FEATURES
• 1.5-A Low-Dropout Voltage Regulator
• Available in 1.5 V, 1.8 V, 2.5 V, and 3.3 V Fixed Output and Adjustable Versions
• Open Drain Power-Good (PG) Status Output (TPS751xxQ)
• Open Drain Power-On Reset With 100ms Delay (TPS753xxQ)
• Dropout Voltage Typically 160 mV at 1.5 A (TPS75133Q)
• Ultralow 75-μA Typical Quiescent Current
• Fast Transient Response
• 2% Tolerance Over Specified Conditions for Fixed-Output Versions
• 20-Pin TSSOP PowerPAD™ (PWP) Package
• Thermal Shutdown Protection

APPLICATIONS
• Telecom
• Servers
• DSP, FPGA Supplies

DESCRIPTION
The TPS753xxQ and TPS751xxQ devices are low-dropout regulators with integrated power-on reset and power-good (PG) functions respectively. These devices are capable of supplying 1.5 A of output current with a dropout of 160 mV (TPS75133Q, TPS75333Q). Quiescent current is 75 μA at full load and drops down to 1 μA when the device is disabled. These devices are designed to have fast transient response for larger load current changes.

Because the PMOS device behaves as a low-value resistor, the dropout voltage is very low (typically 160 mV at an output current of 1.5 A for the TPS75x33Q) and is directly proportional to the output current. Additionally, because the PMOS pass element is a voltage-driven device, the quiescent current is very low and independent of output loading (typically 75 μA over the full range of output current, 1 mA to 1.5 A). These two key specifications yield a significant improvement in operating life for battery-powered systems.

The device is enabled when \( \text{EN} \) is connected to a low-level input voltage. This LDO family also features a sleep mode; applying a TTL high signal to \( \text{EN} \) (enable) shuts down the regulator, reducing the quiescent current to less than 1 μA at \( T_j = +25^\circ C \).

Typical Application Circuit
(Fixed Voltage Options)

DESCRIPTION, CONTINUED

For the TPS751xxQ, the power-good terminal (PG) is an active high, open drain output for use with a power-on reset or a low-battery indicator.

The RESET (SVS, POR, or power on reset) output of the TPS753xxQ initiates a reset in microcomputer and microprocessor systems in the event of an undervoltage condition. An internal comparator in the TPS753xxQ monitors the output voltage of the regulator to detect an undervoltage condition on the regulated output voltage. When the output reaches 95% of its regulated voltage, RESET goes to a high-impedance state after a 100-ms delay. RESET goes to a logic-low state when the regulated output voltage is pulled below 95% (that is, during an overload condition) of its regulated voltage.

The TPS751xxQ and TPS753xxQ are offered in 1.5 V, 1.8 V, 2.5 V and 3.3 V fixed-voltage versions and in an adjustable version (programmable over the range of 1.5 V to 5 V). Output voltage tolerance is specified as a maximum of 2% over line, load, and temperature ranges. The TPS751xxQ and TPS753xxQ families are available in a 20-pin TSSOP (PWP) package.

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

</tr>
</tbody>
</table>

(1) Minimum \( V_{IN} = (V_{OUT} + 1 \) V or 2.7 V, whichever is greater. Maximum \( V_{IN} = 5.5 \) V.

(2) If \( V_{OUT} ≤ 1.8 \) V, then \( V_{IN(min)} = 2.7 \) V, \( V_{IN(max)} = 5.5 \) V:

\[
\text{Line Regulation (mV)} = \frac{\%}{V} \times \frac{V_{OUT}}{V_{IN(max)} - 2.7\text{V}} \times 1000
\]

If \( V_{OUT} ≥ 2.5 \) V, then \( V_{IN(min)} = V_{OUT} + 1 \) V, \( V_{IN(max)} = 5.5 \) V:

\[
\text{Line Regulation (mV)} = \frac{\%}{V} \times \frac{V_{OUT}}{V_{IN(max)} - (V_{OUT} + 1\text{V})} \times 1000
\]

(3) Input voltage equals \( V_{OUT(TYP)} = 100 \) mV; TPS75x33Q input voltage must drop to 3.2 V for this test.

(1). Equivalent series resistance (ESR) refers to the total series resistance, including the ESR of the capacitor, any series resistance added externally, and PWB trace resistance to C_OUT.
APPLICATION INFORMATION

The TPS751xxQ and TPS753xxQ devices include four fixed-output voltage regulators (1.5 V, 1.8 V, 2.5 V and 3.3 V), and an adjustable regulator, the TPS75x01Q (adjustable from 1.5 V to 5 V).

Minimum Load Requirements

The TPS751xxQ and TPS753xxQ families are stable even at zero load; no minimum load is required for operation.

Pin Functions

Enable (EN)

The EN terminal is an input that enables or shuts down the device. If EN is a logic high, the device is in shutdown mode. When EN goes to logic low, then the device is enabled.

Power-Good (PG)—TPS751xxQ

The PG terminal is an open drain, active high output that indicates the status of VOUT (output of the LDO). When VOUT reaches 83% of the regulated voltage, PG goes to a high impedance state. It goes to a low-impedance state when VOUT falls below 83% (that is, an overload condition) of the regulated voltage. The open drain output of the PG terminal requires a pullup resistor.

Sense (SENSE)

The SENSE terminal of the fixed output options must be connected to the regulator output, and the connection should be as short as possible. Internally, SENSE connects to a high-impedance wide-bandwidth amplifier through a resistor-divider network, and noise pickup feeds through to the regulator output. It is essential to route the SENSE connection in such a way to minimize/avoid noise pickup. Adding RC networks between the SENSE terminal and VOUT to filter noise is not recommended because these types of networks may cause the regulator to oscillate.

Reset (RESET)—TPS753xxQ

The RESET terminal is an open drain, active low output that indicates the status of VOUT. When VOUT reaches 95% of the regulated voltage, RESET goes to a high-impedance state after a 100-ms delay. RESET goes to a low-impedance state when VOUT is below 95% of the regulated voltage. The open-drain output of the RESET terminal requires a pullup resistor.

GND/HEATSINK

All GND/HEATSINK terminals are connected directly to the mount pad for thermal-enhanced operation. These terminals could be connected to GND or left floating.

Input Capacitor

For a typical application, an input bypass capacitor (0.22 μF to 1 μF) is recommended for device stability. This capacitor should be as close to the input pins as possible. For fast transient conditions where droop at the input of the LDO may occur because of high inrush current, it is recommended to place a larger capacitor at the input as well. The size of this capacitor depends on the output current and response time of the main power supply, as well as the distance to the load (LDO).

Output Capacitor

As with most LDO regulators, the TPS751xxQ and TPS753xxQ require an output capacitor connected between OUT and GND to stabilize the internal control loop. The minimum recommended capacitance value is 47 μF and the ESR (equivalent series resistance) must be between 100 mΩ and 10 Ω. Solid tantalum electrolytic, aluminum electrolytic, and multilayer ceramic capacitors are all suitable, provided they meet the requirements described in this section. Larger capacitors provide a wider range of stability and better load transient response.
This information, along with the ESR graphs (see Figure 20 and Figure 21), is included to assist in selection of suitable capacitance for the user’s application. When necessary to achieve low height requirements along with high output current and/or high load capacitance, several higher ESR capacitors can be used in parallel to meet these guidelines.

**ESR and Transient Response**

LDOs typically require an external output capacitor for stability. In fast transient response applications, capacitors are used to support the load current while the LDO amplifier is responding. In most applications, one capacitor is used to support both functions.

Besides its capacitance, every capacitor also contains parasitic impedances. These parasitic impedances are resistive as well as inductive. The resistive impedance is called equivalent series resistance (ESR), and the inductive impedance is called equivalent series inductance (ESL). The equivalent schematic diagram of any capacitor can therefore be drawn as shown in Figure 22.

![Figure 22. ESR and ESL](image)

In most cases one can neglect the effect of inductive impedance ESL. Therefore, the following application focuses mainly on the parasitic resistance ESR.

**Figure 23** shows the output capacitor and its parasitic impedances in a typical LDO output stage.

![Figure 23. LDO Output Stage With Parasitic Resistances ESR and ESL](image)
In steady state operation (dc state condition), the load current is supplied by the LDO (solid arrow) and the voltage across the capacitor is the same as the output voltage \( V(\text{C}_{\text{OUT}}) = V_{\text{OUT}} \). This condition means that no current is flowing into the \( \text{C}_{\text{OUT}} \) branch. If \( I_{\text{OUT}} \) suddenly increases (that is, a transient condition), the following events occur:

- The LDO is not able to supply the sudden current need because of its response time \( t_1 \) in Figure 24. Therefore, capacitor \( \text{C}_{\text{OUT}} \) provides the current for the new load condition (the dashed arrow). \( \text{C}_{\text{OUT}} \) now acts like a battery with an internal resistance, ESR. Depending on the current demand at the output, a voltage drop occurs at \( R_{\text{ESR}} \). This voltage is shown as \( V_{\text{ESR}} \) in Figure 23.

- When \( \text{C}_{\text{OUT}} \) is conducting current to the load, initial voltage at the load is \( V_{\text{OUT}} = V(\text{C}_{\text{OUT}}) - V_{\text{ESR}} \). As a result of the discharge of \( \text{C}_{\text{OUT}} \), the output voltage \( V_{\text{OUT}} \) drops continuously until the response time \( t_1 \) of the LDO is reached and the LDO resumes supplying the load. From this point, the output voltage starts rising again until it reaches the regulated voltage. This period is shown as \( t_2 \) in Figure 24.

Figure 24 also shows the impact of different ESRs on the output voltage. The left brackets show different levels of ESRs where number 1 displays the lowest and number 3 displays the highest ESR.

From the above discussion, the following conclusions can be drawn:

- The higher the ESR, the larger the droop at the beginning of load transient.
- The smaller the output capacitor, the faster the discharge time and the bigger the voltage droop during the LDO response period.

**Conclusion**

To minimize the transient output droop, capacitors must have a low ESR and be large enough to support the minimum output voltage requirement.

![Figure 24. Correlation of Different ESRs and Their Influence to the Regulation of \( V_{\text{OUT}} \) at a Load Step From Low-to-High Output Current](image-url)
Programming the TPS75x01Q Adjustable LDO Regulator

The output voltage of the TPS77x01Q adjustable regulator is programmed using an external resistor divider as shown in Figure 25. The output voltage is calculated using Equation 1:

\[ V_{\text{OUT}} = V_{\text{ref}} \times (1 + \frac{R_1}{R_2}) \]  

(1)

Where:
- \( V_{\text{ref}} = 1.1834 \) V typ (the internal reference voltage)

Resistors \( R_1 \) and \( R_2 \) should be chosen for approximately 40\( \mu \)A divider current. Lower value resistors can be used, but offer no inherent advantage and waste more power. Higher values should be avoided as leakage currents at FB increase the output voltage error. The recommended design procedure is to choose \( R_2 = 30.1 \) k\( \Omega \) to set the divider current at approximately 40\( \mu \)A and then calculate \( R_1 \) using Equation 2:

\[ R_1 = \left( \frac{V_{\text{OUT}}}{V_{\text{ref}}} - 1 \right) \times R_2 \]  

(2)

**Figure 25. TPS75x01Q Adjustable LDO Regulator Programming**

Regulator Protection

The TPS751xxQ and TPS753xxQ PMOS-pass transistors have a built-in back diode that conducts reverse currents when the input voltage drops below the output voltage (for example, during power down). Current is conducted from the output to the input and is not internally limited. When extended reverse voltage is anticipated, external limiting may be appropriate.

The TPS751xxQ and TPS753xxQ also feature internal current limiting and thermal protection. During normal operation, the TPS751xxQ and TPS753xxQ limit output current to approximately 3.3 A. When current limiting engages, the output voltage scales back linearly until the overcurrent condition ends. While current limiting is designed to prevent gross device failure, care should be taken not to exceed the power dissipation ratings of the package. If the temperature of the device exceeds +150°C (typ), thermal-protection circuitry shuts it down. Once the device has cooled below +130°C (typ), regulator operation resumes.
Power Dissipation and Junction Temperature

Specified regulator operation is assured to a junction temperature of +125°C; the maximum junction temperature should be restricted to +125°C under normal operating conditions. This restriction limits the power dissipation the regulator can handle in any given application. To ensure the junction temperature is within acceptable limits, calculate the maximum allowable dissipation, \( P_{D(max)} \), and the actual dissipation, \( P_D \), which must be less than or equal to \( P_{D(max)} \).

The maximum-power-dissipation limit is determined using Equation 3:

\[
P_{D(max)} = \frac{T_{J(max)} - T_A}{R_{\theta JA}}
\]  

(3)

where:
- \( T_{J(max)} \) is the maximum allowable junction temperature
- \( R_{\theta JA} \) is the thermal resistance junction-to-ambient for the package; that is, 34.6°C/W for the 20-terminal PWP with no airflow (see Dissipation Ratings Table).
- \( T_A \) is the ambient temperature

The regulator dissipation is calculated using Equation 4:

\[
P_D = (V_{IN} - V_{OUT}) \times I_{OUT}
\]  

(4)

Power dissipation resulting from quiescent current is negligible. Excessive power dissipation triggers the thermal protection circuit.

THERMAL INFORMATION

Thermally-Enhanced TSSOP-20 (PWP–PowerPAD)

The thermally-enhanced PWP package is based on the 20-pin TSSOP, but includes a thermal pad [see Figure 26(c)] to provide an effective thermal contact between the IC and the printed wiring board (PWB).

![Figure 26. Views of Thermally-Enhanced PWP Package](image)

Figure 26. Views of Thermally-Enhanced PWP Package

Traditionally, surface mount and power have been mutually exclusive terms. A variety of scaled-down TO220-type packages have leads formed as gull wings to make them applicable for surface-mount applications. These packages, however, suffer from several shortcomings: they do not address the very low profile requirements (less than 2 mm) of many of today’s advanced systems, and they do not offer a pin-count high enough to accommodate increasing integration. On the other hand, traditional low-power surface-mount packages require power dissipation derating that severely limits the usable range of many high-performance analog circuits.

The PWP package (a thermally-enhanced TSSOP) combines fine-pitch surface-mount technology with thermal performance comparable to much larger power packages.
The PWP package is designed to optimize the heat transfer to the PWB. Because of the very small size and limited mass of a TSSOP package, thermal enhancement is achieved by improving the thermal conduction paths that remove heat from the component. The thermal pad is formed using a lead-frame design (patent pending) and manufacturing technique to provide the user with direct connection to the heat-generating IC. When this pad is soldered or otherwise coupled to an external heat dissipator, high power dissipation in the ultra-thin, fine-pitch, surface-mount package can be reliably achieved.

Because the conduction path has been enhanced, power-dissipation capability is determined by the thermal considerations in the PWB design. For example, simply adding a localized copper plane (heatsink surface) that is coupled to the thermal pad enables the PWP package to dissipate 2.5 W in free air (see Figure 28(a), 8 cm² of copper heatsink and natural convection). Increasing the heatsink size increases the power dissipation range for the component. The power dissipation limit can be further improved by adding airflow to a PWB/IC assembly (see Figure 27 and Figure 28). The line drawn at 0.3 cm² in Figure 27 and Figure 28 indicates performance at the minimum recommended heatsink size, illustrated in Figure 30.

The thermal pad is directly connected to the substrate of the IC, which for the TPS751xxQPWP and TPS753xxQPWP series is a secondary electrical connection to device ground. The heat-sink surface that is added to the PWP can be a ground plane or left electrically isolated. In TO220-type surface-mount packages, the thermal connection is also the primary electrical connection for a given terminal which is not always ground. The PWP package provides up to 16 independent leads that can be used as inputs and outputs. (Note: leads 1, 10, 11, and 20 are internally connected to the thermal pad and the IC substrate.)

![Figure 27. Thermal Resistance vs Copper Heatsink Area](image-url)
Figure 28. Power Ratings of the PWP Package at Ambient Temperatures of +25°C, +55°C, and +105°C
Figure 29 is an example of a thermally-enhanced PWB layout for use with the new PWP package. This board configuration was used in the thermal experiments that generated the power ratings shown in Figure 27 and Figure 28. As discussed earlier, copper has been added on the PWB to conduct heat away from the device. $R_{\text{JA}}$ for this assembly is illustrated in Figure 27 as a function of heatsink area. A family of curves is included to illustrate the effect of airflow introduced into the system.

![Heatsink Area 1 oz Copper](image)

Figure 29. PWB Layout (Including Copper Heatsink Area) for Thermally-Enhanced PWP Package

From Figure 27, $R_{\text{JA}}$ for a PWB assembly can be determined and used to calculate the maximum power-dissipation limit for the component/PWB assembly, with the equation:

$$P_{D(\text{Max})} = \frac{T_{J(\text{Max})} - T_A}{R_{\text{JA (System)}}}$$

(5)

Where $T_{J(\text{Max})}$ is the maximum specified junction temperature (+150°C absolute maximum limit, +125°C recommended operating limit) and $T_A$ is the ambient temperature.

$P_{D(\text{Max})}$ should then be applied to the internal power dissipated by the TPS75133QPWP regulator. The equation for calculating total internal power dissipation of the TPS75133QPWP is:

$$P_{D(\text{total})} = (V_{\text{IN}} - V_{\text{OUT}}) \times I_{\text{OUT}} + V_{\text{IN}} \times I_{Q}$$

(6)

Because the quiescent current of the TPS75133QPWP is very low, the second term is negligible, further simplifying the equation to:

$$P_{D(\text{total})} = (V_{\text{IN}} - V_{\text{OUT}}) \times I_{\text{OUT}}$$

(7)

For the case where $T_A = +55^\circ C$, airflow = 200 ft/min, copper heat-sink area = 4 cm$^2$, the maximum power-dissipation limit can be calculated. First, from Figure 27, we find the system $R_{\text{JA}}$ is 50°C/W; therefore, the maximum power-dissipation limit is:

$$P_{D(\text{Max})} = \frac{T_{J(\text{Max})} - T_A}{R_{\text{JA (System)}}} = \frac{125^\circ C - 55^\circ C}{50^\circ C/W} = 1.4 \text{ W}$$

(8)

If the system implements a TPS75133QPWP regulator, where $V_{\text{IN}} = 5 \text{ V}$ and $I_{\text{OUT}} = 800 \text{ mA}$, the internal power dissipation is:

$$P_{D(\text{total})} = (V_{\text{IN}} - V_{\text{OUT}}) \times I_{\text{OUT}} = (5 - 3.3) \times 0.8 = 1.36 \text{ W}$$

(9)

Comparing $P_{D(\text{total})}$ with $P_{D(\text{Max})}$ reveals that the power dissipation in this example does not exceed the calculated limit. When it does, one of two corrective actions should be made: either raise the power-dissipation limit by increasing the airflow or the heat-sink area, or lower the internal power dissipation of the regulator by reducing the input voltage or the load current. In either case, the above calculations should be repeated with the new system parameters.
Mounting Information

The primary requirement is to complete the thermal contact between the thermal pad and the PWB metal. The thermal pad is a solderable surface and is fully intended to be soldered at the time the component is mounted. Although voiding in the thermal-pad solder-connection is not desirable, up to 50% voiding is acceptable. The data included in Figure 27 and Figure 28 are for soldered connections with voiding between 20% and 50%. The thermal analysis shows no significant difference resulting from the variation in voiding percentage.

Figure 30 shows the solder-mask land pattern for the PWP package. The minimum recommended heat-sink area is also illustrated. This is simply a copper plane under the body extent of the package, including metal routed under terminals 1, 10, 11, and 20.

(1) The marketing status values are defined as follows:
- **ACTIVE**: Product device recommended for new designs.
- **LIFEBUY**: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
- **NRND**: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
- **PREVIEW**: Device has been announced but is not in production. Samples may or may not be available.
- **OBSOLETE**: TI has discontinued the production of the device.

(2) **RoHS**: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".
- **RoHS Exempt**: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.
- **Green**: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

MECHANICAL DATA

PWP (R-PDSO-G20)  PowerPAD™ PLASTIC SMALL OUTLINE

NOTES:
A. All linear dimensions are in millimeters.
B. This drawing is subject to change without notice.
C. Body dimensions do not include mold flash or protrusions. Mold flash and protrusion shall not exceed 0.15 per side.
D. This package is designed to be soldered to a thermal pad on the board. Refer to Technical Brief, PowerPAD Thermally Enhanced Package, Texas Instruments Literature No. SMB002 for information regarding recommended board layout. This document is available at www.ti.com <http://www.ti.com>.
E. See the additional figure in the Product Data Sheet for details regarding the exposed thermal pad features and dimensions.
F. Falls within JEDEC MO-153

PowerPAD is a trademark of Texas Instruments.
THERMAL INFORMATION

This PowerPAD™ package incorporates an exposed thermal pad that is designed to be attached to a printed circuit board (PCB). The thermal pad must be soldered directly to the PCB. After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For additional information on the PowerPAD package and how to take advantage of its heat dissipating abilities, refer to Technical Brief, PowerPAD Thermally Enhanced Package, Texas Instruments Literature No. SLMA002 and Application Brief, PowerPAD Made Easy, Texas Instruments Literature No. SLMA004. Both documents are available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

Exposed Thermal Pad Dimensions

NOTE:  A. All linear dimensions are in millimeters

PowerPAD is a trademark of Texas Instruments
NOTES:
A. All linear dimensions are in millimeters.
B. This drawing is subject to change without notice.
C. Customers should place a note on the circuit board fabrication drawing not to alter the center solder mask defined pad.
D. This package is designed to be soldered to a thermal pad on the board. Refer to Technical Brief, PowerPAD Thermally Enhanced Package, Texas Instruments Literature No. SLMA002, SLMA004, and also the Product Data Sheets for specific thermal information, via requirements, and recommended board layout. These documents are available at www.ti.com <http://www.ti.com>. Publication IPC-7351 is recommended for alternate designs.
E. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Example stencil design based on a 50% volumetric metal load solder paste. Refer to IPC-7525 for other stencil recommendations.
F. Customers should contact their board fabrication site for solder mask tolerances between and around signal pads.
