16	EMIF1_EN_ECC	EMIF1 ECC enable 0x0 = ECC is disabled 0x1 = ECC is enabled	RW	0x0
15:14	EMIF1_REG_PHY_NUM_OF_SAMPLES	Controls the number of DQ samples required for read leveling. The recommended setting for full leveling is 0x3 (128 samples). 0x0 = 4 samples 0x1 = 8 samples. 0x2 = 16 samples 0x3 = 128 samples	RW	0x0
13	EMIF1_REG_PHY_SEL_LOGIC	Selects an algorithm for read leveling. The use of algorithm 1 (set by default) is recommended. 0x0 = Algorithm 1 is used 0x1 = Algorithm 2 is used	RW	0x0

Bits	Field Name	Description	Type	Reset
12	EMIF1_REG_PHY_ALL_DQ_MPR_RD_RESP	Analysis method of DQ bits during read leveling. 0x0: if the DRAM provides a read response on only one DQ bit (this can be any bit, since in this mode all 8 DQ bits are OR-ed together). This is the default setting and works with all memory types (memories send responses on all DQ bits or on a single DQ bit). 0x1: if the DRAM provides a read response on all DQ bits.	RW	0x0
11:9	EMIF1_REG_PHY_OUTP_UT_STATUS_SELECT	Selects the status to be observed on the outputs of the DDR PHYs through <a href="#">CTRL_WKUP_EMIF1_SDRAM_CONFIG_EXT_1</a> register. 0x0 = selects phy_reg_rdlvl_start_ratio[7:0] 0x1 = selects phy_reg_rdlvl_start_ratio[15:8] 0x2 = selects phy_reg_rdlvl_end_ratio[7:0] 0x3 = selects phy_reg_rdlvl_end_ratio[15:8]	RW	0x0
8	RESERVED		R	0x1
7	EMIF1_SDRAM_DISABLE_RESET	DDR3 SDRAM reset disable. 0x0 = DDR3 SDRAM reset signal is enabled. It can be asserted by EMIF 0x1 = DDR3 SDRAM reset signal is disabled. It is forbidden to EMIF to assert it.	RW	0x0
6:5	EMIF1_PHY_RD_LOCAL_ODT	Control of ODT (on – die termination) settings for the device DDR I/Os. ODT is enabled only during read operations when termination is required. 0x0 = ODT disabled 0x1= 60 Ohms 0x2 = 80 Ohms 0x3 =120 Ohms	RW	0x0
4	RESERVED		RW	0x0
3	EMIF1_DFI_CLOCK_PHASE_CTRL	EMIF_FICLK clock phase control (shifting by 180°). For normal operation this bit must always be set to 0x0 (disabled).	RW	0x0
2	EMIF1_EN_SLICE_2	Enable command PHY 2. When using DDR3 this bit can be set to 0x0 or 0x1. For lower power consumption 0x0 is used.	RW	0x1
1	EMIF1_EN_SLICE_1	Enable command PHY 1. 0x1 is the mandatory setting if DDR3 is used. EMIF1_EN_SLICE_0 and EMIF1_EN_SLICE_1 have to be programmed with the same value.	RW	0x1
0	EMIF1_EN_SLICE_0	Enable command PHY 0. 0x1 is the mandatory setting if DDR3 is used. EMIF1_EN_SLICE_0 and EMIF1_EN_SLICE_1 have to be programmed with the same value.	RW	0x1

### 18.7.2.2 IODELAYCONFIG Register Description

**Table 18-1792. CONFIG\_REG\_0**

<b>Address Offset</b>	0x0000 000C	<b>Instance</b>	IODELAYCONFIG
<b>Physical Address</b>	<a href="#">0x4844 A00C</a>		
<b>Description</b>	Calibration Control Register		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																ROM_READ	CALIBRATION_START														

Bits	Field Name	Description	Type	Reset
31:2	RESERVED		R	0x0
1	ROM_READ	Triggers complete ROM read when '1' is written. Cleared when ROM read is complete.	RW	0x0
0	CALIBRATION_START	Triggers hardware calibration when '1' is written. Cleared when hardware completes calibration.	RW	0x0

<b>Address Offset</b>	0x0000 0014	<b>Instance</b>	IODELAYCONFIG
<b>Physical Address</b>	<a href="#">0x4844 A014</a>		
<b>Description</b>	Reference Clock Period Register.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																REFCLK_PERIOD															

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:0	REFCLK_PERIOD	15:0 stores the binary equivalent of reference clock period in units of 10ps. This value (along with calibration results) is used for computing the coarse/fine element delay Example: 0xF0 means 2400ps.	RW	0x21D2

<b>Description</b>	Global Lock Register.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																GLOBAL_LOCK_BIT															

Bits	Field Name	Description	Type	Reset
31:1	RESERVED		R	0x0
0	GLOBAL_LOCK_BIT	Global Lock Bit Register. A '1' in this bit protects the writes to MMRs that store delay line select values. A '0' in this bit indicates that MMRs that store delay line select values are writeable. To write a '0' to this bit, signature of 0x5555 must be used on the MSB bits 16:1 of mdata.	RW	0x1

## Mailbox

---

---

---

This chapter describes the mailbox module in the device.

Topic	Page
<b>19.1 Mailbox Overview</b> .....	<b>5634</b>
<b>19.2 Mailbox Integration</b> .....	<b>5635</b>
<b>19.3 Mailbox Functional Description</b> .....	<b>5642</b>
<b>19.4 Mailbox Programming Guide</b> .....	<b>5648</b>
<b>19.5 Mailbox Register Manual</b> .....	<b>5651</b>

## 19.1 Mailbox Overview

Communication between the on-chip processors of the device uses a queued mailbox-interrupt mechanism.

The queued mailbox-interrupt mechanism allows the software to establish a communication channel between two processors through a set of registers and associated interrupt signals by sending and receiving messages (mailboxes).

The device implements the following mailbox types:

- System mailbox:
  - Number of instances: 13
  - Used for communication between: MPU, DSP1, DSP2, IPU1, and IPU2 subsystems
  - Reference name: MAILBOX(1..13)
- IVA mailbox:
  - Number of instances: 1
  - Used for communication between: IVA local user (ICONT1, or ICONT2) and three external users (selected among MPU, DSP1, DSP2, IPU1, and IPU2 subsystems)
  - Reference name: IVA\_MBOX
- EVEx mailbox (where x = 1, 2):
  - Number of instances: 3 (per EVE)
  - Used for communication between:
    - EVEx local user (ARP32) and three external users (selected among MPU, DSP1, DSP2, IPU1, and IPU2) - EVEx\_MBOX0 and EVEx\_MBOX1 are dedicated for this communication
    - EVE1 and EVE2 local users - EVEx\_MBOX2 is dedicated for this communication
  - Reference name: EVEx\_MBOX(0..2)

Each mailbox module supports the following features:

- Parameters configurable at design time (see [Table 19-1](#)):
  - Number of users
  - Number of mailbox message queues
  - Number of messages (FIFO depth) for each message queue
- 32-bit message width
- Message reception and queue-not-full notification using interrupts
- Support of 16-/32-bit addressing scheme
- Power management support

[Table 19-1](#) shows the configuration of the mailbox modules in the device.

**Table 19-1. Mailbox Configuration in the Device**

Module Parameters	Mailbox Type			
	System Mailbox		IVA Mailbox	EVEx Mailbox (0..2)
	MAILBOX1	MAILBOX2..13		
Number of users	3	4	4	4
Number of mailbox message queues	8	12	6	16
Number of messages (FIFO depth) for each message queue	4		4	4

## 19.2 Mailbox Integration

This section describes the mailbox integration in the device, including information about clocks, resets, and hardware requests.

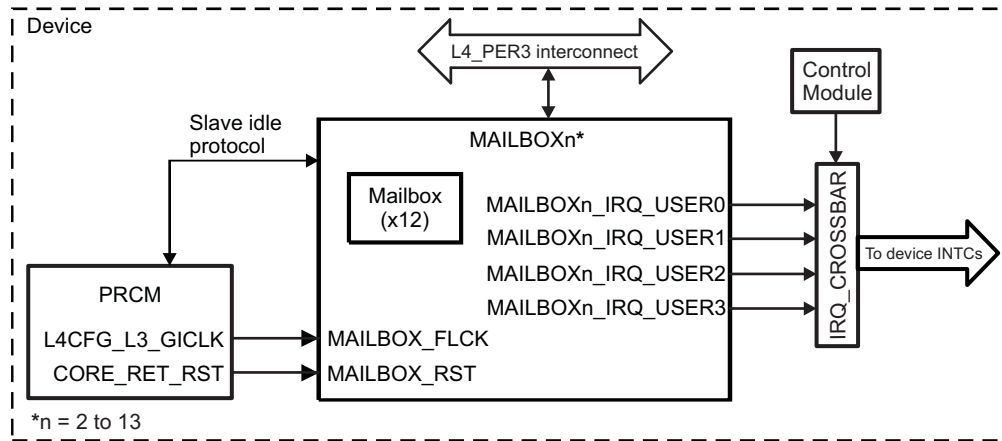

### 19.2.1 System MAILBOX Integration

The integration of MAILBOX1 in the device differs from the integration of the rest of the system mailboxes (MAILBOX2..13). [Figure 19-1](#) and [Figure 19-2](#) show the MAILBOX1 and MAILBOX2..13 integration, respectively.

**Figure 19-1. MAILBOX1 Integration**

**Figure 19-2. MAILBOX2..13 Integration**

**NOTE:** For more information about the Slave idle protocol, see [Section 3.1.1.1.2, Module-Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 19-2](#) through [Table 19-4](#) summarize the MAILBOX(1..13) integration in the device.

**Table 19-2. MAILBOX Integration Attributes**

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
MAILBOX1	PD_COREAON	N/A	L4_CFG
MAILBOX2..13	PD_COREAON	N/A	L4_PER3

**Table 19-3. MAILBOX Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
MAILBOX	MAILBOX_FCLK	L4CFG_L3_GICLK	PRCM	MAILBOX interface clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
MAILBOX	MAILBOX_RST	CORE_RET_RST	PRCM	MAILBOX hardware reset. This reset is asynchronously applied to the MAILBOX registers.

**Table 19-4. MAILBOX Hardware Requests**

Interrupt Requests							
Module Instance	Interrupt Name (Source)	IRQ_CROSSBAR Input (Destination)	Default Mapping	Description			
MAILBOX1	MAILBOX1_IRQ_USER0	IRQ_CROSSBAR_21	MPU_IRQ_26; DSP1_IRQ_52; DSP2_IRQ_52;	MAILBOX1 request.	user	0	interrupt
	MAILBOX1_IRQ_USER1	IRQ_CROSSBAR_135	–	MAILBOX1 request.	user	1	interrupt
	MAILBOX1_IRQ_USER2	IRQ_CROSSBAR_134	IPU1_IRQ_50; IPU2_IRQ_50;	MAILBOX1 request.	user	2	interrupt
MAILBOX2	MAILBOX2_IRQ_USER0	IRQ_CROSSBAR_237	–	MAILBOX2 request.	user	0	interrupt

MAILBOX13_IRQ_USER2	IRQ_CROSSBAR_381	–	MAILBOX13	user	2	interrupt request.
MAILBOX13_IRQ_USER3	IRQ_CROSSBAR_382	–	MAILBOX13	user	3	interrupt request.
<b>No DMA Requests</b>						

**NOTE:** The “Default Mapping” column in [Table 19-4](#), [Table 19-7](#), and [Table 19-10](#) shows the default mapping of module interrupts. These interrupts can also be mapped to other input lines of each device interrupt controller through the IRQ\_CROSSBAR module.

For more information about the IRQ\_CROSSBAR module, see [Chapter 18, Control Module](#).

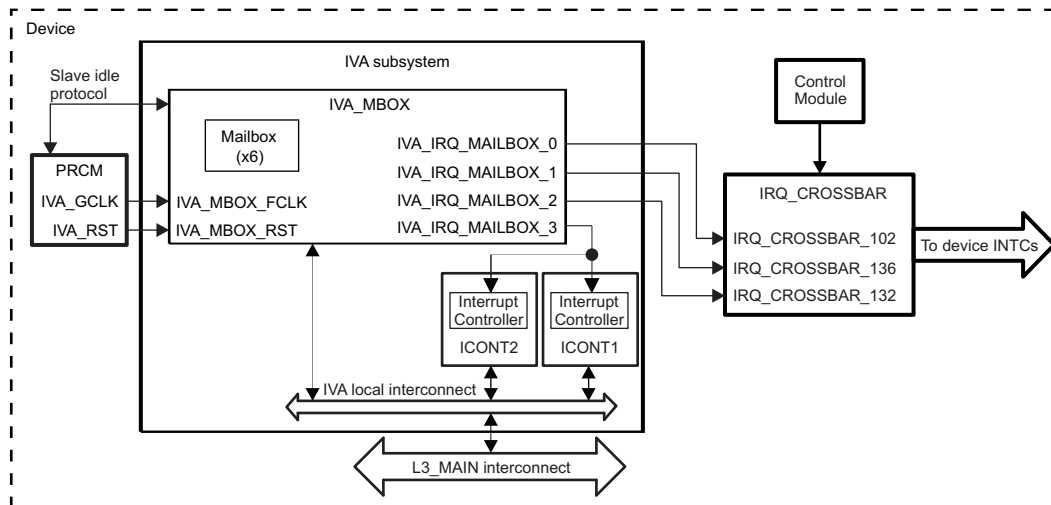

For more information about the device interrupt controllers, see [Chapter 17, Interrupt Controllers](#).

**NOTE:** For information about interrupt source description, see [Section 19.3.4, Mailbox Interrupt Requests](#).

### 19.2.2 IVA Mailbox Integration

[Figure 19-3](#) shows the IVA mailbox integration.

**Figure 19-3. IVA Mailbox Integration**

**NOTE:** The IVA\_IRQ\_MAILBOX\_3 interrupt is mapped on both ICONT1 and ICONT2 interrupt controllers. It is recommended that this interrupt is unmasked at only one interrupt controller at a time. For more information, see [IVA Imaging Controller](#).

[Table 19-5](#) through [Table 19-7](#) summarize the IVA\_MBOX integration in the device.

**Table 19-5. IVA\_MBOX Integration Attributes**

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect

**19.2.3 EVE Mailbox Integration**

Figure 19-4 and Figure 19-5 show the EVE1\_MBOX and EVE2\_MBOX integration, respectively.

**Figure 19-4. EVE1\_MBOX Integration**

**Figure 19-5. EVE2\_MBOX Integration**

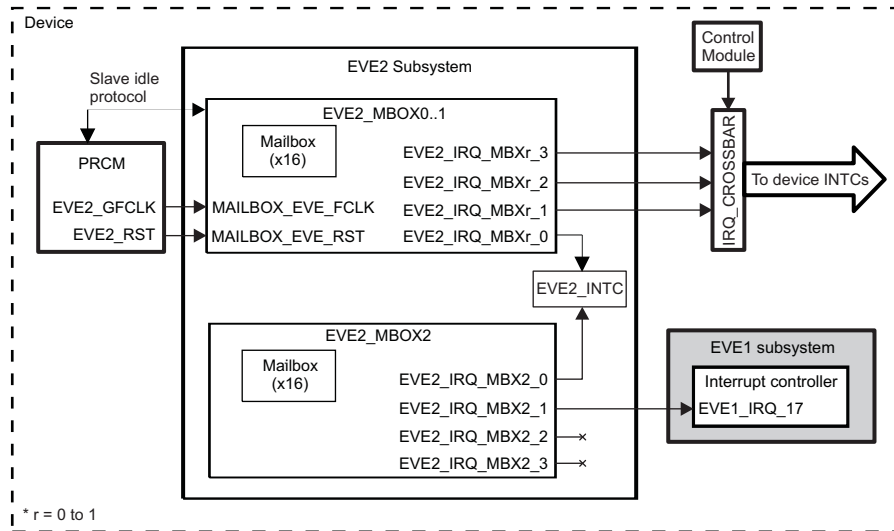

Table 19-8 through Table 19-10 summarize the EVE<sub>x</sub>\_MBOX(0..2) integration in the device.

**Table 19-8. EVE<sub>x</sub>\_MBOX Integration Attributes**

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
EVE1_MBOX	PD_EVE1	N/A	EVE1 local interconnect
EVE2_MBOX	PD_EVE2	N/A	EVE2 local interconnect

**Table 19-9. EVE<sub>x</sub>\_MBOX Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
EVE1_MBOX	MAILBOX_EVE_FCLK	EVE1_GCLK	PRCM	EVE1_MBOX interface clock. This clock is used for all interface and functional operations.
EVE2_MBOX	MAILBOX_EVE_FCLK	EVE2_GCLK	PRCM	EVE2_MBOX interface clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
EVE1_MBOX	MAILBOX_EVE_RST	EVE1_RST	PRCM	EVE1_MBOX hardware reset. This reset is asynchronously applied to the EVE1_MBOX registers.
EVE2_MBOX	MAILBOX_EVE_RST	EVE2_RST	PRCM	EVE2_MBOX hardware reset. This reset is asynchronously applied to the EVE2_MBOX registers.

**Table 19-10. EVE<sub>x</sub>\_MBOX Hardware Requests**

Interrupt Requests				
Module Instance	Interrupt Name (Source)	IRQ_CROSSBAR Input (Destination)	Default Mapping	Description
EVE1_MBOX0	EVE1_IRQ_MBX0_USER0	TBD	–	EVE1_MBOX0 user 0 interrupt request.
	EVE1_IRQ_MBX0_USER1	IRQ_CROSSBAR_284	–	EVE1_MBOX0 user 1 interrupt request.

**Table 19-10. EEx\_MBOX Hardware Requests (continued)**

	EVE1_IRQ_MBX0_USER2	IRQ_CROSSBAR_285	–	EVE1_MBOX0 user 2 interrupt request.
	EVE1_IRQ_MBX0_USER3	IRQ_CROSSBAR_286	–	EVE1_MBOX0 user 3 interrupt request.
EVE1_MBOX1	EVE1_IRQ_MBX1_USER0	TBD	–	EVE1_MBOX1 user 0 interrupt request.
	EVE1_IRQ_MBX1_USER1	IRQ_CROSSBAR_287	–	EVE1_MBOX1 user 1 interrupt request.
	EVE1_IRQ_MBX1_USER2	IRQ_CROSSBAR_288	–	EVE1_MBOX1 user 2 interrupt request.
	EVE1_IRQ_MBX1_USER3	IRQ_CROSSBAR_289	–	EVE1_MBOX1 user 3 interrupt request.
EVE1_MBOX2	EVE1_IRQ_MBX2_USER0	–	EVE1_IRQ_28	EVE1_MBOX2 user 0 interrupt request.
	EVE1_IRQ_MBX2_USER1	–	EVE2_IRQ_16	EVE1_MBOX2 user 1 interrupt request.
	EVE1_IRQ_MBX2_USER2	–	Not connected	EVE1_MBOX2 user 2 interrupt request.
	EVE1_IRQ_MBX2_USER3	–	Not connected	EVE1_MBOX2 user 3 interrupt request.
EVE2_MBOX0	EVE2_IRQ_MBX0_USER0	TBD	–	EVE2_MBOX0 user 0 interrupt request.
	EVE2_IRQ_MBX0_USER1	IRQ_CROSSBAR_293	–	EVE2_MBOX0 user 1 interrupt request.
	EVE2_IRQ_MBX0_USER2	IRQ_CROSSBAR_294	–	EVE2_MBOX0 user 2 interrupt request.
	EVE2_IRQ_MBX0_USER3	IRQ_CROSSBAR_295	–	EVE2_MBOX0 user 3 interrupt request.
EVE2_MBOX1	EVE2_IRQ_MBX1_USER0	TBD	–	EVE2_MBOX1 user 0 interrupt request.
	EVE2_IRQ_MBX1_USER1	IRQ_CROSSBAR_296	–	EVE2_MBOX1 user 1 interrupt request.
	EVE2_IRQ_MBX1_USER2	IRQ_CROSSBAR_297	–	EVE2_MBOX1 user 2 interrupt request.
	EVE2_IRQ_MBX1_USER3	IRQ_CROSSBAR_298	–	EVE2_MBOX1 user 3 interrupt request.
EVE2_MBOX2	EVE2_IRQ_MBX2_USER0	–	EVE2_IRQ_28	EVE2_MBOX2 user 0 interrupt request.
	EVE2_IRQ_MBX2_USER1	–	EVE1_IRQ_17	EVE2_MBOX2 user 1 interrupt request.
	EVE2_IRQ_MBX2_USER2	–	Not connected	EVE2_MBOX2 user 2 interrupt request.
	EVE2_IRQ_MBX2_USER3	–	Not connected	EVE2_MBOX2 user 3 interrupt request.
<b>No DMA Requests</b>				

## 19.3 Mailbox Functional Description

**NOTE:** The functionality of all mailbox instances in the device is the same and is described in this section.

**NOTE:** In this chapter,  $u$  is the user number and  $m$  is the mailbox number as follows:

- For MAILBOX1:  $u = 0$  to 2 and  $m = 0$  to 7;
- For MAILBOX2..13:  $u = 0$  to 3 and  $m = 0$  to 11;
- For IVA\_MBOX:  $u = 0$  to 3 and  $m = 0$  to 5;
- For EVE<sub>x</sub>\_MBOX:  $u = 0$  to 3 and  $m = 0$  to 15;

The mailbox module provides a means of communication through message queues among the users. The individual mailbox modules, or FIFOs, can associate (or de-associate) with any of the processors using the [MAILBOX\\_IRQENABLE\\_SET\\_u](#) (or [MAILBOX\\_IRQENABLE\\_CLR\\_u](#)) register.

Table 19-11 shows the potential users of the mailbox modules in the device.

**Table 19-11. Mailbox Users in the Device**

Mailbox Type		Users			
		User 0	User 1	User 2	User 3
System Mailbox	MAILBOX1	Any of: MPU, DSP1, DSP2, IPU1, IPU2			–
	MAILBOX2..13	Any of: MPU, DSP1, DSP2, IPU1, IPU2			
IVA Mailbox		Any of: MPU, DSP1, DSP2, IPU1, IPU2			IVA local - ICONT, or ICONT2
EVE <sub>x</sub> Mailbox	EVE <sub>x</sub> _MBOX0, EVE <sub>x</sub> _MBOX1	TBD	Any of: MPU, DSP1, DSP2, IPU1, IPU2		
	EVE <sub>x</sub> _MBOX2	EVE1_MBOX2	ARP32 of EVE1	ARP32 of EVE2	–
		EVE2_MBOX2	ARP32 of EVE2	ARP32 of EVE1	–

**NOTE:** It is software responsibility to select a user by mapping (via IRQ\_CROSSBAR) the corresponding mailbox interrupt to the interrupt controller of the appropriate processor subsystem.

Each user has a dedicated interrupt signal from the corresponding mailbox module instance and dedicated interrupt enabling and status registers.

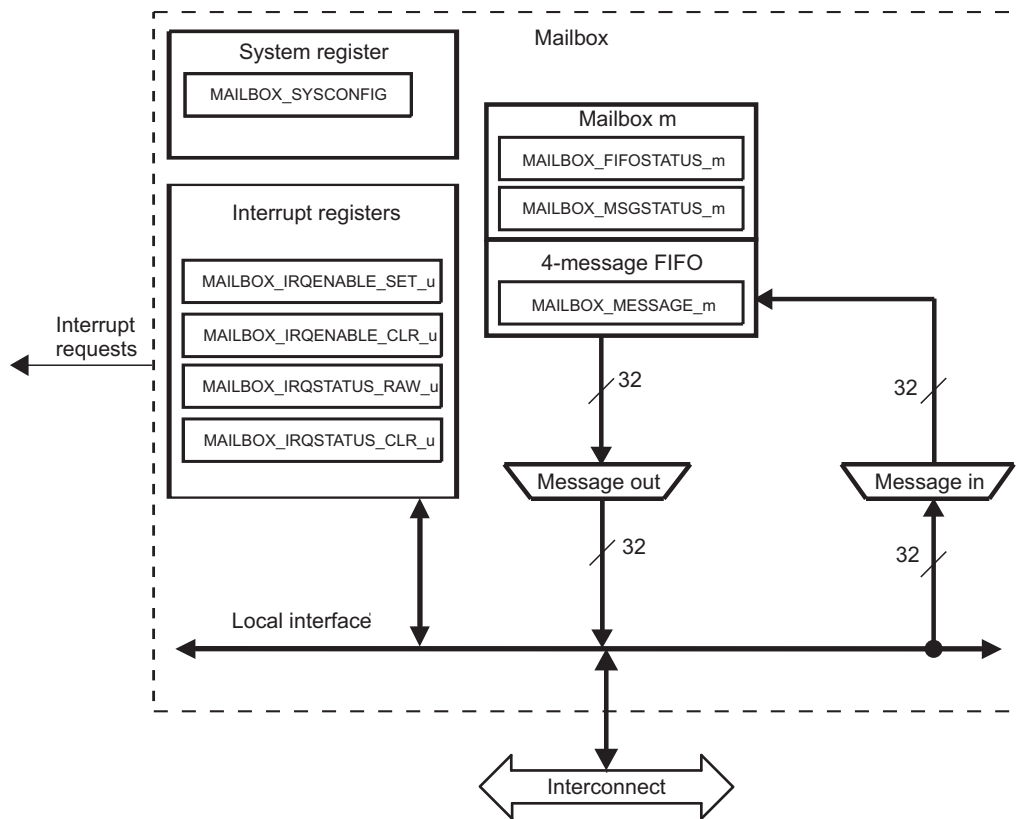

Each [MAILBOX\\_IRQSTATUS\\_RAW\\_u](#)/[MAILBOX\\_IRQSTATUS\\_CLR\\_u](#) interrupt status register corresponds to a particular user.

### 19.3.1 Mailbox Block Diagram

Figure 19-6 shows the mailbox block diagram.

Figure 19-6. Mailbox Block Diagram

### 19.3.2 Mailbox Software Reset

The mailbox module supports a software reset through the `MAILBOX_SYSCONFIG[0]` `SOFTRESET` bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Reading the `MAILBOX_SYSCONFIG[0]` `SOFTRESET` bit gives the status of the software reset:

- Read 1: the software reset is on-going.
- Read 0: the software reset is complete.

The software must ensure that the software reset completes before doing mailbox operations.

### 19.3.3 Mailbox Power Management

Table 19-12 describes power-management features available for the mailbox module.

Table 19-12. Local Power Management Features

Feature	Registers	Description
Clock autogating	N/A	Feature not available
Slave idle modes	<code>MAILBOX_SYSCONFIG[3:2]</code> <code>SIDLEMODE</code> bit field	Force-idle, no-idle and smart-idle modes are available
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	N/A	Feature not available

The mailbox module can be configured using the [MAILBOX\\_SYSCONFIG\[3:2\]](#) SIDLEMODE bit field to one of the following acknowledgment modes:

- Force-idle mode (SIDLEMODE = 0x0): The mailbox module immediately enters the idle state on receiving a low-power-mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state.
- No-idle mode (SIDLEMODE = 0x1): The mailbox module never enters the idle state.
- Smart-idle mode (SIDLEMODE = 0x2): After receiving a low-power-mode request from the PRCM module, the mailbox module enters the idle state only after all asserted output interrupts are acknowledged.

### 19.3.4 Mailbox Interrupt Requests

An interrupt request allows the user of the mailbox to be notified when a message is received or when the message queue is not full. There is one interrupt per user.

[Table 19-13](#) lists the event flags, and their mask, that can cause module interrupts.

**Table 19-13. Interrupt Events**

Non-Maskable Event Flag <sup>(1)</sup>	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
<a href="#">MAILBOX_IRQSTATUS_RAW_u[0+m*2]</a> NEWMSGSTATUSUUM Bm	<a href="#">MAILBOX_IRQSTATUS_CLR_u[0+m*2]</a> NEWMSGSTATUSUUM Bm	<a href="#">MAILBOX_IRQENABLE_CLR_u[0+m*2]</a> NEWMSGSTATUSUUM Bm	<a href="#">MAILBOX_IRQENABLE_SET_u[0+m*2]</a> NEWMSGSTATUSUUM Bm	Mailbox <i>m</i> receives a new message.
<a href="#">MAILBOX_IRQSTATUS_RAW_u[1+m*2]</a> NOTFULLSTATUSUUM Bm	<a href="#">MAILBOX_IRQSTATUS_CLR_u[1+m*2]</a> NOTFULLSTATUSUUM Bm	<a href="#">MAILBOX_IRQENABLE_CLR_u[1+m*2]</a> NOTFULLSTATUSUUM Bm	<a href="#">MAILBOX_IRQENABLE_SET_u[1+m*2]</a> NOTFULLSTATUSUUM Bm	Mailbox <i>m</i> message queue is not full.

<sup>(1)</sup> [MAILBOX\\_IRQSTATUS\\_RAW\\_u](#) register is mostly used for debug purposes.

#### CAUTION

Once an event generating the interrupt request has been processed by the software, it must be cleared by writing a logical 1 in the corresponding bit of the [MAILBOX\\_IRQSTATUS\\_CLR\\_u](#) register.

Writing a logical 1 in a bit of the [MAILBOX\\_IRQSTATUS\\_CLR\\_u](#) register will also clear to 0 the corresponding bit in the appropriate [MAILBOX\\_IRQSTATUS\\_RAW\\_u](#) register.

An event can generate an interrupt request when a logical 1 is written to the corresponding unmask bit in the [MAILBOX\\_IRQENABLE\\_SET\\_u](#) register. Events are reported in the appropriate [MAILBOX\\_IRQSTATUS\\_CLR\\_u](#) and [MAILBOX\\_IRQSTATUS\\_RAW\\_u](#) registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the [MAILBOX\\_IRQENABLE\\_CLR\\_u](#) register. Events are only reported in the appropriate [MAILBOX\\_IRQSTATUS\\_RAW\\_u](#) register.

In case of the [MAILBOX\\_IRQSTATUS\\_RAW\\_u](#) register, the event is reported in the corresponding bit even if the interrupt request generation is disabled for this event.

### 19.3.5 Mailbox Assignment

#### 19.3.5.1 Description

To assign a receiver to a mailbox, set the new message interrupt enable bit corresponding to the desired mailbox in the [MAILBOX\\_IRQENABLE\\_SET\\_u](#) register. The receiver reads the [MAILBOX\\_MESSAGE\\_m](#) register to retrieve a message from the mailbox.

An alternate method for the receiver that does not use the interrupts is to poll the [MAILBOX\\_FIFOSTATUS\\_m](#) and/or [MAILBOX\\_MSGSTATUS\\_m](#) registers to know when to send or retrieve a message to or from the mailbox. This method does not require assigning a receiver to a mailbox. Because this method does not include the explicit assignment of the mailbox, the software must avoid having multiple receivers use the same mailbox, which can result in incoherency.

To assign a sender to a mailbox, set the queue-not-full interrupt enable bit of the desired mailbox in the [MAILBOX\\_IRQENABLE\\_SET\\_u](#) register, where *u* is the number of the sending user. However, direct allocation of a mailbox to a sender is not recommended because it can cause the sending processor to be constantly interrupted.

It is recommended that register polling be used to:

- Check the status of either the [MAILBOX\\_FIFOSTATUS\\_m](#) or [MAILBOX\\_MSGSTATUS\\_m](#) registers
- Write the message to the corresponding [MAILBOX\\_MESSAGE\\_m](#) register, if space is available.

The sender might use the queue-not-full interrupt when the initial mailbox status check indicates the mailbox is full. In this case, the sender can enable the queue-not-full interrupt for its mailbox in the appropriate [MAILBOX\\_IRQENABLE\\_SET\\_u](#) register. This allows the sender to be notified by interrupt only when a FIFO queue has at least one available entry.

Reading the [MAILBOX\\_IRQSTATUS\\_CLR\\_u](#) register determines the status of the new message and the queue-not-full interrupts for a particular user. Writing 1 to the corresponding bit in the [MAILBOX\\_IRQSTATUS\\_CLR\\_u](#) register acknowledges, and subsequently clears, an interrupt.

#### **CAUTION**

Assigning multiple senders or multiple receivers to the same mailbox is not recommended.

### **19.3.6 Sending and Receiving Messages**

#### **19.3.6.1 Description**

When a 32-bit message is written to the [MAILBOX\\_MESSAGE\\_m](#) register, the message is appended into the FIFO queue. This queue holds four messages. If the queue is full, the message is discarded.

Queue overflow can be avoided by first reading the [MAILBOX\\_FIFOSTATUS\\_m](#) register to check that the mailbox message queue is not full before writing a new message to it.

Reading the [MAILBOX\\_MESSAGE\\_m](#) register returns the message at the beginning of the FIFO queue and removes it from the queue. If the FIFO queue is empty when the [MAILBOX\\_MESSAGE\\_m](#) register is read, the value 0 is returned.

The new message interrupt is asserted when at least one message is in the mailbox message FIFO queue. To determine the number of messages in the mailbox message FIFO queue, read the [MAILBOX\\_MSGSTATUS\\_m](#) register.

### **19.3.7 16-Bit Register Access**

#### **19.3.7.1 Description**

So that 16-bit processors can access the mailbox module, the module allows 16-bit register read and write access, with restrictions for the [MAILBOX\\_MESSAGE\\_m](#) registers. The 16-bit half-words are organized in little endian fashion; that is, the least-significant 16 bits are at the low address and the most-significant 16 bits are at the high address (low address + 0x02).

All mailbox module registers can be read or written to directly using individual 16-bit accesses with no restriction on interleaving, except the [MAILBOX\\_MESSAGE\\_m](#) registers, which must always be accessed by either single 32-bit accesses or two consecutive 16-bit accesses.

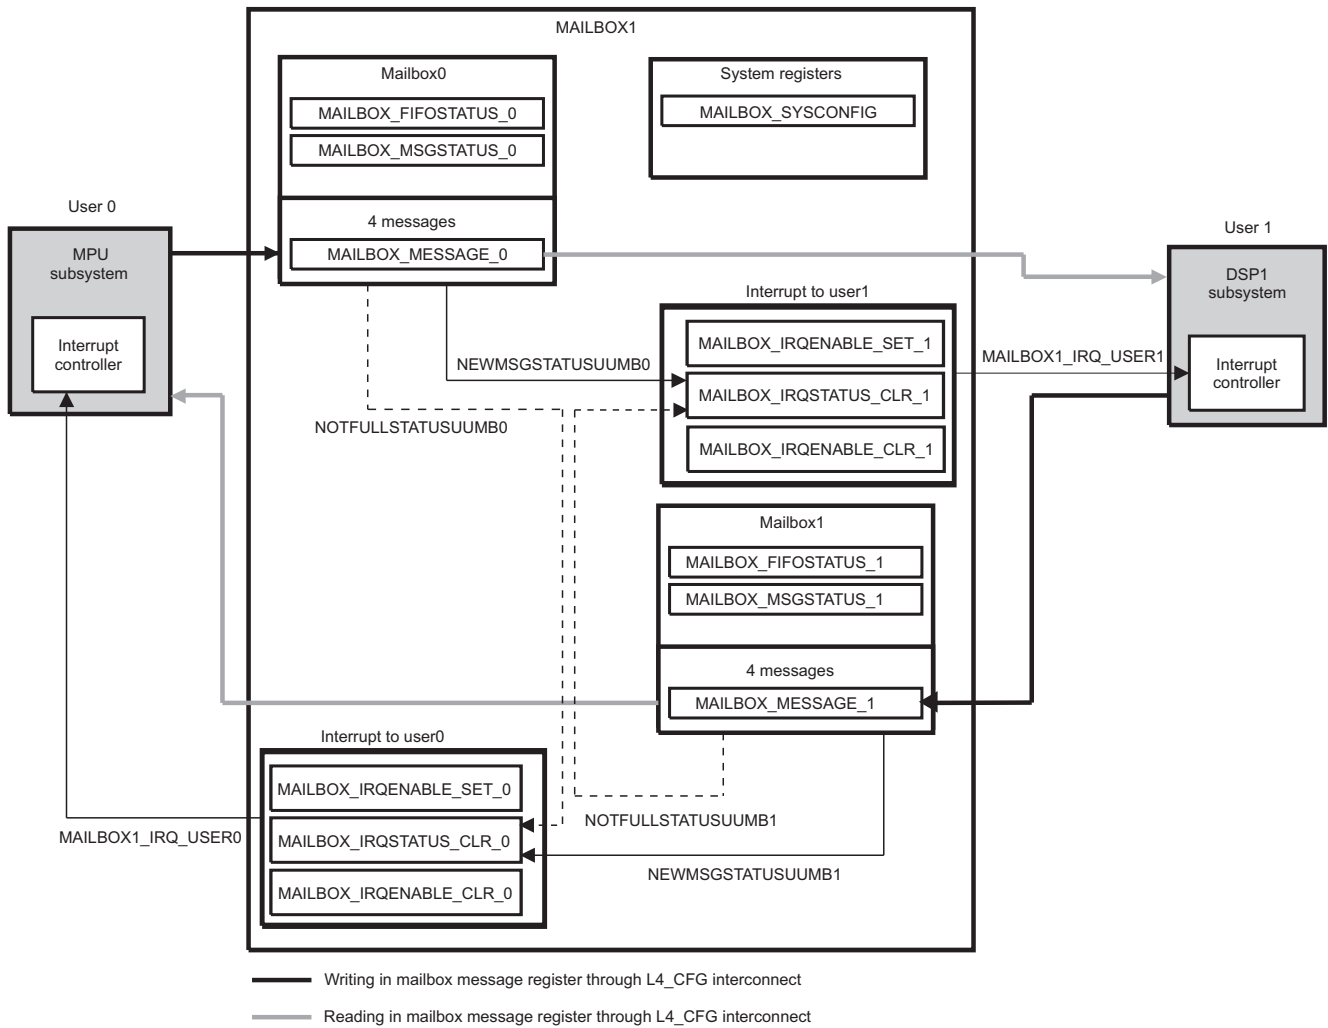

**CAUTION**

When using 16-bit accesses to the [MAILBOX\\_MESSAGE\\_m](#) registers, the order of access must be the least-significant half-word first (low address) and the most-significant half-word last (high address). This requirement is because of the update operation by the message FIFO of the [MAILBOX\\_MSGSTATUS\\_m](#) registers. The update of the FIFO queue contents and the associated status registers and possible interrupt generation occurs only when the most-significant 16 bits of a [MAILBOX\\_MESSAGE\\_m](#) are accessed.

### 19.3.8 Example of Communication

Figure 19-7 shows an example of communication between MPU and DSP1 subsystems.

Figure 19-7. Example of Communication

## 19.4 Mailbox Programming Guide

### 19.4.1 Mailbox Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the mailbox module.

#### 19.4.1.1 Global Initialization

##### 19.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the mailbox module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the mailbox.

See [Section 19.2, Mailbox Integration](#), for further information.

**Table 19-14. Global Initialization of Surrounding Modules for MAILBOX**

Surrounding Modules	Comments
PRCM	MAILBOX functional/interface clock must be enabled.
Interrupt Controllers	MPU, or IPU1, or IPU2, or DSP1, or DSP2 interrupt controller must be configured to enable the interrupt request generation to the corresponding subsystem.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see <a href="#">Section 18.4.6.4, IRQ_CROSSBAR Module Functional Description</a> , in <a href="#">Chapter 18, Control Module</a> .

**Table 19-15. Global Initialization of Surrounding Modules for IVA\_MBOX**

Surrounding Modules	Comments
PRCM	IVA_MBOX functional/interface clock must be enabled.
Interrupt Controllers	MPU, or IPU1, or IPU2, or DSP1, or DSP2, or IVA ICONT1/ICONT2 interrupt controller must be configured to enable the interrupt request generation to the corresponding subsystem.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see <a href="#">Section 18.4.6.4, IRQ_CROSSBAR Module Functional Description</a> , in <a href="#">Chapter 18, Control Module</a> .

**Table 19-16. Global Initialization of Surrounding Modules for EEx\_MBOX**

Surrounding Modules	Comments
PRCM	EEx_MBOX functional/interface clock must be enabled.
Interrupt Controllers	MPU, or IPU1, or IPU2, or DSP1, or DSP2, or EVE interrupt controller must be configured to enable the interrupt request generation to the corresponding subsystem.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see <a href="#">Section 18.4.6.4, IRQ_CROSSBAR Module Functional Description</a> , in <a href="#">Chapter 18, Control Module</a> .

##### 19.4.1.1.2 Mailbox Global Initialization

###### 19.4.1.1.2.1 Main Sequence - Mailbox Global Initialization

This procedure initializes the mailbox module after a power-on or software reset.

**Table 19-17. Mailbox Global Initialization**

Step	Register/ Bit Field / Programming Model	Value
Perform a software reset	<a href="#">MAILBOX_SYSCONFIG[0]</a> SOFTRESET	0x1
Wait until reset is complete	<a href="#">MAILBOX_SYSCONFIG[0]</a> SOFTRESET	= 0x0

**Table 19-17. Mailbox Global Initialization (continued)**

Step	Register/ Bit Field / Programming Model	Value
Set idle mode configuration	<a href="#">MAILBOX_SYSCONFIG</a> [3:2] SIDLEMODE	0x-

## 19.4.1.2 Mailbox Operational Modes Configuration

### 19.4.1.2.1 Mailbox Processing modes

#### 19.4.1.2.1.1 Main Sequence - Sending a Message (Polling Method)

**Table 19-18. Sending a Message (Polling Method)**

Step	Register/ Bit Field / Programming Model	Value
<b>IF</b> : Is FIFO full ?	<a href="#">MAILBOX_FIFOSTATUS_m</a> [0] FIFOFULLMB	= 0x1
Wait until at least one message slot is available	<a href="#">MAILBOX_FIFOSTATUS_m</a> [0] FIFOFULLMB	= 0x0
<b>ELSE</b>		
Write message	<a href="#">MAILBOX_MESSAGE_m</a> [31:0] MESSAGEVALUEMBM	0x----
<b>ENDIF</b>		

#### 19.4.1.2.1.2 Main Sequence - Sending a Message (Interrupt Method)

**Table 19-19. Sending a Message (Interrupt Method)**

Step	Register/ Bit Field / Programming Model	Value
<b>IF</b> : Is FIFO full ?	<a href="#">MAILBOX_FIFOSTATUS_m</a> [0] FIFOFULLMB	= 0x1
Enable interrupt event	<a href="#">MAILBOX_IRQENABLE_SET_u</a> [1+ m*2]	0x1
User (processor) can perform another task until interrupt occurs See <a href="#">Section 19.4.1.3.1</a> for interrupt handling in sending mode		
<b>ELSE</b>		
Write message	<a href="#">MAILBOX_MESSAGE_m</a> [31:0] MESSAGEVALUEMBM	0x----
<b>ENDIF</b>		

#### 19.4.1.2.1.3 Main Sequence - Receiving a Message (Polling Method)

**Table 19-20. Receiving a Message (Polling Method)**

Step	Register/ Bit Field / Programming Model	Value
<b>IF</b> : Number of messages is not equal to 0	<a href="#">MAILBOX_MSGSTATUS_m</a> [2:0] NBOFMSGMB	!= 0x0
Read message	<a href="#">MAILBOX_MESSAGE_m</a> [31:0] MESSAGEVALUEMBM	0x----
<b>ENDIF</b>		

### 19.4.1.2.1.4 Main Sequence - Receiving a Message (Interrupt Method)

**Table 19-21. Receiving a Message (Interrupt Method)**

Step	Register/ Bit Field / Programming Model	Value
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[0 + m*2]	0x1
User (processor) can perform another task until interrupt occurs See <a href="#">Section 19.4.1.3.2</a> for interrupt handling in receiving mode		

### 19.4.1.3 Mailbox Events Servicing

#### 19.4.1.3.1 Events Servicing in Sending Mode

[Table 19-22](#) describes the events servicing in sending mode.

**Table 19-22. Events Servicing in Sending Mode**

Step	Register/ Bit Field / Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	0x1
Write message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	0x1

#### 19.4.1.3.2 Events Servicing in Receiving Mode

[Table 19-23](#) describes the events servicing in receiving mode.

**Table 19-23. Events Servicing in Receiving Mode**

Step	Register/ Bit Field / Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	0x1
<b>IF</b> : Number of messages is not equal to 0 ?	MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB	!= 0x0
Read message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
<b>ELSE</b>		
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	0x1
<b>ENDIF</b>

## Memory Management Units

---

---

This chapter describes the memory management units (MMUs) in the device.

Topic	Page
20.1 MMU Overview.....	5678
20.2 MMU Integration .....	5681
20.3 MMU Functional Description .....	5683
20.4 MMU Low-level Programming Models.....	5695
20.5 MMU Register Manual.....	5699

## 20.1 MMU Overview

A memory management unit (MMU) is a hardware component responsible for handling accesses to memory requested by a processing unit, DMA controller, or other bus requestor. MMU functions include:

- Translation of initiator internal (virtual) addresses to physical addresses (that is, virtual memory management)
- Preventing an initiator from making accesses to unmapped pages of the system memory

This device includes the following MMUs:

- Two top-level (system) MMUs:
  - MMU1 dedicated to EDMA Transfer Controller 0 (TC0), and EDMA Transfer Controller 1 (TC1)
  - MMU2 dedicated to PCIe\_SS1, and PCIeSS2
- One MMU inside the MPU (dual Cortex®-A15) subsystem – MPU\_MMU. This MMU is integrated in the Cortex-A15 processor.
- Two MMUs inside each of the DSP1, and DSP2 subsystems:
  - DSP1 subsystem: DSP1\_MMU0, and DSP1\_MMU1
  - DSP2 subsystem: DSP2\_MMU0, and DSP2\_MMU1
- Two MMUs inside each of the EVE1, and EVE2 subsystems:
  - EVE1 subsystem: EVE1\_MMU0, and EVE1\_MMU1
  - EVE2 subsystem: EVE2\_MMU0, and EVE2\_MMU1
- Two MMUs inside each of the IPU1, and IPU2 subsystems:
  - L1 uncache MMU – IPU1\_UNICACHE\_MMU, and IPU2\_UNICACHE\_MMU
  - L2 MMU – IPU1\_MMU, and IPU2\_MMU
- One MMU inside the 3D GPU (dual SGX544 core) subsystem
- One MMU inside the BB2D subsystem

---

**NOTE:** There is a Physical Address Translator (PAT) module in the Dynamic Memory Manager (DMM), which has similar to the MMU functionality. For more information about this module, see [Section 15.2, Dynamic Memory Manager](#).

---

**NOTE:** This chapter provides a detailed description of the following MMUs:

- System MMUs
- DSP MMUs
- EVE MMUs
- IPU L2 MMU

System MMUs, DSP MMUs and EVE MMUs are fully identical from functional perspective. IPU L2 MMU is different in that it does not support “bypass” functionality.

For more information about:

- Cortex-A15 MMU, see the Arm® *Cortex®-A15 Technical Reference Manual* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).

- 

[Figure 20-1](#) and [Figure 20-2](#) show an overview of system MMU1 and MMU2, respectively. In summary, requests initiated by a given requestor (EDMA TC0 and TC1 [both read and write ports] for system MMU1; PCIe\_SS1 and PCIe\_SS2 for system MMU2) can optionally be routed through the corresponding system MMU. Each requestor’s use (or not) of the MMU is independently controllable via the Control Module CTRL\_CORE\_SMA\_SW\_7 register bitfields. It is recommended that this register is set during system initialization and remain static.

If the MMU loopback path is enabled for a given requestor, requests will be routed via the L3\_MAIN interconnect to the MMU and will again go through the L3 interconnect to the requested physical address. If the MMU loopback path is disabled for a given requestor, those bus requests go directly through the L3\_MAIN interconnect to the requested physical address, thus minimizing bus request latency.

Figure 20-1. System MMU1 Overview

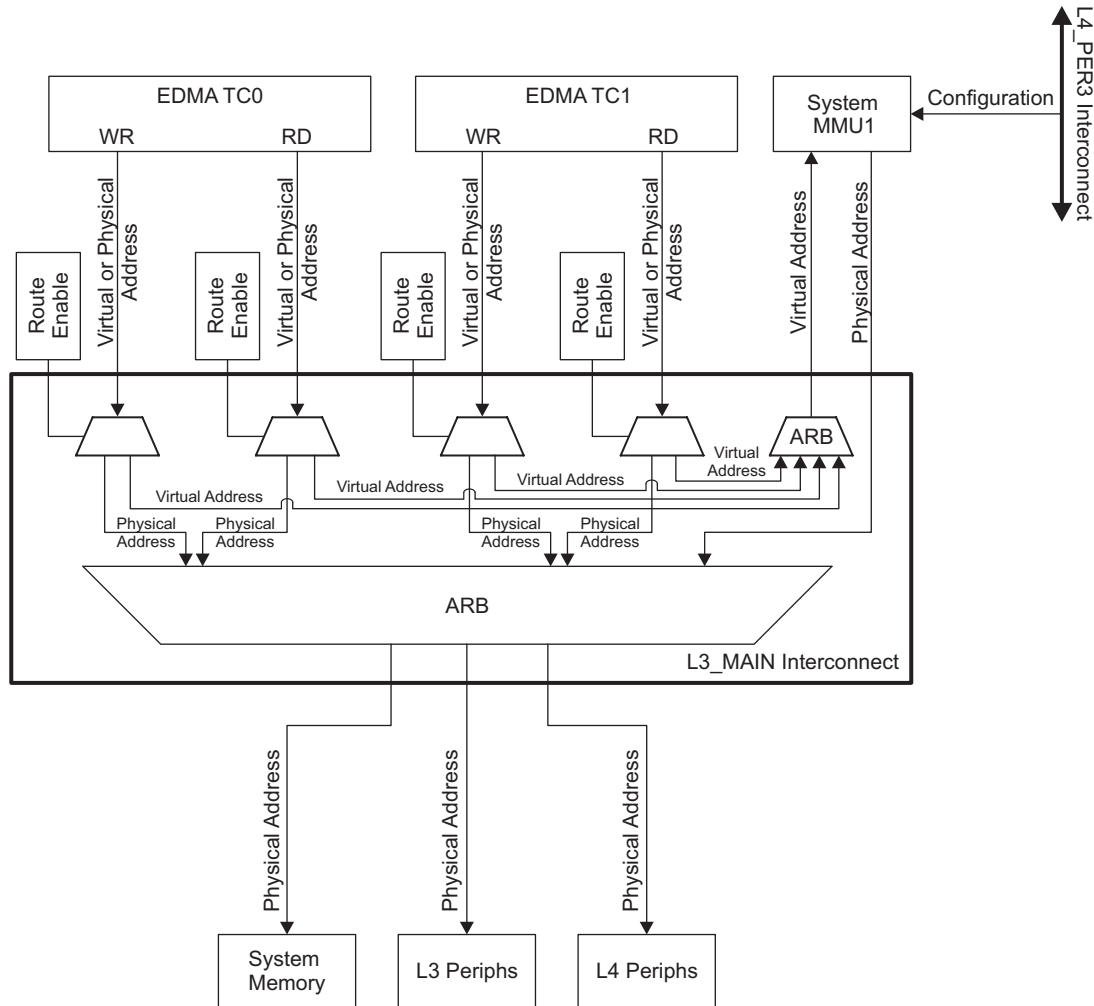

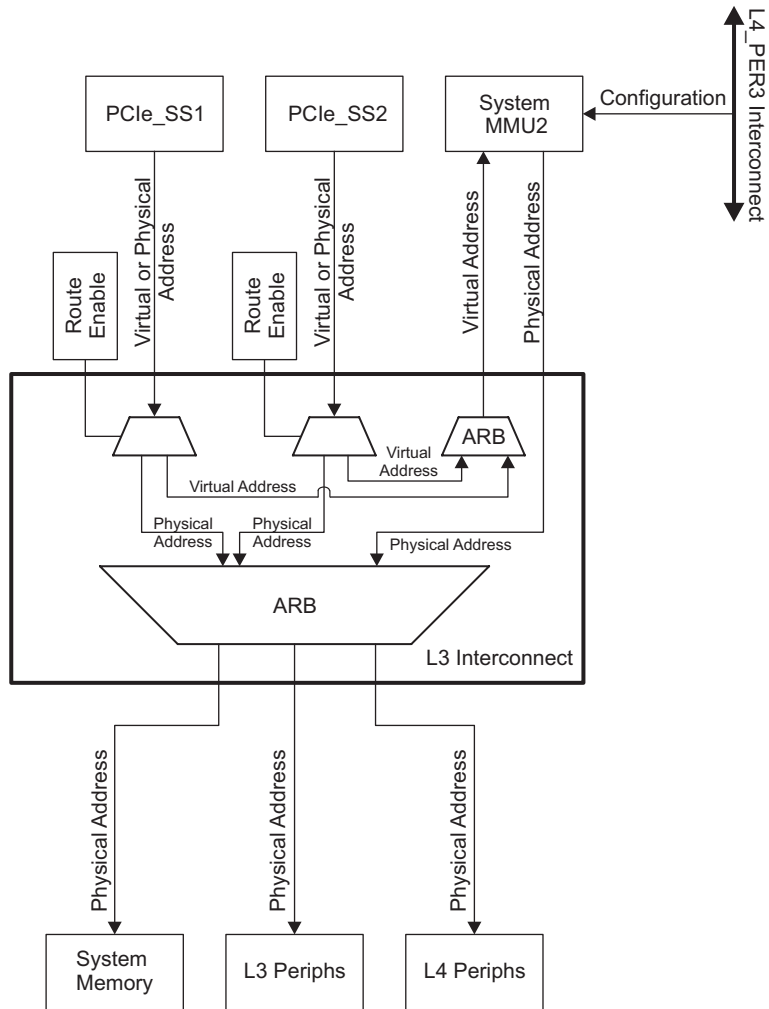

Figure 20-2. System MMU2 Overview

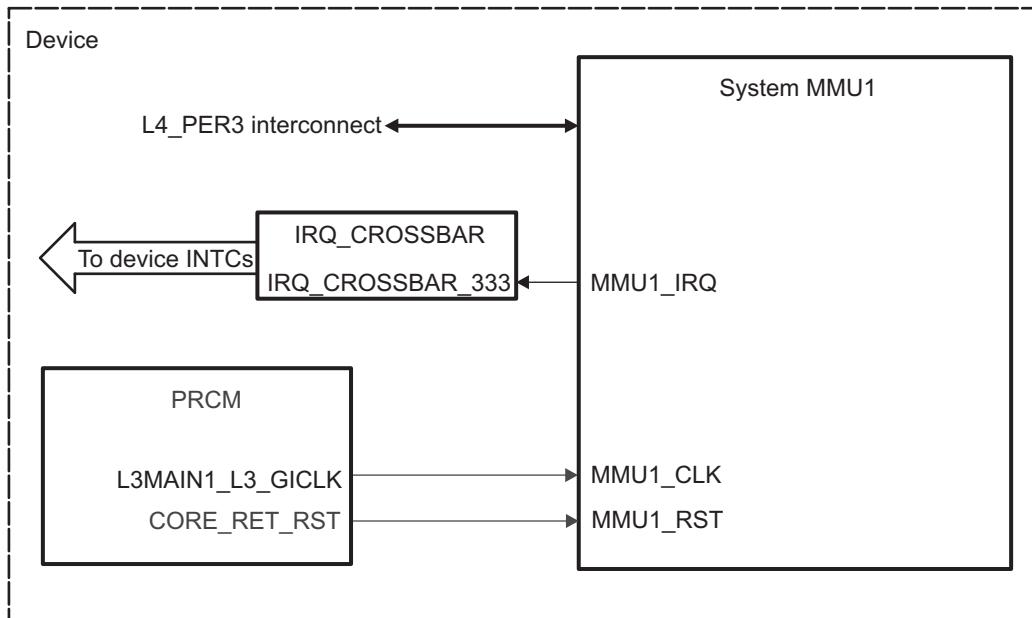

## 20.2 MMU Integration

This section describes the system MMUs integration in the device, including information about clocks, resets, and hardware requests. For more information about DSP, EVE, and IPU MMUs integration, refer to their respective chapters.

Figure 20-3 and Figure 20-4 show system MMU1, and MMU2 integration, respectively.

**Figure 20-3. System MMU1 Integration**

**Figure 20-4. System MMU2 Integration**

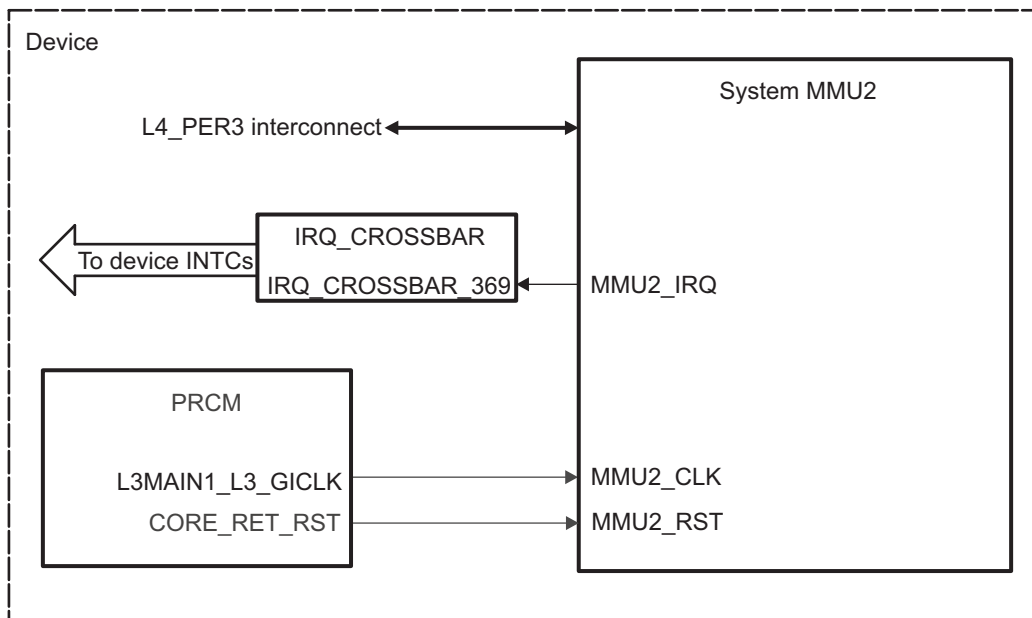

Table 20-1 through Table 20-3 summarize the system MMUs integration.

**Table 20-1. MMU Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect
System MMU1	PD_COREAON	L4_PER3
System MMU2	PD_COREAON	L4_PER3

**Table 20-2. MMU Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
System MMU1	MMU1_CLK	L3MAIN1_L3_GICLK	PRCM	System MMU1 interface/functional clock. This clock is used for all interface and functional operations.
System MMU2	MMU2_CLK	L3MAIN1_L3_GICLK	PRCM	System MMU2 interface/functional clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
System MMU1	MMU1_RST	CORE_RET_RST	PRCM	System MMU1 hardware reset. This reset is asynchronously applied to the MMU1 internal registers.
System MMU2	MMU2_RST	CORE_RET_RST	PRCM	System MMU2 hardware reset. This reset is asynchronously applied to the MMU2 internal registers.

**Table 20-3. MMU Hardware Requests**

Interrupt Requests				
Module Instance	Interrupt Name (Source)	IRQ_CROSSBAR Input (Destination)	Default Mapping	Description
System MMU1	MMU1_IRQ	IRQ_CROSSBAR_333	–	System MMU1 interrupt.
System MMU2	MMU2_IRQ	IRQ_CROSSBAR_369	–	System MMU2 interrupt.

**No DMA Requests**

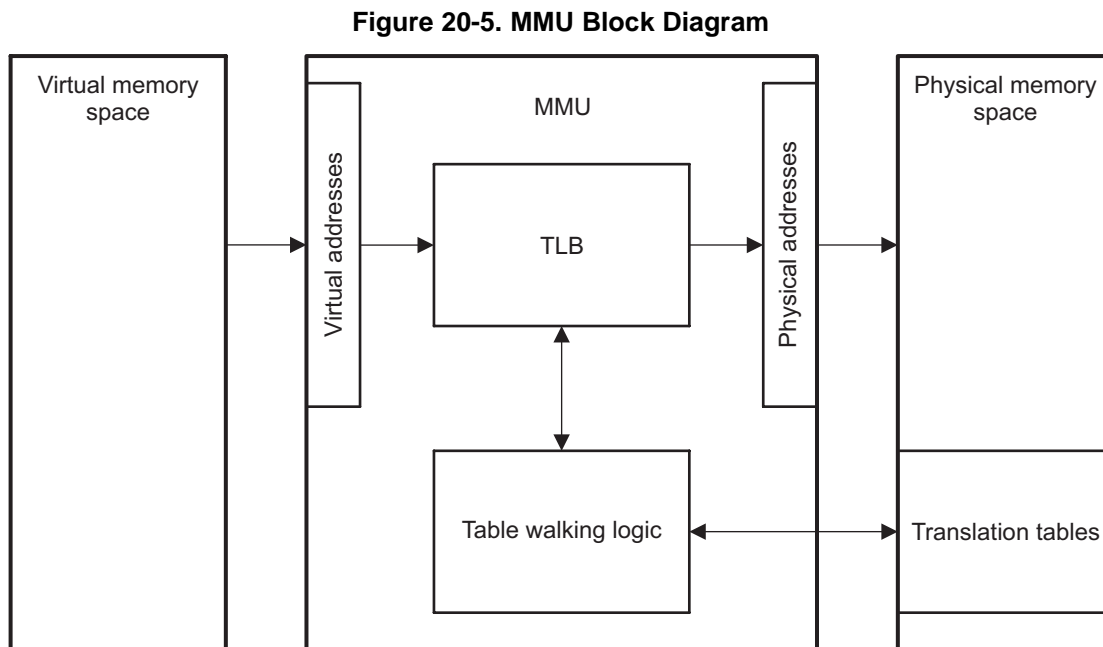

**NOTE:** For a description of the interrupt sources, see [Section 20.3.4, MMU Interrupt Requests](#).

## 20.3 MMU Functional Description

### 20.3.1 MMU Block Diagram

The MMU manages the virtual to physical address translation for external addresses. [Figure 20-5](#) shows the MMU block diagram.

Each table entry describes the translation of one contiguous memory region. For a description of the structure of these tables, see [Section 20.3.1.2, Translation Tables](#).

Two major functional units exist in the MMU to provide address translation automatically based on the table entries:

- The table walker automatically retrieves the correct translation table entry for a requested translation. If two-level translation is used (for the translation of small memory pages), the table walker also automatically reads the required second-level translation table entry. The two-level translation is described later in the chapter.
- The translation look-aside buffer (TLB) stores recently used translation entries, acting like a cache of the translation table.

#### 20.3.1.1 MMU Address Translation Process

Whenever an address translation is requested (that is, for every access with the MMU enabled), the MMU first checks whether the translation is contained in the TLB, which acts like a cache storing recent translations. The TLB can also be programmed manually to ensure that time-critical data can be translated without delay.

If the requested translation is not in the TLB, the table-walking logic retrieves this translation from the translation table(s), and then updates the TLB. The address translation is then performed. [Figure 20-6](#) summarizes the process.

**Figure 20-6. Translation Process**

### 20.3.1.2 Translation Tables

The translation of virtual to physical addresses is based on entries in translation tables that define the following properties:

- Address translation, that is, the correspondence between virtual and physical addresses
- Size of the memory region the entry translates

The virtual addresses index the translation tables. Each virtual address corresponds to exactly one entry in the translation table.

#### 20.3.1.2.1 Translation Table Hierarchy

When developing a table-based address translation scheme, one of the most important design parameters is the memory page size described by each translation table entry. MMU instances support 4-KiB and 64-KiB pages, a 1-MiB section, and a 16-MiB supersection. Using bigger page sizes means a smaller translation table.

Using a smaller page size greatly increases the efficiency of dynamic memory allocation and defragmentation. That is why many operating systems (OSs) can operate on memory blocks as small as 4 KiB; however, the smaller size implies a more complex table structure.

A quick calculation shows that using 4 KiB memory pages with one translation table would require one million entries to span the entire 4-GiB address range. The table itself would be 32 MiB, a size that is not feasible.

However, using bigger pages reduces the flexibility of typical OS memory management. Implementing a two-level hierarchy reconciles these two requirements. Within this hierarchy, one first-level translation table describes the translation properties based on 1 MiB memory regions.

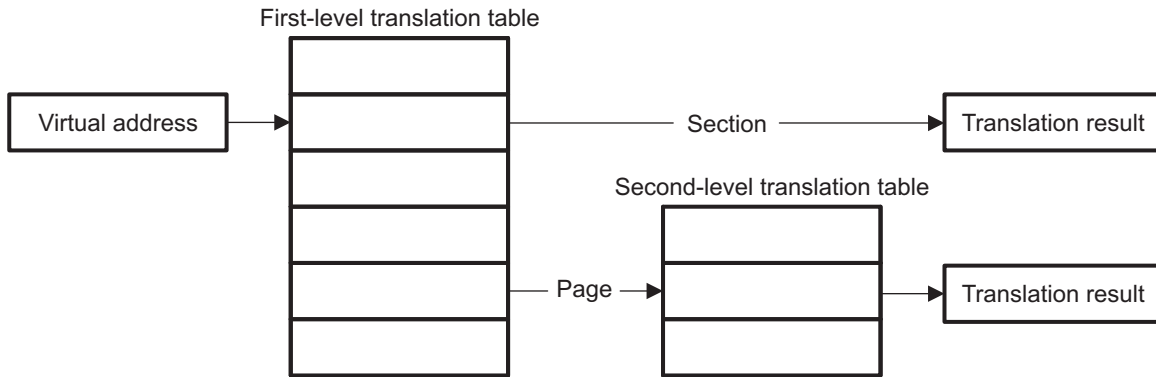

Each of the entries in this first-level translation table can specify the following:

- The translation properties for a big memory section. This memory section can be either 1 MiB (section) or 16 MiB (supersection). In this case, all translation parameters are specified in the first-level translation table entry.
- A pointer to a second-level translation table that specifies individual translation properties based on smaller pages within the 1-MiB page of memory. These pages can be either 64 KiB (large page) or 4

KiB (small page). In this case, the actual translation parameters are specified in the second-level translation table entry. The first-level translation table entry specifies only the base address of the second-level translation table.

This hierarchical approach means that additional translation information for smaller pages must be provided only when the pages are actually used. Figure 20-7 shows the hierarchy.

**Figure 20-7. Translation Hierarchy**

The structure of the first and second-level translation tables and their entries are described in more detail in Section 20.3.1.2.2, *First-Level Translation Table*, and Section 20.3.1.2.3, *Two-Level Translation*.

**20.3.1.2.2 First-Level Translation Table**

The first-level translation table describes the translation properties for 1-MiB sections. To describe a 4-GiB address range requires 4096 32-bit entries (so-called first-level descriptors).

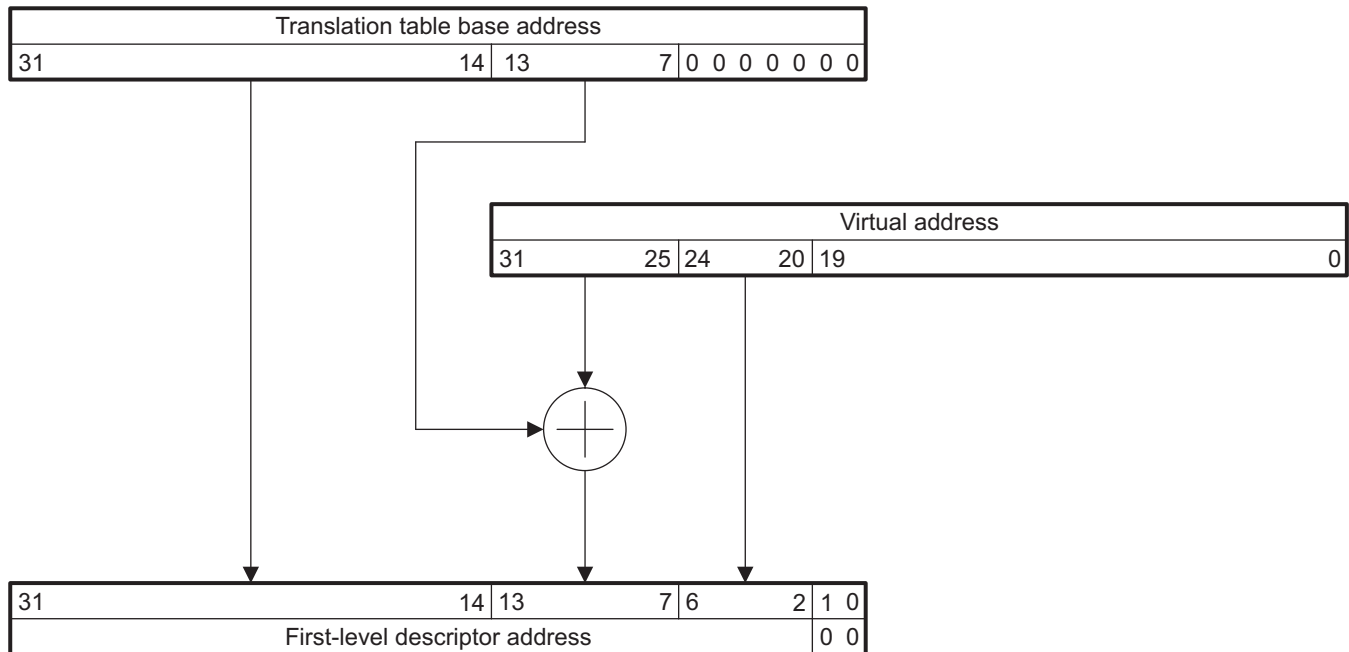

The first-level translation table start address must be aligned on a multiple of the table size with a 128-byte minimum. Consequently, an alignment of at least 16K bytes is required for a complete 4096-entry table; that is, at least the last fourteen address bits must be zero.

The start address of the first-level translation table is specified by the so-called translation table base. The table is indexed by the upper 12-bits of the virtual address. Figure 20-8 shows this mechanism.

**Figure 20-8. First-level Descriptor Address Calculation**

To summarize, the translation table base and the translation table index together define the first-level descriptor address. Figure 20-9 outlines the precise mechanism used to calculate this address.

**Figure 20-9. Detailed First-Level Descriptor Address Calculation**

As an example of this mechanism, consider a translation table base address of 0x8000:0000 and a virtual address of 0x1234:5678. In this case, the first-level descriptor address is  $0x8000:0000 + (0x123 \ll 2) = 0x8000:048C$ .

### 20.3.1.2.2.1 First-Level Descriptor Format

Each first-level descriptor provides either the complete address translation for 1-MiB or 16-MiB sections or provides a pointer to a second-level translation table for 4 KiB or 64 KiB pages. Table 20-4 shows the first-level descriptor format.

**Table 20-4. First-Level Descriptor Format**

First-Level Descriptor Format									
31:24	23:20	19	18	17:10	9:2	1 0			
X							0 0	Fault	
Second-Level Translation Table Base Address					X	0 1	Page		
Section Base Address		X	0	X		1 0	Section		
Supersection Base Address		X		1		X		1 0	Supersection
X							1 1	Fault	

**X = Don't care.** Set to 0 for future compatibility.

### 20.3.1.2.2.2 First-Level Page Descriptor Format

If a translation granularity smaller than 1 MiB is required, a two-level translation process is used. In this case, the first-level block descriptor specifies only the start address of a second-level translation table. The second-level translation table entries specify the actual translation properties.

### 20.3.1.2.2.3 First-Level Section Descriptor Format

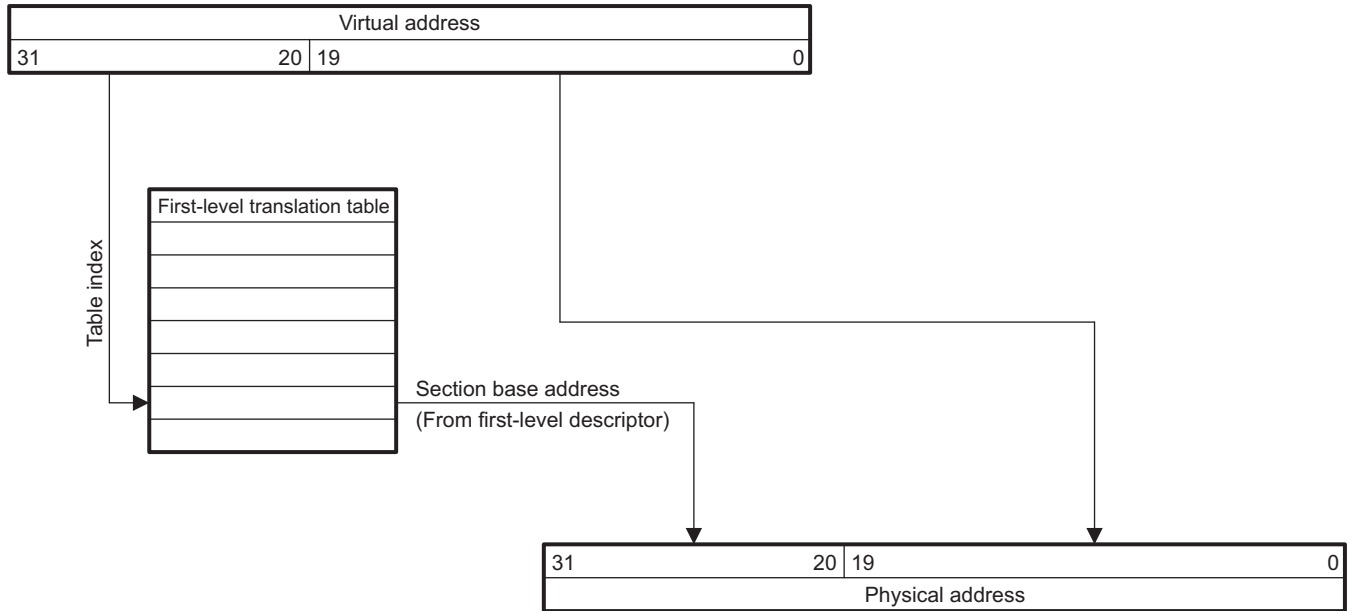

Each section descriptor in the first-level translation table specifies the complete translation properties for a 1-MiB section or a 16-MiB supersection.

**NOTE:** Supersection descriptors must be repeated 16 times, because each descriptor in the first-level translation table describes 1 MiB of memory. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

**20.3.1.2.2.4 Section Translation Summary**

Sections and supersections can be translated based solely on the information in the first-level translation table. Figure 20-10 summarizes the address translation process for a section.

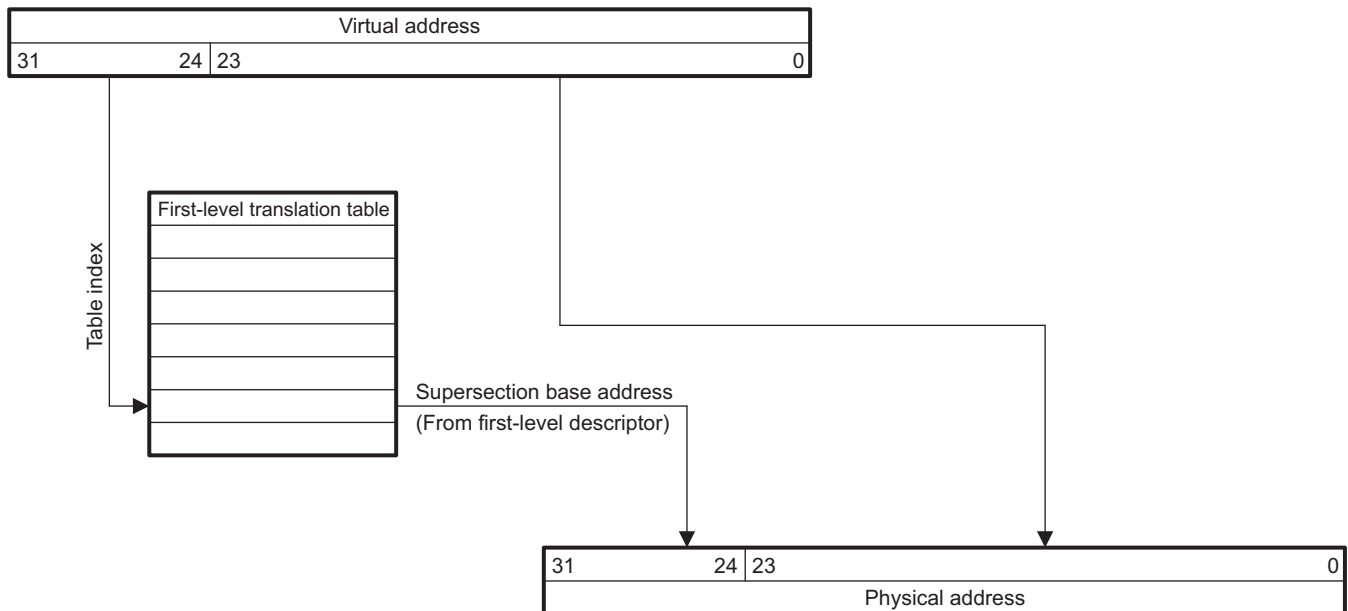

**Figure 20-10. Section Translation Summary**

**20.3.1.2.2.5 Supersection Translation Summary**

The translation of a supersection is similar to the translation of a section. The difference is that for a supersection only bits 31 to 24 index into the first-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a supersection.

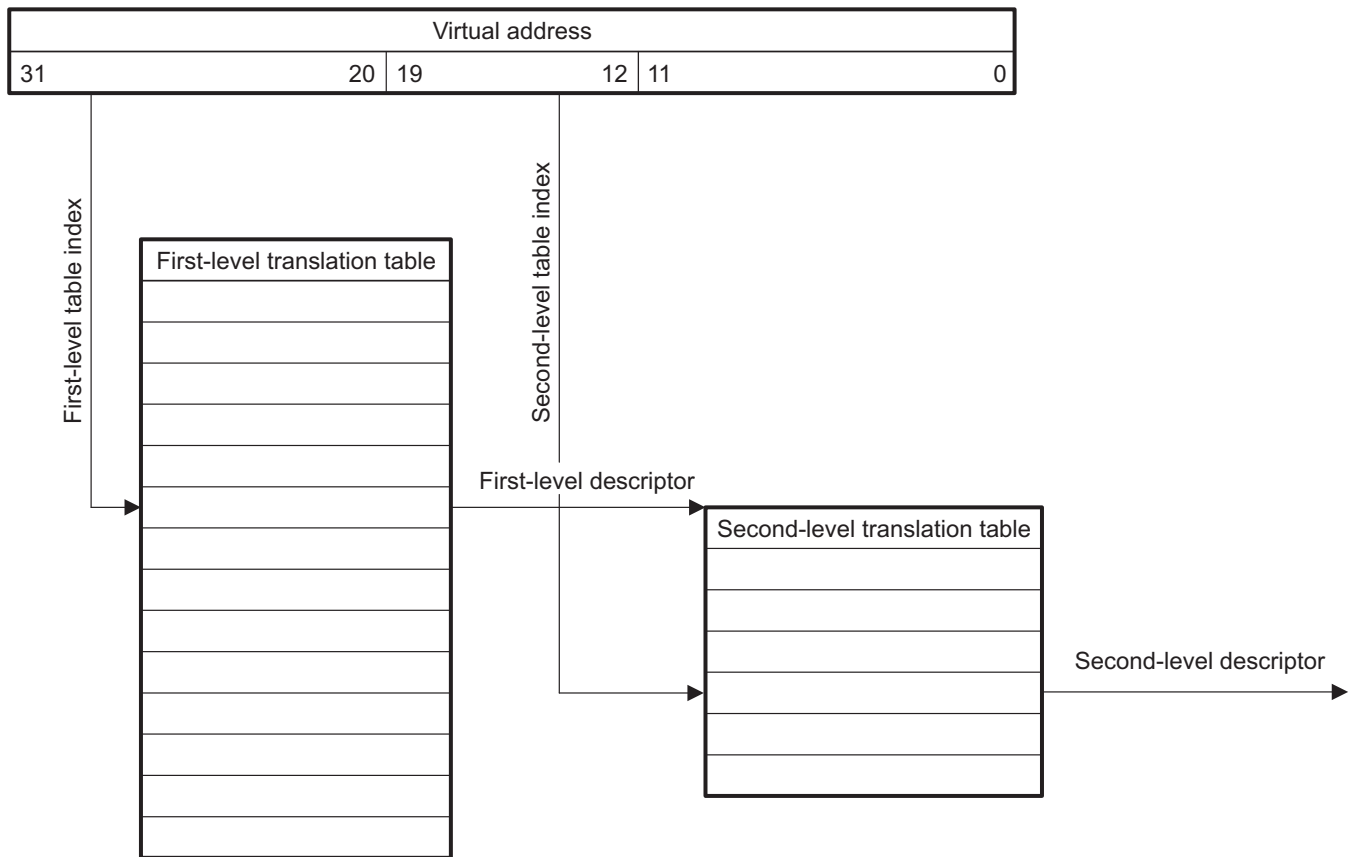

Figure 20-11 shows the translation mechanism for a supersection.

**Figure 20-11. Supersection Translation Summary**

### 20.3.1.2.3 Two-Level Translation

Two-level translation is used when fine-grain granularity is required, that is, when memory sections smaller than 1 MiB are needed. In this case, the first-level descriptor provides a pointer to the base address of a second-level translation table. This second-level table is indexed by bits 19 to 12 of the virtual address. [Figure 20-12](#) shows this indexing mechanism.

Figure 20-12. Two-Level Translation

Each second-level translation table describes the translation of 1 MiB of address space in pages of 64 KiB (large page) or 4 KiB (small page). It consists of 256 second-level descriptors describing 4 KiB each.

**NOTE:** In the case of a large page, the same descriptor must be repeated 16 times. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

20.3.1.2.3.1 Second-Level Descriptor Format

Similar to first-level section descriptors, second-level descriptors provide all of the necessary information for the translation of a large or small page. Table 20-5 shows the format of second-level descriptors.

Table 20-5. Second-Level Descriptor Format

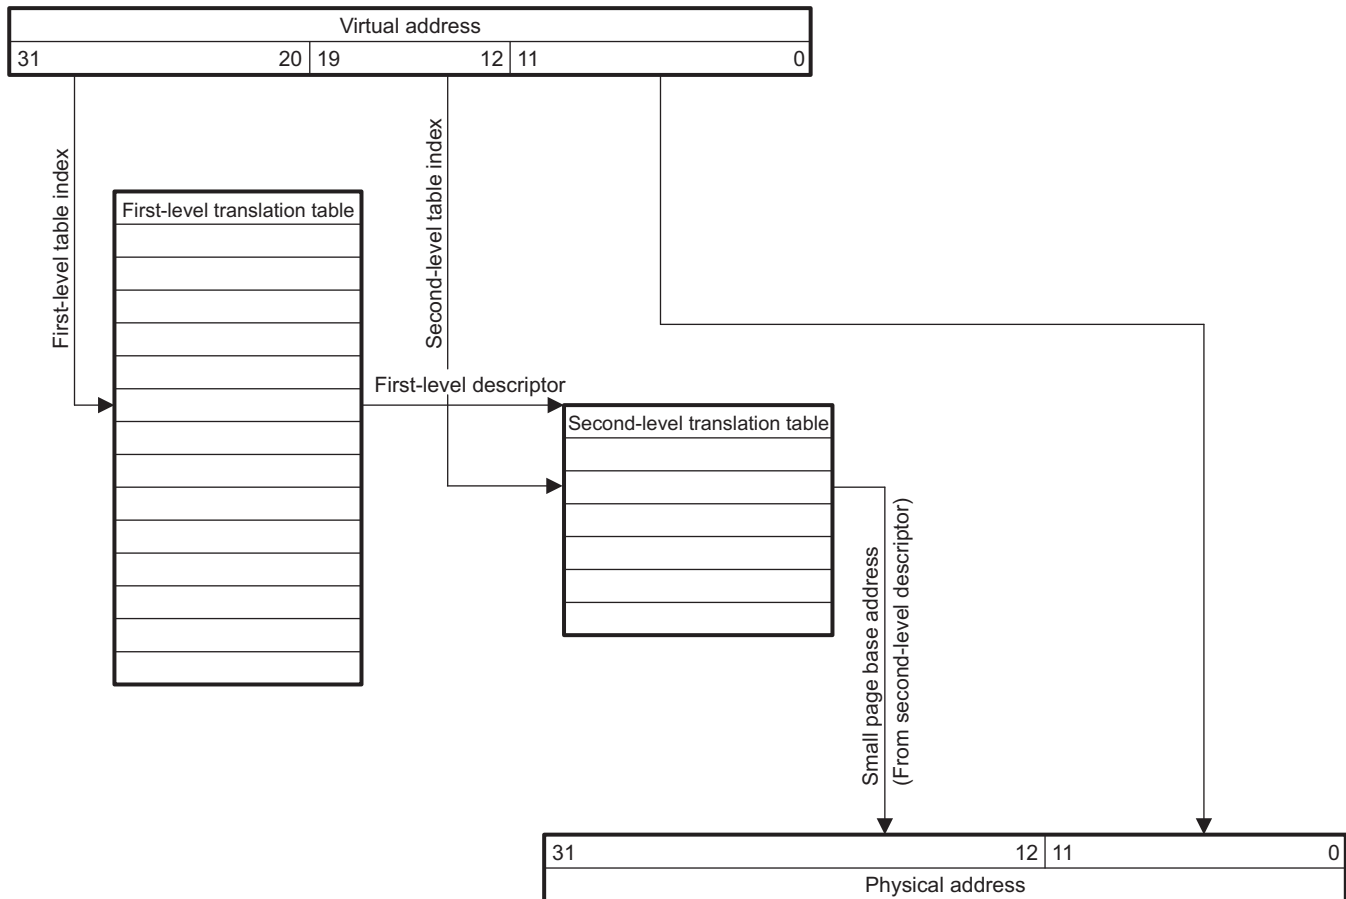

Second-Level Descriptor Format					
31:16	15:12	11:2	1	0	
X				0	0
Large Page Base Address				0	1
Small Page Base Address				1	X
					Fault
					Large Page
					Small Page

X = Don't care. Set to 0 for future compatibility.

20.3.1.2.3.2 Small Page Translation Summary

Figure 20-13 summarizes the translation process for small pages.

Figure 20-13. Small Page Translation Summary

20.3.1.2.3.3 Large Page Translation Summary

The translation of a large page is similar to the translation of a small page. The difference is that, for a large page, only bits 19 to 16 index into the second-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a large page. This is shown in Figure 20-14.

Figure 20-14. Large Page Translation Summary

### 20.3.1.3 Translation Lookaside Buffer

Translating virtual addresses to physical addresses is required for each memory access in systems using an MMU. To accelerate this translation process, a cache, or TLB, holds the result of recent translations.

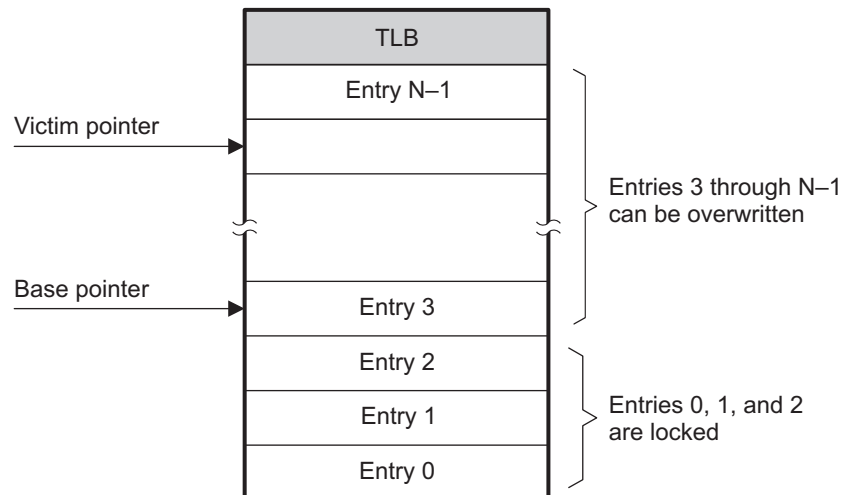

For every translation, the MMU internal logic first checks whether the requested translation is already cached in the TLB. If the translation is cached, this translation is used; otherwise the translation is retrieved from the translation tables and the TLB is updated. If the TLB is full, one of its entries must be replaced. This entry is selected on a random basis.

The first  $n$  TLB entries, where  $n < Total\ Number\ N\ of\ TLB\ Entries$ , can be protected (locked) against being overwritten by setting the TLB base pointer to  $n$ . When this mechanism is used, only unprotected entries can be overwritten. The victim pointer indicates the next TLB entry to be written. Figure 20-15 shows an example of the TLB with  $N$  TLB entries (ranging from 0 to  $N-1$ ). The base pointer contains the value "3" protecting Entry 0, Entry 1, and Entry 2 and the victim pointer points to the next TLB entry to be updated.

---

**NOTE:** The last TLB entry (Entry  $N-1$ ) always remains unprotected.

---

**Figure 20-15. TLB Entry Lock Mechanism**

The table walking logic automatically writes the TLB entries. The entries can also be manually written, which is done typically to ensure that the translation of time-critical data accesses is already present in the TLB so that they execute as fast as possible. The entries must be locked to prevent them from being overwritten.

### 20.3.1.3.1 TLB Entry Format

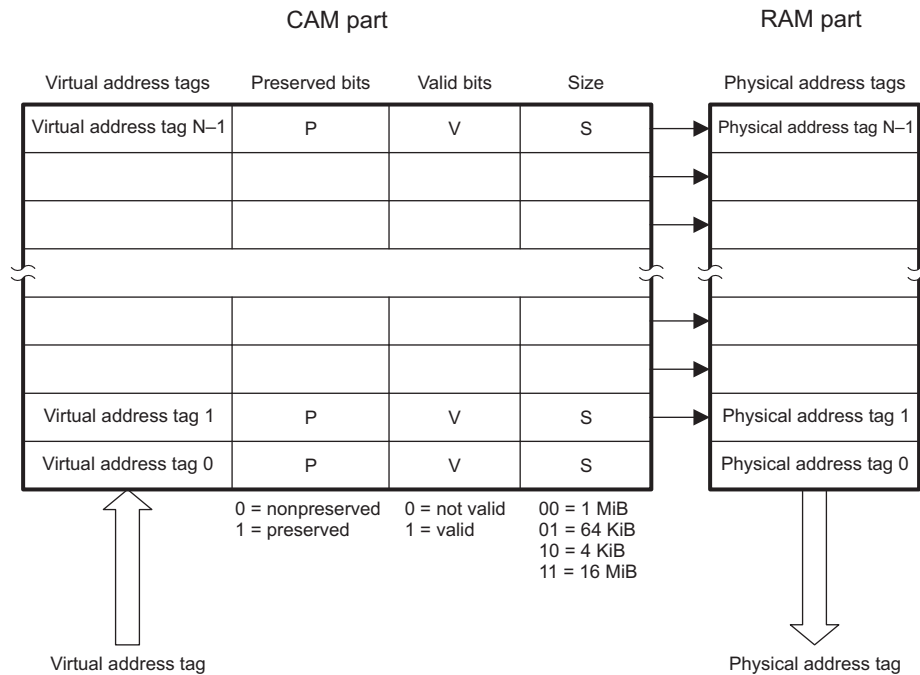

TLB entries consist of two parts:

- The Content Addressable Memory (CAM) part contains the virtual address tag used to determine if a virtual address translation is in the TLB. The TLB acts like a fully associative cache addressed by the virtual address tag. The CAM part also contains the section/page size, as well as the preserved and the valid parameters. See the [MMU\\_CAM](#) register table for more details.
- The Random Addressable Memory (RAM) part contains the address translation that belongs to the virtual address tag. See the [MMU\\_RAM](#) register table for more details.

The valid parameter specifies whether an entry is valid or not. The preserved parameter determines the behavior of an entry in the event of a TLB flush. If an entry is set as preserved, it is not deleted when a TLB is flushed, that is, when [MMU\\_GFLUSH\[0\]](#) GLOBALFLUSH is set to 1. Preserved entries must be deleted manually. [Section 20.3.1.2.2, First-Level Translation Table](#) describes the procedure to delete TLB entries.

[Figure 20-17](#) shows the TLB entry structure.

**Figure 20-16. TLB Entry Structure**

#### 20.3.1.4 No Translation (Bypass) Regions

The MMU provides support for up to four user programmable regions where there is no address translation. Any access to a region specified by the MMU\_BYPASS\_REGIONx\_ADDR and MMU\_BYPASS\_REGIONx\_SIZE registers (where x = 1 to 4) will have no virtual to physical address translation.

#### 20.3.2 MMU Software Reset

To perform a software reset, write 1 in the MMU\_SYSCONFIG[1] SOFTRESET bit. The MMU\_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the MMU\_SYSCONFIG[1] SOFTRESET bit is automatically reset. The software must ensure that the software reset completes before doing MMU operations. When an MMU instance is released from reset, its TLB is empty and the MMU is disabled.

#### 20.3.3 MMU Power Management

Table 20-6 describes the power-management features available for the MMU modules.

**Table 20-6. MMU Local Power Management Features**

Feature	Register
Idle modes	MMU_SYSCONFIG[4:3] IDLEMODE
Clock activity	MMU_SYSCONFIG[9:8] CLOCKACTIVITY
Clock autogating	MMU_SYSCONFIG[0] AUTOIDLE

**NOTE:** The MMU\_SYSCONFIG[9:8] CLOCKACTIVITY bit field is read only.

### 20.3.4 MMU Interrupt Requests

**Table 20-7. MMU Events**

Event Flag	Event Mask	Description
MMU_IRQSTATUS[4] MULTIHITFAULT	MMU_IRQENABLE[4] MULTIHITFAULT	Error due to multiple matches in the TLB
MMU_IRQSTATUS[3] TABLEWALKFAULT	MMU_IRQENABLE[3] TABLEWALKFAULT	Error due to error response received during a Table Walk
MMU_IRQSTATUS[2] EMUMISS	MMU_IRQENABLE[2] EMUMISS	Error due to unrecoverable TLB miss during debug (hardware TWL disabled)
MMU_IRQSTATUS[1] TRANSLATIONFAULT	MMU_IRQENABLE[1] TRANSLATIONFAULT	Error due to invalid descriptor in the translation tables (translation fault)
MMU_IRQSTATUS[0] TLBMISS	MMU_IRQENABLE[0] TLBMISS	Error due to unrecoverable TLB miss (hardware TWL disabled)

### 20.3.5 MMU Error Handling

Table 20-8 summarizes the intended operation for real and potential error conditions.

**Table 20-8. Error Handling**

Item	Condition	Action
1	Table-walk read has an error response.	Treat generally the same as a translation fault, but set the TableWalkFault interrupt status bit to aid in diagnosis
2	MMU is disabled during table-walk.	Not permitted; can result in loss of the current transaction but must not deadlock the MMU.  Avoid this condition by first disabling the table-walk logic and then polling the TWLRunning bit to ensure that no table walk is pending
3	MMU is disabled during an address translation.	Not permitted; can result in access to an unintended location, but must not deadlock MMU.  This condition should be avoided by ensuring that no accesses are pending.
4	TLB is accessed during an address translation or a table walk.	Reading permitted; write should be done with care to ensure that the TLB is self-consistent at all times that a translation can occur.
5	TLB is flushed during address translation or a table walk.	Permitted; the flush is processed first, followed by the TWL update.
6	MMU is disabled while an interrupt is pending.	Not permitted; all pending interrupts should be processed before disabling the MMU.
7	Interrupt is not enabled and a fault/miss happens during translation.	If MMU_GPR[0] FAULT_INTR_DIS = 1 : Error response is sent back. If MMU_GPR[0] FAULT_INTR_DIS = 0 : <ul style="list-style-type: none"> <li>Mreqdebug = 1 (debug access) : Error response is sent back</li> <li>Mreqdebug = 0 (application access) : Error response is not sent. MMU is waiting for TLB to be updated through config port. But since the interrupt is not asserted, system does not know there was a fault. This results in deadlock. Software must take care of this by enabling interrupts.</li> </ul>

## 20.4 MMU Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

### 20.4.1 Global Initialization

#### 20.4.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the MMU module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MMU. For more information, see [Section 20.2, MMU Module Integration](#).

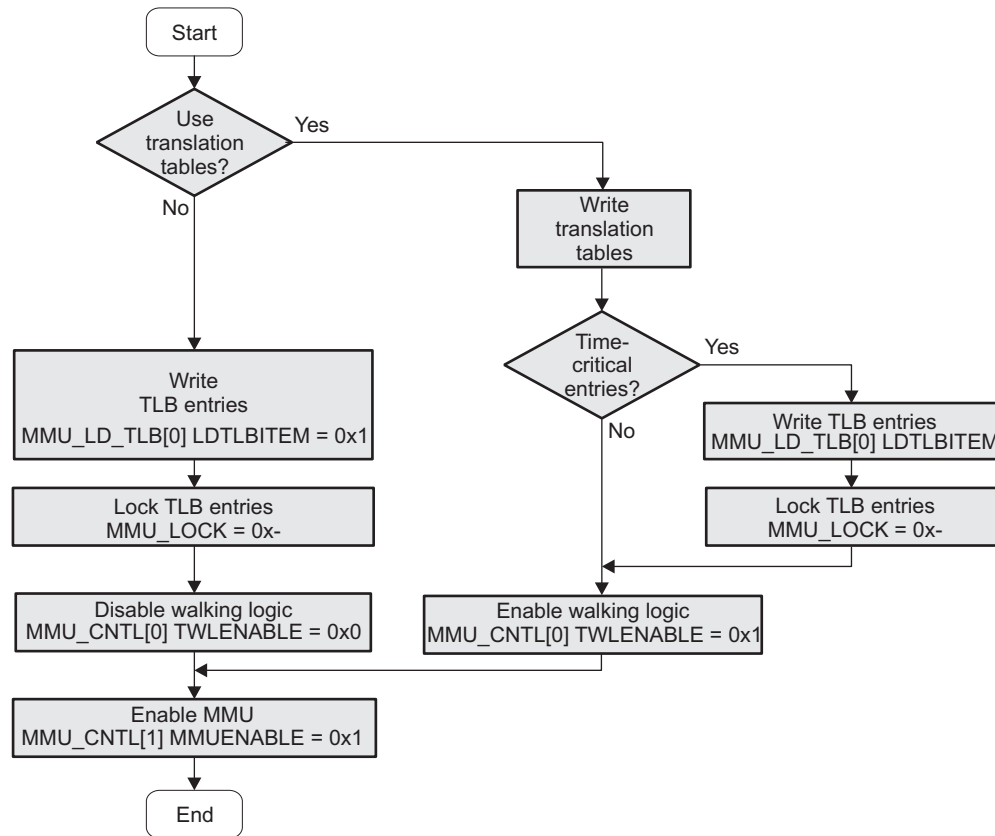

**Table 20-9. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	Enable MMU interface/functional clock.
(optional) Interrupt controller(s)	Configure device interrupt controller(s) to enable the interrupts from MMU.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see <a href="#">Section 18.4.6.4, IRQ_CROSSBAR Module Functional Description</a> , in <a href="#">Chapter 18, Control Module</a> .

#### 20.4.1.2 MMU Global Initialization

##### 20.4.1.2.1 Main Sequence - MMU Global Initialization

[Figure 20-17](#) shows the procedure to initialize the MMU after a power-on or software reset.

**Figure 20-17. MMU Global Initialization**

#### 20.4.1.2.2 Subsequence - Configure a TLB entry

**Table 20-10. Configure a TLB Entry**

Step	Register / Bit Field / Programming Model	Value
Load the Virtual Address Tag	MMU_CAM[31:12] VATAG	0x-
Protect the TLB entry against flush	MMU_CAM[3] P	0x1
Validate the TLB entry	MMU_CAM[2] V	0x1
Define the page size	MMU_CAM[1:0] PAGESIZE	0x-

### 20.4.1.3 Operational Modes Configuration

#### 20.4.1.3.1 Main Sequence - Writing TLB Entries Statically

Writing TLB entries statically avoids the need to write translation tables in memory and is commonly used for relatively small address spaces. This method ensures that the translation of time-critical data accesses execute as fast as possible with entries already present in the TLB. These entries must be locked to prevent them from being overwritten.

**Table 20-11. MMU Writing TLB Entries Statically**

Step	Register/ Bit Field / Programming Model	Value
Execute software reset	MMU_SYSCONFIG[1] SOFTRESET	0x1
Wait for reset to complete	MMU_SYSSTATUS[0] RESETDONE	=0x1
Enable power saving via automatic interface clock gating	MMU_SYSCONFIG[0] AUTOIDLE	0x1
Configure TLB entries	See <a href="#">Table 20-10</a>	
Load the physical Address of the page	MMU_RAM[31:12] PHYSICALADDRESS	0x-
Specify the TLB entry you want to write	MMU_LOCK[8:4] CURRENTVICTIM	0x-
Load the specified entry in the TLB	MMU_LD_TLB[0] LDTLBITEM	0x1
Enable multihit fault and TLB miss	MMU_IRQENABLE[4] MULTIHITFAULT	0x1
	MMU_IRQENABLE[0] TLBMISS	0x1
Enable memory translations	MMU_CNTL[1] MMUENABLE	0x1

#### 20.4.1.3.2 Main Sequence - Protecting TLB Entries

The first  $n$  TLB entries (with  $n <$  total number of TLB entries) can be protected from being overwritten with new translations. This is useful to ensure that certain commonly used or time-critical translations are always in the TLB and do not require retrieval using the table walking process.

**Table 20-12. Protecting TLB Entries**

Step	Register/Bit Field/Programming Model	Value
Locks the TLB entries	MMU_LOCK[14:10] BASEVALUE	0x-

#### 20.4.1.3.3 Main Sequence - Deleting TLB Entries

Two mechanisms exist to delete TLB entries. All unpreserved TLB entries, that is, TLB entries written with the preserved bit set to zero, can be deleted by invoking a TLB flush. The preserved bit should only be used on protected TLB entries, as it does not prevent replacement by the table walking logic.

**Table 20-13. Deleting TLB Entries**

Step	Register / Bit Field / Programming Model	Value
Flush all nonprotected TLB entries	MMU_GFLUSH[0] GLOBALFLUSH	0x1
Flush all TLB entries specified by the CAM register	MMU_FLUSH_ENTRY[0] FLUSHENTRY	0x1

#### 20.4.1.3.4 Main Sequence - Read TLB Entries

TLB entries can be read by the programmer to determine the TLB content at runtime.

**Table 20-14. Read TLB Entries**

Step	Register / Bit Field / Programming Model	Value
Set the current victim pointer	MMU_LOCK[8:4] CURRENTVICTIM	0x-
Read RAM parts of the TLB entry	MMU_READ_RAM	

**Table 20-14. Read TLB Entries (continued)**

<b>Step</b>	<b>Register / Bit Field / Programming Model</b>	<b>Value</b>
Read CAM parts of the TLB entry	<a href="#">MMU_READ_CAM</a>	

## 20.5 MMU Register Manual

### 20.5.1 MMU Instance Summary

**Table 20-15. MMU Instance Summary**

Module Name	Base Address (L3/L4 Access)	Base Address (CPU Private Access)	Size
System MMU1	0x4881 C000	–	176 Bytes
System MMU2	0x4881 E000	–	176 Bytes
DSP1_MMU0	0x40D0 1000	0x01D0 1000	176 Bytes
DSP1_MMU1	0x40D0 2000	0x01D0 2000	176 Bytes
DSP2_MMU0	0x4150 1000	0x01D0 1000	176 Bytes
DSP2_MMU1	0x4150 2000	0x01D0 2000	176 Bytes
EVE1_MMU0	0x4208 1000	0x4008 1000	176 Bytes
EVE1_MMU1	0x4208 2000	0x4008 2000	176 Bytes
EVE2_MMU0	0x4218 1000	0x4008 1000	176 Bytes
EVE2_MMU1	0x4218 2000	0x4008 2000	176 Bytes
IPU1_MMU	0x5888 2000	0x5508 2000	176 Bytes
IPU2_MMU	0x5508 2000	0x5508 2000	176 Bytes

### 20.5.2 MMU Registers

#### 20.5.2.1 MMU Register Summary

**Table 20-16. System MMU Register Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	System MMU1 Physical Address (L4_PER3 Access)	System MMU2 Physical Address (L4_PER3 Access)
<a href="#">MMU_REVISION</a>	R	32	0x0000 0000	0x4881 C000	0x4881 E000

**Table 20-24. MMU\_SYSCONFIG**

<b>Address Offset</b>	0x0000 0010
<b>Physical Address</b>	See <a href="#">Section 20.5.2.1</a>
<b>Description</b>	This register controls the various parameters of the OCP interface
<b>Type</b>	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																CLOCKACTIVITY		RESERVED		IDLEMODE		RESERVED	SOFTRESET	AUTOIDLE							

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Write 0's for future compatibility. Reads return 0	R	0x000000
9:8	CLOCKACTIVITY	Clock activity during wake-up mode 0x0: Functional and OCP clocks can be switched off	R	0x0
7:5	RESERVED	Write 0's for future compatibility Reads returns 0	R	0x0
4:3	IDLEMODE	Idle mode 0x0: Force-idle. An idle request is acknowledged unconditionally 0x1: No-idle. An idle request is never acknowledged 0x2: Smart-idle. Acknowledgement to an idle request is given based on the internal activity of the module 0x3: Reserved. Do not use	RW	0x0
2	RESERVED	Write 0's for future compatibility Reads returns 0	R	0x0
1	SOFTRESET	Software reset. This bit is automatically reset by the hardware. During reads, it always return 0 Write 0x0: No functional effect Write 0x1: The module is reset	W	0x0
0	AUTOIDLE	Internal OCP clock gating strategy 0x0: OCP clock is free-running 0x1: Automatic interconnect clock gating strategy is applied, based on the interconnect interface activity	RW	0x0

# Spinlock

---

---

This chapter describes the Spinlock module of the device.

Topic	Page
<b>21.1 Spinlock Overview .....</b>	<b>5723</b>
<b>21.2 Spinlock Integration .....</b>	<b>5724</b>
<b>21.3 Spinlock Functional Description .....</b>	<b>5725</b>
<b>21.4 Spinlock Programming Guide.....</b>	<b>5727</b>
<b>21.5 Spinlock Register Manual .....</b>	<b>5730</b>

## 21.1 Spinlock Overview

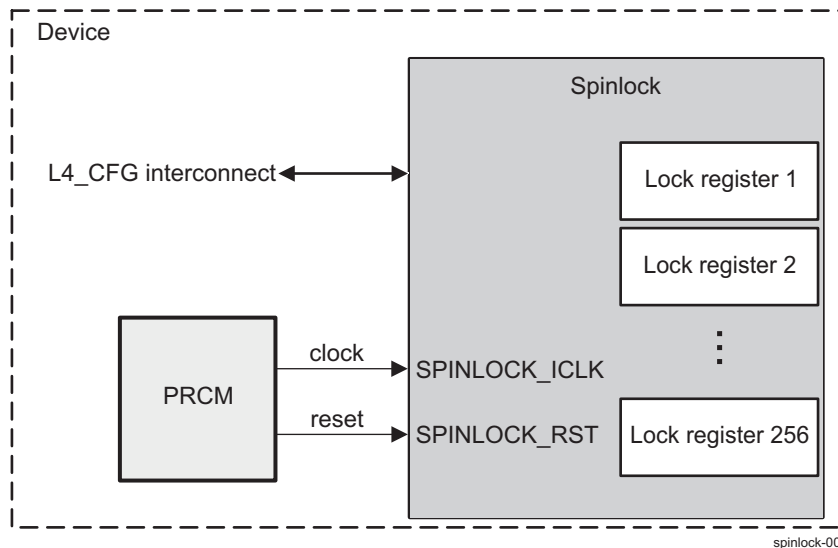

The Spinlock module provides hardware assistance for synchronizing the processes running on multiple processors in the device:

- Dual Cortex®-A15 microprocessor unit (MPU) subsystem
- Digital signal processor (DSP) subsystems – DSP1 and DSP2
- Dual Cortex-M4 image processing unit (IPU) subsystems – IPU1 and IPU2

The Spinlock module implements 256 spinlocks (or hardware semaphores), which provide an efficient way to perform a lock operation of a device resource using a single read-access, avoiding the need of a read-modify-write bus transfer that the programmable cores are not capable of.

Figure 21-1 shows an overview of the Spinlock module.

**Figure 21-1. Spinlock Overview**

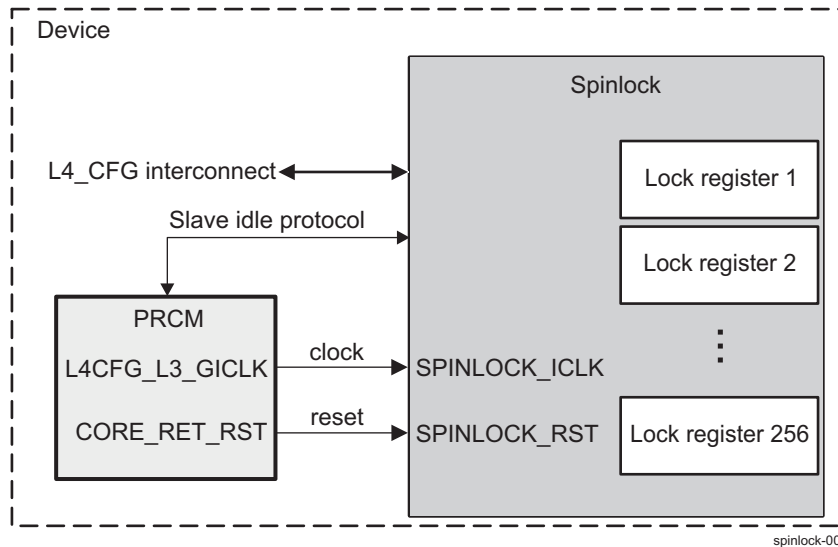

## 21.2 Spinlock Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 21-2 shows the Spinlock integration.

**Figure 21-2. Spinlock Integration**

**NOTE:** For more information about the Slave idle protocol and the wake-up request, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 21-1](#) and [Table 21-2](#) summarize the integration of the module in the device.

**Table 21-1. Spinlock Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect
SPINLOCK	PD_COREAON	L4_CFG

**Table 21-2. Spinlock Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SPINLOCK	SPINLOCK_ICLK	L4CFG_L3_GICLK	PRCM	Spinlock interface/functional clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SPINLOCK	SPINLOCK_RST	CORE_RET_RST	PRCM	Spinlock hardware reset. This reset is asynchronously applied to the Spinlock internal registers.

**NOTE:** The Spinlock module does not support any interrupt and DMA requests.

## 21.3 Spinlock Functional Description

### 21.3.1 Spinlock Software Reset

The Spinlock module can be reset by software through the `SPINLOCK_SYSCONFIG[1]` `SOFTRESET` bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. The `SPINLOCK_SYSTATUS[0]` `RESETDONE` bit can be polled to check the reset status (reading 1 indicates that reset sequence is done; reading 0 indicates that reset sequence is in progress). The software must ensure that the software reset completes before doing Spinlock operations.

### 21.3.2 Spinlock Power Management

Table 21-3 describes power-management features available to the Spinlock module.

**Table 21-3. Spinlock Local Power Management Features**

Feature	Registers	Description
Clock auto gating	<code>SPINLOCK_SYSCONFIG[0]</code> <code>AUTOGATING</code> bit	This bit indicates that the Spinlock module uses an automatic internal interface clock gating strategy, based on interface activity.
Global wake-up enable	<code>SPINLOCK_SYSCONFIG[2]</code> <code>ENAWAKEUP</code> bit	This bit indicates that the wake-up generation feature (at Spinlock module level) is disabled.
Slave idle modes	<code>SPINLOCK_SYSCONFIG[4:3]</code> <code>SIDLEMODE</code> bit field	This bit field indicates that the Spinlock module uses smart-idle mode.

**NOTE:** All Spinlock local power management features are non-configurable – that is, their respective bit fields are read-only and only show the actual hardware implementation.

For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1.4, Clock Domain-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#). For descriptions of `EnaWakeUp`, and `IdleMode` features, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

The Spinlock module is normally idle, except when processing a request from its slave interface port. The smart-idle mode acknowledges idle requests from the PRCM only when the module is prepared to go idle. The Spinlock module is always ready to go idle if it does not have any request that it is processing.

### 21.3.3 About Spinlocks

Spinlocks are present to solve the need for synchronization and mutual exclusion between heterogeneous processors and those not operating under a single, shared operating system. There is no alternative mechanism to accomplish these operations between processors in separate subsystems.

Spinlocks are not the best way to synchronize between tasks or threads on one CPU. Instead, spinlocks are for use in synchronization between different subsystems in the device that don't have any other means of hardware-based synchronization.

Spinlocks do not solve all system synchronization issues. They have limited applicability and should be used with care to implement higher level synchronization protocols.

A spinlock is appropriate for mutual exclusion for access to a shared data structure. It should be used only when:

1. The time to hold the lock is predictable and small (for example, a maximum hold time of less than 200 CPU cycles may be acceptable).
2. The locking task cannot be preempted, suspended, or interrupted while holding the lock (this would make the hold time large and unpredictable).
3. The lock is lightly contended, that is the chance of any other process (or processor) trying to acquire the lock while it is held is small.

If these conditions are met, then the locking code can retry a failed attempt to acquire the lock until success.

If the conditions are not met, then a spinlock is not a good candidate. One alternative is to use a spinlock for critical section control (engineered to meet the conditions) to implement a higher level semaphore that can support preemption, notification, timeout or other higher level properties.

### 21.3.4 Spinlock Functional Operation

The Spinlock module supports 256 spinlocks. It accepts only a single command at a time and processes the command fully before accepting the next command. A lock is requested by reading the `SPINLOCK_LOCK_REG_i[0]` TAKEN bit. There are two states: Taken (`SPINLOCK_LOCK_REG_i[0]` TAKEN = 1) or Not Taken (`SPINLOCK_LOCK_REG_i[0]` TAKEN = 0).

When the status of lock  $i$  (where  $i = 0$  to 255) is Not Taken (free), a read from the `SPINLOCK_LOCK_REG_i` register returns 0 and sets the lock to Taken (locked). When the status of lock  $i$  is Taken, a read returns 1 and does not change the state of the lock.

A write to the `SPINLOCK_LOCK_REG_i` register does not change the state of lock, unless when writing 0 when the lock is in Taken state. By doing this, the requester frees the lock.

#### CAUTION

Only 32-bit reads and writes are supported.

Figure 21-3 shows the `SPINLOCK_LOCK_REG_i` register state diagram.

**Figure 21-3. Lock Register State Diagram**

#### NOTE:

- There is no support to ensure that a lock register is locked and unlocked by the same process. This must be ensured in software.
- There is no support to check that the same initiator that acquired the lock is the one that is freeing the lock.

## 21.4 Spinlock Programming Guide

### 21.4.1 Spinlock Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

#### 21.4.1.1 Surrounding Modules Global Initialization

This procedure initializes the surrounding modules when the Spinlock module is used for the first time after a device reset.

**Table 21-4. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	Spinlock interface clock must be enabled. For more information, see <a href="#">Section 3.6.4.15, CD_L4_CFG Clock Domain</a> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Interconnect	For more information about the L4_CFG interconnect configuration, see <a href="#">Section 14.3, L4 Interconnects</a> .

#### 21.4.1.2 Basic Spinlock Operations

The main spinlock operations are:

- Clear all the Taken spinlocks (only after a system bug recovery)
- Take a spinlock
- Release spinlock

##### 21.4.1.2.1 Spinlocks Clearing After a System Bug Recovery

Module initialization (after reset) is not needed, except after system bug recovery. The following table presents the Spinlock initialization after a system bug recovery. Software should store 0 into each of the [SPINLOCK\\_LOCK\\_REG\\_i](#) registers at system startup to insure that all locks are initialized to Not Taken.

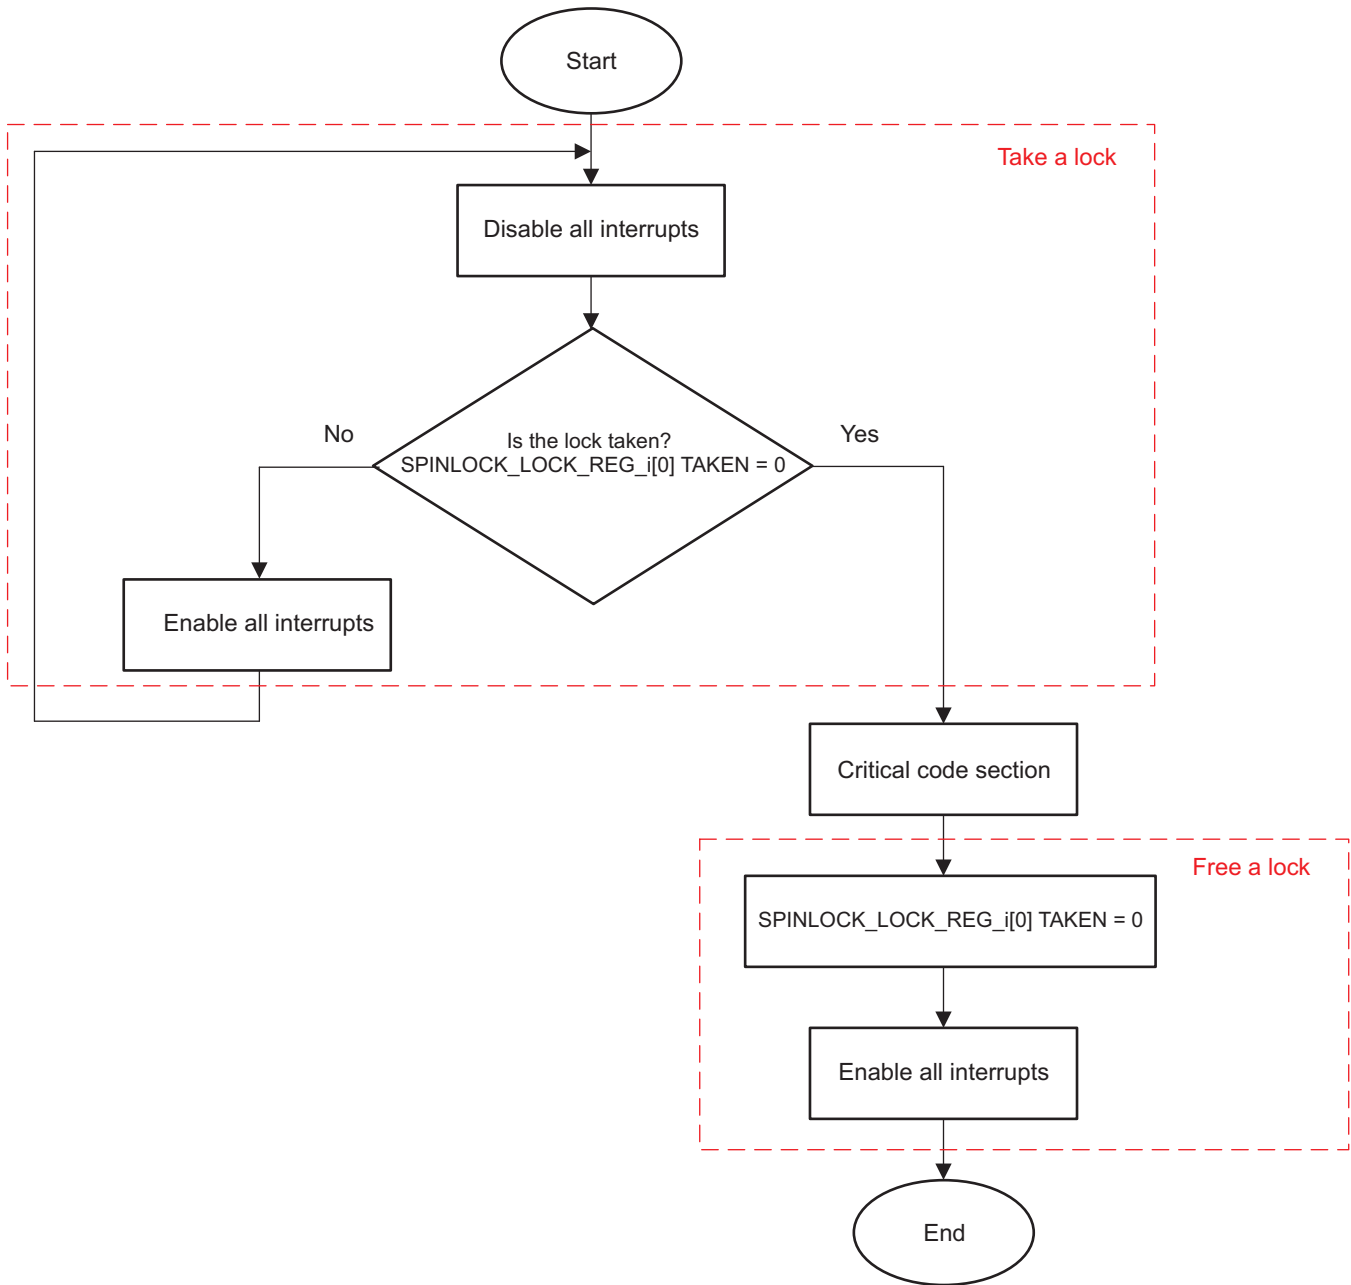

**Table 21-5. Spinlock System Bug Recovery**

Step	Register	Value
IF: <a href="#">SPINLOCK_SYSTATUS[0] IU0</a> == 1?	<a href="#">SPINLOCK_SYSTATUS[0] IU0</a>	
Free the 256 locks	<a href="#">SPINLOCK_LOCK_REG_i[0] TAKEN</a> (i = 0 to 255)	0x0
END		

##### 21.4.1.2.2 Take and Release Spinlock

This procedure configures the take and release (free) operations for the Spinlock module. A spinlock should only be held with interrupts disabled. So, before attempting to obtain the spinlock, software should disable interrupts. Then it should read the [SPINLOCK\\_LOCK\\_REG\\_i\[0\] TAKEN](#) bit to attempt to obtain the lock. If it succeeds, it should proceed directly through the critical section then unlock and re-enable interrupts. If the acquisition attempt fails, the acquisition should be reattempted. To prevent unknown interrupt disabled time, interrupts should be re-enabled and then disabled before reattempting to acquire the lock. [Figure 21-4](#) shows the described above procedure.

## Timers

---

---

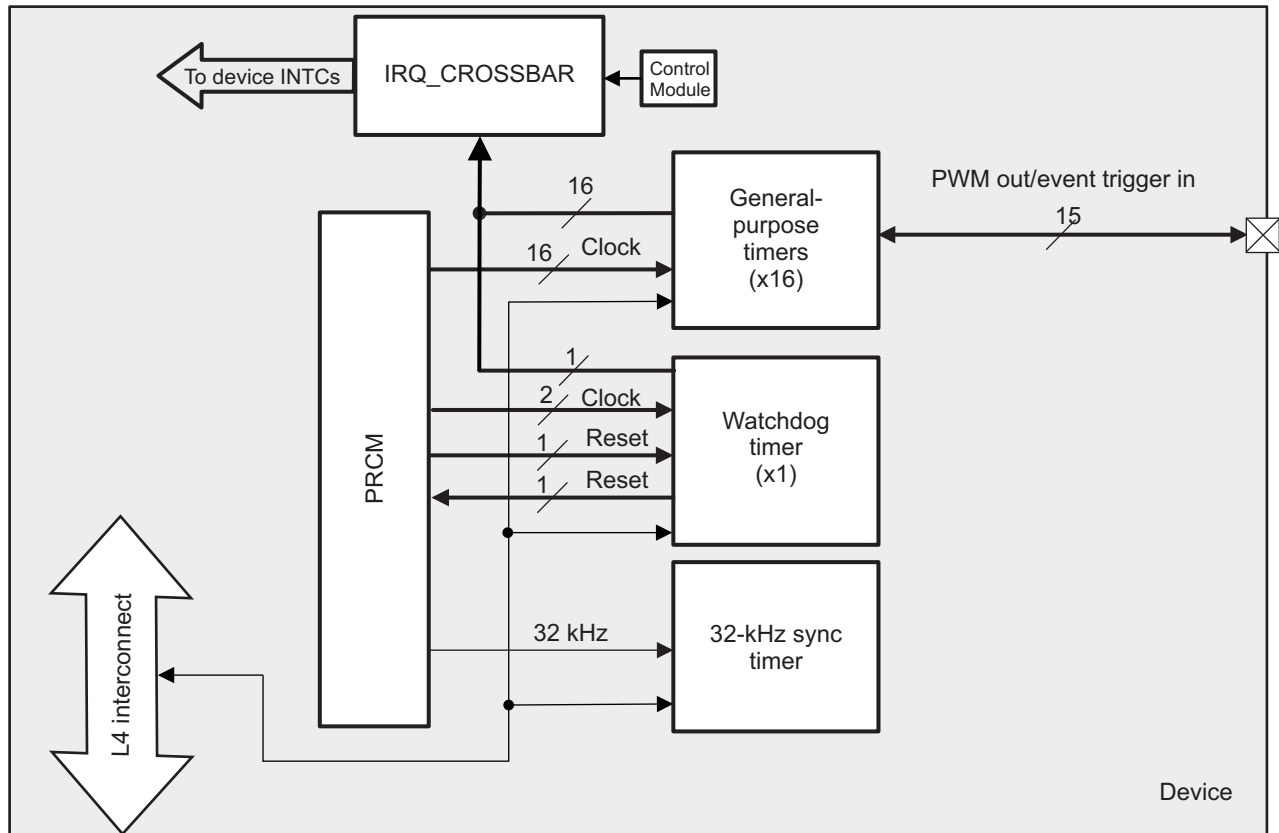

This chapter describes the timer modules for the device.

Topic	Page
<b>22.1 Timers Overview .....</b>	<b>5735</b>
<b>22.2 General-Purpose Timers .....</b>	<b>5736</b>
<b>22.3 32-kHz Synchronized Timer (COUNTER_32K) .....</b>	<b>5792</b>
<b>22.4 Watchdog Timer .....</b>	<b>5799</b>

## 22.1 Timers Overview

The device includes several types of timers used by the system software, including 16 general-purpose (GP) timers, one watchdog timer, and a 32-kHz synchronized timer (COUNTER\_32K). Figure 22-1 is a high-level block diagram of the device timers.

Figure 22-1. Timers Overview

timers-001

The watchdog timer is clocked with 32-kHz clocks. The 32-kHz sync timer, which is reset only at power up, provides the operating system (OS) with a stable timing source that stores the relative time since the last power cycle of the product. The fifteen GP timers, which are useful as basic timers, are included to generate time-stamp-based interrupts to the system software or to use as a source of pulse-width modulation (PWM) signals.

## 22.2 General-Purpose Timers

### 22.2.1 General-Purpose Timers Overview

The device has 16 GP timers: TIMER1 through TIMER16.

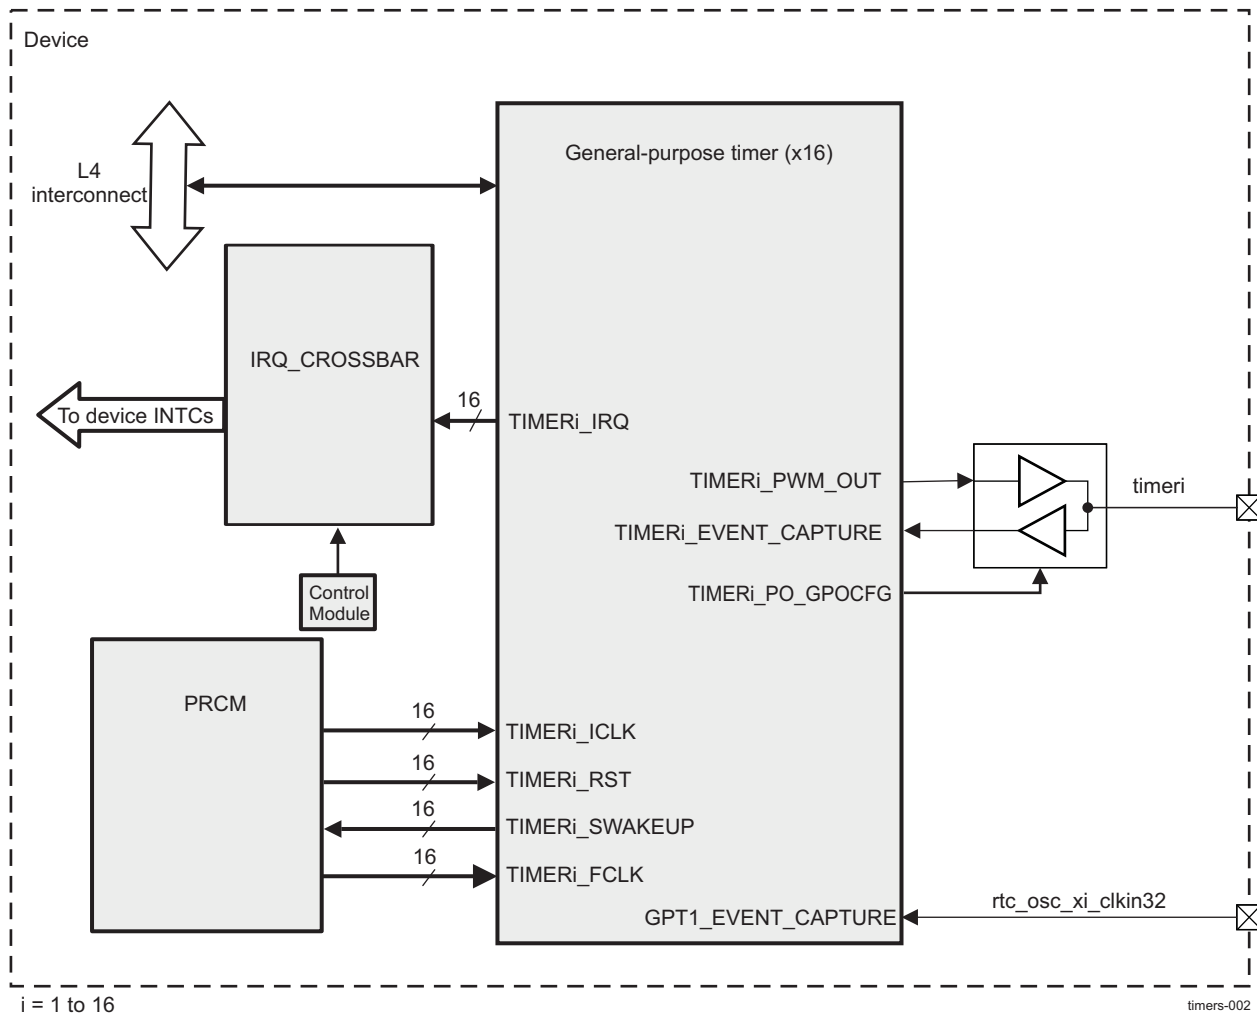

- TIMER1(1ms tick): has its event capture pin tied to 32KHz clock and can be used to gauge the system clock input and detects its frequency among 19.2, 20, or 27 MHz. It includes specific functions to generate accurate tick interrupts to the operating system
- TIMER2 and TIMER10: (1ms tick timers): they include specific functions to generate accurate tick interrupts to the operating system

Each timer (except TIMER12) can be clocked from the system clock (19.2, 20, or 27 MHz) or the 32-kHz clock. The selection of clock source is made at the power, reset, and clock management (PRCM) module level. TIMER12 can be clocked only from the internal oscillator (on-die oscillator). For more information, see [Section 3.6.3.1, PRM Clock Source](#).

Each timer provides an interrupt via the device IRQ\_CROSSBAR.

Each timer is connected to external pin by its PWM output or its event capture input pin (for external timer triggering). [Figure 22-2](#) is an overview of the GP timers.

**Figure 22-2. GP Timers Overview**

#### 22.2.1.1 GP Timer Features

The following are the main features of the GP timer controllers:

- Level 4 (L4) slave interface support:
  - 32-bit data bus width
  - 32-/16-bit access supported
  - 8-bit access not supported
  - 10-bit address bus width
  - Burst mode not supported
  - Write nonposted transaction mode supported
- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Compare and capture modes
- Autoreload mode
- Start/stop mode
- Programmable divider clock source ( $2^n$ , where  $n = [0:8]$ )
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- Dedicated GP output signal for using the `TIMERi_GPO_CFG` signal
- On-the-fly read/write register (while counting)
- 1-ms tick with 32.768-Hz functional clock generated (only `TIMER1`, `TIMER2`, and `TIMER10`)

## 22.2.2 GP Timer Environment

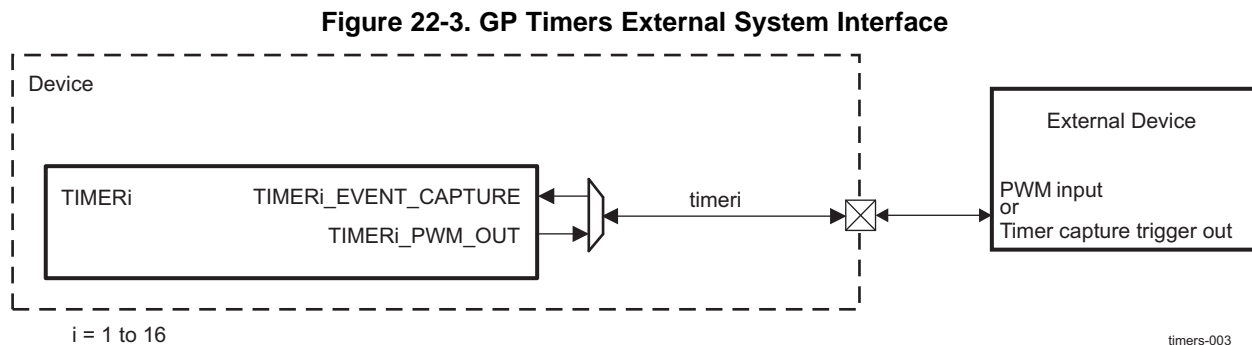

### 22.2.2.1 GP Timer External System Interface

Each timer can send or receive stimulus to/from the external (off-chip) system. In the device all timers are configured to output a PWM pulse or receive an external event signal used as a trigger to capture the current timer count. TIMER1 is also configured to receive an event trigger input (GPT1\_EVENT\_CAPTURE) tied to the internal 32-kHz clock. This event signal gauges the system clock input, detecting its frequency among 19.2, 20, or 27 MHz.

Figure 22-3 shows the external system interface for the GP timers, and Table 22-1 describes the GP timer inputs and outputs.

**NOTE:** Software control must ensure that MUX mode is configured to select the timer<sub>i</sub> (where  $i = 1$  to 16) signal on only one pad. Other pads on which the same signal is multiplexed must be configured in safe mode or non-dmtimer mode to avoid two different pads driving the same signal.

For more information about the configuration of the timer<sub>i</sub> I/O pads, see Section 18.4.6.1.1, *Pad Configuration Registers*.

**Table 22-1. Input/Output Description**

Pin Name	Type <sup>(1)</sup>	Reset Value	Signal Name	Description
timer1	I/O	0	TIMER1_PI_EVENT_CAPTURE TIMER1_PWM_OUT	TIMER1 trigger input/ PWM output
timer2	I/O	0	TIMER2_PI_EVENT_CAPTURE TIMER2_PWM_OUT	TIMER2 trigger input/ PWM output
timer3	I/O	0	TIMER3_PI_EVENT_CAPTURE TIMER3_PWM_OUT	TIMER3 trigger input/ PWM output
timer4	I/O	0	TIMER4_PI_EVENT_CAPTURE TIMER4_PWM_OUT	TIMER4 trigger input/ PWM output
timer5	I/O	0	TIMER5_PI_EVENT_CAPTURE TIMER5_PWM_OUT	TIMER5 trigger input/ PWM output
timer6	I/O	0	TIMER6_PI_EVENT_CAPTURE TIMER6_PWM_OUT	TIMER6 trigger input/ PWM output
timer7	I/O	0	TIMER7_PI_EVENT_CAPTURE TIMER7_PWM_OUT	TIMER7 trigger input/ PWM output
timer8	I/O	0	TIMER8_PI_EVENT_CAPTURE TIMER8_PWM_OUT	TIMER8 trigger input/ PWM output
timer9	I/O	0	TIMER9_PI_EVENT_CAPTURE TIMER9_PWM_OUT	TIMER9 trigger input/ PWM output
timer10	I/O	0	TIMER10_PI_EVENT_CAPTURE TIMER10_PWM_OUT	TIMER10 trigger input/ PWM output
timer11	I/O	0	TIMER11_PI_EVENT_CAPTURE TIMER11_PWM_OUT	TIMER11 trigger input/ PWM output

<sup>(1)</sup> When configured for that function; I = Input, O = Output

**Table 22-1. Input/Output Description (continued)**

Pin Name	Type <sup>(1)</sup>	Reset Value	Signal Name	Description
timer12	I/O	0	TIMER12_PI_EVENT_CAPTURE TIMER12_PWM_OUT	TIMER12 trigger input/ PWM output
timer13	I/O	0	TIMER13_PI_EVENT_CAPTURE TIMER13_PWM_OUT	TIMER13 trigger input/ PWM output
timer14	I/O	0	TIMER14_PI_EVENT_CAPTURE TIMER14_PWM_OUT	TIMER14 trigger input/ PWM output
timer15	I/O	0	TIMER15_PI_EVENT_CAPTURE TIMER15_PWM_OUT	TIMER15 trigger input/ PWM output
timer16	I/O	0	TIMER16_PI_EVENT_CAPTURE TIMER16_PWM_OUT	TIMER16 trigger input/ PWM output

---

**NOTE:** Each `TIMERi_PO_GPOCFG` signal is used to as an output enable to control the function of the `TIMERi` pin (where `i = 1 to 16`) as the PWM output (`PO_GPOCFG = 0`) or capture input (`PO_GPOCFG = 1`).

---

### 22.2.3 GP Timer Integration

Figure 22-4 shows the integration of the GP timer in the device.

Figure 22-4. GP Timer Integration

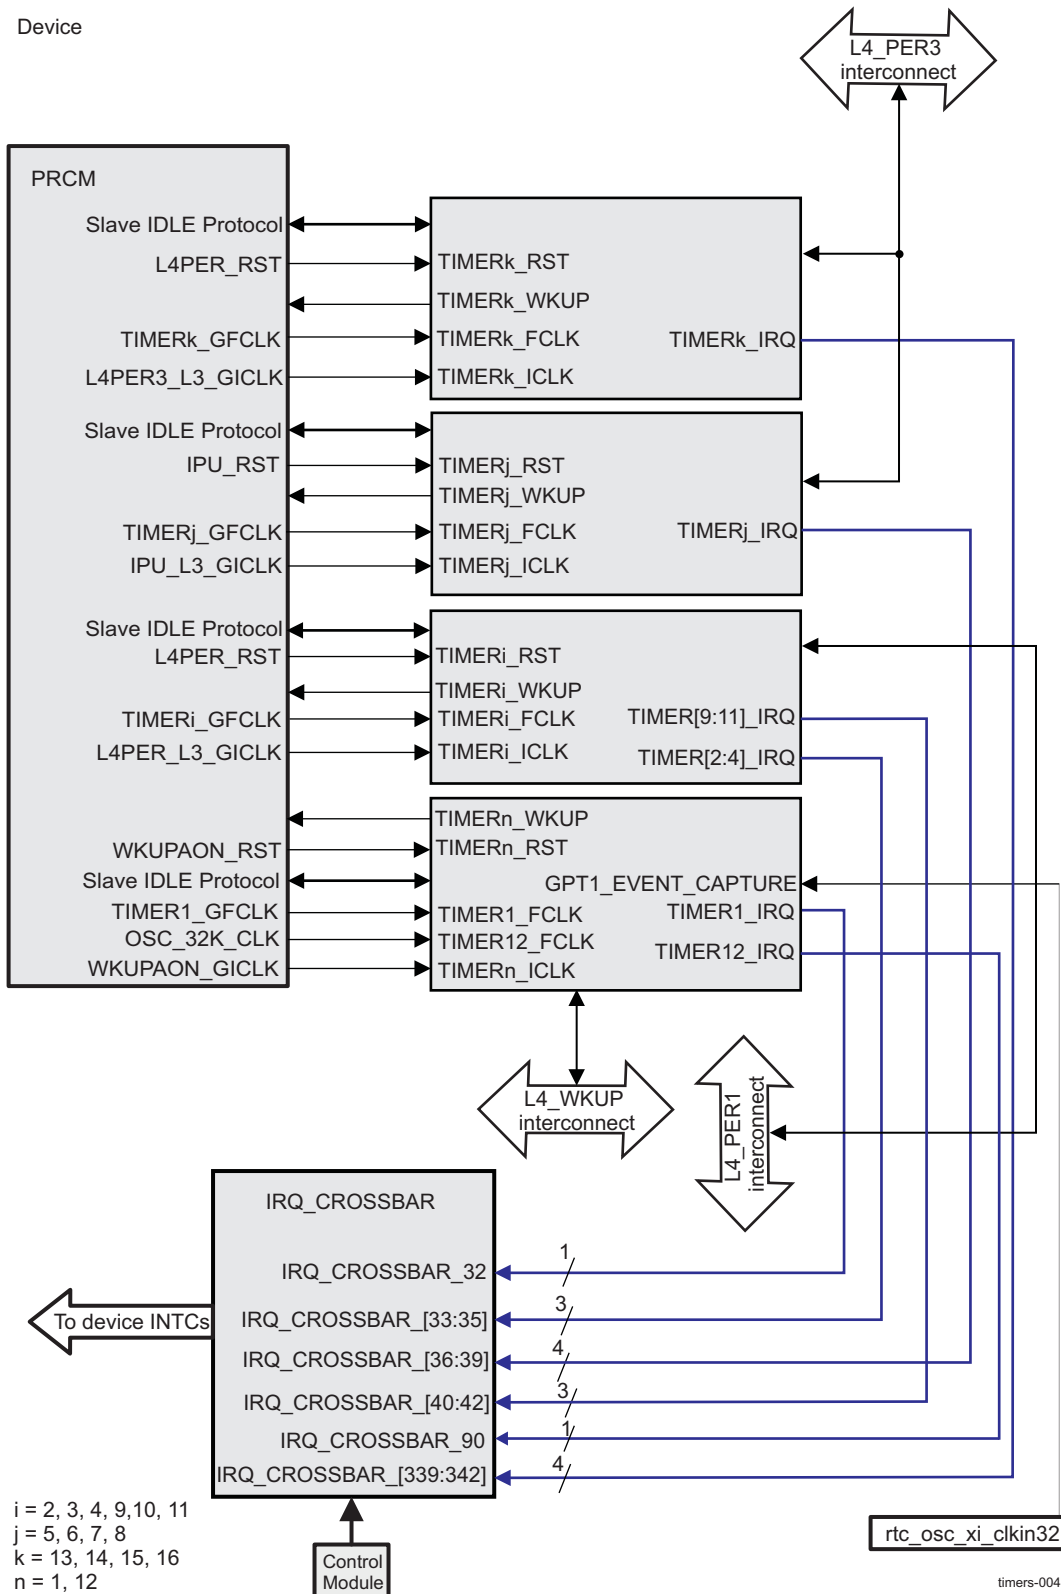

Table 22-2 through Table 22-4 summarize the integration of the module in the device.

**Table 22-2. Integration Attributes**

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
TIMER1	PD_WKUPAON	Yes	L4_WKUP
TIMER2	PD_COREAON	Yes	L4_PER1
TIMER3	PD_COREAON	Yes	L4_PER1
TIMER4	PD_COREAON	Yes	L4_PER1
TIMER5	PD_COREAON	Yes	L4_PER3
TIMER6	PD_COREAON	Yes	L4_PER3
TIMER7	PD_COREAON	Yes	L4_PER3

TIMER15	TIMER15_IRQ	IRQ_CROSSBAR_341	-	TIMER15 interrupt. This IRQ source signal is not mapped by default to any device INTC
TIMER16	TIMER16_IRQ	IRQ_CROSSBAR_342	-	TIMER16 interrupt. This IRQ source signal is not mapped by default to any device INTC
<b>No DMA Requests</b>				

**NOTE:** The “**Default Mapping**” column in [Table 22-4 GP Timers Hardware Requests](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ\_CROSSBAR module.

For more information about the IRQ\_CROSSBAR module, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#). For more information about the device interrupt controllers, see [Chapter 17, Interrupt Controllers](#).

**NOTE:** For the description of the interrupt source, see [Section 22.2.4.5, GP Timer Interrupt](#).

## 22.2.4 GP Timer Functional Description

Each GP timer contains a free-running upward counter with autoreload capability on overflow. The timer counter can be read and written on-the-fly (while counting). Each GP timer includes compare logic to allow an interrupt event on a programmable counter matching value. A dedicated output signal can be pulsed or toggled on either an overflow or a match event. This offers time-stamp trigger signaling or PWM signal sources. A dedicated input signal can be used to trigger an automatic timer counter capture or an interrupt event on a programmable input signal transition. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged into one module interrupt line and one wake-up line.

Each internal interrupt source can be independently enabled and disabled by a dedicated bit in the [IRQSTATUS\\_SET](#) and [IRQSTATUS\\_CLR](#) register for the interrupt features, and a dedicated bit of the [IRQWAKEEN](#) register for the wake-up of TIMER1, TIMER2, and TIMER10. In addition, these timers have a mechanism implemented to generate an accurate tick interrupt.

For all other internal interrupt source can be independently enabled and disabled through the [IRQENABLE\\_SET](#) and [IRQENABLE\\_CLR](#) registers.

For each GP timer implemented in the device, there are two possible clock sources:

- 32-kHz clock
- System clock

Selection of the input clock source is done in the registers in the PRCM configuration (see [Section 22.2.1, GP Timer Overview](#)).

Each GP timer supports three functional modes:

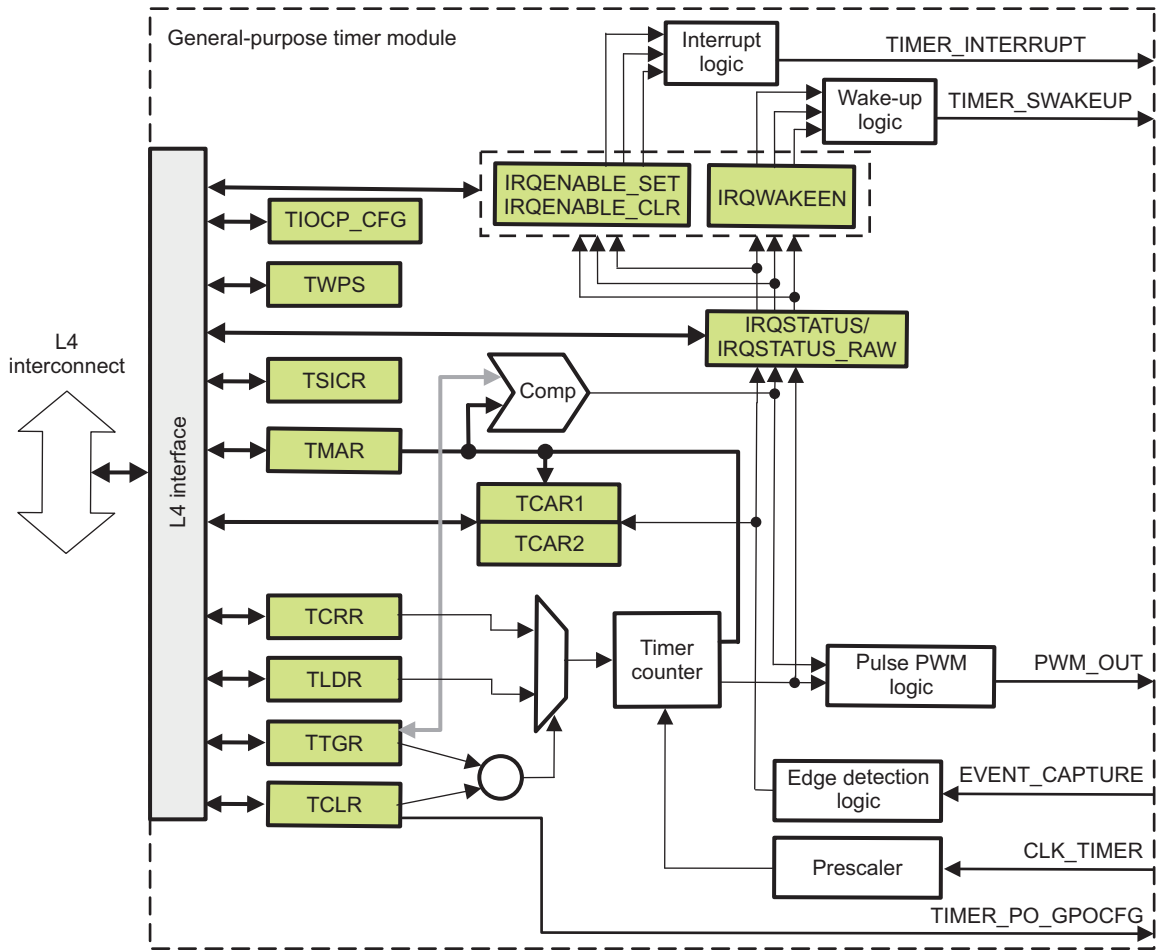

- Timer mode
- Capture mode
- Compare mode

The capture and compare modes are disabled by default after core reset.

### 22.2.4.1 GP Timer Block Diagram

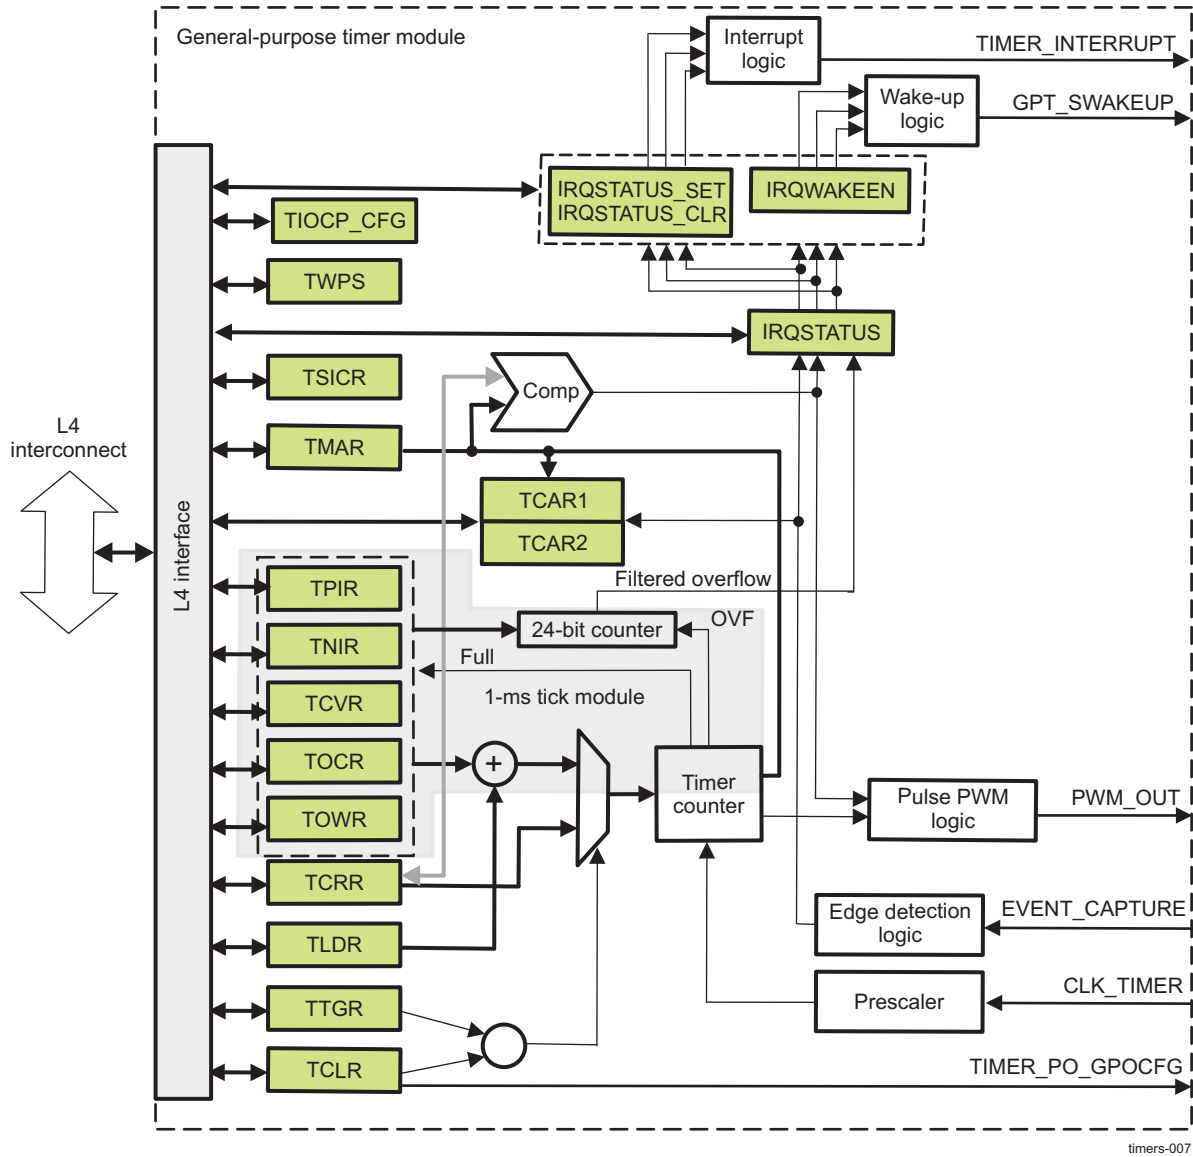

[Figure 22-5](#) is a block diagram of the common GP timers, and [Figure 22-6](#) is a block diagram of the GP timers with a 1-ms tick generation module.

timers-006

Figure 22-6. Block Diagram of TIMER1, TIMER2 and TIMER10

timers-007

## 22.2.4.2 TIMER1, TIMER2 and TIMER10 Power Management

At the PRCM module level, when all conditions to shut off the functional or interface output clocks in the PRCM module are met (see [Section 3.1.1.1.4, Clock Domain-Level Clock Management](#)), the PRCM module automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the `TIOCP_CFG[3:2]` IDLEMODE bit field.

[Table 22-5](#) lists the IDLEMODE settings and the related acknowledgment modes.

**Table 22-5. IDLEMODE Settings**

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The GP timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, because it does not allow the PRCM output clock to be shut off, and thus the power domain to be set to a lower power state.
10	Smart-idle	The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach to efficient system power management.
11	Smart-idleWakeup	The module behaves like in Smart-idle mode, with the exception, that it can issue a wake-up request in sleep mode, if the functional clock is not cut off.

### 22.2.4.2.1 Wake-Up Capability

If the `TIOCP_CFG[3:2]` IDLEMODE bit field sets the smart-idle mode or smart-idle with wakeup mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request if is configured in smart-idle with wakeup mode.

[Figure 22-7](#) shows the wake-up request generation. For more information about the GP timer clock control, [Section 3.6, Clock Management Functional Description](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Figure 22-7. Wake-Up Request Generation

timers-005

For TIMER1, TIMER2 and TIMER10, the timer wake-up-enable register allows masking of the expected source of the wake-up event that generates a wake-up request. The register is synchronously programmed with the interface clock before the PRCM module sends an idle mode request. The expected source of the wake-up event is an overflow (TCRR), a timer match (the compare result of TCRR and TMAR matches the counter value), and a timer capture (detection of an external pulse transition of the correct polarity on the TIMER\_EVENT\_CAPTURE).

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (IRQSTATUS). The pending wake-up event is reset when the set status bit is overwritten with 1.

**NOTE:** The status bit must be reset to re-enter idle mode.

### 22.2.4.3 Power Management of Other GP Timers

At the PRCM module level, when all conditions to shut off the functional or interface output clocks of the PRCM module are met (see Section 3.1.1.1.4, *Clock Domain-Level Clock Management*), the PRCM module automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the TIOCP\_CFG[3:2] IDLEMODE bit field.

Table 22-6 lists the IDLEMODE settings and the related acknowledgment modes.

Table 22-6. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The GP timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, however, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.

**Table 22-6. IDLEMODE Settings (continued)**

IDLEMODE Value	Selected Mode	Description
10	Smart-idle	The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach to efficient system power management.
11	Smart-idleWakeup	The module behaves like in Smart-idle mode, with the exception, that it can issue a wake-up request in sleep mode, if the functional clock is not cut off.

**22.2.4.3.1 Wake-Up Capability**

If the `TIOCP_CFG[3:2]` IDLEMODE bit field sets the smart-idle mode or smart-idle with wakeup mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request if is configured in smart-idle with wakeup mode. This wake-up request is sent only if the `IRQWAKEEN[2:0]` bit field enables the timer wake-up capability.

Figure 22-8 shows the wake-up request generation. For more information about the GP timer clock control, see Section 3.6, *Clock Management Functional Description*, in Chapter 3, *Power, Reset, and Clock Management*.

**Figure 22-8. Wake-Up Request Generation**

timers-014

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (`IRQSTATUS`). The pending wake-up event is reset when the set status bit is overwritten with 1.

**NOTE:** The status bit must be reset to re-enter idle mode.

**22.2.4.4 Software Reset**

Two bits can generate a software reset of the GP timer:

- `TIOCP_CFG[0]` SOFTRESET
- `TSICR[1]` SFT

For both bits, all read accesses return 0.

The `TIOCP_CFG[0]` SOFTRESET bit allows resetting of the functional and interface domains. The `TSICR[1]` SFT bit allows resetting the functional part of the GP timer.

Before accessing or using the GP timer, the local host must ensure that both internal resets are released by reading the `TIOCP_CFG[0]` SOFTRESET bit. This bit monitors the internal reset status.

### 22.2.4.5 GP Timer Interrupts

The timer can issue an overflow interrupt, a timer match interrupt, and a timer capture interrupt. Each internal interrupt source can be independently enabled and disabled in the interrupt-enable register (`IRQSTATUS_SET` for `TIMER1/2/10` and `IRQENABLE_SET` for other timers) and disabled in the interrupt-disable register (`IRQSTATUS_CLR` for `TIMER1/2/10` and `IRQENABLE_CLR` for other timers). When the interrupt event is issued, the associated interrupt status bit is set in the timer status register (`IRQSTATUS`).

### 22.2.4.6 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the timer control register (the `TCLR[0]` ST bit). The timer counter register (`TCRR`) can be loaded when stopped or on-the-fly (while counting). `TCRR` can be loaded directly by a `TCRR` write access with a new timer value. `TCRR` can also be loaded with the value held in the timer load register (`TLDR`) by a trigger register (`TTGR`) write access. The loading of `TCRR` is done regardless of the written value of `TTGR`. The value of `TCRR` can be read when stopped or captured on-the-fly by a `TCRR` read access. The timer is stopped and the counter value is set to 0 when the module reset is asserted. The timer is maintained at stop after the reset is released.

In one-shot mode (the `TCLR[1]` AR bit is set to 0), the counter is stopped after counting overflow occurs (the counter value remains at 0).

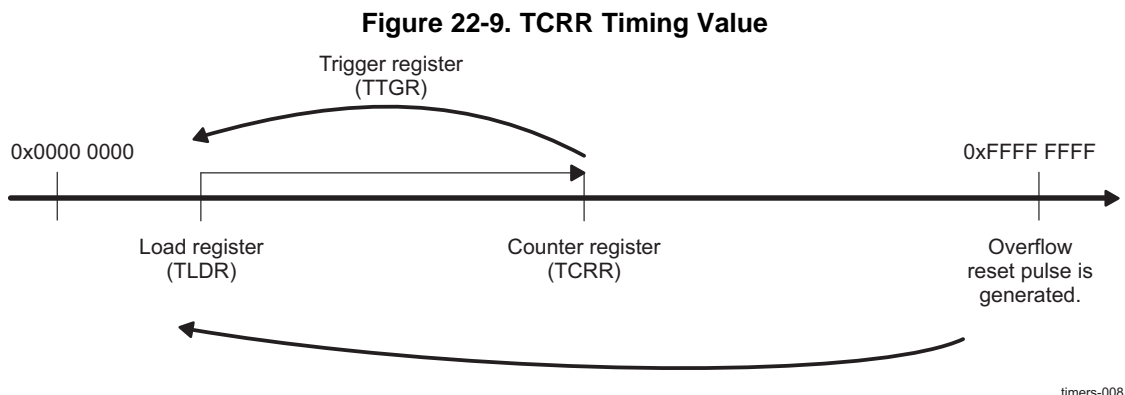

When the autoreload mode is enabled (the `TCLR[1]` AR bit is set to 1), `TCRR` is reloaded with the value of `TLDR` after a counting overflow occurs.

**CAUTION**

Do not put the overflow value (0xFFFF FFFF) in the `TLDR` register because it can lead to undesirable results.

An interrupt can be issued on overflow if the overflow interrupt-enable bit is set in the timer interrupt-enable register (the `IRQSTATUS_SET[1]` `OVF_EN_FLAG` bit is set to 1 for `TIMER1/2/10` and the `IRQENABLE_SET[1]` `OVF_EN_FLAG` bit is set to 1 for other timers). A dedicated output pin (timer PWM) can be programmed in the `TCLR[12]` PT bit through the `TCLR[11:10]` (PT and TRG bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs. The `TCLR[12]` PT bit selects pulse/toggle modulation (the `TCLR[11:10]` TRG bit field selects trigger mode).

Figure 22-9 shows the `TCRR` timing value.

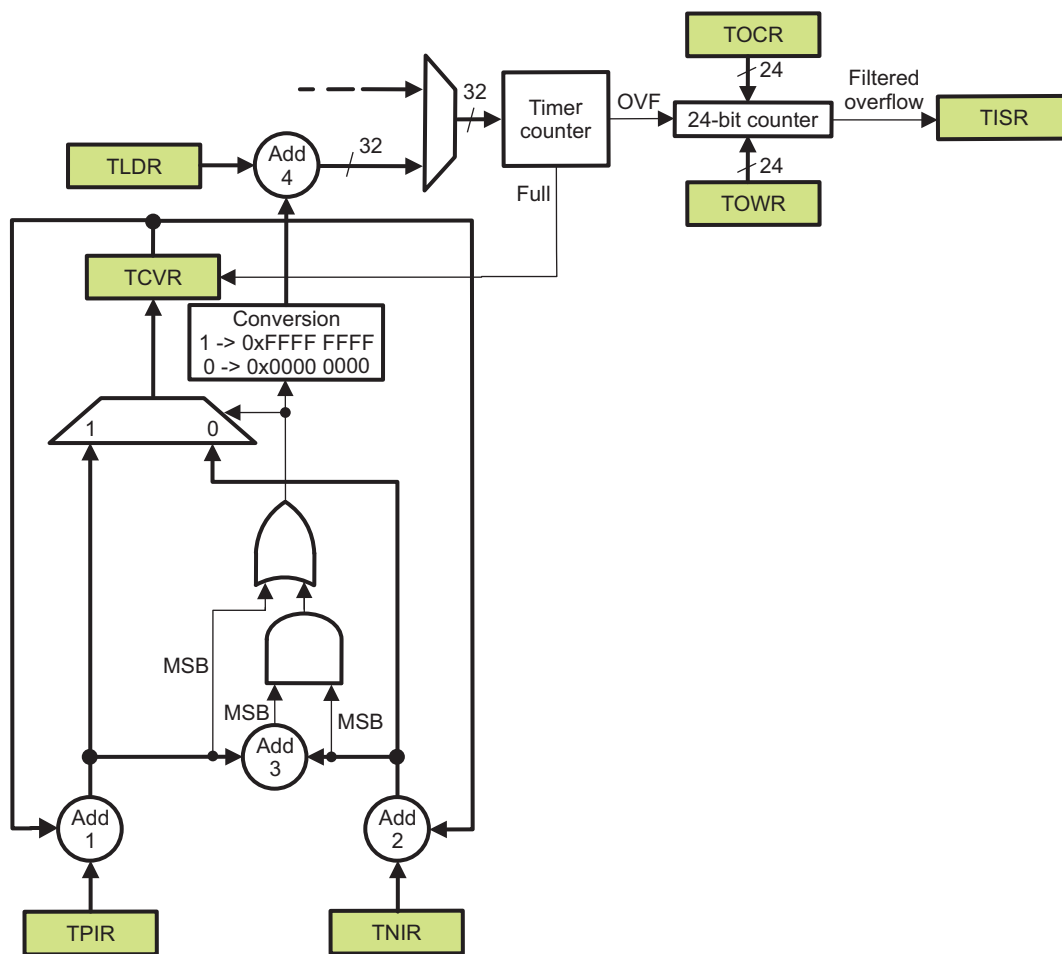

**22.2.4.6.1 1-ms Tick Generation (Only TIMER1, TIMER2 and TIMER10)**

The interrupt period is not exactly 1 ms, because the timer input clock is 32.768 Hz. If the clock counts up to 32, it obtains a 0.977-ms period; if it counts up to 33, it obtains a 1.007-ms period. For large granularity, the error is cumulative and can generate important deviations from the standard value.

To minimize the error between a true 1-ms tick and the tick generated by the 32.768-Hz timer, the sequencing of periods less than 1 ms and periods greater than 1 ms must be shuffled. An additional 1-ms block is used to correct this error. See [Figure 22-10](#).

In this implementation, the increment sequencing is automatically managed by the timer to minimize the error. The user must define only the value of the timer positive increment register (the **TPIR**[31:0] POSITIVE\_INC\_VALUE bit field) and the timer negative increment register (the **TNIR**[31:0] NEGATIVE\_INC\_VALUE bit field). An automatic adaptation mechanism is used to simplify the programming model.

**Figure 22-10. Block Diagram of the 1-ms Tick Module**

timers-009

The **TPIR**, **TNIR**, and **TCVR** registers and adders Add1, Add2, and Add3 are used to define whether the next value loaded in the timer counter register (the **TCRR**[31:0] TIMER\_COUNTER bit field) is the value of the **TLDR**[31:0] LOAD\_VALUE bit field (period less than 1 ms) or the value of **TLDR**[31:0] LOAD\_VALUE -1 (period greater than 1 ms).

[Table 22-7](#) lists the value loaded in the **TCRR** according to the sign of the result of Add1, Add2, and Add3.

MSB = 0: Positive value; MSB = 1: Negative value

**Table 22-7. Value Loaded in TCRR to Generate 1-ms Tick**

Add1 MSB	Add2 MSB	Add3 MSB	Value of TCRR Register
0	0	0	TLDR[31:0] LOAD_VALUE bit field
0	0	1	TLDR[31:0] LOAD_VALUE bit field
0	1	0	TLDR[31:0] LOAD_VALUE bit field
0	1	1	TLDR[31:0] LOAD_VALUE -1
1	0	0	N/A
1	0	1	N/A
1	1	0	TLDR[31:0] LOAD_VALUE -1
1	1	1	TLDR[31:0] LOAD_VALUE -1

The values of the TPIR and TNIR registers are calculated using the following formulas:

- Positive increment value =  $((\text{INTEGER}[F_{\text{clk}} \times T_{\text{tick}}] + 1) \times 1\text{e}6) - (F_{\text{clk}} \times T_{\text{tick}} \times 1\text{e}6)$
- Negative increment value =  $(\text{INTEGER}[F_{\text{clk}} \times T_{\text{tick}}] \times 1\text{e}6) - (F_{\text{clk}} \times T_{\text{tick}} \times 1\text{e}6)$

**NOTE:**  $F_{\text{clk}}$  clock frequency (kHz)

$T_{\text{tick}}$  tick period (ms)

The timer overflow counter register (TOCR) and the timer overflow wrapping register (TOWR) are used to filter interrupts. When the timer overflows, it increments the 24-bit TOCR. When the values in the 24-bit TOCR match the values in the 24-bit TOWR and the timer overflow is asserted, the TOCR is reset and an interrupt is generated to the IRQSTATUS register.

**NOTE:** TOWR has to be set to requested value. For example, if no interrupt needs to be masked TOWR must be set to 0, if one interrupt needs to TOWR must be set to 1, if two interrupt need to be masked TOWR must be set to 2 and so on.

It is important to have in mind that the case when FFFFFFF interrupt need to be masked is not possible.

With the conversion block in reset state (the positive increment register, negative increment register, and counter value register are zeroed), the programming model and the behavior of TIMER1, TIMER2, and TIMER10 remain unchanged.

For 1-ms tick with a 32.768-Hz clock:

- TPIR[31:0] POSITIVE\_INC\_VALUE = 232,000
- TNIR[31:0] NEGATIVE\_INC\_VALUE = -768,000
- TLDR[31:0] LOAD\_VALUE = 0xFFFF FFE0

**NOTE:** Any value of the tick period can be generated with the appropriate value of the TPIR, TNIR, and TLDR.

By default, the TPIR, TNIR, TCVR, TOCR, and TOWR and the associated logic are in reset mode (all 0s) and have no effect on the programming model.

### 22.2.4.7 Capture Mode Functionality

When a transition is detected on the module input pin (EVENT\_CAPTURE), the timer value in the TCRR can be captured and saved in the TCAR1 or TCAR2 register function of the mode selected in the TCLR[13] CAPT\_MODE bit. The edge detection circuitry monitors transitions on the input pin (EVENT\_CAPTURE).

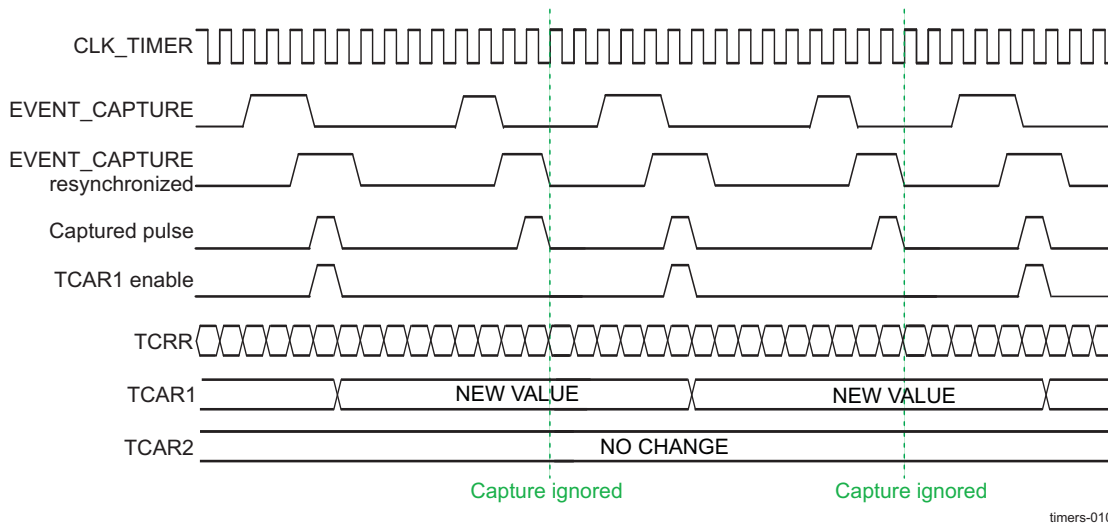

The rising edge, falling edge, or both, can be selected in the **TCLR[9:8]** TCM bit field to trigger the timer counter capture. The module sets the **IRQSTATUS[2]** **TCAR\_IT\_FLAG** bit when an active edge is detected, and at the same time, the counter value **TCRR** is stored in timer capture register **TCAR1** or **TCAR2**, as follows:

- If the **TCLR[13]** **CAPT\_MODE** bit is 0, on the first enabled capture event, the value of the counter register is saved in the **TCAR1** register, and the next events are ignored (no update on the **TCAR1** register and no interrupt triggering) until the detection logic is reset or the **IRQSTATUS[2]** **TCAR\_IT\_FLAG** is cleared by writing 1 to it.
- If the **TCLR[13]** **CAPT\_MODE** bit is 1, on the first enabled capture event, the value of the counter register is saved in the **TCAR1** register, and on the second enabled capture event, the value of the counter register is saved in the **TCAR2** register. If a capture interrupt is enabled, the interrupt triggers on the second event capture. All other events are ignored (no update on **TCAR1/TCAR2** and no interrupt triggering) until the detection logic is reset or the **IRQSTATUS[2]** **TCAR\_IT\_FLAG** bit is cleared by writing 1 to it. This mechanism is useful for period calculation of a clock, if that clock is connected to the **EVENT\_CAPTURE** input pin.

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served. The **IRQSTATUS[2]** **TCAR\_IT\_FLAG** bit is cleared by writing 1 to it or when the edge detection mode bits (the **TCLR[9:8]** TCM bit field) are changed from no-capture mode detection to any other mode. The timer functional clock (input to prescaler) is used to sample the input pin (**EVENT\_CAPTURE**). A negative or positive pulse input can be detected when the pulse time is greater than the functional clock period. An interrupt is issued on edge detection if the capture interrupt-enable bit is set in the **IRQSTATUS\_SET[2]** **TCAR\_EN\_FLAG** bit (for **TIMER1/2/10**) or in the **IRQENABLE\_SET[2]** **TCAR\_EN\_FLAG** bit (for other timers). See the examples in [Figure 22-11](#) and [Figure 22-12](#).

In [Figure 22-11](#), the value of the **TCLR[9:8]** TCM bit field is 0b01, and the **TCLR[13]** **CAPT\_MODE** bit is 0. Only the rising edge of **EVENT\_CAPTURE** triggers a capture in the **TCAR1** and **TCAR2** registers, and only the **TCAR1** register updates.

**Figure 22-11. Capture Wave Example for **TCLR[13]** **CAPT\_MODE** = 0**

In [Figure 22-12](#), the value of the **TCLR[9:8]** TCM bit field is 0b01, and the **TCLR[13]** **CAPT\_MODE** bit is 1. Only the rising edge of **EVENT\_CAPTURE** triggers a capture in the **TCAR1** register on the first enabled event, and the **TCAR2** register updates on the second enabled event.

**Figure 22-12. Capture Wave Example for TCLR[13] CAPT\_MODE = 1**

#### 22.2.4.8 Compare Mode Functionality

When the compare-enable register [TCLR\[6\]](#) CE bit is set to 1, the timer value (the [TCRR\[31:0\]](#) TIMER\_COUNTER bit field) is continuously compared to the value held in the timer match register ([TMAR](#)). The value of the [TMAR\[31:0\]](#) COMPARE\_VALUE bit field can be loaded at any time (timer counting or stopped). When the [TCRR](#) and the [TMAR](#) values match, an interrupt is issued, if the [IRQSTATUS\\_SET\[0\]](#) MAT\_EN\_FLAG bit (for TIMER1, TIMER2, and TIMER10), or the [IRQENABLE\\_SET\[0\]](#) MAT\_EN\_FLAG bit (for other timers) is set.

To prevent any unwanted interrupts due to reset value matching effect, write a compare value to the [TMAR](#) before setting the [TCLR\[6\]](#) CE bit.

The dedicated output pin (timer PWM) can be programmed in the [TCLR\[12\]](#) PT bit through the [TCLR\[11:10\]](#) TRG bit field to generate one positive pulse (timer clock duration) or to invert the current value (toggle mode) when an overflow or a match occurs.

#### 22.2.4.9 Prescaler Functionality

A prescaler can be used to divide the timer counter input clock frequency. The prescaler is enabled when the [TCLR\[5\]](#) PRE bit is set. The [TCLR\[4:2\]](#) PTV bit field sets the  $2^n$  division ratio (prescaler value is  $2^{(PTV + 1)}$ ). The prescaler counter is reset when the timer counter is stopped or reloaded on-the-fly.

[Table 22-8](#) lists the prescaler/timer reload values versus contexts.

**Table 22-8. Prescaler/Timer Reload Values Versus Contexts**

Context	Prescaler	Timer Counter
Overflow (when autoreload is on)	Reset	<a href="#">TLDR[31:0]</a>
<a href="#">TCRR</a> write	Reset	<a href="#">TCRR[31:0]</a>
<a href="#">TTGR</a> write	Reset	<a href="#">TLDR[31:0]</a>
Stop	Reset	Frozen

### 22.2.4.10 Pulse-Width Modulation

The timer can be configured to provide a programmable PWM output. The timer PWM output pin can be configured to toggle on an event. The **TCLR[11:10]** TRG bit field determines on which register value the PWM pin toggles. Either overflow or both overflow and match can be selected to toggle the timer PWM pin when a compare condition occurs.

**NOTE:** In toggle mode, when **TCLR[11:10]** TRG = 0x2 (overflow and match), the first event that toggles the PWM line is an overflow event. If a match event occurs first, it does not toggle the PWM line (see [Figure 22-14](#)).

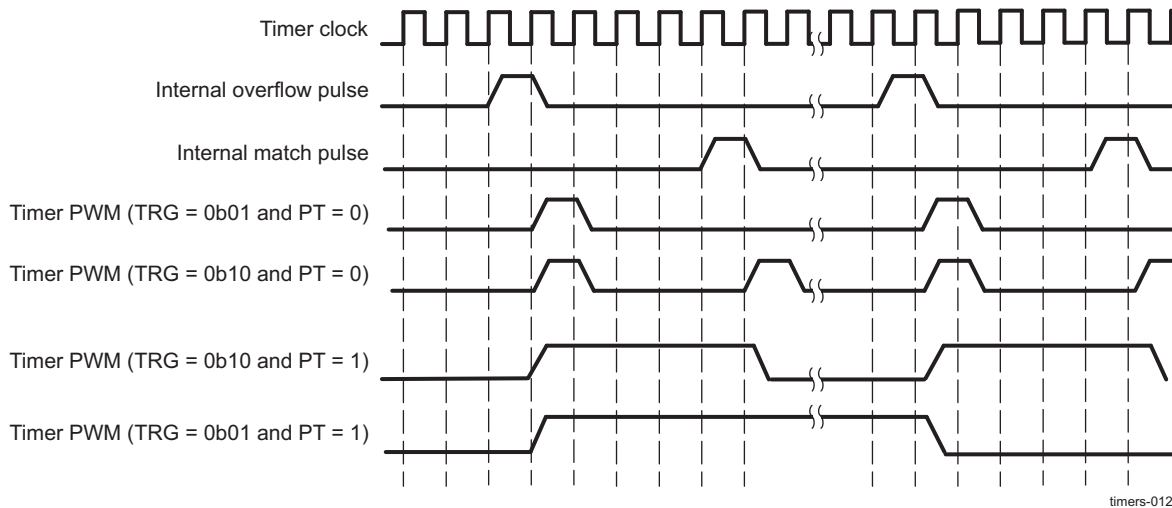

The **TCLR[7]** SCPWM bit can be programmed to set or clear the timer PWM output signal only while the counter is stopped or the trigger is off. This allows setting the output pin to a known state before modulation starts. Modulation synchronously stops when the **TCLR[11:10]** TRG bit field is cleared and overflow occurs. This allows fixing a deterministic state of the output pin when modulation stops.

In [Figure 22-13](#), the internal overflow pulse is set each time the (0xFFFF FFFF – **TLDR**[31:0] **LOAD\_VALUE** + 1) value is reached, and the internal match pulse is set when the counter reaches the value of **TMAR**. Depending on the value of the **TCLR[12]** PT bit and **TCLR[11:10]** TRG bit field, the timer provides pulse or PWM event on the output pin (timer PWM).

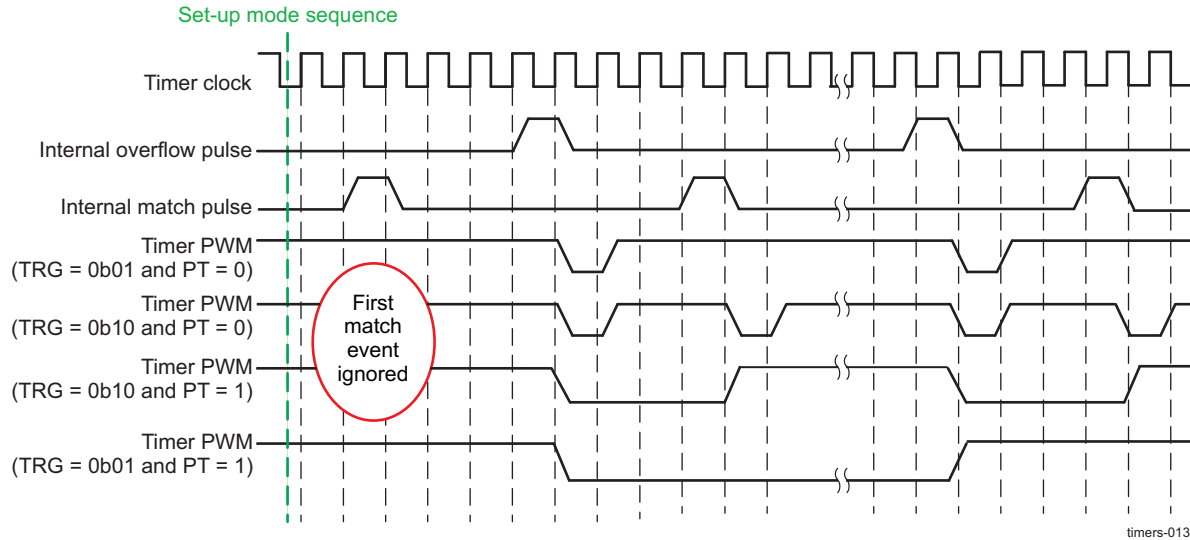

The **TLDR** and **TMAR** must keep values below the overflow value (0xFFFF FFFF) by at least two units. If the PWM trigger events are both overflow and match, the difference between the values kept in the **TMAR** and the value in the **TLDR** must be at least two units. When match event is used, the compare mode **TCLR[6]** CE bit must be set.

In [Figure 22-13](#), the **TCLR[7]** SCPWM bit is set to 0. In [Figure 22-14](#), the **TCLR[7]** SCPWM bit is set to 1. To obtain the desired wave form, start the counter at 0xFFFF FFFE value (to ensure an overflow first) or adjust the line polarity (**TCLR[7]** SCPWM bit).

**Figure 22-13. Timing Diagram of PWM With **TCLR[7]** SCPWM Bit = 0**

**Figure 22-14. Timing Diagram of PWM With TCLR[7] SCPWM Bit = 1**

timers-013

### 22.2.4.11 Timer Counting Rate

The timer rate is defined by the following values:

- Value of the prescaler fields (the **TCLR[5]** PRE bit and **TCLR[4:2]** PTV bit field)
- Value loaded into the **TLDR**

Table 22-9 lists the prescaler clock ratio values.

**Table 22-9. Prescaler Clock Ratio Values**

<b>TCLR[5] PRE</b>	<b>TCLR[4:2] PTV</b>	<b>Divisor (PS)</b>
0	X	1
1	0	2
1	1	4
1	2	8
1	3	16
1	4	32
1	5	64
1	6	128
1	7	256

Thus, the timer overflow rate is expressed as:

$$OVF\_Rate = (0xFFFF FFFF - TLDR + 1) \times (\text{timer-functional clock period}) \times PS$$

With (timer-functional clock period) = 1/(timer-functional clock frequency) and PS = 2<sup>(PTV + 1)</sup> if prescaler is enabled, or PS = 1 if prescaler is disabled.

### CAUTION

Internal resynchronization causes any write to the **TCLR[1]** ST bit to have some latency before the register is updated:

2.5 × functional clock cycles write\_TIMER\_TCLR\_latency 3.5 × functional clock cycles

Remember to consider this latency whenever the timer must be started or stopped by a software change to the **TCLR[1]** ST bit.

### CAUTION

- In non-PWM mode, **TLDR** must be maintained at less than or equal to 0xFFFF FFFE.
- In PWM mode, **TLDR** must be maintained at less than or equal to 0xFFFF FFFD.

For example, with a timer clock input of 32 kHz and the **TCLR[5]** PRE bit set to 0, the timer output period is as listed in [Table 22-10](#).

**Table 22-10. Value and Corresponding Interrupt Period**

<b>TLDR[31:0] LOAD_VALUE</b>	<b>Interrupt Period</b>
0x0000 0000	37 h
0xFFFF 0000	2 s
0xFFFF FFF0	500 μs
0xFFFF FFFE	62.5 μs

#### 22.2.4.12 Timer Under Emulation

During emulation mode, the timer continues to run according to the value of the **TIOCP\_CFG[1]** EMUFREE bit.

If the **TIOCP\_CFG[1]** EMUFREE bit is set to 1, timer execution is not stopped in emulation mode and the interrupt is still generated when overflow or match is reached.

If the **TIOCP\_CFG[1]** EMUFREE bit is set to 0, the prescaler and timer are frozen and both resume on exit from emulation mode. The asynchronous external input pin (timerx\_pwm\_evt, where x = [8:11]) is internally synchronized on two timer-clock rising edges.

#### 22.2.4.13 Accessing GP Timer Registers

All accesses are nonposted until software reconfiguration. All registers are 32 bits wide, accessible through the OCP interface with 16- or 32-bit access (read/write).

Any 16-bit write access must be least-significant bit (LSB) first, and the second write access must be most-significant bit (MSB) first. Write operations to the following GP timer registers can skip the MSB access if it is not necessary to update the 16 MSBs of the register:

- **TIDR** (all GP timers)
- **TIOCP\_CFG** (all GP timers)
- **IRQSTATUS\_SET** (GP timers 1, 2, 10)
- **IRQSTATUS\_RAW** (all GP timers)
- **IRQSTATUS** (all GP timers)
- **IRQENABLE\_SET** (all GP timers except 1,2,10)
- **IRQENABLE\_CLR** (all GP timers except 1,2,10)

- [IRQSTATUS\\_SET](#) (GP timers 1, 2, 10)
- [IRQSTATUS\\_CLR](#) (GP timers 1, 2, 10)
- [IRQWAKEEN](#) (all GP timers)
- [TSICR](#) (all GP timers)

Write operations to the following functional registers must be complete (the MSB must be written even if the MSB data is not used):

- [TCLR](#) (all GP timers)
- [TCRR](#) (all GP timers)
- [TLDR](#) (all GP timers)
- [TTGR](#) (all GP timers)
- [TMAR](#) (all GP timers)
- [TPIR](#) (GP timers 1, 2, 10)
- [TNIR](#) (GP timers 1, 2, 10)
- [TCVR](#) (GP timers 1, 2, 10)
- [TOCR](#) (GP timers 1, 2, 10)
- [TOWR](#) (GP timers 1, 2, 10)

The following L4 synchronous registers are not affected by the posted/nonposted mode selection; the write/read operation is effective and acknowledged (command accepted) after one L4 clock cycle from command assertion:

- [TIDR](#)
- [TIOCP\\_CFG](#)
- [IRQSTATUS](#)
- [IRQSTATUS\\_RAW](#)
- [IRQENABLE\\_SET](#)
- [IRQENABLE\\_CLR](#)
- [IRQSTATUS\\_SET](#)
- [IRQSTATUS\\_CLR](#)
- [IRQWAKEEN](#)
- [TWPS](#)
- [TSICR](#)

#### 22.2.4.13.1 Writing to Timer Registers

The host uses the OCP interface to write to the following registers synchronously with the timer interface clock:

- [TLDR](#)
- [TCRR](#)
- [TCLR](#)
- [TIOCP\\_CFG](#)
- [IRQSTATUS](#)
- [IRQENABLE\\_SET](#)
- [IRQENABLE\\_CLR](#)
- [IRQWAKEEN](#)
- [TTGR](#)
- [TSICR](#)
- [TMAR](#)

TIMER1, TIMER2, and TIMER10 also have the following registers:

- [IRQSTATUS\\_SET](#)
- [IRQSTATUS\\_CLR](#)
- [TPIR](#)
- [TNIR](#)
- [TCVR](#)
- [TOCR](#)
- [TOWR](#)

In 16-bit access mode, the 16 LSBs must be written before writing to the 16 MSBs.

#### **22.2.4.13.1.1 Write Posting Synchronization Mode**

This mode is used if the [TSICR](#)[2] POSTED bit is set to 1.

This mode uses a posted write scheme to update any internal register ([TCLR](#), [TCRR](#), [TLDR](#), [TTGR](#), [TMAR](#), and [TPIR](#), [TNIR](#), [TCVR](#), [TOCR](#), and [TOWR](#) for TIMER1, TIMER2, and TIMER10). Therefore, the write transaction is immediately acknowledged on the open-core protocol (OCP) interface, although the effective write operation occurs later because of a resynchronization in the timer clock domain. The advantage is that neither the interconnect nor the device that requested the write transaction is stalled.

For each register, a status bit is provided in the timer write-posted status ([TWPS](#)) register. In this mode, it is mandatory that software check this status bit before any write access. If a write is attempted to a register with a previous access pending, the previous access is discarded without notice.

The timer module updates the value of the timer counter register synchronously with the OCP clock. Consequently, any read access to [TCRR](#) does not add any resynchronization latency; the current value is always available.

---

**NOTE:** Because the overflow IRQ is generated when the value of [TCRR](#) reaches 0xFFFF FFFF, and not when it changes its value to the value after overflow, it is necessary to wait a delay of (1 × PS × timer functional clock period) before any read access to [TCRR](#) to ensure a correct reading of its content.

---

**NOTE:** If [TTGR](#) register is written during posted write to [TCRR](#), the value to be written to [TCRR](#) will be discarded.

If a posted write to [TCVR](#) is started, the user must not write to [TPIR](#) or [TNIR](#) before the [TCVR](#) write is finished, because the value of [TCVR](#) is re-evaluated, so both the value to be written, and the recalculated value will be discarded.

---

If a write access is pending for a register, reading from this register does not yield a correct result. Software synchronization must be used to avoid incorrect results.

Functional frequency range:  $\text{freq}(\text{timer clock}) < \text{freq}(\text{OCP interface clock}) / 4$ .

#### **22.2.4.13.1.2 Write Nonposting Synchronization Mode**

This mode is used if the [TSICR](#)[2] POSTED bit is set to 0 (default value). It uses a nonposted write scheme to update any internal register. Therefore, the write transaction is not acknowledged on the L4 interface until the effective write operation occurs after the resynchronization in the timer functional clock domain. The drawback is that the interconnect and the device that requested the write transaction are stalled during this period.

The same full resynchronization scheme is used for a read transaction, and the same stall period applies. A register read following a write to the same register is always coherent.

This mode is functional regardless of the ratio between the OCP interface frequency and the timer clock frequency.

### 22.2.4.13.2 Reading From Timer Counter Registers

In 16-bit access mode, reading the 16 LSBs from the timer counter registers ([TCRR](#), [TCAR1](#), and [TCAR2](#)) captures the current timer counter value. This must be followed by reading the 16 MSBs. The synchronization schemes for read posted and read non-posted transactions are the same as the corresponded write transactions described before.

---

**NOTE:** LSB/MSB accesses cannot be interleaved (that is, the sequence LSB register 1, LSB register 2, MSB register 1, MSB register 2 is not supported).

---

The [TCRR](#) is a 32-bit “atomic datum” and its 16-bit capture is done on the 16-bit LSB first to allow atomic LSB16 + MSB16 capture. This capture scheme is also performed for the [TCAR1](#) and [TCAR2](#) registers as they can be changed due to internal processes too. DSP 16 bit accesses can be interleaved with MCU 32 bit accesses.

---

**NOTE:** Reading of counter value of GPTimer5 through GPTimer8 should be done with delay of 10 L4\_PER clock cycles when the functional clock source is 32kHz and the IPU CD is in the hardware AUTO state.

---

---

**NOTE:** Reading of counter value of GPTimer5 through GPTimer8 can be done without any delay when the functional clock source is 32kHz and the IPU CD is in software wakeup mode, or the static dependency between IPU and MPU is enabled.

---

#### 22.2.4.13.2.1 Read Posted

This mode is functional whatever the ratio between the OCP interface frequency and the functional clock frequency are. The recommended functional frequency range is  $\text{freq}(\text{timer}) < \text{freq}(\text{OCP}) / 4$ .

Read posted mode is used if [TSICR](#)[2] POSTED = 0x1 or [TSICR](#)[3] READ\_MODE is set to 0. This mode uses a posted-read scheme for reading any internal timer register. The read transaction is immediately acknowledged on the OCP interface, and the value to be read has been resynchronized. With this method, neither the interconnect nor the device that requested the read transaction are stalled.

Read posted mode applies to [TCRR](#), [TCAR1](#), [TCAR2](#), [TCVR](#), and [TOWR](#), which need resynchronization from functional to OCP clock domains.

#### 22.2.4.13.2.2 Read Non-Posted

This mode is functional regardless of the ratio between the OCP interface frequency and the functional clock frequency. Recommended functional frequency range is  $\text{freq}(\text{timer}) \geq \text{freq}(\text{OCP}) / 4$ .

Read non-posted mode is used if [TSICR](#)[2] POSTED = 0x0 and [TSICR](#)[3] READ\_MODE = 0x1. This mode uses a non-posted read scheme for reading internal timer registers. The read transaction is not acknowledged on the OCP interface until the effective read operation occurs, after the resynchronization in the timer clock domain. The result is that both the interconnect and the device that requested the read transaction are stalled during this period.

This mode applies to [TCRR](#), [TCAR1](#), [TCAR2](#), [TCVR](#), and [TOWR](#), which need resynchronization from functional to OCP clock domains.

### 22.2.4.14 Posted Mode Selection

A choice between two synchronization modes is made taking into account the frequency ratio and the stall periods that can be supported by the system, without impacting the global performance.

The posted mode selection applies only to registers that require synchronization on or from the timer clock domain. For write operation, the registers affected by posted and non-posted selection are [TCLR](#), [TLDR](#), [TCRR](#), [TTGR](#), [TMAR](#), [TPIR](#), [TNIR](#), [TCVR](#), [TOCR](#), and [TOWR](#). For read operation, the registers affected by this selection are: [TCRR](#), [TCAR1](#), [TCAR2](#), [TCVR](#), and [TOWR](#).

The OCP clock domain synchronous registers TIDR, TIOCP\_CFG, IRQSTATUS, IRQSTATUS\_SET, IRQWAKEEN, TWPS, and TSICR are not affected by posted and non-posted mode selection. The operation (read or write) is effective and acknowledged after one OCP clock cycle from the command assertion.

The configuration of posted or non-posted mode can be changed (overwritten) by software by writing in [TSICR\[2\] POSTED](#) bit. The [TSICR\[3\] READ\\_MODE](#) defines how the read operation is performed when the module is configured in non-posted mode (see [TSICR](#)). The following cases are possible:

- [TSICR\[2\] POSTED](#) = 0x1 and [TSICR\[3\] READ\\_MODE](#) = x (don't care): read and write operations are expected in posted mode.
- [TSICR\[2\] POSTED](#) = 0x0 and [TSICR\[3\] READ\\_MODE](#) = 0x0: the write operation is executed in non-posted mode and read is executed in posted mode.
- [TSICR\[2\] POSTED](#) = 0x0 and [TSICR\[3\] READ\\_MODE](#) = 0x1: write is executed in non-posted mode and read is executed in non-posted mode.

## 22.2.5 GP Timer Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

### 22.2.5.1 Global Initialization

#### 22.2.5.1.1 Global Initialization of Surrounding Modules

This section identifies the requirements for initializing the surrounding modules when the GP timer module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the GP timer. For more information, see [Section 22.2.3, GP Timers Integration](#), and [Section 22.2.2, GP Timers Environment](#). [Table 22-11](#) summarizes the surrounding modules.

**Table 22-11. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. For more information about the module configuration, see <a href="#">Section 3.1.1.1.2, Module-Level Clock Management</a> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Control module	The module-specific pad muxing must be set in the control module. For more information about the module configuration, see <a href="#">Section 18.4.6.1.1 Pad Configuration Registers</a> , in <a href="#">Chapter 18, Control Module</a> .
IRQ_CROSSBAR	The IRQ_CROSSBAR configuration must be done to enable the interrupts from the GP timer module. See <a href="#">Section 18.4.6.4, IRQ_CROSSBAR Module Functional Description</a> .

#### 22.2.5.1.2 GP Timer Module Global Initialization

##### 22.2.5.1.2.1 Main Sequence – GP Timer Module Global Initialization

[Table 22-12](#) identifies the main steps for initializing the GP timer module when the module is to be used for the first time.

**Table 22-12. GP Timer Module Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	TIOCP_CFG[0] SOFTRESET	0x1
Wait until reset release?	TIOCP_CFG[0] SOFTRESET	0x0
Configure idle mode.	TIOCP_CFG[3:2] IDLEMODE	0x-
Enable wake-up interrupt events.	IRQWAKEEN[2:0]	0x-
Select posted mode.	TSICR[2] POSTED	0x-

### 22.2.5.2 Operational Mode Configuration

#### 22.2.5.2.1 GP Timer Mode

##### 22.2.5.2.1.1 Main Sequence – GP Timer Mode Configuration

[Table 22-13](#) lists the steps in the GP timer mode configuration.

**Table 22-13. GP Timer Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	0x-
Set prescale timer value.	TCLR[4:2] PTV	0x-
Enable prescaler.	TCLR[5] PRE	0x1

**Table 22-13. GP Timer Mode Configuration (continued)**

Step	Register/Bit Field/Programming Model	Value
Enable overflow interrupt.	<a href="#">IRQSTATUS_SET[1] OVF_EN_FLAG<sup>(1)</sup></a> or <a href="#">IRQENABLE_SET[1] OVF_EN_FLAG<sup>(2)</sup></a>	0x1
Load timer counter value.	<a href="#">TCRR</a>	0x-
Load timer load value.	<a href="#">TLDR</a>	0x-
Start the timer.	<a href="#">TCLR[0] ST</a>	0x1

<sup>(1)</sup> Applies only to TIMER1, TIMER2, and TIMER10.

<sup>(2)</sup> Applies to TIMER3 through TIMER 9 and TIMER11 through TIMER16.

### 22.2.5.2.2 GP Timer Compare Mode

#### 22.2.5.2.2.1 Main Sequence – GP Timer Compare Mode Configuration

[Table 22-14](#) lists the steps in the GP timer compare mode configuration.

**Table 22-14. GP Timer Compare Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	<a href="#">TCLR[1] AR</a>	0x-
Set prescale timer value.	<a href="#">TCLR[4:2] PTV</a>	0x-
Enable prescaler.	<a href="#">TCLR[5] PRE</a>	0x1
Enable match interrupt.	<a href="#">IRQSTATUS_SET[0] MAT_EN_FLAG<sup>(1)</sup></a> or <a href="#">IRQENABLE_SET[0] MAT_EN_FLAG<sup>(2)</sup></a>	0x1
Load timer counter value.	<a href="#">TCRR</a>	0x-
Load timer compare value.	<a href="#">TMAR</a>	0x-
Enable compare mode.	<a href="#">TCLR[6] CE</a>	0x1
Start the timer.	<a href="#">TCLR[0] ST</a>	0x1

<sup>(1)</sup> Applies only to TIMER1, TIMER2, and TIMER10.

<sup>(2)</sup> Applies to TIMER3 through TIMER9 and TIMER11 through TIMER16.

### 22.2.5.2.3 GP Timer Capture Mode

#### 22.2.5.2.3.1 Main Sequence – GP Timer Capture Mode Configuration

[Table 22-15](#) lists the steps in the GP timer capture mode configuration.

**Table 22-15. GP Timer Capture Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Initialize capture mode.	See <a href="#">Section 22.2.5.2.3.2</a> .	
Enable capture interrupt.	<a href="#">IRQENABLE_SET[2] TCAR_EN_FLAG<sup>(1)</sup></a> or <a href="#">IRQSTATUS_SET[2] TCAR_EN_FLAG<sup>(2)</sup></a>	0x1
Start the timer.	<a href="#">TCLR[0] ST</a>	0x1
Detect event.	See <a href="#">Section 22.2.5.2.3.3</a> .	

<sup>(1)</sup> Applies only to TIMER3 through TIMER9 and TIMER11 through TIMER16.

<sup>(2)</sup> Applies only to TIMER1, TIMER2, and TIMER10.

#### 22.2.5.2.3.2 Subsequence – Initialize Capture Mode

[Table 22-16](#) lists the steps to initialize capture mode.

**Table 22-16. Initialize Capture Mode**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	0x-
Set prescale timer value.	TCLR[4:2] PTV	0x-
Enable prescaler.	TCLR[5] PRE	0x1
Select TIMERi (where i = 2 to 11 and 13 to 16). Capture input at device pin timeri.	TCLR[14] GPO_CFG	0x1
Select single or second event capture.	TCLR[13] CAPT_MODE	0x-
Select transition capture mode.	TCLR[9:8] TCM	0x-

### 22.2.5.2.3.3 Subsequence – Detect Event

Table 22-17 lists the steps in detecting an event.

**Table 22-17. Detect Event**

Step	Register/Bit Field/Programming Model	Value
Wait until event detected?	IRQSTATUS[2] TCAR_IT_FLAG	= 0x1
Read timer capture value.	TCAR1 and/or TCAR2	
Clear capture interrupt request.	IRQSTATUS[2] TCAR_IT_FLAG	0x1

### 22.2.5.2.4 GP Timer PWM Mode

#### 22.2.5.2.4.1 Main Sequence – GP Timer PWM Mode Configuration

Table 22-18 lists the steps in the GP timer PWM mode configuration.

**Table 22-18. GP Timer PWM Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	0x-
Set prescale timer value.	TCLR[4:2] PTV	0x-
Enable prescaler.	TCLR[5] PRE	0x1
Select trigger output mode.	TCLR[11:10] TRG	0x-
Select pulse or toggle modulation PWM mode.	TCLR[12] PT	0x-
Select TIMERi (where i = 2 to 11 and 13 to 16) PWM output at device pin timeri.	TCLR[14] GPO_CFG	0x0
Configure PWM output pin default value.	TCLR[7] SCPWM	0x-
Load timer load value.	TLDR	0x-
Load timer compare value.	TMAR	0x-
Enable compare.	TCLR[6] CE	0x1
Start the timer.	TCLR[0] ST	0x1

## 22.2.6 GP Timer Register Manual

### 22.2.6.1 GP Timer Instance Summary

Table 22-19 lists the base address and block size for the GP timer module instances.

**Table 22-19. GP Timer Instance Summary**

Module Name	Base Address L4_PER1 Interconnect	Base Address L4_PER3 Interconnect	Base Address L4_WKUP Interconnect	Size
TIMER2	0x4803 2000	–	–	112 Bytes
TIMER3	0x4803 4000	–	–	92 Bytes
TIMER4	0x4803 6000	–	–	92 Bytes
TIMER9	0x4803 E000	–	–	92 Bytes
TIMER10	0x4808 6000	–	–	112 Bytes
TIMER11	0x4808 8000	–	–	92 Bytes
TIMER5	–	0x4882 0000	--	92 Bytes
TIMER6	–	0x4882 2000	--	92 Bytes
TIMER7	–	0x4882 4000	--	92 Bytes
TIMER8	–	0x4882 6000	--	92 Bytes
TIMER13	--	0x4882 8000	--	92 Bytes
TIMER14	--	0x4882 A000	--	92 Bytes
TIMER15	--	0x4882 C000	--	92 Bytes
TIMER16	--	0x4882 E000	--	92 Bytes
TIMER12	-	-	0x4AE2 0000	92 bytes
TIMER1	--	–	0x4AE1 8000	112 Bytes

### 22.2.6.2 GP Timer Registers

#### 22.2.6.2.1 GP Timer Register Summary

**CAUTION**

The GP timer registers are limited to 32- and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 22-20 through Table 22-25 provide the register summary and associated offset addresses for the 15 GP timer internal registers.

**Table 22-20. TIMER1, TIMER2, and TIMER10 Register Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	TIMER1	TIMER2	TIMER10
				Physical Address L4_WKUP Interconnect	Physical Address L4_PER1 Interconnect	Physical Address L4_PER1 Interconnect

RESERVED																												IDLEMODE	EMUFREE	SOFTRESET	

Bits	Field Name	Description	Type	Reset
31:4	RESERVED	Reserved	R	0x00000000
3:2	IDLEMODE	Power management, req/ack control  0x0: Force-idle mode: local target idle state follows (acknowledges) the system idle requests unconditionally, that is, regardless of the IP module internal requirements. Back-up mode, for debug only.  0x1: No-idle mode: local target never enters idle state. Back-up mode, for debug only.  0x2: Smart-idle mode: local target idle state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module should not generate (IRQ- or DMA-request-related) wake-up events.  0x3: Smart-idle wake-up-capable mode: local target idle state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module may generate (IRQ- or DMA-request-related) wake-up events when in IDLE state. Mode is relevant only if the appropriate IP module <i>swake-up</i> output(s) is (are) implemented.	RW	0x0
1	EMUFREE	Emulation mode  0x0: The timer is frozen in emulation mode (PINSUSPENDN signal active).  0x1: The timer runs free, regardless of PINSUSPENDN value.	RW	0
0	SOFTRESET	Software reset  0x0: Read 0: reset done, no pending action Write 0: No action  0x1: Read 1: initiate software reset Write 1: Reset ongoing	RW	0

RESERVED																GPO_CFG	CAPT_MODE	PT	TRG	TCM	SCPWM	CE	PRE	PTV	AR	ST						

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Reserved	R	0x00000
14	GPO_CFG	General-purpose output - this register directly drives the PO_GPOCFG output. For specific use of the GPO_CFG bit, see <a href="#">Section 22.2.2.1, GP Timer External System Interface</a> .  0x0: PO_GPOCFG drives 0. 0x1: PO_GPOCFG drives 1.	RW	0
13	CAPT_MODE	Capture mode select bit (first/second)  0x0: Single capture: Capture the first enabled capture event in <a href="#">TCAR1</a> . 0x1: Capture on second event: Capture the second enabled capture event in <a href="#">TCAR1</a> and the second enabled capture event in <a href="#">TCAR2</a> .	RW	0
12	PT	Pulse or toggle mode on <a href="#">TIMERi_PWM_out</a> output pin  0x0: Pulse modulation 0x1: Toggle modulation	RW	0
11:10	TRG	Trigger output mode on <a href="#">TIMERi_PWM_out</a> output pin  0x0: No trigger 0x1: Trigger on overflow. 0x2: Trigger on overflow and match. 0x3: Reserved	RW	0x0

Bits	Field Name	Description	Type	Reset
9:8	TCM	Transition capture mode on TIMERi_EVENT_CAPTURE input pin (When the TCM field passed from (00) to any other combination, the TCAR_IT_FLAG and the edge detection logic are cleared.) 0x0: No capture 0x1: Capture on rising edges of TIMERi_EVENT_CAPTURE pin 0x2: Capture on falling edges of TIMERi_EVENT_CAPTURE pin 0x3: Capture on both edges of TIMERi_EVENT_CAPTURE pin	RW	0x0
7	SCPWM	Pulse width modulation output pin default setting This bit must be set or clear while the timer is stopped or the trigger is off. 0x0: Clear the TIMERi_PWM_out output pin and select positive pulse for pulse mode. 0x1: Set the TIMERi_PWM_out output pin and select negative pulse for pulse mode.	RW	0
6	CE	Compare enable 0x0: Compare mode is disable. 0x1: Compare mode is enable.	RW	0
5	PRE	Prescaler enable 0x0: The TIMER clock input pin clocks the counter. 0x1: The divided input pin clocks the counter.	RW	0
4:2	PTV	Prescale clock timer value The timer counter is prescaled with the value $2^{(PTV+1)}$ . Example: PTV = 3, counter increases value (if started) after 16 functional clock periods.	RW	0x0
1	AR	Autoreload mode 0x0: One shot timer 0x1: Autoreload timer	RW	0
0	ST	Start/stop timer control 0x0: Stop timer: Only the counter is frozen. If one-shot mode selected (AR =0), this bit is automatically reset by internal logic when the counter is overflowed. 0x1: Start timer	RW	0

## 22.3 32-kHz Synchronized Timer (COUNTER\_32K)

### 22.3.1 32-kHz Synchronized Timer Overview

The 32-kHz synchronized timer (COUNTER\_32K) is a 32-bit counter clocked by the falling edge of the 32-kHz system clock.

Figure 22-15 is the block diagram of the 32-kHz synchronized timer.

**Figure 22-15. 32-kHz Synchronized Timer Block Diagram**

timers-018

#### 22.3.1.1 32-kHz Synchronized Timer Features

The main features of the 32-kHz synchronized timer controller are:

- L4 slave interface (OCP) support:
  - 32-bit data bus width
  - 32-/16-bit access supported
  - 8-bit access not supported
  - 16-bit address bus width
  - Burst mode not supported
  - Write nonposted transaction mode not supported
- Only read operations are supported on the module registers; no write operation is supported (no error/no action on write).
- Free-running 32-bit upward counter
- Start and keep counting after power-on reset
- Automatic roll over to 0; highest value reached: 0xFFFF FFFF
- On-the-fly read (while counting)

### 22.3.2 32-kHz Synchronized Timer Integration

The synchronized timer is accessible only through the L4\_WKUP interface.

Table 22-74 through Table 22-76 summarize the integration of the module in the device.

**Table 22-74. COUNTER\_32K Integration Attributes**

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
COUNTER_32K	PD_WKUPAON	No	L4_WKUP

**Table 22-75. COUNTER\_32K Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
COUNTER_32K	COUNTER_32K_FCLK	FUNC_32K_CLK	PRCM	COUNTER_32K functional 32KHz clock
COUNTER_32K	COUNTER_32K_ICLK	WKUPAON_GICLK	PRCM	COUNTER_32K interface clock
Resets				
COUNTER_32K	COUNTER_32K_NRESPWRON	WKUPAON_SYS_PWRON_RST	PRM	Reset to COUNTER_32K. Reset all internal logic, running on COUNTER_32K_FCLK
COUNTER_32K	COUNTER_32K_OCPRESETN	WKUPAON_RST	PRM	Reset to COUNTER_32K. Reset all L4 interface logic, running on COUNTER_32K_ICLK.

**Table 22-76. COUNTER\_32K Hardware Requests**

No Interrupt Requests
No DMA Requests

### 22.3.3 32-kHz Synchronized Timer Functional Description

The synchronized timer is a counter that starts on the rising edge of an external asynchronous signal (COUNTER\_32K\_NRESPWRON). When COUNTER\_32K\_NRESPWRON is released (on the rising edge of COUNTER\_32K\_FCLK), the counter starts counting up from the reset value of the counter register on the falling edge of the 32-kHz COUNTER\_32K\_FCLK clock after three inverted 32-kHz clock periods. After reaching its highest value, the counter wraps back to 0 and starts counting again with no additional delay.

Figure 22-16 shows the reset synchronization timing diagram.

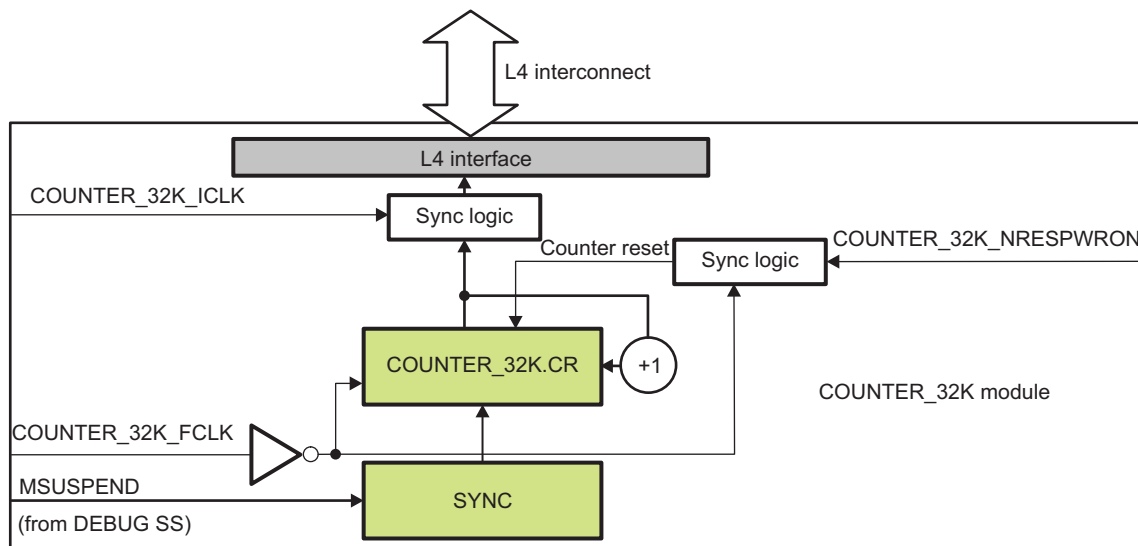

Figure 22-16. Reset Resynchronization Timing Diagram

timers-019

Figure 22-17 is the block diagram of the synchronized timer.

Figure 22-17. COUNTER\_32K Block Diagram

timers-020

The sync logic ensures the correctness of the read transaction by synchronizing the counter register read access on COUNTER\_32K\_ICLK, because the COUNTER\_32K\_ICLK clock signal is completely asynchronous with COUNTER\_32K\_FCLK. The COUNTER\_32K\_NRESPWRON input resets the counter register (CR). The inverted COUNTER\_32K\_FCLK clocks the counter register CR.

The counting is temporally stopped when MSUSPEND control signal (coming from DEBUG SS) is asserted.

#### 22.3.3.1 Reading the 32-kHz Synchronized Timer

The counter register (CR) is 32 bits wide. For correct count capture, it must be accessed as 16-bit LSB access first and 16-bit MSB access next. The value of the counter is read through the L4 interconnect slave interface. Internal synchronization logic allows the reading of the counter value with COUNTER\_32K\_ICLK while the counter is running. The time latency to read the synchronized counter register is one COUNTER\_32K\_ICLK clock period.

The user can select between two synchronization schemes by setting `SYSCONFIG[0]SYNCMODE` bit.

- `SYSCONFIG[0]SYNCMODE = 0x0` - default. In this mode COUNTER\_32K timer uses Gray encode/decode scheme. When the L4 interface sends a LSB16 read request command, the 32 bit coded value is registered directly to the interface domain. Due to the characteristics of this encoding if a read command arrives during a count up event either the old or the new value of `CR` is captured, not a transient value. The captured value will be decoded and send on the SDATA bus. The MSB16 read command reads upper 16 bits of the 32 bit value of counter register captured during the last LSB16 read access.
- `SYSCONFIG[0]SYNCMODE = 0x1` - legacy synchronization scheme. In this mode the value of the `CR` is synchronized to the OCP domain at every count up event. This synchronization is possible because the COUNTER\_32K\_ICLK is much faster than the 32KHz clock (COUNTER\_32K\_FCLK). The drawback of this method is that if the interface clock is switched back after wake up from idle mode, the synchronized value will be updated only at the next count up event, until then it will be incorrect.

### 22.3.4 COUNTER\_32K Timer Register Manual

Table 22-77 lists the base address and block size for the 32-kHz synchronized timer. It is memory-mapped to the L4 peripheral bus memory space.

**Table 22-77. COUNTER\_32K Timer Instance Summary**

Module Name	Module Base Address	Size
L4_WKUP_COUNTER_32K	0x4AE0 4000	52 Bytes

#### 22.3.4.1 COUNTER\_32K Timer Register Mapping Summary

**CAUTION**

The 32-kHz synchronized timer registers are limited to 32- and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 22-78 lists the 32-kHz synchronized timer registers. Table 22-79 through Table 22-83 describe the register bits.

**Table 22-78. COUNTER\_32K Timer Register Summary**

## 22.4 Watchdog Timer

### 22.4.1 Watchdog Timer Overview

The device includes one instance of the 32-bit watchdog timer: WD\_TIMER2. Figure 22-18 shows how the timer is connected in the device.

The watchdog timer is an upward counter capable of generating a pulse on the reset pin and an interrupt to the device system modules following an overflow condition. The WD\_TIMER2 timer serves resets to the PRCM module (its interrupt outputs are unused).

WD\_TIMER2 is located in the PD\_WKUPAON power domain, and can run when the device is in lowest power state above RTC mode (all power domains are off except always-on (AON), WKUP, and RTC domains).

The watchdog timer can be accessed, loaded, and cleared by registers through the L4\_WKUP interface. The watchdog timer has the 32-kHz clock for its timer clock input. WD\_TIMER2 directly generates a warm reset condition on overflow.

WD\_TIMER2 connects to a single target agent port on the L4\_WKUP interconnect.

Figure 22-18. Watchdog Timer Block Diagram

Table 22-85 lists the default state of the watchdog timer in the device.

Table 22-85. Watchdog Timer Default State

Timer	Default State
WD_TIMER2	Enabled Not running

**NOTE:** The default state of the watchdog timer described in Table 22-85 is considered to be its state immediately after ROM code execution. For more information, see Section 32.1, Initialization.

#### 22.4.1.1 Watchdog Timer Features

The main features of the watchdog timer controllers are:

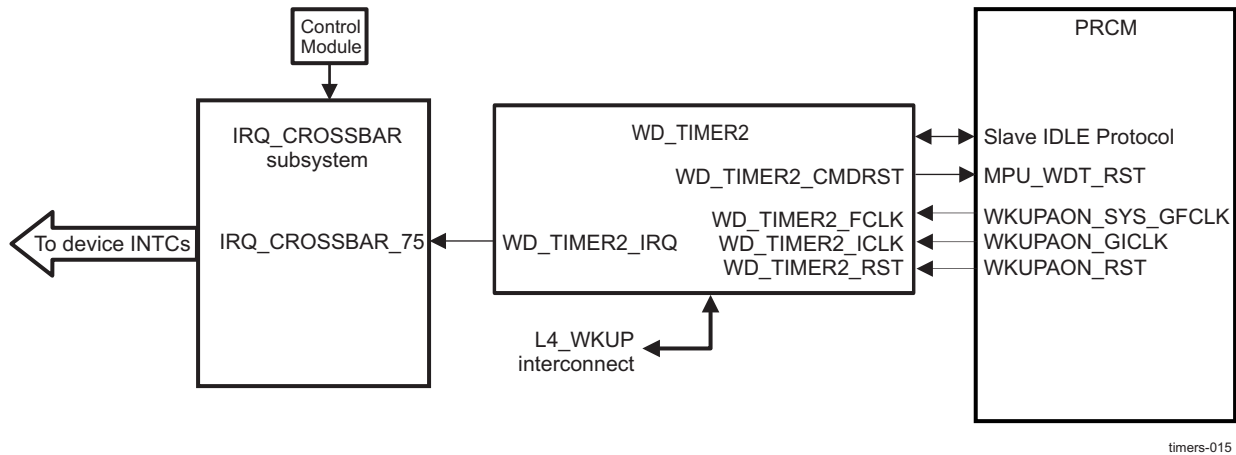

- L4 slave interface support:
  - 32-bit data bus width
  - 32-/16-bit access supported
  - 8-bit access not supported
  - 11-bit address bus width
  - Burst mode not supported
  - Write nonposted mode supported
- Free-running 32-bit upward counter
- Programmable divider clock source ( $2^n$  where  $n = [0:7]$ )
- On-the-fly read/write register (while counting)
- Subset programming model of the GP timer

- The watchdog timer is reset either on power on or after a warm reset before it starts counting.
- Reset or interrupt actions when a timer overflow condition occurs
- The watchdog timer generates a reset or an interrupt in its hardware integration.

### 22.4.2 Watchdog Timer Integration

Figure 22-19 shows the integration of the watchdog timers in the device.

Figure 22-19. Watchdog Timer Integration

timers-015

Table 22-86 through Table 22-88 summarize the integration of the module in the device.

Table 22-86. Watchdog Timer Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
WD_TIMER2	PD_WKUPAON	Yes	L4_WKUP

Table 22-87. Watchdog Timer Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
WD_TIMER2	WD_TIMER2_FCLK	WKUPAON_SYS_GFCLK	PRCM	WD_TIMER2 functional clock
WD_TIMER2	WD_TIMER2_ICLK	WKUPAON_GICLK	PRCM	WD_TIMER2 interface clock
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
WD_TIMER2	WD_TIMER2_RST	WKUPAON_RST	PRM	Reset to WD_TIMER2
	MPU_WDT_RST	WD_TIMER2_CMDRST	WD_TIMER2	Reset to MPU

**NOTE:** WD\_TIMER2 is reset on power on or after a warm reset before it starts counting.

Table 22-88. Watchdog Timer Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination IRQ_CROSSBAR Input	Default Mapping	Description
WD_TIMER2	WD_TIMER2_IRQ	IRQ_CROSSBAR_75	MPU_IRQ_80	WD_TIMER2 interrupt request
No DMA Requests				

**NOTE:** The “**Default Mapping**” column in [Table 22-88 Watchdog Timer Hardware Requests](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ\_CROSSBAR module.

For more information about the IRQ\_CROSSBAR module, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#).

For more information about the device interrupt controllers, see [Chapter 17, Interrupt Controllers](#).

---

## 22.4.3 Watchdog Timer Functional Description

### 22.4.3.1 Power Management

There are two clock domains in the watchdog timer:

- Functional clock domain: WD\_TIMER2\_FCLK is the watchdog timer functional clock. It is used to clock the watchdog timer internal logic.
- Interface clock domain: WD\_TIMER2\_ICLK is the watchdog timer interface clock. It is used to synchronize the watchdog timer L4 port to the L4 interconnect. All accesses from the interconnect are synchronous to WD\_TIMER2\_ICLK.

Table 22-87 lists the source clocks for the watchdog timer in the device. For more information about clock control and domains, see Section 3.6, *Clock Management Functional Description*, in Chapter 3, *Power, Reset, and Clock Management*.

From a global system power-management perspective, when the watchdog timer clocks is no longer required, the watchdog timer can be deactivated at the PRCM module level in the corresponding registers.

At the PRCM module level, when the conditions to shut off the PRCM module functional or interface output clocks are met (for more information, see Section 3.1.1.1.4, *Clock Domain-Level Clock Management*), the PRCM module automatically launches a hardware handshake protocol to ensure the watchdog timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the watchdog timer.

Although this handshake is a hardware function and out of software control, the way on which the watchdog timer acknowledges the PRCM IDLE request is configurable through the WDSC[4:3] IDLEMODE bit field. Table 22-89 lists the settings and related acknowledgment modes of the IDLEMODE bit field.

**Table 22-89. IDLEMODE Settings**

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The watchdog timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent loss of data when the clock is switched off.
01	No-idle	The watchdog timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, however, because it does not allow the PRCM module output clock to be shut off and thus the power domain to be set to a lower power state.
10	Smart-idle	The watchdog timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach for efficient system power management.
11	Smart-idle wakeup-capable mode	The watchdog timer acknowledges the IDLE request, basing its decision on its internal activity. The timer generates (IRQ-request-related) wake-up events when in IDLE state if the WIRQWAKEEN[1:0] bit field is set to 1.

#### 22.4.3.1.1 Wake-Up Capability

If the WDSC[4:3] IDLEMODE bit field sets smart-idle wakeup-capable mode ( $= 0 \times 3$ ), the timer evaluates its internal capability to have the interface clock switched off. When there is no more internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters into sleep mode, ready to issue a wake-up request. This wake-up request is sent only if the WIRQWAKEEN[0] OVW\_WK\_ENA and/or the WIRQWAKEEN[1] DLY\_WK\_ENA bits enable the overflow and/or the delay wake-up capability.

#### 22.4.3.2 Interrupts

Table 22-90 list the event flags, and their masks that cause module interrupts.

**Table 22-90. Watchdog Timer Events**

Event Flag	Event Mask	Mapping	Comments
WIRQSTAT[0] EVENT_OVF	WIRQENSET/WIRQENCLR[0] OVF_IT_ENA	WD_TIMER2_IRQ	Watchdog timer overflow
WIRQSTAT[1] EVENT_DLY	WIRQENSET/WIRQENCLR[1] DLY_IT_ENA	WD_TIMER2_IRQ	Watchdog delay value reached

### 22.4.3.3 General Watchdog Timer Operation

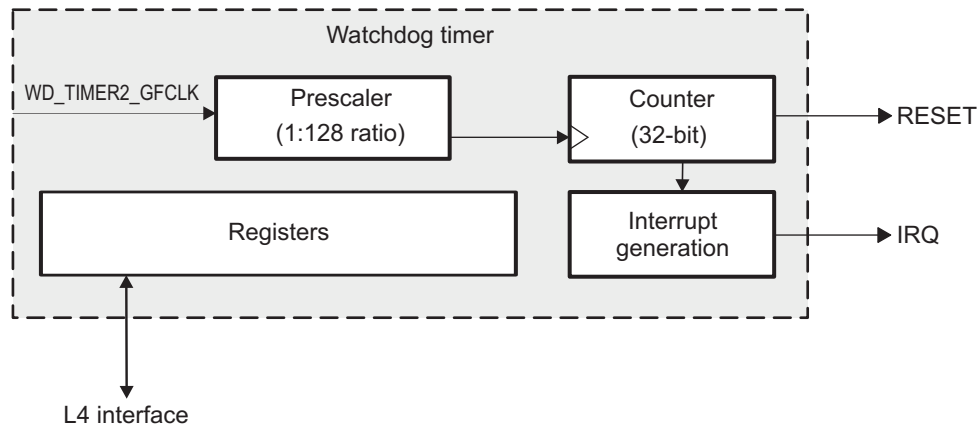

The watchdog timer is based on an upward 32-bit counter coupled with a prescaler. The counter overflow is signaled through two independent signals: a simple reset signal and an interrupt signal, both active low. The use of these signals depends on whether they are connected or not. For this information, see [Figure 22-18](#). The interrupt generation mechanism is controlled through the [WIRQENSET/WIRQENCLR](#) and [WIRQSTAT](#) registers.

The prescaler ratio can be set from 1 to 128 by accessing the [WCLR\[4:2\]](#) PTV bit field and the [WCLR\[5\]](#) PRE bit of the watchdog control register ([WCLR](#)).

The current timer value can be accessed on-the-fly by reading the watchdog timer counter register ([WCRR](#)), modified by accessing the watchdog timer load register ([WLDR](#)) (no on-the-fly update), or reloaded by following a specific reload sequence on the watchdog timer trigger register ([WTGR](#)). A start/stop sequence applied to the watchdog timer start/stop register ([WSPR](#)) can start and stop the watchdog timers.

[Figure 22-20](#) is a functional block diagram of the watchdog timer.

**Figure 22-20. 32-Bit Watchdog Timer Functional Block Diagram**

timers-016

### 22.4.3.4 Reset Context

The watchdog timer is enabled after reset. [Table 22-91](#) lists the default reset values of the two watchdog timer load registers ([WLDR](#)) and prescaler ratios (the [WCLR\[4:2\]](#) PTV bit field). To get these values, software must read the corresponding [WCLR\[4:2\]](#) PTV bit field and the 32-bit register to retrieve the static configuration of the module.

**Table 22-91. Count and Prescaler Default Reset Values**

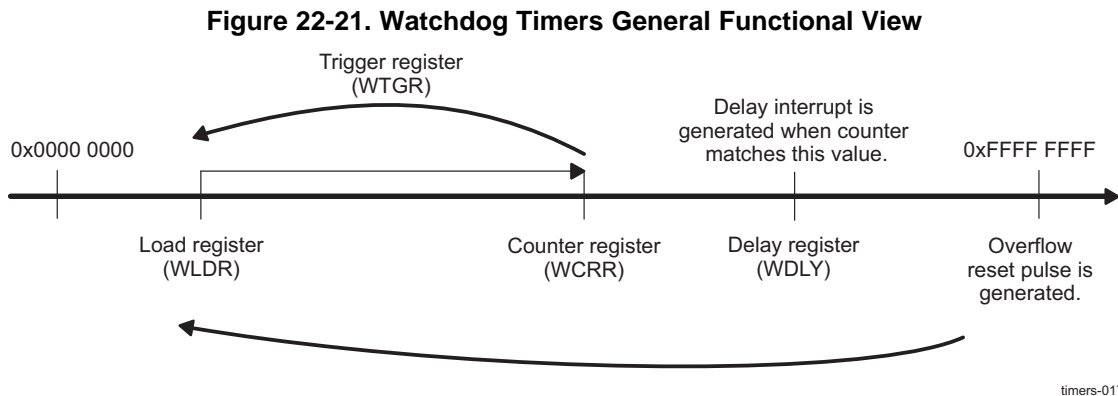

Timer	WLDR Reset Value	PTV Reset Value
WD_TIMER2	0xFFFB 0000	0

### 22.4.3.5 Overflow/Reset Generation

When the **WCRR** overflows, an active-low reset pulse is generated to the PRCM module. This pulse is one prescaled timer clock cycle wide and occurs at the same time as the timer counter overflow.

After reset generation, the counter is automatically reloaded with the value stored in the **WLDR** and the prescaler is reset (the prescaler ratio remains unchanged). When the reset pulse output is generated, the timer counter begins incrementing again.

Figure 22-21 shows a general functional view of the watchdog timers.

### 22.4.3.6 Prescaler Value/Timer Reset Frequency

The watchdog timer is composed of a prescaler stage and a timer counter.

The timer rate is defined by the following values:

- Value of the prescaler fields (the **WCLR**[5] PRE bit and the **WCLR**[4:2] PTV bit field)
- Value loaded into **WLDR**

The prescaler stage is clocked with the timer clock and acts as a clock divider for the timer counter stage. The ratio is managed by accessing the ratio definition field (the **WCLR** [4:2] PTV bit field) and is enabled with the **WCLR**[5] PRE bit.

Table 22-92 lists the prescaler clock ratio values.

**Table 22-92. Prescaler Clock Ratio Values**

WCLR[5] PRE	WCLR[4:2] PTV	Clock Divider (PS)
0	X	1
1	0	1
1	1	2
1	2	4
1	3	8
1	4	16
1	5	32
1	6	64
1	7	128

Thus the watchdog timer overflow rate is expressed as:

$$\text{OVF\_Rate} = (0\text{x}\text{FFFF FFFF} - \text{WLDR} + 1) \times (\text{timer clock period}) \times \text{PS}$$

where wd-functional clock period =  $1 / (\text{timer clock frequency})$  and  $\text{PS} = 2^{(\text{PTV})}$

### CAUTION

Internal resynchronization causes some latency in any software write to **WSPR** before **WSPR** is updated with the programmed value:

$$1.5 \times \text{functional clock cycles} \leq \text{write\_WD\_TIMER\_WSPR\_latency} \leq 2.5 \times \text{functional clock cycles}$$

Remember to consider this latency whenever the watchdog timer must be started or stopped.

For example, for a timer clock input of 32 kHz with a prescaler ratio value of 0x1 (clock divided by 2) and **WCLR**[5] PRE = 1 (clock divider enabled), the reset period is as listed in [Table 22-93](#).

**Table 22-93. Reset Period Examples**

WLDR Value	Reset Period
0x0000 0000	74 h 56 min
0xFFFF 0000	4 s
0xFFFF FFF0	1 ms
0xFFFF FFFF	62.5 $\mu$ s

### CAUTION

- Ensure that the reloaded value allows the correct operation of the application. When a watchdog timer is enabled, software must periodically trigger a reload before the counter overflows. Hence, the value of the **WLDR**[31:0] bit field must be chosen according to the ongoing activity preceding the watchdog reload.
- Due to design reasons, **WLDR**[31:0] = 0xFFFF FFFF is a special case, although such value of **WLDR** is meaningless. When **WLDR** is programmed with the overflow value, a triggering event generates a reset/interrupt one functional clock cycle later, even if the watchdog timer is stopped.

[Table 22-94](#) lists the default reset periods for the watchdog timer.

**Table 22-94. Default Watchdog Timer Reset Periods**

Watchdog Timers	Clock Source	Default Reset Period
WD_TIMER2	32 kHz	10 s

#### 22.4.3.7 Triggering a Timer Reload

To reload the timer counter and reset the prescaler before reaching overflow, a reload command is executed by accessing the **WTGR** using a specific reload sequence.

The specific reload sequence is performed whenever the written value on the **WTGR** differs from its previous value. In this case, reload is executed in the same way as an overflow autoreload, but without the generation of a reset pulse.

The timer counter is loaded with the value of the watchdog timer load register (the [WLDR\[31:0\] TIMER\\_LOAD](#) bit field), and the prescaler is reset.

#### 22.4.3.8 Start/Stop Sequence for Watchdog Timer (Using the WSPR Register)

To start and stop a watchdog timer, access must be made through the [WSPR](#) using a specific sequence.

To disable the timer, follow this sequence:

1. Write 0xXXXX AAAA in the [WSPR](#).
2. Write 0xXXXX 5555 in the [WSPR](#).

To enable the timer, follow this sequence:

1. Write 0xXXXX BBBB in the [WSPR](#).
2. Write 0xXXXX 4444 in the [WSPR](#).

All other write sequences on the [WSPR](#) have no effect on the start/stop feature of the module.

#### 22.4.3.9 Modifying Timer Count/Load Values and Prescaler Setting

To modify the timer counter value (the [WCRR](#)), the prescaler ratio (the [WCLR\[4:2\] PTV](#) bit field), delay configuration value (the [WDLY\[31:0\] DLY\\_VALUE](#) bit field), or the load value (the [WLDR\[31:0\] TIMER\\_LOAD](#) bit field), the watchdog timer must be disabled by using the start/stop sequence (the [WSPR](#)).

After a write access, the load register value and prescaler ratio registers are updated immediately, but new values are considered only after the next consecutive counter overflow or after a new trigger command (the [WTGR](#)).

#### 22.4.3.10 Watchdog Counter Register Access Restriction (WCRR)

A 32-bit shadow register is implemented to read a coherent value of the [WCRR](#) because the [WCRR](#) is directly related to the timer counter value and is updated on the timer clock ([WD\\_TIMER\\_FCLK](#)). The shadow register is updated by a 16-bit LSB read command.

---

**NOTE:** Although the L4 clock ([WD\\_TIMER\\_ICLK](#)) is completely asynchronous with the timer clock ([WD\\_TIMER\\_FCLK](#)), some synchronization is performed to ensure that the value of the [WCRR](#) is not read while it is being incremented.

---

When 32-bit read access is performed, the shadow register is not updated. Read access is performed directly from the accessed register.

To ensure that a coherent value is read inside the [WCRR](#), the first read access is to the lower 16 bits (offset = 0x08), followed by read access to the upper 16 bits (offset = 0x0A).

#### 22.4.3.11 Watchdog Timer Interrupt Generation

When an interrupt source occurs, the interrupt status bit (the [WISR\[0\] OVF\\_IT\\_FLAG](#) or [WISR\[1\] DLY\\_IT\\_FLAG](#) bit) is set to 1. The output interrupt line ([WD\\_TIMER\\_IRQ](#)) is asserted (active high) when status (the [EVENT\\_xxx](#) bit) and enable (the [xxx\\_IT\\_ENA](#) bit) flags are set to 1; the order is not relevant. Writing 1 to the enable bit (the status is already set at 1) also triggers the interrupt in the normal order (enable first, status next). The pending interrupt event is cleared when the set status bit is overwritten by a value of 1 by a write command in the [WISR](#). Reading the [WISR](#) and writing the value back allows a fast interrupt acknowledge process.

The watchdog timer issues an overflow interrupt if this interrupt is enabled in the watchdog interrupt-enable register ([WIER\[0\] OVF\\_IT\\_ENA = 1](#)). When the overflow occurs, the interrupt status bit (the [WISR\[0\] OVF\\_IT\\_FLAG](#) bit) is set to 1. The output interrupt line ([WD\\_TIMER\\_IRQ](#)) is asserted (active high) when status ([OVF\\_IT\\_FLAG](#)) and enable ([OVF\\_IT\\_ENA](#)) flags are set to 1; the order is not relevant. This interrupt can be disabled by setting the [WIER \[0\] OVF\\_IT\\_ENA](#) bit to 1.

The watchdog can issue the delay interrupt if this interrupt is enabled in the interrupt-enable register ([WIER\[1\] DLY\\_IT\\_ENA = 1](#)). When the counter is running and the counter value matches the value stored in the delay configuration register ([WDLY](#)), the corresponding interrupt status bit is set in the watchdog status register ([WISR](#)) and the output interrupt line is asserted (active high) when the flag ([DLY\\_IT\\_FLAG](#)) and enable ([DLY\\_IT\\_ENA](#)) bits are set to 1 in the [WISR](#) and [WIER](#) registers, respectively; the order (normally enable, then flag) is not relevant. This interrupt can be disabled by setting the [WIER\[1\] DLY\\_IT\\_ENA](#) bit to 1.

---

**NOTE:** Writing 0 to the [WISR\[0\] OVF\\_IT\\_FLAG](#) or [WISR\[1\] DLY\\_IT\\_FLAG](#) bit has no effect.

---

The two clock domains are resynchronized because the interrupt event is generated on the functional clock domain ([WD\\_TIMERi\\_FCLK](#)) during the updating of the interrupt status register.

The [WDLY](#) register is used to specify the value of the delay configuration register. The delay time to interrupt is the difference between the reload value stored in the counter load register ([WLDR](#)) and the programmed value in this register ([WDLY](#)).

Use the following formula to estimate the delay time:

Delay time period = ([WDLY](#) – [WLDR](#) + 1) × Timer clock period × Clock divider

Where:

- Timer clock period = 1 / (Timer clock frequency)
- Clock divider = 2PTV

If the counter value ([WCRR](#)) reaches the programmed value ([WDLY](#)), the status bit ([EVENT\\_DLY](#)) is set in the interrupt status register ([WIRQSTAT](#)), and an interrupt occurs if the corresponding enable bit is set in the interrupt enable register ([WIRQENSET](#)).

#### CAUTION

If the reload event occurs (after a triggering sequence or after a reset sequence) before reaching the programmed value (the [WDLY\[31:0\] WDLY\\_VALUE](#) bit field), no interrupt is generated.

Also, no interrupt is generated if the value programmed in the [WDLY](#) register is less than the value stored in the [WLDR](#).

#### 22.4.3.12 Watchdog Timer Under Emulation

During emulation mode, the watchdog timer can or cannot continue to run, according to the value of the [WDSC\[5\] EMUFREE](#) bit of the system configuration register ([WDSC](#)).

- When [EMUFREE](#) is 1, watchdog timer execution is not stopped and a reset pulse is still generated when overflow is reached.
- When [EMUFREE](#) is 0, the counters (prescaler/timer) are frozen and incrementation restarts after exiting emulation mode.

#### 22.4.3.13 Accessing Watchdog Timer Registers

Posted/nonposted selection applies only to functional registers that require synchronization on/from the timer functional clock domain ([WD\\_TIMER2\\_FCLK](#)). For write/read operation, the following registers are affected:

- [WCLR](#)
- [WCRR](#)
- [WLDR](#)
- [WTGR](#)
- [WDLY](#)
- [WSPR](#)

The timer interface clock domain synchronous registers are not affected by the posted/nonposted selection; the write/read operation is effective and acknowledged (command accepted) after one WD\_TIMER\_ICLK cycle from the command assertion. The timer interface clock domain synchronous registers are:

- [WIDR](#)
- [WDSC](#)
- [WDST](#)
- [WISR](#)
- [WIER](#)
- [WWER](#)
- [WWPS](#)

---

**NOTE:** Accesses to WD\_TIMER2 is posted.

---

## 22.4.4 Watchdog Timer Low-Level Programming Model

This section covers the low-level hardware programming sequences for the configuration and use of the module.

### 22.4.4.1 Global Initialization

#### 22.4.4.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the watchdog timer is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the watchdog timer (see [Table 22-95](#)). For more information, see [Section 22.4.2, Watchdog Timer Integration](#).

**Table 22-95. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. For more information about the module configuration, see <a href="#">Section 3.1.1.1.2, Module-Level Clock Management</a> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Control module	Module-specific pad muxing must be set in the control module. For more information about the module configuration, see <a href="#">Section 18.4.6.1.1, Pad Configuration Registers</a> in <a href="#">Chapter 18, Control Module</a> .
IRQ_CROSSBAR	The IRQ_CROSSBAR configuration must be performed to enable the interrupts from the watchdog timer. See <a href="#">Section 18.4.6.4, IRQ_CROSSBAR Module Functional Description</a> , in <a href="#">Chapter 18, Control Module</a> .

### 22.4.4.1.2 Watchdog Timer Module Global Initialization

#### 22.4.4.1.2.1 Main Sequence – Watchdog Timer Module Global Initialization

Table 22-96 lists the steps for initializing the watchdog timer module when the module is to be used for the first time.

**Table 22-96. Watchdog Timer Module Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	WDSC[1] SOFTRESET	0x1
Wait until reset release?	WDSC[1] SOFTRESET	0x0
Configure idle mode.	WDSC[4:3] IDLEMODE	0x-
Enable delay wakeup.	WIRQWAKEEN[1] DLY_WK_ENA	0x1
Enable overflow wakeup.	WIRQWAKEEN[0] OVF_WK_ENA	0x1
Enable delay interrupt.	WIRQENSET[1] ENABLE_DLY	0x1
Enable overflow interrupt.	WIRQENSET[0] ENABLE_OVF	0x1

### 22.4.4.2 Operational Mode Configuration

#### 22.4.4.2.1 Watchdog Timer Basic Configuration

##### 22.4.4.2.1.1 Main Sequence – Watchdog Timer Basic Configuration

Table 22-97 lists the steps for the basic configuration of the watchdog timer.

**Table 22-97. Watchdog Timer Basic Configuration**

Step	Register/Bit Field/Programming Model	Value
Disable the watchdog timer.	See Section 22.4.4.2.1.2.	
Set prescaler value.	WCLR[4:2] PTV	0x-
Enable prescaler.	WCLR[5] PRE	0x1
Load delay configuration value.	WDLY	0x-
Load timer counter value.	WCRR	0x-
Enable the watchdog timer.	See Section 22.4.4.2.1.3.	

##### 22.4.4.2.1.2 Subsequence – Disable the Watchdog Timer

Table 22-98 lists the steps to disable the watchdog timer.

**Table 22-98. Disable the Watchdog Timer**

Step	Register/Bit Field/Programming Model	Value
Write disable sequence Data1.	WSPR	0xXXXX AAAA
Write disable sequence Data2.	WSPR	0xXXXX 5555

##### 22.4.4.2.1.3 Subsequence – Enable the Watchdog Timer

Table 22-99 lists the steps to enable the watchdog timer.

**Table 22-99. Enable the Watchdog Timer**

Step	Register/Bit Field/Programming Model	Value
Write enable sequence Data1.	WSPR	0xXXXX BBBB
Write enable sequence Data2.	WSPR	0xXXXX 4444

## 22.4.5 Watchdog Timer Register Manual

### 22.4.5.1 Watchdog Timer Instance Summary

Table 22-100 lists the base address and address space for the watchdog timer module instances.

**Table 22-100. Watchdog Timer Instance Summary**

Module Name	Module Base Address L4_WKUP Interconnect	Size
WD_TIMER2	0x4AE1 4000	104 Bytes

**NOTE:** Private access is access that does not use the L4 interconnect.

### 22.4.5.2 Watchdog Timer Registers

#### 22.4.5.2.1 Watchdog Timer Register Summary

**CAUTION**

The watchdog timers registers are limited to 32- and 16-bit data accesses; 8-bit access is not allowed and can corrupt register content.

Table 22-101 lists the WD\_TIMER2 registers.

**Table 22-101. WD\_TIMER2 Register Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	WD_TIMER2 Physical Address L4_WKUP Interconnect
WIDR	R	32	0x0000 0000	0x4AE1 4000
WDSC	RW	32	0x0000 0010	0x4AE1 4010
WDST	R	32	0x0000 0014	0x4AE1 4014
WISR	RW	32	0x0000 0018	0x4AE1 4018
WIER	RW	32	0x0000 001C	0x4AE1 401C
WWER	RW	32	0x0000 0020	0x4AE1 4020
WCLR	RW	32	0x0000 0024	0x4AE1 4024
WCRR	RW	32	0x0000 0028	0x4AE1 4028
WLDR	RW	32	0x0000 002C	0x4AE1 402C
WTGR	RW	32	0x0000 0030	0x4AE1 4030
WWPS	R	32	0x0000 0034	0x4AE1 4034
WDLY	RW	32	0x0000 0044	0x4AE1 4044
WSPR	RW	32	0x0000 0048	0x4AE1 4048
WIRQEOI	RW	32	0x0000 0050	0x4AE1 4050
WIRQSTATRAW	RW	32	0x0000 0054	0x4AE1 4054
WIRQSTAT	RW	32	0x0000 0058	0x4AE1 4058
WIRQENSET	RW	32	0x0000 005C	0x4AE1 405C
WIRQENCLR	RW	32	0x0000 0060	0x4AE1 4060
WIRQWAKEEN	RW	32	0x0000 0064	0x4AE1 4064

**NOTE:**

- The [WISR](#) and [WIRQSTATRAW](#) registers have the same functionality. The [WISR](#) register is used for software backward compatibility.
  - The [WIER](#) and [WIRQENSET/WIRQENCLR](#) registers have the same functionality. The [WIER](#) register is used for software backward compatibility.
  - The [WWER](#) and [WIRQWAKEEN](#) registers have the same functionality. The [WWER](#) is used for software backward compatibility.
  - The [WIRQSTATRAW](#) and [WIRQSTAT](#) registers give the same information when read. The [WIRQSTATRAW](#) register is used for debug.
-

### 22.4.5.2.2 Watchdog Timer Register Description

<b>Address Offset</b>	0x0000 0010	<b>Instance</b>	WD_TIMER2
<b>Physical Address</b>	0x4AE1 4010		
<b>Description</b>	This register controls the various parameters of the L4 interface.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																EMUFREE	IDLEMODE	RESERVED	SOFTRESET	RESERVED											

Bits	Field Name	Description	Type	Reset
31:6	RESERVED	Write 0s for future compatibility. Reads return 0.	R	0x0000000
5	EMUFREE	Emulation mode 0x0: Timer counter frozen in emulation 0x1: Timer counter free-running in emulation	RW	0

Bits	Field Name	Description	Type	Reset
4:3	IDLEMODE	Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state.  0x0: Force-idle mode: local target IDLE state follows (acknowledges) the system idle requests unconditionally, that is, regardless of the IP module internal requirements. Backup mode, for debug only.  0x1: No-idle mode: local target never enters IDLE state. Backup mode, for debug only.  0x2: Smart-idle mode: local target IDLE state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module should not generate (IRQ- or DMA-request-related) wake-up events.  0x3: Smart-idle wake-up-capable mode: local target IDLE state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module may generate (IRQ- or DMA-request-related) wake-up events when in IDLE state. Mode is relevant only if the appropriate IP module <i>swake-up</i> output(s) is (are) implemented.	RW	0x2
2	RESERVED	Write 0s for future compatibility. Reads return 0.	R	0
1	SOFTRESET	Software reset. (Optional)  Read 0x0: Reset done, no pending action Write 0x0: No action Write 0x1: Initiate software reset.  Read 0x1: Reset (software or other) ongoing	RW	0
0	RESERVED	Write 0s for future compatibility. Reads return 0.	R	0

## ***Real-Time Clock (RTC)***

---

---

This chapter provides a functional presentation of the Real-Time Clock (RTC) module.

<b>Topic</b>	<b>Page</b>
<b>23.1 RTC Overview.....</b>	<b>5827</b>
<b>23.2 RTC Environment.....</b>	<b>5829</b>
<b>23.3 RTC Integration .....</b>	<b>5830</b>
<b>23.4 RTC Functional Description .....</b>	<b>5832</b>
<b>23.5 RTC Low-Level Programming Guide .....</b>	<b>5840</b>
<b>23.6 RTC Register Manual.....</b>	<b>5841</b>

## 23.1 RTC Overview

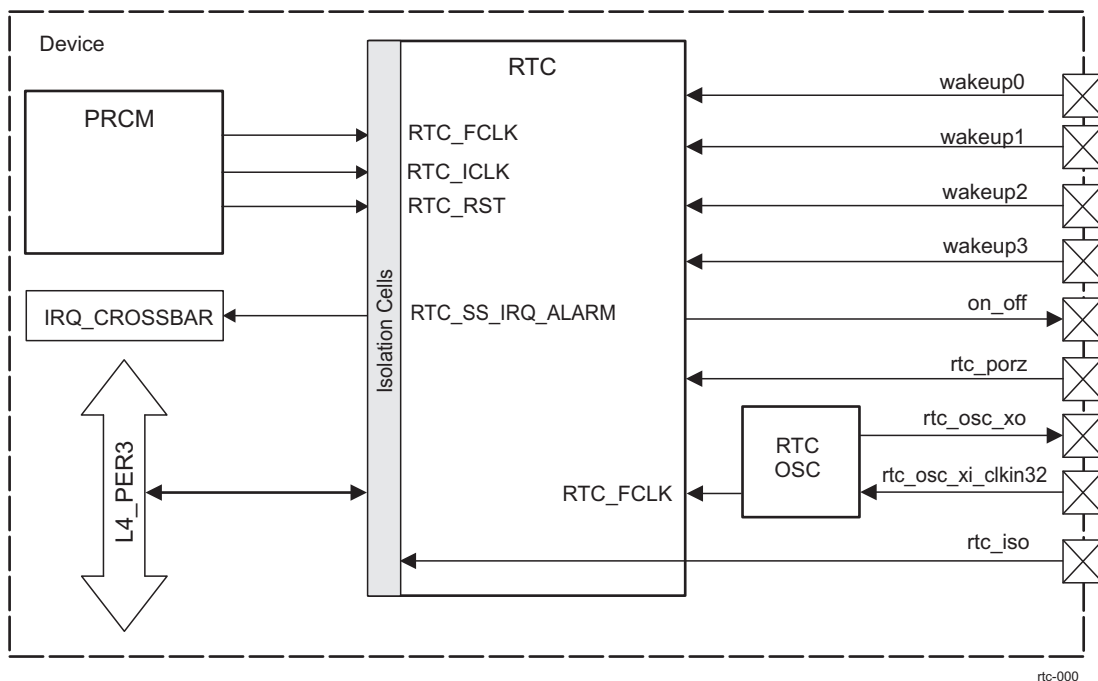

The real-time clock is a precise timer which can generate interrupts on intervals specified by the user. Interrupts can occur every second, minute, hour, or day. The clock can track the passage of real time for durations of several years, provided it has a sufficient power source the entire time.

The basic purpose of the RTC is to keep time of day. The other equally important purpose of the RTC is for Digital Rights management. Some degree of tamper proofing is needed to ensure that simply stopping, resetting, or corrupting the RTC does not go unnoticed so that if this occurs, the application can re-acquire the time of day from a trusted source. Another purpose of the RTC is to wake up the rest of the chip from a power-down state.

Alarms are available to interrupt the host processor at a particular time, or at periodic intervals, such as once per minute or once per day. In addition, the RTC can interrupt the CPU every time the calendar and time registers are updated, or at programmable periodic intervals.

Figure 23-1 shows the RTC functional block diagram.

**Figure 23-1. RTC Block Diagram**

### 23.1.1 RTC Features

The main features of the RTC are:

- 100-year calendar
- Counts seconds, minutes, hours, day of the week, date, month, and year with leap year compensation
- Binary-coded decimal (BCD) representation of time, calendar and alarm
- Alarm interrupt
- Periodic interrupt
- Single interrupt to the host processor
- External 32-kHz clock
- Isolated RTC voltage domain which remains powered during standby (RTC) mode while the rest of chip supplies are turned off
- RTC voltage domain has 3 × 32-bit read/write scratch registers retained in RTC modes
- RTC supports four wakeup input pins:
  - Each input has a filter to detect high or low transition with pulse duration.

- 
- Each pin has the following controls retained in standby mode and modified and read by control module in ON mode.
    - Enable bit (decides if the pin causes wakeup or not)
    - Edge sensitivity (rising, falling, or both causing wakeup)
    - Wake-up flag (sticky bits indicating wake-up source)
  - Allow paths for optional input to GPIO if not used for wakeup.
  - PMIC enable output pin to indicate external switched MAIN domain supplies to turn on or off based on wakeup state

## 23.2 RTC Environment

### 23.2.1 RTC External Interface

The RTC is connected to four external system wake-up signals. The RTC also can operate on external 32-kHz clock and has dedicated power-on reset pin. An external control of the RTC isolation cells is available to isolate RTC from other power domains when the PD\_RTC is the only powered domain.

The RTC module can be configured to produce a power-up/down control signal for the power-management chip (PMIC, if present).

Table 23-1 summarizes the external signals received and produced by the RTC module.

**Table 23-1. RTC External Signals**

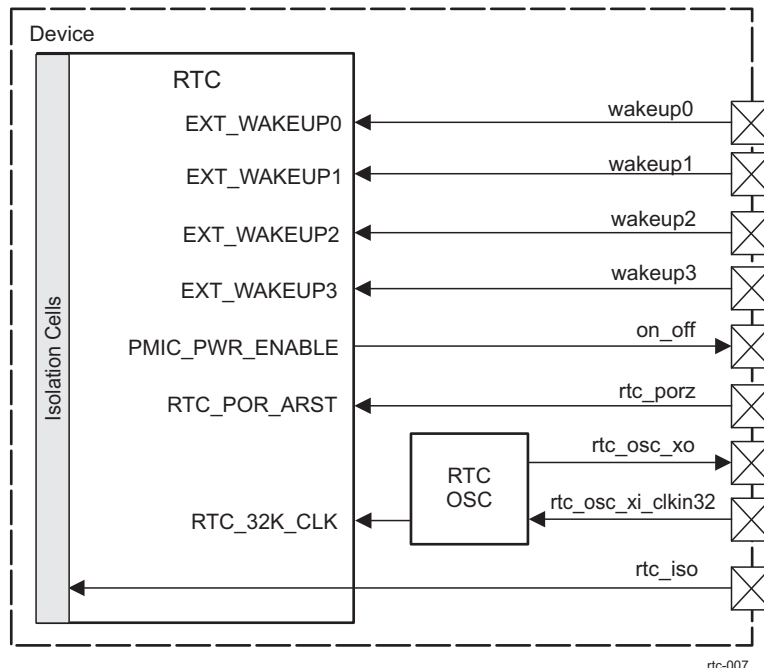

Device-Level Pin	Module-Level Signal	I/O	Description
rtc_osc_xi_clkin32	RTC_32K_CLK	I	RTC clock input
rtc_osc_xo	— <sup>(1)</sup>	O	32k oscillator crystal driver output. Unused if clock is provided from external source (crystal not connected)
wakeup0	EXT_WAKEUP0	I	External wake-up signal
wakeup1	EXT_WAKEUP1	I	External wake-up signal
wakeup2	EXT_WAKEUP2	I	External wake-up signal
wakeup3	EXT_WAKEUP3	I	External wake-up signal
on_off	PMIC_PWR_ENABLE	O	Companion PMIC control output (on/off) (optional)
rtc_porz	RTC_POR_ARST	I	External power-on-reset input (optional)
rtc_iso	— <sup>(2)</sup>	I	External control of isolation cells. This signal must be kept low (0) during RTC mode and high (1) after the device power supplies ramped-up. This can typically be achieved by connecting rtc_iso to the porz (not rtc_porz) with appropriate voltage level translation if necessary.

<sup>(1)</sup> Not a RTC module's signal. Crystal driver output from oscillator.

<sup>(2)</sup> Not a RTC module's signal. Controls isolation cells.

Figure 23-2 shows the described signals.

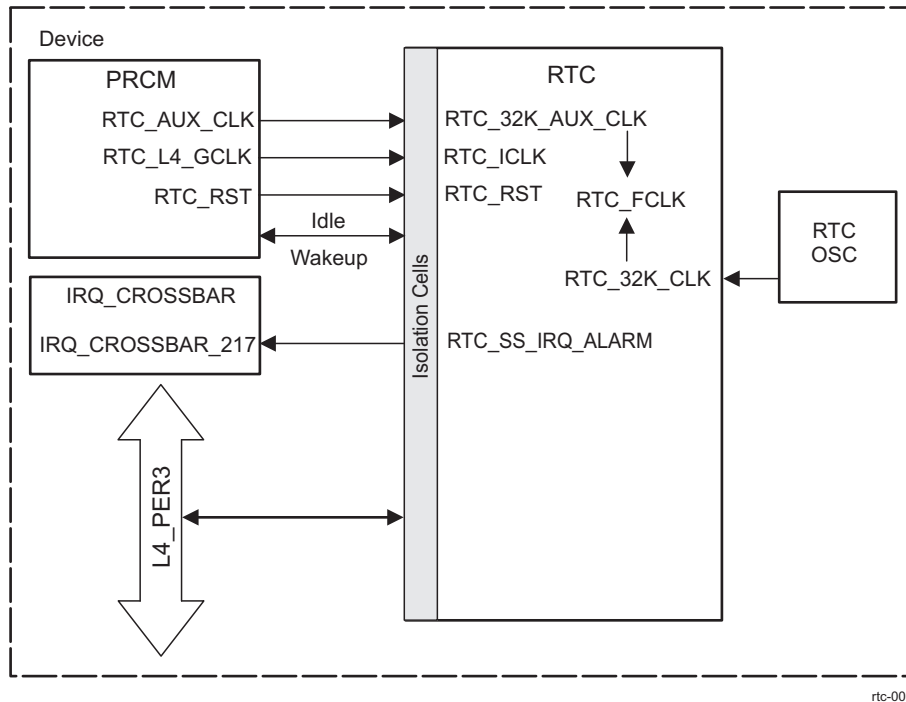

**Figure 23-2. RTC External Signals**

### 23.3 RTC Integration

Figure 23-3 shows the integration of the Real-time clock subsystem inside the device.

**Figure 23-3. RTC Module Integration**

rtc-002

**Table 23-2. RTC Integration Attributes**

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
RTC	PD_RTC	Yes	L4_PER3

**Table 23-3. RTC Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
RTC	RTC_32K_AUX_CLK	RTC_AUX_CLK	PRCM	RTC functional clock from PRCM
	RTC_32K_CLK	rtc_osc_xi	32k RTC Osc	RTC functional clock from oscillator/pin
	RTC_ICLK	RTC_L4_GICLK	PRCM	RTC interface clock
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
RTC	RTC_RST	RTC_RST	PRCM	Real-time clock subsystem PRCM reset signal

**Table 23-4. RTC Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	IRQ_CROSSBAR	Default Mapping	Description
RTC	RTC_SS_IRQ_ALARM	IRQ_CROSSBAR_217	-	Alarm interrupt going to device IRQ_CROSSBAR.

---

**Table 23-4. RTC Hardware Requests (continued)**

---

---

**No DMA Requests**

---

---

**NOTE:** The **Default Mapping** column in [Table 23-4, RTC Hardware Requests](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other inputs of each device Interrupt controller through the IRQ\_CROSSBAR module. For more information about the IRQ\_CROSSBAR module, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#). For more information about the device interrupt controllers, see [Chapter 17, Interrupt Controllers](#).

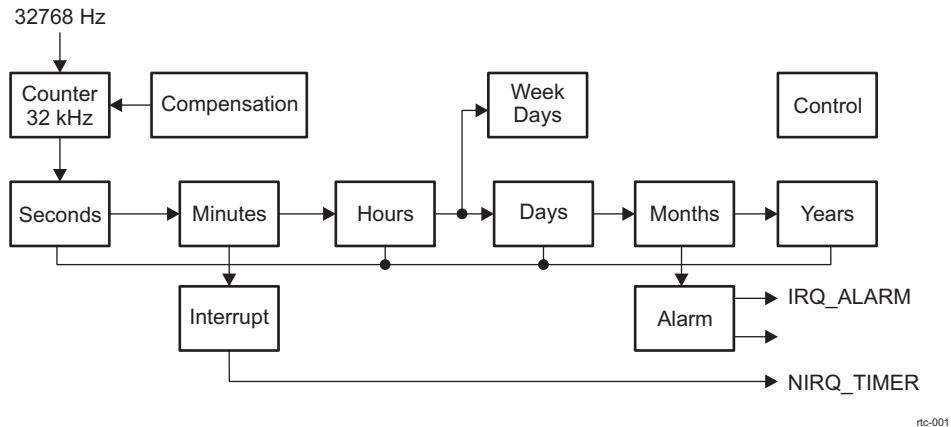

---

## 23.4 RTC Functional Description

This section defines the module interrupt capabilities and requirements.

Figure 23-4 shows the functional block diagram of the RTC module.

**Figure 23-4. RTC Functional Block Diagram**

rtc-001

### 23.4.1 Clock Source

The clock reference for the RTC is an internal 32-kHz clock signal (RTC\_AUX\_CLK from PRCM) or an external clock source of the 32.768 Hz frequency on the RTC\_32K\_CLK pin.

The RTC\_DISABLE bit in the control register ([RTC\\_CTRL\\_REG](#)) can be set to save power; however, the RTC\_DISABLE bit is not to be cleared once it has been set. If the application requires the RTC module to stop and continue, the STOP\_RTC bit in [RTC\\_CTRL\\_REG](#) is used instead.

The selection between external and internal clock is done through the RTC\_OSC\_REG register. Setting the [RTC\\_OSC\\_REG\[3\]](#) K32CLK\_SEL = 1 selects the 32-kHz external/oscillator clock (RTC\_32K\_CLK), setting it to 0 selects the PRM clock (RTC\_AUX\_CLK). [RTC\\_OSC\\_REG\[2\]](#) RES\_SELECT enables the internal feedback resistor. By modifying the [RTC\\_OSC\\_REG\[4\]](#) OSC32K\_GZ bit, software enables or disables the 32-kHz oscillator.

If the RTC module or RTC oscillator is not used, the rtc\_osc\_xi\_clkin32 device pin should be held low and rtc\_osc\_xo should be left unconnected. For more information about rtc pin connection if RTC is not used in the design, see the device-specific data manual.

### 23.4.2 Interrupt Support

#### 23.4.2.1 CPU Interrupts

The RTC generates two interrupt outputs:

- timer\_intr is a timer interrupt.
- alarm\_intr is an alarm interrupt.

These two interrupts are OR-ed inside the RTC subsystem and a single interrupt (RTC\_SS\_IRQ\_ALARM) is passed to the IRQ\_CROSSBAR module.

---

**NOTE:** Both interrupt outputs support high-level and high-pulse.

---

## 23.4.2.2 Interrupt Description

### 23.4.2.2.1 Timer Interrupt (*timer\_intr*)

The timer interrupt can be generated periodically: every second, every minute, every hour, or every day (see [RTC\\_INTERRUPTS\\_REG\[1:0\]](#) for a description of how to set this up). The `IT_TIMER` bit of [RTC\\_INTERRUPTS\\_REG](#) enables this interrupt. The timer interrupt is active-low.

The [RTC\\_STATUS\\_REG](#) bits are only updated at each new interrupt and occur according to [Table 23-5](#). For example, bit 2 (SEC) is set every time one second has passed. Bit 2 is also set when 1 minute has passed, because the completion of 1 minute also marks the completion of 1 second (from 59 seconds to 60 seconds). The same holds true for hours and days: each of them also corresponds to the passing of a second.

Conversely, bit 5 (DAY) is always set when a day has passed. It might also be set when an hour, minute, or second has passed. However, this only occurs when the elapsed hour, minute, or second corresponds to the start of a new day.

**Table 23-5. Interrupt Trigger Events**

STATUS_REG Bit	One Day Has Passed	One Hour Has Passed	One Minute Has Passed	One Second Has Passed
[5] (DAY)	1	0/1 <sup>(1)</sup>	0/1 <sup>(1)</sup>	0/1 <sup>(1)</sup>
[4] (HOUR)	1	1	0/1 <sup>(1)</sup>	0/1 <sup>(1)</sup>
[3] (MIN)	1	1	1	0/1 <sup>(1)</sup>
[2] (SEC)	1	1	1	1

<sup>(1)</sup> This event is triggered only when the elapsed time unit (for example, Day) corresponds to the passage of another unit (for example, Seconds). For example, when the clock ticks from 00:23:59:59 (days : hours : minutes : seconds) to 01:00:00:00.

### 23.4.2.2.2 Alarm Interrupt (*alarm\_intr*)

The alarm interrupt can be generated when the time set into the Timer/Calendar (TC) ALARM registers (see [Section 23.4.3.2](#)) is exactly the same as in the TC registers. This interrupt is then generated, if the `IT_ALARM` bit in the interrupt register ([RTC\\_INTERRUPTS\\_REG](#)) is set. This interrupt is low-level sensitive. The [RTC\\_STATUS\\_REG\[6\]](#) ALARM bit indicates that alarm interrupt has occurred. This interrupt is disabled by setting the [RTC\\_STATUS\\_REG\[6\]](#) ALARM bit to 1.

To set up an alarm:

- Modify the [RTC\\_ALARM\\_SECONDS\\_REG](#), [RTC\\_ALARM\\_MINUTES\\_REG](#), [RTC\\_ALARM\\_HOURS\\_REG](#), [RTC\\_ALARM\\_DAYS\\_REG](#), [RTC\\_ALARM\\_MONTHS\\_REG](#), and [RTC\\_ALARM\\_YEARS\\_REG](#) registers to the exact time an alarm is to be generated.
- Set the `IT_ALARM` bit in [RTC\\_INTERRUPTS\\_REG](#) to enable the alarm interrupt.

When the [RTC\\_PMIC\\_REG\[3:0\]](#) `EXT_WAKEUP_EN` and [RTC\\_PMIC\\_REG\[16\]](#) `PWR_ENABLE_EN` bits are set to 0x1, the `PMIC_PWR_ENABLE` is controlled by [EXT\\_WAKEUP\[3:0\]](#) ALARM and ALARM2.

The ALARM2 is set by writing the exact time and date to generate an alarm in [RTC\\_ALARM2\\_SECONDS\\_REG](#), [RTC\\_ALARM2\\_MINUTES\\_REG](#), [RTC\\_ALARM2\\_HOURS\\_REG](#), [RTC\\_ALARM2\\_DAYS\\_REG](#), [RTC\\_ALARM2\\_MONTHS\\_REG](#), and [RTC\\_ALARM2\\_YEARS\\_REG](#) registers.

### 23.4.3 RTC Programming/Usage Guide

#### 23.4.3.1 Time/Calendar Data Format

The time and calendar data in the RTC is stored in BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. Four bits are assigned to each BCD digit in most time/calendar registers; however, some of the register fields are shorter, because the range of valid numbers may be limited. For example, only three bits are required to represent the day of the week ([RTC\\_WEEKS\\_REG](#)), because only BCD numbers 1 through 7 are required. The following time and calendar registers are supported (BCD Format):

- [RTC\\_SECONDS\\_REG](#) — Second Count (00–59)
- [RTC\\_MINUTES\\_REG](#) — Minute Count (00–59)
- [RTC\\_HOURS\\_REG](#) — Hour Count (12HR: 01–12; 24HR: 00–23)
- [RTC\\_DAYS\\_REG](#) — Day of the Month Count (01–31)
- [RTC\\_WEEKS\\_REG](#) — Day of the Week (0–6: SUN = 0)
- [RTC\\_MONTHS\\_REG](#) — Month Count (01–12; JAN = 1)
- [RTC\\_YEARS\\_REG](#) — Year Count (00–99)

#### 23.4.3.2 Register Access

The three register types are as follows and each has its own access constraints:

- TC registers and TC alarm registers
  - TC registers (see [Section 23.4.3.1](#))
  - TC alarm registers:
    - [RTC\\_ALARM\\_SECONDS\\_REG](#)
    - [RTC\\_ALARM\\_MINUTES\\_REG](#)
    - [RTC\\_ALARM\\_HOURS\\_REG](#)
    - [RTC\\_ALARM\\_DAYS\\_REG](#)
    - [RTC\\_ALARM\\_MONTHS\\_REG](#)
    - [RTC\\_ALARM\\_YEARS\\_REG](#)
    - [RTC\\_ALARM2\\_SECONDS\\_REG](#)
    - [RTC\\_ALARM2\\_MINUTES\\_REG](#)
    - [RTC\\_ALARM2\\_HOURS\\_REG](#)
    - [RTC\\_ALARM2\\_DAYS\\_REG](#)
    - [RTC\\_ALARM2\\_MONTHS\\_REG](#)
    - [RTC\\_ALARM2\\_YEARS\\_REG](#)
- General registers:
  - [RTC\\_CTRL\\_REG](#)
  - [RTC\\_STATUS\\_REG](#)
  - [RTC\\_INTERRUPTS\\_REG](#)
  - [RTC\\_SCRATCH0\\_REG](#)
  - [RTC\\_SCRATCH1\\_REG](#)
  - [RTC\\_SCRATCH2\\_REG](#)
  - [RTC\\_KICK0\\_REG](#)
  - [RTC\\_KICK1\\_REG](#)
  - [RTC\\_REVISION\\_REG](#)
  - [RTC\\_SYSCONFIG\\_REG](#)
  - [RTC\\_IRQWAKEEN](#)
  - [RTC\\_PMIC\\_REG](#)

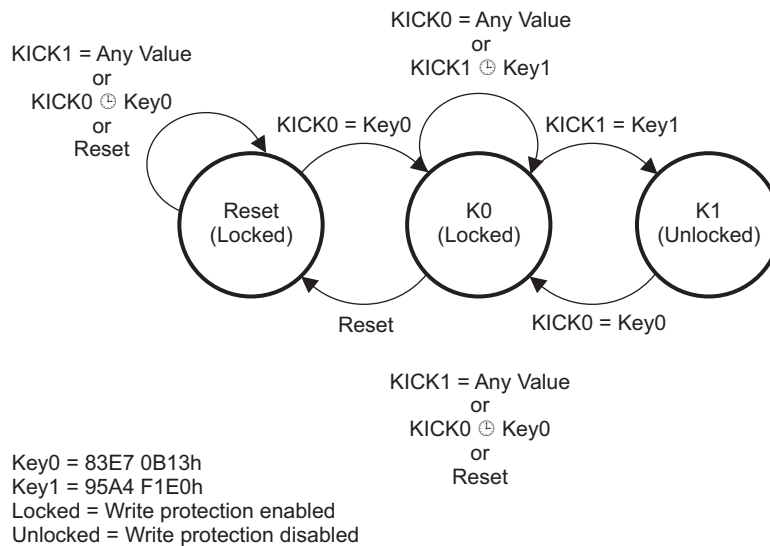

- RTC\_RTL\_DEBOUNCE\_REG
- RTC\_OSC\_REG
- Compensation registers:
  - RTC\_COMP\_LSB\_REG
  - RTC\_COMP\_MSB\_REG

### 23.4.3.3 Register Spurious Write Protection

The module also contains a kicker mechanism (see Figure 23-5) to prevent any spurious writes from changing the register values.

**NOTE:** This mechanism requires two register writes to the KICK0 and KICK1 registers with exact data values before the kicker lock mechanism is released. Once released, the registers are writeable. The KICK0 data is 83E7 0B13h; the KICK1 data is 95A4 F1E0h. The mechanism remains in an unlocked state until a reset or invalid data pattern is written to one of the RTC\_KICK0\_REG or RTC\_KICK1\_REG registers.

**Figure 23-5. Kick Register State Machine Diagram**

- S0 is the Reset/Idle state
- S1 is an write cycle of 83E7 0B13h at KICK0 completed state
- S2 is the UNLOCK register WRT state
- S0 → S1 when write cycle of 83E7 0B13h at KICK0
- S1 → S2 when write cycle of 95A4 F1E0h at KICK1
- S1 → S0 when reset event
- S2 → S0 when reset event or write cycle of NOT 83E7 0B13h at KICK0 or write cycle at KICK1
- S2 → S1 when write cycle of 83E7 0B13h at KICK0

### 23.4.3.4 Reading the Timer/Calendar (TC) Registers

The TC registers have a read-show register. The reading of the SECONDS register updates all TC registers. For example, the Year is updated only on a reading of the SECONDS register. The TC registers are updated every second as the time changes. During a read of the SECONDS register, the RTC copies the current values of the time/date registers into shadow read registers. This isolation assures that the CPU can capture all the time/date values when the SECONDS read request occurs and is not subject to changing register values from time updates.

If desired, the RTC also provides a one-time-triggered minute-rounding feature to round the MINUTE:SECOND registers to the nearest minute (with zero seconds). This feature is enabled by setting the ROUND\_30S bit in the control register ([RTC\\_CTRL\\_REG](#)). The RTC automatically rounds the time values to the nearest minute the next time the SECONDS register is read.

---

**NOTE:** Software should always read the SECONDS register first. However, software does not have to poll any status bit to determine when to read the TC registers. [Table 23-6](#) defines the TC set that gets shadowed.

---

**Table 23-6. RTC Register Names and Values**

Time Unit	Range	Remarks
Year	00 to 99	
Month	01 to 12	
Day	01 to 31	Months 1, 3, 5, 7, 8, 10, 12
	01 to 30	Months 4, 6, 9, 11
	01 to 29	Month 2 (leap year)
	01 to 28	Month 2 (common year)
Week	00 to 06	Day of week
Hour	00 to 23	24-hour mode
	01 to 12	AM/PM mode
Minute	00 to 59	
Seconds	00 to 59	

#### 23.4.3.4.1 Rounding Seconds

Time can be rounded to the closest minute, by setting the ROUND\_30S bit of the control register ([RTC\\_CTRL\\_REG](#)). When this bit is set, TC values are set to the closest minute value at the next second. The ROUND\_30S bit is automatically cleared when rounding time is performed.

**Example:**

- If current time is 10H59M45S, round operation changes time to 11H00M00S.
- If current time is 10H59M29S, round operation changes time to 10H59M00S.

#### 23.4.3.5 Modifying the TC Registers

To write correct data from and to the TC and TC alarm registers and read the TC alarm registers, the MPU must first read the BUSY bit of the status register ([RTC\\_STATUS\\_REG](#)) until BUSY is equal to zero. Once the BUSY flag is zero, there is a 15- $\mu$ s access period in which the MPU can program the TC and TC alarm registers. Once the 15- $\mu$ s access period passes, the BUSY flag must again be read from the STATUS register as previously described. If the MPU accesses the TC registers outside of the access period, then the access is not assured.

The MPU can access the [RTC\\_STATUS\\_REG](#) and the [RTC\\_CTRL\\_REG](#) registers at any time, with the exception of the [RTC\\_CTRL\\_REG](#)[5] bit, which can only be changed when the RTC is stopped. The MPU can stop the RTC by clearing the STOP\_RTC bit of [RTC\\_CTRL\\_REG](#). After clearing this bit, the RUN bit in [RTC\\_STATUS\\_REG](#) must be checked to verify the RTC has stopped. Once this is confirmed, the TC values can be updated. After the values have been updated, the RTC can be restarted by resetting the STOP\_RTC bit.

---

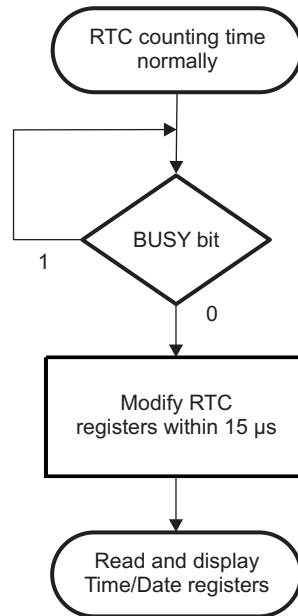

**NOTE:** After writing to a TC register, software must wait four clock cycles before reading the value from the register. If this wait time is not observed and the TC register is accessed, then old data will be read from the register.

---

**CAUTION**

To remove any possibility of interrupting the register read process, which introduces a risk of violating the authorized 15- $\mu$ s access period, TI recommends disabling all incoming interrupts during the register read process.

**Figure 23-6. Flow Control for Updating RTC Registers**

### 23.4.3.5.1 General Registers

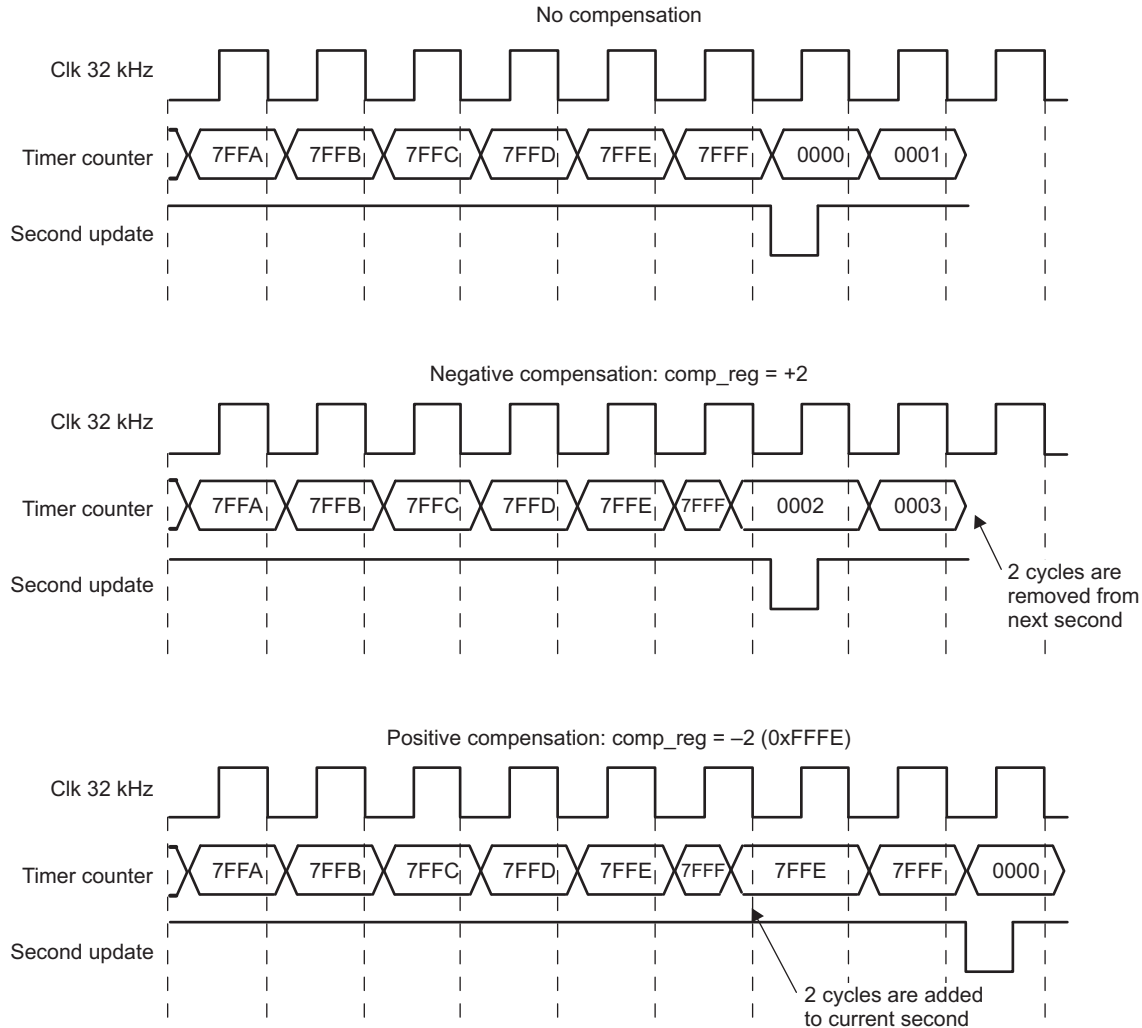

The MPU can access the [RTC\\_STATUS\\_REG](#) and the [RTC\\_CTRL\\_REG](#) registers at any time (except the CTRL\_REG[5] bit, which must be changed only when the RTC is stopped). For the [RTC\\_INTERRUPTS\\_REG](#) register, the MPU should respect the available access period to prevent spurious interrupt.

The RTC\_DISABLE bit of the [RTC\\_CTRL\\_REG](#) register must only be used to completely disable the RTC function. When this bit is set, the 32-kHz clock is gated, and the RTC is frozen. From this point, resetting the RTC\_DISABLE bit to zero can lead to unexpected behavior. To save power, this bit should only be used if the RTC function is unwanted in the application.

### 23.4.3.6 Crystal Compensation

To compensate for any inaccuracy of the 32-kHz oscillator the MPU can perform a calibration of the oscillator frequency, calculate the drift compensation versus a 1-hour period, and load the compensation registers with the drift compensation value. Auto compensation is enabled by the AUTO\_COMP bit in the [RTC\\_CTRL\\_REG](#) register. If the value of the COMP\_REG registers ([RTC\\_COMP\\_LSB\\_REG](#) and [RTC\\_COMP\\_MSB\\_REG](#)) is positive, compensation occurs after the second change event. COMP\_REG cycles are removed from the next second. If the COMP\_REG value is negative, compensation occurs before the second change event. COMP\_REG cycles are added to the current second. This enables compensation with a 1 32-kHz period accuracy each hour. The waveform in [Figure 23-7](#) summarizes positive and negative compensation effect.

Access to the [RTC\\_COMP\\_MSB\\_REG](#) and [RTC\\_COMP\\_LSB\\_REG](#) registers must respect the available access period. These registers should not be updated during compensation (the first second of each hour), but it is alright to update them during the second preceding a compensation event. For example, the MPU could load the compensation value into these registers after each hour event, during an available access period.

**Figure 23-7. Compensation Illustration**

rtc-005

### 23.4.4 Scratch Registers

The RTC provides three general-purpose registers (RTC\_SCRATCHx\_REG) that can be used to store 32-bit words -- these registers have no functional purpose for the RTC. Software using the RTC may find the SCRATCHx\_REG registers to be useful in indicating RTC states. For example, the RTC\_SCRATCHx\_REG (RTC\_SCRATCH0\_REG, RTC\_SCRATCH1\_REG, RTC\_SCRATCH2\_REG) registers may be used to indicate write-protection lock status or unintentional power downs. To indicate write-protection, the software should write a unique value to one of the RTC\_SCRATCHx\_REG registers when write-protection is disabled and another unique value when write-protection is enabled again. In this way, the lock-status of the registers can be determined quickly by reading the RTC\_SCRATCHx\_REG register. To indicate unintentional power downs, the software should write a unique value to one of the RTC\_SCRATCHx\_REG registers when RTC is configured and enabled. If the RTC is unintentionally powered down, the value written to the RTC\_SCRATCHx\_REG register is cleared.

### 23.4.5 Debouncing

The debounce timer uses the 32768-Hz clock or the clock coming from the external oscillator, depending on the SW configurations for the RTC. It allows choosing the timing or accuracy of the "debouncing".

A register receives a bit from the reference pin. Software then chooses the timing if it uses the debouncing feature like a timer, or it chooses the accuracy if it uses the debouncing like a real debouncing. The debouncing is finished when the reference pin stays the same value, defined in [RTC\\_RTL\\_DEBOUNCE\\_REG\[7:0\]](#) DEBOUNCE\_REG, for a defined time.

If the RTC module uses the internal 32-kHz clock then setting the [RTC\\_RTL\\_DEBOUNCE\\_REG\[7:0\]](#) DEBOUNCE\_REG to 0x0 results in a debounce time of 30.52us. Otherwise (DEBOUNCE\_REG = n) the debounce time is 30.52μs × (n + 1). The debounce time may be different, depending on, whether the module uses the internal 32 kHz clock, or an external clock source.

## 23.4.6 Power Management

### 23.4.6.1 Device-Level Power Management

The RTC supports the power idle protocol. The RTC has two SWakeup ports: one for the alarm event and one for a timer event.

When the RTC is in IDLE mode, the clock is turned off and the 32 kHz clock remains on. The time and calendar continue to count in IDLE mode. When the RTC is placed back in FUNCTIONAL mode, the TC registers can be read. The RTC idle mode configuration is done through the [RTC\\_SYSCONFIG\\_REG\[1:0\]](#) IDLEMODE bit (see [Table 23-7](#)).

**Table 23-7. RTC Idle Configuration**

IDLEMODE	Description
0x0	Force IDLE: idle state of the local target follows (acknowledges) the system IDLE request unconditionally
0x1	No-idle mode: RTC never enters idle state
0x2	Smart-idle mode: RTC subsystem waits for all interrupts/events to be serviced before entering in IDLE mode.
0x3	Smart-idle wakeup-capable mode: RTC eventually acknowledges the system IDLE requests, depending on its internal requirements, RTC can generate wakeup events when in idle state.

The Alarm SWakeup event can be used to wake up the RTC when it is in idle state. To do so, the alarm must be set and enabled before RTC enters idle state. Also the wakeup generation for alarm/timer event must be set (bits [1:0] in the [RTC\\_IRQWAKEEN](#) register). Once this is done, the SWakeup event occurs when the alarm event triggers.

---

**NOTE:** SWakeup is not periodic, using Timer SWakeup event to wake up the RTC when in idle state is not recommended. Use Alarm SWakeup instead.

---

There are two idle modes: smart-idle mode and smart-idle wakeup-capable mode. The RTC should be configured to smart-idle wakeup-capable mode in order to use the SWakeup events.

### 23.4.6.2 Subsystem-Level Power Management — PMIC Mode

The RTC generates PMIC\_PWR\_ENABLE control, which can be used to control an external PMIC. The control of the associated PMIC wakeups and alarms is done through the [RTC\\_PMIC\\_REG\[22:0\]](#) bits.

## 23.5 RTC Low-Level Programming Guide

### 23.5.1 Global Initialization

#### 23.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the real time clock is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the RTC.

**Table 23-8. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. For more information about the module configuration, see <a href="#">Section 3.1.1.1.2, Module Level Clock Management</a> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Control module	Module-specific pad muxing must be set in the control module. For more information about the module configuration, see <a href="#">Section 18.4.6.1.1, Pad Configuration Registers</a> in <a href="#">Chapter 18, Control Module</a> .
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see, <a href="#">Section 18.4.6.4, IRQ_CROSSBAR Module Functional Description</a> , in <a href="#">Chapter 18, Control Module</a> .

#### 23.5.1.2 RTC Module Global Initialization

##### 23.5.1.2.1 Main Sequence – RTC Module Global Initialization

[Table 23-9](#) lists the steps for initializing the RTC module when the module is to be used for the first time.

**Table 23-9. RTC Module Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Write 0x83E7 0B13 to the Kick0 Register to unlock register writes	<a href="#">RTC_KICK0_REG</a>	0x83E70B13
Write 0x95A4 F1E0 to the Kick1 Register to unlock register writes	<a href="#">RTC_KICK1_REG</a>	0x95A4F1E0
Select the clock source (internal or external 32-kHz clock)	<a href="#">RTC_OSC_REG</a> [3] 32KCLK_SEL	-
If external clock is selected, start the oscillator. Wait for oscillator to stabilize.	<a href="#">RTC_OSC_REG</a> [4] OSC32K_GZ	0
Enable the 32-kHz clock	<a href="#">RTC_OSC_REG</a> [6] 32KCLK_EN	1
Configure slave idle mode	<a href="#">RTC_SYSCONFIG_REG</a> [1:0] IDLEMODE	0x-
Enable interrupts, if needed	<a href="#">RTC_INTERRUPTS_REG</a> [4:0]	0x-
Enable wakeup interrupts, if needed	<a href="#">RTC_IRQWAKEEN</a> [1:0]	0x-
Set current time	<a href="#">RTC_SECONDS_REG</a> [6:0]	BCD
	<a href="#">RTC_MINUTES_REG</a> [6:0]	BCD
	<a href="#">RTC_HOURS_REG</a> [5:0]	BCD
Set current date	<a href="#">RTC_DAYS_REG</a> [5:0]	BCD
	<a href="#">RTC_MONTHS_REG</a> [4:0]	BCD
	<a href="#">RTC_YEARS_REG</a> [7:0]	BCD
	<a href="#">RTC_WEEKS_REG</a> [2:0]	BCD
Run the real-time clock	<a href="#">RTC_CTRL_REG</a> [0] STOP_RTC	1

## 23.6 RTC Register Manual

### 23.6.1 RTC Instance Summary

**Table 23-10. RTC Instance Summary**

Module Name	Base Address	Size
RTC_SS	0x4883 8000	160 bytes

### 23.6.2 RTC\_SS Registers

#### 23.6.2.1 RTC\_SS Register Summary

**Table 23-11. RTC\_SS Registers Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	RTC_SS Physical Address
<a href="#">RTC_SECONDS_REG</a>	RW	32	0x0000 0000	0x4883 8000
<a href="#">RTC_MINUTES_REG</a>	RW	32	0x0000 0004	0x4883 8004
<a href="#">RTC_HOURS_REG</a>	RW	32	0x0000 0008	0x4883 8008
<a href="#">RTC_DAYS_REG</a>	RW	32	0x0000 000C	0x4883 800C
<a href="#">RTC_MONTHS_REG</a>	RW	32	0x0000 0010	0x4883 8010

### 23.6.2.2 RTC\_SS Register Description

**Table 23-12. RTC\_SECONDS\_REG**

<b>Address Offset</b>	0x0000 0000	<b>Instance</b>	RTC_SS
<b>Physical Address</b>	0x4883 8000		
<b>Description</b>	Used to program the required seconds value of the current time. Seconds are stored in BCD format, the decimal numbers are encoded with their binary equivalent. That is, if seconds value is 45, then SEC0 = 5 and SEC1 = 4.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																SEC1			SEC0												

Bits	Field Name	Description	Type	Reset
31:7	RESERVED	Reserved	R	0x0
6:4	SEC1	Second digit of seconds. Range is 0 to 5	RW	0x0
3:0	SEC0	First digit of seconds. Range is 0 to 9	RW	0x0

## 24.1 Multimaster High-Speed I<sup>2</sup>C Controller

This section describes the high-speed inter-integrated circuit (I<sup>2</sup>C) controller modules in the device.

---

**NOTE:** Not all I<sup>2</sup>C instances support HS-mode operation. See the Device Data Manual for details.

---

### 24.1.1 HS I<sup>2</sup>C Overview

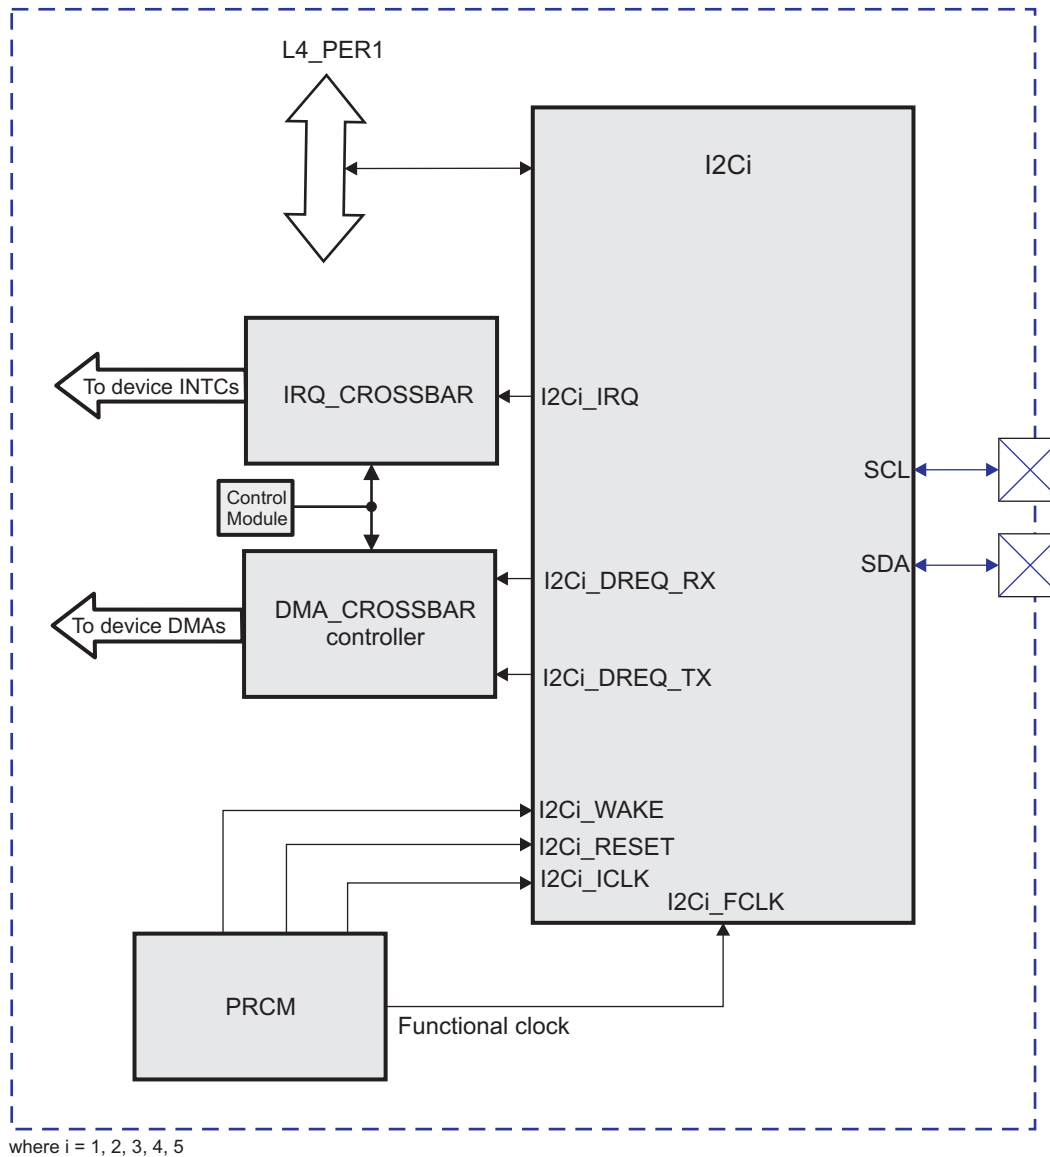

The device contains five multimaster high-speed (HS) inter-integrated circuit (I<sup>2</sup>C) controllers (I2C<sub>*i*</sub> modules, where  $i = 1, 2, 3, 4, 5$ ) each of which provides an interface between a local host (LH), such as a digital signal processor (DSP), and any I<sup>2</sup>C-bus-compatible device that connects through the I<sup>2</sup>C serial bus. External components attached to the I<sup>2</sup>C bus can serially transmit and receive up to 8 bits of data to and from the LH device through the 2-wire I<sup>2</sup>C interface.

Each multimaster HS I<sup>2</sup>C controller can be configured to act like a slave or master I<sup>2</sup>C-compatible device.

I2C1 and I2C2 controllers have dedicated I2C compliant open drain buffers, and support Fast mode (up to 400Kbps). I2C3, I2C4 and I2C5 controllers are multiplexed with standard LVCMOS IO and connected to emulate open drain. I<sup>2</sup>C emulation is achieved by configuring the LVCMOS buffers to output Hi-Z instead of driving high when transmitting logic 1. These controllers support HS mode (up to 3.4Mbps). For the specific IO timing characteristics of the different I<sup>2</sup>C instances, see the device data manual.

[Figure 24-1](#) shows the I<sup>2</sup>C.

Figure 24-1. HS I<sup>2</sup>C Controllers

I2C-001

The multimaster HS I<sup>2</sup>C controllers have the following features:

- Compliant with Philips I<sup>2</sup>C specification version 2.1
- Supports a standard mode (up to 100 kbps) and fast mode (up to 400 kbps)
- Supports HS mode for transfer up to 3.4 Mbps (only for I2C3, I2C4 and I2C5)
- 7-bit and 10-bit device addressing modes
- General call
- Start/Restart/Stop
- Multimaster transmitter/slave receiver mode
- Multimaster receiver/slave transmitter mode
- Combined master transmit/receive and receive/transmit mode
- Built-in FIFOs (16 bytes) for buffered read or write
- Module enable/disable capability
- Programmable multislave channel (responds to four separate addresses)

- Programmable clock generation
- 8-bit-wide data access
- Designed for low power consumption
- Implement Auto Idle mechanism
- Implement Idle Request/Idle Acknowledge handshake mechanism
- Support for asynchronous wakeup mechanism
- Two direct memory access (DMA) channels
- Wide interrupt capability

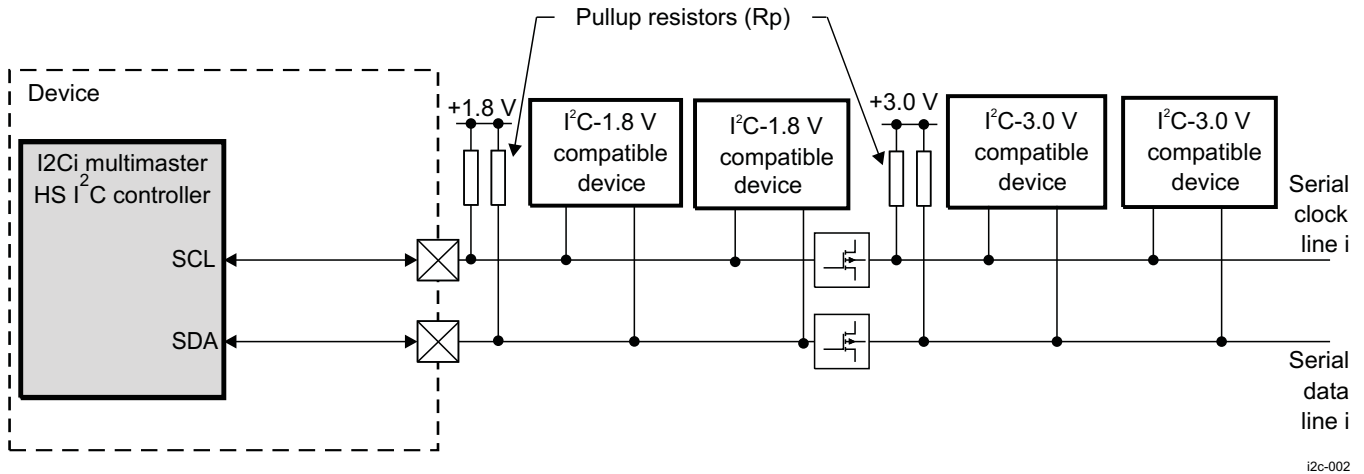

### 24.1.2 HS I<sup>2</sup>C Environment

This section describes the HS I<sup>2</sup>C application fields from an environment point of view (external connections). It describes HS I<sup>2</sup>C connectivity options, lists all possible interfaces, and describes the protocol and data format used in each case.

#### 24.1.2.1 HS I<sup>2</sup>C Typical Application

Figure 24-2 shows the multimaster HS I<sup>2</sup>C controllers and their related connections with I<sup>2</sup>C-compliant devices.

Figure 24-2. HS I<sup>2</sup>C and Typical Connections to I<sup>2</sup>C Devices

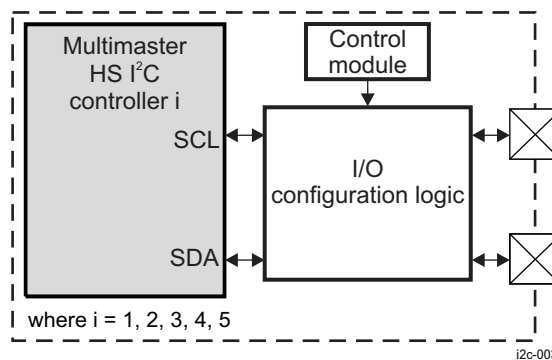

i2c-002

##### 24.1.2.1.1 HS I<sup>2</sup>C Pins for Typical Connections in I<sup>2</sup>C Mode

Figure 24-3 shows the multimaster HS I<sup>2</sup>C controller pins used for typical connections with I<sup>2</sup>C devices.

Figure 24-3. HS I<sup>2</sup>C Interface Signals

i2c-003

##### 24.1.2.1.2 HS I<sup>2</sup>C Interface Typical Connections

Table 24-1 lists the pins associated with the I<sup>2</sup>C interface.

Table 24-1. HS I<sup>2</sup>C Input/Output

Signal	Device Level Signal	I/O <sup>(1)</sup>	Description	Reset Value
SCL	i2cj_scl <sup>(2)</sup>	I/O	I <sup>2</sup> C serial clock line. Open-drain output buffer.	1
SDA	i2cj_sda <sup>(2)</sup>	I/O	I <sup>2</sup> C serial data line. Open-drain output buffer.	1

<sup>(1)</sup> I = Input; O = Output

<sup>(2)</sup> j= 1 and 2

**Table 24-1. HS I<sup>2</sup>C Input/Output (continued)**

Signal	Device Level Signal	I/O <sup>(1)</sup>	Description	Reset Value
SCL	i2ci_scl <sup>(3)</sup>	I/O	I <sup>2</sup> C serial clock line. Emulated open-drain output buffer.	1
SDA	i2ci_sda <sup>(3)</sup>	I/O	I <sup>2</sup> C serial data line. Emulated open-drain output buffer.	1

<sup>(3)</sup> i = 3 to 5

**NOTE:** For the i2ci\_scl and i2ci\_sda signals to work properly, the INPUTENABLE bit of the appropriate CTRL\_CORE\_PAD\_x registers should be set to 0x1 because of retiming purposes.

**NOTE:** The path from a module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. Refer to the sections [Section 18.4.6.1.1 Pad Functional Multiplexing](#) of the chapter *Control Module*, for more information.

### 24.1.2.2 HS I<sup>2</sup>C Typical Connection Protocol and Data Format

#### 24.1.2.2.1 HS I<sup>2</sup>C Serial Data Format

The I<sup>2</sup>C controller operates in 8-bit word data format (byte write access supported for the last access). Each byte transmitted or received on the serial data line is 8 bits long. The number of bytes that can be transmitted or received is not restricted. The data is transferred with the most-significant bit (MSB) first. In receiver mode, each byte is followed by an acknowledge bit from the I<sup>2</sup>C. [Figure 24-4](#) shows a typical I<sup>2</sup>C communication format.

#### 24.1.2.2.2 HS I<sup>2</sup>C Data Validity

The data on the serial data line (SDA) must be stable during the high period of the serial clock line. The high and low states of the data line can change only when the clock signal on the serial clock line (SCL) is low.

[Figure 24-5](#) is an example of data validity requirements.

Figure 24-5. HS I<sup>2</sup>C Bit Transfer on the I<sup>2</sup>C Bus

i2c-005

### 24.1.2.2.3 HS I<sup>2</sup>C Start and Stop Conditions

The I<sup>2</sup>C module generates start (S) and stop (P) conditions when it is configured as a master.

- An S condition is a high-to-low transition on the serial data line while serial clock line is high.
- A P condition is a low-to-high transition on the serial data line while serial clock line is high.

The bus is considered busy after the S condition (the I2Ci. [12] BB bit is 1 to indicate that the bus is busy) and free after the P condition (the I2Ci.I2C\_IRQSTATUS\_RAW [12] BB bit is 0 to indicate that the bus is free).

Figure 24-6 shows the waveforms that occur during an S and a P condition.

Figure 24-6. HS I<sup>2</sup>C S and P Condition Events

i2c-006

**NOTE:** I<sup>2</sup>C controller does not support messages non-compliant with I2C standard. Void messages are non-standard I<sup>2</sup>C messages and will lockup the controller. A void message is a START condition followed by a STOP condition, in other words, while the bus is free the SDA line is pulled low (START) and then released (STOP). This would result in a timeout (software) of the next master transfer which would never complete. A soft reset of the controller is recommended for recovery.

### 24.1.2.2.4 HS I<sup>2</sup>C Addressing

The I<sup>2</sup>C module supports two data formats in fast/standard (F/S) and HS modes:

- 7-bit/10-bit addressing format
- 7-bit/10-bit addressing format with repeated start (Sr) condition

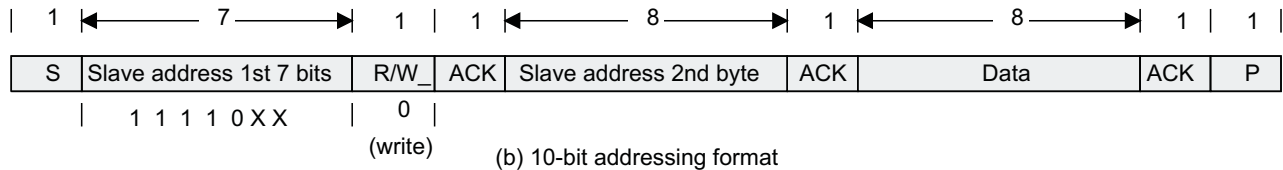

#### 24.1.2.2.4.1 Data Transfer Formats in F/S Mode

Figure 24-7 shows the I<sup>2</sup>C data transfer formats in F/S mode.

**Figure 24-7. HS I<sup>2</sup>C Data Transfer Formats in F/S Mode**

(a) 7-bit addressing format

(b) 10-bit addressing format

(c) Addressing format with repeated start condition

i2c-007

The first word after an S condition consists of 8 bits. In acknowledge mode, an extra dedicated acknowledgment bit is inserted after each byte.

In addressing formats with 7-bit addresses, the first byte is composed of 7 MSB slave address bits and 1 least-significant bit (LSB) R/W<sub>-</sub> bit.

The LSB R/W<sub>-</sub> bit of the address byte indicates the transmission direction of the data bytes that follow it. If R/W<sub>-</sub> is 0, the master writes data to the selected slave; if it is 1, the master reads data from the slave.

In addressing formats with 10-bit addresses, the structure of the first byte is 11110XXY, where XX is the two MSBs of the 10-bit addresses, and Y is the R/W<sub>-</sub> bit. If the R/W<sub>-</sub> bit is 0, the next byte contains the last 8 bits of the slave address. If the R/W<sub>-</sub> bit is 1, the next byte contains data transmitted from the slave to the master.

#### 24.1.2.2.4.2 Data Transfer Format in HS Mode

Figure 24-8 shows the I<sup>2</sup>C data transfer format in HS mode.

**Figure 24-8. HS I<sup>2</sup>C Data Transfer in HS Mode**

S = Start; Sr = repeated start; P = Stop; F/S = Fast/standard mode; HS = High-speed mode

i2c-008

Each multimaster HS I<sup>2</sup>C controller can also operate in HS mode. In this case, after the S condition, the module, which is in F/S mode, writes the master code address (00001XXX, where XXX is the variable portion of the master code) on the bus. No device connected on the same bus acknowledges this address. The module switches the clock to the HS clock and after an Sr condition, and sends the slave address and the data, as shown in Figure 24-8.

#### 24.1.2.2.5 HS I<sup>2</sup>C Master Transmitter

In master transmitter mode, data assembled in one of the previously described data formats is shifted out on the serial data line SDA in sync with the self-generated clock pulses on the serial clock line SCL. The clock pulses are inhibited and SCL is held low when the intervention of the processor is required (XUDF) after a byte is transmitted.

#### 24.1.2.2.6 HS I<sup>2</sup>C Master Receiver

Master receiver mode can be entered only from master transmitter mode. With any of the address formats (a), (b), or (c) (see Figure 24-7), if R/W<sub>0</sub> is high, the module enters master receiver mode after the slave address byte and bit R/W<sub>0</sub> are transmitted. Serial data bits received on bus line SDA are shifted in synchronization with the self-generated clock pulses on SCL.

#### 24.1.2.2.7 HS I<sup>2</sup>C Slave Transmitter

Slave transmitter mode can be entered only from slave receiver mode. With any of the address formats (a), (b), or (c) (see Figure 24-7), the slave transmitter is entered if the slave address byte is the same as its own address and bit R/W<sub>0</sub> is transmitted, if R/W<sub>0</sub> is high. The slave transmitter shifts the serial data out on the data line SDA in sync with the clock pulses that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (XUDF).

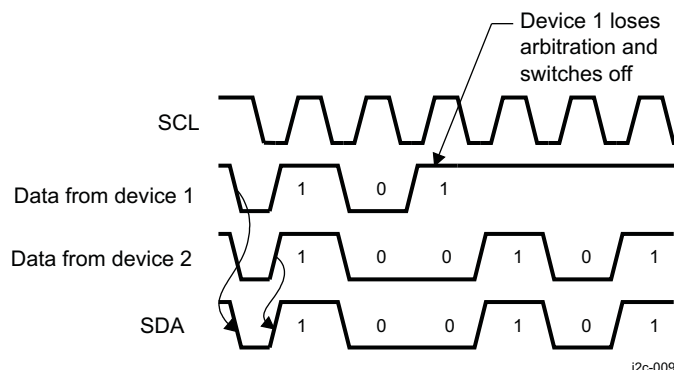

#### 24.1.2.2.8 HS I<sup>2</sup>C Slave Receiver

In this mode, serial data bits received on the bus line SDA are shifted-in in sync with the clock pulses on SCL that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (ROVR) after a byte is received.

#### 24.1.2.2.9 HS I<sup>2</sup>C Bus Arbitration

If two or more master transmitters start a transmission on the same bus almost simultaneously, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial bus by the competing transmitters. When a transmitter senses that a high signal it has presented on the bus has been overruled by a low signal, it switches to the slave receiver mode, sets the arbitration lost (AL) flag, and generates the arbitration lost interrupt. Figure 24-9 shows the arbitration procedure between two devices. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

Figure 24-9. HS I<sup>2</sup>C Arbitration Between Master Transmitters

#### 24.1.2.2.10 HS I<sup>2</sup>C Clock Generation and Synchronization

Under normal conditions, only one master device generates the clock signal, SCL. However, there are two or more master devices during the arbitration procedure, and the clock must be synchronized so that the data output can be compared. The wired-AND property of the clock line means that a device that first generates a low period of the clock line overrules the other devices. At this high/low transition, the clock generators of the other devices are forced to start generation of their own low period. The clock line is

then held low by the device with the longest low period, while the other devices that finish their low periods must wait for the clock line to be released before starting their high periods. A synchronized signal on the clock line is thus obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period. If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the WAIT-state. In this way a slave can slow down a fast master and the slow device can create enough time to store a received byte or prepare a byte to be transmitted (clock stretching).

**NOTE:** In case the SCL or SDA lines are stuck low, a bus clearing operation is supported:

- If the clock line (SCL) is stuck low, the preferential procedure is to reset the bus using the hardware reset signal if your I<sup>2</sup>C devices have hardware reset inputs. If the I<sup>2</sup>C devices do not have hardware reset inputs, cycle power to the devices to activate the mandatory internal power-on reset (POR) circuit.
- If the data line (SDA) is stuck low, the master should send nine clock pulses. The device that held the bus low should release it sometime within those nine clocks. If not, then use the hardware reset or cycle power to clear the bus.

Figure 24-10 shows clock synchronization.

**Figure 24-10. HS I<sup>2</sup>C Clock Generators Synchronization**

i2c-010

### 24.1.3 HS I<sup>2</sup>C Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 24-11 shows the integration of the five HS I<sup>2</sup>C controllers in the device.

Figure 24-11. HS I<sup>2</sup>C Integration

i2c-043

**NOTE:** For more information about the slave idle protocol and the wake-up request, see [Section 3.7, Power Management Functional Description](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 24-2 through Table 24-4 summarize the integration of the module in the device.

**Table 24-2. HS I<sup>2</sup>C Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect

I2C5	I2C5_DREQ_TX	DMA_CROSSBAR_152	-	I2C5 DMA transmit request
	I2C5_DREQ_RX	DMA_CROSSBAR_153	-	I2C5 DMA receive request

**NOTE:** The **Default Mapping** column in [Table 24-4 HS  \$\mu\$ C Hardware Requests](#) shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ\_CROSSBAR and DMA\_CROSSBAR modules, respectively.

For more information about the IRQ\_CROSSBAR module, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#).

For more information about the DMA\_CROSSBAR module, see [Section 18.4.6.5, DMA\\_CROSSBAR Module Functional Description](#), in [Section 18.4.6.5 Chapter 18, Control Module](#).

For more information about the device interrupt controllers, see [Chapter 17, Interrupt Controllers](#).

For more information about the device DMA\_SYSTEM module, see [Section 16.1, System DMA](#).

For more information about the device EDMA module, see [Section 16.2, Enhanced DMA](#).

---

**NOTE:**

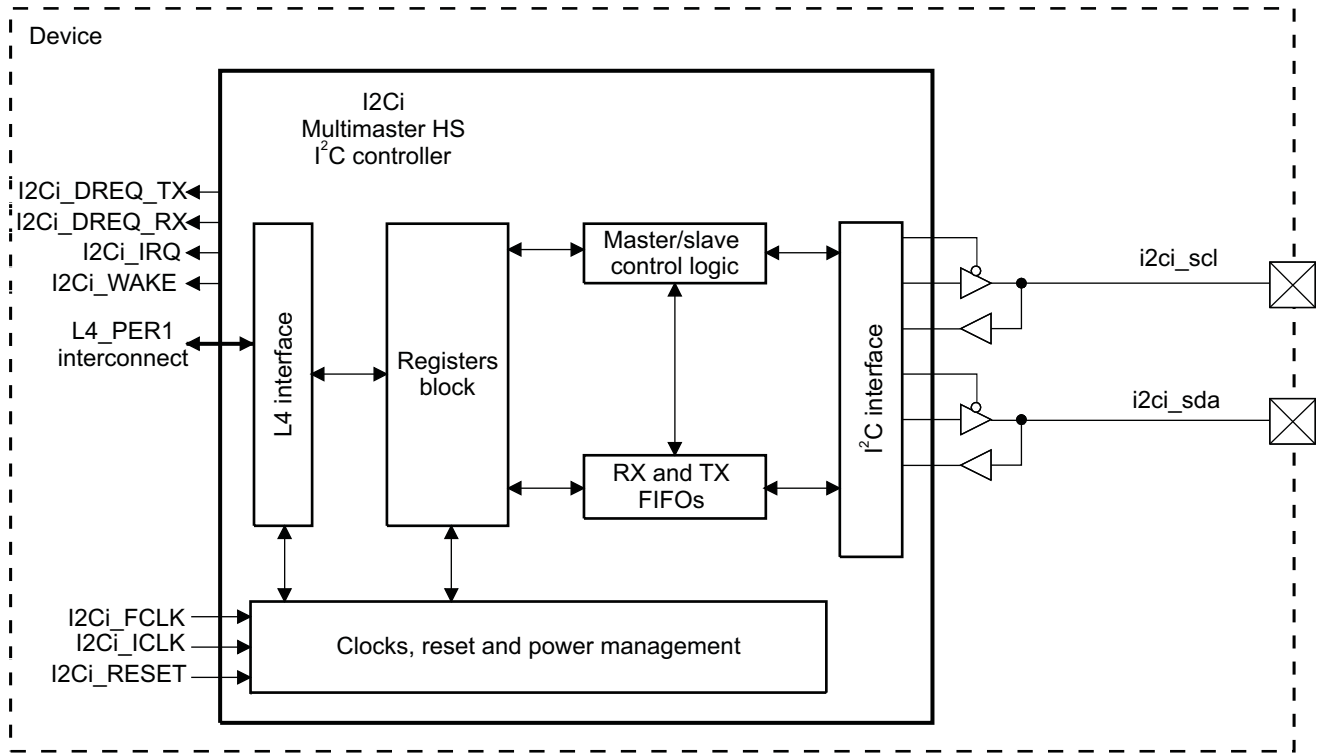

- For a description of interrupt source, see [Table 24-10](#).
  - For a description of DMA source, see [Table 24-11](#).

## 24.1.4 HS I<sup>2</sup>C Functional Description

### 24.1.4.1 HS I<sup>2</sup>C Block Diagram

Figure 24-12 is the multimaster I<sup>2</sup>C HS controller block diagram.

Figure 24-12. HS I<sup>2</sup>C Block Diagram

i = 1 to 5

I2C-017

The five multimaster HS I<sup>2</sup>C controllers can be configured in F/S I<sup>2</sup>C mode or HS I<sup>2</sup>C mode. The operation mode is selected by configuring the I2Ci.I2C\_CON[13:12] OPMODE bit field. Table 24-5 lists the available operation modes.

Table 24-5. HS I<sup>2</sup>C Operation Mode Selection

Operation Mode	Value of I2Ci.I2C_CON[13:12] OPMODE
F/S I <sup>2</sup> C	0x0
HS I <sup>2</sup> C	0x1
Reserved	0x2
Reserved (not used)	0x3

### 24.1.4.2 HS I<sup>2</sup>C Clocks

#### 24.1.4.2.1 HS I<sup>2</sup>C Clocking

Figure 24-13 shows the I<sup>2</sup>C clock generation of the HS I<sup>2</sup>C controllers.

**Figure 24-13. HS I<sup>2</sup>C Clock Generation**

Each multimaster HS I<sup>2</sup>C controller uses the I2Ci\_FCLK functional clock in the PRCM module. The internal sampling clock I2Ci\_INTERNAL\_CLK is generated by dividing the functional clock by the I2Ci.I2C\_PSC[7:0] PSC bit field value + 1 in F/S mode, or in the first phase of HS mode; or by directly using the functional clock in the second phase of HS mode (prescaler is bypassed).

The low time of the I2Ci\_SCLL signal is determined by the I2Ci.I2C\_SCLL[7:0] SCLL bit field in F/S mode and in the first phase of HS mode; or by the I2Ci.I2C\_SCLL[15:8] HSSCLL bit field in the second phase of HS mode.

The high time of the I2Ci\_SCLL signal is determined by the I2Ci.I2C\_SCLH[7:0] SCLH bit field in F/S mode and in the first phase of HS mode; or by the I2Ci.I2C\_SCLH[15:8] HSSCLH bit field in the second phase of HS mode.

Table 24-6 lists the t<sub>LOW</sub> and t<sub>high</sub> values in master mode only (in slave mode, the I<sup>2</sup>C controller does not generate the I<sup>2</sup>C clock).

**Table 24-6. HS I<sup>2</sup>C t<sub>LOW</sub> and t<sub>high</sub> Values of the I<sup>2</sup>C Clock**

Mode	I2Ci Clock	t <sub>LOW</sub>	t <sub>high</sub>
F/S or HS first phase	$I2Ci\_INTERNAL\_CLK = I2Ci\_FCLK / (I2Ci.I2C\_PSC[7:0] PSC \text{ bit field} + 1)$	$(I2Ci.I2C\_SCLL[7:0] SCLL \text{ bit field value} + 7) \times I2Ci\_INTERNAL\_CLK \text{ period}$	$(I2Ci.I2C\_SCLH [7:0] SCLH \text{ bit field value} + 5) \times I2Ci\_INTERNAL\_CLK \text{ period}$
HS second phase	I2Ci_FCLK	$(I2Ci.I2C\_SCLL[15:8] HSSCLL \text{ bit field value} + 7) \times I2Ci\_FCLK \text{ period}$	$(I2Ci.I2C\_SCLH [15:8] HSSCLH \text{ bit field value} + 5) \times I2Ci\_FCLK \text{ period}$

**NOTE:** For HS mode, the I2Ci.I2C\_SCLL[15:8] HSSCLL and I2Ci.I2C\_SCLL[7:0] SCLL bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

For HS mode, the I2Ci.I2C\_SCLH[15:8] HSSCLH and I2Ci.I2C\_SCLH[7:0] SCLH bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

**NOTE:** The equations in Table 24-6 give the SCLL timing values for SCLL/SCLH/HSSCLL/HSSCLH at HS I<sup>2</sup>C controller outputs. Actual t<sub>low</sub> and t<sub>high</sub> periods may vary depending on the board (the load capacitance on the SCLL signal). If necessary, any adjustments to the SCLL/SCLH/HSSCLL/HSSCLH values must be determined by measurements of actual SCL signal on the board.

**CAUTION**

During active mode (the I2Ci.I2C\_CON[15] I2C\_EN bit is set to 1), make no changes to the I2Ci.I2C\_SCLL and I2Ci.I2C\_SCLH registers. Changes may result in unpredictable behavior.

Table 24-7 lists the register values for obtaining the maximum I<sup>2</sup>C bit rates and the maximum period of the filtered spikes in F/S mode and HS mode.

**Table 24-7. HS I<sup>2</sup>C Register Values for Maximum I<sup>2</sup>C Bit Rates in I<sup>2</sup>C F/S, I<sup>2</sup>C HS Modes<sup>(1)</sup>**

	I <sup>2</sup> C Mode for I2Ci,			Description
	Standard Mode	Fast Mode	High-Speed Mode <sup>(2)</sup>	
I2Ci_FCLK frequency (MHz)	96			
<b>I2Ci.I2C_PSC[7:0] PSC</b>	<b>23</b>	<b>9</b>	<b>1</b>	Prescaler value for F/S and HS modes
I2Ci_INTERNAL_CLK frequency (MHz)	4	9.6	96	
<b>I2Ci.I2C_SCLL[7:0] SCLL</b>	<b>13</b>	<b>5</b>	<b>115</b>	Value for F/S mode and first phase of HS mode
<b>I2Ci.I2C_SCLH[7:0] SCLH</b>	<b>15</b>	<b>7</b>	<b>113</b>	Value for F/S mode and first phase of HS mode
Maximum bit rate (Mbps)	0.1	0.4	0.4	F/S mode and first phase in HS mode maximum bit rate
Maximum filter period (ns)	250	104.2	10	
<b>I2Ci.I2C_SCLL[15:8] HSSCLL</b>			<b>12</b>	Values for second phase of HS mode
<b>I2Ci.I2C_SCLH[15:8] HSSCLH</b>			<b>5</b>	Values for second phase of HS mode
HS mode maximum bit rate (Mbps)			3.31	HS mode maximum bit rate
Maximum filter period (ns)			10	

<sup>(1)</sup> Programmable fields are in bold.

<sup>(2)</sup> Supported only on I2C3, I2C4 and I2C5.

---

**NOTE:** This table presents informative values only for the configuration parameters and the I<sup>2</sup>C bus performance obtained according to these values. The delays added by the analog pads are not considered in these figures.

---

**NOTE:** For I2Ci (where i=1, 2, 3, 4, 5)

$$I2Ci\_INTERNAL\_CLK \text{ freq} = I2Ci\_FCLK / (PSC + 1)$$

$$F/S \text{ filter period} = 1 / I2Ci\_INTERNAL\_CLK$$

$$HS \text{ filter period} = 1 / I2Ci\_FCLK \text{ freq}$$

$$HS \text{ bit rate} = I2Ci\_FCLK \text{ freq} / (HSSCLL + 7 + HSSCLH + 5)$$

$$FS \text{ bit rate} = I2Ci\_INTERNAL\_CLK / (SCLL + 7 + SCLH + 5)$$

---

#### 24.1.4.2.2 HS I<sup>2</sup>C Automatic Blocking of the I<sup>2</sup>C Clock Feature

This feature offers the possibility for the LH to command the blocking of the I<sup>2</sup>C clock after the slave addressing phase, when the I<sup>2</sup>C controller is addressed by an external master device using a certain Own Address.

The release of the I<sup>2</sup>C clock can be performed independently for each Own Address (I2Ci.I2C\_OA, and I2Ci.I2C\_OAx registers, where i = 1 to 5, x = 1, 2, 3) by deasserting the corresponding bit in the I2Ci.I2C\_SBLOCK register.

#### 24.1.4.3 HS I<sup>2</sup>C Software Reset

Each multimaster HS I<sup>2</sup>C controller supports the software reset by accessing the I2Ci.I2C\_SYSC[1] SRST bit (1: reset; 0: normal mode).

The software reset status can be checked by accessing the I2Ci.I2C\_SYSS[0] RDONE bit (1: reset is done; 0: reset is ongoing).

To do a software reset, the following steps must be done:

1. Ensure that the module is disabled (clear the I2Ci.I2C\_CON[15] I2C\_EN bit to 0).
2. Set the I2Ci.I2C\_SYSC[1] SRST bit to 1.
3. Enable the module by setting I2Ci.I2C\_CON[15] I2C\_EN bit to 1.
4. Check the I2Ci.I2C\_SYSS[0] RDONE bit until it is set to 1 to indicate the software reset is complete.

---

**NOTE:** The I2Ci.I2C\_CON[15] I2C\_EN bit can hold the functional clock domain of the multimaster HS I<sup>2</sup>C controller in reset after the device reset has been released. When the system bus reset is removed, this bit remains cleared. The functional part of the I<sup>2</sup>C controller is held in reset state while this bit is 0, and all configuration registers can be accessed.

The I2Ci.I2C\_CON[15] I2C\_EN bit must be set to 1 to enable the functional part of the I<sup>2</sup>C controller.

The I2Ci.I2C\_SYSS[0] RDONE bit is asserted only after the module is enabled by setting the I2Ci.I2C\_CON[15] I2C\_EN bit to 1.

---

#### 24.1.4.4 HS I<sup>2</sup>C Power Management

Table 24-8 describes power-management features available for the multimaster HS I<sup>2</sup>C controllers.

**NOTE:**

- For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).
  - For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- 

**Table 24-8. HS I<sup>2</sup>C Local Power-Management Features**

Feature	Registers	Description
Clock auto gating	I2Ci.I2C_SYSC[0] AUTOIDLE	This bit allows a local power optimization inside the module.
Slave idle modes	I2Ci.I2C_SYSC[4:3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available.
Clock activity	I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY	For configuration details, see <a href="#">Table 24-9</a> .
Global wake-up enable	I2Ci.I2C_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.

---

**NOTE:** The voltage controllers, in which the HS I<sup>2</sup>C controller is implemented, have no idle request/acknowledge mechanism. The idle modes for the voltage controllers are directly managed by the PRCM module.

---

**Table 24-9. HS I<sup>2</sup>C Clock Activity Settings**

I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY	Clock State When Module is in IDLE State		Features Available/Unavailable When Module is in IDLE State
	I2Ci_ICLK	I2Ci_FCLK	
00	OFF	OFF	Both clocks are disabled.
10	OFF	ON	Interface clock is disabled; functional clock is enabled
01	ON	OFF	Functional clock is disabled; interface clock is enabled
11	ON	ON	Both clocks are enabled.

### CAUTION

The PRCM module has no hardware means of reading the settings of CLOCKACTIVITY. Thus, software must ensure consistent programming between the I<sup>2</sup>C CLOCKACTIVITY and I<sup>2</sup>C clock PRCM control bits. For a description of the ClockActivity feature, see [Section 3.1.1.2, Module-Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

#### 24.1.4.5 HS I<sup>2</sup>C Interrupt Requests

[Table 24-10](#) lists the event flags, and their mask, that can cause module interrupts.

**Table 24-10. HS I<sup>2</sup>C Events**

Event Flag	Event Unmask	Event Mask	Description
I2Ci.I2C_IRQSTATUS[0] AL	I2Ci.I2C_IRQENABLE_SET[0] AL_IE	I2Ci.I2C_IRQENABLE_CLR [0] AL_IE	Arbitration lost. This bit is automatically set by the hardware when it loses the arbitration in master transmit mode, an interrupt is signaled to the host.
I2Ci.I2C_IRQSTATUS[1] NACK	I2Ci.I2C_IRQENABLE_SET[1] NACK_IE	I2Ci.I2C_IRQENABLE_CLR [1] NACK_IE	No acknowledgement. Bit is set when No Acknowledge is received, an interrupt is signaled to the host.
I2Ci.I2C_IRQSTATUS[2] ARDY	I2Ci.I2C_IRQENABLE_SET[2] ARDY_IE	I2Ci.I2C_IRQENABLE_CLR [2] ARDY_IE	Register access ready. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to the host.
I2Ci.I2C_IRQSTATUS[3] RRDY	I2Ci.I2C_IRQENABLE_SET[3] RRDY_IE	I2Ci.I2C_IRQENABLE_CLR [3] RRDY_IE	Receive data ready. Set to 1 by core when in receiver mode, a new data can be read. An interrupt is signaled to the host.
I2Ci.I2C_IRQSTATUS[4] XRDY	I2Ci.I2C_IRQENABLE_SET[4] XRDY_IE	I2Ci.I2C_IRQENABLE_CLR [4] XRDY_IE	Transmit data ready. Set to 1 by core when transmitter is ready for new data. An interrupt is signaled to the host.
I2Ci.I2C_IRQSTATUS[5] GC	I2Ci.I2C_IRQENABLE_SET[5] GC_IE	I2Ci.I2C_IRQENABLE_CLR [5] GC_IE	General call. Set to 1 by core when General Call address was detected. An interrupt is signaled to the host.
I2Ci.I2C_IRQSTATUS[6] STC	I2Ci.I2C_IRQENABLE_SET[6] STC_IE	I2Ci.I2C_IRQENABLE_CLR [6] STC_IE	Start condition detected. An interrupt is signaled to the host.
I2Ci.I2C_IRQSTATUS[7] AERR	I2Ci.I2C_IRQENABLE_SET[7] AERR_IE	I2Ci.I2C_IRQENABLE_CLR [7] AERR_IE	Bus Access Error. An interrupt is signaled to the host.
I2Ci.I2C_IRQSTATUS[8] BF	I2Ci.I2C_IRQENABLE_SET[8] BF_IE	I2Ci.I2C_IRQENABLE_CLR [8] BF_IE	Bus free. An interrupt is signaled to the host.
I2Ci.I2C_IRQSTATUS[9] AAS	I2Ci.I2C_IRQENABLE_SET[9] AAS_IE	I2Ci.I2C_IRQENABLE_CLR [9] AAS_IE	Address recognized as slave. An interrupt is signaled to the host.
I2Ci.I2C_IRQSTATUS[10] XUDF	I2Ci.I2C_IRQENABLE_SET [10] XUDF_IE	I2Ci.I2C_IRQENABLE_CLR [10] XUDF_IE	Transmit underflow. An interrupt is signaled to the host.
I2Ci.I2C_IRQSTATUS[11] ROVR	I2Ci.I2C_IRQENABLE_SET [11] ROVR_IE	I2Ci.I2C_IRQENABLE_CLR [11] ROVR_IE	Receive overrun. An interrupt is signaled to the host.
I2Ci.I2C_IRQSTATUS[12] BB	N/A	N/A	Bus busy indicator
I2Ci.I2C_IRQSTATUS[13] RDR	I2Ci.I2C_IRQENABLE_SET [13] RDR_IE	I2Ci.I2C_IRQENABLE_CLR [13] RDR_IE	Receive draining. An interrupt is signaled to the host.
I2Ci.I2C_IRQSTATUS[14] XDR	I2Ci.I2C_IRQENABLE_SET [14] XDR_IE	I2Ci.I2C_IRQENABLE_CLR [14] XDR_IE	Transmit draining. An interrupt is signaled to the host.

#### 24.1.4.6 HS I<sup>2</sup>C DMA Requests

Each multimaster HS I<sup>2</sup>C controller can generate two DMA requests to the device DMA controllers through the DMA\_CROSSBAR module. Table 24-11 lists the DMA requests. For information about DMA generation, see Section 24.1.4.8.3, *HS I<sup>2</sup>C FIFO DMA Mode (I<sup>2</sup>C Mode Only)*.

**Table 24-11. HS I<sup>2</sup>C DMA Requests**

Name	Source	Description
I2C1_DREQ_TX	I2C1	I2C1 DMA write request to inform the DMAs to write new data in the I2C1.I2C_DATA[7:0] DATA bit field
I2C1_DREQ_RX	I2C1	I2C1 DMA read request to inform the DMAs to read the data in the I2C1.I2C_DATA[7:0] DATA bit field
I2C2_DREQ_TX	I2C2	I2C2 DMA write request to inform the DMAs to write new data in the I2C2.I2C_DATA[7:0] DATA bit field
I2C2_DREQ_RX	I2C2	I2C2 DMA read request to inform the DMAs to read the data in the I2C2.I2C_DATA[7:0] DATA bit field
I2C3_DREQ_TX	I2C3	I2C3 DMA write request to inform the DMAs to write new data in the I2C3.I2C_DATA[7:0] DATA bit field
I2C3_DREQ_RX	I2C3	I2C3 DMA read request to inform the DMAs to read the data in the I2C3.I2C_DATA[7:0] DATA bit field
I2C4_DREQ_TX	I2C4	I2C4 DMA write request to inform the DMAs to write new data in the I2C4.I2C_DATA[7:0] DATA bit field
I2C4_DREQ_RX	I2C4	I2C4 DMA read request to inform the DMAs to read the data in the I2C4.I2C_DATA[7:0] DATA bit field
I2C5_DREQ_TX	I2C5	I2C5 DMA write request to inform the DMAs to write new data in the I2C5.I2C_DATA[7:0] DATA bit field
I2C5_DREQ_RX	I2C5	I2C5 DMA read request to inform the DMAs to read the data in the I2C5.I2C_DATA[7:0] DATA bit field

---

**NOTE:** For more information about I2Ci\_DREQ\_TX and I2Ci\_DREQ\_RX (where *i* = 1 to 5) signals mapping to DMA\_CROSSBAR, see Section 16.1.3.2, *Mapping of DMA Requests to DMA\_CROSSBAR Inputs*, in Table 24-4, *HS I<sup>2</sup>C Hardware Requests*.

---

#### 24.1.4.7 HS I<sup>2</sup>C Programmable Multislave Channel Feature

This feature allows each multimaster HS I<sup>2</sup>C controller to be addressed using four separate Own Addresses configured in the I2Ci.I2C\_OA and I2Ci.I2C\_OAx registers (where *i* = 1 to 5, *x* = 1, 2, 3). An additional register (I2Ci.I2C\_ACTOA) is used to indicate to the LH which address is used by the external master to communicate with the I<sup>2</sup>C controller.

Each Own Address can be independently configured in 7-bit or 10-bit mode by setting the corresponding bit (I2Ci.I2C\_CON[7] XOA0, I2Ci.I2C\_CON[6] XOA1, I2Ci.I2C\_CON[5] XOA2, or I2Ci.I2C\_CON[4] XOA3).

#### 24.1.4.8 HS I<sup>2</sup>C FIFO Management

Each multimaster HS I<sup>2</sup>C controller implements two internal 8-bit FIFOs, the RX and TX FIFOs.

The depth of the RX and TX FIFOs can be checked by reading the I2Ci.I2C\_BUFSTAT[15:14] FIFODEPTH bit field (0x0: 8 bytes, 0x1: 16 bytes, 0x2: 32 bytes, and 0x3: 64 bytes).

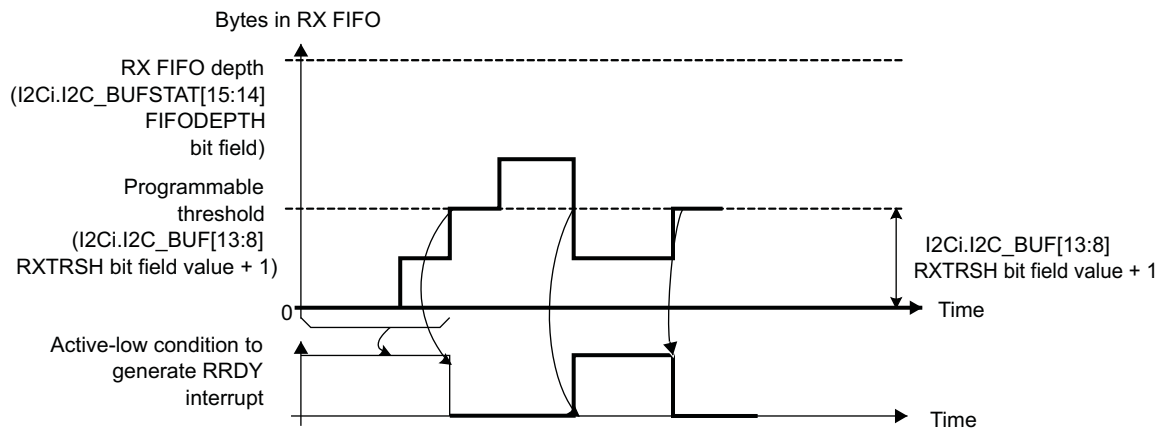

##### 24.1.4.8.1 HS I<sup>2</sup>C FIFO Interrupt Mode

In FIFO interrupt mode (relevant interrupts enabled by the I2Ci.I2C\_IRQENABLE\_SET register), an interrupt signal informs the processor of the receiver and transmitter status. These interrupts are raised when the RX/TX FIFO thresholds (defined by the I2Ci.I2C\_BUF[13:8] RXTRSH bit field value + 1 for the RX FIFO or the I2Ci.I2C\_BUF[5:0] TXTRSH bit field value + 1 for the TX FIFO) are reached; the interrupt signals instruct the LH to transfer data to the destination (from the I<sup>2</sup>C controller in receive mode and/or from any source to the I<sup>2</sup>C controller FIFO in transmit mode).

Figure 24-14 and Figure 24-15 show receive and transmit operations, respectively, from a FIFO management point of view.

**Figure 24-14. HS I<sup>2</sup>C Receive FIFO Interrupt Request Generation**

i = 1 to 5

I2C-019

In Figure 24-14, the RRDY interrupt condition shows that the condition for generating an RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the LH by writing 1 in the corresponding bit. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In receive mode, an RRDY interrupt is generated as soon as the FIFO reaches its receive threshold (I2Ci.I2C\_BUF[13:8] RXTRSH bit field value + 1). The interrupt can be deasserted only when the LH has handled enough bytes to make the number of bytes in the RX FIFO lower than the programmed threshold. For each interrupt, the LH can be configured to read a number of bytes equal to the value of the RX FIFO threshold.

**Figure 24-15. HS I<sup>2</sup>C Transmit FIFO Interrupt Request Generation**

i = 1 to 5

I2C-020

In Figure 24-15, the XRDY interrupt condition shows that the condition for generating an XRDY interrupt is achieved. The interrupt request is generated when TX FIFO is empty or when the TX FIFO threshold is not reached, and the LH can clear the XRDY status bit by setting the I2Ci.I2C\_IRQENABLE\_CLR [4] XRDY\_IE bit to 1 after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In interrupt mode, the module offers two options for the LH application to handle the interrupts:

- When detecting an interrupt request (XRDY or RRDY type), the LH can write/read 1 data byte to/from

the TX/RX FIFO and then clear the interrupt. The module reasserts the interrupt until the interrupt condition is not met.

- When detecting an interrupt request (XRDY or RRDY type), the LH can be programmed to write/read the amount of data bytes specified by the corresponding FIFO threshold (I2C\_BUF[5:0] TXTRSH + 1 or I2C\_BUF[5:0] RXTRSH + 1). In this case, the interrupt condition is cleared and the next interrupt is asserted again when the XRDY or RRDY condition is met again.

If the second-interrupt-serving approach is used, an additional mechanism (draining feature) is implemented for cases where the transfer length is not a multiple of the FIFO threshold value (see Section 24.1.4.8.4, *Draining Feature [I<sup>2</sup>C Mode Only]*).

**NOTE:** In slave transmit mode (the I2Ci.I2C\_CON[10] MST bit is cleared and the I2Ci.I2C\_CON[9] TRX bit is set to 1), the draining feature must not be used, because the transfer length is not known at configuration time, and the external master can end the transfer at any point by not acknowledging 1 data byte. If the draining feature is used in slave transmit mode, data can remain in the TX FIFO without being transmitted over the I<sup>2</sup>C bus. In this case, the TX FIFO must be cleared by setting the I2Ci.I2C\_BUF[6] TXFIFO\_CLR bit.

#### 24.1.4.8.2 HS I<sup>2</sup>C FIFO Polling Mode

In FIFO polling mode (the I2Ci.I2C\_IRQENABLE\_SET [4] XRDY\_IE and I2Ci.I2C\_IRQENABLE\_SET [3] RRDY\_IE bits are disabled), the status of the module (receiver or transmitter) can be checked by polling the I2Ci.I2C\_IRQSTATUS\_RAW [4] XRDY and the I2Ci.I2C\_IRQSTATUS\_RAW [3] RRDY bits (the I2Ci.I2C\_IRQSTATUS\_RAW [13] RDR and I2Ci.I2C\_IRQSTATUS\_RAW [14] XDR bits can also be polled if the draining feature is enabled). The I2Ci.I2C\_IRQSTATUS\_RAW [4] XRDY and I2Ci.I2C\_IRQSTATUS\_RAW [3] RRDY bits accurately reflect the interrupt conditions described in the discussion of FIFO interrupt mode.

#### 24.1.4.8.3 HS I<sup>2</sup>C FIFO DMA Mode

In receive mode, a DMA request is generated by the I2Ci\_DREQ\_RX signal as soon as the RX FIFO exceeds its threshold level (the I2Ci.I2C\_BUF[13:8] RXTRSH bit field value + 1). This request is deasserted when the number of bytes defined by the threshold level is read by the DMA controller.

Figure 24-16 shows the DMA request generation in receive mode.

**Figure 24-16. HS I<sup>2</sup>C Receive FIFO DMA Request Generation**

In transmit mode, a DMA request is automatically asserted by the I2Ci\_DREQ\_TX signal when the TX FIFO is empty. This request is deasserted when the number of bytes (the I2Ci.I2C\_BUF[5:0] TXTRSH bit field value + 1) is written in the FIFO by the DMA controller. If an insufficient number of bytes is written, the DMA request remains active. Figure 24-17 and Figure 24-18 show the DMA TX transfers with different values for the I2Ci.I2C\_BUF[5:0] TXTRSH bit field.

**Figure 24-17. HS I<sup>2</sup>C Transmit FIFO Request Generation (High Threshold)**

**Figure 24-18. HS I<sup>2</sup>C Transmit FIFO Request Generation (Low Threshold)**

The I2C module provides the possibility to the user to clear the RX or TX FIFO, by setting the I2Ci.I2C\_BUF[14]RXFIFO\_CLR and I2Ci.I2C\_BUF[6]TXFIFO\_CLR registers, which act like software reset for the FIFOs. In DMA mode, these bits will also reset the DMA state machines.

The FIFO clearing feature can be used when the following conditions are met:

1. The module is configured as a transmitter
2. The external receiver responds with a NACK in the middle of the transfer
3. There is still data in TX FIFO waiting to be transferred

**24.1.4.8.4 HS I<sup>2</sup>C Draining Feature**

The draining feature is implemented to handle the end of a transfer whose length is not a multiple of the FIFO threshold values (the I2Ci.I2C\_BUF[13:8] RXTRSH bit field value + 1 for the RX threshold and the I2Ci.I2C\_BUF[5:0] TXTRSH field value + 1 for the TX threshold). It can also transfer the remaining number of bytes (because the threshold is not reached).

This feature prevents the LH or the DMA controller from trying more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having fewer bytes in the FIFO than the configured DMA transfer length). Otherwise, an AERR interrupt is generated by the I2C*i*.I2C\_IRQSTATUS\_RAW [7] AERR bit.

The draining mechanism generates an interrupt using the I2C*i*.I2C\_IRQSTATUS\_RAW [13] RDR or I2C*i*.I2C\_IRQSTATUS\_RAW [14] XDR bit at the end of the transfer, informing the LH that it must check the amount of data left to be transferred (the I2C*i*.I2C\_BUFSTAT[13:8] RXSTAT or I2C*i*.I2C\_BUFSTAT[5:0] TXSTAT bit fields) and enable the draining feature of the DMA controller by reconfiguring the DMA transfer length according to this value (when the DMA mode is enabled) or perform only the required number of data accesses (when the DMA mode is disabled).

In receive mode (master or slave), if the RX FIFO threshold (the I2C*i*.I2C\_BUF[13:8] RXTRSH bit field value + 1) is not reached, but the transfer ends on the I<sup>2</sup>C bus and data remains in the RX FIFO (less than the threshold), the receive draining interrupt (the I2C*i*.I2C\_IRQSTATUS\_RAW [13] RDR bit) is asserted to inform the LH that it can read the amount of data in the RX FIFO (the I2C*i*.I2C\_BUFSTAT[13:8] RXSTAT bit field). The LH performs a number of data read accesses equal to the I2C*i*.I2C\_BUFSTAT[13:8] RXSTAT bit field (interrupt or polling mode), or reconfigures the DMA controller with the required value to drain the FIFO.

In master transmit mode, if the TX FIFO threshold (the I2C*i*.I2C\_BUF[5:0] TXTRSH bit field value + 1) is not reached, but the amount of data remaining to be written in the TX FIFO is less than the threshold, the transmit draining interrupt (the I2C*i*.I2C\_IRQSTATUS\_RAW [14] XDR bit) is asserted to inform the LH that it can read the amount of data remaining to be written in the TX FIFO (the I2C*i*.I2C\_BUFSTAT[5:0] TXSTAT bit field). The LH must write the required number of data bytes specified by the I2C*i*.I2C\_BUFSTAT[5:0] TXSTAT bit field value or reconfigure the DMA controller with the value required to transfer the last bytes to the FIFO.

In master mode, the LH can alternately not check the values of the I2C*i*.I2C\_BUFSTAT[5:0] TXSTAT and I2C*i*.I2C\_BUFSTAT[13:8] RXSTAT bit fields, because it can obtain this information internally (by computing the I2C*i*.I2C\_CNT[15:0] DATACOUNT bit field value modulo I2C*i*.I2C\_BUF[13:8] RXTRSH or I2C*i*.I2C\_BUF[5:0] TXTRSH).

By default, the draining feature is disabled; it can be enabled using the I2C*i*.I2C\_IRQENABLE\_SET [14] XDR\_IE or I2C*i*.I2C\_IRQENABLE\_SET [13] RDR\_IE bits (default disabled) only for transfers with lengths not equal to the threshold values (I2C*i*.I2C\_BUF[5:0] TXTRSH bit field value + 1 for the TX threshold or the I2C*i*.I2C\_BUF[13:8] RXTRSH bit field value + 1 for the RX threshold).

#### 24.1.4.9 HS I<sup>2</sup>C Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less in case of F/S operation modes, and any noise that is 10 ns or less in case of HS mode operation. The noise filter is always one period of the I2C*i*\_INTERNAL\_CLK clock. This way, for HS mode operation (prescaler bypassed), the filter suppresses spikes of less than 10.4 ns.

For standard mode (for example, the I2C*i*.I2C\_PSC[7:0] PSC bit field = 4), the maximum width of suppressed spikes is 46.1 ns.

To ensure correct filtering, the prescaler must be programmed accordingly by the I2C*i*.I2C\_PSC[7:0] PSC bit field.

#### 24.1.4.10 HS I<sup>2</sup>C System Test Mode

A system test mode is available for multimaster HS I<sup>2</sup>C controller module testing. This mode is enabled by setting the I2C*i*.I2C\_SYSTEST[15] ST\_EN bit to 1. When this bit is cleared to 0, the I<sup>2</sup>C controller is configured in normal operation mode.

In system test mode, the I2C*i*.I2C\_SYSTEST [13:12] TMODE bit field selects the type of test. [Table 24-12](#) lists the tests available for the multimaster HS I<sup>2</sup>C controllers.

**Table 24-12. HS I<sup>2</sup>C List of Tests**

I2Ci.I2C_SYSTEST[13:12] TMODE	Test	Description
00	Functional mode	Normal operation mode
01	Reserved (not used)	
10	Test of i2ci_scl serial clock line	The i2ci_scl line is driven with a permanent clock as if mastered with the parameters set in the I2Ci.I2C_PSC, I2Ci.I2C_SCLL, and I2Ci.I2C_SCLH registers.
11	Loop-back mode + i2ci_scl/ i2ci_sda I/O	In master transmit mode only, data transmitted out of the I2Ci.I2C_DATA register (write action) is received in the same I2Ci.I2C_DATA register through an internal path through the FIFO buffers. The DMA and interrupt requests are normally generated if they are enabled. Moreover, the i2ci_scl and i2ci_sda are controlled with the I2Ci.I2C_SYSTEST[3:0] bits.

---

**NOTE:** When the I2Ci.I2C\_SYSTEST[13:12] TMODE bit field is set to 11, the I<sup>2</sup>C controller must be configured in I<sup>2</sup>C F/S (I2Ci.I2C\_CON[13:12] OPMODE set to 00) or I<sup>2</sup>C HS mode (I2Ci.I2C\_CON[13:12] OPMODE set to 01).

---

---

**NOTE:** In normal operation mode (the I2Ci.I2C\_SYSTEST[15] ST\_EN bit cleared to 0), the I2Ci.I2C\_SYSTEST[3:0] bits that control the i2ci\_scl, i2ci\_sda lines in system test mode are read-only bits.

---

In system test mode (the I2Ci.I2C\_SYSTEST[15] ST\_EN bit set to 1), the I2Ci.I2C\_IRQSTATUS\_RAW.XRDY, I2C\_IRQSTATUS\_RAW.RRDY, I2C\_IRQSTATUS\_RAW.XUDF, I2C\_IRQSTATUS\_RAW.ROVR, I2C\_IRQSTATUS\_RAW.ARDY and I2C\_IRQSTATUS\_RAW.NACK status bits can be set to 1 when the I2Ci.I2C\_SYSTEST[11] SSB bit is set to 1. Clearing the I2Ci.I2C\_SYSTEST[11] SSB bit to 0 does not clear the I2Ci.I2C\_IRQSTATUS\_RAW bits to 0. The I2Ci.I2C\_IRQSTATUS\_RAW bit field can be cleared to 0 only by writing 1 in the corresponding bits.

## 24.1.5 HS I<sup>2</sup>C Programming Guide

### 24.1.5.1 HS I<sup>2</sup>C Low-Level Programming Models

#### 24.1.5.1.1 HS I<sup>2</sup>C Programming Model

This section describes the programming model of the multimaster HS I<sup>2</sup>C controllers configured in I<sup>2</sup>C mode.

##### 24.1.5.1.1.1 Main Program

###### 24.1.5.1.1.1.1 Configure the Module Before Enabling the I<sup>2</sup>C Controller

Before enabling the I<sup>2</sup>C controller, perform the following steps:

1. Enable the functional and interface clocks (see [Table 24-3](#)).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock by programming the corresponding value in the I2Ci.I2C\_PSC[7:0] PSC bit field. This value depends on the frequency of the functional clock (I2Ci\_FCLK).
3. Program the I2Ci.I2C\_SCLL[7:0] SCLL and I2Ci.I2C\_SCLH[7:0] SCLH bit fields to obtain a bit rate of 100 kbps or 400 kbps. These values depend on the internal sampling clock frequency (see [Table 24-6](#)).
4. (Optional) Program the I2Ci.I2C\_SCLL[15:8] HSSCLL and I2Ci.I2C\_SCLH[15:8] HSSCLH bit fields to obtain a bit rate of 400 kbps or 3.4 Mbps (for the second phase of HS mode). These values depend on the internal sampling clock frequency (see [Table 24-6](#)).
5. Configure the Own Address of the I<sup>2</sup>C controller by storing it in the I2Ci.I2C\_OA register. Up to four Own Addresses can be programmed in the I2Ci.I2C\_OA and I2Ci.I2C\_OAx registers (where x = 1, 2, 3) for each I<sup>2</sup>C controller.

---

**NOTE:** For a 10-bit address, set the corresponding expand Own Address bit in the I2Ci.I2C\_CON register.

---

6. Set the TX threshold (in transmitter mode) and the RX threshold (in receiver mode) by setting the I2Ci.I2C\_BUF[5:0] TXTRSH bit field to (TX threshold – 1) and the I2Ci.I2C\_BUF[13:8] RXTRSH bit field to (RX threshold – 1), where the TX and RX thresholds are greater than or equal to 1.
7. Take the I<sup>2</sup>C controller out of reset by setting the I2Ci.I2C\_CON[15] I2C\_EN bit to 1.

###### 24.1.5.1.1.1.2 Initialize the I<sup>2</sup>C Controller

To initialize the I<sup>2</sup>C controller, perform the following steps:

1. Configure the I2Ci.I2C\_CON register:
  - For master or slave mode, set the I2Ci.I2C\_CON[10] MST bit (0: slave; 1: master).
  - For transmitter or receiver mode, set the I2Ci.I2C\_CON[9] TRX bit (0: receiver; 1: transmitter).
2. If using an interrupt to transmit and receive data, set the corresponding bit in the I2Ci.I2C\_IRQENABLE\_SET register to 1 (the I2Ci.I2C\_IRQENABLE\_SET [4] XRDY\_IE bit for the transmit interrupt, the I2Ci.I2C\_IRQENABLE\_SET [3] RRDY bit for the receive interrupt).
3. If using DMA to receive and transmit data, set the corresponding bit in the I2Ci.I2C\_BUF register to 1 (the I2Ci.I2C\_BUF[15] RDMA\_EN bit for the receive DMA channel, the I2Ci.I2C\_BUF[7] XDMA\_EN bit for the transmit DMA channel).

###### 24.1.5.1.1.1.3 Configure Slave Address and the Data Control Register

In master mode, configure the slave address register by programming the I2Ci.I2C\_SA[9:0] SA bit field and the number of data bytes (I<sup>2</sup>C data payload) associated with the transfer by programming the I2Ci.I2C\_CNT[15:0] DCOUNT bit field.

---

**NOTE:** For a 10-bit address, set the I2Ci.I2C\_CON[8] XSA bit to 1.

---

#### 24.1.5.1.1.1.4 Initiate a Transfer

Poll the I2Ci.I2C\_IRQSTATUS\_RAW [12] BB bit. If it is cleared to 0 (bus not busy), configure the I2Ci.I2C\_CON[0] STT and I2Ci.I2C\_CON[1] STP bits. To initiate a transfer, the I2Ci.I2C\_CON[0] STT bit must be set to 1, and it is not mandatory to set the I2Ci.I2C\_CON[1] STP bit to 1.

#### 24.1.5.1.1.1.5 Receive Data

Poll the I2Ci.I2C\_IRQSTATUS\_RAW [3] RRDY bit, or use the RRDY interrupt (the I2Ci.I2C\_IRQENABLE\_SET [3] RRDY\_IE bit must be set to 1) or the DMA RX channel (the I2Ci.I2C\_BUF[15] RDMA\_EN bit must be set to 1 together with I2C\_DMARXENABLE\_SET) to read the receive data in the I2Ci.I2C\_DATA register.

If the transfer length does not equal the RX FIFO threshold (the I2Ci.I2C\_BUF[13:8] RTRSH bit field + 1), use the draining feature (enable the RDR interrupt by setting the I2Ci.I2C\_IRQENABLE\_SET [13] RDR\_IE bit to 1).

---

**NOTE:** In receive mode only, the I2Ci.I2C\_IRQSTATUS\_RAW [11] ROVR (receive overrun) bit indicates whether the receiver has experienced overrun. An overrun condition occurs when the shift register and the RX FIFO are full. An overrun condition does not result in data loss; the I<sup>2</sup>C controller simply holds i2ci\_scl to low to prevent other bytes from being received.

The I2Ci.I2C\_IRQSTATUS\_RAW[7] AERR bit is set to 1 when a read access is performed in the I2Ci.I2C\_DATA register while the RX FIFO is empty. The corresponding interrupt can be enabled by setting the I2Ci.I2C\_IRQENABLE\_SET [7] AERR\_IE bit to 1.

---

#### 24.1.5.1.1.1.6 Transmit Data

Poll the I2Ci.I2C\_IRQSTATUS\_RAW [4] XRDY bit, or use the XRDY interrupt (the I2Ci.I2C\_IRQENABLE\_SET [4] XRDY\_IE bit must be set to 1) or the DMA TX channel (the I2Ci.I2C\_BUF[7] XDMA\_EN bit must be set to 1 together with I2C\_DMATXENABLE\_SET) to write data to the I2Ci.I2C\_DATA register.

If the transfer length does not equal the TX FIFO threshold (the I2Ci.I2C\_BUF[5:0] TXTRSH bit field + 1), use the draining feature (enable the XDR interrupt by setting the I2Ci.I2C\_IRQENABLE\_SET [14] XDR\_IE bit to 1).

---

**NOTE:** In transmit mode only, the I2Ci.I2C\_IRQSTATUS\_RAW [10] XUDF bit indicates whether the transmitter has experienced underflow.

In master transmit mode, underflow occurs when the shift register and the TX FIFO are empty and there are still some bytes to transmit (the value of the I2Ci.I2C\_CNT[15:0] DCOUNT bit field is not 0).

In slave transmit mode, underflow occurs when the shift register and the TX FIFO are empty and the external I<sup>2</sup>C master device still requests data bytes to be read.

The I2Ci.I2C\_IRQSTATUS\_RAW [7] AERR bit is set to 1 when a write access is performed in the I2Ci.I2C\_DATA register while the TX FIFO is full. The corresponding interrupt can be enabled by setting the I2Ci.I2C\_IRQENABLE\_SET [7] AERR\_IE bit to 1.

---

#### 24.1.5.1.1.2 Interrupt Subroutine Sequence

1. Test for arbitration lost (the I2Ci.I2C\_IRQSTATUS\_RAW [0] AL bit) and resolve accordingly.
2. Test for no acknowledgment (the I2Ci.I2C\_IRQSTATUS\_RAW [1] NACK bit) and resolve accordingly.
3. Test for register access ready (the I2Ci.I2C\_IRQSTATUS\_RAW [2] ARDY bit) and resolve accordingly.
4. Test for receive data ready (the I2Ci.I2C\_IRQSTATUS\_RAW [3] RRDY bit) and resolve accordingly.

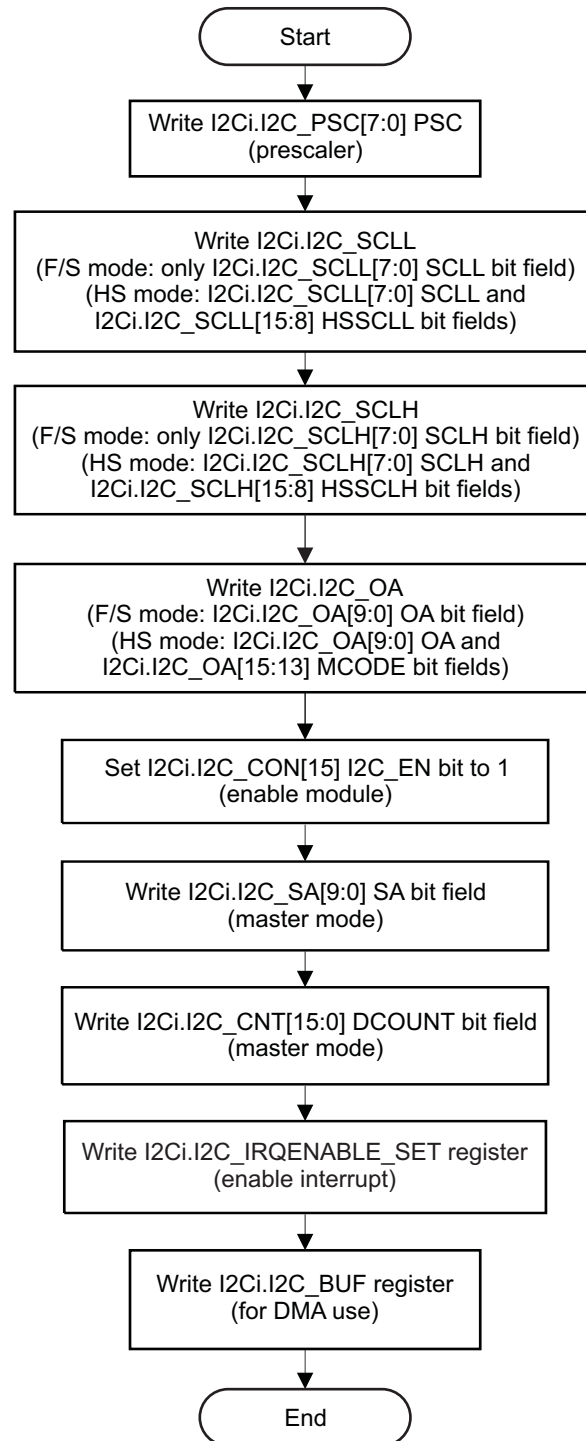

5. Test for transmit data ready (the I2Ci.I2C\_IRQSTATUS\_RAW [4] XRDY bit) and resolve accordingly.
6. Test for general call (the I2Ci.I2C\_IRQSTATUS\_RAW [5] GC bit) and resolve accordingly.
7. Test for start (S) condition (the I2Ci.I2C\_IRQSTATUS\_RAW [6] STC bit) and resolve accordingly. For this test, the functional clock must be inactive.
8. Test for access error (the I2Ci.I2C\_IRQSTATUS\_RAW [7] AERR bit) and resolve accordingly.
9. Test for bus free (the I2Ci.I2C\_IRQSTATUS\_RAW [8] BF bit) and resolve accordingly.

#### 24.1.5.1.1.3 Programming Flow-Diagrams

Figure 24-19 through Figure 24-27 are procedure flow charts for programming the F/S and HS I<sup>2</sup>C modes.

**Figure 24-19. HS I<sup>2</sup>C Setup Procedure**

I2C-024

**Table 24-13. Subprocess Call Summary for Sequence – I<sup>2</sup>C Setup Procedure**

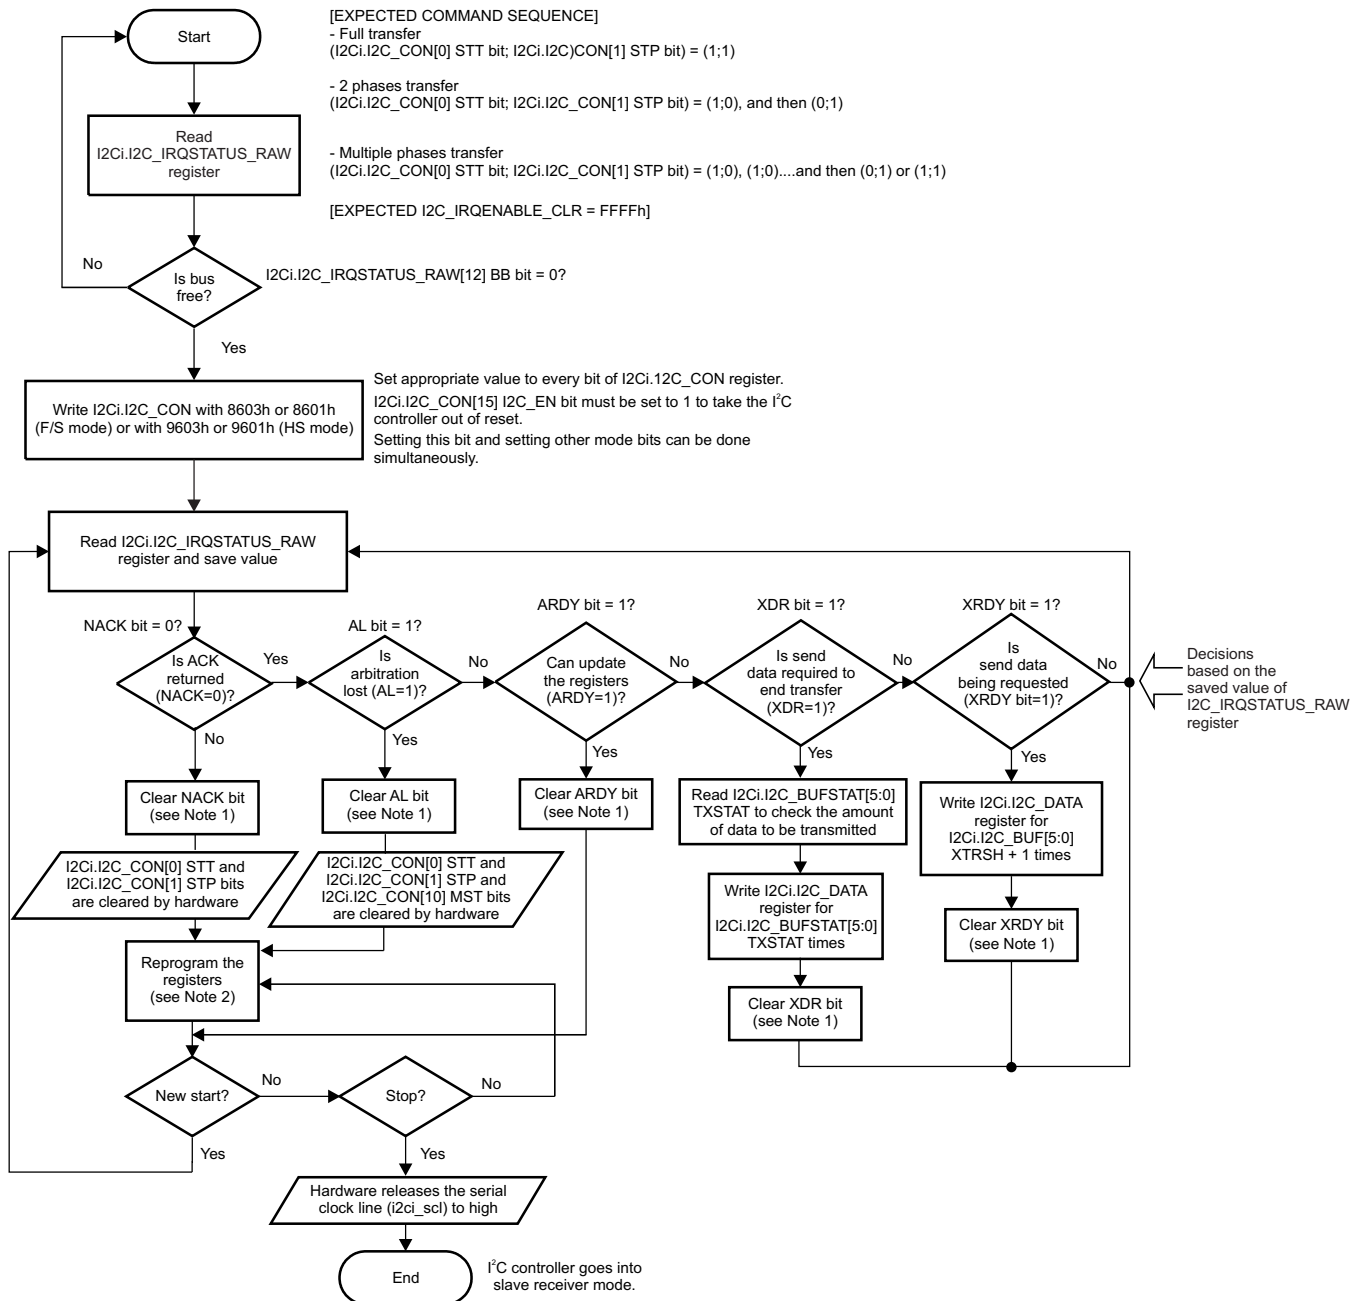

Subprocess Name	Cross-Reference
Pad configuration	See <a href="#">Section 18.4.6.1.1</a> , <i>PAD Configuration Registers</i> in <a href="#">Chapter 18</a> <i>Control Module</i>

**Table 24-14. HS I<sup>2</sup>C Register Call Summary for Sequence – Setup Procedure**

Register Name	Register Name	Register Name
I2Ci.I2C_PSC <sup>(1)</sup>	I2Ci.I2C_CON <sup>(1)</sup>	I2Ci.I2C_BUF <sup>(1)</sup>
I2Ci.I2C_SCLL <sup>(1)</sup>	I2Ci.I2C_SA <sup>(1)</sup>	I2Ci.I2C_IRQENABLE_SET <sup>(1)</sup>
I2Ci.I2C_SCLH <sup>(1)</sup>	I2Ci.I2C_CNT <sup>(1)</sup>	I2Ci.I2C_OA <sup>(1)</sup>

<sup>(1)</sup> i = 1 to 5

**Figure 24-20. HS I<sup>2</sup>C Master Transmitter Mode, Polling Method, in F/S and HS Modes**

- (1) The NACK, AL, ARDY, XDR, and XRDY bits are cleared by writing 1 to each corresponding bit in the I2Ci.I2C\_IRQSTATUS register.
- (2) Reprogram the registers means: I2Ci.I2C\_CON[11] STB and/or I2Ci.I2C\_CON[10] MST bit and/or I2Ci.I2C\_SA[9:0] SA register and/or I2Ci.I2C\_CNT[15:0] DCOUNT register and/or I2Ci.I2C\_CON[0] STT bit and/or I2Ci.I2C\_CON[1] STP bit.

I2C-028

---

**NOTE:** The FIFO clearing can be made when the module is configured as transmitter, the receiver send a NACK in the middle of the transfer, and there is still data in the FIFO.

---

---

**NOTE:** In HS mode, the Sr condition and clock frequency switching are automatically generated by the multimaster HS I<sup>2</sup>C controller.

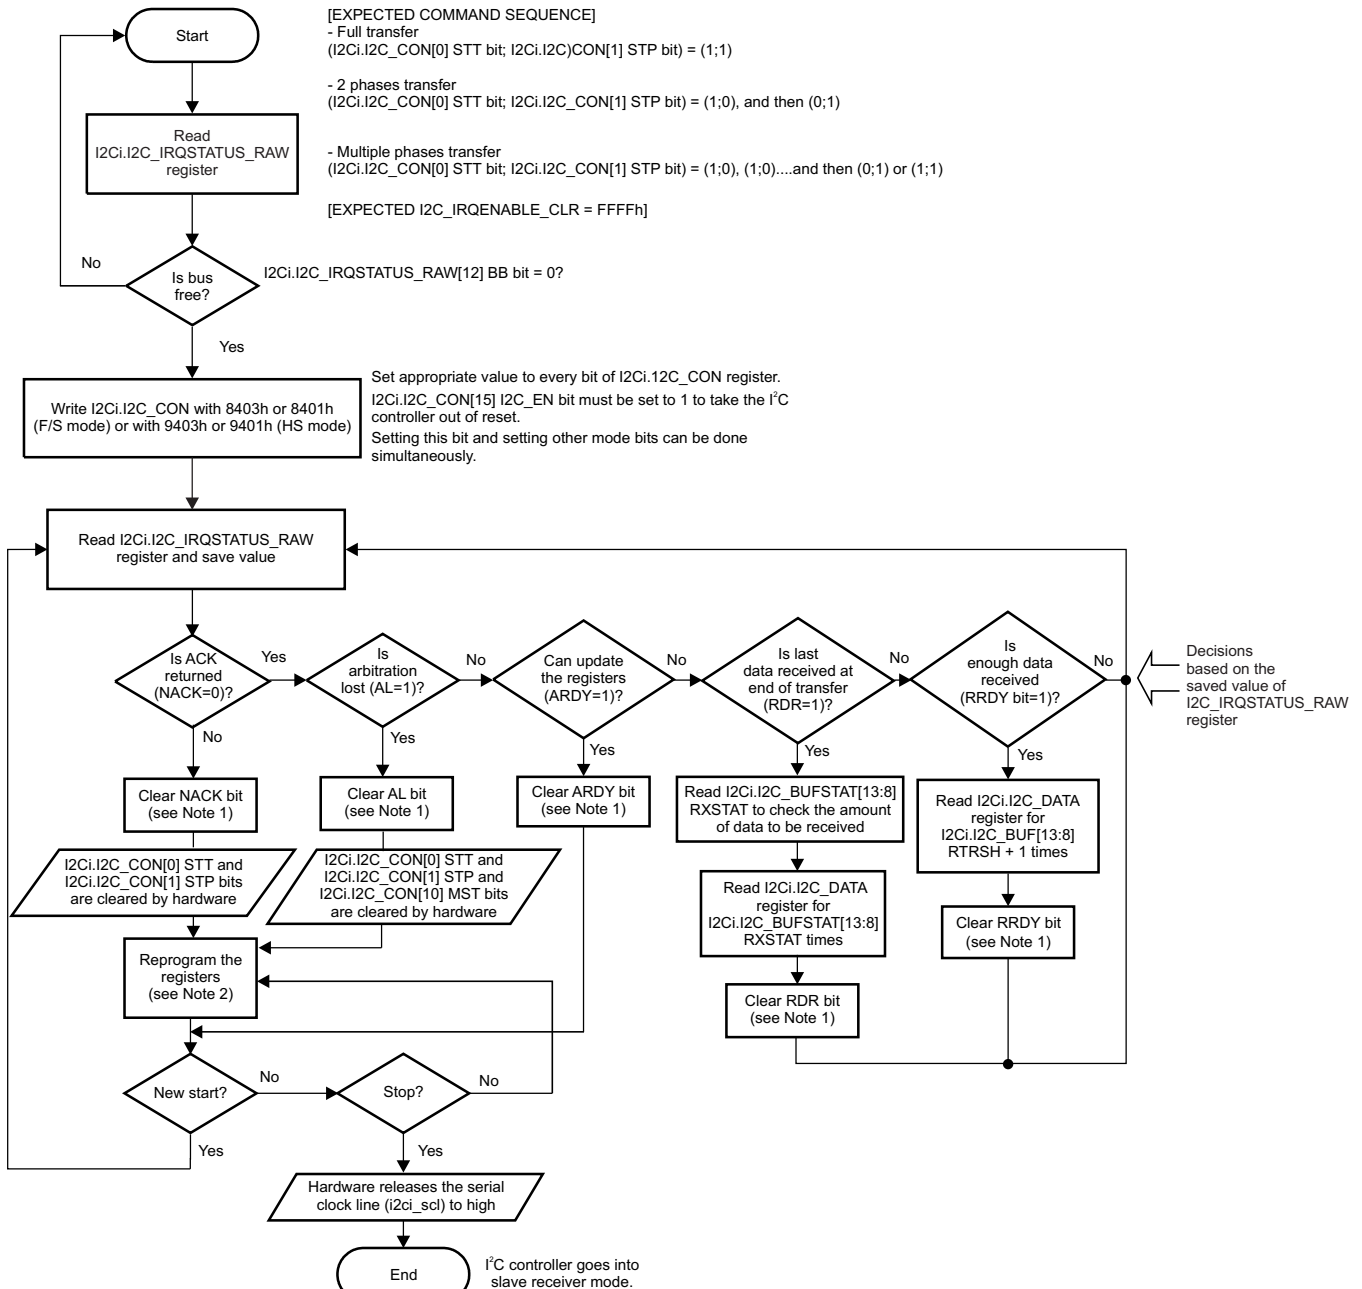

---

<b>Description</b>	Per-event raw interrupt status vector. The raw status is set even if event is not enabled. Write 1 to set the (raw) status. Used mostly for debug		
<b>Type</b>	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED	XDR	RDR	BB	ROVR	XUDF	AAS	BF	AERR	STC	GC	XRDY	RRDY	ARDY	NACK	AL

Bits	Field Name	Description	Type	Reset
15	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0
14	XDR	Transmit draining IRQ status. 0x0: Transmit draining inactive. 0x1: Transmit draining enabled.	RW	0
13	RDR	Receive draining IRQ status. 0x0: Receive draining inactive. 0x1: Receive draining enabled.	RW	0

Bits	Field Name	Description	Type	Reset
12	BB	Bus busy status. Writing into this bit has no effect. Read 0x1: Bus is occupied. Read 0x0: Bus is free.	R	0
11	ROVR	Receive overrun status. Writing into this bit has no effect. Read 0x1: Receiver overrun. Read 0x0: Normal operation.	RW	0
10	XUDF	Transmit underflow status. Writing into this bit has no effect. Read 0x1: Transmit underflow. Read 0x0: Normal operation.	RW	0
9	AAS	Address recognized as slave IRQ status. 0x0: No action. 0x1: Address recognized.	RW	0
8	BF	Bus Free IRQ status. 0x0: No action. 0x1: Bus Free.	RW	0
7	AERR	Access Error IRQ status. 0x0: No action. 0x1: Access Error.	RW	0
6	STC	Start Condition IRQ status. 0x0: No action. 0x1: Start Condition detected.	RW	0

Bits	Field Name	Description	Type	Reset
5	GC	General call IRQ status. Set to 1 by core when General call address detected and interrupt signaled to IRQ_Crossbar.  0x0: No general call detected. 0x1: General call address detected.	RW	0
4	XRDY	Transmit data ready IRQ status. Set to 1 by core when transmitter and when new data is requested. When set to 1 by core, an interrupt is signaled to IRQ_Crossbar.  0x0: Transmission ongoing. 0x1: Transmit data ready.	RW	0
3	RRDY	Receive data ready IRQ status. Set to 1 by core when receiver mode, a new data is able to be read. When set to 1 by core, an interrupt is signaled to IRQ_Crossbar.  0x0: No data available. 0x1: Receive data available.	RW	0
2	ARDY	Register access ready IRQ status. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to IRQ_Crossbar.  0x0: Module busy. 0x1: Access ready.	RW	0
1	NACK	No acknowledgement IRQ status. Bit is set when No Acknowledge has been received, an interrupt is signaled to IRQ_Crossbar.  0x0: Normal operation. 0x1: Not Acknowledge detected.	RW	0
0	AL	Arbitration lost IRQ status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to IRQ_Crossbar. During reads, it always returns 0.  0x0: Normal operation. 0x1: Arbitration lost detected.	RW	0

## 24.2 HDQ/1-Wire

This section describes the HDQ™/1-Wire® interface for the device.

### 24.2.1 HDQ1W Overview

The HDQ1W module implements the hardware protocol of the master functions of the TI/Benchmark HDQ and the Dallas Semiconductor 1-Wire® protocols. These protocols use a single wire for communication between the master (HDQ1W controller) and the slaves (HDQ/1-Wire external compliant devices).

Figure 24-28 shows the HDQ1W.

The HDQ1W has a generic L4 interface and is intended to be used in an interrupt-driven fashion. The 1-pin interface is implemented as an open-drain output at the device level.

The main features supported by the HDQ1W are the following:

- Benchmark HDQ protocol
- Dallas Semiconductor 1-Wire protocol
- Power-down mode

The HDQ1W provides a communication rate of 5 Kbps over an address space of 128 bytes.

A typical application of the HDQ1W is the communication with battery monitor (gas gauge) integrated circuits.

### 24.2.2 HDQ1W Environment

#### 24.2.2.1 HDQ1W Functional Modes

The HDQ1W has two main modes: HDQ and 1-Wire. Each of these modes includes idle, active, and power-down submodes. Table 24-90 lists the HDQ1W functional modes, and Figure 24-29 shows an overview of a typical application.

**Table 24-90. Functional Modes**

Functions	Description
HDQ	Benchmark HDQ protocol
1-Wire	Dallas Semiconductor 1-Wire protocol

**Figure 24-29. HDQ1W Typical Application System Overview**

An external pullup is required, because the two protocols use a return-to-1 mechanism (that is, after any command by any of the connected devices, the line is pulled to a logical high level).

The HDQ1W operates according to a command structure that is programmed into transmit command registers (as described in [Section 24.2.5.1.2, HDQ1W Low-level Programming Model](#)).

The 1-Wire mode runs at slower speeds than the capabilities of the mode.

[Table 24-91](#) describes the external signal of the HDQ/1-Wire compliant module.

**Table 24-91. I/O Description**

Signal	I/O <sup>(1)</sup>	Description	Value at Reset
hdq_sio	I/O	Serial data input/output. Output is open drain type.	HiZ (pulled to 1 by pullup)

<sup>(1)</sup> I = Input; O = Output

**NOTE:** The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see [Section 18.4.6.1.1, Pad Configuration Registers in Chapter 18, Control Module](#).

### 24.2.2.2 HDQ and 1-Wire (SDQ) Protocols

#### 24.2.2.2.1 HDQ Protocol Initialization (Default)

In HDQ mode, the firmware does not require the host to create an initialization pulse to the slave. However, the slave can be reset by using an initialization pulse (also referred to as a break pulse). The initialization pulse is generated by setting the [HDQ\\_CTRL\\_STATUS\[2\] INITIALIZATION](#) bit and then setting the [HDQ\\_CTRL\\_STATUS\[4\] GO](#) bit. The slave does not respond with a presence pulse as it does in the 1-Wire protocol.

The HDQ is a command-based protocol in which the host sends a command byte to the slave. The command directs the slave either to store the next eight bits of data received to a register specified by the command byte (write operation) or to output the eight bits of data from a register specified by the command byte (read operation). The master implementation is a simple byte engine. Sending of the ID, command/address, and data is controlled by firmware. The master engine provides only a single [HDQ\\_TX\\_DATA](#) register.

The command and data bytes consist of a stream of eight bits with a maximum transmission rate of 5 Kbps. The least-significant bit (LSB) of a command or data byte is transmitted first. If a communication time-out occurs between the host and the slave (for example, if the host waits longer than the specified time for the slave to respond, or if this is the first access command), then the host must send an initialization pulse (BREAK) before sending the command again.

The slave detects a break when the HDQ pin is driven to a logic-low state for a specified break time  $t_{(B)}$  or greater. The HDQ pin then returns to its normal ready-high logic state for a specified break-recovery time  $t_{(BR)}$ . The slave is then ready for a command from the host processor. Figure 24-30 shows this behavior.

An interrupt condition indicates a TX-complete, an RX-complete, or a time-out condition. Reading the interrupt status register clears all interrupt conditions. Only one interrupt signal is sent to the microcontroller, and only one overall mask bit can enable or disable the interrupt. The interrupt conditions cannot be individually masked.

Figure 24-30. HDQ Break-Pulse Timing Diagram

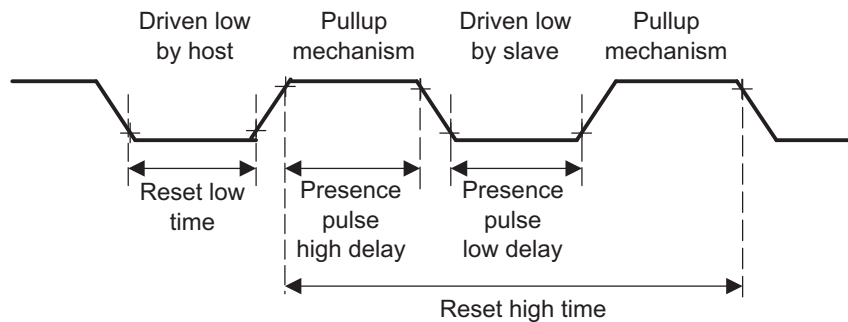

24.2.2.2.2 1-Wire (SDQ) Protocol Initialization

In 1-Wire (SDQ) protocol, the host first sends an initialization pulse (by pulling the line to a logic-low state) and then waits for the slave to respond with a presence pulse before enabling any communication sequence.

As for the initialization pulse, the presence pulse is a low-level pulse on the line initiated by the slave. The timing diagram in Figure 24-31 shows the 1-Wire (SDQ) reset sequence.

Figure 24-31. 1-Wire (SDQ) Reset Timing Diagram

The host drives the line to a logic-low state for a minimum of reset low time. Once the slave detects this pulse, it must drive the line to a logic-low state within the presence pulse high delay for a minimum period of presence pulse low time.

If the slave does not respond within this interval of time, a time-out event occurs and no transaction can be initiated. The host must initiate the reset sequence again before sending any command to the slave.

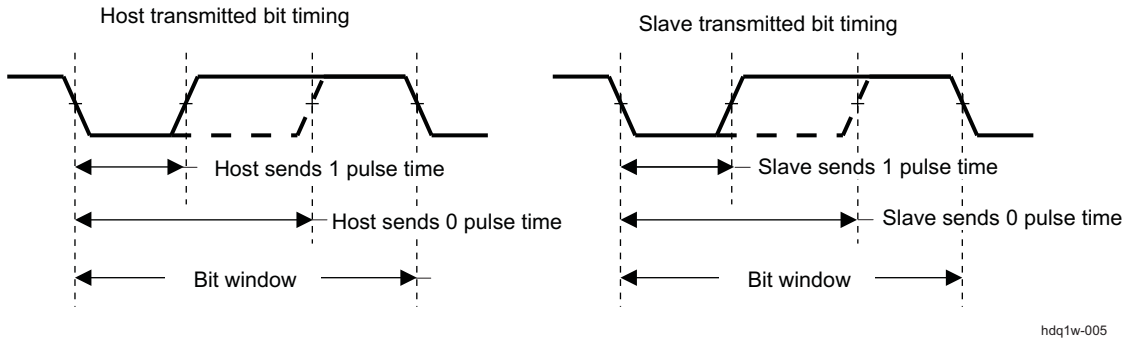

On the other hand, if the slave sends back its presence pulse within the specified time interval, the communication can be enabled after the reset high time.

24.2.2.2.3 Communication Sequence (HDQ and 1-Wire Protocols)

The description in this section applies to both protocols.

After a successful break pulse (HDQ mode) or initialization sequence (1-Wire protocol), the host and slave are ready for bit transmission. Each bit to transmit (either from the host to the slave or from the slave to the host) is preceded by a low-going edge on the line, as shown in [Figure 24-32](#).

**Figure 24-32. HDQ1W Transmitted Bit Timing**

The return-to-1 data-bit frame consists of three distinct sections. The first section starts the transmission when either the slave or the host takes the line to a logic-low state. The next section is the actual data transmission in which the data must be valid during a specified period of time after the negative edge that starts the communication. The final section stops the transmission by returning the HDQ/1-Wire line to a logic-high state. Communication with an HDQ/1-Wire slave always occurs with the LSB being transmitted first.

The command byte of the HDQ/1-Wire protocols consists of eight contiguous valid command bits. The command byte contains two fields: R/W command and address. The R/W bit of the command byte determines whether the command is a read or a write, and the address field containing bits AD6-AD0 indicates the address to be read or written. [Table 24-92](#) lists the command byte values.

**Table 24-92. HDQ/1-Wire Command Byte**

7	6	5	4	3	2	1	0
R/W	AD6	AD5	AD4	AD3	AD2	AD1	AD0

**R/W** Indicates whether the command byte is a read or a write. A 1 indicates a write command; the following eight bits must be written to the register specified by the address field of the command byte. A 0 indicates that the command is a read. On a read command, the slave outputs the requested register contents.

**AD6-AD0** Represent the seven bits labeled AD6-AD0 containing the address portion of the register to be accessed. The communication sequence example in [Figure 24-33](#) shows a read command at address 0x55; the received data is 0x65.

**Figure 24-33. HDQ/1-Wire Communication Sequence**

### 24.2.3 HDQ1W Integration

Figure 24-34 shows HDQ1W integration in the device.

Figure 24-34. HDQ1W Integration

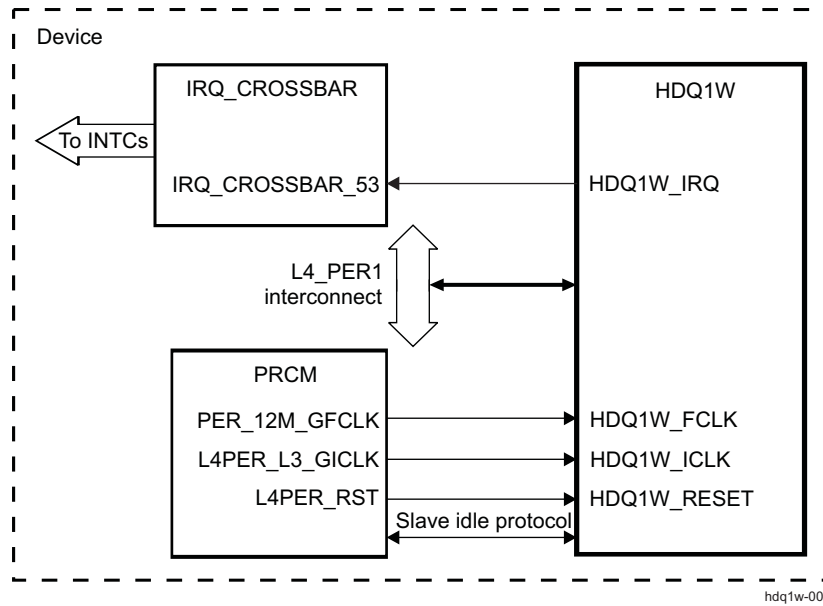

Table 24-93 through Table 24-95 summarize the integration of the module in the device.

Table 24-93. HDQ1W Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
HDQ1W	PD_COREAON	No	L4_PER1

---

**NOTE:** The “**Default Mapping**” column in [Table 24-95, HDQ1W Hardware Requests](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ\_CROSSBAR module.

For more information about the IRQ\_CROSSBAR module, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#).

For more information about the device interrupt controllers, see [Chapter 17, Interrupt Controllers](#).

---

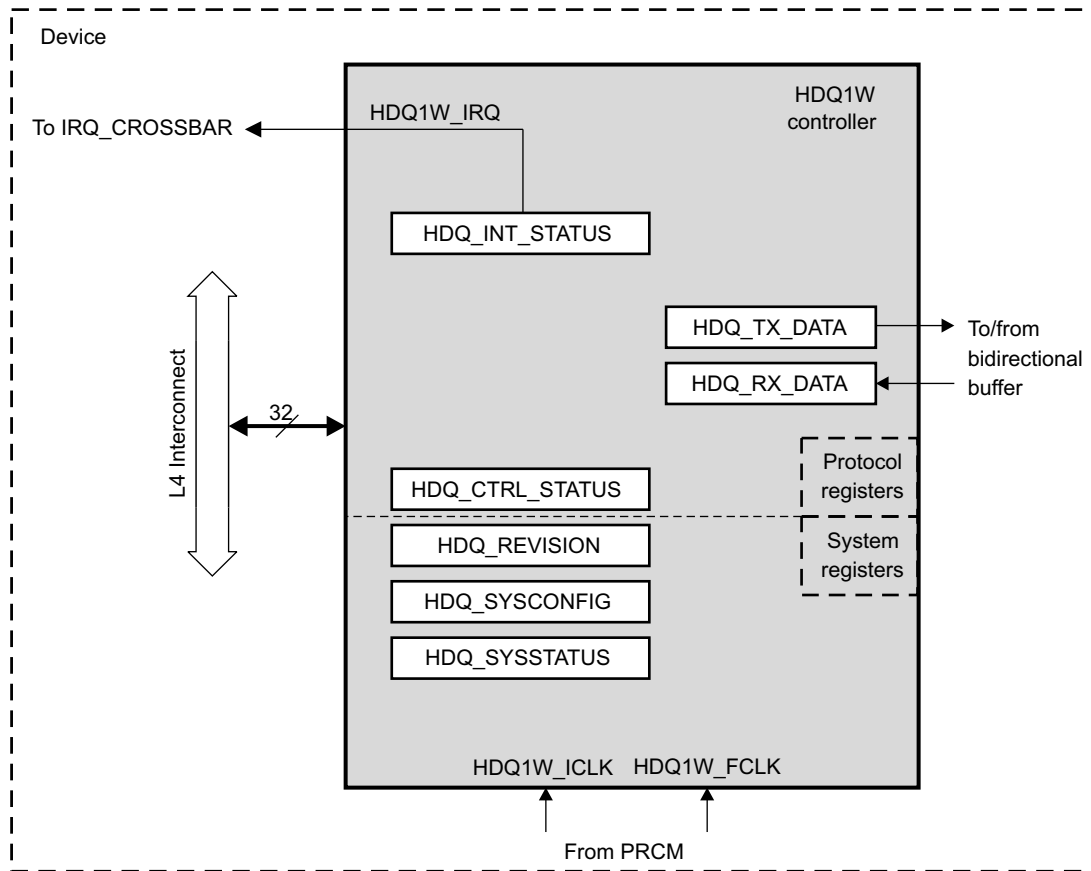

### 24.2.4 HDQ1W Functional Description

The HDQ1W works with HDQ and 1-Wire protocols. The protocols use a single wire to establish communication between the master and the slave. Both protocols use a return-to-1 mechanism; that is, after any command is driven, the line is pulled to a high level. This mechanism requires an external pullup.

#### 24.2.4.1 HDQ1W Block Diagram

Figure 24-35 is the HDQ1W block diagram.

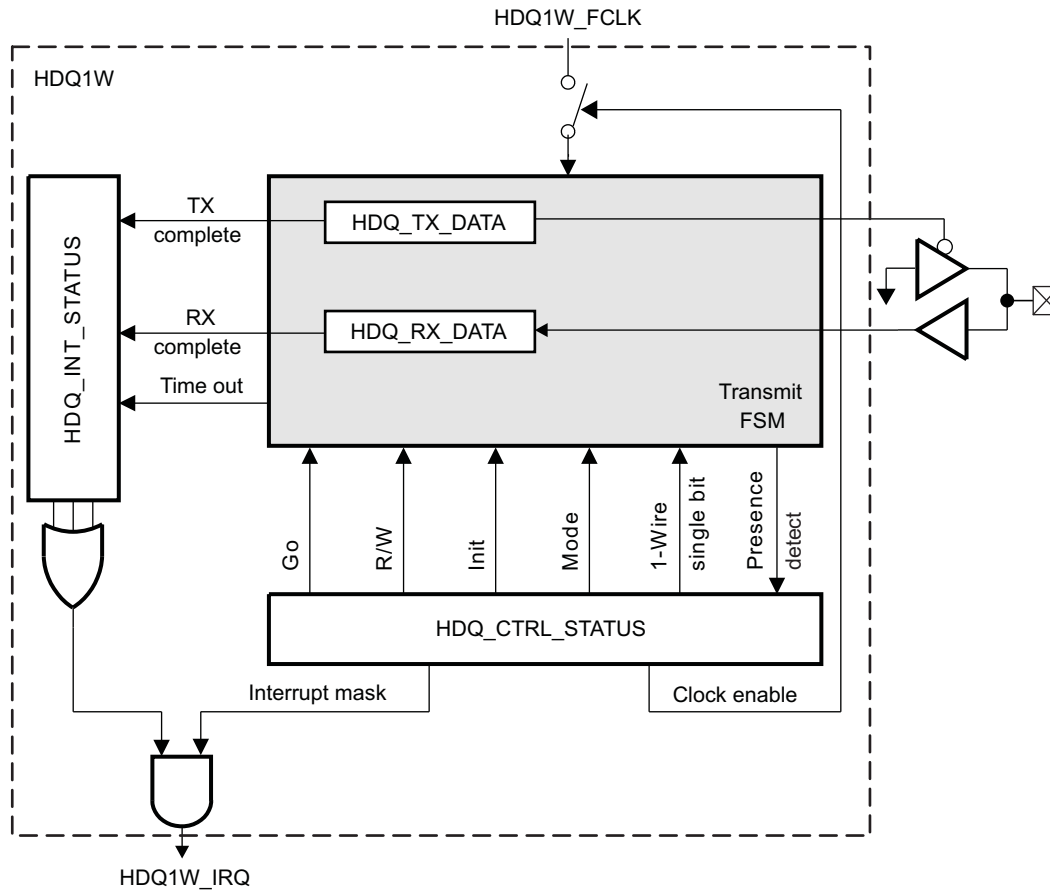

Figure 24-35. HDQ1W Block Diagram

hdq1w-008

The `HDQ_CTRL_STATUS[0] MODE` bit allows selection between the HDQ and 1-Wire protocols. This bit is assumed static for design purposes. The configuration is in HDQ mode by default.

Figure 24-36 shows the protocol-dedicated register scheme.

**Figure 24-36. Protocol Registers Description**

hdq1w-009

The receive and transmit operations of the HDQ1W module are performed with respect to the timing of the slower HDQ protocol. When the 1-Wire protocol is used, it runs at lower speed than its full capabilities, but is still able to meet the timing requirements and practical considerations.

#### 24.2.4.2 HDQ1W Clocking Configuration

##### 24.2.4.2.1 HDQ1W Clocks

The HDQ1W module operates from two clocks: a functional clock (HDQ1W\_FCLK) and an interface clock (HDQ1W\_ICLK). When these clocks are set in the PRCM module, the following rule must be observed:  $HDQ1W\_ICLK \geq HDQ1W\_FCLK$ .

- The HDQ1W\_FCLK functional clock is a fixed clock provided by the PRCM module. It is used to clock the internal module logic.

For more information about the clock and the PRCM register settings, see [Section 3.6.4.6, CD\\_L4PER1 Clock Domain](#), in chapter *Power, Reset, and Clock Management*.

When the HDQ1W no longer requires the HDQ1W\_FCLK, the software can disable it at the PRCM level. The clock is effectively cut, provided the other modules that receive it do not require it either.

- The HDQ1W\_ICLK interface clock runs at L4 interconnect clock speed and is used to trigger access to the HDQ1W L4 interface.

When the HDQ1W no longer requires the HDQ1W\_ICLK (no transfer is in progress), the software can disable it at the PRCM level. The clock is effectively cut, provided the other modules that receive it do not require it either.

### 24.2.4.3 HDQ1W Hardware and Software Reset

Global reset of the module is done at the power, reset, and clock management (PRCM) module level (for more information, see [Section 3.6.4.6, CD\\_L4PER1 Clock Domain](#)) or by setting the [HDQ\\_SYSCONFIG\[1\] SOFTRESET](#) bit to 1. Setting this bit enables an active software reset functionality equivalent to a hardware reset. The HDQ1W\_FCLK functional clock must be enabled from the PRCM level and locally through the [HDQ\\_CTRL\\_STATUS\[5\] CLOCKENABLE](#) bit (set to 1) for the software reset to complete.

### 24.2.4.4 HDQ1W Power Management

[Table 24-96](#) describes power-management features available to the HDQ1W.

**Table 24-96. Local Power-Management Features**

Feature	Registers	Description
Clock auto gating	<a href="#">HDQ_SYSCONFIG</a> [0] AUTOIDLE bit	Auto-idle mode
Slave idle modes	N/A	N/A
Clock enable	<a href="#">HDQ_CTRL_STATUS</a> [5] CLOCKENABLE bit	Power-down mode
Master standby modes	N/A	N/A
Global wake-up enable	N/A	N/A
Wake-up sources enable	N/A	N/A

#### 24.2.4.4.1 Auto-Idle Mode

The HDQ1W provides an auto-idle function in its interconnect clock domain.

The interconnect clock auto-idle power-saving mode is enabled or disabled through the [HDQ\\_SYSCONFIG\[0\] AUTOIDLE](#) bit. When this mode is enabled and there is no activity on the interconnect interface, the interconnect clock (HDQ1W\_ICLK) is disabled inside the module, thereby reducing power consumption. When there is new activity on the interconnect interface, the interconnect clock is restarted with no latency penalty. This mode is disabled by default after a reset.

The auto-idle mode can be enabled in order to reduce power consumption.

#### 24.2.4.4.2 Power-Down Mode

The HDQ1W also provides a power-saving function in its functional clock domain.

Setting the CLOCKENABLE bit in the control and status register ([HDQ\\_CTRL\\_STATUS](#)[5] CLOCKENABLE bit) to 0 shuts off the functional clock (HDQ1W\_FCLK) to the state-machine. The state-machine is reset when the functional clock is disabled; if any transaction is ongoing, it is aborted into the reset state.

Before shutting off the functional clock, the software must wait for transaction-complete interrupt. In write operation the software must check whether the interrupt was generated after address/command byte was sent or after data byte was sent. The functional clock must not be shut off after address/command byte is sent; otherwise, the data is not written to the slave.

The register values are not affected by disabling the functional clock.

#### CAUTION

There is no hardware mechanism to prevent cutting off the HDQ1W clocks while the module is performing a transfer. This would result in loss of data being transferred.

### 24.2.4.5 HDQ Interrupt Requests

The HDQ1W can generate one interrupt:

- HDQ1W\_IRQ: [Table 24-97](#) lists the events that can generate this interrupt.

**Table 24-97. Events**

Event Flag	Event Mask	Sync	Sensitivity	Description
<a href="#">HDQ_INT_STATUS</a> [2] TXCOMPLETE	<a href="#">HDQ_CTRL_STATUS</a> [31] INTERRUPTMASK	Yes	Level	A write operation of one byte was completed.
<a href="#">HDQ_INT_STATUS</a> [1] RXCOMPLETE	<a href="#">HDQ_CTRL_STATUS</a> [31] INTERRUPTMASK	Yes	Level	A byte has been successfully read.
<a href="#">HDQ_INT_STATUS</a> [0] TIMEOUT	<a href="#">HDQ_CTRL_STATUS</a> [31] INTERRUPTMASK	Yes	Level	After a read command initiated by the host, the slave did not pull the line low within the specified time.

#### 24.2.4.6 HDQ Mode (Default)

##### 24.2.4.6.1 HDQ Mode Features

The HDQ mode supports the following:

- Benchmark HDQ protocol
- Power-down mode

##### 24.2.4.6.2 Description

In the HDQ mode, there is no need for the host to create an initialization pulse to the slave. However, the host can reset the slave by using an initialization pulse (also known as a break pulse). Setting the [HDQ\\_CTRL\\_STATUS](#)[2] INITIALIZATION bit and then setting the [HDQ\\_CTRL\\_STATUS](#)[4] GO bit creates this pulse by pulling the line down for a defined duration. When the slave receives the pulse, it is ready for communication but does not respond with a presence pulse.

In a typical write operation, two bytes are sent to the slave. The first byte corresponds to the command/address byte, and the second byte corresponds to the data to be written.

In a typical read operation, the host sends a command/address byte and the slave returns a byte of data.

The master is implemented to send and receive bytes. Sending the command/address and data is controlled by the firmware. The master provides only a single data TX register.

The HDQ protocol is a return-to-1 protocol. Consequently, after a byte is sent to the slave (either command/address + data for a write, or just command/address for a read), the host pulls the line up. The line is set to the high-impedance state in the device and an external pullup brings it to a logical high level.

In the case of a read operation, the slave also drives the line to a logic-low state before sending the requested data.

If the host initiates a read and does not receive data within a specified interval of time (that is, the slave does not drive the line low within this interval), the [HDQ\\_INT\\_STATUS](#)[0] TIMEOUT bit is set, thereby indicating a read failure. The TIMEOUT bit remains set until the host reads the interrupt status register ([HDQ\\_INT\\_STATUS](#)).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out on a transaction. The corresponding bit is set in the interrupt status register ([HDQ\\_INT\\_STATUS](#)). This register is cleared as soon as it is read.

Only one interrupt signal is sent, and only an overall mask can enable or disable the interrupts. These interrupts cannot be individually masked.

##### 24.2.4.6.3 Single-Bit Mode

In HDQ mode, the single-bit mode ([HDQ\\_CTRL\\_STATUS](#)[7] ONE\_WIRE\_SINGLE\_BIT bit set to 1) has no effect because the HDQ protocol supports only byte transfers.

#### **24.2.4.6.4 Interrupt Conditions**

The HDQ1W provides the following interrupt status:

- **Transmission complete:**  
A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in HDQ protocol. This interrupt condition is cleared by reading the interrupt status register ([HDQ\\_INT\\_STATUS](#)).
- **Read complete:**  
In HDQ mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register ([HDQ\\_INT\\_STATUS](#)).
- **Presence detect/time-out:**  
In HDQ mode, the interrupt status indicates that after a read command initiated by the host, the slave did not pull the line low within the specified time. This interrupt condition is cleared by reading the interrupt status register ([HDQ\\_INT\\_STATUS](#)).  
In HDQ mode, a time-out condition is also used to indicate the successful completion of a break pulse. That is, if the master has sent the break pulse, it is indicated with a time-out instead of a TX-complete.

Only one interrupt is generated to the host CPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all the interrupt status bits that were previously set.

#### **24.2.4.7 1-Wire Mode**

##### **24.2.4.7.1 1-Wire Mode Features**

The 1-Wire mode supports the following:

- Dallas Semiconductor 1-Wire protocol
- Power-down mode
- Single-bit mode

##### **24.2.4.7.2 Description**

The 1-Wire mode requires an initialization pulse to be sent to the slave(s) connected on the interface. If a slave is present, it responds with a presence pulse.

The initialization pulse is sent when the [HDQ\\_CTRL\\_STATUS\[2\]](#) INITIALIZATION bit is set and the [HDQ\\_CTRL\\_STATUS\[4\]](#) GO bit is set afterwards.

When the slave receives the initialization pulse, it sends back its presence pulse by pulling down the line for a defined duration. The module detects this low-level pulse and sets the [HDQ\\_CTRL\\_STATUS\[3\]](#) PRESENCEDETECT bit.

In a similar way, if a presence pulse is not received from the slave after an initialization pulse is sent, the PRESENCEDETECT bit remains cleared.

Whether or not a presence pulse is detected after an initialization pulse is sent, the [HDQ\\_INT\\_STATUS\[0\]](#) TIMEOUT bit is set and an interrupt condition is generated.

In 1-Wire mode, the generated interrupt condition means the maximum time allowed for receiving the response has elapsed and the software must check the PRESENCEDETECT bit to determine whether or not there was a presence pulse.

The INITIALIZATION bit is cleared at the end of the initialization pulse at the same time as the TIMEOUT bit is set. The TIMEOUT bit is cleared when the interrupt status register ([HDQ\\_INT\\_STATUS](#)) is read.

For read operations, 1-Wire is a bit-by-bit protocol, which means the slave must be clocked by the host for each bit of the byte to read.

The line is pulled up at the end of the command/address byte. On the first read, the host creates a low-going edge to initiate a bit read. The line is then pulled up (pulled to the high-impedance state by the host and set to a high logical level by the external pullup) and the slave either drives the line low to transmit a 0, or does not drive the line to transmit a 1. This sequence is repeated for each bit to read.

The first bit the host receives is the LSB, and the last bit is the most-significant bit (MSB) in the receive data register ([HDQ\\_RX\\_DATA](#)).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out condition (that is, the time allowed for the slave to indicate its presence has elapsed). A read operation on the interrupt status register clears the interrupt conditions previously set. As in the HDQ mode, only one interrupt signal is sent to the host CPU. Only an overall mask bit can enable or disable the interrupt (the interrupt conditions cannot be masked individually).

#### 24.2.4.7.3 1-Wire Single-Bit Mode Operation

A single-bit mode can be entered by setting the appropriate bit in the control and status register ([ONE\\_WIRE\\_SINGLE\\_BIT](#) bit [HDQ\\_CTRL\\_STATUS\[7\]](#)). In this mode, only one bit of data at a time is transferred between the master and the slave. After the bit is transferred, an interrupt is generated (that is, there is an RX-complete for a read operation and a TX-complete for a write operation). The [ONE\\_WIRE\\_SINGLE\\_BIT](#) bit is cleared by hardware after every single bit is received. Software must set this bit to re-enable reception in single-bit mode. Bit 0 of the RX register ([HDQ\\_RX\\_DATA](#)) is updated each time a bit is received from the slave; bit 0 of the TX register ([HDQ\\_TX\\_DATA](#)) contains the bit to be sent.

#### 24.2.4.7.4 Interrupt Conditions

The HDQ1W provides the following interrupt status:

- **Transmission complete:**  
A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in 1-Wire protocol. This interrupt condition is cleared by reading the interrupt status register ([HDQ\\_INT\\_STATUS](#)).
- **Read complete:**  
In 1-Wire mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register ([HDQ\\_INT\\_STATUS](#)).
- **Presence detect/time-out:**  
In 1-Wire mode, the interrupt status indicates that it is now valid to check the [PRESENCEDETECT](#) bit. This interrupt condition is cleared by reading the interrupt status register ([HDQ\\_INT\\_STATUS](#)).

Only one interrupt is generated to the host CPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all interrupt status bits that were previously set.

#### 24.2.4.7.5 Status Flags

The presence-condition-detected status flag is contained in the [HDQ\\_CTRL\\_STATUS\[3\]](#) [PRESENCEDETECT](#) bit. This is valid only in 1-Wire mode. The flag is updated when the [HDQ\\_INT\\_STATUS\[0\]](#) [TIMEOUT](#) bit is set. Therefore, its correct value shows only after the interrupt is generated. The firmware must wait for the time-out condition; otherwise, the flag keeps its previous value and is undefined.

#### 24.2.4.8 BITFSM Delay

The return-to-one mechanism on the HDQ/1-Wire bus is a simple pull-up resistor. Consequently, an excessive wire load of the HDQ/1-Wire bus can cause a significant delay to the bus rise time. This can prevent the module state machine from working correctly by reading back an improper value caused by the line delay. To correct such condition by software, it is possible to configure the [HDQ\\_CTRL\\_STATUS\[10:8\]](#) [BITFSM](#) register bitfield with the expected line delay. This way the module state machine waits the proper time interval, before reading back the line value. The delay can be adjusted in 1.33  $\mu$ s steps. The default value of [BITFSM](#) = 0x0 corresponds to 1.33  $\mu$ s delay.

Bus delay can be calculated as follows:  $T_{\text{delay}} \approx 2.2 \times R_{\text{pullup}} \times C_{\text{line}}$

See more information in the *Device Data Manual*.

## 24.2.5 HDQ1W Low-Level Programming Model

This section describes the low-level hardware programming sequences for configuration and usage of the module. The basic protocol functions, such as slave initialization (reset), read-byte, and write-byte operations, are described. For a description of the high-level functions, see the HDQ/1-Wire protocol documentation and the slave device datasheet.

### 24.2.5.1 Global Initialization

#### 24.2.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the HDQ1W module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the HDQ1W. Refer to the HDQ1W Module Integration and Environment Sections for further information.

**Table 24-98. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. The interface clock must not be slower than the functional clock ( $HDQ1W\_ICLK \geq HDQ1W\_FCLK$ ). For more information about the module configuration, see <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Control Module	Module specific pad muxing and pullup must be set in the control module. If an external pullup is used, the internal pullup/pulldown must be disabled. For more information about the module configuration, see <a href="#">Chapter 18, Control Module</a> .
IRQ_CROSSBAR/INTC	Interrupt crossbar and interrupt controller configuration must be done to enable the interrupts from HDQ1W module. See <a href="#">Chapter 17, Interrupt Controllers</a> , and <a href="#">Section 18.4.6.4, IRQ_CROSSBAR Module Functional Description</a> .

## 24.2.6 HDQ1W Register Manual

### 24.2.6.1 HDQ1W Instance Summary

**Table 24-108. HDQ1W Instance Summary**

Module Name	Base Address	Size
HDQ1W	0x480B 2000	4 KiB

### 24.2.6.2 HDQ1W Registers

**CAUTION**

The following rules must be observed when accessing the module registers:

- A read from the [HDQ\\_INT\\_STATUS](#) register or the [HDQ\\_RX\\_DATA](#) register is not allowed unless the processor has been interrupted by the module.
- After the release of the GO bit in the [HDQ\\_CTRL\\_STATUS](#) register, no access to the [HDQ\\_TX\\_DATA](#) or [HDQ\\_CTRL\\_STATUS](#) register is allowed until the processor has been interrupted by the module.
- Polling of the [HDQ\\_INT\\_STATUS](#) register by software to determine whether an interrupt was generated is not allowed.

**CAUTION**

The HDQ1W registers are limited to 32-bit data accesses; 16-bit and 8-bit data accesses are not allowed and can corrupt register content.

#### 24.2.6.2.1 HDQ1W Register Summary

## 24.3 UART/IrDA/CIR

This chapter describes the function, operation, and configuration of the universal asynchronous receiver/transmitter (UART)/infrared data association (IrDA)/consumer infrared (CIR) module in the device.

### 24.3.1 UART/IrDA/CIR Overview

The UART is a simple L4 slave peripheral that utilizes the DMA\_SYSTEM or EDMA for data transfer or IRQ polling via CPU. There are 10 UART modules in the device. Only one UART supports IrDA features. Each UART can be used for configuration and data exchange with a number of external peripheral devices or interprocessor communication between devices.

Figure 24-37 shows the UART module overview.

#### 24.3.1.1 UART Features

The UART<sub>i</sub> (where  $i = 1$  to 10) include the following features:

- 16C750 compatibility
- 64-byte FIFO buffer for receiver and 64-byte FIFO for transmitter
- Programmable interrupt trigger levels for FIFOs
- Baud generation based on programmable divisors  $N$  (where  $N = 1 \dots 16,384$ ) operating from a fixed functional clock of 48 MHz or 192 MHz

Oversampling is programmed by software as 16 or 13. Thus, the baud rate computation is one of two options:

- Baud rate = (functional clock / 16) /  $N$
- Baud rate = (functional clock / 13) /  $N$
- This software programming mode enables higher baud rates with the same error amount without changing the clock source
- Break character detection and generation

- Configurable data format:
  - Data bit: 5, 6, 7, or 8 bits
  - Parity bit: Even, odd, none
  - Stop-bit: 1, 1.5, 2 bit(s)
- Flow control: Hardware (RTS/CTS) or software (XON/XOFF)
- The 48 MHz functional clock option allows baud rates up to 3.6Mbps
- The 192 MHz functional clock option allows baud rates up to 12Mbps
- UART1 module has extended modem control signals (DCD, RI, DTR, DSR)
- UART3 supports IrDA

#### 24.3.1.2 IrDA Features

UART3 supports the following IrDA key features:

- Support of IrDA 1.4 slow infrared (SIR), medium infrared (MIR), and fast infrared (FIR) communications:
  - Frame formatting: Addition of variable beginning-of-frame (xBOF) characters and end-of-frame (EOF) characters
  - Uplink/downlink cyclic redundancy check (CRC) generation/detection
  - Asynchronous transparency (automatic insertion of break character)
  - Eight-entry status FIFO (with selectable trigger levels) to monitor frame length and frame errors
  - Framing error, CRC error, illegal symbol (FIR), and abort pattern (SIR, MIR) detection

#### 24.3.1.3 CIR Features

The CIR mode uses a variable pulse-width modulation (PWM) technique (based on multiples of a programmable  $t$  period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on a user-definable frame structure and packet content.

The CIR (UART3 only) includes the following features to provide CIR support for remote-control applications:

- Transmit mode only (receive mode is not supported)
- Free data format (supports any remote-control private standards)
- Selectable bit rate
- Configurable carrier frequency
- 1/2, 5/12, 1/3, or 1/4 carrier duty cycle

## 24.3.2 UART/IrDA/CIR Environment

This section describes the UART/IrDA/CIR connection with an external device.

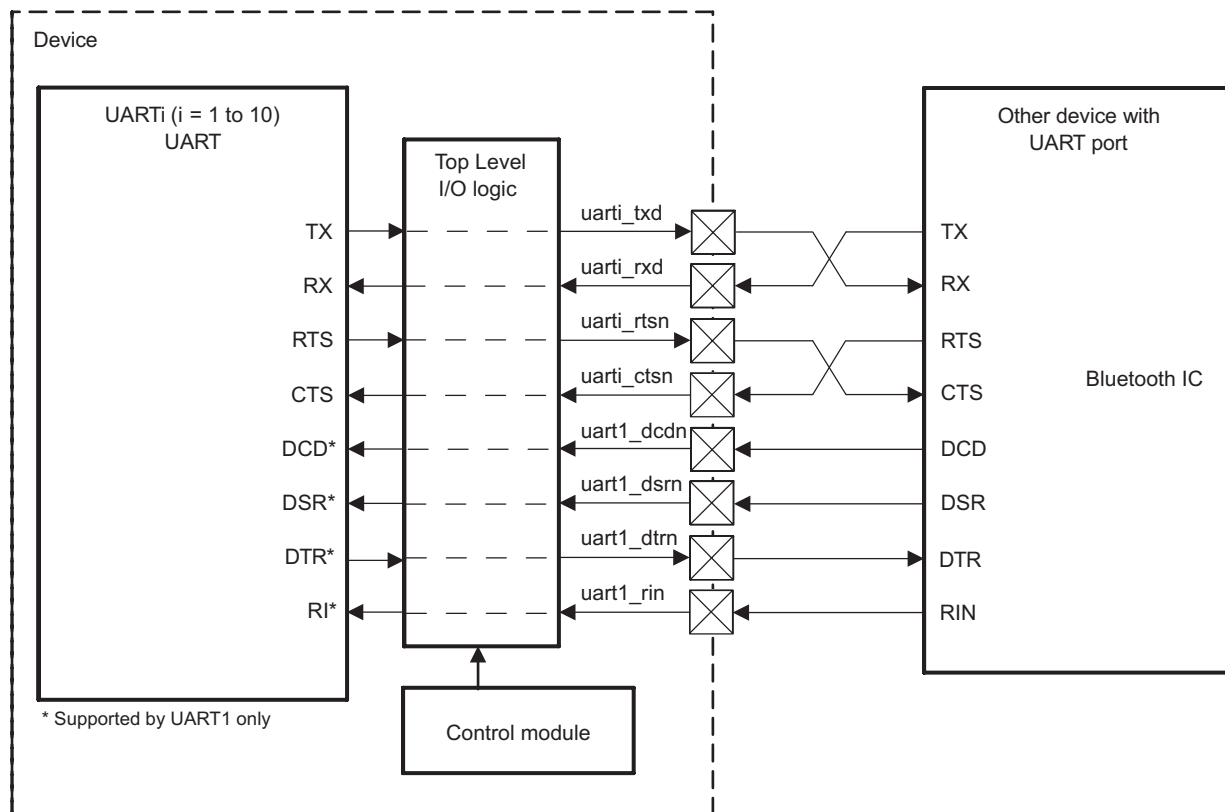

- The UART interface is described in [Section 24.3.2.1](#).
- The IrDA interface is described in [Section 24.3.2.2, IrDA Functional Interfaces](#).
- The CIR interface is described in [Section 24.3.2.3, CIR Functional Interfaces](#).

### 24.3.2.1 UART Interface

#### 24.3.2.1.1 System Using UART Communication With Hardware Handshake

Each UART instance can be easily connected to the UART port of an external IC (see [Figure 24-38](#) ).

**Figure 24-38. UART Mode Bus System Overview**

uart-002

#### 24.3.2.1.2 UART Interface Description

[Table 24-124](#) lists the UART interface input/output (I/O) signals.

**Table 24-124. UART Interface Signals**

Signal	I/O <sup>(1)</sup>	Description	Module Level Reset Value
<b>UARTi Interface Signals<sup>(2)</sup></b>			
uarti_rxd	I	Serial data input.	HiZ
uarti_txd	O	Serial data output	1

<sup>(1)</sup> I = Input; O = Output; I/O = Bidirectional

<sup>(2)</sup> i = 1 to 10

**Table 24-124. UART Interface Signals (continued)**

Signal	I/O <sup>(1)</sup>	Description	Module Level Reset Value
		Because this pin is active high in IrDA mode and the output is muxed, this pin is set to low on reset (when the UARTi.UART_MDR1[2:0] bit field is set to 0x7) and takes the defined inactive level of that signal corresponding to when and how the UARTi.UART_MDR1 register is programmed; that is, the output is 1 (inactive for UART modem modes) and 0 (inactive for IrDA modes).	
uarti_ctsn	I	Clear to send  Active-low modem status signal. Reading the UARTi.UART_MSR[4] NCTS_STS bit checks the condition of uarti_ctsn. Reading the UARTi.UART_MSR[0] CTS_STS bit checks a change of state of uarti_ctsn since the last read of the modem status register. The auto-CTS mode uses uarti_ctsn to control the transmitter.	HiZ
uarti_rtsn	O	Request to send  When active (low), the module is ready to receive data. Setting the UARTi.UART_MCR[1] RTS bit activates uarti_rtsn, which becomes inactive as the result of a module reset, loopback mode, or clearing the UARTi.UART_MCR[1] RTS bit. In auto-RTS mode, uarti_rtsn becomes inactive as a result of the receiver threshold logic.	1
<b>UART1 Modem Signals</b>			
uart1_dcdn	I	Data Carrier Detect  Active-low modem status signal. The condition of uart1_dcdn can be checked by reading UART_MSR[7] NCD_STS register bit. Any change in its state can be detected by reading UART_MSR[3] DCD_STS bit.	HiZ
uart1_dsrn	I	Data Set Ready  Active-low modem status signal. Reading UART_MSR[5] NDSR_STS register bit checks the condition of uart1_dsrn. Reading UART_MSR[1] DSR_STS bit checks a change of state of uart1_dsrn since the last read of the UART_MSR register.	HiZ
uart1_dtrn	O	Data Terminal Ready  When active (low), this signal informs the modem that the module is ready to communicate. It is activated by setting UART_MCR[0] DTR register bit.	1
uart1_rin	I	Ring Indicator  Active-low modem status signal. The condition of uart1_rin can be checked by reading UART_MSR[6] NRI_STS register bit. Any change in its state can be detected by reading UART_MSR[2] RI_STS bit.	HiZ

**NOTE:** The path from a module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. For more information on control module settings, see [Section 18.4.6.1.1, Pad Configuration Registers](#), in [Chapter 18, Control Module](#).

### 24.3.2.1.3 UART Protocol and Data Format

The UART device operates in three modes:

- UART 16x (<= 230.4 kbps)
- UART 16x with autobauding (>= 1200 bps and >= 115.2 kbps)
- UART 13x (>= 460.8 kbps)

**CAUTION**

To be used as a UART, the operating mode must be programmed appropriately in the UARTi.UART\_MDR1[2:0] MODE\_SELECT bit field to select UART, IrDA, or CIR mode.

The UART uses a wired interface for serial communication with a remote device.

The UART is functionally compatible with the TL16C750 UART and earlier designs such as the TL16C550.

Figure 24-39 shows the UART frame data format.

**Figure 24-39. UART Frame Data Format**

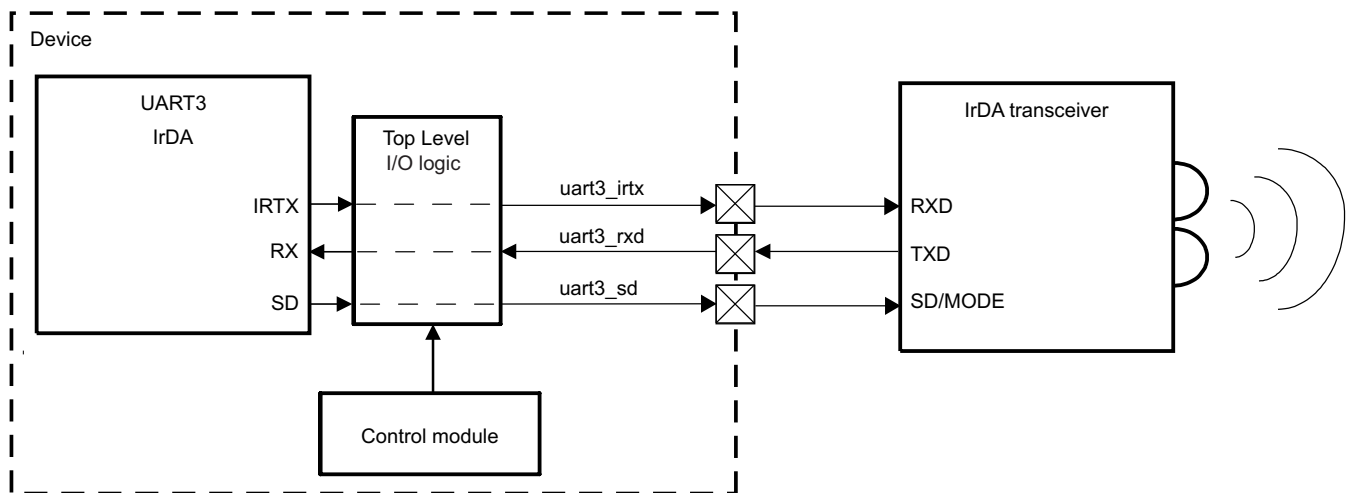

uart-005

### 24.3.2.2 IrDA Functional Interfaces

#### 24.3.2.2.1 System Using IrDA Communication Protocol

As Figure 24-40 shows, UART3 can be connected to an external infrared transceiver in the IrDA modes (FIR, SIR, and MIR).

**Figure 24-40. IrDA System Overview**

uart-003

#### 24.3.2.2.2 IrDA Interface Description

Table 24-125 lists the IrDA interface I/O signals.

**Table 24-125. IrDA I/O Signals**

Signal	I/O <sup>(1)</sup>	Description	Reset
<b>IrDA Signals</b>			
uart3_rxd	I	Serial data input	HiZ
uart3_irtx	O	Serial data output in IrDA modes (SIR, MIR, and FIR). In other modes, this pin is set to the reset value (inactive state).	0
uart3_sd	O	SD mode is used to configure the transceivers. The SD pinout is an inverted value of the UART3.UART_ACREG[6] SD_MOD bit.	1

<sup>(1)</sup> I = Input; O = Output

### 24.3.2.2.3 IrDA Protocol and Data Format

#### 24.3.2.2.3.1 SIR Mode

In SIR mode, data is transferred between the MPU and peripheral devices at speeds of up to 115,200 baud. A SIR transmit frame begins with start flags (a single 0xC0, a multiple 0xC0, or a single 0xC0 preceded by a number of 0xFF flags), followed by frame data and a CRC-16, and ends with a stop flag (0xC1).

The bit format for a single word uses 1 start-bit, 8 data bits, and 1 stop-bit, and is unaffected by the use and settings of the UART3.UART\_LCR register.

The UART3.UART\_BLR[6] XBOF\_TYPE bit selects whether the 0xC0 or 0xFF start patterns are used when multiple start flags are required.

The SIR transmit state-machine attaches start flags, CRC-16, and stop flags, and checks the outgoing data to establish whether data transparency is required.

SIR transparency is carried out if the outgoing data between the start and stop flags contains 0xC0, 0xC1, or 0x7D. If one of these start flags is about to be transmitted, the SIR state-machine sends an escape character (0x7D), inverts the fifth bit of the real data to be sent, and then sends this data immediately after the 0x7D character.

The SIR receive state-machine recovers the receive clock, removes the start flags and any transparency from the incoming data, and determines the frame boundary with reception of the stop flag. The SIR state-machine also checks for errors such as a frame abort (0x7D character followed immediately by a 0xC1 stop flag without transparency), a CRC error, or a frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.UART\_LSR\_IRDA) to find possible errors of the received frame.

---

**NOTE:** The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. See the description of the UART3.UART\_ACREG[5] DIS\_IR\_RX bit. This applies to all three modes: SIR, MIR, and FIR.

---

Infrared output in SIR mode can be 1.6- $\mu$ s or 3/16 encoding, selected by the UART3.UART\_ACREG[7] PULSE\_TYPE bit. In 1.6- $\mu$ s encoding, the infrared pulse width is 1.6  $\mu$ s; and in 3/16th encoding, the infrared pulse width is 3/16th of a bit duration (1/baud rate).

For back-to-back frames, the transmitting device must send at least two start flags at the start of each frame.

---

**NOTE:** Reception supports variable-length stop-bits.

---

#### 24.3.2.2.3.1.1 Frame Format

Figure 24-41 shows the IrDA SIR frame format.

**Figure 24-41. IrDA SIR Frame Format**

uart-006

The CRC is applied on the address (A), control (C), and information (I) bytes.

**NOTE:** The two words of CRC are written to the FIFO in reception.

#### 24.3.2.2.3.1.2 Asynchronous Transparency

Before transmitting a byte, the UART IrDA controller examines each byte of the payload and the CRC field (between BOF and EOF). For each byte equal to 0xC0 (BOF), 0xC1 (EOF), or 0x7D (control escape), the controller performs certain tasks:

- In transmission:
  - Inserts a control escape (CE) byte preceding the byte
  - Complements bit 5 of the byte (that is, exclusive ORs the byte with 0x20)

The byte sent for the CRC computation is the initial byte written in the TX FIFO (before the XOR with 0x20).
- In reception:
 

For the A, C, I, and CRC fields:

  - Compares the byte with the CE byte; if they are not equal, sends the byte to the CRC detector and stores it in the RX FIFO.
  - If the byte is equal to the CE byte, discards the CE byte
  - Complements bit 5 of the byte following the CE
  - Sends the complemented byte to the CRC detector and stores it in the RX FIFO

#### 24.3.2.2.3.1.3 Abort Sequence

The transmitter can prematurely close a frame (abort) by sending the sequence 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

When a 0x7D character that is followed immediately by a 0xC1 character is received without transparency, the receiver treats the frame as an aborted frame.

#### 24.3.2.2.3.1.4 Pulse Shaping

The SIR mode supports the 3/16 and the 1.6- $\mu$ s pulse duration methods. The UART3.UART\_ACREG[7] PULSE\_TYPE bit selects the pulse-width method in transmit mode.

#### 24.3.2.2.3.1.5 Encoder

Serial data from the transmit state-machine are encoded to transmit data to the optoelectronics. While the TX FIFO output is high, the uart3\_irtx line is always low, and the counter used to form a pulse on uart3\_irtx is cleared continuously.

After the TX FIFO output resets to 0, `uart3_irtx` rises on the falling edge of the seventh 16XCLK. On the falling edge of the tenth 16XCLK pulse, `uart3_irtx` falls, creating a 3-clock-wide pulse. While the TX FIFO output stays low, a pulse is transmitted during the seventh clock to the tenth clock of each 16-clock bit cycle.

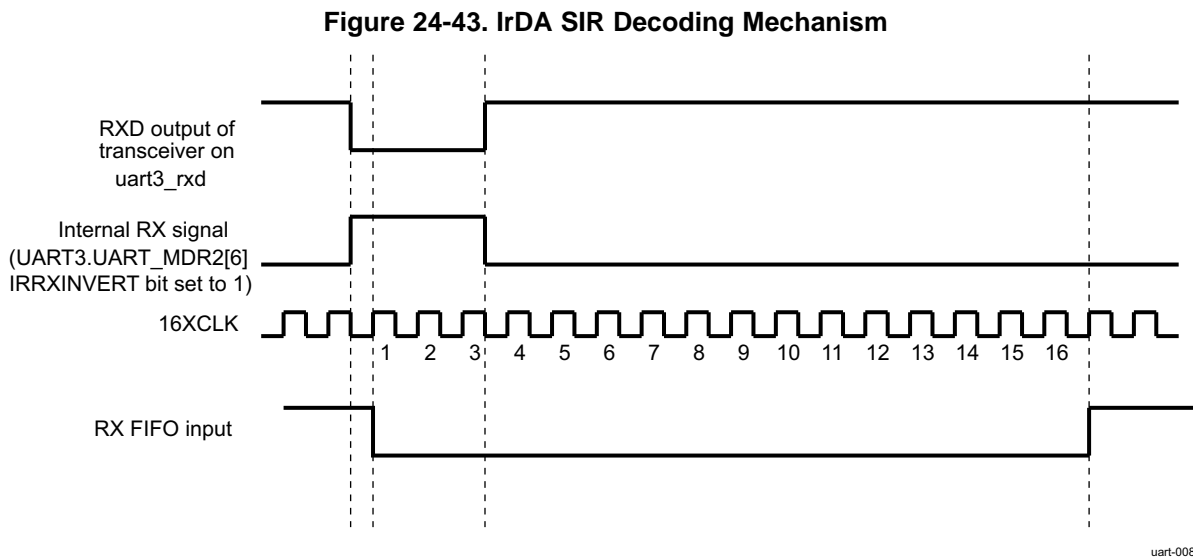

Figure 24-42 shows the IrDA SIR encoding mechanism.

#### 24.3.2.2.3.1.6 Decoder

After reset, the RX FIFO input is high and the 4-bit counter is cleared. When a rising edge is detected on RX, the RX FIFO input falls on the next rising edge of 16XCLK with sufficient setup time. The RX FIFO input stays low for 16 cycles (16XCLK) and then returns to high as required by the IrDA specification. As long as no pulses (rising edges) are detected on the RX, the RX FIFO input remains high.

Figure 24-43 shows the IrDA SIR decoding mechanism.

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. The operation of the `uart3_rxd` input can be disabled using the `UART3.UART_ACREG[5] DIS_IR_RX` bit. The `UART3.UART_MDR2[6] IRRXINVERT` bit can invert the signal from the transceiver (RXD) pin to the IR RX logic in the UART. This inversion is performed by default.

### 24.3.2.2.3.1.7 IR Address Checking

In all IR modes, when address checking is enabled by setting the UART3.UART\_EFR[1:0] bit field (see Table 24-126), only frames intended for the device are written to the RX FIFO. This is to avoid receiving frames not meant for this device in a multipoint infrared environment. To program two frame addresses that the UART3 receives in IrDA mode, use the UART3.UART\_XON1\_ADDR1[7:0] and UART3.UART\_XON2\_ADDR2[7:0] bit fields.

**Table 24-126. UART\_EFR[1:0] IR Address Checking Options**

UART_EFR[1]	UART_EFR[0]	IR Address Checking
0	0	All address-checking operations disabled
0	1	Only address 1 checking enabled
1	0	Only address 2 checking enabled
1	1	All address-checking operations enabled

### 24.3.2.2.3.2 SIR Free-Format Mode

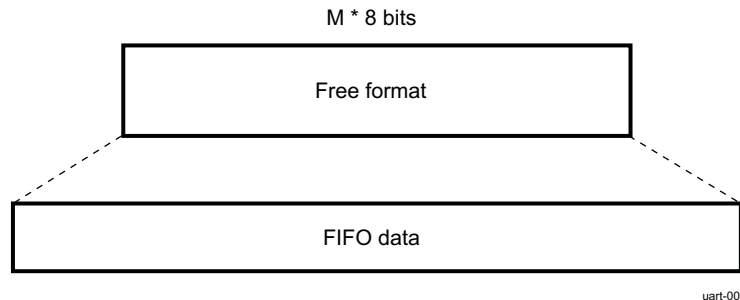

To allow complete software flexibility when transmitting and receiving infrared data packets, the SIR free-format (FF) mode is a subfunction of the existing SIR mode. In FF mode, all frames going to and from the FIFO buffers are untouched with respect to appending and removing control characters and CRC values.

The FF mode corresponds to a UART mode with a pulse modulation of 3/16 of baud rate pulse width.

For example, a normal SIR packet has BOF control and CRC error-checking data appended (transmitting) or removed (receiving) from the data going to and from the FIFOs.

Figure 24-44 shows SIR FF mode.

**Figure 24-44. SIR FF Mode**

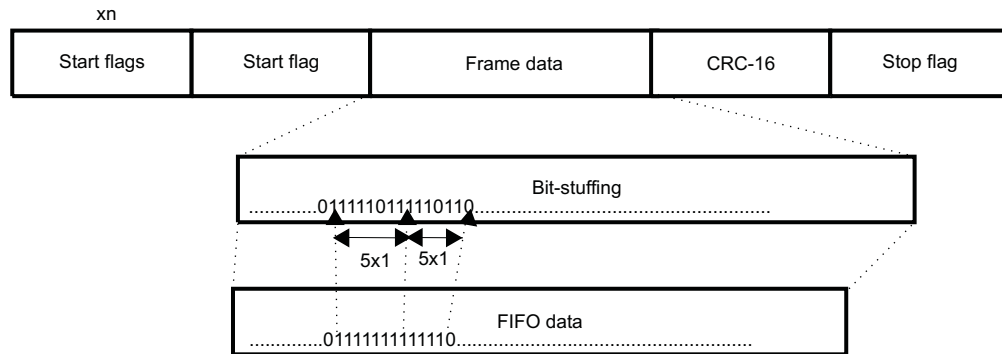

In SIR FF mode, the MPU software must construct (that is, encode and decode) the entire FIFO data packet.

### 24.3.2.2.3.3 MIR Mode

In MIR mode, data is transferred between the MPU and the peripheral devices at 0.576 or 1.152 Mbps. A MIR transmit frame starts with at least two start flags, followed by a frame data and a CRC-16, and ends with a stop flag (see Figure 24-45).

**Figure 24-45. MIR Transmit Frame Format**

On transmit, the MIR state-machine attaches start flags, a CRC-16, and stop flags, as in SIR mode. All fields are transmitted least-significant bit (LSB) of each byte first.

In MIR mode:

- The state-machine looks for consecutive 1s in the frame data and automatically inserts 0 after five consecutive 1s (this is called bit-stuffing).
- 0x7E is used for start and stop flags (unambiguously, not data, because of bit-stuffing).
- An abort sequence requires a minimum of seven consecutive 1s (unambiguously, not data, because of bit-stuffing).
- Back-to-back frames are allowed with three or more stop flags between them. If two consecutive frames are not back to back, the gap between the last stop flag of the first frame and the start flag of the second frame must be separated by at least seven bit durations.

On receive, the MIR receive state-machine recovers the receive clock, removes the start flags, destuffs the incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors such as frame abort, CRC error, and frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.UART\_LSR\_IRDA) to detect errors of the received frame.

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

#### 24.3.2.2.3.3.1 MIR Encoder/Decoder

To meet the MIR baud rate tolerance of 0.1 percent with a 48-MHz clock input, a 42-41-42 encoding/decoding adjustment is performed. The reference start point is the first start flag, and the 42-41-42 cyclic pattern is repeated until the stop flag is sent or detected.

The jitter created this way is within MIR tolerances. The pulse width is not exactly 1/4, but it is within the tolerances defined by IrDA specifications.

Figure 24-46 shows the MIR baud rate adjustment mechanism.

**Figure 24-46. MIR Baud Rate Adjustment Mechanism**

uart-011

**24.3.2.2.3.3.2 SIP Generation**

In the MIR and FIR operation modes, the transmitter must send a serial infrared interaction pulse (SIP) at least once every 500 ms. The SIP informs slow devices (operating in SIR mode) that the medium is occupied.

Figure 24-47 shows the SIP.

**Figure 24-47. SIP**

uart-012

**24.3.2.2.3.4 FIR Mode**

In FIR mode, data is transferred between the MPU and the peripheral devices at 4 Mbps. A FIR transmit frame starts with a preamble that is followed by a start flag, frame data, CRC-32, and ends with a stop flag.

Figure 24-48 shows the FIR transmit frame format.

**Figure 24-48. FIR Transmit Frame Format**

Preamble (16x)	Start flag	Frame data	CRC-32	Stop flag
----------------	------------	------------	--------	-----------

On transmit, the FIR transmit state-machine attaches the preamble, start flag, CRC-32, and stop flag. An abort sequence requires at least two transmissions of 0000. Back-to-back frames are allowed, but each frame must be complete.

The state-machine also encodes the transmit data into 4-PPM format (see Table 24-127) and generates the SIP (see Section 24.3.2.2.3.3.2, SIP Generation).

**Table 24-127. 4-PPM Format**

Data Bit Pair (Bin)	4-PPM Data Symbol (Bin)
00	1000
01	0100
10	0010
11	0001

The four symbols described in [Table 24-127](#) are the legal, encoded data symbols. All other combinations are illegal for encoding data. Some of these illegal symbols are used in the definition of the preamble, start flag, and stop flag because they are unambiguously not data (see [Table 24-128](#)).

**Table 24-128. FIR Preamble, Start Flag, and Stop Flag**

Frame Part	Transmitted Frame (Bin)
Preamble	1000 0000 1010 1000 (16 repeated transmissions)
Start flag	0000 1100 0000 1100 0110 0000 0110 0000
Stop flag	0000 1100 0000 1100 0000 0110 0000 0110

All fields are transmitted LSBs of each byte first (see [Table 24-129](#)).

**Table 24-129. FIR Data Byte Transmission Order Example**

Data Byte (Hex)	Data Byte Pair (Bin)	4-PPM Data Symbol (Bin)	Transmission Order
0x0B	00	1000	4
	00	1000	3
	10	0010	2
	11	0001	1

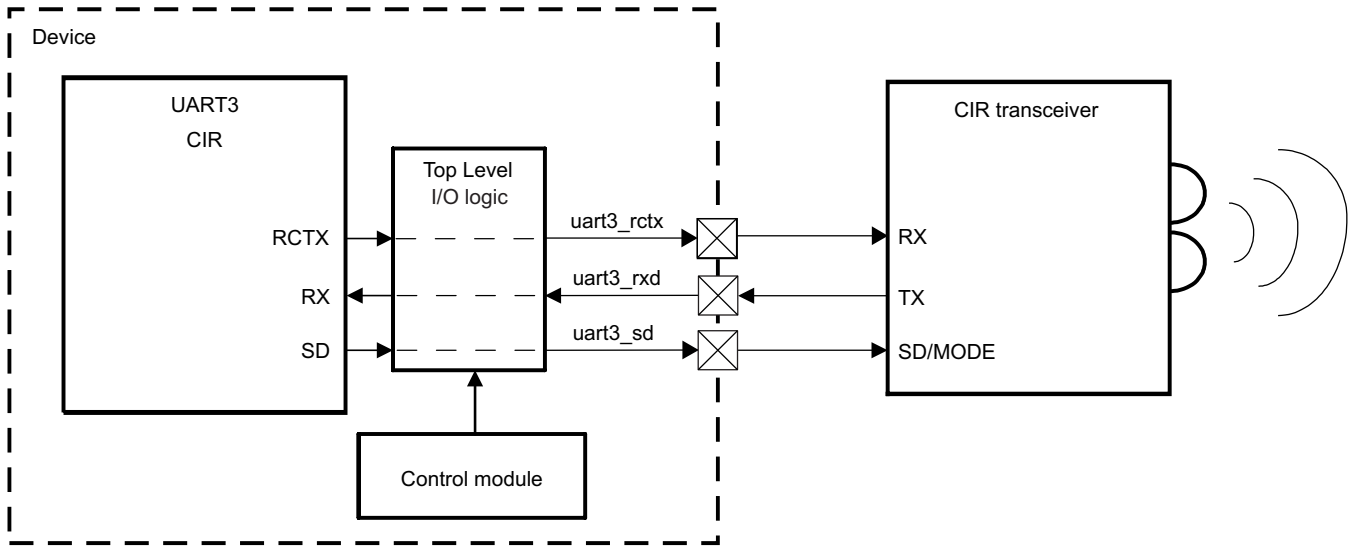

On receive, the FIR receive state-machine recovers the receive clock, removes the preamble and the start flag, decodes the 4-PPM incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors such as illegal symbol, CRC error, and frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.UART\_LSR\_IRDA) to detect errors of the received frame.

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

### 24.3.2.3 CIR Functional Interfaces

#### 24.3.2.3.1 System Using CIR Communication Protocol With Remote Control

UART3 can be connected to an external infrared transceiver in CIR mode (see [Figure 24-49](#)).

**Figure 24-49. CIR System Overview**

uart-004

### 24.3.2.3.2 CIR Interface Description

Table 24-130 lists the CIR interface I/O signals.

**Table 24-130. CIR I/O Signals**

Signal	I/O <sup>(1)</sup>	Description	Reset
<b>CIR Signals</b>			
uart3_rxd	I	Serial data input	HiZ
uart3_rctx	O	Serial data output in CIR mode. In other modes, this pin is set to the reset value (inactive state).	0
uart3_sd	O	SD mode is used to configure the transceivers. The SD pinout is an inverted value of the UART3.UART_ACREG[6] SD_MOD bit.	1

<sup>(1)</sup> I = Input; O = Output

### 24.3.2.3.3 CIR Protocol and Data Format

In CIR mode, the infrared operation functions as a programmable (universal) remote control.

CIR mode uses a variable PWM technique (based on multiples of a programmable  $t$  period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on user-defined frame structure and packet content.

#### 24.3.2.3.3.1 Carrier Modulation

Each modulated pulse that constitutes a digit is a train of on/off pulses (see Figure 24-50).

Figure 24-50. CIR Pulse Modulation

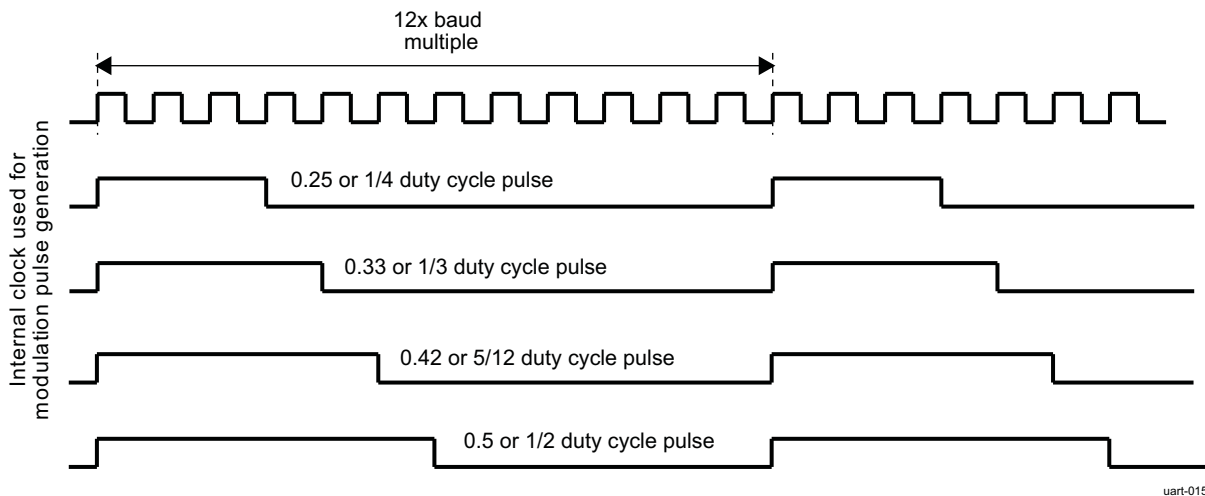

24.3.2.3.3.2 Pulse Duty Cycle

The programmer can choose one of four duty cycles for modulation pulses by setting the appropriate value in the UART3.UART\_MDR2[5:4] CIR\_PULSE\_MODE bit field (1/4, 1/3, 5/12, or 1/2).

Figure 24-51 shows the CIR modulation duty cycles.

Figure 24-51. CIR Modulation Duty Cycle

The transmission logic ensures that all pulses are transmitted completely (no cutoff during transmission). While transmitting continuous bytes back-to-back, no delay is inserted between 2 transmitted bytes. Thus, software must handle the delay between consecutively transmitted bytes if the receiving end requires it.

### 24.3.2.3.3.3 Consumer IR Encoding/Decoding

There are two methods of encoding for remote-control applications:

- Pulse duration encoding (time-extended bit forms): A variable pulse distance, or duration, in which the difference between logic 1 and logic 0 is the length of the pulse width
- Biphase encoding: The encoding of logic 0 and logic 1 is in the change of signal level from 1 to 0 or 0 to 1, respectively.

Japanese manufacturers favor pulse duration encoding; European manufacturers favor biphase encoding.

CIR mode uses a completely flexible free-format encoding in which 1 is transmitted from the TX FIFO as a modulated pulse with duration  $t$ .

Similarly, 0 is transmitted as a blank duration  $T$ . The MPU constructs and deciphers the protocol of the data. For example, the RC-5 protocol using Manchester encoding can be emulated as using a 01 pair for 1 and a 10 pair for 0 (see [Figure 24-52](#)).

**Figure 24-52. RC-5 Bit Encoding**

Because CIR mode logic does not impose a fixed format for infrared packets of data, the MPU software can define the format using simple data structures that are then modulated into an industry standard, such as RC-5 or SIRC. To send a sequence of 0101 in RC-5, the MPU software must write an 8-bit binary character of 10011001 to the data FIFO of the UART.

For SIRC, the modulation length (multiples of  $t$ ) is used to distinguish between 1 and 0. The subsequent SIRC digits show the difference in encoding between this and, for example, RC-5. The pulse width is extended for one digit.

[Figure 24-53](#) shows SIRC bit encoding.

**Figure 24-53. SIRC Bit Encoding**

To construct comprehensive packets constituting remote-control commands, the MPU software must combine a number of 8-bit data characters in a sequence that follows one of the universally accepted formats.

Figure 24-54 shows a standard RC-5 frame as detected by UART3 in CIR mode (the SIRC format follows this). Each field in RC-5 can be considered as two  $t$  pulses (digital bits) from the TX FIFO.

**Figure 24-54. RC-5 Standard Packet Format**

uart-018

Where:

- S1, S2: Start-bits (always 1)
- T: Toggle bit
- A4..A0: Address (or system) bits
- C5..C0: Command bits

The toggle bit T changes when a new command is transmitted to detect when the same key is pressed twice (effectively receiving the same data from the host consecutively). A brief delay in the transmission of the same command is detected by the use of the toggle bit because a code is sent while the MPU transmits characters to the UART for transmission. The address bits define the machine or device for which the infrared transmission is intended, and the command defines the operation.

To accommodate an extended RC-5 format, the S2 bit is replaced by an additional command bit (C6) that lets the command range increase to 7 bits. This format is known as the extended RC-5 format.

SIRC encoding uses the duration of modulation for mark and space; therefore, the duration of data bits in the standard frame length varies.

Figure 24-55 shows the packet format and bit encoding. As Figure 24-56 shows, 1 start-bit of 2.4 ms and control codes are followed by data that constitute the entire frame.

**Figure 24-55. SIRC Packet Format**

uart-019

**NOTE:** The encoding must take a standard duration, but the contents of the data can vary. This implies that the control software for sending and receiving data packets must exercise a scheme of interpacket delay, where successive packets can be sent only after a real-time delay expires.

**Figure 24-56. SIRC Bit Transmission Example**

uart-020

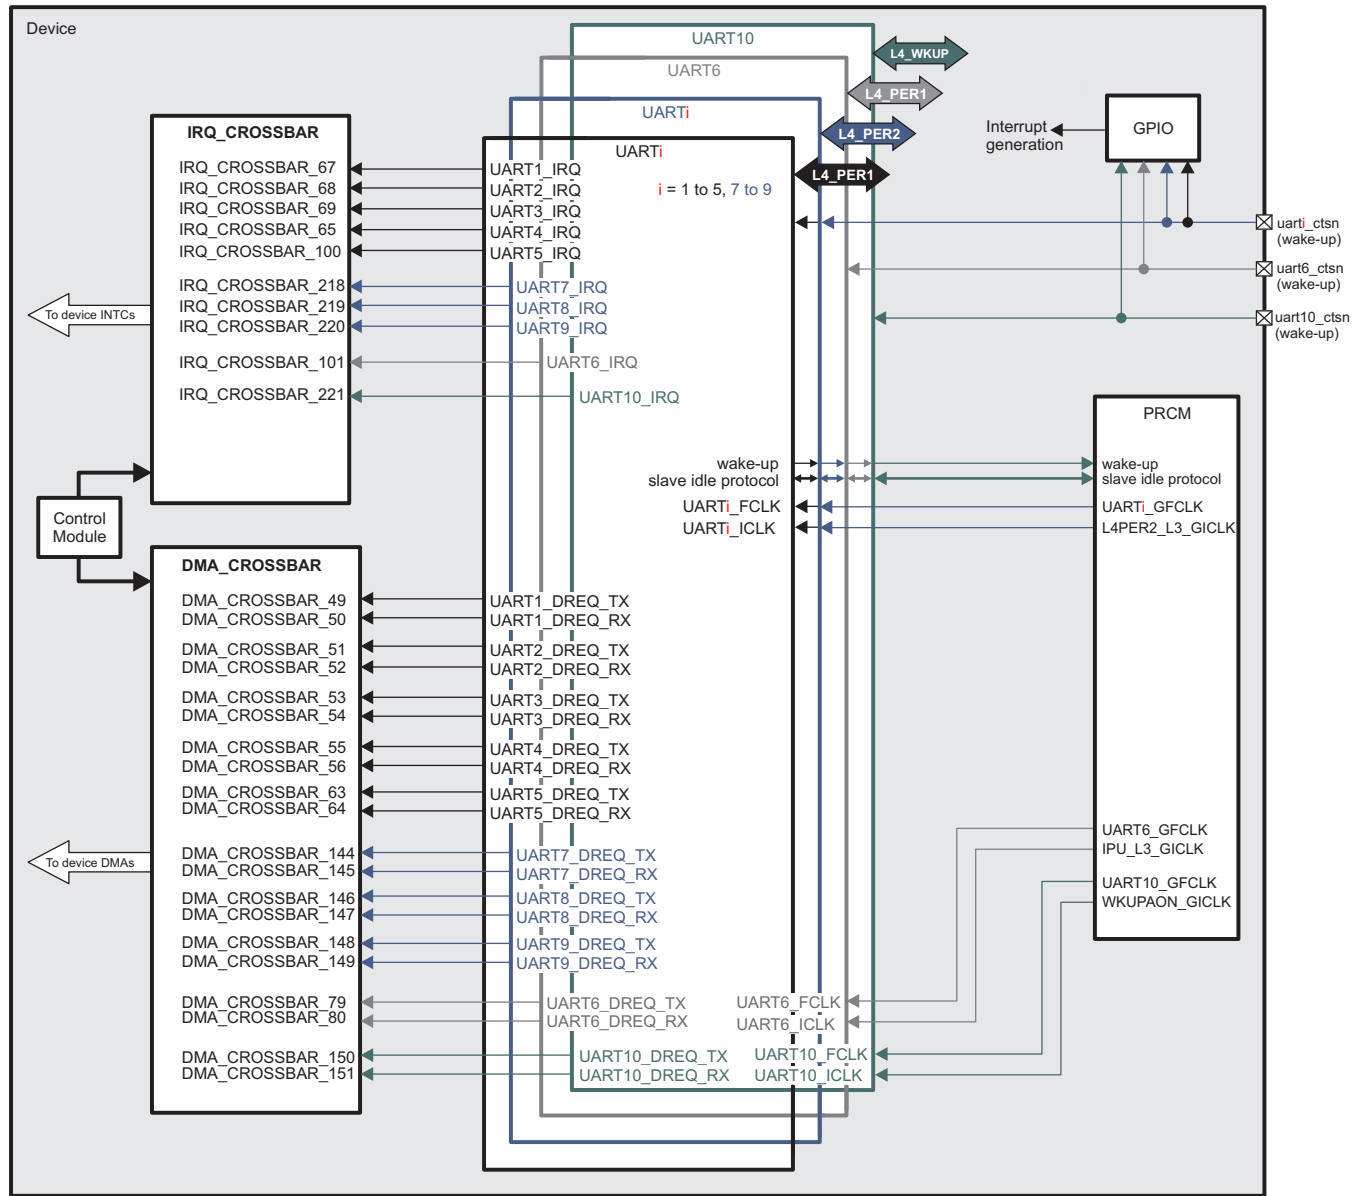

This document does not describe all encoding methods and techniques; the previous information discusses the considerations required to employ different encoding methods for different industry-standard protocols. See industry-standard documentation for specific methods of encoding and protocol use.

### 24.3.3 UART/IrDA/CIR Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 24-57 shows the device internal connections with related modules for UART functions.

Figure 24-57. UART/IrDA/CIR Integration

uart-021

**NOTE:** For more information about the master standby and slave idle protocols and the wake-up request, see [Section 3.1.1.1.4, Clock Domain-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#)

Table 24-131 through Table 24-133 summarize the integration of the module in the device.

**Table 24-131. UART Integration Attributes**

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
UART1	PD_COREAON	Yes	L4_PER1
UART2	PD_COREAON	Yes	L4_PER1
UART3	PD_COREAON	Yes	L4_PER1
UART4	PD_COREAON	Yes	L4_PER1
UART5	PD_COREAON	Yes	L4_PER1
UART6	PD_COREAON	Yes	L4_PER1
UART7	PD_COREAON	Yes	L4_PER2
UART8	PD_COREAON	Yes	L4_PER2
UART9	PD_COREAON	Yes	L4_PER2
UART10	PD_WKUPAON	Yes	L4_WKUP

**Table 24-132. UART Clocks and Resets**

Clocks				
Module Instance	Destination Signal	Source Signal	Source	Description
UART1	UART1_ICLK	L4PER_L3_GICLK	PRCM	UART1 interface clock
	UART1_FCLK	UART1_GFCLK	PRCM	UART1 functional clock
UART2	UART2_ICLK	L4PER_L3_GICLK	PRCM	UART2 interface clock
	UART2_FCLK	UART2_GFCLK	PRCM	UART2 functional clock
UART3	UART3_ICLK	L4PER_L3_GICLK	PRCM	UART3 interface clock
	UART3_FCLK	UART3_GFCLK	PRCM	UART3 functional clock
UART4	UART4_ICLK	L4PER_L3_GICLK	PRCM	UART4 interface clock
	UART4_FCLK	UART4_GFCLK	PRCM	UART4 functional clock

UART5	UART5_DREQ_TX	DMA_CROSSBAR_63	DMA_SYSTEM_DREQ_62 DMA_EDMA_DREQ_62	UART 5 – transmit request
	UART5_DREQ_RX	DMA_CROSSBAR_64	DMA_SYSTEM_DREQ_63 DMA_EDMA_DREQ_63	UART 5 – receive request
UART6	UART6_DREQ_TX	DMA_CROSSBAR_79	DMA_SYSTEM_DREQ_78	UART 6 – transmit request
	UART6_DREQ_RX	DMA_CROSSBAR_80	DMA_SYSTEM_DREQ_79	UART 6 – receive request
UART7	UART7_DREQ_TX	DMA_CROSSBAR_144	-	UART 7 – transmit request.
	UART7_DREQ_RX	DMA_CROSSBAR_145	-	UART 7 – receive request
UART8	UART8_DREQ_TX	DMA_CROSSBAR_146	-	UART 8 – transmit request
	UART8_DREQ_RX	DMA_CROSSBAR_147	-	UART 8 – receive request
UART9	UART9_DREQ_TX	DMA_CROSSBAR_148	-	UART 9 – transmit request
	UART9_DREQ_RX	DMA_CROSSBAR_149	-	UART 9 – receive request
UART10	UART10_DREQ_TX	DMA_CROSSBAR_150	-	UART 10 – transmit request
	UART10_DREQ_RX	DMA_CROSSBAR_151	-	UART 10 – receive request

**NOTE:** The **Default Mapping** column in [Table 24-133, UART Hardware Requests](#), shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ\_CROSSBAR and DMA\_CROSSBAR modules, respectively.

For more information about the IRQ\_CROSSBAR module, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#).

For more information about the DMA\_CROSSBAR module, see [Section 18.4.6.5, DMA\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#).

For more information about the device interrupt controllers, see [Chapter 17, Interrupt Controllers](#).

For more information about the device DMA\_SYSTEM module, see [Section 16.1, System DMA](#).

For more information about the device EDMA module, see [Section 16.2, Enhanced DMA](#).

---

## 24.3.4 UART/IrDA/CIR Functional Description

### 24.3.4.1 Block Diagram

The UART/IrDA/CIR module can be divided into three main blocks:

- FIFO management
- Mode selection
- Protocol formatting

FIFO management is common to all functions and enables the transmission and reception of data from the host processor point of view.

There are two modes:

- Function mode: Routes the data to the chosen function (UART, IrDA, or CIR) and enables the mechanism corresponding to the chosen function
- Register mode: Enables conditional access to registers

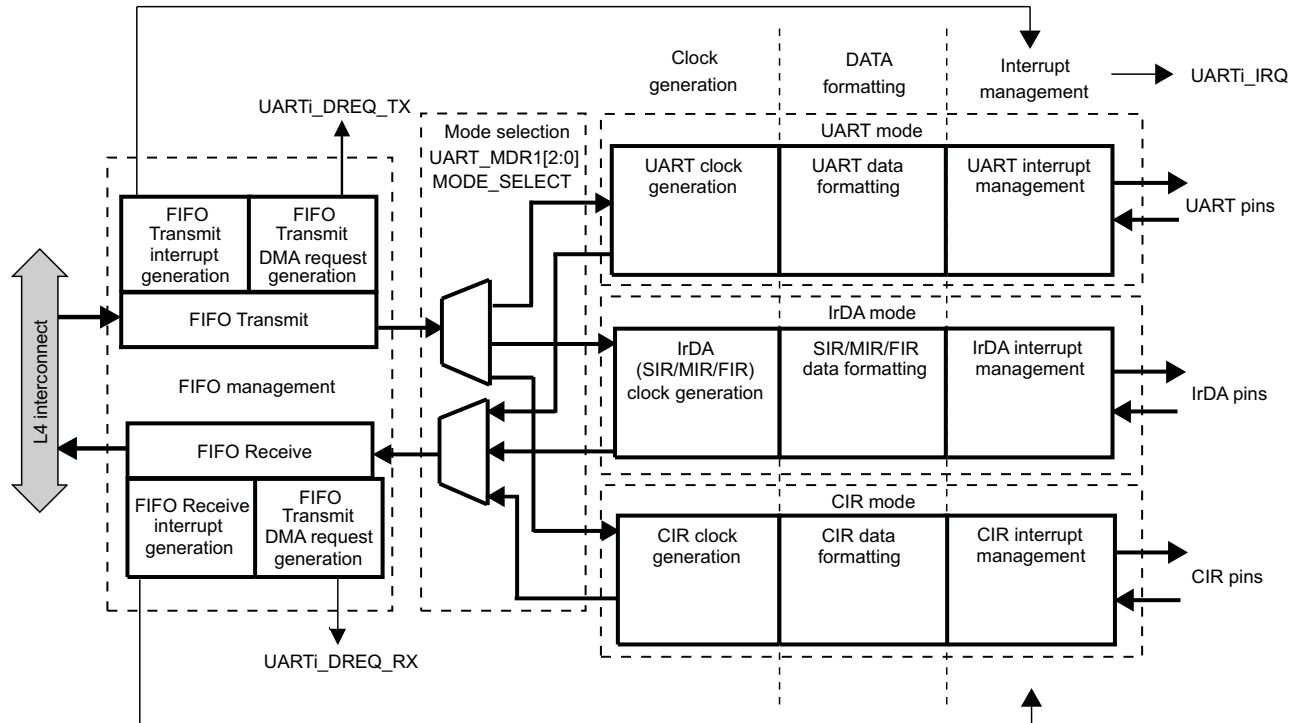

For more information about mode configuration, see [Section 24.3.4.7, Mode Selection](#).

Protocol formatting has three subcategories:

- Clock generation: The 48-MHz input clock generates all necessary clocks.
- Data formatting: Each function uses its own state-machine that is responsible for the transition between FIFO data and frame data associated with it.
- Interrupt management: Different interrupt types are generated depending on the chosen function. In each mode, when an interrupt is generated, the [UART\\_IIR](#) register indicates the interrupt type.
  - UART mode interrupts: Seven interrupts prioritized in six different levels
  - IrDA mode interrupts: Eight interrupts. The interrupt line is activated when any interrupt is generated (there is no priority).
  - CIR mode interrupts: A subset of existing IrDA mode interrupts is used.

In parallel with these functional blocks, a power-saving strategy exists for each function.

[Figure 24-58](#) is the UART/IrDA/CIR block diagram.

**Figure 24-58. UART/IrDA/CIR Functional Block Diagram**

uart-022

#### 24.3.4.2 Clock Configuration

Each UART uses a 48-MHz functional clock for its logic and to generate external interface signals. Each UART uses an interface clock for register accesses. The PRCM module generates and controls all these clocks (for more information, see [Section 3.1.1.1.4, Clock Domain-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#)).

The idle and wake-up processes use a handshake protocol between the PRCM and the UART (for a description of the protocol, see [Section 3.1.1.1.4, Clock Domain Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#)). The UARTi.UART\_SYSC[4:3] IDLEMODE bit field controls UART idle mode.

#### 24.3.4.3 Software Reset

The UARTi.UART\_SYSC[1] SOFTRESET bit controls the software reset; setting this bit to 1 triggers a software reset functionally equivalent to hardware reset.

#### 24.3.4.4 Power Management

##### 24.3.4.4.1 UART Mode Power Management

###### 24.3.4.4.1.1 Module Power Saving

In UART modes, sleep mode is enabled by setting the UARTi.UART\_IER[4] SLEEP\_MODE bit to 1 (when the UARTi.UART\_EFR[4] ENHANCED\_EN bit is set to 1).

Sleep mode is entered when all of the following conditions exist:

- The serial data input line, uarti\_rxd, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- The only pending interrupts are THR interrupts.

Sleep mode is a good way to lower UART power consumption, but this state can be achieved only when the UART is set to modem mode. Therefore, even if the UART has no key role functionally, it must be initialized in a functional mode to take advantage of sleep mode.

In sleep mode, the module clock and baud rate clock are stopped internally. Because most registers are clocked by these clocks, this greatly reduces power consumption. The module wakes up when a change is detected on the `uarti_rxd` line, when data is written to the TX FIFO, and when there is a change in the state of the modem input pins.

An interrupt can be generated on a wake-up event by setting the `UARTi.UART_SCR[4] RX_CTS_WU_EN` bit to 1. To understand how to manage the interrupt, see [Section 24.3.4.5.1.2, Wake-Up Interrupt](#).

---

**NOTE:** There must be no writing to the divisor latches, `UARTi.UART_DLL` and `UARTi.UART_DLH`, to set the baud clock (BCLK) while in sleep mode. It is advisable to disable sleep mode using the `UARTi.UART_IER[4] SLEEP_MODE` bit before writing to the `UARTi.UART_DLL` or `UARTi.UART_DLH` register.

---

#### **24.3.4.4.1.2 System Power Saving**

Sleep and auto-idle modes are embedded power-saving features. Power-reduction techniques can be applied at the system level by shutting down certain internal clock and power domains of the device.

The UART supports an idle req/idle ack handshaking protocol used at the system level to shut down the UART clocks in a clean and controlled manner and to switch the UART from interrupt-generation mode to wake-up generation mode for unmasked events (see the `UARTi.UART_SYSC[2] ENAWAKEUP` bit and the `UARTi.UART_WER` register).

For more information, see [Section 3.1.1.1.2, Module Level Clock Management, Chapter 3, Power, Reset, and Clock Management](#).

#### **24.3.4.4.2 IrDA Mode Power Management (UART3 Only)**

##### **24.3.4.4.2.1 Module Power Saving**

In IrDA modes, sleep mode is enabled by setting the `UART3.UART_MDR1[3] IR_SLEEP` bit to 1.

Sleep mode is entered when all of the following conditions exist:

- The serial data input line, RXD, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

The module wakes up when a change is detected on the RXD line or when data is written to the TX FIFO.

##### **24.3.4.4.2.2 System Power Saving**

System power saving for the IrDA mode has the same function as for the UART mode (see [Section 24.3.4.4.1.2, System Power Saving](#)).

#### **24.3.4.4.3 CIR Mode Power Management (UART3 Only)**

##### **24.3.4.4.3.1 Module Power Saving**

Module power saving for the CIR mode has the same function as for the IrDA mode (see [Section 24.3.4.4.2.1, Module Power Saving](#)).

##### **24.3.4.4.3.2 System Power Saving**

System power saving for the CIR mode has the same function as for the UART mode (see [Section 24.3.4.4.1.2, System Power Saving](#)).

#### 24.3.4.4.4 Local Power Management

Table 24-134 describes power-management features available for the UART.

**NOTE:** For information about source clock gating and the sleep/wake-up transitions description, see [Section 3.1.1.1.2, Module Level Clock Management, Chapter 3, Power, Reset, and Clock Management](#).

**Table 24-134. Local Power-Management Features**

Feature	Registers	Description
Clock autogating	<a href="#">UART_SYSC</a> [0] AUTOIDLE	This bit allows local power optimization in the module by gating the UARTi_ICLK clock on interface activity or gating the UARTi_FCLK clock on internal activity.
Slave idle modes	<a href="#">UART_SYSC</a> [4:3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available.
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	<a href="#">UART_SYSC</a> [2] ENAWAKEUP	This bit enables the wake-up feature at module level.
Wake-Up sources enable	N/A	Feature not available

#### 24.3.4.5 Interrupt Requests

##### 24.3.4.5.1 UART Mode Interrupt Management

###### 24.3.4.5.1.1 UART Interrupts

UART mode includes seven possible interrupts prioritized to six levels.

When an interrupt is generated, the interrupt identification register (UARTi.UART\_IIR) sets the UARTi.UART\_IIR[0] IT\_PENDING bit to 0 to indicate that an interrupt is pending, and indicates the type of interrupt through the UARTi.UART\_IIR[5:1] bit field. [Table 24-135](#) summarizes the interrupt control functions.

**Table 24-135. UART Mode Interrupts**

IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000001	N/A	No Interrupt	N/A	N/A
000110	1	Receiver line status	OE, FE, PE, or BI errors occur in characters in the RX FIFO.	FE, PE, BI: Read the <a href="#">UART_RHR</a> register. OE: Read the <a href="#">UART_LSR</a> register.
001100	2	RX time-out	Stale data in RX FIFO	Read the <a href="#">UART_RHR</a> register.
000100	2	RHR interrupt	DRDY (data ready) (FIFO disabled) RX FIFO above trigger level (FIFO enabled)	Read the <a href="#">UART_RHR</a> register until the interrupt condition disappears
000010	3	THR interrupt	TFE (THR empty) (FIFO disabled) TX FIFO below trigger level (FIFO enabled)	Write to the <a href="#">UART_THR</a> until the interrupt condition disappears
000000	4	Modem status	See the <a href="#">UART_MSR</a> register.	Read the MSR register
010000	5	XOFF interrupt/special character interrupt	Receive XOFF characters/special character	Receive XON character(s), if XOFF interrupt/read of the <a href="#">UART_IIR</a> register, if special character interrupt
100000	6	CTS, RTS	RTS pin or CTS pin change state from active (low) to inactive (high)	Read the <a href="#">UART_IIR</a> register

For the receiver-line status interrupt, the RX\_FIFO\_STS bit (UARTi.UART\_LSR[7]) generates the interrupt.

For the XOFF interrupt, if an XOFF flow character detection caused the interrupt, the interrupt is cleared by an XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the UARTi.UART\_IIR register.

#### 24.3.4.5.1.2 Wake-Up Interrupt

Wake-up interrupt is a special interrupt that works differently from other interrupts. This interrupt is enabled when the UARTi.UART\_SCR[4] RX\_CTS\_WU\_EN bit is set to 1. The UARTi.UART\_IIR register is not modified when this occurs; the UART3.UART\_SSR[1] RX\_CTS\_WU\_STS bit must be checked to detect a wake-up event.

When a wake-up interrupt occurs, it can be cleared only by resetting the UARTi.UART\_SCR[4] RX\_CTS\_WU\_EN bit. This bit must be reenabled (set to 1) after the current wake-up interrupt event is processed to detect the next incoming wake-up event.

#### 24.3.4.5.2 IrDA Mode Interrupt Management

##### 24.3.4.5.2.1 IrDA Interrupts

The IrDA function generates interrupts. All interrupts can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UART3.UART\_IER\_IRDA). The interrupt status of the device can be checked by reading the interrupt identification register (UART3.UART\_IIR\_IRDA).

UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UART3.UART\_IER\_IRDA and UART3.UART\_IIR\_IRDA mappings, depending on the selected mode.

IrDA modes have eight possible interrupts (see Table 24-136). The interrupt line is activated when any interrupt is generated (there is no priority).

**Table 24-136. IrDA Mode Interrupts**

IIR_IRDA Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	RHR interrupt	DRDY (data ready) (FIFO disabled) RX FIFO above trigger level (FIFO enabled)	Read the <a href="#">UART_RHR</a> register until the interrupt condition disappears.
1	THR interrupt	TFE (THR empty) (FIFO disabled) TX FIFO below trigger level (FIFO enabled)	Write to the <a href="#">UART_THR</a> until the interrupt condition disappears.
2	Last byte in RX FIFO	Last byte of frame in RX FIFO is available to be read at the RHR port.	Read the <a href="#">UART_RHR</a> register.
3	RX overrun	Write to the <a href="#">UART_RHR</a> register when the RX FIFO is full.	Read <a href="#">UART_RESUME</a> register.
4	Status FIFO interrupt	Status FIFO triggers level reached.	Read STATUS FIFO.
5	TX status	THR empty before EOF sent. Last bit of transmission of the IrDA frame occurred, but with an underrun error OR Transmission of the last bit of the IrDA frame completed successfully.	Read the <a href="#">UART_RESUME</a> register OR Read the <a href="#">UART_IIR_IRDA</a> register.
6	Receiver line status interrupt	CRC, ABORT, or frame-length error is written into the STATUS FIFO.	Read the STATUS FIFO (read until empty - maximum of eight reads required).
7	Received EOF	Received end-of-frame	Read the <a href="#">UART_IIR_IRDA</a> register.

### 24.3.4.5.2.2 Wake-Up Interrupts

The wake-up interrupt for IrDA mode has the same function as that for UART mode (see [Section 24.3.4.5.1.2, Wake-Up Interrupt](#)).

#### CAUTION

Wake-up interface implementation in this mode is based on the UARTi\_SIDLEACK low-to-high transition instead of the UARTi\_SIDLEACK state.

This does not ensure wake-up event generation as expected when configured in smart-idle mode, and the system wakes up for a short period.

### 24.3.4.5.3 CIR Mode Interrupt Management

#### 24.3.4.5.3.1 CIR Interrupts

The CIR function generates interrupts that can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UART3.UART\_IER\_CIR). The interrupt status of the device can be checked by reading the interrupt identification register (UART3.UART\_IIR\_CIR).

UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UART3.UART\_IER\_CIR and UART3.UART\_IIR\_CIR mappings, depending on the selected mode.

[Table 24-137](#) lists the interrupt modes to be maintained. In CIR mode, the sole purpose of the UART3.UART\_IIR\_CIR[5] bit is to indicate that the last bit of infrared data was passed to the uart3\_rctx pin.

**Table 24-137. CIR Mode Interrupts**

IIR_CIR Bit Number	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
1	THR interrupt	TFE (THR empty) (FIFO disabled) TX FIFO below trigger level (FIFO enabled)	Write to the THR register until the interrupt condition disappears
2	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
3	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
4	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
5	TX status	Transmission of the last bit of the frame is complete successfully	Read the IIR_CIR register
6	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
7	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode

#### 24.3.4.5.3.2 Wake-Up Interrupts

The wake-up interrupt for CIR mode has the same function as that for UART mode (see [Section 24.3.4.5.1.2, Wake-Up Interrupt](#)).

### 24.3.4.6 FIFO Management

The FIFO is accessed by reading and writing the UARTi.UART\_RHR and UARTi.UART\_THR registers. Parameters are controlled using the FIFO control register (UARTi.UART\_FCR) and supplementary control register (UARTi.UART\_SCR). Reading the UARTi.UART\_SSR[0] TX\_FIFO\_FULL bit at 1 means the FIFO is full.

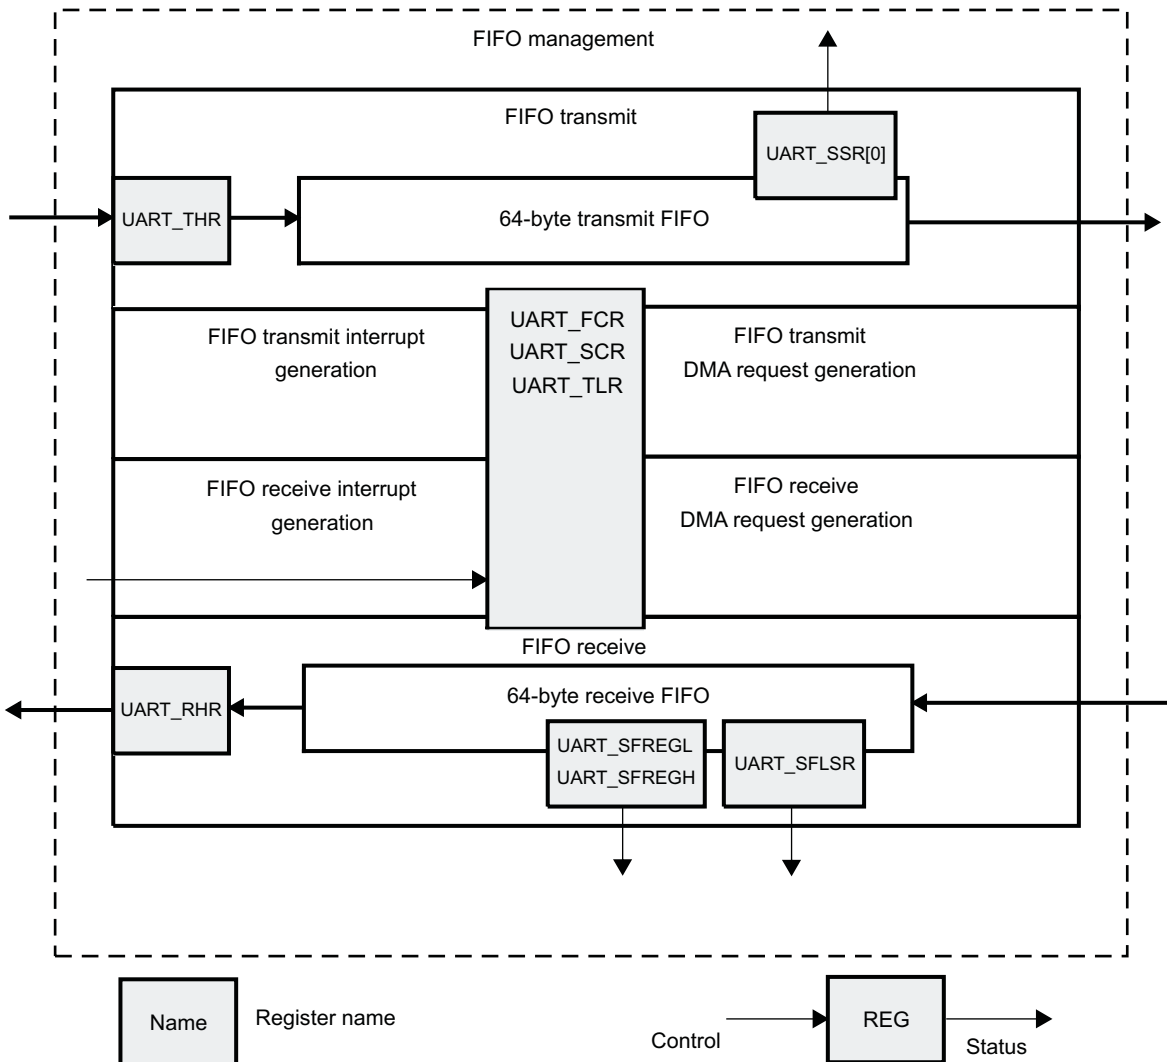

The UARTi.UART\_TLR register controls the FIFO trigger level, which enables DMA and interrupt generation. After reset, transmit (TX) and receive (RX) FIFOs are disabled; thus, the trigger level is the default value of 1 byte. Figure 24-59 shows the FIFO management registers.

**NOTE:** Data in the UARTi.UART\_RHR register is not overwritten when an overflow occurs.

**NOTE:** The UARTi.UART\_SFLSR, UARTi.UART\_SFREGL, and UARTi.UART\_SFREGH status registers are used in IrDA mode only. For information about their use, see Section 24.3.4.8.2.3, IrDA Data Formatting.

**NOTE:** Bits UARTi.UART\_FCR[2] TX\_FIFO\_CLEAR and UARTi.UART\_FCR[1] RX\_FIFO\_CLEAR are automatically cleared by hardware after  $4 * \text{UARTi\_ICLK} + 5 * \text{UARTi\_FCLK}$  clock cycles. This delay is needed to finish the resetting of the corresponding FIFO and DMA control registers.

**Figure 24-59. FIFO Management Registers**

uart-023

### 24.3.4.6.1 FIFO Trigger

#### 24.3.4.6.1.1 Transmit FIFO Trigger

Table 24-138 lists the TX FIFO trigger level settings.

**Table 24-138. TX FIFO Trigger Level Setting Summary**

SCR[6]	TLR[3:0]	TX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit field (8,16, 32, or 56 spaces)
0	!= 0x0	Defined by the UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit field (from 4 to 60 spaces with a granularity of 4 spaces)
1	Value	Defined by the concatenated value of TX_FIFO_TRIG_DMA and TX_FIFO_TRIG (from 1 to 63 spaces with a granularity of 1 space)  <b>Note:</b> The combination of TX_FIFO_TRIG_DMA = 0x0 and TX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of 1 space required). All zeros result in unpredictable behavior.

#### 24.3.4.6.1.2 Receive FIFO Trigger

Table 24-139 lists the RX FIFO trigger-level settings.

**Table 24-139. RX FIFO Trigger-Level Setting Summary**

SCR[7]	TLR[7:4]	RX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.UART_FCR[7:6] RX_FIFO_TRIG bit field (8,16, 56, or 60 characters)
0	!= 0x0	Defined by the UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA bit field (from 4 to 60 characters with a granularity of 4 characters)
1	Value	Defined by the concatenated value of RX_FIFO_TRIG_DMA and RX_FIFO_TRIG (from 1 to 63 characters with a granularity of 1 character)  <b>Note:</b> The combination of RX_FIFO_TRIG_DMA = 0x0 and RX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of 1 character required). All zeros result in unpredictable behavior.

The receive threshold is programmed using the UARTi.UART\_TCR[7:4] RX\_FIFO\_TRIG\_START and UARTi.UART\_TCR[3:0] RX\_FIFO\_TRIG\_HALT bit fields:

- Trigger levels from 0 to 60 bytes are available with a granularity of 4 (trigger level = 4 × [4-bit register value]).
- To ensure correct device operation, ensure that RX\_FIFO\_TRIG\_HALT > RX\_FIFO\_TRIG when auto-RTS is enabled.

$$\text{Delay} = [4 + 16 \times (1 + \text{CHAR\_LENGTH} + \text{Parity} + \text{Stop} - 0.5)] \times \text{Baud\_rate} + 4 \times \text{FCLK}$$

**NOTE:** The RTS signal is deasserted after the UART module receives the data over RX\_FIFO\_TRIG\_HALT. Delay means how long the UART module takes to deassert the RTS signal after reaching RX\_FIFO\_TRIG\_HALT.

- In FIFO interrupt mode with flow control, ensure that the trigger level to HALT transmission is greater than or equal to the RX FIFO trigger level (the UARTi.UART\_TCR[7:4] RX\_FIFO\_TRIG\_START bit field or the UARTi.UART\_FCR[7:6] RX\_FIFO\_TRIG bit field); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist, because a DMA request is sent when a byte is received.

### 24.3.4.6.2 FIFO Interrupt Mode

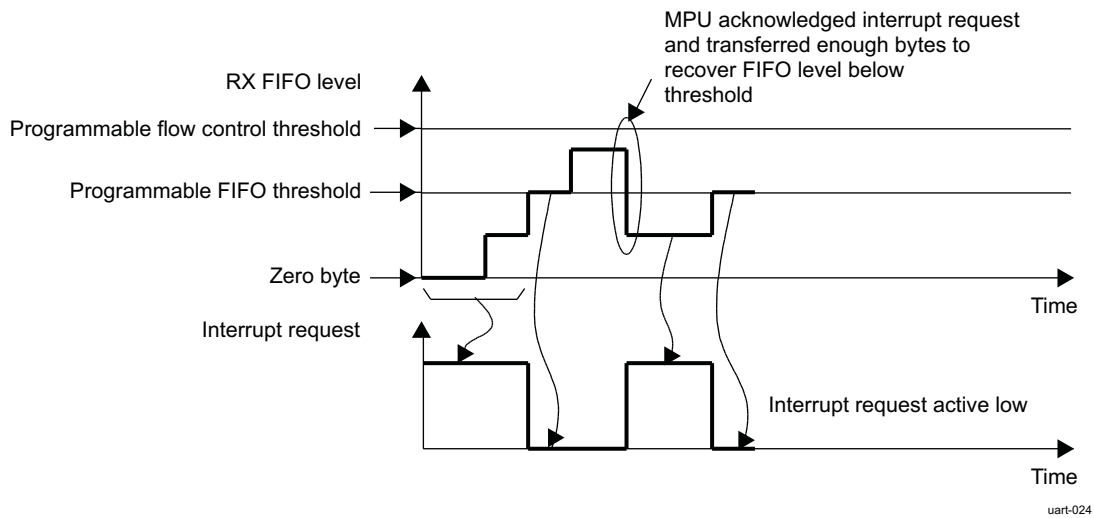

In FIFO interrupt mode (the FIFO control register UARTi.UART\_FCR[0] FIFO\_EN bit is set to 1 and relevant interrupts are enabled by the UARTi.UART\_IER register), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the RX/TX FIFO threshold (the UARTi.UART\_TLR[7:4] RX\_FIFO\_TRIG\_DMA and UARTi.UART\_TLR[3:0] TX\_FIFO\_TRIG\_DMA bit fields or the UARTi.UART\_FCR[7:6] RX\_FIFO\_TRIG and UARTi.UART\_FCR[5:4] TX\_FIFO\_TRIG bit fields, respectively) is reached.

The interrupt signals instruct the MPU to transfer data to the destination (from the UART in receive mode and/or from any source to the UART FIFO in transmit mode).

When UART flow control is enabled with interrupt capabilities, the UART flow control FIFO threshold (the UARTi.UART\_TCR[3:0] RX\_FIFO\_TRIG\_HALT bit field) must be greater than or equal to the RX FIFO threshold.

Figure 24-60 shows the generation of the RX FIFO interrupt request.

**Figure 24-60. RX FIFO Interrupt Request Generation**

In receive mode, no interrupt is generated until the RX FIFO reaches its threshold. Once low, the interrupt can be deasserted only when the MPU has handled enough bytes to put the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

Figure 24-61 shows the generation of the TX FIFO interrupt request.

**Figure 24-61. TX FIFO Interrupt Request Generation**

In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is deasserted when the TX FIFO crosses the threshold level. The interrupt line is deasserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

#### 24.3.4.6.3 FIFO Polled Mode Operation

In FIFO polled mode (the `UARTi.UART_FCR[0]` `FIFO_EN` bit is set to 0 and the relevant interrupts are disabled by the `UARTi.UART_IER` register), the status of the receiver and transmitter can be checked by polling the line status register (`UARTi.UART_LSR`).
