TPS6273x Programmable Output Voltage Ultra-Low Power Buck Converter
With Up to 50 mA / 200 mA Output Current

1 Features
- Industry's Highest Efficiency at Low Output Currents: > 90% With I_{OUT} = 15 µA
- Ultra-Low Power Buck Converter
  - TPS62736 Optimized for 50-mA Output Current
  - TPS62737 Optimized for 200-mA Output Current
- 1.3-V to 5-V Resistor Programmable Output Voltage Range
- 2-V to 5.5-V Input Operating Range
- 380-nA and 375-nA Quiescent Current During Active Operation for TPS62736 and TPS62737
- 10-nA Quiescent Current During Ship Mode Operation
- 2% Voltage Regulation Accuracy
- 100% Duty Cycle (Pass Mode)
- EN1 and EN2 Control
  - Two Power-Off States:
    1. Shipmode (Full Power-Off State)
    2. Standby Mode Includes VIN_OK Indication
- Input Power-Good Indication (VIN_OK)
  - Push-Pull Driver
  - Resistor Programmable Threshold Level

2 Applications
- Ultra-Low Power Applications
- 2-Cell and 3-Cell Alkaline-Powered Applications
- Energy Harvesting
- Solar Chargers
- Thermal Electric Generator (TEG) Harvesting
- Wireless Sensor Networks (WSN)
- Low-Power Wireless Monitoring
- Environmental Monitoring
- Bridge and Structural Health Monitoring (SHM)
- Smart Building Controls
- Portable and Wearable Health Devices
- Entertainment System Remote Controls

3 Description
The TPS6273x family provides a highly integrated ultra low power buck converter solution that is well suited for meeting the special needs of ultra-low power applications such as energy harvesting. The TPS6273x provides the system with an externally programmable regulated supply to preserve the overall efficiency of the power-management stage compared to a linear step-down converter. This regulator is intended to step-down the voltage from an energy storage element such as a battery or super capacitor to supply the rail to low-voltage electronics. The regulated output has been optimized to provide high efficiency across low-output currents (<10 µA) to high currents (200 mA).

The TPS6273x integrates an optimized hysteretic controller for low-power applications. The internal circuitry uses a time-based sampling system to reduce the average quiescent current.

4 Revision History

Changes from Revision B (July 2013) to Revision C  Page

• Added ESD Ratings table, Feature Description section, Device Functional Modes, Application and Implementation
  section, Power Supply Recommendations section, Layout section, Device and Documentation Support section, and
  Mechanical, Packaging, and Orderable Information section. ................................................................. 1

Changes from Revision A (March 2013) to Revision B  Page

• Added the TPS62737 Pinout information ................................................................. 4
• Added graphs for TPS62737 to the Typical Characteristics......................................................... 13
• Added the TPS62737 Application Circuit ................................................................. 21
• Changed Figure 72 ................................................................................................... 28
• Added Figure 73 ................................................................. 28

Changes from Original (October 2012) to Revision A  Page

• Changed the device From: Preview To: Active ................................................................. 1
5 Description (continued)
To further assist users in the strict management of their energy budgets, the TPS6273x toggles the input power-good indicator to signal an attached microprocessor when the voltage on the input supply has dropped below a preset critical level. This signal is intended to trigger the reduction of load currents to prevent the system from entering an undervoltage condition. In addition, independent enable signals allow the system to control whether the converter is regulating the output, monitoring only the input voltage, or to shut down in an ultra-low quiescent sleep state.

The input power-good threshold and output regulator levels are programmed independently through external resistors.

All the capabilities of TPS6273x are packed into a small footprint 14-lead 3.5-mm × 3.5-mm QFN package (RGY).

(1) Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions beyond those indicated under Recommended Operating Conditions is not implied. Exposure to absolute–maximum–rated conditions for extended periods may affect device reliability.

(2) All voltage values are with respect to VSS/ground terminal

8.2 Handling Ratings

9 Detailed Description

9.1 Overview

The TPS6273x family provides a highly integrated ultra low power buck converter solution that is well suited for meeting the special needs of ultra-low power applications such as energy harvesting. The TPS6273x provides the system with an externally programmable regulated supply in order to preserve the overall efficiency of the power-management stage compared to a linear step down converter. This regulator is intended to step-down the voltage from an energy storage element such as a battery or super capacitor in order to supply the rail to low-voltage electronics. The regulated output has been optimized to provide high efficiency across low-output currents (<10 µA) to high currents (200 mA).

The TPS6273x integrates an optimized hysteretic controller for low-power applications. The internal circuitry uses a time-based sampling system to reduce the average quiescent current.

9.2 Functional Block Diagram

9.3 Feature Description

9.3.1 Step-Down (Buck) Converter Operation

The buck regulator in the TPS6273x takes input power from VIN, steps it down and provides a regulated voltage at the OUT pin. It employs pulse frequency modulation (PFM) control to regulate the voltage close to the desired reference voltage. The reference voltage is set by the user programmed resistor divider. The current through the inductor is controlled through internal current sense circuitry. The peak current in the inductor is controlled to maintain high efficiency of the converter across a wide input current range. The TPS62736 converter delivers an average output current of 50 mA with a peak inductor current of 100 mA. The TPS62737 converter delivers an average output current of 200 mA with a peak inductor current of 370 mA. The buck regulator is disabled when
Feature Description (continued)

the voltage on VIN reaches the UVLO condition. The UVLO level is continuously monitored. The buck regulator continues to operate in pass (100% duty cycle) mode, passing the input voltage to the output, as long as VIN is greater than UVLO and less than VIN minus \( I_{\text{OUT}} \times R_{\text{DS(on)-HS}} \). In order to save power from being dissipated through other ICs on this supply rail while allowing for a faster wake up time, the buck regulator can be enabled and disabled through the EN2 pin for systems that desire to completely turn off the regulated output.

9.3.2 Programming OUT Regulation Voltage and VIN_OK

To set the proper output-regulation voltage and input voltage power-good comparator, the external resistors must be carefully selected. Figure 62 illustrates an application diagram which uses the minimal resistor count for setting both VOUT and VIN_OK. Note that VBIAS is nominally 1.21 V per the electrical specification table. Referring to Figure 52, the OUT DC set point is given by Equation 1.

\[
\text{VOUT} = \frac{R_1 + R_2 + R_3}{R_1 + R_2}
\]

(1)

The VIN_OK setting is given by Equation 2.

\[
\text{VIN_OK} = \frac{R_1 + R_2 + R_3}{R_1}
\]

(2)

The sum of the resistors is recommended to be no greater than 13 M\(\Omega\), that is, \( R_{\text{SUM}} = R_1 + R_2 + R_3 = 13 \, \text{M}\Omega \). Due to the sampling operation of the output resistors, lowering \( R_{\text{SUM}} \) only increases quiescent current slightly as can be seen in Figure 22. Higher resistors may result in poor output voltage regulation and/or input voltage power-good threshold accuracies due to noise pickup through the high-impedance pins or reduction of effective resistance due to parasitic resistance created from board assembly residue. See Layout for more details.

If it is preferred to separate the VOUT and VIN_OK resistor strings, two separate strings of resistors could be used as shown in Figure 62. The OUT DC set point is then given by Equation 3.

\[
\text{VOUT} = \frac{R_3 + R_4}{R_4}
\]

(3)

The VIN_OK setting is then given by Equation 4.

\[
\text{VIN_OK} = \frac{R_1 + R_2}{R_1}
\]

(4)

If it is preferred to disable the VIN_OK setting, the VIN_OK_SET pin can be tied to VIN. To set VOUT in this configuration, use Equation 3. To tighten the DC set point accuracy, use external resistors with better than 1% resistor tolerance. Because output voltage ripple has a large effect on input line regulation and the output load regulation, using a larger output capacitor will improve both line and load regulation.

9.3.3 Nano-Power Management and Efficiency

The high efficiency of the TPS6273x is achieved through the proprietary Nano-Power management circuitry and algorithm. This feature essentially samples and holds all references in order to reduce the average quiescent current. That is, the internal circuitry is only active for a short period of time and then off for the remaining period of time at the lowest feasible duty cycle. A portion of this feature can be observed in Figure 66 where the VRDIV node is monitored. Here, the VRDIV node provides a connection to the input (larger voltage level) and generates the output reference (lower-voltage level) for a short period of time. The divided down value of input voltage is compared to VBIAS and the output voltage reference is sampled and held to get the VOUT_SET point. Because this biases a resistor string, the current through these resistors is only active when the Nano-Power management circuitry makes the connection — hence, reducing the overall quiescent current due to the resistors. This process repeats every 64 ms. Similarly, the VIN_OK level is monitored every 64 ms, as shown in Figure 55.
Feature Description (continued)

The efficiency versus output current and efficiency versus input voltage are plotted for three different output voltages for both the TPS62736 and TPS62737 devices in Typical Characteristics. All data points were captured by averaging the overall input current. This must be done, due to the periodic biasing scheme implemented through the Nano-Power management circuitry. The input current efficiency data was gathered using a source meter set to average over at least 25 samples and at the highest accuracy sampling rate. Each data point takes a long period of time to gather in order to properly measure the resulting input current when calculating the efficiency.

9.4 Device Functional Modes

9.4.1 Enable Controls

There are two enable pins implemented in the TPS6273x in order to maximize the flexibility of control for the system. The EN1 pin is considered to be the chip enable. If EN1 is set to a 1 then the entire chip is placed into ship mode. If EN1 is 0 then the chip is enabled. EN2 enables and disables the switching of the buck converter. When EN2 is low, the internal circuitry remains ON and the VIN_OK indicator still functions. This can be used to disable down-stream electronics in case of a low input-supply condition. When EN2 is 1, the buck converter operates normally.

</tr>
<tr>
<td>1</td>
<td>x</td>
<td>Full standby mode. Switching converter and VIN_OK indication is off (ship mode)</td>
</tr>
</tbody>
</table>

9.4.2 Startup Behavior

The TPS6273x has two startup responses: 1) from the ship-mode state (EN1 transitions from high to low), and 2) from the standby state (EN2 transitions from low to high). The first startup response out of the ship-mode state has the longest time duration due to the internal circuitry being disabled. This response is shown in Figure 70 for the TPS62736 and Figure 60 for the TPS62737. The startup time takes approximately 100 ms due to the internal Nano-Power management circuitry needing to complete the 64 ms sample and hold cycle.

Startup from the standby state is shown in Figure 71 for the TPS62736 and Figure 61 for the TPS62737. This response is much faster due to the internal circuitry being pre-enabled. The startup time from this state is entirely dependent on the size of the output capacitor. The larger the capacitor, the longer it will take to charge during startup. The TPS6273x can startup into a prebiased output voltage.
10 Application and Implementation

NOTE
Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

10.1 Application Information
The TPS62736/7 are step down DC-DC converters. Their low quiescent currents make them ideal for battery powered systems that are operated at low duty cycles in order to achieve low total power levels.

10.2 Typical Applications

10.2.1 TPS62737 3-Resistor Typical Application Circuit

![Diagram of TPS62737 3-Resistor Typical Application Circuit]

10.2.1.1 Design Requirements
A 1.8-V, up to 200 mA regulated power rail is needed. The VIN_OK comparator should indicate when the input voltage drops below 2.9 V. No large load transients are expected.

10.2.1.2 Detailed Design Procedure
The recommended 10-µH inductor (TOKO DFE252012C) and 22-µF input capacitor are used. Since no large load transients are expected, the minimum 22-µF output capacitor is used. Had a large load transient been expected, we would have sized the capacitor using \( \text{ITRAN} = \frac{\text{COUT} \times \Delta \text{VOUT}}{\Delta \text{TIME}} \) where \( \Delta \text{VOUT} \) is amount of VOUT droop allowed for the time of the transient.

First set \( \text{RSUM} = R_1 + R_2 + R_3 = 13 \text{ MΩ} \) then solve Equation 2 for \( R_1 = \text{VBIAS} \times \text{RSUM} / \text{VIN_OK} = 1.21 \text{ V} \times 13 \text{ MΩ} / 2.9 \text{ V} = 5.42 \text{ MΩ} \rightarrow 5.49 \text{ MΩ} \) as the closest 1 % resistor.
Typical Applications (continued)

Then solve Equation 2 for $R_2 = V_{BIAS} \times R_{SUM} / V_{OUT} - R_1 = 1.21 \text{ V} \times 13 \text{ M} \Omega / 1.8 \text{ V} - 5.42 \text{ M} \Omega = 3.32 \text{ M} \Omega \rightarrow 3.4 \text{ M} \Omega$ as the closest 1% resistor.

Finally $R_3 = R_{SUM} - R_1 - R_2 = 13 \text{ M} \Omega - 5.42 \text{ M} \Omega - 3.32 \text{ M} \Omega = 4.26 \text{ M} \Omega \rightarrow 4.32 \text{ M} \Omega$ as the closest 1% resistor.

These values yield $V_{OUT} = 1.79 \text{ V}$ and $V_{IN\_OK\ threshold} = 2.91 \text{ V}$.

If using 4 resistors, see Resistor Selection for guidance on sizing the resistors.

10.2.1.2.1 Inductor Selection

The internal-control circuitry is designed to control the switching behavior with a nominal inductance of 10 µH ± 20%. The saturation current of the inductor should be at least 25% higher than the maximum cycle-by-cycle current limit per the electrical specs table ($I_{LIM}$) in order to account for load transients. Because this device is a hysteretic controller, it is a naturally stable system (single order transfer function). However, the smaller the inductor value is, the faster the switching currents are. The speed of the peak current detect circuit sets the inductor of the TPS62736 lower bound to 4.7 µH. When using a 4.7 µH, the peak inductor current will increase when compared to that of a 10-µH inductor. The steady-state operation with a 4.7-µH inductor with a 50-mA load for the TPS62736 is shown in Figure 65.

A list of inductors recommended for this device is shown in Table 4.

10.2.1.2.2 Output Capacitor Selection

The output capacitor is chosen based on transient response behavior and ripple magnitude. The lower the capacitor value, the larger the ripple will become and the larger the droop will be in the case of a transient response. It is recommended to use at least a 22-µF output capacitor for most applications.

10.2.1.2.3 Input Capacitor Selection

The bulk input capacitance is recommended to be a minimum of 4.7 µF ± 20% for the TPS62736 and 22 µF ± 20% for the TPS62737. This bulk capacitance is used to suppress the lower frequency transients produced by the switching converter. There is no upper bound to the input-bulk capacitance. In addition, a high-frequency bypass capacitor of 0.1 µF is recommended in parallel with the bulk capacitor. The high-frequency bypass is used to suppress the high-frequency transients produced by the switching converter.

10.2.1.2.4 Resistor Selection

Equation 1 to Equation 4 are the equations for sizing the external resistors to set the $V_{IN\_OK\ threshold}$ and $V_{OUT}$ regulation value. The spreadsheet at SLVC489 can help size the external resistors.

**Figure 61. Standby-Mode Startup Behavior**
10.2.2 **TPS62736 4-Resistor Typical Application Circuit**

![Diagram of TPS62736 4-Resistor Typical Application Circuit](image)

**10.2.2.1 Design Requirements**

A 2.5-V, up to 50-mA regulated power rail is needed. The VIN_OK comparator should indicate when the input voltage drops below 2.9 V. No large load transients are expected.

**10.2.2.2 Detailed Design Procedure**

The recommended 10-µH inductor (TOKO DFE252012C) and 4.7-µF input capacitor are used. Since no large load transients are expected, the minimum 22-µF output capacitor is used. Had a large load transient been expected, we would have sized the capacitor using $I_{TRAN} = C_{OUT} \times \Delta V_{OUT} / \Delta \text{TIME}$ where $\Delta V_{OUT}$ is amount of VOUT droop allowed for the time of the transient.

First set $R_{SUM} = R_1 + R_2 + R_3 + R_4 = 13 \, \Omega$ then solve Equation 4 for $R_1 = V_{BIAS} \times R_{SUM} / VIN_{OK} = 1.21 \, \text{V} \times 13 \, \text{M} \Omega / 2.9 \, \text{V} = 5.42 \, \text{M} \Omega \rightarrow 5.36 \, \text{M} \Omega$ as the closest 1% resistor.

Then $R_2 = R_{SUM} - R_1 = 13 \, \text{M} \Omega - 5.42 \, \text{M} \Omega = 7.58 \, \text{M} \Omega \rightarrow 7.5 \, \text{M} \Omega$ as the closest 1% resistor.

Solve Equation 3 for $R_4 = V_{BIAS} \times R_{SUM} / VOUT = 1.21 \, \text{V} \times 13 \, \text{M} \Omega / 2.5 \, \text{V} = 6.29 \, \text{M} \Omega \rightarrow 6.34 \, \text{M} \Omega$ as the closest 1% resistor.

Finally $R_3 = R_{SUM} - R_3 = 13 \, \text{M} \Omega - 6.29 \, \text{M} \Omega = 6.71 \, \text{M} \Omega \rightarrow 6.81 \, \text{M} \Omega$ as the closest 1% resistor.

These values yield $VOUT = 2.51 \, \text{V}$ and $VIN_{OK}$ threshold $= 2.90 \, \text{V}$.

If using 3 resistors, see *Resistor Selection* for guidance on sizing the resistors.

11 Power Supply Recommendations

The TPS62736 / 7 ICs require a low impedance power source (e.g. battery, wall adapter) capable of providing between 2.0 V and 5.5 V and up to 100 mA / 370 mA respectively. When the voltage at IN is less than or equal to VOUT, the IC stops switching, turns on the high side FET and provides VOUT = VIN - ILOAD x RDS(on)-HighSideFET.

12 Layout

12.1 Layout Guidelines

To minimize switching noise generation, the step-down converter (buck) power stage external components must be carefully placed. The most critical external component for a buck power stage is its input capacitor. The bulk input capacitor (C_IN1) and high frequency decoupling capacitor (C_IN2) must be placed as close as possible between the power stage input (IN pin 1) and ground (VSS pin 12). Next, the inductor (L1) must be placed as close as possible between the switching node (SW pin 13) and the output voltage (OUT pin 11). Finally, the output capacitor (C_OUT) should be placed as close as possible between the output voltage (OUT pin 11) and GND (VSS pin 12). In the diagram below, the input and output capacitor grounds are connected to VSS pin 12 through vias to the bottom-layer ground plane of the PCB.

To minimize noise pickup by the high impedance voltage setting nodes (VIN_OK_SET pin 8 and VOUT_SET pin 9), the external resistors (R1, R2 and R3) should be placed so that the traces connecting the midpoints of the string are as short as possible. In the diagram below, the connection to VOUT_SET is by a bottom layer trace.

The remaining pins are either NC pins, that should be connected to the PowerPAD™ as shown below, or digital signals with minimal layout restrictions.

In order to maximize efficiency at light load, the use of voltage level setting resistors > 1 MΩ is recommended. However, during board assembly, contaminants such as solder flux and even some board cleaning agents can leave residue that may form parasitic resistors across the physical resistors and/or from one end of a resistor to ground, especially in humid, fast airflow environments. This can result in the voltage regulation and threshold levels changing significantly from those expected per the installed resistor values. Therefore, it is highly recommended that no ground planes be poured near the voltage setting resistors. In addition, the boards must be carefully cleaned, possibly rotated at least once during cleaning, and then rinsed with de-ionized water until the ionic contamination of that water is well above 50 MΩ. If this is not feasible, then it is recommended that the sum of the voltage setting resistors be reduced to at least 5 times below the measured ionic contamination.

12.2 Layout Example

13.3 Trademarks
PowerPAD is a trademark of Texas Instruments. All other trademarks are the property of their respective owners.

13.4 Electrostatic Discharge Caution
These devices have limited built-in ESD protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

13.5 Glossary
SLYZ022 — TI Glossary.
This glossary lists and explains terms, acronyms, and definitions.

14 Mechanical, Packaging, and Orderable Information
The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

(1) The marketing status values are defined as follows:
- **ACTIVE**: Product device recommended for new designs.
- **LIFEBUY**: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
- **NRND**: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
- **PREVIEW**: Device has been announced but is not in production. Samples may or may not be available.
- **OBSOLETE**: TI has discontinued the production of the device.

(2) **RoHS**: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".
- **RoHS Exempt**: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.
- **Green**: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) **MSL, Peak Temp. -** The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) **Important Information and Disclaimer**: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and
continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

*All dimensions are nominal*
NOTES:
A. All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5M–1994.
B. This drawing is subject to change without notice.
C. OFN (Quad Flatpack No–Lead) package configuration.
D. The package thermal pad must be soldered to the board for thermal and mechanical performance.
E. See the additional figure in the Product Data Sheet for details regarding the exposed thermal pad features and dimensions.
\[\text{Pin 1 Index Area Top and Bottom}\]
\[\text{0.20 Nominal Lead Frame}\]
\[\text{Sealing Plane}\]
\[\text{0.05 0.00 Sealing Height}\]
\[\text{0.50 0.30}\]
\[\text{1.50}\]
\[\text{THERMAL PAD}\]
\[\text{SIZE AND SHAPE SHOWN ON PERMANENT SHEET}\]
\[\text{14x 0.30 0.18}\]
\[\text{0.10 0.05 C A B}\]

Pin 1 identifiers are located on both top and bottom of the package and within the zone indicated.

The Pin 1 identifiers are either a molded, marked, or metal feature.

G. Package complies to JEDEC MO-241 variation BA.
THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal Pasting, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

![Exposed Thermal Pad Dimensions](image)

NOTE: All linear dimensions are in millimeters
NOTES:
A. All linear dimensions are in millimeters.
B. This drawing is subject to change without notice.
C. Publication IPC–7351 is recommended for alternate designs.
D. This package is designed to be soldered to a thermal pad on the board. Refer to Application Note, Quad Flat-Pack QFN/SOIC PCB Attachment, Texas Instruments Literature No. SLUA271, and also the Product Data Sheets for specific thermal information, via requirements, and recommended board layout. These documents are available at www.ti.com (http://www.ti.com).
E. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Refer to IPC 7525 for stencil design considerations.
F. Customers should contact their board fabrication site for minimum solder mask web tolerances between signal pads.
IMPORTANT NOTICE AND DISCLAIMER
