Phase-Locked Loop (PLL) Controller

This document describes the operation of the software-programmable phase-locked loop (PLL) controller in the digital signal processors (DSPs) of some of the TMS320C6000™ DSP family. Refer to the device-specific data manual to determine if the PLL controller is used on a particular device.

1 Overview

The PLL controller (Figure 1) features software-configurable PLL multiplier controller, dividers (OSCDIV1, D0, D1, D2, and D3), and reset controller. The PLL controller accepts an input clock, as determined by the logic state on the CLKMODE0 pin, from the CLKin pin or from the on-chip oscillator output signal OSCIN. The PLL controller offers flexibility and convenience by way of software-configurable multiplier and dividers to modify the input signal internally. The resulting clock outputs are passed to the DSP core, peripherals, and other modules inside the C6000™ DSP.

- The input reference clocks to the PLL controller:
  - CLKin: input signal from external oscillator (3.3V), CLKMODE0 = 1
  - OSCIN: output signal from on-chip oscillator (1.2V), CLKMODE0 = 0

- The resulting output clocks from the PLL controller:
  - AUXCLK: internal clock output signal directly from CLKin or OSCIN.
  - CLKOUT3: output of divider OSCDIV1.
  - SYSCLK1: internal clock output of divider D1.
  - SYSCLK2: internal clock output of divider D2.
  - SYSCLK3: internal clock output of divider D3.

Refer to your device-specific data manual on how these inputs and outputs of the PLL controller are used. Some devices may not support all of the above clocks. See the device-specific data manual for the clocks supported.
Figure 1. PLL Controller Block Diagram

A See the device-specific data manual for more detail about the PLL.
2 Functional Description

The following sections describe the multiplier, dividers, and reset controller in the PLL controller.

2.1 Multiplier and Dividers

The PLL controller is capable of programming the PLL through the PLL multiplier control register (PLLM) from a ×1 to ×32 multiplier rate (see the device-specific data manual for the PLL multiplier rates supported on your device). The clock dividers (OSCDIV1, D0, D1, D2, and D3) are programmable from ÷1 to ÷32 divider ratio and may be disabled. When a clock divider is disabled, no clock is output from that clock divider. A divider only outputs a clock when it is enabled in the corresponding OSCDIV1 or PLLDIVn registers.

The input reference clock (either CLKin or OSCIn) is directly output as the auxiliary clock (AUXCLK) for use by some peripherals. For example, the multichannel audio serial port (McASP) uses AUXCLK to generate audio clocks. In addition to AUXCLK, the input reference clock is directly input to the oscillator divider (OSCDIV1). If OSCDIV1 is enabled, OD1EN = 1, the input reference clock is divided down by the value in the oscillator divider ratio bits (RATIO) in OSCDIV1. The output from OSCDIV1 is the output clock CLKOUT3.

The divider D0 and the PLL may also be bypassed. The PLL enable bit (PLLEN) in the PLL control/status register (PLLCR) determines the PLL controller mode. When PLLEN = 1, PLL mode, D0 and PLL are used; when PLLEN = 0, bypass mode, D0 and PLL are bypassed and the input reference clock is directly input to dividers D1, D2, and D3.

When in PLL mode (PLLEN = 1), the input reference clock is supplied to divider D0. If D0 is enabled, D0EN = 1, the input reference clock is divided down by the value in the PLL divider ratio bits (RATIO) in PLLDIV0. The output from divider D0 is input to the PLL. The PLL multiplies the clock by the value in the PLL multiplier bits (PLLM) in the PLL multiplier control register (PLLM). The output from the PLL (PLLOUT) is input to dividers D1, D2, and D3.

When enabled (DnEN = 1), the dividers D1, D2, and D3 divide down by the value in RATIO in PLLDIVn the output clock of the PLL. The output clocks of dividers D1, D2, and D3 have 50% duty cycle and are SYSCLK1, SYSCLK2, and SYSCLK3, respectively.

2.2 Reset Controller

At power up, the device RESET signal may not be asserted long enough to wait for the on-chip or off-chip oscillator to stabilize. This means the input reference clock (either CLKin or OSCIn) may be a bad clock when a device RESET signal is deasserted high. After RESET is deasserted, the reset controller lengthens the asynchronous internal reset signal to ensure that the input clock source is stable.

The reset controller resides within the PLL controller and the main function is to internally lengthen the reset signal from the RESET input pin until the input clock source is stable (after 512 CLKin cycles or 4096 OSCIn cycles). This is to ensure that the rest of the device will see the internal reset deasserted only after the input clock is stabilized. Figure 2 shows the lengthening of the internal reset signal.

The PLL controller multiplier and dividers are bypassed when the internal reset signal is low. The frequency of all clock outputs of the PLL controller (AUXCLK, SYSCLK1, SYSCLK2, SYSCLK3, and CLKOUT3) are fixed to the input reference clock (CLKin or OSCIn) divided by 8. After 512 CLKin cycles or 4096 OSCIn cycles, the reset controller brings the device out of reset and sets the oscillator input stable bit (STABLE) in the PLL control/status register (PLLCR). The dividers are used after this point and are set to their default divide ratio.

Values are latched into the registers at the rising edge of RESET.

\[ N = 4096 \times \text{OSCIN cycles} \] when \( \text{CLKMODE} = 0 \) (input reference clock is OSCIN)

B  Output clocks include AUXCLK, SYSCLK1, SYSCLK2, SYSCLK3, and CLKOUT3 at the PLL controller boundary. Refer to the device-specific data manual for clock behavior at the device pins.
3 Configuration

The following sections provide procedures for initialization, power down, and wake up of the PLL controller.

3.1 Initialization

The PLL and PLL controller are to be initialized by software after reset. The PLL controller registers should be modified only by the CPU or via emulation. The HPI should not be used to directly access the PLL controller registers. The initialization of the PLL controller should be performed as soon as possible at the beginning of the program, before initializing any peripherals. Upon device reset, one of the following two software initialization procedures must be done to properly set up the PLL and PLL controller.

3.1.1 Initialization to PLL Mode (PLLEN = 1)

If the system intends to use divider D0 and PLL, perform the following:

1. In PLLCSR, write PLLEN = 0 (bypass mode).
2. Wait 4 cycles of the slowest of PLLOUT, CLKIN (if CLKMODE = 1), and OSCIN (if CLKMODE = 0).
3. In PLLCSR, write PLLRST = 1 (PLL is reset).
4. Program PLLDIV0, PLLM, and OSCDIV1.
5. Program PLLDIV1-3. Note that there must be wait states between accesses to PLLDIV1-3. Each wait state is 8 cycles of the slowest of the old and new SYSCLK1-3 clock rates. Some devices may also require you to program the PLLDIV1-3 registers in a particular order, to ensure no violation of system clock ratios. See PLL Controller section of the device-specific data manual for other restrictions.
7. In PLLCSR, write PLLRST = 0 to bring PLL out of reset.
8. Wait for PLL to lock. See device-specific data manual for PLL lock time.
9. In PLLCSR, write PLLEN = 1 to enable PLL mode.

Steps 1, 2, and 3 are required when PLLEN and PLLRST bits are not already 0 and 1, respectively. These steps are not required when the device is coming out of reset (they are performed by hardware).

3.1.2 Initialization to Bypass Mode (PLLEN = 0)

If the system intends to bypass divider D0 and PLL, perform the following:

1. In PLLCSR, write PLLEN = 0 (bypass mode).
2. Wait 4 cycles of the slowest of PLLOUT, CLKIN (if CLKMODE = 1), and OSCIN (if CLKMODE = 0).
3. In PLLCSR, write PLLRST = 1 (PLL is reset).
4. Program OSCDIV1.
5. Program PLLDIV1-3. Note that there must be wait states between accesses to PLLDIV1-3. Each wait state is 8 cycles of the slowest of the old and new SYSCLK1-3 clock rates. See PLL Controller section of the device-specific data manual for other restrictions.

Steps 1, 2, and 3 are required when PLLEN and PLLRST bits are not already 0 and 1, respectively. These steps are not required when the device is coming out of reset (they are performed by hardware).

3.2 PLL Power Down

The PLL may be powered down, in which case the PLL controller is in bypass mode and the DSP runs from a divided down version of the input reference clock. The DSP is still able to respond to events because it is still being clocked by the bypass clock (directly from CLKIN or OSCIN), although at a lower frequency.

Perform the following procedure to power down the PLL:

1. In PLLCSR, write PLLEN = 0 (bypass mode).
2. Wait 4 cycles of the slowest of PLLOUT, CLKIN (if CLKMODE = 1), and OSCIN (if CLKMODE = 0).
3. In PLLCSR, write PLLPWRDN = 1 to power down the PLL.
3.3 PLL Power Wake Up

Perform the following procedure to wake up the PLL from its power-down mode:

1. In PLLCSR, write PLLEN = 0 (bypass mode).
2. Wait 4 cycles of the slowest of PLLOUT, CLkin (if CLKMODE = 1), and OSCIN (if CLKMODE = 0).
3. In PLLCSR, write PLLPWRDN = 0 to wake up the PLL.
4. Follow the reset sequence described in Section 3.1.

The PLL controller registers configure the operation of the PLL controller. The PLL controller registers are listed in Table 1. See the device-specific data manual for the memory address of these registers.
