{R_G} \right) \pm I_{IB-} R_F
\]

![Figure 43. Output Offset Voltage Model](image)
APPLICATION INFORMATION

general configurations

When receiving low-level signals, limiting the bandwidth of the incoming signals into the system is often required. The simplest way to accomplish this is to place an RC filter at the noninverting terminal of the amplifier (see Figure 44).

\[ f_{3\text{dB}} = \frac{1}{2\pi R_1 C_1} \]

\[ \frac{V_O}{V_I} = \left(1 + \frac{R_F}{R_G}\right)\left(1 + sR_1 C_1\right) \]

Figure 44. Single-Pole Low-Pass Filter
APPLICATION INFORMATION

circuit layout considerations

To achieve the levels of high frequency performance of the THS6072, follow proper printed-circuit board high frequency design techniques. A general set of guidelines is given below. In addition, a THS6072 evaluation board is available to use as a guide for layout or for evaluating the device performance.

- Ground planes – It is highly recommended that a ground plane be used on the board to provide all components with a low inductive ground connection. However, in the areas of the amplifier inputs and output, the ground plane can be removed to minimize the stray capacitance.

- Proper power supply decoupling – Use a 6.8-μF tantalum capacitor in parallel with a 0.1-μF ceramic capacitor on each supply terminal. It may be possible to share the tantalum among several amplifiers depending on the application, but a 0.1-μF ceramic capacitor should always be used on the supply terminal of every amplifier. In addition, the 0.1-μF capacitor should be placed as close as possible to the supply terminal. As this distance increases, the inductance in the connecting trace makes the capacitor less effective. The designer should strive for distances of less than 0.1 inches between the device power terminals and the ceramic capacitors.

- Sockets – Sockets are not recommended for high-speed operational amplifiers. The additional lead inductance in the socket pins will often lead to stability problems. Surface-mount packages soldered directly to the printed-circuit board is the best implementation.

- Short trace runs/compact part placements – Optimum high frequency performance is achieved when stray series inductance has been minimized. To realize this, the circuit layout should be made as compact as possible, thereby minimizing the length of all trace runs. Particular attention should be paid to the inverting input of the amplifier. Its length should be kept as short as possible. This will help to minimize stray capacitance at the input of the amplifier.

- Surface-mount passive components – Using surface-mount passive components is recommended for high frequency amplifier circuits for several reasons. First, because of the extremely low lead inductance of surface-mount components, the problem with stray series inductance is greatly reduced. Second, the small size of surface-mount components naturally leads to a more compact layout, thereby minimizing both stray inductance and capacitance. If leaded components are used, it is recommended that the lead lengths be kept as short as possible.

general PowerPAD design considerations

The THS6072 is available packaged in a thermally-enhanced DGN package, which is a member of the PowerPAD family of packages. This package is constructed using a downset leadframe upon which the die is mounted [see Figure 45(a) and Figure 45(b)]. This arrangement results in the lead frame being exposed as a thermal pad on the underside of the package [see Figure 45(c)]. Because this thermal pad has direct thermal contact with the die, excellent thermal performance can be achieved by providing a good thermal path away from the thermal pad.

The PowerPAD package allows for both assembly and thermal management in one manufacturing operation. During the surface-mount solder operation (when the leads are being soldered), the thermal pad can also be soldered to a copper area underneath the package. Through the use of thermal paths within this copper area, heat can be conducted away from the package into either a ground plane or other heat dissipating device.

The PowerPAD package represents a breakthrough in combining the small area and ease of assembly of the surface mount with the, heretofore, awkward mechanical methods of heatsinking.
APPLICATION INFORMATION

general PowerPAD design considerations (continued)

Although there are many ways to properly heatsink this device, the following steps illustrate the recommended approach.

1. Prepare the PCB with a top side etch pattern as shown in Figure 46. There should be etch for the leads as well as etch for the thermal pad.

2. Place five holes in the area of the thermal pad. These holes should be 13 mils in diameter. Keep them small so that solder wicking through the holes is not a problem during reflow.

3. Additional vias may be placed anywhere along the thermal plane outside of the thermal pad area. This helps dissipate the heat generated by the THS6072DGN IC. These additional vias may be larger than the 13-mil diameter vias directly under the thermal pad. They can be larger because they are not in the thermal pad area to be soldered, so wicking is not a problem.

4. Connect all holes to the internal ground plane.

5. When connecting these holes to the ground plane, do not use the typical web or spoke via connection methodology. Web connections have a high thermal resistance connection that is useful for slowing the heat transfer during soldering operations. This makes the soldering of vias that have plane connections easier. In this application, however, low thermal resistance is desired for the most efficient heat transfer. Therefore, the holes under the THS6072DGN package should make their connection to the internal ground plane with a complete connection around the entire circumference of the plated-through hole.

6. The top-side solder mask should leave the terminals of the package and the thermal pad area with its five holes exposed. The bottom-side solder mask should cover the five holes of the thermal pad area. This prevents solder from being pulled away from the thermal pad area during the reflow process.

7. Apply solder paste to the exposed thermal pad area and all of the IC terminals.

8. With these preparatory steps in place, the THS6072DGN IC is simply placed in position and run through the solder reflow operation as any standard surface-mount component. This results in a part that is properly installed.
APPLICATION INFORMATION

general PowerPAD design considerations (continued)

The actual thermal performance achieved with the THS6072DGN in its PowerPAD package depends on the application. In the example above, if the size of the internal ground plane is approximately 3 inches × 3 inches, then the expected thermal coefficient, \( \theta_{JA} \), is about 58.4 °C/W. For comparison, the non-PowerPAD version of the THS6072 IC (SOIC) is shown. For a given \( \theta_{JA} \), the maximum power dissipation is shown in Figure 47 and is calculated by the following formula:

\[
P_D = \left( \frac{T_{MAX} - T_A}{\theta_{JA}} \right)
\]

Where:
- \( P_D \) = Maximum power dissipation of THS6072 IC (watts)
- \( T_{MAX} \) = Absolute maximum junction temperature (150°C)
- \( T_A \) = Free-ambient air temperature (°C)
- \( \theta_{JA} = \theta_{JC} + \theta_{CA} \)
  - \( \theta_{JC} \) = Thermal coefficient from junction to case
  - \( \theta_{CA} \) = Thermal coefficient from case to ambient air (°C/W)

MAXIMUM POWER DISSIPATION

VS
FREE-AIR TEMPERATURE

![Graph showing maximum power dissipation vs free-air temperature](image)

NOTE A: Results are with no air flow and PCB size = 3" × 3"

Figure 47. Maximum Power Dissipation vs Free-Air Temperature

More complete details of the PowerPAD installation process and thermal management techniques can be found in the Texas Instruments Technical Brief, *PowerPAD Thermally Enhanced Package*. This document can be found at the TI web site (www.ti.com) by searching on the key word PowerPAD. The document can also be ordered through your local TI sales office. Refer to literature number SLMA002 when ordering.
APPLICATION INFORMATION

general PowerPAD design considerations (continued)

The next consideration is the package constraints. The two sources of heat within an amplifier are quiescent power and output power. The designer should never forget about the quiescent heat generated within the device, especially multi-amplifier devices. Because these devices have linear output stages (Class A-B), most of the heat dissipation is at low output voltages with high output currents. Figure 48 and Figure 49 show this effect, along with the quiescent heat, with an ambient air temperature of 50°C. Obviously, as the ambient temperature increases, the limit lines shown will drop accordingly. The area under each respective limit line is considered the safe operating area. Any condition above this line will exceed the amplifier’s limits and failure may result. When using $V_{CC} = \pm 5$ V, there is generally not a heat problem, even with SOIC packages. But, when using $V_{CC} = \pm 15$ V, the SOIC package is severely limited in the amount of heat it can dissipate. The other key factor when looking at these graphs is how the devices are mounted on the PCB. The PowerPAD devices are extremely useful for heat dissipation. But, the device should always be soldered to a copper plane to fully use the heat dissipation properties of the PowerPAD. The SOIC package, on the other hand, is highly dependent on how it is mounted on the PCB. As more trace and copper area is placed around the device, $\theta_{JA}$ decreases and the heat dissipation capability increases. The currents and voltages shown in these graphs are for the total package.

evaluation board

An evaluation board is available for the THS6072 (literature number SLOP322). This board has been configured for very low parasitic capacitance in order to realize the full performance of the amplifier. A schematic of the evaluation board is shown in Figure 50. The circuitry has been designed so that the amplifier may be used in either an inverting or noninverting configuration. For more information, please refer to the THS6072 EVM User's Guide. To order the evaluation board, contact your local TI sales office or distributor.

(1) The marketing status values are defined as follows:
ACTIVE: Product device recommended for new designs.
LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
PREVIEW: Device has been announced but is not in production. Samples may or may not be available.
_OBSOLETE: TI has discontinued the production of the device.

(2) RoHS: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free". RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption. Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.
