RESERVED																			DFSTRTPTR		RESERVED		ACTV	RESERVED	DSTACTV				RESERVED	WSACTV	SRCACTV	PROGBUSY

Bits	Field Name	Description	Type	Reset
31:13	RESERVED	Reserved	R Return 0's	0x0
12:11	DFSTRTPTR	Dst FIFO Start Pointer Represents the offset to the head entry of Dst Register FIFO, in units of *entries*. Legal values = 0x0 to 0x3	R	0x0
10:9	RESERVED	Reserved	R Return 0's	0x0
8	ACTV	Channel Active Channel Active is a logical-OR of each of the *BUSY/ACTV signals. The ACTV bit must remain high through the life of a TR. 0x0: Channel is idle 0x1: Channel is busy	R	0x1
7	RESERVED	Reserved	R Return 0's	0x0
6:4	DSTACTV	Destination Active State Specifies the number of TRs that are resident in the Dst Register FIFO at a given instant. Legal values are constrained by the DSTREGDEPTH parameter.	R	0x0
3	RESERVED	Reserved	R Return 0's	0x0
2	WSACTV	Write Status Active 0x0: Write status is not pending. Write status has been received for all previously issued write commands. 0x1: Write Status is pending. Write status has not been received for all previously issued write commands.	R	0x0
1	SRCACTV	Source Active State 0x0: Source Active set is idle. Any TR written to Prog Set will immediately transition to Source Active set as long as the Dst FIFO Set is not full (DSTFULL == 1). 0x1: Source Active set is busy either performing read transfers or waiting to perform read transfers for current Transfer Request.	R	0x0

Bits	Field Name	Description	Type	Reset
0	PROGBUSY	Program Register Set Busy 0x0: Program set idle and is available for programming. 0x1: Program set busy. User should poll for PROGBUSY equal to '0' prior to re-programming the Program Register set.	R	0x0

RESERVED														TCCHEN	TCINTEN	RESERVED		TCC						RESERVED				STAT			

Bits	Field Name	Description	Type	Reset
31:18	RESERVED	Reserved	R Return 0's	0x0
17	TCCHEN	Contains the EDMA_TPCC_OPT_n[17] TCCHEN value programmed by the user for the Read or Write transaction that resulted in an error.	R	0x0
16	TCINTEN	Contains the EDMA_TPCC_OPT_n[16] TCINTEN value programmed by the user for the Read or Write transaction that resulted in an error.	R	0x0
15:14	RESERVED	Reserved	R Return 0's	0x0
13:8	TCC	Transfer Complete Code: Contains the EDMA_TPCC_OPT_n[13:8] TCC value programmed by the user for the Read or Write transaction that resulted in an error.	R	0x0
7:4	RESERVED	Reserved	R Return 0's	0x0
3:0	STAT	Transaction Status: Stores the non-zero status/error code that was detected on the read status or write status bus. MS-bit effectively serves as the read vs. write error code. If read status and write status are returned on the same cycle, then the TC chooses non-zero version. If both are non-zero then write status is treated as higher priority. Encoding of errors matches the CBA spec and is summarized here: 0xF =	R	0x0

Interrupt Controllers

This chapter describes the interrupt controllers (INTCs) in the device.

Topic **Page**

12.1 Interrupt Controllers Overview

The device has a large number of interrupts to service the needs of its many peripherals and subsystems. The DSP (x2), IPU, and EVE subsystems are capable of servicing these interrupts via their integrated interrupt controllers. In addition, each processor's interrupt controller is preceded by an Interrupt Controller Crossbar (IRQ_CROSSBAR) that provides flexibility in mapping the device interrupts to processor interrupt inputs. For more information about IRQ crossbar, see Chapter 13, *Control Module*.

C66x DSP Subsystem Interrupt Controller (DSPx_INTC, where x = 1, 2)

There are two Digital Signal Processing (DSP) subsystems in the device - DSP1, and DSP2. Each DSP subsystem integrates an interrupt controller - DSPx_INTC, which interfaces the system events to the C66x core interrupt and exceptions inputs. It combines up to 128 interrupts into 12 prioritized interrupts presented to the C66x CPU.

For detailed information about this module, see Chapter 4, *DSP Subsystem*.

Dual Cortex-M4 IPU Subsystem Interrupt Controller (IPU_Cx_INTC, where x = 1, 2)

There is one Image Processing Unit (IPU) subsystem in the device. The IPU subsystem integrates two Arm® Cortex-M4 cores.

A Nested Vectored Interrupt Controller (NVIC) is integrated within each Cortex-M4. The interrupt mapping is the same for the two cores to facilitate parallel processing. The NVIC supports:

- 96 external interrupts (in addition to 16 Cortex-M4 internal interrupts), which are dynamically prioritized with 16 levels of priority defined for each core
- Low-latency exception and interrupt handling
- Prioritization and handling of exceptions
- Control of the local power management
- Debug accesses to the processor core

For detailed information about this module, refer to Arm *Cortex-M4 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

EVE Subsystem Interrupt Controller (EVE_INTC)

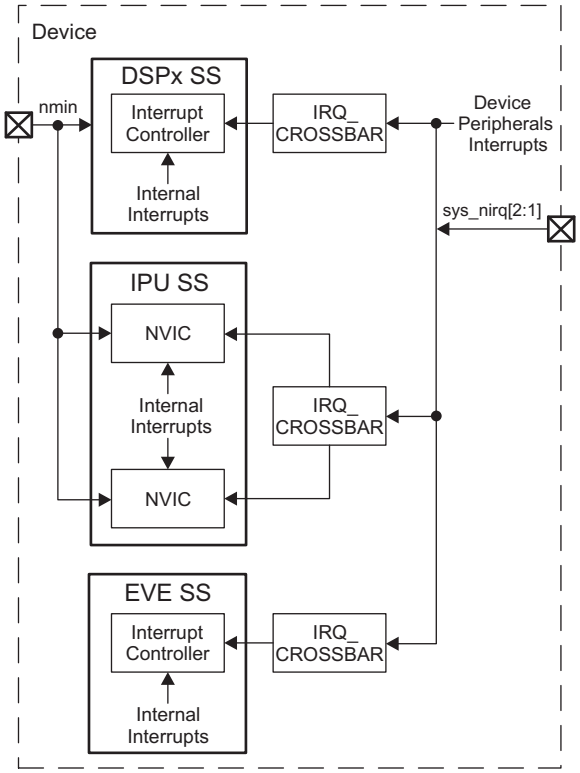
There is one Embedded Video Engine (EVE) subsystems in the device. The EVE subsystem integrates an interrupt controller - EVE_INTC, which handles incoming interrupts, merging them with internal interrupt sources to drive ARP32's interrupt inputs. It also allows ARP32 to generate outgoing interrupts or events to synchronize with other system processors and EDMA.

The EVE_INTC supports up to 32 active-high level interrupt inputs. Its architecture allows both hardware and software prioritization.

For detailed information about this module, see Section 6.1, *Embedded Vision Engine*.

Figure 12-1 shows the top-level block diagram of the interrupt controllers in this device.

Figure 12-1. Interrupt Controllers in the Device



12.2 Interrupt Controllers Environment

Figure 12-2 shows the relationship between the device INTCs and external interrupts.

Figure 12-2. Interrupts From External Devices

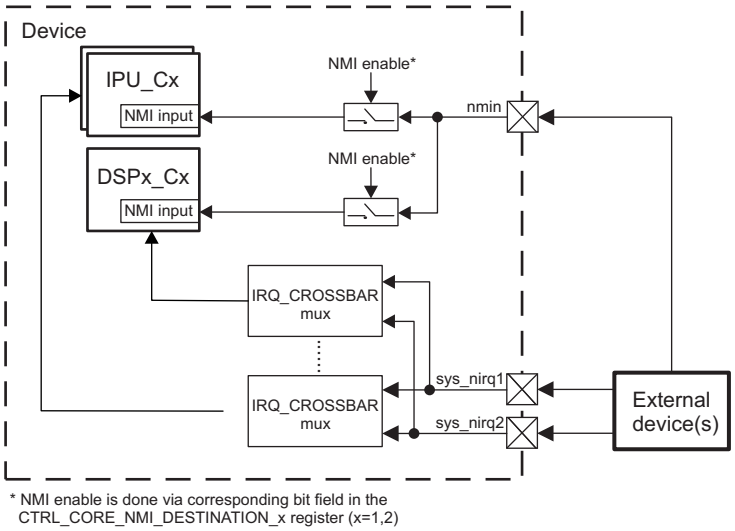


Table 12-1 describes the signals that can be used by external devices to generate interrupts to the device INTCs.

Table 12-1. Interrupts From External Devices

Device Pin	I/O[1]	Description
sys_nirq1	I	External devices can use these pins to generate a system wake-up interrupt event to any device INTC. The user must take care to configure the corresponding IRQ_CROSSBAR properly (via Control Module).
sys_nirq2	I	
nmin	I	External device can use this pin to generate a non-maskable interrupt (NMI) event to the following device processors:
		- IPU_C0, IPU_C1. Upon enable (via Control Module), the NMI is routed directly to the NMI input of Cortex M4 core. Note that NMI can be enabled separately for IPU_C0 and IPU_C1.
		- DSP1, DSP2. Upon enable (via Control Module), the NMI is routed directly to the NMI input of C66x CPU.
		The Control Module registers CTRL_CORE_NMI_DESTINATION_1 and CTRL_CORE_NMI_DESTINATION_2 are used to route the **NMI** signal to the corresponding device processor subsystems as follows: • Writing 0x1 to CTRL_CORE_NMI_DESTINATION_1[7:0] IPU_C1 enables NMI mapping to IPU_C1; • Writing 0x1 to CTRL_CORE_NMI_DESTINATION_2[31:24] IPU_C0 enables NMI mapping to IPU_C0; • Writing 0x1 to CTRL_CORE_NMI_DESTINATION_2[23:16] DSP2 enables NMI mapping to DSP2; • Writing 0x1 to CTRL_CORE_NMI_DESTINATION_2[15:8] DSP1 enables NMI mapping to DSP1; For more information about CTRL_CORE_NMI_DESTINATION_1 and CTRL_CORE_NMI_DESTINATION_2 registers, see Chapter 13, *Control Module*.

(1) I = Input, O = Output

NOTE: External devices can also use the GPIO modules to generate an interrupt to the device INTCs. For more information, see Chapter 20, *General-Purpose Interface*.

12.3 Interrupt Controllers Integration

Table 12-2 through Table 12-5 present the default interrupt mapping of the device INTCs. The mapping of device interrupts to IRQ_CROSSBAR inputs is presented in Table 12-6.

NOTE: All device interrupts (external to the DSP [x2], IPU, and EVE subsystems) are active-high, level-sensitive.

CAUTION

A single interrupt source can be physically mapped to multiple INTCs. With multiple-mapped interrupts, it is strongly recommended to unmask each interrupt source in only one INTC at a time.

12.3.1 Interrupt Requests to DSP1_INTC

Table 12-2 lists the default interrupt sources for the DSP1_INTC. In addition, interrupts DSP1_IRQ_32 through DSP1_IRQ_95 can alternatively be sourced through the DSP1's IRQ_CROSSBAR from one of the 460 multiplexed device interrupts listed in Table 12-6. The CTRL_CORE_DSP1_IRQ_y_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

Table 12-2. DSP1_INTC Default Interrupt Mapping

IRQ Input Line	IRQ_ CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_ CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
DSP1_IRQ_0	N/A	N/A	N/A	CGEM_IRQ_0	CGEM Internal Interrupt
DSP1_IRQ_1	N/A	N/A	N/A	CGEM_IRQ_1	CGEM Internal Interrupt
DSP1_IRQ_2	N/A	N/A	N/A	CGEM_IRQ_2	CGEM Internal Interrupt
DSP1_IRQ_3	N/A	N/A	N/A	CGEM_IRQ_3	CGEM Internal Interrupt
DSP1_IRQ_4	N/A	N/A	N/A	CGEM_IRQ_4	CGEM Internal Interrupt
DSP1_IRQ_5	N/A	N/A	N/A	CGEM_IRQ_5	CGEM Internal Interrupt
DSP1_IRQ_6	N/A	N/A	N/A	CGEM_IRQ_6	CGEM Internal Interrupt
DSP1_IRQ_7	N/A	N/A	N/A	CGEM_IRQ_7	CGEM Internal Interrupt
DSP1_IRQ_8	N/A	N/A	N/A	CGEM_IRQ_8	CGEM Internal Interrupt
DSP1_IRQ_9	N/A	N/A	N/A	CGEM_IRQ_9	CGEM Internal Interrupt
DSP1_IRQ_10	N/A	N/A	N/A	CGEM_IRQ_10	CGEM Internal Interrupt
DSP1_IRQ_11	N/A	N/A	N/A	CGEM_IRQ_11	CGEM Internal Interrupt
DSP1_IRQ_12	N/A	N/A	N/A	CGEM_IRQ_12	CGEM Internal Interrupt
DSP1_IRQ_13	N/A	N/A	N/A	CGEM_IRQ_13	CGEM Internal Interrupt
DSP1_IRQ_14	N/A	N/A	N/A	CGEM_IRQ_14	CGEM Internal Interrupt
DSP1_IRQ_15	N/A	N/A	N/A	CGEM_IRQ_15	CGEM Internal Interrupt
DSP1_IRQ_16	N/A	N/A	N/A	TPCC_INTG	EDMA CC global interrupt
DSP1_IRQ_17	N/A	N/A	N/A	TPCC_INT0	EDMA CC region0 interrupt
DSP1_IRQ_18	N/A	N/A	N/A	TPCC_INT1	EDMA CC region1 interrupt
DSP1_IRQ_19	N/A	N/A	N/A	TPCC_INT2	EDMA CC region2 interrupt
DSP1_IRQ_20	N/A	N/A	N/A	TPCC_INT3	EDMA CC region3 interrupt
DSP1_IRQ_21	N/A	N/A	N/A	FW0_FUNC_ERROR	Firewall0 func access error
DSP1_IRQ_22	N/A	N/A	N/A	FW0_DEBUG_ERROR	Firewall0 debug access error
DSP1_IRQ_23	N/A	N/A	N/A	FW1_FUNC_ERROR	Firewall1 func access error
DSP1_IRQ_24	N/A	N/A	N/A	FW1_DEBUG_ERROR	Firewall1 debug access error
DSP1_IRQ_25	N/A	N/A	N/A	MMU0_INT	DSP MMU0 Interrupt
DSP1_IRQ_26	N/A	N/A	N/A	MMU1_INT	DSP MMU1 Interrupt
DSP1_IRQ_27	N/A	N/A	N/A	TPCC_ERRINT	EDMA CC error interrupt
DSP1_IRQ_28	N/A	N/A	N/A	TPTC_ERRINT0	EDMA TC0 error interrupt
DSP1_IRQ_29	N/A	N/A	N/A	TPTC_ERRINT1	EDMA TC1 error interrupt
DSP1_IRQ_30	N/A	N/A	N/A	NOC_ERRINT	Interconnect error interrupt
DSP1_IRQ_31	NA	N/A	N/A	EDMA_WAKE_INT	EDMA wakeup interrupt

Table 12-2. DSP1_INTC Default Interrupt Mapping (continued)

IRQ Input Line	IRQ_ CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_ CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
DSP1_IRQ_32	1	CTRL_CORE_DSP1_IRQ_32_33[8:0]	1	ELM_IRQ	Error location process completion interrupt
DSP1_IRQ_33	2	CTRL_CORE_DSP1_IRQ_32_33[24:16]	2	EXT_SYS_IRQ_1	External interrupt (active low) via sys_nirq1 pin
DSP1_IRQ_34	3	CTRL_CORE_DSP1_IRQ_34_35[8:0]	3	CTRL_MODULE_CORE_IRQ_SEC_EVTS	Combined firewall error interrupt. For more information, see Section 13.4.6.13.2.
DSP1_IRQ_35	4	CTRL_CORE_DSP1_IRQ_34_35[24:16]	4	L3_MAIN_IRQ_DBG_ERR	L3_MAIN debug error

DSP1_IRQ_107	N/A	N/A	N/A	CGEM_IRQ_27	CGEM Internal Interrupt
DSP1_IRQ_108	N/A	N/A	N/A	CGEM_IRQ_28	CGEM Internal Interrupt
DSP1_IRQ_109	N/A	N/A	N/A	CGEM_IRQ_29	CGEM Internal Interrupt
DSP1_IRQ_110	N/A	N/A	N/A	CGEM_IRQ_30	CGEM Internal Interrupt
DSP1_IRQ_111	N/A	N/A	N/A	CGEM_IRQ_31	CGEM Internal Interrupt
DSP1_IRQ_112	N/A	N/A	N/A	CGEM_IRQ_32	CGEM Internal Interrupt
DSP1_IRQ_113	N/A	N/A	N/A	CGEM_IRQ_33	CGEM Internal Interrupt
DSP1_IRQ_114	N/A	N/A	N/A	CGEM_IRQ_34	CGEM Internal Interrupt
DSP1_IRQ_115	N/A	N/A	N/A	CGEM_IRQ_35	CGEM Internal Interrupt
DSP1_IRQ_116	N/A	N/A	N/A	CGEM_IRQ_36	CGEM Internal Interrupt
DSP1_IRQ_117	N/A	N/A	N/A	CGEM_IRQ_37	CGEM Internal Interrupt
DSP1_IRQ_118	N/A	N/A	N/A	CGEM_IRQ_38	CGEM Internal Interrupt
DSP1_IRQ_119	NA	N/A	N/A	CGEM_IRQ_39	CGEM Internal Interrupt
DSP1_IRQ_120	N/A	N/A	N/A	CGEM_IRQ_40	CGEM Internal Interrupt
DSP1_IRQ_121	N/A	N/A	N/A	CGEM_IRQ_41	CGEM Internal Interrupt
DSP1_IRQ_122	N/A	N/A	N/A	CGEM_IRQ_42	CGEM Internal Interrupt
DSP1_IRQ_123	N/A	N/A	N/A	CGEM_IRQ_43	CGEM Internal Interrupt
DSP1_IRQ_124	N/A	N/A	N/A	CGEM_IRQ_44	CGEM Internal Interrupt
DSP1_IRQ_125	N/A	N/A	N/A	CGEM_IRQ_45	CGEM Internal Interrupt
DSP1_IRQ_126	N/A	N/A	N/A	CGEM_IRQ_46	CGEM Internal Interrupt
DSP1_IRQ_127	N/A		N/A	CGEM_IRQ_47	CGEM Internal Interrupt

NOTE: The "**IRQ_CROSSBAR Default Input Index**" column of Table 12-2 shows which input of the corresponding IRQ_CROSSBAR instance is mapped to its output (and then routed to the corresponding DSP1_INTC input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL_CORE_DSP1_IRQ_y_z register bit fields that are used to control the mapping of device interrupts to DSP1_INTC inputs. For example, the DSP1_IRQ_32_33[8:0] bit field is used to configure which device interrupt would be mapped to the DSP1_IRQ_32 line. The reset value of this bit field is 0x1, meaning that ELM_IRQ would be mapped to DSP1_IRQ_32 by default because it is connected to the IRQ_CROSSBAR_1 input.

'N/A' in this column means that the corresponding interrupt is internal to the DSP1 subsystem. There is no IRQ_CROSSBAR dedicated to the associated DSP1_INTC input line and therefore, the user cannot change its default mapping.

12.3.2 Interrupt Requests to DSP2_INTC

Table 12-3 lists the default interrupt sources for the DSP2_INTC. In addition, interrupts DSP2_IRQ_32 through DSP2_IRQ_95 can alternatively be sourced through the DSP2's IRQ_CROSSBAR from one of the 460 multiplexed device interrupts listed in Table 12-6. The DSP2_IRQ_y_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

Table 12-3. DSP2_INTC Default Interrupt Mapping

IRQ Input Line	IRQ_ CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_ CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
DSP2_IRQ_0	N/A	N/A	N/A	CGEM_IRQ_0	CGEM Internal Interrupt
DSP2_IRQ_1	N/A	N/A	N/A	CGEM_IRQ_1	CGEM Internal Interrupt
DSP2_IRQ_2	N/A	N/A	N/A	CGEM_IRQ_2	CGEM Internal Interrupt
DSP2_IRQ_3	N/A	N/A	N/A	CGEM_IRQ_3	CGEM Internal Interrupt

DSP2_IRQ_126	N/A	N/A	N/A	CGEM_IRQ_46	CGEM Internal Interrupt
DSP2_IRQ_127	N/A		N/A	CGEM_IRQ_47	CGEM Internal Interrupt

NOTE: The "**IRQ_CROSSBAR Default Input Index**" column of Table 12-3 shows which input of the corresponding IRQ_CROSSBAR instance is mapped to its output (and then routed to the corresponding DSP2_INTC input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL_CORE_DSP2_IRQ_y_z register bit fields that are used to control the mapping of device interrupts to DSP2_INTC inputs. For example, the DSP2_IRQ_32_33[8:0] bit field is used to configure which device interrupt would be mapped to the DSP2_IRQ_32 line. The reset value of this bit field is 0x1, meaning that ELM_IRQ would be mapped to DSP2_IRQ_32 by default because it is connected to the IRQ_CROSSBAR_1 input.

'N/A' in this column means that the corresponding interrupt is internal to the DSP2 subsystem. There is no IRQ_CROSSBAR dedicated to the associated DSP2_INTC input line and therefore, the user cannot change its default mapping.

12.3.3 Interrupt Requests to IPU_Cx_INTC

Table 12-4 lists the default interrupt sources for the IPU_Cx_INTC. In addition, device interrupts IPU_IRQ_23 through IPU_IRQ_79 can alternatively be sourced through the IPU's IRQ_CROSSBAR from one of the 460 multiplexed device interrupts listed in Table 12-6. The CTRL_CORE_IPU_IRQ_y_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

Table 12-4. IPU_Cx_INTC Default Interrupt Mapping

IRQ Input Line[(1)]	IRQ_ CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_ CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
IPU_IRQ_0	N/A	N/A	N/A	Reserved	MSP initial value in exception vector table

(1) This column shows the number of the corresponding exception type.

Table 12-4. IPU_Cx_INTC Default Interrupt Mapping (continued)

IRQ Input Line[1]	IRQ_ CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_ CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
IPU_IRQ_1	N/A	N/A	N/A	RESET_IRQ	Reset
IPU_IRQ_2	N/A	N/A	N/A	NMI_IRQ	External NMI input (interrupt from **nmin** device pad)
IPU_IRQ_3	N/A	N/A	N/A	HARD_FAULT_IRQ	All fault conditions, if the fault handle is not enabled
IPU_IRQ_4	N/A	N/A	N/A	MEM_MANAGE_FAULT_IRQ	Memory management fault; access to illegal locations
IPU_IRQ_5	N/A	N/A	N/A	BUS_FAULT_IRQ	Bus error (on AHB intf)
IPU_IRQ_6	N/A	N/A	N/A	USAGE_FAULT_IRQ	Program error
IPU_IRQ_7	N/A	N/A	N/A	Reserved	Reserved
IPU_IRQ_8	N/A	N/A	N/A	Reserved	Reserved
IPU_IRQ_9	NA	N/A	N/A	Reserved	Reserved
IPU_IRQ_10	N/A	N/A	N/A	Reserved	Reserved
IPU_IRQ_11	N/A	N/A	N/A	SV_CALL_IRQ	Service system Call
IPU_IRQ_12	N/A	N/A	N/A	DEBUG_MON_IRQ	BP, WP or external debug req.
IPU_IRQ_13	N/A	N/A	N/A	Reserved	Reserved
IPU_IRQ_14	N/A	N/A	N/A	PEND_SV_IRQ	Pendable request for system device
IPU_IRQ_15	N/A	N/A	N/A	SYS_TICK_TIMER_IRQ	System Tick Timer
IPU_IRQ_16	N/A	N/A	N/A	XLATE_MMU_FAULT_IRQ	xlate_mmu_fault (from L2 MMU)
IPU_IRQ_17	N/A	N/A	N/A	UNICACHE_MMU_IRQ	Unicache or MMU maintenance complete
IPU_IRQ_18	N/A	N/A	N/A	CTM_TIM_EVENT1_IRQ	CTM timer event (timer #1)
IPU_IRQ_19	N/A	N/A	N/A	HWSEM_M4_IRQ	Semaphore interrupt (1 to each core)
IPU_IRQ_20	N/A	N/A	N/A	ICE_NEMU_IRQ	ICECrusher (1 to each core)
IPU_IRQ_21	N/A	N/A	N/A	IPU_IMP_FAULT_IRQ	IPU imprecise fault (from interconnect)
IPU_IRQ_22	N/A	N/A	N/A	CTM_TIM_EVENT2_IRQ	CTM timer event (timer #2)
IPU_IRQ_23	1	CTRL_CORE_IPU_IRQ_23_24[8:0]	20	DISPC_IRQ	Display controller interrupt
IPU_IRQ_24	2	CTRL_CORE_IPU_IRQ_23_24[24:16]	48	Reserved	Reserved by default but can be remapped to a valid interrupt source
IPU_IRQ_25	3	CTRL_CORE_IPU_IRQ_25_26[8:0]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
IPU_IRQ_26	4	CTRL_CORE_IPU_IRQ_25_26[24:16]	96	Reserved	Reserved by default but can be remapped to a valid interrupt source
IPU_IRQ_27	5	CTRL_CORE_IPU_IRQ_27_28[8:0]	126	ISS_IRQ_INT0	ISS interrupt 0[2]

(2) ISS is not supported on the DRA78x family of devices.

Table 12-4. IPU_Cx_INTC Default Interrupt Mapping (continued)

IRQ Input Line[1]	IRQ_ CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_ CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description

IPU_IRQ_77	55	CTRL_CORE_IPU_IRQ_77_78[8:0]	88	Reserved	Reserved by default but can be remapped to a valid interrupt source
IPU_IRQ_78	56	CTRL_CORE_IPU_IRQ_77_78[24:16]	62	Reserved	Reserved by default but can be remapped to a valid interrupt source
IPU_IRQ_79	57	CTRL_CORE_IPU_IRQ_79_80[8:0]	63	Reserved	Reserved by default but can be remapped to a valid interrupt source
IPU_IRQ_80	N/A	N/A	N/A	L1TAG_ECC_SEC_IRQ	SEC interrupt for L1-Tag
IPU_IRQ_81	N/A	N/A	N/A	L1TAG_ECC_DED_IRQ	DED interrupt for L1-Tag
IPU_IRQ_82	N/A	N/A	N/A	L1DATA_ECC_SEC_IRQ	SEC interrupt for L1-Data
IPU_IRQ_83	N/A	N/A	N/A	L1DATA_ECC_DED_IRQ	DED interrupt for L1-Data
IPU_IRQ_84	N/A	N/A	N/A	L2_RAM_ECC_SEC_IRQ	SEC interrupt for L2-RAM
IPU_IRQ_85	N/A	N/A	N/A	L2_RAM_ECC_DED_IRQ	DED interrupt for L2-RAM

NOTE: Exceptions/interrupts IPU_IRQ_[15:0] are all internal to the Cortex-M4 core.

Exceptions/interrupts IPU_IRQ_[79:16] are all external to the Cortex-M4 core – that is, the first Cortex-M4 external interrupt is mapped to IPU_IRQ_16 (exception #16), and the last (sixty-fourth) Cortex-M4 external interrupt is mapped to IPU_IRQ_79 (exception #79).

For more information about Cortex-M4 exception types, refer to Arm *Cortex™-M4 Devices Generic User Guide* (available at http://infocenter.arm.com/help/index.jsp).

NOTE: The "**IRQ_CROSSBAR Default Input Index**" column of Table 12-4 shows which input of the corresponding IRQ_CROSSBAR instance is mapped to its output (and then routed to the corresponding IPU1_Cx_INTC input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL_CORE_IPU1_IRQ_y_z register bit fields that are used to control the mapping of device interrupts to IPU1_Cx_INTC inputs. For example, the IPU1_IRQ_23_24[8:0] bit field is used to configure which device interrupt would be mapped to the IPU1_IRQ_23 line. The reset value of this bit field is 0x14, meaning that DISPC_IRQ would be mapped to IPU1_IRQ_23 by default because it is connected to the IRQ_CROSSBAR_20 input.

'N/A' in this column means that the corresponding interrupt is internal to the IPU1 subsystem. There is no IRQ_CROSSBAR dedicated to the associated IPU1_Cx_INTC input line and therefore, the user cannot change its default mapping.

The CTRL_CORE_IPU1_IRQ_y_z registers control the IRQ_CROSSBAR settings for both NVICs in the IPU1 subsystem. That is, it is not possible to map different interrupts to the same interrupt input of the NVICs in IPU1.

12.3.4 Interrupt Requests to EVE_INTC1

Table 12-5 lists the default interrupt sources for the EVE_INTC1. In addition, device interrupts EVE_IRQ_0 through EVE_IRQ_7 can alternatively be sourced through the EVE's IRQ_CROSSBAR from one of the 460 multiplexed device interrupts listed in Table 12-6. The CTRL_CORE_EVE_IRQ_y_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

Table 12-5. EVE_INTC1 Default Interrupt Mapping

IRQ Input Line	IRQ_ CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_ CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
EVE_IRQ_0	1	CTRL_CORE_EVE_IRQ_0_1[8:0]	1	ELM_IRQ	Error location process completion interrupt
EVE_IRQ_1	2	CTRL_CORE_EVE_IRQ_0_1[24:16]	2	EXT_SYS_IRQ_1	External interrupt (active low) via sys_nirq1 pin
EVE_IRQ_2	3	CTRL_CORE_EVE_IRQ_2_3[8:0]	3	CTRL_MODULE_CORE_IRQ_SEC_EVTS	Combined firewall error interrupt. For more information, see Section 13.4.6.13.2.
EVE_IRQ_3	4	CTRL_CORE_EVE_IRQ_2_3[24:16]	4	L3_MAIN_IRQ_DBG_ERR	L3_MAIN debug error
EVE_IRQ_4	5	CTRL_CORE_EVE_IRQ_4_5[8:0]	5	L3_MAIN_IRQ_APP_ERR	L3_MAIN application or non-attributable error
EVE_IRQ_5	6	CTRL_CORE_EVE_IRQ_4_5[24:16]	6	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE_IRQ_6	7	CTRL_CORE_EVE_IRQ_6_7[8:0]	7	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE_IRQ_7	8	CTRL_CORE_EVE_IRQ_6_7[24:16]	8	Reserved	Reserved by default but can be remapped to a valid interrupt source

EVE_IRQ_12	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_13	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_14	N/A	N/A	N/A	Reserved	Reserved

Table 12-5. EVE_INTC1 Default Interrupt Mapping (continued)

IRQ Input Line	IRQ_ CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_ CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
EVE_IRQ_15	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_16	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_17	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_18	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_19	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_20	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_21	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_22	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_23	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_24	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_25	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_26	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_27	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_28	N/A	N/A	N/A	EVE_MBX2_INT0	EVE Mailbox 2 Interrupt 0
EVE_IRQ_29	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_30	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_31	N/A	N/A	N/A	Reserved	Reserved

NOTE: The "**IRQ_CROSSBAR Default Input Index**" column of Table 12-5 shows which input of the corresponding IRQ_CROSSBAR instance is mapped to its output (and then routed to the corresponding EVE_INTC1 input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL_CORE_EVE1_IRQ_y_z register bit fields that are used to control the mapping of device interrupts to EVE_INTC1 inputs. For example, the EVE1_IRQ_0_1[8:0] bit field is used to configure which device interrupt would be mapped to the EVE1_IRQ_0 line. The reset value of this bit field is 0x1, meaning that ELM_IRQ would be mapped to EVE1_IRQ_0 by default because it is connected to the IRQ_CROSSBAR_1 input.

'N/A' in this column means that the corresponding interrupt is internal to the EVE1 subsystem. There is no IRQ_CROSSBAR dedicated to the associated EVE_INTC1 input line and therefore, the user cannot change its default mapping.

12.3.5 Mapping of Device Interrupts to IRQ_CROSSBAR Inputs

Table 12-6 shows the individual connection between all module IRQs and all IRQ_CROSSBAR inputs.

Table 12-6. Connection of Device IRQs to IRQ_CROSSBAR Inputs

IRQ_CROSSBAR Input	Interrupt Name	Interrupt Source	Description
IRQ_CROSSBAR_0	Reserved	Reserved	Reserved
IRQ_CROSSBAR_1	ELM_IRQ	ELM	Error location process completion interrupt
IRQ_CROSSBAR_2	EXT_SYS_IRQ_1	External system	External interrupt (active low) via sys_nirq1 pin
IRQ_CROSSBAR_3	CTRL_MODULE_CORE_IRQ _SEC_EVTS	CTRL_MODULE_CORE	Combined firewall error interrupt. For more information, see Section 13.4.6.13.2
IRQ_CROSSBAR_4	L3_MAIN_IRQ_DBG_ERR	L3_MAIN	L3_MAIN debug error
IRQ_CROSSBAR_5	L3_MAIN_IRQ_APP_ERR	L3_MAIN	L3_MAIN application or non-attributable error

12.4 Interrupt Controllers Functional Description

For detailed information about each device INTC (including functional description and registers descriptions), see the TRM chapters and Arm documents referenced in Section 12.1, *Interrupt Controllers Overview*.

Control Module

This chapter describes the system control module for the device.

Topic **Page**

13.1 Control Module Overview

The control module is composed of two submodules, the CTRL_MODULE_CORE submodule and the CTRL_MODULE_WKUP submodule. These two submodules represent a set of registers which are used to control the device I/O ports and also various kinds of settings related to the different modules available in this device.

The CTRL_MODULE_CORE submodule has registers for the following features:

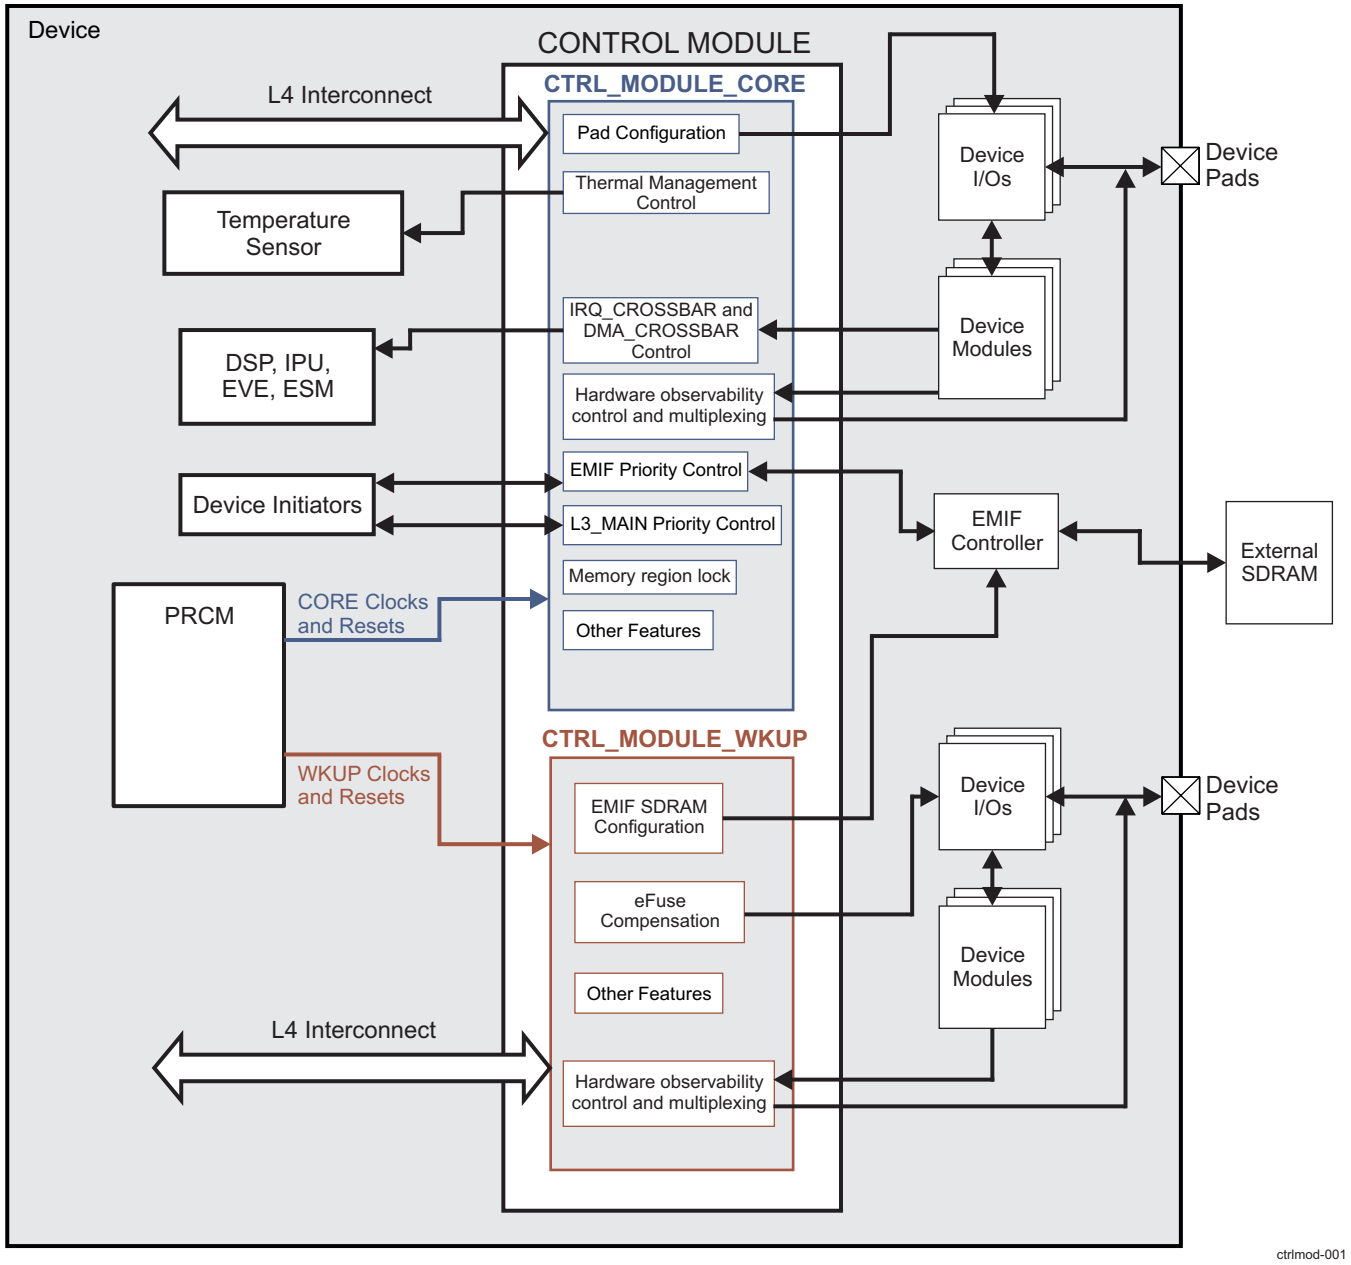
- Pad configuration with following controls:
  - Pad I/O multiplexing
  - Pad pull-up and pull-down configuration
  - Pad input buffer enabling
  - Pad slew rate control
- Device thermal management control and status registers
- IRQ_CROSSBAR and DMA_CROSSBAR control
- Control the priority of initiator accesses to the external SDRAM
- Control the priority of initiators connected to L3_MAIN interconnect
- Memory region lock registers
- Mapping of the device non-maskable interrupt (NMI) to respective cores
- Controls for the LPDDR2/DDR2/DDR3 I/O Cells
- Controls for the LPDDR2/DDR2/DDR3 associated vref-generation cells
- AVS Class 0 associated registers
- Status of the system boot settings
- Firewalls error status
- Settings related to different peripheral modules
- Hardware observability control and multiplexing
- Registers related to PRCM and PLL control
- Registers related to the boot ROM
- Other functions

The CTRL_MODULE_WKUP submodule has registers for the following features:

- Basic EMIF configuration settings
- XTAL Oscilator control
- Efuse I/O compensation
- Hardware observability control and multiplexing
- Other functions

Figure 13-1 represents an overview block diagram of the control module.

Figure 13-1. Control Module Overview Block Diagram



13.2 Control Module Environment

Figure 13-2 shows the control module environment.

Figure 13-2. Control Module Environment

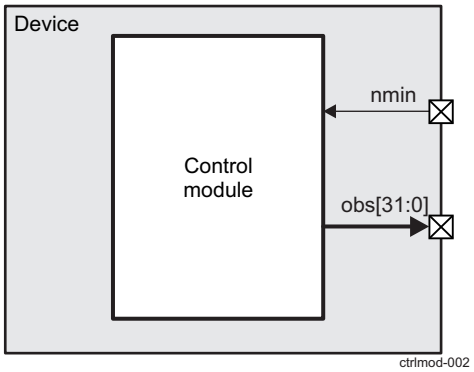


Table 13-1 shows the NMI input and observability output signals.

Table 13-1. Control Module I/O Signals Description

Signal	I/O[1]	Description
nmin	I	External non-maskable interrupt signal[2]
obs[31:0]	O	32 hardware observability signals [3]

(1) I = Input; O = Output; I/O = Bidirectional
(2) For more information, see Section 13.4.6.9, *NMI Mapping to respective cores*
(3) For more information, see Section 13.4.6.14, *Hardware Observability Related Registers*

13.3 Control Module Integration

Figure 13-3 shows the integration of the control module in the device.

Figure 13-3. Control Module Integration

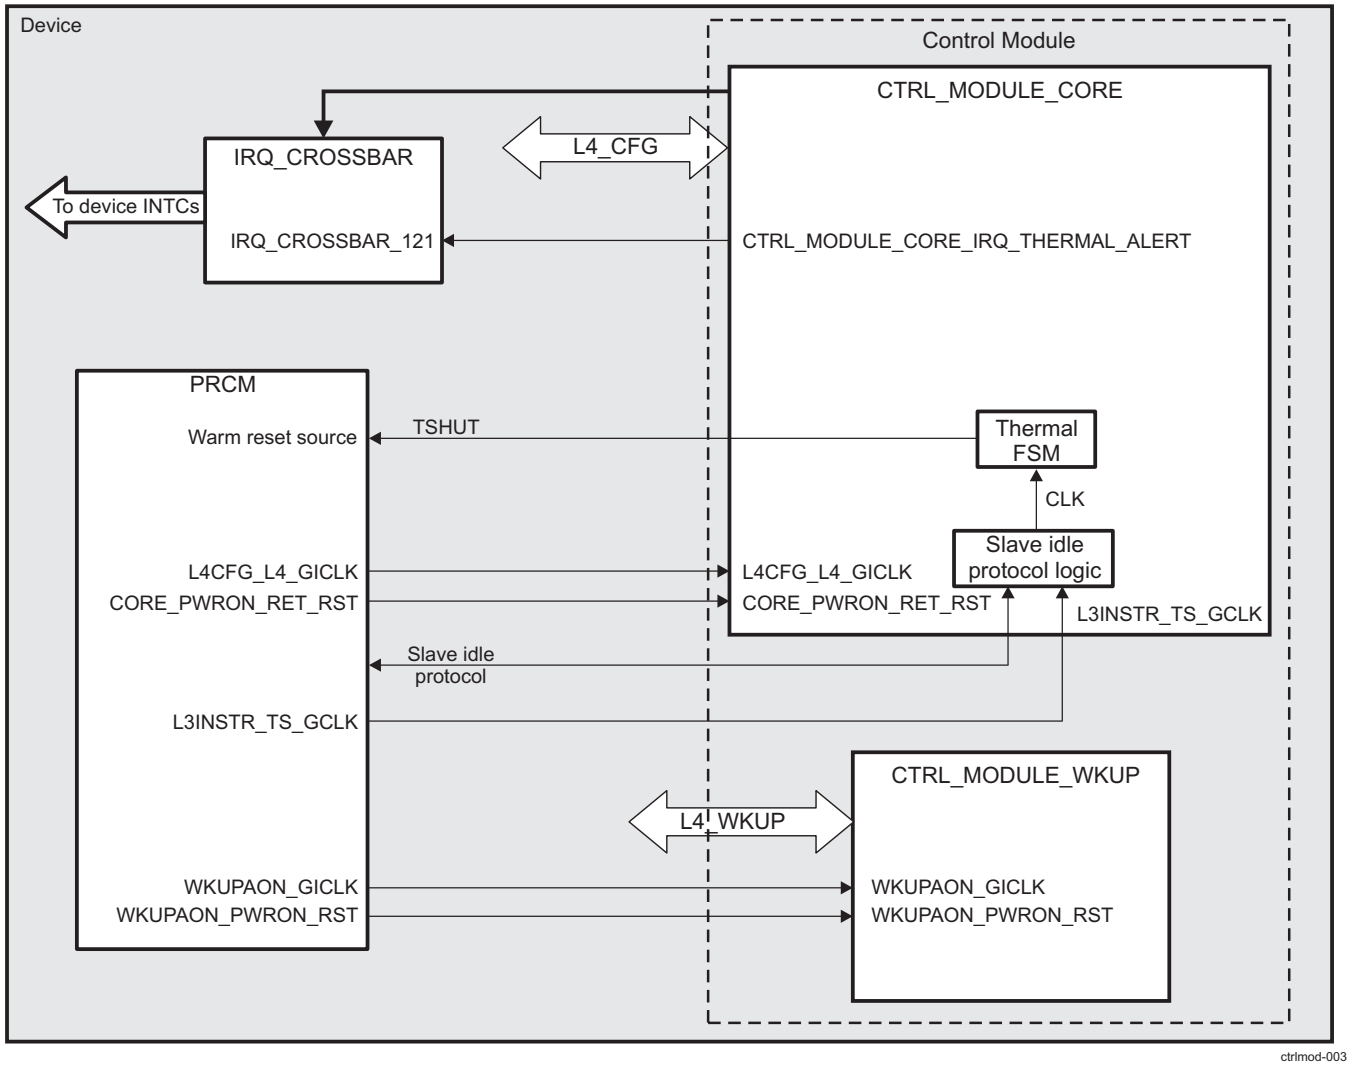

Table 13-2 through Table 13-4 summarize the integration of the Control Module in the device.

Table 13-2. Control Module Integration Attributes

Submodule	Attributes	
	Power Domain	Interconnect
CTRL_MODULE_CORE	PD_COREAON	L4_CFG
CTRL_MODULE_WKUP	PD_WKUPAON	L4_WKUP

Table 13-3. Control Module Clocks and Resets

	Clocks			
Submodule	Destination Signal Name	Source Signal Name	Source	Description

Table 13-3. Control Module Clocks and Resets (continued)

CTRL_MODULE_CORE	L4CFG_L4_GICLK	L4CFG_L4_GICLK	PRCM	Interface clock to the CTRL_MODULE_CORE submodule
	L3INSTR_TS_GCLK	L3INSTR_TS_GCLK	PRCM	Functional clock for the thermal FSM instantiated in the CTRL_MODULE_CORE submodule
CTRL_MODULE_WKUP	WKUPAON_GICLK	WKUPAON_GICLK	PRCM	Interface clock to the CTRL_MODULE_WKUP submodule
		Resets		
CTRL_MODULE_CORE	CORE_PWRON_RET_RST	CORE_PWRON_RET_RST	PRCM	Internal power-on reset (POR) affecting the CTRL_MODULE_CORE submodule
CTRL_MODULE_WKUP	WKUPAON_PWRON_RST	WKUPAON_PWRON_RST	PRCM	Internal POR affecting the CTRL_MODULE_WKUP submodule

Table 13-4. Control Module Hardware Requests

Interrupt Requests				
Submodule	**Source Signal Name**	**Destination IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
CTRL_MODULE_CORE	CTRL_MODULE_CORE_IRQ_THERMAL_ALERT	IRQ_CROSSBAR_121	-	Thermal alert interrupt signal generated when the thermal sensor goes over the tepmerature threshold value. This IRQ source signal is not mapped by default to any device INTC.

NOTE: The "**Default Mapping**" column in Table 13-4 *Control Module Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*.
For more information about the device interrupt controllers, see Chapter 12, *Interrupt Controllers*.

The integration of the control module is the following:

- No wake-up request generation
- No DMA request generation
- No master standby protocol with the PRCM
- Slave idle protocol, between the CTRL_MODULE_CORE submodule and the PRCM, related only to the L3INSTR_TS_GCLK
- One interrupt request to the IRQ_CROSSBAR module
- One (thermal shutdown) TSHUT signal used as PRCM warm reset source
- Two clocks and one reset signal to the CTRL_MODULE_CORE submodule
- One clock and one reset signal to the CTRL_MODULE_WKUP submodule

13.4 Control Module Functional Description

13.4.1 Control Module Clock Configuration

There is no software control over the L4CFG_L4_GICLK and WKUPAON_GICLK clocks neither in the control module nor in the PRCM module. The L4CFG_L4_GICLK clock is automatically gated when there is no access to the CTRL_MODULE_CORE registers and the WKUPAON_GICLK is automatically gated when there is no access to the CTRL_MODULE_WKUP registers. There are clock activity status bits for these two clocks in the PRCM module.

The L3INSTR_TS_GCLK is controlled by the CTRL_CORE_BANDGAP_MASK_1[31:30] SIDLEMODE bit field. For more information, see Section 13.4.6.3.5.

The L3INSTR_TS_GCLK has also the following software controls located in the PRCM module:

- Status: see Chapter 3, *Power, Reset, and Clock Management*
- Divider ratio: see Chapter 3, *Power, Reset, and Clock Management*

13.4.2 Control Module Resets

The control module is not sensitive to software reset. It does not respond to global warm reset too. The control module can be reset only by the internal POR (global cold reset).

Despite the previously stated that control module is not sensitive to global warm reset the following registers are exception of this rule and are sensitive to global warm reset:

- All CTRL_CORE_PAD_x registers
- CTRL_CORE_IPU_WAKEUP
- CTRL_CORE_TESOC_LAST_RESET_INDICATOR
- CTRL_CORE_ROM_AUXBOOT0
- CTRL_CORE_ROM_AUXBOOT1

All other control module registers are sensitive only to global cold reset.

The PRCM provides the CORE_PWRON_RET_RST POR signal to the CTRL_MODULE_CORE and the WKUPAON_PWRON_RST POR signal to the CTRL_MODULE_WKUP. For more information, see Section 3.5.5, *Reset Domains*, in Chapter 3, *Power, Reset, and Clock Management*.

13.4.3 Control Module Power Management

13.4.3.1 Power Management Protocols

The control module, which is slave on the L4 interconnect, does not support master standby or slave idle protocols for handshaking with the PRCM. Only the thermal FSM supports slave idle protocol used to control its functional clock, that is the L3INSTR_TS_GCLK clock.

13.4.4 Hardware Requests

The control module does not generate DMA and wake-up requests. The CTRL_MODULE_CORE submodule generates only one IRQ to the IRQ_CROSSBAR module. This is the CTRL_MODULE_CORE_IRQ_THERMAL_ALERT interrupt. For more information, see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*.

13.4.5 Control Module Initialization

The control module responds to the internal POR. During device initialization, only modules used at boot time are associated with the pads. Other module inputs are internally tied and output buffers are turned off. After POR, software must set the pad configuration registers to appropriate values according to the desired device configuration.

The CTRL_CORE_BOOTSTRAP[15:0] bit field reflects the state of the sysboot[15:0] pads captured at POR in the PRCM module.

13.4.6 Functional Description Of The Various Register Types In CTRL_MODULE_CORE Submodule

The following sections describe the purpose of the various kinds of registers and register groups which reside in the CTRL_MODULE_CORE submodule.

13.4.6.1 Pad Configuration Registers

The pad configuration registers are used to configure most of the device pads. Each pad configuration register is assotiated only with one pad. The name of each register is formed by the corresponding pad name and the prefix "CTRL_CORE_PAD_". Almost all pad configuration registers have same bits. In some of these registers certain bits cannot be present. Figure 13-4 shows the general case in which all the pad configuration register bits are present. Table 13-5 describes these bits.

After POR, software must set the pad configuration registers to appropriate values depending on the desired device configuration.

Figure 13-4. Pad Configuration Register Bits

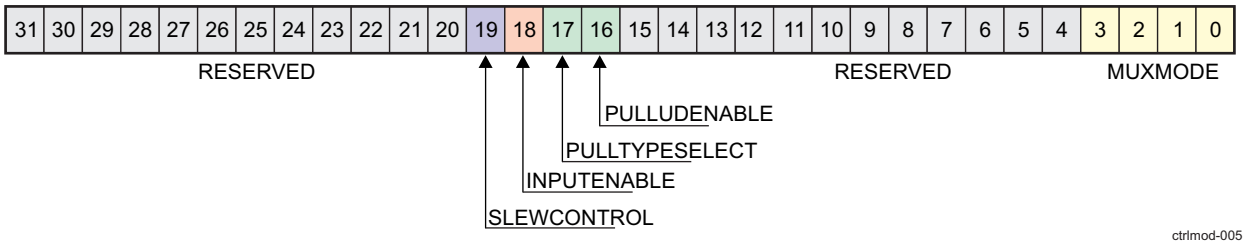

Table 13-5. Description Of The Pad Configuration Register Bits

Bit/Bit Field	Bit Meaning		Description
	0b0	0b1	
SLEWCONTROL	Fast slew is selected	Slow slew is selected	Selects the slew rate for a given pad. The slew rate should be set to the value specified in the device Data Manual for a given mode of operation.
INPUTENABLE	Receive mode is disabled. The pad is configured in output mode only.	Receive mode is enabled. The pad is configured in bidirectional mode.	Enables the input buffer of a given I/O
PULLTYPESELECT	Weak pull-down resistor is selected	Weak pull-up resistor is selected	Weak pull-up or weak pull-down resistor selection for a given pad
PULLUDENABLE	Weak pull-up/pull-ldown resistor is enabled	Weak pull-up/pull-down resistor is disabled	Enables weak pull-up/pull-down feature of a given pad
MUXMODE	This bit field selects one of maximum sixteen possible functions to be available on the corresponding pad. Mostly, only several functions are available.		

When MUXMODE is set to 0x0 the function mapped to the pad corresponds to the name of the pad. In other words, pad names are signal names available when MUXMODE = 0x0.

By default the MUXMODE bit field of most device pads is set to 0xF, which means that there are no signals routed to these pads and the pads are in Hi-Z. The only exception are the sysboot signals available on several pads when MUXMODE = 0xF.

Only MUXMODE values which correspond to defined functions should be used.

NOTE: The default SLEWCONTROL settings in each pad configuration register must be used to guarantee timings, unless specific instructions otherwise are given in the individual timing sub-sections of the device Data Manual. The only exception is when the MUXMODE is configured to select a vout*_* signal. In this case the corresponding SLEWCONTROL bit must be configured to slow slew instead of the default fast slew.

NOTE: When an external pull resistor is desired, the internal pull resistors must be disabled by software because they are enabled by default.

NOTE: For information about the signals available on each pad, see the *Multiplexing Characteristics* table in the device Data Manual.

NOTE: GPIO pins can directly snoop device pads even if those are configured in the other modes. For GPIO output user needs to set pad mux.

The following signals require CTRL_CORE_PAD_x to be programmed with INPUTENABLE=1 for retiming purposes:

- mmc_clk
- gpmc_clk
- i2cj_scl where j=1-2
- spim_sclk where m=1-4
- mcasp1_aclkx, mcasp1_ahclkx, and mcasp1_aclkr
- mcasp2_aclkx, mcasp2_ahclkx, mcasp2_aclkr, mcasp3_aclkx, mcasp3_ahclkx, and mcasp3_aclkr

Except the maximum 16 possible combinations through the MUXMODE bit fields using the bits within CTRL_CORE_SMA_SW_14 and CTRL_CORE_SMA_SW_15 registers an additional signal can be mapped to several device pads. In other words, for these pads there are up to 17 possible signal combinations although not all of them are really implemented. These registers control McASP2, McASP3 and ATL signal multiplexing. If a bit is set to 0x1, function 17 is selected for the corresponding pad. In that case the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF. If a bit is set to 0x0, function 17 is not selected.

13.4.6.2 Pull Selection

There is no automatic gating control to ensure that internal weak pull-up or pull-down resistors on a pad are disconnected whenever pad is configured as output. If a pad is always configured in output mode, it is recommended for user software to disable any internal pull resistor tied to it to avoid unnecessary consumption.

Table 13-6 describes the software controls available for pad internal pull-up and pull-down resistors in the control module pad configuration registers.

Table 13-6. Pull Selection

PULL		Pad Behavior
PULLTYPESELECT	PULLUDENABLE	
0	1	Pull-down selected but not activated
0	0	Pull-down selected and activated
1	1	Pull-up selected but not activated
1	0	Pull-up selected and activated

13.4.6.3 Thermal Management Related Registers

There is one temperature sensor on the device die. It is part of a VBGAPTS cell. This cell has a 10-bit ADC. The ADC converts the temperature values into digital output values proportional to the temperature measured. The VBGAPTS cell is controlled by a dedicated FSM referred to as thermal FSM. The registers associated with this FSM reside in the CTRL_MODULE_CORE submodule. The FSM is clocked by the L3INSTR_TS_GCLK clock. The PRCM module controlls this clock through the slave idle protocol.

The device thermal management related registers can be split into the following classes:

- Temperature sensor control registers
- Registers for the thermal alert comparator block
- Temperature timestamp registers
- Other registers used for:
  - controlling the FIFO
  - controlling the clock provided to the thermal FSM

Figure 13-5 shows the block diagram of the device thermal management.

Figure 13-5. Thermal Management Functional Block Diagram

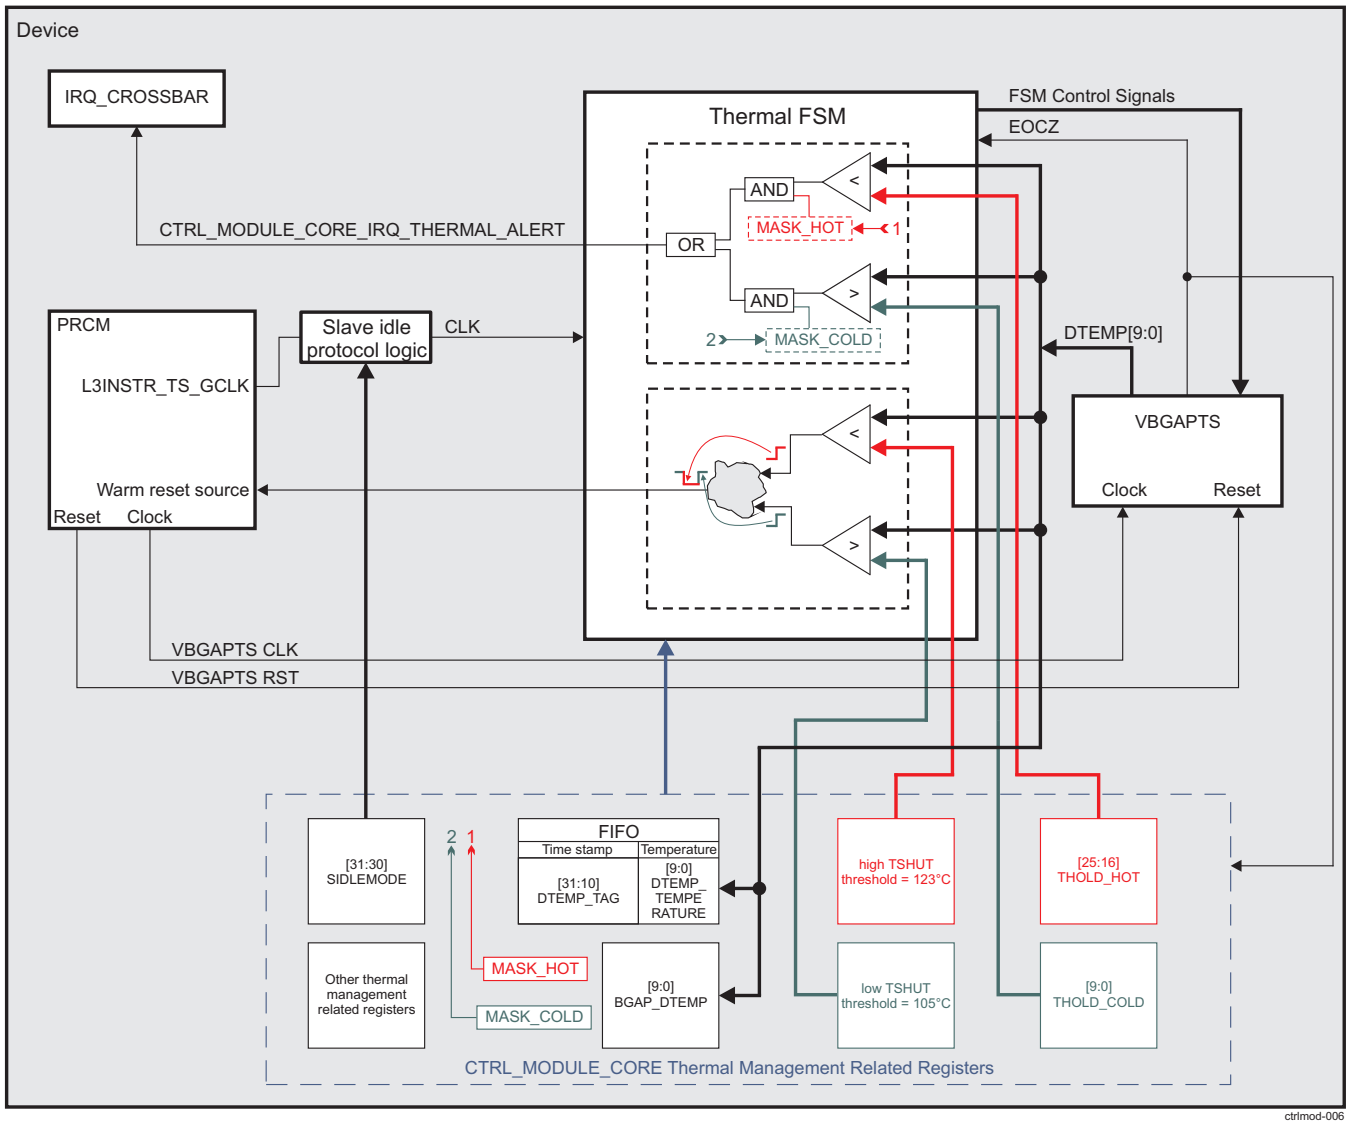

Table 13-7 describes the signals related to the device thermal management logic.

Table 13-7. Thermal Management Signals Description

Signal	I/O[1]	Description
EOCZ	O	End of conversion signal. When low, this signal indicates that the value of DTEMP[9:0] is valid.
DTEMP[9:0]	O	Temperature data from the temperature sensor. This value is valid when EOCZ is low.

(1) I = Input; O = Output

Table 13-7. Thermal Management Signals Description (continued)

Signal	I/O[1]	Description
VBGAPTS CLK	I	Functional clock from the WKUPAON power domain used by the temperature sensor during temperature conversion.
THERMAL ALERT	O	This is an output signal from the thermal FSM mapped as an interrupt request to the IRQ_CROSSBAR module. Software uses this interrupt to implement the device thermal management policy.
TSHUT	O	This is an output signal from the thermal FSM mapped to the PRCM and is used as a warm reset signal. This overheat protection signal is high during normal operation and go low during thermal shutdown event.

The ADC values which correspond to the current temperature are listed in Table 13-10.

13.4.6.3.1 Temperature Sensor Control Registers

The VBGAPTS cell works in continuous conversion mode controlled by the thermal FSM. This means that the temperature is measured at regular time intervals. The start of temperature measurement is initiated automatically by the thermal FSM after it goes out of reset state. To control the main delay between two measurements the CTRL_CORE_BANDGAP_MASK_1[29:27] COUNTER_DELAY bit field is used. After this delay expires the FSM automatically starts a temperature conversion.

The conversion is complete when the CTRL_CORE_TEMP_SENSOR_CORE[10] BGAP_EOCZ_CORE status bits is set to 0x0. After this the valid temperature is written automatically in the CTRL_CORE_TEMP_SENSOR_CORE[9:0] BGAP_DTEMP_CORE bit field, and then software is able to read it. After writing the valid temperature value the FSM waits one clock cycle and start another conversion cycle.

13.4.6.3.2 Registers For The Thermal Alert Comparator Block

There is a comparator block responsible for the thermal alert function of the CTRL_MODULE_CORE thermal management logic. This comparator block is composed of two comparators. One dedicated to low temperature threshold and the other one to high temperature threshold. Software can configure the low temperature threshold through the CTRL_CORE_BANDGAP_THRESHOLD_CORE[9:0] THOLD_COLD_CORE bit field and high temperature threshold through the CTRL_CORE_BANDGAP_THRESHOLD_CORE[25:16] THOLD_HOT_CORE bit field. The values which have to be loaded in these bit fields are the same as those listed in Table 13-10. For example, to set the high temperature threshold value to 120°C, the THOLD_HOT_CORE filed must be loaded with value of 931 (0x3A3).

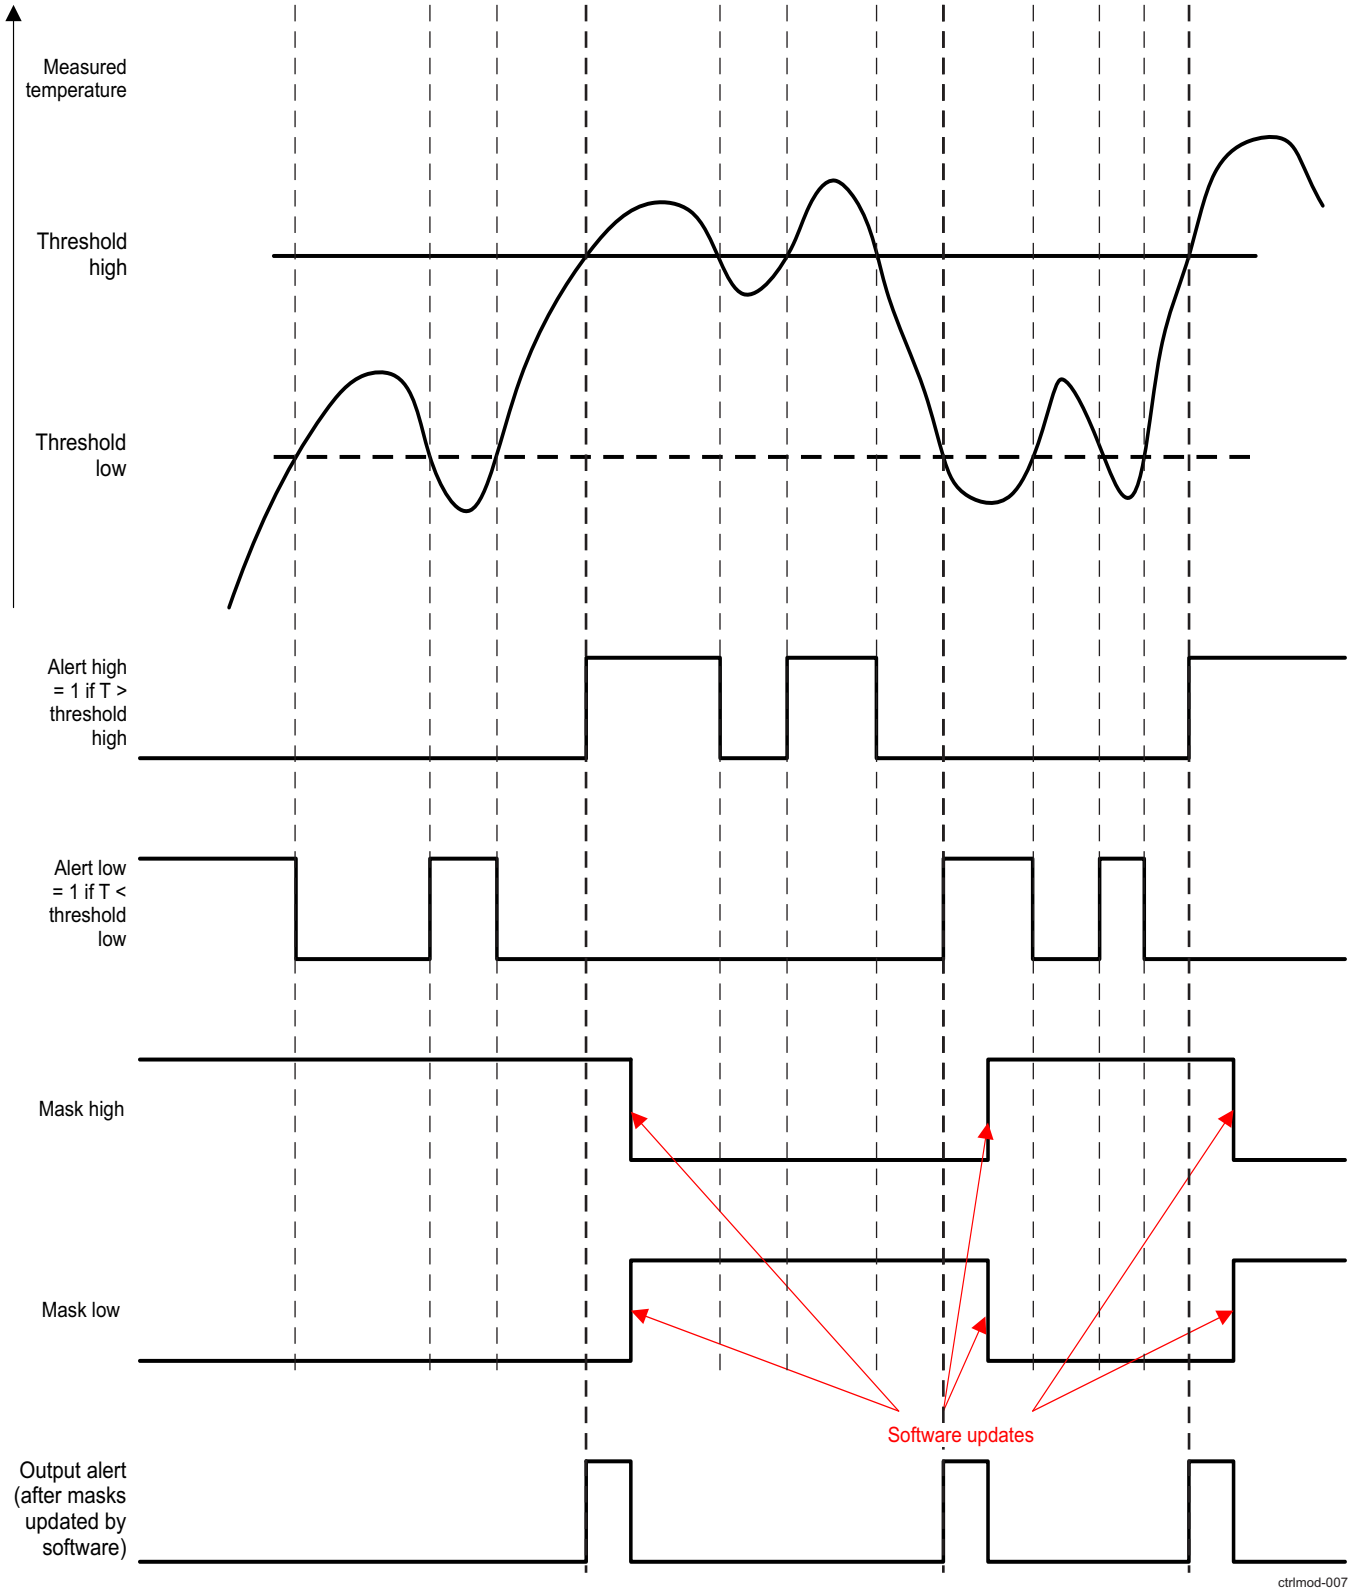
The thermal alert logic provides also a capability to mask the outputs of the comparators associated with low and high temperature thresholds. The low temperature threshold comparator output can be masked by setting to 0x0 the CTRL_CORE_BANDGAP_MASK_1[4] MASK_COLD_CORE bit. The high temperature threshold comparator output can be masked by setting to 0x0 the CTRL_CORE_BANDGAP_MASK_1[5] MASK_HOT_CORE bit.

The masked low and high temperature threshold outputs are ORed (see Figure 13-5) in the CTRL_MODULE_CORE_IRQ_THERMAL_ALERT signal, which delivers an interrupt to the IRQ_CROSSBAR_121 input line of the IRQ_CROSSBAR module. Software can use this interrupt to implement the device thermal management policy. The CTRL_MODULE_CORE_IRQ_THERMAL_ALERT signal is also routed to the CTRL_CORE_BANDGAP_STATUS_1[31] ALERT bit. Value of 0x1 indicates that the CTRL_MODULE_CORE_IRQ_THERMAL_ALERT signal is asserted.

The CTRL_CORE_BANDGAP_STATUS_1[4] COLD_CORE bit indicates the non masked (raw) comparator output for the low temperature threshold. The CTRL_CORE_BANDGAP_STATUS_1[5] HOT_CORE bit indicates the non masked (raw) comparator output for the high temperature threshold.

Figure 13-6 shows the behavior of the thermal alert logic.

Figure 13-6. Behavior Of The Thermal Alert Logic



13.4.6.3.3 Thermal Shutdown Comparator Block

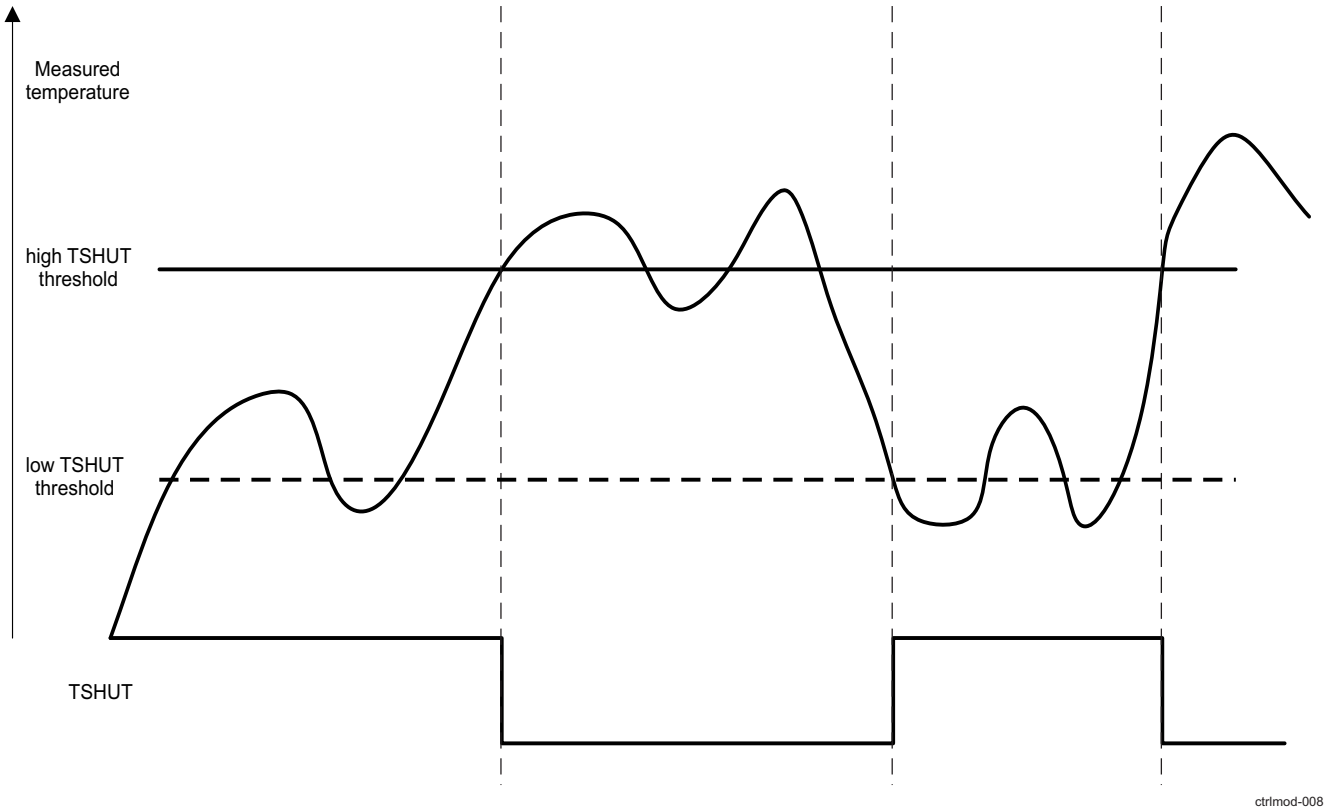
There is also a comparator block responsible for the thermal shutdown (TSHUT) function of the CTRL_MODULE_CORE thermal management logic. This comparator block is also composed of two comparators. One dedicated to low TSHUT threshold and the other one to high TSHUT threshold. The comparator outputs for the low and high TSHUT thresholds are connected to a logic which then generates a single TSHUT signal tied to the PRCM and used as warm reset source. For details, see Figure 13-5.

The values of the low and high TSHUT thresholds are fixed and can be neither overridden nor read by software. The value for the high TSHUT threshold is 123°C (assuming +/-2C temperature sensor accuracy) and for the low TSHUT threshold it is 105°C.

When the high TSHUT threshold is reached, the TSHUT output is activated. To deactivate the TSHUT output, the temperature must go below the value of the low TSHUT threshold.

The TSHUT signal is used as an overheat protection. Figure 13-7 shows the behavior of the TSHUT logic.

Figure 13-7. Behavior Of The Thermal Shutdown Logic



13.4.6.3.4 Temperature Timestamp Registers

Each time when the CTRL_CORE_TEMP_SENSOR_CORE[9:0] BGAP_DTEMP_CORE bit field is updated with new temperature value, this value is also automatically stored into a 5-level deep FIFO and a timestamp is registered too. This FIFO is used to store a brief history for the last few temperature measurements and is also dedicated to temperature timestamping. The FIFO has two fields. The first one is 10 bits wide, 5 levels deep, and is intended to store the temperature values for the last five measurements. The second field is 22 bits wide, 5 levels deep, and acts like a counter for the number of temperature measurements. The FIFO is composed of the following registers:

- CTRL_CORE_DTEMP_CORE_0
- CTRL_CORE_DTEMP_CORE_1
- CTRL_CORE_DTEMP_CORE_2
- CTRL_CORE_DTEMP_CORE_3

- CTRL_CORE_DTEMP_CORE_4

Table 13-8 describes the FIFO.

Table 13-8. FIFO Description

FIFO Levels	Second FIFO Field (22 Bits) – Timestamp Bits [31:10]	Description	First FIFO field (10 Bits) – Temperature Bits [9:0]	Description
Level 1	DTEMP_TAG_CORE_0	Indicates the number of temperature measurements	DTEMP_TEMPERATURE_CORE_0	Indicates the last measured temperature value (the most recent sample)
Level 2	DTEMP_TAG_CORE_1	Indicates the number of temperature measurements minus one (DTEMP_TEMPERATURE_CORE_0 – 1)	DTEMP_TEMPERATURE_CORE_1	Indicates the penultimate measured temperature value
Level 3	DTEMP_TAG_CORE_2	Indicates the number of temperature measurements minus two (DTEMP_TEMPERATURE_CORE_0 – 2)	DTEMP_TEMPERATURE_CORE_2	Indicates temperature value measured before DTEMP_TEMPERATURE_CORE_1
Level 4	DTEMP_TAG_CORE_3	Indicates the number of temperature measurements minus three (DTEMP_TEMPERATURE_CORE_0 – 3)	DTEMP_TEMPERATURE_CORE_3	Indicates temperature value measured before DTEMP_TEMPERATURE_CORE_2
Level 5	DTEMP_TAG_CORE_4	Indicates the number of temperature measurements minus four (DTEMP_TEMPERATURE_CORE_0 – 4)	DTEMP_TEMPERATURE_CORE_4	Indicates temperature value measured before DTEMP_TEMPERATURE_CORE_3 (the oldest sample)

NOTE: DTEMP_TAG_CORE_4 increments its value with one after each fifth temperature measurement.

DTEMP_TAG_CORE_3 increments its value with one after each fourth temperature measurement.

DTEMP_TAG_CORE_2 increments its value with one after each third temperature measurement.

DTEMP_TAG_CORE_1 increments its value with one after each second temperature measurement.

DTEMP_TAG_CORE_0 increments its value with one after each temperature measurement.

13.4.6.3.5 Other Thermal Management Related Registers

- **Controlling the FIFO:**

  Software can stop the FIFO to update with new temperature and timestamp values when setting to 0x1 the CTRL_CORE_BANDGAP_MASK_1[23] FREEZE_CORE bit. This bit is automatically cleared by hardware after the FIFO has been cleared.

  The FIFO is cleared by setting to 0x1 the CTRL_CORE_BANDGAP_MASK_1[20] CLEAR_CORE bit. This bit is automatically set by hardware to 0x0 after the FIFO clearing procedure completes.

- **Controlling the clock provided to the thermal FSM:**

  The thermal FSM complies with the PRCM slave idle protocol. Its functional clock (L3INSTR_TS_GCLK) is automatically gated by PRCM depending on the value of the CTRL_CORE_BANDGAP_MASK_1[31:30] SIDLEMODE bit field. L3INSTR_TS_GCLK clock is also enabled automatically by the PRCM module.

13.4.6.3.6 Summary Of The Thermal Management Related Registers

Table 13-9 summarizes all the thermal management related registers.

Table 13-9. Summary Of The Thermal Management Related Registers

Register Name	Description	Access
CTRL_CORE_TEMP_SENSOR_CORE	Temperature sensor control register	RW
CTRL_CORE_BANDGAP_THRESHOLD_CORE	Register for the thermal alert comparator	RW
CTRL_CORE_BANDGAP_TSHUT_CORE	Register for the thermal shutdown comparator	RW
CTRL_CORE_DTEMP_CORE_0 CTRL_CORE_DTEMP_CORE_1 CTRL_CORE_DTEMP_CORE_2 CTRL_CORE_DTEMP_CORE_3 CTRL_CORE_DTEMP_CORE_4	Temperature timestamp registers	RO
CTRL_CORE_BANDGAP_STATUS_1	Register with status bits for the non masked comparator outputs and the thermal alert signal.	RO
CTRL_CORE_BANDGAP_MASK_1	Register used to mask the comparator outputs for the low and high thermal alert thresholds. This register is also used to control the FIFO and the clock provided to the thermal FSM.	RW

13.4.6.3.7 ADC Values Versus Temperature

Table 13-10 provides all valid ADC values corresponding to the measured temperature which should be read from the CTRL_CORE_TEMP_SENSOR_CORE[9:0] BGAP_DTEMP_CORE bit field. Table 13-10 also provides the values for the low and high temperature thresholds which are configurable through the CTRL_CORE_BANDGAP_THRESHOLD_CORE[9:0] THOLD_COLD_CORE and CTRL_CORE_BANDGAP_THRESHOLD_CORE[25:16] THOLD_HOT_CORE bit fields.

Table 13-10. ADC Values Versus Temperature

13.4.6.4 IRQ_CROSSBAR Module Functional Description

There is an IRQ_CROSSBAR module in the device, which is controlled by registers in the CTRL_MODULE_CORE submodule. The IRQ_CROSSBAR is able to map any of its input signals to any of its outputs. This module is associated with the device interrupt sources. The IRQs from all the device modules are connected to the IRQ_CROSSBAR inputs. Each module IRQ is connected only to one cross-bar input. Each output of the IRQ_CROSSBAR module is connected only to one interrupt line of certain interrupt controller (INTC). Thus, the device IRQs are mapped to the device INTCs through the

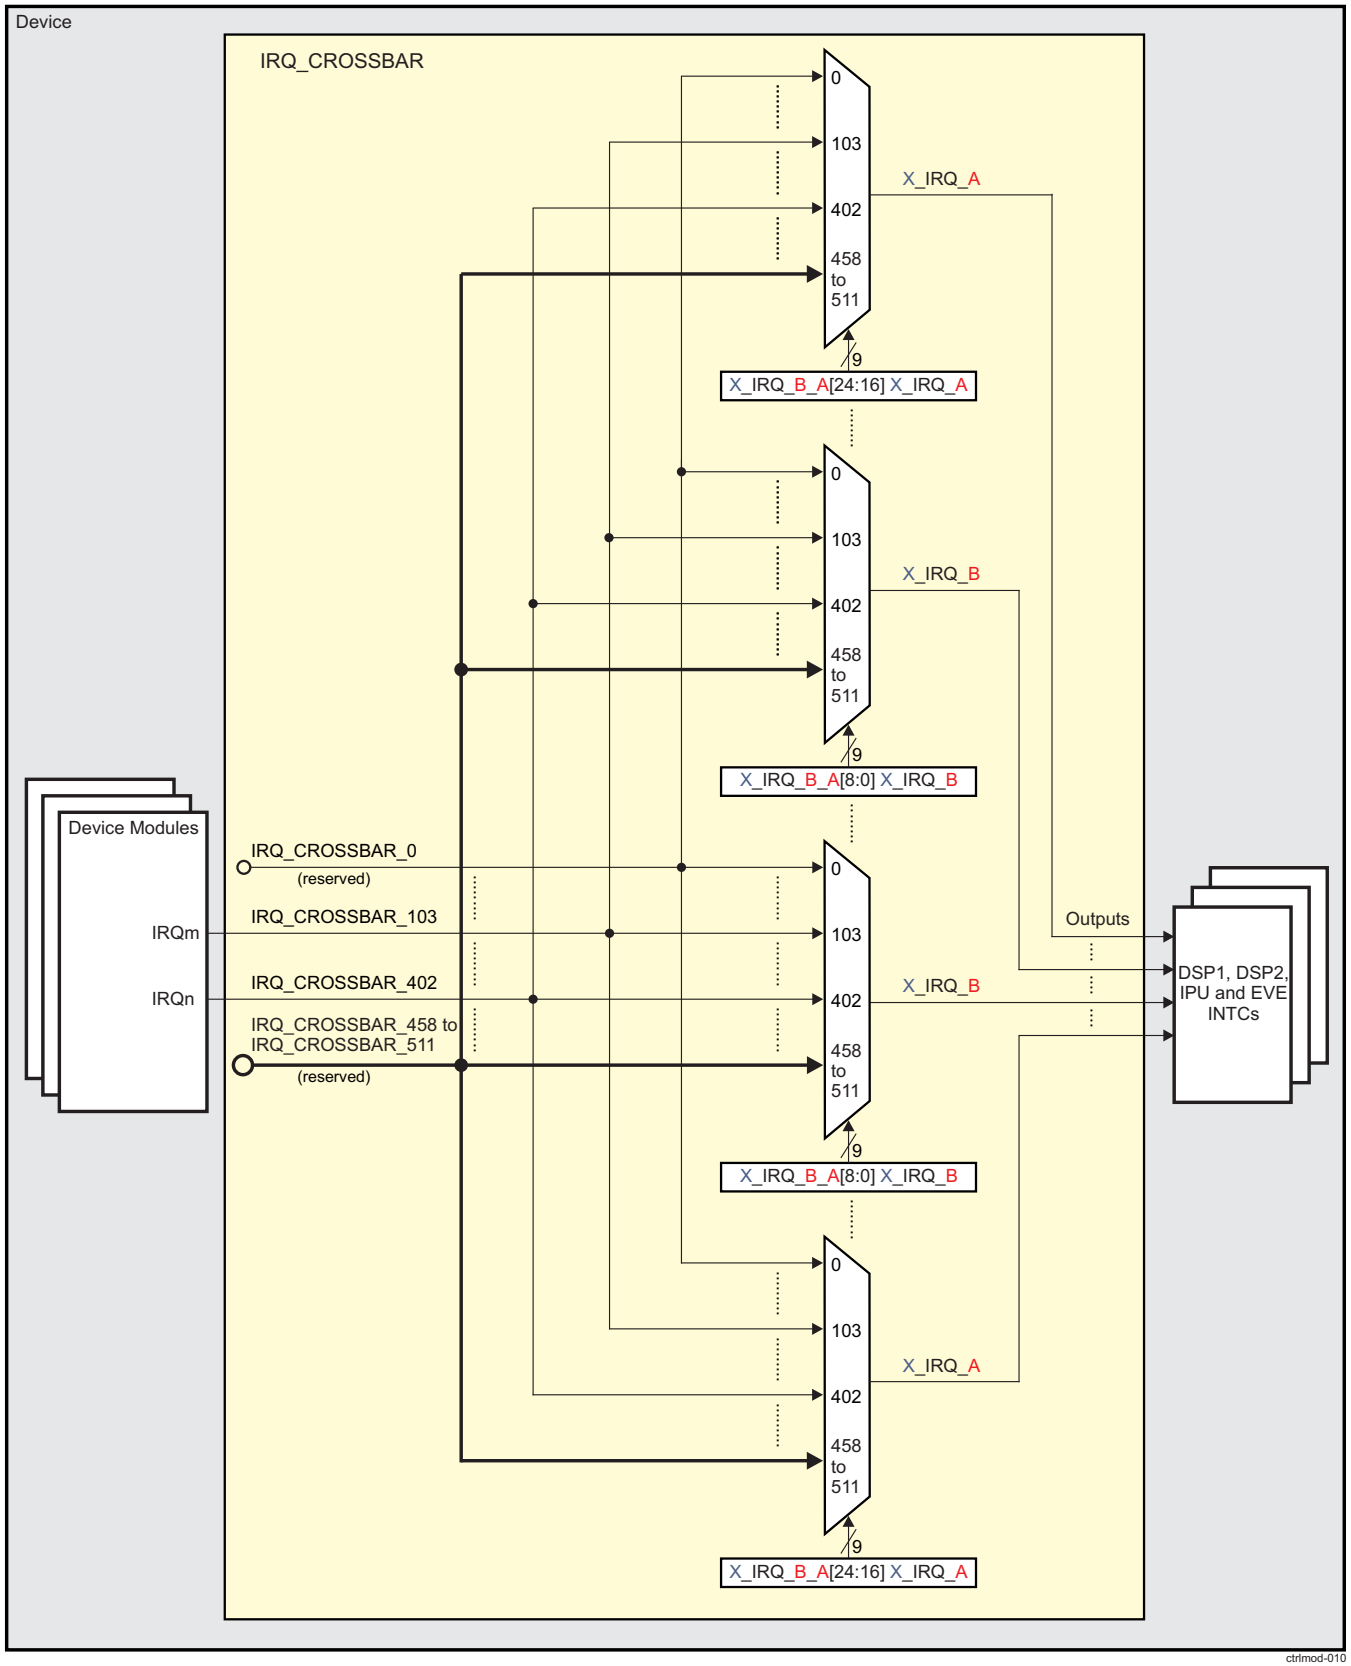
IRQ_CROSSBAR. Some of these IRQs are mapped by default to certain interrupt lines of one of the device INTCs, but there are IRQs which are not mapped by default to any interrupt line of any device INTC. All IRQs, connected to the IRQ_CROSSBAR inputs, can be remapped to other interrupt lines of the different device INTCs through the CTRL_CORE_X_IRQ_B_A registers. Each of these registers has a structure described in Table 13-11.

Table 13-11. Generic Description of the CTRL_CORE_X_IRQ_B_A IRQ_CROSSBAR Control Registers

Bits	Field Name	Description	Type	Note
31:25	RESERVED		R	
24:16	X_IRQ_A	Selects an interrupt source signal for the X_IRQ_A INTC line 0x0: Reserved 0x1: Maps IRQ_CROSSBAR input 1 to X_IRQ_A INTC line 0x2: Maps IRQ_CROSSBAR input 2 to X_IRQ_A INTC line 0x-: ..... 0x67: Maps IRQ_CROSSBAR input 103 to X_IRQ_A INTC line 0x-: ..... 0x1C5 to 0x1FF: Reserved	RW	X is summarization. It is equal to: • DSP1 • DSP2 • IPU • EVE X shows the module name to which interrupt controller all inputs of the IRQ_CROSSBAR module can be mapped to. A is also summarization. It shows the number of the line for the corresponding INTC. A is equal to 0, 1, 2, ..., and so on, depending on the count of the INTC lines controlled by the IRQ_CROSSBAR module. For more details, see Table 13-12.
15:9	RESERVED		R	
8:0	X_IRQ_B	Selects an interrupt source signal for the X_IRQ_B INTC line 0x0: Reserved 0x1: Maps IRQ_CROSSBAR input 1 to X_IRQ_B INTC line 0x2: Maps IRQ_CROSSBAR input 2 to X_IRQ_B INTC line 0x-: ..... 0x67: Maps IRQ_CROSSBAR input 103 to X_IRQ_B INTC line 0x-: ..... 0x1C5 to 0x1FF: Reserved	RW	B is summarization. It shows the number of the line for the corresponding INTC. B is equal to 0, 1, 2, ..., and so on, depending on the count of the INTC lines controlled by the IRQ_CROSSBAR module.

Figure 13-8 represents the way in which the IRQ_CROSSBAR module works. It shows the device modules and their IRQs connected to the IRQ_CROSSBAR inputs, the structure of the cross-bar and its outputs connected to the device INTCs.

Figure 13-8. IRQ_CROSSBAR Module Functional Diagram



Each IRQ_CROSSBAR control register has two 9-bit fields. Each 9-bit field is associated only with one interrupt line. Through this 9-bit field any of the IRQs connected to the IRQ_CROSSBAR inputs can be mapped to the INTC line associated with this 9-bit field. For example, the register CTRL_CORE_DSP1_IRQ_56_57 is associated with DSP1_IRQ_56 and DSP1_IRQ_57. The 9-bit field CTRL_CORE_DSP1_IRQ_56_57[24:16] DSP1_IRQ_57 is associated only with DSP1_IRQ_57 interrupt line of the DSP1 INTC. Setting this bit field to any other value different than its reset value will map another module IRQ to the DSP1_IRQ_57 interrupt line. The default (reset) value of this bit field is 0x1A which corresponds to IRQ_CROSSBAR_26 input. The GPIO3_IRQ_1 is connected to this cross-bar input. Setting another register to 0x1A will cause the GPIO3_IRQ_1 to be mapped to another INTC line. For example, if the CTRL_CORE_DSP1_IRQ_40_41[8:0] DSP1_IRQ_40 is set to 0x1A the GPIO3_IRQ_1 will be mapped to the DSP1_IRQ_40 interrupt line. The same logic also applies to the other interrupt lines of the device INTCs.

In addition, not all of the interrupt lines of a given INTC are controlled by the IRQ_CROSSBAR registers. This means, that there are interrupt lines which are not connected to any IRQ_CROSSBAR output and thus only one IRQ is connected to these interrupt lines. In the most common case these lines are used by interrupt sources internal or specific for the corresponding module, which has an INTC.

Table 13-12 shows which lines of each INTC are associated with the IRQ_CROSSBAR control registers. The rest of the INTC lines (not listed in the table) cannot be controlled by the cross-bar registers.

Table 13-12. Interrupt Lines Associated With The IRQ_CROSSBAR Control Registers

DSP INTC Lines	IPU INTC Lines	EVE INTC Lines
DSP1_IRQ_32 to DSP1_IRQ_95, DSP2_IRQ_32 to DSP2_IRQ_95	IPU_IRQ_23 to IPU_IRQ_80	EVE_IRQ_0 to EVE_IRQ_7

The individual connection between all module IRQs and all IRQ_CROSSBAR inputs is shown in Section 12.3.5, *Mapping of Device Interrupts to IRQ_CROSSBAR Inputs* of Chapter 12, *Interrupt Controllers*.

In addition, there are three IRQ_CROSSBAR registers associated with three channels of the device ESM. The registers are the following:

- CTRL_CORE_ESM_GROUP1_0
- CTRL_CORE_ESM_GROUP1_1
- CTRL_CORE_ESM_GROUP1_2

These three registers follow the same logic as previously described. For example, using the CTRL_CORE_ESM_GROUP1_0[8:0] ESM_GROUP1_0_IRQ_0 bit field any of the device interrupts connected to an IRQ_CROSSBAR input can be mapped to channel ESM_GROUP1_0.

NOTE: ESM is not supported on the DRA78x family of devices.

13.4.6.5 DMA_CROSSBAR Module Functional Description

There is a DMA_CROSSBAR module in the device, which is controlled by registers in the CTRL_MODULE_CORE submodule. The DMA_CROSSBAR is able to map any of its input signals to any of its outputs. This module is associated with the device DMA request (DREQ) source signals. The DREQs from all the device modules are connected to the DMA_CROSSBAR inputs. Each DREQ signal is connected only to one DMA cross-bar input. Each output of the DMA_CROSSBAR module is connected only to one input line of the device DMA modules. The DMAs associated with the DMA_CROSSBAR are the following:

- DMA_EDMA
- DMA_DSP1_EDMA
- DMA_DSP2_EDMA

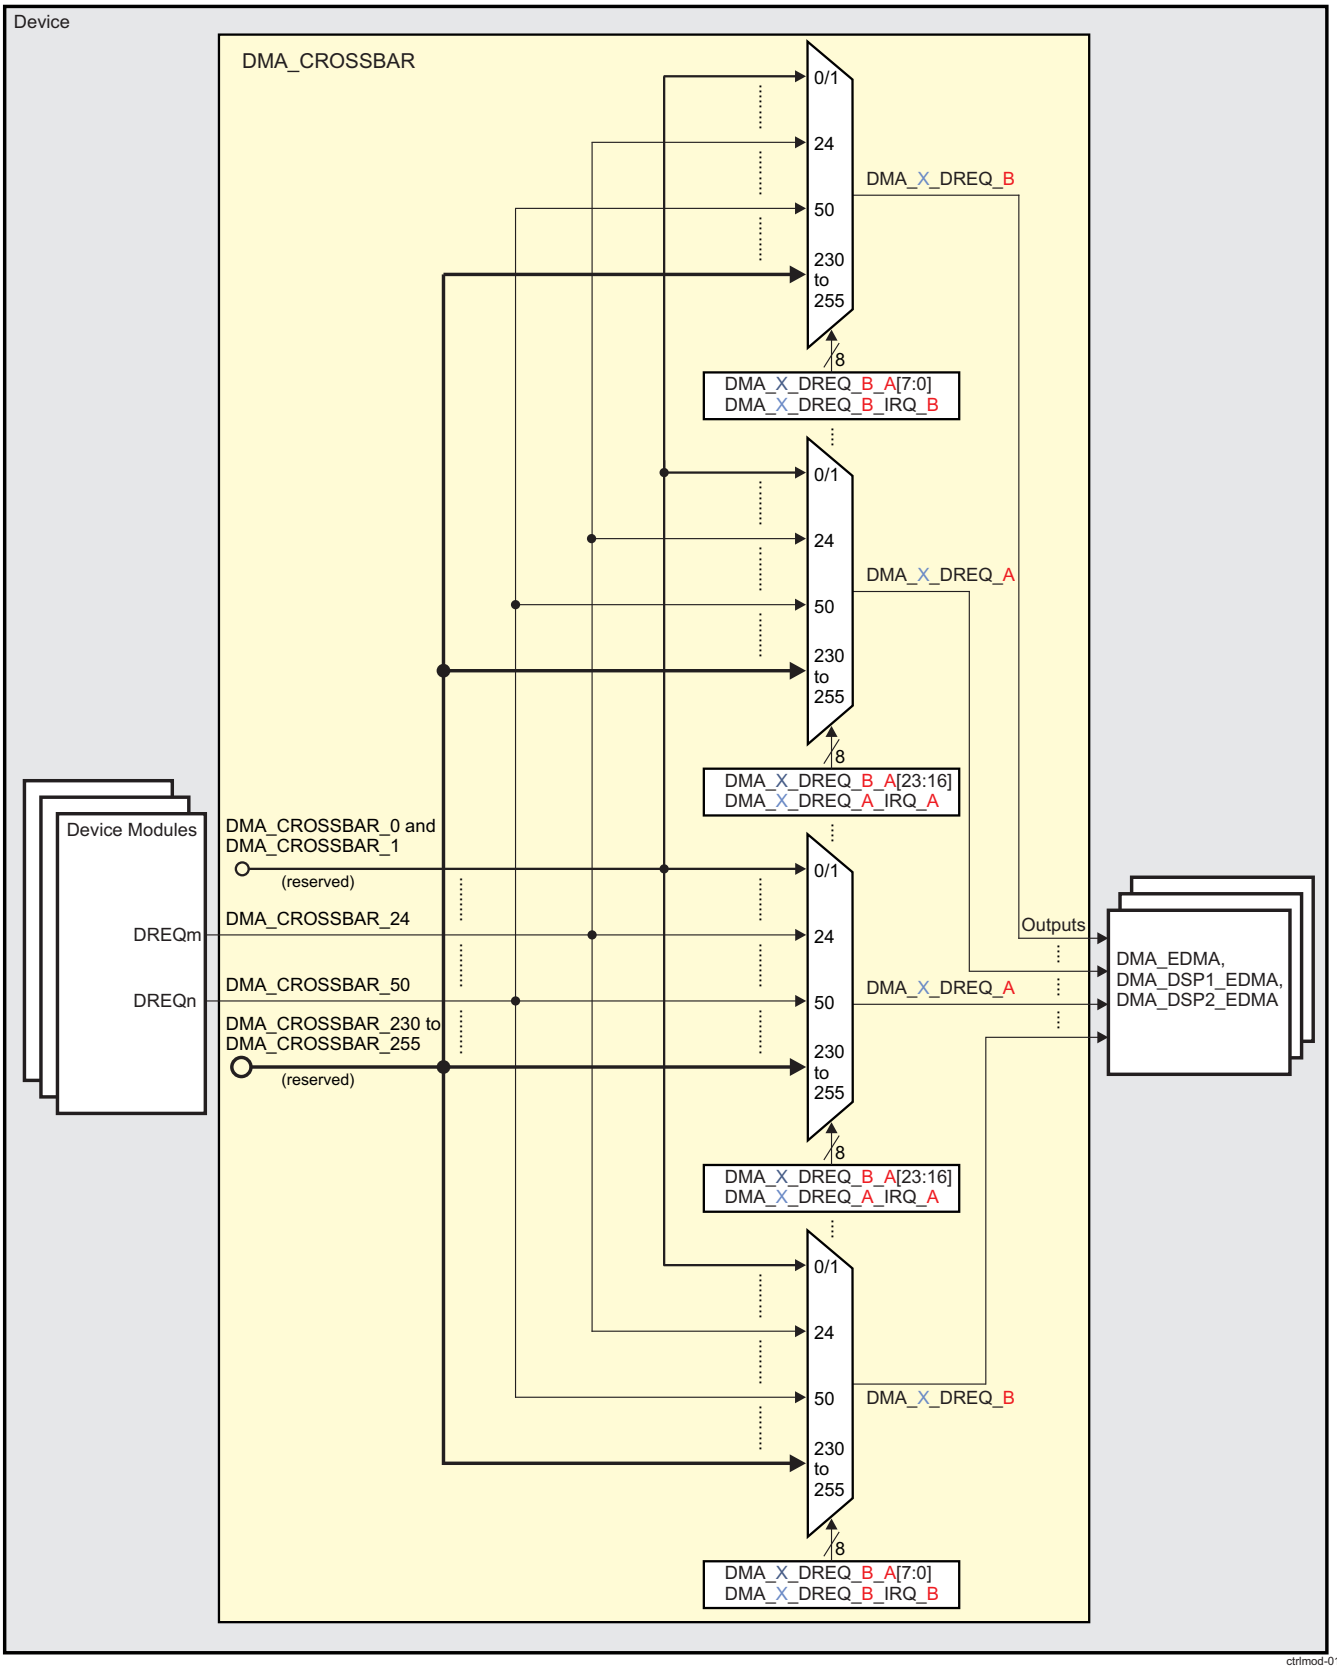
All DREQs, connected to the DMA_CROSSBAR inputs, can be remapped to other lines of the these DMA modules through the CTRL_CORE_DMA_X_DREQ_B_A registers. Each of these registers has a structure described in Table 13-13.

Table 13-13. Generic Description of the CTRL_CORE_DMA_X_DREQ_B_A DMA_CROSSBAR Control Registers

Bits	Field Name	Description	Type	Note
31:24	RESERVED		R	
23:16	DMA_X_DREQ_A_IRQ_A	Selects a DMA request source signal for the DMA_X_DREQ_A_IRQ_A DMA line 0x0: Reserved 0x1: Reserved 0x2: Maps DMA_CROSSBAR input 2 to DMA_X_DREQ_A_IRQ_A DMA line 0x3: Maps DMA_CROSSBAR input 3 to DMA_X_DREQ_A_IRQ_A DMA line 0x-: ..... 0x32: Maps DMA_CROSSBAR input 50 to DMA_X_DREQ_A_IRQ_A DMA line 0x-: ..... 0xE6 to 0xFF: Reserved	RW	X is summarization. It is equal to: • EDMA • DSP1_EDMA • DSP2_EDMA X shows to which DMA all inputs of the DMA_CROSSBAR module can be mapped to. A is also summarization. It shows the number of the DREQ line for the corresponding DMA module. A is equal to 0, 1, 2, ..., and so on, depending on the count of the DMA lines controlled by the DMA_CROSSBAR module. For more details, see Table 13-14.
15:8	RESERVED		R	
7:0	DMA_X_DREQ_B_IRQ_B	Selects a DMA request source signal for the DMA_X_DREQ_B_IRQ_B DMA line 0x0: Reserved 0x1: Reserved 0x2: Maps DMA_CROSSBAR input 2 to DMA_X_DREQ_B_IRQ_B DMA line 0x3: Maps DMA_CROSSBAR input 3 to DMA_X_DREQ_B_IRQ_B DMA line 0x-: ..... 0x32: Maps DMA_CROSSBAR input 50 to DMA_X_DREQ_B_IRQ_B DMA line 0x-: ..... 0xE6 to 0xFF: Reserved	RW	B is also summarization. It shows the number of the DREQ line for the corresponding DMA module. B is equal to 0, 1, 2, ..., and so on, depending on the count of the DMA lines controlled by the DMA_CROSSBAR module. For more details, see Table 13-14.

Figure 13-9 represents the way in which the DMA_CROSSBAR module works. It shows the device modules and their DREQs connected to the DMA_CROSSBAR inputs, the structure of the cross-bar and its outputs connected to the device DMA modules.

Figure 13-9. DMA_CROSSBAR Module Functional Diagram



Each DMA_CROSSBAR control register has two 8-bit fields. Each 8-bit field is associated only with one line of certain DMA module. Through this 8-bit field any of the DREQs connected to the DMA_CROSSBAR inputs can be mapped to the DMA line associated with this 8-bit field. For example, the register CTRL_CORE_DMA_EDMA_DREQ_48_49 is associated with DMA_EDMA_DREQ_48 and DMA_EDMA_DREQ_49 lines. The 8-bit field CTRL_CORE_DMA_EDMA_DREQ_48_49[7:0] DMA_EDMA_DREQ_48_IRQ_48 is associated only with DMA_EDMA_DREQ_48 line of the DMA_EDMA module. Setting this bit field to any other value different than its reset value will map another DREQ from the device modules to the DMA_EDMA_DREQ_48 line. The default (reset) value of this bit field is 0x31 which corresponds to the DMA_CROSSBAR_49 input. The UART1_DREQ_TX is connected to this cross-bar input. Setting another register to 0x31 will cause the UART1_DREQ_TX to be mapped to another DMA line. For example, if the CTRL_CORE_DMA_EDMA_DREQ_40_41[23:16] DMA_EDMA_DREQ_41_IRQ_41 is set to 0x31 the UART1_DREQ_TX will be mapped to the DMA_EDMA_DREQ_41 line. The same logic also applies to the other lines of the device DMAs.

Table 13-14 shows which lines of each DMA are associated with the DMA_CROSSBAR control registers. The rest of the lines (not listed in the table) cannot be controlled by the cross-bar registers.

Table 13-14. DREQ Lines Associated With The DMA_CROSSBAR Control Registers

DMA_EDMA DREQ Lines	DMA_DSP1_EDMA DREQ Lines	DMA_DSP2_EDMA DREQ Lines
DMA_EDMA_DREQ_0 to DMA_EDMA_DREQ_63	DMA_DSP1_DREQ_0 to DMA_DSP1_DREQ_19	DMA_DSP2_DREQ_0 to DMA_DSP2_DREQ_19

The individual connection between all module DREQs and all DMA_CROSSBAR inputs is shown in , *Mapping of DMA Requests to DMA_CROSSBAR Inputs* of Chapter 11, *Enhanced DMA Controllers*.

In addition, the CTRL_CORE_ESM_GROUP1_3 register can be used to map any of the device DREQs connected to a DMA_CROSSBAR input to channel ESM_GROUP1_3 of the device ESM. The same logic as previously described applies when configuring this register.

NOTE: ESM is not supported on the DRA78x family of devices.

13.4.6.6 SDRAM Initiator Priority Registers

The CTRL_CORE_EMIF_INITIATOR_PRIORITY_1 to CTRL_CORE_EMIF_INITIATOR_PRIORITY_8 registers are intended to control the priority of each initiator accessing the EMIF controller. Each 3-bit field in these registers is associated only with one initiator. Setting this bit field to 0x0 means that the corresponding initiator has a highest priority over the others and setting it to 0x7 is for lowest priority. This is useful in case of concurrent access to the external SDRAM from several initiators.

13.4.6.7 L3_MAIN Initiator Priority Registers

The CTRL_CORE_L3_INITIATOR_PRESSURE_1 register is used for controlling the priority of certain initiators on the L3_MAIN. Each 2-bit field in this register is associated only with one initiator. Setting this bit field to 0x3 means that the traffic of this initiator has highest proiroty over the other traffics. A value of 0x0 is for lowest priority. This register provides a dynamic priority escalation for the following L3_MAIN initiators:

- DSP1
- DSP2

13.4.6.8 Memory Region Lock Registers

There are five registers used to lock different memory regions of CTRL_MODULE_CORE memory mapped space. A memory region is locked, means that all wite accesses to this region are ignored. Writing a value unique for each register will lock certain memory region and writing another unique value results in unlocking of the same region. These five registers can lock the entire memory space of the CTRL_MODULE_CORE submodule. Table 13-15 gives more details.

Table 13-15. Memory Region Lock Registers

Register	Memory Space to Lock	Groups of Registers Associated With This Memory Region	Lock/Unlock (register reset value)
CTRL_CORE_MMR_LOCK_1	Region from 0x0000 0100 to 0x0000 079F and from 0x0000 1A00 to 0x0000 1FFF	Thermal management related registers, EMIF initiator priority, L3_MAIN initiator pressure (priority) and other registers	locked
CTRL_CORE_MMR_LOCK_2	Region from 0x0000 07A0 to 0x0000 0D9F	IRQ_CROSSBAR and DMA_CROSSBAR registers	locked
CTRL_CORE_MMR_LOCK_3	Region from 0x0000 0DA0 to 0x0000 0FFF	A few registers associated with device I/Os	locked
CTRL_CORE_MMR_LOCK_4	Region from 0x0000 1000 to 0x0000 13FF	Hardware observability related registers	locked
CTRL_CORE_MMR_LOCK_5	Region from 0x0000 1400 to 0x0000 19FF	Pad configuration registers	locked

NOTE: By default the entire CTRL_MODULE_CORE memory space is locked but the ROM code unlocks it by writing corresponding unlock values to all CTRL_CORE_MMR_LOCK_x registers.

13.4.6.9 NMI Mapping To Respective Cores

Two registers CTRL_CORE_NMI_DESTINATION_1 and CTRL_CORE_NMI_DESTINATION_2 are intended to map the external non-maskable interrupt (NMI) to certain of the device host processors. Writing 0x1 into a bit field of these registers enables the NMI to be mapped to the corresponding processor associated with this bit field. Writing 0x0 disables the NMI mapping to this processor.

13.4.6.10 Software Controls for the LPDDR2/DDR2/DDR3 I/O Cells

NOTE: LPDDR2 is not supported on the DRA78x family of devices.

There are two types of I/O cells associated with the LPDDR2/DDR2/DDR3 interface. These are single-ended and differential I/O cells.

These I/O cells have the following software controls which reside in registers of the CTRL_MODULE_CORE:

- Output impedance controls - I[2:0]
- Slew rate controls - SR[2:0]
- Weak driver controls - WD[1:0]

The I and SR controls apply when the I/Os operate as outputs. The WD controls apply when the I/Os operate as both inputs or outputs.

The bits I[2:0] are used for programming the desired impedance value of the output buffer. Table 13-16 describes the I[2:0] controls which are valid for pull-up and pull-down outputs.

Table 13-16. Output Impedance Controls - I[2:0]

I[2]	I[1]	I[0]	Drive Setting Name	Output Impedance
0	0	0	Imp80	80 Ohms
0	0	1	Imp60	60 Ohms
0	1	0	Imp48	48 Ohms
0	1	1	Imp40	40 Ohms
1	0	0	Imp34	34 Ohms
1	0	1	Reserved	Reserved

Table 13-16. Output Impedance Controls - I[2:0] (continued)

I[2]	I[1]	I[0]	Drive Setting Name	Output Impedance
1	1	0	Reserved	Reserved
1	1	1	Reserved	Reserved

To achieve optimal noise/speed trade-off the slew rate of the output signal can also be programmed using the slew rate control bits SR[2:0] shown in Table 13-17. These SR settings do not affect the DC drive strength of the output buffer. They only control its turn-on time.

Table 13-17. Slew Rate Controls - SR[2:0]

SR[2]	SR[1]	SR[0]	Turn-On Time Level	Note
0	0	0	fastest	All 8 values are valid.
...	...	...		
...	...	...		
1	1	1	slowest	

Weak pull-up, pull-down or keeper option for device LPDDR2/DDR2/DDR3 pads is enabled through the WD[1:0] bits. The weak pull-up or pull-down option is used to define the pad state (high or low) when no signal is driving the pad. The weak keeper option is used to maintain the previous output value when nothing is driving the pad. Table 13-18 describes the WD controls. They are used for avoiding floating pads on the LPDDR2/DDR2/DDR3 interface.

Table 13-18. Weak Driver Controls - WD[1:0]

WD[1]	WD[0]	Single-Ended Operation	Differential Pair Operation	
			padp	padn
0	0	Pull logic disabled	Pull logic disabled	Pull logic disabled
0	1	Weak pullup enabled	Weak pullup enabled	Weak pulldown enabled
1	0	Weak pulldown enabled	Weak pulldown enabled	Weak pullup enabled
1	1	Weak keeper enabled	Weak keeper enabled	Weak keeper enabled

NOTE: To avoid unnecessary power consumption, software must overwrite the Weak Driver (WD) reset values by setting them to 0x0.

It must be taken into account that the I, SR and WD software controls apply for several pads combined in groups, and not for a single pad. For example, writing 0x1 to the CTRL_CORE_CONTROL_DDRCACH1_0[17:16] DDR3CH1_PART5A_WD bit field enables the weak pull-up resistors for all pads in the PART5A group. These are the ddr1_a[15:0] pads. Table 13-19 shows the I, SR and WD controls for the different LPDDR2/DDR2/DDR3 pad groups.

Table 13-19. Software Group Controls for the LPDDR2/DDR2/DDR3 Pads

LPDDR2/DDR2/DDR3 Interface I/O Group Controls	Group Name	EMIF Pads in a Group
CTRL_CORE_CONTROL_DDRCACH1_0[31:29] DDR3CH1_PART0_I CTRL_CORE_CONTROL_DDRCACH1_0[28:26] DDR3CH1_PART0_SR CTRL_CORE_CONTROL_DDRCACH1_0[25:24] DDR3CH1_PART0_WD	PART0	ddr1_casn, ddr1_rasn, ddr1_rst, ddr1_wen, ddr1_csn[0], ddr1_cke, ddr1_odt[0]

Table 13-19. Software Group Controls for the LPDDR2/DDR2/DDR3 Pads (continued)

13.4.6.11 Reference Voltage for the Device LPDDR2/DDR2/DDR3 Receivers

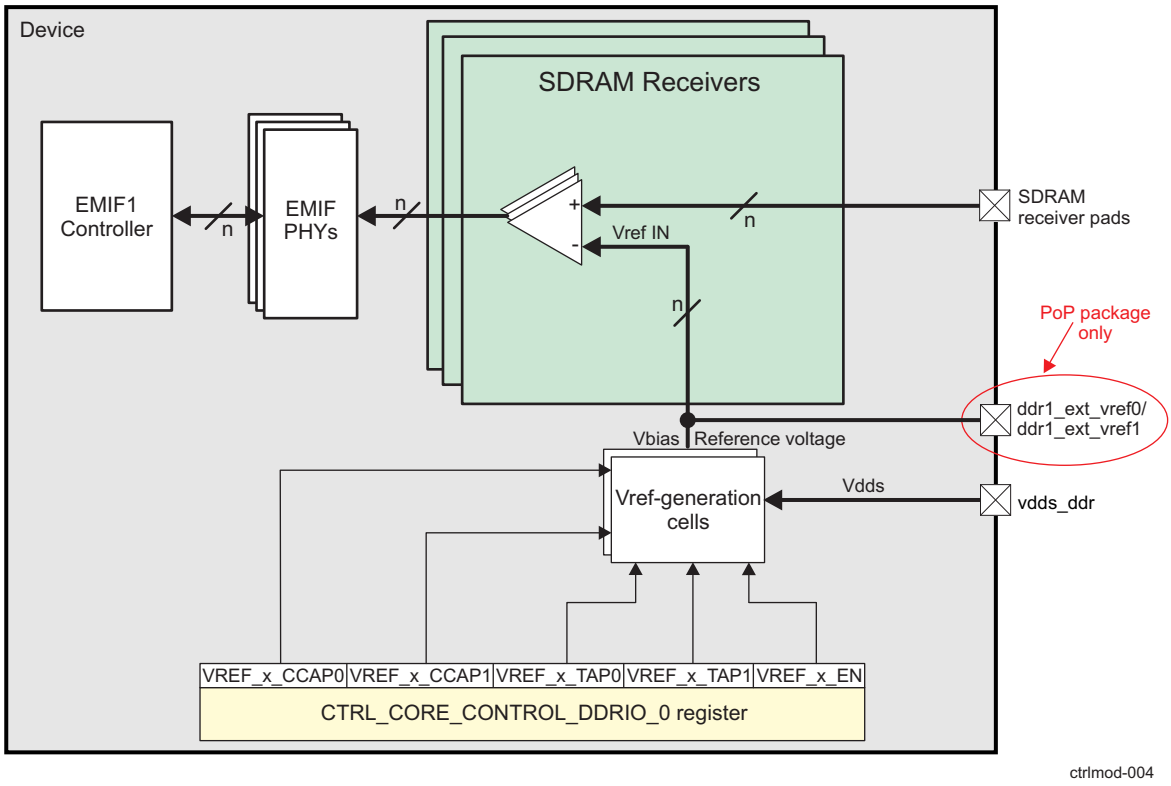
NOTE: LPDDR2 is not supported on the DRA78x family of devices.

The device LPDDR2/DDR2/DDR3 input buffers work in so-called Vref-based receiver mode. In this mode, the buffers act like differential comparators with positive terminal connected to a device pad which receives signals from LPDDR2/DDR2/DDR3 memory and negative terminal connected to a source of reference voltage.

To work properly, a reference voltage must be provided to the device LPDDR2/DDR2/DDR3 input buffers. There are two Vref-generation cells in the device intended to supply this internal reference voltage.

Figure 13-10 shows the Vref-generation cells in the device.

Figure 13-10. Vref-Generation Cells and Their Controls



The control bits for the Vref-generation cells reside in the CTRL_CORE_CONTROL_DDRIO_0 register. There are VREF_x_TAP[1:0] control bits which set the output drive capability of the Vref cells. Table 13-20 lists the possible options for selection of load current sourced from the output of each Vref-generation cell.

Table 13-20. Vref Cell Load Current Selection

VREF_x_TAP1	VREF_x_TAP0	Description
0	0	2-µA load current
0	1	4-µA load current
1	0	8-µA load current
1	1	32-µA load current

According to the noise environment, the user can choose to filter the supplied reference voltage. Two coupling capacitors internal to each Vref-generation cell are available and configurable through the VREF_x_CCAP[1:0] control bits in the CTRL_CORE_CONTROL_DDRIO_0 register as specified in Table 13-21.

Table 13-21. Vref Cell Coupling Capacitor Selection

VREF_x_CCAP1	VREF_x_CCAP0	Capacitor
0	0	No capacitor connected.
0	1	One capacitor connected between Vbias and ground.(1)
1	0	One capacitor connected between Vbias and Vdds.(2)
1	1	One capacitor connected between Vbias and ground and one capacitor connected between Vbias and Vdds.

(1) Vbias is the output of the Vref-generation cell which provides the reference voltage.
(2) Vdds is the power supply voltage of the Vref-generation cell.

The Vref-gereration cells can be enabled by setting to 0x1 the VREF_x_EN bits in the CTRL_CORE_CONTROL_DDRIO_0 register. These cells can be disabled (for leakage improvement and when not in use) by clearing the same VREF_x_EN bits.

Table 13-22 shows the Vref-generation cells control bits and the LPDDR2/DDR2/DDR3 pads used as receivers to which the corresponding Vref cell supplies reference voltage.

Table 13-22. Controls for the Vref-Generation Cells Versus LPDDR2/DDR2/DDR3 Receiver Pads

Vref-generation Cell Control Bits	LPDDR2/DDR2/DDR3 Vref Cell Associated Pads Used as Receivers
CTRL_CORE_CONTROL_DDRIO_0[19] DDRCH1_VREF_DQ0_INT_CCAP0	ddr1_d[7:0], ddr1_d[15:8]

CTRL_CORE_CONTROL_DDRIO_0[13] DDRCH1_VREF_DQ1_INT_CCAP1	
CTRL_CORE_CONTROL_DDRIO_0[12] DDRCH1_VREF_DQ1_INT_TAP0	
CTRL_CORE_CONTROL_DDRIO_0[11] DDRCH1_VREF_DQ1_INT_TAP1	
CTRL_CORE_CONTROL_DDRIO_0[10] DDRCH1_VREF_DQ1_INT_EN	

13.4.6.12 AVS Class 0 Associated Registers

AVS Class 0 attempts to normalize the power consumption across all devices by lowering the operating voltage of certain voltage rails. This procedure of lowering the voltage should be performed in the boot loader after ROM code. The new voltage to be set for each AVS Class 0 supported voltage rail should be read from the eFuse using dedicated registers. Then the power supply output voltage is adjusted to this new voltage value.

The following voltage rails support AVS Class 0:

- vdd_dspeve
- vdd

NOTE: For descriptions of the voltage rails previously listed see the *"Power Supply Signal Descriptions"* table in the device Data Manual.

Table 13-23 shows all registers associated with AVS Class 0. The corresponding AVS Class 0 voltage value can be read from the 12 LSbits of each of the listed registers. They contain the voltage value in hex format. To find the actual value in mV a conversion from hex to decimal value is needed. For example, if the value read from CTRL_CORE_STD_FUSE_OPP_VMIN_CORE_2[11:0] STD_FUSE_OPP_VMIN_CORE_2 is 0x041F, then this corresponds to 1055 mV.

Table 13-23. Registers Associated With AVS Class 0 Voltage

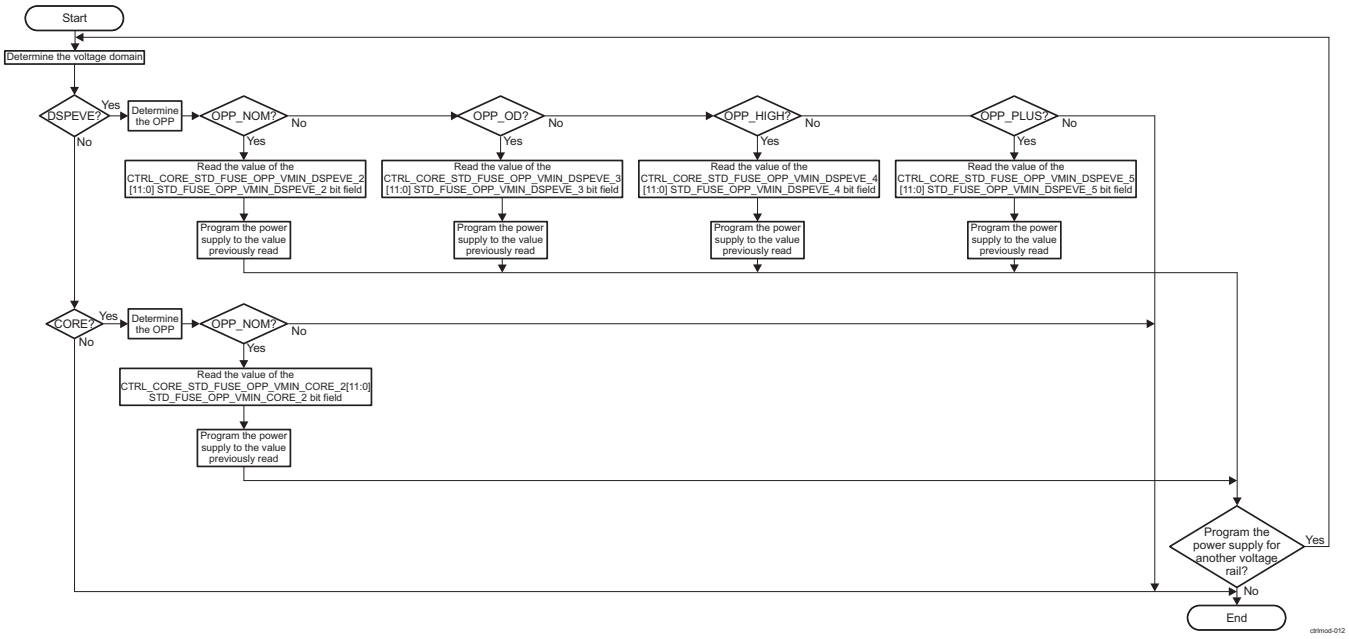
Physical Address	Bit Field Containing the AVS Class 0 Voltage Value	Voltage Rail	Supported OPP
0x4A00 25E0	CTRL_CORE_STD_FUSE_OPP_VMIN_DSPEVE_2[11:0] STD_FUSE_OPP_VMIN_DSPEVE_2	vdd_dspeve	OPP_NOM
0x4A00 25E4	CTRL_CORE_STD_FUSE_OPP_VMIN_DSPEVE_3[11:0] STD_FUSE_OPP_VMIN_DSPEVE_3		OPP_OD
0x4A00 25E8	CTRL_CORE_STD_FUSE_OPP_VMIN_DSPEVE_4[11:0] STD_FUSE_OPP_VMIN_DSPEVE_4		OPP_HIGH
0x4A00 25D8	CTRL_CORE_STD_FUSE_OPP_VMIN_DSPEVE_5[11:0] STD_FUSE_OPP_VMIN_DSPEVE_5		OPP_PLUS
0x4A00 25F4	CTRL_CORE_STD_FUSE_OPP_VMIN_CORE_2[11:0] STD_FUSE_OPP_VMIN_CORE_2	vdd	OPP_NOM

NOTE: Some of the OPPs listed in Table 13-23 may not be supported for some devices. In these cases the voltage values in the corresponding AVS Class 0 registers can be disregarded. For more information about the supported OPPs, see the "*Operating Performance Points*" section of the device Data Manual.

In some cases, the AVS Class 0 voltage that is read from the CTRL_CORE_STD_FUSE_OPP_VMIN_xxx_y registers has a value between two incremental voltage steps of the power supply. If such a case occurs, the higher voltage value should be selected.

Figure 13-11 shows a general example of how AVS Class 0 should be performed.

Figure 13-11. AVS Class 0 Procedure



13.4.6.13 Registers For Other Miscellaneous Functions

13.4.6.13.1 System Boot Status Settings

The CTRL_CORE_BOOTSTRAP register is a status register which indicates the state of the sysboot0 through sysboot15 input signals. Their purpose is to select the boot interface, the device source clock configuration and also other boot related settings.

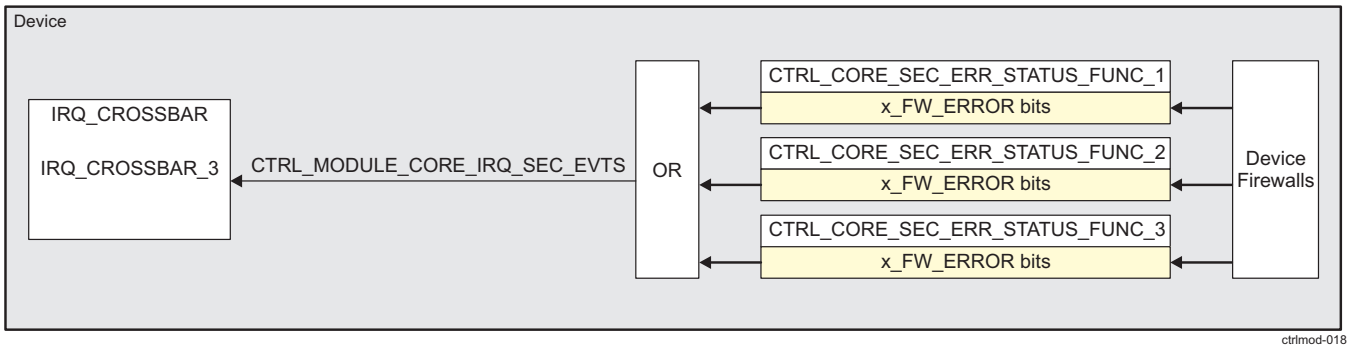
NOTE: For proper device operation, sysboot15 must be tied to vdd and sysboot14 must be tied to vss.

13.4.6.13.2 Firewall Error Status Registers

There are several status registers which show when there is a firewall error. The CTRL_CORE_SEC_ERR_STATUS_FUNC_1, CTRL_CORE_SEC_ERR_STATUS_FUNC_2 and CTRL_CORE_SEC_ERR_STATUS_FUNC_3 registers are used in device normal operation mode. The x_FW_ERROR bits from these three registers are combined into a single interrupt signal sent to the IRQ_CROSSBAR module as shown in Figure 13-12. The CTRL_CORE_SEC_ERR_STATUS_DEBUG_1, CTRL_CORE_SEC_ERR_STATUS_DEBUG_2 and CTRL_CORE_SEC_ERR_STATUS_DEBUG_3 registers are used when the device is in debug mode. These registers have same bits as in the CTRL_CORE_SEC_ERR_STATUS_FUNC_1, CTRL_CORE_SEC_ERR_STATUS_FUNC_2 and CTRL_CORE_SEC_ERR_STATUS_FUNC_3 registers.

All bits in these registers are cleared when the ERROR_LOG_k and L4_IA_ERROR_LOG_L registers are cleared.

Figure 13-12. Combined Firewall Error Interrupt



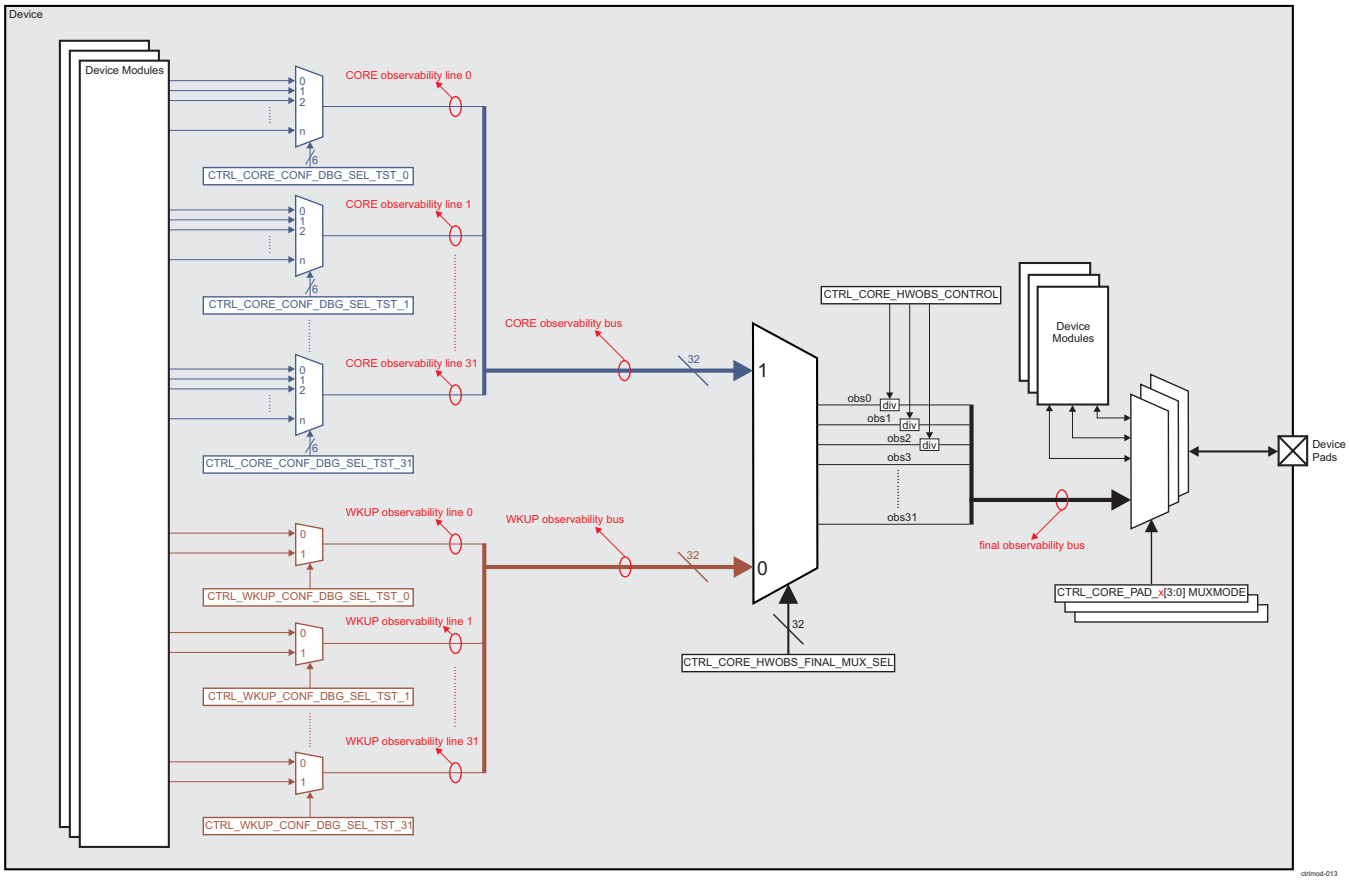
13.4.6.13.3 Settings Related To Different Peripheral Modules

The CTRL_CORE_CONTROL_IO_1 and CTRL_CORE_CONTROL_IO_2 registers have controls for specific settings of several device peripheral modules. For more information, see the bit field descriptions.

13.4.6.14 Hardware Observability Related Registers

There is a set of registers which are associated with the device observability logic. Using these registers a desired module signal can be mapped to dedicated-for-observation pad and then this signal can be observed. Figure 13-13 shows the device observability logic.

Figure 13-13. Hardware Observability Logic



As can be seen on Figure 13-13 there are two 32-bit wide observability buses. One associated with signals in CORE and one with signals in WKUP power domain. The multiplexing of the CORE observable signals is controlled by CTRL_CORE_CONF_DEBUG_SEL_TST_0 through CTRL_CORE_CONF_DEBUG_SEL_TST_31 registers. The multiplexing of the WKUP observable signals is controlled by CTRL_WKUP_CONF_DEBUG_SEL_TST_0 through CTRL_WKUP_CONF_DEBUG_SEL_TST_31 registers. Each of these registers is associated with one observability line. For example, the CTRL_CORE_CONF_DEBUG_SEL_TST_0 register selects one of N observability signals to be mapped to CORE observability line 0.

The CTRL_CORE_HWOBS_FINAL_MUX_SEL register is used to control the final multiplexer which selects CORE or WKUP observable signals to be mapped to the final observability bus. This bus is composed of obs0 through obs31 lines. Each bit in the CTRL_CORE_HWOBS_FINAL_MUX_SEL register is associated with one of these lines. A value of 0x0 selects a WKUP observable signal and 0x1 select CORE observable signal.

Optionally, the frequency of obs0, obs1 and obs2 lines can be divided through the bit fields HWOBS_CLKDIV_SEL, HWOBS_CLKDIV_SEL_1 and HWOBS_CLKDIV_SEL_2 from register CTRL_CORE_HWOBS_CONTROL. This register provides also an option to force all 32 signals (obs0 through obs31) of the observability bus to 0 or to 1 setting to 0x1 bit HWOBS_ALL_ZERO_MODE or bit HWOBS_ALL_ONE_MODE, respectively.

13.4.7 Functional Description Of The Various Register Types In CTRL_MODULE_WKUP Submodule

The following sections describe the purpose of the registers which reside in the CTRL_MODULE_WKUP submodule.

13.4.7.1 Registers For Basic EMIF configuration

The CTRL_WKUP_SECURE_EMIF1_SDRAM_CONFIG register has bits which determine the basic settings of the EMIF controller. These are, for example, settings like CAS write latency, SDRAM drive strength, SDRAM termination resistor values, SDRAM type and others. The CTRL_WKUP_SECURE_EMIF1_SDRAM_CONFIG bit field values are exported upon POR to the EMIF.EMIF_SDRAM_CONFIG register.

The CTRL_WKUP_EMIF1_SDRAM_CONFIG_EXT register is associated with DDR PHY controls, ODT values for device DDR I/Os, some leveling related parameters and others.

Address Offset	0x0000 1000		
Physical Address	0x4A00 3000	**Instance**	CTRL_MODULE_CORE
Description	This register controls the final multiplexor which selects whether CORE or WKUP observable signals are mapped to the final observability bus, that is obs[31:0] bus.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SELECT																															

Bits	Field Name	Description	Type	Reset
31:0	SELECT	Each bit is associated with one observability signal line. Bit 31 selects between CORE and WKUP signal for obs31 line and bit 0 does the same for obs0 line. The same logic applies for all other bits. 0x0: WKUP signal selected. 0x1: CORE signal selected.	RW	0x0

Table 13-938. CTRL_CORE_SMA_SW_17

Address Offset	0x0000 1C9C		
Physical Address	0x4A00 3C9C	**Instance**	CTRL_MODULE_CORE
Description	This register holds some controls and status bits for H14 HS divider of DPLL_GMAC_DSP which is the source of MCAN functional clock (MCAN_CLK).		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SMA_SW_17																				MCAN_CLK_HSDIV_CHANGE_ACK	MCAN_CLK_HSDIV_EN_ACK	MCAN_CLK_TENABLEDIV_SEL	RESERVED	MCAN_CLK_HSDIV_EN	MCAN_CLK_HSDIV_LATCH_EN	MCAN_CLK_HSDIV							

Bits	Field Name	Description	Type	Reset
31:12	SMA_SW_17	OCP Spare Bits	RW	0x0
11	MCAN_CLK_HSDIV_CHANGE_ACK	Acknowledge flag which indicates that the on-the-fly change of H14 divider of DPLL_GMAC_DSP is done. This bit changes its state (0 to 1 or 1 to 0) on each on-the-fly change of H14.	R	0x1
10	MCAN_CLK_HSDIV_EN_ACK	Indicates whether CLKOUTX2_H14 of DPLL_GMAC_DSP is enabled or not. 0x0: CLKOUTX2_H14 is disabled 0x1: CLKOUTX2_H14 is enabled	R	0x0
9	MCAN_CLK_TENABLEDIV_SEL	TENABLEDIV control select for H14 of DPLL_GMAC_DSP 0x0: Control from PRCM 0x1: Control from Control Module (bit CTRL_CORE_SMA_SW_17[6] MCAN_CLK_HSDIV_LATCH_EN)	RW	0x0
8	RESERVED	Reserved	RW	0x0
7	MCAN_CLK_HSDIV_EN	Output clock (CLKOUTX2_H14) enable for H14 of DPLL_GMAC_DSP 0x0: Output clock disabled 0x1: Output clock enabled	RW	0x0
6	MCAN_CLK_HSDIV_LATCH_EN	To be toggled (LO->HI->LO) to latch MCAN_CLK_HSDIV value in H14 of DPLL_GMAC_DSP. This bit takes effect only when bit CTRL_CORE_SMA_SW_17[9] MCAN_CLK_TENABLEDIV_SEL is set to 0x1.	RW	0x0
5:0	MCAN_CLK_HSDIV	This field programs the H14 divider of DPLL_GMAC_DSP. The actual division is equal to this register value+1. 0x0: H14 = /1 0x1: H14 = /2 ... 0x3F: H14 = /64	RW	0x18

Table 13-979. CTRL_WKUP_EMIF1_SDRAM_CONFIG_EXT

Address Offset	0x0000 0144		
Physical Address	0x4AE0 C144	**Instance**	CTRL_MODULE_WKUP
Description	SLICE register for emif1 and emif2		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED														EMIF1_NARROW_ONLY	EMIF1_EN_ECC	EMIF1_REG_PHY_NUM_OF_SAMPLES		EMIF1_REG_PHY_SEL_LOGIC	EMIF1_REG_PHY_ALL_DQ_MPR_RD_RESP	EMIF1_REG_PHY_OUTPUT_STATUS_SELECT			RESERVED	EMIF1_SDRAM_DISABLE_RESET		EMIF1_PHY_RD_LOCAL_ODT		RESERVED		EMIF1_DFI_CLOCK_PHASE_CTRL	EMIF1_EN_SLICE_2	EMIF1_EN_SLICE_1	EMIF1_EN_SLICE_0

Bits	Field Name	Description	Type	Reset
31:18	RESERVED		R	0x0
17	EMIF1_NARROW_ONLY	EMIF1 operates in narrow mode, to allow for data macros to be powered down to save power 0x0 = narrow mode disabled 0x1 = narrow mode enabled	RW	0x0
16	EMIF1_EN_ECC	EMIF1 ECC enable 0x0 = ECC is disabled 0x1 = ECC is enabled	RW	0x0
15:14	EMIF1_REG_PHY_NUM_OF_SAMPLES	Controls the number of DQ samples required for read leveling. The recommended setting for full leveling is 0x3 (128 samples) and for incremental leveling is 0x0 (4 samples). 0x0 = 4 samples 0x1 = 8 samples. 0x2 = 16 samples 0x3 = 128 samples	RW	0x0
13	EMIF1_REG_PHY_SEL_LOGIC	Selects an algorithm for read leveling. The use of algorithm 1 (set by default) is recommended. 0x0 = Algorithm 1 is used 0x1 = Algorithm 2 is used	RW	0x0
12	EMIF1_REG_PHY_ALL_DQ_MPR_RD_RESP	Analysis method of DQ bits during read leveling. 0x0: if the DRAM provides a read response on only one DQ bit (this can be any bit, since in this mode all 8 DQ bits are OR-ed together). This is the default setting and works with all memory types (memories send responses on all DQ bits or on a single DQ bit). 0x1: if the DRAM provides a read response on all DQ bits.	RW	0x0
11:9	EMIF1_REG_PHY_OUTPUT_STATUS_SELECT	Selects the status to be observed on the outputs of the DDR PHYs through CTRL_WKUP_EMIF1_SDRAM_CONFIG_EXT_1 register. 0x0 = selects phy_reg_rdlvl_start_ratio[7:0] 0x1 = selects phy_reg_rdlvl_start_ratio[15:8] 0x2 = selects phy_reg_rdlvl_end_ratio[7:0] 0x3 = selects phy_reg_rdlvl_end_ratio[15:8]	RW	0x0

Bits	Field Name	Description	Type	Reset
8	RESERVED		R	0x1
7	EMIF1_SDRAM_DISABLE_RESET	DDR3 SDRAM reset disable. 0x0 = DDR3 SDRAM reset signal is enabled. It can be asserted by EMIF 0x1 = DDR3 SDRAM reset signal is disabled. It is forbidden to EMIF to assert it.	RW	0x0
6:5	EMIF1_PHY_RD_LOCAL_ODT	Control of ODT (on – die termination) settings for the device DDR I/Os. ODT is enabled only during read operations when termination is required. 0x0 = ODT disabled 0x1= 60 Ohms 0x2 = 80 Ohms 0x3 =120 Ohms	RW	0x0
4	RESERVED		RW	0x0
3	EMIF1_DFI_CLOCK_PHASE_CTRL	EMIF_FICLK clock phase control (shifting by 180°). For normal operation this bit must always be set to 0x0 (disabled).	RW	0x0
2	EMIF1_EN_SLICE_2	Enable command PHY 2. When using DDR3 this bit can be set to 0x0 or 0x1. For lower power consumption 0x0 is used.	RW	0x1
1	EMIF1_EN_SLICE_1	Enable command PHY 1. 0x1 is the mandatory setting if DDR3 is used. EMIF1_EN_SLICE_0 and EMIF1_EN_SLICE_1 have to be programmed with the same value.	RW	0x1
0	EMIF1_EN_SLICE_0	Enable command PHY 0. 0x1 is the mandatory setting if DDR3 is used. EMIF1_EN_SLICE_0 and EMIF1_EN_SLICE_1 have to be programmed with the same value.	RW	0x1

Mailbox

This chapter describes the mailbox module in the device.

Topic **Page**

14.1 Mailbox Overview

Communication between the on-chip processors of the device uses a queued mailbox-interrupt mechanism.

The queued mailbox-interrupt mechanism allows the software to establish a communication channel between two processors through a set of registers and associated interrupt signals by sending and receiving messages (mailboxes).

The device implements the following mailbox types:

- System mailbox:
  - Number of instances: 2
  - Used for communication between: DSP1, DSP2, and IPU subsystems
  - Reference names: MAILBOX1, MAILBOX2
- EVE mailbox:
  - Number of instances: 2
  - Used for communication between: EVE local user (ARP32) and three external users (DSP1, DSP2, and IPU) – EVE_MBOX0 and EVE_MBOX1 are dedicated for this communication
  - Reference names: EVE_MBOX0, EVE_MBOX1

Each mailbox module supports the following features:

- Parameters configurable at design time (see Table 14-1):
  - Number of users
  - Number of mailbox message queues
  - Number of messages (FIFO depth) for each message queue
- 32-bit message width
- Message reception and queue-not-full notification using interrupts
- Support of 16-/32-bit addressing scheme
- Power management support

Table 14-1 shows the configuartion of the mailbox modules in the device.

Table 14-1. Mailbox Configuration in the Device

Module Parameters	Mailbox Type		
	System Mailbox		EVE Mailbox (0, 1)
	MAILBOX1	MAILBOX2	
Number of users	3	4	4
Number of mailbox message queues	8	12	16
Number of messages (FIFO depth) for each message queue	4		4

14.2 Mailbox Integration

This section describes the mailbox integration in the device, including information about clocks, resets, and hardware requests.

14.2.1 System MAILBOX Integration

Figure 14-1 and Figure 14-2 show the MAILBOX1 and MAILBOX2 integration, respectively.

Figure 14-1. MAILBOX1 Integration

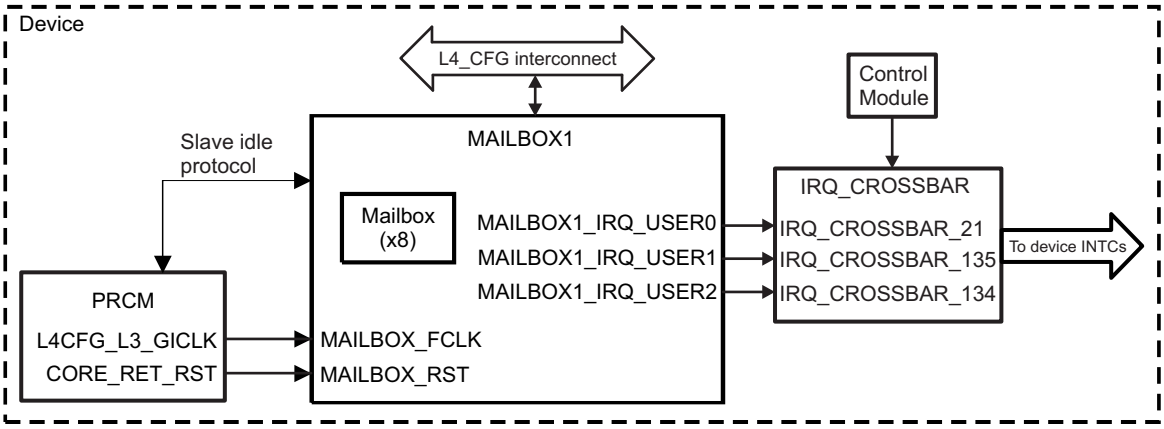

Figure 14-2. MAILBOX2 Integration

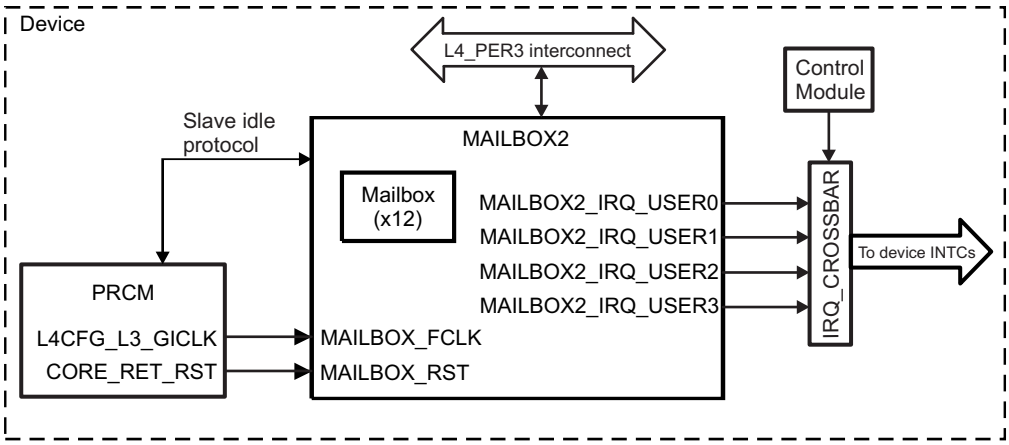

NOTE: For more information about the Slave idle protocol, see Section 3.1.1.1.2, *Module-Level Clock Management* in Chapter 3, *Power, Reset, and Clock Management*.

Table 14-2 through Table 14-4 summarize the MAILBOX1/2 integration in the device.

Table 14-2. MAILBOX Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
MAILBOX1	PD_COREAON	N/A	L4_CFG
MAILBOX2	PD_COREAON	N/A	L4_PER3

Table 14-3. MAILBOX Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
MAILBOX	MAILBOX_FCLK	L4CFG_L3_GICLK	PRCM	MAILBOX interface clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**

Table 14-3. MAILBOX Clocks and Resets (continued)

MAILBOX	MAILBOX_RST	CORE_RET_RST	PRCM	MAILBOX hardware reset. This reset is asynchronously applied to the MAILBOX registers.

Table 14-4. MAILBOX Hardware Requests

Interrupt Requests							
Module Instance	**Interrupt Name (Source)**	**IRQ_CROSSBAR Input (Destination)**	**Default Mapping**	**Description**			
MAILBOX1	MAILBOX1_IRQ_USER0	IRQ_CROSSBAR_21	DSP1_IRQ_52; DSP2_IRQ_52;	MAILBOX1 request.	user	0	interrupt
	MAILBOX1_IRQ_USER1	IRQ_CROSSBAR_135	–	MAILBOX1 request.	user	1	interrupt
	MAILBOX1_IRQ_USER2	IRQ_CROSSBAR_134	IPU_IRQ_50;	MAILBOX1 request.	user	2	interrupt
MAILBOX2	MAILBOX2_IRQ_USER0	IRQ_CROSSBAR_237	–	MAILBOX2 request.	user	0	interrupt
	MAILBOX2_IRQ_USER1	IRQ_CROSSBAR_238	–	MAILBOX2 request.	user	1	interrupt
	MAILBOX2_IRQ_USER2	IRQ_CROSSBAR_239	–	MAILBOX2 request.	user	2	interrupt
	MAILBOX2_IRQ_USER3	IRQ_CROSSBAR_240	–	MAILBOX2 request.	user	3	interrupt
No DMA Requests							

NOTE: The "**Default Mapping**" column in Table 14-4 and Table 14-7 shows the default mapping of module interrupts. These interrupts can also be mapped to other input lines of each device interrupt controller through the IRQ_CROSSBAR module.

For more information about the IRQ_CROSSBAR module, see Chapter 13, *Control Module*.

For more information about the device interrupt controllers, see Chapter 12, *Interrupt Controllers*.

NOTE: For information about interrupt source description, see Section 14.3.4, *Mailbox Interrupt Requests*.

14.2.2 EVE Mailbox Integration

Figure 14-3 shows the EVE_MBOX integration.

Figure 14-3. EVE_MBOX Integration

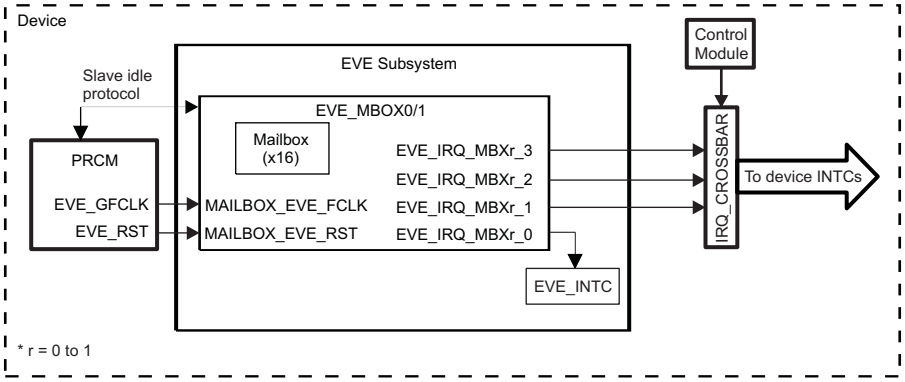

Table 14-5 through Table 14-7 summarize the EVE_MBOX integration in the device.

Table 14-5. EVE_MBOX Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
EVE_MBOX	PD_EVE	N/A	EVE local interconnect

Table 14-6. EVE_MBOX Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
EVE_MBOX	MAILBOX_EVE_FCLK	EVE_GFCLK	PRCM	EVE_MBOX interface clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
EVE_MBOX	MAILBOX_EVE_RST	EVE_RST	PRCM	EVE_MBOX hardware reset. This reset is asynchronously applied to the EVE_MBOX registers.

Table 14-7. EVE_MBOX Hardware Requests

Interrupt Requests				
Module Instance	**Interrupt Name (Source)**	**IRQ_CROSSBAR Input (Destination)**	**Default Mapping**	**Description**
EVE_MBOX0	EVE1_IRQ_MBX0_USER0	TBD	–	EVE_MBOX0 user 0 interrupt request.
	EVE1_IRQ_MBX0_USER1	IRQ_CROSSBAR_284	–	EVE_MBOX0 user 1 interrupt request.
	EVE1_IRQ_MBX0_USER2	IRQ_CROSSBAR_285	–	EVE_MBOX0 user 2 interrupt request.
	EVE1_IRQ_MBX0_USER3	IRQ_CROSSBAR_286	–	EVE_MBOX0 user 3 interrupt request.
EVE_MBOX1	EVE1_IRQ_MBX1_USER0	TBD	–	EVE_MBOX1 user 0 interrupt request.
	EVE1_IRQ_MBX1_USER1	IRQ_CROSSBAR_287	–	EVE_MBOX1 user 1 interrupt request.
	EVE1_IRQ_MBX1_USER2	IRQ_CROSSBAR_288	–	EVE_MBOX1 user 2 interrupt request.
	EVE1_IRQ_MBX1_USER3	IRQ_CROSSBAR_289	–	EVE_MBOX1 user 3 interrupt request.
No DMA Requests				

14.3 Mailbox Functional Description

NOTE: The functionality of all mailbox instances in the device is the same and is described in this section.

NOTE: In this chapter, *u* is the user number and *m* is the mailbox number as follows:

- For MAILBOX1: *u* = 0 to 2 and *m* = 0 to 7;
- For MAILBOX2: *u* = 0 to 3 and *m* = 0 to 11;
- For EVE_MBOX: *u* = 0 to 3 and *m* = 0 to 15;

The mailbox module provides a means of communication through message queues among the users. The individual mailbox modules, or FIFOs, can associate (or de-associate) with any of the processors using the MAILBOX_IRQENABLE_SET_u (or MAILBOX_IRQENABLE_CLR_u) register.

Table 14-8 shows the potential users of the mailbox modules in the device.

Table 14-8. Mailbox Users in the Device

Mailbox Type		Users			
		User 0	User 1	User 2	User 3
System Mailbox	MAILBOX1	Any of: DSP1, DSP2, and IPU[1]			–
	MAILBOX2	Any of: DSP1, DSP2, and IPU[1]			
EVE Mailbox	EVE_MBOX0, EVE_MBOX1	TBD	Any of: DSP1, DSP2, and IPU[1]		

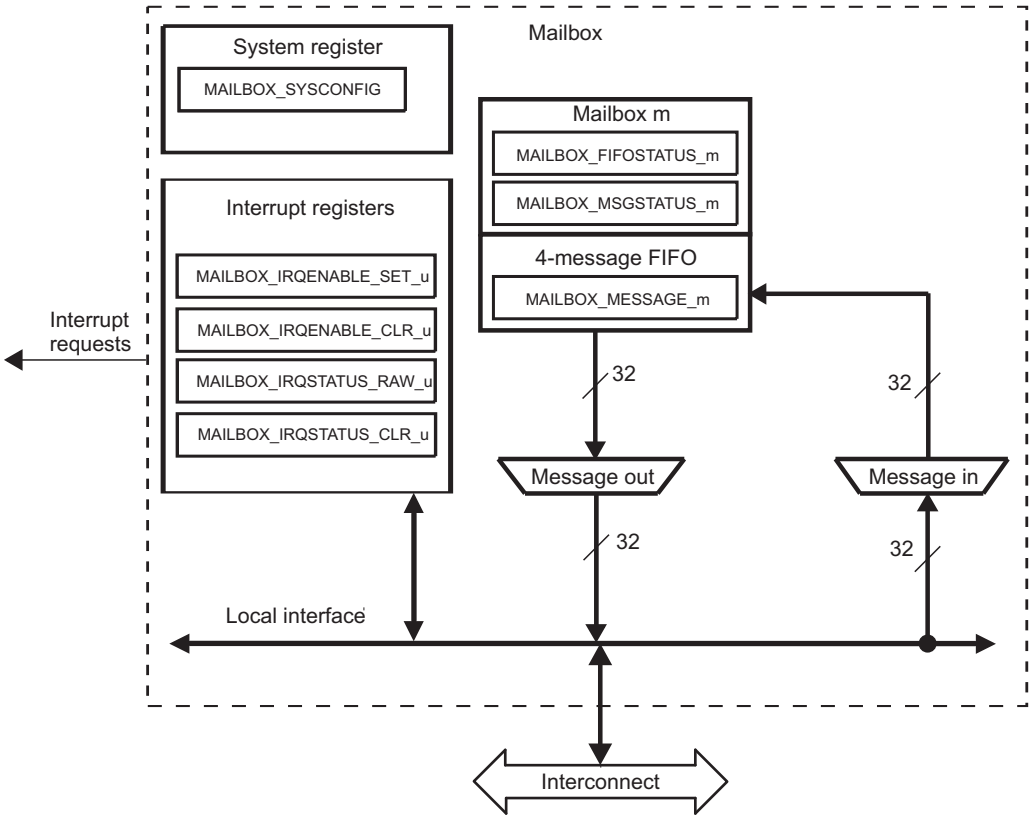
(1) It is software responsibility to select a user by mapping (via IRQ_CROSSBAR) the corresponding mailbox interrupt to the interrupt controller of the appropriate processor subsystem.

Each user has a dedicated interrupt signal from the corresponding mailbox module instance and dedicated interrupt enabling and status registers.
Each MAILBOX_IRQSTATUS_RAW_u/MAILBOX_IRQSTATUS_CLR_u interrupt status register corresponds to a particular user.

14.3.1 Mailbox Block Diagram

Figure 14-4 shows the mailbox block diagram.

Figure 14-4. Mailbox Block Diagram



14.3.2 Mailbox Software Reset

The mailbox module supports a software reset through the MAILBOX_SYSCONFIG[0] SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Reading the MAILBOX_SYSCONFIG[0] SOFTRESET bit gives the status of the software reset:

- Read 1: the software reset is on-going.
- Read 0: the software reset is complete.

The software must ensure that the software reset completes before doing mailbox operations.

14.3.3 Mailbox Power Management

Table 14-9 describes power-management features available for the mailbox module.

Table 14-9. Local Power Management Features

Feature	Registers	Description
Clock autogating	N/A	Feature not available
Slave idle modes	MAILBOX_SYSCONFIG[3:2] SIDLEMODE bit field	Force-idle, no-idle and smart-idle modes are available
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	N/A	Feature not available

The mailbox module can be configured using the MAILBOX_SYSCONFIG[3:2] SIDLEMODE bit field to one of the following acknowledgment modes:

- Force-idle mode (SIDLEMODE = 0x0): The mailbox module immediately enters the idle state on receiving a low-power-mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state.
- No-idle mode (SIDLEMODE = 0x1): The mailbox module never enters the idle state.
- Smart-idle mode (SIDLEMODE = 0x2): After receiving a low-power-mode request from the PRCM module, the mailbox module enters the idle state only after all asserted output interrupts are acknowledged.

14.3.4 Mailbox Interrupt Requests

An interrupt request allows the user of the mailbox to be notified when a message is received or when the message queue is not full. There is one interrupt per user.

Table 14-10 lists the event flags, and their mask, that can cause module interrupts.

Table 14-10. Interrupt Events

Non-Maskable Event Flag[1]	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
MAILBOX_IRQSTATUS_RAW_u[0+m*2] NEWMSGSTATUSUUMBm	MAILBOX_IRQSTATUS_CLR_u[0+m*2] NEWMSGSTATUSUUMBm	MAILBOX_IRQENABLE_CLR_u[0+m*2] NEWMSGSTATUSUUMBm	MAILBOX_IRQENABLE_SET_u[0+m*2] NEWMSGSTATUSUUMBm	Mailbox *m* receives a new message.
MAILBOX_IRQSTATUS_RAW_u[1+m*2] NOTFULLSTATUSUUMBm	MAILBOX_IRQSTATUS_CLR_u[1+m*2] NOTFULLSTATUSUUMBm	MAILBOX_IRQENABLE_CLR_u[1+m*2] NOTFULLSTATUSUUMBm	MAILBOX_IRQENABLE_SET_u[1+m*2] NOTFULLSTATUSUUMBm	Mailbox *m* message queue is not full.

(1) MAILBOX_IRQSTATUS_RAW_u register is mostly used for debug purposes.

CAUTION

Once an event generating the interrupt request has been processed by the software, it must be cleared by writing a logical 1 in the corresponding bit of the MAILBOX_IRQSTATUS_CLR_u register.

Writing a logical 1 in a bit of the MAILBOX_IRQSTATUS_CLR_u register will also clear to 0 the corresponding bit in the appropriate MAILBOX_IRQSTATUS_RAW_u register.

An event can generate an interrupt request when a logical 1 is written to the corresponding unmask bit in the MAILBOX_IRQENABLE_SET_u register. Events are reported in the appropriate MAILBOX_IRQSTATUS_CLR_u and MAILBOX_IRQSTATUS_RAW_u registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the MAILBOX_IRQENABLE_CLR_u register. Events are only reported in the appropriate MAILBOX_IRQSTATUS_RAW_u register.

In case of the MAILBOX_IRQSTATUS_RAW_u register, the event is reported in the corresponding bit even if the interrupt request generation is disabled for this event.

14.3.5 Mailbox Assignment

14.3.5.1 Description

To assign a receiver to a mailbox, set the new message interrupt enable bit corresponding to the desired mailbox in the MAILBOX_IRQENABLE_SET_u register. The receiver reads the MAILBOX_MESSAGE_m register to retrieve a message from the mailbox.

An alternate method for the receiver that does not use the interrupts is to poll the MAILBOX_FIFOSTATUS_m and/or MAILBOX_MSGSTATUS_m registers to know when to send or retrieve a message to or from the mailbox. This method does not require assigning a receiver to a mailbox. Because this method does not include the explicit assignment of the mailbox, the software must avoid having multiple receivers use the same mailbox, which can result in incoherency.

To assign a sender to a mailbox, set the queue-not-full interrupt enable bit of the desired mailbox in the MAILBOX_IRQENABLE_SET_u register, where *u* is the number of the sending user. However, direct allocation of a mailbox to a sender is not recommended because it can cause the sending processor to be constantly interrupted.

It is recommended that register polling be used to:

- Check the status of either the MAILBOX_FIFOSTATUS_m or MAILBOX_MSGSTATUS_m registers
- Write the message to the corresponding MAILBOX_MESSAGE_m register, if space is available.

The sender might use the queue-not-full interrupt when the initial mailbox status check indicates the mailbox is full. In this case, the sender can enable the queue-not-full interrupt for its mailbox in the appropriate MAILBOX_IRQENABLE_SET_u register. This allows the sender to be notified by interrupt only when a FIFO queue has at least one available entry.

Reading the MAILBOX_IRQSTATUS_CLR_u register determines the status of the new message and the queue-not-full interrupts for a particular user. Writing 1 to the corresponding bit in the MAILBOX_IRQSTATUS_CLR_u register acknowledges, and subsequently clears, an interrupt.

CAUTION

Assigning multiple senders or multiple receivers to the same mailbox is not recommended.

14.3.6 Sending and Receiving Messages

14.3.6.1 Description

When a 32-bit message is written to the MAILBOX_MESSAGE_m register, the message is appended into the FIFO queue. This queue holds four messages. If the queue is full, the message is discarded.

Queue overflow can be avoided by first reading the MAILBOX_FIFOSTATUS_m register to check that the mailbox message queue is not full before writing a new message to it.

Reading the MAILBOX_MESSAGE_m register returns the message at the beginning of the FIFO queue and removes it from the queue. If the FIFO queue is empty when the MAILBOX_MESSAGE_m register is read, the value 0 is returned.

The new message interrupt is asserted when at least one message is in the mailbox message FIFO queue. To determine the number of messages in the mailbox message FIFO queue, read the MAILBOX_MSGSTATUS_m register.

14.3.7 16-Bit Register Access

14.3.7.1 Description

So that 16-bit processors can access the mailbox module, the module allows 16-bit register read and write access, with restrictions for the MAILBOX_MESSAGE_m registers. The 16-bit half-words are organized in little endian fashion; that is, the least-significant 16 bits are at the low address and the most-significant 16 bits are at the high address (low address + 0x02).

All mailbox module registers can be read or written to directly using individual 16-bit accesses with no restriction on interleaving, except the MAILBOX_MESSAGE_m registers, which must always be accessed by either single 32-bit accesses or two consecutive 16-bit accesses.

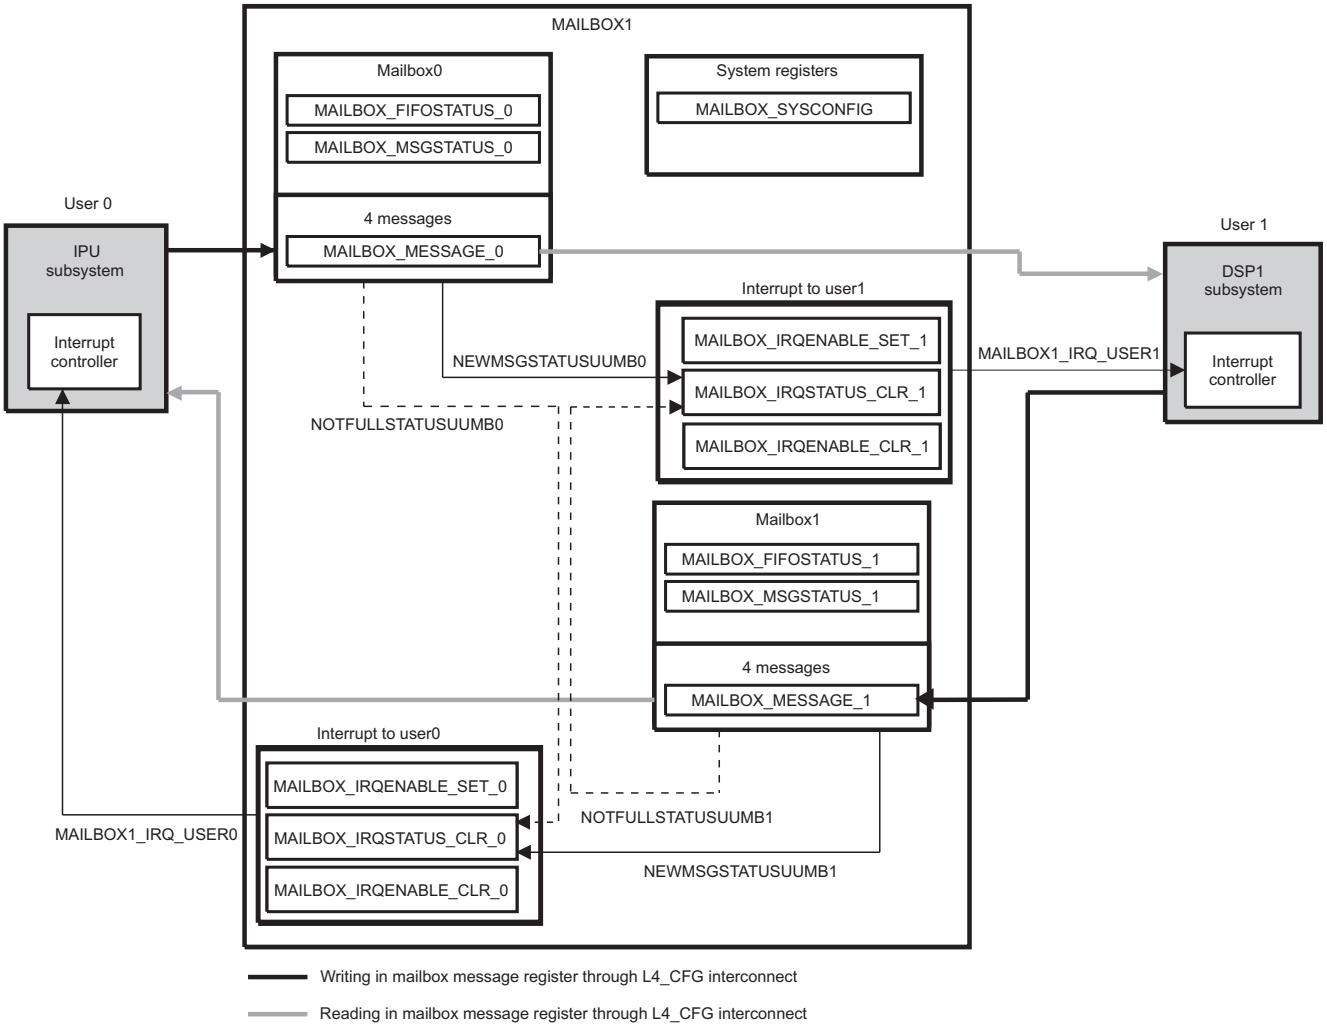
CAUTION

When using 16-bit accesses to the MAILBOX_MESSAGE_m registers, the order of access must be the least-significant half-word first (low address) and the most-significant half-word last (high address). This requirement is because of the update operation by the message FIFO of the MAILBOX_MSGSTATUS_m registers. The update of the FIFO queue contents and the associated status registers and possible interrupt generation occurs only when the most-significant 16 bits of a MAILBOX_MESSAGE_m are accessed.

14.3.8 Example of Communication

Figure 14-5 shows an example of communication between IPU and DSP1 subsystems.

Figure 14-5. Example of Communication



14.4 Mailbox Programming Guide

14.4.1 Mailbox Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the mailbox module.

14.4.1.1 Global Initialization

14.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the mailbox module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the mailbox.

See Section 14.2, *Mailbox Integration*, for further information.

Table 14-11. Global Initialization of Surrounding Modules for MAILBOX

Surrounding Modules	Comments
PRCM	MAILBOX functional/interface clock must be enabled.
Interrupt Controllers	IPU, or DSP1, or DSP2 interrupt controller must be configured to enable the interrupt request generation to the corresponding subsystem.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.

Table 14-12. Global Initialization of Surrounding Modules for EVE_MBOX

Surrounding Modules	Comments
PRCM	EVEx_MBOX functional/interface clock must be enabled.
Interrupt Controllers	IPU, or DSP1, or DSP2, or EVE interrupt controller must be configured to enable the interrupt request generation to the corresponding subsystem.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.

14.4.1.1.2 Mailbox Global Initialization

14.4.1.1.2.1 Main Sequence - Mailbox Global Initialization

This procedure initializes the mailbox module after a power-on or software reset.

Table 14-13. Mailbox Global Initialization

Step	Register/ Bit Field / Programming Model	Value
Perform a software reset	MAILBOX_SYSCONFIG[0] SOFTRESET	0x1
Wait until reset is complete	MAILBOX_SYSCONFIG[0] SOFTRESET	= 0x0
Set idle mode configuration	MAILBOX_SYSCONFIG[3:2] SIDLEMODE	0x-

14.4.1.2 Mailbox Operational Modes Configuration

14.4.1.2.1 Mailbox Processing modes

14.4.1.2.1.1 Main Sequence - Sending a Message (Polling Method)

Table 14-14. Sending a Message (Polling Method)

Step	Register/ Bit Field / Programming Model	Value
IF : Is FIFO full ?	MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB	= 0x1
Wait until at least one message slot is available	MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB	= 0x0
ELSE		
Write message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ENDIF		

14.4.1.2.1.2 Main Sequence - Sending a Message (Interrupt Method)

Table 14-15. Sending a Message (Interrupt Method)

Step	Register/ Bit Field / Programming Model	Value
IF : Is FIFO full ?	MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB	= 0x1
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[1+ m*2]	0x1
User (processor) can perform another task until interrupt occurs See Section 14.4.1.3.1 for interrupt handling in sending mode		
ELSE		
Write message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ENDIF		

14.4.1.2.1.3 Main Sequence - Receiving a Message (Polling Method)

Table 14-16. Receiving a Message (Polling Method)

Step	Register/ Bit Field / Programming Model	Value
IF : Number of messages is not equal to 0	MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB	!= 0x0
Read message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ENDIF		

14.4.1.2.1.4 Main Sequence - Receiving a Message (Interrupt Method)

Table 14-17. Receiving a Message (Interrupt Method)

Step	Register/ Bit Field / Programming Model	Value
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[0 + m*2]	0x1
User (processor) can perform another task until interrupt occurs See Section 14.4.1.3.2 for interrupt handling in receiving mode		

14.4.1.3 Mailbox Events Servicing

14.4.1.3.1 Events Servicing in Sending Mode

Table 14-18 describes the events servicing in sending mode.

Table 14-18. Events Servicing in Sending Mode

Step	Register/ Bit Field / Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	0x1
Write message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	0x1

14.4.1.3.2 Events Servicing in Receiving Mode

Table 14-19 describes the events servicing in receiving mode.

Table 14-19. Events Servicing in Receiving Mode

Step	Register/ Bit Field / Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	0x1
IF : Number of messages is not equal to 0 ?	MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB	!= 0x0
Read message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ELSE		
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	0x1
ENDIF

Memory Management Units

This chapter describes the memory management units (MMUs) in the device.

Topic **Page**

15.1 MMU Overview

A memory management unit (MMU) is a hardware component responsible for handling accesses to memory requested by a processing unit, DMA controller, or other bus requestor. MMU functions include:

- Translation of initiator internal (virtual) addresses to physical addresses (that is, virtual memory management)
- Preventing an initiator from making accesses to unmapped pages of the system memory

This device includes the following MMUs:

- One top-level (system) MMU, dedicated to EDMA Transfer Controller 0 (TC0), and EDMA Transfer Controller 1 (TC1):
- Two MMUs inside each of the DSP1, and DSP2 subsytems:
  - DSP1 subsystem: DSP1_MMU0, and DSP1_MMU1
  - DSP2 subsystem: DSP2_MMU0, and DSP2_MMU1
- Two MMUs inside the EVE subsystem: EVE_MMU0, and EVE_MMU1
- Two MMUs inside the IPU subsystem:
  - L1 unicache MMU – IPU_UNICACHE_MMU
  - L2 MMU – IPU_MMU

NOTE: This chapter provides a detailed description of the following MMUs:

- System MMU
- DSP MMUs
- EVE MMUs
- IPU L2 MMU

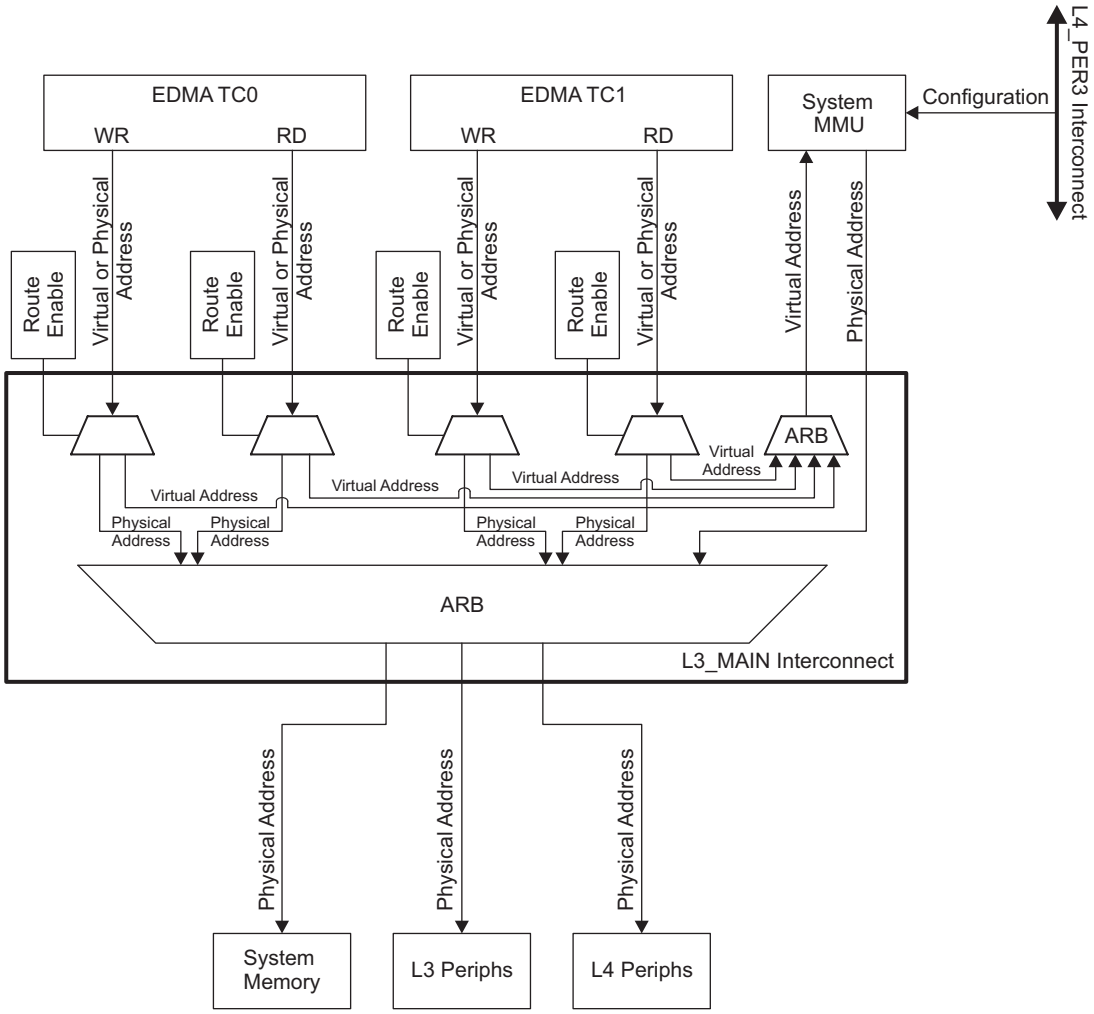
System MMUs, DSP MMUs and EVE MMUs are fully identical from functional perspective. IPU L2 MMU is different in that it does not support “bypass” functionality.

For more information about IPU unicache MMU, see Chapter 5, *Dual Cortex-M4 IPU Subsystem*.

Figure 15-1 shows an overview of system MMU. In summary, requests initiated by a given requestor (EDMA TC0 or TC1 [both read and write ports]) can optionally be routed through the system MMU. Each requestor’s use (or not) of the MMU is independently controllable via the Control Module CTRL_CORE_SMA_SW_7 register bitfields. It is recommended that this register is set during system initialization and remain static.

If the MMU loopback path is enabled for a given requestor, requests will be routed via the L3_MAIN interconnect to the MMU and will again go through the L3_MAIN interconnect to the requested physical address. If the MMU loopback path is disabled for a given requestor, those bus requests go directly through the L3_MAIN interconnect to the requested physical address, thus minimizing bus request latency.

Figure 15-1. System MMU1 Overview



15.2 MMU Integration

This section describes the system MMUs integration in the device, including information about clocks, resets, and hardware requests. For more information about DSP, EVE, and IPU MMUs integration, refer to their respective chapters.

Figure 15-2 shows system MMU integration.

Figure 15-2. System MMU1 Integration

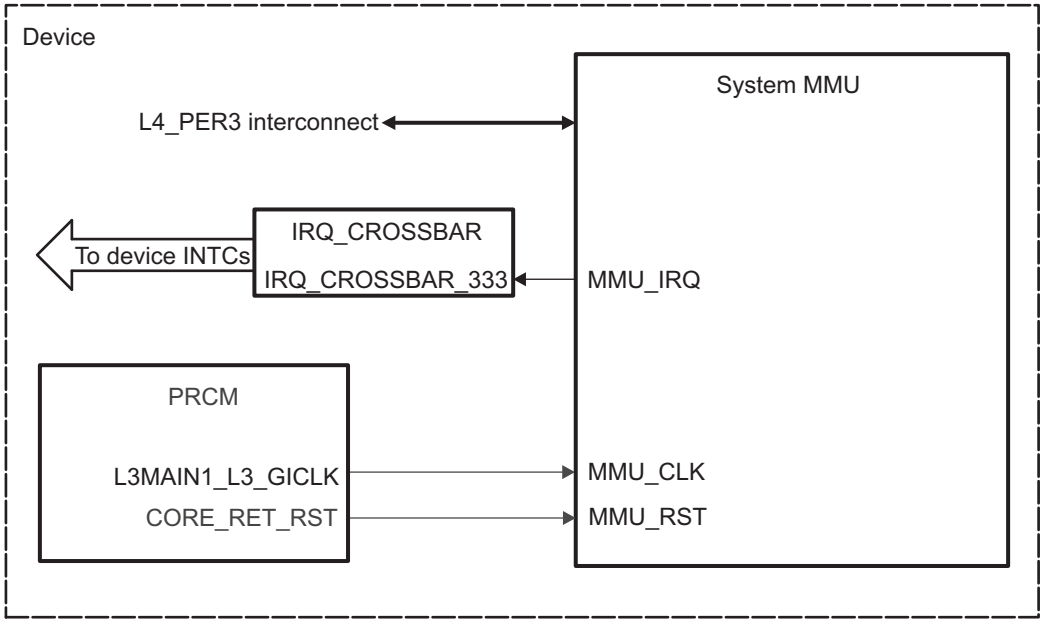


Table 15-1 through Table 15-3 summarize the system MMU integration.

Table 15-1. MMU Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
System MMU	PD_COREAON	L4_PER3

Table 15-2. MMU Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
System MMU	MMU_CLK	L3MAIN1_L3_GICLK	PRCM	System MMU interface/functional clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
System MMU	MMU_RST	CORE_RET_RST	PRCM	System MMU hardware reset. This reset is asynchronously applied to the MMU internal registers.

Table 15-3. MMU Hardware Requests

Interrupt Requests				
Module Instance	**Interrupt Name (Source)**	**IRQ_CROSSBAR Input (Destination)**	**Default Mapping**	**Description**
System MMU	MMU_IRQ	IRQ_CROSSBAR_333	–	System MMU interrupt.
No DMA Requests				

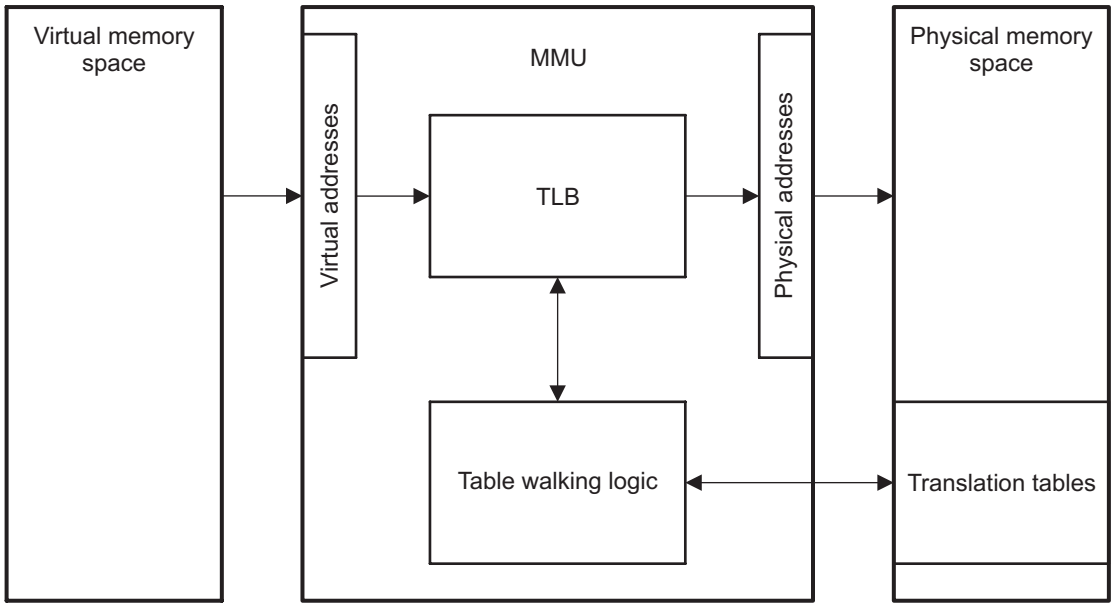
NOTE: For a description of the interrupt sources, see Section 15.3.4, *MMU Interrupt Requests*.

15.3 MMU Functional Description

15.3.1 MMU Block Diagram

The MMU manages the virtual to physical address translation for external addresses. Figure 15-3 shows the MMU block diagram.

Figure 15-3. MMU Block Diagram



Each table entry describes the translation of one contiguous memory region. For a description of the structure of these tables, see Section 15.3.1.2, *Translation Tables*.

Two major functional units exist in the MMU to provide address translation automatically based on the table entries:

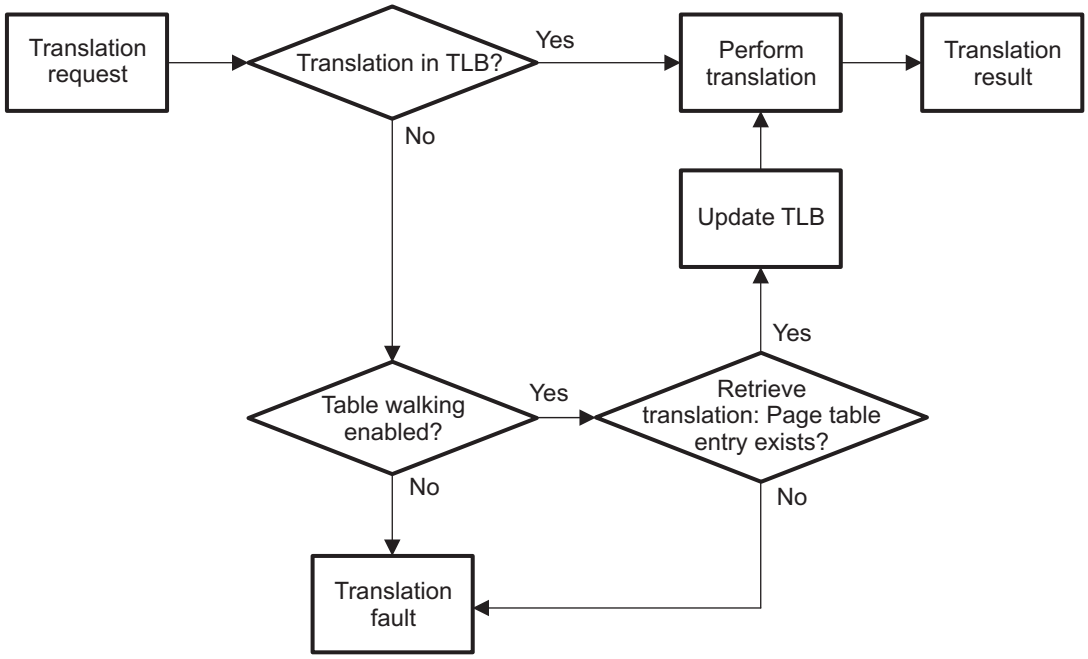
- The table walker automatically retrieves the correct translation table entry for a requested translation. If two-level translation is used (for the translation of small memory pages), the table walker also automatically reads the required second-level translation table entry. The two-level translation is described later in the chapter.
- The translation look-aside buffer (TLB) stores recently used translation entries, acting like a cache of the translation table.

15.3.1.1 MMU Address Translation Process

Whenever an address translation is requested (that is, for every access with the MMU enabled), the MMU first checks whether the translation is contained in the TLB, which acts like a cache storing recent translations. The TLB can also be programmed manually to ensure that time-critical data can be translated without delay.

If the requested translation is not in the TLB, the table-walking logic retrieves this translation from the translation table(s), and then updates the TLB. The address translation is then performed. Figure 15-4 summarizes the process.

Figure 15-4. Translation Process



15.3.1.2 Translation Tables

The translation of virtual to physical addresses is based on entries in translation tables that define the following properties:

- Address translation, that is, the correspondence between virtual and physical addresses
- Size of the memory region the entry translates

The virtual addresses index the translation tables. Each virtual address corresponds to exactly one entry in the translation table.

15.3.1.2.1 Translation Table Hierarchy

When developing a table-based address translation scheme, one of the most important design parameters is the memory page size described by each translation table entry. MMU instances support 4-KiB and 64-KiB pages, a 1-MiB section, and a 16-MiB supersection. Using bigger page sizes means a smaller translation table.

Using a smaller page size greatly increases the efficiency of dynamic memory allocation and defragmentation. That is why many operating systems (OSs) can operate on memory blocks as small as 4 KiB; however, the smaller size implies a more complex table structure.

A quick calculation shows that using 4 KiB memory pages with one translation table would require one million entries to span the entire 4-GiB address range. The table itself would be 32 MiB, a size that is not feasible.

However, using bigger pages reduces the flexibility of typical OS memory management. Implementing a two-level hierarchy reconciles these two requirements. Within this hierarchy, one first-level translation table describes the translation properties based on 1 MiB memory regions.

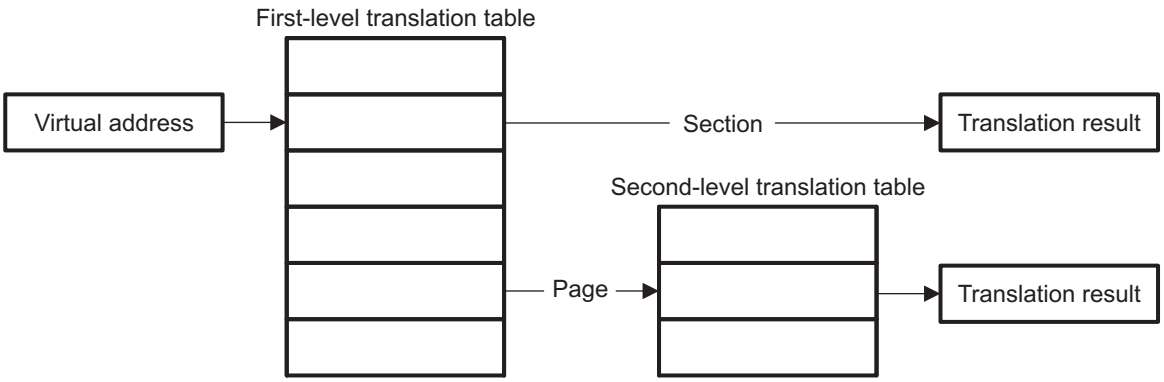
Each of the entries in this first-level translation table can specify the following:

- The translation properties for a big memory section. This memory section can be either 1 MiB (section) or 16 MiB (supersection). In this case, all translation parameters are specified in the first-level translation table entry.
- A pointer to a second-level translation table that specifies individual translation properties based on smaller pages within the 1-MiB page of memory. These pages can be either 64 KiB (large page) or 4

KiB (small page). In this case, the actual translation parameters are specified in the second-level translation table entry. The first-level translation table entry specifies only the base address of the second-level translation table.

This hierarchical approach means that additional translation information for smaller pages must be provided only when the pages are actually used. Figure 15-5 shows the hierarchy.

Figure 15-5. Translation Hierarchy



The structure of the first and second-level translation tables and their entries are described in more detail in Section 15.3.1.2.2, *First-Level Translation Table*, and Section 15.3.1.2.3, *Two-Level Translation*.

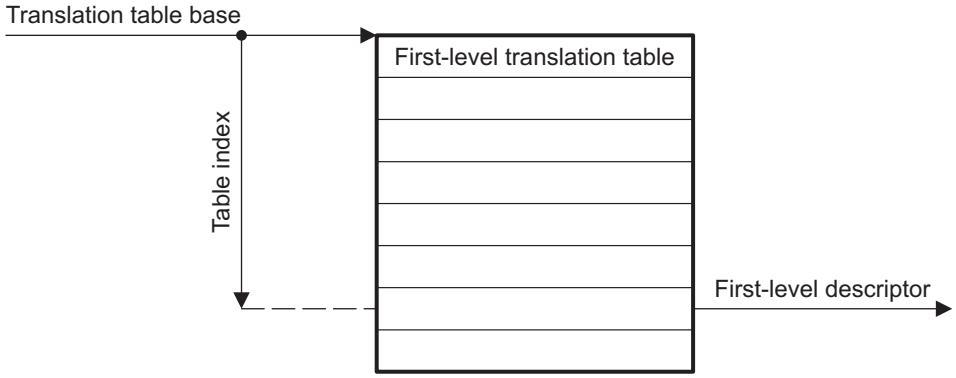
15.3.1.2.2 First-Level Translation Table

The first-level translation table describes the translation properties for 1-MiB sections. To describe a 4-GiB address range requires 4096 32-bit entries (so-called first-level descriptors).

The first-level translation table start address must be aligned on a multiple of the table size with a 128-byte minimum. Consequently, an alignment of at least 16K bytes is required for a complete 4096-entry table; that is, at least the last fourteen address bits must be zero.

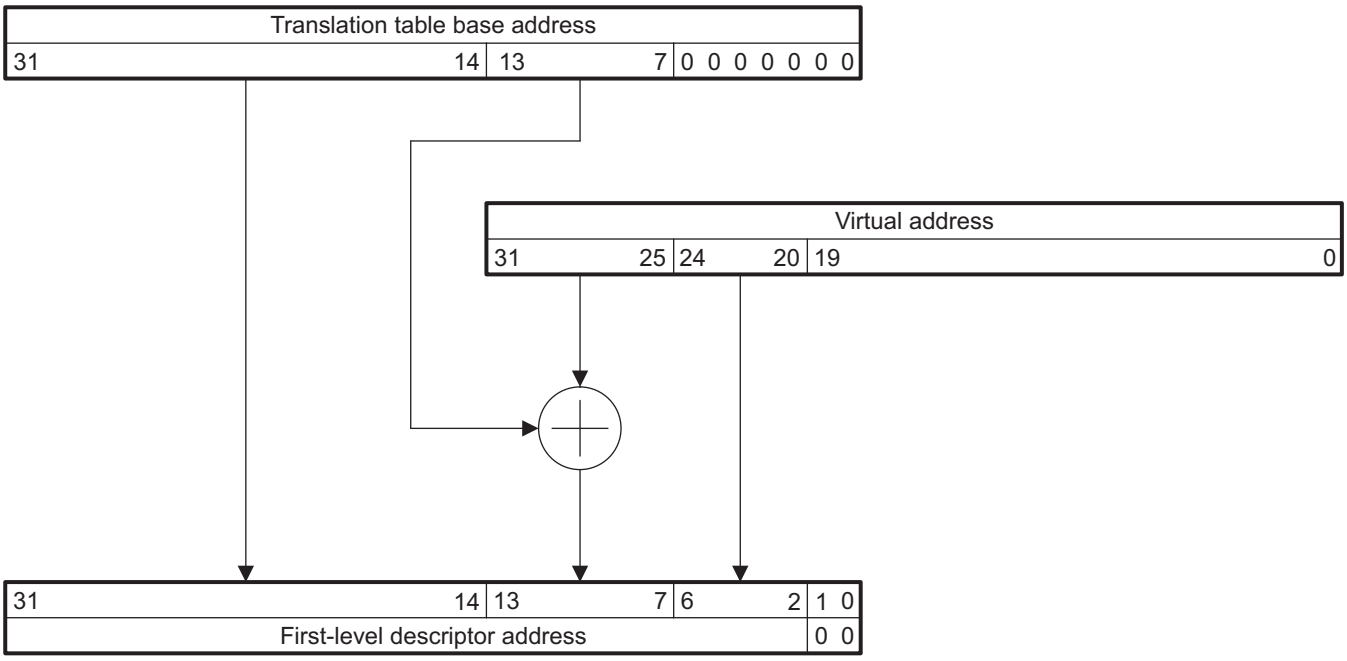
The start address of the first-level translation table is specified by the so-called translation table base. The table is indexed by the upper 12-bits of the virtual address. Figure 15-6 shows this mechanism.

Figure 15-6. First-level Descriptor Address Calculation



To summarize, the translation table base and the translation table index together define the first-level descriptor address. Figure 15-7 outlines the precise mechanism used to calculate this address.

Figure 15-7. Detailed First-Level Descriptor Address Calculation



As an example of this mechanism, consider a translation table base address of 0x8000:0000 and a virtual address of 0x1234:5678. In this case, the first-level descriptor address is 0x8000:0000 + (0x123 << 2) = 0x8000:048C.

15.3.1.2.2.1 First-Level Descriptor Format

Each first-level descriptor provides either the complete address translation for 1-MiB or 16-MiB sections or provides a pointer to a second-level translation table for 4 KiB or 64 KiB pages. Table 15-4 shows the first-level descriptor format.

Table 15-4. First-Level Descriptor Format

First-Level Descriptor Format								
31:24	23:20	19	18	17:10	9:2	1	0	
X						0	0	Fault
Second-Level Translation Table Base Address					X	0	1	Page
Section Base Address		X	0	X		1	0	Section
Supersection Base Address	X		1	X		1	0	Supersection
X						1	1	Fault

X = Don't care. Set to 0 for future compatibility.

15.3.1.2.2.2 First-Level Page Descriptor Format

If a translation granularity smaller than 1 MiB is required, a two-level translation process is used. In this case, the first-level block descriptor specifies only the start address of a second-level translation table. The second-level translation table entries specify the actual translation properties.

15.3.1.2.2.3 First-Level Section Descriptor Format

Each section descriptor in the first-level translation table specifies the complete translation properties for a 1-MiB section or a 16-MiB supersection.

NOTE: Supersection descriptors must be repeated 16 times, because each descriptor in the first-level translation table describes 1 MiB of memory. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

15.3.1.2.2.4 Section Translation Summary

Sections and supersections can be translated based solely on the information in the first-level translation table. Figure 15-8 summarizes the address translation process for a section.

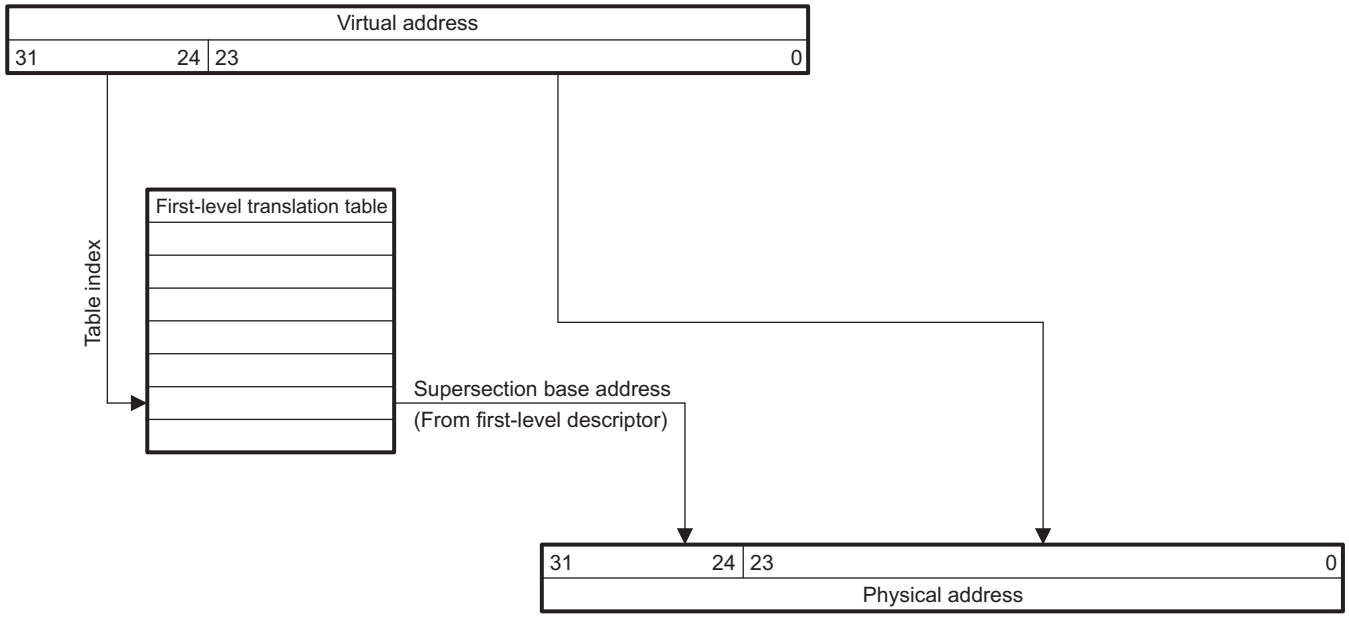
Figure 15-8. Section Translation Summary

15.3.1.2.2.5 Supersection Translation Summary

The translation of a supersection is similar to the translation of a section. The difference is that for a supersection only bits 31 to 24 index into the first-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a supersection.

Figure 15-9 shows the translation mechanism for a supersection.

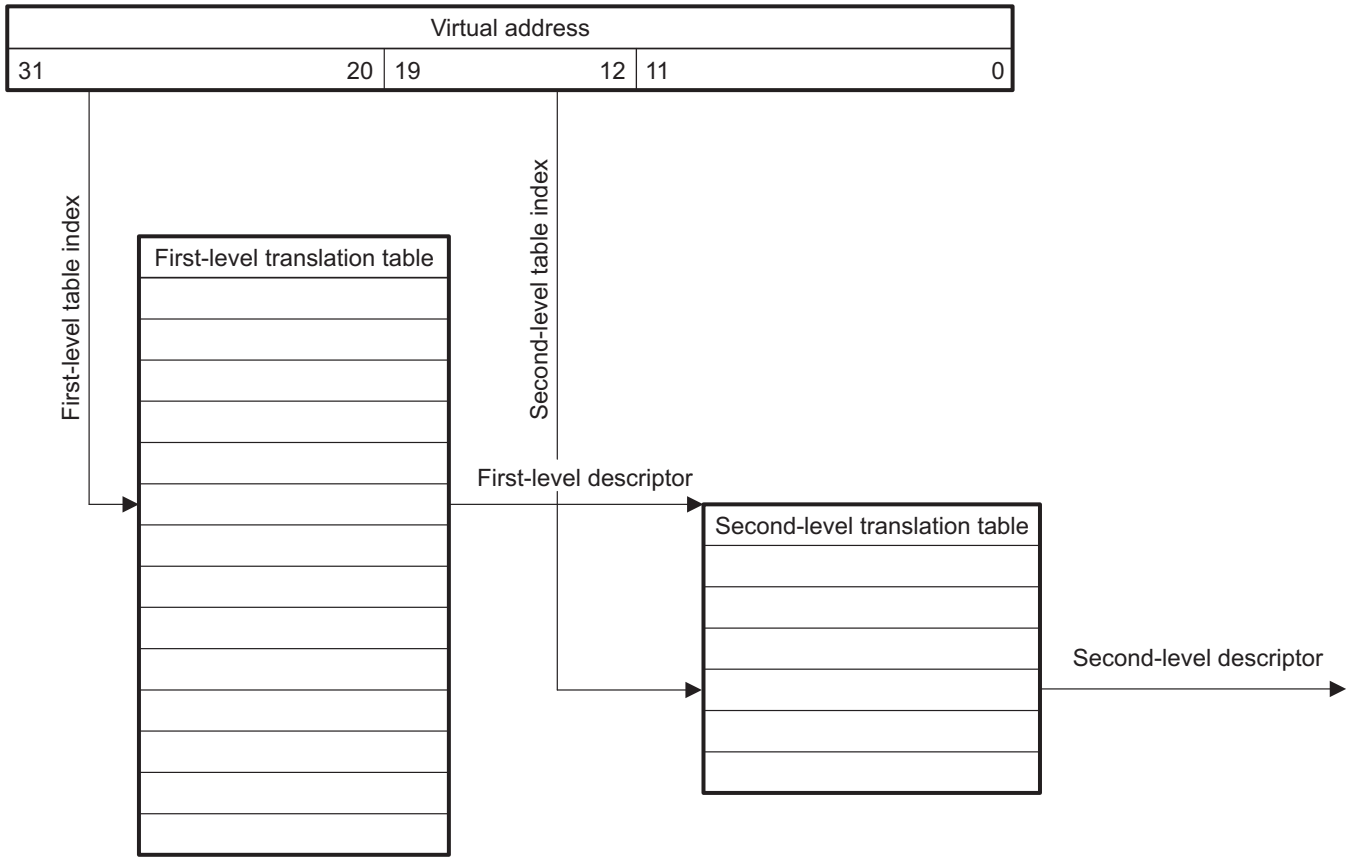
Figure 15-9. Supersection Translation Summary



15.3.1.2.3 Two-Level Translation

Two-level translation is used when fine-grain granularity is required, that is, when memory sections smaller than 1 MiB are needed. In this case, the first-level descriptor provides a pointer to the base address of a second-level translation table. This second-level table is indexed by bits 19 to 12 of the virtual address. Figure 15-10 shows this indexing mechanism.

Figure 15-10. Two-Level Translation



Each second-level translation table describes the translation of 1 MiB of address space in pages of 64 KiB (large page) or 4 KiB (small page). It consists of 256 second-level descriptors describing 4 KiB each.

NOTE: In the case of a large page, the same descriptor must be repeated 16 times. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

15.3.1.2.3.1 Second-Level Descriptor Format

Similar to first-level section descriptors, second-level descriptors provide all of the necessary information for the translation of a large or small page. Table 15-5 shows the format of second-level descriptors.

Table 15-5. Second-Level Descriptor Format

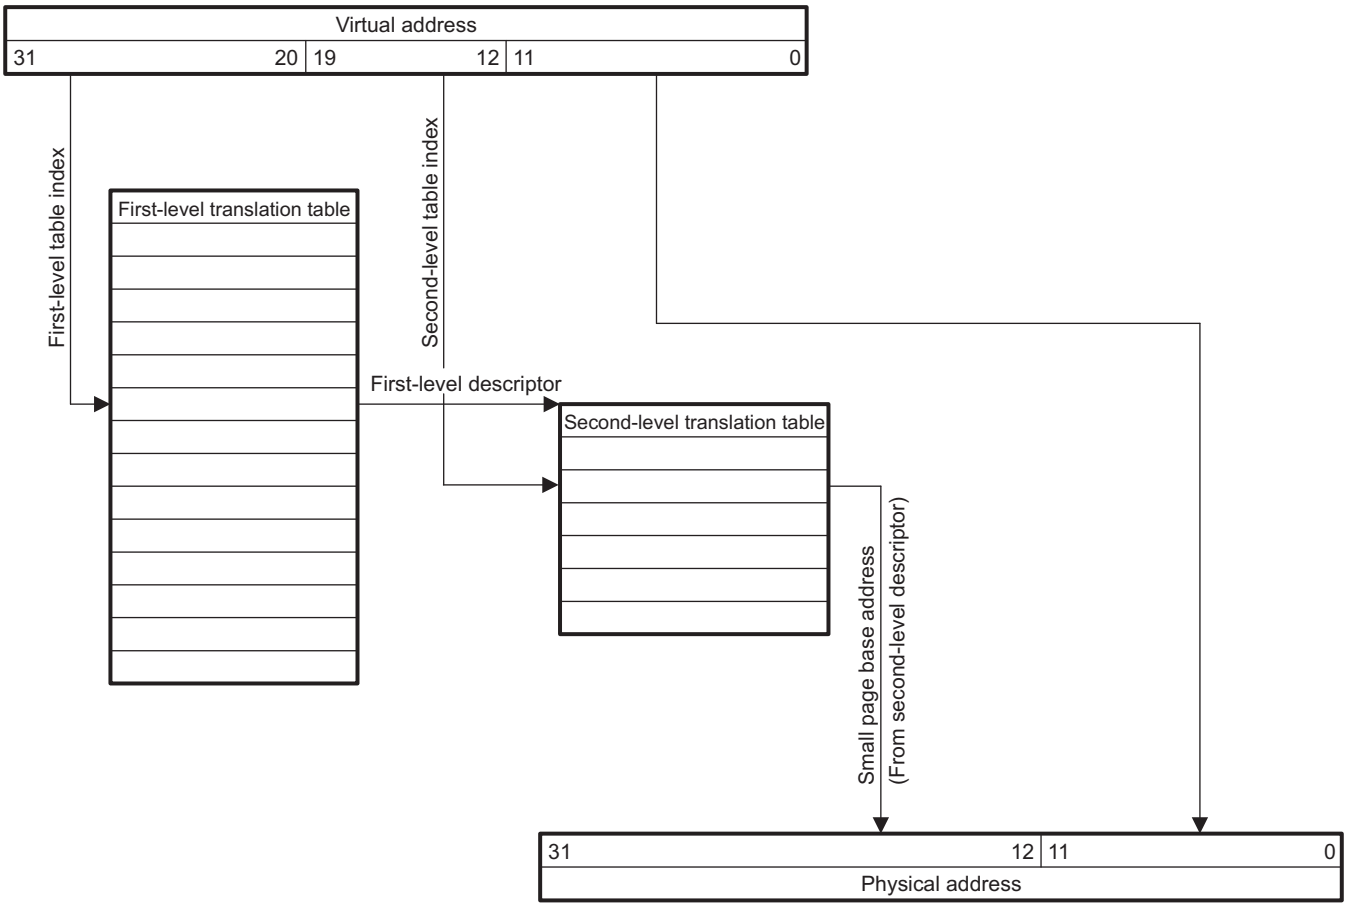
Second-Level Descriptor Format					
31:16	15:12	11:2	1	0	
X			0	0	Fault
Large Page Base Address	X		0	1	Large Page
Small Page Base Address		X	1	X	Small Page

X = Don't care. Set to 0 for future compatibility.

15.3.1.2.3.2 Small Page Translation Summary

Figure 15-11 summarizes the translation process for small pages.

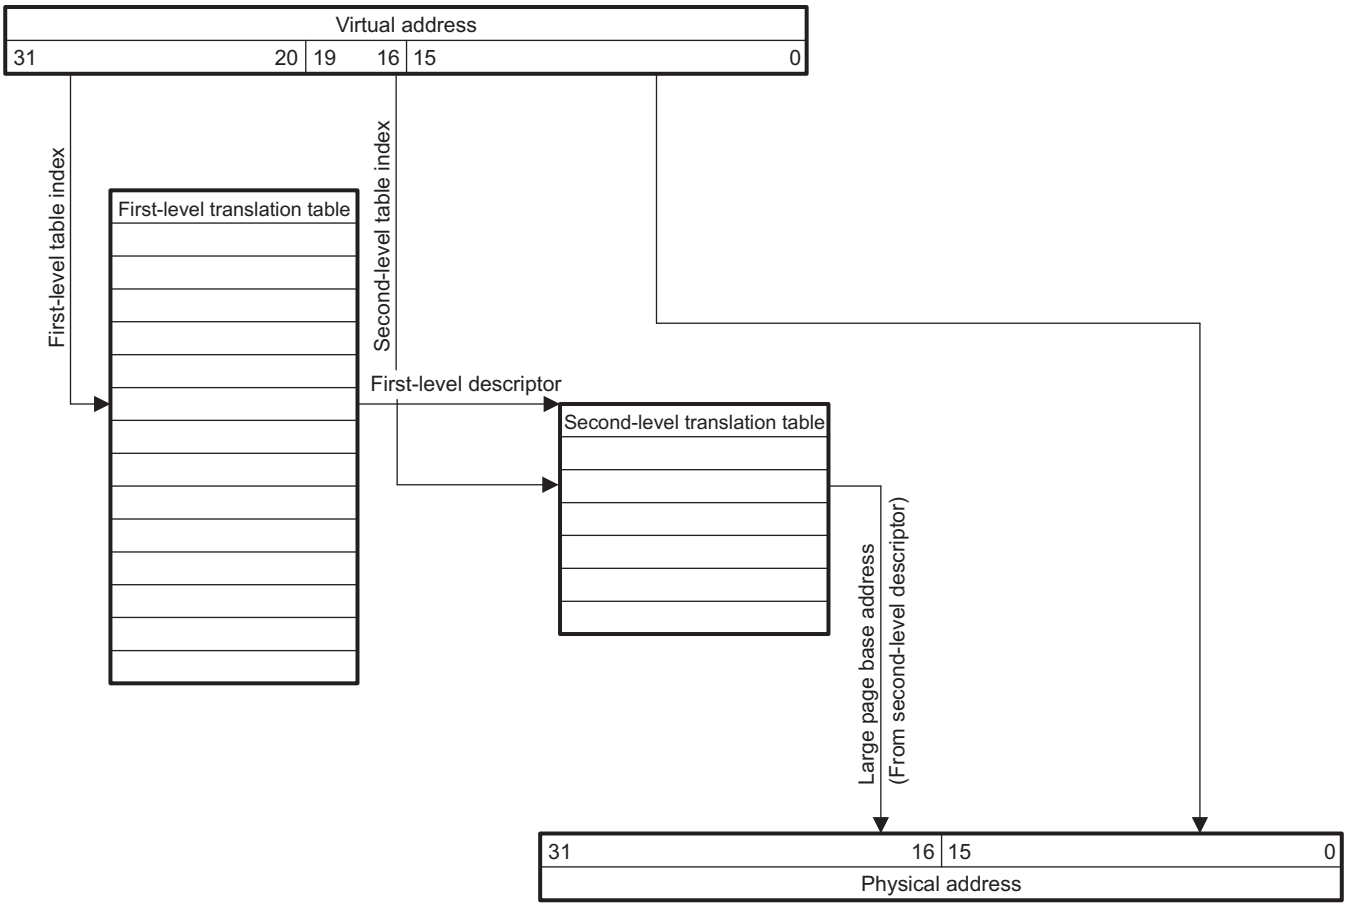
Figure 15-11. Small Page Translation Summary



15.3.1.2.3.3 Large Page Translation Summary

The translation of a large page is similar to the translation of a small page. The difference is that, for a large page, only bits 19 to 16 index into the second-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a large page. This is shown in Figure 15-12.

Figure 15-12. Large Page Translation Summary



15.3.1.3 Translation Lookaside Buffer

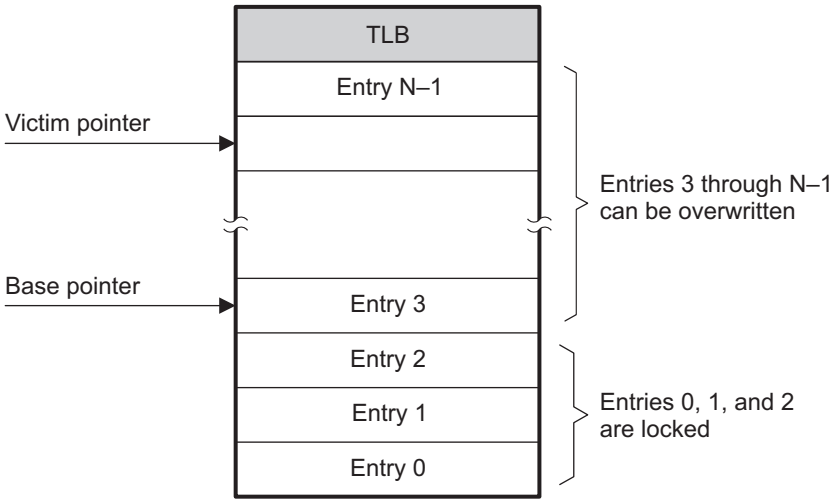
Translating virtual addresses to physical addresses is required for each memory access in systems using an MMU. To accelerate this translation process, a cache, or TLB, holds the result of recent translations.

For every translation, the MMU internal logic first checks whether the requested translation is already cached in the TLB. If the translation is cached, this translation is used; otherwise the translation is retrieved from the translation tables and the TLB is updated. If the TLB is full, one of its entries must be replaced. This entry is selected on a random basis.

The first *n* TLB entries, where *n* < *Total Number N of TLB Entries*, can be protected (locked) against being overwritten by setting the TLB base pointer to *n*. When this mechanism is used, only unprotected entries can be overwritten. The victim pointer indicates the next TLB entry to be written. Figure 15-13 shows an example of the TLB with N TLB entries (ranging from 0 to N-1). The base pointer contains the value "3" protecting Entry 0, Entry 1, and Entry 2 and the victim pointer points to the next TLB entry to be updated.

NOTE: The last TLB entry (Entry N-1) always remains unprotected.

Figure 15-13. TLB Entry Lock Mechanism



The table walking logic automatically writes the TLB entries. The entries can also be manually written, which is done typically to ensure that the translation of time-critical data accesses is already present in the TLB so that they execute as fast as possible. The entries must be locked to prevent them from being overwritten.

15.3.1.3.1 TLB Entry Format

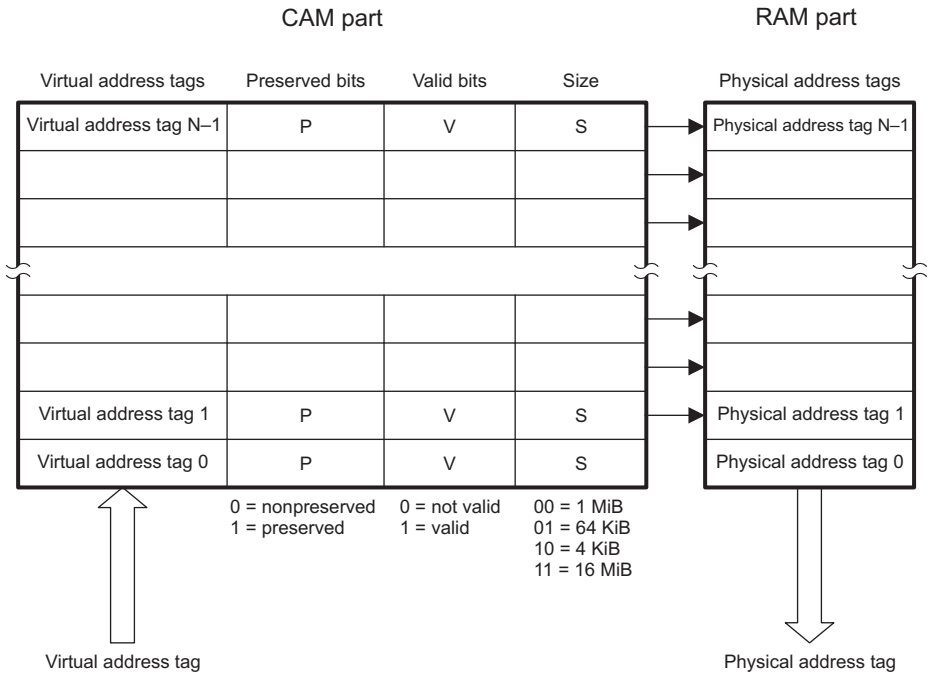
TLB entries consist of two parts:

- The Content Addressable Memory (CAM) part contains the virtual address tag used to determine if a virtual address translation is in the TLB. The TLB acts like a fully associative cache addressed by the virtual address tag. The CAM part also contains the section/page size, as well as the preserved and the valid parameters. See the MMU_CAM register table for more details.
- The Random Addressable Memory (RAM) part contains the address translation that belongs to the virtual address tag. See the MMU_RAM register table for more details.

The valid parameter specifies whether an entry is valid or not. The preserved parameter determines the behavior of an entry in the event of a TLB flush. If an entry is set as preserved, it is not deleted when a TLB is flushed, that is, when MMU_GFLUSH[0] GLOBALFLUSH is set to 1. Preserved entries must be deleted manually. Section 15.3.1.2.2, *First-Level Translation Table* describes the procedure to delete TLB entries.

Figure 15-15 shows the TLB entry structure.

Figure 15-14. TLB Entry Structure



15.3.1.4 No Translation (Bypass) Regions

The MMU provides support for up to four user programmable regions where there is no address translation. Any access to a region specified by the MMU_BYPASS_REGIONx_ADDR and MMU_BYPASS_REGIONx_SIZE registers (where x = 1 to 4) will have no virtual to physical address translation.

15.3.2 MMU Software Reset

To perform a software reset, write 1 in the MMU_SYSCONFIG[1] SOFTRESET bit. The MMU_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the MMU_SYSCONFIG[1] SOFTRESET bit is automatically reset. The software must ensure that the software reset completes before doing MMU operations. When an MMU instance is released from reset, its TLB is empty and the MMU is disabled.

15.3.3 MMU Power Management

Table 15-6 describes the power-management features available for the MMU modules.

Table 15-6. MMU Local Power Management Features

Feature	Register
Idle modes	MMU_SYSCONFIG[4:3] IDLEMODE
Clock activity	MMU_SYSCONFIG[9:8] CLOCKACTIVITY
Clock autogating	MMU_SYSCONFIG[0] AUTOIDLE

NOTE: The MMU_SYSCONFIG[9:8] CLOCKACTIVITY bit field is read only.

15.3.4 MMU Interrupt Requests

Table 15-7. MMU Events

Event Flag	Event Mask	Description
MMU_IRQSTATUS[4] MULTIHITFAULT	MMU_IRQENABLE[4] MULTIHITFAULT	Error due to multiple matches in the TLB
MMU_IRQSTATUS[3] TABLEWALKFAULT	MMU_IRQENABLE[3] TABLEWALKFAULT	Error due to error response received during a Table Walk
MMU_IRQSTATUS[2] EMUMISS	MMU_IRQENABLE[2] EMUMISS	Error due to unrecoverable TLB miss during debug (hardware TWL disabled)
MMU_IRQSTATUS[1] TRANSLATIONFAULT	MMU_IRQENABLE[1] TRANSLATIONFAULT	Error due to invalid descriptor in the translation tables (translation fault)
MMU_IRQSTATUS[0] TLBMISS	MMU_IRQENABLE[0] TLBMISS	Error due to unrecoverable TLB miss (hardware TWL disabled)

15.3.5 MMU Error Handling

Table 15-8 summarizes the intended operation for real and potential error conditions.

Table 15-8. Error Handling

Item	Condition	Action
1	Table-walk read has an error response.	Treat generally the same as a translation fault, but set the TableWalkFault interrupt status bit to aid in diagnosis
2	MMU is disabled during table-walk.	Not permitted; can result in loss of the current transaction but must not deadlock the MMU. Avoid this condition by first disabling the table-walk logic and then polling the TWLRunning bit to ensure that no table walk is pending
3	MMU is disabled during an address translation.	Not permitted; can result in access to an unintended location, but must not deadlock MMU. This condition should be avoided by ensuring that no accesses are pending.
4	TLB is accessed during an address translation or a table walk.	Reading permitted; write should be done with care to ensure that the TLB is self-consistent at all times that a translation can occur.
5	TLB is flushed during address translation or a table walk.	Permitted; the flush is processed first, followed by the TWL update.
6	MMU is disabled while an interrupt is pending.	Not permitted; all pending interrupts should be processed before disabling the MMU.
7	Interrupt is not enabled and a fault/miss happens during translation.	If MMU_GPR[0] FAULT_INTR_DIS = 1 : Error response is sent back. If MMU_GPR[0] FAULT_INTR_DIS = 0 : • Mreqdebug = 1 (debug access) : Error response is sent back • Mreqdebug = 0 (application access) : Error response is not sent. MMU is waiting for TLB to be updated through config port. But since the interrupt is not asserted, system does not know there was a fault. This results in deadlock. Software must take care of this by enabling interrupts.

15.4 MMU Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

15.4.1 Global Initialization

15.4.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the MMU module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MMU. For more information, see Section 15.2, *MMU Module Integration* .

Table 15-9. Global Initialization of Surrounding Modules

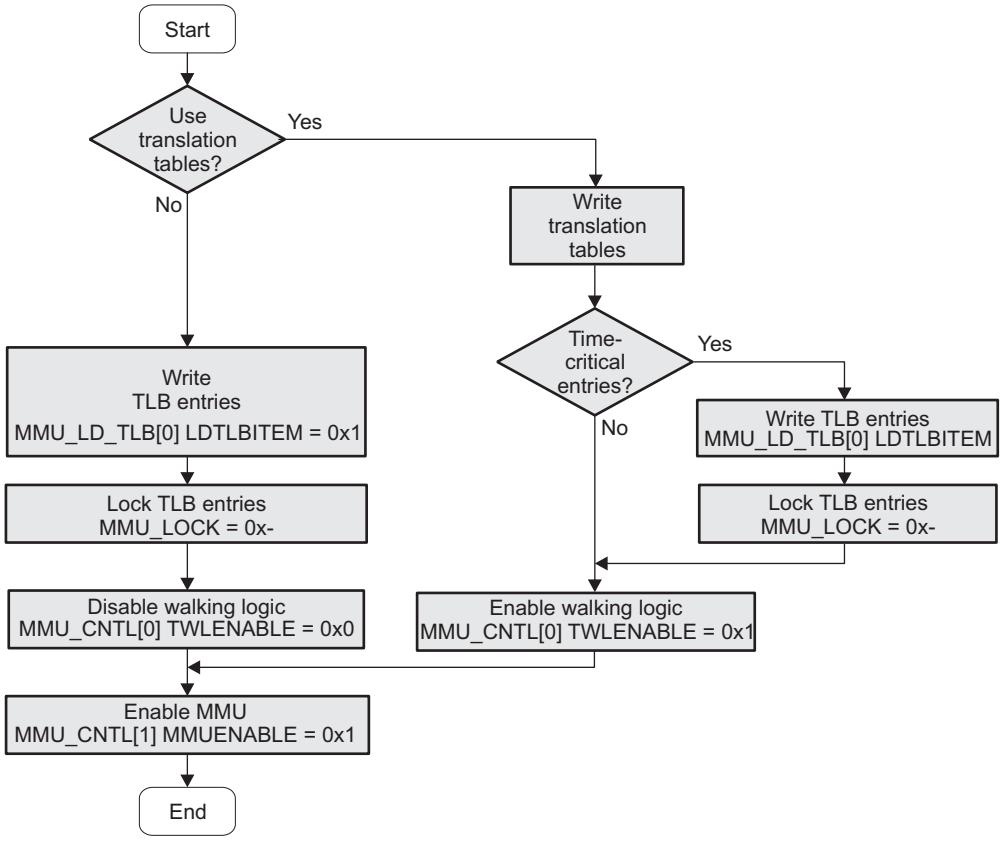
Surrounding Modules	Comments
PRCM	Enable MMU interface/functional clock.
(optional) Interrupt controller(s)	Configure device interrupt controller(s) to enable the interrupts from MMU.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.

15.4.1.2 MMU Global Initialization

15.4.1.2.1 Main Sequence - MMU Global Initialization

Figure 15-15 shows the procedure to initialize the MMU after a power-on or software reset.

Figure 15-15. MMU Global Initialization



15.4.1.2.2 Subsequence - Configure a TLB entry

Table 15-10. Configure a TLB Entry

Step	Register / Bit Field / Programming Model	Value
Load the Virtual Address Tag	MMU_CAM[31:12] VATAG	0x-
Protect the TLB entry against flush	MMU_CAM[3] P	0x1
Validate the TLB entry	MMU_CAM[2] V	0x1
Define the page size	MMU_CAM[1:0] PAGESIZE	0x-

15.4.1.3 Operational Modes Configuration

15.4.1.3.1 Main Sequence - Writing TLB Entries Statically

Writing TLB entries statically avoids the need to write translation tables in memory and is commonly used for relatively small address spaces. This method ensures that the translation of time-critical data accesses execute as fast as possible with entries already present in the TLB. These entries must be locked to prevent them from being overwritten.

Table 15-11. MMU Writing TLB Entries Statically

Step	Register/ Bit Field / Programming Model	Value
Execute software reset	MMU_SYSCONFIG[1] SOFTRESET	0x1
Wait for reset to complete	MMU_SYSSTATUS[0] RESETDONE	=0x1
Enable power saving via automatic interface clock gating	MMU_SYSCONFIG[0] AUTOIDLE	0x1
Configure TLB entries	See Table 15-10	
Load the physical Address of the page	MMU_RAM[31:12] PHYSICALADDRESS	0x-
Specify the TLB entry you want to write	MMU_LOCK[8:4] CURRENTVICTIM	0x-
Load the specified entry in the TLB	MMU_LD_TLB[0] LDTLBITEM	0x1
Enable multihit fault and TLB miss	MMU_IRQENABLE[4] MULTIHITFAULT	0x1
	MMU_IRQENABLE[0] TLBMISS	0x1
Enable memory translations	MMU_CNTL[1] MMUENABLE	0x1

15.4.1.3.2 Main Sequence - Protecting TLB Entries

The first *n* TLB entries (with *n* < total number of TLB entries) can be protected from being overwritten with new translations. This is useful to ensure that certain commonly used or time-critical translations are always in the TLB and do not require retrieval using the table walking process.

Table 15-12. Protecting TLB Entries

Step	Registe/Bit Field/Programming Model	Value
Locks the TLB entries	MMU_LOCK[14:10] BASEVALUE	0x-

15.4.1.3.3 Main Sequence - Deleting TLB Entries

Two mechanisms exist to delete TLB entries. All unpreserved TLB entries, that is, TLB entries written with the preserved bit set to zero, can be deleted by invoking a TLB flush. The preserved bit should only be used on protected TLB entries, as it does not prevent replacement by the table walking logic.

Table 15-13. Deleting TLB Entries

Step	Registet / Bit Field / Programming Model	Value
Flush all nonprotected TLB entries	MMU_GFLUSH[0] GLOBALFLUSH	0x1
Flush all TLB entries specified by the CAM register	MMU_FLUSH_ENTRY[0] FLUSHENTRY	0x1

15.4.1.3.4 Main Sequence - Read TLB Entries

TLB entries can be read by the programmer to determine the TLB content at runtime.

Table 15-14. Read TLB Entries

Step	Register / Bit Field / Programming Model	Value
Set the current victim pointer	MMU_LOCK[8:4] CURRENTVICTIM	0x-
Read RAM parts of the TLB entry	MMU_READ_RAM	

Table 15-14. Read TLB Entries (continued)

Step	Register / Bit Field / Programming Model	Value
Read CAM parts of the TLB entry	MMU_READ_CAM	

15.5 MMU Register Manual

15.5.1 MMU Instance Summary

Table 15-15. MMU Instance Summary

Module Name	Base Address (L3/L4 Access)	Base Address (CPU Private Access)	Size
System MMU	0x4881 C000	–	176 Bytes
DSP1_MMU0	0x40D0 1000	0x01D0 1000	176 Bytes

15.5.2.2 MMU Register Description

Table 15-21. MMU_REVISION

Address Offset	0x0000 0000		
Physical Address	See Section 15.5.2.1	**Instance**	See Table 15-15
Description	This register contains the IP revision code		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REVISION																															

Bits	Field Name	Description	Type	Reset
31:0	REVISION	IP Revision	R	See (1)

(1) TI internal data

Table 15-22. Register Call Summary for Register MMU_REVISION

MMU Register Manual
- MMU Register Summary: [0][1][2][3][4]

Table 15-23. MMU_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	See Section 15.5.2.1	**Instance**	See Table 15-15
Description	This register controls the various parameters of the OCP interface		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																						CLOCKACTIVITY		RESERVED				IDLEMODE		RESERVED	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Write 0's for future compatibility. Reads return 0	R	0x000000
9:8	CLOCKACTIVITY	Clock activity during wake-up mode 0x0: Functional and OCP clocks can be switched off	R	0x0
7:5	RESERVED	Write 0's for future compatibility Reads returns 0	R	0x0
4:3	IDLEMODE	Idle mode 0x0: Force-idle. An idle request is acknowledged unconditionally 0x1: No-idle. An idle request is never acknowledged 0x2: Smart-idle. Acknowledgement to an idle request is given based on the internal activity of the module 0x3: Reserved. Do not use	RW	0x0
2	RESERVED	Write 0's for future compatibility Reads returns 0	R	0x0
1	SOFTRESET	Software reset. This bit is automatically reset by the hardware. During reads, it always return 0 Write 0x0: No functional effect Write 0x1: The module is reset	W	0x0
0	AUTOIDLE	Internal OCP clock gating strategy 0x0: OCP clock is free-running 0x1: Automatic interconnect clock gating strategy is applied, based on the interconnect interface activity	RW	0x0

Spinlock

This chapter describes the Spinlock module of the device.

Topic **Page**

16.1 Spinlock Overview

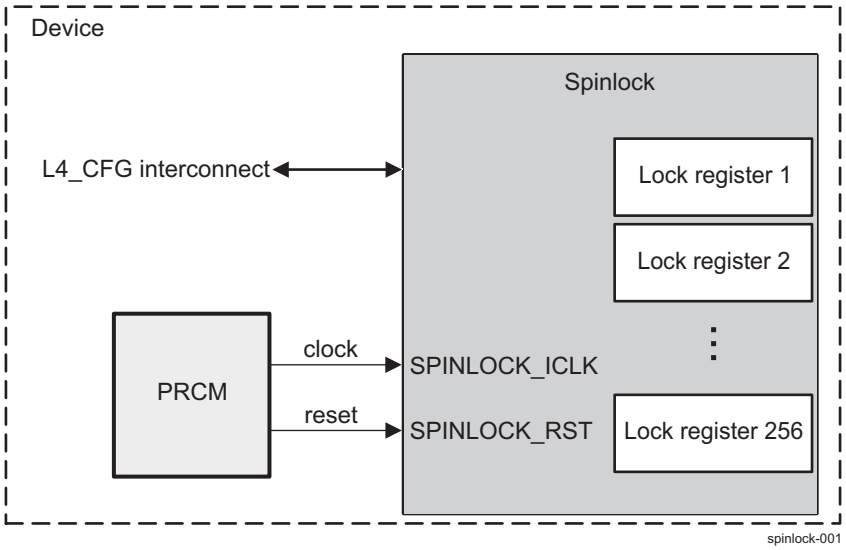
The Spinlock module provides hardware assistance for synchronizing the processes running on multiple processors in the device:

- Digital signal processor (DSP) subsystems – DSP1 and DSP2
- Dual Cortex-M4 image processing unit (IPU) subsystem – IPU

The Spinlock module implements 256 spinlocks (or hardware semaphores), which provide an efficient way to perform a lock operation of a device resource using a single read-access, avoiding the need of a read-modify-write bus transfer that the programmable cores are not capable of.

Figure 16-1 shows an overview of the Spinlock module.

Figure 16-1. Spinlock Overview

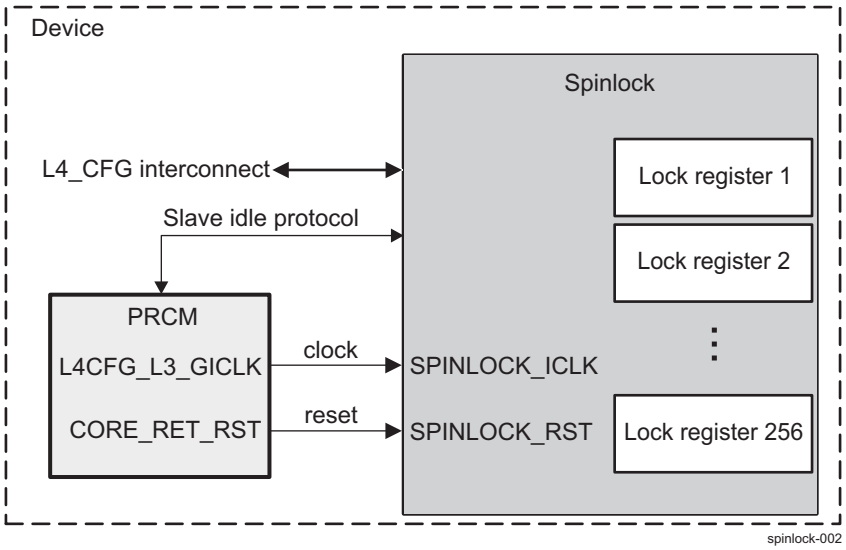


16.2 Spinlock Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 16-2 shows the Spinlock integration.

Figure 16-2. Spinlock Integration



NOTE: For more information about the Slave idle protocol and the wake-up request, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 16-1 and Table 16-2 summarize the integration of the module in the device.

Table 16-1. Spinlock Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
SPINLOCK	PD_COREAON	L4_CFG

Table 16-2. Spinlock Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
SPINLOCK	SPINLOCK_ICLK	L4CFG_L3_GICLK	PRCM	Spinlock interface/functional clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
SPINLOCK	SPINLOCK_RST	CORE_RET_RST	PRCM	Spinlock hardware reset. This reset is asynchronously applied to the Spinlock internal registers.

NOTE: The Spinlock module does not support any interrupt and DMA requests.

16.3 Spinlock Functional Description

16.3.1 Spinlock Software Reset

The Spinlock module can be reset by software through the SPINLOCK_SYSCONFIG[1] SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. The SPINLOCK_SYSTATUS[0] RESETDONE bit can be polled to check the reset status (reading 1 indicates that reset sequence is done; reading 0 indicates that reset sequence is in progress). The software must ensure that the software reset completes before doing Spinlock operations.

16.3.2 Spinlock Power Management

Table 16-3 describes power-management features available to the Spinlock module.

Table 16-3. Spinlock Local Power Management Features

Feature	Registers	Description
Clock auto gating	SPINLOCK_SYSCONFIG[0] AUTOGATING bit	This bit indicates that the Spinlock module uses an automatic internal interface clock gating strategy, based on interface activity.
Global wake-up enable	SPINLOCK_SYSCONFIG[2] ENAWAKEUP bit	This bit indicates that the wake-up generation feature (at Spinlock module level) is disabled.
Slave idle modes	SPINLOCK_SYSCONFIG[4:3] SIDLEMODE bit field	This bit field indicates that the Spinlock module uses smart-idle mode.

NOTE: All Spinlock local power management features are non-configurable – that is, their respective bit fields are read-only and only show the actual hardware implementation.

For information about source clock gating and sleep/wake-up transitions description, see Section 3.1.1.1.4, *Clock Domain-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*. For descriptions of EnaWakeUp, and IdleMode features, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

The Spinlock module is normally idle, except when processing a request from its slave interface port. The smart-idle mode acknowledges idle requests from the PRCM only when the module is prepared to go idle. The Spinlock module is always ready to go idle if it does not have any request that it is processing.

16.3.3 About Spinlocks

Spinlocks are present to solve the need for synchronization and mutual exclusion between heterogeneous processors and those not operating under a single, shared operating system. There is no alternative mechanism to accomplish these operations between processors in separate subsystems.

Spinlocks are not the best way to synchronize between tasks or threads on one CPU. Instead, spinlocks are for use in synchronization between different subsystems in the device that don't have any other means of hardware-based synchronization.

Spinlocks do not solve all system synchronization issues. They have limited applicability and should be used with care to implement higher level synchronization protocols.

A spinlock is appropriate for mutual exclusion for access to a shared data structure. It should be used only when:

1. The time to hold the lock is predictable and small (for example, a maximum hold time of less than 200 CPU cycles may be acceptable).
2. The locking task cannot be preempted, suspended, or interrupted while holding the lock (this would make the hold time large and unpredictable).
3. The lock is lightly contended, that is the chance of any other process (or processor) trying to acquire the lock while it is held is small.

If these conditions are met, then the locking code can retry a failed attempt to acquire the lock until success.

If the conditions are not met, then a spinlock is not a good candidate. One alternative is to use a spinlock for critical section control (engineered to meet the conditions) to implement a higher level semaphore that can support preemption, notification, timeout or other higher level properties.

16.3.4 Spinlock Functional Operation

The Spinlock module supports 256 spinlocks. It accepts only a single command at a time and processes the command fully before accepting the next command. A lock is requested by reading the SPINLOCK_LOCK_REG_i[0] TAKEN bit. There are two states: Taken (SPINLOCK_LOCK_REG_i[0] TAKEN = 1) or Not Taken (SPINLOCK_LOCK_REG_i[0] TAKEN = 0).

When the status of lock *i* (where i = 0 to 255) is Not Taken (free), a read from the SPINLOCK_LOCK_REG_i register returns 0 and sets the lock to Taken (locked). When the status of lock *i* is Taken, a read returns 1 and does not change the state of the lock.

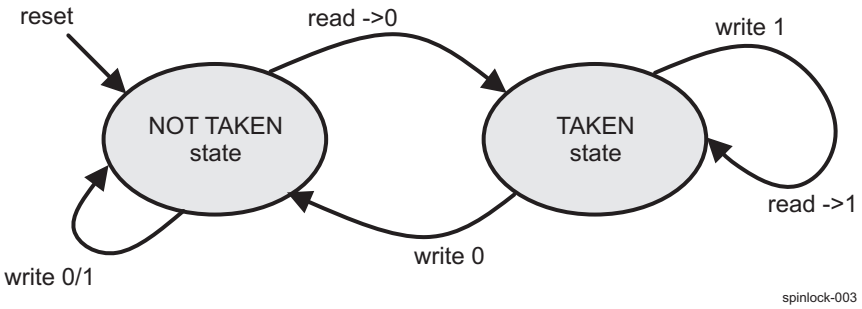
A write to the SPINLOCK_LOCK_REG_i register does not change the state of lock, unless when writing 0 when the lock is in Taken state. By doing this, the requester frees the lock.

CAUTION

Only 32-bit reads and writes are supported.

Figure 16-3 shows the SPINLOCK_LOCK_REG_i register state diagram.

Figure 16-3. Lock Register State Diagram



NOTE:

- There is no support to ensure that a lock register is locked and unlocked by the same process. This must be ensured in software.
- There is no support to check that the same initiator that acquired the lock is the one that is freeing the lock.

16.4 Spinlock Programming Guide

16.4.1 Spinlock Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

16.4.1.1 Surrounding Modules Global Initialization

This procedure initializes the surrounding modules when the Spinlock module is used for the first time after a device reset.

Table 16-4. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Spinlock interface clock must be enabled. For more information, see Section 3.6.4.11, *CD_L4_CFG Clock Domain*, in Chapter 3, *Power, Reset, and Clock Management*.
Interconnect	For more information about the L4_CFG interconnect configuration, see Section 9.3, *L4 Interconnects*.

16.4.1.2 Basic Spinlock Operations

The main spinlock operations are:

- Clear all the Taken spinlocks (only after a system bug recovery)
- Take a spinlock
- Release spinlock

16.4.1.2.1 Spinlocks Clearing After a System Bug Recovery

Module initialization (after reset) is not needed, except after system bug recovery. The following table presents the Spinlock initialization after a system bug recovery. Software should store 0 into each of the SPINLOCK_LOCK_REG_i registers at system startup to insure that all locks are initialized to Not Taken.

Table 16-5. Spinlock System Bug Recovery

Step	Register	Value
IF: SPINLOCK_SYSTATUS[0] IU0 = = 1?	SPINLOCK_SYSTATUS[0] IU0	
Free the 256 locks	SPINLOCK_LOCK_REG_i[0] TAKEN (i = 0 to 255)	0x0
END		

16.4.1.2.2 Take and Release Spinlock

This procedure configures the take and release (free) operations for the Spinlock module. A spinlock should only be held with interrupts disabled. So, before attempting to obtain the spinlock, software should disable interrupts. Then it should read the SPINLOCK_LOCK_REG_i[0] TAKEN bit to attempt to obtain the lock. If it succeeds, it should proceed directly through the critical section then unlock and re-enable interrupts. If the acquisition attempt fails, the acquisition should be reattempted. To prevent unknown interrupt disabled time, interrupts should be re-enabled and then disabled before reattempting to acquire the lock. Figure 16-4 shows the described above procedure.

Timers

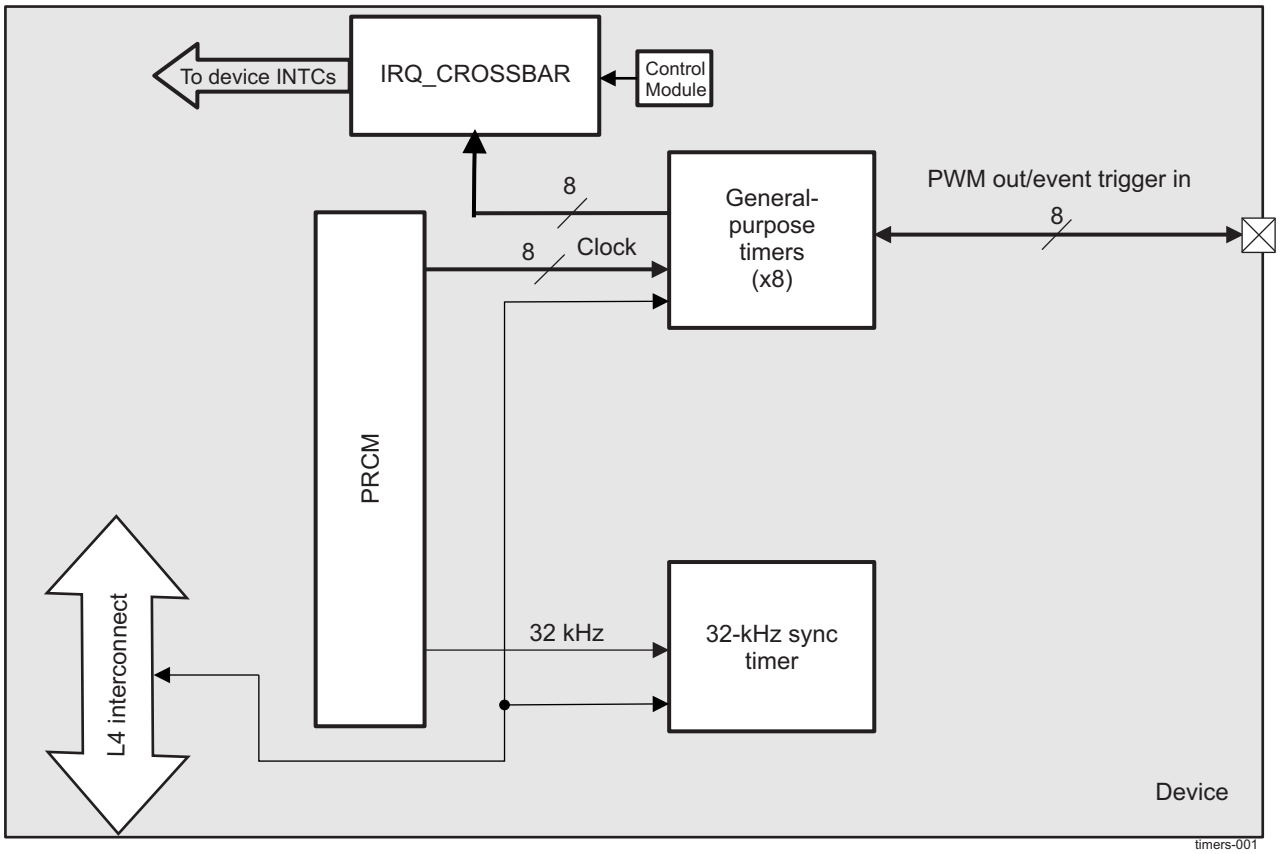
This chapter describes the timer modules for the device.

Topic **Page**

17.1 Timers Overview

The device includes several types of timers used by the system software, including eight general-purpose (GP) timers, and a 32-kHz synchronized timer (COUNTER_32K). Figure 17-1 shows a high-level block diagram of the device timers.

Figure 17-1. Timers Overview



The 32-kHz sync timer, which is reset only at power up, provides the operating system (OS) with a stable timing source that stores the relative time since the last power cycle of the product. The eight GP timers, which are useful as basic timers, are included to generate time-stamp-based interrupts to the system software or to use as a source of pulse-width modulation (PWM) signals.

17.2 General-Purpose Timers

17.2.1 General-Purpose Timers Overview

The device has eight GP timers: TIMER1 through TIMER8.

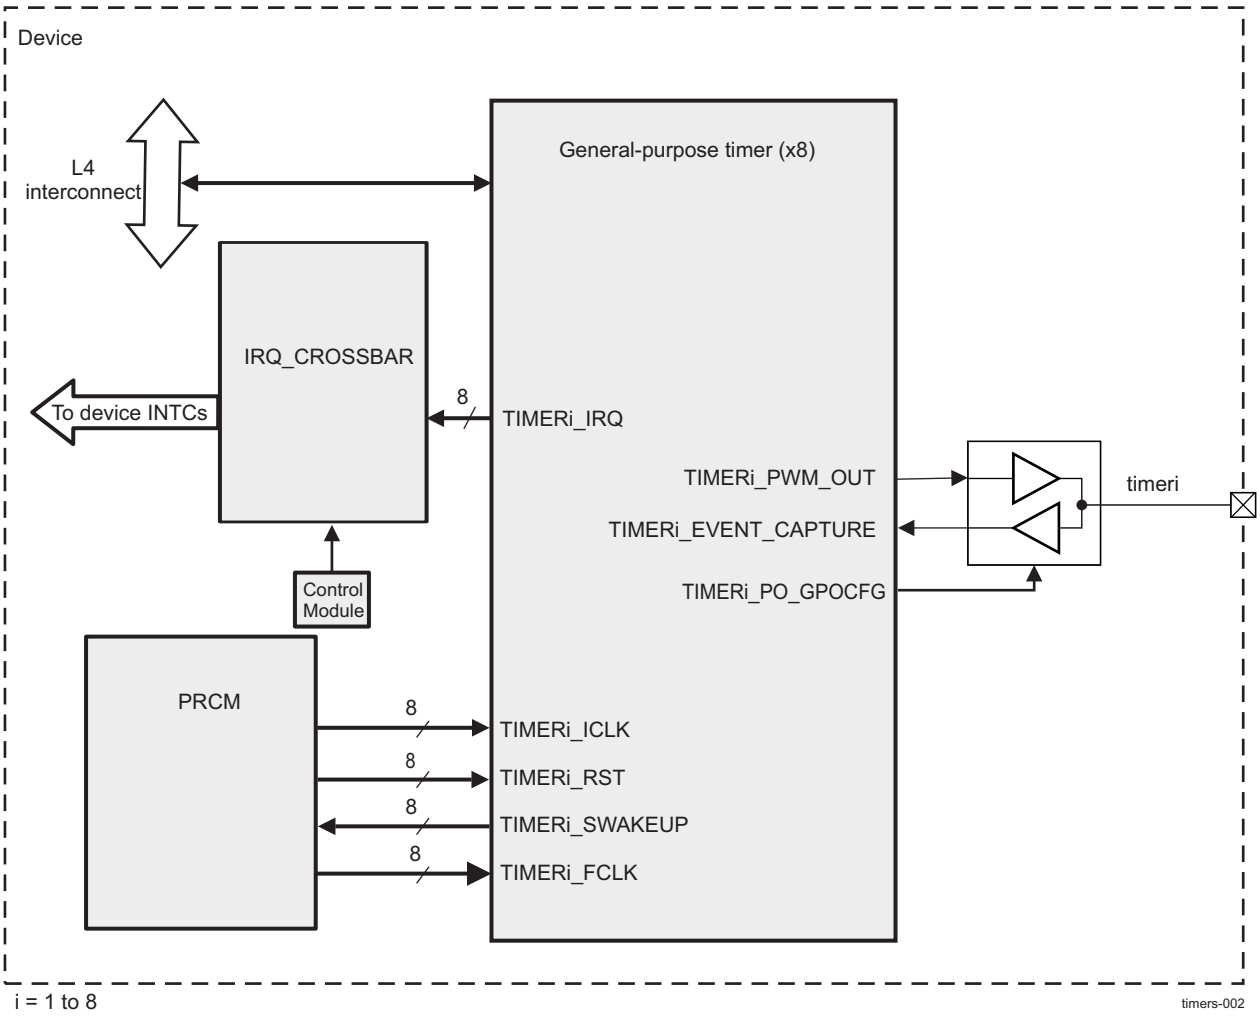
- TIMER1 (1-ms tick) includes a specific function to generate accurate tick interrupts to the operating system and it belongs to the PD_WKUPAON domain.
- TIMER2 through TIMER8 belong to the PD_COREAON module.

Each timer can be clocked from the system clock (19.2, 20, or 27 MHz) or the 32-kHz clock. Select the clock source at the power, reset, and clock management (PRCM) module level.

Each timer provides an interrupt through the device IRQ_CROSSBAR.

Each timer is connected to an external pin by their PWM output or their event capture input pin (for external timer triggering). Figure 17-2 shows an overview of the GP timers.

Figure 17-2. GP Timers Overview



17.2.1.1 GP Timer Features

The following are the main features of the GP timer controllers:

- Level 4 (L4) slave interface support:
  - 32-bit data bus width

  - 32- or 16-bit access supported
  - 8-bit access not supported
  - 10-bit address bus width
  - Burst mode not supported
  - Write nonposted transaction mode supported
- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Compare and capture modes
- Autoreload mode
- Start and stop mode
- Programmable divider clock source (2^n, where n = [0:8])
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- Dedicated GP output signal for using the TIMERi_GPO_CFG signal
- On-the-fly read/write register (while counting)
- 1-ms tick with 32.768-Hz functional clock generated (only TIMER1)

17.2.2 GP Timer Environment

17.2.2.1 GP Timer External System Interface

Each timer can send or receive stimulus to and from the external (off-chip) system. In the device all timers are configured to output a PWM pulse or receive an external event signal used as a trigger to capture the current timer count.

Figure 17-3 shows the external system interface for the GP timers, and Table 17-1 describes the GP timer inputs and outputs.

NOTE: Software control must ensure that MUX mode is configured to select the timeri (where i = 1 to 8) signal on only one pad. Other pads on which the same signal is multiplexed must be configured in safe mode or non-dmtimer mode to avoid two different pads driving the same signal.

For more information about the configuration of the timeri I/O pads, see Section 13.4.6.1, Pad Configuration Registers.

Figure 17-3. GP Timers External System Interface

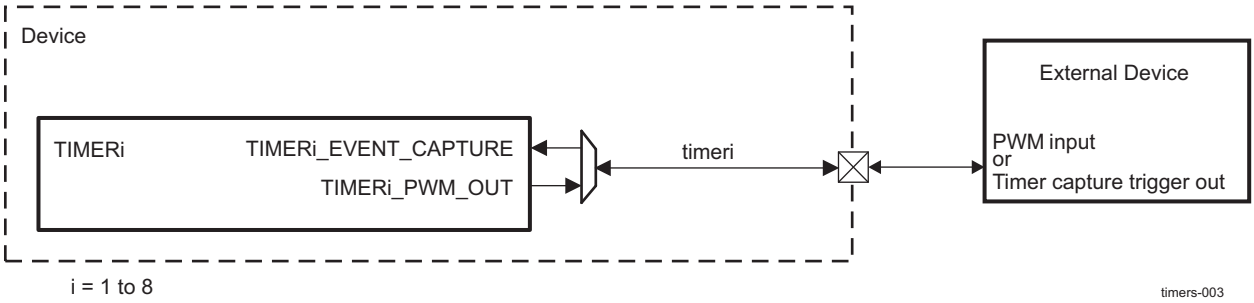


Table 17-1. Input/Output Description

Pin Name	Type (1)	Reset Value	Signal Name	Description
timer1	I/O	0	TIMER1_PI_EVENT_CAPTURE TIMER1_PWM_OUT	TIMER1 trigger input/ PWM output
timer2	I/O	0	TIMER2_PI_EVENT_CAPTURE TIMER2_PWM_OUT	TIMER2 trigger input/ PWM output
timer3	I/O	0	TIMER3_PI_EVENT_CAPTURE TIMER3_PWM_OUT	TIMER3 trigger input/ PWM output
timer4	I/O	0	TIMER4_PI_EVENT_CAPTURE TIMER4_PWM_OUT	TIMER4 trigger input/ PWM output
timer5	I/O	0	TIMER5_PI_EVENT_CAPTURE TIMER5_PWM_OUT	TIMER5 trigger input/ PWM output
timer6	I/O	0	TIMER6_PI_EVENT_CAPTURE TIMER6_PWM_OUT	TIMER6 trigger input/ PWM output
timer7	I/O	0	TIMER7_PI_EVENT_CAPTURE TIMER7_PWM_OUT	TIMER7 trigger input/ PWM output
timer8	I/O	0	TIMER8_PI_EVENT_CAPTURE TIMER8_PWM_OUT	TIMER8 trigger input/ PWM output

(1) When configured for that function; I = Input, O = Output

NOTE: Each TIMERi_PO_GPOCFG signal is used to as an output enable to control the function of the TIMERi pin (where i = 1 to 8) as the PWM output (PO_GPOCFG =0) or capture input (PO_GPOCFG = 1).

17.2.3 GP Timer Integration

Figure 17-4 shows the integration of the GP timer in the device.

Figure 17-4. GP Timer Integration

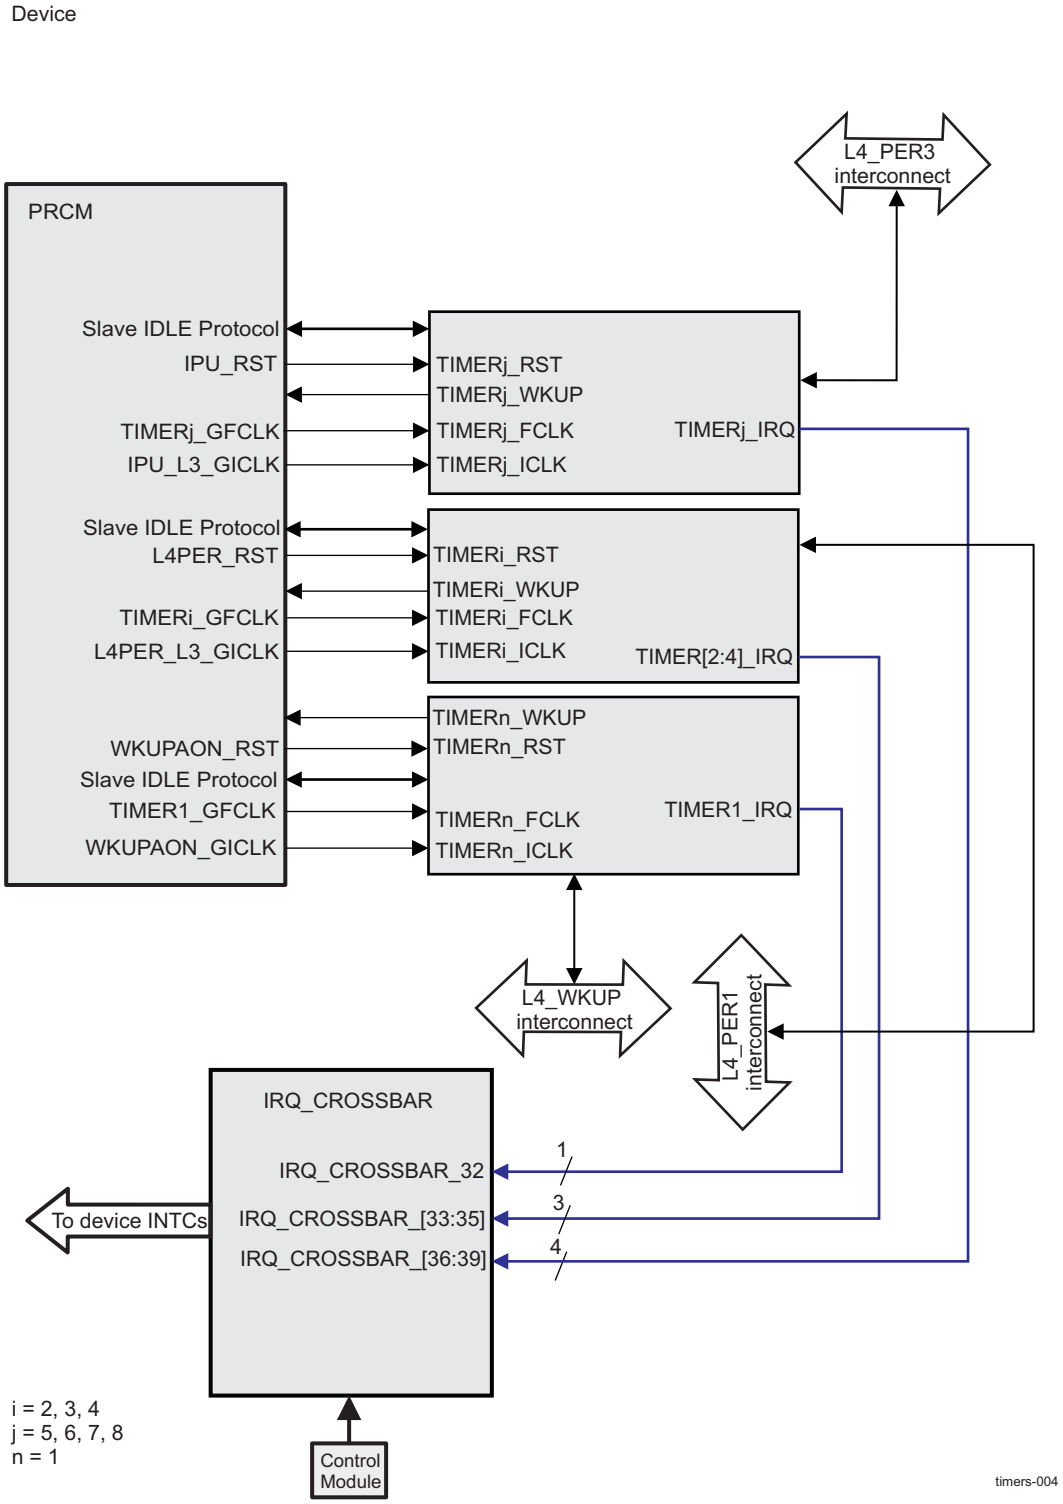

Table 17-2 through Table 17-4 summarize the integration of the module in the device.

Table 17-2. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect

			DSP2_IRQ_70	
No DMA Requests				

NOTE: The Default Mapping column in Table 17-4 shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device interrupt controller through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.
For more information about the device interrupt controllers, see Chapter 12, *Interrupt Controllers*.

NOTE: For the description of the interrupt source, see Section 17.2.4.5, *GP Timer Interrupt*.

17.2.4 GP Timer Functional Description

Each GP timer contains a free-running upward counter with autoreload capability on overflow. The timer counter can be read and written on-the-fly (while counting). Each GP timer includes compare logic to allow an interrupt event on a programmable counter matching value. A dedicated output signal can be pulsed or toggled on either an overflow or a match event. This offers time-stamp trigger signaling or PWM signal sources. A dedicated input signal can be used to trigger an automatic timer counter capture or an interrupt event on a programmable input signal transition. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged into one module interrupt line and one wake-up line.

Each internal interrupt source can be independently enabled and disabled by a dedicated bit in the IRQSTATUS_SET and IRQSTATUS_CLR registers for the interrupt features, and a dedicated bit of the IRQWAKEEN register for the wake-up of TIMER1. In addition, a mechanism implemented in these timers generate an accurate tick interrupt.

For all other internal interrupts, the source can be independently enabled and disabled through the IRQENABLE_SET and IRQENABLE_CLR registers.

For each GP timer implemented in the device, there are two possible clock sources:

- 32-kHz clock
- System clock

The input clock source is selected in the registers in the PRCM configuration (see Section 17.2.1, *GP Timer Overview*).

Each GP timer supports three functional modes:

- Timer mode
- Capture mode
- Compare mode

The capture and compare modes are disabled by default after core reset.

17.2.4.1 GP Timer Block Diagram

Figure 17-5 is a block diagram of the common GP timers, and Figure 17-6 is a block diagram of the GP timers with a 1-ms tick generation module.

Figure 17-5. Block Diagram of TIMER2 Through TIMER8

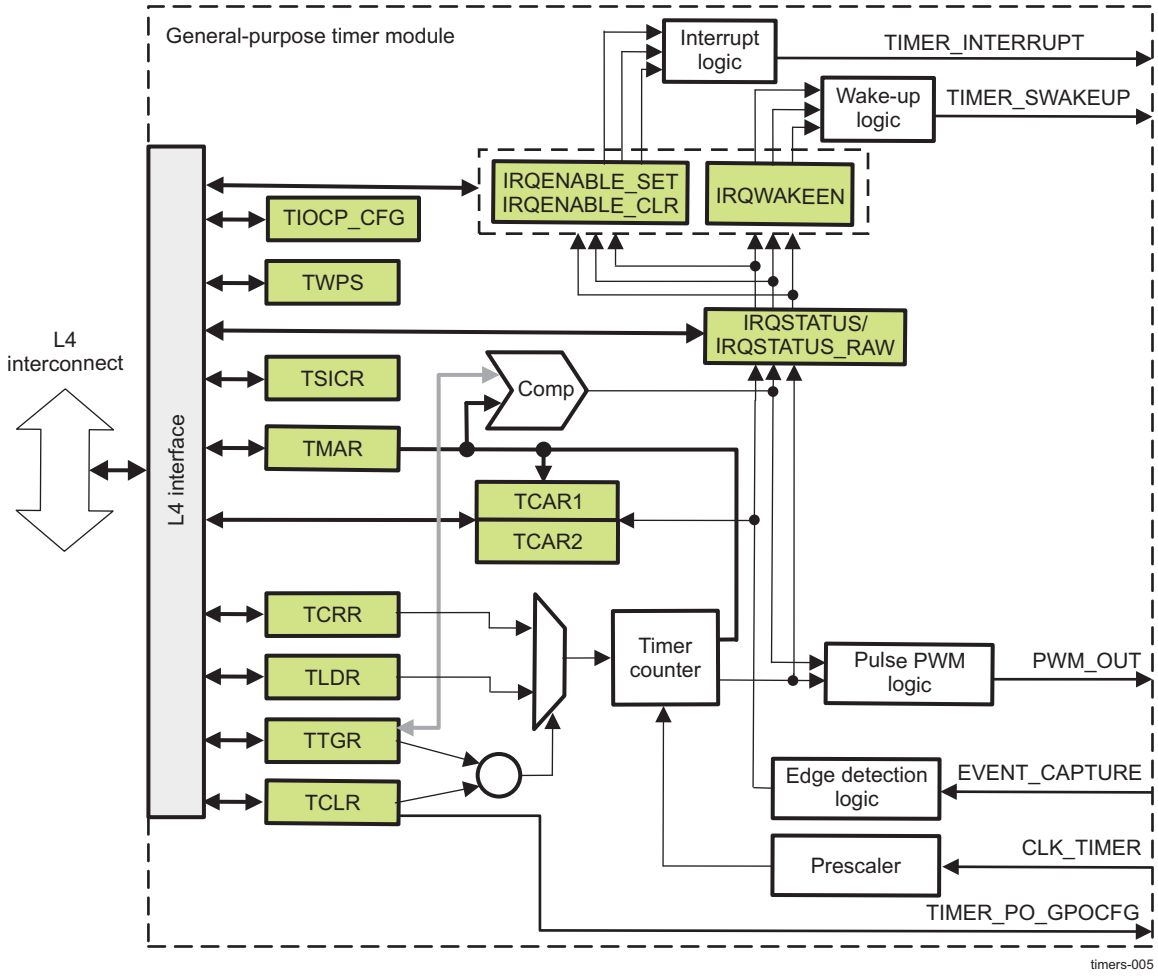

Figure 17-6. Block Diagram of TIMER1

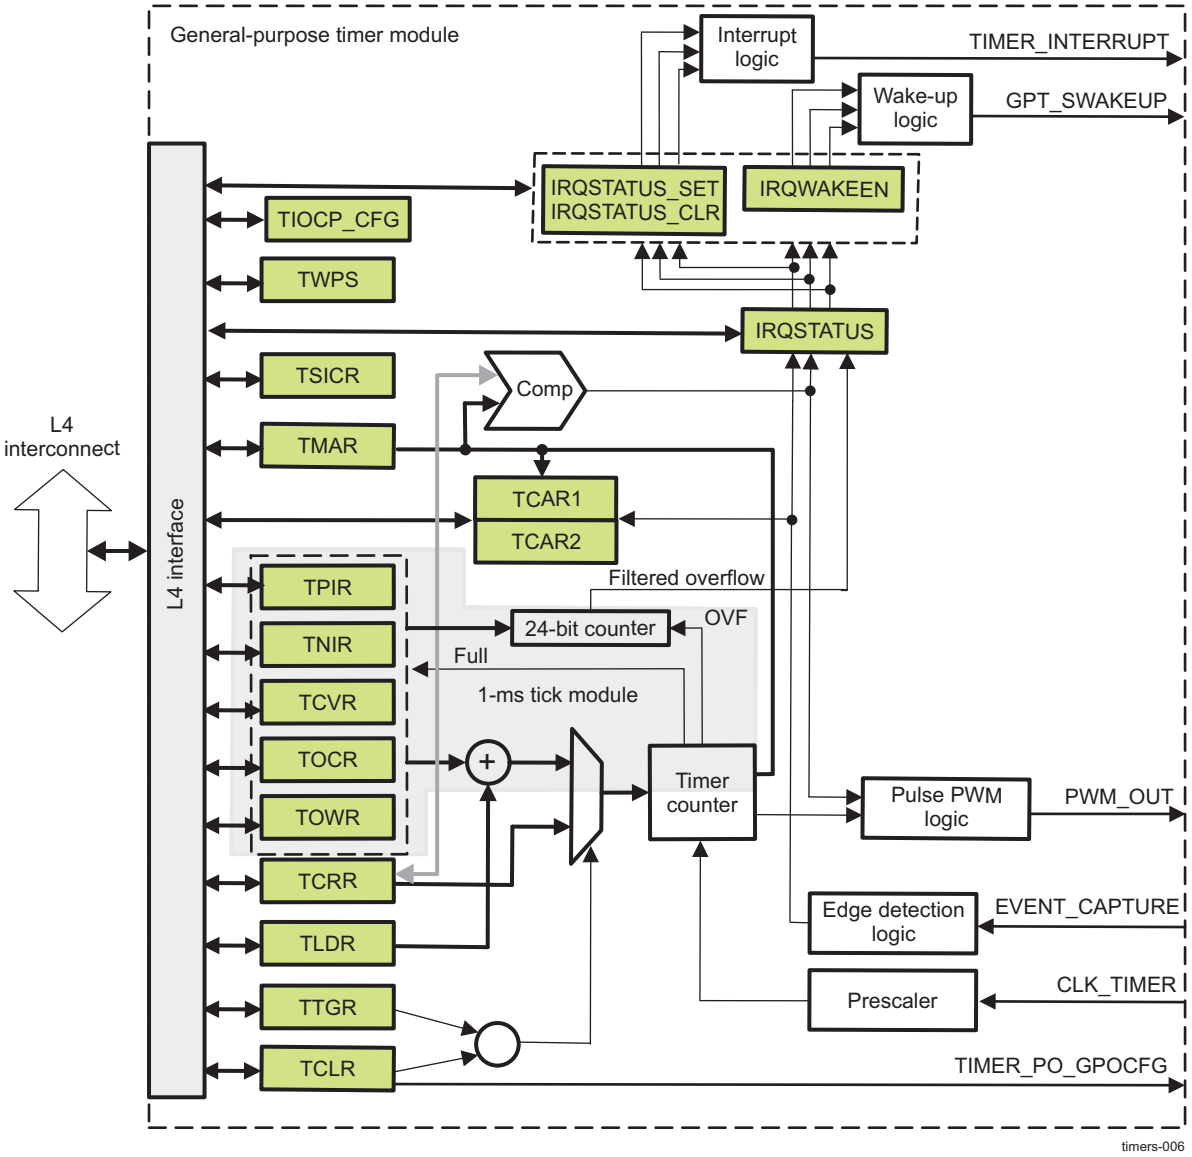


17.2.4.2 TIMER1 Power Management

At the PRCM module level, when all conditions to shut off the functional or interface output clocks in the PRCM module are met (see Section 3.1.1.1.4, *Clock Domain-Level Clock Management*), the PRCM module automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the TIOCP_CFG[3:2] IDLEMODE bit field.

Table 17-5 lists the IDLEMODE settings and the related acknowledgment modes.

Table 17-5. IDLEMODE Settings

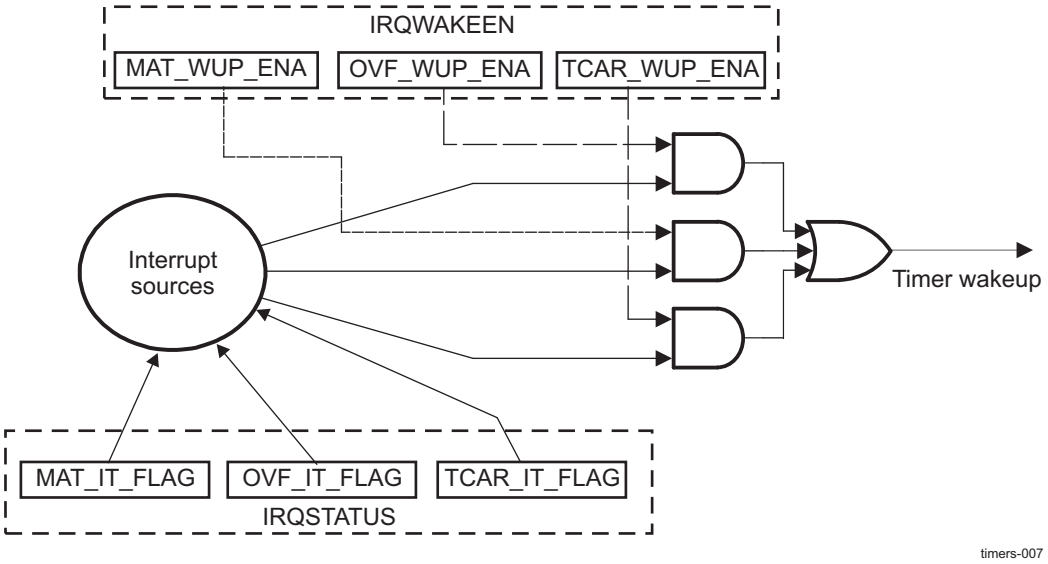
IDLEMODE Value	Selected Mode	Description
00	Force-idle	The GP timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. No-idle mode is not efficient from a power-saving perspective, because it does not allow the PRCM output clock to be shut off, and thus the power domain to be set to a lower power state.
10	Smart-idle	The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach to efficient system power management.
11	Smart-idleWakeup	The module behaves like in smart-idle mode, with the exception, that it can issue a wake-up request in sleep mode, if the functional clock is not cut off.

17.2.4.2.1 Wake-Up Capability

If the TIOCP_CFG[3:2] IDLEMODE bit field sets the smart-idle mode or smart-idle with wakeup mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request if is configured in smart-idle with wakeup mode.

Figure 17-7 shows the wake-up request generation. For more information about the GP timer clock control, see Section 3.6, *Clock Management Functional Description*, in Chapter 3, *Power, Reset and Clock Management*.

Figure 17-7. Wake-Up Request Generation



For TIMER1 the timer wake-up-enable register allows masking of the expected source of the wake-up event that generates a wake-up request. The register is synchronously programmed with the interface clock before the PRCM module sends an idle mode request. The expected source of the wake-up event is an overflow (TCRR), a timer match (the compare result of TCRR and TMAR matches the counter value), and a timer capture (detection of an external pulse transition of the correct polarity on the TIMER_EVENT_CAPTURE).

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (IRQSTATUS). The pending wake-up event is reset when the set status bit is overwritten with 1.

NOTE: The status bit must be reset to re-enter idle mode.

17.2.4.3 Power Management of Other GP Timers

At the PRCM module level, when all conditions to shut off the functional or interface output clocks of the PRCM module are met (see Section 3.1.1.1.4, *Clock Domain-Level Clock Management*), the PRCM module automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the TIOCP_CFG[3:2] IDLEMODE bit field.

Table 17-6 lists the IDLEMODE settings and the related acknowledgment modes.

Table 17-6. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The GP timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. INo-idle mode is not efficient from a power-saving perspective, however, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.

Table 17-6. IDLEMODE Settings (continued)

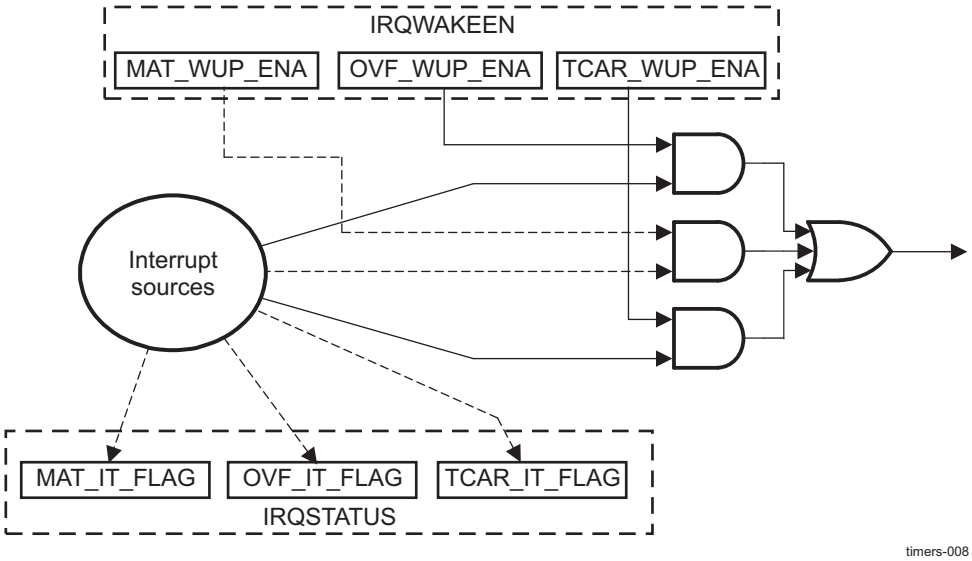
IDLEMODE Value	Selected Mode	Description
10	Smart-idle	The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach to efficient system power management.
11	Smart-idleWakeup	The module behaves like in Smart-idle mode, with the exception, that it can issue a wake-up request in sleep mode, if the functional clock is not cut off.

17.2.4.3.1 Wake-Up Capability

If the TIOCP_CFG[3:2] IDLEMODE bit field sets the smart-idle mode or smart-idle with wakeup mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request if is configured in smart-idle with wakeup mode. This wake-up request is sent only if the IRQWAKEEN[2:0] bit field enables the timer wake-up capability.

Figure 17-8 shows the wake-up request generation. For more information about the GP timer clock control, see Section 3.6, *Clock Management Functional Description*, in Chapter 3, *Power, Reset, and Clock Management*.

Figure 17-8. Wake-Up Request Generation



When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (IRQSTATUS). The pending wake-up event is reset when the set status bit is overwritten with 1.

NOTE: The status bit must be reset to re-enter idle mode.

17.2.4.4 Software Reset

Two bits can generate a software reset of the GP timer:

- TIOCP_CFG[0] SOFTRESET
- TSICR[1] SFT

For both bits, all read accesses return 0.

The TIOCP_CFG[0] SOFTRESET bit allows resetting of the functional and interface domains. The TSICR[1] SFT bit allows resetting the functional part of the GP timer.

Before accessing or using the GP timer, the local host must ensure that both internal resets are released by reading the TIOCP_CFG[0] SOFTRESET bit. This bit monitors the internal reset status.

17.2.4.5 GP Timer Interrupts

The timer can issue an overflow interrupt, a timer match interrupt, and a timer capture interrupt. Each internal interrupt source can be independently enabled and disabled in the interrupt-enable register (IRQSTATUS_SET for TIMER1 and IRQENABLE_SET for other timers) and disabled in the interrupt-disable register (IRQSTATUS_CLR for TIMER1 and IRQENABLE_CLR for other timers). When the interrupt event is issued, the associated interrupt status bit is set in the timer status register (IRQSTATUS).

17.2.4.6 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the timer control register (the TCLR[0] ST bit). The timer counter register (TCRR) can be loaded when stopped or on-the-fly (while counting). TCRR can be loaded directly by a TCRR write access with a new timer value. TCRR can also be loaded with the value held in the timer load register (TLDR) by a trigger register (TTGR) write access. The loading of TCRR is done regardless of the written value of TTGR. The value of TCRR can be read when stopped or captured on-the-fly by a TCRR read access. The timer is stopped and the counter value is set to 0 when the module reset is asserted. The timer is maintained at stop after the reset is released.

In one-shot mode (the TCLR[1] AR bit is set to 0), the counter is stopped after counting overflow occurs (the counter value remains at 0).

When the autoreload mode is enabled (the TCLR[1] AR bit is set to 1), TCRR is reloaded with the value of TLDR after a counting overflow occurs.

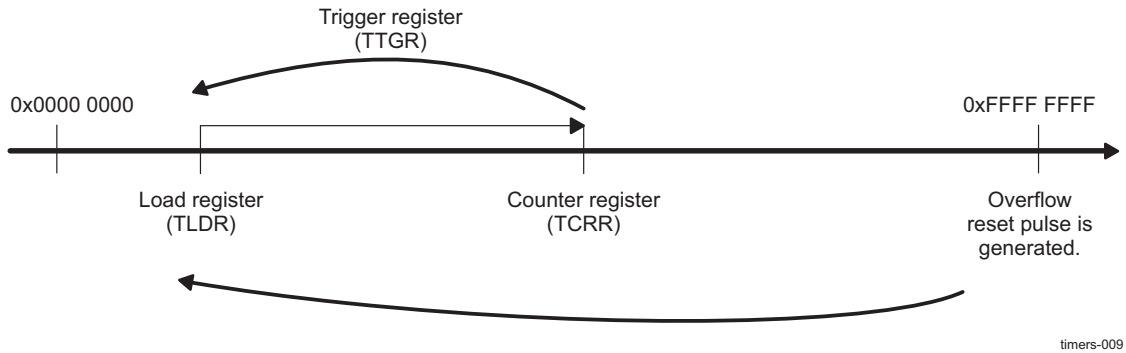
CAUTION

Do not put the overflow value (0xFFFF FFFF) in the TLDR register because it can lead to undesirable results.

An interrupt can be issued on overflow if the overflow interrupt-enable bit is set in the timer interrupt-enable register (the IRQSTATUS_SET[1] OVF_EN_FLAG bit is set to 1 for TIMER1/2/10 and the IRQENABLE_SET[1] OVF_EN_FLAG bit is set to 1 for other timers). A dedicated output pin (timer PWM) can be programmed in the TCLR[12] PT bit through the TCLR[11:10] (PT and TRG bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs. The TCLR[12] PT bit selects pulse/toggle modulation (the TCLR[11:10] TRG bit field selects trigger mode).

Figure 17-9 shows the TCRR timing value.

Figure 17-9. TCRR Timing Value



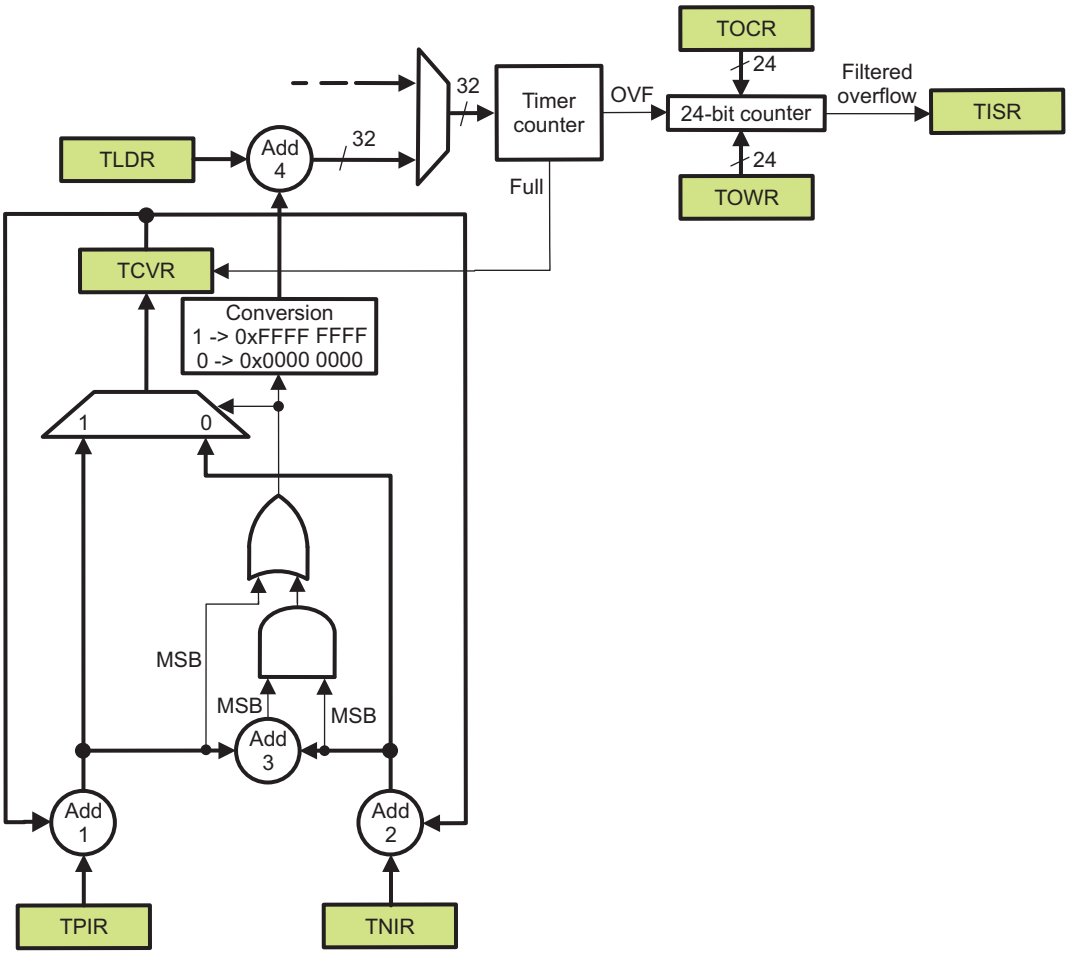
17.2.4.6.1 1-ms Tick Generation (Only TIMER1)

The interrupt period is not exactly 1 ms, because the timer input clock is 32.768 Hz. If the clock counts up to 32, it obtains a 0.977-ms period; if it counts up to 33, it obtains a 1.007-ms period. For large granularity, the error is cumulative and can generate important deviations from the standard value.

To minimize the error between a true 1-ms tick and the tick generated by the 32.768-Hz timer, the sequencing of periods less than 1 ms and periods greater than 1 ms must be shuffled. An additional 1-ms block is used to correct this error. See Figure 17-10.

In this implementation, the increment sequencing is automatically managed by the timer to minimize the error. The user must define only the value of the timer positive increment register (the TPIR[31:0] POSITIVE_INC_VALUE bit field) and the timer negative increment register (the TNIR[31:0] NEGATIVE_INC_VALUE bit field). An automatic adaptation mechanism is used to simplify the programming model.

Figure 17-10. Block Diagram of the 1-ms Tick Module



The TPIR, TNIR, and TCVR registers and adders Add1, Add2, and Add3 are used to define whether the next value loaded in the timer counter register (the TCRR[31:0] TIMER_COUNTER bit field) is the value of the TLDR[31:0] LOAD_VALUE bit field (period less than 1 ms) or the value of TLDR[31:0] LOAD_VALUE –1 (period greater than 1 ms).

Table 17-7 lists the value loaded in the TCRR according to the sign of the result of Add1, Add2, and Add3.

MSB = 0: Positive value; MSB = 1: Negative value

Table 17-7. Value Loaded in TCRR to Generate 1-ms Tick

Add1 MSB	Add2 MSB	Add3 MSB	Value of TCRR Register
0	0	0	TLDR[31:0] LOAD_VALUE bit field
0	0	1	TLDR[31:0] LOAD_VALUE bit field
0	1	0	TLDR[31:0] LOAD_VALUE bit field
0	1	1	TLDR[31:0] LOAD_VALUE –1
1	0	0	N/A
1	0	1	N/A
1	1	0	TLDR[31:0] LOAD_VALUE –1
1	1	1	TLDR[31:0] LOAD_VALUE –1

The values of the TPIR and TNIR registers are calculated using the following formulas:

- Positive increment value = ((INTEGER[F_{clk} × T_{tick}] + 1) × 1e6) – (F_{clk} × T_{tick} × 1e6)
- Negative increment value = (INTEGER[F_{clk} × T_{tick}] × 1e6) – (F_{clk} × T_{tick} × 1e6)

NOTE: F_{clk} clock frequency (kHz)

T_{tick} tick period (ms)

The timer overflow counter register (TOCR) and the timer overflow wrapping register (TOWR) are used to filter interrupts. When the timer overflows, it increments the 24-bit TOCR. When the values in the 24-bit TOCR match the values in the 24-bit TOWR and the timer overflow is asserted, the TOCR is reset and an interrupt is generated to the IRQSTATUS register.

NOTE: TOWR must to be set to requested value. For example, if no interrupt needs to be masked, TOWR must be set to 0; if one interrupt must be masked, TOWR must be set to 1; if two interrupts must be masked TOWR must be set to 2, and so on.

It is important to remember that it is not possible to mask the FFFFFF interrupt.

With the conversion block in reset state (the positive increment register, negative increment register, and counter value register are zeroed), the programming model and the behavior of TIMER1 remain unchanged.

For 1-ms tick with a 32.768-Hz clock:

- TPIR[31:0] POSITIVE_INC_VALUE = 232,000
- TNIR[31:0] NEGATIVE_INC_VALUE = –768,000
- TLDR[31:0] LOAD_VALUE = 0xFFFF FFE0

NOTE: Any value of the tick period can be generated with the appropriate value of the TPIR, TNIR, and TLDR registers.

By default, the TPIR, TNIR, TCVR, TOCR, and TOWR registers and the associated logic are in reset mode (all 0s) and have no effect on the programming model.

17.2.4.7 Capture Mode Functionality

When a transition is detected on the module input pin (EVENT_CAPTURE), the timer value in the TCRR can be captured and saved in the TCAR1 or TCAR2 register function of the mode selected in the TCLR[13] CAPT_MODE bit. The edge detection circuitry monitors transitions on the input pin (EVENT_CAPTURE).

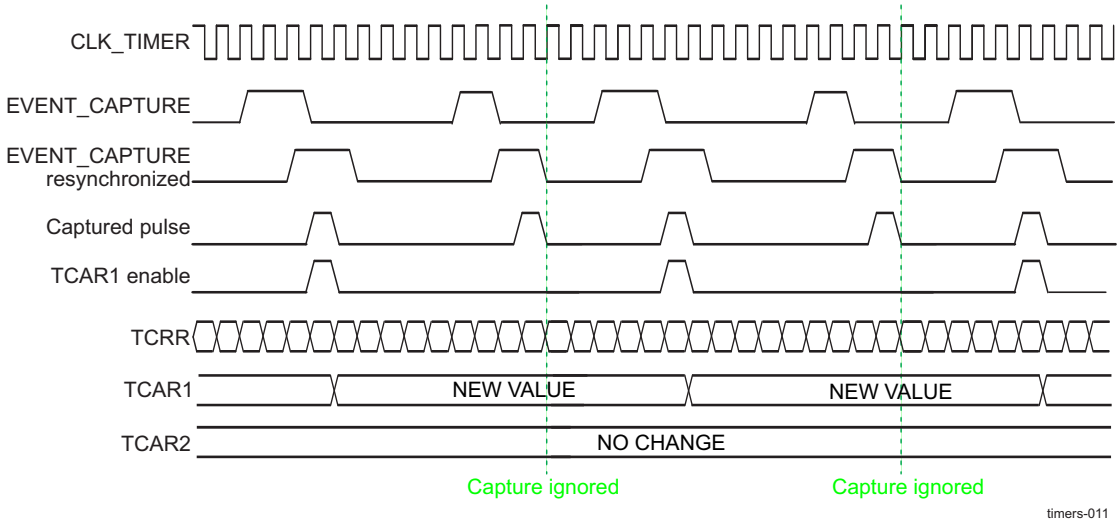
The rising edge, falling edge, or both, can be selected in the TCLR[9:8] TCM bit field to trigger the timer counter capture. The module sets the IRQSTATUS[2] TCAR_IT_FLAG bit when an active edge is detected, and at the same time, the counter value TCRR is stored in timer capture register TCAR1 or TCAR2, as follows:

- If the TCLR[13] CAPT_MODE bit is 0, on the first enabled capture event, the value of the counter register is saved in the TCAR1 register, and the next events are ignored (no update on the TCAR1 register and no interrupt triggering) until the detection logic is reset or the IRQSTATUS[2] TCAR_IT_FLAG is cleared by writing 1 to it.
- If the TCLR[13] CAPT_MODE bit is 1, on the first enabled capture event, the value of the counter register is saved in the TCAR1 register, and on the second enabled capture event, the value of the counter register is saved in the TCAR2 register. If a capture interrupt is enabled, the interrupt triggers on the second event capture. All other events are ignored (no update on TCAR1/TCAR2 and no interrupt triggering) until the detection logic is reset or the IRQSTATUS[2] TCAR_IT_FLAG bit is cleared by writing 1 to it. This mechanism is useful for period calculation of a clock, if that clock is connected to the EVENT_CAPTURE input pin.

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served. The IRQSTATUS[2] TCAR_IT_FLAG bit is cleared by writing 1 to it or when the edge detection mode bits (the TCLR[9:8] TCM bit field) are changed from no-capture mode detection to any other mode. The timer functional clock (input to prescaler) is used to sample the input pin (EVENT_CAPTURE). A negative or positive pulse input can be detected when the pulse time is greater than the functional clock period. An interrupt is issued on edge detection if the capture interrupt-enable bit is set in the IRQSTATUS_SET[2] TCAR_EN_FLAG bit (for TIMER1) or in the IRQENABLE_SET[2] TCAR_EN_FLAG bit (for other timers). See the examples in Figure 17-11 and Figure 17-12.

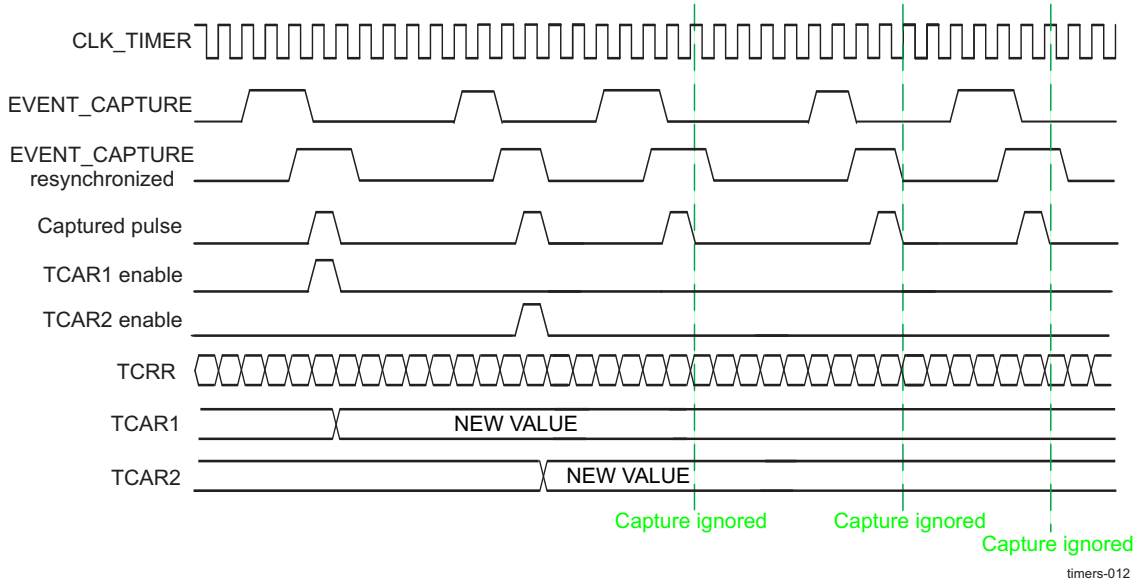
In Figure 17-11, the value of the TCLR[9:8] TCM bit field is 0b01, and the TCLR[13] CAPT_MODE bit is 0. Only the rising edge of EVENT_CAPTURE triggers a capture in the TCAR1 and TCAR2 registers, and only the TCAR1 register updates.

Figure 17-11. Capture Wave Example for TCLR[13] CAPT_MODE = 0



In Figure 17-12, the value of the TCLR[9:8] TCM bit field is 0b01, and the TCLR[13] CAPT_MODE bit is 1. Only the rising edge of EVENT_CAPTURE triggers a capture in the TCAR1 register on the first enabled event, and the TCAR2 register updates on the second enabled event.

Figure 17-12. Capture Wave Example for TCLR[13] CAPT_MODE = 1



17.2.4.8 Compare Mode Functionality

When the TCLR[6] CE bit of the compare-enable register is set to 1, the timer value (the TCRR[31:0] TIMER_COUNTER bit field) is continuously compared to the value held in the timer match register (TMAR). The value of the TMAR[31:0] COMPARE_VALUE bit field can be loaded at any time (timer counting or stopped). When the values of the TCRR and the TMAR registers match, an interrupt is issued, if the IRQSTATUS_SET[0] MAT_EN_FLAG bit (for TIMER1), or the IRQENABLE_SET[0] MAT_EN_FLAG bit (for other timers) is set.

To prevent any unwanted interrupts due to reset value matching effect, write a compare value to the TMAR before setting the TCLR[6] CE bit.

The dedicated output pin (timer PWM) can be programmed in the TCLR[12] PT bit through the TCLR[11:10] TRG bit field to generate one positive pulse (timer clock duration) or to invert the current value (toggle mode) when an overflow or a match occurs.

17.2.4.9 Prescaler Functionality

A prescaler can be used to divide the timer counter input clock frequency. The prescaler is enabled when the TCLR[5] PRE bit is set. The TCLR[4:2] PTV bit field sets the 2^n division ratio (the prescaler value is $2^{(PTV + 1)}$. The prescaler counter is reset when the timer counter is stopped or reloaded on-the-fly.

Table 17-8 lists the prescaler/timer reload values versus contexts.

Table 17-8. Prescaler/Timer Reload Values Versus Contexts

Context	Prescaler	Timer Counter
Overflow (when autoreload is on)	Reset	TLDR[31:0]
TCRR write	Reset	TCRR[31:0]
TTGR write	Reset	TLDR[31:0]
Stop	Reset	Frozen

17.2.4.10 Pulse-Width Modulation

The timer can be configured to provide a programmable PWM output. The timer PWM output pin can be configured to toggle on an event. The TCLR[11:10] TRG bit field determines on which register value the PWM pin toggles. Either overflow or both overflow and match can be selected to toggle the timer PWM pin when a compare condition occurs.

NOTE: In toggle mode, when TCLR[11:10] TRG = 0x2 (overflow and match), the first event that toggles the PWM line is an overflow event. If a match event occurs first, it does not toggle the PWM line (see Figure 17-14).

The TCLR[7] SCPWM bit can be programmed to set or clear the timer PWM output signal only while the counter is stopped or the trigger is off. This allows setting the output pin to a known state before modulation starts. Modulation synchronously stops when the TCLR[11:10] TRG bit field is cleared and overflow occurs. This allows fixing a deterministic state of the output pin when modulation stops.

In Figure 17-13, the internal overflow pulse is set each time the (0xFFFF FFFF – TLDR[31:0] LOAD_VALUE + 1) value is reached, and the internal match pulse is set when the counter reaches the value of TMAR. Depending on the value of the TCLR[12] PT bit and TCLR[11:10] TRG bit field, the timer provides pulse or PWM event on the output pin (timer PWM).

The TLDR and TMAR must keep values below the overflow value (0xFFFF FFFF) by at least two units. If the PWM trigger events are both overflow and match, the difference between the values kept in the TMAR and the value in the TLDR must be at least two units. When match event is used, the compare mode TCLR[6] CE bit must be set.

In Figure 17-13, the TCLR[7] SCPWM bit is set to 0. In Figure 17-14, the TCLR[7] SCPWM bit is set to 1. To obtain the desired wave form, start the counter at 0xFFFF FFFE value (to ensure an overflow first) or adjust the line polarity (TCLR[7] SCPWM bit).

Figure 17-13. Timing Diagram of PWM With TCLR[7] SCPWM Bit = 0

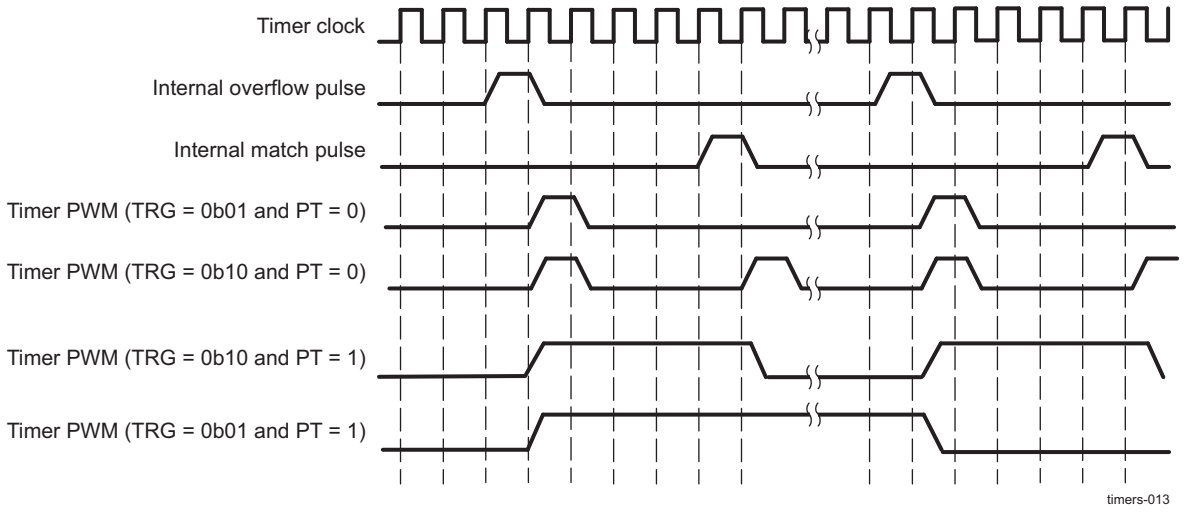


Figure 17-14. Timing Diagram of PWM With TCLR[7] SCPWM Bit = 1

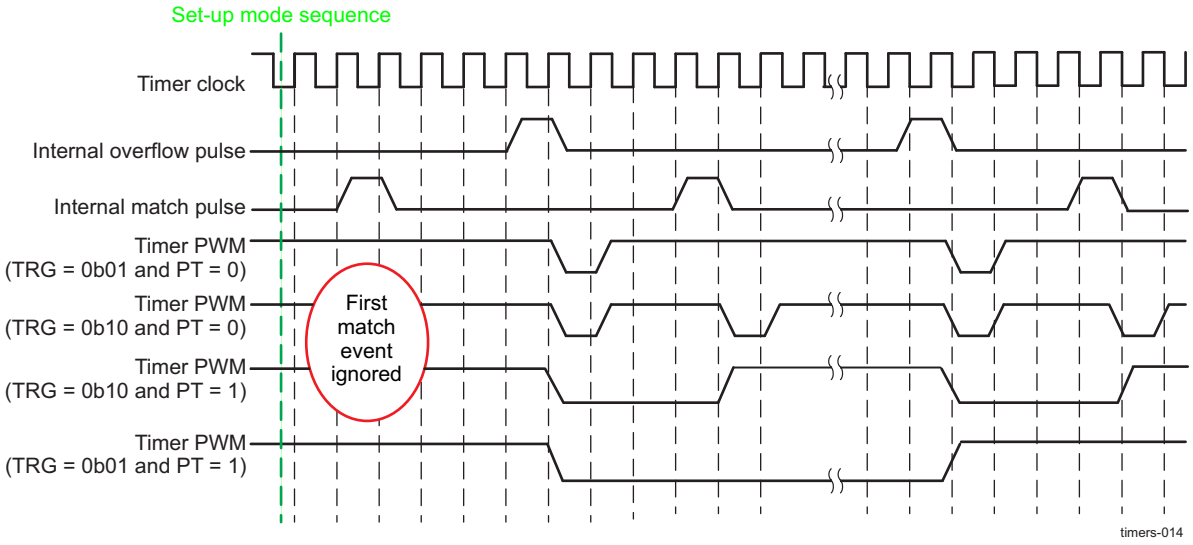

17.2.4.11 Timer Counting Rate

The timer rate is defined by the following values:

- Value of the prescaler fields (the TCLR[5] PRE bit and the TCLR[4:2] PTV bit field)
- Value loaded into the TLDR

Table 17-9 lists the prescaler clock ratio values.

Table 17-9. Prescaler Clock Ratio Values

TCLR[5] PRE	TCLR[4:2] PTV	Divisor (PS)
0	X	1
1	0	2
1	1	4
1	2	8
1	3	16
1	4	32
1	5	64
1	6	128
1	7	256

Thus, the timer overflow rate is expressed as:

OVF_Rate = (0xFFFF FFFF – TLDR + 1) × (timer-functional clock period) × PS

With (timer-functional clock period) = 1/(timer-functional clock frequency) and PS = $2^{(PTV + 1)}$ if prescaler is enabled, or PS = 1 if prescaler is disabled.

NOTE: Internal resynchronization causes any write to the TCLR[1] ST bit to have some latency before the register is updated:

2.5 × functional clock cycles write_TIMER_TCLR_latency 3.5 × functional clock cycles

Remember to consider this latency whenever the timer must be started or stopped by a software change to the TCLR[1] ST bit.

NOTE:

- In non-PWM mode, TLDR must be maintained at less than or equal to 0xFFFF FFFE.
- In PWM mode, TLDR must be maintained at less than or equal to 0xFFFF FFFD.

For example, with a timer clock input of 32 kHz and the TCLR[5] PRE bit set to 0, the timer output period is as listed in Table 17-10.

Table 17-10. Value and Corresponding Interrupt Period

TLDR[31:0] LOAD_VALUE	Interrupt Period
0x0000 0000	37 h
0xFFFF 0000	2 s
0xFFFF FFF0	500 µs
0xFFFF FFFE	62.5 µs

17.2.4.12 Timer Under Emulation

During emulation mode, the timer continues to run according to the value of the TIOCP_ CFG[1] EMUFREE bit.

If the TIOCP_CFG[1] EMUFREE bit is set to 1, timer execution is not stopped in emulation mode and the interrupt is still generated when overflow or match is reached.

If the TIOCP_CFG[1] EMUFREE bit is set to 0, the prescaler and timer are frozen and both resume on exit from emulation mode. The asynchronous external input pin (timerx_pwm_evt, where x = [8:11]) is internally synchronized on two timer-clock rising edges.

17.2.4.13 Accessing GP Timer Registers

All accesses are nonposted until software reconfiguration. All registers are 32 bits wide, accessible through the OCP interface with 16- or 32-bit access (read/write).

Any 16-bit write access must be least significant bit (LSB) first, and the second write access must be most significant bit (MSB) first. Write operations to the following GP timer registers can skip the MSB access if it is not necessary to update the 16 MSBs of the register:

- TIDR (all GP timers)
- TIOCP_CFG (all GP timers)
- IRQSTATUS_SET (GP timer 1)
- IRQSTATUS_RAW (all GP timers)
- IRQSTATUS (all GP timers)
- IRQENABLE_SET (all GP timers except 1)
- IRQENABLE_CLR (all GP timers except 1)
- IRQSTATUS_SET (GP timer 1)
- IRQSTATUS_CLR (GP timer 1)
- IRQWAKEEN (all GP timers)
- TSICR (all GP timers)

Write operations to the following functional registers must be complete (the MSB must be written even if the MSB data is not used):

- TCLR (all GP timers)
- TCRR (all GP timers)
- TLDR (all GP timers)
- TTGR (all GP timers)
- TMAR (all GP timers)

- TPIR (GP timer 1)
- TNIR (GP timer 1)
- TCVR (GP timer 1)
- TOCR (GP timer 1)
- TOWR (GP timer 1)

The following L4 synchronous registers are not affected by the posted/nonposted mode selection; the write/read operation is effective and acknowledged (command accepted) after one L4 clock cycle from command assertion:

- TIDR
- TIOCP_CFG
- IRQSTATUS
- IRQSTATUS_RAW
- IRQENABLE_SET
- IRQENABLE_CLR
- IRQSTATUS_SET
- IRQSTATUS_CLR
- IRQWAKEEN
- TWPS
- TSICR

17.2.4.13.1 Writing to Timer Registers

The host uses the OCP interface to write to the following registers synchronously with the timer interface clock:

- TLDR
- TCRR
- TCLR
- TIOCP_CFG
- IRQSTATUS
- IRQENABLE_SET
- IRQENABLE_CLR
- IRQWAKEEN
- TTGR
- TSICR
- TMAR

TIMER1 also has the following registers:

- IRQSTATUS_SET
- IRQSTATUS_CLR
- TPIR
- TNIR
- TCVR
- TOCR
- TOWR

In 16-bit access mode, the 16 LSBs must be written before writing to the 16 MSBs.

17.2.4.13.1.1 Write Posting Synchronization Mode

This mode is used if the TSICR[2] POSTED bit is set to 1.

This mode uses a posted write scheme to update any internal register (TCLR, TCRR, TLDR, TTGR, TMAR, and TPIR, TNIR, TCVR, TOCR, and TOWR for TIMER1). Therefore, the write transaction is immediately acknowledged on the open-core protocol (OCP) interface, although the effective write operation occurs later because of a resynchronization in the timer clock domain. The advantage is that neither the interconnect nor the device that requested the write transaction is stalled.

For each register, the timer write-posted status (TWPS) register provides a status bit. In this mode, software must check this status bit before any write access. If a write is attempted to a register with a previous access pending, the previous access is discarded without notice.

The timer module updates the value of the timer counter register synchronously with the OCP clock. Consequently, any read access to TCRR does not add any resynchronization latency; the current value is always available.

NOTE: Because the overflow IRQ is generated when the value of TCRR reaches 0xFFFF FFFF, and not when it changes its value to the value after overflow, it is necessary to wait a delay of (1 × PS × timer-functional clock period) before any read access to TCRR to ensure a correct reading of its content.

NOTE: If the TTGR register is written during posted write to TCRR, the value written to TCRR will be discarded.

If a posted write to TCVR is started, the user must not write to TPIR or TNIR before the TCVR write is finished, because the value of TCVR is re-evaluated, so both the value to be written, and the recalculated value will be discarded.

If a write access is pending for a register, reading from this register does not yield a correct result. Software synchronization must be used to avoid incorrect results.

Functional frequency range: freq(timer clock) < freq(OCP interface clock) / 4.

17.2.4.13.1.2 Write Nonposting Synchronization Mode

This mode is used if the TSICR[2] POSTED bit is set to 0 (default value). It uses a nonposted write scheme to update any internal register. Therefore, the write transaction is not acknowledged on the L4 interface until the effective write operation occurs after the resynchronization in the timer functional clock domain. The drawback is that the interconnect and the device that requested the write transaction are stalled during this period.

The same full resynchronization scheme is used for a read transaction, and the same stall period applies. A register read following a write to the same register is always coherent.

This mode is functional regardless of the ratio between the OCP interface frequency and the timer clock frequency.

17.2.4.13.2 Reading From Timer Counter Registers

In 16-bit access mode, reading the 16 LSBs from the timer counter registers (TCRR, TCAR1, and TCAR2) captures the current timer counter value. This must be followed by reading the 16 MSBs. The synchronization schemes for read posted and read non-posted transactions are the same as the corresponded write transactions described before.

NOTE: LSB/MSB accesses cannot be interleaved (that is, the sequence LSB register 1, LSB register 2, MSB register 1, MSB register 2 is not supported).

The TCRR is a 32-bit “atomic datum” and its 16-bit capture is done on the 16-bit LSB first to allow atomic LSB16 + MSB16 capture. This capture scheme is also performed for the TCAR1 and TCAR2 registers as they can be changed due to internal processes too. DSP 16 bit accesses can be interleaved with MCU 32 bit accesses.

NOTE: The counter value of GPTimer5/6/7/8 should be read with a delay of 10 L4_PER clock cycles when the functional clock source is 32kHz and the IPU CD is in the hardware Auto state.

NOTE: The counter value of GPTimer5/6/7/8 can be read without any delay when the functional clock source is 32kHz and the IPU CD is in software Wakeup mode.

17.2.4.13.2.1 Read Posted

This mode is functional whatever the ratio between the OCP interface frequency and the functional clock frequency are. The recommended functional frequency range is freq(timer) < freq(OCP) / 4.

Read posted mode is used if TSICR[2] POSTED = 0x1 or TSICR[3] READ_MODE is set to 0. This mode uses a posted-read scheme for reading any internal timer register. The read transaction is immediately acknowledged on the OCP interface, and the value to be read has been resynchronized. With this method, neither the interconnect nor the device that requested the read transaction are stalled.

Read posted mode applies to TCRR, TCAR1, TCAR2, TCVR, and TOWR, which need resynchronization from functional to OCP clock domains.

17.2.4.13.2.2 Read Non-Posted

This mode is functional regardless of the ratio between the OCP interface frequency and the functional clock frequency. Recommended functional frequency range is freq(timer) >= freq(OCP) / 4.

Read non-posted mode is used if TSICR[2] POSTED = 0x0 and TSICR[3] READ_MODE = 0x1. This mode uses a non-posted read scheme for reading internal timer registers. The read transaction is not acknowledged on the OCP interface until the effective read operation occurs, after the resynchronization in the timer clock domain. The result is that both the interconnect and the device that requested the read transaction are stalled during this period.

This mode applies to TCRR, TCAR1, TCAR2, TCVR, and TOWR, which need resynchronization from functional to OCP clock domains.

17.2.4.14 Posted Mode Selection

A choice between two synchronization modes is made taking into account the frequency ratio and the stall periods that can be supported by the system, without impacting the global performance.

The posted mode selection applies only to registers that require synchronization on or from the timer clock domain. For write operation, the registers affected by posted and non-posted selection are TCLR, TLDR, TCRR, TTGR, TMAR, TPIR, TNIR, TCVR, TOCR, and TOWR. For read operation, the registers affected by this selection are: TCRR, TCAR1, TCAR2, TCVR, and TOWR.

The OCP clock domain synchronous registers TIDR, TIOCP_CFG, IRQSTATUS, IRQSTATUS_SET, IRQWAKEEN, TWPS, and TSICR are not affected by posted and non-posted mode selection. The operation (read or write) is effective and acknowledged after one OCP clock cycle from the command assertion.

The configuration of posted or non-posted mode can be changed (overwritten) by software by writing in TSICR[2] POSTED bit. The TSICR[3] READ_MODE defines how the read operation is performed when the module is configured in non-posted mode (see TSICR). The following cases are possible:

- TSICR[2] POSTED = 0x1 and TSICR[3] READ_MODE = x (don't care): read and write operations are expected in posted mode.
- TSICR[2] POSTED = 0x0 and TSICR[3] READ_MODE = 0x0: the write operation is executed in non-posted mode and read is executed in posted mode.
- TSICR[2]POSTED = 0x0 and TSICR[3] READ_MODE = 0x1: write is executed in non-posted mode and read is executed in non-posted mode.

17.2.5 GP Timer Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

17.2.5.1 Global Initialization

17.2.5.1.1 Global Initialization of Surrounding Modules

This section identifies the requirements for initializing the surrounding modules when the GP timer module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the GP timer. For more information, see Section 17.2.3, *GP Timers Integration*, and Section 17.2.2, *GP Timers Environment*. Table 17-11 summarizes the surrounding modules.

Table 17-11. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. For more information about the module configuration, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
Control module	The module-specific pad muxing must be set in the control module. For more information about the module configuration, see Section 13.4.6.1 *Pad Configuration Registers,* in Chapter 13, *Control Module*.
IRQ_CROSSBAR	The IRQ_CROSSBAR configuration must be done to enable the interrupts from the GP timer module. See Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*.

17.2.5.1.2 GP Timer Module Global Initialization

17.2.5.1.2.1 Main Sequence – GP Timer Module Global Initialization

Table 17-12 identifies the main steps for initializing the GP timer module when the module is to be used for the first time.

Table 17-12. GP Timer Module Global Initialization

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	TIOCP_CFG[0] SOFTRESET	0x1
Wait until reset release?	TIOCP_CFG[0] SOFTRESET	0x0
Configure idle mode.	TIOCP_CFG[3:2] IDLEMODE	0x-
Enable wake-up interrupt events.	IRQWAKEEN[2:0]	0x-
Select posted mode.	TSICR[2] POSTED	0x-

17.2.5.2 Operational Mode Configuration

17.2.5.2.1 GP Timer Mode

17.2.5.2.1.1 Main Sequence – GP Timer Mode Configuration

Table 17-13 lists the steps in the GP timer mode configuration.

Table 17-13. GP Timer Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	0x-
Set prescale timer value.	TCLR[4:2] PTV	0x-
Enable prescaler.	TCLR[5] PRE	0x1

Table 17-13. GP Timer Mode Configuration (continued)

Step	Register/Bit Field/Programming Model	Value
Enable overflow interrupt.	IRQSTATUS_SET[1] OVF_EN_FLAG(1) or IRQENABLE_SET[1] OVF_EN_FLAG(2)	0x1
Load timer counter value.	TCRR	0x-
Load timer load value.	TLDR	0x-
Start the timer.	TCLR[0] ST	0x1

(1) Applies only to TIMER1
(2) Applies to TIMER3 through TIMER8

17.2.5.2.2 GP Timer Compare Mode

17.2.5.2.2.1 Main Sequence – GP Timer Compare Mode Configuration

Table 17-14 lists the steps in the GP timer compare mode configuration.

Table 17-14. GP Timer Compare Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	0x-
Set prescale timer value.	TCLR[4:2] PTV	0x-
Enable prescaler.	TCLR[5] PRE	0x1
Enable match interrupt.	IRQSTATUS_SET[0] MAT_EN_FLAG(1) or IRQENABLE_SET[0]MAT_EN_FLAG(2)	0x1
Load timer counter value.	TCRR	0x-
Load timer compare value.	TMAR	0x-
Enable compare mode.	TCLR[6] CE	0x1
Start the timer.	TCLR[0] ST	0x1

(1) Applies only to TIMER1
(2) Applies to TIMER3 through TIMER8

17.2.5.2.3 GP Timer Capture Mode

17.2.5.2.3.1 Main Sequence – GP Timer Capture Mode Configuration

Table 17-15 lists the steps in the GP timer capture mode configuration.

Table 17-15. GP Timer Capture Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Initialize capture mode.	See Section 17.2.5.2.3.2.	
Enable capture interrupt.	IRQENABLE_SET[2] TCAR_EN_FLAG (1) or IRQSTATUS_SET[2] TCAR_EN_FLAG (2)	0x1
Start the timer.	TCLR[0] ST	0x1
Detect event.	See Section 17.2.5.2.3.3.	

(1) Applies only to TIMER3 through TIMER8
(2) Applies only to TIMER1

17.2.5.2.3.2 Subsequence – Initialize Capture Mode

Table 17-16 lists the steps to initialize capture mode.

Table 17-16. Initialize Capture Mode

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	0x-
Set prescale timer value.	TCLR[4:2] PTV	0x-
Enable prescaler.	TCLR[5] PRE	0x1
Select TIMERi (where i = 2 to 8). Capture input at device pin timeri.	TCLR[14] GPO_CFG	0x1
Select single or second event capture.	TCLR[13] CAPT_MODE	0x-
Select transition capture mode.	TCLR[9:8] TCM	0x-

17.2.5.2.3.3 Subsequence – Detect Event

Table 17-17 lists the steps in detecting an event.

Table 17-17. Detect Event

Step	Register/Bit Field/Programming Model	Value
Wait until event detected?	IRQSTATUS[2] TCAR_IT_FLAG	= 0x1
Read timer capture value.	TCAR1 and/or TCAR2	
Clear capture interrupt request.	IRQSTATUS[2] TCAR_IT_FLAG	0x1

17.2.5.2.4 GP Timer PWM Mode

17.2.5.2.4.1 Main Sequence – GP Timer PWM Mode Configuration

Table 17-18 lists the steps in the GP timer PWM mode configuration.

Table 17-18. GP Timer PWM Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	0x-
Set prescale timer value.	TCLR[4:2] PTV	0x-
Enable prescaler.	TCLR[5] PRE	0x1
Select trigger output mode.	TCLR[11:10] TRG	0x-
Select pulse or toggle modulation PWM mode.	TCLR[12] PT	0x-
Select TIMERi (where i = 2 to 11 and 13 to 16) PWM output at device pin timeri.	TCLR[14] GPO_CFG	0x0
Configure PWM output pin default value.	TCLR[7] SCPWM	0x-
Load timer load value.	TLDR	0x-
Load timer compare value.	TMAR	0x-
Enable compare.	TCLR[6] CE	0x1
Start the timer.	TCLR[0] ST	0x1

17.2.6 GP Timer Register Manual

17.2.6.1 GP Timer Instance Summary

Table 17-19 lists the base address and block size for the GP timer module instances.

Table 17-19. GP Timer Instance Summary

Module Name	Base Address L4_PER1 Interconnect	Base Address L4_PER3 Interconnect	Base Address L4_WKUP Interconnect	Size
TIMER2	0x4803 2000	–	–	92 Bytes
TIMER3	0x4803 4000	–	–	92 Bytes
TIMER4	0x4803 6000	–	–	92 Bytes
TIMER5	–	0x4882 0000	--	92 Bytes
TIMER6	–	0x4882 2000	--	92 Bytes
TIMER7	–	0x4882 4000	--	92 Bytes
TIMER8	–	0x4882 6000	--	92 Bytes
TIMER1	--	–	0x4AE1 8000	112 Bytes

17.2.6.2 GP Timer Registers

17.2.6.2.1 GP Timer Register Summary

CAUTION

The GP timer registers are limited to 32- and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 17-20 through Table 17-22 provide the register summary and associated offset addresses for the 8 GP timer internal registers.

Table 17-20. TIMER1 Register Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	TIMER1 Physical Address L4_WKUP Interconnect

17.2.6.2.2 GP Timer Register Description

Table 17-23 through Table 17-69 describe the individual GP timer registers.

Table 17-23. TIDR

Address Offset	0x0000 0000
Physical Address	See Table 17-20 Table 17-21 Table 17-22 **Instance** See Table 17-19
Description	This read-only register contains the revision number of the module. A write to this register has no effect. This register is used by software to track features, bugs, and compatibility.
Type	R

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REVISION																															

Bits	Field Name	Description	Type	Reset
31: 0	REVISION	IP Revision	R	0x– (1)

(1) TI internal data

Table 17-25. TIOCP_CFG

Address Offset	0x0000 0010		
Physical Address	See Table 17-20 Table 17-21 Table 17-22	**Instance**	See Table 17-19
Description	This register controls the various parameters of the L4 interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												IDLEMODE		EMUFREE	SOFTRESET

Bits	Field Name	Description	Type	Reset
31:4	RESERVED	Reserved	R	0x0000000
3:2	IDLEMODE	Power management, req/ack control 0x0: Force-idle mode: local target idle state follows (acknowledges) the system idle requests unconditionally, that is, regardless of the IP module internal requirements. Back-up mode, for debug only. 0x1: No-idle mode: local target never enters idle state. Back-up mode, for debug only. 0x2: Smart-idle mode: local target idle state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module should not generate (IRQ- or DMA-request-related) wake-up events. 0x3: Smart-idle wake-up-capable mode: local target idle state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module may generate (IRQ- or DMA-request-related) wake-up events when in IDLE state. Mode is relevant only if the appropriate IP module *swake-up* output(s) is (are) implemented.	RW	0x0
1	EMUFREE	Emulation mode 0x0: The timer is frozen in emulation mode (PINSUSPENDN signal active). 0x1: The timer runs free, regardless of PINSUSPENDN value.	RW	0
0	SOFTRESET	Software reset 0x0: Read 0: reset done, no pending action Write 0: No action 0x1: Read 1: initiate software reset Write 1: Reset ongoing	RW	0

Table 17-39. TCLR

Address Offset	0x0000 0038		
Physical Address	See Table 17-20 Table 17-21 Table 17-22	**Instance**	See Table 17-19
Description	This register controls optional features specific to the timer functionality.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																GPO_CFG	CAPT_MODE	PT	TRG		TCM		SCPWM	CE	PRE	PTV			AR	ST	

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Reserved	R	0x00000
14	GPO_CFG	General-purpose output - this register directly drives the PO_GPOCFG output. For specific use of the GPO_CFG bit, see Section 17.2.2.1, *GP Timer External System Interface*. 0x0: PO_GPOCFG drives 0. 0x1: PO_GPOCFG drives 1.	RW	0
13	CAPT_MODE	Capture mode select bit (first/second) 0x0: Single capture: Capture the first enabled capture event in TCAR1. 0x1: Capture on second event: Capture the second enabled capture event in TCAR1 and the second enabled capture event in TCAR2.	RW	0
12	PT	Pulse or toggle mode on TIMERi_PWM_out output pin 0x0: Pulse modulation 0x1: Toggle modulation	RW	0
11:10	TRG	Trigger output mode on TIMERi_PWM_out output pin 0x0: No trigger 0x1: Trigger on overflow. 0x2: Trigger on overflow and match. 0x3: Reserved	RW	0x0
9:8	TCM	Transition capture mode on TIMERi_EVENT_CAPTURE input pin (When the TCM field passed from (00) to any other combination, the TCAR_IT_FLAG and the edge detection logic are cleared.) 0x0: No capture 0x1: Capture on rising edges of TIMERi_EVENT_CAPTURE pin 0x2: Capture on falling edges of TIMERi_EVENT_CAPTURE pin 0x3: Capture on both edges of TIMERi_EVENT_CAPTURE pin	RW	0x0
7	SCPWM	Pulse width modulation output pin default setting This bit must be set or clear while the timer is stopped or the trigger is off. 0x0: Clear the TIMERi_PWM_out output pin and select positive pulse for pulse mode. 0x1: Set the TIMERi_PWM_out output pin and select negative pulse for pulse mode.	RW	0

Bits	Field Name	Description	Type	Reset
6	CE	Compare enable 0x0: Compare mode is disable. 0x1: Compare mode is enable.	RW	0
5	PRE	Prescaler enable 0x0: The TIMER clock input pin clocks the counter. 0x1: The divided input pin clocks the counter.	RW	0
4:2	PTV	Prescale clock timer value The timer counter is prescaled with the value $2^{(PTV+1)}$. Example: PTV = 3, counter increases value (if started) after 16 functional clock periods.	RW	0x0
1	AR	Autoreload mode 0x0: One shot timer 0x1: Autoreload timer	RW	0
0	ST	Start/stop timer control 0x0: Stop timer: Only the counter is frozen. If one-shot mode selected (AR =0), this bit is automatically reset by internal logic when the counter is overflowed. 0x1: Start timer	RW	0

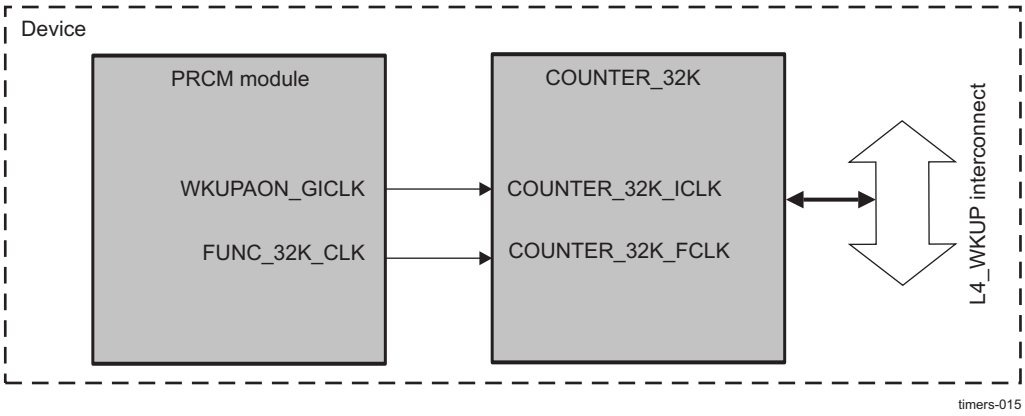
17.3 32-kHz Synchronized Timer (COUNTER_32K)

17.3.1 32-kHz Synchronized Timer Overview

The 32-kHz synchronized timer (COUNTER_32K) is a 32-bit counter clocked by the falling edge of the 32-kHz system clock.

Figure 17-15 is the block diagram of the 32-kHz synchronized timer.

Figure 17-15. 32-kHz Synchronized Timer Block Diagram



17.3.1.1 32-kHz Synchronized Timer Features

The main features of the 32-kHz synchronized timer controller are:

- L4 slave interface (OCP) support:
  - 32-bit data bus width
  - 32-/16-bit access supported
  - 8-bit access not supported
  - 16-bit address bus width
  - Burst mode not supported
  - Write nonposted transaction mode not supported
- Only read operations are supported on the module registers; no write operation is supported (no error/no action on write).
- Free-running 32-bit upward counter
- Start and keep counting after power-on reset
- Automatic roll over to 0; highest value reached: 0xFFFF FFFF
- On-the-fly read (while counting)

17.3.2 32-kHz Synchronized Timer Integration

The synchronized timer is accessible only through the L4_WKUP interface.

Table 17-71 through Table 17-73 summarize the integration of the module in the device.

Table 17-71. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect

17.3.3 32-kHz Synchronized Timer Functional Description

The synchronized timer is a counter that starts on the rising edge of an external asynchronous signal (COUNTER_32K_NRESPWRON). When COUNTER_32K_NRESPWRON is released (on the rising edge of COUNTER_32K_FCLK), the counter starts counting up from the reset value of the counter register on the falling edge of the 32-kHz COUNTER_32K_FCLK clock after three inverted 32-kHz clock periods. After reaching its highest value, the counter wraps back to 0 and starts counting again with no additional delay.

Figure 17-16 shows the reset synchronization timing diagram.

Figure 17-16. Reset Resynchronization Timing Diagram

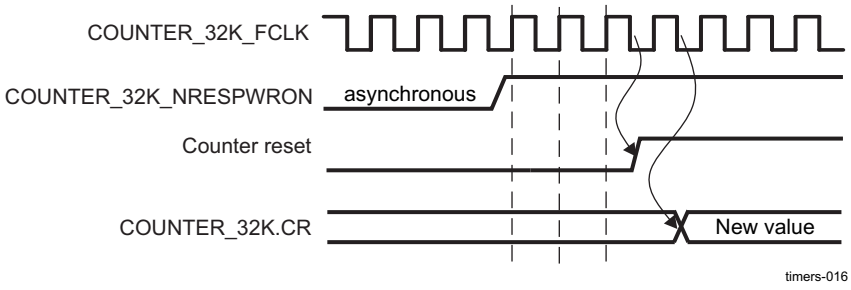

Figure 17-17 is the block diagram of the synchronized timer.

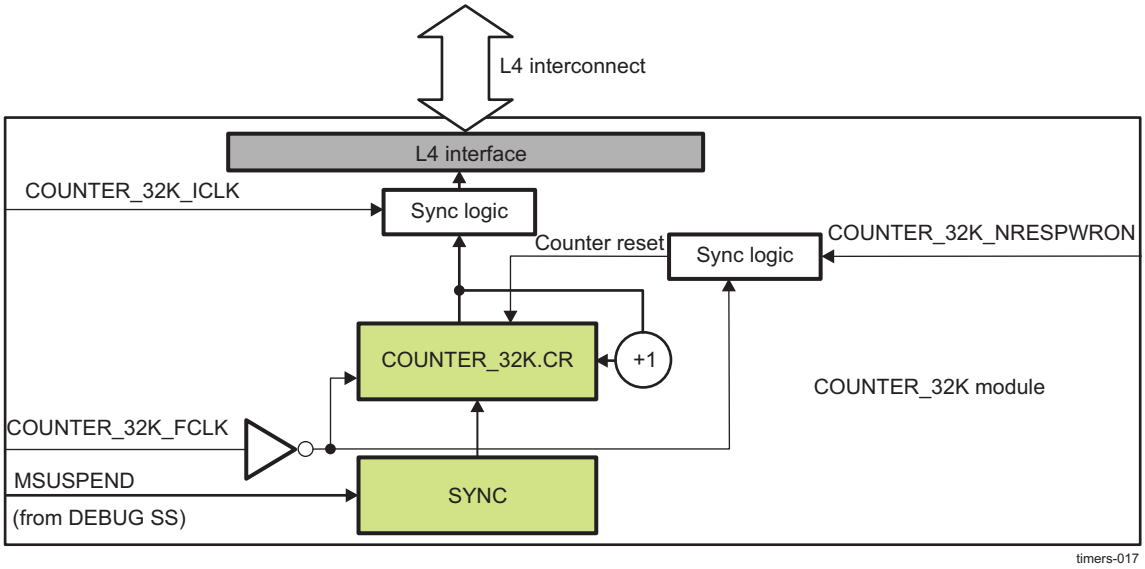
Figure 17-17. CONTER_32K Block Diagram



The sync logic ensures the correctness of the read transaction by synchronizing the counter register read access on COUNTER_32K_ICLK, because the COUNTER_32K_ICLK clock signal is completely asynchronous with COUNTER_32K_FCLK. The COUNTER_32K_NRESPWRON input resets the counter register (CR). The inverted COUNTER_32K_FCLK clocks the counter register CR.

The counting is temporally stopped when MSUSPEND control signal (coming from DEBUG SS) is asserted.

17.3.3.1 Reading the 32-kHz Synchronized Timer

The counter register (CR) is 32 bits wide. For correct count capture, it must be accessed as 16-bit LSB access first and 16-bit MSB access next. The value of the counter is read through the L4 interconnect slave interface. Internal synchronization logic allows the reading of the counter value with COUNTER_32K_ICLK while the counter is running. The time latency to read the synchronized counter register is one COUNTER_32K_ICLK clock period.

The user can select between two syncronization schemes by setting SYSCONFIG[0]SYNCMODE bit.

- SYSCONFIG[0]SYSCMODE = 0x0 - default. In this mode COUNTER_32K timer uses Gray encode/decode scheme. When the L4 interface sends a LSB16 read request command, the 32 bit coded value is registered directly to the interface domain. Due to the characteristics of this encoding if a read command arrives during a count up event either the old or the new value of CR is captured, not a transient value. The captured value will be decoded and send on the SDATA bus. The MSB16 read command reads upper 16 bits of the 32 bit value of counter register captured during the last LSB16 read access.
- SYSCONFIG[0]SYNCMODE = 0x1 - legacy synchronization scheme. In this mode the value of the CR is synchronized to the OCP domain at every count up event. This synchronization is possible because the COUNTER_32K_ICLK is much faster that the 32KHz clock (COUNTER_32K_FCLK). The drawback of this method is that if the interface clock is switched back after wake up from idle mode, the syncronized value will be updated only at the next count up event , until then it will be incorrect.

17.3.4 COUNTER_32K Timer Register Manual

Table 17-74 lists the base address and block size for the 32-kHz synchronized timer. It is memory-mapped to the L4 peripheral bus memory space.

Table 17-74. COUNTER_32KTimer Instance Summary

Module Name	Module Base Address	Size
L4_WKUP_COUNTER_32K	0x4AE0 4000	52 Bytes

17.3.4.1 COUNTER_32K Timer Register Mapping Summary

CAUTION

The 32-kHz synchronized timer registers are limited to 32- and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 17-75 lists the 32-kHz synchronized timer registers. Table 17-76 through Table 17-80 describe the register bits.

Serial Communication Interfaces

This chapter describes the features and operation of the Serial Communication Interfaces (SCI) for the device.

Topic **Page**

18.1 Multimaster I²C Controller

This section describes the two inter-integrated circuit (I²C) controller modules in the device.

NOTE: The device I2C controllers do not support high-speed (HS) mode. See the Device Data Manual for details.

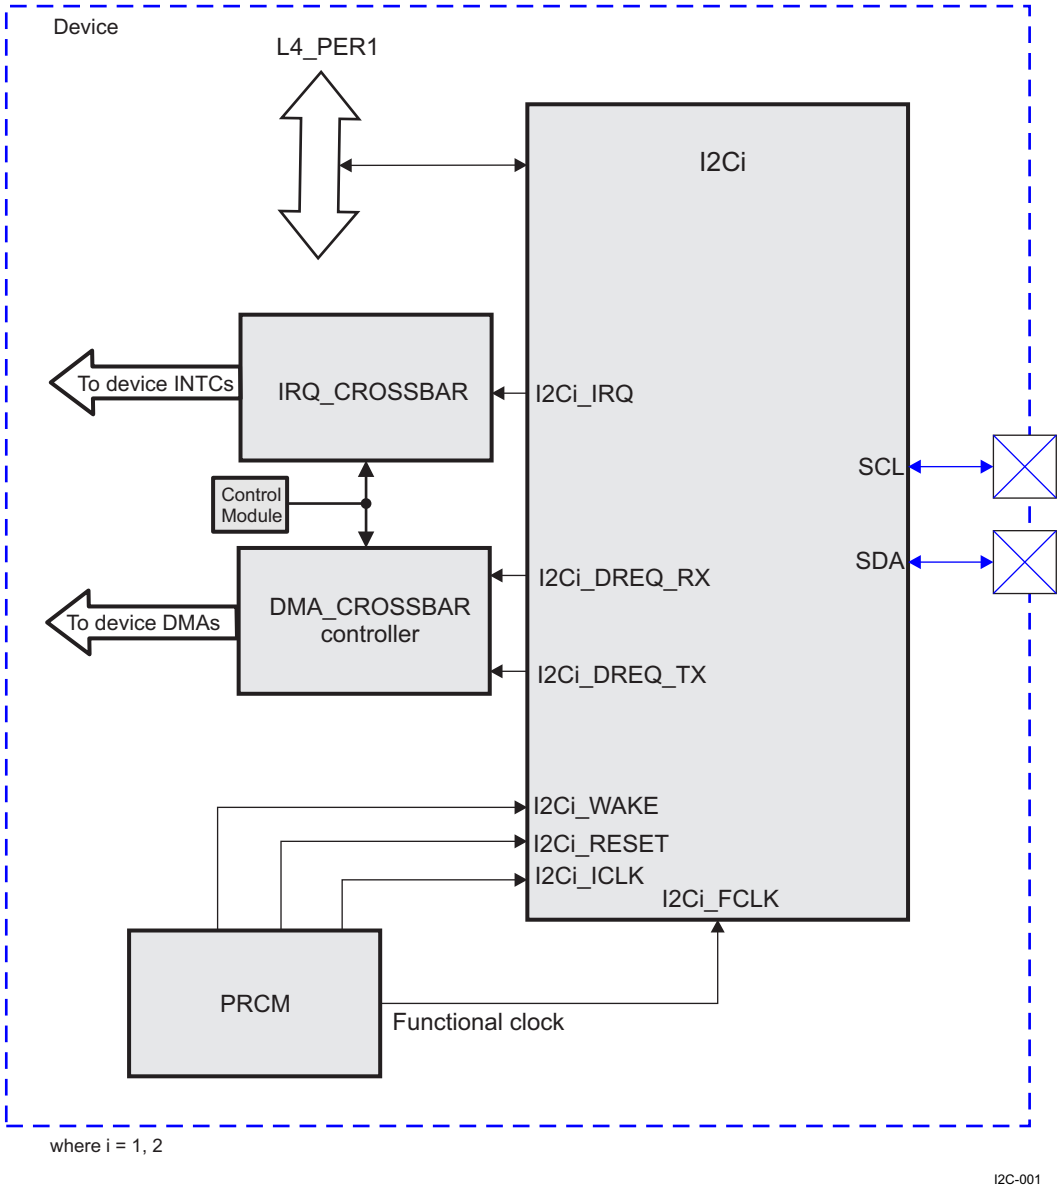
18.1.1 I²C Overview

The device contains two multimaster inter-integrated circuit (I²C) controllers (I2C*i* modules, where *i* = 1, 2) each of which provides an interface between a local host (LH), such as a digital signal processor (DSP), and any I²C-bus-compatible device that connects through the I²C serial bus. External components attached to the I²C bus can serially transmit and receive up to 8 bits of data to and from the LH device through the 2-wire I²C interface.

Each multimaster I²C controller can be configured to act like a slave or master I²C-compatible device.

Figure 18-1 shows the I²C.

Figure 18-1. I²C Controllers



The multimaster I²C controllers have the following features:

- Compliant with Philips I²C specification version 2.1
- Supports a standard mode (up to 100 kbps) and fast mode (up to 400 kbps)
- 7-bit and 10-bit device addressing modes
- General call
- Start/Restart/Stop
- Multimaster transmitter/slave receiver mode
- Multimaster receiver/slave transmitter mode
- Combined master transmit/receive and receive/transmit mode
- Built-in FIFOs (16 bytes) for buffered read or write
- Module enable/disable capability
- Programmable multislave channel (responds to four separate addresses)
- Programmable clock generation

- 8-bit-wide data access
- Designed for low power consumption
- Implement Auto Idle mechanism
- Implement Idle Request/Idle Acknowledge handshake mechanism
- Support for asynchronous wakeup mechanism
- Two direct memory access (DMA) channels
- Wide interrupt capability

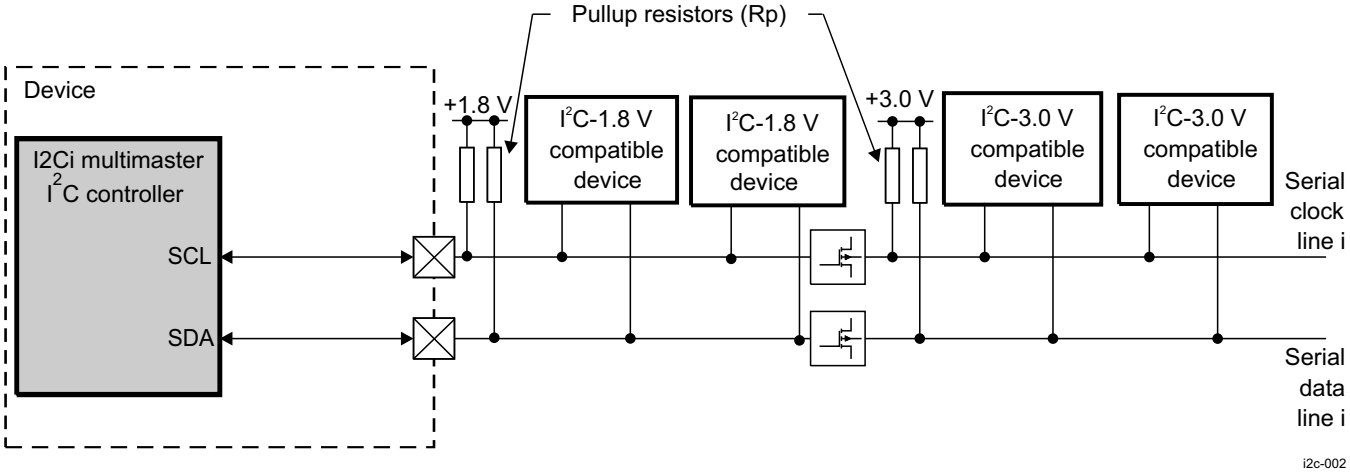
18.1.2 I²C Environment

This section describes the I²C application fields from an environment point of view (external connections). It describes I²C connectivity options, lists all possible interfaces, and describes the protocol and data format used in each case.

18.1.2.1 I²C Typical Application

Figure 18-2 shows the multimaster I²C controllers and their related connections with I²C-compliant devices.

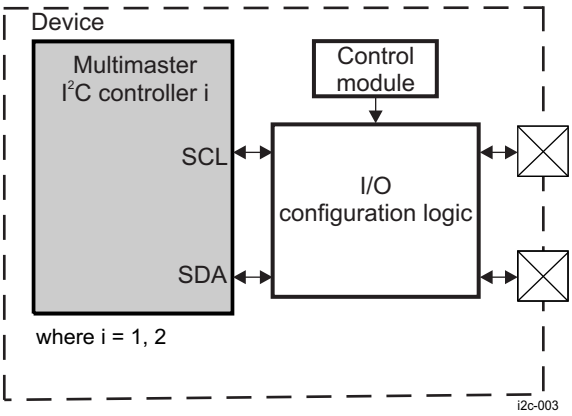
Figure 18-2. I²C and Typical Connections to I²C Devices



18.1.2.1.1 I²C Pins for Typical Connections in I²C Mode

Figure 18-3shows the multimaster I²C controller pins used for typical connections with I²C devices.

Figure 18-3. I²C Interface Signals



18.1.2.1.2 I²C Interface Typical Connections

Table 18-1 lists the pins associated with the I²C interface.

Table 18-1. I²C Input/Output

Signal	Device Level Signal	I/O[1]	Description	Reset Value
SCL	i2c*j*_scl[2]	I/O	I²C serial clock line.	1

(1) I = Input; O = Output
(2) j= 1 and 2

Table 18-1. I²C Input/Output (continued)

Signal	Device Level Signal	I/O[1]	Description	Reset Value
SDA	i2c*j*_sda[2]	I/O	I²C serial data line.	1

NOTE: For the i2c*j*_scl and i2c*i*_scl signals to work properly, the INPUTENABLE bit of the appropriate CTRL_CORE_PAD_x registers should be set to 0x1 because of retiming purposes.

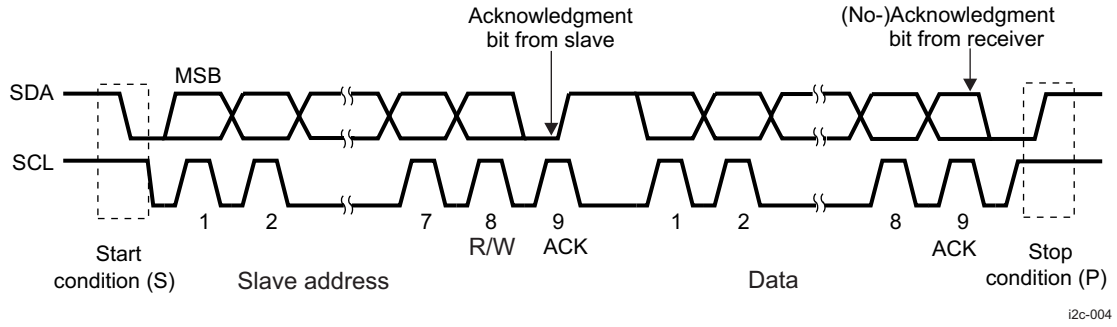
NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. Refer to the sections Section 13.4.6.1 *Pad Functional Multiplexing* of the chapter *Control Module*, for more information.

18.1.2.2 I²C Typical Connection Protocol and Data Format

18.1.2.2.1 I²C Serial Data Format

The I²C controller operates in 8-bit word data format (byte write access supported for the last access). Each byte transmitted or received on the serial data line is 8 bits long. The number of bytes that can be transmitted or received is not restricted. The data is transferred with the most-significant bit (MSB) first. In receiver mode, each byte is followed by an acknowledge bit from the I²C. Figure 18-4 shows a typical I²C communication format.

Figure 18-4. I²C Data Transfer

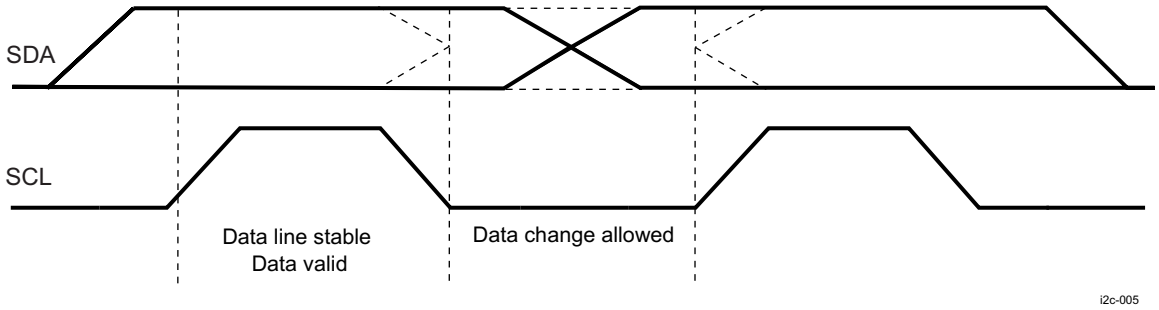


18.1.2.2.2 I²C Data Validity

The data on the serial data line (SDA) must be stable during the high period of the serial clock line. The high and low states of the data line can change only when the clock signal on the serial clock line (SCL) is low.

Figure 18-5 is an example of data validity requirements.

Figure 18-5. I²C Bit Transfer on the I²C Bus



18.1.2.2.3 I²C Start and Stop Conditions

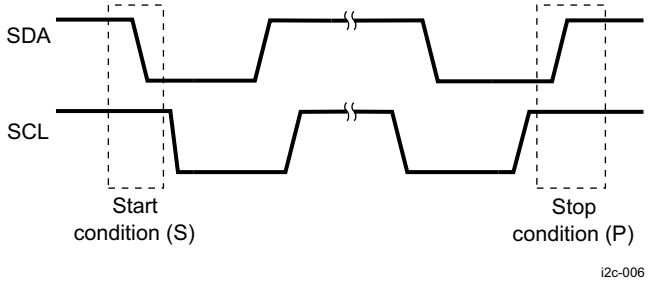
The I²C module generates start (S) and stop (P) conditions when it is configured as a master.

- An S condition is a high-to-low transition on the serial data line while serial clock line is high.
- A P condition is a low-to-high transition on the serial data line while serial clock line is high.

The bus is considered busy after the S condition (the I2C*i*. [12] BB bit is 1 to indicate that the bus is busy) and free after the P condition (the I2C*i*.I2C_IRQSTATUS_RAW [12] BB bit is 0 to indicate that the bus is free).

Figure 18-6 shows the waveforms that occur during an S and a P condition.

Figure 18-6. I²C S and P Condition Events



NOTE: I²C controller does not support messages non-compliant with I2C standard. Void messages are non-standard I²C messages and will lockup the controller. A void message is a START condition followed by a STOP condition, in other words, while the bus is free the SDA line is pulled low (START) and then released (STOP). This would result in a timeout (software) of the next master transfer which would never complete. A soft reset of the controller is recommended for recovery.

18.1.2.2.4 I²C Addressing

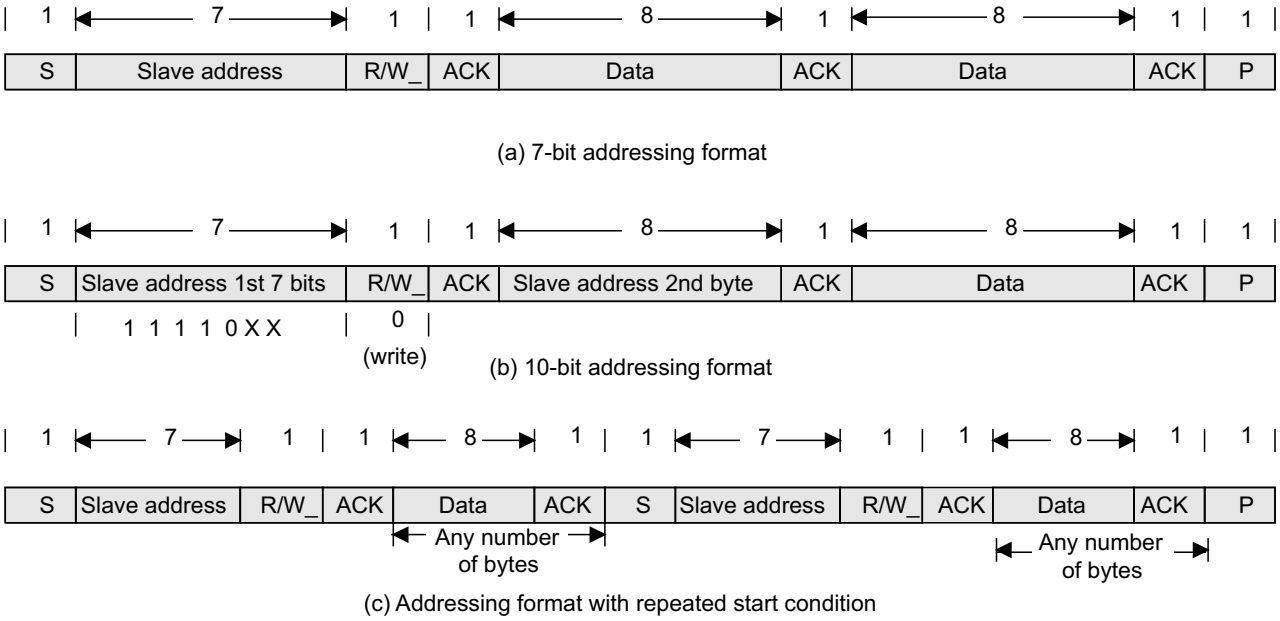
The I²C module supports two data formats in fast/standard (F/S) modes:

- 7-bit/10-bit addressing format
- 7-bit/10-bit addressing format with repeated start (Sr) condition

18.1.2.2.4.1 Data Transfer Formats in F/S Mode

Figure 18-7 shows the I²C data transfer formats in F/S mode.

Figure 18-7. I²C Data Transfer Formats in F/S Mode



The first word after an S condition consists of 8 bits. In acknowledge mode, an extra dedicated acknowledgment bit is inserted after each byte.

In addressing formats with 7-bit addresses, the first byte is composed of 7 MSB slave address bits and 1 least-significant bit (LSB) R/W_ bit.

The LSB R/W_ bit of the address byte indicates the transmission direction of the data bytes that follow it. If R/W_ is 0, the master writes data to the selected slave; if it is 1, the master reads data from the slave.

In addressing formats with 10-bit addresses, the structure of the first byte is 11110XXY, where XX is the two MSBs of the 10-bit addresses, and Y is the R/W_ bit. If the R/W_ bit is 0, the next byte contains the last 8 bits of the slave address. If the R/W_ bit is 1, the next byte contains data transmitted from the slave to the master.

18.1.2.2.5 I²C Master Transmitter

In master transmitter mode, data assembled in one of the previously described data formats is shifted out on the serial data line SDA in sync with the self-generated clock pulses on the serial clock line SCL. The clock pulses are inhibited and SCL is held low when the intervention of the processor is required (XUDF) after a byte is transmitted.

18.1.2.2.6 I²C Master Receiver

Master receiver mode can be entered only from master transmitter mode. With any of the address formats (a), (b), or (c) (see Figure 18-7), if R/W_ is high, the module enters master receiver mode after the slave address byte and bit R/W_ are transmitted. Serial data bits received on bus line SDAI are shifted in synchronization with the self-generated clock pulses on SCLI.

18.1.2.2.7 I²C Slave Transmitter

Slave transmitter mode can be entered only from slave receiver mode. With any of the address formats (a), (b), or (c) (see Figure 18-7), the slave transmitter is entered if the slave address byte is the same as its own address and bit R/W_ is transmitted, if R/W_ is high. The slave transmitter shifts the serial data out on the data line SDA in sync with the clock pulses that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (XUDF).

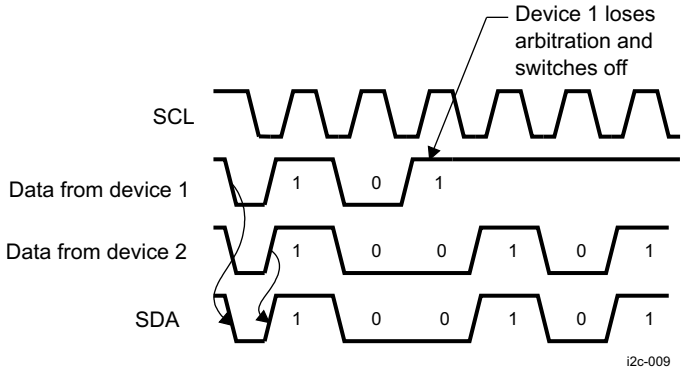
18.1.2.2.8 I²C Slave Receiver

In this mode, serial data bits received on the bus line SDA are shifted-in in sync with the clock pulses on SCL that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (ROVR) after a byte is received.

18.1.2.2.9 I²C Bus Arbitration

If two or more master transmitters start a transmission on the same bus almost simultaneously, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial bus by the competing transmitters. When a transmitter senses that a high signal it has presented on the bus has been overruled by a low signal, it switches to the slave receiver mode, sets the arbitration lost (AL) flag, and generates the arbitration lost interrupt. Figure 18-8 shows the arbitration procedure between two devices. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

Figure 18-8. I²C Arbitration Between Master Transmitters



18.1.2.2.10 I²C Clock Generation and Synchronization

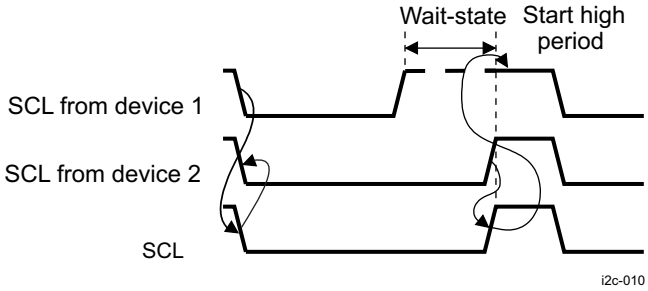
Under normal conditions, only one master device generates the clock signal, SCL. However, there are two or more master devices during the arbitration procedure, and the clock must be synchronized so that the data output can be compared. The wired-AND property of the clock line means that a device that first generates a low period of the clock line overrules the other devices. At this high/low transition, the clock generators of the other devices are forced to start generation of their own low period. The clock line is then held low by the device with the longest low period, while the other devices that finish their low periods must wait for the clock line to be released before starting their high periods. A synchronized signal on the clock line is thus obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period. If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the WAIT-state. In this way a slave can slow down a fast master and the slow device can create enough time to store a received byte or prepare a byte to be transmitted (clock stretching).

NOTE: In case the SCL or SDA lines are stuck low, a bus clearing operation is supported:

- If the clock line (SCL) is stuck low, the preferential procedure is to reset the bus using the hardware reset signal if your I²C devices have hardware reset inputs. If the I²C devices do not have hardware reset inputs, cycle power to the devices to activate the mandatory internal power-on reset (POR) circuit.
- If the data line (SDA) is stuck low, the master should send nine clock pulses. The device that held the bus low should release it sometime within those nine clocks. If not, then use the hardware reset or cycle power to clear the bus.

Figure 18-9 shows clock synchronization.

Figure 18-9. I²C Clock Generators Synchronization

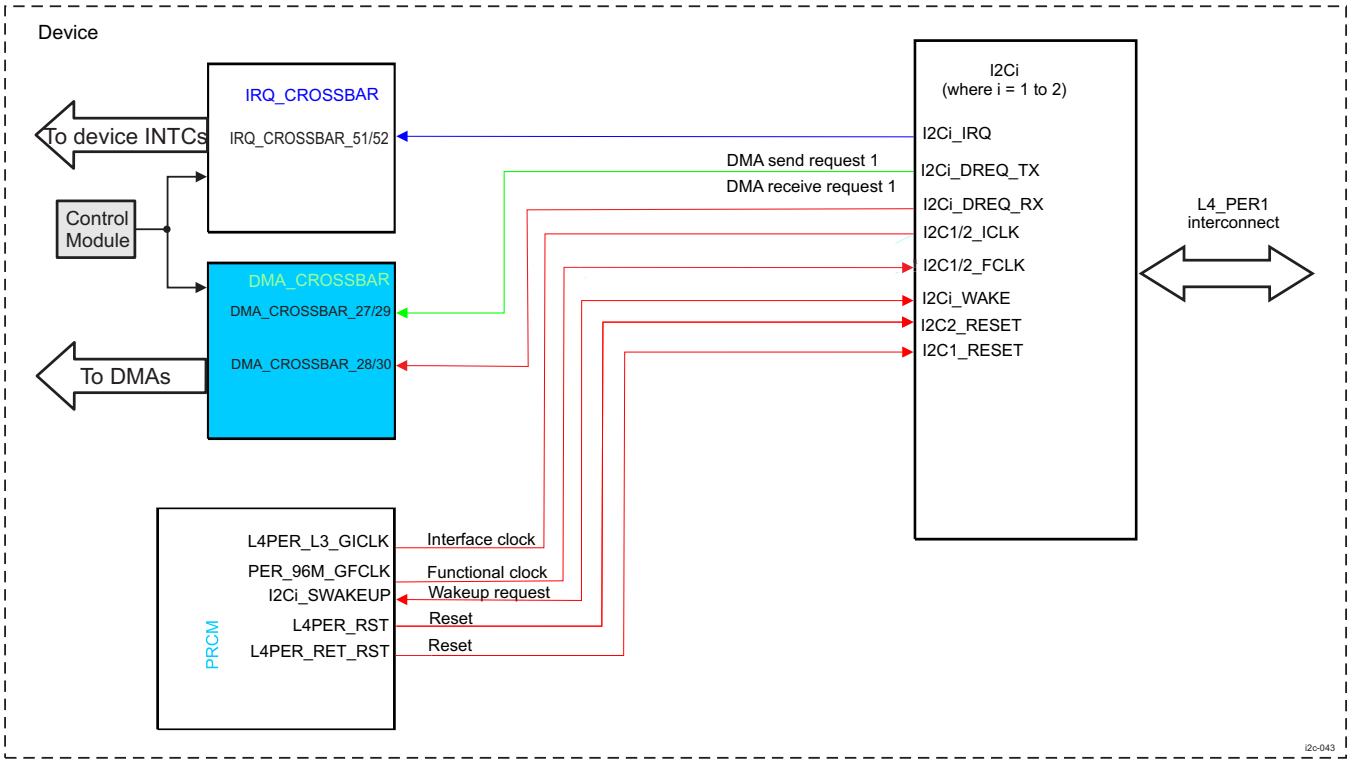


18.1.3 I²C Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 18-10shows the integration of the two I²C controllers in the device.

Figure 18-10. I²C Integration



NOTE: For more information about the slave idle protocol and the wake-up request, see Section 3.7, *Power Management Functional Description*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 18-2 through Table 18-4 summarize the integration of the module in the device.

Table 18-2. I²C Integration Attributes

Module Instance	Attributes

Module Instance	Source Signal Name	Destination DMA_CROSSBAR Input	Default Mapping	Description
I2C1	I2C1_DREQ_TX	DMA_CROSSBAR_27	DMA_EDMA_DREQ_26	I2C1 DMA transmit request
	I2C1_DREQ_RX	DMA_CROSSBAR_28	DMA_EDMA_DREQ_27	I2C1 DMA receive request
I2C2	I2C2_DREQ_TX	DMA_CROSSBAR_29	DMA_EDMA_DREQ_28	I2C2 DMA transmit request
	I2C2_DREQ_RX	DMA_CROSSBAR_30	DMA_EDMA_DREQ_29	I2C2 DMA receive request

NOTE: The "**Default Mapping**" column in Table 18-4 *I²C Hardware Requests* shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.
For more information about the IRQ_CROSSBAR module, see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.
For more information about the DMA_CROSSBAR module, see Section 13.4.6.5, *DMA_CROSSBAR Module Functional Description*, in Section 13.4.6.5Chapter 13, *Control Module*.
For more information about the device interrupt controllers, see Chapter 12, *Interrupt Controllers*.
For more information about the device EDMA module, see Chapter 11, *Enhanced DMA*.

NOTE:

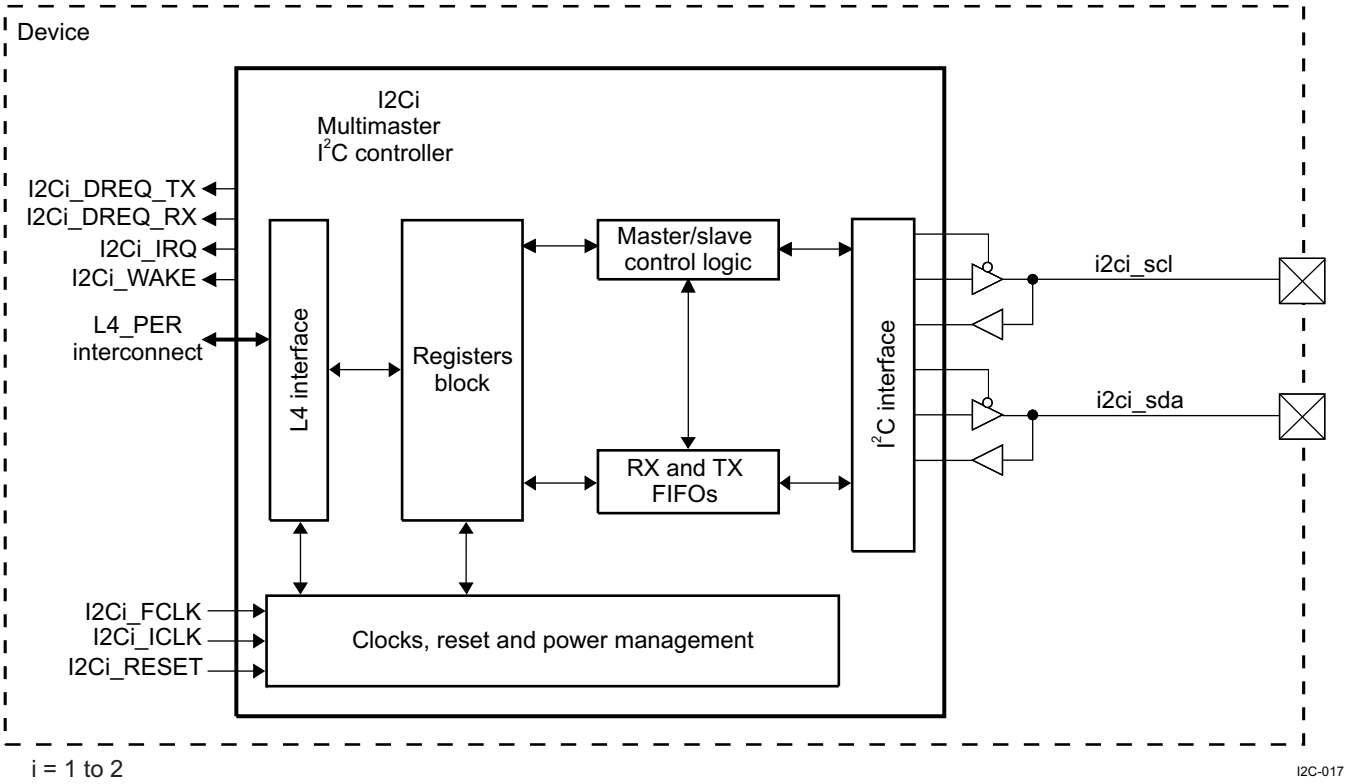
- For a description of interrupt source, see Table 18-10.
- For a description of DMA source, see Table 18-11.

18.1.4 I²C Functional Description

18.1.4.1 I²C Block Diagram

Figure 18-11 is the multimaster I²C controller block diagram.

Figure 18-11. I²C Block Diagram



The two multimaster I²C controllers can be configured in F/S I²C mode . The operation mode is selected by configuring the I2C*i*.I2C_CON[13:12] OPMODE bit field. Table 18-5 lists the available operation modes.

Table 18-5. I²C Operation Mode Selection

Operation Mode	Value of I2C*i*.I2C_CON[13:12] OPMODE Bit Field
F/S I²C	0x0
Reserved	0x1
Reserved	0x2
Reserved (not used)	0x3

18.1.4.2 I²C Clocks

18.1.4.2.1 I²C Clocking

Each multimaster I²C controller uses the I2C*i*_FCLK functional clock in the PRCM module. The internal sampling clock I2C*i*_INTERNAL_CLK is generated by dividing the functional clock by the I2C*i*.I2C_PSC[7:0] PSC bit field value + 1 in F/S mode.

The low time of the I2C*i*_SCLL signal is determined by the I2C*i*.I2C_SCLL[7:0] SCLL bit field in F/S mode.

The high time of the I2C*i*_SCLL signal is determined by the I2C*i*.I2C_SCLH[7:0] SCLH bit field in F/S mode.

Table 18-6 lists the t_{LOW} and t_{high} values in master mode only (in slave mode, the I²C controller does not generate the I²C clock).

Table 18-6. I²C t_{LOW} and t_{high} Values of the I²C Clock

Mode	I2C*i* Clock	t_{LOW}	t_{high}
F/S first phase	I2C*i*_INTERNAL_CLK = I2C*i*_FCLK / (I2C*i*.I2C_PSC[7:0] PSC bit field + 1)	(I2C*i*.I2C_SCLL[7:0] SCLL bit field value + 7) x I2C*i*_INTERNAL_CLK period	(I2Ci.I2C_SCLH [7:0] SCLH bit filed value + 5) x I2Ci_INTERNAL_CLK period

NOTE: The equations in Table 18-6 give the SCLL timing values for SCLL/SCLH/HSSCLL/HSSCLH at I²C controller outputs. Actual tlow and thigh periods may vary depending on the board (the load capacitance on the SCLL signal). If necessary, any adjustments to the SCLL/SCLH/HSSCLL/HSSCLH values must be determined by measurements of actual SCL signal on the board.

CAUTION

During active mode (the I2C*i*.I2C_CON[15] I2C_EN bit is set to 1), make no changes to the I2C*i*.I2C_SCLL and I2C*i*.I2C_SCLH registers. Changes may result in unpredictable behavior.

Table 18-7 lists the register values for obtaining the maximum I²C bit rates and the maximum period of the filtered spikes in F/S modes.

Table 18-7. I²C Register Values for Maximum I²C Bit Rates in I²C F/S Modes(1)

	I²C Mode for I2C*i*,		Description
	Standard Mode	**Fast Mode**	
I2C*i*_FCLK frequency (MHz)	96		
I2C *i* .I2C_PSC[7:0] PSC bit field value	**23**	**9**	Prescaler value for F/S modes
I2C*i*_INTERNAL_CLK frequency (MHz)	4	9.6	
I2C *i* .I2C_SCLL[7:0] SCLL bit field value	**13**	**5**	Value for F/S mode
I2C *i* .I2C_SCLH[7:0] SCLH bit field value	**15**	**7**	Value for F/S mode
Maximum bit rate (Mbps)	0.1	0.4	F/S mode maximum bit rate
Maximum filter period (ns)	250	104.2	
Maximum filter period (ns)			

(1) Programmable fields are in bold.

NOTE: This table presents informative values only for the configuration parameters and the I²C bus performance obtained according to these values. The delays added by the analog pads are not considered in these figures.

NOTE: For I2Ci (where i=1, 2)

I2Ci_INTERNAL_CLK freq = I2Ci_FCLK / (PSC +1)

F/S filter period = 1 / I2Ci_INTERNAL_CLK

FS bit rate = I2Ci_INTERNAL_CLK / (SCLL+ 7 + SCLH + 5)

18.1.4.2.2 I²C Automatic Blocking of the I²C Clock Feature

This feature offers the possibility for the LH to command the blocking of the I²C clock after the slave addressing phase, when the I²C controller is addressed by an external master device using a certain Own Address.

The release of the I²C clock can be performed independently for each Own Address (I2C*i*.I2C_OA, and I2C*i*.I2C_OAx registers, where *i* = 1 to 2, x = 1, 2, 3) by deasserting the corresponding bit in the I2C*i*.I2C_SBLOCK register.

18.1.4.3 I²C Software Reset

Each multimaster I²C controller supports the software reset by accessing the I2C*i*.I2C_SYSC[1] SRST bit (1: reset; 0: normal mode).

The software reset status can be checked by accessing the I2C*i*.I2C_SYSS[0] RDONE bit (1: reset is done; 0: reset is ongoing).

To do a software reset, the following steps must be done:

1. Ensure that the module is disabled (clear the I2C*i*.I2C_CON[15] I2C_EN bit to 0).
2. Set the I2C*i*.I2C_SYSC[1] SRST bit to 1.
3. Enable the module by setting I2C*i*.I2C_CON[15] I2C_EN bit to 1.
4. Check the I2C*i*.I2C_SYSS[0] RDONE bit until it is set to 1 to indicate the software reset is complete.

NOTE: The I2C*i*.I2C_CON[15] I2C_EN bit can hold the functional clock domain of the multimaster I²C controller in reset after the device reset has been released. When the system bus reset is removed, this bit remains cleared. The functional part of the I²C controller is held in reset state while this bit is 0, and all configuration registers can be accessed.

The I2C*i*.I2C_CON[15] I2C_EN bit must be set to 1 to enable the functional part of the I²C controller.

The I2C*i*.I2C_SYSS[0] RDONE bit is asserted only after the module is enabled by setting the I2C*i*.I2C_CON[15] I2C_EN bit to 1.

18.1.4.4 I²C Power Management

Table 18-8 describes power-management features available for the multimaster I²C controllers.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 18-8. I²C Local Power-Management Features

Feature	Registers	Description
Clock auto gating	I2C*i*.I2C_SYSC[0] AUTOIDLE	This bit allows a local power optimization inside the module.
Slave idle modes	I2C*i*.I2C_SYSC[4:3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available.
Clock activity	I2C*i*.I2C_SYSC[9:8] CLOCKACTIVITY	For configuration details, see Table 18-9.
Global wake-up enable	I2C*i*.I2C_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.

NOTE: The voltage controllers, in which the I²C controller is implemented, have no idle request/acknowledge mechanism. The idle modes for the voltage controllers are directly managed by the PRCM module.

Table 18-9. I²C Clock Activity Settings

I2C*i*.I2C_SYSC[9:8] CLOCKACTIVITY	Clock State When Module is in IDLE State		Features Available/Unavailable When Module is in IDLE State
	I2C*i*_ICLK	I2C*i*_ FCLK	
00	OFF	OFF	Both clocks are disabled.
10	OFF	ON	Interface clock is disabled; functional clock is enabled
01	ON	OFF	Functional clock is disabled; interface clock is enabled
11	ON	ON	Both clocks are enabled.

CAUTION

The PRCM module has no hardware means of reading the settings of CLOCKACTIVITY. Thus, software must ensure consistent programming between the I²C CLOCKACTIVITY and I²C clock PRCM control bits. For a description of the ClockActivity feature, see Section 3.1.1.1.2, *Module-Level Clock Management* in Chapter 3, *Power, Reset, and Clock Management*.

18.1.4.5 I²C Interrupt Requests

Table 18-10 lists the event flags, and their mask, that can cause module interrupts.

Table 18-10. I²C Events

Event Flag	Event Unmask	Event Mask	Map to	Description
I2C*i*.I2C_IRQSTATUS[0] AL	I2C*i*.I2C_IRQENABLE_SET[0] AL_IE	I2C*i*.I2C_IRQENABLE_CLR[0] AL_IE	I2C*i*_IRQ	Arbitration lost IRQ enabled status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to the IRQ_Crossbar. During reads, it always returns 0.
I2C*i*.I2C_IRQSTATUS[1] NACK	I2C*i*.I2C_IRQENABLE_SET[1] NACK_IE	I2C*i*.I2C_IRQENABLE_CLR[1] NACK_IE	I2C*i*_IRQ	No acknowledgement IRQ enabled status. Bit is set when No Acknowledge is received, an interrupt is signaled to the IRQ_Crossbar. Write 1 to clear this bit.
I2C*i*.I2C_IRQSTATUS[2] ARDY	I2C*i*.I2C_IRQENABLE_SET[2] ARDY_IE	I2C*i*.I2C_IRQENABLE_CLR[2] ARDY_IE	I2C*i*_IRQ	Register access ready IRQ enabled status. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to the IRQ_Crossbar. Write 1 to clear.
I2C*i*.I2C_IRQSTATUS[3] RRDY	I2C*i*.I2C_IRQENABLE_SET[3] RRDY_IE	I2C*i*.I2C_IRQENABLE_CLR[3] RRDY_IE	I2C*i*_IRQ	Receive data ready IRQ enabled status. Set to 1 by core when receiver mode, a new data can be read. When set to 1 by core, an interrupt is signaled to the IRQ_Crossbar. Write 1 to clear.

Table 18-10. I²C Events (continued)

Event Flag	Event Unmask	Event Mask	Map to	Description
I2C*i*.I2C_IRQSTATUS[4] XRDY	I2C*i*.I2C_IRQENABLE_SET[4] XRDY_IE	I2C*i*.I2C_IRQENABLE_CLR[4] XRDY_IE	I2C*i*_IRQ	Transmit data ready IRQ enabled status. Set to 1 by core when transmitter and when new data is requested. When set to 1 by core, an interrupt is signaled to the IRQ_Crossbar. Write 1 to clear.
I2C*i*.I2C_IRQSTATUS[5] GC	I2C*i*.I2C_IRQENABLE_SET[5] GC_IE	I2C*i*.I2C_IRQENABLE_CLR[5] GC_IE	I2C*i*_IRQ	General call IRQ enabled status. Set to 1 by core when General call address detected and interrupt signaled to the IRQ_Crossbar. Write 1 to clear.
I2C*i*.I2C_IRQSTATUS[6] STC	I2C*i*.I2C_IRQENABLE_SET[6] STC_IE	I2C*i*.I2C_IRQENABLE_CLR[6] STC_IE	I2C*i*_IRQ	Start condition IRQ enabled status.
I2C*i*.I2C_IRQSTATUS[7] AERR	I2C*i*.I2C_IRQENABLE_SET[7] AERR_IE	I2C*i*.I2C_IRQENABLE_CLR[7] AERR_IE	I2C*i*_IRQ	Access Error IRQ enabled status.
I2C*i*.I2C_IRQSTATUS[8] BF	I2C*i*.I2C_IRQENABLE_SET[8] BF_IE	I2C*i*.I2C_IRQENABLE_CLR[8] BF_IE	I2C*i*_IRQ	Access Error IRQ enabled status.
I2C*i*.I2C_IRQSTATUS[9] AAS	I2C*i*.I2C_IRQENABLE_SET[9] AAS_IE	I2C*i*.I2C_IRQENABLE_CLR[9] AAS_IE	I2C*i*_IRQ	Address recognized as slave IRQ enabled status.
I2C*i*.I2C_IRQSTATUS[10] XUDF	I2C*i*.I2C_IRQENABLE_SET [10] XUDF_IE	I2C*i*.I2C_IRQENABLE_CLR[10] XUDF_IE	I2C*i*_IRQ	Transmit underflow enabled status. Writing into this bit has no effect.
I2C*i*.I2C_IRQSTATUS[11] ROVR	I2C*i*.I2C_IRQENABLE_SET [11] ROVR_IE	I2C*i*.I2C_IRQENABLE_CLR[11] ROVR_IE	I2C*i*_IRQ	Receive overrun enabled status. Writing into this bit has no effect.
I2C*i*.I2C_IRQSTATUS[12] BB	Reserved	Reserved	I2C*i*_IRQ	Bus busy enabled status. Writing into this bit has no effect.
I2C*i*.I2C_IRQSTATUS[13] RDR	I2C*i*.I2C_IRQENABLE_SET [13] RDR_IE	I2C*i*.I2C_IRQENABLE_CLR[13] RDR_IE	I2C*i*_IRQ	Receive draining IRQ enabled status.
I2C*i*.I2C_IRQSTATUS[14] XDR	I2C*i*.I2C_IRQENABLE_SET [14] XDR_IE	I2C*i*.I2C_IRQENABLE_CLR[14] XDR_IE	I2C*i*_IRQ	Transmit draining IRQ enabled status.

18.1.4.6 I²C DMA Requests

Each multimaster I²C controller can generate two DMA requests to the device DMA controllers through the DMA_CROSSBAR module. Table 18-11 lists the DMA requests. For information about DMA generation, see Section 18.1.4.8.3, *I²C FIFO DMA Mode (I²C Mode Only)*.

Table 18-11. I²C DMA Requests

Name	Source	Description
I2C1_DREQ_TX	I2C1	I2C1 DMA write request to inform the DMAs to write new data in the I2C1.I2C_DATA[7:0] DATA bit field
I2C1_DREQ_RX	I2C1	I2C1 DMA read request to inform the DMAs to read the data in the I2C1.I2C_DATA[7:0] DATA bit field
I2C2_DREQ_TX	I2C2	I2C2 DMA write request to inform the DMAs to write new data in the I2C2.I2C_DATA[7:0] DATA bit field
I2C2_DREQ_RX	I2C2	I2C2 DMA read request to inform the DMAs to read the data in the I2C2.I2C_DATA[7:0] DATA bit field

NOTE: For more information about I2C*i*_DREQ_TX and I2C*i*_DREQ_RX(where *i* = 1 to 2) signals mapping to DMA_CROSSBAR, see Section 11.3.2, *Mapping of DMA Requests to DMA_CROSSBAR Inputs*, in Table 18-4, *I²C Hardware Requests*.

18.1.4.7 I²C Programmable Multislave Channel Feature

This feature allows each multimaster I²C controller to be addressed using four separate Own Addresses configured in the I2C*i*.I2C_OA and I2C*i*.I2C_OAx registers (where = 1 to 2 , x = 1, 2, 3). An additional register (I2C*i*.I2C_ACTOA) is used to indicate to the LH which address is used by the external master to communicate with the I²C controller.

Each Own Address can be independently configured in 7-bit or 10-bit mode by setting the corresponding bit (I2C*i*.I2C_CON[7] XOA0, I2C*i*.I2C_CON[6] XOA1, I2C*i*.I2C_CON[5] XOA2, or I2C*i*.I2C_CON[4] XOA3).

18.1.4.8 I²C FIFO Management

Each multimaster I²C controller implements two internal 8-bit FIFOs, the RX and TX FIFOs.

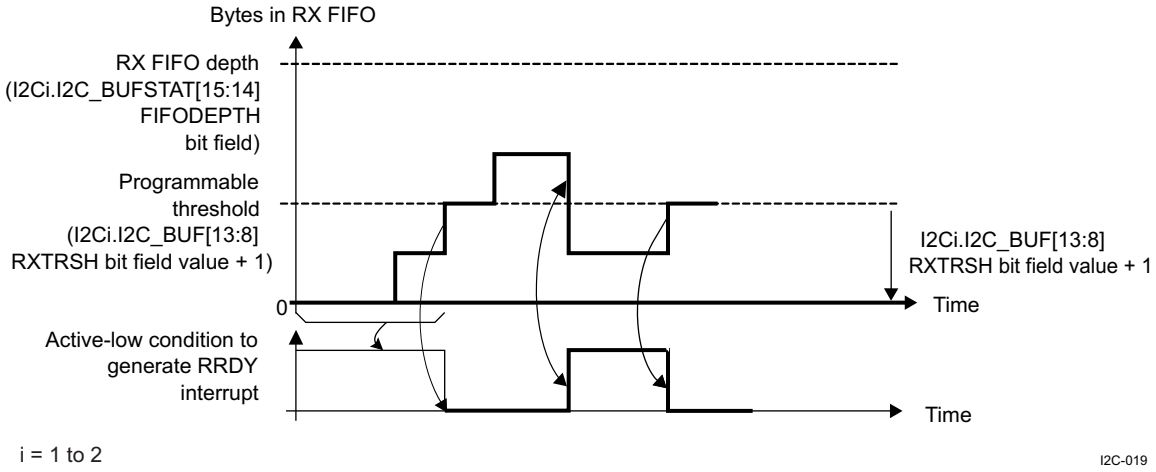
The depth of the RX and TX FIFOs can be checked by reading the I2C*i*.I2C_BUFSTAT[15:14] FIFODEPTH bit field (0x0: 8 bytes, 0x1: 16 bytes, 0x2: 32 bytes, and 0x3: 64 bytes).

18.1.4.8.1 I²C FIFO Interrupt Mode

In FIFO interrupt mode (relevant interrupts enabled by the I2C*i*.I2C_IRQENABLE_SET register), an interrupt signal informs the processor of the receiver and transmitter status. These interrupts are raised when the RX/TX FIFO thresholds (defined by the I2C*i*.I2C_BUF[13:8] RXTRSH bit field value + 1 for the RX FIFO or the I2C*i*.I2C_BUF[5:0] TXTRSH bit field value + 1 for the TX FIFO) are reached; the interrupt signals instruct the LH to transfer data to the destination (from the I²C controller in receive mode and/or from any source to the I²C controller FIFO in transmit mode).

Figure 18-12 and Figure 18-13 show receive and transmit operations, respectively, from a FIFO management point of view.

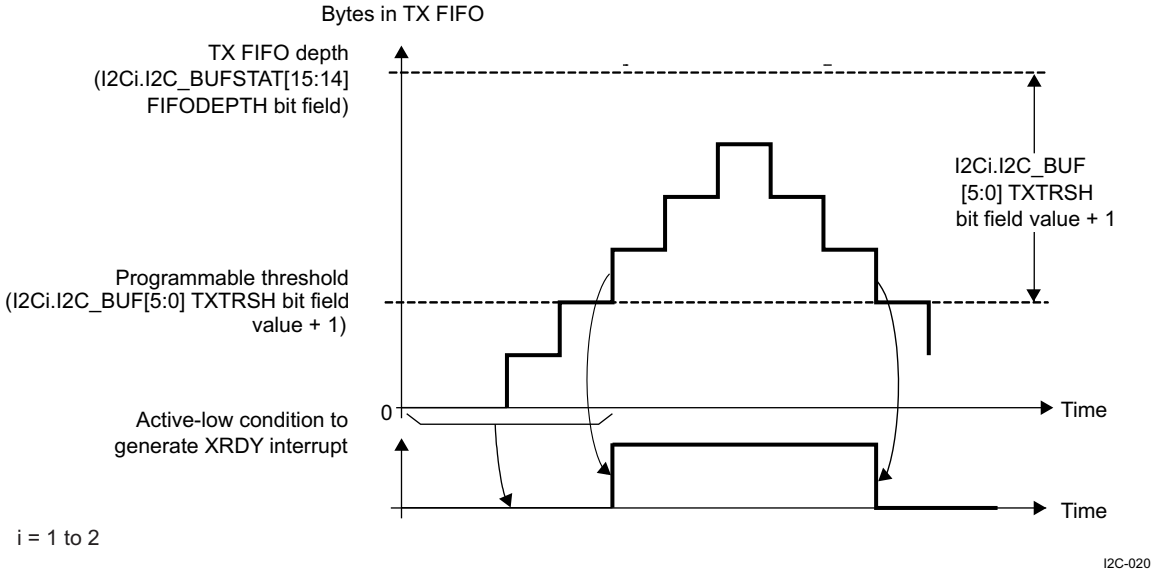
Figure 18-12. I²C Receive FIFO Interrupt Request Generation



In Figure 18-12, the RRDY interrupt condition shows that the condition for generating an RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the LH by writing 1 in the corresponding bit. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In receive mode, an RRDY interrupt is generated as soon as the FIFO reaches its receive threshold (I2C*i*.I2C_BUF[13:8] RXTRSH bit field value + 1). The interrupt can be deasserted only when the LH has handled enough bytes to make the number of bytes in the RX FIFO lower than the programmed threshold. For each interrupt, the LH can be configured to read a number of bytes equal to the value of the RX FIFO threshold.

Figure 18-13. I²C Transmit FIFO Interrupt Request Generation



In Figure 18-13, the XRDY interrupt condition shows that the condition for generating an XRDY interrupt is achieved. The interrupt request is generated when TX FIFO is empty or when the TX FIFO threshold is not reached, and the LH can clear the XRDY status bit by setting the I2C*i*.I2C_IRQENABLE_CLR [4] XRDY_IE bit to 1 after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In interrupt mode, the module offers two options for the LH application to handle the interrupts:

- When detecting an interrupt request (XRDY or RRDY type), the LH can write/read 1 data byte to/from the TX/RX FIFO and then clear the interrupt. The module reasserts the interrupt until the interrupt condition is not met.
- When detecting an interrupt request (XRDY or RRDY type), the LH can be programmed to write/read the amount of data bytes specified by the corresponding FIFO threshold (I2C_BUF[5:0] TXTRSH + 1 or I2C_BUF[5:0] RXTRSH + 1). In this case, the interrupt condition is cleared and the next interrupt is asserted again when the XRDY or RRDY condition is met again.

If the second-interrupt-serving approach is used, an additional mechanism (draining feature) is implemented for cases where the transfer length is not a multiple of the FIFO threshold value (see Section 18.1.4.8.4, *Draining Feature [I²C Mode Only]*).

NOTE: In slave transmit mode (the I2C*i*.I2C_CON[10] MST bit is cleared and the I2C*i*.I2C_CON[9] TRX bit is set to 1), the draining feature must not be used, because the transfer length is not known at configuration time, and the external master can end the transfer at any point by not acknowledging 1 data byte. If the draining feature is used in slave transmit mode, data can remain in the TX FIFO without being transmitted over the I²C bus. In this case, the TX FIFO must be cleared by setting the I2C*i*.I2C_BUF[6] TXFIFO_CLR bit.

18.1.4.8.2 I²C FIFO Polling Mode

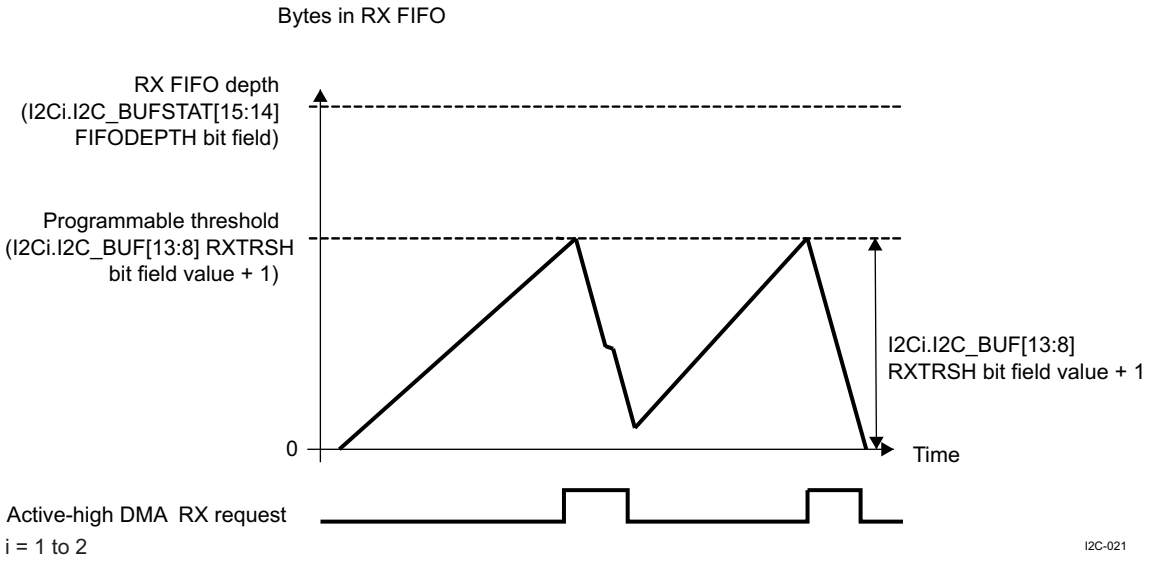
In FIFO polling mode (the I2C*i*.I2C_IRQENABLE_SET [4] XRDY_IE and I2C*i*.I2C_IRQENABLE_SET [3] RRDY_IE bits are disabled), the status of the module (receiver or transmitter) can be checked by polling the I2C*i*.I2C_IRQSTATUS_RAW [4] XRDY and the I2C*i*.I2C_IRQSTATUS_RAW [3] RRDY bits (the I2C*i*.I2C_IRQSTATUS_RAW [13] RDR and I2C*i*.I2C_IRQSTATUS_RAW [14] XDR bits can also be polled if the draining feature is enabled). The I2C*i*.I2C_IRQSTATUS_RAW [4] XRDY and I2C*i*.I2C_IRQSTATUS_RAW [3] RRDY bits accurately reflect the interrupt conditions described in the discussion of FIFO interrupt mode.

18.1.4.8.3 I²C FIFO DMA Mode

In receive mode, a DMA request is generated by the I2C*i*_DREQ_RX signal as soon as the RX FIFO exceeds its threshold level (the I2C*i*.I2C_BUF[13:8] RXTRSH bit field value + 1). This request is deasserted when the number of bytes defined by the threshold level is read by the DMA controller.

Figure 18-14 shows the DMA request generation in receive mode.

Figure 18-14. I²C Receive FIFO DMA Request Generation



In transmit mode, a DMA request is automatically asserted by the I2C*i*_DREQ_TX signal when the TX FIFO is empty. This request is deasserted when the number of bytes (the I2C*i*.I2C_BUF[5:0] TXTRSH bit field value + 1) is written in the FIFO by the DMA controller. If an insufficient number of bytes is written, the DMA request remains active. and show the DMA TX transfers with different values for the I2C*i*.I2C_BUF[5:0] TXTRSH bit field.

Figure 18-15. I²C Transmit FIFO Request Generation (High Threshold)

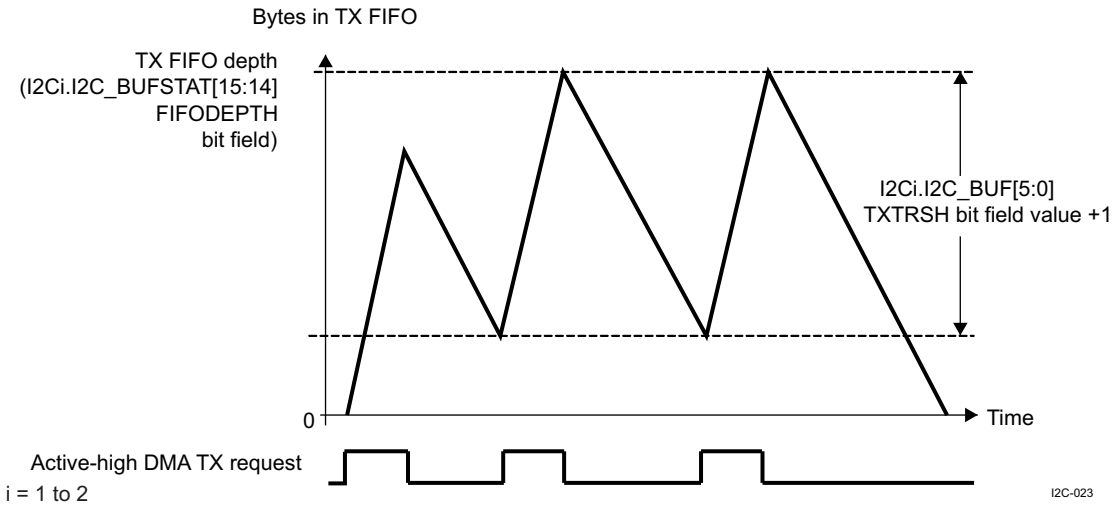


Figure 18-16. I²C Transmit FIFO Request Generation (Low Threshold)

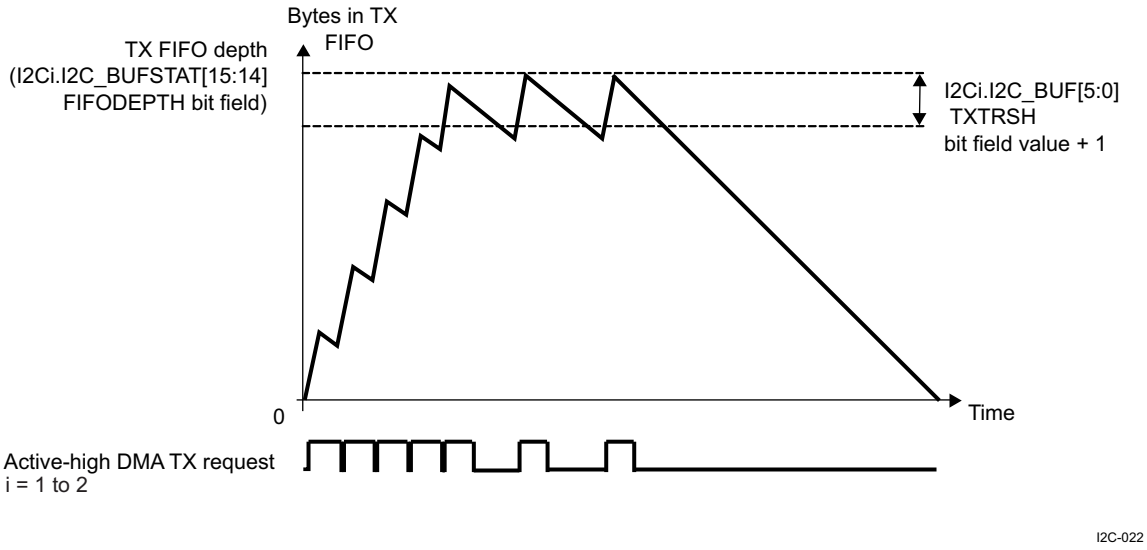

The I2C module provides the possibility to the user to clear the RX or TX FIFO, by setting the I2Ci.I2C_BUF[14]RXFIFO_CLR and I2Ci.I2C_BUF[6]TXFIFO_CLR registers, which act like software reset for the FIFOs. In DMA mode, these bits will also reset the DMA state machines.

The FIFO clearing feature can be used when the following conditions are met:

1. The module is configured as a transmitter
2. The external receiver responds with a NACK in the middle of the transfer
3. There is still data in TX FIFO waiting to be transferred

18.1.4.8.4 I²C Draining Feature

The draining feature is implemented to handle the end of a transfer whose length is not a multiple of the FIFO threshold values (the I2C*i*.I2C_BUF[13:8] RXTRSH bit field value + 1 for the RX threshold and the I2C*i*.I2C_BUF[5:0] TXTRSH field value + 1 for the TX threshold). It can also transfer the remaining number of bytes (because the threshold is not reached).

This feature prevents the LH or the DMA controller from trying more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having fewer bytes in the FIFO than the configured DMA transfer length). Otherwise, an AERR interrupt is generated by the I2C*i*.I2C_IRQSTATUS_RAW [7] AERR bit.

The draining mechanism generates an interrupt using the I2C*i*.I2C_IRQSTATUS_RAW [13] RDR or I2C*i*.I2C_IRQSTATUS_RAW [14] XDR bit at the end of the transfer, informing the LH that it must check the amount of data left to be transferred (the I2C*i*.I2C_BUFSTAT[13:8] RXSTAT or I2C*i*.I2C_BUFSTAT[5:0] TXSTAT bit fields) and enable the draining feature of the DMA controller by reconfiguring the DMA transfer length according to this value (when the DMA mode is enabled) or perform only the required number of data accesses (when the DMA mode is disabled).

In receive mode (master or slave), if the RX FIFO threshold (the I2C*i*.I2C_BUF[13:8] RXTRSH bit field value + 1) is not reached, but the transfer ends on the I²C bus and data remains in the RX FIFO (less than the threshold), the receive draining interrupt (the I2C*i*.I2C_IRQSTATUS_RAW [13] RDR bit) is asserted to inform the LH that it can read the amount of data in the RX FIFO (the I2C*i*.I2C_BUFSTAT[13:8] RXSTAT bit field). The LH performs a number of data read accesses equal to the I2C*i*.I2C_BUFSTAT[13:8] RXSTAT bit field (interrupt or polling mode), or reconfigures the DMA controller with the required value to drain the FIFO.

In master transmit mode, if the TX FIFO threshold (the I2C*i*.I2C_BUF[5:0] TXTRSH bit field value + 1) is not reached, but the amount of data remaining to be written in the TX FIFO is less than the threshold, the transmit draining interrupt (the I2C*i*.I2C_IRQSTATUS_RAW [14] XDR bit) is asserted to inform the LH that it can read the amount of data remaining to be written in the TX FIFO (the I2C*i*.I2C_BUFSTAT[5:0] TXSTAT bit field). The LH must write the required number of data bytes specified by the I2C*i*.I2C_BUFSTAT[5:0] TXSTAT bit field value or reconfigure the DMA controller with the value required to transfer the last bytes to the FIFO.

In master mode, the LH can alternately not check the values of the I2C*i*.I2C_BUFSTAT[5:0] TXSTAT and I2C*i*.I2C_BUFSTAT[13:8] RXSTAT bit fields, because it can obtain this information internally (by computing the I2C*i*.I2C_CNT[15:0] DATACOUNT bit field value modulo I2C*i*.I2C_BUF[13:8] RXTRSH or I2C*i*.I2C_BUF[5:0] TXTRSH).

By default, the draining feature is disabled; it can be enabled using the I2C*i*.I2C_IRQENABLE_SET [14] XDR_IE or I2C*i*.I2C_IRQENABLE_SET [13] RDR_IE bits (default disabled) only for transfers with lengths not equal to the threshold values (I2C*i*.I2C_BUF[5:0] TXTRSH bit field value + 1 for the TX threshold or the I2C*i*.I2C_BUF[13:8] RXTRSH bit field value + 1 for the RX threshold).

18.1.4.9 I²C Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less in case of F/S operation modes. The noise filter is always one period of the I2C*i*_INTERNAL_CLK clock.

For standard mode (for example, the I2C*i*.I2C_PSC[7:0] PSC bit field = 4), the maximum width of suppressed spikes is 46.1 ns.

To ensure correct filtering, the prescaler must be programmed accordingly by the 2C*i*.I2C_PSC[7:0] PSC bit field.

18.1.4.10 I²C System Test Mode

A system test mode is available for multimaster I²C controller module testing. This mode is enabled by setting the I2C*i*.I2C_SYSTEST[15] ST_EN bit to 1. When this bit is cleared to 0, the I²C controller is configured in normal operation mode.

In system test mode, the I2C*i*.I2C_SYSTEST [13:12] TMODE bit field selects the type of test. Table 18-12 lists the tests available for the multimaster I²C controllers.

Table 18-12. I²C List of Tests

I2C*i*.I2C_SYSTEST[13:12] TMODE	Test	Description
00	Functional mode	Normal operation mode
01	Reserved (not used)	
10	Test of i2c*i*_scl serial clock line	The i2c*i*_scl line is driven with a permanent clock as if mastered with the parameters set in the I2C*i*.I2C_PSC, I2C*i*.I2C_SCLL, and I2C*i*.I2C_SCLH registers.
11	Loop-back mode + i2c*i*_scl/ i2c*i*_sda I/O	In master transmit mode only, data transmitted out of the I2C*i*.I2C_DATA register (write action) is received in the same I2C*i*.I2C_DATA register through an internal path through the FIFO buffers. The DMA and interrupt requests are normally generated if they are enabled. Moreover, the i2c*i*_scl and i2c*i*_sda are controlled with the I2C*i*.I2C_SYSTEST[3:0] bits.

NOTE: When the I2C*i*.I2C_SYSTEST[13:12] TMODE bit field is set to 11, the I²C controller must be configured in I²C F/S (I2C*i*.I2C_CON[13:12] OPMODE set to 00).

NOTE: In normal operation mode (the I2C*i*.I2C_SYSTEST[15] ST_EN bit cleared to 0), the I2C*i*.I2C_SYSTEST[3:0] bits that control the i2c*i*_scl, i2c*i*_sda lines in system test mode are read-only bits.

In system test mode (the I2C*i*.I2C_SYSTEST[15] ST_EN bit set to 1), the I2C*i*.I2C_IRQSTATUS_RAW.XRDY, I2C_IRQSTATUS_RAW.RRDY, I2C_IRQSTATUS_RAW.XUDF, I2C_IRQSTATUS_RAW.ROVR, I2C_IRQSTATUS_RAW.ARDY and I2C_IRQSTATUS_RAW.NACK status bits can be set to 1 when the I2C*i*.I2C_SYSTEST[11] SSB bit is set to 1. Clearing the I2C*i*.I2C_SYSTEST[11] SSB bit to 0 does not clear the I2C*i*.I2C_IRQSTATUS_RAW bits to 0. The I2C*i*.I2C_IRQSTATUS_RAW bit field can be cleared to 0 only by writing 1 in the corresponding bits.

18.1.5 I²C Programming Guide

18.1.5.1 I²C Low-Level Programming Models

18.1.5.1.1 I²C Programming Model

This section describes the programming model of the multimaster I²C controllers configured in I²C mode.

18.1.5.1.1.1 Main Program

18.1.5.1.1.1.1 Configure the Module Before Enabling the I²C Controller

Before enabling the I²C controller, perform the following steps:

1. Enable the functional and interface clocks (see Table 18-3).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock by programming the corresponding value in the I2C*i*.I2C_PSC[7:0] PSC bit field. This value depends on the frequency of the functional clock (I2C*i*_FCLK).
3. Program the I2C*i*.I2C_SCLL[7:0] SCLL and I2C*i*.I2C_SCLH[7:0] SCLH bit fields to obtain a bit rate of 100 kbps or 400 kbps. These values depend on the internal sampling clock frequency (see Table 18-6).
4. Configure the Own Address of the I²C controller by storing it in the I2C*i*.I2C_OA register. Up to four Own Addresses can be programmed in the I2C*i*.I2C_OA and I2C*i*.I2C_OAx registers (where x = 1, 2, 3) for each I²C controller.

NOTE: For a 10-bit address, set the corresponding expand Own Address bit in the I2C*i*.I2C_CON register.

5. Set the TX threshold (in transmitter mode) and the RX threshold (in receiver mode) by setting the I2C*i*.I2C_BUF[5:0] TXTRSH bit field to (TX threshold – 1) and the I2C*i*.I2C_BUF[13:8] RXTRSH bit field to (RX threshold – 1), where the TX and RX thresholds are greater than or equal to 1.
6. Take the I²C controller out of reset by setting the I2C*i*.I2C_CON[15] I2C_EN bit to 1.

18.1.5.1.1.1.2 Initialize the I²C Controller

To initialize the I²C controller, perform the following steps:

1. Configure the I2C*i*.I2C_CON register:
   - For master or slave mode, set the I2C*i*.I2C_CON[10] MST bit (0: slave; 1: master).
   - For transmitter or receiver mode, set the I2C*i*.I2C_CON[9] TRX bit (0: receiver; 1: transmitter).
2. If using an interrupt to transmit and receive data, set the corresponding bit in the I2C*i*.I2C_IRQENABLE_SET register to 1 (the I2C*i*.I2C_IRQENABLE_SET [4] XRDY_IE bit for the transmit interrupt, the I2C*i*.I2C_IRQENABLE_SET [3] RRDY bit for the receive interrupt).
3. If using DMA to receive and transmit data, set the corresponding bit in the I2C*i*.I2C_BUF register to 1 (the I2C*i*.I2C_BUF[15] RDMA_EN bit for the receive DMA channel, the I2C*i*.I2C_BUF[7] XDMA_EN bit for the transmit DMA channel).

18.1.5.1.1.1.3 Configure Slave Address and the Data Control Register

In master mode, configure the slave address register by programming the I2C*i*.I2C_SA[9:0] SA bit field and the number of data bytes (I^2C data payload) associated with the transfer by programming the I2C*i*.I2C_CNT[15:0] DCOUNT bit field.

NOTE: For a 10-bit address, set the I2C*i*.I2C_CON[8] XSA bit to 1.

18.1.5.1.1.1.4 Initiate a Transfer

Poll the I2C*i*.I2C_IRQSTATUS_RAW [12] BB bit. If it is cleared to 0 (bus not busy), configure the I2C*i*.I2C_CON[0] STT and I2C*i*.I2C_CON[1] STP bits. To initiate a transfer, the I2C*i*.I2C_CON[0] STT bit must be set to 1, and it is not mandatory to set the I2C*i*.I2C_CON[1] STP bit to 1.

18.1.5.1.1.1.5 Receive Data

Poll the I2C*i*.I2C_IRQSTATUS_RAW [3] RRDY bit, or use the RRDY interrupt (the I2C*i*.I2C_IRQENABLE_SET [3] RRDY_IE bit must be set to 1) or the DMA RX channel (the I2C*i*.I2C_BUF[15] RDMA_EN bit must be set to 1 together with I2C_DMARXENABLE_SET) to read the receive data in the I2C*i*.I2C_DATA register.

If the transfer length does not equal the RX FIFO threshold (the I2C*i*.I2C_BUF[13:8] RTRSH bit field + 1), use the draining feature (enable the RDR interrupt by setting the I2C*i*.I2C_IRQENABLE_SET [13] RDR_IE bit to 1).

NOTE: In receive mode only, the I2C*i*.I2C_IRQSTATUS_RAW [11] ROVR (receive overrun) bit indicates whether the receiver has experienced overrun. An overrun condition occurs when the shift register and the RX FIFO are full. An overrun condition does not result in data loss; the I^2C controller simply holds i2c*i*_scl to low to prevent other bytes from being received.

The I2C*i*.I2C_IRQSTATUS_RAW[7] AERR bit is set to 1 when a read access is performed in the I2C*i*.I2C_DATA register while the RX FIFO is empty. The corresponding interrupt can be enabled by setting the I2C*i*.I2C_IRQENABLE_SET [7] AERR_IE bit to 1.

18.1.5.1.1.1.6 Transmit Data

Poll the I2C*i*.I2C_IRQSTATUS_RAW [4] XRDY bit, or use the XRDY interrupt (the I2C*i*.I2C_IRQENABLE_SET [4] XRDY_IE bit must be set to 1) or the DMA TX channel (the I2C*i*.I2C_BUF[7] XDMA_EN bit must be set to 1 together with I2C_DMATXENABLE_SET) to write data to the I2C*i*.I2C_DATA register.

If the transfer length does not equal the TX FIFO threshold (the I2C*i*.I2C_BUF[5:0] TXTRSH bit field + 1), use the draining feature (enable the XDR interrupt by setting the I2C*i*.I2C_IRQENABLE_SET [14] XDR_IE bit to 1).

NOTE: In transmit mode only, the I2C*i*.I2C_IRQSTATUS_RAW [10] XUDF bit indicates whether the transmitter has experienced underflow.

In master transmit mode, underflow occurs when the shift register and the TX FIFO are empty and there are still some bytes to transmit (the value of the I2C*i*.I2C_CNT[15:0] DCOUNT bit field is not 0).

In slave transmit mode, underflow occurs when the shift register and the TX FIFO are empty and the external I^2C master device still requests data bytes to be read.

The I2C*i*.I2C_IRQSTATUS_RAW [7] AERR bit is set to 1 when a write access is performed in the I2C*i*.I2C_DATA register while the TX FIFO is full. The corresponding interrupt can be enabled by setting the I2C*i*.I2C_IRQENABLE_SET [7] AERR_IE bit to 1.

18.1.5.1.1.2 Interrupt Subroutine Sequence

1. Test for arbitration lost (the I2C*i*.I2C_IRQSTATUS_RAW [0] AL bit) and resolve accordingly.
2. Test for no acknowledgment (the I2C*i*.I2C_IRQSTATUS_RAW [1] NACK bit) and resolve accordingly.
3. Test for register access ready (the I2C*i*.I2C_IRQSTATUS_RAW [2] ARDY bit) and resolve accordingly.
4. Test for receive data ready (the I2C*i*.I2C_IRQSTATUS_RAW [3] RRDY bit) and resolve accordingly.
5. Test for transmit data ready (the I2C*i*.I2C_IRQSTATUS_RAW [4] XRDY bit) and resolve accordingly.
6. Test for general call (the I2C*i*.I2C_IRQSTATUS_RAW [5] GC bit) and resolve accordingly.
7. Test for start (S) condition (the I2C*i*.I2C_IRQSTATUS_RAW [6] STC bit) and resolve accordingly. For this test, the functional clock must be inactive.
8. Test for access error (the I2C*i*.I2C_IRQSTATUS_RAW [7] AERR bit) and resolve accordingly.
9. Test for bus free (the I2C*i*.I2C_IRQSTATUS_RAW [8] BF bit) and resolve accordingly.

18.1.5.1.1.3 Programming Flow Diagrams

Figure 18-17 through Figure 18-25 are procedure flow charts for programming the F/S I²C modes.

Figure 18-17. I²C Setup Procedure

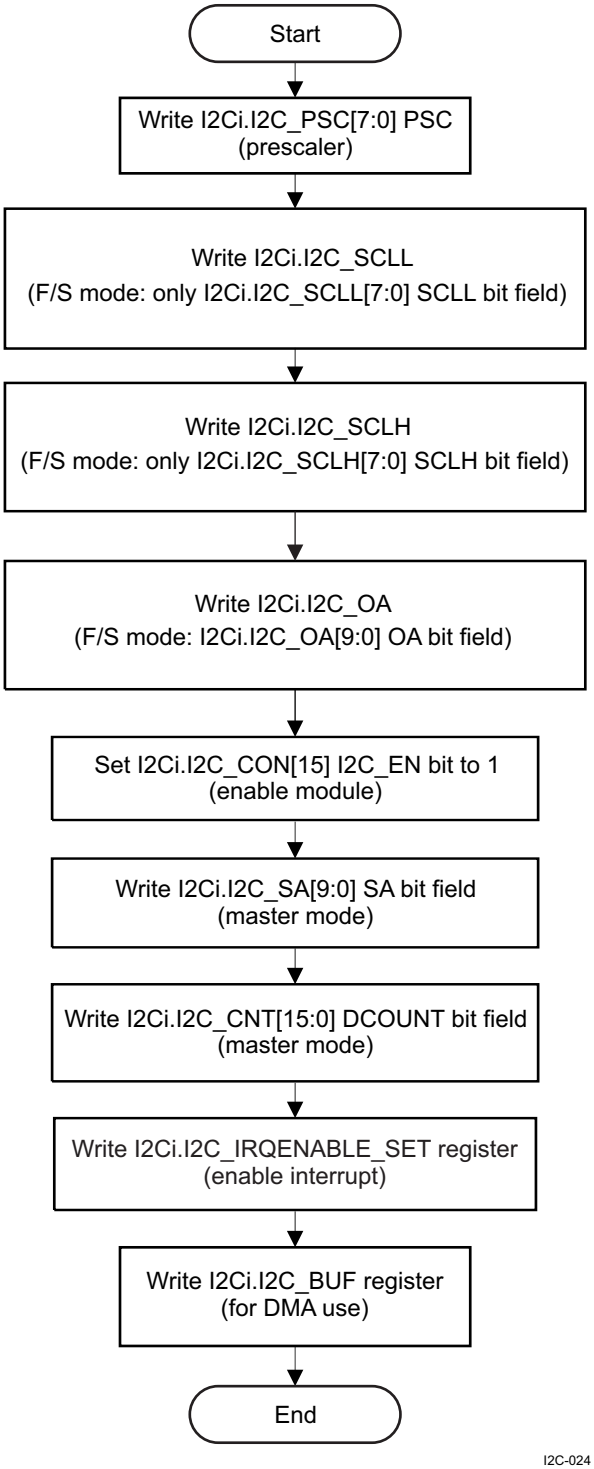

Table 18-13. Subprocess Call Summary for Sequence – I²C Setup Procedure

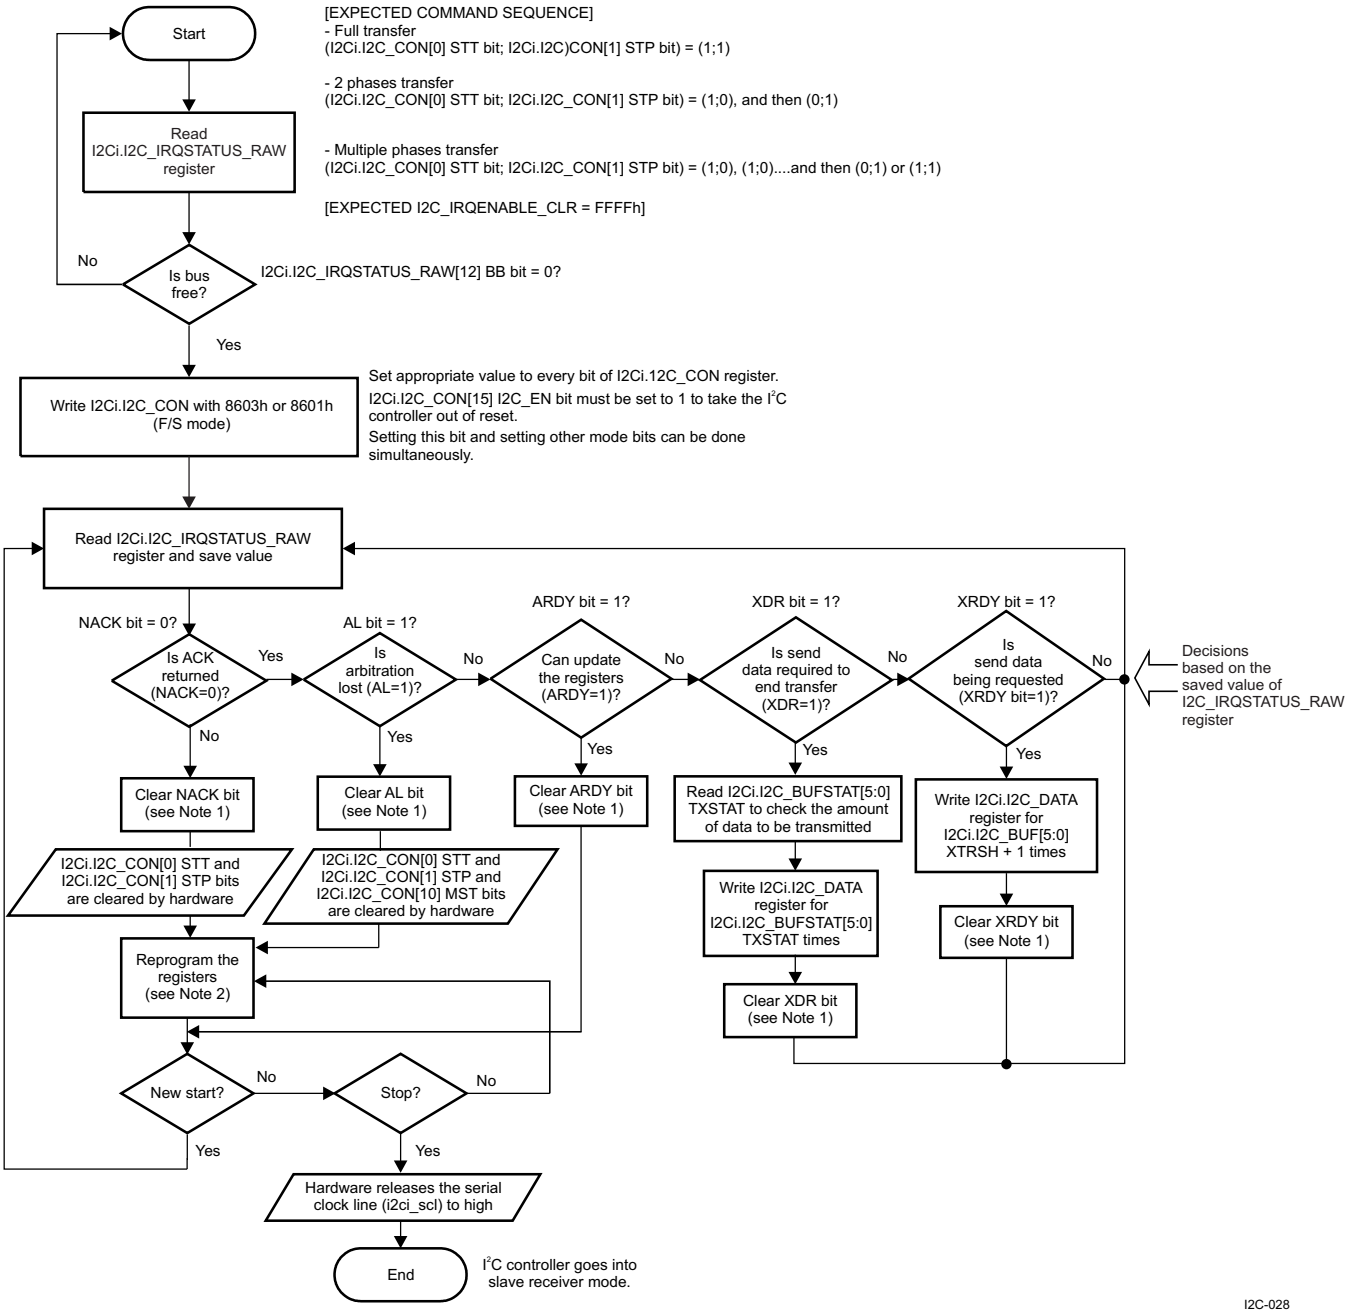
Subprocess Name	Cross-Reference
Pad configuration	See Section 13.4.6.1, *PAD Configuration Registers* in *Chapter 13Control Module*

Table 18-14. I²C Register Call Summary for Sequence – Setup Procedure

Register Name	Register Name	Register Name
I2C*i*.I2C_PSC (1)	I2C*i*.I2C_CON (1)	I2C*i*.I2C_BUF (1)
I2C*i*.I2C_SCLL (1)	I2C*i*.I2C_SA (1)	I2C*i*.I2C_IRQENABLE_SET (1)
I2C*i*.I2C_SCLH (1)	I2C*i*.I2C_CNT (1)	I2C*i*.I2C_OA (1)

(1) *i* = 1 to 2

Figure 18-18. I²C Master Transmitter Mode, Polling Method, in F/S Modes



(1) The NACK, AL, ARDY, XDR, and XRDY bits are cleared by writing 1 to each corresponding bit in the I2C*i*.I2C_IRQSTATUS register.

(2) Reprogram the registers means: I2C*i*.I2C_CON[11] STB and/or I2C*i*.I2C_CON[10] MST bit and/or I2C*i*.I2C_SA[9:0] SA register and/or I2C*i*.I2C_CNT[15:0] DCOUNT register and/or I2C*i*.I2C_CON[0] STT bit and/or I2C*i*.I2C_CON[1] STP bit.

NOTE: The FIFO clearing can be made when the module is configured as transmitter, the receiver send a NACK in the middle of the transfer, and there is still data in the FIFO.

Table 18-15. I²C Register Call Summary for Sequence – Master Transmitter Mode, Polling Method, in F/S Modes

Register Name	Register Name	Register Name
I2C*i*.I2C_IRQSTATUS_RAW [(1)]	I2C*i*.I2C_DATA [(1)]	I2C*i*.I2C_CON [(1)]

12	BB	Bus busy status. Writing into this bit has no effect. Read 0x1: Bus is occupied. Read 0x0: Bus is free.	R	0

Bits	Field Name	Description	Type	Reset
11	ROVR	Receive overrun status. Writing into this bit has no effect. Read 0x1: Receiver overrun. Read 0x0: Normal operation.	RW	0
10	XUDF	Transmit underflow status. Writing into this bit has no effect. Read 0x1: Transmit underflow. Read 0x0: Normal operation.	RW	0
9	AAS	Address recognized as slave IRQ status. 0x0: No action. 0x1: Address recognized.	RW	0
8	BF	Bus Free IRQ status. 0x0: No action. 0x1: Bus Free.	RW	0
7	AERR	Access Error IRQ status. 0x0: No action. 0x1: Access Error.	RW	0
6	STC	Start Condition IRQ status. 0x0: No action. 0x1: Start Condition detected.	RW	0

Bits	Field Name	Description	Type	Reset
5	GC	General call IRQ status. Set to 1 by core when General call address detected and interrupt signaled to IRQ_Crossbar. (1) 0x0: No general call detected. 0x1: General call address detected.	RW	0
4	XRDY	Transmit data ready IRQ status. Set to 1 by core when transmitter and when new data is requested. When set to 1 by core, an interrupt is signaled to IRQ_Crossbar. (1) 0x0: Transmision ongoing. 0x1: Transmit data ready.	RW	0
3	RRDY	Receive data ready IRQ status. Set to 1 by core when receiver mode, a new data is able to be read. When set to 1 by core, an interrupt is signaled to IRQ_Crossbar. (1) 0x0: No data available. 0x1: Receive data available.	RW	0
2	ARDY	Register access ready IRQ status. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to IRQ_Crossbar. (1) 0x0: Module busy. 0x1: Access ready.	RW	0
1	NACK	No acknowledgement IRQ status. Bit is set when No Acknowledge has been received, an interrupt is signaled to IRQ_Crossbar. (1) 0x0: Normal operation. 0x1: Not Acknowledge detected.	RW	0
0	AL	Arbitration lost IRQ status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to IRQ_Crossbar. During reads, it always returns 0. 0x0: Normal operation. 0x1: Arbitration lost detected.	RW	0

(1) Writing 1 in the bit field will only set the respective field to 1, used mainly for debug.

18.2 UART

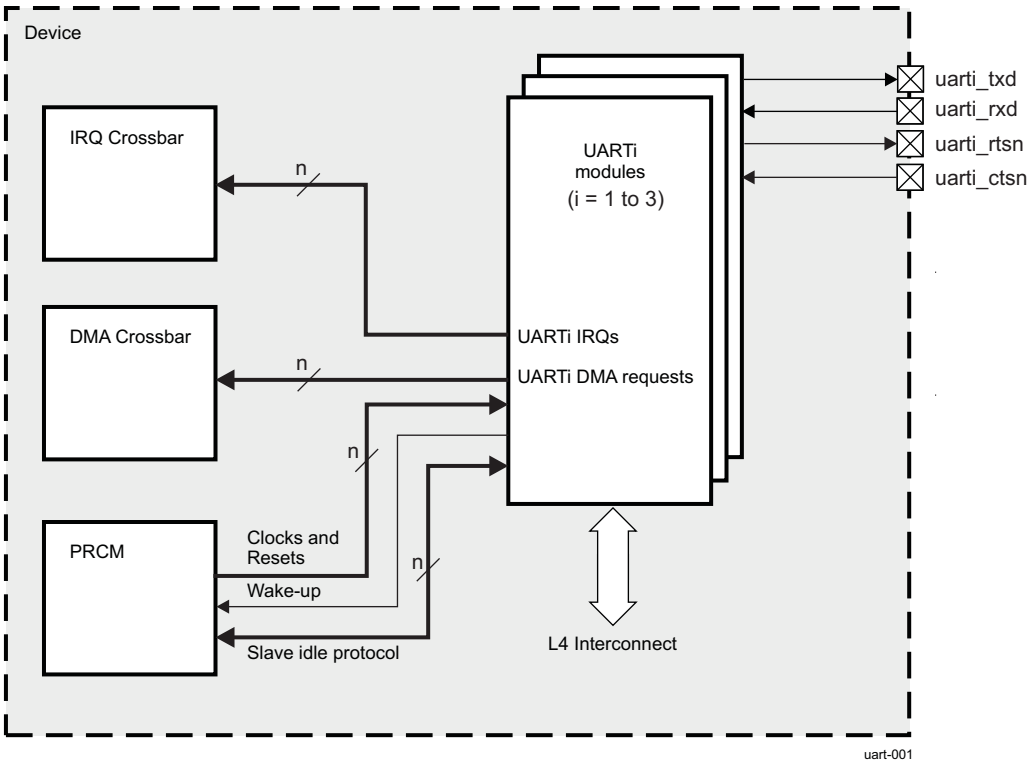
This chapter describes the function, operation, and configuration of the universal asynchronous receiver/transmitter (UART) module in the device.

18.2.1 UART Overview

The UART is a simple L4 slave peripheral that utilizes the EDMA for data transfer or IRQ polling via CPU. There are 3 UART modules in the device. Each UART can be used for configuration and data exchange with a number of external peripheral devices or interprocessor communication between devices.

Figure 18-26 shows the UART module overview.

Figure 18-26. UART Overview



18.2.1.1 UART Features

The UARTi (where i = 1 to 3) include the following features:

- 16C750 compatibility
- 64-byte FIFO buffer for receiver and 64-byte FIFO for transmitter
- Programmable interrupt trigger levels for FIFOs
- Baud generation based on programmable divisors N (where N = 1…16,384) operating from a fixed functional clock of 48 MHz or 192 MHz

Oversampling is programmed by software as 16 or 13. Thus, the baud rate computation is one of two options:

- Baud rate = (functional clock / 16) / N
- Baud rate = (functional clock / 13) / N
- This software programming mode enables higher baud rates with the same error amount without changing the clock source
- Break character detection and generation
- Configurable data format:

  - Data bit: 5, 6, 7, or 8 bits
  - Parity bit: Even, odd, none
  - Stop-bit: 1, 1.5, 2 bit(s)
- Flow control: Hardware (RTS/CTS) or software (XON/XOFF)
- The 48 MHz functional clock option allows baud rates up to 3.6Mbps
- The 192 MHz functional clock option allows baud rates up to 12Mbps

18.2.2 UART Environment

This section describes the UART connection with an external device.

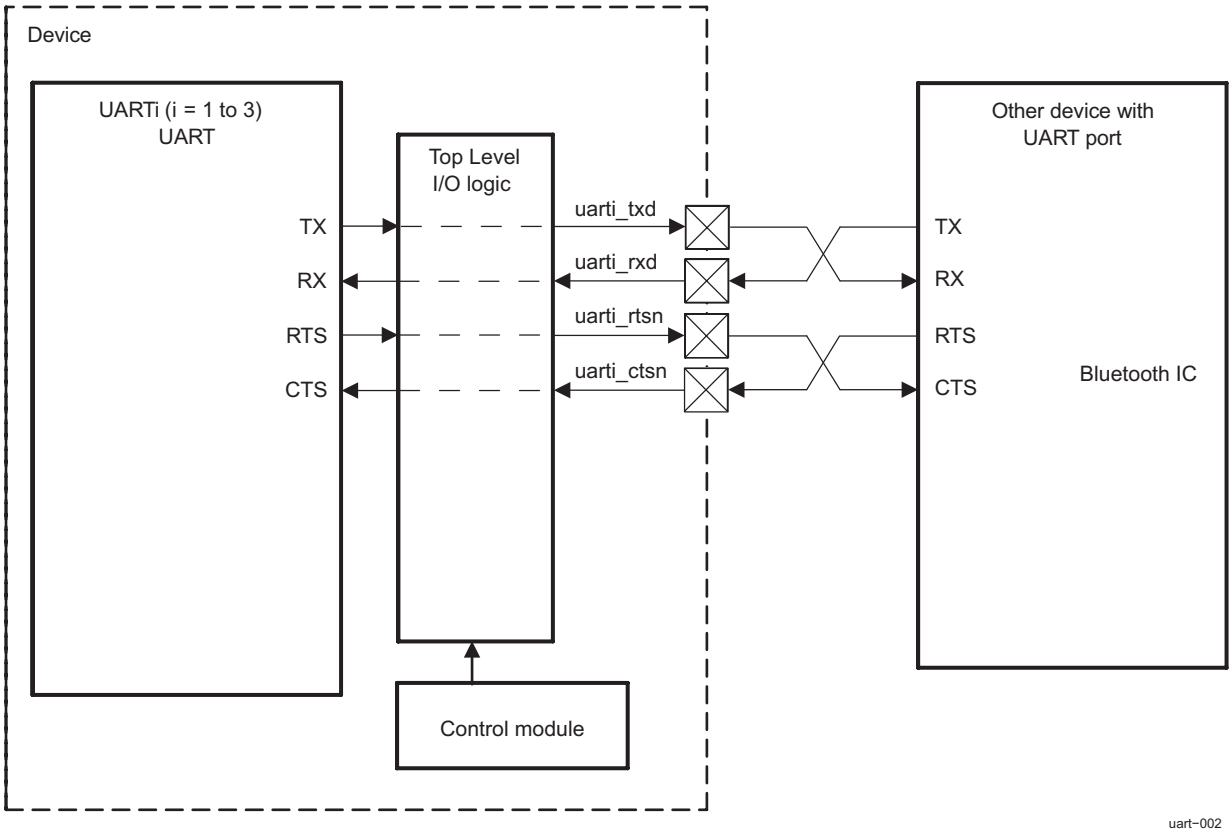
- The UART interface is described in Section 18.2.2.1.

18.2.2.1 UART Interface

18.2.2.1.1 System Using UART Communication With Hardware Handshake

Each UART instance can be easily connected to the UART port of an external IC (seeFigure 18-27).

Figure 18-27. UART Mode Bus System Overview



18.2.2.1.2 UART Interface Description

Table 18-89 lists the UART interface input/output (I/O) signals.

Table 18-89. UART Interface Signals

Signal	I/O[1]	Description	Module Level Reset Value
UARTi Interface Signals[2]			
uarti_rxd	I	Serial data input.	Unknown
uarti_txd	O	Serial data output This pin is set to low on reset (when the UARTi.UART_MDR1[2:0] bit field is set to 0x7) and takes the inactive level when the UARTi.UART_MDR1 register is programmed; that is, the output is 1 (inactive for UART modem modes).	0
uarti_ctsn	I	Clear to send	Unknown

(1) I = Input; O = Output; I/O = Bidirectional
(2) i = 1 to 3

Table 18-89. UART Interface Signals (continued)

Signal	I/O[1]	Description	Module Level Reset Value
		Active-low modem status signal. Reading the UARTi.UART_MSR[4] NCTS_STS bit checks the condition of uarti_ctsn. Reading the UARTi.UART_MSR[0] CTS_STS bit checks a change of state of uarti_ctsn since the last read of the modem status register. The auto-CTS mode uses uarti_ctsn to control the transmitter.	
uarti_rtsn	O	Request to send When active (low), the module is ready to receive data. Setting the UARTi.UART_MCR[1] RTS bit activates uarti_rtsn, which becomes inactive as the result of a module reset, loopback mode, or clearing the UARTi.UART_MCR[1] RTS bit. In auto-RTS mode, uarti_rtsn becomes inactive as a result of the receiver threshold logic.	1

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. For more information on control module settings, see Section 13.4.6.1, *Pad Configuration Registers*, in Chapter 13, *Control Module*.

18.2.2.1.3 UART Protocol and Data Format

The UART device operates in three modes:

- UART 16x (<= 230.4 kbps)
- UART 16x with autobauding (>= 1200 bps and >= 115.2 kbps)
- UART 13x (>= 460.8 kbps)

CAUTION

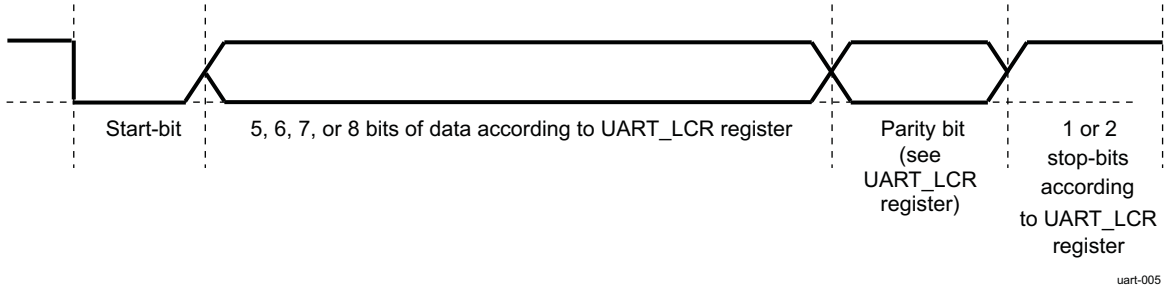
To be used as a UART, the operating mode must be programmed appropriately in the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to select UART.

The UART uses a wired interface for serial communication with a remote device.

The UART is functionally compatible with the TL16C750 UART and earlier designs such as the TL16C550.

Figure 18-28 shows the UART frame data format.

Figure 18-28. UART Frame Data Format

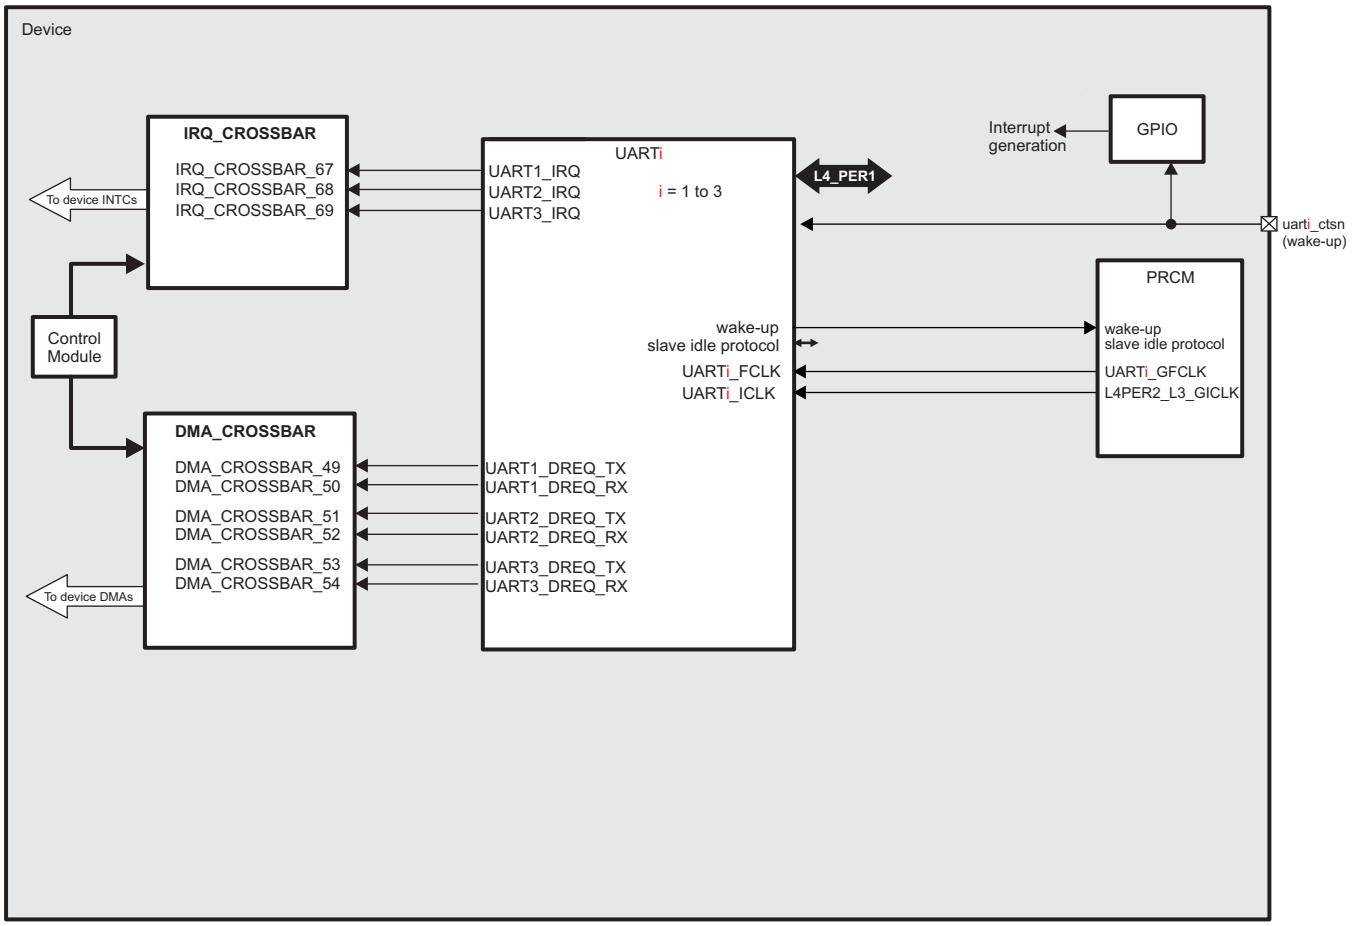


18.2.3 UART Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 18-29 shows the device internal connections with related modules for UART functions.

Figure 18-29. UART Integration



NOTE: For more information about the slave idle and master standby protocols and the wake-up request, see Section 3.1.1.1.4, *Clock Domain-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*

Table 18-90 through Table 18-92 summarize the integration of the module in the device.

Table 18-90. UART Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
UART1	PD_COREAON	Yes	L4_PER1
UART2	PD_COREAON	Yes	L4_PER1
UART3	PD_COREAON	Yes	L4_PER1

Table 18-91. UART Clocks and Resets

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination IRQ_CROSSBAR input**	**Default Mapping**	**Description**
UART1	UART1_IRQ	IRQ_CROSSBAR_67	-	UART module 1 IRQ line
UART2	UART2_IRQ	IRQ_CROSSBAR_68	-	UART module 2 IRQ line
UART3	UART3_IRQ	IRQ_CROSSBAR_69	IPU_IRQ_45	UART module 3 IRQ line
Direct Memory Access (DMA) Requests				
Module Instance	**Source Signal Name**	**Destination DMA_CROSSBAR input**	**Default Mapping**	**Description**
UART1	UART1_DREQ_TX	DMA_CROSSBAR_49	DMA_EDMA_DREQ_48	UART module 1 – transmit request
	UART1_DREQ_RX	DMA_CROSSBAR_50	DMA_EDMA_DREQ_49	UART module 1 – receive request
UART2	UART2_DREQ_TX	DMA_CROSSBAR_51	DMA_EDMA_DREQ_50	UART module 2 – transmit request
	UART2_DREQ_RX	DMA_CROSSBAR_52	DMA_EDMA_DREQ_51	UART module 2 – receive request
UART3	UART3_DREQ_TX	DMA_CROSSBAR_53	DMA_EDMA_DREQ_52	UART module 3 – transmit request
	UART3_DREQ_RX	DMA_CROSSBAR_54	DMA_EDMA_DREQ_53	UART module 3 – receive request

NOTE: The "**Default Mapping**" column in Table 18-92, *UART Hardware Requests*, shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.
For more information about the IRQ_CROSSBAR module, see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.
For more information about the DMA_CROSSBAR module, see Section 13.4.6.5, *DMA_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.
For more information about the device interrupt controllers, see Chapter 12, *Interrupt Controllers*.
For more information about the device EDMA module, see Chapter 11, *Enhanced DMA*.

18.2.4 UART Functional Description

18.2.4.1 Block Diagram

The UART module can be divided into three main blocks:

- FIFO management
- Mode selection
- Protocol formatting

FIFO management is common to all functions and enables the transmission and reception of data from the host processor point of view.

There are two modes:

- Function mode: Routes the data to UART and enables UART function
- Register mode: Enables conditional access to registers

For more information about mode configuration, see Section 18.2.4.7, *Mode Selection*.

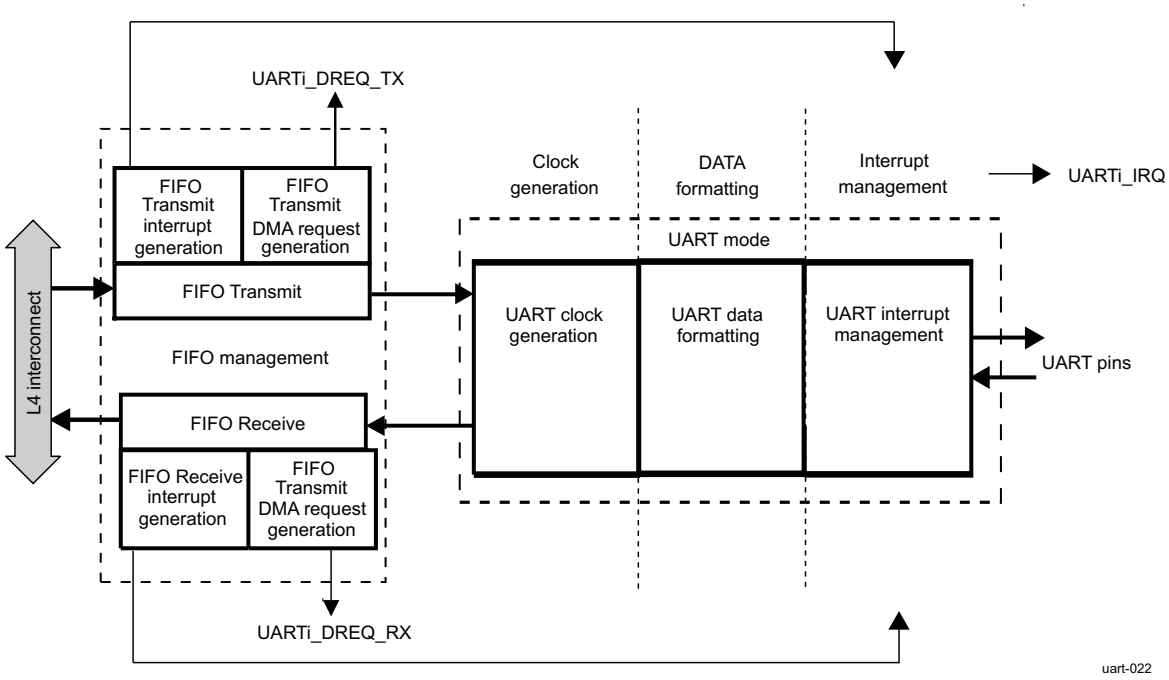
Protocol formatting has three subcategories:

- Clock generation: The 48-MHz input clock generates all necessary clocks.
- Data formatting: Each function uses its own state-machine that is responsible for the transition between FIFO data and frame data associated with it.
- Interrupt management: When an interrupt is generated, the UART_IIR register indicates the interrupt type.
  - Seven interrupts prioritized in six different levels

In parallel with these functional blocks, a power-saving strategy exists for each function.

Figure 18-30 is the UART block diagram.

Figure 18-30. UART Functional Block Diagram



18.2.4.2 Clock Configuration

Each UART uses a 48-MHz functional clock for its logic and to generate external interface signals. Each UART uses an interface clock for register accesses. The PRCM module generates and controls all these clocks (for more information, see Section 3.1.1.1.4, *Clock Domain-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*).

The idle and wake-up processes use a handshake protocol between the PRCM and the UART (for a description of the protocol, see Section 3.1.1.1.4, *Clock Domain Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*). The UARTi.UART_SYSC[4:3] IDLEMODE bit field controls UART idle mode.

18.2.4.3 Software Reset

The UARTi.UART_SYSC[1] SOFTRESET bit controls the software reset; setting this bit to 1 triggers a software reset functionally equivalent to hardware reset.

18.2.4.4 Power Management

18.2.4.4.1 UART Mode Power Management

18.2.4.4.1.1 Module Power Saving

In UART modes, sleep mode is enabled by setting the UARTi.UART_IER[4] SLEEP_MODE bit to 1 (when the UARTi.UART_EFR[4] ENHANCED_EN bit is set to 1).

Sleep mode is entered when all of the following conditions exist:

- The serial data input line, uarti_rxd, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- The only pending interrupts are THR interrupts.

Sleep mode is a good way to lower UART power consumption, but this state can be achieved only when the UART is set to modem mode. Therefore, even if the UART has no key role functionally, it must be initialized in a functional mode to take advantage of sleep mode.

In sleep mode, the module clock and baud rate clock are stopped internally. Because most registers are clocked by these clocks, this greatly reduces power consumption. The module wakes up when a change is detected on the uarti_rxd line, when data is written to the TX FIFO, and when there is a change in the state of the modem input pins.

An interrupt can be generated on a wake-up event by setting the UARTi.UART_SCR[4] RX_CTS_WU_EN bit to 1. To understand how to manage the interrupt, see Section 18.2.4.5.1.2, *Wake-Up Interrupt*.

NOTE: There must be no writing to the divisor latches, UARTi.UART_DLL and UARTi.UART_DLH, to set the baud clock (BCLK) while in sleep mode. It is advisable to disable sleep mode using the UARTi.UART_IER[4] SLEEP_MODE bit before writing to the UARTi.UART_DLL or UARTi.UART_DLH register.

18.2.4.4.1.2 System Power Saving

Sleep and auto-idle modes are embedded power-saving features. Power-reduction techniques can be applied at the system level by shutting down certain internal clock and power domains of the device.

The UART supports an idle req/idle ack handshaking protocol used at the system level to shut down the UART clocks in a clean and controlled manner and to switch the UART from interrupt-generation mode to wake-up generation mode for unmasked events (see the UARTi.UART_SYSC[2] ENAWAKEUP bit and the UARTi.UART_WER register).

For more information, see Section 3.1.1.1.2, *Module Level Clock Management*, Chapter 3, *Power, Reset, and Clock Management*.

18.2.4.4.2 Local Power Management

Table 18-93 describes power-management features available for the UART.

NOTE: For information about source clock gating and the sleep/wake-up transitions description, see Section 3.1.1.1.2, *Module Level Clock Management*, Chapter 3, *Power, Reset, and Clock Management*.

Table 18-93. Local Power-Management Features

Feature	Registers	Description
Clock autogating	UART_SYSC[0] AUTOIDLE	This bit allows local power optimization in the module by gating the UARTi_ICLK clock on interface activity or gating the UARTi_FCLK clock on internal activity.
Slave idle modes	UART_SYSC[4:3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available.
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	UART_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.
Wake-Up sources enable	N/A	Feature not available

18.2.4.5 Interrupt Requests

18.2.4.5.1 UART Interrupt Management

18.2.4.5.1.1 UART Interrupts

UART includes seven possible interrupts prioritized to six levels.

When an interrupt is generated, the interrupt identification register (UARTi.UART_IIR) sets the UARTi.UART_IIR[0] IT_PENDING bit to 0 to indicate that an interrupt is pending, and indicates the type of interrupt through the UARTi.UART_IIR[5:1] bit field. Table 18-94 summarizes the interrupt control functions.

Table 18-94. UART Interrupts

IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000001	None	None	None	None
000110	1	Receiver line status	OE, FE, PE, or BI errors occur in characters in the RX FIFO.	FE, PE, BI: Read the UART_RHR register. OE: Read the UART_LSR register.
001100	2	RX time-out	Stale data in RX FIFO	Read the UART_RHR register.
000100	2	RHR interrupt	DRDY (data ready) (FIFO disable)	Read the UART_RHR register until the interrupt condition disappears.
			RX FIFO above trigger level (FIFO enable)	
000010	3	THR interrupt	TFE (THR empty) (FIFO disable)	Write to the UART_THR until the interrupt condition disappears.
			TX FIFO below trigger level (FIFO enable)	
000000	4	Modem status	See the UART_MSR register.	Read the MSR register.
010000	5	XOFF interrupt/special character interrupt	Receive XOFF characters/special character	Receive XON character(s), if XOFF interrupt/read of the UART_IIR register, if special character interrupt.
100000	6	CTS, RTS	RTS pin or CTS pin change state from active (low) to inactive (high).	Read the UART_IIR register.

For the receiver-line status interrupt, the RX_FIFO_STS bit (UARTi.UART_LSR[7]) generates the interrupt.

For the XOFF interrupt, if an XOFF flow character detection caused the interrupt, the interrupt is cleared by an XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the UARTi.UART_IIR register.

18.2.4.5.1.2 Wake-Up Interrupt

Wake-up interrupt is a special interrupt that works differently from other interrupts. This interrupt is enabled when the UARTi.UART_SCR[4] RX_CTS_WU_EN bit is set to 1. The UARTi.UART_IIR register is not modified when this occurs; the UART3.UART_SSR[1] RX_CTS_WU_STS bit must be checked to detect a wake-up event.

When a wake-up interrupt occurs, it can be cleared only by resetting the UARTi.UART_SCR[4] RX_CTS_WU_EN bit. This bit must be reenabled (set to 1) after the current wake-up interrupt event is processed to detect the next incoming wake-up event.

18.2.4.6 FIFO Management

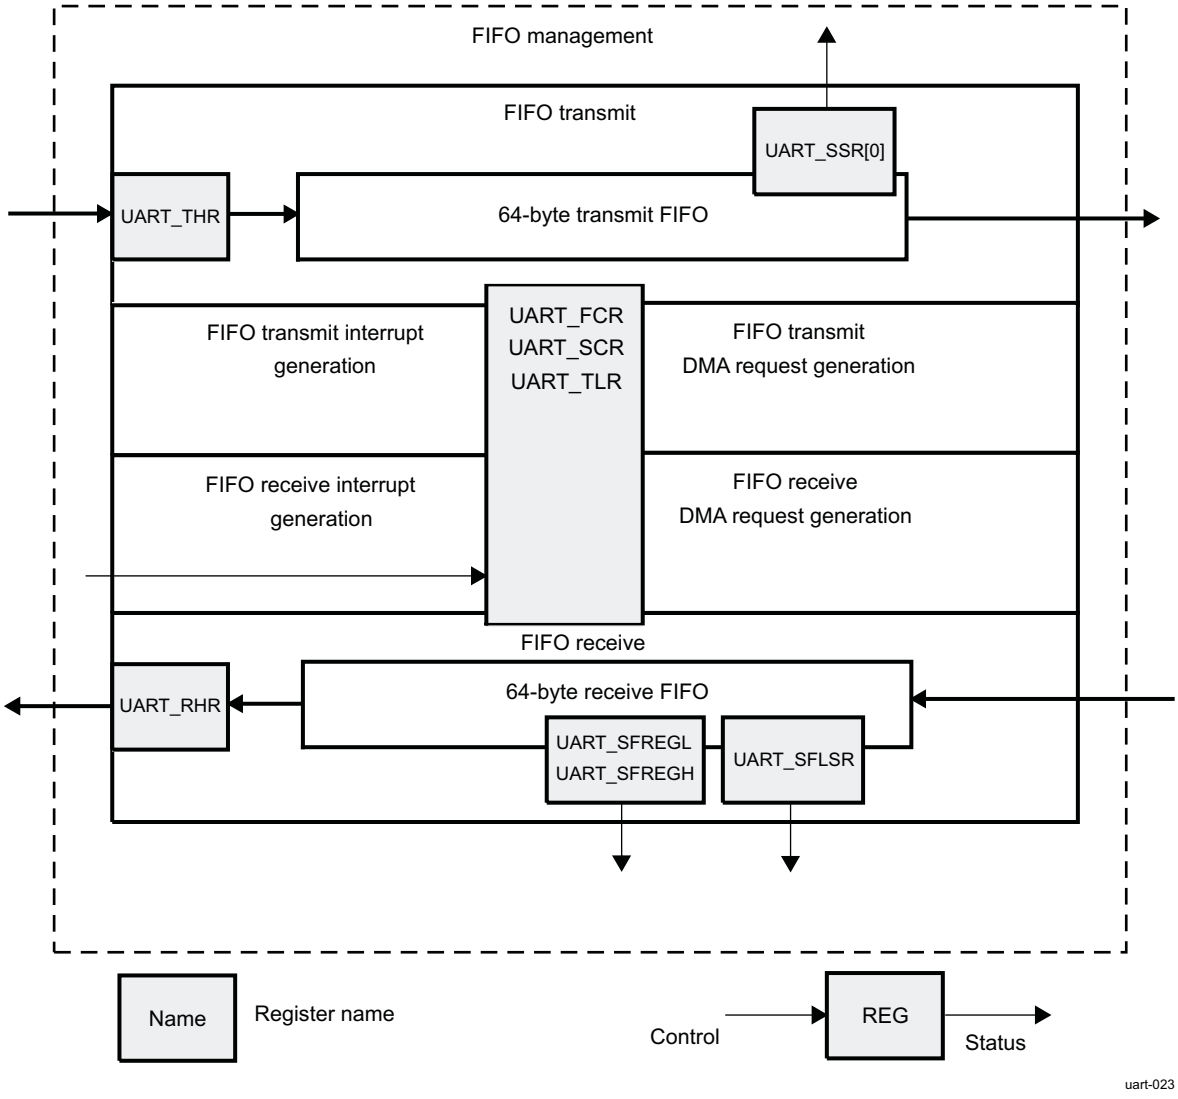
The FIFO is accessed by reading and writing the UARTi.UART_RHR and UARTi.UART_THR registers. Parameters are controlled using the FIFO control register (UARTi.UART_FCR) and supplementary control register (UARTi.UART_SCR). Reading the UARTi.UART_SSR[0] TX_FIFO_FULL bit at 1 means the FIFO is full.

The UARTi.UART_TLR register controls the FIFO trigger level, which enables DMA and interrupt generation. After reset, transmit (TX) and receive (RX) FIFOs are disabled; thus, the trigger level is the default value of 1 byte. Figure 18-31 shows the FIFO management registers.

NOTE: Data in the UARTi.UART_RHR register is not overwritten when an overflow occurs.

NOTE: Bits UARTI.UART_FCR[2] TX_FIFO_CLEAR and UARTI.UART_FCR[1] RX_FIFO_CLEAR are automatically cleared by hardware after 4* UARTi_ICLK + 5* UARTi_FCLK clock cycles. This delay is needed to finish the resetting of the corresponding FIFO and DMA control registers.

Figure 18-31. FIFO Management Registers



18.2.4.6.1 FIFO Trigger

18.2.4.6.1.1 Transmit FIFO Trigger

Table 18-95 lists the TX FIFO trigger level settings.

Table 18-95. TX FIFO Trigger Level Setting Summary

SCR[6]	TLR[3:0]	TX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit field (8,16, 32, or 56 spaces)
0	!= 0x0	Defined by the UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit field (from 4 to 60 spaces with a granularity of 4 spaces)
1	Value	Defined by the concatenated value of TX_FIFO_TRIG_DMA and TX_FIFO_TRIG (from 1 to 63 spaces with a granularity of 1 space) **Note:** The combination of TX_FIFO_TRIG_DMA = 0x0 and TX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of 1 space required). All zeros result in unpredictable behavior.

18.2.4.6.1.2 Receive FIFO Trigger

Table 18-96 lists the RX FIFO trigger-level settings.

Table 18-96. RX FIFO Trigger-Level Setting Summary

SCR[7]	TLR[7:4]	RX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.UART_FCR[7:6] RX_FIFO_TRIG bit field (8,16, 56, or 60 characters)
0	!= 0x0	Defined by the UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA bit field (from 4 to 60 characters with a granularity of 4 characters)
1	Value	Defined by the concatenated value of RX_FIFO_TRIG_DMA and RX_FIFO_TRIG (from 1 to 63 characters with a granularity of 1 character) **Note:** The combination of RX_FIFO_TRIG_DMA = 0x0 and RX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of 1 character required). All zeros result in unpredictable behavior.

The receive threshold is programmed using the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START and UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit fields:

- Trigger levels from 0 to 60 bytes are available with a granularity of 4 (trigger level = 4 × [4-bit register value]).
- To ensure correct device operation, ensure that RX_FIFO_TRIG_HALT > RX_FIFO_TRIG when auto-RTS is enabled.

  Delay = [4 + 16 × (1 + CHAR_LENGTH + Parity + Stop – 0.5)] × Baud_rate + 4 × FCLK

  NOTE: The RTS signal is deasserted after the UART module receives the data over RX_FIFO_TRIG_HALT. Delay means how long the UART module takes to deassert the RTS signal after reaching RX_FIFO_TRIG_HALT.

- In FIFO interrupt mode with flow control, ensure that the trigger level to HALT transmission is greater than or equal to the RX FIFO trigger level (the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START bit field or the UARTi.UART_FCR[7:6] RX_FIFO_TRIG bit field); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist, because a DMA request is sent when a byte is received.

18.2.4.6.2 FIFO Interrupt Mode

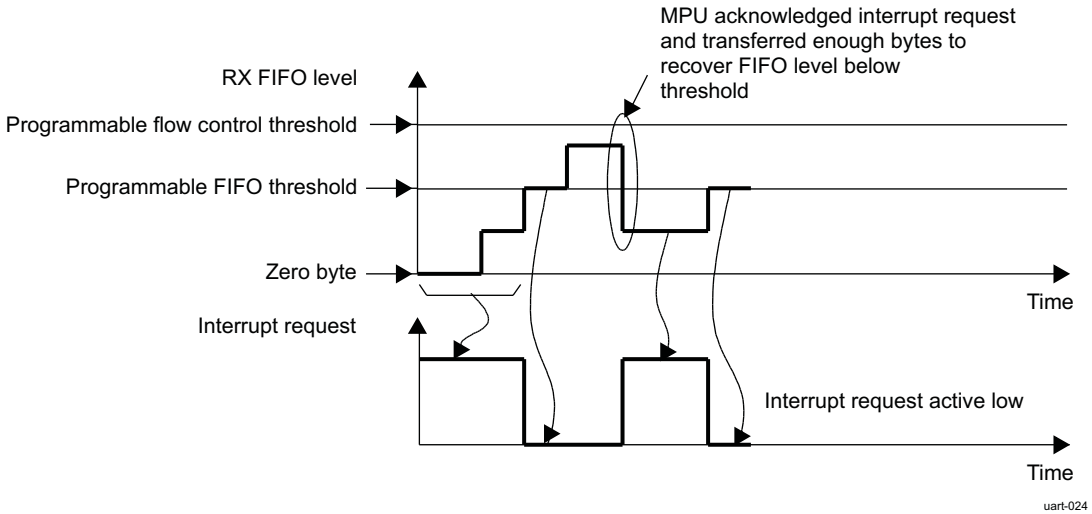
In FIFO interrupt mode (the FIFO control register UARTi.UART_FCR[0] FIFO_EN bit is set to 1 and relevant interrupts are enabled by the UARTi.UART_IER register), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the RX/TX FIFO threshold (the UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA and UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit fields or the UARTi.UART_FCR[7:6] RX_FIFO_TRIG and UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit fields, respectively) is reached.

The interrupt signals instruct the CPU to transfer data to the destination (from the UART in receive mode and/or from any source to the UART FIFO in transmit mode).

When UART flow control is enabled with interrupt capabilities, the UART flow control FIFO threshold (the UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit field) must be greater than or equal to the RX FIFO threshold.

Figure 18-32 shows the generation of the RX FIFO interrupt request.

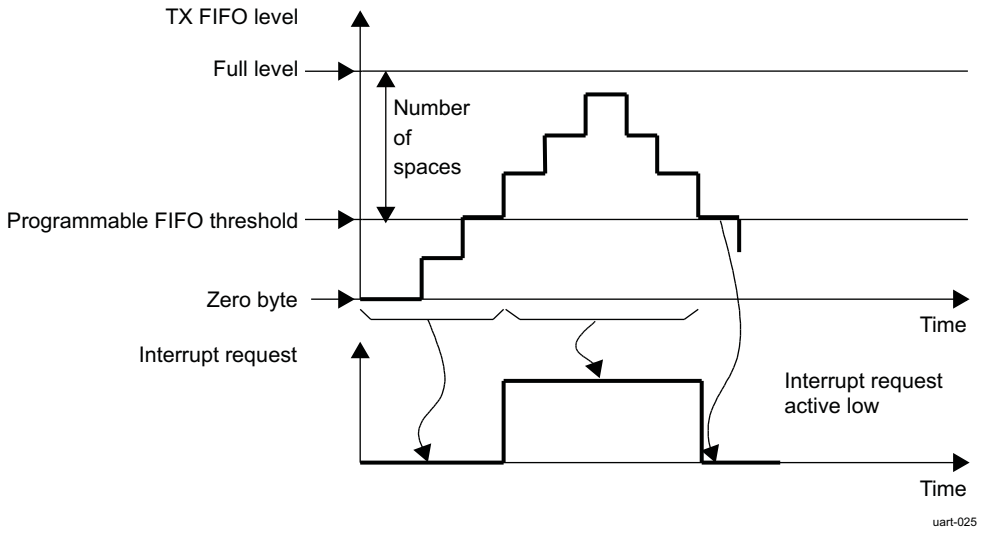
Figure 18-32. RX FIFO Interrupt Request Generation



In receive mode, no interrupt is generated until the RX FIFO reaches its threshold. Once low, the interrupt can be deasserted only when the CPU has handled enough bytes to put the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

Figure 18-33 shows the generation of the TX FIFO interrupt request.

Figure 18-33. TX FIFO Interrupt Request Generation



In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is deasserted when the TX FIFO crosses the threshold level. The interrupt line is deasserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

18.2.4.6.3 FIFO Polled Mode Operation

In FIFO polled mode (the UARTi.UART_FCR[0] FIFO_EN bit is set to 0 and the relevant interrupts are disabled by the UARTi.UART_IER register), the status of the receiver and transmitter can be checked by polling the line status register (UARTi.UART_LSR).

This mode is an alternative to the FIFO interrupt mode of operation in which the status of the receiver and transmitter is automatically determined by sending interrupts to the CPU.

18.2.4.6.4 FIFO DMA Mode Operation

Although the DMA operation includes four modes (DMA modes 0 through 3), the information in Table 18-92, *Hardware Requests*, assumes that mode 1 is used. (Mode 2 and mode 3 are legacy modes that use only one DMA request for each module.)

In mode 2, the remaining DMA request is used for RX. In mode 3, the remaining DMA request is used for TX.

DMA requests in mode 2 and mode 3 use the UARTi_DREQ_TX signals (where i = 1 to 10).

The UARTi_DREQ_RX signals are not used by the module in mode 2 and mode 3:

The DMA mode and signals usage can be selected as follows:

- When the UARTi.UART_SCR[0] DMA_MODE_CTL bit is set to 0, setting the UARTi.UART_FCR[3] DMA_MODE bit to 0 enables DMA mode 0. Setting the UARTi.UART_FCR[3]DMA_MODE bit to 1 enables DMA mode 1.
- When the UARTi.UART_SCR[0]DMA_MODE_CTL bit is set to 1, the UARTi.UART_SCR[2:1] DMA_MODE_2 bit field determines DMA mode 0 to mode 3 based on the supplementary control register (SCR) description.

For example:

- If no DMA operation is desired, set theUARTi.UART_SCR[0]DMA_MODE_CTL bit to 1 and the UARTi.UART_SCR[2:1]DMA_MODE_2 bit field to 0x0. (The DMA_MODE bit is discarded.)
- If DMA mode 1 is desired, set the UARTi.UART_SCR[0]DMA_MODE_CTL bit to 0 and the UARTi.UART_FCR[3]DMA_MODE bit to 1, or set the UARTi.UART_SCR[0]DMA_MODE_CTL bit to 1 and the SCR[2:1]DMA_MODE_2 bit field to 01. (The UARTi.UART_FCR[3]DMA_MODE bit is discarded.)

If the FIFOs are disabled (the UARTi.UART_FCR[0] FIFO_EN bit is set to 0), the DMA occurs in single-character transfers.

When DMA mode 0 is programmed, the signals associated with DMA operation are not active.

Depending on UARTi.UART_MDR3[2] SET_DMA_TX_THRESHOLD, the threshold can be programmed different ways:

- SET_TX_DMA_THRESHOLD = 1:

  The threshold value will be the value of the TX_DMA_THRESHOLD register. If SET_TX_DMA_THRESHOLD + TX trigger spaces 64, then the default method of threshold is used: threshold value = TX FIFO size.
- SET_TX_DMA_THRESHOLD = 0:

  The threshold value = TX FIFO size TX trigger space. The TX DMA line is asserted if the TX FIFO level is lower then the threshold. It remains asserted until TX trigger spaces number of bytes are written into the FIFO. The DMA line is then deasserted and the FIFO level is compared with the threshold value.

18.2.4.6.4.1 DMA sequence to disable TX DMA

In order to disable TX DMA if it is not needed anymore (e.g. all transfers are done and UART idle mode is desired), the following sequence must be use

1. DMA mode 1 is set (both TX/RX DMA) by registers UARTI.UART_SCR[0] = 0 and UARTI.UART_FCR[3] = 1:
   A. Set the UARTI.UART_SCR[2:1]DMA_MODE_2 bit fields to 01 (DMA mode 1)
   B. Set the UARTI.UART_SCR[0]DMA_MODE_CTL bit to1 (this setting of UARTI.UART_SCR[0]DMA_MODE-CTL will ignores UARTI.UART_FCR[3]DMA_MODE_CTL bit)

      NOTE: It is strongly suggested to do steps ‘a’ and ‘b’ in two separate write in order to avoid malfunction of the device.

   C. Set the UARTI.UART_FCR[3]DMA_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UARTI.UART_SCR[0]DMA_MODE_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used.

      NOTE: There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

   D. Set the UARTI.UART_FCR[2:1]DMA_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
   E. Set the UARTI.UART_SCR[2:1]DMA_MODE_2 bit field to 10 (DMA mode 2, RX only).
   F. Set the UARTI.UART_FCR[2:1]DMA_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
   G. Set the UARTI.UART_SCR[2:1] DMA_MODE_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.
2. DMA mode 1 is set (both TX/RX DMA) by registers UARTI.UART_FCR[3] = 0 and UARTI.UART_SCR[0] = 1, UARTI.UART_SCR[2:1] = 01. It is almost the same as above, but steps ‘a’, and ‘b’ can be skipped:
   A. Set the UARTI.UART_FCR[3]DMA_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UARTI.UART_SCR[0]DMA_MODE_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used.

      NOTE: There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

   B. Set the UARTI.UART_FCR[2:1]DMA_MODE bit field to 11 (clear TX and RX FIFO and resets its

counter logic to 0. Returns to 0 after clearing FIFO).

C. Set the UARTI.UART_SCR[2:1]DMA_MODE_2 bit field to 10 (DMA mode 2, RX only).

D. Set the UARTI.UART_FCR[2:1]DMA_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).

E. Set the UARTI.UART_SCR[2:1] DMA_MODE_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.

3. DMA mode 3 is set (TX DMA only) by registers UARTI.UART_FCR[3] = 0 and UARTI.UART_SCR[0] = 1, UARTI.UART_SCR[2:1] = 11. It is the same as above:

A. Set the UARTI.UART_FCR[3]DMA_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UARTI.UART_SCR[0]DMA_MODE_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used.

NOTE: There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

B. Set the UARTI.UART_FCR[2:1]DMA_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).

C. Set the UARTI.UART_SCR[2:1]DMA_MODE_2 bit field to 10 (DMA mode 2, RX only).

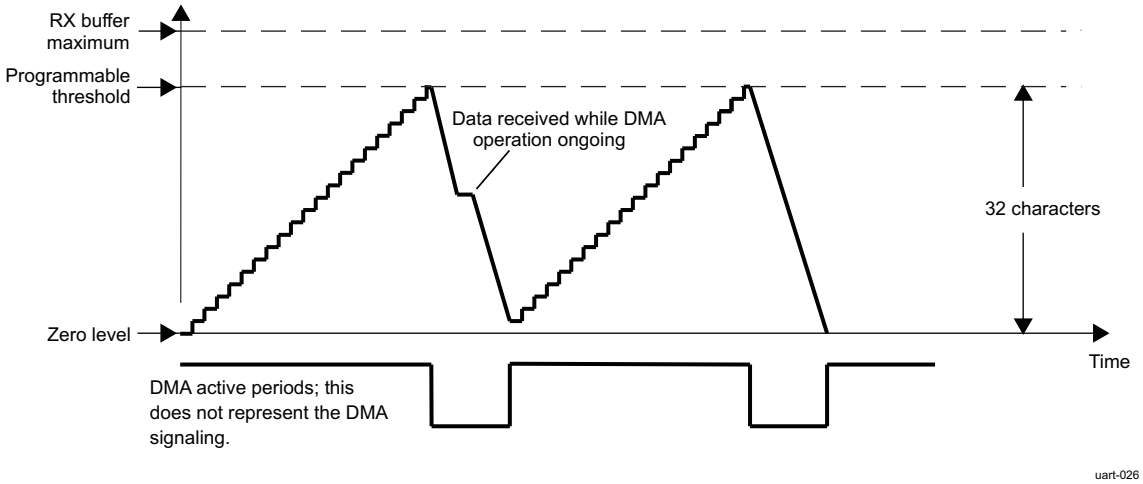
D. Set the UARTI.UART_FCR[2:1]DMA_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).

E. Set the UARTI.UART_SCR[2:1] DMA_MODE_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.

18.2.4.6.4.2 DMA Transfers (DMA Mode 1, 2, or 3)

Figure 18-34 through Figure 18-37 show the supported DMA operations.

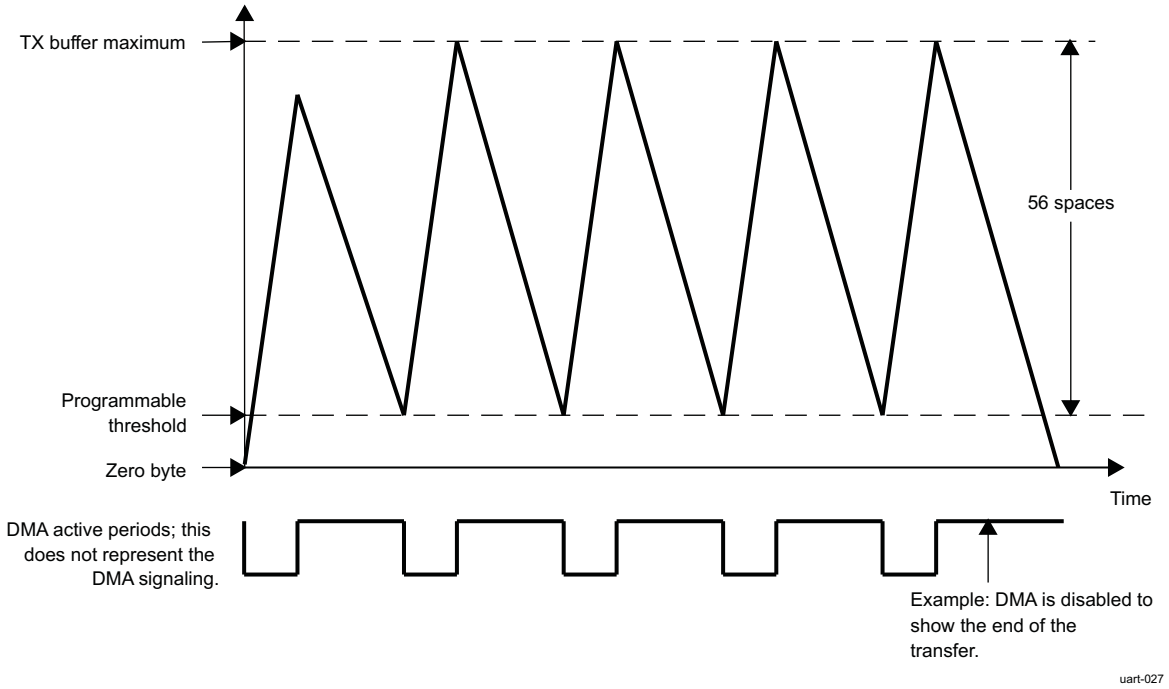
Figure 18-34. Receive FIFO DMA Request Generation (32 Characters)



In receive mode, a DMA request is generated when the RX FIFO reaches its threshold level defined in the trigger level register (UARTi.UART_TLR). This request is deasserted when the number of bytes defined by the threshold level is read by the device DMA controllers.

In transmit mode, a DMA request is automatically asserted when the TX FIFO is empty. This request is deasserted when the number of bytes defined by the number of spaces in the UARTi.UART_TLR register is written by the device DMA controllers. If an insufficient number of characters is written, the DMA request stays active.

Figure 18-35. Transmit FIFO DMA Request Generation (56 Spaces)



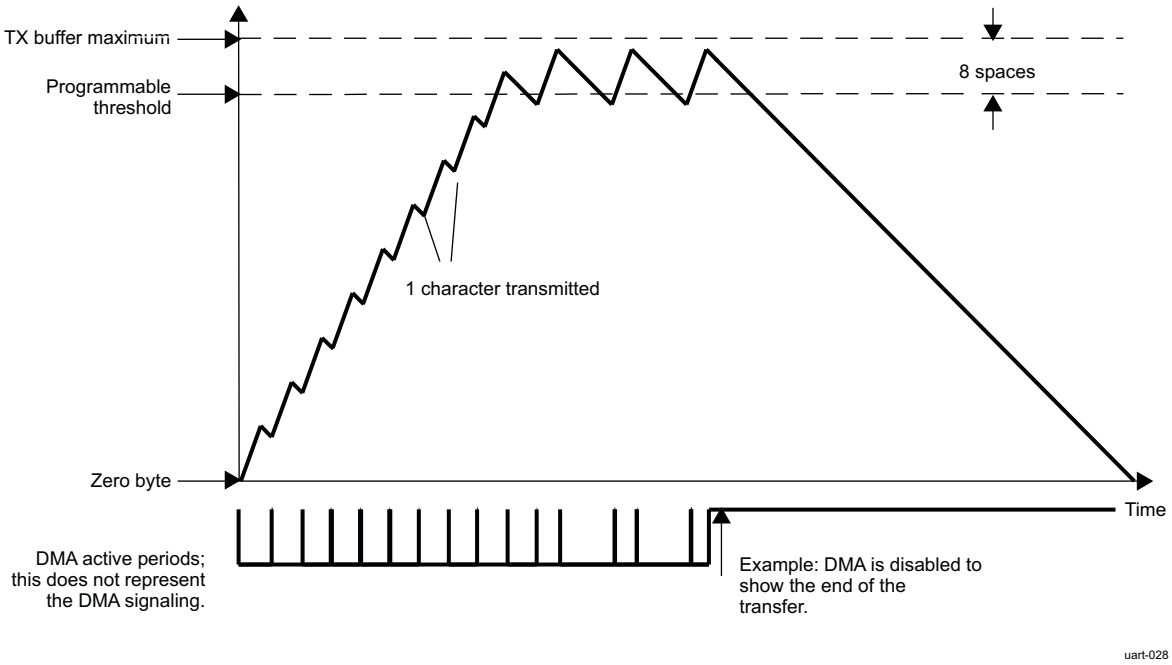
The DMA request is again asserted if the FIFO can receive the number of bytes defined by the UARTi.UART_TLR register.

The threshold can be programmed in a number of ways. Figure 18-35 shows a DMA transfer operating with a space setting of 56 that can arise from using the auto settings in the UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit field or the UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit field concatenated with the TX_FIFO_TRIG bit field.

The setting of 56 spaces in the UART module must correlate with the settings of the device DMA controllers, so that the buffer does not overflow (program the DMA request size of the LH controller to equal the number of spaces in the UART module).

Figure 18-36 shows an example with eight spaces to show the buffer level crossing the space threshold. The LH DMA controller settings must correspond to those of the UART module.

Figure 18-36. Transmit FIFO DMA Request Generation (8 Spaces)

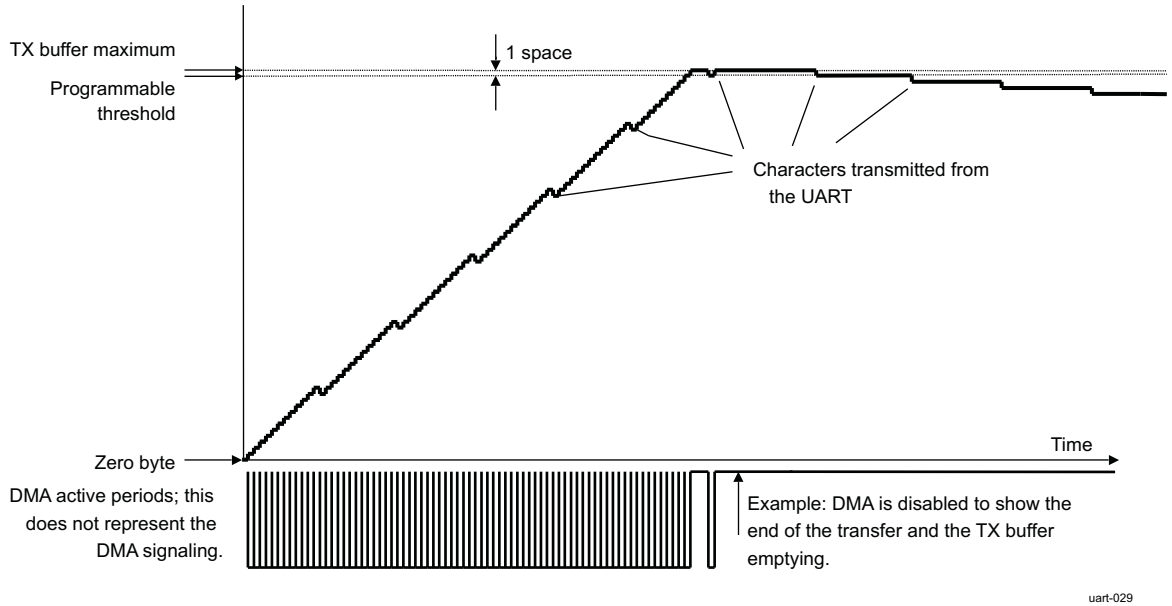


The next example shows the setting of one space that uses the DMA for each transfer of one character to the transmit buffer (see Figure 18-37). The buffer is filled faster than the baud rate at which data is transmitted to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer.

On two occasions, the buffer holds the maximum amount of data words; shortly after this, the DMA is disabled to show the slower transmission of the data words to the TX pin. Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UARTi.UART_DLL and UARTi.UART_DLH registers.

The DMA settings must correspond to the system LH DMA controller settings to ensure correct operation of this logic.

Figure 18-37. Transmit FIFO DMA Request Generation (1 Space)



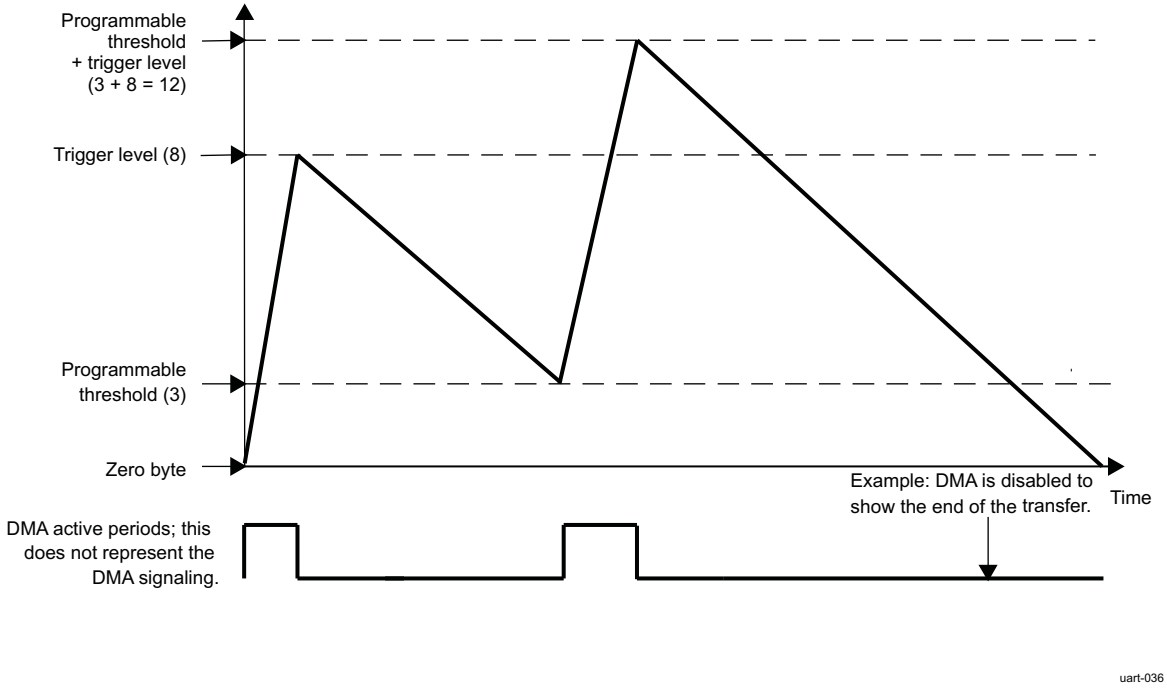
The final example illustrates the setting of eight spaces but setting the TX DMA threshold directly by setting UART_MDR3[1] NONDEFAULT_FREQ bit and UART_TX_DMA_THRESHOLD register (see Figure 18-38). In the example, UART_TX_DMA_THRESHOLD[5:0] TX_DMA_THRESHOLD = 3 and the trigger level is 8. The buffer is filled at a faster rate than the BAUD rate transmits data to the TX pin. The buffer is filled with 8 bytes and the DMA operations stop transferring data to the transmit buffer. When the buffer is emptied to the threshold level by transmission, the DMA operation activates again to fill the buffer with 8 bytes.

Eventually, the buffer will be emptied at the rate specified by the BAUD Rate settings of the UART_DLL and UART_DLH registers.

If the selected threshold level + trigger level exceeds max buffer size, then the original TX DMA threshold method is used to prevent TX overrun, regardless of the UART_MDR3[1] NONDEFAULT_FREQ value.

The DMA settings should correspond to the system Local Host DMA controller settings in order to ensure the correct operation of this logic.

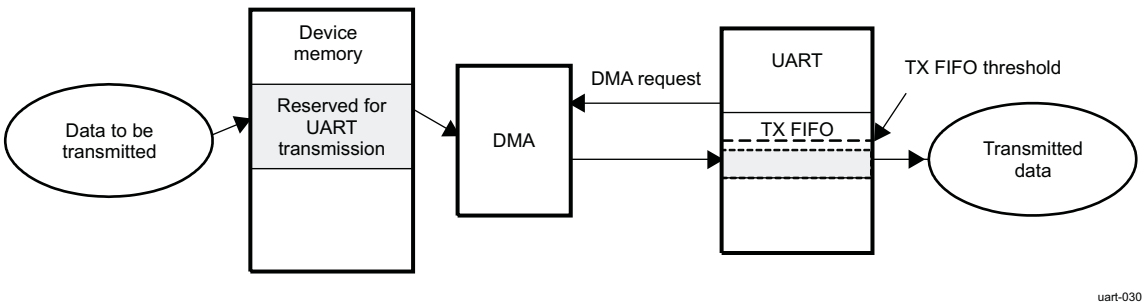
Figure 18-38. Transmit FIFO DMA Request Generation Using Direct TX DMA Threshold Programming. (Threshold = 3; Spaces = 8)



18.2.4.6.4.3 DMA Transmission

Figure 18-39 shows DMA transmission.

Figure 18-39. DMA Transmission



1. Data to be transmitted are put in the device memory reserved for UART transmission by the DMA:

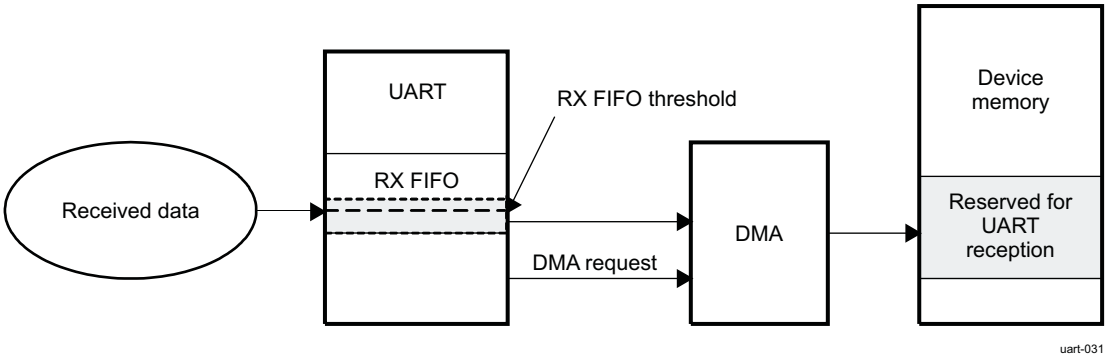
a. Until the TX FIFO trigger level is not reached, a DMA request is generated
b. An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).

2. Data in the TX FIFO are automatically transmitted.
3. The end of the transmission is signaled by the UARTi.UART_THR empty (TX FIFO empty).

18.2.4.6.4.4 DMA Reception

Figure 18-40 shows DMA reception.

Figure 18-40. DMA Reception



1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA:
   a. At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
   b. An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

18.2.4.7 Mode Selection

18.2.4.7.1 Register Access Modes

18.2.4.7.1.1 Operational Mode and Configuration Modes

Register access depends on the register access mode, although register access modes are not correlated to functional mode selection. Three different modes are available:

- Operational mode
- Configuration mode A
- Configuration mode B

Operational mode is the selected mode when the function is active; serial data transfer can be performed in this mode.

Configuration mode A and configuration mode B are used during module initialization steps. These modes enable access to configuration registers, which are hidden in the operational mode. The modes are used when the module is inactive (no serial data transfer processed) and only for initialization or reconfiguration of the module.

The value of the UARTi.UART_LCR register determines the register access mode (see Table 18-97).

Table 18-97. UART Register Access Mode Programming (Using UART_LCR)

Mode	Condition
Configuration mode A	UART_LCR[7] = 0x1 and UART_LCR[7:0] != 0xBF
Configuration mode B	UART_LCR[7] = 0x1 and UART_LCR[7:0] = 0xBF
Operational mode	UART_LCR[7] = 0x0

18.2.4.7.1.2 Register Access Submode

In each access register mode (operational mode or configuration mode A/B), some register accesses are conditional on the programming of a submode (MSR_SPR, TCR_TLR, and XOFF). These registers are identified in Table 18-116, *UART Register Manual*.

Table 18-98 through Table 18-100 summarize the register access submodes.

Table 18-98. Subconfiguration Mode A Summary

Mode	Condition
MSR_SPR	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

Table 18-99. Subconfiguration Mode B Summary

Mode	Condition
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1
XOFF	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)

Table 18-100. Suboperational Mode Summary

Mode	Condition
MSR_SPR	UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

18.2.4.7.2 UART Mode Selection

To select a mode, set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field (see Table 18-101).

Table 18-101. UART Mode Selection

Value	Mode
0x0:	UART 16x mode
0x1:	Reserved
0x2:	UART 16x auto-baud
0x3:	UART 13x mode
0x4:	Reserved
0x5:	Reserved
0x6:	Reserved
0x7:	Disable (default state)

MODE_SELECT is effective when the module is in operational mode (see Section 18.2.4.7.1, *Register Access Modes*).

18.2.4.7.2.1 Registers Available for the UART Function

Only the registers listed in Table 18-102 are used for the UART function.

Table 18-102. UART Mode Register Overview

Address Offset	Registers					
	Configuration Mode A		Configuration Mode B		Operational Mode	
	Read	Write	Read	Write	Read	Write
0x00	UART_DLL	UART_DLL	UART_DLL	UART_DLL	UART_RHR	UART_THR

18.2.4.8 Protocol Formatting

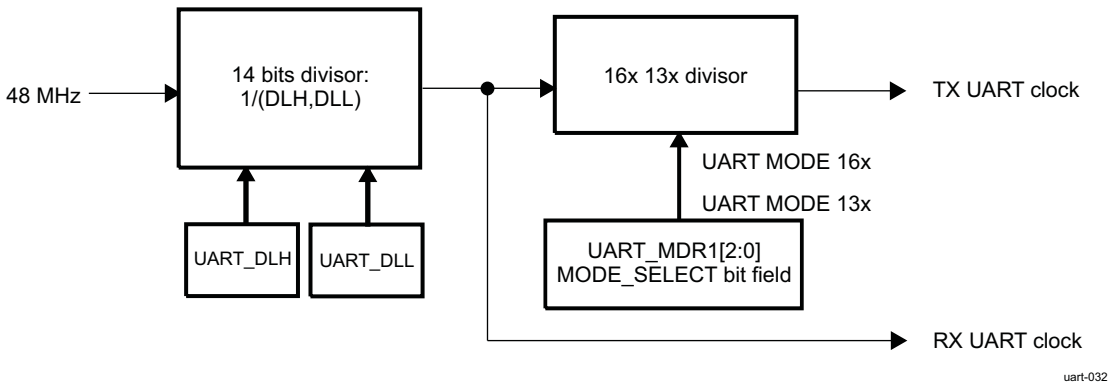
18.2.4.8.1 UART Mode

18.2.4.8.1.1 UART Clock Generation: Baud Rate Generation

The UART function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 18-41 shows the baud rate generator and associated controls.

Figure 18-41. Baud Rate Generation



CAUTION

Before initializing or modifying clock parameter controls (UARTi.UART_DLH, UARTi.UART_DLL), MODE_SELECT = DISABLE (UARTi.UART_MDR1[2:0]) must be set to 0x7. Failure to observe this rule can result in unpredictable module behavior.

18.2.4.8.1.2 Choosing the Appropriate Divisor Value

Two divisor values are:

- UART 16x mode: Divisor value = Operating frequency / (16x baud rate)
- UART 13x mode: Divisor value = Operating frequency / (13x baud rate)

Table 18-103 and Table 18-104 describe the UART baud rate settings.

Table 18-103. UART Baud Rate Settings (48-MHz Clock)

18.2.4.8.1.3 UART Data Formatting

The UART can use hardware flow control to manage transmission and reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals.

The UART is enhanced with the autobauding function. In control mode, autobauding lets the speed, the number of bits per character, and the parity selected be set automatically.

18.2.4.8.1.3.1 Frame Formatting

When autobauding is not used, frame format attributes must be defined in the UARTi.UART_LCR register.

Character length is specified using the UARTi.UART_LCR[1:0] CHAR_LENGTH bit field.

The number of stop-bits is specified using the UARTi.UART_LCR[2] NB_STOP bit.

The parity bit is programmed using the UARTi.UART_LCR[5:3] PARITY_EN, PARITY_TYPE_1, and PARITY_TYPE_2 bit fields (see Table 18-105).

Table 18-105. UART Parity Bit Encoding

PARITY_EN	PARITY_TYPE_1	PARITY_TYPE_2	Parity
0	N/A	N/A	No parity
1	0	0	Odd parity
1	1	0	Even parity
1	0	1	Forced 1
1	1	1	Forced 0

18.2.4.8.1.3.2 Hardware Flow Control

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled and disabled independently by programming the UARTi.UART_EFR[7:6] AUTO_CTS_EN and AUTO_RTS_EN bit fields, respectively.

With auto-CTS, uarti_ctsn must be active before the module can transmit data.

Auto-RTS activates the uarti_rtsn output only when there is enough room in the RX FIFO to receive data. It deactivates the uarti_rtsn output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the UARTi.UART_TCR register determine the levels at which uarti_rtsn is activated and deactivated.

If auto-CTS and auto-RTS are enabled, data transmission does not occur unless the RX FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If auto-CTS and auto-RTS are not enabled, overrun errors occur if the transmit data rate exceeds the RX FIFO latency.

- Auto-RTS:

  Auto-RTS data flow control originates in the receiver block. The RX FIFO trigger levels used in auto-RTS are stored in the UARTi.UART_TCR register. uarti_rtsn is active if the RX FIFO level is below the HALT trigger level in the UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit field. When the RX FIFO HALT trigger level is reached, uarti_rtsn is deasserted. The sending device (for example, another UART) can send an additional byte after the trigger level is reached because it may not recognize the deassertion of RTS until it begins sending the additional byte.

  uarti_rtsn is automatically reasserted when the RX FIFO reaches the RESUME trigger level programmed by the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START bit field. This reassertion requests the sending device to resume transmission.

  In this case, uarti_rtsn is an active-low signal.

- Auto-CTS:

  The transmitter circuitry checks uarti_ctsn before sending the next data byte. When uarti_ctsn is active, the transmitter sends the next byte. To stop the transmitter from sending the next byte, uarti_ctsn must be deasserted before the middle of the last stop-bit currently sent.

  The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled, the uarti_ctsn state changes do not have to trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO, and a receiver overrun error can result.

  In this case, uarti_ctsn is an active-low signal.

18.2.4.8.1.3.3 Software Flow Control

Software flow control is enabled through the enhanced feature register (UARTi.UART_EFR) and the modem control register (UARTi.UART_MCR). Different combinations of software flow control can be enabled by setting different combinations of the UARTi.UART_EFR[3:0] bit field (see Table 18-106).

Two other enhanced features relate to software flow control:

- XON-any function (UARTi.UART_MCR[5]): Operation resumes after receiving any character after the XOFF character is recognized. If special character detect is enabled and special character is received after XOFF1, it does not resume transmission. The special character is stored in the RX FIFO.

  NOTE: The XON-any character is written into the RX FIFO even if it is a software flow character.

- Special character (UARTi.UART_EFR[5]): Incoming data is compared to XOFF2. When the special character is detected, the XOFF interrupt (UARTi.UART_IIR[4]) is set, but it does not halt transmission. The XOFF interrupt is cleared by a read of UARTi.UART_IIR. The special character is transferred to the RX FIFO. Special character does not work with XON2, XOFF2, or sequential XOFFs.

Table 18-106. UART_EFR[3:0] Software Flow Control Options

Bit 3	Bit 2	Bit 1	Bit 0	TX, RX Software Flow Controls
0	0	X	X	No transmit flow control
1	0	X	X	Transmit XON1, XOFF1
0	1	X	X	Transmit XON2, XOFF2

Table 18-106. UART_EFR[3:0] Software Flow Control Options (continued)

Bit 3	Bit 2	Bit 1	Bit 0	TX, RX Software Flow Controls
1	1	X	X	Transmit XON1, XON2: XOFF1, XOFF2(1)
X	X	0	0	No receive flow control
X	X	1	0	Receiver compares XON1, XOFF1
X	X	0	1	Receiver compares XON2, XOFF2
X	X	1	1	Receiver compares XON1, XON2: XOFF1, XOFF2(1)

(1) In these cases, the XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2.
XON1 is defined in the UARTi.UART_XON1_ADDR1[7:0] XON_WORD1 bit field. XON2 is defined in the UARTi.UART_XON2_ADDR2[7:0] XON_WORD2 bit field.
XOFF1 is defined in the UARTi.UART_XOFF1[7:0] XOFF_WORD1 bit field. XOFF2 is defined in the UARTi.UART_XOFF2[7:0] XOFF_WORD2 bit field.

18.2.4.8.1.3.3.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases, XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission stops after transmission of the current character completes. Detection of XOFF also sets the UARTi.UART_IIR[4] bit (if enabled by UARTi.UART_IER[5]) and causes the interrupt line to go low.

To resume transmission, an XON1/2 character must be received (in certain cases, XON1 and XON2 must be received sequentially). When the correct XON characters are received, the UARTi.UART_IIR[4] bit is cleared and the XOFF interrupt disappears.

NOTE: When a parity, framing, or break error occurs while receiving a software flow control character, this character is treated as normal data and is written to the RX FIFO.

When XON-any and special character detect are disabled and software flow control is enabled, no valid XON or XOFF characters are written to the RX FIFO. For example, when UARTi.UART_EFR[1:0] = 0x2, if XON1 and XOFF1 characters are received, they are not written to the RX FIFO.

When pairs of software flow characters are programmed to be received sequentially (UARTi.UART_EFR[1:0] = 0x3), the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

18.2.4.8.1.3.3.2 Transmit (TX)

Two XOFF1 characters are transmitted when the RX FIFO passes the trigger level programmed by UARTi.UART_TCR[3:0]. As soon as the RX FIFO reaches the trigger level programmed by UARTi.UART_TCR[7:4], two XON1 characters are sent, so the data transfer recovers.

NOTE: If software flow control is disabled after an XOFF character is sent, the module transmits XON characters automatically to enable normal transmission.

The transmission of XOFF(s)/XON(s) follows the same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is 5, 6, or 7 characters, the 5, 6, or 7 LSBs of XOFF1/2 and XON1/2 are transmitted. The 5, 6, or 7 bits of a character are seldom transmitted, but this function is included to maintain compatibility with earlier designs.

It is assumed that software flow control and hardware flow control are never enabled simultaneously.

18.2.4.8.1.3.4 Autobauding Modes

In autobauding mode, the UART can extract transfer characteristics (speed, length, and parity) from an "at" (AT) command (ASCII code). These characteristics are used to receive data after an AT and to send data.

The following AT commands are valid:

AT	DATA	<CR>
at	DATA	<CR>
A/		
a/		

A line break during the acquisition of the sequence AT is not recognized, and an echo function is not implemented in hardware.

A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final <CR> (0x0D), are saved to the RX FIFO. The autobaud state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved in the RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The UARTi.UART_UASR register reflects the correct settings for the baud rate detected. Interrupt activity can continue in this fashion when a subsequent character is received. Therefore, it is recommended that the software enable the RHR interrupt when using the autobaud mode.

The following settings are detected in autobaud mode with a module clock of 48 MHz:

- Speed:
  - 115.2K baud
  - 57.6K baud
  - 38.4K baud
  - 28.8K baud
  - 19.2K baud
  - 14.4K baud
  - 9.6K baud
  - 4.8K baud
  - 2.4K baud
  - 1.2K baud
- Length: 7 or 8 bits
- Parity: Odd, even, or space

NOTE: The combination of 7-bit character plus space parity is not supported.

Autobauding mode is selected when the UARTi.UART_MDR1[2:0] MODE_SELECT bit field is set to 0x2. In UART autobauding mode, UARTi.UART_DLL, UARTi.UART_DLH, and UARTi.UART_LCR[5:0] bit field settings are not used; instead, UASR is updated with the configuration detected by the autobauding logic.

UASR Autobauding Status Register Use

This register is used to set up transmission according to the characteristics of the previous reception instead of the UARTi.UART_LCR, UARTi.UART_DLL, and UARTi.UART_DLH registers when the UART is in autobauding mode.

To reset the autobauding hardware (to start a new AT detection) or to set the UART in standard mode (no autobaud), the UARTi.UART_MDR1[2:0] MODE_ SELECT bit field must be set to reset state (0x7) and then to the UART in autobauding mode (0x2) or to the UART in standard mode (0x0).

Use limitation:

- Only 7- and 8-bit characters (5- and 6-bit not supported)
- 7-bit character with space parity not supported
- Baud rate between 1200 and 115,200 bps (10 possibilities)

18.2.4.8.1.3.5 Error Detection

When the UARTi.UART_LSR register is read, the UARTi.UART_LSR[4:2] bit field reflects the error bits (BI: break condition, FE: framing error, PE: parity error) of the character at the top of the RX FIFO (the next character to be read). Therefore, reading the UARTi.UART_LSR register and then reading the UARTi.UART_RHR register identifies errors in a character.

Reading the UARTi.UART_RHR register updates the BI, FE, and PE bits (see Table 18-94 for the UART mode interrupts).

The UARTi.UART_LSR[7] RX_FIFO_STS bit is set when there is an error in the RX FIFO and is cleared only when no errors remain in the RX FIFO.

NOTE: Reading the UARTi.UART_LSR register does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading the UARTi.UART_RHR register.

Reading the UARTi.UART_LSR register clears the OE bit if it is set (see Table 18-94 for the UART mode interrupts).

18.2.4.8.1.3.6 Overrun During Receive

Overrun during receive occurs if the RX state-machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the CPU with the UARTi.UART_IIR[5:1] IT_TYPE bit field set to 0x3 (receiver line status error) and discards the remaining portion of the frame.

Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received, the CPU must:

- Reset the RX FIFO.
- Read the UARTi.UART_RESUME register, which clears the internal flag.

18.2.4.8.1.3.7 Time-Out and Break Conditions

18.2.4.8.1.3.7.1 Time-Out Counter

An RX idle condition is detected when the receiver line (uarti_rxd) is high for a time that equals 4x the programmed word length + 12 bits. uarti_rxd is sampled midway through each bit.

For sleep mode, the counter is reset when there is activity on uarti_rxd.

For the time-out interrupt, the counter counts only when there is data in the RX FIFO, and the count is reset when there is activity on uarti_rxd or when the UARTi.UART_RHR register is read.

18.2.4.8.1.3.7.2 Break Condition

When a break condition occurs, uarti_txd is pulled low. A break condition is activated by setting the UARTi.UART_LCR[6] BREAK_EN bit. The break condition is not aligned on word stream (a break condition can occur in the middle of a character). The only way to send a break condition on a full character is:

1. Reset the TX FIFO (if enabled).
2. Wait for the transmit shift register to empty (the UARTi.UART_LSR[6] TX_SR_E bit is set to 1).

3. Take a guard time according to stop-bit definition.
4. Set the BREAK_EN bit to 1.

The break condition is asserted while the BREAK_EN bit is set to 1.

18.2.5 UART Basic Programming Model

This section describes the procedure for operating the UART with FIFO and DMA or interrupts. This three-part procedure ensures the quick start of the UART. It does not cover every UART feature.

The first programming model covers software reset of the UART. The second programming model describes FIFO and DMA configuration. The last programming model describes protocol, baud rate, and interrupt configuration.

NOTE: Each programming model can be used independently of the other two; for instance, reconfiguring the FIFOs and DMA settings only.

Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see Section 18.2.4.7.1, *Register Access Modes*.

18.2.5.1 Global Initialization

18.2.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the UART module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the UART.

For more information, see Section 18.2.3, *UART Integration*.

Table 18-107. Global Initialization of Surrounding Modules for UART

Surrounding Modules	Comments
PRCM	UART functional and interface clocks must be enabled. For more information, see Chapter 3, *Power, Reset, and Clock Management*.
Control module	Module-specific pad muxing must be set in the control module. For more information, see Chapter 13, *Control Module*.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*
Interrupt controllers	Device INTCs must be configured to enable the interrupt request generation. For information about enabling interrupts, see *Chapter 12, Interrupt Controllers*.
DMA_CROSSBAR	DMA_CROSSBAR configuration must be done to allow module DREQs to be mapped to certain device DMA line. For more information see Section 13.4.6.4, *DMA_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.
DMA controllers	DMA controllers configuration must be done to enable the module DMA channel request.
Interconnects	For information about the L4 interconnect configuration, see Chapter 9, *Interconnect*.

18.2.5.1.2 UART Module Global Initialization

The procedure in Table 18-108 can be used to initialize UART when performing software reset.

Table 18-108. UART Global Initialization

Step	Register/Bit Field/Programming Model	Value
Perform a software reset.	UART_SYSC[1] SOFTRESET	0x1
Wait until reset is finished.	UART_SYSS[0] RESETDONE	= 0x1

18.2.5.2 Mode selection

The Table 18-109 describes how to set different register access mode.

Table 18-109. Configure register access mode

Step	Register/Bit Field/Programming Model	Value
Set the regiser access mode A	UART_LCR[7]DIV_EN	0x1
	UART_LCR[7:0]	!=0xBF
Set the regiser access mode B	UART_LCR[7:0]	0xBF
Set the operational mode	UART_LCR[7]DIV_EN	0x1

18.2.5.3 Submode selection

This section describes how to set different register access submode.

Table 18-110. Configure register access submode TCR_TLR

Step	Register/Bit Field/Programming Model	Value
Configure the submode TCR_TLR		
Configure mode B	see Table 18-109	
Enable writing to register bits UART_MCR[7:5]	UART_EFR[4]ENHANCED_EN	0x1
Configure mode A	see Table 18-109	0x1
Set the submode TCR_TLR	UART_MCR[6]TCR_TLR	0x1

Table 18-111. Configure register access submode MSR_SPR

Step	Register/Bit Field/Programming Model	Value
First option configure the submode MSR_SPR		
Configure mode B	see Table 18-109	
Set the submode MSR_SPR	UART_EFR[4]ENHANCED_EN	0x0
Second option configure the submode MSR_SPR		
Configure mode B	see Table 18-109	
Enable writing to register bits UART_MCR[7:5]	UART_EFR[4]ENHANCED_EN	0x1
Set the submode MSR_SPR	UART_MCR[6]TCR_TLR	0x0

Table 18-112. Configure register access submode XOFF

Step	Register/Bit Field/Programming Model	Value
Configuration of the XOFF		
Configure B	see Table 18-109	
Set the submode XOFF	UART_EFR[4] ENHANCED_EN	0x0

18.2.5.4 Load FIFO trigger and DMA mode settings

18.2.5.4.1 DMA mode Settings

To enable and configure the DMA mode, perform the following steps:

Table 18-113. DMA mode settings

Step	Register/Bit Field/Programming Model	Value
Set the option of DMA mode configuration.	UART_SCR[0] DMA_MODE_CTL	0x-
IF Configure DMA mode 0 and 1	UART_SCR[0] DMA_MODE_CTL	0x0
Select the DMA mode, for more information see Section 18.2.4.6.4	UART_FCR[3] DMA_MODE	0x-
IF Configure DMA mode from 0 to 3	UART_SCR[0] DMA_MODE_CTL	0x1
Select the DMA mode, for more information see Section 18.2.4.6.4	UART_SCR[2:1] DMA_MODE_2	0x-

18.2.5.4.2 FIFO Trigger Settings

In this section is described configuration and settings of FIFO trigger level, which enable DMA and interrupt generation.

Table 18-114. Load FIFO triggers defined by the FCR

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see Table 18-110	0x-
Set the desire RX FIFO trigger level	UART_FCR[5:4]TX_FIFO_TRIG	0x-
Set the desire TX FIFO trigger level	UART_FCR[7:6]RX_FIFO_TRIG	0x-

Table 18-115. Load FIFO triggers defined by the TLR

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see Table 18-110	0x-
Set the desire RX FIFO trigger level	UART_TLR[7:4]RX_FIFO_TRIG_DMA	0x-
Set the desire TX FIFO trigger level	UART_TLR[3:0]TX_FIFO_TRIG_DMA	0x-

Table 18-116. Load FIFO triggers defined by the concatenated value

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see Table 18-110	0x-
Set the register bit	UART_SCR[7]RX_TRIG_GRANU1	0x1
Set the desire RX FIFO trigger level	UART_TLR[7:4]RX_FIFO_TRIG_DMA UART_FCR[7:6]RX_FIFO_TRIG	0x-
Set the register bit	UART_SCR[6]TX_TRIG_GRANU1	0x1
Set the desire TX FIFO trigger level	UART_TLR[3:0]TX_FIFO_TRIG_DMA UART_FCR[5:4]TX_FIFO_TRIG	0x-

18.2.5.5 Protocol, Baud rate and interrupt settings

18.2.5.5.1 Baud rate settings

Table 18-117. Baud rate settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2:0] MODE_SELECT	0x7
Switch to register configuration mode B	see Table 18-109	
Enable access to UART_IER[7:4]	UART_EFR[4] ENHANCED_EN	0x1
Switch register operational mode	see Table 18-109	
Disable sleep mode	UART_IER[4] SLEEP_MODE	0x0
Switch to register configuration mode A or B	see Table 18-109	
Set the appropriate divisor value	UART_DLL[7:0] CLOCK_LSB UART_DLH[5:0] CLOCK_MSB	0x-

18.2.5.5.2 Interrupt settings

Table 18-118. Interrupt settings

Step	Register/Bit Field/Programming Model	Value
Switch to register configuration mode B	see Table 18-109	0x7
Enable access to UART_IER[7:4]	UART_EFR[4] ENHANCED_EN	
Switch register operational mode	see Table 18-109	
Set the desired interrupt configuration (0: Disable the interrupt; 1: Enable the interrupt)	UART_IER[7] CTS_IT UART_IER[6] RTS_IT UART_IER[5] XOFF_IT UART_IER[4] SLEEP_MODE UART_IER[3] MODEM_STS_IT UART_IER[2] LINE_STS_IT UART_IER[1] THR_IT UART_IER[0] RHR_IT	0x-

18.2.5.5.3 Protocol settings

Load the desired protocol formatting (parity, stop-bit, character length) and switch to register operational mode.

Table 18-119. Protocol settings

Step	Register/Bit Field/Programming Model	Value
Load desired protocol formatting, see Section 18.2.4.8.1.3.1, *Frame Formatting*	UART_LCR[5] PARITY_TYPE_2 UART_LCR[4] PARITY_TYPE_1 UART_LCR[3] PARITY_EN UART_LCR[2] NB_STOP UART_LCR[1:0] PARITY_LENGTH	0x-
Swtich to register operational mode	UART_LCR[7] DIV_EN UART_LCR[6] BREAK_EN	0x0

18.2.5.5.4 UART Mode Selection

Table 18-120. UART mode selection

Step	Register/Bit Field/Programming Model	Value
Load the desired UART mode, see Section 18.2.4.7.2, *UART Mode Selection*	UART_MDR1[2:0] MODE_SELECT	0x-

18.2.5.6 Hardware and Software Flow Control Configuration

This section describes the programming steps to enable and configure hardware and software flow control. Hardware and software flow control cannot be used at the same time.

18.2.5.6.1 Hardware Flow Control Configuration

Table 18-121. Hardware Flow Control Configuration

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see Table 18-110	0x7
Load the start and halt trigger value.	UART_TCR[7:4] AUTO_RTS_START UART_TCR[3:0] AUTO_RTS_HALT	0x-
Enable or disable receive and transmit hardware flow control mode.	UART_EFR[7] AUTO_CTS_EN UART_EFR[6] AUTO_RTS_EN	0x-

18.2.5.6.2 Software Flow Control Configuration

Table 18-122. Software Flow Control Configuration

Step	Register/Bit Field/Programming Model	Value
Set the register access submode XOFF	see Table 18-112	
Load the software control characters	UART_XON1_ADDR1[7:0] XON_WORD1 UART_XON2_ADDR2[7:0] XON_WORD2 UART_XOFF1[7:0] XOFF_WORD1 UART_XOFF2[7:0] XOFF_WORD2	0x-
Set the register access submode TCR_TLR	see Table 18-110	
Enable or disable XON any function (0: Disable; 1: Enable).	UART_MCR[5] XON_EN	0x-
Load start and halt trigger value for software flow control	UART_TCR[7:4] AUTO_RTS_START UART_TCR[3:0] AUTO_RTS_HALT	0x-
Enable or disable special character function(0: Disable; 1: Enable)	UART_EFR[5] SPEC_CHAR	0x-
Set the software flow control mode	UART_EFR[3:0] SW_FLOW_CONTROL	0x-

18.2.6 UART Register Manual

18.2.6.1 UART Instance Summary

Table 18-123. UART Instance Summary

18.2.6.2.2 UART Register Description

Table 18-125. UART_THR

Address Offset	0x0000 0000		
Physical Address	0x4806 A000 0x4806 C000 0x4802 0000	**Instance**	UART1 UART2 UART3
Description	The transmitter section consists of the transmit holding register (THR) and the transmit shift register. The THR is a 64-byte FIFO. The local host (LH) writes data to the THR. The data is placed in the transmit shift register where it is shifted out serially on the TX output. If the FIFO is disabled, location 0 of the FIFO stores the data.		
Type	W		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 18-127. UART_RHR

Address Offset	0x0000 0000		
Physical Address	0x4806 A000 0x4806 C000 0x4802 0000	**Instance**	UART1 UART2 UART3
Description	The receiver section consists of the receiver holding register (RHR) and the receiver shift register. The RHR is a 64-byte FIFO. The receiver shift register receives serial data from RX input. The data is converted to parallel data and moved to the RHR. If the FIFO is disabled, location 0 of the FIFO stores the single data character. **Note:** If an overflow occurs, the data in the RHR is not overwritten.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Address Offset	0x0000 0018		
Physical Address	0x4806 A018 0x4806 C018 0x4802 0018	**Instance**	UART1 UART2 UART3
Description	Transmission control register This register stores the RX FIFO threshold levels to start/stop transmission during hardware/software flow control. Notes: Trigger levels from 0 to 60 bytes are available with a granularity of 4. (Trigger level = 4 x [4-bit register value]) The programmer must ensure that UART_TCR[3:0] > UART_TCR[7:4] when auto-RTS or software flow control is enabled to avoid a mis-operation of the device. In FIFO interrupt mode with flow control, the programmer must ensure that the trigger level to halt transmission is greater than or equal to the RX FIFO trigger level (UART_TLR[7:4] or UART_FCR[7:6]); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist because a DMA request is sent each time a byte is received.

Address Offset	0x0000 0020		
Physical Address	0x4806 A020 0x4806 C020 0x4802 0020	**Instance**	UART1 UART2 UART3
Description	Mode definition register 1 The mode of operation can be programmed by writing to MDR1[2:0] and therefore the MDR1 must be programmed on startup after configuration of the configuration registers (UART_DLL, UART_DLH, and UART_LCR). The value of MDR1[2:0] must not be changed again during normal operation. **Note:** If the module is disabled by setting the MODE_SELECT field to 111, interrupt requests can still be generated unless disabled through the interrupt enable register (UART_IER). In this case, UART mode interrupts are visible. Reading the interrupt identification register (UART_IIR) shows UART mode interrupt flags.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Address Offset	0x0000 0038		
Physical Address	0x4806 A038 0x4806 C038 0x4802 0038	**Instance**	UART1 UART2 UART3
Description	UART autobauding status register This status register returns the speed, the number of bits by characters, and the type of the parity in UART autobauding mode. In autobauding mode, the input frequency of the UART modem must be fixed to 48 MHz. Any other module clock frequency results in incorrect baud rate recognition. **Note:** When the UART is in autobauding mode, this register, instead of the UART_LCR, UART_DLL, and UART_DLH registers, is used to set up transmission according to the characteristics of the previous reception. To reset the autobauding hardware (to start a new AT detection), set UART_MDR1[2:0] to 111 (reset value), then set UART_MDR1[2:1] to 010 (UART in autobaud mode). To set the UART to standard mode (no autobaud), set UART_MDR1[2:1] to 000.

Physical Address	0x4806 A05C 0x4806 C05C 0x4802 005C	**Instance**	UART1 UART2 UART3
Description	Wake-up enable register The UART wake-up enable register is used to mask and unmask a UART event that would subsequently notify the system. An event is any activity in the logic that could cause an interrupt and/or an activity that would require the system to wake up. Even if the wakeup is disabled for certain events, if these events are also an interrupt to the UART, the UART registers the interrupt.

18.3 Multichannel Serial Peripheral Interface

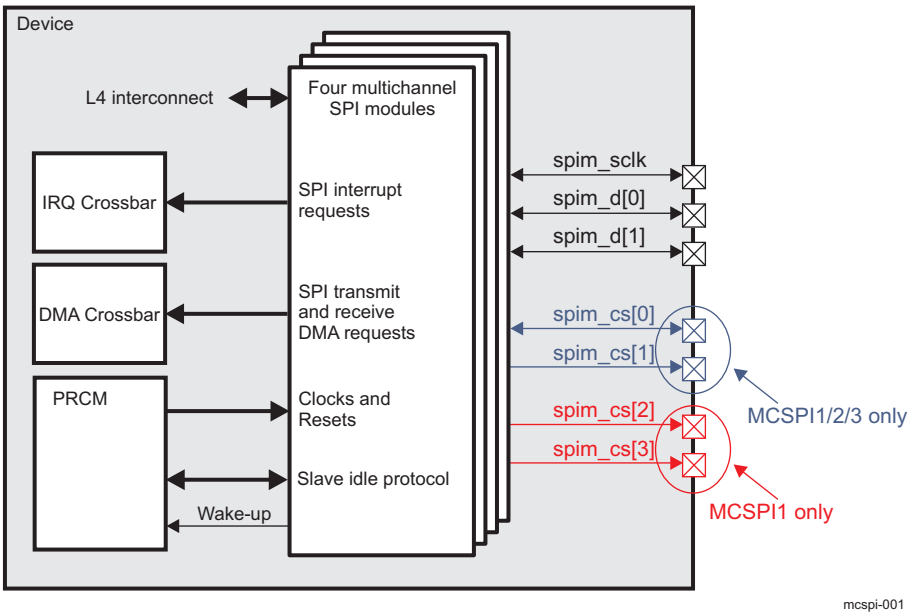
This section describes the four Multichannel Serial Peripheral Interface (McSPI) modules for the device.

18.3.1 McSPI Overview

The SPI is a master/slave synchronous serial bus. There are four separate McSPI modules (McSPI1, McSPI2, McSPI3, and McSPI4) in the device (see Figure 18-42). All these four modules are able to work as both master and slave and support the following chip selects:

- McSPI1: spi1_cs[0], spi1_cs[1], spi1_cs[2], spi1_cs[3]
- McSPI2: spi2_cs[0], spi2_cs[1]
- McSPI3: spi3_cs[0], spi3_cs[1]
- McSPI4: spi4_cs[0]

Figure 18-42. Multichannel SPI Modules



The McSPI modules include the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of SPI word lengths, ranging from 4 to 32 bits
- Up to four master channels, or single channel in slave mode
- Master multichannel mode:
  - Full duplex/half duplex
  - Transmit-only/receive-only/transmit-and-receive modes
  - Flexible input/output (I/O) port controls per channel
  - Programmable clock granularity
  - SPI configuration per channel. This means, clock definition, polarity enabling and word width
- Single interrupt line for multiple interrupt source events
- Power management through wake-up capabilities
- Enable the addition of a programmable start-bit for SPI transfer per channel (start-bit mode)
- Supports start-bit write command
- Supports start-bit pause and break sequence
- Programmable timing control between chip select and external clock generation
- Built-in FIFO available for a single channel

18.3.2 McSPI Environment

18.3.2.1 Basic McSPI Pins for Master Mode

Figure 18-43 shows all of the McSPI interface signals in master mode.

Figure 18-43. McSPI Interface Signals in Master Mode

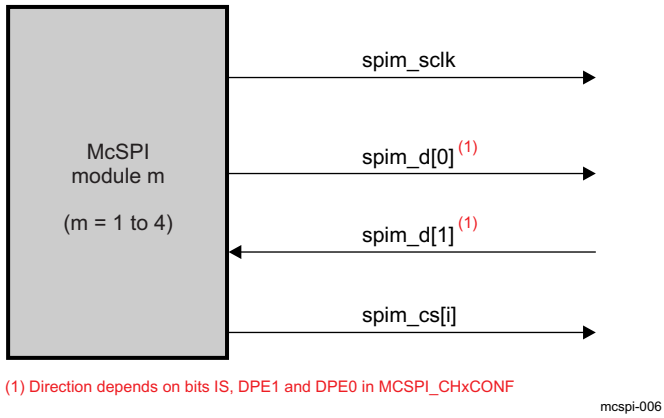


Table 18-193 describes the McSPI I/O in master mode.

Table 18-193. McSPI I/O Description (Master Mode)

Device-Level Signal Name	Module Signal Name	I/O(1)	Description
spim_sclk	SPICLK	O	SPIm module serial clock output
spim_d[0]	SPIDAT[0]	O(2)	SPI Data I/O. Can be configured either as input or as output depending on MCSPI_CHxCONF[18] IS and MCSPI_CHxCONF[16] DPE0.
spim_d[1]	SPIDAT[1]	I(2)	SPI Data I/O. Can be configured either as input or as output depending on MCSPI_CHxCONF[18] IS and MCSPI_CHxCONF[17] DPE1.
spim_cs[i]	SPIEN[x]	O	SPIm module chip-select i output

(1) I = Input; O = Output
(2) Example configuration only.

NOTE: For the spim_sclk signals to work properly, the INPUTENABLE bit of the appropriate CTRL_CORE_PAD_x registers should be set to 0x1 because of retiming purposes.

18.3.2.2 Basic McSPI Pins for Slave Mode

Figure 18-44 shows all of the McSPI interface signals in slave mode.

Figure 18-44. McSPI Interface Signals in Slave Mode

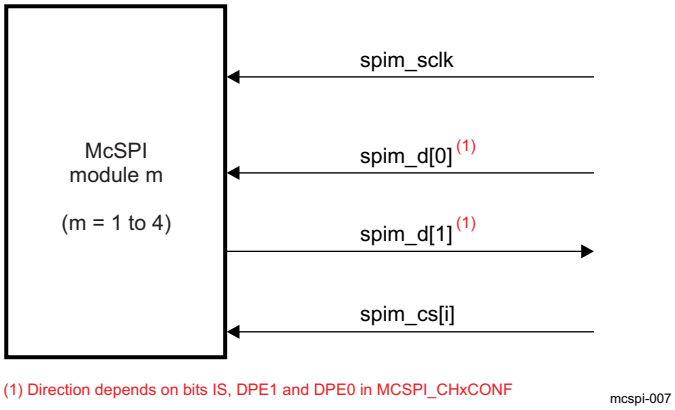

Table 18-194 describes the McSPI I/O in slave mode.

Table 18-194. McSPI I/O Description (Slave Mode)

Device-Level Signal Name	Module Signal Name	I/O(1)	Description
spim_sclk	SPICLK	I	McSPIm module serial clock input
spim_d[0]	SPIDAT[0]	I(2)	SPI Data I/O. Can be configured either as input or as output depending on MCSPI_CHxCONF[18] IS and MCSPI_CHxCONF[16] DPE0.
spim_d[1]	SPIDAT[1]	O(2)	SPI Data I/O. Can be configured either as input or as output depending on MCSPI_CHxCONF[18] IS and MCSPI_CHxCONF[17] DPE1.
spim_cs[i]	SPIEN[x]	I	McSPIm module chip-select i input. Can be selected through MCSPI_CH0CONF[22:21] SPIENSLV bit field

(1) I = Input; O = Output
(2) Example configuration only.

18.3.2.3 Multichannel SPI Protocol and Data Format

The synchronous SPI protocol allows a master device to initiate serial data transfers to a slave device. A slave select line (SPIEN[x]) allows selection of an individual slave SPI device. Slave devices that are not selected do not interfere with SPI bus activities.

McSPI offers the flexibility to modify the following parameters to adapt to the device features:

- Word length

  McSPI supports any SPI word ranging from 4 bits to 32 bits long (the MCSPI_CHxCONF[11:7] WL bit field).

  SPI word length can be changed between transmissions to allow the master device to communicate with peripheral slaves that have different requirements.

- SPI enable (SPIEN[x], for channel x of instance m)

  The polarity of the SPI enable signals is programmable (the MCSPI_CHxCONF[6] EPOL bit). SPIEN[x] signals can be active high or low.

  Assertion of the SPIEN[x] signals is programmable and can be done manually or automatically. The manual assertion mode is available in single master mode only. SPIEN[x] can be kept active between words with the MCSPI_CHxCONF[20] FORCE bit.

  Two consecutive words for two different slave devices can go along with active SPIEN[x] signals with different polarity.

- Programmable start-bit

  In start-bit mode a start-bit is added before the SPI word length to indicate how the next SPI word must be handled. The start-bit is enabled by setting the MCSPI_CHxCONF[23] SBE bit to 1. The MCSPI_CHxCONF[24] SBPOL bit defines the polarity of the start-bit.

- Programmable SPI clock
  - Bit rate

    In master mode, the baud rate of the SPI serial clock is programmable using the 48-MHz reference clock (from the power, reset, and clock managment [PRCM] module). Table 18-195 lists the SPICLK bit rates obtained for data transfer when programming the clock divider (the MCSPI_CHxCONF[5:2] CLKD bit field).

Table 18-195. SPI Master Clock Rates

Divider	Clock Rate
1	48 MHz(1)
2	24 MHz(1)
4	12 MHz
8	6 MHz
16	3 MHz
32	1.5 MHz
64	750 kHz
128	375 kHz
256	~187 kHz
512	~93.7 kHz
1024	~46.8 kHz
2048	~23.4 kHz
4096	~11.7 kHz

(1) These frequencies are not necessarily supported by all SPI modules. For more information, see the *Timing Requirements and Switching Characteristics* chapter in the device data manual.

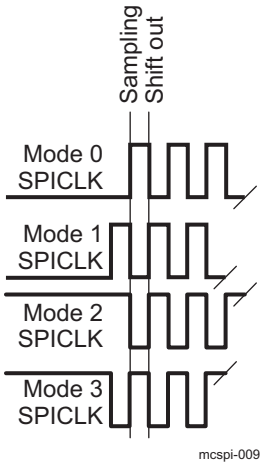
  - Polarity and phase

    The polarity (the MCSPI_CHxCONF[1] POL bit) and the phase (the MCSPI_CHxCONF[0] PHA bit) of the SPI serial clock (SPICLK) are configurable to offer four combinations. Software selects the right combination, depending on the device. See Table 18-196 and Figure 18-45.

Table 18-196. Phase and Polarity Combinations

Polarity (POL)	Phase (PHA)	SPI Mode	Description
0	0	Mode 0	SPICLK is inactive low and sampling occurs at the rising edge.
0	1	Mode 1	SPICLK is inactive low and sampling occurs at the falling edge.
1	0	Mode 2	SPICLK is inactive high and sampling occurs at the falling edge.
1	1	Mode 3	SPICLK is inactive high and sampling occurs at the rising edge.

Figure 18-45. Phase and Polarity Combinations



18.3.2.3.1 Transfer Format

In master and slave modes, the McSPI drives the data lines when SPIEN[x] is asserted.

Each word is transmitted starting with the most-significant bit (MSB).

This section explains the two cases of data transmission determined by the clock phase (PHA) and the type of data transmission using a start-bit (SBE) called the start-bit mode:

- Transmission in mode 0 and mode 2 (PHA = 0)

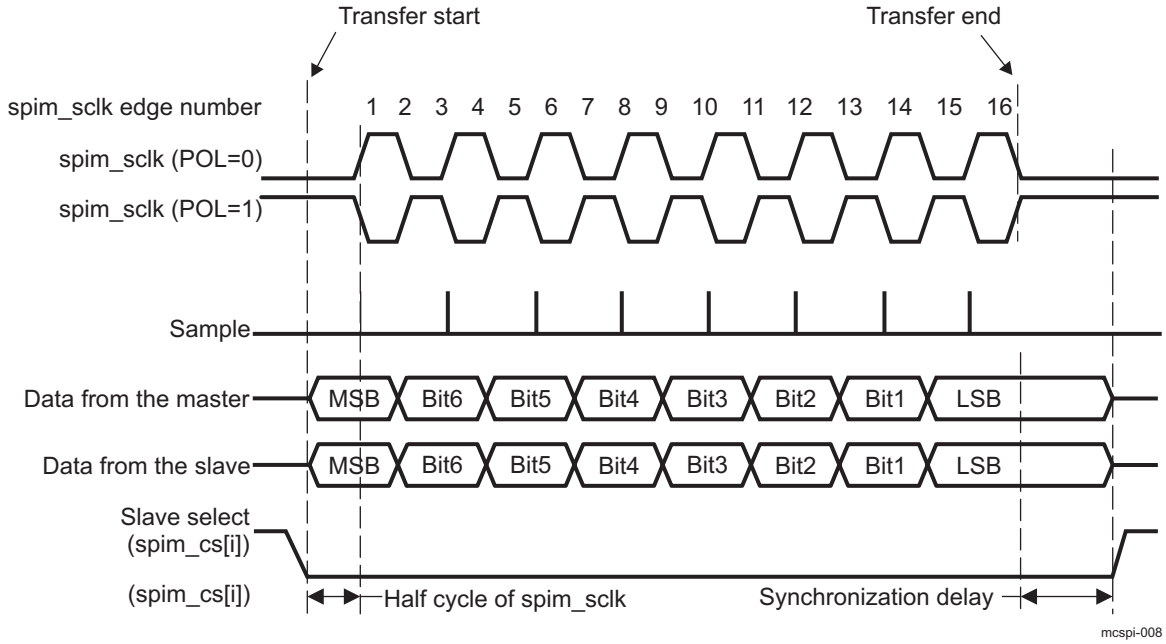
  When PHA = 0, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid one-half cycle of SPICLK after the assertion of SPIEN.

  Therefore, the first edge of the SPICLK line is used by the master to sample the first data bit sent by the slave. On the same edge, the first data bit sent by the master is sampled by the slave.

  On the next SPICLK edge, the received data bit is shifted into the receive shift register and a new data bit is transmitted on the serial data line.

  This process continues for a number of pulses on the SPICLK line defined by the SPI word length programmed in the master device, with data being latched on odd-numbered edges and shifted on even-numbered edges. See Figure 18-46.

Figure 18-46. Full-Duplex Transfer Format With PHA = 0



- Transmission in mode 1 and mode 3 (PHA = 1)

  When PHA = 1, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid on the following SPICLK edge (one-half cycle later). This is the sampling edge for the master and slave. A synchronization delay is added between the activation of SPIEN[x] and the first SPICLK edge.

  The received data bit is shifted into the shift register on the third SPICLK edge.

  This process continues for a number of pulses on the SPICLK line defined by the SPI word length programmed in the master device, with data being latched on even-numbered edges and shifted on odd-numbered edges.

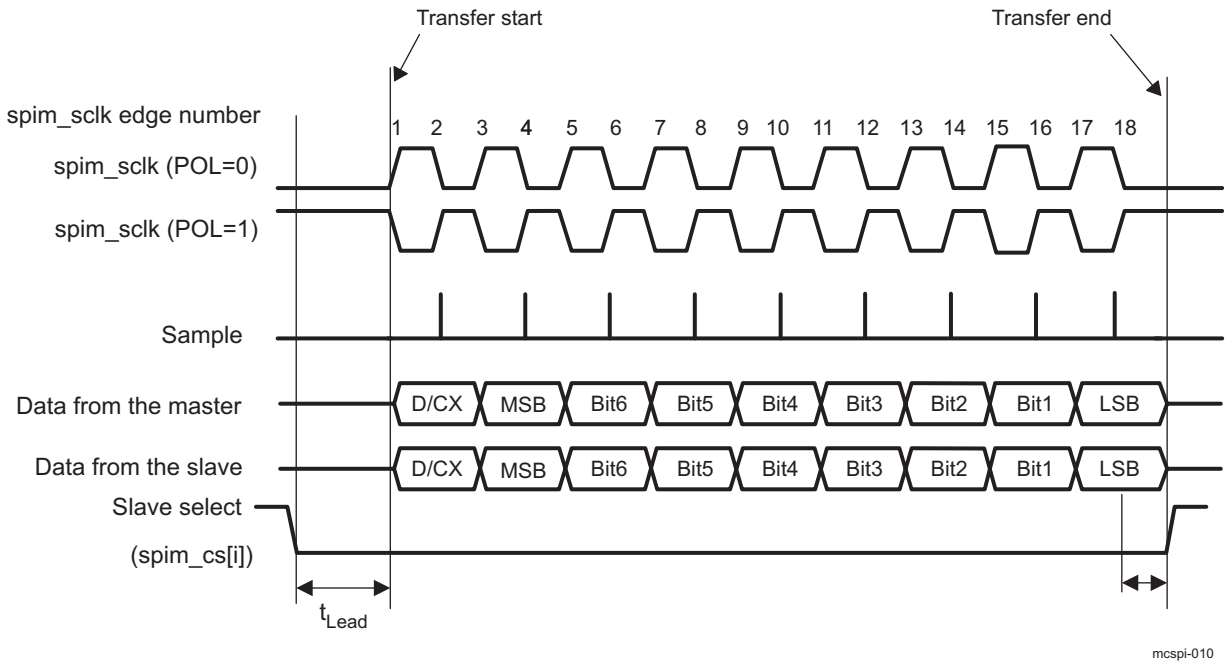
  NOTE: The minimum synchronization delay is one cycle of SPICLK, if the frequency of SPICLK equals the frequency of SPIm_FCLK (McSPIm functional clock) in master mode. The minimum synchronization delay is one-half cycle of SPICLK, if the frequency of SPICLK is lower than the frequency of SPIm_FCLK in the master and slave modes.

- Transmission with a start-bit (SBE = 1)

  When the MCSPI_CHxCONF[23] SBE bit is set to 1, a start-bit is added before the MSB to indicate whether the next SPI word must be handled as a command or as data.

  Figure 18-47 shows an example of a data transfer with an extra start-bit.

Figure 18-47. Extended SPI Transfer With a Start-Bit (SBE = 1)



18.3.2.4 SPI in Master Mode

Figure 18-48 shows a case in master mode (full-duplex) where the McSPI module is connected with two slave devices.

Figure 18-48. McSPI Master Mode (Full Duplex)

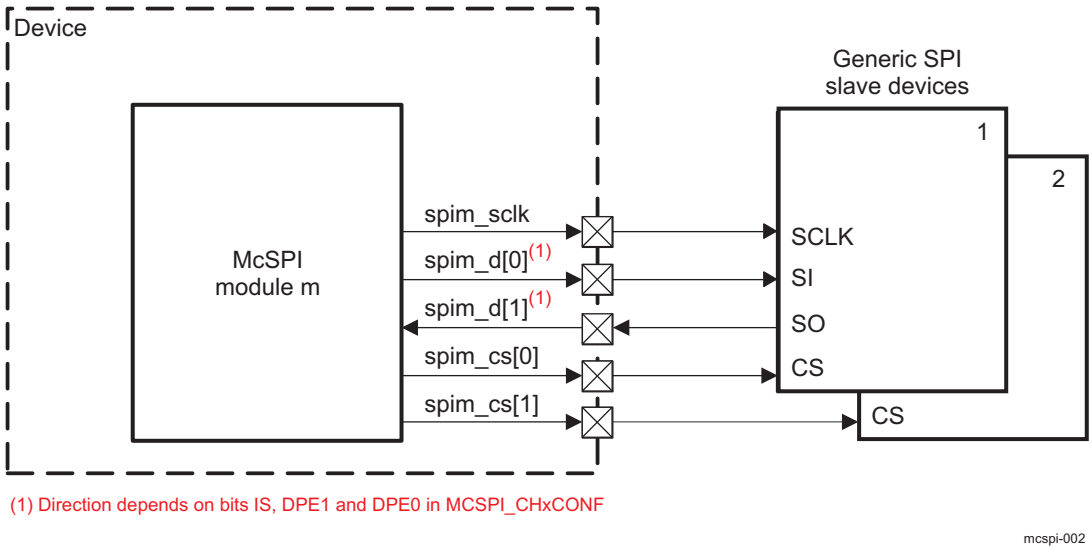


Figure 18-49 shows the master single mode, which can also be configured in receive-only mode.

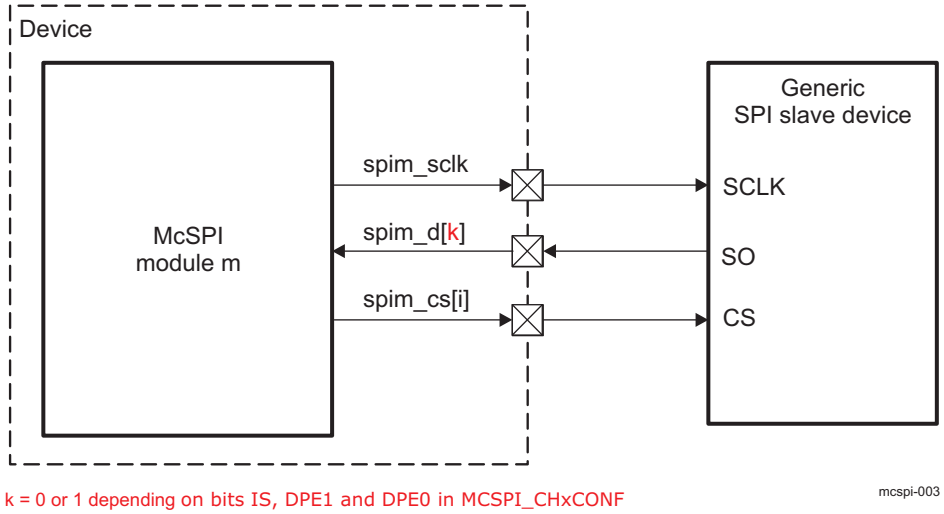
Figure 18-49. McSPI Master Single Mode (Receive Only)



18.3.2.5 SPI in Slave Mode

Figure 18-50 shows a case in slave mode (full-duplex).

NOTE: Only channel 0 can be configured as slave, but the chip-enable signal can be connected to any SPIEN[x] pin and then rerouted internally to channel 0 (the MCSPI_CHxCONF[22:21] SPIENSLV bit field [where x = 0]). For more information, see Section 18.3.4.4, *Slave Mode*.

Figure 18-50. McSPI Slave Mode (Full Duplex)

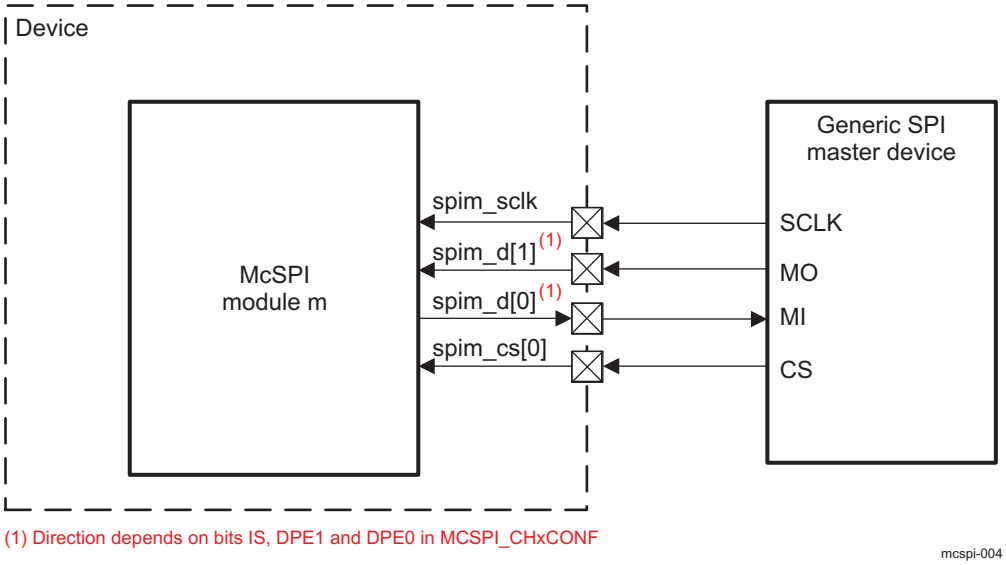


Figure 18-51 shows the slave single mode, which can also be configured in transmit-only mode.

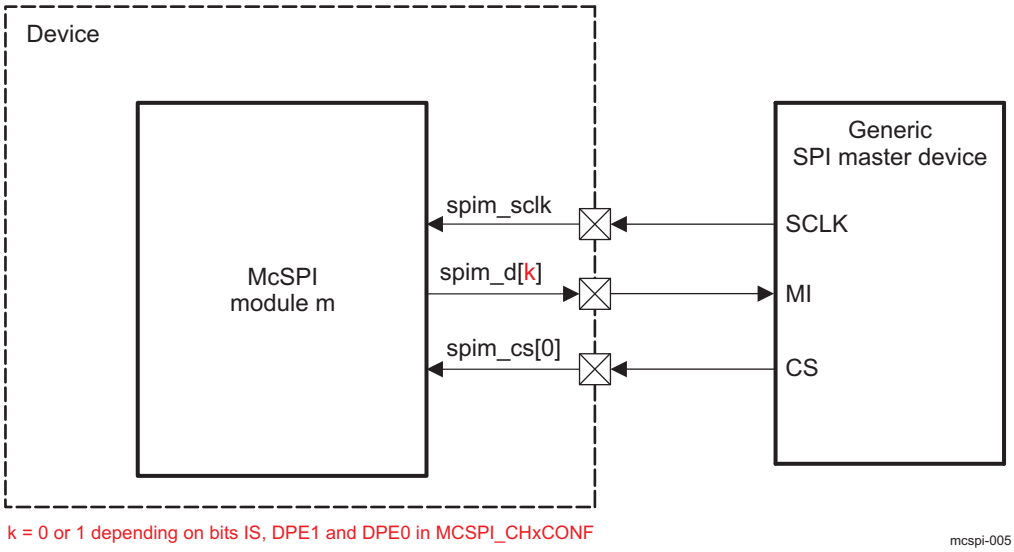
Figure 18-51. McSPI Slave Single Mode (Transmit Only)



18.3.3 McSPI Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 18-52 shows McSPI integration.

Figure 18-52. McSPI Integration

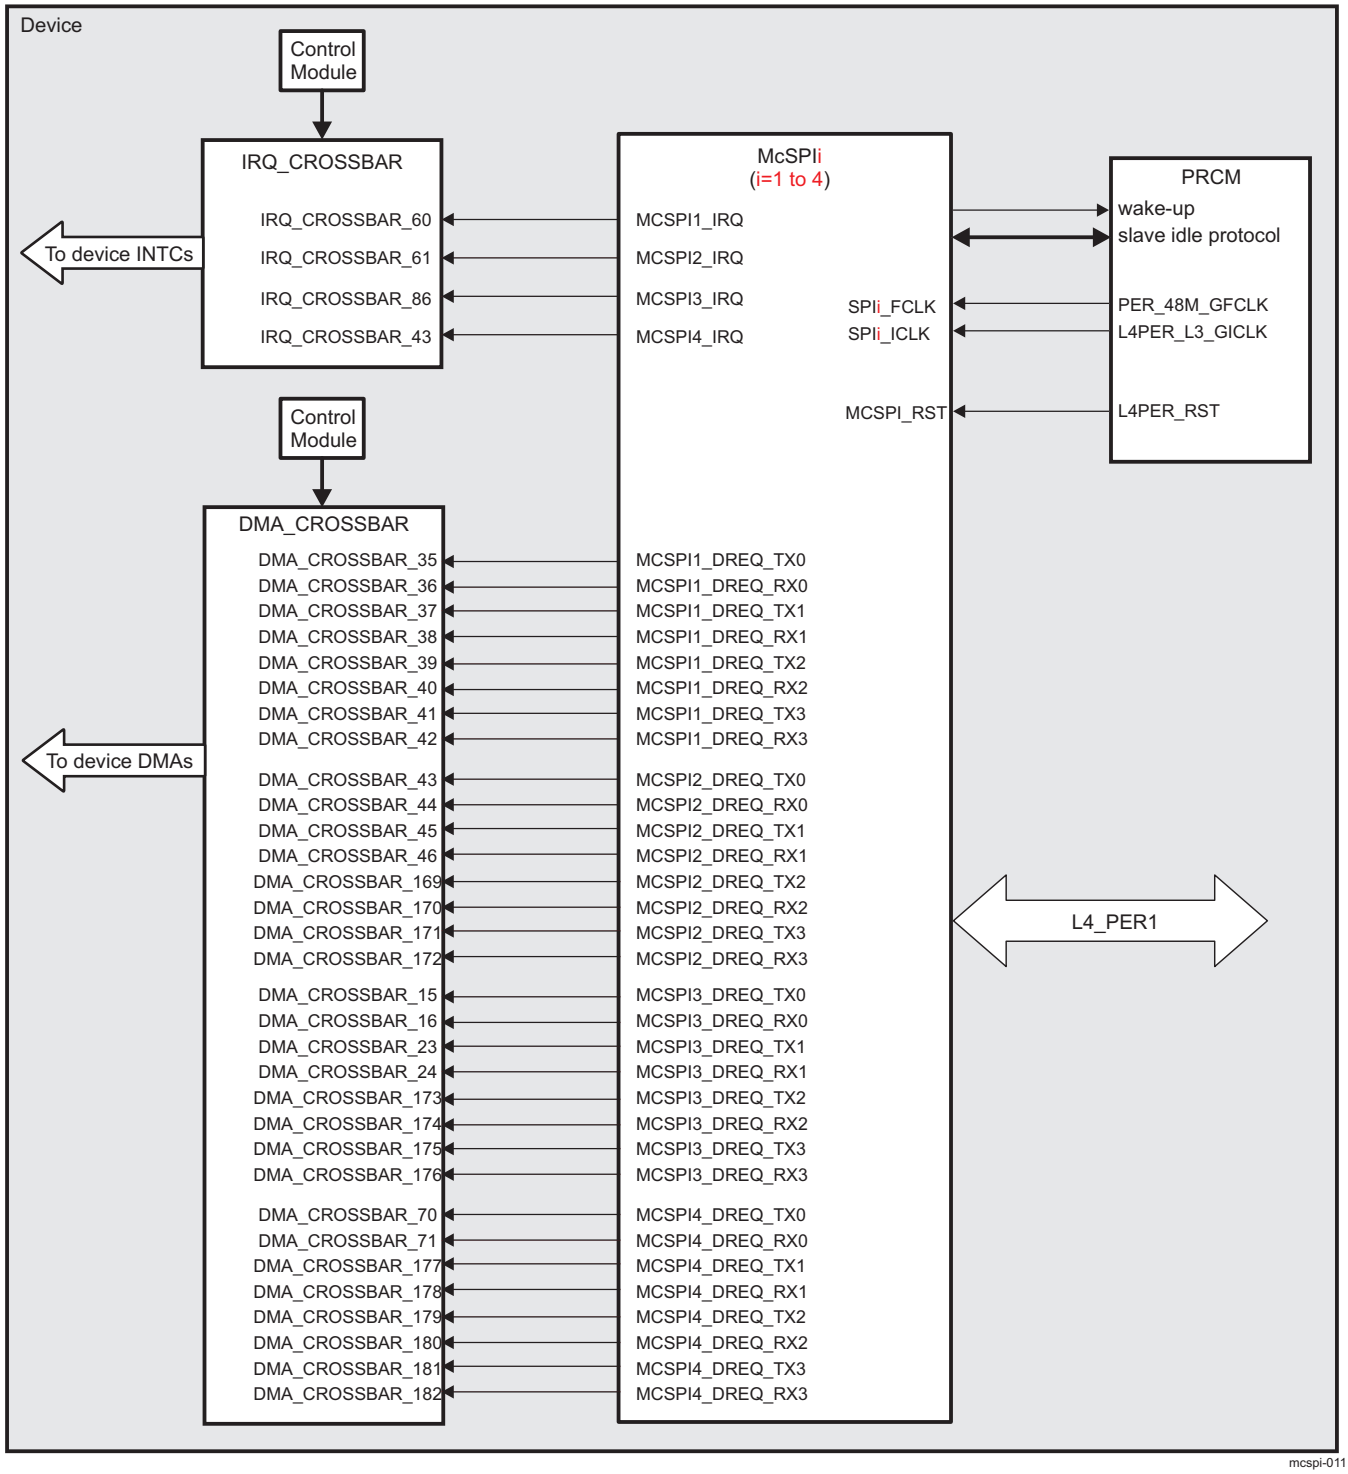


Table 18-197 through Table 18-199 summarize the integration of the module in the device.

Table 18-197. McSPI Integration Attributes

Module Instance	Attributes

	MCSPI4_DREQ_RX3	DMA_CROSSBAR_182	-	McSPI module 4 - receive request channel 3

NOTE: The Default Mapping column in Table 18-199 *McSPI Hardware Requests* shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.
For more information about the IRQ_CROSSBAR module, see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.
For more information about the DMA_CROSSBAR module, see Section 13.4.6.5, *DMA_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.

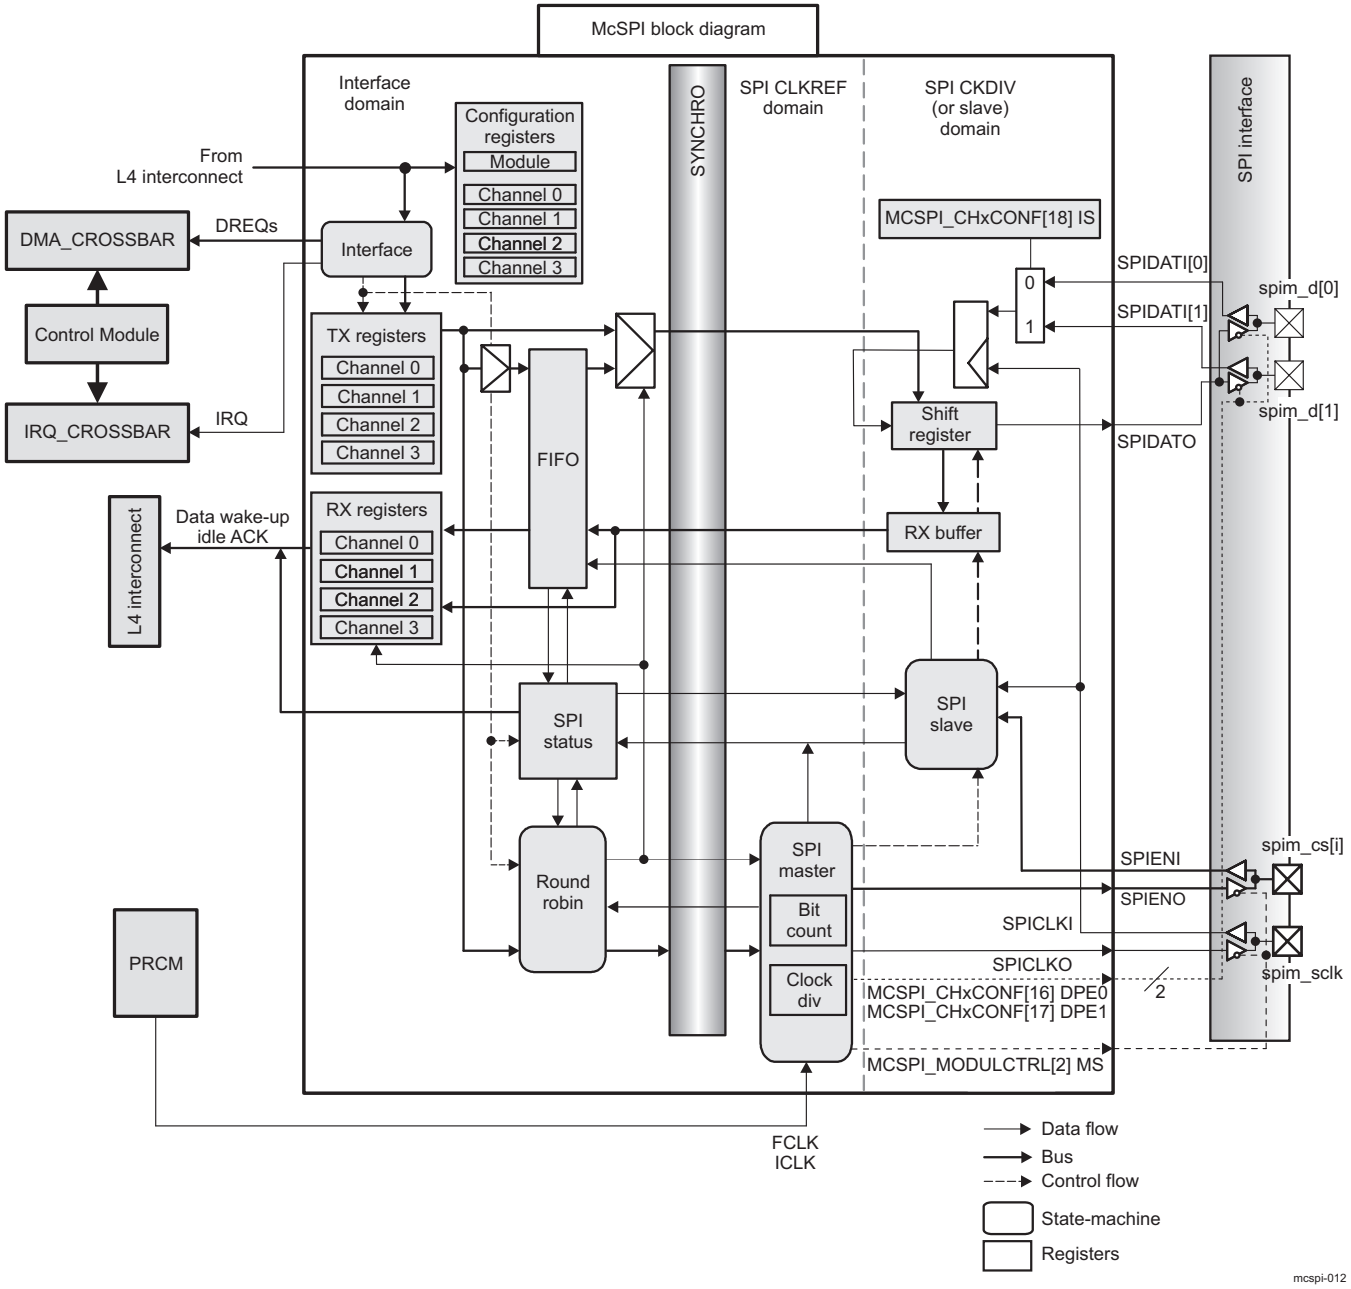
NOTE: For more information about the device interrupt controllers, see Chapter 12, *Interrupt Controllers*.
For more information about the device EDMA module, see Chapter 11, *Enhanced DMA*.

18.3.4 McSPI Functional Description

18.3.4.1 McSPI Block Diagram

Figure 18-53 shows the McSPI module.

Figure 18-53. McSPI Block Diagram



18.3.4.2 Reset

The McSPI module can be reset either by hardware or by software reset. All configuration registers and all state machines are reset by the hardware reset signal (MCSPI_RST). McSPI can be reset by software through the MCSPI_SYSCONFIG[1] SOFTRESET bit. This bit has the same impact on the module as the hardware reset signal. The only exception is that the MCSPI_SYSCONFIG register is not affected by that software reset.

18.3.4.3 Master Mode

18.3.4.3.1 Master Mode Features

The McSPI master mode supports multichannel communication with up to four independent SPI communication channel contexts. The McSPI initiates a data transfer on the data lines (SPIDAT[0] and SPIDAT[1]) and generates clock (SPICLK) and control (SPIEN) signals.

Connected to multiple external devices, the McSPI exchanges data with one SPI device at a time through two main modes (available in slave mode):

- Two-data-pins interface mode (transmit-and-receive mode for full-duplex transmission)
- Single-data-pin interface mode (recommended for half-duplex transmission)

NOTE: There is a fixed chip select line allocation in multichannel master mode. Channel x SPIEN[x] is mapped to spim_cs[i] pin.

Two DMA request events (read and write) allow synchronized accesses of the DMA controller with the activity of McSPI.

Three interrupt events can be used for data transmission and reception in master mode (for more information about interrupts, see Section 18.3.4.7.1, *Interrupt Events in Master Mode*).

18.3.4.3.2 Master Transmit-and-Receive Mode (Full Duplex)

In full-duplex transmission, data is transmitted (shifted out serially on SPIDAT[0]) and received (shifted in serially on SPIDAT[1]) simultaneously on separate data lines.

The master transmit-and-receive mode is programmable per channel (the MCSPI_CHxCONF[13:12] TRM bit field).

Channel access to the shift registers for transmission/reception is based on the MCSPI_TXx transmitter register state, the MCSPI_RXx receiver register state, and round-robin arbitration.

Channels that meet the following rules are included in the round-robin list of active channels scheduled for transmission and/or reception. The arbiter skips channels that do not meet the rules and searches in the rotation for the next enabled channel.

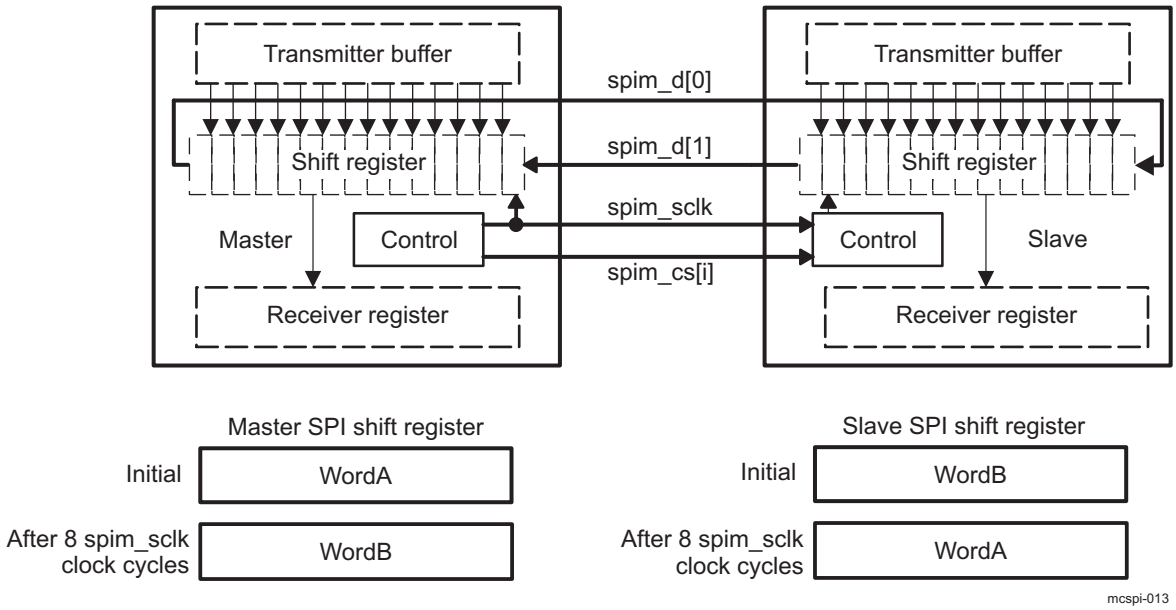
- **Rule 1:** Only enabled channels (the MCSPI_CHxCTRL[0] EN bit) can be scheduled for transmission and/or reception.
- **Rule 2:** If its MCSPI_TXx transmitter register is not empty (the MCSPI_CHxSTAT[1] TXS bit), an enabled channel can be scheduled when the shift register is assigned. If the MCSPI_TXx register is empty when the shift register is assigned, the TXx_UNDERFLOW event is activated, and the next enabled channel with new data to transmit is scheduled (see also transmit-only mode).
- **Rule 3:** An enabled channel can be scheduled if its receive register is not full (the MCSPI_CHxSTAT[0] RXS bit) when the shift register is assigned (see also receive-only mode). Therefore, the MCSPI_RXx register cannot be overwritten. The SPI1.MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set to this mode.

When SPI word transfer completes (the MCSPI_CHxSTAT[2] EOT bit is set), the updated MCSPI_TXx register of the next scheduled channel is loaded into the shift register. The serialization (transmit-and-receive) starts depending on the channel communication configuration. When serialization completes, the received data transfers to the channel receive register.

The serial clock (SPICLK) synchronizes shifting and sampling of the information on the two serial data lines (SPIDAT[0] and SPIDAT[1]). Each time a bit transfers out from the master, 1 bit transfers in from the slave.

Figure 18-54 shows an example of a full-duplex system with a master device (McSPI module *m*) on the left and a slave device on the right. After eight cycles of the serial clock SPICLK, WordA transfers from the master to the slave. At the same time, WordB transfers from the slave to the master.

Figure 18-54. SPI Full-Duplex Transmission (Example)



18.3.4.3.3 Master Transmit-Only Mode (Half Duplex)

The master transmit-only mode prevents a device initiator from reading the MCSPI_RXx register (minimizing data movement) when only transmission is meaningful.

The master transmit-only mode is programmable per channel (the MCSPI_CHxCONF[13:12] TRM bit field). Transmission starts only after data is loaded into the MCSPI_TXx register.

Rule 1 and Rule 2, defined in Section 18.3.4.3.2, apply in this mode.

Rule 3, defined in Section 18.3.4.3.2, does not apply.

In master transmit-only mode, the MCSPI_RXx register state FULL does not prevent transmission and the MCSPI_RXx register is always overwritten with the new SPI word. This event is not significant when only transmission is meaningful. Thus, the RX0_OVERFLOW bit in the MCSPI_IRQSTATUS register is never set in this mode.

The hardware automatically disables the RX_FULL interrupt and the DMA read requests.

The transfer status is given by the MCSPI_CHxSTAT[2] EOT bit.

18.3.4.3.4 Master Receive-Only Mode (Half Duplex)

The master receive mode prevents a device initiator from refilling the MCSPI_TXx register (minimizing data movement) when only reception is meaningful.

The master receive mode is programmable per channel (the MCSPI_CHxCONF[13:12] TRM bit field).

The master receive-only mode enables channel scheduling only on the empty state of the MCSPI_RXx register.

Rule 1 and Rule 3, defined in Section 18.3.4.3.2, apply in this mode.

Rule 2, defined in Section 18.3.4.3.2, does not apply.

In the master receive-only mode, software must write dummy data to the MCSPI_TXx register. Only one dummy write is enough to receive any number of words from the slave. Software must ensure that the MCSPI_TXx register is always full (the TXx_EMPTY bits of MCSPI_IRQSTATUS) when receiving. The content of the MCSPI_TXx register is always loaded into the shift register when the shift register is assigned. After writing the dummy data to the MCSPI_TXx register, the TXx_EMPTY and TXx_UNDERFLOW bits in the MCSPI_IRQSTATUS register are never set in receive-only mode.

The MCSPI_CHxSTAT[2] EOT bit gives the status of serialization. The RXx_FULL bits of the MCSPI_IRQSTATUS register are set when received data is loaded from the shift register to the corresponding MCSPI_RXx register. The MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set in this mode.

18.3.4.3.5 Single-Channel Master Mode

When the McSPI is configured as a master device with a single enabled channel (MCSPI_MODULCTRL[2] MS = 0 and MCSPI_MODULCTRL[0] SINGLE = 1), the assertion of the SPIEN[x] signal is optional depending on device connected to the controller. In 3-pin mode (MCSPI_MODULCTRL[1] PIN34 = 1) the controller starts transmitting data when a write to the MCSPI_TXx register or the FIFO is performed. In 4-pin mode (MCSPI_MODULCTRL[1] PIN34 = 0) the assertion and de-assertion of SPIEN[x] is controlled by software using the MCSPI_CHxCONF[20] FORCE bit.

18.3.4.3.5.1 Programming Tips When Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for the SPI word transfer to complete (wait until the MCSPI_CHxSTAT[2] EOT bit is set to 1) before disabling the current channel and enabling a different channel.
- Disable the current channel, and then enable the other channel.

18.3.4.3.5.2 Force SPIEN[x] Mode

Continuous transfers are allowed manually by keeping the SPIEN[x] signal active for successive SPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the SPIEN[x] line. This mode is supported by all channels and any master sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the SPIEN[x] active mode is supported when:

- A single channel is used (with the MCSPI_MODULCTRL[0] SINGLE bit set to 1).
- Transfer parameters are loaded in the configuration register of the appropriate channel (MCSPI_CHxCONF).

  The state of the SPIEN[x] signal is programmable:

  – Writing 1 to the MCSPI_CHxCONF[20] FORCE bit drives the SPIEN[x] line high when the MCSPI_CHxCONF[6] EPOL bit is set to 0. SPIEN[x] is driven low when the MCSPI_CHxCONF[6] EPOL bit is set to 1.

  – Writing 0 to the MCSPI_CHxCONF[20] FORCE bit drives the SPIEN[x] line low when the MCSPI_CHxCONF[6] EPOL bit is set to 0. SPIEN[x] is driven high when the MCSPI_CHxCONF[6] EPOL bit is set to 1.
- A single channel is enabled (the MCSPI_CHxCTRL[0] EN bit is set to 1). The first enabled channel activates the SPIEN[x] line.

When the channel is enabled, the SPIEN[x] signal activates with the programmed polarity. As in the multichannel master mode, the transfer start depends on the status of the MCSPI_TXx register (the MCSPI_CHxSTAT[1] TXS bit), the status of the MCSPI_RXx register (the MCSPI_CHxSTAT[1] RXS bit), and the defined mode (the MCSPI_CHxCONF[13:12] TRM bit field) of the channel enabled.

The MCSPI_CHxSTAT[2] EOT bit gives the transfer status of each SPI word. The RXx_FULL bit in the MCSPI_IRQSTATUS register is set when received data is loaded from the shift register to the MCSPI_RXx register.

A change in the configuration parameters is propagated directly on the SPI interface. If the SPIEN[x] signal is activated, ensure that the configuration is changed only between SPI words to avoid corrupting the current transfer.

NOTE: To avoid data corruption, SPIEN polarity and SPICLK phase and SPICLK polarity must not be modified when the SPIEN[x] signal is activated.

A delay between SPI words that requires the connected SPI slave device to switch from one configuration to another (for instance, from transmit-only to receive-only) must be handled by software.

At the end of the last SPI word, the channel must be deactivated (the MCSPI_CHxCTRL[0] EN bit set to 0) and SPIEN[x] can be forced to its INACTIVE state using the MCSPI_CHxCONF[20] FORCE bit.

Figure 18-55 and Figure 18-56 show successive transfers with SPIEN[x] maintained active low with a different configuration for each SPI word in single-data-pin and dual-data-pin interface modes, respectively.

Figure 18-55. Continuous Transfers With SPIEN[x] Maintained Active (Single-Data-Pin Interface Mode)

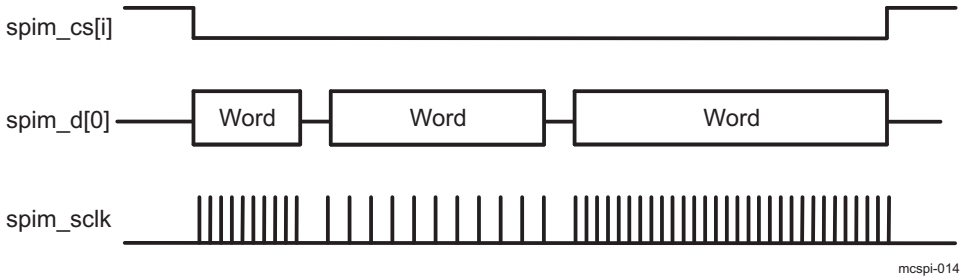


Figure 18-56. Continuous Transfers With SPIEN[x] Maintained Active (Dual-Data-Pin Interface Mode)

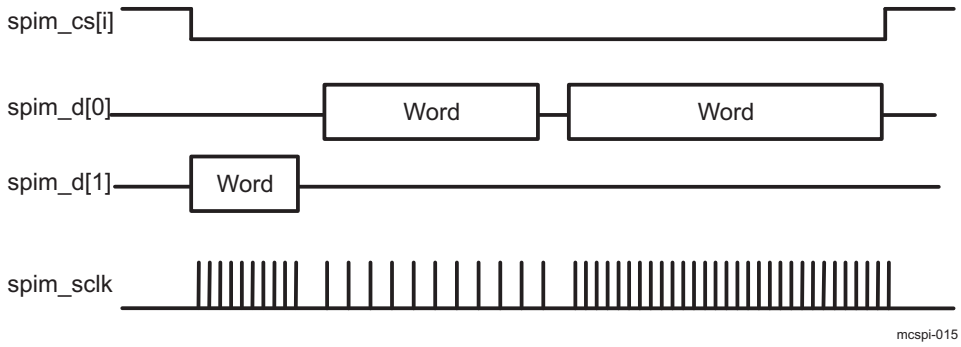


NOTE: The SPIEN[x] signal can be maintained active via software using the MCSPI_CHxCONF[20] FORCE bit only when the MCSPI_MODULCTRL[0] SINGLE bit is set to 0x1.

18.3.4.3.5.3 Turbo Mode

Turbo mode improves the throughput of the SPI interface when a single channel is enabled by allowing transfers until the shift register and the MCSPI_RXx register are full. Turbo mode is time saving when a transfer exceeds two words. This mode is programmable per channel (through the SPI1.MCSPI_CHxCONF[9] TURBO bit).

When several channels are enabled, the TURBO bit has no effect and the channel access to the shift registers remains as previously described.

In turbo mode, Rule 1 and Rule 2 apply, but Rule 3 does not (see Section 18.3.4.3.2, *Master Transmit-and-Receive Mode (Full Duplex)*). An enabled channel can be scheduled if its receive register is full (the MCSPI_CHxSTAT[0] RXS bit) when the shift-register is assigned until the shift register is full.

The MCSPI_RXx register cannot be overwritten in turbo mode. Consequently, the MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set in this mode.

18.3.4.3.6 Start-Bit Mode

In start-bit mode, an extended bit is added before the SPI word to indicate whether the next SPI word must be handled as a command or as data. This feature is available only in master mode. Start-bit mode cannot be used at the same time as turbo mode and/or force SPIEN[x] mode. In this case, only one channel can be used; round-robin arbitration is not possible.

This mode is programmable per channel by setting the MCSPI_CHxCONF[23] SBE bit to 1. The polarity of the extended bit is programmable per channel. When the MCSPI_CHxCONF[24] SBPOL bit is set to 0, the SPI word must be handled as a command. When the MCSPI_CHxCONF[24] SBPOL bit is set to 1, the SPI word must be handled as data. Moreover, start-bit polarity can be changed dynamically during start-bit transfer without disabling the channel for reconfiguration; in this case, users must configure the MCSPI_CHxCONF[24] SBPOL bit before writing the SPI word to be transmitted to the TX register.

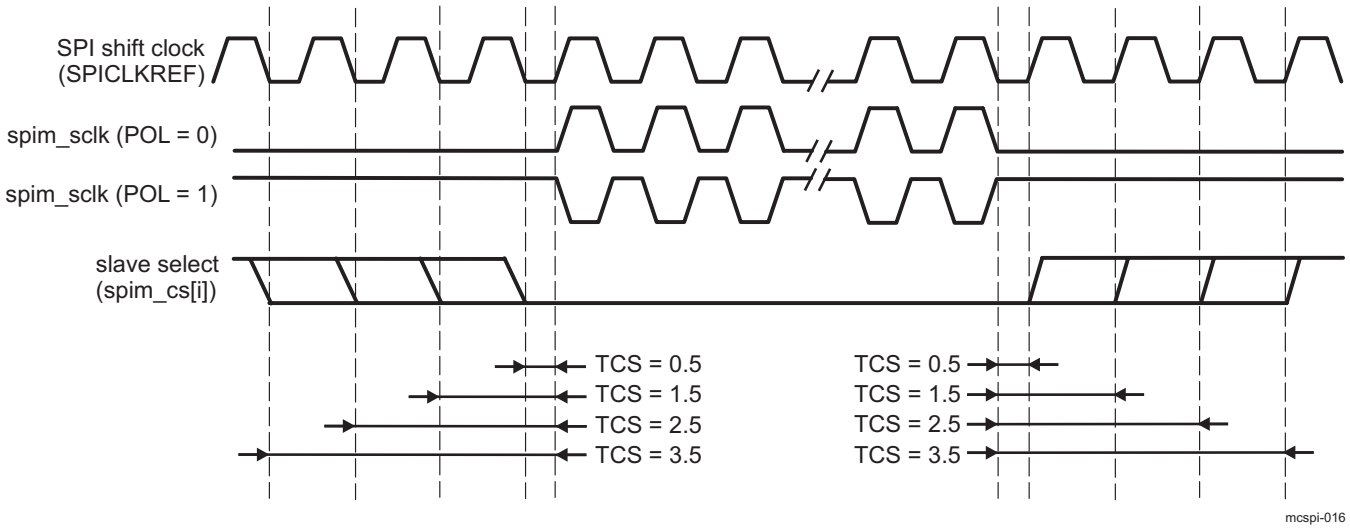
18.3.4.3.7 Chip-Select Timing Control

The chip-select (CS) timing control is available only in master mode with automatic CS generation (the MCSPI_MODULCTRL[0] SINGLE bit set to 0) to add a programmable delay between CS assertion and first clock edge, or CS removal and last clock edge. This option is available only in 4-pin mode when MCSPI_MODULCTRL[1] PIN34 set to 0.

This mode is programmable per channel through the MCSPI_CHxCONF[26:25] TCS0 bit field.

Figure 18-57 shows the CS SPIEN timing controls.

Figure 18-57. CS (SPIEN) Timing Controls



NOTE: Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between CS assertion and the first clock edge with PHA = 1 or between CS removal and the last clock edge with PHA = 0.

18.3.4.3.8 Programmable SPI Clock

In master mode, the baud rate of the SPI serial clock is programmable.

An internal reference clock, SPIm_FCLK, is used as input of a programmable divider (the MCSPI_CHxCONF[5:2] CLKD bit field) to generate the bit rate of the serial output clock SPICLK. Table 18-200 summarizes the supported divisor values.

Table 18-200. SPI Master Clock Rates

Divider	Clock Rate
1	48 MHz(1)
2	24 MHz(1)
4	12 MHz
8	6 MHz
16	3 MHz
32	1.5 MHz
64	750 kHz
128	375 kHz
256	~187 kHz
512	~93.7 kHz
1024	~46.8 kHz
2048	~23.4 kHz
4096	~11.7 kHz
8192 and higher: Division not supported	–

(1) These frequencies are not necessarily supported by all SPI modules. For more information, see the *Timing Requirements and Switching Characteristics* chapter in the device data manual.

18.3.4.3.8.1 Clock Ratio Granularity

By default, the clock division ratio is defined by the MCSPI_CHxCONF[5:2] CLKD bit field with power-of-2 granularity leading to a clock division in the range 1 to 4096; in this case, the duty cycle is always 50 percent. With the MCSPI_CHxCONF[29] CLKG bit, clock division granularity can be changed to one clock cycle; in that case the MCSPI_CHxCTRL[15:8] EXTCLK bit field is concatenated with the MCSPI_CHxCONF[5:2] CLKD bit field to give a 12-bit-wide division ratio in the range 1 to 4096.

When granularity is one clock cycle (the CLKG bit set to 1), for the odd value of the clock ratio, the clock high level lasts one clock cycle more than the low level, depending on the MCSPI_CHxCONF[1] POL and MCSPI_CHxCONF[0] PHA bits (see Table 18-201).

Table 18-201. CLKSPIO High/Low Time Computation

Clock Ratio F_{RATIO}	CLKSPIO High Time	CLKSPIO Low Time
1	T_{HIGH_REF}	T_{LOW_REF}
Even ≥ 2	T_ref × (F_{RATIO}/2)	T_ref × (F_{RATIO}/2)
Odd ≥ (POL = PHA)	T_ref × (F_{RATIO}– 1)/2	T_ref × (F_{RATIO} + 1)/2
Odd ≥ (POL ≠ PHA)	T_ref × (F_{RATIO}+ 1)/2	T_ref × (F_{RATIO} – 1)/2

NOTE: F_{RATIO} = SPICLK frequency (F_{OUT}) division ratio
T_{HIGH} = SPICLK high time period
T_{LOW} = SPICLK low time period
T_ref = FCLK period
T_{HIGH_REF} = FCLK high time period
T_{LOW_REF} = FCLK low time period

If the CLKG bit is set to 1; F_{RATIO} = EXTCLK concatenated with CLKD + 1.

For odd ratio values, the duty cycle is calculated as follows:

Duty_cycle = (1 – 1/F_{RATIO})/2

Table 18-202 shows examples of clock granularity with a clock source frequency of 48 MHz.

Table 18-202. Clock Granularity Examples

EXTCLK	CLKD	CLKG	F_{RATIO}	PHA	POL	T_{HIGH} (ns)	T_{LOW} (ns)	T_{PERIOD} (ns)	Duty Cycle	F_{OUT} (MHz)
X	0	0	1	X	X	10.4	10.4	20.8	50–50	48
X	1	0	2	X	X	20.8	20.8	41.6	50–50	24
X	2	0	4	X	X	41.6	41.6	83.2	50–50	12
X	3	0	8	X	X	83.2	83.2	166.4	50–50	6
0	0	1	1	X	X	10.4	10.4	20.8	50–50	48
0	1	1	2	X	X	20.8	20.8	41.6	50–50	24
0	2	1	3	1	0	41.6	20.8	62.4	66–33	16
0	2	1	3	1	1	20.8	41.6	62.4	33–66	16
0	3	1	4	X	X	41.6	41.6	83.2	50–50	12
5	0	1	81	1	0	852.8	832	1684.8	50.6–49.4	0.592
5	7	1	88	X	X	915.2	915.2	1830.4	50–50	0.545

18.3.4.4 Slave Mode

To select the McSPI slave mode, set the MCSPI_MODULCTRL[2] MS bit.

A McSPI slave device can be connected to up to four external SPI master devices but handles transactions with one SPI master device at a time.

In slave mode, the McSPI initiates data transfer on the data lines (SPIDAT[0] and SPIDAT[1]) when it is selected by an active control signal (SPIEN[x]) and receives an SPI clock (SPICLK) from the external SPI master device. Only channel 0 can be configured as a slave but through the MCSPI_CH0CONF[22:21] SPIENSLV bit field any of the SPIEN[x] signals can be used to select the McSPI module. In slave mode and when the MCSPI_MODULCTRL[1] PIN34 is set to 0x0 (default behavior), the McSPI uses the edge of SPIEN[x] to detect word length. For this reason, SPIEN[x] must become inactive between each word.

When the MCSPI_MODULCTRL[1] PIN34 is set to 0x0, the McSPI does not support SPIEN[x] active between SPI words. In this case, the McSPI uses the edge to detect word length.

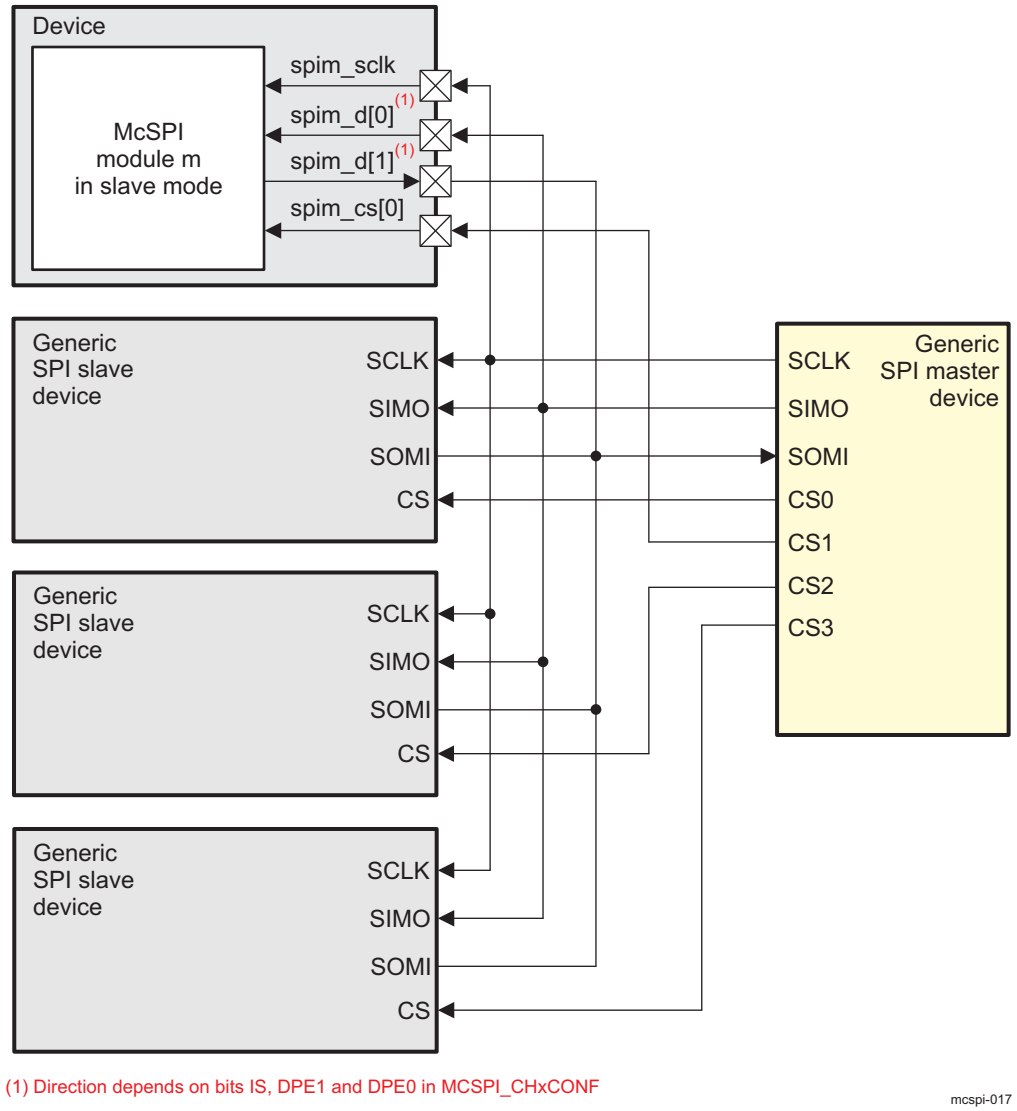
When the MCSPI_MODULCTRL[1] PIN34 is set to 0x1, a multiword transfer can be performed without needing the external SPI master to deactivate SPIEN[x] between each word as in this case the McSPI module works in 3-pin slave mode and SPIEN[x] is not needed.

18.3.4.4.1 Dedicated Resources

Only channel 0 can be enabled in slave mode. In this section, register names such as SPI1.MCSPI_CHxCTRL stand for SPI1.MCSPI_CH0CTRL, where x = 0 (channel 0 control register).

Figure 18-58 shows an example of four slaves wired on a single master device.

Figure 18-58. Example of McSPI Slave With One Master and Multiple Slave Devices on Channel 0



Channel 0 in slave mode has the following resources:

- Its own channel enable, programmable with the MCSPI_CHxCTRL[0] EN bit (where x = 0). This channel must be enabled before transmission and reception.
- For this mode, the slave-select signal can be detected on any of the SPIEN[x] ports. This is programmable with the MCSPI_CHxCONF[22:21] SPIENSLV bit field (where x = 0).
- Its own transmitter register, MCSPI_TXx (where x = 0), on top of the common transmit shift register. If the MCSPI_TXx register is empty, the MCSPI_CHxSTAT[1] TXS bit (where x = 0) is set. If McSPI is selected by an external master (the active signal on the SPIEN[x] port assigned to channel 0), the MCSPI_TXx register content of channel 0 is always loaded into the shift register, whether its content is updated or not. The MCSPI_TXx register must be loaded before McSPI is selected by a master.
- Its own receiver register, MCSPI_RXx (where x = 0), on top of the common receive shift register. If the MCSPI_RXx register is full, the MCSPI_CHxSTAT[0] RXS bit (where x = 0) is set.

NOTE: The MCSPI_TXx and MCSPI_RXx registers of the other channels are not used. Reading from or writing to a channel register other than channel 0 has no effect.

- Its own communication configuration with the following parameters through the MCSPI_CHxCONF register (where x = 0):

- Transmit and receive modes, programmable with the TRM field
- Interface mode (two data pins or single data pin) and data pins assignment, both programmable with the IS and DPE bits. (The SPIm modules are in slave mode after reset and must be properly configured for the modules to act in master mode.)
- SPI word length, programmable with the WL bits
- SPIEN[x] polarity, programmable with the EPOL bit
- SPICLK polarity, programmable with the POL bit
- SPICLK phase, programmable with the PHA bit

The SPICLK frequency of a transfer is controlled by the external SPI master connected to the McSPI slave device. The MCSPI_CHxCONF[5:2] CLKD bit field (where x = 0) is not used in slave mode.

NOTE: The configuration of the channel can be loaded in the MCSPI_CHxCONF register (where x = 0) only when the channel is disabled.

- Two DMA request events, read and write, synchronize read/write accesses of the DMA controller with the activity of McSPI. DMA requests are asserted using the MCSPI_CHxCONF[15] DMAR bit (where x = 0) for reading and the MCSPI_CHxCONF[14] DMAW bit (where x = 0) for writing.
- Four interrupt events (see Section 18.3.4.7.2, *Interrupt Events in Slave Mode*)

18.3.4.4.2 Slave Transmit-and-Receive Mode

The slave receive mode is programmable (set the MCSPI_CHxCONF[13:12] TRM bit field [where x = 0] to 0x0).

In slave transmit-and-receive mode, the MCSPI_TXx register must be loaded before McSPI is selected by an external SPI master device.

After a channel is enabled, transmission and reception proceed with interrupt and DMA request events.

The MCSPI_TXx register content is always loaded in the shift register whether it is updated or not. The event TXx_UNDERFLOW is activated accordingly and does not prevent transmission.

When the SPI word transfer completes (the MCSPI_CHxSTAT0[2] EOT bit [where x = 0] is set to 1), the received data is transferred to the channel receive register.

To use McSPI as a slave transmit-only device, the RXx_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled due to the state of the MCSPI_RXx register (see Section 18.3.4.7.2, *Interrupt Events in Slave Mode*).

18.3.4.4.3 Slave Transmit-Only Mode

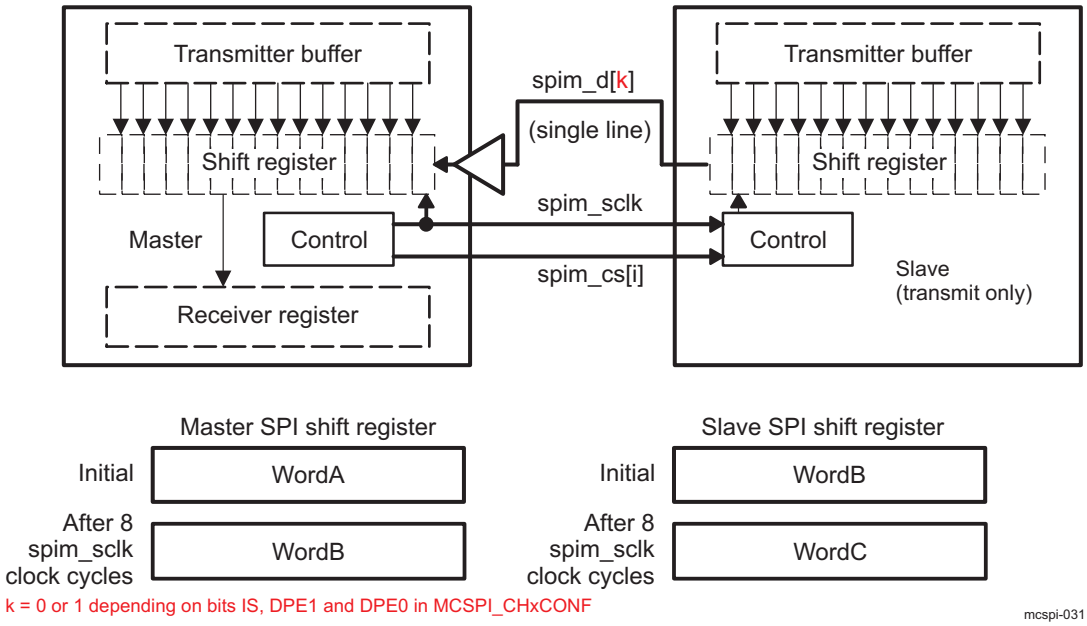
The slave transmit-only mode is programmable (set the MCSPI_CHxCONF[13:12] TRM bit field [where x = 0] to 0x2) and avoids the requirement for a device initiator to read the MCSPI_RXx register (minimizing data movement) only when transmission is meaningful.

To use the McSPI as a slave transmit-only device, the RXx_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled due to the state of the MCSPI_RXx register.

When the SPI word transfer completes, the MCSPI_CHxSTAT[2] EOT bit is set (where x = 0).

Figure 18-59 shows a half-duplex system with a master device on the left and a transmit-only slave device on the right. Each time a bit transfers out from the slave, 1 bit transfers in the master. After eight cycles of the serial clock SPICLK, WordB transfers from the slave to the master.

Figure 18-59. SPI Half-Duplex Transmission (Transmit-Only Slave)



18.3.4.4.4 Slave Receive-Only Mode

The slave receive mode is programmable (set the MCSPI_CHxCONF[13:12] TRM bit field [where x = 0] to 0x1).

In receive-only mode, the MCSPI_TXx register must be loaded before the McSPI is selected by an external SPI master device. The MCSPI_TXx register content is always loaded into the shift register whether it is updated or not. The TXx_UNDERFLOW event is activated accordingly and does not prevent transmission.

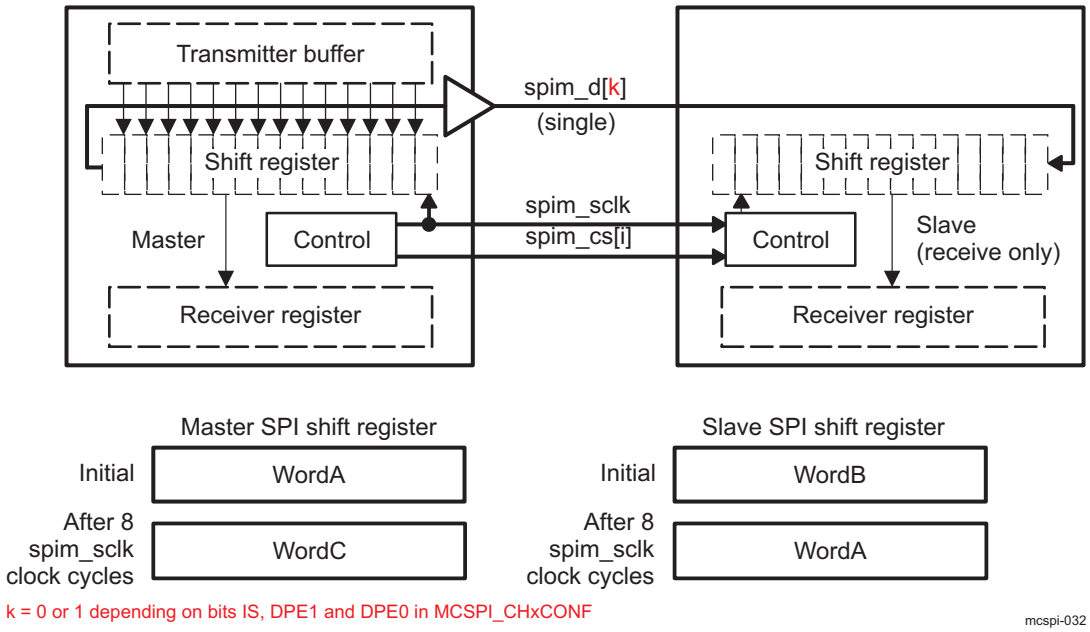
When the SPI word transfer completes (the MCSPI_CHxSTAT0[2] EOT bit [where x = 0] is set to 1), the received data is transferred to the channel receive register.

To use the McSPI as a slave receive-only device, the TXx_EMPTY and TXx_UNDERFLOW interrupts and the DMA write requests must be disabled due to the state of the MCSPI_TXx register.

For a full-duplex transmission, the serial clock (SPICLK) synchronizes shifting and sampling of the information on the single serial data line. For full duplex, two data lines are required. If SPICLK synchronizes on a single serial data line, the data line should be half-duplex.

Figure 18-60 shows a half-duplex system with a master device on the left and a receive-only slave device on the right. Each time a bit transfers out from the master, 1 bit transfers in from the slave. After eight cycles of the serial clock SPICLK, WordA transfers from the master to the slave.

Figure 18-60. SPI Half-Duplex Transmission (Receive-Only Slave)



18.3.4.5 3-Pin or 4-Pin Mode

Depending on targeted application the SPI interface can be configured to use 3 or 4 pins through the MCSPI_MODULCTRL[1] PIN34 bit. If this bit is set to 0, McSPI is in 4-pin mode using the SPICLK, SPIDAT[0], SPIDAT[1] and SPIEN[x] signals. If PIN34 is set to 1 the controller is in 3-pin mode and SPIEN[x] is not used. In this mode all options related to chip select management are useless (EPOL, FORCE and TCS0 bits of MCSPI_CHxCONF). 3-pin and 4-pin operation applies to both master and slave modes.

18.3.4.6 FIFO Buffer Management

The McSPI controller has a built-in 128-byte buffer to unload the DMA or interrupt handler and improve data throughput.

This buffer can be used by only one channel at a time and is selected by setting the MCSPI_CHxCONF[28] FFER or MCSPI_CHxCONF[27] FFEW bit to 1. If several channels are selected and several FIFO enable bit fields are set to 1, the controller forces the buffer not to be used; the driver must set only one FIFO enable bit field.

The buffer can be used in the following modes:

- Master or slave mode
- Transmit-only, receive-only, or transmit-and-receive mode
- Single channel or turbo mode, or normal round-robin mode. In round-robin mode the buffer is used by only one channel.

Every word length (MCSPI_CHxCONF[11:7] WL) is supported.

In transmit-and-receive mode, the buffer can be used in transmit (see Figure 18-61) or receive (see Figure 18-62) directions, or in both directions. If only one direction is chosen in transmit-and-receive mode, the full buffer is used for this direction. In both directions, the buffer is split into two halves, one for each direction (see Figure 18-63).

Figure 18-61. Buffer Used in Transmit Direction Only

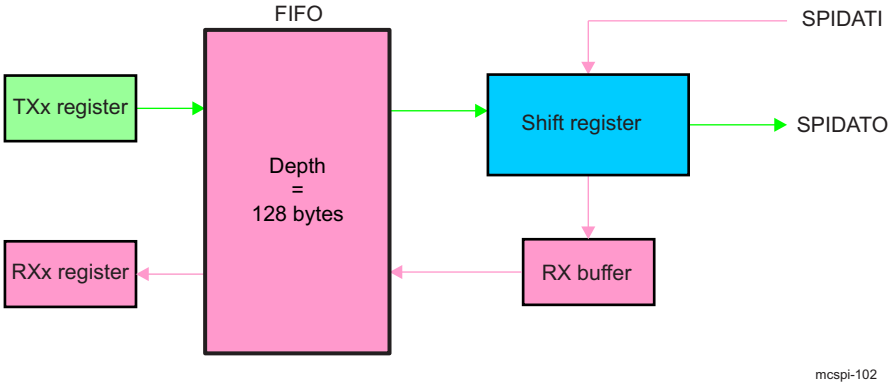


Figure 18-62. Buffer Used in Receive Direction Only

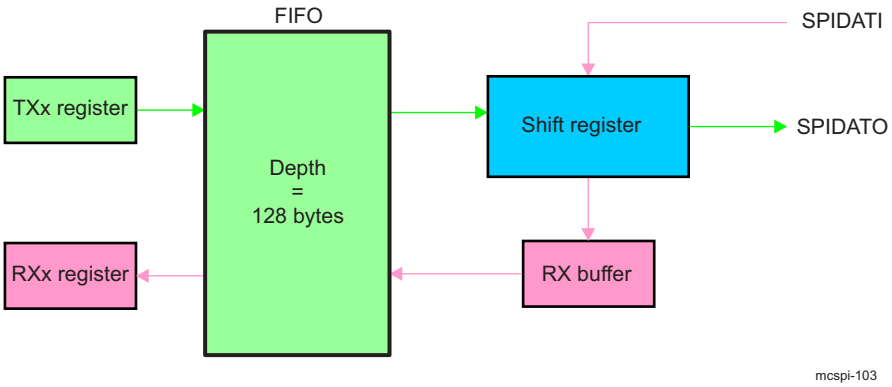

Figure 18-63. Buffer Used for Transmit and Receive Directions

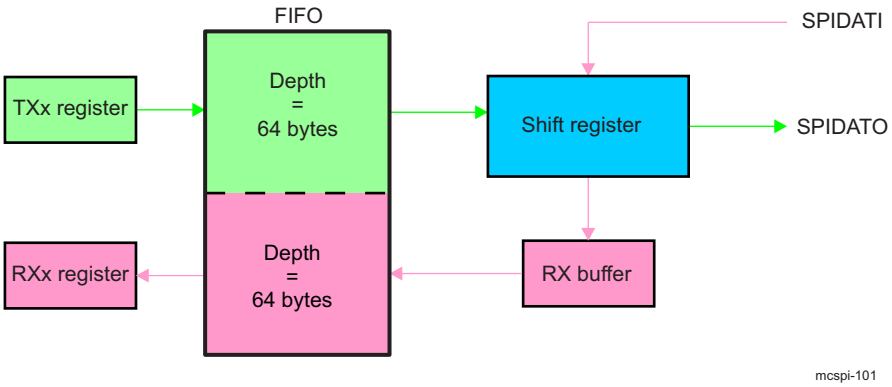


Two levels (MCSPI_XFERLEVEL[5:0] AEL and MCSPI_XFERLEVEL[13:8] AFL) rule the buffer management. The granularity of these levels is 1 byte; it is not aligned with the SPI word length. The driver must set these values as a multiple of the SPI word length defined in MCSPI_CHxCONF[11:7] WL. Table 18-203 lists the number of bytes written in the FIFO, depending on the word length.

Table 18-203. FIFO Writes, Word Length Relationship

	SPI Word Length (WL)		
	3 ≤ WL≤ 7	**8 ≤ WL ≤ 15**	**16 ≤ WL ≤ 31**
Number of bytes written in the FIFO	1 byte	2 bytes	4 bytes

The FIFO buffer pointers are reset when the corresponding channel is enabled or the FIFO configuration changes.

18.3.4.6.1 Buffer Almost Full

The MCSPI_XFERLEVEL[15:8] AFL bit field is needed when the buffer is used to receive an SPI word from a slave (the MCSPI_CHxCONF[28] FFER bit must be set to 1). It defines the almost-full buffer status. See Figure 18-64.

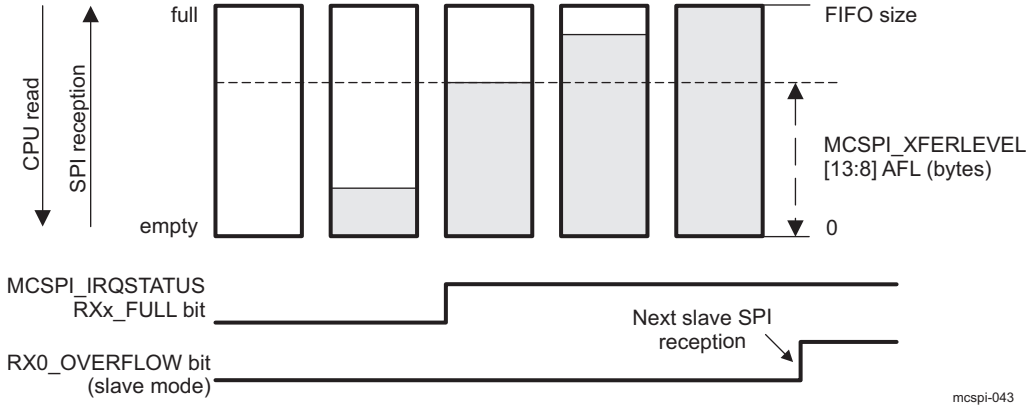
When the FIFO pointer reaches this level, an interrupt or a DMA request is sent to the IRQ_CROSSBAR and then to the desired INTC to enable the system to read AFL + 1 bytes from the receive register.

NOTE: AFL + 1 must correspond to a multiple value of the MCSPI_CHxCONF[11:7] WL bit field.

When DMA is used, the request is deasserted after the first receive register read.

No new request is asserted again as long as the system has not performed the correct number of read accesses.

Figure 18-64. Buffer Almost Full Level (AFL)



NOTE: The MCSPI_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the SPIm_DMA_RXx request is asserted on the same conditions as the MCSPI_IRQSTATUS RXx_FULL flag.

18.3.4.6.2 Buffer Almost Empty

The MCSPI_XFERLEVEL[7:0] AEL bit field is needed when the buffer is used to transmit an SPI word to a slave (the MCSPI_CHxCONF[27] FFEW bit must be set to 1). It defines the almost-empty buffer status. See Figure 18-65.

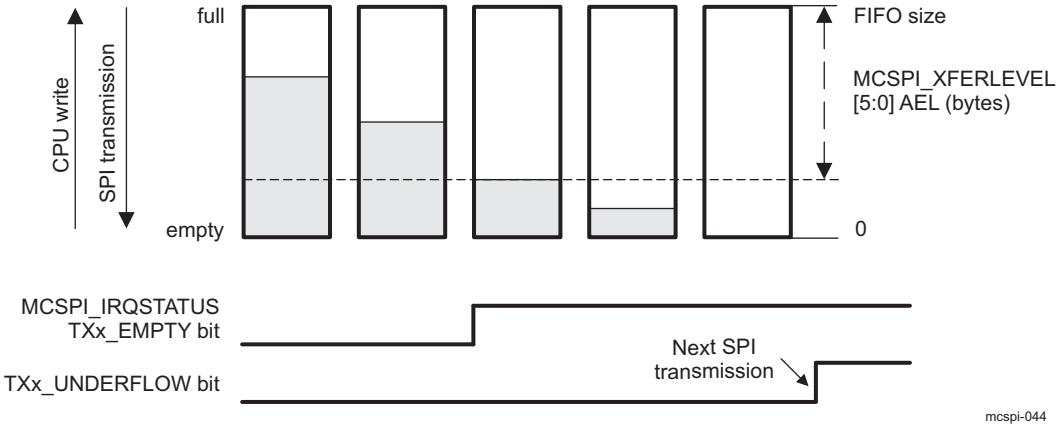
When the FIFO pointer does not reach this level, an interrupt or a DMA request is sent to the IRQ_CROSSBAR and then to the desired INTC to enable the system to write AEL + 1 bytes to the transmit register.

NOTE: AEL + 1 must correspond to a multiple value of the MCSPI_CHxCONF[11:7] WL bit field.

When DMA is used, the request is deasserted after the first transmit register write.

No new request is asserted again as long as the system has not performed the correct number of write accesses.

Figure 18-65. Buffer Almost Empty Level (AEL)



NOTE: The MCSPI_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the SPIm_DMA_TXx request is asserted on the same conditions as the MCSPI_IRQSTATUS TXx_EMPTY flag.

18.3.4.6.3 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user must previously configure in the MCSPI_XFERLEVEL register the AEL and AFL levels and especially the MCSPI_XFERLEVEL[31:16] WCNT bit field to define the number of SPI words to be transferred using the FIFO before enabling the channel.

This counter lets the controller stop the transfer correctly after a defined number of SPI word transfers. If WNCT is set to 0x0000, the counter is not used and the user must stop the transfer manually by disabling the channel; in this case, the user does not know how many SPI transfers have been done. For received words, software must poll the CHxSTAT[5] RXFFE bit and read the MCSPI_RXx receive register to empty the FIFO buffer.

When the end-of-word count interrupt is generated (the MCSPI_IRQSTATUS[17] EOW bit is set), the user can disable the channel and poll the MCSPI_CHxSTAT[5] RXFFE bit to know the last SPI words in the FIFO buffer and read them.

No new request is asserted as long as the system has not performed the correct number of write accesses.

18.3.4.7 Interrupts

Each channel can issue interrupt events.

Each interrupt event has status bits in the MCSPI_IRQSTATUS register (RXx_FULL, TXx_UNDERFLOW, TXx_EMPTY, etc.) (where x = 0, 3) that indicate whether service is required. Each status bit has an interrupt enable bit (a mask) in the MCSPI_IRQENABLE register (RXx_FULL_ENABLE, TXx_UNDERFLOW_ENABLE, TXx_EMPTY_ENABLE, etc.).

When an interrupt occurs and a mask is later applied on it, the interrupt line is not asserted again, even if the interrupt source is not serviced.

The McSPI supports interrupt-driven and polling operations.

18.3.4.7.1 Interrupt Events in Master Mode

In master mode, the interrupt events related to the state of the MCSPI_TXx register are TXx_EMPTY and TXx_UNDERFLOW. The interrupt event related to the state of the MCSPI_RXx register is RXx_FULL.

18.3.4.7.1.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its MCSPI_TXx register is empty (transient event). Enabling a channel automatically triggers this event, except in master receive-only mode (see Section 18.3.4.3.4, *Master Receive-Only Mode*). When the FIFO buffer is enabled (the MCSPI_CHxCONF[27] FFEW bit is set to 1), the MCSPI_IRQSTATUS TXx_EMPTY bit is set as soon as there is enough space in the buffer to write a number of bytes defined by the MCSPI_XFERLEVEL[5:0] AEL bit field.

The MCSPI_TXx register must be loaded with data to remove the source of the interrupt; the MCSPI_IRQSTATUS TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event is asserted as long as a device initiator has not performed the number of writes into the MCSPI_TXx register defined by the MCSPI_XFERLEVEL[5:0] AEL bit field. This device initiator must perform the correct number of writes.

18.3.4.7.1.2 TXx_UNDERFLOW

The event TXx_UNDERFLOW is activated when the channel is enabled and if the MCSPI_TXx register or the FIFO is empty (not updated with new data) when an external master device starts a data transfer with the McSPI (transmit and receive).

The TXx_UNDERFLOW is a harmless warning in master mode.

To avoid having a TXx_UNDERFLOW event at the beginning of a transmission, the TXx_UNDERFLOW event is not activated when no data has been loaded into the MCSPI_TXx register, because the channel is enabled. To avoid having a TXx_UNDERFLOW event, the MCSPI_TXx register must seldom be loaded.

The MCSPI_IRQSTATUS TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

18.3.4.7.1.3 RXx_ FULL

The RXx_FULL event is activated when a channel is enabled and the MCSPI_RXx register becomes filled (transient event). When the FIFO buffer is enabled (the MCSPI_CHxCONF[28] FFER bit is set to 1), RXx_ FULL is asserted as soon as the number of bytes held in the FIFO to be read reaches the MCSPI_XFERLEVEL[13:8] AFL threshold.

The MCSPI_RXx register must be read to remove the source of the interrupt; the MCSPI_IRQSTATUS RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event is asserted as long as a device initiator has not performed AFL + 1 reads into MCSPI_RXx. This device initiator must perform the correct number of reads.

18.3.4.7.1.4 End Of Word Count

The MCSPI_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the MCSPI_XFERLEVEL[31:16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the SPI transfer is halted on the channel using the FIFO buffer as soon as MCSPI_XFERLEVEL[31:16] WCNT is not reloaded and the channel is not re-enabled.

The MCSPI_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

18.3.4.7.2 Interrupt Events in Slave Mode

In slave mode, the interrupt events related to the state of the MCSPI_TXx register are TXx_EMPTY and TXx_UNDERFLOW. The interrupt events related to the state of the MCSPI_RXx are RXx_FULL and RX0_OVERFLOW (channels 1, 2, and 3 do not have a receiver overflow status bit). See the MCSPI_IRQSTATUS register.

18.3.4.7.2.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its MCSPI_TXx register is empty. Enabling the channel automatically raises this event. If the FIFO buffer is enabled (the MCSPI_CHxCONF[27] FFEW bit is set to 1), the TXx_EMPTY event is asserted as soon as there is enough space in buffer to write a number of bytes defined by the MCSPI_XFERLEVEL[5:0] AEL bit field.

The MCSPI_TXx register must be loaded with data to remove the source of the interrupt; the MCSPI_IRQSTATUS TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event is asserted as long as a device initiator has not performed the number of writes into the MCSPI_TXx register defined by MCSPI_XFERLEVEL[5:0] AEL bit field. This device initiator must perform the correct number of writes.

18.3.4.7.2.2 TXx_UNDERFLOW

The TXx_UNDERFLOW event is activated when a channel is enabled and if the MCSPI_TXx register is empty (not updated with new data) when an external master device starts a data transfer with the McSPI (transmit and receive).

When FIFO is enabled, the data emitted while the underflow event is raised is not the last data written in the FIFO but the next data in the FIFO (an old transmitted value or a dummy data in the FIFO has been reset).

TXx_UNDERFLOW indicates an error (data loss) in slave mode.

To avoid having a TXx_UNDERFLOW event at the beginning of a transmission, the TXx_UNDERFLOW event is not activated when no data has been loaded into the MCSPI_TXx register because the channel is enabled.

The MCSPI_IRQSTATUS TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

18.3.4.7.2.3 RXx_FULL

The RXx_FULL event is activated when a channel is enabled and the MCSPI_RXx register is being filled (transient event). When the FIFO buffer is enabled (the MCSPI_CHxCONF[28] FFER bit is set to 1), RXx_FULL is asserted as soon as the number of bytes held in the buffer to read defined by the MCSPI_XFERLEVEL[13:8] AFL bit field.

The MCSPI_RXx register must be read to remove the source of the interrupt; the MCSPI_IRQSTATUS RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event is asserted as long as a device initiator has not performed AFL + 1 reads into MCSPI_RXx. This device initiator must perform the correct number of reads.

18.3.4.7.2.4 RX0_OVERFLOW

The RX0_OVERFLOW event is activated in slave mode in transmit-and-receive mode or receive-only mode when a channel is enabled and the MCSPI_RXx register or FIFO is full when a new SPI word is received. The MCSPI_RXx register is always overwritten with the new SPI word. If the FIFO is enabled, data within the FIFO are overwritten; it must be considered as corrupted. The RX0_OVERFLOW event should not appear in slave mode using the FIFO.

The RX0_OVERFLOW event indicates an error (data loss) in slave mode.

The MCSPI_IRQSTATUS[3] RX0_OVERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

18.3.4.7.2.5 End Of Word Count

The MCSPI_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the MCSPI_XFERLEVEL[31:16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the SPI transfer is halted on the channel using the FIFO buffer as soon as WCNT is not reloaded and the channel is not re-enabled.

The MCSPI_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

18.3.4.7.3 Interrupt-Driven Operation

An interrupt enable bit in the MCSPI_IRQENABLE register can be set to enable each event to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the following must be performed:

1. Read the MCSPI_IRQSTATUS register to identify which event occurred.
2. Read the MCSPI_RXx register that corresponds to the event to remove the source of an RXx_FULL event or write into the MCSPI_TXx register that corresponds to the event to remove the source of a TXx_EMPTY event. No action is required to remove the source of the WKS (wake-up), TXx_UNDERFLOW, and RX0_OVERFLOW events.
3. Set the corresponding bit of the MCSPI_IRQSTATUS register to 1 to clear an interrupt status and then release the interrupt line.

The interrupt status bit must always be reset after channel enabling and before events are enabled as interrupt sources.

18.3.4.7.4 Polling

When the interrupt capability of an event is disabled in the MCSPI_IRQENABLE register, the interrupt line is not asserted, but the status bits in the MCSPI_IRQSTATUS register can be polled by software to detect when the corresponding event occurs.

Once the expected event occurs:

- RXx_FULL: To remove the source of the event, the corresponding MCSPI_RXx register must be read.
- TXx_EMPTY: To remove the source of the event, it must be written into the corresponding MCSPI_TXx register.
- WKS (wake-up), TXx_UNDERFLOW, and RX0_OVERFLOW: No action is required to remove the source of the event.

To clear an interrupt, set the corresponding status bit of the MCSPI_IRQSTATUS register to 1. This does not affect the interrupt line state.

18.3.4.8 DMA Requests

Each McSPI channel, if enabled, can issue DMA requests. There are two DMA request lines per McSPI channel (one for read and one for write).

The DMA read request line is asserted when the McSPI channel is enabled and new data is available in the receive register of the McSPI channel. A DMA read request can be individually masked with the SPI1.MCSPI_CHxCONF[15] DMAR bit. The DMA read request line is deasserted when reading of the MCSPI_RXx register of the McSPI channel completes.

The DMA write request line is asserted when the McSPI channel is enabled and the MCSPI_TXx register of the McSPI channel is empty. A DMA write request can be individually masked with the SPI1.MCSPI_CHxCONF[14] DMAW bit. The DMA write request line is deasserted when loading of the MCSPI_TXx register of the channel completes.

18.3.4.9 Power Saving Management

Power consumption can be optimized by switching off internal clocks (interface and functional clock) when there is no activity. The McSPI is compliant with the idle and wake-up system handshake protocol.

18.3.4.9.1 Normal Mode

In normal mode, internal SPI module clocks are automatically switched off (autogated) when there is no activity in slave or master mode.

Autogating of the module interface clock and functional clock occurs when the following conditions are met:

- The MCSPI_SYSCONFIG[0] AUTOIDLE bit is set.
- In master mode, there is no data to transmit or receive in all channels.
- In slave mode, the McSPI is not selected by the external master and there are no register accesses.

Autogating of the module interface clock and functional clock stops when the following conditions are met:

- In master mode, an internal access occurs.
- In slave mode, an internal access occurs or the McSPI is selected by the external master.

18.3.4.9.2 Idle Mode

At the PRCM module level, when all conditions are met to shut off the PER_48M_GFCLK or L4PER_L3_GICLK output clock, the PRCM module automatically launches a hardware handshake protocol to ensure that the McSPI is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the McSPI.

Although this handshake is completely hardware-oriented and out of software control, the method in which the McSPI module acknowledges the PRCM IDLE request is configurable through the MCSPI_SYSCONFIG[4:3] SIDLEMODE bit field.

The settings of the SIDLEMODE bit field and the related acknowledgment modes are:

- Force-idle mode (the MCSPI_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0): The McSPI module acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully in this case because it does not prevent the loss of data when the clock is switched off.
- No-idle mode (the SIDLEMODE bit field is set to 0x1): The McSPI never acknowledges an IDLE request from the PRCM module and is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient to save power because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
- Smart-idle mode (the SIDLEMODE bit field is set to 0x2): The McSPI acknowledges the IDLE request, basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for efficient system power management.

When configured in smart-idle mode, the McSPI also offers an additional granularity on the PER_48M_GFCLK and L4PER_L3_GICLK gating. The MCSPI_SYSCONFIG[9:8] CLOCKACTIVITY bit field determines which clock shuts down (the PER_48M_GFCLK, L4PER_L3_GICLK, neither clock, or both clocks).

The setting of the CLOCKACTIVITY bit field is used internally to the McSPI to determine on which part of the module the conditions to acknowledge the PRCM IDLE request are tested. For example, if PER_48M_GFCLK is not shut down on a PRCM IDLE request, the McSPI considers only L4PER_L3_GICLK and the associated pending activities before acknowledging the request.

Some McSPI features are associated with L4PER_L3_GICLK and others with PER_48M_GFCLK. Using the CLOCKACTIVITY bit field with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if the McSPI acknowledges an IDLE request.

The settings of the CLOCKACTIVITY bit field and the associated features are:

- CLOCKACTIVITY set to 00: ICLK off and FCLK off, ICLK and FCLK are considered for generating the acknowledge. This setting also means that FCLK and ICLK are likely to be shut down on a PRCM IDLE request.
- CLOCKACTIVITY set to 01: ICLK on and FCLK off, ICLK is not shut down on a PRCM IDLE request; only FCLK is concerned.
- CLOCKACTIVITY set to 10: ICLK off and FCLK on, FCLK is not shut down on a PRCM IDLE request; only ICLK is concerned.
- CLOCKACTIVITY set to 11: ICLK on and FCLK on, none of the clocks are shut down. This means the McSPI can potentially acknowledge the IDLE request without checking the internal functions linked to its clocks.

CAUTION

The PRCM module does not have a hardware means of reading the CLOCKACTIVITY settings. Therefore, software must ensure consistent programming between CLOCKACTIVITY and the PER_48M_GFCLK and L4PER_L3_GICLK control bits in the PRCM module. If the McSPI is disabled in the CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the McSPI clocks. This can lead to unpredictable behavior.

18.3.4.9.2.1 Wake-Up Event in Smart-Idle Mode

The module wake-up feature is enabled when the MCSPI_SYSCONFIG[2] ENAWAKEUP and MCSPI_WAKEUPENABLE[0] WKEN bits are set. Wake-up capability is relevant only when the module is configured in slave mode.

The module generates an asynchronous wake-up request to the system power manager to switch back the interface clock and the functional clock. A wakeup is requested when channel 0 is enabled and an asynchronous selection occurs on the mcspim.csx port associated with channel 0 (see the definition for the MCSPI_CHxCONF[22:21] SPIENSLV bit field [where x = 0] in the register table description).

After the McSPI wake-up request, the system power manager must reactivate the interface clock:

- Before the beginning of the second SPI word serialization when the McSPI is in slave transmit-only mode or in slave transmit-and-receive mode
- Before the end of the second received SPI word in slave receive-only mode. To avoid data loss, the first received SPI word must be read from the MCSPI_RXx register (where x = 0) before the completion of the second SPI word serialization.

Table 18-204 lists the supported cases in smart-idle mode.

Table 18-204. Smart-Idle Mode and Wake-Up Capabilities

Mode	Interface Clock	SPI Clock Ref	Functionality	Wake-Up Event
Master	Must be maintained	Must be maintained	Full functionality, but the module does not generate a new interrupt or DMA request until the system exits wake-up mode	No wake-up event
Slave	Can be switched off	Can be switched off	An SPI word can be transmitted and/or received, but the module does not generate any new interrupts or DMA requests until the system exits wake-up mode.	The module asynchronously sends a wake-up request if an event on the SPIEN[x] port associated with channel 0 is detected.

In wake-up mode, the interrupt and DMA request lines are no longer asserted.

Any access to the module in wake-up mode generates an error as long as the interface clock is alive.

18.3.4.9.2.2 Transitions From Smart-Idle Mode to Normal Mode

The McSPI detects the end of the wake period through the idle and wake-up hardware handshake protocol.

The interrupt status register (the MCSPI_IRQSTATUS[16] WKS bit) is updated with the event causing the wakeup; the wake-up event at the origin of the transition to the normal mode is converted to its corresponding interrupt when enabled by the MCSPI_IRQENABLE[16] WKE bit or the DMA request.

Interrupts and wake-up events have independent enable and disable controls, accessible through the MCSPI_IRQENABLE and MCSPI_WAKEUPENABLE registers. Software must ensure the overall consistency.

The interrupt status register MCSPI_IRQSTATUS is updated with the event causing the wakeup; the wake-up event at the origin of the transition to normal mode is converted to its corresponding interrupt request or DMA request. The module is fully operational.

18.3.4.9.2.3 Force-Idle Mode

Force-idle mode is enabled and exited as follows:

- Force-idle mode is enabled when the MCSPI_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0.
  - In force-idle mode, the McSPI responds unconditionally to the IDLE request by deasserting unconditionally the interrupt and DMA request lines, if asserted. In addition, the wake-up capability is totally inhibited even if the MCSPI_SYSCONFIG[2] ENAWAKEUP and MCSPI_WAKEUPENABLE[0] WKEN bits are set.
  - The transition from normal mode to idle mode does not affect the interrupt event bits of the MCSPI_IRQSTATUS register.
  - In force-idle mode, because the module must be disabled, the interrupt and DMA request lines are likely deasserted. The interface clock and SPI clock provided to the McSPI can be switched off.
  - An IDLE request during an SPI data transfer can lead to an unexpected and unpredictable result. Software must avoid such a request.
- The module exits force-idle mode through the idle and wake-up hardware handshake protocol.

  The module is fully operational. The interrupt and DMA request lines are optionally asserted one clock cycle later.

18.3.5 McSPI Programming Guide

This section describes the low-level hardware programming sequences for the configuration and use of the McSPI module.

18.3.5.1 Global Initialization

18.3.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the McSPI module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the McSPI. For further information, see Section 18.3.3, *McSPI Integration* and Section 18.3.2, *McSPI Environment*.

Table 18-205 lists the information on the global initialization of the surrounding modules.

Table 18-205. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	MCSPI_FCLK functional clock must be enabled. See Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
L4 Interconnect	For information about L4_PER1 interconnect configuration, see Section 9.3, *L4 Interconnects*, in Chapter 9, *Interconnect*.
DMA_CROSSBAR	DMA_CROSSBAR configuration must be done to allow module DREQs to be mapped to certain device DMA line. For more information see Section 13.4.6.5, *DMA_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.
EDMA	EDMA configuration must be done to enable the module DMA channel requests.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*
Device INTCs	Device INTCs must be configured to enable the interrupt request generation. For more information see Chapter 12 *Interrupt Controllers*

18.3.5.1.2 McSPI Global Initialization

18.3.5.1.2.1 Main Sequence – McSPI Global Initialization

The procedure in Table 18-206 can be used to initialize McSPI when performing software reset.

Table 18-206. McSPI Global Initialization

Step	Register/Bit Field/Programming Model	Value
Perform a software reset.	MCSPI_SYSCONFIG[1] SOFTRESET	1
Wait until reset is finished?	MCSPI_SYSSTATUS[0] RESETDONE	=1
Configure static settings (such as SPI master or slave) as required.	MCSPI_MODULCTRL[8:0]	0x-
Write MCSPI_SYSCONFIG	MCSPI_SYSCONFIG	0x-

18.3.5.2 Operational Mode Configuration

18.3.5.2.1 McSPI Operational Modes

The selection of the working mode is done with the MCSPI_CHxCONF register.

Table 18-207. McSPI Receive Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set receive mode for the channel.	MCSPI_CHxCONF[13:12] TRM	0x1
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPI_CHxCONF	0x-
Reset the status bits.	MCSPI_IRQSTATUS	0x0

Table 18-208. McSPI Transmit Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set transmit mode for the channel.	MCSPI_CHxCONF[13:12] TRM	0x2
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPI_CHxCONF	0x-
Reset the status bits.	MCSPI_IRQSTATUS	0x0

Table 18-209. McSPI Transmit-and-Receive Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set transmit and receive mode for the channel.	MCSPI_CHxCONF[13:12] TRM	0x0
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPI_CHxCONF	0x-
Reset the status bits.	MCSPI_IRQSTATUS	0x0

18.3.5.2.1.1 Common Transfer Sequence

McSPI module allows the transfer of one or several words, according to different modes:

- MASTER Normal, MASTER Turbo, SLAVE
- TRANSMIT–RECEIVE, TRANSMIT-ONLY, RECEIVE-ONLY
- Write and Read requests: Interrupts, DMA
- SPIEN[x] lines assertion/deassertion: automatic, manual

For all these sequences, the host process contains the main process and the interrupt routines.

The interrupt routines are called on the interrupt signals or by an internal call if the module is used in polling mode.

Table 18-210 represents the main sequence which is common to all transfers.

In multi-channel master mode, the sequences of different channels can be run simultaneously.

Table 18-210. Common Transfer Sequence (Main Process)

Step	Register/Bit Field/Programming Model	Value
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel x bits]	0b1111
Write MCSPI_IRQENABLE to enable interrupts	MCSPI_IRQENABLE	0x-
Write MCSPI_CHxCONF to configure the channel	MCSPI_CHxCONF	0x-
Start the channel	MCSPI_CHxCTRL[0] EN	1
Wait for the first write request (TX empty or DMA write)		
Write the transmitter register with data	MCSPI_TXx	0x-
Wait for the host event for end of transfer		
Stop the channel	MCSPI_CHxCTRL[0] EN	0

18.3.5.2.1.2 End of Transfer Sequences

The end of transfer depends on the transfer mode. Table 18-211 summarizes the type of end of transfer per transfer mode and gives a reference to the appropriate section for details.

Table 18-211. End of Transfer Sequences

		TRANSMIT-AND-RECEIVE		TRANSMIT-ONLY		RECEIVE-ONLY	
		INTERRUPT	DMA	INTERRUPT	DMA	INTERRUPT	DMA
MASTER Normal	End of transfer sequence	See Section 18.3.5.2.1.3		See Section 18.3.5.2.1.4.1	See Section 18.3.5.2.1.4.2	See Section 18.3.5.2.1.5.1	See Section 18.3.5.2.1.5.2
	Minimum number of word	1	1	1	1	1	2
	DMA transfer size		N		N		N-1
MASTER Turbo	End of transfer sequence	See Section 18.3.5.2.1.3		See Section 18.3.5.2.1.4.1	See Section 18.3.5.2.1.4.2	See Section 18.3.5.2.1.6.1	See Section 18.3.5.2.1.6.2
	Minimum number of word	1	1	1	1	2	3
	DMA transfer size		N		N		N-2
SLAVE	End of transfer sequence	See Section 18.3.5.2.1.3		See Section 18.3.5.2.1.4.1	See Section 18.3.5.2.1.4.2	See Section 18.3.5.2.1.7	
	Minimum number of word	1	1	1	1	1	1
	DMA transfer size		N		N	N	N

The transfer to execute has a size of N words.

The different sequences can be merged in one process to manage transfers of several types. The end of transfer sequences are described from the start of the channel.

In these sequences, some soft variables are used:

- write_count = 0
- read_count = 0
- channel_enable = FALSE
- last_transfer = FALSE
- last_request = FALSE

They are initialized before starting the channel.

18.3.5.2.1.3 Transmit-and-Receive (Master and Slave)

If the requests are configured in DMA, write_count and read_count are assigned with ‘N’ when the DMA handlers have completed their ‘N’ OCP accesses.

Table 18-212. Transmit-and-Receive (Master and Slave) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHxCTRL[0] EN	1
Wait for write_count = N **AND** read_count = N		
Stop the channel	MCSPI_CHxCTRL[0] EN	0

Table 18-213. Transmit-and-Receive (Master and Slave) (Interrupt Routine)

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel x bits]	0b1111
IF: TXx_EMPTY		
Write the transmitter register with data	MCSPI_TXx	0x-
Increment write_count +1		
IF: RXx_FULL		
Read the receiver register	MCSPI_RXx	0x-
Increment read_count +1		
ENDIF		

18.3.5.2.1.4 Transmit-Only (Master and Slave)

18.3.5.2.1.4.1 Based on Interrupt Requests

Table 18-214. Transmit-Only With Interrupts (Master and Slave) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHxCTRL[0] EN	1
Wait until last transfer = TRUE		
Wait for end of transfer	MCSPI_CHxSTAT[2] EOT	=1
Stop the channel	MCSPI_CHxCTRL[0] EN	0

Table 18-215. Transmit-Only With Interrupts (Master and Slave) (Interrupt Routine)

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel x bits]	0b1111
IF: TXx_EMPTY **AND** write_count < N		
Write the transmitter register with data	MCSPI_TXx	0x-
Increment write_count +1		
ELSEIF: write_count ≥ N		
last_transfer = TRUE		
ENDIF		

18.3.5.2.1.4.2 Based on DMA Write Requests

When the DMA handler has completed its ‘N’ OCP accesses, write_count is assigned with ‘N’.

Table 18-216. Transmit-Only With DMA (Master and Slave) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHxCTRL[0] EN	1
Wait until write_count = N		
Disable DMA write request	MCSPI_CHxCONF[14] DMAW	0
Wait until last_transfer = TRUE		
Wait for end of transfer	MCSPI_CHxSTAT[2] EOT	=1
Stop the channel	MCSPI_CHxCTRL[0] EN	0

Table 18-217. Transmit-Only With DMA (Master and Slave) (Interrupt Routine)

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel x bits]	0b1111
IF: TXx_EMPTY **AND** write_count = N		
last_transfer = TRUE		
ENDIF		

18.3.5.2.1.5 Master Normal Receive-Only

18.3.5.2.1.5.1 Based on Interrupt Requests

Table 18-218. Receive-Only With Interrupt (Master Normal) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHxCTRL[0] EN	1
Wait until last_request = TRUE		
Stop the channel	MCSPI_CHxCTRL[0] EN	0
Read the receiver register	MCSPI_RXx	0x-
Increment read_count +1		

Table 18-219. Receive-Only With Interrupt (Master Normal) (Interrupt Routine)

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel x bits]	0b1111
IF: RXx_FULL **AND** read_count = N - 1		
last_request = TRUE		
ELSEIF: read_count ≠ N - 1		
Read the receiver register	MCSPI_RXx	0x-
Increment read_count +1		
ENDIF		

18.3.5.2.1.5.2 Based on DMA Read Requests

When the DMA handler has completed its ‘N-1’ OCP accesses, read_count is assigned with ‘N-1’.

Table 18-220. Receive-Only With DMA (Master Normal) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHxCTRL[0] EN	1
Wait until read_count = N - 1		
Disable DMA read request	MCSPI_CHxCONF[15] DMAR	0
Wait until last_transfer = TRUE		
Stop the channel	MCSPI_CHxCTRL[0] EN	0
Read the receiver register	MCSPI_RXx	0x-
Increment read_count +1		

Table 18-221. Receive-Only With DMA (Master Normal) (Interrupt Routine)

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel x bits]	0b1111

IF: RXx_FULL		
Read the receiver register	MCSPI_RXx	0x-
Increment read_count +1		
ENDIF		

18.3.5.2.1.8 Transfer Procedures With FIFO

These flows describe the transfer with FIFO.

The McSPI module allows the transfer of one or several words, according to different modes:

- MASTER Normal, MASTER Turbo, SLAVE
- TRANSMIT–RECEIVE, TRANSMIT-ONLY, RECEIVE-ONLY
- Write and Read requests: IRQ, DMA

For all these flows, the host process contains the main process and the interrupt routine. This routine is called on the IRQ signals or by an internal call if the module is used in polling mode.

For more information, see Section 18.3.4.6, *FIFO Buffer Management*.

Table 18-228. FIFO Mode Common Sequence (Master) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS	1
Write MCSPI_IRQENABLE to enable interrupts	MCSPI_IRQENABLE	1
Write MCSPI_CHxCONF to configure the channel	MCSPI_CHxCONF	0x-
Write MCSPI_XFERLEVEL	MCSPI_XFERLEVEL	0x-
Start the channel	MCSPI_CHxCTRL[0] EN	1
IF: Receive only		
Wait for the write request (TX empty or DMA write)		
Write for the transmitter register with data	MCSPI_TXx	0x-
ENDIF		
Wait for the host event for end of transfer		
Stop the channel	MCSPI_CHxCTRL[0] EN	0

18.3.5.2.1.8.1 Common Transfer Sequence in FIFO Mode

This flow describes the host sequence for a transfer of any type defined in Section 18.3.5.2.1.8, *Transfer Procedures With FIFO*.

In multi-channel, only one channel can use the FIFO.

Before enabling the FIFO for a channel (MCSPI_CHxCONF[28] FFER and MCSPI_CHxCONF[27] FFEW bits), the host must check that the FIFO is not enabled for another channel, even if these channels are not used.

In transmit-and-receive mode, the FIFO can be enabled for write or read request only, without FIFO for the other request.

In Slave mode, the channel 0 only can be activated. The correct SPIEN line is chosen in MCSPI_CHxCONF[22:21] SPIENSLV bits (where x = 0).

The McSPI module can start the transfer only when the first write request has been released by writing the MCSPI_TXx register, even in receive-only mode (only one write request occurs in this case).

18.3.5.2.1.8.2 End of Transfer Sequences in FIFO Mode

Table 18-229 summarizes the type of end of transfer per transfer mode and gives a reference to the appropriate section for details.

Table 18-229. End of Transfer Sequences in FIFO Mode

Word count	TRANSMIT AND RECEIVE	TRANSMIT-ONLY	RECEIVE-ONLY
Yes	See Figure 18-66	See Figure 18-68	See Figure 18-69
No	See Figure 18-67	See Figure 18-68	See Figure 18-70

The end of transfer sequences are described from the start of the channel.

In these sequences, some soft variables are used:

- write_count = N
- read_count = N
- last_request = FALSE

They are initialized before starting the channel.

18.3.5.2.1.8.3 Transmit-and-Receive With Word Count

Figure 18-66 shows the flow of a transfer in transmit-and-receive mode, with word count.

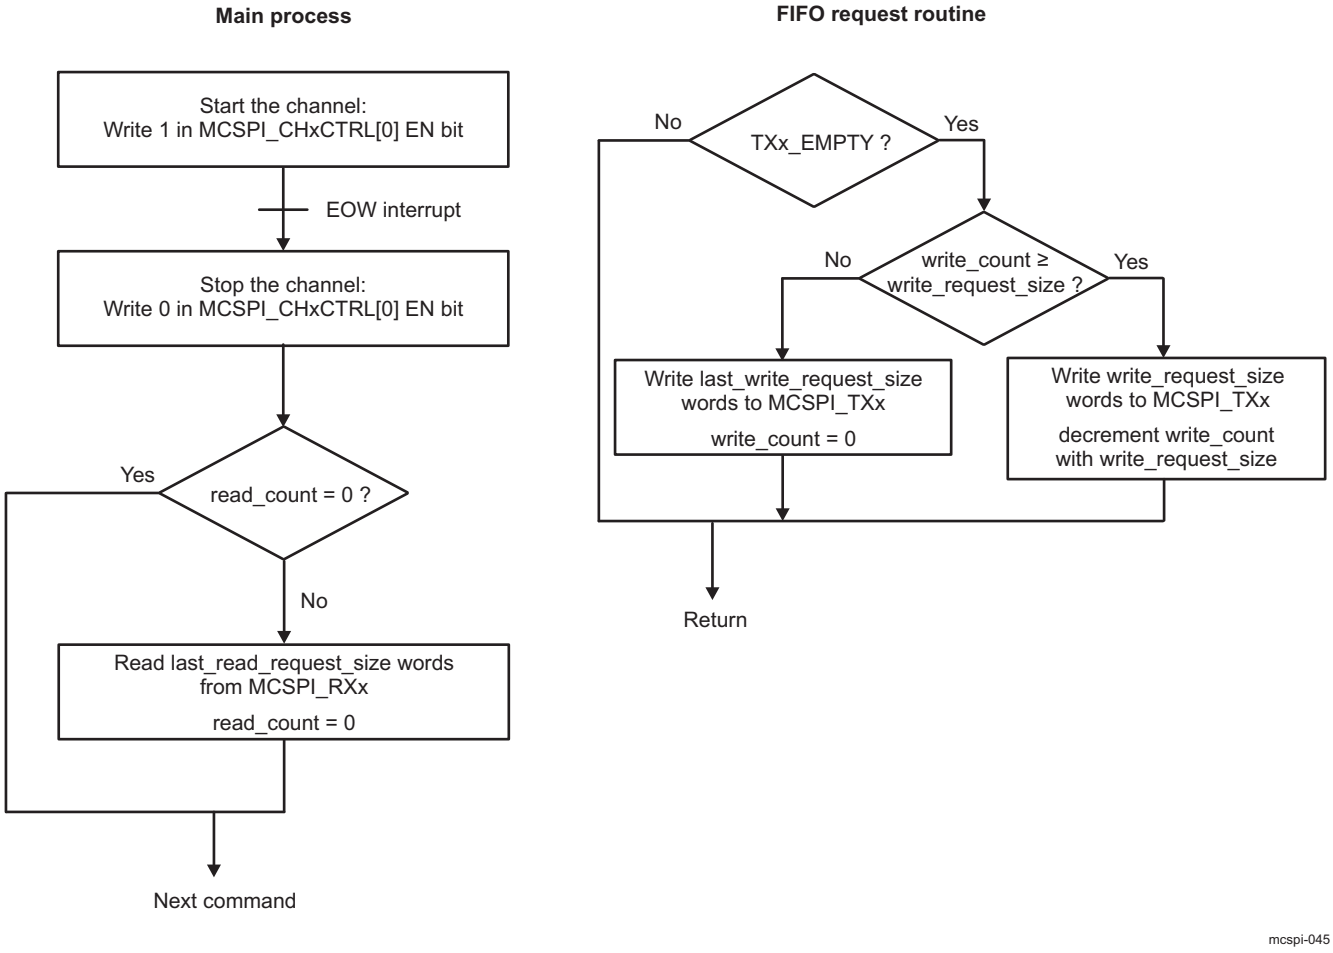

Figure 18-66. FIFO Mode Transmit-and-Receive With Word Count (Master)

18.3.5.2.1.8.4 Transmit-and-Receive Without Word Count

Figure 18-67 shows the flow of a transfer in transmit-and-receive mode, without word count.

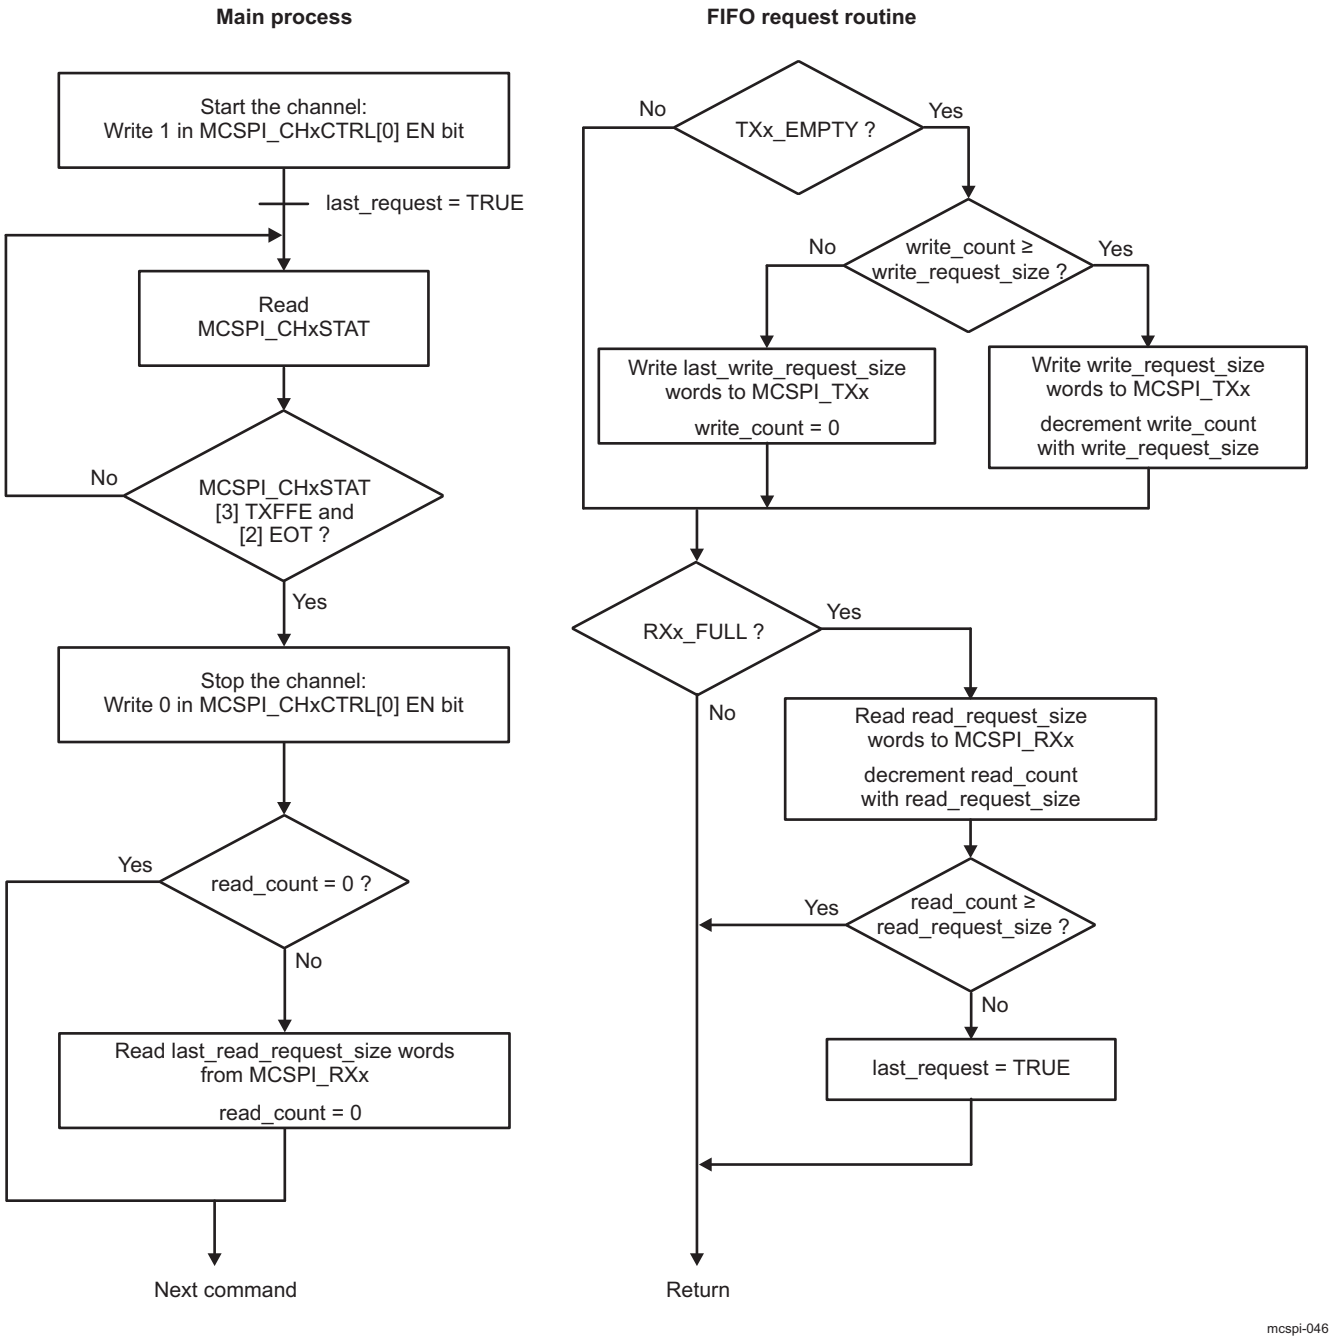

Figure 18-67. FIFO Mode Transmit-and-Receive Without Word Count (Master)

18.3.5.2.1.8.5 Transmit-Only

Figure 18-68 shows the flow of a transfer in transmit-only mode, with or without word count. The difference between word count enabled or not is just on the condition after starting the channel:

- word count enable: wait for EOW interrupt
- word count disable: wait for write_count = 0

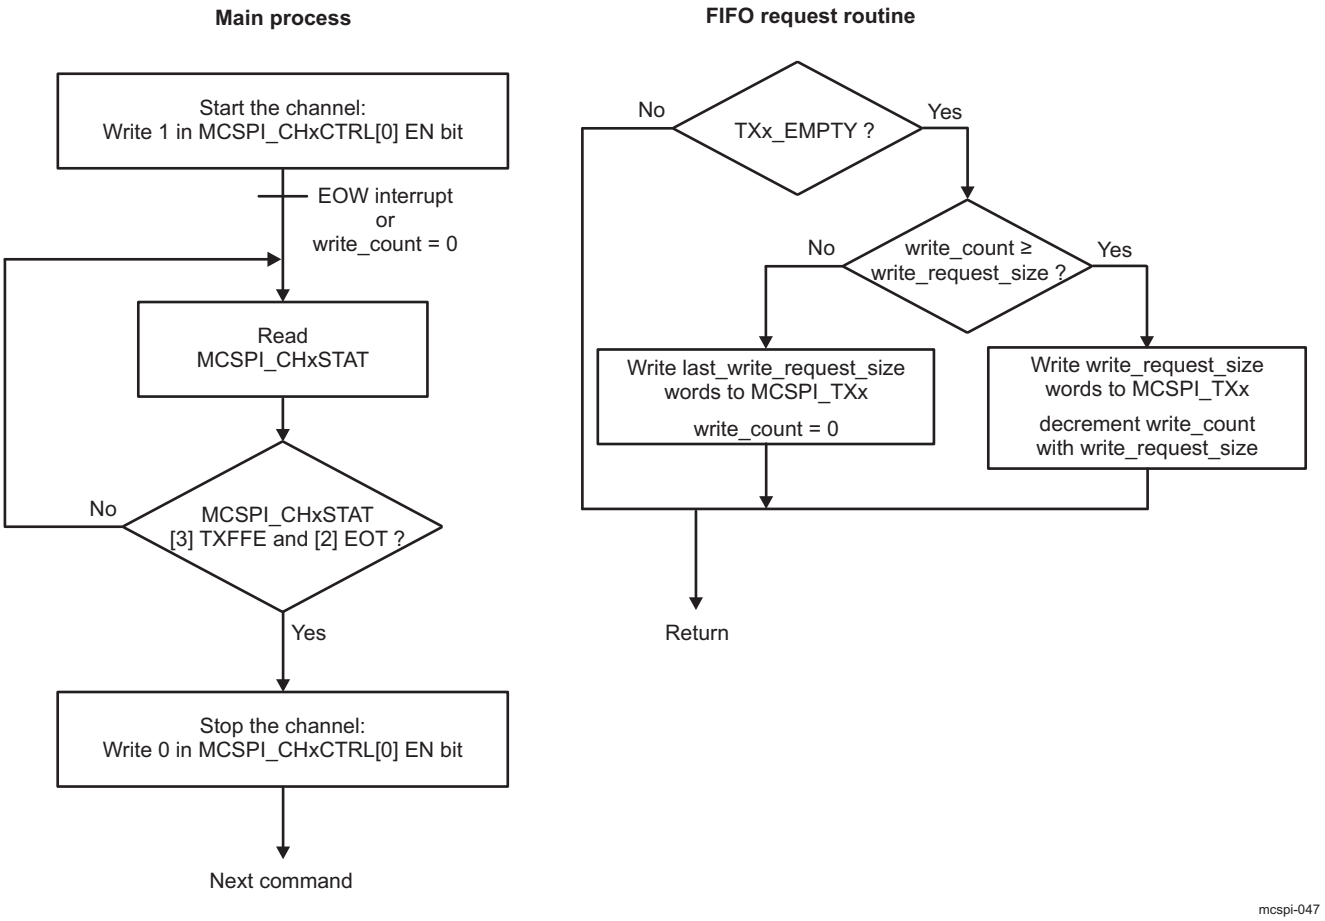

Figure 18-68. FIFO Mode Transmit-Only (Master)

18.3.5.2.1.8.6 Receive-Only With Word Count

Figure 18-69 shows the flow of a transfer in receive-only mode, with word count.

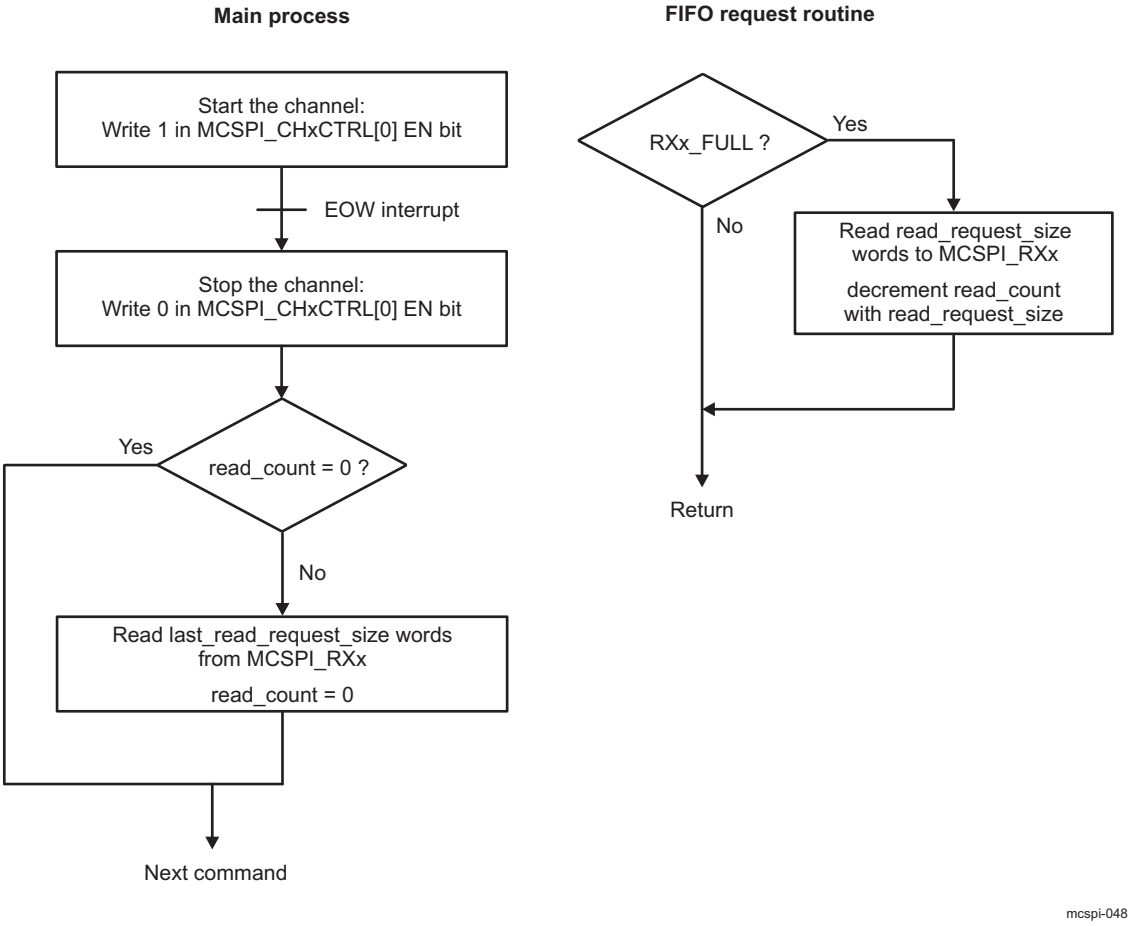

Figure 18-69. FIFO Mode Receive-Only With Word Count (Master)

18.3.5.2.1.8.7 Receive-Only Without Word Count

Figure 18-70 shows the flow of a transfer in receive-only mode, without word count.

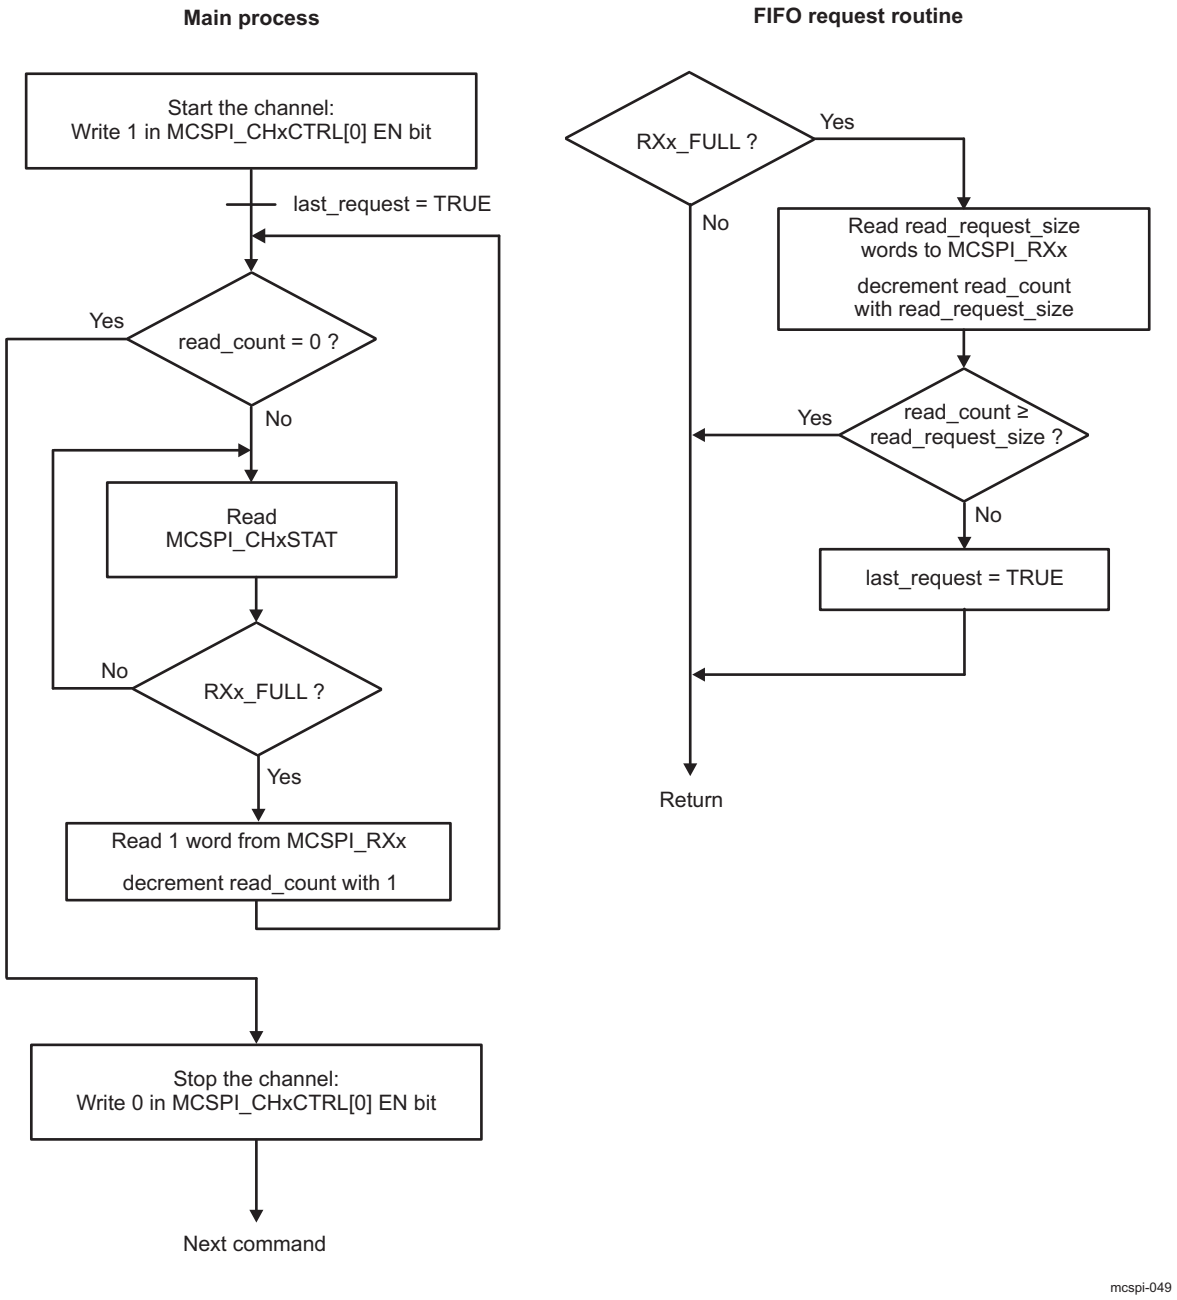

Figure 18-70. FIFO Mode Receive-Only Without Word Count (Master)

18.3.5.3 Common Transfer Procedures Without FIFO – Polling Method

18.3.5.3.1 Receive-Only Procedure – Polling Method

Table 18-230 lists the receive-only procedure using the polling method.

Table 18-230. Receive-Only Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode	See Table 18-207.	
Start the channel.	MCSPI_CHxCTRL[0] EN	1

Table 18-230. Receive-Only Procedure – Polling Method (continued)

Step	Register/Bit Field/Programming Model	Value
Wait for end-of-transfer.	MCSPI_CHxSTAT[2] EOT	=1
Read the receiver register.	MCSPI_RXx	0x-
Stop the channel if no more data is expected.	MCSPI_CHxCTRL[0] EN	0

18.3.5.3.2 Receive-Only Procedure – Interrupt Method

Table 18-231 lists the receive-only procedure using the interrupt method.

Table 18-231. Receive-Only Procedure – Interrupt Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 18-207.	
Start the channel.	MCSPI_CHxCTRL[0] EN	1
Enable the interrupt for the receiver register.	MCSPI_IRQENABLE[2] RX_FULL_ENABLE	1
Wait for interrupt.		
Read the status register.	MCSPI_IRQSTATUS[2] RX_FULL	1
Disable the interrupt if no more data is expected.	MCSPI_IRQENABLE[2] RX_FULL_ENABLE	0
Stop the channel if no more data is expected.	MCSPI_CHxCTRL[0] EN	0
Read the receiver register.	MCSPI_RXx	0x-

18.3.5.3.3 Transmit-Only Procedure – Polling Method

Table 18-232 lists the transmit-only procedure using the polling method.

Table 18-232. Transmit-Only Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 18-208	
Start the channel.	MCSPI_CHxCTRL[0] EN	1
Write the transmitter register with data.	MCSPI_TXx	0x-
Wait until end of transfer?	MCSPI_CHxSTAT[2] EOT	=1
Stop the channel.	MCSPI_CHxCTRL[0] EN	0

18.3.5.3.4 Transmit-and-Receive Procedure – Polling Method

Table 18-232 lists the transmit-and-receive procedure using the polling method.

Table 18-233. Transmit-and-Receive Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 18-209.	
Start the channel.	MCSPI_CHxCTRL[0] EN	1
Write the transmitter register with data.	MCSPI_TXx	0x-
Wait until transmit/receive word?	MCSPI_CHxSTAT[2] EOT	=1
Stop the channel.	MCSPI_CHxCTRL[0] EN	0
Read the receiver register.	MCSPI_TXx	0x-

31:18	RESERVED	Reads return 0	RW	0x0000
17	EOW	End of word count event when a channel is enabled using the FIFO buffer and the channel had sent the number of SPI word defined by MCSPI_XFERLEVEL[31:16] WCNT. Write 0x0: Event status bit unchanged Read 0x0: Event false Read 0x1: Event is pending Write 0x1: Event status bit is reset	RW W1toClr	0
16	WKS	Wake-up event in slave mode when an active control signal is detected on the SPIEN line programmed in the field MCSPI_CHxCONF[22:21] SPIENSLV Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
15	RESERVED	Reads returns 0	RW	0
14	RX3_FULL	Receiver register is full or almost full. Only when Channel 3 is enabled Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
13	TX3_UNDERFLOW	Transmitter register underflow. Only when Channel 3 is enabled. The transmitter register is empty (not updated by host or DMA with new data) before its time slot assignment. Exception: No TX_underflow event when no data has been loaded into the transmitter register since channel has been enabled. Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
12	TX3_EMPTY	Transmitter register is empty or almost empty. Note: Enabling the channel automatically rises this event. Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
11	RESERVED	Reads returns 0.	RW	0
10	RX2_FULL	Receiver register full or almost full. Channel 2 Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
9	TX2_UNDERFLOW	Transmitter register underflow. Channel 2 Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
8	TX2_EMPTY	Transmitter register empty or almost empty. Channel 2 Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
7	RESERVED	Reads returns 0	RW	0
6	RX1_FULL	Receiver register full or almost full. Channel 1 Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
5	TX1_UNDERFLOW	Transmitter register underflow. Channel 1 Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
4	TX1_EMPTY	Transmitter register empty or almost empty. Channel 1 Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
3	RX0_OVERFLOW	Receiver register overflow (slave mode only). Channel 0 Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
2	RX0_FULL	Receiver register full or almost full. Channel 0 Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
1	TX0_UNDERFLOW	Transmitter register underflow. Channel 0 Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
0	TX0_EMPTY	Transmitter register empty or almost empty. Channel 0 Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0

Table 18-254. MCSPI_SYST

Address Offset	0x124		
Physical Address	0x4809 8124 0x4809 A124 0x480B 8124 0x480B A124	**Instance**	McSPI1 McSPI2 McSPI3 McSPI4
Description	This register is used to check the correctness of the system interconnect either internally to peripheral bus, or externally to device I/O pads, when the module is configured in system test (SYSTEST) mode.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																				SSB	SPIENDIR	SPIDATDIR1	SPIDATDIR0	WAKD	SPICLK	SPIDAT_1	SPIDAT_0	SPIEN_3	SPIEN_2	SPIEN_1	SPIEN_0

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Reads returns 0.	RW	0x00000
11	SSB	Set status bit 0x0: No action. Writing 0 does not clear already set status bits. This bit must be cleared before trying to clear a status bit of the MCSPI_IRQSTATUS register. 0x1: Force to 1 all status bits of MCSPI_IRQSTATUS register. Writing 1 into this bit sets to 1 all status bits in the MCSPI_IRQSTATUS register.	RW	0
10	SPIENDIR	Set the direction of the SPIEN[3:0] lines and SPICLK line. 0x0: Output (as in master mode) 0x1: Input (as in slave mode)	RW	0
9	SPIDATDIR1	Set the direction of the SPIDAT[1]. 0x0: Output 0x1: Input	RW	0
8	SPIDATDIR0	Set the direction of the SPIDAT[0]. 0x0: Output 0x1: Input	RW	0
7	WAKD	SWAKEUP output (signal data value of internal signal to system). The signal is driven high or low according to the value written into this bit. 0x0: The pin is driven low. 0x1: The pin is driven high.	RW	0
6	SPICLK	SPICLK line (signal data value) If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the CLKSPI line (high or low), and a write into this bit has no effect. If [10] SPIENDIR = 0 (output mode direction), the CLKSPI line is driven high or low according to the value written into this bit.	RW	0
5	SPIDAT_1	SPIDAT[1] line (signal data value) If [9] SPIDATDIR1 = 0 (output mode direction), the SPIDAT[1] line is driven high or low according to the value written into this bit. If [9] SPIDATDIR1 = 1 (input mode direction), this bit returns the value on the SPIDAT[1] line (high or low), and a write into this bit has no effect.	RW	0

Bits	Field Name	Description	Type	Reset
4	SPIDAT_0	SPIDAT[0] line (signal data value) If [8] SPIDATDIR0 = 0 (output mode direction), the SPIDAT[0] line is driven high or low according to the value written into this bit. If [8] SPIDATDIR0 = 1 (input mode direction), this bit returns the value on the SPIDAT[0] line (high or low), and a write into this bit has no effect.	RW	0
3	SPIEN_3	SPIEN[3] line (signal data value) If [10] SPIENDIR = 0 (output mode direction), the SPIENT[3] line is driven high or low according to the value written into this bit. If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the SPIEN[3] line (high or low), and a write into this bit has no effect.	RW	0
2	SPIEN_2	SPIEN[2] line (signal data value) If [10] SPIENDIR = 0 (output mode direction), the SPIENT[2] line is driven high or low according to the value written into this bit. If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the SPIEN[2] line (high or low), and a write into this bit has no effect.	RW	0
1	SPIEN_1	SPIEN[1] line (signal data value) If [10] SPIENDIR = 0 (output mode direction), the SPIENT[1] line is driven high or low according to the value written into this bit. If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the SPIEN[1] line (high or low), and a write into this bit has no effect.	RW	0
0	SPIEN_0	SPIEN[0] line (signal data value) If [10] SPIENDIR = 0 (output mode direction), the SPIENT[0] line is driven high or low according to the value written into this bit. If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the SPIEN[0] line (high or low), and a write into this bit has no effect.	RW	0

Table 18-256. MCSPI_MODULCTRL

Address Offset	0x128		
Physical Address	0x4809 8128 0x4809 A128 0x480B 8128 0x480B A128	**Instance**	McSPI1 McSPI2 McSPI3 McSPI4
Description	This register is dedicated to the configuration of the serial peripheral interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							FDAA	MOA	INITDLY			SYSTEM_TEST	MS	PIN34	SINGLE

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reads returns 0.	RW	0x000000
8	FDAA	FIFO DMA address 256-bit aligned This bit is used when a FIFO is managed by the module and DMA connected to the controller provides only 256-bit aligned address. If this bit is set the enabled channel which uses the FIFO has its data managed through MCSPI_DAFTX and MCSPI_DAFRX registers instead of MCSPI_TXx and MCSPI_RXx registers. 0x0: FIFO data managed by MCSPI_TXx and MCSPI_RXx registers. 0x1: FIFO data managed by MCSPI_DAFTX and MCSPI_DAFRX registers.	RW	0
7	MOA	Multiple word interface access: this bit can only be used when a channel is enabled using a FIFO. It allows the system to perform multiple SPI word access for a single 32-bit interface word access. This is possible for WL < 16. 0x0: Multiple word access disabled 0x1: Multiple word access enabled with FIFO	RW	0
6:4	INITDLY	Initial SPI delay for first transfer: this field is an option only available in SINGLE master mode. The controller waits for a delay to transmit the first SPI word after channel enabled and corresponding TX register filled. This delay is based on SPI output frequency clock. No clock output provided to the boundary and chip select is not active in 4-pin mode within this period. 0x0: No delay for first spi transfer. 0x1: The controller wait 4 SPI bus clock 0x2: The controller wait 8 SPI bus clock 0x3: The controller wait 16 SPI bus clock 0x4: The controller wait 32 SPI bus clock	RW	0x0
3	SYSTEM_TEST	Enables the system test mode 0x0: Functional mode 0x1: System test mode (SYSTEST)	RW	0
2	MS	Master/slave 0x0: Master - The module generates the SPICLK and SPIEN[3:0]. 0x1: Slave - The module receives the SPICLK and SPIEN[3:0].	RW	1
1	PIN34	Pin mode selection: This bit is used in master or slave mode to configure the SPI pin mode (3-pin or 4-pin). If asserted the controller only uses SIMO, SOMI, and SPICLK clock pin for SPI transfers. 0x0: SPIEN is used as a chip-select. 0x1: SPIEN is not used. In this mode all related options to chip-select have no meaning.	RW	0
0	SINGLE	Single channel/Multi Channel (master mode only) 0x0: More than one channel will be used in master mode. 0x1: Only one channel will be used in master mode. This bit must be set in Force SPIEN[x] mode.	RW	0

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Read returns 0.	R	0x0
29	CLKG	Clock divider granularity this bit defines the granularity of channel clock divider: power of 2 or one clock cycle granularity. When this bit is set the register MCSPI_CHxCTRL[15:8] EXTCLK must be configured to reach a maximum of 4096 clock divider ratio. Then the clock divider ratio is a concatenation of [5:2] CLKD and MCSPI_CHxCTRL[15:8] EXTCLK values 0x0: Clock granularity of power of 2 0x1: One clock cycle granularity	RW	0
28	FFER	FIFO enabled for receive: Only one channel can have this bit field set. 0x0: The buffer is not used to receive data. 0x1: The buffer is used to receive data.	RW	0
27	FFEW	FIFO enabled for transmit: Only one channel can have this bit field set. 0x0: The buffer is not used to transmit data. 0x1: The buffer is used to transmit data.	RW	0
26:25	TCS0	Chip-select time control This 2-bit field defines the number of interface clock cycles between CS toggling and first or last edge of SPI clock. 0x0: 0.5 clock cycle 0x1: 1.5 clock cycles 0x2: 2.5 clock cycles 0x3: 3.5 clock cycles	RW	0x0

Bits	Field Name	Description	Type	Reset
24	SBPOL	Start-bit polarity 0x0: Start-bit polarity is held to 0 during SPI transfer. 0x1: Start-bit polarity is held to 1 during SPI transfer.	RW	0
23	SBE	Start-bit enable for SPI transfer 0x0: Default SPI transfer length as specified by WL bit field 0x1: Start bit D/CX added before SPI transfer. Polarity is defined by bit [24] SBPOL	RW	0
22:21	SPIENSLV	Channel 0 only and slave mode only: SPI slave select signal detection. Reserved bits for other cases. 0x0: Detection enabled only on SPIEN[0] 0x1: Detection enabled only on SPIEN[1] 0x2: Detection enabled only on SPIEN[2] 0x3: Detection enabled only on SPIEN[3]	RW	0x0
20	FORCE	Manual SPIEN assertion to keep SPIEN active between SPI words (single channel master mode only). 0x0: Writing 0 into this bit drives low the SPIEN line when [6] EPOL=0, and drives it high when [6] EPOL=1. 0x1: Writing 1 into this bit drives high the SPIEN line when [6] EPOL=0, and drives it low when [6] EPOL=1.	RW	0
19	TURBO	Turbo mode 0x0: Turbo is deactivated (recommended for single SPI word transfer). 0x1: Turbo is activated to maximize the throughput for multiple SPI words transfer.	RW	0
18	IS	Input Select 0x0: Data line 0 (SPIDAT[0]) selected for reception 0x1: Data line 1 (SPIDAT[1]) selected for reception	RW	1
17	DPE1	Transmission enable for data line 1 0x0: Data line 1 (SPIDAT[1]) selected for transmission 0x1: No transmission on Data Line1 (SPIDAT[1])	RW	1
16	DPE0	Transmission Enable for data line 0 0x0: Data Line0 (SPIDAT[0]) selected for transmission 0x1: No transmission on data line 0 (SPIDAT[0])	RW	0
15	DMAR	DMA read request The DMA read request line is asserted when the channel is enabled and a new data is available in the receive register of the channel. The DMA read request line is deasserted on read completion of the receive register of the channel. 0x0: DMA read request disabled 0x1: DMA read request enabled	RW	0
14	DMAW	DMA write request. The DMA write request line is asserted when The channel is enabled and the transmitter register of the channel is empty. The DMA write request line is deasserted on load completion of the transmitter register of the channel. 0x0: DMA write request disabled 0x1: DMA write request enabled	RW	0

		0x1: SPIEN is held low during the ACTIVE state.		

Bits	Field Name	Description	Type	Reset
5:2	CLKD	Frequency divider for SPICLK (only when the module is a Master SPI device). A programmable clock divider divides the SPI reference clock (FCLK) with a 4-bit value, and results in a new clock SPICLK available to shift-in and shift-out data. By default, the clock divider ratio has a power of 2 granularity when [29] CLKG is cleared. Otherwise, this field is the 4-LSB bit of a 12-bit register concatenated with clock divider extension MCSPI_CHxCTRL[15:8] EXTCLK register. The value description below defines the clock ratio when [29] CLKG is set to 0. 0x0: 1 0x1: 2 0x2: 4 0x3: 8 0x4: 16 0x5: 32 0x6: 64 0x7: 128 0x8: 256 0x9: 512 0xA: 1024 0xB: 2048 0xC: 4096 0xD: 8192 0xE: 16384 0xF: 32768	RW	0x0
1	POL	SPICLK polarity (see Section 18.3.2.3.1, *Transfer Format*) 0x0: SPICLK is held low during the INACTIVE state 0x1: SPICLK is held high during the INACTIVE state	RW	0
0	PHA	SPICLK phase (see Section 18.3.2.3.1, *Transfer Format*) 0x0: Data are latched on odd-numbered edges of SPICLK. 0x1: Data are latched on even-numbered edges of SPICLK.	RW	0

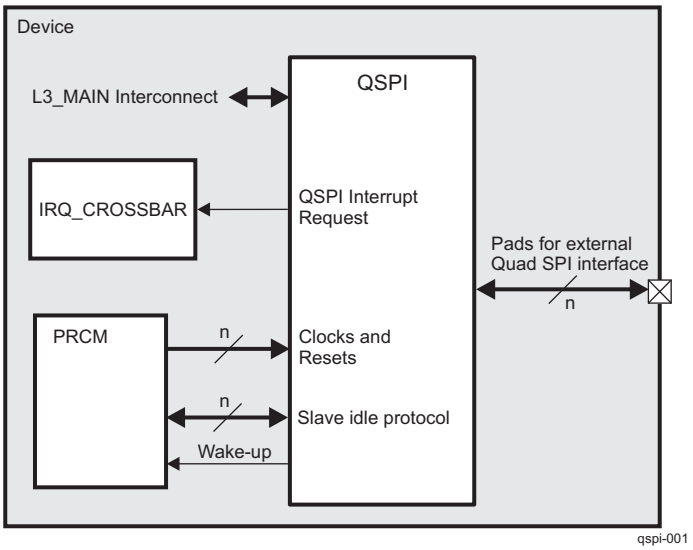
18.4 Quad Serial Peripheral Interface

18.4.1 Quad Serial Peripheral Interface Overview

The quad serial peripheral interface (QSPI) module is a kind of SPI module that allows single, dual, or quad read access to external SPI devices. This module has a memory mapped register interface, which provides a direct interface for accessing data from external SPI devices and thus simplifying software requirements. The QSPI works as a master only.

The one QSPI in the device is primarily intended for fast booting from quad-SPI flash memories. Figure 18-71 shows the QSPI module overview.

Figure 18-71. QSPI Overview



The QSPI supports the following features:

- General SPI features:
  - Programmable clock divider
  - Six pin interface
  - Programmable length (from 1 to 128 bits) of the words transferred
  - Programmable number (from 1 to 4096) of the words transferred
  - 4 external chip-select signals
  - Support for 3-, 4-, or 6-pin SPI interface
  - Optional interrupt generation on word or frame (number of words) completion
  - Programmable delay between chip select activation and output data from 0 to 3 QSPI clock cycles
  - Programmable signal polarities
  - Programmable active clock edge
  - Software-controllable interface allowing for any type of SPI transfer
  - Control through L3_MAIN configuration port
- Serial flash interface (SFI) features:
  - Serial flash read/write interface
  - Additional registers for defining read and write commands to the external serial flash device
  - 1 to 4 address bytes
  - Fast read support, where fast read requires dummy bytes after address bytes; 0 to 3 dummy bytes can be configured.
  - Dual read support

- Quad read support
- Little-endian support (only for memory mapped registers used to configure QSPI controller and not SPI content accesses)
- Linear increment addressing mode only

The QSPI supports only dual and quad reads. Dual or quad writes are not supported. In addition, there is no "pass through" mode supported where the data present on the QSPI input is sent to its output.

NOTE: The QSPI module does not support cache line wrap mode.

18.4.2 QSPI Environment

Figure 18-72 shows a typical connection of the QSPI module to the external quad-SPI flash memory.

Figure 18-72. QSPI Connected to an External Quad-SPI Flash Memory

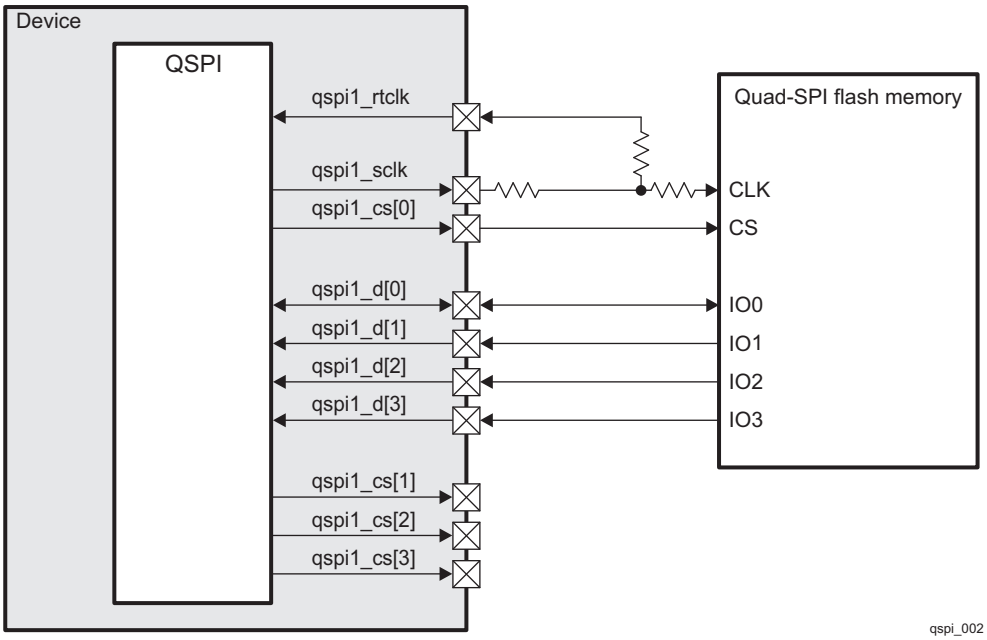


Table 18-274 lists and describes the QSPI I/O signals.

Table 18-274. QSPI I/O Signals

QSPI Signal/Pad name	I/O[1]	Description					
		3-pin[2] SPI Read (Single Read)	3-pin[2] SPI Write (Single Write)	4-pin[2] SPI Read (Single Read)	4-pin[2] SPI Write (Single Write)	4-pin[2] SPI Read (Dual Read)	6-pin[2] SPI Read (Quad Read)
qspi1_d[0]	IO	Used as SPI data input	Used as SPI data output	Not used	Used as SPI data output	Used as SPI data input 0	Used as SPI data input 0
qspi1_d[1]	I	Not used	Not used	Used as SPI data input	Not used	Used as SPI data input 1	Used as SPI data input 1
qspi1_d[2]	I	Not used	Not used	Not used	Not used	Not used	Used as SPI data input 2
qspi1_d[3]	I	Not used	Not used	Not used	Not used	Not used	Used as SPI data input 3
qspi1_sclk	O	Clock for the external SPI device					
qspi1_cs[0]	O	External SPI device chip-select 0					
qspi1_cs[1]	O	External SPI device chip-select 1					
qspi1_cs[2]	O	External SPI device chip-select 2					
qspi1_cs[3]	O	External SPI device chip-select 3					
qspi1_rtclk	I	The qspi1_sclk output must be connected to the qspi1_rtclk input, and is used for controlling the timing of the read return data when the QSPI module operates in Mode 0. In case Mode 3 is used, there is no need to connect the qspi1_sclk to the qspi1_rtclk.					

(1) I = Input; O = Output

(2) This is the pin count at the SPI flash memory side. The pin count at the device side is increased by one because of the qspi1_rtclk signal. References to the pin count throughout this chapter consider the pin count at the SPI flash memory side.

NOTE: In order to ensure proper timing, precise layout and routing requirements must be followed. For layout and routing requirements for all QSPI signals, see section “PCB Guidelines” of the device Data Manual.

18.4.3 QSPI Integration

Figure 18-73 shows the integration of the QSPI module in the device.

Figure 18-73. QSPI Integration

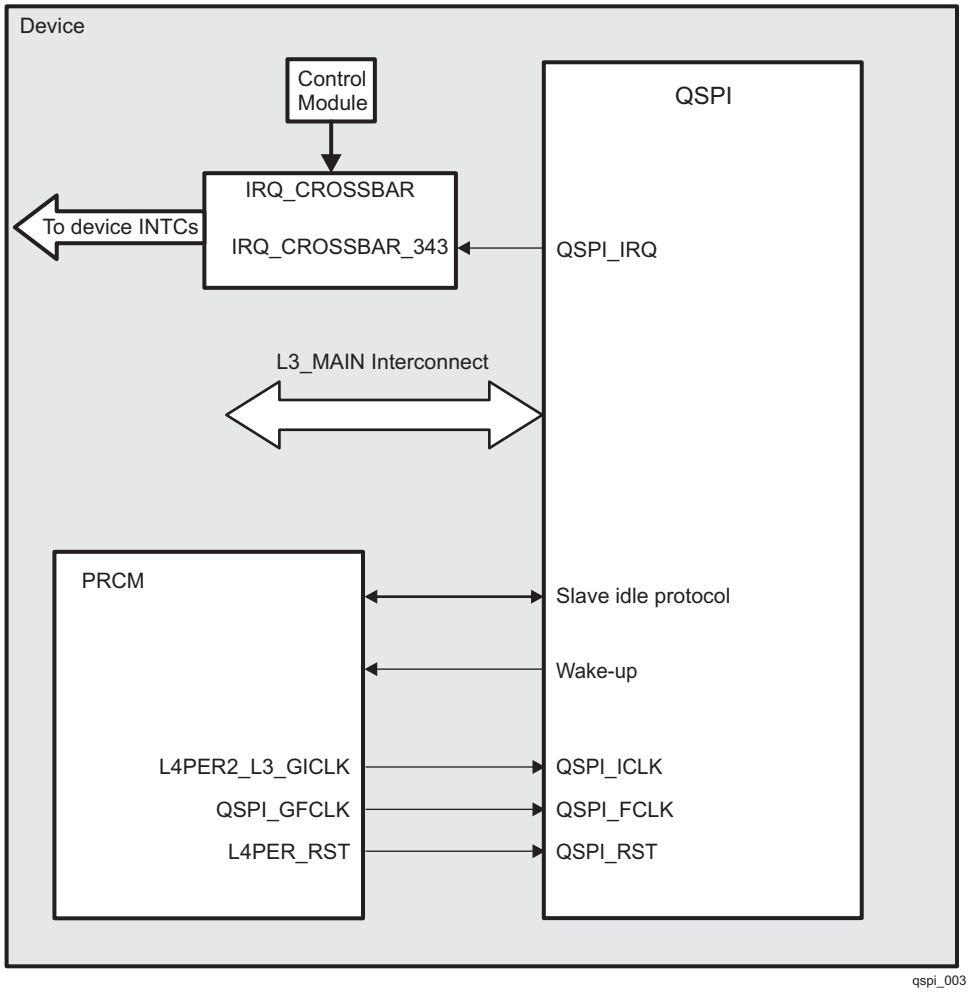

Table 18-275 through Table 18-277 summarize the integration of the QSPI in the device.

Table 18-275. QSPI Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
QSPI	QSPI_IRQ	IRQ_CROSSBAR_343	–	QSPI interrupt request

NOTE: The Default Mapping column in Table 18-277 shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device interrupt controller (INTC) through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.
For more information about the device INTCs, see Chapter 12, *Interrupt Controllers*.

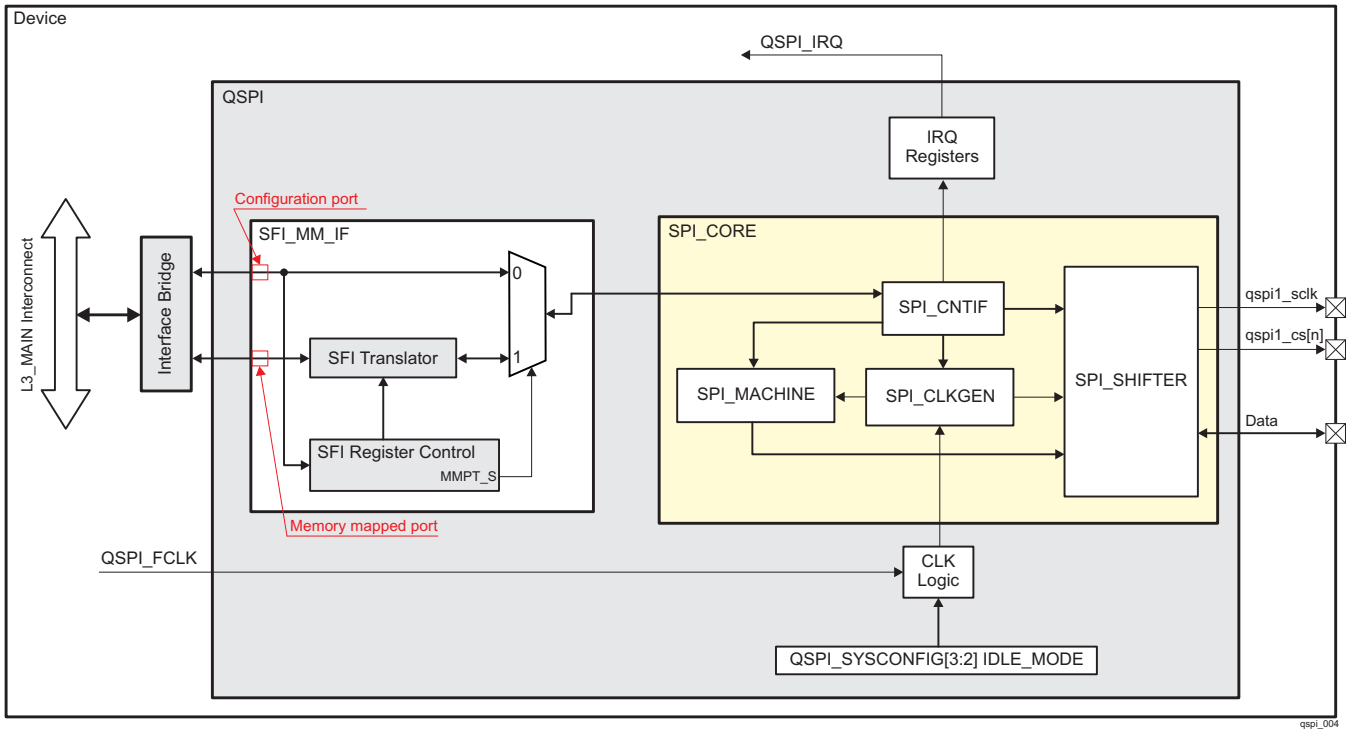
NOTE: For the description of the interrupt source, see Section 18.4.4.3, *QSPI Interrupt Requests*.

18.4.4 QSPI Functional Description

18.4.4.1 QSPI Block Diagram

Iinitial device boot from external SPI flash memory can be accomplished through the QSPI module. The interface is a simple 4-wire SPI used for control or data transfers. The QSPI also supports a 3-wire SPI protocol where the qspi1_d[0] signal is used as a bidirectional for reads and writes. In addition, a 6-wire mode can be used to support quad read devices. Figure 18-74 shows the QSPI block diagram.

Figure 18-74. QSPI Block Diagram



The QSPI is composed of two blocks. The first one is the SFI memory-mapped interface (SFI_MM_IF) and the second one is the SPI core (SPI_CORE). The SFI_MM_IF block is associated only with SPI flash memories and is used for specifying typical for the SPI flash memories settings (read or write command, number of address and dummy bytes, and so on) unlike the SPI_CORE block, which is associated with the SPI interface itself and is used to configure typical SPI settings (chip-select polarity, serial clock inactive state, SPI clock mode, length of the words transferred, and so on).

The SFI_MM_IF comprises the following two subblocks:

- SFI register control
- SFI translator

The SPI_CORE comprises the following four subblocks:

- SPI control interface (SPI_CNTIF)
- SPI clock generator (SPI_CLKGEN)
- SPI control state machine (SPI_MACHINE)
- SPI data shifter (SPI_SHIFTER)

In addition, an interface bridge connects the two ports (configuration port and memory-mapped port) of the SFI_MM_IF block to the L3_MAIN interconnect. There are no software controls associated with this interface bridge.

The QSPI supports long transfers through a frame-style sequence. In its generic SPI use mode, a word can be defined up to 128 bits and multiple words can be transferred during a single access. For each word, a device initiator must read or write the new data and then tell the QSPI to continue the current operation. Using this sequence, a maximum of 4096 128-bit words can be transferred in a single SPI read or write operation. This allows great flexibility when connecting the QSPI to various types of devices.

As opposed to the generic SPI use mode, the communication with serial flash-type devices requires sending a byte command, followed by sending bytes of data. Commands can be sent through the SPI_CORE block to communicate with a serial flash device; however, it is easier to do this using the SFI_MM_IF block because it is intended to ease the communication with serial flash devices. If the SPI_CORE is used to communicate with a serial flash device, software must load the command into the SPI data transfer register with additional configuration fields, perform the byte transfer, then place the data to be sent (or configure for receive) along with additional configuration fields, and perform that transfer. Reads and writes to serial flash devices are more specific. First, the read or write command byte is sent, followed by 1 to 4 bytes of address (corresponding to the address to read/write), then followed by the data write/receive phase. Data is always sent byte oriented. When the address is loaded, data can be continuously read or written, and the address will automatically increment to each byte address internally to the serial flash device.

NOTE: The SFI_MM_IF block only allows reading and writing to an externaly connected SPI flash device. The SFI_MM_IF block does not allow reads or writes to internal configuration and status registers of the SPI flash device. These registers must be accessed through the features of the SPI_CORE block.

18.4.4.1.1 SFI Register Control

The SFI register control block consists of the following five configuration registers:

- QSPI_SPI_SETUP0_REG
- QSPI_SPI_SETUP1_REG
- QSPI_SPI_SETUP2_REG
- QSPI_SPI_SETUP3_REG
- QSPI_SPI_SWITCH_REG

The first four registers let the user define the following:

- Byte command for a serial flash read specified by the QSPI_SPI_SETUPi_REG[7:0] RCMD bit field
- Byte command for a serial flash write specified by the QSPI_SPI_SETUPi_REG[23:16] WCMD bit field
- Number of address bytes required for the particular type of serial flash specified by the

QSPI_SPI_SETUPi_REG[9:8] NUM_A_BYTES bit field

- Number of “dummy bytes” that may be needed to support the fast read mode function of some serial flash devices. The QSPI_SPI_SETUPi_REG[11:10] NUM_D_BYTES bit field specifies the number of "dummy bits." In addition, the QSPI_SPI_SETUPi_REG[28:24] NUM_D_BITS bit field can also specify the number of "dummy bits."
- Whether the read command is single (normal), dual, or quad read mode command. This is specified by the QSPI_SPI_SETUPi_REG[13:12] READ_TYPE bit field. (i is equal to 0, 1, 2 and 3 and means that the QSPI_SPI_SETUPi_REG registers are associated with each of the four supported chip-selects [that is, four supported output SPI flash devices])

The QSPI_SPI_SWITCH_REG register acts as a static switch which allows the configuration port (shown in Figure 18-74) to connect directly to the SPI_CORE block, or allows the memory-mapped port (also shown in Figure 18-74) to connect to the SPI_CORE block. This is done using the QSPI_SPI_SWITCH_REG[0] MMPT_S bit.

In addition, the QSPI_SPI_SWITCH_REG[1] MM_INT_EN bit is used to enable or disable the word complete interrupt during operations using the memory-mapped port.

18.4.4.1.2 SFI Translator

The SFI translator block represents an FSM which, based on the configuration information loaded into the SFI register control block, converts each input read/write sequence into an SPI_CORE configuration sequence for access to the external serial flash memory.

A read sequence is converted into the following actions:

1. SPI chip-select goes active.
2. Read command byte is issued.
3. 1 to 4 address bytes, which correspond to the first address supplied, are issued.
4. 0 to 3 dummy bytes are issued, if “fast read” is supported.
5. Data bytes are read from the external SPI flash memory.
6. SPI chip-select goes inactive.

For linear addressing mode, action 5 is repeated until the byte count to be transferred reaches zero.

A write sequence is identical to a read sequence, except that a write sequence does not use dummy bytes.

Another important aspect with regard to writes is that a serial flash memory location can only be written to if the bits are erased in advance. Erased means the bits are set to 1. This means that writing only changes 1 contents to 0. It is not possible with this write to change the contents of a bit from 0 to 1. An erase command must be performed to do this operation. Erase commands cannot be executed on single byte locations. Depending on device types, there are page, block, and chip erase commands. To perform an erase command, the particular command must be sent over the SPI bus, and an internal register of the serial flash device must then be polled to determine when the erase completes. The erases must be done through the configuration port by software before performing any writes through the memory-mapped port. This means that writes are passed through to the serial flash device, but if the memory locations being modified are not properly erased before the write, the contents may not result in what was sent.

18.4.4.1.3 SPI Control Interface

The SPI control interface contains configuration registers used to configure the SPI core functionality of the QSPI. This block maintains all configuration settings for the SPI core (that is, settings specific for the SPI interface itself but not for the SPI flash memories).

The registers defined for this block are:

- The QSPI_PID register, which is read only and contains QSPI revision associated information
- The QSPI_SPI_CLOCK_CNTRL_REG register, which is used to control external SPI clock (qspi1_sclk)
- The QSPI_SPI_DC_REG register used to define the SPI clock mode and chip-select polarity for the four external SPI devices
- The QSPI_SPI_CMD_REG register used to control the operation of the SPI command. This register is

also used to configure and transfer data.

- Four data registers used for reading the data received and for writing the data to be transferred. These registers are:
  - QSPI_SPI_DATA_REG
  - QSPI_SPI_DATA_REG_1
  - QSPI_SPI_DATA_REG_2
  - QSPI_SPI_DATA_REG_3

  These four registers compose a 128-bit shift register.
- The QSPI_SPI_STATUS_REG register, which contains status information

All of these registers can only be written if the QSPI is not busy. This means that they can be written if the QSPI_SPI_STATUS_REG[0] BUSY bit is 0x0. The QSPI becomes busy when a write to the QSPI_SPI_CMD_REG[18:16] CMD bit field is performed. Writing to this bit field starts an SPI transaction and sets the QSPI_SPI_STATUS_REG[0] BUSY bit to 0x1. The CMD bit field can be written again when the BUSY bit is 0x0. In addition, the start of the SPI transaction is synchronized to the qspi1_sclk clock and clearing of the BUSY bit is synchronized to the QSPI_FCLK clock.

The register group QSPI_SPI_DATA_REG_3, QSPI_SPI_DATA_REG_2, QSPI_SPI_DATA_REG_1 and QSPI_SPI_DATA_REG is treated as a single 128-bit word for shifting data in and out. The QSPI_SPI_DATA_REG_3 register is used for the most significant bits and the QSPI_SPI_DATA_REG is used for the least significant bits.This applies for both reads and writes. For example, after reading a 128-bit word (WLEN = 0x7F) the most significant bit of the data read, that is bit 127, will be located at QSPI_SPI_DATA_REG_3[31] position and the least significant bit, that is bit 0 of the data read, will be located at the QSPI_SPI_DATA_REG[0] position.

The data written to this register group should be right justified so that a data pre-shifting is not required. The QSPI_SPI_CMD_REG[25:19] WLEN bit field determines the location of the most significant bit and the bit position that will be shifted out first during a write. In order to shift out byte data the WLEN bit field should be set to 0x7 and the data byte should be written to the lower byte of the QSPI_SPI_DATA_REG register. By setting the word length to 0x7 the QSPI_SPI_DATA_REG register will look like a pseudo 8-bit shift register. When the user wants to write 40-bit long word the WLEN bit field should be set to 0x27, the 32 least significant bits of data should be written to the QSPI_SPI_DATA_REG and the rest 8 most significant bits of data should be written to the lower byte of the QSPI_SPI_DATA_REG_1 register. By setting WLEN to 0x27 these two registers will look like a pseudo 40-bit shift register. When the word length is greater than 64 bits the QSPI_SPI_DATA_REG_2 register is also used and the previosly described logic applies. The QSPI_SPI_DATA_REG_3 register is used together with the other three data registers when the word length is greater than 96 bits.

When dual or quad read mode is used the number of the words transferred must be even. This number is configured through the QSPI_SPI_CMD_REG[11:0] FLEN bit field.

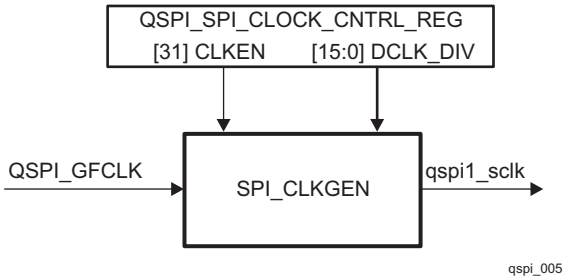
NOTE: The QSPI module does not support a "pass through" mode where the data present on qspi1_d[1] is sent to qspi1_d[0], when 4-pin non-dual read mode is used. This means that setting the QSPI_SPI_CMD_REG[18:16] CMD bit field to 0x1 causes the QSPI only to read from an external device using the qspi1_d[1] pad as an input and if a write to the same external device is desired, the CMD bit field should be set to 0x2, which causes the qspi1_d[0] pad to be used as an output.

18.4.4.1.4 SPI Clock Generator

The SPI clock generator uses the QSPI_FCLK clock as an input, and generates the qspi1_sclk, which is a divided version of the QSPI_FCLK clock. The divide ratio is a 16-bit value configured through the QSPI_SPI_CLOCK_CNTRL_REG[15:0] DCLK_DIV bit field and thus provides a division factor in a range from 1 to 65536. The QSPI_FCLK clock is divided by the DCLK_DIV value + 1 to provide the qspi1_sclk clock. When DCLK_DIV = 0x0 the QSPI_FCLK clock equals the DCLK clock. The value in the DCLK_DIV bit field applies only when the QSPI_SPI_CLOCK_CNTRL_REG[31] CLKEN bit is set to 0x1. Figure 18-75 shows the SPI_CLKGEN block.

If the CLKEN bit is 0x0 the command specified in the QSPI_SPI_CMD_REG[18:16] CMD bit field is not executed and the QSPI_SPI_STATUS_REG[0] BUSY bit is not set. The command is executed only if the CLKEN bit is 0x1 before write to the CMD bit field.

Figure 18-75. SPI_CLKGEN Block



18.4.4.1.5 SPI Control State-Machine

The SPI control state-machine (SPI_MACHINE) manages the operation of the SPI_CORE block. SPI_MACHINE takes control and configuration information from the registers in the SPI_CNTIF block as input and provides control information to the SPI data shifter. This information is used to control the SPI data port. The SPI_MACHINE also generates status information, which is sent back to the SPI_CNTIF block.

Writing a valid value to the QSPI_SPI_CMD_REG[18:16] CMD bit field sets immediately the QSPI_SPI_STATUS_REG[0] BUSY bit to 0x1, activates the corresponding qspi1_cs[n] (n = 0 to 3) and starts the SPI data transaction. The BUSY bit is cleared automatically when QSPI_SPI_CMD_REG[25:19] WLEN number of bits are shifted in or out. If the value of the QSPI_SPI_STATUS_REG[27:16] WDCNT bit field is different than 0x0 and WLEN number of bits are shifted already, the SPI_MACHINE waits until another write to the CMD bit field is performed. If the command written to the CMD bit field is valid, then this increments the value of the WDCNT bit field from 0x0 and starts shifting data in or out again. This is repeated until the WDCNT bit field reaches the frame length (QSPI_SPI_CMD_REG[11:0] FLEN), that is, all words of the frame are shifted or till earlier frame termination occurs. While the SPI_MACHINE is waiting for write to the CMD bit field the corresponding qspi1_cs[n] (n = 0 to 3) remains active and the BUSY flag is set to 0x0. In addition, the bit length for each word can be changed during a frame from 1 to 128 bits using the QSPI_SPI_CMD_REG[25:19] WLEN bit field.

The SPI_MACHINE also provides a mechanism to terminate the frame earlier. This is done by writing an invalid command to the CMD bit field. An invalid command corresponds to the 0x0 and 0x4 (reserved) values of the CMD bit field. Writing one of these values when the the WDCNT bit field is not equal to 0x0 and when the BUSY flag is 0x0 terminates the frame earlier.

The corresponding qspi1_cs[n] (n = 0 to 3) becomes inactive when all words are shifted or when the frame terminates earlier.

18.4.4.1.6 SPI Data Shifter

The SPI data shifter handles the capture and generation of the SPI interface signals. Based on control signals from the SPI_MACHINE and SPI_CNTIF blocks, data is shifted in or out on falling or rising edge of qspi1_sclk clock depending on the SPI clock mode selected. Table 18-278 lists the four defined clock modes of operation for the QSPI.

Table 18-278. SPI Clock Modes Definition

Mode	Settings in the QSPI_SPI_DC_REG Register		Description
	Value of the CKP bits	Value of the CKPH bits	
0	0	0	Data input captured on falling edge of qspi1_sclk clock. Data output generated on falling edge of qspi1_sclk clock
1	0	1	Data input captured on rising edge of qspi1_sclk clock. Data output generated on rising edge of qspi1_sclk clock

Table 18-278. SPI Clock Modes Definition (continued)

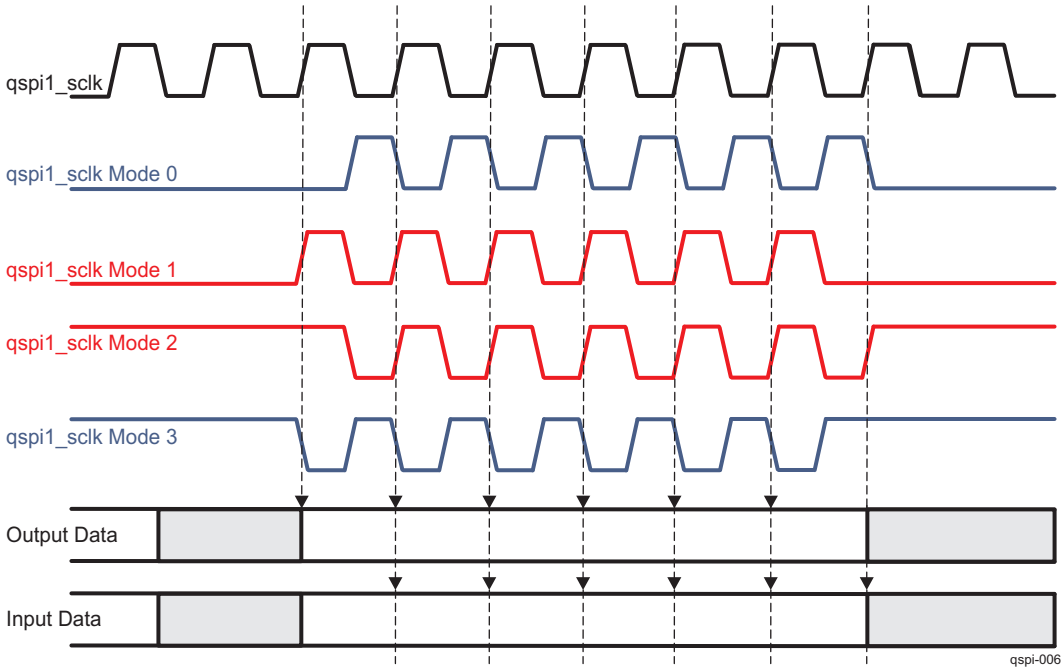
Mode	Settings in the QSPI_SPI_DC_REG Register		Description
	Value of the CKP bits	Value of the CKPH bits	
2	1	0	Data input captured on rising edge of qspi1_sclk clock. Data output generated on rising edge of qspi1_sclk clock
3	1	1	Data input captured on falling edge of qspi1_sclk clock. Data output generated on falling edge of qspi1_sclk clock

NOTE: Mode 1 and Mode 2 are not supported and should not be used.

The CKPi and CKPHi (i = 0 to 3) bits of the QSPI_SPI_DC_REG register control the clock modes. Each of these 4 bits corresponds to an output chip select.

Figure 18-76 shows all four clock modes. In addition, through the DDi (i = 0 to 3) bits of the QSPI_SPI_DC_REG register the data can be delayed from one to three qspi1_sclk clock cycles after the corresponding qspi1_cs[n] (n = 0 to 3) goes active. The active state of each chip-select can also be controlled through the CSPi (i = 0 to 3) bits of the QSPI_SPI_DC_REG register.

Figure 18-76. SPI Clock Modes



18.4.4.2 QSPI Clock Configuration

The QSPI complies with the PRCM slave-idle protocol. The QSPI_FCLK clock is gated based on the values loaded in the QSPI_SYSCONFIG[3:2] IDLE_MODE bit field. Three modes are supported:

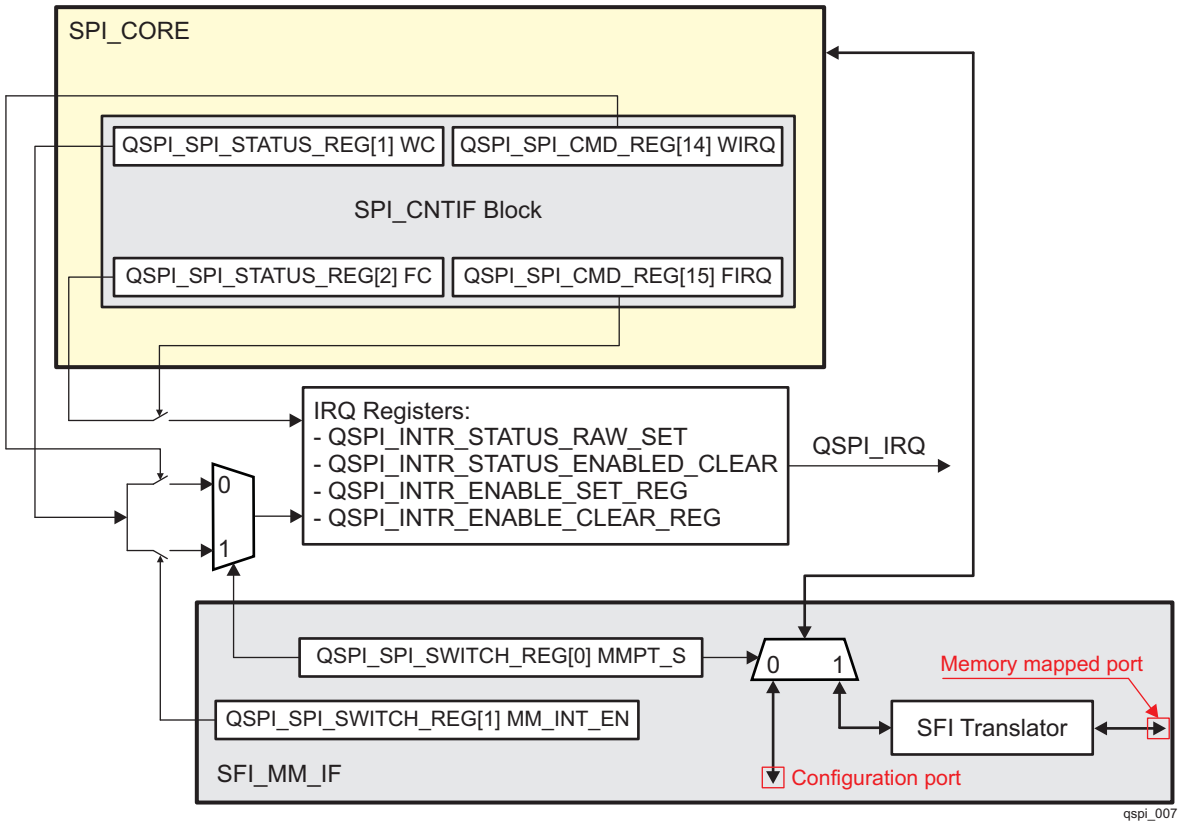
- Force-idle: The QSPI_FCLK clock is gated unconditionally by the QSPI.
- No-idle: The QSPI_FCLK clock is never gated by the QSPI.
- Smart-idle: The QSPI_FCLK clock is gated by the QSPI, depending on its internal requirements.

18.4.4.3 QSPI Interrupt Requests

The QSPI generates one interrupt request which is connected to the IRQ_CROSSBAR module. This interrupt request, QSPI_IRQ, is connected to the IRQ_CROSSBAR_343 input. The QSPI_IRQ interrupt line can be activated by one of the interrupt events listed in Table 18-279.

Figure 18-77 shows a logical representation of the QSPI interrupt generation scheme.

Figure 18-77. Logical Representation of the QSPI Interrupt Generation Scheme



QSPI_SPI_STATUS_REG[1] WC and QSPI_SPI_STATUS_REG[2] FC are status bits indicating whether word or frame transfer is complete. Setting the corresponding interrupt enable bit (WIRQ or FIRQ) in the QSPI_SPI_CMD_REG register allows these events (WC and FC) to generate an interrupt. The WC and FC bits are reset every time the user writes to the QSPI_SPI_CMD_REG register or reads the QSPI_SPI_STATUS_REG register. This is done to keep control parameters from changing the interface protocol signals while a transfer is in progress. Additionally, the QSPI_SPI_SWITCH_REG[1] MM_INT_EN bit is used to enable or disable the word complete interrupt during operations using the memory-mapped port.

When the QSPI_SPI_CMD_REG[14] WIRQ and QSPI_SPI_CMD_REG[15] FIRQ bits are set to 0x1 the following applies:

- The QSPI activates its interrupt line only if the interrupts are enabled by setting to 0x1 the corresponding bits in the QSPI_INTR_ENABLE_SET_REG register. These interrupts can be disabled by setting the corresponding bits in the QSPI_INTR_ENABLE_CLEAR_REG register to 0x1.
- After an interrupt has been serviced, software must clear the corresponding status flag. This is done by setting the corresponding bit in the QSPI_INTR_STATUS_ENABLED_CLEAR register to 0x1, which also clears the corresponding bit in the QSPI_INTR_STATUS_RAW_SET register. The status flags in the QSPI_INTR_STATUS_RAW_SET register are set even if the corresponding interrupt is disabled unlike those in the QSPI_INTR_STATUS_ENABLED_CLEAR register, which are set only if the corresponding interrupt is enabled.
- The QSPI also generates an interrupt if a certain bit in the QSPI_INTR_STATUS_RAW_SET register is set to 0x1 and the corresponding interrupt is enabled through the QSPI_INTR_ENABLE_SET_REG register. This feature is useful during user software debugging. In addition, even if interrupts are not enabled a corresponding raw flag in the QSPI_INTR_STATUS_RAW_SET register is set to 0x1 when an IRQ condition occurs.
- Even if interrupts are not enabled, a certain status bit in the QSPI_INTR_STATUS_RAW_SET register can also be cleared by setting to 0x1 the corresponding bit in the

QSPI_INTR_STATUS_ENABLED_CLEAR register.

It must be considered that the previously described scenario applies if the QSPI_SPI_CMD_REG[14] WIRQ and QSPI_SPI_CMD_REG[15] FIRQ bits are set to 0x1.

NOTE: The QSPI_IRQ interrupt line is activated only if at least one of the following conditions is met:

- The word complete interrupt is enabled:
  - during operations using the memory-mapped port by setting to 0x1 both the QSPI_SPI_SWITCH_REG[1] MM_INT_EN and QSPI_INTR_ENABLE_SET_REG[1] WIRQ_ENA_SET bits.
  - during operations using the configuration port by setting to 0x1 both the QSPI_SPI_CMD_REG[14] WIRQ and QSPI_INTR_ENABLE_SET_REG[1] WIRQ_ENA_SET bits.
- The frame complete interrupt is enabled setting to 0x1 both the QSPI_SPI_CMD_REG[15] FIRQ and QSPI_INTR_ENABLE_SET_REG[0] FIRQ_ENA_SET bits.

The QSPI_IRQ interrupt line is also activated when both the conditions are met.

Table 18-279 lists the event flags and the corresponding mask bits of the sources which can cause interrupts.

Table 18-279. QSPI Events

Event Flag	Event Mask	Description
QSPI_INTR_STATUS_RAW_SET[1] WIRQ_RAW QSPI_INTR_STATUS_ENABLED_CLEAR[1] WIRQ_ENA QSPI_SPI_STATUS_REG[1] WC	QSPI_INTR_ENABLE_SET_REG[1] WIRQ_ENA_SET QSPI_INTR_ENABLE_CLEAR_REG[1] WIRQ_ENA_CLR QSPI_SPI_CMD_REG[14] WIRQ	Word complete interrupt event. Asserted each time after a word is transferred or received.
QSPI_INTR_STATUS_RAW_SET[0] FIRQ_RAW QSPI_INTR_STATUS_ENABLED_CLEAR[0] FIRQ_ENA QSPI_SPI_STATUS_REG[2] FC	QSPI_INTR_ENABLE_SET_REG[0] FIRQ_ENA_SET QSPI_INTR_ENABLE_CLEAR_REG[0] FIRQ_ENA_CLR QSPI_SPI_CMD_REG[15] FIRQ	Frame complete interrupt event. Asserted each time after a frame is transferred or received.

18.4.4.4 QSPI Memory Regions

Two memory regions are associated with the QSPI. The first memory region is dedicated to the configuration port. Using this memory region, all internal registers can be programmed and serial transfers made from the four supported external SPI devices. The L3_MAIN start address at which the configuration port is available is 0x4B30 0000. The second memory region is associated mainly with the memory-mapped port and is used for communication directly with one of the four supported external SPI devices. This memory region starts at 0x5C00 0000 and ends at 0x5FFF FFFF L3_MAIN address.

The CTRL_CORE_CONTROL_IO_2[10:8] QSPI_MEMMAPPED_CS bit field provides a functionality for remapping the previously described address space which starts at 0x5C00 0000 L3_MAIN address to one of the four supported chip selects or to the configuration registers. The CTRL_CORE_CONTROL_IO_2 register resides in the CTRL_MODULE_CORE.

It is important to keep in mind that the configuration port provides an access to all the QSPI registers listed in Table 18-281. These are configuration registers and also four data registers. The configuration registers are used to configure typical SPI and serial flash memory settings and the four data registers are used for read and write operations. When communicating with an external SPI device (but not an SPI flash memory) the SPI_CORE module should be used and the data exchanged is available thorough these four data registers, which can be accessed only through the configuration port. When a communication with an external SPI flash memory is desired, the memory-mapped port should be used.

In other words, to read from an external SPI flash memory, first configure the QSPI through the configuration port and then perform a read through the memory-mapped port.

18.5 Multichannel Audio Serial Port

This section describes the multichannel audio serial port (McASP).

18.5.1 McASP Overview

This section introduces the multichannel audio serial port (McASP) module and describes its main functions and connections in the device.

The McASP functions as a general-purpose audio serial port optimized to the requirements of various audio applications. The McASP module can operate in both transmit and receive modes. The McASP is useful for time-division multiplexed (TDM) stream, Inter-IC Sound (I2S) protocols reception and transmission as well as for an intercomponent digital audio interface transmission (DIT). The McASP has the flexibility to gluelessly connect to a Sony/Philips digital interface (S/PDIF) transmit physical layer component.

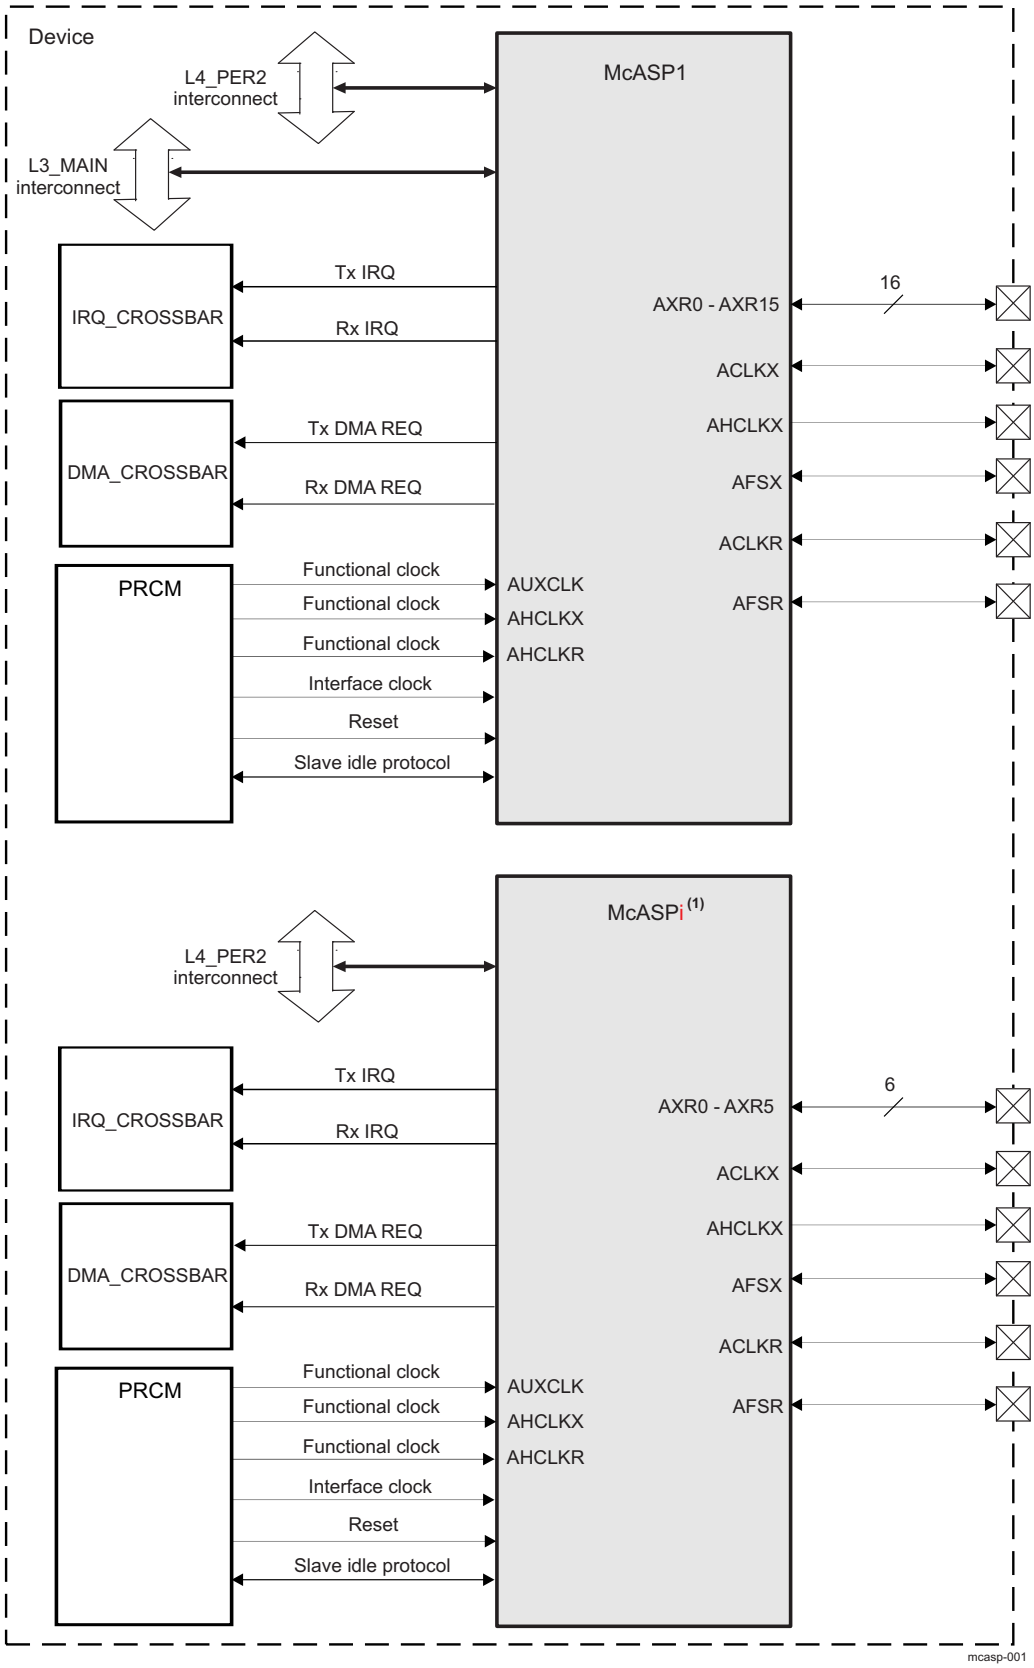
Although intercomponent digital audio interface reception (DIR) mode (i.e. S/PDIF stream receiving) is not natively supported by the McASP module, a specific TDM mode implementation for the McASP receivers allows an easy connection to external DIR components (for example, S/PDIF to I2S format converters).

The device have integrated three McASP modules with:

- McASP1 supporting up to 16 channels with independent TX/RX clock/sync domain
- McASP2 and McASP3 support up to 6 channels with independent TX/RX clock/sync domain.

Figure 18-78 shows the McASP modules in the device.

Figure 18-78. McASP Modules Overview



(1) i = 2 and 3

McASP module includes the following main features:

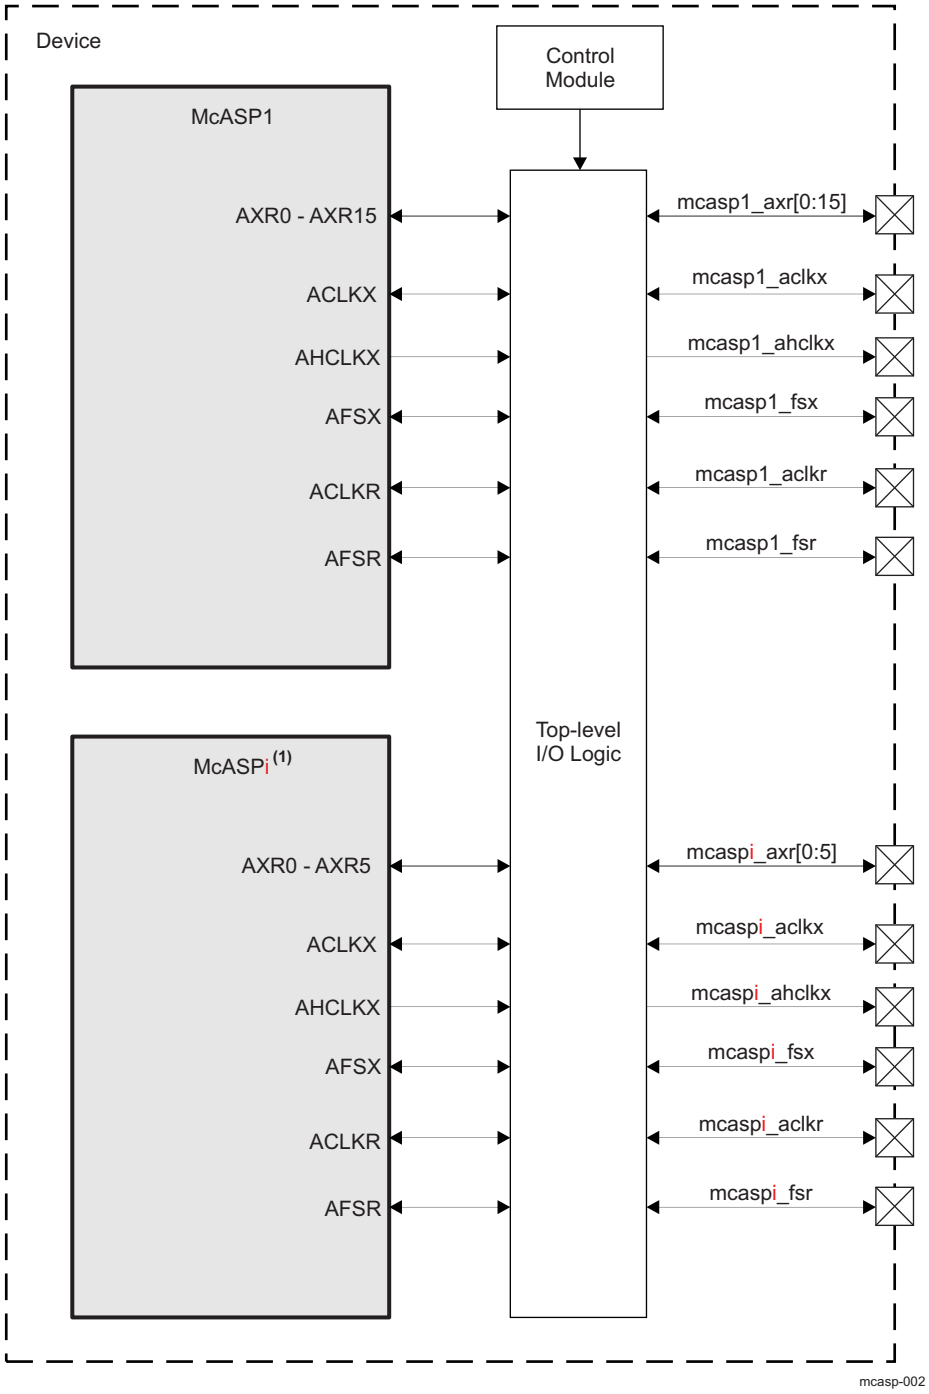
- McASP1 supports up to 16 channels and independent TX/RX clock/sync domains.
- Two modules (McASP2 and McASP3) supporting up to 6 channels each and independent TX/RX clock/sync domains.
- Independent serializer for each AXRx channel of each McASPx module.
- Idle request/acknowledge protocol
- A single 32-bit buffer per serializer for transmit and receive operations
- 2 x interconnect slave interface ports:
  - A configuration (CFG) port supplied with an internal L4-interconnect interface clock
  - A slave DMA data port synchronized with functional clock
- Two independent clock generator modules for transmit and receive.
  - Clocking flexibility allows the McASP to receive and transmit at different rates. For example, the McASP can receive data at 48 kHz but output up-sampled data at 96 kHz or 192 kHz.
- McASP module functional clock can be generated:
  - internally (master mode)
  - supplied over McASP serial interface (slave mode)
  - has a controllable functional clock divide ratio
- Independent transmit and receive modules, each includes:
  - Programmable clock and frame sync generator.
  - TDM streams from 2 to 32, and 384 time slots.
  - Support for time slot sizes of 8, 12, 16, 20, 24, 28, and 32 bits.
  - Data formatter for bit manipulation.
- Glueless connection to audio analog-to-digital converters (ADC), digital-to-analog converters (DAC), codec, digital audio interface receiver (DIR), and S/PDIF transmit physical layer components.
- Wide variety of I2S and similar bit-stream format.
- Integrated digital audio interface transmitter (DIT):
  - S/PDIF, IEC60958-1, AES-3 formats.
  - Enhanced channel status/user data RAM.
- 384-slot TDM with external digital audio interface receiver (DIR) device.
  - For DIR reception, an external DIR receiver integrated circuit should be used with I2S output format and connected to the McASP receive section.
- Support for 2x DMA requests (one per direction):
  - 1 level-sensitive transmit direct memory access (DMA) request common for all of the McASP serializers
  - 1 level-sensitive receive direct memory access (DMA) request common for all of the McASP serializers
  - All transmit DMA requests are mapped to the device DMA crossbar
- One transmit interrupt request common for all serializers
- One receive interrupt request common for all serializers
- Each of the Rx and Tx interrupts is propagated to different host processors via the device Interrupt Crossbar

NOTE: Because a serializer receive and transmit channels data is shared on the same McASP data pin, user can choose to have either Tx or Rx function from a serializer, not both at the same time.

18.5.2 McASP Environment

This section describes the McASP application fields from an environment point of view (external connections), along with the McASP connectivity options. This section also lists all of the possible interfaces and describes the protocol and data format used in each case. Figure 18-79 shows the McASP modules in their environment in the device.

Figure 18-79. McASP Environment



(1) i = 2 and 3

18.5.2.1 McASP Signals

Table 18-322 describes the McASP pins, their corresponding signal names at device level and specifies their links to functions.

Table 18-322. McASP I/O Signals

Module Pin Name	Device Level Signal Name	I/O[1]	Description	Module Pin Reset Value
		McASP1 module		
AXR0	mcasp1_axr[0]	I/O	Audio transmit/receive data - channel 0	HiZ
AXR1	mcasp1_axr[1]	I/O	Audio transmit/receive data - channel 1	HiZ
AXR2	mcasp1_axr[2]	I/O	Audio transmit/receive data - channel 2	HiZ
AXR3	mcasp1_axr[3]	I/O	Audio transmit/receive data - channel 3	HiZ
AXR4	mcasp1_axr[4]	I/O	Audio transmit/receive data - channel 4	HiZ
AXR5	mcasp1_axr[5]	I/O	Audio transmit/receive data - channel 5	HiZ
AXR6	mcasp1_axr[6]	I/O	Audio transmit/receive data - channel 6	HiZ
AXR7	mcasp1_axr[7]	I/O	Audio transmit/receive data - channel 7	HiZ
AXR8	mcasp1_axr[8]	I/O	Audio transmit/receive data - channel 8	HiZ
AXR9	mcasp1_axr[9]	I/O	Audio transmit/receive data - channel 9	HiZ
AXR10	mcasp1_axr[10]	I/O	Audio transmit/receive data - channel 10	HiZ
AXR11	mcasp1_axr[11]	I/O	Audio transmit/receive data - channel 11	HiZ
AXR12	mcasp1_axr[12]	I/O	Audio transmit/receive data - channel 12	HiZ
AXR13	mcasp1_axr[13]	I/O	Audio transmit/receive data - channel 13	HiZ
AXR14	mcasp1_axr[14]	I/O	Audio transmit/receive data - channel 14	HiZ
AXR15	mcasp1_axr[15]	I/O	Audio transmit/receive data - channel 15	HiZ
ACLKX	mcasp1_aclkx	I/O	Transmit bit clock	HiZ
AHCLKX	mcasp1_ahclkx	O	Transmit high-frequency master clock	HiZ
AFSX	mcasp1_fsx	I/O	Transmit frame synchronization	HiZ
ACLKR	mcasp1_aclkr	I/O	Receive bit clock	HiZ
AFSR	mcasp1_fsr	I/O	Receive frame synchronization	HiZ
		McASP2 module		
AXR0	mcasp2_axr[0]	I/O	Audio transmit/receive data - channel 0	HiZ
AXR1	mcasp2_axr[1]	I/O	Audio transmit/receive data - channel 1	HiZ
AXR2	mcasp2_axr[2]	I/O	Audio transmit/receive data - channel 2	HiZ
AXR3	mcasp2_axr[3]	I/O	Audio transmit/receive data - channel 3	HiZ
AXR4	mcasp2_axr[4]	I/O	Audio transmit/receive data - channel 4	HiZ
AXR5	mcasp2_axr[5]	I/O	Audio transmit/receive data - channel 5	HiZ
ACLKX	mcasp2_aclkx	I/O	Transmit bit clock	HiZ
AHCLKX	mcasp2_ahclkx	O	Transmit high-frequency master clock	HiZ
AFSX	mcasp2_fsx	I/O	Transmit frame synchronization	HiZ

AFSR	mcasp2_fsr	I/O	Receive frame synchronization	HiZ
		McASP3 module		
AXR0	mcasp3_axr[0]	I/O	Audio transmit/receive data - channel 0	HiZ
AXR1	mcasp3_axr[1]	I/O	Audio transmit/receive data - channel 1	HiZ
AXR2	mcasp3_axr[2]	I/O	Audio transmit/receive data - channel 2	HiZ
AXR3	mcasp3_axr[3]	I/O	Audio transmit/receive data - channel 3	HiZ
AXR4	mcasp3_axr[4]	I/O	Audio transmit/receive data - channel 4	HiZ
AXR5	mcasp3_axr[5]	I/O	Audio transmit/receive data - channel 5	HiZ
ACLKX	mcasp3_aclkx	I/O	Transmit bit clock	HiZ

(1) I = Input; O = Output; I/O = Bidirectional

Table 18-322. McASP I/O Signals (continued)

Module Pin Name	Device Level Signal Name	I/O[1]	Description	Module Pin Reset Value
AHCLKX	mcasp3_ahclkx	O	Transmit high-frequency master clock	HiZ
AFSX	mcasp3_fsx	I/O	Transmit frame synchronization	HiZ
ACLKR	mcasp3_aclkr	I/O	Receive bit clock	HiZ
AFSR	mcasp3_fsr	I/O	Receive frame synchronization	HiZ

NOTE: For the mcaspx_aclkx, mcaspx_ahclkx and mcaspx_aclkr signals to work properly, the INPUTENABLE bit of the appropriate CTRL_CORE_PAD_x registers should be set to 0x1 because of retiming purposes.

NOTE: The path from module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. For more information, refer to the Section 13.4.6.1, *Pad Configuration Registers*, and Section 13.5, *Control Module Register Manual*, in Chapter 13, *Control Module*.

NOTE: Except the pad configuration registers, additional Control Module registers have to be configured to map McASP2 and McASP3 signals to the device pads. The MUXMODE field of the corresponding pad configuration register has to be set to 0xF and the corresponding bit in CTRL_CORE_SMA_SW_14 and CTRL_CORE_SMA_SW_15 has to be set to 0x1.

NOTE: A serializer AXR data pin is shared between the transmit and receive logic of that serializer. The direction of data is determined in the MCASP_PDIR and the function (Tx or Rx) is selected in the corresponding serializer control register MCASP_XRSRCTLn.

18.5.2.2 Protocols and Data Formats

18.5.2.2.1 Protocols Supported

The McASP supports a wide variety of protocols:

- Transmit section supports:
  - Wide variety of I2S and similar bit-stream formats.
  - TDM streams from 2 to 32 time slots.
  - S/PDIF, IEC60958-1, AES-3 formats.
- Receive section supports:
  - Wide variety of I2S and similar bit-stream formats.
  - TDM streams from 2 to 32 time slots.
  - TDM stream of 384 time slots specifically designed for easy interface to external digital interface receiver (DIR) device transmitting DIR frames to McASP using the I2S protocol (one time slot for each DIR subframe).

The transmit and receive sections of the module may be individually programmed to support the following options on the basic serial protocol:

- Programmable clock and frame sync polarity (rising or falling edge): ACLKR/X, AHCLKR/X, and AFSR/X.
- Slot length (number of bits per time slot): 8, 12, 16, 20, 24, 28, 32 bits supported.
- Word length (bits per word): 8, 12, 16, 20, 24, 28, 32 bits; always less than or equal to the time slot

length.

- First-bit data delay: 0, 1, 2 bit clocks.
- Left/right alignment of word inside slot.
- Bit order: MSB first or LSB first.
- Bit mask/pad/rotate function.
  - Automatically aligns data internally in either Q31 or integer formats.
  - Automatically masks nonsignificant bits (sets to 0, 1, or extends value of another bit).

NOTE: In I2S mode, the transmit and receive sections can support simultaneous transfers on up to all serial data pins operating as 192 kHz stereo channels.

In DIT mode for McASP, additional features of the transmitters are:

- Transmit-only mode 384 time slots (subframe) per frame.
- Biphase encoded LVCMOS output
- Channel status RAM (384 bits).
- User data RAM (384 bits).
- Separate valid bit (V) for subframe A, B.
- Stereo Support Only (Mono means send data 2x via software)

In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to all serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for I2S mode, due to the need to generate Biphase Mark Encoded Data).

NOTE: The McASP does NOT natively support DIR-mode reception (i.e. receiving in the S/PDIF format). To allow this, the McASP can use a DIR-input to I2S-output converter implemented by an external device (i.e. external DIR component). To facilitate reception in this case, the TDM mode of McASP receivers logic is extended to support a non-standard 384-slot TDM stream.

NOTE: An external transceiver must be connected to the McASP port in the device to translate the electrical signals delivered by the McASP (1.2 V or 1.8 V LVCMOS levels) to the electrical levels of the S/PDIF standard.

18.5.2.2.2 Definition of Terms

The serial bitstream transmitted or received by a McASP serializer is a long sequence of 1s and 0s on an audio transmit/receive pins AXRn. However, the sequence has a hierarchical organization that can be described in terms of frames of data, slots, words, and bits.

A basic synchronous serial interface consists of three important components: clock, frame sync, and data. Figure 18-80 shows two of the three basic components: the clock signal (ACLKX/ACLKR) and the data signals AXRn. Figure 18-80 does not specify whether the clock is for transmit (ACLKX) or receive (ACLKR) because the definitions of terms apply to both receive and transmit interfaces. In operation, each transmitter and receiver uses the signals ACLKX and ACLKR as serial clock, respectively. Optionally, a receiver can use ACLKX as the serial clock when a transmitter and receiver (not from the same serializer) of the McASP are configured to operate synchronously.

- Bit:

  A bit is the smallest entity in the serial data stream. The beginning and end of each bit is marked by an edge of the serial clock. The duration of a bit is a serial clock period. A '1' is represented by a logic high on AXRn pins for the entire duration of the bit. A 0 is represented by a logic low on an AXRn pin for the entire duration of the bit.

- Word:

  A word is a group of bits that make up the data being transferred between the McASP and the external

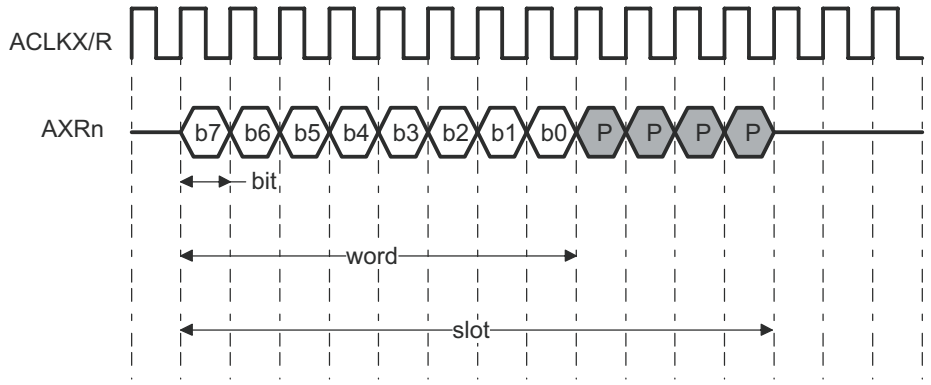
device. Figure 18-80 shows an 8-bit word.

- Slot:

  A slot consists of the bits that make up the word and can consist of additional bits used to pad the word to a convenient number of bits for the interface between the McASP and the external device. In Figure 18-80, the audio data consists of only 8 bits of useful data (8-bit word), but it is padded with four 0s (12-bit slot) to satisfy the desired protocol in interfacing to an external device. Within a slot, the bits can be shifted out of the McASP on an AXRn pin with either MSB or LSB first.

  When the word size is smaller than the slot size, the word can be aligned to the left of the slot (beginning) or to the right of the slot (end). The additional bits in the slot not belonging to the word can be padded with 0, 1, or with one of the bits (typically, the MSB or LSB) from the data word, i.e. left-aligned words within a slot are terminated with padding bits and right-aligned words within a slot are preceded by padding bits to fit in the slot size. Figure 18-81 shows these options.

Figure 18-80. Definition of Bit, Word, and Slot



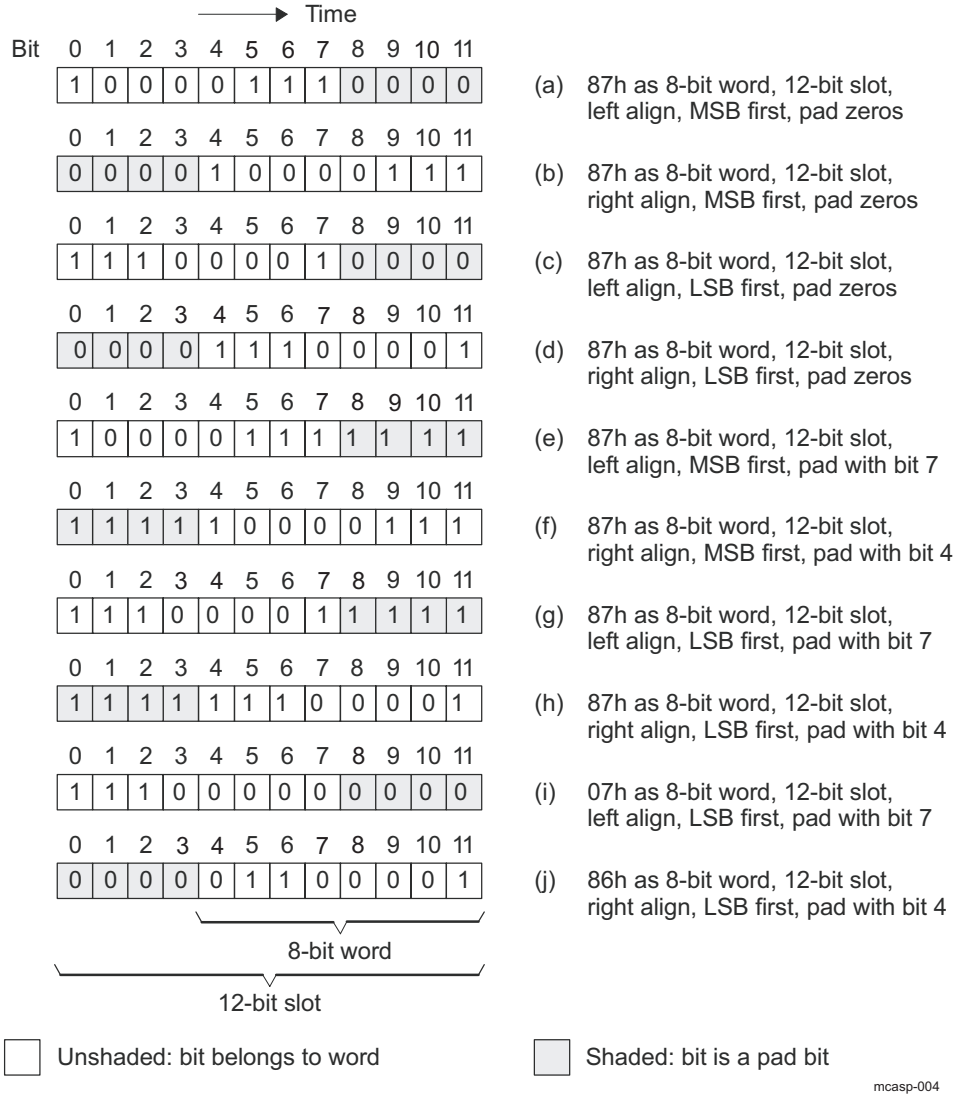
(1) b7:b0 - bits. Bits b7 to b0 form a word.

(2) P - pad bits. Bits b7 to b0, together with the 4 pad bits, form a slot.

(3) In this example, the data is transmitted MSB first, left-aligned.

mcasp-003

Figure 18-81. Bit Order and Word Alignment Within a Slot Examples



- Frame

  The third basic element of a synchronous serial interface is the frame synchronization signal, also referred to as frame sync in this chapter. A frame contains one or multiple slots, as determined by the desired protocol. Figure 18-82 shows an example frame of data and the frame definitions. In operation, the transmitter uses AFSX, and the receiver - AFSR signal. Figure 18-82 does NOT specify whether the frame sync (FS) is for transmit (AFSX) or receive (AFSR) because the definitions of terms apply to both receive and transmit interfaces. In operation, each transmitter/receiver uses AFSX/AFSR as a frame synchronization signal, respectively. Optionally, the receiver can use AFSX as the frame sync when the transmitter and receiver of the McASP are configured to operate synchronously. This example shows two slots in a frame (I2S format) and a frame-sync (FS) duration of a slot length.

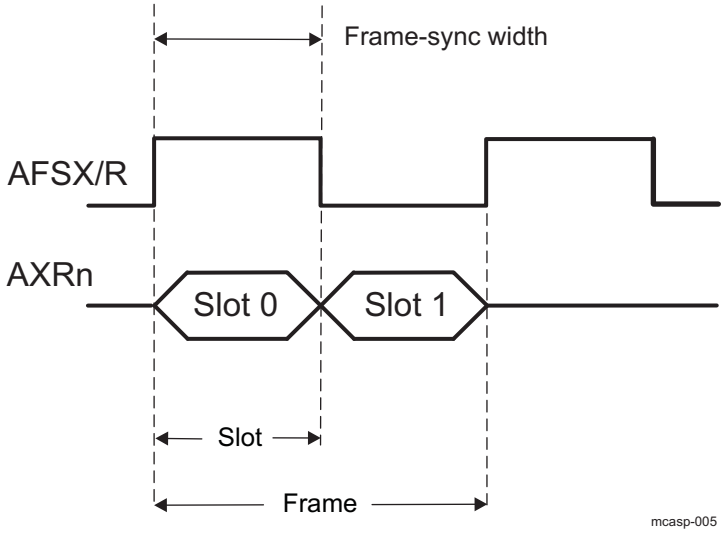
  This section shows only the generic definition of the frame sync. For more information about the frame-sync formats required for the transfer modes and protocols (TDM-mode and DIT-mode supported formats), see Section 18.5.2.2.3, *TDM Format* and Section 18.5.2.2.5, *S/PDIF-Coding Format*.

NOTE: All of the McASP serializers share the same, device pad accessible, clock and frame signals, as follows:

– AHCLKX, ACLKX, and AFSX for the transmitting section

– ACLKR and AFSR for the receiving section

Figure 18-82. Definition of Frame and Frame-Sync Width



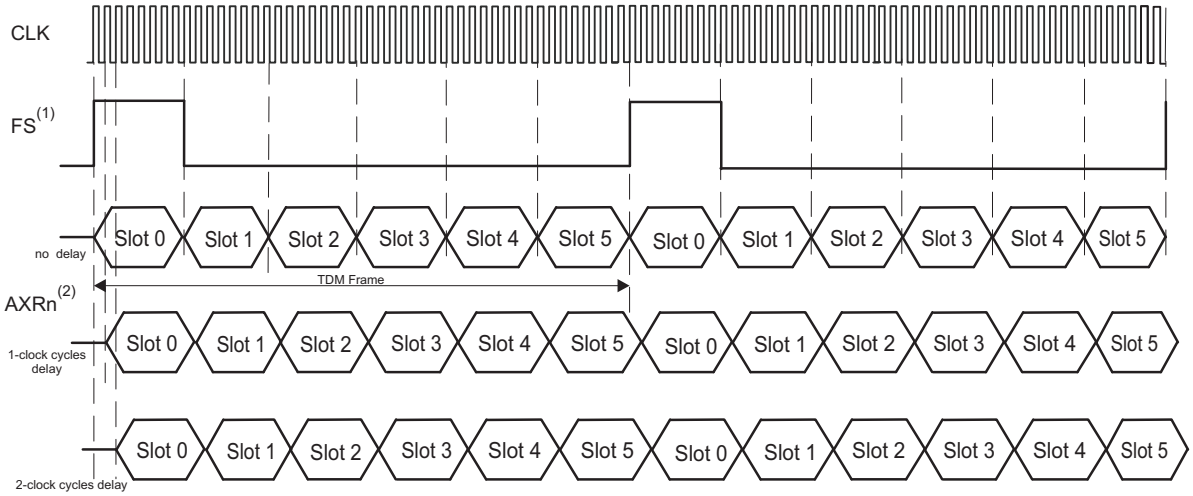
The following terms are used throughout this chapter:

- TDM: Time-division multiplexed. See Section 18.5.2.2.3 for details on the TDM protocol
- I2S: Inter-Integrated Sound protocol, commonly used on audio interfaces. The McASP supports the I2S protocol as part of the TDM mode (when configured as a 2-slot frame).
- DIT: Digital audio interface transmit. The McASP supports transmitting in S/PDIF format on each AXRn data pin.
- DIR: Digital audio interface receive. The McASP does NOT natively support receiving in S/PDIF format on AXRn data pins and requires an external DIR-to-TDM or DIR-to-I2S converter chip for a DIR-frame reception.
- Slot or time slot: For DIT/DIR format, a McASP time slot corresponds to a DIT/DIR subframe.

18.5.2.2.3 TDM Format

The TDM format is used to transfer data between the host CPU and one or more analog-to-digital converter (ADC), digital-to-analog converter (DAC), or S/PDIF receiver (DIR) devices. An example for a 6-slot (channel) TDM transmission on one McASP data pin - AXRn is illustrated on Figure 18-83.

Figure 18-83. TDM Format - 6 channel example



(1) - Frame sync duration of 1 slot - length is shown. A single bit - duration of FS is also supported

(2) - Slot 0 of AXRn stream is being offset with 0-, 1-, and 2- clock cycle delay from the frame sync, respectively.

mcasp-006

The TDM format uses three signals In a basic synchronous serial interface: data (AXRn), clock (CLK) and frame sync (FS). The data signal present on AXRn pin is fully synchronous to the serial clock (ACLKX or ACLKR). The data bits are grouped into words and slots (see also Section 18.5.2.2.2), the latter being also refered to as the "time-slots" or "channels" in TDM terminology. A frame consists of multiple time-slots. Each TDM frame is marked by the frame sync signal (AFSX or AFSR). The TDM transfer is continuous and periodic, with no delays between slots.

Within a certain frame, the last bit of slot N is followed immediately on the next serial clock with the first bit of the next slot N+1. On the boundary between two adjacent TDM-frames, the last bit of the last slot from the frame M, is followed immediately on the next clock cycle with the first bit of the first slot from the next frame M+1. For McASP, there is an option to offset the first bit of the first slot with a 0-,1- or 2-cycle delay from the frame sync signal.

The frame sync - AFSX/AFSR only marks the beginning of slot 0 and start of a new frame. Since it does not determine the boundaries of a slot, there is a requirement for a connected transmitter and receiver to agree on the number of transferred bits per slot.

In a typical audio system involving McASP module, a single TDM data frame is transferred during each sample period Ts of a data converter. The user has following choices to implement multiple channels:

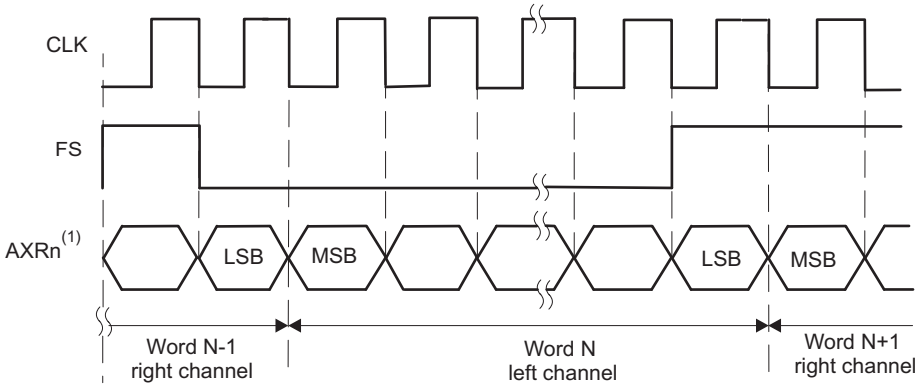
- Use more data slots (on a price of higher speed serial clock) per frame transmitted/received on just one of the available McASP data pins AXRn.
- Use less number of slots per TDM frame (requires a slower serial clock), making them available on several of the McASP pins AXRn.

18.5.2.2.4 I2S Format

The TDM transfer mode of the McASP supports the I2S format when frame is configured to have 2 slots. I2S format is specifically designed to transfer a stereo channel (left and right) over a single data pin AXRn. "Slots" are also commonly referred to as "channels". The frame width duration in the I2S format equals size of a slot. The frame signal is also referred to as "word select" in the I2S format.

The I2S protocol is illustrated on Figure 18-84.

Figure 18-84. I2S Format Overview



(1) - The example shows I2S data MSB-first transmission with 1-clock cycle delay between FS and data MSB

mcasp-036

18.5.2.2.5 S/PDIF Coding Format

The McASP transmitter supports the S/PDIF format with 3.3V biphase-mark encoded output. The S/PDIF format is supported by the DIT- transfer mode of the McASP. This section briefly discusses the S/PDIF coding format.

NOTE: The DIR- reception of S/PDIF format frames is NOT natively supported from the device McASP. For this purpose, an external DIR-to-TDM transfer mode adapter can be used between the remote device S/PDIF transmitter output and the McASP TDM-only compatible receiver input.

18.5.2.2.5.1 Biphase-Mark Code

In S/PDIF format, the digital signal is coded using the biphase-mark code (BMC). For each serializer transmitter n, the clock, frame, and data are embedded in only one signal - the data signal AXRn. In the BMC system, each data bit is encoded into two logical states (00, 01, 10, or 11) at the pin. These two logical states form a cell. The duration of the cell, which equals the duration of the data bit, is called a time interval. A logical 1 is represented by two transitions of the signal within a time interval, which corresponds to a cell with logical states 01 or 10. A logical 0 is represented by one transition within a time interval, which corresponds to a cell with logical states 00 or 11. In addition, the logical level at the start of a cell is inverted from the level at the end of the previous cell. Figure 18-85 and Table 18-323 show how data is encoded to the BMC format.

As shown in Figure 18-85, the clock frequency is twice the unencoded data bit rate. In addition, the clock is always programmed to 128 × f_s, where f_s is the sample rate (see Section 18.5.2.2.5.3, *Frame Format*, for details on how this clock rate is derived based on the S/PDIF format). The device receiving in S/PDIF format can recover the clock and frame information from the BMC signal.

Figure 18-85. Biphase-Mark Code

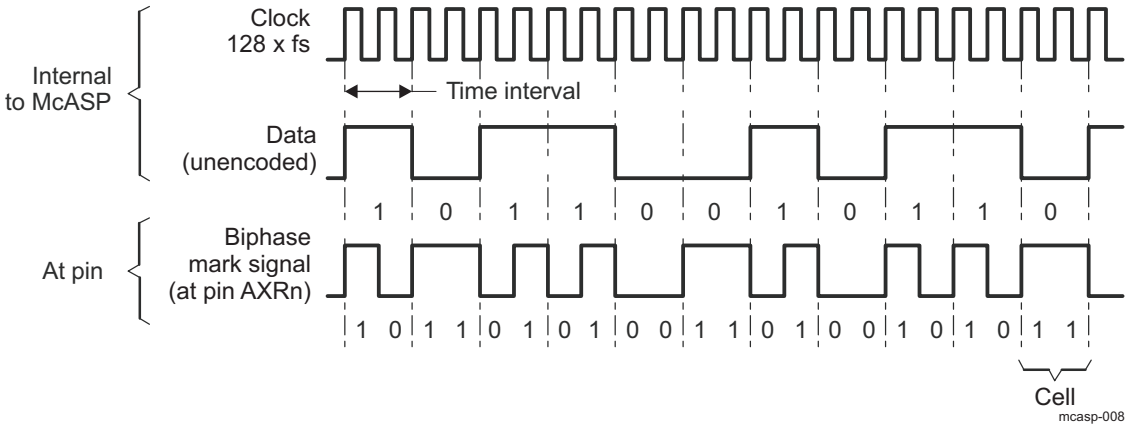


Table 18-323. Biphase-Mark Encoder

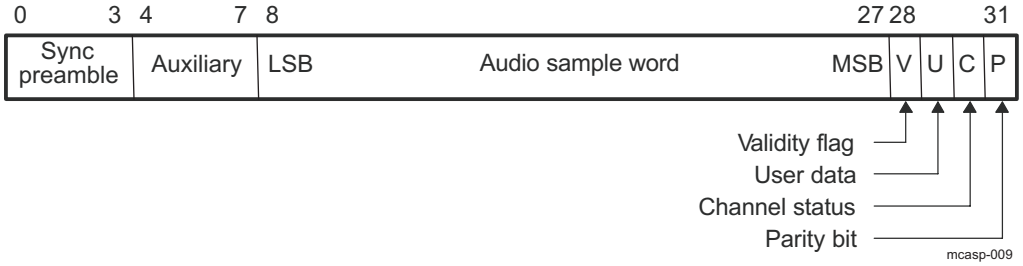
Data (Unencoded)	Previous State at Pin AXRn	BMC-Encoded Cell Output at Pin AXRn
0	0	11
0	1	00
1	0	10
1	1	01

18.5.2.2.5.2 S/PDIF Subframe Format

Every audio sample transmitted in a subframe consists of 32 S/PDIF time intervals (or cells), numbered 0 to 31. Figure 18-86 shows a subframe.

- Time intervals 0–3 carry one of the three permitted preambles to signify the type of audio sample in the current subframe. The preamble is not encoded in BMC format, and therefore the preamble code can contain more than two consecutive 0 or 1 logical states in a row. See Table 18-324.
- Time intervals 4–27 carry the audio sample word in linear 2s-complement representation. The MSB is carried by time interval 27. When a 24-bit coding range is used, the LSB is in time interval 4. When a 20-bit coding range is used, time intervals 8-27 carry the audio sample word with the LSB in time interval 8. Time intervals 4–7 may be used for other applications and are designated auxiliary sample bits.
- If the source provides fewer bits than the interface allows (20 or 24), the unused LSBs are set to logical 0. For a nonlinear PCM audio application or a data application, the main data field can carry any other information.
- Time interval 28 carries the validity bit (V) associated with the main data field in the subframe.
- Time interval 29 carries the user data channel (U) associated with the main data field in the subframe.
- Time interval 30 carries the channel status information (C) associated with the main data field in the subframe. The channel status indicates if the data in the subframe is digital audio or some other type of data.
- Time interval 31 carries a parity bit (P) such that time intervals 4–31 carry an even number of 1s and an even number of 0s (even parity). As listed in Table 18-324, the preambles (time intervals 0–3) are also defined with even parity.

Figure 18-86. S/PDIF Subframe Format



As listed in Table 18-324, the McASP DIT generates only one polarity of preambles, and it assumes the previous logical state is 0. This is because the McASP assures an even-polarity encoding scheme when transmitting in DIT mode. If an underrun condition occurs, the DIT resynchronizes to the correct logic level on the AXRn pin before continuing with the next transmission.

Table 18-324. Preamble Codes

Preamble Code[1]	Previous Logical State	Logical States on pin AXRn[2]	Description
B (or Z)	0	1110 1000	Start of a block and subframe 1
M (or X)	0	1110 0010	Subframe 1
W (or Y)	0	1110 0100	Subframe 2

(1) Historically, preamble codes are referred to as B, M, and W. For use in professional applications, preambles are referred to as Z, X, and Y, respectively.

(2) The preamble is not BMC-encoded. Each logical state is synchronized to the serial clock. These eight logical states make up time slots (cells) 0 to 3 in the S/PDIF stream.

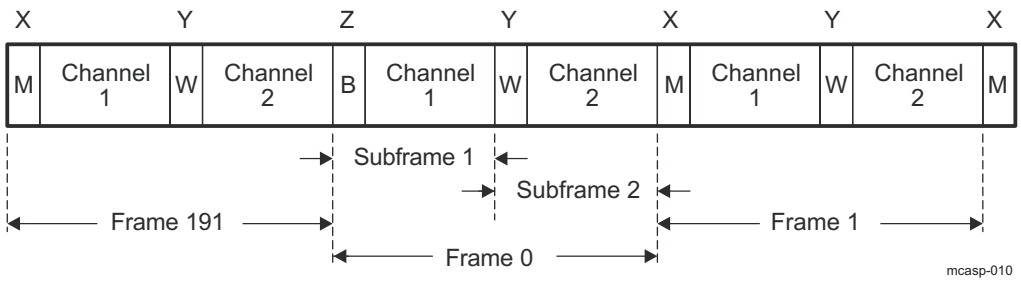
18.5.2.2.5.3 Frame Format

An S/PDIF frame is composed of two subframes (see Figure 18-87). For linear coded audio applications, the rate of frame transmission normally corresponds exactly to the source sampling frequency f_s. The S/PDIF format clock rate is therefore 128 × f_s (128 = 32 cells per subframe × 2 clocks per cell × 2 subframes per sample). For example, for an S/PDIF stream at a 192-kHz sampling frequency, the serial clock is 128 × 192 kHz = 24.58 MHZ.

In 2-channel operation mode, the samples taken from both channels are transmitted by time multiplexing in consecutive subframes. Both subframes contain valid data (cell 28 validity bits for A- and B- channels, both set to '0'). The first subframe (left or A channel in stereophonic operation and primary channel in monophonic operation) normally starts with preamble M. However, the preamble of the first subframe changes to preamble B once every 192 frames to identify the start of the block structure used to organize the channel status information. The second subframe (right or B channel in stereophonic operation and secondary channel in monophonic operation) always starts with preamble W.

In single-channel operation mode in a professional application, the frame format is the same as in the 2-channel mode. Data is carried in the first subframe and may be duplicated in the second subframe. If the second subframe is not carrying duplicate data, cell 28 (validity bit) is set to logical 1.

Figure 18-87. S/PDIF Frame Format



18.5.3 McASP Integration

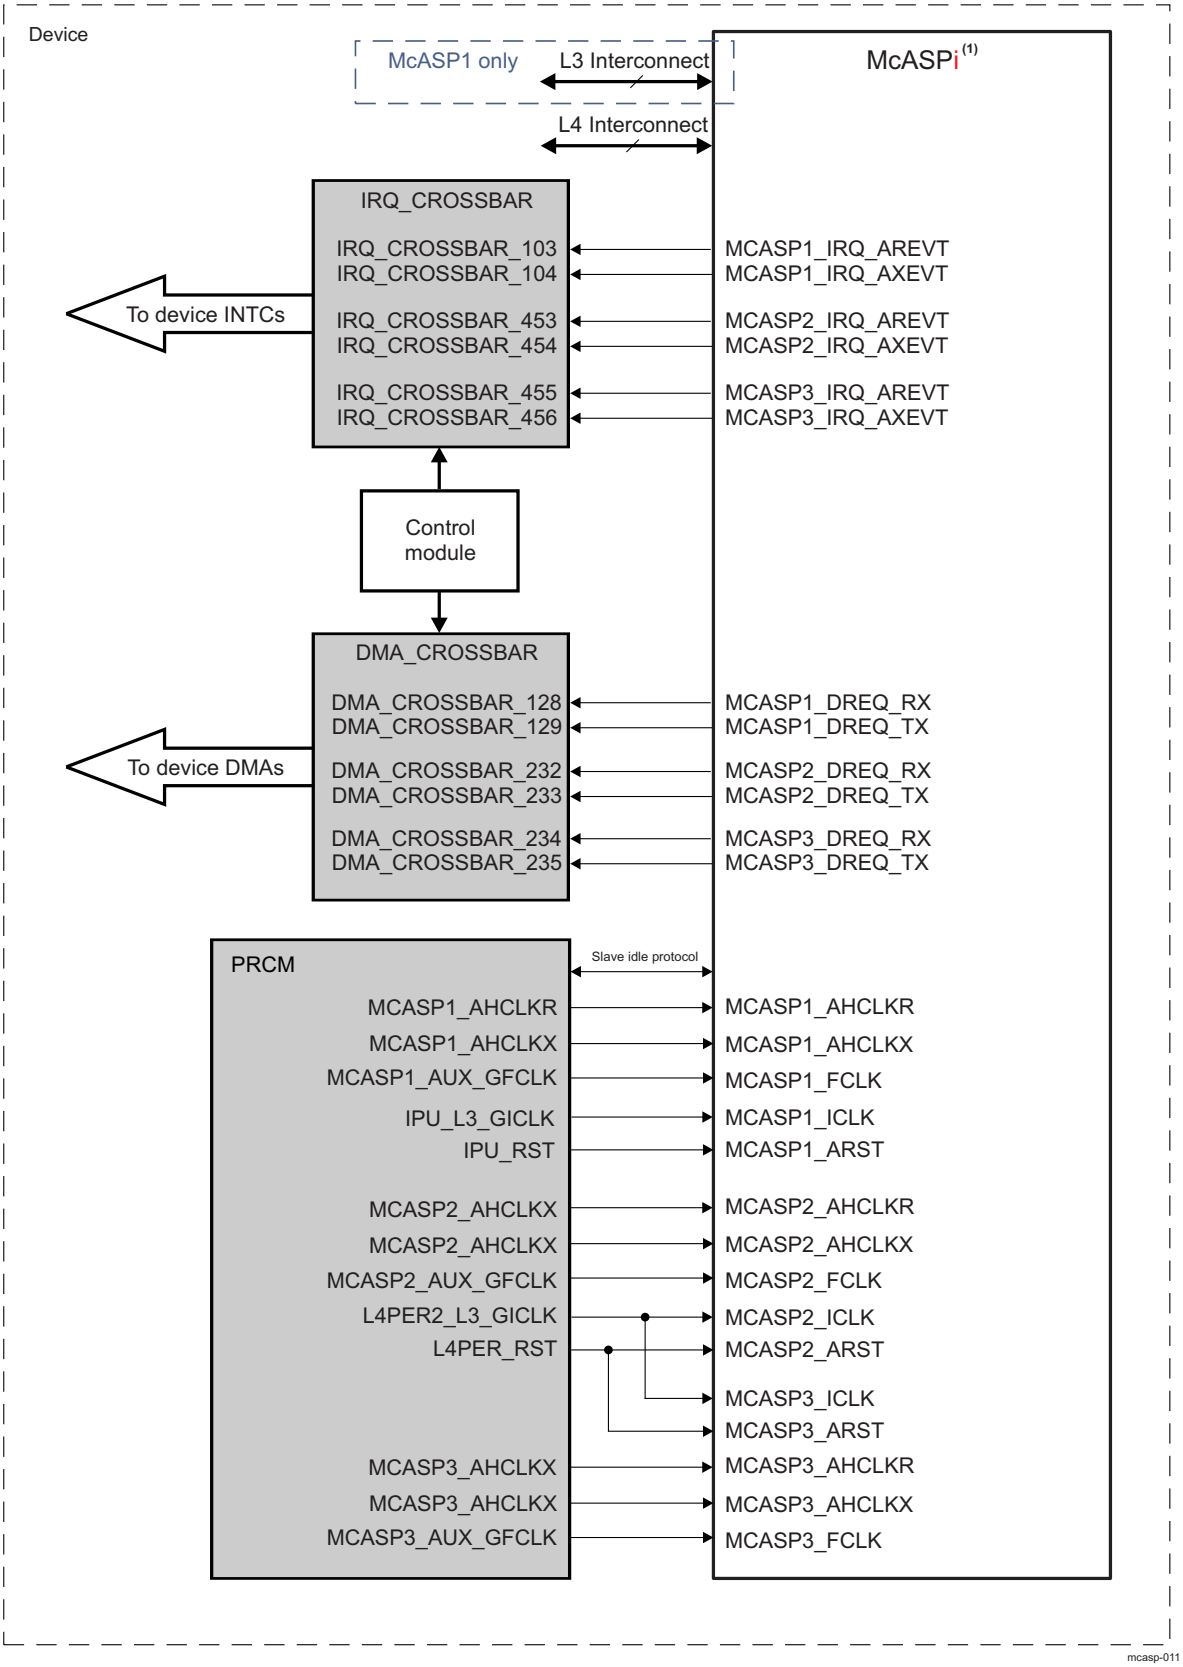
This section describes module integration in the device, including information about clocks, resets, and hardware requests.

McASP module includes the following features:

- Slave idle protocol
- One DMA request for transmit event
- One DMA request for receive event
- One interrupt request (IRQ) for transmit
- One interrupt request (IRQ) for receive

Figure 18-88 shows McASP integration.

Figure 18-88. McASP Integration



(1) i = 1 to 3

NOTE: For more information about the slave idle protocol, see Section 3.1.1.1.2, *Module Level Clock Management* of Chapter 3, *Power, Reset, and Clock Management*.

Table 18-325 through Table 18-327 summarize McASP integration in the device.

Table 18-325. McASP Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
McASP1	PD_COREAON	No	L3_MAIN
			L4_PER2
McASP2	PD_COREAON	No	L4_PER2
McASP3	PD_COREAON	No	L4_PER2

Table 18-326. McASP Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
McASP1	MCASP1_AHCLKR	MCASP1_AHCLKR	PRCM	McASP1 AHCLKR receive high-frequency master clock
	MCASP1_AHCLKX	MCASP1_AHCLKX		McASP1 AHCLKX transmit high-frequency master clock
	MCASP1_FCLK	MCASP1_AUX_GFCLK		McASP1 functional clock
	MCASP1_ICLK	IPU_L3_GICLK		McASP1 interface clock
McASP2	MCASP2_AHCLKR	MCASP2_AHCLKX	PRCM	McASP2 AHCLKR receive high-frequency master clock
	MCASP2_AHCLKX	MCASP2_AHCLKX		McASP2 AHCLKX transmit high-frequency master clock
	MCASP2_FCLK	MCASP2_AUX_GFCLK		McASP2 functional clock
	MCASP2_ICLK	L4PER2_L3_GICLK		McASP2 interface clock
MCASP3	MCASP3_AHCLKR	MCASP3_AHCLKX	PRCM	McASP3 AHCLKR receive high-frequency master clock
	MCASP3_AHCLKX	MCASP3_AHCLKX		McASP3 AHCLKX transmit high-frequency master clock
	MCASP3_FCLK	MCASP3_AUX_GFCLK		McASP3 functional clock
	MCASP3_ICLK	L4PER2_L3_GICLK		McASP3 interface clock
Resets				
McASP1	MCASP1_ARST	IPU_RST	PRCM	McASP1 reset
McASP2	MCASP2_ARST	L4PER_RST	PRCM	McASP2 reset
McASP3	MCASP3_ARST	L4PER_RST	PRCM	McASP3 reset

Table 18-327. McASP Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination IRQ_CROSSBAR Input	Default Mapping	Description
McASP1	MCASP1_IRQ_AREVT	IRQ_CROSSBAR_103	-	McASP1 module receive interrupt request
	MCASP1_IRQ_AXEVT	IRQ_CROSSBAR_104	-	McASP1 module transmit interrupt request

Table 18-327. McASP Hardware Requests (continued)

McASP2	MCASP2_IRQ_AREVT	IRQ_CROSSBAR_453	-	McASP2 module receive interrupt request
	MCASP2_IRQ_AXEVT	IRQ_CROSSBAR_454	-	McASP2 module transmit interrupt request
McASP3	MCASP3_IRQ_AREVT	IRQ_CROSSBAR_455	-	McASP3 module receive interrupt request
	MCASP3_IRQ_AXEVT	IRQ_CROSSBAR_456	-	McASP3 module transmit interrupt request
DMA Requests				
Module Instance	**Source Signal Name**	**Destination DMA_CROSSBAR Input**	**Default Mapping**	**Description**
McASP1	MCASP_DREQ_RX	DMA_CROSSBAR_128	DMA_DSP1_DREQ_0 DMA_DSP2_DREQ_0	McASP module receive event request
	MCASP_DREQ_TX	DMA_CROSSBAR_129	DMA_DSP1_DREQ_1 DMA_DSP2_DREQ_1	McASP module transmit event request
McASP2	MCASP2_DREQ_RX	DMA_CROSSBAR_232	-	McASP2 module receive event request
	MCASP2_DREQ_TX	DMA_CROSSBAR_233	-	McASP2 module transmit event request
McASP3	MCASP3_DREQ_RX	DMA_CROSSBAR_234	-	McASP3 module receive event request
	MCASP3_DREQ_TX	DMA_CROSSBAR_235	-	McASP3 module transmit event request

NOTE: The **Default Mapping** column in Table 18-327 *McASP Hardware Requests* shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.
For more information about the IRQ_CROSSBAR module, see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.
For more information about the DMA_CROSSBAR module, see Section 13.4.6.5, *DMA_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.
For more information about the device interrupt controllers, see Chapter 12, *Interrupt Controllers*.
For more information about the device DSP1_EDMA and DSP2_EDMA modules, see Section 4.3.7, *DSP Integrated EDMA Subsystem*.

NOTE:

- For the description of the interrupt source, see Section 18.5.4.12, *McASP Events and Interrupt Requests*.
- For the description of the DMA source, see Section 18.5.4.13, *DMA Requests*.

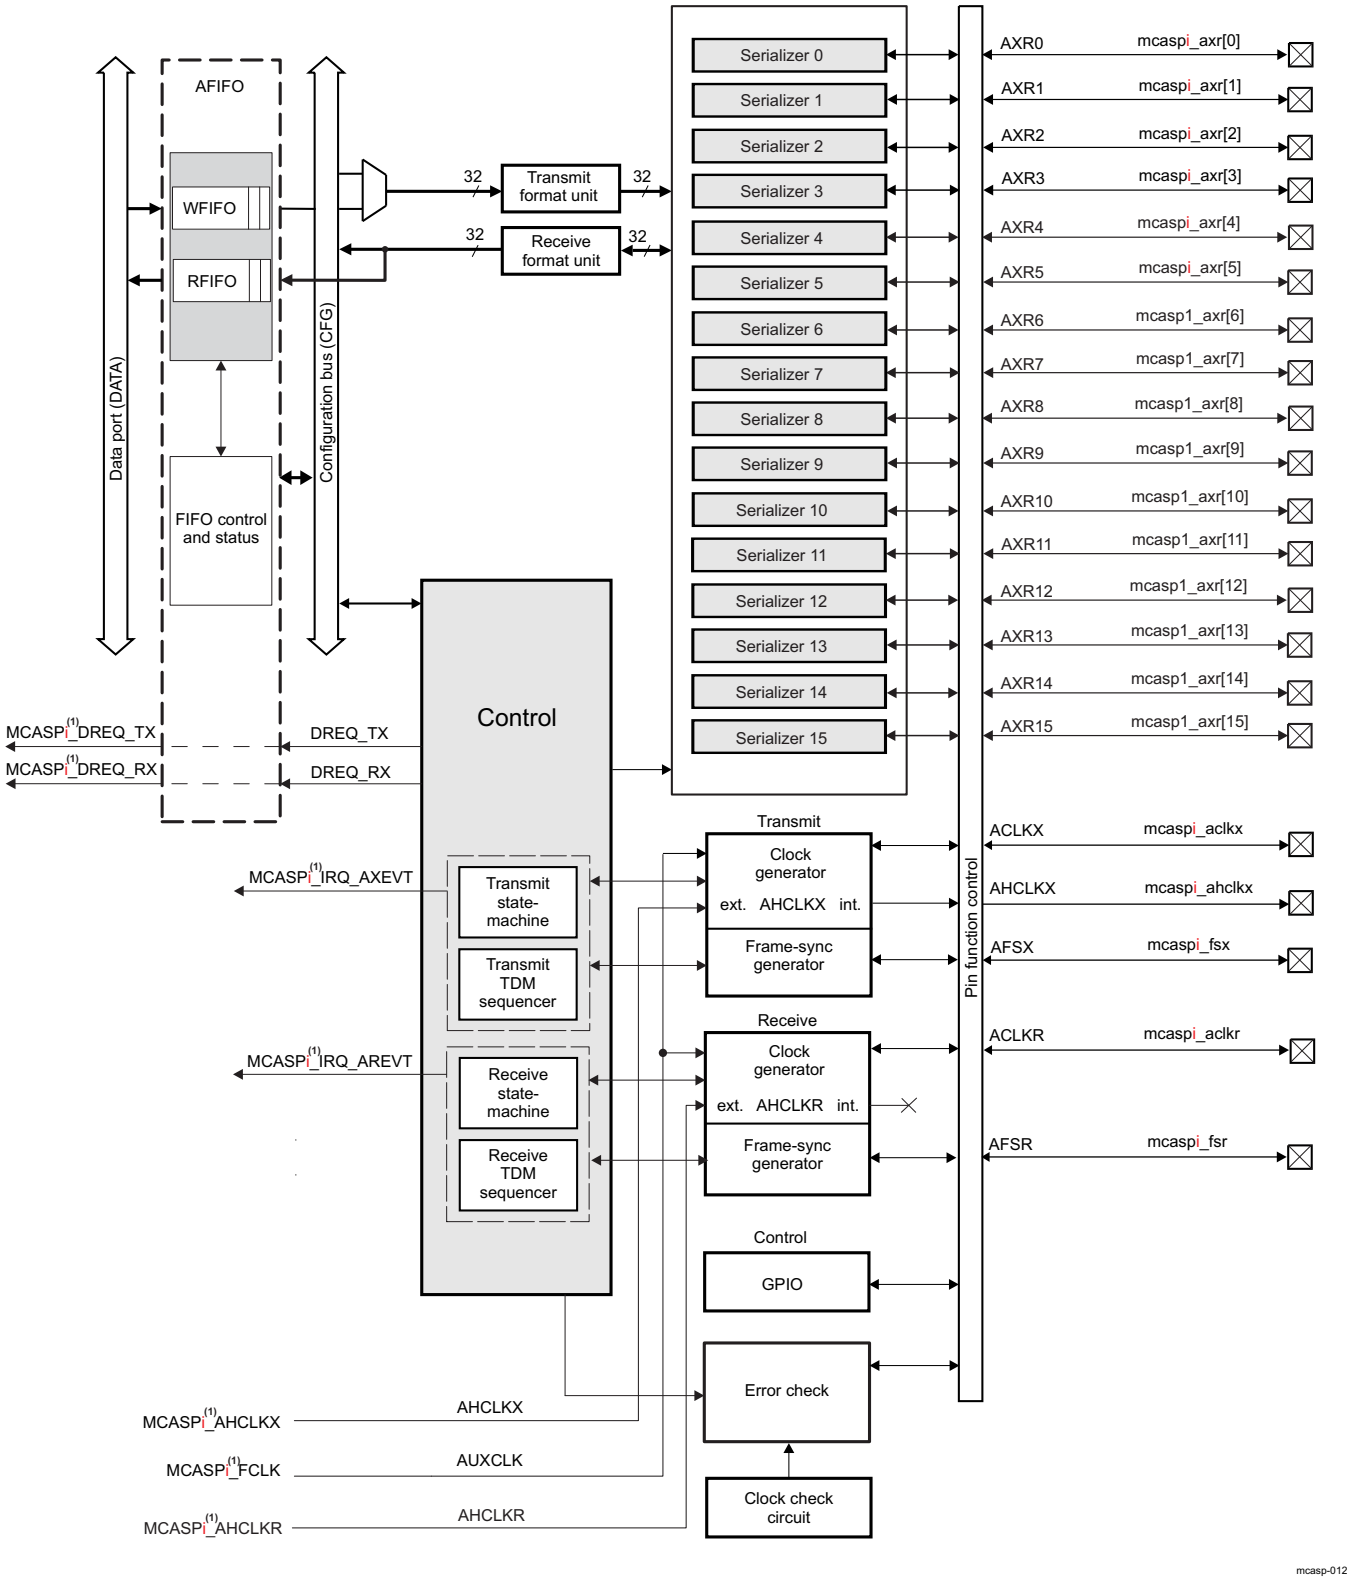
18.5.4 McASP Functional Description

In the text throughout this section a single instance of McASP is described assuming that all modules are functionally identical. For module availability and integration differences, see Section 18.5.2, *McASP Environment*, and Section 18.5.3, *McASP Integration*

18.5.4.1 McASP Block Diagram

Figure 18-89 shows the major blocks of the McASP module. McASP1 has 16 serializers , and McASP2 and McASP3 have 6 serializers each. The serializers share a clock and frame-sync generator, format unit, and error-checking logic independently for the receive and transmit part.

Figure 18-89. McASP Module Block Diagram



(1) i = 1 to 3

NOTE: The internal and external clocks mentioned in this section are with respect to clock and frame-sync generator modules.

18.5.4.2 McASP Clock and Frame-Sync Configurations

There are three scenarios to provide clock source signals for the Tx part and four scenarios for the Rx part of the McASP serializers. The first three scenarios are identical between the Tx and Rx part of the McASP. They feature an asynchronous operation between receiver and transmitter channels using independent Tx/Rx bit rate clock sources (either internal or external).

In the first scenario, the transmit - XCLK and receive - RCLK serial clocks (clock at the bit rate) are generated internally by passing through a couple of clock dividers off the internal functional clock source (AUXCLK). In this case, the bit rate clock is generated internally and is driven out on the pin ACLKX for the Tx part and pin ACLKR for the Rx part, respectively. An internally generated high-frequency clock can be optionally driven out onto the AHCLKX pin for the Tx part to serve as a reference clock for other components in the system.

In the second scenario, an external for the device clock, is passed on the ACLKX (for the TX part) and ACLKR (for the RX part) pins which are configured as inputs. In this case the Rx- /Tx- high-speed clock logic is bypassed for the XCLK/RCLK generation.

In the third (mixed) scenario, an externally driven (master) high-frequency clock is applied on the AHCLKX (for the TX part) pin, which is configured as input. In this case the AHCLKX clock frequency can be divided down via programming the ACLKX associated divider to produce the necessary bit rate clock. The high-speed clock divider can NOT be used.

In the fourth clock generation scenario the bit rate clock for McASP receivers - RCLK is derived from the bit rate clock of the McASP transmitters - XCLK for a synchronous operation between transmitters and receivers. Hence, the whole receiver clock generator logic is bypassed.

A typical role of the McASP frame sync signal is to carry the left/right clock (LRCLK) signal when transmitting and receiving stereo data.

For an asynchronous operation, the AFSX (Tx part) and AFSR (Rx part) frame synchronization signals can be sourced internally or delivered externally independently for the Tx and Rx channels. During synchronous operation the receive frame sync - AFSR signal is derived from the transmit frame sync - AFSX signal. A synchronous and asynchronous mode applies to bit rate clock and frame sync signals at the same time.

18.5.4.2.1 McASP Transmit Clock

The transmit high-speed and transmit clock configuration is controlled by the following registers:

- MCASP_ACLKXCTL
- MCASP_AHCLKXCTL

In case, the transmit bit clock, ACLKX, is generated internally, the MCASP_ACLKXCTL[5] CLKXM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the MCASP_ACLKXCTL[4:0] CLKXDIV bit field) from the source signal.

If the transmit high-frequency master clock, AHCLKX, is also sourced internally (that is first scenario described in Section 18.5.4.2, the MCASP_AHCLKXCTL[15] HCLKXM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the MCASP_AHCLKXCTL[11:0] HCLKXDIV bit field) from the McASP internal clock source AUXCLK.

Internally, the McASP always shifts transmit data at the rising edge of the internal transmit clock - XCLK, (see Figure 18-90). The CLKXP mux determines if ACLKX needs to be inverted to become XCLK. If MCASP_ACLKXCTL[7] CLKXP = 0, the CLKXP mux directly passes ACLKX signal to XCLK. As a result, the McASP shifts transmit data at the rising edge of ACLKX. If MCASP_ACLKXCTL[7] CLKXP = 1, the CLKX mux passes the inverted version of ACLKX to XCLK. As a result, the McASP shifts transmit data at the falling edge of ACLKX.

It can be seen in Figure 18-90 that XCLK is propagated to the Rx clock logic, to allow an internally synchronous operation between McASP transmitters and receivers. This is used for example in the McASP loopback mode.

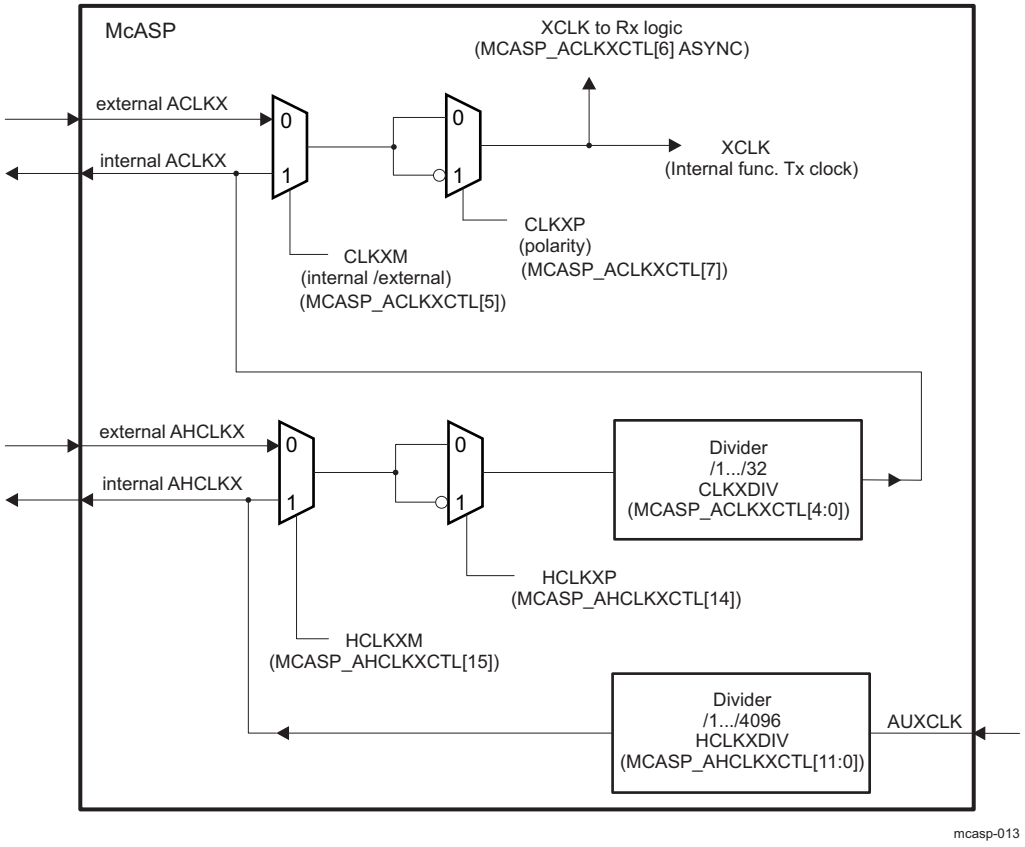
NOTE: The polarity of ACLKX can be controlled in MCASP_ACLKXCTL[7] CLKXP, regardless of ACLKX signal being internally or externally sourced.

In addition, there is an option to invert polarity of the AHCLKX master high speed clock via writing the MCASP_AHCLKXCTL[14] HCLKXP bit.

NOTE: In a similar way, the polarity of AHCLKX clock can be controlled in MCASP_AHCLKXCTL[14] HCLKXP, regardless of the AHCLKX signal being internally or externally sourced.

Figure 18-90 is the block diagram of the transmit clock generator.

Figure 18-90. Transmit Clock Generator Block Diagram



NOTE: In this device:

- ACLKX is mapped on the device ball mcaspi_aclkx, where i = 1 to 3
- internal AHCLKX is mapped on the device ball mcaspi_ahclkx
- external AHCLKX is mapped on MCASPi_AHCLKX clock from the PRCM

For more on McASP integration, see Section 18.5.2, *McASP Environment*, and Section 18.5.3, *McASP Integration*.

18.5.4.2.2 McASP Receive Clock

The McASP receive clock generator is built on a very similar to the transmit clock generator (but independent) circuit.

The receive clock configuration is controlled by the following registers:

- MCASP_ACLKRCTL
- MCASP_AHCLKRCTL

In case, the receive bit clock, ACLKR, is generated internally (but asynchronously to XCLK), the MCASP_ACLKRCTL[5] CLKRM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the MCASP_ACLKRCTL[4:0] CLKRDIV bit field) from the source signal.

If the receive high-frequency master clock, AHCLKR, is also sourced internally (that is, first scenario described in Section 18.5.4.2) and the MCASP_AHCLKRCTL[15] HCLKRM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the MCASP_AHCLKRCTL[11:0] HCLKRDIV bit field) from the McASP internal clock source AUXCLK.

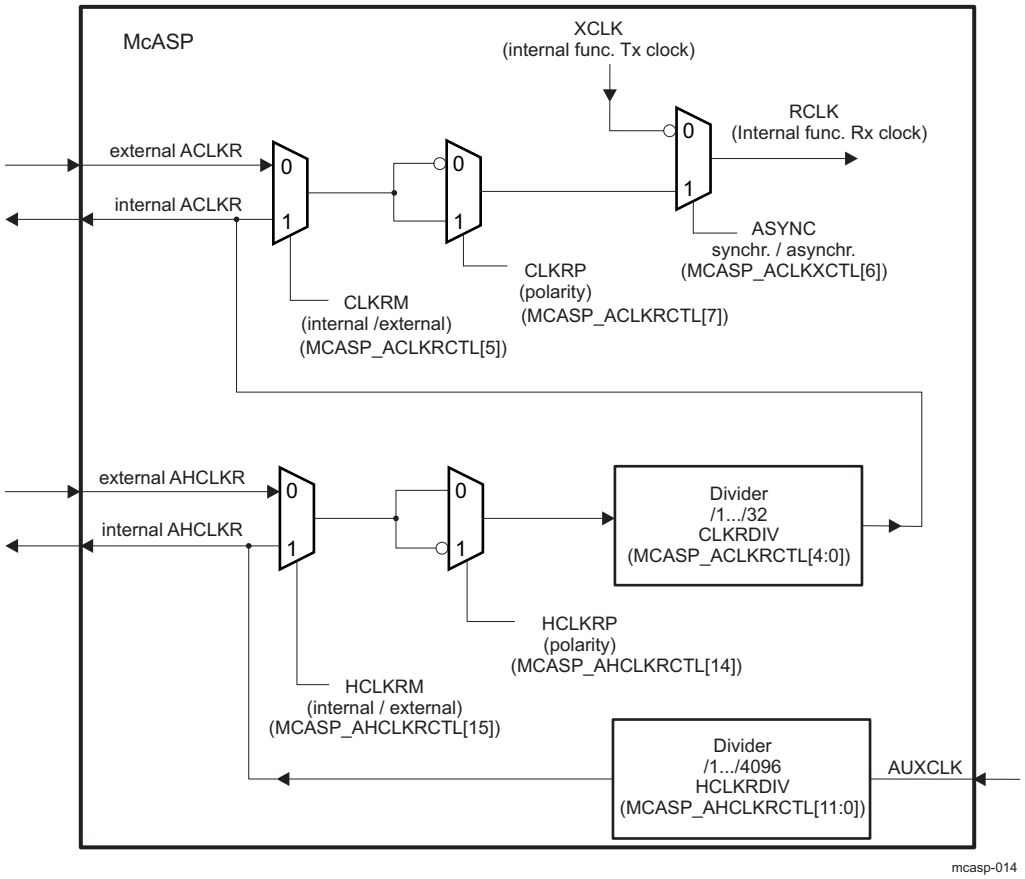
NOTE: The polarity of ACLKR can be controlled in MCASP_ACLKRCTL[7] CLKRP, regardless of ACLKR signal being internally or externally sourced.

In a similar way, the polarity of AHCLKR clock can be controlled in MCASP_AHCLKRCTL[14] HCLKRP, regardless of the AHCLKR signal being internally or externally sourced.

There is an option for the McASP receiver to be configured to operate synchronously to the ACLKX and AFSX signals. The XCLK output of the Tx Clock generator (see Figure 18-90 and Figure 18-91) becomes source of the receive clock (RCLK output), when the MCASP_ACLKXCTL[6] ASYNC bit in the transmit clock control register is set to '0b0'. For more information, refer to Section 18.5.4.2.4.

Figure 18-91 is the block diagram of the receive clock generator.

Figure 18-91. Receive Clock Generator Block Diagram



NOTE: In this device:

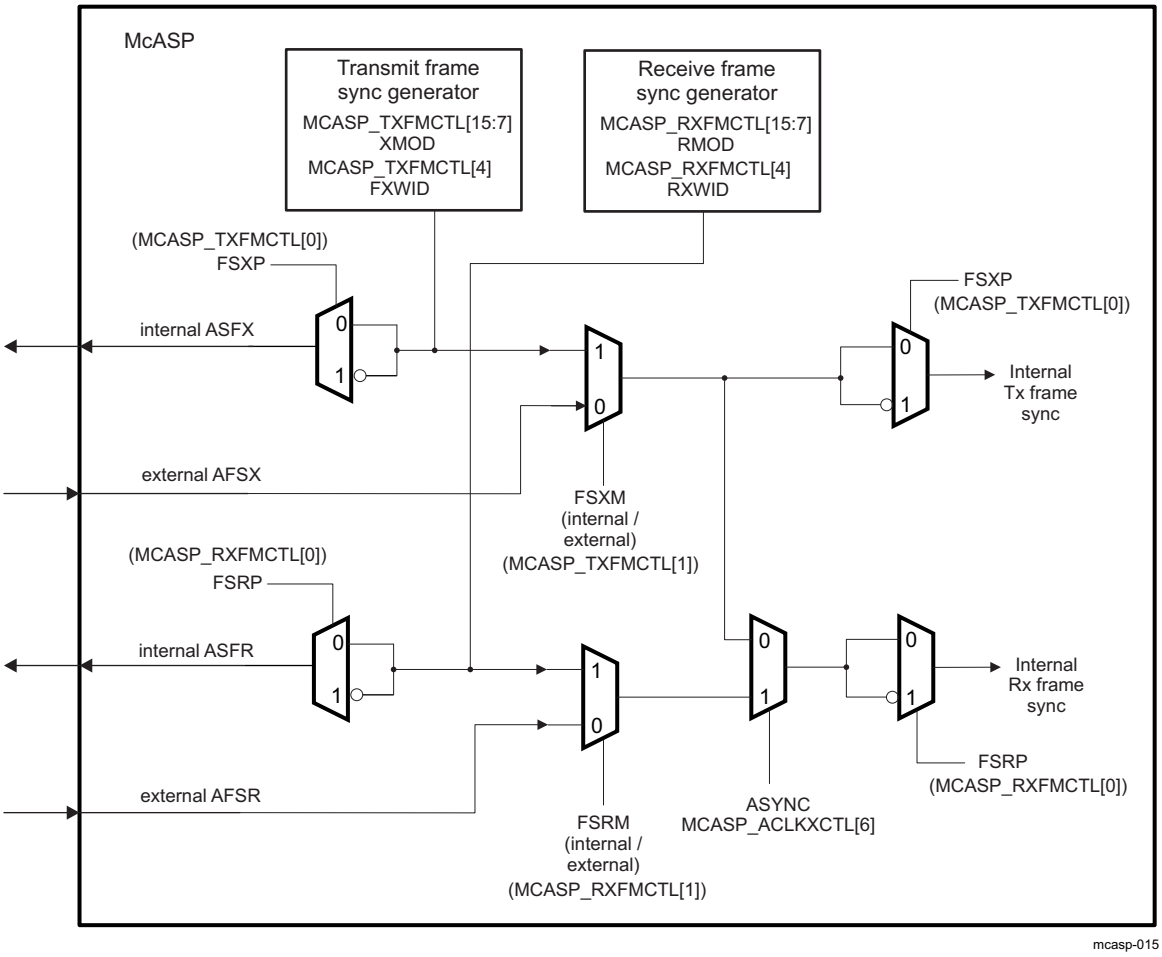
- ACLKR is mapped on the device ball mcaspi_aclkr, where i = 1 to 3
- internal AHCLKR is tied-off
- external AHCLKR is mapped on PRCM MCASPi_AHCLKR from PRCM

For more on McASP integration, see Section 18.5.2, *McASP Environment*, and Section 18.5.3, *McASP Integration*.

18.5.4.2.3 Frame-Sync Generator

There are two different modes for frame sync: burst and TDM. The McASP frame sync generator logic is illustrated in Figure 18-92. I/O buffers are not part of the McASP module, and are not shown in the figure.

Figure 18-92. Frame Sync Generator Block Diagram



NOTE: For more on McASP integration, see Section 18.5.2, *McASP Environment*, and Section 18.5.3, *McASP Integration*.

For the transmit logic, following frame-sync generator configurations can be selected:

- Internally/externally generated frame-sync via configuring bit MCASP_TXFMCTL[1] FSXM
- Frame-sync polarity: Rising edge or falling edge via configuring bit MCASP_TXFMCTL[0] FSXP
- Frame-sync width: "single bit" or "single word" via configuring bit MCASP_TXFMCTL[4] FXWID
- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is defined in the bitfield MCASP_TXFMCTL[15:7] XMOD, as follows:
  - For DIT mode (384 slots) - MCASP_TXFMCTL[15:7] XMOD = 0x180
  - For I2S mode (2 TDM slots) - MCASP_TXFMCTL[15:7] XMOD = 0x2
  - For TDM mode (from 3 to 32 TDM slots) - MCASP_TXFMCTL[15:7] XMOD set in range 0x3 - 0x20
- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in MCASP_TXFMT[17:16] XDATDLY

For the receive logic, following frame-sync generator configurations can be selected:

- Internally/externally generated frame-sync via configuring bit MCASP_RXFMCTL[1] FSRM
- Frame-sync polarity: Rising edge or falling edge via configuring bit MCASP_RXFMCTL[0] FSRP
- Frame-sync width: "single bit" or "single word" via configuring bit MCASP_RXFMCTL[4] FRWID
- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is

defined in the bitfield MCASP_RXFMCTL[15:7] RMOD, as follows:

- For I2S mode (2 TDM slots) - MCASP_RXFMCTL[15:7] RMOD = 0x2
- For TDM mode (from 3 to 32 TDM slots) - MCASP_RXFMCTL[15:7] RMOD set in range 0x3 - 0x20
- For the special 384-slot TDM mode - MCASP_RXFMCTL[15:7] RMOD=0x180

- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in MCASP_RXFMT[17:16] RDATDLY
- Selecting the source (AFSX or AFSR) of receiver internal frame synchronization. This is done in the same bit - MCASP_ACLKXCTL[6] ASYNC, used to define the receiver internal clock source. For more details, refer to Section 18.5.4.2.4.

Regardless of the AFSX/AFSR being internally generated or externally sourced, the polarity of AFSX/AFSR is determined by FSXP/FSRP, respectively, to be either rising or falling edge. If FSXP/FSRP = 0, the frame sync polarity is rising edge. If FSXP/FSRP = 1, the frame sync polarity is falling edge.

NOTE: Certain restrictions apply to the receive and transmit logic settings, when MCASP_ACLKXCTL[6] ASYNC is set to 0b0. They are described in Section 18.5.4.2.4.

18.5.4.2.4 Synchronous and Asynchronous Transmit and Receive Operations

Synchronous Transmit and Receive Operations -

When MCASP_ACLKXCTL[6] ASYNC is written to 0b0, the transmit and receive sections operate synchronously to the transmit section clock and transmit frame sync signals.

Though Rx section may have a different data format, it has to be configured to have the same slot size than the transmit section one. As shown on the Figure 18-91, with the ASYNC bit set to 0b0, the RCLK becomes an inverted version of the transmit clock generator XCLK output.

When MCASP_ACLKXCTL[6] ASYNC = 0b0, both Rx and Tx sections use the same clock and frame sync signals. For this reason, they must be aligned on the following settings:

- MCASP_TXDITCTL[0] DITEN = 0 (that is, transmission in TDM mode is enabled)
- The total number of bits per frame must be the same (that is, RSSZ * RMOD product value must equal XSSZ * XMOD product value)
- The settings in MCASP_ACLKRCTL are NOT considered
- FSXM must match FSRM
- FXWID must match FRWID

For all other settings, the transmit and receive sections may be programmed independently.

Asynchronous Transmit and Receive Operations -

When MCASP_ACLKXCTL[6] ASYNC = 0b1, Tx and Rx operate independently from each other with separate clock and frame sync signals.

NOTE: Synchronous transmit and receive operations are allowed only in the McASP TDM (I2S) mode (i.e. when MCASP_TXDITCTL[0] DITEN=0b0).

18.5.4.3 Serializers

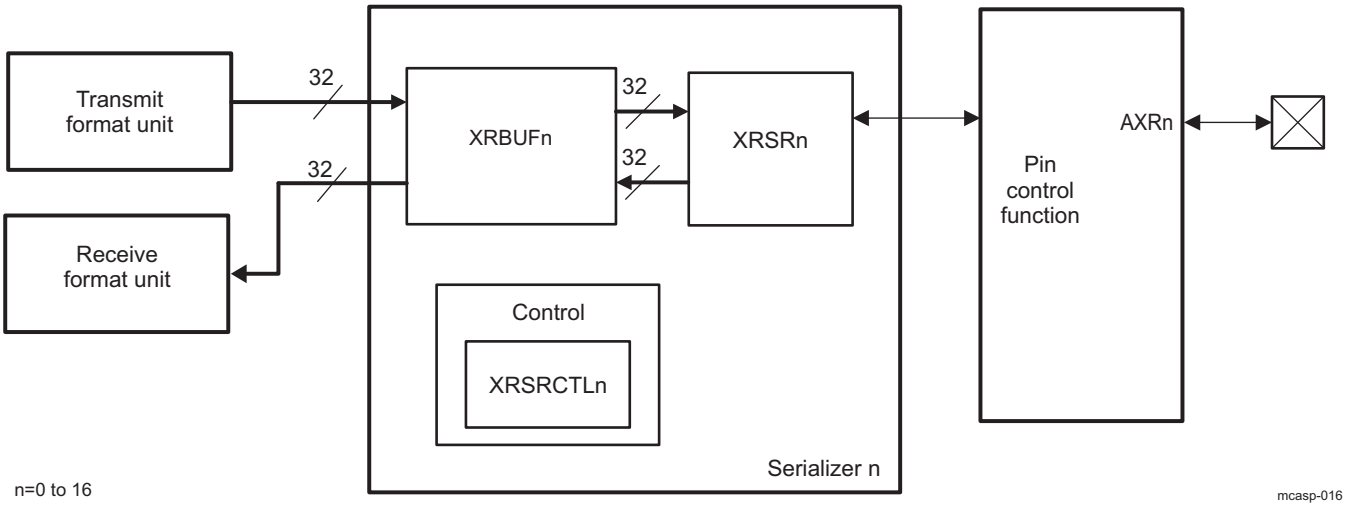
The McASP serializers shift serial data in (Rx) and out (Tx) of the McASP. A given serializer n consists of a shift register (XRSRn) with a single-entry data buffer XRBUFn used either for transmitting (write accessible in register MCASP_TXBUFn) or for receiving (read accessible in register MCASP_RXBUFn) data. In addition, each serializer has a dedicated control register (MCASP_XRSRCTLn) and a serial bidirectional data pin - AXRn. The register MCASP_XRSRCTLn allows n-th serializer to be configured as a transmitter, receiver, or as inactive. There are transmit and receive data formatting units to support data alignment options of the McASP which are shared between all Tx and Rx serializers, respectively.

A given serializer XRSRn shifter configured as a receiver in MCASP_XRSRCTLn, shifts in data through McASP corresponding device level bidirectional data pad AXRn. A given serializer XRSRn shifter configured as a transmitter in MCASP_XRSRCTLn, shifts out data on McASP corresponding device level bidirectional data pad AXRn.

The serializer is clocked from the transmit section clock (ACLKX signal) if configured to transmit or clocked from the receive section clock (ACLKR signal) if configured to receive. A serializer configured to transmit and receive operates in lockstep, which means that for McASP there are at most a couple of zones, one for transmit and one for receive.

Figure 18-93 is the serializer block diagram.

Figure 18-93. Individual Serializer and Connections Within McASP



Transmission on the n-th serializer is performed as follows:

The McASP is serviced by writing data into the register MCASP_TXBUFn, which is an alias of the serializer data buffer - XRBUFn for transmit function. The data automatically passes through the transmit format unit before reaching the XRBUFn register in the serializer. The data is then copied from the XRBUFn to XRSRn and shifted out from AXRn synchronously to the serial clock.

Reception from the n-th serializer is performed as follows:

The data is shifted into the McASP XRSRn serializer register through the AXRn pin, bit by bit. Once the entire slot becomes available within the XRSRn shift register, the data is copied into the serializer data buffer - XRBUFn,and can be accessed in the MCASP_RXBUFn register, which is an alias of the serializer data buffer - XRBUFn for receive function. When software reads the data from this register, the McASP passes the data through the receive format unit, hence it returns the formatted data.

Serializer controls:

A serializer n is configured as inactive via setting bitfield MCASP_XRSRCTLn[1:0] SRMOD to 0x0.

For a transmitting serializer, the MCASP_XRSRCTLn[3:2] DISMOD bitfield, defines the AXRn pin output state, during inactive slots (HIGH, LOW or Hi-Z).

Transmit function for the n-th serializer is selected via setting bitfield MCASP_XRSRCTLn[1:0] SRMOD to 0x1.

Receive function for the n-th serializer is selected via setting bitfield MCASP_XRSRCTLn[1:0] SRMOD to 0x2.

In the DIT-transmission mode (that is S/PDIF format data transmission): in addition to the data, the serializer shifts out other DIT-specific information accordingly (preamble, user data, etc.). For more information, see Section 18.5.2.2.5

18.5.4.4 Format Units

The McASP has one transmit data formatting unit and one receive data formatting unit, shared between the device McASP serializers. These units automatically remap the data bits within the transmitted or received words between a natural format for the device processors (for example, a Q31 representation) and the required format for the external serial device (for example I2S format). During the remapping process, the format unit can also mask off certain bits.

Since all transmitters share the same data formatting unit, the McASP only supports one transmit format at a time. For example, the McASP does NOT transmit in "I2S format" on serializer 0, while transmitting "Left Justified" on serializer 1. Likewise, the receiver section of the McASP only supports one data format at a time, and this format applies to all receiving serializers.

NOTE: The McASP can transmit in one format while receiving in a completely different format.

The bit mask and pad stage of each of Tx and Rx format units includes a full 32-bit mask register, allowing selected individual bits to either pass through the stage unchanged, or be masked off. The bit mask and pad then pad the value of the masked off bits by inserting either a 0, a 1, or one of the original 32 bits as the pad value. The last option allows for sign-extension when the sign bit is selected to pad the remaining bits. The rotate right stage performs bitwise rotation by a multiple of 4 bits (between 0 and 28 bits), programmable by the MCASP_RXFMT/MCASP_TXFMT register. Note that this is a rotation process, not a shifting process, so bit 0 gets shifted back into bit 31 during the rotation. The bit order - reversal stage either passes all 32 bits directly through, or swaps them. This allows for either MSB or LSB first data formats. If bit order reversal is not enabled, then the McASP will naturally transmit and receive in an LSB first order. Finally, note that the RDATDLY/XDATDLY bits in the MCASP_RXFMT/MCASP_TXFMT also determine the data format. For example, the difference between I2S format and left-justified is determined by the delay between the frame sync edge and the first data bit of a given time slot. For I2S format, RDATDLY/XDATDLY should be set to a 1-bit delay, whereas for left-justified format, it should be set to a 0-bit delay. The combination of all the options in MCASP_RXFMT/MCASP_TXFMT means that the McASP supports a wide variety of data formats, both on the serial data lines, and in the device CPU data representation.

18.5.4.4.1 Transmit Format Unit

The McASP transmit formatting unit consists of three stages :

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB-first or LSB-first)

Figure 18-94 shows the transmit formatting unit.

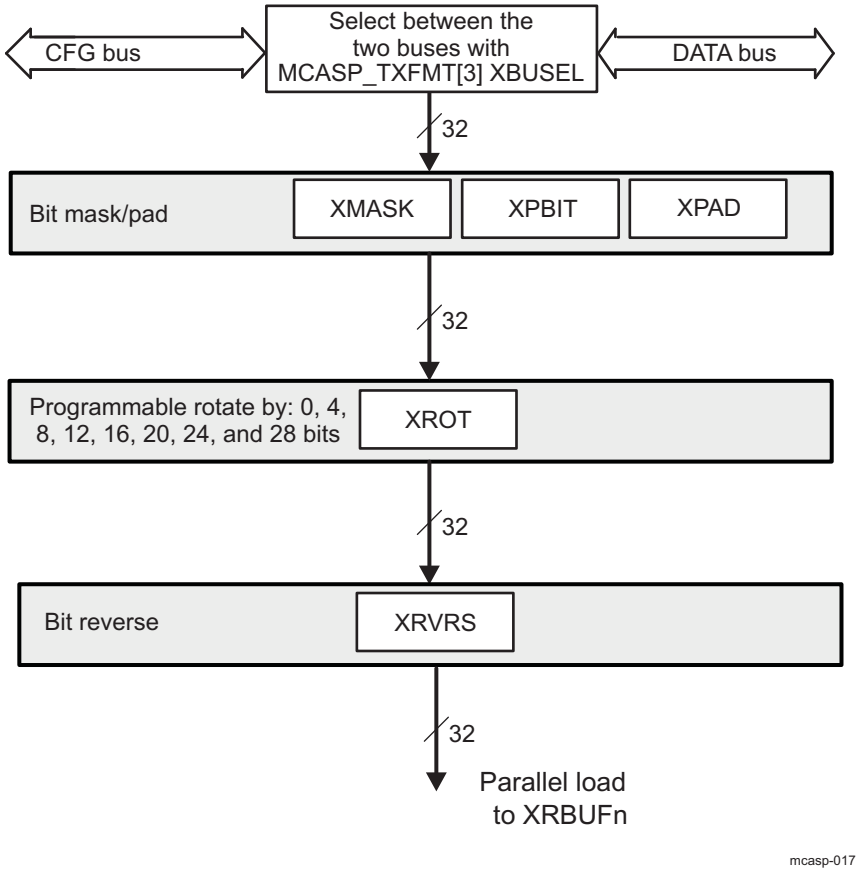
The McASP transmitter supports serial formats of:

- Slot (or Time slot) size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size ≤ Slot size
- Alignment: when more bits/slot than bits/words, then:
  - Left aligned = word shifted first, remaining bits are pad
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB
  - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the bitstream format register - MCASP_TXFMT:

- XRVRS: bit reverse (1) or no bit reverse (0)
- XROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- XSSZ: transmit slot size of 8, 12, 16, 20, 24, 28, or 32 bits

Figure 18-94. Transmit Format Unit



As shown in Figure 18-94, the data to the transmit format unit can come from the configuration port (CFG) or the data port (DATA). The selection is made through the MCASP_TXFMT[3] XBUSEL bit. According to port type selected, data transfer has different behaviour. For more details, refer to the Section 18.5.4.10.1.3, *Transfers Through the DATA Port*, and Section 18.5.4.10.1.4, *Transfers Through the Configuration (CFG) Bus*.

In the transmit format unit (TFU), the input data bits are first masked-off with the MCASP_TXMASK[31:0] XMASK contents. The masked data is then right-rotated to MCASP_TXFMT[2:0] XROT positions, to produce the output word for a TDM- or DIT- transmission.

The bit mask stage includes a full 32-bit mask register, allowing selected individual bits to pass through the stage unchanged or be masked off.

18.5.4.4.1.1 TDM Mode Transmission Data Alignment Settings

The TDM-mode transmission settings are relevant for I2S-protocol and protocols using more than 2 TDM-slots.

XSSZ should always be programmed to match the slot size of the serial stream.

NOTE: Note that, TDM word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the XROT field.

The Table 18-328 show the XRVRS and XROT fields for each serial format and for both integer and Q31 fractional internal representations.

The Table 18-328 assumes that all slot size (SLOT in Table 18-328) and word size (WORD in Table 18-328) options are multiples of 4, since the transmit rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1.

The transmit bit mask/pad unit operates on data as an initial step of the transmit format unit, and the data is aligned in the same representation as it is written to the transmitter (typically Q31 or integer).

Table 18-328. McASP TFU TDM Mode Settings

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_TXFMT bits	
			XROT[1]	XRVRS
MSB first[2]	Left aligned	Q31 fraction	0	1
MSB first	Right aligned	Q31 fraction	SLOT - WORD	1
LSB first	Left aligned	Q31 fraction	32 - WORD	0
LSB first	Right aligned	Q31 fraction	32 - SLOT	0
MSB first[2]	Left aligned	Integer	WORD	1
MSB first	Right aligned	Integer	SLOT	1
LSB first	Left aligned	Integer	0	0
LSB first	Right aligned	Integer	(32 - (SLOT - WORD)) % 32	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator
(2) To transmit in I2S format, select MSB first, left aligned, and also select XDATDLY = 01 (1 bit delay)

18.5.4.4.1.2 DIT Mode Transmission Data Alignment Settings

In case of a DIT-mode (S/PDIF protocol) transmission, while left-aligned Q31 data should be right-rotated to a multiple by 4 positions, no right-rotation is required for a right-aligned Q31 data. Because this is a rotation process, not a shifting process, bit 0 gets shifted back into bit 31 during the process.

The MCASP_TXFMT[17:16] XDATDLY bit field must be set to a 0-bit delay (0x0 value).

For left-aligned Q31 data, the following transmit format unit settings process the data into right-aligned data, ready for transmission:

- MCASP_TXFMT[2:0] XROT =
  - 0x2 (rotate right by 8 bits) - for a 24-bit output audio data
  - 0x3 (rotate right by 12 bits) - for a 20-bit output audio data
  - 0x4 (rotate right by 16 bits) - for a 16-bit output audio data
- MCASP_TXFMT[15] XRVRS = 0x0 – Bit reversal is not enabled; the McASP naturally transmits and receives in a LSB-first order.
- MCASP_TXMASK[32] XMASK = 0xFFFFFF00 – 0xFFFF0000
- MCASP_TXFMT[14:13] XPAD = 0x0 (Pad extra bits with 0s.)

For right-aligned data, the following transmit format unit settings process the data into right-aligned audio data ready for transmission:

- MCASP_TXFMT[2:0] XROT = 0x0 (rotate right by 0 bits regardless of the audio word length)
- MCASP_TXFMT[15] XRVRS = 0x0 – Bit reversal is not enabled; the McASP naturally transmits and receives in a LSB-first order.
- MCASP_TXMASK[32] XMASK = 0x00FFFFFF – 0x0000FFFF
- MCASP_TXFMT[14:13] XPAD = 0x0 (Pad extra bits with 0s.)

The example settings provided in Table 18-329 should be applied to McASP in cases of DIT-transmitting a Q31 data as a 24-bit, 20-bit and 16-bit left- or right- aligned audio word, respectively. Note that the listed settings let the McASP TFU preserve the most significant bits and cut only the LSBs of the original Q31 CPU data:

Table 18-329. McASP TFU DIT-Mode Example Settings

Output Audio Word Alignment	Audio Word Length	Right-rotation (multiple of 4-bit positions)	XMASK	XROT
LEFT	16	16	0xFFFF0000	0x4
LEFT	20	12	0xFFFFF000	0x3
LEFT	24	8	0xFFFFFF00	0x2
RIGHT	16	0	0x0000FFFF	0x0
RIGHT	20	0	0x000FFFFF	0x0
RIGHT	24	0	0x00FFFFFF	0x0

Assuming that a Q31 data word 0xFA5AFxxx (where x-marked nibbles of the data are applied as padding bits of the word) is generated on the McASP CFG (peripheral) port. To transmit a left-aligned 20-bit version of same word, preserving the MSBs, according to the Table 18-329, the user must set XMASK=0xFFFFF000, and to select a right-rotation to 12 positions (XROT=0x3).

- After applying 0-s (XPAD=0) as masking-off bits at the first TFU stage, word is transformed to the word 0xFA5AF000.
- After a rotation by 12 positions to the right is performed in TFU, the 20-bit output word obtained is: 0x000FA5AF.Thus the word gets ready for transmission being mapped with its LS-bit as bit 8 and its MS-bit as bit 27 within a S/PDIF bitstream. This word is shifted in a LSB-to-MSB order (XRVRS = 0x0) out of the XRSR register during a DIT-transmission.

Assuming that a right-aligned Q31 data word - 0x yyyyE4B4 is generated by software on the McASP CFG (peripheral) port (with the presumption that y-marked nibbles of the input data are applied as padding bits). To transmit a right-aligned 16-bit version of same word, preserving the MSBs, according to the table McASP TFU Example Settings, user is supposed to set XMASK=0x0000FFFF, and to select right-rotation to 0 positions (XROT=0x0).

- After masking-off with 0s at first TFU stage, word is transformed to 0x0000E4B4.
- Since no rotation is applied, the 16-bit output word obtained is actually the one obtained in the masking stage – 0x0000E4B4.

The above examples use internal representation in integer and Q31 notation, but other fractional notations are also possible.

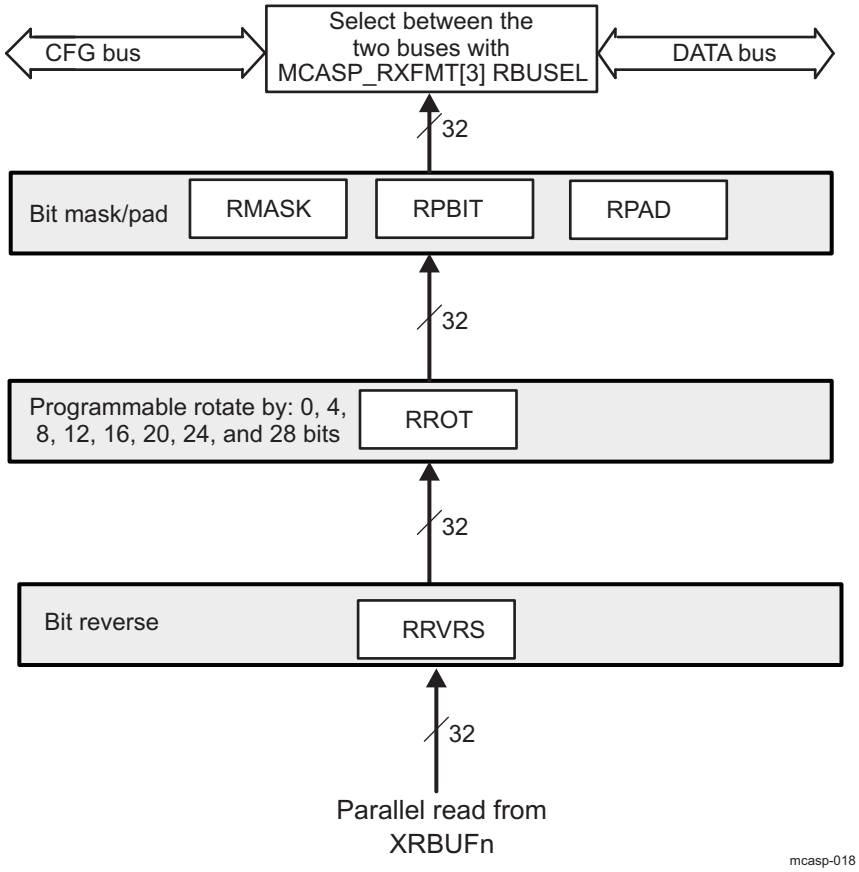
18.5.4.4.2 Receive Format Unit

The McASP receive formatting unit consists of three stages:

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB first or LSB first)

Figure 18-95 shows the receive format unit (RFU).

Figure 18-95. Receive Format Unit



The McASP receiver supports serial formats of:

- Slot or time slot size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size ≤ Slot size
- Alignment when more bits are available per slot than bits per word within the slot, then:
  - Left aligned = word shifted first, remaining bits are pad
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB
  - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the receive bitstream format register - MCASP_RXFMT:

- RRVRS: bit reverse (1) or no bit reverse (0)
- RROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- RSSZ: receive slot size of 8, 12, 16, 20, 24, 28, or 32 bits

As shown on Figure 18-95, the data processed in the RFU can be output to host CPU through the configuration port (CFG) or the data port (DATA). The selection is made through the MCASP_RXFMT[3] RBUSEL bit. According to port type selected, data transfer has different behaviour. For more details, refer to the Section 18.5.4.10.1.3, *Transfers Through the DATA Port*, and Section 18.5.4.10.1.4, *Transfers Through the Configuration (CFG) Bus*.

18.5.4.4.2.1 TDM Mode Reception Data Alignment Settings

RSSZ should always be programmed to match the slot size of the serial stream.

NOTE: Note that the word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the RROT field.

Table 18-330 shows the RRVRS and RROT fields for each serial format and for both integer and Q31 fractional internal representations.

Table 18-330. McASP RFU Settings

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_RXFMT bits	
			RROT[1]	RRVRS
MSB first[2]	Left aligned	Q31 fraction	SLOT	1
MSB first	Right aligned	Q31 fraction	WORD	1
LSB first	Left aligned	Q31 fraction	(32 - (SLOT - WORD)) % 32	0
LSB first	Right aligned	Q31 fraction	0	0
MSB first[2]	Left aligned	Integer	SLOT - WORD	1
MSB first	Right aligned	Integer	0	1
LSB first	Left aligned	Integer	32 - SLOT	0
LSB first	Right aligned	Integer	32 - WORD	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator
(2) To receive in I2S format, select MSB first, left aligned, and also select RDATDLY = 01 (1 bit delay)

The Table 18-330 assumes that all slot size and word size options are multiples of 4; since the receive rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be received in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1. The receive bit mask/pad unit operates on data as the final step of the receive format unit (see Figure 18-95), and the data is aligned in the same representation as it is read from the receiver (typically Q31 or integer, for example).

18.5.4.5 State-Machines

The receive and transmit sections have independent state machines.

Each state-machine controls the interactions between the various units in the McASP Rx and Tx sections, respectively. In addition, each state-machine keeps track of error conditions and serial port status. No serial transfers can occur until the RX/TX state-machine is released from reset.

The transmit state-machine is controlled by the transmit bitstream format register (MCASP_TXFMT) and it reports the McASP status and error conditions in the transmitter status register (MCASP_TXSTAT).

Similarly, the receive state-machine is controlled by the receive bitstream format register (MCASP_RXFMT) and it reports the McASP status and error conditions in the receiver status register (MCASP_RXSTAT).

18.5.4.6 TDM Sequencers

There are separate TDM sequencers for the transmit section and the receive section. Each TDM sequencer keeps track of the slot count. In addition, the TDM sequencer checks the bits of MCASP_RXTDM/MCASP_TXTDM and determines if the McASP should receive/transmit in that time slot.

There are two possibilities for a slot: The McASP either performs Rx/Tx operations during the time slot (transmit/receive bit is active), or the McASP skips Rx/Tx operations during the time slot (transmit/receive bit is inactive). In the latter case, no transfers between the XRBUF and XRSR registers in the serializer would occur during that time slot.

In addition, during time of inactive slots, the serializers programmed as transmitters place their data output pins - AXRn in a predetermined state - logic low, high, or high impedance (tri-stated) as programmed in each serializer control register MCASP_XRSRCTLn[3:2] DISMOD. Refer also to Section 18.5.4.9.2.1, *TDM Time Slots Generation and Processing*, for details on how DMA event or interrupt generations are handled during inactive time slots in TDM mode.

In case of a DIT-transmission (S/PDIF transfers): the time division multiplexing (TDM) sequencer is used to count the 384 subframes (slots) in the DIT block. If currently transmitting slot 1, slot 2 (next value of the TDM slot counter) should be used during the encode phase to select the appropriate C, V, and U bit, because the data encoded and written to a MCASP_TXBUFn register during the current time slot (slot 1) is actually shifted out on the next time slot.

The transmit TDM sequencer is controlled by the MCASP_TXTDM register and reports the current transmit slot to the MCASP_TXTDMSLOT[9:0] XSLOTCNT bit field.

18.5.4.7 McASP Software Reset

The McASP can be put into reset through the global transmit and receive control register (MCASP_GBLCTL). A valid serial clock must be supplied to the McASP to assert the software reset bits in the MCASP_GBLCTL register.

18.5.4.8 McASP Power Management

Table 18-331 describes power-management features available to the McASP.

Table 18-331. Local Power-Management Features

Feature	Registers	Description
Slave idle modes	PWRIDLESYSCONFIG[1:0] IDLE_MODE	Force-idle, no-idle, and smart-idle modes are available.

CAUTION

No wakeup schema is supported for the McASP. To ensure a correct behavior after enabling McASP at device PRCM level, the user software is strongly recommended to choose *No Idle* mode, setting PWRIDLESYSCONFIG[1:0] IDLE_MODE to 0x1. Before disabling McASP at device PRCM level, user software is strongly recommended to choose a *Smart-Idle* mode, setting PWRIDLESYSCONFIG[1:0] IDLE_MODE to 0x2.

18.5.4.9 Transfer Modes

18.5.4.9.1 Burst Transfer Mode

The McASP supports a burst transfer mode, which is useful for nonaudio data such as passing control information between two processors. Burst transfer mode uses a synchronous serial format similar to the TDM mode. The frame sync generation is not periodic or time-driven as in TDM mode, but data driven, and the frame sync is generated for each data word transferred.

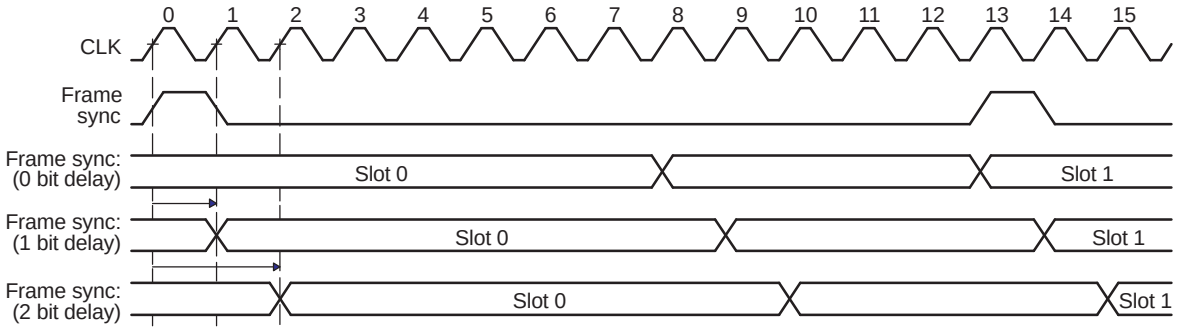
When operating in burst frame sync mode (see Figure 18-96), as specified for transmit (MCASP_TXFMCTL[15:7] = 0) and receive (MCASP_RXFMCTL[15:7] RMOD = 0), one slot is shifted for each active edge of the frame sync signal that is recognized. Additional clocks after the slot and before the next frame sync edge are ignored.

In burst frame sync mode, the frame sync delay may be specified as 0, 1, or 2 serial clock cycles. This is the delay between the frame sync active edge and the start of the slot. The frame sync signal lasts for a single bit clock duration (MCASP_RXFMCTL[4] FRWID = 0, MCASP_TXFMCTL[4] FXWID = 0).

For transmit, when generating the transmit frame sync internally, the frame sync begins when the previous transmission has completed and when all the XBUFn (for every serializer set to operate as a transmitter) has been updated with new data.

For receive, when generating the receive frame sync internally, frame sync begins when the previous transmission has completed and when all the RBUFn (for every serializer set to operate as a receiver) has been read.

Figure 18-96. Burst Frame Sync Mode



The control registers must be configured as follows for the burst transfer mode. The burst mode specific bit fields are in bold face:

- MCASP_PFUNC: The clock, frame, data pins must be configured for McASP function.
- MCASP_PDIR: The clock, frame, data pins must be configured to the direction desired.
- MCASP_PDOUT, MCASP_PDIN, MCASP_PDSET, MCASP_PDCLR: Not applicable. Leave at default.
- MCASP_GBLCTL: Follow the initialization sequence in Section 18.5.5.1.2, *McASP Global Initialization*, to configure this register.
- MCASP_AMUTE: Not applicable. Leave at default.
- MCASP_LBCTL: If loopback mode is desired, configure this register according to Section 24.6.4.14 Loopback Modes, otherwise leave this register at default.
- MCASP_TXDITCTL: DITEN must be left at default 0 to select non-DIT mode. Leave the register at default.
- MCASP_RXMASK/MCASP_TXMASK: Mask desired bits according to Section 18.5.4.4, *Format Units*.
- MCASP_RXFMT/MCASP_TXFMT: Program all fields according to data format desired. See Section 18.5.4.4, *Format Units*.
- MCASP_RXFMT/MCASP_TXFMT: Clear RMOD/XMOD bits to 0 to indicate burst mode. Clear FRWID/FXWID bits to 0 for single bit frame sync duration. Configure other fields as desired.
- MCASP_ACLKRCTL/MCASP_ACLKXCTL: Program all fields according to bit clock desired. See Section 18.5.4.2, *McASP Clock and Frame-Sync Configurations*.
- MCASP_AHCLKRCTL/MCASP_AHCLKXCTL: Program all fields according to high-frequency clock desired. See Section 18.5.4.2, *McASP Clock and Frame-Sync Configurations*.
- MCASP_RXTDM/MCASP_TXTDM: Program RTDMS0/XTDMS0 to 1 to indicate one active slot only. Leave other fields at default.
- MCASP_EVTCTLR/MCASP_EVTCTLX: Program all fields according to interrupts desired.
- MCASP_RXCLKCHK/MCASP_TXCLKCHK: Not applicable. Leave at default.
- MCASP_XRSRCTLn: Program SRMOD to inactive/transmitter/receiver as desired. DISMOD is not applicable and should be left at default.
- MCASP_DITCSRAi, MCASP_DITCSRBi, MCASP_DITUDRAi, MCASP_DITUDRBi: Not applicable. Leave at default.

18.5.4.9.2 Time-Division Multiplexed (TDM) Transfer Mode

The McASP time-division multiplexed (TDM) transfer mode supports the TDM format discussed in Section 18.5.2.2.3.

Transmitting data in the TDM transfer mode requires a minimum set of pins:

- ACLKX - transmit bit clock
- AFSX - transmit frame sync (or commonly called left/right clock)
- One or more serial data pins, AXRn, whose serializers are configured to transmit

For more details on McASP transmitting serializers clock and frame sync options, refer to the Section 18.5.4.2.1, *Transmit Clock*, and Section 18.5.4.2.3, *Frame-Sync Generator* .

Similarly, to receive data in the TDM transfer mode requires a minimum set of pins:

- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)
- One or more serial data pins, AXRn, whose serializers are configured to receive

For more details on McASP receiving serializers clock and frame sync options, refer to Section 18.5.4.2.2, *Receive Clock*, and Section 18.5.4.2.3, *Frame-Sync Generator* .

The control registers must be configured as follows for the TDM mode. The TDM mode specific bit fields are highlighted in bold:

- MCASP_PFUNC: The clock, frame, data pins must be configured for McASP function.
- MCASP_PDIR: The clock, frame, data pins must be configured to the direction desired.
- MCASP_PDOUT, MCASP_PDIN, MCASP_PDSET, MCASP_PDCLR: Not applicable. Leave at default.
- MCASP_GBLCTL: Follow the initialization sequence is described in the Section 18.5.5.2, *Operational Modes Configuration*.
- MCASP_AMUTE: Leave this register at default state.
- MCASP_LBCTL: If loopback mode is desired, configure this register according to Section 18.5.4.14, otherwise leave this register at default.
- MCASP_TXDITCTL: DITEN must be left at default 0 to select TDM mode (transmitters only).
- MCASP_RXMASK/MCASP_TXMASK: Mask desired bits according to Section 18.5.4.4, *Format Units*.
- MCASP_RXFMT/MCASP_TXFMT: Program all fields according to data format desired. See the Section 18.5.4.4, *Format Units*.
- MCASP_RXFMCTL/MCASP_TXFMCTL: Set RMOD/XMOD bits to (0x2 - 0x20) for Rx/Tx (2- 32 slots) TDM mode. In addition, set RMOD to 0x180 if 384-slot TDM stream has to be received by McASP. Configure other fields as desired.
- MCASP_ACLKRCTL/MCASP_ACLKXCTL: Program all fields according to bit clock desired. For more inforamtion, refer to Section 18.5.4.2.
- MCASP_AHCLKRCTL/MCASP_AHCLKXCTL: Program all fields according to high-frequency clock desired. For more details, refer to Section 18.5.4.2.
- MCASP_RXTDM/MCASP_TXTDM: Program all fields according to the time slot characteristics desired.
- MCASP_EVTCTLX: Program all fields according to transmit interrupts desired.
- MCASP_RXCLKCHK/MCASP_TXCLKCHK: Program all fields according to clock checking desired.
- MCASP_XRSRCTLn: Program all fields according to serializer operation desired.

NOTE: The MCASP_DITCSRAi, MCASP_DITCSRBi, MCASP_DITUDRAi, MCASP_DITUDRBi (i=0 to 5) settings are NOT applicable in TDM transfer modes. They have to be kept at their default values.

18.5.4.9.2.1 TDM Time Slots Generation and Processing

TDM mode on the McASP can extend to support multiprocessor applications, with up to 32 time slots per frame. For each of the time slots, the McASP may be configured to participate or to be inactive by configuring MCASP_TXTDM and/or MCASP_RXTDM registers.

The TDM sequencer (separate ones for transmit and receive) functions in this mode. The TDM sequencer counts the slots beginning with the frame sync. For each slot, the TDM sequencer checks the respective bit in either MCASP_TXTDM or MCASP_RXTDM to determine if the McASP transmits/receives in that time slot.

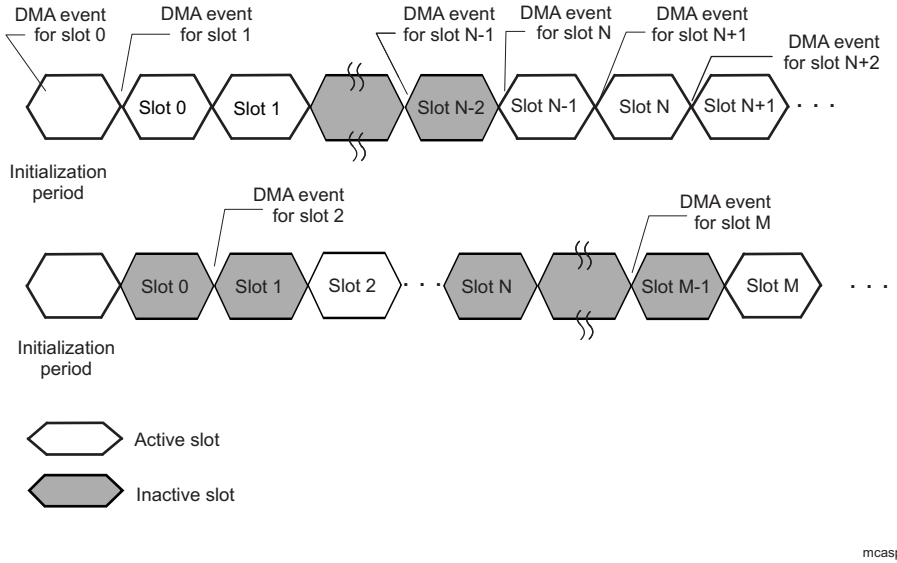
NOTE: If a MCASP_TXTDM/MCASP_RXTDM bit defines an active slot (number of slot matches the bit position), the McASP functions normally during that time slot; otherwise, the McASP is inactive during that time slot; no update to the buffer occurs, and no event is generated. McASP (transmit only) data pins are automatically set to a high-impedance state, 0, or 1 during that slot, as determined by bitfield MCASP_XRSRCTLn[3:2] DISMOD.

Figure 18-97 shows when the transmit DMA event - AXEVT is generated. See Section 18.5.4.10.1, *Data Ready Status and Event/Interrupt Generation* for details on data ready and the initialization period indication. The transmit DMA event for an active time slot (slot N) is generated during the previous time slot (slot N - 1), regardless of the previous time slot (slot N - 1) being active or inactive.

During an active transmit time slot (slot N), if the next time slot (slot N + 1) is configured to be active, the copy from XRBUFn to XRSRn generates the DMA event for time slot N + 1. If the next time slot (slot N + 1) is configured to be inactive, then the DMA event will be delayed to time slot M - 1. In this case, slot M is the next active time slot. The DMA event for time slot M is generated during the first bit time of slot M - 1.

The receive DMA event is generated after data is received in the buffer (looks back in time). If a time slot is disabled, then no data is copied to the buffer for that time slot and no DMA event is generated.

Figure 18-97. Transmit DMA Event (AXEVT) Generation in TDM Time Slots



18.5.4.9.2.2 Special 384-Slot TDM Mode for Connection to External DIR

The McASP receiver also supports a 384 time slot TDM mode (DIR mode), to support S/PDIF receiver ICs whose natural block (block corresponds to McASP frame) size is 384 samples. The receive TDM time slot register (MCASP_RXTDM) should be programmed to all 1s during reception of a DIR block. Other TDM functionalities (for example, inactive slots) are not supported (only the slot counter counts the 384 subframes in a block). To receive data in DIR mode, the following pins are typically needed:

- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)
- In this mode, AFSR should be connected to a DIR which outputs a start of block signal, instead of LRCLK
- One or more serial data pins, AXRn, whose serializers have been configured to receive
- For this special DIR mode, the control registers can be configured just as for TDM mode, except set

RMOD in MCASP_RXFMCTL to 384 (0x180) to receive 384 time slots

18.5.4.9.3 DIT Transfer Mode

The DIT transfer mode of the McASP also supports transmission of audio data in S/PDIF, AES-3, and IEC-60958 formats. These formats are designed to carry audio data between different systems through an optical or coaxial cable. The DIT mode applies only to a serializer configured as transmitter, not as receiver. For a description of the S/PDIF format, see Section 18.5.2.2.5, *S/PDIF Coding Format*.

18.5.4.9.3.1 Transmit DIT Encoding

When the McASP operates in DIT mode, the data transmitted is output as a biphase-mark encoded bitstream, with preamble, channel status, user data, validity, and parity automatically stuffed into the bitstream by the McASP. The McASP includes separate validity bits for even/odd subframes and two 384-bit RAM modules to hold channel status and user data bits.

NOTE: The transmit TDM time slot register (MCASP_TXTDM) should be programmed to all 1s during DIT mode. TDM functionality is not supported in DIT mode, except that the TDM slot counter counts the DIT subframes.

To transmit data in DIT mode, the following pins are typically required:

- AHCLKX – transmit high-frequency master clock (The internal clock source can be used instead.)
- One serial data pin (AXRn) of a serializer n configured to transmit.

For DIT Mode Transmission Data Alignment Settings see Section 18.5.4.4.1.2.

If the McASP is configured to transmit in the DIT mode on more than one serial data pin, the bit streams on all pins will be synchronized. In addition, although they will carry unique audio data, they will carry the same channel status, user data, and validity information.

The actual 24-bit audio data must always be in bit positions 23–0 after passing through the first three stages of the transmit format unit.

18.5.4.9.3.2 Transmit DIT Clock and Frame-Sync Generation

The DIT transmitter works only in the following configuration:

- In the transmit frame control register (MCASP_TXFMCTL):
  - Internally generated transmit frame sync, FSXM = 1
  - Rising-edge frame sync, FSXP = 0
  - Bit-width frame sync, FXWID = 0
  - 384-slot TDM, XMOD = 1 1000 0000b
- In the transmit clock control register (MCASP_ACLKXCTL), ASYNC = 1
- In the transmit bitstream format register (MCASP_TXFMT), XSSZ = 1111 (32-bit slot size)

All combinations of AHCLKX and ACLKX are supported.

The following summarizes the register configurations required for DIT mode. DIT mode-specific bit fields are in bold face:

- MCASP_PFUNC: The data pin - AXRn must be configured for McASP function. If AHCLKX is used, it must also be configured for McASP function. Other pins can be configured to function as GPIOs, if desired.
- MCASP_PDIR: The data pin must be configured as output. If internal clock source AUXCLK is used as the reference clock, it may be output as the AHCLKX device level signal by configuring AHCLKX pin as an output.
- MCASP_GBLCTL: Global initialization
- MCASP_AMUTE: Leave this register at default state.
- MCASP_TXDITCTL: The DITEN bit must be set to 0b1 to enable DIT mode. Configure other bits as

desired.

- MCASP_TXMASK: Mask the desired bits, depending upon left-aligned or right-aligned internal data.
- MCASP_TXFMT: XDATDLY = 0. XRVRS = 0. XPAD = 0. XSSZ = Fh (32-bit slot). XBUSEL = configured as desired. The XROT bit is configured, as described in the Section 18.5.4.4.1.2 .
- MCASP_TXFMCTL: Configure the bits according to former discussions.
- MCASP_ACLKXCTL: ASYNC = 1. Program the CLKXDIV bits to obtain the bit clock rate desired. CLKXM = 1.
- MCASP_AHCLKXCTL: Program the HCLKXDIV bits to obtain the high-frequency bit clock rate desired.
- MCASP_TXTDM: Set to FFFF FFFFh for all active slots for DIT transfers.
- MCASP_EVTCTLX: Program all fields according to the interrupts desired.
- MCASP_TXCLKCHK: Program all fields according to the clock checking desired.
- MCASP_XRSRCTLn: Set SRMOD = 1 (transmitter) for the DIT pins.
- MCASP_DITCSRAi and MCASP_DITCSRBi: Program the channel status bits as desired.
- MCASP_DITUDRAi and MCASP_DITUDRBi: Program the user data bits as desired.

NOTE: In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to 2 serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for TDM (I2S) mode, due to the need to generate Biphase Mark Encoded Data - see Section 18.5.2.2.5.1).

18.5.4.9.3.3 DIT Channel Status and User Data Register Files

The channel status registers (MCASP_DITCSRAi and MCASP_DITCSRBi) and user data registers (MCASP_DITUDRAi and MCASP_DITUDRBi) are not double-buffered. Typically, programmers use one of the synchronizing interrupts, such as the last slot, to create an event at a safe time so the register may be updated. In addition, the software reads the transmit TDM slot counter to determine which word of the register is being used.

It is a software requirement to avoid writing to the word of user data and channel status that are being used to encode the current time slot; otherwise, it is undetermined whether old or new data is used to encode the bitstream.

The DIT subframe format is defined in Section 18.5.2.2.5.2, *S/PDIF Subframe Format*. The channel status information (C) and user data (U) are defined in the following DIT control registers:

- MCASP_DITCSRA0 to MCASP_DITCSRA5: The 192 bits in these six registers contain the channel status information for the left channel within each frame.
- MCASP_DITCSRB0 to MCASP_DITCSRB5: The 192 bits in these six registers contain the channel status information for the right channel within each frame.
- MCASP_DITUDRA0 to MCASP_DITUDRA5: The 192 bits in these six registers contain the user data information for the left channel within each frame.
- MCASP_DITUDRB0 to MCASP_DITUDRB5: The 192 bits in these six registers contain the user data information for the right channel within each frame.
- The S/PDIF block format is shown in Figure 18-87. There are 192 frames within a block (frame 0 to frame 191). There are two subframes within each frame (subframes 1 and 2 for the left and right channels, respectively).

The channel status and user data information sent on each subframe is summarized in Table 18-332.

Table 18-332. Channel Status and User Data for Each DIT Block

Frame	Subframe	Preamble	Channel Status Defined in:	User Data Defined in:

18.5.4.10 Data Transmission and Reception

The McASP is serviced by writing data to the MCASP_TXBUFn registers for transmit operations, and by reading data from the MCASP_RXBUFn registers for receive operations. The McASP sets status flags and notifies the software whenever data is ready to be serviced. The Section 18.5.4.10.1, *Data Ready Status and Event/Interrupt Generation*, discusses data-ready status in details.

The McASP transmit/receive XRBUFn buffer can be accessed through one of the two peripheral ports of the device:

- DATA port: This port is dedicated to DMA initiated data transfers on the device for McASP transmit (Tx) purposes.

- Configuration bus (CFG): The configuration bus- CFG port is used for peripheral configuration control and receive/transmit data transfers initiated by the host CPU in the device.

Section 18.5.4.10.1.3, *Transfers Through the Data Port (DATA)*, and Section 18.5.4.10.1.4, *Transfers Through the Configuration Bus (CFG),* discuss how to perform transfers through the data port (DATA) and the configuration port (CFG), respectively.

A device CPU and DMA usages are discussed in Section 18.5.4.10.1.5, *Using the device CPUs for McASP Servicing*, and Section 18.5.4.10.1.6, *Using the DMA for McASP Servicing*, respectively.

McASP DATA port allows DMAs to access the McASP transmit buffer more efficiently on the L3_MAIN-interconnect or L4_PER2 interconect, using burst transfers. The physical addresses to access these registers are listed in Section 18.5.6.2.5.

18.5.4.10.1 Data Ready Status and Event/Interrupt Generation

18.5.4.10.1.1 Transmit Data Ready

The transmit data ready flag - XDATA in the MCASP_TXSTAT register reflects the data ready status of XRBUFn buffers for all of the active slot transmitting serializers. The XDATA flag is set whenever data is transferred from a transmitting serializer buffer - XRBUFn to its corresponding XRSRn shift register. Thus, the XDATA bit indicates the global event that some of the serializers data buffer - XRBUFn is emptied and ready to accept new data from the host (CPU or DMA). The transmit data ready event is individually indicated per serializer in its corresponding control register MCASP_XRSRCTLn[4] XRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Tx buffer must be serviced (written). When MCASP_TXBUFn is written to by the host, the MCASP_XRSRCTLn[4] XRDY is deasserted to 0b0. As XDATA global flag is an OR-event of all active serializers XRDY flags, it indicates to software the moment, when write service operation has to be initiated by the McASP host (XDATA=0b1). The XRDY flags have to be sequentially scanned by user software to determine which serializer MCASP_TXBUFn register has to be currently written. Once all requested MCASP_TXBUFn are written, the serializers control XRDY flags are cleared to 0b0. As a consequence, XDATA flag is deasserted to 0b0, to indicate to SW that write operation is completed for all serializers.

The global XDATA flag can be cleared when the MCASP_TXSTAT[5] XDATA bit is written to 0b1, or once MCASP_TXBUFn registers of all the serializers, that have previously raised their XRDY flags, are written with corresponding active slot data by the host.

Whenever XDATA is set, the AXEVT event is automatically generated on MCASPi_DREQ_TX line (if enabled in the MCASP_XEVTCTL register) to notify the DMA of the MCASP_TXBUFn empty status. An interrupt - MCASPi_IRQ_AXEVT can be also generated if the XDATA interrupt is enabled in the MCASP_EVTCTLX register (for details, see Section 18.5.4.12.1, *Transmit Data Ready Interrupt*).

For DMA requests, the McASP does not require that MCASP_TXSTAT be read between DMA events. This means that, even if MCASP_TXSTAT already has the XDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

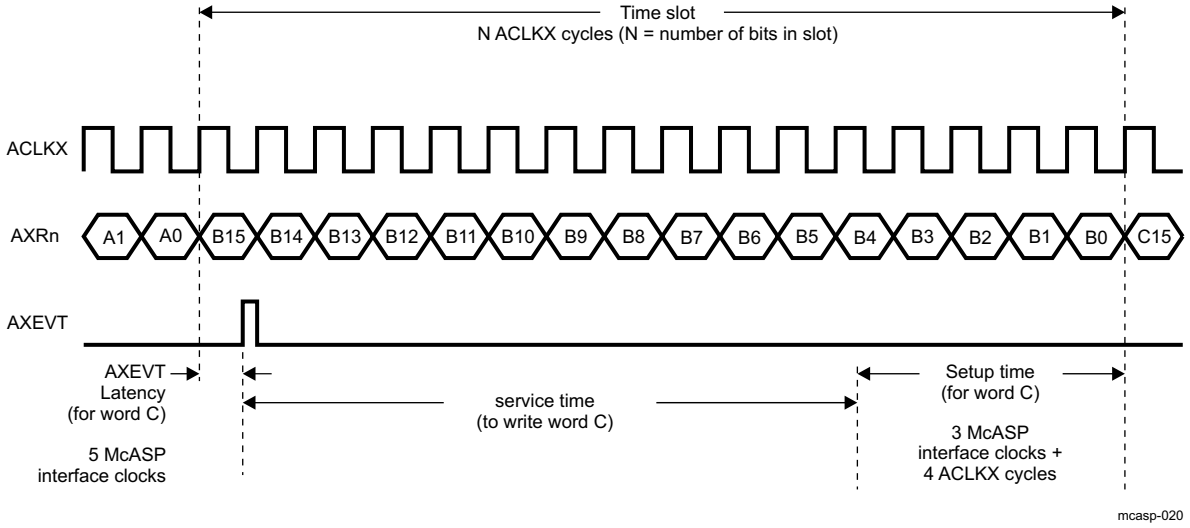
Because the serializer acts in lockstep, only one DMA event is generated to indicate that the transmit serializer is ready to be written to with new data.

Figure 18-98 shows the timing details of when AXEVT is generated at the McASP boundary. In this example, as soon as the last bit (A0) of word A is transmitted, the McASP sets the XDATA flag and generates an AXEVT event. However, it takes up to five McASP interface clocks (AXEVT latency) before AXEVT is active at the McASP boundary. Upon AXEVT, the CPU can begin servicing the McASP by writing word C into the MCASP_TXBUFn (service time). The CPU must write word C into the MCASP_TXBUFn within the setup time required by the McASP (setup time).

The maximum service time (see Figure 18-98) can be calculated as:

Service Time = Time Slot – AXEVT Latency –Setup Time

Figure 18-98. Service Time Upon Transmit DMA Event (AXEVT)



18.5.4.10.1.2 Receive Data Ready

Similarly, the receive data ready flag - RDATA in the MCASP_RXSTAT register reflects the data ready status of XRBUFn buffers for all of the active slot receiving serializers. The RDATA flag is set whenever data is transferred from a receiving serializer shift register XRSRn to its corresponding XRBUFn data buffer. Thus, the RDATA bit indicates the global event that some of the receivers data buffer - RXBUFn already contains received data (i.e. a buffer is full) and is ready to transfer it to the host. The receive data ready event is individually indicated per serializer in its corresponding control register MCASP_XRSRCTLn [5] RRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Rx buffer must be serviced (read). When MCASP_RXBUFn is read from the host, the MCASP_XRSRCTLn [5] RRDY is deasserted to 0b0. As RDATA global flag is an OR-event of all active serializers RRDY flags, it indicates to software the moment, when read service operation has to be initiated by the McASP host (RDATA=0b1). The RRDY flags have to be sequentially scanned by user software to determine which serializer MCASP_RXBUFn register has to be currently read. Once all requested MCASP_RXBUFn are read, the serializers control RRDY flags are cleared to 0b0. As a consequence, RDATA flag is deasserted to 0b0, to indicate to SW that read operation is completed for all serializers.

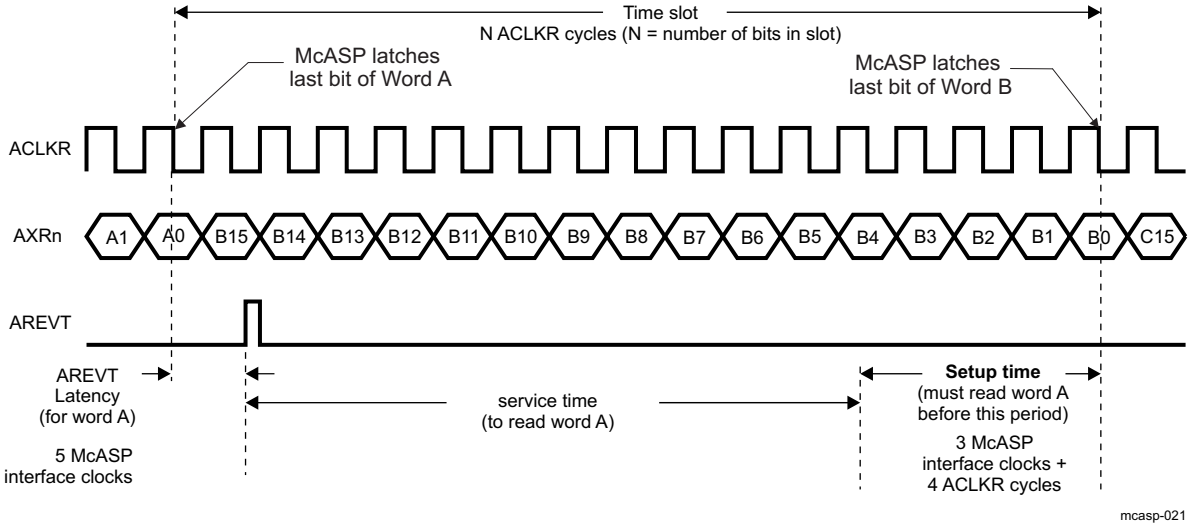
The global RDATA flag can be cleared when the MCASP_RXSTAT[5] RDATA bit is written to 0b1, or once MCASP_RXBUFn registers of all the serializers, that have previously raised their RRDY flags, are read by the host.

Whenever RDATA is set, the AREVT event is automatically generated on MCASPi_DREQ_RX line (if enabled in the MCASP_REVTCTL register) to notify the DMA of the MCASP_RXBUFn full status. An interrupt - MCASPi_IRQ_AREVT can be also generated if the RDATA interrupt is enabled in the MCASP_EVTCTLR register (for details, see Section 18.5.4.12.1, *Receive Data Ready Interrupt*).

Figure 18-99 shows the timing details of when AREVT event is generated at the McASP boundary. In this example, as soon as the last bit (bit A0) of Word A is received, the McASP sets the RDATA flag and generates an AREVT event. However, it takes up to five McASP interface clocks (AREVT Latency) before AREVT is active at the McASP boundary. Upon AREVT, the CPU can begin servicing the McASP by reading Word A from the MCASP_RXBUFn (service time). The CPU must read Word A from the MCASP_RXBUFn register no later than the setup time required by the McASP (Setup Time).

The maximum service time (see Figure 18-99) can be calculated as:
Service Time = Time Slot - AREVT Latency - Setup Time

Figure 18-99. CPU Service Time Upon Receive Event (AREVT)



18.5.4.10.1.3 Transfers Through the Data Port (DATA)

CAUTION

To perform internal transfers through the DATA port, clear the XBUSEL/RBUSEL bit to 0b0 in the MCASP_TXFMT/MCASP_RXFMT register, respectively. Failure to do so may result in software malfunction.

NOTE: McASP1, whose data portis accessible directly via L3_MAIN, does not support FIFO/constant addressing modes. Incrementing transfers must be used instead.

In a typical McASP transfer scenario, the DMA Controller write accesses the XRBUFn transmit buffer through the McASP data port (DATA) on L3_MAIN Interconect for McASP1 and on L4_PER2 Interconect for McASP2/3 . CPU hosts can access both XRBUFn transmit and receive data buffers on their corresponding DATA port address via DATA port corresponding address. To perform transfers through the DATA port, simply have the DMA Controller write the McASP Tx buffer through Interconect DATA port location. Refer to Section 18.5.6.2.5. Although the transfer is passed through an integrated AFIFO transmit/receive buffer, the host (DMA or CPU) must follow the described below procedure to access the data buffers of each serializer, regardless the AFIFO is enabled or disabled. The AFIFO operation is described in Section 18.5.4.11.

For accesses through the DATA port, the DMA/CPU services all the serializers through accessing only a single address. In addition, as can be seen in Section 18.5.6.2.5, the same physical DATA port address is used regardless of a read or write access is performed. The McASP automatically cycles through the active slot transmitting/receiving serializers, internally generating the appropriate offsets.

NOTE: DATA port allows the DMA/CPU to automatically access only the data buffers. There is no way for DMA/CPU to access the McASP configuration registers addressing their corresponding McASP DATA port.

For transmit operations through the DATA port, the host must always write to the same transmit buffer DATA port address (which is same than the receive buffer DATA port adress) to service all of the active slot transmitting serializers. Regardless of McASP serializer 0 being configured inactive or active, the user software must always configure the destination address to match the DATA port location of TXBUF buffer (See Section 18.5.6.2.5).

In addition, the DMA/CPU must write the buffers of all transmitting serializers in incremental (although not necessarily consecutive) order. For example, if only serializers 1 and 3 are set up as active transmitters, to the same transmit buffer DATA port address twice - first data for serializer 1 and second data for serializer 3 upon each transmit data ready event. This exact servicing order must be followed so that data appears in the appropriate serializers.

NOTE: For write transfers through McASP DATA port it is preferable to use DMA on corresponding Interconect. This is because DMAs initiated traffic gets better advantage of the burst transfers supported by DATA port.

For receive operations through the DATA port, the DMA/CPU must always read from the same receive buffer DATA port address (which is same than the transmit buffer DATA port adress) to service all of the active slot receiving serializers. Regardless of McASP serializer 0 being configured inactive or active, the user software must always configure the DMA/CPU source address to match the DATA port location of RXBUF buffer (See Section 18.5.6.2.5).

In addition, reads from the receive buffer for all active slot receiving serializers through the Rx DATA port return data in incremental (although not necessarily consecutive) order. For example, if serializers 0, 1 and 3 are set up as active receivers, the MPU should read from the same receive buffer DATA port address three times to obtain data for serializers 0,1 and 3 in this exact order, upon each receive data ready event.

NOTE: To service a serializer for a transmit or receive operation through the McASP DATA port, the initiator always writes (preferably DMA) and reads from the same address (refer to Section 18.5.6.2.5), respectively.

See Section 18.5.6.2.5, *MCASP_DATA Register Summary*, for more details about XRBUFn buffer physical address corresponding to the McASP DATA port on:

- Main Interconect (L3_MAIN or L4_PER2)

NOTE: When transmitting through the DATA port, the DMA/CPU must write data (at the same address) to each serializer configured as *active* (active slot selected in MCASP_TXTDM) and *transmit* (Tx enabled in MCASP_XRSRCTLn) within each time slot. Failure to do so results in a buffer underrun condition (see Section 18.5.4.15.1, *Buffer Underrun Error - Transmitter*). Similarly, when DMA/CPU receives, data must be read from each serializer configured as *active* (active slot selected in MCASP_RXTDM) and *receive* (Rx enabled in MCASP_XRSRCTLn) within each time slot. Failure to do results in a buffer overrun condition (see Section 18.5.4.15.2, *Buffer Overrun Error - Receiver*).

18.5.4.10.1.4 Transfers Through the Configuration Bus (CFG)

CAUTION

To perform internal transfers through the configuration bus, set the XBUSEL/RBUSEL bit to 1 in the MCASP_TXFMT/MCASP_RXFMT registers, respectively. Failure to do so may result in software malfunction.

NOTE: McASP1, whose data port is accessible directly via L3_MAIN does not support FIFO/constant addressing modes. Incrementing transfers must be used instead.

In this method, the DMA/CPU accesses the XRBUFn transmit or receive buffer through corresponding configuration bus (CFG) address.

The exact XRBUFn transmit/receive buffer physical address for any particular serializer is determined by adding the transmit/receive buffer alias register offset for that particular serializer to the base address of McASP CFG port actual for L4_PER2 accesses. The XRBUFn buffer of the n-th serializer configured as a transmitter is aliased - MCASP_TXBUFn in the CFG port address space. For example, the XRBUF2 transmit buffer is mapped as the MCASP_TXBUF2 register. Similarly, the XRBUFn buffer of the n-th serializer configured as a receiver is aliased - MCASP_RXBUFn in the CFG port address space. For example, the XRBUF3 receive buffer is mapped as the MCASP_RXBUF3 register.

Accessing the XRBUF through the DATA port (see Section 18.5.4.10.1.3) is different than CFG port accesses because the DATA port access demands the same physical address, regardless of transfer direction or current channel index , while accessing through the peripheral configuration port - CFG, the DMA/CPU must provide the exact MCASP_TXBUFn or MCASP_RXBUFn address upon accessing n-th serializer TX or RX buffer, respectively. For more details about MCASP_TXBUFn and MCASP_RXBUFn addresses corresponding to McASP CFG port, see Section 18.5.6.2.1, *MCASP_CFG Register Summary*.

18.5.4.10.1.5 Using a Device CPU for McASP Servicing

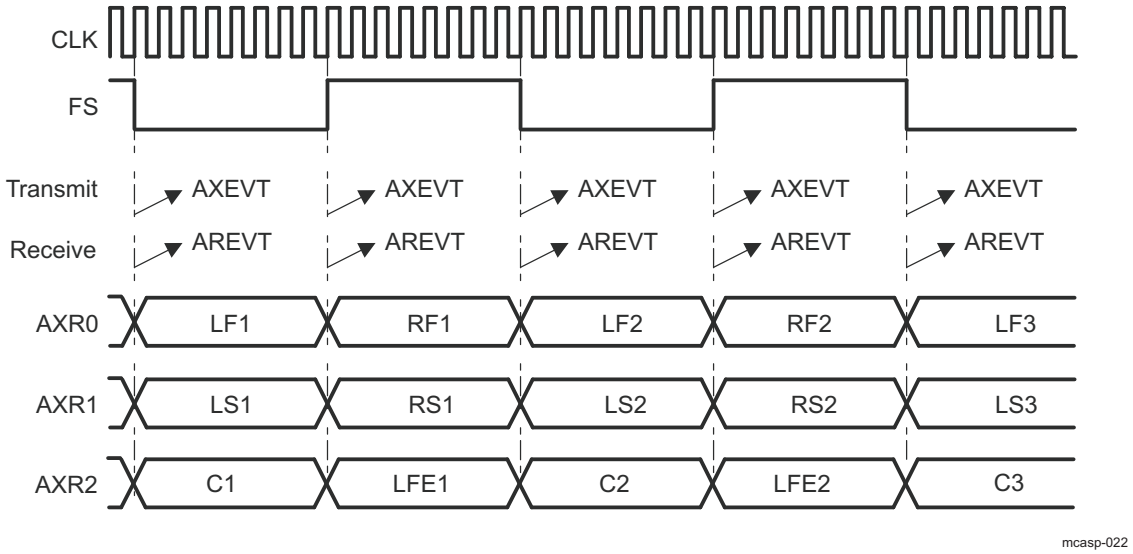
The device CPUs can be used to service the McASP transmit channels through interrupts (upon MCASPi_IRQ_AXEVT and MCASPi_IRQ_AREVT interrupts). Because these interrupt events are connected to device IRQ_CROSSBAR module, they could be software mapped to input IRQ lines of any device CPU. Another way to service the transmit and receive channels, a polling of the XDATA bit in the MCASP_TXSTAT register and RDATA bit in the MCASP_RXSTAT register can be performed by device CPUs, respectively. As discussed in Section 18.5.4.10.1.3, *Transfers Through the Data Port (DATA)*, and Section 18.5.4.10.1.4, *Transfers Through the Configuration Bus (CFG)* , the device CPUs can access McASP XRBUF serializer buffer through their corresponding DATA and CFG port locations.

To use the device CPUs to service the McASP through interrupts, the XDATA/RDATA bit must be enabled in the respective MCASP_EVTCTLX/MCASP_EVTCTLR registers, to generate interrupts MCASPi_IRQ_AXEVT/MCASPi_IRQ_AREVT to the device CPUs upon data ready

18.5.4.10.1.6 Using the DMA for McASP Servicing

The typical scenario is to use the DMA to service the McASP transmit and receive logic through the DATA port, although the DMA can also service the McASP through the configuration bus (CFG). The transfer passes through integrated AFIFO transmit/receive buffer. If AFIFO is enabled, DMA requests are collected and fed to a device DMA controller (see Figure 18-89). The data transfer is managed by the AFIFO according to generated transmit and receive events in the McASP and data is fed to transmit buffers and fetched from receive buffers as described in Section 18.5.4.11. The generation of transmit and receive request is described below. After generation of transmit/receive DMA events from McASP module, these events are collected in AFIFO and on specific AFIFO conditions described in Section 18.5.4.11 the requests (transmit or receive) are forwarded to a DMA controller via MCASPi_DREQ_TX and MCASPi_DREQ_RX outputs. If the AFIFO is disabled (default state) it is transperrant for the McASP module and all request are directly sent to the DMA controller.

Figure 18-100. DMA Transmit and Receive Event in an Audio Example – One Event



In transmit mode, the DMA event - AXEVT (MCASPi_DREQ_TX output), which is triggered upon each XDATA transition from 0 to 1, is used to service the McASP TXBUFn transmit buffers. In receive mode, the DMA event AREVT (MCASPi_DREQ_RX output) which is triggered upon each RDATA transition from 0 to 1, is used to service the McASP RXBUFn receive buffers.

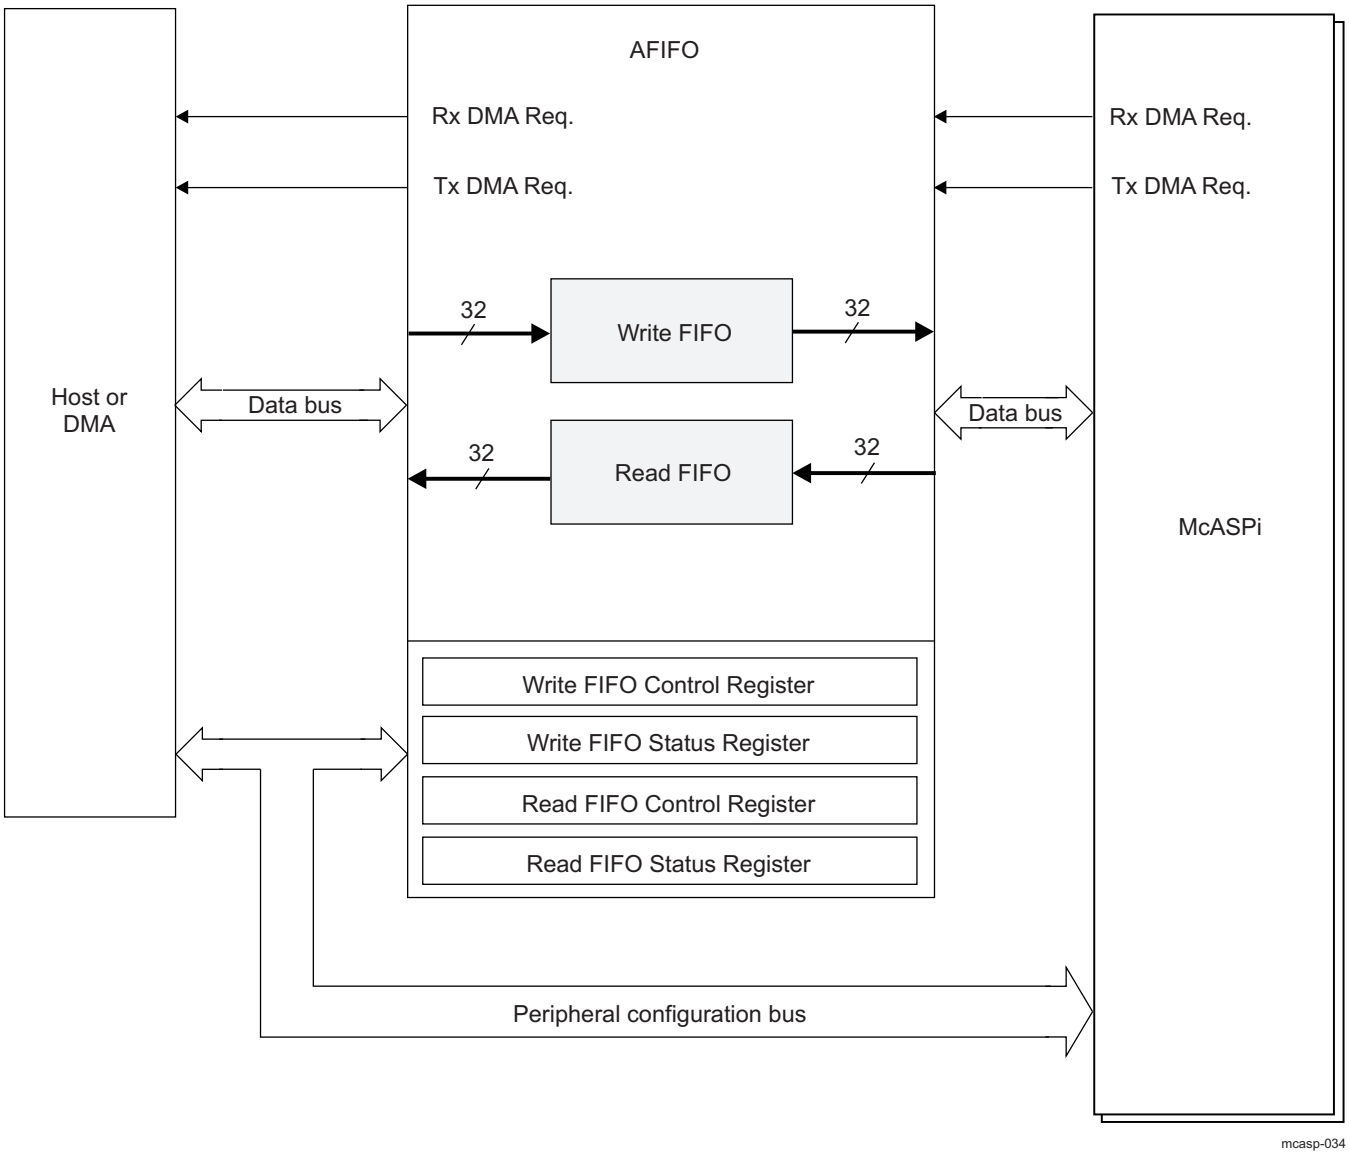
Figure 18-100 is an example of an audio system with six audio channels (LF, RF, LS, RS, C and LFE) transmitted or received through the McASP signals - AXR0, AXR1 and AXR2. It shows the points at which events AXEVT/AREVT are triggered.

In Figure 18-100, a Tx DMA event AXEVT is triggered on each time slot. In the example, AXEVT is triggered for each of the transmit audio channel time slot (time slot for channels LF, LS, and C; and time slot for channels RF, RS, LFE). Transmit DMA events are generated automatically upon transmit data ready, provided that DMA TX requests generation is enabled in the MCASP_XEVTCTL register. Similarly, Rx DMA event AREVT is triggered for each of the receive audio channel time slot. Receive DMA events are generated automatically upon receive data ready, provided that DMA RX requests generation is enabled in the MCASP_REVTCTL register.

18.5.4.11 McASP Audio FIFO (AFIFO)

The AFIFO contains two FIFOs: one Read FIFO (RFIFO), and one Write FIFO (WFIFO). The RFIFO and the WFIFO are the same size: 64 32-bit Words. To ensure backward compatibility with existing software, both the Read and Write FIFOs are disabled by default. See Figure 18-101 for a high-level block diagram of the AFIFO. The AFIFO may be enabled/disabled and configured via the WFIFOCTL and RFIFOCTL registers. Note that if the Read or Write FIFO is to be enabled, it must be enabled prior to initializing the receive/transmit section of the McASP.

Figure 18-101. McASP Audio FIFO (AFIFO) Block Diagram



18.5.4.11.1 AFIFO Data Transmission

When the Write FIFO is disabled, transmit DMA requests pass through directly from the McASP to the host/DMA controller. Whether the WFIFO is enabled or disabled, the McASP generates transmit DMA requests as needed; the AFIFO is “invisible” to the McASP. When the Write FIFO is enabled, transmit DMA requests from the McASP are sent to the AFIFO, which in turn generates transmit DMA requests to the host/DMA controller. If the Write FIFO is enabled, upon a transmit DMA request from the McASP, the WFIFO writes WNUMDMA 32-bit words to the McASP if and when there are at least WNUMDMA words in the Write FIFO. If there are not, the WFIFO waits until this condition has been satisfied. At that point, it writes WNUMDMA words to the McASP. (See description for WFIFOCTL[7:0] WNUMDMA.) If the host CPU writes to the Write FIFO, independent of a transmit DMA request, the WFIFO will accept host writes until full. After this point, excess data will be discarded. Note that when the WFIFO is first enabled, it will immediately issue a transmit DMA request to the host. This is because it begins in an empty state, and is therefore ready to accept data.

18.5.4.11.1.1 Transmit DMA Event Pacer

The AFIFO may be configured to delay making a transmit DMA request to the host until the Write FIFO has enough space for a specified number of words. In this situation, the number of transmit DMA requests to the host or DMA controller is reduced. If the Write FIFO has space to accept WNUMEVT 32-bit words, it generates a transmit DMA request to the host and then waits for a response. Once WNUMEVT words have been written to the FIFO, it checks again to see if there is space for WNUMEVT 32-bit words. If there is space, it generates another transmit DMA request to the host, and so on. In this fashion, the Write FIFO will attempt to stay filled. Note that if transmit DMA event pacing is desired, WFIFOCTL[15:8] WNUMEVT should be set to a non-zero integer multiple of the value in WFIFOCTL[7:0] WNUMDMA. If transmit DMA event pacing is not desired, then the value in WFIFOCTL[15:8] WNUMEVT should be set equal to the value in WFIFOCTL[7:0] WNUMDMA.

18.5.4.11.2 AFIFO Data Reception

When the Read FIFO is disabled, receive DMA requests pass through directly from McASP to the host/DMA controller. Whether the RFIFO is enabled or disabled, the McASP generates receive DMA requests as needed; the AFIFO is “invisible” to the McASP. When the Read FIFO is enabled, receive DMA requests from the McASP are sent to the AFIFO, which in turn generates receive DMA requests to the host/DMA controller. If the Read FIFO is enabled and the McASP makes a receive DMA request, the RFIFO reads RNUMDMA 32-bit words from the McASP, if and when the RFIFO has space for RNUMDMA words. If it does not, the RFIFO waits until this condition has been satisfied; at that point, it reads RNUMDMA words from the McASP. (See description for RFIFOCTL[7:0] RNUMDMA.) If the host CPU reads the Read FIFO, independent of a receive DMA request, and the RFIFO at that time contains less than RNUMEVT words, those words will be read correctly, emptying the FIFO.

18.5.4.11.2.1 Receive DMA Event Pacer

The AFIFO may be configured to delay making a receive DMA request to the host until the Read FIFO contains a specified number of words. In this situation, the number of receive DMA requests to the host or DMA controller is reduced. If the Read FIFO contains at least RNUMEVT 32-bit words, it generates a receive DMA request to the host and then waits for a response. Once RNUMEVT 32-bit words have been read from the RFIFO, the RFIFO checks again to see if it contains at least another RNUMEVT words. If it does, it generates another receive DMA request to the host, and so on. In this fashion, the Read FIFO will attempt to stay empty. Note that if receive DMA event pacing is desired, RFIFOCTL[15:8] RNUMEVT should be set to a non-zero integer multiple of the value in RFIFOCTL[7:0] RNUMDMA. If receive DMA event pacing is not desired, then the value in RFIFOCTL[15:8] RNUMEVT should be set equal to the value in RFIFOCTL[7:0] RNUMDMA.

18.5.4.11.3 Arbitration Between Transmit and Receive DMA Requests

If both the WFIFO and the RFIFO are enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete. If only the WFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete. If only the RFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the receive DMA request. Once a transfer is in progress, it is allowed to complete.

18.5.4.12 McASP Events and Interrupt Requests

Table 18-333 lists all the transmit event flags. Table 18-334 lists all the Receive event flags. Source of each of these TX/RX events can be a TX/RX channel from any McASPi serializer configured as transmitter or receiver respectivly.

Table 18-333. TX Events[1]

Event Mask	Event Flag	Map to [2]	Description
MCASP_EVTCTLX[0] XUNDRN	MCASP_TXSTAT[0] XUNDRN	MCASPi_IRQ_AXEVT	Transmit buffer underrun

(1) Global events for all transmitting serializers in a single McASPi module.
(2) Every McASPi module generates separate IRQ event.

Table 18-333. TX Events[1] (continued)

Event Mask	Event Flag	Map to [2]	Description
MCASP_EVTCTLX[1] XSYNCERR	MCASP_TXSTAT[1] XSYNCERR	MCASPi_IRQ_AXEVT	Unexpected transmit frame sync
MCASP_EVTCTLX[2] XCKFAIL	MCASP_TXSTAT[2] XCKFAIL	MCASPi_IRQ_AXEVT	Transmit clock failure
MCASP_EVTCTLX[3] XDMAERR	MCASP_TXSTAT[7] XDMAERR	MCASPi_IRQ_AXEVT	DATA port transmit error
MCASP_EVTCTLX[4] XLAST	MCASP_TXSTAT[4] XLAST	MCASPi_IRQ_AXEVT	Transmit last slot interrupt
MCASP_EVTCTLX[5] XDATA	MCASP_TXSTAT[5] XDATA	MCASPi_IRQ_AXEVT	Transmit data-ready interrupt
MCASP_EVTCTLX[7] XSTAFRM	MCASP_TXSTAT[6] XSTAFRM	MCASPi_IRQ_AXEVT	Transmit start of frame interrupt
n.a.	MCASP_TXSTAT[8] XERR	n.a.	OR-event of all Tx-error events: (XDMAERR | XCKFAIL | XUNDRN | XSYNCERR). It is cleared ONLY when all error flags are cleared
n.a.	MCASP_TXSTAT[3] XTDMSLOT	n.a.	Qualifies the current TDM slot as an odd or an even slot.

Table 18-334. RX Events[1]

Event Mask	Event Flag	Map to[2]	Description
MCASP_EVTCTLR[0] ROVRN	MCASP_RXSTAT[0] ROVRN	MCASPi_IRQ_AREVT	Receive buffer overrun
MCASP_EVTCTLR[1] RSYNCERR	MCASP_RXSTAT[1] RSYNCERR	MCASPi_IRQ_AREVT	Unexpected receive frame sync
MCASP_EVTCTLR[2] RCKFAIL	MCASP_RXSTAT[2] RCKFAIL	MCASPi_IRQ_AREVT	Receive clock failure
MCASP_EVTCTLR[3] RDMAERR	MCASP_RXSTAT[7] RDMAERR	MCASPi_IRQ_AREVT	DATA port receive error
MCASP_EVTCTLR[4] RLAST	MCASP_RXSTAT[4] RLAST	MCASPi_IRQ_AREVT	Receive last slot
MCASP_EVTCTLR[5] RDATA	MCASP_RXSTAT[5] RDATA	MCASPi_IRQ_AREVT	Receive data-ready
MCASP_EVTCTLR[7] RSTAFRM	MCASP_RXSTAT[6] RSTAFRM	MCASPi_IRQ_AREVT	Receive start of frame
n.a.	MCASP_RXSTAT[8] RERR	n.a.	OR-event of all Rx-error events: (RDMAERR | RCKFAIL | ROVRN | RSYNCERR). RERR event is cleared once all error flags are cleared.
n.a.	MCASP_RXSTAT[3] RTDMSLOT	n.a.	Qualifies the current TDM slot as an odd or an even slot.

(1) Global events for all receiving serializers in a single McASPi module. These events and masks are available in same format for every McASPi module

(2) Every McASP module generates separate IRQ event.

Software has to read the MCASP_TXSTAT/MCASP_RXSTAT register to determine which event occurs at a global level for McASP Tx/Rx logic. In addition user software has to scan the XRDY/RRDY read-only flags in the MCASP_XRSRCTLn registers to determine which active serializer is the actual source of the event.

A Tx interrupt line (MCASPi_IRQ_AXEVT) is asserted (active high) when one of the MCASP_TXSTAT notified events occurs, provided that it is enabled in its corresponding MCASP_EVTCTLX bit. Similarly, a Rx interrupt line (MCASPi_IRQ_AREVT) is asserted (active high) when one of MCASP_RXSTAT notified events occurs, provided that it is enabled in its corresponding MCASP_EVTCTLR bit. See also Section 18.5.4.12.4, *Multiple Interrupts* and the Section 18.5.4.10.1, *Data Ready Status and Event/Interrupt Generation*.

18.5.4.12.1 Transmit Data Ready Event and Interrupt

The transmit data-ready interrupt (XDATA) is generated if XDATA is 1 in the MCASP_TXSTAT register and XDATA is enabled in MCASP_EVTCTLX. The Section 18.5.4.10.1, *Data Ready Status and Event/Interrupt Generation*, provides details on when XDATA is set in the MCASP_TXSTAT register.

A transmit-start-of-frame interrupt (XSTAFRM) is triggered by the recognition of a transmit frame sync.

A transmit-last-slot interrupt (XLAST) is a qualified version of the data-ready interrupt (XDATA). It has the same behavior than the data-ready interrupt, but is further qualified by having the data requested belonging to the last slot (the slot that just ended is the next-to-last TDM slot, the current slot is the last slot).

18.5.4.12.2 Receive Data Ready Event and Interrupt

The receive data-ready interrupt (RDATA) is generated if RDATA is 1 in the MCASP_RXSTAT register and RDATA is enabled in MCASP_EVTCTLR. The Section 18.5.4.10.1, *Data Ready Status and Event/Interrupt Generation*, provides details on when RDATA flag is set in the MCASP_RXSTAT register.

A receiver start of frame (RSTAFRM) interrupt is triggered by the recognition of a receiver frame sync.

A receiver last slot (RLAST) interrupt is a qualified version of the data ready interrupt (RDATA). It has the same behavior as the data ready interrupt, but is further qualified by having the data in the buffer come from the last TDM time slot (the slot that just ended was last TDM slot).

18.5.4.12.3 Error Interrupt

Upon detection, the following error conditions generate interrupt flags:

In the transmit status register (MCASP_TXSTAT):

- Transmit underrun (XUNDRN)
- Unexpected transmit frame sync (XSYNCERR)
- Transmit clock failure (XCKFAIL)
- Transmit DATA port error (XDMAERR)

Each interrupt source also has a corresponding enable bit in the transmit interrupt control register (MCASP_EVTCTLX). If the enable bit is set, an interrupt is requested when the interrupt flag is set in MCASP_TXSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

In the receive status register (MCASP_RXSTAT) :

- Receiver overrun (ROVRN)
- Unexpected receive frame sync (RSYNCERR)
- Receive clock failure (RCKFAIL)
- Receive DATA port error (RDMAERR)

Each interrupt source also has a corresponding enable bit in the receive interrupt control register (MCASP_EVTCTLR). If the enable bit is set, an interrupt is requested when the interrupt flag is set in MCASP_RXSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

18.5.4.12.4 Multiple Interrupts

This only applies to interrupts and not to DMA requests. The following terms are defined:

- **Active Interrupt Request:** a flag in MCASP_TXSTAT is set and the interrupt is enabled in MCASP_EVTCTLX.
- **Outstanding Interrupt Request:** An interrupt request has been issued on one of the McASP transmit interrupt port, but that request has not yet been serviced.
- **Serviced:** The CPUs write to MCASP_TXSTAT to clear one or more of the active interrupt request flags.

The first interrupt request to become active for the serializer with the interrupt flag set in MCASP_TXSTAT/MCASP_RXSTAT and the interrupt enabled in MCASP_EVTCTLX/MCASP_EVTCTLR generates a request on the McASP transmit or receive interrupt port.

If more than one interrupt request becomes active in the same cycle, a single interrupt request is generated on the McASP transmit or receive interrupt port. Subsequent interrupt requests that become active while the first interrupt request is outstanding do not immediately generate a new request pulse on the McASP transmit or receive interrupt port.

The interrupt is serviced with the CPU writing to MCASP_TXSTAT/MCASP_RXSTAT. If any interrupt requests are active after the write, a new request is generated on the McASP transmit or receive interrupt port.

One outstanding interrupt request is allowed on each port, so a transmit and a receive interrupt request may both be outstanding at the same time.

18.5.4.13 DMA Requests

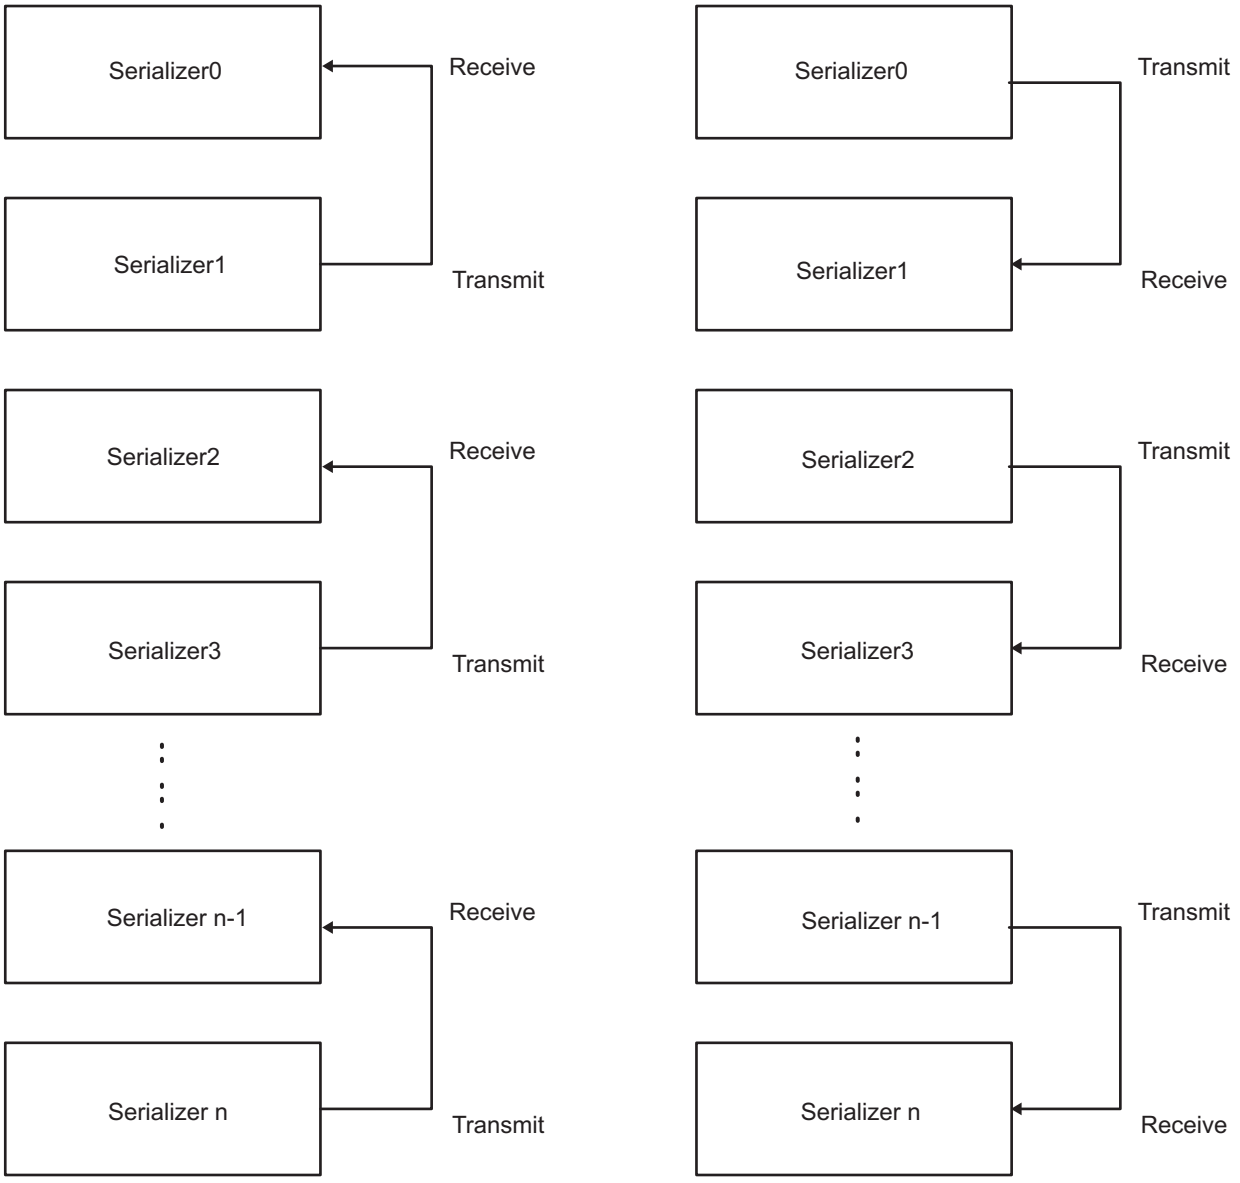
The McASP can generate one DMA request to the DMA_CROSSBAR to transmit (MCASPi_DREQ_TX) or receive (MCASPi_DREQ_RX) data. A DMA request to transmit data is generated if the XDATDMA bit in the MCASP_XEVTCTL register is cleared. A DMA request to receive data is generated if the RDATDMA bit in the MCASP_REVTCTL register is cleared.

18.5.4.14 Loopback Modes

The McASP features a digital loopback mode (DLB) that allows loopback test transfers in TDM mode between McASP transmitters and receivers within the same device. In loopback mode, the output of a transmit serializer is connected internally to the input of a receive serializer. Therefore, a receiver data can be checked against a transmitter data to ensure that the McASP settings are correct. Digital loopback mode applies to TDM mode only (2 to 32 slots in a frame). It does not apply to DIT mode (XMOD = 0x180) or burst mode (XMOD = 0).

Figure 18-102shows the basic logical connection of the serializers in loopback mode.

Figure 18-102. McASP Serializers Operation in Loopback Mode



Two types of loopback connections are possible, selected by the ORD bit in the digital loopback control register - MCASP_LBCTL as follows:

- ORD = 0: Outputs of odd serializers are connected to inputs of even serializers. If this mode is selected, the odd serializers must be configured as transmitters and even serializers as receivers.
- ORD = 1: Outputs of even serializers are connected to inputs of odd serializers. If this mode is selected, the even serializers must be configured as transmitters and odd serializers as receivers.

User can choose in software (bit IOLBEN of the MCASP_LBCTL) between a McASP module internal loopback and a device I/O level loopback.

When a **McASP internal loopback** is selected (MCASP_LBCTL[4] IOLBEN=0b0), it is NOT necessary to configure MCASP_PFUNC and MCASP_PDIR registers for McASP pin settings. Nevertheless, data can be optionally made externally visible at the I/O pin of the transmit serializer, if the pin is configured as a McASP output pin by setting the corresponding MCASP_PFUNC bit to 0 (i.e. to function as McASP, not GPIO) and MCASP_PDIR bit to 1 (output).

When a **device I/O level loopback** is selected (MCASP_LBCTL[4] IOLBEN=0b1), the MCASP_PFUNC and MCASP_PDIR registers must be configured with the appropriate settings for all AXRn pins, according to ORD bit configuration.

In case of device I/O loopback, the connectivity is externally applied between device pads (i.e. reaching device I/O buffers).

Hence, the corresponding padconfiguration registers must be appropriately configured in the device Control Module - CTRL_MODULE_CORE_PAD. For more details, see Section 13.4.6.1, *Pad Configuration Rregisters*, in *Chapter 13, Control Module*.

When In loopback mode, the transmit clock and frame sync are used by both the transmit and receive sections of the McASP. The transmit and receive sections operate synchronously. This is achieved by setting the MODE bitfield of the MCASP_LBCTL register to 0x1 and the ASYNC bit of the MCASP_ACLKXCTL register to 0b0.

18.5.4.14.1 Loopback Mode Configurations

This is a summary of the settings required for digital loopback mode for TDM format :

- The MCASP_LBCTL[0] DLBEN bit must be set to 0b1 to enable a loopback mode. It must be kept at 0b0 during normal McASP operation.
- The MCASP_LBCTL[4] IOLBEN bit must be set to select between internal (McASP local) loopback mode or device I/O level loopback mode.
- The MCASP_LBCTL[3:2] MODE bitfield must be set to 0x1 for both the transmit and receive sections to use the transmit clock and frame sync generator.
- The MCASP_LBCTL[1] ORD must be programmed appropriately to select odd or even serializers to be transmitters or receivers.
- The corresponding serializers must be configured accordingly.
- The bit - MCASP_ACLKXCTL[6] ASYNC must be cleared to 0b0 to ensure synchronous transmit and receive operations.
- The bitfields - MCASP_RXFMCTL[15:7] RMOD and MCASP_TXFMCTL[15:7] XMOD must be set within range (0x2- 0x20) to indicate TDM mode.

NOTE: Loopback mode does not apply to DIT or burst mode, because McASP receivers do NOT natively support DIR - reception.

18.5.4.15 Error Reporting

The McASP includes error-checking capability for the serial protocol and data underrun. In addition, the McASP includes a timer that continually measures the high-frequency master clock every 32 AHCLKX clock cycles. The value of the timer can be read to get a measurement of the clock frequency and has a minimum and maximum range setting that can set an error flag if the master clock goes out of a specified range.

When one or more errors (software selectable) are detected, an interrupt can be generated if desired, based on one or more error sources.

18.5.4.15.1 Buffer Underrun Error -Transmitter

A buffer underrun occurs when a serializer is instructed by the transmit state-machine to transfer data from XRBUFn buffer to XRSRn shift register, but the corresponding (MCASP_TXBUFn) register has not yet been written with new data since the last time the transfer occurred. When this occurs, the transmit state-machine sets the XUNDRN flag.

An underrun is checked only once per time slot. The MCASP_TXSTAT[0] XUNDRN flag is set when an underrun condition occurs. Once set, the XUNDRN flag remains set until the host explicitly writes 1 to the XUNDRN bit to clear it.

In DIT mode, a pair of BMC zeros is shifted out when an underrun occurs (four bit times at 128 bfs). By shifting out a pair of zeros, a clock can be recovered on the receiver. To recover, reset the McASP and restart with the proper initialization.

In TDM mode, during an underrun case, a long stream of zeros are shifted out causing the DACs to mute. To recover, reset the McASP and start again with the proper initialization.

18.5.4.15.2 Buffer Overrun Error-Receiver

A buffer overrun occurs when a serializer is instructed to transfer data from XRSRn shift register to XRBUFn receiver buffer, but the corresponding MCASP_RXBUFn register has not yet been read since the last time the transfer occured. When this occurs, the receiver state machine sets the overrun flag - ROVRN. However, the individual serializer writes over the data in the XRBUFn buffer register (destroying the previous sample) and continues shifting.

An overrun is checked only once per time slot. The MCASP_RXSTAT[0] ROVRN flag is set when an overrun condition occurs. It is possible that an overrun occurs on one time slot but then the host catches up and does not cause an overrun on the following time slots. However, once the ROVRN flag is set, it remains set until the host explicitly writes a 1 to the ROVRN bit to clear the ROVRN bit.

18.5.4.15.3 DATA Port Error - Transmitter

A transmit DATA port error, as indicated by the XDMAERR flag in the MCASP_TXSTAT register, occurs when the DMA or device CPU writes more words to the DATA port of the McASP than it should.

The MCASP_TXSTAT[7] XDMAERR=0b1 indicates that the DMA or device CPU wrote too many words to the McASP DATA port for a given transmit DMA event. Writing too few words results in a transmit underrun error setting XUNDRN in MCASP_TXSTAT.

While XDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or device CPU. The McASP transmitter and the DMA must be reinitialized to resynchronize them.

18.5.4.15.4 DATA Port Error - Receiver

A receive DATA port error, as indicated by the RDMAERR flag in the MCASP_RXSTAT register, occurs when the DMA or device CPU reads more words from the DATA port of the McASP than it should.

The MCASP_RXSTAT[7] RDMAERR indicates that the DMA or device CPU read too many words from the McASP DATA port for a given receive AREVT event. Reading too few words results in a receiver overrun error setting ROVRN in MCASP_RXSTAT.

While RDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or device CPU. The McASP receiver and the DMA must be reinitialized to resynchronize them.

18.5.4.15.5 Unexpected Frame Sync Error

An unexpected frame sync occurs in when:

- in burst mode and TDM mode, the next active edge of the frame sync occurs early such that the current slot will not be completed by the time the next slot is scheduled to begin.
- in TDM mode, an unexpected frame sync occurs also if the frame sync does NOT occur exactly during the correct bit clock (not a cycle earlier or later) and before slot 0.

When an unexpected frame sync occurs, there are two possible actions depending upon when the unexpected frame sync occurs:

1. **Early:** An early unexpected frame sync occurs when the McASP is in the process of completing the current frame and a new frame sync is detected (not including overlap that occurs due to a 1 or 2 bit frame sync delay). When an early unexpected frame sync occurs:

- Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
- Current frame is not resynchronized. The number of bits in the current frame is completed. The next frame sync, which occurs after the current frame is completed, will be resynchronized.

2. **Late:** A late unexpected frame sync occurs when there is a gap or delay between the last bit of the previous frame and the first bit of the next frame. When a late unexpected frame sync occurs (as soon as the gap is detected):
   - Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
   - Resynchronization occurs upon the arrival of the next frame sync.

Late frame sync is detected the same way in burst mode and TDM mode. However, in burst mode, late frame sync is not meaningful and its interrupt enable should not be set.

18.5.4.15.6 Clock Failure Detection

18.5.4.15.6.1 Clock Failure Check Startup

It is initially expected of the clock failure circuits to generate an error until at least one measurement is taken. Therefore, the clock failure interrupts, clock switch, and mute functions should not be enabled immediately, but only after a specific startup procedure.

To start the transmit clock failure check procedure:

1. Configure the transmit clock failure detect logic (XMIN, XMAX, XPS) in the transmit clock check control register (MCASP_TXCLKCHK).
2. Clear the transmit clock failure flag (XCKFAIL) in the transmit status register (MCASP_TXSTAT).
3. Wait until the first measurement is taken (> 32 AHCLKX clock periods).
4. Verify that no clock failure is detected.
5. Repeat Step 2 through Step 4 until the clock is running and is no longer issuing clock failure errors.
6. After the transmit clock is measured and falls within the acceptable range, the following can be enabled:
   1. The transmit clock failure interrupt enable bit (XCKFAIL) in the transmitter interrupt control register (MCASP_EVTCTLX)

To start the receive clock failure check procedure:

1. Configure receive clock failure detect logic (RMIN, RMAX, RPS) in the receive clock check control register (MCASP_RXCLKCHK).
2. Clear receive clock failure flag (RCKFAIL) in the receive status register (MCASP_RXSTAT).
3. Wait until first measurement is taken (> 32 AHCLKR clock periods).
4. Verify no clock failure is detected.
5. Repeat steps 2–4 until clock is running and is no longer issuing clock failure errors.
6. After the receive clock is measured and falls within the acceptable range, the following may be enabled:
   1. the receive clock failure (RCKFAIL) interrupt enable bit in the receive interrupt control register (MCASP_EVTCTLR)

18.5.4.15.6.2 Transmit Clock Failure Check and Recovery

The transmit clock failure check circuit (see Figure 18-103) works off the internal McASP interface clock and the external high-frequency serial clock (AHCLKX). It continually counts the number of interface clocks for every 32 high-rate serial clock (AHCLKX) periods, and stores the count in XCNT of the transmit clock check control register (MCASP_TXCLKCHK) every 32 high-rate serial clock cycles.

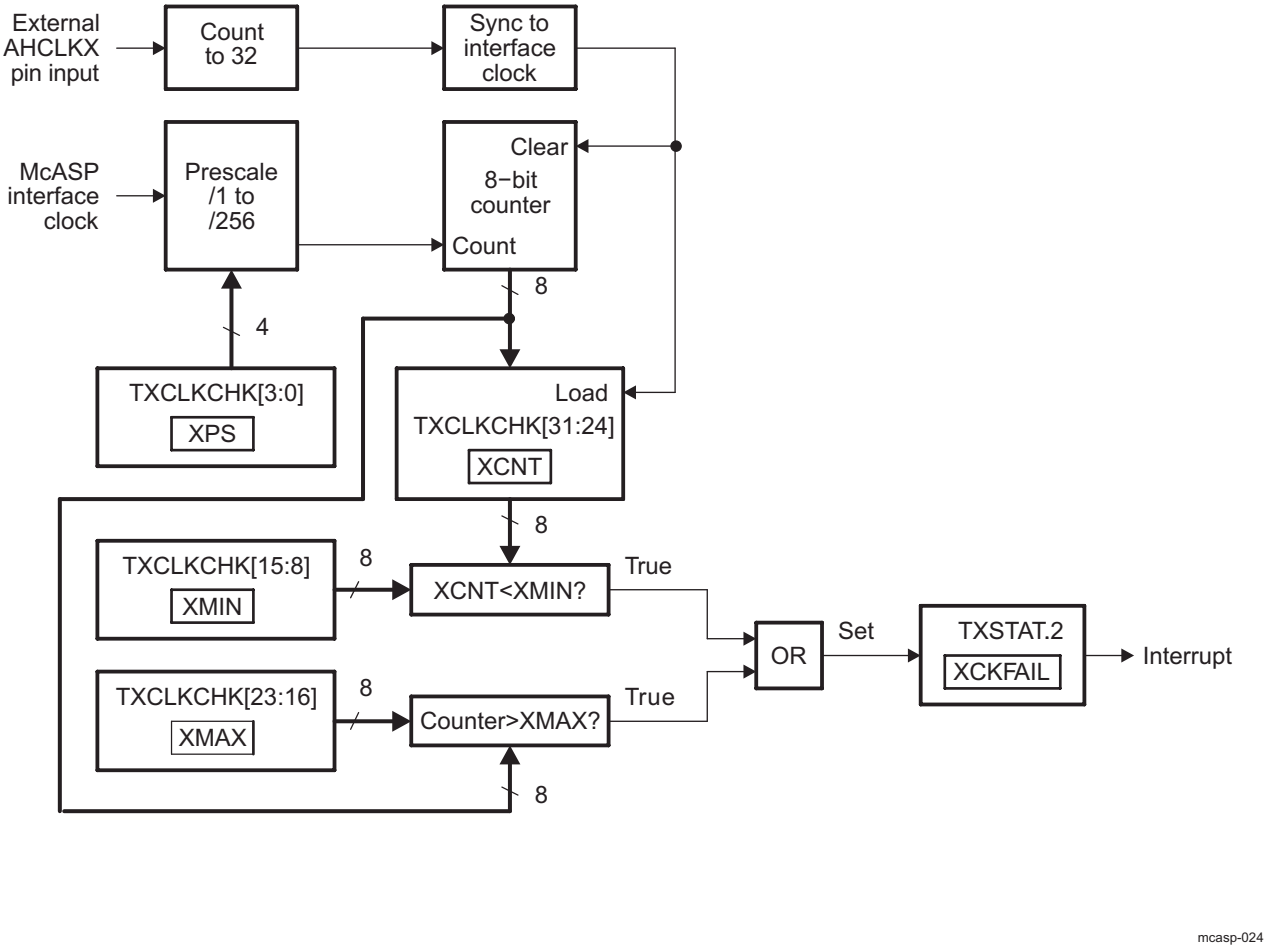
The logic compares the count against a user-defined minimum allowable boundary (XMIN), and automatically flags an interrupt (XCKFAIL in MCASP_TXSTAT) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is less than XMIN. The logic continually compares the current count (from the running interface clock counter) to the maximum allowable boundary (XMAX). This is so that if the external clock completely stops, the counter value is not copied to XCNT. An out-of-range maximum condition occurs when the count is greater than XMAX. The XMIN and XMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

For the transmit clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

If a clock failure is detected, the transmit clock failure flag (XCKFAIL) in MCASP_TXSTAT is set. This causes an interrupt if the transmit clock failure interrupt enable bit (XCKFAIL) in MCASP_EVTCTLX is set.

Figure 18-103. Transmit Clock Failure Detection Circuit Block Diagram



18.5.4.15.6.3 Receive Clock Failure Check and Recovery

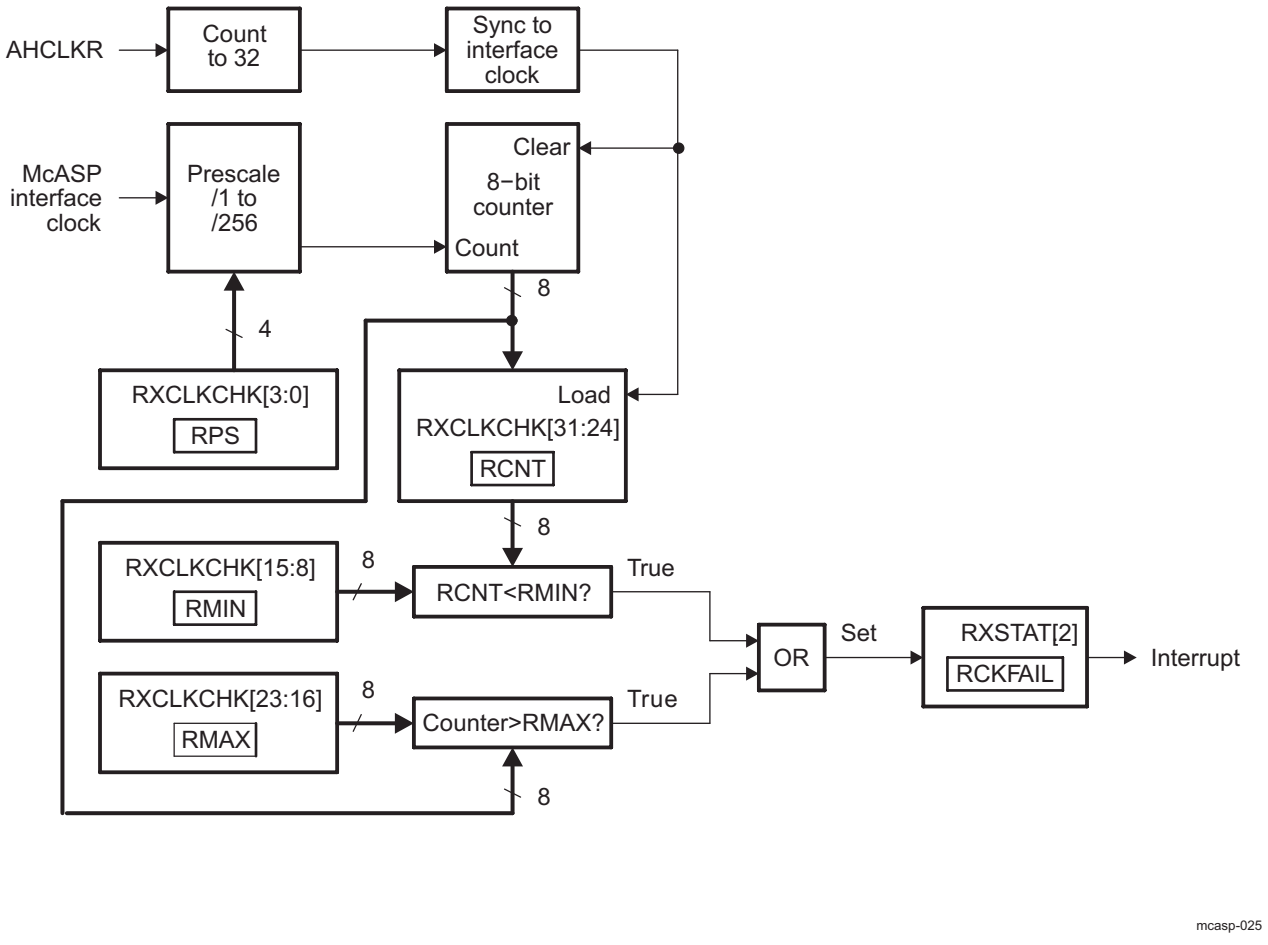
The receive clock failure check circuit (see Figure 18-104) works off both the internal McASP interface clock and the high-frequency serial clock (AHCLKR) coming from the device clock generator. It continually counts the number of interface clocks for every 32 high rate serial clock (AHCLKR) periods, and stores the count in RCNT of the receive clock check control register (MCASP_RXCLKCHK) every 32 high rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (RMIN) and automatically flags an event (RCKFAIL in MCASP_RXSTAT) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is smaller than RMIN. The logic continually compares the current count (from the running interface clock counter) against the maximum allowable boundary (RMAX). This is in case the external clock completely stops, so that the counter value is not copied to RCNT. An out-of-range maximum condition occurs when the count is greater than RMAX. Note that the RMIN and RMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate either that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

In order for the receive clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

Figure 18-104. Receive Clock Failure Detection Circuit Block Diagram



18.5.5 McASP Low-Level Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the McASP module.

18.5.5.1 Global Initialization

18.5.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the McASP module is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the McASP (for more information, see Section 18.5.3, *McASP Integration*, and Section 18.5.2, *McASP Environment*).

Table 18-335, describes the global initialization of surrounding modules.

Table 18-335. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module functional and interface clocks must be enabled. (See Section 3.6, *Clock Management Functional Description*, in Chapter 3, *Power, Reset, and Clock Management*.)
Control module	Module-specific pad muxing and other pad configurations must be set in the control module. (See Section 13.4.6.1, *Pad Configuration Registers*, in Chapter 13, *Control Module*).
(Optional) IRQ_CROSSBAR	Interrupt crossbar configuration must be done to enable the interrupts from the McASP. For more details on IRQ_CROSSBAR module, see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.
(Optional) DMA_CROSSBAR	DMA configuration must be done to enable the McASP DMA data channel requests. For more information on DMA_CROSSBAR module configuration, see Section 13.4.6.5, *DMA_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.
(Optional) L4_PER2 and L3_MAIN Interconnects	For more information about the interconnect configuration, see Section 9.2.1, *L3_MAIN Interconnect Overview* in Section 9.2, *L3 Interconnect*.

NOTE: The IRQ_CROSSBAR and the DMA_CROSSBAR configurations are required when the interrupt and DMA-based communication modes are used. Further initialization of the selected IRQ and DMA controllers of the host CPU must be done for full functionality of the McASP DMA and IRQ lines.

18.5.5.1.2 McASP Global Initialization

18.5.5.1.2.1 Main Sequence – McASP Global Initialization for DIT-Transmission

The procedure in Table 18-336 initializes the McASP serializers transmitters to operate in DIT-mode (S/PDIF-transmission protocol) after a power-on reset (POR).

CAUTION

Before performing McASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the MCASP_GBLCTL register.

Table 18-336. McASP Transmitters Global Initialization for DIT-Mode Operation

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different McASP components.	MCASP_GBLCTL[12:8]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[12:8]	=0x00
3. Configure the local power management.	PWRIDLESYSCONFIG[1:0] IDLE_MODE	0x1
4. Configure the transmit format unit.	See Section 18.5.5.1.2.1.1.	
5. Configure the transmit frame sync generator.	See Section 18.5.5.1.2.1.2.	
6. Configure the transmit clock generator.	See Section 18.5.5.1.2.1.3.	
7. Configure the TDM sequencer—set all slots active.	MCASP_TXTDM[31:0] XTDMS	0xFFFF FFFF
8. Configure the desired n-th serializer (n=0 to 3) for transmit mode operation. (1)	MCASP_XRSRCTLn [1:0] SRMOD	0x1
9. Configure the McASP pins functionality.	See Section 18.5.5.1.2.1.4.	
10. Enable the McASP DIT - transmission mode.	MCASP_TXDITCTL[0] DITEN	0x1 (2)
11. Configure DIT-specific subframe fields.	See Table 18-341.	
12. Release from reset state the divider that outputs the AHCLKX clock. (3)	MCASP_GBLCTL[9] XHCLKRST	0x1
13. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[9] XHCLKRST	=0x1
14. Release from reset state the divider that outputs the ACLKX clock. (3)	MCASP_GBLCTL[8] XCLKRST	0x1
15. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[8] XCLKRST	=0x1

(1) For an unused serializer n, write MCASP_XRSRCTLn [1:0] SRMOD=0x0 to disable it.
(2) This globally configures all active transmitters to operate in DIT-mode.
(3) During reset state the local McASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP_AHCLKXCTL and MCASP_ACLKXCT registers are ignored; hence, the transmission clock does not stop during the reset state of the dividers.

18.5.5.1.2.1.1 Subsequence – Transmit Format Unit Configuration for DIT-Transmission

The procedure in Table 18-337 configures the transmit frame format unit of the McASP module for a DIT-transmission.

NOTE:

- The first transmit data bit always has a 0-bit delay.
- The bitstream is always transmitted in least-significant-bit (LSB)-first order.
- Pad value for extra bits in a certain slot is always 0.

Table 18-337. Transmit Format Unit Configuration for DIT-Transmission

Step	Register/Bit Field/Programming Model	Value
Configure the slot size to 32 bits.	MCASP_TXFMT[7:4] XSSZ	0xF
IF: the data to transmit is left- aligned	Software test condition	
Set data mask in the range 0xFFFF FF00 – 0xFFFF 0000.	MCASP_TXMASK[31:0] XMASK	0x- (1)
Rotate data right by a multiple-of-4- bit positions.	MCASP_TXFMT[2:0] XROT	0x- (1)
ELSE		
Set data mask in the range 0x00FF FFFF– 0x0000 FFFF.	MCASP_TXMASK[31:0] XMASK	0x- (1)
Rotate data right by 0-bit positions.	MCASP_TXFMT[2:0] XROT	0x0
ENDIF		

(1) Refer to Section 18.5.4.4.1, *Transmit Fromat Unit* and Section 18.5.4.4.1.2, *DIT-Mode Transmission Data Alignment Settings.*

Table 18-337. Transmit Format Unit Configuration for DIT-Transmission (continued)

Step	Register/Bit Field/Programming Model	Value
Select to write data to active serializers transmit buffers using peripheral (CFG) or DATA port	MCASP_TXFMT[3] XBUSEL	0x-

18.5.5.1.2.1.2 Subsequence – Transmit Frame Synchronization Generator Configuration for DIT-Transmission

The procedure in Table 18-338 configures the transmit frame synchronization generator of the McASP module.

NOTE: The frame synchronization signal is always rising-edge active and always has a single-bit width.

Table 18-338. Transmit Frame-Synchronization Generator Configuration for DIT-Transmission

Step	Register/Bit Field/Programming Model	Value
Select 384-slot size block.	MCASP_TXFMCTL[15:7] XMOD	0x180
Select internally-generated transmit frame sync.	MCASP_TXFMCTL[1] FSXM	0x1

18.5.5.1.2.1.3 Subsequence – Transmit Clock Generator Configuration for DIT-Transmission

NOTE: By default, the ACLKX and AHCLKX clocks are generated only from the McASP internal clock source.

The procedure in Table 18-339 configures the transmit clock generator of the McASP module.

Table 18-339. Transmit Clock Generator Configuration in DIT-Mode

Step	Register/Bit Field/Programming Model	Value
Set the divisor for the internally generated high frequency clock– AHCLKX.	MCASP_AHCLKXCTL[11:0] HCLKXDIV	0x-
Set he divisor for the internally generated transmission clock– ACLKX.	MCASP_ACLKXCTL[4:0] CLKXDIV	0x-
Configure the transmit clock failure detect logic.	See Section 18.5.4.15.6.1, *Clock Failure Check Startup*.	

18.5.5.1.2.1.4 Subsequence - McASP Pins Functional Configuration

The procedure in Table 18-340 configures the McASP pins for McASP functionality.

Table 18-340. McASP Pins Functional Configuration

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have McASP functionality.	MCASP_PFUNC[31:0]	0x0
Configure the McASP pins as outputs: AFSX AHCLKX ACLKX Desired i-th McASP data pin AXRi is configured as an output for DIT-transmission.	MCASP_PDIR[28] AFSX; MCASP_PDIR[27] AHCLKX; MCASP_PDIR[26] ACLKX; MCASP_PDIR [i] AXRi	0x1 0x1 0x1 0x1

18.5.5.1.2.1.5 Subsequence – DIT-specific Subframe Fields Configuration

The procedure in Table 18-341 configures the DIT-specific subframe fields as part of the S/PDIF format data.

Table 18-341. DIT-Specific Subframe Fields Configuration

Step	Register/Bit Field/Programming Model	Value
Configure the valid bit value for odd time slots.	MCASP_TXDITCTL[3] VB	0x-
Configure the valid bit value for even time slots.	MCASP_TXDITCTL[2] VA	0x-
Configure the user data bit for each subframe A and B in a 384-slot S/PDIF block.	MCASP_DITUDRAi[31:0] DITUDRAi, where i = 0 to 5 MCASP_DITUDRBi[31:0] DITUDRBi, where i = 0 to 5	0x- 0x-
Configure the channel status bit for each subframe A and B in a 384-slot S/PDIF block.	MCASP_DITCSRAi[31:0], where i = 0 to 5 MCASP_DITCSRBi[31:0], where i = 0 to 5	0x- 0x-

18.5.5.1.2.2 Main Sequence – McASP Global Initialization for TDM-Reception

The procedure in Table 18-342 initializes a McASP serializer n receiver(s) to operate in TDM-mode (the only mode supported by McASP receivers) after a power-on reset (POR). This is used for I2S (2-slot TDM) and other TDM-based audio protocols reception.

CAUTION

Before performing McASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the MCASP_GBLCTL register.

NOTE: The McASP receivers support only TDM-frames (including 384-TDM frames) reception. DIT-frames reception (i.e. S/PDIF stream) can be implemented indirectly via an external DIR-chip converter with DIT-input and TDM (I2S)-compatible output connected to device McASP receiver input (TDM-only compatible).

Table 18-342. McASP Receivers Global Initialization for TDM-Mode Operation

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different McASP receive components.	MCASP_GBLCTL[4:0]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[4:0]	=0x00
3. Configure the local power management.	PWRIDLESYSCONFIG[1:0] IDLE_MODE	0x1
4. Configure the receive format unit.	See Section 18.5.5.1.2.2.1.	
5. Configure the receive frame sync generator.	See Section 18.5.5.1.2.2.2.	
6. Configure the receive clock generator.	See Section 18.5.5.1.2.2.3.	
7. Program all bits -RTDMSk (where k=0 to 31) according to the time slot characteristics desired (positions of active versus inactive slots within a frame).	MCASP_RXTDM [k] RTDMSk , where k=0 to 31	0x-
8. Configure the desired n-th serializer for receive mode operation. (1)	MCASP_XRSRCTLn [1:0] SRMOD	0x2
9. Configure the McASP pins functionality.	See Section 18.5.5.1.2.2.4.	

(1) For an unused serializer n, write MCASP_XRSRCTLn [1:0] SRMOD=0x0 to disable it.

Table 18-342. McASP Receivers Global Initialization for TDM-Mode Operation (continued)

Step	Register/Bit Field/Programming Model	Value
10. Optional: Configure a McASP Rx channel for a loopback operation (TDM mode only) in MCASP_LBCTL [31:0].	See Section 18.5.4.14.1, *Loopback Mode Configurations*.	0x-(2)
11. Release from reset state the divider that outputs the AHCLKR clock.(3) See also (4).	MCASP_GBLCTL[1] RHCLKRST	0x1
12. Poll the bit to ensure that it is successfully latched in the register. See also (4).	MCASP_GBLCTL[1] RHCLKRST	=0x1
13. Release from reset state the divider that outputs the ACLKR clock. (3) See also (5).	MCASP_GBLCTL[0] RCLKRST	0x1
14. Poll the bit to ensure that it is successfully latched in the register. See also (5).	MCASP_GBLCTL[0] RCLKRST	=0x1

(2) In this case the receiver clock and frame sync are derived from the McASP transmitter logic, so MCASP_ACLKXCTL[6] ASYNC must be set to 0b0. Neither McASP internal receiver clock and frame sync generators, nor external clock and frame sync source are used.

(3) During reset state the local McASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP_AHCLKRCTL and MCASP_ACLKRCTL registers are ignored; hence, the reception clock does not stop during the reset state of the dividers.

(4) This step is necessary even if external high-frequency serial clocks are used.

(5) This step can be skipped if external serial clocks are used and they are running.

18.5.5.1.2.2.1 Subsequence – Receive Format Unit Configuration in TDM Mode

The procedure in Table 18-343 configures the receive frame format unit of the McASP module for TDM slots reception.

Table 18-343. Receive Format Unit Configuration for TDM-Reception

Step	Register/Bit Field/Programming Model	Value
Configure the desired TDM-slot size	MCASP_RXFMT[7:4] RSSZ	0x-(1)
Set data mask out value (0x0000 0000 - 0xFFFF FFFF).	MCASP_RXMASK[31:0] RMASK	0x-(2)
Select a padding value for masked-out bits.	MCASP_RXFMT[14:13] RPAD	0x-
Specify position (0x0-0x1F) of the bit in corresponding register MCASP_RXBUFn which value to be used as a pad value in case MCASP_RXFMT[14:13] RPAD=0x2.	MCASP_RXFMT[12:8] RPBIT	0x-
Rotate data right by a multiple of 4- bit positions.	MCASP_RXFMT[2:0] RROT	0x- (3)
Received stream bit order (LSB- or MSB-first). Must be set to 0x1 for an I2S stream reception (MSB-first).	MCASP_RXFMT[15] RRVRS	0x- (3)
Specify a delay between frame sync and first bit of data in number of bits. Must be set to 0x1 for an I2S stream reception.	MCASP_RXFMT[17:16] RDATDLY	0x-
Select to read data from active serializers receive buffers using peripheral (CFG) or DATA port	MCASP_RXFMT[3] RBUSEL	0x-

(1) Refer to Section 18.5.4.4.2, *Receive Format Unit*, regarding options for received TDM-slot sizes.

(2) For more details on Rx masking value, refer to Section 18.5.4.4.2.1, *TDM - Mode Reception Data Alignment Settings*

(3) For more details on rotation and received TDM stream bit order, refer to Section 18.5.4.4.2.1, *TDM - Mode Reception Data Alignment Settings* and Table 18-330, *McASP RFU Settings*.

18.5.5.1.2.2.2 Subsequence – Receive Frame Synchronization Generator Configuration in TDM Mode

The procedure in Table 18-344 configures the transmit frame synchronization generator of the McASP module.

NOTE: The same bit - MCASP_ACLKXCTL[6] ASYNC which is used to determine if McASP receivers and transmitters work synchronously on the same clock, is also used to define if receiver frame sync is derived from the transmit frame sync generator, or generated independently in the receiver (either inernally or externally sourced). Hence, the settings in below table Table 18-344 have no effect, if MCASP_ACLKXCTL[6] ASYNC = 0.

Table 18-344. Receive Frame-Synchronization Generator Configuration for TDM-Reception

Step	Register/Bit Field/Programming Model	Value
Select number of TDM slots per frame. Must be set to 0x2, in case of an I2S-reception. For more details on frame-sync generator, refer to Section 18.5.4.2.3.	MCASP_RXFMCTL[15:7] RMOD	0x-(1)
Choose the receive frame sync width -single bit/single word. For more details on frame-sync generator, refer to Section 18.5.4.2.3.	MCASP_RXFMCTL[4] FRWID	0x-
Select start of received frame sync polarity - rising /falling edge. For more details on frame-sync generator, refer to Section 18.5.4.2.3.	MCASP_RXFMCTL[0] FSRP	0x-
IFreceive frame sync - FS is internally generated	Software test condition	
Select internally- generated receive frame sync. For more details on frame-sync generator, refer to Section 18.5.4.2.3.	MCASP_RXFMCTL[1] FSRM	0b1
If McASP receiver is required to output internally generated frame, AFSR pin must be set as an output in step 9 of the sequence documented in the Table 18-342. This must not be done in current step because the frame control register - MCASP_TXFMCTL must be appropriately configured prior to AFSR pin outputting a frame to an external device.	MCASP_PDIR[31] AFSR	0b1
ELSE		
Select externally- generated receive frame sync. For more details on frame-sync generator, refer to Section 18.5.4.2.3.	MCASP_RXFMCTL[1] FSRM	0b0
Setup the AFSR pin as input (device level: mcaspi_fsr)	MCASP_PDIR[31] AFSR	0b0
ENDIF		
To generate McASP receive frame sync in receiver logic, select an asynchronous frame sync.	MCASP_ACLKXCTL[6] ASYNC	0b1

(1) Must be set to 0x180 in case of 384-TDM slot frame reception from a DIR component I2S-output. For more details on TDM-frame settings, refer to Section 18.5.4.9.2 .

18.5.5.1.2.2.3 Subsequence – Receive Clock Generator Configuration

The procedure in Table 18-345 configures the receive clock generator of the McASP module.

NOTE: The settings in below table Table 18-345 have no effect, if MCASP_ACLKXCTL[6] ASYNC = 0 (i.e. receive clock is sourced from the inverted version of the transmit clock). For example, such is the case when McASP loopback mode is used.

Table 18-345. Receive Clock Generator Configuration

Step	Register/Bit Field/Programming Model	Value
To use the McASP receive clock generator, select an asynchronous receiver clock schema (ASYNC=1). Otherwise an inverted version of transmit clock XCLK is used (receiver synchronized with transmitter).	MCASP_ACLKXCTL[6] ASYNC	0b1
IF receive clock - RCLK is internally generated	Software test condition	
The high-speed receive clock - AHCLKR is internally generated based on AUXCLK		
Select an internally-generated high-frequency clock.	MCASP_AHCLKRCTL[15] HCLKRM	0b1
Select the internal high-speed clock source polarity: non-inverted or inverted.	MCASP_AHCLKRCTL[14] HCLKRP	0x-
Set the divisor for the internally generated high-frequency clock – AHCLKR in range (1 - 4096).	MCASP_AHCLKRCTL[11:0] HCLKRDIV	0x-
Select an internally-generated receive clock.	MCASP_ACLKRCTL[5] CLKRM	0b1
Receiver samples on rising/falling edge. Select Rx sampling on the rising edge if transmitter shifts out on falling edge, and vice versa.	MCASP_ACLKRCTL[7] CLKRP	0x-
Set the divisor for the internally generated receive clock– ACLKR in range (1 - 32).	MCASP_ACLKRCTL[4:0] CLKRDIV	0x-
Optional: If McASP receiver is required to output internally generated clock, ACLKR pin must be set as an output in step 9 of the sequence documented in the Table 18-342. This must not be done in current step because the clock control register - MCASP_ACLKRCTL must be appropriately configured prior to ACLKR pin outputting a receive clock to an external device.	MCASP_PDIR[29] ACLKR	0b1
ELSE		
Select an externally-generated receive clock. Note that in this case the AHCLKR signal path and the CLKRDIV divider are NOT used.	MCASP_ACLKRCTL[5] CLKRM	0b0
Receiver samples on rising/falling edge. Select Rx sampling on the rising edge if transmitter shifts out on falling edge, and vice versa.	MCASP_ACLKRCTL[7] CLKRP	0x-
Setup an input directon for the ACLKR pin	MCASP_PDIR[29] ACLKR	0b0
ENDIF		
Configure the transmit clock failure detect logic.	See Section 18.5.4.15.6.1, *Clock Failure Check Startup*.	

18.5.5.1.2.2.4 Subsequence—McASP Receiver Pins Functional Configuration

The procedure in Table 18-346 configures the McASP pins for McASP functionality.

Table 18-346. McASP Receiver Pins Functional Configuration

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have McASP functionality.	MCASP_PFUNC[31:0]	0x0
Configure the McASP pins direction: AFSR ACLKR Desired n-th McASP data pin AXRn is configured as an input for receiving.	MCASP_PDIR[31] AFSR; MCASP_PDIR[29] ACLKR; MCASP_PDIR[n] AXRn;	0x-(1) 0x- (2) 0x0

(1) See Table 18-344.

(2) For more details on McASP clock configurations, refer to Table 18-345.

18.5.5.1.2.3 Main Sequence – McASP Global Initialization for TDM -Transmission

The procedure in Table 18-347 initializes a McASP serializer n transmitter(s) to operate in TDM-mode after a power-on reset (POR). This is used for I2S (2-slot TDM) and other TDM-based audio protocols transmission.

CAUTION

Before performing McASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the MCASP_GBLCTL register.

Table 18-347. McASP Transmitters Global Initialization for TDM-Mode Operation

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different McASP transmit components.	MCASP_GBLCTL[12:8]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[12:8]	=0x00
3. Configure the local power management.	PWRIDLESYSCONFIG[1:0] IDLE_MODE	0x1
4. Configure the transmit format unit.	See Section 18.5.5.1.2.3.1.	
5. Configure the transmit frame sync generator.	See Section 18.5.5.1.2.3.2.	
6. Configure the transmit clock generator.	See Section 18.5.5.1.2.3.3.	
7. Program all bits - XTDMSk, where k=0 to 31, according to the time slot characteristics desired (positions of active versus inactive slots within a frame).	MCASP_TXTDM [k] XTDMSk, where k=0 to 31 (1)	0x-
8. Configure the desired n-th serializer for transmit mode operation. (2)	MCASP_XRSRCTLn[1:0] SRMOD;	0x1
9. Setup all active transmitters to operate in TDM mode.	MCASP_TXDITCTL[0] DITEN	0x0 (3)
10. Configure the McASP pins functionality.	See Section 18.5.5.1.2.3.4.	
11. Optional: Configure a McASP Tx channel for loopback operation (TDM mode only) in MCASP_LBCTL [31:0].	See Section 18.5.4.14.1, *Loopback Mode Configurations*.	0x-
12. Release from reset state the divider that outputs the AHCLKR clock. See (4)	MCASP_GBLCTL[9] XHCLKRST	0x1
13. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[9] XHCLKRST	=0x1
14. Release from reset state the divider that outputs the ACLKR clock. See (4)	MCASP_GBLCTL[8] XCLKRST	0x1
15. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[8] XCLKRST	=0x1

(1) Appropriately program in bitfield MCASP_XRSRCTLn [3:2] DISMOD, the desired level (high-impedance state, 0, or 1) at AXRn output, during time of inactive slots. Note, that this setting does NOT apply when all slots are programmed to be active within a frame (in particular DIT-mode).

(2) For an unused serializer n, write MCASP_XRSRCTLn [1:0] SRMOD=0x0 to disable it.

(3) All active transmit channels operate either in TDM mode or in DIT mode depending on DITEN value. There is no option to choose Tx Mode between DIT and TDM separately per serializer transmitter.

(4) During reset state the local McASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP_AHCLKX and MCASP_ACLKX registers are ignored; hence, the transmission clock does not stop during the reset state of the dividers.

18.5.5.1.2.3.1 Subsequence – Transmit Format Unit Configuration in TDM Mode

The procedure in Table 18-348 configures the transmit frame format unit of the McASP module for TDM slots transmission.

Table 18-348. Transmit Format Unit Configuration for TDM-Transmission

Step	Register/Bit Field/Programming Model	Value
Configure the desired TDM-slot size	MCASP_TXFMT[7:4] XSSZ	0x-(1)
Set data mask out value (0x0000 0000 - 0xFFFF FFFF).	MCASP_TXMASK[31:0] XMASK	0x-(2)
Select a padding value for masked-out bits.	MCASP_TXFMT[14:13] XPAD	0x-
Specify position (0x0-0x1F) of the bit in corresponding register MCASP_TXBUFn which value to be used as a pad value in case MCASP_TXFMT[14:13] XPAD=0x2.	MCASP_TXFMT[12:8] XPBIT	0x-
Rotate data right by a multiple of 4- bit positions.	MCASP_TXFMT[2:0] XROT	0x- (3)
transmitted stream bit order (LSB- or MSB-first). Must be set to 0x1 for an I2S stream transmission (MSB-first).	MCASP_TXFMT[15] XRVRS	0x- (3)
Specify a delay between frame sync and first bit of data in number of bits. Must be set to 0x1 for an I2S stream transmission.	MCASP_TXFMT[17:16] XDATDLY	0x-
Select to write data to active serializers transmit buffers using peripheral (CFG) or DATA port	MCASP_TXFMT[3] XBUSEL	0x-

(1) Refer to Section 18.5.4.4.1, *Transmit Format Unit* , regarding options for transmitted TDM-slot sizes.
(2) For more details on Tx masking value, refer to Section 18.5.4.4.1.1, *TDM - Mode Transmission Data Alignment Settings*
(3) For more details on rotation and transmitd TDM stream bit order, refer to Section 18.5.4.4.1.1, *TDM - Mode Transmission Data Alignment Settings* and Table 18-328, *McASP TFU TDM Mode Settings*.

18.5.5.1.2.3.2 Subsequence – Transmit Frame Synchronization Generator Configuration in TDM Mode

The procedure in Table 18-349 configures the transmit frame synchronization generator of the McASP module.

Table 18-349. Transmit Frame-Synchronization Generator Configuration for TDM-Transmission

Step	Register/Bit Field/Programming Model	Value
Select number of TDM slots per frame (2 - 32). Must be set to 0x2, in case of an I2S-transmission. For more details on frame-sync generator, refer to Section 18.5.4.2.3.	MCASP_TXFMCTL[15:7] XMOD	0x-
Choose the transmit frame sync width -single bit/single word. For more details on frame-sync generator, refer to Section 18.5.4.2.3.	MCASP_TXFMCTL[4] FXWID	0x-
Select start of transmit frame sync polarity - rising /falling edge. For more details on frame-sync generator, refer to Section 18.5.4.2.3.	MCASP_TXFMCTL[0] FSXP	0x-
IF transmit frame sync - FS is internally generated	Software test condition	
Select internally- generated transmit frame sync. For more details on frame-sync generator, refer to Section 18.5.4.2.3.	MCASP_TXFMCTL[1] FSXM	0b1
If McASP transmitter is required to output internally generated frame, AFSX pin must be set as an output in step 10 of the sequence documented in the Table 18-347. This must NOT be done in current step because the frame control register - MCASP_TXFMCTL must be appropriately configured prior to AFSX pin outputting a frame sync to an external device.	MCASP_PDIR[28] AFSX	0b1
ELSE		
Select externally- generated transmit frame sync. For more details on frame-sync generator, refer to Section 18.5.4.2.3.	MCASP_TXFMCTL[1] FSXM	0b0
Setup the AFSX pin as input	MCASP_PDIR[28] AFSX	0b0

18.5.5.1.2.3.3 Subsequence – Transmit Clock Generator Configuration for TDM Cases

The procedure in Table 18-350 configures the transmit clock generator of the McASP module.

Table 18-350. Transmit Clock Generator Configuration for TDM Cases

Step	Register/Bit Field/Programming Model	Value
IF transmit clock - XCLK is internally generated	Software test condition	
IF high-speed transmit clock - AHCLKX is internally generated based on AUXCLK	Software test condition	
Select an internally-generated high-frequency clock.	MCASP_AHCLKXCTL[15] HCLKXM	0b1
Select the high-frequency clock source polarity: non-inverted or inverted.	MCASP_AHCLKXCTL[14] HCLKXP	0x-
Set the divisor for the internally generated high-frequency clock – AHCLKX in range (1 - 4096).	MCASP_AHCLKXCTL[11:0] HCLKXDIV	0x-
Optional: If McASP transmitter is required to output internally generated high-frequency clock, AHCLKX pin must be set as an output in step 10 of the sequence documented in the Table 18-347. This must NOT be done in current step because the clock control register - MCASP_AHCLKXCTL must be appropriately configured prior to AHCLKX pin outputting a high-speed clock to an external device.	MCASP_PDIR[27] AHCLKX	0b1
ELSE		
Select an externally-generated high frequency clock (HCLKXDIV divider can not be used).	MCASP_AHCLKXCTL[15] HCLKXM	0b0
Select the high-speed transmit clock source polarity: non-inverted or inverted.	MCASP_AHCLKXCTL[14] HCLKXP	0x-
Setup an input directon for the AHCLKX pin	MCASP_PDIR[27] AHCLKX	0b0
ENDIF		
Select an internally-generated transmit clock.	MCASP_ACLKXCTL[5] CLKXM	0b1
Transmitter samples on rising/falling edge. Select Tx shifting out data on the rising edge if receiver samples on falling edge, and vice versa.	MCASP_ACLKXCTL[7] CLKXP	0x-
Set the divisor for the internally generated transmit clock– ACLKX in range (1 - 32).	MCASP_ACLKXCTL[4:0] CLKXDIV	0x-
Optional: If McASP transmitter is required to output internally generated clock, ACLKX pin) must be set as an output in step 10 of the sequence documented in the Table 18-347. This must NOT be done in current step because the clock control register - MCASP_ACLKXCTL must be appropriately configured prior to ACLKX pin outputting a transmit clock to an external device.	MCASP_PDIR[26] ACLKX	0b1
ELSE		
Select an externally-generated transmit clock. Note that in this case the AHCLKX signal path and the CLKXDIV divider are NOT used.	MCASP_ACLKXCTL[5] CLKXM	0b0
Transmitter samples on rising/falling edge. Select Tx shifting out data on the rising edge if receiver samples on falling edge, and vice versa.	MCASP_ACLKXCTL[7] CLKXP	0x-
Setup an input directon for the ACLKX pin	MCASP_PDIR[26] ACLKX	0b0
ENDIF		
Configure the transmit clock failure detect logic.	See Section 18.5.4.15.6.1, *Clock Failure Check Startup*.	

18.5.5.1.2.3.4 Subsequence—McASP Transmit Pins Functional Configuration

The procedure in Table 18-351 configures the McASP pins for McASP functionality.

Table 18-351. McASP Transmit Pins Functional Configuration

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have McASP functionality.	MCASP_PFUNC[31:0]	0x0
Configure the McASP pins direction: AFSX AHCLKX ACLKX Desired n-th McASP data pin AXRn is configured as an ouput for transmission.	MCASP_PDIR[28] AFSR; MCASP_PDIR[27] AHCLKR; MCASP_PDIR[26] ACLKR; MCASP_PDIR[n] AXRn	0x-(1) 0x-(2) 0x- (2) 0x1

(1) See Table 18-349.

(2) For more details on McASP clock configurations, refer to Table 18-345.

18.5.5.2 Operational Modes Configuration

18.5.5.2.1 McASP Transmission Modes

18.5.5.2.1.1 Main Sequence – McASP DIT- /TDM- Polling Transmission Method

Figure 18-105 shows the McASP DIT-/TDM- polling method.

Figure 18-105. McASP DIT- /TDM- Transmission Polling Method

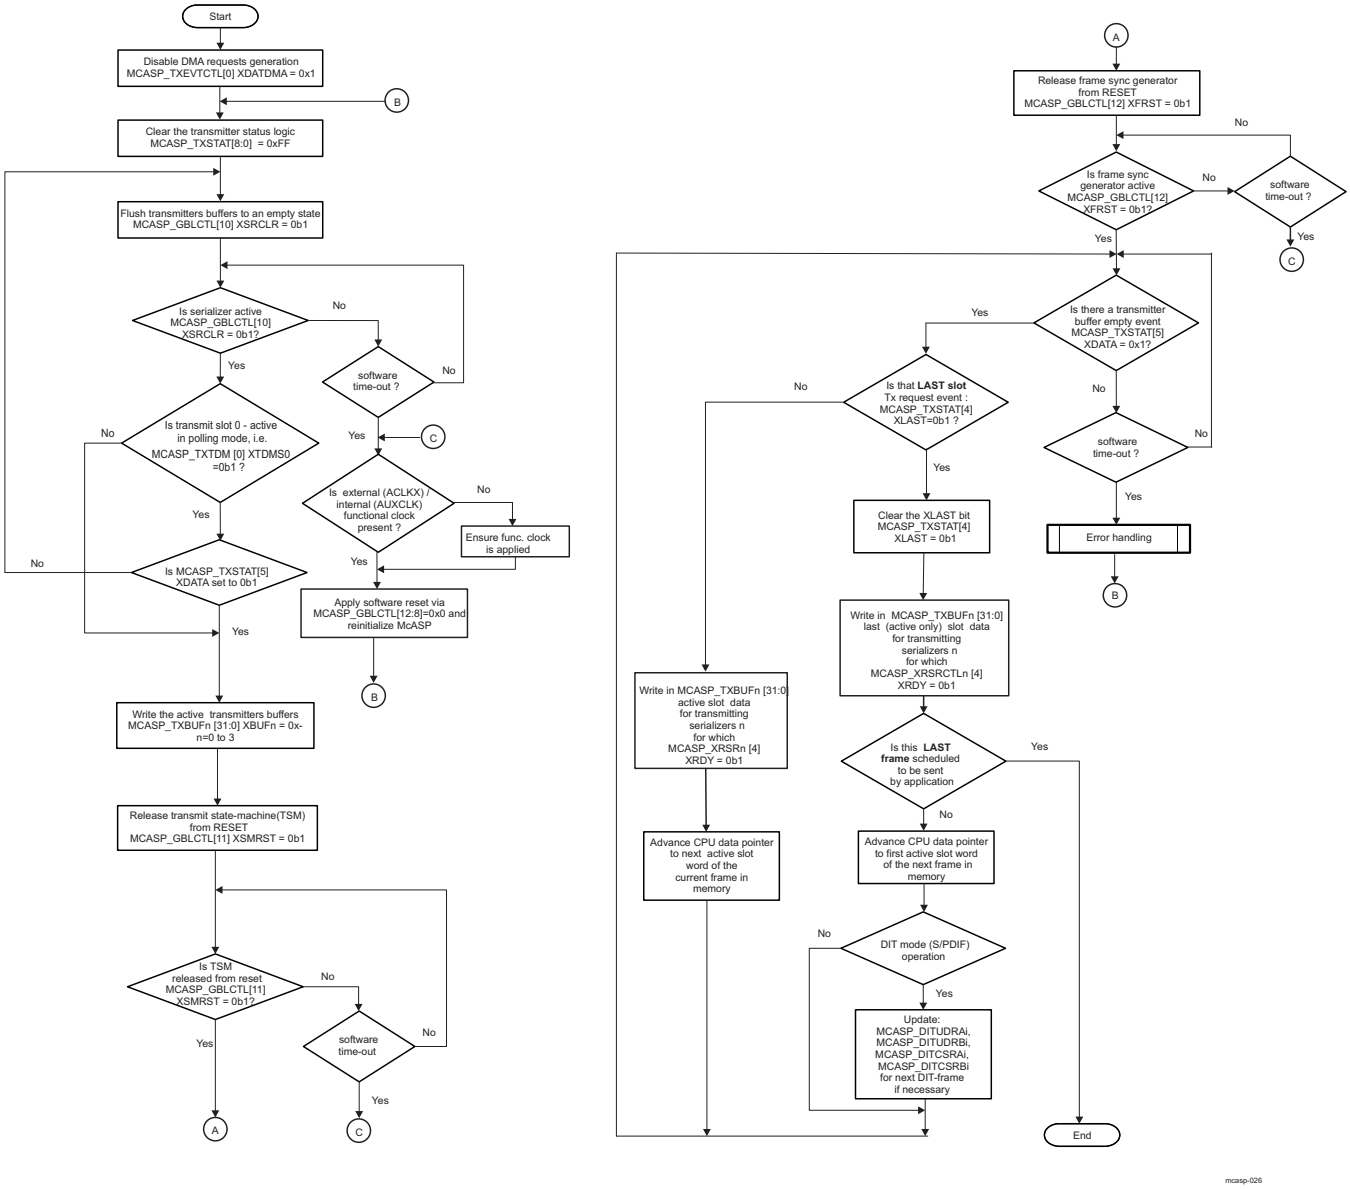


Table 18-352 summarizes the register call for the transmission DIT-/TDM- polling mode.

Table 18-352. Register Call Summary for Main Sequence – McASP DIT-/TDM- Transmission Polling Method

Register Name
MCASP_XEVTCTL
MCASP_TXSTAT
MCASP_GBLCTL

MCASP_DITUDRBi (i=0 to 5)
MCASP_DITCSRAi (i=0 to 5)

Table 18-352. Register Call Summary for Main Sequence – McASP DIT-/TDM- Transmission Polling Method (continued)

Register Name
MCASP_DITCSRBi (i=0 to 5)

Table 18-353 summarizes the subprocess call for the DIT-/TDM- transmission polling mode.

Table 18-353. Subprocess Call Summary for Main Sequence – McASP DIT-/TDM- Transmission Polling Method

Subprocess Name	Cross-Reference
Error handling	Figure 18-111

18.5.5.2.1.2 Main Sequence – McASP DIT- /TDM - Interrupt Transmission Method

Figure 18-106 shows the initial setup for interrupt-based transmission.

Figure 18-106. Subsequence – DIT-/TDM- Transmission Startup Procedure

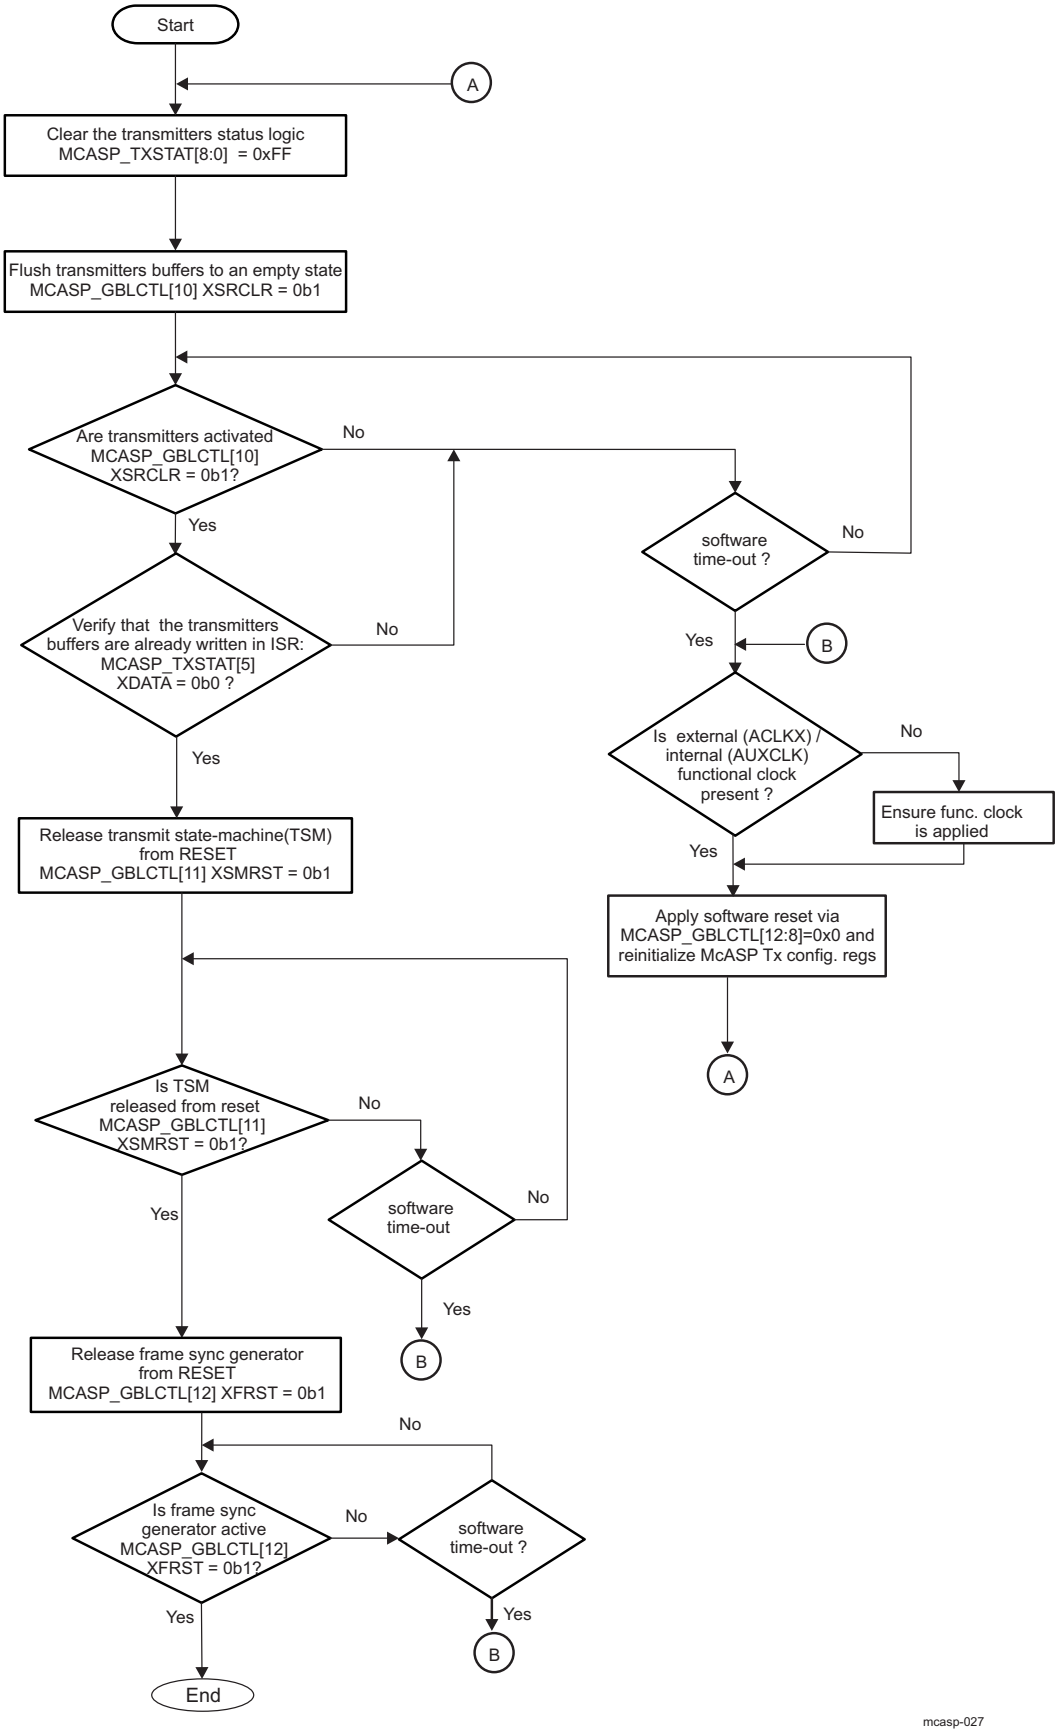

Table 18-354 shows the configuration of the McASP using an interrupt method for DIT-/TDM- transmission.

Table 18-354. McASP DIT-/TDM- Interrupt Transmission Model

Step	Register/Bit Field/Programming Model	Value
Disable Tx DMA requests generation.	MCASP_XEVTCTL[0] XDATDMA	0x1
Enable the data ready event transmit interrupt.	MCASP_EVTCTLX[5] XDATA	0x1
Optional: Enable the transmit error event interrupts.	MCASP_EVTCTLX[2] XCKFAIL MCASP_EVTCTLX[1] XSYNCERR MCASP_EVTCTLX[0] XUNDRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt (useful for DIT user data/ channel status next S/PDIF frame info update.)	MCASP_EVTCTLX [7] XSTAFRM MCASP_EVTCTLX[4] XLAST	0x1 0x1
IFwrite transfer is through the McASP DATA port (MCASP_TXFMT[3] XBUSEL is set to 0b0).	Software test condition (setting is done in step4 of the *McASP Transmitters Global Initialization* - see Table 18-336)	
Enable the DATA port error based interrupt.	MCASP_EVTCTLX[3] XDMAERR	0x1
ELSE		
Disable the DATA port error based interrupt.	MCASP_EVTCTLX[3] XDMAERR	0x0
ENDIF		
DIT/TDM - Transmission Startup Procedure	See Figure 18-106.	

Table 18-355 summarizes the register call to initialize the McASP to transmit using interrupt events.

Table 18-355. Register Call Summary for Subsequence – McASP DIT-/TDM- Transmission Startup Procedure

Register Name	Register Name
MCASP_GBLCTL	MCASP_TXSTAT

18.5.5.2.1.3 Main Sequence –McASP DIT- /TDM - Mode DMA Transmission Method

Table 18-356 shows the configuration of the McASP using the DMA method for transmission. Possible interrupt error event servicing is also considered. Table 18-355 shows the initial setup for DMA - based transmission.

NOTE: Because of the DATA port burst access capability with the DMA method, it is strongly recommended that DMA transfers are initiated through the McASP DATA port.

Table 18-356. McASP DMA Transmission Model with Interrupt Events Servicing

Step	Register/Bit Field/Programming Model	Value
Recommended: Select DATA port to access the transmit buffers.	MCASP_TXFMT[3] XBUSEL	0x0
Enable the Tx DMA requests generation.	MCASP_XEVTCTL[0] XDATDMA	0x0
Enable the Tx DMA error event, because of McASP DATA port usage.	MCASP_EVTCTLX[3] XDMAERR	0x1
Optional: Enable the transmit error event interrupts.	MCASP_EVTCTLX[2] XCKFAIL MCASP_EVTCTLX[1] XSYNCERR MCASP_EVTCTLX[0] XUNDRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt.	MCASP_EVTCTLX [7] XSTAFRM MCASP_EVTCTLX[4] XLAST	0x1 0x1
Disable the data ready event transmit interrupt, as DMA is used to service this request.	MCASP_EVTCTLX[5] XDATA	0x0

Table 18-356. McASP DMA Transmission Model with Interrupt Events Servicing (continued)

Step	Register/Bit Field/Programming Model	Value
DMA startup transmission procedure. This procedure is identical than the one shown in Figure 18-106. The only difference is that DMA automatically services all the AXEVT events raised by the McASP, and no CPU data processing intervention is required. The CPU is involved only in error handling shown in Figure 18-109.	See Figure 18-106.	

18.5.5.2.2 McASP Reception Modes

18.5.5.2.2.1 Main Sequence – McASP Polling Reception Method

Figure 18-107 shows the McASP polling reception method.

NOTE: The McASP polling reception model considers thedevice CPUs as the accessor of audio data from the McASP receive buffers.

Figure 18-107. McASP Polling Reception Method

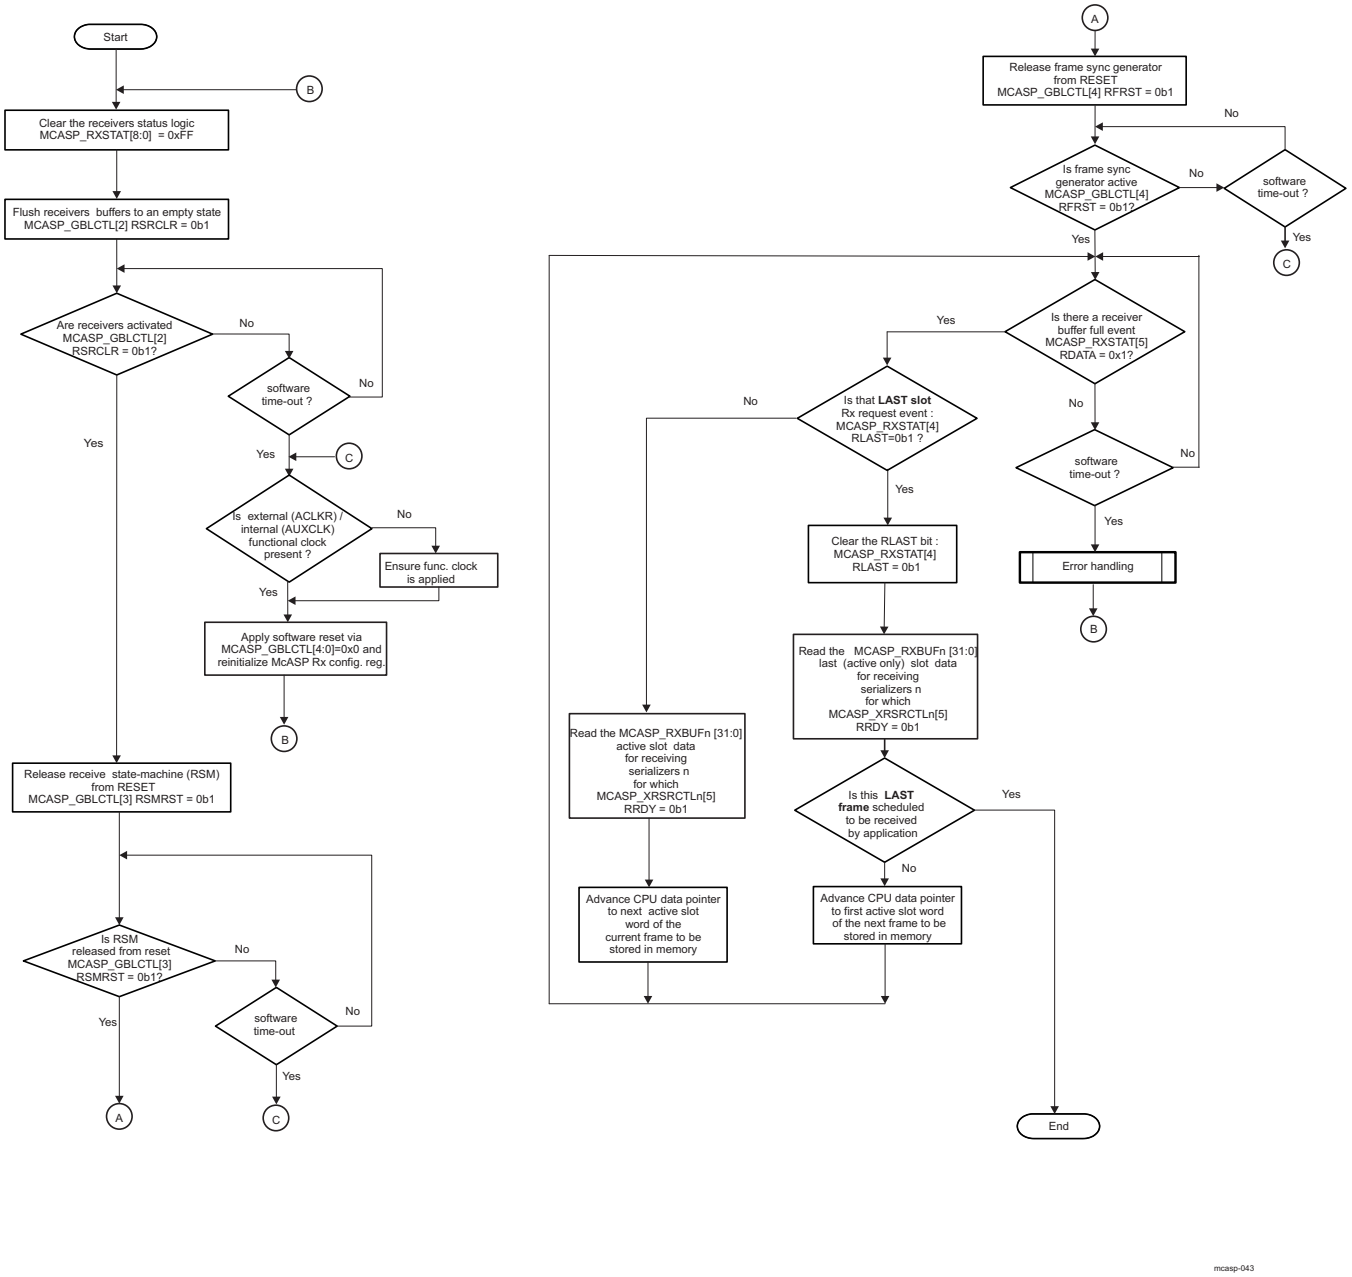

Table 18-357 summarizes the register call for the reception polling mode.

Table 18-357. Register Call Summary for Main Sequence – McASP Reception Polling Method

Register Name
MCASP_RXSTAT
MCASP_GBLCTL
MCASP_RXBUFn
MCASP_XRSRCTLn

Table 18-358 summarizes the subprocess call for the polling mode.

Table 18-358. Subprocess Call Summary for Main Sequence – McASP Reception Polling Method

Subprocess Name	Cross-Reference
Error handling	Figure 18-112

18.5.5.2.2.2 Main Sequence – McASP TDM - Interrupt Reception Method

Figure 18-108 shows the initial setup for interrupt-based reception.

Figure 18-108. Subsequence – TDM - Reception Startup Procedure

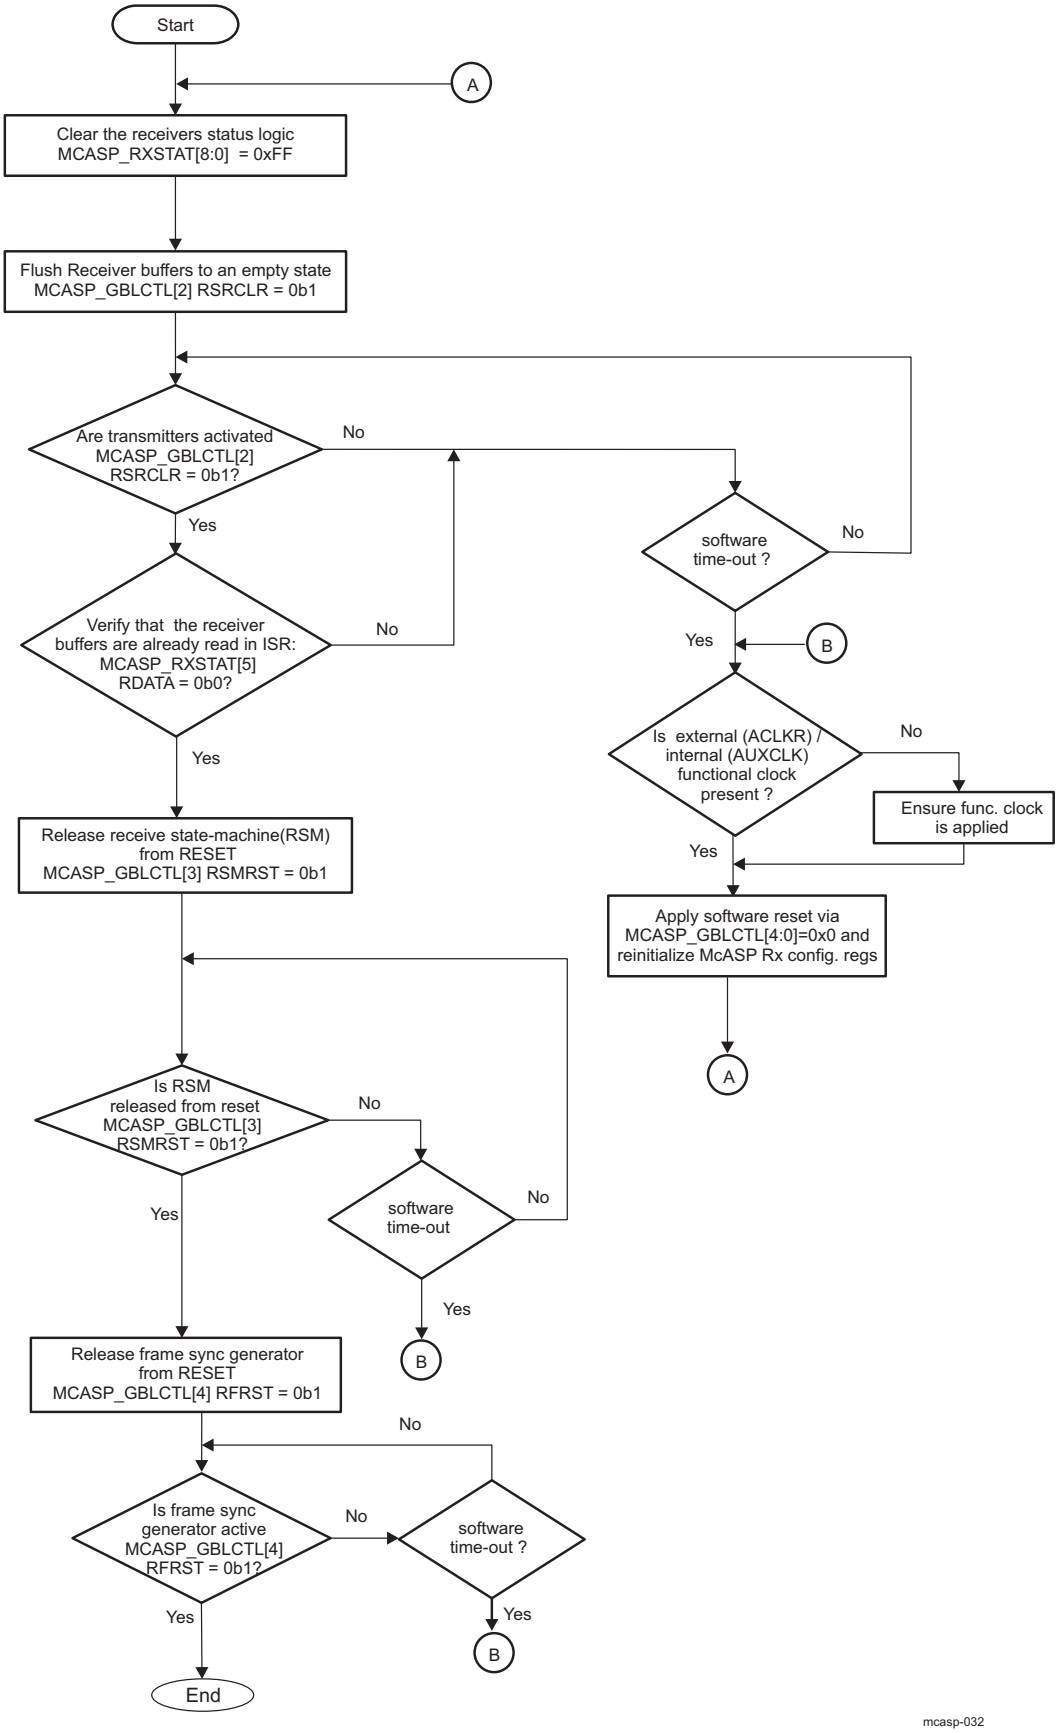

Table 18-359 shows the configuration of the McASP using an interrupt method for TDM- reception.

Table 18-359. McASP TDM- Interrupt Reception Model

Step	Register/Bit Field/Programming Model	Value
Disable Rx DMA requests generation.	MCASP_REVTCTL[0] RDATDMA	0x1
Enable the data ready event receive interrupt.	MCASP_EVTCTLR[5] RDATA	0x1
Optional: Enable the receive error event interrupts.	MCASP_EVTCTLR[2] RCKFAIL MCASP_EVTCTLR[1] RSYNCERR MCASP_EVTCTLR[0] ROVRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt	MCASP_EVTCTLR [7] RSTAFRM MCASP_EVTCTLR[4] RLAST	0x1 0x1
IF read transfer is through the McASP DATA port (MCASP_RXFMT[3] RBUSEL is set to 0b0).	Software test condition (setting is done in step4 of the *McASP Receivers Global Initialization for TDM-Mode Operation* - see Table 18-342)	
Enable the DATA port error based interrupt.	MCASP_EVTCTLR[3] RDMAERR	0x1
ELSE		
Disable the DATA port error based interrupt.	MCASP_EVTCTLR[3] RDMAERR	0x0
ENDIF		
TDM - Transmission Startup Procedure	See Figure 18-108.	

Table 18-360 summarizes the register call to initialize the McASP to transmit using interrupt events.

Table 18-360. Register Call Summary for Subsequence – McASP TDM- Reception Startup Procedure

Register Name	Register Name
MCASP_GBLCTL	MCASP_RXSTAT

18.5.5.2.2.3 Main Sequence – McASP TDM - Mode DMA Reception Method

Table 18-361 shows the configuration of the McASP using the DMA method for reception. Possible interrupt error event servicing is also considered. Table 18-355 shows the initial setup for DMA - based transmission.

NOTE: Because of the DATA port burst access capability with the DMA method, it is strongly recommended that DMA transfers are initiated through the McASP DATA port.

Table 18-361. McASP DMA Reception Model with Interrupt Events Servicing

Step	Register/Bit Field/Programming Model	Value
Recommended: Select DATA port to access the transmit buffers.	MCASP_RXFMT[3] RBUSEL	0x0
Enable the Rx DMA requests generation.	MCASP_REVTCTL[0] RDATDMA	0x0
Enable the Rx DMA error event, because of McASP DATA port usage.	MCASP_EVTCTLR[3] RDMAERR	0x1
Optional: Enable the receive error event interrupts.	MCASP_EVTCTLR2] RCKFAIL MCASP_EVTCTLR[1] RSYNCERR MCASP_EVTCTLR[0] ROVRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt.	MCASP_EVTCTLR [7] RSTAFRM MCASP_EVTCTLR[4] RLAST	0x1 0x1
Disable the data ready event receive interrupt, as DMA is used to service this request.	MCASP_EVTCTLR[5] RDATA	0x0

Table 18-361. McASP DMA Reception Model with Interrupt Events Servicing (continued)

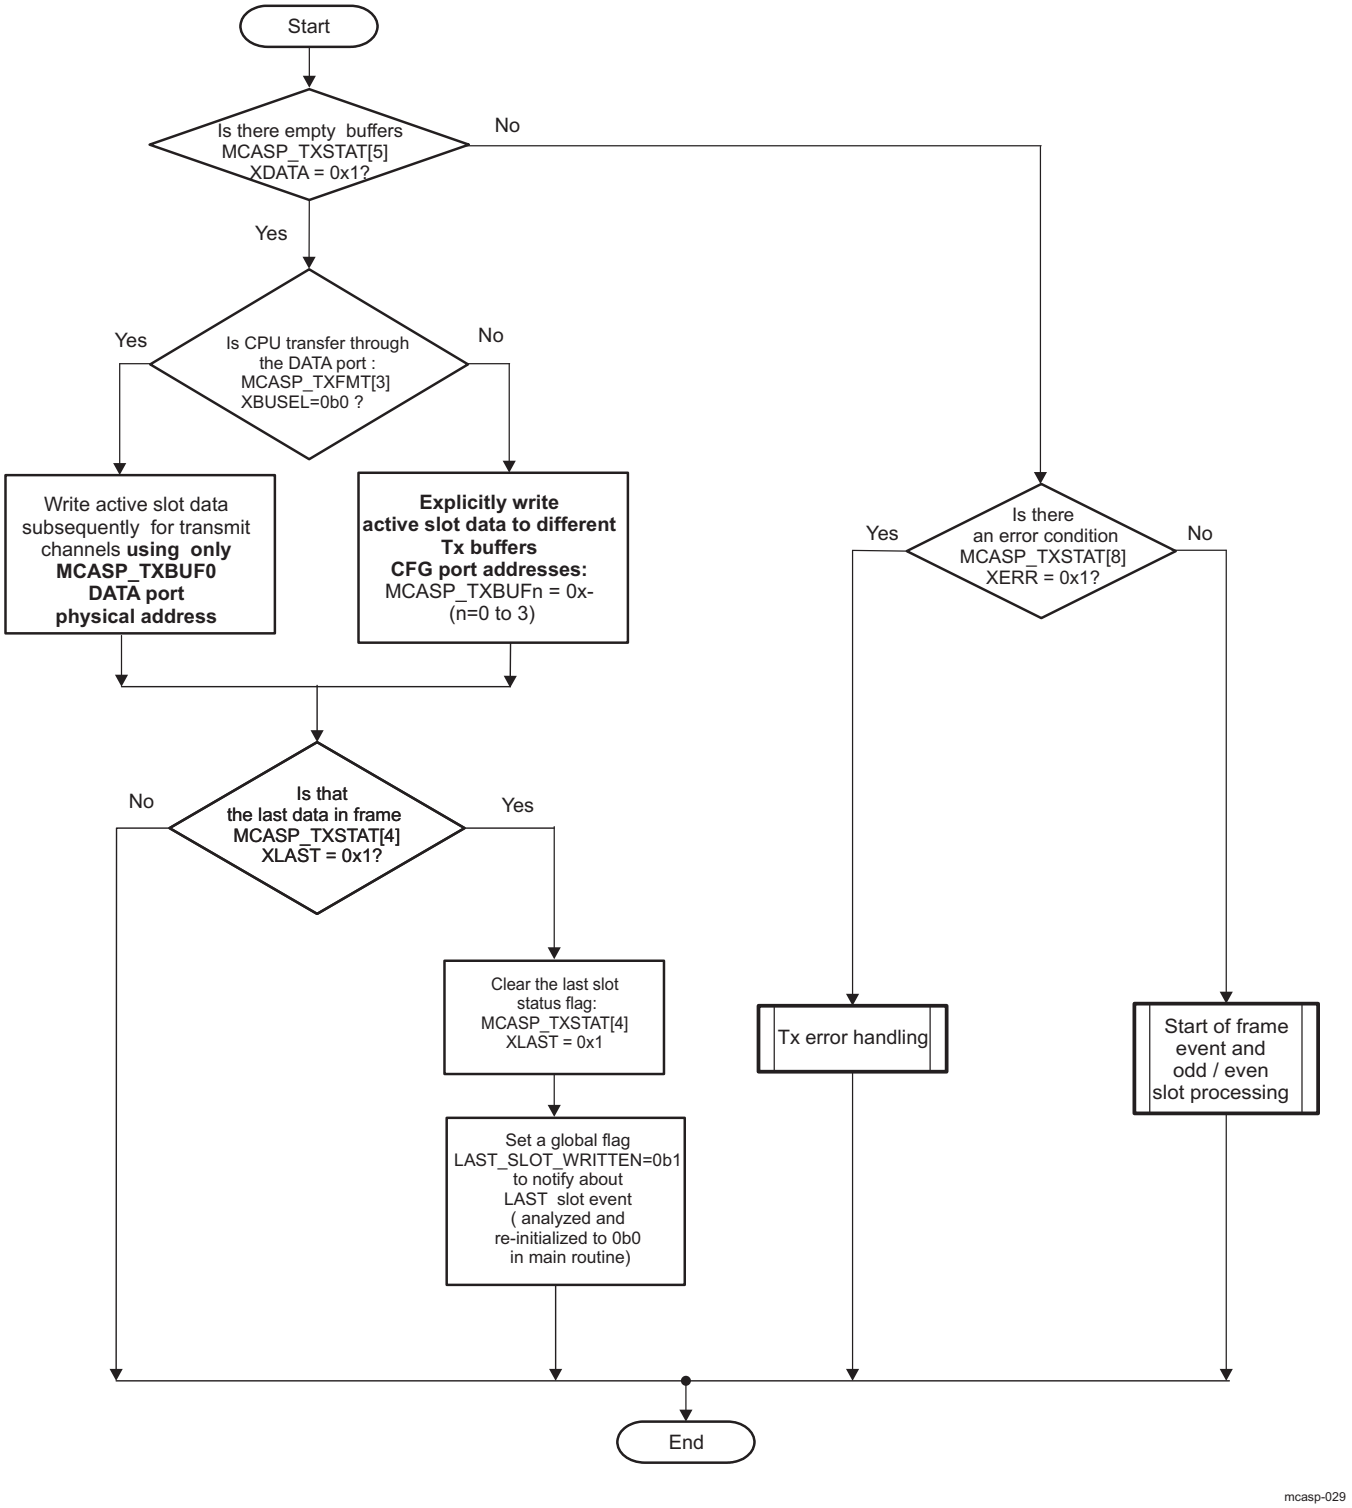
Step	Register/Bit Field/Programming Model	Value
DMA startup reception procedure. This procedure is identical than the one shown in Figure 18-108. The only difference is that DMA automatically services all the AREVT events raised by the McASP, and no CPU data processing intervention is required. The CPU is involved only in error handling shown in Figure 18-110.	See Figure 18-108.	

18.5.5.2.3 McASP Event Servicing

18.5.5.2.3.1 McASP DIT-/TDM- Transmit Interrupt Events Servicing

Figure 18-109 shows the flow of DIT-/TDM- mode transmit interrupt events servicing for the McASP module.

Figure 18-109. McASP Transmit Interrupt Events Servicing



18.5.5.2.3.2 McASP TDM- Receive Interrupt Events Servicing

Figure 18-110 shows the flow of DIT-/TDM- mode transmit interrupt events servicing for the McASP module.

Figure 18-110. McASP Receive Interrupt Events Servicing

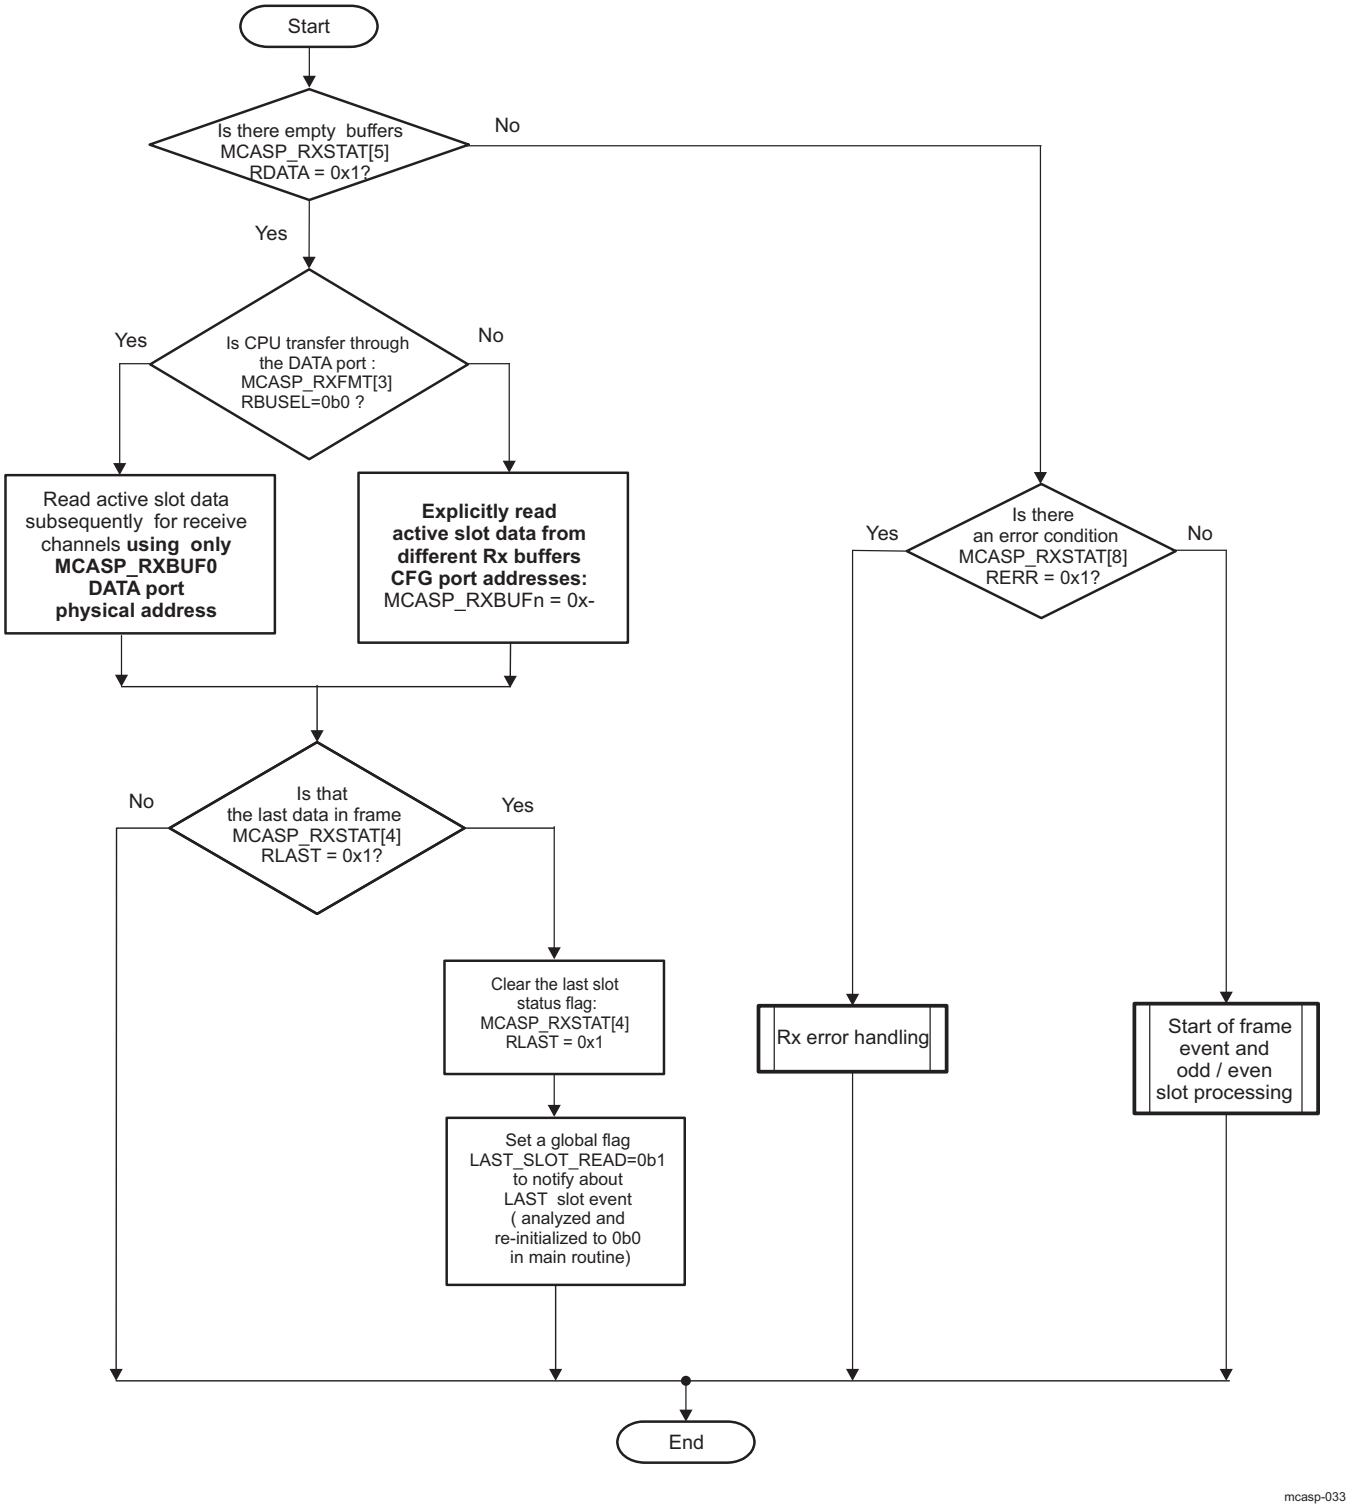


Table 18-362 lists the register call summary for the receive interrupt events servicing.

Table 18-362. Register Call Summary for McASP Receive Interrupt Events Servicing

Register Name	Register Name	Register Name
MCASP_RXSTAT	MCASP_RXBUFn	MCASP_RXFMT

Table 18-363 lists the subprocess call summary for receive interrupt events servicing.

Table 18-363. Subprocess Call Summary for Receive Interrupt Events Servicing

Subprocess Name	Cross-Reference
McASP receive error handling	Figure 18-112
Start of frame handling	Section 18.5.4.12.2

18.5.5.2.3.3 Subsequence – McASP DIT-/TDM -Modes Transmit Error Handling

Figure 18-111 shows the transmit error handling schema for the McASP, which can be implemented as part of the Tx interrupt service routine or as part of the Tx polling sequence.

Figure 18-111. McASP Transmit Error Handling

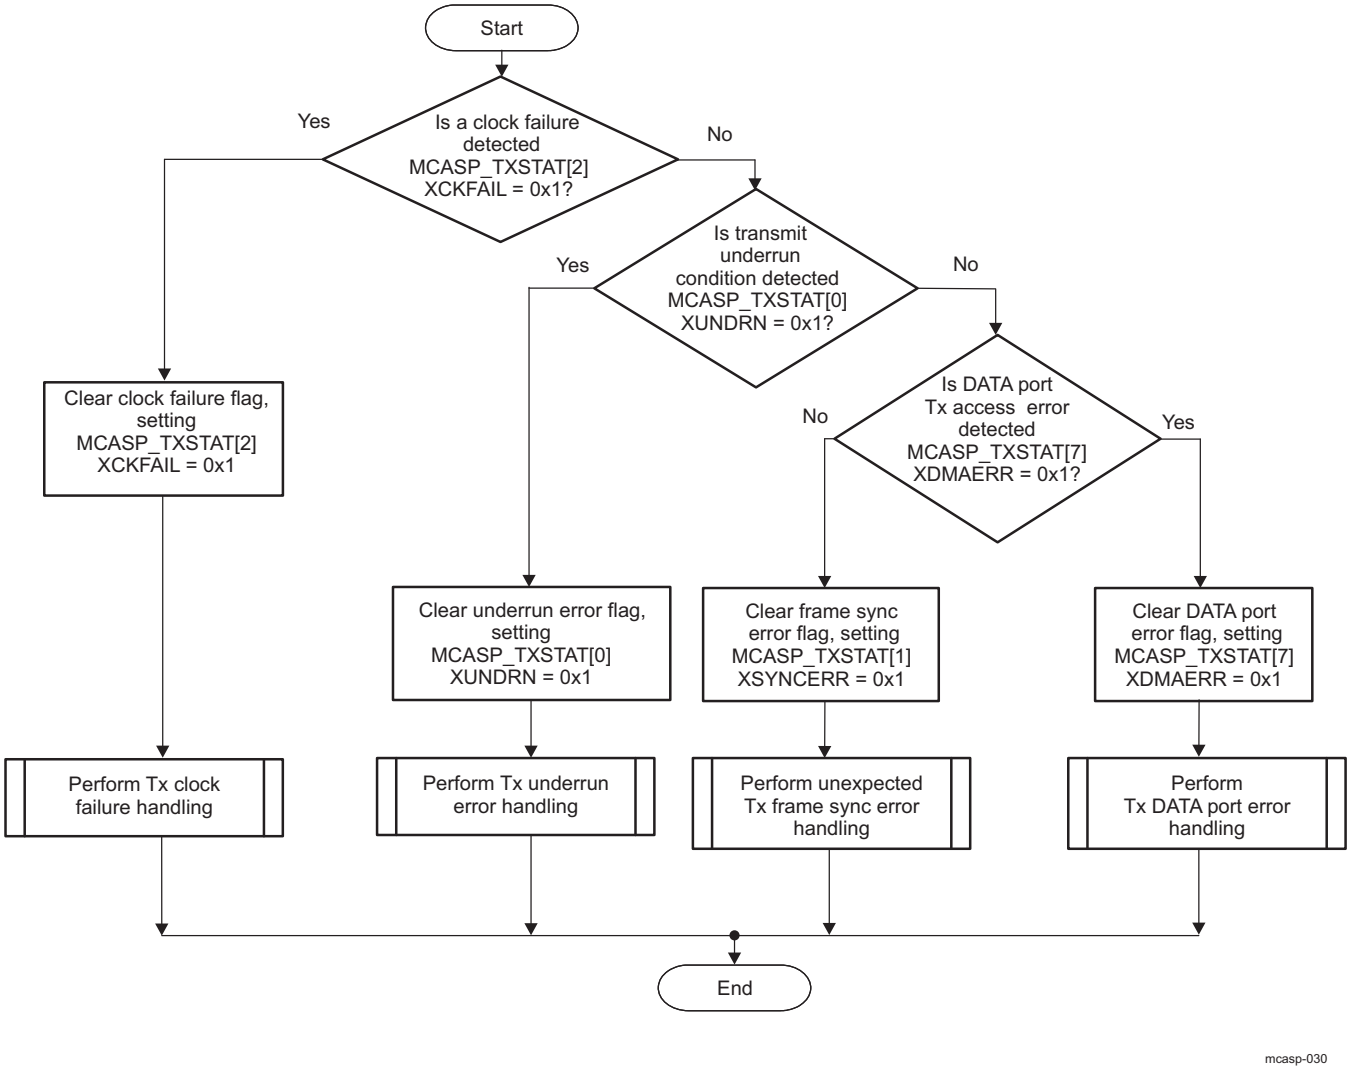

Table 18-364 lists the register call summary for the McASP transmit error handling.

Table 18-364. Register Call Summary for McASP Transmit Error Handling

Register Name
MCASP_TXSTAT

NOTE:

- For more information about transmit clock failure handling, see Section 18.5.4.15.6.2, *Transmit Clock Failure Check and Recovery*.
- For more information about transmit buffer underrun handling, see Section 18.5.4.15.1, *Buffer Underrun Error -Transmitter*.
- For more information about DATA port Tx error handling, see Section 18.5.4.15.3, *DATA Port Error - Transmitter*.
- For more information about unexpected Tx frame sync error handling, see Section 18.5.4.15.5, *Unexpected Frame Sync Error*.

18.5.5.2.3.4 Subsequence – McASP Receive Error Handling

Figure 18-112 shows the receive error handling schema for the McASP, which can ONLY be implemented as part of the Rx polling sequence.

Figure 18-112. McASP Receive Error Handling

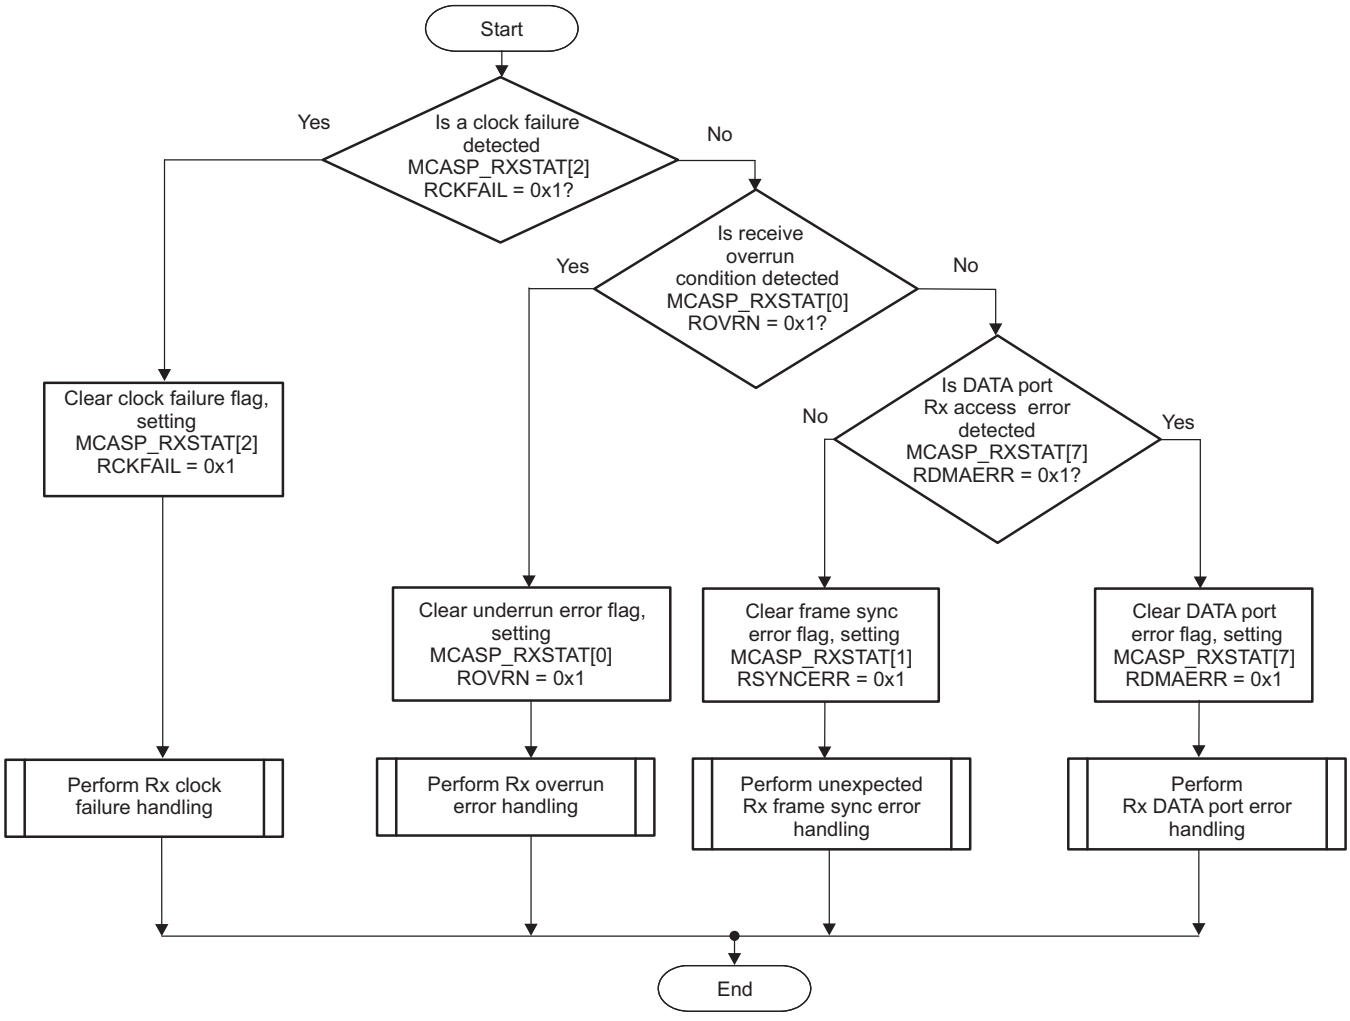

Table 18-365 lists the register call summary for the McASP receive error handling.

Table 18-365. Register Call Summary for McASP Receive Error Handling

Register Name
MCASP_RXSTAT

NOTE:

- For more information about receive clock failure handling, see Section 18.5.4.15.6.3, *Receive Clock Failure Check and Recovery*.
- For more information about receive buffer overrun handling, see Section 18.5.4.15.2, *Buffer Overrun Error - Receiver*.
- For more information about DATA port Rx error handling, see Section 18.5.4.15.4, *DATA Port Error - Receiver*.
- For more information about unexpected Rx frame sync error handling, see Section 18.5.4.15.5, *Unexpected Frame Sync Error*.

(1) i = 0 to 5
(2) n = 0 to 5

NOTE: The address locations listed in Table 18-367 and Table 18-368, *MCASP_CFG Register Mapping Summary*, are relevant for accessing:

- All McASP configuration registers
- MCASP_TXBUFn registers
- MCASP_RXBUFn registers

through the McASP peripheral configuration (CFG) port.

The MCASP_TXFMT[3] XBUSEL bit must be set to 0b1, to allow CFG port write accesses to the McASP XRBUFn buffer. The MCASP_RXFMT[3] RBUSEL bit must be set to 0b1, to allow CFG port read accesses to the McASP XRBUFn buffer.

18.5.6.2.2 MCASP_CFG Register Description

The tables below describe the individual MCASP_CFG register bits.

NOTE: For all of the below described registers the indexes *n* and *N* apply to serializers (not slots).

Register descriptions cover the superset McASP (16 serializers and all signals pinned out). For particular McASP Instance, refer to Section 18.5.2, *McASP Environment*, and Section 18.5.3, *McASP Integration*.

Physical Address	0x4846 0010 0x4846 C010 0x4847 0010	**Instance**	MCASP1_CFG_PER2_L4 MCASP2_CFG_PER2_L4 MCASP3_CFG_PER2_L4
Description	Specifies the function of the pins as either a McASP pin or a GPIO pin. Some register bits might not be functional for all McASP instances, due to corresponding McASP pin not being pinned out on a particular device part number. Refer to device-specific DM for more information on the supported McASP features.

Table 18-377. MCASP_PDOUT

Address Offset	0x0000 0018		
Physical Address	0x4846 0018 0x4846 C018 0x4847 0018	**Instance**	MCASP1_CFG_PER2_L4 MCASP2_CFG_PER2_L4 MCASP3_CFG_PER2_L4

Description

Pin data output register - holds a value for data out at all times, and may be read back at all times. The value held by MCASP_PDOUT is not affected by writing to MCASP_PDIR and MCASP_PFUNC. However, the data value in MCASP_PDOUT is driven out onto the McASP pin only if the corresponding bit in MCASP_PFUNC is set to 1 (GPIO function) and the corresponding bit in MCASP_PDIR is set to 1 (output).

When reading data, it returns the corresponding bit value in MCASP_PDOUT[n]; it does not return the input from the I/O pin.

When writing data, writes to the corresponding MCASP_PDOUT[n] bit.

PDOUT has these aliases or alternate addresses:

- MCASP_PDSET - when written to at this address, writing a 1 to a bit in MCASP_PDSET sets the corresponding bit in MCASP_PDOUT to 1; writing a 0 has no effect and keeps the bits in MCASP_PDOUT unchanged.
- MCASP_PDCLR - when written to at this address, writing a 1 to a bit in MCASP_PDCLR clears the corresponding bit in MCASP_PDOUT to 0; writing a 0 has no effect and keeps the bits in MCASP_PDOUT unchanged

There is only one set of data-out bits, MCASP_PDOUT[31:0]. The other registers, MCASP_PDSET and MCASP_PDCLR, are just different addresses for the same control bits, with different behaviors during writes.

Some register bits might not be functional for all McASP instances, due to corresponding McASP pin not being pinned out on a particular device part number. Refer to device-specific DM for more information on the supported McASP features.

Bits	Field Name	Description	Type	Reset
31	AFSR	Determines drive on AFSR output pin when the corresponding MCASP_PFUNC[31] and MCASP_PDIR[31] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
30	AHCLKR	Determines drive on AHCLKR output pin when the corresponding MCASP_PFUNC[30] and MCASP_PDIR[30] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
29	ACLKR	Determines drive on ACLKR output pin when the corresponding MCASP_PFUNC[29] and MCASP_PDIR[29] bits are set to 1 0x0: The pin drives low. 0x1: The pin drives high.	RW	0

Bits	Field Name	Description	Type	Reset
28	AFSX	Determines drive on AFSX output pin when the corresponding MCASP_PFUNC[28] and MCASP_PDIR[28] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
27	AHCLKX	Determines drive on AHCLKX output pin when the corresponding MCASP_PFUNC[27] and MCASP_PDIR[27] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
26	ACLKX	Determines drive on ACLKX output pin when the corresponding MCASP_PFUNC[26] and MCASP_PDIR[26] bits are set to 1 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
25:16	RESERVED	Reserved	RW	0x000
15	AXR15	Determines drive on AXR15 output pin when the corresponding MCASP_PFUNC[15] and MCASP_PDIR[15] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
14	AXR14	Determines drive on AXR14 output pin when the corresponding MCASP_PFUNC[14] and MCASP_PDIR[14] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
13	AXR13	Determines drive on AXR13 output pin when the corresponding MCASP_PFUNC[13] and MCASP_PDIR[13] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
12	AXR12	Determines drive on AXR12 output pin when the corresponding MCASP_PFUNC[12] and MCASP_PDIR[12] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
11	AXR11	Determines drive on AXR11 output pin when the corresponding MCASP_PFUNC[11] and MCASP_PDIR[11] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
10	AXR10	Determines drive on AXR10 output pin when the corresponding MCASP_PFUNC[10] and MCASP_PDIR[10] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
9	AXR9	Determines drive on AXR9 output pin when the corresponding MCASP_PFUNC[9] and MCASP_PDIR[9] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
8	AXR8	Determines drive on AXR8 output pin when the corresponding MCASP_PFUNC[8] and MCASP_PDIR[8] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
7	AXR	Determines drive on AXR7 output pin when the corresponding MCASP_PFUNC[7] and MCASP_PDIR[7] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
6	AXR6	Determines drive on AXR6 output pin when the corresponding MCASP_PFUNC[6] and MCASP_PDIR[6] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0

Bits	Field Name	Description	Type	Reset
5	AXR5	Determines drive on AXR5 output pin when the corresponding MCASP_PFUNC[5] and MCASP_PDIR[5] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
4	AXR4	Determines drive on AXR4 output pin when the corresponding MCASP_PFUNC[4] and MCASP_PDIR[4] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
3	AXR3	Determines drive on AXR3 output pin when the corresponding MCASP_PFUNC[3] and MCASP_PDIR[3] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
2	AXR2	Determines drive on AXR2 output pin when the corresponding MCASP_PFUNC[2] and MCASP_PDIR[2] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
1	AXR1	Determines drive on AXR1 output pin when the corresponding MCASP_PFUNC[1] and MCASP_PDIR[1] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
0	AXR0	Determines drive on AXR0 output pin when the corresponding MCASP_PFUNC[0] and MCASP_PDIR[0] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0

Table 18-381. MCASP_PDSET

Address Offset	0x0000 001C		
Physical Address	0x4846 001C 0x4846 C01C 0x4847 001C	**Instance**	MCASP1_CFG_PER2_L4 MCASP2_CFG_PER2_L4 MCASP3_CFG_PER2_L4
Description	The pin data set register is an alias of the pin data output register (MCASP_PDOUT) for writes only. Writing a 1 to the MCASP_PDSET bit sets the corresponding bit in MCASP_PDOUT and, if MCASP_PFUNC = 1 (GPIO function) and MCASP_PDIR = 1 (output), drives a logic high on the pin. Some register bits might not be functional for all McASP instances, due to corresponding McASP pin not being pinned out on a particular device part number. Refer to device-specific DM for more information on the supported McASP features.

Table 18-383. MCASP_PDCLR

Address Offset	0x0000 0020		
Physical Address	0x4846 0020 0x4846 C020 0x4847 0020	**Instance**	MCASP1_CFG_PER2_L4 MCASP2_CFG_PER2_L4 MCASP3_CFG_PER2_L4
Description	The pin data clear register is an alias of the pin data output register (MCASP_PDOUT) for writes only. Writing a 1 to the MCASP_PDCLR bit clears the corresponding bit in MCASP_PDOUT and, if MCASP_PFUNC = 1 (GPIO function) and MCASP_PDIR = 1 (output), drives a logic low on the pin. Some register bits might not be functional for all McASP instances, due to corresponding McASP pin not being pinned out on a particular device part number. Refer to device-specific DM for more information on the supported McASP features.

- MCASP_CFG Register Description: [6][7][8][9]

Table 18-385. MCASP_GBLCTL

Address Offset	0x0000 0044		
Physical Address	0x4846 0044 0x4846 C044 0x4847 0044	**Instance**	MCASP1_CFG_PER2_L4 MCASP2_CFG_PER2_L4 MCASP3_CFG_PER2_L4
Description	Global transmit control register - provides initialization of the transmit and receive sections. The bit fields in MCASP_GBLCTL are synchronized and latched by the transmitter and receiver corresponding clocks - ACLKX (bits [12:8]) and ACLKR (bits [4:0]), respectively. Before programming MCASP_GBLCTL, ensure that the serial clocks are running. If the corresponding external serial clocks - ACLKX and ACLKR, are not yet running, select the internal serial clock source in AHCLKXCTL, AHCLKRCTL, ACLKXCTL and ACLKRCTL before programming the MCASP_GBLCTL. Also, after programming any bits in MCASP_GBLCTL, do not proceed until reading back from MCASP_GBLCTL and verifying that the bits in MCASP_GBLCTL are latched.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																			XFRST	XSMRST	XSRCLR	XHCLKRST	XCLKRST	RESERVED				RFRST	RSMRST	RSRCLR	RHCLKRST	RCLKRST

Bits	Field Name	Description	Type	Reset
31:13	RESERVED	Reserved	RW	0x00000
12	XFRST	Transmit frame-sync generator reset enable bit 0x0: The transmit frame-sync generator is reset. 0x1: The transmit frame-sync generator is active. When released from reset, the transmit frame-sync generator begins counting serial clocks and generating frame sync as programmed.	RW	0
11	XSMRST	Transmit state-machine reset enable bit 0x0: The transmit state-machine is held in reset. AXR[n] pin state: If MCASP_PFUNC[n] = 0 and MCASP_PDIR[n] = 1, the corresponding serializer [n] drives the AXR[n] pin to the state specified for inactive time slot. 0x1: The transmit state-machine is released from reset. When released from reset, the transmit state-machine immediately transfers data from XBUF[n] to XRSR[n]. The transmit state-machine sets the underrun flag (XUNDRN) in MCASP_XSTAT, if XBUF[n] have not been preloaded with data before reset is released. The transmit state-machine also immediately begins detecting frame sync and is ready to transmit. Transmission of TDM time slot begins at slot 0 after reset is released.	RW	0

Bits	Field Name	Description	Type	Reset
10	XSRCLR	Transmit serializer clear enable bit. By clearing and then setting this bit, the transmit buffer is flushed to an empty state (XDATA = 1). If XSMRST = 1, XSRCLR = 1, XDATA = 1, and XBUF is not loaded with new data before the start of the next active time slot, an underrun occurs. 0x0: The transmit serializer is cleared. 0x1: The transmit serializer is active. When the transmit serializer is first taken out of reset (XSRCLR changes from 0 to 1), the transmit data ready bit (XDATA) in MCASP_XSTAT is set to indicate XBUF is ready to be written.	RW	0
9	XHCLKRST	Transmit high-frequency clock divider reset enable bit 0x0: The transmitter high-frequency clock divider is held in reset and passes through its input as divide-by-1. 0x1: The transmitter high-frequency clock divider is running.	RW	0
8	XCLKRST	Transmit clock divider reset enable bit 0x0: The transmit clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input. 0x1: The transmit clock divider is running.	RW	0
7:5	RESERVED	Reserved	RW	0x0
4	RFRST	Receive frame sync generator reset enable bit. 0x0: Receive frame sync generator is reset. 0x1: Receive frame sync generator is active. When released from reset, the receive frame sync generator begins counting serial clocks and generating frame sync as programmed.	RW	0
3	RSMRST	Receive state machine reset enable bit. 0x0: Receive state machine is held in reset. 0x1: Receive state machine is released from reset. When released from reset, the receive state machine immediately begins detecting frame sync and is ready to receive. Receive TDM time slot begins at slot 0 after reset is released.	RW	0
2	RSRCLR	Receive serializer clear enable bit. By clearing then setting this bit, the receive buffer is flushed. 0x0: Receive serializers are cleared. 0x1: Receive serializers are active.	RW	0
1	RHCLKRST	Receive high-frequency clock divider reset enable bit. 0x0: Receive high-frequency clock divider is held in reset and passes through its input as divide-by-1. 0x1: Receive high-frequency clock divider is running.	RW	0
0	RCLKRST	Receive clock divider reset enable bit. 0x0: Receive clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input. 0x1: Receive clock divider is running.	RW	0

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED														RDATDLY		RRVRS	RPAD			RPBIT				RSSZ				RBUSEL	RROT		

Bits	Field Name	Description	Type	Reset
31:18	RESERVED		RW	0x0000
17:16	RDATDLY	Receive Frame sync delay of AXR[n] 0x0: 0-bit delay. The first receive data bit, AXR[n], occurs in same ACLKR cycle as the receive frame sync (AFSR). 0x1: 1-bit delay. The first receive data bit, AXR[n], occurs one ACLKR cycle after the receive frame sync (AFSR). 0x2: 2-bit delay. The first receive data bit, AXR[n], occurs two ACLKR cycles after the receive frame sync (AFSR). 0x3: Reserved	RW	0x0
15	RRVRS	Receive serial bitstream order 0x0: Bitstream is LSB first. No bit reversal is performed in receive format bit reverse unit. 0x1: Bitstream is MSB first. Bit reversal is performed in receive format bit reverse unit.	RW	0
14:13	RPAD	Pad value for extra bits in slot not belonging to the word. This field only applies to bits when RMASK[n] = 0. 0x0: Pad extra bits with 0. 0x1: Pad extra bits with 1. 0x2: Pad extra bits with one of the bits from the word as specified by RPBIT bits. 0x3: Reserved	RW	0x0
12:8	RPBIT	RPBIT value determines which bit (as read by the CPU from RBUF[n]) is used to pad the extra bits. This field only applies when RPAD = 2h. 0x0: Pad with value of bit RBUFn[0]. 0x01 - 0x1F: Pad with value of the bit positioned within the range RBUFn[31:1].	RW	0x00
7:4	RSSZ	Receive slot size. 0x0 - 0x2: Reserved 0x3: Slot size is 8 bits 0x4: Reserved 0x5: Slot size is 12 bits 0x6: Reserved 0x7: Slot size is 16 bits 0x8: Reserved 0x9: Slot size is 20 bits 0xA: Reserved 0xB: Slot size is 24 bits 0xC: Reserved 0xD: Slot size is 28 bits 0xE: Reserved 0xF: Slot size is 32 bits	RW	0x0

Bits	Field Name	Description	Type	Reset
3	RBUSEL	Selects whether reads from serializer buffer RBUF[n] originate from the peripheral configuration CFG port or the DATA port. 0x0: Reads from XRBUF[n] originate on DATA port. Reads from XRBUF[n] on the peripheral configuration port are ignored. 0x1: Reads from XRBUF[n] originate on peripheral configuration port. Reads from XRBUF[n] on the DATA port are ignored.	RW	0
2:0	RROT	Right-rotation value for receive rotate right format unit. 0x0: Rotate right by 0 (no rotation). 0x1: Rotate right by 4 bit positions. 0x2: Rotate right by 8 bit positions. 0x3: Rotate right by 12 bit positions. 0x4: Rotate right by 16 bit positions. 0x5: Rotate right by 20 bit positions. 0x6: Rotate right by 24 bit positions. 0x7: Rotate right by 28 bit positions.	RW	0x0

Table 18-409. MCASP_RXSTAT

Address Offset	0x0000 0080		
Physical Address	0x4846 0080 0x4846 C080 0x4847 0080	**Instance**	MCASP1_CFG_PER2_L4 MCASP2_CFG_PER2_L4 MCASP3_CFG_PER2_L4
Description	The receiver status register (MCASP_RXSTAT) provides the receiver status and receive TDM time slot number.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								RERR	RDMAERR	RSTAFRM	RDATA	RLAST	RTDMSLOT	RCKFAIL	RSYNCERR	ROVRN

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		RW	0x00 0000
8	RERR	RERR bit always returns a logic-OR of: ROVRN | RSYNCERR | RCKFAIL | RDMAERR Allows a single bit to be checked to determine if a receiver error has occurred. 0x0: No errors have occurred. 0x1: An error has occurred.	RW	0
7	RDMAERR	Receive DMA error flag. RDMAERR is set when the CPU or DMA reads more serializers through the DMA port in a given time slot than were programmed as receivers. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Receive DMA error did not occur. 0x1: Receive DMA error did occur.	RW	0
6	RSTAFRM	Receive start of frame flag. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: No new receive frame sync (AFSR) is detected. 0x1: A new receive frame sync (AFSR) is detected.	RW	0
5	RDATA	Receive data ready flag. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: No new data in RBUF. 0x1: Data is transferred from XRSR to RBUF and ready to be serviced by the CPUs or DMA. When RDATA is set, it always causes a DMA event (AREVT).	RW	0

Bits	Field Name	Description	Type	Reset
4	RLAST	Receive last slot flag. RLAST is set along with RDATA, if the current slot is the last slot in a frame. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Current slot is not the last slot in a frame. 0x1: Current slot is the last slot in a frame. RDATA is also set.	RW	0
3	RTDMSLOT	Returns the LSB of RSLOT. Allows a single read of MCASP_RXSTAT to determine whether the current TDM time slot is even or odd. 0x0: Current TDM time slot is odd. 0x1: Current TDM time slot is even.	RW	0
2	RCKFAIL	Receive clock failure flag. RCKFAIL is set when the receive clock failure detection circuit reports an error. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Receive clock failure did not occur. 0x1: Receive clock failure did occur.	RW	0
1	RSYNCERR	Unexpected receive frame sync flag. RSYNCERR is set when a new receive frame sync (AFSR) occurs before it is expected. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Unexpected receive frame sync did not occur. 0x1: Unexpected receive frame sync did occur.	RW	0
0	ROVRN	Receiver overrun flag. ROVRN is set when the receive serializer is instructed to transfer data from XRSR to RBUF, but the former data in RBUF has not yet been read by the CPU or DMA. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Receiver overrun did not occur. 0x1: Receiver overrun did occur.	RW	0

Table 18-413. MCASP_RXCLKCHK

Address Offset	0x0000 0088		
Physical Address	0x4846 0088 0x4846 C088 0x4847 0088	**Instance**	MCASP1_CFG_PER2_L4 MCASP2_CFG_PER2_L4 MCASP3_CFG_PER2_L4
Description	The receive clock check control register (RCLKCHK) configures the receive clock failure detection circuit.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RCNT								RMAX								RMIN								RESERVED				RPS			

Bits	Field Name	Description	Type	Reset
31:24	RCNT	0x0 - 0xFF: Receive clock count value (from previous measurement). The clock circuit continually counts the number of interface clocks for every 32 receive high-frequency master clock (AHCLKR) signals, and stores the count in RCNT until the next measurement is taken.	R	0x00
23:16	RMAX	0x00-0xFF: Receive clock maximum boundary. This 8-bit unsigned value sets the maximum allowed boundary for the clock check counter after 32 receive high-frequency master clock (AHCLKR) signals have been received. If the current counter value is greater than RMAX after counting 32 AHCLKR signals, RCKFAIL in MCASP_RXSTAT is set. The comparison is performed using unsigned arithmetic.	RW	0x00
15:8	RMIN	0x00 - 0xFF: Receive clock minimum boundary. This 8-bit unsigned value sets the minimum allowed boundary for the clock check counter after 32 receive high-frequency master clock (AHCLKR) signals have been received. If RCNT is less than RMIN after counting 32 AHCLKR signals, RCKFAIL in RSTAT is set. The comparison is performed using unsigned arithmetic.	RW	0x00
7:4	RESERVED		RW	0x0

Bits	Field Name	Description	Type	Reset
3:0	RPS	Receive clock check prescaler value. 0x0: McASP interface clock divided by 1 0x1: McASP interface clock divided by 2 0x2: McASP interface clock divided by 4 0x3: McASP interface clock divided by 8 0x4: McASP interface clock divided by 16 0x5: McASP interface clock divided by 32 0x6: McASP interface clock divided by 64 0x7: McASP interface clock divided by 128 0x8: McASP interface clock divided by 256 0x9 - 0xF: Reserved	RW	0x0

Table 18-433. MCASP_TXSTAT

Address Offset	0x0000 00C0		
Physical Address	0x4846 00C0 0x4846 C0C0 0x4847 00C0	**Instance**	MCASP1_CFG_PER2_L4 MCASP2_CFG_PER2_L4 MCASP3_CFG_PER2_L4
Description	Transmitter status register - If the McASP logic attempts to set an interrupt flag in the same cycle that the CPU writes to the flag to clear it, the McASP logic has priority and the flag remains set. This also causes the generation of a new interrupt request.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							XERR	XDMAERR	XSTAFRM	XDATA	XLAST	XTDMSLOT	XCKFAIL	XSYNCERR	XUNDRN

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	RW	0x000000
8	XERR	XERR bit always returns a logic-OR of: XUNDRN | XSYNCERR | XCKFAIL | XDMAERR. Allows a single bit to be checked to determine if a transmitter error interrupt has occurred. 0x0: No errors have occurred. 0x1: An error has occurred.	RW	0
7	XDMAERR	Transmit DMA error flag. XDMAERR is set when the CPU or DMA writes more words to the DATA port of the McASP in a given time slot than it should. Causes a transmit interrupt (XINT) if this bit and XDMAERR in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: Transmit DMA error did not occur. 0x1: Transmit DMA error occurred.	RW	0
6	XSTAFRM	Transmit start of frame flag. Causes a transmit interrupt (XINT) if this bit and XSTAFRM in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: No new transmit frame sync (AFSX) is detected. 0x1: A new transmit frame sync (AFSX) is detected.	RW	0

Bits	Field Name	Description	Type	Reset
5	XDATA	Transmit data ready flag. Causes a transmit interrupt (XINT) if this bit and XDATA in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect 0x0: XBUF[n] is written and is full 0x1: Data is copied from XBUF[n] to XRSR[n]. XBUF[n] is empty and ready to be written. XDATA is also set when the transmit serializers are taken out of reset. When XDATA is set, it always causes a DMA event (AXEVT).	RW	0
4	XLAST	Transmit last slot flag. XLAST, along with XDATA, are set if the current slot is the last slot in a frame. Causes a transmit interrupt (XINT) if this bit and XLAST in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect. 0x0: Current slot is not the last slot in a frame. 0x1: Current slot is the last slot in a frame. XDATA is also set.	RW	0
3	XTDMSLOT	Returns the LSB of XSLOT. Allows a single read of XSTAT to determine whether the current TDM time slot is even or odd. read 0x0: Current TDM time slot is odd. read 0x1: Current TDM time slot is even.	R	0
2	XCKFAIL	Transmit clock failure flag. XCKFAIL is set when the transmit clock failure detection circuit reports an error. Causes a transmit interrupt (XINT) if this bit and XCKFAIL in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect. 0x0: Transmit clock failure did not occur. 0x1: Transmit clock failure occurred	RW	0
1	XSYNCERR	Unexpected transmit frame-sync flag. XSYNCERR is set when a new transmit frame sync (AFSX) occurs before it is expected. Causes a transmit interrupt (XINT) if this bit and XSYNCERR in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect. 0x0: Unexpected transmit frame sync did not occur 0x1: Unexpected transmit frame sync occurred.	RW	0
0	XUNDRN	Transmitter underrun flag. XUNDRN is set when the transmit serializer is instructed to transfer data from XBUF[n] to XRSR[n], but XBUF[n] has not yet been serviced with new data since the last transfer. Causes a transmit interrupt (XINT) if this bit and XUNDRN in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect. 0x0: Transmitter underrun did not occur 0x1: Transmitter underrun occurred.	RW	0

XCNT								XMAX								XMIN								RESERVED				XPS			

Bits	Field Name	Description	Type	Reset
31:24	XCNT	Transmit clock count value (from previous measurement). The clock circuit continually counts the number of interface clocks for every 32 transmit high-frequency master clock (AHCLKX) signals, and stores the count in XCNT until the next measurement is taken	R	0x00
23:16	XMAX	0x0 to 0xFF: Transmit clock maximum boundary. This 8-bit unsigned value sets the maximum allowed boundary for the clock check counter after 32 transmit high-frequency master clock (AHCLKX) signals have been received. If the current counter value is greater than XMAX after counting 32 AHCLKX signals, XCKFAIL in XSTAT is set. The comparison is performed using unsigned arithmetic.	RW	0x00
15:8	XMIN	0x0 to 0xFF: Transmit clock minimum boundary. This 8-bit unsigned value sets the minimum allowed boundary for the clock check counter after 32 transmit high-frequency master clock (AHCLKX) signals have been received. If XCNT is less than XMIN after counting 32 AHCLKX signals, XCKFAIL in XSTAT is set. The comparison is performed using unsigned arithmetic.	RW	0x00

RESERVED																										RRDY	XRDY	DISMOD		SRMOD	

Bits	Field Name	Description	Type	Reset
31:6	RESERVED	Reserved	RW	0x0000000
5	RRDY	Receive buffer ready bit. RRDY indicates the current receive buffer state. Always reads 0 when programmed as a transmitter or as inactive. If SRMOD bit is set to receive (2h), RRDY switches from 0 to 1 whenever data is transferred from XRSRn to RBUFn. Read 0x0: Receive buffer (MCASP_RXBUFn) is empty. Read 0x1: Receive buffer (MCASP_RXBUFn) contains data and needs to be read before the start of the next time slot or a receiver overrun occurs.	R	0

Bits	Field Name	Description	Type	Reset
4	XRDY	Transmit buffer ready bit. XRDY indicates the current transmit buffer state. Always reads 0 when programmed as a receiver or as inactive. If SRMOD bit is set to transmit (1h), XRDY switches from 0 to 1 when XSRCLR in GBLCTL is switched from 0 to 1 to indicate an empty transmitter. XRDY remains set until XSRCLR is forced to 0, data is written to the corresponding transmit buffer, or SRMOD bit is changed to receive (2h) or inactive (0). Read 0x0: The transmit buffer (MCASP_TXBUFn) contains data. Read 0x1: The transmit buffer (MCASP_TXBUFn) is empty and needs to be written before the start of the next time slot or a transmit underrun occurs.	R	0
3:2	DISMOD	Serializer pin drive mode bit. Drive on pin when in inactive TDM slot of transmit mode or when serializer is inactive. This field only applies if the pin is configured as a McASP pin (PFUNC = 0). 0x0: Drive on pin is 3-state. 0x1: Reserved 0x2: Drive on pin is logic low. 0x3: Drive on pin is logic high.	RW	0x0
1:0	SRMOD	Serializer mode bit 0x0:The serializer is inactive 0x1:The serializer is operating in transmit mode. 0x2: The serializer is operating in receive mode. 0x3: Reserved	RW	0x0

18.5.6.2.4 MCASP_AFIFO Register Description

Table 18-459. WFIFOCTL

Address Offset	0x0000 0000		
Physical Address	0x4846 1000 0x4846 D000 0x4847 1000	**Instance**	MCASP1_AFIFO_PER2_L4 MCASP2_AFIFO_PER2_L4 MCASP3_AFIFO_PER2_L4
Description	The Write FIFO control register. The WNUMEVT and WNUMDMA values must be set prior to enabling the Write FIFO. If the Write FIFO is to be enabled, it must be enabled prior to taking the McASP out of reset.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED															WENA	WNUMEVT								WNUMDMA							

Bits	Field Name	Description	Type	Reset
31:17	RESERVED	Reserved	R	0x0000 0000
16	WENA	Write FIFO enable bit. 0x0: Write FIFO is disabled (default). Data access by the host must pass through the FIFO block to the McASP transparently. DMA requests must also pass through the FIFO block transparently. WLVL is reset to 0 and pointers are initialized, i.e., the write FIFO is “flushed.” 0x1: Write FIFO is enabled. If write FIFO is to be enabled, it must be enabled prior to enabling McASP.	RW	0
15:8	WNUMEVT	Write word count (32-bit) to generate TX event to host. When Write FIFO has word space for more or equal to this value then transmit event will be generated to host/DMA. This value must be set prior to enabling the write FIFO. 0x0: 0 words. 0x1: 1 word. 0x2: 2 words. 0x3 - 0x40: 3 to 64 words currently in write FIFO. 0x41 - 0xFF: Reserved.	RW	0x10

Bits	Field Name	Description	Type	Reset
7:0	WNUMDMA	Write word count (32-bit words). On the transmit DMA event from McASP the WNUMDMA word will be transferred from DMA engine to McASP. This value must equal the number of McASP serializers used as transmitters. This value must be set prior to enabling the write FIFO. 0x0: 0 words. 0x1: 1 word. 0x2: 2 words. 0x3 - 0x10: 3 to 16 words. 0x11 - 0xFF: Reserved.	RW	0x04

18.5.6.2.5 MCASP_DAT Register Summary

Table 18-467 and Table 18-468 summarize the MCASP_DAT register mapping.

Table 18-467. MCASP_DAT Register Summary 1

Register Name	Type	Register Width (Bits)	Address Offset	MCASP1_DAT L3_MAIN Physical Address
MCASP_RXBUF	R	32	0x0000 0000[1]	0x4580 0000
MCASP_TXBUF	W	32	0x0000 0000[1]	0x4580 0000

[1] 0x000 is just an example DATA port offset value. Actually, whatever the offset value is added to base address, it is ignored (don't care) when an access is performed to XRBUFn RX/TX buffers through the McASP DATA port.

Table 18-468. MCASP_DAT Register Summary 2

Register Name	Type	Register Width (Bits)	Address Offset	MCASP2_DAT L4_PER2 Physical Address	MCASP3_DAT L4_PER2 Physical Address
MCASP_RXBUF	R	32	0x0000 0000[1]	0x4843 6000	0x4843 A000
MCASP_TXBUF	W	32	0x0000 0000[1]	0x4843 6000	0x4843 A000

[1] 0x000 is just an example DATA port offset value. Actually, whatever the offset value is added to base address, it is ignored (don't care) when an access is performed to XRBUFn RX/TX buffers through the McASP DATA port.

NOTE: For MCASP_RXBUF and MCASP_TXBUF buffer accesses through the McASP DATA port, the destination physical address is always the same regardless of current channel index or transfer direction. The MCASP_TXFMT[3] XBUSEL bit must be set to 0b0, to allow write transfers through the DATA port. The MCASP_RXFMT[3] RBUSEL bit must be set to 0b0, to allow read transfers through the DATA port.

NOTE: The McASP DATA port is exclusively assigned for DMAs/device CPUs accesses to the McASP channels transmit and receive buffer registers. All other McASP module registers must be accessed through the McASP CFG (peripheral) port.

NOTE: The McASP1, whose data port is accessible directly via L3_MAIN, do not support FIFO/constant addressing modes. Incrementing transfers must be used instead.

18.5.6.2.6 MCASP_DAT Register Description

Table 18-469. MCASP_RXBUF

18.6 DCAN

This chapter describes the controller area network module (DCAN) in the device.

18.6.1 DCAN Overview

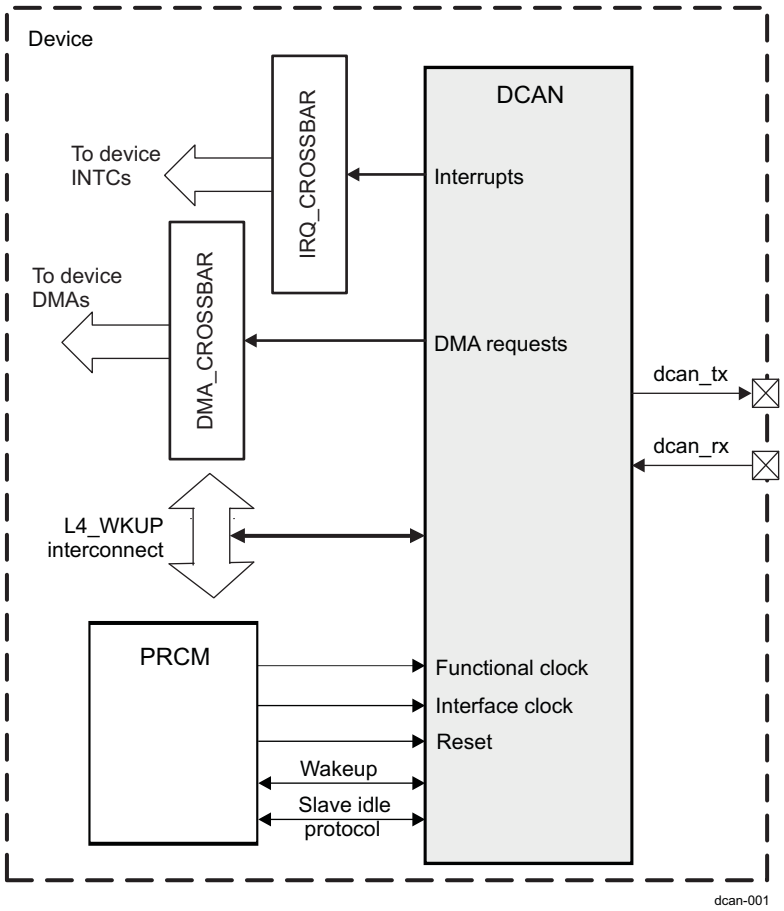
The Controller Area Network (CAN) is a serial communications protocol which efficiently supports distributed real-time applications. CAN has high immunity to electrical interference and the ability to self-diagnose and repair data errors. In a CAN network, many short messages are broadcast to the entire network, which provides for data consistency in every node of the system.

The device supports a single DCAN module.

Connection to the CAN network is performed through external (for the device) transceivers. The DCAN module supports bit rates up to 1 Mbit/s and is compliant to the CAN 2.0B protocol specification.

Figure 18-113 shows the DCAN module highlights.

Figure 18-113. DCAN Overview



18.6.1.1 Features

The DCAN module implements the following features:

- Support for CAN protocol version 2.0 part A, B
- Bit rates up to 1 Mbit/s
- 64 message objects in a dedicated message RAM
- Individual identifier mask for each message object
- Programmable FIFO mode for message objects
- Programmable loop-back modes for self-test operation

- Suspend mode for debug support
- Automatic bus on after Bus-Off state by a programmable 32-bit timer
- Message RAM single error correction and double error detection (SECDED) mechanism
- Direct access to message RAM during test mode
- Support for two interrupt lines: Level 0 and Level 1, plus separate ECC interrupt line
- Local power down and wakeup support
- Automatic message RAM initialization
- Support for DMA access

18.6.2 DCAN Environment

CAN network physical layer consists of two-wire differential bus, usually twisted pair, and provides high level of interference immunity. External CAN transceiver IC is needed to access a CAN bus by the DCAN.

Figure 18-114 shows an overview of a typical DCAN application.

Figure 18-114. DCAN Typical Application

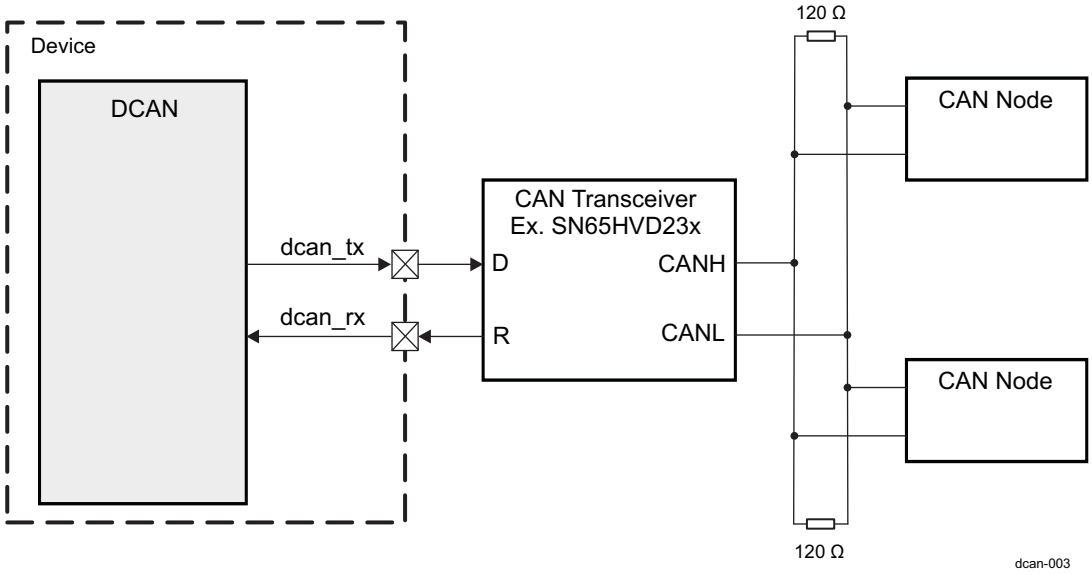


Table 18-473 describes the external signals of the DCAN module.

Table 18-473. DCAN I/O Description

Module Signal	Device Signal	I/O	Description	Value at Reset
CAN_RX	dcan_rx	I	Serial data input from external CAN tranceiver	HiZ
CAN_TX	dcan_tx	O	Serial data output to external CAN tranceiver	1

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see Section 13.4.6.1, *Pad Configuration Registers* of *Chapter 13, Control Module*.

18.6.2.1 CAN Network Basics

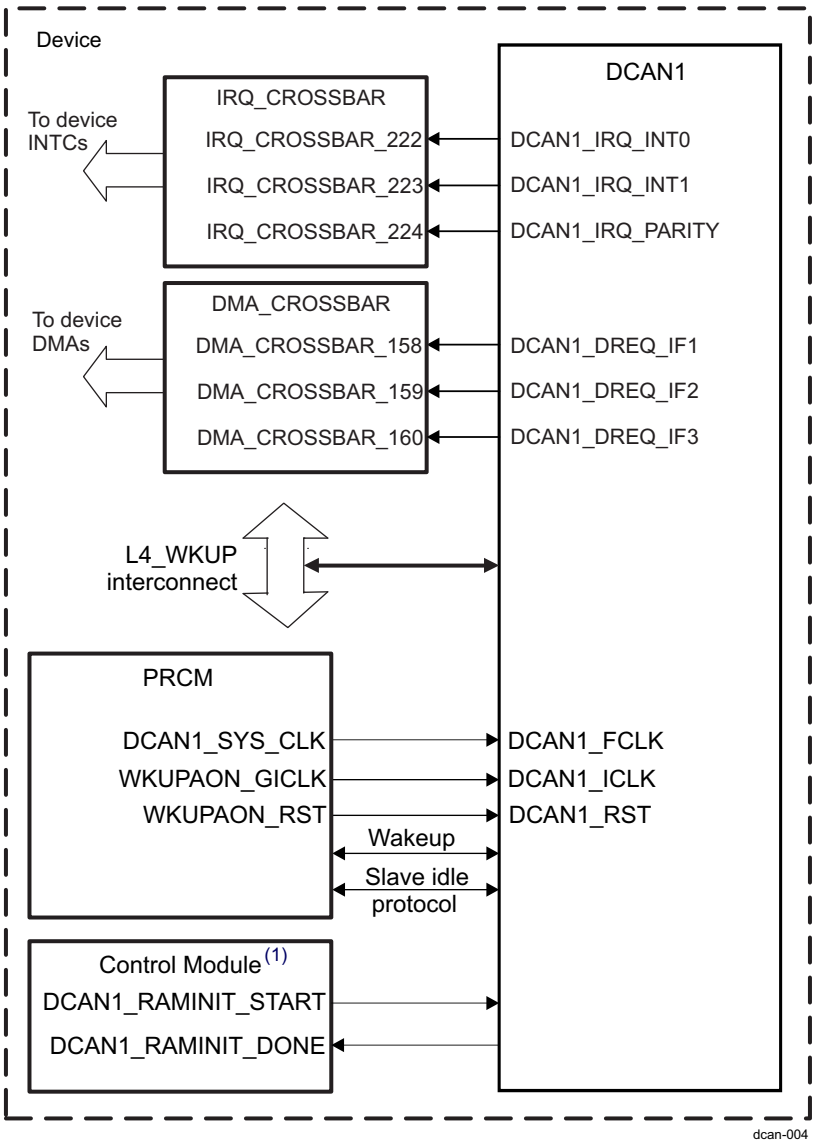
- CAN bus is a 2-wire differential bus using NRZ encoding and has two states:
  - Recessive state (logic 1)
  - Dominant state (logic 0)
- The network is multimaster. When two or more nodes attempt to transmit at the same time, a non-destructive arbitration technique guarantees messages are sent in order of priority and no messages are lost
- The message transmission is multicast. Data messages transmitted are identifier based, not address based
- Content of message is labeled by the identifier that is unique throughout the network (for example, rpm, temperature, position, pressure, etc.)
- All nodes on network receive the message and each performs an acceptance test on the identifier. If message is relevant, it is processed, otherwise it is ignored

- The unique identifier also determines the priority of the message (the lower the numerical value of the identifier, the higher the priority is)
- Data is transmitted and received using message frames, consisting of:
  - Arbitration field
  - Control field
  - Data field (0 ÷ 8 bytes)
  - CRC field
  - ACK field

18.6.3 DCAN Integration

Figure 18-115 shows the integration of the DCAN module in the device. For detailed information on the integration of DCAN see also Table 18-474 through Table 18-476.

Figure 18-115. DCAN Integration



(1) For more information on DCAN RAM Initialization see Section 18.6.4.12.1.3, *DCAN RAM Hardware Initialization*

Table 18-474 through Table 18-476 summarize the integration of the DCAN modules in the device.

Table 18-474. DCAN Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
DCAN	PD_WKUPAON	Yes	L4_WKUP

Table 18-475. DCAN Clocks and Resets

Table 18-476. DCAN Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
DCAN	DCAN_IRQ_INT0	IRQ_CROSSBAR_222	-	Error, Status, and Message Objects interrupt
	DCAN_IRQ_INT1	IRQ_CROSSBAR_223	-	Message Objects interrupt
	DCAN_IRQ_PARITY	IRQ_CROSSBAR_224	-	ECC double bit or single bit error (when correction is disabled) error interrupt
DMA Requests				
Module Instance	**Source Signal Name**	**DMA_CROSSBAR Input**	**Default Mapping**	**Description**
DCAN	DCAN_DREQ_IF1	DMA_CROSSBAR_158	-	DMA request for IF1 register set
	DCAN_DREQ_IF2	DMA_CROSSBAR_159	-	DMA request for IF2 register set
	DCAN_DREQ_IF3	DMA_CROSSBAR_160	-	DMA request for IF3 register set

NOTE: DCAN has no default IRQ mappings through the IRQ_CROSSBAR. For DCAN, the IRQ_CROSSBAR module must be configured prior to unmask interrupts in the interrupt controller(s).
For more information about the IRQ_CROSSBAR module, see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.
For more information about the device interrupt controllers, see Chapter 12, *Interrupt Controllers*.

NOTE: For more information about the DMA_CROSSBAR module, see Section 13.4.6.5, *DMA_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.

NOTE: For the description of the interrupt source, see Section 18.6.4.2, *Interrupt Functionality*.

18.6.4 DCAN Functional Description

The DCAN module performs CAN protocol communication according to ISO 11898-1. The bit rate can be programmed to values up to 1 Mbit/s. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

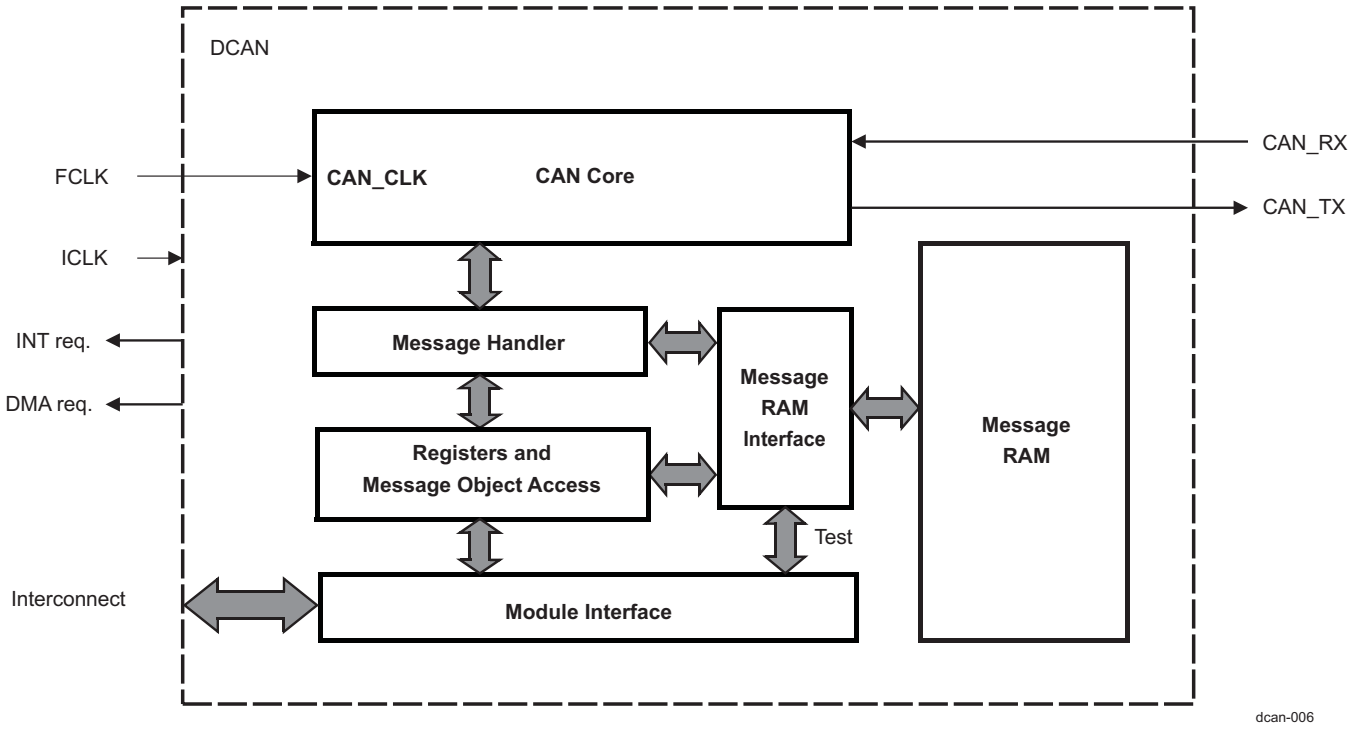
For communication on a CAN network, individual message objects can be configured. The message objects and identifier masks are stored in the message RAM.

All functions concerning the handling of messages are implemented in the message handler. Those functions are acceptance filtering, the transfer of messages between the CAN core and the message RAM, and the handling of transmission requests, as well as the generation of interrupts or DMA requests.

The register set of the DCAN module can be accessed directly via the module interface. These registers are used to control and configure the CAN core and the message handler, and to access the message RAM.

Figure 18-116 shows the DCAN block diagram and its features are described below.

Figure 18-116. DCAN Block Diagram



CAN Core: The CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1 protocol functions.

Message Handler: The message handler is a state machine that controls the data transfer between the single-ported message RAM and the CAN core's Rx/Tx shift register. It also handles acceptance filtering and the interrupt/DMA request generation as programmed in the control registers.

Message RAM: The DCAN enables a storage of 64 CAN messages.

Message RAM Interface: Three interface register sets control the MPU read and write accesses to the message RAM. There are two interface registers sets for read and write access, IF1 and IF2, and one interface register set for read access only, IF3. Additional information can be found in Section 18.6.4.8.12, *Reading From a FIFO Buffer*.

The interface registers have the same word-length as the message RAM.

Registers and Message Object Access: Data consistency is ensured by indirect accesses to the message objects. During normal operation, all software and DMA accesses to the message RAM are done through interface registers. In a dedicated test mode, the message RAM is memory mapped and can be directly accessed by either MPU or DMA.

Module Interface: The DCAN module registers are accessed by the user software through a 32-bit peripheral bus interface.

Clocking: Two clocks are provided to the DCAN module: the peripheral synchronous clock (interface clock [ICLK]) and the peripheral asynchronous clock (functional clock [FCLK]) .

18.6.4.1 Module Clocking Requirements

Two clocks are provided to the DCAN module:

- the peripheral synchronous clock (ICLK) as the general module clock source
- and the peripheral asynchronous clock (FCLK) provided to the CAN core for generating the CAN bit timing.

NOTE: ICLK must always be higher or equal to FCLK, in order to achieve a stable functionality of the DCAN. Here, also the frequency shift of the modulated ICLK has to be considered:

$f_{0,\ ICLK}(OCP) \pm \Delta f_{FM,\ ICLK}(OCP) \geq f_{FCLK}$

For more information on how to configure the relevant clock source registers, see Chapter 3, *PRCM* and the device data manual.

18.6.4.2 Interrupt Functionality

Interrupts can be generated on two interrupt lines: INT0 and INT1. These lines can be enabled by setting the DCAN_CTL[1] IE0 and [17] IE1 bits, respectively. The interrupts are level triggered at the chip level.

The DCAN provides three groups of interrupt sources: message object interrupts, status change interrupts, and error interrupts (see Figure 18-117, *Error and Status Change Interrupts* and Figure 18-118, *Message Objects Interrupts*).

The source of an interrupt can be determined by the interrupt identifiers DCAN_INT[15:0] INT0ID/[23:16] INT1ID. When no interrupt is pending, the register will hold the value zero.

Each interrupt line remains active until the dedicated field in the interrupt register DCAN_INT[15:0] INT0ID/[23:16] INT1ID again reach zero (this means the cause of the interrupt is reset), or until IE0/IE1 are reset.

The value 0x8000 in the INT0ID field indicates that an interrupt is pending because the CAN core has updated (not necessarily changed) the Error and Status register (DCAN_ES). This interrupt has the highest priority. The software can update (reset) the status bits [9] WAKEUPPND, [4] RXOK, [3] TXOK and [2:0] LEC by reading DCAN_ES, but a write access of the software will never generate or reset an interrupt.

Values between 1 and the number of the last message object indicates that the source of the interrupt is one of the message objects, INT0ID resp. INT1ID will point to the pending message interrupt with the highest priority. The Message Object 1 has the highest priority; the last message object has the lowest priority.

An interrupt service routine that reads the message that is the source of the interrupt may read the message and reset the message object's IntPnd at the same time (DCAN_IF1CMD/DCAN_IF2CMD[19] CLRINTPND bit). When IntPnd is cleared, DCAN_INT will point to the next message object with a pending interrupt.

18.6.4.2.1 Message Object Interrupts

Message object interrupts are generated by events from the message objects. They are controlled by the flags IntPnd, TxIE and RxIE that are described in Section 18.6.4.11.1, *Structure of Message Objects*.

Message object interrupts can be routed to either INT0 or INT1 line, controlled by the interrupt multiplexer registers (DCAN_INTMUX12 to DCAN_INTMUX78).

18.6.4.2.2 Status Change Interrupts

The events WAKEUPPND, RXOK, TXOK and LEC in the error and status register (DCAN_ES) belong to the status change interrupts. The status change interrupt group can be enabled by DCAN_CTL[2] SIE bit.

If SIE is set, a status change interrupt will be generated at each CAN frame, independent of bus errors or valid CAN communication, and also independent of the message RAM configuration.

Status change interrupts can only be routed to interrupt line INT0, which has to be enabled by setting DCAN_CTL[1] IE0 = 1.

NOTE: Reading DCAN_ES will clear the WAKEUPPND flag. If in global power-down mode, the WAKEUPPND flag is cleared by such a read access before the DCAN module has been waken up by the system, the DCAN may re-assert the WAKEUPPND flag, and a second interrupt may occur.

18.6.4.2.3 Error Interrupts

The events PER, BOFF and EWARN, monitored in the DCAN_ES register belong to the error interrupts. The error interrupt group can be enabled by setting bit DCAN_CTL[3] EIE = 1.

Error interrupts can only be routed to interrupt line INT0, which has to be enabled by setting DCAN_CTL[1] IE0 = 1.

Figure 18-117. Error and Status Change Interrupts

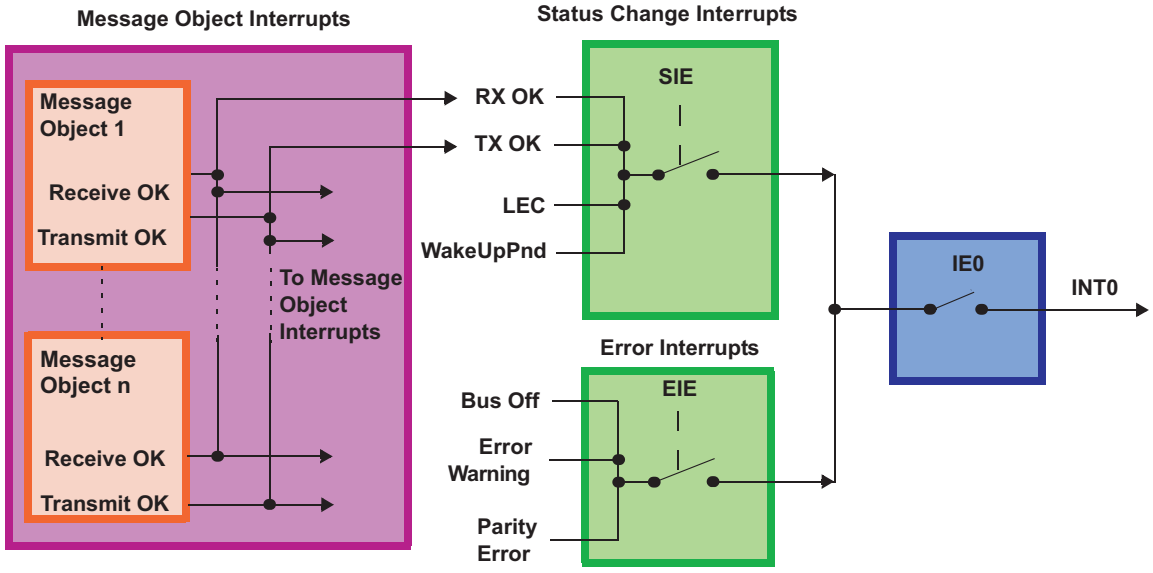


Figure 18-118. Message Objects Interrupts

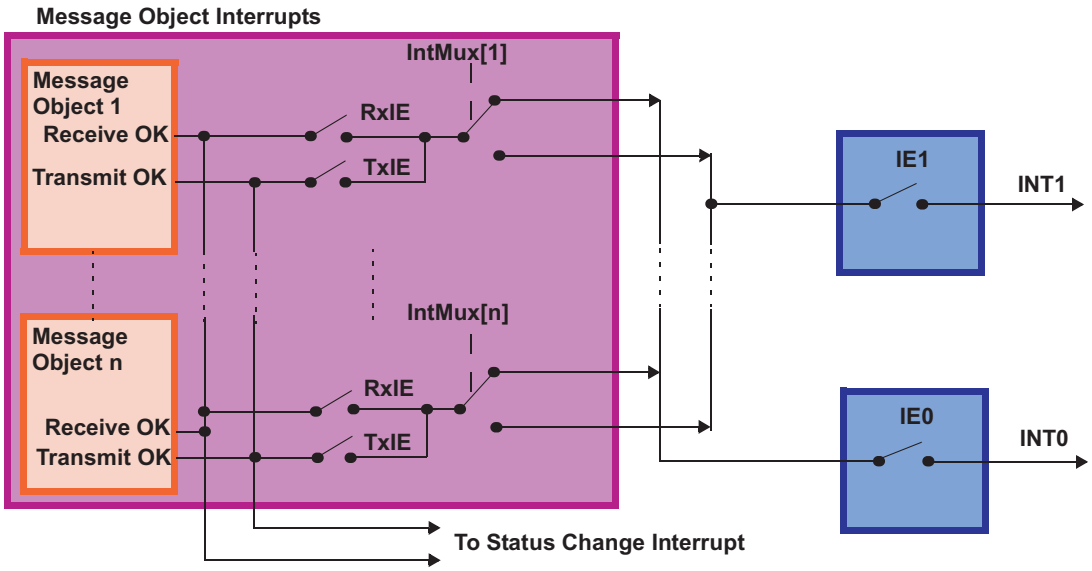


18.6.4.3 DMA Functionality

The DCAN provides three DMA request lines, each indicating new data in one of the three interface register sets IF1, IF2 and IF3.

The update of IF1 and IF2 registers will be initiated by a write access to the IF1 respective IF2 Command Registers (DCAN_IF1CMD, DCAN_IF2CMD).

The IF3 registers content can be automatically updated on reception of CAN messages in message objects which are programmed for automatic IF3 update, see Section 18.6.4.10.2, *IF3 Register Set*.

When a DCAN internal IFx (x = 1 to 3) update is complete, a DMA request will be activated and stays active until the first access to one of the relevant IFx registers. The DMA functionality has to be enabled by setting bit [18] DE0/[19] DE1/[20] DE3 in DCAN_CTL.

18.6.4.4 Local Power-Down Mode

The DCAN supports a local power-down mode, which can be controlled within the DCAN registers.

18.6.4.4.1 Entering Local Power-Down Mode

The local power-down mode is requested by setting the DCAN_CTL[24] PDR bit (=1).

The DCAN then finishes all transmit requests of the message objects. When all requests are done, DCAN waits until a bus idle state is recognized. Then it will automatically set the DCAN_CTL[0] INIT bit to prevent any further CAN transfers, and it will also set the DCAN_ES[10] PDA bit. With setting the PDA bit, the DCAN module indicates that the local power-down mode has been entered.

During local power-down mode, the internal clocks of the DCAN module are turned off, but there is a wakeup logic (see Section 18.6.4.4.2, *Wakeup From Local Power Down*) that can be active, if enabled. Also, the actual contents of the control registers can be read back.

NOTE: In local low-power mode, the software must not clear the INIT bit while PDR is set. If there are any messages in the message RAM which are configured as transmit messages and the application resets the INIT bit, these messages may get sent.

18.6.4.4.2 Wakeup From Local Power Down

There are two ways to wake up the DCAN from local power-down mode:

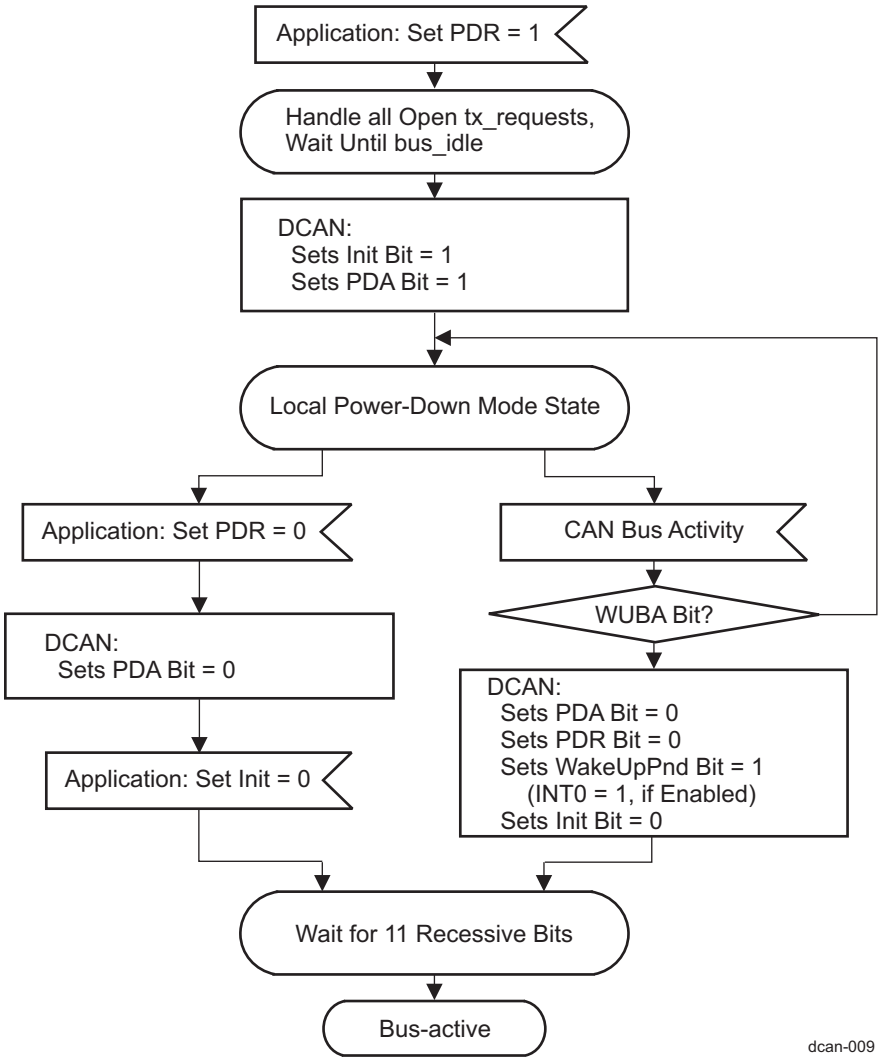
- The application could wake up the DCAN module manually by clearing the DCAN_CTL[24] PDR bit and then clearing the DCAN_CTL[0] INIT.
- Alternatively, a CAN bus activity detection circuit can be activated by setting the wakeup on bus activity bit (DCAN_CTL[25] WUBA). If this circuit is active, on occurrence of a dominant CAN bus level, the DCAN will automatically start the wakeup sequence. It will clear the DCAN_CTL[24] PDR bit and also clear the DCAN_ES[10] PDA bit. The DCAN_ES[10] WAKEUPPND bit will be set. If status interrupts are enabled, also an interrupt will be generated. Finally the DCAN_CTL[0] INIT bit will be cleared.

After the INIT bit has been cleared, the module waits until it detects 11 consecutive recessive bits on the CAN_RX pin and then goes bus-active again.

NOTE: The CAN transceiver circuit has to stay active in order to detect any CAN bus activity while the DCAN is in local power down mode. The first CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power-down and automatic wake-up mode, is lost.

Figure 18-119 shows a flow diagram about entering and leaving local power-down mode.

Figure 18-119. Local Power-Down Mode Flow Diagram



18.6.4.5 SECDED Mechanism

The DCAN module provides a single error correction and double error detection (SECDED) mechanism to ensure data integrity of Message RAM data. For each message object (136 bits) in the Message RAM, 9 ECC bits will be calculated.

The ECC bits are stored in a dedicated RAM. They will be generated on write accesses and will be checked on read accesses.

The SECDED functionality can be enabled or disabled by DCAN_CTL[13:10] PMD bit field.

In case of disabled SECDED, the ECC bits will be left unchanged on write access to data area and no correction or check will be done on read access.

If SECDED is enabled, ECC bits will be automatically generated and checked. The ECC bits are memory mapped as described in Section 18.6.4.11.3, *ECC RAM*.

With the ECCMODE field in the DCAN_ECC_CS register the single bit error correction can be enabled or disabled (default: enabled).

NOTE: During RAM initialization, no SECDED check will be done, but if the PMD bit is set, the ECC bits will be generated.

18.6.4.5.1 Behavior on Single Bit Error

If a single bit error is detected with single bit error correction enabled, the correction will be done and the SEFLG in the DCAN_ECC_CS register will be set.

If single bit error correction is disabled and a single bit error is detected then the SEFLG in the DCAN_ECC_CS register and the the PER bit in the Error and Status register will be set. If error interrupts are enabled, also an interrupt would be generated. In order to avoid the transmission of invalid data over the CAN bus, the MsgVal bit of the message object will be reset.

If single bit error correction is disabled and a single bit error is detected then the IRQ_PARITY signal is generating a high pulse for one interface clock period.

The message object number where the single bit error has occurred will be indicated in the DCAN_ECC_SERR Register.

When single bit error correction is disabled the message object data can be read by the host CPU, independently of single bit errors. Thus, the application has to ensure that the read data is valid, for example, by immediately checking the DCAN_ECC_SERR on single bit error interrupt.

18.6.4.5.2 Behavior on Double Bit Error

If a double bit error is detected, then the DEFLG in the DCAN_ECC_CS register and the PER bit in DCAN_ES will be set. If error interrupts are enabled, also an interrupt would be generated. In order to avoid the transmission of invalid data over the CAN bus, the MsgVal bit of the message object will be reset. The message object number will be indicated in the DCAN_PERR register.

Additionally the signal IRQ_PARITY signalizes - by generating a high pulse for one interface clock period - the double bit error occurrence for the host CPU. The message object data can be read by the host CPU, independently of double bit errors. Thus, the application has to ensure that the read data is valid, for example, by immediately checking the DCAN_PERR register on double bit error interrupt.

18.6.4.5.3 SECDED Testing

Testing of the SECDED mechanism can be implemented by using the diagnostic mode, which is enabled with the DCAN_ECCDIAG register. The following procedure can be used:

1. Disable SECDED using DCAN_CTL register. Enable diagnostic mode using the DCAN_ECCDIAG register
2. Write to corrupt the data (in RDA mode) or ECC bits.
3. Enable SECDED and read data for which ECC is corrupted (either in RDA mode or via IFx registers).

4. Single bit error or double bit error flag will be set in the diagnostic status register (DCAN_ECCDIAG_STAT) and in the DCAN_ECC_CS register, accordingly. A double bit error or a single bit error with single bit error correction disabled also triggers the PER flag.
5. Disable diagnostic mode.

18.6.4.6 Debug/Suspend Mode

The module supports the usage of an external debug unit by providing functions like pausing DCAN activities and making message RAM content accessible via interconnect interface.

Before entering debug/suspend mode, the DCAN will either wait until a started transmission or reception will be finished and bus idle state is recognized, or immediately interrupt a current transmission or reception. This is depending on bit DCAN_CTL[8] IDS in the CAN control register.

Afterwards, the DCAN enters debug/suspend mode, indicated by DCAN_CTL [16] INITDBG flag.

During debug/suspend mode, all DCAN registers can be accessed. Reading reserved bits will return '0'. Writing to reserved bits will have no effect.

Also, the message RAM will be memory mapped. This allows the external debug unit to read the message RAM. For the memory organization, see Section 18.6.4.11.4, *Message RAM Representation in Debug/Suspend Mode*.

NOTE: During debug/suspend mode, the message RAM cannot be accessed via the IFx register sets.

NOTE: Writing to control registers in debug/suspend mode may influence the CAN state machine and further message handling.

For debug support, the auto clear functionality of the following DCAN registers is disabled:

- DCAN_ES register (clear of status flags by read)
- DCAN_IF1CMD/DCAN_IF2CMD command registers (clear of [14] DMAACTIVE flag by read/write)

18.6.4.7 Configuration of Message Objects Description

The whole message RAM should be configured before the end of the initialization, however it is also possible to change the configuration of message objects during CAN communication.

The CAN software driver must offer subroutines that:

- Transfer a complete message structure into a message object. (Configuration)
- Transfer the data bytes of a message into a message object and set TxRqst and NewDat. (Start a new transmission)
- Get the data bytes of a message from a message object and clear NewDat (and IntPnd). (Read received data)
- Get the complete message from a message object and clear NewDat (and IntPnd). (Read a received message, including identifier, from a message object with UMask = '1')

Parameters of the subroutines are the Message Number and a pointer to a complete message structure or to the data bytes of a message structure.

Two examples of assigning the IFx interface register sets to these subroutines are shown here:

In the first method, the tasks of the application program that may access the module are divided into two groups. Each group is restricted to the use of one of the interface register sets. The tasks of one group may interrupt tasks of the other group, but not of the same group.

In the second method, which may be a special case of the first method, there are only two tasks in the application program that access the module. A Read_Message task that uses IF2 or IF3 to get received messages from the message RAM and a Write_Message task that uses IF1 to write messages to be transmitted (or to be configured) into the message RAM. Both tasks may interrupt each other.

18.6.4.7.1 Configuration of a Transmit Object for Data Frames

Table 18-477 shows how a transmit object can be initialized.

Table 18-477. Initialization of a Transmit Object

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	0	appl.	0	appl.	0

The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of the outgoing message. If an 11-bit identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored.

The data length and data itself (DLC[3:0] and Data0-7) are given by the application. TxRqst and RmtEn should not be set before the data is valid.

If the TXIE bit is set, the IntPnd bit will be set after a successful transmission of the message object.

If the RmtEn bit is set, a matching received remote frame will cause the TxRqst bit to be set; the remote frame will autonomously be answered by a data frame.

The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask='1') to allow groups of remote frames with similar identifiers to set the TxRqst bit. The Dir bit should not be masked. For details, see Section 18.6.4.8.8, *Reception of Remote Frames*.

Identifier masking must be disabled (UMask = '0') if no remote frames are allowed to set the TxRqst bit (RmtEn = '0').

18.6.4.7.2 Configuration of a Transmit Object for Remote Frames

It is not necessary to configure transmit objects for the transmission of remote frames. Setting TxRqst for a receive object causes the transmission of a remote frame with the same identifier as the data rrame for which this receive object is configured.

18.6.4.7.3 Configuration of a Single Receive Object for Data Frames

Table 18-478 shows how a receive object for data frames can be initialized.

Table 18-478. Initialization of a single Receive Object for Data Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	0	0	0	appl.	0	0	0	0

The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of accepted received messages. If an 11-bit Identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a data frame with an 11-bit Identifier is received, ID[17:0] is set to '0'.

The data length code (DLC[3:0]) is given by the application. When the message handler stores a data frame in the message object, it will store the received data length code and eight data bytes. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by non specified values.

The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask = '1') to allow groups of data frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. If some bits of the mask bits are set to "don't care," the corresponding bits of the arbitration register (DCAN_IF1ARB, DCAN_IF2ARB, DCAN_IF3ARB) will be overwritten by the bits of the stored data frame.

If the RxIE bit is set, the IntPnd bit will be set when a received data frame is accepted and stored in the message object.

If the TxRqst bit is set, the transmission of a remote frame with the same identifier as actually stored in the arbitration bits will be triggered. The content of the arbitration bits may change if the mask bits are used (UMask = '1') for acceptance filtering.

18.6.4.7.4 Configuration of a Single Receive Object for Remote Frames

Table 18-479 shows how a receive object for remote frames can be initialized.

Table 18-479. Initialization of a Single Receive Object for Remote Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	appl.	0	0	0	0

A receive object for remote frames may be used to monitor remote frames on the CAN bus. The remote frame stored in the receive object will not trigger the transmission of a data frame. Receive objects for remote frames may be expanded to a FIFO buffer (see Section 18.6.4.7.5, *Configuration of a FIFO Buffer*).

UMask must be set to '1.' The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be set to "must-match" or to "don't care," to allow groups of remote frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. For details, see Section 18.6.4.8.8, *Reception of Remote Frames*.

The arbitration bits (ID[28:0] and Xtd bit) may be given by the application. They define the identifier and type of accepted received remote frames. If some bits of the mask bits are set to "don't care," the corresponding bits of the arbitration bits will be overwritten by the bits of the stored remote frame. If an 11-bit Identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a remote frame with an 11-bit Identifier is received, ID[17:0] will be set to '0.'

The data length code (DLC[3:0]) may be given by the application. When the message handler stores a remote frame in the message object, it will store the received data length code. The data bytes of the message object will remain unchanged.

If the RxIE bit is set, the IntPnd bit will be set when a received remote frame is accepted and stored in the message object.

18.6.4.7.5 Configuration of a FIFO Buffer

With the exception of the EoB bit, the configuration of receive objects belonging to a FIFO buffer is the same as the configuration of a single receive object.

To concatenate multiple message objects to a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest number will be the first message object of the FIFO buffer. The EoB bit of all message objects of a FIFO buffer except the last one have to be programmed to zero. The EoB bits of the last message object of a FIFO Buffer is set to one, configuring it as the end of the block.

18.6.4.8 Message Handling

When initialization is finished, the DCAN module synchronizes itself to the traffic on the CAN bus. It does acceptance filtering on received messages and stores those frames that are accepted into the designated message objects. The application has to update the data of the messages to be transmitted and to enable and request their transmission. The transmission is requested automatically when a matching remote frame is received.

The application may read messages which are received and accepted. Messages that are not read before the next messages is accepted for the same message object will be overwritten.

Messages may be read interrupt-driven or after polling of NewDat.

18.6.4.8.1 Message Handler Overview

The message handler state machine controls the data transfer between the Rx/Tx shift register of the CAN core and the message RAM. It performs the following tasks:

- Data transfer from message RAM to CAN core (messages to be transmitted)
- Data transfer from CAN core to the message RAM (received messages)
- Data transfer from CAN core to the acceptance filtering unit
- Scanning of message RAM for a matching message object (acceptance filtering)
- Scanning the same message object after being changed by IF1/IF2 registers when priority is the same or higher as the message the object found by last scanning
- Handling of TxRqst flags
- Handling of interrupt flags

The message handler registers contains status flags of all message objects grouped into the following topics:

- Transmission Request Flags
- New Data Flags
- Interrupt Pending Flags
- Message Valid Registers

Instead of collecting above listed status information of each message object via IFx registers separately, these message handler registers provides a fast and easy way to get an overview, for example, about all pending transmission requests.

All message handler registers are read-only.

18.6.4.8.2 Receive/Transmit Priority

The receive/transmit priority for the message objects is attached to the message number, not to the CAN identifier. Message object 1 has the highest priority, while the last implemented message object has the lowest priority. If more than one transmission request is pending, they are serviced due to the priority of the corresponding message object so messages with the highest priority, for example, can be placed in the message objects with the lowest numbers.

The acceptance filtering for received data frames or remote frames is also done in ascending order of message objects, so a frame that has been accepted by a message object cannot be accepted by another message object with a higher message number. The last message object may be configured to accept any data frame or remote frame that was not accepted by any other message object, for nodes that need to log the complete message traffic on the CAN bus.

18.6.4.8.3 Transmission of Messages in Event Driven CAN Communication

If the shift register of the CAN core is ready for loading and if there is no data transfer between the IFx registers and message RAM, the MSGVAL bits in the Message Valid register (DCAN_MSGVAL12 to DCAN_MSGVAL78) and the TXRQST bits in the transmission request register (DCAN_TXRQ12 to DCAN_TXRQ78) are evaluated. The valid message object with the highest priority pending transmission request is loaded into the shift register by the message handler and the transmission is started. The message object's NewDat bit is reset.

After a successful transmission and if no new data was written to the message object (NewDat = '0') since the start of the transmission, the TxRqst bit will be reset. If TxIE is set, IntPnd will be set after a successful transmission. If the DCAN has lost the arbitration or if an error occurred during the transmission, the message will be retransmitted as soon as the CAN bus is free again. If meanwhile the transmission of a message with higher priority has been requested, the messages will be transmitted in the order of their priority.

If automatic retransmission mode is disabled by setting the DCAN_CTL[5] DAR bit, the behavior of bits TXRQST and NEWDAT in the DCAN_IF1CMD/DCAN_IF2CMD register of the interface register set is as follows:

- When a transmission starts, the TxRqst bit of the respective interface register set is reset, while bit

NewDat remains set.

- When the transmission has been successfully completed, the NewDat bit is reset.

When a transmission failed (lost arbitration or error), bit NewDat remains set. To restart the transmission, the application has to set TxRqst again.

Received remote frames do not require a receive object. They will automatically trigger the transmission of a data frame, if in the matching transmit object the RmtEn bit is set.

18.6.4.8.4 Updating a Transmit Object

The software may update the data bytes of a transmit object any time via the IF1/IF2 interface registers, neither MSGVAL, nor TXRQST have to be reset before the update.

Even if only a part of the data bytes are to be updated, all four bytes in the corresponding IF1/IF2 Data A register (DCAN_IF1DATA/DCAN_IF2DATA) or IF1/IF2 Data B register (DCAN_IF1DATB/DCAN_IF2DATB) have to be valid before the content of that register is transferred to the message object. Either the software has to write all four bytes into the IF1/IF2 data register or the message object is transferred to the IF1/IF2 data register before the software writes the new data bytes.

When only the data bytes are updated, first 0x87 can be written to bits [23:16] of the IF1/IF2 Command register (DCAN_IF1CMD/DCAN_IF2CMD) and then the number of the message object is written to bits [7:0] MESSAGE_NUMBER of the command register, concurrently updating the data bytes and setting TXRQST with NEWDAT.

To prevent the reset of TxRqst at the end of a transmission that may already be in progress while the data is updated, NewDat has to be set together with TxRqst in event driven CAN communication. For details, see Section 18.6.4.8.3, *Transmission of Messages in Event Driven CAN Communication*.

When NewDat is set together with TxRqst, NewDat will be reset as soon as the new transmission has started.

18.6.4.8.5 Changing a Transmit Object

If the number of implemented message objects is not sufficient to be used as permanent message objects only, the transmit objects may be managed dynamically. The software can write the whole message (arbitration, control, and data) into the interface register. The bits [23:16] of the command register (DCAN_IF1CMD/DCAN_IF2CMD) can be set to 0xB7 for the transfer of the whole message object content into the message object. Neither Dir, nor TxRqst have to be reset before this operation.

If a previously requested transmission of this message object is not completed but already in progress, it will be continued; however, it will not be repeated if it is disturbed.

To only update the data bytes of a message to be transmitted, bits [23:16] of the command register (DCAN_IF1CMD/ DCAN_IF2CMD) should be set to 0x87.

NOTE: After the update of the transmit object, the interface register set will contain a copy of the actual contents of the object, including the part that had not been updated.

18.6.4.8.6 Acceptance Filtering of Received Messages

When the arbitration and control bits (Identifier + IDE + RTR + DLC) of an incoming message are completely shifted into the shift register of the CAN core, the message handler starts the scan of the message RAM for a matching valid message object:

- The acceptance filtering unit is loaded with the arbitration bits from the CAN core shift register.
- Then the arbitration and mask bits (including MsgVal, UMask, NewDat, and EoB) of message object 1 are loaded into the acceptance filtering unit and are compared with the arbitration bits from the shift register. This is repeated for all following message objects until a matching message object is found, or until the end of the message RAM is reached.
- If a match occurs, the scanning is stopped and the message handler proceeds depending on the type of the frame (data frame or remote frame) received.

18.6.4.8.7 Reception of Data Frames

The message handler stores the message from the CAN core shift register into the respective message object in the message RAM. Not only the data bytes, but all arbitration bits and the data length code are stored into the corresponding message object. This ensures that the data bytes stay associated to the identifier even if arbitration mask registers are used.

The NewDat bit is set to indicate that new data (not yet seen by the software) has been received. The software should reset the NewDat bit when it reads the message object. If at the time of the reception the NewDat bit was already set, MsgLst is set to indicate that the previous data (supposedly not seen by the software) is lost. If the RxIE bit is set, the IntPnd bit is set, causing the DCAN_INT to point to this message object.

The TxRqst bit of this message object is reset to prevent the transmission of a remote frame, while the requested data frame has just been received.

18.6.4.8.8 Reception of Remote Frames

When a remote frame is received, three different configurations of the matching message object have to be considered:

- Dir = '1' (direction = transmit), RmtEn = '1', UMask = '1' or '0'

  The TxRqst bit of this message object is set at the reception of a matching remote frame. The rest of the message object remains unchanged.
- Dir = '1' (direction = transmit), RmtEn = '0', UMask = '0'

  The remote frame is ignored, this message object remains unchanged.
- Dir = '1' (direction = transmit), RmtEn = '0', UMask = '1'

  The remote frame is treated similar to a received data frame. At the reception of a matching Remote Frame, the TxRqst bit of this message object is reset. The arbitration and control bits (Identifier + IDE + RTR + DLC) from the shift register are stored in the message object in the message RAM and the NewDat bit of this message object is set. The data bytes of the message object remain unchanged.

18.6.4.8.9 Reading Received Messages

The software may read a received message any time via the IFx interface register. The data consistency is guaranteed by the message handler state machine. Typically the software will write first 0x7F to bits [23:16] and then the number of the message object to bits [7:0] MESSAGE_NUMBER of the command register (DCAN_IF1CMD/ DCAN_IF2CMD). That combination will transfer the entire received message from the message RAM into the interface register set. Additionally, the bits NewDat and IntPnd are cleared in the message RAM (not in the interface register set). The values of these bits in the message control register (DCAN_IF1MCTL/DCAN_IF2MCTL/DCAN_IF3MCTL) always reflect the status before resetting the bits. If the message object uses masks for acceptance filtering, the arbitration bits show which of the different matching messages has been received.

The actual value of NewDat shows whether a new message has been received since last time when this message object was read. The actual value of MsgLst shows whether more than one message has been received since the last time when this message object was read. MsgLst will not be automatically reset.

18.6.4.8.10 Requesting New Data for a Receive Object

By means of a remote frame, the software may request another CAN node to provide new data for a receive object. Setting the TxRqst bit of a receive object will cause the transmission of a remote frame with the identifier of the receive object. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the TxRqst bit is automatically reset. Setting the TxRqst bit without changing the contents of a message object requires the value 0x84 in bits [23:16] of the command register (DCAN_IF1CMD/ DCAN_IF2CMD).

18.6.4.8.11 Storing Received Messages in FIFO Buffers

Several message objects may be grouped to form one or more FIFO buffers. Each FIFO buffer configured to store received messages with a particular (group of) identifier(s). arbitration and mask registers of the FIFO buffer's message objects are identical. The end of buffer (EoB) bits of all but the last of the FIFO buffer's message objects are '0'; in the last one the EoB bit is '1.'

Received messages with identifiers matching to a FIFO buffer are stored into a message object of this FIFO buffer, starting with the message object with the lowest message number. When a message is stored into a message object of a FIFO buffer, the NewDat bit of this message object is set. By setting NewDat while EoB is '0', the message object is locked for further write accesses by the message handler until the software has cleared the NewDat bit.

Messages are stored into a FIFO buffer until the last message object of this FIFO buffer is reached. If none of the preceding message objects is released by writing NewDat to '0,' all further messages for this FIFO buffer will be written into the last message object of the FIFO buffer (EoB = '1') and therefore overwrite previous messages in this message object.

18.6.4.8.12 Reading From a FIFO Buffer

Several messages may be accumulated in a set of message objects which are concatenated to form a FIFO buffer before the application program is required (in order to avoid the loss of data) to empty the buffer.

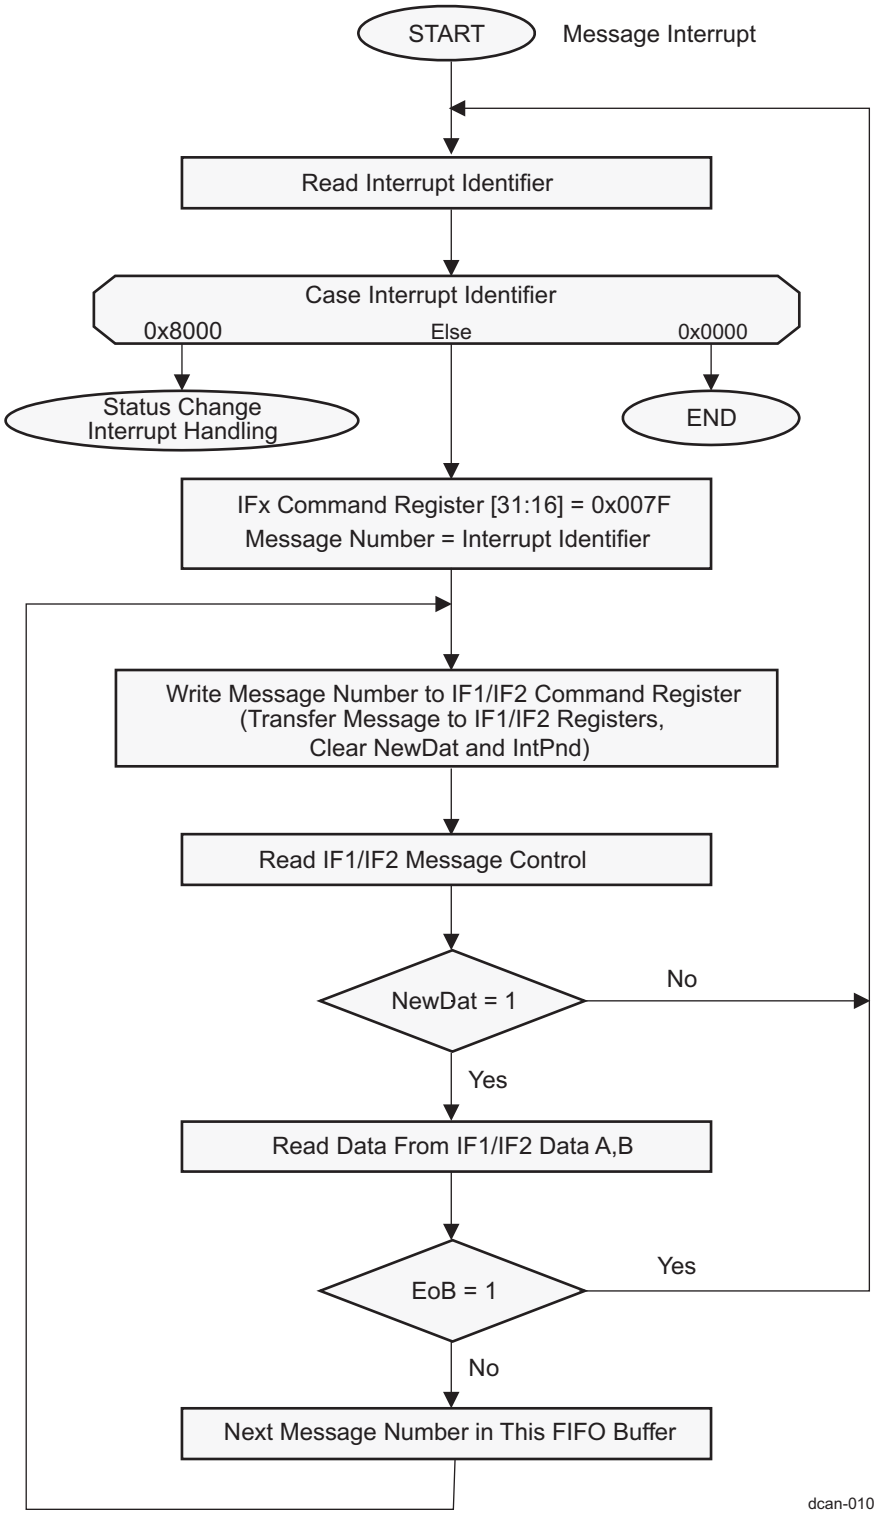
A FIFO buffer of length N will store N–1, plus the last received message since last time it was cleared.

A FIFO buffer is cleared by reading and resetting the NewDat bits of all its message objects, starting at the FIFO Object with the lowest message number. This should be done in a subroutine following the example shown in Figure 18-120.

NOTE: All message objects of a FIFO buffer needs to be read and cleared before the next batch of messages can be stored. Otherwise, true FIFO functionality can not be guaranteed, since the message objects of a partly read buffer will be re-filled according to the normal (descending) priority.

Reading from a FIFO buffer message object and resetting its NewDat bit is handled the same way as reading from a single message object.

Figure 18-120. Software Handling of a FIFO Buffer (Interrupt Driven)



18.6.4.9 CAN Bit Timing

The DCAN supports bit rates between < 1 kBit/s and 1000 kBit/s.

Each member of the CAN network has its own clock generator, typically derived from a crystal oscillator. The bit timing parameters can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes' oscillator periods (f_{osc}) may be different.

The frequencies of these oscillators are not absolutely stable. Small variations are caused by changes in temperature or voltage and by deteriorating components. As long as the variations remain inside a specific oscillator tolerance range (df), the CAN nodes are able to compensate for the different bit rates by resynchronizing to the bit stream.

In many cases, the CAN bit synchronization will amend a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive.

The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

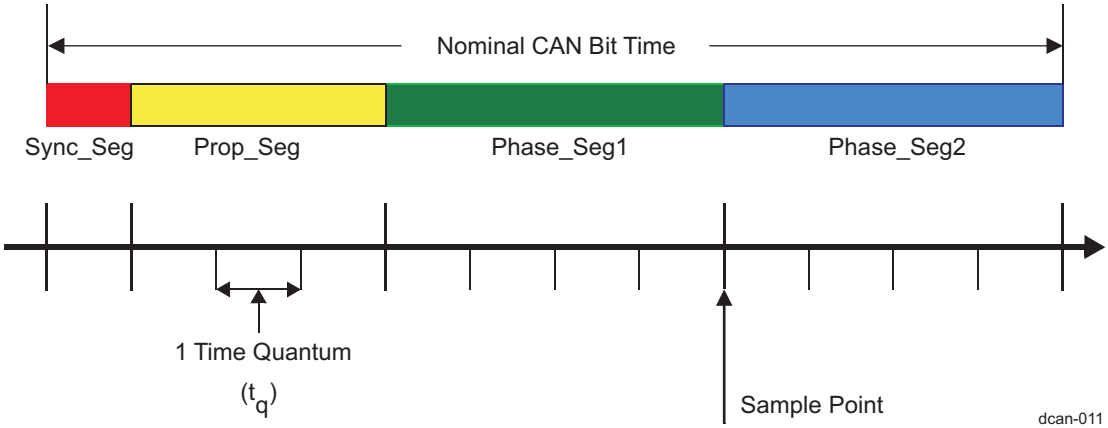
Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly.

18.6.4.9.1 Bit Time and Bit Rate

According to the CAN specification, the bit time is divided into four segments (see Figure 18-121):

- Synchronization segment (Sync_Seg)
- Propagation time segment (Prop_Seg)
- Phase buffer segment 1 (Phase_Seg1)
- Phase buffer segment 2 (Phase_Seg2)

Figure 18-121. Bit Timing



Each segment consists of a specific number of time quanta. The length of one time quantum (t_q), which is the basic time unit of the bit time, is given by the FCLK and the baud rate prescalers (BRPE and BRP). With these two baud rate prescalers combined, divider values from 1 to 1024 can be programmed:

t_q = Baud Rate Prescaler / FCLK

Apart from the fixed length of the synchronization segment, these numbers are programmable. Table 18-480 describes the minimum programmable ranges required by the CAN protocol.

A given bit rate may be met by different bit time configurations.

Table 18-480. Parameters of the CAN Bit Time

Parameter	Range	Remark
Sync_Seg	1 t_q (fixed)	Synchronization of bus input to FCLK
Prop_Seg	[1 … 8] t_q	Compensates for the physical delay times
Phase_Seg1	[1 … 8] t_q	May be lengthened temporarily by synchronization

Table 18-480. Parameters of the CAN Bit Time (continued)

Parameter	Range	Remark
Phase_Seg2	[1 … 8] t_q	May be shortened temporarily by synchronization
Synchronization Jump Width (SJW)	[1 … 4] t_q	May not be longer than either Phase Buffer Segment

NOTE: For proper functionality of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

18.6.4.9.1.1 Synchronization Segment

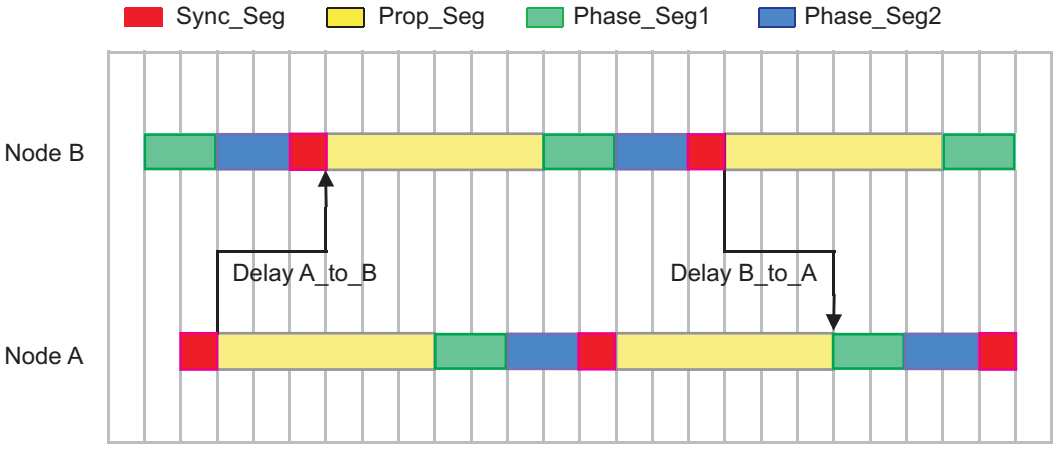
The synchronization segment (Sync_Seg) is the part of the bit time where edges of the CAN bus level are expected to occur. If an edge occurs outside of Sync_Seg, its distance to the Sync_Seg is called the phase error of this edge.

18.6.4.9.1.2 Propagation Time Segment

This part of the bit time is used to compensate physical delay times within the CAN network. These delay times consist of the signal propagation time on the bus and the internal delay time of the CAN nodes.

Any CAN node synchronized to the bit stream on the CAN bus can be out of phase with the transmitter of the bit stream, caused by the signal propagation time between the two nodes. The CAN protocol's nondestructive bitwise arbitration and the dominant acknowledge bit provided by receivers of CAN messages require that a CAN node transmitting a bit stream must also be able to receive dominant bits transmitted by other CAN nodes that are synchronized to that bit stream. The example in Figure 18-122 shows the phase shift and propagation times between two CAN nodes.

Figure 18-122. The Propagation Time Segment



Delay A_to_B ≥ node output delay(A) + bus line delay(AÆB) + node input delay(B)

Prop_Seg ≥ Delay A_to_B + Delay B_to_A

Prop_Seg ≥ 2 [max(node output delay + bus line delay + node input delay)]

dcan-012

In this example, both nodes A and B are transmitters performing an arbitration for the CAN bus. The node A has sent its start of frame bit less than one bit time earlier than node B, therefore node B has synchronized itself to the received edge from recessive to dominant. Since node B has received this edge delay(A_to_B) after it has been transmitted, node B's bit timing segments are shifted with regard to node A. Node B sends an identifier with higher priority and so it will win the arbitration at a specific identifier bit when it transmits a dominant bit while node A transmits a recessive bit. The dominant bit transmitted by node B will arrive at node A after the delay (B_to_A).

Due to oscillator tolerances, the actual position of node A's sample point can be anywhere inside the nominal range of node A's Phase Buffer Segments, so the bit transmitted by node B must arrive at node A before the start of Phase_Seg1. This condition defines the length of Prop_Seg.

If the edge from recessive to dominant transmitted by node B would arrive at node A after the start of Phase_Seg1, it could happen that node A samples a recessive bit instead of a dominant bit, resulting in a bit error and the destruction of the current frame by an error flag.

This error only occurs when two nodes arbitrate for the CAN bus which have oscillators of opposite ends of the tolerance range and are separated by a long bus line; this is an example of a minor error in the bit timing configuration (Prop_Seg too short) that causes sporadic bus errors.

Some CAN implementations provide an optional 3-Sample Mode. The DCAN does not. In this mode, the CAN bus input signal passes a digital low-pass filter, using three samples and a majority logic to determine the valid bit value. This results in an additional input delay of 1 t_q, requiring a longer Prop_Seg.

18.6.4.9.1.3 Phase Buffer Segments and Synchronization

The phase buffer segments (Phase_Seg1 and Phase_Seg2) and the synchronization jump width (SJW) are used to compensate for the oscillator tolerance.

The phase buffer segments surround the sample point and may be lengthened or shortened by synchronization.

The synchronization jump width (SJW) defines how far the resynchronizing mechanism may move the sample point inside the limits defined by the phase buffer segments to compensate for edge phase errors.

Synchronizations occur on edges from recessive to dominant. Their purpose is to control the distance between edges and sample points.

Edges are detected by sampling the actual bus level in each time quantum and comparing it with the bus level at the previous sample point. A synchronization may be done only if a recessive bit was sampled at the previous sample point and if the actual time quantum's bus level is dominant.

An edge is synchronous if it occurs inside of Sync_Seg; otherwise, its distance to the Sync_Seg is the edge phase error, measured in time quanta. If the edge occurs before Sync_Seg, the phase error is negative, else it is positive.

Two types of synchronization exist: hard synchronization and resynchronizing. A hard synchronization is done once at the start of a frame; inside a frame, only resynchronization is possible.

- Hard Synchronization

  After a hard synchronization, the bit time is restarted with the end of Sync_Seg, regardless of the edge phase error. Thus hard synchronization forces the edge which has caused the hard synchronization, to lie within the synchronization segment of the restarted bit time.

- Bit Resynchronizations

  Resynchronization leads to a shortening or lengthening of the Bit time such that the position of the sample point is shifted with regard to the edge.

  When the phase error of the edge which causes resynchronization is positive, Phase_Seg1 is lengthened. If the magnitude of the phase error is less than SJW, Phase_Seg1 is lengthened by the magnitude of the phase error, else it is lengthened by SJW.

  When the phase error of the edge which causes Resynchronization is negative, Phase_Seg2 is shortened. If the magnitude of the phase error is less than SJW, Phase_Seg2 is shortened by the magnitude of the phase error, else it is shortened by SJW.

If the magnitude of the phase error of the edge is less than or equal to the programmed value of SJW, the results of hard synchronization and resynchronization are the same. If the magnitude of the phase error is larger than SJW, the resynchronization cannot compensate the phase error completely, and an error of (phase error - SJW) remains.

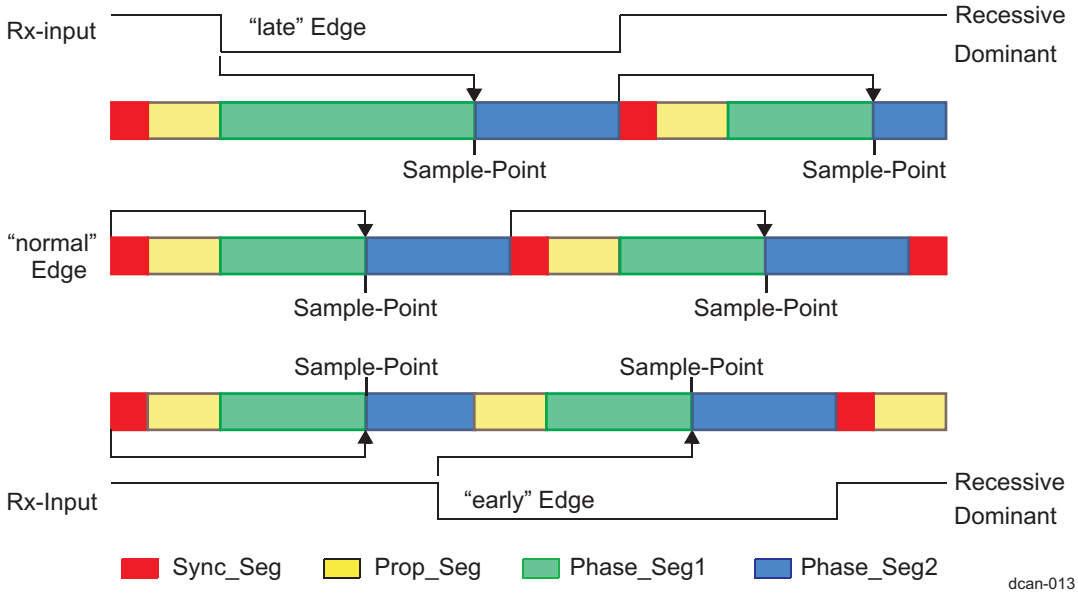
Only one synchronization may be done between two sample points. The synchronizations maintain a minimum distance between edges and sample points, giving the bus level time to stabilize and filtering out spikes that are shorter than (Prop_Seg + Phase_Seg1).

Apart from noise spikes, most synchronizations are caused by arbitration. All nodes synchronize “hard” on the edge transmitted by the “leading” transceiver that started transmitting first, but due to propagation delay times, they cannot become ideally synchronized. The leading transmitter does not necessarily win the arbitration; therefore, the receivers have to synchronize themselves to different transmitters that subsequently take the lead and that are differently synchronized to the previously leading transmitter. The same happens at the acknowledge field, where the transmitter and some of the receivers will have to synchronize to that receiver that takes the lead in the transmission of the dominant acknowledge bit.

Synchronizations after the end of the arbitration will be caused by oscillator tolerance, when the differences in the oscillator’s clock periods of transmitter and receivers sum up during the time between synchronizations (at most ten bits). These summarized differences may not be longer than the SJW, limiting the oscillator’s tolerance range.

Figure 18-123 shows how the phase buffer segments are used to compensate for phase errors. There are three drawings of each two consecutive bit timings. The upper drawing shows the synchronization on a “late” edge, the lower drawing shows the synchronization on an “early” edge, and the middle drawing is the reference without synchronization.

Figure 18-123. Synchronization on Late and Early Edges



In the first example, an edge from recessive to dominant occurs at the end of Prop_Seg. The edge is "late" since it occurs after the Sync_Seg. Reacting to the late edge, Phase_Seg1 is lengthened so that the distance from the edge to the sample point is the same as it would have been from the Sync_Seg to the sample point if no edge had occurred. The phase error of this late edge is less than SJW, so it is fully compensated and the edge from dominant to recessive at the end of the bit, which is one nominal bit time long, occurs in the Sync_Seg.

In the second example, an edge from recessive to dominant occurs during Phase_Seg2. The edge is "early" since it occurs before a Sync_Seg. Reacting to the early edge, Phase_Seg2 is shortened and Sync_Seg is omitted, so that the distance from the edge to the sample point is the same as it would have been from a Sync_Seg to the sample point if no edge had occurred. As in the previous example, the magnitude of this early edge’s phase error is less than SJW, so it is fully compensated.

The phase buffer segments are lengthened or shortened temporarily only; at the next bit time, the segments return to their nominal programmed values.

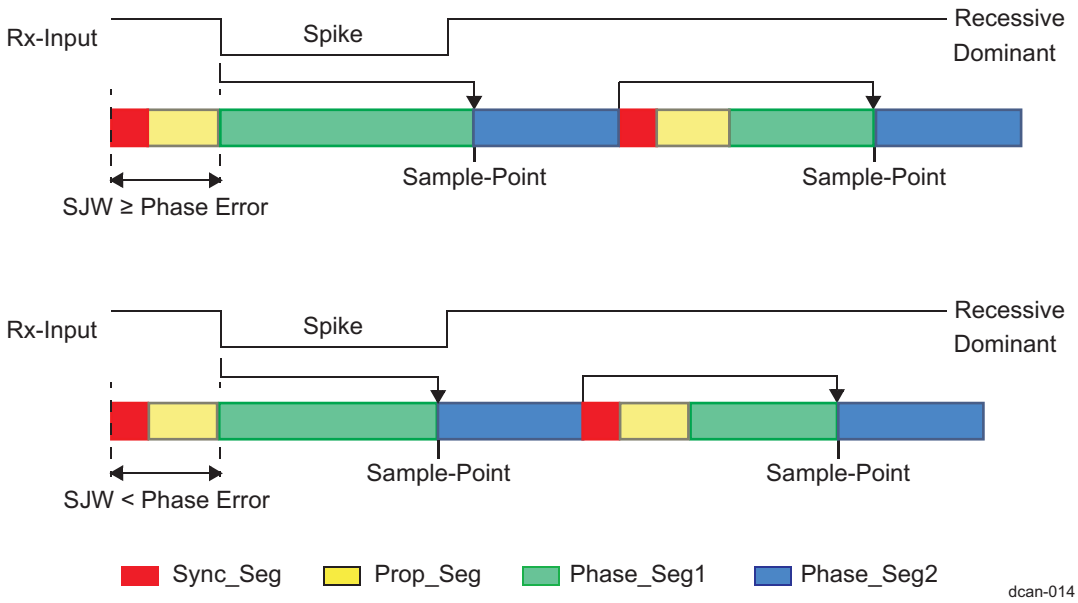
In these examples, the bit timing is seen from the point of view of the CAN implementation’s state machine, where the bit time starts and ends at the sample points. The state machine omits Sync_Seg when synchronizing on an early edge because it cannot subsequently redefine that time quantum of Phase_Seg2 where the edge occurs to be the Sync_Seg.

Figure 18-124 shows how short dominant noise spikes are filtered by synchronizations. In both examples, the spike starts at the end of Prop_Seg and has the length of (Prop_Seg + Phase_Seg1).

In the first example, the synchronization jump width is greater than or equal to the phase error of the spike's edge from recessive to dominant. Therefore the sample point is shifted after the end of the spike; a recessive bus level is sampled.

In the second example, SJW is shorter than the phase error, so the sample point cannot be shifted far enough; the dominant spike is sampled as actual bus level.

Figure 18-124. Filtering of Short Dominant Spikes



18.6.4.9.1.4 Oscillator Tolerance Range

With the introduction of CAN protocol version 1.2, the option to synchronize on edges from dominant to recessive became obsolete. Only edges from recessive to dominant are considered for synchronization. The protocol update to version 2.0 (A and B) had no influence on the oscillator tolerance.

The tolerance range df for an oscillator's frequency f_{osc} around the nominal frequency f_{nom} with:

$$(1 - df) \bullet f_{nom} \le f_{osc} \le (1 + df) \bullet f_{nom}$$

dcan-e015

depends on the proportions of Phase_Seg1, Phase_Seg2, SJW, and the bit time. The maximum tolerance df is the defined by two conditions (both shall be met):

$$\text{I:} \quad df \le \frac{\min(TSeg1, TSeg2)}{2x\left(13x\left(bit\_time - TSeg2\right)\right)}$$

$$\text{II:} \quad df \le \frac{SJW}{20xbit\_time}$$

dcan-e016

It has to be considered that SJW may not be larger than the smaller of the phase buffer segments and that the propagation time segment limits that part of the bit time that may be used for the phase buffer segments.

The combination Prop_Seg = 1 and Phase_Seg1 = Phase_Seg2 = SJW = 4 allows the largest possible oscillator tolerance of 1.58%. This combination with a propagation time segment of only 10% of the bit time is not suitable for short bit times; it can be used for bit rates of up to 125 kBit/s (bit time = 8 µs) with a bus length of 40 m.

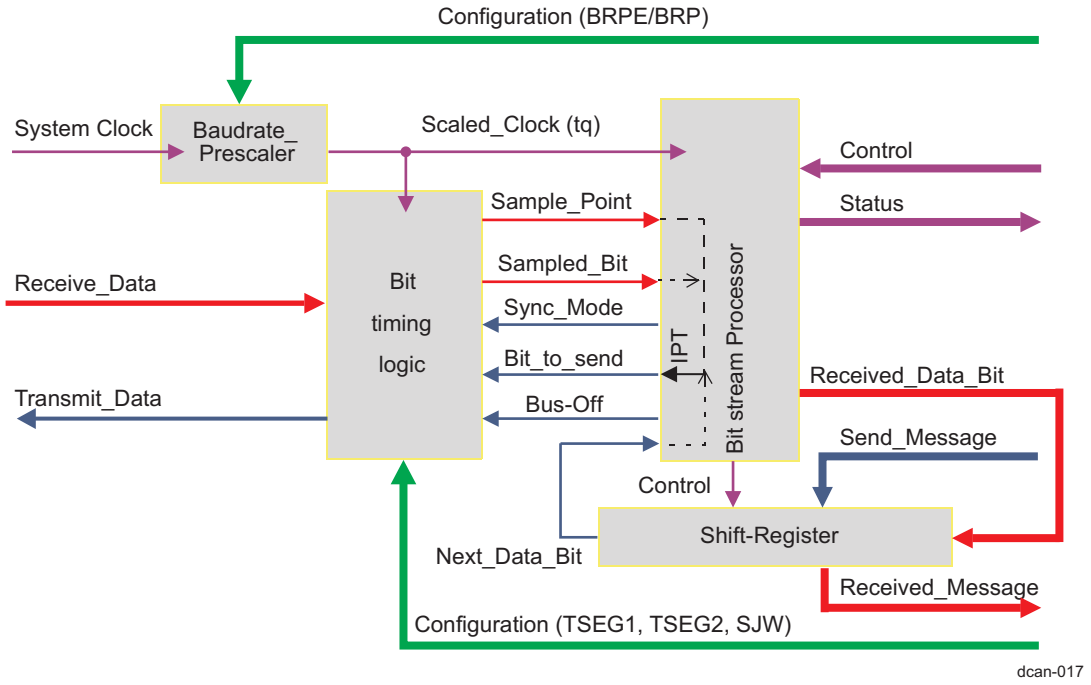
18.6.4.9.2 DCAN Bit Timing Registers

In the DCAN, the bit timing configuration is programmed in DCAN_BTR[14:0], additionally a baud rate prescaler extension of four bits (DCAN_BTR[19:16] BRPE) is provided.

- The sum of Prop_Seg and Phase_Seg1 is set in [11:8] TSEG1
- Phase_Seg2 in [14:12] TSEG2
- SynchronizationJumpWidth in [7:6] SJW
- and baud rate prescaler [5:0] BRP (plus [19:16] BRPE)

Figure 18-125 shows the CAN protocol controller.

Figure 18-125. Structure of the CAN Core's CAN Protocol Controller



In DCAN_BTR register, the components TSEG1, TSEG2, SJW and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1…n], values in the range of [0…n–1] are programmed. That way, e.g., SJW (functional range of [1…4]) is represented by only two bits.

Therefore, the length of the bit time is (programmed values) [TSEG1 + TSEG2 + 3] t_q or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q.

The data in the bit timing register (DCAN_BTR) is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by BRPE/BRP) defines the length of the time quantum (the basic time unit of the bit time); the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the sample point, and occasional synchronizations are controlled by the bit timing state machine, which is evaluated once each time quantum. The rest of the CAN protocol controller, the bit stream processor (BSP) state machine, is evaluated once each bit time, at the sample point.

The shift register serializes the messages to be sent and parallelizes received messages. Its loading and shifting is controlled by the BSP. The BSP translates messages into frames and vice versa. It generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. It is evaluated at the sample point and processes the sampled bus input bit. The time after the sample point that is needed to calculate the next bit to be sent (e.g., data bit, CRC bit, stuff bit, error flag, or idle) is called the information processing time (IPT), which is 0 tq for the DCAN.

Generally, the IPT is CAN controller-specific, but may not be longer than 2 tq. The IPC length is the lower limit of the programmed length of Phase_Seg2. In case of a synchronization, Phase_Seg2 may be shortened to a value less than IPT, which does not affect bus timing.

18.6.4.9.2.1 Calculation of the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting bit time (1 / Bit rate) must be an integer multiple of the CAN clock period.

The bit time may consist of 8 to 25 time quanta. The length of the time quantum t_q is defined by the baud rate prescaler with t_q = (Baud Rate Prescaler) / FCLK. Several combinations may lead to the desired bit time, allowing iterations of the following steps.

First part of the bit time to be defined is the Prop_Seg. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandible CAN bus systems. The resulting time for Prop_Seg is converted into time quanta (rounded up to the nearest integer multiple of t_q).

The Sync_Seg is 1 t_q long (fixed), leaving (bit time – Prop_Seg – 1) t_q for the two Phase Buffer Segments. If the number of remaining t_q is even, the Phase Buffer Segments have the same length, Phase_Seg2 = Phase_Seg1, else Phase_Seg2 = Phase_Seg1 + 1.

The minimum nominal length of Phase_Seg2 has to be regarded as well. Phase_Seg2 may not be shorter than any CAN controller's Information Processing Time in the network, which is device dependent and can be in the range of [0…2] t_q.

The length of the synchronization jump width is set to its maximum value, which is the minimum of four (4) and Phase_Seg1.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formulas given in Table 18-481.

If more than one configurations are possible to reach a certain Bit rate, it is recommended to choose the configuration which allows the highest oscillator tolerance range.

CAN nodes with different clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol compliant configuration of the CAN bit timing.

The resulting configuration is written into the bit timing register (DCAN_BTR):

[14:12] TSEG2 = Phase_Seg2 - 1

[11:8] TSEG1 = Phase_Seg1+ Prop_Seg - 1

[7:6] SJW = SynchronizationJumpWidth - 1

[5:0] BRP = Prescaler - 1

18.6.4.9.2.2 Example for Bit Timing Calculation

In this example, the frequency of FCLK is 20 MHz, BRP is 2, the bit rate is 500 KBit/s.

Table 18-481. Example For Bit Timing

Parameter	Formula	Value	t_q
bit time (500 KBit/s)	1/bit rate, consists of $t_{Sync\text{-}Seg} + t_{TSeg1} + t_{TSeg2}$	2000 ns	20
delay of bus driver		280 ns	-
delay of receiver circuit		29 ns	-
delay of bus line (16 m)	16 × 5.5 ns/m	88 ns	-
t_q	BRP/FCLK	100 ns	1
t_{Sync_Seg}	1 × t_q (fixed)	100 ns	1
t_{Prop_Seg}	INT (2×delays + 1) = 8 × t_q	800 ns	8
t_{Seg1}	$t_{Prop\_Seg} + t_{Phase\_Seg1}$	1400 ns	14

Table 18-481. Example For Bit Timing (continued)

Parameter	Formula	Value	t_q
t_{Seg2}	bit time - ($_{Sync\_Seg}$ + t_{Seg1})	500 ns	5
t_{SJWmax}	MIN (4 × t_q, t_{Phase_Seg1})	400 ns	4

In this example, the bit timing register DCAN_BTR is programmed to:

- BRP = 2 - 1 = 1
- BRPE = 0
- TSEG1 = 14 - 1 = 13 (0xC)
- TSEG2 = 5 - 1 = 4
- SJW = 4 - 1 = 3

18.6.4.10 Message Interface Register Sets

The interface register sets control the software read and write accesses to the message RAM. There are two interface registers sets for read/write access, IF1 and IF2 and one interface register set for read access only, IF3.

Due to the structure of the message RAM, it is not possible to change single bits or bytes of a message object. Instead, always a complete message object in the message RAM is accessed. Therefore the data transfer from the IF1/IF2 registers to the message RAM requires the message handler to perform a read-modify-write cycle: First those parts of the message object that are not to be changed are read from the message RAM into the interface register set, and after the update the whole content of the interface register set is written into the message object.

After the partial write of a message object, those parts of the interface register set that are not selected in DCAN_IF1CMD/DCAN_IF2CMD, will be set to the actual contents of the selected message object.

After the partial read of a message object, those parts of the interface register set that are not selected in DCAN_IF1CMD/DCAN_IF2CMD, will be left unchanged.

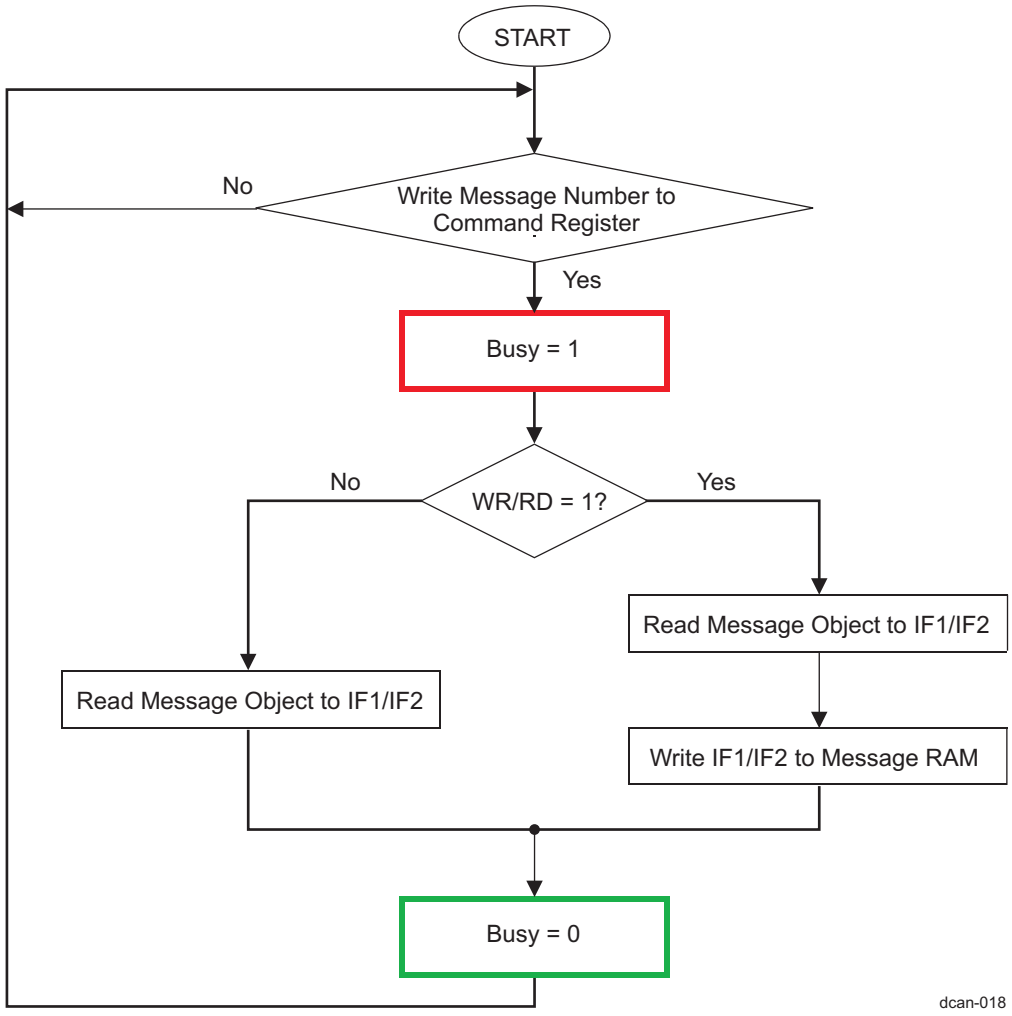
By buffering the data to be transferred, the interface register sets avoid conflicts between concurrent software accesses to the message RAM and CAN message reception and transmission. A complete message object (see Section 18.6.4.11.1, *Structure of Message Objects*) or parts of the message object may be transferred between the message RAM and the IF1/IF2 register set (see Section 18.6.5, *DCAN Register Manual*) in one single transfer. This transfer, performed in parallel on all selected parts of the message object, guarantees the data consistency of the CAN message.

18.6.4.10.1 Message Interface Register Sets 1 and 2

The IF1 and IF2 register sets control the data transfer to and from the message object. DCAN_IF1CMD/DCAN_IF2CMD address the desired message object in the message RAM and specifies whether a complete message object or only parts should be transferred. The data transfer is initiated by writing the message number to the bits [7:0] MESSAGE_NUMBER.

When the software initiates a data transfer between the IF1/IF2 registers and message RAM, the message handler sets the [15] BUSY bit in respective DCAN_IF1CMD/DCAN_IF2CMD to 1. After the transfer has completed, the BUSY bit is set back to 0 (see Figure 18-126).

Figure 18-126. Data Transfer Between IF1/IF2 Registers and Message RAM



18.6.4.10.2 IF3 Register Set

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by software. The intention of this feature of IF3 is to provide an interface for the DMA to read packets efficiently. The automatic update functionality can be programmed for each message object (DCAN_IF3UPD12 to DCAN_IF3UPD78).

All valid message objects in message RAM which are configured for automatic update, will be checked for active NewDat flags. If such a message object is found, it will be transferred to the IF3 register (if no previous DMA transfers are ongoing), controlled by IF3 Observation register (DCAN_IF3OBS). If more than one NewDat flag is active, the message object with the lowest number has the highest priority for automatic IF3 update.

The NewDat bit in the message object will be reset by a transfer to IF3.

If DCAN internal IF3 update is complete, a DMA request is generated. The DMA request stays active until first read access to one of the IF3 registers. The DMA functionality has to be enabled by setting bit DCAN_CTL[20] DE3 = 1.

NOTE: The IF3 register set cannot be used for transferring data into message objects.

18.6.4.11 Message RAM

The DCAN message RAM contains message objects. There are up to 64 message objects in the message RAM.

During normal operation, accesses to the message RAM are performed via the interface register sets, and the software cannot directly access the message RAM.

The interface register sets IF1 and IF2 provide indirect read/write access from the software to the message RAM. The IF1 and IF2 register sets can buffer control and user data to be transferred to and from the message objects.

The third interface register set IF3 can be configured to automatically receive control and user data from the message RAM when a message object has been updated after reception of a CAN message. The software does not need to initiate the transfer from message RAM to IF3 register set.

The message handler avoids potential conflicts between concurrent accesses to message RAM and CAN frame reception/transmission.

There are two modes where the message RAM can be directly accessed by the software:

- Debug/Suspend mode (see Section 18.6.4.11.4, *Message RAM Representation in Debug/Suspend Mode*)
- RAM Direct Access (RDA) mode (see Section 18.6.4.11.5, *Message RAM Representation in Direct Access Mode*)

CAUTION

Writes to the DCAN RAM must not be done while it is in low-power mode. If such writes occur, the behavior is undefined and RAM content is corrupted. It has to be ensured in software that the low-power mode is removed from the DCAN RAM before writing to it.

18.6.4.11.1 Structure of Message Objects

Table 18-482 shows the structure of a message object.

The highlighted fields are those parts of the message object which are represented in dedicated registers. For example, the transmit request flags of all message objects are represented in centralized transmit request registers.

Table 18-482. Structure of a Message Object

UMask	Msk[28:0]	MXtd	MDir	EoB	unused	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
MsgVal	ID[28:0]	Xtd	Dir	DLC[3:0]	Data 0	Data 1	Data 2	Data 3	Data 4	Data 5	Data 6	Data 7

Table 18-483. Message Object Field Descriptions

Field Name	Value	Description
MsgVal		Message valid
	0	The message object is ignored by the message handler.
	1	The message object is to be used by the message handler.
		Note: This bit may be kept at level '1' even when the identifier bits ID[28:0], the control bits Xtd, Dir, or the data length code are changed. It should be reset if the Messages Object is no longer required. The software must reset the MsgVal bit of all unused Messages Objects during the initialization before it resets the INIT bit in the DCAN_CTL register.

Table 18-483. Message Object Field Descriptions (continued)

Field Name	Value	Description
UMask		Use acceptance mask
	0	Mask bits (Msk[28:0], MXtd and MDir) are ignored and not used for acceptance filtering.
	1	Mask bits are used for acceptance filtering.
		Note: If the UMask bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one.
ID[28:0]		Message identifier
	ID[28:0]	29-bit ("extended") identifier bits
	ID[28:18]	11-bit ("standard") identifier bits
Msk[28:0]		Identifier mask
	0	The corresponding bit in the message identifier is not used for acceptance filtering (don't care).
	1	The corresponding bit in the message identifier is used for acceptance filtering.
Xtd		Mask extended identifier
	0	The extended identifier bit (IDE) has no effect on the acceptance filtering.
	1	The extended identifier bit (IDE) is used for acceptance filtering.
		Note: When 11-bit ("standard") Identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered.
Dir		Message direction
	0	Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, the message is stored in this message object.
	1	Direction = transmit: On TxRqst, a data frame is transmitted. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = one).
MDir		Mask message direction
	0	The message direction bit (Dir) has no effect on the acceptance filtering.
	1	The message direction bit (Dir) is used for acceptance filtering.
EOB		End of block
	0	The message object is part of a FIFO Buffer block and is not the last message object of this FIFO Buffer block.
	1	The message object is a single message object or the last message object in a FIFO Buffer Block.
		Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one.
NewDat		New data
	0	No new data has been written into the data bytes of this message object by the message handler since the last time when this flag was cleared by the software.
	1	The message handler or the software has written new data into the data bytes of this message object.
MsgLst		Message lost (only valid for message objects with direction = receive)
	0	No message was lost since the last time when this bit was reset by the software.
	1	The message handler stored a new message into this message object when NewDat was still set, so the previous message has been overwritten.
RxIE		Receive interrupt enable
	0	IntPnd will not be triggered after the successful reception of a frame.
	1	IntPnd will be triggered after the successful reception of a frame.
TxIE		Transmit interrupt enable
	0	IntPnd will not be triggered after the successful transmission of a frame.
	1	IntPnd will be triggered after the successful transmission of a frame.
IntPnd		Interrupt pending
	0	This message object is not the source of an interrupt.
	1	This message object is the source of an interrupt. The interrupt Identifier in the interrupt register (DCAN_INT) will point to this message object if there is no other interrupt source with higher priority.

Table 18-483. Message Object Field Descriptions (continued)

Field Name	Value	Description
RmtEn		Remote enable
	0	At the reception of a remote frame, TxRqst is not changed.
	1	At the reception of a remote frame, TxRqst is set.
TxRqst		Transmit request
	0	This message object is not waiting for a transmission.
	1	The transmission of this message object is requested and is not yet done.
DLC[3:0]		Data length code
	0 - 8	Data frame has 0 - 8 data bytes.
	9 - 15	Data frame has 8 data bytes.
		Note: The data length code of a message object must be defined to the same value as in the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.
Data 0		1st data byte of a CAN data frame
Data 1		2nd data byte of a CAN data frame
Data 2		3rd data byte of a CAN data frame
Data 3		4th data byte of a CAN data frame
Data 4		5th data byte of a CAN data frame
Data 5		6th data byte of a CAN data frame
Data 6		7th data byte of a CAN data frame
Data 7		8th data byte of a CAN data frame
		Note: Byte Data 0 is the first data byte shifted into the shift register of the CAN core during a reception, byte Data 7 is the last. When the message handler stores a data frame, it will write all the eight data bytes into a message object. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by undefined values.

18.6.4.11.2 Addressing Message Objects in RAM

The starting location of a particular message object in RAM is:
Message RAM base address + (message object number) × 0x20

That is, message object 1 starts at offset 0x0020; message object 2 starts at offset 0x0040, etc.

NOTE: Because 0 is not a valid message object number, at offset 0x0000 is not located message object 0, but the last implemented: 64.

The base address for DCAN RAM is 0x4AE3 D000.

Message object number 1 has the highest priority.

Table 18-484. Message RAM Addressing in Debug/Suspend and RDA Modes

Message Object Number	Offset	Word Number	Debug/Suspend Mode, see Section 18.6.4.11.4	RDA Mode, see Section 18.6.4.11.5
64 (last implemented)	0x0000	1	Reserved	Data Bytes 4-7
	0x0004	2	MXtd,MDir,Mask	Data Bytes 0-3
	0x0008	3	Xtd,Dir,ID	ID[27:0],DLC
	0x000C	4	Ctrl	Mask,Xtd,Dir,ID[28]
	0x0010	5	Data Bytes 3-0	Reserved,Ctrl,MXtd,MDir
	0x0014	6	Data Bytes 7-4	-

	0x0054	6	Data Bytes 7-4	-
…	…	…	…	…
63	0x07E0	1	Reserved	Data Bytes 4-7
	0x07E4	2	MXtd,MDir,Mask	Data Bytes 0-3
	0x07E8	3	Xtd,Dir,ID	ID[27:0],DLC
	0x07EC	4	Ctrl	Mask,Xtd,Dir,ID[28]
	0x07F0	5	Data Bytes 3-0	Reserved,Ctrl,MXtd,MDir
	0x07F4	6	Data Bytes 7-4	-

18.6.4.11.3 ECC RAM

On devices with SECDED implementation for the message RAM, the ECC bits are stored in a dedicated ECC RAM area which is memory mapped as follows:

The location of the ECC bits for a particular message object in RAM is:

Message RAM base address + 0x1000 + (message object number) × 0x20

NOTE: 0 is not a valid message object number. Therefore, at address 0x1000, the ECC bits of the last implemented message object are located, that is, 64-th.

Table 18-485. ECC RAM Representation

Address	Msg RAM base + 0x1000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Address	Msg RAM base + 0x17E0

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								ECC[8:0] Message Object 63							

As shown in Figure 1-19 the ECC bits for the last implemented Message Object (here: 128) are located at offset 0x1000; the ECC bits for Message Object 1 are located at offset 0x1020, and the ECC bits for Message Object 127 are located at offset 0x1FE0.

The ECC RAM is only memory mapped if SECDED diagnostic mode is enabled.

18.6.4.11.4 Message RAM Representation in Debug/Suspend Mode

In debug/suspend mode, the message RAM will be memory mapped. This allows the external debug unit to access the message RAM.

NOTE: During debug/suspend mode, the message RAM cannot be accessed via the IFx register sets.

18.6.4.11.5 Message RAM Representation in Direct Access Mode

When the DCAN_TEST[9] RDA bit is set while the DCAN module is in test mode (DCAN_CTL[7] TEST = 1), the software has direct access to the message RAM. Due to the 32-bit bus structure, the RAM is split into word lines to support this feature. The software has access to one word line at a time only.

In RAM direct access mode, the RAM is represented by a continuous memory space within the address frame of the DCAN module, starting at the message RAM base address.

Note: During direct access mode, the message RAM cannot be accessed via the IFx register sets.

Any read or write to the RAM addresses for RAM Direct Access during normal operation mode (TEST bit or RDA bit not set) will be ignored.

18.6.4.12 CAN Operation

After device reset, the DCAN_CTL[0] INIT is set and all CAN protocol functions are disabled. The CAN module must be initialized before operating it. Figure 18-127 illustrates the basic initialization flow for the CAN module.

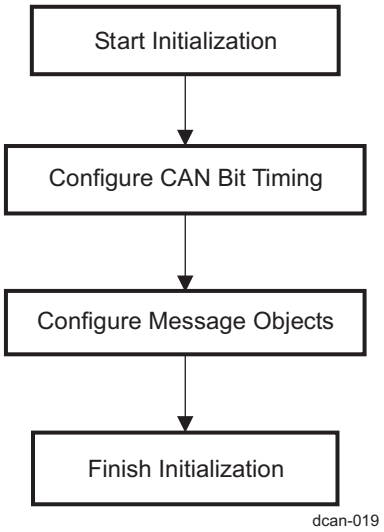
18.6.4.12.1 CAN Module Initialization

A general CAN module initialization would mean the following two critical steps:

- Configuration of the CAN bit timing
- Configuration of message objects

To initialize the CAN controller, the software has to set up the CAN bit timing and those message objects that have to be used for CAN communication. Message objects that are not needed, can be deactivated.

Figure 18-127. CAN Module General Initialization Flow



18.6.4.12.1.1 Configuration of CAN Bit Timing

The CAN module must be in initialization mode to configure the CAN bit timing.

For CAN bit timing software configuration flow, see Figure 18-128, *CAN Bit-Timing Configuration*.

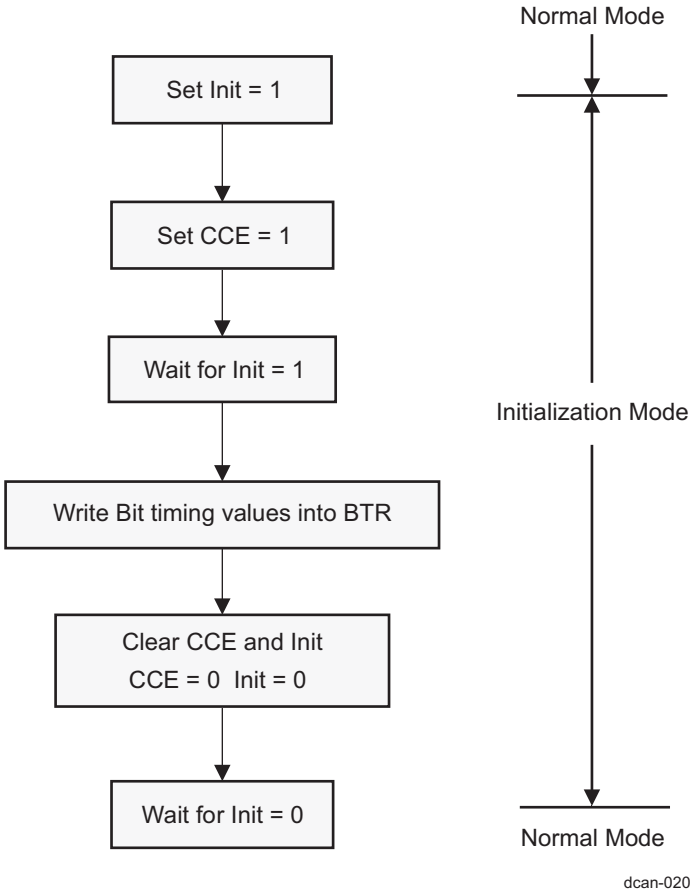
Step 1: Enter *initialization mode* (DCAN_CTL[0] INIT = 1).

While the INIT bit is set, the message transfer from and to the CAN bus is stopped, and the status of the CAN_TX output is recessive (high).

The CAN error counters are not updated. Setting the INIT bit does not change any other configuration register.

Also, note that the CAN module is in initialization mode on device reset and during Bus-Off.

Figure 18-128. CAN Bit-Timing Configuration



Step 2: Set the Configure Change Enable bit (DCAN_CTL[6] CCE = 1).

The access to the Bit Timing register (DCAN_BTR) for the configuration of the bit timing is enabled when both INIT = 1 and CCE = 1.

Step 3: Wait for the INIT bit to get set (=1). This would make sure that the module has entered Initialization mode.

Step 4: Write the bit timing values into DCAN_BTR. See Section 18.6.4.9.2, *DCAN Bit Timing Registers* for the values calculation for a given bit timing.

Step 5: Clear the CCE and INIT bits (=0).

Step 6: Wait for the INIT bit to clear (=0). This would ensure that the module has come out of Initialization mode.

Following these steps, the module comes to operation by synchronizing itself to the CAN bus, provided the DCAN_BTR is configured as per the CAN bus baud rate, although the message objects have to be configured before carrying out any communication.

NOTE: The module will not come out of the Initialization mode if any incorrect DCAN_BTR values are written in step 4.

NOTE: The required message objects should be configured as transmit or receive objects before the start of data transfer as explained in Section 18.6.4.12.1, *CAN Module Initialization*.

18.6.4.12.1.2 Configuration of Message Objects

The message objects can be configured only through the interface registers; the software does not have direct access to the message object (message RAM) . Familiarize yourself with the interface register set (IFx) usage (see Section 18.6.4.10, *Message Interface Register Sets*) and the message object structure (see Section 18.6.4.11, *Message RAM*) before configuring the message objects.

For more information regarding the procedure to configure the message objects, see Section 18.6.4.7, *Configuration of Message Objects Description*. All the message objects should be configured to particular identifiers or set to not valid before the message transfer is started. It is possible to change the configuration of message objects during normal operation (that is between data transfers).

NOTE: The message objects initialization is independent of the bit-timing configuration.

18.6.4.12.1.3 DCAN RAM Hardware Initialization

The memory hardware initialization for the DCAN module is enabled in the device control module. Setting RAMINIT_START to 1, causes RAM initialization with zeros and sets parity bits accordingly. Software must wait for the RAMINIT_DONE bit to be set to ensure successful RAM initialization.

For more details on CTRL_CORE_CONTROL_IO_2 register, see Section 13.5, *Control Module Register Manual*.

18.6.4.12.2 CAN Message Transfer (Normal Operation)

Once the DCAN is initialized and DCAN_CTL[0] INIT bit is reset (=0), the CAN core synchronizes itself to the CAN bus and is ready for message transfer as per the configured message objects.

The software may enable the interrupt lines (DCAN_CTL[1] IE0 and [17] IE1 = 1) at the same time when it clears [0] INIT and [6] CCE = 0. The status interrupts [3] EIE and [2] SIE may be enabled (=1) simultaneously.

The CAN communication can be carried out in any of the following two modes: interrupt and polling.

The DCAN_INT register points to those message objects with IntPnd = 1. It is updated even if the interrupt lines to the host processor are disabled (DCAN_CTL[1] IE0 and [17] IE1 = 0).

The software may poll all MessageObject's NewDat and TxRqst bits in parallel from the DCAN_NWDAT_X and the DCAN_TXRQ_X registers respectively. Polling can be made easier if all transmit objects are grouped at the low numbers and all receive objects are grouped at the high numbers.

Received messages are stored into their appropriate message objects if they pass acceptance filtering.

The whole message (including all arbitration bits, DLC and up to eight data bytes) is stored into the message object. As a consequence (e.g., when the identifier mask is used), the arbitration bits which are masked to "don't care" may change in the message object when a received message is stored.

The software may read or write each message at any time via the interface registers, as the message handler guarantees data consistency in case of concurrent accesses.

If a permanent message object (arbitration and control bits set up during configuration and leaving unchanged for multiple CAN transfers) exists for the message, it is possible to only update the data bytes.

If several transmit messages should be assigned to one message object, the whole message object has to be configured before the transmission of this message is requested.

The transmission of multiple message objects may be requested at the same time. They are subsequently transmitted, according to their internal priority.

Messages may be updated or set to not valid at any time, even if a requested transmission is still pending. However, the data bytes will be discarded if a message is updated before a pending transmission has started.

Depending on the configuration of the message object, a transmission may be automatically requested by the reception of a remote frame with a matching identifier.

18.6.4.12.2.1 Automatic Retransmission

According to the CAN Specification (ISO11898), the DCAN provides a mechanism to automatically retransmit frames which have lost arbitration or have been disturbed by errors during transmission. The frame transmission service will not be confirmed to the user before the transmission is successfully completed.

By default, this automatic retransmission is enabled. It can be disabled by setting bit disable automatic retransmission (DCAN_CTL[5] DAR = 1). Further details to this mode are provided in Section 18.6.4.8.3, *Transmission of Messages in Event Driven CAN Communication*.

18.6.4.12.2.2 Auto-Bus-On

By default, after the DCAN has entered Bus-Off state, the software can start a Bus-Off-Recovery sequence by resetting the DCAN_CTL[0] INIT bit to 0. If this is not done, the module will stay in Bus-Off state.

The DCAN provides an automatic Auto-Bus-On feature which is enabled by bit DCAN_CTL[9] ABO. If set, the DCAN will automatically start the Bus-Off-Recovery sequence. The sequence can be delayed by a user-defined number of interface clock cycles which can be defined in the Auto-Bus-On Time register (DCAN_ABOTR).

NOTE: If the DCAN goes to Bus-Off state due to a massive occurrence of CAN bus errors, it stops all bus activities and automatically sets the INIT bit. Once the INIT bit has been reset by the software or due to the Auto-Bus-On feature, the device will wait for 129 occurrences of bus Idle (equal to 129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus-Off recovery sequence, the error counters will be reset.

18.6.4.12.3 Test Modes

The DCAN module provides several test modes which are mainly intended for production tests or self test.

For all test modes, the DCAN_CTL[7] TEST bit needs to be set to 1. This enables write access to the test register (DCAN_TEST).

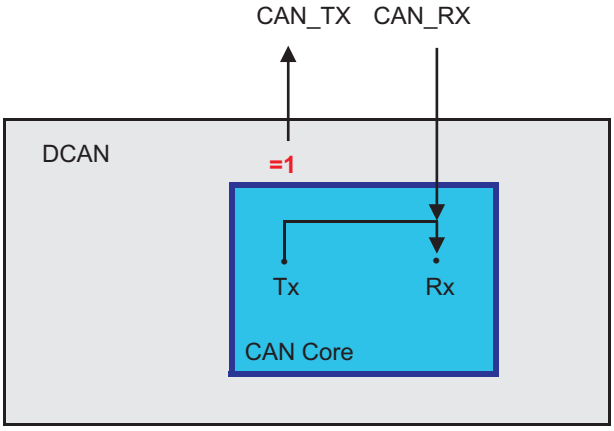
NOTE: It must be ensured by software that all message transfers are completed before entering test mode.

18.6.4.12.3.1 Silent Mode

The silent mode may be used to analyze the traffic on the CAN bus without affecting it by sending dominant bits (e.g., acknowledge bit, overload flag, active error flag). The DCAN is still able to receive valid data frames and valid remote frames, but it will not send any dominant bits. However, these are internally routed to the CAN core.

Figure 18-129 shows the connection of signals CAN_TX and CAN_RX to the CAN core in silent mode. Silent mode can be activated by setting the DCAN_TEST[3] SILENT bit to 1. In ISO 11898-1, the silent mode is called the bus monitoring mode.

Figure 18-129. CAN Core in Silent Mode



18.6.4.12.3.2 Loopback Mode

The loopback mode is mainly intended for hardware self-test functions. In this mode, the CAN core uses internal feedback from Tx output to Rx input. Transmitted messages are treated as received messages, and can be stored into message objects if they pass acceptance filtering. The actual value of the CAN_RX input pin is disregarded by the CAN core. Transmitted messages can still be monitored at the CAN_TX pin.

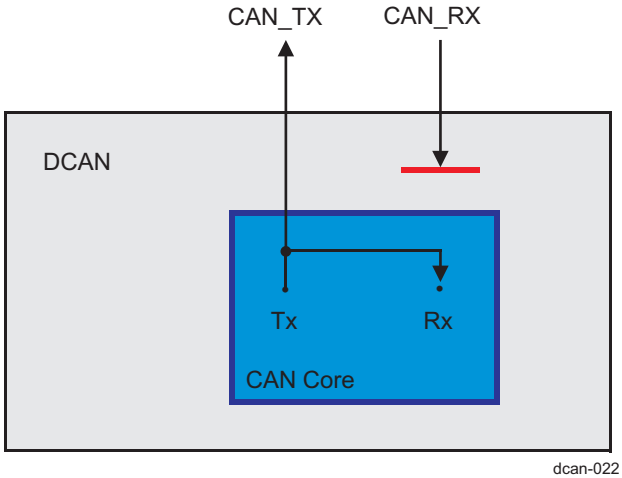
In order to be independent from external stimulation, the CAN core ignores acknowledge sampled in the acknowledge slot of a data/remote frame.

Figure 18-130 shows the connection of signals CAN_TX and CAN_RX to the CAN core in loopback mode.

Loopback mode can be activated by setting bit DCAN_TEST[4] LBACK to 1.

NOTE: In loopback mode, the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN core are disregarded. For including these into the testing, see Section 18.6.4.12.3.3, *External Loopback Mode*.

Figure 18-130. CAN Core in Loopback Mode



18.6.4.12.3.3 External Loopback Mode

The external loopback mode is similar to the loopback mode; however, it includes the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN core. When external loopback mode is selected, the input of the CAN core is connected to the input buffer of the Tx pin.

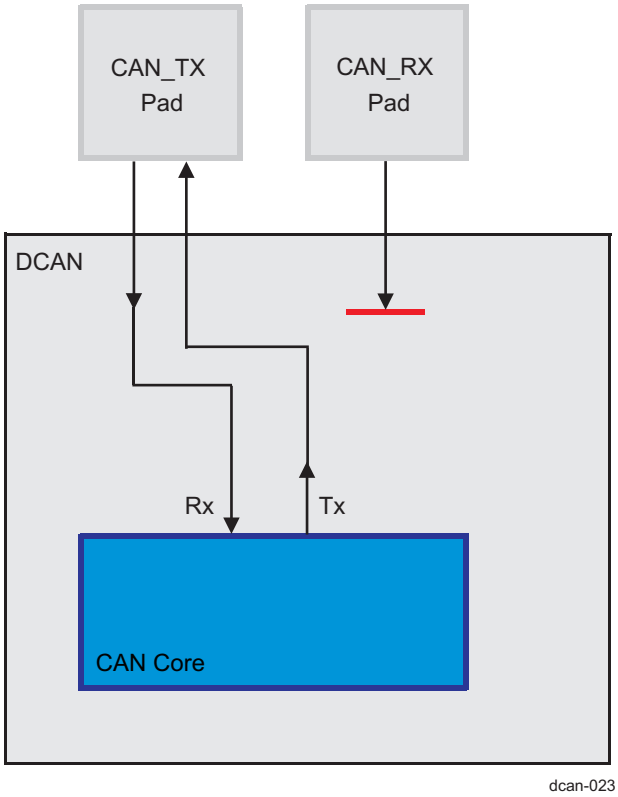
With this configuration, the Tx pin IO circuit can be tested.

External loopback mode can be activated by setting bit DCAN_TEST[8] EXL to 1.

Figure 18-131 shows the connection of signals CAN_TX and CAN_RX to the CAN core in external loopback mode.

NOTE: When loopback mode is active (LBACK bit set), the EXL bit will be ignored.

Figure 18-131. CAN Core in External Loopback Mode

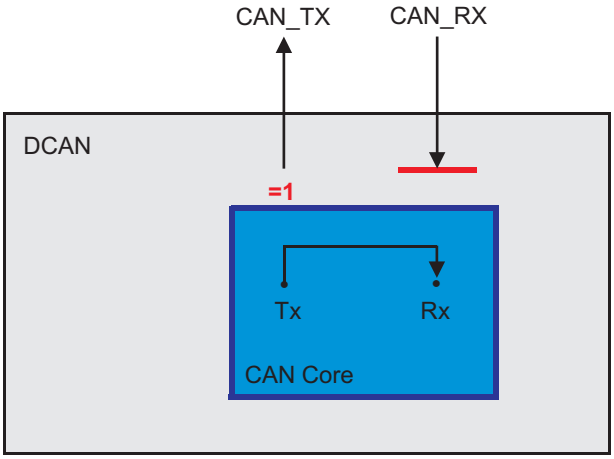


18.6.4.12.3.4 Loopback Mode Combined With Silent Mode

It is also possible to combine loopback mode and silent mode by setting bits DCAN_TEST[4] LBACK and [3] SILENT at the same time. This mode can be used for a "Hot Selftest", that is, the DCAN hardware can be tested without affecting the CAN network. In this mode, the CAN_RX pin is disconnected from the CAN core and no dominant bits will be sent on the CAN_TX pin.

Figure 18-132 shows the connection of the signals CAN_TX and CAN_RX to the CAN core in case of the combination of loopback mode with silent mode.

Figure 18-132. CAN Core in Loop Back Combined With Silent Mode



18.6.4.12.3.5 Software Control of CAN_TX Pin

Four output functions are available for the CAN transmit pin CAN_TX. In addition to its default function (serial data output), the CAN_TX pin can drive constant dominant or recessive values, or it can drive the CAN sample point signal to monitor the CAN core's bit timing.

Combined with the readable value of the CAN_RX pin, this function can be used to check the physical layer of the CAN bus.

The output mode of pin CAN_TX is selected by programming the DCAN_TEST[6:5] TX:

- 0x0: Normal operation, CAN_TX is controlled by the DCAN core
- 0x1: Sample point can be monitored at CAN_TX pin
- 0x2: CAN_TX pin drives a dominant value
- 0x3: CAN_TX pin drives a recessive value.

NOTE: The software control for the CAN_TX pin interferes with CAN protocol functions. For CAN message transfer or any of the test modes (loopback mode, external loopback mode or silent mode), the CAN_TX pin should operate in its default functionality.

18.6.4.13 GPIO Support

The CAN_RX and CAN_TX pins of the DCAN module can be used as general purpose IO pins, if CAN functionality is not needed. This function is controlled by the CAN TX IO control register (DCAN_TIOC) and the CAN RX IO control register (DCAN_RIOC).

18.6.5 DCAN Register Manual

18.6.5.1 DCAN Instance Summary

Table 18-488. DCAN Instance Summary

Module Name	Base Address	Size
DCAN	0x4AE3 C000	8 KiB

18.6.5.2 DCAN Registers

NOTE: After device reset, the registers of the DCAN hold the values shown in the register descriptions.

Additionally, the Bus-Off state is reset and the CAN_TX pin is set to recessive (HIGH). The INIT bit in the DCAN_CTL is set to enable the software initialization. The DCAN will not influence the CAN bus until the software resets INIT to 0.

18.6.5.2.2 DCAN Register Description

Table 18-490. DCAN_CTL

Address Offset	0x0000 0000
Physical Address	0x4AE3 C000 **Instance** DCAN
Description	DCAN control register **NOTE**: The Bus-Off recovery sequence (refer to CAN specification) cannot be shortened by setting or resetting INIT bit. If the module goes Bus-Off, it will automatically set the INIT bit and stop all bus activities. When the INIT bit is cleared by the application again, the module will then wait for 129 occurrences of Bus Idle (129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the bus-off recovery sequence, the error counters will be reset. After the INIT bit is reset, each time when a sequence of 11 recessive bits is monitored, a Bit0 error code is written to DCAN_ES, enabling the software to check whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Field Name	Description	Type	Reset
31:26	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x00
25	WUBA	Automatic wake up on bus activity when in local power-down mode. Note: The CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power down and automatic wake-up mode, will be lost. 0: No detection of a dominant CAN bus level while in local power-down mode. 1: Detection of a dominant CAN bus level while in local power-down mode is enabled. On occurrence of a dominant CAN bus level, the wake up sequence is started (Additional information can be found in *Local Power-Down Mode*).	RW	0
24	PDR	Request for local low power-down mode 0: No application request for local low power-down mode. If the application has cleared this bit while DCAN in local power-down mode, also the INIT bit has to be cleared. 1: Local power-down mode has been requested by application. The DCAN will acknowledge the local power-down mode by setting bit PDA in the DCAN_ES register. The local clocks will be turned off by DCAN internal logic (Additional information can be found in *Local Power-Down Mode*).	RW	0
23:21	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x0
20	DE3	Enable DMA request line for IF3. Note: A pending DMA request for IF3 remains active until first access to one of the IF3 registers. 0: Disabled 1: Enabled	RW	0
19	DE2	Enable DMA request line for IF2. Note: A pending DMA request for IF2 remains active until first access to one of the IF2 registers. 0: Disabled 1: Enabled	RW	0

Bits	Field Name	Description	Type	Reset
18	DE1	Enable DMA request line for IF1. Note: A pending DMA request for IF1 remains active until first access to one of the IF1 registers. 0: Disabled 1: Enabled	RW	0
17	IE1	Interrupt line 1 enable 0: Disabled - Module interrupt INT1 is always low. 1: Enabled - interrupts will assert line INT1 to one; line remains active until pending interrupts are processed.	RW	0
16	INITDBG	Internal init state while debug access 0: Not in debug mode, or debug mode requested but not entered. 1: Debug mode requested and internally entered; the DCAN is ready for debug accesses.	RW	0
15	SWR	Software reset enable. Note: To execute software reset, the following procedure is necessary: 1. Set INIT bit to shut down CAN communication. 2. Set SWR (this) bit additionally to INIT bit. 0: Normal Operation 1: Module is forced to reset state. This bit will automatically get cleared after execution of software reset after one OCP clock cycle.	RW	0
14	RESERVED	This bit is always read as 0. Writes have no effect.	R	0
13:10	PMD	ECCon/off 0x5: function disabled Others: function enabled	RW	0x5
9	ABO	Auto-Bus-On enable 0: The Auto-Bus-On feature is disabled 1: The Auto-Bus-On feature is enabled	RW	0
8	IDS	Interruption debug support enable 0: When Debug/Suspend mode is requested, DCAN will wait for a started transmission or reception to be completed before entering Debug/Suspend mode 1: When Debug/Suspend mode is requested, DCAN will interrupt any transmission or reception, and enter Debug/Suspend mode immediately.	RW	0
7	TEST	Test mode enable 0: Normal Operation 1: Test Mode	RW	0
6	CCE	Configuration change enable 0: The software has no write access to the configuration registers. 1: The software has write access to the configuration registers (when INIT bit is set).	RW	0
5	DAR	Disable automatic retransmission 0: Automatic retransmission of not successful messages enabled. 1: Automatic retransmission disabled.	RW	0
4	RESERVED	This bit is always read as 0. Writes have no effect.	R	0
3	EIE	Error interrupt enable 0: Disabled - PER, BOFF and EWARN bits can not generate an interrupt. 1: Enabled - PER, BOFF and EWARN bits can generate an interrupt at INT0 line and affect the interrupt register.	RW	0

Bits	Field Name	Description	Type	Reset
2	SIE	Status change interrupt enable 0: Disabled - WAKEUPPND, RXOK, TXOK and LEC bits can not generate an interrupt. 1: Enabled - WAKEUPPND, RXOK, TXOK and LEC can generate an interrupt at INT0 line and affect the interrupt register.	RW	0
1	IE0	Interrupt line 0 enable 0: Disabled - Module interrupt INT0 is always low. 1: Enabled - interrupts will assert line INT0 to one; line remains active until pending interrupts are processed.	RW	0
0	INIT	Initialization 0: Normal operation 1: Initialization mode is entered	RW	1

Table 18-492. DCAN_ES

Address Offset	0x0000 0004		
Physical Address	0x4AE3 C004	**Instance**	DCAN
Description	Error and Status Register Interrupts are generated by bits PER, BOFF and EWARN (if EIE bit in DCAN_CTL is 1) and by bits WAKEUPPND, RXOK, TXOK, and LEC (if SIE bit in DCAN_CTL is 1). A change of bit EPASS will not generate an interrupt. Reading the DCAN_ES clears the WAKEUPPND, PER, RXOK and TXOK bits and set the LEC to value '7.' Additionally, the status interrupt value (0x8000) in the DCAN_INT will be replaced by the next lower priority interrupt value. For debug support, the auto clear functionality of DCAN_ES (clear of status flags by read) is disabled when in debug/suspend mode.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																					PDA	WAKEUPPND	PER	BOFF	EWARN	EPASS	RXOK	TXOK	LEC		

Bits	Field Name	Description	Type	Reset
31:11	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x00 0000
10	PDA	Local power-down mode acknowledge 0: DCAN is not in local power-down mode. 1: Application request for setting DCAN to local power-down mode was successful. DCAN is in local power-down mode.	R	0
9	WAKEUPPND	Wake up pending. This bit can be used by the software to identify the DCAN as the source to wake up the system. This bit will be reset if DCAN_ES is read. 0: No Wake Up is requested by DCAN. 1: DCAN has initiated a wake up of the system due to dominant CAN bus while module power down.	R	0
8	PER	Parity error detected. This bit will be reset if DCAN_ES register is read. Read 0: No parity error has been detected since last read access. Read 1: The parity check mechanism has detected a parity error in the Message RAM. Write 0: No effect Write 1: End of interrupt (EOI) for parity error on DCAN_PARITY interrupt line	RW	0
7	BOFF	Bus-Off state 0: The CAN module is not bus-off state. 1: The CAN module is in bus-off state.	R	0
6	EWARN	Warning state 0: Both error counters are below the error warning limit of 96. 1: At least one of the error counters has reached the error warning limit of 96.	R	0
5	EPASS	Error passive state 0: On CAN Bus error, the DCAN could send active error frames. 1: The CAN core is in the error passive state as defined in the CAN Specification.	R	0

Bits	Field Name	Description	Type	Reset
4	RXOK	Received a message successfully. This bit will be reset if DCAN_ES register is read. 0: No message has been successfully received since the last time when this bit was read by the software. This bit is never reset by DCAN internal events. 1: A message has been successfully received since the last time when this bit was reset by a read access of the software (independent of the result of acceptance filtering).	R	0
3	TXOK	Transmitted a message successfully. This bit will be reset if DCAN_ES register is read. 0: No message has been successfully transmitted since the last time when this bit was read by the software. This bit is never reset by DCAN internal events. 1: A message has been successfully transmitted (error free and acknowledged by at least one other node) since the last time when this bit was reset by a read access of the software.	R	0
2:0	LEC	Last error code. The LEC field indicates the type of the last error on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. 0x0: No error 0x1: Stuff error: More than five equal bits in a row have been detected in a part of a received message where this is not allowed. 0x2: Form error: A fixed format part of a received frame has the wrong format. 0x3: Ack error: The message this CAN core transmitted was not acknowledged by another node. 0x4: Bit1 error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. 0x5: Bit0 error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (logical value '0'), but the monitored bus level was recessive. During Bus-Off recovery, this status is set each time a sequence of 11 recessive bits has been monitored. This enables the software to monitor the proceeding of the Bus-Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 0x6: CRC error: In a received message, the CRC check sum was incorrect. (CRC received for an incoming message does not match the calculated CRC for the received data). 0x7: No CAN bus event was detected since the last time the software read DCAN_ES. Any read access to DCAN_ES re-initializes the LEC to value '7.'	R	0x7

Table 18-496. DCAN_BTR

Address Offset	0x0000 000C		
Physical Address	0x4AE3 C00C	**Instance**	DCAN
Description	Bit timing register This register is only writable if CCE and INIT bits in the DCAN_CTL are set. The CAN bit time may be programmed in the range of 8 to 25 time quanta The CAN time quantum may be programmed in the range of 1 to 1024 CAN_CLK periods.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED												BRPE				RESERVED	TSEG2			TSEG1				SJW			BRP				

Bits	Field Name	Description	Type	Reset
31:20	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x000
19:16	BRPE	Baud rate prescaler extension. Valid programmed values are 0 to 15. By programming BRPE the baud rate prescaler can be extended to values up to 1024.	RW	0x0
15	RESERVED	These bits are always read as 0. Writes have no effect.	R	0
14:12	TSEG2	Time segment after the sample point Valid programmed values are 0 to 7. The actual TSeg2 value which is interpreted for the bit timing will be the programmed TSeg2 value + 1.	RW	0x2
11:8	TSEG1	Time segment before the sample point Valid programmed values are 1 to15. The actual TSeg1 value interpreted for the bit timing will be the programmed TSeg1 value + 1.	RW	0x3
7:6	SJW	Synchronization Jump Width Valid programmed values are 0 to 3. The actual SJW value interpreted for the synchronization will be the programmed SJW value + 1.	RW	0x0
5:0	BRP	Baud rate prescaler Value by which the CAN_CLK frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid programmed values are 0 to 63. The actual BRP value interpreted for the bit timing will be the programmed BRP value + 1.	RW	0x1

Table 18-564. DCAN_IF1CMD

Address Offset	0x0000 0100
Physical Address	0x4AE3 C100 **Instance** DCAN
Description	IF1 Command Register The IF1 Command Register (DCAN_IF1CMD) configure and initiate the transfer between the IF1 register set and the message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the software writes the message number to bits [7:0] MESSAGE_NUMBER. With this write operation, the BUSY bit is automatically set to 1 to indicate that a transfer is in progress. After 4 to 14 OCP clock cycles, the transfer between the interface register and the message RAM will be completed and the BUSY bit is cleared. The maximum number of cycles is needed when the message transfer concurs with a CAN message transmission, acceptance filtering, or message storage. If the software writes to both DCAN_IF1CMD/DCAN_IF2CMD consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed. While BUSY bit is one, IF1/IF2 register sets are write protected. For debug support, the auto clear functionality of the IF1/IF2 command registers (clear of DMAACTIVE flag by r/w) is disabled during Debug/Suspend mode. If an invalid Message Number is written to bits [7:0] MESSAGE_NUMBER, the message handler may access an implemented (valid) message object instead.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								WR_RD	MASK	ARB	CONTROL	CLRINTPND	TXRQST_NEWDAT	DATA_A	DATA_B	BUSY	DMAACTIVE	RESERVED						MESSAGE_NUMBER							

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x00
23	WR_RD	Write/Read 0: Direction = Read: Transfer direction is from the message object addressed by MESSAGE_NUMBER to the IF1 register set. 1: Direction = Write: Transfer direction is from the IF1 register set to the message object addressed by MESSAGE_NUMBER.	RW	0
22	MASK	Access mask bits 0: Mask bits will not be changed 1: Direction = Read: The mask bits (identifier mask + MDir + MXtd) will be transferred from the message object addressed by MESSAGE_NUMBER to the IF1 register set. 1: Direction = Write: The mask bits (identifier mask + MDir + MXtd) will be transferred from the IF1 register set to the message object addressed by MESSAGE_NUMBER.	RW	0
21	ARB	Access arbitration bits 0: Arbitration bits will not be changed 1: Direction = Read: The Arbitration bits (Identifier + Dir + Xtd + MsgVal) will be transferred from the message object addressed by MESSAGE_NUMBER to the corresponding IF1 register set. 1: Direction = Write: The Arbitration bits (Identifier + Dir + Xtd + MsgVal) will be transferred from the IF1 register set to the message object addressed by MESSAGE_NUMBER.	RW	0

Bits	Field Name	Description	Type	Reset
20	CONTROL	Access control bits 0: Control bits will not be changed 1: Direction = Read: The message control bits will be transferred from the message object addressed by MESSAGE_NUMBER to the IF1 register set. 1: Direction = Write: The message control bits will be transferred from the IF1 registerset to the message object addressed by MESSAGE_NUMBER. If the TXRQST_NEWDAT bit in this register(Bit [18]) is set, the TXRQST/ NEWDAT bits in the DCAN_IF1MCTL will be ignored.	RW	0
19	CLRINTPND	Clear interrupt pending bit 0: IntPnd bit will not be changed 1: Direction = Read: Clears IntPnd bit in the message object. 1: Direction = Write: This bit is ignored. Copying of IntPnd flag from IF1 Registers to message RAM can only be controlled by the CONTROL flag (Bit [20]).	RW	0
18	TXRQST_NEWDAT	Access transmission request bit 0: Direction = Read: NewDat bit will not be changed. Direction = Write: TxRqst/NewDat bit will be handled according to the CONTROL bit. 1: Direction = Read: Clears NewDat bit in the message object. 1: Direction = Write: Sets TxRqst/NewDat in message object. Note: If a CAN transmission is requested by setting TXRQST_NEWDAT in this register, the TxRqst/NewDat bits in the message object will be set to one independent of the values in DCAN_IF1MCTL. Note: A read access to a message object can be combined with the reset of the control bits IntPnd and NewDat. The values of these bits transferred to the DCAN_IF1MCTL always reflect the status before resetting them.	RW	0
17	DATA_A	Access Data Bytes 0-3 0: Data Bytes 0-3 will not be changed. 1: Direction = Read: The data bytes 0-3 will be transferred from the message object addressed by the MESSAGE_NUMBER to the corresponding IF1 registerset. 1: Direction = Write: The data bytes 0-3 will be transferred from the IF1 registerset to the message object addressed by the MESSAGE_NUMBER. Note: The duration of the message transfer is independent of the number of bytes to be transferred.	RW	0
16	DATA_B	Access Data Bytes 4-7 0: Data Bytes 4-7 will not be changed. 1: Direction = Read: The data bytes 4-7 will be transferred from the message object addressed by MESSAGE_NUMBER to the corresponding IF1 registerset. 1: Direction = Write: The data bytes 4-7 will be transferred from the IF1 registerset to the message object addressed by MESSAGE_NUMBER. Note: The duration of the message transfer is independent of the number of bytes to be transferred.	RW	0

Bits	Field Name	Description	Type	Reset
15	BUSY	Busy flag 0: No transfer between IF1 register set and message RAM is in progress. 1: Transfer between IF1 register set and message RAM is in progress. This bit is set to one after the message number has been written to bits [7:0] MESSAGE_NUMBER. IF1 register set will be write protected. The bit is cleared after read/write action has been finished.	RW	0
14	DMAACTIVE	Activation of DMA feature for subsequent internal IF1 update 0: DMA request line is independent of IF1 activities. 1: DMA is requested after completed transfer between IF1 register set and message RAM. The DMA request remains active until the first read or write to one of the IF1 registers; an exception is a write to MESSAGE_NUMBER when DMAACTIVE is one. Note: Due to the auto reset feature of the DMAACTIVE bit, this bit has to be set for each subsequent DMA cycle separately.	RW	0
13:8	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x00
7:0	MESSAGE_NUMBER	Number of message object in message RAM which is used for data transfer 0x00: Invalid message number 0x01-0x80: Valid message numbers 0x81-0xFF: Invalid message numbers	RW	0x1

Table 18-568. DCAN_IF1ARB

Address Offset	0x0000 0108		
Physical Address	0x4AE3 C108	**Instance**	DCAN
Description	IF1 arbitration register The Arbitration bits ID[28:0], XTD, and DIR are used to define the identifier and type of outgoing messages and (together with the mask bits MSK[28:0], MXTD, and MDIR) for acceptance filtering of incoming messages. A received message is stored into the valid message object with matching identifier and Direction = receive (data frame) or Direction = transmit (remote frame). Extended frames can be stored only in message objects with XTD = 1, standard frames in message objects with XTD = 0. If a received message (data frame or remote frame) matches more than one valid message objects, it is stored into the one with the lowest message number. The bits of the IF1/IF2 arbitration registers mirror the arbitration bits of a message object. The function of the relevant message objects bits is described in Section 18.6.4.11.1 *Structure of Message Objects* While BUSY bit of DCAN_IF1CMD/DCAN_IF2CMD register is one, IF1/IF2 register set is write protected.

Description	IF2 Command Register The IF2 Command Register (DCAN_IF2CMD) configure and initiate the transfer between the IF2 register set and the message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the software writes the message number to bits [7:0] MESSAGE_NUMBER. With this write operation, the BUSY bit is automatically set to 1 to indicate that a transfer is in progress. After 4 to 14 OCP clock cycles, the transfer between the interface register and the message RAM will be completed and the BUSY bit is cleared. The maximum number of cycles is needed when the message transfer concurs with a CAN message transmission, acceptance filtering, or message storage. If the software writes to both DCAN_IF1CMD/DCAN_IF2CMD consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed. While BUSY bit is one, IF1/IF2 register sets are write protected. For debug support, the auto clear functionality of the IF1/IF2 command registers (clear of DMAACTIVE flag by r/w) is disabled during Debug/Suspend mode. If an invalid Message Number is written to bits [7:0] MESSAGE_NUMBER, the message handler may access an implemented (valid) message object instead.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								WR_RD	MASK	ARB	CONTROL	CLRINTPND	TXRQST_NEWDAT	DATA_A	DATA_B	BUSY	DMAACTIVE	RESERVED						MESSAGE_NUMBER							

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x00
23	WR_RD	Write/Read 0: Direction = Read: Transfer direction is from the message object addressed by MESSAGE_NUMBER to the IF2 register set. 1: Direction = Write: Transfer direction is from the IF2 register set to the message object addressed by MESSAGE_NUMBER.	RW	0
22	MASK	Access mask bits 0: Mask bits will not be changed 1: Direction = Read: The mask bits (identifier mask + MDir + MXtd) will be transferred from the message object addressed by MESSAGE_NUMBER to the IF2 register set. 1: Direction = Write: The mask bits (identifier mask + MDir + MXtd) will be transferred from the IF2 register set to the message object addressed by MESSAGE_NUMBER.	RW	0
21	ARB	Access arbitration bits 0: Arbitration bits will not be changed 1: Direction = Read: The Arbitration bits (Identifier + Dir + Xtd + MsgVal) will be transferred from the message object addressed by MESSAGE_NUMBER to the corresponding IF2 register set. 1: Direction = Write: The Arbitration bits (Identifier + Dir + Xtd + MsgVal) will be transferred from the IF2 register set to the message object addressed by MESSAGE_NUMBER.	RW	0

Bits	Field Name	Description	Type	Reset
20	CONTROL	Access control bits 0: Control bits will not be changed 1: Direction = Read: The message control bits will be transferred from the message object addressed by MESSAGE_NUMBER to the IF2 register set. 1: Direction = Write: The message control bits will be transferred from the IF2 registerset to the message object addressed by MESSAGE_NUMBER. If the TXRQST_NEWDAT bit in this register(Bit [18]) is set, the TXRQST/ NEWDAT bits in the DCAN_IF1MCTL/DCAN_IF2MCTL will be ignored.	RW	0
19	CLRINTPND	Clear interrupt pending bit 0: IntPnd bit will not be changed 1: Direction = Read: Clears IntPnd bit in the message object. 1: Direction = Write: This bit is ignored. Copying of IntPnd flag from IF2 Registers to message RAM can only be controlled by the CONTROL flag (Bit [20]).	RW	0
18	TXRQST_NEWDAT	Access transmission request bit 0: Direction = Read: NewDat bit will not be changed. Direction = Write: TxRqst/NewDat bit will be handled according to the CONTROL bit. 1: Direction = Read: Clears NewDat bit in the message object. 1: Direction = Write: Sets TxRqst/NewDat in message object. Note: If a CAN transmission is requested by setting TXRQST_NEWDAT in this register, the TxRqst/NewDat bits in the message object will be set to one independent of the values in DCAN_IF1MCTL/DCAN_IF2MCTL. Note: A read access to a message object can be combined with the reset of the control bits IntPnd and NewDat. The values of these bits transferred to the DCAN_IF1MCTL/DCAN_IF2MCTL always reflect the status before resetting them.	RW	0
17	DATA_A	Access Data Bytes 0-3 0: Data Bytes 0-3 will not be changed. 1: Direction = Read: The data bytes 0-3 will be transferred from the message object addressed by the MESSAGE_NUMBER to the corresponding IF2 registerset. 1: Direction = Write: The data bytes 0-3 will be transferred from the IF2 registerset to the message object addressed by the MESSAGE_NUMBER. Note: The duration of the message transfer is independent of the number of bytes to be transferred.	RW	0
16	DATA_B	Access Data Bytes 4-7 0: Data Bytes 4-7 will not be changed. 1: Direction = Read: The data bytes 4-7 will be transferred from the message object addressed by MESSAGE_NUMBER to the corresponding IF2 registerset. 1: Direction = Write: The data bytes 4-7 will be transferred from the IF2 registerset to the message object addressed by MESSAGE_NUMBER. Note: The duration of the message transfer is independent of the number of bytes to be transferred.	RW	0

Bits	Field Name	Description	Type	Reset
15	BUSY	Busy flag 0: No transfer between IF2 register set and message RAM is in progress. 1: Transfer between IF2 register set and message RAM is in progress. This bit is set to one after the message number has been written to bits [7:0] MESSAGE_NUMBER. IF2 register set will be write protected. The bit is cleared after read/write action has been finished.	RW	0
14	DMAACTIVE	Activation of DMA feature for subsequent internal IF2 update 0: DMA request line is independent of IF2 activities. 1: DMA is requested after completed transfer between IF2 register set and message RAM. The DMA request remains active until the first read or write to one of the IF2 registers; an exception is a write to MESSAGE_NUMBER when DMAACTIVE is one. Note: Due to the auto reset feature of the DMAACTIVE bit, this bit has to be set for each subsequent DMA cycle separately.	RW	0
13:8	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x00
7:0	MESSAGE_NUMBER	Number of message object in message RAM which is used for data transfer 0x00: Invalid message number 0x01-0x80: Valid message numbers 0x81-0xFF: Invalid message numbers	RW	0x1

Table 18-580. DCAN_IF2ARB

Address Offset	0x0000 0128		
Physical Address	0x4AE3 C128	**Instance**	DCAN
Description	IF2 arbitration register The Arbitration bits ID[28:0], XTD, and DIR are used to define the identifier and type of outgoing messages and (together with the mask bits MSK[28:0], MXTD, and MDIR) for acceptance filtering of incoming messages. A received message is stored into the valid message object with matching identifier and Direction = receive (data frame) or Direction = transmit (remote frame). Extended frames can be stored only in message objects with Xtd = 1, standard frames in message objects with Xtd = 0. If a received message (data frame or remote frame) matches more than one valid message objects, it is stored into the one with the lowest message number. The bits of the IF1/IF2 arbitration registers mirror the arbitration bits of a message object. The function of the relevant message objects bits is described in Section 18.6.4.11.1 *Structure of Message Objects* While BUSY bit of DCAN_IF1CMD/DCAN_IF2CMD register is one, IF1/IF2 register set is write protected.

Table 18-588. DCAN_IF3OBS

Address Offset	0x0000 0140		
Physical Address	0x4AE3 C140	**Instance**	DCAN
Description	IF3 Observation Register The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by software (Additional information can be found in Section 18.6.4.11.1 *Structure of Message Objects*). The observation flags (Bits [4:0]) are used to determine, which data sections of the IF3 interface register set have to be read in order to complete a DMA read cycle. After all marked data sections are read, the DCAN is enabled to update the IF3 interface register set with new data. Any access order of single bytes or half-words is supported. When using byte or half-word accesses, a data section is marked as completed, if all bytes are read. NOTE: If IF3 Update Enable is used and no Observation flag is set, the corresponding message objects will be copied to IF3 without activating the DMA request line and without waiting for DMA read accesses. A write access to this register aborts a pending DMA cycle by resetting the DMA line and enables updating of IF3 interface register set with new data. To avoid data inconsistency, the DMA controller should be disabled before reconfiguring IF3 observation register. The status of the current read-cycle can be observed via status flags (Bits [12:8]).

7	EOB	End of Block 0: The message object is part of a FIFO Buffer block and is not the last message object of the FIFO Buffer block. 1: The message object is a single message object or the last message object in a FIFO Buffer Block. Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one.	R	0
6:4	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x0
3:0	DLC	Data Length Code 0-8: Data frame has 0-8 data bits. 9-15: Data frame has 8 data bytes. Note: The data length code of a message object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.	R	0x0

18.7 MCAN

This chapter describes the Modular Controller Area Network (MCAN) module.

18.7.1 MCAN Overview

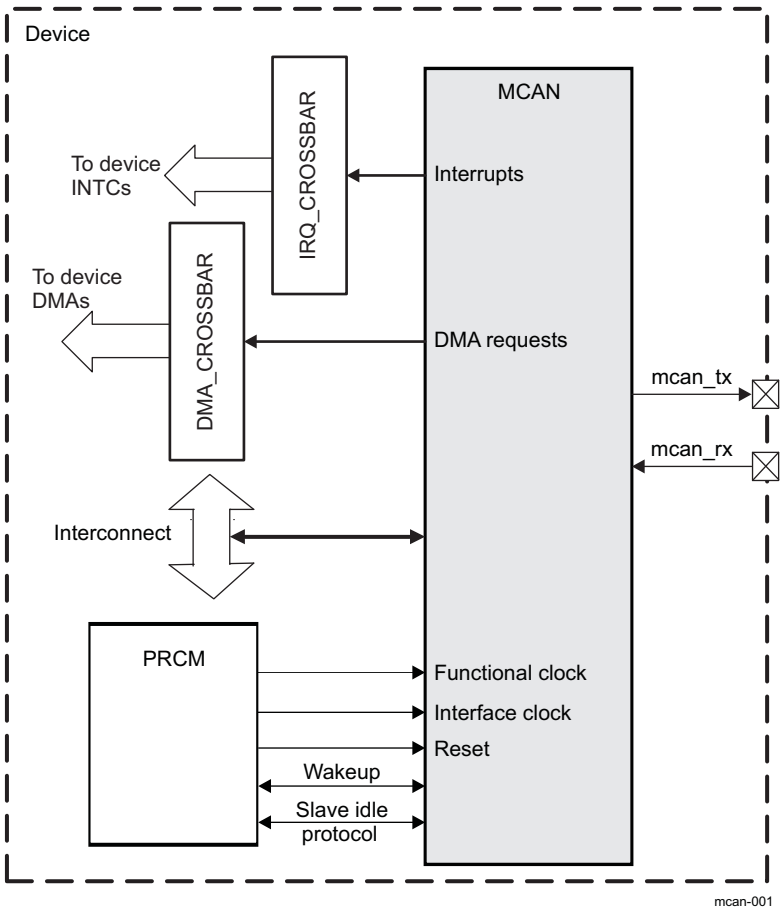
The Controller Area Network (CAN) is a serial communications protocol which efficiently supports distributed real-time control with a high level of security. CAN has high immunity to electrical interference and the ability to self-diagnose and repair data errors. In a CAN network, many short messages are broadcast to the entire network, which provides for data consistency in every node of the system.

The MCAN module supports both classic CAN and CAN FD (CAN with Flexible Data-Rate) specifications. CAN FD feature allows high throughput and increased payload per data frame. The classic CAN and CAN FD devices can coexist on the same network without any conflict.

The device supports one MCAN module connecting to the CAN network through external (for the device) transceiver for connection to the physical layer. The MCAN module supports up to 5 Mbit/s data rate and is compliant to ISO 11898-1:2015.

Figure 18-133 shows the MCAN module overview.

Figure 18-133. MCAN Module Overview



18.7.1.1 Features

The MCAN module implements the following features:

- Conforms with ISO 11898-1:2015
- Full CAN FD support (up to 64 data bytes)
- AUTOSAR and SAE J1939 support

- Up to 32 dedicated Transmit Buffers
- Configurable Transmit FIFO, up to 32 elements
- Configurable Transmit Queue, up to 32 elements
- Configurable Transmit Event FIFO, up to 32 elements
- Up to 64 dedicated Receive Buffers
- Two configurable Receive FIFOs, up to 64 elements each
- Up to 128 filter elements
- Internal Loopback mode for self-test
- Maskable interrupts, two interrupt lines
- Two clock domains (CAN clock/Host clock)
- Parity/ECC support - Message RAM single error correction and double error detection (SECDED) mechanism
- Local power-down and wakeup support
- Timestamp Counter

Not supported features:

- Full Message Memory capacity (4352 words). Only 1600 words implemented.
- Debug on CAN (Debug DMA)
- Host bus read and write bursts
- Host bus firewall
- GPIO mode
- External (IO) Loopback mode
- Device clock domains monitoring (using DCC module)

18.7.2 MCAN Environment

CAN network physical layer consists of two-wire differential bus, usually twisted pair, and provides high level of interference immunity. External CAN transceiver IC is needed to access a CAN bus by the MCAN.

Figure 18-134 shows an overview of a typical MCAN application.

Figure 18-134. MCAN Typical Application

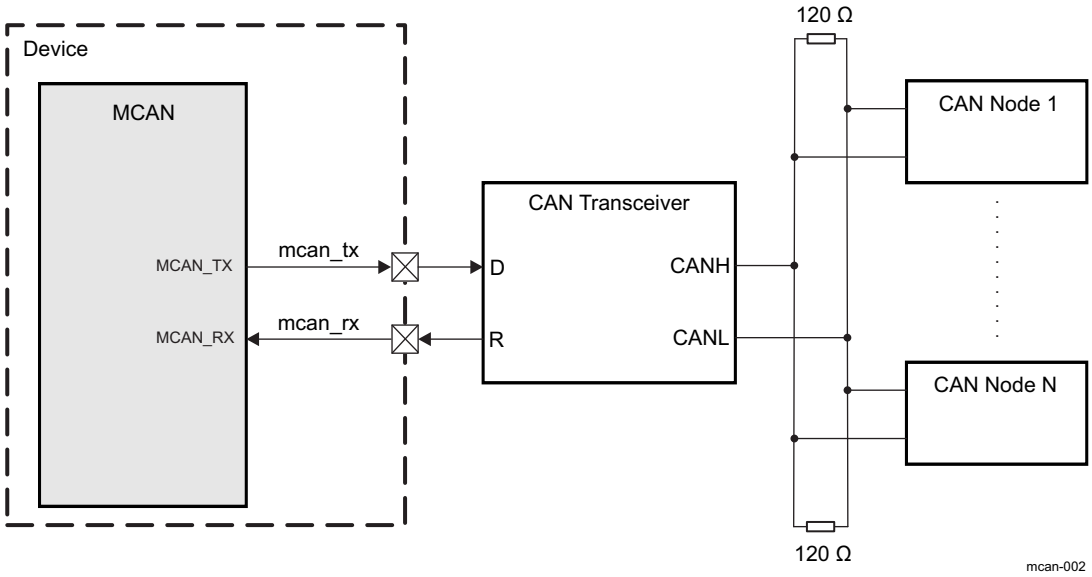


Table 18-612 describes the external signals of the MCAN module.

Table 18-612. MCAN I/O Description

Module Signal	Device Signal	I/O[1]	Description	Value at Reset
MCAN_RX	mcan_rx	I	Serial data input from external CAN tranceiver	HiZ
MCAN_TX	mcan_tx	O	Serial data output to external CAN tranceiver	1

(1) I = Input; O = Output

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see Section 13.4.6.1, *Pad Configuration Registers* of Chapter 13, *Control Module*.

18.7.2.1 CAN Network Basics

- CAN bus is a 2-wire differential bus using Non-Return-to-Zero (NRZ) encoding and has two states:
  - Recessive state (logical 1)
  - Dominant state (logical 0)
- The network is multimaster. When two or more nodes (ECUs) attempt to transmit at the same time, a non-destructive arbitration technique guarantees messages are sent in order of priority and no messages are lost.
- The message transmission is multicast. Data messages transmitted are identifier based, not address based.
- Content of message is labeled by the identifier that is unique throughout the network (for example: rpm, temperature, position, pressure, and so forth).
- All nodes on network receive the message and each performs an acceptance test on the identifier. If

message is relevant, it is processed, otherwise it is ignored.

- The unique identifier also determines the priority of the message (the lower the numerical value of the identifier, the higher the priority is).
- Data is transmitted and received using message frames, consisting of the following basic fields:
  - Arbitration field
  - Control field
  - Data field (up to 8 bytes for Classical CAN and up to 64 bytes for CAN FD)
  - CRC field
  - ACK field

For more information, see *ISO 11898-1:2015: CAN data link layer and physical signalling*.

18.7.3 MCAN Integration

Figure 18-135 shows the integration of the MCAN module in the device.

Figure 18-135. MCAN Integration

Table 18-613 through Table 18-615 summarize the integration of the MCAN module in the device.

	MCAN_DREQ_RX_FE2	DMA_CROSSBAR_		MCAN RX Filter Event 2

NOTE: For more information about the IRQ_CROSSBAR module, see Section 13.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.

For more information about the device interrupt controllers, see Chapter 12, *Interrupt Controllers*.

NOTE: For more information about the DMA_CROSSBAR module, see Section 13.4.6.5, *DMA_CROSSBAR Module Functional Description*, in Chapter 13, *Control Module*.

NOTE: For the description of the interrupt source, see Section 18.7.4.2, *Interrupt and DMA Requests*.

18.7.4 MCAN Functional Description

The MCAN module performs CAN protocol communication according to ISO 11898-1:2015. The bit rate can be programmed to values up to 5 Mbit/s. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

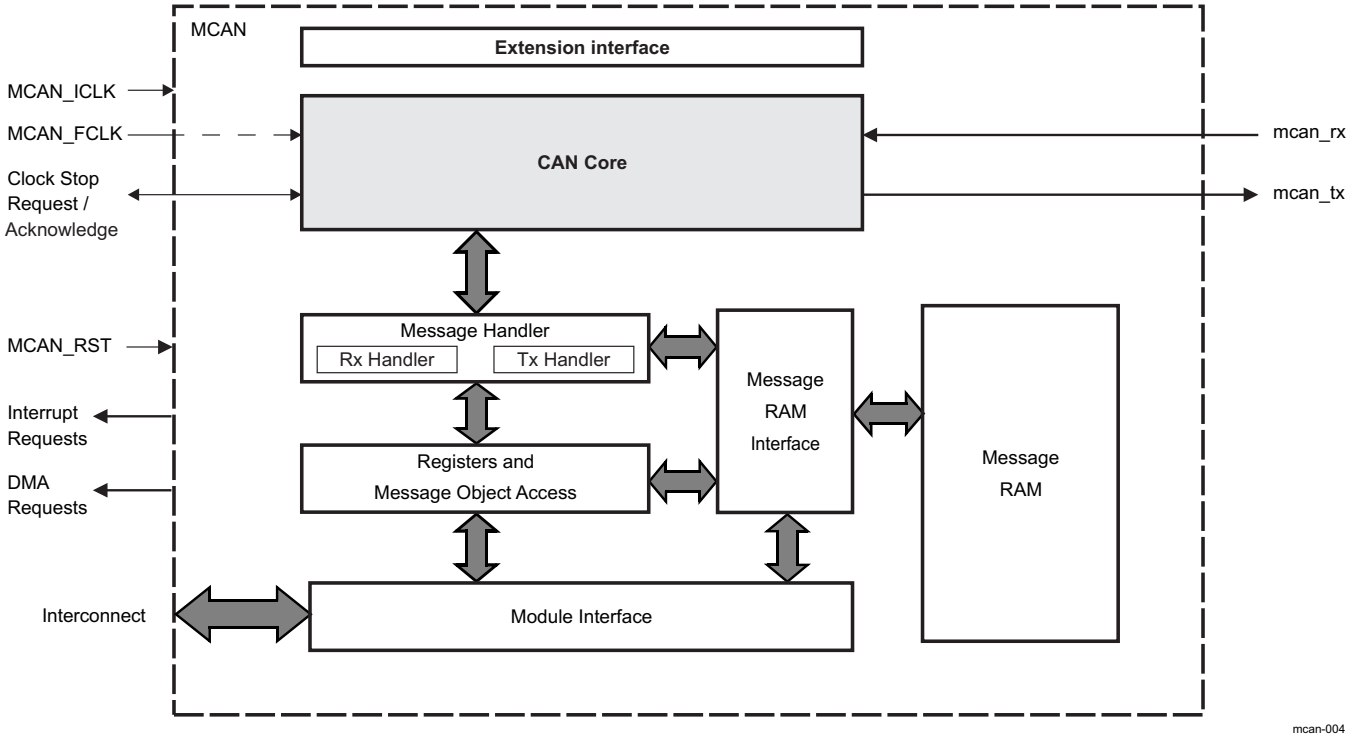
For communication on a CAN network, individual message frames can be configured. The message frames and identifier masks are stored in the Message RAM.

All functions concerning the handling of messages are implemented in the Message Handler.

The register set of the MCAN module can be accessed directly via the module interface. These registers are used to control and configure the CAN core and the Message Handler, and to access the Message RAM.

Figure 18-136 shows the MCAN module block diagram.

Figure 18-136. MCAN Block Diagram



The MCAN module blocks description:

- **CAN Core**: The CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1:2015 protocol functions and supports 11-bit and 29-bit identifiers.
- **Message Handler**: the Message Handler (Rx Handler and Tx Handler) is a state machine that controls the data transfer between the single-ported Message RAM and the CAN core's Rx/Tx shift register. It also handles the acceptance filtering and the Interrupt/DMA request generation as programmed in the control registers.
- **Message RAM**: the main purpose of the Message RAM is to store Rx/Tx messages, Tx Event elements, and Message ID Filter elements (for more information, see Section 18.7.4.11, *Message RAM*).
- **Message RAM Interface**: enables connection between the Message RAM and the other blocks in the MCAN module.
- **Registers and Message Object Access**: Data consistency is ensured by indirect accesses to the message objects. During normal operation, all software and DMA accesses to the Message RAM are done through interface registers. The interface registers have the same word-length as the Message RAM.

- **Module Interface**: The MCAN module registers are accessed by the user software through a 32-bit peripheral bus interface.
- **Clocking**: Two clocks are provided to the MCAN module: the peripheral synchronous clock (interface clock - MCAN_ICLK) and the peripheral asynchronous clock (functional clock - MCAN_FCLK).
- **Extension Interface**: All flags from the Interrupt Register (MCAN_IR) as well as selected internal status and control signals are routed to this interface.

18.7.4.1 Module Clocking Requirements

Two clocks are provided to the MCAN module:

- the peripheral synchronous clock (MCAN_ICLK) as the general module clock source
- and the peripheral asynchronous clock (MCAN_FCLK) provided to the CAN core for generating the CAN bit timing.

Within the MCAN module there is a synchronization mechanism implemented to ensure safe data transfer between the two clock domains. There are synchronization between the signals from the Host clock domain to the CAN clock domain and vice versa and between the reset signal (MCAN_RST) to the Host clock domain and to the CAN clock domain.

NOTE: MCAN_ICLK must always be higher or equal to MCAN_FCLK, in order to achieve a stable functionality of the MCAN module. Here, also the frequency shift of the modulated MCAN_ICLK has to be considered:

$f_{0,\ ICLK}(OCP) \pm \Delta f_{FM,\ ICLK}(OCP) \geq f_{FCLK}$

CAN-FD supports higher speeds of operation and as such has more stringent timing requirements than Classic CAN. For optimal performance, TI recommends using the lowest N-divider value that maintains a working PLL REF_CLK (GMAC_DSP_DPLL_CLK) for the system. Lower N-divider values increase the loop bandwidth of the PLL which in turn improves timing margins for CAN-FD.

For CAN-FD operations > 2 Mbps:

- For 20 MHz input clocks, N = 0 is the preferred configuration.

For CAN-FD operations < 2 Mbps:

- For 20 MHz input clocks, N = 0 is the preferred configuration.
- For 19.2 MHz input clocks, N = 11 is the preferred configuration.

For more information on how to configure the relevant clock source registers, see Chapter 3, *PRCM* and the device data manual.

18.7.4.2 Interrupt and DMA Requests

The MCAN module provides interrupt and DMA requests. They are configured via the Host CPU. The Suspend Mode prevents the interrupt and DMA requests from propagating to the Host CPU (for more information, see Section 18.7.4.4.8.2, *Suspend Mode*).

18.7.4.2.1 Interrupt Requests

The MCAN module has two interrupt lines. The first interrupt line (INT0) is associated with the MCAN core. There are 30 internal interrupt sources. The interrupts are 'level high' interrupts.

For more information, see the following registers:

- Interrupt Register (MCAN_IR)
- Interrupt Enable (MCAN_IE)
- Interrupt Line Select (MCAN_ILS)
- Interrupt Line Enable (MCAN_ILE)

The MCAN module is capable of issuing an ECC interrupt. After clearing the ECC interrupt source, the application software must also write 1 to MCANSS_ECC_EOI[8] ECC_EOI bit (for more information, see Section 18.7.4.7.2, *ECC Aggregator*).

The second interrupt line (INT1) is associated with the External Timestamp Counter. When the External Timestamp Counter rolls over it produces an interrupt (see Section 18.7.4.5.1, *External Timestamp Counter*).

For more information, see the following registers:

- Interrupt Clear Shadow Register (MCANSS_ICS)
- Interrupt Raw Status Register (MCANSS_IRS)
- Interrupt Enable Clear Shadow Register (MCANSS_IECS)
- Interrupt Enable Register (MCANSS_IE)
- Interrupt Enable Status (MCANSS_IES)
- End Of Interrupt (MCANSS_EOI)
- External Timestamp Prescaler (MCANSS_EXT_TS_PRESCALER)
- External Timestamp Unserviced Interrupts Counter (MCANSS_EXT_TS_UNSERVICED_INTR_CNTR)

18.7.4.2.2 DMA Requests

Functional transmit and Filter DMA requests are generated by the MCAN module based on the signaling in the Extention Interface. The DMA signaling uses a simple DMA request active high pulse. Only one Tx DMA event is provided by the MCAN module.

Standard and Extended message filters can be set to issue a pulse when a filter match occurs. These 'Filter Events' can be used to DMA messages from the Rx FIFO. The events are high level single clock cycle (MCAN_ICLK) pulses. Only two Filter DMA events are provided by the MCAN module.

For more information about available Interrupt and DMA Requests, see Section 18.7.3, *MCAN Integration*.

18.7.4.3 Fuseable CAN FD Operation Enable

The Flexible Datarate feature of the MCAN module can be enabled by writing 1 to MCAN_CCCR[8] FDOE bit. A value of 0 on the primary configuration port (mcanss_enable_fdoe) will force the MCAN_CCCR[8] FDOE bit during write to the MCAN_CCCR register which will prevent the device from enabling and using the CAN FD mode.

18.7.4.4 Operating Modes

18.7.4.4.1 Software Initialization

Setting the MCAN_CCCR[0] INIT bit to 1 starts a software initialization. This is done either by software or by a hardware reset, when an uncorrected bit error was detected in the Message RAM, or by going Bus_Off state. While the MCAN_CCCR[0] INIT bit is set, the message transfer is stopped and the status of the output MCAN_TX pin is recessive (high). The counters of the Error Management Logic (EML) are unchanged. Setting the MCAN_CCCR[0] INIT bit does not change any configuration register. Resetting the MCAN_CCCR[0] INIT bit finishes the software initialization. After waiting for the occurrence of a sequence of 11 consecutive recessive bits (indication for Bus_Idle state) the message transfer starts.

Access to the MCAN configuration registers is only enabled when both MCAN_CCCR[0] INIT and MCAN_CCCR[1] CCE bits are set (write protection).

The MCAN_CCCR[1] CCE bit can only be set/reset while the MCAN_CCCR[0] INIT = 1. The MCAN_CCCR[1] CCE bit is automatically reset when the MCAN_CCCR[0] INIT bit is reset.

The following registers are reset when the MCAN_CCCR[1] CCE bit is set:

- MCAN_HPMS - High Priority Message Status
- MCAN_RXF0S - Rx FIFO 0 Status
- MCAN_RXF1S - Rx FIFO 1 Status

- MCAN_TXFQS - Tx FIFO/Queue Status
- MCAN_TXBRP - Tx Buffer Request Pending
- MCAN_TXBTO - Tx Buffer Transmission Occurred
- MCAN_TXBCF - Tx Buffer Cancellation Finished
- MCAN_TXEFS - Tx Event FIFO Status

The Timeout Counter value MCAN_TOCV[15:0] TOC field is preset to the value configured by the MCAN_TOCC[31:16] TOP field when the MCAN_CCCR[1] CCE bit is set.

In addition the Tx Handler and Rx Handler are held in idle state while MCAN_CCCR[1] CCE = 1.

The following registers are only writeable while MCAN_CCCR[1] CCE = 0

- MCAN_TXBAR - Tx Buffer Add Request
- MCAN_TXBCR - Tx Buffer Cancellation Request

MCAN_CCCR[7] TEST and MCAN_CCCR[5] MON bits can only be set by the Host CPU while MCAN_CCCR[0] INIT = 1 and MCAN_CCCR[1] CCE = 1. Both bits may be reset at any time. The MCAN_CCCR[6] DAR bit can only be set/reset while MCAN_CCCR[0] INIT = 1 and MCAN_CCCR[1] CCE = 1.

18.7.4.4.2 Normal Operation

Once the MCAN module is initialized and the MCAN_CCCR[0] INIT bit is reset to zero, the MCAN module synchronizes itself to the CAN bus and is ready for communication. After passing the acceptance filtering, received messages including Message Identifier (ID) and Data Length Code (DLC) are stored into a dedicated Rx Buffer or into Rx FIFO 0/Rx FIFO 1.

For messages to be transmitted dedicated Tx Buffers and/or a Tx FIFO or a Tx Queue can be initialized or updated.

NOTE: Automated transmission on reception of remote frames is not supported.

18.7.4.4.3 CAN FD Operation

There are two variants of CAN FD frame transmission:

- CAN FD frame transmission without bit rate switching
- CAN FD frame transmission where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame

In the CAN frames FDF = recessive (logical 1) signifies a CAN FD frame, FDF = dominant (logical 0) signifies a Classic CAN frame. In a CAN FD frame, the two bits following FDF - res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = dominant and BRS = recessive. Note that the coding of res = recessive is reserved for future expansion of the protocol. In case the MCAN module receives a frame with FDF = recessive and res = recessive, it will signal a Protocol Exception Event by setting the MCAN_PSR[14] EXE bit. When Protocol Exception Handling is enabled (MCAN_CCCR[12] PXHD = 0), this causes the operation state to change from Receiver (MCAN_PSR[4:3] ACT = 10) to Integrating (MCAN_PSR[4:3] ACT = 00) at the next sample point. In case Protocol Exception Handling is disabled (MCAN_CCCR[12] PXHD = 1), the MCAN will treat a recessive res bit as an form error and will respond with an error frame.

CAN FD operation is enabled by programming the MCAN_CCCR[8] FDOE bit. In case MCAN_CCCR[8] FDOE = 1, transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured via the FDF bit in the respective Tx Buffer element.

With MCAN_CCCR[8] FDOE = 0, received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if the FDF bit of a Tx Buffer element is set. The MCAN_CCCR[8] FDOE and MCAN_CCCR[9] BRSE bits can only be changed while the MCAN_CCCR[0] INIT and MCAN_CCCR[1] CCE bits are both set. With MCAN_CCCR[8] FDOE = 0, the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format.

With MCAN_CCCR[8] FDOE = 1 and MCAN_CCCR[9] BRSE = 0, only FDF bit of a Tx Buffer element is evaluated. With MCAN_CCCR[8] FDOE = 1 and MCAN_CCCR[9] BRSE = 1, transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significant higher than in the CAN FD arbitration phase. In this case disable the CAN FD bit rate switching option for transmissions.
- During system startup all nodes are transmitting Classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wake-up messages in CAN Partial Networking have to be transmitted in Classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN communication.

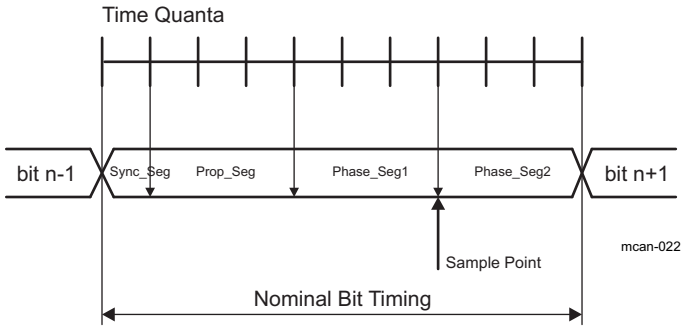
In the CAN FD format, the DLC coding differs from the standard CAN format (see Table 18-616).

Table 18-616. DLC Coding

DLC	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Number of Data Bytes in Standard CAN	0	1	2	3	4	5	6	7	8	8	8	8	8	8	8	8
Number of Data Bytes in CAN FD	0	1	2	3	4	5	6	7	8	12	16	20	24	32	48	64

For CAN FD frames with bit rate switchingIn, the bit timing will be switched inside the frame after the BRS (Bit Rate Switch) bit in case this bit is recessive. In the CAN FD arbitration phase, before the BRS bit, the nominal CAN bit timing (see Figure 18-137) is used as configured by the Nominal Bit Timing and Prescaler Register MCAN_NBTP. In the following CAN FD data phase, the data phase bit timing is used as configured by the Data Bit Timing and Prescaler Register MCAN_DBTP. The bit timing is switched back from the data phase timing at the CRC delimiter or when an error is detected, whichever occurs first.

Figure 18-137. CAN Bit Timing



The maximum configurable data phase bit timing depends on the CAN clock frequency (MCAN_FCLK). Example: with MCAN_FCLK = 20 MHz and the shortest configurable bit time of 4 t_q (time quanta), the bit rate in the data phase is 5 Mbit/s.

For both CAN FD without and CAN FD with bit rate switching the value of the ESI (Error Status Indicator) bit depends on transmitter's error state (see MCAN_PSR[11] RESI bit) monitored at the start of the transmission. If the transmitter has error passive flag the ESI bit is transmitted recessive, else it is transmitted dominant.

18.7.4.4.4 Transmitter Delay Compensation

18.7.4.4.4.1 Description

When only one CAN FD node is transmitting and all others are receivers the length of the bus line has no impact. When transmitting via the MCAN_TX pin the MCAN module receives the transmitted data from its local CAN transceiver via the MCAN_RX pin. The received data is delayed. If the transmitter delay is greater than TSEG1 (time segment before sample point), a bit error is detected.

The MCAN module provides a delay compensation mechanism to compensate the transmitter delay. The compensation mechanism enables transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver. Without transmitter delay compensation the bit rate in the data phase is limited by the transmitter delay.

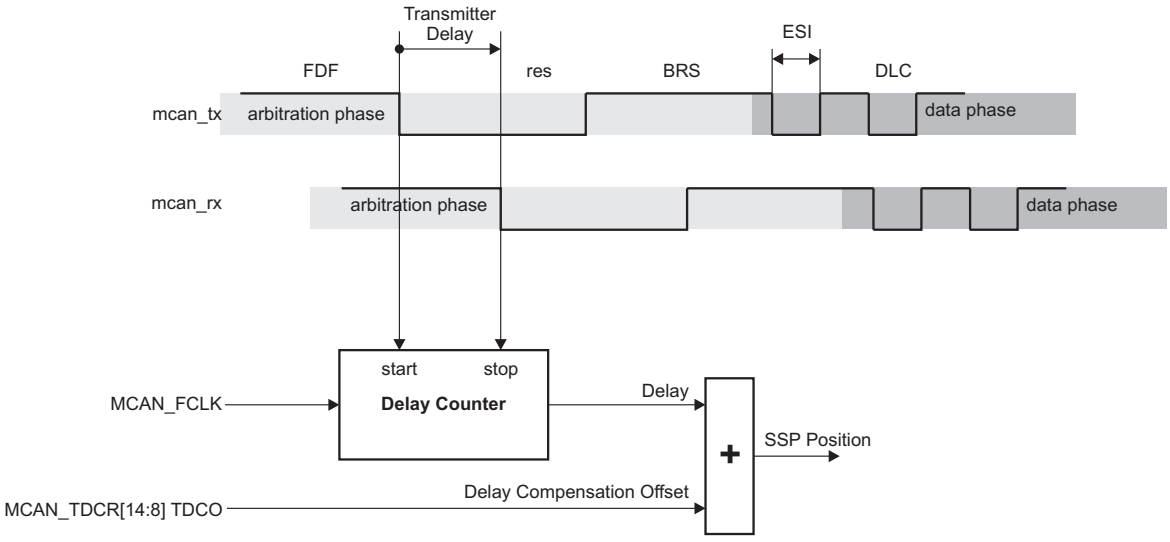
The mechanism enables configurations where the data bit time is shorter than the transmitter delay (it is described in detail in ISO 11898-1:2015). The transmitter delay compensation is enabled by setting the MCAN_DBTP[23] TDC bit to 1.

The delayed transmit data is compared against the received data at the Secondary Sample Point (SSP) in order to check for bit errors during the data phase of transmitting nodes. If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration phase the delay compensation is always disabled.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the MCAN's transmit output MCAN_TX pin through the transceiver to the receive input MCAN_RX pin plus the transmitter delay compensation offset configured by the MCAN_TDCR[14:8] TDCO field (see Figure 18-138). The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (example: half of the bit time in the data phase). The position of the SSP is rounded down to the next integer number of mtq.

The actual transmitter delay compensation value can be checked by reading the MCAN_PSR[22:16] TDCV field. This filed is cleared when the MCAN_CCCR[0] INIT bit is set and is updated at each transmission of CAN FD frame while the MCAN_DBTP[23] TDC bit is set.

Figure 18-138. Transmitter Delay Measurement



18.7.4.4.4.2 Transmitter Delay Compensation Measurement

When transmitter delay compensation is enabled (by programming MCAN_DBTP[23] TDC = 1), the measurement is started within each transmitted CAN FD frame at the falling edge of FDF bit to bit res. The measurement is stopped when this edge is seen at the receive input MCAN_RX pin of the transmitter. The resolution of this measurement is one mtq (see Figure 18-138). The mtq (minimum time quantum) dimension is equal to the CAN clock period (MCAN_FCLK).

The use of a transmitter delay compensation filter window can be enabled by programming MCAN_TDCR[6:0] TDCF field. This filter feature defines a minimum value for the SSP position to avoid the case in which a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in an early taken SSP position. Dominant edges on the MCAN_RX pin, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least MCAN_TDCR[6:0] TDCF field and the MCAN_RX pin is low.

The following boundary conditions have to be considered:

- The sum of the measured delay from the MCAN_TX pin to the MCAN_RX pin and the configured transmitter delay compensation offset (MCAN_TDCR[14:8] TDCO field) has to be less than 6 bit times in the data phase.
- The sum of the measured delay from the MCAN_TX pin to the MCAN_RX pin and the configured transmitter delay compensation offset (MCAN_TDCR[14:8] TDCO) field has to be less or equal 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs.

18.7.4.4.5 Restricted Operation Mode

In Restricted Operation Mode the CAN node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The recieve and transmit error counters (MCAN_ECR[14:8] REC and MCAN_ECR[7:0] TEC) are frozen while CAN error logging (MCAN_ECR[23:16] CEL) is active. The Host CPU can set the MCAN module into Restricted Operation Mode by setting MCAN_CCCR[2] ASM bit. The bit can only be set by the Host CPU at any time when both MCAN_CCCR[2] CCE and MCAN_CCCR[1] INIT bits are set to 1.

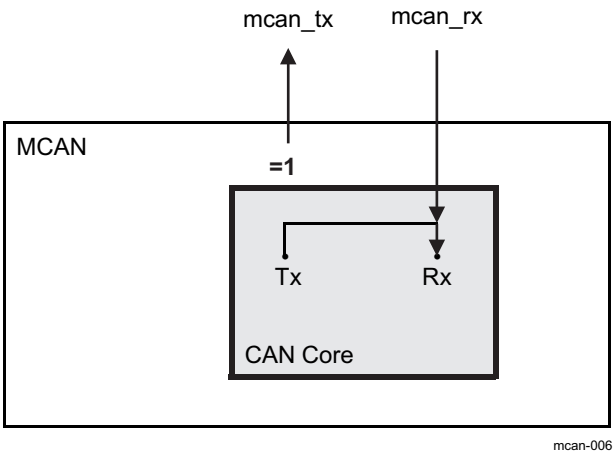
The Restricted Operation Mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave Restricted Operation Mode, the Host CPU has to reset MCAN_CCCR[2] ASM bit. This mode can be used in applications that adapt themselves to different CAN bit rates. In this case the application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame.

NOTE: The Restricted Operation Mode must not be combined with the Loop Back Mode.

18.7.4.4.6 Bus Monitoring Mode

Entering Bus Monitoring Mode is done by setting the MCAN_CCCR[5] MON bit to 1. In this mode (see ISO 11898-1:2015, *Bus Monitoring* section), the MCAN module is able to receive valid data and remote frames, but cannot start a transmission. The MCAN module sends only recessive bits on the CAN bus. If the MCAN module is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the MCAN module monitors this dominant bit, although the CAN bus may remain in recessive state. In Bus Monitoring Mode the MCAN_TXBRP register is held in reset state. The Bus Monitoring Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits. Figure 18-139 shows the connection of the MCAN_TX and MCAN_RX signals to the MCAN module in Bus Monitoring Mode.

Figure 18-139. Connection of Signals in Bus Monitoring Mode



18.7.4.4.7 Disabled Automatic Retransmission (DAR) Mode

According to the CAN Specification (see ISO11898-1:2015, *Recovery Management* section), the MCAN module provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled (see the MCAN_CCCR[6] DAR bit).

18.7.4.4.7.1 Frame Transmission in DAR Mode

In DAR mode all transmissions are automatically cancelled after they started on the CAN bus. A Tx Buffer's Tx Request Pending MCAN_TXBRP[xx] TRPx bit is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

Successful transmission:

- Corresponding Tx Buffer Transmission Occurred MCAN_TXBTO[xx] TOx bit is set
- Corresponding Tx Buffer Cancellation Finished MCAN_TXBCF[xx] CFx bit is not set

Successful transmission in spite of cancellation:

- Corresponding Tx Buffer Transmission Occurred MCAN_TXBTO[xx] TOx bit is set
- Corresponding Tx Buffer Cancellation Finished MCAN_TXBCF[xx] CFx bit is set

Arbitration lost or frame transmission disturbed:

- Corresponding Tx Buffer Transmission Occurred MCAN_TXBTO[xx] TOx bit is not set
- Corresponding Tx Buffer Cancellation Finished MCAN_TXBCF[xx] CFx bit is set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = 10 (transmission in spite of cancellation).

18.7.4.4.8 Power Down (Sleep Mode)

Entering Power Down mode is controlled via the input clock stop request signal (mcanss_clkstp_clkstop_req) or MCAN_CCCR[4] CSR bit. As long as the clock stop request signal is active, the MCAN_CCCR[4] CSR bit is read as 1. When all pending transmission requests have completed, the MCAN module waits until bus idle state is detected. Then the MCAN module sets the MCAN_CCCR[1] INIT to 1 to prevent any further CAN transfers. The MCAN module acknowledges that it is ready for power down by setting the output clock stop acknowledge signal (mcanss_clkstop_clkstop_ack) to 1 and the MCAN_CCCR[3] CSA bit to 1. In this state, before the clocks are switched off, further register accesses can be made. A write access to the MCAN_CCCR[1] INIT bit will have no effect. Now the module clock inputs MCAN_ICLK and MCAN_FCLK may be switched off.

To leave power down mode, the application has to turn on the module clocks before resetting the input clock stop request signal respectively the MCAN_CCCR[4] CSR flag bit. The MCAN will acknowledge this by resetting the output clock stop acknowledge signal respectively the MCAN_CCCR[3] CSA flag bit. Afterwards, the application can restart CAN communication by resetting MCAN_CCCR[1] INIT bit.

18.7.4.4.8.1 External Clock Stop Mode

The MCAN module supports two external clock stop modes:

- Immediate
- Graceful

In a graceful clock stop mode, when the clock stop request is asserted, the MCAN core will respond with clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. The MCAN_CCCR[0] INIT bit will be set, the MCAN core will go and stay Idle.

The automatic wakeup feature is enabled by setting the MCANSS_CTRL[5] AUTOWAKEUP and MCANSS_CTRL[4] WAKEUPREQEN bits to 1 (for more information, see Section 18.7.4.4.8.3, *Wakeup request*). When external clock stop request is removed and no suspend request is active, a read-modify-write to the MCAN_CCCR[0] INIT bit is performed to clear it.

18.7.4.4.8.2 Suspend Mode

The MCAN module supports two suspend modes:

- Immediate
- Graceful

In a graceful suspend mode (see the MCANSS_CTRL[3] FREE and MCANSS_CTRL[2] SOFT bits), when the suspend request is asserted, a clock stop request to the MCAN core is performed. The MCAN core will respond with clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. At that point the MCAN_CCCR[0] INIT bit will be set, the MCAN core will go and stay Idle. The suspend state can be verified by reading MCAN_CCCR[0] INIT bit.

The automatic wakeup feature is enabled by setting the MCANSS_CTRL[5] AUTOWAKEUP and MCANSS_CTRL[4] WAKEUPREQEN bits to 1 (for more information, see Section 18.7.4.4.8.3, *Wakeup request*). When suspend request is removed, if no external clock stop request is active, a read-modify-write to the MCAN_CCCR[0] INIT bit is performed to clear it.

During suspend mode the auto-clear feature is disabled. The following register fields have an auto-clear feature:

- MCAN_ECR[23:16] CEL
- MCAN_PSR[2:0] LEC
- MCAN_PSR[10:8] DLEC
- MCAN_PSR[11] RESI
- MCAN_PSR[12] RBRS
- MCAN_PSR[13] RFDF
- MCAN_PSR[14] PXE

18.7.4.4.8.3 Wakeup request

Issuing a clock stop request puts the MCAN module into Power Down mode (Sleep Mode). During transition from IDLE to ACTIVE, if the MCANSS_CTRL[5] AUTOWAKEUP and MCANSS_CTRL[4] WAKEUPREQEN bits are enabled, after the MCAN Core respond to the removal of the clock stop request with removing the clock stop acknowledge, a read-modify-write will be issued to clear the MCAN_CCCR[0] INIT bit and the MCAN core will resume operation.

If the MCANSS_CTRL[4] WAKEUPREQEN bit is set, the MCAN module provides a wakeup request (SWakeup) on any of the following wakeup events:

- The receive MCAN_RX pin is dominant (logical 0)
- OCP access is performed

To clear the SWakeup in case any of these events is active, the MCANSS_CTRL[4] WAKEUPREQEN bit should be cleared. The MCAN module adds a third wakeup event source - interrupt line 0 (INT0). In this case the SWakeup is cleared by clearing the interrupt source.

18.7.4.4.9 Test Modes

The MCAN_TEST register write access is enabled by setting the test mode enable MCAN_CCCR[7] TEST bit to 1. The MCAN_TEST register allows the configuration of the test modes and test functions.

The CAN transmit MCAN_TX pin has four output functions. One of those functions can be selected by programming the MCAN_TEST[6:5] TX filed. Additionally to its default function (the serial data output) it can drive the CAN Sample Point signal to monitor the MCAN's bit timing and it can drive constant dominant or recessive values.

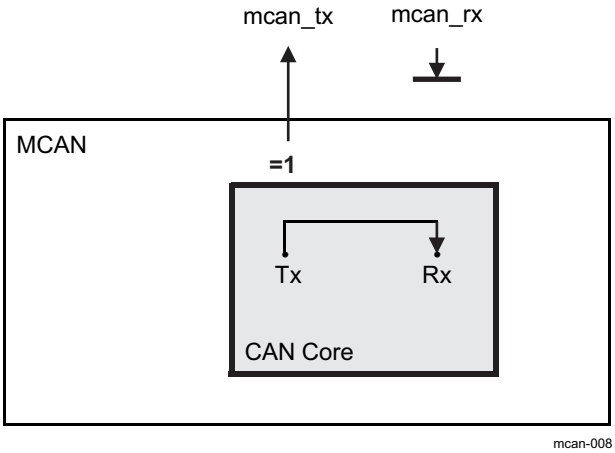
The actual value of the CAN receive MCAN_RX pin can be monitored from MCAN_TEST[7] RX bit. Both functions can be used to check the CAN bus physical layer. Due to the synchronization mechanism between CAN clock (MCAN_FCLK) and Host clock (MCAN_ICLK) domain, there may be a delay of several Host clock periods between writing to the MCAN_TEST[6:5] TX filed until the new configuration is visible at the output MCAN_TX pin. This applies also when reading input MCAN_RX pin via the MCAN_TEST[7] RX bit.

NOTE: Test modes should be used for self test only. The software control for MCAN_TX pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.

18.7.4.4.9.1 Internal Loop Back Mode

The MCAN module can be set into Internal Loop Back Mode by programming MCAN_TEST[4] LBCK and MCAN_CCCR[5] MON bits to 1. The Internal Loop Back Mode is used for a 'Hot Selftest'. The 'Hot Selftest' allows the MCAN module to be tested without affecting a running CAN system connected to the MCAN_TX and MCAN_RX pins. In this mode MCAN_RX pin is disconnected from the MCAN module and MCAN_TX pin is held recessive. Figure 18-140 shows the connection of the MCAN_TX and MCAN_RX pins to the MCAN module in case of Internal Loop Back Mode.

Figure 18-140. Internal Loop Back Mode



18.7.4.5 Timestamp Generation

The MCAN module has integrated a 16-bit wrap-around counter for timestamp generation. The timestamp counter prescaler MCAN_TSCC[19:16] TCP field can be configured to clock the counter in multiples of CAN bit times (1-16). The counter is readable via the MCAN_TSCV[15:0] TSC field. A write access to the MCAN_TSCV register resets the counter to zero. When the timestamp counter wraps around the interrupt MCAN_IR[16] TSW flag is set. On start of a frame reception/transmission the counter value is captured and stored into the timestamp section of an Rx Buffer/Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element. For more information, see Section 18.7.4.11, *Message RAM*.

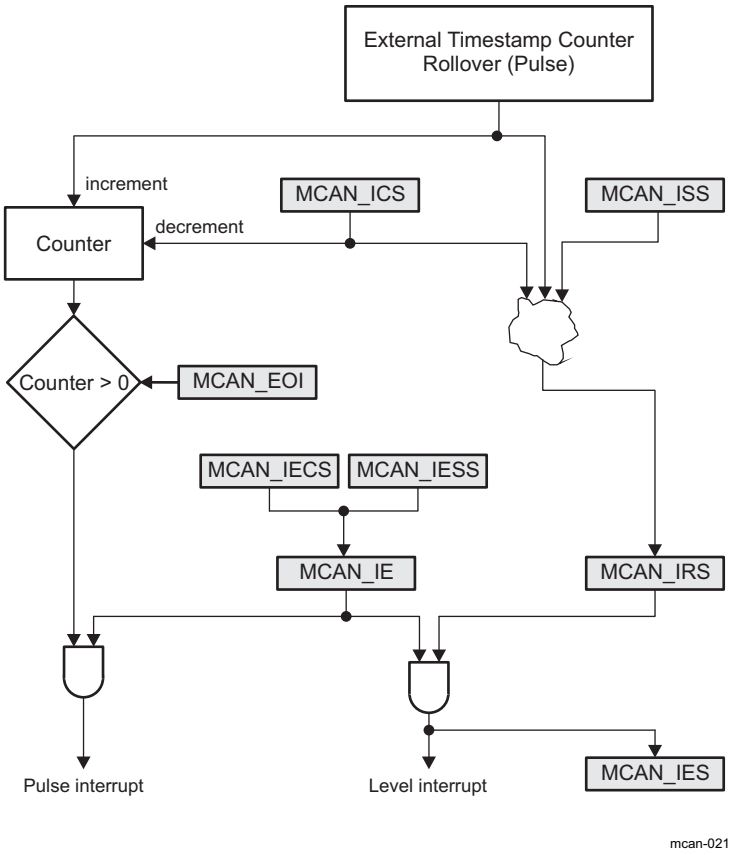
18.7.4.5.1 External Timestamp Counter

For CAN FD operation mode the MCAN core requires an External Timestamp Counter. An externally generated 16-bit vector may substitute the integrated 16-bit CAN bit time counter (internal timestamp counter) for receive and transmit timestamp generation. An external 16-bit timestamp counter can be used by programming the MCAN_TSCC[1:0] TSS field.

The External Timestamp Counter uses the interface clock (MCAN_ICLK) as a reference clock. The MCAN Core accepts a 16-bit timestamp. A 24-bit prescaler provides a programmable resolution for the timestamp (see MCANSS_EXT_TS_PRESCALER[23:0] PRESCALER field). When disabled the counter is reset back to zero. While enabled the counter keeps incrementing. When the timestamp rolls over the MCAN_IRQ_TS interrupt is generated. The MCAN module provides both pulse and level interrupt type for this interrupt.

When the timestamp rolls over the MCANSS_IRS register is set (see Figure 18-141). The MCANSS_IE register can be affected by writing to the MCAN_IESS register to set or to the MCANSS_IECS register to clear. The level interrupt is a reflection of both MCANSS_IRS and MCANSS_IE being set. The MCANSS_IES register reflects the level interrupt. When an rollover event occurs the interrupt counter is incremented. Writing to the MCANSS_ICS register to clear the MCANSS_IRS register will also decrement the interrupt counter. Writing to the MCANSS_EOI register will issue another pulse if the interrupt counter is not zero.

Figure 18-141. External Timestamp Counter Interrupt



18.7.4.6 Timeout Counter

The MCAN module has integrated a 16-bit Timeout Counter. It is used to signal timeout conditions for the Rx FIFO 0, Rx FIFO 1, and Tx Event FIFO Message RAM elements. The Timeout Counter is configured via the MCAN_TOCC register. It is enabled via the MCAN_TOCC[0] ETOC bit. The Timeout Counter operates as down-counter and uses the same prescaler programmed by the MCAN_TSCC[19:16] TCP field as the Timestamp Counter. The actual counter value can be monitored from the MCAN_TOCV[15:0] TOC field. The Timeout Counter can be started only when MCAN_CCCR[1] INIT = 0 and stopped when MCAN_CCCR[1] INIT = 1 (example: when the MCAN enters Bus_Off state). The operation mode is selected by the MCAN_TOCC[2:1] TOS field. When Continuous Mode is selected, the counter starts when MCAN_CCCR[1] INIT = 0, a write to the MCAN_TOCV register presets the counter to the value configured by the MCAN_TOCC[31:16] TOP field and continues down-counting.

In case the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by the MCAN_TOCC[31:16] TOP field. Down-counting is started when the first FIFO element is stored. Writing to the MCAN_TOCV register has no effect. When the counter reaches zero, the interrupt MCAN_IR[18] TOO flag is set.

In Continuous Mode, the counter is immediately restarted at the value configured by the MCAN_TOCC[31:16] TOP field.

18.7.4.7 Safety

The Message Memory is wrapped in an ECC wrapper provididing SECDED parity functionalilty. The ECC wrapper is controlled by an ECC Aggregator.

18.7.4.7.1 ECC Wrapper

The ECC wrapper provides Single Error Correction (SEC) and Double Error Detection (DED) parity to the Message Memory content. It has side band signals for error notification. The ECC Wrapper implements an error injection test mode.

The error correction is done using a lazy write back. When an error is detected, it is noted in a FIFO Queue which waits for an access gap to write the data back and refresh the memory. If a transaction writes new data to the compromised entry before the lazy write back completes, the write back is discarded.

18.7.4.7.2 ECC Aggregator

This section describes the functional details of the ECC Aggregator module.

18.7.4.7.2.1 ECC Aggregator Overview

The ECC Aggregator module supports the following general features:

- Provides a mechanism to control and monitor the ECC RAM in the MCAN module.
- Provides software access to all the ECC related registers.
- Supports software readable status of ECC single/double-bit errors and associated info such as RAM address and data bit(s) that are in error.
- Aggregates level pending status from the ECC RAM into a single interrupt to the Host CPU.

The following feature is not supported:

- Statistics such as tracking the number of single and double-bit errors. If needed, these operations can be handled by software.

18.7.4.7.2.2 ECC Aggregator Registers

There are 3 groups of registers in the ECC aggregator module:

- Global registers - Aggregator Revision Register (MCANSS_ECC_AGGR_REVISION), ECC Vector Register (MCANSS_ECC_VECTOR), Misc Status Register (MCANSS_ECC_MISC_STATUS), ECC Control Register (MCANSS_ECC_CONTROL), and ECC Wrapper Revision Register (MCANSS_ECC_WRAP_REVISION).
- Control and status registers - ECC Error Control Registers (MCANSS_ECC_ERR_CTRL1 and MCANSS_ECC_ERR_CTRL2) and ECC Error Status Registers (MCANSS_ECC_ERR_STAT1 and MCANSS_ECC_ERR_STAT2).
- Interrupt registers - interrupt status, interrupt enable set, interrupt enable clear and EOI (End Of Interrupt) registers that are part of a standard interrupt module. For more information, see the following registers:
  - MCANSS_ECC_SEC_EOI_REG
  - MCANSS_ECC_SEC_STATUS_REG0
  - MCANSS_ECC_SEC_ENABLE_SET_REG0
  - MCANSS_ECC_SEC_ENABLE_CLR_REG0
  - MCANSS_ECC_DED_EOI_REG
  - MCANSS_ECC_DED_STATUS_REG0
  - MCANSS_ECC_DED_ENABLE_SET_REG0
  - MCANSS_ECC_DED_ENABLE_CLR_REG0

18.7.4.7.2.3 Reads to ECC Control and Status Registers

The reads to the ECC control and status registers are triggered by writing a 'read message' to the ECC Vector Register as described below:

- Software writes value (the ECC RAM ID) to the MCANSS_ECC_VECTOR[10-0] ECC_VECTOR field to select the ECC RAM for control or status.

- Software writes 1 to the MCANSS_ECC_VECTOR[15] RD_SVBUS bit to trigger a read.
- Software writes read address to the MCANSS_ECC_VECTOR[23-16] RD_SVBUS_ADDRESS field.
- Software then polls the MCANSS_ECC_VECTOR[24] RD_SVBUS_DONE bit to check if it is 1. This bit indicates that the read operation has completed.
- Software reads the data from the ECC control or status register. The following clock cycle (MCAN_ICLK) returns the read data.

18.7.4.7.2.4 ECC Interrupts

The ECC aggregator module aggregates the level pending status from the ECC RAM into a single EOI-handshake based interrupt to the Host CPU. Software is expected to follow the sequence described below:

- Software enables the interrupts for the ECC RAM by writing to the MCANSS_ECC_SEC_ENABLE_SET_REG0/MCANSS_ECC_DED_ENABLE_SET_REG0 register.
- Software writes the ECC RAM ID in the MCANSS_ECC_VECTOR[10-0] ECC_VECTOR.
- Software writes the MCANSS_ECC_VECTOR[15] RD_SVBUS bit to trigger the read.
- Software writes the MCANSS_ECC_ERR_STAT1 register address to the MCANSS_ECC_VECTOR[23-16] RD_SVBUS_ADDRESS field. Software will need to load the 'read message' in the MCANSS_ECC_VECTOR register again if it needs to read the MCANSS_ECC_ERR_STAT2 register.
- Software polls the MCANSS_ECC_VECTOR[24] RD_SVBUS_DONE bit. When this bit is set, a read of the MCANSS_ECC_ERR_STAT1/MCANSS_ECC_ERR_STAT2 register is performed.
- After the interrupt has been serviced, software will clear the interrupt status by writing to the MCANSS_ECC_ERR_STAT1[8] CLR_ECC_SEC or MCANSS_ECC_ERR_STAT1[9] CLR_ECC_DED bit depending on the type of the ECC error.
- Software has to poll the MCANSS_ECC_ERR_STAT1 register to guarantee that the status bit has been cleared.
- Software will write to the MCANSS_ECC_SEC_EOI_REG/MCANSS_ECC_DED_EOI_REG register to clear the interrupt.
- After clearing the ECC interrupt source, the application software must also write 1 to the MCANSS_ECC_EOI[8] ECC_EOI bit.

18.7.4.8 Rx Handling

The Rx Handler controls the following operations:

- Acceptance filtering
- The transfer of received messages to the Rx Buffers or to one of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1)
- Rx FIFO Put and Get Index operations

18.7.4.8.1 Acceptance Filtering

The MCAN module is capable to configure two sets of acceptance filters - one set for standard and one set for extended identifiers. These filters can be assigned to an Rx Buffer or to one of the two Rx FIFOs.

The main features of the filter elements are:

- Each filter element can be configured as:
  - Range Filter (from - to)
  - Filter for specific IDs (for one or two dedicated IDs)
  - Classic Bit Mask Filter
- Each filter element can be enabled/disabled individually
- Each filter element can be configured for acceptance or rejection filtering
- Filters are checked sequentially and execution (acceptance filtering procedure) stops at the first matching filter element or when the end of the filter list is reached

Related configuration registers are:

- Global Filter Configuration (MCAN_GFC) register
- Standard ID Filter Configuration (MCAN_SIDFC) register
- Extended ID Filter Configuration (MCAN_XIDFC) register
- Extended ID AND Mask (MCAN_XIDAM) register

Depending on the configuration of the filter element (see SFEC/EFEC in Section 18.7.4.11, *Message RAM*) if filter matches, one of the following actions is performed:

- Received frame is stored in FIFO 0 or FIFO 1
- Received frame is stored in Rx Buffer
- Received frame is stored in Rx Buffer and generation of pulse at filter event pin is performed. This is high level single MCAN_ICLK pulse. For more information, see Section 18.7.4.2.1, *DMA Requests*.
- Received frame is rejected
- Set High Priority Message interrupt flag MCAN_IR[8] HPM
- Set High Priority Message interrupt flag MCAN_IR[8] HPM and store received frame in FIFO 0 or FIFO 1

Acceptance filtering starts when complete Message ID is received. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If a filter element matches - the Rx Handler starts writing the received message data in portions of 32 bit to the matching Rx Buffer or Rx FIFO. If an error condition occurs (for example: CRC error), this message is rejected with the following impact on the affected Rx Buffer or Rx FIFO:

- Rx Buffer:
  New Data flag (MCAN_NDAT1/MCAN_NDAT2) of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data (for error type see MCAN_PSR[2:0] LEC respectively MCAN_PSR[10:8] DLEC fields).
- Rx FIFO:
  Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data (for error type see MCAN_PSR[2:0] LEC respectively MCAN_PSR[10:8] DLEC fields). If matching Rx FIFO is configured to operate in overwrite mode, the boundary conditions described in Section 18.7.4.8.2.2 have to be considered.

18.7.4.8.1.1 Range Filter

Each filter element can be configured to operate as Range Filter (Standard Filter Type SFT = 00/Extended Filter Type EFT = 00). The filter matches for all received message frames with IDs in the range from SFID1 to SFID2 (SFID2 ≥ SFID1) respectively in the range from EFID1 to EFID2 (EFID2 ≥ EFID1). For more information see Section 18.7.4.11.5, *Standard Message ID Filter Element* and Section 18.7.4.11.6, *Extended Message ID Filter Element*.

There are two options for range filtering of extended frames:

- Extended Filter Type EFT = 00: The Extended ID AND Mask (MCAN_XIDAM) is used for Range Filtering. The Message ID of received frames is ANDed with the Extended ID AND Mask (MCAN_XIDAM) before the range filter is applied.
- Extended Filter Type EFT = 11: The Extended ID AND Mask (MCAN_XIDAM) is not used for Range Filtering.

18.7.4.8.1.2 Filter for specific IDs

Each filter element can be configured to filter one or two dedicated Message IDs (Standard Filter Type SFT =01/Extended Filter Type EFT =01). To filter only one specific Message ID, the filter element has to be configured with SFID1 = SFID2 respectively EFID1 = EFID2. For more information see Section 18.7.4.11.5, *Standard Message ID Filter Element* and Section 18.7.4.11.6, *Extended Message ID Filter Element*.

18.7.4.8.1.3 Classic Bit Mask Filter

Classic bit mask filtering can filter groups of Message IDs (Standard Filter Type SFT =10/Extended Filter Type EFT =10). This is done by masking single bits of a received Message ID. In this case SFID1/EFID1 element is used as Message ID filter, while SFID2/EFID2 element is used as filter mask.

A 0 bit at the filter mask (SFID2/EFID2) will mask out the corresponding bit position of the configured Message ID filter (SFID1/EFID1) and the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are 1 are relevant for acceptance filtering.

There are two interesting cases:

- All mask bits are 1: a match occurs only when the received Message ID and the configured Message ID filter are identical.
- All mask bits are 0: all Message IDs match.

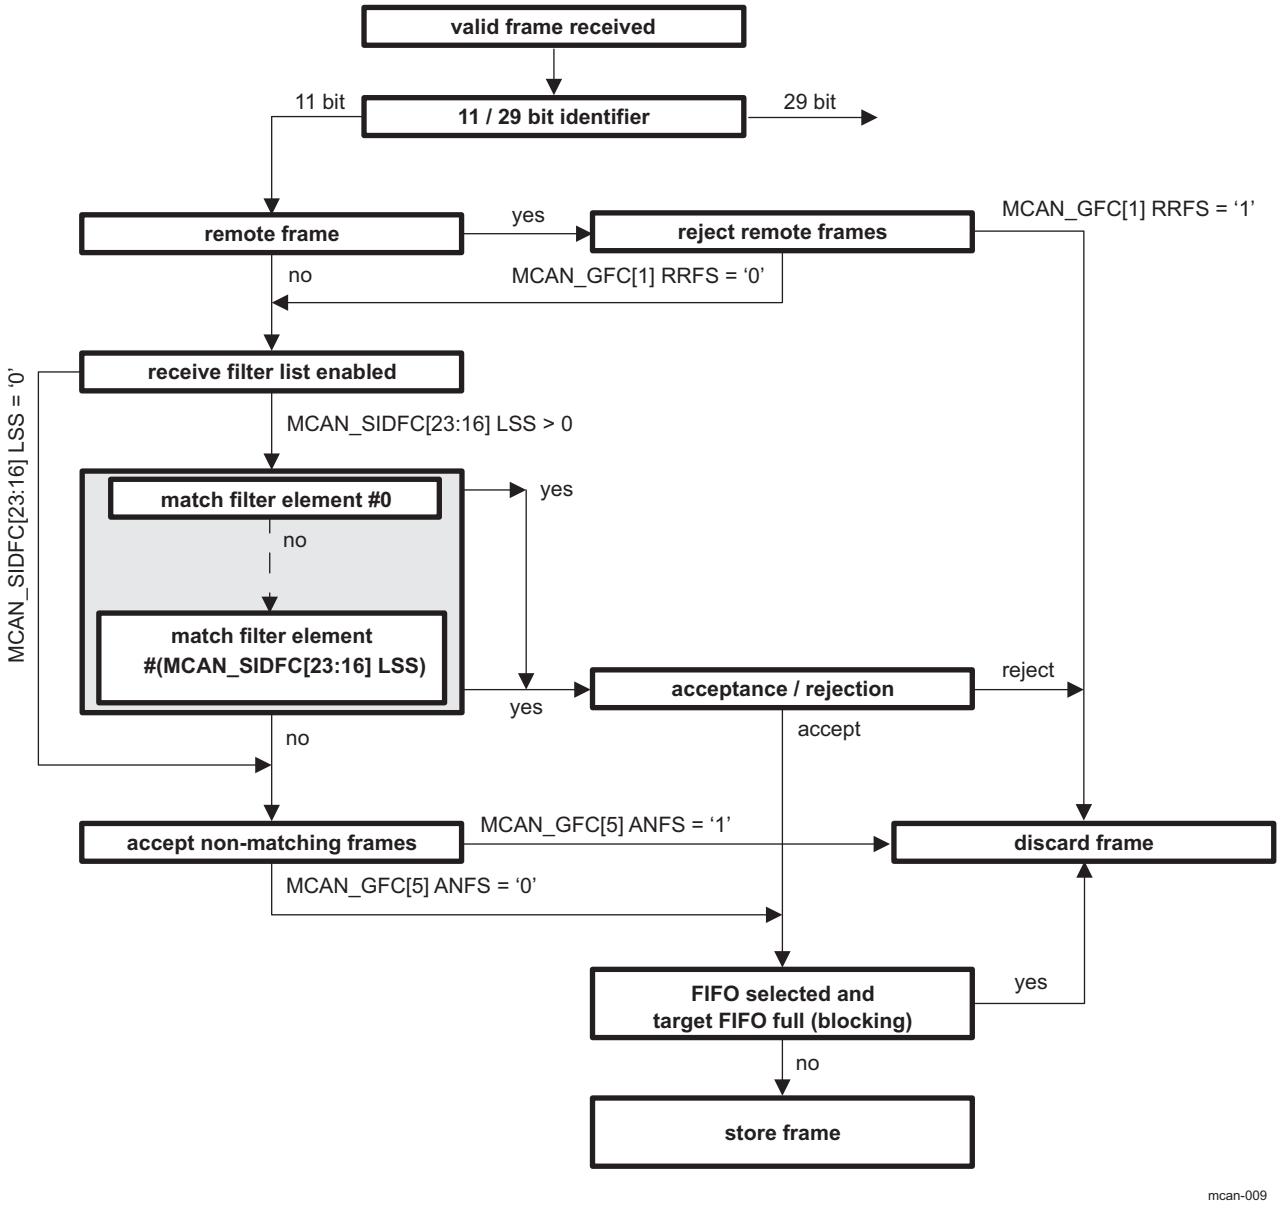
18.7.4.8.1.4 Standard Message ID Filtering

The standard Message ID (11-bit ID) filtering flow is shown in Figure 18-142. Section 18.7.4.11.5, *Standard Message ID Filter Element* describes the standard Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN_GFC) register
- Standard ID Filter Configuration (MCAN_SIDFC) register

Figure 18-142. Standard Message ID Filter Path



18.7.4.8.1.5 Extended Message ID Filtering

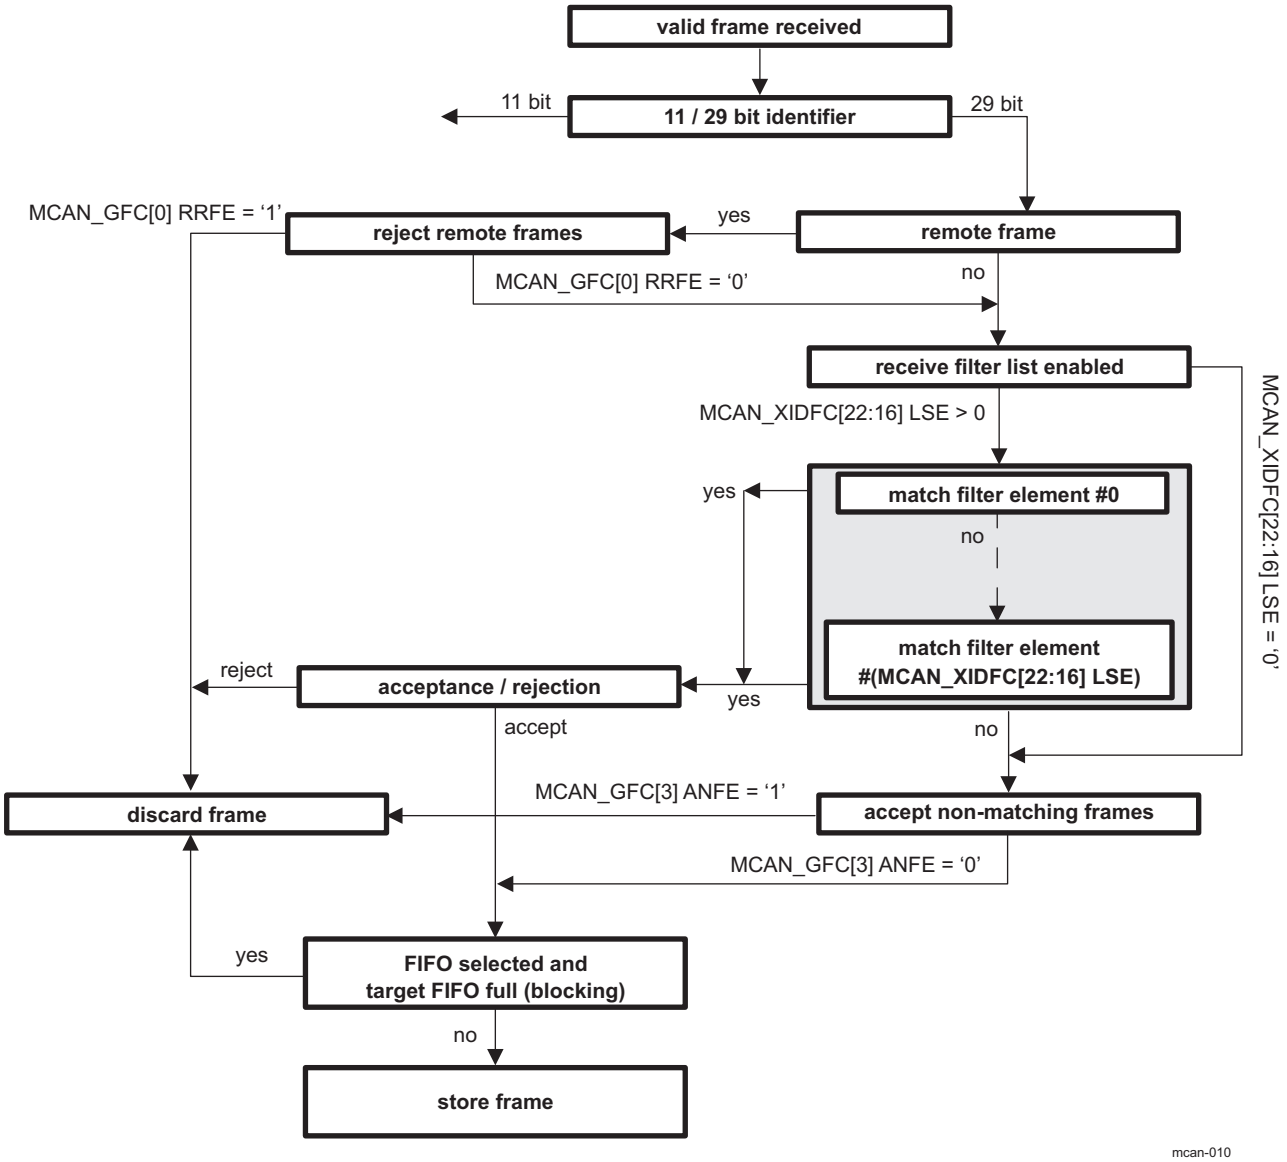
The extended Message ID (29-bit ID) filtering flow is shown in Figure 18-143. Section 18.7.4.11.6, *Extended Message ID Filter Element* describes the extended Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN_GFC) register
- Extended ID Filter Configuration (MCAN_XIDFC) register

Note that before the filter list is executed the received identifier is ANDed with the Extended ID AND Mask (MCAN_XIDAM).

Figure 18-143. Extended Message ID Filter Path



18.7.4.8.2 Rx FIFOs

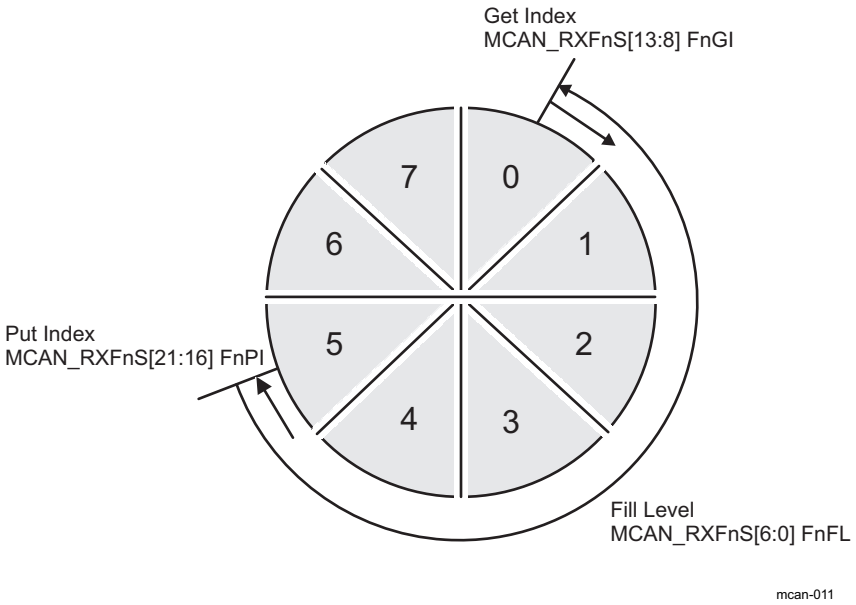
The configuration of the Rx FIFOs (Rx FIFO 0 and Rx FIFO 1) can be done via the MCAN_RXF0C and MCAN_RXF1C registers. Each Rx FIFO can be configured to store up to 64 received messages.

After acceptance filtering the received messages that passed are transferred to the Rx FIFO. The filter mechanisms available for the Rx FIFO 0 and Rx FIFO 1 is described in Section 18.7.4.8.1, *Acceptance Filtering*. Section 18.7.4.11.2, *Rx Buffer and FIFO Element* describes the Rx FIFO element.

The Rx FIFO watermark can be used to prevent an Rx FIFO overflow. If the Rx FIFO fill level reaches the Rx FIFO watermark configured by the MCAN_RXFnC[30:24] FnWM filed (where: n = 0 or 1) an interrupt flag MCAN_IR[1] RF0W/MCAN_IR[5] RF1W is set.

When the Rx FIFO Put Index reaches the Rx FIFO Get Index (MCAN_RXFnS[21:16] FnPI = MCAN_RXFnS[13:8] FnGI) an Rx FIFO Full condition is signalled by the MCAN_RXFnS[24] FnF status bit and interrupt flag MCAN_IR[2] RF0F/MCAN_IR[6] RF1F is set. Figure 18-144 shows Rx FIFO Status. The FIFOs fill level is presented in the MCAN_RXFnS[6:0] FnFL field (the number of elements stored in Rx FIFO).

Figure 18-144. Rx FIFO Status



Rx FIFOs start address in the Message RAM (MCAN_RXFnC[15:2]FnSA field) have to be configured when reading from an Rx FIFO (Rx FIFO Get Index - MCAN_RXFnS[13:8] FnGI). Table 18-617 presents Rx Buffer/Rx FIFO Element Size for different Rx Buffer / Rx FIFO Data Field Size which is configured via the MCAN_RXESC register.

Table 18-617. Rx Buffer/Rx FIFO Element Size

MCAN_RXESC[10:8] RBDS MCAN_RXESC[2:0] F0DS/MCAN_RXESC[6:4] F1DS	Data Field [bytes]	FIFO Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

18.7.4.8.2.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is the default operation mode for the Rx FIFOs. It is configured by the MCAN_RXFnC[31] FnOM = 0.

If an Rx FIFO full condition is reached (MCAN_RXFnS[21:16] FnPI = MCAN_RXFnS[13:8] FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by the MCAN_RXFnS[24] FnF = 1 and interrupt flag MCAN_IR[2] RF0F/MCAN_IR[6] RF1F is set.

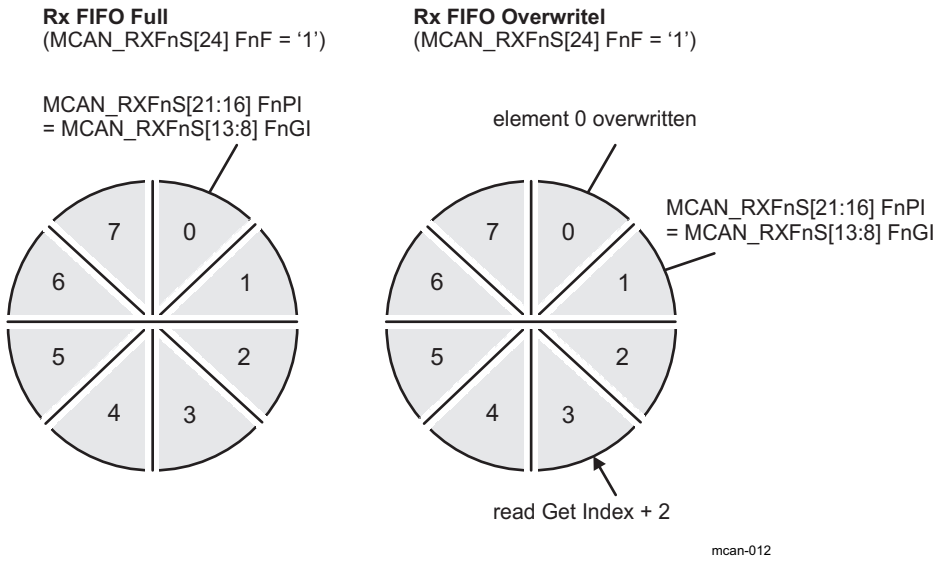
In case a message is received while the corresponding Rx FIFO is full, this message is rejected and the message lost condition is signalled by MCAN_RXFnS[25] RFnL = 1 and interrupt flag MCAN_IR[3] RFnL/MCAN_IR[25] RFnL is set.

18.7.4.8.2.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by the MCAN_RXFnC[31] FnOM = 1. When an Rx FIFO full condition is reached (MCAN_RXFnS[21:16] FnPI = MCAN_RXFnS[13:8] FnGI) signalled by MCAN_RXFnS[24] FnF = 1, the next accepted message for the FIFO will overwrite the oldest FIFO message. Put index/Get index are both incremented by one.

In overwrite mode if an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (Put index) while the Host CPU is reading from the Message RAM (Get index). In this case inconsistent data may be read from the respective Rx FIFO element. The problem is solved by adding an offset to the Get index when reading from the Rx FIFO. The offset depends on how fast the Host CPU accesses the Rx FIFO. Figure 18-145 shows an offset of two with respect to the Get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

Figure 18-145. Rx FIFO Overflow Handling



After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index MCAN_RXFnA[5:0] FnAI. This increments the get index to that element number. In case the Put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (MCAN_RXFnS[24] FnF = 0).

18.7.4.8.3 Dedicated Rx Buffers

The MCAN supports up to 64 dedicated Rx Buffers. The start address of the Rx Buffers section in the Message RAM is configured via MCAN_RXBC[15:2] RBSA field. To store in an Rx Buffer a Standard or Extended Message ID Filter Element with SFEC/EFEC = 111 and SFID2/EFID2[10:9] = 00 has to be configured (see Section 18.7.4.11.5, *Standard Message ID Filter Element* and Section 18.7.4.11.6, *Extended Message ID Filter Element*).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element (the format is the same as for an Rx FIFO element). In addition the flag MCAN_IR[19] DRX (Message stored in Dedicated Rx Buffer) is set.

Table 18-618 shows Example Filter Configuration for Rx Buffers.

Table 18-618. Example Filter Configuration for Rx Buffers

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID message 1	00	00 0000
1	ID message 2	00	00 0001
2	ID message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register MCAN_NDAT1/MCAN_NDAT2 is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host CPU by writing a 1 to the respective bit position.

While an Rx Buffer's New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

18.7.4.8.3.1 Rx Buffer Handling

Rx Buffer Handling include the following steps:

- Reset interrupt flag MCAN_IR[19] DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

18.7.4.9 Tx Handling

The Tx Handler is used to handle the Tx requests. It controls the transfer of transmit messages from the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue to the CAN Core, the Tx Event FIFO, and the Put and Get Index operations. The MCAN module supports up to 32 Tx Buffers. These Tx Buffers can be configured as dedicated Tx Buffers, Tx FIFO, or Tx Queue and as combination of dedicated Tx Buffers/Tx FIFO or dedicated Tx Buffers/Tx Queue. For each Tx Buffer element Classical CAN or CAN FD transmission mode can be configured. Section 18.7.4.11.3 describes the Tx Buffer Element. Table 18-619 shows the possible configurations for message transmission.

Table 18-619. Possible Configurations for Message Transmission

MCAN_CCCR		Tx Buffer Element		Frame Transmission
MCAN_CCCR[9] BRSE	MCAN_CCCR[8] FDOE	FDF	BRS	
ignored	0	ignored	ignored	Classic CAN
0	1	0	ignored	Classic CAN
0	1	1	ignored	CAN FD without bit rate switching
1	1	0	ignored	Classic CAN
1	1	1	0	CAN FD without bit rate switching
1	1	1	1	CAN FD with bit rate switching

When the Tx Buffer Request Pending MCAN_TXBRP register is updated, or when a transmission has been started the Tx Handler starts scanning to check for the highest priority pending Tx request. The Tx Buffer with lowest Message ID has highest priority.

NOTE: AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation.

18.7.4.9.1 Transmit Pause

The transmit pause feature is intended for use in CAN networks where the CAN Message IDs are specific and cannot easily be changed. These Message IDs may have a higher priority than other defined Message IDs, while in a specific application their relative priority should be inverse. This allows for a case where one ECU sends a burst of CAN messages that cause another ECU's CAN messages to be delayed (paused).

The transmit pause feature is enabled by the MCAN_CCCR[14] TXP bit. By default this bit is disabled (MCAN_CCCR[14] TXP = 0). Each time after successfully transmitted message, a pause for two CAN bit times occurs before the start of the next transmission. This allows the other CAN nodes in the network to transmit messages even if their Message IDs have lower priority.

18.7.4.9.2 Dedicated Tx Buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU.

There are two options:

- Each dedicated Tx Buffer is configured with a specific Message ID.
- Two or more dedicated Tx Buffers are configured with the same Message ID. In this case the Tx Buffer with the lowest buffer number is transmitted first.

After the data section has been updated, a transmission is requested by an Add Request. This is done via the MCAN_TXBAR[x]ARn bit (where x = 0 - 31). The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

Table 18-620 shows Tx Buffer/Tx FIFO/Tx Queue Element Size. A Dedicated Tx Buffer allocates Element Size 32-bit words in the Message RAM. The start address of a dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index from 0 to 31 (MCAN_TXFQS[20:16] TFQPI) × Element Size to the Tx Buffer Start Address MCAN_TXBC[15:2] TBSA field.

Table 18-620. Tx Buffer/Tx FIFO/Tx Queue Element Size

MCAN_TXESC[2:0] TBDS	Data Field [bytes]	Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

18.7.4.9.3 Tx FIFO

Tx FIFO mode is configured by setting bit MCAN_TXBC[30] TFQM = 0. The stored in the Tx FIFO messages are transmitted starting with the message referenced by the Get Index MCAN_TXFQS[12:8] TFGI field. After each transmission the Get Index is incremented until the Tx FIFO is empty. The Tx FIFO Free Level MCAN_TXFQS[5:0] TFFL field indicates the number of the available free Tx FIFO elements. The Tx FIFO allows transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN_TXFQS[20:16] TFQPI field. After each Add Request (MCAN_TXBAR[x] ARn = 1) the Put Index is incemented to the next free Tx FIFO element. When the Put Index reaches the Get Index (MCAN_TXFQS[20:16] TFQPI = MCAN_TXFQS[12:8] TFGI), Tx FIFO Full condition is signalled by bit MCAN_TXFQS[21] TFQF = 1. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level MCAN_TXFQS[5:0] TFFL field.

In case a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level MCAN_TXFQS[5:0] TFFL field is recalculated. In case transmission cancellation is applied to any other Tx Buffer - the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates Element Size 32-bit words in the Message RAM (see Table 18-620). The start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN_TXFQS[20:16] TFQPI (from 0 to 31) × Element Size to the Tx Buffer Start Address MCAN_TXBC[15:2] TBSA field.

18.7.4.9.4 Tx Queue

Tx Queue mode is configured by setting bit MCAN_TXBC[30] TFQM = 1. The stored in the Tx Queue messages are transmitted starting with the highest priority message (lowest Message ID). In case two or more Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN_TXFQS[20:16] TFQPI field. Each Add Request cyclically increments the Put Index to the next free Tx Buffer. In case of Tx Queue Full condition (MCAN_TXFQS[21] TFQF = 1), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.

The application may use the MCAN_TXBRP register instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates Element Size 32-bit words in the Message RAM (see Table 18-620). The start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN_TXFQS[20:16] TFQPI (from 0 to 31) × Element Size to the Tx Buffer Start Address MCAN_TXBC[15:2] TBSA field.

18.7.4.9.5 Mixed Dedicated Tx Buffers/Tx FIFO

For this combination the Tx Buffers section in the Message RAM is separated in two parts:

- Dedicated Tx Buffers: the number of Dedicated Tx Buffers is configured by the MCAN_TXBC[21:16] NDTB field
- Tx FIFO: the number of Tx Buffers assigned to the Tx FIFO is configured by the MCAN_TXBC[29:24] TFQS field

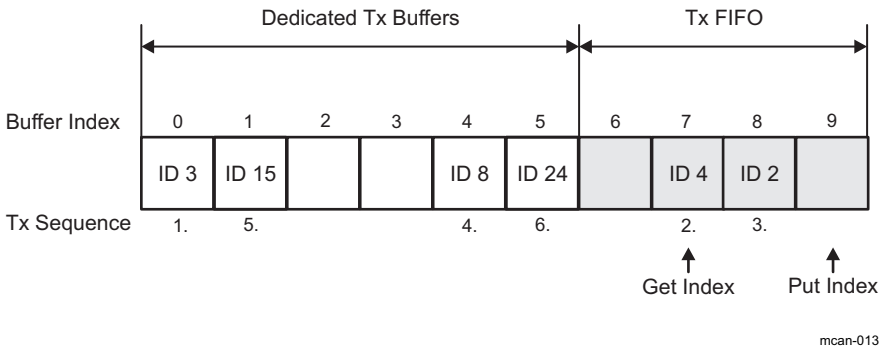
If the MCAN_TXBC[29:24] TFQS field is empty (zero) - only Dedicated Tx Buffers are used.

Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by the MCAN_TXFQS[12:8] TFGI field)
- Buffer with lowest Message ID gets highest priority and is transmitted next

Figure 18-146 shows Mixed Dedicated Tx Buffers/Tx FIFO example.

Figure 18-146. Mixed Dedicated Tx Buffers /Tx FIFO (example)



18.7.4.9.6 Mixed Dedicated Tx Buffers/Tx Queue

For this combination the Tx Buffers section in the Message RAM is separated in two parts:

- Dedicated Tx Buffers: the number of Dedicated Tx Buffers is configured by the MCAN_TXBC[21:16] NDTB field
- Tx Queue: the number of Tx Buffers assigned to the Tx Queue is configured by the MCAN_TXBC[29:24] TFQS field

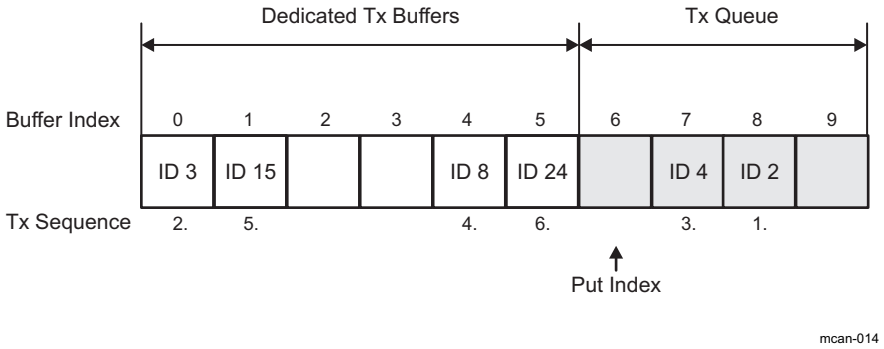
If MCAN_TXBC[29:24] TFQS field is empty (zero) - only Dedicated Tx Buffers are used.

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

Figure 18-147 shows Mixed Dedicated Tx Buffers/Tx Queue example.

Figure 18-147. Mixed Dedicated Tx Buffers /Tx Queue (example)



18.7.4.9.7 Transmit Cancellation

This feature is especially intended for gateway and AUTOSAR based applications. The Host CPU can cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer by setting bit MCAN_TXBCR[n] CRn = 1 (where n = 0 - 31). The corresponding bit position n is equivalent to the number of the Tx Buffer.

Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signalled by setting the corresponding bit of the MCAN_TXBCF register (MCAN_TXBCF[n] CFn = 1).

If transmission from a Tx Buffer is already ongoing and a transmit cancellation is requested, the corresponding MCAN_TXBRP[n] TRPn bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding MCAN_TXBTO[n] TOn and MCAN_TXBCF[n] CFn bits are set. If the transmission was not successful, only the corresponding bit MCAN_TXBCF[n] CFn = 1.

NOTE: If pending transmission is cancelled immediately before this transmission could have been started, a short time window occurs where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

18.7.4.9.8 Tx Event Handling

To support Tx Event Handling the Message RAM has implemented a Tx Event FIFO section. Up to 32 Tx Event FIFO elements can be configured. Section 18.7.4.11.4 describes the Tx Event FIFO element. After message transmission on the CAN bus, Message ID and Timestamp are stored in a Tx Event FIFO element. To link a Tx Event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

A Tx Event FIFO full condition is signalled by the MCAN_IR[14] TEFF bit. In this case no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented (MCAN_TXEFS[12:8] EFGI). In case a Tx Event occurs while the Tx Event FIFO is full, this event is rejected and interrupt flag MCAN_IR[15] TEFL bit is set.

The Tx Event FIFO watermark can be configured to avoid a Tx Event FIFO overflow. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by the MCAN_TXEFC[29:24] EFWM field, interrupt flag MCAN_IR[13] TEFW is set. When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index MCAN_TXEFS[12:8] EFGI field has to be added to the Tx Event FIFO start address MCAN_TXEFC[15:2] EFSA field.

18.7.4.10 FIFO Acknowledge Handling

The Get Indices of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1) and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see MCAN_RXF0A, MCAN_RXF1A, and MCAN_TXEFA). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level.

There are two use cases:

- A single element has been read from the FIFO: the Get Index value is written to the FIFO Acknowledge Index.
- A sequence of elements has been read from the FIFO: the Get Index value (Index of the last element read) is written to the FIFO Acknowledge Index at the end of that read sequence.

The Host CPU has free access to the Message RAM. The special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This can be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFO's Acknowledge Index should not be written because this would set the Get Index to a wrong position and also changes the FIFO's Fill Level. In this case some of the older FIFO elements would be lost.

NOTE: The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The MCAN module does not check for erroneous values.

18.7.4.11 Message RAM

The MCAN module has implemented Message RAM. The main purpose of the Message RAM is to store:

- Receive Messages
- Transmit Messages
- Tx Event Elements
- Message ID Filter Elements

18.7.4.11.1 Message RAM Configuration

The MCAN module is configured to allocate 1600 words in the Message RAM. The Message RAM has a width of 32 bits.

The address range of the Message RAM is from to .

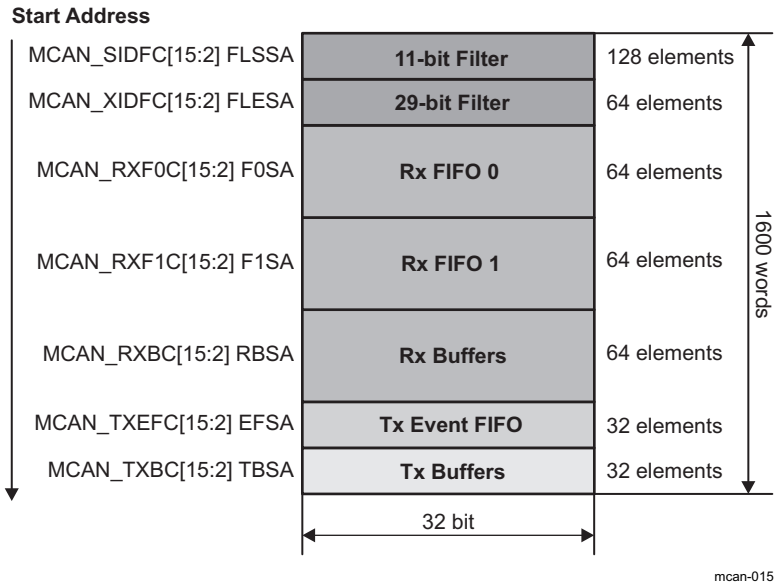
The Message RAM is capable to include each of the sections listed in Figure 18-148. It is not necessary to configure each of the sections (a section in the Message RAM may be 0) and there is not restriction with respect to the sequence of the sections. For parity checking or ECC a respective number of bits has to be added to each word.

When the MCAN module addresses the Message RAM it addresses 32-bit words. The start addresses are configurable and they are 32-bit word addresses.

The element size can be configured for:

- Rx FIFO 0 via the MCAN_RXESC[2:0] F0DS field
- Rx FIFO 1 via the MCAN_RXESC[6:4] F1DS field
- Rx Buffers via the MCAN_RXESC[10:8] RBDS field
- Tx Buffers via the MCAN_TXESC[2:0] TBDS field

Figure 18-148. Message RAM Configuration



The Host CPU configures the following information in the Message RAM:

- Start addresses of the memory sections
- Number of elements in each section
- The size of the elements in some sections

NOTE: The MCAN module does not check for errors in the Message RAM configuration. The configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully. This will prevent falsification or loss of data.

18.7.4.11.2 Rx Buffer and FIFO Element

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via the MCAN_RXESC register.

Figure 18-149 shows Rx Buffer/Rx FIFO element structure.

Figure 18-149. Rx Buffer/Rx FIFO Element Structure

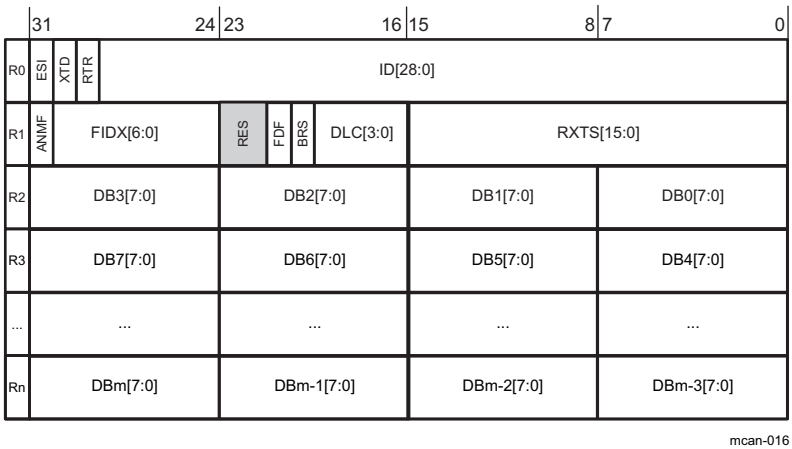


Table 18-621 shows Rx Buffer/Rx FIFO element field descriptions.

Table 18-621. Rx Buffer/Rx FIFO Element Field Descriptions

Word	Bits	Field Name	Description
R0	31	ESI	Error State Indicator • 0x0: Transmitting node is error active • 0x1: Transmitting node is error passive
	30	XTD	Extended Identifier Signals to the Host CPU whether the received frame has a standard or extended identifier. • 0x0: 11-bit standard identifier • 0x1: 29-bit extended identifier
	29	RTR	Remote Transmission Request Signals to the Host CPU whether the received frame is a data frame or a remote frame. • 0x0: Received frame is a data frame • 0x1: Received frame is a remote frame **Note:** There are no remote frames in CAN FD format. In case a CAN FD frame was received (FDF = 1), RTR bit reflects the state of the reserved r1 bit (RES[23]).
	28:0	ID[28:0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier is stored into ID[28:18].
R1	31	ANMF	Accepted Non-matching Frame Acceptance of non-matching frames may be enabled via the MCAN_GFC[5:4] ANFS and MCAN_GFC[3:2] ANFE fields. • 0x0: Received frame matching filter index FIDX field • 0x1: Received frame did not match any Rx filter element
	30:24	FIDX[6:0]	Filter Index 0x0-0x7F (0-127): Index of matching Rx acceptance filter element (invalid if ANMF = 1). Range is 0 to MCAN_SIDFC[23:16] LSS - 1 respectively MCAN_XIDFC[22:16] LSE - 1.
	23:22	RES	Reserved
	21	FDF	FD Format • 0x0: Standard frame format • 0x1: CAN FD frame format (new DLC-coding and CRC)
	20	BRS	Bit Rate Switch • 0x0: Frame received without bit rate switching • 0x1: Frame received with bit rate switching
	19:16	DLC[3:0]	Data Length Code • 0x0-0x8 (0-8): CAN + CAN FD: received frame has 0-8 data bytes • 0x9-0xF (9-15): CAN: received frame has 8 data bytes • 0x9-0xF (9-15): CAN FD: received frame has 12/16/20/24/32/48/64 data bytes
	15:0	RXTS[15:0]	Rx Timestamp Timestamp Counter value captured on start of frame reception. Resolution depending on configuration of the Timestamp Counter Prescaler MCAN_TSCC[19:16] TCP.
R2	31:24	DB3[7:0]	Data Byte 3
	23:16	DB2[7:0]	Data Byte 2
	15:8	DB1[7:0]	Data Byte 1
	7:0	DB0[7:0]	Data Byte 0

Table 18-621. Rx Buffer/Rx FIFO Element Field Descriptions (continued)

Word	Bits	Field Name	Description
R3	31:24	DB7[7:0]	Data Byte 7
	23:16	DB6[7:0]	Data Byte 6
	15:8	DB5[7:0]	Data Byte 5
	7:0	DB4[7:0]	Data Byte 4
...	...	...	...
Rn	31:24	DBm[7:0]	Data Byte m
	23:16	DBm-1[7:0]	Data Byte m-1
	15:8	DBm-2[7:0]	Data Byte m-2
	7:0	DBm-3[7:0]	Data Byte m-3

Note: Depending on the configuration of the element size (MCAN_RXESC), between two and sixteen 32-bit words (Rn = 3-17) are used for storage of a CAN message's data field.

18.7.4.11.3 Tx Buffer Element

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO/Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO/Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler makes difference between dedicated Tx Buffers and Tx FIFO/Tx Queue via the MCAN_TXBC[29:24] TFQS and MCAN_TXBC[21:16] NDTB fields. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via the MCAN_TXESC register.

Figure 18-150 shows Tx Buffer element structure.

Figure 18-150. Tx Buffer Element Structure

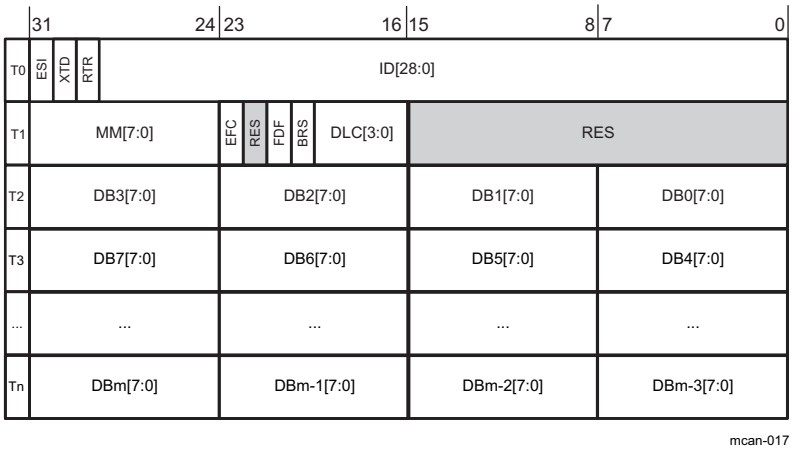

Table 18-622 shows Tx Buffer element field descriptions.

Table 18-622. Tx Buffer Element Field Descriptions

Word	Bits	Field Name	Description
T0	31	ESI	Error State Indicator • 0x0: ESI bit in CAN FD format depends only on error passive flag • 0x1: ESI bit in CAN FD format transmitted recessive **Note:** The ESI bit of the transmit buffer is or'ed with the error passive flag to decide the value of the ESI bit in the transmitted CAN FD frame. As required by the CAN FD protocol specification, an error active node may optionally transmit the ESI bit recessive, but an error passive node will always transmit the ESI bit recessive.
	30	XTD	Extended Identifier • 0x0: 11-bit standard identifier • 0x1: 29-bit extended identifier
	29	RTR	Remote Transmission Request • 0x0: Transmit data frame • 0x1: Transmit remote frame **Note:** When RTR = 1, the MCAN module transmits a remote frame according to ISO11898-1:2015, even if the MCAN_CCCR[8] FDOE bit enables the transmission in CAN FD format.
	28:0	ID[28:0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier has to be written to ID[28:18].
T1	31:24	MM[7:0]	Message Marker Written by Host CPU during Tx Buffer configuration. Copied into Tx Event FIFO element for identification of Tx message status (see also MM[7:0] field in Table 18-623).
	23	EFC	Event FIFO Control • 0x0: Don't store Tx events • 0x1: Store Tx events
	22	RES	Reserved
	21	FDF	FD Format • 0x0: Frame transmitted in Classic CAN format • 0x1: Frame transmitted in CAN FD format
	20	BRS	Bit Rate Switch • 0x0: CAN FD frames transmitted without bit rate switching • 0x1: CAN FD frames transmitted with bit rate switching **Note:** ESI, FDF, and BRS bits are only evaluated when CAN FD operation is enabled vie the MCAN_CCCR[8] FDOE bit. BRS bit is only evaluated when in addition the MCAN_CCCR[9] BRSE = 1.
	19:16	DLC[3:0]	Data Length Code • 0x0-0x8 (0-8): CAN + CAN FD: transmit frame has 0-8 data bytes • 0x9-0xF (9-15): CAN: transmit frame has 8 data bytes • 0x9-0xF (9-15): CAN FD: transmit frame has 12/16/20/24/32/48/64 data bytes
	15:0	RES	Reserved
T2	31:24	DB3[7:0]	Data Byte 3
	23:16	DB2[7:0]	Data Byte 2
	15:8	DB1[7:0]	Data Byte 1
	7:0	DB0[7:0]	Data Byte 0

Table 18-622. Tx Buffer Element Field Descriptions (continued)

Word	Bits	Field Name	Description
T3	31:24	DB7[7:0]	Data Byte 7
	23:16	DB6[7:0]	Data Byte 6
	15:8	DB5[7:0]	Data Byte 5
	7:0	DB4[7:0]	Data Byte 4
...	...	...	...
Tn	31:24	DBm[7:0]	Data Byte m
	23:16	DBm-1[7:0]	Data Byte m-1
	15:8	DBm-2[7:0]	Data Byte m-2
	7:0	DBm-3[7:0]	Data Byte m-3

Note: Depending on the configuration of the element size (MCAN_TXESC), between two and sixteen 32-bit words (Tn = 3-17) are used for storage of a CAN message's data field.

18.7.4.11.4 Tx Event FIFO Element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from the MCAN_TXEFS register.

Figure 18-151 shows Tx Event FIFO element structure.

Figure 18-151. Tx Event FIFO Element Structure

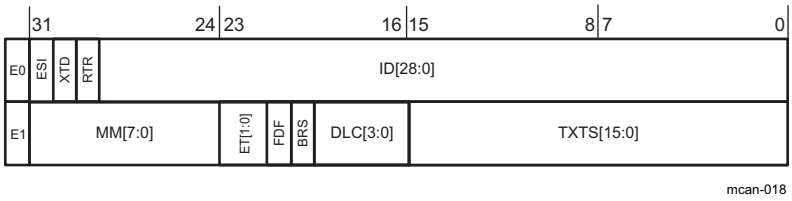

Table 18-623 shows Tx Event FIFO element field descriptions.

Table 18-623. Tx Event FIFO Element Field Descriptions

Word	Bits	Field Name	Description
E0	31	ESI	Error State Indicator • 0x0: Transmitting node is error active • 0x1: Transmitting node is error passive
	30	XTD	Extended Identifier • 0x0: 11-bit standard identifier • 0x1: 29-bit extended identifier
	29	RTR	Remote Transmission Request • 0x0: Data frame transmitted • 0x1: Remote frame transmitted
	28:0	ID[28:0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier has to be written to ID[28:18].

Table 18-623. Tx Event FIFO Element Field Descriptions (continued)

Word	Bits	Field Name	Description
E1	31:24	MM[7:0]	Message Marker Copied from Tx Buffer into Tx Event FIFO element for identification of Tx message status (see also MM[7:0] field in Table 18-622).
	23:22	ET[1:0]	Event Type • 0x0: Reserved • 0x1: Tx event • 0x2: Transmission in spite of cancellation (always set for transmissions in DAR mode) • 0x3: Reserved
	21	FDF	FD Format • 0x0: Standard frame format • 0x1: CAN FD frame format (new DLC-coding and CRC)
	20	BRS	Bit Rate Switch • 0x0: Frame transmitted without bit rate switching • 0x1: Frame transmitted with bit rate switching
	19:16	DLC[3:0]	Data Length Code • 0x0-0x8 (0-8): CAN + CAN FD: frame with 0-8 data bytes transmitted • 0x9-0xF (9-15): CAN: frame with 8 data bytes transmitted • 0x9-0xF (9-15): CAN FD: frame with 12/16/20/24/32/48/64 data bytes transmitted
	15:0	TXTS[15:0]	Tx Timestamp Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler MCAN_TSCC[19:16] TCP filed.

18.7.4.11.5 Standard Message ID Filter Element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, its address is the Filter List Standard Start Address MCAN_SIDFC[15:2] FLSSA field plus the index of the filter element (0-127).

Figure 18-152 shows Standard Message ID Filter element structure.

Figure 18-152. Standard Message ID Filter Element Structure

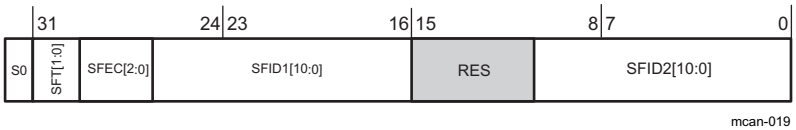

Table 18-624 shows Standard Message ID Filter element field descriptions.

Table 18-624. Standard Message ID Filter Element Field Descriptions

Word	Bits	Field Name	Description
S0	31:30	SFT[1:0]	Standard Filter Type • 0x0: Range filter from SFID1 to SFID2 (SFID2 ≥ SFID1) • 0x1: Dual ID filter for SFID1 or SFID2 • 0x2: Classic filter: SFID1 = filter; SFID2 = mask • 0x3: Filter element disabled **Note:** With SFT = 11 the filter element is disabled and the acceptance filtering continues (same behaviour as with SFEC = 000)
	29:27	SFEC[2:0]	Standard Filter Element Configuration All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = 100, 101, or 110 a match sets interrupt flag MCAN_IR[8]HPM and, if enabled, an interrupt is generated. In this case the MCAN_HPMS register is updated with the status of the priority match. • 0x0: Disable filter element • 0x1: Store in Rx FIFO 0 if filter matches • 0x2: Store in Rx FIFO 1 if filter matches • 0x3: Reject ID if filter matches • 0x4: Set priority if filter matches • 0x5: Set priority and store in FIFO 0 if filter matches • 0x6: Set priority and store in FIFO 1 if filter matches • 0x7: Store into Rx Buffer, configuration of SFT[1:0] ignored
	26:16	SFID1[10:0]	Standard Filter ID 1 When filtering for Rx Buffers this field defines the ID of a standard message to be stored. The received identifiers must match exactly, no masking mechanism is used.
	15:11	RES	Reserved
	10:0	SFID2[10:0]	Standard Filter ID 2 This bit field has a different meaning depending on the configuration of SFEC: • 1) SFEC = 001 - 110 Second ID of standard ID filter element • 2) SFEC = 111 Filter for Rx Buffers
		SFID2[10:9]	This filed is decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. • 0x0: Store message into an Rx Buffer • 0x1: Debug Message A • 0x2: Debug Message B • 0x3: Debug Message C **Note:** Debug feature is not supported.
		SFID2[8:6]	This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICKL period in case the filter matches. **Note:** Only two filter event pins are supported.
		SFID2[5:0]	This field defines the offset to the Rx Buffer Start Address MCAN_RXBC[15:2] RBSA field for storage of a matching message.

18.7.4.11.6 Extended Message ID Filter Element

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, its address is the Filter List Extended Start Address MCAN_XIDFC[15:2] FLESA field plus two times the index of the filter element (0-63).

Figure 18-153 shows Extended Message ID Filter element structure.

Figure 18-153. Extended Message ID Filter Element Structure

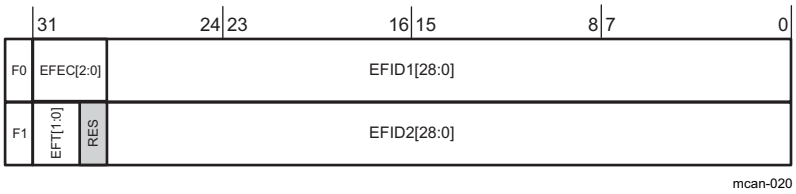

Table 18-625 shows Extended Message ID Filter element field descriptions.

Table 18-625. Extended Message ID Filter Element Field Descriptions

Word	Bits	Field Name	Description
F0	31:29	EFEC[2:0]	Extended Filter Element Configuration All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = 100, 101, or 110 a match sets interrupt flag MCAN_IR[8]HPM and, if enabled, an interrupt is generated. In this case the MCAN_HPMS register is updated with the status of the priority match. • 0x0: Disable filter element • 0x1: Store in Rx FIFO 0 if filter matches • 0x2: Store in Rx FIFO 1 if filter matches • 0x3: Reject ID if filter matches • 0x4: Set priority if filter matches • 0x5: Set priority and store in FIFO 0 if filter matches • 0x6: Set priority and store in FIFO 1 if filter matches • 0x7: Store into Rx Buffer or as debug message, configuration of EFT[1:0] ignored
	28:0	EFID1[28:0]	Extended Filter ID 1 First ID of extended ID filter element. When filtering for Rx Buffers this field defines the ID of an extended message to be stored. The received identifiers must match exactly, only XIDAM masking mechanism (see Section 18.7.4.8.1.5, *Extended Message ID Filtering*) is used.

Table 18-625. Extended Message ID Filter Element Field Descriptions (continued)

Word	Bits	Field Name	Description
F1	31:30	EFT[1:0]	Extended Filter Type • 0x0: Range filter from EFID1 to EFID2 (EFID2 ≥ EFID1) • 0x1: Dual ID filter for EFID1 or EFID2 • 0x2: Classic filter: EFID1 = filter, EFID2 = mask • 0x3: Range filter from EFID1 to EFID2 (EFID2 ≥ EFID1), XIDAM mask not applied
	29	RES	Reserved
	28:0	EFID2[28:0]	Extended Filter ID 2 This bit field has a different meaning depending on the configuration of EFEC: • 1) EFEC = 001 - 110 Second ID of extended ID filter element • 2) EFEC = 111 Filter for Rx Buffers
		EFID2[10:9]	This field decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. • 0x0: Store message into an Rx Buffer • 0x1: Debug Message A • 0x2: Debug Message B • 0x3: Debug Message C **Note:** Debug feature is not supported.
		EFID2[8:6]	This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICKL period in case the filter matches. **Note:** Only two filter event pins are supported.
		EFID2[5:0]	This field defines the offset to the Rx Buffer Start Address MCAN_RXBC[15:2] RBSA field for storage of a matching message.

18.7.5 MCAN Register Manual

18.7.5.1 MCAN Instance Summary

Table 18-626. MCAN Instance Summary

Module Name	Base Address	Size
MCAN		8 KiB

18.7.5.2 MCAN Registers

NOTE: After hardware reset, the registers of the MCAN module hold the values shown in the register descriptions.

Additionally, the Bus_Off state is reset and the MCAN_TX pin is set to recessive (high). The MCAN_CCCR[0] INIT bit is set to enable the software initialization. The MCAN module will not influence the CAN bus until the software resets the MCAN_CCCR[0] INIT bit.

Physical Address	**Instance**
Description	ECC EOI End Of Interrupt for ECC interrupt.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							ECC_EOI	RESERVED							

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	R	0x0
8	ECC_EOI	ECC EOI	W	0x0
7:0	RESERVED	Reserved	R	0x0

MCAN

- Interrupt Requests: [0]
- ECC Aggregator: [1]
- MCAN Register Summary:

Table 18-651. MCAN_CREL

Address Offset	0x0000 1A00
Physical Address	**Instance**
Description	Core Release Register Release dependent constant (version + date).
Type	R

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REL				STEP				SUBSTEP				YEAR				MON								DAY							

Bits	Field Name	Description	Type	Reset
31:28	REL	Core Release One digit, BCD-coded.	R	0x3
27:24	STEP	Step of Core Release One digit, BCD-coded.	R	0x2
23:20	SUBSTEP	Sub-step of Core Release One digit, BCD-coded.	R	0x1
19:16	YEAR	Time Stamp Year One digit, BCD-coded.	R	0x5
15:8	MON	Time Stamp Month Two digits, BCD-coded.	R	0x3
7:0	DAY	Time Stamp Day Two digits, BCD-coded.	R	0x20
