The anti-aliasing filter processes the graphics data to remove some of the vertical aliasing. It is based on a 3-tap FIR filter with fixed coefficients. For each pixel to be output from the graphics pipeline, the pixel above and below the current line must be read from the DMA graphics FIFO. Therefore, three lines of pixels must be stored in the DMA graphics FIFO.

The anti-aliasinging equations for A, R, G, and B components are:

$A_{out}(x,y) = 0.25 \times A_{in}(x,y-1) + 0.5 \times A_{in}(x,y) + 0.25 \times A_{in}(x,y+1)$

$R_{out}(x,y) = 0.25 \times R_{in}(x,y-1) + 0.5 \times R_{in}(x,y) + 0.25 \times R_{in}(x,y+1)$

$G_{out}(x,y) = 0.25 \times G_{in}(x,y-1) + 0.5 \times G_{in}(x,y) + 0.25 \times G_{in}(x,y+1)$

$B_{out}(x,y) = 0.25 \times B_{in}(x,y-1) + 0.5 \times B_{in}(x,y) + 0.25 \times B_{in}(x,y+1)$

For the first line of processing, because there is no pixel above, the value (x,y) is duplicated.

$Out(x,y) = 0.25 \times In(x,y) + 0.5 \times In(x,y) + 0.25 \times In(x,y+1)$

For the last line of processing, because there is no pixel below, the value (x,y) is duplicated.

$Out(x,y) = 0.25 \times In(x,y-1) + 0.5 \times In(x,y) + 0.25 \times In(x,y)$

NOTE: Anti-aliasing filtering is supported only in RGB formats and not in BITMAP formats.

Anti-aliasinging is not supported for pictures with fewer than two lines. In this case, the user must disable the anti-aliasinging processing.

By default, the anti-aliasing filtering is disabled. It can be enabled by setting the DISPC_GFX1_ATTRIBUTES[24] anti-aliasing bit to 0x1.

8.2.4.8.3 DISPC GFX Color Look-Up Table (CLUT)

The graphics pipeline supports conversion of BITMAP formats (1, 2, 4, or 8-bit indexed) into RGB24 format through a Color Look-Up Table (CLUT).

The look-up table consists of 3 separate 256 x 8-bit memories and is indexed by the source BITMAP data. The table is loaded through direct register access by writing to DISPC_GFX1_CLUT register.

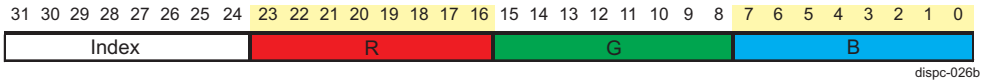
The sequence to load the table is:

1. SW writes (only writes are supported) 32-bit values using single access, or burst access in linear increment burst mode, into DISPC_GFX1_CLUT register. The LSB 24 bits [23:0] are used for the value, and the MSB 8 bits [31:24] are used for the index into the table (see Figure 8-27).
2. Loop to Step 1, if there is a new access to the CLUT register. The SW can access other registers between two accesses to the CLUT register.

SW needs to ensure that there is no visible effect when modifying the table, since it is not under HW control.

The usage of the CLUT is activated when a BITMAP format is selected in the DISPC_GFX1_ATTRIBUTES[6:1] FORMAT register bit-field.

Figure 8-27. DISPC GFX CLUT Data Memory Organization



8.2.4.9 DISPC Video Pipelines

Two identical video pipelines are available, VID1 and VID2. Each video pipeline is connected to the video DMA buffer controller for the input port, and to the overlay managers or WB pipeline. The pixel output is directed to the OVR1, OVR2 or WB path by configuring the DISPC_VID_ATTRIBUTES[16] CHANNELOUT register bit. Table 8-41 summarizes the bit field settings to orient a pipeline to the OVR1, OVR2 or VP1 output. The default value directs all video pipelines to OVR1.

NOTE: It is not possible to change the direction of the video pipelines on the fly. If a video pipeline needs to be connected to a different overlay manager than what it is currently connected, then the following steps need to be performed:

1. Disable the VIDp pipeline by setting the DISPC_VID_ATTRIBUTES[0] ENABLE bit to 0x0.
2. Direct the VIDp pipeline to the new overlay manager by modifying the [16] CHANNELOUT bit in the DISPC_VID_ATTRIBUTES register.
3. Disable the DISPC output that corresponds with the overlay manager to which the VIDp pipeline will be connected next. This is done by setting the following bits to 0x0 for the listed outputs:
   - The DISPC_VP1_CONTROL1[0] VPENABLE bit for VP1 output
4. Enable the VIDp pipeline by writing 0x1 to the DISPC_VID_ATTRIBUTES [0] ENABLE bit.
5. Enable the DISPC output that corresponds with the overlay manager to which the VIDp pipeline will be connected next. This is done by setting the following bits to 0x1 for the listed outputs:
   - The DISPC_VP1_CONTROL1[0] VPENABLE bit for VP1 output

A video pipeline consists of a scaler unit, color space conversion (CSC) unit, VC-1 range mapping unit, one 256-entry Color Look-up Table (CLUT), and some programmable replication logic. The order of the video pipeline unit is configured like follows (see Figure 8-28):

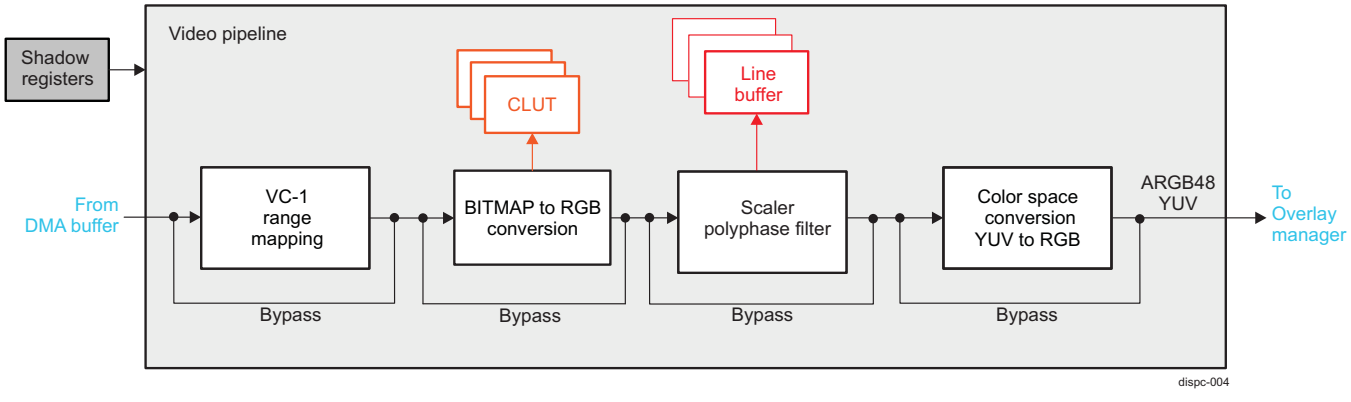
- VC-1 range mapping unit, followed by a color look-up table, then a scaler unit and then a CSC unit. The configuration is used to support RGB, ARGB, and RGBA formats, YUV4:2:2 and YUV420-NV12 (NV21) formats, taking advantage of the scaler to resample the chrominance using five taps horizontally and three or five taps vertically. Each block can be independently bypassed. The 256-entry CLUT is used to convert BITMAP (1, 2, 4, or 8-bit indexed formats) into RGB format.

NOTE: For a BITMAP format data, scaling is not supported. Scaling and color look-up table features are mutually exclusive. If color look-up feature is enabled, then video pipeline scaler has to be disabled.

Table 8-30 lists the input formats supported by the video pipelines.

The video pipeline is enabled by setting the DISPC_VID_ATTRIBUTES[0] ENABLE bit to 0x1.

Figure 8-28. DISPC Video Pipeline Configuration



8.2.4.9.1 DISPC VID Replication Logic

The replication logic (RGB expansion) is used to convert the ARGB pixels into ARGB48 format.

Table 8-32. DISPC VID Replication: ARGB Pixel Formats Remapping Into ARGB48-12121212

Formats	A[11:0] MSB LSB	R[11:0] MSB LSB	G[11:0] MSB LSB	B[11:0] MSB LSB

RGBA16-4444	A[3:0]A[3:0]A[3:0]	R[3:0]R[3:0]R[3:0]	G[3:0]G[3:0]G[3:0]	B[3:0]B[3:0]B[3:0]

8.2.4.9.2 DISPC VID VC-1 Range Mapping Unit

The VC-1 range mapping unit is used when the video frame picture is decoded using a VC-1 codec by the video accelerator. It remaps the Y, Cb, and Cr components. The unit is used primarily for YUV4:2:0-NV12 (NV21) pixel format, but also can be applied to YUV4:2:2 pixel formats (YUV2 and UYVY).

The VC-1 range mapping unit is enabled by setting the DISPC_VID_ATTRIBUTES2[0] VC1ENABLE bit to 0x1. The DISPC_VID_ATTRIBUTES2[3:1] VC1_RANGE_Y and DISPC_VID_ATTRIBUTES2[6:4] VC1_RANGE_CBCR bit fields are two 3-bit values programmed by the user and are independent for each video pipeline. The module is governed by the equations:

Y_{out} = CLIP((((Y_{int} – 128) × (VC1_RANGE_Y + 9) + 4) / 8) + 128)

C_b = CLIP((((C_b – 128) × (VC1_RANGE_CBCR + 9) + 4) / 8) + 128)

C_r = CLIP((((C_r – 128) × (VC1_RANGE_CBCR + 9) + 4) / 8) + 128)

NOTE: The input and output pixel values are unsigned (Y, Cr, and Cb).

The function CLIP () clips to 0 or 255 when minimum or maximum, respectively, are reached; otherwise, the resulting output remains identical.

8.2.4.9.3 DISPC VID Color Look-Up Table (CLUT)

The video pipelines support conversion of BITMAP formats (1, 2, 4, or 8-bit indexed) into RGB24 format through a Color Look-Up Table (CLUT).

The look-up table consists of 3 separate 256 x 8-bit memories and is indexed by the source BITMAP data. The table is loaded through direct register access by writing to DISPC_VID_CLUT register.

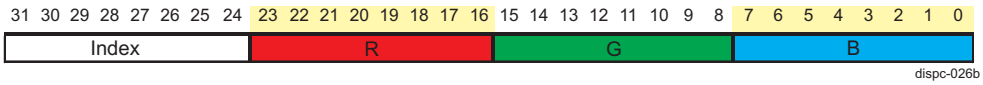
The sequence to load the table is:

1. SW writes (only writes are supported) 32-bit values using single access, or burst access in linear increment burst mode, into DISPC_VID_CLUT register. The LSB 24 bits [23:0] are used for the value, and the MSB 8 bits [31:24] are used for the index into the table (see Figure 8-29).
2. Loop to Step 1, if there is a new access to the CLUT register. The SW can access other registers between two accesses to the CLUT register.

SW needs to ensure that there is no visible effect when modifying the table, since it is not under HW control.

The usage of the CLUT is activated when a BITMAP format is selected in the DISPC_VID_ATTRIBUTES[6:1] FORMAT register bit-field.

Figure 8-29. DISPC VID CLUT Data Memory Organization



8.2.4.9.4 DISPC VID CSC Unit YUV to RGB

The CSC unit converts the video-encoded pixel values from YUV4:4:4 format into RGB36 format (12-bit value per color component: red, green, and blue).

In case of YUV4:2:0 or YUV4:2:2 formats, a chrominance resampling to YUV4:4:4 is required before converting the YUV into RGB values (see Section 8.2.4.9.4.1, *Chrominance Resampling*). YUV4:2:2 or YUV4:2:0 to YUV4:4:4 chrominance resampling is a preprocessing to the color space conversion.

Figure 8-30 through Figure 8-31 show the 3 × 3 11-bit coefficients used to convert from YUV4:4:4 into RGB36. The coefficients are set according to the standard used to encode the pixel data in YUV color space. Table 8-33 summarizes the coefficients with their respective register bit fields.

Table 8-33. DISPC VID Color Space Conversion YUV to RGB Register Bitfield Settings

Coefficients	Bit Field Registers
R_Y	DISPC_VID_CONV_COEF0[10:0] RY
R_{Cr}	DISPC_VID_CONV_COEF0[26:16] RCR
R_{Cb}	DISPC_VID_CONV_COEF1[10:0] RCB
G_Y	DISPC_VID_CONV_COEF1[26:16] GY
G_{Cr}	DISPC_VID_CONV_COEF2[10:0] GCR
G_{Cb}	DISPC_VID_CONV_COEF2[26:16] GCB
B_Y	DISPC_VID_CONV_COEF3[10:0] BY
B_{Cr}	DISPC_VID_CONV_COEF3[26:16] BCR
B_{Cb}	DISPC_VID_CONV_COEF4[10:0] BCB
G offset	DISPC_VID_CONV_COEF5[31:19] GOFFSET
R offset	DISPC_VID_CONV_COEF5[15:3] ROFFSET
B offset	DISPC_VID_CONV_COEF6[15:3] BOFFSET

If the active range for the luminance samples (Y) is [256:3760] and [256:3840] for the chrominance samples (Cb and Cr), the range selection is done by setting the DISPC_VID_ATTRIBUTES[11] FULLRANGE bit to 0x0. The values of R, G, and B output components are clipped to the range [0:4095].

NOTE: The scaling and CSC clipping is set by the same bit, DISPC_VID_ATTRIBUTES[11] FULLRANGE.

Figure 8-30. DISPC VID YCbCr to RGB Registers (FULLRANGE = 0), 12-Bit Outputs

$$\begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_Y & R_{cr} & R_{cb} \\ G_Y & G_{cr} & G_{cb} \\ B_Y & B_{cr} & B_{cb} \end{bmatrix} * \begin{bmatrix} Y_{IN} - 256 \\ Cr_{IN} - 2048 \\ Cb_{IN} - 2048 \end{bmatrix}$$

dispc-005

If the active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:4095], the range selection is done by setting the DISPC_VID_ATTRIBUTES[11] FULLRANGE bit to 0x1. The values of R, G, and B output components are clipped to the range [0:4095].

Figure 8-31. DISPC VID YCbCr to RGB Registers (FULLRANGE = 1), 12-Bit Outputs

$$\begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_Y & R_{cr} & R_{cb} \\ G_Y & G_{cr} & G_{cb} \\ B_Y & B_{cr} & B_{cb} \end{bmatrix} * \begin{bmatrix} Y_{IN} \\ Cr_{IN} - 2048 \\ Cb_{IN} - 2048 \end{bmatrix}$$

dispc-006

8.2.4.9.4.1 DISPC VID Chrominance Resampling

The chrominance resampling is always performed using filtering (the scaler unit filter). Chrominance resampling and rescaling can be combined to support native rescaling of YUV format.

The usage of the scaler unit for resampling the chrominance of YUV4:2:0 and YUV4:2:2 is shown in Figure 8-32 and Figure 8-33, respectively. The settings of the scaler unit to perform chrominance resampling are described in Section 8.2.4.9.5, *DISPC Scaler Unit*.

Figure 8-32. DISPC VID YUV4:2:0 to RGB36 Using Scaler Unit for Resampling Chrominance

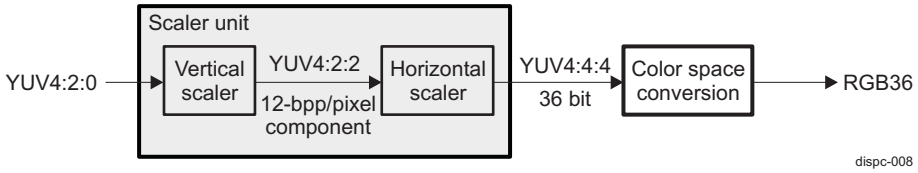


Figure 8-33. DISPC VID YUV4:2:2 to RGB36 Using Scaler Unit for Resampling Chrominance

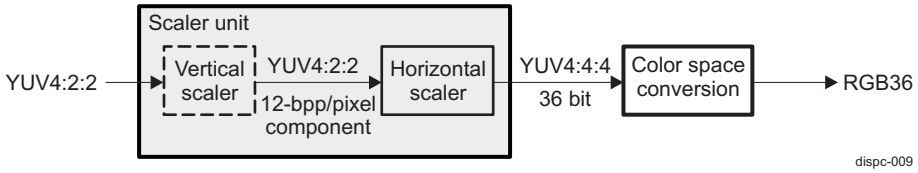


8.2.4.9.5 DISPC VID Scaler Unit

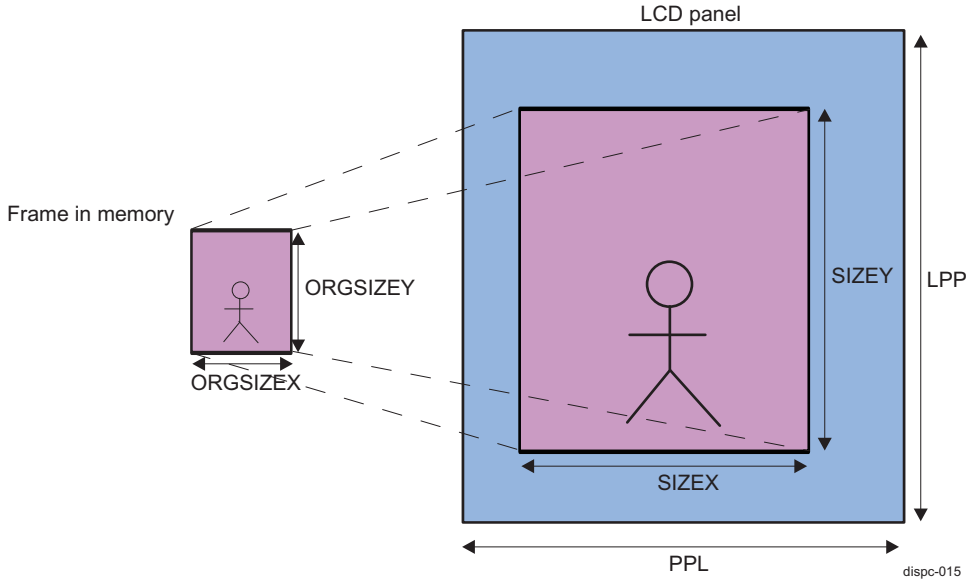
All video formats are supported, including formats with alpha blending. Alpha blending is scaled with the same parameters as RGB color components. For the YUV formats, Y and Cb/Cr are processed independently. The filter is based on a finite impulse response (FIR) filter with 16 phases. The filter is a 5-tap for horizontal filtering, and can be configured for 3 or 5 taps for vertical filtering.The filtering can be used for different processing:

- Upsampling of the picture
- Downsampling of the picture
- Anti-aliasing reduction
- Chrominance resampling in case of YUV data formats

NOTE: The user must ensure that the resizing frame displays in the screen boundaries.

Figure 8-34 shows an example of video upsampling.

Figure 8-34. DISPC Video Upsampling



The upsampling/downsampling filter is a polyphase filter with 5 taps and 16 phases for the horizontal filter, and a programmable number of taps (3 or 5) and 16 phases for the vertical filter. The input buffer has six input memory lines. The following limitations must be considered:

- The upsampling ratio is up to x16.
- The downsampling ratio using 3-tap configuration is down to x0.5 for RGB format.
- The downsampling ratio using 5-tap configuration is down to x0.25 for RGB format.
- If the input format is changed from YUV4:2:2 to YUV4:2:0 (WB pipeline), the downsampling ratio is further reduced:
  - Using 5-tap configuration, the ratio is down to x0.5 for RGB format.
  - Using 3-tap configuration, no downscaling is available.
- Scaling capability of VID pipelines and WB pipeline can be combined to double the maximum rescaling factor.

For vertical upsampling and downsampling in a 3-tap configuration, the equations are:

For RGB formats

$$A_{out}(n)=\left(\sum_{i=-1}^{i=1} C_{vi}(\Phi_y)*A_{in}(n+i)\right)>>7$$

$$R_{out}(n)=\left(\sum_{i=-1}^{i=1} C_{vi}(\Phi_y)*R_{in}(n+i)\right)>>7$$

$$G_{out}(n)=\left(\sum_{i=-1}^{i=1} C_{vi}(\Phi_y)*G_{in}(n+i)\right)>>7$$

$$B_{out}(n)=\left(\sum_{i=-1}^{i=1} C_{vi}(\Phi_y)*B_{in}(n+i)\right)>>7$$

For YUV formats

$$Y_{out}(n)=\left(\sum_{i=-1}^{i=1} C_{vi}(\Phi_y)*Y_{in}(n+i)\right)>>7$$

$$Cr_{out}(n)=\left(\sum_{i=-1}^{i=1} C_{vci}(\Phi_c)*Cb_{in}(n+i)\right)>>7$$

$$Cb_{out}(n)=\left(\sum_{i=-1}^{i=1} C_{vci}(\Phi_c)*Cr_{in}(n+i)\right)>>7$$

dispc-013

(1)

For vertical upsampling and downsampling in a 5-tap configuration, the equations are:

For RGB formats

$$A_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{vi}(\Phi)*A_{in}(n+i)\right)>>7$$

$$R_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{vi}(\Phi)*R_{in}(n+i)\right)>>7$$

$$G_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{vi}(\Phi)*G_{in}(n+i)\right)>>7$$

$$B_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{vi}(\Phi)*B_{in}(n+i)\right)>>7$$

For YUV formats

$$Y_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{vi}(\Phi_y)*Y_{in}(n+i)\right)>>7$$

$$Cb_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{vci}(\Phi_c)*Cb_{in}(n+i)\right)>>7$$

$$Cr_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{vci}(\Phi_c)*Cr_{in}(n+i)\right)>>7$$

dispc-012

(2)

For horizontal upsampling and downsampling in a 5-tap configuration, the equations are:

For RGB formats

$$A_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{hi}(\Phi)*A_{in}(n+i)\right)>>7$$

$$R_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{hi}(\Phi)*R_{in}(n+i)\right)>>7$$

$$G_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{hi}(\Phi)*G_{in}(n+i)\right)>>7$$

$$B_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{hi}(\Phi)*B_{in}(n+i)\right)>>7$$

For YUV formats

$$Y_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{hi}(\Phi_y)*Y_{in}(n+i)\right)>>7$$

$$Cb_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{hci}(\Phi_c)*Cb_{in}(n+i)\right)>>7$$

$$Cr_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{hci}(\Phi_c)*Cr_{in}(n+i)\right)>>7$$

dispc-014

(3)

NOTE: The pixel (n + 1) is the previous pixel with respect to pixel (n). The line (n + 1) is the previous line with respect to line (n).

The coefficients Ci() depend on the phase between input and output pixels.

NOTE: The coefficients are different for Y and Cr, Cb filtering because the calculations are independent due to the chrominance resampling for YUV4:2:2 and YUV4:2:0.

First, the vertical filter is applied to the encoded input pixel data, and then the horizontal filter is applied on the resulting pixel values to generate the output pixel values. The vertical input of the filter consists of six lines of 1280 × 32 bits for 5-tap configurations (see Table 8-34). In case of 3-tap configuration, the scaler input width capability is extended to 2560 pixels wide.

Table 8-34. DISPC VID Line Buffer Width for Scaler Unit

Vertical Taps	Maximum Input Width (Pixels)
3	2560
5	1280 (1)

(1) For the 5-tap configuration, the 6th video line is used on the output of the horizontal scaler, so that horizontal down-scaling can be supported with a minimum clock ratio equal to 1. The maximum output width is limited to 1280 pixels in order to be able to support clock ratio of 1 due to the 6th video line buffer.

At the beginning of frame scaling processing, the first line may be duplicated multiple times depending on the initial vertical phase programmed for the poly-phase filter.

At the end of frame scaling processing, the last line is duplicated if the scaling logic requires loading more lines and the last line has been reached.

Similarly, the first pixel may be duplicated multiple times depending on the initial horizontal phase programmed for the poly-phase filter. The last pixel is duplicated if the scaling logic requires loading more pixels and the last pixel has been reached.

The programmable coefficients of the polyphase filters are signed 10-bit values (except for the central coefficient, which is unsigned). The vertical video scaler has an 8-bit input and a 10-bit output. The vertical scaling changes the 8-bit input into a 10-bit clipped output, and the horizontal scaling takes the 10-bit input.

Figure 8-35 and Figure 8-36 show the scaler macro-architecture for the component A, R, G, B, and Y. Figure 8-37 and Figure 8-38 show the scaler macro-architecture for component Cr and Cb.

NOTE: The scaling and CSC clipping is set by the same bit, DISPC_VID_ATTRIBUTES[11] FULLRANGE.

Figure 8-35. DISPC VID Macro-Architecture of the Horizontal Scaling for A, R, G, B, and Y Components (5-tap Restriction)

15	DISPC_VID_FIR_COEF_H12_15	DISPC_VID_FIR_COEF_H12_15	DISPC_VID_FIR_COEF_H0_1	DISPC_VID_FIR_COEF_H12_1	DISPC_VID_FIR_COEF_H12_1

NOTE: The table cells without color are duplicated from the grey cells.

Similar table approach applies to the vertical scaler (registers DISPC_VID_FIR_COEF_V0_i and DISPC_VID_FIR_COEF_V12_k are used).

Similar table approach applies to the coefficients for CbCr filtering in case of YUV format (registers DISPC_VID_FIR_COEF_H0_C_i and DISPC_VID_FIR_COEF_H12_C_k, and DISPC_VID_FIR_COEF_V0_C_i and DISPC_VID_FIR_COEF_V12_C_k) .

The VID scaler unit vertical or/and horizontal sampling is defined by setting/resetting the DISPC_VID_ATTRIBUTES[8:7] RESIZEENABLE bit field.

A set of configurations must be valid before enabling the video upsampling and downsampling block.

The following fields define the configuration of the video upsampling downsampling block for VID pipelines:

- Vertical upsampling and downsampling increments the value of the [23:0] FIRVINC bit field in DISPC_VID_FIRV and DISPC_VID_FIRV2 registers. The unsigned integer value range is 2^{23}. Software calculates the value using the following equation:

$$FIRVINC = 2^{21} * \left(\frac{MEMSIZEY+1}{SIZEY+1}\right)$$

dispc-066 (4)

- Horizontal upsampling and downsampling increments the value of the the [23:0] FIRHINC bit field in the DISPC_VID_FIRH and DISPC_VID_FIRH2 registers. The unsigned integer value range is 2^{23}. Software calculates the value using the following equation:

$$FIRHINC = 2^{21} * \left(\frac{MEMSIZEH+1}{SIZEH+1}\right)$$

dispc-067 (5)

- Vertical up/downsampling accumulator value, [23:0] VERTICALACCU bit field in DISPC_VID_ACCUV_j and DISPC_VID_ACCUV2_j registers: The accumulator value indicates on which phase the vertical filtering starts. The register DISPC_VID_ACCUV_0 is used for progressive output, and for interlace output DISPC_VID_ACCUV_0 and DISPC_VID_ACCUV_1 registers are used. Similarly, DISPC_VID_ACCUV2_0 and DISPC_VID_ACCUV2_1 are used in progressive or interlace output to set the accumulator value of the Cb and Cr components when scaling YUV format.
- Vertical upsampling and downsampling line buffer configuration DISPC_VID_ATTRIBUTES[21]

VERTICALTAPS bit: The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used.

- Horizontal upsampling and downsampling accumulator value, [23:0] HORIZONTALACCU bit field in DISPC_VID_ACCUH_j and DISPC_VID_ACCUH2_j registers: The accumulator value indicates on which phase the horizontal filtering starts. The register DISPC_VID_ACCUH_0 is used for progressive output, and for interlace output the DISPC_VID_ACCUH_0 and DISPC_VID_ACCUH_1 registers are used. Similarly, DISPC_VID_ACCUH2_0 and DISPC_VID_ACCUH2_1 are used in progressive or interlace output to set the accumulator value of the Cb and Cr components when scaling YUV format.

Table 8-36 lists the DISPC vertical and horizonatal accumulator values and phases.

Table 8-36. DISPC VID Vertical and Horizontal Accumulator Phases

Accumulator Value (MSB bits)	Phases f
0	0
256 or -3840	1
512 or -3584	2
768 or -3328	3
1024 or -3072	4
1280 or -2816	5
1536 or -2560	6
1792 or -2304	7
2048 or -2048	8
2304 or -1792	9
2560 or -1536	10
2816 or -1280	11
3072 or -1024	12
3328 or -768	13
3584 or -512	14
3840 or -256	15

- Vertical upsampling and downsampling central coefficients:
  - The vertical upsampling and downsampling central coefficients are defined in the DISPC_VID_FIR_COEF_V0_i registers. There are 9 registers for the 16 phases with 1 coefficient for each of them. Symetrical implementation is used, so only 9 coefficients are used. Each register contains one 10-bit unsigned coefficient (the central one).
  - Four YUV, the vertical upsampling and downsampling central coefficients are set in DISPC_VID_FIR_COEF_V0_C_i registers.
- Vertical upsampling and downsampling coefficients:
  - The vertical upsampling and downsampling coefficients are defined in the DISPC_VID_FIR_COEF_V12_k registers. There are 16 registers for the 16 phases with 2 coefficient for each of them, so a total of 32 programmable coefficients for the vertical up/down-sampling block. Each register contains two 10-bit signed coefficients.
  - Four YUV, the vertical upsampling and downsampling coefficients are set in DISPC_VID_FIR_COEF_V12_C_k registers.
- Horizontal upsampling and downsampling central coefficients:
  - The horizontal upsampling and downsampling central coefficients are defined in the DISPC_VID_FIR_COEF_H0_i registers. There are 9 registers for the 16 phases with 1 coefficient for each of them. Symetrical implementation is used, so only 9 coefficients are used. Each register contains one 10-bit unsigned coefficient (the central one).
  - Four YUV, the horizontal upsampling and downsampling central coefficients are set in DISPC_VID_FIR_COEF_H0_C_i registers.
- Horizontal upsampling and downsampling coefficients:

– The horizontal upsampling and downsampling coefficients are defined in the DISPC_VID_FIR_COEF_H12_k registers. There are 16 registers for the 16 phases with 2 coefficient for each of them, so a total of 32 programmable coefficients for the horizontal up/down-sampling block. Each register contains two 10-bit signed coefficients.
– Four YUV, the horizontal upsampling and downsampling coefficients are set in DISPC_VID_FIR_COEF_H12_C_k registers.

8.2.4.9.5.1 DISPC Scaling Algorithms

Figure 8-39 and Figure 8-40 show details of the vertical and horizontal upsampling and downsampling finite state-machines (FSMs), respectively.

Figure 8-39. DISPC Vertical Upsampling and Downsampling Algorithm

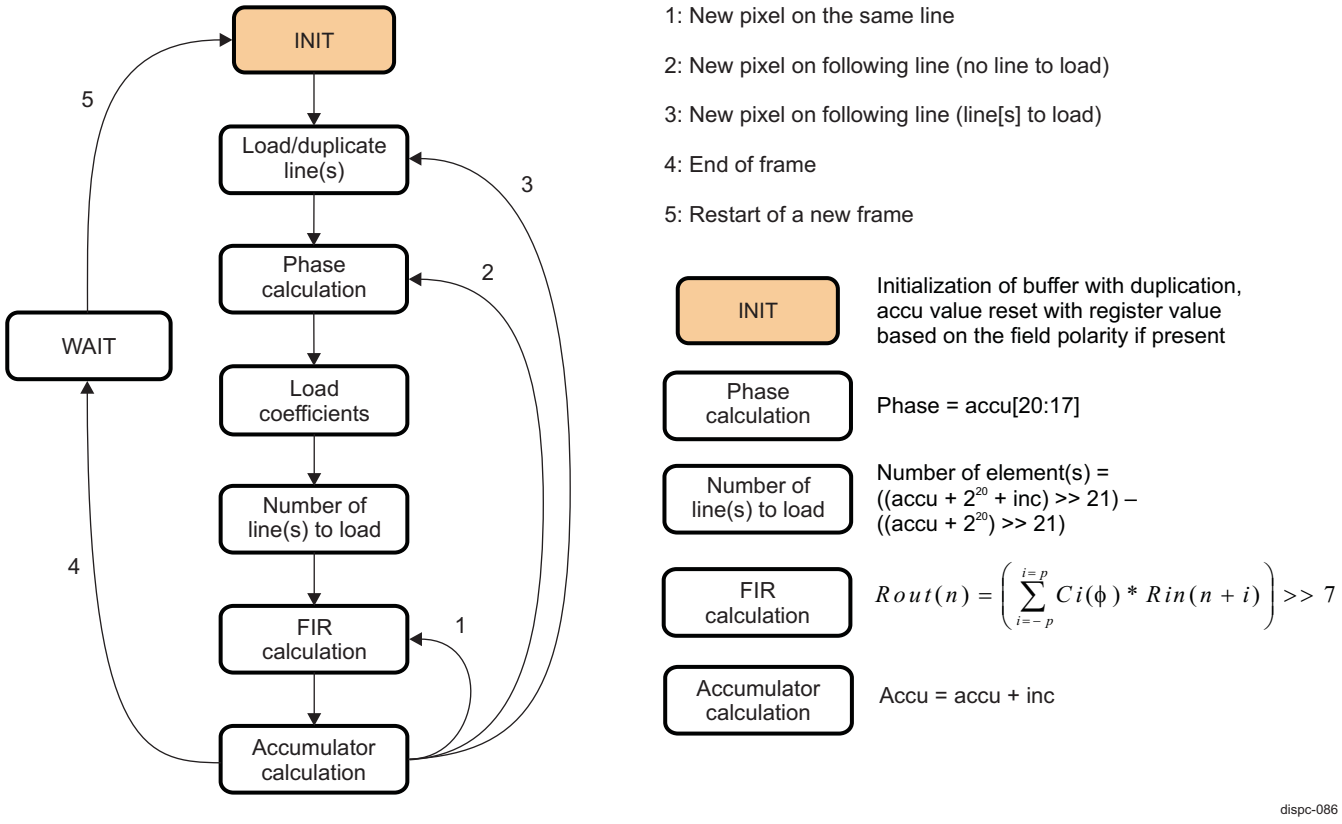

Figure 8-40 shows the horizontal up/downsampling FSM.

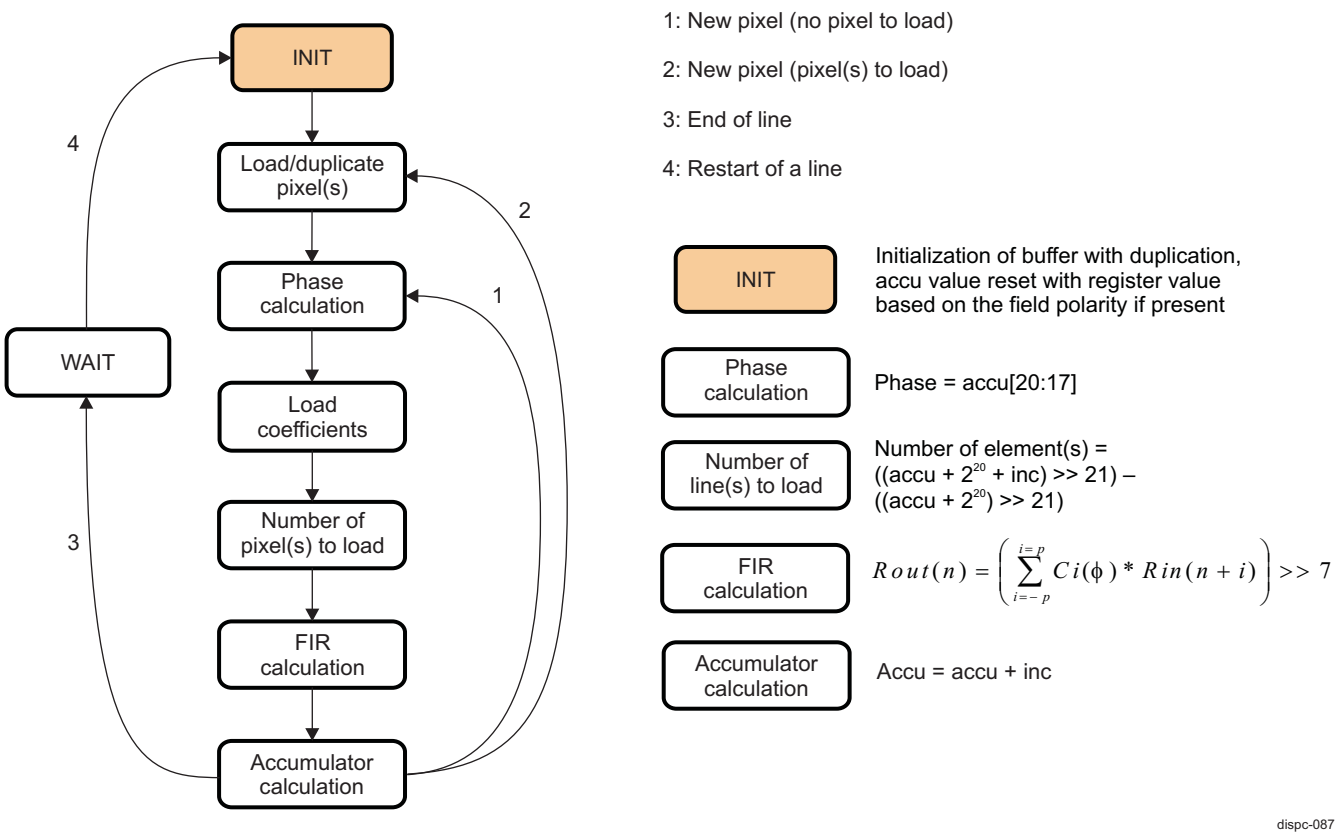
Figure 8-40. DISPC Horizontal Up/Downsampling Algorithm



8.2.4.9.6 DISPC VID Progressive to Interlace conversion

It is possible, in case of YUV420 format, to fetch only one out of two lines of the Y buffer and fetch all the CbCr lines in order to read a field (even lines, if the base address of the Y buffer points to an even line and odd lines, if it points to an odd line) from a YUV420 frame buffers (Y and CrCr buffers). The register configuration required is as follows:

- DISPC_VID_ATTRIBUTES[6:1] FORMAT = 0x3D (YUV420 NV12/NV21 format)
- DISPC_VID_BA_j[31] and DISPC_VID_BA_UV_j[31]= 0x0
- DISPC_VID_ATTRIBUTES[22] DOUBLESTRIDE = 0x0

8.2.4.10 DISPC Write-Back Pipeline

The write-back pipeline is used to store in the system memory the capture of one of the overlay outputs, or the output of one of the pipelines. The WB pipeline consists of a CSC unit, a scaler unit, and an RGB truncation logic. Because the overlay works on ARGB48 format and the video accelerator works on YUV format, the color space conversion from RGB to YUV is used to directly output to memory the format that can be encoded with no extra processing.

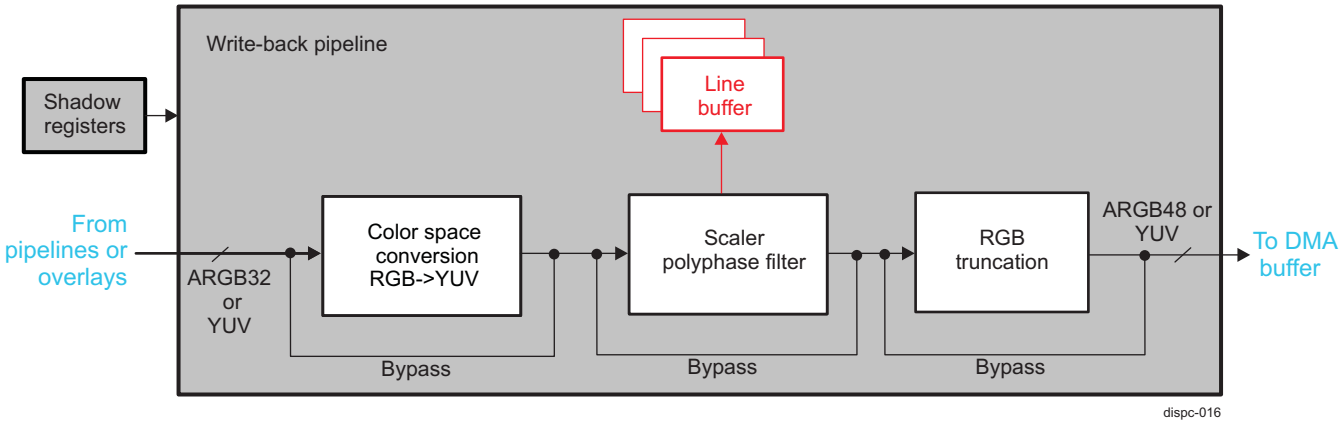
The write-back pipeline is connected to either one of the pipeline outputs (GFX, VID1 or VID2), or to one of the outputs of the overlay managers (OVR1 or OVR2). The input is selected by setting the DISPC_WB_ATTRIBUTES[18:15] CHANNELIN bit field, and the capture frame rate is set in the DISPC_WB_ATTRIBUTES[26:24] CAPTUREMODE bit field.

The output format of the overlay managers is ARGB48-1212121212. The graphics pipeline output is ARGB48. The video pipeline outputs are YUV4:2:2, YUV4:2:0, or ARGB48.

The WB pipeline is enabled by setting the DISPC_WB_ATTRIBUTES[0] ENABLE bit to 0x1.

Figure 8-41 shows the WB pipeline.

Figure 8-41. DISPC Write-Back Pipeline



8.2.4.10.1 DISPC WB CSC Unit RGB to YUV

The RGB-to-YUV CSC unit converts the encoded pixel values from RGB24 into YUV4:4:4 format. For YUV4:2:0 or YUV4:2:2 formats, a chrominance sub-sampling is required after converting the RGB into YUV values. Because of the subsampling, the following limitations must be considered:

- When converting RGB into YUV4:2:0 NV12 (NV21) format:
  - Maximum horizontal downscale = x0.5
  - Maximum vertical downscale = x0.5
- When converting RGB into YUV4:2:2 format:
  - Maximum horizontal downscale = x0.5
  - Maximum vertical downscale = x0.25

Figure 8-42 and Figure 8-43 show the 3 × 3 11-bit coefficients used to convert from RGB24 into YUV4:4:4. The user sets the coefficients according to the standard used to encode the pixel data in YUV color space. Table 8-37 lists the coefficients with their respective bit fields.

Table 8-37. DISPC WB CSC RGB to YUV Bit Field Setting

Coefficients	Bit Fields
Y_R	DISPC_WB_CONV_COEF0[10:0] YR
Y_G	DISPC_WB_CONV_COEF0[26:16] YG
Y_B	DISPC_WB_CONV_COEF1[10:0] YB
Cr_R	DISPC_WB_CONV_COEF1[26:16] CRR
Cr_G	DISPC_WB_CONV_COEF2[10:0] CRG
Cr_B	DISPC_WB_CONV_COEF2[26:16] CRB
Cb_R	DISPC_WB_CONV_COEF3[10:0] CBR
Cb_G	DISPC_WB_CONV_COEF3[26:16] CBG
Cb_B	DISPC_WB_CONV_COEF4[10:0] CBB
G offset	DISPC_WB_CONV_COEF5[31:19] GOFFSET
R offset	DISPC_WB_CONV_COEF5[15:3] ROFFSET
B offset	DISPC_WB_CONV_COEF6[15:3] BOFFSET

If the active range for the luminance samples (Y) is [16:235] and [16:240] for the chrominance samples (Cb and Cr), the values of Y, Cb, and Cr output components are clipped to the range [0:255]. The range selection is done by setting the DISPC_WB_ATTRIBUTES[12] FULLRANGE bit to 0x0.

Figure 8-42. DISPC WB RGB to YCbCr (FULLRANGE = 0)

$$\begin{bmatrix} Y_{OUT} \\ Cb_{OUT} \\ Cr_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cb_R & Cb_G & Cb_B \\ Cr_R & Cr_G & Cr_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 256 \\ 2048 \\ 2048 \end{bmatrix}$$

dispc-017

If the active range for the luminance samples (Y) and or the chrominance samples (Cb and Cr)is [0:255], the values of Y, Cb, and Cr output components are clipped to the range [0:255]. The range selection is done by setting the DISPC_WB_ATTRIBUTES[12] FULLRANGE bit to 0x1.

Figure 8-43. DISPC WB RGB to YCbCr (FULLRANGE = 1)

$$\begin{bmatrix} Y_{OUT} \\ Cb_{OUT} \\ Cr_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cb_R & Cb_G & Cb_B \\ Cr_R & Cr_G & Cr_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 0 \\ 2048 \\ 2048 \end{bmatrix}$$

dispc-018

8.2.4.10.2 DISPC WB Scaler Unit

The functional aspect of the WB pipeline scaler unit is identical to the video pipeline scaler unit (see Section 8.2.4.9.5, *DISPC VID Scaler Unit*), except in the output width when scaling ARGB components. The resulting output format is ARGB32 instead of ARGB48.

The programmable coefficients of the polyphase filters are signed 10-bit values (except for the central coefficient, which is unsigned). The WB scaler component has an 8-bit input and an 8-bit output.

Figure 8-44 and Figure 8-45 show the scaler macro-architecture for the component A, R, G, B, and Y. Figure 8-46 and Figure 8-47 show the scaler macro-architecture for component Cr and Cb.

The scaling output can be clipped to an output range of [0:255] or [16:240] by configuring the DISPC_WB_ATTRIBUTES[12] FULLRANGE bit.

Figure 8-44. DISPC WB Macro-Architecture of the Vertical Scaling for A, R, G, B, and Y Components

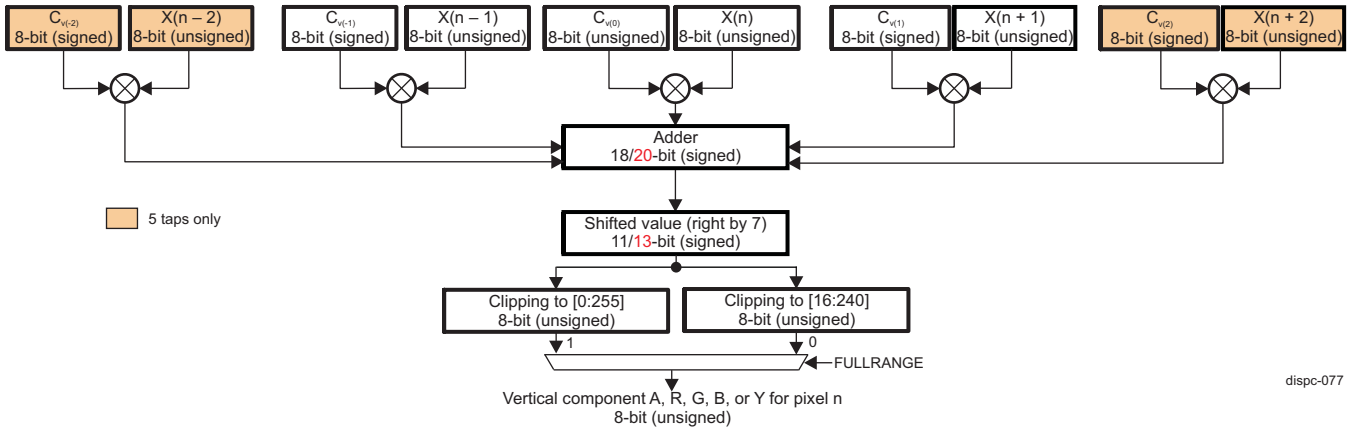


Figure 8-45. DISPC WB Macro-Architecture of the Horizontal Scaling for A, R, G, B, and Y Components

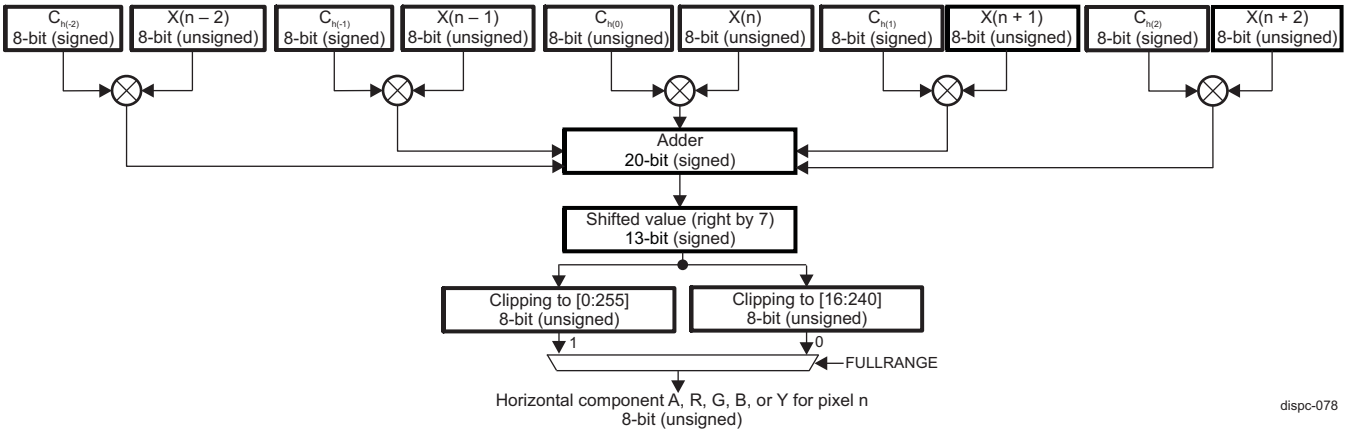

Figure 8-46. DISPC WB Macro-Architecture of the Vertical Scaling for Cr and Cb Components

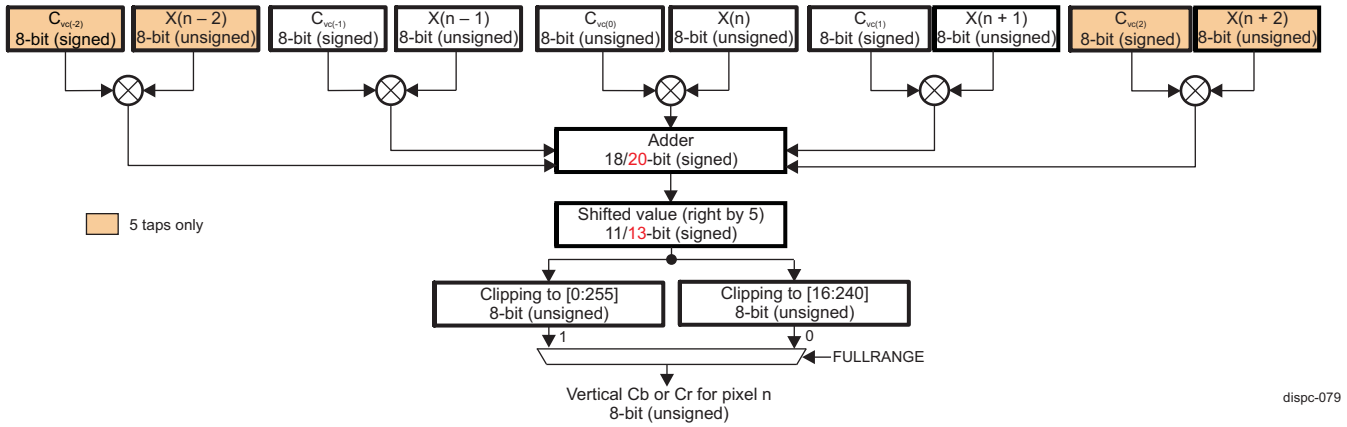

Figure 8-47. DISPC WB Macro-Architecture of the Horizontal Scaling for Cr and Cb Components

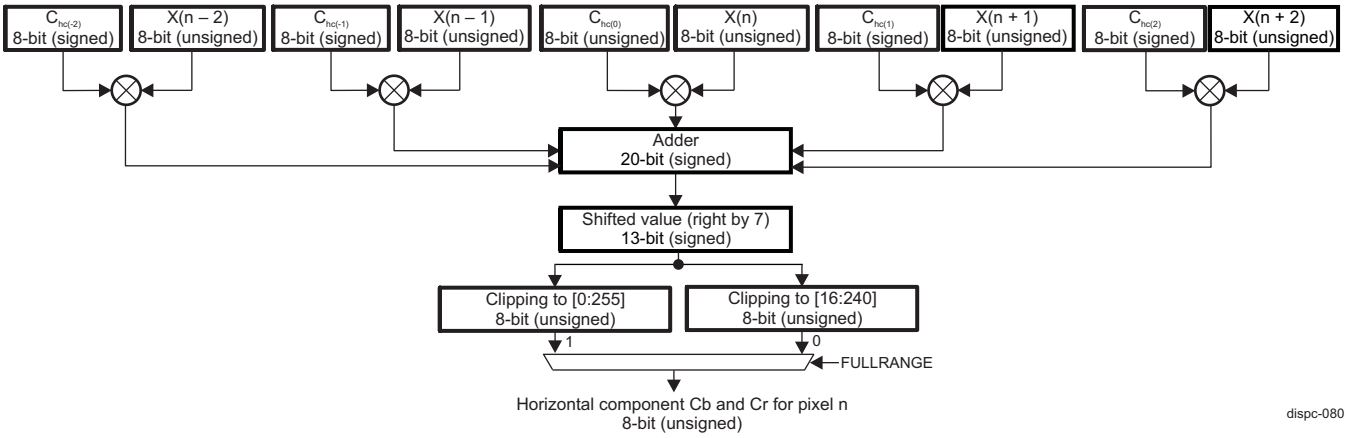

Table 8-38 list all the bit fields in the function to set the coefficients for the WB horizontal scaler in the DISPC_WB_FIR_COEF_H0_i and DISPC_WB_FIR_COEF_H12_k registers.

Table 8-38. DISPC Register Bit Fields Associated to Coefficients for ARGB and Y Configuration in WB Horizontal Scaler

15	DISPC_WB_FIR_COEF_H12_15	DISPC_WB_FIR_COEF_H12_15	DISPC_WB_FIR_COEF_H0_1	DISPC_WB_FIR_COEF_H12_1	DISPC_WB_FIR_COEF_H12_1

NOTE: The Table 8-38 cells without color are duplicated from the grey cells.

Similar table approach applies to the vertical scaler (registers DISPC_WB_FIR_COEF_V0_i and DISPC_WB_FIR_COEF_V12_k).

Similar table approach applies to the coefficients for CbCr filtering in case of YUV format (registers DISPC_WB_FIR_COEF_H0_C_i and DISPC_WB_FIR_COEF_H12_C_k, and DISPC_WB_FIR_COEF_V0_C_i and DISPC_WB_FIR_COEF_V12_C_k) .

The WB scaler unit vertical or/and horizontal sampling is defined by setting/resetting the DISPC_WB_ATTRIBUTES[8:7] RESIZEENABLE bit field.

A set of configuration must be valid before enabling the video up/downsampling block.

The following fields define the configuration of the video up/downsampling block for WB:

- Vertical up/downsampling increments the value of [23:0] FIRVINC bitfield in the DISPC_WB_FIRV and DISPC_WB_FIRV2 registers. The unsigned integer value range is [1:2^{23}]. Software calculates the value using the following equation:

$$FIRVINC = 2^{21} * \left(\frac{SIZEY+1}{MEMSIZEY+1} \right)$$

dispc-066wb (6)

- Horizontal up/downsampling increments the value of the [23:0] FIRHINC bit field in the DISPC_WB_FIRH and DISPC_WB_FIRH2 registers. The unsigned integer value range is [1:2^{23}]. Software calculates the value using the following equation:

$$FIRHINC = 2^{21} * \left(\frac{SIZEX+1}{MEMSIZEX+1} \right)$$

dispc-067wb (7)

- Vertical up/downsampling accumulator value, [23:0] VERTICALACCU bit field in DISPC_WB_ACCUV_j and DISPC_WB_ACCUV2_j registers. The accumulator value indicates on which phase the vertical filtering starts. The register DISPC_WB_ACCUV_0 is used for progressive output, and for interlace output the DISPC_WB_ACCUV_0 and DISPC_WB_ACCUV_1 registers are used. Similarly, DISPC_WB_ACCUV2_0 and DISPC_WB_ACCUV2_1 are used in progressive or interlace output to set the accumulator value of the Cb and Cr components when scaling YUV format.
- Vertical up/downsampling line buffer configuration DISPC_WB_ATTRIBUTES[21] VERTICALTAPS bit: The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used.
- Horizontal up/downsampling accumulator value, [23:0] HORIZONTALACCU bit field in DISPC_WB_ACCUH_j and DISPC_WB_ACCUH2_j registers. The accumulator value indicates on which phase the horizontal filtering starts. The register DISPC_WB_ACCUH_0 is used for progressive output, and for interlace output the DISPC_WB_ACCUH_0 and DISPC_WB_ACCUH_1 registers are used. Similarly, DISPC_WB_ACCUH2_0 and DISPC_WB_ACCUH2_1 are used in progressive or interlace output to set the accumulator value of Cb and Cr components when scaling YUV format.

Table 8-39 lists the DISPC WB vertical and horizontal accumulator values and phases.

Table 8-39. DISPC WB Vertical/Horizontal Accumulator Phase

Accumulator Value (MSB bits)	Phases f
0	0
256 or -3840	1
512 or -3584	2
768 or -3328	3
1024 or -3072	4
1280 or -2816	5
1536 or -2560	6
1792 or -2304	7
2048 or -2048	8
2304 or -1792	9
2560 or -1536	10
2816 or -1280	11
3072 or -1024	12
3328 or -768	13
3584 or -512	14
3840 or -256	15

- Vertical up/downsampling coefficients:
  - The vertical up/downsampling central coefficients are defined in the DISPC_WB_FIR_COEF_V0_i registers. There are 9 registers for the 16 phases with 1 coefficient for each of them. Symetrical implementation is used, so only 9 coefficients are required. Each register contains 10-bit unsigned coefficient (the central one).
  - The vertical up/downsampling coefficients are defined in the DISPC_WB_FIR_COEF_V12_k

registers. There are 16 registers for the 16 phases with 2 coefficients for each of them, so a total of 32 programmable coefficients for the vertical up/downsampling block are used. Each register contains two 10-bit signed coefficients.

Four YUV, the vertical up/downsampling coefficients are set in the DISPC_WB_FIR_COEF_V0_C_i and DISPC_WB_FIR_COEF_V12_C_k registers. Table 8-38 summarizes all coefficients and their respective registers.

- Horizontal up/downsampling coefficients:
  - The horizontal up/downsampling central coefficients are defined in the DISPC_WB_FIR_COEF_H0_i registers. There are 9 registers for the 16 phases with 1 coefficient for each of them. Symetrical implementation is used, so only 9 coefficients are required. Each register contains 10-bit unsigned coefficient (the central one).
  - The vertical up/downsampling coefficients are defined in the DISPC_WB_FIR_COEF_H12_k registers. There are 16 registers for the 16 phases with 2 coefficients for each of them, so a total of 32 programmable coefficients for the vertical up/downsampling block are used. Each register contains two 10-bit signed coefficients.

  Four YUV horizontal up/downsampling coefficients are set in the DISPC_WB_FIR_COEF_H0_C_i and DISPC_WB_FIR_COEF_H12_C_k registers. Table 8-38 summarizes all coefficients and their respective registers.

8.2.4.10.3 DISPC WB RGB Truncation Logic

Truncation logic is used to convert a pixel from ARGB 32-bit format into a lower color depth: 12- or 16-bit format based. The truncation is done by removing the necessary LSB of each component to match the output format.

NOTE: If there is no alpha field in the pixel format description, 0s are used. For example, in RGB12 pixel format, the upper 4 bits are set to 0s because the RGB value is only 12 bits inside a 16-bit container.

8.2.4.11 DISPC Region-Based Mechanism

8.2.4.11.1 Region-Based Mechanism Overview

The region-based mechanism is used in order to display multiple windows using the same layer. The layer can be graphics layer or a video layer. The reconfiguration of a pipeline is performed based on the different region-based interrupts (see Section 8.2.4.4, *DISPC Interrupt Requests*). When all the pixels for the current window have been output, then the pipeline uses the new configuration provided through the shadow registers in order to display the new window re-using the same layer.

It is possible to display unlimited number of windows on the screen using same layer considering the following restriction: only one window horizontally per layer at a given time.

In order to enable the feature, the SW needs to set to 0x1 the [24] REGION_BASED bit within DISPC_GFX1_ATTRIBUTES2, DISPC_VID_ATTRIBUTES2 or DISPC_WB_ATTRIBUTES2 registers.

For the WB pipeline, an additional register DISPC_WB_REGION_BASED_TOTAL_PICTURE_SIZEY, defining the total SIZEY value (total number of lines) of all the windows written back to the memory, needs to be programmed when the Region-based mechanism is enabled for the WB pipeline.

8.2.4.11.2 Region-Based Mechanism for a Single Region Write-Back

A typical use-case for the Region-Based Mechanism in the Write-Back pipeline is to capture one single region at a time per frame, while doing write-back in capture mode. This allows writing back only the region of interest from the entire frame displayed, thereby reducing the write-back bandwidth compared to when the whole frame is written back in a non region-based mode.

In a generic write-back region-based mechanism multiple regions are captured per frame. The last region to capture in a frame is indicated to the HW by resetting the DISPC_WB_ATTRIBUTES2[24] REGION_BASED bit. Due to this, when only a single region capture is needed, a specific programming sequence needs to be followed, which is described in Table 8-40, *DISPC Write-Back Region-Based Configuration Steps*.

Table 8-40 summarizes the configuration steps when the region-based mechanism for a single region is enabled for the WB pipeline.

Table 8-40. DISPC Write-Back Region-Based Configuration Steps

Step	Register/Bit-Field	Value
Initial programming (the very first frame)		
Enable the regional-based feature for WB pipeline.	DISPC_WB_ATTRIBUTES2[24] REGION_BASED	0x1
Configure the attributes of the region.	DISPC_WB_POSITION DISPC_WB_SIZE DISPC_WB_PICTURE_SIZE	- - -
Configure the total number of lines to be captured in the frame to be same as the number of lines in the region DISPC_WB_REGION_BASED_TOTAL_PICTURE_SIZEY.	DISPC_WB_REGION_BASED_TOTAL_PICTURE_SIZEY = DISPC_WB_PICTURE_SIZE[27:16] MEMSIZEY	-
Configure all other shadow registers, associated with the use case.		
Enable WBREGIONBASEDEVENT_IRQ.	DISPC_WB_IRQENABLE[3] WBREGIONBASEDEVENT_EN	0x1
Enable WBSYNC_IRQ.	DISPC_WB_IRQENABLE[4] WBSYNC_EN	0x1
Enable the Video Port (VP1) output.	DISPC_VP1_CONTROL[0] VPENABLE	0x1
Wait for the GOBIT bit to get reset by HW.	DISPC_VP1_CONTROL[5] GOBIT	0x0
From here on the region-based feature is active and will trigger both WBREGIONBASEDEVENT_IRQ and WBSYNC_IRQ every frame until the feature is completely disabled.		
The following actions need to be taken by SW in WBSYNC_IRQ and WBREGIONBASEDEVENT_IRQ routines every time those interrupts are triggered, until region-based feature is disabled.		
In WBSYNC_IRQ routine, reset the regional-based bit.	DISPC_WB_ATTRIBUTES2[24] REGION_BASED	0x0
In WBREGIONBASEDEVENT_IRQ routine, set the region-based bit.	DISPC_WB_ATTRIBUTES2[24] REGION_BASED	0x1
If the attributes of the region to be captured during next frame (position, size, base address) are different than the current region, then the corresponding changes must applied to WB registers.		

8.2.4.12 DISPC Overlay Managers

DISPC implements two identical Overlay Managers (see Figure 8-24, *DISPC Architecture Overview*):

- OVR1, with output assigned to the Video Port (VP1).
- OVR2, with output asiggned to the WB pipeline.

The overlay mechanism consists of displaying more than one layer (GFX, VID1 or VID2 pipeline layers) using:

- A priority rule based on a Z-order: Application can set the ordering layer of the frames.
- Transparency color keys: Destination and source transparency color keys can be set.
- Alpha blending values: Using the A component of a pixel or a blending set by the user for a layer, a level of transparency can be determined.

All pipelines (GFX, VID1 and VID2) can be assigned to one of the overlay managers (OVR1 or OVR2), or directly to the WB pipeline. The overlay managers can be connected to all pipeline outputs simultaneously. The GFX pipeline output is directed using the DISPC_GFX1_ATTRIBUTES[10:8] CHANNELOUT bitfield, while the VID1 and VID2 pipeline outputs are directed using the DISPC_VID_ATTRIBUTES[16:14] CHANNELOUT bit fields. Table 8-41 summarizes the bit field settings to direct a pipeline to the OVR1, OVR2 or WB. The default register value directs all pipelines to OVR1.

Table 8-41. DISPC Pipeline Connection to VP1 or WB Output

	DISPC_GFX1_ATTRIBUTES	DISPC_VID_ATTRIBUTES
Overlay Manager/Output	**[10:8] CHANNELOUT Bitfield**	**[16:14] CHANNELOUT Bitfield**
OVR1/VP1	0x0	0x0
OVR2	0x1	0x1
WB	0x4	0x4

The output of OVR1 is connected to VP1 Color Phase Rotation (CPR) unit through the Gamma table.

NOTE:

- When the pixel format is ARGB or RGBA, the color key match logic uses only the RGB value defined by ARGB or RGBA. The alpha blending factor is ignored.

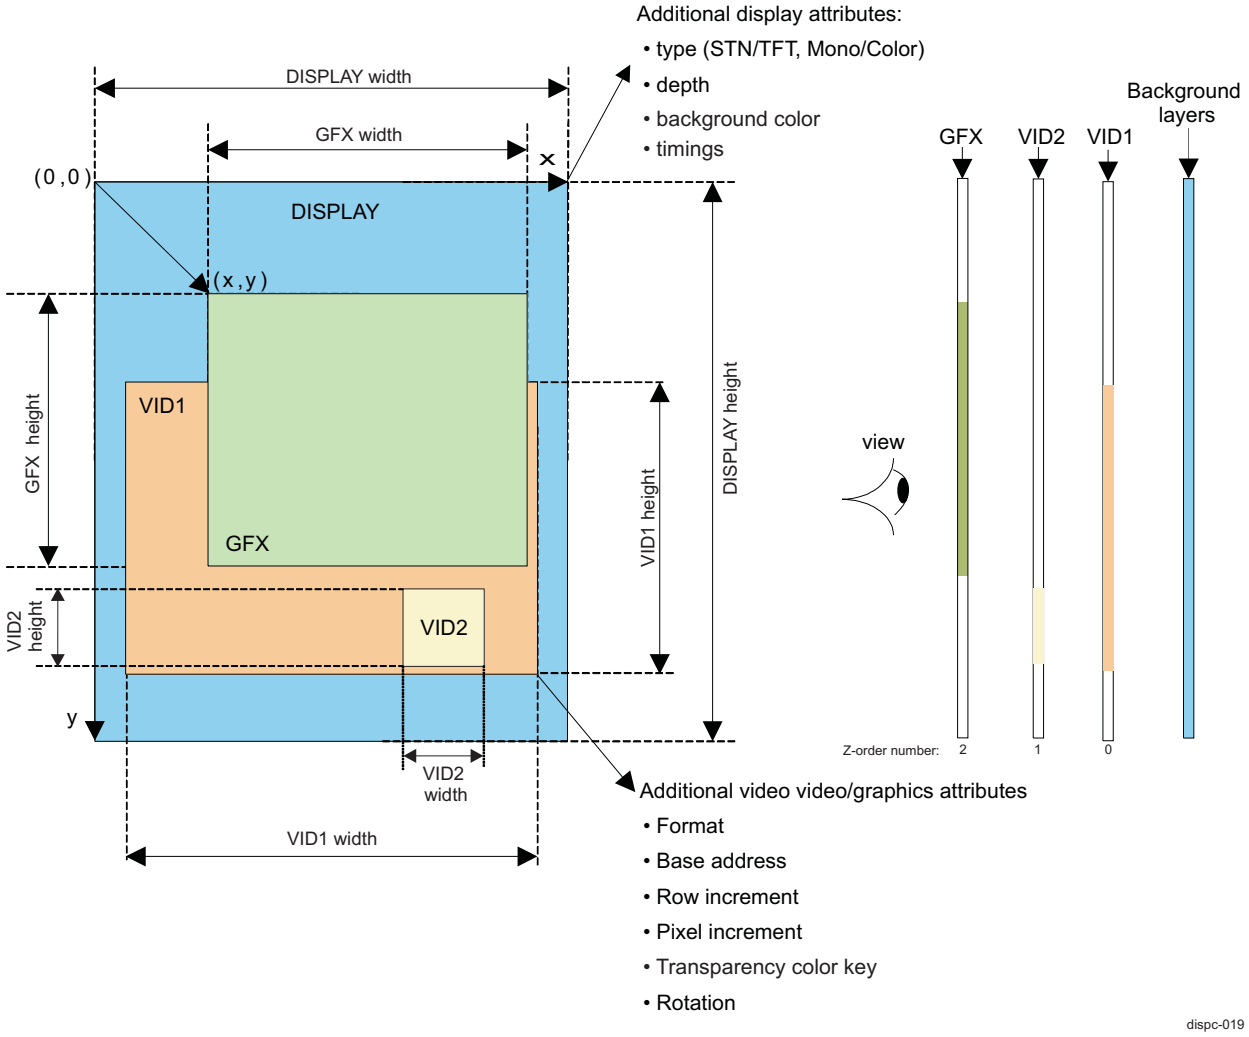
8.2.4.12.1 DISPC Overlay Priority Rule

The overlay manager is configured using the Z-order parameter. The Z-order value defined for each pipeline indicates the visibility order to the window on the screen. If the Z-order value of window A is lower than the Z-order to layer B, layer A is displayed below layer B. The transparency color keys and the alpha blending factors are then used to blend the layers together (see Section 8.2.4.12.2, *DISPC Alpha Blender*, and Section 8.2.4.12.3, *DISPC Transparency Color Keys*). The Z-order for each pipeline is defined in the DISPC_GFX1_ATTRIBUTES[27:25] ZORDER and DISPC_VID_ATTRIBUTES[27:25] ZORDER register bit fields. Each ZORDER bit-field setting must be different for each active pipeline. It is not possible to use the same value for more than one pipeline.

The height and width of each enabled layer (pipeline) must be defined in the [11:0] SIZEX and [27:16] SIZEY bit fields of DISPC_GFX1_SIZE and DISPC_VID_SIZE registers. The x and y positions of each layer must be defined in the [11:0] POSX and [27:16] POSY bit fields of DISPC_GFX1_POSITION and DISPC_VID_POSITION registers. If there are no graphics or video-encoded pixels at a specific position, the programmable, solid background color appears. The solid background color is set in the DISPC_OVR_DEFAULT_COLOR register. Figure 8-48 is an example of priority rule.

The Z-order reordering block must always map the pipelines to the blender logic in the same order - from background to foreground.

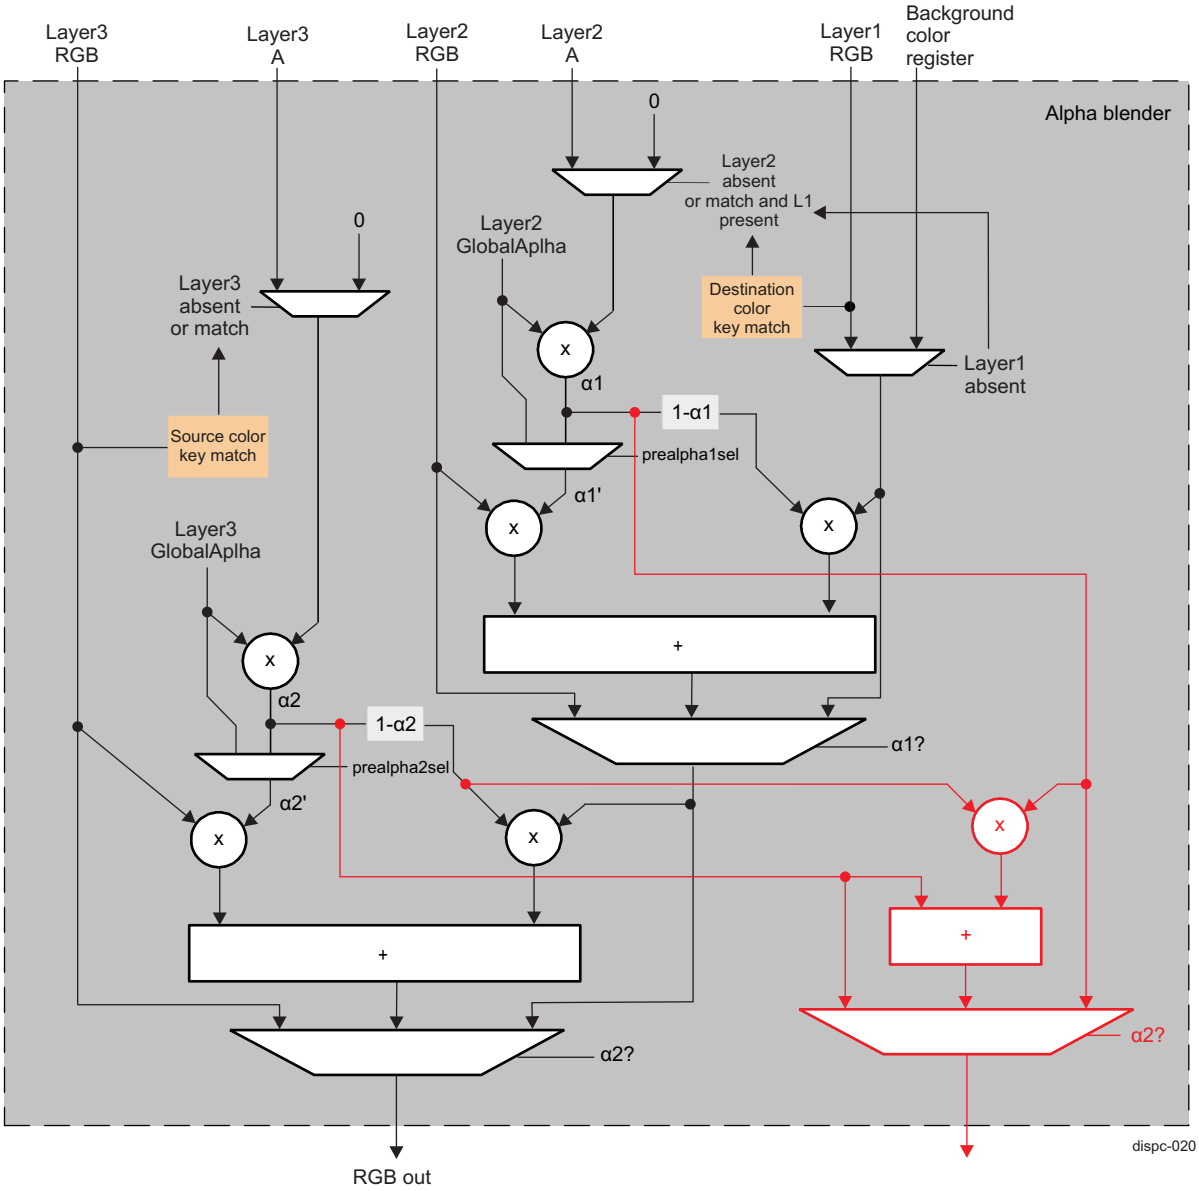
Figure 8-48. DISPC Overlay Example of Priority Rule: From Lower to Higher VID1, VID2, GFX



8.2.4.12.2 DISPC Overlay Alpha Blender

Figure 8-49 shows the alpha blending processing in detail.

Figure 8-49. DISPC Overlay Alpha Blending Architecture With Premultiplied Alpha Support



CAUTION

The Z order of the Source Transparency Layer must have the value 2 (0x2: Z-order 2: layer above all the other layers).

NOTE: 1-alpha operator corresponds to the basic 1s-complement operation.

The alpha blending value is defined by:

- The component value A when using an ARGB or RGBA pixel format.
  - For ARGB-1555, the alpha blending is defined using a 1-bit value. It is converted into an 8-bit value by duplicating the 1-bit value (see Table 8-42).
  - For ARGB-4444, the alpha blending is defined using a 4-bit value. It is converted into an 8-bit value by duplicating the 4-bit value (see Table 8-42).

  - If the pixel format contains no alpha blending value, the pixel alpha value is considered to be 0xFF, and if alpha is equal to 0xFF, there is no multiplication.
  - For BITMAP or YUV formats, there is no alpha blending factor associated with each pixel value. Only the global alpha blending factor associated with the window displaying the BITMAP or YUV format is used.
- Each 12x12 multiplication gives a result on 24 bits, which are shifted to the right to become an 12-bit value. All the values are unsigned.
- The global alpha blending value is set in the DISPC_GFX1_GLOBAL_ALPHA and DISPC_VID_GLOBAL_ALPHA registers, and is updated in synch with the selected output channel.

Table 8-42 lists the percentage of alpha blending in the function of the alpha blending value on 8 bits.

Table 8-42. DISPC Overlay Alpha Blending – ARGB

Alpha Blending 1-Bit Value (ARGB16-1555)	Alpha Blending 4-Bit Value (ARGB16-4444)	Alpha Blending 8-Bit Value (Converted Value or Resulting Alpha)	Percent Blending
0x0	0x0	0x00	100 (transparent)
N/A	0x1	0x11	93.33
N/A	0x2	0x22	86.6
N/A	...	...	...
N/A	0xE	0xEE	6.6
0x1	0xF	0xFF	0 (opaque)

Premultiplied Alpha

The image ARGB may have its RGB component already premultiplied with the alpha (ARGB) where:

- R = A*R
- G = A*G
- B = A*B

In that case, the processing is as follows:

- Color component of premultiplied layers are multiplied with the Global Alpha, if Global Alpha is not equal to 0.
- Color component of the composed underlying layers are multiplied with (1 - A × Global Alpha).

The additional premultiplied alpha option is associated with the pipelines GFX, VID1 and VID2. The option is accessible through the [28] PREMULTIPLYALPHA bit for the respective pipeline register:

- DISPC_GFX1_ATTRIBUTES
- DISPC_VID_ATTRIBUTES

The following settings are available:

- PREMULTIPLYALPHA bit = 0: Source is not premultiplied with alpha. Full blending is done in the DISPC.
- PREMULTIPLYALPHA bit = 1: Source is premultiplied with alpha. Partial blending is done.

NOTE: The *prealphasel* controls in Figure 8-49, correspond to the PREMULTIPLYALPHA of the pipelines mapped on the respective layers.

The logic marked in red in Figure 8-49 corresponds to the alpha value, computed when the write-back channel copies back to memory the premultiplied color component:
A (destination) = A (source) + (1-A (source) × A (destination))

The default value for DISPC_WB_ATTRIBUTES[7] ALPHAENABLE bit is 0x0. When the WB is configured to copy back one of the output channels (output of overlay), the following configurations are available:

- The ALPHAENABLE bit is set to 0x1: The WB pipe copies back to memory the premultiplied alpha calculated through the overlay.

- The ALPHAENABLE bit is set to 0x0: The alpha value is not written back.

NOTE: The DISPC_WB_ATTRIBUTES[7] ALPHAENABLE bit is effective only when one of the output channels is written back, otherwise it is ignored.

8.2.4.12.3 DISPC Overlay Transparency Color Keys

There are two transparency color keys: the source transparency color key and the destination transparency color key. The source transparency color key can be used with BITMAP formats (1-, 2-, 4-, and 8-bpp), YUV, and RGB formats (ARGB, RGB, RGBA, xRGB, and RGBx). In this case the A information is ignored for the comparison between the pixel value and the color key value. It is possible to use YUV formats with some caution, because the comparison is between the input pixel value of the overlay manager from pipeline (GFX or one of the VID pipelines depending on the Z-order) and the color key value. The YUV data is converted to RGB format. If the original format is YUV, the user must consider the color space conversion processing to define the RGB color key value used for the comparison.

The transparency color key is enabled by setting the following bits to 0x1:

- DISPC_OVR_CONFIG[10] TCKLCDENABLE

The transparency color key is determined in the TRANSCOLORKEY bit fields of the following registers:

- DISPC_OVR_TRANS_COLOR_MAX, DISPC_OVR_TRANS_COLOR_MAX2, DISPC_OVR_TRANS_COLOR_MIN and DISPC_OVR_TRANS_COLOR_MIN2

NOTE:

- The video source transparency color key and graphics destination transparency color key cannot be active at the same time.
- For CLUT bitmaps, the palette index is compared to the transparency color key and not to the palette value pointed out by the palette index.

- **Source transparency color key**

  The value of the video source transparency color key defines the range of encoded pixel data considered as a transparent pixel. The encoded pixel values with the source color key value inside the valid range are not visible, and the encoded pixel values of the under layers or solid background color are visible.

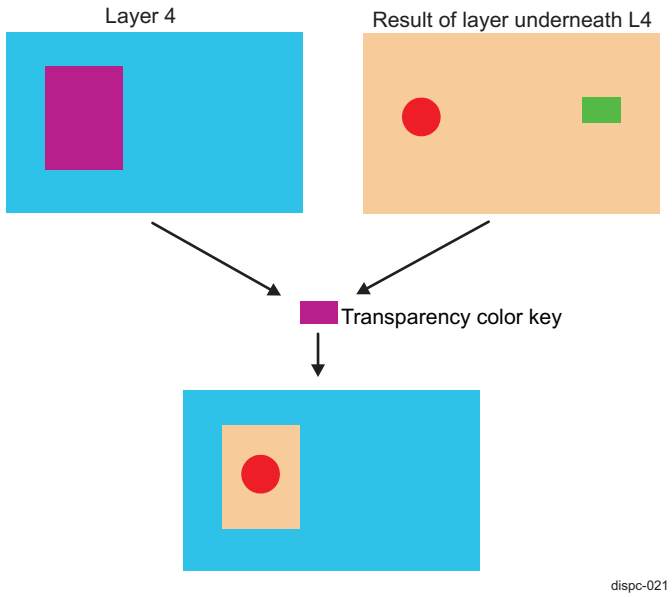
  The scaler can be enabled as a preprocessor in the VID pipelines, but it is necessary to consider the pixel scaling preprocessing in order to define the color key value to be used after the rescaling for the comparison between the input pixel value to the overlay manager and the color key value.

  The source transparency color key mode is selected by setting the following bit to 0x1:

  – DISPC_OVR_CONFIG[11] TCKLCDSELECTION

  Figure 8-50 shows an example of source color key. The pixels with the transparency color key are not displayed; instead, pixels of the resulting layer underneath are shown.

Figure 8-50. DISPC Overlay Source Transparency Color Key Example



- **Destination transparency color key**

  The graphics destination transparency color key values define the range of the encoded pixels in layer 1, which are not displayed. Other layer 1 pixels (not in the range of destination transparency color key value) are displayed over layer 2. The encoded pixels within the range of destination color key values are pixels not visible on the screen because pixels at the same position in layer 2 are visible; otherwise, encoded pixels are visible above layer 2 . The destination transparency color key applies only if layer 1 overlaps layer 2 (see the Z-order section for details on layer position depending on the Z-order parameter in Section 8.2.4.12.1, *DISPC Overlay Priority Rule*); otherwise, the destination transparency color key is ignored.

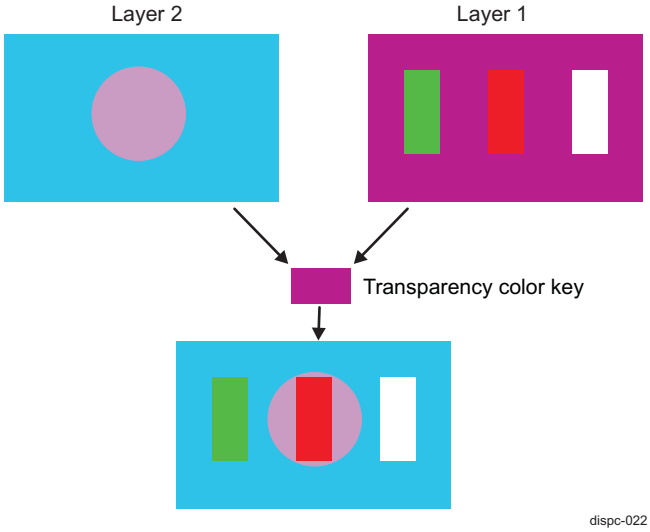
  The scaler can be enabled as a preprocessor in the VID pipelines. It is necessary, however, to consider the pixel scaling preprocessing in order to define the color key value to be used after rescaling for the comparison between the input pixel value to the overlay manager and the color key value.

  The destination transparency color key mode is selected by setting the following bit to 0x0:

  – DISPC_OVR_CONFIG[11] TCKLCDSELECTION

  Figure 8-51 shows an example of the destination color key. The pixels, equal to the transparency color key, are not displayed and are replaced by layer 2 pixels. All other layer 1 pixels, different from the transparency color key, are displayed over layer 2.

Figure 8-51. DISPC Overlay Destination Transparency Color Key Example



8.2.4.13 DISPC Video Port Output

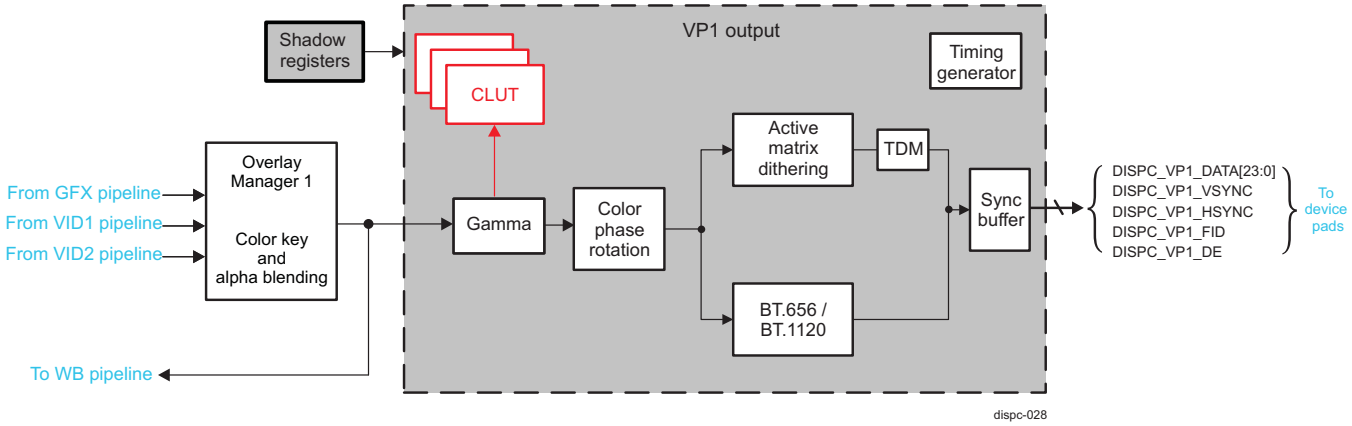
DISPC implemets a single video port output (VP1). It processes data received from Overlay Manager 1 (OVR1). The VP1 output path consist of several processing blocks (see Figure 8-52):

- Gamma correction unit
- Color phase rotation (CPR) (also used for RGB-to-YUV conversion)
- Active matrix dithering with TDM
- BT.656
- BT.1120
- Timing generator

The display subsystem supports active matrix display technology. The configuration of colors depends on the color depth:

- 24 bpp supports 16,777,216 colors.
- 18 bpp supports 262,144 colors.
- 16 bpp supports 65,536 colors.
- 12 bpp supports 4096 colors.

Figure 8-52. DISPC VP1 Output Architecture



NOTE: In BT.656 mode only bits 9 through 0 are used from DISPC_VP1_DATA[23:0] data bus.

8.2.4.13.1 DISPC VP1 Gamma Correction Unit

When performing gamma correction, the selected encoded pixel values based on the color keys by the overlay manager from the video or graphics paths are sent to the gamma curve table. Each component of encoded pixel value is used as a pointer to index 1 out of 256 24-bit gamma curve entries in the table. Each 8-bit component is replaced with the 8-bit table value corresponding to R, G, or B component. The table is loaded by software. It is possible to load only part of the table. For each access to the table, the 24-bit value is associated with index in the table by concatenating the 24-bit value (LSB of 32-bit access) and the 8-bit index value (MSB of the 32-bit access).

The sequence to load the gamma table is:

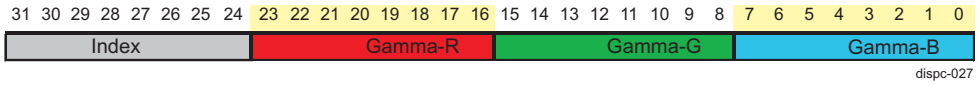
1. SW writes (only writes are supported) 32-bit gamma correction values using single access, or burst access in streaming mode, into DISPC_VP1_GAMMA_TABLE register. The LSB 24 bits [23:0] are used for the value, and the MSB 8 bits [31:24] are used for the index into the table.
2. Loop to Step 1, if there is a new access to the gamma table register. The SW can access other registers between two accesses to the gamma table register.

SW needs to ensure that there is no visible effect when modifying the table, since it is not under HW control.

The usage of the gamma table is activated by setting DISPC_VP1_CONFIG[2] GAMMAENABLE register bit to 0x1.

Figure 8-53 describes the format of one of the gamma curve values in the memory.

Figure 8-53. DISPC Data Memory Organization for Gamma Mode in VP1 Output



8.2.4.13.2 DISPC VP1 Color Phase Rotation Unit

The Color Phase Rotation (CPR) unit can be used to correct the display output colorimetry in case of nonpure white backlight.

The CPR is enabled by setting the DISPC_VP1_CONFIG[15] CPR bit to 0x1. The coefficients are programmed in the following registers:

- Red 10-bit signed coefficients in DISPC_VP1_CPR_COEF_R
- Green 10-bit signed coefficients in DISPC_VP1_CPR_COEF_G
- Blue 10-bit signed coefficients in DISPC_VP1_CPR_COEF_B

The CPR logic is integrated after the overlay manager while using the gamma correction and before the spatial/temporal dithering. The CPR can be selected to correct the nonpure white backlight of the display module by using a programmable matrix to convert the 36-bit RGB pixel value into a new 30-bit RGB pixel value. The matrix is programmed through a set of nine 10-bit signed coefficients. The output of the calculation is clipped to [0:4095]. The CPR is processed by the equation shown in Figure 8-54. Table 8-43 lists all coefficients with their respective register bitfields for settings.

Figure 8-54. DISPC VP1 CPR Matrix

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \begin{bmatrix} Rr & Rg & Rb \\ Gr & Gg & Gb \\ Br & Bg & Bb \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

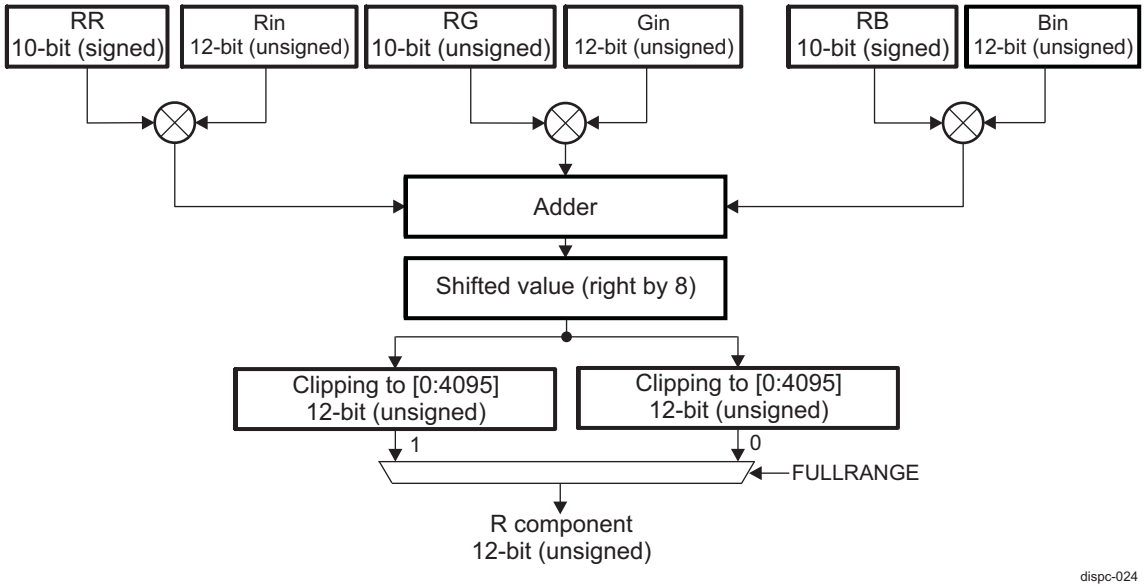
dispc-023

Table 8-43. DISPC VP1 CPR, or RGB to YUV Conversion Coefficients with Associated Register Bitfields

Registers	Bit Field	Color Phase Rotation	RGB to YUV
DISPC_VP1_CPR_COEF_R	RR	Rr	Yr
	RG	Rg	Yg
	RB	Rb	Yb
DISPC_VP1_CPR_COEF_G	GR	Gr	Cbr
	GG	Gg	Cbg
	GB	Gb	Cbb
DISPC_VP1_CPR_COEF_B	BR	Br	Crr
	BG	Bg	Crg
	BB	Bb	Crb

Figure 8-55 shows the CPR macro-architecture.

Figure 8-55. DISPC VP1 CPR Macro-Architecture



8.2.4.13.3 DISPC VP1 Color Space Conversion

The CPR block can be used to perform Color Space Conversion (CSC). Table 8-43 lists the associated coefficients with their respective register bit-fields. The CSC logic uses the CPR registers for the coefficients. Only the upper 10 bits of each color component are used for the CSC processing. The CSC processing is enabled by setting the DISPC_VP1_CONFIG[24] COLORCONVENABLE register bit to 0x1.

The color space conversion on the VP output can be selected in order to convert from 30-bit RGB to YUV444. The matrix is programmed through a set of nine 10-bit signed coefficients. The result is clipped to [64:940] for the luminance and [64:960] for the chrominance, when full-range equals zero (DISPC_VP1_CONFIG[25] FULLRANGE = 0).

Figure 8-56. DISPC VP1 CSC RGB to YUV Registers (FullRange=0)

$$\begin{bmatrix} Y \\ Cr \\ Cb \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} YR & YG & YB \\ CrR & CrG & CrB \\ CbR & CbG & CbB \end{bmatrix} * \begin{bmatrix} R \\ G \\ B \end{bmatrix} + \begin{bmatrix} 0 \\ 128 \\ 128 \end{bmatrix}$$

dispc-098

If the programmed active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:1023], the values Y, Cb, and Cr are clipped to the range [0:1023]. The following equation gives the 11-bit coefficients of the RGB to YUV color space conversion, for full-range (DISPC_VP1_CONFIG[25] FULLRANGE = 1)

Figure 8-57. DISPC VP1 CSC RGB to YUV Registers (FullRange=1)

$$\begin{bmatrix} Y \\ Cr \\ Cb \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} YR & YG & YB \\ CrR & CrG & CrB \\ CbR & CbG & CbB \end{bmatrix} * \begin{bmatrix} R \\ G \\ B \end{bmatrix} + \begin{bmatrix} 0 \\ 128 \\ 128 \end{bmatrix}$$

dispc-098

In order to provide YUV422 data to the BT-656 or BT-1120 blocks, the YUV444 format is converted to YUV422 by sub-sampling the chrominance values. The hardware does this by averaging two-by-two the chrominance samples. The conversion from YUV444 to YUV422 is performed when the color space conversion is enabled.

8.2.4.13.4 DISPC VP1 BT.656 and BT.1120 Modes

The VP1 output can be configured in BT.656 or BT.1120 mode. The following standards are not supported in BT.656 mode:

- BT.470 (Support for conventional Analog TV Systems)
- BT.803 (The avoidance of interference generated by digital television studio equipment)
- BT.1364 (Format of ancillary data signals carried in digital component studio interfaces)

Unsupported formats when BT.1120 mode is used:

- BT.1364 (Support for Ancillary Data during blanking period)

BT.656/BT.1120 modes use embedded EAV/SAV syncs.

Enabling BT.656 or BT.1120 format for VP1 ouput is done by setting DISPC_VP1_CONFIG[20] BT656ENABLE or [21] BT1120ENABLE register bits.

NOTE: It is not posssible to enable BT.656 and BT.1120 mode simultaneously on the same output.

Figure 8-58 shows signal mapping on DISPC_VP1_DATA[23:0] data bus. Bits 9 to 0 are used in BT.656 mode (10-bit).

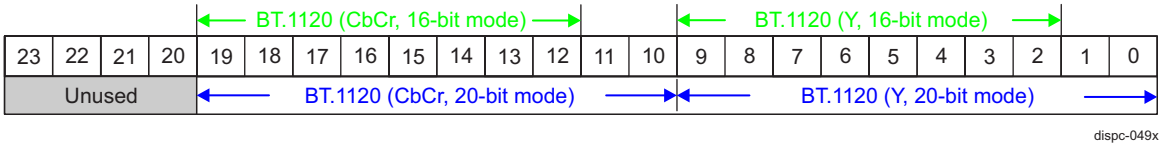
Figure 8-58. DISPC VP1 Data Mapping in BT.656 Mode

23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Unused														BT.656									

NOTE: For compatibility with existing 8-bit interfaces, the two LSB are ignored, and only bits [9:2] are used.

Figure 8-59 shows signal mapping on DISPC_VP1_DATA[23:0] data bus for BT.1120 mode. Bits [19:10] (CbCr) and [9:0] (Y) are used in 20-bit mode. Bits [19:12] (CbCr) and [9:2] (Y) are used in 16-bit mode (YCbCr 4:2:2).

Figure 8-59. DISPC VP1 Data Mapping in BT.1120 Mode



VP1 supports progressive output for embedded syncs interface, when it is configured in BT.656/BT.1120 modes. For more information on timings configuration, see Section 8.2.4.13.7, *DISPC VP1 Timing Generator and Panel Settings*.

8.2.4.13.4.1 DISPC BT Mode Blanking

During the transmission of the video signal, the portion of the stream in-between active video data segments is known as the horizontal blanking interval.

Strictly speaking this entire region is the blanking interval, but this interval also includes the EAV and SAV codes. The remaining bytes of information in a digital blanking interval are filled with values corresponding to the blanking levels of the Cb, Y and Cr signals respectively, and in accordance with the standard multiplex sequence for the stream (CbYCrY..). The blanking levels are as follows:

- Cb = 80h
- Y = 10h
- Cr = 80h.

  The sequence in the BLANKING region of the data stream is therefore: *80h, 10h, 80h, 10h.....80h, 10h*

  For more details on setting the blanking timing values for BT.1120 and/or BT.656 mode, see Section 8.2.4.13.7, *DISPC Timing Generator and Panel Settings*.

8.2.4.13.4.2 DISPC BT Mode EAV and SAV

The End of Active Video(EAV) and Start of Active Video (SAV) parts of the stream are timing codes. Their function can be summarized as follows:

- EAV – marks the end of the active video data within the current line and therefore also the start of the subsequent line.
- SAV – heralds the start of the active video data within the current line.

These codes are embedded within the BT.656 video data stream, thereby eliminating the need for additional timing signals (HSYNC, VSYNC) to be included as part of the interface.

Both EAV and SAV codes are comprised of a sequence of four bytes (FFh – 00h – 00h - XY). The first three bytes in the sequence constitute a fixed preamble. The fourth byte, contains information about the field being transmitted (Field 1 or Field 2 in an interlaced video signal), the state of field blanking (Vertical) and the state of line blanking (Horizontal). The bit assignment for this byte of the code is shown in Figure 8-60, with the function of each bit described inTable 8-44.

Figure 8-60. DISPC BT Mode Bit-Assignment for the Fourth Byte of EAV/SAV Codes

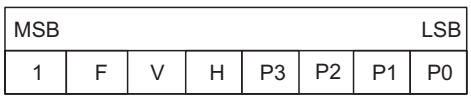


Table 8-44. DISPC BT Mode Bit Function

Bit	Symbol	Function
7	1	Always set to '1'.
6	F	Field bit. 0 – Field 1 1 – Field 2
5	V	Vertical Blanking Status bit. This bit goes High during a vertical field blanking interval, otherwise it remains Low.

Table 8-44. DISPC BT Mode Bit Function (continued)

Bit	Symbol	Function
4	H	Horizontal Blanking Status bit. 0 – byte is part of SAV code (i.e. stream is entering an active video data region for the current line) 1 – byte is part of EAV code (i.e. stream has entered a horizontal blanking interval - start of a new line)
3	P3	Protection bit 3
2	P2	Protection bit 2
1	P1	Protection bit 1
0	P0	Protection bit 0

The protection bits allow for detection and correction of 1-bit errors and the detection of 2-bit errors. The status of P3, P2, P1 and P0 depend on the states of bits F, V and H. This dependency is shown in Table 8-45.

Table 8-45. DISPC BT Mode Status of Protection Bits as F, V and H Vary

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1
1	0	1	1	0	1	0
1	1	0	1	1	0	0
1	1	1	0	0	0	1

8.2.4.13.5 DISPC VP1 Spatial/Temporal Dithering

The spatial/temporal dithering logic can be selected to enhance the quality of the active matrix outputs. The dithering logic is integrated after the CPR and before the TDM. The encoded pixel values are used by spatial/temporal dithering logic to display the data in a lower color depth on the display panel. The spatial/temporal dithering algorithm is based on the (x,y) pixel position and frame rate control. The dithering logic can process the pixels over one frame, two frames, or four frames. The number of frames is selected by setting the DISPC_VP1_CONTROL[31:30] SPATIALTEMPORALDITHERINGFRAMES bit field. In the case of a single frame, only spatial processing is applied. In case of multiple frames, spatial and temporal processing are applied to the pixels. The spatial/temporal dithering logic is enabled by setting the DISPC_VP1_CONTROL[7] STDITHERENABLE bit to 0x1.

NOTE:

- If the interface data bus is smaller than the pixel format size and spatial/temporal dithering is not enabled, the MSBs of the pixel color components are output on the interface data bus.
- If the interface data bus is larger than the pixel format size, by programming the pixel components replication active/inactive, the MSB is replicated to the LSB of the interface data bus.

8.2.4.13.6 DISPC VP1 Multiple Cycle Output Format (TDM)

The pixels are formatted on one or multiple cycles (a maximum of three cycles). On three cycles, two pixels can concatenate and send to the panel. The cycle format is selected through the DISPC_VP1_CONTROL[24:23] TDMCYCLEFORMAT bit field. The number of bits for each cycle is set in the DISPC_VP1_DATA_CYCLE_0 register for the first cycle, the DISPC_VP1_DATA_CYCLE1 register for the second cycle, and the DISPC_VP1_DATA_CYCLE2 register for the third cycle. The interface data bus width, when TDM mode is enabled (DISPC_VP1_CONTROL[20] TDMENABLE = 1), can be 8, 9, 12, or 16 bits, configurable through the DISPC_VP1_CONTROL[22:21] TDMPARALLELMODE bit field.

When the TDM is disabled (DISPC_VP1_CONTROL[20] TDMENABLE = 0), the DISPC outputs the pixels using the conventional formats: active matrix display monochrome/color. When TDM is disabled, the interface data bus width is configured through the DISPC_VP1_CONTROL[10:8] DATALINES bit field.

When using TDM mode, only up to 24-bit per pixel can be output on the interface. For higher color depth, only the upper bits are kept before converting each pixel into TDM output.

Figure 8-61 through Figure 8-64 show various examples of TDM settings in the function of pixel data formats and the interface data bus width.

Figure 8-61. DISPC VP1 TDM 8-Bit Interface Settings

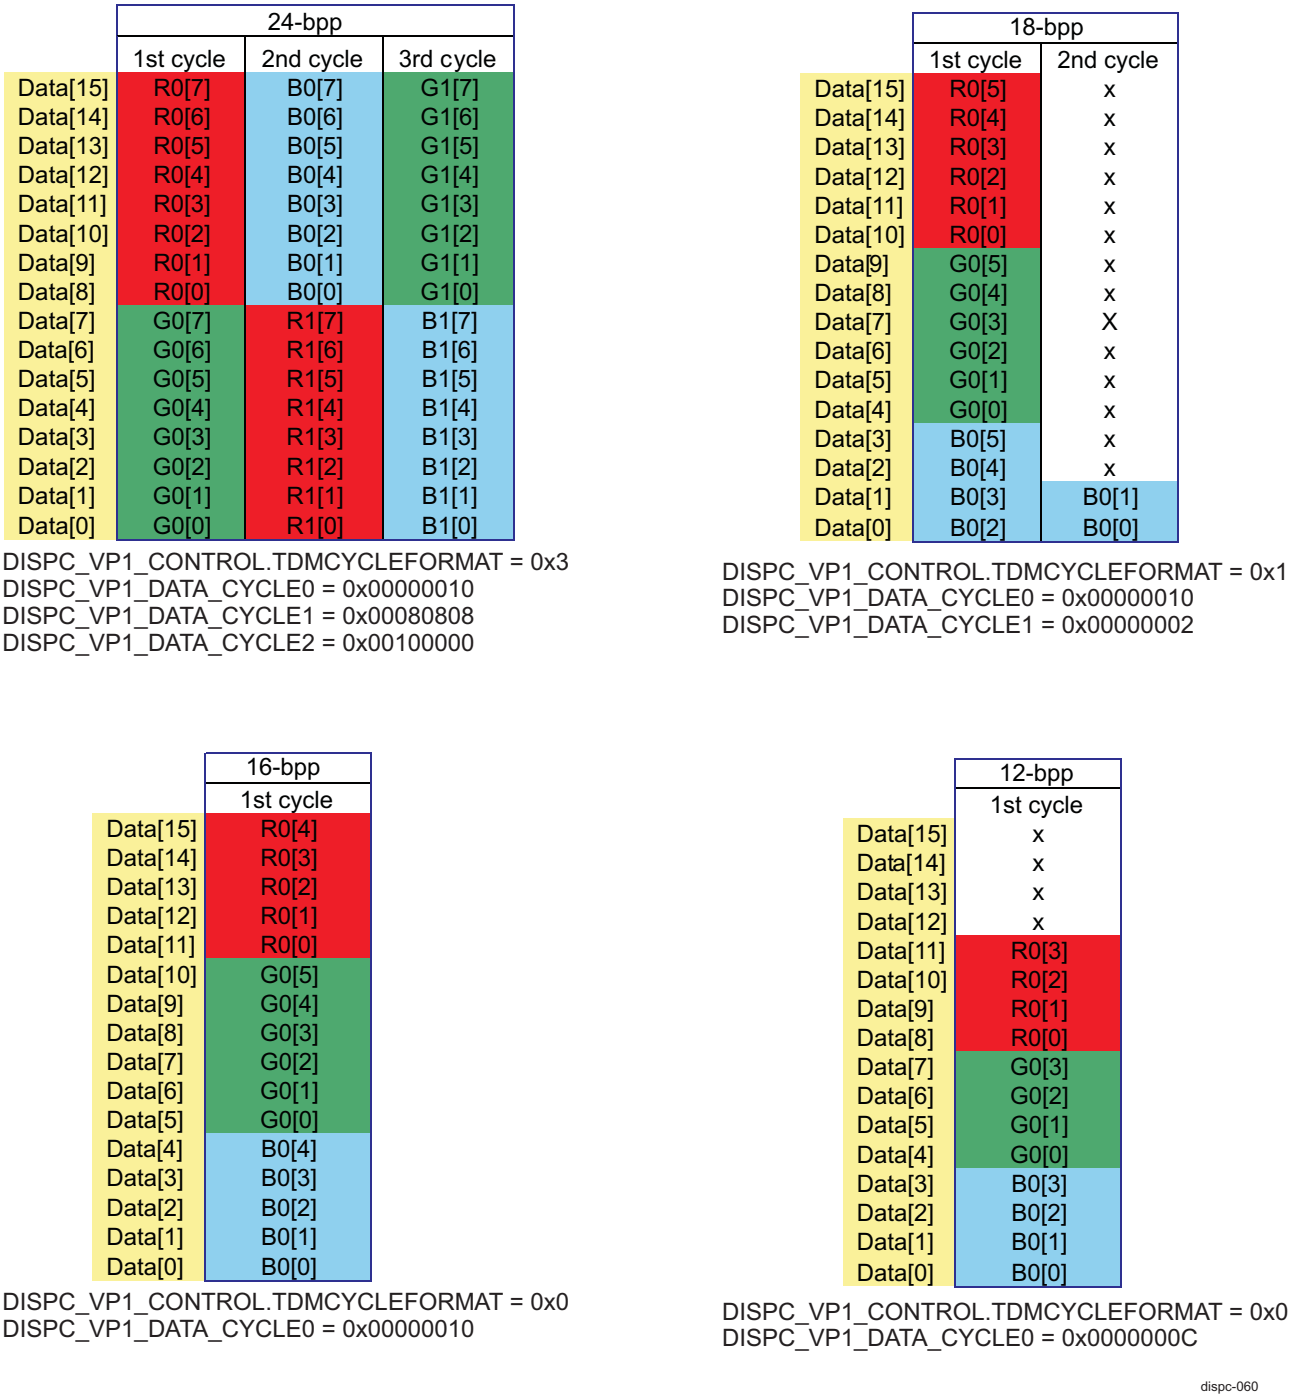
Figure 8-64. DISPC VP1 TDM 16-Bit Interface Settings



8.2.4.13.7 DISPC VP1 Timing Generator and Panel Settings

The VP1 output has a dedicated timing generator supporting progressive and interlaced mode.

The size of the display panel is defined by:

- Number of lines, DISPC_VP1_SIZE_SCREEN[27:16] LPP bit field, with a value from 1 to 4096
- Number of pixels per line, DISPC_VP1_SIZE_SCREEN[11:0] PPL bit field, with a value from 1 to 4096

Standard HSYNC/VSYNC timing generation are programmable for VP1:

- Horizontal front porch is set in the DISPC_VP1_TIMING_H[19:8] HFP bit field.
- Horizontal back porch is set in the DISPC_VP1_TIMING_H[31:20] HBP bit field.
- Horizontal synchronization pulse width is set in the DISPC_VP1_TIMING_H[7:0] HSW bit field.
- Vertical front porch is set in theDISPC_VP1_TIMING_V[19:8] VFP bit field.
- Vertical back porch is set in the DISPC_VP1_TIMING_V[31:20] VBP bit field.
- Vertical synchronization pulse width is set in the DISPC_VP1_TIMING_V[7:0] VSW bit field.

When the output is in BT.1120 or BT.656 mode, the following timing constants are mapped onto the DISPC_VP1_TIMING_H and DISPC_VP1_TIMING_V registers:

- Progressive mode:
  - Horizontal blanking (12 bits) is set in the {DISPC_VP1_TIMING_V[3:0] VSW, DISPC_VP1_TIMING_H[7:0] HSW} bit fields; (up to 2048 bytes of horizontal blanking supported).
  - Vertical frame blanking No 1 is set in the DISPC_VP1_TIMING_V[19:8] VFP bit field.
  - Vertical frame blanking No 2 is set in the DISPC_VP1_TIMING_V[31:20] VBP bit field.
  - Number of lines is set in the DISPC_VP1_SIZE_SCREEN[27:16] LPP bit field
  - Number of pixels per line is set in the DISPC_VP1_SIZE_SCREEN[11:0] PPL bit field.
- Interlaced mode:
  - Horizontal blanking (12 bits) is set in the {DISPC_VP1_TIMING_V[3:0] VSW, DISPC_VP1_TIMING_H[7:0] HSW} bit fields; (up to 2048 bytes of horizontal blanking supported).
  - Vertical field blanking No 1 for Even Field is set in the DISPC_VP1_TIMING_H[19:8] HFP bit field.
  - Vertical field blanking No 2 for Even Field is set in the DISPC_VP1_TIMING_H[31:20] HBP bit field.
  - Vertical field blanking No 1 for Odd Field is set in the DISPC_VP1_TIMING_V[19:8] VFP bit field.
  - Vertical field blanking No 2 for Odd Field is set in the DISPC_VP1_TIMING_V[31:20] VBP bit field.
  - Number of lines per field (even) is set in the DISPC_VP1_SIZE_SCREEN[27:16] LPP bit field.
  - Delta number of odd field compared to even field (in a single line) is set in the DISPC_VP1_SIZE_SCREEN[15:14] DELTA_LPP bit field.
  - Number of pixels per line is set in the DISPC_VP1_SIZE_SCREEN[11:0] PPL bit field.

NOTE: The DELTA_LPP field only controls the output channel and not the size of the field fetched from the frame buffer in memory. This field shall be set to zero for YUV420 format.

Horizontal/vertical synchronization and output enable signals polarity are programmable by setting the DISPC_VP1_POL_FREQ[12] IVS, DISPC_VP1_POL_FREQ[13] IHS, and DISPC_VP1_POL_FREQ[15] IEO bits. These signals can be gated by setting the DISPC_VP1_CONFIG[7] VSYNCGATED and DISPC_VP1_CONFIG[6] HSYNCGATED bits.

The latch of data can be driven on the rising or falling edge of the pixel clock by setting the IPC bit of DISPC_VP1_POL_FREQ[14] IPC and CTRL_CORE_SMA_SW_1[] DSS_CH0_IPC (the values must mach) registers. The drive of the SYNC and VSYNC signals in the function of the pixel clock is done by setting the DISPC_VP1_POL_FREQ[16] RF and CTRL_CORE_SMA_SW_1[] DSS_CH0_RF bit.

The timing generation of FID signal is defined by the DISPC_VP1_CONFIG[22] OUTPUTMODEENABLE bitfield. The selection can be changed only if the VP output is disabled.

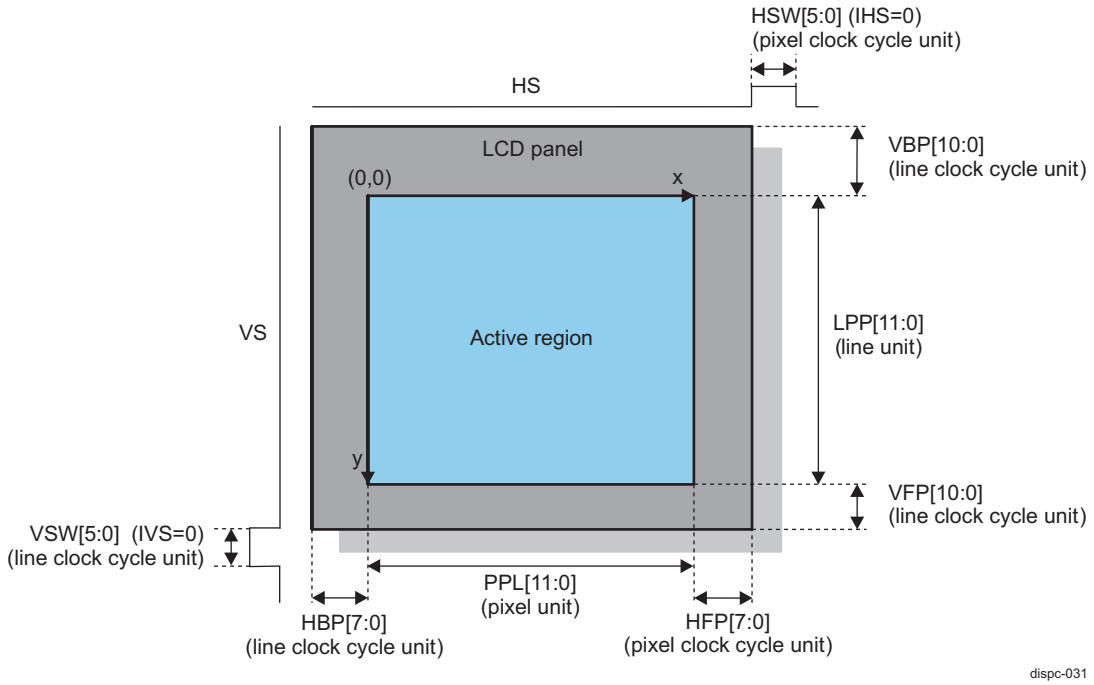
- 0x0 (default): Progressive mode (FID signal is inactive: low level)
- 0x1: Interlaced mode (FID signal transition from low to high and from high to low to indicate on the VP interface the field polarity and internally the FID to be used for the registers with dual value: one for odd field and another one for even field). The FID signal toggles on the rising edge of the VSW pulse.

When in interlaced mode, the DISPC_VP1_CONFIG[23] FIDFIRST bit indicates which field is output first:

- 0x0: Even field first (FID = 0)
- 0x1: Odd field first (FID = 1)

Figure 8-65 shows the timing values description.

Figure 8-65. DISPC VP1 Timing Values (Display Screen)

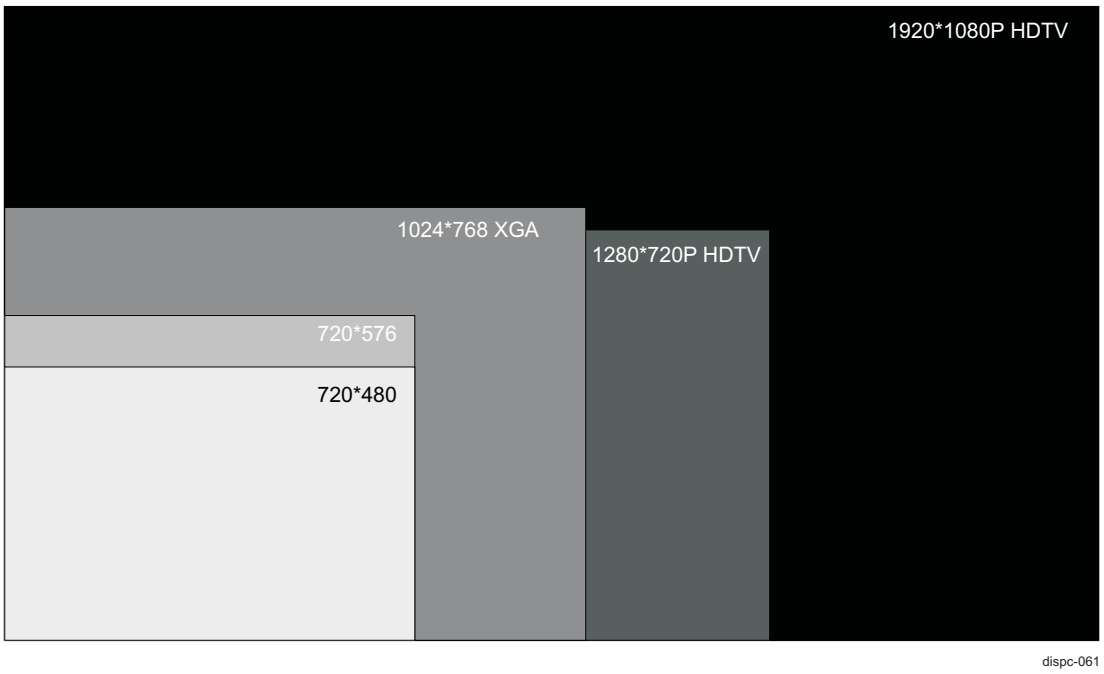


The pixel clock can be gated by setting the DISPC_VP1_CONFIG[5] PIXELCLOCKGATED bit to 0x1.

8.2.4.13.8 DISPC VP1 Configuration for TV Support

Figure 8-66 shows the TV formats supported.

Figure 8-66. DISPC Example TV Timing Formats



The size of a frame (field, if interlaced mode) is defined by the fields:

- Number of lines, DISPC_VP1_SIZE_SCREEN[27:16] LPP bit field, with a value from 1 to 4096

- Number of pixels per line, DISPC_VP1_SIZE_SCREEN[11:0] PPL bit field, with a value from 1 to 4096
- Delta size between odd/even field, DISPC_VP1_SIZE_SCREEN[15:14] DELTA_LPP bit field. This bit field controls only the output channel and not the size of the data field fetched from the frame buffer in memory.

The hold time of the pixels on the data bus is determined in clock cycles by the DISPC_VP1_CONTROL[16:14] HT bit field. The default value at reset time is 0x0 (one cycle).

- When connected to external HDMI encoder, Table 8-46 indicates the DISPC_VP1_SIZE_SCREEN register values for PPL and LPP for each HD standard.

Table 8-46. DISPC VP1 PPL and LLP Value for HD Standard

Standards		Active Pixels/Line	Active Lines	Digital Clock DISPC_VP1_CONTROL[16:14] HT = 0x0	DISPC_VP1_SIZE_SCREEN value
HDTV	720p	1280	720	74.25/74.125 MHz (60/59.99..frames/s)	0x02CF 04FF
	1080i	1920	540	74.25/74.125 MHz (60/59.99..frames/s)	0x021B 077F
	1080p	1920	1080	148.5/148.25 MHz (60/59.99..frames/s)	0x0437 077F
	720p 3D (frame packing)	1280	1470	148.5/148.35/148.5 MHz (60/59.94/50 frames/s)	0x05BD 04FF
	1080p 3D (frame packing)	1920	2205	148.5/148.35 MHz (24/23.98 frames/s)	0x089C 077F
	1080p 3D (side-by-side half)	1920	1080	148.5 MHz (60 frames/s)	0x0437 077F

NOTE: When configuring the DISPC for outputting any supported 3D frame-packing format, the following generic details must be considered:

- As defined by the *HDMI v1.4 Specification*, 3D frame-packing is a video format structure composed of two stereoscopic pictures: left and right.
- The stereoscopic pictures can be processed through the video pipelines (VID1 and VID2). For more information about the configuration of video pipelines, see Section 8.2.4.9, *DISPC Video Pipelines*.
- The 3D frame can be generated by setting the VP1 overlay manager to combine the outputs of the selected video pipelines that hold the pictures. VID1 pipeline must carry the top field of the 3D frame (left stereoscopic picture), and VID2 pipeline must always carry the bottom field of the frame (right stereoscopic picture). The top and bottom fields are separated by an active space area.
- The pipeline carrying each field (top and bottom) of the 3D frame must have its height and width parameters defined in the [27:16] SIZEY and [11:0] SIZEX bit fields of the DISPC_VP1_SIZE_SCREEN register, and its Y and X positions defined in the [26:16] POSY and [10:0] POSX bit fields of the DISPC_VID_POSITION register. The active space area of the 3D frame can be encoded by setting the solid background color for the VP1 output (in the DISPC_OVR_DEFAULT_COLOR and DISPC_OVR_DEFAULT_COLOR2 registers). For more information about the overlay mechanism, see Section 8.2.4.12, *DISPC Overlay Managers*.

3D frame-packing format support using a single pipeline can be achieved using the DISPC region-based feature. Refer to Section 8.2.4.11, *DISPC Region-Based Mechanism*, for more information.

8.2.4.14 DISPC Extended 3D Support

8.2.4.14.1 DISPC Extended 3D Support - Line Alternative Format

The DISPC supports Line Alternative Format for 3D displays, as defined by the HDMI Specification 1.4a.

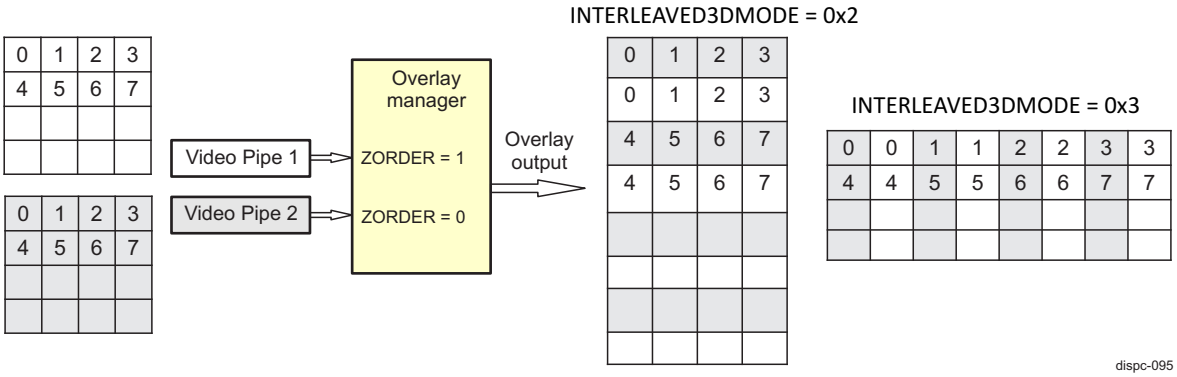
The processing is done in the overlay manager:

- The layers are grouped into two categories based on the z-order. Odd z-order may blend together and will interleave with even z-order pipes, which may blend together.
- Two types of interleaves are possible, line-based interleaving and pixel-based interleaving, to support landscape and portrait screen orientations.

The configuration is done through the DISPC_OVR_CONFIG[9:8] INTERLEAVED3DMODE register bitfield, which specifies the interleave pattern that needs to be added for each overlay manager:

- 0x0: No interleaving happens in the overlay manager
- 0x1: Reserved for future use
- 0x2: All even lines (all pixels) have a contribution from even z-order pipelines. All odd lines (all pixels) have a contribution from the odd z-order pipelines
- 0x3: All even pixels (for all lines) have a contribution from even z-order pipelines. All odd pixels (for all lines) have a contribution from the odd z-order pipelines

Figure 8-67. DISPC Illustration of 3D Interleaving

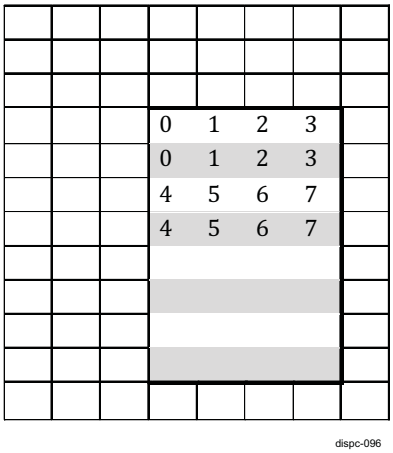


In addition, from Figure 8-67, if DISPC_OVR_CONFIG[9:8] INTERLEAVED3DMODE is programmed as 0x2, in this case the entire screen composited by the overlay manager (defined by PPL x LPP) gets sub-divided into odd and even lines. It is possible for a 3D window created using the two pipelines to have a non-zero position (that is, POSX and POSY not equal to zero).

In such cases, depending on the oddness or evenness of the POSY setting, the first line in the window may come from VID1 or VID2 pipeline.

For instance, if the POSX = 3 and POSY = 3 (set in DISPC_VID_POSITION registers), then the final composited screen with PPL = 8 and LPP = 12 (set in DISPC_VP1_SIZE_SCREEN register) may look like in Figure 8-68:

Figure 8-68. DISPC Illustration of a Non-zero Position of 3D Window



NOTE: In this case the first line comes from the odd-zorder pipeline, that is, the VID1 pipeline.

The following limitations apply to the 3D Line alternative format:

- Software must ensure that the left/right frames are of same size.
- Software must ensure that in case of line interleaving the DISPC_VID_SIZE[27:16] SIZEY bitfield values is not greater than LPP/2.
- Software must ensure that in case of pixel interleaving the DISPC_VID_SIZE[11:0] SIZEX is not greater than PPL/2.
- Software must program POSX and POSY for both left and right frame to be the same.
- Color-keying is not available for 3D formats.
- Since each overlay manager can support 4k x 4k frames, the maximum resolution of each left/right frame must be restricted to 2k x 2k.

8.2.4.14.2 DISPC Extended 3D Support - Frame Packing Format

3D Frame Packing Format support using a single pipeline can be achieved using the region-based feature. Refer to Section 8.2.4.11, *DISPC Region-Based Mechanism*, for more information.

8.2.4.15 DISPC Shadow Registers

Some DISPC registers are termed *shadow registers*. A shadow register change has no direct effect on the configuration of the DISPC. The registers are shadow registers in order the software to change the values of the registers at any time. When all the values for a given configuration are written into the registers, software must set 1 bit only to validate the configuration. When hardware reaches the end of the current frame and sees that the bit field has been set by software, the new configuration is now the configuration used by the hardware.

The bits enabling the hardware to use the new configuration are:

- DISPC_VP1_CONTROL[5] GOBIT bit for all the shadow registers of the pipeliens connected to the VP1 output

NOTE: As a general rule, all shadow registers are updated with the value of their shadow when:

- The interface is enabled, or
- The GOBIT bit-field of the output, which the register is associated to, is set and the output sync is active

11:10	RESERVED	Write 0's for future compatibility. Reads returns 0	R	0x0

Bits	Field Name	Description	Type	Reset
9:8	CLOCKACTIVITY	Clocks activity during wake up mode period 0x0: OCP and Functional clocks can be switched off 0x1: Functional clocks can be switched off and OCP clocks are mantained during wake up period 0x3: OCP and Functional clocks are maintained during wake up period 0x2: OCP clocks can be switched off and Functional clocks are maintained during wake up period	RW	0x0
7:6	RESERVED	Write 0's for future compatibility. Reads returns 0	R	0x0
5	WARMRESET	Warm reset. Set this bit to 1 triggers a module warm reset. The bit is automatically reset by the hardware. During reads, it always returns 0. The warm reset keep the configuration registers unchanged. 0x0: Normal mode 0x1: the warmreset is set	RW	0x0
4:3	SIDLEMODE	Slave interface power management, Idle req/ack control 0x0: Force-idle.An idle request is acknowledged unconditionally 0x1: No-idle. An idle request is never acknowledged 0x3: Reserved 0x2: Smart-idle. Acknowledgement to an idle request is given based on the internal activity of the module.	RW	0x2
2	ENWAKEUP	WakeUp feature control 0x0: Wakeup is disabled 0x1: Wakeup is enabled	RW	0x0
1	SOFTRESET	Software reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset	RW	0x0
0	AUTOIDLE	Internal OCP clock gating strategy 0x0: OCP clock is free-running 0x1: Automatic OCP L3 and L4 clocks gating strategy is applied, based on the OCP interface activity.. Automatic functional clock gating is also applied to the functional clock based on the module activity (for instance DISPC_ pipe _ATTRIBUTES.ENABLE)	RW	0x1

RESERVED			PREMULTIPLYALPHA	ZORDER			ANTIFLICKERg	RESERVED					RESERVED	SELFREFRESHAUTO	RESERVED	SELFREFRESH	ARBITRATION	RESERVED		BUFPRELOAD	CHANNELOUT			NIBBLEMODE	FORMAT					ENABLE

Bits	Field Name	Description	Type	Reset
31	RESERVED		R	0x0
30	RESERVED		R	0x0
29	RESERVED		R	0x0
28	PREMULTIPLYALPHA	The field configures the DISPC GFX to process incoming data as premultiplied alpha data or non premultiplied alpha data. Default setting is non premultiplied alpha data. 0x0: Non premultiplyalpha data color component 0x1: Premultiplyalpha data color component	RW	0x0
27:25	ZORDER	Z-Order defining the priority of the layer compared to others when overlaying. It is SW responsibility to ensure that each layer connected to the same overlay manager has a different z-order value. 0x1: Z-order 1: layer above layer with z-order value of 0 and below layers with z-order values of 2 and 3 0x0: Z-order 0: layer above solid background color and below layer with higher Z-order values. 0x2: Z-order 2: layer above layers with z-order value of 0 and 1 and below layer with z-order value of 3 0x4: Z-order 4: layer above layers with z-order value of 0, 1, 2 and 3 and below layer with z-order value of 5 0x5: Z-order 5: layer above all the other layers except cursor 0x3: Z-order 3: layer above layers with z-order value of 0, 1 and 2 and below layer with z-order value of 4	RW	0x0
24	ANTIFLICKER	Anti-aliasing filtering using a 3-tap filter with hardcoded coefficients (1/4, 1/2, 1/4) 0x0: Anti-aliasing disabled. 0x1: Anti-aliasing enabled.	RW	0x0
23:19	RESERVED		R	0x0
18	RESERVED		R	0x0
17	SELFREFRESHAUTO	Automatic self refresh mode 0x0: The transition from Selfrefresh 'disabled' to 'enabled' is controlled by SW 0x1: The transition from Selfrefresh 'disabled' to 'enabled' is controlled only by HW	RW	0x0
16	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
15	SELFREFRESH	Enables the self refresh of the graphics window from its own DMA buffer. This bit should be set only after havin set the GO bit of the channel and read back a zero in its field. 0x0: The graphics pipeline accesses the interconnect to fetch data from the system memory. 0x1: The graphics pipeline does not need anymore to fetch data from memory. Only the graphics DMA buffer is used. It takes effect after the frame has been loaded in the DMA buffer.	RW	0x0
14	ARBITRATION	Determines the priority of the graphics pipeline. When the graphics pipeline is one of the high priority pipelines. The arbitration wheel gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0x0: The graphics pipeline is one of the normal priority pipeline. 0x1: The graphics pipeline is one of the high priority pipeline.	RW	0x0
13:12	RESERVED		R	0x0
11	BUFPRELOAD	Graphics Preload Value 0x0: H/W prefetches pixels up to the preload value defined in the preload register 0x1: H/W prefetches pixels up to high threshold value	RW	0x0
10:8	CHANNELOUT	Graphics Channel Out configuration wr: immediate 0x0: OVR1 (VP1) 0x1: OVR2 0x4: WB	RW	0x0
7	NIBBLEMODE	Graphics Nibble mode (only for 1-, 2- and 4-bpp) 0x0: Nibble mode is disabled 0x1: Nibble mode is enabled	RW	0x0

Bits	Field Name	Description	Type	Reset
6:1	FORMAT	Graphics format. It defines the pixel format when fetching the graphics picture into memory. 0x9: RGBA32-8888 0x15: BITMAP8 (CLUT is required) 0x8: ABGR32-8888 0x5: ARGB16-1555 0x2E: xRGB32-2101010 0x2: RGBA16-4444 0xB: RGB24-888 (24-bit container) 0x4: BGR16-565 0x32: RESERVED3 0x23: RESERVED1 0x1: ABGR16-4444 0x28: xBGR32_8888 0x0: ARGB16-4444 0x25: xRGB16-1555 0x20: xRGB12-4444 0x3: RGB16-565 0x30: xRGB64-16161616 0x31: RGBX64_16161616 0x11: RGBA64_16161616 0x6: ABGR16-1555 0x2F: xBGR32-2101010 0xA: BGRA32-8888 0x26: xBGR16-1555 0x10: ARGB64-16161616 0x21: xBGR16-4444 0x12: BITMAP1 (CLUT is required) 0x13: BITMAP2 (CLUT is required) 0x2B: RESERVED2 0x14: BITMAP4 (CLUT is required) 0xE: ARGB32-2101010 0x16: RESERVED 0x2A: BGRX32_8888 0x7: ARGB32-8888 0x27: xRGB32-8888 (32-bit container) 0x29: RGBx32-8888 (24-bit RGB aligned on MSB of the 32-bit container) 0xF: ABGR32-2101010 0xC: RESERVED4 0x22: RGBx16-4444	RW	0x0
0	ENABLE	Graphics Enable 0x0: Graphics disabled (graphics pipeline inactive and graphics window not present) 0x1: Graphics enabled (graphics pipeline active and graphics window present on the screen)	RW	0x0

Table 8-100. DISPC_GFX1_POSITION

Address Offset	0x0000 002C		
Physical Address	0x5801 102C	**Instance**	DISPC_GFX1
Description	The register configures the position of the graphics window. Shadow register.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								POSY								RESERVED								POSX							

Bits	Field Name	Description	Type	Reset
31:28	RESERVED		R	0x0
27:16	POSY	Y position of the graphics window. Encoded value (from 0 to 4095) to specify the Y position of the graphics window on the screen. The line at the top has the Y-position 0.	RW	0x0
15:12	RESERVED		R	0x0
11:0	POSX	X position of the graphics window. Encoded value (from 0 to 4095) to specify the X position of the graphics window on the screen. The first pixel on the left of the screen has the X-position 0.	RW	0x0

Table 8-104. DISPC_GFX1_ROW_INC

Address Offset	0x0000 0034		
Physical Address	0x5801 1034	**Instance**	DISPC_GFX1
Description	The register configures the number of bytes to increment at the end of the row. Shadow register.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ROWINC																															

Bits	Field Name	Description	Type	Reset
31:0	ROWINC	Number of bytes to increment at the end of the row Encoded unsigned value to specify the number of bytes to increment at the end of the row in the graphics buffer. The value 0 is invalid. The value 1 means next pixel. The value 1+n*bpp means increment of n pixels. The value 1-(n+1)*bpp means decrement of n pixels.	RW	0x1

Table 8-113. DISPC_WB_ACCUH2_j

Address Offset	0x0000 0008		
Physical Address	0x5801 5008 + (0x4 * j)	**Instance**	DISPC_WB
Description	The register configures the resize accumulator init value for horizontal up/down-sampling of the write-back window It is used for Cb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB (all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter is the color space conversion is done before the filter). When the register is not used by the HW, any value can be used for the bit-fields. Shadow register.		
Type	RW

Table 8-119. DISPC_WB_ATTRIBUTES

Address Offset	0x0000 0020		
Physical Address	0x5801 5020	**Instance**	DISPC_WB
Description	The register configures the attributes of the viwrite back pipeline. Shadow register.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDLENUMBER				IDLESIZE	CAPTUREMODE			ARBITRATION	DOUBLESTRIDE	VERTICALTAPS	RESERVED	WRITEBACKMODE	CHANNELIN			RESERVED			FULLRANGE	COLORCONVENABLE	RESERVED	ALPHAENABLE	RESIZEENABLE	FORMAT							ENABLE

Bits	Field Name	Description	Type	Reset
31:28	IDLENUMBER	Determines the number of idles between requests on the L3 interconnect. It is only used when the write-back pipeline does data transfer from memory to memory. When the output of an overlay is stored in memory through the write-back pipeline in capture mode, the bit-field IDLENUMBER is ignored since a timing generator is used to time the transfer. The number of IDLE cycles is IDLENUMBER (from 0 to 15) if IDLESIZE=0. The number of IDLE cycles is IDLENUMBERx8 (from 0 to 120) if IDLESIZE=1 and BURSTSIZE=2. The number of IDLE cycles is IDLENUMBERx4 (from 0 to 60) if IDLESIZE=1 and BURSTSIZE=1. The number of IDLE cycles is IDLENUMBERx2 (from 0 to 30) if IDLESIZE=1 and BURSTSIZE=0.	RW	0x0

Bits	Field Name	Description	Type	Reset
27	IDLESIZE	Determines if the IDLENUMBER corresponds to a number of bursts or singles. 0x0: The number of idles between requests is defined by IDLENUMBER as number of cycles. 0x1: The number of idles between requests is defined by IDLENUMBER multiplied by burst size as number of cycles.	RW	0x0
26:24	CAPTUREMODE	Defines the frame rate capture. 0x6: Only one out of six frames is captured. The first one is captured then the second one is skipped and so on. 0x1: Only one frame is captured. 0x7: Only one out of seven frames is captured. The first one is captured then the second one is skipped and so on. 0x0: All frames are captures until the write-back channel is disabled or there is no more data generated by the overlay or the pipeline attached to the write-back channel. 0x2: Only one out of two frames is captured. The first one is captured then the second one is skipped and so on. 0x4: Only one out of four frames is captured. The first one is captured then the second one is skipped and so on. 0x5: Only one out of five frames is captured. The first one is captured then the second one is skipped and so on. 0x3: Only one out of three frames is captured. The first one is captured then the second one is skipped and so on.	RW	0x0
23	ARBITRATION	Determines the priority of the write-back pipeline. The write-back pipeline is one of the high priority pipeline. The arbitration gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0x0: The write-back pipeline is one of the normal priority pipeline. 0x1: The write-back pipeline is one of the high priority pipeline.	RW	0x0
22	DOUBLESTRIDE	Determines if the stride for CbCr buffer is the 1x or 2x of the Y buffer stride. It is only used in case of YUV420 and 2D access 0x0: The CbCr stride value is equal to the Y stride. 0x1: The CbCr stride value is double to the Y stride.	RW	0x0
21	VERTICALTAPS	Video Vertical Resize Tap Number 0x0: 3 taps are used for the vertical filtering logic. The 2 other taps are not used. 0x1: 5 taps are used for the vertical filtering logic.	RW	0x0
20	RESERVED		R	0x0
19	WRITEBACKMODE	When connected to the overlay output of a channel the write back can operate as a simple transfer from memory to memory (composition engine) or as a capture channel. 0x0: Capture mode (default mode 0x1: Memory to memory mode	RW	0x0

Bits	Field Name	Description	Type	Reset
18:15	CHANNELIN	WB Channel In configuration wr: immediate 0x0: OVR1 (VP1) 0x1: OVR2 0x4: GFX1SEL 0x7: VID1SEL 0x8: VID2SEL	RW	0x0
14:13	RESERVED		R	0x0
12	FULLRANGE	Color Space Conversion full range setting. 0x0: Limited range selected: 16 subtracted from Y before color space conversion 0x1: Full range selected: Y is not modified before the color space conversion	RW	0x0
11	COLORCONVENABLE	Enable the color space conversion. The HW does not enable/disable the conversion based on the pixel format. The bit-field shall be reset when the format is not YUV. 0x0: Disable Color Space Conversion RGB to YUV 0x1: Enable Color Space Conversion RGB to YUV	RW	0x0
10	RESERVED		R	0x0
9	ALPHAENABLE	Premultiplied alpha enable 0x0: disabled.Disabled. This bit also disable the logic present in the associated channel out that compute the alpha component sent to the WB pipe 0x1: enabled.	RW	0x0
8:7	RESIZEENABLE	Resize Enable 0x0: Disable the resize processing 0x1: Enable the horizontal resize processing 0x3: Enable both horizontal and vertical resize processing 0x2: Enable the vertical resize processing	RW	0x0

Bits	Field Name	Description	Type	Reset
6:1	FORMAT	Write-back Format. It defines the pixel format when storing the write-back picture into memory. 0x9: RGBA32-8888 0x8: ABGR32-8888 0x5: ARGB16-1555 0x2: RGBA16-4444 0xB: RGB24-888 (24-bit container) 0x4: BGR16-565 0x32: RESERVED4 0x23: RESERVED2 0x1: ABGR16-4444 0x3F: UYVY 4:2:2 co-sited 0x28: xBGR32_8888 0x0: ARGB16-4444 0x3E: YUV2 4:2:2 co-sited 0x25: xRGB16-1555 0x3D: NV12/NV21 4:2:0 2 buffers (Y + UV) 0x20: xRGB12-4444 0x3: RGB16-565 0x17: BGR565A8 0x30: xRGB64-16161616 0x11: RGBA64_16161616 0x6: ABGR16-1555 0x31: RGBX64_16161616 0xA: BGRA32-8888 0x26: xBGR16-1555 0x10: ARGB64-16161616 0x21: xBGR16-4444 0x12: RESERVED5 0x2B: RESERVED3 0x18: RESERVED1 0x16: RGB565A8 0x2A: BGRX32_8888 0x7: ARGB32-8888 0x27: xRGB32-8888 (32-bit container) 0x29: RGBx32-8888 (24-bit RGB aligned on MSB of the 32-bit container) 0xC: RESERVED 0x22: RGBx16-4444	RW	0x0

- Region-Based Mechanism for a Single Region Write-Back: [1][2][3][4]
- DISPC_WB Register Summary: [5]

Table 8-123. DISPC_WB_BA_j

Address Offset	0x0000 0028		
Physical Address	0x5801 5028 + (0x4 * j)	**Instance**	DISPC_WB
Description	The register configures the base address of the WB buffer (DISPC_WB_BA__0 DISPC_WB_BA__1 for ping-pong mechanism with external trigger, based on the field polarity otherwise only DISPC_WB_BA__0 is used). Shadow register.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BA																															

Bits	Field Name	Description	Type	Reset
31:0	BA	Write-back base address Base address of the WB buffer (aligned on pixel size boundary except in case of RGB24 packed format, 4-pixel alignment is required; in case of YUV422, 2-pixel alignment is required, and YUV420, byte alignment is supported)). It case of YUV 4:2:0 format, it indicates the base address of the Y buffer. When the TILER is addressed, the bits: [28:27] = 0x0 for 8-bit tiled [28:27] = 0x1 for 16-bit tiled [28:27] = 0x2 for 32-bit tiled [28:27] = 0x3 for page mode [31:29] = 0x0 for 0-degree view [31:29] = 0x1 for 180-degree view + mirroring [31:29] = 0x2 for 0-degree view + mirroring [31:29] = 0x3 for 180-degree view [31:29] = 0x4 for 270-degree view + mirroring [31:29] = 0x5 for 270-degree view [31:29] = 0x6 for 90-degree view [31:29] = 0x7 for 90-degree view + mirroring Otherwise the bits indicated the corresponding bit address to access the SDRAM.	RW	0x0

Table 8-125. DISPC_WB_BA_UV_j

Address Offset	0x0000 0030		
Physical Address	0x5801 5030 + (0x4 * j)	**Instance**	DISPC_WB
Description	The register configures the base address of the UV buffer for the write-back pipeline. (DISPC_WB_BA_UV_0 and DISPC_WB_BA_UV_1 for ping-pong mechanism with external trigger, based on the field polarity, otherwise only DISPC_WB_BA_UV_0 is used)). The register is also used to configure the RGB plane BA for RGB565A8 format. Shadow register.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BA																															

Bits	Field Name	Description	Type	Reset
31:0	BA	Video base address alinged on 16-bit boundary Base address of the UV video buffer used only in case of YUV420-NV12 When the TILER is addressed, the bits: [28:27] = 0x0 for 8-bit tiled [28:27] = 0x1 for 16-bit tiled [28:27] = 0x2 for 32-bit tiled [28:27] = 0x3 for page mode [31:29] = 0x0 for 0-degree view [31:29] = 0x1 for 180-degree view + mirroring [31:29] = 0x2 for 0-degree view + mirroring [31:29] = 0x3 for 180-degree view [31:29] = 0x4 for 270-degree view + mirroring [31:29] = 0x5 for 270-degree view [31:29] = 0x6 for 90-degree view [31:29] = 0x7 for 90-degree view + mirroring Otherwise the bits indicated the corresponding bit address to access the SDRAM.	RW	0x0

Address Offset	0x0000 0158		
Physical Address	0x5801 5158 + (0x4 * i)	**Instance**	DISPC_WB
Description	The bank of registers configure the down/up/down-scaling coefficients for the vertical resize of the video picture associated with the write back pipeline for the phases from 0 to 15. It is used for Crb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB (all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter is the color space conversion is done before the filter). When the register is not used by the HW, any value can be used for the bit-fields. Shadow register.

Address Offset	0x0000 0008		
Physical Address	0x5801 7008 + (0x4 * j) 0x5801 8008 + (0x4 * j)	**Instance**	DISPC_VID1 DISPC_VID2
Description	The register configures the resize accumulator init value for horizontal up/down-sampling of the video window (DISPC_VID#n_ACCU2__0 DISPC_VID#n_ACCU2__1 for ping-pong mechanism with external trigger, based on the field polarity) It is used for Cb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB (all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter is the color space conversion is done before the filter). When the register is not used by the HW, any value can be used for the bit-fields. Shadow register.		
Type	RW

Bits	Field Name	Description	Type	Reset
31	RESERVED		R	0x0
30	RESERVED		R	0x0
29	RESERVED		R	0x0
28	PREMULTIPLYALPHA	The field configures the DISPC VID1 to process incoming data as premultiplied alpha data or non premultiplied alpha data. Default setting is non premultiplied alpha data. 0x0: Non premultiplyalpha data color component 0x1: Premultiplyalpha data color component	RW	0x0
27:25	ZORDER	Z-Order defining the priority of the layer compared to others when overlaying. It is SW responsibility to ensure that each layer connected to the same overlay manager has a different z-order value. 0x1: Z-order 1: layer above layer with z-order value of 0 and below layers with z-order values of 2 and 3 0x0: Z-order 0: layer above solid background color and below layer with higher Z-order values. 0x2: Z-order 2: layer above layers with z-order value of 0 and 1 and below layer with z-order value of 3 0x4: Z-order 4: layer above layers with z-order value of 0, 1, 2 and 3 and below layer with z-order value of 5 0x5: Z-order 5: layer above all the other layers except cursor 0x3: Z-order 3: layer above layers with z-order value of 0, 1 and 2 and below layer with z-order value of 4	RW	0x0
24	SELFREFRESH	Enables the self refresh of the video window from its own DMA buffer only. 0x0: The video pipeline accesses the interconnect to fetch data from the system memory. 0x1: The video pipeline does not need anymore to fetch data from memory. Only the DMA buffer associated with the video1 is used. It takes effect after the frame has been loaded in the DMA buffer.	RW	0x0

Bits	Field Name	Description	Type	Reset
23	ARBITRATION	Determines the priority of the video pipeline. The video pipeline is one of the high priority pipeline. The arbitration gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0x0: The video pipeline is one of the normal priority pipeline. 0x1: The video pipeline is one of the high priority pipeline.	RW	0x0
22	DOUBLESTRIDE	Determines if the stride for CbCr buffer is the 1x or 2x of the Y buffer stride. It is only used in case of YUV420 and 2D access 0x0: The CbCr stride value is equal to the Y stride. 0x1: The CbCr stride value is double to the Y stride.	RW	0x0
21	VERTICALTAPS	Video Vertical Resize Tap Number. The vertial poly-phase filter can be configured in 3-tap or 5-tap configuration. According to the number of taps, the maximum input picture width is double while using 3-tap compared to 5-tap. 0x0: 3 taps are used for the vertical filtering logic. The 2 other taps are not used. The associated bit-fields for the 2 other taps coefficients do not need to be initialized. 0x1: 5 taps are used for the vertical filtering logic.	RW	0x0
20	RESERVED		R	0x0
19	BUFPRELOAD	Video Preload Value 0x0: H/W prefetches pixels up to the preload value defined in the preload register 0x1: H/W prefetches pixels up to high threshold value	RW	0x0
18	RESERVED	Write 0's for future compatibility. Reads return 0.	R	0x0
17	SELFREFRESHAUTO	Automatic self refresh mode 0x0: The transition from SELFREFRESH <disabled> to <enabled> is controlled by SW. 0x1: The transition from SELFREFRESH <disabled> to <enabled> is controlled only by HW.	RW	0x0
16:14	CHANNELOUT	Video Channel Out configuration wr: immediate 0x0: OVR1 (VP1) 0x1: OVR2 0x4: WB	RW	0x0
13:12	RESERVED		R	0x0
11	FULLRANGE	Color Space Conversion full range setting. 0x0: Limited range selected: 16 subtracted from Y before color space conversion 0x1: Full range selected: Y is not modified before the color space conversion	RW	0x0
10	NIBBLEMODE	Video Nibble mode (only for 1-, 2- and 4-bpp) 0x0: Nibble mode is disabled 0x1: Nibble mode is enabled	RW	0x0
9	COLORCONVENABLE	Enable the color space conversion. The HW does not enable/disable the conversion based on the pixel format. The bit-field shall be reset when the format is not YUV. 0x0: Disable Color Space Conversion YUV to RGB 0x1: Enable Color Space Conversion YUV to RGB	RW	0x0

Bits	Field Name	Description	Type	Reset
8:7	RESIZEENABLE	Video Resize Enable 0x0: Disable both horizontal and vertical resize processing 0x1: Enable the horizontal resize processing 0x3: Enable both horizontal and vertical resize processing 0x2: Enable the vertical resize processing	RW	0x0

Bits	Field Name	Description	Type	Reset
6:1	FORMAT	Video Format. It defines the pixel format when fetching the video frame buffer. 0x9: RGBA32-8888 0x15: BITMAP8 (CLUT is required) 0x8: ABGR32-8888 0x5: ARGB16-1555 0x2E: xRGB32-2101010 0x2: RGBA16-4444 0x4: BGR16-565 0x32: RESERVED4 0x23: RESERVED2 0x1: ABGR16-4444 0x3F: UYVY 4:2:2 co-sited 0x28: xBGR32_8888 0x0: ARGB16-4444 0x3E: YUV2 4:2:2 co-sited 0xB: RGB24-888 (24-bit container) 0x3D: NV12/N21 4:2:0 2 buffers (Y + UV) 0x20: xRGB12-4444 0x3: RGB16-565 0x17: BGR565A8 0x30: xRGB64-16161616 0x31: RGBX64_16161616 0x11: RGBA64_16161616 0x6: ABGR16-1555 0x2F: xBGR32-2101010 0xA: BGRA32-8888 0x26: xBGR16-1555 0x10: ARGB64-16161616 0x21: xBGR16-4444 0x25: xRGB16-1555 0x12: BITMAP1 (CLUT is required) 0x13: BITMAP2 (CLUT is required) 0x2B: RESERVED3 0x18: RESERVED1 0x14: BITMAP4 (CLUT is required) 0xE: ARGB32-2101010 0x16: RGB565A8 0x2A: BGRX32_8888 0x7: ARGB32-8888 0x27: xRGB32-8888 (32-bit container) 0x29: RGBx32-8888 (24-bit RGB aligned on MSB of the 32-bit container) 0xF: ABGR32-2101010 0xC: RESERVED 0x22: RGBx16-4444	RW	0x0

Table 8-250. DISPC_VID_PICTURE_SIZE

Address Offset	0x0000 020C		
Physical Address	0x5801 720C 0x5801 820C	**Instance**	DISPC_VID1 DISPC_VID2
Description	The register configures the size of the video picture associated with the video layer before up/down-scaling. Shadow register.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED				MEMSIZEY												RESERVED				MEMSIZEX											

Bits	Field Name	Description	Type	Reset
31:28	RESERVED		R	0x0
27:16	MEMSIZEY	Number of lines of the video picture Encoded value (from 1 to 4096) to specify the number of lines of the video picture in memory (program to value minus one). When predecimation is set, the value represents the size of the image after predecimation but the max size of the unpredecimated image size in memory is still bounded to 2exp(11).	RW	0x0
15:12	RESERVED		R	0x0
11:0	MEMSIZEX	Number of pixels of the video picture Encoded value (from 1 to 4096) to specify the number of pixels of the video picture in memory (program to value minus one). The size is limited to the size of the line buffer of the vertical sampling block in case the video picture is processed by the vertical filtering unit. (program to value minus one). When predecimation is set, the value represents the size of the image after predecimation but the max size of the unpredecimated image size in memory is still bounded to 2exp(11).	RW	0x0

Bits	Field Name	Description	Type	Reset
16	BUFFERHANDSHAKE	Controls the handsSHAKE between DMA buffer and STALL signal in order to prevent from underflow. The bit shall be set to 0 when the module is not in STALL mode. 0x0: Only the STALL signal (generated by RFBI or DSI2 depending on which IP uses the LCD output) is used regardless of the DMA buffer fullness information in order to provide data to the RFBI or DSI2 module. 0x1: The STALL signal (generated by RFBI or DSI2 depending on which IP uses the LCD output) is used in combination with the DMA buffer fullness information in order to provide data to the RFBI or DSI2 module only when it does not generated buffer underflow.	RW	0x0
15	CPR	Color Phase Rotation Control VP output). It shall be reset when ColorConvEnable bit-field is set to 1. Shadow bit-field. 0x0: Color Phase Rotation Disabled 0x1: Color Phase Rotation Enabled	RW	0x0
14:9	RESERVED	Write 0's for future compatibility. Reads return 0	R	0x0
8	EXTERNALSYNCEN	Selects between external sync and internal sync mode for the VP output. 0x0: Internal sync mode selected 0x1: External sync mode selected.	RW	0x0
7	VSYNCGATED	VSYNC Gated Enabled (VP output) Shadow bit-field. 0x0: VSYNC Gated Disabled 0x1: VSYNC Gated Enabled	RW	0x0
6	HSYNCGATED	HSYNC Gated Enabled (VP output) Shadow bit-field. 0x0: HSYNC Gated Disabled 0x1: HSYNC Gated Enabled	RW	0x0
5	PIXELCLOCKGATED	Pixel Clock Gated Enabled (VP output) Shadow bit-field. 0x0: Pixel Clock Gated Disabled 0x1: Pixel Clock Gated Enabled	RW	0x0
4	PIXELDATAGATED	Pixel Data Gated Enabled (VP output) Shadow bit-field. 0x0: Pixel Data Gated Disabled 0x1: Pixel Data Gated Enabled	RW	0x0
3	HDMIMODE	Configures the timing generator in HDMI compatible mode to generate same timings as HDMI wrapper timings. 0x0: Disable HDMI mode. 0x1: Enable HDMI mode timings: - vertical FSM starts with the VFP period (instead of VSYNC) - last frame ends with the last pixel of data state.	RW	0x0
2	GAMMAENABLE	Enable the gamma Shadow bit-field. 0x0: Gamma disabled 0x1: Gamma enabled	RW	0x0
1	DATAENABLEGATED	DE Gated Enable Shadow bit-field. 0x0: DE signal is not gated 0x1: DE signal is gated.	RW	0x0
0	PIXELGATED	Pixel Gated Enable Shadow bit-field. 0x0: Pixel clock always toggles (only in TFT mode) 0x1: Pixel clock only toggles when there is valid data to display. (only in TFT mode)	RW	0x0

VBP								VFP																VSW							

Bits	Field Name	Description	Type	Reset
31:20	VBP	Vertical back porch Encoded value (from 0 to 4095) to specify the number of line clock periods to add to the beginning of a frame. When in BT mode and interlaced, this field corresponds to the vertical field blanking No 2 for Odd Field. When in BT and in progressive mode, this field corresponds to the Vertical frame blanking No 2 . before the first set of pixels is output to the display.	RW	0x0
19:8	VFP	Vertical front porch Encoded value (from 0 to 4095) to specify the number of line clock periods to add to the end of each frame. When in BT mode and interlaced, this field corresponds to the vertical field blanking No 1 for Odd Field. When in BT and in progressive mode, this field corresponds to the Vertical frame blanking No 2 .	RW	0x0
7:0	VSW	Vertical synchronization pulse width Encoded value (from 1 to 256) to specify the number of line clock periods (program to value minus one) to pulse the frame clock (VSYNC) pin at the end of each frame after the end of frame wait (VFP) period elapses. Frame clock uses as VSYNC signal in active mode. When in BT mode, the lsb 4-bits of this field (VSW[3:0]) corresponds to the MSB 4-bits of the 12-bit horizontal blanking(BT_HBLANK= {VSW[3:0],HSW[7:0]}).	RW	0x0

8.3 Video Encoder

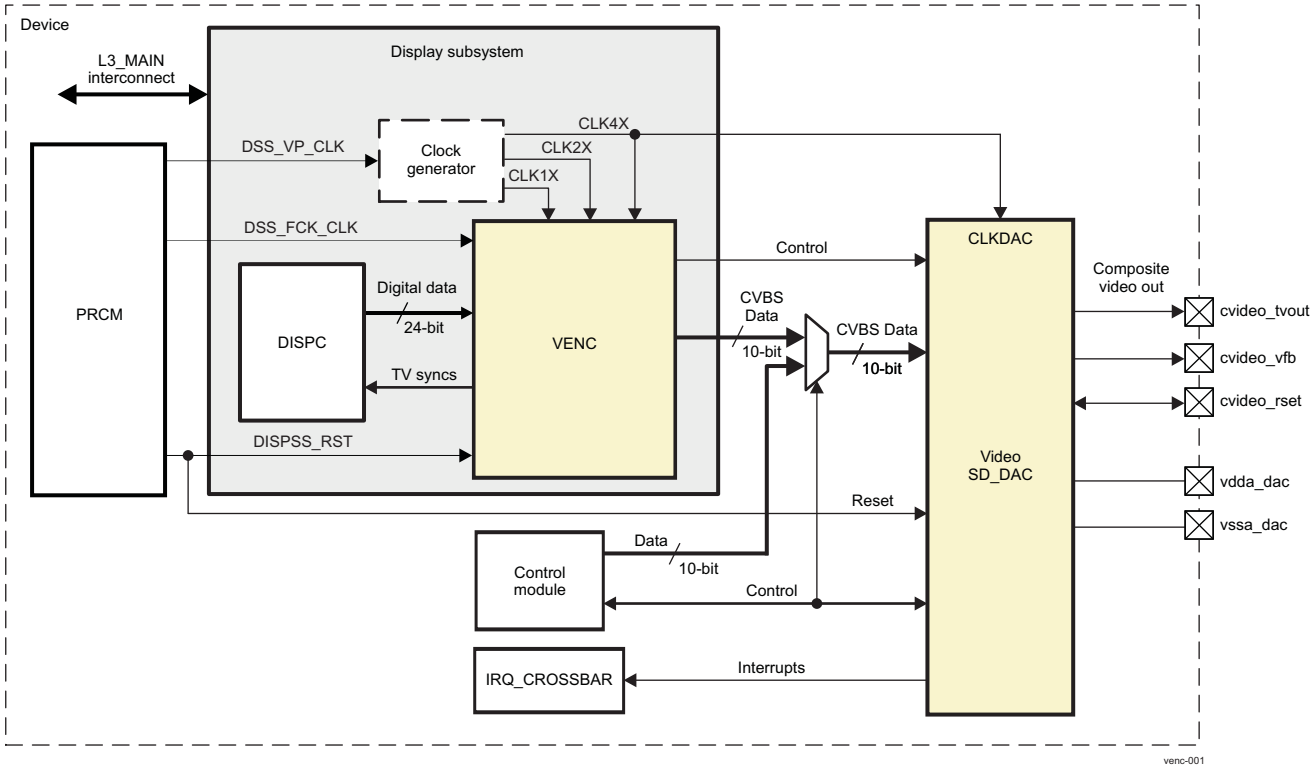
This section describes the video encoder (VENC) and associated video standard definition DAC (SD_DAC) modules for the device.

8.3.1 Video Encoder Overview

The VENC module provides the logic to display analog video on a TV set.

Figure 8-69 shows a block diagram of the video encoder and SD_DAC in the display subsystem.

Figure 8-69. Video Encoder Overview



The video encoder includes the following features:

- Supports the following standards for composite video (CVBS) :
  - NTSC-J, M
  - PAL-B, D, G, H, I
  - PAL-M
- Input data interface compatible with the following protocols:
  - 24-bit input bus compatible with external sync
  - RGB 4:4:4
- 10-bit interface for internal digital-to-analog converter (DAC) that supports:
  - 1.1V digital power supply, 1.8V analog power supply
  - 10-bit resolution
  - Sample rate of up to 60 megasamples per second (MSPS)
  - Supports Composite Video standart output
  - Supports TVOUT buffer bypass mode (DAC only mode)
  - Full-scale voltage output: 1.2 Vpp with a 75-Ω load
  - Internal TV-detect feature to detect both open and short conditions
  - Suitable for low-power wireless applications

- TV output data supports ITU-R BT 470-7 recommendation standard for consumer market
- Master clock input 13.5 MHz, 27 MHz (supports ITU-R 601 sampling for NTSC/PAL), and 54 MHz
- Programmable horizontal sync, vertical timing, and waveforms
- Programmable subcarrier frequency and SCH
- Internal test pattern generation (color bar, flat field, color burst)
- 2x/4x oversampling
- TV detection gating pulse generation
- Supports square pixel sampling (NTSC: 12.27 MHz, 24.54 MHz, 49.09 MHz PAL: 14.75 MHz, 29.5 MHz, 59 MHz)

CAUTION

In square pixel mode, an external clock generator is required to provide sampling frequencies.

8.3.2 Video Encoder Environment

To display analog video on a TV set, the path used is as follow:

- Display controller
- Video encoder
- 10-bit SD_DAC with video amplifier

The display controller module receives synchronization signals from the video encoder and synchronously sends pixel data to the video encoder with these signals. The digital output of the display controller is always a 24-bit RGB value based on a pixel request from the video encoder. For more information on the display controller settings and features, see Section 8.2, *Display Controller*.

The video encoder converts RGB video signals to conform to the NTSC/PAL standards analog video. The video encoder includes an integrated synchronization signal generator and a video digital-to-analog converter (SD_DAC) with video amplifiers, data manager, luma stage, chroma stage, modulator, and a control interface.

The video encoder also provides the synchronization signals to the display controller: VSYNC, active VIDeo (AVID), and field ID (FID).

NOTE: To enhance the TV color display, it is highly recommended to set the DSS.DSS_VENC_CTRL[1] DAC_DEMEN register bit. See Section 8.1.3, *Display Subsystem Register Manual*.

Figure 8-70 through Figure 8-72 show the TV display interface in composite mode.

Figure 8-70. Video Encoder Environment, Normal Mode DC-Coupling

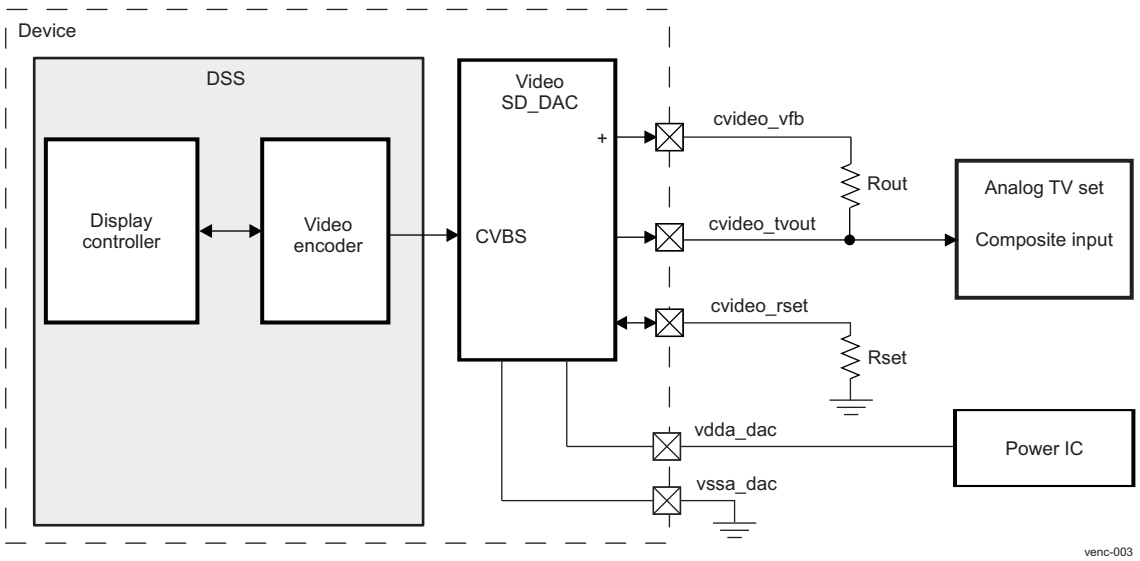


Figure 8-71. Video Encoder Environment, Normal Mode AC-Coupling

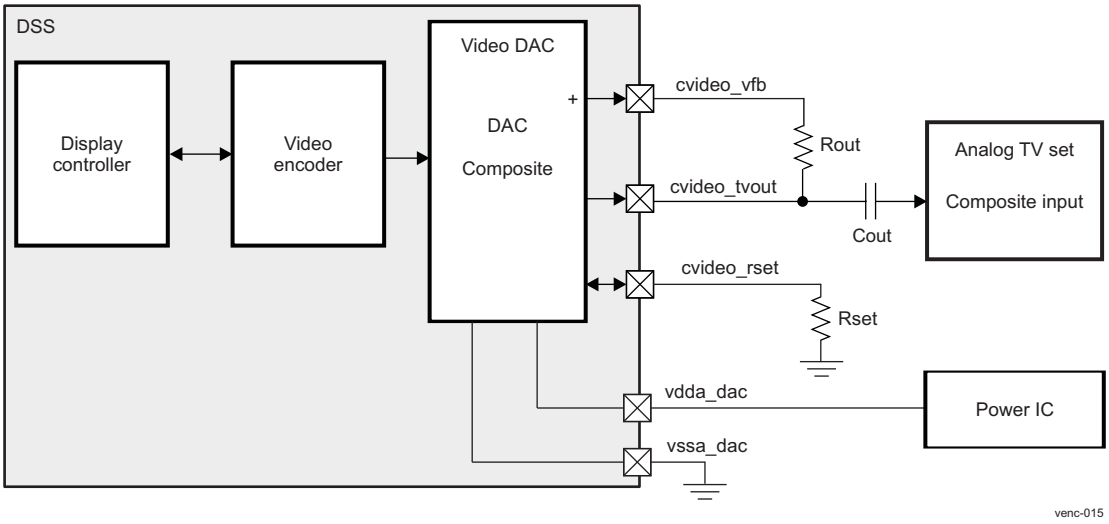

Figure 8-72. Video Encoder Environment, Bypass Mode

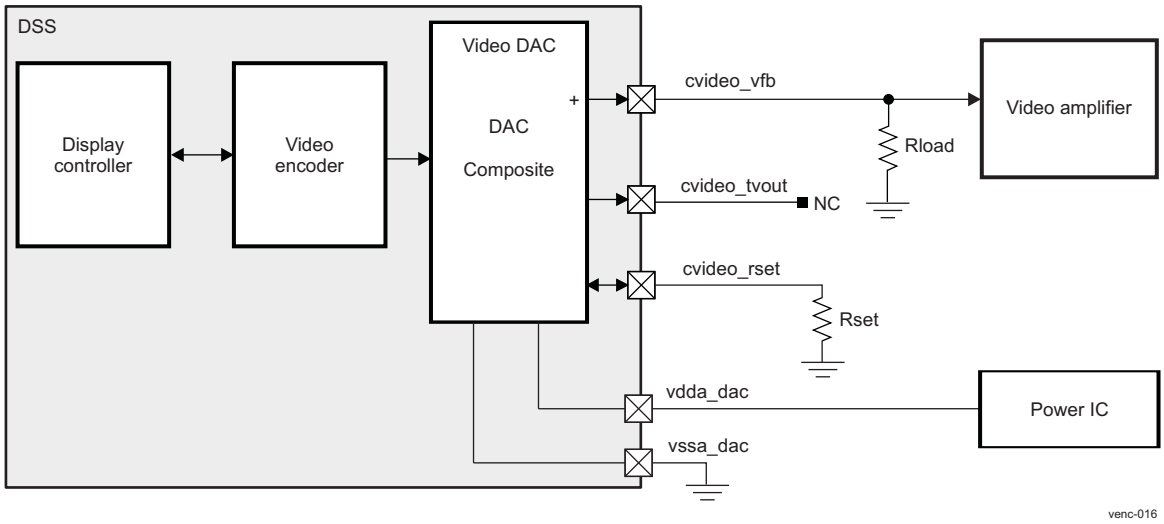

Table 8-310 describes the interface signals to/from the TV set for TV display support.

Table 8-310. TV Display Interface Pins

Pin Name	Type[1]	Description
cvideo_tvout	O	Composite video output. An external resistor (Rout) is connected between this node and the *cvideo_vfb* pin. The nominal value of Rout is 2700 Ω. This is the output node that drives the load (75 Ω). In AC-coupling mode, a series capacitor (Cout) must be connected. The nominal value for Cout is ≥ 200 µF.
cvideo_vfb	O	In Normal mode (video DAC+Buffer), it acts as the buffer feedback node. An external resistor (Rout) shall be connected between this node and *cvideo_tvout* pin. In TVOUT Bypass mode, it acts as the video DAC output. A load resistor (Rload) shall be connected to the pin to ground. The nominal value of Rload is 1500 Ω.

(1) I = input; O = output; power = power pin

Table 8-310. TV Display Interface Pins (continued)

Pin Name	Type[1]	Description
cvideo_rset	I/O	External resistor (Rset) shall be connected to this pin to set the reference current of the video DAC. The value of the resistor depends on the mode of operation (Normal or TVOUT Bypass). In Normal mode, the nominal value for Rset is 4700 Ω. In TVOUT Bypass mode, the nominal value for Rset is 10000 Ω.
vdda_dac	Power	Analog supply voltage for the video DAC
vssa_dac	Power	Analog ground for the video DAC

CAUTION

- *cvideo_tvout* is a very high-frequency analog signal and must be routed with extreme care. As a result, the path of this signal must be as short as possible, and as isolated as possible from other interfering signals.
- During board design, the onboard traces and parasites must be matched for the channel. *cvideo_vfb* pin is the most sensitive pins in the TV out system. Low onboard resistance and capacitance is required for the traces that connect the Rout to the *cvideo_vfb* and *cvideo_tvout* pins. The resistance on those trace affects output impedance matching. Therefore, Rout resistor is suggested to be placed as close as possible to the device pins. The onboard traces lead to the TV OUT pin must have a characteristic impedance of 75 Ohm starting from the closest possible place to the device pin output.
- If the TV output is not used, the following configuration for the SD_DAC pins must be applied:
  - vdda_dac: Must be grounded
  - vssa_dac: Must be grounded
  - cvideo_rset: Must be floating, left unconnected
  - cvideo_tvout: Must be floating, left unconnected
  - cvideo_vfb: Must be floating, left unconnected
- To avoid current leakage, the following register bits must be set to 0:
  - DSS.DSS_VENC_CTRL[2] DAC_POWERDN_BGZ
  - DSS.VENC_OUTPUT_CONTROL[1] COMPOSITE_ENABLE
  - CONTROL.CTRL_CORE_SD_DAC_CONTROL[3] TVOUTBYPASS

Table 8-311 lists the typical values of the external components for different modes of the TV display interface.

Table 8-311. Typical Values for Rout, Rset, Rload, and Cout

	Composite, DC-Coupled	Composite, AC-Coupled	Bypass Mode	Unit
Rout	2700	2700	N/A	Ω
Rset	4700	4700	10,000	Ω
Rload	N/A	N/A	1500	Ω
Cout	N/A	≥ 220	N/A	µF

8.3.3 Video Encoder Integration

This section describes the integration of the VENC and video SD_DAC modules, and details clocks, resets, hardware requests, and power modes.

Figure 8-73 shows the integration of the VENC and SD_DAC in the device.

Figure 8-73. Video Encoder Integration

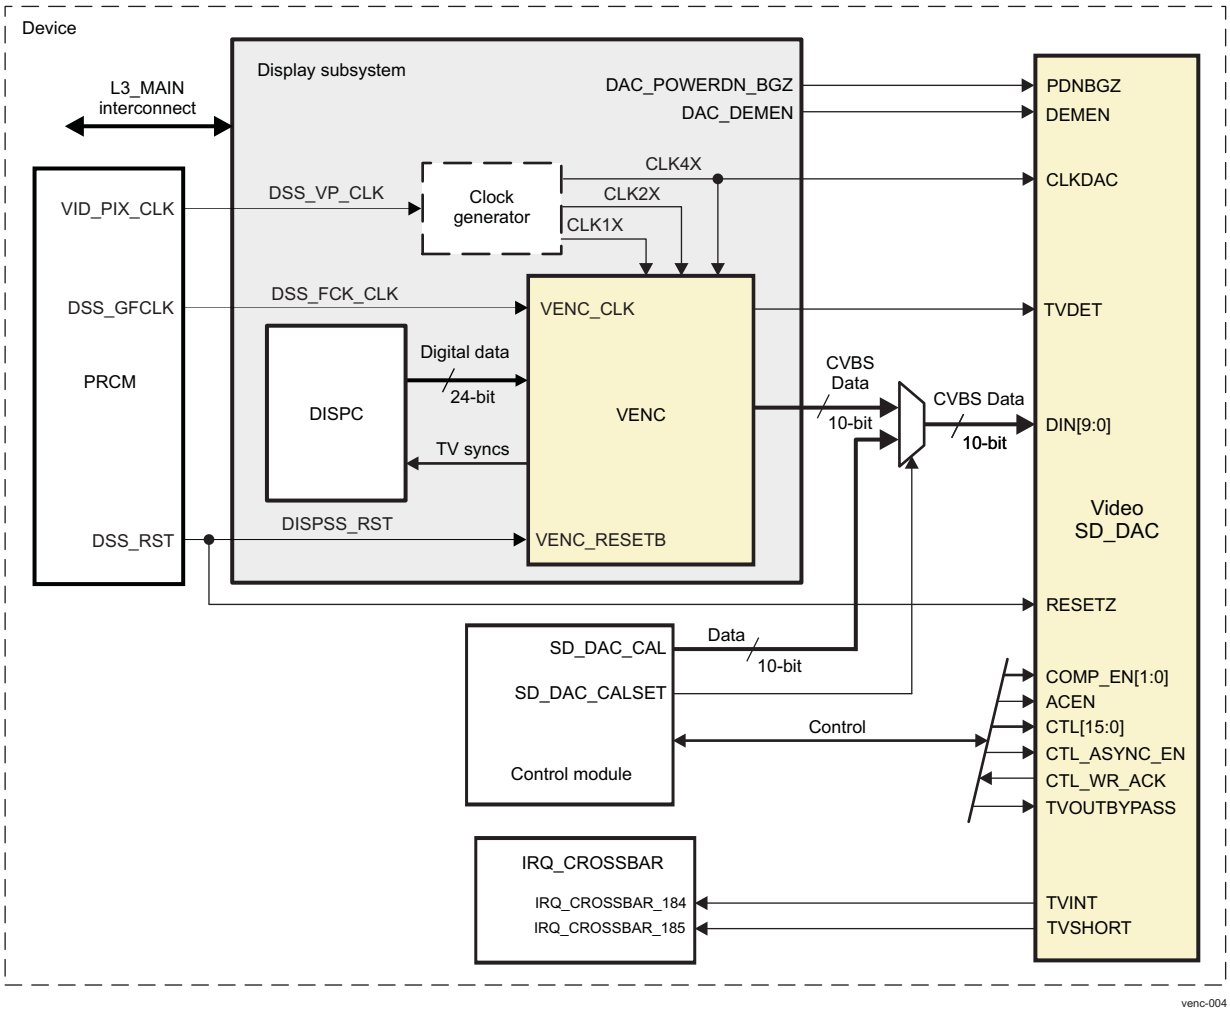

Table 8-312 shows the interrupt requests generated by the SD_DAC.

Table 8-312. Video SD_DAC Interrupt Requests

		Interrupt Requests		
Module Instance	**Source Signal Name**	**Destination IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
SD_DAC	SD_DAC_IRQ_TVINT	IRQ_CROSSBAR_184	-	Interrupt for TV load detection from SD_DAC
	SD_DAC_IRQ_TVSHORT	IRQ_CROSSBAR_185	-	Interrupt for TV short detection from SD_DAC

NOTE: The "**Default Mapping**" column in Table 8-312 shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.
For more information about the device interrupt controllers, see Chapter 12, *Interrupt Controllers*.

Table 8-313 describes the various Video encoder and SD_DAC clocks.

Table 8-313. Video Encoder and SD_DAC Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
Video encoder	VENC_CLK	DSS_GFCLK	PRCM	VENC interface clock
	CLK1X CLK2X CLK4X	VID_PIX_CLK (indirect)	PRCM DSS clock generator	VENC functional clocks, generated on DSS level through division and gating. Refer to Section 8.1.2.2, *Display Subsystem Clocks*, for more details.
SD_DAC	CLKDAC	VID_PIX_CLK (indirect)	PRCM DSS clock generator	Functional clock for SD_DAC module. Gating control is available on DSS level. Refer to Section 8.1.2.2, *Display Subsystem Clocks*, for more details.
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
Video encoder SD_DAC	VENC_RESETB RESETZ	DSS_RST	PRCM	Reset signal from the PRCM module.

NOTE: For information about PRCM clock gating and management, see Chapter 3,*Power, Reset, and Clock Management*.

- **Video encoder functional clocks:**

  Three balanced clocks are provided to VENC module from DSS top level. Gating control for CLK4X clock is available through DSS.DSS_VENC_CTRL[0] VENC_CLOCK_4X_ENABLE bit (see Section 8.1.2.2, *Display Subsystem Clocks*).

Table 8-314. Digital Clock Division for the Video Encoder

VENC Clock Input	DSS Clock Generator Output
CLK4X	VID_PIX_CLK or 0 (gated)
CLK2X	VID_PIX_CLK/2
CLK1X	VID_PIX_CLK/4

NOTE: For proper video SD_DAC configuration, clock output CLK4X shall always be active by setting the DSS.DSS_VENC_CTRL[0] VENC_CLOCK_4X_ENABLE bit to 1 (see Section 8.1.3, *DSS Register Manual*).

CAUTION

DSS must be enabled first before VENC, in order the source clocks feeding VENC to be running before enabling the VENC.

VENC must be disabled before DSS, in order the source clocks feeding the VENC to be running before disabling the VENC. If DSS is disabled before VENC, the functional clocks will stop abruptly.

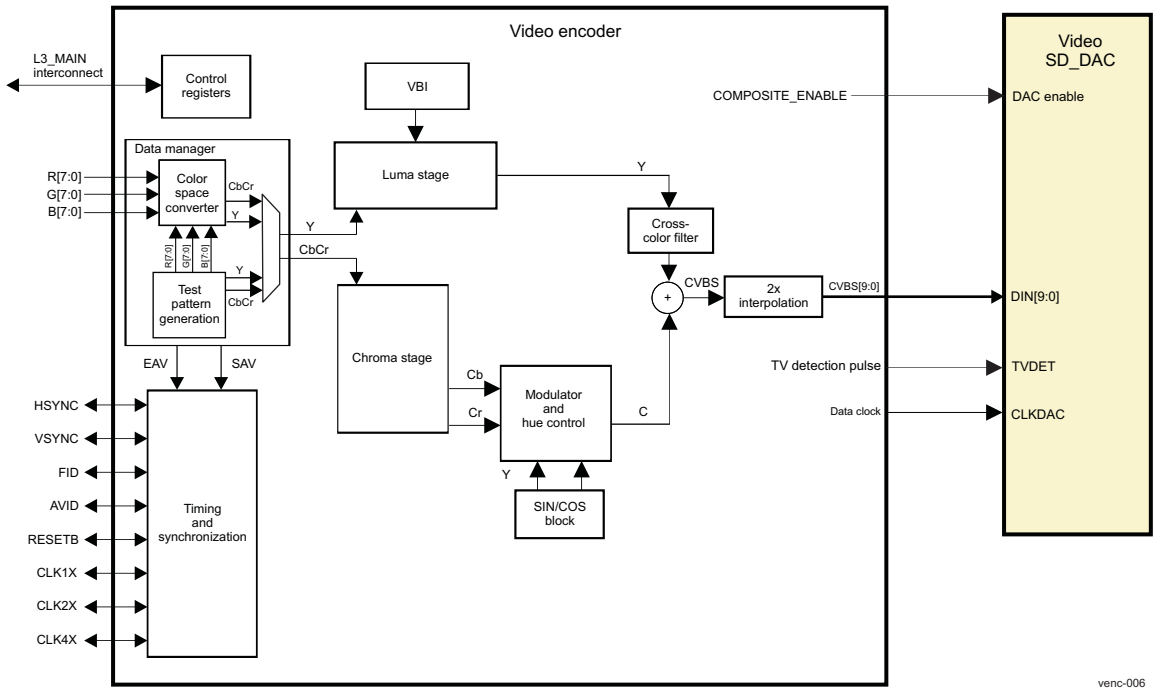
- **Video SD_DAC clock:**

  The video data sent from VENC to SD_DAC is latched on the positive edge of the CLKDAC clock.

8.3.4 Video Encoder Functional Description

Figure 8-74 shows an overview of the video encoder architecture.

Figure 8-74. Video Encoder Architecture Overview



8.3.4.1 Video Encoder Data Manager

The data manager allows user to select two sources of data inputs, by programming VENC_F_CONTROL[7:6] SVDS bitfield:

- Data coming from the Display Controller, when SVDS = 0x0.
- Data coming from the test pattern generation, when SVDS = 0x1 or 0x2 (default value).

The source is selected

8.3.4.1.1 Video Encoder Color Space Converter

In the display subsystem, the input format from the display controller is always 24-bit RGB coming from the display controller or the test pattern generation. The RGB-to-YCbCr color space converter converts the 24-bit RGB pixel data into 16-bit YCbCr 4:2:2 data.

8.3.4.1.2 Video Encoder Test Pattern Generation

For diagnostic purposes, the data manager can be forced to output 100/100 color bar RGB/YCbCr data. To use the test pattern generation, the VENC_F_CONTROL[7:6] SVDS bitfield shall be set to 0x1. If VENC_F_CONTROL[1:0] FMT bitfield is set to 0x0, then the 24-bits RGB test pattern data will be converted into 16-bit YCbCr 4:2:2 data by the Color Space Converter. Otherwise, if VENC_F_CONTROL[1:0] FMT bitfield is set to 0x2, then 16-bit YCbCr 4:2:2 test pattern data are outputed directly, the color space converted is bypassed. Table 8-315 resume the test paten generator data.

Table 8-315. Video Encoder 100/100 Color Bar Table

COLOR	R	G	B	Y	Cb	Cr
White	255	255	255	235	128	128
Yellow	255	255	0	210	16	146
Cyan	0	255	255	170	166	16

Table 8-315. Video Encoder 100/100 Color Bar Table (continued)

Green	0	255	0	145	54	34
Magenta	255	0	255	106	202	222
Red	255	0	0	81	90	240
Blue	0	0	255	41	240	110
Black	0	0	0	16	128	128

8.3.4.2 Video Encoder Luma Stage

The luma stage includes a luma pipeline delay, luma shaping, 2x interpolation filter, and luma variable delay. The luma pipeline delay block is used to match luma path length to chroma path length. In the luma gain shaper, a programmable gain is first applied to the luminance data output. The luminance gain is defined by the VENC_GAIN_Y register. Horizontal sync, vertical sync, and setup insertion are then performed.

Black level and blank level are programmable through the VENC_BLACK_LEVEL and VENC_BLANK_LEVEL registers. All the transition edges of the luminance signal, such as sync edges and active video edges, are properly shaped and filtered to keep the bandwidth within the standards.

After all required components of the luminance signal are added, the resulting signal is low-passed and interpolated to 2x-pixel rate. This 2x interpolation simplifies the external analog reconstruction filter design and improves the signal-to-noise ratio.

8.3.4.3 Video Encoder Chroma Stage

The chroma stage includes a low-pass filter, first-stage 2x interpolation, chroma gain shaper, and second-stage 2x interpolation. A pair of programmable gains adjusts the time-multiplexed U/V signal. The gains for U and V are independently controlled by the VENC_GAIN_U and VENC_GAIN_V register bits.

8.3.4.4 Video Encoder Subcarrier and Burst Generation

The encoder uses a 32-bit subcarrier increment to synthesize the subcarrier. The value of the subcarrier increments required to generate the desired subcarrier frequency for NTSC and PAL format is found by:

$S\_CARR = ROUND ([F_{sc}/F_{CLK2X}] \times 2^{32})$

where:

F_{sc} = Frequency of the subcarrier

F_{CLK2X} = Frequency of the internal video encoder

The VENC_S_CARR register controls the subcarrier frequency. The VENC_C_PHASE register controls the phase of the subcarrier. The phase of the color subcarrier is reset to VENC_C_PHASE. Table 8-316 presents the VENC_S_CARR register values depending the standard and pixel type used.

Table 8-316. VENC_S_CARR Register Recommended Values

Standard	Pixel Type	Subcarrier Frequency (Fsc) (MHz)	Fclkenc (MHz)	VENC_S_CARR Register Value (hexa)
NTSC-M, J	ITU-R601	3.579545	27	0x21F07C1F
PAL-M	ITU-R601	3.5756083125	27	0x21E6EFE3
PAL-B, D, G, H, I	ITU-R601	4.43361875	27	0x2A098ACB
NTSC-M, J	Square pixel	3.579545	24.5454(1)	0x25555555
PAL-M	Square pixel	3.579561149	24.5454(1)	0x1F15C01E
PAL-B, D, G, H, I	Square pixel	4.43361875	29.50(1)	0x26798C0C

(1) In square pixel mode, an external clock generator is needed to provide sampling frequencies (49.09 MHz for NTSC square pixel or 59 MHz for PAL square pixel).

The color subcarrier reset has four modes:

- No reset
- Reset every two lines
- Reset every two fields
- Reset every eight fields

The VENC_C_PHASE register can be used to adjust the SCH (subcarrier to horizontal sync phase). The VENC_BSTAMP_WSS_DATA[6:0] BSTAP bit field sets the amplitude of the color burst.

Phase alternation line refers to the encoding scheme in which the subcarrier alternates between two phases every scan line. Setting to 0x1, the VENC_M_CONTROL[1] PAL bit enables phase alternation line encoding. Otherwise, a normal subcarrier is generated. .Two possible alternation sequences are possible by setting the VENC_M_CONTROL[5] PALPHS bit.

8.3.4.5 Video Encoder Vertical Blanking Interval

8.3.4.5.1 Video Encoder Closed Caption Encoding

The encoder can be programmed to encode closed-caption (CC) data and extended data in the selected line. The data stream consists of 7-bit US-ASCII code and 1 odd-parity bit (see Video Encoder Closed-Caption Data Format).

Video Encoder Closed-Caption Data Format

MSB							LSB
Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Odd parity

The standard service encodes closed caption in both fields; the extended service encodes closed caption in even fields. When set to 1, the VENC_L21_WC_CTL[0] L21EN bit enables closed-caption encoding in odd fields. When set to 1, the VENC_L21_WC_CTL[1] L21EN bit enables closed-caption encoding in even fields.

To select the scan line where the CC data are encoded, program the VENC_LN_SEL[4:0] SLINE bit field.

CAUTION

The setting of the VENC_LN_SEL[4:0] SLINE bit field value depends on the video standard:

- PAL mode: Because there is a one-line offset, program the desired line number – 1. To activate the closed caption on line 21 (0x15), program the value 0x15 – 1 = 0x14. The default value is 0x15 + 1 = 0x16 (line 22).
- NTSC mode: Because there is a four-line offset, program the desired line number – 4. To activate the closed caption on line 21 (0x15), program the value 0x15 – 4 = 0x11. The default value is 0x15 + 4 = 0x19 (line 25).

The VENC_LN_SEL[25:16] LN21_RUNIN bit field should be kept at reset value (0x10B). Four closed-caption data registers contain the data to be encoded. The VENC_LINE21[15:8] L21O and VENC_LINE21[7:0] L21O bit fields contain the first and the second bytes, respectively, of closed-caption data to be encoded in the odd field. The VENC_LINE21[31:24] L21E and VENC_LINE21[23:16] L21E bit fields contain the first and the second bytes, respectively, of data to be encoded in the even field.

Immediately after the closed-caption data is written to the registers, in either the odd field or even field, the corresponding closed-caption status bit (VENC_STATUS[4] CCE or VENC_STATUS[3] CCO) is reset to 0 to indicate that the closed-caption data is available in the closed-caption data registers and yet to be encoded.

Immediately after the closed-caption data is encoded, the VENC_STATUS[4] CCE bit or the VENC_STATUS[3] CCO bit is set to 1 to indicate that the closed-caption data has been encoded and is ready to accept new data. As seen in Figure 8-75, a null character is automatically inserted if the closed-caption data is not written to the closed-caption data registers in time for encoding.

The running clock frequency is controlled by the VENC_CC_CARR_WSS_CARR[15:0] FCC bit field which should be kept at reset value (0x2631) to get 5034960.5Hz (32xfline) for NTSC-601. The closed-caption running clock common frequencies are detailed in Table 8-317.

Table 8-317. Video Encoder Closed-Caption RunClock Frequency Settings

	NTSC-601	PAL-601	NTSC Square Pixel	PAL Square Pixel
VENC_CC_CARR_WSS_CARR[15:0] FCC bit field value	0x2631	0x25ED	0x2A03	0x22B6

The closed-caption data is encoded in nonreturn-to-zero (NRZ) format. Additionally, the data translates to the IRE scale as follows:

- 0 = 0 IRE
- Sync pulse = -40 IRE
- 1 = 50 IRE

Figure 8-75 shows the parameters of closed-caption line data implemented in different standards.

Figure 8-75. Video Encoder Closed Captioning Timing

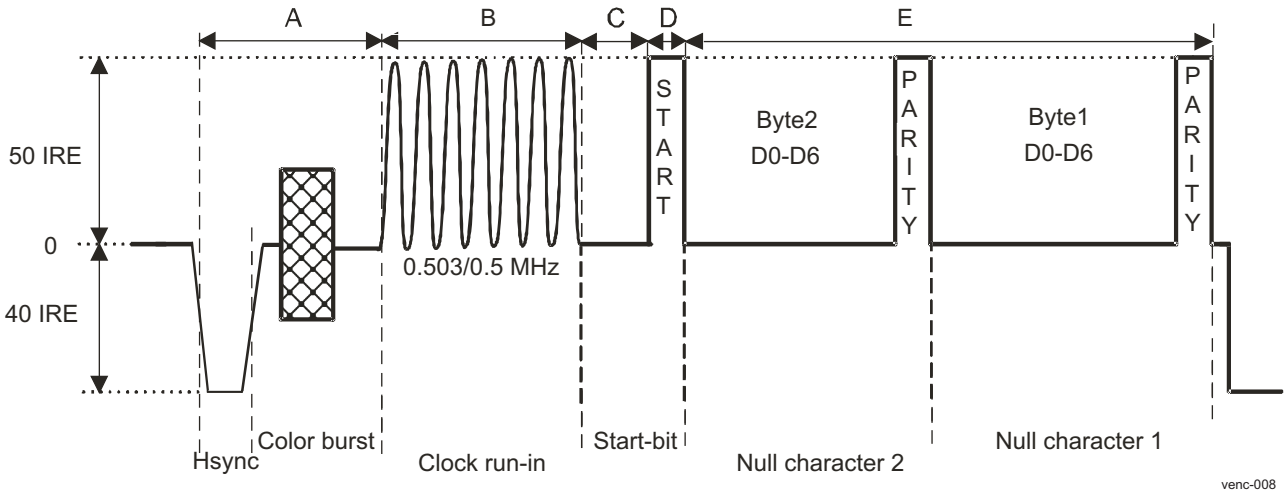


Table 8-318. Video Encoder Closed-Caption Standard Timing Values

Intervals	Description	Timing Values for Encoding			Timing Values for Decoding		
		Minimal	Nominal	Maximal	Lower Bound	Nominal	Upper Bound
A	HSYNC to clock running	10.250 µs	10.500 µs	10.750 µs	10.000 µs	10.500 µs	11.000 µs
B	Clock running		12.910 µs			12.910 µs	
C	Clock running to third start bit		3.972 µs			3.972 µs	
D	Start bit		1.986 µs			1.986 µs	
E	Data characters		31.778 µs			31.778 µs	

NOTE:

- The interval A is controlled by the VENC_LN_SEL[25:16] LN21_RUNIN bit field.
- The interval B is controlled by VENC_CC_CARR_WSS_CARR[15:0] FCC bit field.

All timing values listed in Table 8-318 are measured from the mid-point (half amplitude) on all edges.

For a complete description of closed-caption standard including CGMS-A copy protection, see the CEA-608-x standard.

8.3.4.5.2 Video Encoder Wide-Screen Signaling (WSS) Encoding

The encoder can embed data, encoded in accordance with the IEC61880 and ITU-R 1119 data insertion standard, within the vertical blanking interval.

The encoder supports WSS data insertion on line 20 of every frame in the NTSC format. WSS data insertion is enabled by activating the VENC_L21_WC_CTL[14:13] EVEN_ODD_EN bit and by programming the VENC_BSTAMP_WSS_DATA[27:8] WSS_DATA bit field.

The running clock frequency is controlled by the VENC_CC_CARR_WSS_CARR[31:16] FWSS bit field. The wide-screen signaling running clock common frequencies are detailed in Table 8-319

Table 8-319. Video Encoder Wide-Screen Signaling RunClock Frequency Settings

	NTSC-601	PAL-601	NTSC Square Pixel	PAL Square Pixel
VENC_CC_CARR_WSS_CARR[31:16] FWSS bit field value	0x043F	0x2F72	0x04AC	0x2B6D

To select the line where the WSS data are encoded, program the VENC_L21_WC_CTL[12:8] LINE bit field.

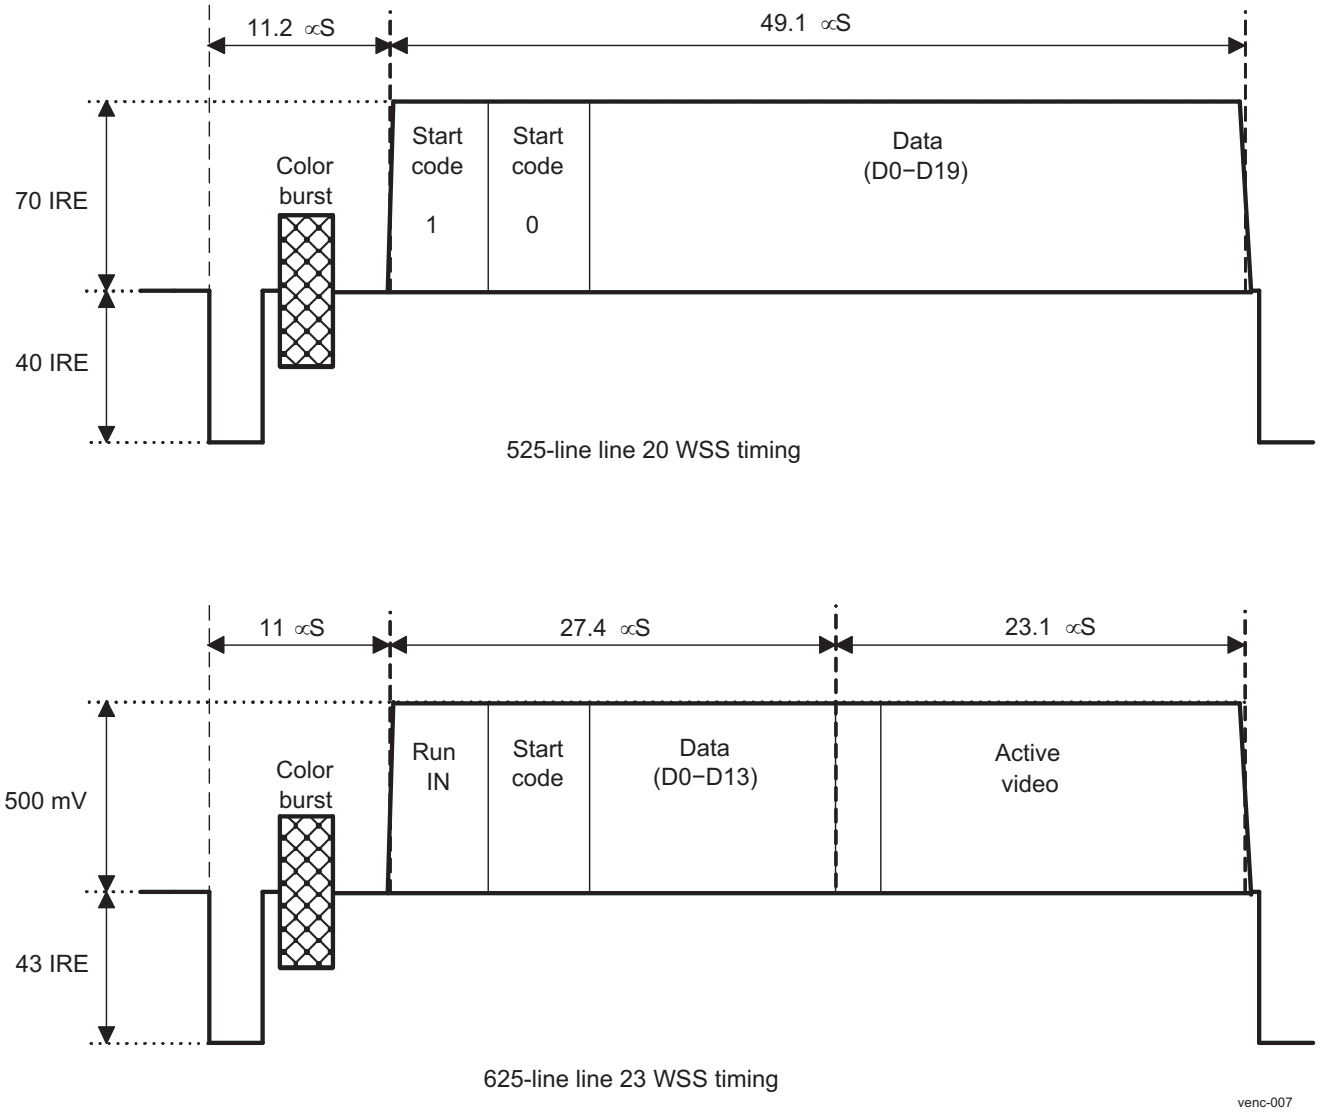
CAUTION

The setting of the VENC_L21_WC_CTL[12:8] LINE bit field value depends on the video standard:

- PAL mode: Because there is a one-line offset, program the desired line number – 1. The recommended value on line 23 is 0x16 + 1 = 0x17. The default value is 0x14 + 1 = 0x15 (line 21).
- NTSC mode: Because there is a four-line offset, program the desired line number – 4. The recommended value on line 20 is 0x10 + 4 = 0x14. The default value is 0x14 + 4 = 0x18 (line 24).

The WSS encoding block assumes that a full 10-bit video range is used to determine the 70 percent of peak-white amplitude of a logic-1 bit. The encoder also supports WSS data insertion on line 23 in the PAL format. Both waveforms are shown in Figure 8-76.

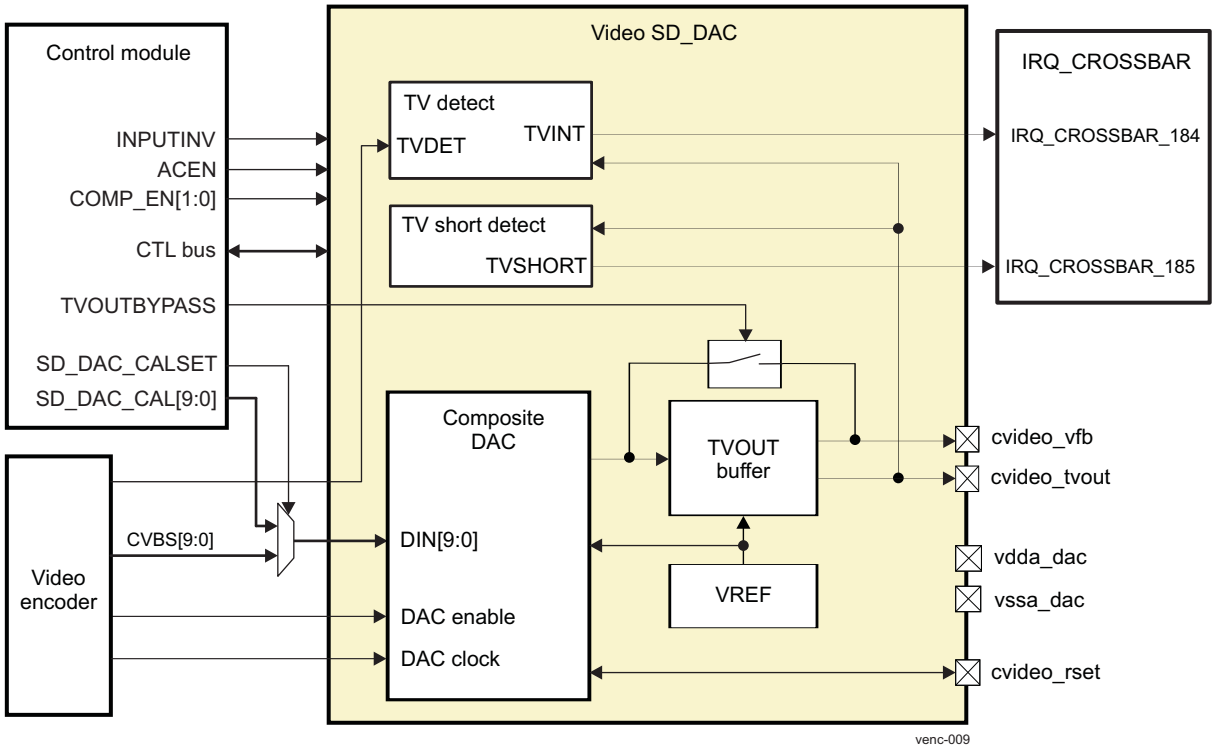
Figure 8-76. Video Encoder WSS Timing



8.3.4.6 Video Encoder SD_DAC

Figure 8-77 shows the architecture of the 10-bit video SD_DAC.

Figure 8-77. Video SD_DAC Architecture



The display subsystem provides the necessary control signals to interface the memory frame buffer directly to external displays. A 10-bit video SD_DAC is used to generate the video analog signal. The video SD_DAC also includes a TV detection/disconnection and power-down mode features.

8.3.4.6.1 Video SD_DAC DC/AC Coupled TV Load

The 10-bit video DAC supports both DC-coupled and AC-coupled TV loads. The CONTROL.CTRL_CORE_SD_DAC_CONTROL[2] ACEN bit is used to define which output coupling is used. This bit is the first one to be programmed according to the TV load on the PCB board.

NOTE: When DC coupling is used, there is a DC offset at the TVOUT output.

8.3.4.6.2 Video SD_DAC TV Detection/Disconnection Pulse Generation and Use

8.3.4.6.2.1 TV Detection/Disconnection Pulse Generation

The TV detect block is an integral part of the video SD_DAC module.

NOTE:

- The TV disconnection feature is recommended for power saving purpose. The TV detection/disconnection is only operational when video out is active. Therefore to detect cable connection automatically, it is necessary to periodically activate the video out to test for cable presence.

This block compares the output (*cvideo_tvout*) to reference voltage, to sense the condition of the load. To operate, the TV detect requires two digital signals, TVACEN and TVDET. The TVACEN signal indicates to both TVOUT buffer and the TV detect circuit, if the load is AC or DC coupling, to adjust accordingly. TVDET is a digital pulse at the frequency of the TV sync pulses. The operation of the circuit is based on the difference in voltage levels in the output of the buffer depending of the load status. The TV detect block compares the output against a couple of references and the result is latched at the start of every sync pulse. The status is read later in with the TVDET pulse rising edge.

The following registers are used to set the TV detection/disconnection pulse:

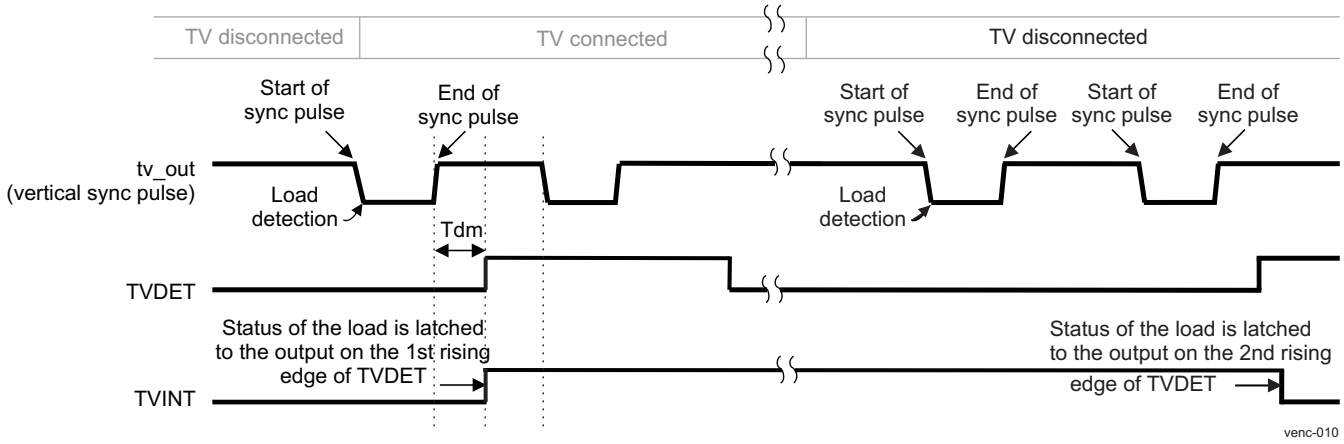
- The VENC_TVDETGP_INT_START_STOP_X register defines which pixels are used to start and stop the pulse inside their respective line.
- The VENC_TVDETGP_INT_START_STOP_Y register defines which lines are used to start and stop the pulse.
- The VENC_GEN_CTRL[0] EN bit enables or disables the TVDET pulse (0: Disable; 1: Enable).
- The VENC_GEN_CTRL[16] TVDP bit sets the TVDET pulse polarity (0: Active low; 1: Active high).

8.3.4.6.2.2 Recommended TV Detection/Disconnection Pulse Waveform

To enable the detection/disconnection of the load, the circuit requires that the TVDET pulse resembles the following waveform. By using the video encoder registers, the TVDET pulse polarity, start and stop is programmable. The only critical parameter is Tdm, which should be longer than the delay through the DAC and TVOUT buffer, which is at least 750 ns.

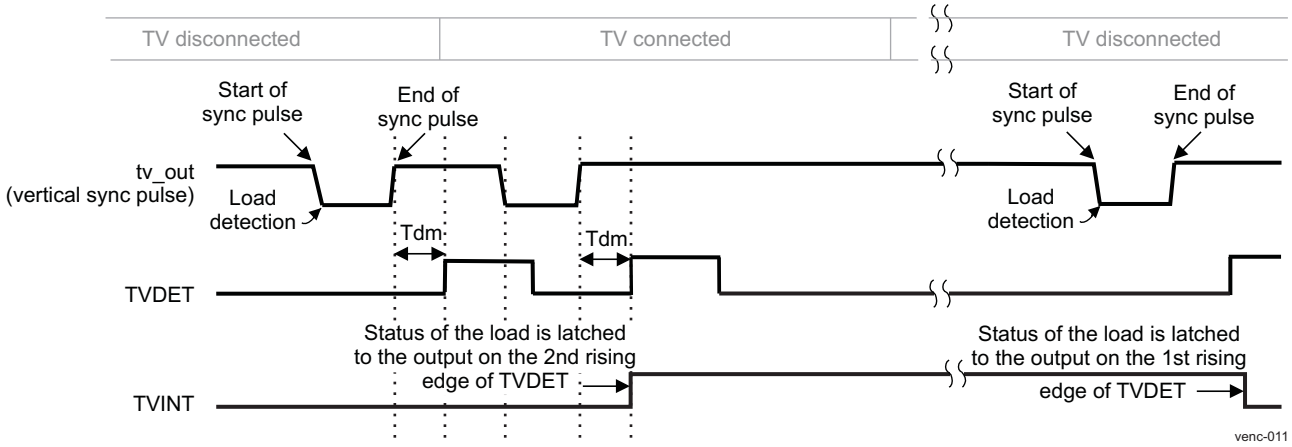
If DC-coupling is selected, the TVINT output signal for TV detection is latched at the rising edge of the first TVDET signal but the TVINT output signal for TV disconnection is latched after the next rising edge of the TVDET signal that happens during the next VSYNC timing. Figure 8-78 shows the waveforms for the DC-coupling TV detect pulse (TVDET) when load is connected and disconnected.

Figure 8-78. Video SD_DAC DC-Coupling TV Detect Waveforms for TV Connected and Disconnected



If AC-coupling is selected, the TVINT output signal for TV detection is latched after the next rising edge of the TVDET signal that happens during the next VSYNC timing but the TVINT output signal for TV disconnection is latched at the rising edge of the first TVDET signal. Figure 8-79 shows the waveforms for the ac-coupling TV detect pulse (TVDET) when load is connected and disconnected.

Figure 8-79. Video SD_DAC AC-Coupling TV Detect Waveforms for TV Connected and Disconnected



NOTE:

- When setting the VENC_TVDETGP_INT_START_STOP_X register, software users must ensure that the TVDET signal is in the active area. To avoid any problem, the TVDET signal must not be longer than one line.
- The activation of the TVDET signal will not have a visual impact on the *cvideo_tvout* output signal.

8.3.4.6.2.3 TV Detection/Disconnection Use

The TV-detection/TV-disconnection is based on the difference in voltage levels in the output of the TV buffer depending on the load status. The operation is slightly different for AC and for DC operation.

- For DC operation, the *cvideo_tvout* voltage is compared against a voltage reference that makes the comparator trigger in each sync pulse while the load is connected. For DC-coupling mode, see Figure 8-80.
- For AC operation, the *cvideo_tvout* voltage is compared against a voltage reference that makes the comparator trigger in each sync pulse while the load is disconnected. For AC-coupling mode, see Figure 8-81.

In both cases, the TVINT output signal produces a logic 1 when a load is connected, and a logic 0 when a load is disconnected.

NOTE: Because the video SD_DAC and the video encoder must be awake for connection detection, consider that the video SD_DAC can take up to 10 µs to wake up.

Figure 8-80. Video SD_DAC Signal Waveform Proposal for TV Detection/Disconnection in DC-Coupling Mode

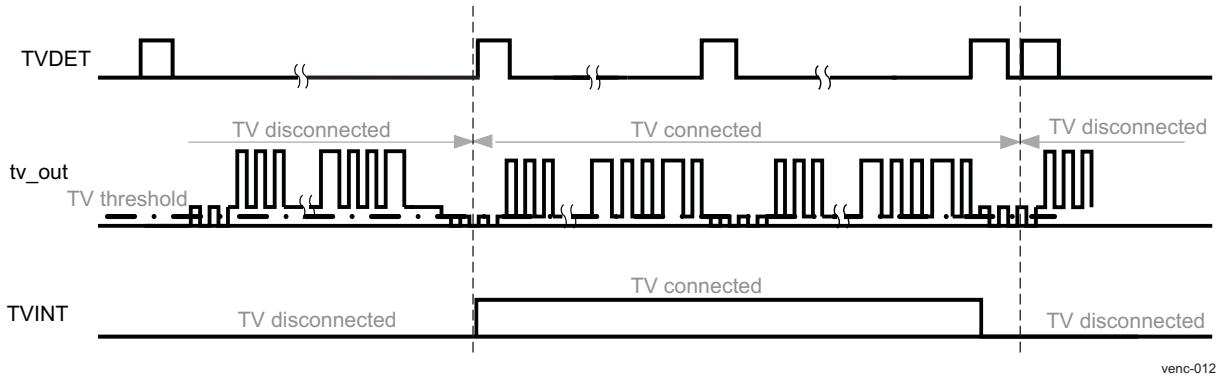


Figure 8-81. Video SD_DAC Signal Waveform Proposal for TV Detection/Disconnection in AC-Coupling Mode

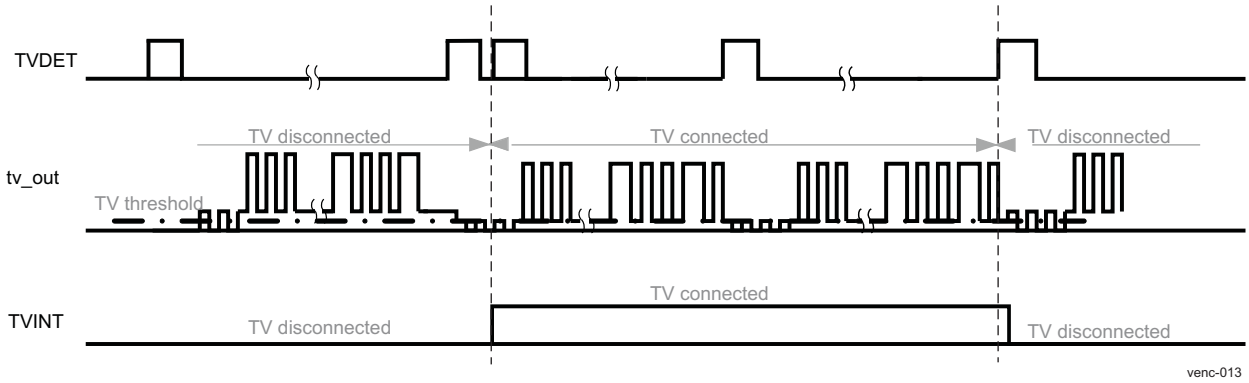


8.3.4.6.3 Video SD_DAC TV Short Detection

A TV short-detection circuit, which can detect a short circuit condition at *cvideo_tvout* output during the vertical sync pulse, is integrated in the video SD_DAC module (see Figure 8-77).

When the output is shorted to ground, the TVSHORT signal turns to logic high. The TVSHORT signal is internally mapped in the device to allow interrupt generation (see Section 8.3.3, *Video Encoder Integration*). TV short detection is valid after two video frames pass with the short/no-short condition.

TV short detection has priority over TV load detection (see Section 8.3.4.6.2.2, *TV Detection/Disconnection Pulse Generation and Use*). Whenever a short is detected (with load or no-load), TVINT output is masked as long as the short remains. When released, the TV load detection resumes.

CAUTION

If TV short is detected, the video SD_DAC must be powered down by setting the DSS.DSS_VENC_CTRL[2] DAC_POWERDN_BGZ bit to 0.

8.3.4.6.4 Video SD_DAC Normal Mode

The normal mode of operation (DAC + TVOUT buffer) is the default mode of the video SD_DAC, with the CONTROL.CTRL_CORE_SD_DAC_CONTROL[3] TVOUTBYPASS bit set to 0 at device reset. The output of the DAC is internally connected to the TVOUT buffer, which can drive the composite video signal to 75 Ω load directly. For information about external connectivity, see Section 8.3.2, *Video Encoder Environment*.

In normal mode, higher input values of the DAC code result in lower output voltage levels by default, because of the inverting configuration of the TVOUT buffer.

8.3.4.6.5 Video SD_DAC Bypass Mode

The 10-bit video SD_DAC has a TVOUT buffer bypass mode that turns off the TVOUT buffer and redirects directly the DAC output to the *cvideo_vfb* pin.

This bypass mode is activated by setting the CONTROL.CTRL_CORE_SD_DAC_CONTROL[3] TVOUTBYPASS bit to 1. The reset value of the TVOUTBYPASS bit is 0 (that is, the TVOUT buffer is not bypassed).

NOTE: In bypass mode:

- *cvideo_rset* pin requires a Rset resistor connected to the ground. The typical value of the Rset resistor is 10000 Ω.
- *cvideo_vfb* pin requires a Rload resistor connected to the ground. The typical value of the Rload resistor is 1500 Ω.

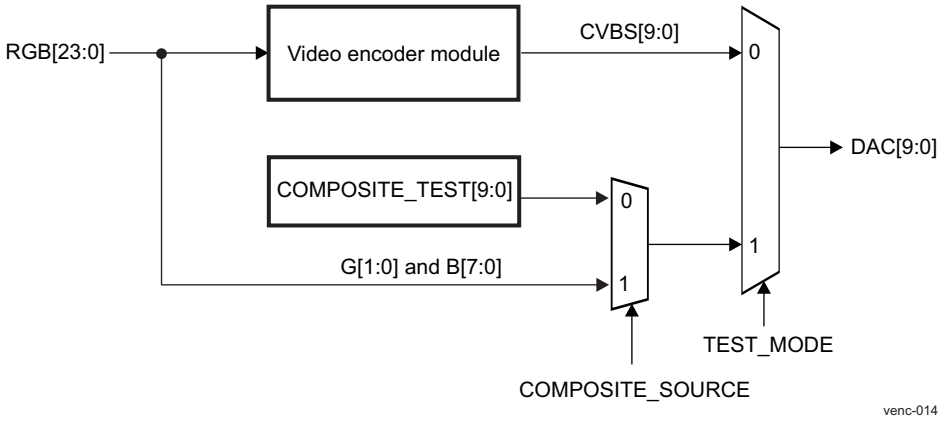
CAUTION

- The TV detect feature is not available in bypass mode.
- In bypass mode, an external video amplifier is needed on the *cvideo_vfb* pin.

8.3.4.6.6 Video SD_DAC Test Mode

10-bit external or internal datas values can be used to stimulate the DAC in debug mode, as shown in Figure 8-82.

Figure 8-82. Video SD_DAC Test Mode in Composite Video Mode



- Setting to 0x1 the VENC_OUTPUT_CONTROL[4] TEST_MODE bit will place the DAC under test.
- By setting the value of the VENC_OUTPUT_CONTROL[6] COMPOSITE_SOURCE bit to:
  - 0x0: the DAC input is coming from VENC_OUTPUT_TEST[9:0] COMPOSITE_TEST bit field
  - 0x1: the DAC input is coming from the display controller G[1:0], B[7:0]. To perform this configuration, the video encoder shall be configured to generate correct timing signals with the display controller, even if the video encoder is bypassed from data path perspective.

8.3.4.6.7 Video SD_DAC Power Management

After device reset, the DSS.DSS_VENC_CTRL[2] DAC_POWERDN_BGZ bit is set to 0, and the video SD_DAC is in power-down state.

Table 8-320 lists the possible SD_DAC power-management configurations and the corresponding register settings.

Table 8-320. Video SD_DAC Power Management Configurations

Power Management Controls				
DSS_VENC_CTRL [2] DAC_POWERDN_BGZ bit	**VENC_OUTPUT_CONTROL [1] COMPOSITE_ENABLE bit**	**CTRL_CORE_SD_DAC_CONTROL [3] TVOUTBYPASS bit**	**CTRL_CORE_SD_DAC_CONTROL [2] ACEN bit**	**Power State**
0	x	x	x	Total power down. Bandgap powered down.
1	0	x	x	Standby (analog in power down except bandgap/LDO)
1	1	0	0	Full power up in DC normal mode
1	1	0	1	Full power up in AC normal mode
1	1	1	x	Full power up in TVOUT bypass mode (DAC-only mode)

8.3.5 Video Encoder Programming Guide

8.3.5.1 Video Encoder Low-level Programming Models

8.3.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the video emodule is to be used for the first time after a device reset. This initialization of the surrounding modules is based on the integration and environment of the video encoder (for more information, see Section 8.3.2 and Section 8.3.3).

CAUTION

DSS must be enabled first before VENC, in order the source clocks feeding VENC to be running before enabling the VENC.

VENC must be disabled before DSS, in order the source clocks feeding the VENC to be running before disabling the VENC. If DSS is disabled before VENC, the functional clocks will stop abruptly.

Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. See Chapter 3, *Power, Reset, and Clock Management*
Control module	Module-specific pad muxing and configuration must be set in the control module. See Chapter 13, *Control Module*.
Display controller	See Section 8.2, *Display Controller,* for more information about the configuration.

8.3.5.1.2 Video Encoder Global Initialization

8.3.5.1.2.1 Main Sequence—Start Video Encoder

Start Video Encoder details the procedure to initialize the video encoder after a power-on or software reset.

Start Video Encoder

Step	Register/Bit Field/Programming Model	Value
Perform a video encoder reset.	See Section 8.3.5.1.2.3.	
Save the DSS VP1 IRQ enable register value (DSS VP interrupts context).	DISPC_VP1_IRQENABLE	
Reset all DSS VP1 IRQ.	DISPC_VP1_IRQENABLE	0x00
Configure the video encoder registers for PAL 601 or NTSC 601.	See Table 8-321.	0x--
Set the input video source and format.	VENC_F_CONTROL	See Table 8-321.
Set the synchronization modes.	VENC_SYNC_CTRL	See Table 8-321.
Configure the TV connection detection (optional).	See Section 8.3.5.1.2.4.	
Enable the composite video signal output.	See Section 8.3.5.1.2.6.	
Enable the display controller pipeline	See the display controller programming guide	
Wait until the first VSYNC pulse signal.		
Clear the SYNCLOST interrupt.	DISPC_VP1_IRQSTATUS[4] VPSYNCLOST_IRQ	0x1
Restore the DSS IRQ enable register.	DISPC_VP1_IRQENABLE	0x--

8.3.5.1.2.2 Main Sequence—Stop Video Encoder

Start Video Encoder details the procedure to stop the output of the composite signal.

Start Video Encoder

Step	Register/Bit Field/Programming Model	Value
Perform TV disconnection detection (optional).	See Section 8.3.5.1.2.5.	
Disable the composite video signal output.	See Section 8.3.5.1.2.7.	

8.3.5.1.2.3 Subsequence—Video Encoder Software Reset

Reset Video Encoder details the reset procedure.

Reset Video Encoder

Step	Register/Bit Field/Programming Model	Value
Activate reset.	VENC_F_CONTROL[8] RESET	0x1
Wait until reset is complete.	VENC_F_CONTROL[8] RESET	0x0

NOTE: Before changing the standard (NTSC or PAL) and related registers, a software reset is required to properly initialize the VENC module.

8.3.5.1.2.4 Subsequence—TV Connection Detection

TV Connection Detection Subsequence details the TV connection detection procedure.

TV Connection Detection Subsequence

Step	Register/Bit Field/Programming Model	Value
Set the pixel TV detection start and stop value.	VENC_TVDETGP_INT_START_STOP_X	0x--
Set the line TV detection start and stop value.	VENC_TVDETGP_INT_START_STOP_Y	0x--
Set the polarity of TV detection.	VENC_GEN_CTRL[16] TVDP	0x--
Enable TV detection.	VENC_GEN_CTRL[0] EN	0x1
Enable the composite video signal output.	See Section 8.3.5.1.2.6.	
Wait until TVINT = 1.		

CAUTION

- If ac coupling is selected, two TVDET pulses are required to set high the TVINT signal. Due to the internal logic of the video SD_DAC, the TVINT signal is generated after the next positive edge of the TVDET signal that happens during the next VSYNC timing.
- If dc coupling is selected, only one TVDET pulse is required to set high the TVINT signal.

8.3.5.1.2.5 Subsequence—TV Disconnection Detection

TV Disconnection Detection Subsequence details the TV disconnection detection procedure.

TV Disconnection Detection Subsequence

Step	Register/Bit Field/Programming Model	Value
Set the pixel TV detection start and stop value.	VENC_TVDETGP_INT_START_STOP_X	0x--
Set the line TV detection start and stop value.	VENC_TVDETGP_INT_START_STOP_Y	0x--
Set the polarity of TV detection.	VENC_GEN_CTRL[16] TVDP	0x--
Enable TV disconnection.	VENC_GEN_CTRL[0] EN	0x1
Wait until TVINT = 0.		

CAUTION

- If dc coupling is selected, two TVDET pulses are required to set low the TVINT signal. Because of the internal logic of the video SD_DAC, the TVINT signal is generated after the next positive edge of the TVDET signal that happens during the next VSYNC timing.
- If ac coupling is selected, only one TVDET pulse is required to set low the TVINT signal.

8.3.5.1.2.6 Subsequence—Enable Video Composite Signal Output

Enable Video Composite Signal Output details the procedure to enable the video composite signal output.

Enable Video Composite Signal Output

Step	Register/Bit Field/Programming Model	Value
Enable the composite video signal output.	VENC_OUTPUT_CONTROL	0x0000 000A
Power up the vdda_dac voltage for SD_DAC and the TVOUT buffer.		

8.3.5.1.2.7 Subsequence—Disable Video Composite Signal Output

Disable Video Composite Signal Output details the procedure to enable the video composite signal output.

Disable Video Composite Signal Output

Step	Register/Bit Field/Programming Model	Value
Disable the composite video signal output.	VENC_OUTPUT_CONTROL	0x00000000
Power down the vdda_dac voltage for SD_DAC and the TVOUT buffer.		

8.3.6 Video Encoder Use Case and Tips

8.3.6.1 Video Encoder Register Settings

Table 8-321 lists the register values to use in typical video encoder applications.

These values are validated programming values only for NTSC 601 and PAL 601 standards with a TV display resolution of 720×488 and 720×576, respectively.

Table 8-321. Video Encoder Register Programming Values

Register Name	NTSC 601	PAL 601
VENC_F_CONTROL	0x00000000	0x00000000
VENC_VIDOUT_CTRL	0x00000001	0x00000001

VENC_OUTPUT_CONTROL	0x0000000A	0x0000000A
VENC_OUTPUT_TEST	0x00000000	0x00000000

NOTE: The following display controller fields must be programmed to the NTSC 601 video standard:

- DISPC_VP1_SIZE_SCREEN[11:0] PPL = 720 - 1 = 719 = 0x2CF
- DISPC_VP1_SIZE_SCREEN[27:16] LPP = (488/2) - 1 = 243 = 0xF3

The following display controller fields must be programmed to the PAL 601 video standard:

- DISPC_VP1_SIZE_SCREEN[11:0] PPL = 720 - 1 = 719 = 0x2CF
- DISPC_VP1_SIZE_SCREEN[27:16] LPP = (576/2) - 1 = 287 = 0x11F

For both standards, the base addresses should be handle as follow:

- DISPC_GFX1_BA0 or DISPC_VID_BA0 = Base address of even bit field data
- DISPC_GFX1_BA1 or DISPC_VID_BA1 = Base address of odd bit field data

SLX is an abbreviation for SonicsLX®.

Topic **Page**

9.1 Interconnect Overview

9.1.1 Terminology

The following terminology is critical to understanding the interconnect:

- Initiator: Module able to initiate read and write requests to the chip interconnect (typically: processors, DMA, etc.).
- Target: Unlike an initiator, a target module cannot generate read/write requests to the chip interconnect, but it can respond to these requests. However, it may generate interrupts or a DMA request to the system (typically: peripherals, memory controllers).

NOTE: A module can have several separate ports; therefore, a module can be an initiator and a target.

- Agent: Each connection of one module to one interconnect is done using an agent, which is an adaptation (sometimes configurable) between the module and the interconnect. A target module is connected by a target agent (TA), and an initiator module is connected by an initiator agent (IA).
- Interconnect: The decoding, routing, and arbitration logic that enables the connection between multiple initiator modules and multiple target modules connected on it. Quality of service (QoS) is guaranteed.
- Register target (RT): Special TA used to access the interconnect internal configuration registers
- Data-flow signal: Any signal that is part of a clearly identified transfer or data flow (typically: command, address, byte enables, etc.). Signal behaviour is defined by the protocol semantics.
- Sideband signal: Any signal whose behaviour is not associated to a precise transaction or data flow.
- Out-of-band error: Any signal whose behaviour is associated to a device error-reporting scheme, as opposed to in-band errors.

NOTE: Interrupt requests and DMA requests are not routed by the interconnect in the device.

- Firewall: A programmable feature integrated in a target agent or L4 interconnect to prevent unauthorized access to or from a module. A firewall can be configured using three criteria:
  - Initiator requesting access
  - Address space access
  - Type of access
- ConnID: Any transaction in the system interconnect is tagged by an in-band qualifier ConnID, which uniquely identifies the initiator at a given interconnect point. A ConnID is transmitted in band with the request and is used for firewall and error-logging mechanism.
- Firewall comparison mechanism: A comparison made in the firewall between access in-band qualifiers and access permissions that are programmed in the firewall configuration registers. If the comparison is successful, access is allowed; otherwise, access is denied.
- MCmd qualifier: Command bus that indicates the type of transfer requested. Table 9-1 lists the commands encoded. For information specific to L3 Interconnect error logging, see *L3 Firewall Error-Logging Registers*

Table 9-1. MCmd Qualifier Description

MCmd[2:0]	Transaction Type
0 0 0	Idle
0 0 1	Write
0 1 0	Read
0 1 1	ReadEx
1 0 0	Read link
1 0 1	Write nonposted
1 1 0	Write conditional

Table 9-1. MCmd Qualifier Description (continued)

MCmd[2:0]	Transaction Type
1 1 1	Write broadcast

- MReqInfo qualifier: Three MReqInfo qualifiers describe the access during the use of the firewall comparison mechanism, as described in Table 9-2.

Table 9-2. MReqInfo Qualifier Description

Qualifiers	Description
MReqType	0: Data access
	1: Opcode fetch
MReqSupervisor	0: User mode
	1: Supervisor mode
MReqDebug	0: Functional access
	1: Debug access

- Register that configures the combination of the MReqInfo, allowing access permission to the target module (TM) based on the MReqInfo in-band qualifier values.
- SError: Target that indicates an error condition to the initiator.
- SResp qualifier: Response from the target to the initiator concerning the transaction, as described in Table 9-3.

Table 9-3. SResp Qualifier Description

SResp[1:0]	Description
0 0	No response
0 1	Data valid/accept
1 0	Not used
1 1	Error

- MTagID: Interconnect qualifier generated by the L3_MAIN masters which purpose is to identify whether reordering is allowed or not relative to other transactions. Strong ordering is ensured by using same MTagID values between transactions. Reordering is allowed by using different MTagID values between transactions.
  The MTagID values may or may not be changed by the interconnect, but the intended reordering restriction must match what came from the master. In other words, the interconnect allocates dynamically MTagID values in such a way that the intended reordering restrictions from each master are honored.

9.1.2 Architecture Overview

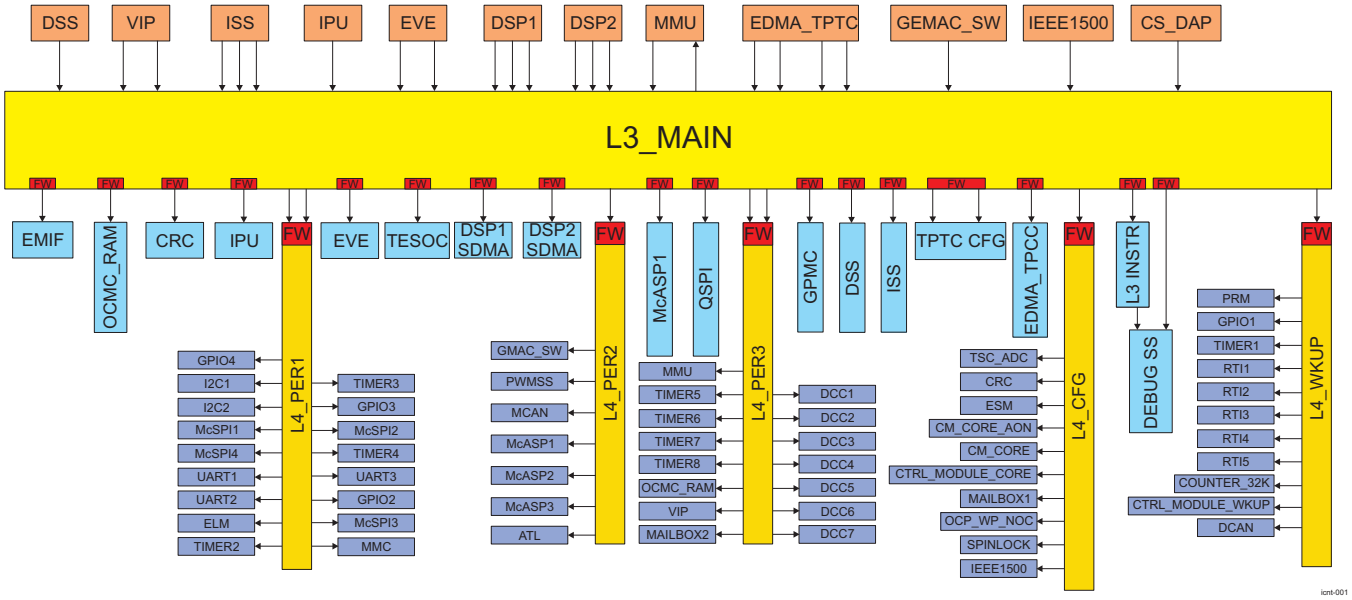
The device memory hierarchy includes four levels:

- L1 and L2 memory spaces are associated with the IPU and DSP subsystems.
- The chip-level interconnect consists of one L3 interconnect and five L4 interconnects. It enables communication among the modules and subsystems in the device.

Figure 9-2 shows an overview of the L3 and L4 interconnect architecture.

NOTE: ISS, CRC, TESOC, ESM and DCC1 to DCC7 are not supported on the DRA78x family of devices.

Figure 9-1. Interconnect Overview



- L3 handles many types of data transfers, especially exchanges with system-on-chip/external memories. L3 transfers data with a maximum width of 128 bits from the initiator to the target. The L3 interconnect is a little-endian platform
- The L4 is composed of the following:
  - L4_CFG: Includes the majority of the firewall configuration interface for level 3 (L3) system modules and peripheral interconnect;
  - L4_PER: Includes the main peripherals that require direct memory access access. L4_PER has three instances L4_PER1, L4_PER2 and L4_PER3. These three instances has the following ports connecting them to the L3_MAIN interconnect:
    - L4_PER1_P1, L4_PER1_P2
    - L4_PER2_P1
    - L4_PER3_P1, L4_PER3_P2

    Through the L3_MAIN interconnect, different initiators can access each of these ports. For information about which port can be accessed by each initiator, see Figure 9-3.
  - L4_WKUP: Includes peripherals attached to the WKUP power domain.

Modules are connected to the interconnect through an IA for the initiator module and a TA for target modules. Each module/subsystem connection is statically configured to tune the access, depending on the characteristics of the module.

To unauthorize a module or L4 interconnect access, some TAs include configurable firewalls (FWs). A firewall restricts or filters the accesses allowed to an initiator according to different access criteria. The firewalls can usually be configured by software.

The L3 and L4 interconnect default settings are fully functional; they enable all possible functional data paths and a minimal default protection setting.

9.2 L3_MAIN Interconnect

This section describes the L3_MAIN interconnect and its components. With the exception of register points, each component includes functions for the request and response networks.

9.2.1 L3_MAIN Interconnect Overview

The L3_MAIN interconnect links cores in a flexible topology that couples low power with high performance. Innovative physical structures and advanced protocols ensure bandwidth and latency to individual IP cores, providing dedicated connections between IP cores and logical connections over a shared interconnect.

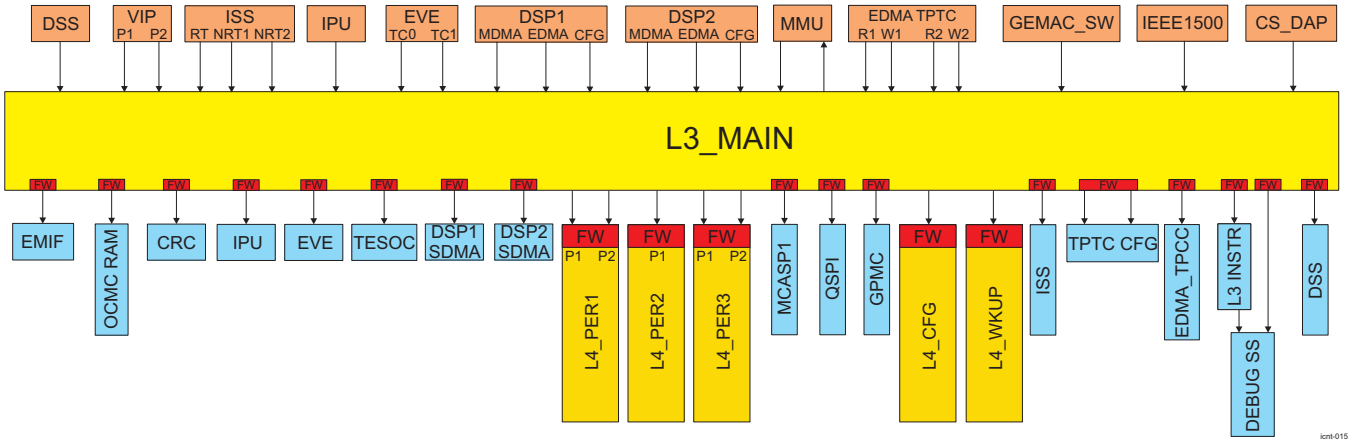
The main features of the L3_MAIN interconnects are:

- NIUs: Master NIUs for the IAs and slave NIUs for the TAs
- A partially depleted cross-bar exchange network
- A special internal slave NIU for accessing L3_MAIN interconnect configuration registers
- QoS management for real-time hardware operators, while maintaining optimal memory latency for CPU access to memory resources
- True little-endian platform
- Transaction errors tracking and logging registers
- All signaling support for chip-level power-management infrastructure
- One interrupt line signaling transaction error
- One interrupt line for reporting satistical events on the L3_MAIN interconnect

Figure 9-2 shows an overview of the L3 interconnect and the peripherals attached to it.

NOTE: ISS, CRC and TESOC are not supported on the DRA78x family of devices.

Figure 9-2. L3_MAIN Interconnect Overview



9.2.2 L3_MAIN Interconnect Integration

Table 9-4 through Table 9-6 summarize the integration of the module in the device.

Table 9-4. Integration Attributes

Module Instance	Attributes
	Power Domain
L3_MAIN	PD_COREAON

Table 9-5. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
L3_MAIN	L3_CLK1	L3MAIN1_L3_GICLK	PRCM	Functional and interface clock
	L3_CLK2	L3INSTR_L3_GICLK	PRCM	Functional and interface clock
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
L3_MAIN_MAIN	L3_CORE_RET_RST	CORE_PWRON_RET_RST	PRCM	Reset of L3_MAIN interconnect registers
	L3_CORE_RST	CORE_RST	PRCM	Reset of L3_MAIN interconnect

Table 9-6. Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination IRQ_CROSSBAR Input**	**Defalut Mapping**	**Description**
L3_MAIN	L3_MAIN_IRQ_DBG_ERR	IRQ_CROSSBAR_4	DSP1_IRQ_35 DSP2_IRQ_35 EVE_IRQ_3	Interrupt indicating debug error occurrence.
	L3_MAIN_IRQ_APP_ERR	IRQ_CROSSBAR_5	DSP1_IRQ_36 DSP2_IRQ_36 EVE_IRQ_4	Interrupt indicating application error occurrence.
	L3_MAIN_IRQ_STAT_ALARM	IRQ_CROSSBAR_11	DSP1_IRQ_42 DSP2_IRQ_42	Statistic collector alarm interrupt.

NOTE: The "**Default Mapping**" column in Table 9-6 *Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.
For more information about the device interrupt controllers, see Chapter 12, *Interrupt Controllers*.

9.2.3 L3_MAIN Interconnect Functional Description

9.2.3.1 Module Use in L3_MAIN Interconnect

The L3_MAIN interconnect network components have ConnID values for each master NIU or slave NIU. The ID uniquely identifies the master NIU or the slave NIU for an interconnect transfer. The interconnect uses ConnIDs for a number of purposes, including the following:

- Slave NIUs for error logging
- Power disconnect slave NIU for error logging
- FLAGMUXes for masking interrupts
- Statistic Collectors (STATCOLL) for configuring and monitoring: The STATCOLL components compute the traffic statistics within a user-defined window and periodically report to the user through the debug interface.
- Bandwidth regulator for configuration

9.2.3.2 Module Distribution

Master NIUs and slave NIUs provide the interface to connect the different modules to their associated interconnect.

Table 9-7 and Table 9-8 list all modules and subsystems with their associated agents. The agents are listed for each L3_MAIN interconnect domain.

9.2.3.2.1 L3_MAIN Interconnect Agents

Any initiator or target core is connected to the L3_MAIN interconnect through an NIU. NIUs act as entry points to the L3_MAIN interconnect, and also include various programming registers. Table 9-7 lists the supported master NIU ports.

Table 9-7. Master NIUs

Master NIU	Description
DSS1_INIT	Display SubSystem initiator port. One 128b initiator port
VIP_P1_INIT	Port 1 of VIP-128b initiator port.
VIP_P2_INIT	Port 2 of VIP-128b initiator port.
ISS_RT_INIT	ISS real time (RT) initiator port. One 128b initiator port. Note: ISS is not supported on the DRA78x family of devices.
ISS_NRT1_INIT	ISS non real time (NRT) initiator port 1. One 128b initiator port.
ISS_NRT2_INIT	ISS non real time (NRT) initiator port 2. One 128b initiator port.
IPU_INIT	IPU initiator port. One 64b initiator port
EVE_TC0_INIT	Embedded Vision Engine 1 (EVE) initiator port 1 (P1). One 128b initiator port.
EVE_TC1_INIT	Embedded Vision Engine 1 (EVE) initiator port 1 (P2). One 128b initiator port.
DSP1_MDMA_INIT	DSP1 Initiator port. One 128b MDMA interconnect initiator port (used also for cache requests)
DSP1_EDMA_INIT	DSP1 initiator port. One 128b EDMA interconnect initiator port.
DSP1_CFG_INIT	One 32b configuration initiator port.
DSP2_MDMA_INIT	DSP2 Initiator port. One 128b MDMA interconnect initiator port (used also for cache requests)
DSP2_EDMA_INIT	DSP2 initiator port. One 128b EDMA interconnect initiator port.
DSP2_CFG_INIT	One 32b configuration initiator port.
MMU_INIT	MMU initiator port.One 128b initiator port.
TPTC1_WR_INIT	EDMA TPTC initiator write port 1. One 128b initiator port.
TPTC1_RD_INIT	EDMA TPTC initiator read port 1. One 128b initiator port.
TPTC2_WR_INIT	EDMA TPTC initiator write port 2. One 128b initiator port.

Table 9-7. Master NIUs (continued)

Master NIU	Description
TPTC2_RD_INIT	EDMA TPTC initiator read port 2. One 128b initiator port.
GMAC_SW_INIT	GMAC_SW 32b initiator port.
IEEE1500_2_OCP_INIT	IEEE1500 32b initiator port.
DEBUGSS_CS_DAP_INIT	Debug subsystem CS_DAP 32b initiator port.

Table 9-8 lists the supported slave NIU ports.

Table 9-8. Slave NIUs

Slave NIU	Description
EMIF_P1_TARG	EMIF 128b target port.
OCMC_RAM_TARG	On-chip memory controller 128b target port.
CRC_TARG	CRC 64b target port. Note: CRC is not supported on the DRA78x family of devices.
IPU_TARG	IPU 64b target port.
EVE_TARG	EVE 128b target port.
TESOC_TARG	Tester-On-Chip 128b target port. Note: TESOC is not supported on the DRA78x family of devices.
DSP1_SDMA_TARG	128b target port for system requests to DSP1 memory or DSP1 address space.
DSP2_SDMA_TARG	128b target port for system requests to DSP2 memory or DSP2 address space.
L4_PER1_P1_TARG (L4_PER_P0_TARG)	L4_PER1 32b target port 1 (P1).
L4_PER1_P2_TARG (L4_PER_P1_TARG)	L4_PER1 32b target port 2 (P2).
L4_PER2_P1_TARG (L4_PER_P3_TARG)	L4_PER2 32b target port 1 (P1).
L4_PER3_P1_TARG (L4_PER_P6_TARG)	L4_PER3 32b target port 1 (P1).
L4_PER3_P2_TARG (L4_PER_P7_TARG)	L4_PER3 32b target port 2 (P2).
MCASP1_TARG	McASP 32b target port.
QSPI_TARG	QSPI 32b target port.
GPMC_TARG	GPMC 32b target port.
L4_CFG_TARG	L4_CFG 32b target port.
L4_WKUP_TARG	L4_WKUP 32b target port.
ISS_TARG	ISS 32b target port. Note: ISS is not supported on the DRA78x family of devices.
TPTC1_TARG	EDMA TPTC 32b target port 1.
TPTC2_TARG	EDMA TPTC 32b target port 2.
EDMA_TPCC_TARG	EDMA TPCC 32b target port.
L3_INSTR_TARG	L3 instrumentation 32b target port.
DEBUGSS_CT_TBR_TARG	Debug subsystem CT_TBR 64b target port.
DSS_TARG	Display subsystem 32b target port.
MMU_TARG	Memory management unit 128b target port.

9.2.3.2.2 L3_MAIN Connectivity Matrix

The L3 interconnect is divided into two clock domains L3_CLK1 and L3_CLK2. L3_CLK1 domain is further splitted into two sub groups:

- L3_CLK1_1: Low-power domain
- L3_CLK1_2: Peripherals and multimedia

L3_CLK2 is instrumentation (debug) associated. The two clock elements (L3_CLK1 and L3_CLK2) are implemented in different clock domains.

9.2.3.2.2.1 Clock Domain Mapping of the L3_MAIN Interconnect Modules

Each clock domain (L3_CLK1 and L3_CLK2) has it own host, flag mux, slave NIUs, and bandwidth regulators. Table 9-9 lists the relationships between these domains and these elements.

Table 9-9. L3_MAIN Clock Domains and Elements

Figure 9-3shows the functional paths between the L3_MAIN master NIUs and the L3_MAIN and L4 slave NIU agents. The functional paths in L3_MAIN are indicated by the following:

- A cell contains the letter C when a functional path exists.
- A cell is empty when a functional path does not exist.

NOTE: ISS, CRC and TESOC are not supported on the DRA78x family of devices.

icnt-002

9.2.3.2.3 Master NIU Identification

A master NIU ID (ConnID) is assigned to every module in the device. The ID uniquely identifies the master NIU for an interconnect transfer (see Table 9-10). The interconnect uses ConnID values for a number of purposes, including:

- Master source identification for the protection mechanism
- Response route generation
- Firewall error logging
- L3_MAIN interconnect error logging

All L3_MAIN firewalls use 4-bit ConnID values from several registers in the control module instead of the L3_MAIN ConnIDs. Thus appropriate grouping of initiators based on a configurable ConnID can be done. The 4-bit ConnID is equal to bits[7:4] of the L3_MAIN 8-bit ConnID. The reset values of these control module registers mach the value of bits[7:4]. The registers are the following:

- CTRL_CORE_FIREWALL_CONNID_CONTROL_0

- CTRL_CORE_FIREWALL_CONNID_CONTROL_1
- CTRL_CORE_FIREWALL_CONNID_CONTROL_2
- CTRL_CORE_FIREWALL_CONNID_CONTROL_3

Table 9-10. ConnID Values

8-bit ConnID (hex)	4-bit ConnID (hex)	Master NIU
10	1	DEBUGSS_CS_DAP_INIT
14	1	IEEE1500_2_OCP_INIT
20	2	DSP1_MDMA_INIT
24	2	DSP1_CFG_INIT
28	2	DSP1_EDMA_INIT
2C	2	DSP2_EDMA_INIT
30	3	DSP2_CFG_INIT
34	3	DSP2_MDMA_INIT
42	4	EVE_TC0_INIT
60	6	IPU_INIT
70	7	TPTC1_WR_INIT
72	7	TPTC1_RD_INIT
74	7	TPTC2_WR_INIT
76	7	TPTC2_RD_INIT
80	8	DSS1_INIT
86	8	MMU_INIT
90	9	VIP_P1_INIT
92	9	VIP_P2_INIT
AC	A	GMAC_SW_INIT
C0	C	ISS_RT_INIT Note: ISS is not supported on the DRA78x family of devices.
C4	C	ISS_NRT1_INIT
C8	C	ISS_NRT2_INIT
D2	D	EVE_TC1_INIT
E0	E	STATCOLL1
E0	E	STATCOLL2
E0	E	STATCOLL3
E0	E	STATCOLL4

The 8-bit ConnID values are used by error decoding to distinguish the different initiators, see Section 9.2.3.8.4, *Example for Decoding Standard/Custom Errors Logged in L3_MAIN*. They are also used by the EMIF controller. The 4-bit ConnID values are used by the firewalls to allow or not an access to a slave NIU, see Table 9-16.

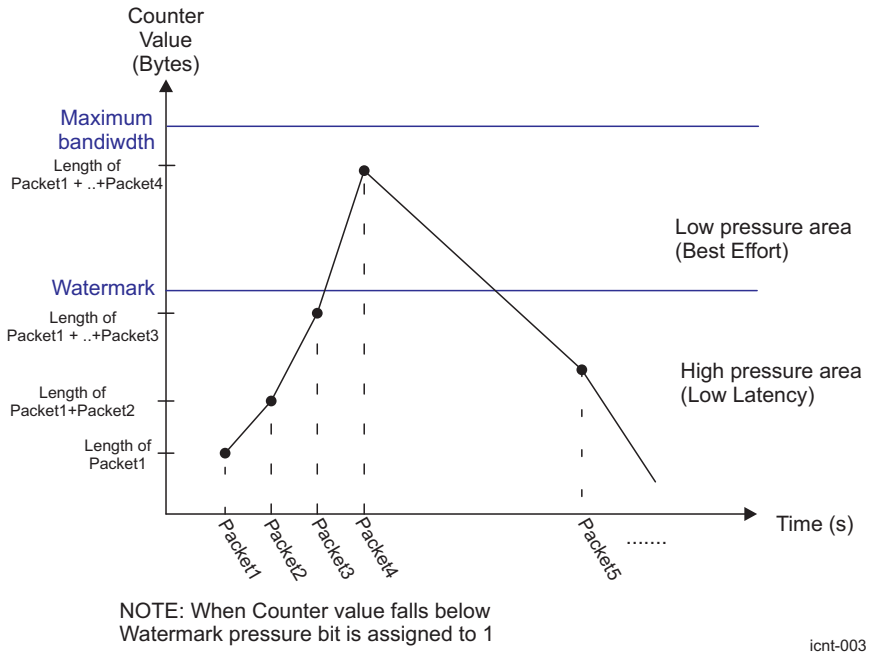
9.2.3.3 Bandwidth Regulators

The bandwidth regulators prevent master NIUs from consuming too much bandwidth of a link, or a slave NIU that is shared between several data flows: packets are then transported at a slower rate. The value of a bandwidth can be programmed in the bandwidth regulator. When the bandwidth is below the programmed value, the pressure bit is set to 1, giving priority to this master. When the bandwidth is above the programmed value, the pressure bit is set to 0 and the concerned master has the same weight as others.

A counter is used to store the sum of data lengths (in bytes) of each packet passing through the bandwidth regulator, and a value equal to the expected bandwidth is subtracted from the counter at each clock cycle. The value of the counter is compared to a programmable threshold (called Watermark), and this comparison determines whether the packet is processed with high pressure for minimum latency or low pressure for best effort processing.

The bandwidth regulator monitors the traffic using open connections between the initiators and the targets. If there is insufficient bandwidth allocated to the connection, the bandwidth regulator can increase the pressure on connections. Generally, the connection is a dataflow between master and slave NIUs. In some cases, the bandwidth regulator is attached to the master and monitors single dataflow to a target (single connection).

Figure 9-4. Bandwidth Regulator Pressure Settings



When Counter Value (bytes) falls below Watermark, the pressure bit is assigned to 1

The bandwidth regulator effective resolution is set to 8.3125 MBps. The maximum average bandwidth (max watermark value) computed in a moving window is set to up to 4096 bytes of payload. These settings are implemented by hardware.

The following is an example of bandwidth regulator settings:

Suppose the bandwidth regulator is set to run at 200 MHz and the application requires an expected bandwidth of 165.888 MBps (±5 MBps), computed through a moving window of 5 µs (1000 cycles). To attribute high pressure on all packet requests, the watermark could be set to the maximum bandwidth needed in the 5-µs window.

Considering the example, the settings of the bandwidth regulator are:

- L3_BW_REGULATOR_WATERMARK[11:0] WATERMARK = moving window × expected bandwidth = 829.44 bytes = 0x33D
- L3_BW_REGULATOR_BANDWIDTH[15:0] BANDWIDTH = ceil(165.888/8.3125) = ceil(19.956) = 20d = 0x14

The bandwidth registers regulate the packet flow by applying flow control on the RX port, thus ensuring that the traffic does not exceed the allocated bandwidth. The next packet is sent only when an internal timer expires. The registers in this group are:

- L3_BW_REGULATOR_WATERMARK: Gives the amount of data allowed to exceed the average bandwidth during a short time period
- L3_BW_REGULATOR_PRESS: Describes the pressure applied to outgoing packets
- L3_BW_REGULATOR_CLEARHISTORY: Resets the traffic counter when set to 1. This register is

used after an update in the L3_BW_REGULATOR_BANDWIDTH and L3_BW_REGULATOR_WATERMARK registers (see Section 9.2.5.1.7, *L3 BW Regulator Register Summary and Description*).

Bandwidth regulators are mainly used to give priority to the following master NIUs:

- IPU_INIT
- EVE_TC0_INIT
- EVE_TC1_INIT
- DSP1_MDMA_INIT
- DSP2_MDMA_INIT
- GMAC_SW_INIT

Priority to the following master NIUs is given by setting their internal MFlag signals:

- DSS1_INIT
- VIP_P1_INIT
- VIP_P2_INIT
- ISS_RT_INIT

NOTE: ISS is not supported on the DRA78x family of devices.

9.2.3.4 Bandwidth Limiters

Bandwidth limiters are added to control the bandwidth of:

- ISS_NRT1_INIT
- ISS_NRT2_INIT
- *IPU_INIT*
- *EVE_TC0_INIT*
- *EVE_TC1_INIT*
- *DSP1_MDMA_INIT*
- DSP1_EDMA_INIT
- *DSP2_MDMA_INIT*
- DSP2_EDMA_INIT
- MMU_INIT
- TPTC1_WR_INIT
- TPTC1_RD_INIT
- TPTC2_WR_INIT
- TPTC2_RD_INIT

This prevents a large number of RD requests being processed together, thus avoiding a large number of RD responses.

NOTE: The following initiator NIUs have also bandwith regulators:

- *IPU_INIT*
- *EVE_TC0_INIT*
- *EVE_TC1_INIT*
- *DSP1_MDMA_INIT*
- *DSP2_MDMA_INIT*

The bandwidth limiter regulates the packet flow in the L3_MAIN interconnect by applying flow control when a user-defined bandwidth limit is reached. The next packet is served only after an internal timer expires, thus ensuring that traffic does not exceed the allocated bandwidth. Bandwidth limiter can be used with a watermark mechanism that allows traffic to temporarily exceeds the peak bandwidth.

The registers in this group are:

- L3_BW_LIMITER_WATERMARK_0: Gives the amount of data allowed to exceed the average bandwidth during a short time period. To set the actual watermark to n bytes, the register must be set to n + 1.
- L3_BW_LIMITER_CLEARHISTORY: Resets the traffic counter when set to 1.
- L3_BW_LIMITER_BANDWIDTH_FRACTIONAL and L3_BW_LIMITER_BANDWIDTH_INTEGER: These two registers are used to set the average payload bandwidth.

Example of setting the Bandwidth Limiters:

L3_BW_LIMITER_BANDWIDTH_FRACTIONAL must be set to BandwidthConf [4 down to 0] and L3_BW_LIMITER_BANDWIDTH_INTEGER contains the remaining BandiwdthConf bits, shifted to the right. BandwidthConf = AverageBandwidth / EffectiveResolution, where EffectiveResolution parameter is set to 8.3125 MHz at design time

AverageBandwidth is a parameter representing the value to which the payload bandwidth must be limited in average; this parameter depends on the use case and is the reason that makes the content of the registers variable. In addition the maximum packet length is 8 cells, that is 32 bytes.

Assuming that the use case requires that in average the payload bandwidth is limited to 200 MB/s, then registers must be set to the following values:

BandwidthConf = 200 MBps / 8.3125 MHz = 38 (0x26)

L3_BW_LIMITER_BANDWIDTH_FRACTIONAL = LSBs [4 down to 0] of BandwidthConf = 0x6.

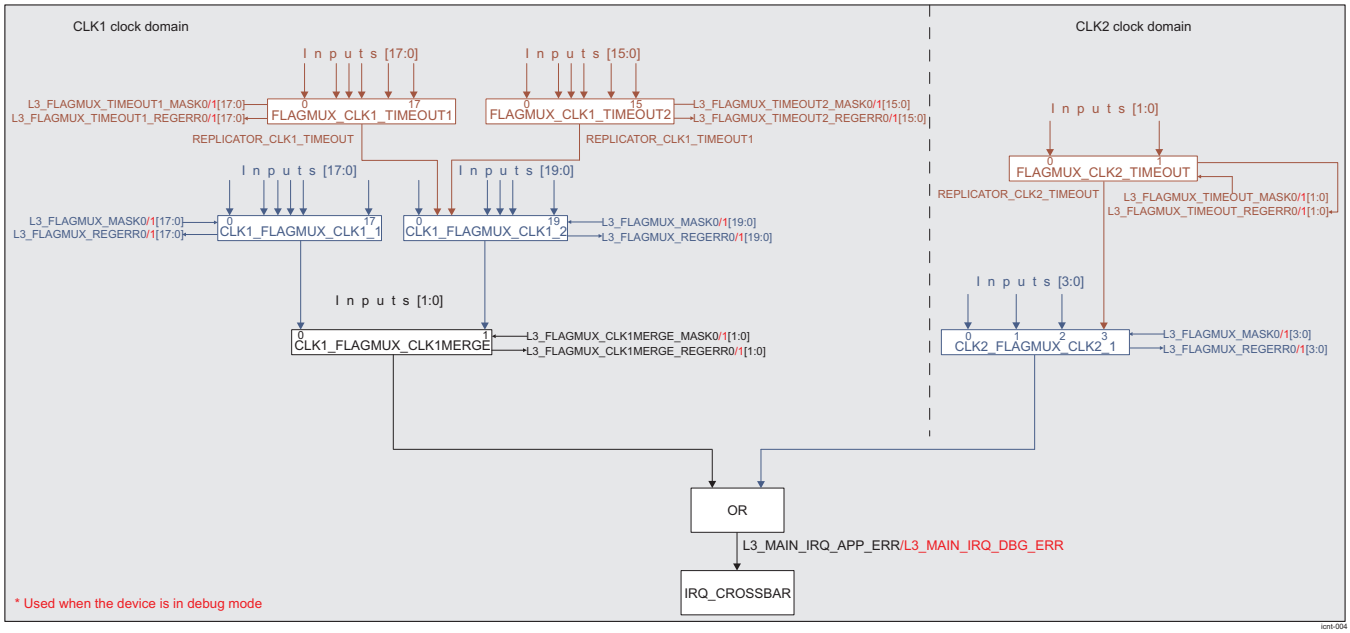
L3_BW_LIMITER_BANDWIDTH_INTEGER = the remaining bits of BandwidthConf shifted to the right = 0x1.

By setting L3_BW_LIMITER_WATERMARK to 65 (L3_BW_LIMITER_WATERMARK_0 = 0x41), the bandwidth limiter is able to send three packets consecutively during peaks, therefore exceeding the peak traffic with two packets (64 bytes)

9.2.3.5 Flag Muxing

Flag muxing is used to collect information such as errors and interrupts from slave NIUs and interconnect firewalls. The result signals are then sent to the IRQ_CROSSBAR module without interfering with the interconnect traffic. Figure 9-5 shows the flag muxing scheme.

Figure 9-5. Flag Muxing Scheme



The following three flag muxes collect information from targets in L3_CLK1 and L3_CLK2 clock domains:

- CLK1_FLAGMUX_CLK1_1
- CLK1_FLAGMUX_CLK1_2
- CLK2_FLAGMUX_CLK2_1

There are three L3_FLAGMUX_MASK0 registers each associated with a single flag mux of the previously listed. Each bit in these registers is associated with only one source. If a bit is set to 0x0, the corresponding flag is masked which means that the input source is disabled, and if set to 0x1 the flag is unmasked. There are also three L3_FLAGMUX_REGERR0 status registers for checking the source of error. A value of 0x1 indicates that the corresponding flag is set, that is, an error is generated. Table 9-11 shows the mapping between the input sources and the bits in L3_FLAGMUX_MASK0 and L3_FLAGMUX_REGERR0 registers. The missing values are reserved and writing to these bits has no effect.

Table 9-11. Flag Mux Input Mapping

Flag Mux	Corresponding bit in registers L3_FLAGMUX_MASK0 and L3_FLAGMUX_REGERR0 (Flag Mux Input)	Flag Mux Input Sources
CLK1_FLAGMUX_CLK1_1	1	EMIF_P1
	2	DSP2_SDMA
	3	TESOC Note: TESOC is not supported on the DRA78x family of devices.
	5	DSP1_SDMA
	6	EVE
	7	DSS
	8	GPMC
	10	L4_CFG
	11	L4_WKUP
	13	IPU
	14	EDMA_TPCC
	15	TPTC1 (EDMA)

Table 9-11. Flag Mux Input Mapping (continued)

Flag Mux	Corresponding bit in registers L3_FLAGMUX_MASK0 and L3_FLAGMUX_REGERR0 (Flag Mux Input)	Flag Mux Input Sources
	16	TPTC2 (EDMA)
	17	MMU
CLK1_FLAGMUX_CLK1_2	0	HOST_CLK1_1
	1	HOST_CLK1_2
	2	REPLICATOR_CLK1_TIMEOUT
	4	REPLICATOR_CLK1_TIMEOUT1
	5	L4_PER2_P1 (L4_PER_P3)
	6	L4_PER1_P1 (L4_PER_P0)
	7	L4_PER1_P2 (L4_PER_P1)
	8	L4_PER3_P2 (L4_PER_P7)
	9	L4_PER3_P1 (L4_PER_P6)
	10	MCASP1
	12	OCMC_RAM
	16	QSPI
	18	CRC Note: CRC is not supported on the DRA78x family of devices.
	19	ISS Note: ISS is not supported on the DRA78x family of devices.
CLK2_FLAGMUX_CLK2_1	0	L3_INSTR
	1	DEBUGSS_CT_TBR
	2	HOST_CLK2_1
	3	REPLICATOR_CLK2_TIMEOUT

Each of the three flag muxes has also the following two registers:

- L3_FLAGMUX_STDHOSTHDR_COREREG register for identification of the attached core type
- L3_FLAGMUX_STDHOSTHDR_VERSIONREG register for identification of the characteristics of the attached core

There is also a separate mux (CLK1_FLAGMUX_CLK1MERGE) that merges the outputs of the CLK1_FLAGMUX_CLK1_1 and CLK1_FLAGMUX_CLK1_2 flag muxes. Its functionality follows the same logic as the functionality of the flag muxes previously described. The following registers are available:

- L3_FLAGMUX_CLK1MERGE_MASK0 register for enabling/disabling the corresponding input sources
- L3_FLAGMUX_CLK1MERGE_REGERR0 status register for checking the source of error
- L3_FLAGMUX_CLK1MERGE_STDHOSTHDR_COREREG register for identification of the attached core type
- L3_FLAGMUX_CLK1MERGE_STDHOSTHDR_VERSIONREG register for identification of the characteristics of the attached core

In addition, it must be taken into account that the following registers (already described) with suffix "0" are used when the device is in application mode:

- L3_FLAGMUX_MASK0
- L3_FLAGMUX_REGERR0
- L3_FLAGMUX_CLK1MERGE_MASK0
- L3_FLAGMUX_CLK1MERGE_REGERR0

The following registers with suffix "1" are used when the device is in debug mode:

- L3_FLAGMUX_MASK1

- L3_FLAGMUX_REGERR1
- L3_FLAGMUX_CLK1MERGE_MASK1
- L3_FLAGMUX_CLK1MERGE_REGERR1

Both register groups have identical bits and follow same logic. The only difference is that registers with suffix "0" are used in application mode and registers with suffix "1" are used in debug mode.

9.2.3.5.1 Time-out Flag Muxing

If a target does not respond after a fixed number of clock cycles, a time-out error flag is generated if enabled. There are three time-out flag muxes:

- FLAGMUX_CLK1_TIMEOUT1 with registers L3_FLAGMUX_TIMEOUT1_MASK0 and L3_FLAGMUX_TIMEOUT1_REGERR0
- FLAGMUX_CLK1_TIMEOUT2 with registers L3_FLAGMUX_TIMEOUT2_MASK0 and L3_FLAGMUX_TIMEOUT2_REGERR0
- FLAGMUX_CLK2_TIMEOUT with registers L3_FLAGMUX_TIMEOUT_MASK0 and L3_FLAGMUX_TIMEOUT_REGERR0

Each bit in the _MASK0 registers previously listed is associated with only one time-out source. If a bit is set to 0x0, the corresponding time-out flag is masked, and if set to 0x1 the flag is unmasked. To check the source of time-out error the corresponding bit in one of the three previously listed _REGERR0 registers should be read. A value of 0x1 indicates that a time-out error has occurred.

Table 9-12 shows the mapping between the time-out input sources and the bits in _MASK0 and _REGERR0 registers. The missing values are reserved and writing to these bits has no effect.

Table 9-12. L3 Time-out Flag Mapping

Time-out Flag Mux	Flag Mux Input (Corresponding bit in registers _MASK0 and _REGERR0)	Flag Mux Time-out Input Sources
FLAGMUX_CLK1_TIMEOUT1	2	DSP1_SDMA
	3	DSP2_SDMA
	4	DSS
	5	EVE
	6	IPU
	7	MMU
	8	EMIF_P1
	9	TESOC Note: TESOC is not supported on the DRA78x family of devices.
	11	L4_PER_P0
	12	L4_PER_P1
	13	L4_PER_P3
	14	L4_PER_P7
	15	L4_PER_P6
	16	L4_CFG
	17	L4_WKUP
FLAGMUX_CLK1_TIMEOUT2	2	ISS Note: ISS is not supported on the DRA78x family of devices.
	4	QSPI
	6	EDMA_TPCC
	7	TPTC1
	8	TPTC2
	11	MCASP1
	12	OCMC_RAM

Table 9-12. L3 Time-out Flag Mapping (continued)

Time-out Flag Mux	Flag Mux Input (Corresponding bit in registers _MASK0 and _REGERR0)	Flag Mux Time-out Input Sources
	14	GPMC
	15	CRC Note: CRC is not supported on the DRA78x family of devices.
FLAGMUX_CLK2_TIMEOUT	0	L3_INSTR
	1	DEBUGSS_CT_TBR

For example, to enable IPU time-out error the L3_FLAGMUX_TIMEOUT1_MASK0[6] bit must be set to 0x1. To check whether IPU time-out error has occurred the L3_FLAGMUX_TIMEOUT1_REGERR0[6] bit must be read.

9.2.3.6 Statistic Collectors Group

Statistic collectors are internal masters that share the same master address as the master NIUs. These components compute the traffic statistics within a defined window and periodically report through the DEBUG interface. The key features of the statistic collector are:

- Nonintrusive monitoring
- Programmable filters and counters
- Collects results at a programmable time interval

Event detectors are programmed through the L3_STCOL_REQEVT and L3_STCOL_RSPEVT configuration registers for request and response ports, respectively. The following events can be identified:

- Word transfer
- WAIT cycles
- Flow control
- Payload transfers
- Latency measurements

Performance monitoring is enabled through the L3_STCOL_EN register. The L3_STCOL_SOFTEN register enables software to monitor the performance. Event muxes are programmed through the L3_STCOL_EVTMUX_SEL0 configuration register, which determines which port will be monitored by a filter configured by the filter registers (see Section 9.2.5.1.9).

Filters are programmed through the L3_STCOL_FILTER_i_GLOBALEN configuration register, along with additional selection criteria programmed through the mask/match registers (see Table 9-221). A filter can be configured to accept or reject:

- Read operations
- Write operations
- Errors
- Addresses

Filter operation is programmed through the L3_STCOL_OP registers (see Table 9-221).

There are four statistic collectors used for traffic monitoring on device ports. For more detailed description regarding statistic collectors, see *L3 Target Load Monitoring* and *L3 Master Latency Monitoring* in Chapter 26 *On-Chip Debug Support*.

9.2.3.7 L3_MAIN Protection and Firewalls

Device protection relies on L3 firewalls and their configuration.

9.2.3.7.1 L3_MAIN Firewall Reset

The values of the L3_MAIN firewall registers upon reset are tied in hardware or exported from the control module registers.

Values exported from the control module are intended to give defined rights to the firewalls at reset and thus ensure the content after going out of reset.

The L3_MAIN firewall registers are located in the CORE_AON power domain and thus no retention capability is needed. The control module registers are reset by a cold reset only, whereas the L3_MAIN firewall registers are reset by clearing the REGUPDATE_CONTROL[1] FW_LOAD_REQ bit. When the REGUPDATE_CONTROL[1] FW_LOAD_REQ bit comes back automatically to 1, the exported values are loaded.

CAUTION

Before reprogramming the firewall registers and/or before using the FW_LOAD_REQ mechanism, the request must be asserted by configuring the REGUPDATE_CONTROL[0] BUSY_REQ bit.

To load the exported values at run time:

1. Set the REGUPDATE_CONTROL[0] BUSY_REQ bit to 0x1 to ensure that no transaction can reach the slave NIU (suspend).
2. Clear the REGUPDATE_CONTROL[1] FW_LOAD_REQ bit by writing 0x1 to it.
3. Wait until the REGUPDATE_CONTROL[1] FW_LOAD_REQ bit is reset to 0x1 by hardware.
4. Set the REGUPDATE_CONTROL[0] BUSY_REQ bit to 0x0 to allow transactions to reach the slave NIU (resume).

To reprogram the firewall registers at run time:

1. Write 0x1 to the REGUPDATE_CONTROL register.
2. Update the firewall registers.
3. Write 0x0 to the REGUPDATE_CONTROL register.

NOTE: While reprogramming the firewall registers at run time it must be taken into account that the REGUPDATE_CONTROL[1] FW_LOAD_REQ bit is written as '0' because a value of '1' reloads the firewall default values.

NOTE: At reset, exported values from the control module can modify hardware reset values.

9.2.3.7.2 Power Management

As part of the system-wide power-management scheme, the L3_MAIN interconnect goes into IDLE state after receiving a request from the power, reset, and clock management (PRCM) module after all commands are serviced. This function is handled by hardware.

To reduce power consumption, the L3_MAIN interconnect automatically performs internal clock autogating. This is managed by hardware; no software configurations or settings are required.

L3_MAIN supports a partial retention scheme. Retention is performed on the follwoing registers:

- Statistic collectors
- Bandwidth regulators
- Bandwidth limiters
- Firewalls
- Flag muxes

This process prevents reconfiguration after a clock domain switches off.

9.2.3.7.3 L3_MAIN Firewall Functionality

The access to the slave NIUs is granted only to master NIUs according to in-band attributes sent in each transaction crossing the L3_MAIN interconnect, such as:

- MCMD: Specifies the type of access (read or write) required by the master NIU
- ConnID: Used to determine the permission of the master NIU
- MReqInfo: Transaction attribute adding information about the access type

Table 9-13 lists the MReqInfo values.

Table 9-13. MReqInfo Values

Qualifier	Access Definition	Access Description
MReqDebug	0: Functional 1: Debug	When set, indicates that the request has been issued by a master NIU in DEBUG state
MReqType	00: Processor data access 01: Processor instruction access 10: DMA access 11: Other	Indicates whether the request is for processor instruction fetch, processor data access or DMA access
MReqSupervisor	0: User 1: Privilege	When set, indicates that the request is qualified with the supervisor attribute. It can be provided by a processor running in supervisor mode or by a module that inherited this attribute from the processor (DMA channel with a supervisor attribute).

The firewall comparison mechanism enables access to a protected slave NIU only when a correct combination of three MReqInfo in-band parameters is transmitted.

MReqInfo is a combination of a fixed 4-bit pattern that corresponds to a combination of the parameters MReqDebug, MReqType, and MReqSupervisor. See Table 9-14.

Table 9-14. L3_MAIN ReqInfo Mapping

ReqInfo Name		MReqDebug	MReqType	MReqSupervisor
Master NIUs	MMU_INIT	x		x

9.2.3.7.3.1 Protection Regions

Each slave NIU address space is subdivided into protection regions. The regions are configurable with a size of 4-KiB granularity.

Table 9-15 lists the number of protected regions for each slave NIU.

Table 9-15. Slave NIU Firewall and Region Configuration

Firewall name	Slave NIU	Number of Firewall Regions
EMIF_FW	EMIF_P1_TARG	24
OCMC_RAM_FW	OCMC_RAM_TARG	24
CRC_FW Note: CRC is not supported on the DRA78x family of devices.	CRC_TARG	4
IPU_FW	IPU_TARG	4
EVE_FW	EVE_TARG	1

Table 9-15. Slave NIU Firewall and Region Configuration (continued)

Firewall name	Slave NIU	Number of Firewall Regions
TESOC_FW Note: TESOC is not supported on the DRA78x family of devices.	TESOC_TARG	4
DSP1_SDMA_FW	DSP1_SDMA_TARG	1
DSP2_SDMA_FW	DSP2_SDMA_TARG	1
MCASP1_FW	MCASP1_TARG	1
QSPI_FW	QSPI_TARG	4
GPMC_FW	GPMC_TARG	8
ISS_FW Note: ISS is not supported on the DRA78x family of devices.	ISS_TARG	4
TPTC_FW	TPTC1_TARG and TPTC2_TARG	2
EDMA_TPCC_FW	EDMA_TPCC_TARG	1
L3_INSTR_FW	L3_INSTR_TARG	1
DEBUGSS_CT_TBR_FW	DEBUGSS_CT_TBR_TARG	2
DSS_FW	DSS_TARG	8

Two types of regions are distinguished in a slave NIU firewall:

- Default region: Available in all slave NIUs. The default region covers the entire slave NIU address range. Other firewall-configured regions must reset or overlay the default region, because it always has the lowest priority.
- Normal region: The number of normal regions varies in a slave NIU; they have identical capabilities (see Table 9-15).

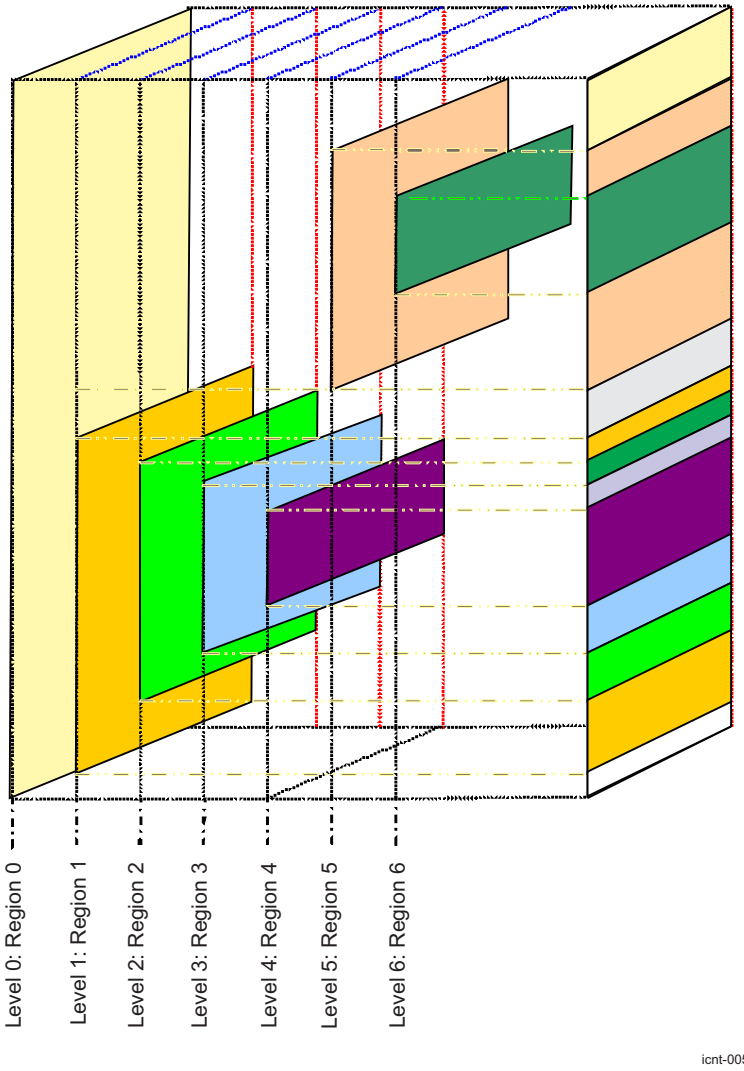
Each region has the following characteristics:

- Start address: Physical slave NIU start address
- End address: Physical slave NIU end address
- Specific access rights (see Section 9.2.3.7.3.3, *Protection Mechanism per Region Examples*)
- Priority level

Depending on its priority level, a region can override the settings of another region; the access rights of the region with the highest priority apply. All regions have a fixed (not configurable) priority level that corresponds to their number: Region 0 has priority level 0 (lowest), region 1 has priority level 1, and so on.

Figure 9-6 shows the priority level with associated regions. This priority level scheme allows multiplying the flexibility and capability of the firewall. Figure 9-6 shows a 7-region firewall setting that creates 16 regions (twice the number of regions created than originally available).

Figure 9-6. L3 Interconnect Region Overlay and Priority Level Overview



The address range covered by the regions is defined in the START_REGION_i and END_REGION_i registers. The boundary checks are done on a minimum size of 4-KiB pages; thus, bits [11:0] of those 32-bit registers are not checked.

The address space size of the slave NIUs ([bits [31:12]) depends on the size of the slave NIU to protect (that is, if a memory is only 48KiB, then the size is defined through bits [16:12] of the slave NIU start and end address registers of the firewall region (START_REGION_i[16:12] and END_REGION_i[16:12]).

To enable/disable regions the END_REGION_i[0] END_REGION_i_ENABLE bit should be set/cleared.

There is only one multiport firewall in this device. This is the TPTC_FW firewall which has two ports. The firewall configuration applies to all ports but there is one set of error logging registers per port. The ERROR_LOG_0 register logs errors for traffic going to the TPTC1_TARG and the ERROR_LOG_1 register logs errors for traffic going to the TPTC2_TARG.

The EMIF firewall (EMIF_FW) has 4 GiB address space and protects both the SDRAM and the EMIF configuration registers. Although the SDRAM is accessible at address space 0x8000_0000 through 0xFFFF_FFFF (total of 2GiB) the EMIF_FW sees that range in its address space at addresses 0x0000_0000 through 0x7FFF_FFFF. This means, to protect the SDRAM the start address in the START_REGION_i register should be 0x0000_0000, and not 0x8000_0000. The EMIF configuration registers are accessible through system base address 0x4C00_0000. But in the EMIF_FW address space that address is mapped to 0x8000_0000. In other words, EMIF_FW sees the EMIF configuration registers at 0x8000_0000. This means, to protect the EMIF configuration registers the start address in the START_REGION_i register should be 0x8000_0000, and not 0x4C00_0000.

9.2.3.7.3.2 L3_MAIN Firewall Registers Overview

Table 9-16 and Table 9-17 list the L3_MAIN firewall permission-setting registers.

Table 9-16. L3_MAIN Firewall Read/Write Permission-Setting Register

Register Name	Bits	Field Name	4-bit ConnID Value (hex) (see Table 9-10)	Field Modifiability
MRM_PERMISSION_REGION_HIGH_j	31	W15	ConnID = F write permission	RW
	30	R15	ConnID = F read permission	RW
	29	W14	ConnID = E write permission	RW
	28	R14	ConnID = E read permission	RW
	27	W13	ConnID = D write permission	RW
	26	R13	ConnID = D read permission	RW
	25	W12	ConnID = C write permission	RW
	24	R12	ConnID = C read permission	RW
	23	W11	ConnID = B write permission	RW
	22	R11	ConnID = B read permission	RW
	21	W10	ConnID = A write permission	RW
	20	R10	ConnID = A read permission	RW
	19	W9	ConnID = 9 write permission	RW
	18	R9	ConnID = 9 read permission	RW
	17	W8	ConnID = 8 write permission	RW
	16	R8	ConnID = 8 read permission	RW
	15	W7	ConnID = 7 write permission	RW
	14	R7	ConnID = 7 read permission	RW
	13	W6	ConnID = 6 write permission	RW
	12	R6	ConnID = 6 read permission	RW
	11	W5	ConnID = 5 write permission	RW
	10	R5	ConnID = 5 read permission	RW
	9	W4	ConnID = 4 write permission	RW
	8	R4	ConnID = 4 read permission	RW
	7	W3	ConnID = 3 write permission	RW
	6	R3	ConnID = 3 read permission	RW
	5	W2	ConnID = 2 write permission	RW
	4	R2	ConnID = 2 read permission	RW
	3	W1	ConnID = 1 write permission	RW
	2	R1	ConnID = 1 read permission	RW
	1	W0	ConnID = 0 write permission	RW
	0	R0	ConnID = 0 read permission	RW

Table 9-17. L3_MAIN Firewall Permission-Setting Register

Register name	Type of Permission	Bits	Field Name	Description	Field Modifiability
MRM_PERMISSION_REGION_LOW_j	Reserved	31:16	Reserved		
	Debug	15	PUB_PRV_DEBUG	PUBLIC PRIVILEGE DOMAIN DEBUG ALLOWED	RW
		14	PUB_USR_DEBUG	PUBLIC USER DOMAIN DEBUG ALLOWED	RW
	Reserved	13:12	Reserved		
	Access	11	PUB_PRV_READ	PUBLIC PRIVILEGE READ ACCESS ALLOWED	RW
		10	PUB_PRV_WRITE	PUBLIC PRIVILEGE WRITE ACCESS ALLOWED	RW
		9	PUB_PRV_EXE	PUBLIC PRIVILEGE EXE ACCESS ALLOWED	RW
		8	PUB_USR_READ	PUBLIC USER READ ACCESS ALLOWED	RW
		7	PUB_USR_WRITE	PUBLIC USER WRITE ACCESS ALLOWED	RW
		6	PUB_USR_EXE	PUBLIC USER EXE ACCESS ALLOWED	RW

9.2.3.7.3.3 Protection Mechanism per Region Examples

The access permission of each region is configurable and defined through the MRM_PERMISSION_REGION_HIGH_j and MRM_PERMISSION_REGION_LOW_j registers (see Section 9.2.3.7.3.2, *L3_MAIN Firewall Registers Overview*).

Master NIU permissions:

1. To give read access to the master NIU with 4-bit ConnID = n(1), set the MRM_PERMISSION_REGION_HIGH_j[n × 2] Rn bit.
2. To give write access to the master NIU with 4-bit ConnID = n(1), set the MRM_PERMISSION_REGION_HIGH_j[n × 2 + 1] Wn bit.

(1) - n should be first converted from hex to decimal value

Debug permissions:

1. To give privilege debug access, set the MRM_PERMISSION_REGION_LOW_j[15] PUB_PRV_DEBUG bit.
2. To give user debug access, set the MRM_PERMISSION_REGION_LOW_j[14] PUB_USR_DEBUG bit.

User, read, write, and executable permissions:

1. To give privileged read access, set the MRM_PERMISSION_REGION_LOW_j[11] PUB_PRV_READ bit.
2. To give privileged write access, set the MRM_PERMISSION_REGION_LOW_j[10] PUB_PRV_WRITE bit.
3. To give privileged executable access, set the MRM_PERMISSION_REGION_LOW_j[9] PUB_PRV_EXE bit.
4. To give user read access, set the MRM_PERMISSION_REGION_LOW_j[8] PUB_USR_READ bit.
5. To give user write access, set the MRM_PERMISSION_REGION_LOW_j[7] PUB_USR_WRITE bit.
6. To give user executable access, set the MRM_PERMISSION_REGION_LOW_j[6] PUB_USR_EXE bit.

Example: To provide debug write privilege access to the master NIU with 4-bit ConnID = 0x8, set to 0x1 the following bits:

- MRM_PERMISSION_REGION_HIGH_j[17] W8
- MRM_PERMISSION_REGION_LOW_j[15] PUB_PRV_DEBUG

9.2.3.7.3.4 L3_MAIN Firewall Error Logging

If a protection violation error is detected, the following signals are generated:

- An in-band error (SRESP = ERROR) is generated to the master NIU of the access.
- An out-band error is sent to the control module
- An interrupt is generated to the IRQ_CROSSBAR.

The L3_MAIN interconnect does not differentiate errors generated by firewalls from all other supported types of errors.

An in-band error is generated by modules each time an access is not allowed. When an in-band error is sent back into the transaction it is seen as an external prefetch or data abort by the initiator, depending on whether the transaction was an instruction fetch or a data access.

Information about in-band errors is logged into two registers:

- ERROR_LOG_k: Logs the information about the start/end address of the hit region and the qualifiers of the transaction
- LOGICAL_ADDR_ERRLOG_k[31:12]: Logs the address of the failed access

Table 9-18 lists the L3_MAIN firewall error-logging registers.

Table 9-18. L3 Firewall Error-Logging Registers

Register Name	Register Field Name	Field Modifiability	Parameter Comments
ERROR_LOG_k	RESERVED[31:24]	Read only	Reads return 0s.
	BLK_BURST_VIOLATION[23]	Read/write	Read 0x1: 2D burst not allowed or exceeds allowed size. Write to clear the ERROR_LOG_k and LOGICAL_ADDR_ERRLOG_k registers.
	RESERVED[22]	Read only	Read return 0s.
	REGION_START_ERRLOG[21:17]	Read/write	Read: Wrong access hit this region number. Write to clear the ERROR_LOG_k and LOGICAL_ADDR_ERRLOG_k registers.
	REGION_END_ERRLOG[16:12]	Read/write	Read: Wrong access hit this region number. Write to clear the ERROR_LOG_k and LOGICAL_ADDR_ERRLOG_k registers.
	REQINFO_ERRLOG[11:0]	Read/write	Mapping of the error according to the reqinfo vector: ConnID [3:0] MCMD [0] [3] MReqDebug [1] MReqSupervisor [0] MReqType

L3 firewall errors can be cleared by writing to the ERROR_LOG_k register in the firewall that recorded the error. Clearing the ERROR_LOG_k register deasserts the corresponding error if it exists.

The L3 firewall register ERROR_LOG_k must be cleared before clearing the CTRL_CORE_SEC_ERR_STATUS_FUNC_i (i = 1, 2 and 3) and CTRL_CORE_SEC_ERR_STATUS_DEBUG_i (i = 1, 2 and 3) registers in the control module.

When a protection violation occurs, an interrupt is sent to the IRQ_CROSSBAR and depending on the functional mode an error is logged in:

- the CTRL_CORE_SEC_ERR_STATUS_FUNC_i registers when the device is in application mode
- the CTRL_CORE_SEC_ERR_STATUS_DEBUG_i registers when the device is in debug mode

For more information, see Chapter 13, *Control Module*.

9.2.3.8 L3_MAIN Interconnect Error Handling

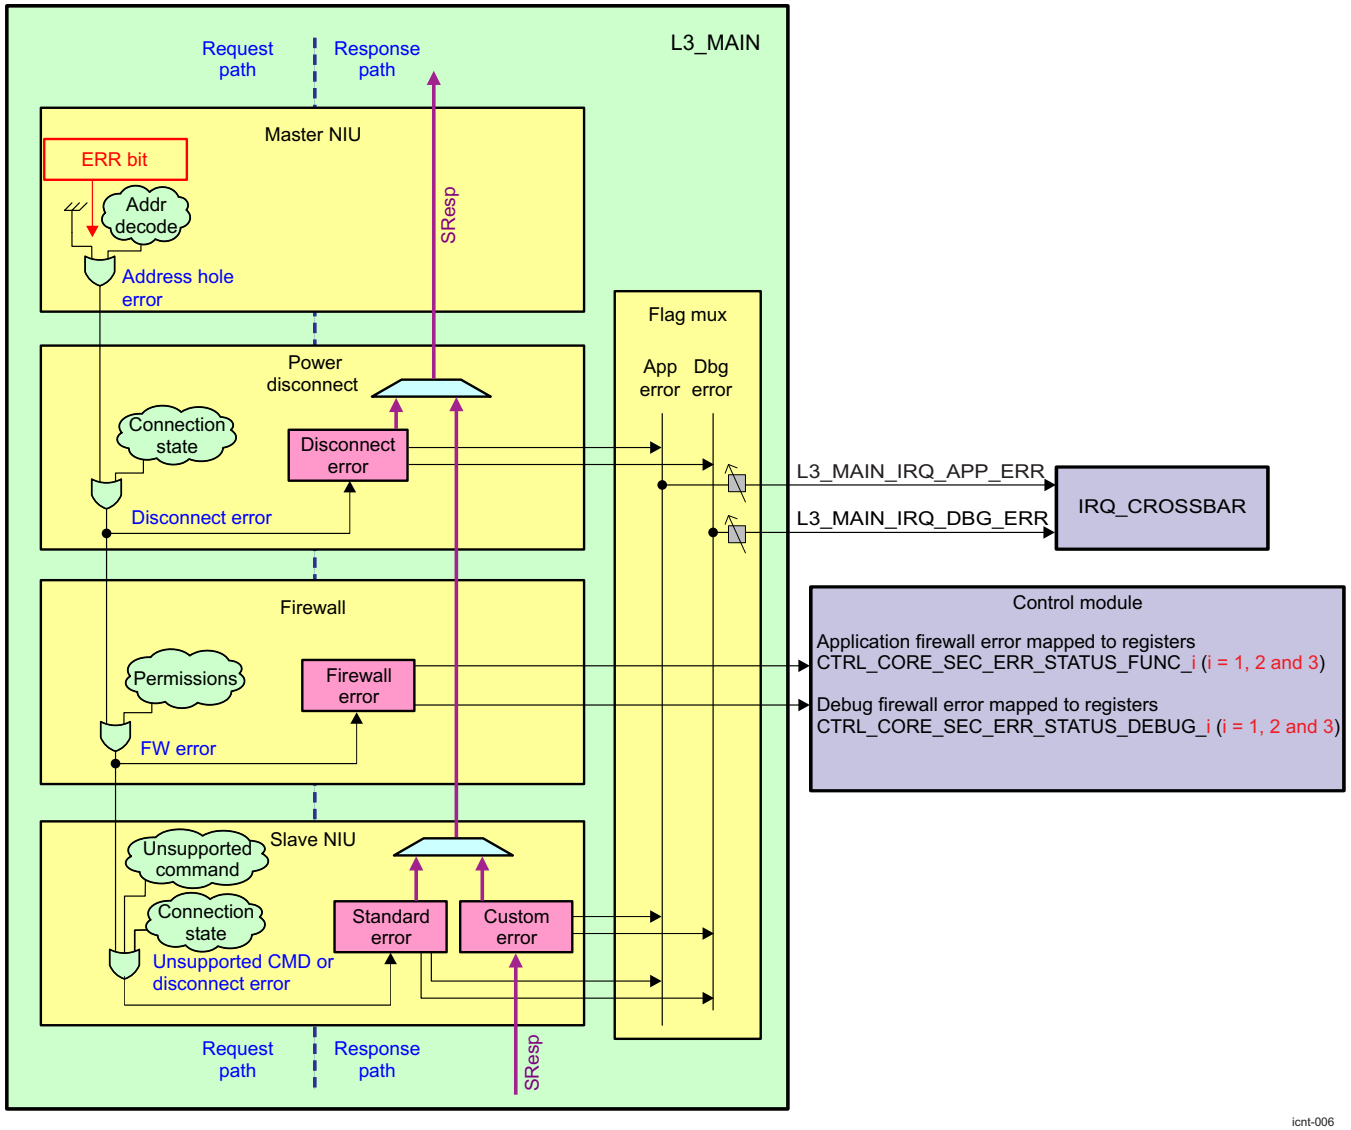
Error logging is enabled in the L3_MAIN interconnect. The three major types of errors are:

- Slave NIU errors
- Firewall errors (see Section 9.2.3.7.3.4, *L3_MAIN Firewall Error Logging*)
- Flag mux errors

9.2.3.8.1 Global Error-Routing Scheme

Figure 9-7 shows the L3_MAIN global error-routing scheme.

Figure 9-7. L3_MAIN Global Error-Routing Scheme



9.2.3.8.2 Slave NIU Error Logging

Error logging is implemented only at slave NIUs. Because the interconnect does not support master NIU error logging, an erroneous packet must be created and sent to one of the slave NIUs. The slave NIU that receives an erroneous packet is predictable but can change per master (see Table 9-19).

Table 9-19. L3_MAIN Connectivity and Holes Error Routing

Master	Connectivity and Hole Errors Logged Into Slave NIUs
All initiators	GPMC_TARG

The slave NIU can:

- be configured to report standard errors (errors generated within the interconnect):
  - Firewall error (protection violation):
    this error indicates that a request was rejected by a firewall and is reported to the control module. For more information, see Section 9.2.3.7.3.4, *L3_MAIN Firewall Error Logging.*
  - Address hole:
    this error reports an unknown address for a request. The address map is local to each master NIU; therefore, an address hole error is reported each time a master NIU requests an access to a slave NIU to which it is not logically connected, even if this address exists in the global L3_MAIN address map. This error is detected only once per burst.
  - Unsupported commands:
    this error reports that the master NIU sent a command that cannot be processed, because the slave NIU cannot accept it and no conversion to another command is possible. This error is detected only once per burst.
- be configured to report custom errors: basically, when the slave answer is SResp = ERR
- be configured to report severity level, for standard error and custom errors:
  - None: error logging for this type of error is disabled.
  - Error: error is logged for this type of error.
  - Fault: error is logged and interrupt is generated for this type of error.
- generate interrupt on two IRQ lines depending on the MReqDebug qualifier:
  - Application error - on L3_MAIN_IRQ_APP_ERR line
  - Debug error - on L3_MAIN_IRQ_DBG_ERR line

  By default, all slave NIUs are configured with standard and custom error levels set to Fault. The errors are reported on the flag muxes (see Figure 9-7), depending on the access type, application or debug. For more information, see Section 9.2.3.5, *Flag Muxing*.

  The slave NIU power-disconnect component also has error logging enabled, because in this case the slave NIU is in a clock domain that is switched off and therefore cannot catch the error. By nature, this component can generate only standard errors. By default, it is configured with the error level set to Fault.

  Wake up on demand: If an error packet reaches a slave NIU that is set with MDiscBehave = 1 (wake up on demand), then the active signal is asserted and L3 processes the error generation when the slave is awake. Although this is inefficient, it simplifies NIU implementation and should not be a problem because errors are supposed to occur only during software debug.

9.2.3.8.3 Severity Level of Standard and Custom Errors

The slave NIU registers are important for error logging.

- The L3_TARG_STDERRLOG_SVRTSTDLVL register shows the severity level for standard errors. According to the severity level, error logging is disabled, enabled with level ERROR, or enabled with level ERROR and flag FAULT.
- The L3_TARG_STDERRLOG_SVRTCUSTOMLVL register shows the severity level for custom errors.
- The L3_TARG_STDERRLOG_MAIN register (the main register for error-logging management) shows the validity of the logged information, standard or custom.
- The L3_TARG_STDERRLOG_HDR register stores packets in case of a standard error.
- The L3_TARG_STDERRLOG_MSTADDR register returns the MSTADDR field of the logged packet.
- The L3_TARG_STDERRLOG_SLVADDR register returns the SLVADDR field of the stored packet.
- The L3_TARG_STDERRLOG_INFO register saves the information field of the logged packet.

9.2.3.8.4 Example for Decoding Standard/Custom Errors Logged in L3_MAIN

Following is a procedure that must be followed for identifying Standard/Custom errors logged in L3_MAIN:

- Read registers L3_HOST_STDERRLOG_MAIN and L3_TARG_STDERRLOG_MAIN:
  - bit[0]STDERRLOG_MAIN_ERRLOGVLD = 0 -> No error
  - bit[0]STDERRLOG_MAIN_ERRLOGVLD = 1 -> Error
  - Error type is visible through:
    - bit[1]STDERRLOG_MAIN_ERRTYPE = 0 -> Standard Error (FW error, Address Hole, Unsupported command)
    - bit[1]STDERRLOG_MAIN_ERRTYPE = 1 -> Custom Error
- Standard Error:
  - Read L3_TARG_STDERRLOG_HDR[3:0] STDERRLOG_HDR_OPCODE
  - Read L3_TARG_STDERRLOG_MSTADDR[7:0] STDERRLOG_MSTADDR - > 8-bit NTTP master address used to distinguish the different initiators (see Table 9-10). That master address is also referred to as ConnID or MConnID.
  - Read L3_TARG_STDERRLOG_SLVADDR[4:0] STDERRLOG_SLVADDR -> NTTP Slave Address of the logged packet
  - Read L3_TARG_STDERRLOG_INFO[7:0]STDERRLOG_INFO -> see , *Terminology* for details.

The procedure for Custom error is the same, but the *_STDERRLOG_CUSTOMINFO_* registers should be read.

9.2.4 L3_MAIN Interconnect Programming Guide

9.2.4.1 L3 _MAIN Interconnect Low-Level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the L3_MAIN interconnect module.

9.2.4.1.1 Global Initialization

9.2.4.1.1.1 Global Initialization of Surrounding Modules

This section identifies the requirements for initializing the surrounding modules when the L3_MAIN interconnect module is to be used for the first time after a device reset. The initialization of surrounding modules is based on the integration of the L3_MAIN interconnect. For more information, see Section 9.2.2, *L3_MAIN Interconnect Integration* .

Table 9-20. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	For information about the configuration of the PRCM module, see Chapter 3, *Power, Reset, and Clock Management*.
Control module	For information about the configuration of the control module, see Chapter 13, *Control Module*.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*
Device INTCs	Device INTCs must be configured to enable the interrupt request generation. For more information see Chapter 12 *Interrupt Controllers*

9.2.4.2 Operational Modes Configuration

9.2.4.2.1 L3_MAIN Interconnect Error Analysis Mode

9.2.4.2.1.1 Main Sequence: L3_MAIN Interconnect Error Analysis Mode

The information required to analyze an error source is logged in several registers. The number of registers to access depends on the error source.

Figure 9-8 shows the software sequence required in most cases.

Figure 9-8. Typical Error Analysis Sequence

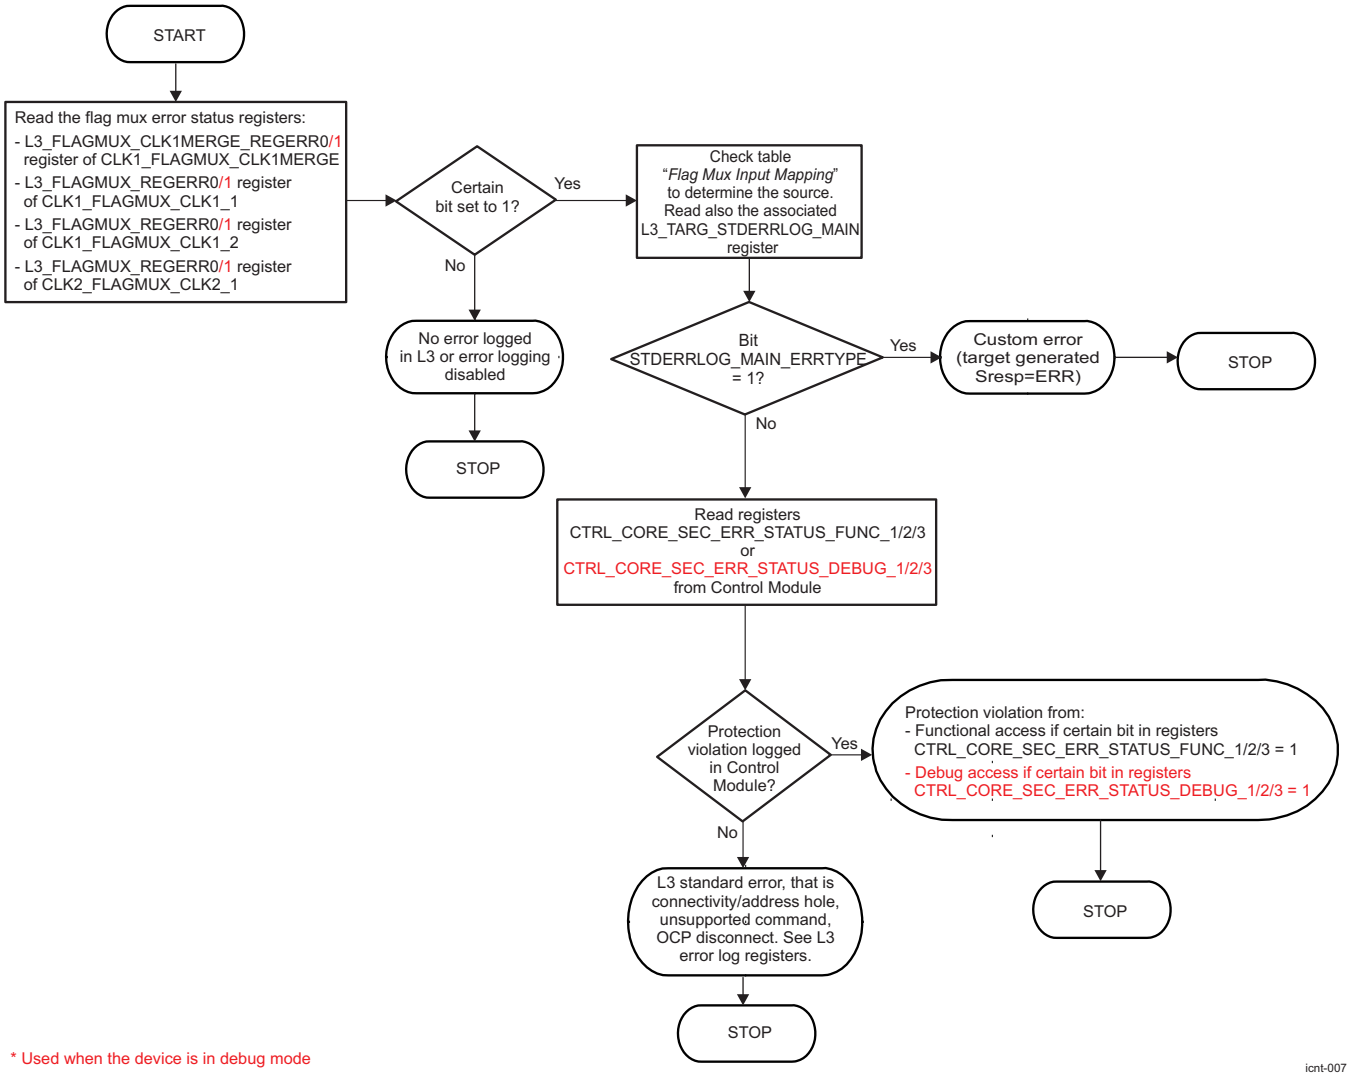


Table 9-21 lists the subprocess call summary for error analysis mode in the main sequence.

Table 9-21. Subprocess Call Summary for Main Sequence – Error Analysis Mode

Subprocess	Cross-Reference
L3 interconnect error analysis	See Section 9.2.4.2.1, *L3_MAIN Interconnect Error Analysis Mode.*
L3_MAIN interconnect protection violation error identification	See Section 9.2.4.2.1.1.2, *Subsequence: L3_MAIN Interconnect Protection Violation Error Identification.*

Table 9-21. Subprocess Call Summary for Main Sequence – Error Analysis Mode (continued)

Subprocess	Cross-Reference
L3_MAIN interconnect unsupported command/address hole error identification	See Section 9.2.4.2.1.1.3, *Subsequence: L3_MAIN Interconnect Standard Error Identification.*
L3_MAIN interconnect reset FLAGMUX and module	See Section 9.2.4.2.1.1.4, *Subsequence: L3_MAIN Interconnect FLAGMUX Configuration.*

9.2.4.2.1.1.1 Subsequence: L3_MAIN Custom Error Identification

The procedure listed in Table 9-22 describes custom error identification.

Table 9-22. Custom Error Identification

Step	Register/Bit Field/Programming Model	Value
IF: Is custom error detected?	L3_TARG_STDERRLOG_MAIN[1] STDERRLOG_MAIN_ERRTYPE	=0x1
Read information field of the response packet.	L3_TARG_STDERRLOG_CUSTOMINFO_INFO[7:0] STDERRLOG_CUSTOMINFO_INFO	xxx
Read the address of the initiator that caused error.	L3_TARG_STDERRLOG_CUSTOMINFO_MSTADDR[7:0] STDERRLOG_CUSTOMINFO_MSTADDR	xxx
Read the type of operation (read/write).	L3_TARG_STDERRLOG_CUSTOMINFO_OPCODE[1:0] STDERRLOG_CUSTOMINFO_OPCODE	xxx
ENDIF		

9.2.4.2.1.1.2 Subsequence: L3_MAIN Interconnect Protection Violation Error Identification

The procedure listed in Table 9-23 describes protection violation error identification and where it is logged in the control module registers. Two types of errors are logged: application errors and debug errors.

Table 9-23. L3_MAIN Protection Violation Error Identification

Step	Register/Bit Field/Programming Model	Value
Read the burst violation.	ERROR_LOG_k[23] BLK_BURST_VIOLATION	xxx
Read the initiator ConnID [3:0].	ERROR_LOG_k[11:8]	xxx
Read the command (MCMD [0]) that caused the error.	ERROR_LOG_k[7]	xxx
Read the address of the request that caused the error.	LOGICAL_ADDR_ERRLOG_k[31:0] SLVOFS_LOGICAL	xxx
IF: Is it an application error?	L3_FLAGMUX_REGERR0 [REGERROR0]	0x0
Read the status bits to see which module firewall has worked.	CTRL_CORE_SEC_ERR_STATUS_FUNC_i	xxx
Clear the status bits.	CTRL_CORE_SEC_ERR_STATUS_FUNC_i	xxx
Clear the status bit.	L3_TARG_STDERRLOG_MAIN [31] STDERRLOG_MAIN_CLRLOG	0x0
ELSE IF	L3_FLAGMUX_REGERR1[7:0] REGERROR1	= 0x1
Read the status bits to see the module.	CTRL_CORE_SEC_ERR_STATUS_DEBUG_i	xxx
Clear the status bits.	CTRL_CORE_SEC_ERR_STATUS_DEBUG_i	xxx
Clear the status bit.	L3_TARG_STDERRLOG_MAIN[31] STDERRLOG_MAIN_CLRLOG	0x0
ENDIF		
Clear the burst violation.	ERROR_LOG_k[23] BLK_BURST_VIOLATION	0x0
Clear the error status.	ERROR_LOG_k[21:17] REGION_START_ERRLOG	0x00

9.2.4.2.1.1.3 Subsequence: L3_MAIN Interconnect Standard Error Identification

The procedure listed in Table 9-24 describes the identification of standard errors inside the L3_MAIN interconnect. The standard errors are: unsupported command, address hole, and disconnect.

Table 9-24. L3_MAIN Standard Error Identification

Step	Register/Bit Field/Programming Model	Value
IF: Is an error detected?	L3_TARG_STDERRLOG_MAIN[18] STDERRLOG_MAIN_ERRCNT	= 0x1
Read the corresponding flag.	L3_FLAGMUX_REGERR0[REGERROR0]	xxx
Read the corresponding flag.	L3_FLAGMUX_REGERR1[REGERROR1]	xxx
Localize the slave NIU that generated the error.	See Table 9-11.	
ELSE		
Clear the error log.	L3_TARG_STDERRLOG_MAIN[31] STDERRLOG_MAIN_CLRLOG	0x0
Clear the severity error status.	L3_TARG_STDERRLOG_SVRTSTDLVL[1:0] STDERRLOG_SVRTSTDLVL_0	0x2
ENDIF		

9.2.4.2.1.1.4 Subsequence: L3_MAIN Interconnect FLAGMUX Configuration

The procedures listed in Table 9-25 and Table 9-26 give information about the configuration of FLAGMUX masks.

Table 9-25. FLAGMUX Configuration

Step	Register/Bit Field/Programming Model	Value
Set the FLAGMUX masks to mask an event.	L3_FLAGMUX_MASK0[MASK0] L3_FLAGMUX_MASK1[MASK1]	xxx
Read the REGERR bits to see if an error is recorded.	L3_FLAGMUX_REGERR0[REGERR0] L3_FLAGMUX_REGERR1[REGERR1]	xxx
Clear the slave NIU error log and the FLAGMUX error.	L3_TARG_STDERRLOG_MAIN[31] STDERRLOG_SVRTSTDLVL_0	0x1

Table 9-26. FLAGMUX_CLK1_TIMEOUT1 and FLAGMUX_CLK1_TIMEOUT2 Configuration

Step	Register/Bit Field/Programming Model	Value
Enable time-out for target.	L3_FLAGMUX_TIMEOUTx_MASK0[MASK0]	xxx
Read the REGERR bits to see if an error is recorded.	L3_FLAGMUX_TIMEOUTx_REGERR0[REGERR0]	xxx

Table 9-27. FLAGMUX_CLK2_TIMEOUT Configuration

Step	Register/Bit Field/Programming Model	Value
Enable time-out for target.	L3_FLAGMUX_TIMEOUT_MASK0[1:0] MASK0	xxx
Read the REGERR bits to see if an error is recorded.	L3_FLAGMUX_TIMEOUT_REGERR0[1:0] REGERR0	xxx

9.2.5 L3_MAIN Interconnect Register Manual

9.2.5.1 L3_MAIN Register Group Summary

The registers in the L3 interconnect are divided into the following groups:

- Firewall registers (see Table 9-29)
- HOST registers (see Table 9-52)
- TARG registers (see Table 9-88)
- Flag Muxing registers (see Section 9.2.5.1.4 through Section 9.2.5.1.6)
- Bandwidth Regulator registers (see Table 9-186)
- Bandwidth Limiter registers (see Table 9-202)
- STATCOLL registers (see Table 9-221)

9.2.5.1.1 L3_MAIN Firewall Registers Summary and Description

NOTE: ISS, CRC and TESOC are not supported on the DRA78x family of devices.

Table 9-28. L3_MAIN Firewall Instance Summary

Module Name	Base Address	Size
DEBUGSS_CT_TBR_FW	0x4A22 4000	4KiB
DSP1_SDMA_FW	0x4A17 1000	4KiB
DSP2_SDMA_FW	0x4A17 3000	4KiB

9.3 L4 Interconnects

This section details the device L4 interconnects.

9.3.1 L4 Interconnect Overview

The device uses three separate L4 interconnect structures to connect peripheral modules. All L4s handle transfers with peripherals but are located in distinct power domains.

Figure 9-9 is an overview of the L4 interconnects and the peripherals attached to them.

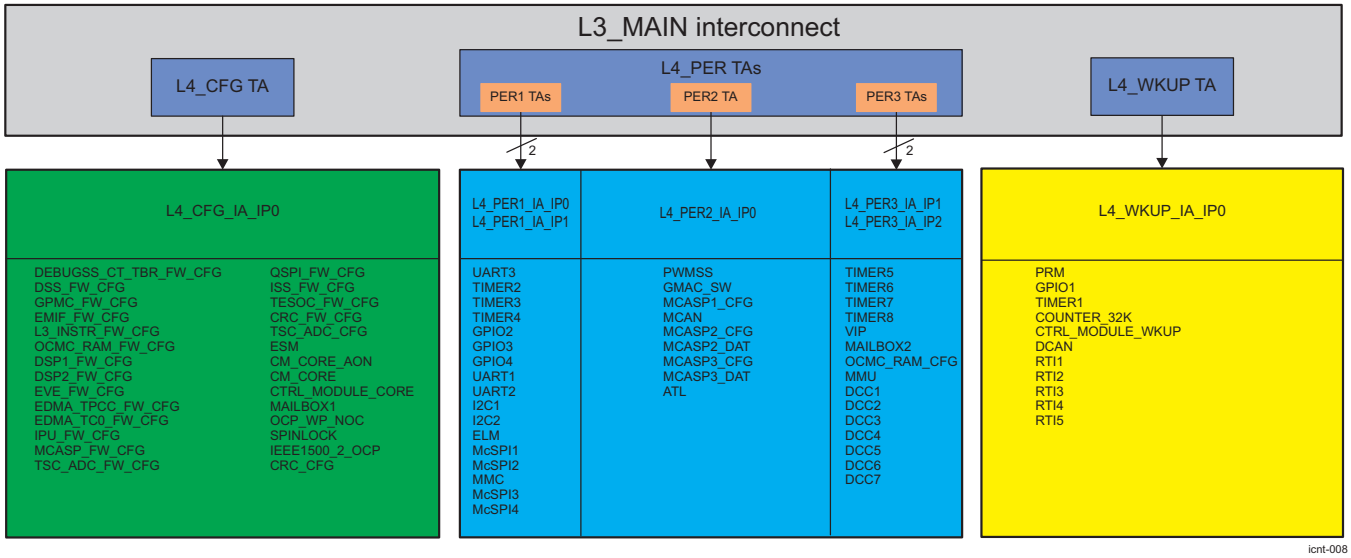
The L4 interconnect is composed of the following interconnects:

- L4_CFG: Includes the majority of the configuration interface for L3_MAIN system modules and peripheral interconnect
- L4 PER: Includes the main peripherals in the device. L4_PER is further divided into three sub-interconnects: L4_PER1, L4_PER2 and L4_PER3. Each of these L4_PERx sub-interconnects is connected to L3_MAIN initiators via the following ports:
  - L4_PER1_P1, L4_PER1_P2
  - L4_PER2_P1
  - L4_PER3_P1, L4_PER3_P2

  L3_MAIN initiators access the L4_PERx peripherals through these ports. All peripherals attached to L4_PER1and L4_PER3 are visible through the two L4_PER1 and L4_PER3 ports. For information about which initiator can access which L4_PERx port, see Figure 9-3.
- L4_WKUP: Includes peripherals attached to the WKUP power domain

NOTE: ISS, CRC, TESOC, ESM and DCC1 to DCC7 are not supported on the DRA78x family of devices.

Figure 9-9. L4 Interconnect Overview



The main features of the L4 interconnects are:

- Seven ports from L3_MAIN interconnect onto 5 parallel L4 interconnects
- One or two 32-bit initiator ports for each L4 interconnect instance (7 in total)
- 8-, 16-, or 32-bit data, single, or burst transactions
- Little-endian platform
- Non-blocking architecture with fair arbitration between masters
- Target interfaces: Fully synchronous or divided synchronous clock frequencies

- L4_CFG and L4_PER1, L4_PER2, L4_PER3 frequency equals half of L3 frequency
- Protection logic that provides user-configurable access control to targets by each initiator

9.3.2 L4 Interconnect Integration

Table 9-334 and Table 9-335 summarize the integration of the module in the device.

Table 9-334. Integration Attributes

Module Instance	Attributes
	Power Domain
L4_PER1, L4_PER2, L4_PER3	PD_COREAON
L4_CFG	PD_COREAON
L4_WKUP	PD_WKUPAON

Table 9-335. Clocks and Resets

9.3.3 L4 Interconnect Functional Description

9.3.3.1 Module Distribution

IAs and TAs provide the interface to connect the different modules to their associated interconnect.

Table 9-336 through Table 9-345 list all the modules and subsystems with their associated agents. The agents are listed for each L4 interconnect domain.

9.3.3.1.1 L4_PER1 Interconnect Agents

The L4_PER1 interconnect handles transfers only to peripherals in the PER power domain. Table 9-336 lists the L4_PER1 TAs.

Table 9-336. L4_PER1 TAs

Module Target Name	Description
UART3_TARG	Universal Asynchronous Receiver/Transmitter target port
TIMER2_TARG	General Purpose Timer 2 target port
TIMER3_TARG	TIMER3 target port
TIMER4_TARG	TIMER4 target port
GPIO2_TARG	GPIO2 target port
GPIO3_TARG	GPIO3 target port
GPIO4_TARG	GPIO4 target port
UART1_TARG	UART1 target port
UART2_TARG	UART2 target port
I2C1_TARG	I2C1 target port
I2C2_TARG	I2C2 target port
ELM_TARG	Error Location Module target port
MCSPI1_TARG	Multi-channel Serial Peripheral Interface 1 target port
MCSPI2_TARG	MCSPI2 target port
MMC_TARG	MMC target port
MCSPI3_TARG	MCSPI3 target port
MCSPI4_TARG	MCSPI4 target port

Two ports communicate between the L3_MAIN interconnect and the L4_PER1 interconnect to allow the L3_MAIN initiators to access the L4_PER1 targets. Table 9-337 lists the L4_PER1 IAs.

For the list of initiators authorized to access the L4_PER1 peripherals, see Figure 9-3.

Table 9-337. L4_PER1 IAs

Module Iniator Name	Description
L4_PER1_IA_IP0	L4_PER1 Initiator Port 0 (IP0)
L4_PER1_IA_IP1	L4_PER1 Initiator Port 1 (IP1)

9.3.3.1.2 L4_PER2 Interconnect Agents

The L4_PER2 interconnect handles transfers only to peripherals in the PER power domain. Table 9-338 lists the L4_PER2 TAs.

Table 9-338. L4_PER2 TAs

Module Target Name	Description
MCASP1_CFG_TARG	MCASP_CFG target port
PWMSS_TARG	Pulse-Width Modulation target port

Table 9-338. L4_PER2 TAs (continued)

Module Target Name	Description
MCAN_TARG	MCAN target port
GMAC_SW_TARG	Ethernet Controller target port
ATL_TARG	Audio Tracking Logic target port
MCASP2_DAT_TARG	MCASP2_DAT target port
MCASP2_CFG_TARG	MCASP2_CFG target port
MCASP3_DAT_TARG	MCASP3_DAT target port
MCASP3_CFG_TARG	MCASP3_CFG target port

One port communicates between the L3_MAIN interconnect and the L4_PER2 interconnect to allow the L3_MAIN initiators to access the L4_PER2 targets. Table 9-339 lists the L4_PER2 IA.

For the list of initiators authorized to access the L4_PER2 peripherals, see Figure 9-3.

Table 9-339. L4_PER2 IA

Module Iniator Name	Description
L4_PER2_IA_IP0	L4_PER2 Initiator Port 0 (IP0)

9.3.3.1.3 L4_PER3 Interconnect Agents

The L4_PER3 interconnect handles transfers only to peripherals in the PER power domain. Table 9-340 lists the L4_PER3 TAs.

Table 9-340. L4_PER3 TAs

Module Target Name	Description
TIMER5_TARG	TIMER5 target port
TIMER6_TARG	TIMER6 target port
TIMER7_TARG	TIMER7 target port
TIMER8_TARG	TIMER8 target port
VIP_TARG	VIP target port
MAILBOX2_TARG	Mailbox 2 target port
OCMC_RAM_CFG_TARG	OCMC_RAM target port
MMU_TARG	MMU target port
DCC1_TARG	DCC1 target port Note: DCC1 to DCC7 are not supported on the DRA78x family of devices.
DCC2_TARG	DCC2 target port
DCC3_TARG	DCC3 target port
DCC4_TARG	DCC4 target port
DCC5_TARG	DCC5 target port
DCC6_TARG	DCC6 target port
DCC7_TARG	DCC7 target port

Two ports communicate between the L3_MAIN interconnect and the L4_PER3 interconnect to allow the L3_MAIN initiators to access the L4_PER3 targets. Table 9-341 lists the L4_PER3 IAs.

For the list of initiators authorized to access the L4_PER3 peripherals, see Figure 9-3.

Table 9-341. L4_PER3 IAs

Module Iniator Name	Description
L4_PER3_IA_IP1	L4_PER3 Initiator Port 1 (IP1)
L4_PER3_IA_IP2	L4_PER3 Initiator Port 2 (IP2)

9.3.3.1.4 L4_CFG Interconnect Agents

The L4_CFG interconnect handles only transfers to peripherals in the CORE power domain. Table 9-342 lists the L4_CFG TAs.

Table 9-342. L4_CFG TAs

Module Target Name	Description
DEBUGSS_CT_TBR_FW_CFG_TARG	Debug subsystem firewall
DSS_FW_CFG_TARG	DSS firewall
GPMC_FW_CFG_TARG	GPMC firewall
EMIF_FW_CFG_TARG	EMIF firewall
L3_INSTR_FW_CFG_TARG	L3 Instrumentation firewall
OCMC_RAM_FW_CFG_TARG	OCMC_RAM firewall
DSP1_FW_CFG_TARG	DSP1 firewall
DSP2_FW_CFG_TARG	DSP2 firewall
EVE_FW_CFG_TARG	EVE firewall
EDMA_TPCC_FW_CFG_TARG	EDMA Channel Controller firewall
EDMA_TC0_FW_CFG_TARG	EDMA Transfer Controller firewall
IPU_FW_CFG_TARG	IPU firewall
MCASP1_FW_CFG_TARG	McASP firewall
TSC_ADC_FW_CFG_TARG	ADC firewall
QSPI_FW_CFG_TARG	QSPI firewall
ISS_FW_CFG_TARG	ISS firewall Note: ISS is not supported on the DRA78x family of devices.
TESOC_FW_CFG_TARG	TESOC firewall Note: TESOC is not supported on the DRA78x family of devices.
CRC_FW_CFG_TARG	CRC firewall Note: CRC is not supported on the DRA78x family of devices.
TSC_ADC_CFG_TARG	ADC configuration target port
ESM_TARG	ESM target port Note: ESM is not supported on the DRA78x family of devices.
CM_CORE_AON_TARG	CM_CORE_AON target port
CM_CORE_TARG	CM_CORE target port
CTRL_MODULE_CORE_TARG	CTRL_MODULE_CORE target port
MAILBOX1_TARG	Mailbox1 target port
OCP_WP_NOC_TARG	OCP watchpoint target port
SPINLOCK_TARG	Spinlock target port
IEEE1500_2_OCP_TARG	IEEE1500 target port
CRC_CFG_TARG	CRC configuration target port

One port communicates between the L3_MAIN interconnect and the L4_CFG interconnect to allow the L3_MAIN initiators to access the L4_CFG targets. Table 9-343 lists the L4_CFG IA.

For the list of initiators authorized to access the L4_CFG peripherals, see Figure 9-3.

Table 9-343. L4_CFG IA

Module Iniator Name	Description
L4_CFG_IA_IP0	L4_CFG Initiator Port (IP0)

9.3.3.1.5 L4_WKUP Interconnect Agents

The L4-WKUP interconnect handles transfers only to peripherals in the WKUP power domain. Table 9-344 lists the TAs. Table 9-345 lists the L4 WKUP IA.

Table 9-344. L4_WKUP TAs

Module Target Name	Description
PRM_TARG	PRM target port
GPIO1_TARG	GPIO1 target port
TIMER1_TARG	Timer 1 target port
COUNTER_32K_TARG	Counter 32k timer
CTRL_MODULE_WKUP_TARG	CTRL_MODULE_WKUP target port
DCAN_TARG	DCAN target port
RTI1_TARG	RTI1 target port
RTI2_TARG	RTI2 target port
RTI3_TARG	RTI3 target port
RTI4_TARG	RTI4 target port
RTI5_TARG	RTI5 target port

Table 9-345. L4_WKUP IA

Module Iniator Name	Description
L4_WKUP_IA_IP0	L4_WKUP Initiator Port (IP0)

9.3.3.2 Power Management

As part of the system-wide power-management scheme, the L4 interconnects go into IDLE state after receiving a request from the PRCM module after all commands are serviced. This function is handled by hardware. For more information, see Chapter 3, *Power, Reset, and Clock Management*.

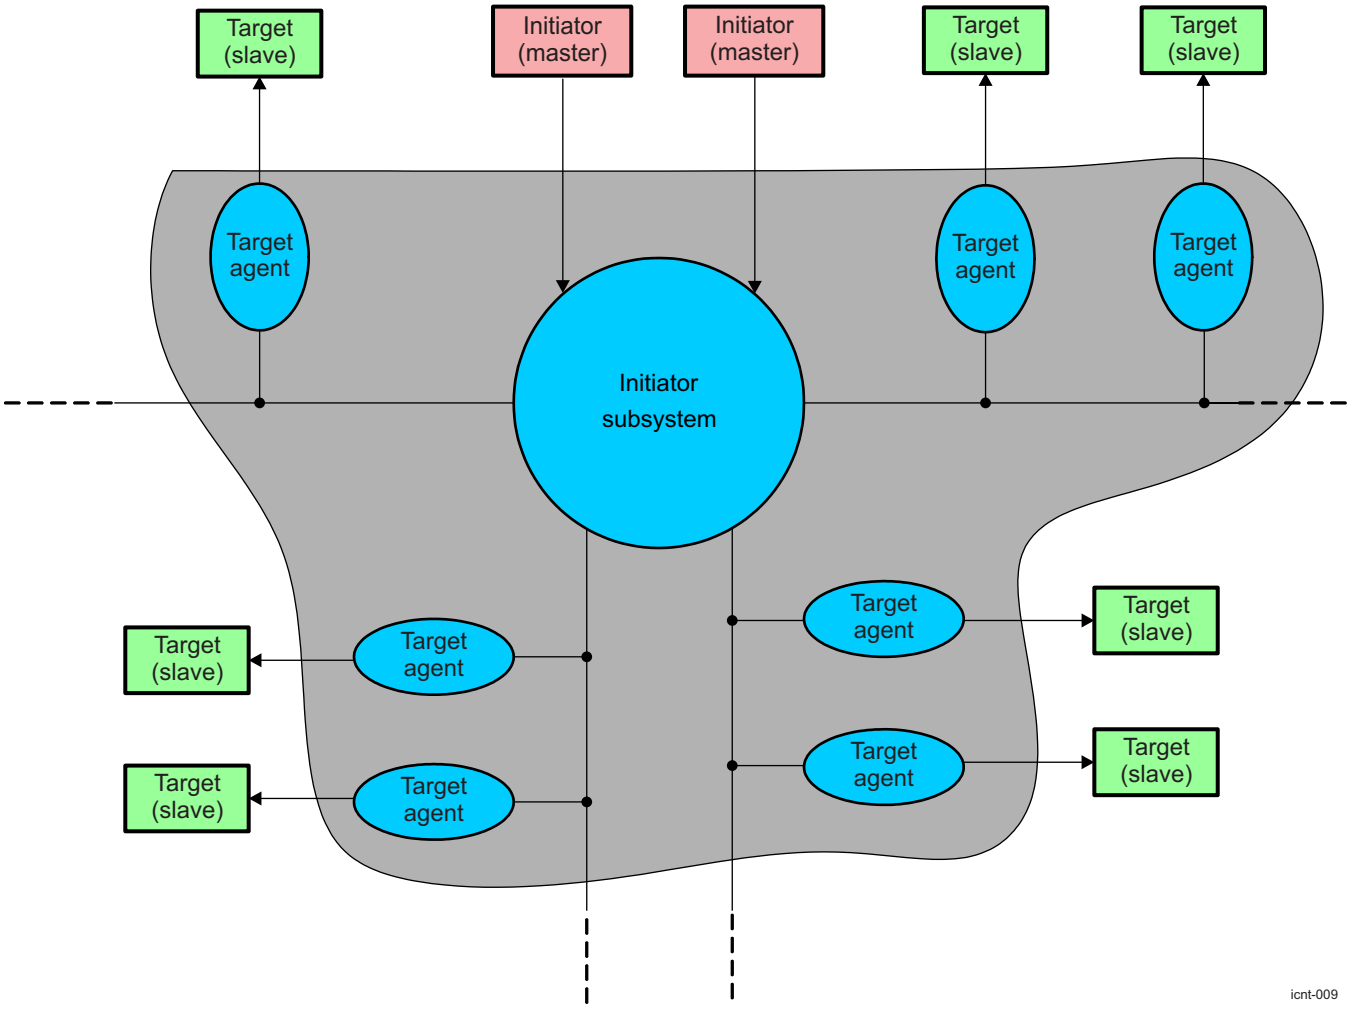
To reduce power consumption, each L4 interconnect automatically performs internal clock autogating. This is managed by hardware; no software configurations or settings are required.

L4_CFG, L4_PER1, L4_PER2, L4_PER3, and L4_WKUP are located in the always-on power domain and no retention is needed for these L4 interconnects.

9.3.3.3 L4 Firewalls

Figure 9-10 is an internal view of the L4 interconnects in the overall interconnect. This architecture, with one initiator subsystem centralizing all initiator master requests and distributing them to all target modules (peripherals), enables the L4 interconnect firewall functions to be centralized at the L4 initiator subsystem level. The L4 firewall filters the accesses based on the configurable protection groups defined in the L4 address protection (AP) registers. Each module or TA is assigned to a protection group. The configuration is also defined in the L4 AP and is programmable on a module-per-module basis.

Figure 9-10. L4 Initiator-Target Connectivity



NOTE: As Figure 9-10 shows, targets are attached to branches. Branches do not impact the function of the L4 interconnect but are present to simplify timing closure and reduce active power consumption.

Because of the large address spaces and the number of peripherals connected to an L4 interconnect, two parameters are used to set up access permission:

- Programmable groups for initiators:
  - Eight protection groups for the L4 interconnect
- Segments divided into regions
  - 78 regions for the L4_PER1 interconnect
  - 33 regions for the L4_PER2 interconnect
  - 93 regions for the L4_PER3 interconnect
  - 111 regions for the L4_CFG interconnect
  - 44 regions for the L4_WKUP interconnect

NOTE: There might be regions which are not used so the actual region count may not be the same as the listed above.

Protection group members are TAs with the same protection settings. A region is programmed to allow access to an unique selectable protection group. For better protection, different regions are grouped into protection group regions and associated with a protection group member.

9.3.3.3.1 Protection Group

The following registers are used to define a protection group:

- The CONNID_BIT_VECTOR field of register L4_AP_PROT_GROUP_MEMBERS_k_L defines which initiator belongs to a group. A protection group is accessible by an initiator when the bit position corresponding to its ConnID is set to 1 in the CONNID_BIT_VECTOR field. Table 9-346 lists the L3 ConnIDs available at L4 level. They are 4-bit ConnIDs and are equal to bits [5:2] of the 6-bit L3_MAIN ConnIDs.
- The L4_AP_PROT_GROUP_ROLES_k_L register defines the initiator requests accepted or not by the L4 firewalls depending on the combination of MReqDebug and MReqSupervisor qualifiers. Each bit of this register corresponds to an unique combination of these two qualifiers. To accept a request with combination n, bit n of the L4_AP_PROT_GROUP_ROLES_k_L register must be set to 1. Table 9-347 lists all possible combinations and the corresponding bits which have to be set to 1 for accepting particular combination.

NOTE: Permissions are identical for read and write accesses in L4 interconnect.

k indicates the protection group number.

L indicates the region number.

Table 9-346. L4 ConnID Definition

ConnID	L3 Initiator
0x1	DEBUGSS_CS_DAP_INIT, IEEE1500_2_OCP_INIT
0x2	DSP1_MDMA_INIT, DSP1_EDMA_INIT, DSP1_CFG_INIT, DSP2_EDMA_INIT
0x3	DSP2_MDMA_INIT, DSP2_CFG_INIT
0x4	EVE_TC0_INIT
0x6	IPU_INIT
0x7	TPTC1_WR_INIT, TPTC1_RD_INIT, TPTC2_WR_INIT, TPTC2_RD_INIT
0x8	DSS1_INIT, MMU_INIT
0x9	VIP_P1_INIT, VIP_P2_INIT
0xA	GMAC_SW_INIT
0xC	ISS_RT_INIT, ISS_NRT1_INIT, ISS_NRT2_INIT Note: ISS is not supported on the DRA78x family of devices.
0xD	EVE_TC1_INIT

Table 9-347. L4 Qualifiers Combination

MReqSupervisor	MReqDebug	Bit Positions In Register L4_AP_PROT_GROUP_ROLES_k_L Which Have To Be Set To 1
0	0	2
0	1	3
1	0	6
1	1	7

Table 9-348 shows an example how to set the CONNID_BIT_VECTOR field.

Table 9-348. Example For Setting The CONNID_BIT_VECTOR Field Of Register L4_AP_PROT_GROUP_MEMBERS_k_L

Initiator	Access Allowed?	CONNID_BIT_VECTOR	Bits
Reserved	-	0	0
DEBUGSS_CS_DAP_INIT, IEEE1500_2_OCP_INIT	N	0	1
DSP1_MDMA_INIT, DSP1_EDMA_INIT, DSP1_CFG_INIT, DSP2_EDMA_INIT	N	0	2
DSP2_MDMA_INIT, DSP2_CFG_INIT	N	0	3
EVE_TC0_INIT	Y	1	4
Reserved	-	0	5
IPU_INIT	Y	1	6
TPTC1_WR_INIT, TPTC1_RD_INIT, TPTC2_WR_INIT, TPTC2_RD_INIT	N	0	7
DSS1_INIT, MMU_INIT	N	0	8
VIP_P1_INIT, VIP_P2_INIT	N	0	9
GMAC_SW_INIT	N	0	10
Reserved	-	0	11
ISS_RT_INIT, ISS_NRT1_INIT, ISS_NRT2_INIT Note: ISS is not supported on the DRA78x family of devices.	N	0	12
EVE_TC1_INIT	N	0	13
Reserved	-	0	14
Reserved	-	0	15

Setting to 0x1 bits 4 and 6 in the L4_AP_PROT_GROUP_MEMBERS_k_L (for example, k = 1) register defines that group 1 can be accessed by the following initiators:

- EVE_TC0_INIT
- IPU_INIT

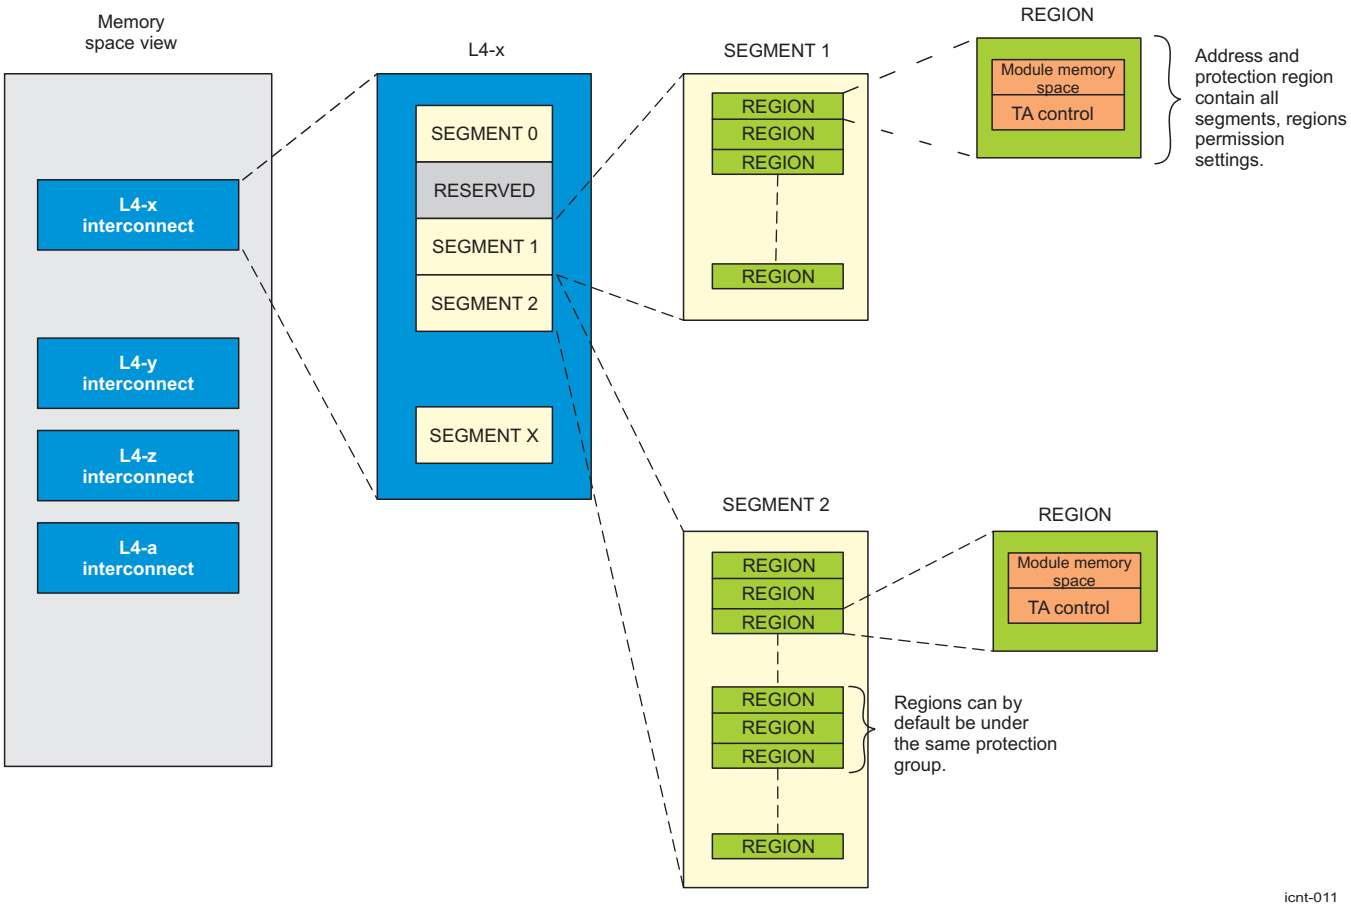
Protection group 1 can be applied to multiple protection regions with no limitation. Each protection region that is configured with protection group 1 enables permission access only to the two initiators.

The L4_AP_REGION_l_H[22:20] PROT_GROUP_ID bit field determines with which protection group the region l is associated.

9.3.3.3.2 Segments and Regions

The protection mechanism for L4 interconnects is based on a hierarchical segmentation, as shown in Figure 9-11. By default, some regions are attached to specific protection group members. This specificity lets users set up the permission access to certain types of modules requiring the same access protection without managing region allocation.

Figure 9-11. L4 Segmentation



All interconnect address spaces are covered by regions. Table 9-349 through Table 9-353 list the module mapping with their addresses, region numbers, and default protection group allocated to them.

NOTE: Module refers to the configuration registers of the module.

TA (Target Agent) refers to the interconnect configuration registers of the TA associated with the module.

9.3.3.3.3 L4 Firewall Address and Protection Register Settings

Table 9-354 lists the settings of the AP registers relative to an L4 interconnect firewall. These values are computed based on the physical implementation of each L4 interconnect.

Table 9-354. L4 Firewall Register Description Overview

Register Type	Register Name	Bits	Field	Description
Segment	L4_AP_SEGMENT_i_L (1)	31:0	BASE	Segment base address
	L4_AP_SEGMENT_i_H (1)	5:0	SIZE	Segment size equals to 2^{SIZE}
Protection groups	L4_AP_PROT_GROUP_MEMBERS_k_L (2)	15:0	CONNID_BIT_VECTOR	For L4 ConnID, see Table 9-346.
	L4_AP_PROT_GROUP_ROLES_k_L (2)	31:0	ENABLE	Defines the initiator requests accepted or not by the L4 firewalls depending on combination of L4 qualifiers.
Region setting	L4_AP_REGION_l_L (3)	20:0	BASE	Defines the base address of a region with respect to its segment base address
	L4_AP_REGION_l_H (3)	31:28	MADDRSPACE	Target interconnect MAddrSpace
		26:24	SEGMENT_ID	Segment ID number of the region
		22:20	PROT_GROUP_ID	Protection group member attached to the region
		18:17	BYTE_DATA_WIDTH_EXP	Determines the number of bytes in an access
		14:8	PHY_TARGET_ID	Physical target ID
		6:1	SIZE	Size of the region equals to 2^{SIZE}
		0	ENABLE	Enables the region protection

(1) i = 0 to 1 for L4_PER1_AP
i = 0 for L4_PER2_AP
i = 0 for L4_PER3_AP
i = 0 to 2 for L4_CFG_AP
i = 0 to 3 for L4_WKUP_AP

(2) k = 0 to 7 for L4_PER1_AP
k = 0 to 7 for L4_PER2_AP
k = 0 to 7 for L4_PER3_AP
k = 0 to 7 for L4_CFG_AP
k = 0 to 7 for L4_WKUP_AP

(3) l = 0 to 77 for L4_PER1_AP
l = 0 to 32 for L4_PER2_AP
l = 0 to 92 for L4_PER3_AP
l = 0 to 110 for L4_CFG_AP
l = 0 to 43 for L4_WKUP_AP

9.3.3.4 L4 Error Detection and Reporting

9.3.3.4.1 IA and TA Error Detection and Logging

The L4 interconnect provides mechanisms for handling internally detected errors or errors reported by modules attached to the L4 target ports.

NOTE: L4_IA denotes the IA for all L4 interconnects: L4_PER1, L4_PER2, L4_PER3, L4_CFG, and L4_WKUP.

L4_TA denotes the TA for all L4 interconnects: L4_PER1, L4_PER2, L4_PER3, L4_CFG, and L4_WKUP.

The L4 interconnects handle four types of errors:

- No target core found or address hole, detected and logged at IA
- Unsupported command, detected and logged at IA
- Protection violation, detected and logged at IA (see Section 9.3.3.3, *L4 Firewalls*)
- Target does not service a request before a time-out expires. The error is detected and logged at TA (see Section 9.3.3.4.2, *Time-Out*).

Table 9-355 lists the value of the L4_IA_ERROR_LOG_L[25:24] CODE bit field stored when an error occurs.

Table 9-355. L4 CODE Bit Field Definition

CODE (bits 1:0)	Error Type	REQ_INFO	Secondary	ConnID	CMD
0	No error				
1	Unsupported command	x	x	x	x
2	Address hole	x	x	x	x
3	Protection violation	x		x	x

- No target core found/address hole: This error indicates that a request was addressed to a hole in the L4 address map. When this error occurs, an in-band error response is returned to the L3 level. The error is also logged into the L4_IA_AGENT_STATUS_L[27] INBAND_ERROR bit. Additionally, an address hole error code is logged to the L4_IA_ERROR_LOG_L[25:24] CODE bit field.
- Unsupported command: This error indicates that the command type of the request is not supported by the accessed target register. The error is logged into the L4_IA_AGENT_STATUS_L[27] INBAND_ERROR bit. An unsupported command error code is written to the L4_IA_ERROR_LOG_L[25:24] CODE bit field for the initiator interface.
- Protection violation: This error indicates that a request is not issued from an allowed initiator member or is issued with the inappropriate ReqInfo qualifiers associated with the target region. This error is reported using an in-band error and is written to the L4_IA_AGENT_STATUS_L[27] INBAND_ERROR bit. A protection violation error code is saved into the L4_IA_ERROR_LOG_L[25:24] CODE bit field for the same initiator interface. A protection violation is also logged in the L4_IA_AGENT_STATUS_L[31] PROT_ERROR_SECONDARY bit when the device is in debug mode or in the L4_IA_AGENT_STATUS_L[30] PROT_ERROR_PRIMARY bit when the device is in application mode.

  The L4_IA_ERROR_LOG_L[30] SECONDARY bit indicates whether the error occurred in application or debug.

  The L4_IA_ERROR_LOG_H[15:0] REQ_INFO bit field returns the type of access (MreqInfo qualifier) that has caused the error.

  The L4_IA_ERROR_LOG_L[13:8] CONNID bit field returns the ConnID of the initiator that has caused the error.

  The L4_IA_ERROR_LOG_ADDR_L[31:0] ADDR register logs the address for error conditions.

9.3.3.4.2 Time-Out

A time-out mechanism can be enabled at the interconnect level and on a per-target basis. If the mechanism is enabled for a TA and interconnect and commands are not accepted or responses are not returned within the expected delay, the L4 interconnect generates an error event.

The error is logged in the L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT bit. The affected TA enters an error state that causes it to send an error response to any new request targeted at it. To recover from this state, system software must reset the TA. The time-out is counted starting from the moment a command is presented to the target, regardless of the target response to this command.

The L4 interconnect implements a centralized time-base circuit that broadcasts a set of four periodic pulse signals to all connected TAs. The time-base circuit offers four possible sets of four time-base signals. The time-base signals are selected by programming the L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE bit field.

The selected time-base signals are available at any TA. Each TA can be programmed to refer to one of these four time-base signals, using the L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT bit field. These four signals are referred to as 1X time-base, 4X time-base, 16X time-base, and 64X time-base.

Table 9-356 lists all values in number of L4 clock cycles.

Table 9-356. L4 Time-out Link and TA Programming

	L4_TA_AGENT_CONTROL_L [10:8] REQ_TIMEOUT				
L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE	0	1	2	3	4
0	All L4 time-out features are disabled.				
1	Locally disabled	64	256	1024	4096
2		256	1024	4096	16,384
3		1024	4096	16,384	65,536
4		4096	16,384	65,536	262,144

The default reset value is 0x2 for REQ_TIMEOUT and 0x4 for TIMEOUT_BASE, implying 16,384 clock cycles.

A time-out condition is detected when the command acceptance or the response is not received after a delay of from one to three time-base periods.

Example:

- L4 frequency = 65MHz, 15.3-µs period
- TIMEOUT_BASE = 4 in the L4_LA_NETWORK_CONTROL_L register
- REQ_TIMEOUT = 2 in the L4_TA_AGENT_CONTROL_L for TA A
- REQ_TIMEOUT = 4 in the L4_TA_AGENT_CONTROL_L for TA B

At agent A, the time-base unit is 16,384 cycles. A time-out is issued when a request to the attached module is not accepted, or no response is sent after a delay of 252 µs to 756 µs.

At agent B, the time-base unit is 262,144 cycles. A time-out is issued when a request to the attached module is not accepted or no response is sent after a delay of 4 ms to 12 ms.

When a time-out condition is detected, the TA logs the error in the L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT bit, and it also reports the error to the IA, which forwards it to the L3 interconnects.

After the time-out is detected and logged, the behavior of the attached module is ignored. A new request targeting the module arriving at the timed-out TA receives an error response. If the request is addressed to the agent internal registers, it is processed normally.

To recover from a time-out error, software is assumed to first reset the faulty module and then the TA using the L4_TA_AGENT_CONTROL_L[0] OCP_RESET bit.

9.3.3.4.3 Error Reporting

Figure 9-12 shows the error-reporting scheme used in the L4 interconnects. All L4 in-band errors are reported to their respective L3 TA, where errors are converted in an out-of band error signals (L3_MAIN_IRQ_APP_ERR and L3_MAIN_IRQ_DBG_ERR) going to the IRQ_CROSSBAR.

To enable interrupt reporting in case of error occurrence, one or all of the following bits (depending on user's desire) must be set to 0x1:

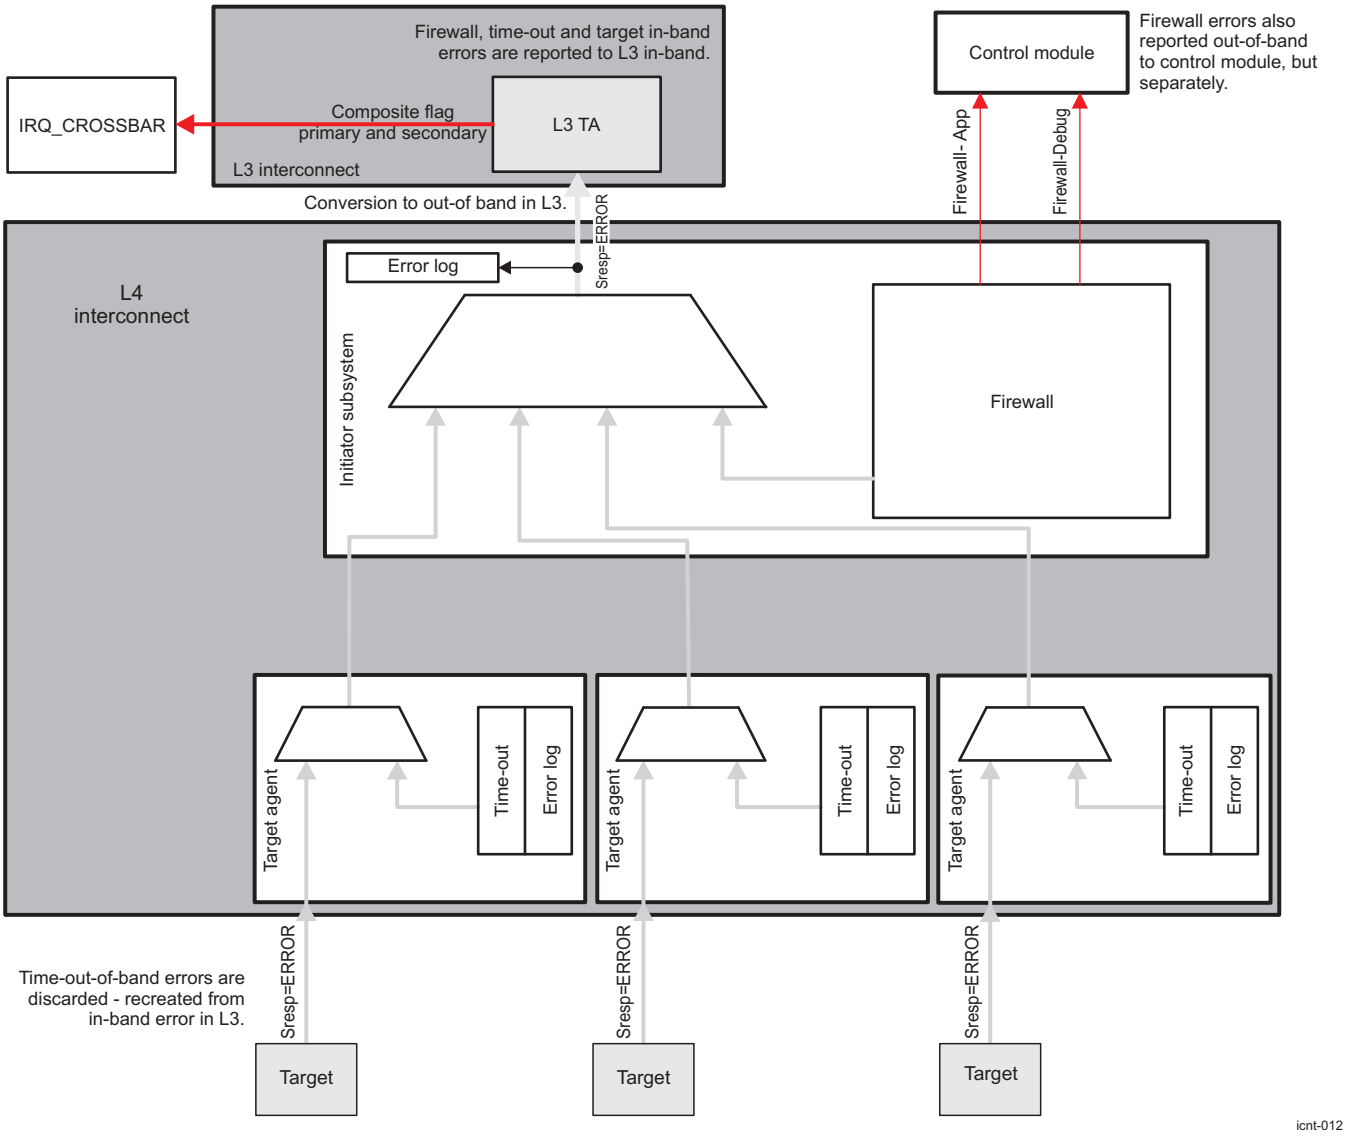
- CLK1_FLAGMUX_CLK1_1.L3_FLAGMUX_MASK0[10] for L4_CFG
- CLK1_FLAGMUX_CLK1_1.L3_FLAGMUX_MASK0[11] for L4_WKUP
- CLK1_FLAGMUX_CLK1_2.L3_FLAGMUX_MASK0[5] for L4_PER2_P1
- CLK1_FLAGMUX_CLK1_2.L3_FLAGMUX_MASK0[6] for L4_PER1_P1
- CLK1_FLAGMUX_CLK1_2.L3_FLAGMUX_MASK0[7] for L4_PER1_P2
- CLK1_FLAGMUX_CLK1_2.L3_FLAGMUX_MASK0[8] for L4_PER3_P2
- CLK1_FLAGMUX_CLK1_2.L3_FLAGMUX_MASK0[9] for L4_PER3_P1

The following bits must also be set to 0x1:

- L3_FLAGMUX_CLK1MERGE_MASK0[1]

- L3_FLAGMUX_CLK1MERGE_MASK0[0]

Figure 9-12. L4 Error Reporting



9.3.3.4.4 Error Recovery

Setting the L4_TA_AGENT_CONTROL_L[0] OCP_RESET bit to 1 initiates the software reset period. Software reset must be asserted for at least 16 cycles of the target module interface clock, which can be a divided clock with respect to the L4 clock.

During the software reset period:

- Requests sent to the target module receive error responses. Therefore, if the faulty request is part of a DMA transfer, it is necessary to stop the DMA to prevent unwanted errors.
- Requests sent to the TA register block are processed as usual.
- The L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT status bit is cleared.

Setting the L4_TA_AGENT_CONTROL_L[0] OCP_RESET bit to 0 terminates the software reset period.

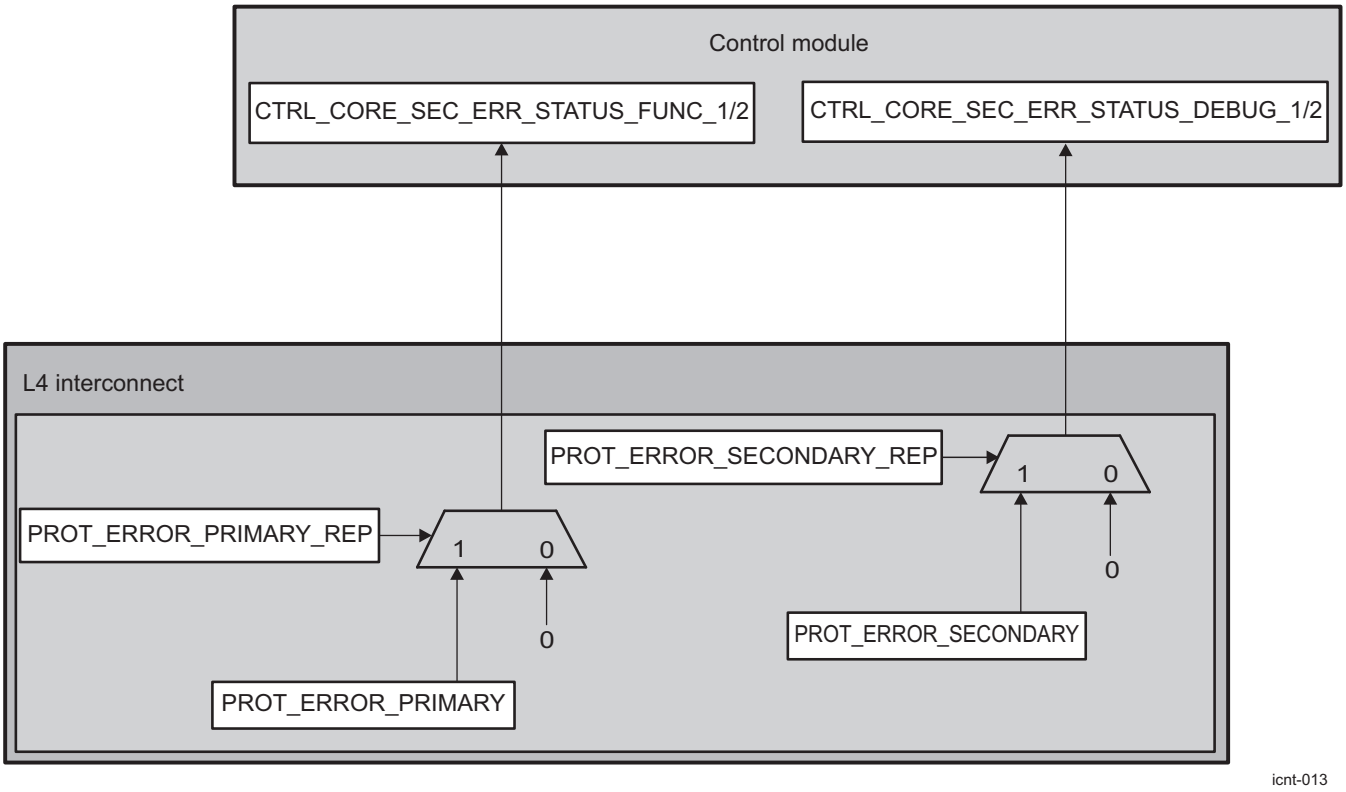
Reset the attached module to complete the recovery.

9.3.3.4.5 Firewall Error Logging in the Control Module

When a protection violation occurs, an interrupt is sent to the IRQ_CROSSBAR. An in-band error is sent back to L3 IA and an out-of-band error is logged in the CTRL_CORE_SEC_ERR_STATUS_FUNC_1/2 register (used in application mode) or in the CTRL_CORE_SEC_ERR_STATUS_DEBUG_1/2 register (used in debug mode). These out-of-band errors are enabled at the L4 IA level by setting to 0x1 the L4_IA_AGENT_CONTROL_L[31] PROT_ERROR_SECONDARY_REP bit when the device is in debug mode or the L4_IA_AGENT_CONTROL_L[30] PROT_ERROR_PRIMARY_REP bit when the device is in application mode.

Figure 9-13 shows the global protection error reporting to the control module.

Figure 9-13. Protection Violation Out-of-Band Error Reporting



9.3.4 L4 Interconnect Programming Guide

9.3.4.1 L4 Interconnect Low-level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the L4 interconnect module.

9.3.4.1.1 Global Initialization

9.3.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the L4 interconnects are used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the L4 interconnects. For more information, see Section 9.3.2, *L4 Interconnect Integration*.

Table 9-357 lists the surrounding modules.

Table 9-357. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	For information about the configuration of the PRCM module, see Chapter 3, *Power, Reset, and Clock Management*.
Control module	For information about the configuration of the control module, see Chapter 13, *Control Module*.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*
Device INTCs	Device INTCs must be configured to enable the interrupt request generation. For more information see Chapter 12 *Interrupt Controllers*
L3_MAIN interconnect	For more information about the L3_MAIN interconnect configuration, see Section 9.2, *L3_MAIN Interconnect*.

9.3.4.1.2 Operational Modes Configuration

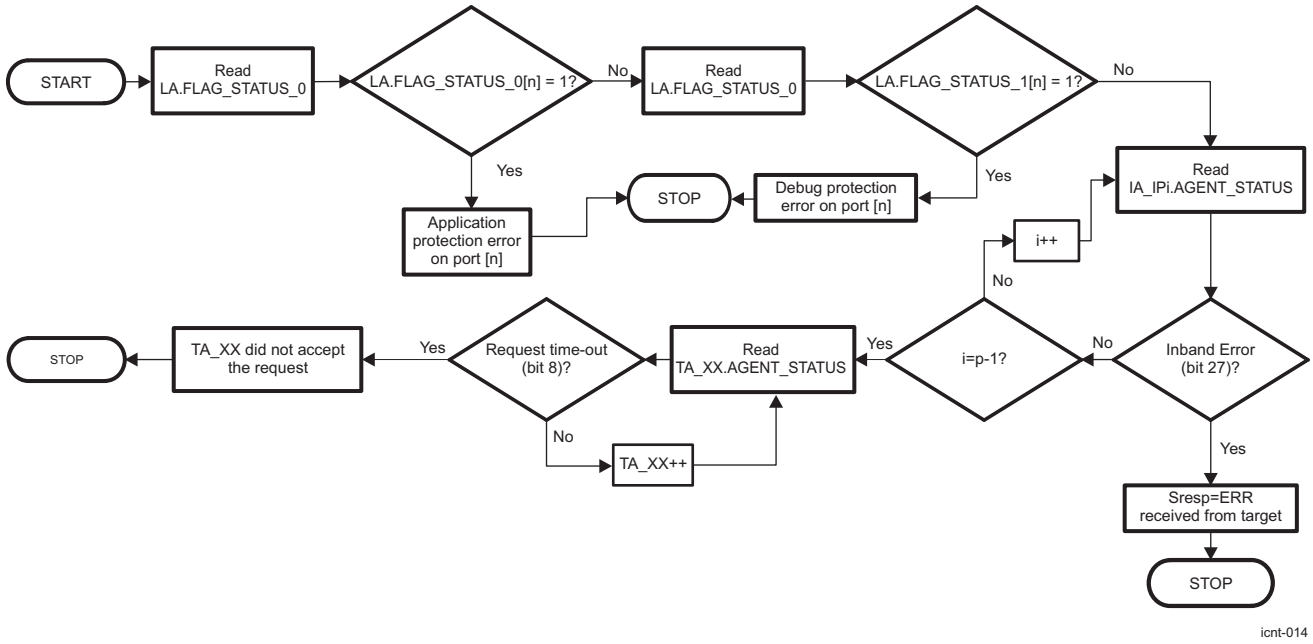
9.3.4.1.2.1 L4 Interconnect Error Analysis Mode

9.3.4.1.2.1.1 Main Sequence: L4 Interconnect Error Analysis Mode

The information required to analyze an error source is logged in several registers. The number of registers to access depends on the error source.

Figure 9-14 shows the software sequence required in most cases.

Figure 9-14. Typical Error Analysis Sequence



NOTE: L4 interconnects don't log any address or other specific information for a custom error returned from any target IP. They rather pass an error response up to the master supposed to analyze it.

In case of posted writes, the master access completes before it actually completed at the end slave level, this way no error response is sent back to the master, making it impossible to have a direct way of uderstanding the origin of L4 error during posted writes. However, even though no address is logged, an error flag is generated and needs to be processed.

9.3.4.1.2.1.2 Subsequence: L4 Interconnect Protection Violation Error Identification

This procedure describes the protection violation error identification (see Table 9-358).

Table 9-358. Protection Violation Error Identification

Step	Register/Bit Field/Programming Model	Value
Read multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	0x-
Read the initiator ConnID.	L4_IA_ERROR_LOG_L[13:8] CONNID	0x-
Read the command that has caused the error.	L4_IA_ERROR_LOG_L[2:0] CMD	0x-
Read address of request that has caused the error.	L4_IA_ERROR_LOG_ADDR_L[31:0] ADDR	0x-
IF: Is it a primary error?	L4_IA_AGENT_STATUS_L[30] PROT_ERROR_PRIMARY	0x1
Read status bits.	CTRL_CORE_SEC_ERR_STATUS_FUNC_1/2	0x-
Write 1 to clear status bits.	CTRL_CORE_SEC_ERR_STATUS_FUNC_1[16] L4_PERIPH1_FW_ERROR	0x1
	CTRL_CORE_SEC_ERR_STATUS_FUNC_1[17] L4_CONFIG_FW_ERROR	0x1
	CTRL_CORE_SEC_ERR_STATUS_FUNC_1[22] L4_WAKEUP_FW_ERROR	0x1
	CTRL_CORE_SEC_ERR_STATUS_FUNC_2[4] L4_PERIPH2_FW_ERROR	0x1
	CTRL_CORE_SEC_ERR_STATUS_FUNC_2[5] L4_PERIPH3_FW_ERROR	0x1

Table 9-358. Protection Violation Error Identification (continued)

Step	Register/Bit Field/Programming Model	Value
Write 1 to clear IA status bit.	L4_IA_AGENT_STATUS_L[30] PROT_ERROR_PRIMARY	0x1
ELSE		
Read status bits.	CTRL_CORE_SEC_ERR_STATUS_DEBUG_1/2	0x-
Write 1 to clear status bits.	CTRL_CORE_SEC_ERR_STATUS_DEBUG_1[16] L4_PERIPH1_DBGFW_ERROR	0x1
	CTRL_CORE_SEC_ERR_STATUS_DEBUG_1[17] L4_CONFIG_DBGFW_ERROR	0x1
	CTRL_CORE_SEC_ERR_STATUS_DEBUG_1[22] L4_WAKEUP_DBGFW_ERROR	0x1
	CTRL_CORE_SEC_ERR_STATUS_DEBUG_2[4] L4_PERIPH2_DBGFW_ERROR	0x1
	CTRL_CORE_SEC_ERR_STATUS_DEBUG_2[5] L4_PERIPH3_DBGFW_ERROR	0x1
Write 1 to clear IA status bit	L4_IA_AGENT_STATUS_L[31] PROT_ERROR_SECONDARY	0x1
ENDIF		
Write 1 to clear multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	0x1
Write 1 to clear in-band error status.	L4_IA_AGENT_STATUS_L[24] INBAND_ERROR	0x1

9.3.4.1.2.1.3 Subsequence: L4 Interconnect Unsupported Command/Address Hole Error Identification

This procedure describes the identification of unsupported command/address hole error (see Table 9-359).

Table 9-359. Unsupported Command/Address Hole Error Identification

Step	Register/Bit Field/Programming Model	Value
Read multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	0x-
Read the initiator ConnID.	L4_IA_ERROR_LOG_L[11:8] CONNID	0x-
Read command that has caused the error.	L4_IA_ERROR_LOG_L[2:0] CMD	0x-
Read the address of the request that has caused the error.	L4_IA_ERROR_LOG_ADDR_L[31:0] ADDR	0x-
Read secondary status.	L4_IA_ERROR_LOG_L[30] SECONDARY	0x-
Write 1 to clear secondary status.	L4_IA_ERROR_LOG_L[30] SECONDARY	0x1
Write 1 to clear multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	0x1
Write 1 to clear inband error status.	L4_IA_AGENT_STATUS_L[24] INBAND_ERROR	0x1

9.3.4.1.2.1.4 Subsequence: L4 Interconnect Reset TA and Module

This procedure describes the reset TA and module (see Table 9-360).

Table 9-360. Reset TA and Module

Step	Register/Bit Field/Programming Model	Value
Reset TA.	L4_TA_AGENT_CONTROL_L[0] OCP_RESET	0x1
Wait until target module clock = 16 cycles.		
Write 0 to clear TA time-out status.	L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT	0x0
Write 0 to clear TA reset.	L4_TA_AGENT_CONTROL_L[0] OCP_RESET	0x0
Reset the attached module.	For more information, see the respective module chapter.	

9.3.4.1.2.2 L4 Interconnect Time-Out Configuration Mode

9.3.4.1.2.2.1 Main Sequence: L4 Interconnect Time-Out Configuration Mode

This procedure describes the time-out configuration sequence (see Table 9-361).

Table 9-361. Time-Out Configuration

Step	Register/Bit Field/Programming Model	Value
Disable time-out.	L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE	0x0
Clear TA time-out error status.(1)	L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT	0x1
Set time-out at TA level.(1)	L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT	0x-
Set time-out base.	L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE	0x-

(1) Required for each TA.

9.3.4.1.2.3 L4 Interconnect Firewall Configuration Mode

9.3.4.1.2.3.1 Main Sequence: L4 Interconnect Firewall Configuration Mode

This procedure describes the firewall configuration sequence (see Table 9-362).

Table 9-362. Firewall Configuration

Step	Register/Bit Field/Programming Model	Value
Define the members of protection group k. In other words, define which initiators can access the protection group k. For ConnID values, see Table 9-346 .	L4_AP_PROT_GROUP_MEMBERS_k_L[15:0] CONNID_BIT_VECTOR(1)	0x-
For the protection group k define the initiator requests accepted or not by the L4 firewalls depending on combination of L4 qualifiers. For more details, see Table 9-347	L4_AP_PROT_GROUP_ROLES_k_L[31:0] ENABLE(1)	0x-
Assign the region l to a protection group.	L4_AP_REGION_l_H[22:20] PROT_GROUP_ID(2)	0x-

(1) Required for each protection group.
(2) Required for each region.

9.3.5 L4 Interconnects Register Manual

Table 9-363 through Table 9-367 list all L4 register blocks for IA, TA, AP, and LA. Each module instance is shown with the module register mapping and bit and bit field definitions.

9.3.5.1 L4 Interconnects Instance Summary

NOTE: ISS, CRC, TESOC, ESM and DCC1 to DCC7 are not supported on the DRA78x family of devices.

Table 9-363. L4_PER1 Instance Summary

Module Name	L3_MAIN Base Address	Size

- L4 Target Agent (L4 TA) Register Summary: [0][1][2][3][4][5][6][7][8][9][10][11][12][13][14][15][16][17][18][19][20][21][22][23][24][25][26][27][28][29][30]

Table 9-437. L4_TA_AGENT_CONTROL_L

Address Offset	0x0000 0020		
Physical Address	See Table 9-396 to Table 9-428	**Instance**	See Table 9-396 to Table 9-428
Description	Enable error reporting		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED							SERROR_REP	RESERVED													REQ_TIMEOUT			RESERVED							OCP_RESET

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Read returns 0.	R	0x00
24	SERROR_REP	Enable logging of error	R	0x0
23:11	RESERVED	Read returns 0.	R	0x0
10:8	REQ_TIMEOUT	Time-out Bound. Values are: 0 - No time-out 1 - 1x base cycles. 2 - 4x base cycles. 3 - 16x base cycles. 4 - 64x base cycles.	RW	0x2
7:1	RESERVED	Read returns 0.	R	0x00
0	OCP_RESET	The OCP_RESET field controls the OCP reset signal to the attached core. Setting this bit clears any pending transfers and resets the OCP interface. The bit must be cleared to deassert the OCP reset signal. When the software reset feature is available on a target agent, the target agent OCP must also have a reset signal directed to the target core.	RW	0

Address Offset	0x0000 0024		
Physical Address	0x4800 0824 0x4840 0824 0x4880 0824 0x4A00 0824 0x4AE0 0824	**Instance**	L4_PER1_LA L4_PER2_LA L4_PER3_LA L4_CFG_LA L4_WKUP_LA
Description	Control interconnect global power control		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED							CLOCK_GATE_DISABLE	RESERVED			THREAD0_PRI	RESERVED											EXT_CLOCK	RESERVED							

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Read returns 0.	R	0x00
24	CLOCK_GATE_DISABLE	When set to 1 this field disables all clock gating.	RW	0
23:21	RESERVED	Read returns 0.	R	0x0
20	THREAD0_PRI	Sets thread priority. If the field is set to 0, the default, all initiator threads are treated the same. Setting the THREAD0_PRI field to 1 assigns a higher arbitration priority to thread 0 of the first initiator OCP interface. To avoid starvation, arbitration is imposed by the initiator subsystem. When multiple requests from different initiator threads are dispatched to targets simultaneously, the oldest request is dispatched first. If thread 0 is assigned a higher priority, a request on thread 0 always wins arbitration. Assigning thread 0 of the first initiator OCP the highest priority on a request or response can result in the starvation of other threads.	R	1
19:9	RESERVED	Read returns 0.	R	0x000
8	EXT_CLOCK	Global external clock control. When set to 1, the ext_clk_off_i signal on the initiator subsystem instructs the entire L4 to shut off.	R	1
7:0	RESERVED	Read returns 0.	R	0x00

14:8	PHY_TARGET_ID	Physical target ID	R	See Table 9-495 to Table 9-499
7	RESERVED	Read returns 0.	R	0x0
6:1	SIZE	Define the size of the region in bytes. 2^{SIZE} equals the region.	R	See Table 9-495 to Table 9-499
0	ENABLE	0x0: Disable the region. No access allowed 0x1: Enable the region.	R	0x1

Memory Subsystem

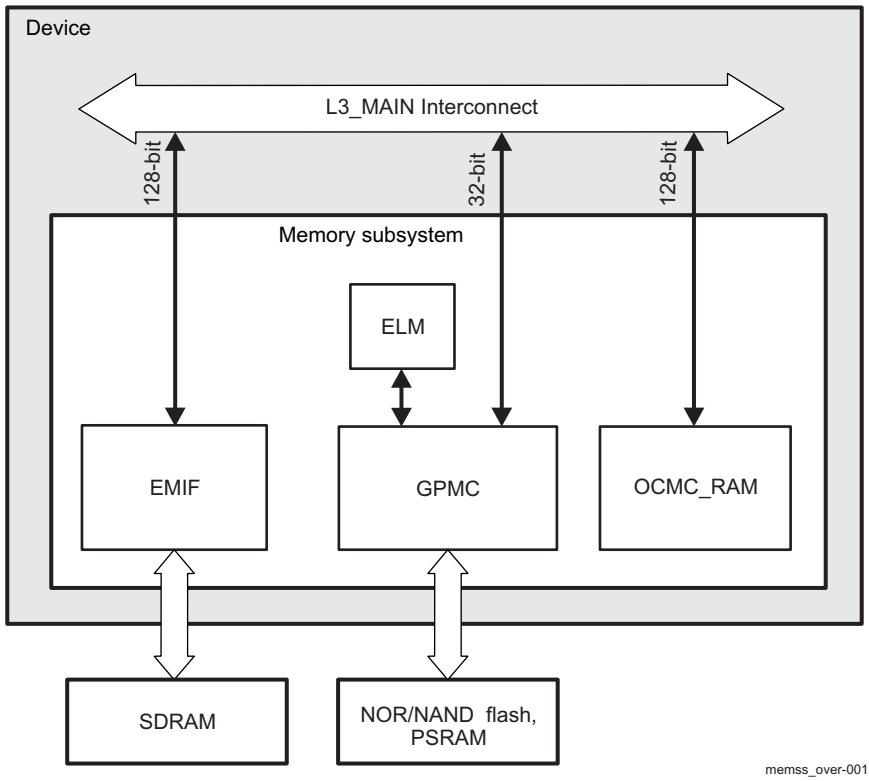
This chapter describes the Memory Subsystem for the device.

Topic **Page**

10.1 Memory Subsystem Overview

Figure 10-1 shows a functional diagram of all memory subsystems in the device.

Figure 10-1. Memory Subsystem Functional Diagram



10.1.1 EMIF Overview

NOTE: LPDDR2 is not supported on the DRA78x family of devices.

The EMIF module provides connectivity between DDR memory types and manages data bus read/write accesses between external memory and device subsystems which have master access to the L3_MAIN interconnect and DMA capability.

The EMIF module has the following capabilities:

- Supports JEDEC standard-compliant LPDDR2/DDR2-SDRAM and DDR3/DDR3L-SDRAM memory types
- 2-GiB SDRAM address range over one chip-select.
- Supports SDRAM devices with one, two, four or eight internal banks
- Data bus widths:
  - 128-bit L3_MAIN (system) interconnect data bus width
  - 32-bit SDRAM data bus width
  - 16-bit SDRAM data bus width used in narrow mode
- Supported CAS latencies:
  - DDR3: 5, 6, 7, 8, 9, 10 and 11
  - DDR2: 2, 3, 4, 5, 6 and 7
  - LPDDR2: 3, 4, 5, 6, 7, and 8
- Supports 256-, 512-, 1024-, and 2048-word page sizes

- Supported burst length: 8
- Supports sequential burst type
- SDRAM auto initialization from reset or configuration change
- Supports self refresh and power-down modes for low power
- Partial array self-refresh mode for low power when DDR3 is used
- Output impedance (ZQ) calibration for DDR3
- Supports on-die termination (ODT) for DDR2 and DDR3
- Supports prioritized refresh
- Programmable SDRAM refresh rate and backlog counter
- Programmable SDRAM timing parameters
- Write and read leveling/calibration and data eye training for DDR3.
- ECC on the SDRAM data bus:
  - 7-bit ECC over 32-bit data
  - 6-bit ECC over 16-bit data when narrow mode is used
  - 1-bit error correction and 2-bit error detection
  - Programmable address ranges to define ECC protected region
  - ECC calculated and stored on all writes to ECC protected address region
  - ECC verified on all reads from ECC protected address region
  - Statistics for 1-bit ECC and 2-bit ECC errors
  - The total width of the ECC DDR data bus is 8 bits

The EMIF module does not support:

- Burst chop for DDR3
- Interleave burst type
- Auto precharge because of better Bank Interleaving performance
- OCD calibration for DDR2
- CAS Read Latency of 2 and CAS Write Latency of 1 for DDR2
- DLL disabling from EMIF side

10.1.2 GPMC Overview

The General Purpose Memory Controller (GPMC) is an external memory controller of the device. Its data access engine provides a flexible programming model for communication with all standard memories.

The GPMC supports the following various access types:

- Asynchronous read/write access
- Asynchronous read page access (4, 8, and 16 Word16)
- Synchronous read/write access
- Synchronous read/write burst access without wrap capability (4, 8 and 16 Word16)
- Synchronous read/write burst access with wrap capability (4, 8 and 16 Word16)
- Address-data-multiplexed (AD) access
- Address-address-data (AAD) multiplexed access
- Little- and big-endian access

The GPMC can communicate with a wide range of external devices:

- External asynchronous or synchronous 8-bit wide memory or device (non burst device)
- External asynchronous or synchronous 16-bit wide memory or device
- External 16-bit non-multiplexed NOR flash device
- External 16-bit address and data multiplexed NOR Flash device

- External 8-bit and 16-bit NAND flash device
- External 16-bit pseudo-SRAM (pSRAM) device

The main features of the GPMC are:

- 8- or 16-bit-wide data path to external memory device
- Supports up to eight CS regions of programmable size and programmable base addresses in a total address space of 1 GiB
- Supports transactions controlled by a firewall
- On-the-fly error code detection using the Bose-ChaudhurI-Hocquenghem (BCH) (t = 4, 8, or 16) or Hamming code to improve the reliability of NAND with a minimum effect on software (NAND flash with 512-byte page size or greater)
- Fully pipelined operation for optimal memory bandwidth use
- The clock to the external memory is provided from GPMC functional clock divided by 1, 2, 3, or 4
- Supports programmable autoclock gating when no access is detected
- Independent and programmable control signal timing parameters for setup and hold time on a per-chip basis. Parameters are set according to the memory device timing parameters, with a timing granularity of one GPMC functional clock cycle.
- Flexible internal access time control (WAIT state) and flexible handshake mode using external WAIT pin monitoring
- Support bus keeping
- Support bus turnaround
- Prefetch and write posting engine associated with a device DMA controller to achieve full performance from the NAND device with minimum effect on NOR/SRAM concurrent access

NOTE: Page mode is available only in nonmultiplexed mode.

10.1.3 ELM Overview

In the case of NAND modules with no internal correction capability, sometimes referred to as bare NAND, the correction process can be delegated to the error location module (ELM) used in conjunction with the GPMC.

The ELM supports the following features:

- 4, 8, and 16 bits per 512-byte block error location based on BCH algorithm
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation when error location process completes:
  - When the full page has been processed in page mode
  - For each syndrome polynomial (checksum-like information) in continuous mode

10.1.4 OCM Overview

There is one on-chip memory controller (OCMC) in the device.

The OCM Controller supports the following features:

- L3_MAIN data interface:
  - Used for maximum throughput performance
  - 128-bit data bus width
  - Burst supported
- L4 interface:
  - Used for access to configuration registers
  - 32-bit data bus width

  - Only single accesses supported
  - The L4 associated OCMC clock is two times lower than the L3 associated OCMC clock
- Error correction and detection:
  - Single error correction and dual error detection
  - 9-bit Hamming error correction code (ECC) calculated on 128-bit data word which is concatenated with memory address bits
  - Hamming distance of 4
  - Enable/Disable mode control through a dedicated register
  - Single bit error correction on a read transaction
  - Exclusion of repeated addresses from correctable error address trace history
  - ECC valid for all write transactions to an enabled region
  - Sub-128-bit writes supported via read modify write
- ECC Error Status Reporting:
  - Trace history buffer (FIFO) with depth of 4 for corrected error address
  - Trace history buffer with depth of 4 for non correctable error address and also including double error detection
  - Interrupt generation for correctable and uncorrectable detected errors
- ECC Diagnostics Configuration:
  - Counters for single error correction (SEC), double error detection (DED) and address error events (AEE)
  - Programmable threshold registers for exceptions associated with SEC, DED and AEE counters
  - Register control for enabling and disabling of diagnostics
  - Configuration registers and ECC status accessible through L4 interconnect
- Circular buffer for sliced based VIP frame transfers:
  - Up to 12 programmable circular buffers mapped with unique virtual frame addresses
  - On the fly (with no additional latency) address translation from virtual to OCMC circular buffer memory space
  - Virtual frame size up to 8 MiB and circular buffer size up to 1 MiB
  - Error handling and reporting of illegal CBUF addressing
  - Underflow and Overflow status reporting and error handling
  - Last access read/write address history
- Two Interrupt outputs configured independently to service either ECC or CBUF interrupt events

The OCM controller does not have a memory protection logic and does not support endianism conversion.

10.2 EMIF Controller

This section describes mainly the features and functions of the external memory interface (EMIF) controller and also its associated PHYs.

10.2.1 EMIF Controller Overview

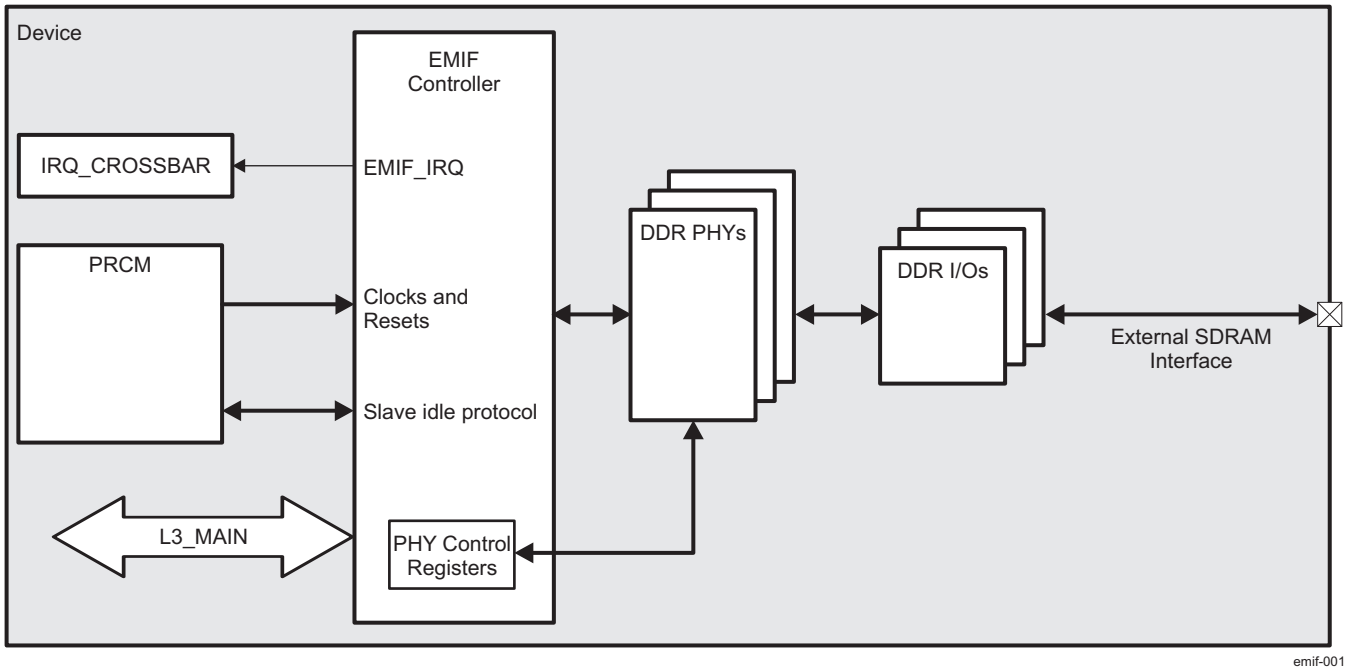
The EMIF controller provides connectivity between the device and LPDDR2/DDR2/DDR3/DDR3L types of memories and manages data bus read/write accesses between external memories and the device subsystems which have access to the L3_MAIN interconnect and DMA capability too.

NOTE: LPDDR2 is not supported on the DRA78x family of devices.

The EMIF features are introduced in Section 10.1.1 *EMIF Overview* of Section 10.1 *Memory Subsystem Overview*.

The device includes one EMIF controller. Figure 10-2 shows an overview of this EMIF controller and also the connections to the other surrounding modules. As can be seen on Figure 10-2 the EMIF is not directly available on device pads. That is, it is not directly connected to the external SDRAM. There are DDR PHYs and then DDR I/Os between the EMIF controller and external SDRAM. The EMIF controller, the DDR PHYs and the DDR I/Os work like a single unit to manage data exchanges to and from external memories. To achieve successful data transaction between an internal device initiator and external SDRAM all these three components must be used.

Figure 10-2. EMIF Controller Overview



10.2.2 EMIF Module Environment

This section describes the external connections of the EMIF module.

Figure 10-3 shows an example EMIF DDR2/DDR3/DDR3L configuration without ECC memory connected.

Figure 10-4 shows an example EMIF DDR2/DDR3/DDR3L configuration with ECC memory connected.

Figure 10-5 shows an example EMIF LPDDR2 configuration without ECC memory connected.

Figure 10-6 shows an example EMIF LPDDR2 configuration with ECC memory connected.

For simplification the DDR PHYs and DDR I/Os are not shown. Only the I/O signals and their corresponding EMIF pins are shown.

NOTE: LPDDR2 is not supported on the DRA78x family of devices.

Figure 10-3. EMIF DDR2/DDR3/DDR3L Configuration Without ECC

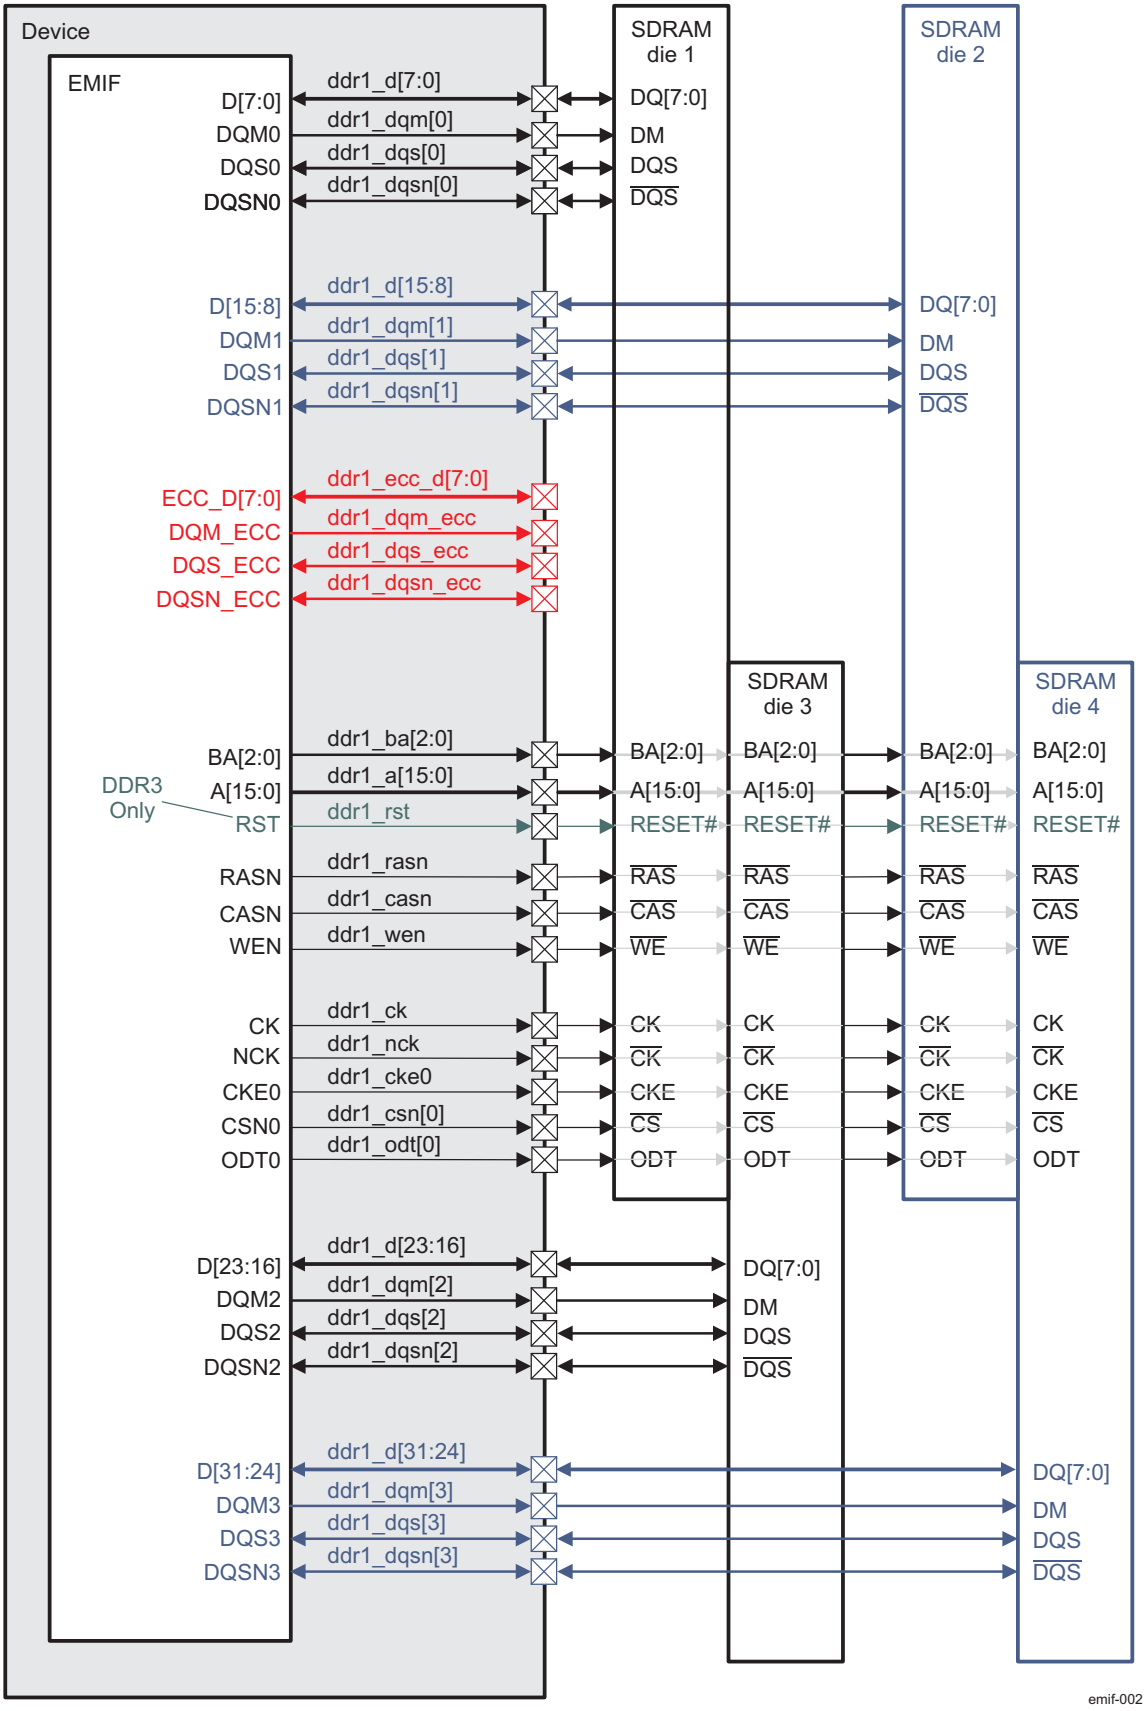


Figure 10-4. EMIF DDR2/DDR3/DDR3L Configuration With ECC

CA7	ddr1_ba[0]	O	Command/Address bus - bit 7
CA8	ddr1_ba[1]	O	Command/Address bus - bit 8

(1) I = Input; O = Output

(2) These signals are available only in non-PoP package. For more information about signal availability in PoP and non-PoP packages, see the corresponding device data manual.

Table 10-2. EMIF Module I/O Signals Used For Connection to LPDDR2 Memories (continued)

EMIF Pin Name	Device I/O Signal Names	I/O[1]	Description
CA9	ddr1_ba[2]	O	Command/Address bus - bit 9

The CKE0 memory pin is dynamically driven by the EMIF module according to the memory interface activity.

The ddr1_cke0 pad can also be forced to tri-state by a dedicated Control Module register. For more information, see Section 10.2.4.18 *Forcing CKE to tri-state*.

The DDR memory connected to the DDR ECC bus does NOT need to be the same part number as the DDR memories connected to the DDR data bus. However, some constraints do apply. When selecting a memory for the DDR ECC bus, the following restrictions must be adhered to.

Compared to the DDR memories on the data bus, the DDR ECC memory must:

- Match the same DDR type (for example, DDR3) and speed grade
- Have an equal number of internal banks
- Have an equal number of columns
- Have a greater or equal number of rows

In addition,

- Unused pins should be properly tied off as described in the routing guidelines of the device data manual.
- EMIF register settings should be configured to satisfy the larger minimum timing requirements and the smaller maximum timing requirements between the two different DDR memories to ensure that all DDR memories connected to the EMIF channel are running within their specified range.

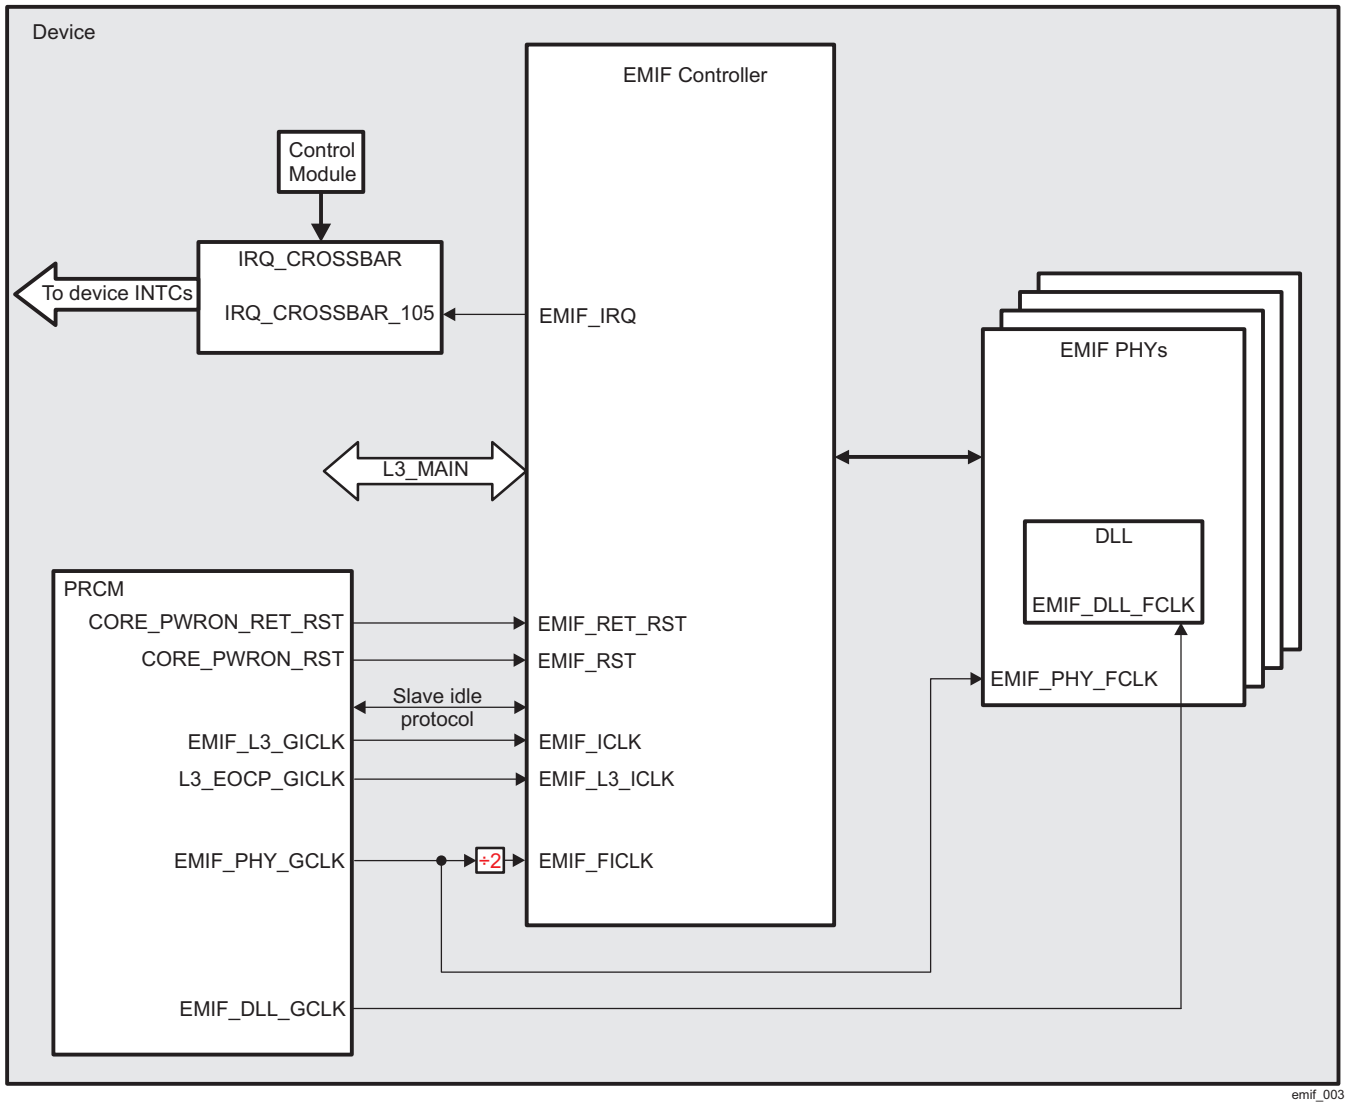
NOTE: For a full list of supported DDR device types, frequencies, and topologies, refer to the routing guidelines of the device data manual.

10.2.3 EMIF Module Integration

This section describes the integration of the EMIF module in the device and includes information about clocks, resets, and hardware requests.

Figure 10-7 shows the integration of the EMIF module in the device.

Figure 10-7. EMIF Module Integration



NOTE: For more information about the slave idle protocol, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 10-3 through Table 10-5 summarize the integration of the EMIF module in the device.

Table 10-3. EMIF Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
EMIF	PD_COREAON	No	L3_MAIN

Table 10-4. EMIF Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
EMIF	EMIF_ICLK	EMIF_L3_GICLK	PRCM	Interface clock for EMIF used for driving the L3 interface logic and for SDRAM Read Data FIFO.
	EMIF_L3_ICLK	L3_EOCP_GICLK	PRCM	Additional interface clock for EMIF which frequency is equal to EMIF_L3_GICLK interface clock. Used for command/write data pre-FIFO to Command/Write Data FIFO paths.
	EMIF_PHY_FCLK	EMIF_PHY_GCLK	PRCM	Common functional clock for the EMIF associated PHYs. This clock is equal to the DDR-SDRAM clock rate.
	EMIF_FICLK	EMIF_PHY_GCLK/2	PRCM	Functional and interface clock for the EMIF. This clock runs at half the DDR-SDRAM clock rate.
	EMIF_DLL_FCLK	EMIF_DLL_GCLK	PRCM	Common functional clock for all DLLs associated with the EMIF PHYs.
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
EMIF	EMIF_RET_RST	CORE_PWRON_RET_RST	PRCM	Power-on reset
	EMIF_RST	CORE_PWRON_RST	PRCM	Power-on reset

Table 10-5. EMIF Hardware Requests

Interrupt Requests				
Module Instance	**IRQ Source Name**	**IRQ_CROSSBAR Input**	**Default IRQ Source Mapping**	**Description**
EMIF	EMIF_IRQ	IRQ_CROSSBAR_105	-	EMIF interrupt request. This IRQ source signal is not mapped by default to any device INTC.

NOTE: The "**Default IRQ Source Mapping**" column in Table 10-5 *EMIF Hardware Requests* shows the default mapping of the IRQ sources listed in column "**IRQ Source Name**" to a certain interrupt line of one of the device interrupt controllers. These IRQ sources can also be mapped to other interrupt lines of each device interrupt controller through the IRQ_CROSSBAR module. For more information about the IRQ_CROSSBAR module, see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*. For more information about the device interrupt controllers, see Chapter 12, *Interrupt Controllers*.

NOTE: For the description of the interrupt source, see Section 10.2.4.5, *Interrupt Requests*.

10.2.4 EMIF Functional Description

10.2.4.1 Block Diagram

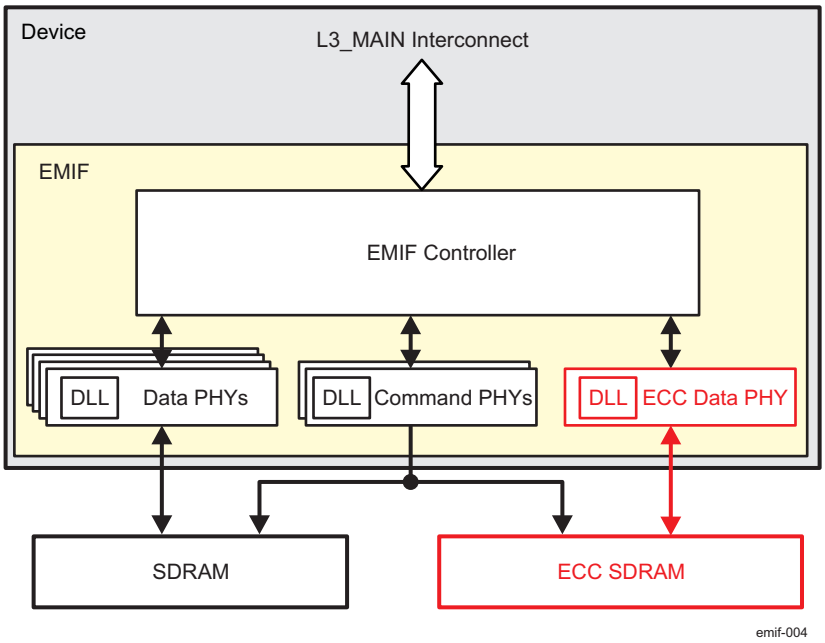
The EMIF module provides an interface to LPDDR2, DDR2 and DDR3/DDR3L SDRAM memories.

Figure 10-8 shows the interconnection between the EMIF module and the other modules.

Digital locked loops (DLLs) are used to delay the input DQS signals during reads so that these strobe signals can be used to latch incoming data on the DQ pins, as required by the DDR standard.

Physical layers (PHYs) convert single-data rate (SDR) signals to DDR signals.

Figure 10-8. EMIF Block Diagram



10.2.4.1.1 Local Interface

The EMIF controller has only one local (on-chip) interface. It is called system interface and connects the EMIF to the L3_MAIN interconnect. The system interface is used to request all external memory device accesses, to access the EMIF registers, and to transfer all data to and from the EMIF controller.

10.2.4.1.2 FIFO Description

The EMIF module contains the following FIFOs:

- Command FIFO
- Write data FIFO
- Return command FIFO
- Two read data FIFOs

Figure 10-9 shows the overall architecture of the EMIF FIFOs.

Figure 10-9. FIFO Block Diagram

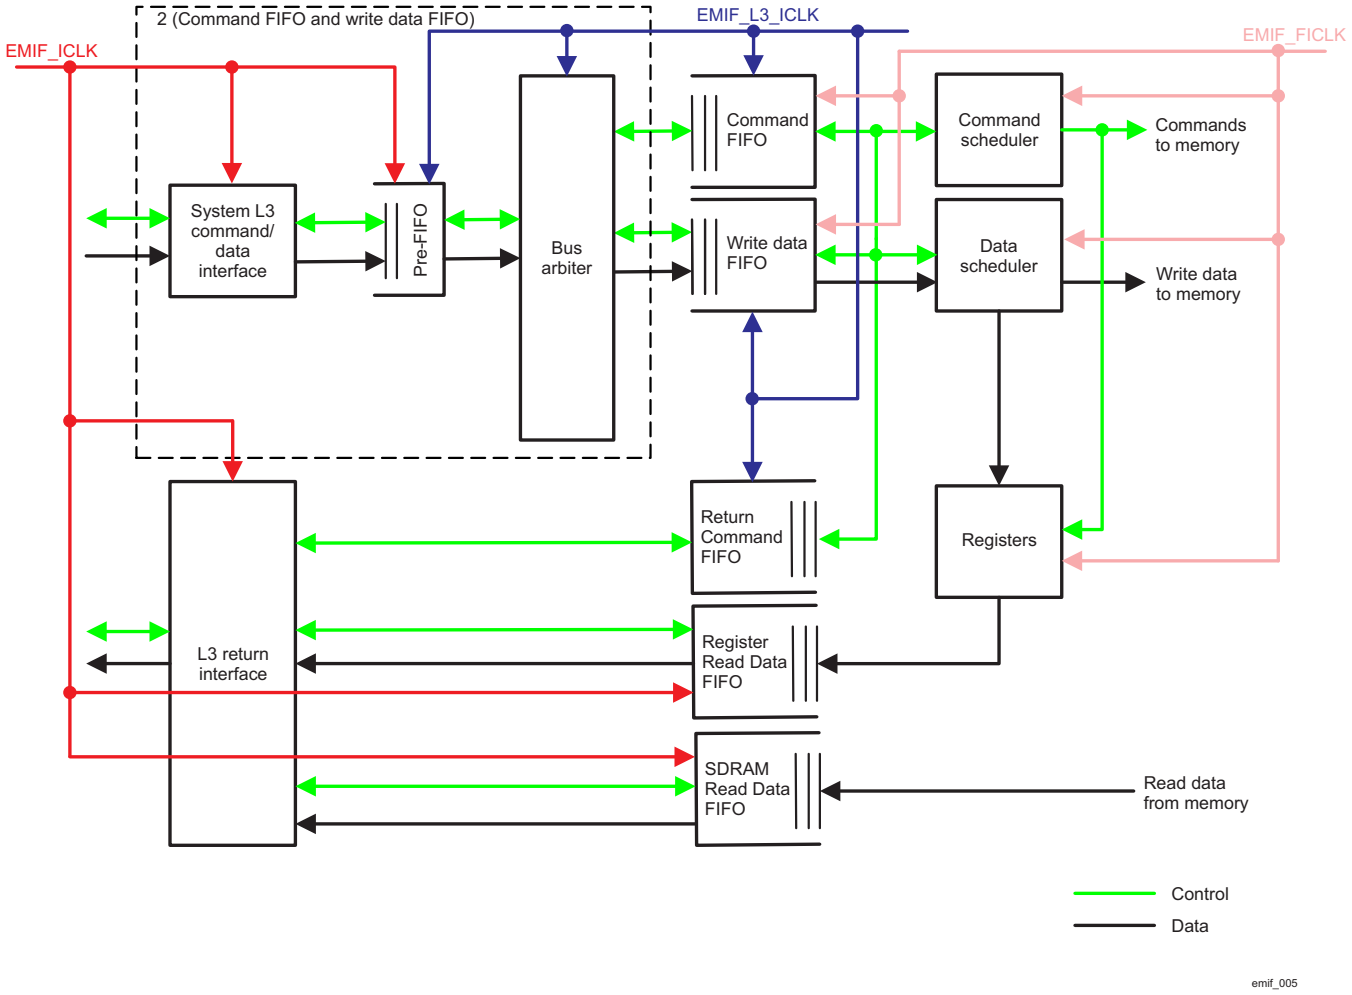


Table 10-6 lists the allocation of the entries.

Table 10-6. FIFO Allocation

Parameter	Local System Interface Entries
Pre Command FIFO	6
Command FIFO	Programmable (1)
Pre Write FIFO	6
Write Data FIFO (256-bit)	Up to (19 × 256 bits) + 6
Return Command FIFO	22
SDRAM Read Data FIFO	22
Register Read Data FIFO	2

(1) The total number of entries in the command FIFO is 10.

The command FIFO stores all the commands coming in on the local command interface. The allocation of entries in the command FIFO is programmable using the EMIF_OCP_CONFIG[27:24] SYS_THRESH_MAX bit field.

The write data FIFO stores the write data for all write transactions coming in on the local write data interface.

The return command FIFO stores all the return transactions that have to be issued to the local return interface. These include the write status return and the read data return commands.

Two read data FIFOs store the read data to be sent to the local return interface. One read data FIFO stores read data from the memory mapped registers. The other read data FIFO stores read data from external memory.

A write command is executed only when four local words of the corresponding data are received in the write data FIFO, or when it is the last data, and if there is space in the return command FIFO. The EMIF schedules a read-only if the results can fit into the return command FIFO and the corresponding read data FIFOs.

10.2.4.1.3 Arbitration of Commands in the Command FIFO

The EMIF looks at all the commands stored in the command FIFO to schedule commands to the external memory. All commands with the same MTagID on a particular local interface complete in order. The EMIF does not ensure ordering between commands with different MTagIDs. For information about MTagID, see Section 9.1.1, *Terminology* in Chapter 9, *Interconnect*.

The EMIF must also open and close SDRAM banks and maintain the refresh counts for an SDRAM. The priority of SDRAM commands with respect to refresh levels are:

1. SDRAM refresh request when refresh-must level is reached (highest priority)
2. ZQ calibration
3. Leveling
4. local request for a read or write
5. local request for a write
6. SDRAM activate commands
7. SDRAM deactivate commands
8. SDRAM power-down request
9. SDRAM refresh request when refresh-may or release level is reached
10. SDRAM self-refresh request (lowest priority)

To avoid continuous blocking effect which can be caused by a continuous stream of high-priority commands which thus block the lower priority commands, the EMIF momentarily raises the priority of the oldest command over all other commands when the time for the oldest command configured through the EMIF_COS_CONFIG[7:0] PR_OLD_COUNT bit field expires.

It should be taken into account that while performing the scheduling algorithm described, the EMIF may also encounter a condition in which continuous stream of SDRAM commands to a row in an open bank can block commands to another row in the same bank.

In addition to this scheduling, the highest priority condition is a reset command. If this condition occurs, the EMIF abandons what it is currently doing and begins its start-up sequence. In this case, commands and data stored in the FIFOs are lost. The EMIF also starts its start-up sequence whenever the EMIF_SDRAM_CONFIG register is written and the EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS bit is set to 0. In this case, commands and data stored in the FIFOs are not lost. The EMIF ensures that in-flight read or write transactions to the SDRAM are complete before starting the initialization sequence.

All the accesses to an SDRAM are pipelined to maximize use of the external bus. All of these are done while fulfilling the access timing requirements of an SDRAM.

10.2.4.2 Clock Management

The EMIF can gate EMIF_FICLK. There is an internal mechanism that can stop EMIF_FICLK automatically. EMIF_FICLK is stopped only after the SDRAM is put into self-refresh mode and the power-idle protocol on the local bus completes. The EMIF_FICLK frequency can be changed only after putting the external SDRAM in self-refresh mode.

The EMIF waits for the DLL lock before performing any memory access.

EMIF_FICLK frequency is equal to half of the EMIF_PHY_FCLK frequency.

10.2.4.3 Reset

The EMIF does not support a software reset.

The EMIF supports a global warm reset mode, during which the EMIF keeps the SDRAM content. Upon a request from the PRCM module indicating a need to enter global warm reset mode, the EMIF does the following:

1. During leveling operation, EMIF will immediately exit this mode and automatically perform a write to the MR1 register of DDR3 memory to disable the leveling at the memory side too.
2. EMIF completes the ongoing access, and then puts the SDRAM in self-refresh mode. If the EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS field is set to 1, the EMIF does not put SDRAM in self-refresh mode.
3. EMIF clears all its FIFO contents.
4. EMIF does not wait for all interrupts to be serviced.

To exit the global warm reset:

1. If the EMIF was in Self Refresh state, it will exit Self Refresh state.
2. If leveling was enabled at the time of a global warm reset, a PHY reset must occur to bring the PHY back into a known state, as it may have been left in a leveling state upon warm reset assertion. To guarantee that the SDRAM memory clocks are off when issuing PHY reset, software can use the EMIF_POWER_MANAGEMENT_CONTROL register to enter self refresh before asserting the PHY reset.

10.2.4.4 System Power Management

10.2.4.4.1 Power-Down Mode

The EMIF supports SDRAM power-down mode for low power. The EMIF automatically puts the SDRAM into power-down mode after it is idle for EMIF_POWER_MANAGEMENT_CONTROL[15:12] PD_TIM number of DDR clock cycles and the EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE bit field is set to 0x4. In power-down mode, the EMIF does not stop the clocks to the SDRAM. The EMIF maintains CKE pin low to maintain the power-down mode.

If refresh-must level is not reached before power-down entering, EMIF will not precharge all SDRAM banks before it issues the power-down command. As a result of this EMIF puts the SDRAM in active power-down mode. If refresh-must level is reached before power-down entering, EMIF will precharge all SDRAM banks and before it issues the power-down command, EMIF issues refreshes until refresh-release level is reached. As a result of this EMIF puts the SDRAM in precharge power-down mode.

When the SDRAM is in power-down mode, the EMIF services register accesses normally.

If the SDRAM is in power-down mode and one of the following occurs, the EMIF brings SDRAM out of power-down mode:

- EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE bit field is changed from 0x4 to some other value.
- An SDRAM access is requested.
- The refresh-must level is reached.

If refresh-must level brings the SDRAM out of power-down mode, EMIF puts it in power-down again when the refreshes are complete and keeps this state until the next SDRAM request.

To exit power-down, the EMIF:

1. Drives CKE high after t_cke + 1 cycles have elapsed since the power-down command was issued. The value of t_cke is taken from EMIF_SDRAM_TIMING_2[2:0] T_CKE bit field.
2. Waits for EMIF_SDRAM_TIMING_2[30:28] T_XP + 1 cycles
3. Enters its idle state and can issue any commands

10.2.4.4.2 LPDDR2 Deep Power-Down Mode

NOTE: LPDDR2 is not supported on the DRA78x family of devices.

For ultimate power savings, the EMIF supports deep power-down mode for LPDDR2.

The SDRAM can be forced into deep power-down mode through software by setting the EMIF_POWER_MANAGEMENT_CONTROL[11] DPD_EN bit to 0x1. In this case the EMIF continues normal operation until all SDRAM access requests are serviced. At this point the EMIF issues a deep power-down command. The EMIF then maintains CKE pin low to maintain deep power-down mode. In deep power-down mode, the EMIF automatically stops the clocks to the SDRAM.

Setting the EMIF_POWER_MANAGEMENT_CONTROL[11] DPD_EN bit to 1 overrides the setting of the EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE bit field. Therefore, if the SDRAM is in any other power-saving mode, and the EMIF_POWER_MANAGEMENT_CONTROL[11] DPD_EN bit is set to 1, the EMIF exits those modes and goes into deep power-down mode.

When the SDRAM is in deep power-down mode, the EMIF services register accesses normally.

If the EMIF_POWER_MANAGEMENT_CONTROL[11] DPD_EN bit is set to 0x0, the EMIF brings the SDRAM out of deep power-down mode.

10.2.4.4.3 Self-Refresh Mode

The EMIF supports SDRAM self-refresh mode for low power. The EMIF automatically puts the SDRAM into self-refresh mode after the EMIF is idle for EMIF_POWER_MANAGEMENT_CONTROL[7:4] SR_TIMING number of DDR clock cycles and the EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE bit field is set to 0x2. The EMIF will complete all pending refreshes before it puts the SDRAM into self-refresh. Therefore, after the expiration of SR_TIMING, the EMIF will start issuing refreshes to complete the refresh backlog, and then issue a self-refresh command to the SDRAM.

In self-refresh mode, the EMIF automatically stops the SDRAM clock. The EMIF drives CKE pin low to maintain self-refresh mode.

When the SDRAM is in self-refresh mode, the EMIF services register accesses normally.

If the SDRAM is in self-refresh mode and one of the following occurs, the EMIF brings SDRAM out of self-refresh mode:

- The EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE bit field is changed from 0x2 to some other value.
- SDRAM access is requested.
- EMIF_SDRAM_TIMING_2[2:0] T_CKE + 1 cycles have elapsed since the last self-refresh command.

To exit self-refresh, for LPDDR2, the EMIF:

1. Waits for EMIF_SDRAM_TIMING_2[2:0] T_CKE + 1 cycles have elapsed since the self-refresh command was issued and enables clocks
2. Drives CKE pin high
3. Waits for EMIF_SDRAM_TIMING_2[24:16] T_XSNR + 1 cycles
4. Starts an auto-refresh cycle in the next cycle. It also services all refreshes down to the refresh-release level.
5. Enters its idle state and can issue any commands

To exit self-refresh, for DDR2, the EMIF:

1. Enables the SDRAM clock
2. Drives CKE pin high
3. Waits EMIF_SDRAM_TIMING_2[24:16] T_XSNR + 1 cycles
4. Starts a refresh cycle in the next cycle.
5. Enters its idle state and can issue any other command except write or read command. A write or a read command is issued only after EMIF_SDRAM_TIMING_2[15:6] T_XSRD + 1 cycles clock cycles

have elapsed since pin CKE is driven high.

To exit self-refresh, for DDR3, the EMIF does the following:

1. Enables the SDRAM clock
2. Drives CKE pin high
3. Waits EMIF_SDRAM_TIMING_2[24:16] T_XSNR + 1 cycles
4. Starts a refresh cycle in the next cycle. EMIF also services all refreshes down to the refresh-release level.
5. Enters its idle state and can issue any other command except write or read command. A write or a read command is issued only after EMIF_SDRAM_TIMING_2[15:6] T_XSRD + 1 cycles clock cycles have elapsed since pin CKE is driven high.

To use partial array self-refresh, the EMIF_SDRAM_REFRESH_CONTROL[26:24] PASR bits must be appropriately programmed. The EMIF performs bank interleaving when EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0x0. Because the SDRAM is partially refreshed during partial array self-refresh, for software ease, it is recommended that the IBANK_POS bit field to be set to 0x1, 0x2, or 0x3 depending on the scheme used. If IBANK_POS is set to 0x0, software must move critical data into the banks that are going to be refreshed during partial array self-refresh.

10.2.4.5 Interrupt Requests

The EMIF controller generates one interrupt request (EMIF_IRQ) which is connected to the IRQ_CROSSBAR module. This interrupt line can be asserted by one of the interrupt events listed in Table 10-7.

The EMIF controller generates an interrupt on its interrupt line only if the interrupts are enabled by setting to 0x1 the corresponding bits in the EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_SET register. These interrupts can be disabled by setting to 0x1 the corresponding bits in the EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_CLEAR register. After the interrupt has been serviced the corresponding status flag must be cleared by software. This is done by setting to 0x1 the corresponding bit in the EMIF_SYSTEM_OCP_INTERRUPT_STATUS register which also clears the corresponding bit in the EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS register. The status flags in the EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS register are set even if the corresponding interrupt is disabled unlike those in the EMIF_SYSTEM_OCP_INTERRUPT_STATUS register, which are set only if the corresponding interrupt is enabled. An interrupt is also generated by the EMIF controller, if certain bit in the EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS register is set to 0x1 and the corresponding interrupt is enabled through the EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_SET register. This feature is useful when user software debugging is performed. In addition, even if interrupts are not enabled, certain status bit in EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS register can be cleared by setting to 0x1 the corresponding bit in the EMIF_SYSTEM_OCP_INTERRUPT_STATUS register.

The EMIF sets both the EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[0] ERR_SYS and EMIF_SYSTEM_OCP_INTERRUPT_STATUS[0] ERR_SYS bits to 0x1, if access request for an unsupported command type or an unsupported addressing mode is received.

The EMIF sets both the EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[3] WR_ECC_ERR_SYS and EMIF_SYSTEM_OCP_INTERRUPT_STATUS[3] WR_ECC_ERR_SYS bits to 0x1, if a write access with byte count that is not multiple of the ECC quanta or with a non ECC quanta aligned address is performed within the address range protected by the ECC.

The EMIF sets both the EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[4] TWOBIT_ECC_ERR_SYS and EMIF_SYSTEM_OCP_INTERRUPT_STATUS[4] TWOBIT_ECC_ERR_SYS bits to 0x1, if 2-bit ECC error for a read access performed within the address range protected by the ECC occurs.

The EMIF sets both the EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[5] ONEBIT_ECC_ERR_SYS and EMIF_SYSTEM_OCP_INTERRUPT_STATUS[5] ONEBIT_ECC_ERR_SYS bits to 0x1, if the threshold for 1-bit ECC error is reached. For more information about the EMIF ECC feature, see Section 10.2.4.15, *Error Correction And Detection Feature*.

Table 10-7 lists the event flags and their corresponding event mask bits of the sources which can cause module interrupts.

Table 10-7. Events

Event Flag	Event Mask	Description
EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[5] ONEBIT_ECC_ERR_SYS/ EMIF_SYSTEM_OCP_INTERRUPT_STATUS[5] ONEBIT_ECC_ERR_SYS	EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_SET[5] ONEBIT_ECC_ERR_SYS/ EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_CLEAR[5] ONEBIT_ECC_ERR_SYS	Interrupt if one bit ECC error threshold is reached
EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[4] TWOBIT_ECC_ERR_SYS/ EMIF_SYSTEM_OCP_INTERRUPT_STATUS[4] TWOBIT_ECC_ERR_SYS	EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_SET[4] TWOBIT_ECC_ERR_SYS/ EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_CLEAR[4] TWOBIT_ECC_ERR_SYS	Interrupt for two bit error detection
EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[3] WR_ECC_ERR_SYS/ EMIF_SYSTEM_OCP_INTERRUPT_STATUS[3] WR_ECC_ERR_SYS	EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_SET[3] WR_ECC_ERR_SYS/ EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_CLEAR[3] WR_ECC_ERR_SYS	Interrupt for memory access made to a non-quanta aligned location or done with byte count not multiple of the ECC quanta
EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[1] TA_SYS / EMIF_SYSTEM_OCP_INTERRUPT_STATUS[1] TA_SYS	EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_SET[1] EN_TA_SYS / EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_CLEAR[1] EN_TA_SYS	Interrupt for LPDDR2 temperature alert
EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[0] ERR_SYS/ EMIF_SYSTEM_OCP_INTERRUPT_STATUS[0] ERR_SYS	EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_SET[0] EN_ERR_SYS/ EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_CLEAR[0] EN_ERR_SYS	Interrupt for command or address error

10.2.4.6 SDRAM Refresh Scheduling

The EMIF uses two counters to schedule the Refresh (REF) commands: a 13-bit decrementing refresh interval counter and a 4-bit refresh backlog counter. The interval counter is used to define the rate at which connected SDRAM devices are refreshed. It is loaded with the value of the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field at reset (only the 13 LSBs are taken). The interval counter decrements by 1 each cycle until it reaches 0x0, at which point it reloads from the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field and restarts decrementing. The counter also reloads and restarts decrementing whenever the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field is updated.

The refresh backlog counter records the number of the outstanding REF commands which the EMIF controller currently has. The backlog counter increments by 1 each time the interval counter reloads (unless it has reached its maximum value of 8). The backlog counter decrements by 1 each time the EMIF issues a REF command (unless it is already 0). For the range of values that the backlog counter can take, there are three levels of urgency with which the EMIF must perform refresh cycle in which it issues REF commands:

1. Refresh-may level is reached when the backlog count is greater than 0x0, which indicates that there is a refresh backlog and if the EMIF is not busy and there are no open SDRAM banks, the EMIF must perform refresh cycle.
2. Refresh-release level is reached when the backlog count is greater than 0x4, which indicates that the refresh backlog is getting bigger and if the EMIF is not busy it must perform refresh cycle even if there is an open SDRAM bank.
3. Refresh-must level is reached when the backlog count is greater than 0x7, which indicates that the refresh backlog is becoming excessive and the EMIF must perform refresh cycle before any new memory access request being serviced. The EMIF starts servicing new memory accesses after the refresh-release level is cleared.

The two counters do not operate when SDRAM is in self-refresh mode. They start tracking the missed refreshes (the outstanding REF commands) only after initialization is complete in case of DDR2/DDR3. For LPDDR2, the refresh counters will start tracking missed refreshes after RESET command is issued. For LPDDR2, the EMIF will also ensure that no more than 8 REF (Refresh) commands are issued in any rolling tREFBW (=4*8*tRFC) window.

The time between two REF commands is set through the EMIF_SDRAM_TIMING_3[12:4] T_RFC bit field.

10.2.4.7 SDRAM Initialization

NOTE: To avoid error responses from the EMIF controller the SDRAM initialization must be performed per 16-Byte blocks if EMIF_SDRAM_CONFIG[15:14] NARROW_MODE = 0x0 or per 8-Byte blocks if EMIF_SDRAM_CONFIG[15:14] NARROW_MODE = 0x1.

10.2.4.7.1 DDR2 SDRAM Initialization

On coming out of reset, the EMIF controller begins the DDR2 initialization sequence after a write to any one of the following three registers, providing that the corresponding listed conditions are met:

1. EMIF_SDRAM_CONFIG
   a. Condition 1: EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS = 0 (that is, cleared before the write to EMIF_SDRAM_CONFIG)
2. EMIF_SDRAM_TIMING_1
   a. Condition 1: EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS = 0 (that is, cleared before the write to EMIF_SDRAM_TIMING_1) AND
   b. Condition 2: The write access modifies the register bit field T_WR (bits 20:17)
3. EMIF_SDRAM_REFRESH_CONTROL
   a. Condition 1: EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS = 0 AND
   b. Condition 2: The write access modifies the register bit field SRT (bit 29), ASR (bit 28), or PASR (bits 26:24).

For the first DDR2 initialization sequence, the EMIF controller performs the following actions:

1. Drives the CKE pin low.
2. After 16 SDRAM refresh rate intervals, issues a NOP command with CKE pin held high. The SDRAM refresh rate is as defined in the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field.
3. After 1 SDRAM refresh rate interval, issues Precharge all Banks command.
4. Issues EMRS command to the DDR2 EMR(2) register (bits BA[2:0] = 0x2) with bits A[15:0] = 0x0.
5. Issues EMRS command to the DDR2 EMR(3) register (bits BA[2:0] = 0x3) with bits A[15:0] = 0x0.
6. Issues EMRS command to the DDR2 EMR(1) register (bits BA[2:0] = 0x1) with bits A[15:0] set as in Table 10-8.

Table 10-8. Load Value For The EMR(1) Register During DDR2 SDRAM Initialization

Bits	Value	Description
A[15:13]	0x0	Reserved
A[12]	0x0	Output buffer enabled
A[11]	0x0	RDQS disable
A[10]	EMIF_SDRAM_CONFIG[23] DDR2_DDQS	Differential DQS enable value
A[9:7]	0x0	Exit OCD calibration mode
A[6], A[2]	EMIF_SDRAM_CONFIG[26:24] DDR_TERM	DDR2 termination resistor value. For DDR2 the EMIF_SDRAM_CONFIG[26] bit is not used.
A[5:3]	0x0	Additive latency = 0
A[1]	EMIF_SDRAM_CONFIG[19:18] SDRAM_DRIVE	SDRAM drive strength. For DDR2 the EMIF_SDRAM_CONFIG[19] bit is not used.
A[0]	EMIF_SDRAM_CONFIG[20] DDR_DISABLE_DLL = 0x0	Enable DLL

7. Issues MRS command to the DDR2 MR register (BA[2:0] = 0x0) with A[15:0] set as in Table 10-9.

Table 10-9. Load Value For The MR Register During DDR2 SDRAM Initialization

Bits	Value	Description
A[15:13]	0x0	Reserved
A[12]	0x0	Active power down exit time - fast exit
A[11:9]	EMIF_SDRAM_TIMING_1[20:17] T_WR	Write recovery for autoprecharge
A[8]	0x1	DLL reset
A[7]	0x0	Normal mode
A[6:4]	EMIF_SDRAM_CONFIG[13:10] CL	CAS latency value. For DDR2 the EMIF_SDRAM_CONFIG[13] bit is not used.
A[3]	0x0	Sequential burst type
A[2:0]	0x3	Burst length of 8

8. After 267 clock cycles, issues Precharge all Banks command.
9. After two Refresh commands, issues MRS command to the DDR2 MR register (BA[2:0] = 0x0) with A[15:0] set as in Table 10-10.

Table 10-10. Another Load Value For The MR Register During DDR2 SDRAM Initialization

Bits	Value	Description
A[15:9]	Equal to Step 7	
A[8]	0x0	No DLL reset
A[7:0]	Equal to Step 7	

10. Issues EMRS command to the DDR2 EMR(1) register (bits BA[2:0] = 0x1) with bits A[15:0] equal to Step 6.
11. The EMIF enters its IDLE state.

The EMIF updates the DDR Mode registers if the DDR2 initialization sequence is triggered again. However, the EMIF controller starts from Step 3.

The EMIF does not perform any transactions until the DDR2 initialization sequence is complete.

When the EMIF comes out of reset, the delay time in Step 2 resulting from the 16 refresh rate intervals + 8 cycles is approximately 16 × REFRESH_RATE / input frequency.

NOTE: The values of the bit fields in the EMIF_SDRAM_CONFIG register are loaded by the control module at reset. These values must not be modified during run time, because they reflect the used hardware SDRAM memory configurations.

10.2.4.7.2 DDR3/DDR3L SDRAM Initialization

On coming out of reset, the EMIF controller begins the DDR3 initialization sequence after a write to any one of the following three registers, providing that the corresponding listed conditions are met.

1. EMIF_SDRAM_CONFIG
   a. Condition 1: EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS = 0 (that is, cleared before the write to EMIF_SDRAM_CONFIG)
2. EMIF_SDRAM_TIMING_1
   a. Condition 1: EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS = 0 (that is, cleared before the write to EMIF_SDRAM_TIMING_1) AND
   b. Condition 2: The write access modifies the register bit field T_WR (bits 20:17)
3. EMIF_SDRAM_REFRESH_CONTROL
   a. Condition 1: EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS = 0 AND
   b. Condition 2: The write access modifies the register bit field SRT (bit 29), ASR (bit 28), or PASR (bits 26:24).

For the first DDR3 initialization sequence, the EMIF controller performs the following actions:

1. After 7 SDRAM refresh rate intervals, de-asserts the RST pin.
2. After 16 SDRAM refresh rate intervals, issues a NOP command with CKE pin held high. The SDRAM refresh rate is as defined in the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field.
3. After 1 SDRAM refresh rate interval, issues MRS command to the DDR3/DDR3L MR2 register (bits BA[2:0] = 0x2) with bits A[15:0] set as in Table 10-11

Table 10-11. Load Value For The MR2 Register During DDR3/DDR3L SDRAM Initialization

Bits	Value	Description
A[15:11]	0x0	Reserved
A[10:9]	EMIF_SDRAM_CONFIG[22:21] DYN_ODT	Dynamic ODT value
A[8]	0x0	Reserved
A[7]	EMIF_SDRAM_REFRESH_CONTROL[29] SRT	Self-refresh temperature range
A[6]	EMIF_SDRAM_REFRESH_CONTROL[28] ASR	Auto self-refresh enable
A[5]	0x0	Reserved
A[4:3]	EMIF_SDRAM_CONFIG[17:16] CWL	CAS write latency
A[2:0]	EMIF_SDRAM_REFRESH_CONTROL[26:24] PASR	Partial array self-refresh

4. After T_RFC + 1 DDR clock cycles, issues MRS command to the DDR3/DDR3L MR3 register (bits BA[2:0] = 0x3) with A[15:0] = 0x0
5. After T_RFC + 1 DDR clock cycles, issues MRS command to the DDR3/DDR3L MR1 register (BA[2:0] = 0x1) with A[15:0] set as in Table 10-12

Table 10-12. Load Value For The MR1 Register During DDR3/DDR3L SDRAM Initialization

Bits	Value	Description
A[15:13]	0x0	Reserved
A[12]	0x0	Output buffer enabled
A[11]	0x0	TDQS disable
A[10]	0x0	Reserved
A[9], A[6], A[2]	EMIF_SDRAM_CONFIG[26:24] DDR_TERM	DDR3/DDR3L termination resistor value
A[8]	0x0	Reserved
A[7]	0x0	Write leveling disabled
A[5], A[1]	EMIF_SDRAM_CONFIG[19:18] SDRAM_DRIVE	SDRAM drive strength
A[4:3]	0x0	Additive latency = 0
A[0]	EMIF_SDRAM_CONFIG[20] DDR_DISABLE_DLL = 0x0	Enable SDRAM DLL

6. After T_RFC + 1 DDR clock cycles, issues MRS command to the DDR3/DDR3L MR0 register (BA[2:0] = 0x0) with A[15:0] set as in Table 10-13

Table 10-13. Load Value For The MR0 Register During DDR3/DDR3L SDRAM Initialization

Bits	Value	Description
A[15:13]	0x0	Reserved
A[12]	0x0	Slow exit. The DDR3 SDRAM DLL is “OFF” after entering precharge power-down.

Table 10-13. Load Value For The MR0 Register During DDR3/DDR3L SDRAM Initialization (continued)

Bits	Value	Description
A[11:9]	EMIF_SDRAM_TIMING_1[20:17] T_WR	Write recovery for autoprecharge
A[8]	0x1	DLL reset
A[7]	0x0	Normal mode
A[6:4], A[2]	EMIF_SDRAM_CONFIG[13:10] CL	Value for CAS latency
A[3]	0x0	Nibble sequential read burst type
A[1:0]	0x0	Burst length of 8

7. After T_RFC + 1 DDR clock cycles, issues a ZQCL command to start long ZQ calibration
8. Waits for t_{DLLK} and t_{ZQinit} to complete
9. Issues REF command
10. The EMIF enters its IDLE state.

The EMIF updates the DDR Mode registers if the DDR3 initialization sequence is triggered again. However, the EMIF controller first issues a precharge command and then starts from Step 3.

The EMIF does not perform any transactions until the DDR3/DDR3L initialization sequence is complete.

When the EMIF comes out of reset, the delay time in Step 2 resulting from the 16 refresh rate intervals + 8 cycles is approximately 16 × REFRESH_RATE / input frequency.

10.2.4.7.3 LPDDR2 SDRAM Initialization

NOTE: LPDDR2 is not supported on the DRA78x family of devices.

When coming out of reset, if the EMIF_SDRAM_CONFIG[31:29] SDRAM_TYPE bit field is equal to 4, the EMIF performs an LPDDR2 initialization sequence as follows:

1. Drives the CKE pin high and starts to issue NOP commands continuously
2. After 16 SDRAM refresh rate intervals, issues a Precharge-All command. The SDRAM refresh rate is defined in the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field.
3. Issues a RESET command
4. The EMIF enters its IDLE state.
5. Software then must initialize LPDDR2 using the EMIF_LPDDR2_MODE_REG_CONFIG and EMIF_LPDDR2_MODE_REG_DATA registers. Software must enable refreshes by writing 1 in the EMIF_LPDDR2_MODE_REG_CONFIG[30] REFRESH_EN bit during the last MRW command.

The EMIF also performs the initialization sequence whenever the EMIF_SDRAM_CONFIG register is written and the LPDDR2 initialization was not performed previously because the EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS bit was set to 0. Once the EMIF performs initialization, rewriting to the EMIF_SDRAM_CONFIG register does not cause reinitialization.

The EMIF does not perform any transactions until the LPDDR2 initialization sequence completes.

When the EMIF comes out of reset, the delay time in step 2 resulting from the 16 refresh rate intervals + 8 cycles is approximately 16 × EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE / input frequency.

10.2.4.8 DDR3/DDR3L Read-Write Leveling

The EMIF supports one type of write/read leveling for DDR3/DDR3L memories - full leveling.

The full leveling consists of three parts:

1. Write leveling
2. Read data eye training

3. Read DQS gate training

Write leveling

The goal of write leveling is to locate the delay between the rising edge of the write DQS signal and the rising edge of the SDRAM memory clock (CK). When this delay is identified, the system is able to accurately align the write DQS signal with the DDR3 memory clock. During Write leveling, the ODT function must be on and proper ODT values must be selected at the external memory side by setting Rtt_Nom (A9, A6, A2) bits in MR1 register of the external DDR3 memory. For more information about write leveling, see the *DDR3 SDRAM Standard*, section *Write leveling*.

Read data eye training

Through the read data eye training the delay between the rising edge of the read DQS signal and the rising and falling edges of the associated DQ data eye is determined. By identifying these delays, the midpoint between them can be calculated and thus the rising edge of the read DQS signal can be accurately centered within the DQ data eye.

Read DQS gate training

Read DQS Gate training is used for timing the internal read window during a read operation as opposed to the write leveling and read data eye training which are used for skew compensation of external signals. The goal of read DQS gate training is to locate the shortest delay that can be applied to each DQS gate such that it functions properly, then find the longest delay that can be applied to each DQS gate and keep its proper function again, and then align the midpoint of the DQS gate delay between these two.

10.2.4.8.1 Full Leveling

The EMIF does not perform full leveling after initialization upon reset. Full leveling must be triggered by software after the EMIF's registers are properly configured.

Full leveling is triggered by setting the EMIF_READ_WRITE_LEVELING_CONTROL[31] RDWRLVLFULL_START bit to 0x1. The leveling execution order is as follows:

1. Write leveling
2. Read DQS gate training
3. Read data eye training

After leveling procedure has finished the EMIF_READ_WRITE_LEVELING_CONTROL[31] RDWRLVLFULL_START bit clears itself automatically.

NOTE: SDRAM Refreshes must be disabled before triggering full leveling.

NOTE: The EMIF_EXT_PHY_CONTROL_2 through EMIF_EXT_PHY_CONTROL_21 registers have to be configured only in case of software leveling.

10.2.4.8.2 Software Leveling

In case of software leveling, the following registers must be configured:

- EMIF_EXT_PHY_CONTROL_2 to EMIF_EXT_PHY_CONTROL_6 containing the PHY_REG_FIFO_WE_SLAVE_RATIO value
- EMIF_EXT_PHY_CONTROL_26 to EMIF_EXT_PHY_CONTROL_30 containing the REG_PHY_GATELVL_INIT_RATIO value
- EMIF_EXT_PHY_CONTROL_25 containing the DQ offset value

The bit fields of the EMIF_EXT_PHY_CONTROL_2 to EMIF_EXT_PHY_CONTROL_6 registers must be loaded with same values. The bit fields of the EMIF_EXT_PHY_CONTROL_26 to EMIF_EXT_PHY_CONTROL_30 registers must also be loaded with same values.

The REG_PHY_DQ_OFFSET fields in register EMIF_EXT_PHY_CONTROL_25 must be loaded with 0x40. That value corresponds to quarter cycle shift between the DQS signals and the data to be written to the SDRAM.

To calculate the PHY_REG_FIFO_WE_SLAVE_RATIO value one of the following two formulas can be used:

- 0x80 + 2*[(Board Delay in ps)*0x100]/(Clock Period in ps). This formula is used when the EMIF_DDR_PHY_CONTROL_1[18] PHY_INVERT_CLKOUT bit is set to 0x1.
- 2*[(Board Delay in ps)*0x100]/(Clock Period in ps). This formula is used when the EMIF_DDR_PHY_CONTROL_1[18] PHY_INVERT_CLKOUT bit is set to 0x0.

The Board Delay in the previously described formulas is measured directly from the board. It depends on the trace length. When the calculated value for PHY_REG_FIFO_WE_SLAVE_RATIO is greater than 0x20, then a value of 0x27 must be used. That means, 0x27 must be loaded in registers EMIF_EXT_PHY_CONTROL_2 to EMIF_EXT_PHY_CONTROL_6.

To calculate the REG_PHY_GATELVL_INIT_RATIO value the following formula is used:

REG_PHY_GATELVL_INIT_RATIO = PHY_REG_FIFO_WE_SLAVE_RATIO – 0x20

When the calculated value for REG_PHY_GATELVL_INIT_RATIO is less than 0x0, then a value of 0x0 must be used. When the calculated value is greater than or equal to 0x0, then that value is used for registers EMIF_EXT_PHY_CONTROL_26 to EMIF_EXT_PHY_CONTROL_30.

In addition, when read DQS gate training is not performed the PHY_REG_FIFO_WE_SLAVE_RATIO value is used. When read DQS gate training is performed REG_PHY_GATELVL_INIT_RATIO is used and PHY_REG_FIFO_WE_SLAVE_RATIO is don't care.

NOTE: Software leveling is not recommended to be used. Hardware leveling must be used instead.

10.2.4.9 EMIF Access Cycles

By default, the EMIF keeps its SDRAM $\overline{CS}$ signal high (CS is active-low). To direct a command to only one of the SDRAMs, EMIF asserts its $\overline{CS}$ signal to the SDRAM for the duration of the command.

The EMIF always performs burst accesses to the SDRAM. Multiple SDRAM bursts may need to service a single local burst request. Table 10-14 through Table 10-19 show a few examples how EMIF performs SDRAM accesses for a linear incrementing transaction type. T0, T1, etc. are clock cycles. R0 is read starting at column 0, R8 is read starting at column 8, and R16 is read starting at column 16. D0-1 is the data from column 0 and 1, D2-3 is the data from column 2 and 3, and so on.

				D4-5	D6-7	D8-9	D10-11	D12-13	D14-15	D16-17	D18-19	Unused	Unused

Table 10-19. 64-Byte Linear Read Starting at Address 0x18 (All DDR)

T0	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10	T11	T12	T13
R6		R8				R16							
				D6-7	Unused	D8-9	D10-11	D12-13	D14-15	D16-17	D18-19	D20-21	Unused

The EMIF uses the unused data phases in the preceding figures by issuing successive read commands if there are reads to open banks pending in the command FIFO.

The write data conversion from SDR to DDR is done outside the EMIF.

10.2.4.10 Turnaround Time

Table 10-20 lists the turnaround time that EMIF introduces on the data bus for various back-to-back accesses. The EMIF takes advantage of the CAS latencies and packs the commands as close as possible on the control bus to introduce the following turnaround time on the data bus.

Table 10-20. Turnaround Time

Current Access	Next Access	Turnaround Time (Number of DDR Clock Cycles)
SDRAM write	SDRAM read	EMIF_SDRAM_TIMING_1[2:0] T_WTR + 1 + CL
SDRAM read	SDRAM write	EMIF_SDRAM_TIMING_1[31:29] T_RTW + 1

10.2.4.11 PHY DLL Calibration

When running in normal locked mode, the PHY DLL gets a reference clock (EMIF_DLL_FCLK) from the PRCM, which is used by the DLL master to lock to the right frequency and provide the control code for a full period phase shift to the slave. The slave uses this code as a control for its internal delay line to produce the required delay for the signal considered.

When working in locked mode, the delay lines only get an updated control value from the master DLLs when an explicit dll_calib command is issued by the EMIF controller. Failure to send such commands on a timely basis will result in inaccurate delay-line information if there is a significant voltage and temperature drift in the system. It is recommended to issue at least one command every 100 µs. EMIF automatically sends ctrl_update commands for:

- Refresh Exit
- Self Refresh Exit
- phy_ready asserted during initialization

The PHY also internally generates a control value update upon completion of a leveling operation. Control is also added when leveling is not used and there are gradual voltage changes during frequency change. The EMIF_DLL_CALIB_CTRL register can be programmed to generate a phy_dll_calib for a periodic interval based on EMIF_FICLK cycles, so allow continued memory access as voltage is changing. A safe window of no activity will be guaranteed for this periodic generation of phy_dll_calib. In addition, a one shot generator for phy_pll_calib has also been added that will generate a single phy_dll_calib by setting the EMIF_MISC_REG[0] DLL_CALIB_OS bit to 1.

10.2.4.12 SDRAM Address Mapping

From the system point of view, the external SDRAM is seen as one block of SDRAM. If two external 64-MiB devices are used, a 128-MiB memory block is observed. If two external 32-MiB devices are used, a 64-MiB block is observed.

Table 10-21 shows the SDRAM address space.

Table 10-21. SDRAM Addressing Space

Module Name	Base Address
EMIF-CSN0-SDRAM	0x8000 0000

When addressing SDRAM, if the EMIF_SDRAM_CONFIG[28:27] IBANK_POS bit field is set to 0, the EMIF uses the following two bit fields to determine the mapping from the source address to the SDRAM row, column and bank:

- EMIF_SDRAM_CONFIG[6:4] IBANK
- EMIF_SDRAM_CONFIG[2:0] PAGESIZE

If the EMIF_SDRAM_CONFIG[28:27] IBANK_POS bit field is set to 1, 2, or 3, the EMIF uses the following three bit fields to determine the mapping from the source address to the SDRAM row, column and bank:

- EMIF_SDRAM_CONFIG[6:4] IBANK
- EMIF_SDRAM_CONFIG[2:0] PAGESIZE
- EMIF_SDRAM_CONFIG[9:7] ROWSIZE

In all cases the EMIF considers its SDRAM address space to be a single logical block, regardless of the number of physical devices.

10.2.4.12.1 Address Mapping for IBANK_POS = 0 and EBANK_POS = 0

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0 and EMIF_SDRAM_CONFIG_2[27] EBANK_POS = 0, Table 10-22 lists which source address bits (MAddr) are mapped to the SDRAM row, column and bank bits for all combinations of IBANK and PAGESIZE.

Table 10-22. Local Address to SDRAM Address Mapping for IBANK_POS = 0 and EBANK_POS = 0

MAddr[31:N] N = 1 if 16-bit data bus width; N = 2 if 32-bit data bus width					
row address		bank address		column address	
ROWSIZE value	row width (bits)	IBANK value	bank[2:0] width (bits)	PAGESIZE value	col width (bits)
In this case the ROWSIZE bit field is not used	16	0	0	0	8
		1	1	1	9
		2	2	2	10
		3	3	3	11

NOTE: The ROWSIZE bit field is unused in case of IBANK_POS = 0 and EBANK_POS = 0.

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0, the effect of the address-mapping scheme is that as the source address increments across the SDRAM pages, EMIF moves to page with the same number as in the previous bank. This movement across the banks continues until the same page is accessed in all banks and then EMIF moves to the next page in the first bank. The EMIF uses this movement across internal banks while remaining on the same page to maximize the number of the open SDRAM banks within the overall SDRAM space.

Thus, the EMIF can keep a maximum of 8 banks open at a time, and can interleave among all of them.

10.2.4.12.2 Address Mapping for IBANK_POS = 1 and EBANK_POS = 0

Table 10-23 list the local address to SDRAM address mapping when IBANK_POS = 1 and EBANK_POS = 0.

Table 10-23. Local Address to SDRAM Address Mapping for IBANK_POS = 1 and EBANK_POS = 0

MAddr[31:N] N = 1 if 16-bit data bus width; N = 2 if 32-bit data bus width							
bank address[2]		row address		bank address[1:0]		column address	
IBANK value	bank[2] width (bits)	ROWSIZE value	row width (bits)	IBANK value	bank[1:0] width (bits)	PAGESIZE value	col width (bits)
0	0	0	9	0	0	0	8
1	0	1	10	1	1	1	9
2	0	2	11	2	2	2	10
3	1	3	12	3	2	3	11
		4	13				
		5	14				
		6	15				
		7	16				

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 1, the EMIF interleaves banks the same as for EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0 but the interleaving of banks is limited to four banks. Thus, the EMIF can keep a maximum of 8 banks open at a time but can interleave among only 4 of them.

10.2.4.12.3 Address Mapping for IBANK_POS = 2 and EBANK_POS = 0

Table 10-24 list the local address to SDRAM address mapping when IBANK_POS = 2 and EBANK_POS = 0.

Table 10-24. Local Address to SDRAM Address Mapping for IBANK_POS = 2 and EBANK_POS = 0

MAddr[31:N] N = 1 if 16-bit data bus width; N = 2 if 32-bit data bus width							
bank address[2:1]		row address		bank address[0]		column address	
IBANK value	bank[2:1] width (bits)	ROWSIZE value	row width (bits)	IBANK value	bank[0] width (bits)	PAGESIZE value	col width (bits)
0	0	0	9	0	0	0	8
1	0	1	10	1	1	1	9
2	1	2	11	2	1	2	10
3	2	3	12	3	1	3	11
		4	13				
		5	14				
		6	15				
		7	16				

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 2, the EMIF interleaves banks the same as for EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0 but the interleaving of banks is limited to two banks. Thus, the EMIF can keep a maximum of 8 banks open at a time but can interleave among only 2 of them.

10.2.4.12.4 Address Mapping for IBANK_POS = 3 and EBANK_POS = 0

Table 10-25 list the local address to SDRAM address mapping when IBANK_POS = 3 and EBANK_POS = 0.

Table 10-25. Local Address to SDRAM Address Mapping for IBANK_POS = 3 and EBANK_POS = 0

MAddr[31:N] N = 1 if 16-bit data bus width; N = 2 if 32-bit data bus width					
bank address		row address		column address	
IBANK value	bank width (bits)	ROWSIZE value	row width (bits)	PAGESIZE value	col width (bits)
0	0	0	9	0	8
1	1	1	10	1	9
2	2	2	11	2	10
3	3	3	12	3	11
		4	13		
		5	14		
		6	15		
		7	16		

If EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 3, the bank interleaving is not possible for EMIF.

10.2.4.12.5 Address Mapping for IBANK_POS = 0 and EBANK_POS = 1

Table 10-26 list the local address to SDRAM address mapping when IBANK_POS = 0 and EBANK_POS = 1.

Table 10-26. Local Address to SDRAM Address Mapping for IBANK_POS = 0 and EBANK_POS = 1

MAddr[31:N] N = 1 if 16-bit data bus width; N = 2 if 32-bit data bus width					
row address		bank address		column address	
ROWSIZE value	row width (bits)	IBANK value	bank width (bits)	PAGESIZE value	col width (bits)
0	9	0	0	0	8
1	10	1	1	1	9
2	11	2	2	2	10
3	12	3	3	3	11
4	13				
5	14				
6	15				
7	16				

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0, and EMIF_SDRAM_CONFIG_2[27] EBANK_POS = 1, the EMIF can keep a maximum of 8 banks open at a time and can interleave among all of them.

10.2.4.12.6 Address Mapping for IBANK_POS = 1 and EBANK_POS = 1

Table 10-27 list the local address to SDRAM address mapping when IBANK_POS = 1 and EBANK_POS = 1.

Table 10-27. Local Address to SDRAM Address Mapping for IBANK_POS = 1 and EBANK_POS = 1

MAddr[31:N] N = 1 if 16-bit data bus width; N = 2 if 32-bit data bus width							
bank address[2]		row address		bank address[1:0]		column address	
IBANK value	bank[2] width (bits)	ROWSIZE value	row width (bits)	IBANK value	bank[1:0] width (bits)	PAGESIZE value	col width (bits)
0	0	0	9	0	0	0	8
1	0	1	10	1	1	1	9

Table 10-27. Local Address to SDRAM Address Mapping for IBANK_POS = 1 and EBANK_POS = 1 (continued)

MAddr[31:N] N = 1 if 16-bit data bus width; N = 2 if 32-bit data bus width							
bank address[2]		row address		bank address[1:0]		column address	
IBANK value	bank[2] width (bits)	ROWSIZE value	row width (bits)	IBANK value	bank[1:0] width (bits)	PAGESIZE value	col width (bits)
2	0	2	11	2	2	2	10
3	1	3	12	3	2	3	11
		4	13				
		5	14				
		6	15				
		7	16				

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 1, and EMIF_SDRAM_CONFIG_2[27] EBANK_POS = 1, the EMIF can keep a maximum of 8 banks open at a time but can interleave among only 4 of them.

10.2.4.12.7 Address Mapping for IBANK_POS = 2 and EBANK_POS = 1

Table 10-28 list the local address to SDRAM address mapping when IBANK_POS = 2 and EBANK_POS = 1.

Table 10-28. Local Address to SDRAM Address Mapping for IBANK_POS = 2 and EBANK_POS = 1

MAddr[31:N] N = 1 if 16-bit data bus width; N = 2 if 32-bit data bus width							
bank address[2:1]		row address		bank address[0]		column address	
IBANK value	bank[2:1] width (bits)	ROWSIZE value	row width (bits)	IBANK value	bank[0] width (bits)	PAGESIZE value	col width (bits)
0	0	0	9	0	0	0	8
1	0	1	10	1	1	1	9
2	1	2	11	2	1	2	10
3	2	3	12	3	1	3	11
		4	13				
		5	14				
		6	15				
		7	16				

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 2 and EMIF_SDRAM_CONFIG_2[27] EBANK_POS = 1, the EMIF can keep a maximum of 8 banks open at a time but can interleave among only 2 of them.

10.2.4.12.8 Address Mapping for IBANK_POS = 3 and EBANK_POS = 1

Table 10-29 list the local address to SDRAM address mapping when IBANK_POS = 3 and EBANK_POS = 1.

Table 10-29. Local Address to SDRAM Address Mapping for IBANK_POS = 3 and EBANK_POS = 1

MAddr[31:N] N = 1 if 16-bit data bus width; N = 2 if 32-bit data bus width					
bank address		row address		column address	
IBANK value	bank width (bits)	ROWSIZE value	row width (bits)	PAGESIZE value	col width (bits)
0	0	0	9	0	8
1	1	1	10	1	9
2	2	2	11	2	10
3	3	3	12	3	11
		4	13		

Table 10-29. Local Address to SDRAM Address Mapping for IBANK_POS = 3 and EBANK_POS = 1 (continued)

MAddr[31:N] N = 1 if 16-bit data bus width; N = 2 if 32-bit data bus width					
bank address		row address		column address	
IBANK value	bank width (bits)	ROWSIZE value	row width (bits)	PAGESIZE value	col width (bits)
		5	14		
		6	15		
		7	16		

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 3 and EMIF_SDRAM_CONFIG_2[27] EBANK_POS = 1, the bank interleaving is not possible for EMIF.

10.2.4.13 Output Impedance Calibration

The EMIF controller supports automatic output impedance (ZQ) calibration for LPDDR2 and DDR3/DDR3L memories. This feature is not supported by DDR2 memories. The ZQ calibration can be enabled by setting to 0x1 the EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[30] ZQ_CS0EN bit. The EMIF supports three types of ZQ calibration commands:

- ZQINIT: ZQ calibration command during initialization
- ZQCL: ZQ calibration long command
- ZQCS: ZQ calibration short command

For DDR3/DDR3L, the EMIF automatically issues ZQINIT command during initialization. For LPDDR2, software must issue a ZQINIT command (MRW to mode register 10). The EMIF issues ZQCS command each time the EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[15:0] ZQ_REFINTERVAL bit field expires. In other words, the ZQ_REFINTERVAL defines the interval between two ZQCS commands. When ZQCS command is issued, the EMIF waits and blocks any other command for EMIF_SDRAM_TIMING_3[20:15] ZQ_ZQCS + 1 number of DDR clock cycles.

If the EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[28] ZQ_SFEXITEN bit field is set to 0x1, the EMIF issues ZQCL command every time it exits self-refresh, active power-down and precharge power-down modes. When ZQCL command is issued, the EMIF waits and blocks any other command for (EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[17:16] ZQ_ZQCL_MULT + 1) × (EMIF_SDRAM_TIMING_3[20:15] ZQ_ZQCS + 1) number of DDR clock cycles.

The ZQINIT is a non periodic command issued only once during DDR initialization as opposed to the ZQCL and ZQCS calibration commands which are issued by the EMIF periodically at regular intervals.

10.2.4.14 LPDDR2 Temperature Monitoring

NOTE: LPDDR2 is not supported on the DRA78x family of devices.

The EMIF supports automatic temperature monitoring to facilitate the software update of the refresh rate according to the temperature changes of the LPDDR2. Temperature monitoring can be enabled per chip select by setting the EMIF_TEMPERATURE_ALERT_CONFIG[31] TA_CS1EN and EMIF_TEMPERATURE_ALERT_CONFIG[30] TA_CS0EN bits.

The EMIF polls the temperature of the LPDDR2 (issues an MRR command to mode register 4) every time the EMIF_TEMPERATURE_ALERT_CONFIG[21:0] TA_REFINTERVAL bit field expires. In other words, TA_REFINTERVAL defines the interval between temperature alert polls. If the EMIF sees a 1 on bit 7 of the read data value from the MRR, which indicates the temperature has changed, the EMIF_SYSTEM_OCP_INTERRUPT_STATUS[1] TA_SYS bit is set and the module sends an interrupt. When the interrupt is received, software must update the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field to the required value as per the temperature change.

If the EMIF_TEMPERATURE_ALERT_CONFIG[28] TA_SFEXITEN bit is set to 1, the EMIF polls for temperature change every time it exits self-refresh, active power-down, and precharge power-down modes.

Because the EMIF is performing a LPDDR2 mode register read, it needs information about how the LPDDR2 is connected. The EMIF_TEMPERATURE_ALERT_CONFIG[27:26] TA_DEVWDT and EMIF_TEMPERATURE_ALERT_CONFIG[25:24] TA_DEVCNT bit fields provide the necessary information to the EMIF for MRR data compare. For example, if TA_DEVWDT is set to 0, which indicates 8-bit devices are used, and if TA_DEVCNT is set to 2, which indicates four devices are used to form a 32-bit bus, the mask used for checking is 0b1111, that is, the EMIF expects data on each byte lane on a 32-bit bus.

10.2.4.15 Error Correction And Detection Feature

For data integrity, the EMIF supports ECC on the data written or read from the SDRAM and is enabled by programming the EMIF_ECC_CTRL_REG register. 7-bit ECC is calculated over 32-bit data when in 32-bit DDR mode. 6-bit ECC is calculated over 16-bit data when in 16-bit DDR mode. The ECC is calculated for all accesses that are within the address ranges protected by ECC. The address ranges are specified in the EMIF_ECC_ADDRESS_RANGE_1 and EMIF_ECC_ADDRESS_RANGE_2 registers. Both registers have identical bits and functionality. This provides flexibility allowing two non-overlapping memory regions to be ECC protected.

NOTE: For LPDDR2 ECC is supported only in 16-bit narrow mode.

The system must ensure that any burst access with starting address in the ECC protected region must not cross over to the un-protected region and vice-versa. The ECC is stored inside the SDRAM during writes. If a write access with byte count that is not a multiple of ECC quanta or with a non quanta aligned address is performed within the address range protected by ECC, the EMIF will send out a write ECC error interrupt. The EMIF will also report an error on the system response interface. In this case, the EMIF will perform the write to the SDRAM. However, the ECC value written to the SDRAM will be corrupted. The EMIF will also log the MConnID, MCmd and MBurstSeq for the first error transaction in the EMIF_OCP_ERROR_LOG register.

The ECC quanta is either 32-bit or 16-bit based on the EMIF_SDRAM_CONFIG[15:14] NARROW_MODE bit field. For 32-bit mode (128 bits per EMIF clock cycle), an ECC quanta is 32 bits. For 16-bit narrow mode (64 bits per EMIF clock cycle), the ECC quanta is 16 bits.

Once ECC is enabled the entire protected region must be initialized with data. These writes must be quanta-sized and quanta-aligned.

The ECC is read and verified during reads. For 1-bit ECC error in the data, the EMIF will correct the data and send it on the system return interface. The EMIF will log the starting address of the SDRAM burst in an internal 4 deep address FIFO. The internal FIFO will store the first four 1-bit ECC errors. The EMIF_1B_ECC_ERR_ADDR_LOG register will display the address on top of the internal FIFO. The software must write a 0x1 to the EMIF_1B_ECC_ERR_ADDR_LOG register to pop the FIFO and display the next address stored. For subsequent reads in the ECC regions, the FIFO will be loaded with the address for the next 1-bit ECC error if it is not full. It must be noted that no address comparison will be performed, that is, if a single address has ECC errors back-to-back, that address will be logged twice.

The number of 1-bit ECC errors can be counted using the EMIF_1B_ECC_ERR_CNT register. The EMIF also supports programming a threshold and a window in the EMIF_1B_ECC_ERR_THRSH register. The window is programmed in number of refresh periods. When the programmed window value is 0x0, that is, window is disabled, and the internal error count meets the programmed threshold, the EMIF will generate a 1-bit ECC error interrupt. When the programmed window value is non-zero, that is, window is enabled, the EMIF will generate a 1-bit ECC error interrupt only if the internal error count meets the programmed threshold in that window. The internal error count is reset every time the window expires. The software can use this to gauge the degree of 1-bit ECC errors occurring in the system.

For diagnosis, the EMIF supports a 1-Bit ECC data error distribution register (EMIF_1B_ECC_ERR_DIST_1) that represent whether an error has occurred in a given data channel location. This is advantageous to detect whether the errors are random or systemic. The distribution registers will be overlay of all 1-bit ECC errors until the software clears the register. Therefore, multiple bits could be set as a result of multiple 1-bit ECC errors occurring over multiple read accesses.

For 2-bit ECC errors in the data, the EMIF will generate a 2-bit ECC error interrupt. For any bit errors in the address, the EMIF will generate an address error interrupt. It must be noted that the EMIF will neither correct the data for these uncorrectable errors. Along with generating the interrupts, the EMIF will also report an error on the system return interface. In this case the EMIF will send the resultant data from the ECC correction logic. The read data received from the memory may have further been corrupted by the ECC correction logic since it will have attempted to correct the read data but failed due to uncorrectable error.

For all uncorrectable ECC errors listed above, the EMIF will log the starting address of the SDRAM burst in the EMIF_2B_ECC_ERR_ADDR_LOG register. This register will show the address of the first uncorrectable error. After the software clears the register, it will be loaded with the address for the next uncorrectable error.

In the event that the EMIF detects a single bit ECC error, although the error is corrected on the returned data, the data in the SDRAM is not corrected. It is the responsibility of the system software to correct the ECC error at that location. To the extent possible, the system software should correct multiple bit errors with the caveat that the returned data was not corrected but corrupted by the ECC correction logic.

10.2.4.16 Class of Service

The commands in the Command FIFO can be mapped to two classes of service namely 1 and 2. The mapping of commands to a particular class of service can be done based on the priority or the master ID. The mapping based on priority can be done by setting the appropriate values in the EMIF_PRIORITY_TO_CLASS_OF_SERVICE_MAPPING register. The mapping based on master ID can be done by setting the appropriate values of master ID and the masks in the EMIF_CONNECTION_ID_TO_CLASS_OF_SERVICE_1_MAPPING and EMIF_CONNECTION_ID_TO_CLASS_OF_SERVICE_2_MAPPING registers. There are 3 master ID and mask values that can be set for each class of service. In conjunction with the masks, each class of service can have a maximum of 144 master IDs mapped to it. For example, a master ID value of 0xFF along with a mask value of 0x3 will map all master IDs from 0xF8 to 0xFF to that particular class of service.

Each class of service has an associated latency counter (EMIF_COS_CONFIG[23:16] COS_COUNT_1 and EMIF_COS_CONFIG[15:8] COS_COUNT_2). When the latency counter for a command expires, that is, reaches the value programmed for the class of service that the command belongs to, that command is executed next. If there is more than one command that has expired latency counter, the command with the highest priority is executed first. One exception to this rule is, if the EMIF_COS_CONFIG[7:0] PR_OLD_COUNT value expires for the oldest command in the queue. That command is executed first irrespective of priority or class of service. This is done to prevent the continuous blocking effect.

The EMIF_COS_CONFIG[7:0] PR_OLD_COUNT value is used to identify when the oldest command in the command FIFO has timed out. At this point during the arbitration process, this oldest command is issued regardless of the priority of the other commands in the FIFO. This feature is disabled when writing 0x0 to the EMIF_COS_CONFIG[7:0] PR_OLD_COUNT bit field. After issuing the oldest command, the other remaining commands in the FIFO are reordered by age. The next oldest command in the FIFO is given highest priority again and issued after the EMIF_COS_CONFIG[7:0] PR_OLD_COUNT value expires. If a new value in the PR_OLD_COUNT bit field is written during counting, that is, before PR_OLD_COUNT expires, the counter keeps working but if this value is smaller the oldest command is issued sooner and if this value is larger the oldest command is issued later.

The master ID mapping allows the same master ID to be put in both class of service 1 and 2. Also, a transaction might belong to one class of service if viewed by master ID and might belong to another class of service if viewed by priority. In these cases, the command will belong to both class of service. The EMIF will try executing the command as soon as possible, when the smaller of the two counters (EMIF_COS_CONFIG[23:16] COS_COUNT_1 and EMIF_COS_CONFIG[15:8] COS_COUNT_2) expires.

10.2.4.17 Performance Counters

The EMIF_PERFORMANCE_COUNTER_1 and EMIF_PERFORMANCE_COUNTER_2 registers are used to monitor or calculate the EMIF Controller bandwidth and efficiency. These counters are able to count events such as accesses made to EMIF, Activate (ACT) commands sent to SDRAM, read and write accesses made to EMIF, and other events. Each counter counts independently of the other. In addition to the ability of events counting, the counters can also filter the events from a particular master or address space. The events counting and filter enabling are configured using the EMIF_PERFORMANCE_COUNTER_CONFIG register. The filter value used is configured through the EMIF_PERFORMANCE_COUNTER_MASTER_REGION_SELECT register. Each counter can be configured independently.

Table 10-30 lists all the events that can be counted and whether a filter can be applied to a particular event. A filter is applied to an event if the following bits are set to 0x1 for that event:

- For Performance Counter 1: EMIF_PERFORMANCE_COUNTER_CONFIG[15] CNTR1_MCONNID_EN and EMIF_PERFORMANCE_COUNTER_CONFIG[14] CNTR1_REGION_EN;
- For Performance Counter 2: EMIF_PERFORMANCE_COUNTER_CONFIG[31] CNTR2_MCONNID_EN and EMIF_PERFORMANCE_COUNTER_CONFIG[30] CNTR2_REGION_EN.

Table 10-30. Performance Counter Filter Configuration

CNTRn_CFG[1]	CNTRn_REGION_EN	CNTRn_MCONNID_EN	Description
0x0	0x0	0x0 or 0x1	Count the accesses made to EMIF
0x1	0x0	0x0 or 0x1	Count the Activate (ACT) commands sent to SDRAM
0x2	0x0 or 0x1	0x0 or 0x1	Count the read accesses made to EMIF
0x3	0x0 or 0x1	0x0 or 0x1	Count the write accesses made to EMIF
0x4	0x0	0x0	Count number of EMIF_FICLK clock cycles during which the local Command FIFO is full
0x5	0x0	0x0	Count number of EMIF_FICLK clock cycles during which the local Write Data FIFO is full
0x6	0x0	0x0	Count number of EMIF_FICLK clock cycles during which the local Read Data FIFO is full
0x7	0x0	0x0	Count number of EMIF_FICLK clock cycles during which the local Return Command FIFO is full
0x8	0x0 or 0x1	0x0 or 0x1	Count number of priority elevations
0x9	0x0	0x0	Count number of EMIF_FICLK clock cycles that a command was pending
0xA	0x0	0x0	Count number of EMIF_FICLK cycles used by the EMIF controller for reads and writes.
0xB - 0xF	0x0	0x0	Reserved for future use.

(1) n = 1 or 2

NOTE: When the MReqDebug qualifier is set to 0x1 for a particular local command, the performance counters are not incremented for that particular command if the CNTRn_CFG values are equal to 0x0, 0x1, 0x2, 0x3, or 0xA.

NOTE: The EMIF performance counters cannot distinguish between single access and burst access. In both cases they are incremented by 1. If the actual SDRAM bandwidth of an initiator has to be measured the EMIF performance counters may not be sufficient.

10.2.4.17.1 Performance Counters General Examples

- **General Example for Counting All Write Accesses made to EMIF**
  If the EMIF_PERFORMANCE_COUNTER_1 register is used to count all write accesses made to EMIF from master with connection ID equal to 0x86 (this is the system MMU) the following steps should be performed:

  - To enable the writes counting, the EMIF_PERFORMANCE_COUNTER_CONFIG[3:0] CNTR1_CFG bit field must be set to 0x3.
  - The EMIF_PERFORMANCE_COUNTER_MASTER_REGION_SELECT[15:8] MCONNID1 bit field must be set to 0x86.
  - To enable filtering, the EMIF_PERFORMANCE_COUNTER_CONFIG[15] CNTR1_MCONNID_EN bit must be set to 0x1.

    With this configuration EMIF_PERFORMANCE_COUNTER_1 counts every write made to the EMIF from master 0x86 to any address space. This does not include accesses from other masters and commands other than writes.

- **General Example for Counting Total Accesses made to EMIF**
  If the EMIF_PERFORMANCE_COUNTER_2 register is used to count total accesses made to EMIF regardless of the address space or master the following steps should be performed:
  - To enable counting of all accesses to the SDRAM, the EMIF_PERFORMANCE_COUNTER_CONFIG[19:16] CNTR2_CFG bit field must be set to 0x0.
  - To disable filtering, both the EMIF_PERFORMANCE_COUNTER_CONFIG[31] CNTR2_MCONNID_EN and EMIF_PERFORMANCE_COUNTER_CONFIG[30] CNTR2_REGION_EN bits must be set to 0x0.

    With this configuration EMIF_PERFORMANCE_COUNTER_2 counts every access made to the EMIF. This includes all accesses from all masters and to any address space.
- **General Example for Counting All Read Accesses made to EMIF**
  If the EMIF_PERFORMANCE_COUNTER_1 register is used to count all read accesses made to EMIF from master with connection ID equal to 0x86 (this is the system MMU) to address space 0x0 the following steps should be performed:
  - To enable the reads counting, the EMIF_PERFORMANCE_COUNTER_CONFIG[3:0] CNTR1_CFG bit field must be set to 0x2.
  - The EMIF_PERFORMANCE_COUNTER_MASTER_REGION_SELECT[15:8] MCONNID1bit field must be set to 0x86
  - The EMIF_PERFORMANCE_COUNTER_MASTER_REGION_SELECT[1:0] REGION_SEL1 bit field must be set to 0x0.
  - To enable filtering, both the EMIF_PERFORMANCE_COUNTER_CONFIG[15] CNTR1_MCONNID_EN and the EMIF_PERFORMANCE_COUNTER_CONFIG[14] CNTR1_REGION_EN bits must be set to 0x1.

    With this configuration, EMIF_PERFORMANCE_COUNTER_1 counts every read made to the EMIF from master 0x86 to address space 0x0. This does not include accesses from other masters or to other address spaces and does not include commands other than reads.

10.2.4.18 Forcing CKE to tri-state

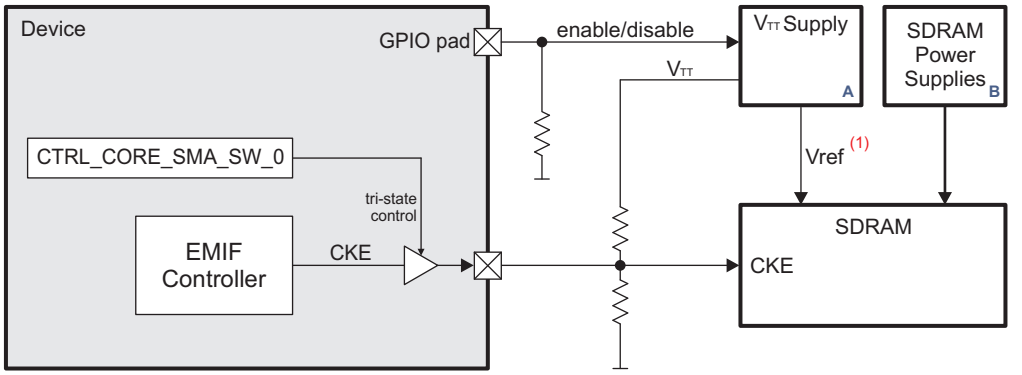
The CKE pad can be forced to tri-state when the CTRL_CORE_SMA_SW_0[0] CKE_ASSERTION bit is set to 0x1. This functionality facilitates fast resume by allowing a strong external pull-down resistor to hold the CKE memory pad low thus keeping the SDRAM in self-refresh while the device is completely powered off. Figure 10-10 and the following example sequence provide more details how this functionality can be used:

- When device is running configure EMIF for self refresh. As a result it drives CKE low.
- Disable V_{TT} supply (can be controlled through a device GPIO pad).
- Ramp down all power rails to the device. When power is already off, EMIF doesn't drive CKE low. The external pull-down does this instead. Note that only V_{TT} must be off. All SDRAM supplies (including V_{REF}) must be on.
- After these three steps the device is completely powered off and the SDRAM is in self-refresh. The waking-up from this state is system specific.
- To resume from self-refresh the CKE pad must be forced to tri-state by writing 0x1 to one of the CKE_ASSERTION bits previously mentioned. Then EMIF must be configured for self-refresh so that its state becomes consistent with the actual SDRAM state.
- Write 0x0 to the corresponding CKE_ASSERTION bit to release CKE driver from tri-state. This allows

EMIF to take control over CKE which is now driven low as EMIF has already been configured for self-refresh.

- Enable V_{TT} supply.
- Access the SDRAM to bring it out of self refresh and resume application.

Figure 10-10. Example for Using the CKE Tri-state Functionality



NOTE: In case the device is powered off but the SDRAM is in self-refresh (as previously described) it must be taken into account that the SDRAM RESET# signal has to be controlled externally to preserve the SDRAM contents. This is needed as ddr1_rst signal is not controlled by the CTRL_CORE_SMA_SW_0 register and therefore cannot be used.

10.2.5 EMIF Programming Guide

10.2.5.1 EMIF Low-Level Programming Models

This section describers the low-level hardware programming sequences for the configuration and use of the EMIF module.

10.2.5.1.1 Global Initialization

Table 10-31. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. See Chapter 3, *Power, Reset, and Clock Management*.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*
Device INTCs	Device INTCs must be configured to enable the interrupt request generation. For more information see Chapter 12 *Interrupt Controllers*

10.2.5.1.1.1 EMIF Configuration Sequence

Table 10-32 shows all steps needed to configure and use the EMIF.

Table 10-32. EMIF Configuration Sequence

Step	Register/ Bit Field	Value
Configure DPLL_DDR to the required frequency:		
· **IF** DPLL_DDR is locked:	CM_IDLEST_DPLL_DDR[0] ST_DPLL_CLK	0x1
Unlock DPLL_DDR	CM_CLKMODE_DPLL_DDR[2:0] DPLL_EN	0x6
· **ENDIF**		
· Configure the DPLL multiplier and divider factors	CM_CLKSEL_DPLL_DDR[18:8] DPLL_MULT and CM_CLKSEL_DPLL_DDR[6:0] DPLL_DIV	0x-
· Configure the M2 post-divider factor	CM_DIV_M2_DPLL_DDR[4:0] DIVHS	0x-
· Configure the H11 post-divider factor	CM_DIV_H11_DPLL_DDR[5:0] DIVHS	0x-
· Lock the DPLL_DDR	CM_CLKMODE_DPLL_DDR[2:0] DPLL_EN	0x7
Disable DLL Override	CM_DLL_CTRL[0] DLL_OVERRIDE	0x0
Configure the output impedance, slew rate and weak pull resistors of the DDR IO cells. For more information, see *Software Controls for the DDR3 I/O Cells*.	CTRL_CORE_CONTROL_DDRCACH1_0	0x-
	CTRL_CORE_CONTROL_DDRCH1_0	
	CTRL_CORE_CONTROL_DDRCH1_1	
	CTRL_CORE_CONTROL_DDRCH1_2	
If needed, configure the Vref-Generation Cells. For more information, see *Reference Voltage for the Device DDR3 Receivers*.	CTRL_CORE_CONTROL_DDRIO_0	0x-
Set the number of DQ samples required for read leveling	CTRL_WKUP_EMIF1_SDRAM_CONFIG_EXT[15:14] EMIF1_REG_PHY_NUM_OF_SAMPLES	0x3
Choose SDRAM read response on only one DQ bit during read leveling	CTRL_WKUP_EMIF1_SDRAM_CONFIG_EXT[12] EMIF1_REG_PHY_ALL_DQ_MPR_RD_RESP	0x0
Configure ODT for the device DDR IOs	CTRL_WKUP_EMIF1_SDRAM_CONFIG_EXT [6:5] EMIF1_PHY_RD_LOCAL_ODT	0x1 for 60 Ohms
		0x2 for 80 Ohms
		0x3 for 120 Ohms

Table 10-32. EMIF Configuration Sequence (continued)

Step	Register/ Bit Field	Value
IF ECC is used:		
Enable ECC	CTRL_WKUP_EMIF1_SDRAM_CONFIG_EXT[16] EMIF1_EN_ECC	0x1
ENDIF		
Based on the memory type other bits from CTRL_WKUP_EMIF1_SDRAM_CONFIG_EXT can also be configured.		
Read the EMIF_IODFT_TLGC register	EMIF_IODFT_TLGC	RD_VAL_1
Read the EMIF_TEMPERATURE_ALERT_CONFIG register	EMIF_TEMPERATURE_ALERT_CONFIG	RD_VAL_2
Read the EMIF_DDR_PHY_CONTROL_2 register	EMIF_DDR_PHY_CONTROL_2	RD_VAL_3
IF External warm reset or global warm software reset has occurred:	PRM_RSTST[5]EXTERNAL_WARM_RST or PRM_RSTST[1] GLOBAL_WARM_SW_RST	0x1 0x1
Reset the DDR PHY	EMIF_IODFT_TLGC[10] RESET_PHY	0x1
ENDIF		
Program the necessary ratio values to the EMIF_EXT_PHY_CONTROL_1 register	EMIF_EXT_PHY_CONTROL_1[29:20] PHY_REG_CTRL_SLAVE_RATIO2 (LPDDR2 only)	0x80 if PHY_INVERT_CLKOUT = 0x0 or 0x100 if PHY_INVERT_CLKOUT = 0x1
	EMIF_EXT_PHY_CONTROL_1[19:10] PHY_REG_CTRL_SLAVE_RATIO1 (DDR2/DDR3 only)	0x80 if PHY_INVERT_CLKOUT = 0x0 or 0x100 if PHY_INVERT_CLKOUT = 0x1
	EMIF_EXT_PHY_CONTROL_1[9:0] PHY_REG_CTRL_SLAVE_RATIO0 (DDR2/DDR3 only)	0x80 if PHY_INVERT_CLKOUT = 0x0 or 0x100 if PHY_INVERT_CLKOUT = 0x1
Program the shadow register of EMIF_EXT_PHY_CONTROL_1	EMIF_EXT_PHY_CONTROL_1_SHADOW	EMIF_EXT_PHY_CONTROL_1
If software leveling will be used, program registers EMIF_EXT_PHY_CONTROL_2 through EMIF_EXT_PHY_CONTROL_21 and their corresponding shadow registers **NOTE: Software leveling is not recommended to be used. Hardware leveling must be used instead.**	EMIF_EXT_PHY_CONTROL_2/EMIF_EXT_PHY_CONTROL_2_SHADOW through EMIF_EXT_PHY_CONTROL_21/EMIF_EXT_PHY_CONTROL_21_SHADOW	0x-

Table 10-32. EMIF Configuration Sequence (continued)

Step	Register/ Bit Field	Value
Program the necessary delay values to the EMIF_EXT_PHY_CONTROL_22 register	EMIF_EXT_PHY_CONTROL_22 [24:16] PHY_REG_FIFO_WE_IN_DELAY (1) (2)	Recommended value is 0x0
	EMIF_EXT_PHY_CONTROL_22 [8:0] PHY_REG_CTRL_SLAVE_DELAY (1) (2)	Recommended value is 0x0
Program the shadow register of EMIF_EXT_PHY_CONTROL_22	EMIF_EXT_PHY_CONTROL_22_SHADOW (1) (2)	EMIF_EXT_PHY_CONTROL_22
Program the necessary delay values to the EMIF_EXT_PHY_CONTROL_23 register	EMIF_EXT_PHY_CONTROL_23[24:16] PHY_REG_WR_DQS_SLAVE_DELAY (1) (2)	Recommended value is 0x0
	EMIF_EXT_PHY_CONTROL_23[8:0] PHY_REG_RD_DQS_SLAVE_DELAY (1) (2)	Recommended value is 0x0
Program the shadow register of EMIF_EXT_PHY_CONTROL_23	EMIF_EXT_PHY_CONTROL_23_SHADOW (1) (2)	EMIF_EXT_PHY_CONTROL_23
Program the EMIF_EXT_PHY_CONTROL_24 register	EMIF_EXT_PHY_CONTROL_24[30:24] REG_PHY_DQ_OFFSET_HI (3)	0x-
	EMIF_EXT_PHY_CONTROL_24[16] REG_PHY_GATELVL_INIT_MODE	Recommended value is 0x1
	EMIF_EXT_PHY_CONTROL_24[12] REG_PHY_USE_RANK0_DELAYS(2)	0x1
	EMIF_EXT_PHY_CONTROL_24[8:0] REG_PHY_WR_DATA_SLAVE_DELAY (1)(2)	Recommended value is 0x0
Program the shadow register of EMIF_EXT_PHY_CONTROL_24	EMIF_EXT_PHY_CONTROL_24_SHADOW	EMIF_EXT_PHY_CONTROL_24
Program the necessary offset ratio values to the EMIF_EXT_PHY_CONTROL_25 register	EMIF_EXT_PHY_CONTROL_25[27:21] REG_PHY_DQ_OFFSET3 (3)	0x-
	EMIF_EXT_PHY_CONTROL_25[20:14] REG_PHY_DQ_OFFSET2 (3)	0x-
	EMIF_EXT_PHY_CONTROL_25[13:7] REG_PHY_DQ_OFFSET1 (3)	0x-
	EMIF_EXT_PHY_CONTROL_25[6:0] REG_PHY_DQ_OFFSET0 (3)	0x-
Program the shadow register of EMIF_EXT_PHY_CONTROL_25	EMIF_EXT_PHY_CONTROL_25_SHADOW	EMIF_EXT_PHY_CONTROL_25
If hardware leveling (read-write leveling) will be used, program with zeros registers EMIF_EXT_PHY_CONTROL_26 through EMIF_EXT_PHY_CONTROL_35 and their corresponding shadow registers	EMIF_EXT_PHY_CONTROL_26/ EMIF_EXT_PHY_CONTROL_26_SHADOW through EMIF_EXT_PHY_CONTROL_35/ EMIF_EXT_PHY_CONTROL_35_SHADOW	0x0
Program the EMIF_EXT_PHY_CONTROL_36 register	EMIF_EXT_PHY_CONTROL_36	0x-
Program the shadow register of EMIF_EXT_PHY_CONTROL_36	EMIF_EXT_PHY_CONTROL_36_SHADOW	EMIF_EXT_PHY_CONTROL_36
Define the SDRAM refresh rate in the shadow register of EMIF_SDRAM_REFRESH_CONTROL	EMIF_SDRAM_REFRESH_CONTROL_SHADOW [15:0] REFRESH_RATE_SHDW	0x-

(1) These values are only used when CM_DLL_CTRL[0] DLL_OVERRIDE is set to 0x1. This is used only for debug purposes.
(2) The values of these fields do not depend on the board topology.
(3) These fields control the delay between the corresponding DQ byte lane and DQS/DQSN pair. Their values should correspond to delay of 1/4 clock cycle to center the DQ relative to the rising/falling edges of DQS/DQSN. Regardless of topology, it is recommended that all the DQ bits are skew matched to the corresponding DQS/DQSN pair.

Table 10-32. EMIF Configuration Sequence (continued)

Step	Register/ Bit Field	Value
Define the SDRAM refresh rate	EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE	REFRESH_RATE_SHDW
Disable SDRAM initialization and refreshes	EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS	0x1
Configure the timing parameters in EMIF_SDRAM_TIMING_1 (4)		0x-
Program the shadow register of EMIF_SDRAM_TIMING_1	EMIF_SDRAM_TIMING_1_SHADOW (4)	EMIF_SDRAM_TIMING_1
Configure the timing parameters in EMIF_SDRAM_TIMING_2 (4)		0x-
Program the shadow register of EMIF_SDRAM_TIMING_2	EMIF_SDRAM_TIMING_2_SHADOW (4)	EMIF_SDRAM_TIMING_2
Configure the timing parameters in EMIF_SDRAM_TIMING_3 (4)		0x-
Program the shadow register of EMIF_SDRAM_TIMING_3	EMIF_SDRAM_TIMING_3_SHADOW (4)	EMIF_SDRAM_TIMING_3
Program the EMIF_LPDDR2_NVM_TIMING (5) and EMIF_LPDDR2_NVM_TIMING_SHADOW (5) registers. **NOTE: These registers are not supported. They are kept only for code compatibility.**		0x0
Disable automatic power management	EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE	0x0
Define the number of DDR clock cycles after which the EMIF puts the external SDRAM in Power Down mode when EMIF is idle	EMIF_POWER_MANAGEMENT_CONTROL[15:12] PD_TIM	0x-
Define the number of DDR clock cycles after which the EMIF puts the external SDRAM in Self Refresh mode when EMIF is idle	EMIF_POWER_MANAGEMENT_CONTROL[7:4] SR_TIM	0x-
Program the shadow register of EMIF_POWER_MANAGEMENT_CONTROL	EMIF_POWER_MANAGEMENT_CONTROL_SHADOW	EMIF_POWER_MANAGEMENT_CONTROL
Configure the System and MPU maximum number of commands in the command FIFO	EMIF_OCP_CONFIG[27:24] SYS_THRESH_MAX	0x-
	EMIF_OCP_CONFIG[23:20] MPU_THRESH_MAX	0x-
Program the EMIF_IODFT_TLGC register	EMIF_IODFT_TLGC	RD_VAL_1
Determine the required wait time after a phy_dll_calib is generated before another command can be sent	EMIF_DLL_CALIB_CTRL[19:16] ACK_WAIT	0x-
Determine the interval between phy_dll_calib generation	EMIF_DLL_CALIB_CTRL[8:0] DLL_CALIB_INTERVAL	0x-
Program the shadow register of EMIF_DLL_CALIB_CTRL	EMIF_DLL_CALIB_CTRL_SHADOW	EMIF_DLL_CALIB_CTRL
Define the interval (number of refresh periods) between ZQCS commands	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[15:0] ZQ_REFINTERVAL	0x-
Define the number of ZQCS intervals that build the ZQCL duration	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[17:16] ZQ_ZQCL_MULT	0x-
Enable issuing of ZQCL on Self-Refresh, Active Power-Down, and Precharge Power-Down exit	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[28] ZQ_SFEXITEN	0x1
Enable ZQ calibration for CS0	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[30] ZQ_CS0EN	0x1
Program the EMIF_TEMPERATURE_ALERT_CONFIG register	EMIF_TEMPERATURE_ALERT_CONFIG	RD_VAL_2

(4) Values loaded in these registers depend on OPP.

(5) Writes to these registers do not have any impact. It's up to the user to skip these steps.

Table 10-32. EMIF Configuration Sequence (continued)

Step	Register/ Bit Field	Value
Program the EMIF_READ_WRITE_LEVELING_RAMP_WINDOW register. **NOTE: Incremental leveling is not supported on this device.**		0x-

IF special (6) use-cases:		

(6) In some special use-cases with features like suspend to RAM where EMIF may be reset but SDRAM content needs to be maintained correctly across such an event. In such cases, when EMIF is configured at first boot with hardware leveling enabled, the hardware leveling output from EMIF_PHY_STATUS_x registers is copied to the EMIF_EXT_PHY_CONTROL_x registers. When EMIF comes back from a reset state and needs to be reconfigured without losing SDRAM content, the EMIF_READ_WRITE_LEVELING_RAMP_CONTROL[31] RDWRLVL_EN bit must be 0 and hardware leveling must not be triggered. In this case, the EMIF_EXT_PHY_CONTROL_2 through EMIF_EXT_PHY_CONTROL_21 registers take effect. Here it is expected that SDRAM is moved to self-refresh mode before EMIF enters reset state and SDRAM content is maintained correctly by appropriate circuitry external to the SoC.

Table 10-32. EMIF Configuration Sequence (continued)

Step	Register/ Bit Field	Value
Copy EMIF_PHY_STATUS_12 through EMIF_PHY_STATUS_16 to EMIF_EXT_PHY_CONTROL_2 through EMIF_EXT_PHY_CONTROL_6		
Copy EMIF_PHY_STATUS_7 through EMIF_PHY_STATUS_11 to EMIF_EXT_PHY_CONTROL_7 through EMIF_EXT_PHY_CONTROL_11		
Copy EMIF_PHY_STATUS_17 through EMIF_PHY_STATUS_26 to EMIF_EXT_PHY_CONTROL_12 through EMIF_EXT_PHY_CONTROL_21		
Mask read data eye training, DQS gate training and write leveling training to disable the use of registers EMIF_PHY_STATUS_7 through EMIF_PHY_STATUS_26 registers	EMIF_DDR_PHY_CONTROL_1[27:25]	0x7
Program the shadow register of EMIF_DDR_PHY_CONTROL_1	EMIF_DDR_PHY_CONTROL_1_SHADOW	EMIF_DDR_PHY_CONTROL_1
Disable read-write leveling	EMIF_READ_WRITE_LEVELING_RAMP_CONTROL[31] RDWRLVLFULL_START	0x0
ENDIF		
Clear the ECC control register	EMIF_ECC_CTRL_REG	0x0
ENDIF		

10.2.5.1.2 Operational Modes Configuration

10.2.5.1.2.1 EMIF Output Impedance Calibration Mode

Table 10-33. EMIF Output Impedance Calibration Mode

Step	Register/ Bit Field / Programming Model	Value
Enable ZQ callibration for CS0.	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[30] ZQ_CS0EN	0x1
Define the interval (number of refresh periods) between ZQCS commands.	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[15:0] ZQ_REFINTERVAL	0x-
Define the number of ZQCL durations that build the ZQINIT duration.	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[19:18] ZQ_ZQINIT_MULT	0x-
Define the number of ZQCS intervals that build the ZQCL duration.	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[17:16] ZQ_ZQCL_MULT	0x-
Enable the issuing of ZQ-Long Command on Self-Refresh, Active Power-Down, and Precharge Power-Down exit.	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[28] ZQ_SFEXITEN	0x1

10.2.5.1.2.2 EMIF SDRAM Self-Refresh

Table 10-34. EMIF SDRAM Self-Refresh Entering

Step	Register/ Bit Field / Programming Model	Value
Define the number of DDR clock cycles after which the EMIF puts the external SDRAM in Self Refresh mode, when EMIF is idle.	EMIF_POWER_MANAGEMENT_CONTROL[7:4] SR_TIM	0x-
Enable the Self-Refresh mode	EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE	0x2
Write the shadow register of EMIF_POWER_MANAGEMENT_CONTROL	EMIF_POWER_MANAGEMENT_CONTROL_SHADOW	0x-

Table 10-35. EMIF SDRAM Self-Refresh Exiting

Step	Register/ Bit Field / Programming Model	Value
Change LP_MODE bitfield from 0x2 to any value.	EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE	0x-
Write the shadow register of EMIF_POWER_MANAGEMENT_CONTROL	EMIF_POWER_MANAGEMENT_CONTROL_SHADOW	0x-

10.2.5.1.2.3 EMIF SDRAM Power-Down Mode

Table 10-36. EMIF SDRAM Power-Down Mode Entering

Step	Register/ Bit Field / Programming Model	Value
Define the number of DDR clock cycles after which the EMIF puts the external SDRAM in Power Down mode, when EMIF is idle.	EMIF_POWER_MANAGEMENT_CONTROL[15:12] PD_TIM	0x-
Enable (enter) the Power-down mode	EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE	0x4
Write the shadow register of EMIF_POWER_MANAGEMENT_CONTROL	EMIF_POWER_MANAGEMENT_CONTROL_SHADOW	0x-

Table 10-37. EMIF SDRAM Power-Down Mode Exiting

Step	Register/ Bit Field / Programming Model	Value
Change LP_MODE bitfield from 0x4 to any value.	EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE	0x-
Write the shadow register of EMIF_POWER_MANAGEMENT_CONTROL	EMIF_POWER_MANAGEMENT_CONTROL_SHADOW	0x-

10.2.5.1.2.4 EMIF LPDDR2-SDRAM Deep Power-Down Mode

Table 10-38. EMIF LPDDR2-SDRAM Deep Power-Down Mode Entering

Step	Register/ Bit Field / Programming Model	Value
Define the number of DDR clock cycles after which the EMIF puts the external SDRAM in Power saving mode, when EMIF is idle.	EMIF_POWER_MANAGEMENT_CONTROL[3:0] CS_TIM	0x-
Enable (enter) the Deep Power-Down mode	EMIF_POWER_MANAGEMENT_CONTROL[11] DPD_EN	0x1
Write the shadow register of EMIF_POWER_MANAGEMENT_CONTROL	EMIF_POWER_MANAGEMENT_CONTROL_SHADOW	0x-

Table 10-39. EMIF LPDDR2-SDRAM Deep Power-Down Mode Exiting

Step	Register/ Bit Field / Programming Model	Value
Clear DPD_EN bit.	EMIF_POWER_MANAGEMENT_CONTROL[11] DPD_EN	0
Write the shadow register of EMIF_POWER_MANAGEMENT_CONTROL	EMIF_POWER_MANAGEMENT_CONTROL_SHADOW	0x-

10.2.5.1.2.5 LPDDR2 Temperature Monitoring Mode

Table 10-40. LPDDR2 Temperature Monitoring Mode

Step	Register/ Bit Field / Programming Model	Value
Determine which chip-select (0 or 1) is used for temperature alert polling	EMIF_TEMPERATURE_ALERT_CONFIG[31] TA_CS1EN EMIF_TEMPERATURE_ALERT_CONFIG[30] TA_CS0EN	0x-
Define the interval (number of refresh periods) between temperature alert polls.	EMIF_TEMPERATURE_ALERT_CONFIG[21:0] TA_REFINTERVAL	0x-
Define the width of the physical memory device	EMIF_TEMPERATURE_ALERT_CONFIG[27:26] TA_DEVWDT	0x-
Define which external byte lanes contain a device for temperature monitoring (which devices to be polled).	EMIF_TEMPERATURE_ALERT_CONFIG[25:24] TA_DEVCNT	0x-
(Optional) Enable the issuing of a temperature alert poll on Self-Refresh exit (poll for temperature change every time EMIF exits Self-Refresh, Active Power-Down, and Precharge Power-Down modes).	EMIF_TEMPERATURE_ALERT_CONFIG[28] TA_SFEXITEN	0x1
Enable System L3 interrupt for SDRAM temperature alert.	EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_SET[1] EN_TA_SYS	0x1

10.2.5.1.2.6 EMIF ECC Configuration

Table 10-41. EMIF ECC Configuration

Step	Register/ Bit Field / Programming Model	Value
Before configuring the EMIF ECC registers, the ECC must be enabled from the Control Module	CTRL_WKUP_EMIF1_SDRAM_CONFIG_EXT [16] EMIF1_EN_ECC	0x1
Configure the address ranges which have to be ECC protected	EMIF_ECC_ADDRESS_RANGE_1 and EMIF_ECC_ADDRESS_RANGE_2 (1)	0x-
Enable the first ECC protected address range	EMIF_ECC_CTRL_REG[0] REG_ECC_ADDR_RGN_1_EN	0x1
Enable the second ECC protected address range	EMIF_ECC_CTRL_REG[1] REG_ECC_ADDR_RGN_2_EN (1)	0x1
Configure whether the EMIF accesses within the address ranges defined by EMIF_ECC_ADDRESS_RANGE_1 and EMIF_ECC_ADDRESS_RANGE_2 are ECC protected (=0x1) or the EMIF accesses outside these address ranges are ECC protected (=0x0).	EMIF_ECC_CTRL_REG[30] REG_ECC_ADDR_RGN_PROT	0x-
(Optional) Configure the thresholds to generate 1-bit error interrupt	EMIF_1B_ECC_ERR_THRSH	0x-
Enable ECC	EMIF_ECC_CTRL_REG[31] REG_ECC_EN	0x1
Initialize the ECC protected memory regions with quanta-sized and quanta-aligned data		
Clear the status flags and other status history	EMIF_1B_ECC_ERR_CNT	Read the register value and write it back to clear
	EMIF_1B_ECC_ERR_DIST_1	0xFFFF FFFF
	EMIF_2B_ECC_ERR_ADDR_LOG	0x1
	EMIF_SYSTEM_OCP_INTERRUPT_STATUS [5:3]	0x7

(1) It is not mandatory to enable both address ranges. This is provided for flexibility allowing two non-overlapping ECC protected regions to be created.

NOTE: The xxx_RATIO8 and xxx_RATIO9 bit fields are associated with the ECC data PHY and must be loaded with values same as in the xxx_RATIO0 through xxx_RATIO7 bit fields from registers EMIF_EXT_PHY_CONTROL_xx. This must be taken into account to avoid unexpected behavior and possible errors, if ECC is used.

10.2.6 EMIF Register Manual

NOTE: LPDDR2 is not supported on the DRA78x family of devices.

Table 10-42 lists the EMIF instance.

10.2.6.1 EMIF Instance Summary

Table 10-42. EMIF Instance Summary

Module Name	Base Address	Size
EMIF	0x4C00 0000	16 MiB

10.2.6.2 EMIF Registers

Many register values are programmed with full-speed DDR clock cycles, whereas EMIF always runs at half the speed of this clock. Because EMIF is only capable of decrementing these values at half speed (taking into account the minus 1 programming model) the following model applies for data issued on a lower bus:

- REG_VALUE = 0 → 2 DDR clocks
- REG_VALUE = 1 → 2 DDR clocks
- REG_VALUE = 2 → 4 DDR clocks
- REG_VALUE = 3 → 4 DDR clocks
- REG_VALUE = 4 → 6 DDR clocks
- REG_VALUE = 5 → 6 DDR clocks
- REG_VALUE = 6 → 8 DDR clocks
- REG_VALUE = 7 → 8 DDR clocks

Activate and deactivate commands use the upper bus. Register values associated with these operations follow the general rule:

- REG_VALUE = 0 → 1 DDR clocks
- REG_VALUE = 1 → 2 DDR clocks
- REG_VALUE = 2 → 2 DDR clocks
- REG_VALUE = 3 → 4 DDR clocks
- REG_VALUE = 4 → 4 DDR clocks
- REG_VALUE = 5 → 6 DDR clocks
- REG_VALUE = 6 → 6 DDR clocks

NOTE: Shadow registers are loaded on any frequency change or SidleReq/SidleAck transition at the point where the EMIF has put SDRAM into self-refresh mode.

Table 10-43 summarizes the EMIF register mapping.

10.2.6.2.1 EMIF Register Summary

Table 10-43. EMIF Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	EMIF Physical Address

Table 10-46. EMIF_STATUS

Address Offset	0x0000 0004		
Physical Address	0x4C00 0004	**Instance**	EMIF
Description	SDRAM Status Register (STATUS)		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BE	DUAL_CLK_MODE	FAST_INIT	RESERVED																					RDLVLGATETO	RDLVLTO	WRLVLTO	RESERVED	PHY_DLL_READY	RESERVED		

Bits	Field Name	Description	Type	Reset
31	BE	Big endian mode select for 8 and 16-bit devices, set to 1 for big endian or 0 for little endian operation. In current implementation, only 32-bit devices are supported - this bit is don't care.	R	0
30	DUAL_CLK_MODE	Dual Clock mode. Defines whether the EMIF_L3_ICLK and EMIF_FICLK clock are asynchronous. EMIF_L3_ICLK and EMIF_FICLK clock are asynchronous, if set to 1.	R	0
29	FAST_INIT	Fast Init. Defines whether the EMIF fast initialization mode has been enabled. Fast initialization is enabled if set to 1.	R	0
28:7	RESERVED	Reserved	R	0x00 0000
6	RDLVLGATETO	Read DQS Gate Training Timeout. Value of 1 indicates read DQS gate training has timed out because read DQS gate training done was not received from the PHY.	R	0
5	RDLVLTO	Read Data Eye Training Timeout. Value of 1 indicates read data eye training has timed out because read data eye training done was not received from the PHY.	R	0
4	WRLVLTO	Write Leveling Timeout. Value of 1 indicates write leveling has timed out because write leveling done was not received from the PHY.	R	0
3	RESERVED		R	0
2	PHY_DLL_READY	DDR PHY Ready. The DDR PHY is ready for normal operation, if set to 1.	R	0
1:0	RESERVED	Reserved	R	0x0

Table 10-48. EMIF_SDRAM_CONFIG

Address Offset	0x0000 0008		
Physical Address	0x4C00 0008	**Instance**	EMIF
Description	SDRAM Config Register. A write to this register will cause the EMIF to start the SDRAM initialization sequence. **CAUTION:** This register is loaded with values by control module at device reset.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SDRAM_TYPE			IBANK_POS		DDR_TERM			DDR2_DDQS		DYN_ODT		DDR_DISABLE_DLL		SDRAM_DRIVE		CWL		NARROW_MODE		CL		ROWSIZE		IBANK			RESERVED	PAGESIZE			

Bits	Field Name	Description	Type	Reset
31:29	SDRAM_TYPE	SDRAM Type selection. This field is loaded from e-fuse. Set to 2 for DDR2 Set to 3 for DDR3 Set to 4 for LPDDR2 All other values are reserved. **Please check the device data manual for supported DDR memory types.**	RW	0x0
28:27	IBANK_POS	Internal bank position. See Section 10.2.4.12, *SDRAM Address Mapping*.	RW	0x0
26:24	DDR_TERM	DDR3 termination resistor value. Set to 0 to disable termination. For DDR3, set to 1 for RZQ/4, set to 2 for RZQ/2, set to 3 for RZQ/6, set to 4 for RZQ/12, and set to 5 for RZQ/8. All other values are reserved.	RW	0x0
23	DDR2_DDQS	Differential DQS enable. Set to 0 for single ended DQS (**Not supported**). Set to 1 for differential DQS.	RW	0
22:21	DYN_ODT	DDR3 Dynamic ODT. **Not supported**. Set to 0 to turn off dynamic ODT.	RW	0x0
20	DDR_DISABLE_DLL	Disable DLL select. Set to 1 to disable DLL inside SDRAM.	RW	0
19:18	SDRAM_DRIVE	SDRAM drive strength. For DDR2, set to 0 for normal, and set to 1 for weak drive strength. For DDR3, set to 0 for RZQ/6 and set to 1 for RZQ/7. All other values are reserved.	RW	0x0
17:16	CWL	DDR3 CAS Write latency. Value of 0, 1, 2, and 3 (CAS write latency of 5, 6, 7, and 8) are supported. Use the lowest value supported for best performance. All other values are reserved.	RW	0x0
15:14	NARROW_MODE	SDRAM data bus width. Set to 0 for 32-bit data bus width. Set to 1 for 16-bit data bus width. All other values are reserved.	RW	0x0

Bits	Field Name	Description	Type	Reset
13:10	CL	CAS Latency (referred to as read latency (RL) in some SDRAM specs). The value of this field defines the CAS latency to be used when accessing connected SDRAM devices. Values of 2, 3, 4 and 5 (CAS latency of 2, 3, 4 and 5) are supported for DDR2. Values of 2, 4, 6, 8, 10, 12 and 14 (CAS latency of 5, 6, 7, 8, 9, 10 and 11) are supported for DDR3. Values of 3, 4, 5, 6, 7, and 8 (CAS latency of 3, 4, 5, 6, 7, and 8) are supported for LPDDR2-SDRAM. The write latency (WL) is tied to the RL for the LPDDR2. See the LPDDR2 SDRAM standard. All other values are reserved.	RW	0x0
9:7	ROWSIZE	Row Size. Defines the number of row address bits of connected SDRAM devices. Set to 0 for 9 row bits, Set to 1 for 10 row bits, Set to 2 for 11 row bits, Set to 3 for 12 row bits, Set to 4 for 13 row bits, Set to 5 for 14 row bits, Set to 6 for 15 row bits, Set to 7 for 16 row bits. This field is only used when EMIF_SDRAM_CONFIG[28:27] IBANK_POS field is set to 1, 2, or 3 or EBANK_POS field in EMIF_SDRAM_CONFIG_2 register is set to 1.	RW	0x0
6:4	IBANK	Internal Bank setup. Defines number of banks inside connected SDRAM devices. Set to 0 for 1 bank, Set to 1 for 2 banks, Set to 2 for 4 banks, Set to 3 for 8 banks. All other values are reserved.	RW	0x0
3	RESERVED		R	0
2:0	PAGESIZE	Page Size. Defines the internal page size of connected SDRAM devices. Set to 0 for 256-word page (8 column bits), Set to 1 for 512-word page (9 column bits), Set to 2 for 1024-word page (10 column bits), Set to 3 for 2048-word page (11 column bits). All other values are reserved.	RW	0x0

Table 10-52. EMIF_SDRAM_REFRESH_CONTROL

Address Offset	0x0000 0010		
Physical Address	0x4C00 0010	**Instance**	EMIF
Description	SDRAM Refresh Control Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
INITREF_DIS	RESERVED	SRT	ASR	RESERVED	PASR			RESERVED								REFRESH_RATE															

Bits	Field Name	Description	Type	Reset
31	INITREF_DIS	Initialization and Refresh disable. When set to 1, EMIF will disable SDRAM initialization and refreshes, but will carry out SDRAM write/read transactions.	RW	1
30	RESERVED		R	0
29	SRT	DDR3 Self Refresh temperature range. Set to 0 for normal operating temperature range and set to 1 for extended operating temperature range when the ASR field is set to 0. This bit must be set to 0 if the ASR field is set to 1. A write to this field will cause the EMIF to start the SDRAM initialization sequence.	RW	0
28	ASR	DDR3 Auto Self Refresh enable. Set to 1 for auto Self Refresh enable. Set to 0 for manual Self Refresh reference indicated by the SRT field. A write to this field will cause the EMIF to start the SDRAM initialization sequence.	RW	0
27	RESERVED		R	0
26:24	PASR	Partial Array Self Refresh. These bits get loaded into the Extended Mode Register of DDR3 during initialization. For DDR3, set to 0 for full array, set to 1 or 5 for 1/2 array, set to 2 or 6 for 1/4 array, set to 3 or 7 for 1/8 array, and set to 4 for 3/4 array to be refreshed. All other values are reserved. A write to this field will cause the EMIF to start the SDRAM initialization sequence.	RW	0x0
23:16	RESERVED		R	0x00
15:0	REFRESH_RATE	Refresh Rate. Value in this field is used to define the rate at which connected SDRAM devices will be refreshed. SDRAM refresh rate = REFRESH_RATE / EMIF_PHY_FCLK. A 533-MHz DDR clock rate system that requires a 7.8 µs refresh rate would need 7.8 × 533 = 4157 or 0x103D value to be written. To avoid lock-up situations, the programmer must not program REFRESH_RATE < (6 × EMIF_SDRAM_TIMING_3[12:4] T_RFC). **NOTE:** The SDRAM refresh rate can be changed on-the-fly by writing to this field. When changing the SDRAM refresh rate all timing parameters that use the refresh rate value have to be recalculated. For example, tRASmax specified in the EMIF_SDRAM_TIMING_3[3:0] T_RAS_MAX field must be recalculated.	RW	0x0000

Table 10-56. EMIF_SDRAM_TIMING_1

Address Offset	0x0000 0018		
Physical Address	0x4C00 0018	**Instance**	EMIF
Description	SDRAM Timing 1 Register. If this register is byte written, care must be taken that all the fields are written before performing any accesses to the SDRAM.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
T_RTW			T_RP				T_RCD				T_WR				T_RAS					T_RC						T_RRD			T_WTR		

Bits	Field Name	Description	Type	Reset
31:29	T_RTW	Minimum number of DDR clock cycles between Read to Write data phases, minus one.	RW	0x0
28:25	T_RP	Minimum number of DDR clock cycles from Precharge to Activate or Refresh, minus one.	RW	0x0
24:21	T_RCD	Minimum number of DDR clock cycles from Activate to Read or Write, minus one.	RW	0x0

Bits	Field Name	Description	Type	Reset
20:17	T_WR	Minimum number of DDR clock cycles from last Write transfer to Precharge, minus one.	RW	0x0
16:12	T_RAS	Minimum number of DDR clock cycles from Activate to Precharge, minus one. T_RAS value needs to be bigger than or equal to T_RDC value.	RW	0x00
11:6	T_RC	Minimum number of DDR clock cycles from Activate to Activate, minus one.	RW	0x00
5:3	T_RRD	Minimum number of DDR clock cycles from Activate to Activate for a different bank, minus one. For an 8-bank, this field must be equal to ((tFAW / (4 × tCK)) - 1).	RW	0x0
2:0	T_WTR	Minimum number of DDR clock cycles from last Write to Read, minus one.	RW	0x0

Table 10-64. EMIF_SDRAM_TIMING_3

Address Offset	0x0000 0028		
Physical Address	0x4C00 0028	**Instance**	EMIF
Description	SDRAM Timing 3 Register. If this register is byte written, care must be taken that all the fields are written before performing any accesses to the SDRAM.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
T_PDLL_UL				RESERVED				T_CKESR			ZQ_ZQCS					T_TDQSCKMAX			T_RFC										T_RAS_MAX						

Bits	Field Name	Description	Type	Reset
31:28	T_PDLL_UL	Minimum number of DDR clock cycles for PHY DLL to unlock. A value of N will be equal to N x 128 clocks.	RW	0x0
27:24	RESERVED		R	0x0
23:21	T_CKESR	Minimum number of DDR clock cycles for which SDRAM must remain in Self Refresh, minus one.	RW	0x0
20:15	ZQ_ZQCS	Number of DDR clock cycles for a ZQCS command, minus one.	RW	0x00
14:13	T_TDQSCKMAX	Number of DDR clock that satisfies tDQSCKmax for LPDDR2, minus one.	RW	0x0
12:4	T_RFC	Minimum number of DDR clock cycles from Refresh or Load Mode to Refresh or Activate, minus one.	RW	0x000
3:0	T_RAS_MAX	Maximum number of REFRESH_RATE intervals from Activate to Precharge command. This field must be equal to ((tRASmax / tREFI)-1) rounded down to the next lower integer. Value for T_RAS_MAX can be calculated as follows: If tRASmax = 120 us and tREFI = 15.7 us, then T_RAS_MAX = ((120/15.7)-1) = 6.64. Round down to the next lower integer. Therefore, the programmed value must be 6.	RW	0x0

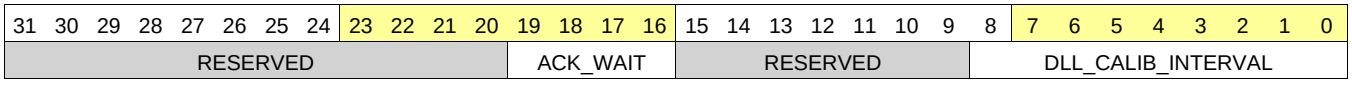
Table 10-100. EMIF_DLL_CALIB_CTRL

Address Offset	0x0000 0098		
Physical Address	0x4C00 0098	**Instance**	EMIF
Description	Control register to force idle window time to generate a phy_dll_calib that can be used for updating PHY DLLs during voltage ramps. NOTE: Should always be loaded via the shadow register.		
Type	RW		



Bits	Field Name	Description	Type	Reset
31:20	RESERVED		R	0x000
19:16	ACK_WAIT	The ack_wait determines the required wait time after a phy_dll_calib is generated before another command can be sent. Value program is in terms of EMIF_FICLK cycle count. **CAUTION:** 5 must be the minimum value ever programmed.	RW	0x9
15:9	RESERVED		R	0x00

Bits	Field Name	Description	Type	Reset
8:0	DLL_CALIB_INTERVAL	This field determines the interval between phy_dll_calib generation. This value is multiplied by a precounter of 16 EMIF_FICLK cycles. Program this field one less the value you are targeting; program 1 to achieve interval of 2 (minimum interval supported). Programming zero turns off function. Note the final intervals between dll_calib generation is also a function of ACK_WAIT. Final periodic interval is calculated by: ((DLL_CALIB_INTERVAL + 1) × 16) + ACK_WAIT	RW	0x000

30:24	RDWRLVLINC_PRE	Incremental leveling pre-scalar in number of refresh periods. The value programmed is minus one the required value. Refresh period is defined by REFRESH_RATE in EMIF_SDRAM_REFRESH_CONTROL register. **NOTE: Incremental leveling is not supported on this device.**	RW	0x00

Bits	Field Name	Description	Type	Reset
23:16	RDLVLINC_INT	Incremental read data eye training interval. Number of RDWRLVLINC_PRE intervals between incremental read data eye training. A value of 0 will disable incremental read data eye training. **NOTE: Incremental leveling is not supported on this device.**	RW	0x00
15:8	RDLVLGATEINC_INT	Incremental read DQS gate training interval. Number of RDWRLVLINC_PRE intervals between incremental read DQS gate training. A value of 0 will disable incremental read DQS gate training. **NOTE: Incremental leveling is not supported on this device.**	RW	0x00
7:0	WRLVLINC_INT	Incremental write leveling interval. Number of RDWRLVLINC_PRE intervals between incremental write leveling. A value of 0 will disable incremental write leveling. **NOTE: Incremental leveling is not supported on this device.**	RW	0x00

Table 10-126. EMIF_DDR_PHY_CONTROL_1

Address Offset	0x0000 00E4		
Physical Address	0x4C00 00E4	**Instance**	EMIF
Description	PHY control register 1		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED				RDLVL_MASK	RDLVLGATE_MASK	WRLVL_MASK	RESERVED			PHY_HALF_DELAYS	PHY_CLK_STALL_LEVEL	PHY_DIS_CALIB_RST	PHY_INVERT_CLKOUT	PHY_DLL_LOCK_DIFF								PHY_FAST_DLL_LOCK	RESERVED				READ_LATENCY						

Bits	Field Name	Description	Type	Reset
31:28	RESERVED	Reserved	RW	0x0
27	RDLVL_MASK	Writing a 1 to this field will mask read data eye training during full leveling command, plus drives reg_phy_use_rd_data_eye_level control low to allow user to use programmed ratio values.	RW	0
26	RDLVLGATE_MASK	Writing a 1 to this field will mask dqs gate training during full leveling command, plus drives reg_phy_use_rd_dqs_level control low to allow user to use programmed ratio values.	RW	0
25	WRLVL_MASK	Writing a 1 to this field will mask write leveling training during full leveling command, plus drives reg_phy_use_wr_level control low to allow user to use programmed ratio values.	RW	0
24:22	RESERVED	Reserved	RW	0x0
21	PHY_HALF_DELAYS	Adjust slave delay line delays to support 2× mode 1: 2× mode (MDLL clock is half the rate of PHY) 0: 1× mode (MDLL clock rate is same as PHY)	RW	0

Bits	Field Name	Description	Type	Reset
20	PHY_CLK_STALL_LEVEL	Enable variable idle value for delay lines. Enable during normal operations to avoid differential aging in the delay lines.	RW	0
19	PHY_DIS_CALIB_RST	Disable the dll_calib (internally generated) signal from resetting the Read Capture FIFO pointers and portions of data PHYs. Debug only. Note: dll_calib is generated by 1. EMIF_MISC_REG[0] DLL_CALIB_OS set to 1,or 2. by the PHY when it detects that the clock frequency variation has exceeded the bounds set by PHY_DLL_LOCK_DIFF or 3. periodically throughout the leveling process.	RW	0
18	PHY_INVERT_CLKOUT	Inverts the polarity of DRAM clock. 0: core clock is passed on to DRAM 1: inverted core clock is passed on to DRAM	RW	0
17:10	PHY_DLL_LOCK_DIFF	The maximum number of delay line taps variation while maintaining the master DLL lock. When the PHY is in locked state and the variation on the clock exceeds the variation indicated by this field, the lock signal is de-asserted and a dll_calib signal is generated. To prevent the dll_calib signal from being asserted in the middle of traffic when the clock jitter exceeds the variation, this register needs to be set to a value which will ensure that the lock will not be lost. Recommended value is 16.	RW	0x02
9	PHY_FAST_DLL_LOCK	Controls master DLL to lock fast or average logic must be part of locking process. Set to 1 before OPP transition commences, and set back to 0 after OPP transition completes. 1: MDLL lock is asserted based on single sample 0: MDLL lock is asserted based on average of 16 samples.	RW	0
8:5	RESERVED	Reserved	RW	0x00
4:0	READ_LATENCY	This field defines the read latency for the read data from SDRAM in number of DDR clock cycles. This field is used by the EMIF as well as the PHY. READ_LATENCY = RL + reg_phy_rdc_we_to_re -1. EMIF uses above equation to calculate reg_phy_rdc_we_to_re and forward it to the PHY. For DDR3, the true RL is used, not the decoded value. See JEDEC spec. The write latency (WL) is tied to the RL for the LPDDR2. See the LPDDR2 SDRAM standard.	RW	0x01E

REG_1B_ECC_ERR_DIST_1																															

Bits	Field Name	Description	Type	Reset
31:0	REG_1B_ECC_ERR_DIST_1	1-bit ECC error distribution over data bus bit 31:0. A value of 1 on a bit indicates 1-bit error on the corresponding bit on the data bus. Writing a 1 to any bit will clear that bit. Writing a 0 has no effect.	RW	0x0

REG_1B_ECC_ERR_ADDR																															

Bits	Field Name	Description	Type	Reset
31:0	REG_1B_ECC_ERR_ADDR	1-bit ECC error address. Most significant bits of the starting address(es) related to the SDRAM reads that had a 1-bit ECC error. This field displays up to four addresses logged in the 4 deep address logging FIFO. Writing a 0x1 will pop one element of the FIFO. Writing a 0x2 will pop all elements of the FIFO. Writing any other alue will have no effect.	RW	0x0

Description	Data macro 1, write DQ (data) DLL Slave Ratio Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								PHY_REG_WR_DATA_SLAVE_RATIO3								RESERVED								PHY_REG_WR_DATA_SLAVE_RATIO2							

Bits	Field Name	Description	Type	Reset
31:26	RESERVED		R	0x0
25:16	PHY_REG_WR_DATA_SLAVE_RATIO3	The user programmable ratio value for the write DQ slave DLL in PHY data macro 1, chip select 1. This is the fraction of a clock cycle in units of 256ths. In other words, the full-cycle tap value from the master DLL will be scaled by this number over 256 to get the delay value for the slave delay line. **NOTE: Chip select 1 is not supported on this device.**	RW	0x40
15:10	RESERVED		R	0x0
9:0	PHY_REG_WR_DATA_SLAVE_RATIO2	The user programmable ratio value for the write DQ slave DLL in PHY data macro 1, chip select 0. This is the fraction of a clock cycle in units of 256ths. In other words, the full-cycle tap value from the master DLL will be scaled by this number over 256 to get the delay value for the slave delay line.	RW	0x40

10.3 General-Purpose Memory Controller

This section describes the features and functions of the device GPMC controller.

10.3.1 GPMC Overview

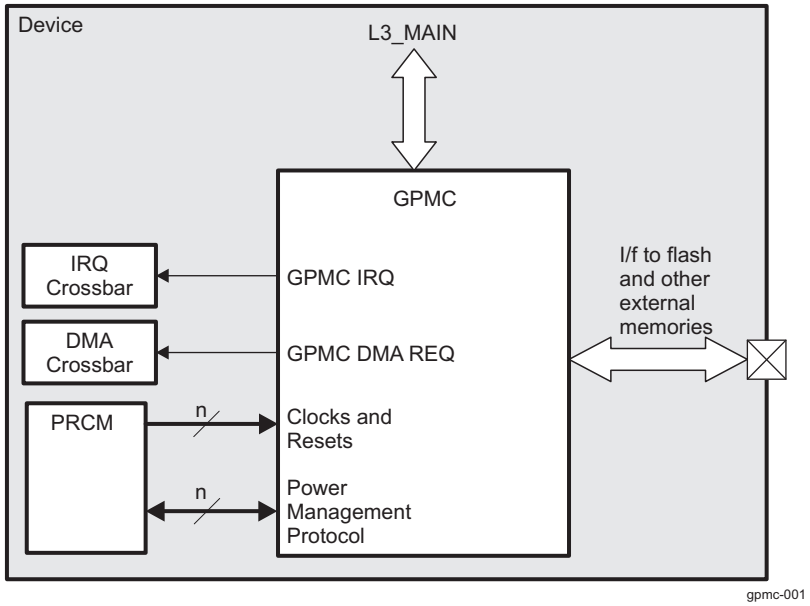
The general-purpose memory controller (GPMC) is a unified memory controller dedicated for interfacing with external memory devices like:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (available only in nonmultiplexed mode) burst NOR flash devices
- NAND flash
- Pseudo-SRAM devices

Figure 10-11 shows the GPMC module overview.

The GPMC features are introduced in Section 10.1.2, *GPMC Overview* of Section 10.1, *Memory Subsystem Overview*.

Figure 10-11. GPMC Overview



10.3.2 GPMC Environment

This section describes the GPMC application fields from an environment point of view (external connections). It describes GPMC connectivity options, and gives three possible interfaces.

10.3.2.1 GPMC Modes

This section shows three GPMC external connections options:

- Figure 10-12 shows a connection between the GPMC and a 16-bit synchronous address/data-multiplexed (or AAD-multiplexed, but this protocol uses fewer address pins) external memory device.
- Figure 10-13 shows a connection between the GPMC and a 16-bit synchronous nonmultiplexed external memory device.
- Figure 10-14 shows a connection between the GPMC and an 8-bit synchronous non-multiplexed external memory device.
- Figure 10-15 shows a connection between the GPMC and a 8-bit NAND device.

Figure 10-12. GPMC to 16-Bit Address/Data-Multiplexed Memory

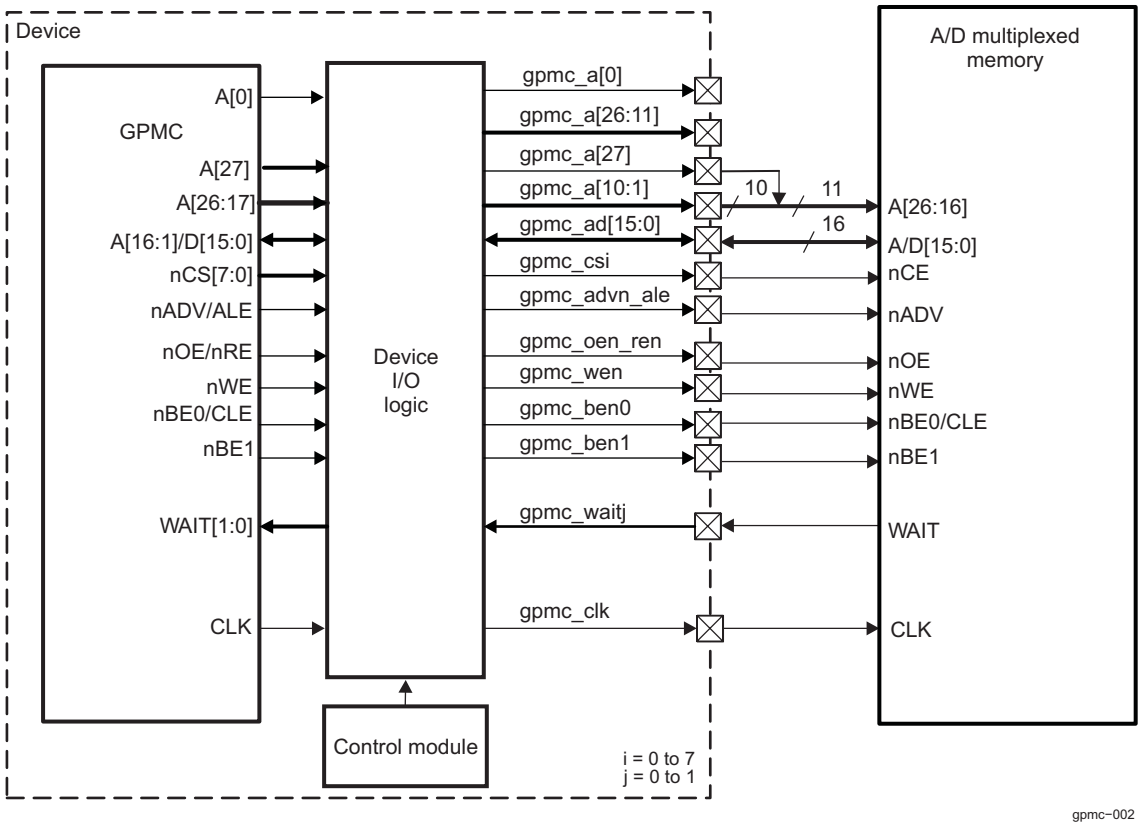


Figure 10-13. GPMC to 16-Bit Nonmultiplexed Memory

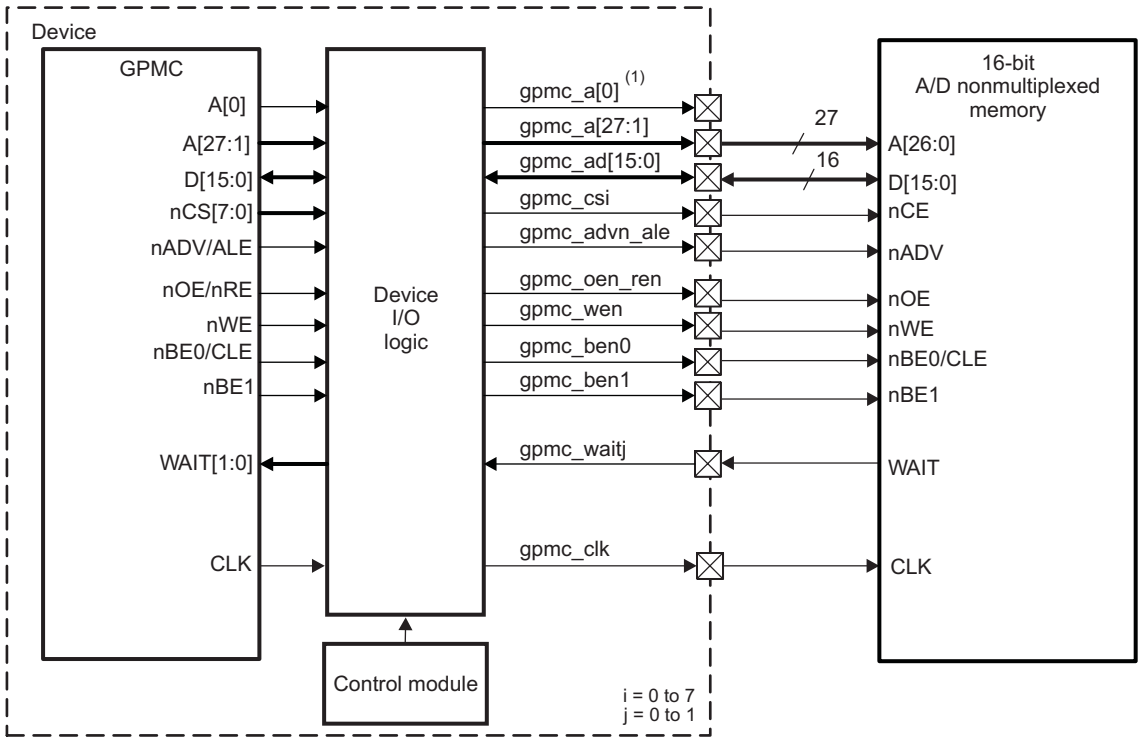

Note (1): the gpmc_a[0] pin is not used with 16-bit memory devices

Figure 10-14. GPMC to 8-Bit Nonmultiplexed Memory

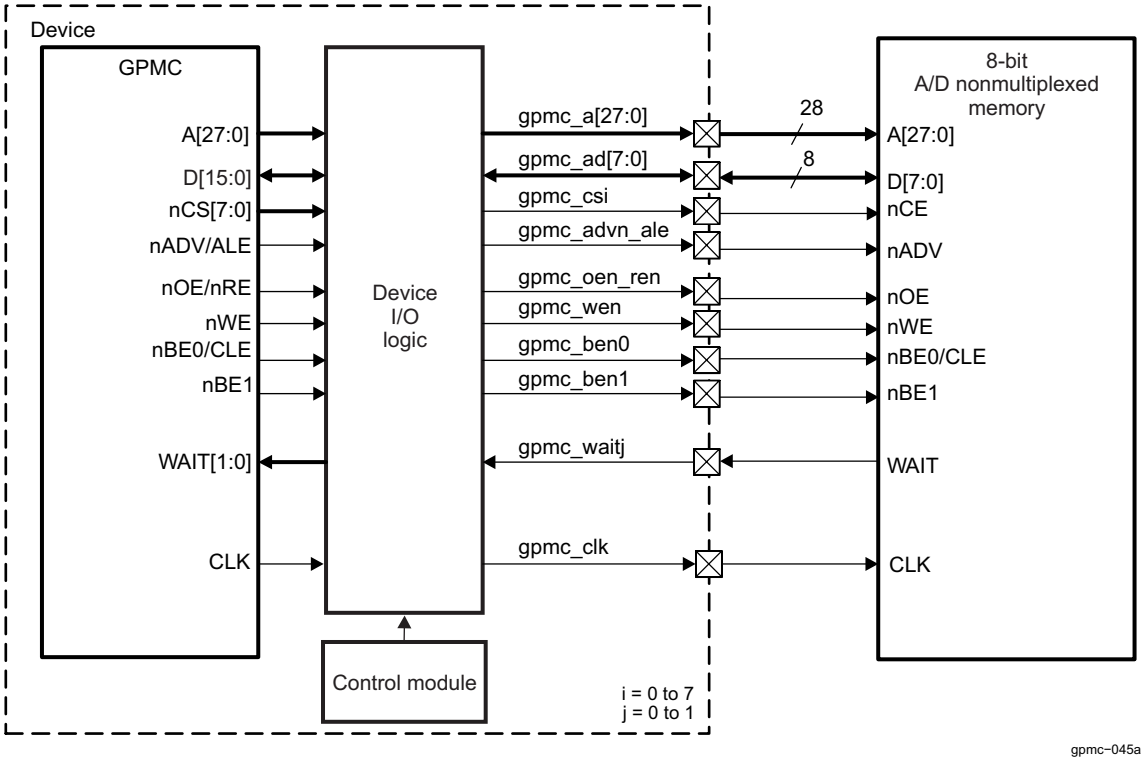

Figure 10-15. GPMC to 8-Bit NAND Device

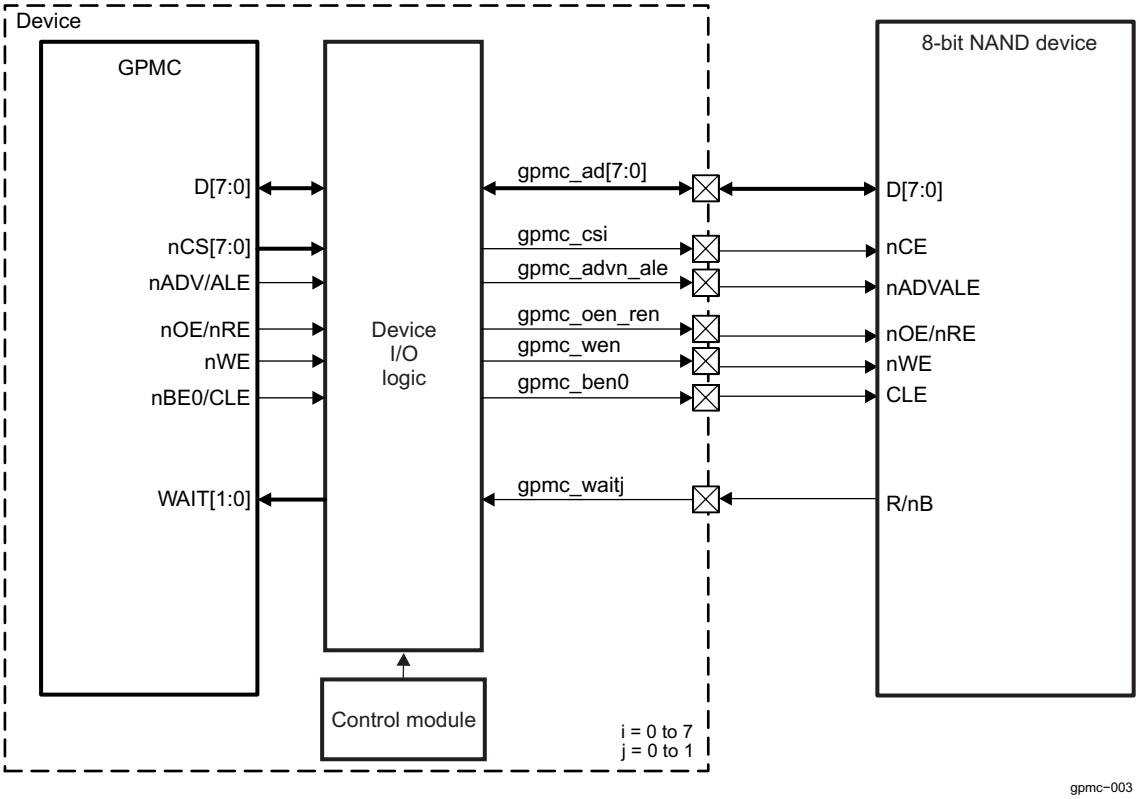

10.3.2.2 GPMC Signals

Table 10-358 lists the GPMC subsystem input/output (I/O) pins.

Table 10-358. GPMC I/O Description

Pin Name	Device Signal	I/O[1]	Description
A[27:0]	gpmc_a[27:0]	O	28-bit output address bus
A[16:1]/D[15:0]	gpmc_ad[15:0]	I/O	Multiplexed address/data
nCS[7:0]	gpmc_cs[7:0]	O	Chip-selects (active low)
CLK	gpmc_clk	O	Clock generated for the external memory or device
nADV/ALE	gpmc_advn_ale	O	Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories.
nOE/nRE	gpmc_oen_ren	O	Output enable (active low). Also used as read enable (active low) for NAND protocol memories.
nWE	gpmc_wen	O	Write enable (active low)
nBE0/CLE	gpmc_ben0	O	Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories.
nBE1	gpmc_ben1	O	Upper-byte enable (active low).
WAIT[1:0]	gpmc_wait[1:0]	I	External wait signal for NOR and NAND protocol memories. The wait signals can be mapped on any of the chip-select.

(1) I = Input; O = Output

NOTE: For the gpmc_clk signal to work properly, the INPUTENABLE bit of the appropriate CTRL_CORE_PAD_x register should be set to 0x1 because of retiming purposes.

Table 10-359 shows the use of address and data GPMC controller pins based on the type of external device.

Table 10-359. GPMC Pin Multiplexing Options

gpmc_ad[0]	A1/D0	D0	D0	D0	D0

(1) Used to effectively address 8-bit (only) non-multiplexed memories

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 0x00.

Address mapping supports address/data-multiplexed 16-bit-wide devices:

- The NOR flash memory controller still supports nonmultiplexed address and data memory devices.
- Multiplexing mode can be selected through the GPMC_CONFIG1_i[9:8] MUXADDDATA bit field (where i = 0 to 7).
- Asynchronous page mode is not supported for multiplexed address and data devices.

10.3.3 GPMC Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

- No master standby protocol
- Supports slave idle protocol with device PRCM
- Supports Auto Idle
- No wake-up request
- One direct memory access request mapped to the device DMA crossbar (DMA_CROSSBAR)

- One interrupt request mapped via the device interrupt crossbar (IRQ_CROSSBAR) to all device integrated interrupt controllers
- One clock for functional and interface domains

Figure 10-16 shows GPMC integration.

Figure 10-16. GPMC Integration

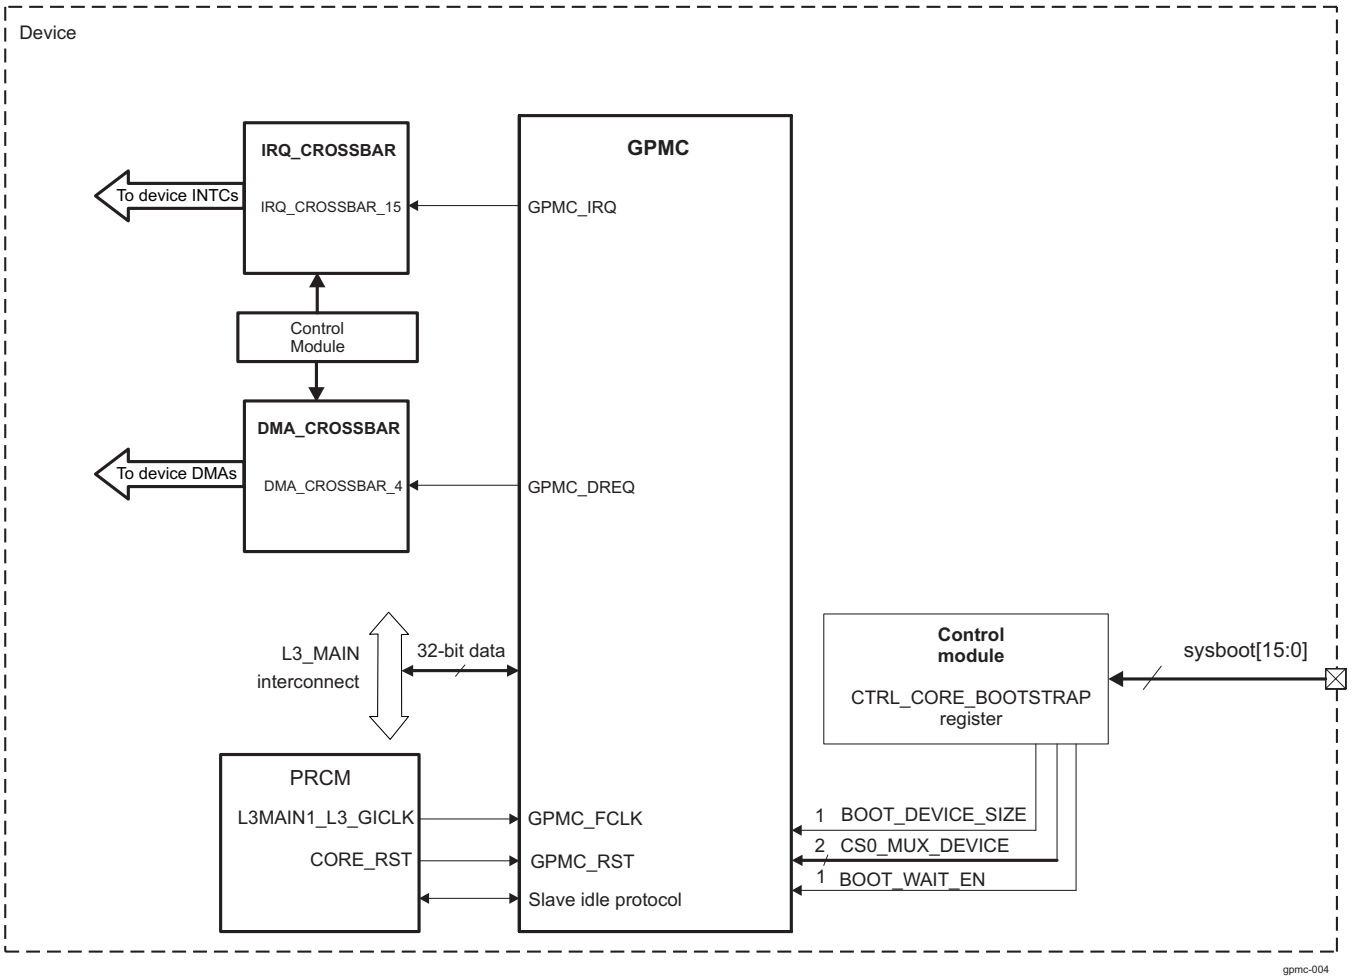

Table 10-360, Table 10-361 and Table 10-362 summarize the integration of the module in the device.

Table 10-360. GPMC Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
GPMC	PD_COREAON	No	L3_MAIN

NOTE:

- For the description of the operation performance point (OPP) configuration, see Section 3.1.1.1.2, *Module Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
- For information about frequencies associated with each OPP, see the device data manual.

Table 10-361. GPMC Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
GPMC	GPMC_FCLK	L3MAIN1_L3_GICLK	PRCM	Functional clock
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
GPMC	GPMC_RST	CORE_RET_RST	PRCM	GPMC reset

NOTE: For the clock description, see Section 10.3.4.2, *GPMC Clock Configuration*.

Table 10-362. GPMC Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
GPMC	GPMC_IRQ	IRQ_CROSSBAR_15	DSP1_IRQ_46 DSP2_IRQ_46	GPMC interrupt
DMA Requests				
Module Instance	**Source Signal Name**	**Destination DMA_CROSSBAR Input**	**Default Mapping**	**Description**
GPMC	GPMC_DREQ	DMA_CROSSBAR_4	DMA_EDMA_DREQ_3	DMA request from GPMC prefetch engine.

NOTE: The "**Default Mapping**" column in Table 10-362 *GPMC Hardware Requests* shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.
For more information about the IRQ_CROSSBAR module, see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.
For more information about the DMA_CROSSBAR module, see Section 13.4.6.5, *DMA_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.
For more information about the device interrupt controllers, see Chapter 12, *Interrupt Controllers*.
For more information about the device EDMA module, see Chapter 11, *Enhanced DMA*.

NOTE: For the description of the interrupt source, see Section 10.3.4.5, *GPMC Interrupt Requests*.

10.3.4 GPMC Functional Description

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the eight configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, 16-bit word, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single synchronous or single asynchronous read or write mode.
- To simulate a programmable internal-wait-state, an external wait pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC_FCLK) is used as a time reference to specify the following:

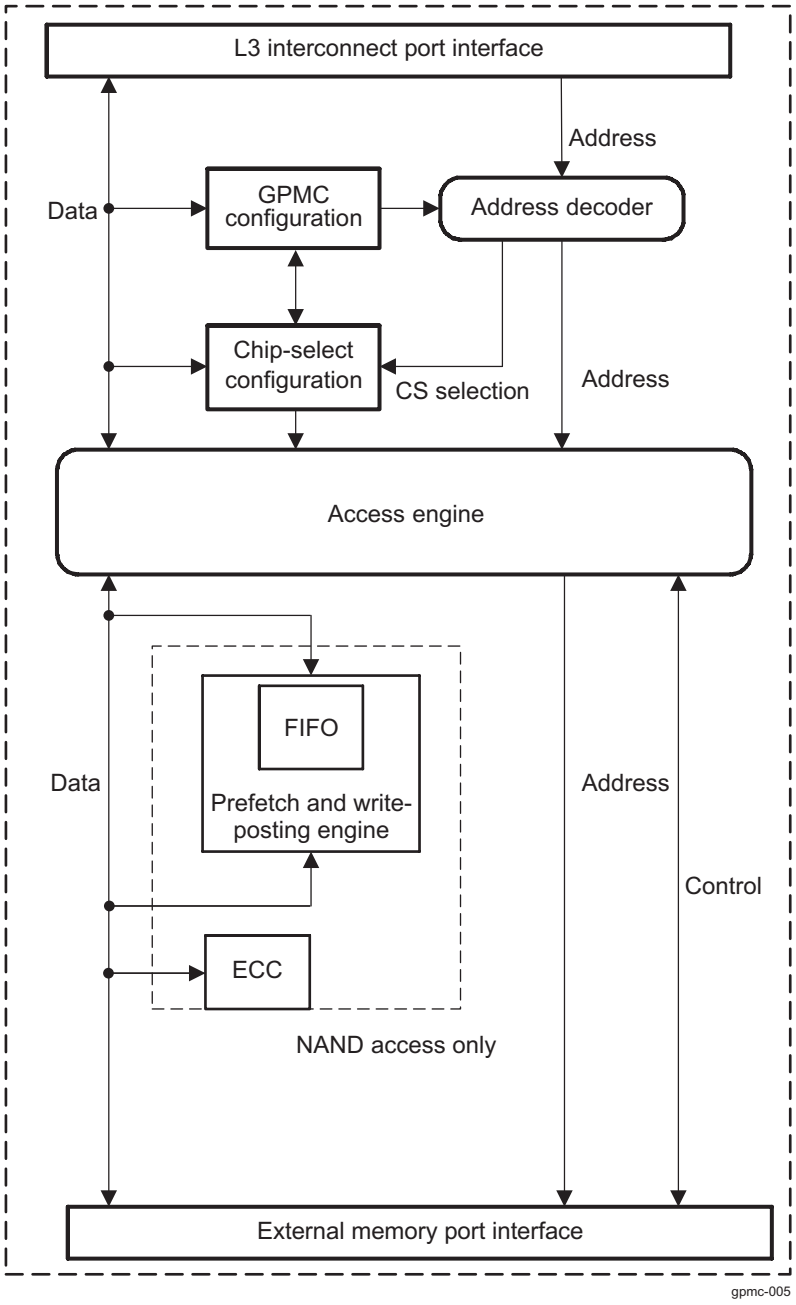
- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

10.3.4.1 GPMC Block Diagram

Figure 10-17 shows the GPMC functional block diagram. The GPMC consists of six blocks:

- L3 interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

Figure 10-17. GPMC Block Diagram



The GPMC can access various external devices. The flexible programming model allows a wide range of attached device types and access schemes.

Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC can generate the timing of all control signals depending on the attached device and access type.

Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate control signal timing for the device type.

10.3.4.2 GPMC Clock Configuration

Table 10-363 describes the GPMC clocks.

Table 10-363. GPMC Clocks

Signal	I/O[1]	Description
GPMC_FCLK	I	Functional and interface clock
gpmc_clk	O	External clock provided to synchronous external memory devices

(1) I = Input; O = Output

The gpmc_clk is generated by the GPMC from the internal GPMC_FCLK clock. The source of the GPMC_FCLK is described in Table 10-361. The gpmc_clk is configured using the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field (where i = 0 to 7), as shown in Table 10-364.

Table 10-364. gpmc_clk Configuration

Source Clock	GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER	gpmc_clk Generated Clock Provided to External Memory Device
GPMC_FCLK	00	GPMC_FCLK
	01	GPMC_FCLK/2
	10	GPMC_FCLK/3
	11	GPMC_FCLK/4

10.3.4.3 GPMC Software Reset

The GPMC can be reset by software through the GPMC_SYSCONFIG[1] SOFTRESET bit. Setting the bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Hardware and software resets initialize all GPMC registers and the finite state-machine (FSM) immediately and unconditionally. The GPMC_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. Software must ensure that the software reset completes before performing GPMC operations.

10.3.4.4 GPMC Power Management

GPMC power is supplied by the CORE power domain, and GPMC power management complies with system power-management guidelines.

Table 10-365 describes the power-management features available for the GPMC module.

NOTE:

- For information about source clock gating and sleep/wake-up transitions, see Section 3.1.1.1, *Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
- For descriptions of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.6, *Clock Management Functional Description*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 10-365. GPMC Local Power-Management Features

Feature	Registers	Description
Clock autogating	GPMC_SYSCONFIG[0] AUTOIDLE	This bit allows a local power optimization inside the module, by gating the GPMC_FCLK clock upon the internal activity.
Slave idle modes	GPMC_SYSCONFIG[4:3] SIDLEMODE	Force-idle, no-idle and smart-idle wake-up modes are available.
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	N/A	Feature not available

10.3.4.5 GPMC Interrupt Requests

The GPMC generates one interrupt request (see Figure 10-16).

Table 10-366 lists the event flags, and their mask, that can cause module interrupts.

Table 10-366. GPMC Interrupt Events

Event Flag	Event Mask	Sensitivity	Description
GPMC_IRQSTATUS[9] WAIT1EDGE DETECTIONSTATUS	GPMC_IRQENABLE[9] WAIT1EDGE DETECTIONENABLE	Edge	Wait1 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait1 signal. The rising or falling edge detection of Wait1 is selected through the GPMC_CONFIG[9] WAIT1PINPOLARITY bit.
GPMC_IRQSTATUS[8] WAIT0EDGE DETECTIONSTATUS	GPMC_IRQENABLE[8] WAIT0EDGE DETECTIONENABLE	Edge	Wait0 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait0 signal. The rising or falling edge detection of Wait0 is selected through the GPMC_CONFIG[8] WAIT0PINPOLARITY bit.
GPMC_IRQSTATUS[1] TERMINAL COUNTSTATUS	GPMC_IRQENABLE[1] TERMINAL COUNTENABLE	Level	Terminal count event: Triggered on prefetch process completion; that is, when the number of currently remaining data to be requested reaches 0
GPMC_IRQSTATUS[0] FIFOEVENTSTATUS	GPMC_IRQENABLE[0] FIFOEVENTENABLE	Level	FIFO event interrupt: Indicates available FIFO levels for write-posting mode and prefetch mode. GPMC_PREFETCH_CONFIG1[2] DMAMODE must be set to 0.

10.3.4.6 L3 Interconnect Interface

The GPMC L3 interconnect interface is a pipelined interface including a 16 × 32-bit word write buffer.

Any system host can issue external access requests through the GPMC.

The device system can issue the following requests through this interface:

- One 8-, 16-, or 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 × 32, 4 × 32, 8 × 32, and 16 × 32, with the burst base address aligned on the total burst size, are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line for specific event control.

It is recommended to program the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH bit field according to the page length of the effective attached device and to enable the GPMC_CONFIG1_i[31] WRAPBURST bit if the attached device supports wrapping burst.

It is possible, however, to emulate wrapping burst on a nonwrapping memory by providing relevant addresses within the page or by splitting transactions. Bursts larger than the memory page length are chopped into multiple burst transactions. Because of the alignment requirements, a page boundary is never crossed.

10.3.4.7 GPMC Address and Data Bus

The current application supports GPMC connection to NAND devices and to address/data-multiplexed memories or devices. Connection to address/data-nonmultiplexed memories or devices is supported with an address range up to 256 MB (that is, 28 address bits in 8-bit mode or 27 address bits in 16-bit mode).

Depending on the GPMC configuration of each chip-select, address and data bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

- For address/data-multiplexed and AAD-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit-wide NOR devices do not use GPMC I/O: gpmc_ad[15:8] for data (they are used for address if needed).
- 16-bit-wide NAND devices do not use GPMC I/O: gpmc_a[27:16].
- 8-bit-wide NAND devices do not use GPMC I/O: gpmc_a[27:16] and GPMC I/O: gpmc_ad[15:8].

10.3.4.7.1 GPMC I/O Configuration Setting

NOTE: In this section and the following sections, the i in GPMC_CONFIGx_i stands for the GPMC chip-select i, where i = 0 to 7.

To select a NAND device, program the following register fields:

- GPMC_CONFIG1_i[11:10] DEVICETYPE = 0b10
- GPMC_CONFIG1_i[9:8] MUXADDDATA = 0b00

To select an address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11:10] DEVICETYPE = 0b00
- GPMC_CONFIG1_i[9:8] MUXADDDATA = 0b10

To select an address/address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11:10] DEVICETYPE = 0b00
- GPMC_CONFIG1_i[9:8] MUXADDDATA = 0b01

To select an address/data-nonmultiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11:10] DEVICETYPE = 0b00
- GPMC_CONFIG1_i[9:8] MUXADDDATA = 0b00

10.3.4.7.2 GPMC CS0 Default Configuration at Device Reset

To ensure a correct, fast external boot with a GPMC access on device reset, several pins are sampled:

- The "sysboot0" through "sysboot5" pins (device boundary) define the sequence of interfaces and devices to use for booting (i.e. SYSBOOT[5:0] vector). They are sampled by the control module at reset and used later by the device ROM code. For more information, see Section 25.2.4, *Sysboot Configuration*, in Chapter 25, *Initialization*.
- Additional pins are used to configure reset values in the GPMC_CONFIG1_i register (where i = 0) as explained in the following and in Table 10-367:
  - The *bootdevicesize* input pin (at the GPMC boundary) defines the size of the attached device on chip-select 0 (CS0) and is used to configure the GPMC_CONFIG1_i[13:12] DEVICESIZE bit field (where i = 0). The BOOT_DEVICE_SIZE signal is propagated from the device Control Module. Its value 0b0 (8-bit memories) or 0b1 (16-bit memories) can be externally determined upon booting by **user hardware** via the device external input signal - "sysboot13".
  - The *cs0muxdevice* input pin (at the GPMC boundary) selects whether or not the device attached to CS0 is an address/data-multiplexed device. The input pin is used to configure the GPMC_CONFIG1_i[9:8] MUXADDDATA bit field (where i = 0). The CS0_MUX_DEVICE[1:0] signal is propagated from the Control Module. Its value 0x0 **(non-muxed memory attached)** or 0x2 **(Addr-Data Mux memory attached)** can be externally determined upon booting by **user hardware** via combining the device external input signals - "sysboot12" and "sysboot11", i.e. SYSBOOT[12:11].
  - The *bootwaiten* input pin (at the GPMC boundary) enables the monitoring on CS0 of the wait pin at device reset release time for read accesses. The input pin is used to configure the GPMC_CONFIG1_i[22] WAITREADMONITORING bit (where i = 0). The BOOT_WAIT_EN signal is

propagated from the Control Module. Its value 0x0 **(wait pin is not monitored for read accesses)** or 0x1 **(wait pin is monitored for read accesses)** can be externally determined upon booting by **user hardware** via the device external input signal - "sysboot10".

NOTE: If WAIT pin monitoring function is enabled upon booting (i.e. BOOT_WAIT_EN="1"), the default (power-on-reset) monitored input for CS0 is always the device gpmc_wait0 input.

Table 10-367. Boot Control Interface Input Signals Description

Signal Name	Width	Description
BOOT_DEVICE_SIZE	1	Size of the device attached on CS0 0b00: 8-bit 0b01: 16-bit 0b10: Reserved (not used) 0b11: Reserved (not used)
CS0_MUX_DEVICE	2	Multiplexing mode of the device on CS0 0b00: Nonmultiplexed device on CS0 0b01: AAD-multiplexed device on CS0 (address-address-data) 0b10: Address/data-multiplexed device on CS0 0b11: Reserved
BOOT_WAIT_EN	1	Wait monitoring on CS0 at device reset release time for read accesses 0: Wait pin is not monitored 1: Wait pin is monitored

CAUTION

Using the internal boot code, the entire CS0 configuration can be modified before the first CS0 access. For more information, see Section 25.8, *Memory Booting*, and Section 25.9 , *Image Format*, in Chapter 25, *Initialization*. This modification of internal boot code is necessary for two external devices:

- NAND device attached to CS0
- Nonmultiplexed memory device attached to CS0

At reset time, the device can boot from the internal ROM.

The reset values of the timing control parameters are defined to cope with direct boot on address and data-multiplexed NOR flash devices, nonmultiplexed NOR flash devices, or any asynchronous device with large timing margins, assuming a low GPMC_FCLK frequency (for example, 19.2 MHz) at boot time.

For a multiplexed access, the address 16 low-order bits are presented onto gpmc_ad[15:0], while the high-order bits are presented onto gpmc_a[26:16]. If the external chip interface to the memories uses a 16-bit data bus, the high-order address bits are sampled on the address bus.

The reset values of timing parameters used at boot time are:

- CSONTIME = 1
- CSRDOFFTIME = 16
- ADVONTIME = 4
- ADVRDOFFTIME = 5
- OEONTIME = 6
- OEOFFTIME = 16
- RDACCESSTIME = 15
- RDCYCLETIME = 17

For an AAD-multiplexed access, all address bits are passed onto the data bus using two nADV rising edges. The first rising edge latches the address most-significant bit (MSB) down to bit 17, while the second rising edge latches address bits 16 down to 1. This configuration is only used for 16-bit memories.

The reset values of these timing parameters used at boot time are:

- ADVAADMUXONTIME = 1
- ADVAADMUXRDOFFTIME = 2
- OEAADMUXONTIME = 1
- OEAADMUXOFFTIME = 3

10.3.4.8 Address Decoder and Chip-Select Configuration

Addresses are decoded accordingly with the address request of the chip-select and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and eight sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file must be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated). Section 10.3.7, *GPMC Register Manual*, provides the GPMC register locations. For the map of GPMC memory locations, see Chapter 2, *Memory Mapping*.

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

10.3.4.8.1 Chip-Select Base Address and Region Size

Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 512-MiB address space. For more information, see Chapter 2, *Memory Mapping*.

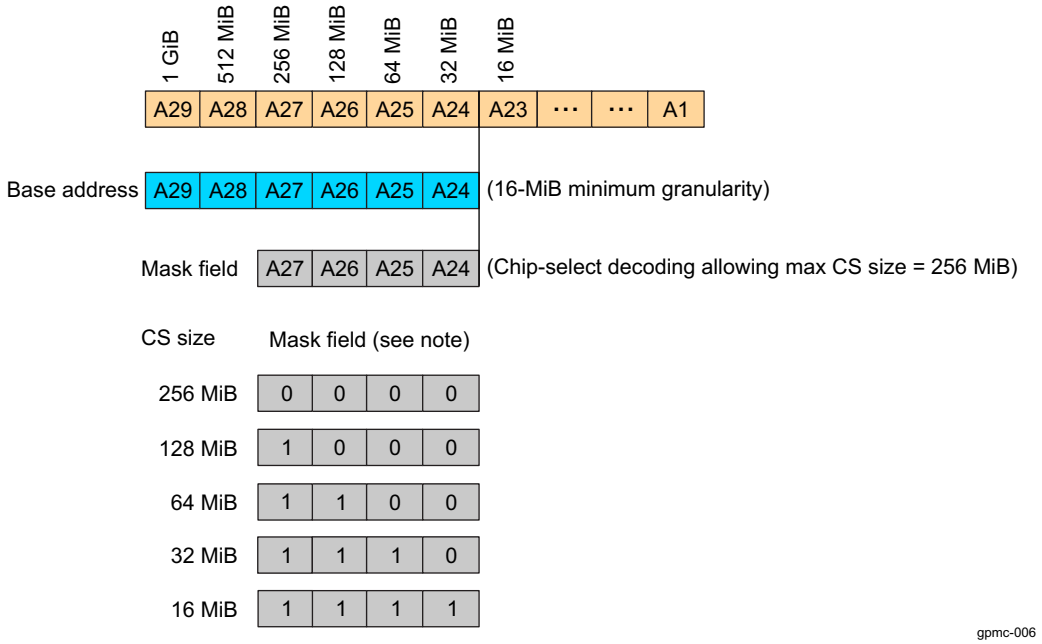
NOTE: Even though GPMC supports total address space of 1GB, only 512MB are physically available in this device.

The GPMC 512-MiB address space can be divided into a maximum of eight chip-select regions with programmable base address and programmable chip-select size. The chip-select size is programmable from 16 MiB to 256 MiB (must be a power-of-two) and is defined by the mask field. Attached memory smaller than the programmed chip-select region size is accessed through the entire chip-select region (aliasing).

Each chip-select has a 6-bit base address encoding and 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-two address value. During access decoding, the value of the register base address is used to compare the address with the address bit line mapping, as shown in Figure 10-18 (with A0 as the device system byte-address line). The base address is programmed through the GPMC_CONFIG7_i[5:0] BASEADDRESS bit field.
- The register mask is used to exclude some address lines from the decoding. A register mask bit field set to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The value of the register mask must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the GPMC_CONFIG7_i[11:8] MASKADDRESS bit field.

Figure 10-18. Chip-Select Address Mapping and Decoding Mask



Following is an example mapping that divides the 512MB memory reach into two 256MB regions:

- 1st 256MB region – 0x0000 0000 to 0x0FFF FFFF – program base address for that chip select equal to 0x0
- 2nd 256MB region – 0x1000 0000 to 0x1FFF FFFF – program base address for that chip select equal to 0x10

Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the GPMC_CONFIG7_i[6] CSVALID bit (where i stands for the GPMC chip-select value, 0 to 7). In addition, a chip-select configuration can be disabled only if there is no ongoing access to that chip-select. This requires monitoring the activity of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of overlapping chip-selects, an error is generated and no access occurs on either chip-select.

CS0 is the only chip-select region enabled after a power up or GPMC reset.

CAUTION

Although the GPMC interface can drive up to eight chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers to allow the slowest device to maintain the total load on the lines.

10.3.4.8.2 Access Protocol

10.3.4.8.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the GPMC_CONFIG1_i[11:10] DEVICETYPE parameter (where i = 0 to 7) for:

- Random-access synchronous or asynchronous memory, such as NOR flash and SRAM

- NAND flash asynchronous devices

NOTE: For more information about the NAND flash GPMC basic programming model and NAND support, see Section 10.3.4.12, *NAND Device Basic Programming Model*, and Section 10.3.4.12.1, *NAND Memory Device in Byte or Word16 Stream Mode*.

10.3.4.8.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the GPMC_CONFIG1_i[13:12] DEVICESIZE bit field (where i = 0 to 7) to interface with a 16- or 8-bit-wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to the external device data-bus width and little-endian data organization.

10.3.4.8.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 0b00), an address- and data-multiplexing protocol can be selected through the GPMC_CONFIG1_i[9:8] MUXADDDATA bit field (where i = 0 to 7). The nADV signal must be used as the external device address latch control signal. For the associated chip-select configuration, nADV assertion and deassertion time and nOE assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device. See Section 10.3.3, *GPMC Integration*.

NOTE: This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data-multiplexing protocol. See Section 10.3.4.12, *NAND Device Basic Programming Model*.

10.3.4.8.3 External Signals

NOTE: The "DIR" (direction control) output signal is NOT pinned out on any of the device pads. It is an internal signal only representing a signal direction on the GPMC data bus.

10.3.4.8.3.1 Wait Pin Monitoring Control

GPMC access time can be dynamically controlled using an external gpmc_wait pin when the external device access time is not deterministic and cannot be defined and controlled using only the GPMC internal RDACCESSTIME, WRACCESSTIME, and PAGEBURSTACCESSTIME wait-state generator.

The GPMC features two input wait pins: gpmc_wait1, and gpmc_wait0. These pins allow control of external devices with different wait pin polarity. They also allow the overlap of wait pin assertion from different devices without affecting access to devices for which the wait pin is not asserted.

- The GPMC_CONFIG1_i[17:16] WAITPINSELECT bit field (where i = 0 to 7) selects which input gpmc_wait pin is used for the device attached to the corresponding chip-select.
- The polarity of the wait pin is defined through the WAITxPINPOLARITY bit of the GPMC_CONFIG register. A wait pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When a wait pin is inactive, data is valid.

The GPMC access engine can be configured per chip-select to monitor or not the wait pin of the external memory device, based on the access type: read or write.

- The GPMC_CONFIG1_i[22] WAITREADMONITORING bit defines whether or not the wait pin must be monitored during read accesses.
- The GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit defines whether or not the wait pin must be monitored during write accesses.

The GPMC access engine can be configured to monitor the wait pin of the external memory device asynchronously or synchronously with the GPMC_CLK clock, depending on the access type: synchronous or asynchronous (the GPMC_CONFIG1_i[29] READTYPE and GPMC_CONFIG1_i[27] WRITETYPE bits).

10.3.4.8.3.1.1 Wait Monitoring During Asynchronous Read Access

When wait pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with wait pin monitoring enabled, the wait pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through wait pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a wait invalid timing window and is set to such a value that the wait pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait monitoring pipelining is also applicable to multiple accesses (access within a page).

- Wait monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, wait monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, wait monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

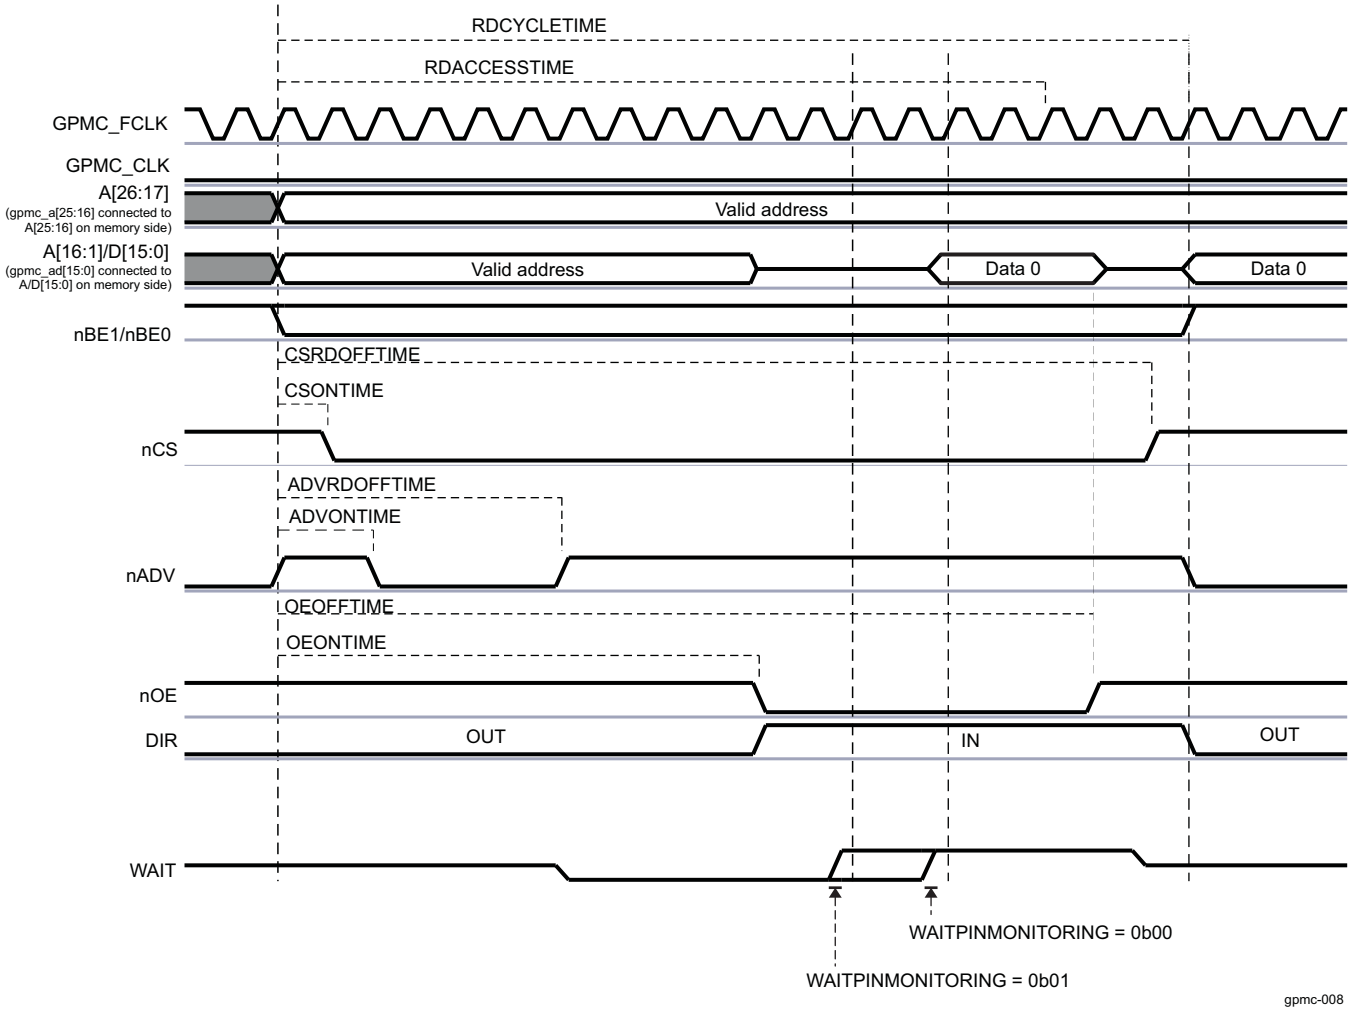
When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME bit field (where i = 0 to 7).

NOTE:

- The WAITMONITORINGTIME parameter does not delay the wait pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and no GPMC_CLK clock is provided to the external device. Still, because GPMCFCLKDIVIDER is used as a divider for the GPMC clock, it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 10-19 shows wait behavior during an asynchronous single read access.

Figure 10-19. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)



NOTE: The WAIT signal is active low. GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME = 0b00, or 0b01.

10.3.4.8.3.1.2 Wait Monitoring During Asynchronous Write Access

When wait pin monitoring is enabled for write accesses (GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit = 0x1), the wait invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the wait pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- Wait monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- Wait monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME bit field (where i = 0 to 7).

NOTE:

- The WAITMONITORINGTIME parameter does not delay the wait pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and even though no clock is provided to the external device. Still, because the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field is used as a divider for the GPMC clock, it must be programmed to define the correct WAITMONITORINGTIME delay.

10.3.4.8.3.1.3 Wait Monitoring During Synchronous Read Access

During synchronous accesses with wait pin monitoring enabled, the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle in which it is captured. Alternatively, it can be sampled one or two GPMC_CLK cycles ahead of the clock cycle to which it applies. This pipelining is applicable to the entire burst access and to all data phases in the burst access. This wait pipelining depth is programmed in the GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME bit field (where i = 0 to 7), and is expressed as a number of GPMC_CLK clock cycles.

In synchronous mode, when wait pin monitoring is enabled (the GPMC_CONFIG1_i[22] WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state detection.

Depending on the programmed value of WAITMONITORINGTIME, the wait pin must be at a valid level, either asserted or deasserted:

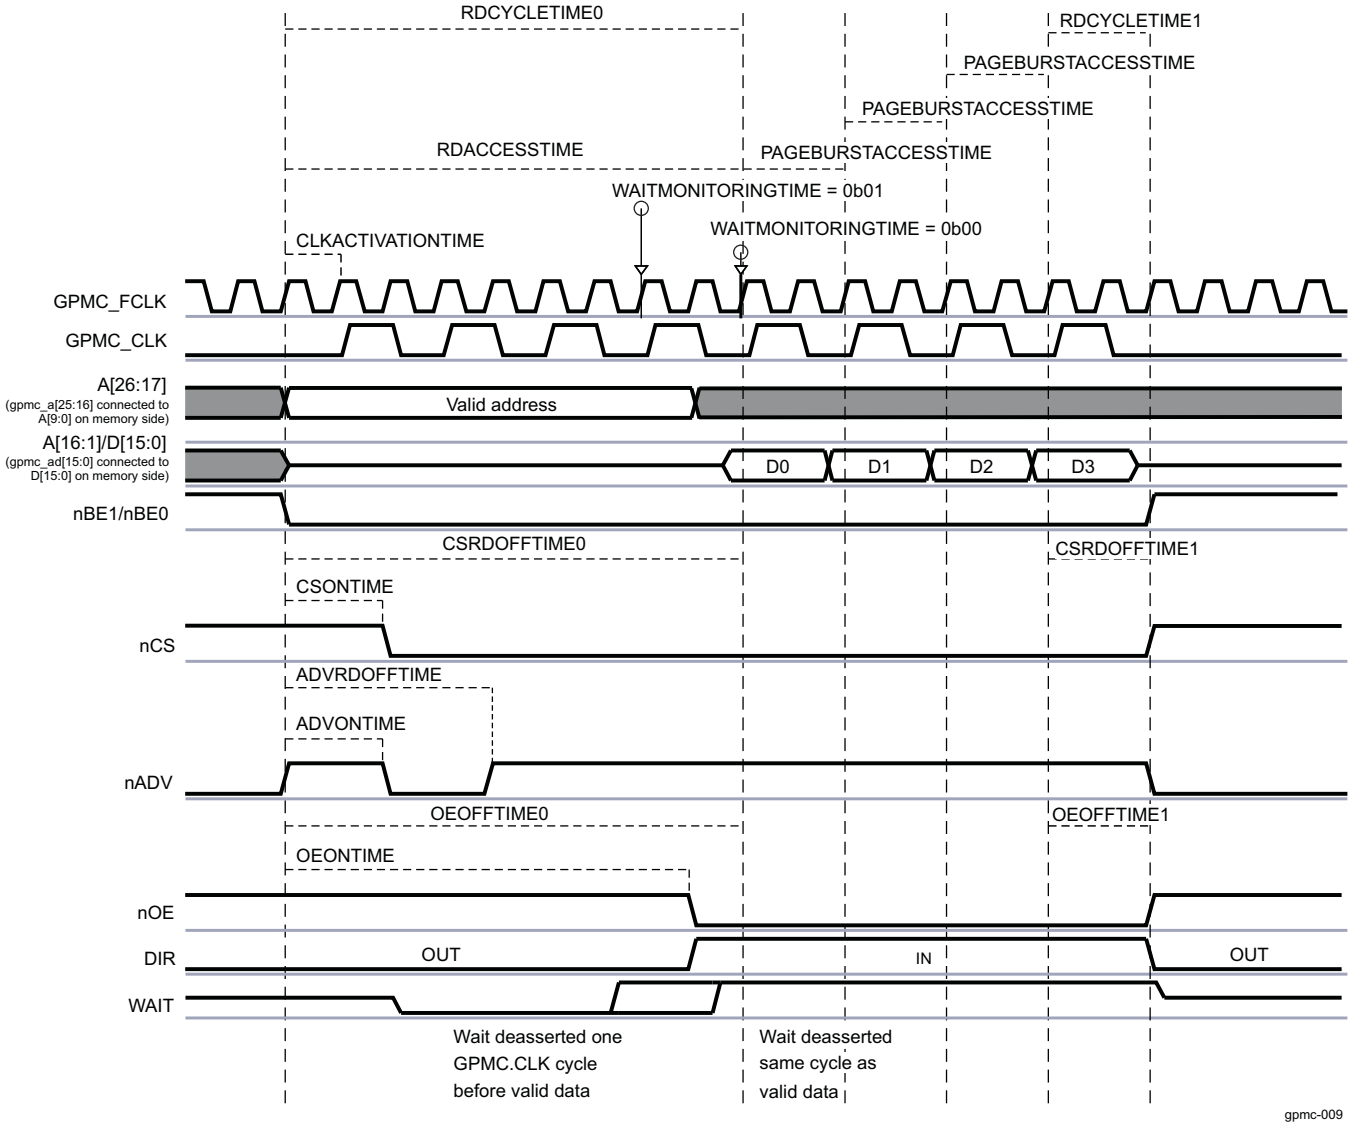
- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 (at RDACCESSTIME completion)
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the WAIT-INACTIVE state. The wait pipelining-depth programming applies to the whole burst access.

- Wait monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), wait monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), wait monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 10-20 shows wait behavior during a synchronous read burst access.

Figure 10-20. Wait Behavior During a Synchronous Read Burst Access



NOTE: The WAIT signal is active low. WAITMONITORINGTIME = 00, 01.

10.3.4.8.3.1.4 Wait Monitoring During Synchronous Write Access

During synchronous accesses with wait pin monitoring enabled (the WAITWRITEMONITORING bit), the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

If enabled, external wait pin monitoring can be used in combination with WRACCESSTIME to delay the GPMC_CLK capture edge of the effective memory device.

Wait-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Wait-monitoring pipelining definition applies to whole burst accesses:

- Wait monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, wait monitored as active indicates that the data

bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.

- Wait monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, wait monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

NOTE: Wait monitoring is supported for all configurations except GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME = 0x0 (where i = 0 to 7) for write bursts with a clock divider of 1 or 2 (the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field is equal to 0x0 or 0x1, respectively).

10.3.4.8.3.1.5 Wait With NAND Device

For information about the use of the wait pin for communication with a NAND flash external device, see Section 10.3.4.12.2, *NAND Device-Ready Pin*.

10.3.4.8.3.1.6 Idle Cycle Control Between Successive Accesses

10.3.4.8.3.1.6.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device must be delayed (in other words, control the nCS/nOE deassertion to data bus in high-impedance delay).

The bus turnaround is a time-out counter starting after nCS or nOE deassertion time, whichever occurs first, and delays the next access start-cycle time. The counter is programmed through the GPMC_CONFIG6_i[3:0] BUSTURNAROUND bit field (where i = 0 to 7).

After a read access to a chip-select with a nonzero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

- A write access to any chip-select (the same or different chip-select from which the data was read)
- A read access to a different chip-select than the chip-select from which the data was read access
- A read or write access to a chip-select associated with an address/data-multiplexed device

NOTE: Bus keeping starts after bus turnaround completion so that DIR changes from IN to OUT after bus turnaround. The bus does not have enough time to go into high-impedance even though it can be driven with the same value before bus turnaround timing.

BUSTURNAROUND delay runs in parallel with GPMC_CONFIG6_i[3:0] CYCLE2CYCLEDELAY bi field delays. BUSTURNAROUND is a timing parameter for the ending chip-select access, while CYCLE2CYCLEDELAY is a timing parameter for the following chip-select access. The effective minimum delay between successive accesses is driven by these delay timing parameters and by the access type of the following access (see Figure 10-21 through Figure 10-23).

Another way to prevent bus contention is to define an earlier nCS or nOE deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but it also affects all accesses of this specific chip-select.

Figure 10-21. Read-to-Read for an Address-Data Multiplexed Device, on Different Chip-Select, Without Bus Turnaround (nCS Attached to a Fast Device)

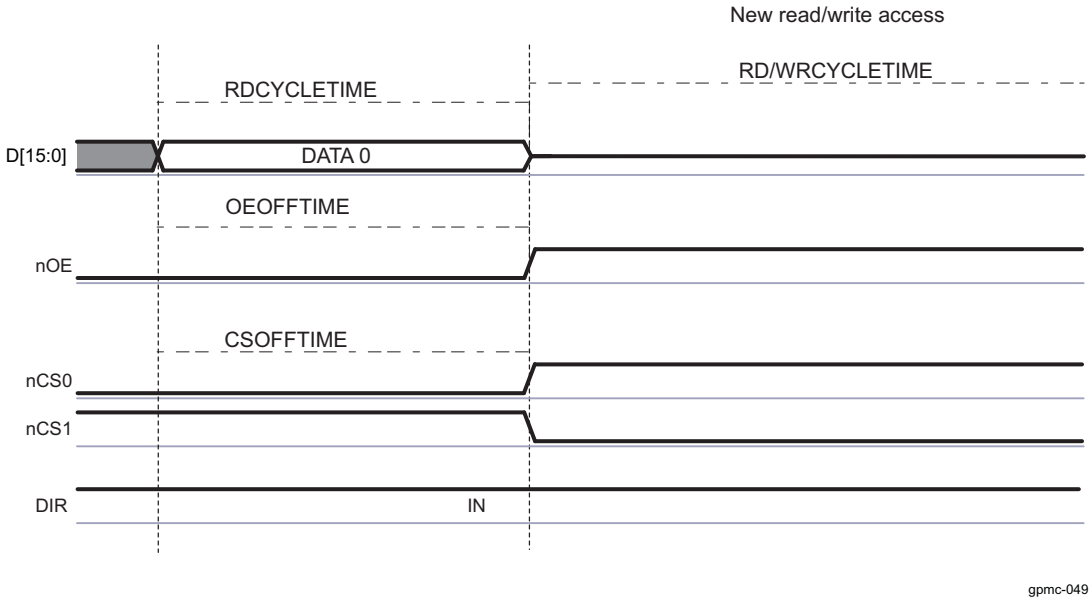


Figure 10-22. Read- to-Read/Write for an Address-Data Multiplexed Device, on Different Chip-Select, With Bus Turnaround

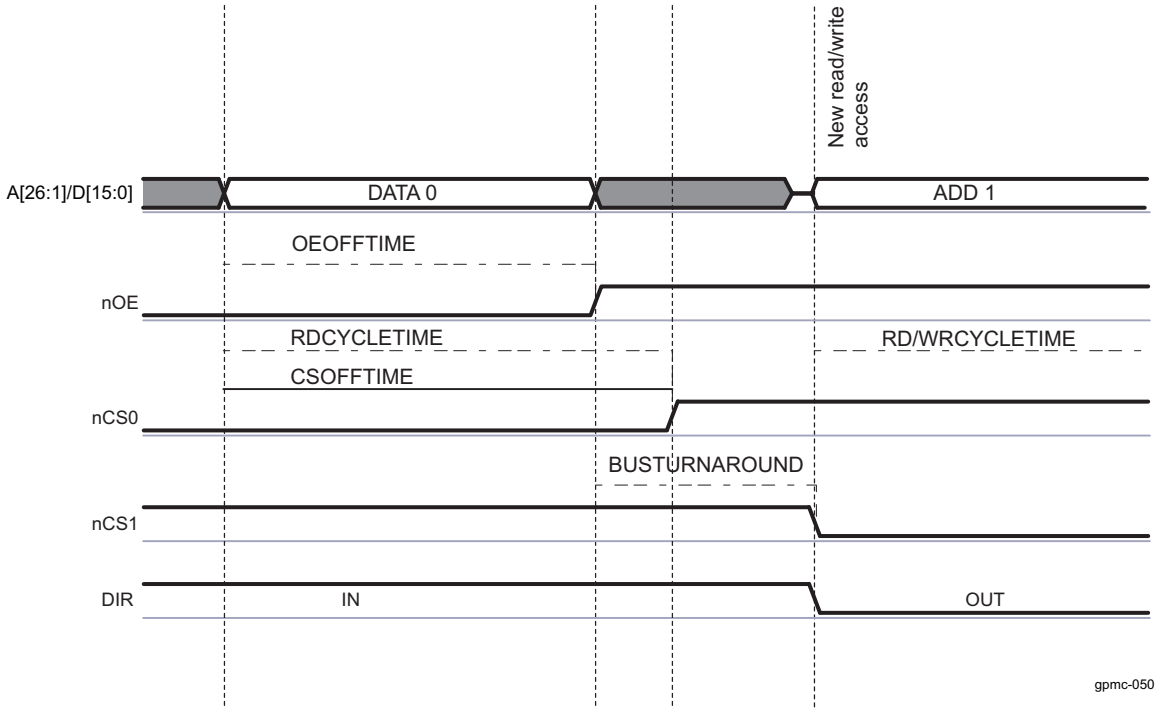

Figure 10-23. Read-to-Read/Write for a Address-Data or AAD-Multiplexed Device, on Same Chip-Select, With Bus Turnaround

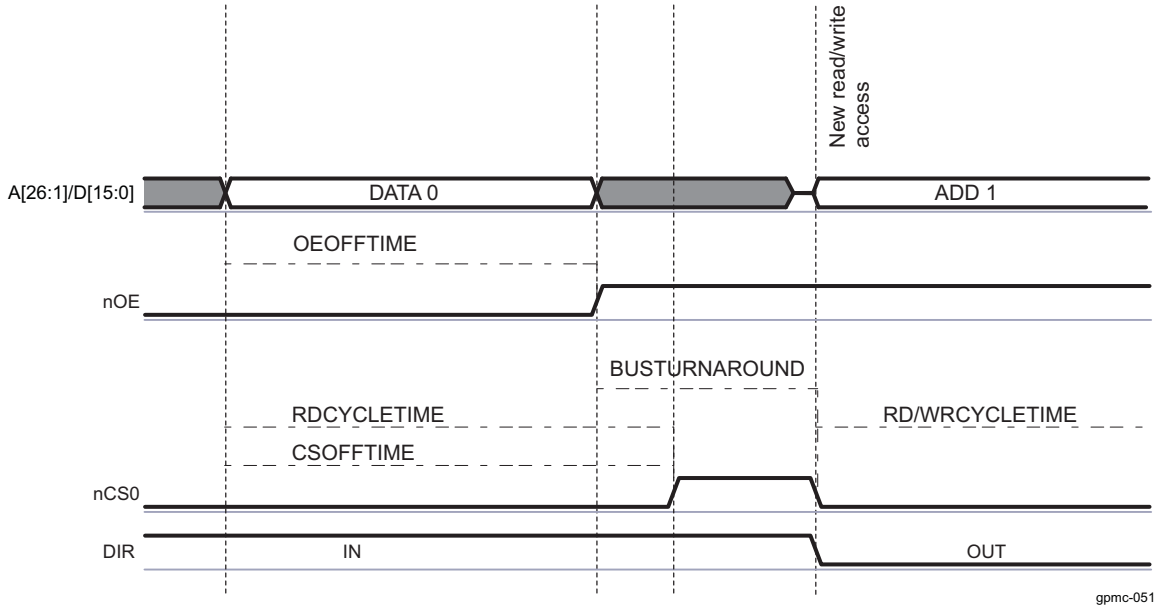


10.3.4.8.3.1.6.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMECSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN bit (where i = 0 to 7) enables insertion of a minimum number of GPMC_FCLK cycles, defined by the GPMC_CONFIG6_i[11:8] CYCLE2CYCLEDELAY bit field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMECSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDOFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during 32-bit word or burst accesses split into successive single accesses when the single-access mode is used (GPMC_CONFIG1_i[30] READMULTIPLE = 0 or GPMC_CONFIG1_i[28] WRITEMULTIPLE = 0).

All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC.CLK) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC.CLK at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC.FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

10.3.4.8.3.1.6.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (nCS, nADV/ALE, nBE0/CLE, nOE/RE, nWE) assertion and deassertion timing parameters and on the device timing parameters, the assertion times of some control signals may overlap between the successive accesses to a different chip-select. Similarly, some control signals (WE, OE/RE) may not respect required transition times.

To work around overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If the GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN bit is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC_FCLK cycles.

NOTE: CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN must be set in the GPMC_CONFIG6_i registers to get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select, respectively.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. The BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, because bus turnaround does not apply to all access types. For more information about bus turnaround, see Section 10.3.4.8.3.1.6.1, *Bus Turnaround (BUSTURNAROUND)*.

Table 10-368 describes the configuration required for idle cycle insertion.

Table 10-368. Idle Cycle Insertion Configuration

1st Access Type	BUSTURNAROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2CYCLE SAMECSEN Parameter	CYCLE2CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	= 0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Different	Nonmuxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	R/W	Any	Muxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	W	Any	Any	0	0	BUSTURNAROUND cycles are inserted.
W	> 0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	= 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	= 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.
R/W	> 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).
R/W	> 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

10.3.4.8.3.1.7 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit (where i stands for the GPMC chip-select value, 0 to 7). Increasing all access timing parameters allows support of slow devices.

10.3.4.8.3.2 Reset

No reset signal is sent to the external memory device by the GPMC. For more information about external-device reset, see Chapter 3, *Power, Reset, and Clock Management*.

The PRCM module provides an input pin, global_rst_n, to the GPMC:

- The global_rst_n pin is activated during device warm reset and cold reset.
- The global_rst_n pin initializes the internal state-machine and the internal configuration registers.

10.3.4.8.3.3 Byte Enable (nBE1/nBE0)

Byte enable signals (nBE1/nBE0) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

10.3.4.8.4 Error Handling

When an error occurs in the GPMC, the error information is stored in the GPMC_ERR_TYPE register and the address of the illegal access is stored in the GPMC_ERR_ADDRESS register. The GPMC keeps only the first error abort information until the GPMC_ERR_TYPE register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the GPMC_ERR_TYPE[0] ERRORVALID bit.

- ERRORNOTSUPPADD occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1KiB.
- ERRORNOTSUPPMCMD occurs when an unsupported command request is decoded at the L3 interconnect interface.
- ERRORTIMEOUT: A time-out mechanism prevents the system from hanging. The start value of the 9-bit time-out counter is defined in the GPMC_TIMEOUT_CONTROL register and enabled with the GPMC_TIMEOUT_CONTROL[0] TIMEOUTENABLE bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, and then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. An interrupt generation is handled at interconnect level.

10.3.4.9 Timing Setting

The GPMC offers maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For more information about GPMC_CLK and GPMC_FCLK see Section 10.3.4.9.6, *GPMC_CLK*.

NOTE: In the following sections, the start access time refers to the time at which the access begins.

10.3.4.9.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME / WRCYCLETIME)

The GPMC_CONFIG5_i[4:0] RDCYCLETIME and GPMC_CONFIG5_i[12:8] WRCYCLETIME bit fields (where i = 0 to 7) define the address bus and byte-enable valid times for read and write accesses. To ensure a correct duty cycle of GPMC_CLK between accesses, RDCYCLETIME and WRCYCLETIME are expressed in GPMC_FCLK cycles and must be multiples of the GPMC_CLK cycle. The RDCYCLETIME and WRCYCLETIME bit fields can be set with a granularity of 1 or 2 through the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

When RDCYCLETIME or WRCYCLETIME completes, if they are not already deasserted, all control signals (nCS, nADV/ALE, nOE/RE, nWE, and BE0/CLE) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitches. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

NOTE: All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC.CLK) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC.CLK at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC.FCLK cycles.

If no inactive cycles are required between successive accesses to the same chip-select or a different chip-select (GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN = 0 or GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN = 0, where i = 0 to 7), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals (nCS, nADV/ALE, nBE0/CLE, nWE, and nOE/RE) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses (that is, CYCLE2CYCLESAMECSEN = 1 or CYCLE2CYCLEDIFFCSEN = 1), the control signals are forced to their respective default reset values for the number of GPMC_FCLK cycles defined in CYCLE2CYCLEDELAY.

10.3.4.9.2 nCS: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME / CSWROFFTIME / CSEXTRADELAY)

The GPMC_CONFIG2_i[3:0] CSONTIME bit field (where i = 0 to 7) defines the nCS signal-assertion time relative to the start access time. It is common for read and write accesses.

The GPMC_CONFIG2_i[12:8] CSRDOFFTIME (read access) and GPMC_CONFIG2_i[20:16] CSWROFFTIME (write access) bit fields define the nCS signal deassertion time relative to start access time.

The CSONTIME, CSRDOFFTIME, and CSWROFFTIME parameters apply to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte-enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte-enable hold time after chip-select deassertion.

nCS signal transitions, as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME, can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG2_i[7] CSEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on the nCS assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. CSEXTRADELAY is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but it can also be used for all GPMC configurations. If enabled, CSEXTRADELAY applies to all parameters that control nCS transitions.

The CSEXTRADELAY bit must be used carefully to avoid control signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the nCS signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

10.3.4.9.3 nADV/ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME /

ADVEXTRADELAY/ADVAADMUXONTIME/ADVAADMUXRDOFFTIME/ADVAADMUXWROFFTIME)

The GPMC_CONFIG3_i[3:0] ADVONTIME field (where i = 0 to 7) defines the nADV/ALE signal-assertion time relative to start access time. It is common to read and write accesses.

The GPMC_CONFIG3_i[12:8] ADVRDOFFTIME (read access) and GPMC_CONFIG3_i[20:16] ADVWROFFTIME (write access) bit fields define the nADV/ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte-enable valid setup time control before nADV/ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte-enable valid hold time control after nADV/ALE deassertion. ADVRDOFFTIME and ADVWROFFTIME apply to synchronous and asynchronous modes.

The nADV/ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG3_i[7] ADVEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on nADV/ALE assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, ADVEXTRADELAY applies to all parameters controlling nADV/ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than nADV/ALE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME, GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME, and GPMC_CONFIG3_i[30:28] ADVAADMUXWROFFTIME parameters have the same functions as ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME, but apply to the first address phase in the AAD-multiplexed protocol. The user must ensure that ADVAADMUXxxOFFTIME is programmed to a value less than or equal to ADVxxOFFTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. ADVAADMUXxxOFFTIME can be programmed to the same value as ADVONTIME if no high nADV pulse is needed between the two AAD-multiplexed address phases, which is the typical case in synchronous mode. In this configuration, nADV is kept low until it reaches the correct ADVxxOFFTIME.

For more information about the use of ADVONTIME, ADVRDOFFTIME, ADVWROFFTIME, and ADVAADMUXRDOFFTIME and ADVAADMUXWROFFTIME for command latch enable (CLE) and address latch enable (ALE) use for a NAND flash interface, see Section 10.3.4.12, *NAND Access Description*.

10.3.4.9.4 nOE/nRE: Output Enable/Read Enable Signal Control Assertion/Deassertion Time (OEONTIME / OEOFFTIME / OEEXTRADELAY / OEAADMUXONTIME / OEAADMUXOFFTIME)

The GPMC_CONFIG4_i[3:0] OEONTIME bit field (where i = 0 to 7) defines the nOE/nRE signal assertion time relative to start access time. It applies only to read accesses.

The GPMC_CONFIG4_i[12:8] OEOFFTIME bit field defines the nOE/nRE signal deassertion time relative to start access time. It applies only to read accesses. nOE/nRE is not asserted during a write cycle.

The OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME parameters apply to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before nOE/nRE assertion. OEOFFTIME can be used to control an address and byte-enable valid hold time control after nOE/nRE assertion.

The OEAADMUXONTIME and OEAADMUXOFFTIME parameters have the same functions as OEONTIME and OEOFFTIME, but apply to the first OE assertion in the AAD-multiplexed protocol for a read phase, or to the only OE assertion for a write phase. The user mut ensure that OEAADMUXOFFTIME is programmed to a value less than OEONTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. OEAADMUXOFFTIME must never be equal to OEONTIME because the AAD-multiplexed protocol requires a second address phase with the nOE signal deasserted before nOE can be asserted again to define a read command.

The nOE/RE signal transitions as controlled through OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG4_i[7] OEEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on the nOE/RE assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. If enabled, OEEXTRADELAY applies to all parameters controlling nOE/nRE transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than the nOE/RE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

NOTE: When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until nOE assertion time.

10.3.4.9.5 nWE: Write Enable Signal Control Assertion/Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)

The GPMC_CONFIG4_i[19:16] WEONTIME bit field (where i = 0 to 7) defines the nWE signal-assertion time relative to start access time. The GPMC_CONFIG4_i[28:24] WEOFFTIME bit field defines the nWE signal-deassertion time relative to start access time. These bit fields apply only to write accesses. nWE is not asserted during a read cycle.

WEONTIME can be used to control an address and byte-enable valid setup time control before nWE assertion. WEOFFTIME can be used to control an address and byte-enable valid hold time control after nWE assertion.

nWE signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG4_i[23] WEEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on nWE assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. If enabled, WEEXTRADELAY applies to all parameters controlling nWE transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the nWE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

10.3.4.9.6 GPMC_CLK

GPMC_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC_CLK clock frequency is the GPMC_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field (where i = 0 to 7), with a guaranteed 50-percent duty cycle. For information about the duty cycle error, see the device data manual.
- The GPMC_CLK clock is activated only when the access in progress is defined as synchronous (read or write access).
- The GPMC_CLK clock frequency is defined by the GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME bit field (where i = 0 to 7) defines the number of GPMC_FCLK cycles from start access time to GPMC_CLK activation.
- The GPMC_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC_CLK clock is kept low when access is defined as asynchronous.

CAUTION

When the cycle time completes, the GPMC_CLK may be high because of the GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC_CLK clock within the required 50-percent duty cycle, the user must extend the RDCYCLETIME or WRCYCLETIME value.

NOTE: To ensure a correct external clock cycle, the following rules must be applied:

- (RDCYCLETIME CLKACTIVATIONTIME) must be a multiple of (GPMCFCLKDIVIDER + 1).
- The PAGEBURSTACCESSTIME value must be a multiple of (GPMCFCLKDIVIDER + 1).

10.3.4.9.7 GPMC_CLK and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC_CLK edge can be controlled in the following ways:

- For the GPMC_CLK signal, the GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME bit field (where i = 0 to 7) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC_CLK allows setup and hold control of the control-signal assertion and deassertion times.
- When GPMC_CLK runs at the GPMC_FCLK frequency so that GPMC_CLK edge and control-signal transitions refer to the same GPMC_FCLK edge, the control-signal transitions can be delayed by a half-GPMC_FCLK period to provide minimum setup and hold times. This half-GPMC_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEEXTRADELAY, or WEEXTRADELAY parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC_FCLK cycle.

10.3.4.9.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read/write access time durations can be programmed independently through the GPMC_CONFIG5_i[20:16] RDACCESSTIME and GPMC_CONFIG6_i[28:24] WRACCESSTIME bit fields (where i = 0 to 7). This allows nOE and GPMC data-capture timing parameters to be independent of nWE and memory device data capture timing parameters. The RDACCESSTIME and WRACCESSTIME bit fields can be set with a granularity of 1 or 2 through the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

10.3.4.9.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, the GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field (where i = 0 to 7) defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC_FCLK cycles from the start access time to the GPMC_FCLK rising edge corresponding to the GPMC_CLK rising edge used for the first data capture.

GPMC_CLK, which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. The GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field must be greater than RDACCESSTIME to let the GPMC latch the last return data using the internally retimed GPMC_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access in asynchronous and synchronous modes. For more information about wait monitoring, see Section 10.3.4.8.3.1, *Wait Pin Monitoring Control*.

10.3.4.9.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC_CONFIG6_i[28:24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a wait invalid timing window and must be set to a correct value so that the gpmc_wait pin is at a valid state two GPMC_CLK cycles before WRACCESSTIME completes. For more information about wait monitoring, see Section 10.3.4.8.3.1, *Wait Pin Monitoring Control*.

In synchronous write mode , for single or burst accesses, WRACCESSTIME defines the number of GPMC_FCLK cycles from the start access time to the GPMC_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data-capture GPMC_CLK edge for a synchronous write access. For more information about wait monitoring, see Section 10.3.4.8.3.1, *Wait Pin Monitoring Control*.

10.3.4.9.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

The GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME bit field (where i = 0 to 7) can be set with a granularity of 1 or 2 through theGPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

10.3.4.9.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME bit field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access. For more information about wait monitoring, see Section 10.3.4.8.3.1, *Wait Pin Monitoring Control*.

10.3.4.9.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory device data capture GPMC_CLK edge in synchronous write mode. For more information about wait monitoring, see Section 10.3.4.8.3.1, *Wait Pin Monitoring Control*.

10.3.4.9.10 Bus Keeping Support

At the end cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completes to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

10.3.4.10 NOR Access Description

For each chip-select configuration, the read access can be specified as asynchronous or synchronous access through the GPMC_CONFIG1_i[29] READTYPE bit (where i = 0 to 7). For each chip-select configuration, the write access can be specified as synchronous or asynchronous access through the GPMC_CONFIG1_i[27] WRITETYPE bit where (i = 0 to 7).

Asynchronous and synchronous read and write access time and related control signals are controlled through timing parameters that refer to GPMC_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface (GPMC_CLK) to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For more information about asynchronous and synchronous access, see the descriptions of GPMC_CLK, RdAccessTime, WrAccessTime, and wait pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

NOTE: The address bus and nBE[1:0] are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

10.3.4.10.1 Asynchronous Access Description

This section describes:

- Asynchronous single-read operation on an address/data multiplexed device
- Asynchronous single write operation on an address/data-multiplexed device
- Asynchronous single read operation on an AAD-multiplexed device
- Asynchronous single write operation on an AAD-multiplexed device
- Asynchronous multiple (page) read operation on a non-multiplexed device

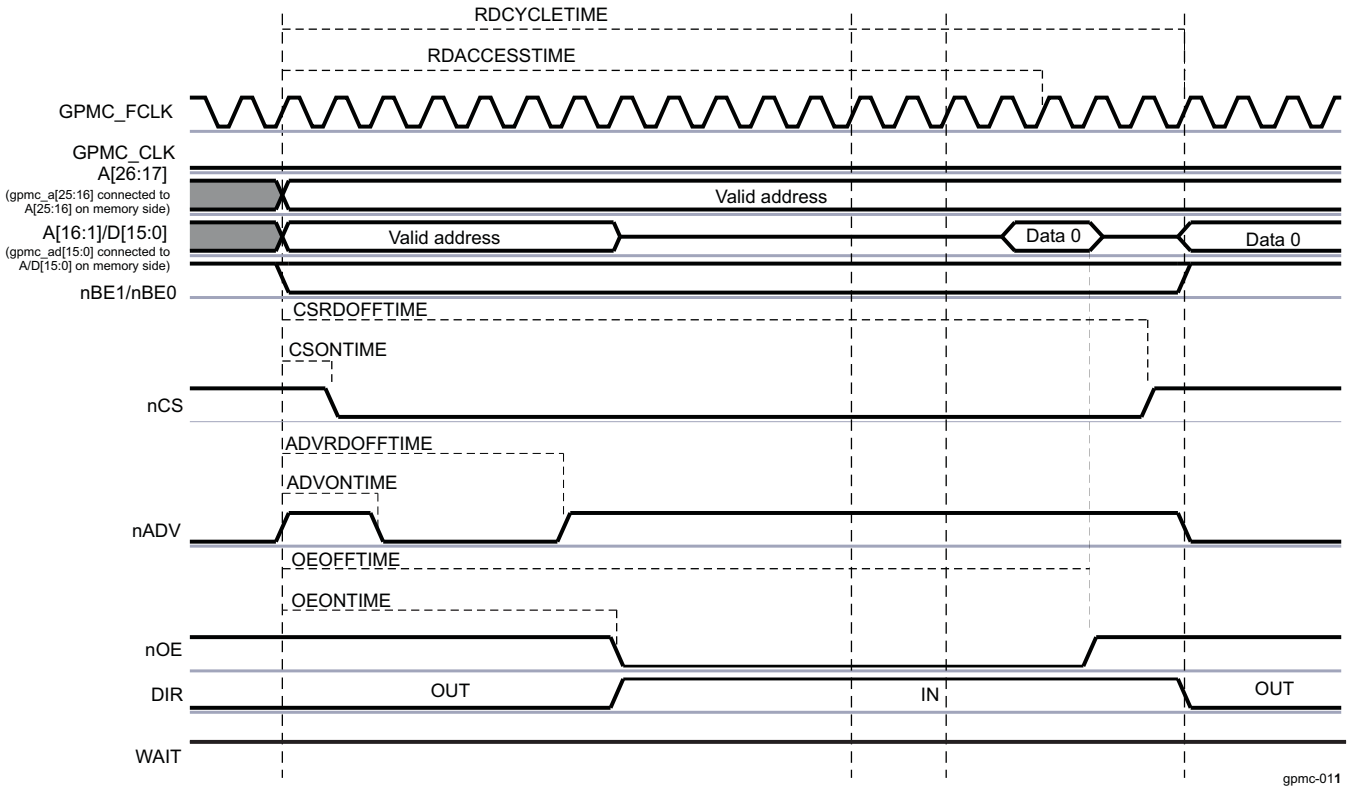
In asynchronous operations GPMC_CLK is not provided outside the GPMC and is kept low.

10.3.4.10.1.1 Access on Address/Data Multiplexed Devices

10.3.4.10.1.1.1 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

Figure 10-24 shows an asynchronous single read operation on an address/data-multiplexed device.

Figure 10-24. Asynchronous Single Read on an Address/Data-Multiplexed Device



For formulas to calculate timing parameters, see Section 10.3.5.6.1, *GPMC Timing Parameters Formulas*.

Table 10-400 lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see Section 10.3.4.8.2.3, *Address/Data-Multiplexing Interface*.

Address bits (A[16:1] from a GPMC perspective, A[15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits gpmc_a[27:16] are placed on the address bus. The address phase ends at nOE assertion, when the DIR signal goes from OUT to IN.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CSONTIME bit field. It controls the address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12:8] CSRDOFFTIME bit field. It controls the address hold time from nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.

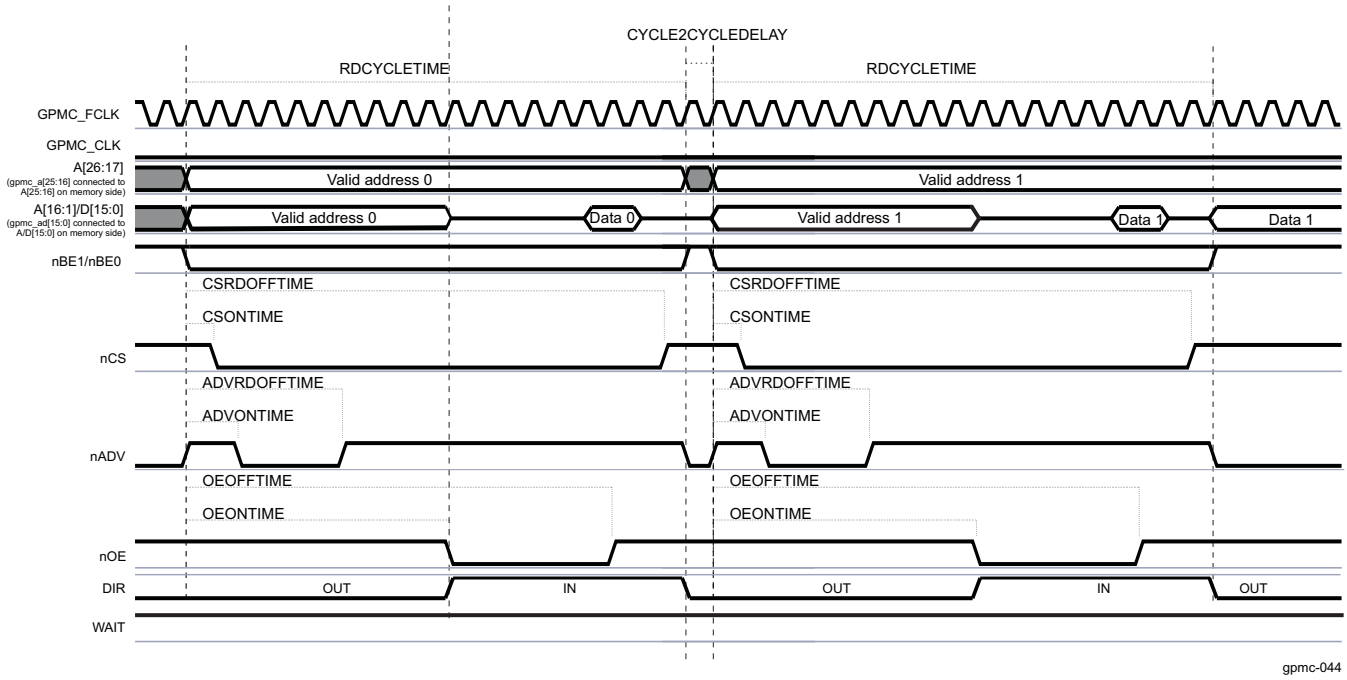
- Read data is latched when RDACCESSTIME completes. Access time is defined in the GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that nOE is asserted.
- The end of the access is defined by the GPMC_CONFIG5_i[4:0] RDCYCLETIME parameter.

In the GPMC, when a 16-bit wide device is attached to the controller, a 32-bit word write access is split into two 16-bit word write accesses. For more information about GPMC access size and type adaptation, see Section 10.3.4.10.5, *System Burst Versus External Device Burst Support*.

Between two successive accesses, if an nCS pulse is needed:

- The GPMC_CONFIG6_i[11:8] CYCLE2CYCLEDELAY bit field can be programmed with the GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN bit enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

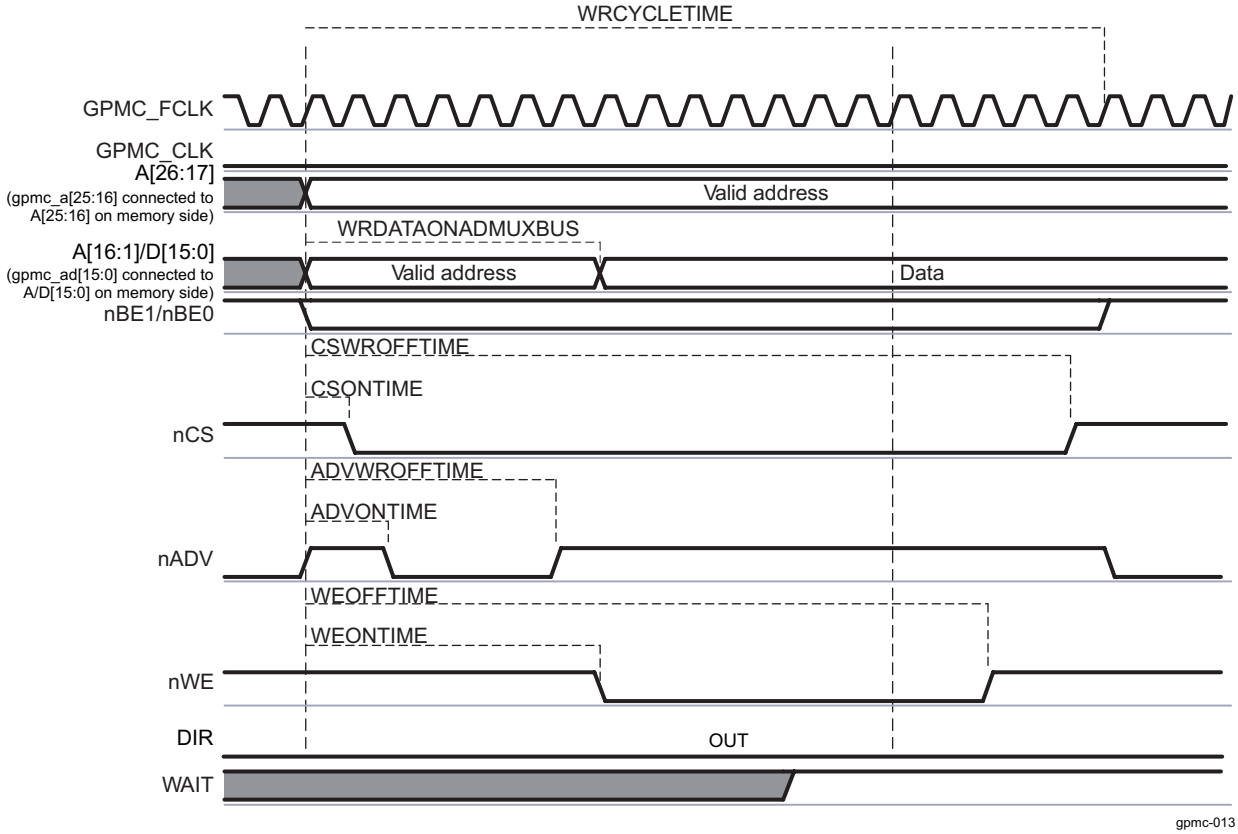
Figure 10-25. Two Asynchronous Single-Read Accesses on an Address/Data-Multiplexed Device (32-Bit Read Split Into 2 x 16-Bit Read)



10.3.4.10.1.1.2 Asynchronous Single-Write Operation on an Address/Data-Multiplexed Device

Figure 10-26 shows an asynchronous single-write operation on an address/data-multiplexed device.

Figure 10-26. Asynchronous Single-Write on an Address/Data-Multiplexed Device



For formulas to calculate timing parameters, see Section 10.3.5.6.1, *GPMC Timing Parameters Formulas*.

Table 10-400 lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the address bus until nWE assertion time. For more information, see Section 10.3.4.8.2.3, *Address/Data-Multiplexing Interface*.

The nCS and nADV signals are controlled in the same way as for a asynchronous single-read operation on an address/data-multiplexed device.

- Write enable signal nWE:
  - nWE assertion indicates a write cycle.
  - nWE assertion time is controlled by the GPMC_CONFIG4_i[19:16] WEONTIME bit field.
  - nWE deassertion time is controlled by the GPMC_CONFIG4_i[28:24] WEOFFTIME bit field.
- Direction signal DIR: DIR signal is OUT during the entire access.
- The end of the access is defined by the GPMC_CONFIG5_i[12:8] WRCYCLETIME parameter.

Address bits A[16:1] (GPMC point of view) are placed on the address/data bus at the start of cycle time, and the remaining address bits A[26:17] are placed on the address bus.

Data is driven on the address/data bus at a GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS time.

NOTE: Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See Section 10.3.4.9.10, *Bus Keeping Support*.

10.3.4.10.1.1.3 Asynchronous Multiple (Page) Write Operation on an Address/Data-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for address/data-multiplexed devices.

If the GPMC_CONFIG1_i[28] WRITEMULTIPLE bit is enabled (0x1) with the GPMC_CONFIG1_i[27] WRITETYPE bit as asynchronous (0x0), the GPMC processes single asynchronous accesses.

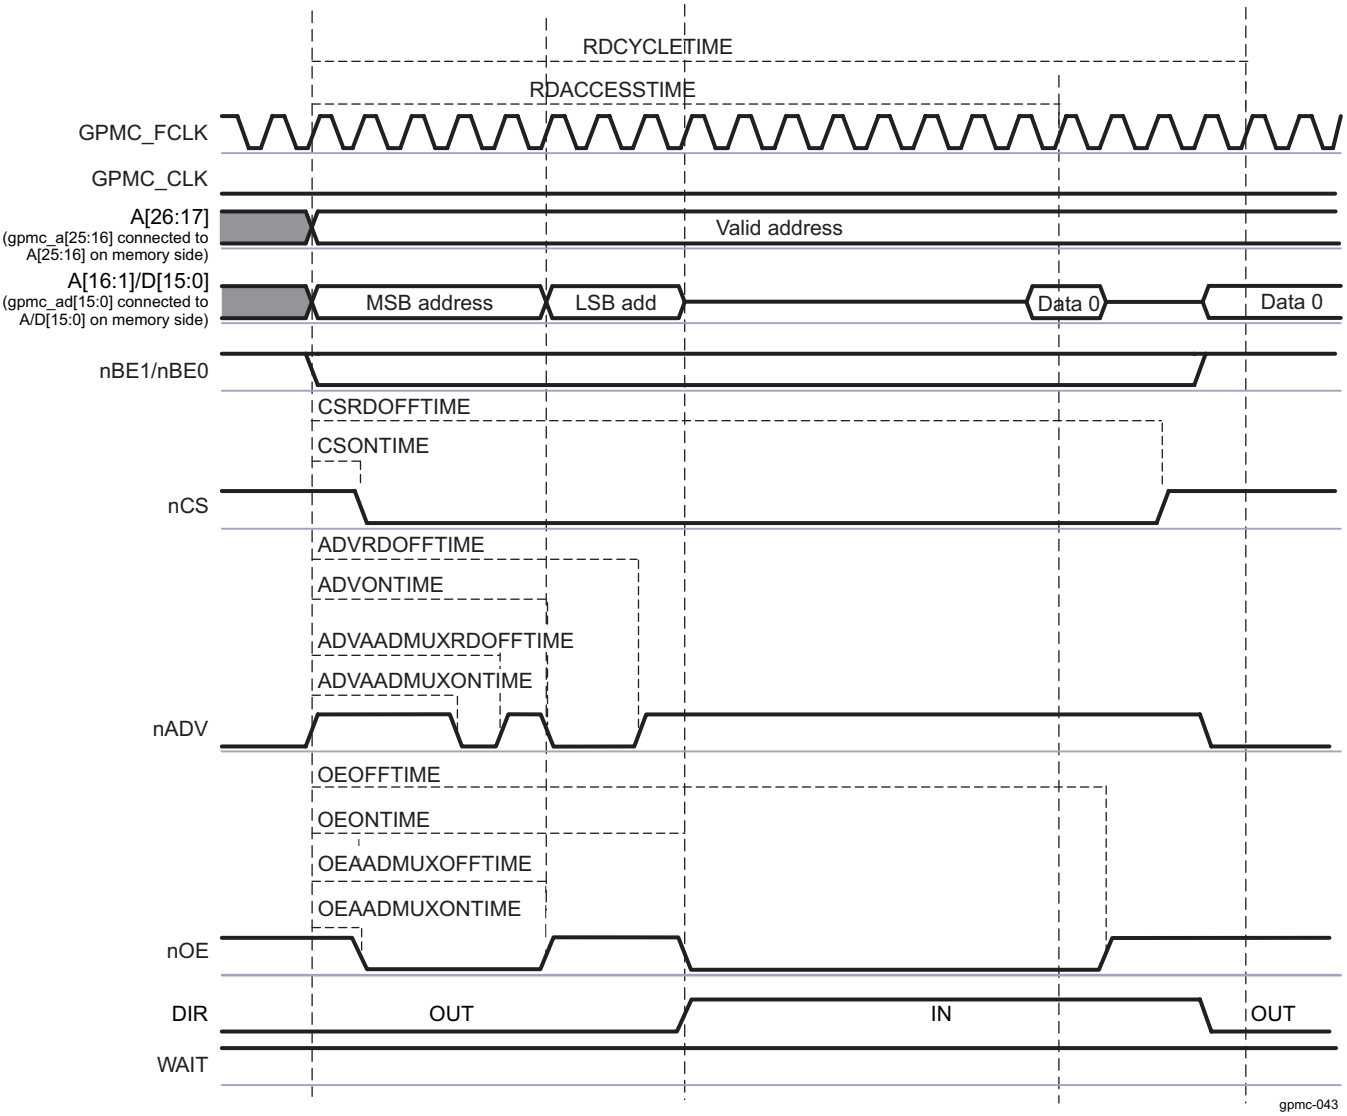
For accesses on nonmultiplexed devices, see Section 10.3.4.10.3, *Asynchronous and Synchronous Accesses in Nonmultiplexed Mode*.

10.3.4.10.1.2 Access on Address/Address/Data-Multiplexed Devices

10.3.4.10.1.2.1 Asynchronous Single Read Operation on an AAD-Multiplexed Device

Figure 10-27 shows an asynchronous single-read operation on an AAD-multiplexed device.

Figure 10-27. Asynchronous Single Read on an AAD-Multiplexed Device



For formulas to calculate timing parameters, see Section 10.3.5.6.1, *GPMC Timing Parameters Formulas*.

Table 10-400 lists the timing bit fields to set up to configure the GPMC in asynchronous single write mode.

When the GPMC generates a read access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The first address phase ends at the first nOE deassertion time. The second phase for LSB address is qualified with nOE driven high. The second address phase ends at the second nOE assertion time, when the DIR signal goes from OUT to IN.

The nCS and DIR signals are controlled in the same way as for an asynchronous single-read operation on an address/data-multiplexed device.

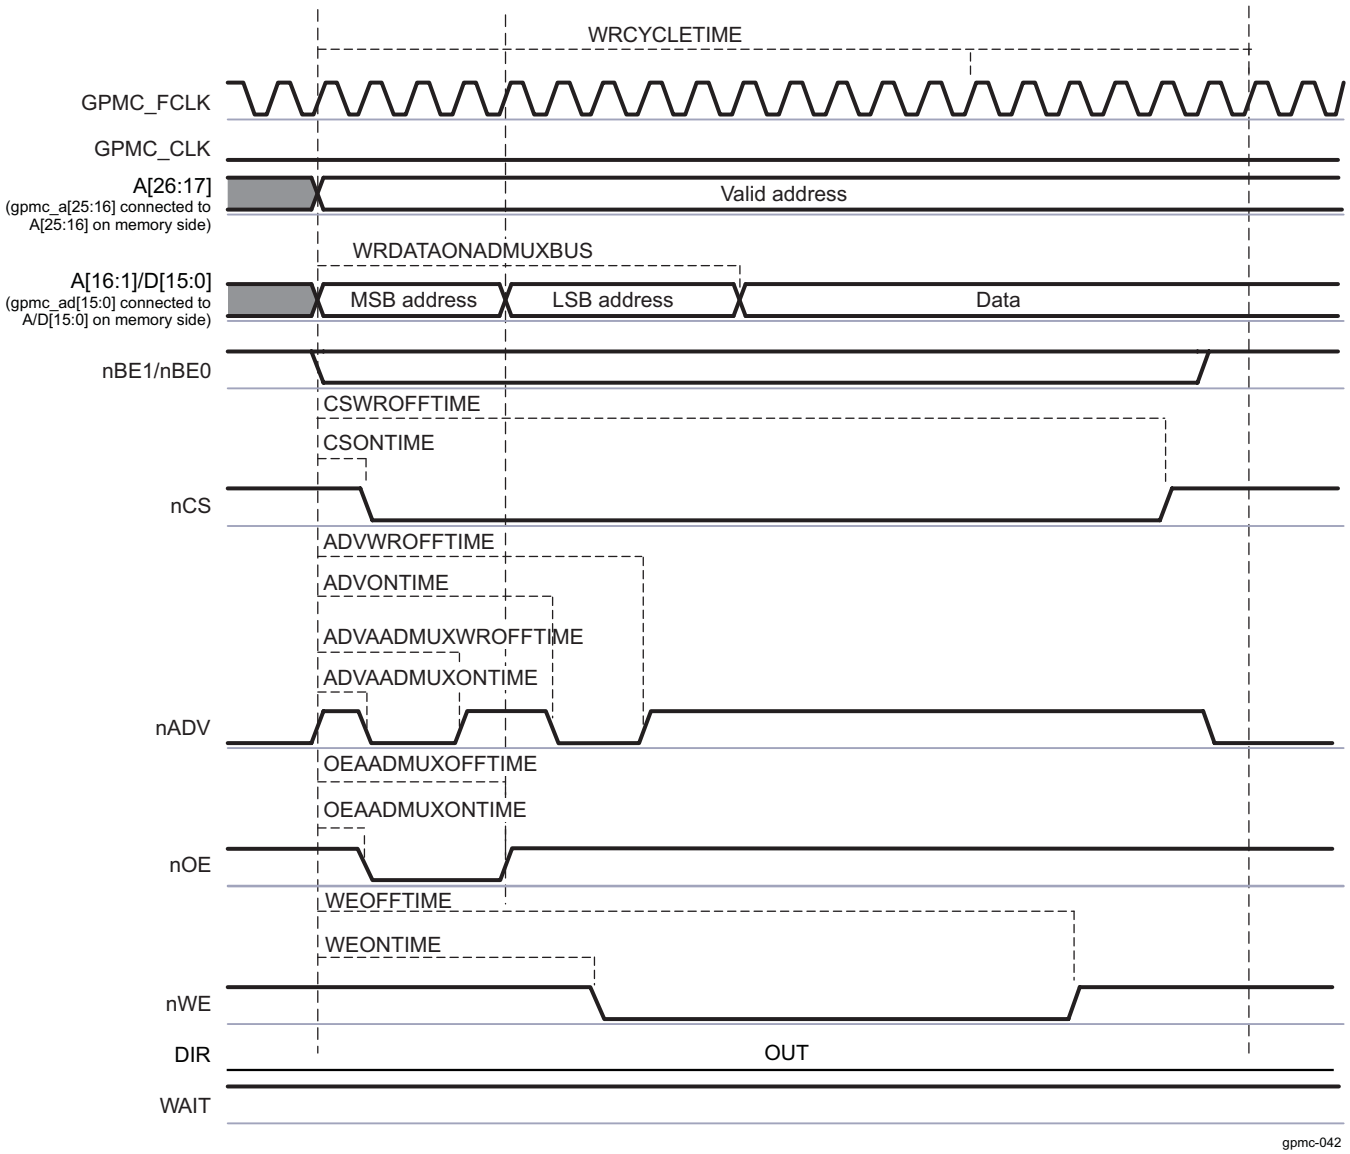
- Address valid signal nADV. nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME bit field.

  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output Enable signal nOE. nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC_CONFIG3_i[15:13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.

10.3.4.10.1.2.2 Asynchronous Single-Write Operation on an AAD-Multiplexed Device

Figure 10-28 shows an asynchronous single-write operation on an AAD-multiplexed device.

Figure 10-28. Asynchronous Single Write on an AAD-Multiplexed Device



For formulas to calculate timing parameters, see Section 10.3.5.6.1, *GPMC Timing Parameters Formulas*.

Table 10-400 lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, nWE, and DIR signals are controlled in the same way as for an asynchronous single-write operation on an address/data-multiplexed device. See Table 10-391.

- Address valid signal nADV is asserted and deasserted twice during a write transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[30:28] ADVAADMUXWROFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[20:16] ADVWROFFTIME bit field.
- Output enable signal nOE is asserted during the address phase of a write transaction:
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME bit field.
  - nOE deassertion time is controlled by the GPMC_CONFIG3_i[15:13] OEAADMUXOFFTIME bit field.

The address bits for the first address phase are driven onto the data bus until nOE deassertion. Data is driven onto the address/data bus at the clock edge defined by the GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS parameter.

10.3.4.10.1.2.3 Asynchronous Multiple (Page) Read Operation on an AAD-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for AAD-multiplexed devices.

If the GPMC_CONFIG1_i[28] WRITEMULTIPLE bit is enabled (0x1) with the GPMC_CONFIG1_i[27] WRITETYPE bit as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on nonmultiplexed devices, see Section 10.3.4.10.3, *Asynchronous and Synchronous Accessed in Nonmultiplexed Mode*.

10.3.4.10.2 Synchronous Access Description

This section describes read and write synchronous accesses on address/data-multiplexed devices. All information in this section can be applied to any type of memory (nonmultiplexed, address and data-multiplexed, or AAD-multiplexed) with the difference limited to the address phase. For accesses on nonmultiplexed devices, see Section 10.3.4.10.3, *Asynchronous and Synchronous Accessed in Nonmultiplexed Mode*.

In synchronous operations:

- The GPMC_CLK clock is provided outside the GPMC when accessing the memory device.
- The GPMC_CLK clock is derived from the GPMC_FCLK clock using the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field. In the following section i stands for the chip-select number, i = 0 to 7.
- The GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME bit field specifies that the GPMC_CLK is provided outside the GPMC for 0 to 2 GPMC_FCLK cycles after start access time until RDCYCLETIME or WRCYCLETIME completes.

10.3.4.10.2.1 Synchronous Single Read

Figure 10-29 and Figure 10-30 show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

Figure 10-29. Synchronous Single Read (GPMCFCLKDIVIDER = 0)

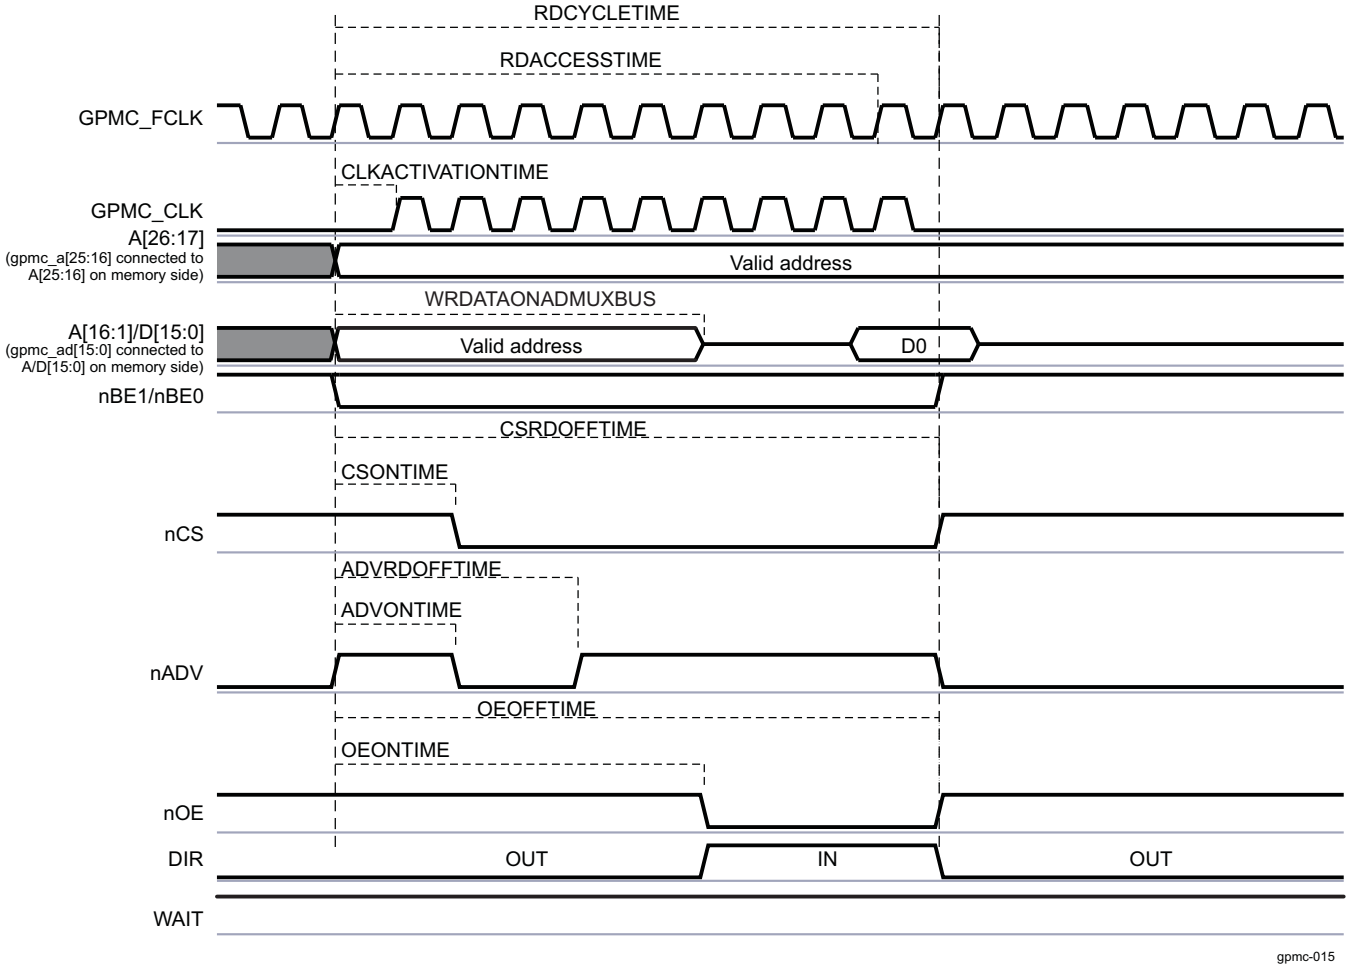


Figure 10-30. Synchronous Single Read (GPMCFCLKDIVIDER = 1)

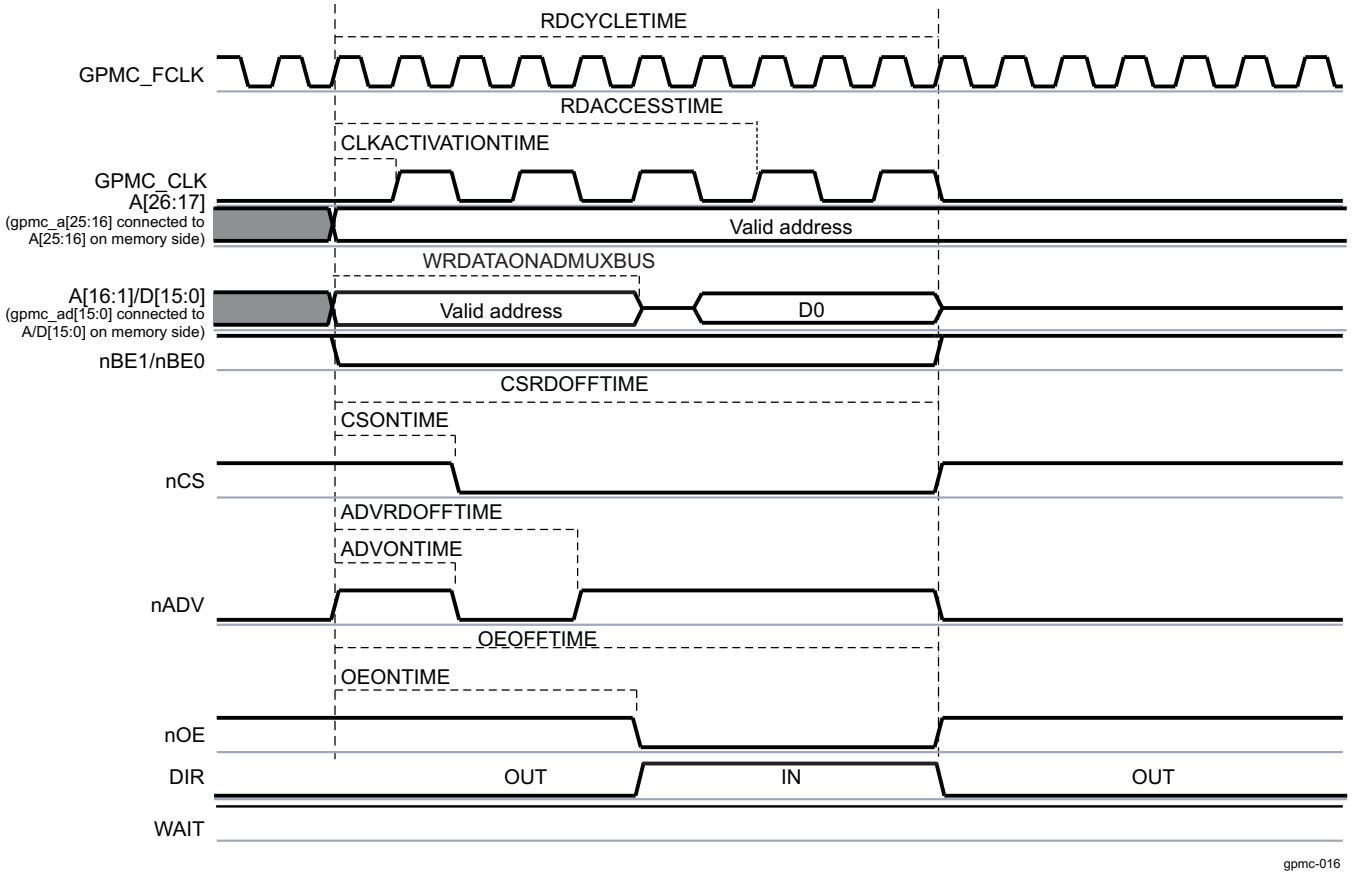

For formulas to calculate timing parameters, see Section 10.3.5.6.1, *GPMC Timing Parameters Formulas*.

Table 10-400 lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see Section 10.3.4.8.2.3, *Address/Data-Multiplexing Interface*.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CSONTIME bit field and ensures address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12:8] CSRDOFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.
- Initial latency for the first read data is controlled by GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field or by monitoring the WAIT signal.
- Total access time (the GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus time from RDACCESSTIME to CSRDOFFTIME.

- Direction signal DIR: DIR goes from OUT to IN at the same time as nOE assertion.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS and DIR signals are controlled in the same way as for a synchronous single-read operation on an address/data-multiplexed device.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC_CONFIG3_i[15:13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 10.3.4.9.10, *Bus Keeping Support*.

10.3.4.10.2.2 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst With Wraparound Capability)

Figure 10-31 and Figure 10-32 show a synchronous multiple-read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

Figure 10-31. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)

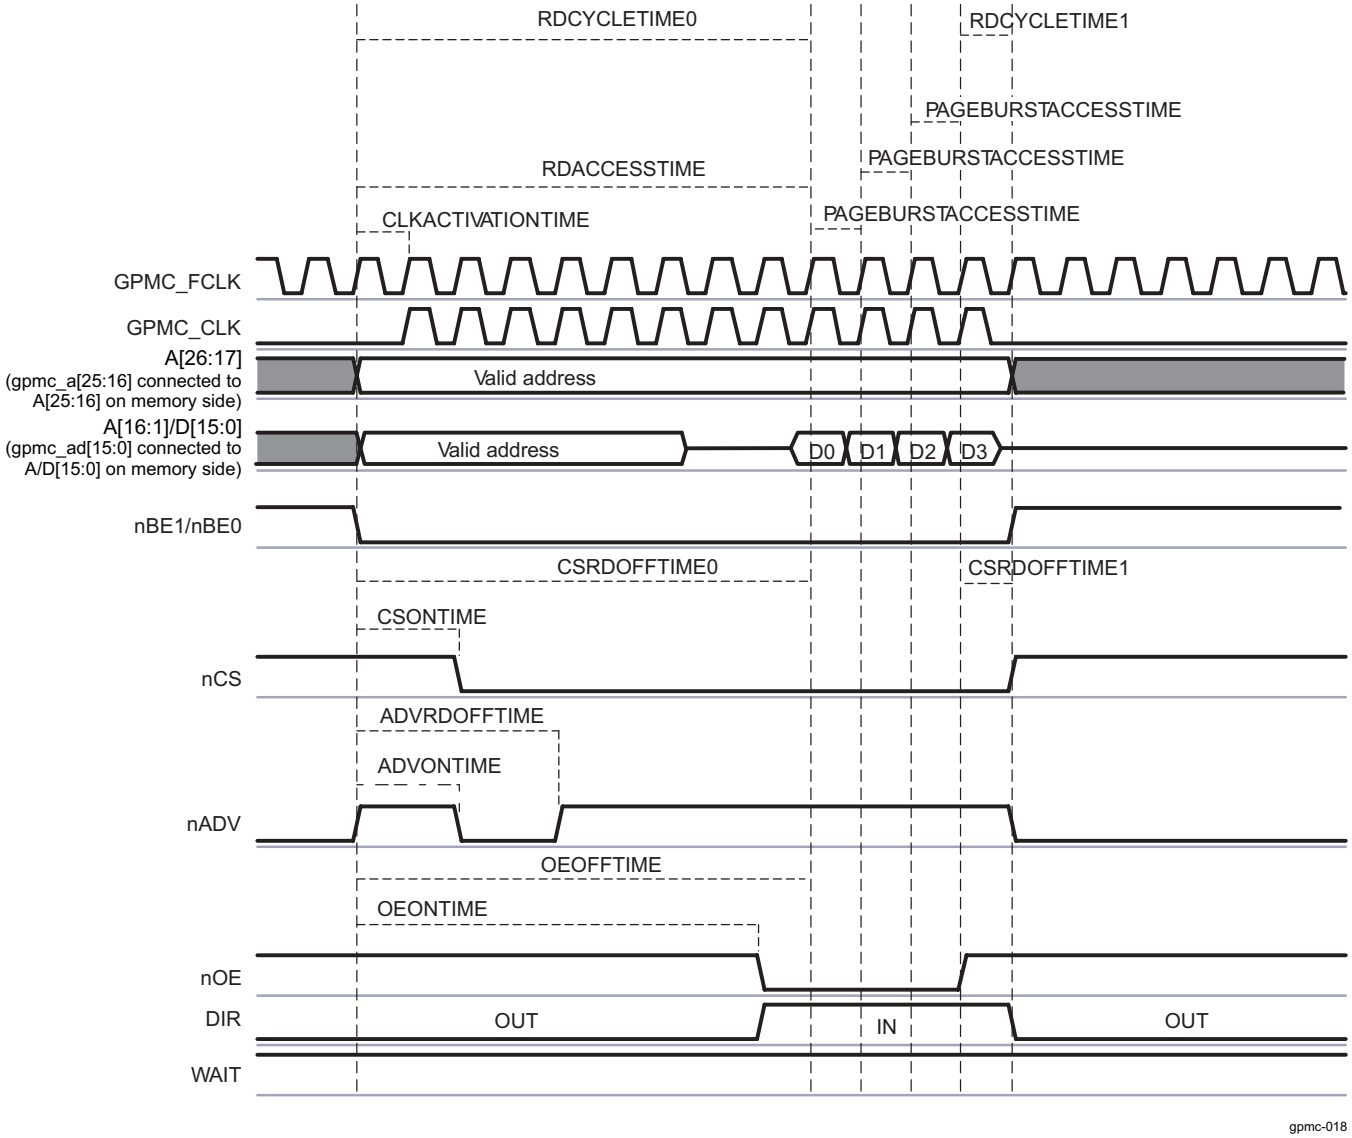

Figure 10-32. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)

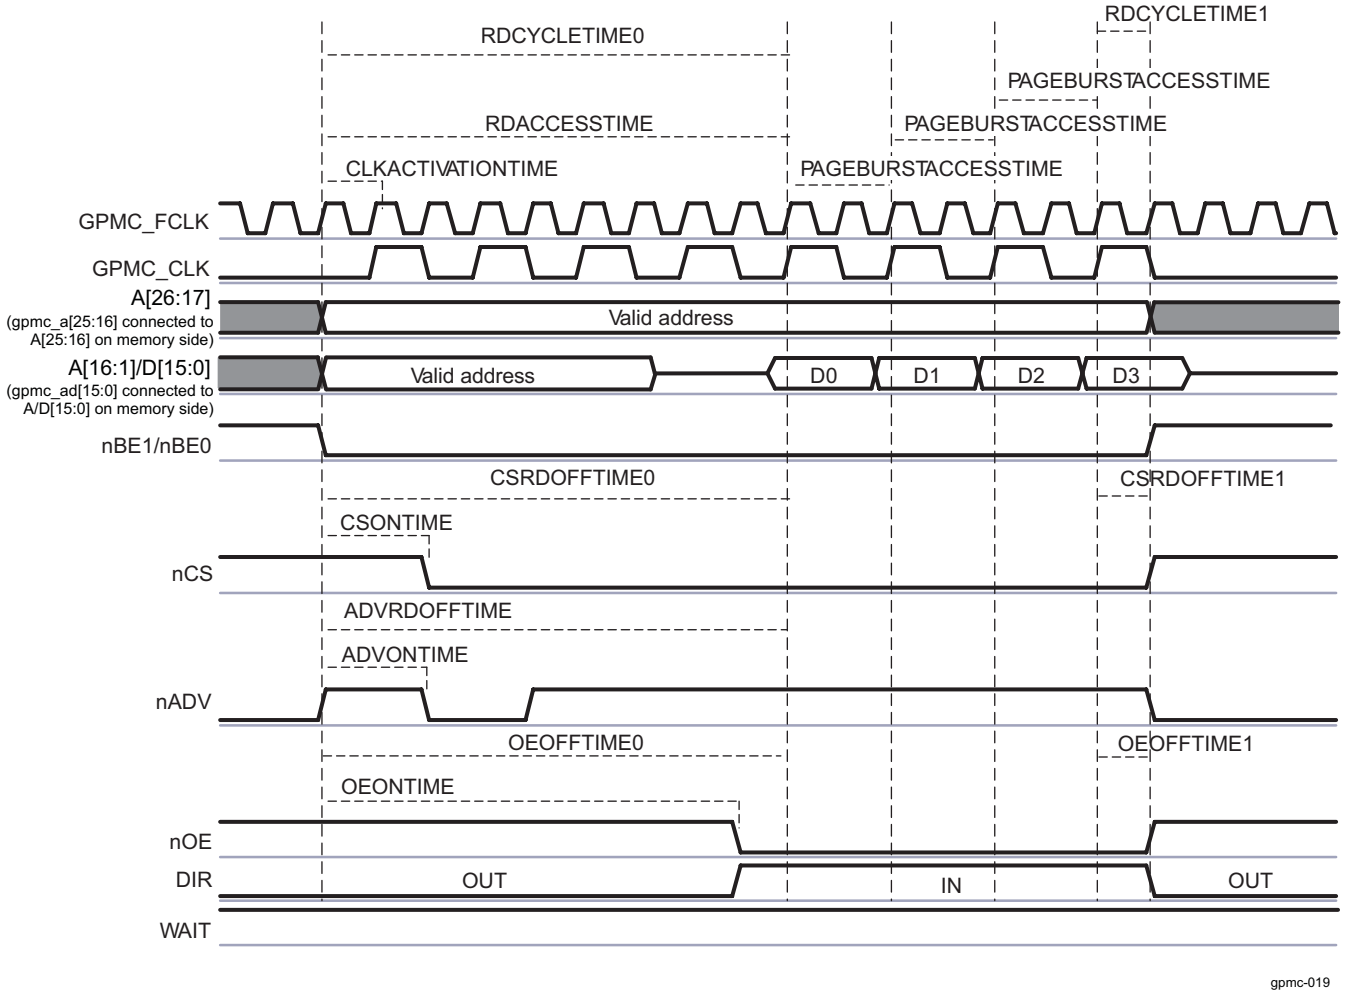


When the GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME bit field multiplied by the number of remaining data transactions.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as for a synchronous single-read operation. See Table 10-386.

Initial latency for the first read data is controlled by RDACCESSTIME or by monitoring the WAIT signal. Successive read data are provided by the memory device every one or two GPMC_CLK cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field and the memory-device internal configuration. Depending on the device page length, the GPMC checks the device page crossing during a new burst request and purposely inserts initial latency (of RDACCESSTIME) when required.

Total access time GPMC_CONFIG5_i[4:0] RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time from nCS deassertion. In Figure 10-32, the programmed value of RDCYCLETIME equals RDCYCLETIME0 + RDCYCLETIME1.

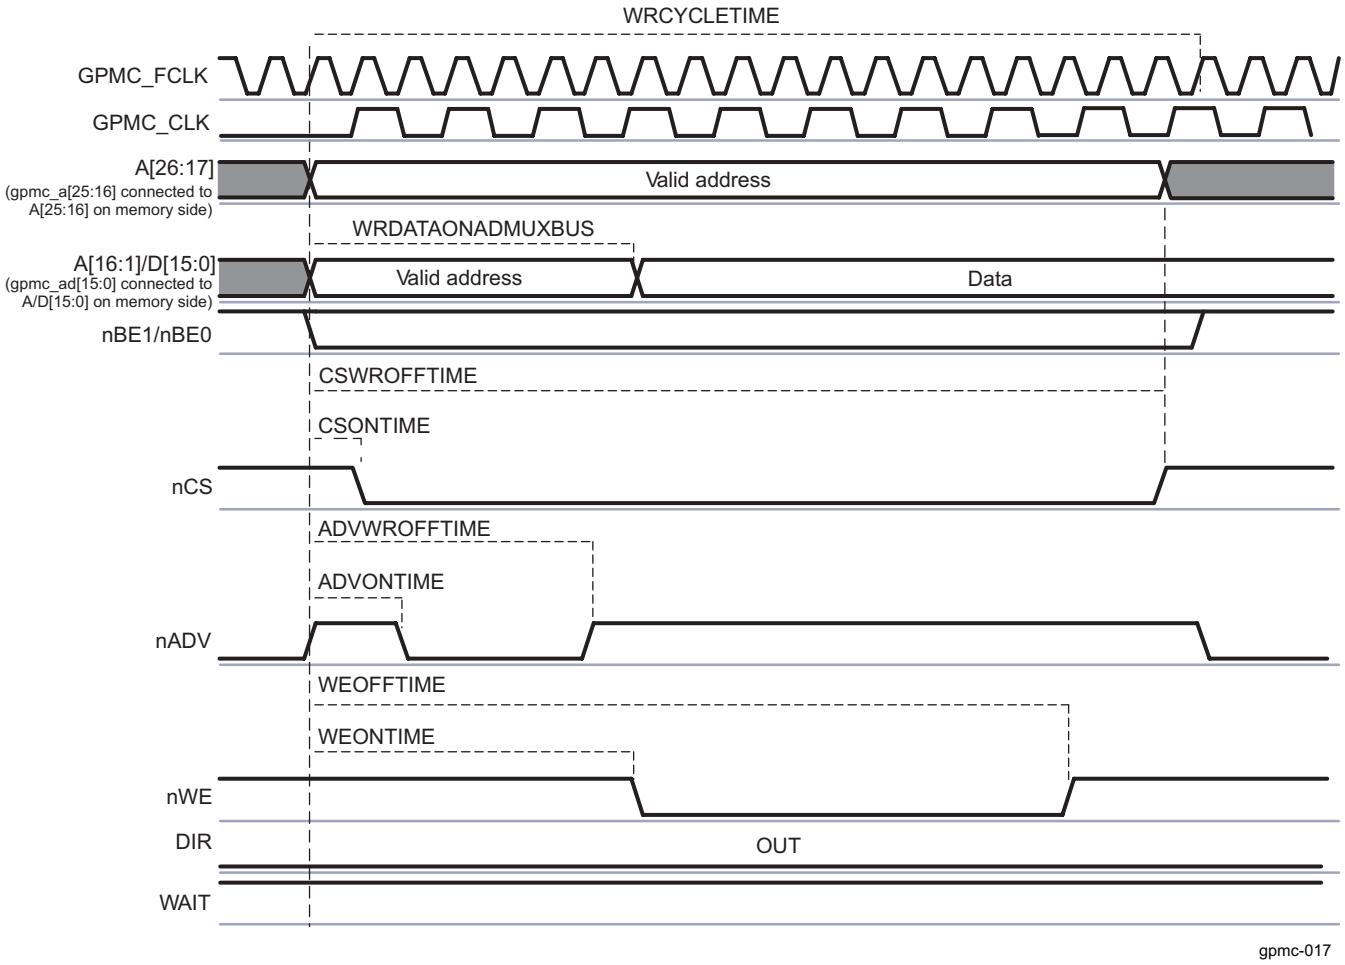
After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 10.3.4.9.10, *Bus Keeping Support*.

Burst wraparound is enabled through the GPMC_CONFIG1_i[31] WRAPBURST bit and allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary through the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH bit field.

10.3.4.10.2.3 Synchronous Single Write

Burst write mode is used for synchronous single or burst accesses.

Figure 10-33. Synchronous Single Write on an Address/Data-Multiplexed Device



When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus (with address bits A[16:1]) until the GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS bit field time. The first data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

10.3.4.10.2.4 Synchronous Multiple (Burst) Write

Synchronous burst write mode provides synchronous single or consecutive accesses.

Figure 10-34 shows a synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

Figure 10-34. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode

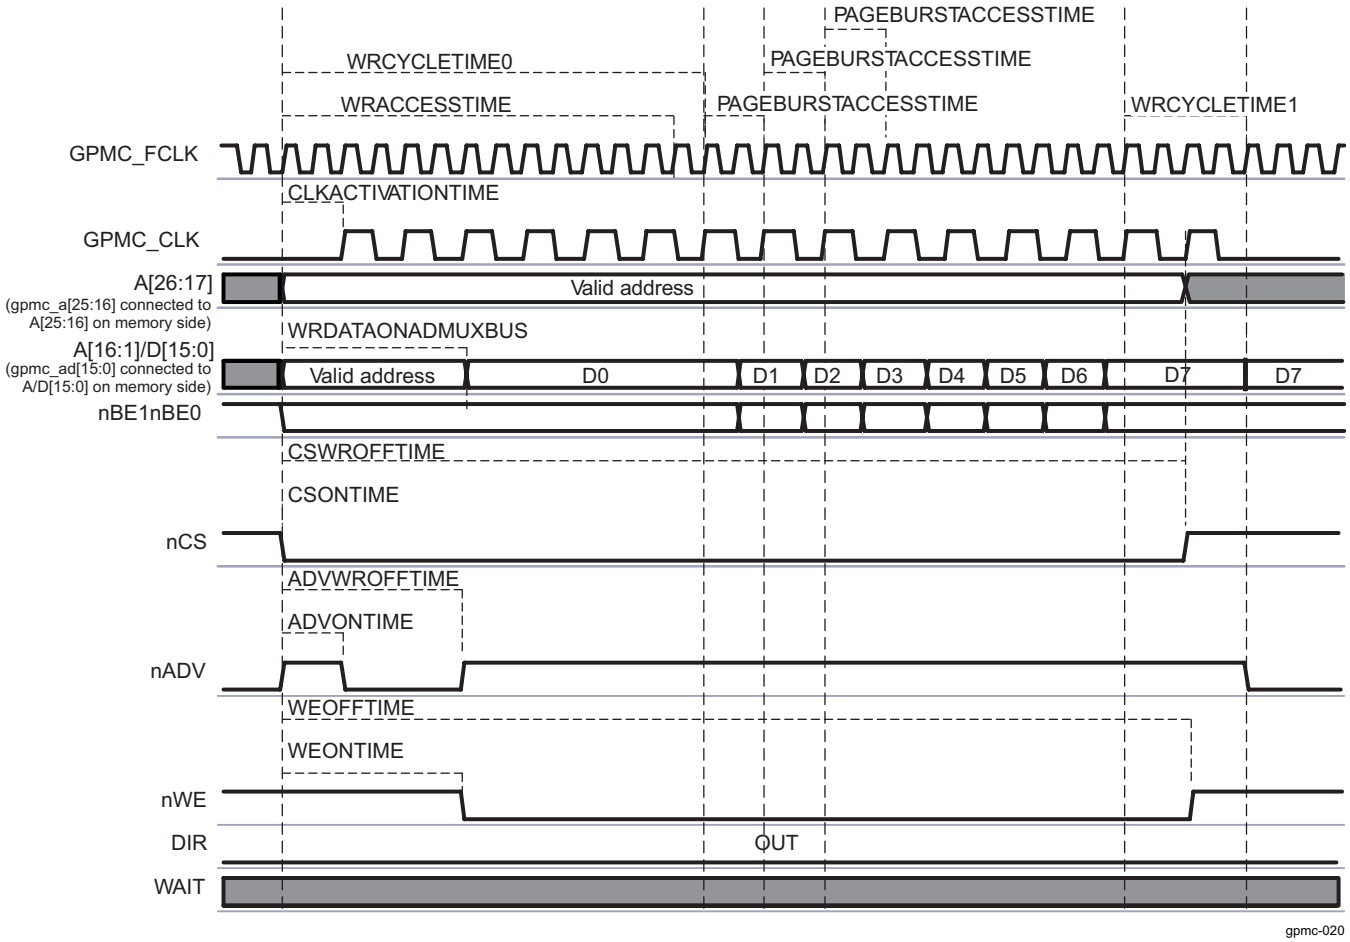


Figure 10-35 shows the same synchronous burst write access when the chip-select is configured in address/address/data-multiplexed (AAD-multiplexed) mode.

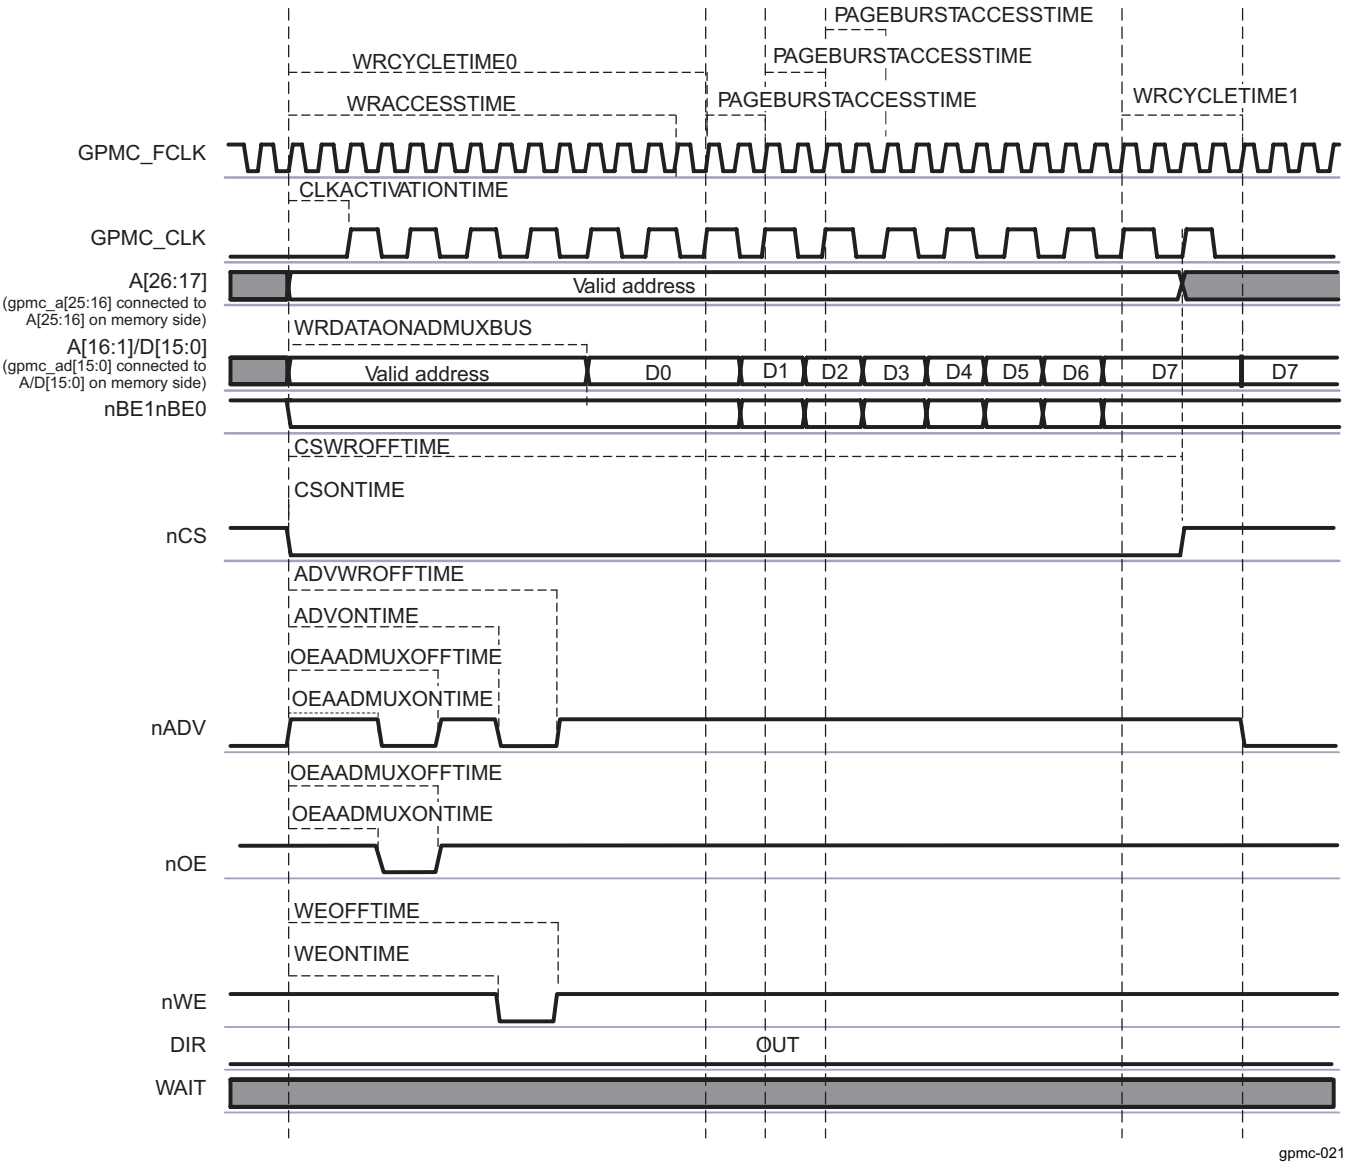
Figure 10-35. Synchronous Multiple Write (Burst Write) in Address/Address/Data-Multiplexed Mode



The first data of the burst is driven on the A/D bus at the GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS bit field.

When WRACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME bit field multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see Section 10.3.4.8.2.3, *Address/Data-Multiplexing Interface*.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CSONTIME bit field (where i = 0 to 7) and ensures address setup time to nCS assertion.
  - nCS deassertion time controlled by the GPMC_CONFIG2_i[20:16] CSWROFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.

  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[20:16] ADVWROFFTIME bit field.
- Write enable signal nWE:
  - nWE assertion indicates a read cycle.
  - nWE assertion time is controlled by the GPMC_CONFIG4_i[19:16] WEONTIME bit field.
  - nWE deassertion time is controlled by the GPMC_CONFIG4_i[28:24] WEOFFTIME bit field.

NOTE: The nWE falling edge must not be used to control the time when the burst first data is driven in the address/data bus, because some new devices require the nWE signal to be low during the address phase.

- Direction signal DIR is OUT during the entire access.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, and DIR signals are controlled as previously described..

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC_CONFIG4_i[15:13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.

First write data is driven by the GPMC at GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS, when in address/data-multiplexed configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME GPMC_FCLK cycles. The last data of the synchronous burst write is driven until GPMC_CONFIG5_i[12:8] WRCYCLETIME completes.

- WRACCESSTIME is defined in the GPMC_CONFIG6_i[28:24] bit field.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time GPMC_CONFIG5_i[12:8] WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from nCS deassertion. In Figure 10-34, the programmed value of WRCYCLETIME equals WRCYCLETIME0 + WRCYCLETIME1. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See Section 10.3.4.9.10, *Bus Keeping Support*.

10.3.4.10.3 Asynchronous and Synchronous Accesses in Nonmultiplexed Mode

Page mode is available only in nonmultiplexed mode.

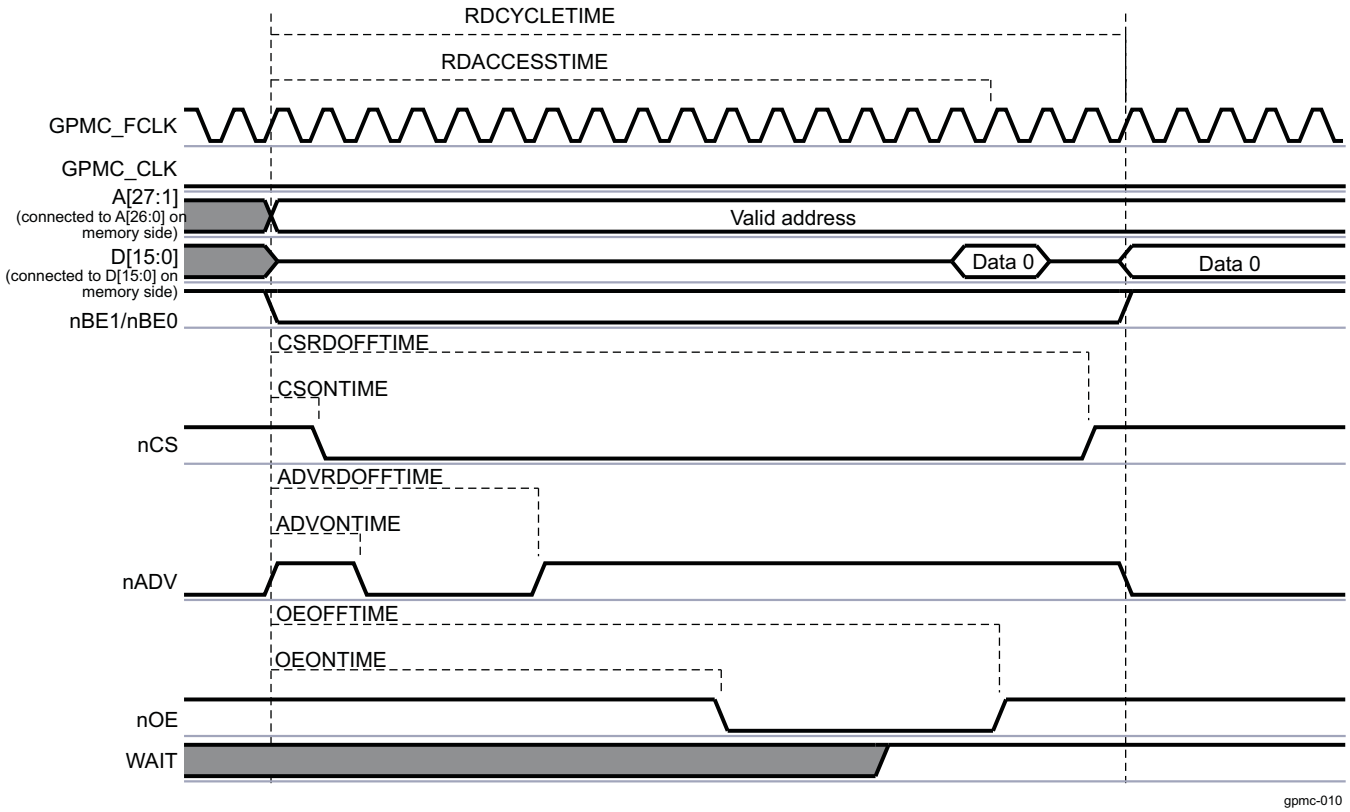
- Asynchronous single-read operation on a nonmultiplexed device
- Asynchronous single-write operation on a nonmultiplexed device
- Asynchronous multiple- (page mode) read operation on a nonmultiplexed device

- Synchronous operations on a nonmultiplexed device

10.3.4.10.3.1 Asynchronous Single-Read Operation on Nonmultiplexed Device

Figure 10-36 shows an asynchronous single-read operation on a nonmultiplexed device.

Figure 10-36. Asynchronous Single Read on an Address/Data-Nonmultiplexed Device



The 27-bit address (For a 16-bit data memory device, hence GPMC A[0] is not necessary to be output) is driven onto the address bus A[27:1] and the 16-bit data is driven onto the data bus D[15:0].

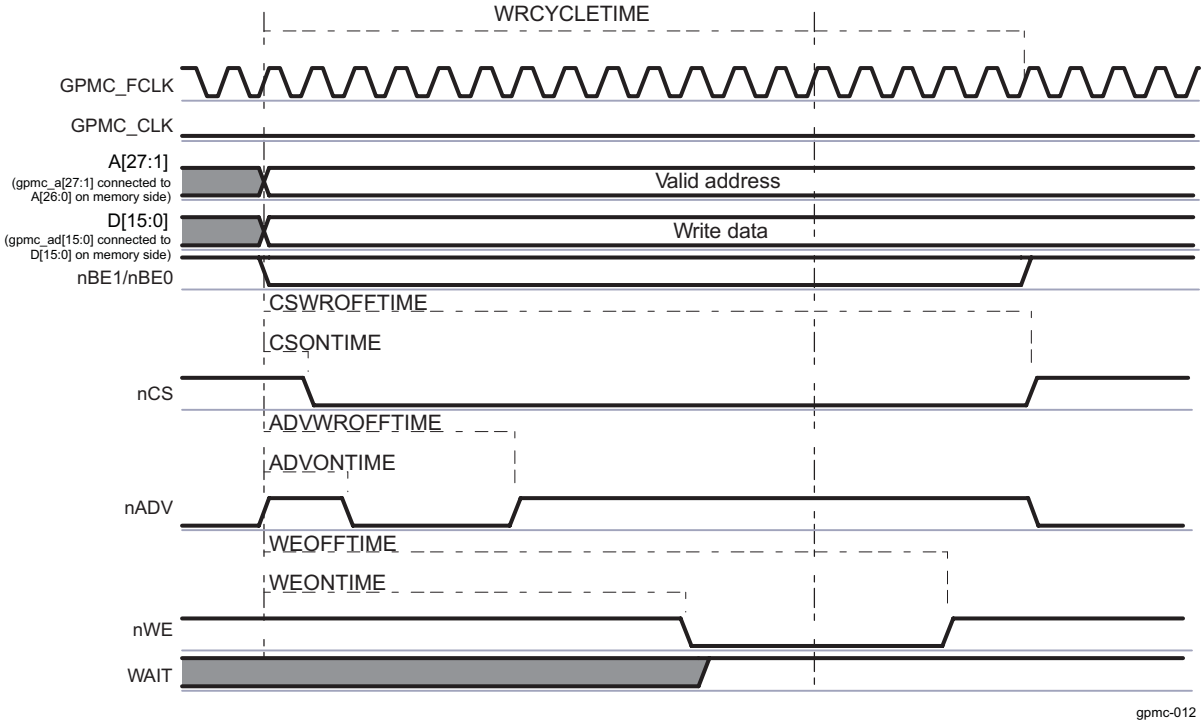
Read data is latched at GPMC_CONFIG1_5[20:16] RDACCESSTIME completion time. The end of the access is defined by the GPMC_CONFIG1_5[4:0] RDCYCLETIME parameter.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 10-391).

10.3.4.10.3.2 Asynchronous Single-Write Operation on Nonmultiplexed Device

Figure 10-37 shows an asynchronous single-write operation on a nonmultiplexed device.

Figure 10-37. Asynchronous Single Write on an Address/Data-Nonmultiplexed Device

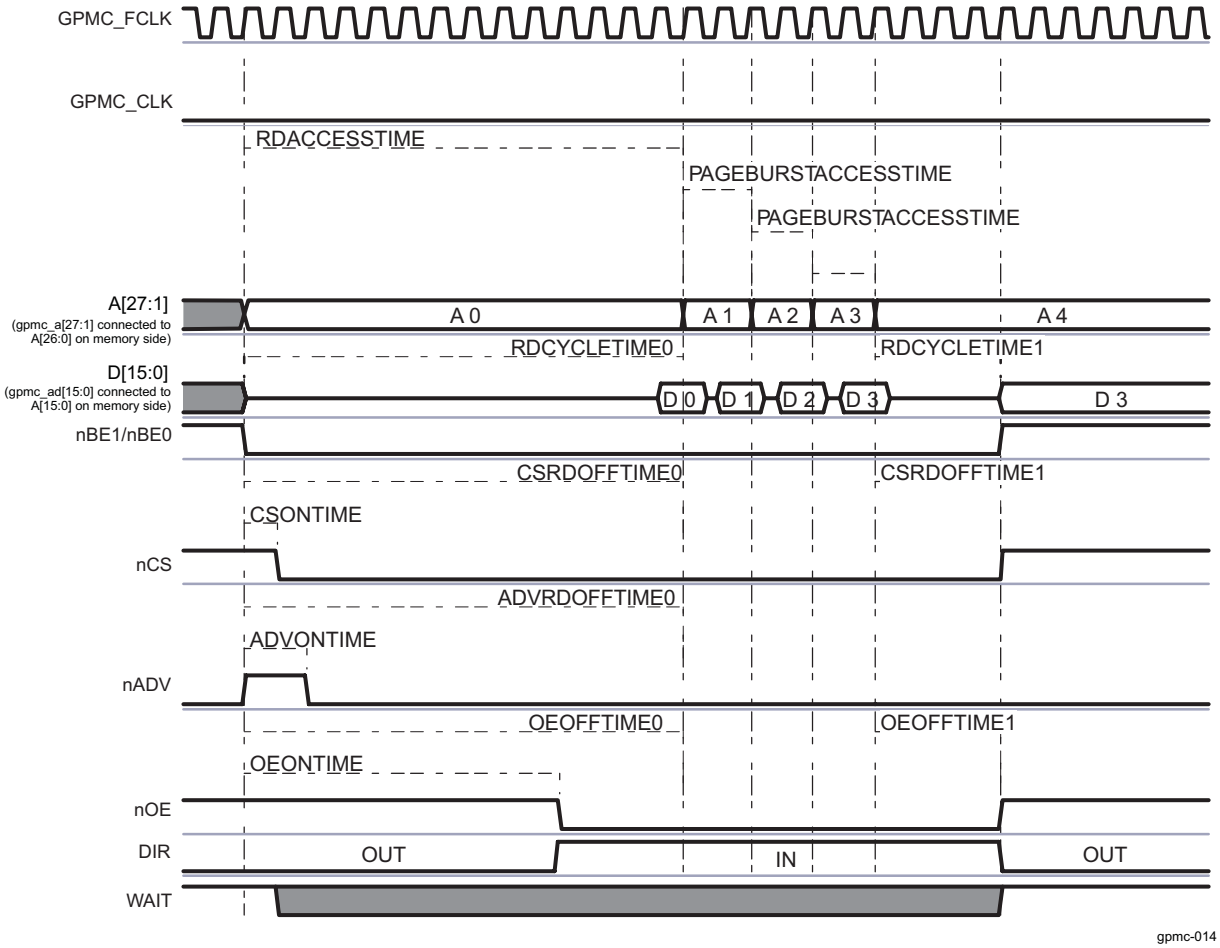


The nCS, nADV, nWE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 10-391).

10.3.4.10.3.3 Asynchronous Multiple (Page Mode) Read Operation on Nonmultiplexed Device

Figure 10-38 shows an asynchronous multiple-read operation on a nonmultiplexed device in which two word32 host read accesses to the GPMC are split into one multiple- (page mode of 4 word16) read access to the attached device.

Figure 10-38. Asynchronous Multiple (Page Mode) Read



NOTE: The WAIT signal is active low.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 10-391).

When RDACCESSTIME completes, control signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at GPMC_CONFIG5_i[20:16] RDACCESSTIME completion time (where i = 0 to 7). The end of the access is defined by the GPMC_CONFIG5_i[4:0] RDCYCLETIME parameter.

During consecutive accesses, the GPMC increments the address after each data read completes.

Delay between successive read data in the page is controlled by the GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Page crossing is possible only with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME, plus the address hold time, starting from the nCS deassertion.

- The read cycle time is defined in the GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field.
- In Figure 10-38, the programmed value of RDCYCLETIME equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

10.3.4.10.3.4 Synchronous Operations on a Nonmultiplexed Device

All information for this section is equivalent to similar operations for address/data-multiplexed or AAD-multiplexed accesses. The only difference resides in the address phase. See Section 10.3.5.3, *GPMC Configuration in NOR Mode*.

10.3.4.10.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The GPMC_CONFIG1_i[30] READMULTIPLE and GPMC_CONFIG1_i[28] WRITMULTIPLE bits (where i = 0 to 7) are associated with the READTYPE and WRITETYPE parameters.

NOTE:

- Asynchronous write page mode is not supported.
- 8-bit-wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
- Not applicable to NAND device interfacing

10.3.4.10.5 System Burst vs External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte-enable-controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two, four, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length bursts. The maximum length that can be issued is defined per chip-select by the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH bit field (where i = 0 to 7). When the value of ATTACHEDDEVICEPAGELENGTH is less than the length of the system burst request (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the value of the ATTACHEDDEVICEPAGELENGTH bit field must correspond to the maximum length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the GPMC_CONFIG1_i[31] WRAPBURST bit (where i = 0 to 7) must be set to 1. Similarly DEVICEPAGELENGTH is set to 4 and 8 for memories supporting 4 and 8 Word16-length-wrapping burst, respectively.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the value of ATTACHEDDEVICEPAGELENGTH.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed-burst length mode and a continuous-burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH bit field is set accordingly to 4 or 8 words.

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-word boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the value of ATTACHEDDEVICEPAGELENGTH. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait-states between data accesses. If the memory does not behave this way (nonzero wait-state burstable memory), wait pin monitoring must be enabled to dynamically control data access completion within the burst.

NOTE: When the system burst request length is less than the value of ATTACHEDDEVICEPAGELENGTH, the GPMC proceeds with the required accesses.

10.3.4.11 pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The GPMC_CONFIG1_i[11:10] DEVICETYPE bit field (where i = 0 to 7) must be set to 0b00.

The pSRAM device uses the NOR protocol. It supports the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or they can automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum nCS high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

10.3.4.12 NAND Access Description

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to *chip enable don't care* NAND devices, because the chip-select allocated to the NAND device must be deasserted if accesses to other chip-selects are requested.

10.3.4.12.1 NAND Memory Device in Byte or 16-bit Word Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data stream-oriented (byte or 16-bit word).

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as ALE (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as CLE (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

10.3.4.12.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC_CONFIG7_i register (where i = 0 to 7) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16MiB, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

CAUTION

To allow correct command, address, and data-access controls, the GPMC_CONFIG1_i register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters listed in Table 10-369. Failure to comply with these settings corrupts the NAND interface protocol.

Table 10-369. Chip-Select Configuration for NAND Interfacing

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i[31] (1)	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i[30]	0	Single access
READTYPE	GPMC_CONFIG1_i[29]	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i[28]	0	Single access
WRITETYPE	GPMC_CONFIG1_i[27]	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i[26:25]	0b00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i[24:23]	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i[22]	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i[21]	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i[19:18]	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT	GPMC_CONFIG1_i[17:16]		Select which wait is monitored by edge detectors
DEVICESIZE	GPMC_CONFIG1_i[13:12]	0b00 or 0b01	8- or 16-bit interface
DEVICETYPE	GPMC_CONFIG1_i[11:10]	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1_i[9:8]	0b00	Nonmultiplexed mode

(1) i = 0 to 7

Table 10-369. Chip-Select Configuration for NAND Interfacing (continued)

Bit Field	Register	Value	Comments
TIMEPARAGRANULARITY	GPMC_CONFIG1_i[4]	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	GPMC_CONFIG1_i[1:0]	Don't care	Asynchronous mode

The GPMC_CONFIG1_i to GPMC_CONFIG4_i registers (where i = 0 to 7) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

10.3.4.12.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The software driver must issue the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i register locations (where i = 0 to 7) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i register locations must be posted for faster operations (where i = 0 to 7). The GPMC_CONFIG[0] NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An GPMC_STATUS[0] EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

The GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i registers (where i = 0 to 7) are 32-bit word locations, which means any 32-or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit-wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32- or 16-bit word access to these registers, but it must consider the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i registers can be used, and any of the four byte locations of the registers is valid.

The same applies to a GPMC_NAND_COMMAND_i and a GPMC_NAND_ADDRESS_i (where i = 0 to 7) 32-bit word write access to a 16-bit-wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid.

10.3.4.12.1.3 Command Latch Cycle

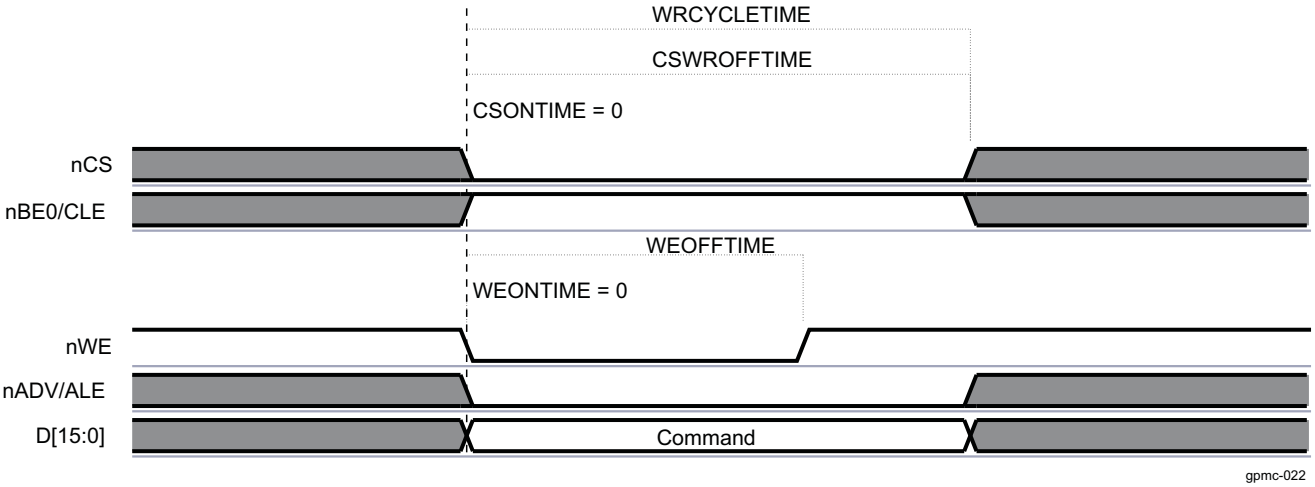
Writing data at the GPMC_NAND_COMMAND_i location (where i = 0 to 7) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.

- ALE and nRE (nOE) are maintained inactive.

Figure 10-39 shows the NAND command latch cycle.

Figure 10-39. NAND Command Latch Cycle



NOTE: CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

NAND flash memories do not use byte-enable signals.

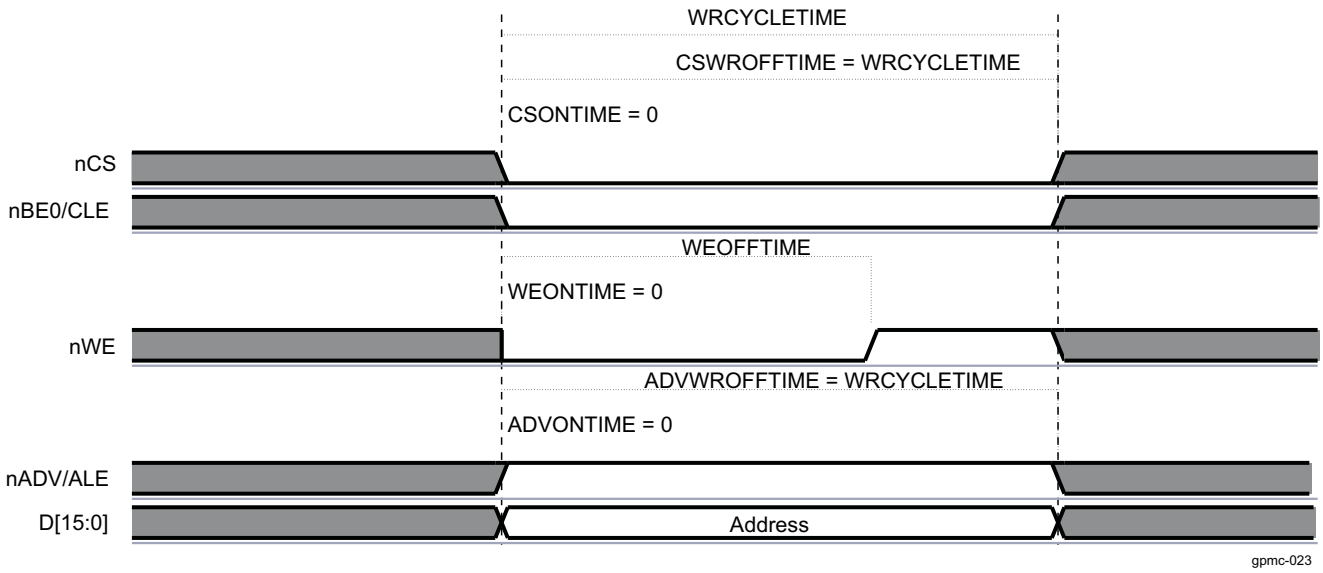
10.3.4.12.1.4 Address Latch Cycle

Writing data at the GPMC_NAND_ADDRESS_i location (where i = 0 to 7) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 10-40 shows the NAND address latch cycle.

Figure 10-40. NAND Address Latch Cycle



NOTE: ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

10.3.4.12.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC_NAND_DATA_i location (where i = 0 to 7) mapped in the chip-select-associated control register region. GPMC_NAND_DATA_i is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

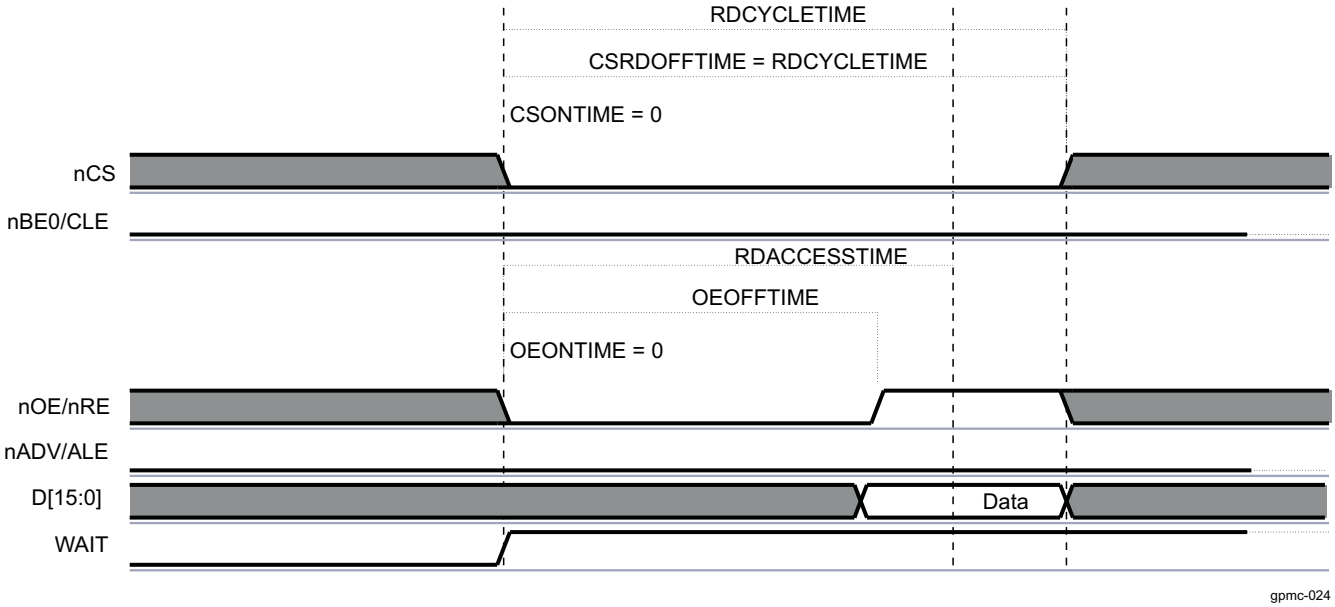
Reading data from the GPMC_NAND_DATA_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device timing parameters.

ALE, CLE, and nWE are maintained inactive.

Figure 10-41 shows the NAND data read cycle.

Figure 10-41. NAND Data Read Cycle

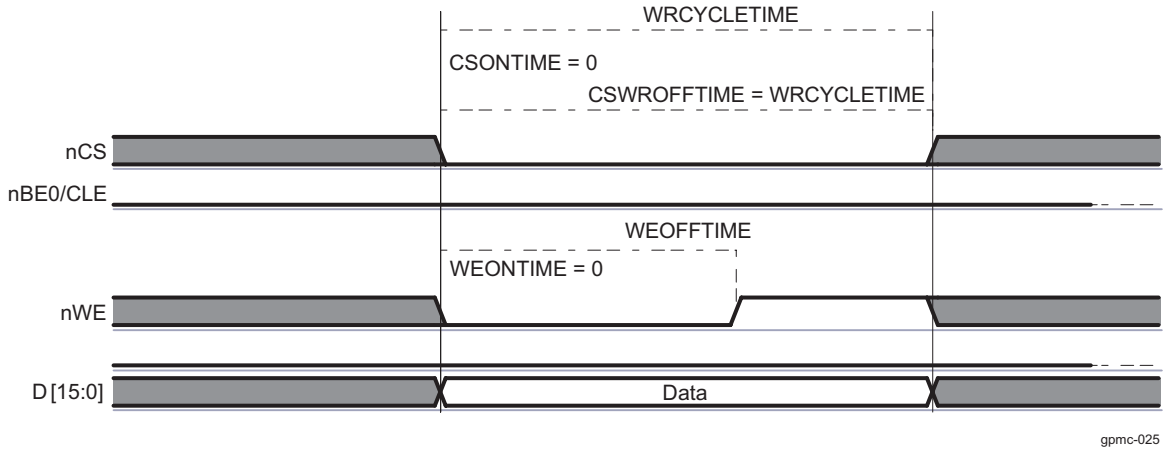


Writing data to the GPMC_NAND_DATA_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and nRE (nOE) are maintained inactive.

Figure 10-42 shows the NAND data write cycle.

Figure 10-42. NAND Data Write Cycle



10.3.4.12.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by nCS-to-data-valid timing and has faster nRE-to-data-valid timing. Successive accesses with nCS deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that nCS always stays low between two accesses to the same chip-select. Moreover, an nCS deassertion time between the same chip-select NAND accesses is likely to be required as follows: the nCS deassertion requires programming CYCLETIME and RDACCESSTIME according to the nCS-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce the following on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSRDOFFTIME
- CSWROFFTIME
- ADVRDOFFTIME
- ADVWROFFTIME
- OEOFFTIME
- WEOFFTIME

For more information about optimal prefetch engine access, see Section 10.3.4.12.4, *Prefetch and Write-Posting Engine*.

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high-to-data bus in three-state mode. This requires a bus turnaround setting (BUSTURNAROUND = 1) so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND flash are not affected by the programmed bus turnaround delay.

10.3.4.12.1.7 Read and Write Access Size Adaptation

10.3.4.12.1.7.1 8-Bit-Wide NAND Device

Host 16- and 32-bit word read and write access requests to a chip-select associated with an 8-bit-wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit-wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the cs is associated with an 8-bit-wide NAND device.

10.3.4.12.1.7.2 16-Bit-Wide NAND Device

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit-wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit-wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit-wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit-wide NAND device must be avoided, especially when ECC calculation is enabled. 8- or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit-wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

10.3.4.12.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the wait GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 micro second) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

NOTE: If a read access to a NAND flash is done using wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the GPMC_CONFIG1_i[21] WAITWRITEMONITORING and GPMC_CONFIG1_i[22] WAITREADMONITORING bits to 0, where i = 0 to 7), and use one of the following methods instead:

- Use software to poll the WAITxSTATUS bit (where x = 0 to 2) of the GPMC_STATUS .
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC_IRQENABLE register bits[11:8]).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed wait bit in the GPMC_STATUS register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

10.3.4.12.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the GPMC_STATUS WAITxSTATUS bit (where x = 0 to 2). Software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

10.3.4.12.2.2 Ready Pin Monitored by Hardware Interrupt

Each gpmc_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC_CONFIG WAITxPINPOLARITY bits (where x = 0 to 2) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit (where x = 0 to 2) of the GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC_IRQENABLE register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register is set.

The WAITMONITORINGTIME bit field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register according to the gpmc_wait pin used for NAND device ready signal monitoring.

10.3.4.12.3 ECC Calculator

The GPMC includes an error code correction (ECC) calculator circuitry that enables ECC calculation on the fly during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the GPMC_ECC_CONFIG[16] ECCALGORITHM bit:

1. Hamming code for 1-bit error code correction on 8- or 16-bit NAND flash organized with page size greater than 512 bytes
2. Bose-Chaudhurl-Hocquenghem (BCH) code for 4- to 16-bit error correction

The GPMC does not handle the error code correction directly. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (2D) (row and column) bit parity accumulation. This parity accumulation is accomplished on the programmed number of bytes or 16-bit words read from the memory device, or is written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the GPMC_ECC_CONFIG[3:1] ECCCS bit field. Even if two chip-selects use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

10.3.4.12.3.1 Hamming Code

All references to ECC in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a 2D (row and column) bit parity accumulation known as the Hamming code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and the software NAND driver must read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time, and parallel computations on different chip-selects are not possible. Because it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. Software must ensure that only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is complete.

10.3.4.12.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (GPMC_ECCj_RESULT, where j = 1 to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially: one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The value of the GPMC_ECCj_RESULT register is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

The GPMC_ECC_CONTROL[3:0] ECCPOINTER bit field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The value of the GPMC_ECCj_RESULT register (where j = 1 to 9) can be considered valid when ECCPOINTER equals j + 1. When the GPMC_ECCj_RESULT register (where j = 9) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC_ECC_CONTROL[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each GPMC_ECCj_RESULT register, where j = 1 to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZE bits (where j = 1 to 9) in the GPMC_ECC_SIZE_CONFIG register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in the GPMC_ECCj_RESULT register).

The ECCSIZE0 and ECCSIZE1 bit fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2-KiB data page, 8-bit-wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC_ECCj_RESULT registers (j = 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1:8] RESULTSIZE bits are set to 0, and the ECC9RESULTSIZE bit is set to 1.

10.3.4.12.3.1.2 ECC Enabling

The GPMC_ECC_CONFIG[3:1] ECCCS bit field selects the allocated chip-select. The GPMC_ECC_CONFIG[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The following fields must not be changed or cleared while an ECC computation is in progress:

- CCPOINTER
- ECCCLEAR
- ECCSIZE
- ECCjRESULTSIZE (where j = 1 to 9)
- ECC16B
- ECCCS

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

Table 10-370 describes the ECC enable settings.

Table 10-370. ECC Enable Settings

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0–3	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0/1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0–7	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CONTROL	0–7	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.

Table 10-370. ECC Enable Settings (continued)

Bit Field	Register	Value	Comments
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECCSIZE0
ECCjRESULTSIZE (j from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

10.3.4.12.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 10-43 and Figure 10-44. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

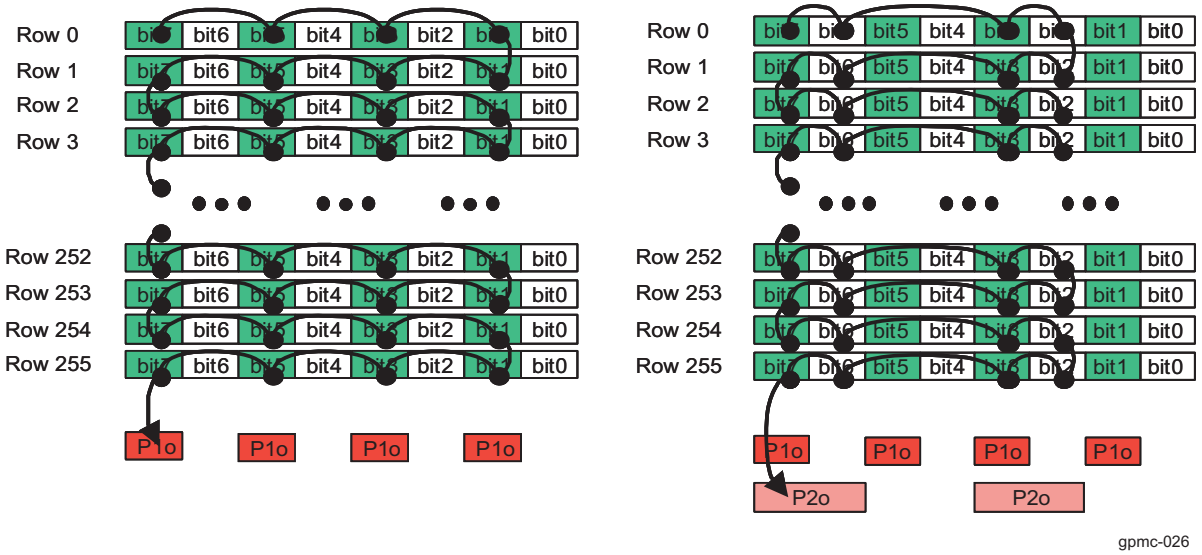
P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream
P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream
P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream
P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

Figure 10-43. Hamming Code Accumulation Algorithm (1/2)

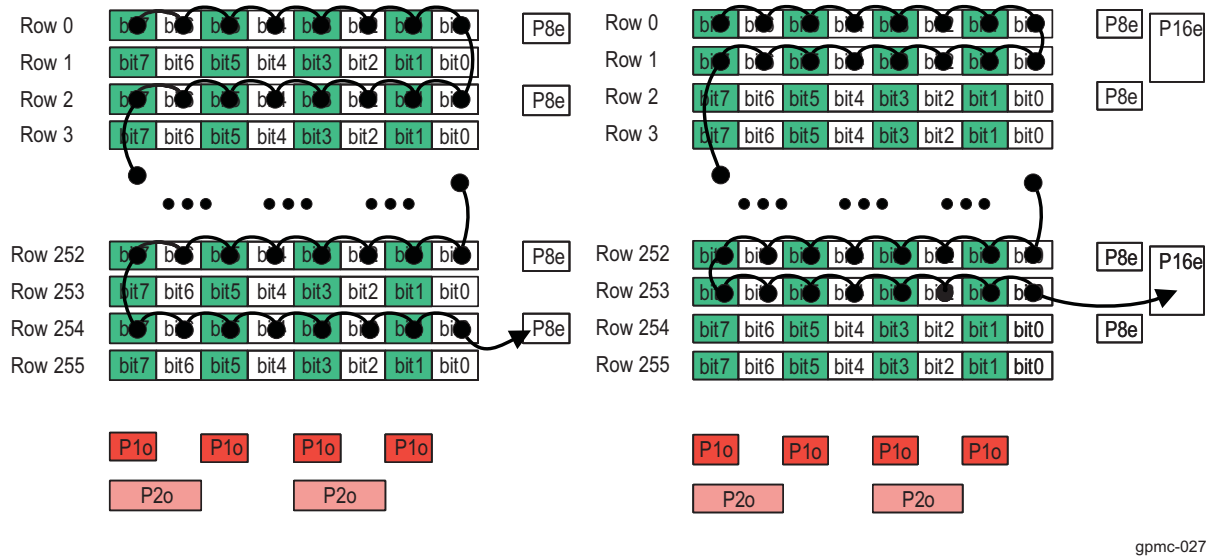


For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

P8e = row0 XOR row2 XOR row4 XOR ... XOR row254
P8o = row1 XOR row3 XOR row5 XOR ... XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253
P16o = row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255

Figure 10-44. Hamming Code Accumulation Algorithm (2/2)



Unused parity bits in the result registers are set to 0.

Figure 10-45 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

Figure 10-45. ECC Computation for a 256-Byte Data Stream (Read or Write)

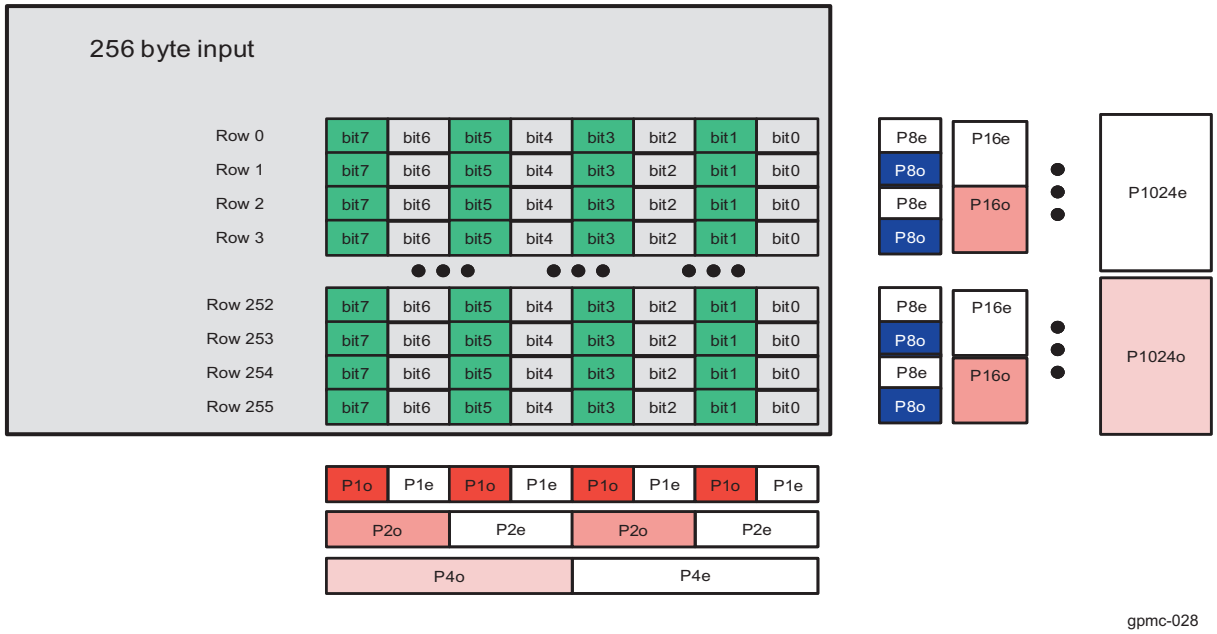


Figure 10-46 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

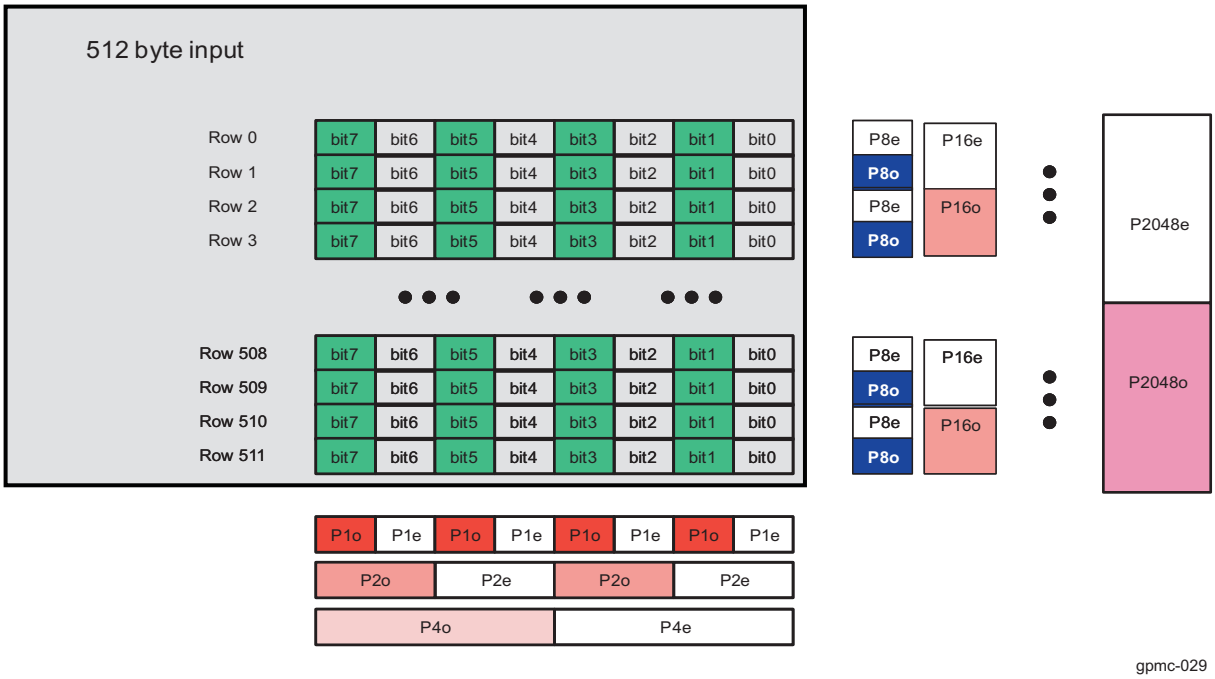
Figure 10-46. ECC Computation for a 512-Byte Data Stream (Read or Write)



For a 2-KiB page, four 512 bytes ECC calculations plus 1 for the spare area are required. Results are stored in the GPMC_ECCj_RESULT registers (where j = 1 to 9).

10.3.4.12.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, 1 bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). Software must correct the corresponding bit.
- If only 1 bit in the parity result is 1, it is an ECC error and the read data is correct.

10.3.4.12.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit-based ECC computation is used for 8-bit-wide NAND device interfacing.

The 8-bit-based ECC computation can be used for 16-bit-wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit-wide NAND devices. In this case, the 16-bit-wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the LSB of the 16-bit-wide data is ordered first in the byte stream used for 8-bit-based ECC computation.

10.3.4.12.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on an 16-bit word is used for 16-bit-wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit-wide NAND device, and the GPMC_ECC_CONFIG[7] ECC16B bit must be set to 0 when interfacing an 8-bit-wide NAND device.

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit-based ECC and on columns for a 16-bit based ECC. Figure 10-47 and Figure 10-48 show a 128 Word16 ECC computation scheme and a 256 16-bit word ECC computation scheme.

Figure 10-47. 128 Word16 ECC Computation

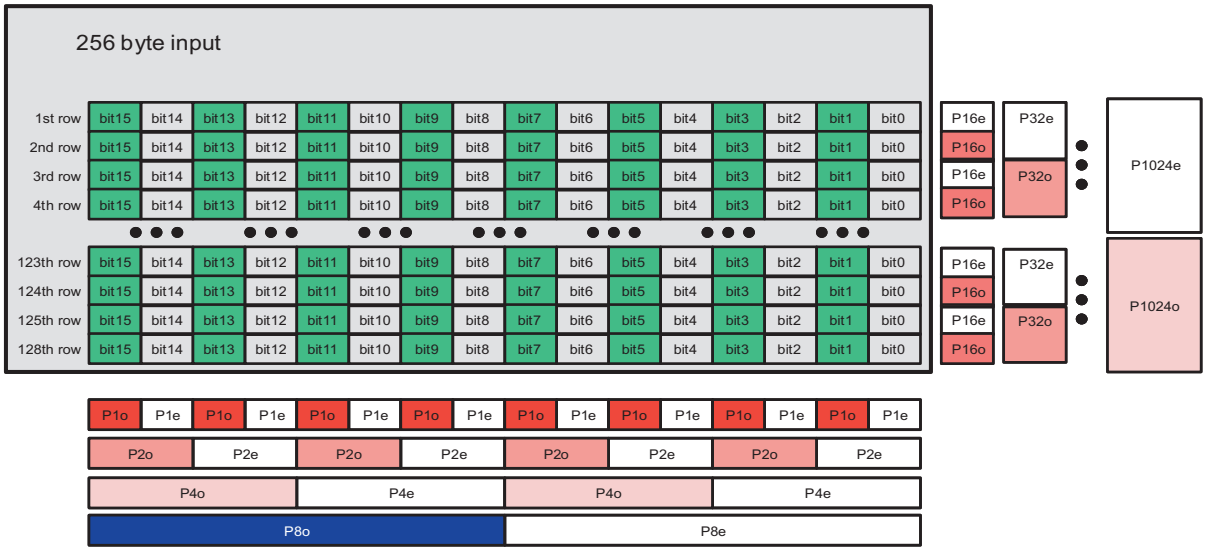


Figure 10-48. 256 Word16 ECC Computation

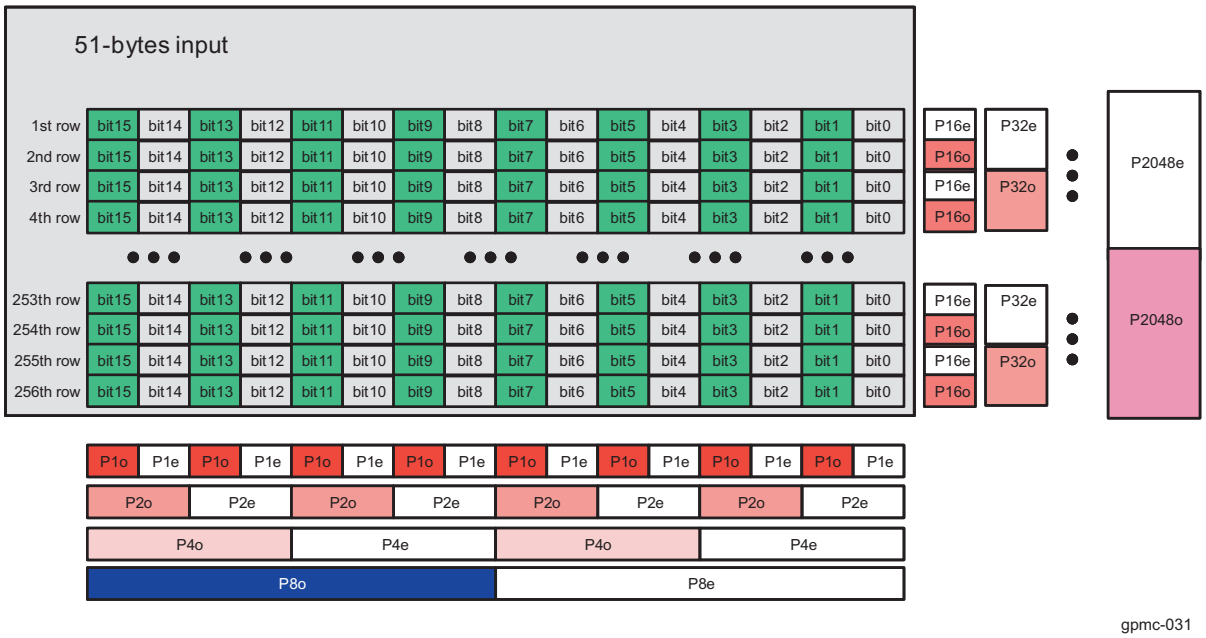


10.3.4.12.3.2 BCH Code

All references to ECC in this subsection refer to the 4- to 16-bit error correction BCH code.

10.3.4.12.3.2.1 Requirements

1. Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, and then some spare bytes, including the BCH ECC (and other information). The NAND device can cache a full page, including spares, for read and write accesses.
   - Typical page write sequence:
     – Sequential write to NAND cache of main data plus spare data, for a page. ECC is calculated on the fly. Calculated ECC can be inserted on the fly in the spares or replaced by dummy

accesses.
  - When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
  - NAND writes its cache line (page) to the array.
- Typical page read sequence:
  - Sequential read of a page. ECC is calculated on the fly.
  - The status of the ECC module buffers determines the presence of errors.

2. Accesses to several memories can be interleaved by the GPMC, but only one of those memories at a time can be a NAND using the BCH engine; in other words, only one BCH calculation (for example, for a single page) can be ongoing at any time. The sequential nature of NAND accesses ensures that the data is always written or read out in the same order. BCH-relevant accesses are selected by the chip-selects of the GPMC.
3. Each page can hold up to 4KiB of data, spare bytes not included. This means up to 8 × 512-byte BCH messages. Because all the data is written or read out first, followed by the BCH ECC, the BCH engine must be able to hold eight 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.

   The BCH module can store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.
4. NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least four cycles of the GPMC internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least four clock cycles after optimization when using the BCH calculator.
5. The spare area is assumed to be large enough to hold the BCH ECC; that is, to have a message of at least 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (the maximum codeword is 1023 bytes long, ECC included, which leaves much space to cover spare bytes).

10.3.4.12.3.2.2 Memory Mapping of BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message M(x). In a standard case, 512 bytes of data (that is, 2^{12} bits = 4096 bits) are seen as a polynomial of degree $2^{12} – 1 = 4095$, with parameters ranging from M0 to M4095. For 512 bytes of data, 52 bits are required for 4-bit error correction, 104 bits are required for 8-bit error correction, and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial R(x) of degree 103 (or 51, depending on the selected mode). The complete codeword C(x) is the concatenation of M(x) and R(x), as described in Table 10-371.

Table 10-371. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)

	Message M(x)			ECC R(x)		
Bit Number	M4095	...	M0	R103	...	R0

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message M(x) of degree ((512 + 3) × 8) – 1 = 4119, for a total of 3 + 13 = 16 spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in the following registers (where i = 0 to 7):

- GPMC_BCH_RESULT0_i
- GPMC_BCH_RESULT1_i
- GPMC_BCH_RESULT2_i
- GPMC_BCH_RESULT3_i

10.3.4.12.3.2.2.1 Memory Mapping of Data Message

The data message mapping must follow the following rules:

- Bit endianness within a byte is little-endian; that is, the bytes LSB is also the lowest-degree polynomial parameter: a byte b7-b0 (with b0 the LSB) represents a segment of polynomial b7 * $x^{(7+i)}$ + b6 * $x^{(6+i)}$ + ... + b0 * x^{i}
- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the 16-bit words in the NAND is big-endian (that is, the same message mapped in 8- and 16-bit memories has the same content at the same byte address).

NOTE: The BCH module has no visibility over actual addresses. The most important point is the sequence of data words the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, which produces the mapping patterns described in the following.

Table 10-372 and Table 10-373 describe the mapping of the same 512-byte vector (typically, a BCH message) in the NAND memory space. The byte address is only an offset modulo 512 (0x200), because the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are, respectively, the bits M0 and M(2^{12}–1) of the codeword mapping discussed previously. In both cases the data vectors are aligned; that is, their boundaries coincide with the RAM data word boundaries.

Table 10-372. Aligned Message Byte Mapping in 8-Bit NAND

Byte Offset	8-Bit Word
0x000	(MSB) Byte 511 (0x1FF)
0x001	Byte 510 (0x1FE)
...	...
0x1FF	Byte 0 (0x0) (LSB)

Table 10-373. Aligned Message Byte Mapping in 16-Bit NAND

Byte Offset	16-Bit Word MSB	16-Bit Word LSB
0x000	Byte 510 (0x1FE)	(MSB) Byte 511 (0x1FF)
0x002	Byte 508 (0x1FC)	Byte 509 (0x1FD)
...	...	...
0x1FE	Byte 0 (0x0)	(LSB) Byte 1 (0x1)

Table 10-374 through Table 10-379 list the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on the ECC of another sector).

Table 10-374. Aligned Nibble Mapping of Message in 8-Bit NAND

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Least Significant Nibble
1	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...	...	...
S/2 – 2	Nibble 3	Nibble 2
S/2 – 1	Nibble 1	Nibble 0 (LSB)

Table 10-375. Misaligned Nibble Mapping of Message in 8-Bit NAND

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Least Significant Nibble
1	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...	...	...
(S + 1) / 2 – 2	Nibble 2	Nibble 1
(S + 1) / 2 – 1	Nibble 0 (LSB)	

Table 10-376. Aligned Nibble Mapping of Message in 16-Bit NAND

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Least Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...		...	
S/2 – 4	Nibble 5	Nibble 4	Nibble 7	Nibble 6
S/2 – 2	Nibble 1	Nibble 0 (LSB)	Nibble 3	Nibble 2

Table 10-377. Misaligned Nibble Mapping of Message in 16-Bit NAND (1 Unused Nibble)

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Least Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...		...	
(S + 1) / 2 – 4	Nibble 4	Nibble 3	Nibble 6	Nibble 5
(S + 1) / 2 – 2	Nibble 0 (LSB)		Nibble 2	Nibble 1

Table 10-378. Misaligned Nibble Mapping of Message in 16-Bit NAND (2 Unused Nibbles)

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Least Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...		...	
(S + 2) / 2 – 4	Nibble 3	Nibble 2	Nibble 5	Nibble 4
(S + 2) / 2 – 2			Nibble 1	Nibble 0 (LSB)

Table 10-379. Misaligned Nibble Mapping of Message in 16-Bit NAND (3 Unused Nibbles)

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Least Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...		...	
(S + 3) / 2 – 4	Nibble 2	Nibble 1	Nibble 4	Nibble 3
(S + 3) / 2 – 2			Nibble 0 (LSB)	

Many other cases exist than those given in the previous tables; for example, where the message does not start on a word boundary.

10.3.4.12.3.2.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. Software must fetch those 13 bytes (or 6 bytes) from the module interface and then store them to the spare area (page write) in the NAND or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is software-controlled.

It is advised, however, to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error is detected. The creation of this codeword must be made as straightforward as possible.

There are cases in which the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on the fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on the fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

10.3.4.12.3.2.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described as follows. To better understand and see the real-life read and write sequences implemented with each mode, see Section 10.3.4.12.3.2.3, *Supported NAND Page Mappings and ECC Schemes*.

For each mode:

- A sequence describes the mode in pseudo language, with, for each section, the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0, and size1.
- A checksum condition is given. If the checksum condition is not respected for a given mode, the module behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Wrapping modes 8 through 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for t = 4 ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

10.3.4.12.3.2.2.4 Manual Mode (0x0)

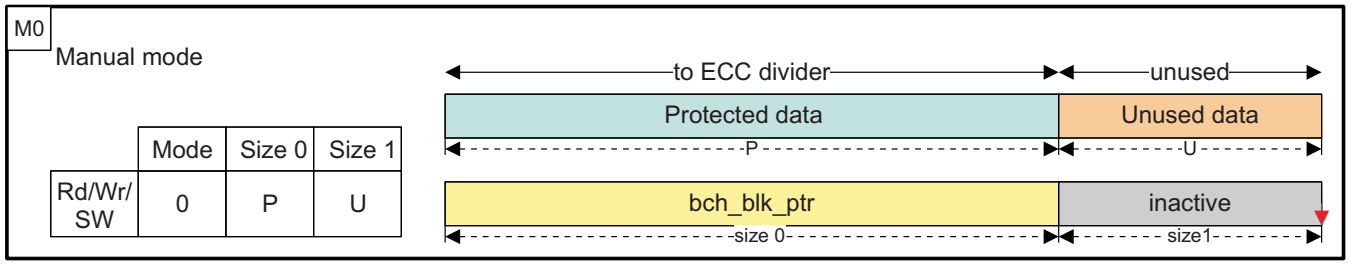
This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port, containing the appropriate data, must be made. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles must be skipped, a number of unused nibbles must be programmed in GPMC_ECC_SIZE_CONFIG[29:22] ECCSIZE1 In the same example, 5 nibbles to process + 3 to discard = 8 nibbles = 2 × 16-bit accesses. Software must set:

- GPMC_ECC_SIZE_CONFIG[19:12] ECCSIZE0 = 0x5
- GPMC_ECC_SIZE_CONFIG[29:22] ECCSIZE1 = 0x3

NOTE: In the following figures, size and size0 are the same parameter.

Figure 10-49. Manual Mode Sequence and Mapping



gpmc-032

Section processing sequence:

- One time with buffer
  - size0 nibbles of data, processing ON
  - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

In the following sections, S is the number of sectors in the page.

10.3.4.12.3.2.2.5 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + size1)

10.3.4.12.3.2.2.6 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - 1 nibble pad spare, processing OFF
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + 1 + size1)

10.3.4.12.3.2.2.7 Mode 0x2

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + size1)

10.3.4.12.3.2.2.8 Mode 0x3

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – size1)

10.3.4.12.3.2.2.9 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = size0 + (S – size1)

10.3.4.12.3.2.2.10 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – (1 + size1))

10.3.4.12.3.2.2.11 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)

  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – size1)

10.3.4.12.3.2.2.12 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – (1 + size1))

10.3.4.12.3.2.2.13 Mode 0x5

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + size1)

10.3.4.12.3.2.2.14 Mode 0xB (11)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + 1 + size1)

10.3.4.12.3.2.2.15 Mode 0x6

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + size1)

10.3.4.12.3.2.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply to the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in Section 10.3.4.12.3.2.2.1, *Memory Mapping of Data Message*.

Each of the following sections gives a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In Figure 10-50 through Figure 10-52, the tables on the left summarize the mode, size0, and size1 parameters to program for, respectively, write and read processing of a page, with the given mapping, where:

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC (in nibbles)
- S is the number of Sectors per page (two in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. The processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1 KiB + spares; that is, S = 2 sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can happen only in the codeword that was actually written to the NAND, not in the mathematical codeword of $n = 2^{13} – 1 = 8191$ bits; that codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, the programmed sizes, and the sector number (all sizes in nibbles):

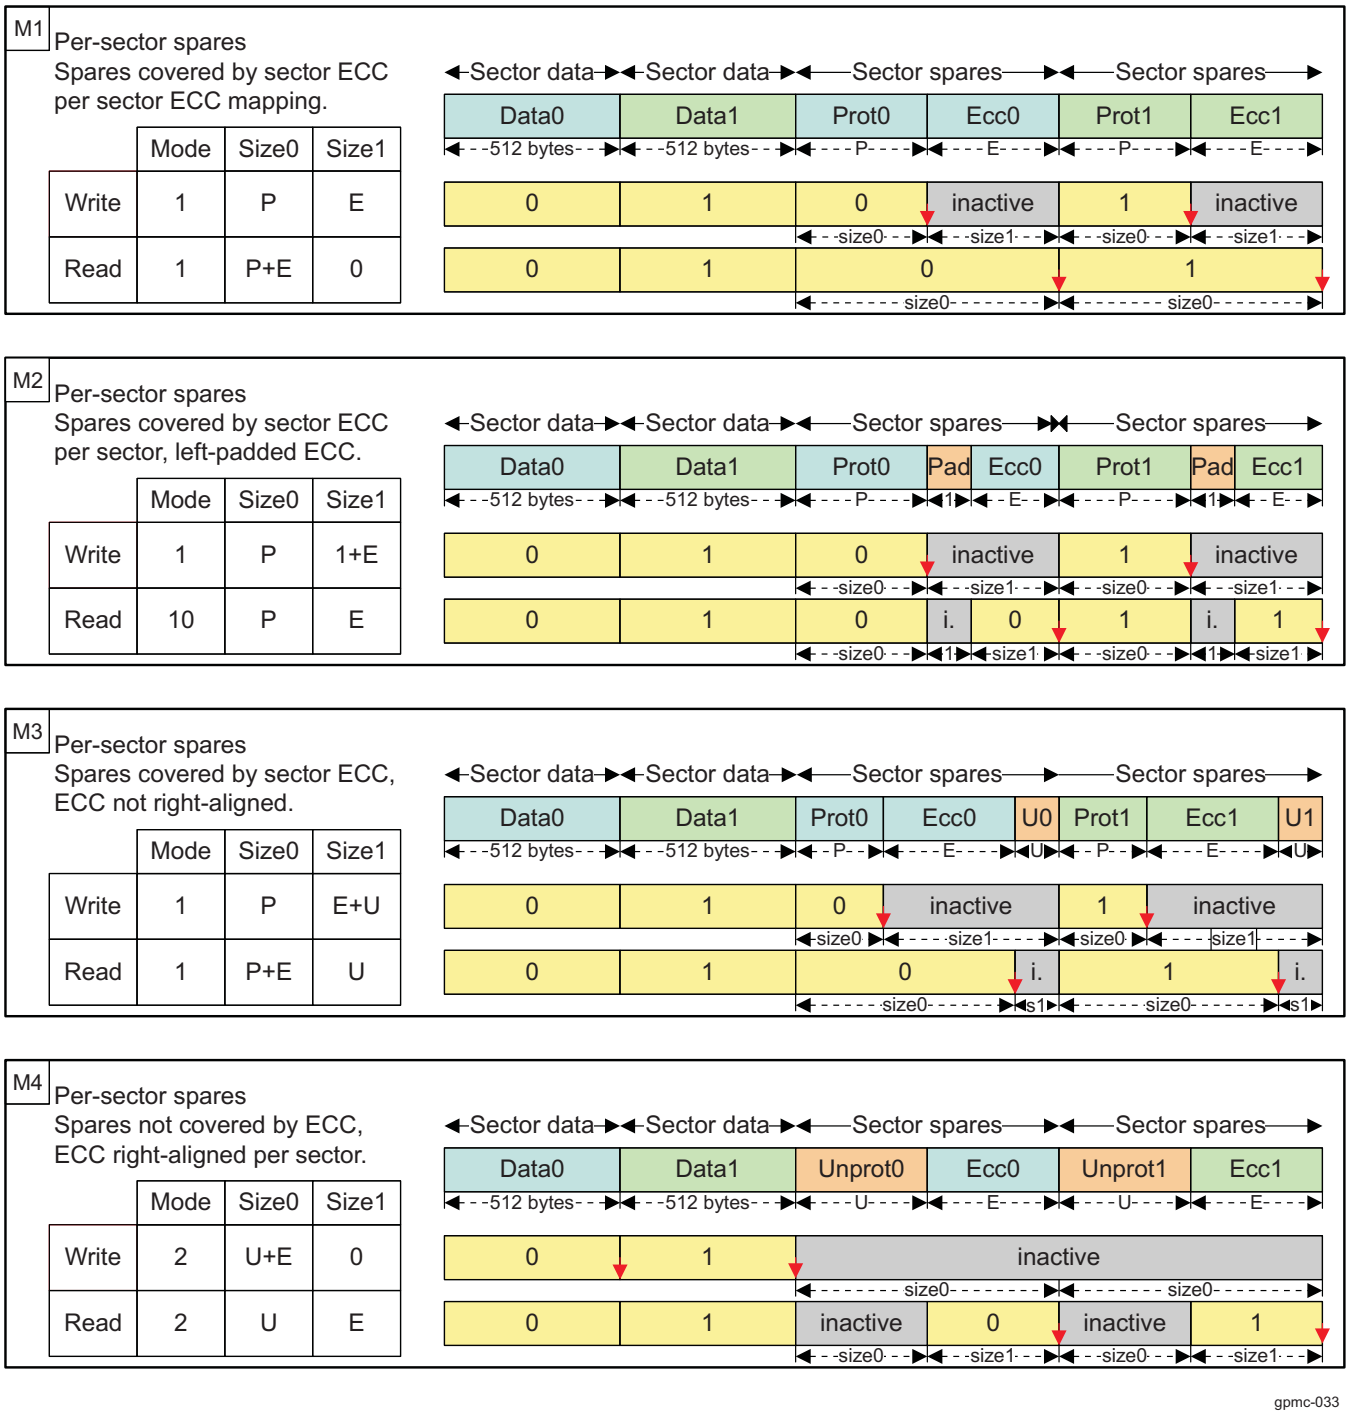
- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
  - All sectors: (512) + P + E
- Spares pooled and protected by sector 0 (below: see M5-M6):
  - Sector 0 codeword: (512) + P + E
  - Other sectors: (512) + E
- Unprotected spares (below: see M4-M7-M8-M11-M12):
  - All codewords (512) + E

10.3.4.12.3.2.3.1 Per-Sector Spare Mappings

In these schemes, each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of:

- ECC, which must be located after the data it protects
- Other data, which may or may not be protected by the ECC for its sector.

Figure 10-50. NAND Page Mapping and ECC: Per-Sector Schemes



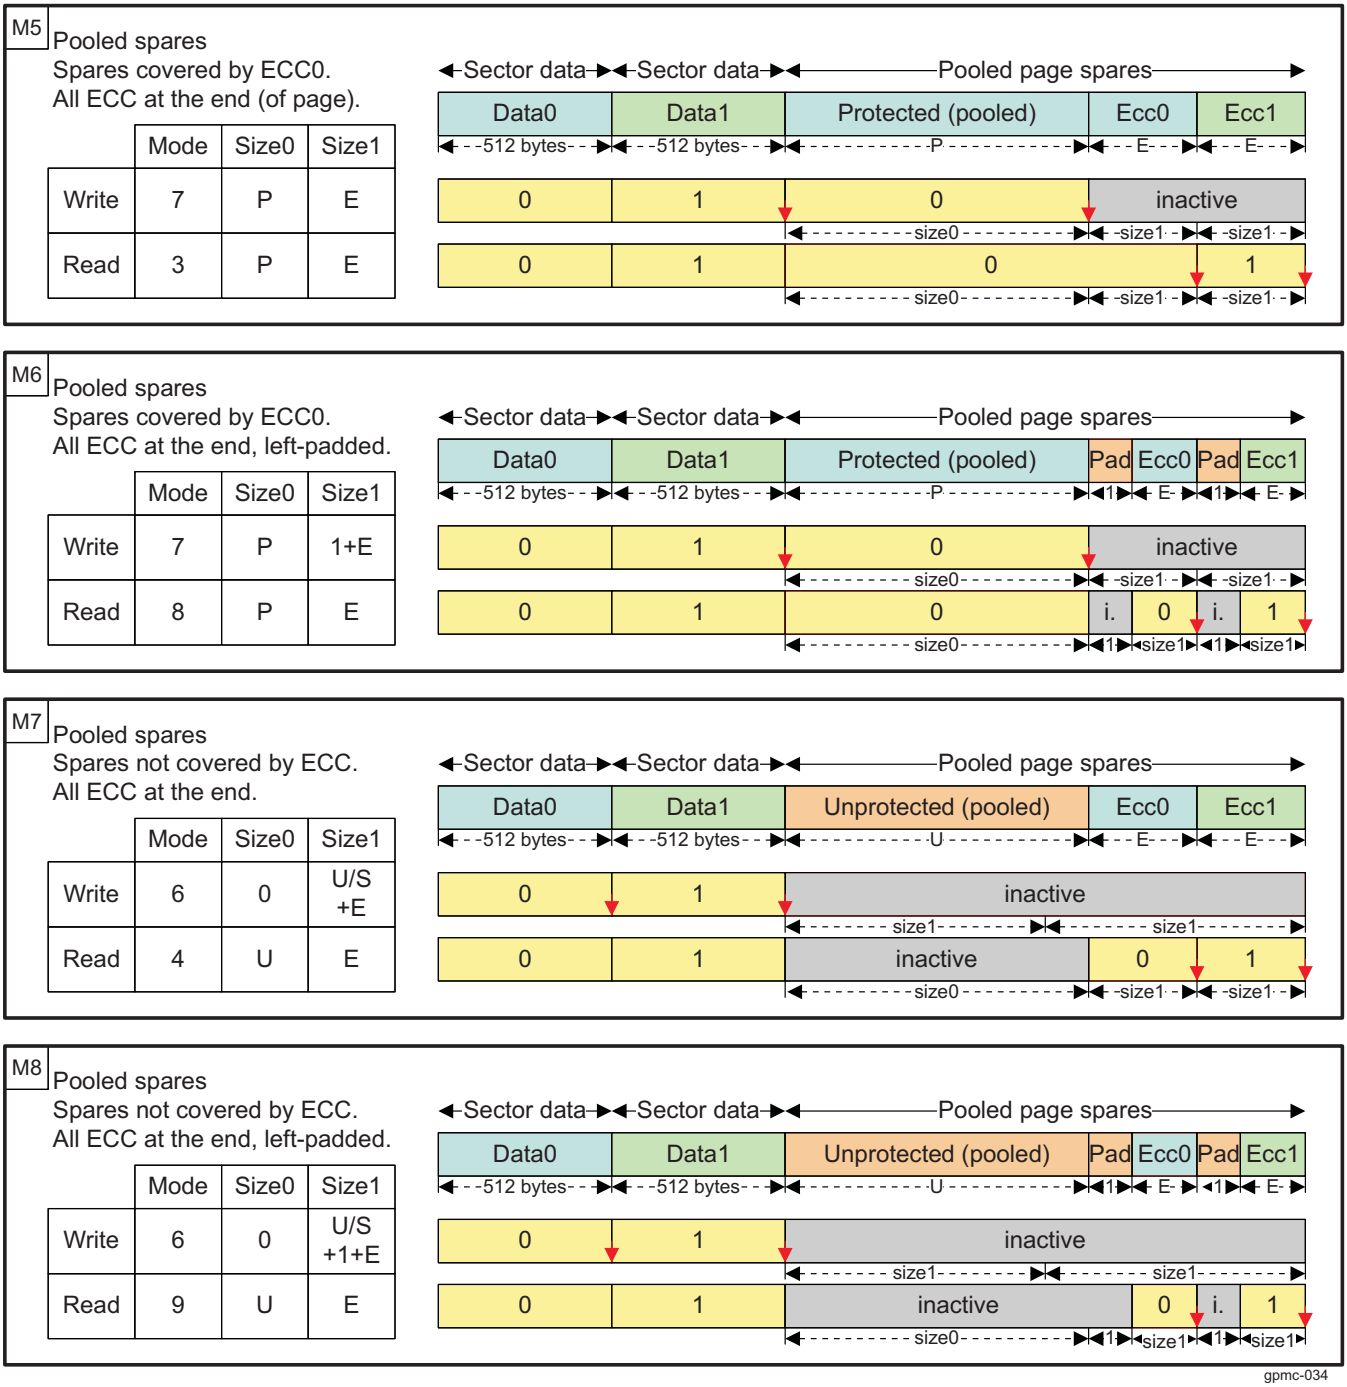
gpmc-033

10.3.4.12.3.2.3.2 Pooled Spare Mapping

In the following schemes, the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.
- The non-ECC spare data may or may not be covered by the ECC of sector 0.

Figure 10-51. NAND Page Mapping and ECC: Pooled Spare Schemes

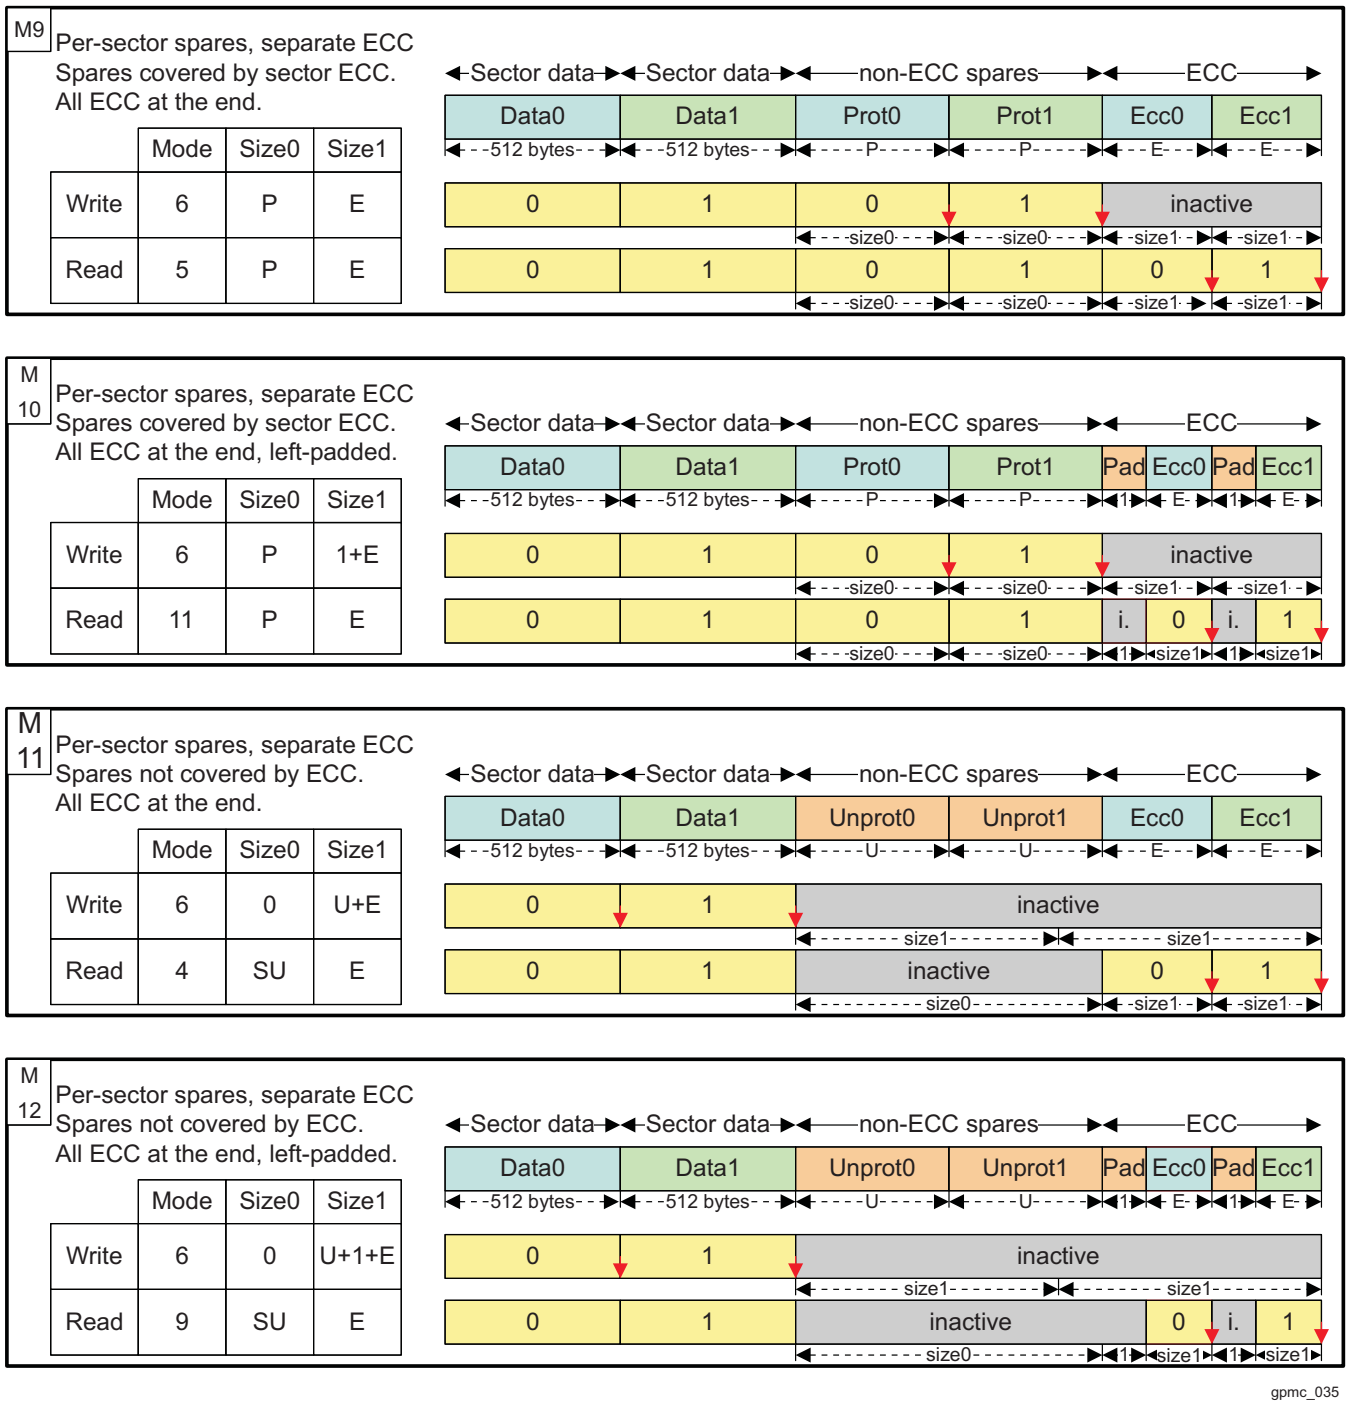


10.3.4.12.3.2.3.3 Per-Sector Spare Mapping, with ECC Separated at the End of the Page

In these schemes, each 512-byte sector of the main area is associated with two sections of the spare area.

- ECC section, all aligned at the end of the page
- Other data section, aligned before the ECCs, each of which may or may not be protected by the ECC for its sector.

Figure 10-52. NAND Page Mapping and ECC: Per-Sector Schemes, With Separate ECC



10.3.4.12.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the IPU system frequency; such NAND read or write accesses issued by the processor affect the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the L3 interface; as a default, the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64-byte (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled by a device host processor through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or by a device DMA module through DMA request synchronization, with a programmable request byte size in prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. As a consequence, it is limited to NAND data-stream access. The engine relies on the NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, engine data read and write sequencing is based solely on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the GPMC_PREFETCH_CONFIG1[19:16] PFPWWEIGHTEDPRIO bit field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

NOTE: The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

10.3.4.12.4.1 General Facts About the Engine Configuration

The engine can be configured only if the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is deasserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC_PREFETCH_CONFIG1[26:24] ENGINECSSELECTOR bit field.

In prefetch and write-posting modes, the engine uses byte or 16-bit word access requests, respectively, for an 8- or 16-bit-wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT bit fields must be programmed accordingly as a number of bytes.

When the GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the following registers (where i = 0 to 7):

- GPMC_NAND_COMMAND_i
- GPMC_NAND_ADDRESS_i
- GPMC_NAND_DATA_i

The FIFO entry on the L3 interconnect port can be accessed with byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32 bits wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC_PREFETCH_STATUS[30:24] FIFOPOINTER bit field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots that can be written in write-posting mode. The GPMC_PREFETCH_STATUS[13:0] COUNTVALUE bit field monitors the number of remaining bytes to be read or written by the engine according to the value of the TRANSFERCOUNT bit field. The FIFOPOINTER and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit-wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPOINTER equals 0 (that is, the FIFO is empty), a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPOINTER equals 0 (that is, the FIFO is full), a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

10.3.4.12.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is cleared.

The NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (that is, reset, configured, and enabled) before the prefetch engine is started so that the ECC is computed correctly on all data read by the prefetch engine.

When the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it sets the STARTENGINE bit only when the NAND device is in a ready state (that is, data is valid for prefetching).

When the SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active-to-inactive WAIT signal transition is detected. The transition detector must be cleared before any transition detection (see Section 10.3.4.12.2.2, *Ready Pin Monitored by Hardware Interrupt*). The GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR bit field selects which gpmc_wait pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit before NAND address phase completion when in synchronized mode. The prefetch engine starts when an active-to-inactive WAIT signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by the GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT bit field.

Table 10-380 describes the prefetch mode configuration.

Table 10-380. Prefetch Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Prefetch engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active.
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13:0]		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1[17:16]	0 to 1	Selects wait pin edge detector (if GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE = 0x1)
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 10.3.4.12.4.6, *Optimizing NAND Access Using the Prefetch and Write-Posting Engine*.
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30:28]		Number of clock cycle removed to timing parameters
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

10.3.4.12.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by a device host processor or a DMA module channel.

In draining mode, the FIFO status can be monitored through the GPMC_PREFETCH_STATUS[30:24] FIFOPOINTER bit field or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. The FIFOPOINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, all the available bytes must be read, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the GPMC_PREFETCH_STATUS[13:0] COUNTVALUE bit field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the TERMINALCOUNTSTATUS bit must be cleared. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is valid only when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel that owns this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

10.3.4.12.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is set.

The NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are calculated properly on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT accesses are complete.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must be issued only when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

Table 10-381 describes the write-posting configuration.

Table 10-381. Write-Posting Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Write-posting engine can be configured only if STARTENGINE is set to 0.

Table 10-381. Write-Posting Mode Configuration (continued)

Bit Field	Register	Value	Comments
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13:0]		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 10.3.4.12.4.6, *Optimizing NAND Access Using the Prefetch and Write-Posting Engine*.
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30:28]		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

10.3.4.12.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by a device host processor or a DMA module channel.

In filling mode, the FIFO status can be monitored through the FIFOPOINTER or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. FIFOPOINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, enough bytes must be written to fill the FIFO or to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit.

The posting completion can be monitored through the GPMC_PREFETCH_STATUS[13:0] COUNTVALUE bit field. COUNTVALUE indicates the current number of remaining data to be written based on the value of the TRANSFERCOUNT bit field. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the TERMINALCOUNTSTATUS bit must be cleared. The TERMINALCOUNTSTATUS bit must always be cleared before asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The value of the COUNTVALUE bit field is valid only if the write-posting engine is active and started, and an interrupt is issued only when COUNTVALUE reaches 0; that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the DMAMode bit field in the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel that owns this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request completes.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, the DMA or IPU fills the FIFO with no consideration for the associated byte enables. Any byte stored in the FIFO is written into the memory device.

10.3.4.12.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

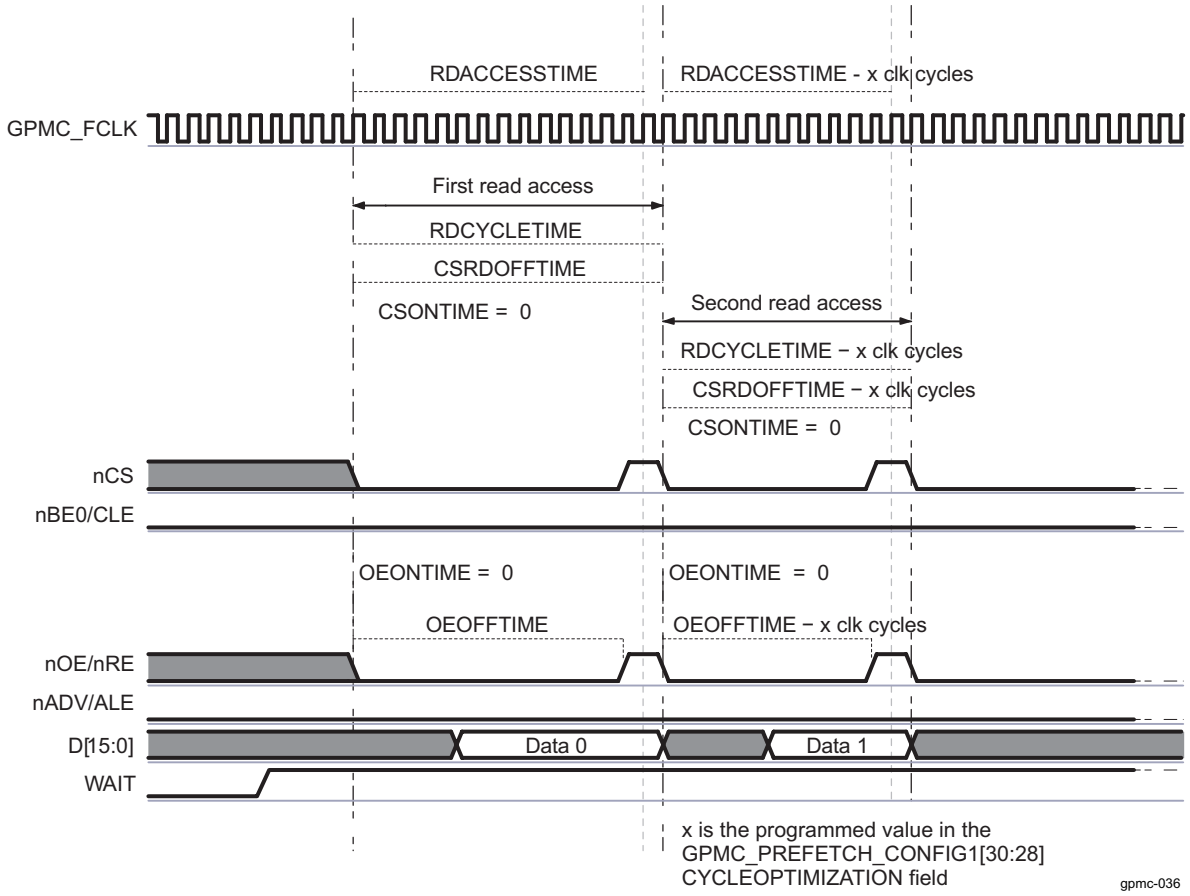
Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC_NAND_DATA_i location, where i = 0 to 7) are never optimized.

The GPMC_PREFETCH_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION bit field defines the number of GPMC_FCLK cycles to be suppressed from the following timing parameters:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSOFFTIME
- ADVOFFTIME
- OEOFFTIME
- WEOFFTIME

Figure 10-53 shows that in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION bit field.

Figure 10-53. NAND Read Cycle Optimization Timing Description



10.3.4.12.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC_PREFETCH_CONFIG1[19:16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 0x2. Considering that the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

10.3.5 GPMC Basic Programming Model

10.3.5.1 GPMC High-Level Programming Model Overview

The goal of the basic high-level programming model is to introduce a top-down approach to users that need to configure the GPMC module.

Figure 10-54 and Table 10-382 through Table 10-384 show a programming model top-level diagram for the GPMC, and a description of each step. Each block of the diagram is described in one of the following sections through a set of registers to configure.

Figure 10-54. Programming Model Top-Level Diagram

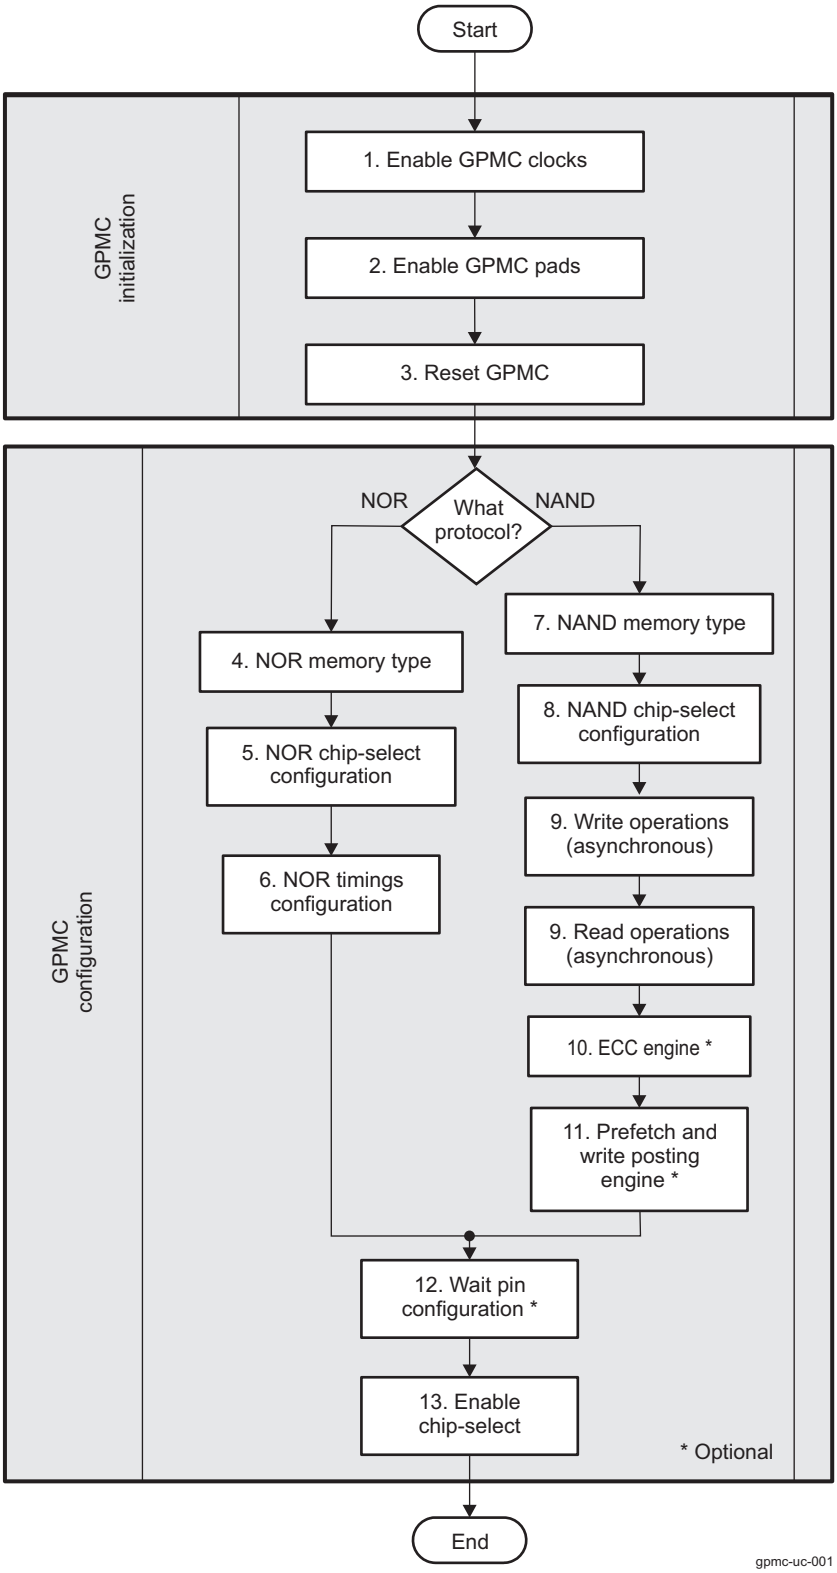


Table 10-382. GPMC Initialization

Step	Description
Enable GPMC clocks.	Module interface and functional clocks must be enabled. See Chapter 3, *Power, Reset, and Clock Management*.
Enable GPMC pads.	Module-specific pad multiplexing and configuration must be set in the control module. See Section 13.4.6.1, *Pad Configuration Registers* in Chapter 13, *Control Module*.
Reset GPMC.	See Table 10-385.

Table 10-383. GPMC Configuration in NOR Mode

Step	Description
NOR Memory Type	See Table 10-386.
NOR Chip-Select Configuration	See Table 10-387.
NOR Timings Configuration	See Table 10-388.
Wait Pin Configuration	See Table 10-396.
Enable Chip-Select	See Table 10-397.

Table 10-384. GPMC Configuration in NAND Mode

Step	Description
NAND Memory Type	See Table 10-391.
NAND Chip-Select Configuration	See Table 10-392.
Write Operations (Asynchronous)	See Table 10-393.
Read Operations (Asynchronous)	See Table 10-393.
ECC Engine	See Table 10-394.
Prefetch and Write-Posting Engine	See Table 10-395.
Wait Pin Configuration	See Table 10-396.
Enable Chip-Select	See Table 10-397.

10.3.5.2 GPMC Initialization

Table 10-413 describes the settings required to prepare the GPMC; that is enabling its clock and pads, and proceeding to a GPMC reset.

Table 10-385. Reset GPMC

Subprocess Name	Register/Bit Field	Value
Start a software reset.	GPMC_SYSCONFIG[1] SOFTRESET	0x1
Wait until	GPMC_SYSSTATUS[0] RESETDONE =	0x1

10.3.5.3 GPMC Configuration in NOR Mode

This section gives a generic configuration for parameters related to the NOR memory connected to the GPMC.

Table 10-386. NOR Memory Type

Subprocess Name	Register / Bit Field	Value
Set the NOR protocol.	GPMC_CONFIG1_i[11:10] DEVICETYPE	0x0
Set a device size.	GPMC_CONFIG1_i[13:12] DEVICESIZE	x
Select an address and data multiplexing protocol.	GPMC_CONFIG1_i[9] MUXADDDATA	x
Set the attached device page length.	GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH	x

Table 10-386. NOR Memory Type (continued)

Subprocess Name	Register / Bit Field	Value
Set the wrapping burst capabilities.	GPMC_CONFIG1_i[31] WRAPBURST	x
Select a timing signals latencies factor.	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Select an output clock frequency (1).	GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER	x
Choose an output clock activation time (1).	GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME	x
Set a single or multiple access for read operations (1).	GPMC_CONFIG1_i[30] READMULTIPLE	x
Set a synchronous or asynchronous mode for read operations.	GPMC_CONFIG1_i[29] READTYPE	x
Set a single or multiple access for write operations.	GPMC_CONFIG1_i[28] WRITEMULTIPLE	x
Set a synchronous or asynchronous mode for write operations.	GPMC_CONFIG1_i[27] WRITETYPE	x

(1) Applies only to synchronous configurations (or nonmultiplexed asynchronous for multiple access one)

Table 10-387. NOR Chip-Select Configuration

Subprocess Name	Register/Bit Field	Value
Select the chip-select base address.	GPMC_CONFIG7_i[5:0] BASEADDRESS	x
Select the chip-select mask address.	GPMC_CONFIG7_i[11:8] MASKADDRESS	x

Table 10-388. NOR Timings Configuration

Subprocess Name	Register/Bit Field	Value
Configure adequate timing parameters in various memory modes.	See Section 10.3.5.6, *GPMC Timing Parameters*	

Table 10-389. Wait Pin Configuration

Subprocess Name	Register/Bit Field	Value
Enable or disable wait pin monitoring for read operations.	GPMC_CONFIG1_i[22] WAITREADMONITORING	x
Enable or disable wait pin monitoring for write operations.	GPMC_CONFIG1_i[21] WAITWRITEMONITORING	x
Select a wait pin monitoring time.	GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME	x
Choose the input wait pin for the chip-select.	GPMC_CONFIG1_i[17:16] WAITPINSELECT	x

Table 10-390. Enable Chip-Select

Subprocess Name	Register/Bit Field	Value
When all parameters are configured, enable the chip-select.	GPMC_CONFIG7_i[6] CSVALID	x

10.3.5.4 GPMC Configuration in NAND Mode

This section gives a generic configuration for parameters related to the NAND memory connected to the GPMC.

Table 10-391. NAND Memory Type

Subprocess Name	Register/Bit Field	Value
Set the NAND protocol.	GPMC_CONFIG1_i[11:10] DEVICETYPE	0x2
Set a device size.	GPMC_CONFIG1_i[13:12] DEVICESIZE	x
Set the address and data multiplexing protocol to non-multiplexed attached device.	GPMC_CONFIG1_i[9] MUXADDDATA	0x0
Select a timing signals latencies factor.	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x

Table 10-391. NAND Memory Type (continued)

Subprocess Name	Register/Bit Field	Value
Set a synchronous or asynchronous mode and a single or multiple access for read and write operations.	See Section 10.3.5.5, *Set Memory Access*.	x

Table 10-392. NAND Chip-Select Configuration

Subprocess Name	Register/Bit Field	Value
Select the chip-select base address.	GPMC_CONFIG7_i[5:0] BASEADDRESS	x
Select the chip-select minimum granularity (16MiB).	GPMC_CONFIG7_i[11:8] MASKADDRESS	x

Table 10-393. Asynchronous Read and Write Operations

Subprocess Name	Register/Bit Field	Value
Configure adequate timing parameters in asynchronous modes	See Section 10.3.5.6, *GPMC Timing Parameters*.	

Table 10-394. ECC Engine

Subprocess Name	Register/Bit Field	Value
Select the ECC result register where the first ECC computation is stored (applies only to Hamming).	GPMC_ECC_CONTROL[3:0] ECCPOINTER	x (1)
Clear all ECC result registers.	GPMC_ECC_CONTROL[8] ECCCLEAR	Write 1 to clear.
Define ECCSIZE0 and ECCSIZE1.	GPMC_ECC_SIZE_CONFIG[19:12] ECCSIZE0 and [29:22] ECCSIZE1	x (2)
Select the size of each of the 9 result registers (size specified by ECCSIZE0 or ECCSIZE1).	GPMC_ECC_SIZE_CONFIG[j-1] ECCjRESULTSIZE where j = 1 to 9	x
Select the chip-select where ECC is computed.	GPMC_ECC_CONFIG[3:1] ECCCS	x
Select the Hamming code or BCH code ECC algorithm in use.	GPMC_ECC_CONFIG[16] ECCALGORITHM	x
Select word size for ECC calculation.	GPMC_ECC_CONFIG[7] ECC16B	x
If the BCH code is used, Set an error correction capability and Select a number of sectors to process.	GPMC_ECC_CONFIG[13:12] ECCBCHTSEL and GPMC_ECC_CONFIG[6:4] ECCTOPSECTOR	x
Enable the ECC computation.	GPMC_ECC_CONFIG[0] ECCENABLE	0x1

(1) This parameter depends on the numbers of sectors in a page.
(2) Depends on the size of each sector in the NAND page

Table 10-395. Prefetch and Write-Posting Engine

Subprocess Name	Register/Bit Field	Value
Disable the engine before configuration.	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x0
Select the chip-select associated with a NAND device where the prefetch engine is active.	GPMC_PREFETCH_CONFIG1[26:24] ENGINECSSELECTOR	x
Select access direction through prefetch engine, read or write.	GPMC_PREFETCH_CONFIG1[0] ACCESSMODE	x
Select the threshold used to issue a DMA request.	GPMC_PREFETCH_CONFIG1[14:8] FIFOTHRESHOLD	x
Select DMA synchronized mode or software manual mode.	GPMC_PREFETCH_CONFIG1[2] DMAMODE	x
Select if the engine immediately starts accessing the memory upon STARTENGINE assertion or if hardware synchronization based on a WAIT signal is used.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which wait pin edge detector should start the engine in synchronized mode.	GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR	x

Table 10-395. Prefetch and Write-Posting Engine (continued)

Subprocess Name	Register/Bit Field	Value
Enter a number of clock cycles removed to timing parameters (for all back-to-back accesses to the NAND flash except the first one).	GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION	x
Enable the prefetch postwrite engine.	GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE	0x1
Select the number of bytes to be read or written by the engine to the selected chip-select.	GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT	x
Start the prefetch engine.	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x1

Table 10-396. Wait Pin Configuration

Subprocess Name	Register/Bit Field	Value
Selects when the engine starts the access to chip-select.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which wait pin edge detector should start the engine in synchronized mode.	GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR	x

Table 10-397. Enable Chip-Select

Subprocess Name	Register/Bit Field	Value
When all parameters are configured, enable the chip-select.	GPMC_CONFIG7_i[6] CSVALID	x

10.3.5.5 Set Memory Access

This section describes the bit field to configure to set the GPMC in various memory modes. Table 10-398 and Table 10-399 provide check lists for mode parameters and access type parameters, respectively.

Table 10-398. Mode Parameters Check List

Register	Bit	Name	Asynchronous				Synchronous			
			Single Read Access	Single Write Access	Multiple Read (Page) Access	Multiple Write (Page) Access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access
GPMC_CONFIG1_i	30	READMULTIPLE	0x0	–	0x1 (1)	N/S	0x0	–	0x1	–
GPMC_CONFIG1_i	29	READTYPE	0x0	–	0x0 (1)	N/S	0x1	–	0x1	–
GPMC_CONFIG1_i	28	WRITEMULTIPLE	–	0x0	- (1)	N/S	–	0x0	–	0x1
GPMC_CONFIG1_i	27	WRITETYPE	–	0x0	- (1)	N/S	–	0x1	–	0x1

(1) Multiple read is not supported in address/data-multiplexed and AAD-multiplexed modes. Multiple read is supported in nonmultiplexed mode.

Table 10-399. Access Type Parameters Check List

Register	Bit	Name	Access Type		
			Nonmultiplexed	Address/ Data-Multiplexed	AAD-Multiplexed
GPMC_CONFIG1_i	9:8	MUXADDDATA	0x0	0x2	0x1

10.3.5.6 GPMC Timing Parameters

Figure 10-55 shows a programming model diagram for the NOR interfacing timing parameters.

Figure 10-55. NOR Interfacing Timing Parameters Diagram

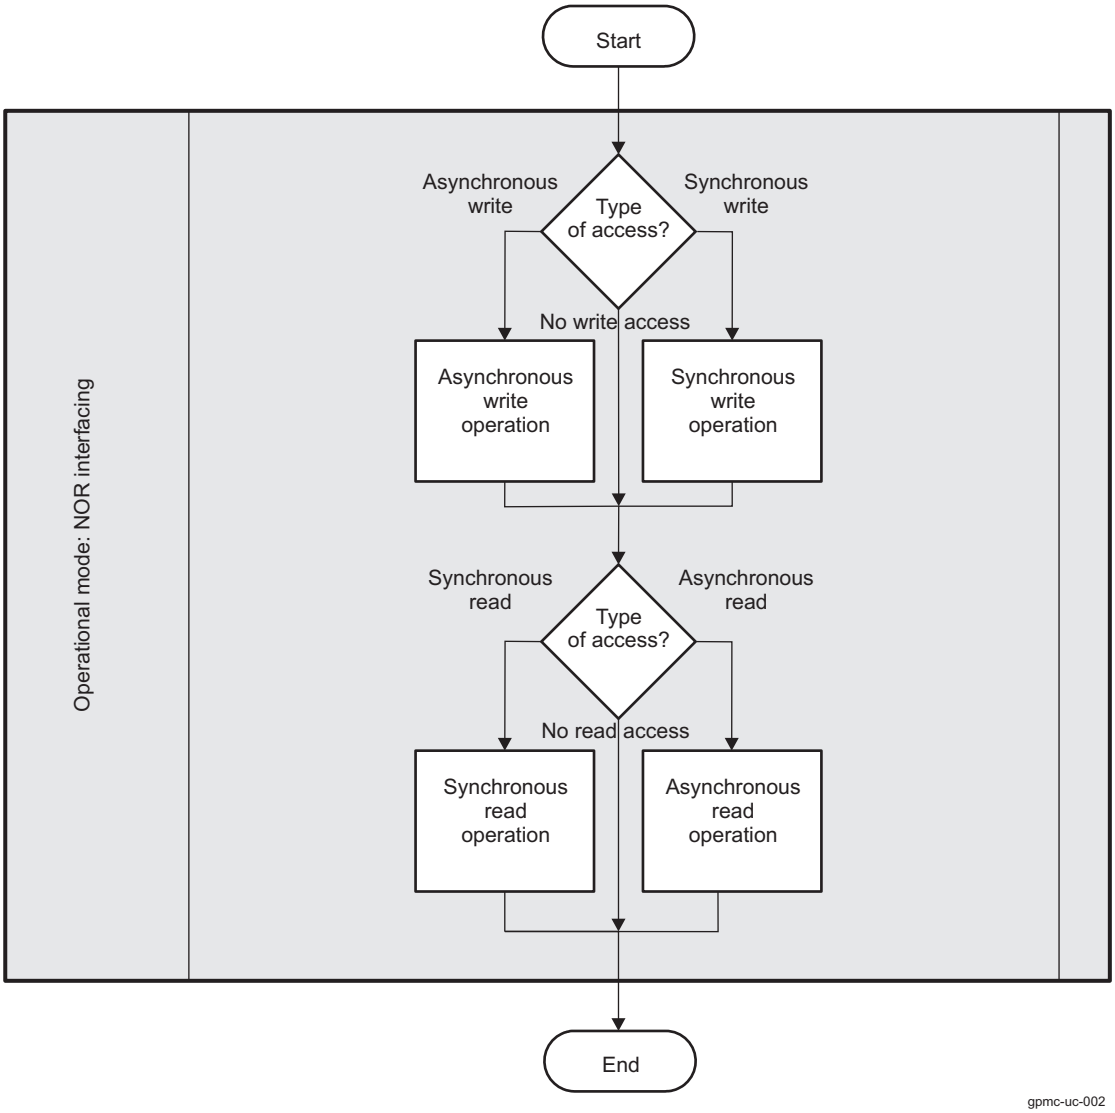

Table 10-400 lists the bit fields to configure adequate timing parameters in various memory modes.

Table 10-400. Timing Parameters

			Asynchronous			Synchronous				Access Type		
Register	Bit	Name	Single Read Access	Single Write Access	Multiple Read (Page) access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access	Non-multiplexed	Address / Data-Multiplexed	AAD Multiplexed
GPMC_CONFIG1_i	9	MUXADDDATA	y	y	y	y	y	y	y	y	y	y
GPMC_CONFIG1_i	29	READTYPE	y		y	y		y		y	y	y
GPMC_CONFIG1_i	30	READMULTIPLE	y		y	y		y		y	y	y
GPMC_CONFIG1_i	27	WRITETYPE		y			y		y	y	y	y
GPMC_CONFIG1_i	28	WRITEMULTIPLE		y			y		y	y	y	y
GPMC_CONFIG1_i	31	WRAPBURST						y	y	y	y	y
GPMC_CONFIG1_i	26:25	CLKACTIVATIONTIME				y	y	y	y	y	y	y
GPMC_CONFIG1_i	19:18	WAITMONITORINGTIME	y	y	y	y	y	y	y	y	y	y
GPMC_CONFIG1_i	4	TIMEPARAGRANULARITY	y	y	y	y	y	y	y	y	y	y
GPMC_CONFIG2_i	20:16	CSWROFFTIME		y			y		y	y	y	y
GPMC_CONFIG2_i	12:8	CSRDOFFTIME	y		y	y		y		y	y	y
GPMC_CONFIG2_i	7	CSEXTRADELAY	y	y	y	y	y	y	y	y	y	y

10.3.5.6.1 GPMC Timing Parameters Formulas

This section is intended to help the user calculate the GPMC timing bit field values. Formulas are not listed exhaustively.

The section describes:

- NAND flash interface timing parameters formulas
- Synchronous NOR flash timing parameters formulas
- Asynchronous NOR flash timing parameters formulas

For complete information, such as OPP and board effects on timings, see the device data manual.

10.3.5.6.1.1 NAND Flash Interface Timing Parameters Formulas

This section lists formulas to calculate NAND timing parameters. This is the case when GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x2. Table 10-401 describes the NAND timing parameters.

Table 10-401. NAND Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – gpmc_wen valid time
B	ns	Delay time – gpmc_cs valid to gpmc_wen valid
C	ns	Delay time – gpmc_ben0/gpmc_advn_ale high to gpmc_wen valid
D	ns	Delay time – gpmc_ad[15:0] valid to gpmc_wen valid
E	ns	Delay time – gpmc_wen invalid to gpmc_ad[15:0] invalid
F	ns	Delay time – gpmc_wen invalid to gpmc_ben0/gpmc_advn_ale invalid
G	ns	Delay time – gpmc_wen invalid to gpmc_cs invalid
H	ns	Cycle time – Write cycle time
I	ns	Delay time – gpmc_cs valid to gpmc_oen_ren valid
J	ns	Setup time – gpmc_ad[15:0] valid to gpmc_oen_ren invalid
K	ns	Pulse duration – gpmc_oen_ren valid time
L	ns	Cycle time – Read cycle time
M	ns	Delay time – gpmc_oen_ren invalid to gpmc_cs invalid

The configuration parameters are calculated through the following formulas. For more information, see the device data manual.

A = (WEOffTime – WEOnTime) * (TimeParaGranularity + 1) * GPMC_FCLK period

B = ((WEOnTime – CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEExtraDelay – CSExtraDelay)) * GPMC_FCLK period

C = ((WEOnTime – ADVOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEExtraDelay - ADVExtraDelay)) * GPMC_FCLK period

D = (WEOnTime * (TimeParaGranularity + 1) + 0.5 * WEExtraDelay) * GPMC_FCLK period

E = (WrCycleTime – WEOffTime * (TimeParaGranularity + 1) – 0.5 * WEExtraDelay) * GPMC_FCLK period

F = (ADVWrOffTime – WEOffTime * (TimeParaGranularity + 1) + 0.5 * (ADVExtraDelay – WEExtraDelay) * GPMC_FCLK period

G = (CSWrOffTime – WEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSExtraDelay – WEExtraDelay) * GPMC_FCLK period

H = WrCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK period

I = ((OEOnTime – CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (OEExtraDelay – CSExtraDelay)) * GPMC_FCLK period

J = ((RdAccessTime – OEOffTime) * (TimeParaGranularity + 1) – 0.5 * OEExtraDelay)) * GPMC_FCLK period

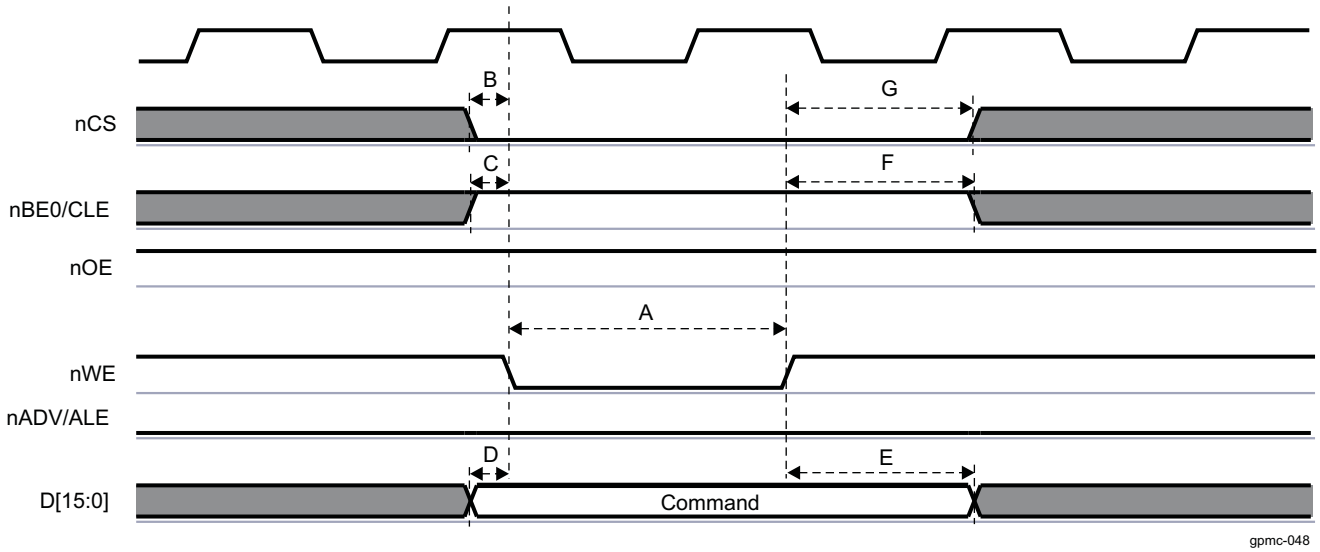
K = (OEOffTime – OEOnTime) * (1 + TimeParaGranularity) * GPMC_FCLK period

L = RdCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK period

M = (CSRdOffTime – OEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSExtraDelay - OEExtraDelay) * GPMC_FCLK period

Figure 10-56 shows a simplified example of command latch cycle timing where formulas are associated with signal waves.

Figure 10-56. NAND Command Latch Cycle Timing Simplified Example



10.3.5.6.1.2 Synchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to calculate synchronous NOR timing parameters. This is the case when GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to synchronous mode. Table 10-402 describes the synchronous NOR formulas.

Table 10-402. Synchronous NOR Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – gpmc_cs low
B	ns	Delay time – address bus valid to gpmc_clk first edge
		Delay time – gpmc_ben0/gpmc_ben1 valid to gpmc_clk first edge
C	ns	Pulse duration – gpmc_ben0/gpmc_ben1 low
D	ns	Delay time – gpmc_clk rising edge to gpmc_ben0/gpmc_ben1 invalid
		Delay time – gpmc_clk rising edge to gpmc_advn_ale invalid
E	ns	Delay time – gpmc_clk rising edge to gpmc_cs invalid
		Delay time – gpmc_clk rising edge to gpmc_oen_ren invalid
F	ns	Delay time – gpmc_clk rising edge to gpmc_cs transition
G	ns	Delay time – gpmc_clk rising edge to gpmc_advn_ale transition
H	ns	Delay time – gpmc_clk rising edge to gpmc_oen_ren transition
I	ns	Delay time – gpmc_clk rising edge to gpmc_wen transition
J	ns	Delay time – gpmc_clk rising edge to gpmc_ad data bus transition
		Delay time – gpmc_clk rising edge to gpmc_ben0/gpmc_ben1 transition
K	ns	Pulse duration – gpmc_advn_ale low
L	ns	Delay time – gpmc_wait invalid to first data latching gpmc_clk edge

The configuration parameters are calculated through the following formulas. For more information, see the device data manual.

1. For single read accesses:

   A = (CSRDOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (RDCYCLETIME – RDACCESSTIME) * GPMC_FCLK period
   E = (CSRDOFFTIME – RDACCESSTIME) * GPMC_FCLK period

2. For burst read accesses (where n is the page burst access number):

   A = (CSRDOFFTIME – CSONTIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = (RDCYCLETIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (RDCYCLETIME – (RDACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period
   E = (CSRDOFFTIME – (RDACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period

3. For burst write accesses (where n is the page burst access number):

   A = (CSWROFFTIME – CSONTIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = (WRCYCLETIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (WRCYCLETIME – (RDACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period
   E = (CSWROFFTIME – (RDACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period

4. For all accesses:

   For nCS falling edge (chip-select activated):

   - Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
   - Case where GPMCFCLKDIVIDER = 0x1:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSONTIME are odd) or (CLKACTIVATIONTIME and CSONTIME are even)
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.
   - Case where GPMCFCLKDIVIDER = 0x2:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME) is a multiple of 3
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
     F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
   - Case where GPMCFCLKDIVIDER = 0x3:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME) is a multiple of 4
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
     F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
     F = (3 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

   For nCS rising edge (chip-select deactivated) in reading mode:

   - Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
   - Case where GPMCFCLKDIVIDER = 0x1:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSRDOFFTIME are odd) or (CLKACTIVATIONTIME and CSRDOFFTIME are even)
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.

- Case where GPMCFCLKDIVIDER = 0x2:
  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME) is a multiple of 4
  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
  F = (3 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nCS rising edge (chip-select deactivated) in writing mode:

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSWROFFTIME are odd) or (CLKACTIVATIONTIME and CSWROFFTIME are even)
  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME) is a multiple of 4
  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
  F = (3 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nADV falling edge (nADV activated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVONTIME are odd) or (CLKACTIVATIONTIME and ADVONTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME) is a multiple of 4
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME –

CLKACTIVATIONTIME – 1) is a multiple of 4
G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
G = (3 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nADV rising edge (nADV deactivated) in reading mode:

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVRDOFFTIME are odd) or (CLKACTIVATIONTIME and ADVRDOFFTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVRDOFFTIME – CLKACTIVATIONTIME) is a multiple of 4
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
  G = (3 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nADV rising edge (nADV deactivated) in writing mode:

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVWROFFTIME are odd) or (CLKACTIVATIONTIME and ADVWROFFTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME) is a multiple of 4
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
  G = (3 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nOE falling edge (nOE activated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and OEONTIME are odd) or (CLKACTIVATIONTIME and OEONTIME are even)

H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period otherwise.

- Case where GPMCFCLKDIVIDER = 0x2:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME) is a multiple of 3
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME) is a multiple of 4
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
  H = (3 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nOE rising edge (nOE deactivated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and OEOFFTIME are odd) or (CLKACTIVATIONTIME and OEOFFTIME are even)
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME) is a multiple of 4
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
  H = (3 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nWE falling edge (nWE activated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and WEONTIME are odd) or (CLKACTIVATIONTIME and WEONTIME are even)
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME) is a multiple of 3
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME) is a multiple of 4

I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
I = (3 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nWE rising edge (nWE deactivated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and WEOFFTIME are odd) or (CLKACTIVATIONTIME and WEOFFTIME are even)
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME) is a multiple of 4
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
  I = (3 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For gpmc_nadv low pulse duration:

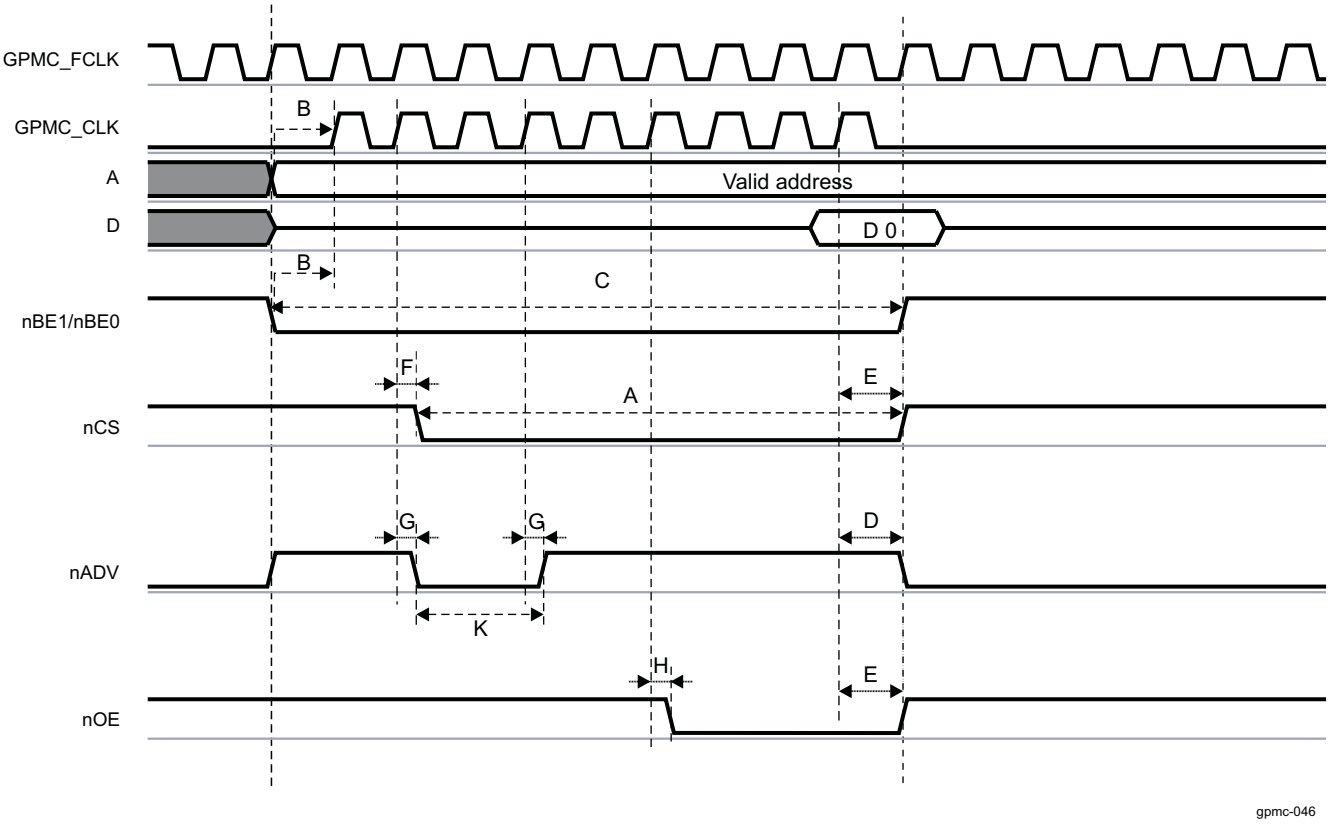
- Read operation:
  K = (ADVRDOFFTIME – ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
- Write operation:
  K = (ADVWROFFTIME – ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

For gpmc_wait invalid to first data latching gpmc_clk edge:

- L = WAITMONITORINGTIME * (GPMCFCLKDIVIDER + 1) * GPMC_FCLK period + GPMC_CLK period

Figure 10-57 shows a simplified example of a synchronous NOR single read where formulas are associated with signal waves.

Figure 10-57. Synchronous NOR Single Read Simplified Example



10.3.5.6.1.3 Asynchronous NOR Flash Timing Parameters Formulas

This section lists all the formulas to calculate asynchronous NOR timing parameters. This is the case when GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to asynchronous mode. Table 10-403 describes the asynchronous NOR formulas.

Table 10-403. Asynchronous NOR Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – gpmc_cs low
B	ns	Delay time – gpmc_cs valid to gpmc_advn_ale invalid
C	ns	Delay time – gpmc_cs valid to gpmc_oen_ren invalid (single read)
D	ns	Pulse duration – address bus valid - 2nd, 3rd and 4th accesses
E	ns	Delay time – gpmc_cs valid to gpmc_wen valid
F	ns	Delay time – gpmc_cs valid to gpmc_wen invalid
G	ns	Address invalid duration between two successive R/W accesses
H	ns	Setup time – read data valid before gpmc_oen_ren high
I	ns	Delay time – gpmc_cs valid to gpmc_oen_ren invalid (burst read)
J	ns	Delay time – address bus valid to gpmc_cs valid
		Delay time – data bus valid to gpmc_cs valid
		Delay time – gpmc_ben0/gpmc_ben1 valid to gpmc_cs valid
K	ns	Delay time – gpmc_cs valid to gpmc_advn_ale valid
L	ns	Delay time – gpmc_cs valid to gpmc_oen_ren valid
M	ns	Delay time – gpmc_cs valid to first data latching edge
N	ns	Pulse duration – gpmc_ben0/gpmc_ben1 valid time

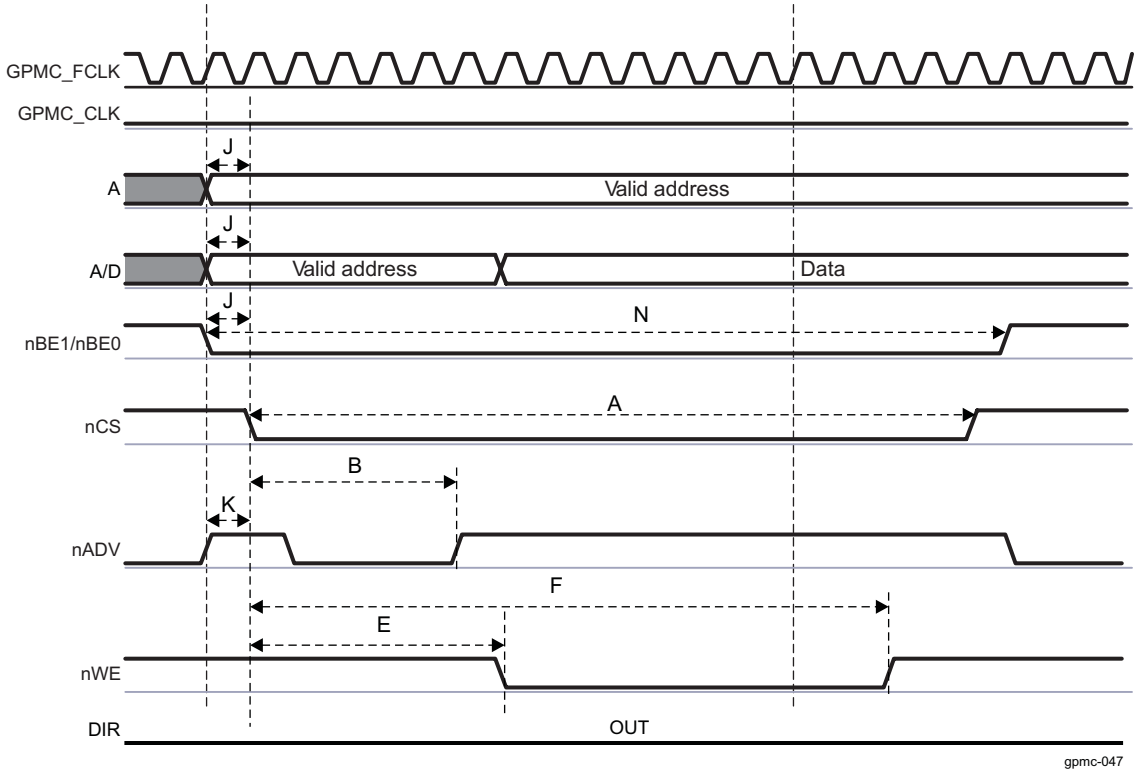
Table 10-403. Asynchronous NOR Formulas Description (continued)

Configuration Parameter	Unit	Description
O	ns	Delay time – gpmc_cs valid to gpmc_advn_ale valid

The configuration parameters are calculated through the following formulas. These formulas are not exhaustive. For more information, see the device data manual.

- gpmc_cs low pulse:
  For single read: A = (CSRDOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst read: A = (CSRDOFFTIME – CSONTIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
  For single write: A = (CSWROFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst write: A = (CSWROFFTIME – CSONTIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
- gpmc_cs valid to gpmc_advn_ale invalid delay:
  For reading: B = ((ADVRDOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
  For writing: B = ((ADVWROFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- C = ((OEOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- D = PAGEBURSTACCESSTIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
- E = ((WEONTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- F = ((WEOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- G = CYCLE2CYCLEDELAY * GPMC_FCLK period
- H = ((OEOFFTIME – RDACCESSTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * OEEXTRADELAY) * GPMC_FCLK period
- I = ((OEOFFTIME + (N – 1) * PAGEBURSTACCESSTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period, where N = page burst access number
- J = (CSONTIME * (TIMEPARAGRANULARITY + 1) + 0.5 * CSEXTRADELAY) * GPMC_FCLK period
- K = ((ADVONTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- L = ((OEONTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- M = ((RDACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) – 0.5 * CSEXTRADELAY) * GPMC_FCLK period
- gpmc_ben0/gpmc_ben1 pulse:
  For single read: N = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst read: N = (RDCYCLETIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
  For burst write: N = (WRCYCLETIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
- O = ((WRCYCLETIME + (N – 1) * PAGEBURSTACCESSTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
  Figure 10-58 shows a simplified example of an asynchronous NOR single write where formulas are associated with signal waves.

Figure 10-58. Asynchronous NOR Single Write Simplified Example



NOTE: Write multiple access is not supported in asynchronous mode. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

10.3.6 GPMC Use Cases and Tips

10.3.6.1 How to Set GPMC Timing Parameters for Typical Accesses

10.3.6.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8- or 16-bit-wide memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples describe how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104-MHz clock frequency
- Read access time: 80 ns

10.3.6.1.2 Typical GPMC Setup

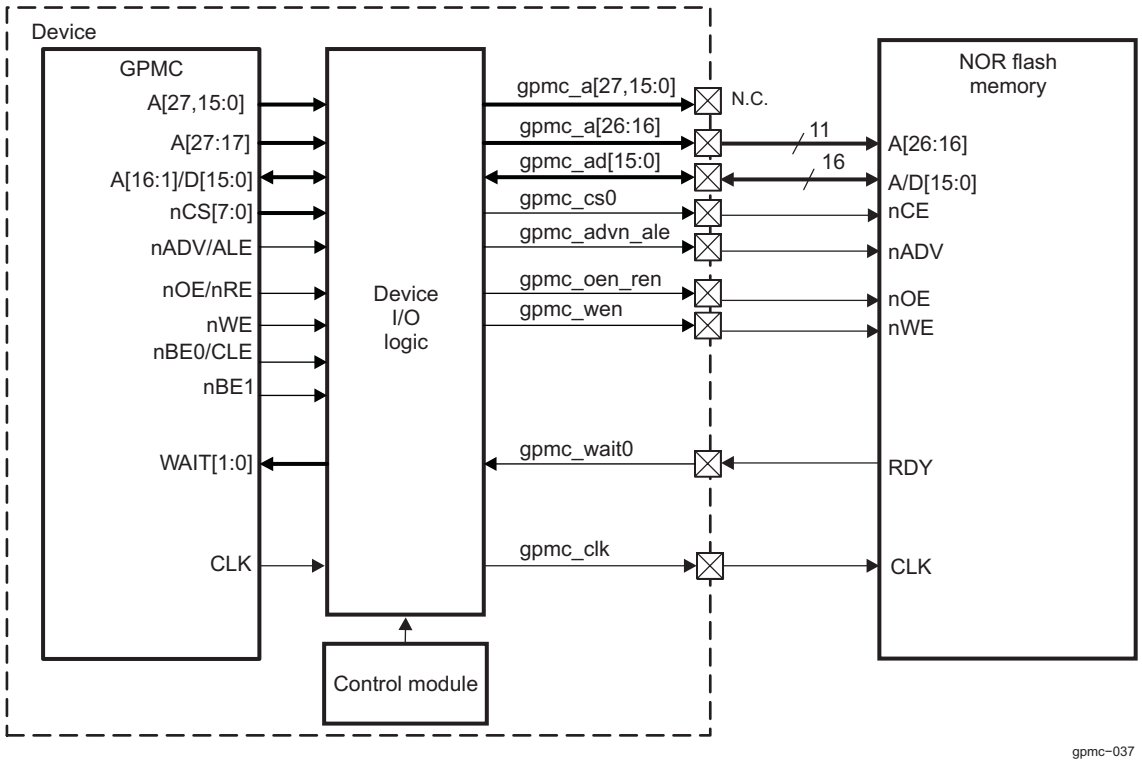
Table 10-404 lists some of the I/Os of the GPMC module.

Table 10-404. GPMC Signals

Signal Name	I/0	Description
GPMC_FCLK	Internal	Functional and interface clock. Acts as the time reference.
gpmc_clk	O	External clock provided to the external device for synchronous operations
gpmc_a[26:16]	O	Address
gpmc_ad[15:0]	I/O	Data-multiplexed with addresses A[16:1] on memory side
gpmc_csx	O	Chip-select (where x = 0, or 1)
gpmc_advn_ale	O	Address valid enable
gpmc_oen_ren	O	Output enable (read access only)
gpmc_wen	O	Write enable (write access only)
gpmc_wait[1:0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

Figure 10-59 shows the typical connection between the GPMC module and an attached NOR Flash memory.

Figure 10-59. GPMC Connection to an External NOR Flash Memory



The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

10.3.6.1.2.1 GPMC Configuration for Synchronous Burst Read Access

NOTE: The examples in Section 10.3.6.1.2.1 through Section 10.3.6.1.2.3 are based on a clock rate of 104 MHz. Refer to the device Data Manual for the maximum frequency appropriate for this device and to the memory datasheet for the maximum frequency for the particular memory device.

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 10-405 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 10-406 shows how to calculate timings for the GPMC using the memory parameters.

Figure 10-60 shows the synchronous burst read access.

Table 10-405. Useful Timing Parameters on the Memory Side

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	nCS setup time to clock	0
tACS	Address setup time to clock	3
tIACC	Synchronous access time	80

Table 10-405. Useful Timing Parameters on the Memory Side (continued)

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tBACC	Burst access time valid clock to output delay	5,2
tCEZ	Chip-select to High-Z	7
tOEZ	Output enable to High-Z	7
tAVC	nADV setup time	6
tAVD	nAVD pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

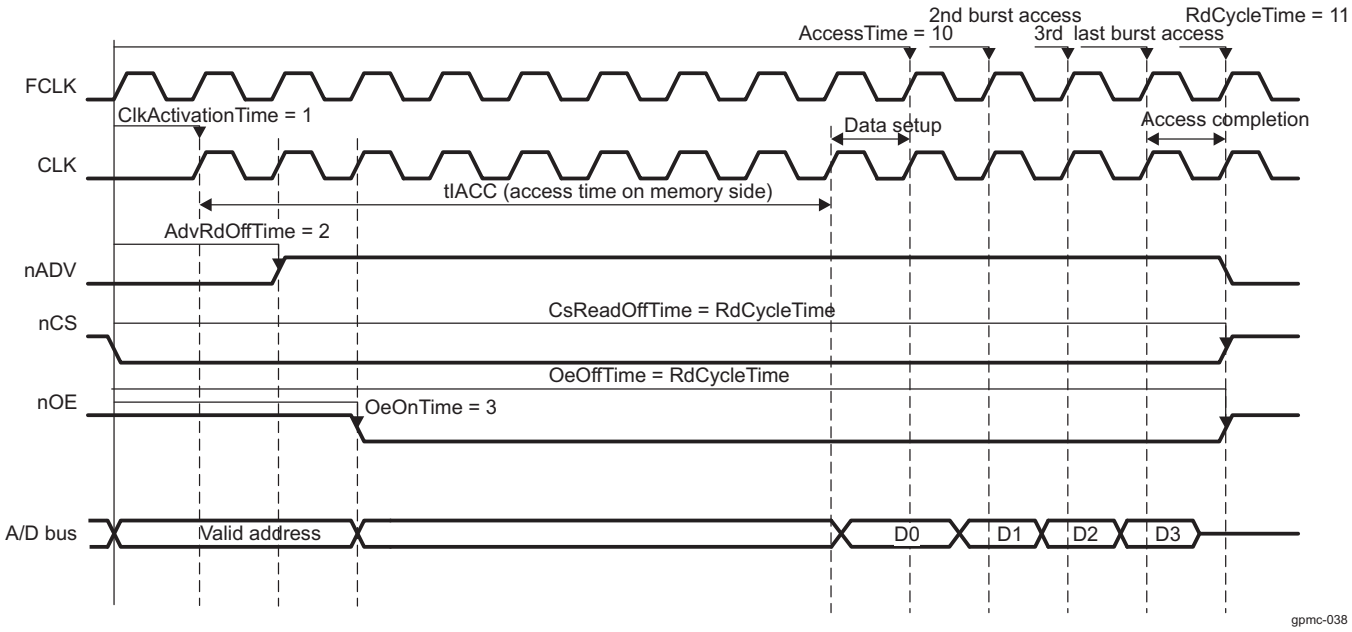
- Read access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle (T = 9,615 ns). The read access time between two bursts of data is tBACC = 5.2 ns. Therefore, data setup time is a clock period – tBACC = 4,415 ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

Table 10-406. Calculating GPMC Timing Parameters

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
GPMC FCLK Divider	–	–	–	GPMCFCLKDIVIDER = 0x0
ClkActivation Time	min (tCES, tACS)	3	1	CLKACTIVATIONTIME = 0x1
RdAccessTime	roundmax (ClkActivationTime + tIACC + DataSetupTime)	94.03: (9,615 + 80 + 4,415)	10: roundmax (94.03 / 9,615)	RDACCESSTIME = 0x0A
PageBurst RdAccessTime	roundmax (tBACC)	roundmax (5.2)	1	PAGEBURSTACCESSTIME = 0x1
RdCycleTime	RdAccess time + max (tCEZ, tOEZ)	101.03: (94.03 + 7)	11	RDCYCLETIME = 0x0B
CsOnTime	tCES	0	0	CSONTIME = 0x0
CsReadOffTime	RdCycleTime	-	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAVC (1)	0	0	ADVONTIME = 0x0
AdvRdOffTime	tAVD + tAVC (2)	12	2	ADVRDOFFTIME = 0x02
OeOnTime (3)	(ClkActivationTime + tACH) < OeOnTime (ClkActivationTime + tIACC)	–	3, for instance	OEONTIME = 0x3
OeOffTime	RdCycleTime	–	11	OEOFFTIME = 0x0B

(1) The external clock provided to the NOR flash is not yet available.
(2) AdvRdOffTime – AdvOnTime = tAVD; thus, AdvRdOffTime = tAVD + AdvOnTime = tAVD + tAVC.
(3) OeOnTime must ensure that addresses are available. It must not exceed the availability of the first burst of data.

Figure 10-60. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)



10.3.6.1.2.2 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 10-407 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 10-408 shows how to calculate timings for the GPMC using the memory parameters.

Figure 10-61 shows the asynchronous read access.

Table 10-407. AC Characteristics for Asynchronous Read Access

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from nCS low	80
tAAVDS	Address setup time to rising edge of nADV	3
tAVDP	nADV low time	6
tCAS	nCS setup time to nADV	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Z	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

RdCycleTime = RdAccessTime + AccessCompletion = RdAccessTime + 1 clock cycle + tOEZ:

1. On the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 10-407: the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus.

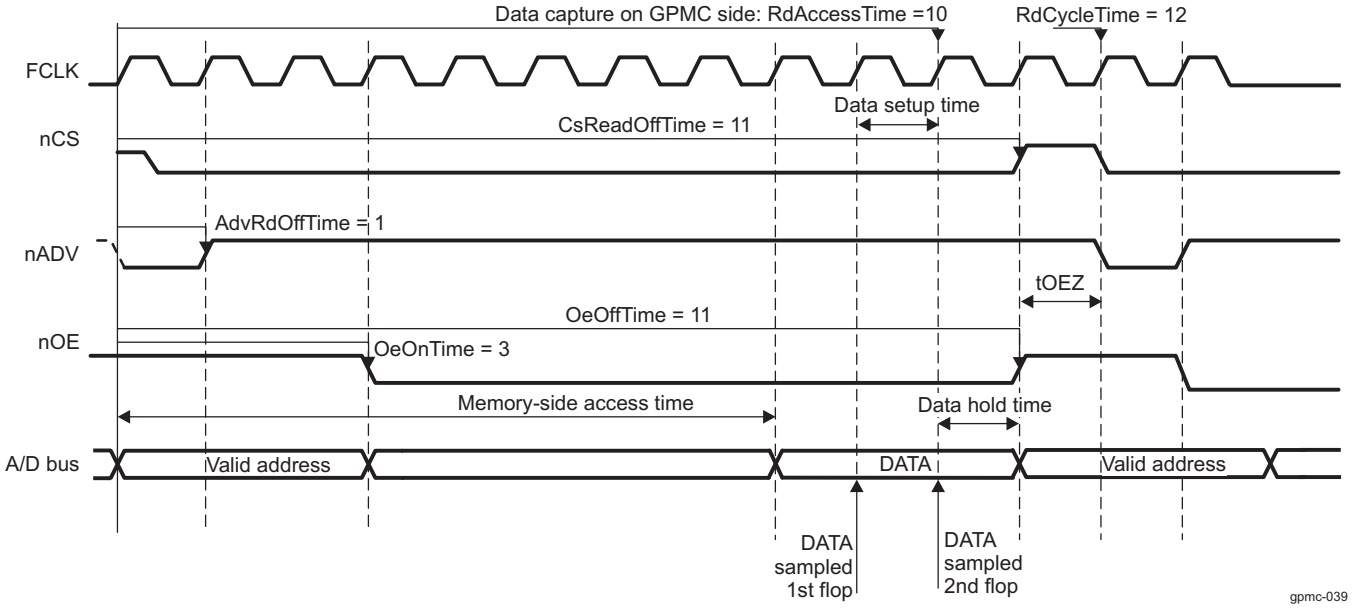
   The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.
2. To read the data correctly, the GPMC must be configured to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
3. There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS deassertion while reading the data). This data hold time is one clock cycle (that is, RdAccessTime + 1).

4. To complete the access, nOE/nCS signals are driven to High-Z. RdAccessTime + 1 + tOEZ is the read cycle time.
5. Addresses can now be relatched and a new read cycle begun.

Table 10-408. GPMC Timing Parameters for Asynchronous Read Access

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime		n/a (asynchronous mode)		
RdAccessTime	round max (tCE)	80	10	RDACCESSTIME = 0x0A
PageBurstAccess Time	N/A (single access)			
RdCycleTime	RdAccessTime + 1cycle + tOEZ	96, 615	12	RDCYCLETIME = 0x0C
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsReadOffTime	RdAccessTime + 1 cycle	89, 615	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAAVDS	3	1	ADVONTIME = 0X1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 0x01
OeOnTime	OeOnTime >= AdvRdOffTime (multiplexed mode)	-	3, for instance	OEONTIME = 0x3
OeOffTime	RdAccessTime + 1cycle	89, 615	11	OEOFFTIME = 0x0B

Figure 10-61. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)



10.3.6.1.2.3 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9, 615 ns).

Table 10-410 shows how to calculate timings for the GPMC using the memory parameters.

Table 10-409 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 10-62 shows the synchronous burst write access.

Table 10-409. AC Characteristics for Asynchronous Single Write (Memory Side)

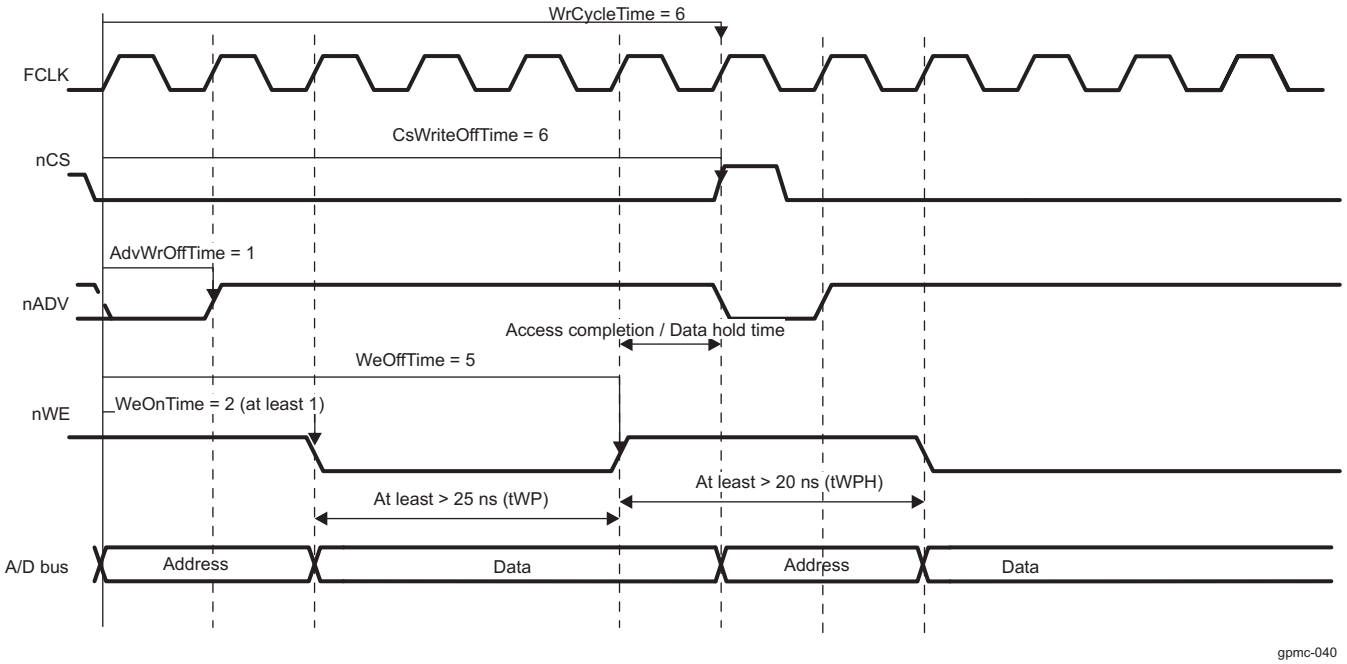
AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60
tAVDP	nADV low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	nCS setup time to nWE	3
tCAS	nCS setup time to nADV	0
tAVSC	nADV setup time	3

For asynchronous single write access, write cycle time is WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1. For the AccesCompletion, the GPMC requires one cycle of data hold time (nCS deassertion). For more information, see the device data manual.

Table 10-410. GPMC Timing Parameters for Asynchronous Single Write

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Registers Configuration
ClkActivationTime	N/A (asynchronous mode)			
WdAccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime	N/A (single access)			
WrCycleTime	WeOffTime + AccessCompletion	57, 615	6	WRCYCLETIME = 0x06
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsWrOffTime	WeOffTime + 1	57, 615	6	CSWROFFTIME = 0x06
AdvOnTime	tAVSC	3	1	ADVONTIME = 0x1
AdvWrOffTime	tAVSC + tAVDP	9	1	ADVWROFFTIME = 0x01
WeOnTime	tCS	3	1	WEONTIME = 0x1
WeOffTime	tCS + tWP + tWPH	48	5	WEOFFTIME = 0x05

Figure 10-62. Asynchronous Single Write Access (Timing Parameters in Clock Cycles)



10.3.6.2 How to Choose a Suitable Memory to Use With the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

10.3.6.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or devices, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit-wide asynchronous or synchronous memory or device (only 8-bit: nonburst device)
- 16-bit address and data-multiplexed NOR flash devices (pSRAM, OneNAND™, etc.)
- 8- and 16-bit NAND flash devices

10.3.6.2.1.1 Memory Pin Multiplexing

This section describes the interfacing differences of the GPMC supported memories.

Table 10-411. Supported Memories Interfaces

Function	16-Bit Address/ Data-Multiplexed pSRAM or NOR Flash [1]	OneNAND	16-Bit NAND	8-Bit NAND
gpmc_a[27]	A27

gpmc_wait1	WAIT1		R/nB1	

10.3.6.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device; that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Because of its high density NAND is best suited to devices that require high capacity data storage, such as pictures, music, and data files. NAND nonvolatility makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 10-412 summarizes the NAND interface signals level applied to external device or memories.

Table 10-412. NAND Interface Bus Operations Summary

Bus Operation	CLE	ALE	nCE	nWE [1]	nRE [1]
Read (cmd input)	H	L	L	RE	H
Read (add input)	L	H	L	RE	H

[1] RE stands for rising edge; FE stands for falling edge

Table 10-412. NAND Interface Bus Operations Summary (continued)

Bus Operation	CLE	ALE	nCE	nWE [1]	nRE [1]
Write (cmd input)	H	L	L	RE	H
Write (add input)	L	H	L	RE	H
Data input	L	L	L	RE	H
Data output	L	L	L	H	FE
Busy (during read)	x	x	H [2]	H [2]	H [2]
Busy (during program)	x	x	x	x	x
Busy (during erase)	x	x	x	x	x
Standby	x	x	H	x	x

[2] Can be nCE high, or WE and nRE high.

10.3.6.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND, which is a sequential access device, NOR is directly addressable; that is, it is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities, it also has slow write and erase functions when compared to the NAND architecture.

Table 10-413 summarizes the level of the NOR interface signals applied to external devices or memories.

Table 10-413. NOR Interface Bus Operations Summary

Bus Operation	CLK	nADV	nCS	nOE	nWE	WAIT	DQ[15:0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

10.3.6.2.1.4 Other Technologies

Other supported device types interact with the GPMC through the NOR interface protocol.

OneNAND is a high-density, low-power memory device. OneNAND is based on single- or multilevel-cell NAND core with SRAM and logic. It interfaces as a synchronous NOR flash and has synchronous write capability. It reads faster than conventional NAND and writes faster than conventional NOR flash. Hence, it is appropriate for mass storage and code storage.

pSRAM (pseudo-static random access memory) is a low-power memory device. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR flash. It also has synchronous write capability.

10.3.6.2.1.5 Supported Protocols

The GPMC supports the following interface protocols when communicating with external memory or external devices:

- Asynchronous read/write access
- Asynchronous read page access (4, 8, 16 Word16)
- Synchronous read/write access
- Synchronous read burst access without wrap capability (4, 8, 16 Word16)
- Synchronous read burst access with wrap capability (4, 8, 16 Word16)

10.3.6.2.2 GPMC Features and Settings

The features and settings of the GPMC are:

- Supported device type: Up to four NAND or NOR protocol external memories or devices
- Operating voltage: 1.8 V, 3.3 V
- Maximum operating frequency provided externally: See the device data manual for precise information.
- Maximum GPMC addressing capability: 512MiB divided into eight chip-selects
- Maximum supported memory size: 256MiB (must be a power-of-two)
- Minimum supported memory size: 16MiB (must be a power-of-two). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8, 16 bits wide
- Burst and page access: burst of 4, 8, 16 Word16
- Supports bus keeping
- Supports bus turnaround

10.3.7 GPMC Register Manual

This section provides information about the GPMC instance in this product. Table 10-415 provides a summary of the GPMC registers. The remaining parts of this section describe the registers within the module instance.

10.3.7.1 GPMC Register Summary

Table 10-414. GPMC Instance Summary

Module Name	Base Address	Size
GPMC	0x5000 0000	16 MiB

Table 10-415. GPMC Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address GPMC
GPMC_REVISION	R	32	0x0000 0000	0x5000 0000
GPMC_SYSCONFIG	RW	32	0x0000 0010	0x5000 0010
GPMC_SYSSTATUS	R	32	0x0000 0014	0x5000 0014
GPMC_IRQSTATUS	RW	32	0x0000 0018	0x5000 0018
GPMC_IRQENABLE	RW	32	0x0000 001C	0x5000 001C
GPMC_TIMEOUT_CONTROL	RW	32	0x0000 0040	0x5000 0040
GPMC_ERR_ADDRESS	RW	32	0x0000 0044	0x5000 0044
GPMC_ERR_TYPE	RW	32	0x0000 0048	0x5000 0048
GPMC_CONFIG	RW	32	0x0000 0050	0x5000 0050
GPMC_STATUS	RW	32	0x0000 0054	0x5000 0054
GPMC_CONFIG1_i (1)	RW	32	0x0000 0060 + (0x0000 0030 * i)	0x5000 0060 + (0x0000 0030 * i)
GPMC_CONFIG2_i (1)	RW	32	0x0000 0064 + (0x0000 0030 * i)	0x5000 0064 + (0x0000 0030 * i)
GPMC_CONFIG3_i (1)	RW	32	0x0000 0068 + (0x0000 0030 * i)	0x5000 0068 + (0x0000 0030 * i)
GPMC_CONFIG4_i (1)	RW	32	0x0000 006C + (0x0000 0030 * i)	0x5000 006C + (0x0000 0030 * i)
GPMC_CONFIG5_i (1)	RW	32	0x0000 0070 + (0x0000 0030 * i)	0x5000 0070 + (0x0000 0030 * i)
GPMC_CONFIG6_i (1)	RW	32	0x0000 0074 + (0x0000 0030 * i)	0x5000 0074 + (0x0000 0030 * i)
GPMC_CONFIG7_i (1)	RW	32	0x0000 0078 + (0x0000 0030 * i)	0x5000 0078 + (0x0000 0030 * i)
GPMC_NAND_COMMAND_i (1)	W	32	0x0000 007C + (0x0000 0030 * i)	0x5000 007C + (0x0000 0030 * i)
GPMC_NAND_ADDRESS_i (1)	W	32	0x0000 0080 + (0x0000 0030 * i)	0x5000 0080 + (0x0000 0030 * i)
GPMC_NAND_DATA_i (1)	RW	32	0x0000 0084 + (0x0000 0030 * i)	0x5000 0084 + (0x0000 0030 * i)
GPMC_PREFETCH_CONFIG1	RW	32	0x0000 01E0	0x5000 01E0
GPMC_PREFETCH_CONFIG2	RW	32	0x0000 01E4	0x5000 01E4
GPMC_PREFETCH_CONTROL	RW	32	0x0000 01EC	0x5000 01EC
GPMC_PREFETCH_STATUS	RW	32	0x0000 01F0	0x5000 01F0
GPMC_ECC_CONFIG	RW	32	0x0000 01F4	0x5000 01F4
GPMC_ECC_CONTROL	RW	32	0x0000 01F8	0x5000 01F8
GPMC_ECC_SIZE_CONFIG	RW	32	0x0000 01FC	0x5000 01FC
GPMC_ECCj_RESULT (2)	RW	32	0x0000 0200 + (0x0000 0004 * j)	0x5000 0200 + (0x0000 0004 * j)
GPMC_BCH_RESULT0_i (1)	RW	32	0x0000 0240 + (0x0000 0010 * i)	0x5000 0240 + (0x0000 0010 * i)
GPMC_BCH_RESULT1_i (1)	RW	32	0x0000 0244 + (0x0000 0010 * i)	0x5000 0244 + (0x0000 0010 * i)
GPMC_BCH_RESULT2_i (1)	RW	32	0x0000 0248 + (0x0000 0010 * i)	0x5000 0248 + (0x0000 0010 * i)
GPMC_BCH_RESULT3_i (1)	RW	32	0x0000 024C + (0x0000 0010 * i)	0x5000 024C + (0x0000 0010 * i)
GPMC_BCH_RESULT4_i (1)	RW	32	0x0000 0300 + (0x0000 0010 * i)	0x5000 0300 + (0x0000 0010 * i)
GPMC_BCH_RESULT5_i (1)	RW	32	0x0000 0304 + (0x0000 0010 * i)	0x5000 0304 + (0x0000 0010 * i)
GPMC_BCH_RESULT6_i (1)	RW	32	0x0000 0308 + (0x0000 0010 * i)	0x5000 0308 + (0x0000 0010 * i)
GPMC_BCH_SWDATA	RW	32	0x0000 02D0	0x5000 02D0

(1) i = 0 to 7 for GPMC
(2) j = 0 to 8 for GPMC

10.3.7.2 GPMC Register Descriptions

NOTE: All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except to GPMC_NAND_DATA_i register, are little-endian. If the GPMC_NAND_DATA_i register location is accessed, the endianness is access-dependent.

In this section i corresponds to the chip-select number, where i = 0 to 7.

Table 10-416. GPMC_REVISION

Address Offset	0x0000 0000		
Physical Address	0x5000 0000	**Instance**	GPMC
Description	This register contains the IP revision code.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REVISION																															

Bits	Field Name	Description	Type	Reset
31:0	REVISION	IP revision	R	TI internal data

Table 10-418. GPMC_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x5000 0010	**Instance**	GPMC
Description	This register controls the various parameters of the interconnect.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																											IDLEMODE		RESERVED	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0000000
4:3	IDLEMODE	0x0: Force-idle. An idle request is acknowledged unconditionally. 0x1: No-idle. An idle request is never acknowledged. 0x2: Smart-idle. Acknowledgment to an idle request is given based on the internal activity of the module. 0x3: Do not use.	RW	0x0
2	RESERVED	Write 0 for future compatibility Read returns 0.	RW	0x0
1	SOFTRESET	Software reset. Set this bit to 1 triggers a module reset. This bit is automatically reset by hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset.	RW	0x0

Bits	Field Name	Description	Type	Reset
0	AUTOIDLE	Internal interface clock-gating strategy 0x0: Interface clock is free-running. 0x1: Automatic Interface clock gating strategy is applied, based on the interconnect activity.	RW	0x0

Table 10-420. GPMC_SYSSTATUS

Address Offset	0x0000 0014		
Physical Address	0x5000 0014	**Instance**	GPMC
Description	This register provides status information about the module, excluding the interrupt status information.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								RESERVED							RESETDONE

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0.	R	0x000000
7:1	RESERVED	Read returns 0 (reserved for interconnect-socket status information).	R	0x00
0	RESETDONE	Internal reset monitoring 0x0: Internal module reset is ongoing. 0x1: Reset is complete.	R	0x-

Table 10-422. GPMC_IRQSTATUS

Address Offset	0x0000 0018		
Physical Address	0x5000 0018	**Instance**	GPMC
Description	This interrupt status register regroups all the status of the module internal events that can generate an interrupt.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																						WAIT1EDGEDETECTIONSTATUS	WAIT0EDGEDETECTIONSTATUS	RESERVED						TERMINALCOUNTSTATUS	FIFOEVENTSTATUS

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000000
9	WAIT1EDGEDETECTIONSTATUS	Status of the Wait1 Edge Detection interrupt Read 0x0: A transition on WAIT1 input pin has not been detected. Write 0x0: WAIT1EDGEDETECTIONSTATUS bit is unchanged. Read 0x1: A transition on WAIT1 input pin has been detected. Write 0x1: WAIT1EDGEDETECTIONSTATUS bit is reset.	RW	0x0
8	WAIT0EDGEDETECTIONSTATUS	Status of the Wait0 Edge Detection interrupt Read 0x0: A transition on WAIT0 input pin has not been detected. Write 0x0: WAIT0EDGEDETECTIONSTATUS bit is unchanged. Read 0x1: A transition on WAIT0 input pin has been detected. Write 0x1: WAIT0EDGEDETECTIONSTATUS bit is reset.	RW	0x0
7:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00
1	TERMINALCOUNTSTATUS	Status of the TerminalCountEvent interrupt Read 0x0: Indicates that CountValue is greater than 0 Write 0x0: TERMINALCOUNTSTATUS bit is unchanged. Read 0x1: Indicates that CountValue is equal to 0 Write 0x1: TERMINALCOUNTSTATUS bit is reset.	RW	0x0
0	FIFOEVENTSTATUS	Status of the FIFOEvent interrupt Read 0x0: Indicates that less than GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bytes are available in prefetch mode and less than FIFOTHRESHOLD bytes free places are available in write-posting mode Write 0x0: FIFOEVENTSTATUS bit is unchanged. Read 0x1: Indicates that at least GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bytes are available in prefetch mode and at least FIFOTHRESHOLD bytes free places are available in write-posting mode Write 0x1: FIFOEVENTSTATUS bit is reset.	RW	0x0

Table 10-424. GPMC_IRQENABLE

Address Offset	0x0000 001C		
Physical Address	0x5000 001C	**Instance**	GPMC
Description	The interrupt enable register allows to mask/unmask the module internal sources of interrupt, on a event-by-event basis.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																						WAIT1EDGEDETECTIONENABLE	WAIT0EDGEDETECTIONENABLE	RESERVED						TERMINALCOUNTEVENTENABLE	FIFOEVENTENABLE

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000000
9	WAIT1EDGEDETECTIONENABLE	Enables the Wait1 Edge Detection interrupt 0x0: Wait1EdgeDetection interrupt is masked. 0x1: Wait1EdgeDetection event generates an interrupt if occurs.	RW	0x0
8	WAIT0EDGEDETECTIONENABLE	Enables the Wait0 Edge Detection interrupt 0x0: Wait0EdgeDetection interrupt is masked. 0x1: Wait0EdgeDetection event generates an interrupt if occurs.	RW	0x0
7:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00
1	TERMINALCOUNTEVENTENABLE	Enables TerminalCountEvent interrupt issuing in prefetch or write-posting mode 0x0: TerminalCountEvent interrupt is masked. 0x1: TerminalCountEvent interrupt is not masked.	RW	0x0
0	FIFOEVENTENABLE	Enables the FIFOEvent interrupt 0x0: FIFOEvent interrupt is masked. 0x1: FIFOEvent interrupt is not masked.	RW	0x0

Table 10-425. Register Call Summary for Register GPMC_IRQENABLE

GPMC Functional Description • GPMC Interrupt Requests: [0][1][2][3] • NAND Device-Ready Pin: [4] • Ready Pin Monitored by Hardware Interrupt: [5] • FIFO Control in Prefetch Mode: [6][7] • FIFO Control in Write-Posting Mode: [8][9]

Table 10-426. GPMC_TIMEOUT_CONTROL

Address Offset	0x0000 0040		
Physical Address	0x5000 0040	**Instance**	GPMC
Description	The GPMC_TIMEOUT_CONTROL register allows the user to set the start value of the timeout counter.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																TIMEOUTSTARTVALUE								RESERVED							TIMEOUTENABLE

Bits	Field Name	Description	Type	Reset
31:13	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00000
12:4	TIMEOUTSTARTVALUE	Start value of the time-out counter 0x000: Zero GPMC_FCLK cycle 0x001: One GPMC_FCLK cycle ... 0x1FF: 511 GPMC_FCLK cycles	RW	0x1FF
3:1	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
0	TIMEOUTENABLE	Enable bit of the TimeOut feature 0x0: TimeOut feature is disabled. 0x1: TimeOut feature is enabled.	RW	0x0

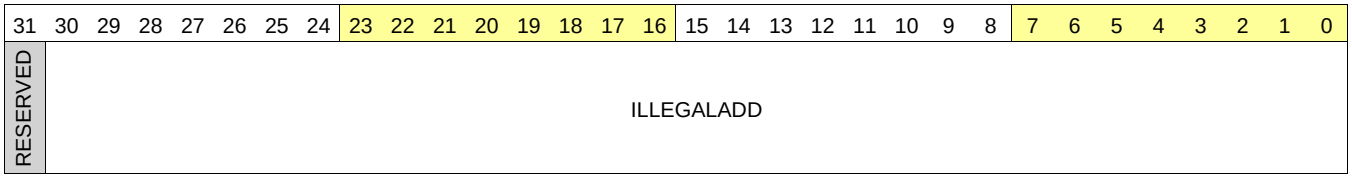
Table 10-428. GPMC_ERR_ADDRESS

Address Offset	0x0000 0044		
Physical Address	0x5000 0044	**Instance**	GPMC
Description	The GPMC_ERR_ADDRESS register stores the address of the illegal access when an error occurs.		
Type	RW		



Bits	Field Name	Description	Type	Reset
31	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
30:0	ILLEGALADD	Address of illegal access A30: 0 for memory region, 1 for GPMC register region A29-A0: 1 GiB maximum	R	0x00000000

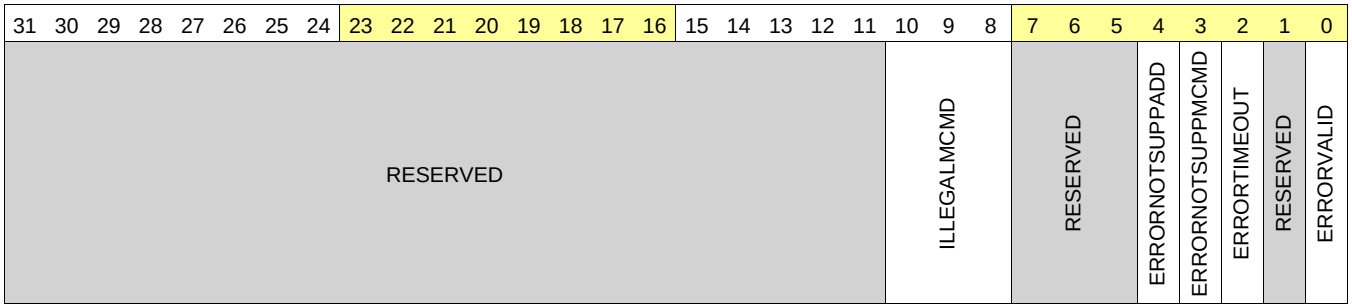
Table 10-430. GPMC_ERR_TYPE

Address Offset	0x0000 0048		
Physical Address	0x5000 0048	**Instance**	GPMC
Description	The GPMC_ERR_TYPE register stores the type of error when an error occurs.		
Type	RW		



Bits	Field Name	Description	Type	Reset
31:11	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000000
10:8	ILLEGALMCMD	System command of the transaction that caused the error	R	0x0
7:5	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
4	ERRORNOTSUPPADD	Not supported address error 0x0: No error occurs. 0x1: The error is due to a nonsupported address.	R	0x0

Bits	Field Name	Description	Type	Reset
3	ERRORNOTSUPPMCMD	Not supported command error 0x0: No error occurs. 0x1: The error is due to a nonsupported command	R	0x0
2	ERRORTIMEOUT	Time-out error 0x0: No error occurs. 0x1: The error is due to a timeout.	R	0x0
1	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
0	ERRORVALID	Error validity status - Must be explicitly cleared with a write 1 transaction 0x0: All error fields no longer valid 0x1: Error detected and logged in the other error fields	RW	0x0

Table 10-432. GPMC_CONFIG

Address Offset	0x0000 0050		
Physical Address	0x5000 0050	**Instance**	GPMC
Description	The configuration register allows global configuration of the GPMC.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																						WAIT1PINPOLARITY	WAIT0PINPOLARITY	RESERVED						RESERVED	NANDFORCEPOSTEDWRITE

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000000
9	WAIT1PINPOLARITY	Selects the polarity of input pin WAIT1 0x0: WAIT1 active low 0x1: WAIT1 active high	RW	0x1
8	WAIT0PINPOLARITY	Selects the polarity of input pin WAIT0 0x0: WAIT0 active low 0x1: WAIT0 active high	RW	0x0
7:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00
1	RESERVED	Write 0 for future compatibility. Read returns 0.	RW	0x0

Bits	Field Name	Description	Type	Reset
0	NANDFORCEPOSTEDWRITE	Enables the Force Posted Write feature to NAND Cmd/Add/Data location 0x0: Disables Force Posted Write 0x1: Enables Force Posted Write	RW	0x0

Table 10-433. Register Call Summary for Register GPMC_CONFIG

GPMC Functional Description
- GPMC Interrupt Requests: [0][1]

Table 10-434. GPMC_STATUS

Address Offset	0x0000 0054		
Physical Address	0x5000 0054	**Instance**	GPMC
Description	The status register provides global status bits of the GPMC.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																						WAIT1STATUS	WAIT0STATUS	RESERVED							EMPTYWRITEBUFFERSTATUS

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000000
9	WAIT1STATUS	Is a copy of input pin WAIT1. (Reset value is WAIT1 input pin sampled at device reset.) 0x0: WAIT1 asserted (inactive state) 0x1: WAIT1 deasserted	R	0x-
8	WAIT0STATUS	Is a copy of input pin WAIT0. (Reset value is WAIT0 input pin sampled at device reset.) 0x0: WAIT0 asserted (inactive state) 0x1: WAIT0 deasserted	R	0x-
7:1	RESERVED	Write 0s for future compatibility. Reads returns 0	RW	0x00
0	EMPTYWRITEBUFFERSTATUS	Stores the empty status of the write buffer 0x0: Write buffer is not empty. 0x1: Write buffer is empty.	R	0x1

Table 10-436. GPMC_CONFIG1_i

Address Offset	0x0000 0060 + (0x0000 0030 * i)	**Index**	i = 0 to 7
Physical Address	0x5000 0060 + (0x0000 0030 * i)	**Instance**	GPMC
Description	The configuration register 1 sets signal control parameters per chip-select.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WRAPBURST	READMULTIPLE	READTYPE	WRITEMULTIPLE	WRITETYPE	CLKACTIVATIONTIME			ATTACHEDDEVICEPAGELENGTH		WAITREADMONITORING	WAITWRITEMONITORING	RESERVED		WAITMONITORINGTIME		WAITPINSELECT		RESERVED		DEVICESIZE		DEVICETYPE		MUXADDDATA		RESERVED			TIMEPARAGRANULARITY	RESERVED		GPMCFCLKDIVIDER	

Bits	Field Name	Description	Type	Reset
31	WRAPBURST	Enables the wrapping burst capability. Must be set if the attached device is configured in wrapping burst 0x0: Synchronous wrapping burst not supported 0x1: Synchronous wrapping burst supported	RW	0x0
30	READMULTIPLE	Selects the read single or multiple access 0x0: Single access 0x1: Multiple access (burst if synchronous, page if asynchronous)	RW	0x0
29	READTYPE	Selects the read mode operation 0x0: Read asynchronous 0x1: Read synchronous	RW	0x0
28	WRITEMULTIPLE	Selects the write single or multiple access 0x0: Single access 0x1: Multiple access (burst if synchronous, considered as single if asynchronous)	RW	0x0
27	WRITETYPE	Selects the write mode operation 0x0: Write asynchronous 0x1: Write synchronous	RW	0x0

Bits	Field Name	Description	Type	Reset
26:25	CLKACTIVATIONTIME	Output GPMC_CLK activation time 0x0: First rising edge of GPMC_CLK at start access time 0x1: First rising edge of GPMC_CLK one GPMC_FCLK cycle after start access time 0x2: First rising edge of GPMC_CLK two GPMC_FCLK cycles after start access time 0x3: Reserved	RW	0x0
24:23	ATTACHEDDEVICEPAGELENGTH	Specifies the attached device page (burst) length 0x0: 4 words 0x1: 8 words 0x2: 16 words 0x3: Reserved (1 word = interface size)	RW	0x0
22	WAITREADMONITORING	Selects the Wait monitoring configuration for Read accesses (Reset value is *bootwaiten* input pin sampled at device reset) 0x0: Wait pin is not monitored for read accesses. 0x1: Wait pin is monitored for read accesses.	RW	0x-
21	WAITWRITEMONITORING	Selects the Wait monitoring configuration for Write accesses 0x0: Wait pin is not monitored for write accesses. 0x1: Wait pin is monitored for write accesses.	RW	0x0
20	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
19:18	WAITMONITORINGTIME	Selects input pin Wait monitoring time 0x0: Wait pin is monitored with valid data. 0x1: Wait pin is monitored one GPMC_CLK cycle before valid data. 0x2: Wait pin is monitored two GPMC_CLK cycle before valid data. 0x3: Reserved	RW	0x0
17:16	WAITPINSELECT	Selects the input wait pin for this chip-select (The reset value is HW fixed to 0x0 for CS0-CS7) 0x0: Wait input pin is WAIT0. 0x1: Wait input pin is WAIT1. 0x2, 0x3: Reserved	RW	0x0
15:14	RESERVED	Write 0s for future compatibility. Reads returns 0	RW	0x0
13:12	DEVICESIZE	Selects the device size attached (Reset value is *bootdevicesize* input pin sampled at device reset for CS0 and 0x1 for CS1 to CS7) 0x0: 8 bit 0x1: 16 bit 0x2: Reserved 0x3: Reserved	RW	0x-
11:10	DEVICETYPE	Selects the attached device type 0x0: NOR flash-like, asynchronous and synchronous devices 0x1: Reserved 0x2: NAND flash-like devices, stream mode 0x3: Reserved	RW	0x0

Bits	Field Name	Description	Type	Reset
9:8	MUXADDDATA	Enables the address and data multiplexed protocol (Reset value is *cs0muxdevice* input pin sampled at device reset for CS0 and 0 for CS1-CS7) 0x0: Nonmultiplexed attached device 0x1: AAD-multiplexed protocol device 0x2: Address and data multiplexed attached device 0x3: Reserved	RW	0x-
7:5	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
4	TIMEPARAGRANULARITY	Signals timing latencies scalar factor (RD/WRCYCLETIME, RD/WRACCESSTIME, PAGEBURSTACCESSTIME, CSONTIME, CSRD/WROFFTIME, ADVONTIME, ADVRD/WROFFTIME, OEONTIME, OEOFFTIME, WEONTIME, WEOFFTIME, CYCLE2CYCLEDELAY, BUSTURNAROUND, TIMEOUTSTARTVALUE, WRDATAONADMUXBUS) 0x0: x1 latencies 0x1: x2 latencies	RW	0x0
3:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
1:0	GPMCFCLKDIVIDER	Divides the GPMC_FCLK clock 0x0: GPMC_CLK frequency = GPMC_FCLK frequency 0x1: GPMC_CLK frequency = GPMC_FCLK frequency / 2 0x2: GPMC_CLK frequency = GPMC_FCLK frequency / 3 0x3: GPMC_CLK frequency = GPMC_FCLK frequency /4	RW	0x0

Table 10-454. GPMC_NAND_DATA_i

Address Offset	0x0000 0084 + (0x0000 0030 * i)	**Index**	i = 0 to 7
Physical Address	0x5000 0084 + (0x0000 0030 * i)	**Instance**	GPMC
Description	This register is not a true register,only an address location.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GPMC_NAND_DATA																															

Bits	Field Name	Description	Type	Reset
31:0	GPMC_NAND_DATA	This register is not a true register, only an address location. Reading data from the GPMC_NAND_DATA_i location or from any location in the associated chip-select memory region activates an asynchronous read access.	W	0x-

Table 10-456. GPMC_PREFETCH_CONFIG1

Address Offset	0x0000 01E0		
Physical Address	0x5000 01E0	**Instance**	GPMC
Description	Prefetch engine configuration 1		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED	CYCLEOPTIMIZATION			ENABLEOPTIMIZEDACCESS	ENGINECSSELECTOR			PFPWENROUNDROBIN	RESERVED			PFPWWEIGHTEDPRIO				RESERVED	FIFOTHRESHOLD							ENABLEENGINE	RESERVED	WAITPINSELECTOR		SYNCHROMODE	DMAMODE	RESERVED	ACCESSMODE

Bits	Field Name	Description	Type	Reset
31	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
30:28	CYCLEOPTIMIZATION	Define the number of GPMC_FCLK cycles to be subtracted from RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, CSRDOFFTIME, CSWROFFTIME, ADVRDOFFTIME, ADVWROFFTIME, OEOFFTIME, WEOFFTIME 0x0: 0 GPMC_FCLK cycle 0x1: 1 GPMC_FCLK cycle ... 0x7: 7 GPMC_FCLK cycles	RW	0x0
27	ENABLEOPTIMIZEDACCESS	Enables access cycle optimization 0x0: Access cycle optimization is disabled. 0x1: Access cycle optimization is enabled.	RW	0x0
26:24	ENGINECSSELECTOR	Selects the chip-select where Prefetch Postwrite engine is active 0x0: CS0 0x1: CS1 0x2: CS2 0x3: CS3 0x4: CS4 0x5: CS5 0x6: CS6 0x7: CS7	RW	0x0
23	PFPWENROUNDROBIN	Enables the PFPW RoundRobin arbitration 0x0: Prefetch Postwrite engine round robin arbitration is disabled. 0x1: Prefetch Postwrite engine round robin arbitration is enabled.	RW	0x0
22:20	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
19:16	PFPWWEIGHTEDPRIO	When an arbitration occurs between a DMA and a PFPW engine access, the DMA is always serviced. If the PFPWEnRoundRobin is enabled, 0x0: The next access is granted to the PFPW engine. 0x1: The next two accesses are granted to the PFPW engine. ..., 0xF: The next 16 accesses are granted to the PFPW engine.	RW	0x0
15	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
14:8	FIFOTHRESHOLD	Selects the maximum number of bytes read from the FIFO or written to the FIFO by the host on a DMA or interrupt request 0x00: 0 byte 0x01: 1 byte ... 0x40: 64 bytes	RW	0x40
7	ENABLEENGINE	Enables the Prefetch Postwite engine 0x0: Prefetch Postwrite engine is disabled. 0x1: Prefetch Postwrite engine is enabled.	RW	0x0
6	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
5:4	WAITPINSELECTOR	Select which wait pin edge detector should start the engine in synchronized mode 0x0: Selects Wait0 EdgeDetection 0x1: Selects Wait1 EdgeDetection 0x2, 0x3: Reserved	RW	0x0
3	SYNCHROMODE	Selects when the engine starts the access to chip-select 0x0: Engine starts the access to chip-select as soon as STARTENGINE is set 0x1: Engine starts the access to chip-select as soon as STARTENGINE is set AND wait to nonwait edge detection on the selected wait pin	RW	0x0

Bits	Field Name	Description	Type	Reset
2	DMAMODE	Selects interrupt synchronization or DMA request synchronization 0x0: Interrupt synchronization is enabled. Only interrupt line is activated on FIFO threshold crossing. 0x1: DMA request synchronization is enabled. A DMA request protocol is used.	RW	0x0
1	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
0	ACCESSMODE	Selects prefetch read or write-posting accesses 0x0: Prefetch read mode 0x1: Write-posting mode	RW	0x0

10.4 Error Location Module

10.4.1 Error Location Module Overview

When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as *bare NANDs*, the correction process is delegated to the memory controller.

The general-purpose memory controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-Chaudhuri-Hocquenghem (BCH) algorithm. The error-location module (ELM) extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM relies on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as *uncorrectable* in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

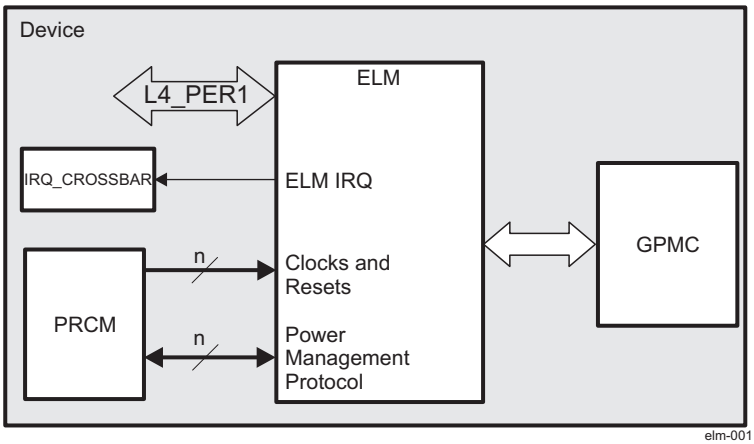
When the error-location process completes, an interrupt is triggered to inform the software that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

The ELM has the following features:

- 4, 8 and 16 bits per 512-byte block error-location based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
  - When the full page has been processed in page mode
  - For each syndrome polynomial in continuous mode

Figure 10-63 shows the ELM overview.

Figure 10-63. ELM Overview



10.4.2 ELM Integration

The ELM extracts error addresses from generated syndrome polynomials.

The ELM is used with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND flash page and stored in GPMC registers are passed to the ELM. A host processor can then correct the data block by flipping the bits to which the ELM error-location outputs point.

Figure 10-64 shows the integration of the ELM subsystem in the device.

Figure 10-64. ELM Integration

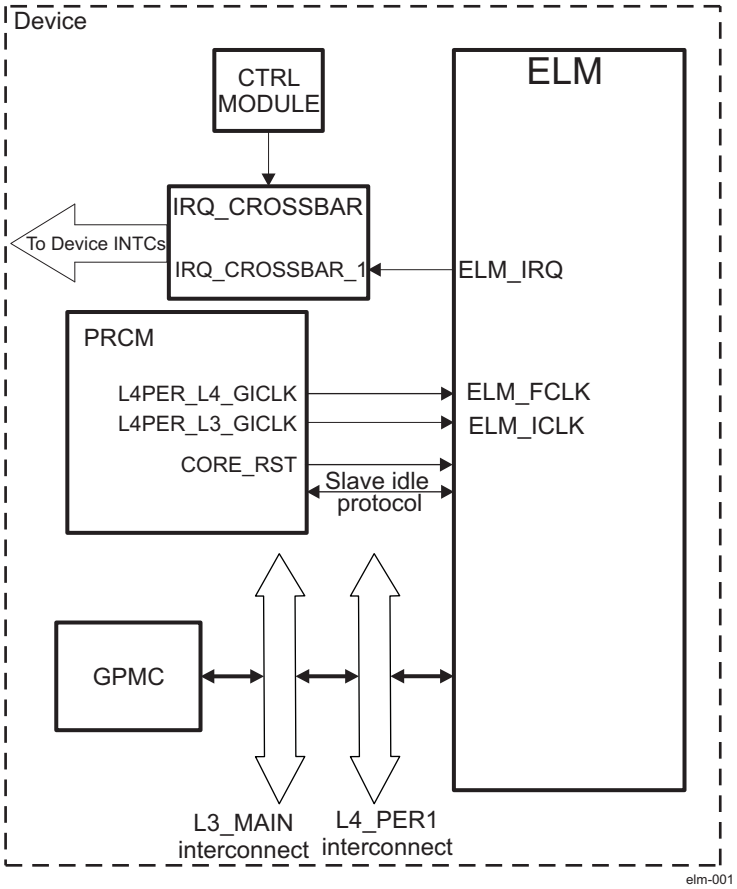


Table 10-488 through Table 10-490 summarize the integration of the module in the device.

Table 10-488. ELM Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
ELM	PD_COREAON	No	L4_PER1

Interrupt Requests				
Module Instance	**Source Signal Name**	**IRQ_CROSSBAR**	**Default Mapping**	**Description**
ELM	ELM_IRQ	IRQ_CROSSBAR_1	DSP1_IRQ_32 DSP2_IRQ_32 EVE_IRQ_0	BCH error-location module interrupt

NOTE: The "**Default Mapping**" column in Table 10-490 *ELM Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module. For more information about the IRQ_CROSSBAR module, see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*. For more information about the device interrupt controllers, see Chapter 12, *Interrupt Controllers*.

10.4.3 ELM Functional Description

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

10.4.3.1 ELM Software Reset

To perform a software reset, set the ELM_SYSCONFIG[1] SOFTRESET bit to 1. The ELM_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the ELM_SYSCONFIG[1] SOFTRESET bit is automatically reset.

10.4.3.2 ELM Power Management

Table 10-491 describes the power-management features available to the ELM.

NOTE:

- For information about source clock gating and a description of the sleep/wake-up transitions, see the Section 3.6.4.5, *CD_L4_PER1 Clock Domain*, in Chapter 3, *Power, Reset, and Clock Management*.
- For a general description of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.6, *Clock Management Functional Description*, in Chapter 3, *Power, Reset, and Clock Management*

Table 10-491. Local Power-Management Features

Feature	Registers	Description
Clock autogating	ELM_SYSCONFIG[0] AUTOGATING	This bit allows a local power optimization inside the module by gating the ELM_FCLK clock upon the interface activity.
Slave idle modes	ELM_SYSCONFIG[4:3] SIDLEMODE	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	ELM_SYSCONFIG[8] CLOCKACTIVITY	The clock can be switched off or maintained during the wake-up period.
Master standby modes	N/A	
Global wake-up enable	N/A	
Wake-up sources enable	N/A	

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the ELM CLOCKACTIVITY and ELM clock PRCM control bits. For a description of the ClockActivity feature, see Chapter 3, *Power, Reset, and Clock Management*.

10.4.3.3 ELM Interrupt Requests

Table 10-492 lists the event flags, and their masks, that can cause module interrupts.

Table 10-492. Events

Event Flag	Event Mask	Description
ELM_IRQSTATUS[8] PAGE_VALID	ELM_IRQENABLE[8] PAGE_MASK	Page interrupt
ELM_IRQSTATUS[7] LOC_VALID_7	ELM_IRQENABLE[7] LOCATION_MASK_7	Error-location interrupt for syndrome polynomial 7
ELM_IRQSTATUS[6] LOC_VALID_6	ELM_IRQENABLE[6] LOCATION_MASK_6	Error-location interrupt for syndrome polynomial 6
ELM_IRQSTATUS[5] LOC_VALID_5	ELM_IRQENABLE[5] LOCATION_MASK_5	Error-location interrupt for syndrome polynomial 5
ELM_IRQSTATUS[4] LOC_VALID_4	ELM_IRQENABLE[4] LOCATION_MASK_4	Error-location interrupt for syndrome polynomial 4
ELM_IRQSTATUS[3] LOC_VALID_3	ELM_IRQENABLE[3] LOCATION_MASK_3	Error-location interrupt for syndrome polynomial 3
ELM_IRQSTATUS[2] LOC_VALID_2	ELM_IRQENABLE[2] LOCATION_MASK_2	Error-location interrupt for syndrome polynomial 2
ELM_IRQSTATUS[1] LOC_VALID_1	ELM_IRQENABLE[1] LOCATION_MASK_1	Error-location interrupt for syndrome polynomial 1
ELM_IRQSTATUS[0] LOC_VALID_0	ELM_IRQENABLE[0] LOCATION_MASK_0	Error-location interrupt for syndrome polynomial 0

10.4.3.4 Processing Initialization

ELM_LOCATION_CONFIG global setting parameters must be set before using the error-location engine. The ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL bit field defines the error-correction level used (4-,8-, or 16-bit error correction). The ELM_LOCATION_CONFIG[26:16] ECC_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

Software can choose to use the ELM in continuous mode or page mode. If all ELM_PAGE_CTRL[i] SECTOR_i bits (i is the syndrome polynomial number, where i = 0 to 7) are reset, continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently. Results for a syndrome can be retrieved and acknowledged at any time, regardless of the status of the other seven processing contexts.
- Page mode: Syndrome polynomials are grouped into atomic entities: only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all ELM_IRQENABLE[i] LOCATION_MASK_i bits (where i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the ELM_IRQENABLE[8] PAGE_MASK bit must be set to 1 when in page mode.

Software initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: ELM_SYNDROME_FRAGMENT_0_i to ELM_SYNDROME_FRAGMENT_6_i. The first six registers can be written in any order, but ELM_SYNDROME_FRAGMENT_6_i must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit).

As soon as one validity bit is asserted (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x1, where i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i registers (where i = 0 to 7) are not reset. Software must not consider them until the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit is set.

10.4.3.5 Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 1 and the ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS bit field is set to 0x0.
- Too many errors are detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 0 while the ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if ECC_CORRECTABLE is 0.

If the engine completes early, the associated error-location registers ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i (where i = 0 to 7) are not updated.

In all other cases, the engine goes through the entire error-location process. Each time an error location is found, it is logged in the associated ECC_ERROR_LOCATION bit field. The first error detected is logged in the ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION bit field; the second is logged in the ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION bit field, and so on.

Table 10-493 describes the ELM_LOCATION_STATUS_i value decoding.

Table 10-493. ELM_LOCATION_STATUS_i Value Decoding

ECC_CORRECTABLE Value	ECC_NB_ERRORS Value	Status	Number of Errors Detected	Action Required
1	0	OK	0	None
1	≠ 0	OK	ECC_NB_ERRORS	Correct the data buffer read based on the ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i results.
0	Any	Failed	Unknown	Software-dependent

10.4.3.6 Processing Completion

When the processing for a given syndrome polynomial completes, its ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit is reset. It must not be set again until the exit status registers, ELM_LOCATION_STATUS_i (where i = 0 to 7) for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit (where i = 0 to 7) is set. The processing exit status is available from the associated ELM_LOCATION_STATUS_i register, and error locations are stored in order in the ECC_ERROR_LOCATION bit fields. Software must read only valid error-location registers based on the number of errors detected and located.

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in ELM_PAGE_CTRL are reset), an interrupt is triggered whenever a ELM_IRQSTATUS[i] LOC_VALID_i bit is asserted. Software must read the ELM_IRQSTATUS register to determine which polynomial is processed and retrieve the exit status and error locations (ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i). When done, software must clear the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit by setting it to 1. Other status bits must be set to 0 so that other interrupts are not unintentionally cleared. When using this mode, the ELM_IRQSTATUS[8] PAGE_VALID interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the ELM_IRQENABLE[i] LOCATION_MASK_i bits are cleared. A page is defined using the ELM_PAGE_CTRL register. Each SECTOR_i bit set means the corresponding polynomial i is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the ELM_IRQSTATUS[i] LOC_VALID_i bits. The module triggers an ELM_IRQSTATUS[8] PAGE_VALID interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the ELM_IRQSTATUS register must be cleared by using a single atomic-write access.

NOTE: Do not modify page setting parameters in the ELM_PAGE_CTRL register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the ELM_PAGE_CTRL[i] SECTOR_i bits (where i = 0 to 7) are processed as usual, but are essentially ignored. Software must manually poll the ELM_IRQSTATUS bits to check for their status.

10.4.4 ELM Basic Programming Model

10.4.4.1 ELM Low-Level Programming Model

10.4.4.1.1 Processing Initialization

Table 10-494. ELM Processing Initialization

Step	Register/Bit Field/Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management.	ELM_SYSCONFIG[4:3] SIDLEMODE	Set value.
Defines the error-correction level used	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	Set value.
Defines the maximum buffer length	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	Set value.
Sets the ELM in continuous mode or page mode	ELM_PAGE_CTRL	Set value.
If continuous mode is used	All ELM_PAGE_CTRL[i] SECTOR_i (where i = 0 to 7)	0x0
Enables interrupt for syndrome polynomial i	ELM_IRQENABLE[i] LOCATION_MASK_i	0x1

Table 10-494. ELM Processing Initialization (continued)

Step	Register/Bit Field/Programming Model	Value
else (page mode is used)	One syndrome polynomial i is set ELM_PAGE_CTRL[i] SECTOR_i (where i = 0 to 7)	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	All ELM_IRQENABLE[i] LOCATION_MASK_i = 0x0 and ELM_IRQENABLE[8] PAGE_MASK = 0x1	Set value.
endif		Set value.
Set the input syndrome polynomial i.	ELM_SYNDROME_FRAGMENT_0_i	Set value.
	ELM_SYNDROME_FRAGMENT_1_i	Set value.
	ELM_SYNDROME_FRAGMENT_5_i	Set value.
	ELM_SYNDROME_FRAGMENT_6_i	Set value.
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID	0x1

10.4.4.1.2 Read Results

The engine goes through the entire error-location process and results can be read. Table 10-495 and Table 10-496 describe the processing completion for continuous and page modes, respectively.

Table 10-495. ELM Processing Completion for Continuous Mode

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Read for which i the error-location process is complete.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1
if the process fails (too many errors)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependant.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers. Software must correct errors in the data buffer.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
endif		
Clear the corresponding i interrupt.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1

A new syndrome polynomial can be processed after the end of processing (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x0) and after the exit status register check (ELM_LOCATION_STATUS_i).

Table 10-496. ELM Processing Completion for Page Mode

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
Repeat the following actions the necessary number of times. That is, once for each valid defined block in the page.		

Table 10-496. ELM Processing Completion for Page Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Read the process exit status.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	
if the process fails (too many errors)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependent.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
endif		
End Repeat		
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM_IRQSTATUS[i] LOC_VALID_i = 0x1 for all syndrome polynomials i used in the page).

10.4.4.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM is programmed for an 8-bit error-correction capability in continuous mode (see Table 10-497). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a nonzero polynomial syndrome is reported from the GPMC (polynomial syndrome 0 is used in the ELM):

- P = 0x0A16ABE115E44F767BFB0D0980

Table 10-497. Use Case: Continuous Mode

Step	Register/Bit Field/Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG[4:3] SIDLEMODE	0x2
Defines the error-correction level used: 8 bits	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	0x1
Defines the maximum buffer length: 528 bytes (2 × 528 = 1056)	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	0x420
Sets the ELM in continuous mode	ELM_PAGE_CTRL	0
Enables interrupt for syndrome polynomial 0	ELM_IRQENABLE[0] LOCATION_MASK_0	0x1
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (where i = 0)	0xFB0D0980
	ELM_SYNDROME_FRAGMENT_1_i (where i = 0)	0xE44F767B
	ELM_SYNDROME_FRAGMENT_2_i (where i = 0)	0x16ABE115
	ELM_SYNDROME_FRAGMENT_3_i (where i = 0)	0x0000000A
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 0)	0x1
Wait until process is complete for syndrome polynomial 0: IRQ_ELM is generated or poll the status register.		
Read that error-location process is complete for syndrome polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1
Read the process exit status: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 0)	0x1

Table 10-497. Use Case: Continuous Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Read the number of errors: Four errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (where i = 0)	0x4
Read the error-location bit addresses for syndrome polynomial 0 of the first four registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452.	ELM_ERROR_LOCATION_0_i (where i = 0)	0x1AF
	ELM_ERROR_LOCATION_1_i (where i = 0)	0x426
	ELM_ERROR_LOCATION_2_i (where i = 0)	0x775
	ELM_ERROR_LOCATION_3_i (where i = 0)	0xD7C
Clear the corresponding interrupt for polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, and then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in Table 10-498 are given in decimal format.

Table 10-498. 16-Bit NAND Sector Buffer Address Map

NAND Memory Address	Message Bit Addresses in Memory Word															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

263	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and flip this bit. The same process must be repeated for all detected errors.

10.4.4.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for an 16-bit error-correction capability in page mode (see Table 10-499). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF
- P1 = 0xBAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EB

- P2 = 0x69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189
- P3 = 0x0

Table 10-499. Use Case: Page Mode

Step	Register/Bit Field/Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG[4:3] SIDLEMODE	0x2
Defines the error-correction level used: 16 bits	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	0x2
Defines the maximum buffer length: 528 bytes	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	0x420
Sets the ELM in page mode (four blocks in a page)	ELM_PAGE_CTRL[0] SECTOR_0	0x1
	ELM_PAGE_CTRL[1] SECTOR_1	0x1
	ELM_PAGE_CTRL[2] SECTOR_2	0x1
	ELM_PAGE_CTRL[3] SECTOR_3	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	ELM_IRQENABLE	0x100
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (where i = 0)	0xE0B718EF
	ELM_SYNDROME_FRAGMENT_1_i (where i = 0)	0xA329AA05
	ELM_SYNDROME_FRAGMENT_2_i (where i = 0)	0x8330B5CC
	ELM_SYNDROME_FRAGMENT_3_i (where i = 0)	0xB0693DB2
	ELM_SYNDROME_FRAGMENT_4_i (where i = 0)	0x318E05BE
	ELM_SYNDROME_FRAGMENT_5_i (where i = 0)	0x12ADDB5A
	ELM_SYNDROME_FRAGMENT_6_i (where i = 0)	0xE8B0
Set the input syndrome polynomial 1.	ELM_SYNDROME_FRAGMENT_0_i (where i = 1)	0xE5F935EB
	ELM_SYNDROME_FRAGMENT_1_i (where i = 1)	0x79C6BA10
	ELM_SYNDROME_FRAGMENT_2_i ((where i = 1)	0xBE093336
	ELM_SYNDROME_FRAGMENT_3_i (where i = 1)	0x0948DF08
	ELM_SYNDROME_FRAGMENT_4_i (where i = 1)	0xC22E6669
	ELM_SYNDROME_FRAGMENT_5_i (where i = 1)	0x49A0D932
	ELM_SYNDROME_FRAGMENT_6_i (where i = 1)	0xBAD0
Set the input syndrome polynomial 2.	ELM_SYNDROME_FRAGMENT_0_i (where i = 2)	0x60BA3189
	ELM_SYNDROME_FRAGMENT_1_i (where i = 2)	0x1579EF7D
	ELM_SYNDROME_FRAGMENT_2_i (where i = 2)	0x54556EA0
	ELM_SYNDROME_FRAGMENT_3_i (where i = 2)	0xA6498FEE
	ELM_SYNDROME_FRAGMENT_4_i (where i = 2)	0xEC3697FA
	ELM_SYNDROME_FRAGMENT_5_i (where i = 2)	0xB86ABCD5
	ELM_SYNDROME_FRAGMENT_6_i (where i = 2)	0x69D9
Set the input syndrome polynomial 3.	ELM_SYNDROME_FRAGMENT_0_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_1_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_2_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_3_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_4_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_5_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_6_i (where i = 3)	0x0
Initiates the computation process for syndrome polynomial 0	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 0)	0x1
Initiates the computation process for syndrome polynomial 1	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 1)	0x1
Initiates the computation process for syndrome polynomial 2	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 2)	0x1

Table 10-499. Use Case: Page Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Initiates the computation process for syndrome polynomial 3	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 3)	0x1
Wait until process is complete for syndrome polynomial 0, 1, 2, and 3: Wait until the ELM_IRQ interrupt is generated or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
Read the process exit status for syndrome polynomial 0: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 0)	0x1
Read the process exit status for syndrome polynomial 1: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 1)	0x1
Read the process exit status for syndrome polynomial 2: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 2)	0x1
Read the process exit status for syndrome polynomial 3: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 3)	0x1
Read the number of errors for syndrome polynomial 0: four errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (where i = 0)	0x4
Read the number of errors for syndrome polynomial 1: two errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (where i = 1)	0x2
Read the number of errors for syndrome polynomial 2: one error detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (where i = 2)	0x1
Read the number of errors for syndrome polynomial 3: no errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (where i = 3)	0x0
Read the error-location bit addresses for syndrome polynomial 0 of the first four registers:	ELM_ERROR_LOCATION_0_i (where i = 0)	0x1FE
	ELM_ERROR_LOCATION_1_i (where i = 0)	0x617
	ELM_ERROR_LOCATION_2_i (where i = 0)	0x650
	ELM_ERROR_LOCATION_3_i (where i = 0)	0xA83
Read the error-location bit addresses for syndrome polynomial 1 of the first two registers:	ELM_ERROR_LOCATION_0_i (where i = 1)	0x4
	ELM_ERROR_LOCATION_1_i (where i = 1)	0x1036
Read the errors location bit addresses for syndrome polynomial 2 of the first registers:	ELM_ERROR_LOCATION_0_i (where i = 1)	0x3E8
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

10.4.5.2.2 ELM Register Description

Table 10-502 through Table 10-562 describe the individual ELM registers.

Table 10-502. ELM_REVISION

Address Offset	0x0000 0000		
Physical Address	0x4807 8000	**Instance**	ELM
Description	This register contains the IP revision code. (A write or reset of to this register has no effect.)		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REVISION																															

Bits	Field Name	Description	Type	Reset
31:0	REVISION	IP Revision (TI internal data)	R	0x-

Table 10-503. Register Call Summary for Register ELM_REVISION

Error Location Module
- ELM Register Summary: [0]

Table 10-504. ELM_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x4807 8010	**Instance**	ELM
Description	This register allows controlling various parameters of the OCP interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							CLOCKACTIVITYOCP	RESERVED			SIDLEMODE		RESERVED	SOFTRESET	AUTOGATING

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	R	0x000000
8	CLOCKACTIVITYOCP	OCP clock activity when module is in IDLE mode (during wake-up mode period) 0x0: OCP clock can be switched off. 0x1: OCP clock is maintained during wake-up period.	RW	0
7:5	RESERVED	Reserved	R	0x0
4:3	SIDLEMODE	Slave interface power management (IDLE req/ack control) 0x0: Force-idle. IDLE request is acknowledged unconditionally and immediately (Default *Dumb* mode for safety) 0x1: No-idle. IDLE request is never acknowledged. 0x2: Smart-idle. The acknowledgment to an IDLE request is given based on the internal activity. 0x3: Reserved - do not use	RW	0x2

Bits	Field Name	Description	Type	Reset
2	RESERVED	Reserved	R	0
1	SOFTRESET	Module software reset This bit is automatically reset by hardware (during reads, it always returns 0). It has same effect as the OCP hardware reset. 0x0: Normal mode 0x1: Start soft reset sequence.	RW	0
0	AUTOGATING	Internal OCP clock gating strategy (no module visible effect other than saving power) 0x0: OCP clock is free-running. 0x1: Automatic internal OCP clock gating strategy is applied based on the OCP interface activity.	RW	1

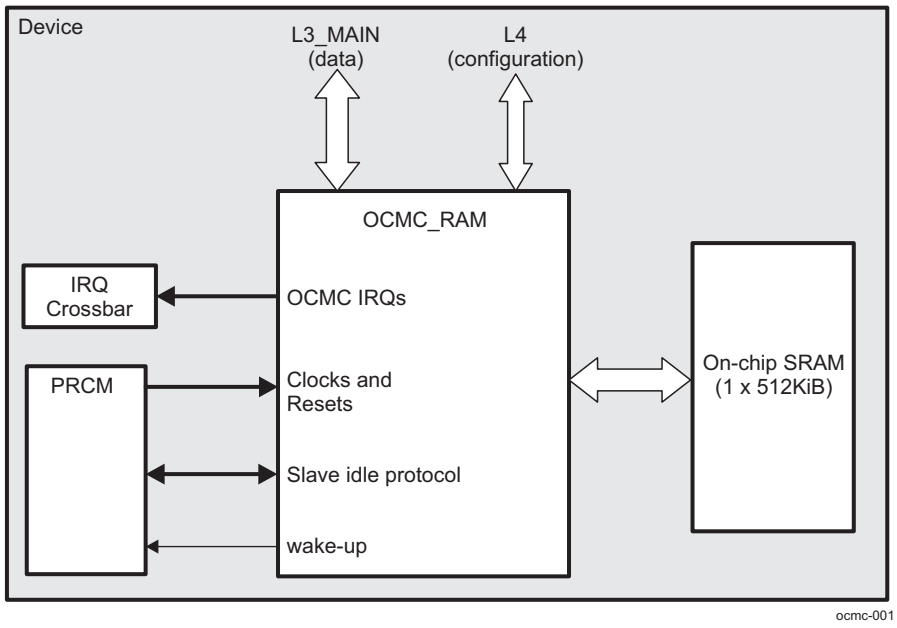
10.5 On-Chip Memory (OCM) Subsystem

10.5.1 OCM Subsystem Overview

The OCM subsystem consists of one OCM Controller (OCMC) that is associated with the on-chip RAM. This is the OCMC_RAM with 512 KiB of dedicated memory space. The OCM controller is also introduced in Section 10.1.4, *OCM Overview* of Section 10.1, *Memory Subsystem Overview*.

Figure 10-65 shows theOCMC_RAM controller.

Figure 10-65. OCMC_RAM Overview



10.5.2 OCM Subsystem Integration

Figure 10-66 shows the integration of the OCMC_RAM in the device.

Figure 10-66. OCMC_RAM Integration

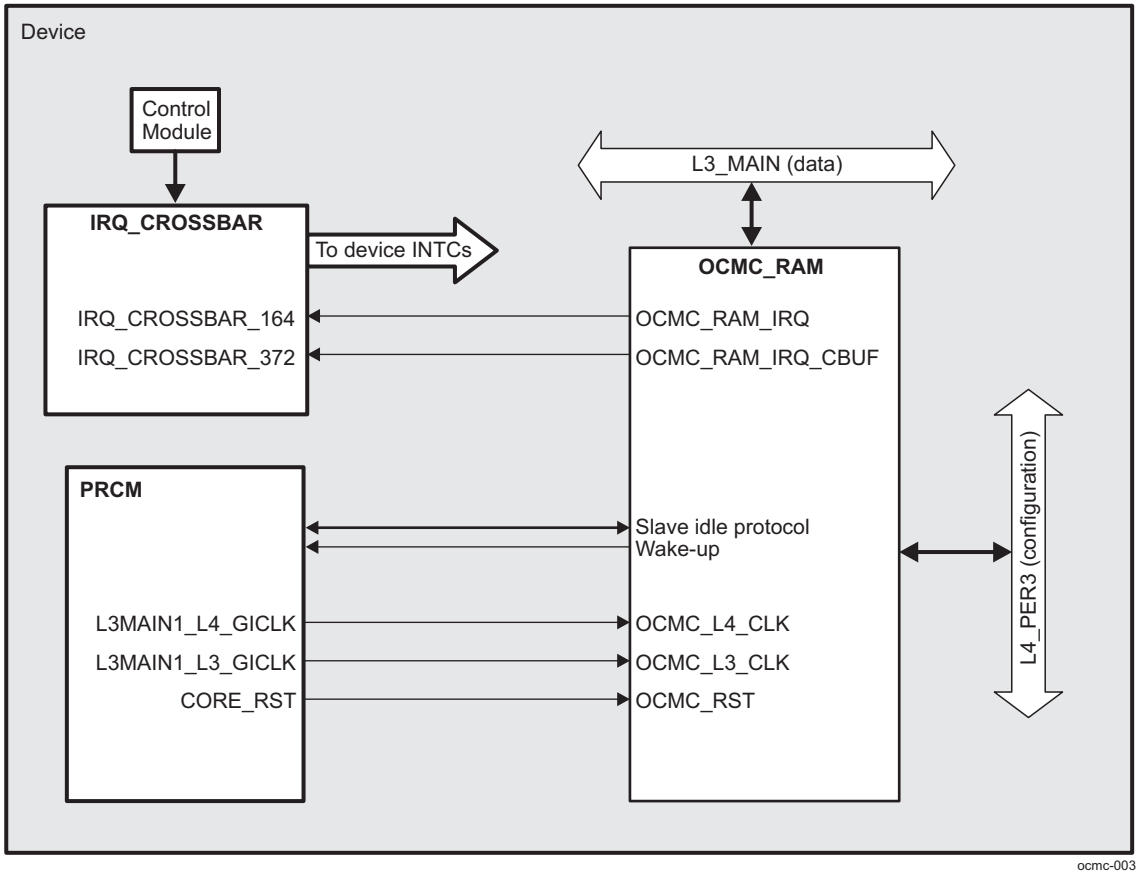


Table 10-564 through Table 10-566 summarize the integration of the OCMC_RAM in the device.

Table 10-564. OCMC_RAM Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
OCMC_RAM	PD_COREAON	Yes	L3_MAIN
			L4_PER3

Table 10-565. OCMC_RAM Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
OCMC_RAM	OCMC_L3_CLK	L3MAIN1_L3_GICLK	PRCM	Clock used to drive and receive data over the L3 data bus. This is also the processing clock of the OCM Controller and the SRAM. With this clock all internal data transfers are clocked.
	OCMC_L4_CLK	L3MAIN1_L4_GICLK	PRCM	Clock used to drive and receive data over the L4_PER3 configuration bus. This clock should run at half the OCMC_L3_CLK clock rate.
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
OCMC_RAM	OCMC_RST	CORE_RST	PRCM	Reset signal for the OCMC_RAM

Table 10-566. OCMC_RAM Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
OCMC_RAM	OCMC_RAM_IRQ	IRQ_CROSSBAR_164	-	First OCMC_RAM interrupt request. This IRQ source signal is not mapped by default to any device INTC.
	OCMC_RAM_IRQ_CBUF	IRQ_CROSSBAR_372	-	Second OCMC_RAM interrupt request. This IRQ source signal is not mapped by default to any device INTC.

NOTE: The "**Default Mapping**" column in Table 10-566 *OCMC_RAM Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.
For more information about the device interrupt controllers, see Chapter 12, *Interrupt Controllers*.

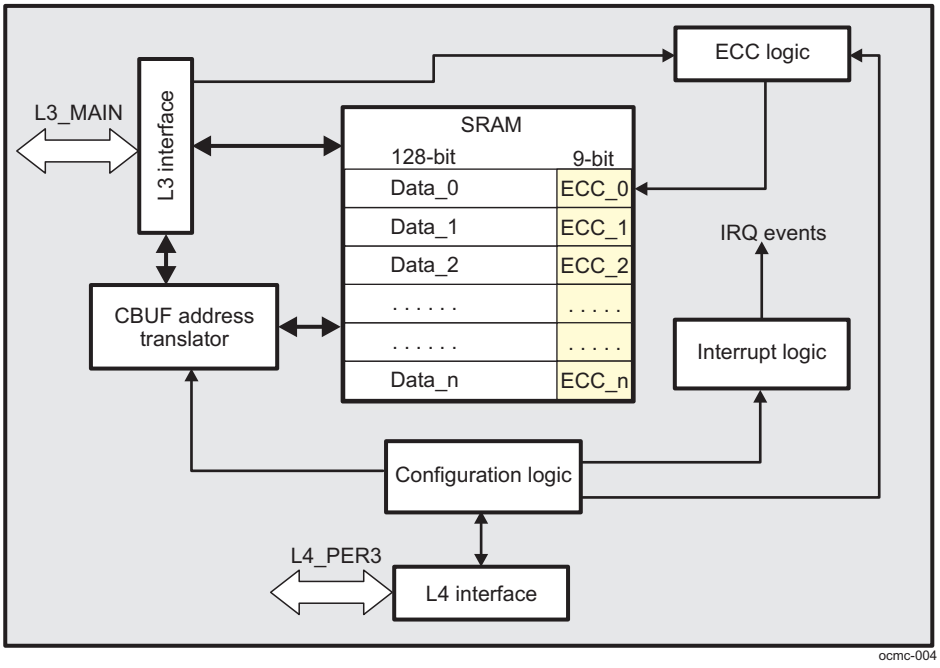
NOTE: For description of the interrupt sources, see Section 10.5.3.4, *Interrupt Requests*.

10.5.3 OCM Subsystem Functional Desctiption

10.5.3.1 Block Diagram

Figure 10-67 shows the OCMC block diagram.

Figure 10-67. OCMC Block Diagram



The module is composed by the following main blocks:

- L3 interface used for data transactions
- L4 interface used for configuration
- CBUF address translator which converts the L3_MAIN VBUF addresses into SRAM addresses
- ECC logic to support single error correction and double error detection
- SRAM used for storring data and the corresponding for each 128-bit word ECC
- Interrupt logic used for generating interrupt requests
- Configuration logic in which reside the registers used for configuring the OCM controller operation modes

10.5.3.2 Resets

The OCMC_RST is the reset signal for the OCM controller which asynchronously resets the whole internal logic of the controller, including all configuration registers. It does not reset the SRAM. In addition, the OCMC_SYSCONFIG_RST[0] SW_RST bit provides a software way to reset the OCM controller. In this case all of its internal logic is reset except the configuration registers accessible through the L4_PER3.

10.5.3.3 Clock Management

The OCM controller complies with the PRCM slave idle protocol. The OCMC_L3_CLK and OCMC_L4_CLK clocks are gated based on the values loaded in the OCMC_SYSCONFIG_PM[3:2] IDLEMODE bit field.

10.5.3.4 Interrupt Requests

The OCM controller generates two interrupt requests, OCMC_RAM_IRQ and OCMC_RAM_IRQ_CBUF.

The OCMC_RAM_IRQ line is associated with the following registers:

- INTR0_STATUS_RAW_SET - interrupt raw status register
- INTR0_STATUS_ENABLED_CLEAR - interrupt status register
- INTR0_ENABLE_SET - interrupt enable register
- INTR0_ENABLE_CLEAR - interrupt disable register

The OCMC_RAM_IRQ_CBUF line is associated with the following registers:

- INTR1_STATUS_RAW_SET - interrupt raw status register
- INTR1_STATUS_ENABLED_CLEAR - interrupt status register
- INTR1_ENABLE_SET - interrupt enable (event unmask) register
- INTR1_ENABLE_CLEAR - interrupt disable (event mask) register

Both the register groups previously described have identical bits. When for example, only one event occurs one or the two IRQ lines will be asserted depending on the masks applied to the INTR0_ENABLE_SET and INTR1_ENABLE_SET registers. When for example, a short frame detection event occurs and if both the INTR0_ENABLE_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND and INTR1_ENABLE_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND bits are set to 0x1, then both the OCMC_RAM_IRQ and OCMC_RAM_IRQ_CBUF lines are asserted. If only the INTR0_ENABLE_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND bit is set to 0x1, then only the OCMC_RAM_IRQ line is asserted and the OCMC_RAM_IRQ_CBUF line remains inactive (deasserted). Thus depending on the mask applied one IRQ line of the OCM controller can be associated only with CBUF events for example, and the other one IRQ line can be associated with ECC events. In other words, two unique interrupts can be provided.

Table 10-567 lists the interrupt events which can assert the two interrupt lines of the OCM controller.

The OCM controller asserts each of its interrupt lines only if the interrupts are enabled by setting to 0x1 the corresponding bits in the INTR0_ENABLE_SET/INTR1_ENABLE_SET register. These interrupts can be disabled by setting to 0x1 the corresponding bits in the INTR0_ENABLE_CLEAR/INTR1_ENABLE_CLEAR register. After the interrupt has been serviced the corresponding status flag must be cleared by software. This is done by setting to 0x1 the corresponding bit in the INTR0_STATUS_ENABLED_CLEAR/INTR1_STATUS_ENABLED_CLEAR register which also

clears the corresponding bit in the INTR0_STATUS_RAW_SET/INTR1_STATUS_RAW_SET register. The status flags in the INTR0_STATUS_RAW_SET/INTR1_STATUS_RAW_SET register are set even if the corresponding interrupt is disabled as opposed to those in the INTR0_STATUS_ENABLED_CLEAR/INTR1_STATUS_ENABLED_CLEAR register, which are set only if the corresponding interrupt is enabled. An interrupt is also generated by the OCM controller, if certain bit in the INTR0_STATUS_RAW_SET/INTR1_STATUS_RAW_SET register is set to 0x1 and the corresponding interrupt is enabled through the INTR0_ENABLE_SET/INTR1_ENABLE_SET register. This is useful when user software debugging is performed. Additionally, even if interrupts are not enabled, certain status bit in the INTR0_STATUS_RAW_SET/INTR1_STATUS_RAW_SET register can be cleared by setting to 0x1 the corresponding bit in the INTR0_STATUS_ENABLED_CLEAR/INTR1_STATUS_ENABLED_CLEAR register.

For additional details regarding the CBUF related events, see Section 10.5.3.11, *CBUF Mode Error Handling*.

Table 10-567. OCMC_RAM Events

Event Flag	Event Mask	Description
INTR0_STATUS_RAW_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND/INTR1_STATUS_RAW_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND and INTR0_STATUS_ENABLED_CLEAR[14] CBUF_SHORT_FRAME_DETECT_FOUND/INTR1_STATUS_ENABLED_CLEAR[14] CBUF_SHORT_FRAME_DETECT_FOUND	INTR0_ENABLE_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND/INTR1_ENABLE_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND and INTR0_ENABLE_CLEAR[14] CBUF_SHORT_FRAME_DETECT_FOUND/INTR1_ENABLE_CLEAR[14] CBUF_SHORT_FRAME_DETECT_FOUND	This bit indicates a short frame detection. It is set if at least one of the bits in the STATUS_CBUF_SHORT_FRAME_DETECT register is set to 0x1.
INTR0_STATUS_RAW_SET[13] CBUF_UNDERFLOW_ERR_FOUND/INTR1_STATUS_RAW_SET[13] CBUF_UNDERFLOW_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[13] CBUF_UNDERFLOW_ERR_FOUND/INTR1_STATUS_ENABLED_CLEAR[13] CBUF_UNDERFLOW_ERR_FOUND	INTR0_ENABLE_SET[13] CBUF_UNDERFLOW_ERR_FOUND/INTR1_ENABLE_SET[13] CBUF_UNDERFLOW_ERR_FOUND and INTR0_ENABLE_CLEAR[13] CBUF_UNDERFLOW_ERR_FOUND/INTR1_ENABLE_CLEAR[13] CBUF_UNDERFLOW_ERR_FOUND	Indicates CBUF underflow detction. This bit is set if at least one of the bits in the STATUS_CBUF_UNDERFLOW register is set to 0x1.
INTR0_STATUS_RAW_SET[12] CBUF_OVERFLOW_WRAP_ERR_FOUND/INTR1_STATUS_RAW_SET[12] CBUF_OVERFLOW_WRAP_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[12] CBUF_OVERFLOW_WRAP_ERR_FOUND/INTR1_STATUS_ENABLED_CLEAR[12] CBUF_OVERFLOW_WRAP_ERR_FOUND	INTR0_ENABLE_SET[12] CBUF_OVERFLOW_WRAP_ERR_FOUND/INTR1_ENABLE_SET[12] CBUF_OVERFLOW_WRAP_ERR_FOUND and INTR0_ENABLE_CLEAR[12] CBUF_OVERFLOW_WRAP_ERR_FOUND/INTR1_ENABLE_CLEAR[12] CBUF_OVERFLOW_WRAP_ERR_FOUND	Indicates Cbuf_Overflow_Wrap event
INTR0_STATUS_RAW_SET[11] CBUF_OVERFLOW_MID_ERR_FOUND/INTR1_STATUS_RAW_SET[11] CBUF_OVERFLOW_MID_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[11] CBUF_OVERFLOW_MID_ERR_FOUND/INTR1_STATUS_ENABLED_CLEAR[11] CBUF_OVERFLOW_MID_ERR_FOUND	INTR0_ENABLE_SET[11] CBUF_OVERFLOW_MID_ERR_FOUND/INTR1_ENABLE_SET[11] CBUF_OVERFLOW_MID_ERR_FOUND and INTR0_ENABLE_CLEAR[11] CBUF_OVERFLOW_MID_ERR_FOUND/INTR1_ENABLE_CLEAR[11] CBUF_OVERFLOW_MID_ERR_FOUND	Indicates Cbuf_Overflow_Mid event
INTR0_STATUS_RAW_SET[10] CBUF_READ_SEQUENCE_ERR_FOUND/INTR1_STATUS_RAW_SET[10] CBUF_READ_SEQUENCE_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[10] CBUF_READ_SEQUENCE_ERR_FOUND/INTR1_STATUS_ENABLED_CLEAR[10] CBUF_READ_SEQUENCE_ERR_FOUND	INTR0_ENABLE_SET[10] CBUF_READ_SEQUENCE_ERR_FOUND/INTR1_ENABLE_SET[10] CBUF_READ_SEQUENCE_ERR_FOUND and INTR0_ENABLE_CLEAR[10] CBUF_READ_SEQUENCE_ERR_FOUND/INTR1_ENABLE_CLEAR[10] CBUF_READ_SEQUENCE_ERR_FOUND	This flag indicates that at least one CBUF read address is not incrementing in raster scan order(1).

(1) The LAST_ILLEGAL_OCMC_ADDR register stores the last illegal L3_MAIN address caused the assertion of this event.

Table 10-567. OCMC_RAM Events (continued)

Event Flag	Event Mask	Description
INTR0_STATUS_RAW_SET[9] CBUF_VBUF_READ_START_ERR_FOUND/INTR1_STATUS_RAW_SET[9] CBUF_VBUF_READ_START_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[9] CBUF_VBUF_READ_START_ERR_FOUND/INTR1_STATUS_ENABLED_CLEAR[9] CBUF_VBUF_READ_START_ERR_FOUND	INTR0_ENABLE_SET[9] CBUF_VBUF_READ_START_ERR_FOUND/INTR1_ENABLE_SET[9] CBUF_VBUF_READ_START_ERR_FOUND and INTR0_ENABLE_CLEAR[9] CBUF_VBUF_READ_START_ERR_FOUND/INTR1_ENABLE_CLEAR[9] CBUF_VBUF_READ_START_ERR_FOUND	This flag indicates when at least one of the CBUF read accesses does not start at the VBUF start address(1).
INTR0_STATUS_RAW_SET[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND /INTR1_STATUS_RAW_SET[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND /INTR1_STATUS_ENABLED_CLEAR[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND	INTR0_ENABLE_SET[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND /INTR1_ENABLE_SET[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND and INTR0_ENABLE_CLEAR[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND /INTR1_ENABLE_CLEAR[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND	This flag indicates when at least one of the CBUF read addresses is out of the CBUF address range(1).
INTR0_STATUS_RAW_SET[7] CBUF_WRITE_SEQUENCE_ERR_FOUND/INTR1_STATUS_RAW_SET[7] CBUF_WRITE_SEQUENCE_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[7] CBUF_WRITE_SEQUENCE_ERR_FOUND/INTR1_STATUS_ENABLED_CLEAR[7] CBUF_WRITE_SEQUENCE_ERR_FOUND	INTR0_ENABLE_SET[7] CBUF_WRITE_SEQUENCE_ERR_FOUND/INTR1_ENABLE_SET[7] CBUF_WRITE_SEQUENCE_ERR_FOUND and INTR0_ENABLE_CLEAR[7] CBUF_WRITE_SEQUENCE_ERR_FOUND/INTR1_ENABLE_CLEAR[7] CBUF_WRITE_SEQUENCE_ERR_FOUND	This flag indicates that at least one CBUF write address is not incrementing in raster scan order(1).
INTR0_STATUS_RAW_SET[6] CBUF_VBUF_WRITE_START_ERR_FOUND/INTR1_STATUS_RAW_SET[6] CBUF_VBUF_WRITE_START_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[6] CBUF_VBUF_WRITE_START_ERR_FOUND/INTR1_STATUS_ENABLED_CLEAR[6] CBUF_VBUF_WRITE_START_ERR_FOUND	INTR0_ENABLE_SET[6] CBUF_VBUF_WRITE_START_ERR_FOUND/INTR1_ENABLE_SET[6] CBUF_VBUF_WRITE_START_ERR_FOUND and INTR0_ENABLE_CLEAR[6] CBUF_VBUF_WRITE_START_ERR_FOUND/INTR1_ENABLE_CLEAR[6] CBUF_VBUF_WRITE_START_ERR_FOUND	This flag indicates when at least one of the CBUF write accesses does not start at the VBUF start address(1).
INTR0_STATUS_RAW_SET[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND/INTR1_STATUS_RAW_SET[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND/INTR1_STATUS_ENABLED_CLEAR[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND	INTR0_ENABLE_SET[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND/INTR1_ENABLE_SET[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND and INTR0_ENABLE_CLEAR[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND/INTR1_ENABLE_CLEAR[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND	This flag indicates when at least one of the CBUF write addresses is out of the CBUF address range(1).
INTR0_STATUS_RAW_SET[4] CBUF_VIRTUAL_ADDR_ERR_FOUND/INTR1_STATUS_RAW_SET[4] CBUF_VIRTUAL_ADDR_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[4] CBUF_VIRTUAL_ADDR_ERR_FOUND/INTR1_STATUS_ENABLED_CLEAR[4] CBUF_VIRTUAL_ADDR_ERR_FOUND	INTR0_ENABLE_SET[4] CBUF_VIRTUAL_ADDR_ERR_FOUND/INTR1_ENABLE_SET[4] CBUF_VIRTUAL_ADDR_ERR_FOUND and INTR0_ENABLE_CLEAR[4] CBUF_VIRTUAL_ADDR_ERR_FOUND/INTR1_ENABLE_CLEAR[4] CBUF_VIRTUAL_ADDR_ERR_FOUND	This flag indicates when a virtual address error is detected. This is a general interrupt event which is not associated with any specific CBUF(1).
INTR0_STATUS_RAW_SET[3] OUT_OF_RANGE_ERR_FOUND/INTR1_STATUS_RAW_SET[3] OUT_OF_RANGE_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[3] OUT_OF_RANGE_ERR_FOUND/INTR1_STATUS_ENABLED_CLEAR[3] OUT_OF_RANGE_ERR_FOUND	INTR0_ENABLE_SET[3] OUT_OF_RANGE_ERR_FOUND/INTR1_ENABLE_SET[3] OUT_OF_RANGE_ERR_FOUND and INTR0_ENABLE_CLEAR[3] OUT_OF_RANGE_ERR_FOUND/INTR1_ENABLE_CLEAR[3] OUT_OF_RANGE_ERR_FOUND	General interrupt for an access made with illegal VBUF address(1).

Table 10-567. OCMC_RAM Events (continued)

Event Flag	Event Mask	Description
INTR0_STATUS_RAW_SET[2] ADDR_ERR_FOUND/INTR1_STATUS_RAW_SET[2] ADDR_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[2] ADDR_ERR_FOUND/INTR1_STATUS_ENABLED_CLEAR[2] ADDR_ERR_FOUND	INTR0_ENABLE_SET[2] ADDR_ERR_FOUND/INTR1_ENABLE_SET[2] ADDR_ERR_FOUND and INTR0_ENABLE_CLEAR[2] ADDR_ERR_FOUND/INTR1_ENABLE_CLEAR[2] ADDR_ERR_FOUND	This status flag is set when the value of the STATUS_ERROR_CNT[23:20] ADDR_ERROR_CNT bit field reaches the threshold counter value configured through the CFG_OCMC_ECC_ERROR[23:20] CFG_ADDR_ERR_CNT_MAX bit field. The status remains asserted until the counter is not cleared. This is done by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST[2] CLEAR_ADDR_ERR_CNT bit. If the counter is not cleared another interrupt is re-issued.
INTR0_STATUS_RAW_SET[1] DED_ERR_FOUND/INTR1_STATUS_RAW_SET[1] DED_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[1] DED_ERR_FOUND/INTR1_STATUS_ENABLED_CLEAR[1] DED_ERR_FOUND	INTR0_ENABLE_SET[1] DED_ERR_FOUND/INTR1_ENABLE_SET[1] DED_ERR_FOUND and INTR0_ENABLE_CLEAR[1] DED_ERR_FOUND/INTR1_ENABLE_CLEAR[1] DED_ERR_FOUND	This status flag is set when the value of the STATUS_ERROR_CNT[19:16] DED_ERROR_CNT bit field reaches the threshold counter value configured through the CFG_OCMC_ECC_ERROR[19:16] CFG_DED_CNT_MAX bit field. The status remains asserted until the counter is not cleared. This is done by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST[1] CLEAR_DED_ERR_CNT bit. If the counter is not cleared another interrupt is re-issued.
INTR0_STATUS_RAW_SET[0] SEC_ERR_FOUND/INTR1_STATUS_RAW_SET[0] SEC_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[0] SEC_ERR_FOUND/INTR1_STATUS_ENABLED_CLEAR[0] SEC_ERR_FOUND	INTR0_ENABLE_SET[0] SEC_ERR_FOUND/INTR1_ENABLE_SET[0] SEC_ERR_FOUND and INTR0_ENABLE_CLEAR[0] SEC_ERR_FOUND/INTR1_ENABLE_CLEAR[0] SEC_ERR_FOUND	This status flag is set when the value of the STATUS_ERROR_CNT[15:0] SEC_ERROR_CNT bit field reaches the threshold counter value configured through the CFG_OCMC_ECC_ERROR[15:0] CFG_SEC_CNT_MAX bit field. The status remains asserted until the counter is not cleared. This is done by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST[0] CLEAR_SEC_ERR_CNT bit. If the counter is not cleared another interrupt is re-issued.

10.5.3.5 OCM Subsystem Memory Regions

The SRAM associated with the OCMC_RAM is accessible through the L3_MAIN interconnect. The start address is 0x4030 0000 and the end address is 0x4037 FFFF. That is address space of 512KiB. The configuration registers of the OCMC_RAM are accessible through the L4_PER3 starting at address 0x4880 4000.

10.5.3.6 OCM Controller Modes Of Operation

The OCM controller supports four modes of operation. Each of these modes is selected through the CFG_OCMC_ECC[2:0] CFG_OCMC_MODE bit field. The four supported modes are the following:

- Non-ECC mode (Data Access) - Accesses to the SRAM are non-ECC-enabled and an ECC is not calculated.
- Non-ECC mode (Code Access) - The L3_MAIN address is mapped to the SRAM memory space where the ECC code is stored. This mode allows read and write access to the 9-bit ECC word associated with each 128-bit data word. This mode is used for test purposes.
- Full-ECC mode - Accesses to the SRAM are ECC-enabled and a 9-bit ECC is calcualted for each 128 bits of data.
- Block-ECC mode - A 9-bit ECC is calcualted only for a 128KiB block of the SRAM. Accesses outside the 128KiB ECC-enabled block are non-ECC data acceses. In other words, a 9-bit ECC will be calculated not for each 128-bit data word of the whole SRAM space, but for each 128-bit data word within the boundaries of this 128KiB block of the SRAM. The selection of a 128KiB ECC-enabled block is done using bits[19:0] of the CFG_OCMC_ECC_MEM_BLK register. Each bit specifies which 128KiB block of the SRAM is ECC-enabled. 0x1 is the active value for each bit. In addition, more than one 128KiB ECC-enabled block can be selected.

The default mode of operation for the OCM controller is the non-ECC data access mode.

10.5.3.7 ECC Associated FIFOs

There are three FIFOs used when ECC mode is enabled. Each FIFO is four level deep. The FIFOs are the following:

- Address FIFO for single errors also referred to as SEC FIFO
- Address FIFO for double errors also referred to as DED FIFO
- Address FIFO for address errors also referred to as ADDRERR FIFO

The SEC FIFO stores the SRAM addresses at which a single error is detected. The FIFO is able to store up to four unique addresses of the single errors occured. If there are more than four single errors associated with unique addresses, then only the first four addresses are stored in the FIFO. In case of occurrence of multiple correctable errors, the addresses are stored in the order the errors occurred. The SEC FIFO can be optionally configured to store all addresses of the single errors occured including also the repeated addresses. This is done by setting to 0x0 the CFG_OCMC_ECC_ERROR[24] CFG_DISCARD_DUP_ADDR bit. The SEC FIFO can be cleared by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST[0] CLEAR_SEC_ERR_CNT bit or by reding FIFO's content one by one through the STATUS_SEC_ERROR_TRACE[17:0] ADDRESS_128BIT bit field which points to the SEC FIFO. In addition, the STATUS_SEC_ERROR_TRACE[18] VALID bit shows whether the FIFO is empty or not. A value of 0x1 means that the SEC FIFO is not empty and valid address can be read.

The DED FIFO stores the SRAM addresses when a double error is detected. The FIFO is able to store up to four unique addresses, but it can also be configured to store the repeated addresses by setting to 0x0 the CFG_OCMC_ECC_ERROR[24] CFG_DISCARD_DUP_ADDR bit. The STATUS_DED_ERROR_TRACE[17:0] ADDRESS_128BIT bit field points to the DED FIFO. The STATUS_DED_ERROR_TRACE[18] VALID bit shows whether the FIFO is empty or not. The DED FIFO can be cleared by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST[1] CLEAR_DED_ERR_CNT bit or by reading its content one by one through the STATUS_DED_ERROR_TRACE[17:0] ADDRESS_128BIT.

The ADDRERR FIFO stores the SRAM addresses where the single error occured is an addres error. The STATUS_ADDR_TRANSLATION_ERROR_TRACE[17:0] ADDRESS_128BIT bit field points to the ADDRERR FIFO. The STATUS_ADDR_TRANSLATION_ERROR_TRACE[18] VALID bit shows whether the FIFO is empty or not. The ADDRERR FIFO can be cleared by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST[2] CLEAR_ADDR_ERR_CNT bit or by reading its content one by one through the STATUS_ADDR_TRANSLATION_ERROR_TRACE[17:0] ADDRESS_128BIT pointer. The ADDRERR FIFO is also able to store up to four unique addresses and can also be configured to store repeated addresses by setting to 0x0 the CFG_OCMC_ECC_ERROR[24] CFG_DISCARD_DUP_ADDR bit.

10.5.3.8 ECC Counters And Corrected Bit Distribution Register

There are three counters which are used to count different types of errors occured when the ECC mode is enabled. The counters are the following:

- SEC Counter - STATUS_ERROR_CNT[15:0] SEC_ERROR_CNT. This is the counter for the single errors occured. It keeps track of all single errors. That is, even for those with error addresses that have already been logged.
- DED Counter - STATUS_ERROR_CNT[19:16] DED_ERROR_CNT. This is the counter for the double error detections.
- ADDRERR Counter - STATUS_ERROR_CNT[23:20] ADDR_ERROR_CNT. This is the counter for the address errors found when a single error occurs. That is, when the single error is an addres error.

When a single error in the 128-bit data word occurs and this error is corrected, the OCM controller indicates for the corrected bit of this 128-bit word by setting to 0x1 a corresponding bit in the corrected bit distribution register. This is a 128-bit register composed by the following registers:

- STATUS_SEC_ERROR_DISTR_0[31:0] SEC_BIT_ERROR_FOUND - Bits [31:0] of the corrected 128-bit data word.
- STATUS_SEC_ERROR_DISTR_1[31:0] SEC_BIT_ERROR_FOUND - Bits [63:32] of the corrected 128-bit data word.
- STATUS_SEC_ERROR_DISTR_2[31:0] SEC_BIT_ERROR_FOUND - Bits [95:64] of the corrected 128-bit data word.
- STATUS_SEC_ERROR_DISTR_3[31:0] SEC_BIT_ERROR_FOUND - Bits [127:96] of the corrected 128-bit data word.

When a single error in the ECC itself occurs, the OCM controller indicates for this error by setting to 0x1 a corresponding bit in the STATUS_SEC_ERROR_DISTR_4[7:0] SEC_ECC_CODE_ERROR_FOUND bit field. The parity bit is not associated with this bit field.

10.5.3.9 ECC Support

The ECC mode is enabled through the CFG_OCMC_ECC[2:0] CFG_OCMC_MODE bit field. When enabled a 9-bit Hamming ECC is calculated and stored for each consecutive 128-bit block of the SRAM. The ECC is calculated based on a codeword constructed by concatenating the 128 bits of data with the address bits A21 through A4 of the L3_MAIN. The ECC generated is Hamming(155,146) code and has a Hamming distance of 4. The OCM controller uses this code to validate the content of the SRAM, to correct a single bit error that occurs within the 128-bit boundary or to determine if a non-correctable error has occurred within the 128-bit boundary.

During write transactions and when ECC is enabled, for every 128-bit data word, the ECC is calculated and stored in a 9-bit field of the SRAM associated only with the address where that 128-bit data word is written. If an initiator performs a write transaction which is less than 128 bits or it is non-128-bit aligned transaction, then the content of all 128 bits is read, the new sub-quanta of data is inserted and the ECC is calculated based on all 128 bits.

During read transactions and when ECC is enabled, the ECC is calcualated based on the memory address (bits A21 through A4) and the 128-bit data word read from the SRAM. This ECC is then compared to the ECC stored at the address when the data was written to the SRAM. If the two ECCs are matching then the data is transferred to the requesting initiator without further exceptions. If the two ECCs are not matching then a check is made to determine if the error is correctable or not. If the error is not correctable, that is a double error, then the address of the erroneous word is stored in the DED FIFO, the STATUS_ERROR_CNT[19:16] DED_ERROR_CNT counter is incremented by 1 and the double error flag is asserted. The double error flag is indicated by the INTR0_STATUS_RAW_SET[1] DED_ERR_FOUND/INTR1_STATUS_RAW_SET[1] DED_ERR_FOUND bits, but its assertion depends on the threshold configured through the CFG_OCMC_ECC_ERROR[19:16] CFG_DED_CNT_MAX bit field. For more information see, Table 10-567, *OCMC_RAM Events*.

In case of a single error, the OCM controller first determines whether the erroneous bit is in the data, address or the ECC itself. In this case the following applies:

- If the single error is located in the data read, then the erroneous bit is corrected and the data is passed to the requesting initiator. The erroneous bit is corrected also in the SRAM location by the auto re-write

feature of the OCM controller if this feature is enabled by setting to 0x1 the CFG_OCMC_ECC[3] CFG_ECC_SEC_AUTO_CORRECT bit field. In addition, the address of the corrected data word is pushed to the SEC FIFO and the STATUS_ERROR_CNT[15:0] SEC_ERROR_CNT counter is incremented by 1. The single error flag is asserted too, but only if the value of the STATUS_ERROR_CNT[15:0] SEC_ERROR_CNT counter reaches the threshold configured by the CFG_OCMC_ECC_ERROR[15:0] CFG_SEC_CNT_MAX bit field. The single error flag is indicated by the INTR0_STATUS_RAW_SET[0] SEC_ERR_FOUND/INTR1_STATUS_RAW_SET[0] SEC_ERR_FOUND bits. For more information see, Table 10-567, *OCMC_RAM Events*.

- If the single error is located in the address portion of the quanta, then the data is passed to the requesting initiator unchanged and the STATUS_ERROR_CNT[23:20] ADDR_ERROR_CNT and STATUS_ERROR_CNT[15:0] SEC_ERROR_CNT counters are incremented by 1. The address associated with this error is stored in the ADDRERR FIFO and the address error flag is asserted. This flag is indicated by the INTR0_STATUS_RAW_SET[2] ADDR_ERR_FOUND/INTR1_STATUS_RAW_SET[2] ADDR_ERR_FOUND bits, but its assertion depends on the threshold configured through the CFG_OCMC_ECC_ERROR[23:20] CFG_ADDR_ERR_CNT_MAX bit field. For more information see, Table 10-567, *OCMC_RAM Events*.
- If the single error is located in the ECC itself, then the data is passed to the initiator unchanged but the STATUS_ERROR_CNT[15:0] SEC_ERROR_CNT counter is incremented by 1 and the address associated with this error is stored in the SEC FIFO.

Table 10-568 summarizes the actions taken by the OCM controller for the different error types.

Table 10-568. OCMC Error Handling In Case Of Different Error Types

Error Type	Data Returned	SRAM Data/ECC Update	SEC Counter	SEC FIFO	DED Counter	DED FIFO	ADDRERR Counter	ADDRERR FIFO	Error Bit Distribution
Single data error	Corrected	Data corrected/ECC re-generated	Incremented by 1	Address written	-	-	-	-	The content of the corrected bit distribution register is updated
Single address error	Unchanged	ECC re-generated	Incremented by 1	-	-	-	Incremented by 1	Address written	-
Single ECC error	Unchanged	ECC re-generated	Incremented by 1	Address written	-	-	-	-	The content of the STATUS_SEC_ERROR_DISTR_4[7:0] SEC_ECC_CODE_ERROR_FOUND bit field is updated
Double error	Unchanged	-	-	-	Incremented by 1	Address written	-	-	-

If ECC has to be used, before performing SRAM read/write operations the following steps should be performed:

- Configuring the ECC registers
- Enabling the ECC
- Initializing the SRAM with data
- Clearing the status flags

Table 10-569 describes in detail the steps to be performed.

Table 10-569. OCMC ECC Configuration

Step	Associated Register/ Bit Field	Value
(Optional) Enable the error response on L3_MAIN for a non-correctable error	CFG_OCMC_ECC[4] CFG_ECC_ERR_SRESP_EN	0x1
(Optional) Enable data auto correction in case of a single error	CFG_OCMC_ECC[3] CFG_ECC_SEC_AUTO_CORRECT	0x1
Enable the memory blocks to be ECC protected, if ECC block mode is used	CFG_OCMC_ECC_MEM_BLK[19:0] CFG_ECC_ENABLED_128K_BLK	0x-

Table 10-569. OCMC ECC Configuration (continued)

Step	Associated Register/ Bit Field	Value
(Optional) Configure the address errors count needed for triggering an interrupt	CFG_OCMC_ECC_ERROR[23:20] CFG_ADDR_ERR_CNT_MAX	0x-
(Optional) Configure the DED count needed for triggering an interrupt	CFG_OCMC_ECC_ERROR[19:16] CFG_DED_CNT_MAX	0x-
(Optional) Configure the SEC count needed for triggering an interrupt	CFG_OCMC_ECC_ERROR[15:0] CFG_SEC_CNT_MAX	0x-
Enable ECC	CFG_OCMC_ECC[2:0] CFG_OCMC_MODE	0x2 for full ECC or 0x3 for block ECC mode
Initialize the memory with data		
Clear the error counters in the STATUS_ERROR_CNT register	CFG_OCMC_ECC_CLEAR_HIST[2:0]	0x7
Clear the SEC bit distribution history from the following registers:	CFG_OCMC_ECC_CLEAR_HIST[3] CLEAR_SEC_BIT_DISTR	0x1
• STATUS_SEC_ERROR_DISTR_0		
• STATUS_SEC_ERROR_DISTR_1		
• STATUS_SEC_ERROR_DISTR_2		
• STATUS_SEC_ERROR_DISTR_3		
• STATUS_SEC_ERROR_DISTR_4		

10.5.3.10 Circular Buffer (CBUF) Support

The OCM controller provides up to 12 programmable circular buffers that are mapped to virtual video frames to support sliced based on-the-fly video frame processing. Each circular buffer must be programmed with the following:

- Unique virtual frame start address - configured through CBUF_i_VBUF_START_ADDR[31:4] ADDR.
- Unique virtual frame end address - configured through CBUF_i_VBUF_END_ADDR[31:4] ADDR.
- SRAM start address - configured through CBUF_i_OCMC_START_ADDR[31:4] ADDR.
- SRAM size allocated for that circular buffer - configured through CBUF_i_OCMC_BUF_SIZE[19:4] BUF_SIZE.

The circular buffer mode is enabled when the CFG_OCMC_CBUF_EN[0] CBUF_MODE_EN bit is set to 0x1. In addition, to enable certain circular buffer the corresponding bit in the CFG_OCMC_CBUF_EN[27:16] bit field must be set to 0x1. For example, to enable CBUF_0 both the CFG_OCMC_CBUF_EN[0] CBUF_MODE_EN and CFG_OCMC_CBUF_EN[16] CBUF_EN_0 bits must be set to 0x1.

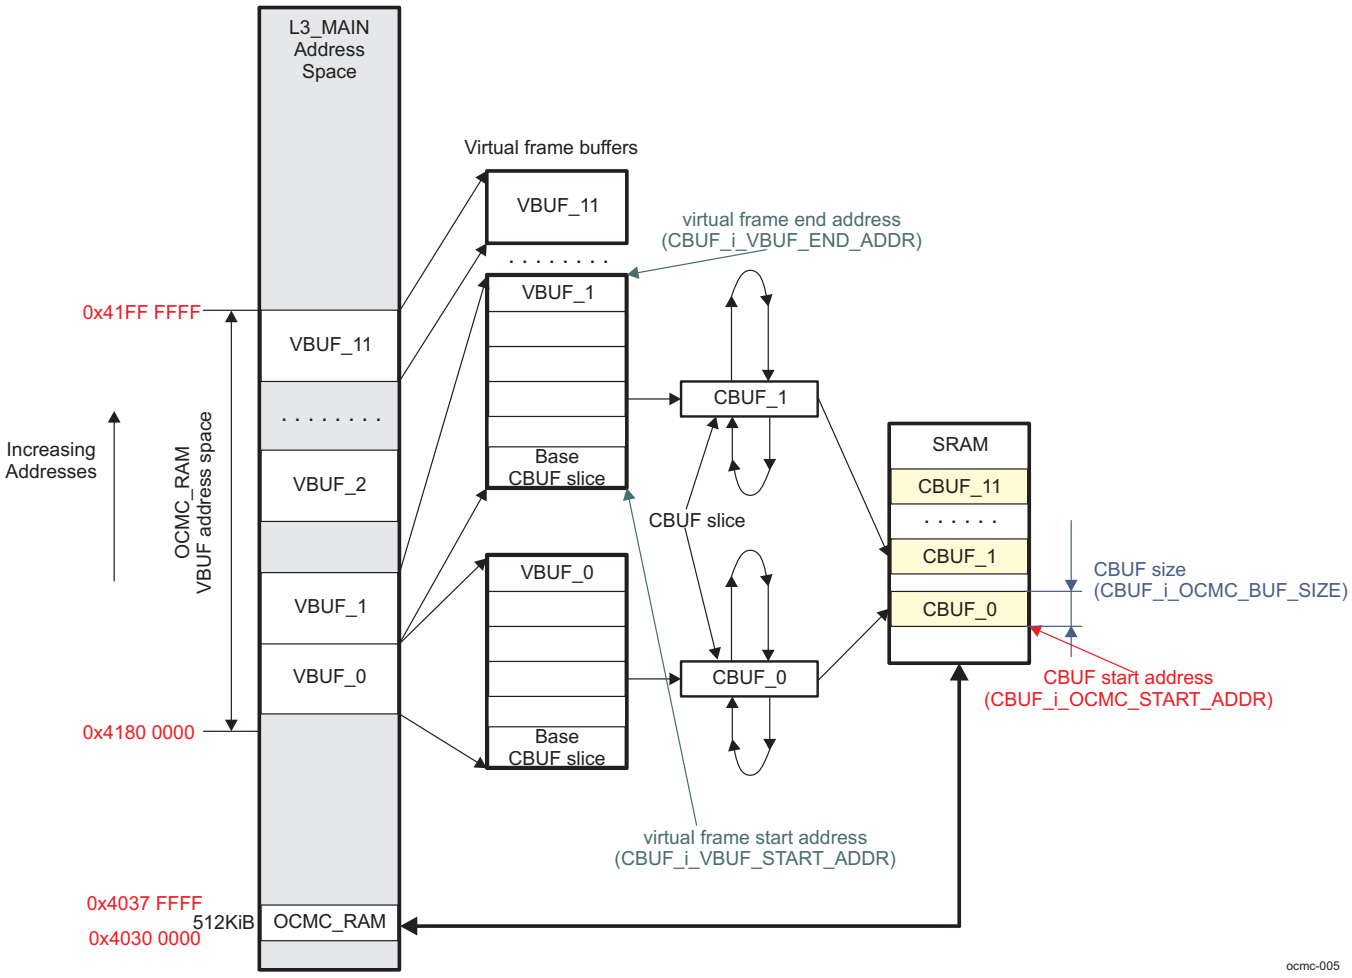
The data transfers are made to the virtual frame addresses. The OCM controller translates these virtual addresses to SRAM addresses allocated for the CBUF. The address translation is done on-the-fly without leading to any additional latency and therefore has no performance impact on the overall operation of the OCM controller.

The L3_MAIN address range associated with the virtual frame addresses is the following:

- For OCMC_RAM the start address is 0x4180 0000 and the end address is 0x41FF FFFF.

When an initiator performs an access to these L3_MAIN addresses, these virtual frame addresses will be translated automatically by the OCM controller into SRAM addresses. Figure 10-68 shows the address mapping of the virtual frame addresses to CBUF addresses.

Figure 10-68. VBUF to CBUF Address Mapping



It must be taken into account that the start address of a virtual frame always begins at the start of the CBUF. Since the virtual frame buffer size is not necessarily to be a multiple of the CBUF size, the last VBUF write location may not be the last line of the CBUF. As the CBUF read and write pointers are independently managed the initiators that are writing to and reading from the CBUF should be coordinated in order to avoid overflow and underflow conditions.

10.5.3.11 CBUF Mode Error Handling

For each L3_MAIN write or read access associated with the virtual frame buffer, the OCM controller performs various address error checks to prevent illegal CBUF accesses from causing false overflow and underflow conditions. Once the L3_MAIN VBUF address is determined as valid, the OCM controller further checks for overflow and underflow conditions to properly handle the access to the CBUF during each one of these conditions and to notify for error condition an external host.

For more information regarding all CBUF events see, Table 10-567, *OCMC_RAM Events*.

10.5.3.11.1 VBUF Address Not Mapped to a CBUF Memory Space

The L3_MAIN VBUF address should be mapped to a valid CBUF region. If this address is mapped to none of the configured CBUF regions, then the OCM controller generates a virtual address error or out of range CBUF address error event. It is possible both virtual address error and out of range CBUF address error to be generated. The L3_MAIN VBUF address caused these two events can be read through the LAST_ILLEGAL_OCMC_ADDR[31:0] ADDR bit field.

Virtual address error is generated when the L3_MAIN VBUF address is lower than the virtual frame start address. This is indicated by asserting the INTR0_STATUS_RAW_SET[4] CBUF_VIRTUAL_ADDR_ERR_FOUND/INTR1_STATUS_RAW_SET[4] CBUF_VIRTUAL_ADDR_ERR_FOUND bit.

The out of range CBUF address error is generated when the L3_MAIN VBUF address is greater than the virtual frame end address. This error is an indication of an unexpected change in the frame size or a long frame and should be handled immediately to prevent further memory corruption. The out of range CBUF address error can be caused when performing write or read access. The out of range CBUF write address error is indicated by the STATUS_CBUF_WR_OUT_OF_RANGE_ERR[11:0] CBUF_ERR bit field. The out of range CBUF read address error is indicated by the STATUS_CBUF_RD_OUT_OF_RANGE_ERROR[11:0] CBUF_ERR bit field. Each bit in these registers is associated only with one CBUF. Bit 0 corresponds to CBUF_0, bit 1 corresponds to CBUF_1 and so on. A value of 0x1 for each bit means that there is an error (CBUF address is out of CBUF range) for the corresponding CBUF. Writing 0x1 for each bit clears the status.

The INTR0_STATUS_RAW_SET[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND/INTR1_STATUS_RAW_SET[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_WR_OUT_OF_RANGE_ERR[11:0] CBUF_ERR bit field is set to 0x1.

The INTR0_STATUS_RAW_SET[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND/INTR1_STATUS_RAW_SET[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_RD_OUT_OF_RANGE_ERROR[11:0] CBUF_ERR bit field is set to 0x1.

10.5.3.11.2 VBUF Access Not Starting At The Base Address

After (hardware of software) reset or on a new frame start condition, a frame write or read access for any VBUF must start from its virtual frame start address (CBUF_i_VBUF_START_ADDR[31:4] ADDR). If this is not met the OCM controller ignors all accesses which don't start at address CBUF_i_VBUF_START_ADDR[31:4] ADDR and also generates an interrupt. The STATUS_CBUF_WR_VBUF_START_ERR[11:0] CBUF_ERR register contains the status bits of this interrupt which are associated with frame write access. The STATUS_CBUF_VBUF_RD_START_ERROR[11:0] CBUF_ERR register contains the status bits associated with frame read access. Each bit in these two registers is associated only with one CBUF. A value of 0x1 for each bit means that the read/write access does not start at the VBUF start address.

While this error condition exists, no updates to the CBUF channel status registers are made. An exception to this constraint is when the last read/write access is still within the base CBUF slice. The enforcing of a frame starting at VBUF starting address is not done in this case to allow random access within the same CBUF. However, this will be flagged and handled as a short frame occurrence.

The INTR0_STATUS_RAW_SET[6] CBUF_VBUF_WRITE_START_ERR_FOUND/INTR1_STATUS_RAW_SET[6] CBUF_VBUF_WRITE_START_ERR_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_WR_VBUF_START_ERR[11:0] CBUF_ERR bit field is set to 0x1.

The INTR0_STATUS_RAW_SET[9] CBUF_VBUF_READ_START_ERR_FOUND/INTR1_STATUS_RAW_SET[9] CBUF_VBUF_READ_START_ERR_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_VBUF_RD_START_ERROR[11:0] CBUF_ERR bit field is set to 0x1.

10.5.3.11.3 Illegal Address Change Between Two Same Type Accesses

The OCM controller requires both read and write accesses to a virtual frame buffer to be performed in the positive raster scan order, that is, successive write or read accesses should be to a higher address except on a new frame start for which the address jumps back down to the beginning of the virtual frame buffer. The OCM controller checks to make sure that a virtual address meets one of the following conditions:

- It is within the same CBUF slice as the last access of the same type (read or write)
- It is within the next CBUF slice of the last access of the same type (read or write)
- The virtual address is to the VBUF frame start address

Based on these constraints, the OCM controller generates an write/read address sequence error interrupt and invalidates the access, that is, writes are disabled and reads return unknown data, if the following two conditions are met:

- The current access address is not to a current or next CBUF slice space
- The current access address is not to the base of the virtual frame buffer (the first CBUF slice)

The random accesses within the current CBUF slice are permited to allow some variations in the line width of the captured video which often happens with weak video signal conditions.

To avoid illegal CBUF slice backward switching, the modules capturing the input video and sending it to the CBUF of the OCM controller should limit the maximum width of a line width to be less than the stride size (in pixels). This guarantees that a start of a new line does not point back to the previous CBUF slice.

If a write or read address sequence error event is detected on an access, the OCM controller will simply invalidate the accesses and will not update the CBUF status registers.

The bits in the STATUS_CBUF_WR_ADDR_SEQ_ERROR[11:0] CBUF_ERR bit field indicate write address sequence error event.

The bits in the STATUS_CBUF_RD_ADDR_SEQ_ERROR[11:0] CBUF_ERR bit field indicate read address sequence error event.

In both the registers each bit is associated only with one CBUF.

The INTR0_STATUS_RAW_SET[7] CBUF_WRITE_SEQUENCE_ERR_FOUND/INTR1_STATUS_RAW_SET[7] CBUF_WRITE_SEQUENCE_ERR_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_WR_ADDR_SEQ_ERROR[11:0] CBUF_ERR bit field is set to 0x1.

The INTR0_STATUS_RAW_SET[10] CBUF_READ_SEQUENCE_ERR_FOUND/INTR1_STATUS_RAW_SET[10] CBUF_READ_SEQUENCE_ERR_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_RD_ADDR_SEQ_ERROR[11:0] CBUF_ERR bit field is set to 0x1.

10.5.3.11.4 Illegal Frame SIze (Short Frame Detection)

If a frame write access for any VBUF begins from its virtual frame start address without a CBUF software reset and the last write address is not the virtual frame end address or is in the last CBUF slice, then the previous frame is considered to be short. This includes the case where a new frame write happens twice without a new frame read in between, which is an indication of an extremely short frame. When a short frame event is detected, the OCM controller generates a short frame detection interrupt and temporarily disables overflow checking on the write access, including also the current access, until a frame read happens in order to avoid false overflow indication on a suspended read side following the short frame detection.

If the last write address is in the last CBUF slice the short frame detection can be ignored if the CFG_OCMC_CBUF_ERR_HANDLER[1] SHORT_FRAME_PREV_EOF_SEL bit is set to 0x1.

The STATUS_CBUF_SHORT_FRAME_DETECT[11:0] CBUF_ERR bit field has status flags to indicate a short frame detection for each CBUF. When a short frame condition occurs the corresponding bit is set to 0x1.

The INTR0_STATUS_RAW_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND/INTR1_STATUS_RAW_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_SHORT_FRAME_DETECT[11:0] CBUF_ERR bit field is set to 0x1.

In addition, the short frame detection enabling/disabling is controlled by the CFG_OCMC_CBUF_ERR_HANDLER[0] SHORT_FRAME_DETECT_CHECK_EN bit.

10.5.3.11.5 CBUF Overflow

For each valid CBUF write access, the write address is compared to the last read address for an overflow condition. If an overflow is detected, the corresponding CBUF overflow status bit in the STATUS_CBUF_OVERFLOW_MID or STATUS_CBUF_OVERFLOW_WRAP registers is set to 0x1 and an interrupt is generated. This interrupt condition exists until the corresponding overflow status bit is cleared.

There are two types of overflow conditions referred to as Cbuf_overflow_wrap and Cbuf_overflow_mid.

Cbuf_overflow_wrap occurs in case at least one of the following two:

- VBUF write address – VBUF frame start address < CBUF size
- VBUF write address – VBUF frame start address > VBUF last read address – Current VBUF start address

Cbuf_overflow_mid occurs in case at least one of the following two:

- VBUF write address – VBUF frame start address > CBUF size
- VBUF write address – VBUF last read address > CBUF size

If an overflow condition is detected on a CBUF write access, the OCM controller generates a CBUF overflow (Cbuf_overflow_wrap or Cbuf_overflow_mid) interrupt and enter an overflow error handling state. In this state, the OCM controller do the following in the default error handling configuration:

- When a Cbuf_Overflow_Wrap condition occurs (write buffer wraparound with read from previous frame still remaining), writes are disabled but reads are serviced normally. This mechanism preserves the back end of the previous frame and discards the new frame which is already showing signs of overflowing. Writes will be re-enabled automatically on write to the virtual frame start address which indicates the next frame after the overflowed frame has begun. The overflow (and underflow) check for this CBUF will be disabled until detection of write to/read from the virtual frame start address. The module which reads should not start reading the next frame (which is being discarded) or stop reading the frame if the read of this new frame has already started. This mechanism allows both write and read sides to re-synchronize on the next frame after one-frame drop.
- When a Cbuf_Overflow_Mid condition occurs, writes and reads are serviced normally allowing the read side to catch up to the write side. The overflow (and underflow) check will be disabled until first a write to the virtual frame start address and then a read from the virtual frame start address is detected. This mechanism allows the frame with a “momentary” overflow condition to be saved. The reader side has an option to stop reading and discarding the data by just resetting its CBUF read pointer at the next frame start, if the read side is too far back.

These steps are taken to minimize the frame loss due to an overflow condition. To support the previously described behavior but to allow software to override the default error handling behavior the following controls are available:

- CFG_OCMC_CBUF_ERR_HANDLER[7:6] OVERFLOW_CHECK_REENABLE_SEL
- CFG_OCMC_CBUF_ERR_HANDLER[5:4] OVERFLOW_WRITE_HANDLER_SEL

In addition, the overflow check can be enabled or disabled through the CFG_OCMC_CBUF_ERR_HANDLER[2] OVERFLOW_ERR_CHECK_EN bit.

10.5.3.11.6 CBUF Underflow

According to the CBUF operation a read request can only be made when there are enough number of video lines written to the CBUF. Therefore, there should not be any underflow conditions due to normal processing speed variations. An underflow condition occurs when the VBUF read address is greater than the last VBUF write address. To detect an abnormal failure in the read/write mechanism which could cause an underflow condition, each valid CBUF read access is checked for an underflow condition and if detected, an underflow interrupt is generated for the selected CBUF. The STATUS_CBUF_UNDERFLOW[11:0] CBUF_ERR bit field has status flags indicating when underflow occurs. This interrupt condition exists until the corresponding underflow status bit in the STATUS_CBUF_UNDERFLOW register is cleared.

If an underflow is detected on a CBUF read access, the OCM controller generates an underflow interrupt and continues to perform reads and writes normally, but the return data will not be correct while the underflow condition exists.

To avoid a false underflow detection at the end of a frame (due to external decoders sending short last line or due to interlaced input video having different number of lines in even/odd fields), the CFG_OCMC_CBUF_ERR_HANDLER[8] UNDERFLOW_LAST_CBUF_SLICE_DISABLE bit can be set to 0x1 which disables the underflow checking in the last CBUF slice.

The INTR0_STATUS_RAW_SET[13] CBUF_UNDERFLOW_ERR_FOUND/INTR1_STATUS_RAW_SET[13] CBUF_UNDERFLOW_ERR_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_UNDERFLOW[11:0] CBUF_ERR bit field is set to 0x1.

In addition, the underflow check can be enabled or disabled through the CFG_OCMC_CBUF_ERR_HANDLER[3] UNDERFLOW_ERR_CHECK_EN bit.

10.5.3.12 Status Reporting

The OCM controller keeps a history of last valid write and read addresses for each CBUF. The CBUF_k_LAST_WR_ADDR register stores the address for the last valid write and the CBUF_k_LAST_RD_ADDR register stores the address for the last valid read access.

The OCMC_ECC generates also a general VBUF mode error event for an access made with illegal VBUF address. The INTR0_STATUS_RAW_SET[3] OUT_OF_RANGE_ERR_FOUND/INTR1_STATUS_RAW_SET[3] OUT_OF_RANGE_ERR_FOUND bit indicates for this event.

RESERVED																												IDLEMODE		RESERVED	

Bits	Field Name	Description	Type	Reset
31:4	RESERVED		R	0x0
3:2	IDLEMODE	Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state. 0x0: Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, that is, regardless of the IP module's internal requirements. Backup mode, for debug only. 0x1: No-idle mode: local target never enters idle state. Backup mode, for debug only 0x2: Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module shall not generate IRQ-request-related wakeup events. 0x3: Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module may generate IRQ-request-related wakeup events when in idle state.	RW	0x2
1:0	RESERVED		R	0x0

Table 10-628. CFG_OCMC_CBUF_RESET

Address Offset	0x0000 0204		
Physical Address	0x4880 4204	**Instance**	OCMC_RAM
Description	Writing 1 to bit n will set a reset bit to clear the corresponding CBUF_n address translation logic. Sliding CBUF frame tracking will be cleared so that the CBUF now points to the base of the virtual frame buffer. Normally, a reset is not required since the CBUF logic will clear itself when a VBUF access is to the base of the virtual frame.

Enhanced DMA

This chapter describes the Enhanced Direct Memory Access (EDMA) controller.

Topic **Page**

11.1 EDMA Module Overview

The enhanced direct memory access module, also called EDMA, performs high-performance data transfers between two slave points, memories and peripheral devices without microprocessor unit (MPU) or digital signal processor (DSP) support during transfer. EDMA transfer is programmed through a logical EDMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

The EDMA can also perform transfers between external memories and between device subsystems internal memories, with some performance loss caused by resource sharing between the read and write ports.

EDMA controller is based on two major principal blocks:

- EDMA third-party channel controller (EDMA_TPCC)
- EDMA third-party transfer controller (EDMA_TPTC)

The **TPCC** is a high flexible Channel Controller. It serves as an user interface and an event interface for the EDMA controller. The EDMA_TPCC serves to prioritize incoming software requests or events from peripherals and submits transfer requests (TRs) to the transfer controller.

The **TPTC** performs read and write transfers by EDMA ports to the slave peripherals as programmed in the "Active" and "Pending" set of the registers. The transfer controllers are responsible for data movement and issue read/write commands to the source and destination addresses that are programmed for a given transfer in the EDMA_TPCC.

The SoC integrates the following EDMA instances:

- One system-level EDMA
- One DSP internal EDMA (per DSP)
- One EVE internal EDMA (per EVE)

Each of these EDMA modules consists of:

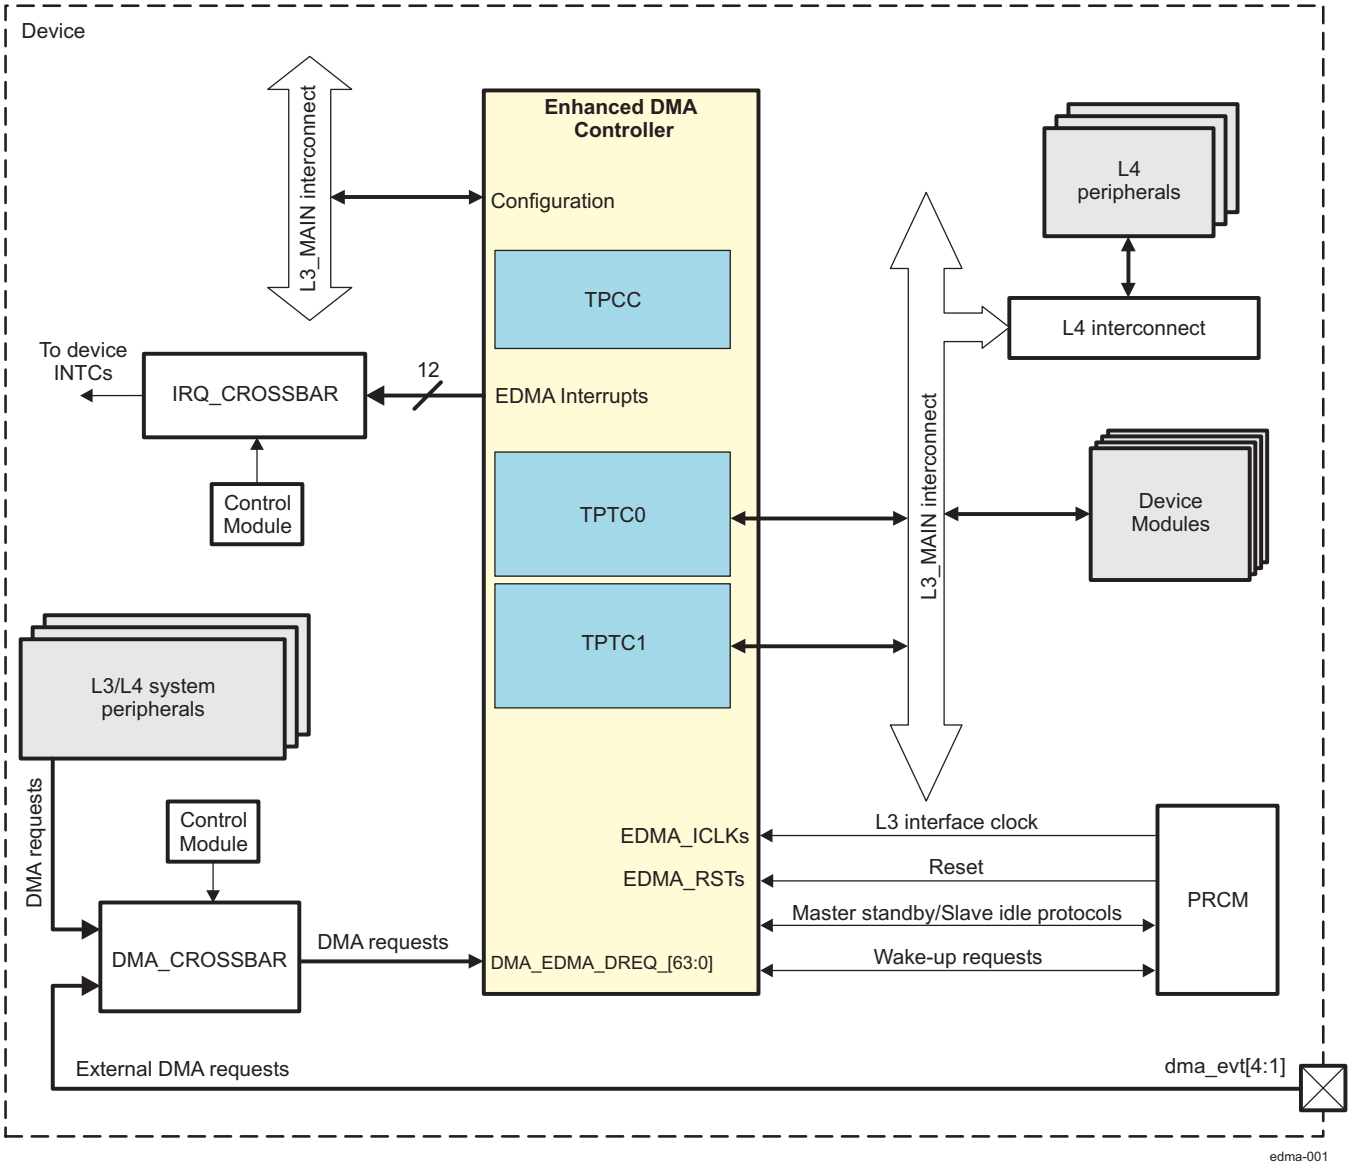
- One TPCC instance
- Two TPTC instances

NOTE: All EDMA modules in the SoC are functionally identical. Note that some of the configuration parameters may be different for the various EDMA instances (see Section 11.1.2, *EDMA Controllers Configuration*).

This chapter is mostly focused on describing the system-level EDMA module (in terms of configuration and integration in the SoC). For details on DSPx_EDMA / EVEx_EDMA integration, see their respective chapters.

Figure 11-1 shows an overview of the EDMA module.

Figure 11-1. EDMA Module Overview



The device CPUs can configure the EDMA controller blocks through the L3_MAIN interconnect.

11.1.1 EDMA Features

The **EDMA_TPCC** channel controller has following features:

- Fully orthogonal transfer description:
  - Three transfer dimensions.
  - A-synchronized transfers: one-dimension serviced per event.
  - AB-synchronized transfers: two-dimensions serviced per event.
  - Independent indexes on source and destination.
  - Chaining feature allows a 3-D transfer based on a single event.
- Flexible transfer definition:
  - Increment or FIFO transfer addressing modes.
  - Linking mechanism allows automatic PaRAM set update.

  - Chaining allows multiple transfers to execute with one event.
- Interrupt generation for the following:
  - Transfer completion.
  - Error conditions.
- Debug visibility:
  - Queue water marking/threshold.
  - Error and status recording to facilitate debug.
- 64 DMA request channels:
  - Event synchronization.
  - Manual synchronization (CPU(s) write to event set registers EDMA_TPCC_ESR and EDMA_TPCC_ESRH).
  - Chain synchronization (completion of one transfer triggers another transfer).
- Eight QDMA channels:
  - QDMA channels trigger automatically upon writing to a parameter RAM (PaRAM) set entry.
  - Support for programmable QDMA channel to PaRAM mapping.
- 512 PaRAM sets:
  - Each PaRAM set can be used for a DMA channel, QDMA channel, or link set.
- Two transfer controllers/event queues.
- 16 event entries per event queue.
- Memory protection support:
  - Proxy memory protection for TR submission.
  - Active memory protection for accesses to PaRAM and registers.

The **EDMA_TPTC** transfer controller has the following features:

- Two transfer controllers (TC).
- 128-bit wide read and write ports per TC.
- Up to four in-flight transfer requests (TRs).
- Programmable priority level.
- Supports two-dimensional transfers with independent indexes on source and destination (EDMA_TPCC manages the 3rd dimension).
- Support for increment or constant addressing mode transfers.
- Interrupt and error support.
- Memory-Mapped Register (MMR) bit fields are fixed position in 32-bit MMR regardless of endianness.

EDMA controller uses the shared MMU1 module for transfering to and from DSP module. This provides several benefits including:

- Protection of Host CPU memory regions from accidental corruption by EDMA TPTCs.
- Direct allocation of buffers in user space without the need for translation between CPU and DSP applications utilizing EDMA TPTCs.

Accesses by the EDMA TPTCs (both TPTC0 and TPTC1) may optionally be routed through the MMU1.

The TPTC0 and TPTC1 routing allows EDMA transfer controller to be used to perform transfers using only the virtual addresses of the associated buffers.

For more information about MMU1 module refer to Chapter 15 *Memory Management Units*.

NOTE: The device DSP integrated EDMA controller instances (DSP_EDMA_TPCC, DSP_EDMA_TPTC0 and DSP_EDMA_TPTC1) are functionally identical with the device EDMA controller instances (EDMA_TPCC, EDMA_TPTC0 and EDMA_TPTC1). The only difference is that the DSP_EDMA instances are located at different physical addresses.

For detail information about DSPSS refer to Chapter 4 *DSP Subsystem*.

11.1.2 EDMA Controllers Configuration

Table 11-1 summarizes the configuration for each of the EDMA channel controllers present on the SoC.

Table 11-1. EDMA Channel Controllers Configuration

Parameter	SYS_EDMA CC Configuration	DSPx_EDMA CC Configuration	EVEx_EDMA CC Configuration
Number of DMA channels (NUM_DMACH)	64	64	16
Number of QDMA channels (NUM_QDMACH)	8	8	8
Number of interrupt channels (NUM_INTCH)	64	64	16
Number of PaRAM set entries (NUM_PARAMENTRY)	512	128	128
Number of event queues (NUM_EVQUE)	2	2	2
Number of transfer controllers (NUM_TC)	2	2	2
Memory protection existence (MPEXIST)	Yes	Yes	Yes
Number of memory protection and shadow regions (NUM_REGIONS)	8	8	8
Channel mapping existence (CHMAPEXIST)	Yes	Yes	Yes

Table 11-2 summarizes the configuration of each of the EDMA transfer controllers present on the SoC.

Table 11-2. EDMA Transfer Controllers Configuration

Parameter	SYS_EDMA TC0 / TC1 Configuration	DSPx_EDMA TC0 / TC1 Configuration	EVEx_EDMA TC0 / TC1 Configuration
Data FIFO size (FIFOSIZE)	1024 bytes	2048 bytes	2048 bytes
Bus width (BUSBYTE)	16 bytes	16 bytes	16 bytes
Number of destination FIFO register sets (DSTREGDEPTH)	4 entries	4 entries	4 entries
Default burst size (DBS)	Defined by CTRL_CORE_CONTROL_IO_1 register	Defined by DSP_SYS_BUS_CONFIG register	Defined by EVE_BUS_CONFIG register

11.2 EDMA Controller Environment

The EDMA controller supports external DMA requests through the dma_evt[4:1] pins (see Table 11-3). A logical channel can be configured to respond to an external synchronization request.

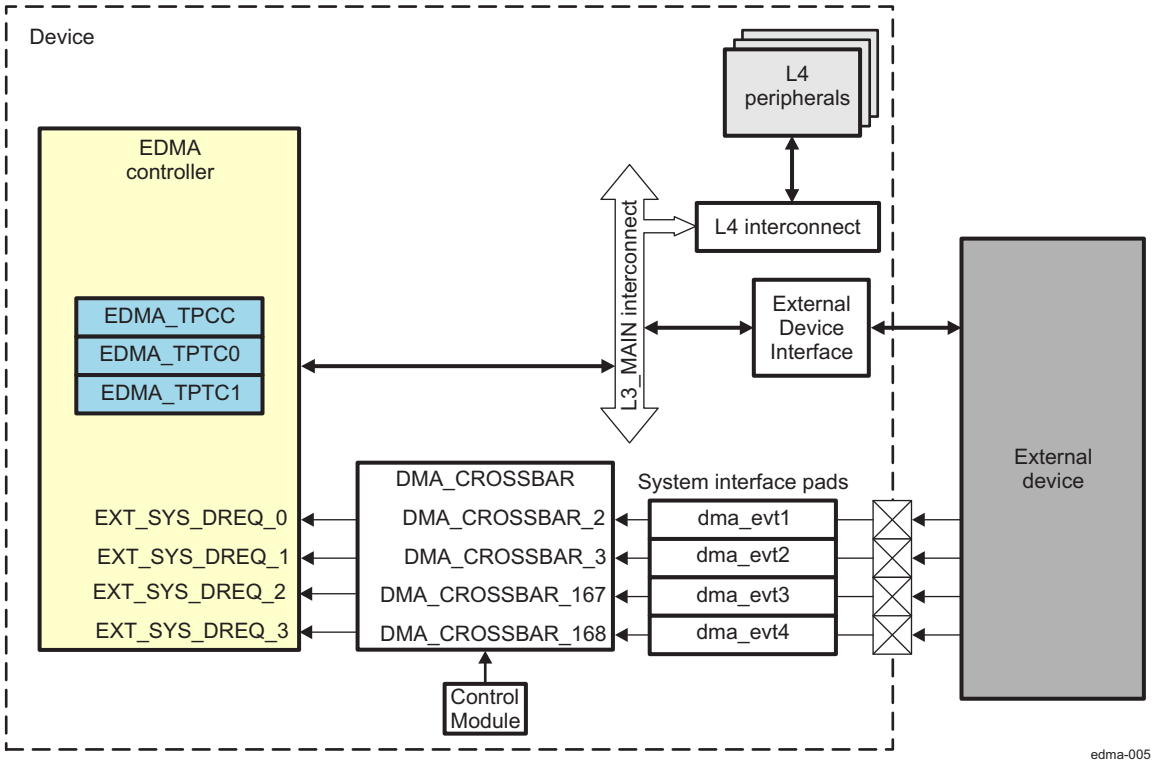
Table 11-3. External EDMA Request Signals

Pin Name	DMA_CROSSBAR Input	Signal Name	I/O[1]	Description	Module Reset Value
dma_evt1	DMA_CROSSBAR_2	EXT_SYS_DREQ_0	I	External DMA request 0 (system expansion)	Z
dma_evt2	DMA_CROSSBAR_3	EXT_SYS_DREQ_1	I	External DMA request 1 (system expansion)	Z
dma_evt3	DMA_CROSSBAR_167	EXT_SYS_DREQ_2	I	External DMA request 2 (system expansion)	Z
dma_evt4	DMA_CROSSBAR_168	EXT_SYS_DREQ_3	I	External DMA request 3 (system expansion)	Z

(1) I = Input, O = Output

Figure 11-2 shows an example of how to use the external hardware DMA request pins in the EDMA environment.

Figure 11-2. Example of External DMA Requests Use



An external device can use the external DMA request pins to start a logical channel transfer. The transfer can be a memory-to-memory transfer in which the source memory is in the external device.

By default, the external DMA request signals are not available on external pins after a cold reset. For more information about multiplexing out the two signal lines to pins, refer to Chapter 13, *Control Module*.

All 64 DMA request lines are transition sensitive.

11.3 EDMA Controller Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 11-3 shows the EDMA controller integration.

Figure 11-3. EDMA Controller Integration

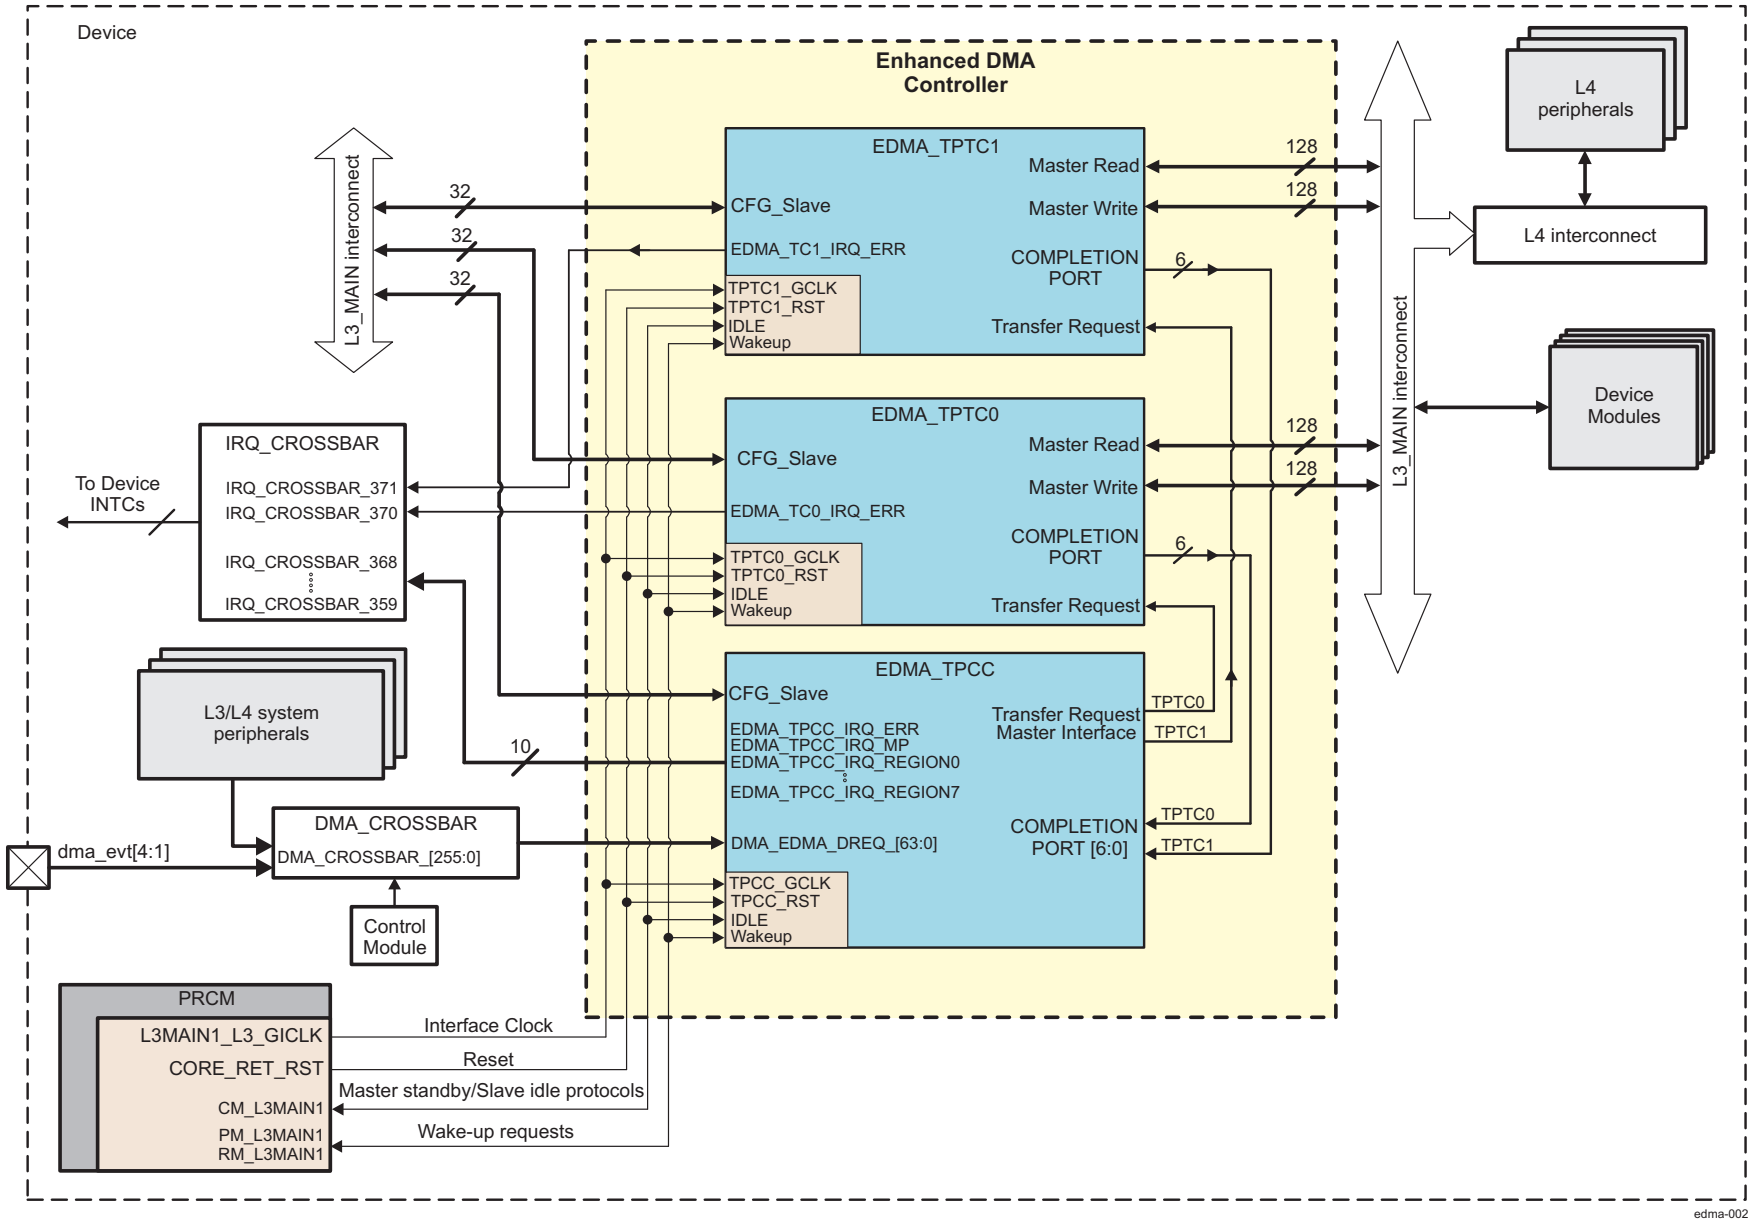


Table 11-4 through Table 11-6 summarize the integration of the module in the device.

Table 11-4. EDMA Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
EDMA_TPCC	PD_COREAON	L3_MAIN
EDMA_TPTC0		
EDMA_TPTC1		

Table 11-5. EDMA Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
EDMA_TPCC	EDMA_TPCC_GCLK	L3MAIN1_L3_GICLK	PRCM	Interface clock. It supports the configuration port. For information about PRCM clock gating and management, see Chapter 3, *Power, Reset, and Clock Management*.
EDMA_TPTC0	EDMA_TPTC0_GCLK			
EDMA_TPTC1	EDMA_TPTC1_GCLK			
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
EDMA_TPCC	EDMA_TPCC_RST	CORE_RET_RST	PRCM	Hardware retention reset. It initializes all internal logic of the EDMA contrller modules, all global registers, and some of the per-channel registers, implemented in flip-flops. However, all remaining per-channel registers are memory-based, and, therefore, are not reset (have undefined values). Thus, when programming a channel for the first time, all bits that have undefined reset values must be configured before enabling the channel. For information about PRCM reset sources and distribution, see Chapter 3, *Power, Reset, and Clock Management*.
EDMA_TPTC0	EDMA_TPTC0_RST			
EDMA_TPTC1	EDMA_TPTC1_RST			

Table 11-6. EDMA Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination IRQ_CROSSBAR INPUT**	**Default mapping**	**Description**
EDMA_TPCC	EDMA_TPCC_IRQ_ERR	IRQ_CROSSBAR_359	-	TPCC error interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_MP	IRQ_CROSSBAR_360	-	TPCC memory protection interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION0	IRQ_CROSSBAR_361	-	TPCC Region 0 interrupt. This IRQ source signal is not mapped by default to any device INTC.

Table 11-6. EDMA Hardware Requests (continued)

	EDMA_TPCC_IRQ_REGION1	IRQ_CROSSBAR_362	-	TPCC Region 1 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION2	IRQ_CROSSBAR_363	-	TPCC Region 2 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION3	IRQ_CROSSBAR_364	-	TPCC Region 3 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION4	IRQ_CROSSBAR_365	-	TPCC Region 4 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION5	IRQ_CROSSBAR_366	-	TPCC Region 5 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION6	IRQ_CROSSBAR_367	-	TPCC Region 6 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION7	IRQ_CROSSBAR_368	-	TPCC Region 7 interrupt. This IRQ source signal is not mapped by default to any device INTC.
EDMA_TPTC0	EDMA_TC0_IRQ_ERR	IRQ_CROSSBAR_370	-	TPTC0 error interrupt. This IRQ source signal is not mapped by default to any device INTC.
EDMA_TPTC1	EDMA_TC1_IRQ_ERR	IRQ_CROSSBAR_371	-	TPTC1 error interrupt. This IRQ source signal is not mapped by default to any device INTC.

NOTE: The "**Default Mapping**" column in Table 11-6 *EDMA Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR or DMA_CROSSBAR modules.
For more information about the IRQ_CROSSBAR and DMA_CROSSBAR modules, see sections: Section 13.4.6.4*IRQ_CROSSBAR Module Functional Description* and Section 13.4.6.5 *DMA_CROSSBAR Module Functional Description*, in Chapter 13 *Control Module*.
For more information about the device interrupt controllers, see Chapter 12 *Interrupt Controllers*.

NOTE: For a description of the interrupt source, see Section 11.4.9, *EDMA interrupts*.

11.3.1 DMA Requests to the EDMA Controller

Table 11-7 lists the default DMA sources for the EDMA controller. In addition, the EDMA inputs (DMA_EDMA_DREQ_[63:0]) can alternatively be sourced through the associated DMA_CROSSBAR from one of the 256 multiplexed device DMA sources listed in Table 11-8. The CTRL_CORE_DMA_EDMA_DREQ_y_z registers (where *y* and *z* are indexes of EDMA input lines) in the Control Module are used to select between the default DMA sources and the multiplexed DMA sources.

Table 11-7. EDMA Default Request Mapping

DMA Request Line	DMA_ CROSSBAR Instance Number	DMA_CROSSBAR Configuration Register	DMA_ CROSSBAR Default Input Index	Default DMA Source Name	Default DMA Source Description
DMA_EDMA_DREQ_0	1	CTRL_CORE_DMA_EDMA_DREQ_0_1[7:0]	1	Reserved	Reserved
DMA_EDMA_DREQ_1	2	CTRL_CORE_DMA_EDMA_DREQ_0_1[23:16]	2	EXT_SYS_DREQ_0	External DMA request 0 (system expansion)
DMA_EDMA_DREQ_2	3	CTRL_CORE_DMA_EDMA_DREQ_2_3[7:0]	3	EXT_SYS_DREQ_1	External DMA request 1 (system expansion)
DMA_EDMA_DREQ_3	4	CTRL_CORE_DMA_EDMA_DREQ_2_3[23:16]	4	GPMC_DREQ	GPMC data transmit request from prefetch engine
DMA_EDMA_DREQ_4	5	CTRL_CORE_DMA_EDMA_DREQ_4_5[7:0]	5	Reserved	Reserved
DMA_EDMA_DREQ_5	6	CTRL_CORE_DMA_EDMA_DREQ_4_5[23:16]	6	DISPC_DREQ	Frame update request
DMA_EDMA_DREQ_6	7	CTRL_CORE_DMA_EDMA_DREQ_6_7[7:0]	7	CT_TBR_DREQ	DEBUG subsystem CT_TBR request
DMA_EDMA_DREQ_7	8	CTRL_CORE_DMA_EDMA_DREQ_6_7[23:16]	8	Reserved	Reserved
DMA_EDMA_DREQ_8	9	CTRL_CORE_DMA_EDMA_DREQ_8_9[7:0]	9	ISS_DREQ_1	ISS DMA request 1(1)
DMA_EDMA_DREQ_9	10	CTRL_CORE_DMA_EDMA_DREQ_8_9[23:16]	10	ISS_DREQ_2	ISS DMA request 2(1)
DMA_EDMA_DREQ_10	11	CTRL_CORE_DMA_EDMA_DREQ_10_11[7:0]	11	Reserved	Reserved
DMA_EDMA_DREQ_11	12	CTRL_CORE_DMA_EDMA_DREQ_10_11[23:16]	12	ISS_DREQ_3	ISS DMA request 3(1)
DMA_EDMA_DREQ_12	13	CTRL_CORE_DMA_EDMA_DREQ_12_13[7:0]	13	ISS_DREQ_4	ISS DMA request 4(1)
DMA_EDMA_DREQ_13	14	CTRL_CORE_DMA_EDMA_DREQ_12_13[23:16]	14	Reserved	Reserved
DMA_EDMA_DREQ_14	15	CTRL_CORE_DMA_EDMA_DREQ_14_15[7:0]	15	MCSPI3_DREQ_TX0	McSPI3 transmit request channel 0
DMA_EDMA_DREQ_15	16	CTRL_CORE_DMA_EDMA_DREQ_14_15[23:16]	16	MCSPI3_DREQ_RX0	McSPI3 receive request channel 0
DMA_EDMA_DREQ_16	17	CTRL_CORE_DMA_EDMA_DREQ_16_17[7:0]	17	Reserved	Reserved
DMA_EDMA_DREQ_17	18	CTRL_CORE_DMA_EDMA_DREQ_16_17[23:16]	18	Reserved	Reserved
DMA_EDMA_DREQ_18	19	CTRL_CORE_DMA_EDMA_DREQ_18_19[7:0]	19	Reserved	Reserved
DMA_EDMA_DREQ_19	20	CTRL_CORE_DMA_EDMA_DREQ_18_19[23:16]	20	Reserved	Reserved
DMA_EDMA_DREQ_20	21	CTRL_CORE_DMA_EDMA_DREQ_20_21[7:0]	21	Reserved	Reserved
DMA_EDMA_DREQ_21	22	CTRL_CORE_DMA_EDMA_DREQ_20_21[23:16]	22	Reserved	Reserved
DMA_EDMA_DREQ_22	23	CTRL_CORE_DMA_EDMA_DREQ_22_23[7:0]	23	MCSPI3_DREQ_TX1	McSPI3 transmit request channel 1
DMA_EDMA_DREQ_23	24	CTRL_CORE_DMA_EDMA_DREQ_22_23[23:16]	24	MCSPI3_DREQ_RX1	McSPI3 receive request channel 1
DMA_EDMA_DREQ_24	25	CTRL_CORE_DMA_EDMA_DREQ_24_25[7:0]	25	Reserved	Reserved
DMA_EDMA_DREQ_25	26	CTRL_CORE_DMA_EDMA_DREQ_24_25[23:16]	26	Reserved	Reserved
DMA_EDMA_DREQ_26	27	CTRL_CORE_DMA_EDMA_DREQ_26_27[7:0]	27	I2C1_DREQ_TX	I2C1 transmit request
DMA_EDMA_DREQ_27	28	CTRL_CORE_DMA_EDMA_DREQ_26_27[23:16]	28	I2C1_DREQ_RX	I2C1 receive request
DMA_EDMA_DREQ_28	29	CTRL_CORE_DMA_EDMA_DREQ_28_29[7:0]	29	I2C2_DREQ_TX	I2C2 transmit request
DMA_EDMA_DREQ_29	30	CTRL_CORE_DMA_EDMA_DREQ_28_29[23:16]	30	I2C2_DREQ_RX	I2C2 receive request

(1) ISS is not supported on the DRA78x family of devices.

Table 11-7. EDMA Default Request Mapping (continued)

DMA Request Line	DMA_ CROSSBAR Instance Number	DMA_CROSSBAR Configuration Register	DMA_ CROSSBAR Default Input Index	Default DMA Source Name	Default DMA Source Description
DMA_EDMA_DREQ_30	31	CTRL_CORE_DMA_EDMA_DREQ_30_31[7:0]	31	Reserved	Reserved
DMA_EDMA_DREQ_31	32	CTRL_CORE_DMA_EDMA_DREQ_30_31[23:16]	32	Reserved	Reserved
DMA_EDMA_DREQ_32	33	CTRL_CORE_DMA_EDMA_DREQ_32_33[7:0]	33	Reserved	Reserved
DMA_EDMA_DREQ_33	34	CTRL_CORE_DMA_EDMA_DREQ_32_33[23:16]	34	Reserved	Reserved
DMA_EDMA_DREQ_34	35	CTRL_CORE_DMA_EDMA_DREQ_34_35[7:0]	35	MCSPI1_DREQ_TX0	McSPI1 transmit request channel 0

DMA_EDMA_DREQ_60	61	CTRL_CORE_DMA_EDMA_DREQ_60_61[7:0]	61	MMC_DREQ_TX	MMC transmit request
DMA_EDMA_DREQ_61	62	CTRL_CORE_DMA_EDMA_DREQ_60_61[23:16]	62	MMC_DREQ_RX	MMC receive request

Table 11-7. EDMA Default Request Mapping (continued)

DMA Request Line	DMA_ CROSSBAR Instance Number	DMA_CROSSBAR Configuration Register	DMA_ CROSSBAR Default Input Index	Default DMA Source Name	Default DMA Source Description
DMA_EDMA_DREQ_62	63	CTRL_CORE_DMA_EDMA_DREQ_62_63[7:0]	63	UART5_DREQ_TX	UART5 transmit request
DMA_EDMA_DREQ_63	64	CTRL_CORE_DMA_EDMA_DREQ_62_63[23:16]	64	UART5_DREQ_RX	UART5 receive request

11.3.2 Mapping of DMA Requests to DMA_CROSSBAR Inputs

NOTE: The information about the DMA_CROSSBAR module, see in the Section 13.4.6.5*DMA_CROSSBAR Module Functional Description* from the *Control Module* in the device TRM.

Table 11-8 lists the DMA_CROSSBAR inputs request mapping.

NOTE: All DREQs from column “Device Module DREQs” can also be mapped to an input of the device ESM using dedicated DMA_CROSSBAR register. For more information, see *IRQ_CROSSBAR Registers Associated With The Device ESM* in *Control Module*

NOTE: ESM is not supported on the DRA78x family of devices.

Table 11-8. Connection of The Device DREQs to The DMA_CROSSBAR Inputs

DMA_CROSSBAR Input	Device Module DREQs	Description
DMA_CROSSBAR_0	Reserved	Reserved
DMA_CROSSBAR_1	Reserved	Reserved
DMA_CROSSBAR_2	EXT_SYS_DREQ_0	External DMA request 0 (system expansion) - coming from SOC IOs. Level sensitive only
DMA_CROSSBAR_3	EXT_SYS_DREQ_1	External DMA request 1 (system expansion) - coming from SOC IOs. Level sentitive only
DMA_CROSSBAR_4	GPMC_DREQ	GPMC request from prefetch engine
DMA_CROSSBAR_5	Reserved	Reserved
DMA_CROSSBAR_6	DISPC_DREQ	The line trigger signal to synchronize a memory to memory logical channel in the DMA is generated by the Display Controller IP.
DMA_CROSSBAR_7	CT_TBR_DREQ	DMA request coming from CT_TBR in DEBUGSS (used to be External DMA request 2 - coming from SOC IOs)
DMA_CROSSBAR_8	Reserved	Reserved
DMA_CROSSBAR_9	ISS_DREQ_1	ISS DMA request 1[(1)]
DMA_CROSSBAR_10	ISS_DREQ_2	ISS DMA request 2[(1)]
DMA_CROSSBAR_11	Reserved	Reserved
DMA_CROSSBAR_12	ISS_DREQ_3	ISS DMA request 3[(1)]
DMA_CROSSBAR_13	ISS_DREQ_4	ISS DMA request 4[(1)]
DMA_CROSSBAR_14	Reserved	Reserved
DMA_CROSSBAR_15	MCSPI3_DREQ_TX0	McSPI module 3 - transmit request channel 0
DMA_CROSSBAR_16	MCSPI3_DREQ_RX0	McSPI module 3 - receive request channel 0
DMA_CROSSBAR_17 to DMA_CROSSBAR_22	Reserved	Reserved
DMA_CROSSBAR_23	MCSPI3_DREQ_TX1	McSPI module 3 - transmit request channel 1
DMA_CROSSBAR_24	MCSPI3_DREQ_RX1	McSPI module 3 - receive request channel 1
DMA_CROSSBAR_25	Reserved	Reserved
DMA_CROSSBAR_26	Reserved	Reserved
DMA_CROSSBAR_27	I2C1_DREQ_TX	I2C module 1 - transmit request
DMA_CROSSBAR_28	I2C1_DREQ_RX	I2C module 1 - receive request
DMA_CROSSBAR_29	I2C2_DREQ_TX	I2C module 2 - transmit request
DMA_CROSSBAR_30	I2C2_DREQ_RX	I2C module 2 - receive request
DMA_CROSSBAR_31 to DMA_CROSSBAR_34	Reserved	Reserved
DMA_CROSSBAR_35	MCSPI1_DREQ_TX0	McSPI module 1 - transmit request channel 0
DMA_CROSSBAR_36	MCSPI1_DREQ_RX0	McSPI module 1 - receive request channel 0
DMA_CROSSBAR_37	MCSPI1_DREQ_TX1	McSPI module 1 - transmit request channel 1
DMA_CROSSBAR_38	MCSPI1_DREQ_RX1	McSPI module 1 - receive request channel 1

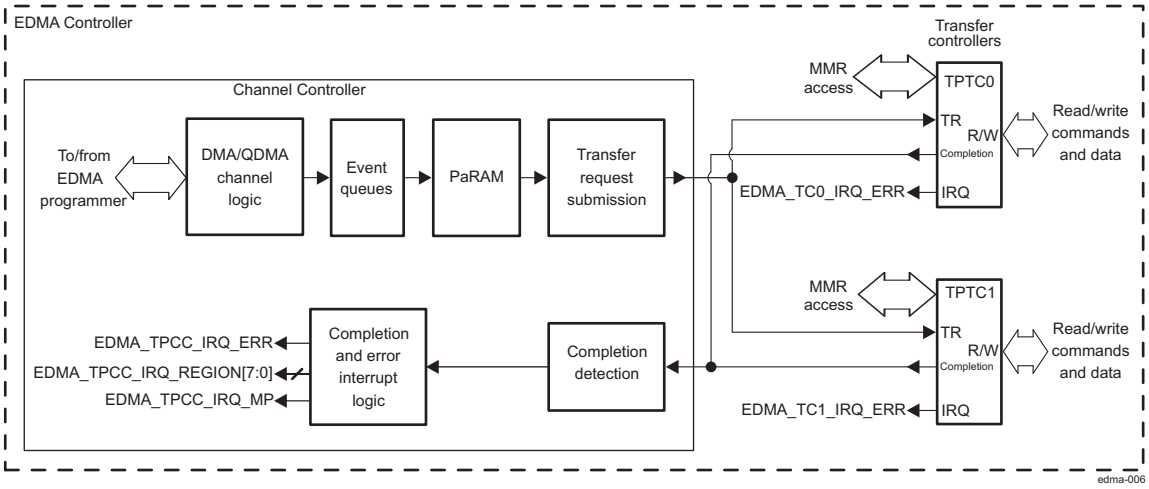
11.4 EDMA Controller Functional Description

This chapter discusses the architecture of the EDMA controller.

11.4.1 Block Diagram

Figure 11-4 shows the functional block diagram of the EDMA controller.

Figure 11-4. EDMA Controller Block Diagram



11.4.1.1 Third-Party Channel Controller

The TPCC is the EDMA transfer scheduler responsible for scheduling, arbitrating, and issuing user programmed transfers to the two TPTCs.

Figure 11-5 shows a functional block diagram of the EDMA channel controller (EDMA_TPCC).

The main blocks of the EDMA_TPCC are as follows:

- Parameter RAM (PaRAM): The PaRAM maintains parameter sets for channel and reload parameter sets. The PaRAM must be written with the transfer context for the desired channels and link parameter sets. EDMA_TPCC processes and sets based on a trigger event and submits a transfer request (TR) to the transfer controllers.
- EDMA event and interrupt processing registers: Allows mapping of events to parameter sets, enable/disable events, enable/disable interrupt conditions, and clearing interrupts.
- Completion detection: The completion detect block detects completion of transfers by the EDMA_TPTCs or slave peripherals. The completion of transfers can be used optionally to chain trigger new transfers or to assert interrupts.
- Event queues: Event queues form the interface between the event detection logic and the transfer request submission logic.
- Memory protection registers: Memory protection registers define the accesses (privilege level and requestor(s)) that are allowed to access the DMA channel shadow region view(s) and regions of PaRAM.

Other functions include the following:

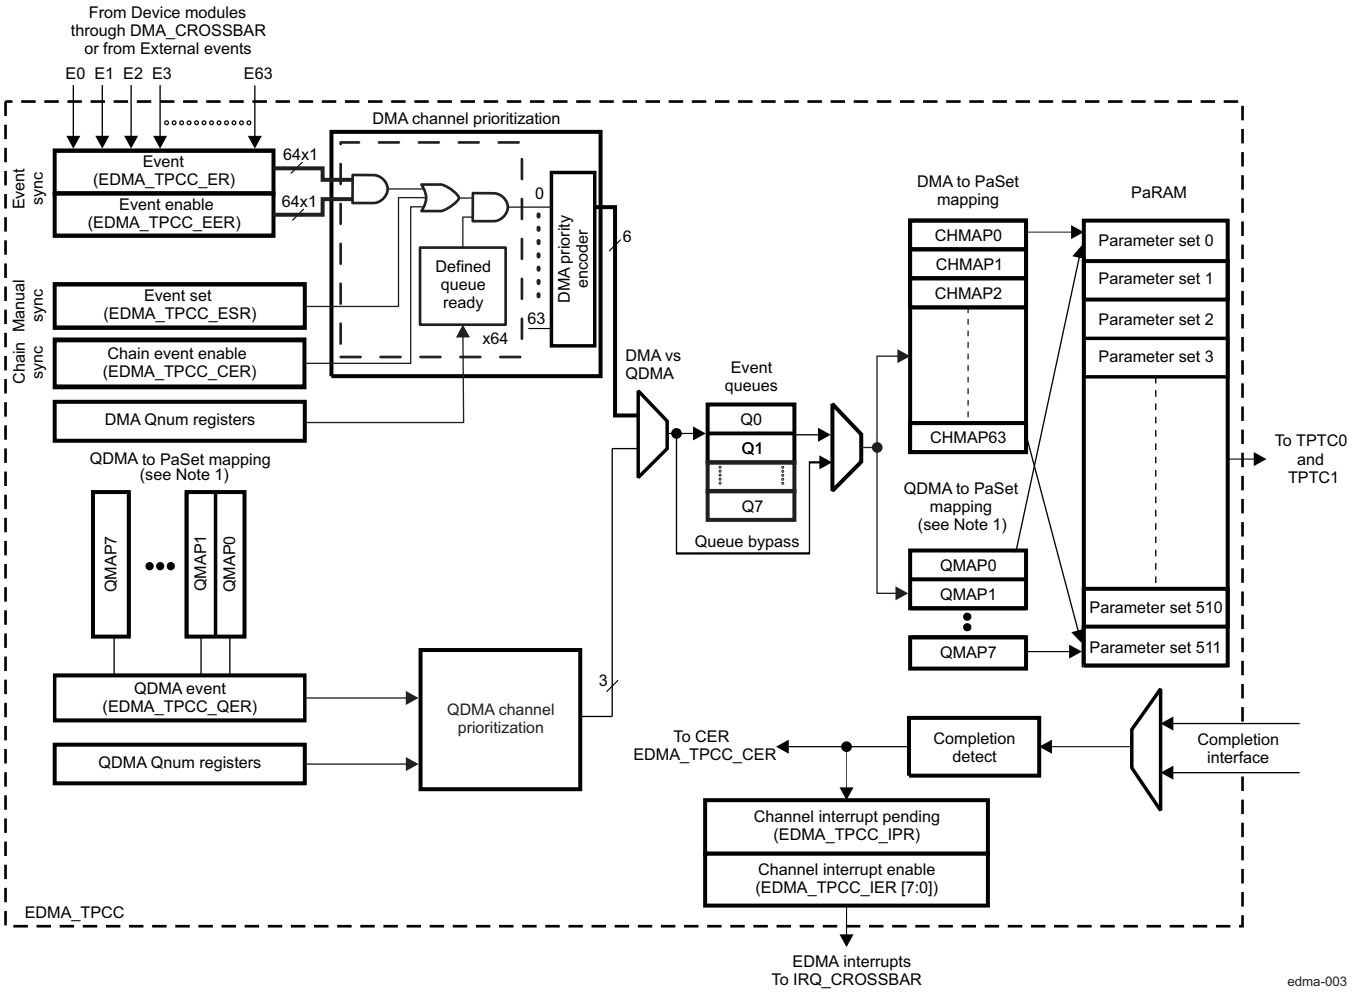
- Region registers: Region registers allow DMA resources (DMA channels and interrupts) to be assigned to unique regions that different EDMA programmers own (for example, DSPs).
- Debug registers: Debug registers allow debug visibility by providing registers to read the queue status, controller status, and missed event status.

The EDMA_TPCC includes two channel types: DMA channels (64 channels) and QDMA channels (8 channels).

Each channel is associated with a given event queue/transfer controller and with a given PaRAM set. The main difference between a DMA channel and a QDMA channel is the method that the system uses to trigger transfers.

Figure 11-5 is a block diagram of the EDMA_TPCC.

Figure 11-5. EDMA Channel Controller Block Diagram



(1) Although it is depicted twice in Figure 11-5, there is only one physical register set for the QDMA to PaRAM set mapping block.

The EDMA_TPCC supports up to 64 DMA channels and up to 8 QDMA channels. These channels are identical, except for how they are triggered:

- DMA channels are triggered by external events (such as McSPI modules TX event and McSPI modules RX event) by the event set registers EDMA_TPCC_ESR and EDMA_TPCC_ESRH, or through chaining register EDMA_TPCC_CER.
- QDMA channels are triggered automatically (auto-triggered) by the CPU. QDMAs allow a minimum number of linear writes to be issued to the TPCC to force a series of transfers to occur.

The TPCC arbitrates among pending DMA and QDMA events with a fixed [64:1] and [8:1] priority encoder for these events, respectively (a low channel number corresponds to a high priority).

DMA events are always higher priority than QDMA events. The higher-priority event is placed in the event queue to await submission to the transfer controllers, which occurs at the earliest opportunity. Each event queue is serviced in FIFO order, with a maximum of 16 queued events per event queue. If more than one TPTC is ready to be programmed with a transmission request (TR), the event queues are serviced with fixed priority: Q0 is higher than Q1. When an event is ready to be queued and the event queue and the TC channel are empty, the event bypasses the event queue and goes directly to the PaRAM processing logic for submission to the appropriate TC. If the transfer request TR bus or PaRAM processing are busy, the bypass path is not used. The bypass is not used to dequeue for a higher-priority event.

Events are extracted from the event queue when the EDMA_TPTC is available for a new TR to be programmed into the EDMA_TPTC (signaled with the empty signal, indicating an empty program register set). As an event is extracted from the event queue, the associated PaRAM entry is processed and submitted to the TPTC as a TR. The TPCC updates the appropriate counts and addresses in the PaRAM entry in anticipation of the next trigger event for that PaRAM entry.

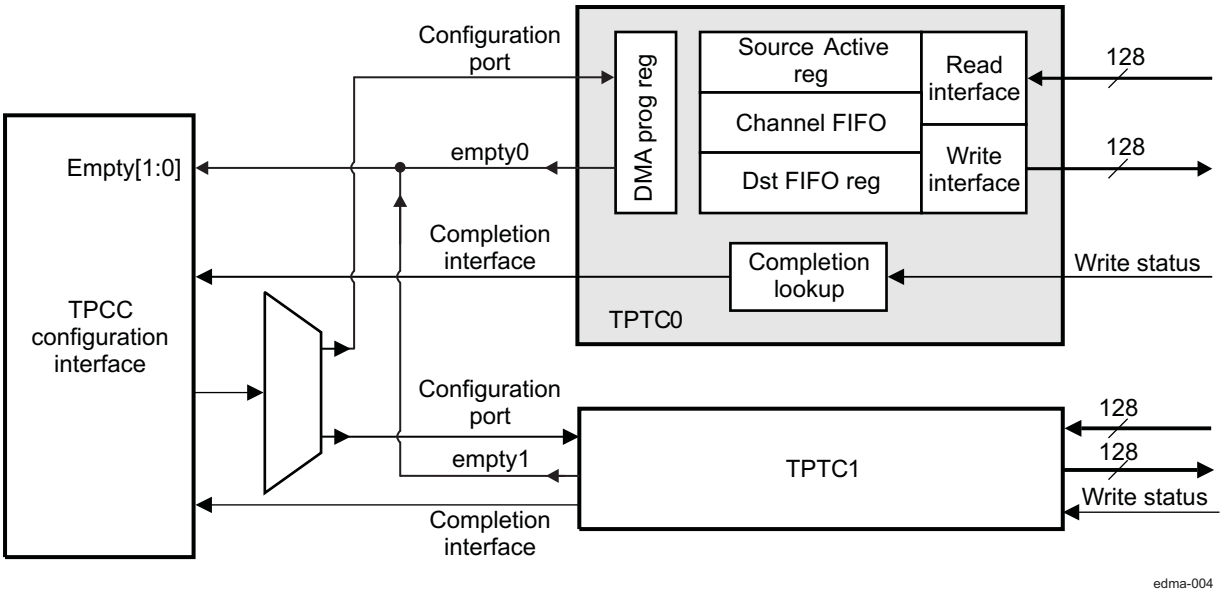
The EDMA_TPCC also has an error detection logic that causes an error interrupt generation on various error conditions (for example: missed events EDMA_TPCC_EMR and EDMA_TPCC_EMRH registers, exceeding event queue thresholds in EDMA_TPCC_CCERR register, etc.).

11.4.1.2 Third-Party Transfer Controller

The TPTC module is the EDMA transfer engine that generates transfers as programmed in dedicated working registers, using two dedicated master ports: a read-only port and a write-only port.

Figure 11-6 shows a functional block diagram and of the EDMA transfer controller (EDMA_TPTC) and its connection to the EDMA_TPCC.

Figure 11-6. TPTC Block Diagram



NOTE: The port data bus width of the instances of the TPTC is fixed at 128 bits.

Two instances of the EDMA_TPTC generate concurrent traffic on the L3_MAIN interconnect. Each TC controller consists of the following components:

- DMA Program Register Set: Stores the context for the DMA transfer that is loaded into the active register set when the current active register set completes. The CPU or TPCC programs the Program Register Set, not the active register set. For typical standalone operation, the CPU programs the Program Register while the TC services the Active register set. The Program Register set includes ownership control such that CPU software and the EDMA stay synchronized relative to one another.
- Source Active Register Set : Stores the context (src/dst/cnt/etc) for the DMA Transfer Request (TR) in

progress in the Read Controller. The Active register set is split into independent Source and Destination, because the source interconnect controller and the distant interconnect controller operate independently of one another.

- Destination FIFO Register Set: Stores the context (src/dst/cnt/etc) for the DMA Transfer Request (TR) in progress, or pending, in the Write Controller. The pending register must allow the source controller to begin processing a new TR while the distant register set processes the previous TR.
- Channel FIFO: Temporary holding buffer for in-flight data. The read return data of the source peripheral is stored in the Data FIFO, and then is written to the destination peripheral by the write command/data bus.
- Read Controller/Interconnect Read Interface: The Interconnect read interface issues optimally sized read commands to the source peripheral, based on a burst size of 128 bytes and available landing space in the channel FIFO.
- Write controller/Interconnect Write interface: The local interconnect write interface issues optimally sized write commands to the destination peripheral, based on a burst size of 128 bytes and available data in the channel FIFO.
- Completion interface: sends completion codes to the EDMA_TPCC when a transfer completes and generates interrupts and chained events in the TPCC module.
- Configuration port: Slave interface that provides read/write access to program registers and read access to all memory-mapped TPTC registers.

When one EDMA_TPTC module is idle and receive its first TR, DMA program register set receives the TR, where it transitions to the DMA source active set and the destination FIFO register set immediately. The second TR (if pending from EDMA_TPCC) is loaded into the DMA program set, ensuring it can start as soon as possible when the active transfer completes. As soon as the current active set is exhausted, the TR is loaded from the DMA program register set into the DMA source active register set as well as to the appropriate entry in the destination FIFO register set.

The read controller issues read commands controlled by the rules of command fragmentation and optimization. These are issued only when the data FIFO has space available for the data read. When sufficient data is in the data FIFO, the write controller starts issuing a write command again following the rules for command fragmentation and optimization.

Depending on the number of entries, the read controller can process up to two or four transfer requests ahead of the destination subject to the amount of free data FIFO.

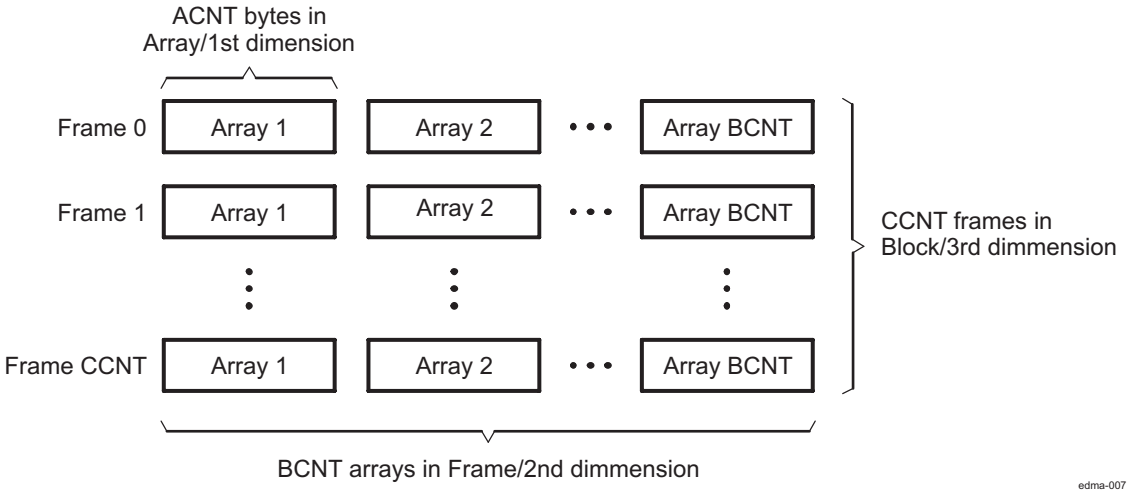
11.4.2 Types of EDMA controller Transfers

An EDMA transfer is always defined in terms of three dimensions. Figure 11-7 shows the three dimensions used by EDMA controller transfers. These three dimensions are defined as:

- 1st Dimension or Array (A): The 1st dimension in a transfer consists of EDMA_TPCC_ABCNT_n[15:0] ACNT contiguous bytes.
- 2nd Dimension or Frame (B): The 2nd dimension in a transfer consists of EDMA_TPCC_ABCNT_n[31:16] BCNT arrays of ACNT bytes. Each array transfer in the 2nd dimension is separated from each other by an index programmed using bit-fields EDMA_TPCC_BIDX_n[15:0] SBIDX or EDMA_TPCC_BIDX_n[31:16] DBIDX.
- 3rd Dimension or Block (C): The 3rd dimension in a transfer consists of CCNT frames of BCNT arrays of ACNT bytes. The Count for 3rd Dimension is defined in register EDMA_TPCC_CCNT_n[15:0] CCNT. Each transfer in the 3rd dimension is separated from the previous by an index programmed using EDMA_TPCC_CIDX_n[15:0] SCIDX or EDMA_TPCC_CIDX_n[31:16] DCIDX.

NOTE: The reference point for the index depends on the synchronization type. The amount of data transferred upon receipt of a trigger/synchronization event is controlled by the synchronization types (EDMA_TPCC_OPT_n[2] SYNCDIM bit). For these three dimensions, only two synchronization types are supported: A-synchronized transfers and AB-synchronized transfers.

Figure 11-7. Definition of ACNT, BCNT, and CCNT



11.4.2.1 A-Synchronized Transfers

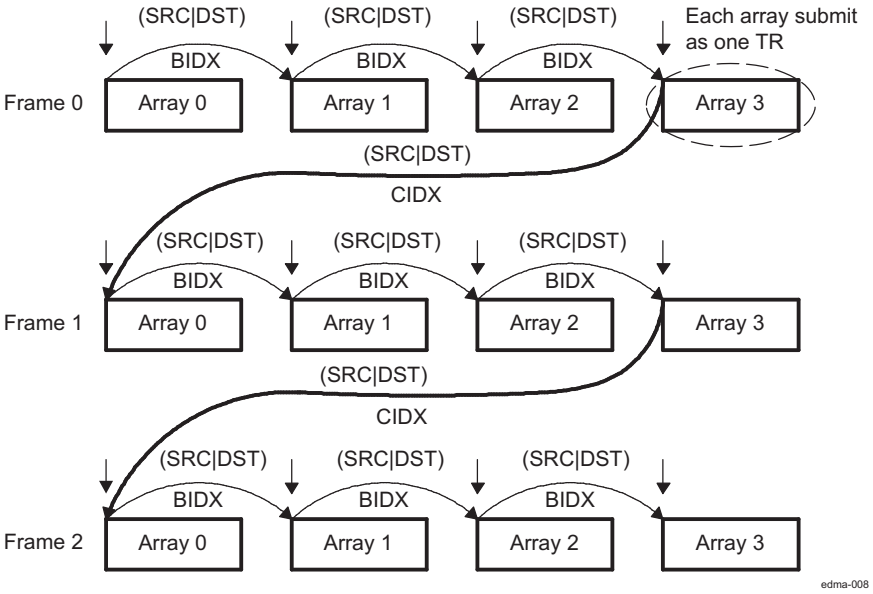
In an A-synchronized transfer, each EDMA sync event initiates the transfer of the 1st dimension of EDMA_TPCC_ABCNT_n[15:0] ACNT bytes, or one array of ACNT bytes. Each event/TR packet conveys the transfer information for one array only. Thus, BCNT × CCNT events are needed to completely service a PaRAM set.

Arrays are always separated by EDMA_TPCC_BIDX_n[15:0]SBIDX and EDMA_TPCC_BIDX_n[31:16] DBIDX, as shown in Figure 11-8, where the start address of Array N is equal to the start address of Array N – 1 plus source (SRC) or destination (DST) in EDMA_TPCC_BIDX_n register.

Frames are always separated by EDMA_TPCC_CIDX_n[15:0] SCIDX and EDMA_TPCC_CIDX_n[31:16] DCIDX. For A-synchronized transfers, after the frame is exhausted, the address is updated by adding SRCCIDX/DSTCIDX to the beginning address of the last array in the frame. As in Figure 11-8, SRCCIDX / DSTCIDX is the difference between the start of Frame 0 Array 3 to the start of Frame 1 Array 0.

Figure 11-8 shows an A-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of n (ACNT) bytes. In this example, a total of 12 sync events (BCNT × CCNT) exhaust a PaRAM set. See Figure 11-8 for details on parameter set updates.

Figure 11-8. A-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)



11.4.2.2 AB-Synchronized Transfers

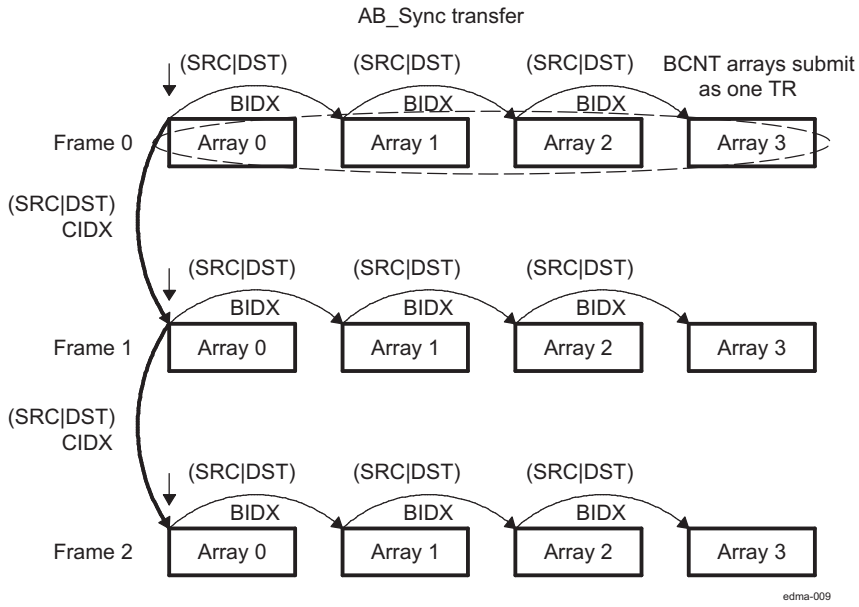
In a AB-synchronized transfer, each EDMA sync event initiates the transfer of 2 dimensions or one frame. Each event/TR packet conveys information for one entire frame of BCNT_n arrays of ACNT_n bytes. Thus, EDMA_TPCC_CCNT_n events are needed to completely service a PaRAM set.

Arrays are always separated by EDMA_TPCC_BIDX_n[15:0] SBIDX and EDMA_TPCC_BIDX_n[31:16] DBIDX as shown in Figure 11-9. Frames are always separated by SRCCIDX and DSTCIDX.

Note that for AB-synchronized transfers, after a TR for the frame is submitted, the address update is to add EDMA_TPCC_CIDX_n[15:0] SCIDX / EDMA_TPCC_CIDX_n[31:16] DCIDX to the beginning address of the beginning array in the frame. This is different from A-synchronized transfers where the address is updated by adding SRCCIDX/DSTCIDX to the start address of the last array in the frame. See Section 11.4.3.6 *Parameter Set Updates* for details on parameter set updates.

Figure 11-9 shows an AB-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of *n* (ACNT) bytes. In this example, a total of 3 sync events (CCNT) exhaust a PaRAM set; that is, a total of 3 transfers of 4 arrays each completes the transfer.

Figure 11-9. AB-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)



NOTE: ABC-synchronized transfers are not directly supported. It can be logically achieved by chaining between multiple AB-synchronized transfers.

11.4.3 Parameter RAM (PaRAM)

The EDMA controller is a RAM-based architecture. The transfer context (source/destination addresses, count, indexes, etc.) for DMA or QDMA channels is programmed in a parameter RAM table in EDMA_TPCC. The PaRAM table is segmented into multiple PaRAM sets. Each PaRAM set includes eight four-byte PaRAM set entries (32-bytes total per PaRAM set), which includes typical DMA transfer parameters such as source address, destination address, transfer counts, indexes, options, etc.

The PaRAM structure supports flexible ping-pong, circular buffering, channel chaining, and auto-reloading (linking).

The contents of the PaRAM include the following:

- 512 PaRAM sets
- 64 channels that are direct mapped and can be used as link or QDMA sets if not used for DMA channels

- 64 channels remain for link or QDMA sets

By default, all channels map to PaRAM set to 0, they should be remapped before use by EDMA_TPCC_DCHMAPN_m and EDMA_TPCC_QCHMAPN_j registers.

Table 11-9. EDMA Parameter RAM Contents

PaRAM Set Number	Base Address	Parameters[1]
0	EDMA Base Address + 4000h to EDMA Base Address + 401Fh	PaRAM set 0
1	EDMA Base Address + 4020h to EDMA Base Address + 403Fh	PaRAM set 1
2	EDMA Base Address + 4040h to EDMA Base Address + 405Fh	PaRAM set 2
3	EDMA Base Address + 4060h to EDMA Base Address + 407Fh	PaRAM set 3
4	EDMA Base Address + 4080h to EDMA Base Address + 409Fh	PaRAM set 4
5	EDMA Base Address + 40A0h to EDMA Base Address + 40BFh	PaRAM set 5
6	EDMA Base Address + 40C0h to EDMA Base Address + 40DFh	PaRAM set 6
7	EDMA Base Address + 40E0h to EDMA Base Address + 40FFh	PaRAM set 7
8	EDMA Base Address + 4100h to EDMA Base Address + 411Fh	PaRAM set 8
9	EDMA Base Address + 4120h to EDMA Base Address + 413Fh	PaRAM set 9
...	...	...
63	EDMA Base Address + 47E0h to EDMA Base Address + 47FFh	PaRAM set 63
64	EDMA Base Address + 4800h to EDMA Base Address + 481Fh	PaRAM set 64
65	EDMA Base Address + 4820h to EDMA Base Address + 483Fh	PaRAM set 65
...	...	...
510	EDMA Base Address + 7FC0h to EDMA Base Address + 7FDFh	PaRAM set 510
511	EDMA Base Address + 7FE0h to EDMA Base Address + 7FFFh	PaRAM set 511

(1) The device has 8 QDMA channels that can be mapped to any parameter set number from 0 to 511.

11.4.3.1 PaRAM

Each parameter set of PaRAM is organized into eight 32-bit words or 32 bytes, as shown in Figure 11-10 and described in Table 11-10. Each PaRAM set consists of 16-bit and 32-bit parameters.

Figure 11-10. PaRAM Set

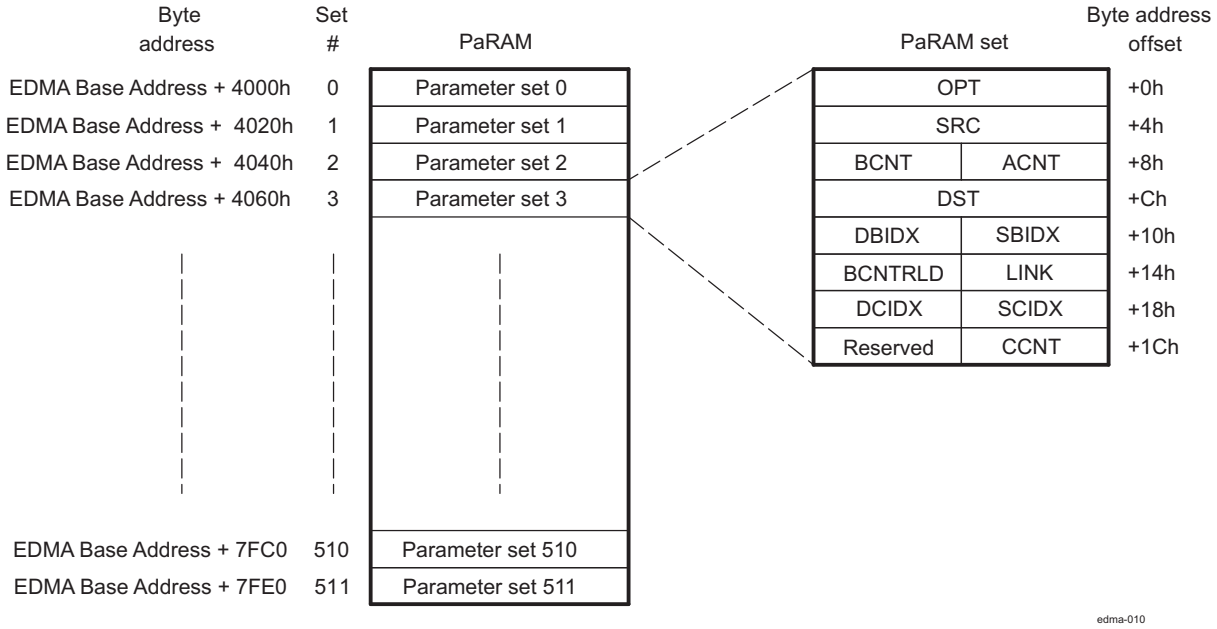


Table 11-10. EDMA Channel Parameter Description

Offset Address (bytes)	Acronym	Parameter	Description
0h	OPT	Channel Options EDMA_TPCC_OPT_n register	Transfer configuration options
4h	SRC	Channel Source Address EDMA_TPCC_SRC_n register	The byte address from which data is transferred
8h[1]	ACNT	Count for 1st Dimension EDMA_TPCC_ABCNT_n[15:0] ACNT bit-field.	Unsigned value specifying the number of contiguous bytes within an array (first dimension of the transfer). Valid values range from 1 to 65 535.
	BCNT	Count for 2nd Dimension EDMA_TPCC_ABCNT_n[31:16] BCNT bit-field.	Unsigned value specifying the number of arrays in a frame, where an array is ACNT bytes. Valid values range from 1 to 65 535.
Ch	DST	Channel Destination Address EDMA_TPCC_DST_n register	The byte address to which data is transferred
10h[1]	SBIDX	Source BCNT Index EDMA_TPCC_BIDX_n[15:0] SBIDX bit-field.	Signed value specifying the byte address offset between source arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
	DBIDX	Destination BCNT Index EDMA_TPCC_BIDX_n[31:16] DBIDX bit-field.	Signed value specifying the byte address offset between destination arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
14h[1]	LINK	Link Address EDMA_TPCC_LNK_n[15:0] LINK bit-field	The PaRAM address containing the PaRAM set to be linked (copied from) when the current PaRAM set is exhausted. A value of FFFFh specifies a null link.
	BCNTRLD	BCNT Reload EDMA_TPCC_LNK_n[31:16] BCNTRLD bit-field	The count value used to reload BCNT when BCNT decrements to 0 (TR is submitted for the last array in 2nd dimension). Only relevant in A-synchronized transfers.
18h[1]	SCIDX	Source CCNT index. EDMA_TPCC_CIDX_n[15:0] SCIDX bit-field.	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last source array in a frame to the beginning of the first source array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first source array in a frame to the beginning of the first source array in the next frame.
	DCIDX	Destination CCNT index. EDMA_TPCC_CIDX_n[31:16] DCIDX bit-field.	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last destination array in a frame to the beginning of the first destination array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first destination array in a frame to the beginning of the first destination array in the next frame.
1Ch	CCNT	Count for 3rd Dimension. EDMA_TPCC_CCNT_n[15:0] CCNT bit-field.	Unsigned value specifying the number of frames in a block, where a frame is BCNT arrays of ACNT bytes. Valid values range from 1 to 65 535.
	Reserved	Reserved	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

(1) If OPT, SRC, or DST is the trigger word for a QDMA transfer then it is required to do a 32-bit access to that field. Furthermore, it is recommended to perform only 32-bit accesses on the parameter RAM for best code compatibility. For example, switching the endianness of the processor will swap addresses of the 16-bit fields, but 32-bit accesses avoid the issue entirely.

11.4.3.2 EDMA Channel PaRAM Set Entry Fields

11.4.3.2.1 Channel Options Parameter (OPT)

For detailed information about the channel options parameter, see the EDMA_TPCC_OPT_n register description in Section 11.7.2.2.1, *EDMA_TPCC Register Description*.

11.4.3.2.2 Channel Source Address (SRC)

The 32-bit source address parameter specifies the starting byte address of the source. For SAM in increment mode, there are no alignment restrictions imposed by EDMA. For SAM in constant addressing mode, it must program the source address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). If this rule is not observed, the EDMA_TPTC returns an error. Refer to Section 11.4.12.3 *Error Generation* for additional details.

11.4.3.2.3 Channel Destination Address (DST)

The 32-bit destination address parameter specifies the starting byte address of the destination. For DAM in increment mode, there are no alignment restrictions imposed by EDMA. For DAM in constant addressing mode, it must program the destination address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). If this rule is not observed, the EDMA_TPTC returns an error. Refer to Section 11.4.12.3 *Error Generation* for additional details.

11.4.3.2.4 Count for 1st Dimension (ACNT)

EDMA_TPCC_ABCNT_n[15:0] ACNT represents the number of bytes within the 1st dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65 535. Therefore, the maximum number of bytes in an array is 65 535 bytes (64K – 1 bytes). ACNT must be greater than or equal to 1 for a TR to be submitted to EDMA_TPTC. A transfer with ACNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in EDMA_TPCC_OPT_n.

Refer to Section 11.4.3.5 *Dummy Versus Null Transfer Comparison* and Section 11.4.5.3 *Dummy or Null Completion* for details on dummy/null completion conditions.

11.4.3.2.5 Count for 2nd Dimension (BCNT)

EDMA_TPCC_ABCNT_n[15:0] BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT are between 1 and 65 535. Therefore, the maximum number of arrays in a frame is 65 535 (64K – 1 arrays). A transfer with BCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in EDMA_TPCC_OPT_n.

Refer to Section 11.4.3.5 *Dummy Versus Null Transfer Comparison* and Section 11.4.5.3 *Dummy or Null Completion* for details on dummy/null completion conditions.

11.4.3.2.6 Count for 3rd Dimension (CCNT)

EDMA_TPCC_CCNT_n[15:0] CCNT is a 16-bit unsigned value that specifies the number of frames in a block. Valid values for CCNT are between 1 and 65 535. Therefore, the maximum number of frames in a block is 65 535 (64K – 1 frames). A transfer with CCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in EDMA_TPCC_OPT_n.

A CCNT value of 0 is considered either a null or dummy transfer.

Refer to Section 11.4.3.5 *Dummy Versus Null Transfer Comparison* and Section 11.4.5.3 *Dummy or Null Completion* for details on dummy/null completion conditions.

11.4.3.2.7 BCNT Reload (BCNTRLD)

EDMA_TPCC_LNK_n[31:16] BCNTRLD is a 16-bit unsigned value used to reload the EDMA_TPCC_ABCNT_n[15:0] BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-synchronized transfers. In this case, the EDMA_TPCC decrements the BCNT value by 1 on each TR submission. When BCNT reaches 0, the EDMA_TPCC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value.

For AB-synchronized transfers, the EDMA_TPCC submits the BCNT in the TR and the EDMA_TPTC decrements BCNT appropriately. For AB-synchronized transfers, BCNTRLD is not used.

11.4.3.2.8 Source B Index (SBIDX)

EDMA_TPCC_BIDX_n[15:0] SBIDX is a 16-bit signed value (2s complement) used for source address modification between each array in the 2nd dimension. Valid values for EDMA_TPCC_BIDX_n[15:0] SBIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-synchronized and AB-synchronized transfers. Some examples:

- EDMA_TPCC_BIDX_n[15:0] SBIDX = 0000h (0): no address offset from the beginning of an array to the beginning of the next array. All arrays are fixed to the same beginning address.
- EDMA_TPCC_BIDX_n[15:0] SBIDX = 0003h (+3): the address offset from the beginning of an array to the beginning of the next array in a frame is 3 bytes. For example, if the current array begins at address 1000h, the next array begins at 1003h.
- EDMA_TPCC_BIDX_n[15:0] SBIDX = FFFFh (–1): the address offset from the beginning of an array to the beginning of the next array in a frame is –1 byte. For example, if the current array begins at address 5054h, the next array begins at 5053h.

11.4.3.2.9 Destination B Index (DBIDX)

EDMA_TPCC_BIDX_n[31:16] DBIDX is a 16-bit signed value (2s complement) used for destination address modification between each array in the 2nd dimension. Valid values for EDMA_TPCC_BIDX_n[31:16] DBIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-synchronized and AB-synchronized transfers. Refer to Section 11.4.3.2.8 *Source B Index (SBIDX)* for examples.

11.4.3.2.10 Source C Index (SCIDX)

EDMA_TPCC_CIDX_n[15:0] SCIDX is a 16-bit signed value (2s complement) used for source address modification in the 3rd dimension. Valid values for EDMA_TPCC_CIDX_n[15:0] SCIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-synchronized and AB-synchronized transfers.

NOTE: When SCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 11-8), while the current array in an AB-synchronized transfer is the first array in the frame (Figure 11-9).

11.4.3.2.11 Destination C Index (DCIDX)

EDMA_TPCC_CIDX_n[31:16] DCIDX is a 16-bit signed value (2s complement) used for destination address modification in the 3rd dimension. Valid values are between –32 768 and 32 767. It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array TR in the next frame. It applies to both A-synchronized and AB-synchronized transfers.

NOTE: When DCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 11-8), while the current array in a AB-synchronized transfer is the first array in the frame (Figure 11-9).

11.4.3.2.12 Link Address (LINK)

The EDMA_TPCC provides a mechanism, called linking, to reload the current PaRAM set upon its natural termination (that is, after the count fields are decremented to 0) with a new PaRAM set. The 16-bit parameter EDMA_TPCC_LNK_n[15:0] LINK specifies the byte address offset in the PaRAM from which the EDMA_TPCC loads/reloads the next PaRAM set during linking.

It must program the link address to point to a valid aligned 32-byte PaRAM set. The 5 LSBs of the LINK field should be cleared to 0.

The EDMA_TPCC ignores the upper 2 bits of the LINK entry, allowing the flexibility of programming the link address as either an absolute/literal byte address or use the PaRAM-base-relative offset address. Therefore, if it use the literal address with a range from 4000h to 7FFFh, it will be treated as a PaRAM-base-relative value of 0000h to 3FFFh.

It should check that the programed value in the EDMA_TPCC_LNK_n[15:0] LINK field is correctly, so that link update is requested from a PaRAM address that falls in the range of the available PaRAM addresses on the device.

Value of FFFFh in EDMA_TPCC_LNK_n[15:0] LINK bit-field is referred to as a NULL link that should cause the EDMA_TPCC to perform an internal write of 0 to all entries of the current PaRAM set, except for the EDMA_TPCC_LNK_n[15:0] LINK field is set to FFFFh. Also, see Section 11.4.5 *Completion of a DMA Transfer* for details on terminating a transfer.

11.4.3.3 Null PaRAM Set

A null PaRAM set is defined as a PaRAM set where all count fields (EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, and EDMA_TPCC_CCNT_n[15:0] CCNT) are cleared to 0. If a PaRAM set associated with a channel is a NULL set, then when serviced by the EDMA_TPCC, the bit corresponding to the channel is set in the associated event missed register (EDMA_TPCC_EMR, EDMA_TPCC_EMRH, or EDMA_TPCC_QEMR). This bit remains set in the associated secondary event register (EDMA_TPCC_SER, EDMA_TPCC_SERH, or EDMA_TPCC_QSER).
This implies that any future events on the same channel are ignored by the EDMA_TPCC and it is required to clear the bit in EDMA_TPCC_SER, EDMA_TPCC_SERH, or EDMA_TPCC_QSER for the channel. This is considered an error condition, since events are not expected on a channel that is configured as a null transfer.

11.4.3.4 Dummy PaRAM Set

A dummy PaRAM set is defined as a PaRAM set where at least one of the count fields (EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, or EDMA_TPCC_CCNT_n[15:0] CCNT) is cleared to 0 and at least one of the count fields is nonzero.

If a PaRAM set associated with a channel is a dummy set, then when serviced by the EDMA_TPCC, it will not set the bit corresponding to the channel (DMA/QDMA) in the event missed register (EDMA_TPCC_EMR, EDMA_TPCC_EMRH, or EDMA_TPCC_QEMR) and the secondary event register (EDMA_TPCC_SER, EDMA_TPCC_SERH, or EDMA_TPCC_QSER) bit gets cleared similar to a normal transfer. Future events on that channel are serviced. A dummy transfer is a legal transfer of 0 bytes.

11.4.3.5 Dummy Versus Null Transfer Comparison

There are some differences in the way the EDMA_TPCC logic treats a dummy versus a null transfer request. A null transfer request is an error condition, but a dummy transfer is a legal transfer of 0 bytes. A null transfer causes an error bit (E*n*) in EDMA_TPCC_EMR to get set and the E*n* bit in EDMA_TPCC_SER remains set, essentially preventing any further transfers on that channel without clearing the associated error registers.

Table 11-11 summarizes the conditions and effects of null and dummy transfer requests.

Table 11-11. Dummy and Null Transfer Request

Feature	Null TR	Dummy TR
EDMA_TPCC_EMR / EDMA_TPCC_EMRH / EDMA_TPCC_QEMR is set	Yes	No
EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER remains set	Yes	No
Link update (STATIC = 0 in EDMA_TPCC_OPT_n)	Yes	Yes
EDMA_TPCC_QER is set	Yes	Yes
EDMA_TPCC_IPR / EDMA_TPCC_IPRH, EDMA_TPCC_CER / EDMA_TPCC_CERH is set using early completion	Yes	Yes

11.4.3.6 Parameter Set Updates

When a TR is submitted for a given DMA/QDMA channel and its corresponding PaRAM set, the EDMA_TPCC is responsible for updating the PaRAM set in anticipation of the next trigger event. For events that are not final, this includes address and count updates; for final events, this includes the link update.

The specific PaRAM set entries that are updated depend on the channel's synchronization type (A-synchronized or B-synchronized) and the current state of the PaRAM set. A B-update refers to the decrementing of EDMA_TPCC_ABCNT_n[31:16] BCNT in the case of A-synchronized transfers after the submission of successive TRs. A C-update refers to the decrementing of CCNT in the case of A-synchronized transfers after BCNT TRs for EDMA_TPCC_ABCNT_n[15:0] ACNT byte transfers have submitted. For AB-synchronized transfers, a C-update refers to the decrementing of EDMA_TPCC_CCNT_n[15:0] CCNT after submission of every transfer request.

Refer to Table 11-12 for details and conditions on the parameter updates. A link update occurs when the PaRAM set is exhausted, as described in Section 11.4.3.7 *Linking Transfers*.

After the TR is read from the PaRAM (and is in process of being submitted to EDMA_TPTC), the following fields are updated if needed:

- A-synchronized: BCNT, CCNT, SRC, DST.
- AB-synchronized: CCNT, SRC, DST.

The following fields are not updated (except for during linking, where all fields are overwritten by the link PaRAM set):

- A-synchronized: EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_LNK_n[31:16] BCNTRLD, EDMA_TPCC_BIDX_n[15:0] SBIDX, EDMA_TPCC_BIDX_n[31:16] DBIDX, EDMA_TPCC_CIDX_n[15:0] SCIDX, EDMA_TPCC_CIDX_n[31:16] DCIDX, EDMA_TPCC_OPT_n, EDMA_TPCC_LNK_n[15:0]LINK.
- AB-synchronized: EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, EDMA_TPCC_LNK_n[31:16] BCNTRLD, EDMA_TPCC_BIDX_n[15:0] SBIDX, EDMA_TPCC_BIDX_n[31:16] DBIDX, EDMA_TPCC_CIDX_n[15:0] SCIDX, EDMA_TPCC_CIDX_n[31:16] DCIDX, EDMA_TPCC_OPT_n, EDMA_TPCC_LNK_n[15:0]LINK.

NOTE: PaRAM updates only pertain to the information that is needed to properly submit the next transfer request to the EDMA_TPTC. Updates that occur while data is moved within a transfer request are tracked within the transfer controller, and is detailed in Section 11.4.12 *EDMA Transfer Controller (EDMA_TPTC)*. For A-synchronized transfers, the EDMA_TPCC always submits a TRP for EDMA_TPCC_ABCNT_n[15:0] ACNT bytes (EDMA_TPCC_ABCNT_n[31:16] BCNT = 1 and EDMA_TPCC_CCNT_n[15:0] CCNT = 1). For AB-synchronized transfers, the EDMA_TPCC always submits a TRP for EDMA_TPCC_ABCNT_n[15:0] ACNT bytes of BCNT arrays (EDMA_TPCC_CCNT_n[15:0] CCNT = 1). The EDMA_TPTC is responsible for updating source and destination addresses within the array based on EDMA_TPCC_ABCNT_n[15:0] ACNT and EDMA_TPCC_OPT_n[10:8] FWID. For AB-synchronized transfers, the EDMA_TPTC is also responsible to update source and destination addresses between arrays based on EDMA_TPCC_BIDX_n[15:0] SBIDX and EDMA_TPCC_BIDX_n[31:16] DBIDX.

Table 11-12 shows the details of parameter updates that occur within EDMA_TPCC for A-synchronized and AB-synchronized transfers.

Table 11-12. Parameter Updates in EDMA_TPCC (for Non-Null, Non-Dummy PaRAM Set)

	A-Synchronized Transfer			AB-Synchronized Transfer		
	B-Update	C-Update	Link Update	B-Update	C-Update	Link Update
Condition:	BCNT > 1	BCNT == 1 && CCNT > 1	BCNT == 1 && CCNT == 1	N/A	EDMA_TPCC_CCNT_n[15:0] CCNT > 1	EDMA_TPCC_CCNT_n[15:0] CCNT == 1
SRC	+= SBIDX	+= SCIDX	= Link.EDMA_TPCC_SRC_n	in EDMA_TPTC	+= SCIDX	= Link.EDMA_TPCC_SRC_n
DST	+= DBIDX	+= DCIDX	= Link.EDMA_TPCC_DST_n	in EDMA_TPTC	+= DCIDX	= Link.EDMA_TPCC_DST_n
ACNT	None	None	= Link.EDMA_TPCC_ABCNT_n[15:0] ACNT	None	None	= Link.EDMA_TPCC_ABCNT_n[15:0] ACNT
BCNT	–= 1	= BCNTRLD	= Link.EDMA_TPCC_ABCNT_n[31:16] BCNT	in EDMA_TPTC	N/A	= Link.EDMA_TPCC_ABCNT_n[31:16] BCNT
CCNT	None	–= 1	= Link.EDMA_TPCC_CCNT_n[15:0] CCNT	in EDMA_TPTC	-=1	= Link.EDMA_TPCC_CCNT_n[15:0] CCNT

DCIDX	None	None	= Link.EDMA_TPCC_BIDX_n[31:16] DBIDX	None	None	= Link.EDMA_TPCC_BIDX_n[31:16] DBIDX
LINK	None	None	= Link.EDMA_TPCC_LNK_n[15:0]LINK	None	None	= Link.EDMA_TPCC_LNK_n[15:0]LINK
BCNTRLD	None	None	= Link.EDMA_TPCC_LNK_n[31:16] BCNTRLD	None	None	= Link.EDMA_TPCC_LNK_n[31:16] BCNTRLD
OPT[1]	None	None	= LINK.EDMA_TPCC_OPT_n	None	None	= LINK.EDMA_TPCC_OPT_n

(1) In all cases, no updates occur if EDMA_TPCC_OPT_n[3] STATIC == 1 for the current PaRAM set.

NOTE: The EDMA_TPCC includes no special hardware to detect when an indexed address update calculation overflows/underflows. The address update will wrap across boundaries as programmed by the user. It should ensure that no transfer is allowed to cross internal port boundaries between peripherals. A single TR must target a single source/destination slave endpoint.

11.4.3.7 Linking Transfers

The EDMA_TPCC provides a mechanism known as linking, which allows the entire PaRAM set to be reloaded from a location within the PaRAM memory map (for both DMA and QDMA channels). Linking is especially useful for maintaining ping-pong buffers, circular buffering, and repetitive/continuous transfers with no CPU intervention. Upon completion of a transfer, the current transfer parameters are reloaded with the parameter set pointed that the 16-bit link address field of the current parameter set points to. Linking only occurs when the EDMA_TPCC_OPT_n[3] STATIC bit is cleared.

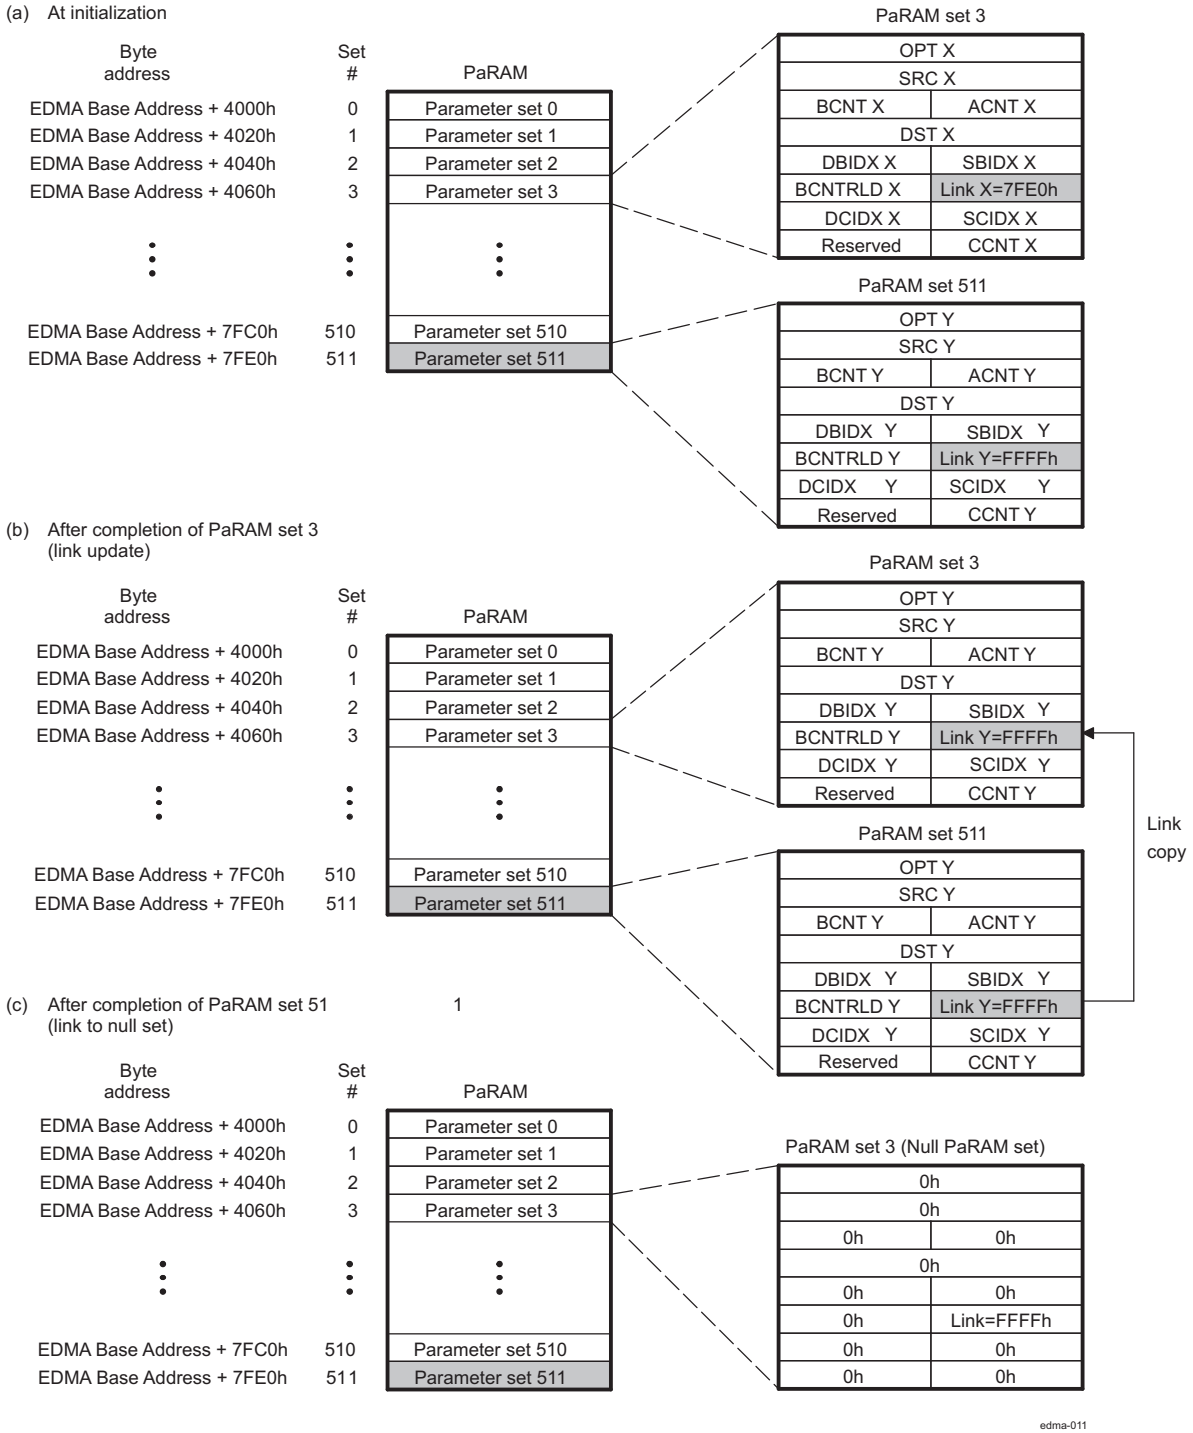
NOTE: It should always link a transfer (EDMA or QDMA) to another useful transfer. If it must terminate a transfer, then link the transfer to a NULL parameter set. Refer to Section 11.4.3.3 *Null PaRAM Set*.

The link update occurs after the current PaRAM set event parameters have been exhausted. An event's parameters are exhausted when the EDMA channel controller has submitted all of the transfers that are associated with the PaRAM set.

A link update occurs for null and dummy transfers depending on the state of the EDMA_TPCC_OPT_n[3] STATIC bit and the EDMA_TPCC_LNK_n[15:0] LINK field. In both cases (null or dummy), if the value of EDMA_TPCC_LNK_n[15:0] LINK is FFFFh, then a null PaRAM set (with all 0s and EDMA_TPCC_LNK_n[15:0] LINK set to FFFFh) is written to the current PaRAM set. Similarly, if EDMA_TPCC_LNK_n[15:0] LINK is set to a value other than FFFFh, then the appropriate PaRAM location that EDMA_TPCC_LNK_n[15:0] LINK points to is copied to the current PaRAM set.

Once the channel completion conditions are met for an event, the transfer parameters that are located at the link address are loaded into the current DMA or QDMA channel's associated parameter set. This indicates that the EDMA_TPCC reads the entire set (eight words) from the PaRAM set specified by EDMA_TPCC_LNK_n[15:0] LINK and writes all eight words to the PaRAM set that is associated with the current channel. Figure 11-11 shows an example of a linked transfer.

Figure 11-11. Linked Transfer

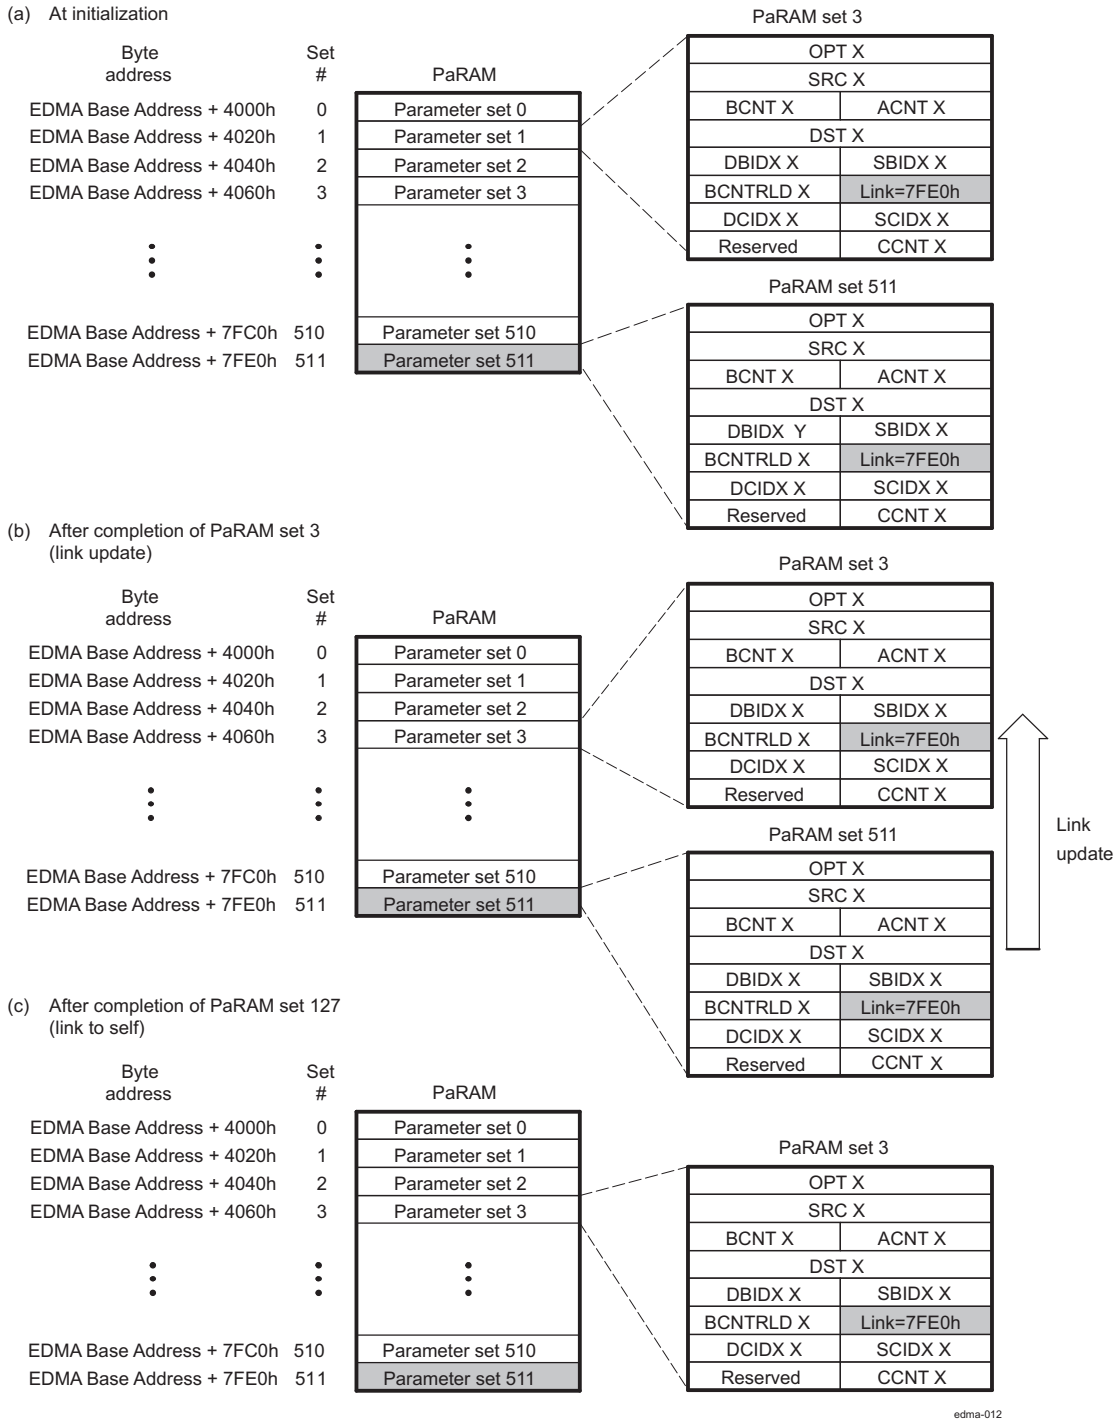


Any PaRAM set in the PaRAM can be used as a link/reload parameter set. The PaRAM sets associated with peripheral synchronization events (refer to Section 11.4.6 *Event, Channel, and PaRAM Mapping*) only use for linking if the corresponding events are disabled.

If a PaRAM set location is defined as a QDMA channel PaRAM set (by EDMA_TPCC_QCHMAPN_j register), then copying the link PaRAM set into the current QDMA channel PaRAM set is recognized as a trigger event. It is latched in EDMA_TPCC_QER because a write to the trigger word was performed. This feature is used to create a linked list of transfers using a single QDMA channel and multiple PaRAM sets. Refer to Section 11.4.4.2 *QDMA Channels*.

Linking to itself replicates the behavior of auto-initialization, thus facilitating the use of circular buffering and repetitive transfers. After an EDMA channel exhausts its current PaRAM set, it reloads all of the parameter set entries from another PaRAM set, which is initialized with values that are identical to the original PaRAM set. Figure 11-12 shows an example of a linked to self transfer. Here, the PaRAM set 511 has the link field pointing to the address of parameter set 511 (linked to self).

Figure 11-12. Link-to-Self Transfer



NOTE: If the in EDMA_TPCC_OPT_n[3] STATIC bit is set for a PaRAM set, then link updates are not performed.

11.4.3.8 Constant Addressing Mode Transfers/Alignment Issues

If either EDMA_TPCC_OPT_n[0] SAM or EDMA_TPCC_OPT_n[1] DAM is set (constant addressing mode), then the source or destination address must be aligned to a 256-bit aligned address, respectively, and the corresponding EDMA_TPCC_BIDX_n is an even multiple of 32 bytes (256 bits). The EDMA_TPCC does not recognize errors here, but the EDMA_TPTC asserts an error if this is not true. Refer to Section 11.4.12.3 *Error Generation*.

NOTE: The constant addressing (CONST) mode has limited applicability. The EDMA is configured for the constant addressing mode (EDMA_TPCC_OPT_n[0] SAM / EDMA_TPCC_OPT_n[1] DAM = 1) only if the transfer source or destination (on-chip memory, off-chip memory controllers, slave peripherals) support the constant addressing mode. If the constant addressing mode is not supported, the similar logical transfer can be achieved using the increment (INCR) mode (EDMA_TPCC_OPT_n[0] SAM / EDMA_TPCC_OPT_n[1] DAM =0) by appropriately programming the count and indices values.

11.4.3.9 Element Size

The EDMA controller does not use element-size and element-indexing. Instead, all transfers are defined in terms of all three dimensions: EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, and EDMA_TPCC_CCNT_n[15:0] CCNT. An element-indexed transfer is logically achieved by programming EDMA_TPCC_ABCNT_n[15:0] ACNT to the size of the element and EDMA_TPCC_ABCNT_n[31:16] BCNT to the number of elements that need to be transferred. For example: If there are 16-bit audio data and 256 audio samples that must be transferred to a serial port, therefore the EDMA_TPCC_ABCNT_n[15:0] ACNT = 2 (2 bytes) and EDMA_TPCC_ABCNT_n[31:16] BCNT = 256.

11.4.4 Initiating a DMA Transfer

There are multiple ways to initiate a programmed data transfer using the EDMA_TPCC channel controller. Transfers on DMA channels are initiated by three sources.

They are listed as follows:

- **Event-triggered transfer request** (this is the typical usage of EDMA controller): A peripheral, system, or externally-generated event triggers a transfer request.
- **Manually-triggered transfer request:**The CPU manually triggers a transfer by writing a 1 to the corresponding bit in the event set registers (EDMA_TPCC_ESR / EDMA_TPCC_ESRH).
- **Chain-triggered transfer request:** A transfer is triggered on the completion of another transfer or sub-transfer.

Transfers on QDMA channels are initiated by two sources. They are as follows:

- **Auto-triggered transfer request:** Writing to the programmed trigger word triggers a transfer.
- **Link-triggered transfer requests:** Writing to the trigger word triggers the transfer when linking occurs.

11.4.4.1 DMA Channels

11.4.4.1.1 Event-Triggered Transfer Request

When an event is asserted from a peripheral or device pins, it gets latched in the corresponding bit of the event register (EDMA_TPCC_ER[31:0] E*n* = 1). For more information about peripheral events to EDMA events mapping, refer to *the device data manual*.
If the corresponding event in the event enable register (EDMA_TPCC_EER) is enabled (EDMA_TPCC_EER[31:0] E*n* = 1), then the EDMA_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

If the PaRAM set is valid (not a NULL set), then a transfer request packet (TRP) is submitted to the EDMA_TPTC and the EDMA_TPCC_ER[31:0] E*n* bit is cleared. At this point, a new event can be safely received by the EDMA_TPCC.

If the PaRAM set associated with the channel is a NULL set (see Section 11.4.3.3 *Null PaRAM Set*), then no transfer request (TR) is submitted and the corresponding EDMA_TPCC_ER[31:0] E*n* bit is cleared and simultaneously the corresponding channel bit is set in the event miss register (EDMA_TPCC_EMR[31:0] E*n* = 1) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include cleaning the event missed error before re-triggering the DMA channel.

When an event is received, the corresponding event bit in the event register is set (EDMA_TPCC_ER[31:0] E*n* = 1), regardless of the state of EDMA_TPCC_EER[31:0] E*n*. If the event is disabled when an external event is received (EDMA_TPCC_ER[31:0] E*n* = 1 and EDMA_TPCC_EER[31:0] E*n* = 0), the EDMA_TPCC_ER[31:0] E*n* bit remains set. If the event is subsequently enabled (EDMA_TPCC_EER[31:0] E*n* = 1), then the pending event is processed by the EDMA_TPCC and the TR is processed/submitted, after which the EDMA_TPCC_ER[31:0] E*n* bit is cleared.

If an event is being processed (prioritized or is in the event queue) and another sync event is received for the same channel prior to the original being cleared (EDMA_TPCC_ER[31:0] E*n* != 0), then the second event is registered as a missed event in the corresponding bit of the event missed register (EDMA_TPCC_EMR[31:0] E*n* = 1).

11.4.4.1.2 Manually-Triggered Transfer Request

The CPU or any peripheral device module initiates a DMA transfer by writing to the event set register EDMA_TPCC_ESR. Writing a 1 to an event bit in the EDMA_TPCC_ESR results in the event being prioritized/queued in the appropriate event queue, regardless of the state of the EDMA_TPCC_EER[31:0] E*n* bit. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see Section 11.4.3.3 *Null PaRAM Set*), then no transfer request (TR) is submitted and the corresponding EDMA_TPCC_ER[31:0] E*n* bit is cleared and simultaneously the corresponding channel bit is set in the event miss register EDMA_TPCC_EMR[31:0] E*n* = 1 to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include clearing the event missed error before re-triggering the DMA channel.

If an event is being processed (prioritized or is in the event queue) and the same channel is manually set by a write to the corresponding channel bit of the event set register EDMA_TPCC_ESR[31:0] E*n* = 1 prior to the original being cleared EDMA_TPCC_ESR[31:0] E*n* = 0, then the second event is registered as a missed event in the corresponding bit of the event missed register EDMA_TPCC_EMR[31:0] E*n* = 1.

11.4.4.1.3 Chain-Triggered Transfer Request

Chaining is a mechanism by which the completion of one transfer automatically sets the event for another channel. When a chained completion code is detected, the value of which is dictated by the transfer completion code EDMA_TPCC_OPT_n[17:12] TCC of the PaRAM set associated with the channel, it results in the corresponding bit in the chained event register EDMA_TPCC_CER to be set EDMA_TPCC_CER[31:0] E[TCC] = 1).

Once a bit is set in EDMA_TPCC_CER, the EDMA_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see Section 11.4.3.3 *Null PaRAM Set*), then no transfer request (TR) is submitted and the corresponding EDMA_TPCC_CER[31:0] E*n* bit is cleared and simultaneously the corresponding channel bit is set in the event miss register EDMA_TPCC_EMR[31:0] E*n* = 1 to indicate that the event was discarded due to a null TR being serviced. In this case, the error condition must be cleared before the DMA channel can be re-triggered. Good programming practices might include clearing the event missed error before re-triggering the DMA channel.

If a chaining event is being processed (prioritized or queued) and another chained event is received for the same channel prior to the original being cleared EDMA_TPCC_CER[31:0] E*n* != 0), then the second chained event is registered as a missed event in the corresponding channel bit of the event missed register EDMA_TPCC_EMR[31:0] E*n* = 1.

NOTE: Chained event registers EDMA_TPCC_CER, event registers EDMA_TPCC_ER, and event set registers EDMA_TPCC_ESR operate independently. An event E*n* can be triggered by any of the trigger sources (event-triggered, manually-triggered, or chain-triggered).

11.4.4.2 QDMA Channels

11.4.4.2.1 Auto-triggered and Link-Triggered Transfer Request

QDMA-based transfer requests are issued when a QDMA event gets latched in the QDMA event register EDMA_TPCC_QER[31:0] E*n* = 1. A bit corresponding to a QDMA channel is set in the QDMA event register EDMA_TPCC_QER when the following occurs:

- A CPU (or any device module) write occurs to a PaRAM address that is defined as a QDMA channel trigger word (programmed in the QDMA channel mapping register EDMA_TPCC_QCHMAPN_j for the particular QDMA channel and the QDMA channel is enabled via the QDMA event enable register EDMA_TPCC_QEER[31:0] E*n* = 1.
- EDMA_TPCC performs a link update on a PaRAM set address that is configured as a QDMA channel matches EDMA_TPCC_QCHMAPN_j settings and the corresponding channel is enabled via the QDMA event enable register EDMA_TPCC_QEER[31:0] E*n* = 1.

Once a bit is set in EDMA_TPCC_QER, the EDMA_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If a bit is already set in EDMA_TPCC_QER[31:0] E*n* = 1 and a second QDMA event for the same QDMA channel occurs prior to the original being cleared, the second QDMA event gets captured in the QDMA event miss register EDMA_TPCC_QEMR[7:0] E*n* = 1.

11.4.4.3 Comparison Between DMA and QDMA Channels

The primary difference between DMA and QDMA channels is the event/channel synchronization.

QDMA events are either auto-triggered or link triggered. Auto-triggering allows QDMA channels to be triggered by CPU(s) with a minimum number of linear writes to PaRAM. Link triggering allows a linked list of transfers to be executed, using a single QDMA PaRAM set and multiple link PaRAM sets.

A QDMA transfer is triggered when a CPU (or other device modules) writes to the trigger word of the QDMA channel parameter set (auto-triggered) or when the EDMA_TPCC performs a link update on a PaRAM set that has been mapped to a QDMA channel (link triggered).

NOTE: The CPUs triggered (manually triggered) DMA channels, in addition to writing to the PaRAM set, it is required to write to the event set register EDMA_TPCC_ESR to kick-off the transfer.

QDMA channels are typically for cases where a single event accomplishes a complete transfer since the CPU (or other device modules) must reprogram some portion of the QDMA PaRAM set in order to re-trigger the channel. QDMA transfers are programmed with EDMA_TPCC_ABCNT_n[31:0] BCNT =1 and EDMA_TPCC_CCNT_n[15:0] CCNT = 1 for A-synchronized transfers, and EDMA_TPCC_CCNT_n[15:0] CCNT = 1 for AB-synchronized transfers.

Additionally, since linking is also supported (if EDMA_TPCC_OPT_n[3] STATIC = 0) for QDMA transfers, it allows to initiate a linked list of QDMAs, so when EDMA_TPCC copies over a link PaRAM set (including the write to the trigger word), the current PaRAM set mapped to the QDMA channel automatically recognizes as a valid QDMA event and initiate another set of transfers as specified by the linked set.

11.4.5 Completion of a DMA Transfer

A parameter set for a given channel is complete when the required number of transfer requests is submitted (based on receiving the number of synchronization events). The expected number of TRs for a non-null/non-dummy transfer is shown in Table 11-13 for both synchronization types along with state of the PaRAM set prior to the final TR being submitted. When the counts (EDMA_TPCC_ABCNT_n[31:0] BCNT and/or EDMA_TPCC_CCNT_n[15:0] CCNT) are this value, the next TR results in:

- Final chaining or interrupt codes sent by the transfer controllers (instead of intermediate).
- Link updates (linking to either null or another valid link set).

Table 11-13. Expected Number of Transfers for Non-Null Transfer

Sync Mode	Counts at time 0	Total # Transfers	Counts prior to final TR
A-synchronized	ACNT BCNT CCNT	(BCNT × CCNT) TRs of ACNT bytes each	EDMA_TPCC_ABCNT_n[31:0] BCNT == 1 && EDMA_TPCC_CCNT_n[15:0] CCNT == 1
AB-synchronized	ACNT BCNT CCNT	CCNT TRs for ACNT × BCNT bytes each	EDMA_TPCC_CCNT_n[15:0] CCNT == 1

The PaRAM OPT field must program with a specific transfer completion code TCC or EDMA_TPCC_OPT_n[17:12] TCC along with the other EDMA_TPCC_OPT_n fields ([22] TCCHEN, [20] TCINTEN, [23] ITCCHEN, and [21] ITCINTEN bits) to indicate whether the completion code is to be used for generating a chained event or/and for generating an interrupt upon completion of a transfer.

The specific EDMA_TPCC_OPT_n[17:12] TCC value (6-bit binary value) programmed dictates which of the 64-bits in the chain event register EDMA_TPCC_CER [TCC] and/or interrupt pending register EDMA_TPCC_IPR [TCC] is set.

It can selectively program whether the transfer controller sends back completion codes on completion of the final transfer request (TR) of a parameter set EDMA_TPCC_OPT_n[22] TCCHEN or EDMA_TPCC_OPT_n[20] TCINTEN, for all but the final transfer request (TR) of a parameter set EDMA_TPCC_OPT_n[23] ITCCHEN or EDMA_TPCC_OPT_n[21] ITCINTEN), or for all TRs of a parameter set (both). Refer to Section 11.4.8 *Chaining EDMA Channels* for details on chaining (intermediate/final chaining) and Section 11.4.9 *EDMA Interrupts* for details on intermediate/final interrupt completion.

A completion detection interface exists between the EDMA channel controller and transfer controller(s). This interface sends back information from the transfer controller to the channel controller to indicate that a specific transfer is completed. Completion of a transfer is used for generating chained events and/or generating interrupts to the CPU(s).

All DMA/QDMA PaRAM sets must also specify a link address value. For repetitive transfers such as ping-pong buffers, the link address value must point to another predefined PaRAM set. Alternatively, a non-repetitive transfer must set the link address value to the null link value. The null link value is defined as FFFFh. Refer to Section 11.4.3.7 *Linking Transfers* for more details.

NOTE: Any incoming events that are mapped to a null PaRAM set results in an error condition. The error condition must clear before the corresponding channel is used again. Refer to Section 11.4.3.5 *Dummy Versus Null Transfer Comparison*.

There are three ways the EDMA_TPCC gets updated/informed about a transfer completion: normal completion, early completion, and dummy/null completion. This applies to both chained events and completion interrupt generation.

11.4.5.1 Normal Completion

In normal completion mode EDMA_TPCC_OPT_n[11] TCCMODE = 0, the transfer or sub-transfer is considered to be complete when the EDMA channel controller receives the completion codes from the EDMA transfer controller. In this mode, the completion code to the channel controller is posted by the transfer controller after it receives a signal from the destination peripheral. Normal completion is typically used to generate an interrupt to inform the CPU that a set of data is ready for processing.

11.4.5.2 Early Completion

In early completion mode EDMA_TPCC_OPT_n[11] TCCMODE = 1, the transfer is considered to be complete when the EDMA channel controller submits the transfer request (TR) to the EDMA transfer controller. In this mode, the channel controller generates the completion code internally. Early completion is typically useful for chaining, as it allows subsequent transfers to be chained-triggered while the previous transfer is still in progress within the transfer controller, maximizing the overall throughput of the set of the transfers.

11.4.5.3 Dummy or Null Completion

This is a variation of early completion. Dummy or null completion is associated with a dummy set Section 11.4.3.4 or null set Section 11.4.3.3. In both cases, the EDMA channel controller does not submit the associated transfer request to the EDMA transfer controller(s). However, if the set (dummy/null) has the OPT field programmed to return completion code (intermediate/final interrupt/chaining completion), then it sets the appropriate bits in the interrupt pending registers EDMA_TPCC_IPR and EDMA_TPCC_IPRH or chained event register EDMA_TPCC_CER and EDMA_TPCC_CERH. The internal early completion path is used by the channel controller to return the completion codes internally (that is, EDMA_TPCC generates the completion code).

11.4.6 Event, Channel, and PaRAM Mapping

Several of the 64 DMA channels are tied to a specific hardware event, thus allowing events from device peripherals or external hardware (via the dma_evt[4:1] pins) to trigger transfers. A DMA channel typically requests a data transfer when it receives its event (apart from manually-triggered, chain-triggered, and other transfers). The amount of data transferred per synchronization event depends on the channel's configuration (EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, EDMA_TPCC_CCNT_n[15:0] CCNT, etc.) and the synchronization type (A-synchronized or AB-synchronized).

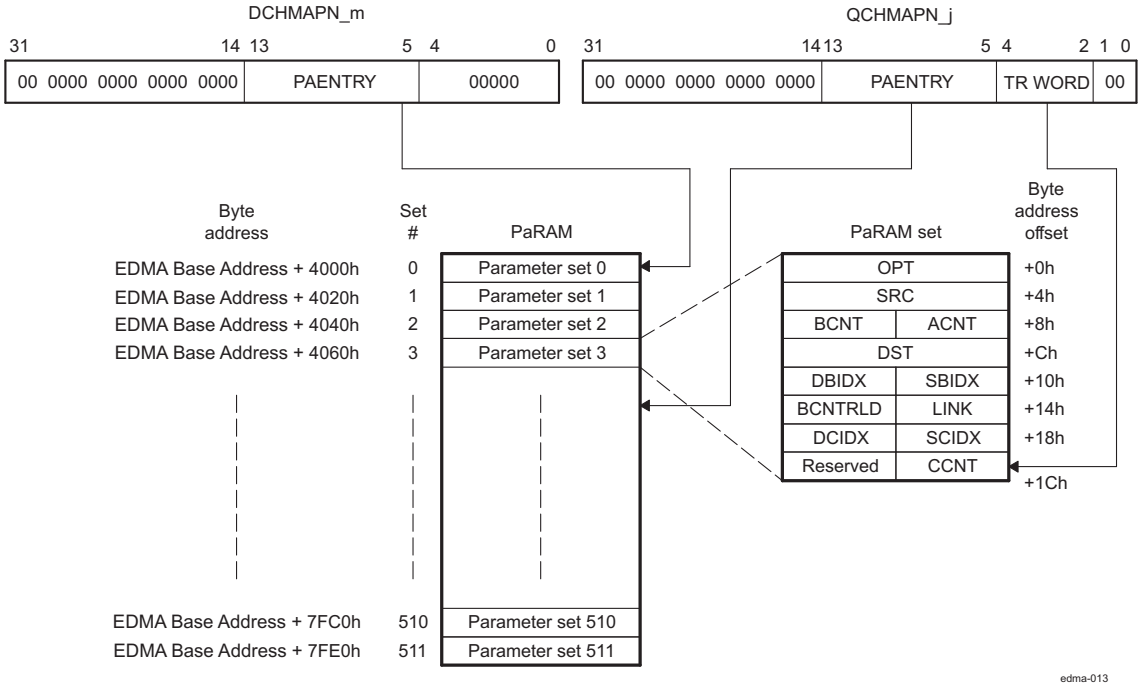
The association of an event to a channel is fixed within the EDMA Channel Controller, that is, each DMA channel has one specific event associated with it. The EDMA event crossbar can be used to select which level events (of which there are more than 64) are mapped to the 64 input events to the EDMA Channel Controller. The default mapping and event crossbar mapping are defined in Section 11.3.1, *EDMA Requests to the EDMA Controller*. The event crossbar mapping is controlled by the device Control Modules registers refer to Section 13.4.6.4 *IRQ_CROSSBAR Module Functional Description*, in Chapter 13 *Control Module*.

In an application, if a channel does not use the associated synchronization event or if it does not have an associated synchronization event (unused), that channel can be used for manually-triggered or chained-triggered transfers, for linking/reloading, or as a QDMA channel.

11.4.6.1 DMA Channel to PaRAM Mapping

The mapping between the DMA channel numbers and the PaRAM sets is programmable (see Table 11-9). The DMA channel mapping registers EDMA_TPCC_DCHMAPN_m in the EDMA_TPCC provide programmability that allows the DMA channels to be mapped to any of the PaRAM sets in the PaRAM memory map. Figure 11-13 illustrates the use of EDMA_TPCC_DCHMAPN_m. There is one EDMA_TPCC_DCHMAPN_m register per channel.

Figure 11-13. DMA Channel and QDMA Channel to PaRAM Mapping



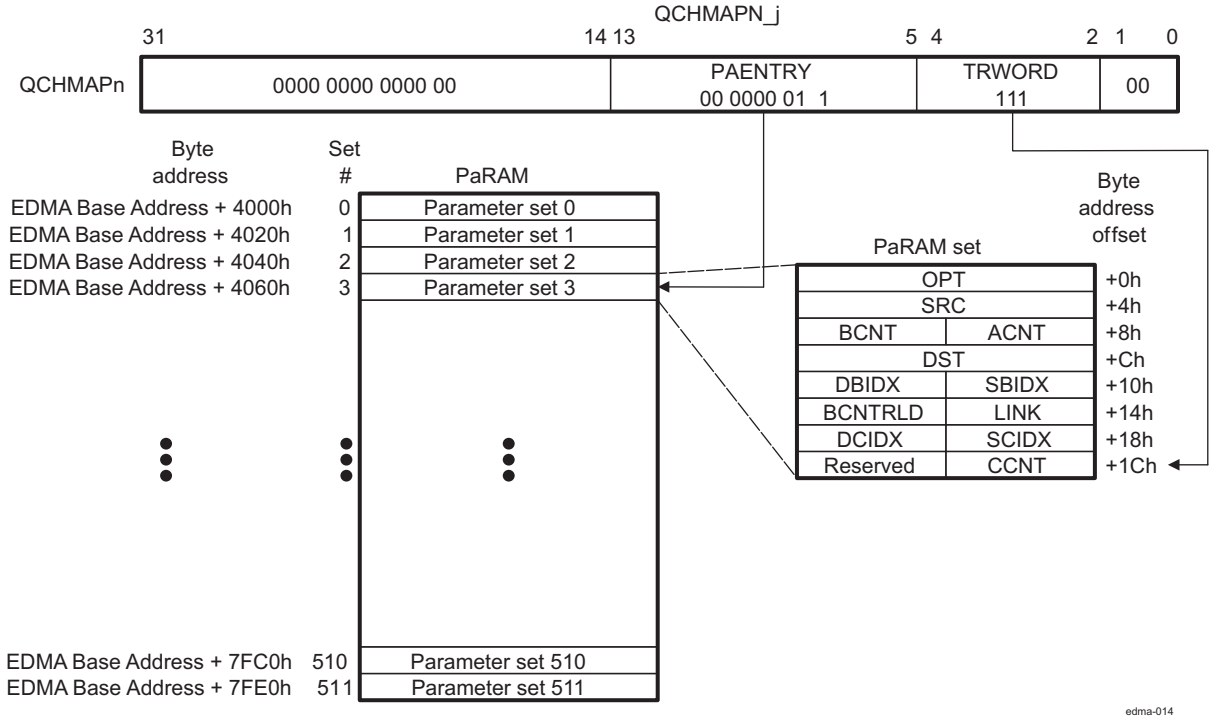
11.4.6.2 QDMA Channel to PaRAM Mapping

The mapping between the QDMA channels and the PaRAM sets is programmable. The QDMA channel mapping register EDMA_TPCC_QCHMAPN_j in the EDMA_TPCC allows to map the QDMA channels to any of the PaRAM sets in the PaRAM memory map. Figure 11-14 illustrates the use of EDMA_TPCC_QCHMAPN_j.

EDMA_TPCC_QCHMAPN_j[4:2] TRWORD bit-field allows to program the trigger word in the PaRAM set for the QDMA channel. A trigger word is one of the eight words in the PaRAM set. For a QDMA transfer to occur, a valid TR synchronization event for EDMA_TPCC is a write to the trigger word in the PaRAM set pointed to by EDMA_TPCC_QCHMAPN_j for a particular QDMA channel. By default, QDMA channels are mapped to PaRAM set 0.

It must appropriately re-map PaRAM set 0 before use.

Figure 11-14. QDMA Channel to PaRAM Mapping



11.4.7 EDMA Channel Controller Regions

The EDMA channel controller divides its address space into eight regions. Individual channel resources are assigned to a specific region, where each region is typically assigned to a specific device module uses the EDMA controller.

Application software can use regions or to ignore them altogether. It can be used active memory protection in conjunction with regions so that only a specific device module which uses the EDMA (for example, privilege identification) or privilege level (for example, user vs. supervisor) is allowed access to a given region, and thus to a given DMA or QDMA channel. This allows robust system-level DMA code where each EDMA initiator only modifies the state of the assigned resources. Memory protection is described in Section 11.4.10 *Memory Protection*.

11.4.7.1 Region Overview

The EDMA channel controller memory-mapped registers are divided in three main categories:

1. Global registers
2. Global region channel registers
3. Shadow region channel registers

The global registers are located at a single/fixed location in the EDMA_TPCC memory map. These registers control EDMA resource mapping and provide debug visibility and error tracking information.

The channel registers (including DMA, QDMA, and interrupt registers) are accessible via the global channel region address range, or in the shadow *n* channel region address range(s). For example, the event enable register EDMA_TPCC_EER is visible at the global address of EDMA Base Address + 1020h or region addresses of EDMA Base Address + 2020h for region 0, EDMA Base Address + 2220h for region 1, … EDMA Base Address + 2E20h for region 7.

The DMA region access enable registers EDMA_TPCC_DRAEM_k and the QDMA region access enable registers EDMA_TPCC_QRAEN_k control the underlying control register bits that are accessible via the shadow region address space (except for EDMA_TPCC_IEVAL and EDMA_TPCC_IEVAL_RN_k registers). Table 11-14 lists the registers in the shadow region memory map. Refer to Table 11-30 *EDMA_TPCC register mapping summary* for the complete global and shadow region memory maps.

Table 11-14. Shadow Region Registers

EDMA_TPCC_DRAEM_k	EDMA_TPCC_DRAEHM_k	EDMA_TPCC_QRAEN_k

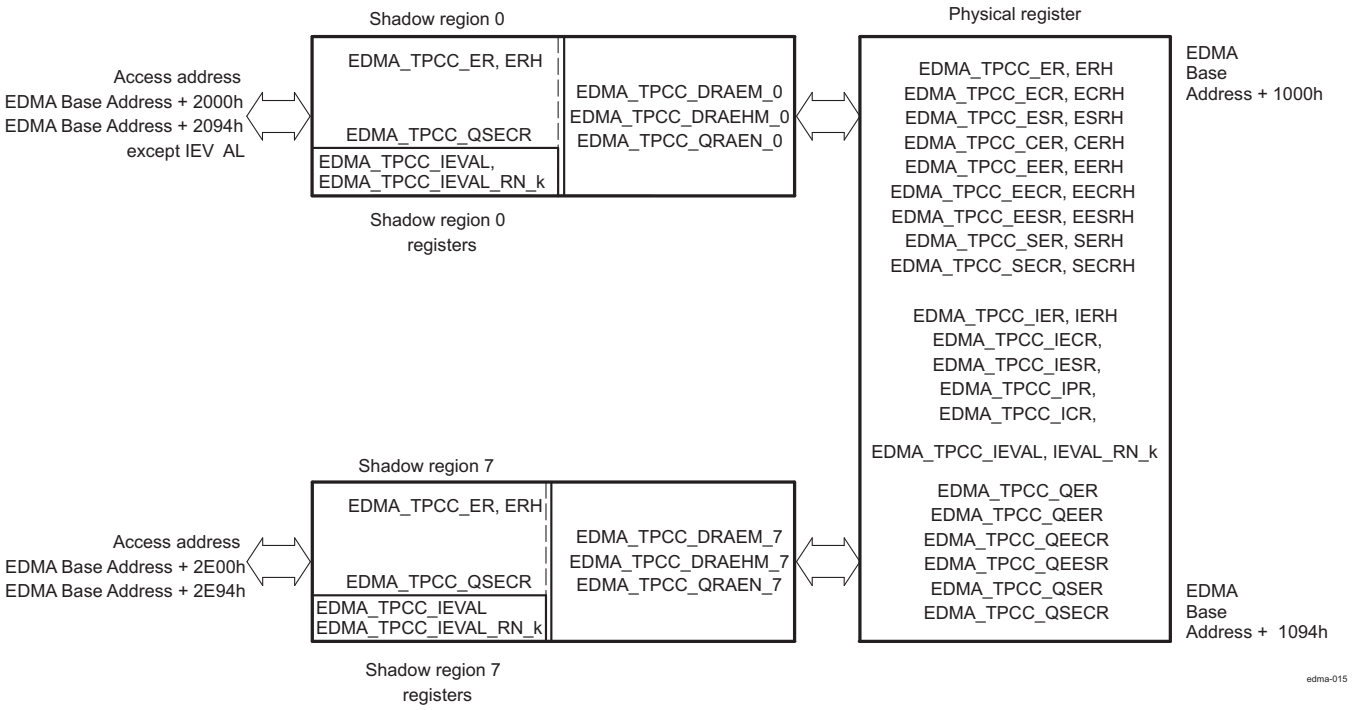
Figure 11-15 illustrates the conceptual view of the regions.

Figure 11-15. Shadow Region Registers



11.4.7.2 Channel Controller Regions

There are eight EDMA shadow regions (and associated memory maps). Associated with each shadow region are a set of registers defining which channels and interrupt completion codes belong to that region. These registers are user-programmed per region to assign ownership of the DMA/QDMA channels to a region.

- EDMA_TPCC_DRAEM_k and EDMA_TPCC_DRAEHM_k: One register pair exists for each of the shadow regions. The number of bits in each register pair matches the number of DMA channels (64 DMA channels). These registers need to be programmed to assign ownership of DMA channels and interrupt (or EDMA_TPCC_OPT_n[17:12] TCC codes) to the respective region. Accesses to DMA and interrupt registers via the shadow region address view are filtered through the DRAEM/DRAEHM pair. A value of 1 in the corresponding EDMA_TPCC_DRAEM_k[31:0] / EDMA_TPCC_DRAEHM_k[31:0] bit implies that the corresponding DMA interrupt channel is accessible; a value of 0 in the corresponding EDMA_TPCC_DRAEM_k[31:0] / EDMA_TPCC_DRAEHM_k[31:0] bit forces writes to be discarded and returns a value of 0 for reads.
- EDMA_TPCC_QRAEN_k: One register exists for every region. The number of bits in each register matches the number of QDMA channels (4 QDMA channels). These registers must be programmed to assign ownership of QDMA channels to the respective region. To enable a channel in a shadow region using shadow region 0 EDMA_TPCC_QEER, the corresponding bits in QRAE must be set or writing into EDMA_TPCC_QEESR there will be no the desired effect.
- EDMA_TPCC_MPPAN_k and EDMA_TPCC_MPPAG: One register exists for every region. This register defines the privilege level, requestor, and types of accesses allowed to a region's memory-mapped registers.

It is typical for an application to have a unique assignment of QDMA/DMA channels (and, therefore, a given bit position) to a given region.

The use of shadow regions allows restricted access to EDMA resources (DMA channels, QDMA channels, TCC, interrupts) by tasks in a system by setting or clearing bits in the EDMA_TPCC_DRAEM_k / EDMA_TPCC_QRAEN_k registers.

If exclusive access to any given channel / TCC code is required for a region, then only that region's EDMA_TPCC_DRAEM_k / EDMA_TPCC_QRAEN_k have the associated bit set.

Example 11-1. Resource Pool Division Across Two Regions

This example illustrates a resource pool division across two regions, assuming region 0 must be allocated 16 DMA channels (0-15) and 1 QDMA channel (0) and 32 TCC codes (0-15 and 48-63).

Region 1 needs to be allocated 16 DMA channels (16-32) and the remaining 7 QDMA channels (1-7) and TCC codes (16-47).

EDMA_TPCC_DRAEM_k should be equal to the OR of the bits that are required for the DMA channels and the TCC codes:

```
Region 0: DRAEHM, DRAEM = 0xFFFF0000, 0x0000FFFF QRAEN = 0x0000001
Region 1: DRAEHM, DRAEM = 0x0000FFFF, 0xFFFF0000 QRAEN = 0x00000FE
```

11.4.7.3 Region Interrupts

In addition to the EDMA_TPCC global completion interrupt, there is an additional completion interrupt line that is associated with every shadow region. Along with the interrupt enable register EDMA_TPCC_IER, DRAEM acts as a secondary interrupt enable for the respective shadow region interrupts. Refer to Table 11-6 *Hardware Request* for more information about EDMA Interrupts.

11.4.8 Chaining EDMA Channels

The channel chaining capability for the EDMA allows the completion of an EDMA channel transfer to trigger another EDMA channel transfer. The purpose is to allow the ability to chain several events through one event occurrence.

Chaining is different from linking (Section 11.4.3.7 *Linking Transfers*). The EDMA link feature reloads the current channel parameter set with the linked parameter set. The EDMA chaining feature does not modify or update any channel parameter set. It provides a synchronization event to the chained channel (see Section 11.4.4.1.3 *Chain-Triggered Transfer Request*).

Chaining is achieved at either final transfer completion or intermediate transfer completion, or both, of the current channel. Consider a channel *m* (DMA/QDMA) required to chain to channel *n*. Channel number *n* (0-63) needs to be programmed into the EDMA_TPCC_OPT_n[17:12] TCC bit-field of channel *m* channel options parameter (OPT) set.

- If final transfer completion chaining EDMA_TPCC_OPT_n[22] TCCHEN = 1 is enabled, the chain-triggered event occurs after the submission of the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).

- If intermediate transfer completion chaining EDMA_TPCC_OPT_n[23] ITCCHEN = 1 is enabled, the chain-triggered event occurs after every transfer request, except the last of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion chaining (EDMA_TPCC_OPT_n[22] TCCHEN = 1 and EDMA_TPCC_OPT_n[23] ITCCHEN = 1) are enabled, then the chain-trigger event occurs after every transfer request is submitted or completed (depending on early or normal completion).

Table 11-15 illustrates the number of chain event triggers occurring in different synchronized scenarios. Consider channel 31 programmed with EDMA_TPCC_ABCNT_n[15:0] ACNT = 3, EDMA_TPCC_ABCNT_n[31:16] BCNT = 4, EDMA_TPCC_CCNT_n[15:0] CCNT = 5, and EDMA_TPCC_OPT_n[17:12] TCC = 30.

Table 11-15. Chain Event Triggers

	(Number of chained event triggers on channel 30)	
Options	**A-Synchronized**	**AB-Synchronized**
EDMA_TPCC_OPT_n[22] TCCHEN = 1, EDMA_TPCC_OPT_n[23] ITCCHEN = 0	1 (Owing to the last TR)	1 (Owing to the last TR)
EDMA_TPCC_OPT_n[22] TCCHEN = 0, EDMA_TPCC_OPT_n[23] ITCCHEN = 1	19 (Owing to all but the last TR)	4 (Owing to all but the last TR)
EDMA_TPCC_OPT_n[22] TCCHEN = 1, EDMA_TPCC_OPT_n[23] ITCCHEN = 1	20 (Owing to a total of 20 TRs)	5 (Owing to a total of 5 TRs)

11.4.9 EDMA Interrupts

The EDMA interrupts are divided into 2 categories: transfer completion interrupts and error interrupts.

There are nine region interrupts, eight shadow regions and one global region. The transfer completion interrupts are listed in Table 11-16. The transfer completion interrupts and the error interrupts from the transfer controllers are all routed to the device interrupt controllers INTCs through the inputs of the IRQ_CROSSBAR module.

Table 11-16. EDMA Transfer Completion Interrupts

Name	Description
EDMA_TPCC_INT0	EDMA_TPCC Transfer Completion Interrupt Shadow Region 0
EDMA_TPCC_INT1	EDMA_TPCC Transfer Completion Interrupt Shadow Region 1
EDMA_TPCC_INT2	EDMA_TPCC Transfer Completion Interrupt Shadow Region 2
EDMA_TPCC_INT3	EDMA_TPCC Transfer Completion Interrupt Shadow Region 3
EDMA_TPCC_INT4	EDMA_TPCC Transfer Completion Interrupt Shadow Region 4
EDMA_TPCC_INT5	EDMA_TPCC Transfer Completion Interrupt Shadow Region 5
EDMA_TPCC_INT6	EDMA_TPCC Transfer Completion Interrupt Shadow Region 6
EDMA_TPCC_INT7	EDMA_TPCC Transfer Completion Interrupt Shadow Region 7

Table 11-17. EDMA Error Interrupts

Name	Description
EDMA_TPCC_ERRINT	EDMA_TPCC Error Interrupt
EDMA_TPCC_MPINT	EDMA_TPCC Memory Protection Interrupt
EDMA_TC0_ERRINT	TC0 Error Interrupt
EDMA_TC1_ERRINT	TC1 Error Interrupt

11.4.9.1 Transfer Completion Interrupts

The EDMA_TPCC is responsible for generating transfer completion interrupts to the CPU(s) (and other EDMA masters). The EDMA generates a single completion interrupt per shadow region, as well as one for the global region on behalf of all 64 channels. The various control registers and bit fields facilitate EDMA interrupt generation.

The software architecture must either use the global interrupt or the shadow interrupts, but not both.

The transfer completion code EDMA_TPCC_OPT_n[17:12] TCC value is directly mapped to the bits of the interrupt pending register EDMA_TPCC_IPR / EDMA_TPCC_IPRH.

For example, if EDMA_TPCC_OPT_n[17:12] TCC = 10 0001b, EDMA_TPCC_IPRH[1] is set after transfer completion, and results in interrupt generation to the CPU(s) if the completion interrupt is enabled for the CPU. See Section 11.4.9.1.1 *Enabling Transfer Completion Interrupts* for details about enabling EDMA transfer completion interrupts.

When a completion code is returned (as a result of early or normal completions), the corresponding bit in EDMA_TPCC_IPR / EDMA_TPCC_IPRH registers is set if transfer completion interrupt (final/intermediate) is enabled in the channel options parameter (OPT) for a PaRAM set associated with the transfer.

Table 11-18. Transfer Complete Code (TCC) to EDMA_TPCC Interrupt Mapping

TCC values in EDMA_TPCC_OPT_n[17:12] TCC (EDMA_TPCC_OPT_n[20] TCINTEN / EDMA_TPCC_OPT_n[21] ITCINTEN = 1)	EDMA_TPCC_IPR Bit Set	TCC values in EDMA_TPCC_OPT_n[17:12] TCC (EDMA_TPCC_OPT_n[20] TCINTEN / EDMA_TPCC_OPT_n[21] ITCINTEN = 1)	EDMA_TPCC_IPRH Bit Set[1]
0	EDMA_TPCC_IPR[0]	20h	EDMA_TPCC_IPR[32] / EDMA_TPCC_IPRH[0]
1	EDMA_TPCC_IPR[1]	21h	EDMA_TPCC_IPR[33] / EDMA_TPCC_IPRH[1]
2h	EDMA_TPCC_IPR[2]	22h	EDMA_TPCC_IPR[34] / EDMA_TPCC_IPRH[2]
3h	EDMA_TPCC_IPR[3]	23h	EDMA_TPCC_IPR[35] / EDMA_TPCC_IPRH[3]
4h	EDMA_TPCC_IPR[4]	24h	EDMA_TPCC_IPR[36] / EDMA_TPCC_IPRH[4]
...	...	...	...
1Eh	EDMA_TPCC_IPR[30]	3Eh	EDMA_TPCC_IPR[62] / EDMA_TPCC_IPRH[30]
1Fh	EDMA_TPCC_IPR[31]	3Fh	EDMA_TPCC_IPR[63] / EDMA_TPCC_IPRH[31]

(1) Bit fields EDMA_TPCC_IPR [32-63] correspond to bits 0 to 31 in EDMA_TPCC_IPRH, respectively.

The transfer completion code (TCC) can program to any value for a DMA/QDMA channel. A direct relation between the channel number and the transfer completion code value does not need to exist. This allows multiple channels having the same transfer completion code value to cause a CPU to execute the same interrupt service routine (ISR) for different channels.

If the channel is used in the context of a shadow region and it intends for the shadow region interrupt to be asserted, then ensure that the bit corresponding to the TCC code is enabled in EDMA_TPCC_IER / EDMA_TPCC_IERH and in the corresponding shadow region's DMA region access registers (EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k).

Interrupt generation can be enabled at either final transfer completion or intermediate transfer completion, or both. Consider channel *m* as an example.

- If the final transfer interrupt (EDMA_TPCC_OPT_n[20] TCINTEN = 1) is enabled, the interrupt occurs after the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).

- If the intermediate transfer interrupt (EDMA_TPCC_OPT_n[21] ITCINTEN = 1) is enabled, the interrupt occurs after every transfer request, except the last TR of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion interrupts (EDMA_TPCC_OPT_n[20] TCINTEN = 1, and EDMA_TPCC_OPT_n[21] ITCINTEN = 1) are enabled, then the interrupt occurs after every transfer request is submitted or completed (depending on early or normal completion).

Table 11-19 shows the number of interrupts that occur in different synchronized scenarios. Consider channel 31, programmed with ABCNT_n[15:0] ACNT = 3, EDMA_TPCC_ABCNT_n[31:16] BCNT = 4, EDMA_TPCC_CCNT_n[15:0]CCNT = 5, and EDMA_TPCC_OPT_n[17:12] TCC = 30.

Table 11-19. Number of Interrupts

Options	A-Synchronized	AB-Synchronized
EDMA_TPCC_OPT_n[20] TCINTEN = 1, EDMA_TPCC_OPT_n[21] ITCINTEN = 0	1 (Last TR)	1 (Last TR)
EDMA_TPCC_OPT_n[20] TCINTEN = 0, EDMA_TPCC_OPT_n[21] ITCINTEN = 1	19 (All but the last TR)	4 (All but the last TR)
EDMA_TPCC_OPT_n[20] TCINTEN = 1, EDMA_TPCC_OPT_n[21] ITCINTEN = 1	20 (All TRs)	5 (All TRs)

11.4.9.1.1 Enabling Transfer Completion Interrupts

For the EDMA channel controller to assert a transfer completion to the external environment, the interrupts must be enabled in the EDMA_TPCC. This is in addition to setting up the EDMA_TPCC_OPT_n[20] TCINTEN and EDMA_TPCC_OPT_n[21] ITCINTEN bits of the associated PaRAM set.

The EDMA channel controller has interrupt enable registers EDMA_TPCC_IER / EDMA_TPCC_IERH and each bit location in EDMA_TPCC_IER / EDMA_TPCC_IERH serves as a primary enable for the corresponding interrupt pending registers EDMA_TPCC_IPR / EDMA_TPCC_IPRH.

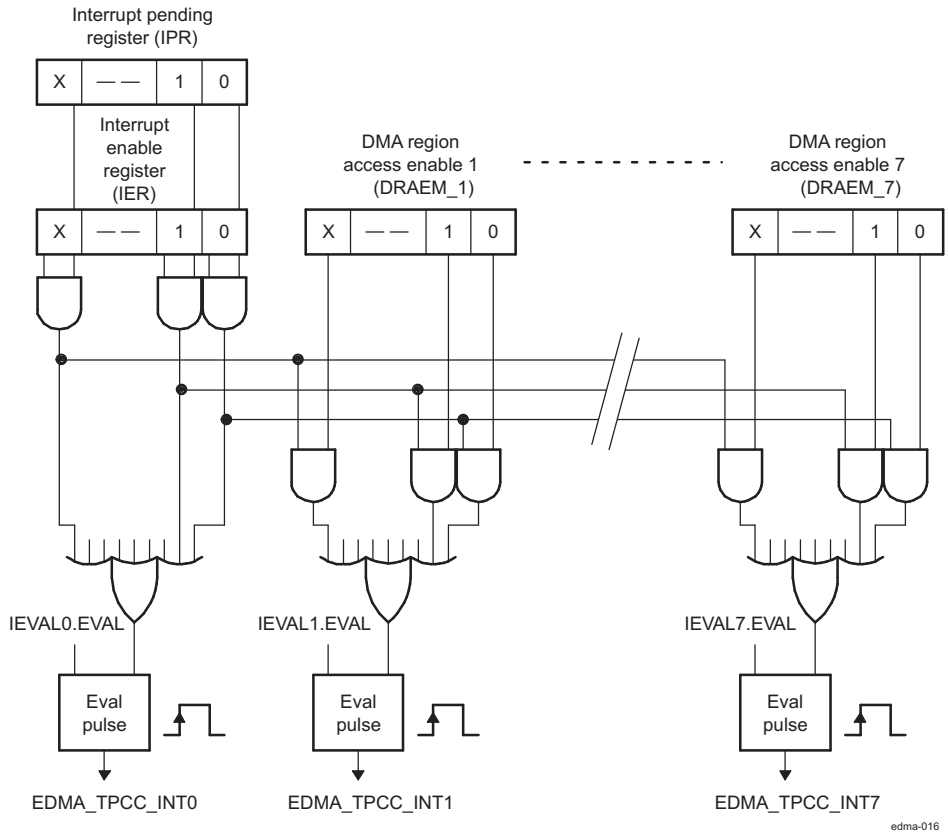
All of the interrupt registers (EDMA_TPCC_IER, EDMA_TPCC_IESR, EDMA_TPCC_IECR, and EDMA_TPCC_IPR) are either manipulated from the global DMA channel region, or by the DMA channel shadow regions. The shadow regions provide a view to the same set of physical registers that are in the global region.

The EDMA channel controller has a hierarchical completion interrupt scheme that uses a single set of interrupt pending registers EDMA_TPCC_IPR / EDMA_TPCC_IPRH and single set of interrupt enable registers EDMA_TPCC_IER / EDMA_TPCC_IERH. The programmable DMA region access enable registers EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k provides a second level of interrupt masking. The global region interrupt output is gated based on the enable mask that is provided by EDMA_TPCC_IER / EDMA_TPCC_IERH, see Figure 11-16

The region interrupt outputs are gated by EDMA_TPCC_IER and the specific EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k associated with the region.

Figure 11-16 shows the Interrupt diagram of the EDMA controller.

Figure 11-16. Interrupt Diagram



The EDMA_TPCC generates the transfer completion interrupts that are associated with each shadow region, the following conditions must be true:

- EDMA_TPCC_INT0: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_0[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_0[1] E1) | …|(EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_0[31] E63)
- EDMA_TPCC_INT1: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_1[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_1[1] E1) | …| (EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_1[31] E63)
- EDMA_TPCC_INT2: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_2[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_2[1] E1) | …|(EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_2[31] E63)....
- Up to EDMA_TPCC_INT7: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_7[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_7[1] E1) | …|(EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_7[31] E63)

NOTE: The EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k for all regions are expected to be set up at system initialization and to remain static for an extended period of time. The interrupt enable registers are used for dynamic enable/disable of individual interrupts.

Because there is no relation between the EDMA_TPCC_OPT_n[17:12] TCC value and the DMA/QDMA channel, it is possible, the DMA channel 0 to have the EDMA_TPCC_OPT_n[17:12] TCC = 63 in its associated PaRAM set. This mean that if a transfer completion interrupt is enabled (EDMA_TPCC_OPT_n[20] TCINTEN or EDMA_TPCC_OPT_n[21] ITCINTEN is set), then based on the TCC value, EDMA_TPCC_IPRH[31] E63 is set up on completion. For proper channel operations and interrupt generation using the shadow region map - program the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k that is associated with the shadow region to have read/write access to both bit 0 (corresponding to channel 0) and bit 63 (corresponding to EDMA_TPCC_IPRH bit that is set upon completion).

11.4.9.1.2 Clearing Transfer Completion Interrupts

Transfer completion interrupts that are latched to the interrupt pending registers (EDMA_TPCC_IPR / EDMA_TPCC_IPRH) are cleared by writing a 1 to the corresponding bit in the interrupt pending clear register (EDMA_TPCC_ICR / EDMA_TPCC_ICRH). For example, a write of 1 to EDMA_TPCC_ICR[0] E0 clears a pending interrupt in EDMA_TPCC_IPR[0] E0.

If an incoming transfer completion code TCC (EDMA_TPCC_OPT_n[17:12] TCC) gets latched to a bit in EDMA_TPCC_IPR / EDMA_TPCC_IPRH, then additional bits that get set due to a subsequent transfer completion does not result in asserting the EDMA_TPCC completion interrupt. In order for the completion interrupt to be pulsed, the required transition is from a state where no enabled interrupts are set to a state where at least one enabled interrupt is set.

11.4.9.2 EDMA Interrupt Servicing

Upon completion of a transfer (early or normal completion), the EDMA channel controller sets the appropriate bit in the interrupt pending registers (EDMA_TPCC_IPR / EDMA_TPCC_IPRH), as the transfer completion codes specify. If the completion interrupts are appropriately enabled, then the CPU enters the interrupt service routine (ISR) when the completion interrupt is asserted.

After servicing the interrupt, the ISR should clear the corresponding bit in EDMA_TPCC_IPR/EDMA_TPCC_IPRH, thereby enabling recognition of future interrupts. The EDMA_TPCC only asserts additional completion interrupts when all EDMA_TPCC_IPR / EDMA_TPCC_IPRH bits clear.

When one interrupt is serviced many other transfer completions may result in additional bits being set in EDMA_TPCC_IPR / EDMA_TPCC_IPRH, thereby resulting in additional interrupts. Each of the bits in EDMA_TPCC_IPR / EDMA_TPCC_IPRH may need different types of service therefore, the ISR must check all pending interrupts and continue until all of the posted interrupts are serviced appropriately.

Examples of pseudo code for a CPU interrupt service routine for an EDMA_TPCC completion interrupt are shown in Example 11-2 and Example 11-3.

The ISR routine in Example 11-2 is more exhaustive and incurs a higher latency.

Example 11-2. Interrupt Servicing

The pseudo code:

1. Reads the interrupt pending register EDMA_TPCC_IPR / EDMA_TPCC_IPRH.
2. Performs the operations needed.
3. Writes to the interrupt pending clear register EDMA_TPCC_ICR / EDMA_TPCC_ICRH to clear the corresponding EDMA_TPCC_IPR / EDMA_TPCC_IPRH bit(s).
4. Reads EDMA_TPCC_IPR / EDMA_TPCC_IPRH again:
   a. If EDMA_TPCC_IPR / EDMA_TPCC_IPRH is not equal to 0, repeat from step 2 (implies occurrence of new event between step 2 to step 4).

Example 11-2. Interrupt Servicing (continued)

b. If EDMA_TPCC_IPR / EDMA_TPCC_IPRH is equal to 0, assure that all of the enabled interrupts are inactive.

NOTE: An event may occur during step 4 while the EDMA_TPCC_IPR / EDMA_TPCC_IPRH bits are read as 0 and the application is still in the interrupt service routine. If this happens, a new interrupt is recorded in the device interrupt controller and a new interrupt generates as soon as the application exits in the interrupt service routine.

Example 11-3 is less rigorous, with less burden on the software in polling for set interrupt bits, but can occasionally cause a race condition as mentioned above.

Example 11-3. Interrupt Servicing

If any enabled and pending (possibly lower priority) interrupts are left, force the interrupt logic to reassert the interrupt pulse by setting the EDMA_TPCC_IEVAL[0] EVAL bit in the interrupt evaluation register.

The pseudo code is as follows:

1. Enters ISR.
2. Reads EDMA_TPCC_IPR / EDMA_TPCC_IPRH.
3. For the condition that is set in EDMA_TPCC_IPR / EDMA_TPCC_IPRH:
   a. Service interrupt as the application requires.
   b. Clear the bit for serviced conditions (others may still be set, and other transfers may have resulted in returning the TCC to EDMA_TPCC after step 2).
4. Reads EDMA_TPCC_IPR / EDMA_TPCC_IPRH prior to exiting the ISR:
   a. If EDMA_TPCC_IPR / EDMA_TPCC_IPRH is equal to 0, then exit the ISR.
   b. If EDMA_TPCC_IPR / EDMA_TPCC_IPRH is not equal to 0, then set EDMA_TPCC_IEVAL so that upon exit of ISR, a new interrupt triggers if any enabled interrupts are still pending.

11.4.9.3 Interrupt Evaluation Operations

The EDMA_TPCC has interrupt evaluate registers EDMA_TPCC_IEVAL that exist in the global region and in each shadow region. The registers in the shadow region are the only registers in the DMA channel shadow region memory map that are not affected by the settings for the DMA region access enable registers EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k. Writing a 1 to the EDMA_TPCC_IEVAL[0] EVAL bit in the registers that are associated with a particular shadow region results in pulsing the associated region interrupt (global or shadow), if any enabled interrupt (via EDMA_TPCC_IER / EDMA_TPCC_IERH) is still pending EDMA_TPCC_IPR / EDMA_TPCC_IPRH. This register assures that the CPU does not miss the interrupts (or the EDMA master associated with the shadow region) if the software architecture chooses not to use all interrupts. Refer to Example 11-3 about the use of EDMA_TPCC_IEVAL in the EDMA interrupt service routine (ISR).

Similarly an error evaluation register EDMA_TPCC_EEVAL exists in the global region. Writing a 1 to the EDMA_TPCC_EEVAL[0] EVAL bit causes the pulsing of the error interrupt if any pending errors are in EDMA_TPCC_EMR / EDMA_TPCC_EMRH, EDMA_TPCC_QEMR, or EDMA_TPCC_CCERR. See Section 11.4.9.4 *Error Interrupts* for additional information regarding error interrupts.

NOTE: While using EDMA_TPCC_IEVAL for shadow region completion interrupts, check that the EDMA_TPCC_IEVAL operated upon is from that particular shadow region memory map.

11.4.9.4 Error Interrupts

The EDMA_TPCC error registers provide the capability to differentiate error conditions (event missed, threshold exceed, etc.). Additionally, setting the error bits in these registers results in asserting the EDMA_TPCC error interrupt. If the EDMA_TPCC error interrupt is enabled in the device interrupt controller(s), then it allows the CPU(s) to handle the error conditions.

The EDMA_TPCC has a single error interrupt (EDMA_TPCC_ERRINT) that is asserted for all EDMA_TPCC error conditions. There are four conditions that cause the error interrupt:

- DMA missed events: for all 64 DMA channels. DMA missed events are latched in the event missed registers EDMA_TPCC_EMR / EDMA_TPCC_EMRH.
- QDMA missed events: for all 8 QDMA channels. QDMA missed events are latched in the QDMA event missed register EDMA_TPCC_QEMR.
- Threshold exceed: for all event queues. These are latched in EDMA_TPCC error register EDMA_TPCC_CCERR.
- TCC error: for outstanding transfer requests that are expected to return completion code EDMA_TPCC_OPT_n[22] TCCHEN or EDMA_TPCC_OPT_n[23] TCINTEN bit is set to 1, exceeding the maximum limit of 63. This is also latched in the EDMA_TPCC error register EDMA_TPCC_CCERR.

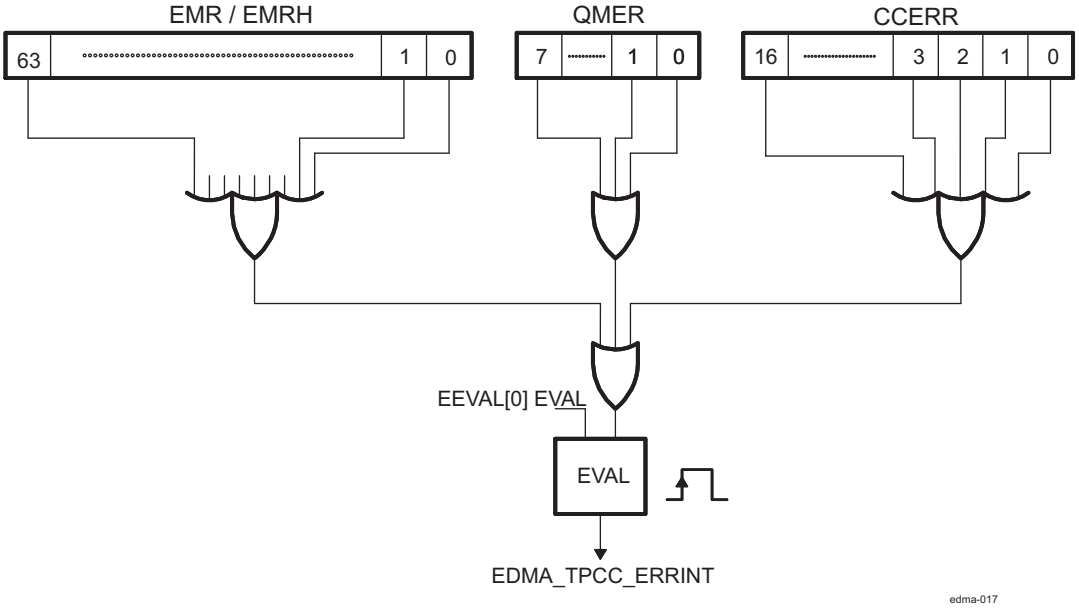
Figure 11-17 illustrates the EDMA_TPCC error interrupt generation operation.

If any of the bits are set in the error registers due to any error condition, the EDMA_TPCC_ERRINT is always asserted, as there are no enables for masking these error events. Similar to transfer completion interrupts (EDMA_TPCC_INT), the error interrupt also only pulses when the error interrupt condition transitions from no errors being set to at least one error being set. If additional error events are latched prior to the original error bits clearing, the EDMA_TPCC does not generate additional interrupt.

To reduce the burden on the software, there is an error evaluate register EDMA_TPCC_EEVAL that allows re-evaluation of pending set error events/bits, similar to the interrupt evaluate register EDMA_TPCC_IEVAL. Unlike the EDMA_TPCC_IEVAL functionality, the EDMA_TPCC_EEVAL register must be written with ‘1’ after any error interrupts are serviced (even when all pending errors are cleared) in order for subsequent errors to trigger a new interrupt.

NOTE: It is good practice to enable the error interrupt in the device interrupt controller and to associate an interrupt service routine with it to address the various error conditions appropriately. Doing so puts less burden on the software (polling for error status), it provides a good debug mechanism for unexpected error conditions.

Figure 11-17. Error Interrupt Operation



11.4.10 Memory Protection

The EDMA channel controller supports two kinds of memory protection: active and proxy.

11.4.10.1 Active Memory Protection

Active memory protection is a feature that allows or prevents read and write accesses to the EDMA_TPCC registers. Active memory protection is achieved by a set of memory protection permissions attribute EDMA_TPCC_MPPAN_k registers.

The EDMA_TPCC register map is divided into three categories:

- a global region.
- a global channel region.
- eight shadow regions.

Each shadow region consists of the respective shadow region registers and the associated PaRAM. For more detailed information regarding the contents of a shadow region, refer to Table 11-30 *EDMA_TPCC Registers Mapping Summary*.

Each of the eight shadow regions has an associated EDMA_TPCC_MPPAN_k registers that defines the specific requestor(s) and types of requests that are allowed to the regions resources.

The global channel region is also protected with a memory-mapped register EDMA_TPCC_MPPAG. The EDMA_TPCC_MPPAG applies to the global region and to the global channel region, except the other EDMA_TPCC_MPPAN_k registers themselves.

Table 11-20 shows the accesses that are allowed or not allowed to the EDMA_TPCC_MPPAG and EDMA_TPCC_MPPAN_k. The active memory protection uses the EDMA_TPCC_OPT_n[31] PRIV and EDMA_TPCC_OPT_n[27:24] PRIVID attributes of the EDMA peripheral modules. TheEDMA_TPCC_OPT_n[31] PRIV is the privilege level (i.e., user vs. supervisor).

The EDMA_TPCC_OPT_n[27:24] PRIVID refers to a privilege ID with a number that is associated with an EDMA peripheral modules.

Table 11-20. Allowed Accesses

Access	Supervisor	User
Read	Yes	Yes
Write	Yes	No

Table 11-21 describes the EDMA_TPCC_MPPAN_k register mapping for the shadow regions (which includes shadow region registers and PaRAM addresses).

The region-based EDMA_TPCC_MPPAN_k registers are used to protect accesses to the DMA shadow regions and the associated region PaRAM. Because there are eight regions, there are eight EDMA_TPCC_MPPAN_k region registers (MPPA[0-7]).

Table 11-21. MPPA Registers to Region Assignment

Register	Registers Protect	Address Range	PaRAM Protect[1]	Address Range
EDMA_TPCC_MPPAG	Global Range	0000h-1FFCh	N/A	N/A
EDMA_TPCC_MPPAN_k. MPPAN_0	DMA Shadow 0	2000h-21FCh	1st octant	4000h-47FCh
MPPAN_1	DMA Shadow 1	2200h-23FCh	2nd octant	4800h-4FFCh
MPPAN_2	DMA Shadow 2	2400h-25FCh	3rd octant	5000h-57FCh
MPPAN_3	DMA Shadow 3	2600h-27FCh	4th octant	5800h-5FFCh
MPPAN_4	DMA Shadow 4	2800h-29FCh	5th octant	6000h-67FCh
MPPAN_5	DMA Shadow 5	2A00h-2BFCh	6th octant	6800h-6FFCh
MPPAN_6	DMA Shadow 6	2C00h-2DFCh	7th octant	7000h-77FCh
MPPAN_7	DMA Shadow 7	2E00h-2FFCh	8th octant	7800h-7FFCh

(1) The PARAM region is divided into 8 regions referred to as an octant.

Example *Access denied.*

Write access to shadow region 7's event enable set register EDMA_TPCC_EESR:

1. The original value of the event enable register EDMA_TPCC_EER at address offset 0x1020 is 0x0.
2. The EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[7] NS is set to prevent user level accesses (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 0, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[2] UR = 0), but it allows supervisor level accesses (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[4] SW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[5] SR = 1) with a privilege ID of 0. (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[10] AID0 = 1).
3. EDMA peripheral modules with a privilege ID of 0 attempts to perform a user-level write of a value of 0xFF00FF00 to shadow region 7's event enable set register EDMA_TPCC_EESR at address offset 0x2E30.

NOTE: The EDMA_TPCC_EER is a read-only register and the only way that write to it is by writing to the EDMA_TPCC_EESR. There is only one physical register for EDMA_TPCC_EER, EDMA_TPCC_EESR, etc. and that the shadow regions only provide to the same physical set.

4. Since the EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 0, though the privilege ID of the write access is set to 0, the access is not allowed and the EDMA_TPCC_EER is not written too.

Table 11-22. Example Access Denied

Register	Value	Description
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Value in EDMA_TPCC_EER to begin with.
EDMA_TPCC_EESR (offset 0x2E30)	0xFF00 FF00 ↓	Value attempted to be written to shadow region 7's EDMA_TPCC_EESR. This is done by an EDMA connected device module with a privilege level of User and Privilege ID of 0.
EDMA_TPCC_MPPAN_k (offset 0x082C)	0x0000 04B0	Memory Protection Filter EDMA_TPCC_MPPAN_k[10] AID0 = 1, EDMA_TPCC_MPPAN_k[1] UW = 0, EDMA_TPCC_MPPAN_k[2] UR = 0, EDMA_TPCC_MPPAN_k[4] SW = 1, EDMA_TPCC_MPPAN_k[5] SR = 1.
	X	Access Denied
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Final value of EDMA_TPCC_EER

Example *Access Allowed*

Write access to shadow region 7's event enable set register EDMA_TPCC_EESR:

1. The original value of the event enable register EDMA_TPCC_EER at address offset 0x1020 is 0x0.
2. The EDMA_TPCC_MPPAN_k.EDMA_TPCC_MPPAN_7 is set to allow user-level accesses (EDMA_TPCC_MPPAN_k.EDMA_TPCC_MPPAN_7[1] UW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[2] UR = 1) and supervisor-level accesses (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[4] SW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[5] SR = 1) with a privilege ID of 0. (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[10] AID0 = 1).
3. EDMA peripheral modules with a privilege ID of 0, attempts to perform a user-level write of a value of 0xABCD0123 to shadow region 7's event enable set register EDMA_TPCC_EESR at address offset 0x2E30.

NOTE: The EDMA_TPCC_EER is a read-only register and the only way that write to it is by writing to the EDMA_TPCC_EESR. There is only one physical register for EDMA_TPCC_EER, EDMA_TPCC_EESR, etc. and that the shadow regions only provide to the same physical set.

4. Since the EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 1 and EDMA_TPCC_MPPAN_k. MPPAN_7[10] AID0 = 1, the user-level write access is allowed.
5. The accesse to shadow region registers are masked by their respective EDMA_TPCC_DRAEM_k

register. In this example, the EDMA_TPCC_DRAEM_k. EDMA_TPCC_DRAEM_7 is set of 0x9FF00FC2.

6. The value finally written to EDMA_TPCC_EER is 0x8BC00102.

Table 11-23. Example Access Allowed

Register	Value	Description
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Value in EER to begin with.
EDMA_TPCC_EESR (offset 0x2E30)	0xFF00 FF00	Value attempted to be written to shadow region 7's EESR. This is done by an EDMA peripheral module with a privilege level of User and Privilege ID of 0.
EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7 (offset 0x082C)	0x0000 04B3	Memory Protection Filter EDMA_TPCC_MPPAN_k[10] AID = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[2] UR = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[4] SW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[5] SR = 1.
	√ ↓	Access allowed.
EDMA_TPCC_DRAEM_k. EDMA_TPCC_DRAEM_7 (offset 0x0378)	0x9FF0 0FC2 ↓	DMA Region Access Enable Filter
EDMA_TPCC_EESR (offset 0x2E30)	0x8BC0 0102 ↓	Value written to shadow region 7's EESR. This is done by an EDMA peripheral module with a privilege level of User and a Privilege ID of 0.
EDMA_TPCC_EER (offset 0x1020)	↓ 0xBC0 0102	Final value of EER.

11.4.10.2 Proxy Memory Protection

Proxy memory protection allows an EDMA transfer programmed by a given peripheral module connected to EDMA, to have its permissions travel with the transfer through the EDMA_TPTC. The permissions travel along with the read transactions to the source and the write transactions to the destination endpoints. The EDMA_TPCC_OPT_n[31] PRIV bit and EDMA_TPCC_OPT_n[27:24] PRIVID bit is set with the peripheral module's PRIV value and PRIVID values, respectively, when any part of the PaRAM set is written.

The EDMA_TPCC_OPT_n[31] PRIV is the privilege level (i.e., user vs. supervisor). The EDMA_TPCC_OPT_n[27:24] PRIVID refers to a privilege ID with a number that is associated with an peripheral module connected to EDMA.

These options are part of the TR that are submitted to the transfer controller. The transfer controller uses the above values on their respective read and write command bus so that the target endpoints can perform memory protection checks based on these values.

Consider a parameter set that is programmed by a CPU in user privilege level for a simple transfer with the source buffer on an L2 page and the destination buffer on an L1D page. The EDMA_TPCC_OPT_n[31] PRIV is 0 for user-level and the CPU has a EDMA_TPCC_OPT_n[27:24] PRIVID to 0.

The PaRAM set is shown in Figure 11-18.

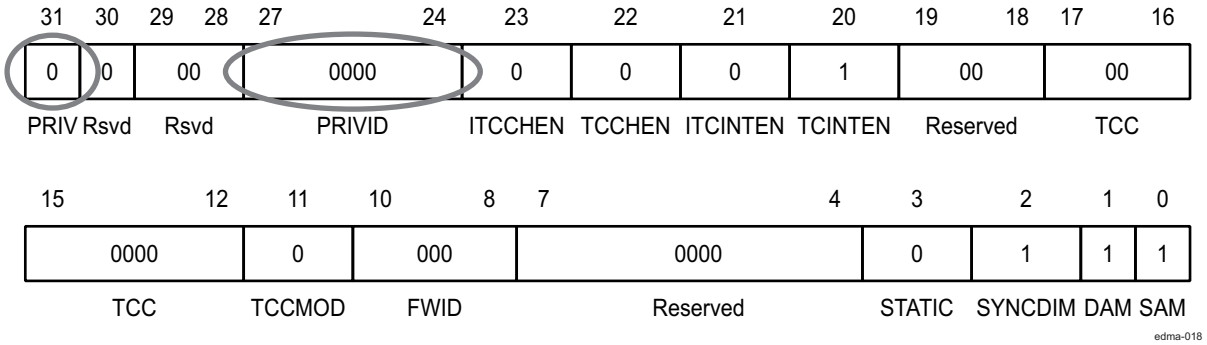
Figure 11-18. PaRAM Set Content for Proxy Memory Protection Example

(a) EDMA Parameters

Parameter Contents		Parameter	
0010 0007h		Channel Options Parameter (OPT)	
009F 0000h		Channel Source Address (SRC)	
0001h	0004h	Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
00F0 7800h		Channel Destination Address (DST)	
0001h	0001h	Destination BCNT Index (DBIDX)	Source BCNT Index (SBIDX)
0000h	FFFFh	BCNT Reload (BCNTRLD)	Link Address (LINK)
0001h	1000h	Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
0000h	0001h	Reserved	Count for 3rd Dimension (CCNT)

Figure 11-19. Channel Options Parameter (OPT) Example

(b) Channel Options Parameter (OPT_n) Content



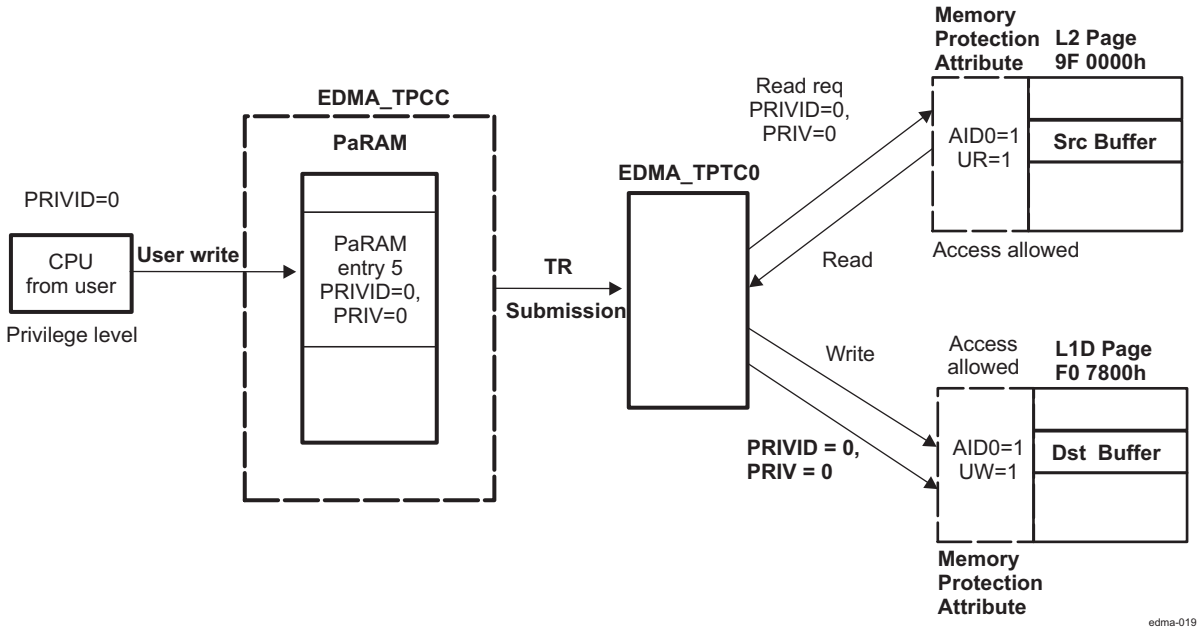
The EDMA_TPCC_OPT_n[31] PRIV and EDMA_TPCC_OPT_n[27:24] PRIVID information travels along with the read and write requests that are issued to the source and destination memories.

For example, if the access attributes that are associated with the L2 page with the source buffer only allow supervisor read, write accesses EDMA_TPCC_MPPAN_k[4] SW and EDMA_TPCC_MPPAN_k[5] SR, the user-level read request above is refused. Similarly, if the access attributes that are associated with the L1D page with the destination buffer only allow supervisor read and write accesses (EDMA_TPCC_MPPAN_k[4] SW, EDMA_TPCC_MPPAN_k[5] SR), the user-level write request above is refused. For the transfer to succeed, the source and destination pages must have user-read and user-write permissions, respectively, along with allowing accesses from a PRIVID = 0.

Because the privilege level and privilege identification travel with the read and write requests, EDMA acts as a proxy.

Figure 11-20 illustrates the propagation of EDMA_TPCC_OPT_n[31] PRIV and EDMA_TPCC_OPT_n[27:24] PRIVID at the boundaries of all the interacting entities (CPU, EDMA_TPCC, EDMA_TPTCs, and slave memories).

Figure 11-20. Proxy Memory Protection Example



11.4.11 Event Queue(s)

Event queues are a part of the EDMA channel controller. Event queues form the interface between the event detection logic in the EDMA_TPCC and the transfer request (TR) submission logic of the EDMA_TPCC. Each queue is 16 entries deep. Each event queue can queue a maximum of 16 events. If there are more than 16 events, then the events that cannot find a place in the event queue remain set in the associated event register and the CPU does not stall.

There are two event queues for the device: Queue0, Queue1. Events in Queue0 result in submission of its associated transfer requests (TRs) to TC0. The transfer requests that are associated with events in Queue1 are submitted to TC1.

An event that wins prioritization against other DMA and/or QDMA pending events is placed at the tail of the appropriate event queue. Each event queue is serviced in FIFO order. Once the event reaches the head of its queue and the corresponding transfer controller is ready to receive another TR, the event is de-queued and the PaRAM set corresponding to the de-queued event is processed and submitted as a transfer request packet (TRP) to the associated EDMA transfer controller.

Queue0 has highest priority and Queue1 has the lowest priority, if Queue0 and Queue1 both have at least one event entry and if both TC0 and TC1 can accept transfer requests, then the event in Queue0 is de-queued first and its associated PaRAM set is processed and submitted as a transfer request (TR) to TC0.

Refer to Section 11.4.11.4 for system-level performance considerations. All of the event entries in all of the event queues are software readable (not writeable) by accessing the event entry registers EDMA_TPCC_Q0E_p and EDMA_TPCC_Q1E_p. Each event entry register characterizes the queued event in terms of the type of event (manual, event, chained or auto-triggered) and the event number. Refer to Section 11.7.2.2.1 *EDMA_TPCC Register Description* for EDMA_TPCC_Q0E_p / EDMA_TPCC_Q1E_p descriptions of the bit fields.

11.4.11.1 DMA/QDMA Channel to Event Queue Mapping

Each of the 64 DMA channels and eight QDMA channels are programmed independently to map to a specific queue, using the DMA queue number register EDMA_TPCC_DMAQNUMN_k and the QDMA queue number register EDMA_TPCC_QDMAQNUM. The mapping of DMA/QDMA channels is critical to achieving the desired performance level for the EDMA and most importantly, in meeting real-time deadlines. Refer to Section 11.4.11.4 *System-level Performance Considerations*.

NOTE: If an event is ready to be queued and both the event queue and the EDMA transfer controller that is associated to the event queue are empty, then the event bypasses the event queue, and moves the PaRAM processing logic, and eventually to the transfer request submission logic for submission to the EDMA_TPTC. In this case, the event is not logged in the event queue status registers.

11.4.11.2 Queue RAM Debug Visibility

There are two event queues and each queue has 16 entries. These 16 entries are managed in a circular FIFO. There is a queue status register EDMA_TPCC_QSTATN_i associated with each queue. These along with all of the 16 entries per queue can be read via registers EDMA_TPCC_QSTATN_i and Q0E_p / Q1E_p, respectively.

These registers provide user visibility.

The event queue entry register (Q*x*E*y* Q0E_p / Q1E_p) uniquely identifies the specific event type (event-triggered, manually-triggered, chain-triggered, and QDMA events) along with the event number (for all DMA/QDMA event channels) that are in the queue or have been de-queued (passed through the queue).

Each of the 16 entries in the event queue are read using the EDMA_TPCC memory-mapped register. To see the history of the last 16 TRs that have been processed by the EDMA on a given queue, read the event queue registers. This provides user/software visibility and is helpful for debugging real-time issues (typically post-mortem), involving multiple events and event sources.

The queue status register (QSTAT*n* EDMA_TPCC_QSTATN_i) includes fields for the start pointer EDMA_TPCC_QSTATN_i[3:0] STRTPTR which provides the offset to the head entry of an event. It also includes a field called EDMA_TPCC_QSTATN_i[12:8] NUMVAL that provides the total number of valid entries residing in the event queue at a given instance of time. The EDMA_TPCC_QSTATN_i[3:0] STRTPTR is used to index appropriately into the 16 event entries. EDMA_TPCC_QSTATN_i[12:8] NUMVAL number of entries starting from STRTPTR are indicative of events still queued in the respective queue. The remaining entry must be read to determine what's already de-queued and submitted to the associated transfer controller.

11.4.11.3 Queue Resource Tracking

The EDMA_TPCC event queue includes watermarking/threshold logic that allows to keep track of maximum usage of all event queues. This is useful for debugging real-time deadline violations that may result from head-of-line blocking on a given EDMA event queue.

The maximum number of events are programed that the queue up in an event queue by programming the threshold value (between 0 to 15) in the queue watermark threshold A register EDMA_TPCC_QWMTHRA. The maximum queue usage is recorded actively in the watermark EDMA_TPCC_QSTATN_i[20:16] WM field of the queue status register, that keeps getting updated based on a comparison of number of valid entries, which is also visible in the EDMA_TPCC_QSTATN_i[12:8] NUMVAL bit and the maximum number of entries.

If the queue usage is exceeded, this status is visible in the EDMA_TPCC registers: the QTHRXCD*n* bits in the channel controller error register EDMA_TPCC_CCERR[7:0] and the EDMA_TPCC_QSTATN_i[24] THRXCD bit, where *n* stands for the event queue number. Any bits that are set in EDMA_TPCC_CCERR also generate an EDMA_TPCC error interrupt.

11.4.11.4 Performance Considerations

The main system bus infrastructure (L3) arbitrates bus requests from all of the masters (TCs, CPU(S), and other bus masters) to the shared slave resources (peripherals and memories).

The priorities of transfer requests (read and write commands) from the EDMA transfer controllers with respect to other masters within the device IRQ_CROSSBAR are programmed using the Control Module registers. The EDMA_TPCC_QUEPRI register has no affect.

Therefore, the priority of unloading queues has a secondary affect compared to the priority of the transfers as they are executed by the EDMA_TPTC (dictated by the priority set using the Control Module registers, refer to Section 13.5 *Control Module Register Manual* in Chapter 13 *Control Module* chapter).

11.4.12 EDMA Transfer Controller (EDMA_TPTC)

The EDMA channel controller is the user-interface of the EDMA and the EDMA transfer controller (EDMA_TPTC) is the data movement engine of the EDMA controller. The EDMA_TPCC submits transfer requests (TR) to the EDMA_TPTC and the EDMA_TPTC performs the data transfers dictated by the TR, so the EDMA_TPTC is a slave to the EDMA_TPCC.

11.4.12.1 Architecture Details

11.4.12.1.1 Command Fragmentation

The TC read and write controllers in conjunction with the source and destination register sets are responsible for issuing optimally-sized reads and writes to the slave endpoints. An optimally-sized command is defined by the transfer controller default burst size (DBS), which is defined in Section 11.4.12.5 *EDMA_TPTC Configuration*.

The EDMA_TPTC attempts to issue the largest possible command size as limited by the DBS value or the EDMA_TPCC_ABCNT_n[15:0] ACNT and EDMA_TPCC_ABCNT_n[31:16] BCNT value of the TR. EDMA_TPTC obeys the following rules:

- The read/write controllers always issue commands less than or equal to the DBS value.
- The first command of a 1D transfer command always aligns the address of subsequent commands to the DBS value.

Table 11-24 lists the TR segmentation rules that are followed by the EDMA_TPTC. In summary, if the EDMA_TPCC_ABCNT_n[15:0] ACNT value is larger than the DBS value, then the EDMA_TPTC breaks the EDMA_TPCC_ABCNT_n[15:0] ACNT array into DBS-sized commands to the source/destination addresses. Each EDMA_TPCC_ABCNT_n[31:16] BCNT number of arrays are then serviced in succession.

For BCNT arrays of ACNT bytes (that is, a 2D transfer), if the EDMA_TPCC_ABCNT_n[15:0] ACNT value is less than or equal to the DBS value, then the TR may be optimized into a 1D-transfer in order to maximize efficiency. The optimization takes place if the EDMA_TPTC recognizes that the 2D-transfer is organized as a single dimension (EDMA_TPCC_ABCNT_n[15:0] ACNT == EDMA_TPCC_BIDX_n) and the ACNT value is a power of 2.

Table 11-24 lists conditions in which the optimizations are performed.

Table 11-24. Read/Write Command Optimization Rules

ACNT ≤ DBS	ACNT is power of 2	BIDX = ACNT	BCNT ≤ 1023	SAM/DAM = Increment	Description
Yes	Yes	Yes	Yes	Yes	Optimized
No	x	x	x	x	Not Optimized
x	No	x	x	x	Not Optimized
x	x	No	x	x	Not Optimized
x	x	x	No	x	Not Optimized
x	x	x	x	No	Not Optimized

11.4.12.1.2 TR Pipelining

TR pipelining refers to the ability of the source active set to proceed ahead of the destination active set. Essentially, the reads for a given TR may already be in progress while the writes of a previous TR may not have completed.

The number of outstanding TRs is limited by the number of destination FIFO register entries.

TR pipelining is useful for maintaining throughput on back-to-back small TRs. It minimizes the startup overhead because reads start in the background of a previous TR writes.

Example 11-4. Command Fragmentation (DBS = 64)

The pseudo code:

1. EDMA_TPTCn_PCNT[15:0] ACNT = 8, EDMA_TPTCn_PCNT[31:16] BCNT = 8, EDMA_TPTCn_PBIDX[15:0] SBIDX = 8, EDMA_TPTCn_PBIDX[31:16] DBIDX = 10, EDMA_TPTCn_PSRC[31:0] SADDR = 64, EDMA_TPTCn_SADST[31:0] DADDR = 191

   Read Controller: This is optimized from a 2D-transfer to a 1D-transfer such that the read side is equivalent to EDMA_TPTCn_PCNT[15:0] ACNT = 64, EDMA_TPTCn_PCNT[31:16] BCNT = 1.

   Cmd0 = 64 byte

   Write Controller: Because DBIDX != ACNT, it is not optimized.

   Cmd0 = 8 byte, Cmd1 = 8 byte, Cmd2 = 8 byte, Cmd3 = 8 byte, Cmd4 = 8 byte, Cmd5 = 8 byte, Cmd6 = 8 byte, Cmd7 = 8 byte.

2. EDMA_TPTCn_PCNT[15:0] ACNT=128, EDMA_TPTCn_PCNT[31:16] BCNT = 1, EDMA_TPTCn_PSRC[31:0] SADDR = 63, EDMA_TPTCn_SADST[31:0] DADDR = 513

   Read Controller: Read address is not aligned.

   Cmd0 = 1 byte, (now the SADDR is aligned to 64 for the next command)

   Cmd1 = 64 bytes

   Cmd2 = 63 bytes

   Write Controller: The write address is also not aligned.

   Cmd0 = 63 bytes, (now the DADDR is aligned to 64 for the next command)

   Cmd1 = 64 bytes

   Cmd2 = 1 byte

11.4.12.1.3 Performance Tuning

By default, reads are as issued as fast as possible. In some cases, the reads issued by the EDMA_TPTC could fill the available command buffering for a slave, delaying other (potentially higher priority) masters from successfully submitting commands to that slave. The rate at which read commands are issued by the EDMA_TPTC is controlled by the EDMA_TPTCn_RDRATE register. The EDMA_TPTCn_RDRATE register defines the number of cycles that the EDMA_TPTC read controller waits before issuing subsequent commands for a given TR, thus minimizing the chance of the EDMA_TPTC consuming all available slave resources. The EDMA_TPTCn_RDRATE[2:0] RDRATE value must be set to a relatively small value if the transfer controller is targeted for high priority transfers and to a higher value if the transfer controller is targeted for low priority transfers.

In contrast, the Write Interface does not have any performance turning knobs because writes always have an interval between commands as write commands are submitted along with the associated write data.

11.4.12.2 Memory Protection

The transfer controller plays an important role in handling proxy memory protection. There are two access properties associated with a transfer: for instance, the privilege id (system-wide identification assigned to a master) of the master initiating the transfer, and the privilege level (user versus supervisor) used to program the transfer. This information is maintained in the PaRAM set when it is programmed in the channel controller. When a TR is submitted to the transfer controller, this information is made available to the EDMA_TPTC and used by the EDMA_TPTC while issuing read and write commands. The read or write commands have the same privilege identification, and privilege level as that programmed in the EDMA transfer in the channel controller.

11.4.12.3 Error Generation

Errors are generated if enabled under three conditions:

- EDMA_TPTC detection of an error signaled by the source or destination address.
- Attempt to read or write to an invalid address in the configuration memory map.

- Detection of a constant addressing mode TR violating the constant addressing mode transfer rules (the source/destination addresses and source/destination indexes must be aligned to 32 bytes).

Either or all error types may be disabled. If an error bit is set and enabled, the error interrupt for the concerned transfer controller is generated.

11.4.12.4 Debug Features

The DMA program register set, DMA source active register set, and the destination FIFO register set are used to derive a brief history of TRs serviced through the transfer controller.

Additionally, the EDMA_TPTC status register EDMA_TPTCn_TCSTAT has dedicated bit fields to indicate the ongoing activity within different parts of the transfer controller:

- The EDMA_TPTCn_TCSTAT[1] SRCACTV bit indicates whether the source active set is active.
- The EDMA_TPTCn_TCSTAT[6:4] DSTACTV bit indicates the number of TRs resident in the destination register active set at a given instance.
- The EDMA_TPTCn_TCSTAT[0] PROGBUSY bit indicates whether a valid TR is present in the DMA program set.

NOTE: If the TRs are in progression, it must realize that there is a chance that the values read from the EDMA_TPTC status registers will be inconsistent since the EDMA_TPTC changes the values of these registers due to ongoing activities.

It is recommended that to ensure no additional submission of TRs to the EDMA_TPTC in order to facilitate ease of debug.

11.4.12.4.1 Destination FIFO Register Pointer

The destination FIFO register pointer is implemented as a circular buffer with the start pointer being EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR and a buffer depth of usually 2 or 4. The EDMA_TPTC maintains two important status details in EDMA_TPTCn_TCSTAT that are used during advanced debugging, if necessary. The EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR is a start pointer, the index to the head of the destination FIFO register. The EDMA_TPTCn_TCSTAT[6:4] DSTACTV is a counter for the number of valid (occupied) entries. These registers are used to get a brief history of transfers.

Examples of some register field values and their interpretation:

- EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR = 0x0 and EDMA_TPTCn_TCSTAT[6:4] DSTACTV = 0x0 implies that no TRs are stored in the destination FIFO register.
- EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR = 0x1 and EDMA_TPTCn_TCSTAT[6:4] DSTACTV = 0x2 implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 1 and the second pending TR is read from the destination FIFO register entry 2.
- EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR = 0x3 and EDMA_TPTCn_TCSTAT[6:4] DSTACTV = 0x2 implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 3 and the second pending TR is read from the destination FIFO register entry 0.

11.4.12.5 EDMA_TPTC Configuration

Table 11-25 provides the configuration of the individual EDMA transfer controllers present on the device. The DBS for each transfer controller is defined by Control Module register (CTRL_CORE_CONTROL_IO_1) settings.

Table 11-25. EDMA Transfer Controller Configurations

Name	TC0	TC1
EDMA_TPTCn_TCCFG[2:0] FIFOSIZE	1024 bytes	1024 bytes
EDMA_TPTCn_TCCFG[5:4] BUSWIDTH	16 bytes	16 bytes
EDMA_TPTCn_TCCFG[9:8] DSTREGDEPTH	4 entries	4 entries

Table 11-25. EDMA Transfer Controller Configurations (continued)

Name	TC0	TC1
DBS	Defined by CTRL_CORE_CONTROL_IO_1[9:8] TC0_DEFAULT_BURST_SIZE	Defined by CTRL_CORE_CONTROL_IO_1[13:12] TC1_DEFAULT_BURST_SIZE

11.4.13 Event Dataflow

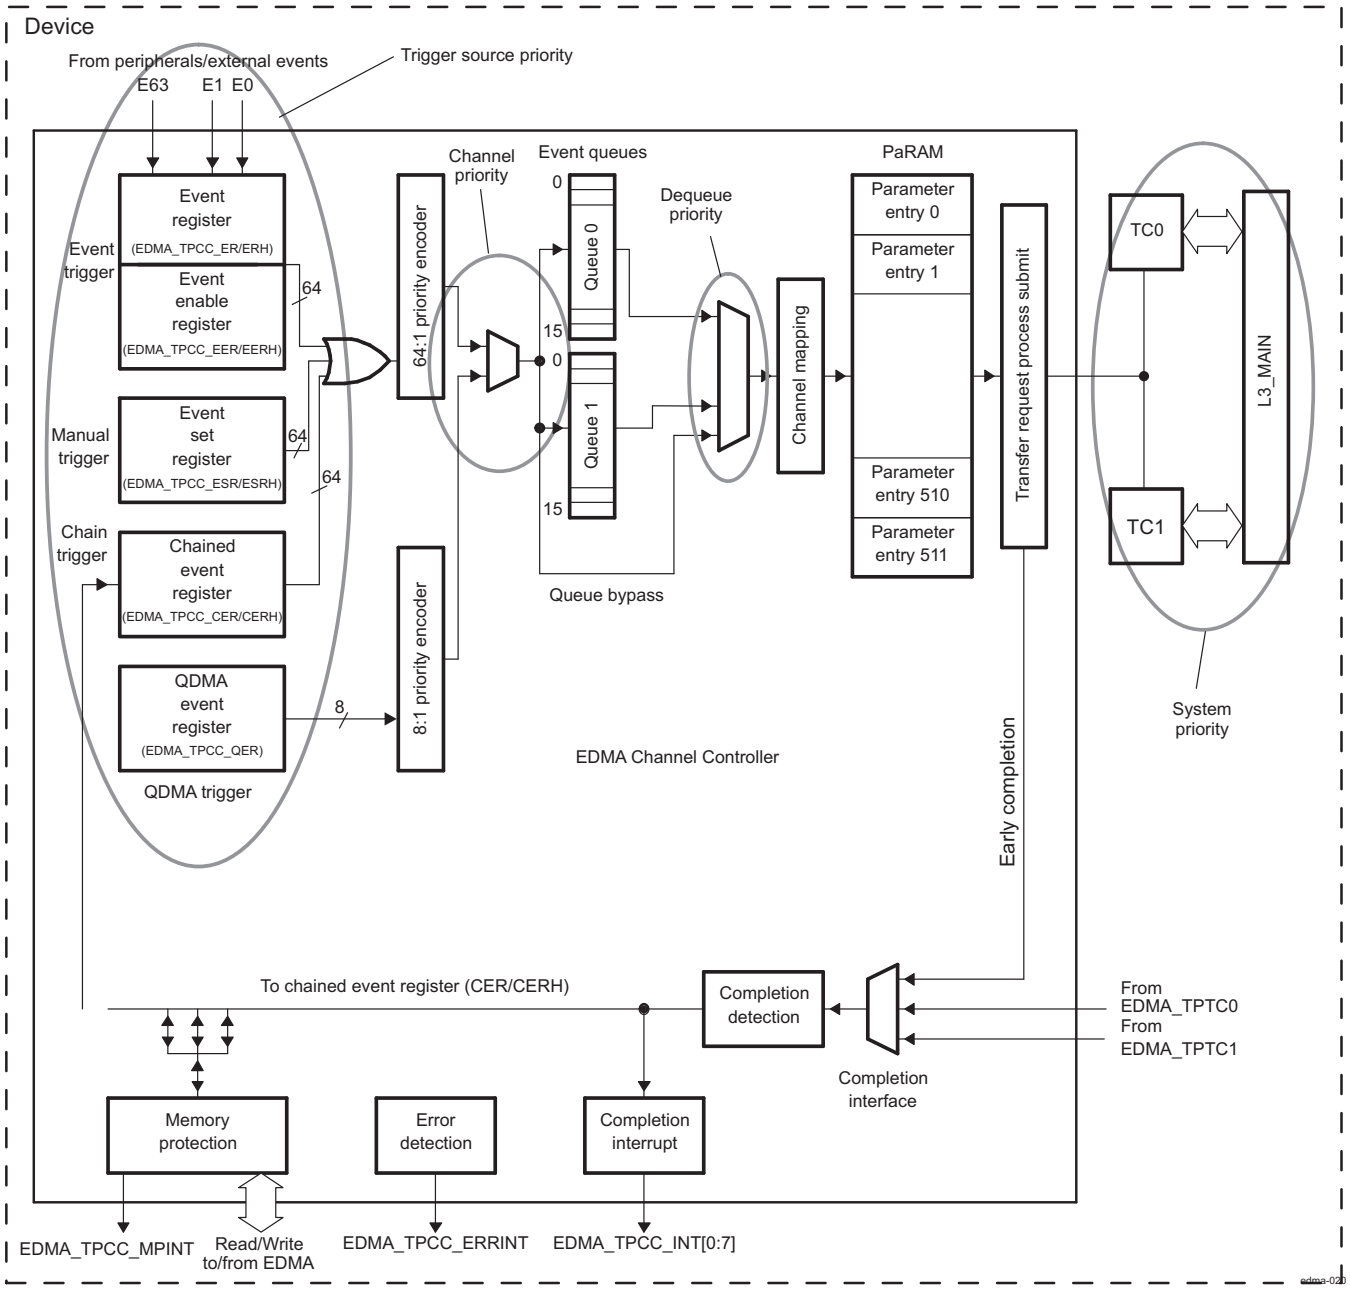
This section summarizes the data flow of a single event, from the time the event is latched to the channel controller to the time the transfer completion code is returned. The following steps list the sequence of EDMA_TPCC activity:

1. Event is asserted from an external source (peripheral or external interrupt). This also is similar for a manually-triggered, chained-triggered, or QDMA-triggered event. The event is latched into the EDMA_TPCC_ER[31:0]E*n* / EDMA_TPCC_ERH[31:0] E*n* (or EDMA_TPCC_CER[31:0] E*n* / EDMA_TPCC_CERH[31:0] E*n*, EDMA_TPCC_ESR[31:0] E*n* / EDMA_TPCC_ESRH[31:0] E*n*, EDMA_TPCC_QER[7:0] E*n*) bit.
2. Once an event is prioritized and queued into the appropriate event queue, the EDMA_TPCC_SER[31:0] E*n* \ EDMA_TPCC_SERH[31:0] E*n* (or EDMA_TPCC_QSER[7:0] E*n*) bit is set to inform the event prioritization / processing logic to disregard this event since it is already in the queue. Alternatively, if the transfer controller and the event queue are empty, then the event bypasses the queue.
3. The EDMA_TPCC processing and the submission logic evaluates the appropriate PaRAM set and determines whether it is a non-null and non-dummy transfer request (TR).
4. The EDMA_TPCC clears the EDMA_TPCC_ER[31:0] E*n*/ EDMA_TPCC_ERH[31:0] E*n* (or EDMA_TPCC_CER[31:0] E*n* / EDMA_TPCC_CERH[31:0] E*n*, EDMA_TPCC_ESR[31:0]E*n* / EDMA_TPCC_ESRH[31:0] E*n*, EDMA_TPCC_QER[31:0] E*n*) bit and the EDMA_TPCC_SER[31:0] E*n*/EDMA_TPCC_SERH[31:0] E*n* bit as soon as it determines the TR is non-null. In the case of a null set, the EDMA_TPCC_SER[31:0] E*n*/ EDMA_TPCC_SERH[31:0] E*n* bit remains set. It submits the non-null/non-dummy TR to the associated transfer controller. If the TR was programmed for early completion, the EDMA_TPCC immediately sets the interrupt pending register (EDMA_TPCC_IPR[31:0] I[TCC] / EDMA_TPCC_IPRH[31:0] I[TCC] - 32).
5. If the TR was programmed for normal completion, the EDMA_TPCC sets the interrupt pending register (EDMA_TPCC_IPR[31:0] I[TCC] / EDMA_TPCC_IPRH[31:0] I[TCC]) when the EDMA_TPTC informs the EDMA_TPCC about completion of the transfer (returns transfer completion codes).
6. The EDMA_TPCC programs the associated EDMA_TPTC's Program Register Set with the TR.
7. The TR is then passed to the Source Active set and the DST FIFO Register Set, if both the register sets are available.
8. The Read Controller processes the TR by issuing read commands to the source slave endpoint. The Read Data lands in the Data FIFO of the EDMA_TPTC*n*.
9. As soon as sufficient data is available, the Write Controller begins processing the TR by issuing write commands to the destination slave endpoint.
10. This continues until the TR completes and the EDMA_TPTC*n* then signals completion status to the EDMA_TPCC.

11.4.14 EDMA controller Prioritization

The EDMA controller has many implementation rules to deal with concurrent events/channels, transfers, etc. The following subsections detail various arbitration details whenever there might be occurrence of concurrent activity. Figure 11-21 shows the different places EDMA priorities come into play.

Figure 11-21. EDMA Prioritization



11.4.14.1 Channel Priority

The EDMA event registers EDMA_TPCC_ER and EDMA_TPCC_ERH capture up to 64 events, the QDMA event register EDMA_TPCC_QER captures QDMA events for all QDMA channels therefore, it is possible for events to occur simultaneously on the DMA/QDMA event inputs. For events arriving simultaneously, the event associated with the lowest channel number is prioritized for submission to the event queues (for DMA events, channel 0 has the highest priority and channel 63 has the lowest priority, for QDMA events, channel 0 has the highest priority and channel 7 has the lowest priority). This mechanism only sorts simultaneous events for submission to the event queues.

If a DMA and QDMA event occurs simultaneously, the DMA event always has prioritization against the QDMA event for submission to the event queues.

11.4.14.2 Trigger Source Priority

If a EDMA channel is associated with more than one trigger source (event trigger, manual trigger, and chain trigger), and if multiple events are set simultaneously for the same channel (EDMA_TPCC_ER[31:0] E*n* = 1, EDMA_TPCC_ESR[31:0] E*n* = 1 , EDMA_TPCC_CER[31:0] E*n* = 1) , then the EDMA_TPCC always services these events in the following priority order: event trigger (via EDMA_TPCC_ER) is higher priority than chain trigger (via EDMA_TPCC_CER) and chain trigger is higher priority than manual trigger (via EDMA_TPCC_ESR).

This implies that if for channel 0, both EDMA_TPCC_ER[0] E0 = 1 and EDMA_TPCC_CER[0] E0 = 1 at the same time, then the EDMA_TPCC_ER[0] E0 event is always queued before the EDMA_TPCC_CER[0] E0 event.

11.4.14.3 Dequeue Priority

The priority of the associated transfer request (TR) is further mitigated by which event queue is being used for event submission (dictated by EDMA_TPCC_DMAQNUMN_k and EDMA_TPCC_QDMAQNUM). For submission of a TR to the transfer request, events need to be de-queued from the event queues. Queue 0 has the highest dequeue priority and queue 1 the lowest.

11.4.15 EDMA Power, Reset and Clock Management

11.4.15.1 Clock and Power Management

The EDMA channel controller and transfer controller are clocked from L3MIAN1_L3_GICLK interface clock. The EDMA system runs at the L3 clock frequency.

The Auto clock gating for the EDMA_TPCC module is controlled by the EDMA_TPCC_CLKGDIS[0] CLKGDIS bit at the module level.

The L3MIAN1_L3_GICLK interface clock to EDMA controller's modules are controlled by the following registers in the PRCM module:

- PRCM.CM_L3MAIN1_TPCC_CLKCTRL - manages EDMA_TPCC module clock.
- PRCM.CM_L3MAIN1_TPTC1_CLKCTRL - manages EDMA_TPTC0 module clock.
- PRCM.CM_L3MAIN1_TPTC2_CLKCTRL - manages EDMA_TPTC1 module clock.

EDMA_TPCC and EDMA_TPTC0 and EDMA_TPTC1 modules have wakeup depandaces to several device modules. The wakeup dependency based on EDMA modules service requests are controlled by registers in PRCM module:

- PRCM.PM_L3MAIN1_TPCC_WKDEP - controls wakeup dependency based on TPCC service requests.
- PRCM.PM_L3MAIN1_TPTC1_WKDEP - controls wakeup dependency based on TPTC0 service requests.
- PRCM.PM_L3MAIN1_TPTC2_WKDEP - controls wakeup dependency based on TPTC1 service requests.

  The EDMA_TPCC, EDMA_TPTC0 and EDMA_TPTC1 can be placed in reduced-power modes to conserve power during periods of low activity. The power management of the peripheral is controlled by the PRCM module. The PRCM acts as a master controller for power management for all peripherals on the device.

  The EDMA controller can be idled on receiving a clock stop request from the PRCM. The requests to EDMA_TPCC and EDMA_TPTC0 and EDMA_TPTC1 are separate. In general, it should be verified that there are no pending activities in the EDMA controller

NOTE: When EDMA controler modules no longer require the interface clock, software can disable it at the PRCM level by configuring the MODULEMODE bit field (PRCM.CM_L3MAIN1_TPCC_CLKCTRL[1:0], PRCM.CM_L3MAIN1_TPTC1_CLKCTRL[1:0], PRCM.CM_L3MAIN1_TPTC2_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At the PRCM level, when all the conditions to shut off the L3MIAN1_L3_GICLK clock are met the PRCM module automatically launches a hardware handshake protocol to ensure EDMA modules are ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the EDMA modules. For more information, refer to Chapter 3, *Power, Reset, and Clock Management*.

11.4.15.2 Reset Considerations

A hardware resets the EDMA (EDMA_TPCC, EDMA_TPTC0 and EDMA_TPTC1) and the EDMA configuration registers. The PaRAM memory contents are undefined after device reset and it should not rely on parameters to be reset to a known state. The PaRAM entry must be initialized to a desired value before it is used. The EDMA modules are reset by CORE_RET_RST reset signal from PRCM.

11.4.16 Emulation Considerations

During debug when using the emulator, the CPU(s) may be halted on an execute packet boundary for single-stepping, benchmarking, profiling, or other debug purposes. During an emulation halt, the EDMA channel controller and transfer controller operations continue. Events continue to be latched and processed and transfer requests continue to be submitted and serviced.

Since EDMA is involved in servicing multiple master and slave peripherals, it is not feasible to have an independent behavior of the EDMA for emulation halts. EDMA functionality would be coupled with the peripherals it is servicing, which might have different behavior during emulation halts.

11.5 EDMA Transfer Examples

The EDMA channel controller performs a variety of transfers depending on the parameter configuration. The following sections provide a description and PaRAM configuration for some typical use case scenarios.

11.5.1 Block Move Example

The most basic transfer performed by the EDMA is a block move. During device operation it is often necessary to transfer a block of data from one location to another, usually between on-chip and off-chip memory.

In this example, a section of data is to be copied from external memory to internal L2 SRAM as shown in Figure 11-22.

The source address for the transfer is set to the start of the data block in external memory, and the destination address is set to the start of the data block in L2. If the data block is less than 64K bytes, the PaRAM configuration shown in Figure 11-23 holds true with the synchronization type set to A-synchronized and indexes cleared to 0. If the amount of data is greater than 64K bytes, EDMA_TPCC_ABCNT_n[31:16] BCNT and the B-indexes need to be set appropriately with the synchronization type set to AB-synchronized. The EDMA_TPCC_OPT_n[3] STATIC bit is set to prevent linking.

This transfer example may also be set up using QDMA. For successive transfer submissions, of a similar nature, the number of cycles used to submit the transfer are fewer depending on the number of changing transfer parameters. The QDMA trigger word must be programed to be the highest numbered offset in the PaRAM set that undergoes change.

Figure 11-23 shows the parameters Block Move transfer.

Figure 11-22. Block Move Example

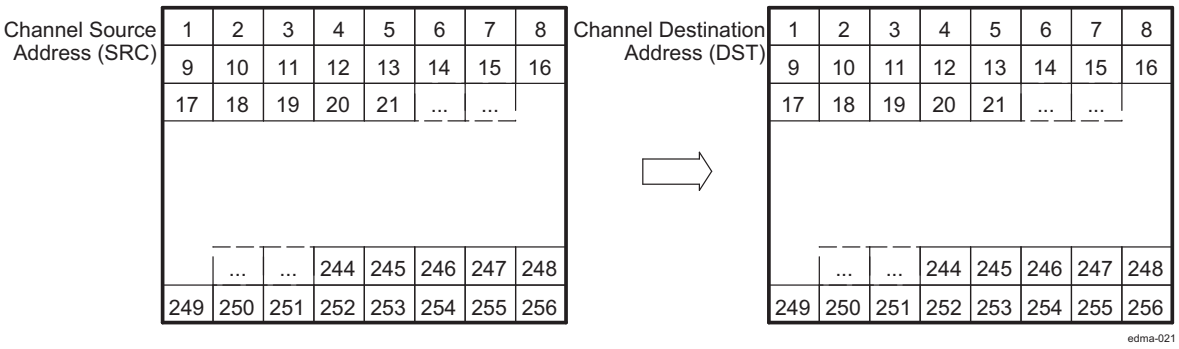


Figure 11-23. Block Move Example PaRAM Configuration

(a) EDMA Parameters

Parameter Contents	
0010 0008h	
Channel Source Address (SRC)	
0001h	0100h
Channel Destination Address (DST)	
0000h	0000h
0000h	FFFFh
0000h	0000h
0000h	0001h

Parameter	
Channel Options Parameter (OPT)	
Channel Source Address (SRC)	
Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
Channel Destination Address (DST)	
Destination BCNT Index (DBIDX)	Source BCNT Index (SBIDX)
BCNT Reload (BCNTRLD)	Link Address (LINK)
Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
Reserved	Count for 3rd Dimension (CCNT)

(b)Channel Options Parameter (OPT) Content

- EDMA_TPCC_OPT_n[3] STATIC = 0x1
- EDMA_TPCC_OPT_n[20] TCINTEN = 0x1

11.5.2 Subframe Extraction Example

The EDMA can efficiently extract a small frame of data from a larger frame of data. By performing a 2D-to-1D transfer, the EDMA retrieves a portion of data for the CPU to process. In this example, a 640 × 480-pixel frame of video data is stored in external memory. Each pixel is represented by a 16-bit halfword. The CPU extracts a 16 × 12-pixel subframe of the image for processing. To facilitate more efficient processing time by the CPU, the EDMA places the subframe in internal L2 SRAM. Figure 11-24 shows the transfer of a subframe from external memory to L2.

The same PaRAM entry options are used for QDMA channels, as well as DMA channels. The EDMA_TPCC_OPT_n[3] STATIC bit is set to prevent linking. For successive transfers, only changed parameters need to be programmed before triggering the channel.

Figure 11-25 shows the parameters for Subframe Extraction transfer.

Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
Reserved	Count for 3rd Dimension (CCNT)

(b)Channel Options Parameter (OPT) Content

- EDMA_TPCC_OPT_n[2] SYNCDIM = 0x1
- EDMA_TPCC_OPT_n[3] STATIC = 0x1
- EDMA_TPCC_OPT_n[20] TCINTEN = 0x1

11.5.3 Data Sorting Example

Many applications require the use of multiple data arrays, it is often desirable to have the arrays arranged such that the first elements of each array are adjacent, the second elements are adjacent, and so on. Often this is not how the data is presented to the device. Either data is transferred via a peripheral with the data arrays arriving one after the other or the arrays are located in memory with each array occupying a portion of contiguous memory spaces. For these instances, the EDMA can reorganize the data into the desired format.

To determine the parameter set values, the following need to be considered:

- ACNT - Program this to be the size in bytes of an element.
- BCNT - Program this to be the number of elements in a frame.
- CCNT - Program this to be the number of frames.
- SBIDX - Program this to be the size of the element or ACNT.
- DBIDX - CCNT × ACNT
- SCIDX - ACNT × BCNT
- DCIDX - ACNT

The synchronization type needs to be AB-synchronized and the EDMA_TPCC_OPT_n[3] STATIC bit is 0 to allow updates to the parameter set. It is advised to use normal EDMA channels for sorting.

It is not possible to sort this with a single trigger event. Instead, the channel can be programmed to be chained to itself. After BCNT elements get sorted, intermediate chaining could be used to trigger the channel again causing the transfer of the next BCNT elements and so on. Figure 11-27 shows the parameter set programming for this transfer, assuming channel 0 and an element size of 4 bytes.

Figure 11-26 shows the Data Sorting transfer

11.5.4 Peripheral Servicing Example

The EDMA channel controller also services peripherals in the background of CPU operation, without requiring any CPU intervention. Through proper initialization of the EDMA channels, they can be configured to continuously service on-chip and off-chip peripherals throughout the device operation. Each event available to the EDMA has its own dedicated channel, and all channels operate simultaneously. The only requirements are to use the proper channel for a particular transfer and to enable the channel event in the event enable register EDMA_TPCC_EER. When programming an EDMA channel to service a peripheral, it is necessary to know how data is to be presented to the processor. Data is always provided with some kind of synchronization event as either one element per event (non-bursting) or multiple elements per event (bursting).

11.5.4.1 Non-bursting Peripherals

Non-bursting peripherals include the on-chip multichannel audio serial port (McASP) and many external devices, such as codecs. Regardless of the peripheral, the EDMA channel configuration is the same.

The McASP transmit and receive data streams are treated independently by the EDMA. The transmit and receive data streams can have completely different counts, data sizes, and formats.

To transfer the incoming data stream to its proper location in DDR memory, the EDMA channel must be set up for a 1D-to-1D transfer with A-synchronization. Because an event (AREVT) is generated for every word as it arrives, it is necessary to have the EDMA issue the transfer request for each element individually. Figure 11-29 shows the parameters for this transfer. The source address of the EDMA channel is set to the data port address (DAT) for McASP, and the destination address is set to the start of the data block in DDR. Because the address of serializer buffer is fixed, the source B index is cleared to 0 (no modification) and the destination B index is set to 0x2 (increment).

Based on the premise that serial data is typically a high priority, the EDMA channel should be programmed to be on queue 0.

Figure 11-28 shows servicing incoming McASP data.

11.5.4.2 Bursting Peripherals

Higher bandwidth applications require that multiple data elements be presented to the processor core for every synchronization event. This frame of data can either be from multiple sources that are working simultaneously or from a single high-throughput peripheral that streams data to/from the processor.

In this example, a port is receiving a video frame from a camera and presenting it to the DSP one array at a time. The video image is 640 × 480 pixels, with each pixel represented by a 16-bit element. The image is to be stored in external memory.

To transfer data from an external peripheral to an external buffer one array at a time based on EVT*n* , channel *n* must be configured. Due to the nature of the data (a video frame made up of arrays of pixels) the destination is essentially a 2D entity. Figure 11-31 shows the parameters to service the incoming data with a 1D-to-2D transfer using AB-synchronization. The source address is set to the location of the video framer peripheral, and the destination address is set to the start of the data buffer. Because the input address is static, the BDIX_n[15:0] SBIDX is 0 (no modification to the source address). The destination is made up of arrays of contiguous, linear elements; therefore, the EDMA_TPCC_BIDX_n[31:16] DBIDX is set to pixel size, 2 bytes. EDMA_TPCC_ABCNT_n[15:0] ANCT is equal to the pixel size, 2 bytes. EDMA_TPCC_ABCNT_n[31:16] BCNT is set to the number of pixels in an array, 640. EDMA_TPCC_CCNT_n[15:0] CCNT is equal to the total number of arrays in the block, 480. EDMA_TPCC_CIDX_n[15:0] SCIDX is 0 because the source address undergoes no increment. The EDMA_TPCC_CIDX_n[31:16] DCIDX is equal to the difference between the starting addresses of each array. Because one pixel is 16 bits (2 bytes), EDMA_TPCC_CIDX_n[31:16] DCIDX is equal to 640 × 2.

11.5.4.3 Continuous Operation

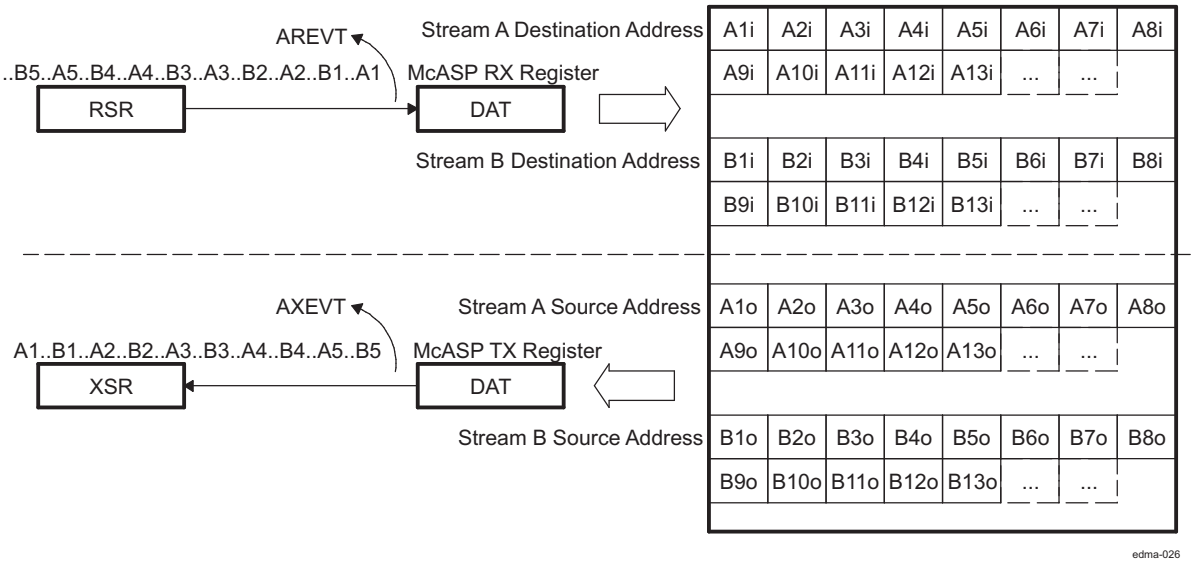
Configuring an EDMA channel to receive a single frame of data is useful, and is applicable to some systems. A majority of the time, however, data is going to be continuously transmitted and received throughout the entire operation of the processor. In this case, it is necessary to implement some form of linking such that the EDMA channels continuously reload the necessary parameter sets. In this example, McASP is configured to transmit and receive data on a T1 array. To simplify the example, only two channels are active for both transmit and receive data streams. Each channel receives packets of 128 elements. The packets are transferred from the serial port to internal memory and from internal memory to the serial port, as shown in Figure 11-32.

The McASP generates AREVT for every element received and generates AXEVT for every element transmitted. To service the data streams, them DMA channels associated with the McASP must be setup for 1D-to-1D transfers with A-synchronization.

Figure 11-33 shows the parameter entries for the channel for these transfers. To service the McASP continuously throughout DSP operation, the channels must be linked to a duplicate PaRAM set in the PaRAM. After all frames have been transferred, the EDMA channels reload and continue.

Figure 11-34 shows the reload parameters for the channel.

Figure 11-32. Servicing Continuous McASP Data Example



11.5.4.3.1 Receive Channel

EDMA channel 15 services the incoming data stream of McASP. The source address is set to that of the receive serializer buffer, and the destination address is set to the first element of the data block. Because there are two data channels being serviced, A and B, they are to be located separately within the L2 SRAM.

To facilitate continuous operation, a copy of the PaRAM set for the channel is placed in PaRAM set 64. The LINK option is set and the link address is provided in the PaRAM set. Upon exhausting the channel 15 parameter set, the parameters located at the link address are loaded into the channel 15 parameter set and operation continues. This function continues throughout device operation until halted by the CPU.

11.5.4.3.2 Transmit Channel

EDMA channel 12 services the outgoing data stream of McASP. In this case the destination address needs no update, hence, the parameter set changes accordingly. Linking is also used to allow continuous operation by the EDMA channel, with duplicate PaRAM set entries at PaRAM set 65.

11.5.4.4 Ping-Pong Buffering

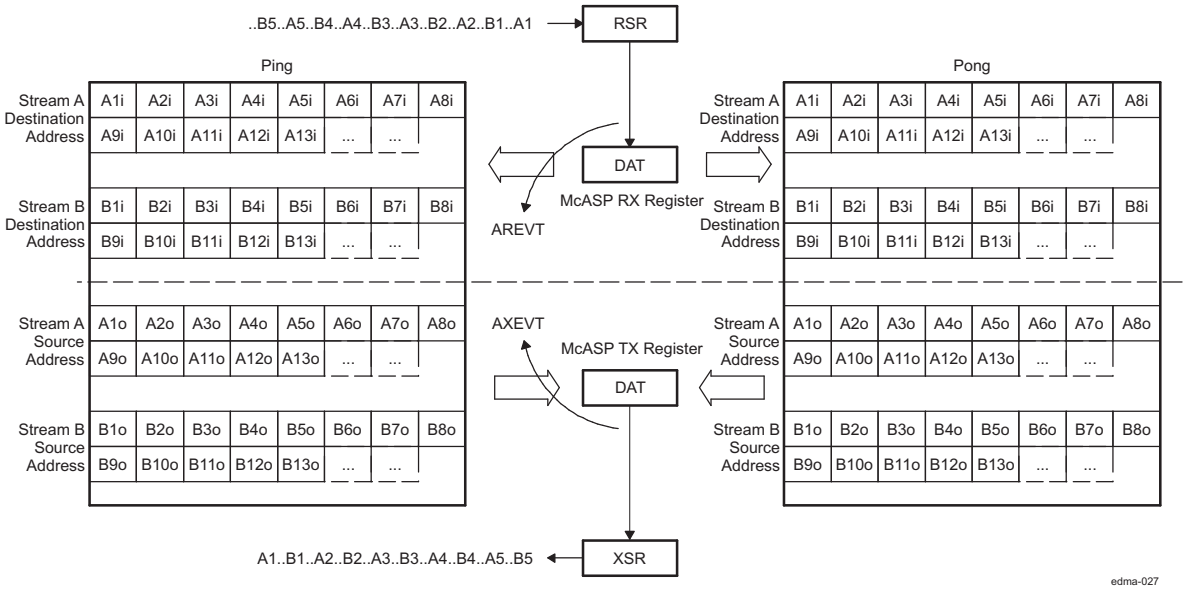
Although the previous configuration allows the EDMA to service a peripheral continuously, it presents a number of restrictions to the CPU. Because the input and output buffers are continuously being filled/emptied, the CPU must match the pace of the EDMA very closely to process the data. The EDMA receive data must always be placed in memory before the CPU accesses it, and the CPU must provide the output data before the EDMA transfers it. Though not impossible, this is an unnecessary challenge. It is particularly difficult in a 2-level cache scheme.

Ping-pong buffering is a simple technique that allows the CPU activity to be distanced from the EDMA activity. This means that there are multiple (usually two) sets of data buffers for all incoming and outgoing data streams. While the EDMA transfers the data into and out of the ping buffers, the CPU manipulates the data in the pong buffers. When both CPU and EDMA activity completes, they switch. The EDMA then writes over the old input data and transfers the new output data. Figure 11-35 shows the ping-pong scheme for this example.

To change the continuous operation example, such that a ping-pong buffering scheme is used, the EDMA channels need only a moderate change. Instead of one parameter set, there are two; one for transferring data to/from the ping buffers and one for transferring data to/from the pong buffers. As soon as one transfer completes, the channel loads the PaRAM set for the other and the data transfers continue. Figure 11-36 shows the EDMA channel configuration required.

Each channel has two parameter sets, ping and pong. The EDMA channel is initially loaded with the ping parameters (Figure 11-37). The link address for the ping set is set to the PaRAM offset of the pong parameter set (Figure 11-37). The link address for the pong set is set to the PaRAM offset of the ping parameter set (Figure 11-38). The channel options, count values, and index values are all identical between the ping and pong parameters for each channel. The only differences are the link address provided and the address of the data buffer.

Figure 11-35. Ping-Pong Buffering for McASP Data Example



11.5.4.4.1 Synchronization with the CPU

To utilize the ping-pong buffering technique, the system must signal the CPU when to begin to access the new data set. After the CPU finishes processing an input buffer (ping), it waits for the EDMA to complete before switching to the alternate (pong) buffer. In this example, both channels provide their channel numbers as their report word and set the EDMA_TPCC_OPT_n[20] TCINTEN bit to generate an interrupt after completion. When channel 15 fills an input buffer, the E15 bit in the interrupt pending register

EDMA_TPCC_IPR is set; when channel 12 empties an output buffer, the E12 bit in EDMA_TPCC_IPR is set. The CPU must manually clear these bits. With the channel parameters set, the CPU polls EDMA_TPCC_IPR to determine when to switch. The EDMA and CPU could alternatively be configured such that the channel completion interrupts the CPU. By doing this, the CPU could service a background task while waiting for the EDMA to complete.

11.5.4.5 Transfer Chaining Examples

The following examples explain the intermediate transfer complete chaining function.

11.5.4.5.1 Servicing Input/Output FIFOs with a Single Event

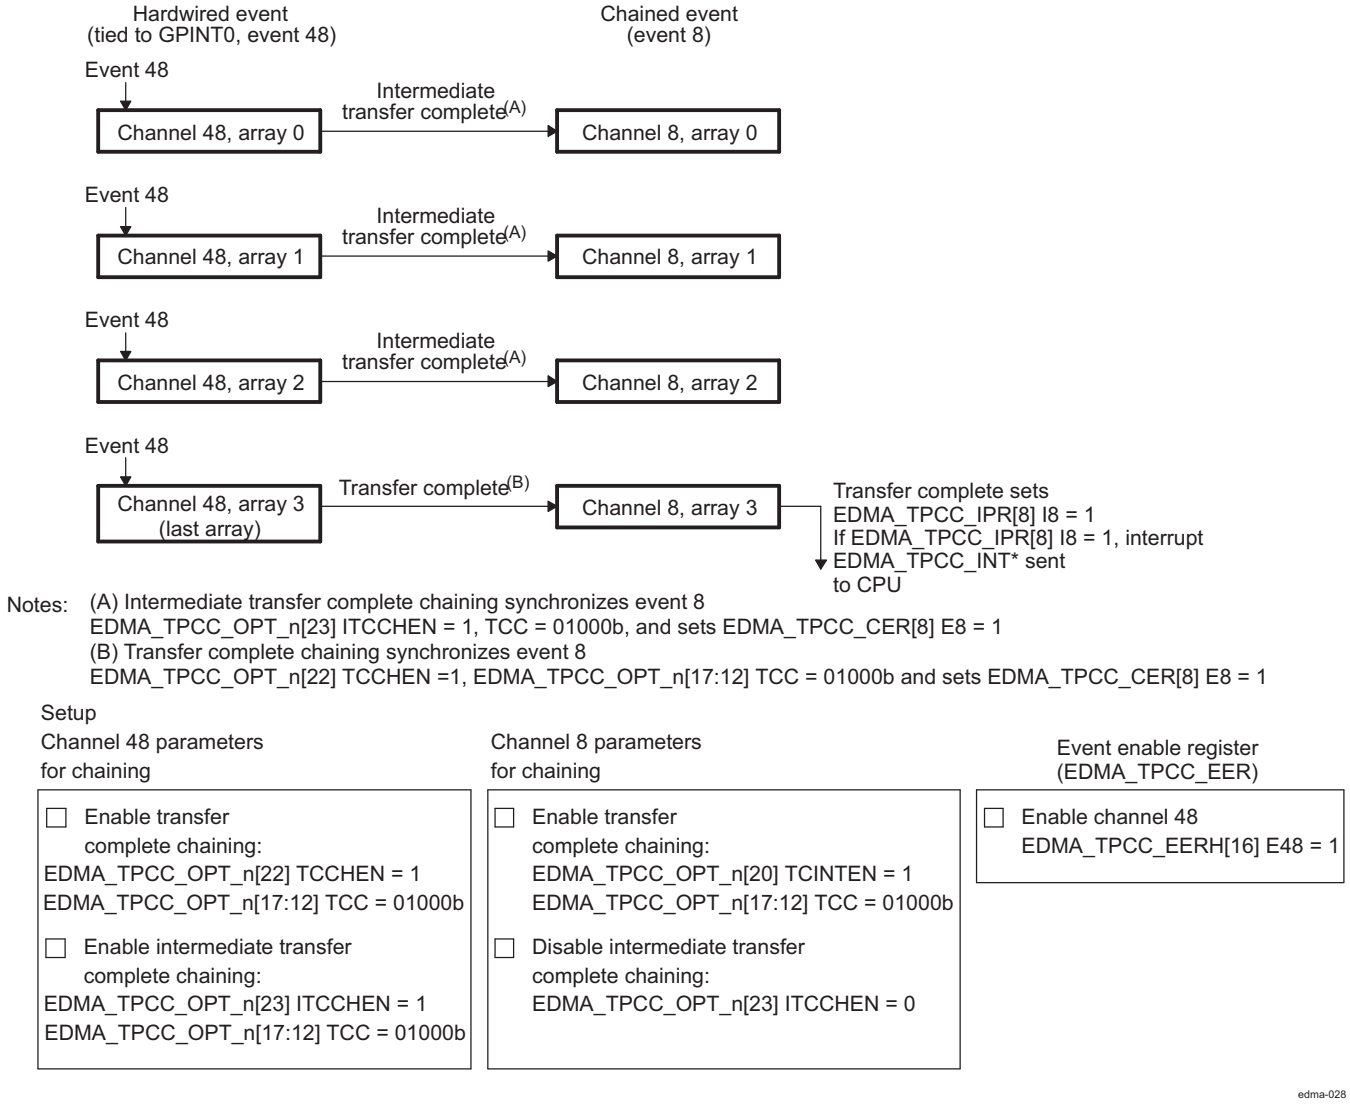
Many systems require the use of a pair of external FIFOs that must be serviced at the same rate. One FIFO buffers data input, and the other buffers data output. The EDMA channels that service these FIFOs can be set up for AB-synchronized transfers. While each FIFO is serviced with a different set of parameters, both can be signaled from a single event.

For example, an external interrupt pin can be tied to the status flags of one of the FIFOs. When this event arrives, the EDMA needs to perform servicing for both the input and output streams. Without the intermediate transfer complete chaining feature this would require two events, and thus two external interrupt pins. The intermediate transfer complete chaining feature allows the use of a single external event (for example, a GPIO event). Figure 11-39 shows the EDMA setup and illustration for this example.

A GPIO event (in this case, GPINT0) triggers an array transfer. Upon completion of each intermediate array transfer of channel 48, intermediate transfer complete chaining sets the E8 bit (specified by TCC of 8) in the chained event register EDMA_TPCC_CER and provides a synchronization event to channel 8. Upon completion of the last array transfer of channel 48, transfer complete chaining—not intermediate transfer complete chaining—sets the E8 bit in EDMA_TPCC_CER (specified by EDMA_TPCC_OPT_n[11] TCCMODE: TCC) and provides a synchronization event to channel 8. The completion of channel 8 sets the I8 bit (specified by EDMA_TPCC_OPT_n[11] TCCMODE: TCC) in the interrupt pending register EDMA_TPCC_IPR, which can generate an interrupt to the CPU, if the I8 bit in the interrupt enable register EDMA_TPCC_IER is set.

Figure 11-39 shows the Intermediate Transfer Completion Chaining Example.

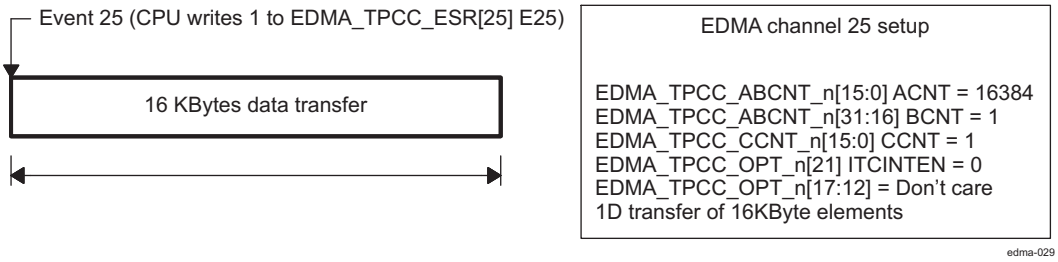
Figure 11-39. Intermediate Transfer Completion Chaining Example



11.5.4.5.2 Breaking Up Large Transfers with Intermediate Chaining

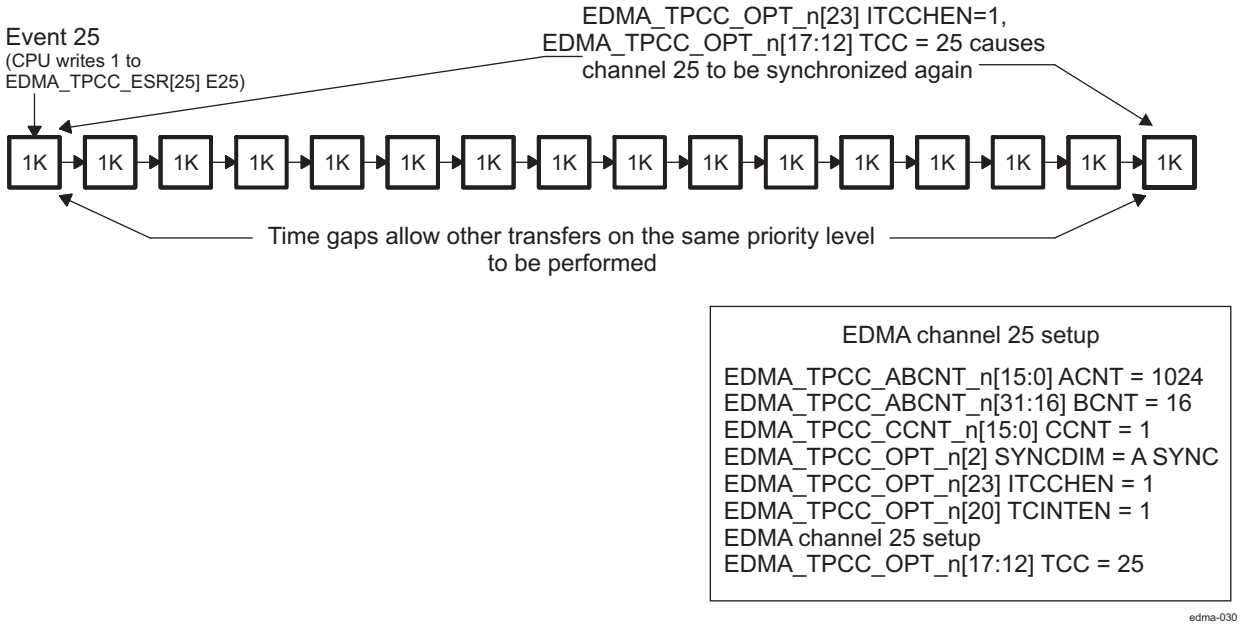
Another feature of intermediate transfer chaining EDMA_TPCC_OPT_n[23] ITCCHEN is for breaking up large transfers. A large transfer may lock out other transfers of the same priority level for the duration of the transfer. For example, a large transfer on queue 0 from the internal memory to the external memory using the EMIF may starve other EDMA transfers on the same queue. In addition, this large high-priority transfer may prevent the EMIF for a long duration to service other lower priority transfers. When a large transfer is considered to be high priority, it should be split into multiple smaller transfers. Figure 11-40 shows the EDMA setup and illustration of an example single large block transfer.

Figure 11-40. Single Large Block Transfer Example



The intermediate transfer chaining enable EDMA_TPCC_OPT_n[23] ITCCHEN provides a method to break up a large transfer into smaller transfers. For example, to move a single large block of memory (16K bytes), the EDMA performs an A-synchronized transfer. The element count is set to a reasonable value, where reasonable derives from the amount of time it would take to move this smaller amount of data. Assume 1 Kbyte is a reasonable small transfer in this example. The EDMA is set up to transfer 16 arrays of 1 Kbyte elements, for a total of 16K byte elements. The EDMA_TPCC_OPT_n[17:12] TCC field in the channel options parameter (OPT) is set to the same value as the channel number and EDMA_TPCC_OPT_n[23] ITCCHEN are set. In this example, EDMA channel 25 is used and EDMA_TPCC_OPT_n[17:12] TCC is also set to 25. The EDMA_TPCC_OPT_n[20] TCINTEN may also be set to trigger interrupt 25 when the last 1 Kbyte array is transferred. The CPU starts the EDMA transfer by writing to the appropriate bit of the event set register EDMA_TPCC_ESR[25] E25. The EDMA transfers the first 1 Kbyte array. Upon completion of the first array, intermediate transfer complete code chaining generates a synchronization event to channel 25, a value specified by the EDMA_TPCC_OPT_n[17:12] TCC field. This intermediate transfer completion chaining event causes EDMA channel 25 to transfer the next 1 Kbyte array. This process continues until the transfer parameters are exhausted, at which point the EDMA has completed the 16K byte transfer. This method breaks up a large transfer into smaller packets, thus providing natural time slices in the transfer such that other events may be processed. Figure 11-41 shows the EDMA setup and illustration of the broken up smaller packet transfers.

Figure 11-41. Smaller Packet Data Transfers Example



11.5.5 Setting Up an EDMA Transfer

The following list provides a quick guide for the typical steps involved in setting up a transfer.

Step 1. Initiating a DMA/QDMA channel

1. Determine the type of channel (QDMA or DMA) to be used.
2. Channel mapping
   i. If using a QDMA channel, program the EDMA_TPCC_QCHMAPN_j with the parameter set number to which the channel maps and the trigger word.
   ii. If using a DMA channel, program the EDMA_TPCC_DCHMAPN_m with the parameter set number to which the channel maps.
3. If the channel is being used in the context of a shadow region, ensure the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k for the region is properly set up to allow read write accesses to bits in the event registers and interrupt registers in the Shadow region memory map. The subsequent steps in this process should be done using the respective shadow region registers. (Shadow region descriptions and usage are provided in Section 11.4.7.1.)
4. Determine the type of triggering used.
   i. If external events are used for triggering (DMA channels), enable the respective event in EDMA_TPCC_EER / EDMA_TPCC_EERH by writing into EDMA_TPCC_EESR / EDMA_TPCC_EESRH.
   ii. If QDMA Channel is used, enable the channel in EDMA_TPCC_QEER by writing into EDMA_TPCC_QEESR.
5. Queue setup
   i. If a QDMA channel is used, set up the EDMA_TPCC_QDMAQNUM to map the channel to the respective event queue.
   ii. If a DMA channel is used, set up the EDMA_TPCC_DMAQNUMN_k to map the event to the respective event queue.

Step 2. Parameter set setup

1. Program the PaRAM set number associated with the channel. Note that

NOTE: If it is a QDMA channel, the PaRAM entry that is configured as trigger word is written to last. Alternatively, enable the QDMA channel (step 1-b-ii above) just before the write to the trigger word.

Step 3. Interrupt setup

1. Enable the interrupt in the EDMA_TPCC_IER / EDMA_TPCC_IERH by writing into EDMA_TPCC_IESR / EDMA_TPCC_IESRH.
2. Ensure that the EDMA_TPCC completion interrupt (either the global or the shadow region interrupt) is enabled properly in the device interrupt controller.
3. Ensure the EDMA_TPCC completion interrupt (this refers to either the Global interrupt or the shadow region interrupt) is enabled properly in the Device Interrupt controller.
4. Set up the interrupt controller properly to receive the expected EDMA interrupt.

Step 4. Initiate transfer

1. This step is highly dependent on the event trigger source:
   i. If the source is an external event coming from a peripheral, the peripheral will be enabled to start generating relevant EDMA events that can be latched to the EDMA_TPCC_ER transfer.
   ii. For QDMA events, writes to the trigger word (step 2-a above) will initiate the transfer.
   iii. Manually triggered transfers will be initiated by writes to the Event Set Registers EDMA_TPCC_ESR / EDMA_TPCC_ESRH.
   iv. Chained-trigger events initiate when a previous transfer returns a transfer completion code equal to the chained channel number.

Step 5. Wait for completion

1. If the interrupts are enabled as mentioned in step 3 above, then the EDMA_TPCC will generate a completion interrupt to the CPU whenever transfer completion results in setting the corresponding bits in the interrupt pending register EDMA_TPCC_IPR / EDMA_TPCC_IPRH. The set bits must be cleared in the EDMA_TPCC_IPR / EDMA_TPCC_IPRH by writing to corresponding bit in EDMA_TPCC_ICR / EDMA_TPCC_ICRH.
2. If polling for completion (interrupts not enabled in the device controller), then the application code can wait on the expected bits to be set in the EDMA_TPCC_IPR / EDMA_TPCC_IPRH. Again, the set bits in the EDMA_TPCC_IPR / EDMA_TPCC_IPRH must be manually cleared via EDMA_TPCC_ICR / EDMA_TPCC_ICRH before the next set of transfers is performed for the same transfer completion code values.

11.6 EDMA Debug Checklist and Programming Tips

This section lists some tips to keep in mind while debugging applications using the EDMA controller.

11.6.1 EDMA Debug Checklist

Table 11-26 provides some common issues and their probable causes and resolutions.

Table 11-26. Debug Checklist

Issue	Description/Solution
The transfer associated with the channel does not happen. The channel does not get serviced.	The EDMA_TPCC may not service a transfer request, even though the associated PaRAM set is programmed appropriately. Check for the following: 1) Verify that events are enabled, i.e., if an external/peripheral event is latched in Event Registers EDMA_TPCC_ER / EDMA_TPCC_ERH, check that the event is enabled in the Event Enable Registers EDMA_TPCC_EER / EDMA_TPCC_EERH. Similarly, for QDMA channels, check that QDMA events are appropriately enabled in the QDMA Event Enable Register EDMA_TPCC_QEER. 2) Verify that the DMA or QDMA Secondary Event Register EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER bits corresponding to the particular event or channel are not set.
The Secondary Event Registers bits are set, not allowing additional transfers to occur on a channel.	It is possible that a trigger event was received when the parameter set associated with the channel/event was a NULL set for a previous transfer on the channel. This is typical in two cases: 1) QDMA channels: Typically if the parameter set is non-static and expected to be terminated by a NULL set (i.e., EDMA_TPCC_OPT_n[3] STATIC = 0x0, EDMA_TPCC_LNK_n[15:0] LINK = 0xFFFF), the parameter set is updated with a NULL set after submission of the last TR. Because QDMA channels are auto-triggered, this update caused the generation of an event. An event generated for a NULL set causes an error condition and results in setting the bits corresponding to the QDMA channel in the EDMA_TPCC_QEMR and EDMA_TPCC_QSER. This will disable further prioritization of the channel. 2) DMA channels used in a continuous mode: The peripheral may be set up to continuously generate infinite events (for instance, in case of McASP, every time the data shifts out from the DXR register, it generates an XEVT). The parameter set may be programmed to expect only a finite number of events and to be terminated by a NULL link. After the expected number of events, the parameter set is reloaded with a NULL parameter set. Because the peripheral will generate additional events, an error condition is set in the EDMA_TPCC_SER[31:0] E*n* and EDMA_TPCC_EMR[31:0] E*n* set, preventing further event prioritization. Check the number of events received is limited to the expected number of events for which the parameter set is programmed, or check the bits corresponding to particular channel or event are not set in the Secondary event registers (EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER) and Event Missed Registers (EDMA_TPCC_EMR / EDMA_TPCC_EMRH / EDMA_TPCC_QEMR) before trying to perform subsequent transfers for the event/channel.
Completion interrupts are not asserted, or no further interrupts are received after the first completion interrupt.	Check the following: 1) The interrupt generation is enabled in the EDMA_TPCC_OPT_n of the associated PaRAM set (EDMA_TPCC_OPT_n[20] TCINTEN = 0x1 and/or EDMA_TPCC_OPT_n[20] ITCINTEN = 0x1). 2) The interrupts are enabled in the EDMA Channel Controller, via the Interrupt Enable Registers (EDMA_TPCC_IER / EDMA_TPCC_IERH). 3) The corresponding interrupts are enabled in the device interrupt controller. 4) The set interrupts are cleared in the interrupt pending registers (EDMA_TPCC_IPR / EDMA_TPCC_IPRH) before exiting the transfer completion interrupt service routine (ISR). See Section 11.4.9.1.2 *Clearing Transfer Complerion Interrupts* for details on writing EDMA ISRs. 5) If working with shadow region interrupts, make sure that the DMA Region Access registers (EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k) are set up properly, because the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k registers act as secondary enables for shadow region completion interrupts, along with the EDMA_TPCC_IER / EDMA_TPCC_IERH registers. If working with shadow region interrupts, make sure that the bits corresponding to the transfer completion code EDMA_TPCC_OPT_n[17:12] TCC value are also enabled in the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k registers. For instance, if the PaRAM set associated with Channel 0 returns a completion code of 63 EDMA_TPCC_OPT_n[17:12] TCC = 63, ensure that EDMA_TPCC_DRAEHM_k[31] E63 is also set for a shadow region completion interrupt because the interrupt pending register bit set will be EDMA_TPCC_IPRH[31] I63 (not EDMA_TPCC_IPR[0] I0).

11.6.2 EDMA Programming Tips

1. For several registers, the setting and clearing of bits needs to be done via separate dedicated registers.

   For example, the Event Register (EDMA_TPCC_ER / EDMA_TPCC_ERH) can only be cleared by writing a 1 to the corresponding bits in the Event Clear Registers (EDMA_TPCC_ECR / EDMA_TPCC_ECRH). Similarly, the Event Enable Register (EDMA_TPCC_EER / EDMA_TPCC_EERH) bits can only be set with writing of 0x1 to the Event Enable Set Registers (EDMA_TPCC_EESR / EDMA_TPCC_EESRH) and cleared with writing of 0x1 to the corresponding bits in the Event Enable Clear Register (EDMA_TPCC_EECR / EDMA_TPCC_EECRH).
2. Writes to the shadow region memory maps are governed by region access registers (EDMA_TPCC_DRAE / EDMA_TPCC_DRAEHM_k / EDMA_TPCC_QRAEN_k). If the appropriate channels are not enabled in these registers, read/write access to the shadow region memory map is not enabled.
3. When working with shadow region completion interrupts, ensure that the DMA Region Access Registers (EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k) for every region are set in a mutually exclusive way (unless it is a requirement for an application). If there is an overlap in the allocated channels and transfer completion codes (setting of Interrupt Pending Register bits) in the region resource allocation, it results in multiple shadow region completion interrupts.

   For example, if EDMA_TPCC_DRAEM_k.DRAEM_0[0] E0 and EDMA_TPCC_DRAEM_k.DRAEM_1[0] E0 are both set, then on completion of a transfer that returns a TCC = 0x0, they will generate both shadow region 0 and 1 completion interrupts.
4. While programming a non-dummy parameter set, ensure the EDMA_TPCC_CCNT_n[15:0] CCNT is not left to zero.
5. Enable the EDMA_TPCC error interrupt in the device controller and attach an interrupt service routine (ISR) to ensure that error conditions are not missed in an application and are appropriately addressed with the ISR.
6. Depending on the application, it can want to break large transfers into smaller transfers and use self-chaining to prevent starvation of other events in an event queue.
7. In applications where a large transfer is broken into sets of small transfers using chaining or other methods, it chooses to use the early chaining option to reduce the time between the sets of transfers and increase the throughput.

   However, keep in mind that with early completion, all data might have not been received at the end point when completion is reported because the EDMA_TPCC internally signals completion when the TR is submitted to the EDMA_TPTC, potentially before any data has been transferred.
8. The event queue entries can be observed to determine the last few events if there is a system failure (provided the entries were not bypassed).

Table 11-58. EDMA_TPCC_EMR

Address Offset	0x0000 0300		
Physical Address	0x4330 0300 0x40D1 0300 0x4151 0300 0x01D1 0300 0x420A 0300	**Instance**	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP2_EDMA_TPCC DSP_EDMA_TPCC EVE_EDMA_TPCC
Description	Event Missed Register: The Event Missed register is set if 2 events are received without the first event being cleared or if a Null TR is serviced. Chained events (CER), Set Events (ESR), and normal events (ER) are treated individually. If any bit in the EMR register is set (and all errors (including EDMA_TPCC_QEMR / EDMA_TPCC_CCERR) were previously clear), then an error will be signaled with TPCC error interrupt.

0	QTHRXCD0	Queue Threshold Error for Q0: 0x0: Watermark/threshold has not been exceeded. 0x1: Watermark/threshold has been exceeded. QTHRXCD0 can be cleared by writing a '1' to corresponding bit in EDMA_TPCC_CCERRCLR register. If any bit in the EDMA_TPCC_CCERR register is set (and all errors (including EDMA_TPCC_EMR/EDMA_TPCC_QEMR) were previously clear), then an error will be signaled with the TPCC error interrupt.	R	0x0

Table 11-110. EDMA_TPCC_ER

Address Offset	0x0000 1000		
Physical Address	0x4330 1000 0x40D1 1000 0x4151 1000 0x01D1 1000 0x420A 1000	**Instance**	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP2_EDMA_TPCC DSP_EDMA_TPCC EVE_EDMA_TPCC

Table 11-110. EDMA_TPCC_ER (continued)

Description	Event Register: If EDMA_TPCC_ER.En bit is set and the EDMA_TPCC_EER.En bit is also set, then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. EDMA_TPCC_ER.En bit is set when the input event #n transitions from inactive (low) to active (high), regardless of the state of EDMA_TPCC_EER.En bit. EDMA_TPCC_ER.En bit is cleared when the corresponding event is prioritized and serviced. If the EDMA_TPCC_ER.En bit is already set and a new inactive to active transition is detected on the input event #n input AND the corresponding bit in the EDMA_TPCC_EER register is set, then the corresponding bit in the Event Missed Register is set. Event N can be cleared via sw by writing a '1' to the EDMA_TPCC_ECR pseudo-register.

Physical Address	0x4330 1018 0x40D1 1018 0x4151 1018 0x01D1 1018 0x420A 1018	**Instance**	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP2_EDMA_TPCC DSP_EDMA_TPCC EVE_EDMA_TPCC
Description	Chained Event Register: If EDMA_TPCC_CER.En bit is set (regardless of state of EDMA_TPCC_EER.En), then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. EDMA_TPCC_CER.En bit is set when a chaining completion code is returned from one of the 3PTCs via the completion interface, or is generated internally via Early Completion path. EDMA_TPCC_CER.En bit is cleared when the corresponding event is prioritized and serviced. If the EDMA_TPCC_CER.En bit is already set and the corresponding chaining completion code is returned from the TC, then the corresponding bit in the Event Missed Register is set. EDMA_TPCC_CER.En cannot be set or cleared via software.

Table 11-126. EDMA_TPCC_EER

Address Offset	0x0000 1020		
Physical Address	0x4330 1020 0x40D1 1020 0x4151 1020 0x01D1 1020 0x420A 1020	**Instance**	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP2_EDMA_TPCC DSP_EDMA_TPCC EVE_EDMA_TPCC
Description	Event Enable Register: Enables DMA transfers for EDMA_TPCC_ER.En pending events. EDMA_TPCC_ER.En is set based on externally asserted events (via tpcc_eventN_pi). This register has no effect on Chained Event Register (EDMA_TPCC_CER) or Event Set Register (EDMA_TPCC_ESR). Note that if a bit is set in EDMA_TPCC_ER.En while EDMA_TPCC_EER.En is disabled, no action is taken. If EDMA_TPCC_EER.En is enabled at a later point (and EDMA_TPCC_ER.En has not been cleared via SW) then the event will be recognized as a valid 'TR Sync' EDMA_TPCC_EER.En is not directly writeable. Events can be enabled via writes to EDMA_TPCC_EESR and can be disabled via writes to EDMA_TPCC_EECR register. EDMA_TPCC_EER.En = 0: EDMA_TPCC_ER.En is not enabled to trigger DMA transfers. EDMA_TPCC_EER.En = 1: EDMA_TPCC_ER.En is enabled to trigger DMA transfers.

Table 11-148. EDMA_TPCC_IERH

Address Offset	0x0000 1054		
Physical Address	0x4330 1054 0x40D1 1054 0x4151 1054 0x01D1 1054 0x420A 1054	**Instance**	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP2_EDMA_TPCC DSP_EDMA_TPCC EVE_EDMA_TPCC
Description	Int Enable Register (High Part) EDMA_TPCC_IERH.In is not directly writeable. Interrupts can be enabled via writes to EDMA_TPCC_IESRH and can be disabled via writes to EDMA_TPCC_IECRH register. EDMA_TPCC_IERH. In = 0: EDMA_TPCC_IPRH.In is NOT enabled for interrupts. EDMA_TPCC_IERH. In = 1: EDMA_TPCC_IPRH.In IS enabled for interrupts.

Table 11-168. EDMA_TPCC_QER

Address Offset	0x0000 1080		
Physical Address	0x4330 1080 0x40D1 1080 0x4151 1080 0x01D1 1080 0x420A 1080	**Instance**	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP2_EDMA_TPCC DSP_EDMA_TPCC EVE_EDMA_TPCC
Description	QDMA Event Register: If EDMA_TPCC_QER.En bit is set, then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. EDMA_TPCC_QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. EDMA_TPCC_QER.En bit is cleared when the corresponding event is prioritized and serviced. EDMA_TPCC_QER.En is also cleared when user writes a '1' to the EDMA_TPCC_QSECR.En bit. If the EDMA_TPCC_QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and EDMA_TPCC_QEER register is set, then the corresponding bit in the QDMA Event Missed Register is set.

Description	QDMA Secondary Event Clear Register The secondary event clear register is used to clear the status of the EDMA_TPCC_QSER and EDMA_TPCC_QER register (note that this is slightly different than the EDMA_TPCC_SER operation, which does not clear the EDMA_TPCC_ER.En register). CPU write of '1' to the EDMA_TPCC_QSECR.En bit clears the EDMA_TPCC_QSER.En and EDMA_TPCC_QER.En register fields. CPU write of '0' has no effect..

Table 11-180. EDMA_TPCC_ER_RN_k

Address Offset	0x0000 2000 + (0x200 * k)		
Physical Address	0x4330 2000 + (0x200 * k) 0x40D1 2000 + (0x200 * k) 0x4151 2000 + (0x200 * k) 0x01D1 2000 + (0x200 * k) 0x420A 2000 + (0x200 * k)	**Instance**	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP2_EDMA_TPCC DSP_EDMA_TPCC EVE_EDMA_TPCC
Description	Event Register If EDMA_TPCC_ER.En bit is set and the EDMA_TPCC_EER.En bit is also set, then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. EDMA_TPCC_ER.En bit is set when the input event #n transitions from inactive (low) to active (high), regardless of the state of EDMA_TPCC_EER.En bit. EDMA_TPCC_ER.En bit is cleared when the corresponding event is prioritized and serviced. If the EDMA_TPCC_ER.En bit is already set and a new inactive to active transition is detected on the input event #n input AND the corresponding bit in the EDMA_TPCC_EER register is set, then the corresponding bit in the Event Missed Register is set. Event N can be cleared via sw by writing a '1' to the EDMA_TPCC_ECR pseudo-register.

Table 11-192. EDMA_TPCC_CER_RN_k

Address Offset	0x0000 2018 + (0x200 * k)		
Physical Address	0x4330 2018 + (0x200 * k) 0x40D1 2018 + (0x200 * k) 0x4151 2018 + (0x200 * k) 0x01D1 2018 + (0x200 * k) 0x420A 2018 + (0x200 * k)	**Instance**	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP2_EDMA_TPCC DSP_EDMA_TPCC EVE_EDMA_TPCC
Description	Chained Event Register If EDMA_TPCC_CER.En bit is set (regardless of state of EDMA_TPCC_EER.En), then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. EDMA_TPCC_CER.En bit is set when a chaining completion code is returned from one of the 3PTCs via the completion interface, or is generated internally via Early Completion path. EDMA_TPCC_CER.En bit is cleared when the corresponding event is prioritized and serviced. If the EDMA_TPCC_CER.En bit is already set and the corresponding chaining completion code is returned from the TC, then the corresponding bit in the Event Missed Register is set. EDMA_TPCC_CER.En cannot be set or cleared via software.

Description	Int Enable Register (High Part) EDMA_TPCC_IERH.In is not directly writeable. Interrupts can be enabled via writes to EDMA_TPCC_IESRH and can be disabled via writes to EDMA_TPCC_IECRH register. EDMA_TPCC_IERH.In = 0: EDMA_TPCC_IPRH.In is NOT enabled for interrupts. EDMA_TPCC_IERH.In = 1: EDMA_TPCC_IPRH.In IS enabled for interrupts.

Table 11-238. EDMA_TPCC_QER_RN_k

Address Offset	0x0000 2080 + (0x200 * k)		
Physical Address	0x4330 2080 + (0x200 * k) 0x40D1 2080 + (0x200 * k) 0x4151 2080 + (0x200 * k) 0x01D1 2080 + (0x200 * k) 0x420A 2080 + (0x200 * k)	**Instance**	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP2_EDMA_TPCC DSP_EDMA_TPCC EVE_EDMA_TPCC
Description	QDMA Event Register If EDMA_TPCC_QER.En bit is set, then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. EDMA_TPCC_QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. EDMA_TPCC_QER.En bit is cleared when the corresponding event is prioritized and serviced. EDMA_TPCC_QER.En is also cleared when user writes a '1' to the EDMA_TPCC_QSECR.En bit. If the EDMA_TPCC_QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and EDMA_TPCC_QEER register is set, then the corresponding bit in the QDMA Event Missed Register is set.

Description	QDMA Secondary Event Clear Register CPU write of '0' has no effect. The secondary event clear register is used to clear the status of the EDMA_TPCC_QSER and EDMA_TPCC_QER register (note that this is slightly different than the EDMA_TPCC_SER operation, which does not clear the EDMA_TPCC_ER.En register). CPU write of '1' to the EDMA_TPCC_QSECR.En bit clears the EDMA_TPCC_QSER.En and EDMA_TPCC_QER.En register fields.

PRIV	RESERVED				PRIVID			ITCCHEN	TCCHEN	ITCINTEN	TCINTEN	WIMODE	RESERVED	TCC						TCCMODE	FWID			RESERVED				STATIC	SYNCDIM	DAM	SAM

Bits	Field Name	Description	Type	Reset
31	PRIV	Privilege level privilege level (supervisor vs. user) for the host/cpu/dma that programmed this PaRAM Entry. Value is set with the vbus priv value when any part of the PaRAM Entry is written. Not writeable via vbus wdata bus. Is readable via VBus rdata bus. 0x0: User level privilege 0x1: Supervisor level privilege	R	0x0
30:28	RESERVED	Reserved	R	0x0
27:24	PRIVID	Privilege ID Privilege ID for the external host/cpu/dma that programmed this PaRAM Entry. This value is set with the vbus privid value when any part of the PaRAM Entry is written. Not writeable via vbus wdata bus. Is readable via VBus rdata bus.	R	0x0
23	ITCCHEN	Intermediate transfer completion chaining enable 0x0: Intermediate transfer complete chaining is disabled. 0x1: Intermediate transfer complete chaining is enabled.	RW	0x0
22	TCCHEN	Transfer complete chaining enable 0x0: Transfer complete chaining is disabled. 0x1: Transfer complete chaining is enabled.	RW	0x0

Bits	Field Name	Description	Type	Reset
21	ITCINTEN	Intermediate transfer completion interrupt enable 0x0: Intermediate transfer complete interrupt is disabled. 0x1: Intermediate transfer complete interrupt is enabled (corresponding EDMA_TPCC_IER[TCC] bit must be set to 1 to generate interrupt)	RW	0x0
20	TCINTEN	Transfer complete interrupt enable 0x0: Transfer complete interrupt is disabled. 0x1: Transfer complete interrupt is enabled (corresponding EDMA_TPCC_IER[TCC] bit must be set to 1 to generate interrupt)	RW	0x0
19	WIMODE	Backward compatibility mode 0x0: Normal operation 0x1: WI Backwards Compatibility mode, forces BCNT to be adjusted by '1' upon TR submission (0 means 1, 1 means 2, ...) and forces ACNT to be treated as a word-count (left shifted by 2 by hardware to create byte cnt for TR submission)	RW	0x0
18	RESERVED	Reserved	R	0x0
17:12	TCC	Transfer Complete Code The 6-bit code is used to set the relevant bit in EDMA_TPCC_CER (bit EDMA_TPCC_CER[TCC]) for chaining or in EDMA_TPCC_IER (bit EDMA_TPCC_IER[TCC]) for interrupts.	RW	0x0
11	TCCMODE	Transfer complete code mode: Indicates the point at which a transfer is considered completed. Applies to both chaining and interrupt. 0x0: Normal Completion. A transfer is considered completed after the transfer parameters are returned to the CC from the TC (which was returned from the peripheral) 0x1: Early Completion, A transfer is considered completed after the CC submits a TR to the TC. CC generates completion code internally.	RW	0x0
10:8	FWID	FIFO width: Applies if either SAM or DAM is set to FIFO mode. Pass-thru to TC.	RW	0x0
7:4	RESERVED	Reserved	R	0x0
3	STATIC	Static Entry 0x0: Entry is updated as normal 0x1: Entry is static, Count and Address updates are not updated after TRP is submitted. Linking is not performed.	RW	0x0
2	SYNCDIM	Transfer Synchronization Dimension: 0x0: A-Sync, Each event triggers the transfer of ACNT elements. 0x1: AB-Sync, Each event triggers the transfer of BCNT arrays of ACNT elements.	RW	0x0
1	DAM	Destination Address Mode: Destination Address Mode within an array. Pass-thru to TC. 0x0: INCR, Dst addressing within an array increments. Dst is not a FIFO. 0x1: FIFO, Dst addressing within an array wraps around upon reaching FIFO width.	RW	0x0
0	SAM	Source Address Mode: Source Address Mode within an array. Pass-thru to TC. 0x0: INCR, Src addressing within an array increments. Source is not a FIFO. 0x1: FIFO, Src addressing within an array wraps around upon reaching FIFO width.	RW	0x0

Description	A and B byte count		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCNT																ACNT															

Bits	Field Name	Description	Type	Reset
31:16	BCNT	BCNT: Count for 2nd Dimension: BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT can be anywhere between 1 and 65535. Therefore, the maximum number of arrays in a frame is 65535 (64K-1 arrays). BCNT=1 means 1 array in the frame, and BCNT=0 means 0 arrays in the frame. In normal mode, a BCNT of '0' is considered as either a Null or Dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. If the EDMA_TPCC_OPT_n.WIMODE bit is set, then the programmed BCNT value will be incremented by '1' before submission to TC. I.e., 0 means 1, 1 means 2, 2 means 3, ..., 0xFFFE means 0xFFFF. A value of 0xFFFF is an illegal value that will be treated as a Null TR.	RW	0x0

Bits	Field Name	Description	Type	Reset
15:0	ACNT	ACNT: number of bytes in 1st dimension: ACNT represents the number of bytes within the first dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65535. Therefore, the maximum number of bytes in an array is 65535 bytes (64K-1 bytes). ACNT must be greater than or equal to '1' for a TR to be submitted to TC. An ACNT of '0' is considered as either a null or dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. If the EDMA_TPCC_OPT_n.WIMODE bit is set then the ACNT field represents a word count. The CC must internally multiply by 4 to translate the word count to a byte count prior to submission to the TC. The 2 MSBs of the 16-bit ACNT are reserved and should always be written as 'b00 by the user. If user writes a value other than 0, it will still be treated as 0 since the multiply-by-4 operation (to translate between a word count and a byte count) will drop the 2 msbits. For dummy and null transfer definition, the ACNT definition will disregard the 2 msbits. I.e., a programmed ACNT value of 0x8000 in WI-mode will be treated as 0 byte transfer, resulting in null or dummy operation dependent on the state of BCNT and CCNT.	RW	0x0

Description	Link and Reload parameters		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCNTRLD																LINK															

Bits	Field Name	Description	Type	Reset
31:16	BCNTRLD	BCNT Reload: BCNTRLD is a 16-bit unsigned value used to reload the BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-Sync'ed transfers. In this case, the CC decrements the BCNT value by one on each TR submission. When BCNT (conceptually) reaches zero, then the CC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value. For AB-synchronized transfers, the CC submits the BCNT in the TR and therefore the TC is responsible to keep track of BCNT, not thus BCNTRLD is a don't care field.	RW	0x0

Bits	Field Name	Description	Type	Reset
15:0	LINK	Link Address: The CC provides a mechanism to reload the current PaRAM Entry upon its natural termination (i.e., after count fields are decremented to '0') with a new PaRAM Entry. This is called 'linking'. The 16-bit parameter LINK specifies the byte address offset in the PaRAM from which the CC loads/reloads the next PaRAM entry in the link. The CC should disregard the value in the upper 2 bits of the LINK field as well as the lower 5-bits of the LINK field. The upper two bits are ignored such that the user can program either the 'literal' byte address of the LINK parameter or the 'PaRAM base-relative' address of the link field. Therefore, if the user uses the literal address with a range from 0x4000 to 0x7FFF, it will be treated as a PaRAM-base-relative value of 0x0000 to 0x3FFF. The lower-5 bits are ignored and treated as 'b00000, thereby guaranteeing that all Link pointers point to a 32-byte aligned PaRAM entry. In the latter case (5-lsbs), behavior is undefined for the user (i.e., don't have to test it). In the former case (2 msbs), user should be able to take advantage of this feature (i.e., do have to test it). If a Link Update is requested to a PaRAM address that is beyond the actual range of implemented PaRAM, then the Link will be treated as a Null Linkand all 0s plus 0xFFFF will be written to the current entry location. A LINK value of 0xFFFF is referred to as a NULL link which should cause the CC to write 0x0 to all entries of the current PaRAM Entry except for the LINK field which is set to 0xFFFF. The Priv/Privid state is overwritten to 0x0 when linking. MSBs and LSBS should not be masked when comparing against the 0xFFFF value. I.e., a value of 0x3FFE is a non-NULL PaRAM link field.	RW	0x0

DCIDX																SCIDX															

Bits	Field Name	Description	Type	Reset
31:16	DCIDX	Destination Frame Index: DCIDX is a 16-bit signed value (2's complement) used for destination address modification for the 3rd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array in the next frame. It applies to both A-sync and AB-sync transfers. Note that when DCIDX is applied, the current array in an A-sync transfer is the last array in the frame, while the current array in a ABsync transfer is the first array in the frame.	RW	0x0
15:0	SCIDX	Source Frame Index: SCIDX is a 16-bit signed value (2's complement) used for source address modification for the 3rd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-sync and AB-sync transfers. Note that when SCIDX is applied, the current array in an A-sync transfer is the last array in the frame, while the current array in a AB-sync transfer is the first array in the frame.	RW	0x0

11.7.2.2.2 EDMA_TPTC0 and EDMA_TPTC1 Register Description

Table 11-266 through Table 11-338 describe the individual EDMA_TPTC0 and EDMA_TPTC1 module registers.

Table 11-266. EDMA_TPTCn_PID

Address Offset	0x0000 0000		
Physical Address	0x4340 0000 0x4350 0000 0x40D0 5000 0x4150 5000 0x40D0 6000 0x4150 6000 0x01D0 5000 0x01D0 6000	**Instance**	SYS_EDMA_TPTC0 SYS_EDMA_TPTC1 DSP1_EDMA_TPTC0 DSP2_EDMA_TPTC0 DSP1_EDMA_TPTC1 DSP2_EDMA_TPTC1 DSP_EDMA_TPTC0 DSP_EDMA_TPTC1
Description	Peripheral ID Register		
Type	R
