1 Features

- Generates Positive and Negative Gates, and Source Driver Voltages and Back-Plane Bias From a Single, Low-Voltage Input Supply
- Supports 9.7-Inch and Larger Panel Sizes
- 3-V to 6-V Input Voltage Range
- Boost Converter for Positive Rail Base
- Inverting Buck-Boost Converter for Negative Rail Base
- Two Adjustable LDOs for Source Driver Supply
  - TPS65185 LDO1: 15 V, 120 mA (VPOS)
  - TPS65185 LDO2: –15 V, 120 mA (VNEG)
  - TPS651851 LDO1: 15 V, 200 mA at $V_{IN} \geq 3.6$ V (VPOS)
  - TPS651851 LDO2: –15 V, 200 mA at $V_{IN} \geq 3.6$ V (VNEG)
- Accurate Output Voltage Tracking
  - VPOS – VNEG = ±50 mV
- Two Charge Pumps for Gate Driver Supply
  - CP1: 22 V, 15 mA (VDDH)
  - CP2: –20 V, 15 mA, (VEE)
- Adjustable VCOM Driver for Accurate Panel-Backplane Biasing
  - 0 V to –5.11 V
  - ± 1.5% accuracy (±10 mV)
  - 9-Bit Control (10-mV Nominal Step Size)
- Active Discharge on All Rails
- Integrated 10-Ω, 3.3-V Power Switch for Disabling System Power Rail to E-Ink Panel

2 Applications

- Power Supply for Active Matrix E Ink Vizplex Panels
- Electronic Paper Display (EPD) Power Supplies
- E-Book Readers
- Dual-Display Phone and Tablets
- Application Processors With Integrated or Software Timing Controller (OMAP™)

3 Description

The TPS65185x device is a single-chip power supply designed to for E Ink Vizplex displays used in portable e-reader applications, and the device supports panel sizes up to 9.7 inches and greater. Two high efficiency DC-DC boost converters generate ±16-V rails that are boosted to 22 V and –20 V by two change pumps to provide the gate driver supply for the Vizplex panel. Two tracking LDOs create the ±15-V source driver supplies that support up to 120/200 mA (TPS65185/TPS651851) of output current. All rails are adjustable through the I²C interface to accommodate specific panel requirements.

4 Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

Changes from Revision F (June 2017) to Revision G

- Added the load switch and updated the negative and positive charge pumps in the Typical Application Schematic figure. 1
- Added capacitor connection to the pin description for INT_LDO, VB, VCOM, VCOM_PWR, VDDH_D, VEE_D, VIN, VIN_P, VN, VNEG, VNEG_IN, VPOS, VPOS_IN, VREF in the Pin Functions table. 5
- Changed the Power-Up and Power-Down Timing Diagram. 13
- Changed the Functional Block Diagram. 18
- Changed the schematic in the Typical Application section. 49

Changes from Revision E (February 2017) to Revision F

- Updated pin out drawing to match Pin Functions table. 4

Changes from Revision D (December 2016) to Revision E

- Changed the maximum input voltage for TPS651851 from 5.9 V to 6 V. 7
- Changed the V_IN range to the V_OUT and V_DIFF parameters in the Electrical Characteristics table. 9
- Changed the Electrostatic Discharge Caution statement. 53

Changes from Revision C (August 2015) to Revision D

- Added TPS651851 device to the data sheet. 1
- Added the input voltage range for TPS651851. 1
- Added TPS651851 LDO1 and LDO2 current limit of 200 mA. 1
- Updated the switch current limit to 2.5 A on DCDC1 for TPS651851. 8
- Updated the LDO1 ILOAD current limit for TPS651851. 9
- Updated the LDO1 ILIMIT current limit for TPS651851. 9
• Updated the LDO2 ILOAD current range for different VIN conditions ................................................................. 9
• Updated the LDO2 ILIMIT output current limit to different VIN conditions .......................................................... 9
• Updated the output voltage range (VDDH_OUT) conditions on charge pump 1 ...................................................... 10
• Added the ILOAD current range option for TPS651851 on CP1 ........................................................................ 10
• Added the ILOAD current range option for TPS651851 on CP2 ........................................................................ 10
• Added Receiving Notification of Documentation Updates to Device and Documentation Support section .......... 53

Changes from Revision B (October 2011) to Revision C

Page
• Added ESD Ratings table, Feature Description section, Device Functional Modes, Application and Implementation section, Power Supply Recommendations section, Layout section, Device and Documentation Support section, and Mechanical, Packaging, and Orderable Information section ........................................................................................................ 1
5  Description (continued)
Accurate back-plane biasing is provided by a linear amplifier that can be adjusted from 0 V to –5.11 V with 9-bit control through the serial interface; it can source or sink current depending on panel condition. The TPS65185x supports automatic panel kickback voltage measurement, which eliminates the need for manual VCOM calibration in the production line. The measurement result can be stored in non-volatile memory to become the new VCOM power-up default value.

TPS65185 is available in two packages, a 48-pin 7-mm × 7-mm VQFN (RGZ) with 0.5-mm pitch, and a 48-pin 6-mm × 6-mm VQFN (RSL) with 0.4-mm pitch. The TPS651851 is available in a 48-pin 6-mm × 6-mm VQFN (RSL) with 0.4-mm pitch.

</tr>
</tbody>
</table>

(1) Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under Recommended Operating Conditions is not implied. Exposure to absolute maximum rated conditions for extended periods may affect device reliability.

(2) All voltage values are with respect to network ground terminal.

(3) It is recommended that copper plane in proper size on board be in contact with die thermal pad to dissipate heat efficiently. Thermal pad is electrically connected to PBKG, which is supposed to be tied to the output of buck-boost converter. Thus wide copper trace in the buck-boost output will help heat dissipated efficiently.

7.2 ESD Ratings

<table>
<thead>
<tr>
<th>VALUE</th>

<tr>
<td>Charged-device model (CDM), per JEDEC specification JESD22-C101(^{(2)})</td>
<td>±500</td>
</tr>
</tbody>
</table>

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.

(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

![Figure 1. I²C Data Transmission Timing](image-url)
(1) Minimum delay time between WAKEUP rising edge and IC ready to accept I²C transaction.

(2) The device does not enter the SLEEP state until the final discharge delay time has elapsed.

Note: In this example, the first power-up sequence is started by pulling the PWRUP pin high (rising edge). Power-down is initiated by pulling the WAKEUP pin low (device enters sleep mode after rails are discharged). The second power-up sequence is initiated by pulling the WAKEUP pin high while the PWRUP pin is also high (power up from sleep to active).

8 Detailed Description

8.1 Overview

The TPS65185x device provides two adjustable LDOs, inverting buck-boost converter, boost converter, thermistor monitoring, and flexible power-up and power-down sequencing. The system can be supplied by a regulated input voltage ranging from 3 V to 6 V. The device is characterized across a –10°C to 85°C temperature range, best suited for personal electronic applications.

The I²C interface provides comprehensive features for using the TPS65185x. All rails can be enabled or disabled. Power-up and power-down sequences can also be programmed through the I²C interface, as well as thermistor configuration and interrupt configuration. Voltage adjustment can also be controlled by the I²C interface.

The adjustable LDOs can supply up to 120 mA (TPS65185) and 200 mA (TPS651851) of current. The default output voltages for each LDO can be adjusted through the I²C interface. LDO1 (VPOS) and LDO2 (VNEG) track each other in a way that they are of opposite sign but same magnitude. The sum of VLDO1 and VLOD2 is specified to be less than 50 mV.

There are two charge pumps: where VDDH and VEE are 10 mA and 12 mA (TPS65185) and VDDH and VEE are 15 mA and 15 mA (TPS651851) respectively. These charge pumps boost the DC-DC boost converters ±16-V rails to provide a gate channel supply.

The power good functionality is open-drain output, if any of the four power rails (CP1, CP2, LDO1, LDO2) are not in regulation, encounters a fault, or is disabled the pin is pulled low. PWR_GOOD remains low if one of the rails is not enabled by the host and only after all rails are in regulation PWR_GOOD is released to HiZ state (pulled up by external resistor).

The TPS65185x provides circuitry to bias and measure an external NTC to monitor the display panel temperature in a range from –10°C to 85°C with and accuracy of ±1°C from 0°C to 50°C. Temperature measurement are triggered by the controlling host and the last temperature reading is always stored in the TMST_VALUE register. Interrupts are issued when the temperature exceeds the programmable HOT, or drops below the programmable COLD threshold, or when the temperature has changed by more than a user-defined threshold from the baseline value.

This device has the following two package options:
- TPS65185: 48-Pin, 0.5-mm Pitch, 7 mm × 7 mm × 0.9 mm (QFN) RGZ
- TPS65185 and TPS651851: 48-Pin, 0.4 mm Pitch, 6 mm × 6 mm × 0.9 mm (QFN) RSL
8.2 Functional Block Diagram
8.3 Feature Description

8.3.1 Wake-Up and Power-Up Sequencing

The power-up and power-down order and timing is defined by user register settings. The default settings support the E Ink Vizplex panel and typically do not need to be changed.

In SLEEP mode the TPS65185x is completely turned off, the I₂C registers are reset, and the device does not accept any I₂C transaction. Pull the WAKEUP pin high with the PWRUP pin low and the device enters STANDBY mode which enables the I₂C interface. Write to the UPSEQ0 register to define the order in which the output rails are enabled at power-up and to the UPSEQ1 registers to define the power-up delays between rails. Finally, set the ACTIVE bit in the ENABLE register to 1 to execute the power-up sequence and bring up all power rails. Alternatively pull the PWRUP pin high (rising edge).

After the ACTIVE bit has been set, the negative boost converter (VN) is powered up first, followed by the positive boost (VB). The positive boost enable is gated by the internal power-good signal of the negative boost. Once VB is in regulation, it issues an internal power-good signal and after delay time UDLY1 has expired, STROBE1 is issued. The rail assigned to STROBE1 will power up next and after its power-good signal has been asserted and delay time UDLY2 has expired, STROBE2 is issued. The sequence continues until STROBE4 has occurred and the last rail has been enabled.

To power down the device, set the STANDBY bit of the ENABLE register to 1 or pull the PWRUP pin low (falling edge) and the TPS65185x will power down in the order defined by DWNSEQx registers. The delay times DDLY2, DDLY3, and DDLY4 are weighted by a factor of DFCTR which allows the user to space out the power down of the rails to avoid crossing during discharge. DFCTR is located in register DWNSEQ1. The positive boost (VB) is shut down together with the last rail at STROBE4. However, the negative boost (VN) remains up and running for another 100 ms (discharge delay) to allow complete discharge of all rails. After the discharge delay, VN is powered down and the device enters STANDBY or SLEEP mode, depending on the WAKEUP pin.

If either the ACTIVE bit is set or the PWRUP pin is pulled high while the device is powering down, the power-down sequence (STROBE1-4) is completed first, followed by a power-up sequence. VB and VN may or may not be powered down and the discharge delay may be cut short depending on the relative timing of STROBE4 to the new power-up event.

During power-up, if the STANDBY bit is set or the PWRUP pin is pulled low, the power-up sequence is aborted and the power-down sequence starts immediately.

8.3.2 Dependencies Between Rails

Charge pumps, LDOs, and VCOM driver are dependent on the positive and inverting buck-boost converters and several dependencies exist that affect the power-up sequencing. These dependencies are listed below.

- Inverting buck-boost (DCDC2) must be in regulation before positive boost (DCDC1) can be enabled. Internally, DCDC1 enable is gated by DCDC2 power good.
- Positive boost (DCDC1) must be in regulation before LDO2 (VNEG) can be enabled. Internally LDO2 enable is gated DCDC1 power-good.
- Positive boost (DCDC1) must be in regulation before VCOM can be enabled. Internally VCOM enable is gated by DCDC1 power good.
- Positive boost (DCDC1) must be in regulation before negative charge pump (CP2) can be enabled. Internally CP2 enable is gated by DCDC1 power good.
- Positive boost (DCDC1) must be in regulation before positive charge pump (CP1) can be enabled. Internally CP1 enable is gated by DCDC1 power good.
- LDO2 must be in regulation before LDO1 can be enabled. Internally LDO1 enable is gated by LDO2 power good.
Feature Description (continued)

TOP: Power-up sequence is defined by assigning strobes to individual rails. STROBE1 is the first strobe to occur after ACTIVE bit is set and STROBE4 is the last event in the sequence. Strobes are assigned to rails in UPSEQ0 register and delays between STROBES are defined in UPSEQ1 register.

BOTTOM: Power-down sequence is independent of power-up sequence. Strobes and delay times for power down sequence are set in DWNSEQ0 and DWNSEQ1 register.

Figure 20. Power-Up and Power-Down Sequence

8.3.3 Soft Start
TPS65185x supports soft start for all rails, that is, inrush current is limited during startup of DCDC1, DCDC2, LDO1, LDO2, CP1 and CP2. If DCDC1 or DCDC2 are unable to reach power-good status within 50 ms, the corresponding UV flag is set in the interrupt registers, the interrupt pin is pulled low, and the device enters STANDBY mode. LDO1, LDO2, positive and negative charge pumps also have a 50-ms power-good time-out limit. If either rail is unable to power up within 50 ms after it has been enabled, the corresponding UV flag is set and the interrupt pin is pulled low. However, the device will remain in ACTIVE mode in this case.

8.3.4 Active Discharge
TPS65185x provides low-impedance discharge paths for the display power rails (VEE, VNEG, VPOS, VDDH, and VCOM) which are enabled whenever the corresponding rail is disabled. The discharge paths are connected to the rails on the PCB which allows adding external resistors to customize the discharge time. However, external resistors are not required.
Feature Description (continued)

Active discharge remains enabled for 100 ms after the last rail has been disabled (STROBE4 has been executed). During this time the negative boost converter (VN) remains up. After the discharge delay, VN is shut down and the device enters STANDBY or SLEEP mode, depending on the state of the WAKEUP pin.

8.3.5 VPOS/VNEG Supply Tracking

LDO1 (VPOS) and LDO2 (VNEG) track each other in a way that they are of opposite sign but same magnitude. The sum of VLDO1 and VLOD2 is specified to be < 50 mV.

8.3.6 V3P3 Power Switch

The integrated power switch is used to cut the 3.3-V supply to the EPD panel and is controlled through the V3P3_EN pin of the ENABLE register. In SLEEP mode the switch is automatically turned off and its output is discharged to ground. The default power-up state is OFF. To turn the switch ON, set the V3P3_EN bit to 1.

8.3.7 VCOM Adjustment

VCOM is the output of a power-amplifier with an output voltage range of 0 V to –5.11 V, adjustable in 10-mV steps. In a typical application VCOM is connected to the VCOM terminal of the EPD panel and the amplifier is controlled through the VCOM_CTRL pin. With VCOM_CTRL high, the amplifier drives the VCOM pin to the voltage specified by the VCOM1 and VCOM2 register. When pulled low, the amplifier turns off and VCOM is actively discharged to ground through VCOM_DIS pin. If active discharge is not desired, simply leave the VCOM_DIS pin open.

For ease of design, the VCOM_CTRL pin may also be tied to the battery or IO supply. In this case, VCOM is enabled with STROBE4 during the power-up sequence and disabled on STROBE1 of the power-down sequence. Therefore VCOM is the last rail to be enabled and the first to be disabled.

8.3.7.1 Kick-Back Voltage Measurement

TPS65185x can perform a voltage measurement on the VCOM pin to determine the kick-back voltage of the panel. This allows in-system calibration of VCOM. To perform a kick-back voltage measurement, follow these steps:

- Pull the WAKEUP pin and the PWRUP pin high to enable all output rails.
- Set the HiZ bit in the VCOM2 register. This puts the VCOM pin in a high-impedance state.
- Drive the panel with the Null waveform. Refer to E-Ink specification for detail.
- Set the ACQ bit in the VCOM2 register to 1. This starts the measurement routine.
- When the measurement is complete, the ACQC (Acquisition Complete) bit in the INT1 register is set and the nINT pin is pulled low.
- The measurement result is stored in the VCOM[8:0] bits of the VCOM1 and VCOM2 register.

The measurement result is not automatically programmed into nonvolatile memory. Changing the power-up default is described in the following paragraph.
Feature Description (continued)

8.3.7.2 Storing the VCOM Power-Up Default Value in Memory

The power-up default value of VCOM can be user-set and programmed into nonvolatile memory. To do so, write the default value to the VCOM[8:0] bits of the VCOM1 and VCOM2 register, then set the PROG bit in VCOM2 register to 1. First, all power rails are shut down, then the VCOM[8:0] value is committed to nonvolatile memory such that it becomes the new power-up default. Once programming is complete, the PRGC bit in the INT1 register is set and the nINT pin is pulled low. To verify that the new value has been saved properly, first write the VCOM[8:0] bits to 0x000h, then pull the WAKEUP pin low. After the WAKEUP pin is pulled back high, read the VCOM[8:0] bits to verify that the new default value is correct.

![Figure 21. Block Diagram of VCOM Circuit](image-url)
Feature Description (continued)

- **Setup**
  - Pull WAKEUP= HIGH
  - Pull PWRUP= HIGH
  - Write HiZ = 1
  - Device enters ACTIVE mode
  - All power rails are up except VCOM
  - VCOM pin is in HiZ state
  - Processor drives panel with NULL waveform

- **Measurement**
  - Write ACQ = 1
  - Starts A/D conversion
  - Wait for ACQC interrupt
  - Indicates A/D conversion is complete
  - If AVG[1:0] is <> 00, interrupt is issued
  - after all conversions are complete and
  - average has been calculated
  - Read result from VCOM/2 registers
  - Check result and decide to keep the
  - value or repeat measurement
  - Pull PWRUP= LOW
  - Write HiZ = 0
  - Device enters STANDBY mode

- **Programming**
  - Write PROG= 1
  - Starts the EEPROM programming cycle
  - Power must not be interrupted
  - Wait for PRGC interrupt
  - Indicates programming is complete

- **Verification**
  - Pull WAKEUP = LOW
  - Device enters SLEEP mode
  - Pull WAKEUP = HIGH
  - Device enters STANDBY mode
  - Read VCOM[8:0]
  - Compare against written value to
  - confirm new default has been
  - programmed correctly

*Figure 22. VCOM Calibration Flow*
Feature Description (continued)

8.3.8 Fault Handling And Recovery

The TPS65185x monitors input/output voltages and die temperature. The device will take action if operating conditions are outside normal limits when the following is encountered:

- Thermal Shutdown (TSD)
- Positive Boost Under Voltage (VB_UV)
- Inverting Buck-Boost Under Voltage (VN_UV)
- Input Undervoltage Lockout (UVLO)

It shuts down all power rails and enters STANDBY mode. Shut-down follows the order defined by DWNSEQx registers. The exception is VCOM fault which leads to immediate shutdown of all rails. Once a fault is detected, the PWR_GOOD and nINT pins are pulled low and the corresponding interrupt bit is set in the interrupt register. Power rails cannot be re-enabled unless the interrupt bits have been cleared by reading the INT1 and INT2 register. Alternatively, toggling the WAKEUP pin also resets the interrupt bits. As the PWRUP input is edge sensitive, the host must toggle the PWRUP pin to re-enable the rails through GPIO control, i.e. it must bring the PWRUP pin low before asserting it again. Alternatively, rails can be re-enabled through the I²C interface.

Whenever the TPS65185x encounters undervoltage on VNEG (VNEG_UV), VPOS (VPOS_UV), VEE (VEE_UV) or VDDH (VDDH_UV), rails are not shut down but the PWR_GOOD and nINT is pulled low with the corresponding interrupt bit set. The device remains in ACTIVE mode and recovers automatically once the fault has been removed.

8.3.9 Power Good Pin

The power good pin (PWR_GOOD) is an open-drain output that is pulled high (by an external pullup resistor) when all four power rails (CP1, CP2, LDO1, LDO2) are in regulation and is pulled low if any of the rails encounters a fault or is disabled. PWR_GOOD remains low if one of the rails is not enabled by the host and only after all rails are in regulation PWR_GOOD is released to HiZ state (pulled up by external resistor).

8.3.10 Interrupt Pin

The interrupt pin (nINT) is an open drain output that is pulled low whenever one or more of the INT1 or INT2 bits are set. The nINT pin is released (returns to HiZ state) and fault bits are cleared once the register with the set bit has been read by the host. If the fault persists, the nINT pin will be pulled low again after a maximum of 32 µs.

Interrupt events can be masked by resetting the corresponding enable bit in the INT_EN1 and INT_EN2 register, that is, the user can determine which events cause the nINT pin to be pulled low. The status of the enable bits affects the nINT pin only and has no effect on any of the protection and monitoring circuits or the INT1/INT2 bits themselves.

Persisting faults such as thermal shutdown can cause the nINT pin to be pulled low for an extended period of time which can keep the host in a loop trying to resolve the interrupt. If this behavior is not desired, set the corresponding mask bit after receiving the interrupt and keep polling the INT1 and INT2 register to see when the fault condition has disappeared. After the fault is resolved, unmask the interrupt bit again.

8.3.11 Panel Temperature Monitoring

The TPS65185x provides circuitry to bias and measure an external Negative Temperature Coefficient Resistor (NTC) to monitor the display panel temperature in a range from –10°C to 85°C with an accuracy of ±1°C from 0°C to 50°C. Temperature measurement must be triggered by the controlling host and the last temperature reading is always stored in the TMST_VALUE register. Interrupts are issued when the temperature exceeds the programmable HOT, or drops below the programmable COLD threshold, or when the temperature has changed by more than a user-defined threshold from the baseline value. Details are explained in Hot, Cold, and Temperature-Change Interrupts.
Feature Description (continued)

8.3.11.1 NTC Bias Circuit

Figure 23 below shows the block diagram of the NTC bias and measurement circuit. The NTC is biased from an internally generated 2.25-V reference voltage through an integrated 7.307-kΩ bias resistor. A 43-kΩ resistor is connected parallel to the NTC to linearize the temperature response curve. The circuit is designed to work with a nominal 10-kΩ NTC and achieves accuracy of ±1°C from 0°C to 50°C. The voltage drop across the NTC is digitized by a 10-bit SAR ADC and translated into an 8-bit two’s complement by digital per Table 1.

A temperature measurement is triggered by setting the READ_THERM bit of the TMST1 register to 1. During the A/D conversion the CONV_END bit of the TMST1 register reads 0, otherwise it reads 1. At the end of the A/D conversion the EOC bit in the INT2 register is set and the temperature value is available in the TMST_VALUE register.
8.3.11.2 Hot, Cold, and Temperature-Change Interrupts

Each temperature acquisition is compared against the programmable TMST_HOT and TMST_COLD thresholds and to the baseline temperature, to determine if the display is within allowed operating temperature range and if the temperature has changed by more than a user-defined threshold since the last update. The first temperature reading after the WAKEUP pin has been pulled high automatically becomes the baseline temperature. Any subsequent reading is compared against the baseline temperature. If the difference is equal or greater than the threshold value, an interrupt is issued (DTX bit in register INT1 is set to 1) and the latest value becomes the new baseline. If the difference is less than the threshold value, no action is taken. The threshold value is defined by DT[1:0] bits in the TMST1 register and has a default value of ±2°C. In summary:

- When the temperature is equal or less than the TMST_COLD[3:0] threshold, the TMST_COLD interrupt bit of the INT1 register is set, and the nINT pin is pulled low.
- When the temperature is greater than TMST_COLD but lower then TMST_HOT, no action is taken.
- When the temperature is equal or greater than the TMST_HOT[3:0] threshold, the TMST_HOT interrupt bit of the INT1 register is set, and the nINT pin is pulled low.
- If the last temperature is different from the baseline temperature by ±2°C (default) or more, the DTX interrupt bit of the INT1 register is set. The latest temperature becomes the new baseline temperature. By default the DTX interrupt is disabled, that is, the nINT pin is not pulled low unless the DTX_EN bit was previously set high.
- If the last temperature change is less than ±2°C (default), no action is taken.

8.3.11.3 Typical Application of the Temperature Monitor

In a typical application the temperature monitor and interrupts are used in the following manner:

- After the WAKEUP pin has been pulled high, the Application Processor (AP) writes 0x80h to the TMST1 register (address 0x0Dh). This starts the temperature measurement.
- The AP waits for the EOC interrupt. Alternatively the AP can poll the CONV_END bit in register TMST1. This will notify the AP that the A/D conversion is complete and the new temperature reading is available in the TMST_VALUE register (address 0x00h).
- The AP reads the temperature value from the TMST_VALUE register (address 0x00h).
- If the temperature changes by ±2°C (default) or more from the first reading, the processor is notified by the DTX interrupt. The A/P may or may not decide to select a different set of wave forms to drive the panel.
- If the temperature is outside the allowed operating range of the panel, the processor is notified by the THOT and TCOLD interrupts, respectively. It may or may not decide to continue with the page update.
- Once an overtemperature or undertemperature has been detected, the AP must reset the TMST_HOT_EN or TMST_COLD_EN bits, respectively, to avoid the nINT pin to be continuously pulled low. The TMST_HOT and TMST_COLD interrupt bits then must be polled continuously, to determine when the panel temperature recovers to the normal operating range. Once the temperature has recovered, the TMST_HOT_EN or TMST_COLD_EN bits must be set to 1 again and normal operation can resume.
8.4 Device Functional Modes

The TPS65185x has three modes of operation, SLEEP, STANDBY, and ACTIVE. SLEEP mode is the lowest-power mode in which all internal circuitry is turned off. In STANDBY, all power rails are shut down but the device is ready to accept commands through the I²C interface. In ACTIVE mode one or more power rails are enabled.

8.4.1 SLEEP

This is the lowest power mode of operation. All internal circuitry is turned off, registers are reset to default values and the device does not respond to I²C communications. TPS65185x enters SLEEP mode whenever WAKEUP pin is pulled low.

8.4.2 STANDBY

In STANDBY all internal support circuitry is powered up and the device is ready to accept commands through the I²C interface but none of the power rails are enabled. The device enters STANDBY mode when the WAKEUP pin is pulled high and either the PWRUP pin is pulled low or the STANDBY bit is set. The device also enters STANDBY mode if input UVLO, positive boost undervoltage (VB_UV), or inverting buck-boost undervoltage (VN_UV) is detected, thermal shutdown occurs, or the PROG bit is set (see Figure 22).

8.4.3 ACTIVE

The device is in ACTIVE mode when any of the output rails are enabled and no fault condition is present. This is the normal mode of operation while the device is powered up.

8.4.4 Mode Transitions

8.4.4.1 SLEEP → ACTIVE

WAKEUP pin is pulled high with PWRUP pin high. Rails come up in the order defined by the UPSEQx registers (OK to tie WAKEUP and PWRUP pin together).

8.4.4.2 SLEEP → STANDBY

WAKEUP pin is pulled high with PWRUP pin low. Rails will remain powered down.

8.4.4.3 STANDBY → ACTIVE

WAKEUP pin is high and PWRRUP pin is pulled high (rising edge) or the ACTIVE bit is set. Output rails will power up in the order defined by the UPSEQx registers.

8.4.4.4 ACTIVE → STANDBY

WAKEUP pin is high and STANDBY bit is set or PWRUP pin is pulled low (falling edge). Rails are shut down in the order defined by DWNSEQx registers. Device also enters STANDBY in the event of thermal shutdown (TSD), UVLO, positive boost or inverting buck-boost undervoltage (UV), VCOM fault (VCOMF), or when the PROG bit is set (see Figure 22).

8.4.4.5 STANDBY → SLEEP

WAKEUP pin is pulled low while none of the output rails are enabled.

8.4.4.6 ACTIVE → SLEEP

WAKEUP pin is pulled low while at least one output rail is enabled. Rails are shut down in the order defined by DWNSEQx registers.
Device Functional Modes (continued)

Figure 24. Global State Diagram
8.5 Programming

8.5.1 I²C Bus Operation

The TPS65185x hosts a slave I²C interface that supports data rates up to 400 kbit/s and auto-increment addressing and is compliant to I²C standard 3.0.

<table>
<thead>
<tr>

- **A** Acknowledge
- **A6 ... A0** Device Address
- **D7 ... D0** Data
- **R/nW** Read / not Write
- **P** Stop Condition
- **S7 ... S0** Sub-Address

**Figure 25. Subaddress in I²C Transmission**

The I²C Bus is a communications link between a controller and a series of slave terminals. The link is established using a two-wire bus consisting of a serial clock signal (SCL) and a serial data signal (SDA). The serial clock is sourced from the controller in all cases where the serial data line is bi-directional for data communication between the controller and the slave terminals. Each device has an open drain output to transmit data on the serial data line. An external pullup resistor must be placed on the serial data line to pull the drain output high during data transmission.

Data transmission is initiated with a start bit from the controller as shown in Figure 27. The start condition is recognized when the SDA line transitions from high to low during the high portion of the SCL signal. Upon reception of a start bit, the device will receive serial data on the SDA input and check for valid address and control information. If the appropriate slave address bits are set for the device, then the device will issue an acknowledge pulse and prepare to receive the register address. Depending on the R/nW bit, the next byte received from the master is written to the addressed register (R/nW = 0) or the device responds with 8-bit data from the register (R/nW = 1). Data transmission is completed by either the reception of a stop condition or the reception of the data word sent to the device. A stop condition is recognized as a low to high transition of the SDA input during the high portion of the SCL signal. All other transitions of the SDA line must occur during the low portion of the SCL signal. An acknowledge is issued after the reception of valid address, sub-address, and data words. The I²C interfaces will auto-sequence through register addresses, so that multiple data words can be sent for a given I²C transmission. See Figure 26 and Figure 27 for details.

9 Application and Implementation

NOTE
Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI’s customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information
The TPS65185x device is used to power display screens in E-book applications, specifically E-Ink Vizplex display, by connecting the screen to the positive and negative charge pump, LDO1, LDO2, and VCOM rails. The device supports display screens up to 9.7 inches.

9.2 Typical Application

![Figure 46. Typical Application Schematic](image-url)

Typical Application (continued)

9.2.1 Design Requirements
For this design example, use the parameters listed in Table 20 as the input parameters.

<table>
<thead>
<tr>
<th>VOLTAGE</th>
<th>SEQUENCE (STROBE)</th>

<td>15 V</td>
</tr>
<tr>
<td>VDDH (Charge pump 1)</td>
<td>22 V</td>
</tr>
</tbody>
</table>

9.2.2 Detailed Design Procedure
For the positive boost regulator (DCDC1) a 10-μF capacitor can be used as the input capacitor value; two 4.7-μF capacitors are used as output capacitors to reduce ESR along with a 2.2-μH inductor. For the inverting buck-boost regulator (DCDC2), a 10-μF capacitor can be used at the input capacitor value; two 4.7-μF capacitors are used as output capacitors to reduce ESR along with a 4.7-μH inductor. The charge pump pins VDDH_D and VEE_D require 100-nF capacitors to ground for reliable operation. An ESR capacitor with a value of 20 mΩ is expected for all capacitors, and ceramic X5R material or better is recommended. These values are the typical values used; additional inductor and capacitor values can be used for improved functionality; however, the components should be rated the same as the recommended external components listed in Table 21.

![Figure 50. VDDH Charge Pump Efficiency](image4)

10 Power Supply Recommendations

The device is designed to operate with an input voltage supply range from 3 V to 6 V, where Figure 5 and Figure 6 show how lower input supply voltages can result in larger inrush currents. This input supply can be from a externally regulated supply. If the input supply is located more than a few inches from the TPS65185x, additional bulk capacitance may be required in addition to the ceramic bypass capacitors. An electrolytic capacitor with a value of 10 µF is a typical choice.
11 Layout

11.1 Layout Guidelines
1. PBKG (Die substrate) must connect to VN (–16 V) with short, wide trace. Wide copper trace will improve heat dissipation.
2. The thermal pad is internally connected to PBKG and must not be connected to ground, but connected to VN with a short wide copper trace.
3. Inductor traces must be kept on the PCB top layer free of any vias.
4. Feedback traces must be routed away from any potential noise source to avoid coupling.
5. Output caps must be placed immediately at output pin.
6. The VIN pins must be bypassed to ground with low ESR ceramic bypass capacitors.

11.2 Layout Example

12 Device and Documentation Support

12.1 Device Support

12.1.1 Third-Party Products Disclaimer
TI’S PUBLICATION OF INFORMATION REGARDING THIRD-PARTY PRODUCTS OR SERVICES DOES NOT
CONSTITUTE AN ENDORSEMENT REGARDING THE SUITABILITY OF SUCH PRODUCTS OR SERVICES
OR A WARRANTY, REPRESENTATION OR ENDORSEMENT OF SUCH PRODUCTS OR SERVICES, EITHER
ALONE OR IN COMBINATION WITH ANY TI PRODUCT OR SERVICE.

12.2 Documentation Support

12.2.1 Related Documentation
For related documentation see the following:
• Texas Instruments, TPS65185 Evaluation Module user's guide
• Texas Instruments, Understanding Undervoltage Lockout in Display Power Devices application report

12.3 Receiving Notification of Documentation Updates
To receive notification of documentation updates, navigate to the device product folder on ti.com. In the upper
right corner, click on Alert me to register and receive a weekly digest of any product information that has
changed. For change details, review the revision history included in any revised document.

12.4 Community Resources
The following links connect to TI community resources. Linked contents are provided "AS IS" by the respective
contributors. They do not constitute TI specifications and do not necessarily reflect TI’s views; see TI’s Terms of
Use.

TI E2E™ Online Community TI’s Engineer-to-Engineer (E2E) Community. Created to foster collaboration
among engineers. At e2e.ti.com, you can ask questions, share knowledge, explore ideas and help
solve problems with fellow engineers.

Design Support TI’s Design Support Quickly find helpful E2E forums along with design support tools and
contact information for technical support.

12.5 Trademarks
OMAP, E2E are trademarks of Texas Instruments.
Vizplex is a trademark of E Ink Corporation.
E Ink is a registered trademark of E Ink Corporation.
All other trademarks are the property of their respective owners.

12.6 Electrostatic Discharge Caution
This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with
appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more
susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

12.7 Glossary
SLYZ022 — Ti Glossary.
This glossary lists and explains terms, acronyms, and definitions.

13 Mechanical, Packaging, and Orderable Information
The following pages include mechanical, packaging, and orderable information. This information is the most
current data available for the designated devices. This data is subject to change without notice and revision of
this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

</tbody>
</table>

(1) The marketing status values are defined as follows:
- **ACTIVE**: Product device recommended for new designs.
- **LIFEBUY**: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
- **NRND**: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
- **PREVIEW**: Device has been announced but is not in production. Samples may or may not be available.
- **OB Solete**: TI has discontinued the production of the device.

(2) **RoHS**: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".
- **RoHS Exempt**: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.
- **Green**: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) **MSL, Peak Temp.**: The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.
Lead/Ball Finish

Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

*All dimensions are nominal*
Images above are just a representation of the package family, actual package may vary. Refer to the product data sheet for package details.
NOTES:

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. The package thermal pad must be soldered to the printed circuit board for thermal and mechanical performance.
NOTES: (continued)

4. This package is designed to be soldered to a thermal pad on the board. For more information, see Texas Instruments literature number SLUA271 (www.ti.com/lit/slua271).

5. Vias are optional depending on application, refer to device data sheet. If any vias are implemented, refer to their locations shown on this view. It is recommended that vias under paste be filled, plugged or tented.
EXAMPLE STENCIL DESIGN

VQFN - 1 mm max height

PLASTIC QUAD FLATPACK - NO LEAD

NOTES: (continued)

6. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.
NOTES:
A. All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5M–1994.
B. This drawing is subject to change without notice.
C. Quad Flatpack, No-leads (QFN) package configuration.
D. The package thermal pad must be soldered to the board for thermal and mechanical performance.
E. See the additional figure in the Product Data Sheet for details regarding the exposed thermal pad features and dimensions.
THERMAL PAD MECHANICAL DATA

RSL (S-PVQFN-N48) PLASTIC QUAD FLATPACK NO-LEAD

THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

NOTE: All linear dimensions are in millimeters
NOTES:
A. All linear dimensions are in millimeters.
B. This drawing is subject to change without notice.
C. Publication IPC-7351 is recommended for alternate designs.
D. This package is designed to be soldered to a thermal pad on the board. Refer to Application Note, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271, and also the Product Data Sheets for specific thermal information, via requirements, and recommended board layout. These documents are available at www.ti.com <http://www.ti.com>.
E. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Refer to IPC 7525 for stencil design considerations.
F. Customers should contact their board fabrication site for recommended solder mask tolerances and via tenting recommendations for vias placed in the thermal pad.
