About This Manual

This document describes the operation of the high-resolution extension to the pulse width modulator (HRPWM) module described in this reference guide is a Type 0 HRPWM. See the TMS320x28xx, 28xxx DSP Peripheral Reference Guide (SPR566) for a list of all devices with an HRPWM module of the same type, to determine the differences between types, and for a list of device-specific differences within a type.

Notational Conventions

This document uses the following conventions.

- Hexadecimal numbers are shown with the suffix h. For example, the following number is 40h hexadecimal (decimal 64).
- Registers in this document are shown in figures and described in tables.
  - Each register figure shows a rectangle divided into fields that represent the fields of the register. Each field is labeled with its bit name, its beginning and ending bit numbers above, and its read/write properties below. A legend explains the notation used for the properties.
  - Reserved bits in a register figure designate a bit that is used for future device expansion.

Related Documentation From Texas Instruments

SPRUF80 — TMS320x2833x, 2823x System Control and Interrupts Reference Guide describes the various interrupts and system control features of the 2833x and 2823x digital signal controllers (DSCs).

SPRU812 — TMS320x2833x, 2823x Analog-to-Digital Converter (ADC) Reference Guide describes how to configure and use the on-chip ADC module, which is a 12-bit pipelined ADC.

SPRU949 — TMS320x2833x, 2823x DSC External Interface (XINTF) Reference Guide describes the XINTF, which is a nonmultiplexed asynchronous bus, as it is used on the 2833x and 2823x devices.

SPRU963 — TMS320x2833x, 2823x Boot ROM Reference Guide describes the purpose and features of the bootloader (factory-programmed boot-loading software) and provides examples of code. It also describes other contents of the device on-chip boot ROM and identifies where all of the information is located within that memory.

SPRUF87 — TMS320x2833x, 2823x Multichannel Buffered Serial Port (McBSP) Reference Guide describes the McBSP available on the 2833x and 2823x devices. The McBSPs allow direct interface between a DSP and other devices in a system.

SPRUF88 — TMS320x2833x, 2823x Direct Memory Access (DMA) Module Reference Guide describes the DMA on the 2833x and 2823x devices.

SPRUG04 — TMS320x2833x, 2823x Enhanced Pulse Width Modulator (ePWM) Module Reference Guide describes the main areas of the enhanced pulse width modulator that include digital motor control, switch mode power supply control, UPS (uninterruptible power supplies), and other forms of power conversion.

SPRUG02 — TMS320x2833x, 2823x High-Resolution Pulse Width Modulator (HRPWM) Reference Guide describes the operation of the high-resolution extension to the pulse width modulator (HRPWM).

SPRUG4 — TMS320x2833x, 2823x Enhanced Capture (eCAP) Module Reference Guide describes the enhanced capture module. It includes the module description and registers.

SPRUG05 — TMS320x2833x, 2823x Enhanced Quadrature Encoder Pulse (eQEP) Module Reference Guide describes the eQEP module, which is used for interfacing with a linear or rotary incremental encoder to get position, direction, and speed information from a rotating machine in high-performance motion and position control systems. It includes the module description and registers.

SPRUEU1 — TMS320x2833x, 2823x Enhanced Controller Area Network (eCAN) Reference Guide describes the eCAN that uses established protocol to communicate serially with other controllers in electrically noisy environments.

SPRUFZ5 — TMS320x2833x, 2823x Serial Communications Interface (SCI) Reference Guide describes the SCI, which is a two-wire asynchronous serial port, commonly known as a UART. The SCI modules support digital communications between the CPU and other asynchronous peripherals that use the standard non-return-to-zero (NRZ) format.

SPRUEU3 — TMS320x2833x, 2823x DSC Serial Peripheral Interface (SPI) Reference Guide describes the SPI - a high-speed synchronous serial input/output (I/O) port - that allows a serial bit stream of programmed length (one to sixteen bits) to be shifted into and out of the device at a programmed bit-transfer rate.

SPRUG03 — TMS320x2833x, 2823x Inter-Integrated Circuit (I2C) Module Reference Guide describes the features and operation of the inter-integrated circuit (I2C) module.

Tools Guides—
SPRU513 — TMS320C28x Assembly Language Tools v5.0.0 User's Guide describes the assembly language tools (assembler and other tools used to develop assembly language code), assembler directives, macros, common object file format, and symbolic debugging directives for the TMS320C28x device.
SPRU514 — TMS320C28x Optimizing C/C++ Compiler v5.0.0 User’s Guide describes the TMS320C28x™ C/C++ compiler. This compiler accepts ANSI standard C/C++ source code and produces TMS320 DSP assembly language source code for the TMS320C28x device.

SPRU608 — TMS320C28x Instruction Set Simulator Technical Overview describes the simulator, available within the Code Composer Studio for TMS320C2000 IDE, that simulates the instruction set of the C28x™ core.

SPRU625 — TMS320C28x DSP/BIOS 5.32 Application Programming Interface (API) Reference Guide describes development using DSP/BIOS.
High-Resolution Pulse Width Modulator (HRPWM)

This document is used in conjunction with the device-specific Enhanced Pulse Width Modulator (ePWM) Module Reference Guide.

The HRPWM module extends the time resolution capabilities of the conventionally derived digital pulse width modulator (PWM). HRPWM is typically used when PWM resolution falls below ~ 9-10 bits. This occurs at PWM frequencies greater than ~200 kHz when using a CPU/system clock of 100 MHz. The key features of HRPWM are:

• Extended time resolution capability
• Used in both duty cycle and phase-shift control methods
• Finer time granularity control or edge positioning using extensions to the Compare A and Phase registers
• Implemented using the A signal path of PWM, i.e., on the EPWMxA output.
• Self-check diagnostics software mode to check if the micro edge positioner (MEP) logic is running optimally

1 Introduction

The ePWM peripheral is used to perform a function that is mathematically equivalent to a digital-to-analog converter (DAC). As shown in Figure 1, where $T_{SYSCLKOUT} = 10$ ns (i.e. 100 MHz clock), the effective resolution for conventionally generated PWM is a function of PWM frequency (or period) and system clock frequency.

Figure 1. Resolution Calculations for Conventionally Generated PWM

If the required PWM operating frequency does not offer sufficient resolution in PWM mode, you may want to consider HRPWM. As an example of improved performance offered by HRPWM, Table 1 shows resolution in bits for various PWM frequencies. These values assume a 100 MHz SYSCLK frequency and a MEP step size of 180 ps. See the device-specific datasheet for typical and maximum performance specifications for the MEP.

Although each application may differ, typical low frequency PWM operation (below 250 kHz) may not require HRPWM. HRPWM capability is most useful for high frequency PWM requirements of power conversion topologies such as:

- Single-phase buck, boost, and flyback
- Multi-phase buck, boost, and flyback
- Phase-shifted full bridge
- Direct modulation of D-Class power amplifiers
2 Operational Description of HRPWM

The HRPWM is based on micro edge positioner (MEP) technology. MEP logic is capable of positioning an edge very finely by sub-dividing one coarse system clock of a conventional PWM generator. The time step accuracy is on the order of 150 ps. See the device-specific data sheet for the typical MEP step size on a particular device. The HRPWM also has a self-check software diagnostics mode to check if the MEP logic is running optimally, under all operating conditions. Details on software diagnostics and functions are in Section 2.4.

Figure 2 shows the relationship between one coarse system clock and edge position in terms of MEP steps, which are controlled via an 8-bit field in the Compare A extension register (CMPAHR).

![Figure 2. Operating Logic Using MEP](image)

To generate an HRPWM waveform, configure the TBM, CCM, and AQM registers as you would to generate a conventional PWM of a given frequency and polarity. The HRPWM works together with the TBM, CCM, and AQM registers to extend edge resolution, and should be configured accordingly. Although many programming combinations are possible, only a few are needed and practical. These methods are described in Section 2.5.

Registers discussed but not found in this document can be seen in the device-specific Enhanced Pulse Width Modulator (ePWM) Module Reference Guide.

The HRPWM operation is controlled and monitored using the following registers:

2.1 Controlling the HRPWM Capabilities

The MEP of the HRPWM is controlled by two extension registers, each 8-bits wide. These two HRPWM registers are concatenated with the 16-bit TBPHS and CMPA registers used to control PWM operation.

- TBPHSHR - Time Base Phase High Resolution Register
- CMPAHR - Counter Compare A High Resolution Register
HRPWM capabilities are controlled using the Channel A PWM signal path. Figure 4 shows how the HRPWM interfaces with the 8-bit extension registers.

2.2 Configuring the HRPWM

Once the ePWM has been configured to provide conventional PWM of a given frequency and polarity, the HRPWM is configured by programming the HRCNFG register located at offset address 20h. This register provides configuration options for the following key operating modes:

**Edge Mode** — The MEP can be programmed to provide precise position control on the rising edge (RE), falling edge (FE) or both edges (BE) at the same time. FE and RE are used for power topologies requiring duty cycle control, while BE is used for topologies requiring phase shifting, e.g., phase shifted full bridge.

**Control Mode** — The MEP is programmed to be controlled either from the CMPAHR register (duty cycle control) or the TBPHSHR register (phase control). RE or FE control mode should be used with CMPAHR register. BE control mode should be used with TBPHSHR register.

**Shadow Mode** — This mode provides the same shadowing (double buffering) option as in regular PWM mode. This option is valid only when operating from the CMPAHR register and should be chosen to be the same as the regular load option for the CMPA register. If TBPHSHR is used, then this option has no effect.

2.3 Principle of Operation

The MEP logic is capable of placing an edge in one of 255 (8 bits) discrete time steps (see device-specific data sheet for typical MEP step size). The MEP works with the TBM and CCM registers to be certain that time steps are optimally applied and that edge placement accuracy is maintained over a wide range of PWM frequencies, system clock frequencies and other operating conditions. **Table 3** shows the typical range of operating frequencies supported by the HRPWM.

<table>

(1) System frequency = SYSCLKOUT, i.e., CPU clock. TBCLK = SYSCLKOUT.

(2) Table data based on a MEP time resolution of 180 ps (this is an example value, see the device-specific data sheet for MEP limits.

(3) MEP steps applied = TSYSCLKOUT/180 ps in this example.

(4) PWM minimum frequency is based on a maximum period value, i.e., TBPRD = 65535. PWM mode is asymmetrical up-count.

(5) Resolution in bits is given for the maximum PWM frequency stated.
2.3.1 Edge Positioning

In a typical power control loop (e.g., switch modes, digital motor control [DMC], uninterruptible power supply [UPS]), a digital controller (PID, 2pole/2zero, lag/lead, etc.) issues a duty command, usually expressed in a per unit or percentage terms. Assume that for a particular operating point, the demanded duty cycle is 0.405 or 40.5% on time and the required converter PWM frequency is 1.25 MHz. In conventional PWM generation with a system clock of 100 MHz, the duty cycle choices are in the vicinity of 40.5%. In Figure 5, a compare value of 32 counts (i.e., duty = 40% ) is the closest to 40.5% that you can attain. This is equivalent to an edge position of 320 ns instead of the desired 324 ns. This data is shown in Table 4.

By utilizing the MEP, you can achieve an edge position much closer to the desired point of 324 ns. Table 4 shows that in addition to the CMPA value, 22 steps of the MEP (CMPAHR register) will position the edge at 323.9 6 ns, resulting in almost zero error. In this example, it is assumed that the MEP has a step resolution of 180 ps.

(1) System clock, SYSCLKOUT and TBCLK = 100 MHz, 10 ns
(2) For a PWM Period register value of 80 counts, PWM Period = 80 x 10 ns = 800 ns, PWM frequency = 1/800 ns = 1.25 MHz
(3) Assumed MEP step size for the above example = 180 ps

See the device-specific data manual for typical and maximum MEP values.

2.3.2 Scaling Considerations

The mechanics of how to position an edge precisely in time has been demonstrated using the resources of the standard CMPA and MEP (CMPAHR) registers. In a practical application, however, it is necessary to seamlessly provide the CPU a mapping function from a per-unit (fractional) duty cycle to a final integer (non-fractional) representation that is written to the [CMPA:CMPAHR] register combination.

To do this, first examine the scaling or mapping steps involved. It is common in control software to express duty cycle in a per-unit or percentage basis. This has the advantage of performing all needed math calculations without concern for the final absolute duty cycle, expressed in clock counts or high time in ns. Furthermore, it makes the code more transportable across multiple converter types running different PWM frequencies.

To implement the mapping scheme, a two-step scaling procedure is required.
Assumptions for this example:

- System clock, SYSCLKOUT = 10 ns (100 MHz)
- PWM frequency = 1.25 MHz (1/800 ns)
- Required PWM duty cycle, PWMDuty = 0.405 (40.5%)
- PWM period in terms of coarse steps, PWMperiod (800 ns/10 ns) = 80
- Number of MEP steps per coarse step at 180 ps (10 ns/180 ps), MEP_ScaleFactor = 55
- Value to keep CMPAHR within the range of 1-255 and fractional rounding constant (default value) = 1.5 (0180h in Q8 format)

Step 1: Percentage Integer Duty value conversion for CMPA register

CMPA register value = \( \text{int}(\text{PWMDuty} \times \text{PWMperiod}) \); int means integer part
= \( \text{int}(0.405 \times 80) \)
= \( \text{int}(32.4) \)

CMPA register value = 32 (20h)

Step 2: Fractional value conversion for CMPAHR register

CMPAHR register value = \( (\text{frac}(\text{PWMDuty} \times \text{PWMperiod}) \times \text{MEP}_\text{ScaleFactor} + 1.5) \ll 8 \); frac means fractional part
= \( (\text{frac}(32.4) \times 55 + 1.5) \ll 8 \) Shift is to move the value as CMPAHR high byte
= \( (0.4 \times 55 + 1.5) \ll 8 \)
= \( (22 + 1.5) \ll 8 \)
= 23.5 \times 256; Shifting left by 8 is the same as multiplying by 256.
= 6016

CMPAHR value = 1780h CMPAHR value = 1700h, lower 8 bits will be ignored by hardware.
NOTE: The MEP scale factor (MEP_ScaleFactor) varies with the system clock and DSP operating conditions. TI provides an MEP scale factor optimizing (SFO) software C function, which uses the built in diagnostics in each HRPWM and returns the best scale factor for a given operating point.

The scale factor varies slowly over a limited range so the optimizing C function can be run very slowly in a background loop.

The CMPA and CMPAHR registers are configured in memory so that the 32-bit data capability of the 28x CPU can write this as a single concatenated value, i.e., [CMPA:CMPAHR].

The mapping scheme has been implemented in both C and assembly, as shown in Section 2.5. The actual implementation takes advantage of the 32-bit CPU architecture of the 28xx, and is somewhat different from the steps shown in Section 2.3.2.

For time critical control loops where every cycle counts, the assembly version is recommended. This is a cycle optimized function (11 SYSCLKOUT cycles) that takes a Q15 duty value as input and writes a single [CMPA:CMPAHR] value.

2.3.3 Duty Cycle Range Limitation

In high resolution mode, the MEP is not active for 100% of the PWM period. It becomes operational:

- 3 SYSCLK cycles after the period starts when diagnostics are disabled
- 6 SYSCLK cycles after the period starts when SFO diagnostics are running

Duty cycle range limitations are illustrated in Figure 6. This limitation imposes a lower duty cycle limit on the MEP. For example, precision edge control is not available all the way down to 0% duty cycle. Although for the first 3 or 6 cycles, the HRPWM capabilities are not available, regular PWM duty control is still fully operational down to 0% duty. In most applications this should not be an issue as the controller regulation point is usually not designed to be close to 0% duty cycle. To better understand the useable duty cycle range, see Table 5.

(1) System clock - \( T_{SYSCLKOUT} = 10\) ns
System clock = TBCLK = 100 MHz

If the application demands HRPWM operation in the low percent duty cycle region, then the HRPWM can be configured to operate in count-down mode with the rising edge position (REP) controlled by the MEP. This is illustrated in Figure 7. In this case, low percent duty limitation is no longer an issue. However, there will be a maximum duty limitation with same percent numbers as given in Table 5.
2.4 Scale Factor Optimizing Software (SFO)

The micro edge positioner (MEP) logic is capable of placing an edge in one of 255 discrete time steps. As previously mentioned, the size of these steps is on the order of 150 ps (see device-specific data sheet for typical MEP step size on your device). The MEP step size varies based on worst-case process parameters, operating temperature, and voltage. MEP step size increases with decreasing voltage and increasing temperature and decreases with increasing voltage and decreasing temperature. Applications that use the HRPWM feature should use the TI-supplied MEP scale factor optimizer (SFO) software function. The SFO function helps to dynamically determine the number of MEP steps per SYSCLKOUT period while the HRPWM is in operation.

To utilize the MEP capabilities effectively during the Q15 duty to [CMPA:CMPAHR] mapping function (see Section 2.3.2), the correct value for the MEP scaling factor (MEP_ScaleFactor) needs to be known by the software. To accomplish this, each HRPWM module has built in self-check and diagnostics capabilities that can be used to determine the optimum MEP_ScaleFactor value for any operating condition. TI provides a C-callable library containing two SFO functions that utilize this hardware and determines the optimum MEP_ScaleFactor. As such, MEP Control and Diagnostics registers are reserved for TI use.

2.5 HRPWM Examples Using Optimized Assembly Code

The best way to understand how to use the HRPWM capabilities is through two real examples:

1. Simple buck converter using asymmetrical PWM (i.e. count-up) with active high polarity.
2. DAC function using simple R+C reconstruction filter.

The following examples all have Initialization/configuration code written in C. To make these easier to understand, the #defines shown below are used. Note, #defines introduced in TMS320x2833x Enhanced Pulse Width Modulator (ePWM) Module Reference Guide (literature number SPRU791) are also used.

**Example 1** This example assumes MEP step size of 150 ps and does not use the SFO library.
Example 1. #Defines for HRPWM Header Files

```c
#include <stdint.h>

#define HR_PWM_MODULE 0x1
#define HR_PWM_MODE 0x2
#define HR_PWM_RESOLUTION 0x3
#define HR_PWM_MODE_UPCOUNT 0x4
#define HR_PWM_MODE_DOWNCOUNT 0x5
#define HR_PWM_TRIGGER 0x6
```

2.5.1 Implementing a Simple Buck Converter

In this example, the PWM requirements are:
- PWM frequency = 1 MHz (i.e., TBPRD = 100)
- PWM mode = asymmetrical, up-count
- Resolution = 12.7 bits (with a MEP step size of 150 ps)

Figure 8 and Figure 9 show the required PWM waveform. As explained previously, configuration for the ePWM1 module is almost identical to the normal case except that the appropriate MEP options need to be enabled/selected.

Figure 8. Simple Buck Controlled Converter Using a Single PWM

Figure 9. PWM Waveform Generated for Simple Buck Controlled Converter
The example code shown consists of two main parts:

- Initialization code (executed once)
- Run time code (typically executed within an ISR)

**Example 2** shows the Initialization code. The first part is configured for conventional PWM. The second part sets up the HRPWM resources.

This example assumes MEP step size of 150 ps and does not use the SFO library.

**Example 2. HRPWM Buck Converter Initialization Code**

```c
void HrBuckDrvCnf(void)
{
    // Config for conventional PWM first
    EPwm1Regs.TBCTL.bit.PRLDL = TB_IMMEDIATE; // set Immediate load
    EPwm1Regs.TBPRD = 100; // Period set for 1000 kHz PWM
    hrBuck_period = 200; // Used for Q15 to Q0 scaling
    EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;
    EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE; // EPWM1 is the Master
    EPwm1Regs.TBCTL.bit.SYNCOSEL = TB_SYNC_DISABLE;
    EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1;
    // Note: ChB is initialized here only for comparison purposes, it is not required
    EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO;
    EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
    EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO; // optional
    EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW; // optional
    EPwm1Regs.AQCTLA.bit.ZRO = AQ_SET;
    EPwm1Regs.AQCTLA.bit.CAU = AQ_CLEAR;
    EPwm1Regs.AQCTLB.bit.ZRO = AQ_SET; // optional
    EPwm1Regs.AQCTLB.bit.CBU = AQ_CLEAR; // optional
    // Now configure the HRPWM resources
    EALLOW; // Note these registers are protected
    EPwm1Regs.HRCNFG.all = 0x0; // clear all bits first
    EPwm1Regs.HRCNFG.bit.EDGMODE = HR_FEP; // Control Falling Edge Position
    EPwm1Regs.HRCNFG.bit.CTLMODE = HR_CMP; // CMPAHR controls the MEP
    EPwm1Regs.HRCNFG.bit.HRLOAD = HR_CTR_ZERO; // Shadow load on CTR=Zero
    EDIS;
    MEP_ScaleFactor = 66*256; // Start with typical Scale Factor
    // value for 100 MHz
    // Note: Use SFO functions to update
    // MEP_ScaleFactor dynamically
}
```

**Example 3** shows an assembly example of run-time code for the HRPWM buck converter.

**Example 3. HRPWM Buck Converter Run-Time Code**

```assembly
EPWM1_BASE .set 0x6800
CMPAHR1 .set EPWM1_BASE+0x8
;===============================================
HRBUCK_DRV; (can execute within an ISR or loop)
;===============================================
MOVW DP, #_HRBUCK_In
MOVL XAR2, @_HRBUCK_In ; Pointer to Input Q15 Duty (XAR2)
MOVL XAR3, #CMPAHR1 ; Pointer to HRPWM CMPA reg (XAR3)
; Output for EPWM1A (HRPWM)
MOV T,*XAR2 ; T <= Duty
21
```

**Operational Description of HRPWM**
Example 3. HRPWM Buck Converter Run-Time Code (continued)

```
MPYU ACC, T, @_hrbuck_period ; Q15 to Q0 scaling based on Period
MOV T, @_MEP_ScaleFactor ; MEP scale factor (from optimizer s/w)
MPYU P, T, @AL ; P <= T * AL, Optimizer scaling
MOVH @AL, P ; AL <= P, move result back to ACC
ADD ACC, #0x180 ; MEP range and rounding adjustment
MOVL *XAR3, ACC ; CMPA: CMPAHR(31:8) <= ACC
; Output for EPWM1B (Regular Res) Optional - for comparison purpose only
MOV *+XAR3[2], AH ; Store ACCH to regular CMPPB
```

2.5.2 Implementing a DAC function Using an R+C Reconstruction Filter

In this example, the PWM requirements are:

- PWM frequency = 400 kHz (i.e., TBPRD = 250)
- PWM mode = Asymmetrical, Up-count
- Resolution = 14 bits (MEP step size = 150 ps)

Figure 10 and Figure 11 show the DAC function and the required PWM waveform. As explained previously, configuration for the ePWM1 module is almost identical to the normal case except that the appropriate MEP options need to be enabled/selected.

**Figure 10. Simple Reconstruction Filter for a PWM Based DAC**

**Figure 11. PWM Waveform Generated for the PWM DAC Function**

The example code shown consists of two main parts:
- Initialization code (executed once)
- Run time code (typically executed within an ISR)

This example assumes a typical MEP_ScaleFactor and does not use the SFO library.

Example 4 shows the Initialization code. The first part is configured for conventional PWM. The second part sets up the HRPWM resources.
Example 4. PWM DAC Function Initialization Code

```c
void HrPwmDacDrvCnf(void) {
  // Config for conventional PWM first
  EPwm1Regs.TBCTL.bit.PRDLD = TB_IMMEDIATE; // Set Immediate load
  EPwm1Regs.TBPRD = 250; // Period set for 400 kHz PWM
  hrDAC_period = 250; // Used for Q15 to Q0 scaling
  EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;
  EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE; // EPWM1 is the Master
  EPwm1Regs.TBCTL.bit.SYNCOSEL = TB_SYNC_DISABLE;
  EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1;
  EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
  // Note: ChB is initialized here only for comparison purposes, it is not required
  EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO;
  EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
  EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO; // optional
  EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW; // optional
  EPwm1Regs.AQCTLA.bit.ZRO = AQ_SET;
  EPwm1Regs.AQCTLA.bit.CAU = AQ_CLEAR;
  EPwm1Regs.AQCTLB.bit.ZRO = AQ_SET; // optional
  EPwm1Regs.AQCTLB.bit.CBU = AQ_CLEAR; // optional
  // Now configure the HRPWM resources
  EALLOW; // Note these registers are protected
  // and act only on ChA.
  EPwm1Regs.HRCNFG.all = 0x0; // Clear all bits first
  EPwm1Regs.HRCNFG.bit.EDGMODE = HR_FEP; // Control falling edge position
  EPwm1Regs.HRCNFG.bit.CTLMODE = HR_CMP; // CMPAHR controls the MEP.
  EPwm1Regs.HRCNFG.bit.HRLOAD = HR_CTR_ZERO; // Shadow load on CTR=Zero.
  EDIS;
  MEP_ScaleFactor = 66*256; // Start with typical Scale Factor
  // value for 100 MHz.
  // Use SFO functions to update
  // MEP_ScaleFactor dynamically
}
```

Example 5 shows an assembly example of run-time code that can execute in a high-speed ISR loop.
Example 5. PWM DAC Function Run-Time Code

```assembly
EPWM1_BASE .set 0x6800
CMPAHR1 .set EPWM1_BASE+0x8

;=====================================================================
HRPWM_DAC_DRV; (can execute within an ISR or loop)
;=====================================================================

MOVW DP, #_HRDAC_In
MOVL XAR2, @_HRDAC_In  ; Pointer to input Q15 duty (XAR2)
MOVL XAR3, #CMPAHR1    ; Pointer to HRPWM CMPA reg (XAR3)

; Output for EPWM1A (HRPWM)
MOV T, XAR2             ; T <= duty
MPY ACC, T, @hrDAC_period ; Q15 to Q0 scaling based on period
ADD ACC, @hrDAC_period<<15 ; Offset for bipolar operation
MOV T, @MEP_ScaleFactor ; MEP scale factor (from optimizer s/w)
MPYU P, T, @AL          ; P <= T * AL, optimizer scaling
MOVL *XAR3, ACC         ; MEP range and rounding adjustment

; Output for EPWM1B (Regular Res) Optional - for comparison purpose only
MOV **XAR3[2], AH      ; Store ACCH to regular CMPB
```

In SFO_TI_Build_V5.lib/SFO_TI_Build_V5B.lib, the diagnostic software has been optimized to use less memory, to minimize the calibration time, and to support up to 16 HRPWM channels. Table 11 provides functional description of the two SFO library routines in SFO_TI_Build_V5.lib/SFO_TI_Build_V5B.lib.

NOTE: For the F2833x floating point devices, when compiling application code for floating point (fpu32 mode), libraries utilized by the application code must also be compiled for floating point. The SFO_TI_Build_fpu.lib and SFO_TI_Build_V5_fpu.lib are available as the floating point compiled equivalents to the fixed point SFO_TI_Build.lib and SFO_TI_Build_V5.lib libraries. The SFO functions in the fpu-version libraries are C-code-compatible to their fixed-point equivalents.
### Table 11. SFO V5 Library Routines

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int SFO_MepDis_V5(n)</td>
<td>Scale Factor Optimizer V5 with MEP Disabled</td>
</tr>
</tbody>
</table>

This routine is very similar to the SFO_MepDis() routine in the original SFO library, but with one change. It now returns a 1 when MEP-disabled calibration is complete, or a 0 while calibration is still running.

This function runs faster than the SFO_V5() routine and cannot be used on an ePWM channel while HRPWM capabilities are enabled for that channel. If there is a spare ePWM channel available in the system, SFO_MepDis_V5() can be run for that channel, and the resulting MEP_ScaleFactor[n] value can be copied into the MEP_ScaleFactor[n] for all other channels.

If SYSCLKOUT = TBCLK = 100 MHz and assuming the MEP step size is 150 ps:

- Typical value at 100 MHz = 66 MEP steps per unit TBCLK (10 ns)

The function returns a value in the variable array:

MEP_ScaleFactor[n] Number of MEP steps/SYSCLKOUT

If TBCLK is not equal to SYSCLKOUT, then the returned value must be adjusted to reflect the correct TBCLK:

MEP steps per TBCLKK = MEP_ScaleFactor[n] * (SYSCLKOUT/TBCLK)

Example: If TBCLK = SYSCLKOUT/2,

MEP steps per TBCLK = MEP_ScaleFactor[n] * (100/50) = 66 * 2 = 132

**Constraints when using this function:**
- SFO_MepDis_V5(n) can be used with SYSCLKOUT from 50 MHz to 100 MHz (or maximum SYSCLK frequency). MEP diagnostics logic uses SYSCLKOUT and not TBCLK. Hence, the SYSCLKOUT restriction is an important constraint.
- If TBCLK does not equal SYSCLKOUT, the TBCLK frequency must be great enough so that MEP steps per TBCLK do not exceed 255. This is due to the restriction that there can be no more than 255 MEP steps in a coarse step. For this reason, it is highly recommended that TBCLK=SYSCLKOUT.
- This function cannot be run on an ePWM channel with HRPWM capabilities enabled. Running the SFO_MepDis_V5 function continuously in an application will generate an inaccurate waveform on the HRPWM channel output pin.

**Usage:**
- If one of the ePWM modules is running in normal ePWM mode, then it can be used to run the SFO diagnostics function. Here, the single MEP_ScaleFactor value obtained for that channel can be copied and used as the MEP_ScaleFactor for the other ePWM modules which are running HRPWM modules. MEP steps are similar but may not be identical.
- This routine returns a 1 when calibration is finished on the specified channel or a 0 if calibration is still running.
- The ePWM module that is not active in HRPWM mode is still fully operational in conventional PWM mode and used to drive PWM pins. The SFO function only makes use of the MEP diagnostics logic in the HRPWM circuitry.
- SFO_MepDis_V5(n) function does not require a starting Scale Factor value.
- The other ePWM modules operating in HRPWM mode incur only a 3-cycle minimum duty cycle limitation.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int SFO_MepEn_V5(n)</td>
<td>Scale Factor Optimizer V5 with MEP Enabled</td>
</tr>
</tbody>
</table>

This function runs slower than the SFO_MepDis_V5() routine and runs SFO diagnostics on an ePWM channel with HRPWM capabilities enabled for that channel.

If SYSCLK = TBCLK = 100 MHz, and assuming MEP step size is 150 ps:

- Typical value at 100 MHz = 66 MEP steps per unit TBCLK (10 ns)

The function returns a value in the variable array:

MEP_ScaleFactor(n) = Number of MEP steps/SYSCLKOUT

= Number of MEP steps/TBCLK
Table 11. SFO V5 Library Routines (continued)

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Constraints when using this function:</td>
<td></td>
</tr>
<tr>
<td>• This routine must be run on one channel at a time and cannot be run on multiple channels concurrently. When it has finished updating the MEP_ScaleFactor for a channel, it will return a 1. If it is still calibrating, it will return a 0. A background loop should exist in the ISR code which calls SFO_MepEn_V5(n) repeatedly until it returns a 1. Then the function can be called for the next channel. (1)</td>
<td></td>
</tr>
</tbody>
</table>

**NOTE:** Unlike the original SFO_MepEn(n) routine, this routine cannot run on multiple channels concurrently. Do not call SFO_MepEn_V5(n) for another channel until the function returns a 1 for the current channel. Otherwise, the MEP_ScaleFactor for both channels will become corrupted.

**NOTE:** SFO_MepEn_V5(n) in SFO_TI_Build_V5.lib supports only the following HRPWM configuration:
• HRCNFG[HRLOAD] = 0 (load on CTR = ZERO)
• HRCNFG[EDGMODE] = 10 (falling edge MEP control)
An upgraded version of SFO_MepEn_V5(n) in SFO_TI_Build_V5B.lib supports all available HRPWM configurations. When using this version, the HRCNFG register must be initialized with the appropriate configuration after calling SFO_MepDis_V5(n) to seed the MEP_ScaleFactor[n] and prior to calling SFO_MepEn_V5(n).

• The SFO_MepEn_V5(n) function requires a SYSCLKOUT between 60 MHz and maximum SYSCLK frequency only. MEP diagnostics logic uses SYSCLKOUT and not TBCLK. Hence the SYSCLKOUT restriction is an important constraint. It is highly recommended that TBCLK = SYSCLKOUT.

**Usage:**
• After calling SFO_MepDis(n) to seed MEP_ScaleFactor[n], and prior to using the SFO_MepEn(n) function in SFO_TI_Build_V5B.lib, the HRCNFG register must be initialized with the desired HRPWM configuration. Otherwise, calibration will not be initiated, and calls to SFO_MepEn_V5(n) will continuously return 0.
• The SFO_MepEn_V5(n) function requires a starting scale factor value, MEP_ScaleFactor[0]. MEP_ScaleFactor[0] needs to be initialized to a typical MEP step size value. To do this, SFO_MepDis_V5(n) can be run on an ePWM channel while the HRPWM is disabled, and the resulting MEP_ScaleFactor[n] value can be copied into MEP_ScaleFactor[0].
• If there are drastic environmental changes to your system (i.e. temperature/voltage), it is generally a good idea to re-seed MEP_ScaleFactor[0] with a new typical MEP step size value for the changed conditions.
• Because SFO_MepEn_V5(n) can be run on only one channel at a time, it is only recommended for systems where there are no spare HRPWM channels available, so SFO calibration must be performed on all channels with HRPWM capabilities enabled. In this case, a 6-cycle MEP inactivity zone exists at the start of each PWM period on all HRPWM channels. See Section 2.3.3 on duty cycle range limitations.
• The function returns:
  • A one when it has finished SFO calibration for the current channel
  • A zero when SFO diagnostics are still running for the channel
  • A two as an error indicator after calibration has completed if the resulting MEP_ScaleFactor for the channel differs from the original MEP_ScaleFactor[0] seed value by more than +/-15

The function must be called repetitively before it will return a 1. This function takes a longer time to complete than the SFO_MepDis_V5(n) calibration.

---

(1) If SFO calibration must be run on multiple channels at a time while HRPWM capabilities are enabled, the previous version of the SFO library, SFO_TI_Build.lib, which uses more memory resources, can be used instead, and SFO_MepEn(n) can run concurrently for up to 4 ePWM channels with HRPWM enabled.
Table 11. SFO V5 Library Routines (continued)

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>If it returns a 2, the MEP_ScaleFactor for the channel has finished updating and is outside the typical drift range of MEP_ScaleFactor[0] +/- 15 even with large temperature and voltage variations. If the reason for large difference between the seed and the channel scale factor is known and acceptable, the user may choose to ignore the return value of 2, and treat it as a return value of 1, indicating that calibration is complete. Otherwise, if the large difference is unexpected, there are steps to take to remedy the error: 1. Check your code to ensure SFO_MepEn_V5(n) is not being called on more than one channel at a time. 2. If the above is not effective, run SFO_MepDis_V5(n) again and re-seed Mep_ScaleFactor[0]. 3. If neither of the above 2 steps work, there may be a system problem. The application firmware should perform shutdown or an appropriate recovery procedure. • If all ePWM modules are using the same TBCLK prescalers, it is possible to run the SFO_MepEn_V5(n) function for only one ePWM module and to use the MEP_ScaleFactor value for that module for the other modules also. In this case only one ePWM module incurs the 6-cycle duty limitation, and the remaining modules incur only a 3-cycle minimum duty limitation. This assumes that all HRPWM modules' MEP steps are similar but may not be identical.</td>
</tr>
</tbody>
</table>

A.2 Software Usage

Software library functions int SFO_MepEn_V5(int n) and int SFO_MepDis_V5(int n) calculate the MEP scale factor for ePWMn Modules, where n = the ePWM channel number. The scale factor value, which represents the number of micro-steps available in a system clock period, is returned in a global array of integer values called MEP_ScaleFactor[x], where x is the maximum number of HRPWM channels for a device plus one. For example, if the maximum number of HRPWM channels for a device is 16, the scale factor array would be MEP_ScaleFactor[17]. Both SFO_MepEn_V5 and SFO_MepDis_V5 themselves also return a 1 when calibration has completed, indicating the MEP_ScaleFactor has been successfully updated for the channel, and a 0 when calibration is still on-going. A return of 2 represents an out-of-range error.

</tbody>
</table>

To use the HRPWM feature of the ePWMs, it is recommended that the SFO functions in TI_Build_V5.lib be used as described here. The examples below are specific to the TMS320F28044 device, which includes a maximum of 16 HRPWM channels. For different devices which may have fewer HRPWM channels, modifications will be required in Step 1 and Step 2 below.
**Step 1. Add "Include" Files**

The SFO_V5.h file needs to be included as follows. This include file is mandatory when using the SFO V5 library functions. For the TMS320F28044 device, the C2804x C/C++ Header Files and Peripheral Examples (literature number SPRC324) DSP2804x_Device.h and DSP2804x_PWM_defines.h files are necessary as will, as they are used by all TI software examples for the device. These file names will change in accordance with your specific device. These include files are optional if customized header files are used in the end application. See example below.

**Example 1. A Sample of How to Add "Include" Files**

```c
#include "DSP2804x_Device.h" //DSP2804x Headerfile
#include "DSP2804x_EPWM_defines.h" //init defines
#include "SFO_V5.h" //SFO V5 lib functions (needed for HRPWM)
```

**Step 2. Define Number of HRPWM Channels Used**

In the SFO_V5.h file, the maximum number of HRPWM's used for a particular device must be defines. PWM_CH must equal the number of HRPWM channels plus one. For instance, for the TMS320F28044 where there are 16 possible HRPWM channels, PWM_CH can be set to 17. For the TMS320F2809, where there are 6 possible HRPWM channels, PWM_CH can be set to 7. See example below.

To save static variable memory, fewer than the maximum number of HRPWM channels may be defined with some caution. To do this, PWM_CH can be set to the largest ePWM channel number plus one. For instance, if only ePWM1A and ePWM2A channels are required as HRPWM channels, PWM_CH can be set to 3. However, if only ePWM15A and ePWM16A channels are required as HRPWM channels, PWM_CH must still be set to 17.

**Example 2. Defining Number of HRPWM Channels Used (Plus One)**

```c
//SFO_V5.H
//NOTE: THIS IS A VERY IMPORTANT STEP> PWM_CH MUST BE DEFINED FIRST BEFORE
//BUILDING CODE #define PWM_CH 17
//F28044 has a maximum of 16 HRPWM channels (17=16+1)
//For a device with maximum of 6 HRPWM channels, PWM_CH = 7
//For a device with maximum of 4 HRPWM channels, PWM_CH = 5
//For a device with maximum of 3 HRPWM channels, PWM_CH = 4
```

**Step 3. Element Declaration**

Declare an array of integer variables with a length equal to PWM_CH, and an array of pointers to EPWM register structures. The array of pointers will include pointers for up to 16 EPWM register structures plus one dummy pointer in location EPWM[0] for a device with 16 EPWM channels. Likewise, it will include pointers for up to 3 EPWM register structures plus one for a device with 3 EPWM registers.

**Example 3. Declaring Elements Required by SFO_TI_Build_V5.lib**

```c
int MEP_ScaleFactor[PWM_Ch] = {0,0,0,0,0, //Scale factor values for ePWM 1-16
0,0,0,0, //and MEP_ScaleFactor[0]
0,0,0,0, //For Fewer HRPWM channels, these
0,0,0,0}; //will be fewer zeros initialized

//Declare a volatile array of pointers to EPWM register structures.
//Only point to registers that exist. If a device has only 6 EPWMs (PWM_CH is 7),
//the array will include pointers for up to 6 EPWM register structures plus one
//dummy pointer in the EPWM[0] location.
volatile struct EPWM_REGS *ePWM[PWM_CH] = {0, &EPwm1Regs, &EPwm2Regs,
```
Step 4. MEP_ScaleFactor

After power up, the SFO_MepEn_V5(n) function needs a typical scale factor starting seed value in MEP_ScaleFactor[0]. This value can be conveniently determined using one of the ePWM modules to run the SFO_MepDis_V5(n) function prior to initializing the PWM settings for the application. The SFO_MepDis_V5(n) function does not require a starting scale factor value.

As part of the one-time initialization code prior to using MEP_ScaleFactor, include the following:

Example 4. Initializing With a Scale Factor Value

```c
//MEP_ScaleFactor varaibles initialized using function SFO_MepDis_V5
Uint16 i;
for(i=1; i<PWM_CH; i++) //for channels 1-16
{
    while (SFO_MepDis_V5(i) == 0); //Calls MepDis until MEP_ScaleFactor updated
}
//initialize MEP_ScaleFactor[0] with a typical MEP seed value

//required for SFO_MepEn_V5
MEP_ScaleFactor[0] = MEP_ScaleFactor[1];
```

Step 5. Application Code

While the application is running, fluctuations in both device temperature and supply voltage may be expected. To be sure that optimal scale factors are used for each ePWM modules, the SFO function should be re-run periodically as part of a slower background loop. Some examples of this are shown here in the below example.

Example 5. SFO Function Calls

```c
main()
{
    Uint16 current_ch = 1; //keeps track of current HRPWM channel being calibrated
    Uint16 status;
    //user code
    // Case 1: all ePWMs are running in HRPWM mode
    // here, the minimum duty cycle limitation is 6 clock cycles
    status = SFO_MepEn_V5(current_ch); // MepEn called here
    if(status == 1) // if MEP_ScaleFactor has been updated
    {
        current_ch++; // move on to the next channel
    }
    else if( status == 2) // if MEP_ScaleFactor differs from
    {
        error(); // MEP_ScaleFactor[0] seed by more than
            // +/-15, flag an error
    }
    if(current_ch == PWM_CH) // if last channel has been reached
    {
        current_ch=1; // go back to channel 1
    }
    // Case 2: All ePWMs except one are running in HRPWM mode.
    // One of the ePWM channels (ePWM16 in this example is used
    // for SFO_MepDis_V5 scale factor calibration.
    // Here, the minimum duty cycle limitation is 3 clock cycles.
    while( SFO_MepDis_V5(16) == 0); //wait until MEP_ScaleFactor[16] updates
    for(i=1; i<PWM_CH-1; i++) //update scale factors for ePWM 1-15
    {
        MEP_ScaleFactor[i] = MEP_ScaleFactor[16];
    }
}
```
NOTE: See the hrpwm_sfo_v5 example in your device-specific Header Files and Peripheral Examples software package available on the TI website.
Appendix B Revision History

This document was revised and lists only revisions made in this most recent version. The scope of the revisions was limited to technical changes as shown in Table 13.
