IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

About This Manual

This reference guide describes the architecture, system hardware, peripherals, and general operation of the TMS320Lx2407A/x2406A/x2404A/x2403A/x2402A/x2401A digital signal processor (DSP) controllers. This book is also applicable to TMS320Lx2407/2406/2402 and future derivatives of the 240x family.

For a description of the CPU, assembly language instructions, and XDS510 emulator, refer to *TMS320F/C24x DSP Controllers Reference Guide: CPU and Instruction Set* (literature number SPRU160). This reference guide should be used in conjunction with SPRU160.

Notational Conventions

This document uses the following conventions:

- Program listings, program examples, and interactive displays are shown in a special typeface similar to a typewriter's. Examples use a bold version of the special typeface for emphasis; interactive displays use a bold version of the special typeface to distinguish commands that you enter from items that the system displays (such as prompts, command output, error messages, etc.).

Here is a sample program listing:

```
0011  0005  0001         .field    1, 2
0012  0005  0003         .field    3, 4
0013  0005  0006         .field    6, 3
0014  0006         .even
```

Here is an example of a system prompt and a command that you might enter:

```
C:   csr -a /user/ti/simuboard/utilities
```
In syntax descriptions, the instruction, command, or directive is in a **bold typeface** and parameters are in an *italic typeface*. Portions of a syntax that are in bold should be entered as shown; portions of a syntax that are in italics describe the type of information that should be entered. Here is an example of a directive syntax:

```plaintext
.asect "section name", address
```

.asect is the directive. This directive has two parameters, indicated by section name and address. When you use .asect, the first parameter must be an actual section name, enclosed in double quotes; the second parameter must be an address.

Square brackets [ ] identify an optional parameter. If you use an optional parameter, you specify the information within the brackets; you don’t enter the brackets themselves. Here’s an example of an instruction that has an optional parameter:

```plaintext
LACC 16-bit constant [, shift]
```

The LACC instruction has two parameters. The first parameter, 16-bit constant, is required. The second parameter, shift, is optional. As this syntax shows, if you use the optional second parameter, you must precede it with a comma.

Square brackets are also used as part of the pathname specification for VMS pathnames; in this case, the brackets are actually part of the pathname (they are not optional).

Braces { } indicate a list. The symbol | (read as or) separates items within the list. Here’s an example of a list:

```plaintext
{ * | *+ | *− }
```

This provides three choices: *, *+, or *−.

Unless the list is enclosed in square brackets, you must choose one item from the list.

Some directives can have a varying number of parameters. For example, the .byte directive can have up to 100 parameters. The syntax for this directive is:

```plaintext
.byte value1 [, ... , value_n]
```

This syntax shows that .byte must have at least one value parameter, but you have the option of supplying additional value parameters, separated by commas.
Information About Cautions and Warnings

This document may contain cautions.

This is an example of a caution statement.
A caution statement describes a situation that could potentially
damage your software or equipment.

Related Documentation From Texas Instruments

The following books describe the C24x and related support tools. To obtain a
copy of any of these TI documents, call the Texas Instruments Literature Re-
response Center at (800) 477-8924. When ordering, please identify the book by
its title and literature number. Many of these documents are located on the In-

TMS320C24x DSP Controllers CPU and Instruction Set Reference Guide
(literature number SPRU160) describes the TMS320C24x™ 16-bit
fixed-point digital signal processor controller. Covered are its
architecture, internal register structure, data and program addressing,
and instruction set. Also includes instruction set comparisons and design
considerations for using the XDS510™ emulator.

TMS320LF2407, TMS320LF2406, TMS320LF2402 DSP Controllers
(literature number SPRS094) data sheet contains the electrical and
timing specifications for these devices, as well as signal descriptions and
pinouts for all of the available packages.

TMS320LF2407A, TMS320LF2406A, TMS320LF2403A, TMS320LF2402A,
TMS320LC2406A, TMS320LC2404A, TMS320LC2402A DSP
Controllers (literature number SPRS145) data sheet contains the
electrical and timing specifications for these devices, as well as signal
descriptions and pinouts for all of the available packages.

TMS320LF2401A, TMS320LC2401A DSP Controllers (literature number
SPRS161) data sheet contains the electrical and timing specifications for
these devices, as well as signal descriptions and pinouts for available
packages.
Related Documentation From Texas Instruments

**TMS320C1x/C2x/C2xx/C5x Code Generation Tools Release 6.60 Getting Started Guide** (literature number SPRU121) describes how to install the TMS320C1x, TMS320C2x, TMS320C2xx, and TMS320C5x assembly language tools and the C compiler for the C1x, C2x, C2xx, and C5x devices. The installations for MS-DOS™, OS/2™, SunOS™, and Solaris™ systems are covered.

**TMS320C1x/C2x/C2xx/C5x Assembly Language Tools User’s Guide** (literature number SPRU018) describes the assembly language tools (assembler, linker, and other tools used to develop assembly language code), assembler directives, macros, common object file format, and symbolic debugging directives for the C1x, C2x, C2xx, and C5x generations of devices.

**TMS320C2x/C2xx/C5x Optimizing C Compiler User’s Guide** (literature number SPRU024) describes the C2x/C2xx/C5x C compiler. This C compiler accepts ANSI standard C source code and produces TMS320™ assembly language source code for the C2x, C2xx, and C5x generations of devices.

**XDS51x Emulator Installation Guide** (literature number SPNU070) describes the installation of the XDS510™, XDS510PP™, and XDS510WS™ emulator controllers. The installation of the XDS511™ emulator is also described.

**JTAG/MPSD Emulation Technical Reference** (literature number SPDU079) provides the design requirements of the XDS510™ emulator controller, discusses JTAG designs (based on the IEEE 1149.1 standard), and modular port scan device (MPSD) designs.

**Code Composer Studio User’s Guide** (literature number SPRU328) explains how to use the Code Composer Studio™ development environment to build and debug embedded real-time DSP applications.

Contents

1 Introduction ................................................................. 1-1
   Summarizes the TMS320 family of products. Introduces the TMS320x240xA DSP controllers and lists their key features.
   1.1 TMS320 Family Overview ........................................... 1-2
   1.2 TMS320C240xA Series of DSP Controllers ......................... 1-3
   1.3 Peripheral Overview .................................................. 1-5
   1.4 New Features in 240xA Devices ..................................... 1-6
   1.5 240xA Highlights ..................................................... 1-7

2 System Configuration and Interrupts .................................. 2-1
   Describes the system configuration, interrupts, and how the peripheral interrupt expansion (PIE) is used to increase interrupt requests capacity.
   2.1 Architecture Summary ............................................... 2-2
   2.2 Configuration Registers ............................................. 2-3
      2.2.1 System Control and Status Registers 1 and 2 (SCSR1, SCSR2) 2-3
      2.2.2 Device Identification Number Register (DINR) ............... 2-8
   2.3 Interrupt Priority and Vectors ..................................... 2-9
   2.4 Peripheral Interrupt Expansion (PIE) Controller .................. 2-13
      2.4.1 Interrupt Hierarchy ............................................. 2-15
      2.4.2 Interrupt Request Structure ................................... 2-15
      2.4.3 Interrupt Acknowledge ........................................ 2-16
   2.5 Interrupt Vectors ................................................... 2-17
      2.5.1 Phantom Interrupt Vector ...................................... 2-18
      2.5.2 Software Hierarchy ............................................ 2-19
      2.5.3 Nonmaskable Interrupt (NMI) .................................. 2-19
   2.6 Interrupt Operation Sequence ..................................... 2-21
   2.7 Interrupt Latency ................................................... 2-24
   2.8 Sample ISR Code .................................................... 2-25
   2.9 CPU Interrupt Registers ............................................ 2-26
      2.9.1 Interrupt Flag Register (IFR) .................................. 2-26
      2.9.2 Interrupt Mask Register (IMR) ................................ 2-28
   2.10 Peripheral Interrupt Registers .................................... 2-30
      2.10.1 Peripheral Interrupt Vector Register (PIVR) ................ 2-30
      2.10.2 Peripheral Interrupt Request Registers (PIRQR0, 1, 2) .... 2-31
      2.10.3 Peripheral Interrupt Acknowledge Registers (PIACKR0, 1, 2) 2-34
Contents

2.11 Reset .................................................. 2-38
2.12 Illegal Address Detect .................................. 2-38
2.13 External Interrupt Control Registers ................. 2-39
  2.13.1 External Interrupt 1 Control Register (XINT1CR) ...... 2-39
  2.13.2 External Interrupt 2 Control Register (XINT2CR) ...... 2-40

3 Memory .................................................. 3-1
Describes the RAM, ROM, and Flash availability on the 240xA devices.
  3.1 On-Chip RAM ........................................... 3-2
    3.1.1 Dual-Access On-Chip RAM ............................ 3-2
    3.1.2 Single-Access On-Chip Program/Data RAM .............. 3-2
  3.2 Factory Masked On-Chip ROM ............................. 3-3
  3.3 Flash .................................................. 3-3
    3.3.1 Flash Program Memory ............................... 3-3
    3.3.2 Flash Control Mode Register (FCMR) ................... 3-3
    3.3.3 Flash Control Register Access ........................ 3-4
    3.3.4 Flash Programming at Variable Frequencies ............ 3-4
  3.4 Overview of Memory and I/O Spaces ..................... 3-5
  3.5 Program Memory ....................................... 3-6
    3.5.1 Program Memory Configuration ........................ 3-6
  3.6 Data Memory .......................................... 3-8
    3.6.1 Global Data Memory .................................. 3-11
  3.7 I/O Space ............................................. 3-12
  3.8 XMIF Qualifier Signal Description ....................... 3-13
  3.9 Program and Data Spaces ................................ 3-16
  3.10 I/O Space ............................................. 3-16
  3.11 Wait-State Generation .................................. 3-17
    3.11.1 Generating Wait States With the READY Signal ....... 3-17
    3.11.2 Generating Wait States With the 2407A Wait-State Generator 3-17

4 Clocks and Low-Power Modes ................................ 4-1
Describes the PLL, CPU, and watchdog (WD) timer clocks.
  4.1 Pins ................................................... 4-2
  4.2 Phase-Locked Loop (PLL) ............................... 4-2
    4.2.1 Overview ........................................... 4-2
    4.2.2 Operation .......................................... 4-4
    4.2.3 PLL-Bypass Mode .................................... 4-6
  4.3 Watchdog Timer Clock .................................... 4-7
    4.3.1 Watchdog Suspend .................................... 4-7
  4.4 Low-Power Modes ....................................... 4-8
    4.4.1 Clock Domains ....................................... 4-8
    4.4.2 Wake-Up From Low-Power Modes ......................... 4-9
    4.4.3 Powering Down the Flash ............................. 4-11

5 Digital Input/Output (I/O) ................................ 5-1
Describes the digital I/O ports module.
  5.1 Digital I/O Ports Register Implementation on 240xA Devices ........ 5-2
5.2 Differences in GPIO Implementation in the 240xA .......................................................... 5-4
5.3 I/O Mux Control Registers .................................................................................................. 5-4
  5.3.1 I/O Mux Control Register A ......................................................................................... 5-4
  5.3.2 I/O Mux Output Control Register B ............................................................................. 5-5
  5.3.3 I/O Mux Output Control Register C ............................................................................. 5-7
5.4 Data and Direction Control Registers .................................................................................. 5-8

6 Event Manager (EV) .............................................................................................................. 6-1
Describes the event manager (EV) module. Includes descriptions of the general-purpose timer, compare units, pulse-width modulation waveform circuits, capture units, and quadrature encoder pulse circuits.

  6.1 Event Manager (EV) Functional Blocks ........................................................................... 6-2
    6.1.1 Differences Between C240 EV and 240xA EV ......................................................... 6-5
    6.1.2 EV Pins ..................................................................................................................... 6-6
    6.1.3 Power Drive Protection Interrupt (PDPINTx, x = A or B) ......................................... 6-8
    6.1.4 EV Registers ............................................................................................................ 6-9
    6.1.5 EV Interrupts ............................................................................................................ 6-9
  6.2 Event Manager (EV) Register Addresses ......................................................................... 6-11
  6.3 Figure 6–13 General-Purpose (GP) Timers .................................................................... 6-14
    6.3.1 GP Timer Counting Operation .................................................................................... 6-22
    6.3.2 GP Timer Compare Operation .................................................................................... 6-27
    6.3.3 Timer Control Registers (TxCON and GPTCONA/B) ................................................. 6-32
    6.3.4 Generation of PWM Outputs Using the GP Timers .................................................... 6-38
    6.3.5 GP Timer Reset ........................................................................................................ 6-38
  6.4 Compare Units .................................................................................................................. 6-39
    6.4.1 Compare Units Registers .......................................................................................... 6-41
    6.4.2 Compare Unit Interrupts ............................................................................................ 6-47
    6.4.3 Compare Unit Reset ................................................................................................... 6-47
  6.5 PWM Circuits Associated With Compare Units ............................................................... 6-48
    6.5.1 PWM Generation Capability of Event Manager ......................................................... 6-49
    6.5.2 Programmable Dead-Band (Dead-Time) Unit .......................................................... 6-50
    6.5.3 Output Logic ............................................................................................................. 6-55
  6.6 PWM Waveform Generation With Compare Units and PWM Circuits .......................... 6-57
    6.6.1 Generation of PWM Outputs With Event Manager .................................................. 6-58
    6.6.2 Register Setup for PWM Generation ......................................................................... 6-58
    6.6.3 Asymmetric PWM Waveform Generation ................................................................. 6-59
    6.6.4 Symmetric PWM Waveform Generation ................................................................. 6-60
    6.6.5 Double Update PWM Mode ...................................................................................... 6-61
  6.7 Space Vector PWM .......................................................................................................... 6-62
    6.7.1 3-Phase Power Inverter ............................................................................................. 6-62
    6.7.2 Space Vector PWM Waveform Generation with Event Manager ................................ 6-64
    6.7.3 Space Vector PWM Boundary Conditions ............................................................... 6-66
  6.8 Capture Units ................................................................................................................... 6-68
    6.8.1 Capture Unit Features ................................................................................................ 6-70
6.8.2 Operation of Capture Units ........................................... 6-71
6.8.3 Capture Unit Registers .................................................. 6-72
6.8.4 Capture Unit FIFO Stacks ............................................. 6-78
6.8.5 Capture Interrupt ....................................................... 6-79

6.9 Quadrature Encoder Pulse (QEP) Circuit ........................... 6-80
6.9.1 QEP Pins ................................................................. 6-80
6.9.2 QEP Circuit Time Base ............................................... 6-80
6.9.3 Decoding ............................................................... 6-81
6.9.4 QEP Counting .......................................................... 6-82
6.9.5 Register Setup for the QEP Circuit ................................. 6-82

6.10 Event Manager (EV) Interrupts ..................................... 6-84
6.10.1 EV Interrupt Request and Service ............................... 6-84
6.10.2 EV Interrupt Flag Registers .................................... 6-87

7 Analog-to-Digital Converter (ADC) .................................. 7-1
Describes the analog-to-digital converter (ADC), includes a list of features, explains the clock prescaler, and provides register descriptions.

7.1 Features ........................................................................... 7-2
7.2 ADC Overview ............................................................... 7-4
7.2.1 Autoconversion Sequencer: Principle of Operation .......... 7-4
7.2.2 Uninterrupted Autosequenced Mode .............................. 7-8
7.2.3 Sequencer Start/Stop Mode (Sequencer “Start/Stop” Operation With Multiple “Time-Sequenced Triggers”) .......... 7-10
7.2.4 Input Trigger Description ............................................. 7-13
7.2.5 Interrupt Operation During Sequenced Conversions ...... 7-13

7.3 ADC Clock Prescaler ....................................................... 7-17
7.4 Calibration ....................................................................... 7-19

7.5 Register Bit Descriptions ............................................... 7-20
7.5.1 ADC Control Register 1 (ADCTRL1) ......................... 7-20
7.5.2 ADC Control Register 2 (ADCTRL2) ......................... 7-26
7.5.3 Maximum Conversion Channels Register (MAXCONV) ... 7-31
7.5.4 Autosequence Status Register (AUTO_SEQ_SR) ........ 7-33
7.5.5 ADC Input Channel Select Sequencing Control Registers (CHSELSEQn) ........................................... 7-35
7.5.6 ADC Conversion Result Buffer Registers (RESULTn) ... 7-37

7.6 ADC Conversion Clock Cycles .......................................... 7-38

8 Serial Communications Interface (SCI) .............................. 8-1
Describes the architecture, functions, and programming of the of the Serial Communications Interface (SCI) module.

8.1 C240 SCI vs. LF/LC240xA SCI ......................................... 8-2
8.1.1 SCI Physical Description ............................................. 8-2
8.1.2 Architecture ............................................................. 8-5
8.1.3 SCI Module Register Addresses ................................. 8-5
8.1.4 Multiprocessor and Asynchronous Communication Modes 8-7
## Contents

8.2 SCI Programmable Data Format ................................................. 8-8
8.3 SCI Multiprocessor Communication ........................................... 8-9
  8.3.1 Idle-Line Multiprocessor Mode ........................................... 8-10
  8.3.2 Address-Bit Multiprocessor Mode ...................................... 8-13
8.4 SCI Communication Format .................................................. 8-15
  8.4.1 Receiver Signals in Communication Modes .............................. 8-16
  8.4.2 Transmitter Signals in Communication Modes ......................... 8-17
8.5 SCI Port Interrupts ............................................................ 8-18
8.6 SCI Baud Rate Calculations ................................................ 8-19
8.7 SCI Module Registers ....................................................... 8-20
  8.7.1 SCI Communication Control Register (SCICCR) ..................... 8-21
  8.7.2 SCI Control Register 1 (SCICTL1) ..................................... 8-23
  8.7.3 Baud-Select Registers (SCIHBAUD, SCILBAUD) ..................... 8-26
  8.7.4 SCI Control Register 2 (SCICTL2) ..................................... 8-27
  8.7.5 Receiver Status Register (SCIRXST) .................................. 8-28
  8.7.6 Receiver Data Buffer Registers (SCIRXEMU, SCIRXBUF) ............ 8-30
  8.7.7 Transmit Data Buffer Register (SCITXBUF) .......................... 8-31
  8.7.8 Priority Control Register (SCIPRI) .................................... 8-32

9 Serial Peripheral Interface (SPI) .............................................. 9-1
  Describes the architecture, functions, and programming of the serial peripheral interface (SPI) module.

  9.1 C240 SPI vs. LF/LC240xA SPI ............................................. 9-2
  9.1.1 SPI Physical Description ............................................... 9-2
  9.2 Overview of SPI Module Registers ...................................... 9-5
  9.3 SPI Operation .............................................................. 9-7
    9.3.1 Introduction to Operation .......................................... 9-7
    9.3.2 SPI Module Slave and Master Operation Modes .................... 9-8
  9.4 SPI Interrupts ............................................................. 9-10
    9.4.1 SPI Interrupt Control Bits .......................................... 9-10
    9.4.2 Data Format .......................................................... 9-11
    9.4.3 Baud Rate and Clocking Schemes ................................... 9-12
    9.4.4 SPI Clocking Schemes ............................................... 9-13
    9.4.5 Initialization Upon Reset .......................................... 9-15
    9.4.6 Data Transfer Example .............................................. 9-16
  9.5 SPI Module Registers .................................................... 9-18
    9.5.1 SPI Configuration Control Register (SPICCR) ..................... 9-19
    9.5.2 SPI Operation Control Register (SPICTL) .......................... 9-21
    9.5.3 SPI Status Register (SPISTS) ....................................... 9-22
    9.5.4 SPI Baud Rate Register (SPIBRR) ................................... 9-24
    9.5.5 SPI Emulation Buffer Register (SPIRXEMU) ....................... 9-25
    9.5.6 SPI Serial Receive Buffer Register (SPIRXBUF) ................. 9-26
    9.5.7 SPI Serial Transmit Buffer Register (SPITXBUF) ................ 9-27
    9.5.8 SPI Serial Data Register (SPIDAT) ................................ 9-28
### 10 CAN Controller Module

*Describes the CAN controller module, interface signals, CAN peripheral registers, and mailbox RAM, layout, and operations.*

- 10.1 Introduction .................................................. 10-2
- 10.2 Overview of the CAN Network .................................. 10-3
  - 10.2.1 CAN Protocol Overview .................................. 10-3
  - 10.2.2 CAN Controller Architecture ............................. 10-4
  - 10.2.3 Memory Map .............................................. 10-6
- 10.3 Message Objects ............................................ 10-9
  - 10.3.1 Mailbox Layout .......................................... 10-10
  - 10.3.2 Message Buffers ......................................... 10-12
  - 10.3.3 Write Access to Mailbox RAM ............................ 10-12
  - 10.3.4 Transmit Mailbox ........................................ 10-13
  - 10.3.5 Receive Mailbox .......................................... 10-13
  - 10.3.6 Handling of Remote Frames .............................. 10-14
  - 10.3.7 Mailbox Configurations .................................. 10-15
  - 10.3.8 Acceptance Filter ....................................... 10-16
- 10.4 CAN Control Registers ...................................... 10-19
  - 10.4.1 Mailbox Direction/Enable Register (MDER) ............... 10-19
  - 10.4.2 Transmit Control Register (TCR) ......................... 10-20
  - 10.4.3 Receive Control Register (RCR) ........................ 10-22
  - 10.4.4 Master Control Register (MCR) .......................... 10-23
  - 10.4.5 Bit Configuration Registers (BCRn) ...................... 10-25
- 10.5 Status Registers ........................................... 10-30
  - 10.5.1 Error Status Register (ESR) ............................ 10-30
  - 10.5.2 Global Status Register (GSR) ........................... 10-32
  - 10.5.3 CAN Error Counter Register (CEC) ....................... 10-34
- 10.6 Interrupt Logic ............................................ 10-35
  - 10.6.1 CAN Interrupt Flag Register (CAN_IFR) ................. 10-36
  - 10.6.2 CAN Interrupt Mask Register (CAN_IMR) ................. 10-38
- 10.7 Configuration Mode .......................................... 10-39
- 10.8 Power-Down Mode (PDM) ..................................... 10-40
- 10.9 Suspend Mode ................................................ 10-41

### 11 Watchdog (WD) Timer

*Describes the features and operation of the watchdog (WD) timer module. Covers the architecture and the registers used to implement WD functions.*

- 11.1 Watchdog Timer Features ..................................... 11-2
- 11.2 Watchdog Timer Operations .................................. 11-4
  - 11.2.1 Overview of WD Timer Operations ......................... 11-4
  - 11.2.2 Watchdog Timer Clock ................................... 11-4
11.2.3 Watchdog Suspend ........................................ 11-4
11.2.4 Operations of the WD Timer ............................ 11-5
11.3 Watchdog Control Registers ............................... 11-8
  11.3.1 WD Counter Register ................................. 11-8
  11.3.2 WD Reset Key Register ............................... 11-9
  11.3.3 WD Timer Control Register ......................... 11-9

12 240xA-240 Family Compatibility .......................... 12-1
   Describes compatibility issues between the 240xA and the 240 family of processors.
  12.1 General .................................................. 12-2
  12.2 Event Manager .......................................... 12-3
  12.3 Analog-to-Digital Converter ............................ 12-4
  12.4 Serial Communications Interface ....................... 12-4
  12.5 Serial Peripheral Interface ........................... 12-4
  12.6 Watchdog Timer ........................................ 12-4

13 240xA-24x Family Compatibility .......................... 13-1
   Describes the major differences between the 24x and the 240xA family of processors.
  13.1 Introduction ............................................. 13-2
  13.1.1 Migrating Code from 24x to 240x/240xA Devices .... 13-3
  13.2 24x-240xA DSP Overview .............................. 13-4
  13.3 Memory Map ............................................. 13-5
  13.3.1 Program Space ...................................... 13-5
  13.4 System Features ....................................... 13-6
  13.4.1 Oscillator and PLL .................................. 13-6
  13.4.2 Watchdog Clock ..................................... 13-7
  13.4.3 System Control Registers ......................... 13-8
  13.5 Digital I/O (GPIO Pins) ............................... 13-11
  13.5.1 Digital I/O and Shared Pin Functions for the 240xA 13-11
  13.6 Event Manager Module (EVB) .......................... 13-14
  13.6.1 Input Qualification Circuitry ...................... 13-14

A Revision History ............................................. A-1
   Provides a summary or changes made in this revision.
  A.1 Changes Made in This Revision ......................... A-2

B Programmable Register Address Summary .................. B-1
   Provides a summary of all programmable registers on TMS320X240xA devices.

C Program Examples ........................................... C-1
   Presents program examples for the 240xA.
  C.1 About These Program Examples ......................... C-2
  C.2 Program Examples ....................................... C-4

D TMS320F240x/240xA Boot ROM Loader: Protocols and Interfacing ........................................ D-1
   Describes the boot-load sequence and discusses SPI synchronous and SCI asynchronous transfer protocol and data formats.
  D.1 Introduction ............................................. D-2
E Flash/ROM Code Security For LF/LC240xA DSP Devices .............................................. E-1

Describes the Flash/ROM code security features, lists the code security module (CSM) registers, and discusses programming considerations for the TMS320LF/LC240xA devices with and without code security.

E.1 Flash/ROM Security Feature ................................................................. E-2
  E.1.1 Functional Description ............................................................... E-2
  E.1.2 CSM Impact on Other On-Chip Resources ............................... E-3
  E.1.3 Incorporating Code Security in User Applications ................... E-4

E.2 Technical Definitions ..................................................................... E-5

E.3 Environments that Require Security Unlocking ................................. E-7
  E.3.1 Password Match Flow ............................................................... E-7

E.4 Unsecuring Considerations for Devices With/Without Code Security .......... E-9
  E.4.1 Case 1: Device With Code Security ....................................... E-9
  E.4.2 Case 2: Device Without Code Security ................................... E-9

E.5 DOs and DON’Ts to Protect Security Logic...................................... E-10
  E.5.1 DOs ......................................................................................... E-10
  E.5.2 DON’Ts ................................................................................ E-10

E.6 CSM Features – Summary .............................................................. E-12

E.7 CSM — Frequently Asked Questions ............................................. E-13

F Glossary ..................................................................................... F-1

Explains terms, abbreviations, and acronyms used throughout this book.

The TMS320Lx240xA series of devices are members of the TMS320™ family of digital signal processors (DSPs) designed to meet a wide range of digital motor control (DMC) and other embedded control applications. This series is based on the C2xLP 16-bit, fixed-point, low-power DSP CPU, and is complemented with a wide range of on-chip peripherals and on-chip ROM or flash program memory, plus on-chip dual-access RAM (DARAM).

This reference guide describes the following 240xA devices: 2407A, 2406A, 2404A, 2403A, 2402A, and 2401A.

This chapter provides an overview of the current TMS320 family, describes the background and benefits of the 240xA DSP controller products, and introduces the 240xA devices. These low-cost DSPs are intended to enable multiple applications for a nominal price.

Throughout this book, all devices are referred to as 240xA devices. This book is applicable for both the 240x and 240xA families of devices and will be applicable for future derivatives of the 240xA family. Any feature that is not applicable for the 240x family is highlighted as appropriate. This book should be used in conjunction with the TMS320F/C24x DSP Controllers Reference Guide: CPU and Instruction Set (literature number SPRU180) and the appropriate device data sheet. Device errata are updated as and when an exception to functional specification of the silicon is discovered. Refer to the latest errata for exceptions to functional specifications and possible workarounds.

1.1 TMS320 Family Overview

The TMS320 family consists of fixed-point, floating-point, multiprocessor digital signal processors (DSPs), and fixed-point DSP controllers. TMS320 DSPs have an architecture designed specifically for real-time signal processing. The 240xA series of DSP controllers combines this real-time processing capability with controller peripherals to create an ideal solution for control system applications. The following characteristics make the TMS320 family the right choice for a wide range of processing applications:

- Very flexible instruction set
- Inherent operational flexibility
- High-speed performance
- Innovative parallel architecture
- Cost effectiveness

In 1982, Texas Instruments introduced the TMS32010, the first fixed-point DSP in the TMS320 family. Before the end of the year, *Electronic Products* magazine awarded the TMS32010 the title “Product of the Year”. Today, the TMS320 family consists of these generations: C1x, C2x, C20x, C24x, C5x, C54x, and C6x fixed-point DSPs; C3x and C4x floating-point DSPs; and C8x multiprocessor DSPs. The 240xA devices are considered part of the 24x generation of fixed-point DSPs, and members of the C2000 platform.

Devices within a generation of a TMS320 platform have the same CPU structure but different on-chip memory and peripheral configurations. Spin-off devices use new combinations of on-chip memory and peripherals to satisfy a wide range of needs in the worldwide electronics market. By integrating memory and peripherals onto a single chip, TMS320 devices reduce system costs and save circuit board space.
1.2 TMS320C240xA Series of DSP Controllers

Designers have recognized the opportunity to redesign existing digital motor control (DMC) systems to use advanced algorithms that yield better performance and reduce system component count. DSPs enable:

- Design of robust controllers for a new generation of inexpensive motors, such as AC induction, DC permanent magnet, and switched-reluctance motors
- Full variable-speed control of brushless motor types that have lower manufacturing cost and higher reliability
- Energy savings through variable-speed control, saving up to 25% of the energy used by fixed-speed controllers
- Increased fuel economy, improved performance, and elimination of hydraulic fluid in automotive electronic power steering (EPS) systems
- Reduced manufacturing and maintenance costs by eliminating hydraulic fluid in automotive electronic braking systems
- More efficient and quieter operation due to diminished torque ripple, resulting in less loss of power, lower vibration, and longer life
- Elimination or reduction of memory lookup tables through real-time polynomial calculation, thereby reducing system cost
- Use of advanced algorithms that can reduce the number of sensors required in a system
- Control of power switching inverters, along with control algorithm processing
- Single-processor control of multimotor systems

Control-Based Applications

The 240xA DSP controllers are designed to meet the needs of control-based applications. By integrating the high performance of a DSP core and the on-chip peripherals of a microcontroller into a single-chip solution, the 240xA series yields a device that is an affordable alternative to traditional microcontroller units (MCUs) and expensive multichip designs. At 40 million instructions per second (MIPS), the 240xA DSP controllers offer significant performance over traditional 16-bit microcontrollers and microprocessors. (240x devices operate at 30 MIPS.)
The 16-bit, fixed-point DSP core of the 240xA device provides analog designers a digital solution that does not sacrifice the precision and performance of their systems. In fact, system performance can be enhanced through the use of advanced control algorithms for techniques such as adaptive control, Kalman filtering, and state control. The 240xA DSP controllers offer reliability and programmability. Analog control systems, on the other hand, are hardwired solutions and can experience performance degradation due to aging, component tolerance, and drift.

**Reduced Development Time**

The high-speed central processing unit (CPU) allows the digital designer to process algorithms in real time rather than approximate results with look-up tables. The instruction set of these DSP controllers, which incorporates both signal processing instructions and general-purpose control functions, coupled with the extensive development support available for the 240xA devices, reduces development time and provides the same ease of use as traditional 8- and 16-bit microcontrollers. The instruction set also allows you to retain your software investment when moving from other general-purpose TMS320 fixed-point DSPs. It is source- and object-code compatible with the other members of the 24x generation, source-code compatible with the C2x generation, and upwardly source-code compatible with the C5x generation of DSPs from Texas Instruments.

The 240xA architecture is also well-suited for processing control signals. It uses a 16-bit word length along with 32-bit registers for storing intermediate results, and has two hardware shifters available to scale numbers independently of the CPU. This combination minimizes quantization and truncation errors, and increases processing power for additional functions. Such functions might include a notch filter that could cancel mechanical resonances in a system or an estimation technique that could eliminate state sensors in a system.

The 240xA DSP controllers take advantage of an existing set of peripheral functions that allow Texas Instruments to quickly configure various series members for different price/performance points or for application optimization. This library of both digital- and mixed-signal peripherals includes:

- Event manager
- Controller Area Network (CAN)
- Serial communications ports (SCI, SPI)
- Analog-to-digital converters (ADC)
- Safety features such as watchdog timer and power drive protection

The DSP controller peripheral library is continually growing and changing to suit the needs of tomorrow’s embedded control marketplace.
1.3 Peripheral Overview

The peripheral set for the 240xA devices includes:

- Event Manager: Timers and PWM generators for digital motor control
- CAN Interface: Controller Area Network (CAN) 2.0b compatible, with six mailboxes
- A/D: 10-bit analog-to-digital converter
- SPI: Serial Peripheral Interface – synchronous serial port
- SCI: Serial Communications Interface – asynchronous serial port (universal asynchronous receiver and transmitter – UART)
- Watchdog timer
- General-purpose bidirectional digital I/O (GPIO) pins

Note:

For device pinouts, electrical characteristics, and timing specifications of LF240x devices, see the following data sheet:

*TMS320LF2407, TMS320LF2406, TMS320LF2402 DSP Controllers Data Sheet* (literature number SPRS094).

For LF/LC240xA devices, see the following data sheets:

*TMS320LF2407A, TMS320LF2406A, TMS320LF2403A, TMS320LF2402A, TMS320LC2406A, TMS320LC2404A, TMS320LC2402A DSP Controllers Data Sheet* (literature number SPRS145);

*TMS320LF2401A, TMS320LC2401A DSP Controllers Data Sheet* (literature number SPRS161).
1.4 New Features in 240xA Devices

The following new features were added in the 240xA devices: (compared to 240x devices)

- 40-MHz operation (as compared to 30 MHz for the 240x family)
- Code security for on-chip Flash/ROM
- Input qualifier circuitry for PDPINTx, CAPn, XINTn, and ADCSOC pins
- Status of the PDPINTx pin is reflected in the COMCONx register
## 1.5 240xA Highlights

Available device configurations and their features are shown in Table 1–1.

2.1 Architecture Summary

The 240xA devices are implemented as ASIC customizable digital signal processors (cDSPs™). In the CPU, program ROM/FLASH is implemented as ASIC hard macros as shown in the shaded blocks in Figure 2-1. The CPU uses the LP256 hard macro which consists of the TMS320C2xx DSP CPU core, 544 x 16 words of dual-access RAM (DARAM), the analysis/JTAG logic, the internal memory interface, and the logic interface. The logic interface, however, is not used in the 240xA.

The peripherals interface to the internal memory interface of the CPU through the PBUS interface. All on-chip peripherals are accessed through the peripheral bus, PBUS. At lower frequencies, all peripheral accesses (reads and writes) are zero-wait-state, single-cycle accesses. All peripherals, excluding the watchdog timer counter, are clocked by the CPU clock. A third ASIC module is the 10-bit A/D converter.

These devices have up to 41 bit-selectable digital I/O ports. Most or all of these I/O ports are multiplexed with other functions, such as event manager signals, serial communication port signals, or interrupts. Most of these multiplexed digital I/O pins come up in their digital I/O pin mode as an input following a device reset. For a detailed description of the architecture and instruction set, refer to the TMS320F/C24x DSP Controllers Reference Guide: CPU and Instruction Set (SPRU160).

- 1 Clock to module is enabled and running normally

**Bit 5**  **SPI CLKEN.** SPI module clock enable control bit
- 0 Clock to module is disabled (i.e., shut down to conserve power)
- 1 Clock to module is enabled and running normally

**Bit 4**  **CAN CLKEN.** CAN module clock enable control bit
- 0 Clock to module is disabled (i.e., shut down to conserve power)
- 1 Clock to module is enabled and running normally

**Bit 3**  **EVB CLKEN.** EVB module clock enable control bit
- 0 Clock to module is disabled (i.e., shut down to conserve power)
- 1 Clock to module is enabled and running normally

**Bit 2**  **EVA CLKEN.** EVA module clock enable control bit
- 0 Clock to module is disabled (i.e., shut down to conserve power)
- 1 Clock to module is enabled and running normally
Note:
In order to modify/read the register contents of any peripheral, the clock to that peripheral must be enabled by writing a 1 to the appropriate bit.

Bit 1  Reserved

Bit 0  ILLADR. Illegal Address detect bit

If an illegal address has occurred this bit will be set. It is up to software to clear this bit following an illegal address detect. This bit is cleared by writing a 1 to it and should be cleared as part of the initialization sequence. Note: An illegal address access will cause an NMI.

Figure 2–3. System Control and Status Register 2 (SCSR2) — Address 07019h

<table>
<thead>
<tr>
<th>15–8</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>6</td>
</tr>
</tbody>
</table>

    | Reserved | I/P QUAL | WD OVERRIDE | XMIF HI-Z | BOOT EN | MP/MC | DON | PON |
|------|----------|------------|-----------|----------|--------|------|-----|-----|
| RW-0 | RC-1     | RW-0       | RW-BOOT   | RW-EN pin| RW-MP/MC pin | RW-1 | RW-1 |

Note:  
R = Read access, W = Write access, C = Clear, -0 = value after reset

Bits 15–7  Reserved. Writes have no effect; reads are undefined

Bit 6  Input Qualifier Clocks.

An input-qualifier circuitry qualifies the input signal to the CAP1–6, XINT1/2, ADCSOC, and PDPINTA/B pins in the 240xA devices. The I/O functions of these pins do not use the input-qualifier circuitry. The state of the internal input signal will change only after the pin is held high/low for 6 (or 12) clock edges. This ensures that a glitch smaller than (or equal to) 5 (or 11) CLKOUT cycles wide will not change the internal pin input state. The user must hold the pin high/low for 6 (or 12) cycles to ensure that the device will see the level change.

This bit determines the width of the glitches (in number of internal clock cycles) that will be blocked. Note that the internal clock is not the same as CLKOUT, although its frequency is the same as CLKOUT.

- 0  The input-qualifier circuitry blocks glitches up to 5 clock cycles long
- 1  The input-qualifier circuitry blocks glitches up to 11 clock cycles long
Bit 5  **Watchdog Override.** (WD protect bit)

After RESET, this bit gives you the ability to protect the WD function from being disabled through software (by setting the WDDIS bit = 1 in the WDCR). This bit is a clear-only bit and defaults to a 1 after reset, *Note: this bit is cleared by writing a 1 to it.*

- 0  Protects the WD from being disabled by software. This bit cannot be set to 1 by software. It is a clear-only bit, cleared by writing a 1. Clearing this bit would enable the WD if it were currently disabled.
- 1  This is the default reset value and allows the user to disable the WD through the WDDIS bit in the WDCR. Once cleared however, this bit can no longer be set to 1 by software, thereby protecting the integrity of the WD timer.

Bit 4  **XMIF Hi-Z Control**

This bit controls the state of the external memory interface (XMIF) signals.

- 0  XMIF signals in normal driven mode; i.e., not Hi-Z (high impedance)
- 1  All XMIF signal are forced to Hi-Z state

*Note:*
This bit is a reserved bit on all devices other than LF2407/2407A, and must be written only as a zero.

Bit 3  **Boot Enable**

This bit reflects the state of the **BOOT_EN / XF** pin at the time of reset. After reset and device has “Booted up”, this bit can be changed in software to re-enable Flash memory visibility, or return to active Boot ROM.

- 0  Enable Boot ROM — Address space 0000 — 00FF is now occupied by the on-chip Boot ROM Block. Flash memory is totally disabled in this mode. Note: There is no on-chip boot ROM in ROM devices (i.e., LC240xA)
- 1  Disable Boot ROM — Program address space 0000 — 7FFF is mapped to on-chip Flash Memory in the case of LF2407A and LF2406A. In the case of LF2402A, addresses 0000 – 1FFF are mapped

---

**Note:**
This bit is applicable only for the 240xA devices, not for the 240x devices since they lack an input-qualifier circuitry.
Bit 2  **Microprocessor / Microcontroller Select**

This bit reflects the state of the MP/MC pin at time of reset. After reset, this bit can be changed in software to allow dynamic mapping of memory on and off chip.

0  Set to Microcontroller mode — Program Address range 0000 — 7FFF is mapped internally (i.e., Flash)

1  Set to Microprocessor mode — Program Address range 0000 — 7FFF is mapped externally (i.e., Customer provides external memory device.)

Note: MP/MC pin is available only in LF2407A and LF2407.

2.3 Interrupt Priority and Vectors

A centralized interrupt expansion scheme is implemented in order to accommodate the large number of peripheral interrupts with the six maskable interrupts supported by the CPU. Table 2–2 provides the interrupt source priority and vectors for the 240xA devices. The details of the 240xA interrupt expansion scheme are explained in Chapter 2.

**Note:** Shaded interrupts are new interrupts added to 240xA by virtue of EVB.

Interrupts of nonexistent peripherals may not be applicable to a particular device. For example, SPI and CAN interrupts are not applicable to the 2402A device.
2.4 Peripheral Interrupt Expansion (PIE) Controller

The 240xA CPU supports one nonmaskable interrupt (NMI) and six maskable prioritized interrupt requests (INT1–INT6) at the core level. The 240xA devices have many peripherals, and each peripheral is capable of generating one or more interrupts in response to many events at the peripheral level.

Because the C240xA CPU does not have sufficient capacity to handle all peripheral interrupt requests at the core level, a centralized interrupt controller (PIE) is required to arbitrate the interrupt requests from various sources such as peripherals and other external pins (see Figure 2–5).
Figure 2–5. Peripheral Interrupt Expansion Block Diagram
2.4.1 Interrupt Hierarchy

The number of interrupt slots available is expanded by having two levels of hierarchy in the interrupt request system. Both the interrupt request/acknowledge hardware and the interrupt service routine software have two levels of hierarchy.

2.4.2 Interrupt Request Structure

At the lower level of the hierarchy, the peripheral interrupt requests (PIRQ) from several peripherals to the interrupt controller are ORed together to generate an interrupt request (INTn) to the CPU. This is the core level interrupt request. There is an interrupt flag bit and an interrupt enable bit located in the peripheral configuration registers for each event that can cause a PIRQ. There is also one PIRQ for each event. If an interrupt causing event occurs in a peripheral and the corresponding interrupt enable bit is set, the interrupt request from the peripheral to the interrupt controller will be asserted. This interrupt request simply reflects the status of the peripheral’s interrupt flag, gated with the interrupt enable bit. When the interrupt flag is cleared, the interrupt request is cleared.

Some peripherals may have the capability to make either a high-priority or a low-priority interrupt request. If a peripheral has this capability, the value of its interrupt priority bit is also transmitted to the interrupt controller. The interrupt request (PIRQ) continues to be asserted until it is either automatically cleared by an interrupt acknowledge or cleared by the software.

At the upper level of the hierarchy, the ORed PIRQs generate interrupt (INTn) requests to the CPU. The request to the C240xA CPU is a low-going pulse of two CPU clock cycles. The PIE controller generates an INTn pulse when any of the PIRQs controlling the INTn become active. If any of the PIRQs capable of asserting the CPU interrupt request are still active in the cycle following an interrupt acknowledge for the INTn, another INTn pulse is generated. An interrupt acknowledge clears the highest priority pending PIRQ. Note that the interrupts are automatically cleared only at the core level and not at the peripheral level. The interrupt controller (not the peripherals) defines the following:

- Which CPU interrupt request gets asserted by which peripheral
- Relative priority of each peripheral interrupt requests

This is shown in Table 2–2, 240xA Interrupt Source Priority and Vectors, on page 2-9.
2.4.3 Interrupt Acknowledge

The hierarchical interrupt expansion scheme requires one interrupt acknowledge signal for each peripheral interrupt request to the interrupt controller. When the CPU asserts its interrupt acknowledge, it simultaneously puts a value on the program address bus, which corresponds to the CPU interrupt being acknowledged. (It does this to fetch the interrupt vector from program memory: each INTn has a vector stored in a dedicated program memory address.) This value is shown in Table 2-2, 240xA Interrupt Source Priority and Vectors, on page 2-9. The PIE controller decodes this value to determine which of the CPU interrupt requests is being acknowledged. It then generates a peripheral interrupt acknowledge in response to the highest-priority currently asserted PIRQ associated with that CPU interrupt.
2.5 Interrupt Vectors

When the CPU receives an interrupt request, it does not know which peripheral event caused the request. To enable the CPU to distinguish between all of these events, a unique peripheral interrupt vector is generated in response to an active peripheral interrupt request. This vector is loaded into the peripheral interrupt vector register (PIVR) in the PIE controller. It can then be read by the CPU and used to generate a vector to branch to the interrupt service routine (ISR) which corresponds to the event being acknowledged.

In effect there are two vector tables: The CPU's vector table which is used to get to the first, general interrupt service routine (GISR) in response to a CPU interrupt request; and the peripheral vector table which is used to get to the event specific interrupt service routine (SISR) corresponding to the event which caused the PIRQ. The code in the GISR should read the PIVR, and after saving any necessary context, use this value to generate a vector to the SISR.

Figure 2–6 shows an example of how XINT1 (external interrupt in high-priority mode) generates an interrupt. For XINT1 in high-priority mode, a value of 0001h is loaded into the PIVR register. The CPU ascertains the value that was loaded in the PIVR register and uses this value to determine which peripheral caused the interrupt, and then branches to the appropriate SISR. Such a branch to the SISR could be a conditional branch (BCND) which is executed on the condition that the PIVR register holds a particular value. An alternative scheme would be to left-shift the PIVR register by one bit while loading it in the accumulator and adding a fixed offset value. Program control could then branch to the address value stored in the accumulator (using the BACC instruction). This address would point to the SISR.
2.5.1 Phantom Interrupt Vector

The phantom interrupt vector is an interrupt system integrity feature. If the CPU's interrupt acknowledge is asserted but there is no associated peripheral interrupt request asserted, the phantom vector is used so that this fault is handled in a controlled manner. The phantom interrupt vector is required when, for example, the CPU executes a software interrupt instruction with an argument corresponding to a peripheral interrupt (usually INT1–INT6). Another example is when a peripheral makes an interrupt request but its INTn flag was cleared by software before the CPU acknowledged the request. In this case, there may be no peripheral interrupt request asserted to the interrupt controller; and therefore, the controller does not know which peripheral interrupt vector to load into the PIVR. In these two situations, the phantom interrupt vector is loaded into the PIVR in lieu of a peripheral interrupt vector.
2.5.2 Software Hierarchy

There are two levels of interrupt service routine hierarchy: the general interrupt service routine (GISR), and the specific interrupt service routine (SISR). There is one GISR for each maskable prioritized request (INT1–INT6) to the CPU which performs all necessary context saves before it fetches the peripheral interrupt vector from the PIVR. This vector is used to generate a branch to the SISR. There is one SISR for every interrupt request (IRQn) from a peripheral to the interrupt controller, and this SISR performs the required actions in response to the peripheral interrupt request.

The GISR must read the peripheral interrupt vector from the PIVR before interrupts are re-enabled. (All interrupts are automatically disabled when an interrupt is taken.) If the PIVR is not read before interrupts are re-enabled and another interrupt is asserted, a new peripheral interrupt vector will be loaded into the PIVR, causing permanent loss of the original peripheral interrupt vector.

Nonmaskable interrupts such as reset and NMI are not part of PIE. The PIE controller does not support expansion of nonmaskable interrupts.

2.5.3 Nonmaskable Interrupt (NMI)

The 240xA devices do not have an NMI pin like the 240 or 241/242/243 devices. NMI will be asserted when access to any illegal address is made. When NMI is asserted, the code will branch to 0024h in program memory, which is the NMI vector. There is no control register corresponding to the NMI feature.

The following caution should be observed while using the SARAM on 240xA devices that lack an external memory interface (XMIF): The last 2 words in SARAM cannot be used to store a RET or Branch instruction. This is because when a RET or Branch instruction reaches the execute phase of the pipeline, the next two instruction words have already been fetched. Since addresses 8800h and above are illegal in 240xA devices that lack XMIF, this asserts an NMI. As an example, the following code snippet will work:

87FB  xxxxx
87FC  xxxxx
87FD  RET
87FE  xxxxx
87FF  xxxxx

However, if the RET instruction is pushed down to 87FE or 87FF, an NMI will be asserted.
The following code snippet illustrates the behavior of unconditional branch:

```
87FB   NOP
87FC   B "address"
87FE   xxxxx
87FF   xxxxx
```

This will work fine. However, if the B occupies 87FD or above, then NMI will be asserted. TBLR and TBLW instructions can operate on data at locations 87FE or 87FF without any issue.
2.6 Interrupt Operation Sequence

An interrupt generating event occurs in a peripheral. Refer to Figure 2−7 for the interrupt responses and flow in each module of the 240xA. The interrupt flag (IF) bit corresponding to that event is set in a register in the peripheral. If the corresponding interrupt enable (IE) bit is set, the peripheral generates an interrupt request to the PIE controller by asserting its PIRQ. If the interrupt is not enabled, the IF remains set until cleared by software. If the interrupt is enabled at a later time, and the interrupt flag is still set, the PIRQ will immediately be asserted.

If no unacknowledged CPU interrupt request of the same priority level (INTn) has previously been sent, the PIRQ causes the PIE controller to generate a CPU interrupt request (INTn). This pulse is active low for two CPU clock cycles.

The interrupt request to the CPU sets the corresponding flag in the CPU’s interrupt flag register (IFR). If the CPU interrupt has been enabled by setting the corresponding bit in the CPU’s interrupt mask register (IMR), the CPU stops what it is doing, masks all other maskable interrupts by setting the INTM bit, saves some context, and starts executing the general interrupt service routine (GISR) for that interrupt priority level (INTn). The CPU generates an interrupt acknowledge automatically which is accompanied by a value on the program address bus (PAB) corresponding to the interrupt priority level being responded to. For example, if INT3 is asserted, its vector 0006h is loaded in the PAB. This is the interrupt vector corresponding to INTn (refer to Table 2−2 240xA Interrupt Source Priority and Vectors, on page 2-9).

The PIE controller decodes the PAB value and generates a peripheral interrupt acknowledge to clear the PIRQ bit associated with the CPU interrupt being acknowledged. The PIE controller then loads the peripheral interrupt vector register (PIVR) with the appropriate peripheral interrupt vector (or the phantom interrupt vector) from the table stored in the PIE controller.

When the GISR has completed any necessary context saves, it reads the PIVR and uses that interrupt vector to branch to the specific interrupt service routine (SISR) for the interrupt event which occurred in the peripheral.

**Note:** Re-enabling interrupts

Interrupts must not be re-enabled until the PIVR has been read; otherwise, its contents can get overwritten by a subsequent interrupt.
This page is intentionally left blank.
Interrupt Operation Sequence

System Configuration and Interrupts

Figure 2-7. 240xA Interrupt Response and Flow

**Peripheral Flow**

- Start
- Peripheral interrupt occurs
- Interrupt flag (IF) set in peripheral register (PR)
- Interrupt enable (IE) = 1 in PR?
- No → IE set by SW
- Yes → Interrupt generation awaits IE to be set or software clear of the IF bit set in peripheral register
- PIE Flow
  - PIRQ generated to PIE
  - PIRQ triggers PIE flags to be set and the respective INTx is generated
  - CPU receives INTx
  - CPUFlow
    - Respective IFR bit is set
      - IMR bit = 1?
        - Yes → INTM = 0?
          - Yes → IFR bit is cleared, INTM is set, PC jumps to INTx vector address 0000-000Ch
          - No → INTM logic waits INTM to be cleared
        - No → Interrupt generation logic awaits IMR bit to be set or software clear of the IFR bit
    - No → PIE logic also enables pending INTx
    - PIE logic loads PIV value into PIVR
    - Next pending INTx issued to CPU

**CPU Flow**

- CPUFlow
  - CPU recognizes the INTx and issues interrupt acknowledge
- CPU interrupt acknowledge clears interrupt request in PIE (PIRQn)
- PIE logic also enables pending INTx
- Next pending INTx issued to CPU

**Peripheral interrupt occurs**

**Interrupt flag (IF) set in peripheral register (PR)**

**Interrupt enable (IE) = 1 in PR?**

**IE set by SW**

**PIE Flow**

- PIE Flow
  - PIRQ generated to PIE
  - PIRQ triggers PIE flags to be set and the respective INTx is generated
  - CPU receives INTx
  - CPUFlow
    - Respective IFR bit is set
      - IMR bit = 1?
        - Yes → INTM = 0?
          - Yes → IFR bit is cleared, INTM is set, PC jumps to INTx vector address 0000-000Ch
          - No → INTM logic waits INTM to be cleared
        - No → Interrupt generation logic awaits IMR bit to be set or software clear of the IFR bit
    - No → PIE logic also enables pending INTx
    - PIE logic loads PIV value into PIVR
    - Next pending INTx issued to CPU

**CPU Flow**

- CPUFlow
  - CPU recognizes the INTx and issues interrupt acknowledge
- CPU interrupt acknowledge clears interrupt request in PIE (PIRQn)
- PIE logic also enables pending INTx
- Next pending INTx issued to CPU

**CPU branches to GISR**

- User code saves context, reads PIVR for PIV value
- PIV = phantom vector?
  - Yes → Interrupt service for phantom vector
  - No → Based on PIV branch to SISR

**GISR Flow**

- GISR Flow
  - Based on PIV branch to SISR
  - SISR user code to service the peripheral interrupt
  - Clear IF bit in peripheral register, clear INTM bit
  - Return

**SISR Flow**

- SISR Flow
  - SISR user code to service the peripheral interrupt
  - Clear IF bit in peripheral register, clear INTM bit
  - Return

**Note:**

- IF – Interrupt flag. This bit has to be cleared by s/w or future interrupts will be ignored.
- IE – Interrupt enable
- GISR – General ISR
- SISR – Specific ISR
- PR – Peripheral register, EVIFRA, etc.
## 2.7 Interrupt Latency

There are three components to interrupt latency:

1) **Synchronization** is the time it takes for the request generated in response to the occurrence of an interrupt generating event to be recognized by the PIE controller and converted into a request to the CPU.

2) **Core Latency** is the time it takes for the CPU to recognize the enabled interrupt request, clear its pipeline, and begin fetching the first instruction from the CPU's interrupt vector table. There is a minimum core latency of four CPU cycles. If a higher priority maskable interrupt is requested during this minimum latency period, it is masked until the ISR for the interrupt being serviced re-enables the interrupt. The latency can be longer than the minimum if the interrupt request occurs during an uninterruptible operation; for example, a repeat loop, a multicycle instruction, or during a wait-stated access. If a higher-priority interrupt occurs during this additional latency period, it gets serviced before the original lower-priority interrupt, assuming both are enabled.

3) **ISR Latency** is the time it takes to get to the specific interrupt service routine (ISR) code for the event that caused the acknowledged interrupt. ISR latency can vary depending on how much context saving is required.
2.8 Sample ISR Code

; This sample ISR code illustrates how to branch to an SISR corresponding to a peripheral interrupt. No context save is done.
; Timer 1 period interrupt is assumed

main code

B GISR2 ; This instruction resides at 0004h of PM

;========================================================================
; ISRs
;========================================================================

GISR2: LDP #PIVR >> 7h ; Load the data page containing PIVR
LA CL PIVR ; Load PIVR value in the accumulator
XOR #0027h ; Timer 1 period interrupt?
BC ND SISR27,eq ; Branch to T1PINT if Accumulator = 0
 ; Else reload PIVR in the accumulator and continue
 ; checking for other peripheral interrupts

SISR27: ........... ; Execute the ISR specific to T1PINT
 ; After executing the SISR, clear the flag bit
 ; that asserted the interrupt, so that future
 ; interrupts may be recognized

EXIT_ISR
CL RC INTM ; Before exiting the SISR, clear the interrupt
RET ; mode bit
2.9 CPU Interrupt Registers

The CPU interrupt registers in the upper level of hierarchy include the following:

- Interrupt flag register (IFR)
- Interrupt mask register (IMR)

2.9.1 Interrupt Flag Register (IFR)

The interrupt flag register (IFR), a 16-bit, memory-mapped register at address 0006h in data-memory space, is used to identify and clear pending interrupts. The IFR contains flag bits for all the maskable interrupts (INT1–INT6).

When a maskable interrupt is requested, the flag bit in the corresponding peripheral control register is set to 1. If the corresponding mask bit is also 1, the interrupt request is sent to the CPU, setting the corresponding flag in the IFR. This indicates that the interrupt is pending or waiting for acknowledgement.

You can read the IFR to identify pending interrupts and write to the IFR to clear pending interrupts. To clear a single interrupt, write a one to the corresponding IFR bit. All pending interrupts can be cleared by writing the current contents of the IFR back into the IFR.

The following events also clear an IFR flag:

- The CPU acknowledges the interrupt.
- The 240xA is reset.

Notes:

1) To clear an IFR bit, you must write a one to it, not a zero.

2) When a maskable interrupt is acknowledged, only the IFR bit is cleared automatically. The flag bit in the corresponding peripheral control register is not cleared. If an application requires that the control register flag be cleared, the bit must be cleared by software.

3) When an interrupt is requested by an INTR instruction and the corresponding IFR bit is set, the CPU does not clear the bit automatically. If an application requires that the IFR bit be cleared, the bit must be cleared by software.

4) IMR and IFR registers pertain to core-level interrupts. All peripherals have their own interrupt mask and flag bits in their respective control/configuration registers. Note that several peripheral interrupts are grouped under one core-level interrupt.
Figure 2–8. Interrupt Flag Register (IFR) — Address 0006h

<td>RW1C-0</td>
<td>RW1C-0</td>
<td>RW1C-0</td>
<td>RW1C-0</td>
<td>RW1C-0</td>
</tr>
</tbody>
</table>

**Note:** 0 = Always read as zeros, R = Read access, W1C = Write 1 to this bit to clear it, -0 = value after reset

**Bits 15–6 Reserved.** These bits are always read as zeros.

**Bit 5 INT6.** Interrupt 6 flag. This bit is the flag for interrupts connected to interrupt level INT6.
- 0 No INT6 interrupt is pending
- 1 At least one INT6 interrupt is pending. Write a 1 to this bit to clear it to 0 and clear the interrupt request

**Bit 4 INT5.** Interrupt 5 flag. This bit is the flag for interrupts connected to interrupt level INT5.
- 0 No INT5 interrupt is pending
- 1 At least one INT5 interrupt is pending. Write a 1 to this bit to clear it to 0 and clear the interrupt request

**Bit 3 INT4.** Interrupt 4 flag. This bit is the flag for interrupts connected to interrupt level INT4.
- 0 No INT4 interrupt is pending
- 1 At least one INT4 interrupt is pending. Write a 1 to this bit to clear it to 0 and clear the interrupt request

**Bit 2 INT3.** Interrupt 3 flag. This bit is the flag for interrupts connected to interrupt level INT3.
- 0 No INT3 interrupt is pending
- 1 At least one INT3 interrupt is pending. Write a 1 to this bit to clear it to 0 and clear the interrupt request

**Bit 1 INT2.** Interrupt 2 flag. This bit is the flag for interrupts connected to interrupt level INT2.
- 0 No INT2 interrupt is pending
- 1 At least one INT2 interrupt is pending. Write a 1 to this bit to clear it to 0 and clear the interrupt request

**Bit 0 INT1.** Interrupt 1 flag. This bit is the flag for interrupts connected to interrupt level INT1.
- 0 No INT1 interrupt is pending
- 1 At least one INT1 interrupt is pending. Write a 1 to this bit to clear it to 0 and clear the interrupt request
2.9.2 Interrupt Mask Register (IMR)

The IMR is a 16-bit, memory-mapped register located at address 0004h in data memory space. The IMR contains mask bits for all the maskable interrupt levels (INT1–INT6). Neither NMI nor RS is included in the IMR; thus, IMR has no effect on these interrupts.

You can read the IMR to identify masked or unmasked interrupt levels, and you can write to the IMR to mask or unmask interrupt levels. To unmask an interrupt level, set its corresponding IMR bit to one. To mask an interrupt level, set its corresponding IMR bit to zero. When an interrupt is masked, it is not acknowledged, regardless of the value of the INTM bit. When an interrupt is unmasked, it is acknowledged if the corresponding IFR bit is one and the INTM bit is zero.

The IMR is shown in Figure 2–9, and descriptions of the bits follow the figure.

Figure 2–9. Interrupt Mask Register (IMR) — Address 0004h

Note: 0 = Always read as zeros, R = Read access, W = Write access, bit values are not affected by a device reset

Bits 15–6 **Reserved**. These bits are always read as zeros.

Bit 5 **INT6**. Interrupt 6 mask. This bit masks or unmaps interrupt level INT6.

- 0 Level INT6 is masked
- 1 Level INT6 is unmasked

Bit 4 **INT5**. Interrupt 5 mask. This bit masks or unmaps interrupt level INT5.

- 0 Level INT5 is masked
- 1 Level INT5 is unmasked

Bit 3 **INT4**. Interrupt 4 mask. This bit masks or unmaps interrupt level INT4.

- 0 Level INT4 is masked
- 1 Level INT4 is unmasked

Bit 2 **INT3**. Interrupt 3 mask. This bit masks or unmaps interrupt level INT3.

- 0 Level INT3 is masked
- 1 Level INT3 is unmasked
CPU Interrupt Registers

Bit 1  **INT2.** Interrupt 2 mask. This bit masks or unmasks interrupt level INT2.

  0  Level INT2 is masked
  1  Level INT2 is unmasked

Bit 0  **INT1.** Interrupt 1 mask. This bit masks or unmasks interrupt level INT1.

  0  Level INT1 is masked
  1  Level INT1 is unmasked

**Note:**

The IMR bits are not affected by a device reset.
2.10 Peripheral Interrupt Registers

The peripheral interrupt registers include the following:

- Peripheral interrupt vector register (PIVR)
- Peripheral interrupt request register 0 (PIRQR0)
- Peripheral interrupt request register 1 (PIRQR1)
- Peripheral interrupt request register 2 (PIRQR2)
- Peripheral interrupt acknowledge register 0 (PIACKR0)
- Peripheral interrupt acknowledge register 1 (PIACKR1)
- Peripheral interrupt acknowledge register 2 (PIACKR2)

Note:

PIRQR0/1/2 and PIACKR0/1/2 are control registers internal to the PIE module used for generating interrupts (INT1 – INT6) to the CPU. While programming, these registers can be ignored since they monitor the internal operation of the PIE. These registers are used for test purposes and are not intended for user applications.

2.10.1 Peripheral Interrupt Vector Register (PIVR)

The peripheral interrupt vector register (PIVR) is a 16-bit read-only register. It is located at address 701Eh (in data space).

During the peripheral interrupt acknowledge cycle, the PIVR is loaded with the interrupt vector of the highest-priority pending interrupt associated with the CPU interrupt (INTn) being acknowledged (or the phantom interrupt vector). The PIVR is shown in Figure 2–10.

**Bits 15–0 V15–V0.** Interrupt vector. This register contains the peripheral interrupt vector of the most recently acknowledged peripheral interrupt.
2.10.2 Peripheral Interrupt Request Registers (PIRQR0, 1, 2)

The peripheral interrupt request registers (PIRQRx) enable:

- The state of the peripheral interrupt requests to be read
- A simulated assertion of a particular peripheral interrupt request

PIRQR0 is shown in Figure 2–11, PIRQR1 is shown in Figure 2–12, and PIRQR2 is shown in Figure 2–13.

![Peripheral Interrupt Request Register 0 (PIRQR0) — Address 7010h](image)

**Bits 15–0**  
**IRQ0.15–IRQ0.0**

- 0 Corresponding peripheral interrupt is not pending
- 1 Peripheral Interrupt is pending

**Note:** Writing a 1 sends IRQ to core; writing a 0 has no effect.

2.10.3 Peripheral Interrupt Acknowledge Registers (PIACKR0, 1, 2)

The peripheral interrupt acknowledge registers (PIACKRx) are memory mapped to enable an easy test of the peripheral interrupt acknowledges. There are three of these 16-bit registers; and therefore, the PIE controller can support up to 48 peripheral interrupts. These registers are generally used for test purposes only and are not for user applications. PIACKR0 is shown in Figure 2–14, PIACKR1 is shown in Figure 2–15, and PIACKR2 is shown in Figure 2–16.

2-34
Bits 15–0  IACK0.15–IACK0.0. Peripheral interrupt acknowledge bits. Writing a one causes the corresponding peripheral interrupt acknowledge to be asserted, which clears the corresponding peripheral interrupt request. Note that asserting the interrupt acknowledge by writing to this register does not update the PIVR. Reading the register always returns zeros.

2.11 Reset

The 240xA devices have two sources of reset:

- An external reset pin
- A watchdog timer timeout

The reset pin is an I/O pin. If there is an internal reset event (watchdog timer), the reset pin is put into output mode and driven low to indicate to external circuits that the 240xA device is resetting itself.

The external reset pin and watchdog timer reset are ORed together to drive the reset input to the CPU.

2.12 Illegal Address Detect

The decode logic has the capability to detect accesses to illegal addresses (all unimplemented addresses including reserved registers in each peripheral’s memory map). The occurrence of an illegal access sets the illegal address flag (ILLADR) in System Control and Status Register 1 (SCSR1). See section 2.2.1, System Control and Status Registers 1 and 2 (SCSR1, SCSR2), on page 2-3. The detection of an illegal address generates a nonmaskable interrupt (NMI). The illegal address condition is asserted whenever illegal addresses are accessed. The illegal address flag (ILLADR) remains set following an illegal address condition until it is cleared by software. A common reason for illegal address access (and hence, NMI) is incorrect data page initialization.
2.13 External Interrupt Control Registers

The two external interrupt control registers that control and monitor XINT1 and XINT2 pin activities are XINT1CR and XINT2CR. In the 240xA devices, the XINT1 and XINT2 pins must be held low for six (or 12) CLKOUT cycles before they are recognized by the core.

This chapter describes the RAM, ROM, and Flash availability on the 240xA.

In addition to single-access RAM (SARAM) and dual-access RAM (DARAM – B0, B1, B2), which is part of the CPU core, the 240xA devices include flash EPROM or ROM for additional on-chip program memory. Devices with an LF prefix are flash devices and those with an LC prefix are ROM devices.

The 2407A device has a 16-bit address bus that can access the following three individually selectable spaces (192K words total):

- 64K-word program space
- 64K-word data space
- 64K-word I/O space

This chapter shows memory maps for program, data, and I/O spaces. It also describes available 240xA memory configuration options.

3.1 On-Chip RAM

The 240xA on-chip RAM includes on-chip dual-access RAM (DARAM) and on-chip single-access program/data RAM (SARAM).

3.1.1 Dual-Access On-Chip RAM

All Lx240xA devices have 544 words × 16 bits of on-chip DARAM, which can be accessed twice per machine cycle. The 544 words are divided into three blocks: B0, B1, and B2. This memory is primarily intended to hold data but, in the case of B0, can also hold programs. B0 can be configured in one of two ways depending on the value of the CNF bit. CNF = 0 maps B0 in data memory, while CNF = 1 maps B0 in program memory.

In the pipeline operation, the CPU reads data on the third cycle and writes data on the fourth cycle. However, DARAM allows the CPU to write and read in one cycle; the CPU writes to DARAM on the master phase of the cycle and reads from DARAM on the slave phase. For example, suppose two instructions, A and B, store the accumulator value to DARAM and load the accumulator with a new value from DARAM. Instruction A stores the accumulator value during the master phase of the CPU cycle, and instruction B loads the new value to the accumulator during the slave phase. Because part of the dual-access operation is a write, it only applies to RAM.

3.1.2 Single-Access On-Chip Program/Data RAM

Some of the Lx240xA devices have up to 2K 16-bit words of single-access RAM (SARAM). The addresses associated with the SARAM can be used for both data memory and program memory, and are software configurable to either external memory or the internal SARAM.

When configured as external, these addresses can be used for off-chip program memory. SARAM is accessed only once per CPU cycle. When the CPU requests multiple accesses, the SARAM schedules the accesses by providing a not-ready condition to the CPU and then executing the accesses one per cycle. For example, if the instruction sequence involves storing the accumulator value and then loading a value to the accumulator, it would take two cycles to complete in SARAM, compared to one cycle in DARAM.
3.2 Factory Masked On-Chip ROM

The on-chip ROM in ROM devices is mapped in program memory space. This ROM is always enabled since these devices lack an external memory interface. This ROM is programmed with customer-specific code.

3.3 Flash

The on-chip flash in flash devices is mapped in program memory space. This flash memory is always enabled in devices that lack an external memory interface. For the 2407A, which has an external memory interface, the MP/MC pin determines whether the on-chip program memory (flash) or the off-chip program memory (customer design specific) is accessed.

3.3.1 Flash Program Memory

The Flash module is used to provide permanent program storage. The Flash can be programmed and electrically erased many times to allow code development. The 240xA Flash is similar to that on the 24x devices, with some key differences and enhancements. 240xA Flash features are as follows:

- Flash run-time execution at 3.3 V
- Flash programming requires a 5-V supply (±5%) at V_{CCP} pin
- Flash has multiple sectors that can be protected while erasing
- Flash programming registers are similar to those on the 24x devices
- Flash programming is done through CPU
- 240xA devices come with JTAG interface to aid programming and emulation
- A 256-word Boot ROM is available on 240xA devices to enable programming through SCI or SPI ports

The following sections explain the Flash programming registers and their bit functions. Flash programming utilities will be provided by Texas Instruments (TI). Refer to the TI’s web page (www.ti.com, under 24x Flash tools) for revisions of these utilities.

3.3.2 Flash Control Mode Register (FCMR)

The Flash control mode register is in internal I/O space FF0Fh. This register is a dummy register address to enable the Flash in Flash array mode or in Flash control register mode.
The Flash control registers are used to program the Flash array. These registers are a part of the Flash wrapper and are mapped at the same start address as the Flash array itself. These registers are not visible (disabled) during Flash array mode (i.e., Flash read). During the Flash control register mode, the Flash program control registers are enabled and the Flash array is disabled (i.e., not accessible to CPU).

### 3.3.3 Flash Control Register Access

In addition to the flash memory array, the flash module has four registers that control operations on the flash array. At any given time, you can access the memory array in the flash module (array-access mode) or you can access the control registers (register-access mode) but you cannot access both simultaneously. The flash module has a flash-access control register that selects between the two access modes. This register is the flash control mode register (FCMR) and is mapped at FF0Fh in I/O space. This is a special type of I/O register that cannot be read. The register functions as follows:

- An OUT instruction, using the register address as an I/O port, places the flash module in register-access mode. The data operand used is insignificant. For example:

  ```
  OUT   dummy, 0FF0Fh; Selects register-access mode
  ```

- An IN instruction, using the register address as an I/O port, places the flash module in array-access mode. The data operand used is insignificant. For example:

  ```
  IN    dummy, 0FF0Fh; Selects array-access mode
  ```

The flash array is not directly accessible as memory in register-access mode, and the control registers are not directly accessible in array-access mode. When operating as a program memory to store code, the flash module operates in array-access mode. In user applications, the FCMR is used to power down the flash prior to entering the LPM2 mode.

### 3.3.4 Flash Programming at Variable Frequencies

The embedded flash EEPROM on LF240x/LF240xA devices can be programmed at frequencies ranging from 15 MHz to 40 MHz. For information on configuring the flash programming utilities to program the flash at any particular frequency, refer to the documentation included with the flash programming utilities.
In the case of serial port flash programming utilities, the available number of frequencies is limited further by the serial port synchronization protocol implemented within the Boot ROM. See Appendix C, *TMS320F240x Boot ROM Loader: Protocols and Interfacing.*

### 3.4 Overview of Memory and I/O Spaces

The 240xA design is based on an enhanced Harvard architecture. These devices have multiple memory spaces accessible on three parallel buses: a program address bus (PAB), a data-read address bus (DRAB), and a data-write address bus (DWAB). Each of the three buses access different memory spaces for different phases of the device’s operation. Because the bus operations are independent, it is possible to access both the program and data spaces simultaneously. Within a given machine cycle, the CALU can execute as many as three concurrent memory operations.

The 240xA address map is organized into three individually selectable spaces:

- **Program memory** (64K words) contains the instructions to be executed, as well as immediate data used during program execution.

- **Data memory** (64K words) holds data used by the instructions.

- **Input/output (I/O) space** (64K words) interfaces to external peripherals and may contain on-chip registers.

These spaces provide a total address space of 192K words. The 240xA devices include on-chip memory to aid in system performance and integration.

The advantages of operating from on-chip memory are:

- Higher performance than external memory (because the wait states required for slower external memories are avoided)
- Lower cost than external memory
- Lower power consumption than external memory

The advantage of operating from external memory is the ability to access a larger address space. Only the 2407A has an external memory interface. Other devices have only on-chip memory. Refer to the device data sheets for the corresponding memory maps.
3.5 Program Memory

In addition to storing the user code, the program memory also stores immediate operands and table information. A maximum of 64K 16-bit words can be addressed in the program memory for 240xA. This number includes on-chip DARAM and flash EEPROM/ROM. Whenever an off-chip memory location needs to be accessed, the appropriate control signals for external access (PS, DS, STRB, etc.) are automatically generated.

Figure 3–1 shows the LF2407A program memory map.

3.5.1 Program Memory Configuration

Two factors determine the configuration of program memory:

- **CNF bit.** The CNF bit (bit 12) of status register ST1 determines whether DARAM B0 is in on-chip program space:
  - **CNF = 0.** The 256 words are mapped as external memory.
  - **CNF = 1.** The 256 words of DARAM B0 are configured for program use. At reset, B0 is mapped to data space (CNF = 0).
**MP/MC pin.** The level on the MP/MC pin determines whether program instructions are read from on-chip flash/ROM or external memory:

- **MP/MC = 0.** The device is configured in microcontroller mode. The on-chip ROM/flash EEPROM is accessible. The device fetches the reset vector from on-chip memory. Accesses to program memory addresses 0000h–7FFFh will be made to on-chip memory in the case of 2407A. Refer to the respective memory maps for other devices.

- **MP/MC = 1.** The device is configured in microprocessor mode. The device fetches the reset vector from external memory. Accesses to program memory addresses 0000h–7FFFh will be made to off-chip memory of the 2407A. Refer to the respective memory maps for other devices.

Regardless of the value of MP/MC, the 240xA fetches its reset vector at location 0000h in program memory. Note that there is no MP/MC pin available on devices that lack an external memory interface.
3.6 Data Memory

Data memory space addresses up to 64K of 16-bit words. 32K words are internal memory (0000h to 7FFFh). Internal data memory includes memory-mapped registers, DARAM, and peripheral memory-mapped registers. The remaining 32K words of memory (8000h to FFFFh) form part of the external data memory. Note that addresses 8000h–FFFFh are not accessible in 2406A, 2404A, and 2402A.

Figure 3–2 shows the data memory map for the 2407A. Each device has three on-chip DARAM blocks: B0, B1, and B2. B0 is configurable as data memory or program memory. It is the same memory block accessible either as data memory or program memory, depending on the CNF bit. Blocks B1 and B2 are available for data memory only. External data memory is available only on the 2407A.

Data memory can be addressed with either of two addressing modes: direct-addressing or indirect-addressing.

When direct addressing is used, data memory is addressed in blocks of 128 words called data pages. Figure 3–3 shows how these blocks are addressed. The entire 64K of data memory consists of 512 data pages labeled 0 through 511. The current data page is determined by the value in the 9-bit data page pointer (DP) in status register ST0. Each of the 128 words on the current page is referenced by a 7-bit offset taken from the instruction that is using direct addressing. Therefore, when an instruction uses direct addressing, you must specify both the data page (with a preceding instruction) and the offset (in the instruction that accesses data memory).

An access to the following address spaces in the data memory is illegal and generates an NMI. In addition to these addresses, an access to any of the reserved addresses within the peripheral register maps is also illegal.

Data Page 0 Address Map

The data memory also includes the device’s memory-mapped registers (MMR), which reside at the top of data page 0 (addresses 0000h–007Fh). Note the following:

- The two registers that can be accessed with zero wait states are:
  - Interrupt mask register (IMR)
  - Interrupt flag register (IFR)

- The test/emulation reserved area is used by the test and emulation systems for special information transfers.

Note: Do Not Write to Test/Emulation Addresses

Writing to the test/emulation addresses can cause the device to change its operating mode, and therefore, affect the operation of an application.
The scratch-pad RAM block (B2) includes 32 words of DARAM that provide for variable storage without fragmenting the larger RAM blocks, whether internal or external. This RAM block supports dual-access operations and can be addressed via any data-memory addressing mode.

Table 3–1 shows the address map of data page 0.

**Data Memory Configuration**

Two factors that contribute to the configuration of data memory are:

- **CNF bit.** The CNF bit (bit 12) of status register ST1 determines whether the on-chip DARAM B0 is mapped to data space or program space.
  - **CNF = 1.** B0 is used for program space.
  - **CNF = 0.** B0 is used for data space.

At reset, B0 is mapped into data space (CNF = 0).

**3.6.1 Global Data Memory**

**Note:**

Global Data Memory is not available in the 240xA. Hence, the global memory allocation register (GREG) is a reserved location and should not be accessed.
### 3.7 I/O Space

The I/O-space memory addresses up to 64K 16-bit words. Figure 3–4 shows the I/O space address map for the 2407A.

Memory 3-15
3.9 Program and Data Spaces

PS and STRB are inactive (high) for accesses to on-chip program memory and data memory. The external data and address busses are active only when accesses are made to external memory locations, except when in bus visibility (BVIS) mode (see section 3.11, Wait-State Generation).

Two cycles are required on all external writes, including a half-cycle before WE goes low and a half-cycle after WE goes high. This prevents data contention on the external buses.

3.10 I/O Space

I/O space accesses are distinguished from program and data memory accesses by IS going low. All 64K I/O words (external I/O port and on-chip I/O registers) are accessed via the IN and OUT instructions.

While accesses are made to the on-chip I/O mapped registers, signals IS and STRB are made inactive, that is, driven to the high state. The external address and data bus is only active when accesses are made to external I/O memory locations.

Two cycles are required on all external writes, including a half-cycle before WE goes low and a half-cycle after WE goes high. This prevents data contention on the external busses.
3.11 Wait-State Generation

Wait states are necessary when you want to interface the 2407A with slower external logic and memory. By adding wait states, you lengthen the time the CPU waits for external memory or an external I/O port to respond when the CPU reads from or writes to that memory or port. Specifically, the CPU waits one extra cycle (one CLKOUT cycle) for every wait state. The wait states operate on CLKOUT cycle boundaries.

To avoid bus conflicts, writes from the 2407A always take at least two CLKOUT cycles. The 2407A offers two options for generating wait states:

- **The READY signal.** With the READY signal, you can externally generate any number of wait states.
- **The on-chip wait-state generator.** With this generator, you can generate zero to seven wait states.

3.11.1 Generating Wait States With the READY Signal

When READY is low, the 2407A waits one CLKOUT cycle and checks READY again. The 2407A will not continue executing until READY is driven high; therefore, if the READY signal is not used, it should be pulled high during external accesses.

The READY pin can be used to generate any number of wait states. However, when the 2407A operates at full speed, it cannot respond fast enough to provide a READY-based wait state for the first cycle. For extended wait states using external READY logic, the on-chip wait-state generator must be programmed to generate at least one wait state.

Note: The READY pin has no effect on accesses to internal memory.

3.11.2 Generating Wait States With the 2407A Wait-State Generator

The software wait-state generator can be programmed to generate zero to seven wait states for a given off-chip memory space (program, data, or I/O). This wait-state generator has the bit fields shown in Figure 3–7 and described after the figure.
Figure 3–7. 2407A Wait-State Generator Control Register (WSGR) — I/O-Space Address FFFFh (2407A)

<table>

<td>W-111</td>
<td>W-111</td>
<td>W-111</td>
</tr>
</tbody>
</table>

**Note:** 0 = Always read as zeros; W = Write access; -n = value after reset

**Bits 15–11**  **Reserved.** Bits 15–11 are reserved and always read as 0s.

**Bits 10–9**  **Bus visibility modes.** Bits 10–9 allow selection of various bus visibility modes while running from internal program and/or data memory. These modes provide a method of tracing internal bus activity.

- **Bit 10**  **Bit 9**  **Visibility mode**
  - 0 0 Bus visibility OFF (reduces power and noise)
  - 0 1 Bus visibility OFF (reduces power and noise)
  - 1 0 Data-address bus output to external address bus
  - 1 1 Program-address bus o/p to external address bus

**Note:** On the 2407A device, the bus visibility is turned off until the device is unsecured.

**Bits 8–6**  **ISWS — I/O-space wait-state bits.** Bits 8–6 determine the number of wait states (0–7) that are applied to reads from and writes to off-chip I/O space. At reset, the three ISWS bits become 111, setting seven wait states for reads from and writes to off-chip I/O space.

**Bits 5–3**  **DSWS — Data-space wait-state bits.** Bits 5–3 determine the number of wait states (0–7) that are applied to reads from and writes to off-chip data space. At reset, the three DSWS bits become 111, setting seven wait states for reads from and writes to off-chip data space.

**Bits 2–0**  **PSWS — Program-space wait-state bits.** Bits 2–0 determine the number of wait states (0–7) that are applied to reads from and writes to off-chip program space. At reset, the three PSWS bits become 111, setting seven wait states for reads from and writes to off-chip program space.

Table 3–3 shows how to set the number of wait states you want for each type of off-chip memory.

</tbody>
</table>

In summary, while the READY signal remains high, the wait-state generator inserts from zero to seven wait states to a given memory space, depending on the values of PSWS, DSWS, and ISWS. The READY signal may then be driven low to generate additional wait states. If m is the number of CLKOUT cycles required for a particular read or write operation and w is the number of wait states added, the operation will take (m + w) cycles. At reset, all WSGR bits are set to 1, making seven wait states the default for every memory space.
The 240xA devices use the phase-locked loop (PLL) circuit embedded in the 240xA CPU core to synthesize the on-chip clocks from a lower frequency external clock.
4.1 Pins

There are three device pins associated with clocks:

- **XTAL1/CLKIN** – This is the clock input from the external crystal to the on-chip oscillator. If an external oscillator is used, its output must be connected to this pin.

- **XTAL2** – This is the clock output from the on-chip oscillator to drive the external crystal.

- **CLKOUT/IOPE0** – This is the clock output pin. It is multiplexed with GPIO pin IOPE0. This pin can be used to output the device (CPU) clock or the watchdog timer clock. The clock select control bits are in System Control and Status Register 1 (SCSR1), described in section 2.2.1 on page 2-3. This pin is configured to output CLKOUT from the CPU following a device reset.

4.2 Phase-Locked Loop (PLL)

The PLL used in the 240xA device is different than the one used in the 24x device. The 240xA PLL supports multiplication factors ranging from 0.5 to 4 times the input clock frequency.

4.2.1 Overview

This module contains a phased-locked loop (PLL), crystal oscillator, clock monitor circuit, clock enable circuit, and prescaler.

The purpose of using a PLL is to multiply the external frequency reference to a higher frequency for use internally. This avoids having high frequency signals sent to externally packaged pins, which could cause excessive EMI. PLLs also avoid the use of crystals above 20 – 25 MHz. Such crystals usually operate in overtone mode and require extra tank circuit components.

The advantages of using a PLL-based clock module are:

1) Lower EMI due to lower external oscillator frequencies.
2) Lower cost crystals and resonators can be used.
3) Avoids overtone crystals that require tank circuits.

The PLL’s main disadvantage over a simple oscillator is that they can be sensitive to noise if proper board decoupling/layout practices are not adhered to, and thus, require more system-level design effort to insure low jitter, robust operation.
Main features:

- Oscillator operates with both resonators and crystals
- Covers external CLKIN frequencies from 4 MHz to 20 MHz
- External low-pass loop filter allows maximum flexibility and trade-off between acquisition time and noise immunity
- Phase-frequency detector assures lock to the fundamental reference frequency

*Terms applicable to the PLL module:*

- Charge Pump (CP): a circuit used to convert the pulse-width modulated correction signals into an analog control voltage.
- Electro-Magnetic Interference (EMI): the radio frequency noise radiated by a circuit which could disturb the proper operation of other equipment; the radio frequency noise radiated by other equipment which could disturb the proper operation of the subject circuit.
- Jitter: The maximum positive or negative deviation of a clock edge with respect to its normal position within a single clock period expressed in nanoseconds or in percent of one clock period.
- Lock: The condition in which the PLL’s output is synchronized to the phase and frequency of its reference input.
- Phase-Frequency Detector (PFD): a circuit which compares two signals in both phase and frequency. It is not fooled by one signal being a harmonic or sub-harmonic of the other signal.
- Phase Locked Loop (PLL): an oscillator circuit whose output frequency is typically an integer multiple of its reference input frequency.
- Voltage Controlled Oscillator (VCO): an oscillator whose output frequency is proportional to a control voltage input.
4.2.2 Operation

The sections that follow describe the operation and operating modes of the PLL.

4.2.2.1 Resonator/Crystal Oscillator

The oscillator requires two external pins: XTAL1/CLKIN and XTAL2 which are connected to the resonator/crystal and load capacitors (Figure 4–1). The oscillator is a single-stage inverter held in bias by an integrated bias resistor. This resistor is disabled only during leakage test measurements and HALT mode.

Figure 4–1. Reference Resonator/Crystal

To reduce EMI, keep all of these routes short and minimize loop areas.

Note: Validating Resonator/Crystal Vendors

Texas Instruments strongly encourages each customer to submit samples of the device to the resonator/crystal vendor for validation. They are equipped to determine which load capacitors will best tune their resonator/crystal to the DSP for optimum start-up and operation over temperature/voltage extremes. They also factor in a margin for the device process variations.

4.2.2.2 External Oscillator

The PLL can also be driven by an external oscillator whose output is connected to XTAL1/CLKIN pin. XTAL2 is left open in this case.
4.2.2.3 Loop Filter Components

The 240xA PLL needs external R-C components for the loop filter (see device data sheet for more details). Keep the loop filter (R1, C2, and C2) components close to their pins (PLLF and PLLF2). This is the primary entry point for noise which can result in increased jitter.

All PCB traces pertaining to the PLL circuit must be kept as short as possible. In addition, the loop area formed by the loop filter components, PCB traces, and DSP chip should be as small as possible. A bypass capacitor (0.1 µF to 0.01 µF, ceramic) should be connected between the PLLVCCA and VSS pins.

4.2.2.4 Power Connections

The diagram of Figure 4–2 illustrates how to minimize jitter and EMI by properly filtering VDD, and by using private traces up to the pins as much as possible.

While Cbypass is required for proper circuit operation, the “T” filter is optional and is needed only if minimal CPU CLOCK jitter is required in the application. This is a function of the amount of system noise on the circuit board. Because this noise is difficult to quantify, optimal results are obtained experimentally.

Figure 4–2. Power and Ground Connections
You should adhere to the following guidelines when connecting the PLL pins:

1) Connect the VCCA pin to the low-pass T filter with short leads. This 10-MHz cutoff filter is not essential but may improve jitter significantly and reduce EMI.
2) Keep the traces short to ensure that C_bypass (0.01 to 0.1 µF ceramic) is closely coupled to the VCCA and VSS pins.
3) Minimize the loop area formed by these traces, the chip, and the bypass capacitor. Large loop areas increase EMI. Avoid nearby noisy traces which may couple noise back into the clock module pins.

### 4.2.3 PLL-Bypass Mode

The 240x/240xA devices feature a mode in which the on-chip PLL can be bypassed. This mode is entered by pulling the TRST, TMS, and TMS2 pins low upon reset. In this mode, not only is the PLL bypassed, but so is the PLL clock prescaler. Therefore, changing SCSR1 register bits 11, 10, and 9 in bypass mode will have no effect. The only way to change the speed in bypass mode is to change the input frequency. For example, if a CPU clock speed of 30 MHz is desired, then a 30 MHz CLkin must be supplied. To summarize, the device operates at the same speed as the input clock frequency. The external loop filter components are not needed in the bypass mode.

#### 4.2.3.1 Input Clock Specification in PLL-Bypass Mode

- If the on-chip oscillator is used (i.e., a quartz crystal/ceramic resonator is used as the clock source), then the min and max CLkin frequencies are 4 MHz and 20 MHz, respectively.
- If the on-chip oscillator is not used (i.e., an external oscillator is used as the clock source), then the min and max CLkin frequencies are 4 MHz and 40 MHz (30 MHz for 240x devices), respectively.
4.3 Watchdog Timer Clock

A low frequency clock, WDCLK, is used to clock the watchdog timer. WDCLK has a nominal frequency of 78125 Hz when CPUCLK = 40 MHz. WDCLK is derived from the CLKOUT of the CPU. This ensures that the watchdog timer continues to count when the CPU is in IDLE1 or IDLE 2 mode (see section 4.4, Low-Power Modes, on page 4-8).

The WDCLK is generated in the watchdog timer peripheral.

\[
WDCLK = \frac{CLKOUT}{512}
\]

4.3.1 Watchdog Suspend

WDCLK is stopped when the CPU’s suspend signal goes active. This is achieved by stopping the clock input to the clock divider, which generates WDCLK from CLKIN.
4.4 Low-Power Modes

The 240xA has an IDLE instruction. When executed, the IDLE instruction stops the clocks to all circuits in the CPU; however, the clock output from the CPU continues to run. With this instruction, the CPU clocks can be shut down to save power. The CPU exits the IDLE state if it resets or if it receives an interrupt request.

4.4.1 Clock Domains

All 240xA-based devices have the following two clock domains:

- The CPU clock domain consists of the clock for most of the CPU logic.
- The system clock domain consists of the peripheral clock (which is derived from CLKOUT of the CPU) and the clock for the interrupt logic in the CPU.

When the CPU goes into IDLE mode, the CPU clock domain is stopped while the system clock domain continues to run. This mode is also known as IDLE1 mode. The 240xA CPU contains support for a second IDLE mode, IDLE2, implemented in external logic. By asserting the IDLE2 input to the 240xA CPU, both the CPU clock domain and the system clock domain are stopped, allowing further power savings. A third low-power mode, HALT mode, which is the deepest mode, is possible if the oscillator and WDCLK are also shut down. In HALT mode, the input clock to the PLL is shut off.

The low-power modes do not change the state of the GPIO pins. The pins maintain the same state which they were in prior to entering the low-power mode. Also, the GPIO pins are not put into the high-impedance state and the internal pullup/pulldown is not turned off while in low-power modes.

There are two control bits, LPM (1:0) that specify which of the three possible low-power modes is entered when the IDLE instruction is executed. This is described in Table 4–1. These bits are located in system control and status register 1 (SCSR1) described in section 2.2.1, on page 2-3.
4.4.2 Wake-Up From Low-Power Modes

A wake-up from a low-power mode can occur for several reasons. The sections that follow describe how the device exits low-power modes.

4.4.2.1 Reset

A reset (from any source) causes the device to exit any of the IDLE modes. If the device is halted, the reset initially starts the oscillator; however, initiation of the CPU reset sequence may be delayed while the oscillator powers up before clocks are generated.

4.4.2.2 External interrupts

The external interrupts, XINTx, can cause the device to exit any of the low-power modes, except HALT. If the device is in IDLE2 mode, the synchronous logic connected to the external interrupt pins is bypassed with combinatorial logic that recognizes the interrupt on the pin, starts the clocks, and then allows the clocked logic to generate an interrupt request to the PIE controller.

4.4.2.3 Wake-Up Interrupts

Some peripherals have the capability to start the device clocks and then generate an interrupt in response to certain external events, such as activity on a communication line. As an example, the CAN wake-up interrupt can assert the CAN error interrupt request even when there are no clocks running.
4.4.2.4 Exiting Low-Power Modes — Some Examples

As outlined in Table 4−1, peripheral interrupts are used to wake up the device from different low-power modes. The “wake-up” action (and the subsequent behavior of the device) is dependent upon the following:

- Whether the peripheral interrupt in question has been enabled at the peripheral level
- Whether the IMR.n bit corresponding to the peripheral interrupt in question has been enabled
- The status of the INTM bit in the ST0 register

Following are two examples of low-power mode wake-up:

1) Using XINT1 to wake up from LPM0

When XINT1 is used to wake up the device from LPM0, two things can happen based on how the XINT1 interrupt is configured. If the XINT1 interrupt is enabled (by setting the appropriate bit in the XINT1CR register and setting bit 0 in IMR to 1) and the INTM bit is zero, a valid XINT1 signal will first take the device out of LPM0 and will also force the device to the appropriate interrupt vector. However, if INTM = 1, upon an XINT1 interrupt, the DSP will wake up and continue executing the instruction following the IDLE instruction.

2) Using PDPINTA to wake up from LPM2 (HALT)

Case 1:
PDPINTA is enabled at peripheral level; the corresponding IMR bit is 1 (enabled); INTM = 0 – Upon wake-up from HALT, code branches to INT1 vector.

Case 2:
PDPINTA is enabled at peripheral level; the corresponding IMR bit is 1 (enabled); INTM = 1 – Upon wake-up from HALT, code starts executing the next instruction after the IDLE instruction.

Case 3:
PDPINTA is enabled at peripheral level; the corresponding IMR bit is 0 (disabled); INTM = 1 – Device does not come out of LPM2.

NOTES:

1) Clock to EVA must be enabled in order for PDPINTA to pull the device out of reset.

2) When the PDPINTA pin is used to wake up the device from LPM2, it must be held low for 4096 CLKIN cycles + (6 or 12) CLKOUT cycles. For a device with a 10-MHz CLKIN and 40-MHz
CLKOUT, this translates into about 410 µs. The 4096 cycles are required to initiate a clock output to the CPU. The remaining 12 cycles trigger a valid PDPINTA interrupt.

3) PDPINTA has both a synchronous path and an asynchronous path. The asynchronous path is used to wake up from HALT; i.e., the clocks are turned on asynchronously by PDPINTA. Once clocks start, it generates an interrupt. However, PDPINTA must be held low long enough for the first clock’s edge to catch it.

4.4.3 Powering Down the Flash

The Flash module can be powered down before entering the LPM2 mode. This operation is done while executing code from on-chip RAM, such as SARAM or B0. This mode achieves the lowest possible current consumption. Following is the sequence of instructions that powers down the Flash module:

```
; Flash-module power-down routine
;-----------------------------------
LDP #0h ; Set DP=0
SPLK #0008h,60h ; 0008 puts the flash in powerdown mode
OUT 60h,0FF0Fh ; Puts the FLASH in control reg access mode
LACL #0h ; 0000h is the address of the Pump Control Register
TBLW 60h ; This write powers down the flash.
```

The LPM2 mode can be exited by using either the RS or PDPINTx signals. While RS automatically powers up the Flash module, the following sequence of instructions should be executed if PDPINTx is used (to exit LPM2) to power up the Flash module:

```
; Flash-module power-up routine
;-----------------------------------
LDP #0h ; Set DP=0
SPLK #0000h,60h ; 0000 pulls the flash out of powerdown mode
OUT 60h,0FF0Fh ; Puts the FLASH in control reg access mode
LACL #0h ; 0000h is the address of the Pump Control Register
TBLW 60h ; This write powers up the FLASH.
IN 60h,0FF0Fh ; Puts the FLASH in Array access mode
```

---

*Clocks and Low-Power Modes*
After the Flash is powered up, a read of a known location in Flash may be done to ensure that the Flash is ready for application use. For example, 0000h in Program memory usually has a “branch” instruction whose opcode is 7980h. Therefore, address 0000h could be read and checked for 7980h to validate Flash power-up.
The digital I/O ports module provides a flexible method for controlling both dedicated I/O and shared pin functions. All I/O and shared pin functions are controlled using nine 16-bit registers. These registers are divided into two types:

- I/O MUX Control registers (MCRx) – Used to control the multiplexor selection that chooses between the primary function of a pin or the general-purpose I/O function.

- Data and Direction Control registers (PxDATDIR) – Used to control the data and data direction of bidirectional I/O pins.

The GPIO pins are controlled through “data-memory mapped registers.” Note that there is no relationship between the GPIO pins and the I/O space of the device.

5.1 Digital I/O Ports Register Implementation on 240xA Devices

Table 5–1 lists the registers available to the digital I/O module as implemented on the 240xA devices. These registers are memory-mapped to data space from 7090h through 709Fh. All reserved bits are unimplemented: reads return zero and writes have no effect.

Note that when multiplexed I/O pins are configured for peripheral functions or as GPIO outputs, the pin status can be monitored by reading the I/O data register.

5.2 Differences in GPIO Implementation in the 240xA

There are several differences in the 240xA GPIO implementation when compared with the 241/242/243.

- In the 240xA devices, when the bit value in an MCRx register (OCRx register in 24x) is one, the primary function is always chosen. Likewise, when the bit value is zero, the GPIO function is always chosen. There are no exceptions, as in the case of 24x, where XF, BIT, and CLKOUT pins have a different configuration.

- Also, some pins (such as XF and CLKOUT) are paired with different GPIO pins compared to the 24x (i.e., the "primary function/GPIO pin" mapping/pairing is not exactly identical to the 24x.

- Due to the addition of two GPIO ports, E and F, a new MUX Control register (MCRC) has been added.

5.3 I/O Mux Control Registers

There are three I/O mux control registers: I/O mux control register A (MCRA), I/O mux control register B (MCRB), and I/O mux control register C (MCRC).

Notes:

1. Due to the absence of the W/R/IOPC0, BIO/IOPC1, and SPISTE/IOPC5 pins, bits 0, 1, and 5 of MCRB must be treated as reserved in the 2402A.

2. Due to the absence of SPI and CAN modules (in 2402A), bits 2, 3, 4, 6, and 7 of MCRB should always be written with 0. The corresponding pins work as GPIO pins only.

3. Due to the absence of the CAN module and W/R function in 2404A, bits 0, 6, and 7 of MCRB should always be written with 0. The corresponding pins work as GPIO pins only.

4. Due to the absence of the W/R function in 2406A, bit 0 of MCRB should always be written with 0. The corresponding pin works as a GPIO pin only.
5.3.3 I/O Mux Output Control Register C

† These pins are not available on 2402A devices.
This chapter describes the 240xA Event Manager (EV) module. Most of the EV pins are shared with general-purpose digital I/O signals. This pin sharing and how it is controlled is described in Chapter 5, *Digital Input/Output (I/O)*.

The EV module provides a broad range of functions and features that are particularly useful in motion control and motor control applications. There are differences in terms of the functionality between the EV module of 240xA devices and the EV module of 240 devices. (However, the EV modules in the 24x and 240xA families of DSPs are exactly identical in terms of functionality.)

Note that all devices of the 240xA family (with the exception of the 2402A) have two EV modules as opposed to one EV module in the 241/242/243 devices.

6.1 Event Manager (EV) Functional Blocks

All devices of the 240xA family, with the exception of the 2402A, have two event managers, EVA and EVB. These two event managers are exactly identical to each other in terms of functionality and register mapping/bit definition. For the sake of brevity, only the functionality of EVA is explained. Minor differences (such as naming conventions and register addresses) are highlighted as appropriate.

Each EV module in the 240xA device contains the following functional blocks:

- Two general-purpose (GP) timers (described in section 6.3 on page 6-14)
- Three compare units (described in section 6.4 on page 6-39)
- Pulse-width modulation (PWM) circuits that include space vector PWM circuits, dead-band generation units, and output logic (described in section 6.5 on page 6-48, section 6.6 on page 6-57, and section 6.7 on page 6-62, respectively)
- Three capture units (described in section 6.8 on page 6-68)
- Quadrature encoder pulse (QEP) circuit (described in section 6.9, on page 6-80)
- Interrupt logic (described in section 6.10 on page 6-84)

Figure 6−1 shows a block diagram of the EVA module and Figure 6−2 shows a block diagram of the EVB module.
Figure 6–1. Event Manager A (EVA) Block Diagram
Figure 6–2. Event Manager B (EVB) Block Diagram
6.1.1 Differences Between C240 EV and 240xA EV

- The single-up count and single-up/down count modes have been removed from the remaining GP timers. **Software change:** The four timer modes are now decoded with TMODE1–0. This decoding is different from the C240 EV. TMODE2 is now a reserved bit.
- There is no 32-bit timer mode.
- The GP Timers do not stay at the period register value, FFFh or 0000h when operating in directional-up/down count mode (including QEP mode). They now reverse direction when one of these end points is reached.
- A capture 3 event is now able to start the ADC.
- The capture units of a particular EV can now use any timer associated with that EV as a time base.
- The capture interrupt flag gets set when a capture event occurs only if there are one or more capture events stored in the FIFO already.
- The Capture FIFO status bits are now RW. Bits 5–0 of CAPFIFO are now unnecessary and are reserved.
- Both locations in the capture FIFO can be read individually, not just the top location.
- The QEP logic can only clock GP timer 2 for EVA and GP timer 4 for EVB.
- The three simple compare units have been removed.
- The compare mode of the (full) compare units has been removed. They now only operate in PWM mode.
- The dead band counters have been reduced from 8 bits to 4 bits. The dead band prescaler has been increased from 3 bits to 5 bits, adding two more prescale values: x/16 and x/32. **Software change:** There are now three DBTPSx bits. DBTPS0 moves to bit 2 of DBTCON, DBTPS1 moves to bit 2 of DBTCON, DBTPS1 moves to bit 3, and bit 4 becomes DBTPS2.
- Any register bits associated with the removed functions are now reserved (not implemented).
- Most interrupt control logic has been removed from each peripheral. Each peripheral now simply has one interrupt request signal and associated enable for each interrupt flag. The peripheral interrupt vector table (containing the peripheral interrupt vectors) is now located in the peripheral interrupt expansion (PIE) controller.
Software writing a 1 to the interrupt flag, which has been identified by the interrupt vector ID, is required to clear the flag. Reading the interrupt vector ID no longer automatically clears the associated flag.

PDPINTA/B is now enabled following reset.

Only one write is required to initialize COMCONA/B, not two as on the C240.

### 6.1.2 EV Pins

Each EV module has eight device pins available for compare/PWM outputs:

- **Two GP timer compare/PWM output pins:**

<table>
<thead>
<tr>
<th>EVA</th>
<th>EVB</th>
</tr>
</thead>
<tbody>
<tr>
<td>T1CMP/T1PWM</td>
<td>T3CMP/T3PWM</td>
</tr>
<tr>
<td>T2CMP/T2PWM</td>
<td>T4CMP/T4PWM</td>
</tr>
</tbody>
</table>

- **Six (full) compare/PWM output pins:**

<table>
<thead>
<tr>
<th>EVA</th>
<th>EVB</th>
</tr>
</thead>
<tbody>
<tr>
<td>PWM1</td>
<td>PWM7</td>
</tr>
<tr>
<td>PWM2</td>
<td>PWM8</td>
</tr>
<tr>
<td>PWM3</td>
<td>PWM9</td>
</tr>
<tr>
<td>PWM4</td>
<td>PWM10</td>
</tr>
<tr>
<td>PWM5</td>
<td>PWM11</td>
</tr>
<tr>
<td>PWM6</td>
<td>PWM12</td>
</tr>
</tbody>
</table>

The EVA module uses three device pins, CAP1/QEP1, CAP2/QEP2, and CAP3, as capture or quadrature encoder pulse inputs.

The EVB module uses three device pins, CAP4/QEP3, CAP5/QEP4, and CAP6, as capture or quadrature encoder pulse inputs.

The timers in the EV module can be programmed to operate based on an external clock or the internal device clock. The device pin TCLKINA/B supplies the external clock input.

The device pin TDIRA/B is used to specify the counting direction when a GP timer is in directional up-/down-counting mode.

The device pins are summarized in Table 6–1, *Event Manager A Pins*, and Table 6–2, *Event Manager B Pins*.

### 6.1.3 Power Drive Protection Interrupt (PDPINTx, x = A or B)

The PDPINTx is a safety feature that is provided for the safe operation of systems such as power converters and motor drives. PDPINTx can be used to inform the monitoring program of motor drive abnormalities such as over-voltage, over-current, and excessive temperature rise. If the PDPINTx interrupt is unmasked, all PWM output pins will be put in the high-impedance state immediately after the PDPINTx pin is driven low. An interrupt will also be generated.

The interrupt flag associated with PDPINTx is also set when such an event occurs; however, it must wait until the transition on PDPINTx has been qualified and synchronized with the internal clock. The qualification and synchronization cause a delay of two clock cycles. The setting of the flag does not depend on whether or not the PDPINTx interrupt is masked: it happens when a qualified transition occurs on the PDPINTx pin. This interrupt is enabled following reset. If the PDPINTx interrupt is disabled, the action of driving the PWM outputs to the high-impedance state (upon a valid PDPINTx interrupt) is also disabled.
6.1.3.1 240xA-Specific Features for PDPINTx Function

- In 240xA devices, the status of the PDPINTx pin is reflected in bit 8 of the COMCONx register.
- The PDPINTx pin must be held low for 6 (or 12) CLKOUT cycles before it is recognized by the core.

6.1.4 EV Registers

The Event Manager registers occupy two 64-word (16-bit) frames of address space. The Event Manager module decodes the lower six-bits of the address; while the upper 10 bits of the address are decoded by the peripheral address decode logic, which provides a module select to the Event Manager when the peripheral address bus carries an address within the range designated for the EV on that device.

On 240xA devices (as with the C240 device), EVA registers are located in the range 7400h to 7431h. EVB registers are located in the range of 7500h to 7531h.

The undefined registers and undefined bits of the EV registers all return zero when read by user software. Writes have no effect. See Section 6.2, Event Manager(EV) Register Addresses, on page 6-11.

6.1.5 EV Interrupts

The Event Manager interrupts are arranged into three groups. Each group is assigned one CPU interrupt (INT2, 3 or 4). Since each group has multiple interrupt sources, the CPU interrupt requests are processed by the peripheral interrupt expansion (PIE) module. The 240xA interrupt requests have the following stages of response:

- **Interrupt source.** If peripheral interrupt conditions occur, the respective flag bits in registers EVxIFRA, EVxIFRB, or EVxIFRC (x = A or B) are set. Once set, these flags remain set until explicitly cleared by the software. It is mandatory to clear these flags in the software or future interrupts will not be recognized.

- **Interrupt enable.** The Event Manager interrupts can be individually enabled or disabled by interrupt mask registers EVxIMRA, EVxIMRB, and EVxIMRC (x = A or B). Each bit is set to 1 to enable/unmask the interrupt or cleared to 0 to disable/mask the interrupt.
**Event Manager (EV) Functional Blocks**

- **PIE request.** If both interrupt flag bits and interrupt mask bits are set, then the peripheral issues a peripheral interrupt request to the PIE module. The PIE module can receive more than one interrupt from the peripheral. The PIE logic records all the interrupt requests and generates the respective CPU interrupt (INT1, 2, 3, or 4) based on the preassigned priority of the received interrupts. See Table 2–2, *240xA Interrupt Source Priority and Vectors*, on page 2-9 for priority and vector values.

- **CPU response.** On receipt of an INT1, 2, 3, or 4 interrupt request, the respective bit in the CPU interrupt flag register (IFR) will be set. If the corresponding interrupt mask register (IMR) bit is set and INTM bit is cleared, then the CPU recognizes the interrupt and issues an acknowledgement to the PIE. Following this, the CPU finishes executing the current instruction and branches to the interrupt vector corresponding to INT1, 2, 3, or 4. At this time, the respective IFR bit will be cleared and the INTM bit will be set disabling further interrupt recognition. The interrupt vector contains a branch instruction for the interrupt service routine. From here, the interrupt response is controlled by the software.

- **PIE response.** The PIE logic uses the acknowledge signal from the core to clear the PIRQ bit that issued the CPU interrupt. Along with this, the PIE updates its PIVR register with the interrupt vector, unique to the peripheral interrupt, that was just acknowledged. After this, the PIE hardware works in parallel to the current interrupt software to generate a CPU interrupt and other pending interrupts, if any.

- **Interrupt software.** The interrupt software has two levels of response.
  
  - **Level 1 (GISR).** In the first level the software should do any context save and read the PIVR register from PIE module to decide which interrupt group caused the interrupt. Since the PIVR value is unique, it can be used to branch to the interrupt service routine specific to this interrupt condition.

  - **Level 2 (SISR).** This level is optional and could reside as a part of level 1. However, at this stage the interrupt software has explicit responsibility to avoid improper interrupt response. After executing the interrupt specific code, the routine should clear the interrupt flag in the EVxIFRA, EVxIFRB, or EVxIFRC that caused the serviced interrupt. Code will return after enabling the CPU’s global interrupt bit INTM (clear INTM bit).
6.2 Event Manager (EV) Register Addresses

6.3 Figure 6−13 General-Purpose (GP) Timers

There are two general-purpose (GP) timers in each module. These timers can be used as independent time bases in applications such as:

- The generation of a sampling period in a control system
- Providing a time base for the operation of the quadrature encoder pulse (QEP) circuit (GP timer 2/4 only) and the capture units
- Providing a time base for the operation of the compare units and associated PWM circuits to generate PWM outputs

**Timer Functional Blocks**

Figure 6−3 shows a block diagram of a GP timer. Each GP timer includes:

- One readable and writeable (RW) 16-bit up and up/down counter register TxCNT (x = 1, 2, 3, 4) (see Figure 6−4). This register stores the current value of the counter and keeps incrementing or decrementing depending on the direction of counting.
- One RW 16-bit timer compare register (shadowed), TxCMPR (x = 1, 2, 3, 4) (see Figure 6−5)
- One RW 16-bit timer period register (shadowed), TxPR (x = 1, 2, 3, 4) (see Figure 6−6)
- RW 16-bit individual timer control register, TxCON (x = 1, 2, 3, 4) (see Figure 6−13)
- Programmable prescaler applicable to both internal and external clock inputs
- Control and interrupt logic
- One GP timer compare output pin, TxCMP (x = 1, 2, 3, 4)
- Output conditioning logic

Another overall control register, GPTCONA/B, specifies the action to be taken by the timers on different timer events, and indicates the counting directions of the GP timers. GPTCONA/B is readable and writeable, although writing to the status bits has no effect.

**Note:**

Timer 2 can select the period register of timer 1 as its period register. In Figure 6−3, the mux is applicable only when the figure represents timer 2.

Timer 4 can select the period register of timer 3 as its period register. In Figure 6−3, the mux is applicable only when the figure represents timer 4.

GP Timer Inputs

The inputs to the GP timers are:

- The internal device (CPU) clock
- An external clock, TCLKINA/B, that has a maximum frequency of one-fourth that of the device clock
Direction input, TDIRA/B, for use by the GP timers in directional up-/down-counting mode

Reset signal, RESET

When a timer is used with the QEP circuit, the QEP circuit generates both the timer’s clock and the counting direction.

**GP Timer Outputs**

The outputs of the timers are:

- GP timer compare outputs TxCMP, x = 1, 2, 3, 4
- ADC start-of-conversion signal to ADC module
- Underflow, overflow, compare match, and period match signals to its own compare logic and to the compare units
- Counting direction indication bits

**Individual GP Timer Control Register (TxCON)**

The operational mode of a timer is controlled by its individual control register TxCON. Bits in the TxCON register determine:

- Which of the four counting modes the timer is in
- Whether an internal or external clock is to be used by the GP timer
- Which of the eight input clock prescale factors (ranging from 1 to 1/128) is used
- On which condition the timer compare register is reloaded
- Whether the timer is enabled or disabled
- Whether the timer compare operation is enabled or disabled
- Which period register is used by timer 2, its own, or timer 1’s period register (EVA)
- Which period register is used by timer 4, its own, or timer 3’s period register (EVB)

**Overall GP Timer Control Register (GPTCONA/B)**

The control register GPTCONA/B specifies the action to be taken by the timers on different timer events and indicates their counting directions.
**General-Purpose (GP) Timers**

**GP Timer Compare Registers**

The compare register associated with a GP timer stores the value to be constantly compared with the counter of the GP timer. When a match happens, the following events occur:

- A transition occurs on the associated compare output according to the bit pattern in GPTCONA/B
- The corresponding interrupt flag is set
- A peripheral interrupt request is generated if the interrupt is unmasked

The compare operation of a GP timer can be enabled or disabled by the appropriate bit in TxCON.

The compare operation and outputs can be enabled in any of the timer modes, including QEP mode.

**GP Timer Period Register**

The value in the period register of a GP timer determines the period of the timer. A GP timer resets to 0, or starts counting downward when a match occurs between the period register and the timer counter, depending on which counting mode the timer is in.

**Double Buffering of GP Timer Compare and Period Registers**

The compare and period registers, TxCMPR and TxPR, of a GP timer are shadowed. A new value can be written to any of these registers at any time during a period. However, the new value is written to the associated shadow register. For the compare register, the content in the shadow register is loaded into the working (active) register only when a certain timer event specified by TxCON occurs. For the period register, the working register is reloaded with the value in its shadow register only when the value of the counter register TxCNT is 0. The condition on which a compare register is reloaded can be one of the following:

- Immediately after the shadow register is written
- On underflow; that is, when the GP timer counter value is 0
- On underflow or period match; that is, when the counter value is 0 or when the counter value equals the value of the period register

The double buffering feature of the period and compare registers allows the application code to update the period and compare registers at any time during
a period in order to change the timer period and the width of the PWM pulse for the period that follows. On-the-fly change of the timer period value, in the case of PWM generation, means on-the-fly change of PWM carrier frequency.

**Note:**
The period register of a GP timer should be initialized before its counter is initialized to a non-zero value. Otherwise, the value of the period register will remain unchanged until the next underflow.

Note that a compare register is transparent (the newly loaded value goes directly into the active register) when the associated compare operation is disabled. This applies to all Event Manager compare registers.

**GP Timer Compare Output**

The compare output of a GP timer can be specified active high, active low, forced high, or forced low, depending on how the GPTCONA/B bits are configured. It goes from low to high (high to low) on the first compare match when it is active high (low). It then goes from high to low (low to high) on the second compare match if the GP timer is in an up-/down-counting mode, or on period match if the GP timer is in up-counting mode. The timer compare output becomes high (low) right away when it is specified to be forced high (low).

**Timer Counting Direction**

The counting directions of the GP timers are reflected by their respective bits in GPTCONA/B during all timer operations as follows:

- 1 represents the up-counting direction
- 0 represents the down-counting direction

The input pin TDIRA/B determines the direction of counting when a GP timer is in directional up-/down-counting mode. When TDIRA/B is high, upward counting is specified; when TDIRA/B is low, downward counting is specified.

**Timer Clock**

The source of the GP timer clock can be the internal device clock or the external clock input, TCLKINA/B. The frequency of the external clock must be less than or equal to one-fourth of that of the device clock. GP timer 2 (EVA) and GP timer 4 (EVB) can be used with the QEP circuits, in directional
General-Purpose (GP) Timers

up-/down-counting mode. In this case, the QEP circuits provide both the clock and direction inputs to the timer.

A wide range of prescale factors are provided for the clock input to each GP timer.

QEP-Based Clock Input

The quadrature encoder pulse (QEP) circuit, when selected, can generate the input clock and counting direction for GP timer 2/4 in the directional up-/down-counting mode. This input clock cannot be scaled by GP timer prescaler circuits (that is, the prescaler of the selected GP timer is always one if the QEP circuit is selected as the clock source). Furthermore, the frequency of the clock generated by the QEP circuits is four times that of the frequency of each QEP input channel because both the rising and falling edges of both QEP input channels are counted by the selected timer. The frequency of the QEP input must be less than or equal to one-fourth of that of the device clock.

GP Timer Synchronization

GP timer 2 can be synchronized with GP timer 1 (for EVA) and GP timer 4 can be synchronized with GP timer 3 (for EVB) by proper configuration of T2CON and T4CON, respectively, in the following ways:

- EVA:
  Set the T2SWT1 bit in T2CON to start GP timer 2 counting with the TENABLE bit in T1CON (thus, both timer counters start simultaneously)

- EVA:
  Initialize the timer counters in GP timers 1 and 2 with different values before starting synchronized operation

- EVA:
  Specify that GP timer 2 uses the period register of GP timer 1 as its period register (ignoring its own period register) by setting SELT1PR in T2CON

- EVB:
  Set the T4SWT3 bit in T4CON to start GP timer 4 counting with the TENABLE bit in T3CON (thus, both timer counters start simultaneously)

- EVB:
  Initialize the timer counters in GP timers 3 and 4 with different values before starting synchronized operation

- EVB:
  Specify that GP timer 4 uses the period register of GP timer 3 as its period register (ignoring its own period register) by setting SELT3PR in T4CON
This allows the desired synchronization between GP timer events. Since each GP timer starts the counting operation from its current value in the counter register, one GP timer can be programmed to start with a known delay after the other GP timer.

**Starting the A/D Converter with a Timer Event**

The bits in GPTCONA/B can specify that an ADC start signal be generated on a GP timer event such as underflow, compare match, or period match. This feature provides synchronization between the GP timer event and the ADC start without any CPU intervention.

**GP Timer in Emulation Suspend**

The GP timer control register bits also define the operation of the GP timers during emulation suspend. These bits can be set to allow the operation of GP timers to continue when an emulation interrupt occurs making in-circuit emulation possible. They can also be set to specify that the operation of GP timers stops immediately, or after completion of the current counting period, when emulation interrupt occurs.

Emulation suspend occurs when the device clock is stopped by the emulator, for example, when the emulator encounters a break point.

**GP Timer Interrupts**

There are sixteen interrupt flags in the EVAIFRA, EVAIFRB, EVBIFRA, and EVBIFRB registers for the GP timers. Each of the four GP timers can generate four interrupts upon the following events:

- Overflow: TxOFINT \((x = 1, 2, 3, \text{ or } 4)\)
- Underflow: TxUFINT \((x = 1, 2, 3, \text{ or } 4)\)
- Compare match: TxCINT \((x = 1, 2, 3, \text{ or } 4)\)
- Period match: TxPINT \((x = 1, 2, 3, \text{ or } 4)\)

A timer compare event (match) happens when the content of a GP timer counter is the same as that of the compare register. The corresponding compare interrupt flag is set one clock cycle after the match if the compare operation is enabled.
An overflow event occurs when the value of the timer counter reaches FFFFh. An underflow event occurs when the timer counter reaches 0000h. Similarly, a period event happens when the value of the timer counter is the same as that of the period register. The overflow, underflow, and period interrupt flags of the timer are set one clock cycle after the occurrence of each individual event. Note that the definition of overflow and underflow is different from their conventional definitions.

6.3.1 GP Timer Counting Operation

Each GP timer has four possible modes of operation:

- **Stop/Hold mode**
- **Continuous Up-Counting mode**
- **Directional Up-/Down-Counting mode**
- **Continuous Up-/Down-Counting mode**

The bit pattern in the corresponding timer control register TxC0n determines the counting mode of a GP timer. The timer enabling bit, TxC0n[6], enables or disables the counting operation of a timer. When the timer is disabled, the counting operation of the timer stops and the prescaler of the timer is reset to x/1. When the timer is enabled, the timer starts counting according to the counting mode specified by other bits of TxC0n.

**Stop/Hold Mode**

In this mode the GP timer stops and holds at its current state. The timer counter, the compare output, and the prescale counter all remain unchanged in this mode.

**Continuous Up-Counting Mode**

The GP timer in this mode counts up according to the scaled input clock until the value of the timer counter matches that of the period register. On the next rising edge of the input clock after the match, the GP timer resets to zero and starts counting up again.

The period interrupt flag of the timer is set one clock cycle after the match between the timer counter and period register. A peripheral interrupt request is generated if the flag is not masked. An ADC start is sent to the ADC module at the same time the flag is set, if the period interrupt of this timer has been selected by the appropriate bits in GPTCONA/B to start the ADC.
One clock cycle after the GP timer becomes 0, the underflow interrupt flag of the timer is set. A peripheral interrupt request is generated by the flag if it is unmasked. An ADC start is sent to the ADC module at the same time if the underflow interrupt flag of this timer has been selected by appropriate bits in GPTCONA/B to start ADC.

The overflow interrupt flag is set one clock cycle after the value in TxCNT matches FFFFh. A peripheral interrupt request is generated by the flag if it is unmasked.

The duration of the timer period is (TxPR) + 1 cycles of the scaled clock input except for the first period. The duration of the first period is the same if the timer counter is zero when counting starts.

The initial value of the GP timer can be any value between 0h and FFFFh inclusive. When the initial value is greater than the value in the period register, the timer counts up to FFFFh, resets to zero, and continues the operation as if the initial value was zero. When the initial value in the timer counter is the same as that of the period register, the timer sets the period interrupt flag, resets to zero, sets the underflow interrupt flag, and then continues the operation again as if the initial value was zero. If the initial value of the timer is between zero and the contents of the period register, the timer counts up to the period value and continue to finish the period as if the initial counter value was the same as that of the period register.

The counting direction indication bit in GPTCONA/B is one for the timer in this mode. Either the external or internal device clock can be selected as the input clock to the timer. TDIRA/B input is ignored by the GP timer in this counting mode.

The continuous up-counting mode of the GP timer is particularly useful for the generation of edge-triggered or asynchronous PWM waveforms and sampling periods in many motor and motion control systems.

Figure 6–7 shows the continuous up-counting mode of the GP timer.
Figure 6–7. GP Timer Continuous Up-Counting Mode (TxPR = 3 or 2)

As shown in Figure 6–7, GP Timer Continuous Up-Counting Mode (TxPR = 3 or 2), no clock cycle is missed from the time the counter reaches the period register value to the time it starts another counting cycle.

**Directional Up-/Down-Counting Mode**

The GP timer in directional up-/down-counting mode counts up or down according to the scaled clock and TDIRA/B inputs. The GP timer starts counting up until its value reaches that of the period register (or FFFFh if the initial count is greater than the period) when the TDIRA/B pin is held high. When the timer value equals that of its period register (or FFFFh) the timer resets to zero and continues counting up to the period again. When TDIRA/B is held low, the GP timer counts down until its value becomes zero. When the value of the timer has counted down to zero, the timer reloads its counter with the value in the period register and starts counting down again.

The initial value of the timer can be any value between 0000h to FFFFh. When the initial value of the timer counter is greater than that of the period register, the timer counts up to FFFFh before resetting itself to zero and counting up to the period. If TDIRA/B is low when the timer starts with a value greater than the period register, it counts down to the value of the period register and continues counting down to zero, at which point the timer counter gets reloaded with the value from the period register as normal.

The period, underflow, and overflow interrupt flags, interrupts, and associated actions are generated on respective events in the same manner as they are generated in the continuous up-counting mode.

The latency from a change of TDIRA/B to a change of counting direction is one clock cycle after the end of the current count (that is, after the end of the current prescale counter period).
The direction of counting is indicated for the timer in this mode by the corresponding direction indication bit in GPTCONA/B: 1 means counting up; 0 means counting down. Either the external clock from the TCLKINA/B pin or the internal device clock can be used as the input clock for the timer in this mode.

Figure 6–8 shows the directional up-/down-counting mode of the GP timers.

**Continuous Up-/Down-Counting Mode**

This mode of operation is the same as the directional up-/down-counting mode, but the TDIRA/B pin has no effect on the counting direction. The counting direction only changes from up to down when the timer reaches the period value (or FFFFh if the initial timer value is greater than the period). The timer direction only changes from down to up when the timer reaches zero.

The period of the timer in this mode is $2^{*}(\text{TxPR})$ cycles of the scaled clock input, except for the first period. The duration of the first counting period is the same if the timer counter is zero when counting starts.

The initial value of the GP timer counter can be any value between 0h and FFFFh inclusive. When the initial value is greater than that of the period register, the timer counts up to FFFFh, resets to zero, and continues the
General-Purpose (GP) Timers

operation as if the initial value was zero. When the initial value in the timer counter is the same as that of the period register, the timer counts down to zero and continues again as if the initial value was zero. If the initial value of the timer is between zero and the contents of the period register, the timer counts up to the period value and continues to finish the period as if the initial counter value was the same as that of the period register.

The period, underflow, and overflow interrupt flags, interrupts, and associated actions are generated on respective events in the same manner as they are generated in continuous up-counting mode.

The counting direction indication bit for this timer in GPTCONA/B is one when the timer counts upward and zero when the timer counts downward. Either the external clock from the TCLKINA/B pin or the internal device clock can be selected as the input clock. TDIRA/B input is ignored by the timer in this mode.

Figure 6−9 shows the continuous up-/down-counting mode of the GP timer.

Figure 6−9. GP Timer Continuous Up-/Down-Counting Mode (TxPR = 3 or 2)

Continuous up-/down-counting mode is particularly useful in generating centered or symmetric PWM waveforms found in a broad range of motor/motion control and power electronics applications.
6.3.2 GP Timer Compare Operation

Each GP timer has an associated compare register TxCMPR and a PWM output pin TxPWM. The value of a GP timer counter is constantly compared to that of its associated compare register. A compare match occurs when the value of the timer counter is the same as that of the compare register. Compare operation is enabled by setting TxCON[1] to one. If it is enabled, the following happens on a compare match:

- The compare interrupt flag of the timer is set one clock cycle after the match
- A transition occurs on the associated PWM output according to the bit configuration in GPTCONA/B, one device clock cycle after the match
- If the compare interrupt flag has been selected by the appropriate GPTCONA/B bits to start ADC, an ADC start signal is generated at the same time the compare interrupt flag is set

A peripheral interrupt request is generated by the compare interrupt flag if it is unmasked.

**PWM Transition**

The transition on the PWM output is controlled by an asymmetric and symmetric waveform generator and the associated output logic, and depends on the following:

- Bit definition in GPTCONA/B
- Counting mode the timer is in
- Counting direction when the counting mode is continuous-up/-down mode

**Asymmetric/Symmetric Waveform Generator**

The asymmetric/symmetric waveform generator generates an asymmetric or symmetric PWM waveform based on the counting mode the GP timer is in.

**Asymmetric Waveform Generation**

An asymmetric waveform (Figure 6–10) is generated when the GP timer is in continuous up-counting mode. When the GP timer is in this mode, the output of the waveform generator changes according to the following sequence:

- zero before the counting operation starts
- remains unchanged until the compare match happens
toggles on compare match
remains unchanged until the end of the period
resets to zero at the end of a period on period match, if the new compare value for the following period is not zero

The output is one for the whole period, if the compare value is zero at the beginning of a period. The output does not reset to zero if the new compare value for the following period is zero. This is important because it allows the generation of PWM pulses of 0% to 100% duty cycle without glitches. The output is zero for the whole period if the compare value is greater than the value in the period register. The output is one for one cycle of the scaled clock input if the compare value is the same as that of the period register.

One characteristic of asymmetric PWM waveforms is that a change in the value of the compare register only affects one side of the PWM pulse.

**Figure 6–10. GP Timer Compare/PWM Output in Up-Counting Mode**

*Symmetric Waveform Generation*

A symmetric waveform (Figure 6–11) is generated when the GP timer is in continuous up-/down-counting modes. When the GP timer is in this mode, the state of the output of the waveform generator is determined by the following:

- zero before the counting operation starts
- Remains unchanged until first compare match
General-Purpose (GP) Timers

- Toggles on the first compare match
- Remains unchanged until the second compare match
- Toggles on the second compare match
- Remains unchanged until the end of the period
- Resets to zero at the end of the period if there is no second compare match, and the new compare value for the following period is not zero

The output is set to one at the beginning of a period and remains one until the second compare match if the compare value is zero at the beginning of a period. After the first transition, the output remains one until the end of the period if the compare value is zero for the second half of the period. When this happens, the output does not reset to zero if the new compare value for the following period is still zero. This is done again to assure the generation of PWM pulses of 0% to 100% duty cycle without any glitches. The first transition does not happen if the compare value is greater than or equal to that of the period register for the first half of the period. However, the output still toggles when a compare match happens in the second half of the period. This error in output transition, often as a result of calculation error in the application routine, is corrected at the end of the period because the output resets to zero, unless the new compare value for the following period is zero. In this case, the output remains one, which again puts the output of the waveform generator in the correct state.

**Note:**

The output logic determines what the active state is for all output pins.
Output Logic

The output logic further conditions the output of the waveform generator to form the ultimate PWM output that controls different kinds of power devices. The PWM output can be specified active high, active low, forced low, and forced high by proper configuration of the appropriate GPTCONA/B bits.

The polarity of the PWM output is the same as that of the output of the associated asymmetric/symmetric waveform generator when the PWM output is specified active high.

The polarity of the PWM output is the opposite of that of the output of the associated asymmetric/symmetric waveform generator when the PWM output is specified active low.

The PWM output is set to one (or zero) immediately after the corresponding bits in GPTCONA/B are set, and the bit pattern specifies that the state of PWM output is forced high (or low).

In summary, during a normal counting mode, transitions on the GP timer PWM outputs happen according to Table 6–11 for the continuous up-counting mode and according to Table 6–12 for the continuous up-/down-counting mode, assuming compare is enabled.

Setting active means setting high for active high and setting low for active low. Setting inactive means the opposite.

The asymmetric/symmetric waveform generation, based on the timer counting mode and the output logic, is also applicable to the compare units.

</table>

All GP timer PWM outputs are put in the high-impedance state when any of the following events occurs:

- GPTCONA/B[6] is set to zero by software
- PDPINTx is pulled low and is not masked
- Any reset event occurs
- TxCON[1] is set to zero by software

Active/Inactive Time Calculation

For the continuous up-counting mode, the value in the compare register represents the elapsed time between the beginning of a period and the occurrence of the first compare match (length of the inactive phase). This elapsed time is equal to the period of the scaled input clock multiplied by the value of TxCMPR. Therefore, the length of the active phase (the output pulse width) is given by $(TxPR) − (TxCMPR) + 1$ cycle of the scaled input clock.

For the continuous up-/down-counting mode, the compare register can have a different value while counting down from the value while counting up. The length of the active phase (output pulse width) for up-/down-counting modes is given by $(TxPR) − (TxCMPR)_{up} + (TxPR) − (TxCMPR)_{dn}$ cycles of the scaled input clock, where $(TxCMPR)_{up}$ is the compare value on the way up and $(TxCMPR)_{dn}$ is the compare value on the way down.
When the value in TxCMPR is zero, the GP timer compare output is active for the whole period if the timer is in the up-counting mode. For the up-/down-counting mode, the compare output is active at the beginning of the period if \((\text{TxCMPR})_{\text{up}}\) is zero. The output remains active until the end of the period if \((\text{TxCMPR})_{\text{dn}}\) is also zero.

The length of the active phase (the output pulse width) is zero when the value of TxCMPR is greater than that of TxPR for up-counting modes. For the up-/down-counting mode, the first transition is lost when \((\text{TxCMPR})_{\text{up}}\) is greater than or equal to \((\text{TxPR})\). Similarly, the second transition is lost when \((\text{TxCMPR})_{\text{dn}}\) is greater than or equal to \((\text{TxPR})\). The GP timer compare output is inactive for the entire period if both \((\text{TxCMPR})_{\text{up}}\) and \((\text{TxCMPR})_{\text{dn}}\) are greater than or equal to \((\text{TxPR})\) for the up-/down-counting mode.

Figure 6–10, *GP Timer Compare/PWM Output in Up-Counting Mode* (page 6-28) shows the compare operation of a GP timer in the up-counting mode. Figure 6–11, *GP Timer Compare/PWM Output in Up-/Down-Counting Modes* (page 6-30) shows the compare operation of a GP timer in the up-/down-counting mode.

### 6.3.3 Timer Control Registers (TxCON and GPTCONA/B)

The addresses of the GP timer registers are given in Table 6–3 and Table 6–4 on page 6-11. The bit definition of the individual GP timer control registers, TxCON, is shown in Figure 6–12. The bit definition of the overall GP timer control registers, GPTCONA and GPTCONB, are shown in Figure 6–13 (on page 6-35) and Figure 6–14 (on page 6-36), respectively.

#### Individual GP Timer Control Register (TxCON; \(x = 1, 2, 3, \text{ or } 4\))

**Note:**

Each Timer Control Register (TxCON) is independently configurable.

6.3.4 Generation of PWM Outputs Using the GP Timers

Each GP timer can independently be used to provide a PWM output channel. Thus, up to two PWM outputs may be generated by the GP timers.

PWM Operation

To generate a PWM output with a GP timer, a continuous up- or up-/down-counting mode can be selected. Edge-triggered or asymmetric PWM waveforms are generated when a continuous-up count mode is selected. Centered or symmetric PWM waveforms are generated when a continuous-up/-down mode is selected. To set up the GP timer for the PWM operation, do the following:

- Set up TxPR according to the desired PWM (carrier) period
- Set up TxCON to specify the counting mode and clock source, and start the operation
- Load TxCMPR with values corresponding to the on-line calculated widths (duty cycles) of PWM pulses

The period value is obtained by dividing the desired PWM period by the period of the GP timer input clock, and subtracting one from the resulting number when the continuous up-counting mode is selected to generate asymmetric PWM waveforms. When the continuous up-/down-counting mode is selected to generate symmetric PWM waveforms, this value is obtained by dividing the desired PWM period by two times the period of the GP timer input clock.

The GP timer can be initialized the same way as in the previous example. During run time, the GP timer compare register is constantly updated with newly determined compare values corresponding to the newly determined duty cycles.

6.3.5 GP Timer Reset

When any RESET event occurs, the following happens:

- All GP timer register bits, except for the counting direction indication bits in GPTCONA/B, are reset to 0; thus, the operation of all GP timers is disabled. The counting direction indication bits are all set to 1
- All timer interrupt flags are reset to 0
- All timer interrupt mask bits are reset to 0, except for PDPINTx; thus, all GP timer interrupts are masked except for PDPINTx
- All GP timer compare outputs are put in the high-impedance state
6.4 Compare Units

There are three (full) compare units (compare units 1, 2, and 3) in the EVA module and three (full) compare units (compare units 4, 5, and 6) in the EVB module. Each compare unit has two associated PWM outputs. The time base for the compare units is provided by GP timer 1 (for EVA) and by GP timer 3 (for EVB).

The compare units in each EV module include:

- Three 16-bit compare registers (CMPR1, CMPR2, and CMPR3 for EVA; and CMPR4, CMPR5, and CMPR6 for EVB), all with an associated shadow register, (RW)
- One 16-bit compare control register (COMCONA for EVA, and COMCONB for EVB), (RW)
- One 16-bit action control register (ACTRA for EVA, and ACTRB for EVB), with an associated shadow register, (RW)
- Six PWM (3-state) output (compare output) pins (PWMy, y = 1, 2, 3, 4, 5, 6 for EVA and PWMz, z = 7, 8, 9, 10, 11, 12 for EVB)
- Control and interrupt logic

The functional block diagram of a compare unit is shown in Figure 6–15.

Figure 6–15. Compare Unit Block Diagram
(For EVA: x = 1, 2, 3; y = 1, 3, 5; z = 1.
For EVB: x = 4, 5, 6; y = 7, 9, 11; z = 3.)
Compare Units

The time base for the compare units and the associated PWM circuits is provided by GP timer 1 (for EVA) or GP timer 3 (for EVB), which can be in any of its counting modes when the compare operation is enabled. Transitions occur on the compare outputs.

Compare Inputs/Outputs

The inputs to a compare unit include:

- Control signals from control registers
- GP timer 1/3 (T1CNT/T3CNT) and its underflow and period match signals
- RESET

The output of a compare unit is a compare match signal. If the compare operation is enabled, this match signal sets the interrupt flag and causes transitions on the two output pins associated with the compare unit.

Compare Operation Modes

The operation mode of the compare units is determined by the bits in COMCONx. These bits determine:

- Whether the compare operation is enabled
- Whether the compare outputs are enabled
- The condition on which the compare registers are updated with the values in their shadow registers
- Whether space vector PWM mode is enabled

Operation

The following paragraph describes the operation of the EVA compare unit. The operation of the EVB compare unit is identical. For EVB, GP timer 3 and ACTRB are used.

The value of the GP timer 1 counter is continuously compared with that of the compare register. When a match is made, a transition appears on the two outputs of the compare unit according to the bits in the action control register (ACTRA). The bits in ACTRA can individually specify each output to be toggled active high or toggled active-low (if not forced high or low) on a compare match. The compare interrupt flag associated with a compare unit is set when a compare match is made between GP timer 1 and the compare register of this
compare unit, if compare is enabled. A peripheral interrupt request is generated by the flag if the interrupt is unmasked. The timing of output transitions, setting of interrupt flags, and generation of interrupt requests are the same as that of the GP timer compare operation. The outputs of the compare units in compare mode are subject to modification by the output logic, dead band units, and the space vector PWM logic.

Register Setup for Compare Unit Operation

The register setup sequence for compare unit operation requires:

<table>

6.4.1 Compare Units Registers

The addresses of registers associated with compare units and associated PWM circuits are shown in Table 6−5, Addresses of EVA Compare Control Registers on page 6-11, and in Table 6−6, Addresses of EVB Compare Control Registers on page 6-12. These registers are discussed in the subsections that follow.

Compare Control Registers (COMCONA and COMCONB)

The operation of the compare units is controlled by the compare control registers (COMCONA and COMCONB). The bit definition of COMCONA is summarized in Figure 6−16 and that of COMCONB is summarized in Figure 6−17. COMCONA and COMCONB are readable and writeable.

Bits 11−10 ACTRLD1, ACTRLD0. Action control register reload condition.

00 When T3CNT = 0 (on underflow)
01 When T3CNT = 0 or T3CNT = T3PR (on underflow or period match)
10 Immediately
11 Reserved

Bit 9 FCOMPOE. Compare output enable. Active PDPI NTB clears this bit to zero.

0 PWM output pins are in high-impedance state; that is, they are disabled
1 PWM output pins are not in high-impedance state; that is, they are enabled

Bit 8 PDPI NTB STATUS. This bit reflects the current status of the PDPI NTB pin. An application could poll this bit to determine whether the fault that activated this pin has disappeared. (This bit is applicable to 240xA devices only — it is reserved on 240x devices and returns a zero when read.)

Bits 7–0 Reserved. Read returns zero; writes have no effect.

**Compare Action Control Registers (ACTRA and ACTRB)**

The compare action control registers (ACTRA and ACTRB) control the action that takes place on each of the six compare output pins (PWMx, where \( x = 1−6 \) for ACTRA, and \( x = 7−12 \) for ACTRB) on a compare event, if the compare operation is enabled by COMCONx[15]. ACTRA and ACTRB are double-buffered. The condition on which ACTRA and ACTRB is reloaded is defined by bits in COMCONx. ACTRA and ACTRB also contain the SVRDIR, D2, D1, and D0 bits needed for space vector PWM operation. The bit configuration of ACTRA is described in Figure 6–18 and that of ACTRB is described in Figure 6–19.

6.4.2 Compare Unit Interrupts

There is a maskable interrupt flag in EVAIFRA and EVBIFRA for each compare unit. The interrupt flag of a compare unit is set one clock cycle after a compare match, if a compare operation is enabled. A peripheral interrupt request is generated by the flag if it is unmasked.

6.4.3 Compare Unit Reset

When any reset event occurs, all register bits associated with the compare units are reset to zero and all compare output pins are put in the high-impedance state.
6.5 PWM Circuits Associated With Compare Units

The PWM circuits associated with compare units make it possible to generate six PWM output channels (per EV) with programmable dead-band and output polarity. The EVA PWM circuits functional block diagram is shown in Figure 6−20. It includes the following functional units:

- Asymmetric/Symmetric Waveform Generators
- Programmable Dead-Band Unit (DBU)
- Output Logic
- Space Vector (SV) PWM State Machine

The EVB PWM circuits functional block diagram is identical to that of the EVA's with the corresponding change of configuration registers.

The asymmetric/symmetric waveform generators are the same as those of the GP timers. The dead-band units and output logic are discussed in sections 6.5.2 and 6.5.3, respectively. The space vector PWM state machine and the space vector PWM technique are described later in this chapter.

Figure 6−20. PWM Circuits Block Diagram
The PWM circuits are designed to minimize CPU overhead and user intervention when generating pulse width modulated waveforms used in motor control and motion control applications. PWM generation with compare units and associated PWM circuits are controlled by the following control registers: T1CON, COMCONA, ACTRA, and DBTCONA (in case of EVA); and T3CON, COMCONB, ACTRB, and DBTCONB (in case of EVB).

### 6.5.1 PWM Generation Capability of Event Manager

The PWM waveform generation capability of each event manager module (A and B) is summarized as follows:

- Five independent PWM outputs, three of which are generated by the compare units; the other two are generated by the GP timer compares – plus three additional PWM outputs, dependent on the three compare unit PWM outputs
- Programmable dead-band for the PWM output pairs associated with the compare units
- Minimum dead-band duration of one device clock cycle
- Minimum PWM pulsewidth and pulsewidth increment/decrement of one clock cycle
- 16-bit maximum PWM resolution
- On-the-fly change of PWM carrier frequency (double buffered period registers)
- On-the-fly change of PWM pulsewidths (double buffered compare registers)
- Power Drive Protection Interrupt
- Programmable generation of asymmetric, symmetric, and space vector PWM waveforms
- Minimum CPU overhead because of the auto-reloading of the compare and period registers
6.5.2 Programmable Dead-Band (Dead-Time) Unit

EVA and EVB have their own programmable dead-band units (DBTCONA and DBTCONB, respectively). The programmable dead-band unit features:

- One 16-bit dead-band control register, DBTCONx (RW)
- One input clock prescaler: x/1, x/2, x/4, etc., to x/32
- Device (CPU) clock input
- Three 4-bit down-counting timers
- Control logic

Dead-Band Timer Control Registers A and B (DBTCONA and DBTCONB)

The operation of the dead-band unit is controlled by the dead-band timer control registers (DBTCONA and DBTCONB). The bit description of DBTCONA is given in Figure 6–21 and that of DBTCONB is given in Figure 6–22.

**Inputs and Outputs of Dead-Band Unit**

The inputs to the dead-band unit are PH1, PH2, and PH3 from the asymmetric/symmetric waveform generators of compare units 1, 2, and 3, respectively.

The outputs of the dead-band unit are DTPH1, DTPH1_, DTPH2, DTPH2_, DTPH3, and DTPH3_, corresponding to PH1, PH2, and PH3, respectively.

**Dead Band Generation**

For each input signal PHx, two output signals, DTPHx and DTPHx_, are generated. When dead-band is not enabled for the compare unit and its associated outputs, the two signals are exactly the same. When the dead-band unit is enabled for the compare unit, the transition edges of the two signals are separated by a time interval called dead-band. This time interval is determined by the DBTCONx bits. If you assume that the value in DBTCONx[11–8] is m, and that the value in DBTCONx[4–2] corresponds to prescaler \(x/p\), then the dead-band value is \((p^*m)\) device clock cycles.

Table 6–13, on page 6-53, shows the dead-band generated by typical bit combinations in DBTCONx. The values are based on a 25 ns device clock. Figure 6–23, on page 6-54, shows the block diagram of the dead-band logic for one compare unit.

Note: Table values are given in μs.
Figure 6–23. Dead-Band Unit Block Diagram (x = 1, 2, or 3)

Note: Signals such as PHx, DTPHx, and DTPHx are internal to the device, and as such, external monitoring/control of these signals is not possible.
Other Important Features of Dead-Band Units

The dead-band unit is designed to prevent an overlap under any operating situation between the turn-on period of the upper and lower devices controlled by the two PWM outputs associated with each compare unit. This includes those situations where you have loaded a dead-band value greater than that of the duty cycle, and when the duty cycle is 100% or 0%. As a result, the PWM outputs associated with a compare unit do not reset to an inactive state at the end of a period when dead band is enabled for the compare unit.

6.5.3 Output Logic

The output logic circuit determines the polarity and/or the action that must be taken on a compare match for outputs PWMx, for \( x = 1−12 \). The outputs associated with each compare unit can be specified active low, active high, forced low, or forced high. The polarity and/or the action of the PWM outputs can be programmed by proper configuration of bits in the ACTR register. The PWM output pins can all be put in the high-impedance state by any of the following:

- Software clearing the COMCONx[9] bit
- Hardware pulling PDPINTx low when PDPINTx is unmasked
- The occurrence of any reset event

Active PDPINTx (when enabled) and system reset override the bits in COMCONx and ACTRx

Figure 6–24, on page 6-56, shows a block diagram of the output logic circuit (OLC). The inputs of Output Logic for the compare units are:

- DTPH1, DTPH1_, DTPH2, DTPH2_, DTPH3, and DTPH3_ from the dead-band unit and compare match signals
- The control bits of ACTRx
- PDPINTx and RESET

The outputs of the Output Logic for the compare units are:

- PWMx, \( x = 1−6 \) (for EVA)
- PWMy, \( y = 7−12 \) (for EVB)
Figure 6–24. Output Logic Block Diagram (x = 1, 2, or 3; y = 1, 2, 3, 4, 5, or 6)
6.6 PWM Waveform Generation With Compare Units and PWM Circuits

A pulse width modulated (PWM) signal is a sequence of pulses with changing pulse widths. The pulses are spread over a number of fixed-length periods so that there is one pulse in each period. The fixed period is called the PWM (carrier) period and its inverse is called the PWM (carrier) frequency. The widths of the PWM pulses are determined, or modulated, from pulse to pulse according to another sequence of desired values, the modulating signal.

In a motor control system, PWM signals are used to control the on and off time of switching power devices that deliver the desired current and energy to the motor windings (see Figure 6–27 on page 6-62). The shape and frequency of the phase currents and the amount of energy delivered to the motor windings control the required speed and torque of the motor. In this case, the command voltage or current to be applied to the motor is the modulating signal. The frequency of the modulating signal is typically much lower than the PWM carrier frequency.

**PWM Signal Generation**

To generate a PWM signal, an appropriate timer is needed to repeat a counting period that is the same as the PWM period. A compare register is used to hold the modulating values. The value of the compare register is constantly compared with the value of the timer counter. When the values match, a transition (from low to high, or high to low) happens on the associated output. When a second match is made between the values, or when the end of a timer period is reached, another transition (from high to low, or low to high) happens on the associated output. In this way, an output pulse is generated whose on (or off) duration is proportional to the value in the compare register. This process is repeated for each timer period with different (modulating) values in the compare register. As a result, a PWM signal is generated at the associated output.

**Dead Band**

In many motion/motor and power electronics applications, two power devices, an upper and a lower, are placed in series on one power converter leg. The turn-on periods of the two devices must not overlap with each other in order to avoid a shoot-through fault. Thus, a pair of non-overlapping PWM outputs is often required to properly turn on and off the two devices. A dead time (dead-band) is often inserted between the turning-off of one transistor and the turning-on of the other transistor. This delay allows complete turning-off of one transistor before the turning-on of the other transistor. The required time delay is specified by the turning-on and turning-off characteristics of the power transistors and the load characteristics in a specific application.
6.6.1 Generation of PWM Outputs With Event Manager

Each of the three compare units, together with GP timer 1 (in the case of EVA) or GP timer 3 (in the case of EVB), the dead-band unit, and the output logic in the event manager module, can be used to generate a pair of PWM outputs with programmable dead-band and output polarity on two dedicated device pins. There are six such dedicated PWM output pins associated with the three compare units in each EV module. These six dedicated output pins can be used to conveniently control 3-phase AC induction or brushless DC motors. The flexibility of output behavior control by the compare action control register (ACTRx) also makes it easy to control switched reluctance and synchronous reluctance motors in a wide range of applications. The PWM circuits can also be used to conveniently control other types of motors such as DC brush and stepper motors in single or multi-axis control applications. Each GP timer compare unit, if desired, can also generate a PWM output based on its own timer.

Asymmetric and Symmetric PWM Generation

Both asymmetric and symmetric PWM waveforms can be generated by every compare unit on the EV module. In addition, the three compare units together can be used to generate 3-phase symmetric space vector PWM outputs. PWM generation with GP timer compare units has been described in the GP timer sections. Generation of PWM outputs with the compare units is discussed in this section.

6.6.2 Register Setup for PWM Generation

All three kinds of PWM waveform generations with compare units and associated circuits require configuration of the same Event Manager registers. The setup process for PWM generation includes the following steps:

- Setup and load ACTRx
- Setup and load DBTCONx, if dead-band is to be used
- Initialize CMPRx
- Setup and load COMCONx
- Setup and load T1CON (for EVA) or T3CON (for EVB) to start the operation
- Rewrite CMPRx with newly determined values
6.6.3 Asymmetric PWM Waveform Generation

The edge-triggered or asymmetric PWM signal is characterized by modulated pulses which are not centered with respect to the PWM period, as shown in Figure 6−25. The width of each pulse can only be changed from one side of the pulse.

Figure 6−25. Asymmetric PWM Waveform Generation With Compare Unit and PWM Circuits

(x = 1, 3, or 5)

To generate an Asymmetric PWM signal, GP timer 1 is put in the continuous up-counting mode and its period register is loaded with a value corresponding to the desired PWM carrier period. The COMCONx is configured to enable the compare operation, set the selected output pins to be PWM outputs, and enable the outputs. If dead-band is enabled, the value corresponding to the required dead-band time should be written by software into the DBT(3:0) bits in DBTCONx(11:8). This is the period for the 4-bit dead-band timers. One dead-band value is used for all PWM output channels.

By proper configuration of ACTRx with software, a normal PWM signal can be generated on one output associated with a compare unit while the other is held low (or off) or high (or on), at the beginning, middle, or end of a PWM period. Such software controlled flexibility of PWM outputs is particularly useful in switched reluctance motor control applications.
After GP timer 1 (or GP timer 3) is started, the compare registers are rewritten every PWM period with newly determined compare values to adjust the width (the duty cycle) of PWM outputs that control the switch-on and -off duration of the power devices. Since the compare registers are shadowed, a new value can be written to them at any time during a period. For the same reason, new values can be written to the action and period registers at any time during a period to change the PWM period or to force changes in the PWM output definition.

### 6.6.4 Symmetric PWM Waveform Generation

A centered or symmetric PWM signal is characterized by modulated pulses which are centered with respect to each PWM period. The advantage of a symmetric PWM signal over an asymmetric PWM signal is that it has two inactive zones of the same duration: at the beginning and at the end of each PWM period. This symmetry has been shown to cause less harmonics than an asymmetric PWM signal in the phase currents of an AC motor, such as induction and DC brushless motors, when sinusoidal modulation is used. Figure 6–26 shows two examples of symmetric PWM waveforms.

![Figure 6–26. Symmetric PWM Waveform Generation With Compare Units and PWM Circuits (x = 1, 3, or 5)](image)

The generation of a symmetric PWM waveform with a compare unit is similar to the generation of an asymmetric PWM waveform. The only exception is that GP timer 1 (or GP timer 3) now needs to be put in continuous up-/down-counting mode.
There are usually two compare matches in a PWM period in symmetric PWM waveform generation, one during the upward counting before period match, and another during downward counting after period match. A new compare value becomes effective after the period match (reload on period) because it makes it possible to advance or delay the second edge of a PWM pulse. An application of this feature is when a PWM waveform modification compensates for current errors caused by the dead-band in AC motor control.

Because the compare registers are shadowed, a new value can be written to them at any time during a period. For the same reason, new values can be written to the action and period registers at any time during a period to change the PWM period or to force changes in the PWM output definition.

### 6.6.5 Double Update PWM Mode

The 240xA Event Manager supports “Double Update PWM Mode.” This mode refers to a PWM operation mode in which the position of the leading edge and the position of the trailing edge of a PWM pulse are independently modifiable in each PWM period. To support this mode, the compare register that determines the position of the edges of a PWM pulse must allow (buffered) compare value update once at the beginning of a PWM period and another time in the middle of a PWM period.

The compare registers in 240xA Event Managers are all buffered and support three compare value reload/update (value in buffer becoming active) modes. These modes have earlier been documented as compare value reload conditions. The reload condition that supports double update PWM mode is reloaded on underflow (beginning of PWM period) OR period (middle of PWM period). Double update PWM mode can be achieved by using this condition for compare value reload.
6.7 Space Vector PWM

Space vector PWM refers to a special switching scheme of the six power transistors of a 3-phase power converter. It generates minimum harmonic distortion to the currents in the windings of a 3-phase AC motor. It also provides more efficient use of supply voltage in comparison with the sinusoidal modulation method.

6.7.1 3-Phase Power Inverter

The structure of a typical 3-phase power inverter is shown in Figure 6−27, where $V_a$, $V_b$, and $V_c$ are the voltages applied to the motor windings. The six power transistors are controlled by $DTPH_x$ and $DTPH_{x_}$ ($x = a, b, and c$). When an upper transistor is switched on ($DTPH_x = 1$), the lower transistor is switched off ($DTPH_{x_} = 0$). Thus, the on and off states of the upper transistors (Q1, Q3, and Q5) or, equivalently, the state of $DTPH_x$ ($x = a, b, and c$) are sufficient to evaluate the applied motor voltage $U_{out}$.

![Figure 6−27. 3-Phase Power Inverter Schematic Diagram](image)

**Power Inverter Switching Patterns and the Basic Space Vectors**

When an upper transistor of a leg is on, the voltage $V_x$ ($x = a, b, or c$) applied by the leg to the corresponding motor winding is equal to the voltage supply $U_{dc}$. When it is off, the voltage applied is zero. The on and off switching of the upper transistors ($DTPH_x$, $x = a, b, or c$) have eight possible combinations. The eight combinations and the derived motor line-to-line and phase voltage in terms of DC supply voltage $U_{dc}$ are shown in Table 6−14, on page 6-63, where $a, b,$ and $c$ represent the values of $DTPH_a, DTPH_b, and DTPH_c$, respectively.

**Note:** 0 = off, 1 = on

Mapping the phase voltages corresponding to the eight combinations onto the d-q plane by performing a d-q transformation (which is equivalent to an orthogonal projection of the 3-vectors \( (a, b, c) \) onto the two dimensional plane perpendicular to the vector \((1, 1, 1)\), the d-q plane), results in six nonzero vectors and two zero vectors. The nonzero vectors form the axes of a hexagonal. The angle between two adjacent vectors is 60 degrees. The two zero vectors are at the origin. These eight vectors are called the basic space vectors and are denoted by \( U_0, U_{60}, U_{120}, U_{180}, U_{240}, U_{300}, O_{000}, \) and \( O_{111} \). The same transformation can be applied to the demanded voltage vector \( U_{out} \) to be applied to a motor. Figure 6–28 shows the projected vectors and the projected desired motor voltage vector \( U_{out} \).

The d axis and q axis of a d-q plane correspond here to the horizontal and vertical geometrical axes of the stator of an AC machine.

The objective of the space vector PWM method is to approximate the motor voltage vector \( U_{out} \) by a combination of these eight switching patterns of the six power transistors.
The binary representations of two adjacent basic vectors are different in only one bit; that is, only one of the upper transistors switches when the switching pattern switches from $U_x$ to $U_{x+60}$ or from $U_{x+60}$ to $U_x$. Also, the zero vectors $O_{000}$ and $O_{111}$ apply no voltage to the motor.

**Approximation of Motor Voltage with Basic Space Vectors**

The projected motor voltage vector $U_{\text{out}}$, at any given time, falls into one of the six sectors. Thus, for any PWM period, it can be approximated by the vector sum of two vector components lying on the two adjacent basic vectors:

$$U_{\text{out}} = T_1 U_x + T_2 U_{x+60} + T_0 (O_{000} \text{ or } O_{111})$$

where $T_0$ is given by $T_p - T_1 - T_2$ and $T_p$ is the PWM carrier period. The third term on the right side of the equation does not affect the vector sum $U_{\text{out}}$. The generation of $U_{\text{out}}$ is beyond the scope of this context. For more details on space vector PWM and motor control theory, see *The Field Orientation Principle in Control of Induction Motors* by Andrzej M. Trzynadlowski (The Kluwer International Series in Engineering and Computer Science, Vol. 258:Power).

The above approximation means that the upper transistors must have the on and off pattern corresponding to $U_x$ and $U_{x+60}$ for the time duration of $T_1$ and $T_2$, respectively, in order to apply voltage $U_{\text{out}}$ to the motor. The inclusion of zero basic vectors helps to balance the turn on and off periods of the transistors, and thus their power dissipation.

**6.7.2 Space Vector PWM Waveform Generation with Event Manager**

The EV module has built-in hardware to greatly simplify the generation of symmetric space vector PWM waveforms. Software is used to generate space vector PWM outputs.
Software

To generate space vector PWM outputs, the user software must:

- Configure ACTRx to define the polarity of the compare output pins
- Configure COMCONx to enable compare operation and space vector PWM mode, and set the reload condition for CMPRx to be underflow
- Put GP timer 1 (or GP timer 3) in continuous up-/down-counting mode to start the operation

The user software then needs to determine the voltage $U_{out}$ to be applied to the motor phases in the two dimensional d-q plane, decompose $U_{out}$, and perform the following for each PWM period:

- Determine the two adjacent vectors, $U_x$ and $U_{x+60}$
- Determine the parameters $T_1$, $T_2$, and $T_0$
- Write the switching pattern corresponding to $U_x$ in ACTRx[14−12] and 1 in ACTRx[15], or the switching pattern of $U_{x+60}$ in ACTRx[14−12] and 0 in ACTRx[15]
- Put (1/2 $T_1$) in CMPR1 and (1/2 $T_1 + 1/2 T_2$) in CMPR2

Space Vector PWM Hardware

The space vector PWM hardware in the EV module does the following to complete a space vector PWM period:

- At the beginning of each period, sets the PWM outputs to the (new) pattern $U_y$ defined by ACTRx[14−12]
- On the first compare match during up-counting between CMPR1 and GP timer 1 at (1/2 $T_1$), switches the PWM outputs to the pattern of $U_{y+60}$ if ACTRx[15] is 1, or to the pattern of $U_y$ if ACTRx[15] is 0 ($U_{0−60} = U_{300}$, $U_{360+60} = U_{60}$)
- On the second compare match during up-counting between CMPR2 and GP timer 1 at (1/2 $T_1 + 1/2 T_2$), switches the PWM outputs to the pattern (000) or (111), whichever differs from the second pattern by one bit
- On the first compare match during down-counting between CMPR2 and GP timer 1 at (1/2 $T_1 + 1/2 T_2$), switches the PWM outputs back to the second output pattern
- On the second compare match during down-counting between CMPR1 and GP timer 1 at (1/2 $T_1$), switches the PWM outputs back to the first pattern
**Space Vector PWM Waveforms**

The space vector PWM waveforms generated are symmetric with respect to the middle of each PWM period; and for this reason, it is called the symmetric space vector PWM generation method. Figure 6−29 shows examples of the symmetric space vector PWM waveforms.

**The Unused Compare Register**

Only two compare registers are used in space vector PWM output generation. The third compare register, however, is still constantly compared with GP timer 1. When a compare match happens, the corresponding compare interrupt flag remains set and a peripheral interrupt request is generated, if the flag is unmasked. Therefore, the compare register that is not used in space vector PWM output generation can still be used to time events happening in a specific application. Also, because of the extra delay introduced by the state machine, the compare output transitions are delayed by one clock cycle in space vector PWM mode.

**6.7.3 Space Vector PWM Boundary Conditions**

All three compare outputs become inactive when both compare registers (CMPR1 and CMPR2) are loaded with a zero value in space vector PWM mode. It is the user’s responsibility to assure that $(\text{CMPR1}) \leq (\text{CMPR2}) \leq (\text{T1PR})$ in the space vector PWM mode; otherwise, unpredictable behavior may result.

SVRDIR=1, (D2 D1 D0)=(101)
6.8 Capture Units

Capture units enable logging of transitions on capture input pins. There are six capture units, three is each EV module. Capture Units 1, 2, and 3 are associated with EVA and Capture Units 4, 5, and 6 are associated with EVB. Each capture unit is associated with a capture input pin.

Each EVA capture unit can choose GP timer 2 or 1 as its time base; however, CAP1 and CAP2 cannot choose a different timer between themselves as their timebase. Each EVB capture unit can choose GP timer 4 or 3 as its time base; however, CAP4 and CAP5 cannot choose a different timer between themselves as their timebase.

The value of the GP timer is captured and stored in the corresponding 2-level-deep FIFO stack when a specified transition is detected on a capture input pin (CAPx). Figure 6–30 shows a block diagram of an EVA capture unit and Figure 6–31 shows a block diagram of an EVB capture unit.
Figure 6–30. Capture Units Block Diagram (EVA)
6.8.1 Capture Unit Features

Capture units have the following features:

- One 16-bit capture control register (CAPCONA for EVA, CAPCONB for EVB), (RW)
- One 16-bit capture FIFO status register (CAPFIFOA for EVA, CAPFIFOB for EVB)
- Selection of GP timer 1 or 2 (for EVA) and GP timer 3 or 4 (for EVB) as the time base
Capture Units

- Three 16-bit 2-level-deep FIFO stacks, one for each capture unit
- Six Schmitt-triggered capture input pins, CAP1 through CAP6, one input pin for each capture unit. (All inputs are synchronized with the device/CPU clock: in order for a transition to be captured, the input must hold at its current level to meet the two rising edges of the device clock. In 240xA devices, the input must be held for a duration mandated by the input qualifier circuitry. Input pins CAP1 and CAP2 (CAP4 and CAP5 in EVB) can also be used as QEP inputs to QEP circuit).
- User-specified transition detection (rising edge, falling edge, or both edges)
- Six maskable interrupt flags, one for each capture unit

6.8.2 Operation of Capture Units

After a capture unit is enabled, a specified transition on the associated input pin causes the counter value of the selected GP timer to be loaded into the corresponding FIFO stack. At the same time, if there are already one or more valid capture values stored in the FIFO stack (CAPxFIFO bits not equal to zero), the corresponding interrupt flag is set. If the flag is unmasked, a peripheral interrupt request is generated. The corresponding status bits in CAPFIFOx are adjusted to reflect the new status of the FIFO stack each time a new counter value is captured in a FIFO stack. The latency from the time a transition happens in a capture input to the time the counter value of the selected GP timer is locked is two clock cycles. In 240xA devices, additional latency due to the input qualifier circuitry must be taken into account.

All capture unit registers are cleared to zero by a RESET condition.

Capture Unit Time Base Selection

For EVA, Capture Unit 3 has a separate time base selection bit from Capture Units 1 and 2. This allows the two GP timers to be used at the same time, one for Capture Units 1 and 2, and the other for Capture Unit 3. For EVB, Capture Unit 6 has a separate time base selection bit.

Capture operation does not affect the operation of any GP timer or the compare/PWM operations associated with any GP timer.
Capture Unit Setup

For a capture unit to function properly, the following register setup must be performed:

1) Initialize the CAPFIFOx and clear the appropriate status bits.
2) Set the selected GP timer in one of its operating modes.
3) Set the associated GP timer compare register or GP timer period register, if necessary.
4) Set up CAPCONA or CAPCONB as appropriate.

6.8.3 Capture Unit Registers

The operation of the capture units is controlled by four 16-bit control registers, CAPCONA/B and CAPFIFOA/B. TxCON (x = 1, 2, 3, or 4) registers are also used to control the operation of the capture units since the time base for capture circuits can be provided by any of these timers. Table 6-7 and Table 6-8 on page 6-12 show the addresses of these registers.

*Capture FIFO Status Register A (CAPFIFOA)*

CAPFIFOA contains the status bits for each of the three FIFO stacks of the capture units. The bit description of CAPFIFOA is given in Figure 6–34. If a write occurs to the CAPnFIFOA status bits at the same time as they are being updated (because of a capture event), the write data takes precedence.
The write operation to the CAPFIFOx registers can be used as a programming advantage. For example, if a “01” is written into the CAPnFIFO bits, the EV module is led to “believe” that there is already an entry in the FIFO. Subsequently, every time the FIFO gets a new value, a capture interrupt will be generated.

**Figure 6-34. Capture FIFO Status Register A (CAPFIFOA) — Address 7422h**

**Capture FIFO Status Register B (CAPFIFOB)**

CAPFIFOB contains the status bits for each of the three FIFO stacks of the capture units. The bit description of CAPFIFOB is given in Figure 6−35. If a write occurs to the CAPnFIFOB status bits at the same time as they are being updated (because of a capture event), the write data takes precedence.

The write operation to the CAPFIFOx registers can be used as a programming advantage. For example, if a “01” is written into the CAPnFIFO bits, the EV module is led to “believe” that there is already an entry in the FIFO. Subsequently, every time the FIFO gets a new value, a capture interrupt will be generated.

6.8.4 Capture Unit FIFO Stacks

Each capture unit has a dedicated 2-level-deep FIFO stack. The top stack consists of CAP1FIFO, CAP2FIFO, and CAP3FIFO (in the case of EVA) or CAP4FIFO, CAP5FIFO, and CAP6FIFO (in the case of EVB). The bottom stack consists of CAP1FBOT, CAP2FBOT, and CAP3FBOT (in the case of EVA) or CAP4FBOT, CAP5FBOT, and CAP6FBOT (in the case of EVB). The top-level register of any of the FIFO stacks is a read-only register that always contains the oldest counter value captured by the corresponding capture unit. Therefore, a read access to the FIFO stack of a capture unit always returns the oldest counter value stored in the stack. When the oldest counter value in the top register of the FIFO stack is read, the newer counter value in the bottom register of the stack, if any, is pushed into the top register.

If desired, the bottom register of the FIFO stack can be read. Reading the bottom register of the FIFO stack causes the FIFO status bits to change to 01 (has one entry) if they were previously 10 or 11. If the FIFO status bits were previously 01 when the bottom FIFO register is read, they will change to 00 (empty).

First Capture

The counter value of the selected GP timer (captured by a capture unit when a specified transition happens on its input pin) is written into the top register of the FIFO stack, if the stack is empty. At the same time, the corresponding status bits are set to 01. The status bits are reset to 00 if a read access is made to the FIFO stack before another capture is made.

Second Capture

If another capture occurs before the previously captured counter value is read, the newly captured counter value goes to the bottom register. In the meantime, the corresponding status bits are set to 10. When the FIFO stack is read before another capture happens, the older counter value in the top register is read out, the newer counter value in the bottom register is pushed up into the top register, and the corresponding status bits are set to 01.
The appropriate capture interrupt flag is set by the second capture. A peripheral interrupt request is generated if the interrupt is not masked.

**Third Capture**

If a capture happens when there are already two counter values captured in the FIFO stack, the oldest counter value in the top register of the stack is pushed out and lost, the counter value in the bottom register of the stack is pushed up into the top register, the newly captured counter value is written into the bottom register, and the status bits are set to 11 to indicate that one or more older captured counter values have been lost.

The appropriate capture interrupt flag is also set by the third capture. A peripheral interrupt request is generated if the interrupt is not masked.

**6.8.5 Capture Interrupt**

When a capture is made by a capture unit and there is already at least one valid value in the FIFO (indicated by CAPxFIFO bits not equal to zero), the corresponding interrupt flag is set, and if unmasked, a peripheral interrupt request is generated. Thus, a pair of captured counter values can be read by an interrupt service routine if the interrupt is used. If an interrupt is not desired, either the interrupt flag or the status bits can be polled to determine if two captures have occurred allowing the captured counter values to be read.

The write operation to the CAPFIFOx registers can be used as a programming advantage. For example, if a “01” is written into the CAPnFIFO bits, the EV module is led to “believe” that there is already an entry in the FIFO. Subsequently, every time the FIFO gets a new value, a capture interrupt will be generated.
6.9 Quadrature Encoder Pulse (QEP) Circuit

Each Event Manager module has a quadrature encoder pulse (QEP) circuit. The QEP circuit decodes and counts the quadrature encoded input pulses on pins CAP1/QEP1 and CAP2/QEP2 (in case of EVA) or CAP4/QEP3 and CAP5/QEP4 (in case of EVB). The QEP circuit can be used to interface with an optical encoder to get position and speed information from a rotating machine.

6.9.1 QEP Pins

The two QEP input pins are shared between capture units 1 and 2 (or 3 and 4, for EVB), and the QEP circuit.

6.9.2 QEP Circuit Time Base

The time base for the QEP circuit is provided by GP timer 2 (GP timer 4, in case of EVB). The GP timer must be put in directional-up/down count mode with the QEP circuit as the clock source. Figure 6−36 shows the block diagram of the QEP circuit for EVA and Figure 6−37 shows the block diagram of the QEP circuit for EVB.

Figure 6−36. Quadrature Encoder Pulse (QEP) Circuit Block Diagram for EVA
6.9.3 Decoding

Quadrature encoded pulses are two sequences of pulses with a variable frequency and a fixed phase shift of a quarter of a period (90 degrees). When generated by an optical encoder on a motor shaft, the direction of rotation of the motor can be determined by detecting which of the two sequences is the leading sequence. The angular position and speed can be determined by the pulse count and pulse frequency.

**QEP Circuit**

The direction detection logic of the QEP circuit in the EV module determines which one of the sequences is the leading sequence. It then generates a direction signal as the direction input to GP timer 2 (or 4). The timer counts up if CAP1/QEP1 (CAP4/QEP3 for EVB) input is the leading sequence, and counts down if CAP2/QEP2 (CAP5/QEP4 for EVB) is the leading sequence.

Both edges of the pulses of the two quadrature encoded inputs are counted by the QEP circuit. Therefore, the frequency of the clock generated by the QEP logic to GP timer 2 (or 4) is four times that of each input sequence. This quadrature clock is connected to the clock input of GP timer 2 (or 4).
**Quadrature Encoded Pulse Decoding Example**

Figure 6–38 shows an example of quadrature encoded pulses and the derived clock and counting direction.

**Figure 6–38. Quadrature Encoded Pulses and Decoded Timer Clock and Direction**

QEP1

QEP2

---

### 6.9.4 QEP Counting

GP timer 2 (or 4) always starts counting from its current value. A desired value can be loaded to the GP timer’s counter prior to enabling the QEP mode. When the QEP circuit is selected as the clock source, the timer ignores the TDIRA/B and TCLKINA/B input pins.

### GP Timer Interrupt and Associated Compare Outputs in QEP Operation

Period, underflow, overflow, and compare interrupt flags for a GP timer with a QEP circuit clock are generated on respective matches. A peripheral interrupt request can be generated by an interrupt flag, if the interrupt is unmasked.

### 6.9.5 Register Setup for the QEP Circuit

To start the operation of the QEP circuit in EVA:

1) Load GP timer 2’s counter, period, and compare registers with desired values.

2) Configure T2CON to set GP timer 2 in directional-up/down mode with the QEP circuits as clock source, and enable the selected timer.
To start the operation of the QEP circuit in EVB:

1) Load GP timer 4s counter, period, and compare registers with desired values, if necessary.

2) Configure T4CON to set GP timer 4 in directional-up/down mode with the QEP circuits as clock source, and enable the selected timer.
6.10 Event Manager (EV) Interrupts

EV interrupt events are organized into three groups: A, B, and C. Each group is associated with a different interrupt flag and interrupt enable register. There are several event manager peripheral interrupt requests in each EV interrupt group. Table 6–16 shows all EVA interrupts, their priority, and grouping; and Table 6–17 shows all EVB interrupts, their priority, and grouping. There is an interrupt flag register and a corresponding interrupt mask register for each EV interrupt group, as shown in Table 6–15. A flag in EVAIFRx (x = A, B, or C) is masked (will not generate a peripheral interrupt request) if the corresponding bit in EVAIMRx is zero.

6.10.1 EV Interrupt Request and Service

When a peripheral interrupt request is acknowledged, the appropriate peripheral interrupt vector is loaded into the peripheral interrupt vector register (PIVR) by the PIE controller. The vector loaded into the PIVR is the vector for the highest priority pending enabled event. The vector register can be read by the interrupt service routine (ISR).

Interrupt Generation

When an interrupt event occurs in the EV module, the corresponding interrupt flag in one of the EV interrupt flag registers is set to one. A peripheral interrupt request is generated to the Peripheral Interrupt Expansion controller, if the flag is locally unmasked (the corresponding bit in EVAIMRx is set to one).
Interrupt Vector

The peripheral interrupt vector corresponding to the interrupt flag that has the highest priority among the flags that are set and enabled is loaded into the PIVR when an interrupt request is acknowledged (this is all done in the peripheral interrupt controller, external to the event manager peripheral).

**Note: Failure to Clear the Interrupt Flag Bit**

The interrupt flag bit in the peripheral register must be cleared by software writing a 1 to the bit in the ISR. Failure to clear this bit will prevent future interrupt requests by that source.

6.10.2 EV Interrupt Flag Registers

Addresses of the EVA and EVB interrupt registers are shown in Table 6-9 and Table 6-10, respectively, on page 6-13. The registers are all treated as 16-bit memory mapped registers. The unused bits all return zero when read by software. Writing to unused bits has no effect. Since EVxIFRx are readable registers, occurrence of an interrupt event can be monitored by software polling the appropriate bit in EVxIFRx when the interrupt is masked.

7.1 Features

- 10-bit ADC core with built-in Sample and Hold (S/H)
- Fast conversion time (S/H + Conversion): 500 ns
- Sixteen (16) multiplexed analog inputs (ADCIN0 – ADCIN15). Eight in 2402A
- Autosequencing capability – up to 16 “autoconversions” in a single session. Each conversion session can be programmed to select any one of the 16 input channels
- Two independent 8-state sequencers (SEQ1 and SEQ2) that can be operated individually in dual-sequencer mode or cascaded into one large 16-state sequencer (SEQ) in cascaded mode
- Four Sequencing Control Registers (CHSELSEQn) that determine the sequence of analog channels that are taken up for conversion in a given sequencing mode
- Sixteen (individually addressable) result registers to store the converted values (RESULT0 – RESULT15)
- Multiple trigger sources for start-of-conversion (SOC) sequence
  - Software: Software immediate start (using SOC SEQn bit)
  - EVA: Event manager A (multiple event sources within EVA)
  - EVB: Event manager B (multiple event sources within EVB)
  - External: ADCSOC pin
- Flexible interrupt control allows interrupt request on every end-of-sequence (EOS) or every other EOS
- Sequencer can operate in start/stop mode, allowing multiple time-sequenced triggers to synchronize conversions
- EVA and EVB can independently trigger SEQ1 and SEQ2, respectively. (This is applicable for dual-sequencer mode only.)
- Sample-and-hold acquisition time window has separate prescale control
- Calibration mode
- The 240x/240xA ADC is not compatible with the 24x ADC. Therefore, code written for the 24x ADC cannot be ported to a 240x/240xA device.

† The calibration feature available in 240x devices has some restrictions in usage. See the following device errata for details: TMS320LF2402 DSP Controller Silicon Errata (literature number SPRZ157), TMS320LF2406 DSP Controller Silicon Errata (literature number SPRZ153), and TMS320LF2407 DSP Controller Silicon Errata (literature number SPRZ158). Note that the calibration and self-test features are not supported on the 240xA devices. Hence, bits 0, 1, 2, and 3 of the ADCTRL1 register must be treated as "reserved" in 240xA devices and must be written with zeroes. Furthermore, the functionality of bit 14 of ADCTRL2 is restricted to RST_SEQ1 only.
7.2 ADC Overview

7.2.1 Autoconversion Sequencer: Principle of Operation

The ADC sequencer consists of two independent 8-state sequencers (SEQ1 and SEQ2) that can also be cascaded together to form one 16-state sequencer (SEQ). The word “state” represents the number of autoconversions that can be performed with the sequencer. Block diagrams of the single (16-state, cascaded) and dual (two 8-state, separated) sequencer modes are shown in Figure 7–1 and Figure 7–2, respectively.

In both cases, the ADC has the ability to autosequence a series of conversions. For every conversion, any one of the available 16 input channels can be selected through the analog mux. After conversion, the digital value of the selected channel is stored in the appropriate result register (RESULTn). (The first result is stored in RESULT0, the second result in RESULT1, and so on). It is also possible to sample the same channel multiple times, allowing the user to perform “over-sampling”, which gives increased resolution over traditional single sampled conversion results.

---

**Note: Dual-Sequencer Mode**

In the dual-sequencer mode, the SOC request from the “inactive” sequencer will be taken up as soon as the sequence initiated by the “active” sequencer is completed. For example, assume that the A/D converter is busy catering to SEQ2. When SEQ1 initiates an SOC, the A/D converter takes up the request from SEQ1 after completing the sequence initiated by SEQ2; i.e., the SEQ1 conversion starts immediately after the current SEQ2 conversion finishes.
Figure 7–1. Block Diagram of Autosequenced ADC in Cascaded Mode

Note: Possible values are:
Channel select = 0 to 15
MAXCONV = 0 to 15
Figure 7-2. Block Diagram of Autosequenced ADC With Dual Sequencers

Note: Possible values:
Channel select = 0 to 15
MAX CONV1 = 0 to 7
MAX CONV2 = 8 to 15

Note:
There is only one A/D converter in the DSP. This converter is shared by the two sequencers in Dual-Sequencer mode.
The sequencer operation for both 8-state and 16-state modes is almost identical; the few differences are highlighted in Table 7–2.

</tr>
</tbody>
</table>

For convenience, the sequencer states will be subsequently referred to as:

- For SEQ1: CONV00 to CONV07
- For SEQ2: CONV08 to CONV15
- For Cascaded SEQ: CONV00 to CONV15

The analog input channel selected for each sequenced conversion is defined by CONVnn bit fields in the ADC input channel select sequencing control registers (CHSELSEQn). (See section 7.5.5., ADC Input Channel Select Sequencing Control Registers, on page 7-35.) CONVnn is a 4-bit field that specifies any one of the 16 channels for conversion. Since a maximum of 16 conversions in a sequence is possible when using the sequencers in cascaded mode, 16 such 4-bit fields (CONV00 – CONV15) are available and are spread across four 16-bit registers (CHSELSEQ1 – CHSELSEQ4). The CONVnn bits can have any value from 0 to 15. The analog channels can be chosen in any desired order and the same channel may be selected multiple times.
7.2.2 Uninterrupted Autosequenced Mode

The following description applies to the 8-state sequencers (SEQ1 or SEQ2). In this mode, SEQ1/SEQ2 can autosequence up to eight conversions of any channel in a single sequencing session. The result of each conversion is stored in one of the eight result registers (RESULT0 – RESULT7 for SEQ1 and RESULT8 – RESULT15 for SEQ2). These registers are filled from the lowest address to the highest address.

The number of conversions in a sequence is controlled by MAX CONVn (a 3-bit or 4-bit field in the MAXCONV register), which is automatically loaded into the sequencing counter status bits (SEQ CNTR3 – 0) in the autosequence status register (AUTO_SEQ_SR) at the start of an autosequenced conversion session. The MAX CONVn field can have a value ranging from zero to seven. SEQ CNTRn bits count down from their loaded value as the sequencer starts from state CONV00 and continues sequentially (CONV01, CONV02, and so on) until SEQ CNTRn has reached zero. The number of conversions completed during an autosequencing session is equal to (MAX CONVn + 1).

Example 7–1. Conversion in Dual-Sequencer Mode Using SEQ1

Suppose seven conversions are desired from SEQ1 (i.e., Channels 2, 3, 2, 3, 6, 7, and 12 need to be converted as part of the autosequenced session), then MAX CONV1 should be set to 6 and the CHSELSEQn registers should be set to the values shown in the table below:

<table>
<thead>
<tr>
<th>Bits 15–12</th>
<th>Bits 11–8</th>
<th>Bits 7–4</th>
<th>Bits 3–0</th>
<th>CHSELSEQn</th>
</tr>
</thead>
<tbody>
<tr>
<td>70A3h</td>
<td>3</td>
<td>2</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>70A4h</td>
<td>x</td>
<td>12</td>
<td>7</td>
<td>6</td>
</tr>
<tr>
<td>70A5h</td>
<td>x</td>
<td>x</td>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>70A6h</td>
<td>x</td>
<td>x</td>
<td>x</td>
<td>x</td>
</tr>
</tbody>
</table>

Note: Values are in decimal, and x = don’t care

Conversion begins once the start-of-conversion (SOC) trigger is received by the sequencer. The SOC trigger also loads the SEQ CNTR n bits. Those channels that are specified in the CHSELSEQ n registers are taken up for conversion, in the predetermined sequence. The SEQ CNTR n bits are decremented by one automatically after every conversion. Once SEQ CNTR n reaches zero, two things can happen depending on the status of the continuous run bit (CONT RUN) in the ADCTRL1 register.
If CONT RUN is set, the conversion sequence starts all over again automatically (i.e., SEQ CNTR n gets reloaded with the original value in MAX CONV1 and SEQ1 state is set to CONV00). In this case, you must ensure that the result registers are read before the next conversion sequence begins. The arbitration logic designed into the ADC ensures that the result registers are not corrupted should a contention arise (ADC module trying to write into the result registers while you try to read from them at the same time).

Figure 7–3. Flow Chart for Uninterrupted Autosequenced Mode

1. Initialize the ADC registers
2. SOC trigger arrives
3. MAXCONV value gets loaded into AUTO_SEQ_SR register
4. Conversion begins. AUTO_SEQ_SR register is decremented by one for every conversion
5. Current conversion complete. Digital result is written into corresponding RESULTn register
6. All conversions complete? (AUTO_SEQ_SR = 0 ?)
7. Set INT FLAG SEQn
8. Stop

Note: Flow chart corresponds to CONT RUN bit = 0.
If CONT RUN is not set, the sequencer stays in the last state (CONV06, in this example) and SEQ CNTR n continues to hold a value of zero. Since the interrupt flag is set every time SEQ CNTR n reaches zero, you can (if needed) manually reset the sequencer (using the RST SEQn bit in the ADCTRL2 register) in the interrupt service routine (ISR), so that SEQ CNTR n gets reloaded with the original value in MAX CONV1 at the next SOC and SEQ1 state is set to CONV00. This feature is useful in the Start/Stop operation of the sequencer. Example 7−1 also applies to SEQ2 and the cascaded 16-state sequencer (SEQ) with differences outlined in Table 7−2.

7.2.3 Sequencer Start/Stop Mode (Sequencer “Start/Stop” Operation With Multiple “Time-Sequenced Triggers”)

In addition to the uninterrupted autosequenced mode, any sequencer (SEQ1, SEQ2, or SEQ) can be operated in a stop/start mode which is synchronized to multiple start-of-conversion (SOC) triggers, separated in time. This mode is identical to Example 7−1, but the sequencer is allowed to be retriggered without being reset to the initial state CONV00, once it has finished its first sequence (i.e., the sequencer is not reset in the interrupt service routine). Therefore, when one conversion sequence ends, the sequencer stays in the current conversion state. The continuous run bit (CONT RUN) in the ADCTRL1 register must be set to zero (i.e., disabled) for this mode.

Example 7−2. Sequencer Start/Stop Operation

Requirement: To start three autoconversions (e.g., $I_1, I_2, I_3$) off trigger 1 (underflow) and three autoconversions (e.g., $V_1, V_2, V_3$) off trigger 2 (period). Triggers 1 and 2 are separated in time by, say, 25 $\mu$s and are provided by Event Manager A (EVA). See Figure 7−4. Only SEQ1 is used in this case.

Note: Triggers 1 and 2 may be an SOC signal from EVA, external pin, or software. The same trigger source may occur twice to satisfy the dual-trigger requirement of this example.
Here MAX CONV1 is set to 2 and the ADC Input Channel Select Sequencing Control Registers (CHSELSEQn) are set to:

<table>
<thead>
<tr>
<th>Bits 15–12</th>
<th>Bits 11–8</th>
<th>Bits 7–4</th>
<th>Bits 3–0</th>
</tr>
</thead>
<tbody>
<tr>
<td>70A3h</td>
<td>V₁</td>
<td>I₃</td>
<td>I₂</td>
</tr>
<tr>
<td>70A4h</td>
<td>x</td>
<td>x</td>
<td>V₃</td>
</tr>
<tr>
<td>70A5h</td>
<td>x</td>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>70A6h</td>
<td>x</td>
<td>x</td>
<td>x</td>
</tr>
</tbody>
</table>

Once reset and initialized, SEQ1 waits for a trigger. With the first trigger, three conversions with channel-select values of: CONV00 (I₁), CONV01 (I₂), and CONV02 (I₃) are performed. SEQ1 then waits at current state for another trigger. Twenty-five microseconds later when the second trigger arrives, another three conversions occur, with channel-select values of CONV03 (V₁), CONV04 (V₂), and CONV05 (V₃).

The value of MAX CONV1 is automatically loaded into SEQ CNTR n for both trigger cases. If a different number of conversions are required at the second trigger point, you must (at some appropriate time before the second trigger) change the value of MAX CONV1 through software, otherwise, the current (originally loaded) value will be reused. This can be done by an ISR that changes the value of MAX CONV1 at the appropriate time. The interrupt operation modes are described in section 7.2.5, *Interrupt Operation During Sequenced Conversions*, on page 7-13.
At the end of the second autoconversion session, the ADC result registers will have the following values:

<table>
<thead>
<tr>
<th>Buffer Register</th>
<th>ADC conversion result buffer</th>
</tr>
</thead>
<tbody>
<tr>
<td>RESULT0</td>
<td>$I_1$</td>
</tr>
<tr>
<td>RESULT1</td>
<td>$I_2$</td>
</tr>
<tr>
<td>RESULT2</td>
<td>$I_3$</td>
</tr>
<tr>
<td>RESULT3</td>
<td>$V_1$</td>
</tr>
<tr>
<td>RESULT4</td>
<td>$V_2$</td>
</tr>
<tr>
<td>RESULT5</td>
<td>$V_3$</td>
</tr>
<tr>
<td>RESULT6</td>
<td>$x$</td>
</tr>
<tr>
<td>RESULT7</td>
<td>$x$</td>
</tr>
<tr>
<td>RESULT8</td>
<td>$x$</td>
</tr>
<tr>
<td>RESULT9</td>
<td>$x$</td>
</tr>
<tr>
<td>RESULT10</td>
<td>$x$</td>
</tr>
<tr>
<td>RESULT11</td>
<td>$x$</td>
</tr>
<tr>
<td>RESULT12</td>
<td>$x$</td>
</tr>
<tr>
<td>RESULT13</td>
<td>$x$</td>
</tr>
<tr>
<td>RESULT14</td>
<td>$x$</td>
</tr>
<tr>
<td>RESULT15</td>
<td>$x$</td>
</tr>
</tbody>
</table>

At this point, SEQ1 keeps “waiting” at the current state for another trigger. Now, the user can reset SEQ1 (by software) to state CONV00 and repeat the same trigger 1, 2 sessions.
7.2.4 Input Trigger Description

Each sequencer has a set of trigger inputs that can be enabled/disabled. The valid input triggers for SEQ1, SEQ2, and cascaded SEQ is as follows:

<table>
<thead>
<tr>
<th>SEQ1 (sequencer 1)</th>
<th>SEQ2 (sequencer 2)</th>
<th>Cascaded SEQ</th>
</tr>
</thead>
<tbody>
<tr>
<td>Software trigger (software SOC)</td>
<td>Software trigger (software SOC)</td>
<td>Software trigger (software SOC)</td>
</tr>
<tr>
<td>Event manager A (EVA SOC)</td>
<td>Event manager B (EVB SOC)</td>
<td>Event manager A (EVA SOC)</td>
</tr>
<tr>
<td>External SOC pin (ADC SOC)</td>
<td></td>
<td>External SOC pin (ADC SOC)</td>
</tr>
</tbody>
</table>

Note that:

- An SOC trigger can initiate an autoconversion sequence whenever a sequencer is in an idle state. An idle state is either CONV00 prior to receiving a trigger, or any state which the sequencer lands on at the completion of a conversion sequence, i.e., when SEQ CNTR n has reached a count of zero.

- If an SOC trigger occurs while a current conversion sequence is underway, it sets the SOC SEQn bit (which would have been cleared on the commencement of a previous conversion sequence) in the ADCTRL2 register. If yet another SOC trigger occurs, it is lost (i.e., when the SOC SEQn bit is already set (SOC pending), subsequent triggers will be ignored).

- Once triggered, the sequencer cannot be stopped/halted in mid sequence. The program must either wait until an End-of-Sequence (EOS) or initiate a sequencer reset, which brings the sequencer immediately back to the idle start state (CONV00 for SEQ1 and cascaded cases; CONV08 for SEQ2).

- When SEQ1/2 are used in cascaded mode, triggers going to SEQ2 are ignored, while SEQ1 triggers are active. Cascaded mode can be viewed as SEQ1 with 16 states instead of eight.

7.2.5 Interrupt Operation During Sequenced Conversions

The sequencer can generate interrupts under two operating modes. These modes are determined by the Interrupt-Mode-Enable Control bits in ADCTRL2.

A variation of Example 7–2 can be used to show how interrupt mode 1 and mode 2 are useful under different operating conditions.
**Case 1:** Number of samples in the first and second sequences are not equal

- **Mode 1** Interrupt operation (i.e., Interrupt request occurs at every EOS)
  1) Sequencer is initialized with MAX CONVn = 1 for converting I₁ and I₂
  2) At ISR “a”, MAX CONVn is changed to 2 (by software) for converting V₁, V₂, and V₃
  3) At ISR “b”, the following events take place:
     1) MAX CONVn is changed to 1 again for converting I₁ and I₂.
     2) Values I₁, I₂, V₁, V₂, and V₃ are read from ADC result registers.
     3) The sequencer is reset.
  4) Steps 2 and 3 are repeated. Note that the interrupt flag is set every time SEQ CNTR n reaches zero and both interrupts are recognized.

**Case 2:** Number of samples in the first and second sequences are equal

- **Mode 2** Interrupt operation (i.e., Interrupt request occurs at every other EOS)
  1) Sequencer is initialized with MAX CONVn = 2 for converting I₁, I₂, and I₃ (or V₁, V₂, and V₃).
  2) At ISR “b” and “d”, the following events take place:
     1) Values I₁, I₂, I₃, V₁, V₂, and V₃ are read from ADC result registers.
     2) The sequencer is reset.
  3) Step 2 is repeated. Note that the interrupt flag is set every time SEQ CNTR n reaches zero. This would happen after the ADC has finished converting I₁, I₂, and I₃ and also after converting V₁, V₂, and V₃. But, only the EOS generated after the conversion of V₁, V₂, and V₃ triggers the interrupt.
Case 3: Number of samples in the first and second sequences are equal (with dummy read)

- Mode 2 Interrupt operation (i.e., Interrupt request occurs at every other EOS)

1) Sequencer is initialized with MAX CONVn = 2 for I₁, I₂, x sampling

2) At ISR “b” and “d”, the following events take place:
   1) Values I₁, I₂, x, V₁, V₂, and V₃ are read from ADC result registers.
   2) The sequencer is reset.

3) Step 2 is repeated. Note that the third I-sample (x) is a dummy sample, and is not really required. However, to minimize ISR overhead and CPU intervention, advantage is taken of the “every other” Interrupt request feature of Mode 2.

The S/H block in the 240xA ADC can be tailored to accommodate the variation in source impedances. This is achieved by the ACQ PS3–ACQ PS0 bits and the CPS bit in the ADCTR1 register. The analog-to-digital conversion process can be divided into two time segments, as shown in Figure 7–6.

**Figure 7–6. ADC Conversion Time**

The time segments are:
- S/H window: \((2 \times \text{PS})\)
- Conversion: \((11 \times \text{ACLK})\)
- 1 complete ADC conversion

**PS** = a prescaled CPU clock

PS will be the same as the CPU clock if the prescaler = 1 (i.e., ACQ PS3–ACQ PS0 bits are all zero) and if CPS = 0. For any other value of the prescaler, the magnitude of PS will be magnified (effectively increasing the S/H window time) as described by the “Acquisition Time Window” column in the bit description for ACQ PS3–ACQ PS0. If the CPS bit is made 1, the S/H window is doubled. This doubling of the S/H window is in addition to the “stretching” provided by the prescaler. Figure 7–7 shows the role played by the various prescaler bits in the ADC module. Note that PS and ACLOCK will be equal to CPU clock if CPS = 0.
Figure 7–7. Clock Prescalers in 240xA ADC

- PS

S/H
  - (2 * PS)

A/D converter
  - (11 * ACLK)
7.4 Calibration

In the calibration mode, the sequencers are not operational and the ADCINn pins are not connected to the A/D converter. The signal that gets connected to the A/D converter input is determined by BRG ENA (Bridge Enable) and HI/LO (V\textsubscript{REFHI}/V\textsubscript{REFLO} selection) bits. These two signals connect either V\textsubscript{REFLO} or V\textsubscript{REFHI} or their midpoint to the A/D converter input and a single conversion is then done. The calibration mode can calculate the zero, midpoint, or full-scale offset errors of the ADC. The 2’s complement of the offset error should then be loaded in the CALIBRATION register. (The 2’s complement operation is applicable for “negative” errors only.) From that point on, the ADC hardware automatically adds the offset error to the converted value.

\textit{Figure 7−8. CALIBRATION Register − Address 70B8h}

\begin{verbatim}
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
+---+---+---+---+---+---+---+---+
| D9 | D8 | D7 | D6 | D5 | D4 | D3 | D2 |
+---+---+---+---+---+---+---+---+
| 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
+---+---+---+---+---+---+---+---+
| D1 | D0 | 0  | 0  | 0  | 0  | 0  | 0  |
+---+---+---+---+---+---+---+---+
\end{verbatim}

To summarize, the CALIBRATION register stores the end result of calibration in the calibration mode. In the normal mode of the ADC, the value in the CALIBRATION register is automatically added to the output of the ADC before the result is stored in the RESULT\textsubscript{n} register.
7.5  Register Bit Descriptions

7.5.1  ADC Control Register 1 (ADCTRL1)

Figure 7–9. ADC Control Register 1 (ADCTRL1) — Address 70A0h

Note: R = Read access, W = Write access, S = Set only, -0 = value after reset

Bit 15  Reserved

Bit 14  RESET. ADC module software reset

This bit causes a master reset on the entire ADC module. All register bits and sequencer state machines are reset to the initial state as occurs when the device reset pin is pulled low (or after a power-on reset).

0  No effect
1  Resets entire ADC module (bit is then set back to 0 by ADC logic)

Note: Using the RESET Bit in the ADCTRL1 Register

The ADC module is reset during a system reset. If an ADC module reset is desired at any other time, you can do so by writing a 1 to this bit. After a NOP, you can then write the appropriate values to the ADCTRL1 register bits:

SPLK #01xxxxxxxxxxxxxxxxxh,ADCTRL1; Resets the ADC (RESET = 1)
NOP ; Provides the required delay
SPLK #00xxxxxxxxxxxxxxxxxh,ADCTRL1; Takes the ADC out of Reset
(RESET = 0)

Note that the second SPLK is not required if the default configuration is sufficient.
Bits 13, 12  **SOFT and FREE.** Soft and Free bits

These bits determine what occurs when an emulation-suspend occurs (due to the debugger hitting a breakpoint, for example). In free-run mode, the peripheral can continue with whatever it is doing. In stop mode, the peripheral can either stop immediately or stop when the current operation (i.e., the current conversion) is complete.

Notes: 1) Period of \( T_{\text{clk}} \) is dependent on the “Conversion Clock Prescale” bit (Bit 7); i.e., CPS = 0: \( T_{\text{clk}} = 1/\text{CLK} \) (example, for CLK = 30 MHz, \( T_{\text{clk}} = 33 \text{ ns} \))
CPS = 1: \( T_{\text{clk}} = 2 \times (1/\text{CLK}) \) (example, for CLK = 30 MHz, \( T_{\text{clk}} = 66 \text{ ns} \))
2) Source impedance \( Z \) is a design estimate only.

Notes: 1) Period of $T_{clk}$ is dependent on the “Conversion Clock Prescale” bit (Bit 7); i.e., CPS = 0: $T_{clk} = 1/CLK$ (example, for CLK = 40 MHz, $T_{clk} = 25\text{ ns}$)
CPS = 1: $T_{clk} = 2 × (1/CLK)$ (example, for CLK = 40 MHz, $T_{clk} = 50\text{ ns}$)
2) Source impedance Z is a design estimate only.
Register Bit Descriptions

**Bit 7**  
**CPS. Conversion clock prescale**  
This bit defines the ADC conversion logic clock prescale  
- 0  \( F_{\text{clk}} = \text{CLK}/1 \)  
- 1  \( F_{\text{clk}} = \text{CLK}/2 \)  
CLK = CPU clock frequency

**Bit 6**  
**CONT RUN. Continuous run**  
This bit determines whether the sequencer operates in continuous conversion mode or start-stop mode. This bit can be written while a current conversion sequence is active. This bit will take effect at the end of the current conversion sequence; i.e., software can set/clear this bit until EOS has occurred, for valid action to be taken. In the continuous conversion mode, there is no need to reset the sequencer; however, the sequencer must be reset in the start-stop mode to put the converter in state CONV00.  
- 0  Start-stop mode. Sequencer stops after reaching EOS. This is used for multiple time-sequenced triggers.  
- 1  Continuous conversion mode. After reaching EOS, the sequencer starts all over again from state CONV00 (for SEQ1 and cascaded) or CONV08 (for SEQ2).

**Bit 5**  
**INT PRI. ADC interrupt request priority**  
- 0  High priority  
- 1  Low priority

**Bit 4**  
**SEQ CASC. Cascaded sequencer operation**  
This bit determines whether SEQ1 and SEQ2 operate as two 8-state sequencers or as a single 16-state sequencer (SEQ).  
- 0  Dual-sequencer mode. SEQ1 and SEQ2 operate as two 8-state sequencers.  
- 1  Cascaded mode. SEQ1 and SEQ2 operate as a single 16-state sequencer (SEQ).

**Bit 3**  
**CAL ENA. Offset calibration enable**  
When set to 1, CAL ENA disables the input channel multiplexer, and connects the calibration reference selected by the bits HI/LO and BRG ENA to the ADC core inputs. The calibration conversion can then be started by setting bit 14 of ADCTRL2 register (STRT CAL) to 1. Note that CAL ENA should be set to 1 first before the STRT CAL bit can be used.  
Note: This bit should not be set to 1 if STEST ENA = 1  
- 0  Calibration mode disabled  
- 1  Calibration mode enabled
Register Bit Descriptions

Bit 2  **BRG ENA.** Bridge enable

Together with the HI/LO bit, BRG ENA allows a reference voltage to be converted in calibration mode. See the description of the HI/LO bit for reference voltage selections during calibration.

- 0  Full reference voltage is applied to the ADC input
- 1  A reference midpoint voltage is applied to the ADC input

Bit 1  **HI/LO.** $V_{REFHI}/V_{REFLO}$ selection

When the fail self-test mode is enabled (STEST ENA = 1), HI/LO defines the test voltage to be connected. In calibration mode, HI/LO defines the reference source polarity; see Table 7–5. In normal operating mode, HI/LO has no effect.

- 0  $V_{REFLO}$ is used as precharge value at ADC input
- 1  $V_{REFHI}$ is used as precharge value at ADC input

### Bit 13: SOC SEQ1

Start-of-conversion (SOC) trigger for Sequencer 1 (SEQ1). This bit can be set by the following triggers:

- S/W – Software writing a 1 to this bit
- EVA – Event Manager A
- EVB – Event Manager B (only in cascaded mode)
- EXT – External pin (i.e., the ADCSOC pin)

When a trigger occurs, there are three possibilities:

**Case 1:** SEQ1 idle and SOC bit clear  
SEQ1 starts immediately (under arbiter control). This bit is set and cleared, allowing for any “pending” trigger requests.

**Case 2:** SEQ1 busy and SOC bit clear  
Bit is set signifying a trigger request is pending. When SEQ1 finally starts after completing current conversion, this bit will be cleared.

**Case 3:** SEQ1 busy and SOC bit set  
Any trigger occurring in this case will be ignored (lost).

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
</table>
| 0     | Clears a pending SOC trigger.  
  Note: If the sequencer has already started, this bit will automatically be cleared, and hence, writing a zero will have no effect; i.e., an already started sequencer cannot be stopped by clearing this bit. |
| 1     | Software trigger – Start SEQ1 from currently stopped position (i.e., Idle mode) |

**Note:**  
The RST SEQ1 (ADCTRL2.14) and the SOC SEQ1 (ADCTRL2.13) bits should not be set in the same instruction. This will reset the sequencer, but will not start the sequence. The correct sequence of operation is to set the RST SEQ1 bit first, and the SOC SEQ1 bit in the following instruction. This ensures that the sequencer is reset and a new sequence started. This sequence applies to the RST SEQ2 (ADCTRL2.6) and SOC SEQ2 (ADCTRL2.5) bits also.

### Bit 12: SEQ1 BSY

SEQ1 Busy  
This bit is set to a 1 while the ADC autoconversion sequence is in progress. It is cleared when the conversion sequence is complete.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Sequencer is Idle (i.e., waiting for trigger)</td>
</tr>
<tr>
<td>1</td>
<td>Conversion sequence is in progress</td>
</tr>
</tbody>
</table>
Checking for End-of-Sequence

After a start-of-sequence (SOC) is initiated, four NOPs need to be executed before polling the SEQ1 or SEQ2 BSY bit.

Example code:

```assembly
ADC_LOOP1:
  LDP  #ADCTRL1>>7
  SPLK #0100000000000000b,ADCTRL2 ;Reset for SEQ1
  SPLK #0010000000000000b,ADCTRL2 ;SOC for SEQ1
  NOP ;Wait for Busy bit to set.
  NOP
  NOP
  CHK_EOS1:
    BIT ADCTRL2, 3 ; Wait for SEQ1 Busy bit to clear
    BCND CHK_EOS1, TC ; If TC=1, keep looping.
```

A better approach would be to check the INT FLAG SEQn bit for end-of-sequence. This does not require NOPs, as the bit should already be cleared prior to starting a sequenced conversion. To reiterate, the NOPs are required only when polling the SEQn BUSY bit; interrupt-driven conversions do not have this requirement.

<table>
<thead>
<tr>
<th>Bits 11–10</th>
<th>INT ENA SEQ1. Interrupt-mode-enable control for SEQ1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 11</td>
<td>Bit 10</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

† This means that the last completed sequence is the first of the two sequences needed to assert an interrupt.
### Register Bit Descriptions

**Bit 9**  
**INT FLAG SEQ1.** ADC interrupt flag bit for SEQ1  
This bit indicates whether an interrupt event has occurred or not. This bit must be cleared by the user writing a 1 to it.  
- 0: No interrupt event  
- 1: An interrupt event has occurred.  

**Bit 8**  
**EVA SOC SEQ1.** Event Manager A SOC mask bit for SEQ1  
- 0: SEQ1 cannot be started by EVA trigger.  
- 1: Allows SEQ1/SEQ to be started by Event Manager A trigger. The Event Manager can be programmed to start a conversion on various events. See chapter 6, *Event Manager (EV)*, for details.  

**Bit 7**  
**EXT SOC SEQ1.** External signal start-of-conversion bit for SEQ1  
- 0: No action  
- 1: Setting this bit enables an ADC autoconversion sequence to be started by a signal from the ADCSOC device pin.  

**Bit 6**  
**RST SEQ2.** Reset SEQ2  
- 0: No action  
- 1: Immediately resets SEQ2 to an initial “pretriggered” state, i.e., waiting for a trigger at CONV08. A currently active conversion sequence will be aborted.
Bit 5  SOC SEQ2. Start-of-conversion trigger for Sequencer 2 (SEQ2)  
(Only applicable in dual-sequencer mode; ignored in cascaded mode.)

This bit can be set by the following triggers:

- S/W – Software writing of 1 to this bit
- EVB – Event Manager B

When a trigger occurs, there are three possibilities:

**Case 1:** SEQ2 idle and SOC bit clear
SEQ2 starts immediately (under arbiter control) and the bit is cleared, allowing
for any pending trigger requests.

**Case 2:** SEQ2 busy and SOC bit clear
Bit is set signifying a trigger request is pending. When SEQ2 finally starts after
completing current conversion, this bit will be cleared.

**Case 3:** SEQ2 busy and SOC bit set
Any trigger occurring in this case will be ignored (lost).

0  Clears a Pending SOC trigger.
   Note: If the sequencer has already started, this bit will automatical-
   ly be cleared, and hence, writing a zero will have no effect; i.e., an
   already started sequencer cannot be stopped by clearing this bit.

1  Software trigger – Start SEQ2 from currently stopped position (i.e.,
   Idle mode)

Bit 4  SEQ2 BSY. SEQ2 Busy

This bit is set to a 1 while the ADC autoconversion sequence is in progress.
It is cleared when the conversion sequence is complete.

0  Sequencer is idle (i.e., waiting for trigger).
1  Conversion sequence is in progress.
### Bits 3–2
**INT ENA SEQ2.** Interrupt-mode-enable control for SEQ2

<table>
<thead>
<tr>
<th>Bit 3</th>
<th>Bit 2</th>
<th>Operation Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>Interrupt is Disabled</td>
</tr>
</tbody>
</table>
| 0     | 1     | Interrupt **Mode 1**
   |       | Interrupt requested immediate on INT FLAG SEQ2 flag set                                |
| 1     | 0     | Interrupt **Mode 2**
   |       | Interrupt requested only if INT FLAG SEQ2 flag is already set. If clear†, INT FLAG SEQ2 flag is set and INT request is suppressed. (This mode allows Interrupt requests to be generated for every other EOS) |
| 1     | 1     | Reserved                                                                               |

† This means that the last completed sequence is the first of the two sequences needed to assert an interrupt.

### Bit 1
**INT FLAG SEQ2.** ADC interrupt flag bit for SEQ2

This bit indicates whether an interrupt event has occurred or not. This bit must be cleared by the user writing a 1 to it.

<td>RW-0</td>
<td>RW-0</td>
</tr>
</tbody>
</table>

**Note:**  
R = Read access, W = Write access, x = undefined, -0 = value after reset
Bits 15–7  Reserved

Bits 6–0  MAX CONVn. MAX CONVn bit field defines the maximum number of conversions executed in an autoconversion session. The bit fields and their operation vary according to the sequencer modes (dual/cascaded).

- For SEQ1 operation, bits MAX CONV1_2 – 0 are used.
- For SEQ2 operation, bits MAX CONV2_2 – 0 are used.
- For SEQ operation, bits MAX CONV1_3 – 0 are used.

An autoconversion session always starts with the initial state and continues sequentially until the end state if allowed. The result buffer is filled in a sequential order. Any number of conversions between 1 and (MAX CONVn +1) can be programmed for a session.

Example 7–3. MAXCONV Register Bit Programming

If only five conversions are required, then MAX CONVn is set to four.

**Case 1:** Dual mode SEQ1 and cascaded mode
Sequencer goes from CONV00 to CONV04, and the five conversion results are stored in the registers Result 00 to Result 04 of the Conversion Result Buffer.

**Case 2:** Dual mode SEQ2
Sequencer goes from CONV08 to CONV12, and the five conversion results are stored in the registers Result 08 to Result 12 of the Conversion Result Buffer.

**MAX CONV1 Value >7 for Dual-Sequencer Mode**

If a value for MAX CONV1, which is greater than 7, is chosen for the dual-sequencer mode (i.e., two separate 8-state sequencers), then SEQ CNTR n will continue counting past seven, causing the sequencer to wrap around to CONV00 and continue counting.

Note:  
R = Read access, x = undefined, -0 = value after reset

Bits 15–12  Reserved

Bits 11–8  SEQ CNTR 3 – SEQ CNTR 0. Sequencing counter status bits

The SEQ CNTR n 4-bit status field is used by SEQ1, SEQ2, and the cascaded sequencer.
SEQ2 is irrelevant in cascaded mode.

At the start of an autosequenced session, SEQ CNTR n is loaded with the value from MAX CONVn. The SEQ CNTR n bits can be read at any time during the countdown process to check status of the sequencer. This value, together with the SEQ1 and SEQ2 Busy bits, uniquely identifies the progress or state of the active sequencer at any point in time.

**Bit 7**  
Reserved

**Bits 6–4**  
SEQ2-State2 – SEQ2-State0

Reflects the state of SEQ2 sequencer at any point of time. If necessary, you can poll these bits to read interim results before an EOS. SEQ2 is irrelevant in cascaded mode.

**Bits 3–0**  
SEQ1-State3 – SEQ1-State0

Reflects the state of SEQ1 sequencer at any point of time. If need be, user can poll these bits to read interim results before an EOS.

**Note:** The AUTO_SEQ_SR register and the RESULTn registers of the 240xA ADC module are “Read-only.” Any attempt to write to these registers causes an NMI.

**Notes:**
1) Buffer addresses = 70A8h to 70B7h (i.e., 16 registers)
2) The 10-bit conversion result (D9–D0) is left-justified.
3) The AUTO_SEQ_SR register and the RESULTn registers of the 240xA ADC module are “Read-only.” Any attempt to write to these registers causes an NMI.
7.6 ADC Conversion Clock Cycles

The conversion time is a function of the number of conversions performed in a given sequence. The conversion cycle can be divided into five phases:

- Start-of-sequence sync-up (SOS synch)
  The SOS synch applies only to the first conversion in a sequence.

- Acquisition time (ACQ)

- Conversion time (CONV)

- End-of-Conversion cycle (EOC)
  The ACQ, CONV, and EOC apply to all conversions in a sequence

- End-of-Sequence flag-setting cycle (EOS)
  The EOS applies only to the last conversion in a sequence.

Each category is listed in Table 7−9 with the number of CLKOUT cycles it takes to complete.

Table 7−9. ADC Conversion Phases vs CLKOUT cycles

<table>
<thead>
<tr>
<th>Datasheet Nomenclature</th>
<th>Conversion phase</th>
<th>CLKOUT cycles (CPS = 0)</th>
<th>CLKOUT cycles (CPS = 1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>( t_d(SOC−SH) )</td>
<td>SOS synch</td>
<td>2</td>
<td>2 or 3†</td>
</tr>
<tr>
<td>( t_w(SH) )</td>
<td>ACQ</td>
<td>2†</td>
<td>4‡</td>
</tr>
<tr>
<td>( t_w(C) )</td>
<td>CONV</td>
<td>10</td>
<td>20</td>
</tr>
<tr>
<td>( t_d(EOC) )</td>
<td>EOS</td>
<td>1</td>
<td>2</td>
</tr>
</tbody>
</table>

† When CPS = 1, a start-of-sequence can take an extra CLKOUT cycle to sync up with the ADC clock (ADCCCLK) depending on which cycle the SOC bit is set in software.
‡ The ACQ value is dependent on the ACQ PSn bits. Values shown in Table 7−9 are applicable when ACQ PS = 0. As an example, values for ACQ when ACQ PS = 1, 2, and 3 are shown in Table 7−10. This table can be extrapolated for all ACQ PS values.

Table 7−10. ACQ Values When ACQ PS = 1, 2, and 3

<table>
<thead>
<tr>
<th>ACQ PS</th>
<th>(CPS = 0)</th>
<th>(CPS = 1)</th>
</tr>
</thead>
<tbody>
<tr>

<td>ACQ = 6</td>
<td>ACQ = 12</td>
</tr>
<tr>
<td>3</td>
<td>ACQ = 8</td>
<td>ACQ = 16</td>
</tr>
</tbody>
</table>
Example 7–4. Calculating the Conversion Time for a Multiple Conversion Sequence With \( CPS = 0 \) and \( ACQ = 0 \):

1\textsuperscript{st} conversion – 15 CLKOUT cycles
2\textsuperscript{nd} conversion – 13 CLKOUT cycles
3\textsuperscript{rd} conversion – 13 CLKOUT cycles
Last conversion – 14 CLKOUT cycles.

Example 7–5. Calculating the Conversion Time for a Single Conversion Sequence With \( CPS = 1 \) and \( ACQ = 1 \):

1\textsuperscript{st} and only conversion – 33 or 34 CLKOUT cycles.
This chapter describes the architecture, functions, and programming of the serial communications interface (SCI) module. All registers in this peripheral are eight bits wide.

The programmable SCI supports asynchronous serial (UART) digital communications between the CPU and other asynchronous peripherals that use the standard NRZ (non-return-to-zero) format. The SCI's receiver and transmitter are double buffered, and each has its own separate enable and interrupt bits. Both may be operated independently or simultaneously in the full-duplex mode.

To ensure data integrity, the SCI checks received data for break detection, parity, overrun, and framing errors. The bit rate (baud) is programmable to over 65,000 different speeds through a 16-bit baud-select register.

For convenience, references to a bit in a register are abbreviated using the register name followed by a period and the number of the bit. For example, the notation for bit 6 of the SCI priority control register (SCIPRI) is SCIPRI.6.
8.1 C240 SCI vs. LF/LC240xA SCI

Multiplexing the SCI pins with general-purpose I/O is controlled by bits in the digital I/O peripheral. As a consequence, the register SCIPC2 (705Eh) has been removed.

The CLKENA bit in SCICTL1 (7051h) has been removed, since it served no purpose in 2-pin SCI implementations.

The function of the SCIENA bit in SCICCR (7050h) has changed, and is now a LOOP BACK ENA test mode bit. The enable function is no longer required for correct operation of the SCI.

There is no difference with respect to the 241/242/243 SCI functionality; however, the clock for the SCI must be enabled during peripheral initialization (by writing a 1 to bit 6 of the SCSRI register).

8.1.1 SCI Physical Description

The SCI module, shown in Figure 8–1 on page 8-4, has the following key features:

- Two I/O pins
  - SCIRXD (SCI receive data input)
  - SCITXD (SCI transmit data output)
- Programmable bit rates to over 65,000 different speeds through a 16-bit baud select register
  - Range with 40-MHz CLKOUT: 76 bps to 2500 kbps
  - Number of bit rates: 64K
- Programmable data word length from one to eight bits
- Programmable number of stop bits (one or two)
- Internally generated serial clock
- Four error detection flags
  - Parity error
  - Overrun error
  - Framing error
  - Break detect error
Two wake-up multiprocessor modes
- Idle-line wake-up
- Address-bit wake-up

Half- or full-duplex operation

Double-buffered receive and transmit functions

A transmitter and a receiver that can be operated by interrupts or by polling status flags:
- Transmitter: TXRDY flag (indicates when the transmitter buffer register is ready to receive another character from the CPU core) and TX EMPTY flag (indicates when the transmit shift register is empty)
- Receiver: RXRDY flag (indicates when the receiver buffer register is ready to receive another character from the external world), BRKDT flag (indicates when a break condition occurs), and RX ERROR (monitors four interrupt conditions)

Separate enable bits for transmitter and receiver interrupts

Separate error interrupts for multiple error conditions

NRZ (non-return-to-zero) format
Figure 8–1. SCI Block Diagram

Note: All SCI registers are eight bits wide. These eight bits are mapped to the lower eight bits of the 16-bit words.
8.1.2 Architecture

The major elements used in full-duplex operation are shown in Figure 8–1, *SCI Block Diagram*, and include:

- A transmitter (TX) and its major registers (upper half of Figure 8–1)
  - SCITXBUF — transmitter data buffer register. Contains data (loaded by the CPU) to be transmitted
  - TXSHF register — transmitter shift register. Accepts data from register SCITXBUF and shifts data onto the SCITXD pin, one bit at a time

- A receiver (RX) and its major registers (lower half of Figure 8–1)
  - RXSHF register — receiver shift register. Shifts data in from SCIRXD pin, one bit at a time
  - SCIRXBUF — receiver data buffer register. Contains data to be read by the CPU. Data from a remote processor is loaded into register RXSHF and then into registers SCIRXBUF and SCIRXEMU

- A programmable baud generator

- Data-memory-mapped control and status registers (see section, 8.1.3, *SCI Module Register Addresses*.

The SCI receiver and transmitter can operate either independently or simultaneously.

8.1.3 SCI Module Register Addresses

Table 8–1 on page 8-6 lists the addresses of the SCI registers.

8.1.4 Multiprocessor and Asynchronous Communication Modes

The SCI has two multiprocessor protocols, the idle-line multiprocessor mode (see section 8.3.1 on page 8-10) and the address-bit multiprocessor mode (see section 8.3.2 on page 8-13). These protocols allow efficient data transfer between multiple processors.

The SCI offers the universal asynchronous receiver/transmitter (UART) communications mode for interfacing with many popular peripherals. The asynchronous mode (see section 8.4 on page 8-15) requires two lines to interface with many standard devices such as terminals and printers that use RS-232-C formats. Data transmission characteristics include:

- One start bit
- One to eight data bits
- An even/odd parity bit or no parity bit
- One or two stop bits
8.2 SCI Programmable Data Format

SCI data, both receive and transmit, is in NRZ (non-return-to-zero) format. The NRZ data format, shown in Figure 8–2, consists of:

- One start bit
- One to eight data bits
- An even/odd parity bit (optional)
- One or two stop bits
- An extra bit to distinguish addresses from data (address-bit mode only)

The basic unit of data is called a character and is one to eight bits in length. Each character of data is formatted with a start bit, one or two stop bits, and optional parity and address bits. A character of data with its formatting information is called a frame and is shown in Figure 8–2.

![Figure 8–2. Typical SCI Data Frame Formats](image)

To program the data format, use the SCICCR register. The bits used to program the data format are shown in Table 8–2.

8.3 SCI Multiprocessor Communication

The multiprocessor communication format allows one processor to efficiently send blocks of data to other processors on the same serial link. On one serial line, there should be only one transfer at a time. In other words, there can be only one talker on a serial line at a time.

**Address Byte**

The first byte of a block of information that the talker sends contains an address byte that is read by all listeners. Only listeners with the correct address can be interrupted by the data bytes that follow the address byte. The listeners with an incorrect address remain uninterrupted until the next address byte.

**Sleep Bit**

All processors on the serial link set their SCI’s SLEEP bit (SCICTL1.2) to 1 so that they are interrupted only when the address byte is detected. When a processor reads a block address that corresponds to the CPU’s device address as set by your application software, your program must clear the SLEEP bit to enable the SCI to generate an interrupt on receipt of each data byte.

Although the receiver still operates when the SLEEP bit is 1, it does not set RXRDY, RXINT, or any of the receiver error status bits to 1 unless the address byte is detected and the address bit in the received frame is a 1 (applicable to address-bit mode). The SCI does not alter the SLEEP bit; your software must alter the SLEEP bit.

**Recognizing the Address Byte**

A processor recognizes an address byte differently, depending on the multiprocessor mode used. For example:

- The *idle-line mode* (section 8.3.1 on page 8-10) leaves a quiet space before the address byte. This mode does not have an extra address/data bit and is more efficient than the address-bit mode for handling blocks that contain more than ten bytes of data. The idle-line mode should be used for typical non-multiprocessor SCI communication.

- The *address-bit mode* (section 8.3.2 on page 8-13) adds an extra bit (that is, an address bit) into every byte to distinguish addresses from data. This mode is more efficient in handling many small blocks of data because, unlike the idle mode, it does not have to wait between blocks of data. Howev-
er, at a high transmit speed, the program is not fast enough to avoid a 10-bit idle in the transmission stream.

**Controlling the SCI TX and RX Features**

The multiprocessor mode is software selectable via the ADDR/IDLE MODE bit (SCICCR.3). Both modes use the TXWAKE flag bit (SCICTL1.3), RXWAKE flag bit (SCIRXST.1), and the SLEEP flag bit (SCICTL1.2) to control the SCI transmitter and receiver features of these modes.

**Receipt Sequence**

In both multiprocessor modes, the receive sequence is:

1) At the receipt of an address block, the SCI port wakes up and requests an interrupt (bit RX/BK INT ENA-SCICTL2.1 must be enabled to request an interrupt). It reads the first frame of the block, which contains the destination address.

2) A software routine is entered through the interrupt and checks the incoming address. This address byte is checked against its device address byte stored in memory.

3) If the check shows that the block is addressed to the device CPU, the CPU clears the SLEEP bit and reads the rest of the block; if not, the software routine exits with the SLEEP bit still set and does not receive interrupts until the next block start.

**8.3.1 Idle-Line Multiprocessor Mode**

In the idle-line multiprocessor protocol (ADDR/IDLE MODE bit=0), blocks are separated by having a longer idle time between the blocks than between frames in the blocks. An idle time of ten or more high-level bits after a frame indicates the start of a new block. The time of a single bit is calculated directly from the baud value (bits per second). The idle-line multiprocessor communication format is shown in Figure 8−3 (ADDR/IDLE MODE bit is SCICCR.3).
**Figure 8–3. Idle-Line Multiprocessor Communication Format**

![Diagram showing idle-line communication format](image)

**Idle-Line Mode Steps**

The steps followed by the idle-line mode:

1) SCI wakes up after receipt of the block-start signal.

2) The processor recognizes the next SCI interrupt.

3) The interrupt service routine compares the received address (sent by a remote transmitter) to its own.

4) If the CPU *is being addressed*, the service routine clears the SLEEP bit and receives the rest of the data block.

5) If the CPU *is not being addressed*, the SLEEP bit remains set. This lets the CPU continue to execute its main program without being interrupted by the SCI port until the next detection of a block start.

**Block Start Signal**

There are two ways to send a block-start signal:

- **Method 1**: Deliberately leave an idle time of ten bits or more by delaying the time between the transmission of the last frame of data in the previous block and the transmission of the address frame of the new block.
Method 2: The SCI port first sets the TXWAKE bit (SCICTL1.3) to 1 before writing to the SCITXBUF register. This sends an idle time of exactly 11 bits. In this method, the serial communications line is not idle any longer than necessary. (A don’t care byte has to be written to SCITXBUF after setting TXWAKE, and before sending the address, so as to transmit the idle time.)

Wake-UP Temporary (WUT) Flag

Associated with the TXWAKE bit is the wake-up temporary (WUT) flag. WUT is an internal flag, double-buffered with TXWAKE. When TXSHF is loaded from SCITXBUF, WUT is loaded from TXWAKE, and the TXWAKE bit is cleared to 0. This arrangement is shown in Figure 8–4. (Figure 8–1, SCI Block Diagram on page 8-4 shows this in additional detail.)

Figure 8–4. Double-Buffered WUT and TXSHF

Sending a Block Start Signal

To send out a block-start signal of exactly one frame time during a sequence of block transmissions:

1) Write a 1 to the TXWAKE bit.

2) Write a data word (content not important: a don’t care) to the SCITXBUF register (transmit data buffer) to send a block-start signal. (The first data word written is suppressed while the block-start signal is sent out and ignored after that.) When the TXSHF (transmit shift register) is free again, SCITXBUF’s contents are shifted to TXSHF, the TXWAKE value is shifted to WUT, and then TXWAKE is cleared.

Because TXWAKE was set to a 1, the start, data, and parity bits are replaced by an idle period of 11 bits transmitted following the last stop bit of the previous frame.

3) Write a new address value to SCITXBUF.

A don’t-care data word must first be written to register SCITXBUF so that the TXWAKE bit value can be shifted to WUT. After the don’t-care data word is
shifted to the TXSHF register, the SCITXBUF (and TXWAKE if necessary) can be written to again because TXSHF and WUT are both double-buffered.

**Receiver Operation**

The receiver operates regardless of the SLEEP bit. However, the receiver neither sets RXRDY nor the error status bits, nor does it request a receive interrupt *until an address frame is detected.*

**8.3.2 Address-Bit Multiprocessor Mode**

In the address-bit protocol (ADDR/IDLE MODE bit=1), frames have an extra bit called an address bit that immediately follows the last data bit. The address bit is set to 1 in the first frame of the block and to 0 in all other frames. The idle period timing is irrelevant (see Figure 8−5, ADDR/IDLE MODE bit in SCICCR.3).

**Sending an Address**

The TXWAKE bit value is placed in the address bit. During transmission, when the SCITXBUF register and TXWAKE are loaded into the TXSHF register and WUT respectively, TXWAKE is reset to 0 and WUT becomes the value of the address bit of the current frame. Thus, to send an address:

1) Set the TXWAKE bit to 1 and write the appropriate address value to the SCITXBUF register.

   When this address value is transferred to the TXSHF register and shifted out, its address bit is sent as a 1. This flags the other processors on the serial link to read the address.

2) Write to SCITXBUF and TXWAKE after TXSHF and WUT are loaded. (Can be written to immediately since both TXSHF and WUT are both double-buffered.

3) Leave the TXWAKE bit set to 0 to transmit non-address frames in the block.

**Note: The Address-bit format is for transfers of 11 bytes or less**

As a general rule, the address-bit format is typically used for data frames of 11 bytes or less. This format adds one bit value (1 for an address frame, 0 for a data frame) to all data bytes transmitted. The idle-line format is typically used for data frames of 12 bytes or more.
Figure 8–5. Address-Bit Multiprocessor Communication Format
8.4 SCI Communication Format

The SCI asynchronous communication format uses either single line (one way) or two line (two way) communications. In this mode, the frame consists of a start bit, one to eight data bits, an optional even/odd parity bit, and one or two stop bits (shown in Figure 8–6). There are eight SCICLK periods per data bit.

The receiver begins operation on receipt of a valid start bit. A valid start bit is identified by four consecutive internal SCICLK periods of zero bits as shown in Figure 8–6. If any bit is not zero, then the processor starts over and begins looking for another start bit.

For the bits following the start bit, the processor determines the bit value by making three samples in the middle of the bits. These samples occur on the fourth, fifth, and sixth SCICLK periods, and bit-value determination is on a majority (two out of three) basis. Figure 8–6 illustrates the asynchronous communication format for this with a start bit showing how edges are found and where a majority vote is taken.

Since the receiver synchronizes itself to frames, the external transmitting and receiving devices do not have to use a synchronized serial clock. The clock can be generated locally.

Figure 8–6. SCI Asynchronous Communications Format
8.4.1 Receiver Signals in Communication Modes

Figure 8−7 illustrates an example of receiver signal timing that assumes the following conditions:

- Address-bit wake-up mode (address bit does not appear in idle-line mode)
- Six bits per character

Figure 8−7. SCI RX Signals in Communication Modes

Notes:
1) Flag bit RXENA (SCICTL1.0) goes high to enable the receiver.
2) Data arrives on the SCIRXD pin, start bit detected.
3) Data is shifted from RXSHF to the receiver buffer register (SCIRXBUF); an interrupt is requested. Flag bit RXRDY (SCIRXST.6) goes high to signal that a new character has been received.
4) The program reads SCIRXBUF; flag RXRDY is automatically cleared.
5) The next byte of data arrives on the SCIRXD pin; the start bit is detected, then cleared.
6) Bit RXENA is brought low to disable the receiver. Data continues to be assembled in RXSHF but is not transferred to the receiver buffer register.
8.4.2 Transmitter Signals in Communication Modes

Figure 8–8 illustrates an example of transmitter signal timing that assumes the following conditions:

- Address-bit wake-up mode (address bit does not appear in idle-line mode)
- Three bits per character

**Figure 8–8. SCI TX Signals in Communications Mode**

![Diagram of SCI TXSignals in Communications Mode]

**Notes:**

1) Bit TXENA (SCICTL1.1) goes high, enabling the transmitter to send data.
2) SCITXBUF is written to; thus, (1) the transmitter is no longer empty, and (2) TXRDY goes low.
3) The SCI transfers data to the shift register (TXSHF). The transmitter is ready for a second character (TXRDY goes high), and it requests an interrupt (to enable an interrupt, bit TX INT ENA — SCICTL2.0 — must be set).
4) The program writes a second character to SCITXBUF after TXRDY goes high (item 3). (TXRDY goes low again after the second character is written to SCITXBUF.)
5) Transmission of the first character is complete. Transfer of the second character to shift register TXSHF begins.
6) Bit TXENA goes low to disable the transmitter; the SCI finishes transmitting the current character.
7) Transmission of the second character is complete; transmitter is empty and ready for new character.
8.5 SCI Port Interrupts

The SCI’s receiver and transmitter can be interrupt controlled. The SCICTL2 register has one flag bit (TXRDY) that indicates active interrupt conditions, and the SCIRXST register has two interrupt flag bits (RXRDY and BRKDT), plus the RX ERROR interrupt flag which is a logical OR of the FE, OE and PE conditions. The transmitter and receiver have separate interrupt-enable bits. When not enabled, the interrupts are not asserted; however, the condition flags remain active, reflecting transmission and receipt status.

The SCI has independent peripheral interrupt vectors for the receiver and transmitter. Peripheral interrupt requests can be either high priority or low priority. This is indicated by the priority bits which are output from the peripheral to the PIE controller. SCI interrupts can be programmed to assert the high- or low-priority levels by the SCIRX PRIORITY (SCIPRI.5) and SCITX PRIORITY (SCIPRI.6) control bits. When both RX and TX interrupt requests are made at the same priority level, the receiver always has higher priority than the transmitter, reducing the possibility of receiver overrun.

The operation of peripheral interrupts is described in the Peripheral Interrupt Expansion controller chapter of the device specification of which this SCI chapter is a part.

☑ If the RX/BK INT ENA bit (SCICTL2.1) is set, the receiver peripheral interrupt request is asserted when one of the following events occurs:

- The SCI receives a complete frame and transfers the data in the RXSHF register to the SCIRXBUF register. This action sets the RXRDY flag (SCIRXST.6) and initiates an interrupt.
- A break detect condition occurs (the SCIRXD is low for ten bit periods following a missing stop bit). This action sets the BRKDT flag bit (SCIRXST.5) and initiates an interrupt.

☑ If the TX INT ENA bit (SCICTL2.0) is set, the transmitter peripheral interrupt request is asserted whenever the data in the SCITXBUF register is transferred to the TXSHF register, indicating that the CPU can write to SCITXBUF; this action sets the TXRDY flag bit (SCICTL2.7) and initiates an interrupt.

**Note:**

Interrupt generation due to the RXRDY and BRKDT bits is controlled by the RX/BK INT ENA bit (SCICTL2.1). Interrupt generation due to the RX ERROR bit is controlled by the RX ERR INT ENA bit (SCICTL1.6).
8.6 SCI Baud Rate Calculations

The internally generated serial clock is determined by the device clock frequency (CLKOUT) and the baud-select registers. The SCI uses the 16-bit value of the baud-select registers to select one of the 64K different serial clock rates possible for a given device clock.

See the bit descriptions in section 8.7.3, Baud-Select Registers, on page 8-26 for the formula to use when calculating the SCI asynchronous baud.

Table 8–3 shows the baud-select values for common SCI bit rates.

Table 8–3. Asynchronous Baud Register Values for Common SCI Bit Rates

</tbody>
</table>

Note: The maximum CLKOUT frequency for 240xA devices is 40 MHz.
The functions of the SCI are software configurable. Sets of control bits, organized into dedicated bytes, are programmed to initialize the desired SCI communications format. This includes operating mode and protocol, baud value, character length, even/odd parity or no parity, number of stop bits, and interrupt priorities and enables. The SCI is controlled and accessed through registers listed in Figure 8–9, and described in the sections that follow.

</tr>
</tbody>
</table>

Note: R = Read access, W = Write access, -0 = value after reset

Bit 7 STOP BITS. SCI number of stop bits.

This bit specifies the number of stop bits transmitted. The receiver checks for only one stop bit.

0 One stop bit
1 Two stop bits

Bit 6 PARITY. SCI parity odd/even selection.

If the PARITY ENABLE bit (SCICCR.5) is set, PARITY (bit 6) designates odd or even parity (odd or even number of bits with the value of 1 in both transmitted and received characters).

0 Odd parity
1 Even parity

Bit 5 PARITY ENABLE. SCI parity enable.

This bit enables or disables the parity function. If the SCI is in the address-bit multiprocessor mode (set using bit 3 of this register), the address bit is included in the parity calculation (if parity is enabled). For characters of less than eight bits, the remaining unused bits should be masked out of the parity calculation.

0 Parity disabled; no parity bit is generated during transmission or is expected during reception
1 Parity is enabled

Bit 4 LOOP BACK ENA. Loop Back test mode enable.

This bit enables the Loop Back test mode where the Tx pin is internally connected to the Rx pin.

0 Loop Back test mode disabled
1 Loop Back test mode enabled
**Bit 3**  
**ADDR/IDLE MODE.** SCI multiprocessor mode control bit.

This bit selects one of the multiprocessor protocols

<table>
<thead>
<tr>

<td>Address-bit mode protocol selected</td>
</tr>
</tbody>
</table>

Multiprocessor communication is different from the other communication modes because it uses SLEEP and TXWAKE functions (bits SCICTL1.2 and SCICTL1.3, respectively). The idle-line mode is usually used for normal communications because the address-bit mode adds an extra bit to the frame. The idle-line mode does not add this extra bit and is compatible with RS-232 type communications.

**Bits 2–0**  
**SCI CHAR2–0.** Character-length control bits 2 – 0.

These bits select the SCI character length from one to eight bits. Characters of less than eight bits are right-justified in SCIRXBUF and SCIRXEMU and are padded with leading zeros in SCIRXBUF. SCITXBUF doesn’t need to be padded with leading zeros. Table 8–4 lists the bit values and character lengths for SCI CHAR2-0 bits.

</tr>
</tbody>
</table>

Note: R = Read access, W = Write access, S = Set only, -0 = value after reset

- **Bit 7** Reserved. Reads return zero; writes have no effect.
- **Bit 6** RX ERR INT ENA. SCI receive error interrupt enable.
  
  Setting this bit enables an interrupt if the RX ERROR bit (SCIRXST.7) becomes set because of errors occurring.
  
  - 0 Receive error interrupt disabled
  - 1 Receive error interrupt enabled

- **Bit 5** SW RESET. SCI software reset (active low).
  
  Writing a 0 to this bit initializes the SCI state machines and operating flags (registers SCICTL2 and SCIRXST) to the reset condition.

  The SW RESET bit does not affect any of the configuration bits.

  All affected logic is held in the specified reset state until a 1 is written to SW RESET (the bit values following a reset are shown beneath each register diagram in this section). Thus, after a system reset, re-enable the SCI by writing a 1 to this bit.

  Clear this bit after a receiver break detect (BRKDT flag, bit SCIRXST.5).

  SW RESET affects the operating flags of the SCI, but it neither affects the configuration bits nor restores the reset values.

  Once SW RESET is asserted, the flags are frozen until the bit is de-asserted.

  Table 8–5 lists the affected flags.

</tbody>
</table>

**Bit 4**  
**Reserved.** Reads return zero; writes have no effect.

**Bit 3**  
**TXWAKE.** SCI transmitter wakeup method select.

The TXWAKE bit controls selection of the data-transmit feature, depending on which transmit mode (idle-line or address-bit) is specified at the ADDR/IDLE MODE bit (SCICCR.3)

- 0 Transmit feature is not selected
- 1 Transmit feature selected is dependent on the mode, idle-line or address-bit:
  - In *idle-line* mode: write a 1 to TXWAKE, then write data to register SCITXBUF to generate an idle period of 11 data bits
  - In *address-bit* mode: write a 1 to TXWAKE, then write data to SCITXBUF to set the address bit for that frame to 1

TXWAKE is not cleared by the SW RESET bit (SCICTL1.5); it is cleared by a system reset or the transfer of TXWAKE to the WUT flag.

**Bit 2**  
**SLEEP.** SCI sleep.

In a multiprocessor configuration, this bit controls the receiver sleep function. Clearing this bit brings the SCI out of the sleep mode.

- 0 Sleep mode disabled
- 1 Sleep mode enabled
The receiver still operates when the SLEEP bit is set; however, operation does not update the receiver buffer ready bit (SCIRXST.6, RXRDY) or the error status bits (SCIRXST.5–2: BRKDT, FE, OE, and PE) unless the address byte is detected. SLEEP is not cleared when the address byte is detected.

**Bit 1 TXENA.** SCI transmitter enable.

Data is transmitted through the SCITXD pin only when TXENA is set. If reset, transmission is halted but only after all data previously written to SCITXBUF has been sent.

- 0 Transmitter disabled
- 1 Transmitter enabled

**Bit 0 RXENA.** SCI receiver enable.

Data is received on the SCIRXD pin and is sent to the receiver shift register and then the receiver buffers. This bit enables or disables the receiver (transfer to the buffers).

- 0 Prevent received characters from transfer into the SCIRXEMU and SCIRXBUF receiver buffers
- 1 Send received characters to SCIRXEMU and SCIRXBUF

Clearing RXENA stops received characters from being transferred to the two receiver buffers and also stops the generation of receiver interrupts. However, the receiver shift register can continue to assemble characters. Thus, if RXENA is set during the reception of a character, the complete character will be transferred into the receiver buffer registers, SCIRXEMU and SCIRXBUF.
8.7.3 Baud-Select Registers (SCIHBAUD, SCILBAUD)

The values in SCIHBAUD and SCILBAUD specify the baud rate for the SCI.

Figure 8–12. Baud-Select MSbyte Register (SCIHBAUD) — Address 7052h

Note: R = Read access, W = Write access, S = Set only, -0 = value after reset

Bits 15–0 BAUD15–BAUD0. SCI 16-bit baud selection.

Registers SCIHBAUD (MSbyte) and SCILBAUD (LSbyte) are concatenated to form a 16-bit baud value, BRR.

The internally-generated serial clock is determined by the CLKOUT signal and the two baud-select registers. The SCI uses the 16-bit value of these registers to select one of 64K serial clock rates for the communication modes.

The SCI baud rate is calculated using the following equation:

\[
\text{SCI Asynchronous Baud} = \frac{\text{CLKOUT}}{(BRR + 1) \times 8}
\]

Alternatively,

\[
BRR = \frac{\text{CLKOUT}}{\text{SCI Asynchronous Baud} \times 8} - 1
\]

Note that the above formulas are applicable only when \(1 \leq BRR \leq 65535\). If \(BRR = 0\), then

\[
\text{SCI Asynchronous Baud} = \frac{\text{CLKOUT}}{16}
\]

Where: BRR = the 16-bit value (in decimal) in the baud-select registers.
8.7.4 SCI Control Register 2 (SCICTL2)

SCICTL2 enables the receive-ready, break-detect, and transmit-ready interrupts as well as transmitter-ready and -empty flags.

Figure 8−14. SCI Control Register 2 (SCICTL2) — Address 7054h

<table>
<thead>
<tr>
<th>Bit 7</th>
<th>Bit 6</th>
<th>Bit 5−2</th>
<th>Bit 1</th>

<td>Reserved</td>
<td>RX/BK INT ENA</td>
<td>TX INT ENA</td>
</tr>
<tr>
<td>R-1</td>
<td>R-1</td>
<td>R-0</td>
<td>RW-0</td>
<td>RW-0</td>
</tr>
</tbody>
</table>

**Note:** R = Read access, W = Write access, -n = value after reset

**Bit 7** TXRDY. Transmitter buffer register ready flag.

When set, this bit indicates that the transmit data buffer register, SCITXBUF, is ready to receive another character. Writing data to the SCITXBUF automatically clears this bit. When set, this flag asserts a transmitter interrupt request if the interrupt-enable bit, TX INT ENA (SCICTL2.0), is also set. TXRDY is set to 1 by enabling the SW RESET bit (SCICLT2.7) or by a system reset.

- 0: SCITXBUF is full
- 1: SCITXBUF is ready to receive the next character

**Bit 6** TX EMPTY. Transmitter empty flag.

This flag's value indicates the contents of the transmitter’s buffer register (SCITXBUF) and shift register (TXSHF). An active SW RESET (SCICLT1.2), or a system reset, sets this bit. This bit does not cause an interrupt request.

- 0: Transmitter buffer or shift register or both are loaded with data
- 1: Transmitter buffer and shift registers are both empty

**Bits 5−2** Reserved.

Reads return zero; writes have no effect.

**Bit 1** RX/BK INT ENA. Receiver-buffer/break interrupt enable.

This bit controls the interrupt request caused by either the RXRDY flag or the BRKDT flag (bits SCIRXST.6 and .5) being set. However, RX/BK INT ENA does not prevent the setting of these flags.

- 0: Disable RXRDY/BRKDT interrupt
- 1: Enable RXRDY/BRKDT interrupt

**Bit 0** TX INT ENA. SCITXBUF-register interrupt enable.

This bit controls the interrupt request caused by setting the TXRDY flag bit (SCICLT2.7). However, it does not prevent the TXRDY flag from being set (being set indicates that register SCITXBUF is ready to receive another character).
SCI Module Registers

8.7.5 Receiver Status Register (SCIRXST)

SCIRXST contains seven bits that are receiver status flags (two of which can generate interrupt requests). Each time a complete character is transferred to the receiver buffers (SCIRXEMU and SCIRXBUF), the status flags are updated. Figure 8-16 on page 8-30 shows the relationships between several of the register’s bits.

Figure 8–15. Receiver Status Register (SCIRXST) — Address 7055h

<td></td>
<td>SCI break-detect flag.</td>
</tr>
<tr>
<td></td>
<td>The RX ERROR flag indicates that one of the error flags in the receiver status register is set. RX ERROR is a logical OR of the break detect, framing error, overrun, and parity error enable flags (bits 5−2: BRKDT, FE, OE, and PE).</td>
<td></td>
<td>When a new character is ready to be read from the SCIRXBUF register, the receiver sets this bit, and a receiver interrupt is generated if the RX/BK INT ENA bit (SCICTL2.1) is a 1. RXRDY is cleared by a reading of the SCIRXBUF register, by an active SW RESET, or by a system reset.</td>
<td></td>
<td>The SCI sets this bit when a break condition occurs. A break condition occurs when the SCI receiver data line (SCIRXD) remains continuously low for at</td>
</tr>
<tr>
<td>0</td>
<td>No error flags set</td>
<td>0</td>
<td>No new character in SCIRXBUF</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
least ten bits, beginning after a missing first stop bit. The occurrence of a break causes a receiver interrupt to be generated if the RX/BK INT ENA bit is a 1, but it does not cause the receiver buffer to be loaded. A BRKDT interrupt can occur even if the receiver SLEEP bit is set to 1. BRKDT is cleared by an active SW RESET or by a system reset. It is not cleared by receipt of a character after the break is detected. In order to receive more characters, the SCI must be reset by toggling the SW RESET bit or by a system reset.

- **Bit 4** FE. SCI framing-error flag.
  - The SCI sets this bit when an expected stop bit is not found. Only the first stop bit is checked. The missing stop bit indicates that synchronization with the start bit has been lost and that the character is incorrectly framed. The FE bit is reset by a clearing of the SW RESET bit or by a system reset.
  - 0 No framing error detected
  - 1 Framing error detected

- **Bit 3** OE. SCI overrun-error flag.
  - The SCI sets this bit when a character is transferred into registers SCIRXEMU and SCIRXBUF before the previous character is fully read by the CPU. The previous character is overwritten and lost. The OE flag bit is reset by an active SW RESET or by a system reset.
  - 0 No overrun error detected
  - 1 Overrun error detected

- **Bit 2** PE. SCI parity-error flag.
  - This flag bit is set when a character is received with a mismatch between the number of 1s and its parity bit. The address bit is included in the calculation. If parity generation and detection is not enabled, the PE flag is disabled and read as 0. The PE bit is reset by an active SW RESET or a system reset.
  - 0 No parity error or parity is disabled
  - 1 Parity error is detected
Bit 1  **RXWAKE.** Receiver wakeup-detect flag.

A value of 1 in this bit indicates detection of a receiver wakeup condition. In the address-bit multiprocessor mode (SCICCR.3 = 1), RXWAKE reflects the value of the address bit for the character contained in SCIRXBUF. In the idle-line multiprocessor mode, RXWAKE is set if the SCIRXD data line is detected as idle. RXWAKE is a read-only flag, cleared by one of the following:

- The transfer of the first byte after the address byte to SCIRXBUF
- The reading of SCIRXBUF
- An active SW RESET
- A system reset

Bit 0  **Reserved.** Reads return zero; writes have no effect.

RX ERROR = 1 when any of bits 5 through 2 is a 1 value

---

**8.7.6 Receiver Data Buffer Registers (SCIRXEMU, SCIRXBUF)**

Received data is transferred from RXSHF to SCIRXEMU and SCIRXBUF. When the transfer is complete, the RXRDY flag (bit SCIRXST.6) is set, indicating that the received data is ready to be read. Both registers contain the same data; they have separate addresses but are not physically separate buffers. The only difference is that reading SCIRXEMU does not clear the RXRDY flag; however, reading SCIRXBUF clears the flag.

**8.7.6.1 Emulation Data Buffer**

Normal SCI data-receive operations read the data received from the SCIRXBUF register. The SCIRXEMU register is used principally by the emulator (EMU) because it can continuously read the data received for screen updates without clearing the RXRDY flag. SCIRXEMU is cleared by a system reset.

This is the register which should be used in an emulator watch window to view the contents of SCIRXBUF register.
SCI Module Registers

SCIRXEMU is not physically implemented, it is just a different address location to access the SCIRXBUF register without clearing the RXRDY flag.

Note:  
R = Read access, -0 = value after reset

8.7.6.2 Receiver Data Buffer (SCIRXBUF)

When the current data received is shifted from RXSHF to the receiver buffer, flag bit RXRDY is set and the data is ready to be read. If the RX/BK INT ENA bit (SCICTL2.1) is set, this shift also causes an interrupt. When SCIRXBUF is read, the RXRDY flag is reset. SCIRXBUF is cleared by a system reset.

8.7.7 Transmit Data Buffer Register (SCITXBUF)

Data bits to be transmitted are written to SCITXBUF. These bits must be right-justified because the leftmost bits are ignored for characters less than eight bits long. The transfer of data from this register to the TXSHF transmitter shift register sets the TXRDY flag (SCICTL2.7), indicating that SCITXBUF is ready to receive another set of data. If bit TX INT ENA (SCICTL2.0) is set, this data transfer also causes an interrupt.

8.7.8 Priority Control Register (SCIPRI)

SCIPRI contains the receiver and transmitter interrupt priority select bits and controls the SCI operation on the XDS emulator during a program-suspend event, such as hitting a breakpoint.

Figure 8-20. SCI Priority Control Register (SCIPRI) — Address 705Fh

<table>
<thead>

<td>RW-0</td>
<td>RW-0</td>
<td>R-0</td>
</tr>
</tbody>
</table>

**Note:** R = Read access, W = Write access, -0 = value after reset

**Bit 7** **Reserved.** Reads return zero; writes have no effect.

**Bit 6** **SCITX PRIORITY.** SCI transmitter interrupt priority select. This bit specifies the priority level of the SCI transmitter interrupts.
- 0 Interrupts are high-priority requests
- 1 Interrupts are low-priority requests

**Bit 5** **SCIRX PRIORITY.** SCI receiver interrupt priority select. This bit specifies the priority level of the SCI receiver interrupts.
- 0 Interrupts are high-priority requests
- 1 Interrupts are low-priority requests

**Bits 4,3** **SCI SOFT and FREE bits.** These bits determine what occurs when an emulation suspend event occurs (for example, when the debugger hits a breakpoint). The peripheral can continue whatever it is doing (free-run mode), or if in stop mode, it can either stop immediately or stop when the current operation (the current receive/transmit sequence) is complete.

**Bit 4** **Bit 3**
- **SOFT**
  - 0 0 Immediate stop on suspend
  - 1 0 Complete current receive/transmit sequence before stopping
  - X 1 Free run. Continues SCI operation regardless of suspend

**Bits 2–0** **Reserved.** Reads return zero; writes have no effect.
The serial peripheral interface (SPI) is a high-speed synchronous serial input/output (I/O) port that allows a serial bit stream of programmed length (one to sixteen bits) to be shifted into and out of the device at a programmed bit-transfer rate. The SPI is normally used for communications between the DSP controller and external peripherals or another controller. Typical applications include external I/O or peripheral expansion via devices such as shift registers, display drivers, and analog-to-digital converters (ADCs).

Most SPI registers are eight bits in width (except for the data registers), a carryover from the 8-bit version of the SPI on the TMS320C240 device. The upper 8 bits return zeros when read.

9.1 C240 SPI vs. LF/LC240xA SPI

This SPI has 16-bit transmit and receive capability, with double-buffered transmit and double-buffered receive. All data registers are 16-bits wide.

The SPI is no longer limited to a maximum transmission rate of \( \text{CLKOUT} / 8 \) in slave mode. The maximum transmission rate in both slave mode and master mode is now \( \text{CLKOUT} / 4 \).

Note that there is a software change required since writes of transmit data to the serial data register, SPIDAT (and the new transmit buffer, SPITXBUF), must be left-justified. On the C240, these writes had to be left-justified within an 8-bit register. Now they must be left-justified within a 16-bit register.

The control and data bits for general-purpose bit I/O multiplexing have been removed from this peripheral, along with the associated registers, SPIPC1 (704Dh) and SPIPC2 (704Eh). These bits are now in the General-Purpose I/O registers.

The polarity of the SPI SW RESET bit in 240xA is the opposite of the 240 SPI.

9.1.1 SPI Physical Description

The SPI module, as shown in Figure 9–1, consists of:

- Four I/O pins:
  - SPISIMO (SPI slave in, master out)
  - SPISOMI (SPI slave out, master in)
  - SPICLK (SPI clock)
  - SPISTE (SPI slave transmit enable)

- Master and slave mode operations

- SPI serial receive buffer register (SPIRXBUF)
  This buffer register contains the data that is received from the network and that is ready for the CPU to read

- SPI serial transmit buffer register (SPITXBUF)
  This buffer register contains the next character to be transmitted when the current transmit has completed

- SPI serial data register (SPIDAT).
  This data shift register serves as the transmit/receive shift register

- SPICLK phase and polarity control
- State control logic
- Memory-mapped control and status registers

The basic function of the strobe (SPISTE) pin is to act as a transmit enable input for the SPI module in slave mode. It stops the shift register so it cannot receive data and puts the SPISOMI pin in the high-impedance state.
Figure 9−1. SPI Module Block Diagram

† SPISTE of a slave device is driven low by the master.
9.2 Overview of SPI Module Registers

Nine registers inside the SPI module (listed in Table 9–1) control the SPI operations:

- **SPICCR** (SPI configuration control register). Contains control bits used for SPI configuration
  - SPI module software reset
  - SPICLK polarity selection
  - Four SPI character-length control bits

- **SPICTL** (SPI operation control register). Contains control bits for data transmission
  - Two SPI interrupt enable bits
  - SPICLK phase selection
  - Operational mode (master/slave)
  - Data transmission enable

- **SPISTS** (SPI status register). Contains two receive buffer status bits and one transmit buffer status bit
  - RECEIVER OVERRUN
  - SPI INT FLAG
  - TX BUF FULL FLAG

- **SPIBRR** (SPI baud rate register). Contains seven bits that determine the bit transfer rate

- **SPIRXEMU** (SPI receive emulation buffer register). Contains the received data. This register is used for emulation purposes only. The SPIRXBUF should be used for normal operation

- **SPIRXBUF** (SPI receive buffer — the serial receive buffer register). Contains the received data

- **SPITXBUF** (SPI transmit buffer — the serial transmit buffer register). Contains the next character to be transmitted
Overview of SPI Module Registers

- **SPIDAT (SPI data register).** Contains data to be transmitted by the SPI, acting as the transmit/receive shift register. Data written to SPIDAT is shifted out on subsequent SPICLK cycles. For every bit shifted out of the SPI, a bit from the receive bit stream is shifted into the other end of the shift register.

- **SPIPRI (SPI priority register).** Contains bits that specify interrupt priority and determine SPI operation on the XDS™ emulator during program suspensions.

9.3 SPI Operation

This section describes the operation of the SPI. Included are explanations of the operation modes, interrupts, data format, clock sources, and initialization. Typical timing diagrams for data transfers are given.

9.3.1 Introduction to Operation

Figure 9–2 shows typical connections of the SPI for communications between two controllers: a master and a slave.

The master initiates data transfer by sending the SPICLK signal. For both the slave and the master, data is shifted out of the shift registers on one edge of the SPICLK and latched into the shift register on the opposite SPICLK clock edge. If the CLOCK PHASE bit (SPICTL.3) is high, data is transmitted and received a half-cycle before the SPICLK transition (see section 9.3.2, SPI Module Slave and Master Operation Modes, on page 9-8). As a result, both controllers send and receive data simultaneously. The application software determines whether the data is meaningful or dummy data. There are three possible methods for data transmission:

- Master sends data; slave sends dummy data.
- Master sends data; slave sends data.
- Master sends dummy data; slave sends data.

The master can initiate data transfer at any time because it controls the SPICLK signal. The software, however, determines how the master detects when the slave is ready to broadcast data.
9.3.2 SPI Module Slave and Master Operation Modes

The SPI can operate in master or slave mode. The MASTER/SLAVE bit (SPICTL.2) selects the operating mode and the source of the SPICLK signal.

Master Mode

In the master mode (MASTER/SLAVE = 1), the SPI provides the serial clock on the SPICLK pin for the entire serial communications network. Data is output on the SPISIMO pin and latched from the SPISOMI pin.

The SPIBRR register determines both the transmit and receive bit transfer rate for the network. SPIBRR can select 126 different data transfer rates.

Data written to SPIDAT or SPITXBUF initiates data transmission on the SPISIMO pin, MSB (most significant bit) first. Simultaneously, received data is shifted through the SPISOMI pin into the LSB (least significant bit) of SPIDAT. When the selected number of bits has been transmitted, the received data is transferred to the SPIRXBUF (buffered receiver) for the CPU to read. Data is stored right-justified in SPIRXBUF.

When the specified number of data bits has been shifted through SPIDAT, the following events occur:

- SPIDAT contents are transferred to SPIRXBUF.
- SPI INT FLAG bit (SPISTS.6) is set to 1.
SPI Operation

- If there is valid data in the transmit buffer SPI TXBUF, as indicated by the TXBUF FULL bit in SPISTS, this data is transferred to SPI DAT and is transmitted; otherwise, SPI CLK stops after all bits have been shifted out of SPI DAT.
- If the SPI INT ENA bit (SPICTL.0) is set to 1, an interrupt is asserted.

In a typical application, the SPISTE pin serves as a chip-enable pin for a slave SPI device and drives this pin high again after transmitting the master data. This pin is driven low by the master before transmitting data to the slave and is taken high after the transmission is complete.

Slave Mode

In the slave mode (MASTER/SLAVE = 0), data shifts out on the SPI SOMI pin and in on the SPI SIMO pin. The SPI CLK pin is used as the input for the serial shift clock, which is supplied from the external network master. The transfer rate is defined by this clock. The SPI CLK input frequency should be no greater than the CLKOUT frequency divided by 4.

Data written to SPI DAT or SPI TXBUF is transmitted to the network when appropriate edges of the SPI CLK signal are received from the network master. Data written to the SPI TXBUF register will be transferred to the SPI DAT register when all bits of the character to be transmitted have been shifted out of SPI DAT. If no character is currently being transmitted when SPI TXBUF is written to, the data will be transferred immediately to SPI DAT. To receive data, the SPI waits for the network master to send the SPI CLK signal and then shifts the data on the SPI SIMO pin into SPI DAT. If data is to be transmitted by the slave simultaneously, and SPI TXBUF has not been previously loaded, the data must be written to SPI TXBUF or SPI DAT before the beginning of the SPI CLK signal.

When the TALK bit (SPICTL.1) is cleared, data transmission is disabled, and the output line (SPI SOMI) is put into the high-impedance state. If this occurs while a transmission is active, the current character is completely transmitted even though SPI SOMI is forced into the high-impedance state. This ensures that the SPI is still able to receive incoming data correctly. This TALK bit allows many slave devices to be tied together on the network, but only one slave at a time is allowed to drive the SPI SOMI line.

The SPISTE pin operates as the slave-select pin. An active-low signal on the SPISTE pin allows the slave SPI to transfer data to the serial data line; an inactive-high signal causes the slave SPI’s serial shift register to stop and its serial output pin to be put into the high-impedance state. This allows many slave devices to be tied together on the network, although only one slave device is selected at a time.
9.4 SPI Interrupts

9.4.1 SPI Interrupt Control Bits

Five control bits are used to initialize the SPI's interrupts:

- SPI INT ENA bit (SPICTL.0)
- SPI INT FLAG bit (SPISTS.6)
- OVERRUN INT ENA bit (SPICTL.4)
- RECEIVER OVERRUN FLAG bit (SPISTS.7)
- SPI PRIORITY bit (SPIPRI.6)

9.4.1.1 SPI INT ENA Bit (SPICTL.0)

When the SPI interrupt-enable bit is set and an interrupt condition occurs, the corresponding interrupt is asserted.

0 Disable SPI interrupts
1 Enable SPI interrupts

9.4.1.2 SPI INT FLAG Bit (SPISTS.6)

This status flag indicates that a character has been placed in the SPI receiver buffer and is ready to be read.

When a complete character has been shifted into or out of SPIDAT, the SPI INT FLAG bit (SPISTS.6) is set, and an interrupt is generated if enabled by the SPI INT ENA bit (SPICTL.0). The interrupt flag remains set until it is cleared by one of the following events:

- The interrupt is acknowledged (this is different from the C240).
- The CPU reads the SPIRXBUF (reading the SPIRXEMU does not clear the SPI INT FLAG bit).
- The device enters IDLE2 or HALT mode with an IDLE instruction.
- Software clears the SPI SW RESET bit (SPICCR.7).
- A system reset occurs.

When the SPI INT FLAG bit is set, a character has been placed into the SPIRXBUF and is ready to be read. If the CPU does not read the character by the time the next complete character has been received, the new character is...
SPI Interrupts

written into SPIRXBUF, and the RECEIVER OVERRUN Flag bit (SPISTS.7) is set.

9.4.1.3 OVERRUN INT ENA Bit (SPICTL.4)

Setting the overrun interrupt enable bit allows the assertion of an interrupt whenever the RECEIVER OVERRUN Flag bit (SPISTS.7) is set by hardware. Interrupts generated by SPISTS.7 and by the SPI INT FLAG bit (SPISTS.6) share the same interrupt vector.

0 Disable RECEIVER OVERRUN Flag bit interrupts
1 Enable RECEIVER OVERRUN Flag bit interrupts

9.4.1.4 RECEIVER OVERRUN FLAG Bit (SPISTS.7)

The RECEIVER OVERRUN Flag bit is set whenever a new character is received and loaded into the SPIRXBUF before the previously received character has been read from the SPIRXBUF. The RECEIVER OVERRUN Flag bit must be cleared by software.

9.4.1.5 SPI PRIORITY Bit (SPIPRI.6)

The value of the SPI PRIORITY bit determines the priority of the interrupt request from the SPI.

0 Interrupts are high-priority requests
1 Interrupts are low-priority requests

9.4.2 Data Format

Four bits (SPICCR.3–0) specify the number of bits (1 to 16) in the data character. This information directs the state control logic to count the number of bits received or transmitted to determine when a complete character has been processed. The following statements apply to characters with fewer than 16 bits:

- Data must be left-justified when written to SPIDAT and SPITXBUF.
- Data read back from SPIRXBUF is right-justified.
- SPIRXBUF contains the most recently received character, right-justified, plus any bits that remain from previous transmission(s) that have been shifted to the left (shown in Example 9−1).
Example 9–1. Transmission of Bit from SPIRXBUF

Conditions:
1) Transmission character length = 1 bit (specified in bits SPICCR.3–0)
2) The current value of SPIDAT = 737Bh

<table>

</tr>
</thead>
<tbody>
<tr>
<td>1 1 1 0 0 1 1 0 1 1 1 1 0 1 1 x</td>
</tr>
</tbody>
</table>

Note: x = 1 if SPISOMI data is high; x = 0 if SPISOMI data is low; master mode is assumed.

9.4.3 Baud Rate and Clocking Schemes

The SPI module supports 125 different baud rates and four different clock schemes. Depending on whether the SPI clock is in slave or master mode, the SPICLK pin can receive an external SPI clock signal or provide the SPI clock signal, respectively.

- In the slave mode, the SPI clock is received on the SPICLK pin from the external source, and can be no greater than the CLKOUT frequency divided by 4.
- In the master mode, the SPI clock is generated by the SPI and is output on the SPICLK pin, and can be no greater than the CLKOUT frequency divided by 4.

Baud Rate Determination

Equation 9–1 shows how to determine the SPI baud rates.

Equation 9–1. SPI Baud-Rate Calculations

- For SPIBRR = 3 to 127:
  
  \[
  \text{SPI Baud Rate} = \frac{\text{CLKOUT}}{(\text{SPIBRR} + 1)}
  \]
SPI Interrupts

For SPIBRR = 0, 1, or 2:

\[
\text{SPI Baud Rate} = \frac{\text{CLKOUT}}{4}
\]

where:

CLKOUT = CPU clock frequency of the device
SPIBRR = Contents of the SPIBRR in the master SPI device

To determine what value to load into SPIBRR, you must know the device system clock (CLKOUT) frequency (which is device-specific) and the baud rate at which you will be operating.

Example 9–2 shows how to determine the maximum baud rate at which a 240xA can communicate. Assume that CLKOUT = 40 MHz.

**Example 9–2. Maximum Baud-Rate Calculation**

\[
\text{Maximum SPI Baud Rate} = \frac{\text{CLKOUT}}{4} = \frac{40 \times 10^6}{4} = 10 \times 10^6 \text{ bps}
\]

9.4.4 SPI Clocking Schemes

The CLOCK POLARITY bit (SPICCR.6) and the CLOCK PHASE bit (SPICTL.3) control four different clocking schemes on the SPICLK pin. The CLOCK POLARITY bit selects the active edge, either rising or falling, of the clock. The CLOCK PHASE bit selects a half-cycle delay of the clock. The four different clocking schemes are as follows:

- **Falling Edge Without Delay.** The SPI transmits data on the falling edge of the SPICLK and receives data on the rising edge of the SPICLK.
- **Falling Edge With Delay.** The SPI transmits data one half-cycle ahead of the falling edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
- **Rising Edge Without Delay.** The SPI transmits data on the rising edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
- **Rising Edge With Delay.** The SPI transmits data one half-cycle ahead of the rising edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.
The selection procedure for the SPI clocking scheme is shown in Table 9–2. Examples of these four clocking schemes relative to transmitted and received data are shown in Figure 9–3.

Figure 9–3. SPICLK Signal Options

Note: Previous data bit
For the SPI, SPICLK symmetry is retained only when the result of (SPIBRR+1) is an even value. When (SPIBRR + 1) is an odd value and SPIBRR is greater than 3, SPICLK becomes asymmetrical. The low pulse of SPICLK is one CLKOUT longer than the high pulse when the CLOCK POLARITY bit is clear (0). When the CLOCK POLARITY bit is set to 1, the high pulse of the SPICLK is one CLKOUT longer than the low pulse, as shown in Figure 9−4.

Figure 9−4. SPI: SPICLK-CLKOUT Characteristic when (BRR + 1) is Odd, BRR > 3, and CLOCK POLARITY = 1

9.4.5 Initialization Upon Reset

A system reset forces the SPI peripheral module into the following default configuration:

- Unit is configured as a slave module (MASTER/SLAVE = 0)
- Transmit capability is disabled (TALK = 0)
- Data is latched at the input on the falling edge of the SPICLK signal
- Character length is assumed to be one bit
- SPI interrupts are disabled
- Data in SPIDAT is reset to 0000h
- SPI module pin functions are selected as general-purpose inputs (this is done in I/O Mux control register B [MCRB])

To change this SPI configuration:

1) Clear the SPI SW RESET bit (SPICCR.7) to 0 to force the SPI to the reset state.
2) Initialize the SPI configuration, format, baud rate, and pin functions as desired.
3) Set the SPI SW RESET bit to 1 to release the SPI from the reset state.
4) Write to SPIDAT or SPITXBUF (this initiates the communication process in the master).
5) Read SPIRXBUF after the data transmission has completed (SPISTS.6 = 1) to determine what data was received.
9.4.5.1 Proper SPI Initialization Using the SPI SW RESET Bit

To prevent unwanted and unforeseen events from occurring during or as a result of initialization changes, clear the SPI SW RESET bit (SPICCR.7) before making initialization changes, and then set this bit after initialization is complete.

Note:
Do not change SPI configuration when communication is in progress.

9.4.6 Data Transfer Example

The timing diagram, shown in Figure 9–5, illustrates an SPI data transfer between two devices using a character length of five bits with the SPICLK being symmetrical.

The timing diagram with SPICLK unsymmetrical (Figure 9–4) shares similar characterizations with Figure 9–5 except that the data transfer is one CLKOUT cycle longer per bit during the low pulse (CLOCK POLARITY = 0) or during the high pulse (CLOCK POLARITY = 1) of the SPICLK.

Figure 9–5, Five Bits per Character, is applicable for 8-bit SPI only and is not for 24x devices that are capable of working with 16-bit data. The figure is shown for illustrative purposes only.
Figure 9−5. Five Bits per Character

Master SPI
Int flag
Slave SPI
Int flag
SPISOMI from slave
SPISIMO from master

SPICLK signal options:
CLOCK POLARITY = 0
CLOCK PHASE = 0
CLOCK POLARITY = 0
CLOCK PHASE = 1
CLOCK POLARITY = 1
CLOCK PHASE = 0
CLOCK POLARITY = 1
CLOCK PHASE = 1

A. Slave writes 0D0h to SPIDAT and waits for the master to shift out the data.
B. Master sets the slave SPISTE signal low (active).
C. Master writes 058h to SPIDAT, which starts the transmission procedure.
D. First byte is finished and sets the interrupt flags.
E. Slave reads 0Bh from its SPIRXBUF (right-justified).
F. Slave writes 04Ch to SPIDAT and waits for the master to shift out the data.
G. Master writes 06Ch to SPIDAT, which starts the transmission procedure.
H. Master reads 01Ah from the SPIRXBUF (right−justified).
I. Second byte is finished and sets the interrupt flags.
J. Master reads 89h and the slave reads 8Dh from their respective SPIRXBUF. After the user’s software masks off the unused bits, the master receives 09h and the slave receives 0Dh.
K. Master clears the slave SPISTE signal high (inactive).
### 9.5 SPI Module Registers

The SPI is controlled and accessed through registers in the control register file. Figure 9–6 lists the SPI control registers and bit numbers.

<td>RW-0</td>
<td>RW-0</td>
<td>RW-0</td>
</tr>
</tbody>
</table>

Note: R = Read access, W = Write access, -0 = value after reset

Bit 7  
**SPI SW RESET.** SPI Software Reset. When changing configuration, you should clear this bit before the changes and set this bit before resuming operation. (See Section 9.4.5.1 on page 9-16.)

0   Initializes the SPI operating flags to the reset condition.

Specifically, the RECEIVER OVERRUN Flag bit (SPISTS.7), the SPI INT FLAG bit (SPISTS.6), and the TXBUF FULL Flag bit (SPISTS.5) are cleared. The SPI configuration remains unchanged. If the module is operating as a master, the SPICLK signal output returns to its inactive level.

1   SPI is ready to transmit or receive the next character.

When the SPI SW RESET bit is a 0, a character written to the transmitter will not be shifted out when this bit is set. A new character must be written to the serial data register.

Bit 6  
**CLOCK POLARITY.** Shift Clock Polarity. This bit controls the polarity of the SPICLK signal. CLOCK POLARITY and CLOCK PHASE (SPICTL.3) control four clocking schemes on the SPICLK pin. See Section 9.4.4, *SPI Clocking Schemes*, on page 9-13.

0   Data is output on rising edge and input on falling edge. When no SPI data is sent, SPICLK is at low level.

The data input and output edges depend on the value of the CLOCK PHASE bit (SPICTL.3) as follows:

- **CLOCK PHASE = 0:** Data is output on the rising edge of the SPICLK signal; input data is latched on the falling edge of the SPICLK signal.

- **CLOCK PHASE = 1:** Data is output one half-cycle before the first rising edge of the SPICLK signal and on subsequent falling edges of the SPICLK signal; input data is latched on the rising edge of the SPICLK signal.
Data is output on falling edge and input on rising edge. When no SPI data is sent, SPICLK is at high level.

The data input and output edges depend on the value of the CLOCK PHASE bit (SPICTL.3) as follows:

- **CLOCK PHASE = 0**: Data is output on the falling edge of the SPICLK signal; input data is latched on the rising edge of the SPICLK signal.

- **CLOCK PHASE = 1**: Data is output one half-cycle before the first falling edge of the SPICLK signal and on subsequent rising edges of the SPICLK signal; input data is latched on the falling edge of the SPICLK signal.

**Bits 5–4**  **Reserved.** Reads return zero; writes have no effect.

**Bits 3–0**  **SPI CHAR3–SPI CHAR0.** Character Length Control Bits 3–0. These four bits determine the number of bits to be shifted in or out as a single character during one shift sequence.

Table 9–3 lists the character length selected by the bit values.

**Table 9–3. Character Length Control Bit Values**

<td>RW-0</td>
<td>RW-0</td>
<td>RW-0</td>
<td>RW-0</td>
</tr>
</tbody>
</table>

**Note:**  
R = Read access, W = Write access, -0 = value after reset

- **Bits 7−5**  
  Reserved. Reads return zero; writes have no effect.

- **Bit 4**  
  **OVERRUN INT ENA.** Overrun Interrupt Enable. Setting this bit causes an interrupt to be generated when the RECEIVER OVERRUN Flag bit (SPISTS.7) is set by hardware. Interrupts generated by the RECEIVER OVERRUN Flag bit and the SPI INT FLAG bit (SPISTS.6) share the same interrupt vector.

  - 0 Disable RECEIVER OVERRUN Flag bit (SPISTS.7) interrupts
  - 1 Enable RECEIVER OVERRUN Flag bit (SPISTS.7) interrupts

- **Bit 3**  
  **CLOCK PHASE.** SPI Clock Phase Select. This bit controls the phase of the SPICLK signal.

  - 0 Normal SPI clocking scheme, depending on the CLOCK POLARITY bit (SPICCR.6)
  - 1 SPICLK signal delayed by one half-cycle; polarity determined by the CLOCK POLARITY bit

  CLOCK PHASE and CLOCK POLARITY (SPICCR.6) make four different clocking schemes possible (see Figure 9−3). When operating with CLOCK PHASE high, the SPI (master or slave) makes the first bit of data available after SPIDAT is written and before the first edge of the SPICLK signal, regardless of which SPI mode is being used.

- **Bit 2**  
  **MASTER/SLAVE.** SPI Network Mode Control. This bit determines whether the SPI is a network master or slave. During reset initialization, the SPI is automatically configured as a network slave.

  - 0 SPI configured as a slave.
  - 1 SPI configured as a master.

- **Bit 1**  
  **TALK.** Master/Slave Transmit Enable. The TALK bit can disable data transmission (master or slave) by placing the serial data output in the high-impedance state. If this bit is disabled during a transmission, the transmit shift
SPI Module Registers

register continues to operate until the previous character is shifted out. When the TALK bit is disabled, the SPI is still able to receive characters and update the status flags. TALK is cleared (disabled) by a system reset.

0  Disables transmission:
   - Slave mode operation: If not previously configured as a general-purpose I/O pin, the SPISOMI pin will be put in the high-impedance state.
   - Master mode operation: If not previously configured as a general-purpose I/O pin, the SPISIMO pin will be put in the high-impedance state.
1  Enables transmission

For the 4-pin option, ensure to enable the receiver’s SPISTE input pin.

Bit 0  SPI INT ENA. SPI Interrupt Enable. This bit controls the SPI’s ability to generate a transmit/receive interrupt. The SPI INT FLAG bit (SPISTS.6) is unaffected by this bit.

0  Disables interrupt
1  Enables interrupt

9.5.3 SPI Status Register (SPISTS)

SPISTS contains the receive buffer status bits.

Figure 9–9. SPI Status Register (SPISTS) — Address 7042h

Note:  R = Read access, C = Clear, -0 = value after reset
†The RECEIVER OVERRUN FLAG bit and the SPI INT FLAG bit share the same interrupt vector.
‡Writing a 0 to bits 5, 6, and 7 has no effect.

Bit 7  RECEIVER OVERRUN FLAG. SPI Receiver Overrun Flag. This bit is a read/clear-only flag. The SPI hardware sets this bit when a receive or transmit operation completes before the previous character has been read from the buffer. The bit indicates that the last received character has been overwritten and therefore lost (when the SPIRXBUF was overwritten by the SPI module before the previous character was read by the user application). The SPI requests
SPI Module Registers

one interrupt sequence each time this bit is set if the OVERRUN INT ENA bit (SPICTL.4) is set high. The bit is cleared in one of three ways:

- Writing a 1 to this bit
- Writing a 0 to SPI SW RESET (SPICCR.7)
- Resetting the system

If the OVERRUN INT ENA bit (SPICTL.4) is set, the SPI requests only one interrupt upon the first occurrence of setting the RECEIVER OVERRUN Flag bit. Subsequent overruns will not request additional interrupts if this flag bit is already set. This means that in order to allow new overrun interrupt requests the user must clear this flag bit by writing a 1 to SPISTS.7 each time an overrun condition occurs. In other words, if the RECEIVER OVERRUN Flag bit is left set (not cleared) by the interrupt service routine, another overrun interrupt will not be immediately re-entered when the interrupt service routine is exited.

However, the RECEIVER OVERRUN Flag bit should be cleared during the interrupt service routine because the RECEIVER OVERRUN Flag bit and SPI INT FLAG bit (SPISTS.6) share the same interrupt vector. This will alleviate any possible doubt as to the source of the interrupt when the next byte is received.

Bit 6   **SPI INT FLAG.** SPI Interrupt Flag. SPI INT FLAG is a read-only flag. The SPI hardware sets this bit to indicate that it has completed sending or receiving the last bit and is ready to be serviced. The received character is placed in the receiver buffer at the same time this bit is set. This flag causes an interrupt to be requested if the SPI INT ENA bit (SPICTL.0) is set. This bit is cleared in one of three ways:

- Reading SPIRXBUF
- Writing a 0 to SPI SW RESET (SPICCR.7)
- Resetting the system

Bit 5   **TX BUF FULL FLAG.** SPI Transmit Buffer Full Flag. This read-only bit gets set to 1 when a character is written to the SPI Transmit buffer SPITXBUF. It is cleared when the character is automatically loaded into SPIDAT when the shifting out of a previous character is complete. It is cleared at reset.

Bits 4–0 **Reserved.** Reads return zero; writes have no effect.
9.5.4 SPI Baud Rate Register (SPIBRR)

SPIBRR contains the bits used for baud-rate selection.

Figure 9–10. SPI Baud Rate Register (SPIBRR) — Address 7044h

<td>RW-0</td>
<td>RW-0</td>
</tr>
</tbody>
</table>

**Note:** R = Read access, W = Write access, -0 = value after reset

**Bit 7** Reserved. Reads return zero; writes have no effect.

**Bits 6–0** SPI BIT RATE 6–SPI BIT RATE 0. SPI Bit Rate (Baud) Control. These bits determine the bit transfer rate if the SPI is the network master. There are 125 data-transfer rates (each a function of the CPU clock, CLKOUT) that can be selected. One data bit is shifted per SPICLK cycle. (SPICLK is the baud rate clock output on the SPICLK pin.)

If the SPI is a network slave, the module receives a clock on the SPICLK pin from the network master; therefore, these bits have no effect on the SPICLK signal. The frequency of the incoming SPICLK from the master should not exceed CLKOUT/4.

In master mode, the SPI clock is generated by the SPI and is output on the SPICLK pin. The SPI baud rates are determined by the following formula:

**SPI Baud-Rate Calculations**

- For SPIBRR = 3 to 127:
  
  \[
  \text{SPI Baud Rate} = \frac{\text{CLKOUT}}{(\text{SPIBRR} + 1)}
  \]

- For SPIBRR = 0, 1, or 2:
  
  \[
  \text{SPI Baud Rate} = \frac{\text{CLKOUT}}{4}
  \]

where: CLKOUT = CPU clock frequency of the device
SPIBRR = Contents of the SPIBRR in the master SPI device
9.5.5 SPI Emulation Buffer Register (SPIRXEMU)

SPIRXEMU contains the received data. Reading SPIRXEMU does not clear the SPI INT FLAG bit (SPISTS.6). This is not a real register but a dummy address from which the contents of SPIRXBUF can be read by the emulator without clearing the SPI INT FLAG.

Note: R = Read access, -0 = value after reset

Bits 15–0 ERXB15–ERXB0. Emulation Buffer Received Data. SPIRXEMU functions almost identically to SPIRXBUF, except that reading SPIRXEMU does not clear the SPI INT FLAG bit (SPISTS.6). Once the SPIDAT has received the complete character, the character is transferred to SPIRXEMU and SPIRXBUF, where it can be read. At the same time, SPI INT FLAG is set.

This mirror register was created to support emulation. Reading SPIRXBUF clears the SPI INT FLAG bit (SPISTS.6). In the normal operation of the emulator, the control registers are read to continually update the contents of these registers on the display screen. SPIRXEMU was created so that the emulator can read this register and properly update the contents on the display screen. Reading SPIRXEMU does not clear the SPI INT FLAG bit, but reading SPIRXBUF clears this flag. In other words, SPIRXEMU enables the emulator to emulate the true operation of the SPI more accurately.

It is recommended that you view SPIRXEMU in the normal emulator run mode.
9.5.6 SPI Serial Receive Buffer Register (SPIRXBUF)

SPIRXBUF contains the received data. Reading SPIRXBUF clears the SPI INT FLAG bit (SPISTS.6).

Figure 9–12. SPI Serial Receive Buffer Register (SPIRXBUF) — Address 7047h

Note:  
- R = Read access, -0 = value after reset

**Bits 15–0  RXB15–RXB0.** Received Data. Once SPIDAT has received the complete character, the character is transferred to SPIRXBUF, where it can be read. At the same time, the SPI INT FLAG bit (SPISTS.6) is set. Since data is shifted into the SPI's most significant bit first, it is stored right-justified in this register.
9.5.7 SPI Serial Transmit Buffer Register (SPITXBUF)

SPITXBUF stores the next character to be transmitted. Writing to this register sets the TX BUF FULL Flag bit (SPISTS.5). When transmission of the current character is complete, the contents of this register are automatically loaded in SPIDAT and the TX BUF FULL Flag is cleared. If no transmission is currently active, data written to this register falls through into the SPIDAT register and the TX BUF FULL Flag is not set.

In master mode, if no transmission is currently active, writing to this register initiates a transmission in the same manner that writing to SPIDAT does.

Note: R = Read access, W = Write access, -0 = value after reset

Bits 15–0 TXB15–TXB0. Transmit Data Buffer. This is where the next character to be transmitted is stored. When the transmission of the current character has completed, if the TX BUF FULL Flag bit is set, the contents of this register is automatically transferred to SPIDAT, and the TX BUF FULL Flag is cleared.

Note:

 Writes to SPITXBUF must be left-justified.
9.5.8 SPI Serial Data Register (SPIDAT)

SPIDAT is the transmit/receive shift register. Data written to SPIDAT is shifted out (MSB) on subsequent SPICLK cycles. For every bit (MSB) shifted out of the SPI, a bit is shifted into the LSB end of the shift register.

<td>RW-0</td>
<td>RW-0</td>
</tr>
</tbody>
</table>

Note: R = Read access, W = Write access, -0 = value after reset

Bits 15–0 SDAT15–SDAT0. Serial Data. Writing to the SPIDAT performs two functions:

- It provides data to be output on the serial output pin if the TALK bit (SPICTL.1) is set.

- When the SPI is operating as a master, a data transfer is initiated. When initiating a transfer, see the CLOCK POLARITY bit (SPICCR.6) described in section 9.5.1, SPI Configuration Control Register on page 9-19, and the CLOCK PHASE bit (SPICTL.3) described in section 9.5.2, SPI Operation Control Register on page 9-21, for the requirements.

In master mode, writing dummy data to SPIDAT initiates a receiver sequence. Since the data is not hardware-justified for characters shorter than sixteen bits, transmit data must be written in left-justified form, and received data read in right-justified form.
9.5.9 SPI Priority Control Register (SPIPRI)

SPIPRI selects the interrupt priority level of the SPI interrupt and controls the SPI operation on the XDS emulator during program suspends, such as hitting a breakpoint.

Figure 9−15. SPI Priority Control Register (SPIPRI) — Address 704Fh

Figure 9–21. SPISTE Behavior in Slave Mode (Slave’s SPISTE is driven low during the entire 16 bits of transmission.)
This chapter describes the controller area network (CAN) module available on some members of the 24x/240xA family. The interface signals, configuration registers, and mailbox RAM are described in detail; however, the CAN protocol itself is not discussed in depth. For details on the protocol, refer to *CAN Specification, Version 2.0*, by Robert Bosch GmbH, Germany. The CAN module is a full-CAN controller designed as a 16-bit peripheral and is fully compliant with the CAN protocol, version 2.0B.

10.1 Introduction

The CAN peripheral supports the following features:

- Full implementation of CAN protocol, version 2.0B
  - Standard and extended identifiers
  - Data and remote frames
- Six mailboxes for objects with data lengths of 0- to 8-bytes
  - Two receive mailboxes (MBOX0,1), two transmit mailboxes (MBOX4,5)
  - Two configurable transmit/receive mailboxes (MBOX2,3)
- Local acceptance mask registers (LAMn) for mailboxes 0 and 1 and mailboxes 2 and 3
- Programmable bit rate
- Programmable interrupt scheme
- Programmable wake-up on bus activity
- Automatic reply to a remote request
- Automatic re-transmission in case of error or loss of arbitration
- Bus failure diagnostic
  - Bus on/off
  - Error passive/active
  - Bus error warning
  - Bus stuck dominant
  - Frame error report
  - Readable error counter
- Self-Test Mode
  - The CAN peripheral operates in a loopback mode
  - Receives its own transmitted message and generates its own acknowledge signal
- Two-Pin Communication
  - The CAN module uses two pins for communication, CANTX and CANRX
  - These two pins are connected to a CAN transceiver chip, which in turn is connected to a CAN bus
10.2 Overview of the CAN Network

The controller area network (CAN) uses a serial multimaster communication protocol that efficiently supports distributed real-time control with a very high level of data integrity, and communication speeds of up to 1 Mbps. The CAN bus is ideal for applications operating in noisy and harsh environments, such as in the automotive and other industrial fields that require reliable communication.

Prioritized messages of up to eight bytes in data length can be sent on a multimaster serial bus using an arbitration protocol and an error-detection mechanism for a high level of data integrity.

10.2.1 CAN Protocol Overview

The CAN protocol supports four different frame types for communication:

- **Data frames** that carry data from a transmitter node to receiver node(s)
- **Remote frames** that are transmitted by a node to request the transmission of a data frame with the same identifier
- **Error frames** that are transmitted by any node on a bus-error detection
- **Overload frames** that provide an extra delay between the preceding and the succeeding data frames or remote frames

In addition, *CAN Specification Version 2.0B* defines two different formats that differ in the length of the identifier field: standard frames with an 11-bit identifier and extended frames with a 29-bit identifier.

CAN standard data frames contain from 44 to 108 bits, and CAN extended data frames contain 64 to 128 bits. Furthermore, up to 23 stuff bits can be inserted in a standard data frame and up to 28 stuff bits in an extended data frame, depending on the data-stream coding. The overall maximum data frame length is 131 bits for a standard frame and 156 bits for an extended frame.

In Figure 10–1, bit fields within the data frame identify:

- Start of the frame
- Arbitration field containing the identifier and the type of message being sent
- Control field containing the number of data
- Up to 8 bytes of data
- Cyclic redundancy check (CRC)
- Acknowledgment
- End-of-frame bits
Figure 10–1. CAN Data Frame

</tr>
</tbody>
</table>

Arbitration field which contains:

- 11-bit identifier + RTR bit for standard frame format
- 29-bit identifier + SRR bit + IDE bit + RTR bit for extended frame format

Where:

- RTR = Remote Transmission Request
- SRR = Substitute Remote Request
- IDE = Identifier Extension

Note: Unless otherwise noted, numbers are amount of bits in field.

10.2.2 CAN Controller Architecture

Figure 10–2 shows the basic architecture of the CAN controller.

Figure 10–2. TMS320x240xA CAN Module Block Diagram
The CAN module is a 16-bit peripheral that accesses the following:

- Control/status registers
- Mailbox RAM

**Control/Status Registers:** The CPU performs 16-bit accesses to the control/status registers. The CAN peripheral always presents full 16-bit data to the CPU bus during read cycles.

**Mailbox RAM:** Writing/reading from the mailbox RAM is always wordwise (16 bits) and the RAM always presents the full 16-bit word on the bus.

Table 10–1 shows the configuration details of the mailboxes.

</tr>
</tbody>
</table>

**Note:** All unimplemented register bits are read as zero; writes have no effect. All register bits are initialized to zero unless otherwise stated in the definition.
The mailboxes are located in one $48 \times 16$ RAM with 16-bit access and can be written to or read by the CPU (user) or CAN. The CAN write or read access, as well as the CPU read access, needs one clock cycle. The CPU write access needs two clock cycles because the CAN controller performs a read-modify-write cycle; and therefore, inserts one wait state for the CPU.

Table 10–3 shows the mailbox locations in the RAM.

10.3 Message Objects

CAN allows messages to be sent, received, and stored by using data frames. Figure 10−4 illustrates the structure of the data frames with extended and standard identifiers.

**Figure 10−4. CAN Data Frame Structure**

---

Data frame contains:

- **SOF**: Start of Frame – signifies the start of frame
- **Identifier**: 
  - **Message priority** – determines the priority of the message when two or more nodes are contending for the bus
  - **Message filtering** – determines if a transmitted message will be received by CAN modules
- **RTR**: Remote Transmission Request bit – differentiates a data frame from a remote frame
- **SRR**: Substitute Remote Request bit – this bit occupies the position as RTR would in a standard frame
- **IDE**: Identifier Extension bit – differentiates standard and extended frames
- **r0, r1**: reserved
- **DLC**: Data Length Code – denotes the number of bytes (0 to 8) in a data frame
- **Data**: Four 16-bit words are used to store the (maximum) 8-byte data field of a CAN message
Message Objects

- **CRC**: contains a 16-bit checksum calculated on most parts of the message. This checksum is used for error detection.
- **ACK**: Data Acknowledge
- **EOF**: End of Frame

### 10.3.1 Mailbox Layout

#### 1) Mailbox RAM:

The mailbox RAM is the area where the CAN frames are stored before they are transmitted, and after they are received. Each mailbox has four 16-bit registers which can store a maximum of 8 bytes (MBXnA, MBXnB, MBXnC, and MBXnD). Mailboxes that are not used for storing messages may be used as normal memory by the CPU.

#### 2) Message Identifiers:

Each one of the six mailboxes has its own message identifier stored in two 16-bit registers. Figure 10–5 shows the message identifier high word and Figure 10–6 shows the message identifier low word.

**Figure 10–5. Message Identifier for High-Word Mailboxes 0–5 (MSGIDnH)**

<table>
<thead>
<tr>
<th>IDE</th>
<th>AME</th>
<th>AAM</th>
<th>IDH[28:16]</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW</td>
<td>RW</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Note:** R = Read access; W = Write access

**Bit 15 IDE.** Identifier Extension Bit.

- 0 The received message has a standard identifier (11 bits).†
- 1 The received message has an extended identifier (29 bits).‡

† In case of a receive mailbox
‡ In case of a transmit mailbox

**Bit 14 AME.** Acceptance Mask Enable Bit.

- 0 No acceptance mask will be used. All identifier bits in the received message and the receive MBOX must match in order to store the message.
- 1 The corresponding acceptance mask is used.

This bit will not be affected by a reception.

This bit is relevant for receive mailboxes only. Hence, it is applicable for MBOX0 and MBOX1 and also for MBOX2 and MBOX3, if they are configured as receive mailboxes. It is a don’t care for mailboxes 4 and 5.
**Bit 13**  
**AAM.** Auto Answer Mode Bit.

- **0** Transmit mailbox: The mailbox does not reply to remote requests automatically. If a matching identifier is received, it is not stored.
- **1** Transmit mailbox: If a matching remote request is received, the CAN peripheral answers by sending the contents of the mailbox.
- **Receive mailbox**: No influence on a receive mailbox.

This bit is only used for mailboxes 2 and 3. This bit will not be affected by a reception.

**Bits 12–0**  
**IDH[28:16].** Upper 13 Bits of extended identifier. For a standard identifier, the 11-bit identifier will be stored in bits 12 to 2 of the MSGID’s upper word.

**Figure 10–6. Message Identifier for Low-Word Mailboxes 0–5 (MSGIDnL)**

<table>
<thead>
<tr>
<th>IDL[15:0]</th>
<th>RW</th>
</tr>
</thead>
</table>

**Note:**  
R = Read access; W = Write access

**Bits 15–0**  
**IDL[15:0].** The lower part of the extended identifier is stored in these bits.

**3) Message Control Field:**

Each one of the six mailboxes has its own “Message Control Field”. Figure 10–7 illustrates the layout and default mode of the message control field.

**Figure 10–7. Message Control Field (MSGCTRLn)**

<table>
<thead>
<tr>
<th>15–5</th>
<th>4</th>
<th>3–0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved</td>
<td>RTR</td>
<td>DLC[3:0]</td>
</tr>
</tbody>
</table>

**Note:**  
R = Read access; W = Write access

**Bits 15–5**  
**Reserved.**

**Bit 4**  
**RTR.** Remote Transmission Request bit.

- **0** Data frame.
- **1** Remote frame.
**Bits 3−0**  
**DLC.** Data Length Code.

This value determines how many data bytes are used for transmission. This field will be updated by the received data frame (i.e., the DLC value of the data frame received will be copied in this field).

- **0001** 1 byte  
- **0010** 2 bytes  
- **0011** 3 bytes  
- **0100** 4 bytes  
- **0101** 5 bytes  
- **0110** 6 bytes  
- **0111** 7 bytes  
- **1000** 8 bytes

### 10.3.2 Message Buffers

Message storage is implemented by RAM. The contents of the storage elements are used to perform the functions of acceptance filtering, transmission, and interrupt handling.

The mailbox module provides six mailboxes, each consisting of 8 bytes of data, 29 identifier bits, and several control bits. Mailboxes 0 and 1 are for reception; mailboxes 2 and 3 are configurable as receive or transmit; and mailboxes 4 and 5 are transmit mailboxes. Mailboxes 0 and 1 share one acceptance mask, while mailboxes 2 and 3 share a different mask.

---

**Note:** **Unused Message Mailboxes**

Unused mailbox RAM may be used as normal memory. Because of this, you must ensure that no CAN function uses the RAM area. This is usually done by disabling the corresponding mailbox or by disabling the CAN function.

---

### 10.3.3 Write Access to Mailbox RAM

There are two different types of write accesses to the Mailbox RAM:

1) write access to the identifier of a mailbox  
2) write access to the data or control field

---

**Note:**

Write accesses to the identifier can only be accomplished when the mailbox is disabled (MEn = 0 in MDER register).  

---
During accesses to the data field or control field, it is critical that the data does not change while the CAN module is reading it. Therefore, a write access to the data field or control field is disabled for a receive mailbox. For transmit mailboxes, the access is usually denied if the transmit request set (TRS) bit or the transmit request reset (TRR) bit is set. In these cases, a write-denied interrupt flag (WDIF) is asserted. A way to access mailboxes 2 and 3 is to set the change data field request (CDR) bit before accessing the mailbox data.

After the CPU access is finished, the CPU must clear the CDR flag by writing a 0 to it. The CAN module checks for that flag before and after reading the mailbox. If the CDR flag is set during the mailbox checks, the CAN module does not transmit the message but continues to look for other transmit requests. The setting of the CDR flag also stops the write-denied interrupt (WDI) from being asserted. CAN read/write and CPU read accesses to the mailbox RAM take one clock cycle. CPU writes to the mailbox RAM take two clock cycles.

### 10.3.4 Transmit Mailbox

Mailboxes 4 and 5 are transmit mailboxes only; whereas, mailboxes 2 and 3 can be configured for reception or transmission.

The CPU stores the data to be transmitted in a mailbox that is configured as a transmit mailbox. After writing the data and the identifier into RAM, and provided the corresponding TRS bit has been set, the message is sent.

If more than one mailbox is configured as a transmit mailbox and more than one corresponding TRS bit is set, the messages are sent one after another, in falling order, beginning with the highest enabled mailbox.

If a transmission fails due to a law of arbitration or an error, the message transmission will be re-attempted.

### 10.3.5 Receive Mailbox

Mailboxes 0 and 1 are receive-only mailboxes. Mailboxes 2 and 3 can be configured for reception or transmission.

The identifier of each incoming message is compared to the identifiers held in the receive mailboxes by using the appropriate identifier mask. When equality is detected, the received identifier, the control bits, and the data bytes are written into the matching RAM location. At the same time, the corresponding receive message pending (RMPn) bit is set and a mailbox interrupt (MIFx) is generated if enabled. If the current identifier does not match, the message is not stored. The RMPn bit has to be reset by the CPU after reading the data.
If a second message has been received for this mailbox and the RMP bit is already set, the corresponding receive message lost (RML) bit is set. In this case, the stored message is overwritten with the new data if the overwrite protection control (OPC) bit is cleared. Otherwise, the next mailboxes are checked.

**Note:**

For the mailbox interrupt flag (MIFn) bits in the CAN_IFR register to be set, the corresponding bits in the CAN_IMR register must be enabled. If “polling” is desired to complete transmission or reception of messages (as opposed to interrupts), the following bits must be used:

- For transmission: TAn bits in the TCR register
- For reception: RMPn bits in the RCR register

### 10.3.6 Handling of Remote Frames

Remote frame handling can only be done with mailboxes 0 to 3; mailboxes 4 and 5 cannot handle remote frames.

**Receiving a Remote Request**

If a remote request is received (the incoming message has the remote transmission request bit [RTR] = 1), the CAN module compares the identifier to all identifiers of the mailboxes using the appropriate masks in descending order starting with the highest mailbox number.

In case of a matching identifier with the message object configured as a transmit mailbox and the auto-answer mode bit (AAM) in the message set, the message object is marked to be sent (TRS bit is set). See Figure 10−8 (A).

In case of a matching identifier with the message object configured as a transmit mailbox and the AAM bit not set, the message is not received. See Figure 10−8 (B).

After finding a matching identifier in a send mailbox, no further compare is done.

In case of a matching identifier with the message object configured as a receive mailbox, the message is handled like a data frame and the RMP bit in the receive control register (RCR) is set. The CPU then has to decide how to handle the situation. See Figure 10−8 (E).

If the CPU wants to change the data in a message object that is configured as a remote frame mailbox (AAM bit set), it has to set the mailbox number (MBNR)
in the master control register and the CDR in the master control register first. The CPU may then perform the access and clear the CDR to tell the CAN module that the access is finished. Until the CDR is cleared, the transmission of this mailbox is not performed. Since the TRS bit is not affected by the CDR, a pending transmission is stacked after the CDR is cleared. Thus, the newest data will be sent.

In order to change the identifier in the mailbox, the message object must be disabled first (ME bit in the MDER = 0).

**Sending a Remote Request**

If the CPU wants to request data from another node, it may configure the message object as a receive mailbox (only mailboxes 2 and 3) and set the TRS bit. See Figure 10−8 (F). In this case, the module sends a remote frame request and receives the data frame in the same mailbox that sent the request. Therefore, only one mailbox is necessary to do a remote request.

### 10.3.7 Mailbox Configurations

A mailbox can be configured in four different ways:

- Transmit mailbox (mailboxes 4 and 5 or 2 and 3 configured as transmit) can only transmit messages.
- Receive mailbox (mailboxes 0 and 1) can only receive messages.
- Mailboxes 2 and 3 configured as receive mailboxes can transmit a remote request frame and wait for the corresponding data frame if the TRS bit is set.
- Mailboxes 2 and 3 configured as transmit mailboxes can transmit a data frame wherever a remote request frame is received for the corresponding identifier, if the AAM bit is set.

**Note:**

After successful transmission of a remote frame, the TRS bit is reset but no transmit acknowledge (TA) or mailbox interrupt flag is set.
10.3.8 Acceptance Filter

The identifier of the incoming message is first compared to the message identifier of the receive mailbox (which is stored in the mailbox in MSGIDnH and MSGIDnL registers). Then the appropriate acceptance mask is used to mask out the bits of the identifier that should not be compared. The local acceptance mask can be disabled by setting the acceptance mask enable (AME) bit to 0 in the message identifier high word (MSGIDn) field.

Local Acceptance Mask (LAM)

The local acceptance filtering allows the user to locally mask (that is, treat as a *don’t care*) any identifier bit of the incoming message.

Local acceptance mask register LAM1 is used for mailboxes 2 and 3 while local acceptance mask register LAM0 is used for mailboxes 0 and 1. During
a reception, mailboxes 3 and 2 are checked before mailboxes 1 and 0. Figure 10–9 illustrates the LAMn_H high word and Figure 10–10 illustrates the LAMn_L low word.

Figure 10–9. Local Acceptance Mask Register n (0, 1) High Word (LAMn_H) – Addresses 710Bh, 710Dh

<table>
<thead>
<tr>

<td></td>
<td>RW-0</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bit 15</th>
<th>LAMI: Local acceptance mask identifier extension bit.</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The identifier extension bit stored in the mailbox determines which messages are received (standard or extended).</td>
</tr>
<tr>
<td>1</td>
<td>Standard and extended frames can be received. In case of an extended frame, all 29 bits of the identifier are stored in the mailbox and all 29 bits of the global acceptance mask register are used for the filter. In case of a standard frame, only the first eleven bits (bits 12–2 of LAMn_H) of the identifier and the local acceptance mask are used. The AME bit of the MBX must be 1 to receive both standard and extended identifiers.</td>
</tr>
</tbody>
</table>

When LAMI = 1:
1) The IDE bit of the receive mailbox is a “don’t care”. The IDE bit of the receive mailbox is overwritten by the IDE bit of the transmitted message.
2) The filtering criterion must be satisfied in order to receive a message.
3) The number of bits to be compared is a function of the value of the IDE bit of the transmitted message.

When LAMI = 0:
The IDE bit of the receive mailbox determines the number of bits to be compared.

**NOTE:** The definition for the IDE bit changes depending on the value of the LAMI bit:
When LAMI = 1:
IDE = 1: The RECEIVED message had an extended identifier.
IDE = 0: The RECEIVED message had a standard identifier.
When LAMI = 0:
IDE = 1: The TO BE RECEIVED message must have an extended identifier.
IDE = 0: The TO BE RECEIVED message must have a standard identifier.
## Message Objects

### Bits 14–13
**Reserved.**

### Bits 12–0  \( \text{LAMn}[28:16] \)**. Upper 13 bits of the local acceptance mask.
- **0**: Received identifier bit value must match the identifier bit of the receive mailbox. For example, if bit 27 of LAM is zero, then bit 27 of the transmitted MSGID and bit 27 of the receive mailbox MSGID must be the same.
- **1**: Accept a 0 or a 1 (*don't care*) for the corresponding bit of the receive identifier.

### Figure 10–10. Local Acceptance Mask Register \( n \) (0, 1) Low Word (LAMn_L) – Addresses 710Ch, 710Eh

<table>
<thead>
<tr>
<th>15–0</th>

<tr>
<td>RW-0</td>
</tr>
</tbody>
</table>

**Note:**  \( R = \text{Read access}; \ W = \text{Write access}; \text{value following dash \((-\)} = \text{value after reset} \)

### Bits 15–0  \( \text{LAMn}[15:0] \)**. Lower part of the local acceptance mask. These bits enable the masking of any identifier bit of an incoming message.
- **0**: Received identifier bit value must match the identifier bit of the receive mailbox.
- **1**: Accept a 0 or a 1 (*don't care*) for the corresponding bit of the receive identifier.
10.4 CAN Control Registers

The control register bits allow mailbox functions to be manipulated. Each register performs a specific function, such as enabling or disabling the mailbox, controlling the transmit/receive mail function, and handling interrupts.

10.4.1 Mailbox Direction/Enable Register (MDER)

The Mailbox Direction/Enable register (MDER) consists of the Mailbox Enable (ME) and the Mailbox Direction (MD) bits. In addition to enabling/disabling the mailboxes, MDER is used to select the direction (transmit/receive) for mailboxes 2 and 3. Mailboxes that are disabled may be used as additional memory for the DSP. Figure 10–11 illustrates this register.

Figure 10–11. Mailbox Direction/Enable Register (MDER) — Address 7100h

</tr>
</tbody>
</table>

Note: \( R = \) Read access; \( W = \) Write access; value following dash (−) = value after reset

Bits 15–8 Reserved.

Bits 7–6 \( MD_n \). Mailbox direction for mailbox \( n \). Mailboxes 2 and 3 can be configured as a transmit or receive mailbox.

Mailbox direction bits are defined as follows:

0 Transit mailbox.
1 Receive mailbox.

After power-up, all bits are cleared.

Bits 5–0 \( ME_n \). Mailbox-enable for mailbox \( n \). Each mailbox can be enabled or disabled. If the bit \( ME_n \) is 0, the corresponding mailbox \( n \) is disabled. The mailbox must be disabled before writing to any identifier field.

If the corresponding bit in ME is set, the write access to the identifier of a message object is denied and the mailbox is enabled for the CAN module.

Mailboxes that are disabled may be used as additional memory for the DSP.
Mailbox enable bits are defined as follows:

0 Disable mailbox.
1 Enable mailbox.

10.4.2 Transmit Control Register (TCR)

The transmit control register (TCR) contains bits that control the transmission of messages (see Figure 10−12).

The control bits to set or reset a transmission request (TRS and TRR, respectively) can be written independently. In this way, a write access to these registers does not set bits that were reset because of a completed transmission.

After power-up, all bits are cleared.

<td>RS-0</td>
<td>RS-0</td>
</tr>
</tbody>
</table>

Note: R = Read access; C = Clear; S = Set only; value following dash (−) = value after reset

**Bits 15−12** TAn. Transmission Acknowledge (for mailbox n).

If the message in mailbox n was sent successfully, bit TAn is set.

Bits TAn are reset by writing a 1 from the CPU. This also clears the interrupt if an interrupt was generated. Writing a 0 has no effect. If the CPU tries to reset the bit while the CAN tries to set it, the bit is set.

These bits set a mailbox interrupt flag (MIFx) in the IF register. The MIFx bits initiate a mailbox interrupt if enabled; that is, if the corresponding interrupt mask bit in the IM register is set.

**Bits 11−8** AAn. Abort Acknowledge (for mailbox n).

If transmission of the message in mailbox n is aborted, bit AAn is set and the AAIF bit in the IF register is set. The AAIF bit generates an error interrupt if enabled.

Bits AAn are reset by writing a 1 from the CPU. Writing a 0 has no effect. If the CPU tries to reset a bit and the CAN tries to set the bit at the same time, the bit is set.
**Bits 7–4**  
**TRSn. Transmission Request Set (for mailbox n).**

In order to initiate a transfer, the TRSn bit has to be set in the TCR register. After this, the entire transmission procedure and possible error handling is done without any CPU involvement.

If TRSn is set, write access to the corresponding mailbox is denied, and the message in mailbox \( n \) will be transmitted. Several TRS bits can be set simultaneously.

TRS bits can be set by the CPU (user) or the CAN module and reset by internal logic. If the CPU tries to set a bit while the CAN tries to clear it, the bit is set. TRS bits are set by the user writing a 1. Writing a 0 has no effect.

In the event of a remote frame request, the TRS bits are set by the CAN module for mailboxes 2 and 3.

The TRSn bits are reset after a successful or an aborted transmission (if an abort is requested).

A write to a mailbox with TRS set will have no effect and will generate the WDIF interrupt if enabled. A successful transmission initiates a mailbox interrupt, if enabled.

TRS bits are used for mailboxes 4 and 5, and also for 2 and 3 if they are configured for transmission.

**Bits 3–0**  
**TRRn. Transmission Request Reset (for mailbox n).**

TRR bits can only be set by the CPU (user) and reset by internal logic. In case the CPU tries to set a bit while the CAN module tries to clear it, the bit is set. The TRR bits are set by the user writing a 1. Writing a 0 has no effect.

If TRRn is set, write access to the corresponding mailbox \( n \) is denied. A write access will initiate a WDIF interrupt, if enabled. If TRRn is set and the transmission which was initiated by TRSn is not currently processed, the corresponding transmission request will be cancelled. If the corresponding message is currently processed, this bit is reset in the event of:

1) A successful transmission
2) An abort due to a lost arbitration
3) An error condition detected on the CAN bus line

If the transmission is successful, the status bit TAn is set. If the transmission is aborted, the corresponding status bit AAn is set. In case of an error condition, an error status bit is set in the ESR.

The status of the TRR bits can be read from the TRS bits. For example, if TRS is set and a transmission is ongoing, TRR can only be reset by the actions
described above. If the TRS bit is reset and the TRR bit is set, no effect occurs because the TRR bit will be immediately reset.

### 10.4.3 Receive Control Register (RCR)

The receive control register (RCR) contains the bits which control the reception of messages and remote frame handling.

Figure 10–13. Receive Control Register (RCR) — Address 7102h

<table>
<thead>
<tr>
<th>15</th>

</tr>
<tr>
<td>7</td>
<td>6</td>
<td>5</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

RFP3, RFP2, RFP1, RFP0, RML3, RML2, RML1, RML0

Bits 15–12 **RFPn**. Remote Frame Pending Register (for mailbox n).

Whenever a remote frame request is received by the CAN Peripheral, the corresponding bit RFPn is set.

It may be cleared by the CPU if the TRSn is not set; otherwise, it is reset automatically. If the CPU tries to reset a bit and the CAN Peripheral tries to set the bit at the same time, the bit is cleared.

If the AAM bit in the MSGIDn register is not set (and thus no answer is sent automatically), the CPU must clear bit RFPn after handling the event.

If the message is sent successfully, RFPn is cleared by the CAN Peripheral.

The CPU cannot interrupt an ongoing transfer.

Bits 11–8 **RMLn**. Receive Message Lost (for mailbox n).

If an old message is overwritten by a new one in mailbox n, bit RMLn is set. RMLn is not set in mailboxes that have the OPCn bit set. Thus, a message may be lost without notification.

These bits can only be reset by the CPU and can be set by the internal logic. They can be cleared by writing a 1 to RMPn. If the CPU tries to reset a bit and the CAN tries to set the bit at the same time, the bit is set.

If one or more RML bits in the RCR register are set, the RMLIF in the CAN_IFR register is also set. This may initiate an interrupt if the RMLIM bit in the CAN_IMR register is set.
Bits 7–4 RMPn. Received Message Pending (for mailbox n).

If a received message is stored in mailbox n, the RMPn bit is set.

The RMP bits can only be reset by the CPU and are set by the CAN internal logic. The RMPn and RMLn bits are cleared by writing a 1 to the RMPn bit at the corresponding bit location. If the CPU tries to reset a bit and the CAN tries to set the bit at the same time, the bit is set.

A new incoming message will overwrite the stored one if the OPCn bit is cleared. If not, the next mailboxes are checked for a matching identifier. When the old message is overwritten, the corresponding status bit RMLn is set.

The RMP bits in the RCR register set the mailbox interrupt flag (MIFx) bit in the CAN_IFR register if the corresponding interrupt mask bit in the CAN_IMR register is set. The MIFx flag initiates a mailbox interrupt if enabled.

Bits 3–0 OPCn. Overwrite Protection Control (for mailbox n).

If there is an overflow condition for mailbox n, the new message is stored/ignored depending on the OPCn value. If the corresponding OPCn bit is set to 1, the old message is protected against being overwritten by the new message. Thus, the next mailboxes are checked for a matching identifier. If no other mailbox is found, the message is lost without further notification. If OPCn bit is not set, the old message is overwritten by the new one.

10.4.4 Master Control Register (MCR)

MCR is used to control the behavior of the CAN core module.

**Figure 10–14. Master Control Register (MCR) — Address 7103h**

<td></td>
</tr>
</tbody>
</table>

**Note:** R = Read access; W = Write access; value following dash (−) = value after reset

**Bits 15–14** Reserved.

**Bit 13** SUSP. Action on emulator suspend. The value of the SUSP bit has no effect on the receive mailboxes.

0 **Soft mode.** The peripheral shuts down during suspend after the current transmission is completed.

1 **Free mode.** The peripheral continues to run in suspend.
Bit 12  **CCR.** Change Configuration Request.
        0  The CPU requests normal operation. It also exits the bus-off state after the obligatory bus-off recovery sequence.
        1  The CPU requests write access to the bit configuration registers (BCRn). Flag CCE in the GSR indicates if the access is granted. CCR must be set while writing to bit timing registers BCR1 and BCR2. This bit will automatically be set to 1 if the bus-off condition is valid and the ABO bit is not set. Thus, it has to be reset to exit the bus-off mode.

Bit 11  **PDR.** Power-Down Mode Request.
        Before the CPU enters its IDLE mode (if IDLE shuts off the peripheral clocks), it must request a CAN power down by writing to the PDR bit. The CPU must then poll the PDA bit in the GSR, and enter IDLE only after PDA is set.
        0  The power-down mode is not requested (normal operation).
        1  The power-down mode is requested.

Bit 10  **DBO.** Data Byte Order.
        0  The data is received or transmitted in the following order: Data byte 3, 2, 1, 0, 7, 6, 5, 4.
        1  The data is received or transmitted in the following order: Data byte 0, 1, 2, 3, 4, 5, 6, 7.

**Note:**
The DBO bit is used to define the order in which the data bytes are stored in the mailbox when received and in which the data bytes are transmitted. Byte 0 is the first byte in the message and Byte 7 is the last one as shown in the figure of the CAN message (Figure 10–4).

Bit 9  **WUBA.** Wake Up on Bus Activity.
        0  The module leaves the power-down mode only after the user writes a 0 to clear PDR.
        1  The module leaves the power-down mode upon detecting any dominant value on the CAN bus.
Bit 8  **CDR.** Change Data Field Request.

The CDR bit is applicable for mailboxes 2 and 3 only and in the following situation: 1) either (or both) of these mailboxes are configured for transmission and 2) the corresponding AAM bit (MSGIDxH.13) is set.

0  The CPU requests normal operation.
1  The CPU requests write access to the data field of the mailbox in MBNR (also located in MCR). The CDR bit must be cleared by the CPU after accessing the mailbox. The CAN module does not transmit the mailbox if the CDR is set. This is checked by the state machine before and after it reads the data from the mailbox to store it in the transmit buffer.

Bit 7  **ABO.** Auto Bus On.

0  The bus-off state may only be left after $128 \times 11$ consecutive recessive bits on the bus and after having reset the CCR bit.
1  After the bus-off state, the module goes back to the bus-on state after $128 \times 11$ consecutive recessive bits.

Bit 6  **STM.** Self-Test Mode.

0  The module is in normal mode.
1  The module is in Self-Test mode. In this mode, the CAN module generates its own ACK signal. Thus, it enables operation without a bus connected to the module. The message is not sent but read back and stored in the appropriate mailbox. The remote frame handling with Auto Answer mode set is not implemented in STM. The received message ID will not be stored in the receive mailbox in this mode.

Bits 5–2  **Reserved.**

Bits 1–0  **MBNR.** Mailbox Number (for CDR bit assertion).

The CPU requests a write access to the data field for the mailbox having this number and configured for Remote Frame Handling. These are mailboxes 2 (10) or 3 (11), but not 0, 1, 4 or 5.

10.4.5 Bit Configuration Registers (BCRn)

The bit configuration registers (BCR1 and BCR2) are used to configure the CAN node with the appropriate network timing parameters. These registers must be programmed before using the CAN module and are writeable only in configuration mode. The CCR bit (MCR.12) must be set to put the CAN module in configuration mode. Figure 10–15 and Figure 10–16 illustrate BCR2 and BCR1, respectively.
Note:
To avoid unpredictable behavior, BCR1 and BCR2 should never be programmed with values not allowed by the CAN protocol specification.

The length of a bit on the CAN bus is determined by the parameters time segment 1 (TSEG1) and 2 (TSEG2) and by the baud rate prescaler value (BRP). All controllers on the CAN bus must have the same baud rate and bit length. At different clock frequencies of the individual controllers, the baud rate has to be adjusted by the given parameters. In the bit timing logic, the conversion of the parameters to the required bit timing is realized.

Figure 10−15. Bit Configuration Register 2 (BCR2) — Address 7104h

15−8

| Reserved |

7−0

BRP[7:0]

RW-0

Note:  R = Read access; W = Write access; value following dash (−) = value after reset

Bits 15–8  Reserved.

Bits 7–0  BRP. Baud Rate Prescaler.

Bits 7 to 0 of this field specify the duration of a time quantum (TQ) in CAN module system clock units. The length of one TQ is defined by:

\[
TQ = \left( \frac{1}{CLKOUT} \right) (BRP + 1) \text{ ns}
\]

If BRP = BCR2 = 0, then 1 TQ = 1 CPU clock cycle.
## CAN Control Registers

### Figure 10–16. Bit Configuration Register 1 (BCR1) — Address 7105h

<td>RW-0</td>
</tr>
</tbody>
</table>

**Note:**
- R = Read access; W = Write access; value following dash (−) = value after reset

**Bits 15–11**  
Reserved.

**Bit 10**  
**SBG.** Synchronization on both edges.  
- 0: The CAN module resynchronizes on the falling edge only.  
- 1: Reserved

**Bits 9–8**  
**SJW.** Synchronization jump width.  
SJW indicates by how many units of TQ a bit is allowed to be lengthened or shortened when resynchronizing with the receive data stream on the CAN bus. The synchronization is performed with the falling edge (SBG = 0). SJW is programmable from 1 to 4 TQ.

**Note:**
Since the SJW[1:0] value is enhanced by one by the CAN module, the value that is written in bits [1:0] is actually (SJW − 1), where SJW is the timing segment referred to in Figure 10–17, CAN Bit Timing.

**Bit 7**  
**SAM.** Sample point setting.  
This parameter sets the number of samples used by the CAN module to determine the actual level of the CAN bus. When the SAM bit is set, the level determined by the CAN bus corresponds to the result from the majority decision of the last three values. The sample points are at the sample point and twice before with a distance of 1/2 TQ.  
- 0: The CAN module samples only once.  
- 1: The CAN module samples three times and makes a majority decision.

**Bits 6–3**  
**TSEG1[3:0].** Time segment 1.  
This parameter specifies the length of the TSEG1 segment in TQ units.
TSEG1 combines PROP SEG and PHASE SEG1 segments (CAN protocol).

\[ \text{TSEG1} = \text{PROP SEG} + \text{PHASE SEG1}. \]

The value of TSEG1 is programmable from 3 to 16 TQ and must be greater than or equal to TSEG2.

**Note:**

Since the TSEG1[3:0] value is enhanced by one by the CAN module, the value that is written in bits [3:0] is actually \((TSEG1 - 1)\), where TSEG1 is the timing segment referred to in Figure 10−17, CAN Bit Timing.

**Bits 2−0**  
**TSEG2[2:0].** Time segment 2.

TSEG2 defines the length of PHASE SEG2 in TQ units.

The value of TSEG2 is programmable from 2 to 8 TQ in compliance with the formula:

\[(\text{SJW} + 1) \leq \text{TSEG2} \leq 8\]

**Note:**

Since the TSEG2[2:0] value is enhanced by one by the CAN module, the value that is written in bits [2:0] is actually \((TSEG2 - 1)\), where TSEG2 is the timing segment referred to in Figure 10−17 CAN Bit Timing.

**Note:**

The user-defined values for the SJW, TSEG1, and TSEG2 parameters are enhanced by one (by the internal logic) when the CAN module accesses these parameters.
CAN Bit Timing

Baud rate is calculated as follows (in bits per second):

$$\text{Baud Rate} = \frac{\text{CLKOUT}}{(\text{BRP} + 1) \times \text{Bit Time}} = \frac{1}{\text{TQ} \times \text{Bit Time}}$$

where Bit Time = number of TQ per bit

Bit Time = (TSEG1 + 1) + (TSEG2 + 1) + 1

BRP = Baud rate prescaler

Note: TSEG1 and TSEG2 are the values written by the user in BCR1 register.

10.5 Status Registers

The two status registers are the error status register (ESR) and the global status register (GSR). As indicated by their names, ESR provides information about any type of error encountered and GSR provides information about all functions of the CAN peripheral. Figure 10–18 and Figure 10–19 illustrate the ESR and the GSR, respectively.

10.5.1 Error Status Register (ESR)

The error status register (see Figure 10–18) is used to display errors that occurred during operation. Only the first error is stored. Subsequent errors do not change the status of the register. These registers are cleared by writing a 1 to them except for the SA1 flag, which is cleared by any recessive bit on the bus.

Bits 8 to 3 are error bits that can be read and cleared by writing a 1 to them. Bits 2 to 0 are status bits that cannot be cleared, only read.

**Bits 15–9**  
Reserved.

**Bit 8**  
FER. Form Error Flag.

0 The CAN module was able to send and receive correctly.

1 A Form Error occurred on the bus. This means that one or more of the fixed-form bit fields had the wrong level on the bus.

**Bit 7**  
BEF. Bit Error Flag.

0 The CAN module was able to send and receive correctly.

1 The received bit does not match the transmitted bit outside of the arbitration field; or during transmission of the arbitration field, a dominant bit was sent but a recessive bit was received.

</table>

**Note:** R = Read access; value following dash (−) = value after reset

**Bits 15–6** Reserved.

**Bit 5** SMA. Suspend Mode Acknowledge.
- 0 The CAN peripheral is not in suspend mode.
- 1 The CAN peripheral has entered suspend mode.

This bit is set after a latency of 1 clock cycle up to the length of one frame after the SUSPEND signal is activated.

**Bit 4** CCE. Change Configuration Enable.
- 0 Write access to the configuration registers is denied.
- 1 The CPU has write access to the configuration registers BCR while the CCR bit (MCR.12) is set. Access is granted after reset or when the CAN module reaches the idle state.

This bit is set after a latency of 1 clock cycle up to the length of one frame.

**Bit 3** PDA. Power-Down Mode Acknowledge.

Before the CPU enters its IDLE mode (to potentially shut off ALL device clocks), it must request a CAN power down by writing to the PDR bit in MCR. The CPU must then poll the PDA bit and enter IDLE only after PDA is set.
- 0 Normal operation.
- 1 The CAN peripheral has entered the power-down mode.

This bit is set after a latency of 1 clock cycle up to the length of one frame.

**Bit 2** Reserved.

**Bit 1** RM. The CAN module is in the Receive Mode.

This bit reflects what the CBM is actually doing regardless of mailbox configuration.
- 0 The CAN core module is not receiving a message.
- 1 The CAN core module is receiving a message.
Bit 0  **TM.** The CAN module is in the Transmit Mode.

This bit reflects what the CBM is actually doing regardless of mailbox configuration.

0  The CAN core module is not transmitting a message.
1  The CAN core module is transmitting a message.
10.5.3 CAN Error Counter Register (CEC)

The CAN module contains two error counters: the receive error counter (REC) and the transmit error counter (TEC). The values of both counters can be read from the CEC register via the CPU interface. Figure 10−20 illustrates the CEC.

Figure 10−20. CAN Error Counter Register (CEC) — Address 7108h

<table>
<thead>
<tr>
<th>15−8</th>
</tr>
</thead>
<tbody>
<tr>
<td>TEC[7:0]</td>
</tr>
<tr>
<td>R-0</td>
</tr>
<tr>
<td>7−0</td>

</tbody>
</table>

<table>
<thead>
<tr>
<th>7−0</th>
</tr>
</thead>
<tbody>
<tr>
<td>REC[7:0]</td>
</tr>
<tr>
<td>R-0</td>
</tr>
</tbody>
</table>

Note: R = Read access; value following dash (−) = value after reset

After exceeding the error passive limit (128), REC is not increased any further. When a message is received correctly, the counter is set again to a value between 119 and 127. After reaching the bus-off status, TEC is undefined, while REC is cleared and its function is changed: It will be incremented after every 11 consecutive recessive bits on the bus. These 11 bits correspond to the gap between two telegrams on the bus. If the receive counter reaches 128, the module changes automatically back to the status bus-on if the ABO bit in MCR is set. Otherwise, it changes when the recovery sequence of 11 × 128 bits has finished and the CCR bit in the MCR register is reset by the DSP. All internal flags are reset and the error counters are cleared. The configuration registers keep the programmed values.

After the power-down mode, the error counters stay unchanged. They are cleared when entering the configuration mode.
10.6 Interrupt Logic

There are two interrupt requests from the CAN peripheral to the peripheral interrupt expansion (PIE) controller: the mailbox interrupt and the error interrupt. Both interrupts can assert either a high-priority request or a low-priority request to the CPU. The following events may initiate an interrupt:

- **Mailbox Interrupt**
  - A message was transmitted or received successfully. This event asserts the Mailbox interrupt.

- **Abort Acknowledge Interrupt**
  - A “send transmission” operation was aborted. This event asserts the Error interrupt.

- **Write Denied Interrupt**
  - The CPU tried to write to a mailbox but was not allowed to. This event asserts the Error interrupt.

- **Wake-up Interrupt**
  - After wake-up, this interrupt is generated. This event asserts the Error interrupt, even when clocks are not running.

- **Receive Message Lost Interrupt**
  - An old message was overwritten by a new one. This event asserts the Error interrupt.

- **Bus-Off Interrupt**
  - The CAN module enters the bus-off state. This event asserts the Error interrupt.

- **Error Passive Interrupt**
  - The CAN module enters the error passive mode. This event asserts the Error interrupt.

- **Warning Level Interrupt**
  - One or both of the error counters is greater than or equal to 96. This event asserts the Error interrupt.

Note: While servicing a CAN interrupt, the user should check all the bits in the CAN_IFR register to ascertain if more than one bit has been set. The corresponding interrupt service routines (ISRs) should be executed for all the set bits. This must be done since the core interrupt will be asserted only once, even if multiple bits are set in the CAN_IFR register.
10.6.1 CAN Interrupt Flag Register (CAN_IFR)

The interrupt flag bits are set if the corresponding interrupt condition occurs. The appropriate mailbox interrupt request is asserted only if the corresponding interrupt mask in CAN_IMR register is set. The peripheral interrupt request stays active until the interrupt flag is cleared by the CPU by writing a 1 to the appropriate bit. An interrupt acknowledge does not clear the interrupt flags. The MIFx flags cannot be cleared by writing to the IF register; instead, they must be cleared by writing a 1 to the appropriate TA bit in the TCR register for a transmit mailbox (mailboxes 2 to 5), or the RMP bit in the RCR register for the receive mailbox (mailboxes 0 to 3).

In order to recognize future interrupts, the flag bit of the current interrupt(s) must be cleared immediately upon entering the ISR. One method of implementing this is to copy the CAN_IFR register in a memory variable and then clear the set bits in CAN_IFR. The memory variable could then be read to determine the appropriate routines to be executed.

Note:  
R = Read access; C = Clear; value following dash (−) = value after reset

**Bits 15–14**  
Reserved.

**Bits 13–8**  
MIFx. Mailbox Interrupt Flag (receive/transmit).

- 0 No message was transmitted or received.
- 1 The corresponding mailbox transmitted or received a message successfully.

Each of the six mailboxes may initiate an interrupt. These interrupts can be a receive or a transmit interrupt depending on the mailbox configuration. If one of the configurable mailboxes is configured as Remote Request Mailbox (AAM set) and a remote frame is received, a transmit interrupt is set after sending the corresponding data frame. If a remote frame is sent, a receive interrupt is set after the reception of the desired data frame.
There is one interrupt mask bit for each mailbox. If a message is received, the corresponding RMPn bit in the RCR is set. If a message is sent, the corresponding TAn bit in the TCR register is set. The setting of the RMPn bit or the TAn bit also sets the appropriate MIFx flag in the CAN_IFR register if the corresponding interrupt mask bit is set. The MIFx flag generates an interrupt. The MIMx mask bits in the CAN_IMR register determine if an interrupt can be generated by a mailbox.

**Bit 7**  
Reserved.

**Bit 6**  
**RMLIF.** Receive Message Lost Interrupt Flag.  
0  No message was lost.  
1  An overflow condition has occurred in at least one of the receive mailboxes.

**Bit 5**  
**AAIF.** Abort Acknowledge Interrupt Flag.  
0  No transmission was aborted.  
1  A “send transmission” operation was aborted.

**Bit 4**  
**WDIF.** Write Denied Interrupt Flag.  
0  The write access to the mailbox was successful.  
1  The CPU tried to write to a mailbox but was not allowed to.

**Bit 3**  
**WUIF.** Wake-Up Interrupt Flag.  
0  The module is still in the sleep mode or in normal operation.  
1  The module has left the sleep mode.

**Bit 2**  
**BOIF.** Bus-Off Interrupt Flag.  
0  The CAN module is still in the bus-on mode.  
1  The CAN has entered the bus-off mode.

**Bit 1**  
**EPIF.** Error Passive Interrupt Flag.  
0  The CAN module is not in the error-passive mode.  
1  The CAN module has entered the error-passive mode.

**Bit 0**  
**WLIF.** Warning Level Interrupt Flag.  
0  None of the error counters has reached the warning level.  
1  At least one of the error counters has reached the warning level.
10.6.2 CAN Interrupt Mask Register (CAN_IMR)

The setup for the interrupt mask register (see Figure 10–22) is the same as for the interrupt flag register (CAN_IFR) with the addition of the interrupt priority selection bits MIL and EIL. If a mask bit is set, the corresponding interrupt request to the PIE controller is enabled.

An additional control bit is included in this register:

Bit 15 MIL. Mailbox Interrupt Priority Level.

For the mailbox interrupts MIF5 – MIF0.

0 The mailbox interrupts generate high-priority requests.

1 The mailbox interrupts generate low-priority requests.

Bit 14 Reserved.

Bits 13–8 See section 10.6.1, CAN Interrupt Flag Register (CAN_IFR), on page 10-36.

Bit 7 EIL. Error Interrupt Priority Level.

For the error interrupts RMLIF, AAIF, WDIF, WUIF, BOIF, EPIF, and WLIF.

0 The named interrupts generate high-priority requests.

1 The named interrupts generate low-priority requests.

Bits 6–0 See section 10.6.1, CAN Interrupt Flag Register (CAN_IFR), on page 10-36.
10.7 Configuration Mode

The CAN module must be initialized before activation. This is only possible when the module is in the configuration mode, which is set by programming CCR with 1. The initialization can be performed only if the status bit CCE confirms the request by getting 1. Afterwards, the bit configuration registers can be written. The module is activated again by programming the control bit CCR with zero. After a hardware reset, the configuration mode is active.

Figure 10–23. CAN Initialization
10.8 Power-Down Mode (PDM)

If the peripheral clocks are to be shut off by the device low-power mode, the CAN peripheral's own low-power mode must be requested before a device low-power mode is entered by executing the IDLE instruction.

Before the CPU enters its IDLE mode prior to the device low-power mode that potentially shuts off all device clocks, it must first request a CAN peripheral power down by writing a 1 to the PDR bit in MCR. If the module is transmitting a message when PDR is set, the transmission is continued until a successful transmission, a lost arbitration, or an error condition on the CAN bus line occurs. Then the PDA is asserted. Thus, the module causes no error condition on the CAN bus line. When the module is ready to enter the power-down mode, the status bit PDA is set. The CPU must then poll the PDA bit in GSR, and only enter IDLE after PDA is set.

On exiting the power-down mode, the PDR flag in the MCR must be cleared by software, or automatically, if the WUBA bit in MCR is set and there is bus activity on the CAN bus line. When detecting a dominant signal on the CAN bus, the wake-up interrupt flag (WUIF) is asserted. The power-down mode is exited as soon as the clock is switched on. There is no internal filtering for the CAN bus line.

The automatic wake-up on bus activity can be enabled or disabled by setting the configuration bit WUBA. If there is any activity on the CAN bus line, the module begins its power-up sequence. The module waits until detecting 11 consecutive recessive bits on the RX pin and goes to bus active afterwards. The first message, which initiates the bus activity, cannot be received.

When WUBA is enabled, the error interrupt WUIF is asserted automatically to the PIE controller, which will handle it as a wake-up interrupt and restart the device clocks if they are stopped.

After leaving the sleep mode with a wake up, the PDR and PDA are cleared. The CAN error counters remain unchanged.
10.9 Suspend Mode

The suspend mode can operate in either Free mode, where the CAN peripheral continues to operate regardless of the suspend signal being active, or Soft mode, where the CAN peripheral stops operation at the end of the current transmission. Suspend mode is entered when the CPU activates the SUSPEND signal. The SUSP bit in MCR determines which of the two suspend modes (Free or Soft) is entered.

When the module enters the Soft suspend mode, the status bit SMA (in GSR) is set. If the module is actually transmitting a message when the SUSPEND signal is activated, the transmission is continued until a successful transmission, a lost arbitration, or an error condition on the CAN bus line occurs. Otherwise, it enters suspend mode immediately and sets the SMA bit.

In Free mode, the peripheral ignores the suspend signal and continues to operate, receiving and transmitting messages.

Either way, the module causes no error condition on the CAN bus line.

When suspended (in Soft mode), the module does not send or receive any messages. The module is not active on the CAN bus line. Acknowledge flags and error flags are not sent. The error counters and all other internal registers are frozen. Suspend is only asserted when a system is being debugged with an in-circuit emulator.

In case the module is in bus-off mode when suspend mode is requested, it enters suspend mode immediately. It does, however, still count the $128 \times 11$ recessive bits needed to return to the bus-on mode. All error counters are undefined in that state. The bus-off flag and the error-passive flag are set.

The module leaves the suspend mode when the SUSPEND signal is deactivated. It waits for the next 11 recessive bits on the bus and goes back to normal operation. This is called the idle mode (different from the CPU’s IDLE mode). The module waits for the next message or tries to send one itself. When the module is in bus-off mode, it continues to wait for the bus-on condition. This occurs when $128 \times 11$ recessive bits are received. It also counts those that occurred during the suspend mode.

Note: The clock is not switched off internally for suspend or low-power mode.

For easy reference, Table 10–5 provides a listing of the CAN notation, definition, and register and bit number.

† The DBO (data byte order) bit is located in the MCR register and is used to define the order in which the data bytes are stored in the mailbox when received and the order in which the data bytes are transmitted. Byte 0 is the first byte in the message and Byte 7 is the last one shown in the CAN message.
The watchdog (WD) timer peripheral monitors software and hardware operations, and implements system reset functions upon CPU disruption. If the software goes into an improper loop, or if the CPU becomes temporarily disrupted, the WD timer overflows to assert a system reset.

Most conditions that temporarily disrupt chip operation and inhibit proper CPU function can be cleared and reset by the watchdog function. By its consistent performance, the watchdog increases the reliability of the CPU, thus ensuring system integrity.

All registers in this peripheral are eight bits in width and are attached to the lower byte of the peripheral data bus of the 16-bit CPU.

The only difference between the 240xA WD timer and that of the C240 is the lack of real-time interrupt capability.

This implementation of the WD timer generates its own watchdog clock locally by dividing down the CLKOUT from CPU.

### Chapter 11

**Watchdog (WD) Timer**

The watchdog (WD) timer peripheral monitors software and hardware operations, and implements system reset functions upon CPU disruption. If the software goes into an improper loop, or if the CPU becomes temporarily disrupted, the WD timer overflows to assert a system reset.

Most conditions that temporarily disrupt chip operation and inhibit proper CPU function can be cleared and reset by the watchdog function. By its consistent performance, the watchdog increases the reliability of the CPU, thus ensuring system integrity.

All registers in this peripheral are eight bits in width and are attached to the lower byte of the peripheral data bus of the 16-bit CPU.

The only difference between the 240xA WD timer and that of the C240 is the lack of real-time interrupt capability.

This implementation of the WD timer generates its own watchdog clock locally by dividing down the CLKOUT from CPU.

11.1 Watchdog Timer Features

The WD module includes the following features:

- 8-bit WD counter that generates a system reset upon overflow
- 6-bit free-running counter that feeds the WD counter via the WD counter prescale
- A WD reset key (WDKEY) register that clears the WD counter when the correct combination of values are written, and generates a reset if an incorrect value is written to the register
- WD check bits that initiate a system reset if the WD timer is corrupted
- Automatic activation of the WD timer once system reset is released
- A WD prescale with six selections from the 6-bit free-running counter

Figure 11–1 shows a block diagram of the WD module
Watchdog Timer Features

---|---
WDCNTR | Watchdog Counter Register
WDKEY | Watchdog Reset Key Register
WDCR | Watchdog Control Register

† Writing to bits WDCR.5−3 with anything but the correct pattern (101) generates a system reset.
‡ These prescale values are with respect to the WDCLK signal.
11.2 Watchdog Timer Operations

11.2.1 Overview of WD Timer Operations

Three registers control the WD operations:

- WD Counter Register (WDCNTR) — This register contains the value of the WD counter
- WD Key Register (WDKEY) — This register clears the WDCNTR when a 55h value followed by an AAh value is written to WDKEY
- WD Control Register (WDCR) — This register contains the following control bits used for watchdog configuration:
  - WD disable bit
  - WD flag bit
  - WD check bits (three)
  - WD prescale select bits (three)

11.2.2 Watchdog Timer Clock

The watchdog timer clock (WDCLK) is a low-frequency clock used to clock the watchdog timer. WDCLK has a nominal frequency of 78125 Hz when CPUCLK = 40 MHz. WDCLK is derived from the CLKOUT of the CPU. This ensures that the watchdog continues to count when the CPU is in IDLE1 or IDLE 2 mode (see section 4.4, Low-Power Modes, on page 4-8). WDCLK is generated in the watchdog peripheral. The frequency of WDCLK can be calculated from:

\[ WDCLK = \frac{\text{CLKOUT}}{512} \]

WDCLK is seen at the CLKOUT pin only when the watchdog is enabled. If the watchdog is enabled, the watchdog counter should be reset before it overflows; otherwise, the DSP will be reset.

11.2.3 Watchdog Suspend

WDCLK is stopped when the CPU’s suspend signal goes active. This is achieved by stopping the clock input to the clock divider which generates WDCLK from CLKOUT.

Note that the watchdog timer clock does not run when the real-time monitor is running. This is different from the F/C240.
11.2.4 Operations of the WD Timer

The WD timer is an 8-bit resetable incrementing counter that is clocked by the output of the prescaler. The timer protects against system software failures and CPU disruption by providing a system reset when the WDKEY register is not serviced before a watchdog overflow. This reset returns the system to a known starting point. Software then clears the WDCNTR register by writing a correct data pattern to the WD key logic.

A separate internal clocking signal (WDCLK) is generated by the on-chip clock module and is active in all operational modes except the HALT mode. WDCLK enables the WD timer to function, regardless of the state of any register bit(s) on the chip, except during the HALT low-power mode, which disables the WDCLK signal. The current state of WDCNTR can be read at any time during its operation.

11.2.4.1 WD Prescale Select

The 8-bit WDCNTR can be clocked directly by the WDCLK signal or through one of six taps from the free-running counter. The 6-bit free-running counter continuously increments at a rate provided by WDCLK. The WD functions are enabled as long as WDCLK is provided to the module. Any one of the six taps (or the direct input from WDCLK) can be selected by the WD prescale select (bits WDPS2–0) as the input to the time base for the WDCNTR. This prescale provides selectable watchdog overflow rates of from 3.28 ms to 209.7 ms for a WDCLK rate of 78125 Hz. While the chip is in normal operating mode, the free-running counter cannot be stopped or reset, except by a system reset. Clearing WDCNTR does not clear the free-running counter.

11.2.4.2 Servicing the WD Timer

The WDCNTR is reset when the proper sequence is written to the WDKEY before the WDCNTR overflows. The WDCNTR is reset-enabled when a value of 55h is written to the WDKEY. When the next AAh value is written to the WDKEY, then the WDCNTR actually is reset. Any value written to the WDKEY other than 55h or AAh causes a system reset. Any sequence of 55h and AAh values can be written to the WDKEY without causing a system reset; only a write of 55h followed by a write of AAh to the WDKEY resets the WDCNTR.
Table 11–1 shows a typical sequence written to WDKEY after power-up.

### Table 11–1. Typical WDKEY Register Power-Up Sequence

<table>
<thead>
<tr>
<th>Sequential Step</th>
<th>Value Written to WDKEY</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>

</tr>
<tr>
<td>11</td>
<td>23h</td>
<td>System reset due to an improper key value written to WDKEY.</td>
</tr>
</tbody>
</table>

Step 3 above is the first action that enables the WDCNTR to be reset. The WDCNTR is not actually reset until step 6. Step 8 re-enables the WDCNTR to be reset, and step 9 resets the WDCNTR. Step 10 again re-enables the WDCNTR to be reset. Writing the wrong key value to the WDKEY in step 11 causes a system reset.

A WDCNTR overflow or an incorrect key value written to the WDKEY also sets the WD flag (WDFLAG). After a reset, the program reads this flag to determine the source of the reset. After reset, WDFLAG should be cleared by the software to allow the source of subsequent resets to be determined. WD resets are not prevented when the flag is set.

### 11.2.4.3 WD Reset

When the WDCNTR overflows, the WD timer asserts a system reset. Reset occurs one WDCNTR clock cycle (either WDCLK or WDCLK divided by a prescale value) later. The reset cannot be disabled in normal operation as long as WDCLK is present. The WD timer is, however, disabled in the oscillator power-down mode when WDCLK is not active. For software development or flash programming purposes, the WD timer can be disabled by setting the WDDIS bit in the WD control register (WDCR.6). Note that there is no WDDIS pin in the 240xA devices. The “watchdog override” bit in the SCSR2 register provides the functionality of the WDDIS pin.
11.2.4.4 WD Check Bit Logic

The WD check bits (WDCR.5−3, described in detail in section 11.3.3 on page 11-9) are continuously compared to a constant value (101_2). If writes to the WD check bits do not match this value, a system reset is generated. This functions as a logic check in case the software improperly writes to the WDCR, or if an external stimulus (such as voltage spikes, EMI, or other disruptive sources) corrupt the contents of the WDCR. Writing to bits WDCR.5-3 with anything but the correct pattern (101_2) generates a system reset.

The check bits are always read as zeros (000_2), regardless of what value has been written to them.

11.2.4.5 WD Setup

The WD timer operates independently of the CPU and is always enabled. It does not need any CPU initialization to function. When a system reset occurs, the WD timer defaults to the fastest WD timer rate available (3.28 ms for a 78125-Hz WDCLK signal). As soon as reset is released internally, the CPU starts executing code, and the WD timer begins incrementing. This means that, to avoid a premature reset, WD setup should occur early in the power-up sequence.
11.3 Watchdog Control Registers

The WD module control registers are shown in Table 11-2 and discussed in detail in the sections that follow the table.

11.3.1 WD Counter Register

The 8-bit WD counter register (WDCNTR) contains the current value of the WD counter. This register continuously increments at a rate selected through the WD control register. When WDCNTR overflows, an additional single-cycle delay (either WDCLK or WDCLK divided by a prescale value) is incurred before system reset is asserted. Writing the proper sequence to the WD reset key register clears WDCNTR and prevents a system reset. However, it does not clear the free-running counter.

</tr>
</tbody>
</table>

Note: R = Read access, -0 = value after reset

Bits 7–0 D7–D0. Data Values. These read-only data bits contain the 8-bit WD counter value. Writing to this register has no effect.
11.3.2 WD Reset Key Register

The WD reset key register clears the WDCNTR register when a 55h followed by an AAh is written to WDKEY. Any combination of AAh and 55h is allowed, but only a 55h followed by an AAh resets the counter. Any other value causes a system reset.

Note:  
R = Read access, W = Write access, -0 = value after reset

Bits 7–0  
D7–D0. Data Values. These write-only data bits contain the 8-bit WD reset key value. When read, the WDKEY register does not return the last key value but rather returns the contents of the WDCR register.

11.3.3 WD Timer Control Register

WDCR contains control bits used for watchdog configuration. These include flag bits that indicate if the WD timer initiated a system reset; check bits that assert a system reset if an incorrect value is written to the WDCR register; and watchdog prescale select bits that select the counter overflow tap which is used to clock the WD counter.

</tbody>
</table>

Note:  
R = Read access, C = Clear by writing 1, W = Write access, Wc = Write access conditional on WD OVERRIDE bit being equal to 1, -0 = value after reset, -x = value after reset determined by action/inaction of WD timer

Bit 7  
WDFLAG: Watchdog Flag Bit. This bit indicates if a system reset was asserted by the WD timer. The bit is set to 1 by a WD-generated reset.

0 Indicates that the WD timer has not asserted a reset since the bit was last cleared
1 Indicates that the WD timer has asserted a reset since the bit was last cleared
### Watchdog Control Registers

#### Note: Power-on reset (POR) and WDFLAG

The power-on reset (POR) state of the WDFLAG bit is undefined. This could cause confusion if the user code attempts to differentiate a watchdog-initiated reset from a power-on reset. If an application implements a mechanism to differentiate a POR from other types of reset, the WDFLAG bit must be cleared after a POR. Once this is done, the WDFLAG bit can be set only by a watchdog reset.

Bits 2–0  **WDPS2–WDPS0.** Watchdog Prescale Select Bits. These bits select the counter overflow tap that is used to clock the WD counter. Each selection sets up the maximum time that can elapse before the WD key logic is serviced. Table 11–3 shows the overflow times for each prescaler setting when the WDCLK is running at 78125 Hz. Because the WD timer counts 257 clocks before overflowing, the times given are the minimum for overflow (reset). The maximum timeout can be up to 1/256 longer than the times listed in Table 11–3 because of the added uncertainty resulting from not clearing the prescaler.

† Generated by a 40-MHz clock
This chapter describes the compatibility issues between the 240xA and 240 family of processors.

The software changes required between 240 code and 240xA code have been kept to a minimum. A majority of the register addresses, bit positions, and functions are identical between the 240 and 240xA devices.

12.1 General

The 240 is a 5-V part, whereas the 240xA devices operate on 3.3 V.

Low-power mode 2 (HALT) is the lowest power mode on the 240xA. It is similar to the LPM3 (oscillator power down) on the 240. There is no equivalent to LPM2 (PLL power down) on the 240. The low-power-mode bits are in a different register (SCSR1) and in different bit positions on the 240xA.

Software reset is not available. However a software reset can be achieved by writing an incorrect key to the watchdog timer after setting a flag in memory to indicate that this was a software reset, and not a true watchdog time-out.

Illegal address detection does not have 100% coverage on the 240; however, it does on 240xA devices. Furthermore, an illegal address generates a reset on the 240, and an NMI on the 240xA. The NMI service routine must poll the ILLADDR bit in SCSR1 to determine whether the NMI was caused by an illegal address.

External interrupts XINT2 and XINT3 on the 240 are similar to external interrupts XINT1 and XINT2 on the 240xA. The addresses of the registers are different, however, and the general-purpose I/O multiplexing control bits are located in the digital I/O registers, not in the external interrupt control registers. The external interrupt flags are cleared by writing a 1 to the flag bit. This is in order to be consistent with the other peripherals.

The CLOCKOUT control bits are in a different register (SCSR1) and bit position.

A code security module (CSM) has been added to the 240xA devices.
12.2 Event Manager

In order to port code from 240 to 240xA:

- The GP timer 3 must not be used.
- The single-up count and single-up/down count modes of the GP timers must not be used. The decoding of the timer modes from the TMODE1−0 bits has changed, and this code will have to be modified when porting code from the 240 to the 240xA.
- The 32-bit timer mode cannot be used.
- Capture 4 on the 240 cannot be used, when porting code from the 240 to the 240xA.
- The capture units can use either GP Timer 1 or 2 as a time base.
- When porting code from the the 240 to the 240xA, the capture interrupt code needs to allow for the fact that an interrupt is usually generated after every second capture and not every capture as on the 240.
- The QEP logic can clock GP timer 1 or 2.
- The three simple compare units cannot be used.
- The compare mode of the (full) compare units cannot be used; only the PWM mode can be used.
- Software must change from 240 to 240xA to comprehend the changes to the dead-band counters and dead-band prescaler.
- All general interrupt service routines must be changed to get their peripheral interrupt vectors from the PIVR (701Eh) and not one of EVIVRA, EVIVRB or EVIVRC. Reading from PIVR does not clear interrupt flags. Interrupt flags must be cleared manually.
- Some pins in the EV have an “input qualification” circuitry. See the TMS320LF2407A, TMS320LF2406A, TMS320LF2403A, TMS320LF2402A, TMS320LC2406A, TMS320LC2404A, TMS320LC2402A DSP Controllers Data Sheet (literature number SPRS145) for more details.
12.3 Analog-to-Digital Converter

When compared to the 240 ADC, the 240xA ADC has been significantly enhanced. As a result, code written for the 240 ADC cannot be ported to the 240xA.

12.4 Serial Communications Interface

Some code changes are required. This is code that switches the SCI pins between their SCI functions and their digital I/O functions, and accesses them in digital I/O mode. When porting code from a 240 to a 240xA device, it must access the relevant bits in the digital I/O peripheral instead of the SCIPC2 register.

The SCI has free and soft emulation modes.

12.5 Serial Peripheral Interface

This SPI is no longer limited to a maximum transmission rate of CLKOUT / 8 in slave mode. The maximum transmission rate in both slave mode and master mode is now CLKOUT / 4.

Some code changes are required. This is code that switches the SPI pins between their SPI functions and their digital I/O functions, and accesses them in digital I/O mode. When code is ported from 240 to 240xA devices, it must access the relevant bits in the digital I/O peripheral instead of the SCIPC1 and SCIPC2 register.

When code is ported from a 240 to a 240xA device, writes of transmit data to the serial data register, SPIDAT, must be left-justified within a 16-bit register, not within an 8-bit register.

The SPI has free and soft emulation modes.

12.6 Watchdog Timer

When porting code from 240 to 240xA devices, all code that uses the RTI peripheral (if any) must be removed.
Chapter 13

240xA-24x Family Compatibility

This chapter discusses the compatibility issues between the 24x (241/242/243) devices and the 240x/240xA devices.

It outlines the points to be considered while migrating from the 24x family to the 240x/240xA family.

13.1 Introduction

This chapter highlights the major differences (in terms of features/peripherals) between the 240xA and the 24x (TMS320F243/F241/C242) family of DSP devices. The 240xA devices share most of the 24x features; however, 240xA devices have some enhancements. The common features, differences, and enhancements are described in Table 13−1 and Table 13−2.

13.1.1 Migrating Code from 24x to 240x/240xA Devices

All 240x/240xA peripherals (with the exception of ADC) are functionally identical to those in 24x devices. Hence, code written for the 24x can be easily ported to 240x/240xA devices. However, due to feature enhancements in the 240x/240xA devices, the following points should be kept in mind:

1) 240x/240xA devices operate at higher clock speeds. This warrants a change in the values written to the event manager registers (that control parameters such as PWM frequency) and other registers that affect the communication speed in serial devices such as the SPI, SCI, and CAN.

2) After reset in the 240x/240xA devices, the clock to all of the peripherals is disabled. The peripheral clock must be enabled as part of the peripheral initialization. This requirement does not apply to 24x devices since clock to the peripherals is always on.

2) F243 and LF2407A are not pin-compatible.
3) 240xA ADC is not compatible with 24x ADC.
13.3 Memory Map

13.3.1 Program Space

Figure 13−1. LF2407A Memory Map for Program Space

Note: When boot ROM is enabled, on-chip locations 0000−00FFh in program memory is mapped to the bootloader. Boot ROM and Flash Memory share the same starting address, and hence, are not visible (active) at the same time. If the BOOT EN/XF pin = 0 during reset, the BOOT EN bit in SCSR2 register (bit 3) will be set and enable the Boot ROM at 0000 in program space. While Boot ROM is enabled, the entire Flash memory will be disabled. The SCSR2.3 bit should be disabled (0) to have Flash array enabled instead of Boot ROM. See Appendix D for bootloader details.
13.4 System Features

This section presents some of the system features that are new to the 240xA devices. Understanding these key features will help with system initialization and 24x-to-240xA migration.

13.4.1 Oscillator and PLL

Unlike the 24x device, the 240xA devices have a 5-pin PLL with a 3-bit ratio control to provide eight different CPU clock options. Table 13–4 describes the pins that are used for the PLL/Oscillator module and Table 13–5 lists the oscillator/PLL frequency input specification. PLL is preceded by an on-chip oscillator which can accept a resonator or a crystal. The PLL accepts the on-chip oscillator or external clock as its input clock. Refer to TMS320LF2407A, TMS320LF2406A, TMS320LF2403A, TMS320LF2402A, TMS320LC2406A, TMS320LC2404A, TMS320LC2402A DSP Controllers Data Sheet (literature number SPRS145) for clock circuits and recommended values for the external filter components.

13.4.2 Watchdog Clock

Watchdog clock generation logic is different in 240xA devices with respect to 24x devices. Unlike the fixed PLL (x4) in 24x, the 240xA devices have a variable clock from the PLL. This changes the input clock options for the watchdog module. The clock flow diagram below explains the watchdog clock generation logic.

240xA devices have a watchdog override bit in the SCSR2 register, which is similar to the WDDIS pin available on the 24x devices. Refer to the description of SCSR2 register bit 5 (section 2.2.1 on page 2-3) for details on this bit function.

Figure 13−2. 240xA Watchdog Clock Generation Logic

![Watchdog Clock Generation Logic Diagram]

13.4.2.1 Other Low-Power Management Features

All 240xA devices have a clock-enable bit in the SCSR1 register to save power and selectively enable peripheral functions. At reset, these peripheral clock-enable bits are disabled, and the applications software should enable the required modules. The peripheral clocks of the following peripherals can be independently enabled/disabled. See section 2.2.1 on page 2-3 for bit descriptions of the SCSR1 register.

13.4.3 System Control Registers

240xA devices have two system control and status registers: SCSR1 and SCSR2 (see section 2.2.1 on page 2-3). These registers have control and status bits for several on-chip modules. These register bits should be initialized after reset to enable/disable on-chip functionality for the selected application. 24x has only one SCSR register and all its on-chip peripherals are powered up after reset. The SCSR2 register is unique to 240xA and its peripherals are disabled after reset.

13.4.3.1 Boot EN/XF Pin Operation

During the Reset phase (i.e., RS low), this pin functions as a Boot EN input pin, and its logic level is latched into bit 3 of the SCSR2 register. If the bit is set to 1, Boot ROM is active.

At the completion of the reset phase (rising edge of RS), this pin will be XF output (external flag) function, and the Boot EN function is no longer available through this pin. However, the Boot EN bit in SCSR2 can be used to control the visibility of the Boot ROM or the Flash array.

13.4.3.2 Fast RD Strobe Operation

LF2407 is the only device that supports external memory interface (XMIF) to expand the internal memory space with the addition of external memory devices. The interface offers decode signals for Program, Data, and I/O space. LF2407 external memory interface signals have critical timings while interfacing zero-wait-state memory at higher CPU clock speeds. CPU memory reads are single-cycle and read-enable (RD) timing is critical to meet the output-enable timing for memories that can be interfaced to this device. To alleviate the memory read interface timing, an additional signal W/R is provided to be used as output-enable signal instead of RD. W/R is essentially an inverted R/W signal from the core.

In the LF2407A device, the W/R signal will remain low all the time after reset and will go high during external write cycles. In other LF240xA devices, the W/R signal will remain low all the time after reset until the application configures it as a GPIO pin and drives it to the desired level. During reset, this pin floats and gets pulled up by the internal pullup circuitry. If an application needs this pin to be low even during reset, then an external pulldown resistor may be added.

In LC240xA devices, the W/R signal will remain “pulled up” all the time from reset until the application configures it as a GPIO pin and drives it to the desired level.

13.5 Digital I/O (GPIO Pins)

Some members of the 240xA family have more GPIO pins than the 24x devices. This necessitates additional registers. The bit definitions for some multiplexed pins such as XF, CLKOUT, etc. are different from those of the 24x. See Chapter 5 for more details.

Note that when multiplexed I/O pins are in input mode, the pin is connected to both the I/O data register and the shared peripheral. The I/O Mux control register (MCRx) in 240xA devices is synonymous to the OCRx in 24x devices. Both MCRx and OCRx have the same function in 240xA and 24x devices, respectively.

13.5.1 Digital I/O and Shared Pin Functions for the 240xA

LF2407 device has a total of 41 pins shared between primary functions and I/Os.

Table 13–7 lists all the pins that are shared between the primary functions and the dedicated I/O Ports A, B, C, D, E, F.

13.6 Event Manager Module (EVB)

The event manager module available on 240xA devices is identical to the event manager in the 24x family. EVA and EVB are exactly identical modules, except that their registers start at 7400h and 7500h, respectively, in the peripheral space. The functional description of the event manager, available in the TMS320F243/F241/C242 DSP Controllers Reference Guide (literature number SPRU276C), is applicable to EVB as well. EVA and EVB modules and signals are uniquely identified and in Table 13–8 for comparison.

13.6.1 Input Qualification Circuitry

Some pins in the EV have an “input qualification” circuitry. See the TMS320LF2407A, TMS320LF2406A, TMS320LF2403A, TMS320LF2402A, TMS320LC2406A, TMS320LC2404A, TMS320LC2402A DSP Controllers Data Sheet (literature number SPRS145) for more details.
This document was revised to SPRU357C from SPRU357B.
The scope of the revisions was limited to adding technical changes as described on the next page.
A.1 Changes Made in This Revision

The following changes were made in this revision:

<table>
<thead>
<tr>
<th>Page</th>
<th>Additions/Modifications/Deletions</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-7</td>
<td>Updated Related Documentation section</td>
</tr>
<tr>
<td>v</td>
<td>Added Trademarks</td>
</tr>
<tr>
<td>1-5</td>
<td>Modified the bullets in Section 1.3</td>
</tr>
<tr>
<td>1-7</td>
<td>Added LF2401A and LC2401A to Table 1−1</td>
</tr>
<tr>
<td>1-9</td>
<td>Added note to Figure 1−1</td>
</tr>
<tr>
<td>2-2</td>
<td>Modified last sentence in the second paragraph of Section 2.1.</td>
</tr>
<tr>
<td>2-5</td>
<td>Changed the description of Bit 0 of SCSR1 Register.</td>
</tr>
<tr>
<td>2-6</td>
<td>Changed the description of Bit 5 of SCSR2 Register</td>
</tr>
<tr>
<td>2-8</td>
<td>Changed the description of Bits 3–0 in DINR Register</td>
</tr>
<tr>
<td>2-19</td>
<td>Added new data to Section 2.5.3, Nonmaskable Interrupt (NMI)</td>
</tr>
<tr>
<td>3-17</td>
<td>Modified first paragraph in Section 3.11.2</td>
</tr>
<tr>
<td>4-9</td>
<td>Modified Table 4−1 in the Exit Condition column</td>
</tr>
<tr>
<td>5-2</td>
<td>Replaced Figure 5−1, Shared Pin Configuration.</td>
</tr>
<tr>
<td>5-7</td>
<td>Changed secondary pin function of Bit 14, IOPF6 in the MCRC Register to reserved</td>
</tr>
<tr>
<td>5-7</td>
<td>Added a note to Table 5–4</td>
</tr>
<tr>
<td>6-39</td>
<td>Changed the first paragraph of Section 6.4, Compare Units</td>
</tr>
<tr>
<td>6-39</td>
<td>Modified Figure 6–12, Compare Unit Block Diagram</td>
</tr>
<tr>
<td>6-40</td>
<td>Modified first paragraph on page 6-40, changing GP timer 2 to GP timer 3</td>
</tr>
<tr>
<td>6-43</td>
<td>Changed description of Bit 8 of the COMCONA Register</td>
</tr>
<tr>
<td>6-44</td>
<td>Changed description of Bit 8 of the COMCONB Register</td>

<td>Modified second bullet item (conversion time rates) in Section 7.1, Features</td>
</tr>
<tr>
<td>7-5</td>
<td>Modified Figure 7–1</td>
</tr>
<tr>
<td>7-6</td>
<td>Modified Figure 7–2</td>
</tr>
<tr>
<td>7-34</td>
<td>Added a note to description of bits 3–0 of AUTO_SEQ_SR Register</td>
</tr>
<tr>
<td>7-37</td>
<td>Added a note to Figure 7–14</td>
</tr>
<tr>
<td>7-38</td>
<td>Added data sheet nomenclature column to Table 7–9</td>
</tr>
<tr>
<td>8-23</td>
<td>Modified description of Bit 6 of RX ERR INT ENA in Figure 8–11</td>
</tr>
<tr>
<td>8-28</td>
<td>Modified first paragraph of Section 8.7.5, Receiver Status Register (SCIRXST)</td>
</tr>
<tr>
<td>9-6</td>
<td>Changed bits from “illegal” to “reserved” in Table 9–1</td>
</tr>
<tr>
<td>9-9</td>
<td>Modified last paragraph in Master Mode</td>
</tr>
<tr>
<td>9-24</td>
<td>Modified description of bits 6:0 in Figure 9–10</td>
</tr>
<tr>
<td>9-35</td>
<td>Modified title of Figure 9–21</td>
</tr>
<tr>
<td>10-17</td>
<td>Modified description of bit 15 in Figure 10–9</td>
</tr>
<tr>
<td>10-24</td>
<td>Modified description of bit 9 (WUBA) in Figure 10–14</td>
</tr>
<tr>
<td>10-27</td>
<td>Modified descriptions for Bits 10–0 in BCR1 Register (Figure 10–16)</td>
</tr>
</tbody>
</table>
## Changes Made in This Revision

<table>

</tr>
</thead>
<tbody>
<tr>
<td>10-29</td>
<td>Modified Figure 10–17</td>
</tr>
<tr>
<td>10-29</td>
<td>Replaced Table 10–4</td>
</tr>
<tr>
<td>11-10</td>
<td>Changed description of Bit 6 in the WDCR Register (Figure 11–4) and changed reset information on bits 5:3</td>
</tr>
<tr>
<td>12-2</td>
<td>Added new first paragraph and new last paragraph to Section 12.1</td>
</tr>
<tr>
<td>12-3</td>
<td>Added a new bullet item to port code instructions in Section 12.2</td>
</tr>
<tr>
<td>13-4</td>
<td>Added a row to Table 13–3 for the CSM</td>
</tr>
<tr>
<td>13-9</td>
<td>Modified Section 13.4.3.2, Fast RD Strobe Operation</td>
</tr>
<tr>
<td>13-14</td>
<td>Added Section 13.6.1, Input Qualification Circuitry</td>
</tr>
<tr>
<td>C-24</td>
<td>Replaced code for REM_ANS.asm and REM_REQ.asm</td>
</tr>
<tr>
<td>D-12</td>
<td>Replaced code for BOOT.asm</td>
</tr>
</tbody>
</table>
Table B–1 starting on page B-2 shows the peripheral register map for 240xA devices. The shaded table entries represent the registers that are in addition to the 24x registers. These additions are also explained in the data sheet titled TMS320LF2407A, TMS320LF2406A, TMS320LF2403A, TMS320LF2402A, TMS320LC2406A, TMS320LC2404A, TMS320LC2402A DSP Controllers (literature number SPRS145), and TMS320LF2401A DSP Controller (literature number SPRS161). Note that:

- The ADC registers are completely different from those in the 24x.
- The ADC register map has been moved from 7030h to 70A0h.
- The second event manager (EVB) has been placed at 7500h.

Table B–2 on page B-9 shows the code security module (CSM) registers.

This appendix provides:

- A brief introduction to the tools used for generating executable COFF files that run on the 240xA devices.
- Sample programs to test some of the peripherals available in the 240xA devices.

This appendix is not intended to teach you how to use the software development tools. The following documents cover these tools in detail:

- *TMS320C1x/C2x/C2xx/C5x Assembly Language Tools User’s Guide* (literature number SPRU018)
- *TMS320C2x/C2xx/C5x Optimizing C Compiler User’s Guide* (literature number SPRU024)
- *TMS320C2xx C Source Debugger User’s Guide* (literature number SPRU151)

For further information about ordering these documents, see *Related Documentation From Texas Instruments* on page v of the Preface.

C.1 About These Program Examples

Figure C−1 illustrates the basic process for generating executable COFF files:

1) Use any ASCII editor to create:
   - An assembly language program (*test.asm* in the figure)
   - A linker command file (*240xA.cmd* in the figure) that defines address ranges according to the architecture of the particular device and where the various sections of the user code should be located

2) Assemble the program. The command shown under Step 2 in the figure generates an object file (.obj) and list file (.lst) containing a listing of assembler messages.

3) Use the linker to bring together the information in the object file and the command file and create an executable file (*test.out* in the figure). The command shown also generates a map file, which explains how the linker assigned the individual sections in the memory.

**Note:**
The procedure here applies to the PC™ development environment and is given only as an example.

---

**Figure C−1. Procedure for Generating Executable Files**

**Step 1**
Using any ASCII editor, create source program
*test.asm*
and command file
*240xA.cmd*

**Step 2**
Assemble source program
*dspa test.asm −l −v2xx −s*

**Output files**
*test.lst* − error listings
*test.obj* − assembled file

**Step 3**
Run linker
*dsplnk test.obj 240xA.cmd −o test.out −m*
*test.map*

**Output files**
*test.out* − executable file
*test.map* − map file
### Table C−1. Common Files For All Example Programs

<table>
<thead>
<tr>
<th>Program</th>
<th>Functional Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>240xA_PM.cmd</td>
<td>Linker command file that defines the program, data, and I/O memory maps of the target hardware. It also locates the various sections in the user code into predetermined segments of memory. This .cmd file locates user code (vectors and .text sections) in program memory beginning at 0000h.</td>
</tr>
<tr>
<td>240xA.h</td>
<td>Header file that designates labels for the addresses of the various registers.</td>
</tr>
<tr>
<td>vector.h</td>
<td>File that contains the vectors for various interrupts.</td>
</tr>
</tbody>
</table>

### Table C−2. Program Examples

<table>
<thead>
<tr>
<th>Program</th>
<th>Functional Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPI.asm</td>
<td>Program to output serial data through the SPI port</td>
</tr>
<tr>
<td>SCI.asm</td>
<td>Program to check the SCI module in 240xA</td>
</tr>
<tr>
<td>PC_ECHO.asm</td>
<td>Program to echo received characters back to the source</td>
</tr>
<tr>
<td>ADC.asm</td>
<td>Program to check ADC of 240xA</td>
</tr>
<tr>
<td>GPIO_OUT.asm</td>
<td>Program that checks GPIO pins of 240xA as outputs</td>
</tr>
<tr>
<td>GPIO_IN.asm</td>
<td>Program that checks GPIO pins of 240xA as inputs</td>
</tr>
<tr>
<td>REM_ANS.asm</td>
<td>Programs that perform RTR (Remote Transmission Request) operations in the CAN module</td>
</tr>
<tr>
<td>REM_REQ.asm</td>
<td></td>
</tr>
<tr>
<td>EV_T1INT.asm</td>
<td>Program to check the operation of timer 1 in EVA</td>
</tr>
<tr>
<td>CAP.asm</td>
<td>Program to check the operation of capture units in the EV modules</td>
</tr>
</tbody>

Program Examples

File Name: SPI.asm
Description: PROGRAM TO OUTPUT SERIAL DATA THROUGH THE SPI PORT
This program outputs a set of incrementing words (that roll over) through the SPI. If a Digital-to-analog (DAC) converter is connected to the SPI, the DAC outputs a sawtooth waveform. The program sends data to the serial DAC by means of the SPI. For this example, the TLC5618 serial DAC from TI was used.

Program Examples

;===========================================================================
* File Name: SCI.asm
* Description: PROGRAM TO PERFORM A LOOPBACK IN THE SCI MODULE
* This program is capable of doing either an internal loopback or an external
* loopback, depending on the value written in SCICCR. SCITXD-SCIRXD pins
* should be connected together, if external loopback is desired. This is not
* required for an internal loopback. The SCI receives the bit-stream and stores
* the received data in memory (60h and above) for verification.
* An 8 bit value is transmitted through the SCITXD pin at a baud rate of
* 9600 bits/sec. A counter is used to determine how many times data is
* transmitted and received.
* This code is useful to determine the health of the SCI hardware quickly
* without the aid of any other equipment.

File name : CAP.asm

Description : PROGRAM TO CHECK THE CAPTURE UNITS OF 240X

This program checks the Capture units of EVA & EVB. On each EV module,
* the capture units are setup to detect different transitions. On EVA,
* CAP1 detects a rising edge, CAP2 detects a falling edge and CAP3 detects
* both edges. All capture interrupts are enabled. Timers 1 & 2 provide
* input signals (through external connections) and also serve as a
* time-base for these capture units. Upon detection, the capture interrupt
* reads the proper CAPFIFO value to ensure that the capture units detected
* the correct transition. The same scheme is implemented on EVB, to check
* CAP4,5 and 6 using Timers 3 and 4.

Both Timers count in CONTINUOUS-UP mode.
* CAP1 is rising edge detect (T1 CMP Active low)
* CAP2 is falling edge detect (T1 CMP Active low)
* CAP3 on both edges (T2 CMP Active high)

This program tests the following in EVA :-
* CAP1 & CAP2 using Timer 1
* CAP3 using Timer 2

This program tests the following in EVB :-
* CAP4 & CAP5 using Timer 3
* CAP6 using Timer 4

COMMENTS: Connect T1CMP to CAP1,2; T2CMP to CAP3 inputs
* Connect T3CMP to CAP4,5; T4CMP to CAP6 inputs

PERIPHERAL CODE : 5 (EVA) and 6 (EVB)
* TEST CODE : CAP 1,2,3,4,5,6 − 1,2,3,1,2,3 respectively

D.1 Introduction

The LF240xA/LF240x Digital Signal Processors (DSPs) include on-chip read-only memory (ROM) containing bootloader code. This code loads code from an external serial boot device at reset and transfers control to the code loaded from the external device. This chapter describes working with this feature of the device.

The LF240xA/LF240x device Boot ROM offers the user two options: it can load code through either asynchronous or synchronous serial transfer.

The synchronous transfer is done through the serial peripheral interface (SPI), and the asynchronous transfer is done through the serial communications interface (SCI). The code is loaded to a user-specified location which is completely flexible; it can be anywhere in program memory where RAM is available. The serial transfer packet must contain the address as specified in the applicable Serial Transfer Format, which is described in section D.2, Protocol Definitions, on page D-6.

D.1.1 Boot-Load Sequence

There are a few things that must be set up correctly for the control to transfer to the Boot ROM and a valid boot load to occur:

1) **Microcontroller mode.** In the case of LF2407A/LF2407, the device must be placed in microcontroller mode by pulling the MP/MC pin LOW.

2) **Boot ROM loader invocation.** The bootloader is invoked by pulling the BOOT EN/XF pin low through a resistor, prior to device reset. This transfers control to the boot-load program located in the on-chip ROM. At reset time, internal logic takes a “snapshot” of this pin and, if this pin is a low level, then the Boot ROM appears in the memory map as shown in Figure D−2 on page D-5. Otherwise, the on-chip flash memory is enabled and the program counter begins execution at 0000h. This pin can be driven high/low or through a jumper via a resistor, allowing control of the boot sequence of the DSP. The resistor must be present since the XF pin is an output at all other times.

3) **PLL Multiplier selection** (available on LF240xA only). Bootloader code sets the PLL to multiply the incoming clock by either x2 or x4. This selection is made by looking at the state of the IOPA0 pin at reset. If this pin is pulled low, the PLL is set to multiply by x2. If the pin is pulled high, the PLL is set to multiply the incoming clock by a factor of x4. It is recommended that this pin be pulled high or low through a resistor since this pin will be an output when set to the primary function. Refer to Table D−1 on
page D-8 for the effect on the SCI bootload lock. Also note that the combination of the PLL multiplication factor chosen and the input clock frequency must result in a clock rate less than or equal to the maximum CPU clock rate allowed for the device.

On the LF240x devices, the PLL multiplication factor is always set to x4 by the Boot ROM initialization code.

4) **SCI or SPI selection.** The bootloader code selects the source of the incoming code, depending on the state of the IOPC2 pin on the device. The code takes a snapshot of this pin after being invoked, and determines which loader (SPI or SCI) to invoke based on the status of this pin.

- If IOPC2 is pulled low, an SCI transfer is commenced.
- If IOPC2 is pulled high, an SPI transfer is commenced.

**Note that the SPI selection is invalid on devices without the SPI.** It is suggested that this pin should be driven via a resistor as well, because SPISIMO will be an output if the SPI is used at any time during the operation of the system.

5) **Destination check.** The incoming destination is now compared to the range FE00h to FFFFh. If the destination matches this range, the CNF bit (Bit 12) in status register ST1 is set, configuring the DARAM memory block B0 to Program Memory Space. No other checks are performed and it is entirely up to the host/external boot device to supply a valid combination of the memory destination address and the length for the incoming code. This means that the target code must fit into the internal memory or external memory must be available.

6) **Data transfer.** Once the incoming destination and length are fetched (this protocol is defined in separate sections for the SCI and SPI), the actual data transfer commences. The fetch is basically destination, length, and data with no error-checking. On the SCI, the incoming data is echoed back allowing the host to implement error-checking, if desired.

7) **Execution of incoming code.** Once the Boot ROM loader completes transfer of the packet, a branch is made into the incoming code.

8) **Watchdog.** The watchdog timer on the device is active during the entire sequence and is being reset at key points in the code. When a branch is made into the user code, it is the responsibility of the user code to handle watchdog overflow as appropriate.

9) **Restrictions on the incoming code.**

- The combination of the destination address and transfer length **must** point to valid locations. There is absolutely **no** error-handling whatsoever.
The combination also must point to a memory block that is contiguous.

The address check is performed only on the first location of the incoming destination. It is expected that this allows enough space for the rest of the incoming words. This means that if you have external program memory at range FDFEh to FDFFh (two words) and you attempt to load code into the range FDFEh to FEFFh (attempting to use the internal memory FE00h to FEFFh), this combination is invalid since the destination check will not switch B0 into the program space upon encountering the destination FDFEh. Lastly, the incoming address and length are expected to be 16 bits, as defined in the SPI and SCI transfer protocols.

Figure D−1. Example Hardware Configuration for LF240xA Boot ROM Operation

Note: For LF240x devices, the bootloader sets the PLL to x4 mode. For LF240xA devices, the multiplier depends on the state of the IOPA0 pin. For a list of valid CLKIN frequencies, refer to Table D−1, Clock Speeds At Which Baud Rate Locks, on page D-8.
Figure D–2. Memory Maps for the LF240xA/LF240x Devices in Microcontroller Mode

† When CNF = 1, addresses FE00h–FEFFh and FF00h–FFFFh are mapped to the same physical block (B0) in program-memory space. For example, a write to FE00h has the same effect as a write to FF00h. For simplicity, addresses FE00h–FEFFh are referred to as reserved when CNF = 1.

Note: When boot ROM is enabled, on-chip locations 0000–00FFh in program memory is mapped to the bootloader. Boot ROM and Flash Memory share the same starting address, and hence, are not visible (active) at the same time. If the BOOT ENXF pin = 0 during reset, the BOOT EN bit in SCSR2 register (bit 3) will be set and will enable the Boot ROM at 0000 in program space. While Boot ROM is enabled, the entire Flash memory will be disabled. The SCSR2.3 bit should be disabled (0) to have Flash array enabled instead of Boot ROM. See Appendix D for bootloader details.
D.2 Protocol Definitions

The transfer of data is done according to a defined protocol for the SPI and SCI. The protocol for the synchronous transfer over the SPI is discussed in section D.2.1, and the protocol for the SCI transfer is discussed in section D.2.2.

D.2.1 SPI Synchronous Transfer Protocol and Data Formats

The ROM loader expects an 8-bit-wide SPI-compatible EEPROM device to be present on the SPI pins as indicated in Figure D–1, *Example Hardware Configuration for LF240xA Boot ROM Operation*, on page D-4. If the download is to be performed from an SPI port on another device, then that device must be set up to operate in the slave mode and mimic a serial EEPROM. Immediately after entering the SPI loader, the pin functions for the SPI pins are set to primary, and the SPI is initialized. The initialization is done at the slowest speed possible. The data transfer is done in “burst” mode for the EEPROM. The transfer is carried out entirely in byte mode (SPI at 8 bits/character). A step-by-step description of the sequence follows:

1) The SPI is initialized.

2) The XF pin is now used as a chip-select for the EEPROM.

3) The SPI outputs a read command for the EEPROM (03h).

4) The SPI sends the EEPROM an address 0000h; that is, the host requires that the EEPROM must have the downloadable packet beginning at address 0000h in the EEPROM.

5) From this point onward, the next two bytes fetched constitute the destination address.

   The most significant byte of this word is the byte read first, and the least significant byte is the next byte fetched. This is true of all word transfers on the SPI.

6) The next word (two bytes) fetched is the length N.

7) The destination is checked to see if it is in the range FE00h to FFFFh. If necessary, the DARAM block B0 is configured in program memory space.

8) From now on, N words are fetched and stored in program memory at the address pointed to by destination. The EEPROM is read off in one continuous burst.

9) Finally, once the last word is stored, a simple branch is made into the code at the destination address; therefore, the entry point for the boot-loaded code must be at the destination address.

D.2.2 SCI Asynchronous Transfer Protocol and Data Formats

The SCI-based loader operation is more involved than the SPI-based loader operation. The SCI-based loader incorporates a mechanism for baud-rate matching. Once the baud rate from the host is matched, the SCI loader commences the transfer. Section D.2.2.1 describes the baud rate protocol.

D.2.2.1 Baud Rate Protocol

The baud rate over the communication link is always 38400 bps. The baud rate protocol is necessary because the LF240xA device may be operated at different speeds. The underlying assumption for the baud rate matching is that the device is clocked at a clock frequency from a given, predetermined set. The host is required to send “probe” characters, with the hexadecimal value 0Dh (same as the carriage return character). The target listens in on the serial port, at the set speeds, in succession. Every time a character is detected, it is compared to 0Dh. If more than three characters do not match, the target tries a new baud rate. If the baud rate is correct and the character matches 0Dh, then the target expects to receive nine successive 0Dh characters. If any other character is received, the baud match fails. Once the nine characters are received correctly, the target sends an acknowledge character. Once the acknowledge character is sent, each and every character hereafter is bounced back to the host to ensure data transfer integrity. All the communications are with 8 bit characters, 1 stop bit, and no parity. Baud rate locks are possible at clock speeds/CLKIN combinations listed in Table D−1, Clock Speeds at Which Baud Rate Locks, on page D-8 A flowchart of the baud rate match protocol is shown in Figure D−4, Flowchart for the Serial Loader Baud Rate Match Algorithm, on page D-9.

† Note that these clocking options are valid only on the LF240xA; i.e., not available on the LF240x.

D.2.2.2 Data Transfer

Once the communications are synchronized, the actual data transfer is commenced. The first two bytes fetched are interpreted as the destination. The next two bytes fetched are the length. Once the destination is known, a check is performed to see if the destination lies within B0. If it does, then the bootloader will switch the block B0 into program memory and transfer code into B0. After this, the user code is transferred to the destination and then a branch is executed to the first address of the code. So, as is the case with the SPI, the entry point of the code must be at the first location for the SCI.

D.2.2.3 SCI Data Transfer Completion

A noteworthy point is the completion of transmission of the SCI data echo. There can be a character still in transmission when the control is transferred to the user code. So, if the user code does anything which disturbs the transmission of the SCI, then that last character may be lost. An example is changing the bit definition of the SCI transmit pin. If this is allowed, the host must take this fact into account. A second possible option is to incorporate a small delay in the user code, or perform an SCI check to confirm that the character transmission is complete.

E.1 Flash/ROM Security Feature

TMS320LF2407A, LF2406A, LF2403A, LF2402A (LF240xA) flash devices and LC2406A, LC2404A and LC2402A (LC240xA) ROM devices are designed with on-chip Flash and ROM memories in program space. These memories range from 32K words to 6K words depending on the device derivative in this family. All of these devices have a code security logic that can protect access to their respective Flash or ROM program memory spaces.

E.1.1 Functional Description

In many applications, there is an increasing need to have code security once the application code is fully developed and released to production. Security is defined with respect to the read access to on-chip program memory, and prevents unauthorized copying of proprietary code. The security module is intended to block the CPU’s read access to on-chip program memory. This in effect blocks read access to Flash/ROM through the JTAG port or external peripherals. The Security Mode Table (Table E–1) explains the conditions under which the 240xA devices are considered secure or unsecure.

</tr>
</tbody>
</table>
**Mode 1:** This is the typical mode that would be employed in the end-customer application. The application code stored in on-chip flash/ROM free runs. In this mode, the device is unsecure, since the core should be able to read the contents of on-chip flash/ROM to be able to execute it. The JTAG port is left unconnected. Connecting the JTAG connector would immediately secure the device, thereby thwarting any attempt to read the contents of flash/ROM. To reiterate, during run-time execution of the application, the device will run the application without any impact from the “Code Security Module (CSM)”, which is inactive. If visibility to flash/ROM contents is desired, the device must be first unsecured.

**Mode 2:** If the DSP is powered up in microprocessor mode, the device is immediately secured. If a code running in external memory needs to access the on-chip flash memory, the device must be first unsecured.

**Mode 3:** If access to on-chip flash/ROM is desired using a debugger (via JTAG), the device must be first unsecured.

**Mode 4:** If the on-chip bootloader is invoked, the device is immediately secured. If the bootloader transfers any code that needs access to on-chip flash, the device must be first unsecured.

In all the four modes, the device is unsecured by executing the “Password Match Flow (PMF)”.

### E.1.2 CSM Impact on Other On-Chip Resources

The CSM has no impact whatsoever on the following on-chip resources:

- **RAM blocks such as DARAM and SARAM** – These memory blocks can be freely accessed and code run from them, whether the device is in secure or unsecure mode.

- **Boot ROM contents** – Visibility to the boot ROM contents is not impacted by the CSM; however, invoking the boot ROM code would immediately secure the device.

- **On-chip peripheral registers** – The peripheral registers can be initialized by code running off on-chip program memory, whether the device is in secure or unsecure.

To summarize, it is possible to load code onto on-chip program RAM via the JTAG connector without any impact from the CSM. The code can be debugged and the peripheral registers initialized, independent of whether the device is in secure or unsecure mode.
E.1.3 Incorporating Code Security in User Applications

Code security is typically not required in the development phase of a project; however, security is needed once a robust code is developed. Before such a code is programmed in the flash memory (or committed to ROM), a password should be chosen to secure the device. Once a password is in place, the device is secured (i.e., programming a password at the appropriate locations is the action that secures the device). From that time on, access to debug the contents of flash/ROM by any means (via JTAG, code running off external/on-chip memory etc.) requires the supply of a valid password. A password is not needed to run the code out of flash/ROM (such as in a typical end-customer usage); however, access to flash/ROM contents for debug purpose requires a password.
### E.2 Technical Definitions

- **Secure** – CPU’s read access to the on-chip Flash/ROM memory locations is blocked. This is also referred to as the *Code Secure mode* of the device. This in effect blocks the JTAG debugger read access to on-chip flash or ROM locations. Furthermore, the flash cannot be cleared, erased or programmed while the device is in the secure mode. The device must be unsecured before these operations can commence.

- **Unsecure** – CPU’s read access to on-chip Flash/ROM memory locations is not blocked. All program memory locations are unprotected and; therefore, allows unhindered CPU read and flash programming operations.

- **Password** – 64-bit data (four 16-bit words) that is used to secure or unsecure the device.

- **Password locations (PWL)** – Code security password locations in Flash/ROM memory (0040h, 0041h, 0042h and 0043h). These locations store the password pre-determined by the system designer.

  In flash devices, the password can be changed anytime if the old password is known. In ROM devices, the password cannot be changed after the device is manufactured by Texas Instruments (TI).

  If PWL have all 64 bits as ones or zeros, the device is unsecure. Since new flash devices have erased flash (all ones), the device comes up in unsecure mode. To summarize, a device with a cleared/erased flash array is unsecure.

- **KEY registers** – User accessible registers (four 16-bit words) which will be used to secure or unsecure the device. These registers are mapped in the data memory space at addresses 77F0h, 77F1h, 77F2h and 77F3h.

E.3 Environments that Require Security Unlocking

Following are the typical situations under which unsecuring may be required:

- Code development using debuggers (such as Code Composer)

  This is the most common environment during the design phase of a product.

- Flash programming using TI's flash utilities

  Flash programming is common during code development and testing. Once the user supplies the necessary password, the flash utilities disable the security logic before attempting to program the flash. The flash utilities can disable the code security logic in new devices without any authorization, since new devices come with an erased flash. However, reprogramming devices (that already contain custom passwords) require passwords to be supplied to the flash utilities in order to enable programming.

- Custom environment defined by the application

  In addition to the above, access to flash/ROM memory contents may be required in situations such as:
  - Using the on-chip bootloader to program the flash
  - Executing code from external memory (LF2407A device only) and requiring access to flash for code libraries, etc.

The unsecuring sequence is identical in all the above situations. This sequence is referred to as the password match flow (PMF) for simplicity. The following flowcharts explain the sequence of operation that is required every time the user attempts to unsecure a device. Code examples are also listed for clarity.

E.3.1 Password Match Flow

Password match flow (PMF) is essentially a sequence of four dummy reads from password locations (PWL) followed by four writes to KEY registers.

Figure E–1 explains how PMF helps to initialize the security logic registers and disable security logic. See the flowchart boxes for the actual instructions that accomplish the PMF.
Environments that Require Security Unlocking

Figure E−1. Password Match Flow (PMF)

Start

Flash/ROM Device secure, after reset or runtime

KEY = Undefined

Do dummy Read of PWL, 0040−0043h

Example code for dummy read

LDP  #0
BLPD #40h, 60h : update high word
BLPD #41h, 60h : third word
BLPD #42h, 60h : second word
BLPD #43h, 60h : low word

Is PWL = all 0's or F's?

Write the Password to KEY registers

Correct Password ?

Device unsecure! CPU can access on chip Flash/ROM !

240xA instructions

Example to update KEY register
Assume xpwd has password

LDP  #0EFh : page EFh
SPLK  #hpwd, 77F0h : high word
SPLK  #tpwd, 77F1h : third word
SPLK  #spwd, 77F2h : second word
SPLK  #ipwd, 77F3h : low word
E.4 Unsecuring Considerations for Devices With/Without Code Security

Case 1 and Case 2 provide unsecuring considerations for devices with and without code security.

E.4.1 Case 1: Device With Code Security

A device with code security should have a predetermined password stored in the PWL (locations 0040h through 0043h in program memory). The following are steps to unsecure this device:

1) Perform a dummy read of the PWL.

2) Write the password into the KEY registers (locations 77F0h through 77F3h in data memory).

3) If the password is correct, the device becomes unsecure; otherwise, it stays secure.

E.4.2 Case 2: Device Without Code Security

A device without code security should have 0000 0000 0000 0000h or FFFF FFFF FFFF FFFFh stored in the PWL. The following are steps to use this device:

1) Perform a dummy read of the PWL.

2) The device can be used soon after this operation is completed.

Note: A dummy read operation must be performed prior to using the device, even though the device is not protected with a password.
DOs and DON'Ts to Protect Security Logic

E.5 DOs and DON'Ts to Protect Security Logic

E.5.1 DOs

- To keep the debug and code development phase simple, use the device in the unsecure mode; i.e., use 0000 0000 0000 0000h or FFFF FFFF FFFF FFFFh as PWL words (or use a password that is easy to remember). Use passwords after the development phase when the code is frozen.

- Recheck the passwords in PWL before programming the COFF file using flash utilities.

- While migrating code from 240x or 24x devices to the 240xA devices, recheck the PWL contents before committing the code to flash memory. Note that program memory locations 0040h through 0043h in 240x/24x devices are not reserved for passwords and these locations can contain user code. If 0040h–0043h contain code, it would inadvertently secure the 240xA device.

- Refer to Table E-1, Security Mode Table, on page E-2 and its conditions before designing the reset circuit for the LC/LF240xA devices.

E.5.2 DON'Ts

There are some situations when the code security feature could be compromised. However, awareness of these situations during the design phase could eliminate any possibility of code security being violated. Some design configurations to be avoided are:

- An application code should not transfer control to any code that could be loaded through a peripheral (such as SCI or CAN). For example, suppose that a customer develops their own version of the bootloader to be able to bootloader from CAN. Typically, this program would initialize the CAN module, transfer a piece of code through the CAN bus onto on-chip RAM and then transfer control to the loaded code. A hacker could potentially transfer a piece of code that could read the flash/ROM contents and then output the same through any on-chip peripheral or the external memory interface, if present. This is not a concern with the boot-ROM embedded in the LF240xA device since the device is secured the moment the on-chip boot-loader is invoked.
DOs and DON'Ts to Protect Security Logic

- LF2407A is the only device that has external memory interface (XMIF). This device can execute code in microprocessor mode using external memory. If the device powers up in microprocessor mode (MP/MC pin = 1), the on-chip flash memory will be disabled and the flash access will remain secure. If on-chip flash access is desired, it can be done only if the password is known. The CPU has to initiate a PMF and flash access will be granted, if the password is valid. However, if the device powers up in micro-controller mode (MP/MC pin = 0) and branches to an external memory address, the flash memory cannot be protected. A hacker could potentially have code in the external memory that could read the flash/ROM contents.

- Similarly, code running in flash should not transfer control to on-chip boot ROM. A hacker could potentially transfer a piece of code that could read the flash contents.
E.6 CSM Features – Summary

1) The flash is unsecured after a reset, if the following conditions are met:
   - The JTAG connector is not connected.
   - The device is powered up in microcomputer mode (MP/MC pin is low).
   - The on-chip boot ROM is not invoked.

   Violating any one of the three conditions mentioned above would immedi-
   ately secure the device.

2) The standard way of running code out of the flash is to program the flash
   with the code and powering up the DSP in microcomputer mode. Since the
   flash is unsecured after reset (provided none of the security conditions are
   violated), the code will function correctly.

3) Connecting a JTAG emulator at any time will immediately put the flash into
   secure mode. In addition, running the ROM bootloader at reset, or having
   the MP/MC pin high at reset also puts the flash into secure mode. This
   functionality keeps hackers from accessing the flash by using the emula-
   tor, by trying to bootloader code into the device that copies the flash contents
   to the outside world, or by booting up directly into external memory and
   running code that tries to copy the flash contents to the outside world.
E.7 CSM — Frequently Asked Questions

What is CSM?

CSM is a security feature incorporated in TMS320Lx240xA DSP controllers. It prevents access/visibility to on-chip Flash/ROM memory (in program space) to unauthorized persons—i.e., it prevents duplication/reverse engineering of proprietary code.

What do the terms “secure” and “unsecure” mean?

“Secure” means access to on-chip flash/ROM memory is protected. “Unsecure” means access to on-chip flash/ROM memory is not protected—i.e., the contents of the flash/ROM could be read by any means (through a debugging tool such as Code Composer, for example).

Under what conditions is the device unsecure?

A device is unsecure when the device comes up in the intended application mode in which code is executed from on-chip flash/ROM, without JTAG connector connected—i.e., the device is brought up in “microcontroller” mode upon reset (with the on-chip ROM bootloader disabled). Note that this is the typical usage of the DSP in an end-product.

Under what conditions is the device secure?

1) When the on-chip ROM bootloader is invoked.
2) When the JTAG connector is connected.
3) When the DSP is powered up in MP mode.
4) When the KEY register values and the PWL values are different.

Can you explain the terms PWL and KEY registers?

PWL stands for “Password locations”. These are memory locations at addresses 40h to 43h in on-chip flash/ROM which store the passwords. PWL is mapped in program memory space.

The KEY registers are memory locations at addresses 77F0h to 77F3h in on-chip data memory space. Writing the password to the KEY register is part of the procedure to unlock the device.
How do I secure a device?

You secure a device by ensuring the presence of passwords (other than FFFFFFFFFFFFFFh or 0000000000000000h) in the PWL.

ROM: Place password into ROM code at location 40h–43h. This password will be fabricated into the ROM with the ROM code.

Flash: Program addresses 40h–43h with a password other than all zeros or all ones.

How do I unsecure a device?

You unsecure a device by executing the following steps:

1) Do a “dummy” read of PWL. The word “dummy” implies that the destination address of this read is insignificant. Only the read of the PWL is important.

2) Write the passwords to the KEY. The value of these passwords should already be known by the user and should match the value stored in the PWL.

Should I program all 64 bits of the password?

For maximum protection, it is advisable to program all 64 bits.

I don’t want to use the CSM. Can I “bypass” it?

There is no way to “bypass” the CSM in TMS320Lx240xA DSP controllers. If code security is not a concern, you can program the “dummy” passwords (FFFFFFFFFFFFFh or 0000000000000000h) in the PWL.

I have programmed the PWL with “dummy” passwords. Do I still need to perform dummy reads of the PWL when I am doing JTAG emulation/debug?

A dummy read of the PWL is still essential to gain visibility to on-chip flash/ROM. A write to the KEY is not required. In situations where a debugger is used, a read of the PWL by the debugger (in the disassembly window) is sufficient. For example, right-click in the disassembly window, select Start Address, and enter 0x0040 in the box. This will unsecure the on-chip ROM/FLASH.

Are there any precautions I should observe while developing code?

During the code-development phase, it is a good idea to use the dummy passwords (or stick to a single password).
Should I incorporate routines to “unsecure” the device in my application code?

There is no need to incorporate routines to “unsecure” the device in your application code. Recall that the device comes up as “unsecure” when you power it up in “microcontroller” mode (without JTAG connector connected/with the on-chip ROM bootloader disabled). Unsecuring is necessary only when you need visibility to ROM/Flash on a currently secured device.

Is CSM applicable to any other memory space?

No, it is applicable only to on-chip Flash/ROM memory.

Should the device be unsecure to run application code?

Yes. The device must be unsecure in order to be able to execute code out of on-chip Flash/ROM memory.

I don’t need code security. Can I store code in PWL also?

This is not advisable. Keeping tab of the password may be difficult, especially if code changes are microcontroller. It is a good practice to define a password section in the project to isolate the PWL from the rest of the code. This forces the user code to begin at 44h and precludes the possibility of code starting from 40h. This practice is especially advantageous when migrating code from LF240x, where code starts at 40h.

How does the presence of CSM affect flash programming of LF240xA devices? Or, I successfully programmed the flash once, but I am unable to do it again. What could be wrong?

The device must be first unsecured before Clear/Erase/Program (CEP) can be performed. Update the key.asm program with the correct passwords. Assemble and link the program using key.bat. Then run unlock.bat to unsecure the device. You should now be able to clear/erase/program.

After I invoked Code Composer, I couldn’t see my code (programmed in flash) in the disassembly window. I see some “garbage” code instead. What could be wrong?

The device is still in secure mode. In order to be able to view your code in the disassembly window, the device must first be unsecured.
Can you provide me a simple code to unsecure the device?

The following code can be executed from B0 or SARAM:

```
.text

LDP #00E0h ; (E0=224)(E0*80=7000)
SPLK #006Fh, 7029h ; Disable Watchdog

LDP #0h ; Dummy read of the PWL
BLPD #0040h,60h ; update high word
BLPD #0041h,60h ; third word
BLPD #0042h,60h ; second word
BLPD #0043h,60h ; low word

LDP #0EFh ; Writing the password
SPLK #00123h, 77F0h ; to the KEY registers.
SPLK #04567h, 77F1h ; Replace the words shown
SPLK #089ABh, 77F2h ; with the appropriate
SPLK #0CDEFh, 77F3h ; passwords.

LOOP B LOOP
```

I forgot the password I programmed in PWL. Will I be able to reprogram the flash?

No. Not unless you know which COFF file you used to program the flash. It is for this reason you should always store a known value in the PWL during the code development phase.

Are there any restrictions on debug capabilities when secure mode is used?

No. Once the device is unsecured, the CSM has no impact on debug capabilities.

Are all of the ‘Real-Time’ capabilities still available?

Yes. CSM does not impact the ‘Real-Time’ capabilities.

Does the addition of Secure Mode require any modifications to the Application Code itself?

The only requirement is the presence of passwords in the PWL.
Are there any 'bad practices' which should be avoided (which compromise security)?

Please refer to section E.5, DOs and DON'Ts to Protect Security Logic, of this reference guide.

In mass production, can the Flash be programmed, and made secure, in ONE, fast, operation?

There is no special operation needed "to secure" a device, other than ensuring the presence of passwords in the PWL.

Do the BLPD and TBLR instructions still work when in secure mode? If so, what prevents a 'Trojan Horse' program...attached to the external bus, from copying from Program to Data space, then allowing data space to be copied to the UART...or being visible via JTAG?

No, BLPD and TBLR do not work when the device is in secure mode. Using the external bus implies Microprocessor mode. The device is secured in MP mode. The device will also be secured immediately when the JTAG connector is connected.
A0–A15: Collectively, the external address bus; the 16 pins are used in parallel to address external data memory, program memory, or I/O space.

ACC: See accumulator.

ACCH: *Accumulator high word.* The upper 16 bits of the accumulator. See also accumulator.

ACCL: *Accumulator low word.* The lower 16 bits of the accumulator. See also accumulator.

accumulator: A 32-bit register that stores the results of operations in the central arithmetic logic unit (CALU) and provides an input for subsequent CALU operations. The accumulator also performs shift and rotate operations.

address: The location of program code or data stored in memory.

addressing mode: A method by which an instruction interprets its operands to acquire the data it needs. See also *direct addressing; immediate addressing; indirect addressing.*

analog-to-digital (A/D) converter: A circuit that translates an analog signal to a digital signal.

AR: See auxiliary register.

AR0–AR7: Auxiliary registers 0 through 7. See auxiliary register.

ARAU: See auxiliary register arithmetic unit (ARAU).

ARB: See auxiliary register pointer buffer (ARB).

ARP: See auxiliary register pointer (ARP).

auxiliary register: One of eight 16-bit registers (AR7–AR0) used as pointers to addresses in data space. The registers are operated on by the auxiliary register arithmetic unit (ARAU) and are selected by the auxiliary register pointer (ARP).
auxiliary register arithmetic unit (ARAU): A 16-bit arithmetic unit used to increment, decrement, or compare the contents of the auxiliary registers. Its primary function is manipulating auxiliary register values for indirect addressing.

auxiliary register pointer (ARP): A 3-bit field in status register ST0 that points to the current auxiliary register.

auxiliary register pointer buffer (ARB): A 3-bit field in status register ST1 that holds the previous value of the auxiliary register pointer (ARP).

B0: An on-chip block of dual-access RAM that can be configured as either data memory or program memory, depending on the value of the CNF bit in status register ST1.

B1: An on-chip block of dual-access RAM available for data memory.

B2: An on-chip block of dual-access RAM available for data memory.

BIO pin: A general-purpose input pin that can be tested by the conditional branch instruction (BCND) that causes a branch when BIO is driven low externally.

bit-reversed indexed addressing: A method of indirect addressing that allows efficient I/O operations by resequencing the data points in a radix-2 fast Fourier transform (FFT) program. The direction of carry propagation in the ARAU is reversed.

bootloader: A built-in segment of code that transfers code from an external source to a 16-bit external program destination at reset.

branch: A switching of program control to a nonsequential program-memory address.

BRR: The value in the baud select registers (SPI).
C bit: See carry bit.

CALU: See central arithmetic logic unit (CALU).

carry bit: Bit 9 of status register ST1; used by the CALU for extended arithmetic operations and accumulator shifts and rotates. The carry bit can be tested by conditional instructions.

central arithmetic logic unit (CALU): The 32-bit wide main arithmetic logic unit for the 24x CPU that performs arithmetic and logic operations. It accepts 32-bit values for operations, and its 32-bit output is held in the accumulator.

CLKIN: Input clock signal. A clock source signal supplied to the on-chip clock generator at the CLKin/X2 pin or generated internally by the on-chip oscillator. The clock generator divides or multiplies CLKin to produce the CPU clock signal, CLKOUT.

CLKOUT: Master clock output signal. The output signal of the on-chip clock generator. The CLKOUT high pulse signifies the CPU’s logic phase (when internal values are changed), and the CLKOUT low pulse signifies the CPU’s latch phase (when the values are held constant).

CNF bit: DARAM configuration bit. Bit 12 in status register ST1. CNF is used to determine whether the on-chip RAM block B0 is mapped to program space or data space.

codec: A device that codes in one direction of transmission and decodes in another direction of transmission.

COFF: Common object file format. A system of files configured according to a standard developed by AT&T. These files are relocatable in memory space.

context saving/restoring: Saving the system status when the device enters a subroutine (such as an interrupt service routine) and restoring the system status when exiting the subroutine. On the 24x, only the program counter value is saved and restored automatically; other context saving and restoring must be performed by the subroutine.

CPU: Central processing unit. The 24x CPU is the portion of the processor involved in arithmetic, shifting, and Boolean logic operations, as well as the generation of data- and program-memory addresses. The CPU includes the central arithmetic logic unit (CALU), the multiplier, and the auxiliary register arithmetic unit (ARAU).
**CPU cycle**: The time required for the CPU to go through one logic phase (during which internal values are changed) and one latch phase (during which the values are held constant).

**current AR**: See *current auxiliary register*.

**current auxiliary register**: The auxiliary register pointed to by the auxiliary register pointer (ARP). The auxiliary registers are AR0 (ARP = 0) through AR7 (ARP = 7). See also *auxiliary register; next auxiliary register*.

**current data page**: The data page indicated by the content of the data page pointer (DP). See also *data page; DP*.

**D0–D15**: Collectively, the external data bus; the 16 pins are used in parallel to transfer data between the 24x and external data memory, program memory, or I/O space.

**DARAM**: *Dual-access RAM*. RAM that can be accessed twice in a single CPU clock cycle. For example, your code can read from and write to DARAM in the same clock cycle.

**DARAM configuration bit (CNF)**: See *CNF bit*.

**data-address generation logic**: Logic circuitry that generates the addresses for data memory reads and writes. This circuitry, which includes the auxiliary registers and the ARAU, can generate one address per machine cycle. See also *program-address generation logic*.

**data page**: One block of 128 words in data memory. Data memory contains 512 data pages. Data page 0 is the first page of data memory (addresses 0000h–007Fh); data page 511 is the last page (addresses FF80h–FFFFh). See also *data page pointer (DP); direct addressing*.

**data page 0**: Addresses 0000h–007Fh in data memory; contains the memory-mapped registers, a reserved test/emulation area for special information transfers, and the scratch-pad RAM block (B2).

**data page pointer (DP)**: A 9-bit field in status register ST0 that specifies which of the 512 data pages is currently selected for direct address generation. When an instruction uses direct addressing to access a data-memory value, the DP provides the nine MSBs of the data-memory address, and the instruction provides the seven LSBs.

**data-read address bus (DRAB)**: A 16-bit internal bus that carries the address for each read from data memory.
data read bus (DRDB): A 16-bit internal bus that carries data from data memory to the CALU and the ARAU.

data-write address bus (DWAB): A 16-bit internal bus that carries the address for each write to data memory.

data write bus (DWEB): A 16-bit internal bus that carries data to both program memory and data memory.

decode phase: The phase of the pipeline in which the instruction is decoded. See also pipeline; instruction-fetch phase; operand-fetch phase; instruction-execute phase.

direct addressing: One of the methods used by an instruction to address data-memory. In direct addressing, the data-page pointer (DP) holds the nine MSBs of the address (the current data page), and the instruction word provides the seven LSBs of the address (the offset). See also indirect addressing.

DP: See data page pointer (DP).

DRAB: See data-read address bus (DRAB).

DRDB: See data read bus (DRDB).

DS: Data memory select pin. The 24x asserts DS to indicate an access to external data memory (local or global).

DSWS: Data-space wait-state bit(s). A value in the wait-state generator control register (WSGR) that determines the number of wait states applied to reads from and writes to off-chip data space.

dual-access RAM: See DARAM.

dummy cycle: A CPU cycle in which the CPU intentionally reloads the program counter with the same address.

DWAB: See data-write address bus (DWAB).

DWEB: See data write bus (DWEB).

execute phase: The fourth phase of the pipeline; the phase in which the instruction is executed. See also pipeline; instruction-fetch phase; instruction-decode phase; operand-fetch phase.

external interrupt: A hardware interrupt triggered by an external event sending an input through an interrupt pin.
**FIFO buffer:** *First-in, first-out buffer.* A portion of memory in which data is stored and then retrieved in the same order in which it was stored. The synchronous serial port has two four-word-deep FIFO buffers: one for its transmit operation and one for its receive operation.

**flash memory:** Electrically erasable and programmable, nonvolatile (read-only) memory.

**general-purpose input/output pins:** Pins that can be used to accept input signals or send output signals. These pins are the input pin `BIO`, the output pin `XF`, and the GPIO pins.

**hardware interrupt:** An interrupt triggered through physical connections with on-chip peripherals or external devices.

**IFR:** See interrupt flag register (IFR).

**immediate addressing:** One of the methods for obtaining data values used by an instruction; the data value is a constant embedded directly into the instruction word; data memory is not accessed.

**immediate operand/immediate value:** A constant given as an operand in an instruction that is using immediate addressing.

**IMR:** See interrupt mask register (IMR).

**indirect addressing:** One of the methods for obtaining data values used by an instruction. When an instruction uses indirect addressing, data memory is addressed by the current auxiliary register. See also direct addressing.

**input clock signal:** See CLKIN.

**input shifter:** A 16- to 32-bit left barrel shifter that shifts incoming 16-bit data from 0 to 16 positions left relative to the 32-bit output.
instruction-decode phase: The second phase of the pipeline; the phase in which the instruction is decoded. See also pipeline; instruction-fetch phase; operand-fetch phase; instruction-execute phase.

instruction-execute phase: The fourth phase of the pipeline; the phase in which the instruction is executed. See also pipeline; instruction-fetch phase; instruction-decode phase; operand-fetch phase.

instruction-fetch phase: The first phase of the pipeline; the phase in which the instruction is fetched from program-memory. See also pipeline; instruction-decode phase; operand-fetch phase; instruction-execute phase.

instruction register (IR): A 16-bit register that contains the instruction being executed.

instruction word: A 16-bit value representing all or half of an instruction. An instruction that is fully represented by 16 bits uses one instruction word. An instruction that must be represented by 32 bits uses two instruction words (the second word is a constant).

internal interrupt: A hardware interrupt caused by an on-chip peripheral.

interrupt: A signal sent to the CPU that (when not masked or disabled) forces the CPU into a subroutine called an interrupt service routine (ISR). This signal can be triggered by an external device, an on-chip peripheral, or an instruction (INTR, NMI, or TRAP).

interrupt flag register (IFR): A 16-bit memory-mapped register that indicates pending interrupts. Read the IFR to identify pending interrupts and write to the IFR to clear selected interrupts. Writing a 1 to any IFR flag bit clears that bit to 0.

interrupt latency: The delay between the time an interrupt request is made and the time it is serviced.

interrupt mask register (IMR): A 16-bit memory-mapped register used to mask external and internal interrupts. Writing a 1 to any IMR bit position enables the corresponding interrupt (when INTM = 0).

interrupt mode bit (INTM): Bit 9 in status register ST0; either enables all maskable interrupts that are not masked by the IMR or disables all maskable interrupts.

interrupt service routine (ISR): A module of code that is executed in response to a hardware or software interrupt.

interrupt trap: See interrupt service routine (ISR).
**interrupt vector**: A branch instruction that leads the CPU to an interrupt service routine (ISR).

**interrupt vector location**: An address in program memory where an interrupt vector resides. When an interrupt is acknowledged, the CPU branches to the interrupt vector location and fetches the interrupt vector.

**INTM bit**: See *interrupt mode bit (INTM)*.

**I/O-mapped register**: One of the on-chip registers mapped to addresses in I/O (input/output) space. These registers, which include the registers for the on-chip peripherals, must be accessed with the IN and OUT instructions. See also *memory-mapped register*.

**IR**: See *instruction register (IR)*.

**IS**: *I/O space select pin*. The 24x asserts IS to indicate an access to external I/O space.

**ISR**: See *interrupt service routine (ISR)*.

**ISWS**: *I/O-space wait-state bit(s)*. A value in the wait-state generator control register (WSGR) that determines the number of wait states applied to reads from and writes to off-chip I/O space.

**latch phase**: The phase of a CPU cycle during which internal values are held constant. See also *logic phase; CLKOUT1*.

**logic phase**: The phase of a CPU cycle during which internal values are changed. See also *latch phase; CLKOUT1*.

**long-immediate value**: A 16-bit constant given as an operand of an instruction that is using immediate addressing.

**LSB**: *Least significant bit*. The lowest order bit in a word. When used in plural form (LSBs), refers to a specified number of low-order bits, beginning with the lowest order bit and counting to the left. For example, the four LSBs of a 16-bit value are bits 0 through 3. See also *MSB*.

**machine cycle**: See *CPU cycle*.

**maskable interrupt**: A hardware interrupt that can be enabled or disabled through software. See also *nonmaskable interrupt*.
master clock output signal: See CLKOUT1.

master phase: See logic phase.

memory-mapped register: One of the on-chip registers mapped to addresses in data memory. See also I/O-mapped register.

microcontroller mode: A mode in which the on-chip ROM or flash memory in program memory space is enabled. This mode is selected with the MP/MC pin.

microprocessor mode: A mode in which the on-chip ROM or flash memory is disabled and external program memory is enabled. This mode is selected with the MP/MC pin.

microstack (MSTACK): A register used for temporary storage of the program counter (PC) value when an instruction needs to use the PC to address a second operand.

MIPS: Million instructions per second.

MP/MC pin: A pin that indicates whether the processor is operating in microprocessor mode or microcontroller mode. MP/MC high selects microprocessor mode; MP/MC low selects microcontroller mode. This pin is used to execute the on-chip bootloader/user code at reset. When MP/MC is held low during reset, program control transfers to on-chip non-volatile memory at location 0000h. When MP/MC is held high, control transfers to 0000h in external program memory.

MSB: Most significant bit. The highest order bit in a word. When used in plural form (MSBs), refers to a specified number of high-order bits, beginning with the highest order bit and counting to the right. For example, the eight MSBs of a 16-bit value are bits 15 through 8. See also LSB.

MSTACK: See microstack.

multiplier: A part of the CPU that performs 16-bit \( \times \) 16-bit multiplication and generates a 32-bit product. The multiplier operates using either signed or unsigned 2's-complement arithmetic.

next AR: See next auxiliary register.

next auxiliary register: The register that is pointed to by the auxiliary register pointer (ARP) when an instruction that modifies ARP is finished executing. See also auxiliary register; current auxiliary register.
**nonmaskable interrupt**: An interrupt that can be neither masked by the interrupt mask register (IMR) nor disabled by the INTM bit of status register ST0.

**NPAR**: *Next program address register.* Part of the program-address generation logic. This register provides the address of the next instruction to the program counter (PC), the program address register (PAR), the micro stack (MSTACK), or the stack.

**operand**: A value to be used or manipulated by an instruction; specified in the instruction.

**operand-fetch phase**: The third phase of the pipeline; the phase in which an operand or operands are fetched from memory. See also *pipeline; instruction-fetch phase; instruction-decode phase; instruction-execute phase.*

**output shifter**: 32- to 16-bit barrel left shifter. Shifts the 32-bit accumulator output from 0 to 7 bits left for quantization management, and outputs either the 16-bit high or low half of the shifted 32-bit data to the data write bus (DWEB).

**OV bit**: *Overflow flag bit.* Bit 12 of status register ST0; indicates whether the result of an arithmetic operation has exceeded the capacity of the accumulator.

**overflow (in a register)**: A condition in which the result of an arithmetic operation exceeds the capacity of the register used to hold that result.

**overflow mode**: The mode in which an overflow in the accumulator causes the accumulator to be loaded with a preset value. If the overflow is in the positive direction, the accumulator is loaded with its most positive number. If the overflow is in the negative direction, the accumulator is filled with its most negative number.

**OVM bit**: *Overflow mode bit.* Bit 11 of status register ST0; enables or disables overflow mode. See also *overflow mode.*

**PAB**: See *program address bus (PAB).*

**PAR**: *Program address register.* A register that holds the address currently being driven on the program address bus for as many cycles as it takes to complete all memory operations scheduled for the current machine cycle.
PC: See program counter (PC).

PCB: Printed circuit board.

pending interrupt: A maskable interrupt that has been successfully requested but is awaiting acknowledgement by the CPU.

pipeline: A method of executing instructions in an assembly line fashion. The 24x pipeline has four independent phases. During a given CPU cycle, four different instructions can be active, each at a different stage of completion. See also instruction-fetch phase; instruction-decode phase; operand-fetch phase; instruction-execute phase.

PLL: Phase lock loop circuit.

PM bits: See product shift mode bits (PM).

power-down mode: The mode in which the processor enters a dormant state and dissipates considerably less power than during normal operation. This mode is initiated by the execution of an IDLE instruction. During a power-down mode, all internal contents are maintained so that operation continues unaltered when the power-down mode is terminated. The contents of all on-chip RAM also remains unchanged.

PRDB: See program read bus (PRDB).

PREG: See product register (PREG).

product register (PREG): A 32-bit register that holds the results of a multiply operation.

product shifter: A 32-bit shifter that performs a 0-, 1-, or 4-bit left shift, or a 6-bit right shift of the multiplier product based on the value of the product shift mode bits (PM).

product shift mode: One of four modes (no-shift, shift-left-by-one, shift-left-by-four, or shift-right-by-six) used by the product shifter.

product shift mode bits (PM): Bits 0 and 1 of status register ST1; they identify which of four shift modes (no-shift, left-shift-by-one, left-shift-by-four, or right-shift-by-six) will be used by the product shifter.

program address bus (PAB): A 16-bit internal bus that provides the addresses for program-memory reads and writes.

program-address generation logic: Logic circuitry that generates the addresses for program memory reads and writes, and an operand address in instructions that require two registers to address operands. This circuitry can generate one address per machine cycle. See also data-address generation logic.
**program control logic:** Logic circuitry that decodes instructions, manages the pipeline, stores status of operations, and decodes conditional operations.

**program counter (PC):** A register that indicates the location of the next instruction to be executed.

**program read bus (PRDB):** A 16-bit internal bus that carries instruction code and immediate operands, as well as table information, from program memory to the CPU.

**PS:** *Program select pin.* The 24x asserts PS to indicate an access to external program memory.

**PSLWS:** *Lower program-space wait-state bits.* A value in the wait-state generator control register (WSGR) that determines the number of wait states applied to reads from and writes to off-chip lower program space (addresses 0000h–7FFFh). See also PSUWS.

**PSUWS:** *Upper program-space wait-state bits.* A value in the wait-state generator control register (WSGR) that determines the number of wait states applied to reads from and writes to off-chip upper program space (addresses 8000h–FFFFh). See also PSLWS.

**RD:** *Read select pin.* The 24x asserts RD to request a read from external program, data, or I/O space. RD can be connected directly to the output enable pin of an external device.

**READY:** *External device ready pin.* Used to create wait states externally. When this pin is driven low, the 24x waits one CPU cycle and then tests READY again. After READY is driven low, the 24x does not continue processing until READY is driven high.

**repeat counter (RPTC):** A 16-bit register that counts the number of times a single instruction is repeated. RPTC is loaded by an RPT instruction.

**reset:** A way to bring the processor to a known state by setting the registers and control bits to predetermined values and signaling execution to start at address 0000h.

**reset pin (RS):** A pin that causes a reset.

**reset vector:** The interrupt vector for reset.

**return address:** The address of the instruction to be executed when the CPU returns from a subroutine or interrupt service routine.
RPTC: See repeat counter (RPTC).

RS: Reset pin. When driven low, causes a reset on any 24x device.

R/W: Read/write pin. Indicates the direction of transfer between the 24x and external program, data, or I/O space.

scratch-pad RAM: Another name for DARAM block B2 in data space (32 words).

short-immediate value: An 8-, 9-, or 13-bit constant given as an operand of an instruction that is using immediate addressing.

sign bit: The MSB of a value when it is seen by the CPU to indicate the sign (negative or positive) of the value.

sign extend: Fill the unused high order bits of a register with copies of the sign bit in that register.

sign-extension mode (SXM) bit: Bit 10 of status register ST1; enables or disables sign extension in the input shifter. It also differentiates between logic and arithmetic shifts of the accumulator.

slave phase: See latch phase.

software interrupt: An interrupt caused by the execution of an INTR, NMI, or TRAP instruction.

software stack: A program control feature that allows you to extend the hardware stack into data memory with the PSHD and POPD instructions. The stack can be directly stored and recovered from data memory, one word at time. This feature is useful for deep subroutine nesting or protection against stack overflow.

ST0 and ST1: See status registers ST0 and ST1.

stack: A block of memory reserved for storing return addresses for subroutines and interrupt service routines. The 24x stack is 16 bits wide and eight levels deep.

status registers ST0 and ST1: Two 16-bit registers that contain bits for determining processor modes, addressing pointer values, and indicating various processor conditions and arithmetic logic results. These registers can be stored into and loaded from data memory, allowing the status of the machine to be saved and restored for subroutines.
**Glossary**

**STRB:** *External access active strobe.* The 24x asserts \( \text{STRB} \) during accesses to external program, data, or I/O space.

**SXM bit:** See *sign-extension mode bit (SXM).*

**TC bit:** *Test/control flag bit.* Bit 11 of status register ST1; stores the results of test operations done in the central arithmetic logic unit (CALU) or the auxiliary register arithmetic unit (ARAU). The TC bit can be tested by conditional instructions.

**temporary register (TREG):** A 16-bit register that holds one of the operands for a multiply operation; the dynamic shift count for the LACT, ADDT, and SUBT instructions; or the dynamic bit position for the BITT instruction.

**TOS:** *Top of stack.* Top level of the 8-level last-in, first-out hardware stack.

**TREG:** See *temporary register (TREG).*

**TTL:** *Transistor-transistor logic.*

**vector:** See *interrupt vector.*

**vector location:** See *interrupt vector location.*

**wait state:** A CLKOUT cycle during which the CPU waits when reading from or writing to slower external memory.

**wait-state generator:** An on-chip peripheral that generates a limited number of wait states for a given off-chip memory space (program, data, or I/O). Wait states are set in the wait-state generator control register (WSGR).

**WE:** *Write enable pin.* The 24x asserts \( \text{WE} \) to request a write to external program, data, or I/O space.

**WSGR:** *Wait-state generator control register.* This register, which is mapped to I/O memory, controls the wait-state generator.

**XF bit:** *XF-pin status bit.* Bit 4 of status register ST1 that is used to read or change the logic level on the XF pin.
XF pin:  *External flag pin.* A general-purpose output pin whose status can be read or changed by way of the XF bit in status register ST1.

XINT1–XINT2: External pins used to generate general-purpose hardware interrupts.

**Z**

zero fill: A way to fill the unused low or high order bits in a register by inserting 0s.

SCI control register 2 (SCICTL2) 8-27
SCI priority control register (SCIPRI) 8-32
transmit data buffer register (SCITXBUF) 8-31
SCI physical description
error detection flags 8-2
half- or full-duplex operation 8-3
I/O pins 8-2
non-return-to-zero format 8-3
programmable bit rates 8-2
programmable data word length 8-2
receive and transmit functions 8-3
separate enable bits for TX and RX interrupts 8-3
separate error interrupts for multiple error conditions 8-3
serial clock, internally generated 8-2
transmitter and receiver operation 8-3
wake-up multiprocessor modes 8-3
serial peripheral interface (SPI) 9-1
240xA to 240 family compatibility 12-4
block diagram 9-4
C240 SPI vs. LF/LC240xA SPI 9-2
interrupts 9-10
baud rate and clocking schemes 9-12
baud rate determination 9-12
example of baud rate calculations for SPIBRR = 0, 1, or2 9-13
example of baud rate calculations for SPIBRR = 3 to 127 9-12
example of maximum baud rate calculation 9-13
clocking schemes 9-13
selection guide 9-14
SPICLK signal options 9-14
SPICLK-CLKOUT characteristics 9-15
data format 9-11
example transmission of bit from SPIRXBUF 9-12
data transfer example 9-16
five bits per character 9-17
initialization upon reset 9-15
proper SPI initialization using the SPI SW RESET bit 9-16
SPI interrupt control bits 9-10
OVERRUN INT ENA bit (SPICTL.4) 9-11
RECEIVER OVERRUN FLAG bit (SPISTS.7) 9-11
SPI INT ENA bit (SPICTL.0) 9-10
SPI INT FLAG bit (SPISTS.6) 9-10
SPI PRIORITY bit (SPIPRI.6) 9-11
operation 9-7
introduction 9-7
master mode 9-8
master/slave connection, figure 9-8
slave mode 9-9
physical description
I/O pins 9-2
master and slave mode operations 9-2
memory-mapped status and control registers 9-3
SPI serial data register (SPIDAT) 9-2
SPI serial receive buffer register (SPIRXBUF) 9-2
SPI serial transmit buffer register (SPITXBUF) 9-2
SPICLK phase and polarity control 9-2
static and control logic 9-3
SPI module registers
overview 9-5
register addresses 9-6
SPI baud rate register (SPIBRR) 9-24
SPI configuration control register (SPICCR) 9-19
character length control bit values 9-20
SPI emulation buffer register (SPIRXEMU) 9-25
SPI example waveforms 9-30
CLOCK POLARITY = 0, CLOCK PHASE = 0 9-30
CLOCK POLARITY = 0, CLOCK PHASE = 1 9-31
CLOCK POLARITY = 1, CLOCK PHASE = 0 9-32
CLOCK POLARITY = 1, CLOCK PHASE = 1 9-33
SPISTE behavior in master mode 9-34
SPISTE behavior in slave mode 9-35
SPI operation control register (SPICTL) 9-21
SPI priority control register (SPIPRI) 9-29
SPI serial data register (SPIDAT) 9-2
SPI serial receive buffer register (SPIRXBUF) 9-26
SPI serial transmit buffer register (SPITXBUF) 9-27
SPI status register (SPISTS) 9-22

SOF, CAN data frame 10-9
SOS synch, start-of-sequence sync-up 7-38
SPI (serial peripheral interface) 9-1
block diagram 9-4
C240 SPI vs. LF/LC240xA SPI 9-2
interrupts 9-10
baud rate and clocking schemes 9-12
baud rate determination 9-12
example of baud rate calculations for SPIBRR = 0, 1, or 2 9-13
example of baud rate calculations for SPIBRR = 3 to 127 9-12
example of maximum baud rate calculation 9-13
clocking schemes 9-13
selection guide 9-14
SPICLK signal options 9-14
SPICLK-CLKOUT characteristics 9-15
data format 9-11
example transmission of bit from SPIRXBUF 9-12
data transfer example 9-16
five bits per character 9-17
initialization upon reset 9-15
proper SPI initialization using the SPI SW RESET bit 9-16
SPI interrupt control bits 9-10
OVERRUN INT ENA bit (SPICTL.4) 9-11
RECEIVER OVERRUN FLAG bit (SPISTS.7) 9-11
SPI INT ENA bit (SPICTL.0) 9-10
SPI INT FLAG bit (SPISTS.6) 9-10
SPI PRIORITY bit (SPIPRI.6) 9-11
operation 9-7
introduction 9-7
master mode 9-8
master/slave connection, figure 9-8
slave mode 9-9
physical description 9-2
I/O pins 9-2
master and slave mode operations 9-2
memory-mapped control and status registers 9-3
interrupt priority and vectors 2-9
240xA interrupt source priority and vectors table 2-9
peripheral interrupt expansion (PIE) controller 2-13
block diagram interrupt
acknowledge 2-16
hierarchy 2-15
NMI (nonmaskable) 2-19
operation sequence 2-21
request structure 2-15
request, figure 2-18
vectors 2-17
vectors, phantom 2-18
vectors, software hierarchy 2-19
system control registers, 240xA devices 13-8
Boot EN/XF pin operation 13-8
fast RD strobe operation 13-9

T
TAn (transmission acknowledge for mailbox n) 10-20
TCR (transmission control register) 10-20
timer x control register (TxCON), x = 1,2,3, or 4 6-33
TMS320 family advantages 1-2
development 1-2
overview 1-2
transmit mailboxes 10-13
transmitter signals in communication modes, SCI (serial communications interface) 8-17
TRRn (transmission request reset for mailbox n) 10-21
TRSn (transmission request set for mailbox n) 10-21

W
wait state, definition F-14
wait-state generation 3-17
setting the number of wait states with the 2407A WSGR bits 3-19
with the 2407A wait-state generator 3-17
with the READY signal 3-17
wake up from low-power modes
external interrupts 4-9
reset 4-9
wake-up interrupts 4-9
wake-up temporary (WUT), SCI (serial communications interface), double buffered WUT and TXSHF 8-12
wake-up temporary (WUT) flag, SCI (serial communications interface) 8-12
watchdog clock, 240xA devices 13-7
watchdog suspend 4-7
watchdog timer, 240xA to 240 family compatibility 12-4
watchdog timer (WD) features 11-1
block diagram of the WD module 11-3
operation overview 11-4
watchdog suspend 11-4
watchdog timer clock (WDCLK) 11-4
operations 11-4
operations of the WD timer 11-5
servicing the WD timer 11-5
WD check bit logic 11-7
WD prescale select 11-5
WD reset 11-6
WD setup 11-7
WD timer clock 11-4
WD timer control registers power-up sequence, typical 11-6
WD counter register (WDCNTR) 11-8
WD counter register (WDCNTR) table 11-8
WD overflow (timeout) selections 11-11
WD reset key register (WDKEY) 11-9
WD timer control register (WDCR) 11-9
WD timer clock 11-4
waveforms, SPI (serial peripheral interface), examples 9-30
CLOCK POLARITY = 0, CLOCK PHASE = 0 9-30
CLOCK POLARITY = 0, CLOCK PHASE = 1 9-31
CLOCK POLARITY = 1, CLOCK PHASE = 0 9-32
CLOCK POLARITY = 1, CLOCK PHASE = 1 9-33
SPISTE behavior in master mode 9-34
SPISTE behavior in slave mode 9-35
WDCNTR, watchdog counter register 11-8
