<sup>(2)</sup> j = 0 to 8 for GPMC

### 15.4.7.2 GPMC Register Descriptions

**NOTE:** All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except to [GPMC\\_NAND\\_DATA\\_i](#) register, are little-endian. If the [GPMC\\_NAND\\_DATA\\_i](#) register location is accessed, the endianness is access-dependent.

In this section *i* corresponds to the chip-select number, where *i* = 0 to 7.

**Table 15-502. GPMC\_REVISION**

<b>Address Offset</b>	0x0000 0000	<b>Instance</b>	GPMC
<b>Physical Address</b>	<a href="#">0x5000 0000</a>		
<b>Description</b>	This register contains the IP revision code.		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REVISION																															

Bits	Field Name	Description	Type	Reset
31:0	REVISION	IP revision	R	T1 internal data

**Table 15-504. GPMC\_SYSCONFIG**

<b>Address Offset</b>	0x0000 0010	<b>Instance</b>	GPMC
<b>Physical Address</b>	<a href="#">0x5000 0010</a>		
<b>Description</b>	This register controls the various parameters of the interconnect.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												IDLEMODE	RESERVED	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x00000000
4:3	IDLEMODE	0x0: Force-idle. An idle request is acknowledged unconditionally. 0x1: No-idle. An idle request is never acknowledged. 0x2: Smart-idle. Acknowledgment to an idle request is given based on the internal activity of the module. 0x3: Do not use.	RW	0x0
2	RESERVED	Write 0 for future compatibility Read returns 0.	RW	0x0
1	SOFTRESET	Software reset. Set this bit to 1 triggers a module reset. This bit is automatically reset by hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset.	RW	0x0

Bits	Field Name	Description	Type	Reset
0	AUTOIDLE	Internal interface clock-gating strategy 0x0: Interface clock is free-running. 0x1: Automatic Interface clock gating strategy is applied, based on the interconnect activity.	RW	0x0

**Table 15-508. GPMC\_IRQSTATUS**

<b>Address Offset</b>	0x0000 0018	<b>Instance</b>	GPMC
<b>Physical Address</b>	0x5000 0018		
<b>Description</b>	This interrupt status register regroups all the status of the module internal events that can generate an interrupt.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																WAIT1EDGEDETECTIONSTATUS		WAIT0EDGEDETECTIONSTATUS		RESERVED						TERMINALCOUNTSTATUS		FIFOEVENTSTATUS			

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000000
9	WAIT1EDGEDETECTIONSTATUS	Status of the Wait1 Edge Detection interrupt Read 0x0: A transition on WAIT1 input pin has not been detected. Write 0x0: WAIT1EDGEDETECTIONSTATUS bit is unchanged. Read 0x1: A transition on WAIT1 input pin has been detected. Write 0x1: WAIT1EDGEDETECTIONSTATUS bit is reset.	RW	0x0
8	WAIT0EDGEDETECTIONSTATUS	Status of the Wait0 Edge Detection interrupt Read 0x0: A transition on WAIT0 input pin has not been detected. Write 0x0: WAIT0EDGEDETECTIONSTATUS bit is unchanged. Read 0x1: A transition on WAIT0 input pin has been detected. Write 0x1: WAIT0EDGEDETECTIONSTATUS bit is reset.	RW	0x0
7:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00
1	TERMINALCOUNTSTATUS	Status of the TerminalCountEvent interrupt Read 0x0: Indicates that CountValue is greater than 0 Write 0x0: TERMINALCOUNTSTATUS bit is unchanged. Read 0x1: Indicates that CountValue is equal to 0 Write 0x1: TERMINALCOUNTSTATUS bit is reset.	RW	0x0
0	FIFOEVENTSTATUS	Status of the FIFOEvent interrupt Read 0x0: Indicates that less than <a href="#">GPMC_PREFETCH_STATUS[16]</a> FIFOTHRESHOLDSTATUS bytes are available in prefetch mode and less than FIFOTHRESHOLD bytes free places are available in write-posting mode Write 0x0: FIFOEVENTSTATUS bit is unchanged. Read 0x1: Indicates that at least <a href="#">GPMC_PREFETCH_STATUS[16]</a> FIFOTHRESHOLDSTATUS bytes are available in prefetch mode and at least FIFOTHRESHOLD bytes free places are available in write-posting mode Write 0x1: FIFOEVENTSTATUS bit is reset.	RW	0x0

Bits	Field Name	Description	Type	Reset
31	WRAPBURST	Enables the wrapping burst capability. Must be set if the attached device is configured in wrapping burst 0x0: Synchronous wrapping burst not supported 0x1: Synchronous wrapping burst supported	RW	0x0
30	READMULTIPLE	Selects the read single or multiple access 0x0: Single access 0x1: Multiple access (burst if synchronous, page if asynchronous)	RW	0x0
29	READTYPE	Selects the read mode operation 0x0: Read asynchronous 0x1: Read synchronous	RW	0x0
28	WRITEMULTIPLE	Selects the write single or multiple access 0x0: Single access 0x1: Multiple access (burst if synchronous, considered as single if asynchronous)	RW	0x0
27	WRITETYPE	Selects the write mode operation 0x0: Write asynchronous 0x1: Write synchronous	RW	0x0

Bits	Field Name	Description	Type	Reset
26:25	CLKACTIVATIONTIME	Output GPMC_CLK activation time 0x0: First rising edge of GPMC_CLK at start access time 0x1: First rising edge of GPMC_CLK one GPMC_FCLK cycle after start access time 0x2: First rising edge of GPMC_CLK two GPMC_FCLK cycles after start access time 0x3: Reserved	RW	0x0
24:23	ATTACHEDDEVICEPAGELENGTH	Specifies the attached device page (burst) length 0x0: 4 words 0x1: 8 words 0x2: 16 words 0x3: Reserved (1 word = interface size)	RW	0x0
22	WAITREADMONITORING	Selects the Wait monitoring configuration for Read accesses (Reset value is <i>bootwaiten</i> input pin sampled at device reset) 0x0: Wait pin is not monitored for read accesses. 0x1: Wait pin is monitored for read accesses.	RW	0x-
21	WAITWRITEMONITORING	Selects the Wait monitoring configuration for Write accesses 0x0: Wait pin is not monitored for write accesses. 0x1: Wait pin is monitored for write accesses.	RW	0x0
20	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
19:18	WAITMONITORINGTIME	Selects input pin Wait monitoring time 0x0: Wait pin is monitored with valid data. 0x1: Wait pin is monitored one GPMC_CLK cycle before valid data. 0x2: Wait pin is monitored two GPMC_CLK cycle before valid data. 0x3: Reserved	RW	0x0
17:16	WAITPINSELECT	Selects the input wait pin for this chip-select (The reset value is HW fixed to 0x0 for CS0-CS7) 0x0: Wait input pin is WAIT0. 0x1: Wait input pin is WAIT1. 0x2, 0x3: Reserved	RW	0x0
15:14	RESERVED	Write 0s for future compatibility. Reads returns 0	RW	0x0
13:12	DEVICESTYPE	Selects the device size attached (Reset value is <i>bootdevicesize</i> input pin sampled at device reset for CS0 and 0x1 for CS1 to CS7) 0x0: 8 bit 0x1: 16 bit 0x2: Reserved 0x3: Reserved	RW	0x-
11:10	DEVICETYPE	Selects the attached device type 0x0: NOR flash-like, asynchronous and synchronous devices 0x1: Reserved 0x2: NAND flash-like devices, stream mode 0x3: Reserved	RW	0x0

Bits	Field Name	Description	Type	Reset
9:8	MUXADDDATA	Enables the address and data multiplexed protocol (Reset value is <i>cs0muxdevice</i> input pin sampled at device reset for CS0 and 0 for CS1-CS7)  0x0: Nonmultiplexed attached device 0x1: AAD-multiplexed protocol device 0x2: Address and data multiplexed attached device 0x3: Reserved	RW	0x-
7:5	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
4	TIMEPARAGRANULARITY	Signals timing latencies scalar factor (RD/WRCYCLETIME, RD/WRACCESSTIME, PAGEBURSTACCESSTIME, CSONTIME, CSRD/WROFFTIME, ADVONTIME, ADVRD/WROFFTIME, OEONTIME, OEOFFTIME, WEONTIME, WEOFFTIME, CYCLE2CYCLEDELAY, BUSTURNAROUND, TIMEOUTSTARTVALUE, WRDATAONADMUXBUS)  0x0: x1 latencies 0x1: x2 latencies	RW	0x0
3:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
1:0	GPMCFCLKDIVIDER	Divides the GPMC_FCLK clock  0x0: GPMC_CLK frequency = GPMC_FCLK frequency 0x1: GPMC_CLK frequency = GPMC_FCLK frequency / 2 0x2: GPMC_CLK frequency = GPMC_FCLK frequency / 3 0x3: GPMC_CLK frequency = GPMC_FCLK frequency / 4	RW	0x0

RESERVED	CYCLOPTIMIZATION		ENABLEOPTIMIZEDACCESS	ENGINECSSELECTOR	PPFWENROUNDROBIN	RESERVED	PPFWWEIGHTEDPRIO	RESERVED	FIFOTHRESHOLD								ENABLEENGINE	RESERVED	WAITPINSELECTION	SYNCHROMODE	DMAMODE	RESERVED	ACCESSMODE								

Bits	Field Name	Description	Type	Reset
31	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
30:28	CYCLEOPTIMIZATION	Define the number of GPMC_FCLK cycles to be subtracted from RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, CSRDOFFTIME, CSWROFFTIME, ADVRDOFFTIME, ADVWROFFTIME, OEOFFTIME, WEOFFTIME 0x0: 0 GPMC_FCLK cycle 0x1: 1 GPMC_FCLK cycle ... 0x7: 7 GPMC_FCLK cycles	RW	0x0
27	ENABLEOPTIMIZEDACCESS	Enables access cycle optimization 0x0: Access cycle optimization is disabled. 0x1: Access cycle optimization is enabled.	RW	0x0
26:24	ENGINECSSELECTOR	Selects the chip-select where Prefetch Postwrite engine is active 0x0: CS0 0x1: CS1 0x2: CS2 0x3: CS3 0x4: CS4 0x5: CS5 0x6: CS6 0x7: CS7	RW	0x0
23	PFPWENROUNDROBIN	Enables the PFPW RoundRobin arbitration 0x0: Prefetch Postwrite engine round robin arbitration is disabled. 0x1: Prefetch Postwrite engine round robin arbitration is enabled.	RW	0x0
22:20	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
19:16	PFPWWEIGHTEDPRIO	When an arbitration occurs between a DMA and a PFPW engine access, the DMA is always serviced. If the PFPWEnRoundRobin is enabled, 0x0: The next access is granted to the PFPW engine. 0x1: The next two accesses are granted to the PFPW engine. ... 0xF: The next 16 accesses are granted to the PFPW engine.	RW	0x0
15	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
14:8	FIFOTHRESHOLD	Selects the maximum number of bytes read from the FIFO or written to the FIFO by the host on a DMA or interrupt request 0x00: 0 byte 0x01: 1 byte ... 0x40: 64 bytes	RW	0x40
7	ENABLEENGINE	Enables the Prefetch Postwrite engine 0x0: Prefetch Postwrite engine is disabled. 0x1: Prefetch Postwrite engine is enabled.	RW	0x0
6	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
5:4	WAITPINSELECTOR	Select which wait pin edge detector should start the engine in synchronized mode 0x0: Selects Wait0 EdgeDetection 0x1: Selects Wait1 EdgeDetection 0x2, 0x3: Reserved	RW	0x0
3	SYNCHROMODE	Selects when the engine starts the access to chip-select 0x0: Engine starts the access to chip-select as soon as STARTENGINE is set 0x1: Engine starts the access to chip-select as soon as STARTENGINE is set AND wait to nonwait edge detection on the selected wait pin	RW	0x0

Bits	Field Name	Description	Type	Reset
2	DMAMODE	Selects interrupt synchronization or DMA request synchronization  0x0: Interrupt synchronization is enabled. Only interrupt line is activated on FIFO threshold crossing.  0x1: DMA request synchronization is enabled. A DMA request protocol is used.	RW	0x0
1	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
0	ACCESSMODE	Selects prefetch read or write-posting accesses  0x0: Prefetch read mode  0x1: Write-posting mode	RW	0x0

## 15.5 Error Location Module

### 15.5.1 Error Location Module Overview

When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as *bare NANDs*, the correction process is delegated to the memory controller.

The general-purpose memory controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-Chaudhuri-Hocquenghem (BCH) algorithm. The error-location module (ELM) extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM relies on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as *uncorrectable* in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

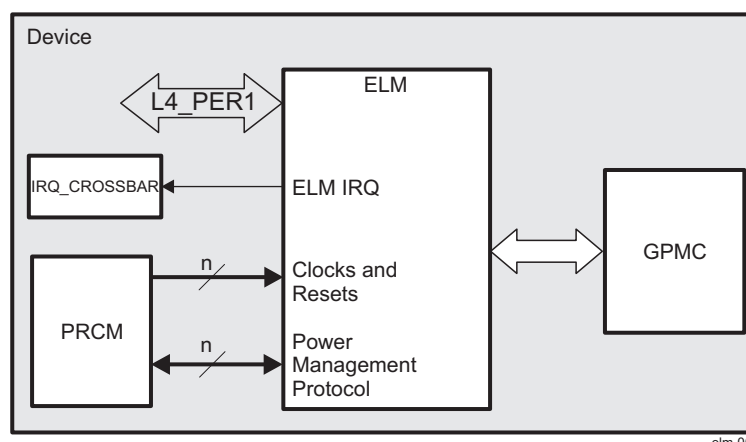

When the error-location process completes, an interrupt is triggered to inform the software that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

The ELM has the following features:

- 4, 8 and 16 bits per 512-byte block error-location based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
  - When the full page has been processed in page mode
  - For each syndrome polynomial in continuous mode

Figure 15-104 shows the ELM overview.

**Figure 15-104. ELM Overview**

elm-001

### 15.5.2 ELM Integration

The ELM extracts error addresses from generated syndrome polynomials.

The ELM is used with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND flash page and stored in GPMC registers are passed to the ELM. The microprocessor unit (MPU) can then correct the data block by flipping the bits to which the ELM error-location outputs point.

Figure 15-105 shows the integration of the ELM subsystem in the device.

Figure 15-105. ELM Integration

Table 15-574 through Table 15-576 summarize the integration of the module in the device.

Table 15-574. ELM Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
ELM	PD_COREAON	No	L4_PER1

**Table 15-575. ELM Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
ELM	ELM_FCLK	L4PER_L4_GICLK	PRCM	Functional clock
	ELM_ICLK	L4PER_L3_GICLK	PRCM	Interface clock
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
ELM	ELM_RST	L4PER_RST	PRCM	Module hardware reset

**Table 15-576. ELM Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	IRQ_CROSSBAR	Default Mapping	Description
ELM	ELM_IRQ	IRQ_CROSSBAR_1	MPU_IRQ_4	BCH error-location module interrupt
			DSP1_IRQ_32	BCH error-location module interrupt
			DSP2_IRQ_32	BCH error-location module interrupt
			EVE1_IRQ_1	BCH error-location module interrupt
			EVE2_IRQ_1	BCH error-location module interrupt

**NOTE:** The “Default Mapping” column in [Table 15-576 ELM Hardware Requests](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ\_CROSSBAR module. For more information about the IRQ\_CROSSBAR module, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#). For more information about the device interrupt controllers, see [Chapter 17, Interrupt Controllers](#).

### 15.5.3 ELM Functional Description

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

#### 15.5.3.1 ELM Software Reset

To perform a software reset, set the [ELM\\_SYSCONFIG\[1\] SOFTRESET](#) bit to 1. The [ELM\\_SYSSTATUS\[0\] RESETDONE](#) bit indicates that the software reset is complete when its value is 1. When the software reset completes, the [ELM\\_SYSCONFIG\[1\] SOFTRESET](#) bit is automatically reset.

#### 15.5.3.2 ELM Power Management

[Table 15-577](#) describes the power-management features available to the ELM.

**NOTE:**

- For information about source clock gating and a description of the sleep/wake-up transitions, see the [Section 3.6.4.6, CD\\_L4\\_PER1 Clock Domain](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- For a general description of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.6, Clock Management Functional Description](#), in [Chapter 3, Power, Reset, and Clock Management](#)

**Table 15-577. Local Power-Management Features**

Feature	Registers	Description
Clock autogating	<a href="#">ELM_SYSCONFIG</a> [0] AUTOGATING	This bit allows a local power optimization inside the module by gating the ELM_FCLK clock upon the interface activity.
Slave idle modes	<a href="#">ELM_SYSCONFIG</a> [4:3] SIDLEMODE	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	<a href="#">ELM_SYSCONFIG</a> [8] CLOCKACTIVITY	The clock can be switched off or maintained during the wake-up period.
Master standby modes	N/A	
Global wake-up enable	N/A	
Wake-up sources enable	N/A	

**CAUTION**

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the ELM CLOCKACTIVITY and ELM clock PRCM control bits. For a description of the ClockActivity feature, see [Chapter 3, Power, Reset, and Clock Management](#).

**15.5.3.3 ELM Interrupt Requests**

[Table 15-578](#) lists the event flags, and their masks, that can cause module interrupts.

**Table 15-578. Events**

Event Flag	Event Mask	Description
<a href="#">ELM_IRQSTATUS</a> [8] PAGE_VALID	<a href="#">ELM_IRQENABLE</a> [8] PAGE_MASK	Page interrupt
<a href="#">ELM_IRQSTATUS</a> [7] LOC_VALID_7	<a href="#">ELM_IRQENABLE</a> [7] LOCATION_MASK_7	Error-location interrupt for syndrome polynomial 7
<a href="#">ELM_IRQSTATUS</a> [6] LOC_VALID_6	<a href="#">ELM_IRQENABLE</a> [6] LOCATION_MASK_6	Error-location interrupt for syndrome polynomial 6
<a href="#">ELM_IRQSTATUS</a> [5] LOC_VALID_5	<a href="#">ELM_IRQENABLE</a> [5] LOCATION_MASK_5	Error-location interrupt for syndrome polynomial 5
<a href="#">ELM_IRQSTATUS</a> [4] LOC_VALID_4	<a href="#">ELM_IRQENABLE</a> [4] LOCATION_MASK_4	Error-location interrupt for syndrome polynomial 4
<a href="#">ELM_IRQSTATUS</a> [3] LOC_VALID_3	<a href="#">ELM_IRQENABLE</a> [3] LOCATION_MASK_3	Error-location interrupt for syndrome polynomial 3
<a href="#">ELM_IRQSTATUS</a> [2] LOC_VALID_2	<a href="#">ELM_IRQENABLE</a> [2] LOCATION_MASK_2	Error-location interrupt for syndrome polynomial 2
<a href="#">ELM_IRQSTATUS</a> [1] LOC_VALID_1	<a href="#">ELM_IRQENABLE</a> [1] LOCATION_MASK_1	Error-location interrupt for syndrome polynomial 1
<a href="#">ELM_IRQSTATUS</a> [0] LOC_VALID_0	<a href="#">ELM_IRQENABLE</a> [0] LOCATION_MASK_0	Error-location interrupt for syndrome polynomial 0

### 15.5.3.4 Processing Initialization

[ELM\\_LOCATION\\_CONFIG](#) global setting parameters must be set before using the error-location engine. The [ELM\\_LOCATION\\_CONFIG\[1:0\]](#) ECC\_BCH\_LEVEL bit field defines the error-correction level used (4-, 8-, or 16-bit error correction). The [ELM\\_LOCATION\\_CONFIG\[26:16\]](#) ECC\_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

Software can choose to use the ELM in continuous mode or page mode. If all [ELM\\_PAGE\\_CTRL\[i\]](#) SECTOR\_i bits (i is the syndrome polynomial number, where i = 0 to 7) are reset, continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently. Results for a syndrome can be retrieved and acknowledged at any time, regardless of the status of the other seven processing contexts.
- Page mode: Syndrome polynomials are grouped into atomic entities: only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all [ELM\\_IRQENABLE\[i\]](#) LOCATION\_MASK\_i bits (where i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the [ELM\\_IRQENABLE\[8\]](#) PAGE\_MASK bit must be set to 1 when in page mode.

Software initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: [ELM\\_SYNDROME\\_FRAGMENT\\_0\\_i](#) to [ELM\\_SYNDROME\\_FRAGMENT\\_6\\_i](#). The first six registers can be written in any order, but [ELM\\_SYNDROME\\_FRAGMENT\\_6\\_i](#) must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the [ELM\\_SYNDROME\\_FRAGMENT\\_6\\_i\[16\]](#) SYNDROME\_VALID bit).

As soon as one validity bit is asserted ([ELM\\_SYNDROME\\_FRAGMENT\\_6\\_i\[16\]](#) SYNDROME\_VALID = 0x1, where i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated [ELM\\_LOCATION\\_STATUS\\_i](#) and [ELM\\_ERROR\\_LOCATION\\_0\\_i](#) to [ELM\\_ERROR\\_LOCATION\\_15\\_i](#) registers (where i = 0 to 7) are not reset. Software must not consider them until the corresponding [ELM\\_IRQSTATUS\[i\]](#) LOC\_VALID\_i bit is set.

### 15.5.3.5 Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the [ELM\\_LOCATION\\_STATUS\\_i\[8\]](#) ECC\_CORRECTABLE bit is set to 1 and the [ELM\\_LOCATION\\_STATUS\\_i\[4:0\]](#) ECC\_NB\_ERRORS bit field is set to 0x0.
- Too many errors are detected; that is, when the [ELM\\_LOCATION\\_STATUS\\_i\[8\]](#) ECC\_CORRECTABLE bit is set to 0 while the [ELM\\_LOCATION\\_STATUS\\_i\[4:0\]](#) ECC\_NB\_ERRORS bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if ECC\_CORRECTABLE is 0.

If the engine completes early, the associated error-location registers [ELM\\_ERROR\\_LOCATION\\_0\\_i](#) to [ELM\\_ERROR\\_LOCATION\\_15\\_i](#) (where i = 0 to 7) are not updated.

In all other cases, the engine goes through the entire error-location process. Each time an error location is found, it is logged in the associated ECC\_ERROR\_LOCATION bit field. The first error detected is logged in the [ELM\\_ERROR\\_LOCATION\\_0\\_i\[12:0\]](#) ECC\_ERROR\_LOCATION bit field; the second is logged in the [ELM\\_ERROR\\_LOCATION\\_1\\_i\[12:0\]](#) ECC\_ERROR\_LOCATION bit field, and so on.

Table 15-579 describes the [ELM\\_LOCATION\\_STATUS\\_i](#) value decoding.

**Table 15-579. ELM\_LOCATION\_STATUS\_i Value Decoding**

ECC_CORRECTABLE Value	ECC_NB_ERRORS Value	Status	Number of Errors Detected	Action Required
1	0	OK	0	None

**Table 15-579. ELM\_LOCATION\_STATUS\_i Value Decoding (continued)**

1	≠ 0	OK	ECC_NB_ERRORS	Correct the data buffer read based on the <a href="#">ELM_ERROR_LOCATION_0_i</a> to <a href="#">ELM_ERROR_LOCATION_15_i</a> results.
0	Any	Failed	Unknown	Software-dependent

### 15.5.3.6 Processing Completion

When the processing for a given syndrome polynomial completes, its [ELM\\_SYNDROME\\_FRAGMENT\\_6\\_i\[16\]](#) SYNDROME\_VALID bit is reset. It must not be set again until the exit status registers, [ELM\\_LOCATION\\_STATUS\\_i](#) (where i = 0 to 7) for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding `ELM_IRQSTATUS[i] LOC_VALID_i` bit (where  $i = 0$  to  $7$ ) is set. The processing exit status is available from the associated `ELM_LOCATION_STATUS_i` register, and error locations are stored in order in the `ECC_ERROR_LOCATION` bit fields. Software must read only valid error-location registers based on the number of errors detected and located.

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the `ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID` bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in `ELM_PAGE_CTRL` are reset), an interrupt is triggered whenever a `ELM_IRQSTATUS[i] LOC_VALID_i` bit is asserted. Software must read the `ELM_IRQSTATUS` register to determine which polynomial is processed and retrieve the exit status and error locations (`ELM_LOCATION_STATUS_i` and `ELM_ERROR_LOCATION_0_i` to `ELM_ERROR_LOCATION_15_i`). When done, software must clear the corresponding `ELM_IRQSTATUS[i] LOC_VALID_i` bit by setting it to 1. Other status bits must be set to 0 so that other interrupts are not unintentionally cleared. When using this mode, the `ELM_IRQSTATUS[8] PAGE_VALID` interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the `ELM_IRQENABLE[i] LOCATION_MASK_i` bits are cleared. A page is defined using the `ELM_PAGE_CTRL` register. Each `SECTOR_i` bit set means the corresponding polynomial  $i$  is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the `ELM_IRQSTATUS[i] LOC_VALID_i` bits. The module triggers an `ELM_IRQSTATUS[8] PAGE_VALID` interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the `ELM_IRQSTATUS` register must be cleared by using a single atomic-write access.

---

**NOTE:** Do not modify page setting parameters in the `ELM_PAGE_CTRL` register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

---

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the `ELM_PAGE_CTRL[i] SECTOR_i` bits (where  $i = 0$  to  $7$ ) are processed as usual, but are essentially ignored. Software must manually poll the `ELM_IRQSTATUS` bits to check for their status.

## 15.5.4 ELM Basic Programming Model

### 15.5.4.1 ELM Low-Level Programming Model

#### 15.5.4.1.1 Processing Initialization

**Table 15-580. ELM Processing Initialization**

Step	Register/Bit Field/Programming Model	Value
Resets the module	<code>ELM_SYSCONFIG[1] SOFTRESET</code>	0x1
Wait until reset is done.	<code>ELM_SYSSTATUS[0] RESETDONE</code>	0x1
Configure the slave interface power management.	<code>ELM_SYSCONFIG[4:3] SIDLEMODE</code>	Set value.
Defines the error-correction level used	<code>ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL</code>	Set value.
Defines the maximum buffer length	<code>ELM_LOCATION_CONFIG[26:16] ECC_SIZE</code>	Set value.
Sets the ELM in continuous mode or page mode	<code>ELM_PAGE_CTRL</code>	Set value.
<b>If</b> continuous mode is used	All <code>ELM_PAGE_CTRL[i] SECTOR_i</code> (where $i = 0$ to $7$ )	0x0
Enables interrupt for syndrome polynomial $i$	<code>ELM_IRQENABLE[i] LOCATION_MASK_i</code>	0x1
<b>else</b> (page mode is used)	One syndrome polynomial $i$ is set <code>ELM_PAGE_CTRL[i] SECTOR_i</code> (where $i = 0$ to $7$ )	0x1
Disable all interrupts for syndrome polynomial and enable <code>PAGE_MASK</code> interrupt.	All <code>ELM_IRQENABLE[i] LOCATION_MASK_i = 0x0</code> and <code>ELM_IRQENABLE[8] PAGE_MASK = 0x1</code>	Set value.
<b>endif</b>		Set value.

**Table 15-580. ELM Processing Initialization (continued)**

Step	Register/Bit Field/Programming Model	Value
Set the input syndrome polynomial i.	<a href="#">ELM_SYNDROME_FRAGMENT_0_i</a>	Set value.
	<a href="#">ELM_SYNDROME_FRAGMENT_1_i</a>	Set value.
	<a href="#">ELM_SYNDROME_FRAGMENT_5_i</a>	Set value.
	<a href="#">ELM_SYNDROME_FRAGMENT_6_i</a>	Set value.
Initiates the computation process	<a href="#">ELM_SYNDROME_FRAGMENT_6_i</a> [16] SYNDROME_VALID	0x1

### 15.5.4.1.2 Read Results

The engine goes through the entire error-location process and results can be read. [Table 15-581](#) and [Table 15-582](#) describe the processing completion for continuous and page modes, respectively.

**Table 15-581. ELM Processing Completion for Continuous Mode**

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Read for which i the error-location process is complete.	<a href="#">ELM_IRQSTATUS</a> [i] LOC_VALID_i	0x1
<b>if</b> the process fails (too many errors) It is software dependant.	<a href="#">ELM_LOCATION_STATUS_i</a> [8] ECC_CORRECTABLE	0x0
<b>else</b> (process successful, the engine completes)	<a href="#">ELM_LOCATION_STATUS_i</a> [8] ECC_CORRECTABLE	0x1
Read the number of errors.	<a href="#">ELM_LOCATION_STATUS_i</a> [4:0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers. Software must correct errors in the data buffer.	<a href="#">ELM_ERROR_LOCATION_0_i</a> [12:0] ECC_ERROR_LOCATION	
	<a href="#">ELM_ERROR_LOCATION_1_i</a> [12:0] ECC_ERROR_LOCATION	
	... <a href="#">ELM_ERROR_LOCATION_15_i</a> [12:0] ECC_ERROR_LOCATION	
<b>endif</b>		
Clear the corresponding i interrupt.	<a href="#">ELM_IRQSTATUS</a> [i] LOC_VALID_i	0x1

A new syndrome polynomial can be processed after the end of processing ([ELM\\_SYNDROME\\_FRAGMENT\\_6\\_i](#)[16] SYNDROME\_VALID = 0x0) and after the exit status register check ([ELM\\_LOCATION\\_STATUS\\_i](#)).

**Table 15-582. ELM Processing Completion for Page Mode**

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	<a href="#">ELM_IRQSTATUS</a> [8] PAGE_VALID	0x1
<b>Repeat</b> the following actions the necessary number of times. That is, once for each valid defined block in the page.		
Read the process exit status.	<a href="#">ELM_LOCATION_STATUS_i</a> [8] ECC_CORRECTABLE	
<b>if</b> the process fails (too many errors) It is software dependent.	<a href="#">ELM_LOCATION_STATUS_i</a> [8] ECC_CORRECTABLE	0x0
<b>else</b> (process successful, the engine completes)	<a href="#">ELM_LOCATION_STATUS_i</a> [8] ECC_CORRECTABLE	0x1
Read the number of errors.	<a href="#">ELM_LOCATION_STATUS_i</a> [4:0] ECC_NB_ERRORS	

**Table 15-582. ELM Processing Completion for Page Mode (continued)**

Step	Register/Bit Field/Programming Model	Value
Read the error-location bit addresses for syndrome polynomial $i$ of the ECC_NB_ERRORS first registers.	ELM_ERROR_LOCATION_0_ $i$ [12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_ $i$ [12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_ $i$ [12:0] ECC_ERROR_LOCATION	
<b>endif</b>		
<b>End Repeat</b>		
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed ( $ELM_IRQSTATUS[i]$  LOC\_VALID\_ $i$  = 0x1 for all syndrome polynomials  $i$  used in the page).

#### 15.5.4.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM is programmed for an 8-bit error-correction capability in continuous mode (see Table 15-583). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a nonzero polynomial syndrome is reported from the GPMC (polynomial syndrome 0 is used in the ELM):

- $P = 0x0A16ABE115E44F767BFB0D0980$

**Table 15-583. Use Case: Continuous Mode**

Step	Register/Bit Field/Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG[4:3] SIDLEMODE	0x2
Defines the error-correction level used: 8 bits	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	0x1
Defines the maximum buffer length: 528 bytes (2 × 528 = 1056)	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	0x420
Sets the ELM in continuous mode	ELM_PAGE_CTRL	0
Enables interrupt for syndrome polynomial 0	ELM_IRQENABLE[0] LOCATION_MASK_0	0x1
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_ $i$ (where $i = 0$ )	0xFB0D0980
	ELM_SYNDROME_FRAGMENT_1_ $i$ (where $i = 0$ )	0xE44F767B
	ELM_SYNDROME_FRAGMENT_2_ $i$ (where $i = 0$ )	0x16ABE115
	ELM_SYNDROME_FRAGMENT_3_ $i$ (where $i = 0$ )	0x0000000A
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_ $i$ [16] SYNDROME_VALID (where $i = 0$ )	0x1
Wait until process is complete for syndrome polynomial 0: IRQ_ELM is generated or poll the status register.		
Read that error-location process is complete for syndrome polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1
Read the process exit status: All errors were successfully located.	ELM_LOCATION_STATUS_ $i$ [8] ECC_CORRECTABLE (where $i = 0$ )	0x1
Read the number of errors: Four errors detected.	ELM_LOCATION_STATUS_ $i$ [4:0] ECC_NB_ERRORS (where $i = 0$ )	0x4

**Table 15-583. Use Case: Continuous Mode (continued)**

Step	Register/Bit Field/Programming Model	Value
Read the error-location bit addresses for syndrome polynomial 0 of the first four registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452.	<a href="#">ELM_ERROR_LOCATION_0_i</a> (where i = 0)	0x1AF
	<a href="#">ELM_ERROR_LOCATION_1_i</a> (where i = 0)	0x426
	<a href="#">ELM_ERROR_LOCATION_2_i</a> (where i = 0)	0x775
	<a href="#">ELM_ERROR_LOCATION_3_i</a> (where i = 0)	0xD7C
Clear the corresponding interrupt for polynomial 0.	<a href="#">ELM_IRQSTATUS[0] LOC_VALID_0</a>	0x1

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, and then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in [Table 15-584](#) are given in decimal format.

**Table 15-584. 16-Bit NAND Sector Buffer Address Map**

NAND Memory Address	Message Bit Addresses in Memory Word															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

263	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and flip this bit. The same process must be repeated for all detected errors.

#### 15.5.4.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for an 16-bit error-correction capability in page mode (see [Table 15-585](#)). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF
- P1 = 0xBAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EB
- P2 = 0x69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189

- P3 = 0x0

**Table 15-585. Use Case: Page Mode**

Step	Register/Bit Field/Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG[4:3] SIDLEMODE	0x2
Defines the error-correction level used: 16 bits	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	0x2
Defines the maximum buffer length: 528 bytes	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	0x420
Sets the ELM in page mode (four blocks in a page)	ELM_PAGE_CTRL[0] SECTOR_0	0x1
	ELM_PAGE_CTRL[1] SECTOR_1	0x1
	ELM_PAGE_CTRL[2] SECTOR_2	0x1
	ELM_PAGE_CTRL[3] SECTOR_3	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	ELM_IRQENABLE	0x100
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (where i = 0)	0xE0B718EF
	ELM_SYNDROME_FRAGMENT_1_i (where i = 0)	0xA329AA05
	ELM_SYNDROME_FRAGMENT_2_i (where i = 0)	0x8330B5CC
	ELM_SYNDROME_FRAGMENT_3_i (where i = 0)	0xB0693DB2
	ELM_SYNDROME_FRAGMENT_4_i (where i = 0)	0x318E05BE
	ELM_SYNDROME_FRAGMENT_5_i (where i = 0)	0x12ADDB5A
	ELM_SYNDROME_FRAGMENT_6_i (where i = 0)	0xE8B0
Set the input syndrome polynomial 1.	ELM_SYNDROME_FRAGMENT_0_i (where i = 1)	0xE5F935EB
	ELM_SYNDROME_FRAGMENT_1_i (where i = 1)	0x79C6BA10
	ELM_SYNDROME_FRAGMENT_2_i (where i = 1)	0xBE093336
	ELM_SYNDROME_FRAGMENT_3_i (where i = 1)	0x0948DF08
	ELM_SYNDROME_FRAGMENT_4_i (where i = 1)	0xC22E6669
	ELM_SYNDROME_FRAGMENT_5_i (where i = 1)	0x49A0D932
	ELM_SYNDROME_FRAGMENT_6_i (where i = 1)	0xBAD0
Set the input syndrome polynomial 2.	ELM_SYNDROME_FRAGMENT_0_i (where i = 2)	0x60BA3189
	ELM_SYNDROME_FRAGMENT_1_i (where i = 2)	0x1579EF7D
	ELM_SYNDROME_FRAGMENT_2_i (where i = 2)	0x54556EA0
	ELM_SYNDROME_FRAGMENT_3_i (where i = 2)	0xA6498FEE
	ELM_SYNDROME_FRAGMENT_4_i (where i = 2)	0xEC3697FA
	ELM_SYNDROME_FRAGMENT_5_i (where i = 2)	0xB86ABCD5
	ELM_SYNDROME_FRAGMENT_6_i (where i = 2)	0x69D9
Set the input syndrome polynomial 3.	ELM_SYNDROME_FRAGMENT_0_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_1_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_2_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_3_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_4_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_5_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_6_i (where i = 3)	0x0
Initiates the computation process for syndrome polynomial 0	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 0)	0x1
Initiates the computation process for syndrome polynomial 1	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 1)	0x1
Initiates the computation process for syndrome polynomial 2	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 2)	0x1
Initiates the computation process for syndrome polynomial 3	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 3)	0x1

**Table 15-585. Use Case: Page Mode (continued)**

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial 0, 1, 2, and 3: Wait until the ELM_IRQ interrupt is generated or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
Read the process exit status for syndrome polynomial 0: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 0)	0x1
Read the process exit status for syndrome polynomial 1: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 1)	0x1
Read the process exit status for syndrome polynomial 2: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 2)	0x1
Read the process exit status for syndrome polynomial 3: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 3)	0x1
Read the number of errors for syndrome polynomial 0: four errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (where i = 0)	0x4
Read the number of errors for syndrome polynomial 1: two errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (where i = 1)	0x2
Read the number of errors for syndrome polynomial 2: one error detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (where i = 2)	0x1
Read the number of errors for syndrome polynomial 3: no errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (where i = 3)	0x0
Read the error-location bit addresses for syndrome polynomial 0 of the first four registers:	ELM_ERROR_LOCATION_0_i (where i = 0) ELM_ERROR_LOCATION_1_i (where i = 0) ELM_ERROR_LOCATION_2_i (where i = 0) ELM_ERROR_LOCATION_3_i (where i = 0)	0x1FE 0x617 0x650 0xA83
Read the error-location bit addresses for syndrome polynomial 1 of the first two registers:	ELM_ERROR_LOCATION_0_i (where i = 1) ELM_ERROR_LOCATION_1_i (where i = 1)	0x4 0x1036
Read the errors location bit addresses for syndrome polynomial 2 of the first registers:	ELM_ERROR_LOCATION_0_i (where i = 1)	0x3E8
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

## 15.5.5 ELM Register Manual

### 15.5.5.1 ELM Instance Summary

Table 15-586 summarizes the ELM instance.

**Table 15-586. ELM Instance Summary**

Module Name	Base Address	Size
ELM	0x4807 8000	4 KiB

### 15.5.5.2 ELM Registers

#### 15.5.5.2.1 ELM Register Summary

Table 15-587 summarizes the ELM register mapping.

**Table 15-587. ELM Registers Mapping Summary**

**Table 15-590. ELM\_SYSCONFIG**

<b>Address Offset</b>	0x0000 0010		
<b>Physical Address</b>	0x4807 8010	<b>Instance</b>	ELM
<b>Description</b>	This register allows controlling various parameters of the OCP interface.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																CLOCKACTIVITYOCP	RESERVED	SIDLEMODE	RESERVED	SOFTRESET	AUTOGATING										

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	R	0x0000000
8	CLOCKACTIVITYOCP	OCP clock activity when module is in IDLE mode (during wake-up mode period) 0x0: OCP clock can be switched off. 0x1: OCP clock is maintained during wake-up period.	RW	0
7:5	RESERVED	Reserved	R	0x0
4:3	SIDLEMODE	Slave interface power management (IDLE req/ack control) 0x0: Force-idle. IDLE request is acknowledged unconditionally and immediately (Default <i>Dumb</i> mode for safety) 0x1: No-idle. IDLE request is never acknowledged. 0x2: Smart-idle. The acknowledgment to an IDLE request is given based on the internal activity. 0x3: Reserved - do not use	RW	0x2

Bits	Field Name	Description	Type	Reset
2	RESERVED	Reserved	R	0
1	SOFTRESET	Module software reset This bit is automatically reset by hardware (during reads, it always returns 0). It has same effect as the OCP hardware reset. 0x0: Normal mode 0x1: Start soft reset sequence.	RW	0
0	AUTOGATING	Internal OCP clock gating strategy (no module visible effect other than saving power) 0x0: OCP clock is free-running. 0x1: Automatic internal OCP clock gating strategy is applied based on the OCP interface activity.	RW	1

## 15.6 On-Chip Memory (OCM) Subsystem

### 15.6.1 OCM Subsystem Overview

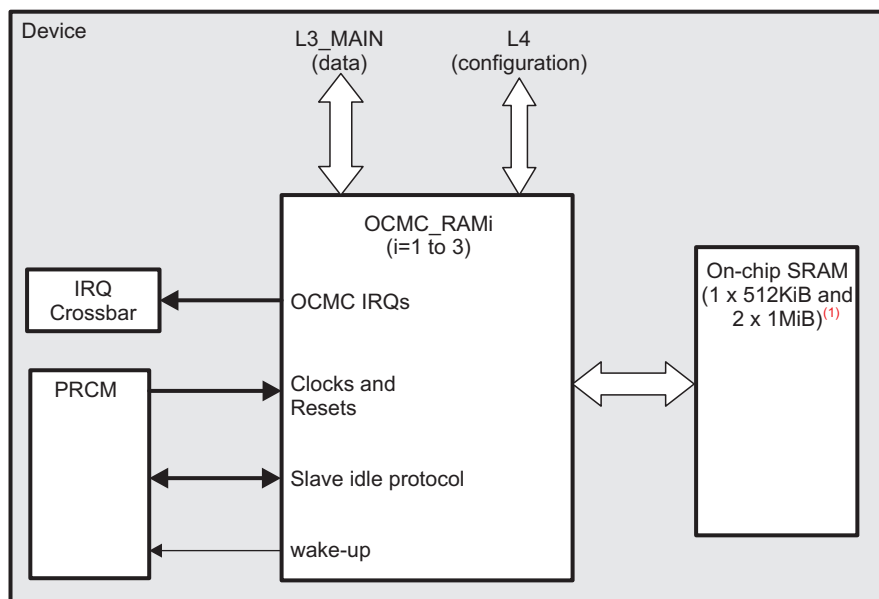

The OCM subsystem consists of three OCM Controllers (OCMC) that are associated with the on-chip RAM. The OCM controllers are also introduced in [Section 15.1.6, OCM Overview](#) of [Section 15.1, Memory Subsystem Overview](#).

The RAM associated controllers are as follows:

- OCMC\_RAM1 with 512 KiB of dedicated memory space.
- OCMC\_RAM2 with 1024 KiB of dedicated memory space.
- OCMC\_RAM3 with 1024 KiB of dedicated memory space.

[Figure 15-106](#) shows the three OCMC\_RAM controllers.

**Figure 15-106. OCMC\_RAMi (i = 1 to 3) Overview**

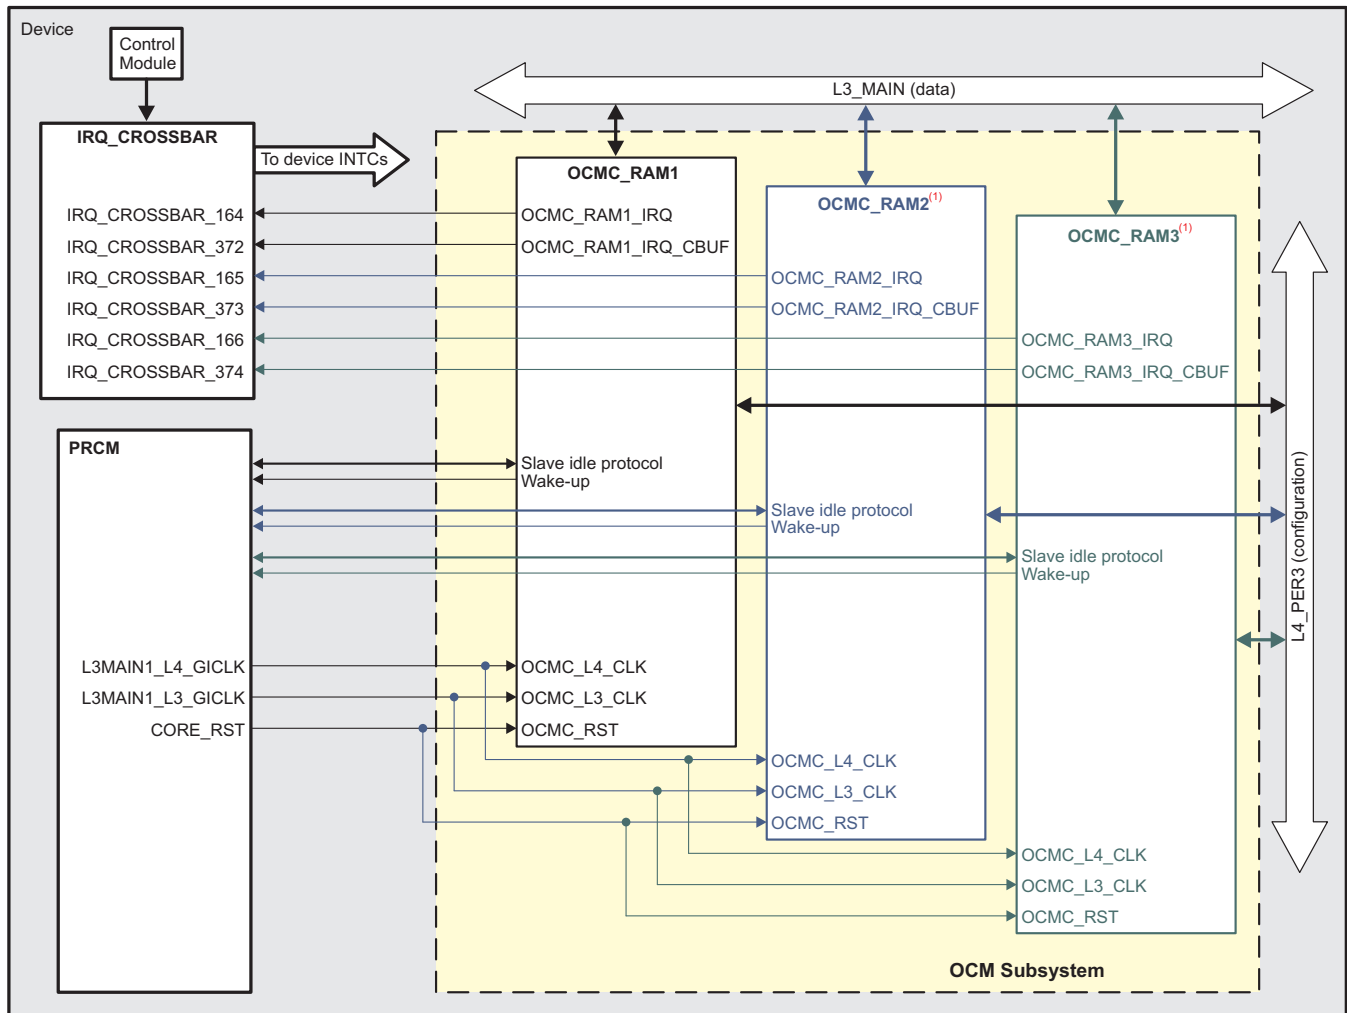

(1) Presence of RAM bank is device part number dependent. For more information, see the device Data Manual.

ocmc-001

### 15.6.2 OCM Subsystem Integration

[Figure 15-107](#) shows the integration of the OCM Subsystem in the device.

Figure 15-107. OCM Subsystem Integration

(1) OCMC\_RAM2 and OCMC\_RAM3 banks are not present on DRA74x devices, but are included in some of the DRA75x devices. For details, see the device data manual.

ocmc-003

Table 15-650 through Table 15-652 summarize the integration of the OCM Subsystem in the device.

Table 15-650. OCM Subsystem Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
OCMC_RAM1	PD_COREAON	Yes	L3_MAIN
			L4_PER3
OCMC_RAM2	PD_COREAON	Yes	L3_MAIN
			L4_PER3
OCMC_RAM3	PD_COREAON	Yes	L3_MAIN
			L4_PER3

Table 15-651. OCM Subsystem Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description

**Table 15-651. OCM Subsystem Clocks and Resets (continued)**

OCMC_RAM1	OCMC_L3_CLK	L3MAIN1_L3_GICLK	PRCM	Clock used to drive and receive data over the L3 data bus. This is also the processing clock of the OCM Controller and the SRAM. With this clock all internal data transfers are clocked.
	OCMC_L4_CLK	L3MAIN1_L4_GICLK	PRCM	Clock used to drive and receive data over the L4_PER3 configuration bus. This clock should run at half the OCMC_L3_CLK clock rate.
OCMC_RAM2	OCMC_L3_CLK	L3MAIN1_L3_GICLK	PRCM	Clock used to drive and receive data over the L3 data bus. This is also the processing clock of the OCM Controller and the SRAM. With this clock all internal data transfers are clocked.
	OCMC_L4_CLK	L3MAIN1_L4_GICLK	PRCM	Clock used to drive and receive data over the L4_PER3 configuration bus. This clock should run at half the OCMC_L3_CLK clock rate.
OCMC_RAM3	OCMC_L3_CLK	L3MAIN1_L3_GICLK	PRCM	Clock used to drive and receive data over the L3 data bus. This is also the processing clock of the OCM Controller and the SRAM. With this clock all internal data transfers are clocked.
	OCMC_L4_CLK	L3MAIN1_L4_GICLK	PRCM	Clock used to drive and receive data over the L4_PER3 configuration bus. This clock should run at half the OCMC_L3_CLK clock rate.

**Resets**

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
OCMC_RAM1	OCMC_RST	CORE_RST	PRCM	Reset signal for the OCM Subsystem
OCMC_RAM2	OCMC_RST	CORE_RST	PRCM	
OCMC_RAM3	OCMC_RST	CORE_RST	PRCM	

**Table 15-652. OCM Subsystem Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	Destination IRQ_CROSSBAR Input	Default Mapping	Description
OCMC_RAM1	OCMC_RAM1_IRQ	IRQ_CROSSBAR_164	-	First OCMC_RAM1 interrupt request. This IRQ source signal is not mapped by default to any device INTC.
	OCMC_RAM1_IRQ_CBUF	IRQ_CROSSBAR_372	-	Second OCMC_RAM1 interrupt request. This IRQ source signal is not mapped by default to any device INTC.
OCMC_RAM2	OCMC_RAM2_IRQ	IRQ_CROSSBAR_165	-	First OCMC_RAM2 interrupt request. This IRQ source signal is not mapped by default to any device INTC.
	OCMC_RAM2_IRQ_CBUF	IRQ_CROSSBAR_373	-	Second OCMC_RAM2 interrupt request. This IRQ source signal is not mapped by default to any device INTC.

**Table 15-652. OCM Subsystem Hardware Requests (continued)**

OCMC_RAM3	OCMC_RAM3_IRQ	IRQ_CROSSBAR_166	-	First OCMC_RAM3 interrupt request. This IRQ source signal is not mapped by default to any device INTC.
	OCMC_RAM3_IRQ_CBUF	IRQ_CROSSBAR_374	-	Second OCMC_RAM3 interrupt request. This IRQ source signal is not mapped by default to any device INTC.

**NOTE:** The “Default Mapping” column in [Table 15-652 OCM Subsystem Hardware Requests](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ\_CROSSBAR module.  
 For more information about the IRQ\_CROSSBAR module, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#).  
 For more information about the device interrupt controllers, see [Chapter 17, Interrupt Controllers](#).

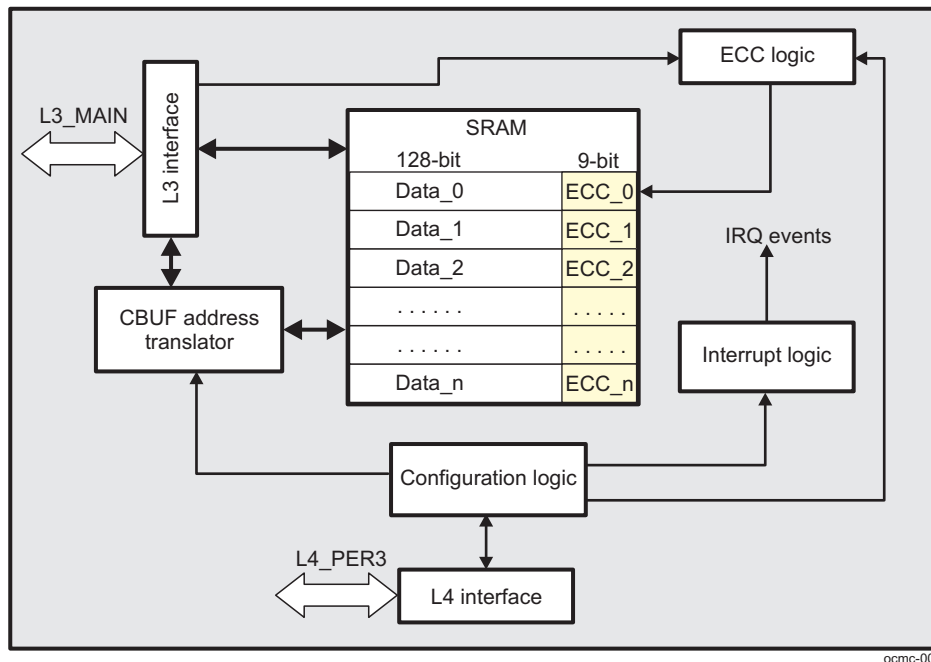

**NOTE:** For description of the interrupt sources, see [Section 15.6.3.4, Interrupt Requests](#).

### 15.6.3 OCM Subsystem Functional Description

#### 15.6.3.1 Block Diagram

[Figure 15-108](#) shows the OCMC block diagram.

**Figure 15-108. OCMC Block Diagram**

The module is composed by the following main blocks:

- L3 interface used for data transactions
- L4 interface used for configuration

- CBUF address translator which converts the L3\_MAIN VBUF addresses into SRAM addresses
- ECC logic to support single error correction and double error detection
- SRAM used for storing data and the corresponding for each 128-bit word ECC
- Interrupt logic used for generating interrupt requests
- Configuration logic in which reside the registers used for configuring the OCM controller operation modes

### 15.6.3.2 Resets

The OCMC\_RST is the reset signal for the OCM controller which asynchronously resets the whole internal logic of the controller, including all configuration registers. It does not reset the SRAM. In addition, the [OCMC\\_SYSCONFIG\\_RST\[0\]](#) SW\_RST bit provides a software way to reset the OCM controller. In this case all of its internal logic is reset except the configuration registers accessible through the L4\_PER3.

### 15.6.3.3 Clock Management

The OCM controller complies with the PRCM slave idle protocol. The OCMC\_L3\_CLK and OCMC\_L4\_CLK clocks are gated based on the values loaded in the [OCMC\\_SYSCONFIG\\_PM\[3:2\]](#) IDLEMODE bit field.

### 15.6.3.4 Interrupt Requests

The OCM controller generates two interrupt requests, OCMC\_RAMi\_IRQ and OCMC\_RAMi\_IRQ\_CBUF (*i* = 1, 2 and 3. *i* depends on the device part number).

The OCMC\_RAMi\_IRQ line is associated with the following registers:

- [INTR0\\_STATUS\\_RAW\\_SET](#) - interrupt raw status register
- [INTR0\\_STATUS\\_ENABLED\\_CLEAR](#) - interrupt status register
- [INTR0\\_ENABLE\\_SET](#) - interrupt enable register
- [INTR0\\_ENABLE\\_CLEAR](#) - interrupt disable register

The OCMC\_RAMi\_IRQ\_CBUF line is associated with the following registers:

- [INTR1\\_STATUS\\_RAW\\_SET](#) - interrupt raw status register
- [INTR1\\_STATUS\\_ENABLED\\_CLEAR](#) - interrupt status register
- [INTR1\\_ENABLE\\_SET](#) - interrupt enable (event unmask) register
- [INTR1\\_ENABLE\\_CLEAR](#) - interrupt disable (event mask) register

Both the register groups previously described have identical bits. When for example, only one event occurs one or the two IRQ lines will be asserted depending on the masks applied to the [INTR0\\_ENABLE\\_SET](#) and [INTR1\\_ENABLE\\_SET](#) registers. When for example, a short frame detection event occurs and if both the [INTR0\\_ENABLE\\_SET\[14\]](#) CBUF\_SHORT\_FRAME\_DETECT\_FOUND and [INTR1\\_ENABLE\\_SET\[14\]](#) CBUF\_SHORT\_FRAME\_DETECT\_FOUND bits are set to 0x1, then both the OCMC\_RAMi\_IRQ and OCMC\_RAMi\_IRQ\_CBUF lines are asserted. If only the [INTR0\\_ENABLE\\_SET\[14\]](#) CBUF\_SHORT\_FRAME\_DETECT\_FOUND bit is set to 0x1, then only the OCMC\_RAMi\_IRQ line is asserted and the OCMC\_RAMi\_IRQ\_CBUF line remains inactive (deasserted). Thus depending on the mask applied one IRQ line of the OCM controller can be associated only with CBUF events for example, and the other one IRQ line can be associated with ECC events. In other words, two unique interrupts can be provided.

[Table 15-653](#) lists the interrupt events which can assert the two interrupt lines of the OCM controller.

The OCM controller asserts each of its interrupt lines only if the interrupts are enabled by setting to 0x1 the corresponding bits in the [INTR0\\_ENABLE\\_SET/INTR1\\_ENABLE\\_SET](#) register. These interrupts can be disabled by setting to 0x1 the corresponding bits in the [INTR0\\_ENABLE\\_CLEAR/INTR1\\_ENABLE\\_CLEAR](#) register. After the interrupt has been serviced the corresponding status flag must be cleared by software. This is done by setting to 0x1 the corresponding bit in the [INTR0\\_STATUS\\_ENABLED\\_CLEAR/INTR1\\_STATUS\\_ENABLED\\_CLEAR](#) register which also clears the corresponding bit in the [INTR0\\_STATUS\\_RAW\\_SET/INTR1\\_STATUS\\_RAW\\_SET](#) register. The status flags in the [INTR0\\_STATUS\\_RAW\\_SET/INTR1\\_STATUS\\_RAW\\_SET](#) register are set even if the

corresponding interrupt is disabled as opposed to those in the [INTRO\\_STATUS\\_ENABLED\\_CLEAR/INTR1\\_STATUS\\_ENABLED\\_CLEAR](#) register, which are set only if the corresponding interrupt is enabled. An interrupt is also generated by the OCM controller, if certain bit in the [INTRO\\_STATUS\\_RAW\\_SET/INTR1\\_STATUS\\_RAW\\_SET](#) register is set to 0x1 and the corresponding interrupt is enabled through the [INTRO\\_ENABLE\\_SET/INTR1\\_ENABLE\\_SET](#) register. This is useful when user software debugging is performed. Additionally, even if interrupts are not enabled, certain status bit in the [INTRO\\_STATUS\\_RAW\\_SET/INTR1\\_STATUS\\_RAW\\_SET](#) register can be cleared by setting to 0x1 the corresponding bit in the [INTRO\\_STATUS\\_ENABLED\\_CLEAR/INTR1\\_STATUS\\_ENABLED\\_CLEAR](#) register.

For additional details regarding the CBUF related events, see [Section 15.6.3.11, CBUF Mode Error Handling](#).

**Table 15-653. OCM Subsystem Events (continued)**

Event Flag	Event Mask	Description
<b>INTR0_STATUS_RAW_SET</b> [2] <b>ADDR_ERR_FOUND/INTR1_STATUS_RAW_SE</b> <b>ET</b> [2] <b>ADDR_ERR_FOUND</b> and <b>INTR0_STATUS_ENABLED_CLEAR</b> [2] <b>ADDR_ERR_FOUND/INTR1_STATUS_ENABL</b> <b>ED_CLEAR</b> [2] <b>ADDR_ERR_FOUND</b>	<b>INTR0_ENABLE_SET</b> [2] <b>ADDR_ERR_FOUND/INTR1_ENABLE_SET</b> [2] <b>ADDR_ERR_FOUND</b> and <b>INTR0_ENABLE_CLEAR</b> [2] <b>ADDR_ERR_FOUND/INTR1_ENABLE_CLEAR</b> [ 2] <b>ADDR_ERR_FOUND</b>	This status flag is set when the value of the <b>STATUS_ERROR_CNT</b> [23:20] <b>ADDR_ERROR_CNT</b> bit field reaches the threshold counter value configured through the <b>CFG_OCMC_ECC_ERROR</b> [23:20] bit field. The status remains asserted until the counter is not cleared. This is done by setting to 0x1 the <b>CFG_OCMC_ECC_CLEAR_HIST</b> [2] bit. If the counter is not cleared another interrupt is re-issued.
<b>INTR0_STATUS_RAW_SET</b> [1] <b>DED_ERR_FOUND/INTR1_STATUS_RAW_SE</b> <b>T</b> [1] <b>DED_ERR_FOUND</b> and <b>INTR0_STATUS_ENABLED_CLEAR</b> [1] <b>DED_ERR_FOUND/INTR1_STATUS_ENABL</b> <b>D_CLEAR</b> [1] <b>DED_ERR_FOUND</b>	<b>INTR0_ENABLE_SET</b> [1] <b>DED_ERR_FOUND/INTR1_ENABLE_SET</b> [1] <b>DED_ERR_FOUND</b> and <b>INTR0_ENABLE_CLEAR</b> [1] <b>DED_ERR_FOUND/INTR1_ENABLE_CLEAR</b> [1] <b>DED_ERR_FOUND</b>	This status flag is set when the value of the <b>STATUS_ERROR_CNT</b> [19:16] <b>DED_ERROR_CNT</b> bit field reaches the threshold counter value configured through the <b>CFG_OCMC_ECC_ERROR</b> [19:16] bit field. The status remains asserted until the counter is not cleared. This is done by setting to 0x1 the <b>CFG_OCMC_ECC_CLEAR_HIST</b> [1] bit. If the counter is not cleared another interrupt is re-issued.
<b>INTR0_STATUS_RAW_SET</b> [0] <b>SEC_ERR_FOUND/INTR1_STATUS_RAW_SE</b> <b>T</b> [0] <b>SEC_ERR_FOUND</b> and <b>INTR0_STATUS_ENABLED_CLEAR</b> [0] <b>SEC_ERR_FOUND/INTR1_STATUS_ENABLED</b> <b>_CLEAR</b> [0] <b>SEC_ERR_FOUND</b>	<b>INTR0_ENABLE_SET</b> [0] <b>SEC_ERR_FOUND/INTR1_ENABLE_SET</b> [0] <b>SEC_ERR_FOUND</b> and <b>INTR0_ENABLE_CLEAR</b> [0] <b>SEC_ERR_FOUND/INTR1_ENABLE_CLEAR</b> [0] <b>SEC_ERR_FOUND</b>	This status flag is set when the value of the <b>STATUS_ERROR_CNT</b> [15:0] <b>SEC_ERROR_CNT</b> bit field reaches the threshold counter value configured through the <b>CFG_OCMC_ECC_ERROR</b> [15:0] bit field. The status remains asserted until the counter is not cleared. This is done by setting to 0x1 the <b>CFG_OCMC_ECC_CLEAR_HIST</b> [0] bit. If the counter is not cleared another interrupt is re-issued.

### 15.6.3.5 OCM Subsystem Memory Regions

The SRAM associated with the OCMC\_RAM1 is accessible through the L3\_MAIN interconnect. The start address is 0x4030 0000 and the end address is 0x4037 FFFF. That is address space of 512KiB. The configuration registers of the OCMC\_RAM1 are accessible through the L4\_PER3 starting at address 0x4880 4000.

The SRAM associated with the OCMC\_RAM2 is accessible through the L3\_MAIN interconnect. The start address is 0x4040 0000 and the end address is 0x404F FFFF. That is address space of 1MiB. The configuration registers of the OCMC\_RAM2 are accessible through the L4\_PER3 starting at address 0x4880 A000.

The SRAM associated with the OCMC\_RAM3 is accessible through the L3\_MAIN interconnect. The start address is 0x4050 0000 and the end address is 0x405F FFFF. That is address space of 1MiB. The configuration registers of the OCMC\_RAM3 are accessible through the L4\_PER3 starting at address 0x4881 0000.

---

**NOTE:** OCMC\_RAM2 and OCMC\_RAM3 banks are not present on DRA74x devices, but are included in some of the DRA75x devices. For details, see the device data manual.

---

### 15.6.3.6 OCM Controller Modes Of Operation

The OCM controller supports four modes of operation. Each of these modes is selected through the [CFG\\_OCMC\\_ECC\[2:0\]](#) CFG\_OCMC\_MODE bit field. The four supported modes are the following:

- Non-ECC mode (Data Access) - Accesses to the SRAM are non-ECC-enabled and an ECC is not calculated.
- Non-ECC mode (Code Access) - The L3\_MAIN address is mapped to the SRAM memory space where the ECC code is stored. This mode allows read and write access to the 9-bit ECC word associated with each 128-bit data word. This mode is used for test purposes.
- Full-ECC mode - Accesses to the SRAM are ECC-enabled and a 9-bit ECC is calculated for each 128 bits of data.
- Block-ECC mode - A 9-bit ECC is calculated only for a 128KiB block of the SRAM. Accesses outside the 128KiB ECC-enabled block are non-ECC data accesses. In other words, a 9-bit ECC will be calculated not for each 128-bit data word of the whole SRAM space, but for each 128-bit data word within the boundaries of this 128KiB block of the SRAM. The selection of a 128KiB ECC-enabled block is done using bits[19:0] of the [CFG\\_OCMC\\_ECC\\_MEM\\_BLK](#) register. Each bit specifies which 128KiB block of the SRAM is ECC-enabled. 0x1 is the active value for each bit. In addition, more than one 128KiB ECC-enabled block can be selected.

The default mode of operation for the OCM controller is the non-ECC data access mode.

### 15.6.3.7 ECC Associated FIFOs

There are three FIFOs used when ECC mode is enabled. Each FIFO is four level deep. The FIFOs are the following:

- Address FIFO for single errors also referred to as SEC FIFO
- Address FIFO for double errors also referred to as DED FIFO
- Address FIFO for address errors also referred to as ADDRERR FIFO

The SEC FIFO stores the SRAM addresses at which a single error is detected. The FIFO is able to store up to four unique addresses of the single errors occurred. If there are more than four single errors associated with unique addresses, then only the first four addresses are stored in the FIFO. In case of occurrence of multiple correctable errors, the addresses are stored in the order the errors occurred. The SEC FIFO can be optionally configured to store all addresses of the single errors occurred including also the repeated addresses. This is done by setting to 0x0 the [CFG\\_OCMC\\_ECC\\_ERROR\[24\]](#) CFG\_DISCARD\_DUP\_ADDR bit. The SEC FIFO can be cleared by setting to 0x1 the [CFG\\_OCMC\\_ECC\\_CLEAR\\_HIST\[0\]](#) CLEAR\_SEC\_ERR\_CNT bit or by reading FIFO's content one by one through the [STATUS\\_SEC\\_ERROR\\_TRACE\[17:0\]](#) ADDRESS\_128BIT bit field which points to the SEC FIFO. In addition, the [STATUS\\_SEC\\_ERROR\\_TRACE\[18\]](#) VALID bit shows whether the FIFO is empty or not. A value of 0x1 means that the SEC FIFO is not empty and valid address can be read.

The DED FIFO stores the SRAM addresses when a double error is detected. The FIFO is able to store up to four unique addresses, but it can also be configured to store the repeated addresses by setting to 0x0 the [CFG\\_OCMC\\_ECC\\_ERROR\[24\]](#) CFG\_DISCARD\_DUP\_ADDR bit. The [STATUS\\_DED\\_ERROR\\_TRACE\[17:0\]](#) ADDRESS\_128BIT bit field points to the DED FIFO. The [STATUS\\_DED\\_ERROR\\_TRACE\[18\]](#) VALID bit shows whether the FIFO is empty or not. The DED FIFO can be cleared by setting to 0x1 the [CFG\\_OCMC\\_ECC\\_CLEAR\\_HIST\[1\]](#) CLEAR\_DED\_ERR\_CNT bit or by reading its content one by one through the [STATUS\\_DED\\_ERROR\\_TRACE\[17:0\]](#) ADDRESS\_128BIT.

The ADDRERR FIFO stores the SRAM addresses where the single error occurred is an address error. The [STATUS\\_ADDR\\_TRANSLATION\\_ERROR\\_TRACE\[17:0\]](#) ADDRESS\_128BIT bit field points to the ADDRERR FIFO. The [STATUS\\_ADDR\\_TRANSLATION\\_ERROR\\_TRACE\[18\]](#) VALID bit shows whether the FIFO is empty or not. The ADDRERR FIFO can be cleared by setting to 0x1 the [CFG\\_OCMC\\_ECC\\_CLEAR\\_HIST\[2\]](#) CLEAR\_ADDR\_ERR\_CNT bit or by reading its content one by one through the [STATUS\\_ADDR\\_TRANSLATION\\_ERROR\\_TRACE\[17:0\]](#) ADDRESS\_128BIT pointer. The ADDRERR FIFO is also able to store up to four unique addresses and can also be configured to store repeated addresses by setting to 0x0 the [CFG\\_OCMC\\_ECC\\_ERROR\[24\]](#) CFG\_DISCARD\_DUP\_ADDR bit.

### 15.6.3.8 ECC Counters And Corrected Bit Distribution Register

There are three counters which are used to count different types of errors occurred when the ECC mode is enabled. The counters are the following:

- SEC Counter - [STATUS\\_ERROR\\_CNT\[15:0\]](#) SEC\_ERROR\_CNT. This is the counter for the single errors occurred. It keeps track of all single errors. That is, even for those with error addresses that have already been logged.
- DED Counter - [STATUS\\_ERROR\\_CNT\[19:16\]](#) DED\_ERROR\_CNT. This is the counter for the double error detections.
- ADDRERR Counter - [STATUS\\_ERROR\\_CNT\[23:20\]](#) ADDR\_ERROR\_CNT. This is the counter for the address errors found when a single error occurs. That is, when the single error is an address error.

When a single error in the 128-bit data word occurs and this error is corrected, the OCM controller indicates for the corrected bit of this 128-bit word by setting to 0x1 a corresponding bit in the corrected bit distribution register. This is a 128-bit register composed by the following registers:

- [STATUS\\_SEC\\_ERROR\\_DISTR\\_0\[31:0\]](#) SEC\_BIT\_ERROR\_FOUND - Bits [31:0] of the corrected 128-bit data word.
- [STATUS\\_SEC\\_ERROR\\_DISTR\\_1\[31:0\]](#) SEC\_BIT\_ERROR\_FOUND - Bits [63:32] of the corrected 128-bit data word.
- [STATUS\\_SEC\\_ERROR\\_DISTR\\_2\[31:0\]](#) SEC\_BIT\_ERROR\_FOUND - Bits [95:64] of the corrected 128-bit data word.
- [STATUS\\_SEC\\_ERROR\\_DISTR\\_3\[31:0\]](#) SEC\_BIT\_ERROR\_FOUND - Bits [127:96] of the corrected 128-bit data word.

When a single error in the ECC itself occurs, the OCM controller indicates for this error by setting to 0x1 a corresponding bit in the [STATUS\\_SEC\\_ERROR\\_DISTR\\_4\[7:0\]](#) SEC\_ECC\_CODE\_ERROR\_FOUND bit field. The parity bit is not associated with this bit field.

### 15.6.3.9 ECC Support

The ECC mode is enabled through the [CFG\\_OCMC\\_ECC\[2:0\]](#) CFG\_OCMC\_MODE bit field. When enabled a 9-bit Hamming ECC is calculated and stored for each consecutive 128-bit block of the SRAM. The ECC is calculated based on a codeword constructed by concatenating the 128 bits of data with the address bits A21 through A4 of the L3\_MAIN. The ECC generated is Hamming(155,146) code and has a Hamming distance of 4. The OCM controller uses this code to validate the content of the SRAM, to correct a single bit error that occurs within the 128-bit boundary or to determine if a non-correctable error has occurred within the 128-bit boundary.

During write transactions and when ECC is enabled, for every 128-bit data word, the ECC is calculated and stored in a 9-bit field of the SRAM associated only with the address where that 128-bit data word is written. If an initiator performs a write transaction which is less than 128 bits or it is non-128-bit aligned transaction, then the content of all 128 bits is read, the new sub-quanta of data is inserted and the ECC is calculated based on all 128 bits.

During read transactions and when ECC is enabled, the ECC is calculated based on the memory address (bits A21 through A4) and the 128-bit data word read from the SRAM. This ECC is then compared to the ECC stored at the address when the data was written to the SRAM. If the two ECCs are matching then the data is transferred to the requesting initiator without further exceptions. If the two ECCs are not matching then a check is made to determine if the error is correctable or not. If the error is not correctable, that is a double error, then the address of the erroneous word is stored in the DED FIFO, the [STATUS\\_ERROR\\_CNT\[19:16\]](#) DED\_ERROR\_CNT counter is incremented by 1 and the double error flag is asserted. The double error flag is indicated by the [INTR0\\_STATUS\\_RAW\\_SET\[1\]](#) DED\_ERR\_FOUND/[INTR1\\_STATUS\\_RAW\\_SET\[1\]](#) DED\_ERR\_FOUND bits, but its assertion depends on the threshold configured through the [CFG\\_OCMC\\_ECC\\_ERROR\[19:16\]](#) CFG\_DED\_CNT\_MAX bit field. For more information see, [Table 15-653, OCM Subsystem Events](#).

In case of a single error, the OCM controller first determines whether the erroneous bit is in the data, address or the ECC itself. In this case the following applies:

- If the single error is located in the data read, then the erroneous bit is corrected and the data is passed to the requesting initiator. The erroneous bit is corrected also in the SRAM location by the auto re-write feature of the OCM controller if this feature is enabled by setting to 0x1 the [CFG\\_OCMC\\_ECC\[3\]](#) CFG\_ECC\_SEC\_AUTO\_CORRECT bit field. In addition, the address of the corrected data word is pushed to the SEC FIFO and the [STATUS\\_ERROR\\_CNT\[15:0\]](#) SEC\_ERROR\_CNT counter is incremented by 1. The single error flag is asserted too, but only if the value of the [STATUS\\_ERROR\\_CNT\[15:0\]](#) SEC\_ERROR\_CNT counter reaches the threshold configured by the [CFG\\_OCMC\\_ECC\\_ERROR\[15:0\]](#) CFG\_SEC\_CNT\_MAX bit field. The single error flag is indicated by the [INTR0\\_STATUS\\_RAW\\_SET\[0\]](#) SEC\_ERR\_FOUND/[INTR1\\_STATUS\\_RAW\\_SET\[0\]](#) SEC\_ERR\_FOUND bits. For more information see, [Table 15-653, OCM Subsystem Events](#).
- If the single error is located in the address portion of the quanta, then the data is passed to the requesting initiator unchanged and the [STATUS\\_ERROR\\_CNT\[23:20\]](#) ADDR\_ERROR\_CNT and [STATUS\\_ERROR\\_CNT\[15:0\]](#) SEC\_ERROR\_CNT counters are incremented by 1. The address associated with this error is stored in the ADDRERR FIFO and the address error flag is asserted. This flag is indicated by the [INTR0\\_STATUS\\_RAW\\_SET\[2\]](#) ADDR\_ERR\_FOUND/[INTR1\\_STATUS\\_RAW\\_SET\[2\]](#) ADDR\_ERR\_FOUND bits, but its assertion depends on the threshold configured through the [CFG\\_OCMC\\_ECC\\_ERROR\[23:20\]](#) CFG\_ADDR\_ERR\_CNT\_MAX bit field. For more information see, [Table 15-653, OCM Subsystem Events](#).
- If the single error is located in the ECC itself, then the data is passed to the initiator unchanged but the [STATUS\\_ERROR\\_CNT\[15:0\]](#) SEC\_ERROR\_CNT counter is incremented by 1 and the address associated with this error is stored in the SEC FIFO.

[Table 15-654](#) summarizes the actions taken by the OCM controller for the different error types.

**Table 15-654. OCMC Error Handling In Case Of Different Error Types**

Error Type	Data Returned	SRAM Data/ECC Update	SEC Counter	SEC FIFO	DED Counter	DED FIFO	ADDRERR Counter	ADDRERR FIFO	Error Bit Distribution
Single data error	Corrected	Data corrected/ECC re-generated	Incremented by 1	Address written	-	-	-	-	The content of the corrected bit distribution register is updated
Single address error	Unchanged	ECC re-generated	Incremented by 1	-	-	-	Incremented by 1	Address written	-

**Table 15-654. OCMC Error Handling In Case Of Different Error Types (continued)**

Error Type	Data Returned	SRAM Data/ECC Update	SEC Counter	SEC FIFO	DED Counter	DED FIFO	ADDRER R Counter	ADDRER R FIFO	Error Bit Distribution
Single ECC error	Unchanged	ECC re-generated	Incremented by 1	Address written	-	-	-	-	The content of the <a href="#">STATUS_SEC_ERROR_DISTR_4[7:0]</a> SEC_ECC_CODE_ERROR_FOUND bit field is updated
Double error	Unchanged	-	-	-	Incremented by 1	Address written	-	-	-

If ECC has to be used, before performing SRAM read/write operations the following steps should be performed:

- Configuring the ECC registers
- Enabling the ECC
- Initializing the SRAM with data
- Clearing the status flags

[Table 15-655](#) describes in detail the steps to be performed.

**Table 15-655. OCMC ECC Configuration**

Step	Associated Register/ Bit Field	Value
(Optional) Enable the error response on L3_MAIN for a non-correctable error	<a href="#">CFG_OCMC_ECC</a> [4] <a href="#">CFG_ECC_ERR_SRESP_EN</a>	0x1
(Optional) Enable data auto correction in case of a single error	<a href="#">CFG_OCMC_ECC</a> [3] <a href="#">CFG_ECC_SEC_AUTO_CORRECT</a>	0x1
Enable the memory blocks to be ECC protected, if ECC block mode is used	<a href="#">CFG_OCMC_ECC_MEM_BLK</a> [19:0] <a href="#">CFG_ECC_ENABLED_128K_BLK</a>	0x-
(Optional) Configure the address errors count needed for triggering an interrupt	<a href="#">CFG_OCMC_ECC_ERROR</a> [23:20] <a href="#">CFG_ADDR_ERR_CNT_MAX</a>	0x-
(Optional) Configure the DED count needed for triggering an interrupt	<a href="#">CFG_OCMC_ECC_ERROR</a> [19:16] <a href="#">CFG_DED_CNT_MAX</a>	0x-
(Optional) Configure the SEC count needed for triggering an interrupt	<a href="#">CFG_OCMC_ECC_ERROR</a> [15:0] <a href="#">CFG_SEC_CNT_MAX</a>	0x-
Enable ECC	<a href="#">CFG_OCMC_ECC</a> [2:0] <a href="#">CFG_OCMC_MODE</a>	0x2 for full ECC or 0x3 for block ECC mode
Initialize the memory with data		
Clear the error counters in the <a href="#">STATUS_ERROR_CNT</a> register	<a href="#">CFG_OCMC_ECC_CLEAR_HIST</a> [2:0]	0x7
Clear the SEC bit distribution history from the following registers:	<a href="#">CFG_OCMC_ECC_CLEAR_HIST</a> [3] <a href="#">CLEAR_SEC_BIT_DISTR</a>	0x1
• <a href="#">STATUS_SEC_ERROR_DISTR_0</a>		
• <a href="#">STATUS_SEC_ERROR_DISTR_1</a>		
• <a href="#">STATUS_SEC_ERROR_DISTR_2</a>		
• <a href="#">STATUS_SEC_ERROR_DISTR_3</a>		
• <a href="#">STATUS_SEC_ERROR_DISTR_4</a>		

### 15.6.3.10 Circular Buffer (CBUF) Support

The OCM controller provides up to 12 programmable circular buffers that are mapped to virtual video frames to support sliced based on-the-fly video frame processing. Each circular buffer must be programmed with the following:

- Unique virtual frame start address - configured through [CBUF\\_i\\_VBUF\\_START\\_ADDR](#)[31:4] ADDR.

- Unique virtual frame end address - configured through `CBUF_i_VBUF_END_ADDR[31:4]` ADDR.
- SRAM start address - configured through `CBUF_i_OCMC_START_ADDR[31:4]` ADDR.
- SRAM size allocated for that circular buffer - configured through `CBUF_i_OCMC_BUF_SIZE[19:4]` BUF\_SIZE.

The circular buffer mode is enabled when the `CFG_OCMC_CBUF_EN[0]` CBUF\_MODE\_EN bit is set to 0x1. In addition, to enable certain circular buffer the corresponding bit in the `CFG_OCMC_CBUF_EN[27:16]` bit field must be set to 0x1. For example, to enable CBUF\_0 both the `CFG_OCMC_CBUF_EN[0]` CBUF\_MODE\_EN and `CFG_OCMC_CBUF_EN[16]` CBUF\_EN\_0 bits must be set to 0x1.

The data transfers are made to the virtual frame addresses. The OCM controller translates these virtual addresses to SRAM addresses allocated for the CBUF. The address translation is done on-the-fly without leading to any additional latency and therefore has no performance impact on the overall operation of the OCM controller.

The L3\_MAIN address ranges associated with the virtual frame addresses are the following:

- For OCMC\_RAM1 the start address is 0x4180 0000 and the end address is 0x41FF FFFF.
- For OCMC\_RAM2 the start address is 0x4900 0000 and the end address is 0x497F FFFF.
- For OCMC\_RAM3 the start address is 0x4980 0000 and the end address is 0x49FF FFFF.

---

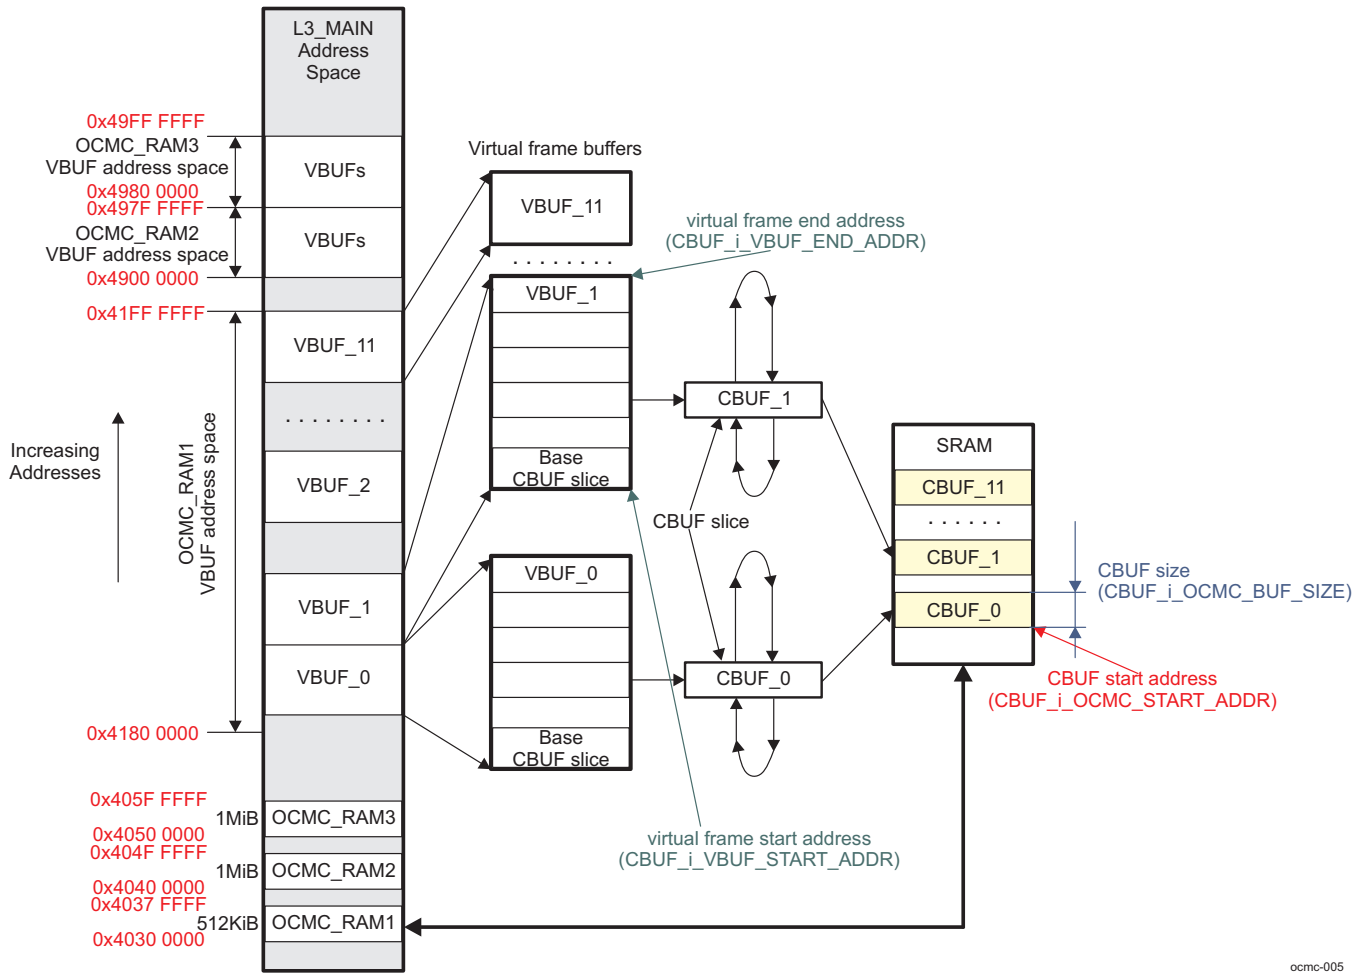

**NOTE:** OCMC\_RAM2 and OCMC\_RAM3 banks are not present on DRA74x devices, but are included in some of the DRA75x devices. For details, see the device data manual.

---

When an initiator performs an access to these L3\_MAIN addresses, these virtual frame addresses will be translated automatically by the OCM controller into SRAM addresses. [Figure 15-109](#) shows the address mapping of the virtual frame addresses to CBUF addresses.

Figure 15-109. VBUF to CBUF Address Mapping

ocmc-005

It must be taken into account that the start address of a virtual frame always begins at the start of the CBUF. Since the virtual frame buffer size is not necessarily to be a multiple of the CBUF size, the last VBUF write location may not be the last line of the CBUF. As the CBUF read and write pointers are independently managed the initiators that are writing to and reading from the CBUF should be coordinated in order to avoid overflow and underflow conditions.

### 15.6.3.11 CBUF Mode Error Handling

For each L3\_MAIN write or read access associated with the virtual frame buffer, the OCM controller performs various address error checks to prevent illegal CBUF accesses from causing false overflow and underflow conditions. Once the L3\_MAIN VBUF address is determined as valid, the OCM controller further checks for overflow and underflow conditions to properly handle the access to the CBUF during each one of these conditions and to notify for error condition an external host.

For more information regarding all CBUF events see, [Table 15-653, OCM Subsystem Events](#).

#### 15.6.3.11.1 VBUF Address Not Mapped to a CBUF Memory Space

The L3\_MAIN VBUF address should be mapped to a valid CBUF region. If this address is mapped to none of the configured CBUF regions, then the OCM controller generates a virtual address error or out of range CBUF address error event. It is possible both virtual address error and out of range CBUF address error to be generated. The L3\_MAIN VBUF address caused these two events can be read through the [LAST\\_ILLEGAL\\_OCMC\\_ADDR\[31:0\]](#) ADDR bit field.

Virtual address error is generated when the L3\_MAIN VBUF address is lower than the virtual frame start address. This is indicated by asserting the [INTRO\\_STATUS\\_RAW\\_SET\[4\]](#) [CBUF\\_VIRTUAL\\_ADDR\\_ERR\\_FOUND/INTR1\\_STATUS\\_RAW\\_SET\[4\]](#) [CBUF\\_VIRTUAL\\_ADDR\\_ERR\\_FOUND](#) bit.

The out of range CBUF address error is generated when the L3\_MAIN VBUF address is greater than the virtual frame end address. This error is an indication of an unexpected change in the frame size or a long frame and should be handled immediately to prevent further memory corruption. The out of range CBUF address error can be caused when performing write or read access. The out of range CBUF write address error is indicated by the [STATUS\\_CBUF\\_WR\\_OUT\\_OF\\_RANGE\\_ERR\[11:0\]](#) [CBUF\\_ERR](#) bit field. The out of range CBUF read address error is indicated by the [STATUS\\_CBUF\\_RD\\_OUT\\_OF\\_RANGE\\_ERROR\[11:0\]](#) [CBUF\\_ERR](#) bit field. Each bit in these registers is associated only with one CBUF. Bit 0 corresponds to CBUF\_0, bit 1 corresponds to CBUF\_1 and so on. A value of 0x1 for each bit means that there is an error (CBUF address is out of CBUF range) for the corresponding CBUF. Writing 0x1 for each bit clears the status.

The [INTRO\\_STATUS\\_RAW\\_SET\[5\]](#) [CBUF\\_WR\\_OUT\\_OF\\_RANGE\\_ERR\\_FOUND/INTR1\\_STATUS\\_RAW\\_SET\[5\]](#) [CBUF\\_WR\\_OUT\\_OF\\_RANGE\\_ERR\\_FOUND](#) bit is asserted if at least one of the bits in the [STATUS\\_CBUF\\_WR\\_OUT\\_OF\\_RANGE\\_ERR\[11:0\]](#) [CBUF\\_ERR](#) bit field is set to 0x1.

The [INTRO\\_STATUS\\_RAW\\_SET\[8\]](#) [CBUF\\_READ\\_OUT\\_OF\\_RANGE\\_ERR\\_FOUND/INTR1\\_STATUS\\_RAW\\_SET\[8\]](#) [CBUF\\_READ\\_OUT\\_OF\\_RANGE\\_ERR\\_FOUND](#) bit is asserted if at least one of the bits in the [STATUS\\_CBUF\\_RD\\_OUT\\_OF\\_RANGE\\_ERROR\[11:0\]](#) [CBUF\\_ERR](#) bit field is set to 0x1.

#### 15.6.3.11.2 VBUF Access Not Starting At The Base Address

After (hardware or software) reset or on a new frame start condition, a frame write or read access for any VBUF must start from its virtual frame start address ([CBUF\\_i\\_VBUF\\_START\\_ADDR\[31:4\]](#) [ADDR](#)). If this is not met the OCM controller ignores all accesses which don't start at address [CBUF\\_i\\_VBUF\\_START\\_ADDR\[31:4\]](#) [ADDR](#) and also generates an interrupt. The [STATUS\\_CBUF\\_WR\\_VBUF\\_START\\_ERR\[11:0\]](#) [CBUF\\_ERR](#) register contains the status bits of this interrupt which are associated with frame write access. The [STATUS\\_CBUF\\_VBUF\\_RD\\_START\\_ERROR\[11:0\]](#) [CBUF\\_ERR](#) register contains the status bits associated with frame read access. Each bit in these two registers is associated only with one CBUF. A value of 0x1 for each bit means that the read/write access does not start at the VBUF start address.

While this error condition exists, no updates to the CBUF channel status registers are made. An exception to this constraint is when the last read/write access is still within the base CBUF slice. The enforcing of a frame starting at VBUF starting address is not done in this case to allow random access within the same CBUF. However, this will be flagged and handled as a short frame occurrence.

The [INTRO\\_STATUS\\_RAW\\_SET\[6\]](#) [CBUF\\_VBUF\\_WRITE\\_START\\_ERR\\_FOUND/INTR1\\_STATUS\\_RAW\\_SET\[6\]](#) [CBUF\\_VBUF\\_WRITE\\_START\\_ERR\\_FOUND](#) bit is asserted if at least one of the bits in the [STATUS\\_CBUF\\_WR\\_VBUF\\_START\\_ERR\[11:0\]](#) [CBUF\\_ERR](#) bit field is set to 0x1.

The [INTRO\\_STATUS\\_RAW\\_SET\[9\]](#) [CBUF\\_VBUF\\_READ\\_START\\_ERR\\_FOUND/INTR1\\_STATUS\\_RAW\\_SET\[9\]](#) [CBUF\\_VBUF\\_READ\\_START\\_ERR\\_FOUND](#) bit is asserted if at least one of the bits in the [STATUS\\_CBUF\\_VBUF\\_RD\\_START\\_ERROR\[11:0\]](#) [CBUF\\_ERR](#) bit field is set to 0x1.

#### 15.6.3.11.3 Illegal Address Change Between Two Same Type Accesses

The OCM controller requires both read and write accesses to a virtual frame buffer to be performed in the positive raster scan order, that is, successive write or read accesses should be to a higher address except on a new frame start for which the address jumps back down to the beginning of the virtual frame buffer. The OCM controller checks to make sure that a virtual address meets one of the following conditions:

- It is within the same CBUF slice as the last access of the same type (read or write)
- It is within the next CBUF slice of the last access of the same type (read or write)
- The virtual address is to the VBUF frame start address

Based on these constraints, the OCM controller generates an write/read address sequence error interrupt and invalidates the access, that is, writes are disabled and reads return unknown data, if the following two conditions are met:

- The current access address is not to a current or next CBUF slice space
- The current access address is not to the base of the virtual frame buffer (the first CBUF slice)

The random accesses within the current CBUF slice are permitted to allow some variations in the line width of the captured video which often happens with weak video signal conditions.

To avoid illegal CBUF slice backward switching, the modules capturing the input video and sending it to the CBUF of the OCM controller should limit the maximum width of a line width to be less than the stride size (in pixels). This guarantees that a start of a new line does not point back to the previous CBUF slice.

If a write or read address sequence error event is detected on an access, the OCM controller will simply invalidate the accesses and will not update the CBUF status registers.

The bits in the [STATUS\\_CBUF\\_WR\\_ADDR\\_SEQ\\_ERROR](#)[11:0] CBUF\_ERR bit field indicate write address sequence error event.

The bits in the [STATUS\\_CBUF\\_RD\\_ADDR\\_SEQ\\_ERROR](#)[11:0] CBUF\_ERR bit field indicate read address sequence error event.

In both the registers each bit is associated only with one CBUF.

The [INTR0\\_STATUS\\_RAW\\_SET](#)[7]

[CBUF\\_WRITE\\_SEQUENCE\\_ERR\\_FOUND](#)/[INTR1\\_STATUS\\_RAW\\_SET](#)[7]

[CBUF\\_WRITE\\_SEQUENCE\\_ERR\\_FOUND](#) bit is asserted if at least one of the bits in the [STATUS\\_CBUF\\_WR\\_ADDR\\_SEQ\\_ERROR](#)[11:0] CBUF\_ERR bit field is set to 0x1.

The [INTR0\\_STATUS\\_RAW\\_SET](#)[10]

[CBUF\\_READ\\_SEQUENCE\\_ERR\\_FOUND](#)/[INTR1\\_STATUS\\_RAW\\_SET](#)[10]

[CBUF\\_READ\\_SEQUENCE\\_ERR\\_FOUND](#) bit is asserted if at least one of the bits in the [STATUS\\_CBUF\\_RD\\_ADDR\\_SEQ\\_ERROR](#)[11:0] CBUF\_ERR bit field is set to 0x1.

#### **15.6.3.11.4 Illegal Frame Size (Short Frame Detection)**

If a frame write access for any VBUF begins from its virtual frame start address without a CBUF software reset and the last write address is not the virtual frame end address or is in the last CBUF slice, then the previous frame is considered to be short. This includes the case where a new frame write happens twice without a new frame read in between, which is an indication of an extremely short frame. When a short frame event is detected, the OCM controller generates a short frame detection interrupt and temporarily disables overflow checking on the write access, including also the current access, until a frame read happens in order to avoid false overflow indication on a suspended read side following the short frame detection.

If the last write address is in the last CBUF slice the short frame detection can be ignored if the [CFG\\_OCMC\\_CBUF\\_ERR\\_HANDLER](#)[1] [SHORT\\_FRAME\\_PREV\\_EOF\\_SEL](#) bit is set to 0x1.

The [STATUS\\_CBUF\\_SHORT\\_FRAME\\_DETECT](#)[11:0] CBUF\_ERR bit field has status flags to indicate a short frame detection for each CBUF. When a short frame condition occurs the corresponding bit is set to 0x1.

The [INTR0\\_STATUS\\_RAW\\_SET](#)[14]

[CBUF\\_SHORT\\_FRAME\\_DETECT\\_FOUND](#)/[INTR1\\_STATUS\\_RAW\\_SET](#)[14]

[CBUF\\_SHORT\\_FRAME\\_DETECT\\_FOUND](#) bit is asserted if at least one of the bits in the [STATUS\\_CBUF\\_SHORT\\_FRAME\\_DETECT](#)[11:0] CBUF\_ERR bit field is set to 0x1.

In addition, the short frame detection enabling/disabling is controlled by the [CFG\\_OCMC\\_CBUF\\_ERR\\_HANDLER](#)[0] [SHORT\\_FRAME\\_DETECT\\_CHECK\\_EN](#) bit.

### 15.6.3.11.5 CBUF Overflow

For each valid CBUF write access, the write address is compared to the last read address for an overflow condition. If an overflow is detected, the corresponding CBUF overflow status bit in the [STATUS\\_CBUF\\_OVERFLOW\\_MID](#) or [STATUS\\_CBUF\\_OVERFLOW\\_WRAP](#) registers is set to 0x1 and an interrupt is generated. This interrupt condition exists until the corresponding overflow status bit is cleared.

There are two types of overflow conditions referred to as `Cbuf_overflow_wrap` and `Cbuf_overflow_mid`.

`Cbuf_overflow_wrap` occurs in case at least one of the following two:

- VBUF write address – VBUF frame start address < CBUF size
- VBUF write address – VBUF frame start address > VBUF last read address – Current VBUF start address

`Cbuf_overflow_mid` occurs in case at least one of the following two:

- VBUF write address – VBUF frame start address > CBUF size
- VBUF write address – VBUF last read address > CBUF size

If an overflow condition is detected on a CBUF write access, the OCM controller generates a CBUF overflow (`Cbuf_overflow_wrap` or `Cbuf_overflow_mid`) interrupt and enter an overflow error handling state. In this state, the OCM controller do the following in the default error handling configuration:

- When a `Cbuf_Overflow_Wrap` condition occurs (write buffer wraparound with read from previous frame still remaining), writes are disabled but reads are serviced normally. This mechanism preserves the back end of the previous frame and discards the new frame which is already showing signs of overflowing. Writes will be re-enabled automatically on write to the virtual frame start address which indicates the next frame after the overflowed frame has begun. The overflow (and underflow) check for this CBUF will be disabled until detection of write to/read from the virtual frame start address. The module which reads should not start reading the next frame (which is being discarded) or stop reading the frame if the read of this new frame has already started. This mechanism allows both write and read sides to re-synchronize on the next frame after one-frame drop.
- When a `Cbuf_Overflow_Mid` condition occurs, writes and reads are serviced normally allowing the read side to catch up to the write side. The overflow (and underflow) check will be disabled until first a write to the virtual frame start address and then a read from the virtual frame start address is detected. This mechanism allows the frame with a “momentary” overflow condition to be saved. The reader side has an option to stop reading and discarding the data by just resetting its CBUF read pointer at the next frame start, if the read side is too far back.

These steps are taken to minimize the frame loss due to an overflow condition. To support the previously described behavior but to allow software to override the default error handling behavior the following controls are available:

- [CFG\\_OCMC\\_CBUF\\_ERR\\_HANDLER\[7:6\]](#) OVERFLOW\_CHECK\_REENABLE\_SEL
- [CFG\\_OCMC\\_CBUF\\_ERR\\_HANDLER\[5:4\]](#) OVERFLOW\_WRITE\_HANDLER\_SEL

In addition, the overflow check can be enabled or disabled through the [CFG\\_OCMC\\_CBUF\\_ERR\\_HANDLER\[2\]](#) OVERFLOW\_ERR\_CHECK\_EN bit.

### 15.6.3.11.6 CBUF Underflow

According to the CBUF operation a read request can only be made when there are enough number of video lines written to the CBUF. Therefore, there should not be any underflow conditions due to normal processing speed variations. An underflow condition occurs when the VBUF read address is greater than the last VBUF write address. To detect an abnormal failure in the read/write mechanism which could cause an underflow condition, each valid CBUF read access is checked for an underflow condition and if detected, an underflow interrupt is generated for the selected CBUF. The [STATUS\\_CBUF\\_UNDERFLOW\[11:0\]](#) CBUF\_ERR bit field has status flags indicating when underflow occurs. This interrupt condition exists until the corresponding underflow status bit in the [STATUS\\_CBUF\\_UNDERFLOW](#) register is cleared.

If an underflow is detected on a CBUF read access, the OCM controller generates an underflow interrupt and continues to perform reads and writes normally, but the return data will not be correct while the underflow condition exists.

To avoid a false underflow detection at the end of a frame (due to external decoders sending short last line or due to interlaced input video having different number of lines in even/odd fields), the [CFG\\_OCMC\\_CBUF\\_ERR\\_HANDLER\[8\]](#) UNDERFLOW\_LAST\_CBUF\_SLICE\_DISABLE bit can be set to 0x1 which disables the underflow checking in the last CBUF slice.

The [INTR0\\_STATUS\\_RAW\\_SET\[13\]](#) CBUF\_UNDERFLOW\_ERR\_FOUND/[INTR1\\_STATUS\\_RAW\\_SET\[13\]](#) CBUF\_UNDERFLOW\_ERR\_FOUND bit is asserted if at least one of the bits in the [STATUS\\_CBUF\\_UNDERFLOW\[11:0\]](#) CBUF\_ERR bit field is set to 0x1.

In addition, the underflow check can be enabled or disabled through the [CFG\\_OCMC\\_CBUF\\_ERR\\_HANDLER\[3\]](#) UNDERFLOW\_ERR\_CHECK\_EN bit.

### 15.6.3.12 Status Reporting

The OCM controller keeps a history of last valid write and read addresses for each CBUF. The [CBUF\\_k\\_LAST\\_WR\\_ADDR](#) register stores the address for the last valid write and the [CBUF\\_k\\_LAST\\_RD\\_ADDR](#) register stores the address for the last valid read access.

The OCMC\_ECC generates also a general VBUF mode error event for an access made with illegal VBUF address. The [INTR0\\_STATUS\\_RAW\\_SET\[3\]](#) OUT\_OF\_RANGE\_ERR\_FOUND/[INTR1\\_STATUS\\_RAW\\_SET\[3\]](#) OUT\_OF\_RANGE\_ERR\_FOUND bit indicates for this event.

## 15.6.4 OCM Subsystem Register Manual

### 15.6.4.1 OCM Subsystem Instance Summary

**Table 15-656. OCM Subsystem Instance Summary**

Module Name	Module Base Address	Size
OCMC_RAM1	0x4880 4000	4KiB
OCMC_RAM2	0x4880 A000	4KiB
OCMC_RAM3	0x4881 0000	4KiB

**NOTE:** OCMC\_RAM2 and OCMC\_RAM3 banks are not present on DRA74x devices, but are included in some of the DRA75x devices. For details, see the device data manual.

<b>Description</b>			
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								CFG_ECC_OPT_NON_ECC_READ	CFG_ECC_ERR_SRESP_EN	CFG_ECC_SEC_AUTO_CORRECT	CFG_OCMC_MODE				

Bits	Field Name	Description	Type	Reset
31:6	RESERVED		R	0x0
5	CFG_ECC_OPT_NON_ECC_READ	Optimize read latency for non-ECC read. Returns the data one cycle faster if the read access is from a non-ECC enabled space. 0x0: Disable 0x1: Enable	RW	0x0
4	CFG_ECC_ERR_SRESP_EN	ECC non-correctable error SRESP enable. Enables ERR return on L3 OCP SRESP when a non-correctable data (DED) or address error is detected. 0x0: Disable 0x1: Enable	RW	0x0
3	CFG_ECC_SEC_AUTO_CORRECT	SEC error auto correction mode. Enables the OCM Controller to automatically update the wrong data word with the corrected word. 0x0: Disable 0x1: Enable (If the OCM Controller is performing a read-modify operation for a sub-128b write to an ECC enabled memory, the error found during the read phase will be corrected always regardless of the value of this bit)	RW	0x0
2:0	CFG_OCMC_MODE	OCM Controller memory access modes. 0x0: Non-ECC mode (data access) 0x1: Non-ECC mode (code access) 0x2: Full ECC enabled mode 0x3: Block ECC enabled mode 0x4-0x7: Reserved (internally defaults to 0x0 mode)	RW	0x0

<b>Physical Address</b>	0x4880 4204 0x4880 A204 0x4881 0204		
<b>Description</b>	Writing 1 to bit n will set a reset bit to clear the corresponding CBUF_n address translation logic. Sliding CBUF frame tracking will be cleared so that the CBUF now points to the base of the virtual frame buffer. Normally, a reset is not required since the CBUF logic will clear itself when a VBUF access is to the base of the virtual frame.

## DMA Controllers

---

---

---

This chapter describes the features and operation of the device System DMA (DMA\_SYSTEM) and Enhanced DMA (EDMA) controllers.

Topic	Page
16.1 System DMA.....	3986
16.2 Enhanced DMA.....	4070

## 16.1 System DMA

This chapter describes the system direct memory access (DMA\_SYSTEM) module.

### 16.1.1 DMA\_SYSTEM Module Overview

The system direct memory access (DMA\_SYSTEM) module, also called DMA4, performs high-performance data transfers between memories and peripheral devices without microprocessor unit (MPU) or digital signal processor (DSP) support during transfer. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

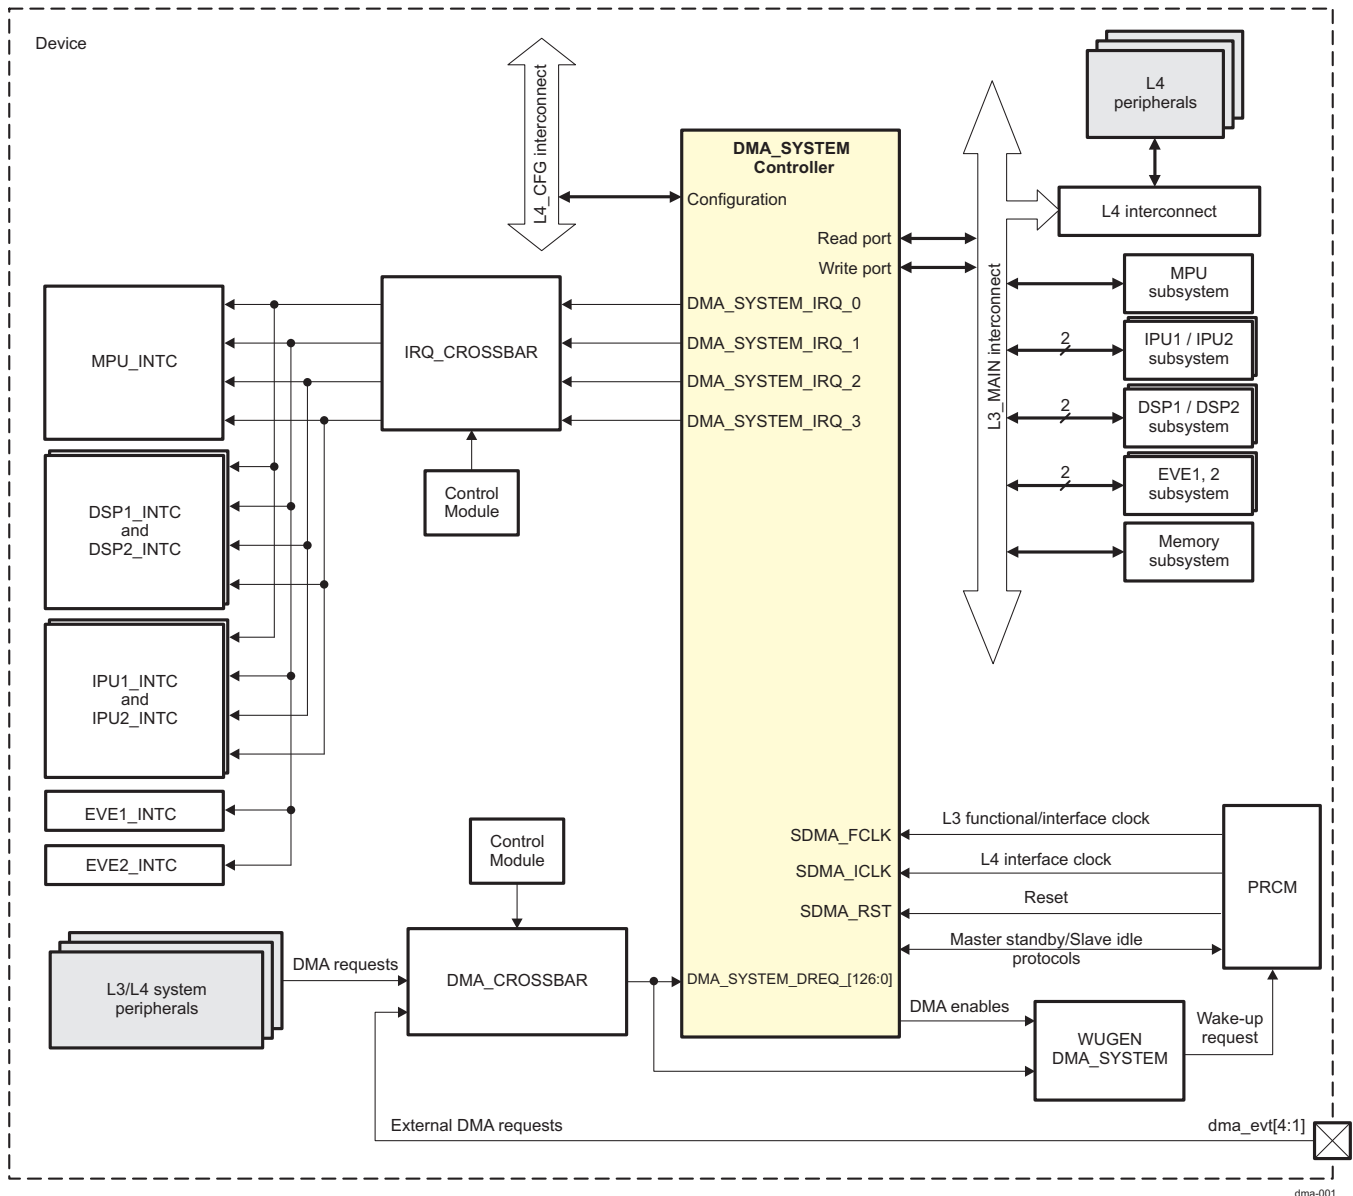

The DMA controller includes the following main features:

- Data transfer support in either direction between:
  - Memory and memory
  - Memory and peripheral device
- 32 logical DMA channels supporting:
  - Multiple concurrent transfers
  - Independent transfer profile for each channel
  - 8-bit, 16-bit, or 32-bit data element transfer size
  - Software-triggered or hardware-synchronized transfers
  - Flexible source and destination address generation
  - Burst read and write - max burst size is 16
  - Chained multiple-channel transfers
  - Endianism conversion
  - Draining
  - Linked-list support for descriptor types 1, 2, and 3
- First-come, first-serve DMA scheduling with fixed priority
- Up to 127 Hardware DMA requests
- DMA\_CROSSBAR
- Constant fill
- Transparent copy
- Four programmable interrupt request output lines
- FIFO depth: 256 x 64-bit
- Data buffering
- FIFO budget allocation
- Power-management support
- Auto-idle power-saving support

Figure 16-1 shows an overview of the DMA\_SYSTEM module.

Figure 16-1. DMA\_SYSTEM Overview

The DMA\_SYSTEM module has three ports: one read, one write, and one configuration port, and provides multiple logical channel support. A dynamically allocated FIFO queue memory pool provides buffering between the read and write ports, which are multithreaded (two threads for the write port and four threads for the read port); this means that each transaction is flagged by a thread ID (0, 1, 2, or 3) in the request direction and in the response direction. This allows the read port to have four outstanding requests at a time. The write port has two threads budget available.

The MPU (or DSP) configures the DMA\_SYSTEM through the L4\_CFG interconnect.

## 16.1.2 DMA\_SYSTEM Controller Environment

The DMA\_SYSTEM controller supports external DMA requests through the dma\_evt[4:1] pins (see Table 16-1). A logical channel can be configured to respond to an external synchronization request.

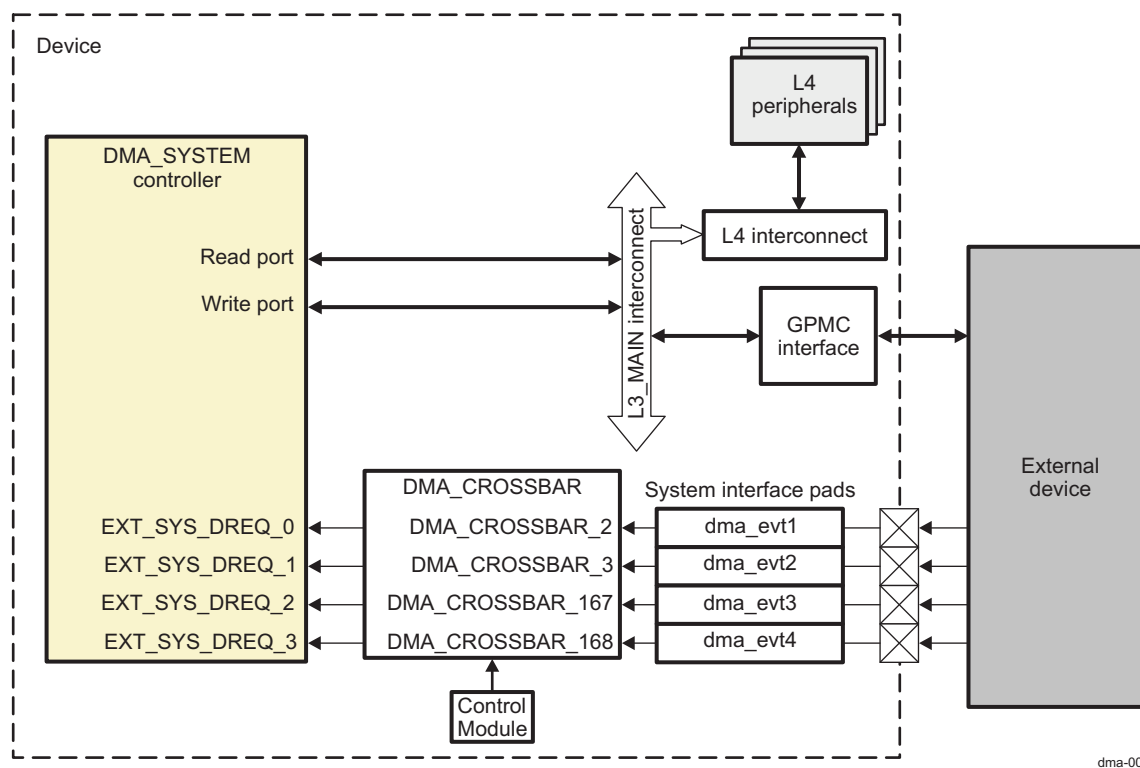

**Table 16-1. External DMA\_SYSTEM Request Signals**

Pin Name	DMA_CROSSBAR Input	Signal Name	I/O <sup>(1)</sup>	Description	Module Reset Value
dma_evt1	DMA_CROSSBAR_2	EXT_SYS_DREQ_0	I	External DMA request 0 (system expansion)	Z
dma_evt2	DMA_CROSSBAR_3	EXT_SYS_DREQ_1	I	External DMA request 1 (system expansion)	Z
dma_evt3	DMA_CROSSBAR_167	EXT_SYS_DREQ_2	I	External DMA request 2 (system expansion)	Z
dma_evt4	DMA_CROSSBAR_168	EXT_SYS_DREQ_3	I	External DMA request 3 (system expansion)	Z

<sup>(1)</sup> I = Input, O = Output

Figure 16-2 shows an example of how to use the external hardware DMA request pins in the DMA\_SYSTEM environment.

**Figure 16-2. Example of External DMA Requests Use**

An external device can use the external DMA request pins to start a logical channel transfer over the general-purpose memory controller (GPMC) interface. The transfer can be a memory-to-memory transfer in which the source memory is in the external device.

By default, the external DMA request signals are not available on external pins after a cold reset. For more information about multiplexing out the two signal lines to pins, see [Section 18.4.6.1.1, Pad Configuration Registers](#) in the [Chapter 18, Control Module](#).

All 127 DMA request lines are transition sensitive.

For a transition-sensitive DMA request (see [Figure 16-3](#)), the line must be maintained low (asserted) until the first DMA access is complete, after which the line must be maintained high (deasserted) for greater than one clock cycle (DMA\_L3\_GICLK):

- When the deassertion time is less than one clock cycle, the DMA\_SYSTEM may not detect the deassertion.
- When the channel is enabled one cycle after a DMA request is disabled, the channel detects the DMA request and starts the corresponding transfer.
- When the channel is enabled two cycles after the DMA request is disabled, the channel does not detect the DMA request.

**Figure 16-3. Transition-Sensitive DMA Request Scheme**

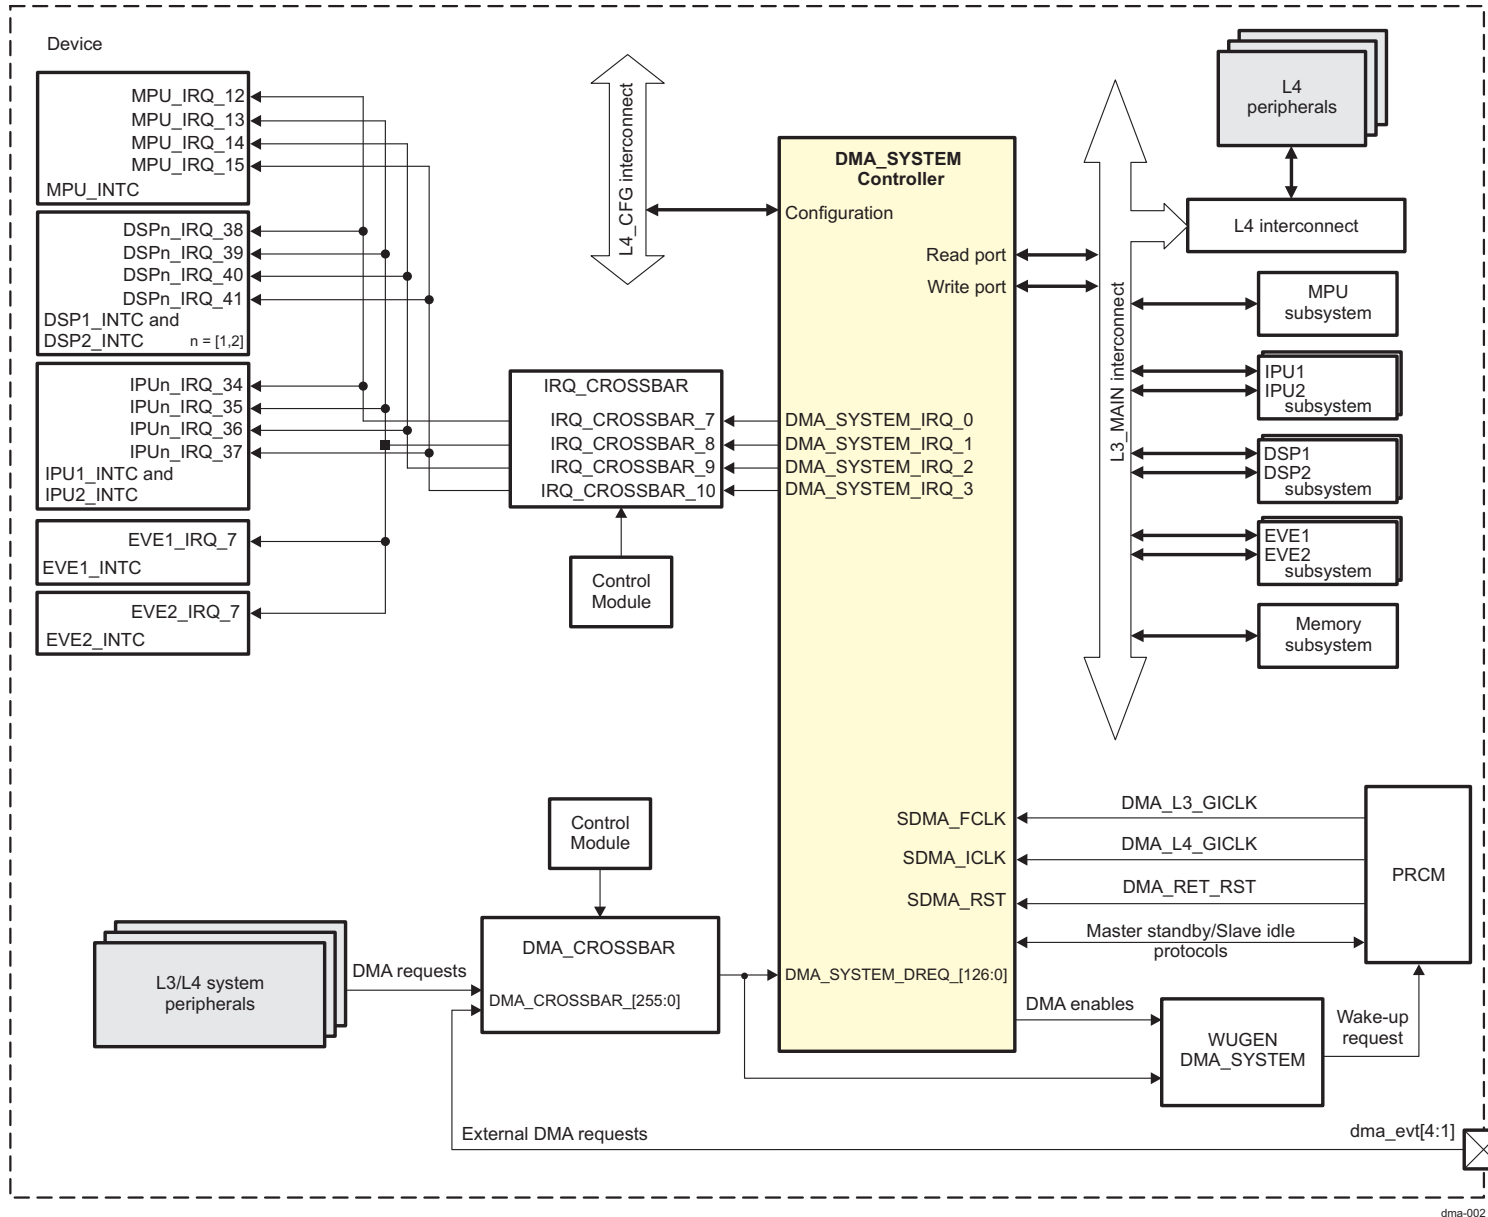

dma-012

### 16.1.3 DMA\_SYSTEM Module Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

[Figure 16-4](#) shows the DMA\_SYSTEM controller integration.

Figure 16-4. DMA\_SYSTEM Controller Integration

dma-002

**NOTE:** For more information about the system DMA wake-up generator (WUGEN\_DMA\_SYSTEM), the master standby/slave idle protocols, and the wake-up request, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 16-2](#) through [Table 16-4](#) summarize the integration of the module in the device.

**Table 16-2. DMA\_SYSTEM Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect
DMA_SYSTEM	PD_COREAON	L3_MAIN and L4_CFG

**Table 16-3. DMA\_SYSTEM Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
DMA_SYSTEM	SDMA_FCLK	DMA_L3_GICLK	PRCM	Functional clock for all internal logic and for the two master read and write ports. For information about the power, reset, and clock management (PRCM) clock gating and management, see <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
	SDMA_ICLK	DMA_L4_GICLK		Interface clock. It supports the configuration port. For information about PRCM clock gating and management, see <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
DMA_SYSTEM	SDMA_RST	DMA_RET_RST	PRCM	Hardware retention reset. It initializes all internal logic of the DMA_SYSTEM module, all global registers, and some of the per-channel registers, implemented in flip-flops. However, all remaining per-channel registers are memory-based, and, therefore, are not reset (have undefined values). Thus, when programming a channel for the first time, all bits that have undefined reset values must be configured before enabling the channel. For information about PRCM reset sources and distribution, see <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .

**Table 16-4. DMA\_SYSTEM Hardware Requests**

Interrupt Requests					
Module Instance	Source Signal Name	Destination IRQ_CROSSBAR INPUT	Default Mapping	Destination	Description
DMA_SYSTEM	DMA_SYSTEM_IRQ_0	IRQ_CROSSBAR_7	MPU_IRQ_12	Cortex-A15 MPU INTC	DMA_SYSTEM interrupt request 0. For information about the MPU_INTC, see <a href="#">Section 17.3.1 Interrupt Requests to MPU_INTC</a> .

**Table 16-4. DMA\_SYSTEM Hardware Requests (continued)**

		DSP1_IRQ_39	DSP1 INTC	
		DSP2_IRQ_39	DSP2 INTC	
		EVE1_IRQ_7	EVE1 INTC	DMA_SYSTEM interrupt request 1. For information about the EVE1_INTC, see <i>Interrupt Requests to EVE1_INTC</i> .
		EVE2_IRQ_7	EVE2 INTC	DMA_SYSTEM interrupt request 1. For information about the EVE2_INTC, see <i>Interrupt Requests to EVE2_INTC</i> .
DMA_SYSTEM_IRQ_2	IRQ_CROSSBAR_9	MPU_IRQ_14	Cortex-A15 MPU INTC	DMA_SYSTEM interrupt request 2
		IPU1_IRQ_36	IPU1 INTC	
		IPU2_IRQ_36	IPU2 INTC	
		DSP1_IRQ_40	DSP1 INTC	
		DSP2_IRQ_40	DSP2 INTC	
DMA_SYSTEM_IRQ_3	IRQ_CROSSBAR_10	MPU_IRQ_15	Cortex-A15 MPU INTC	DMA_SYSTEM interrupt request 3
		IPU1_IRQ_37	IPU1 INTC	
		IPU2_IRQ_37	IPU2 INTC	
		DSP1_IRQ_41	DSP1 INTC	
		DSP2_IRQ_41	DSP2 INTC	

---

**NOTE:** The “**Default Mapping**” column in [Table 16-4 Hardware Requests](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ\_CROSSBAR or DMA\_CROSSBAR modules.

For more information about the IRQ\_CROSSBAR and DMA\_CROSSBAR modules, see sections: [Section 18.4.6.4 IRQ\\_CROSSBAR Module Functional Description](#) and [DMA\\_CROSSBAR Module Functional Description](#), in [Chapter 18 Control Module](#).

For more information about the device interrupt controllers, refer to [Chapter 17 Interrupt Controllers](#) in the device TRM.

---

**NOTE:** For a description of the interrupt source, see [Section 16.1.4.2, DMA\\_SYSTEM Controller Interrupt Requests](#).

---

### 16.1.3.1 DMA Requests to the DMA\_SYSTEM Controller

[Table 16-5](#) lists the default DMA sources for the DMA\_SYSTEM controller. In addition, the DMA\_SYSTEM inputs (DMA\_SYSTEM\_DREQ\_[126:0]) can alternatively be sourced through the associated DMA\_CROSSBAR from one of the 256 multiplexed device DMA sources listed in [Table 16-6](#). The CTRL\_CORE\_DMA\_SYSTEM\_DREQ\_y\_z registers (where y and z are indexes of DMA\_SYSTEM input lines) in the Control Module are used to select between the default DMA sources and the multiplexed DMA sources.

**Table 16-5. DMA\_SYSTEM Default Request Mapping**

DMA Request Line	DMA CROSSBAR Instance Number	DMA_CROSSBAR Configuration Register	DMA CROSSBAR Default Input Index	Default DMA Source Name	Default DMA Source Description
DMA_SYSTEM_DREQ_0	1	<a href="#">CTRL_CORE_DMA_SYSTEM_DREQ_0_1</a> [7:0]	1	Reserved	Reserved by default but can be remapped to a valid DMA source

### 16.1.3.2 Mapping of DMA Requests to DMA\_CROSSBAR Inputs

**NOTE:** For information about the DMA\_CROSSBAR module, refer to [Section 18.4.6.5](#), *DMA\_CROSSBAR Module Functional Description* in [Chapter 18](#), *Control Module*.

[Table 16-6](#) shows the mapping of device DMA requests to DMA\_CROSSBAR inputs.

**Table 16-6. Connection of The Device DREQs to The DMA\_CROSSBAR Inputs**

DMA_CROSSBAR Input	Device Module DREQs	Description
DMA_CROSSBAR_0	Reserved	Reserved
DMA_CROSSBAR_1	Reserved	Reserved
DMA_CROSSBAR_2	EXT_SYS_DREQ_0	External DMA request 0 (system expansion) - coming from SOC I/Os. Level sensitive only
DMA_CROSSBAR_3	EXT_SYS_DREQ_1	External DMA request 1 (system expansion) - coming from SOC I/Os - level sensitive only
DMA_CROSSBAR_4	GPMC_DREQ	GPMC request from prefetch engine
DMA_CROSSBAR_5	Reserved	Reserved
DMA_CROSSBAR_6	DISPC_DREQ	The line trigger signal to synchronize a memory to memory logical channel in the DMA4 (system DMA) is generated by the Display Controller IP.
DMA_CROSSBAR_7	CT_TBR_DREQ	DMA request coming from CT_TBR in DEBUGSS (used to be External DMA request 2 - coming from SOC I/Os)
DMA_CROSSBAR_8 to DMA_CROSSBAR_14	Reserved	Reserved
DMA_CROSSBAR_15	MCSPI3_DREQ_TX0	McSPI module 3 - transmit request channel 0
DMA_CROSSBAR_16	MCSPI3_DREQ_RX0	McSPI module 3 - receive request channel 0
DMA_CROSSBAR_17 to DMA_CROSSBAR_22	Reserved	Reserved
DMA_CROSSBAR_23	MCSPI3_DREQ_TX1	McSPI module 3 - transmit request channel 1
DMA_CROSSBAR_24	MCSPI3_DREQ_RX1	McSPI module 3 - receive request channel 1
DMA_CROSSBAR_25	I2C3_DREQ_TX	I2C module 3 - transmit request
DMA_CROSSBAR_26	I2C3_DREQ_RX	I2C module 3 - receive request
DMA_CROSSBAR_27	I2C1_DREQ_TX	I2C module 1 - transmit request
DMA_CROSSBAR_28	I2C1_DREQ_RX	I2C module 1 - receive request
DMA_CROSSBAR_29	I2C2_DREQ_TX	I2C module 2 - transmit request
DMA_CROSSBAR_30	I2C2_DREQ_RX	I2C module 2 - receive request
DMA_CROSSBAR_31 to DMA_CROSSBAR_34	Reserved	Reserved
DMA_CROSSBAR_35	MCSPI1_DREQ_TX0	McSPI module 1 - transmit request channel 0
DMA_CROSSBAR_36	MCSPI1_DREQ_RX0	McSPI module 1 - receive request channel 0
DMA_CROSSBAR_37	MCSPI1_DREQ_TX1	McSPI module 1 - transmit request channel 1
DMA_CROSSBAR_38	MCSPI1_DREQ_RX1	McSPI module 1 - receive request channel 1
DMA_CROSSBAR_39	MCSPI1_DREQ_TX2	McSPI module 1 - transmit request channel 2
DMA_CROSSBAR_40	MCSPI1_DREQ_RX2	McSPI module 1 - receive request channel 2
DMA_CROSSBAR_41	MCSPI1_DREQ_TX3	McSPI module 1 - transmit request channel 3
DMA_CROSSBAR_42	MCSPI1_DREQ_RX3	McSPI module 1 - receive request channel 3
DMA_CROSSBAR_43	MCSPI2_DREQ_TX0	McSPI module 2 - transmit request channel 0
DMA_CROSSBAR_44	MCSPI2_DREQ_RX0	McSPI module 2 - receive request channel 0
DMA_CROSSBAR_45	MCSPI2_DREQ_TX1	McSPI module 2 - transmit request channel 1
DMA_CROSSBAR_46	MCSPI2_DREQ_RX1	McSPI module 2 - receive request channel 1
DMA_CROSSBAR_47	MMC2_DREQ_TX	MMC/SD2 transmit request
DMA_CROSSBAR_48	MMC2_DREQ_RX	MMC/SD2 receive request
DMA_CROSSBAR_49	UART1_DREQ_TX	UART module 1 - transmit request

**Table 16-6. Connection of The Device DREQs to The DMA\_CROSSBAR Inputs (continued)**

DMA_CROSSBAR Input	Device Module DREQs	Description
DMA_CROSSBAR_50	UART1_DREQ_RX	UART module 1 - receive request
DMA_CROSSBAR_51	UART2_DREQ_TX	UART module 2 - transmit request
DMA_CROSSBAR_52	UART2_DREQ_RX	UART module 2 - receive request
DMA_CROSSBAR_53	UART3_DREQ_TX	UART module 3 - transmit request (Also infrared - IRDA)
DMA_CROSSBAR_54	UART3_DREQ_RX	UART module 3 - receive request (Also infrared - IRDA)
DMA_CROSSBAR_55	UART4_DREQ_TX	UART module 4 – transmit request
DMA_CROSSBAR_56	UART4_DREQ_RX	UART module 4 – receive request
DMA_CROSSBAR_57	MMC4_DREQ_TX	MMC/SD4 transmit request
DMA_CROSSBAR_58	MMC4_DREQ_RX	MMC/SD4 receive request
DMA_CROSSBAR_59	Reserved	Reserved
DMA_CROSSBAR_60	Reserved	Reserved
DMA_CROSSBAR_61	MMC1_DREQ_TX	MMC/SD1 transmit request
DMA_CROSSBAR_62	MMC1_DREQ_RX	MMC/SD1 receive request
DMA_CROSSBAR_63	UART5_DREQ_TX	UART module 5 – transmit request (used to be External DMA request 3 - coming from SOC IOs)
DMA_CROSSBAR_64	UART5_DREQ_RX	UART module 5 – receive request (used to be USIM receive request)
DMA_CROSSBAR_65 to DMA_CROSSBAR_69	Reserved	Reserved
DMA_CROSSBAR_70	MCSPi4_DREQ_TX0	McSPI module 4 - transmit request channel 0
DMA_CROSSBAR_71	MCSPi4_DREQ_RX0	McSPI module 4 - receive request channel 0
DMA_CROSSBAR_72 to DMA_CROSSBAR_75	Reserved	Reserved
DMA_CROSSBAR_76	DSS_DREQ	Display subsystem HDMI Audio DMA request
DMA_CROSSBAR_77	MMC3_DREQ_TX	MMC/SD3 transmit request
DMA_CROSSBAR_78	MMC3_DREQ_RX	MMC/SD3 receive request
DMA_CROSSBAR_79	UART6_DREQ_TX	UART module 6 – transmit request (used to be USIM transmit request)
DMA_CROSSBAR_80	UART6_DREQ_RX	UART module 6 – receive request (used to be USIM receive request)
DMA_CROSSBAR_81 to DMA_CROSSBAR_123	Reserved	Reserved
DMA_CROSSBAR_124	I2C4_DREQ_TX	I2C module 4 - transmit request
DMA_CROSSBAR_125	I2C4_DREQ_RX	I2C module 4 - receive request
DMA_CROSSBAR_126	Reserved	Reserved
DMA_CROSSBAR_127	Reserved	Reserved
DMA_CROSSBAR_128	McASP1_DREQ_RX	McASP receive event
DMA_CROSSBAR_129	McASP1_DREQ_TX	McASP transmit event
DMA_CROSSBAR_130	McASP2_DREQ_RX	McASP receive event
DMA_CROSSBAR_131	McASP2_DREQ_TX	McASP transmit event
DMA_CROSSBAR_132	McASP3_DREQ_RX	McASP receive event
DMA_CROSSBAR_133	McASP3_DREQ_TX	McASP transmit event
DMA_CROSSBAR_134	McASP4_DREQ_RX	McASP receive event
DMA_CROSSBAR_135	McASP4_DREQ_TX	McASP transmit event
DMA_CROSSBAR_136	McASP5_DREQ_RX	McASP receive event
DMA_CROSSBAR_137	McASP5_DREQ_TX	McASP transmit event
DMA_CROSSBAR_138	McASP6_DREQ_RX	McASP receive event
DMA_CROSSBAR_139	McASP6_DREQ_TX	McASP transmit event
DMA_CROSSBAR_140	McASP7_DREQ_RX	McASP receive event

**Table 16-6. Connection of The Device DREQs to The DMA\_CROSSBAR Inputs (continued)**

DMA_CROSSBAR Input	Device Module DREQs	Description
DMA_CROSSBAR_141	McASP7_DREQ_TX	McASP transmit event
DMA_CROSSBAR_142	McASP8_DREQ_RX	McASP receive event
DMA_CROSSBAR_143	McASP8_DREQ_TX	McASP receive event
DMA_CROSSBAR_144	UART7_DREQ_TX	UART module 7 - transmit request
DMA_CROSSBAR_145	UART7_DREQ_RX	UART module 7 - receive request
DMA_CROSSBAR_146	UART8_DREQ_TX	UART module 8 - transmit request
DMA_CROSSBAR_147	UART8_DREQ_RX	UART module 8 - receive request
DMA_CROSSBAR_148	UART9_DREQ_TX	UART module 9 - transmit request
DMA_CROSSBAR_149	UART9_DREQ_RX	UART module 9 - receive request
DMA_CROSSBAR_150	UART10_DREQ_TX	UART module 10 - transmit request
DMA_CROSSBAR_151	UART10_DREQ_RX	UART module 10 - receive request
DMA_CROSSBAR_152	I2C5_DREQ_TX	I2C module 5 - transmit request
DMA_CROSSBAR_153	I2C5_DREQ_RX	I2C module 5 - receive request
DMA_CROSSBAR_154	VCP1_DREQ_RX	VCP RX Event
DMA_CROSSBAR_155	VCP1_DREQ_TX	VCP TX Event
DMA_CROSSBAR_156	VCP2_DREQ_RX	VCP RX Event
DMA_CROSSBAR_157	VCP2_DREQ_TX	VCP TX Event
DMA_CROSSBAR_158	DCAN1_DREQ_IF1	DCAN IF1 Event
DMA_CROSSBAR_159	DCAN1_DREQ_IF2	DCAN IF2 Event
DMA_CROSSBAR_160	DCAN1_DREQ_IF3	DCAN IF3 Event
DMA_CROSSBAR_161	DCAN2_DREQ_IF1	DCAN IF1 Event
DMA_CROSSBAR_162	DCAN2_DREQ_IF2	DCAN IF2 Event
DMA_CROSSBAR_163	DCAN2_DREQ_IF3	DCAN IF3 Event
DMA_CROSSBAR_164 to DMA_CROSSBAR_166	Reserved	Reserved
DMA_CROSSBAR_167	EXT_SYS_DREQ_2	External DMA request 2 (system expansion) - coming from SOC IOs. Level sensitive only
DMA_CROSSBAR_168	EXT_SYS_DREQ_3	External DMA request 3 (system expansion) - coming from SOC IOs. Level sensitive only
DMA_CROSSBAR_169	MCSPi2_DREQ_TX2	McSPI module 2 - transmit request channel 2
DMA_CROSSBAR_170	MCSPi2_DREQ_RX2	McSPI module 2 - receive request channel 2
DMA_CROSSBAR_171	MCSPi2_DREQ_TX3	McSPI module 2 - transmit request channel 3
DMA_CROSSBAR_172	MCSPi2_DREQ_RX3	McSPI module 2 - receive request channel 3
DMA_CROSSBAR_173	MCSPi3_DREQ_TX2	McSPI module 3 - transmit request channel 2
DMA_CROSSBAR_174	MCSPi3_DREQ_RX2	McSPI module 3 - receive request channel 2
DMA_CROSSBAR_175	MCSPi3_DREQ_TX3	McSPI module 3 - transmit request channel 3
DMA_CROSSBAR_176	MCSPi3_DREQ_RX3	McSPI module 3 - receive request channel 3
DMA_CROSSBAR_177	MCSPi4_DREQ_TX1	McSPI module 4 - transmit request channel 1
DMA_CROSSBAR_178	MCSPi4_DREQ_RX1	McSPI module 4 - receive request channel 1
DMA_CROSSBAR_179	MCSPi4_DREQ_TX2	McSPI module 4 - transmit request channel 2
DMA_CROSSBAR_180	MCSPi4_DREQ_RX2	McSPI module 4 - receive request channel 2
DMA_CROSSBAR_181	MCSPi4_DREQ_TX3	McSPI module 4 - transmit request channel 3
DMA_CROSSBAR_182	MCSPi4_DREQ_RX3	McSPI module 4 - receive request channel 3
DMA_CROSSBAR_183 to DMA_CROSSBAR_186	Reserved	Reserved
DMA_CROSSBAR_187	GPIO1_DREQ_EVT	GPIO module 1 - event/interrupt 1
DMA_CROSSBAR_188	GPIO2_DREQ_EVT	GPIO module 2 - event/interrupt 1
DMA_CROSSBAR_189	GPIO3_DREQ_EVT	GPIO module 3 - event/interrupt 1
DMA_CROSSBAR_190	GPIO4_DREQ_EVT	GPIO module 4 - event/interrupt 1

**Table 16-6. Connection of The Device DREQs to The DMA\_CROSSBAR Inputs (continued)**

<b>DMA_CROSSBAR Input</b>	<b>Device Module DREQs</b>	<b>Description</b>
DMA_CROSSBAR_191	GPIO5_DREQ_EVT	GPIO module 5 - event/interrupt 1
DMA_CROSSBAR_192	GPIO6_DREQ_EVT	GPIO module 6 - event/interrupt 1
DMA_CROSSBAR_193	GPIO7_DREQ_EVT	GPIO module 7 - event/interrupt 1
DMA_CROSSBAR_194	GPIO8_DREQ_EVT	GPIO module 8 - event/interrupt 1
DMA_CROSSBAR_195	PWMSS1_DREQ_ePWM0_EVT	eHRPWM0 event/interrupt
DMA_CROSSBAR_196	PWMSS2_DREQ_ePWM1_EVT	eHRPWM1 event/interrupt
DMA_CROSSBAR_197	PWMSS3_DREQ_ePWM2_EVT	eHRPWM2 event/interrupt
DMA_CROSSBAR_198	PWMSS1_DREQ_eQEP0_EVT	eQEP0 event/interrupt
DMA_CROSSBAR_199	PWMSS2_DREQ_eQEP1_EVT	eQEP1 event/interrupt
DMA_CROSSBAR_200	PWMSS3_DREQ_eQEP2_EVT	eQEP2 event/interrupt
DMA_CROSSBAR_201	PWMSS1_DREQ_eCAP0_EVT	eCAP0 event/interrupt
DMA_CROSSBAR_202	PWMSS2_DREQ_eCAP1_EVT	eCAP1 event/interrupt
DMA_CROSSBAR_203	PWMSS3_DREQ_eCAP2_EVT	eCAP2 event/interrupt
DMA_CROSSBAR_204 to DMA_CROSSBAR_255	Reserved	Reserved

### 16.1.4 DMA\_SYSTEM Functional Description

The DMA\_SYSTEM module provides high-performance data transfers between memories and peripheral devices with low processor use. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

Figure 16-5 shows the DMA\_SYSTEM controller top-level block diagram.

Figure 16-5. DMA\_SYSTEM Controller Top-Level Block Diagram

dma-005

#### 16.1.4.1 DMA\_SYSTEM Controller Power Management

Table 16-7 describes power-management features available for the DMA\_SYSTEM controller.

**NOTE:**

- For information about source clock gating and sleep/wake-up transitions, see section [Section 3.1.1.1 Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- For a description of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.1.1.2 Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

**Table 16-7. Local Power-Management Features**

Feature	Registers	Description
Clock auto gating	<a href="#">DMA4_OCP_SYSCONFIG</a> [0] AUTOIDLE bit	This bit allows local power optimization inside the module by gating the SDMA_ICLK clock upon the interface activity.
Slave idle modes	<a href="#">DMA4_OCP_SYSCONFIG</a> [4:3] SIDLEMODE bit field	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	<a href="#">DMA4_OCP_SYSCONFIG</a> [9:8] CLOCKACTIVITY bit field	For configuration details, see <a href="#">Table 16-8</a> .
Master standby modes	<a href="#">DMA4_OCP_SYSCONFIG</a> [13:12] MIDLEMODE bit field	Force-standby, no-standby, and smart-standby modes are available.
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	N/A	Feature not available

**Table 16-8. Clock Activity Settings**

SDMA_CLOCKACTIVITY Values	Clock State When Module is in IDLE State	
	SDMA_ICLK	SDMA_FCLK
00	Off	Off
10	Off	On
01	On	Off
11	On	On

**CAUTION**

Because the PRCM module cannot read CLOCKACTIVITY settings through hardware, software must ensure consistent programming between the SDMA\_CLOCKACTIVITY and DMA\_SYSTEM clock PRCM control bits. For a description of the ClockActivity feature, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

**16.1.4.2 DMA\_SYSTEM Controller Interrupt Requests**

DMA4 has four interrupt lines (L<sub>j</sub>, where j = 0, 1, 2, 3). Each logical channel can request an interrupt over any line. The attachment of a channel interrupt event to one of these four external lines is programmable. Software determines whether it attaches a channel interrupt to a single IRQ line or to multiple IRQ lines.

There are two different registers per interrupt line:

- The [DMA4\\_IRQSTATUS\\_Lj](#) CH\_31\_0\_Lj field shows the status of the different sources of interrupt. If the [DMA4\\_IRQENABLE\\_Lj](#) bit is 1, channel *i* is the source of interrupt in line *j*. In contrast to the [DMA4\\_CSRi](#) registers, the [DMA4\\_IRQSTATUS\\_Lj](#) registers are updated regardless of the corresponding bits in the [DMA4\\_IRQENABLE\\_Lj](#) registers.
- The [DMA4\\_IRQENABLE\\_Lj](#) CH\_31\_0\_Lj\_EN field masks/unmasks the channel interrupt. If the [DMA4\\_IRQENABLE\\_Lj](#) bit is set to 0, channel interrupt *i* of the line *j* is masked.

Each logical channel can generate a number of different interrupt events when enabled (that is, set to 1) in the [DMA4\\_CICRi](#) register. Each status bit is updated in the [DMA4\\_CSRi](#) register only when the corresponding enable bit is enabled in the [DMA4\\_CICRi](#) register.

To determine an interrupt source when an interrupt rises on an interrupt line L<sub>j</sub>:

- Identify the channel (LCH<sub>i</sub>) generating the interrupt.  
Read [DMA4\\_IRQSTATUS\\_Lj.LCHi](#) (LCH<sub>0</sub> to LCH<sub>3</sub>). If LCH<sub>*i*</sub> = 1, channel *i* is the originator of the interrupt.
- Identify the interrupt event.

Read the LCHi [DMA4\\_CSRi](#). For example, if the drop event (the [DMA4\\_CSRi\[1\]](#) DROP bit) is 1, a request collision will occur.

The interrupt event status bit in the [DMA4\\_CSRi](#) register is immediately reset after it is written to 1.

The interrupt status bit in the [DMA4\\_IRQSTATUS\\_Lj](#) register is cleared after it is written to 1.

### 16.1.4.2.1 Interrupt Generation

The DMA\_SYSTEM module has four interrupt request output lines, DMA\_SYSTEM\_IRQ\_0 to DMA\_SYSTEM\_IRQ\_3. One or more logical channels can be programmed to generate an interrupt request on any of these lines when any one of the maskable DMA events listed in [Table 16-9](#) occurs.

**Table 16-9. Logical DMA Channel Events**

Event	Description
End of packet	A packet transfer completed.
End of block	A block transfer completed.
End of frame	A frame transfer completed.
End of super block	A super block transfer completed.
Half of frame	Half of the current frame transferred.
Start of last frame	The first element of the last frame transferred.
Transaction error	A transaction error is returned by the interconnect in either the read or write port.
Address error	An attempt was made to perform a DMA access to an address not aligned on an ES boundary. Condition to occur: if <a href="#">DMA4_CENi[23:0]</a> CHANNEL_ELMNT_NBR = 0x000000 or <a href="#">DMA4_CFNi[15:0]</a> CHANNEL_FRAME_NBR = 0x0000 or <a href="#">DMA4_CSDPi[1:0]</a> DATA_TYPE = 0x3.
Supervisor transaction error	An error occurred, for example, when an unauthorized initiator (that is not a supervisor) tries to use a supervisor transfer.
Drain end	Drain is completed ( <a href="#">DMA4_CCRi[10]</a> WR_ACTIVE becomes 0).
Drop error	A drop event interrupt is generated when a DMA request is being serviced while a second one is asserted and a third one arrives before the second DMA request is serviced.

The logical DMA channels that generate an interrupt on a particular IRQ output are specified through the [DMA4\\_IRQENABLE\\_Lj](#) register (where *j* is the IRQ number: 0, 1, 2, or 3). The events that generate an interrupt for a particular channel can be configured through the channel [DMA4\\_CICRi](#) register.

When an interrupt is detected, the logical DMA channel generating the event can first be identified by reading the [DMA4\\_IRQSTATUS\\_Lj](#) register. The event causing the interrupt then can be identified by reading the interrupt status via the relevant DMA channel [DMA4\\_CSRi](#) register.

### 16.1.4.3 Logical Channel Transfer Overview

As [Figure 16-5](#) shows, the DMA\_SYSTEM module has one read port and one write port operating independently of one another. Buffering is provided between the read and write ports through a FIFO queue memory pool that is shared dynamically between the active logical channels.

- Logical channel synchronization

A logical channel is described as hardware-synchronized when the DMA transfers are triggered by DMA requests from a hardware device. Alternatively, a logical channel is described as nonsynchronized when the DMA transfer is triggered by software.

- Logical channel activation

A logical channel becomes active as follows:

- For hardware-synchronized transfers, when the logical channel is enabled and the hardware DMA request line is asserted
- For software-triggered (nonsynchronized) transfers, as soon as software enables the logical channel

- Logical channel transfer composition

A DMA transfer is divided automatically into a number of transactions. Depending on the logical

channel context configured, the transfer size, start address alignment, addressing mode, and configured maximum burst size, each transaction can be a single access or a burst of accesses.

- Logical channel scheduling

When several logical channels are active at the same time, schedulers manage the read and write ports. The scheduling of logical channel transfers is similar for both read and write ports. When a logical channel becomes active, it is added to the tail of a scheduling queue. If more than one logical channel becomes active at the same time, the one with the lower number is queued first. This mechanism provides a first-come, first-serve scheduling scheme between the concurrently active logical channels.

In addition, each read and write port has a high-priority queue and a low-priority queue. The priority bits (WRITE\_PRIORITY and READ\_PRIORITY) in the logical channel `DMA4_CCRi` register determine whether a logical channel is queued as high or low priority. A software-configurable 8-bit priority counter gives weighting to the priority write queue. For every N (1 to 255) schedules from the priority write queue, one is scheduled from the regular write queue. A channel that is scheduled goes to the end of the queue after it completes its turn on the port. The relative weighting of the scheduling of the high-priority queue to the low priority queue is programmable from 1:1 to 1:256 through the DMA global channel register using the `DMA4_GCR[23:16] ARBITRATION_RATE` bit field.

---

**NOTE:** The `DMA4_GCR[23:16] ARBITRATION_RATE` bit field does not depend on the `DMA4_GCR[13:12] HI_THREAD_RESERVED` bit field. The `ARBITRATION_RATE` bit field depends on the `DMA4_CCRi[26] WRITE_PRIORITY` bit and the `DMA4_CCRi[6] READ_PRIORITY` bit.

---

- Read/write port access scheduling policy

When either the read or write port becomes available, the port access scheduler selects the next logical channel for which to perform a DMA transaction from either the high- or low-priority queue.

When the current DMA transaction (single or burst access) is complete and the full DMA transfer is not finished, the logical channel returns to the tail of the queue. Because the port access scheduling is on a per-transaction basis, a logical channel can be queued repeatedly this way several times during its block transfer.

The `DMA_SYSTEM` module can have up to four outstanding read transactions and two outstanding write transactions in the system interconnect; four read and two write thread IDs exist. For an arbitration cycle to occur, these two conditions must be met:

- At least one channel is requesting
- At least one free thread ID is available

On an arbitration cycle, the scheduler grants the highest priority channel that has an active request, allocates the thread ID, and tags this thread as busy. At a given time, a channel cannot be allocated for more than one thread ID.

---

**NOTE:** If more than one channel is active, each channel is given a thread ID for the current service only, not for the whole channel transfer.

---

When only one channel is enabled, only one thread is allocated for the channel. In such a situation the channel can have maximum of four outstanding commands (without getting the responses) without rescheduling the channel at the end of each transaction. Each command can be either single access (8-bit, 16-bit or 32-bit) or burst access (2 × M, 4 × M, 8 × M or 16 × M, where M can be 8, 16, or 32 bits).

When nonburst alignment is at the beginning of the transfer, the channel is rescheduled for each smaller access until burst-aligned. When the end of the transfer is not burst-aligned, the channel is rescheduled for each of the remaining smaller accesses.

For a logical channel transfer completion, when the last access is written to the destination, the logical channel becomes inactive. If enabled, an interrupt request is generated (see [Section 16.1.4.2.1, Interrupt Generation](#)).

#### 16.1.4.4 FIFO Queue Memory Pool

A FIFO queue memory pool provides buffering between the read and write ports. The hardware allocates the space dynamically to a number of FIFO queues, and each queue is associated with an active logical channel.

To avoid a memory pool overflow, if there are fewer entries in the FIFO queue memory pool than are required for the maximum configured source burst size of the next logical channel to be scheduled, the logical channel is returned to the tail of the queue, and the port access scheduler continues to search the queue until it finds a logical channel that can be scheduled.

The maximum FIFO depth that can be allocated to each individual logical channel can be limited globally through the `DMA4_GCR[7:0] MAX_CHANNEL_FIFO_DEPTH` bit field. This value should be configured to allow a fair allocation of the memory pool between the active channels.

A logical channel is scheduled if it has not yet reached its allocation limit, even if the access to be performed will exceed this limit. This means that the effective number of entries used by a particular logical channel is limited to the configured maximum entries per channel + channel maximum configured burst size (in words) 1.

#### 16.1.4.5 Addressing Modes

A DMA transfer block consists of a number of frames (FN). Each frame consists of a number of elements (EN), and each element can have a size of 8, 16, or 32 bits (ES), as follows:

$$\text{transfer block size} = \text{FN} \times \text{EN} \times \text{ES}$$

The FN, EN, and ES are common for the source and destination. However, the way in which the data is represented (addressing profile/mode) is independently programmable for the source and destination devices, using one of these four addressing modes:

- Constant: The address remains the same for consecutive element accesses.
- Post-increment: The address increases by the ES, even across consecutive frames.
- Single-index: The address increases by the ES plus the element index (EI) value minus 1 (even across consecutive frames).
- Double-index: The address increases by the ES plus the EI value minus 1 within a frame. When a full frame is transferred, the address increases by the ES plus the frame index (FI) value minus 1.

The ES, EI, and FI values are expressed in bytes. The EI and FI values can be positive or negative.

When calculating the EI and FI values, it is critical to note that, after an element is accessed, the logical channel address pointer equals the address of the last byte (highest address) of the accessed element. The correct value for the EI or FI must be such that, when added to the logical channel address pointer, it results in the address of the first byte (lowest address) of the next element to be accessed.

The EI and FI values must be configured so that the address of each element in the transfer is aligned on an ES boundary.

Consequently, the single-index addressing mode with EI = 1 or double-index addressing mode with EI = 1 and FI = 1 is equivalent to post-increment addressing.

---

**NOTE:** The source and destination start addresses must also be aligned on an ES boundary.

---

When the address of an element to be accessed is not aligned on an ES boundary, the transfer is stopped and a misaligned address error interrupt occurs, if enabled (see [Section 16.1.4.2.1, Interrupt Generation](#)).

The `DMA4_CFNi` register configures the FN in a block.

The `DMA4_CENi` register configures the EN.

The `DMA4_CSDPi` register configures the ES.

The `DMA4_CSSAi` and `DMA4_CDSAi` registers configure the source and destination start addresses.

The `DMA4_CCRi` register configures the source and destination addressing modes.

The [DMA4\\_CSEIi](#), [DMA4\\_CSFIi](#), [DMA4\\_CDEIi](#), and [DMA4\\_CDFIi](#) registers configure the source EI, source FI, destination EI, and destination FI, respectively.

The addressing profiles are expressed as equations as follows:

Equation 1. Constant addressing:

$$A(n + 1) = A(n)$$

---

**NOTE:** Constant addressing mode with DMA4 to/from DDR memory is not supported on the device. To fill the DDR memory with a single value, the constant fill feature of the DMA4 must be used, instead of a constant-addressing mode transfer.

---

Equation 2. Post-increment addressing:

$$A(n + 1) = A(n) + ES$$

Equation 3. Single-indexed addressing:

$$A(n + 1) = A(n) + ES + (EI - 1)$$

Equation 4. Double-indexed addressing:

When not at the end of a frame or transfer (that is, when the element counter  $\neq 0$ ):

$$A(n + 1) = A(n) + ES + (EI - 1)$$

When at the end of a frame but not at the end of the transfer (that is, when the element counter = 0 and the frame counter  $\neq 0$ ):

$$A(n + 1) = A(n) + ES + (FI - 1)$$

Calculate the element and frame index as follows:

Equation 5. Element index

$$EI = [(Stride - EI - 1) * ES] + 1$$

Equation 6. Frame index

$$FI = [(Stride - FI - 1) * ES] + 1$$

where:

$A(n)$ : Byte address of the element  $n$  within the transfer.

ES is in bytes, ES{1, 2, 4}.

EI is in bytes, specified in a configuration register, 32768 EI 32767.

Stride EI: The difference in the number of elements between the start of the current element  $n$  to the start of next element,  $n+1$ .

Element counter: A counter that is (re)initiated with the number of elements per frame or per transfer. Decreased by 1 for each element transferred. The initial value is configured in the register DMA channel element number, [DMA4\\_CENi](#).

FI is in bytes, specified in a configuration register, 2147483648 FI 2147483647.

Stride FI: The difference in the number of elements between the start of the last element of the current frame and the beginning of the first element of the next frame.

Frame counter: A counter that is (re)initiated with the FN per transfer. Decreased by 1 for each frame transferred. The initial value is configured in the register DMA channel frame number, [DMA4\\_CFNi](#).

[Figure 16-6](#) shows how a stride EI and FI are defined. When handling complex configurations, using strides can make it easier to calculate EI and FI because you can calculate in elements instead of bytes. (This approach is used in the 90-degree clockwise image rotation example shown in [Figure 16-10](#).) The double-index addressing example shown in [Figure 16-6](#) uses ES = 4, EN = 2, EI = 5, FI = 5, and FN = 2.

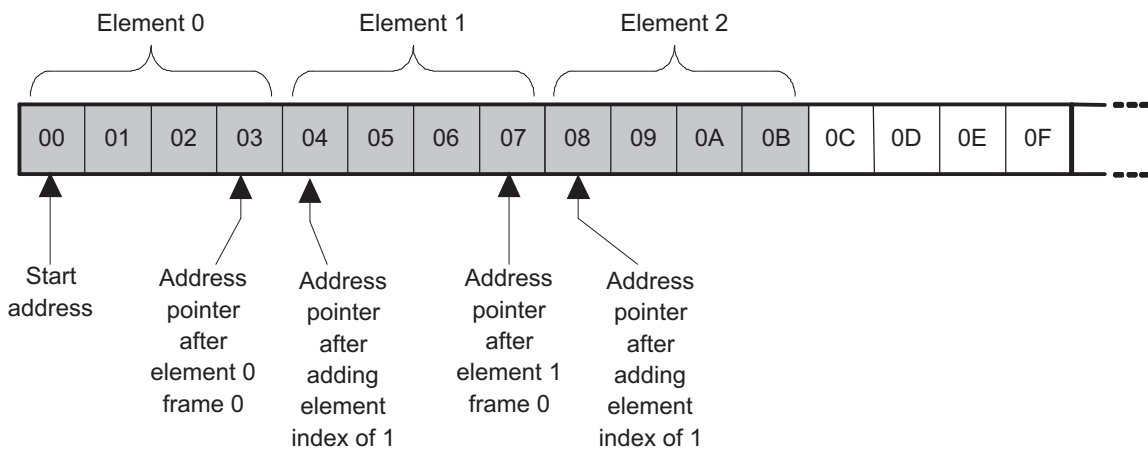

[Figure 16-6](#) through [Figure 16-9](#) show examples of addressing mode configurations. [Table 16-10](#) lists parameter values for the examples.

**Figure 16-6. Example Showing Double-Index Addressing, Elements, Frames, and Strides**

dma-011

**Figure 16-7. Addressing Mode Example (a)**

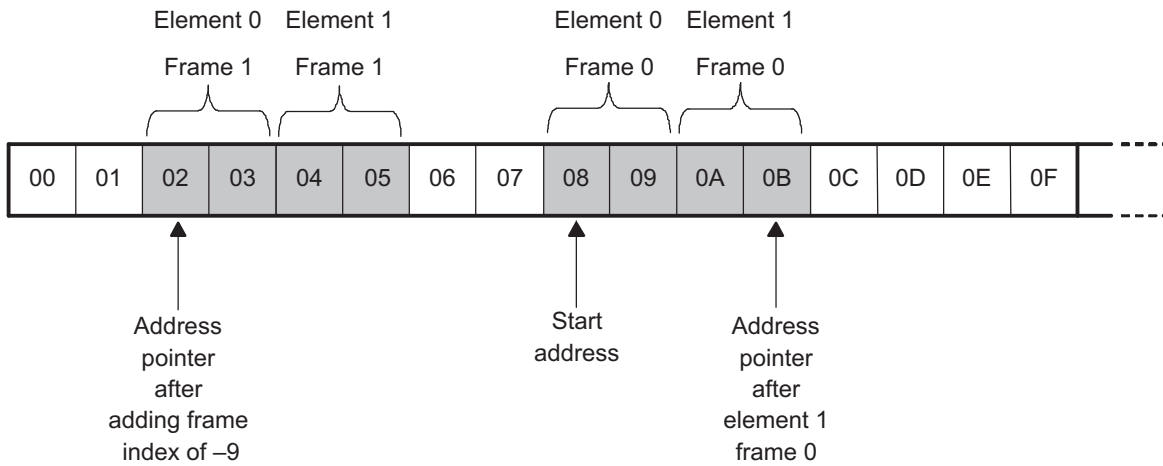

dma-010

**Figure 16-8. Addressing Mode Example (b)**

dma-009

Figure 16-9. Addressing Mode Example (c)

dma-008

Table 16-10. Parameter Values for Addressing Mode Examples (a), (b), and (c)

Parameter	Example (a)	Example (b)	Example (c)
Addressing mode	Single index (or post-increment)	Double index	Double index
Start address	0	0	8
ES	4 (32-bit)	4 (32-bit)	2 (16-bit)
EN	3	2	2
EI	1	5	1
FN	1	2	2
Frame index	N/A	5	-9

Double indexing can occur on source (read) or destination (write). Equations for rotation of  $xx$  degrees on destination are obtained by taking equations for rotation of  $(360 - xx)$  degrees on source, and swapping the width ( $x$ ) and height ( $y$ ) of the image in them. The opposite is also true. Table 16-11 lists the equations for 90-, 180-, and 270-degree rotations.

Table 16-11. Equations for Rotation

		90° Rotation	180° Rotation	270° Rotation
Double indexing on destination (write)	Base address	$ES*(y-1)$	$ES*(x*y-1)$	$ES*y*(x-1)$
	EI	$ES*(y-1) + 1$	$1-2*ES$	$1-ES*(y + 1)$
	FI	$1 ES*[(x-1)*y + 2]$	$1-2*ES$	$1+ES*(x-1)*y$
Double indexing on source (read)	Base address	$ES*x*(y-1)$	$ES*(x*y-1)$	$ES*(x-1)$
	EI	$1-ES*(x + 1)$	$1-2*ES$	$ES*(x-1) + 1$
	FI	$1+ES*(y-1)*x$	$1-2*ES$	$1 ES*[(y-1)*x + 2]$

Table 16-12 and Figure 16-10 show the configuration required to perform a 90-degree clockwise rotation of a 240 x 160 pixel, 32-bit image. The EI, frame size, and FI values are configured so that the image is rotated line-by-line starting at the left end of the top line.

**NOTE:** The FI value for the destination is negative so that the first pixel of each subsequent line of the source image is written to the correct location at the destination.

Equation 5 and Equation 6 calculate the destination, FI and EI. The example assumes that the image lines are stored at consecutive addresses in memory, meaning that both EI and FI on the source side are 1.

**Rotations:**

Section 16.1.5.7, *90-Degree Clockwise Image Rotation*, describes how to program an example of a 90-degree clockwise image rotation.

Observe that:

- One pixel = one element
- One line = one DMA frame
- Pixel size = element size = ES

**Table 16-12. Example Parameter Values for a 90-Degree Clockwise Image Rotation**

Parameter	Source Value	Destination Value
Bits per pixel	32	32
ES	4	4
Image width	SW	SH
Image height	SH	SW
Stride elements (stride EI)	1 element	SH
Stride frames (stride FI)	1 element	$-(SW-1)*SH + 1 = 38,241$ elements
Start address	0x100000	$0x200000 + (SH - 1) \times ES = 0x20027C$
EN	SW	SW
EI	$[(Stride EI - 1) \times ES] + 1 = 1$	$[(Stride EI - 1) \times ES] + 1 = 637$
FN	SH	SH
FI	$[(Stride FI - 1) \times ES] + 1 = 1$	$[(Stride FI - 1) \times ES] + 1 = 152,967$

**Figure 16-10. Example of a 90-Degree Clockwise Image Rotation**

**16.1.4.6 Packed Accesses**

To pack data means to group data to match the bus size, thus optimizing a transfer. When the logical channel ES is less than the DMA module read/write port size, and the addressing profile supports it (post-increment mode or single- or double-index mode with EI = 1), the number of elements to transfer in each read/write port access can be maximized by specifying that the source or destination is packed through the channel DMA4\_CSDPi register. Thus:

- For a read/write port size of 32 bits, the source or destination can be configured as packed for transfer

ESs of 8 bits (four elements per access) and 16 bits (two elements per access).

- For a read/write port size of 64 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (eight elements per access), 16 bits (four elements per access), and 32 bits (two elements per access).

Depending on the start address and transfer length, the first or last packed access can be only partially filled. This is indicated to the source or destination using the byte-enable signals.

#### 16.1.4.7 Burst Transactions

Transfer performance can be improved so that the source or destination and addressing profile supports it. This can be achieved by configuring the logical channel to perform burst transactions consisting of multiple instead of single accesses. The channel can be programmed to use burst sizes equal to 16, 32, or 64 bytes through the [DMA4\\_CSDPi](#) register, with the read burst size programmable independently of the write burst size. Typically, the optimal burst size is 64 bytes (16 accesses for a 32-bit read/write port size or 8 accesses for a 64-bit read/write port size).

To obtain the maximum benefit from burst transactions, the source and destination start addresses must be aligned with the burst size. If this is not the case, the start of the transfer can consist of a number of smaller (single or burst) transactions until the first burst size boundary is reached.

Similarly, if the end of the transfer is not aligned on a burst size boundary, the final part of the transfer can consist of a number of smaller transactions.

---

**NOTE:** If post-incrementing is used, data must be packed to DMA data-port width, to use burst.

---

#### 16.1.4.8 Endianism Conversion

The source and destination are each specified as little-endian or big-endian through the [DMA4\\_CSDPi](#) register for the particular logical channel. If the endianism of the source and destination differ, and if the logical channel ES is less than the DMA\_SYSTEM module read/write port size, an endianism conversion is applied to the data before it is written to the destination.

When transferring data between a source and a destination with different endianism, it is important to specify an ES that equals the type of data being transferred to preserve the correct data image at the destination.

In the system, endianism conversion can be performed in more than one place. It is possible to instruct the source and/or destination to lock the endianism (that is, to not perform a conversion) through the logical DMA channel [DMA4\\_CSDPi](#) register.

---

**NOTE:** Because the device is little-endian by construction, the DMA\_SYSTEM endianism registers must never be set to big-endian.

If DMA\_SYSTEM is used to execute endian conversion by setting the source and destination to different endianism values, it is important to consider that the L3\_MAIN interconnect also executes endian conversion if the DMA\_SYSTEM and the source or destination have a different data bus width.

---

#### 16.1.4.9 Transfer Synchronization

A logical channel can be programmed for software-triggered or hardware synchronized transfers.

##### 16.1.4.9.1 Software Synchronization

A transfer is software-triggered when the logical channel is set up and started by software. To specify a software-triggered transfer, set the channel DMA [DMA4\\_CCRi\[4:0\]](#) and [DMA4\\_CCRi\[20:19\]](#) bit fields to 0. The transfer starts as soon as the DMA [DMA4\\_CCRi\[7\]](#) bit is set (when it enters the scheduling process).

### 16.1.4.9.2 Hardware Synchronization

A transfer is hardware-synchronized if the logical channel activation is driven by hardware requests from the source or destination target. A hardware-synchronized transfer is specified by configuring the DMA request line number in the channel `DMA4_CCRi` register to a value that corresponds to the DMA request line from the source or destination that generates the DMA requests. The DMA request numbers to be configured are specified in the DMA request mapping (see [Table 16-9](#)).

Specify the DMA request number in the `DMA4_CCRi[4:0]` SYNCHRO\_CONTROL and `DMA4_CCRi[20:19]` SYNCHRO\_CONTROL\_UPPER bit fields. After the `DMA4_CCRi[7]` ENABLE bit is set, the logical channel becomes enabled but not activated (it does not enter the scheduling process), which means that channel registers are not updated until the first DMA request is received.

---

**NOTE:** The channel synchronization control registers are 1-based. For example, to enable the `S_DMA_1` request, the `DMA4_CCRi[4:0]` SYNCHRO\_CONTROL bit field must be set to `0x2` (DMA request number + 1).

---

**NOTE:** A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared among several chained logical channels.

---

For hardware synchronization, the amount of data to be transferred for each assertion of the DMA request line is configured through the frame synchronization (FS) and block synchronization (BS) bits in the logical channel `DMA4_CCRi` register and the `DMA4_CCRi[5]` FS and `DMA4_CCRi[18]` BS bits, respectively.

The amount of data can be any of the following:

- A single element transfer: A complete element defined by data type. For example, 8/16/32 bits are transferred in response to a DMA request.
- A full frame: A complete frame of several elements is transferred in response to a DMA request.
- A full block (a full channel transfer): A complete block of several frames is transferred in response to a DMA request.
- A full packet (a full channel transfer): A complete packet of several elements is transferred in response to a DMA request.

Packets allow the size of each part of the full DMA transfer to be configured independently of the organization of the data to be transferred (typically a number of elements). This can be useful when the source or destination has a buffer (such as a FIFO queue) with a size unrelated to the frame size of the transfer. The packet size then can be set to the size of the buffer.

Packet transfer must be used only where the source or destination is addressed in constant addressing mode, because FI registers are reused to specify the packet size.

To support the burst mode, the logical channel must also be configured in target-port packed access mode.

The packet size is configured based on the `DMA4_CCRi[24]` SEL\_SRC\_DST\_SYNC bit through either the channel `DMA4_CDFIi` register (source synchronized) or the `DMA4_CSFII` register (destination synchronized).

When the logical channel transfer block is not an exact multiple of the packet size, the final packet consists of the remaining elements in the transfer, using burst or single accesses to complete the block transfer.

The maximum transfer size, regardless of the packet size, is always as follows:

$$\text{Block\_size} = \text{Number\_of\_Frame\_in\_Block} * \text{Number\_of\_Element\_in\_Frame} * \text{Element\_Size}$$

- Synchronized at the source

The DMA module optimizes the transfer with respect to the number and size of burst transactions for the given source and destination addressing profiles and configured maximum burst sizes. When writing to the destination is slower than reading from the source, data is buffered in the channel FIFO queue. If the transfer is packet-synchronized at the source, the end-of-packet interrupt is disabled (see [Section 16.1.4.13, Reprogramming an Active Channel](#)).

For a source synchronized transfer, buffering can be enabled or disabled by setting the [DMA4\\_CCRi\[25\] BUFFERING\\_DISABLE](#) bit. For a packet source synchronization with buffering disabled and the packed/burst across the packet boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the packet transfer size. However, for a packet source synchronized transfer with buffering enabled and with the packed/burst across the packet boundary, the DMA module waits for the next DMA request(s) to read enough data to issue an atomic packed/burst write transaction (assuming that the address is packed/burst aligned).

---

**NOTE:** Buffering is not performed between frames, even if it is enabled. If the packed/burst is across the frame boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the frame transfer size.

---

- Synchronized at the destination

The performance of a hardware-synchronized transfer can be improved by using the prefetch mode, enabled through the channel [DMA4\\_CCRi\[23\] PREFETCH](#) bit. Data is prefetched on the read port side before the DMA request received and buffered in the FIFO queue. Up to a full transfer block can be prefetched, although this can be limited by the specified maximum channel FIFO queue depth (see [Section 16.1.4.4, FIFO Queue Memory Pool](#)).

Buffering disable is not allowed for a destination-synchronized transfer.

---

**NOTE:** Behavior is undefined when prefetch is enabled and a transfer is synchronized to the source.

Regardless of whether buffering is enabled, the last transaction in the frame or in the block is write nonposted (WNP) even if the write mode is specified as write last nonposted (WLNP; the [DMA4\\_CSDPi\[17:16\] WRITE\\_MODE](#) bit field = 0x2). However, in a packet synchronization mode, the last transaction of each packet in the transfer is WNP only if the buffering disable is on (even if the write mode is specified as WLNP).

Regardless of whether buffering is enabled, the packet interrupt is not generated in the packet source synchronized mode.

---

### CAUTION

The [DMA4\\_CCRi\[25\] BUFFERING\\_DISABLE](#) bit must be filled with an allowed value, as specified in [Table 16-13](#).

**Table 16-13. Buffering Disable**

	<b>BUFFERING_DISABLE</b> (0: Buffering enable, 1: Buffering disable)	
Destination synchronized	0	Allowed
	1	Not allowed
Source synchronized	0	Allowed
	1	Allowed

- Synchronized transfer monitoring using CDAC ([DMA4\\_CDACi](#)):

Context is restored only when the channel becomes active on a DMA request (not at software enable). The channel is software-enabled first, and then a DMA request is asserted followed by the first context restore.

The CDAC register is writable; thus, the CDAC can be initialized to monitor the transfer and determine whether the transfer is started (for more information, see [Section 16.1.5.4, Synchronized Transfer Monitoring Using CDAC](#)).

---

**NOTE:** For 16-bit transactions, start reading from or writing to the LSByte first to enable the register update. This is not an issue for 32-bit read-write transactions.

---

#### 16.1.4.10 Thread Budget Allocation

When several concurrent channels are latency critical and hardware synchronized, a specific latency cannot be ensured until the target is served. This situation occurs when the number of concurrent channels is greater than the number of available threads.

---

**NOTE:** Four threads are available on the read port, and two threads are available on the write port.

---

For a hardware-synchronized transfer (memory to peripheral), a minimum bandwidth for a latency-critical transfer must be ensured to avoid collisions between two hardware requests.

Because it is latency critical, the software user is responsible for the following:

- Programming the synchronized channel as a high-priority channel
- Reserving one or several threads for high-priority channels

The proposed implementation is as follows (see [Section 16.1.5.5, Concurrent Software and Hardware Synchronization](#)):

Prevent the regular channel queue from exceeding more than a programmable (3, 2, or 1) number of threads on the read port and no more than one thread on the write port. This number can be set in the global register `DMA4_GCR[13:12]`.

The thread reservation is programmable for maximum use of thread resources for concurrent, low-priority channel transfer. Programmability can also allow a partial throughput control by limiting in software the number of concurrent outstanding requests that break the pipelining.

Depending on the `DMA4_GCR [13:12]` value, the following threadID on the read/write ports are allocated for a high-priority channel:

Read port priority thread reservation:

- `DMA4_GCR[13:12] = 0x0` => No ThreadID is reserved for high-priority channels.
- `DMA4_GCR[13:12] = 0x1` => Read ThreadID 0 is reserved for high-priority channels.
- `DMA4_GCR[13:12] = 0x2` => Read ThreadID 0 and Read ThreadID 1 are reserved for high-priority channels.
- `DMA4_GCR[13:12] = 0x3` => Read ThreadID 0, Read ThreadID 1, and Read ThreadID 2 are reserved for high-priority channels.

Write port priority thread reservation:

- `DMA4_GCR[13:12] = 0x0` => No ThreadID is reserved for high-priority channels
- `DMA4_GCR[13:12] = 0x1` => Write ThreadID 0 is reserved for high-priority channels.
- `DMA4_GCR[13:12] = 0x2` => Write ThreadID 0 is reserved for high-priority channels.
- `DMA4_GCR[13:12] = 0x3` => Write ThreadID 0 is reserved for high-priority channels.

Regardless of whether the enabled channels are high priority, only the setting of the `DMA4_GCR[13:12]` value forces the thread reservation to these values. Set the appropriate value to avoid losing threads using only regular channels.

To have an independent read and write priority context, a per-channel bit (`DMA4_CCRI[26]`) is added for write priority, and the previous priority bit becomes read priority bit (`DMA4_CCRI[6]`).

---

**NOTE:** The device has one priority bit per logical channel, not one priority bit per port.

---

#### 16.1.4.11 FIFO Budget Allocation

To avoid fully occupying the FIFO with a high-priority transfer while low-priority channels wait in the arbitration queue, two separate FIFO budgets are specified: one for high-priority channels and one for low-priority channels. This is defined in the [DMA4\\_GCR](#) register, allowing the user to share the FIFO budget between the low- and high-priority channels. The amount of the FIFO allocated by the low- and high-priority channels is fixed by the value set in the [DMA4\\_GCR\[15:14\] HI\\_LO\\_FIFO\\_BUDGET](#) field. The maximum channel FIFO depth is limited by the [HI\\_LO\\_FIFO\\_BUDGET](#) field as follows:

If the channel is low priority:

- When [HI\\_LO\\_FIFO\\_BUDGET](#) = 0x1, then low priority cannot exceed 75 percent of the total FIFO.
- When [HI\\_LO\\_FIFO\\_BUDGET](#) = 0x2, then low priority cannot exceed 25 percent of the total FIFO.
- When [HI\\_LO\\_FIFO\\_BUDGET](#) = 0x3, then low priority cannot exceed 50 percent of the total FIFO.

If channel is high priority

- When [HI\\_LO\\_FIFO\\_BUDGET](#) = 0x1, then high priority cannot exceed 25 percent of the total FIFO.
- When [HI\\_LO\\_FIFO\\_BUDGET](#) = 0x2, then high priority cannot exceed 75 percent of the total FIFO.
- When [HI\\_LO\\_FIFO\\_BUDGET](#) = 0x3, then high priority cannot exceed 50 percent of the total FIFO.

The user must perform the following equation:

- For a high-priority channel:  $(\text{Per\_Channel\_Maximum FIFO Depth} + 1) \times \text{Number of High Channel} = < \text{High Budget FIFO}$
- For a low-priority channel:  $(\text{Per\_Channel\_Maximum FIFO Depth} + 1) \times \text{Number of Low Channel} = < \text{Low Budget FIFO}$

---

**NOTE:** Ensure that *Number of High Channel* means *Number of Active High-Priority Channel* and that *Number of Low Channel* means *Number of Active Low-Priority Channel*.

---

#### 16.1.4.12 Chained Logical Channel Transfers

Chaining multiple logical channels permits transfers consisting of multiple parts to be executed without repeated software intervention. This results in better performance than the alternative of software setting up and starting each transfer separately. Each part of a chained transfer can have the data addressed in a different manner that permits the programming of a variety of complex transfers. For example:

- Interlaced video data with one logical channel configured to transfer the even lines and another logical channel configured to transfer the odd lines
- Protocol headers with a separate DMA4 channel configured to transfer each field in the header

Channels can be chained through each channel [DMA4\\_CLNK\\_CTRLi](#) register. When the transfer for the first channel completes, the next channel in the chain is enabled. The number of channels in the chain that are configured for hardware-synchronized transfers is flexible (although typically it may be all, none, or simply the first one). The DMA request line number must be set to 0 to specify that any or all of the channels in a chain are software-triggered or nonsynchronized.

The last channel in a chain can be chained to the first channel to create a continuously looping chain. The continuously looping transfer can be stopped on the fly at a specific channel by disabling the [DMA4\\_CLNK\\_CTRLi\[15\] ENABLE\\_LNK](#) bit. The looping transfer stops after the specified channel transfer is complete.

---

**NOTE:** A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared between several chained logical channels.

---

For more information about the programming model, see [Section 16.1.5, DMA\\_SYSTEM Basic Programming Model](#).

### 16.1.4.13 Reprogramming an Active Channel

A currently active logical DMA channel can be disabled through the `DMA4_CCRi[7]` ENABLE bit. When an ongoing transaction is complete and the read-active and write-active bits in the `DMA4_CCRi` register (`DMA4_CCRi[9]` RD\_ACTIVE and `DMA4_CCRi[10]` WR\_ACTIVE) are reset, the channel can be reprogrammed for a new transfer.

### 16.1.4.14 Packet Synchronization

A packet transfer notion is related to the behavior of some peripherals, which have certain buffering capability and requires to transfer the buffer content once an element number threshold is reached (a hardware DMA request is generated). To associate a frame synchronization to each DMA request is possible, but this limits the maximum transfer size. Indeed the maximum transfer size is proportional to the FIFO depth of the peripheral:

$$\text{maximum\_transfer\_size} = \text{peripheral\_FIFO\_depth} \times \text{number\_of\_frame\_in\_block}$$

The packet synchronization allows to dissociate the transfer size from the FIFO depth of the peripheral. Only Constant addressing mode is allowed on a read port or a write port if source target or destination target is packet synchronized respectively.

Example:

Consider a camera interface with a FIFO\_depth of 128 words and a FIFO\_element\_number\_threshold of 128, and a picture to transfer with a size 320 lines by 240 columns. If frame synchronization is associated with each DMA request then the maximum transfer size that can be performed is  $128 \times 2^{16}$  words. In this case, a frame is 128-word long, which does not fit the size of a line, and it is not possible to generate an interrupt at the end of line. However, by introducing the packet transfer notion, which is related to the peripheral FIFO behavior/structure, the maximum transfer size ( $\text{maximum\_transfer\_size} = 2^{24} \times 2^{16}$  words) is independent of both peripheral\_FIFO\_depth and FIFO\_element\_number\_threshold. This allows a long-enough transfer within one channel context and rotation operation on a large image format.

The main features of DMA Packet transfer are as follows:

- **DMA Packet\_Data\_Size** for each DMA Request: The Peripheral\_element\_number\_threshold (the number of elements in a packet) shares the `DMA4_CSFl` and `DMA4_CDFl` configuration registers. If the peripheral is the source target, the addressing mode is constant, and the `DMA4_CSFl[15:0]` bit field is used to specify the packet data size in the `DMA4_CSFl` register. The user must set the `DMA4_CCRi[24]` SEL\_SRC\_DST\_SYNC bit to 1. If the peripheral is the destination target, the addressing mode is constant, the `DMA4_CDFl[15:0]`, is used to specify the packet data size (PKT\_ELNT\_NBR), and the bit field [31:16] is unused. To specify the packet data size in the `DMA4_CDFl` register, the user must set the `DMA4_CCRi[24]` SEL\_SRC\_DST\_SYNC bit to 0.

---

**NOTE:** The packet size can be a submultiple or non-submultiple of a frame size. If DMA Packet\_Data\_Size is aligned on the DMA channel block data size boundary, then DMA transfers the last data in the channel block boundary and stops at the block boundary for the last packet DMA Request. If the Packet\_Data\_size is not aligned on the block boundary, the remaining data smaller than a packet size are transferred using burst or single accesses to complete the block.

---

- **DMA Packet\_Data\_Transfer** does not affect DMA channel capabilities in term of packing and bursting. The packet synchronization mode is active when `DMA4_CCRi[5]` FS = `DMA4_CCRi[18]` BS = 1. Then:
  - If `DMA4_CCRi[24]` SEL\_SRC\_DST\_SYNC = 0, the `DMA4_CDFl[15:0]` bit field gives the number of elements in the packet and the `DMA4_CDFl[31:16]` bit field is unused for the packet size.
  - If `DMA4_CCRi[24]` SEL\_SRC\_DST\_SYNC = 1, the `DMA4_CSFl[15:0]` bit field gives the number of elements in the packet and the `DMA4_CSFl[31:16]` bit field is unused for the packet size.

**NOTE:** The maximum transfer size, regardless of the packet size, is always:

$$\text{Block\_size} = \text{Number\_of\_Frame\_in\_Block} \times \text{Number\_of\_Element\_in\_Frame} \times \text{Element\_Size}.$$

If DMA channel packet/burst access is across the packet boundary, the DMA hardware automatically splits this packing/burst access into multiple smaller accesses that are aligned on the packet boundary. Otherwise, the DMA transfers data as a usual packing/burst access.

#### 16.1.4.15 Graphics Acceleration Support

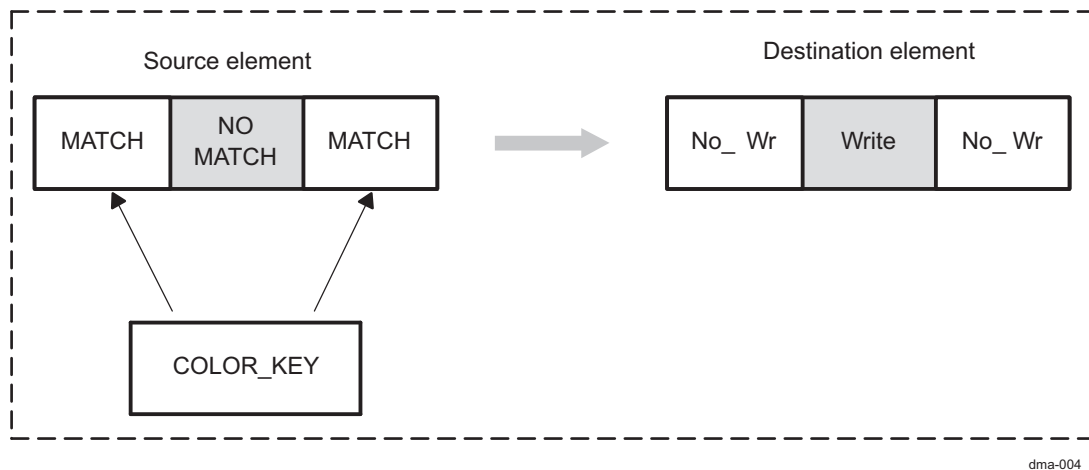

The DMA\_SYSTEM supports two graphic acceleration features: transparent copy and constant fill.

Only one of these features can be enabled at a time through the [DMA4\\_CCRi](#) register for the particular logical DMA channel.

The transparent copy feature enables specification of a particular color through the [DMA4\\_COLORi](#) register so that when it is recognized in the data from the source, it is not copied to the corresponding location in the destination but instead leaves the data in the corresponding location in the destination as it is.

Figure 16-11 shows the 2-D graphic transparent color block diagram.

**Figure 16-11. 2-D Graphic Transparent Color Block Diagram**

The constant fill feature provides the ability to specify a particular color through the [DMA4\\_COLORi](#) register for every specified location in the destination. In this case, the transfer consists only of writing to the destination without reading from a source.

Both features support 8, 16, and 24 bpp, depending on what is specified as the DMA transfer ES through the [DMA4\\_CSDPi](#) register. An ES of 32 bits corresponds to 24 bpp. During a 32-bit (24 bpp) transfer, the 8 most-significant bits (MSBs) ([31:24]) are 0. Both features are compatible with packed and burst transactions.

#### 16.1.4.16 Supervisor Modes

A logical DMA channel can be configured to operate in supervisor mode through the [DMA4\\_CCRi](#)[22] SUPERVISOR bit. This must be done using supervisor access. Once a channel is configured in supervisor mode, the channel configuration is protected from nonsupervisor accesses. All DMA transactions on a supervisor channel are supervisor transactions.

#### 16.1.4.17 Posted and Nonposted Writes

A logical channel can be configured in its [DMA4\\_CSDPi](#)[17:16] bits to use one of three write access handshake modes for the destination:

- Nonposted write: Each write must complete before transfer can continue or complete.

- Posted write: Transfer continues without waiting for each write to complete (may improve performance with slow devices).
- Posted with final write nonposted: Transfer continues without waiting for each write to complete, but final write completes before transfer can complete.

#### 16.1.4.18 Disabling a Channel During Transfer

When a channel is disabled during a transfer, the channel undergoes an abort, unless it is hardware-source-synchronized with buffering enabled ([DMA4\\_CCRi\[25\] BUFFERING\\_DISABLE = 0](#)). If this is the case, the FIFO is drained to prevent the loss of data. For more information about this feature, see [Section 16.1.4.19, FIFO Draining Mechanism](#).

#### 16.1.4.19 FIFO Draining Mechanism

When a source-synchronized channel is disabled during a transfer, the current hardware request (element/packet/frame/block) service completes and the channel [DMA4\\_CCRi\[9\] RD\\_ACTIVE](#) bit is set to 0, which means the channel is not active on the read port. The remaining data in the corresponding disabled channel FIFO is drained onto the write port and transferred to the programmed destination as in normal transfer.

At the end of the draining the [DMA4\\_CCRi\[10\] WR\\_ACTIVE](#) bit is set to 0 (channel is no longer active on the write port) and if the [DMA4\\_CICRi\[12\] DRAIN\\_END\\_IE](#) is set to 1, the [DMA4\\_CSRI\[12\] DRAIN\\_END](#) status bit is updated and an interrupt is generated.

Once a channel is disabled during a transfer, it must wait for the [DMA4\\_CCRi\[9\] RD\\_ACTIVE](#) and [DMA4\\_CCRi\[10\] WR\\_ACTIVE](#) bits to become 0 before being reenabled for a new transfer. The FIFO drain for a channel occurs only in the following cases:

- If the channel is a source synchronized channel and [DMA4\\_CCRi\[25\] BUFFERING\\_DISABLE = 0](#) and
- If the channel is not a solid fill channel and
- If the channel is not a transparent and copy channel and
- If the channel is a hardware, synchronized channel

---

**NOTE:** For a self-linked or chain-linked channel, the user must disable the [DMA4\\_CLNK\\_CTRLi\[15\] ENABLE\\_LINK](#) bit before disabling the channel.

---

In all other cases, the channel undergoes an abort.

#### 16.1.4.20 Linked List

##### 16.1.4.20.1 Overview

The DMA\_SYSTEM supports the logical transfer-descriptor loader feature. A transfer descriptor represents a set of values that maps to a set of logical channel configuration registers.

A logical channel transfer descriptor can be loaded by DMA from memories, and then successive transfer descriptors can be autonomously loaded based on a linked-list scheme. This enables DMA4 scatter-gather transfers with minimum MPU support by removing successive channel configuration processing and associated interrupt handling overheads. It also optimizes DMA4 channel resources by enabling efficient transfer serialization on a single logical channel versus concurrent (multiple) logical channel use.

Different types of transfer descriptors are supported (full or partial logical channel configuration registers are set). This optimizes the memory size required for storing a long linked list, because parameter changes are limited to only a few logical channel configuration registers.

### 16.1.4.20.2 Link-List Transfer Profile

A linked-list transfer can be seen as a super-block transfer (where the block is composed of FN frames and each frame includes EN elements). The block size (FN x EN x ES) can be changed in the linked list by loading an updated transfer descriptor.

The end of the super block is signaled in the last descriptor associated with the last block. Generally, for a given link-list transfer, the logical channel is set at the beginning of the transfer and the logical channel configurations for the subsequent blocks are slightly changed. Thus, the descriptor can be limited to an update of only few parameters, such as FN or EN. This assumes that the content of unmodified registers is preserved when a new descriptor is loaded.

A transfer descriptor is composed of a set of channel configuration register values with the addition of the next-descriptor pointer register ([DMA4\\_CNDPi](#)) and a channel-descriptor parameter register ([DMA4\\_CDPi](#)). The next-descriptor pointer is the 32-bit address pointer from where the next transfer descriptor is to be loaded. The next-descriptor pointer is mapped depending on the descriptor type (1, 2, or 3).

### 16.1.4.20.3 Descriptors

A transfer descriptor is a set of values that maps to a set of logical channel configuration registers. The descriptor contains the parameters associated with a transfer profile (transfer size, source or destination addresses, etc). Four different types of transfer descriptors are supported to optimize the memory size required to store a long linked list and to minimize MPU use to create and maintain the descriptor list.

A transfer descriptor is a list of 32-bit values. A descriptor must be 32-bit aligned in memory. Only the 30 least-significant bits (LSBs) of the next-descriptor address pointer are updated from the descriptor, and the DMA4 forces the 2 LSBs to 0 on generation of the pointer address. The descriptor size is variable, depending on the descriptor type and the `Nxt_Dv` and `Nxt_Sv` bit fields.

Transfer descriptor bit mapping is the same as DMA4 logical-channel configuration register bit mapping, with the following exceptions:

- `Src_Element_index` and `Dst_Element_index` are concatenated in the same 32-bit location.
- [DMA4\\_CICRi](#) (interrupt event mask)
- CFN (frame number)
- Bit fields:
  - P: Corresponds to the `PAUSE_LINK_LIST` bit:
    - When set to 1 in the descriptor, the channel is suspended when the descriptor load completes.
    - The user must not set the `PAUSE_LINK_LIST` bit through the configuration port. Otherwise, behavior is undefined.
    - When set to 0 (through the configuration port) after pause, the linked-list channel resumes its transfer (descriptor load or data load).
  - B: Corresponds to the end-of-block enable bit (`BLOCK_IE`) of the [DMA4\\_CICRi](#) register; valid only for type 3. This value is don't care for descriptor types 1 and 2, where [DMA4\\_CICRi](#) is fully specified.
  - `Nxt_Dv`, `Nxt_Sv`: Mapped in the [DMA4\\_CDPi](#) register. They indicate one of the following possibilities:
    - Next descriptor contains an updated destination or source address.
    - Next descriptor does not update the source or destination address, but increments the last source or destination address (from the end of the last transfer).
    - The next source address and/or destination address are the last valid ones in the configuration memory. This means that the corresponding location in the configuration memory is not updated (assuming that they were initialized at least once in the past). This is also called wrapping addressing.
  - `Next_Descriptor_Type`: Specifies the next descriptor type that corresponds to the `NEXT_DESCRIPTOR_TYPE` bit field in the [DMA4\\_CDPi](#) register

**Table 16-18. Type 3 With Source or Destination Address Update**

	3	3	2	2	2	2	2	2	2	2	2	2	1	1	1	1	1	1	1	1	1	1	1	9	8	7	6	5	4	3	2	1	0

Ptr+ 0x4	N_type		B	Dv	Sv	Element_number																											
Ptr	Next_descriptor_address_pointer																										R	P					
																											sv						

#### 16.1.4.20.4 Linked-List Control and Monitoring

##### 16.1.4.20.4.1 Transfer Mode Setting

Four descriptor types are available in [DMA4\\_CDPi\[9:8\] TRANSFER\\_MODE](#) to distinguish the different transfer modes:

- [DMA4\\_CDPi\[9:8\] TRANSFER\\_MODE = 00](#): The current channel is using normal mode.
- [DMA4\\_CDPi\[9:8\] TRANSFER\\_MODE = 01](#): The current channel is using link-list channel mode for a type 1, 2, or 3 descriptor.

The reset value is normal mode ([DMA4\\_CDPi\[9:8\] TRANSFER\\_MODE = 0](#)).

##### 16.1.4.20.4.2 Starting a Linked List

Like a nonlinked-list transfer, a link transfer starts under host control by enabling the associated logical channel (set the [DMA4\\_CCRi\[7\] ENABLE](#) bit to 1). The [DMA4\\_CDPi\[10\] FAST](#) bit sets the start mode of the link-list transfer:

In nonfast-start mode, the logical channel configuration is fully initialized so that the transfer can start without descriptor loading.

In fast-start mode, the descriptor pointer and other inputs are given. The channel starts by loading the descriptor and then starts the data transfer phase.

##### 16.1.4.20.4.3 Monitoring a Linked-List Progression

In addition to the [DMA4\\_CCENi](#) (remaining elements) and [DMA4\\_CCFNi](#) (remaining frames) registers that are used to monitor the transfer progress, a per-channel register, [DMA4\\_CCDNi](#) (channel current active descriptor number), monitors which descriptor in the list is active. The user must initialize the [DMA4\\_CCDNi](#) register to 0 during the initial configuration. When the [DMA4\\_CCDNi](#) register is updated, the [DMA4\\_CCFNi](#) and the [DMA4\\_CCENi](#) registers are updated. The user must also initialize the [DMA4\\_CCFNi](#) and [DMA4\\_CCENi](#) registers to 0xFFFF and to 0xFFFFFFFF, respectively, to track the effective transfer start of synchronized transfer.

##### 16.1.4.20.4.4 Interrupt During Linked-List Execution

Any logical channel source of interrupt can be triggered during a linked-list execution, if the interrupt source is enabled during the initial configuration in [CICR](#). The [DMA4\\_CICRi](#) register can also be updated during the linked-list execution if descriptor types 1 and 2 are used.

The use of an interrupt event in a link execution can be difficult, because the link can progress in parallel with interrupt service routine (ISR) execution. This makes it difficult to synchronize them unless system assumptions are used. The most appropriate synchronization model is to get an interrupt-only on linked-list completion, when the last transfer block is complete. This prevents the interrupt from occurring during the link execution. An end-of-super-block interrupt event available in the [DMA4\\_CICRi](#) and [DMA4\\_CSRi](#) registers can be enabled at initial configuration or when using descriptor types 1 and 2. To prevent the use of descriptor type 1 or 2 to update [BLOCK\\_IE](#) (full [DMA4\\_CICRi](#) update), a dedicated [BLOCK\\_IE](#) bit field is also available in a type 3 descriptor.

#### 16.1.4.20.4.5 *Pause a Linked List*

When the channel is suspended, it remains enabled.

The pause behaves differently, depending on the transfer mode:

- Normal transfer mode: If the user sets the [DMA4\\_CDPi\[7\] PAUSE\\_LINK\\_LIST](#) bit to 1, the channel completes the current read and write transactions and then suspends the channel. The channel can be resumed by setting the channel [DMA4\\_CDPi\[7\] PAUSE\\_LINK\\_LIST](#) bit to 0.
- Linked-list type 1, 2, or 3 mode: The user must not set the [DMA4\\_CDPi\[7\] PAUSE\\_LINK\\_LIST](#) bit through the configuration port; otherwise, transfer behavior is undefined.

A [PAUSE\\_LINK\\_LIST](#) bit (P) is set to 1 in the descriptor.

- The channel is suspended after the descriptor load, translation, and configuration memory update are complete.
- The linked list can be resumed by resetting the [DMA4\\_CDPi\[7\] PAUSE\\_LINK\\_LIST](#) bit (through the configuration port).

#### 16.1.4.20.4.6 *Stop a Linked List (Abort or Drain)*

The channel can be stopped for a drain or an abort. These cases are exclusive.

##### 16.1.4.20.4.6.1 *Drain*

- Drain conditions:

A channel is a drain candidate if it is a hardware-source-synchronized transfer with [DMA4\\_CCRi\[25\] BUFFERING\\_DISABLE](#) = 0 and should not be doing any of the graphics operation (transparent copy or solid-color fill).

- Drain trigger:

A drain candidate channel is drained if it is disabled ([DMA4\\_CCRi\[7\] ENABLE](#) = 0) or if it receives a transaction error on the read port.

- Drain behavior with a type 1, 2, or 3 descriptor. Drain trigger can occur in two situations:
  - During descriptor loading: Any ongoing current transaction is complete and the channel is aborted.
  - During data loading: The read is completed at the boundary of the request (element/frame/packet/block boundary), the FIFO is drained to the destination, and then a [DRAIN\\_END](#) interrupt can be asserted.

##### 16.1.4.20.4.6.2 *Abort*

- Abort condition:

A channel is an abort candidate if it is software-synchronized, hardware-destination-synchronized, solid color-fill, transparent-color fill, or hardware-source-synchronized with [DMA4\\_CCRi\[25\] BUFFERING\\_DISABLE](#) = 1.

- Abort trigger:

A channel is an abort candidate if it is disabled ([DMA4\\_CCRi\[7\] ENABLE](#) = 0), if it receives a transaction error on the read or write port, or if there is a [MISALIGNMENT\\_ERROR](#).

- Abort behavior with a type 1, 2, or 3 descriptor:

If an abort trigger occurs, the channel aborts immediately after completion of current read/write transactions and then the FIFO is cleaned up.

In type 1, 2, or 3, if an abort trigger or drain trigger occurs during the descriptor load phase, the channel aborts.

#### 16.1.4.20.4.7 *Status Bit Behavior*

This section describes the behavior of the [DMA4\\_CSRi\[6\] SYNC](#), [DMA4\\_CCRi\[9\] RD\\_ACTIVE](#) and [DMA4\\_CCRi\[10\] WR\\_ACTIVE](#) status bits:

- For a hardware-synchronized channel in linked-list mode, the [DMA4\\_CSRi\[6\] SYNC](#) bit becomes active ([DMA4\\_CSRi\[6\] SYNC](#) = 1) when the first data load transaction is scheduled and remains active

- until the last data load transaction in the block (not super block) is descheduled ([DMA4\\_CSRI\[6\]](#) SYNC = 0). The SYNC bit is not active during the descriptor load phase.
- The [DMA4\\_CCRi\[9\]](#) RD\_ACTIVE bit is active during the data load phase and the descriptor load phase. It becomes active when the first read transaction is scheduled. It becomes inactive:
    - When (during the descriptor load phase) the last descriptor write request is descheduled
    - When (during the data load phase) the last read transaction in the block (not super block) is descheduled for software-synchronized transfer or destination-synchronized transfer with prefetch enabled
    - When (during the data load phase) the last read transaction in the request (element/frame/packet/block sync) is descheduled for hardware-source-synchronized transfer or hardware-destination-synchronized transfer without prefetch
  - The [DMA4\\_CCRi\[10\]](#) WR\_ACTIVE bit is active only during the data load phase. It becomes active when the first write transaction is scheduled and becomes inactive:
    - Until the last write transaction in the block (not super block) is descheduled and the FIFO is cleaned up for software-synchronized transfer
    - Until the last write transaction in the request (element/frame/packet/block sync) is descheduled and the FIFO is cleaned up for hardware-source-synchronized transfer (with [DMA4\\_CCRi\[25\]](#) BUFFERING\_DISABLE = 0) or hardware-destination-synchronized transfer.

#### 16.1.4.20.4.8 *Linked-List Channel Linking*

Channel linking for inter- and intra-super blocks is supported for type 1, 2, and 3 descriptors.

Assume that CHx and CHz are linked-list channels using generic descriptors. If CHx is composed of N descriptors and CHz is composed of M descriptors, then in nonfast mode:

CHx: CHx[Data1]-> CHx[DES1] -> . -> CHx[DESN]->CHx[DataN + 1]

CHz: CHz[Data1]-> CHz[DES1] -> . -> CHz[DESM]->CHz[DataM + 1]

It is possible to link CHx to CHz or CHx to itself after the completion of the CHx transfer (end of super block). To do this, the user must set the [DMA4\\_CLNK\\_CTRLi\[15\]](#) ENABLE\_LNK bit to 1 and the [DMA4\\_CLNK\\_CTRLi\[4:0\]](#) NEXTLCH\_ID bit to z (or to x for self linking) through the last descriptor using a type 1 descriptor. The sequence is:

CHx: CHx[Data1]-> CHx[DES1] -> . -> CHx[DESN]-CHx[DataN+1] -> CHz: CHz[Data1]-> CHz[DES1] -> . -> CHz[DESM]->CHz[DataM+1]

It is also possible to link CHx to CHz during the CHx transfer and before the end of super block. The user must set the [DMA4\\_CLNK\\_CTRLi\[15\]](#) ENABLE\_LNK bit to 1 and the [DMA4\\_CLNK\\_CTRLi\[4:0\]](#) NEXTLCH\_ID bit to z through descriptor p (CHx[DESp]) using a type 1 descriptor. The sequence is:

CHx: CHx[Data1]-> CHx[DES1] ->. -> CHx[DESp]->CHx[Data(p + 1)] -> CHz[Data1]-> CHz[DES1] -> .

The user must continue the linking until channels CHx and CHz complete their super-block transfers; otherwise, the channels remain enabled.

---

**NOTE:** In channel linking, the head of a chain can be in fast mode or nonfast mode. All channels that are not in the head of the chain can be in nonfast mode only. In self-linking, the channel cannot be in fast mode.

---

---

**NOTE:** If channel CHx links to CHz in the middle of the superblock transfer (remember link bit can be set through Type-1 descriptor load), CHx is disabled after the corresponding data load and enables the channel CHz.

---

## 16.1.5 DMA\_SYSTEM Basic Programming Model

### 16.1.5.1 Setup Configuration

After a hardware reset, program all fields in the logical channel registers to default values for any channels used, because most fields are undefined following reset.

Before programming any DMA transfers, the priority arbitration rate and the maximum FIFO depth must be configured through the [DMA4\\_GCR](#) register, and any required interrupts must be enabled through the [DMA4\\_IRQENABLE\\_Lj](#) registers and the logical channel [DMA4\\_CICRi](#) registers.

Software clears the [DMA4\\_CSRi](#) register and the IRQSTATUS bit for the different interrupt lines before enabling the channel.

### 16.1.5.2 Software-Triggered (Nonsynchronized) Transfer

To program a software-triggered DMA transfer:

1. Configure the transfer parameters in the logical DMA channel registers:

- [DMA4\\_CSDPi](#):
  - Transfer ES (8, 16, or 32 bits) in the DMA [DMA4\\_CSDPi\[1:0\]](#) bit field.
  - Read and write port access types (single/burst), DMA [DMA4\\_CSDPi\[8:7\]](#) and [DMA4\\_CSDPi\[15:14\]](#) bit fields
  - Source and destination endianness, DMA [DMA4\\_CSDPi\[21\]](#) and [DMA4\\_CSDPi\[19\]](#) bits
  - Write mode (posted or nonposted) and DMA [DMA4\\_CSDPi\[17:16\]](#) bit field
  - Source or destination packed or nonpacked (if the ES is less than the read/write port size), DMA [DMA4\\_CSDPi\[6\]](#) and [DMA4\\_CSDPi\[13\]](#) bits
- [DMA4\\_CENi](#): EN
- [DMA4\\_CFNi](#): FN per transfer block
- [DMA4\\_CSSAi](#) and [DMA4\\_CDSAi](#): Source and destination start address (aligned with transfer ES)
- [DMA4\\_CCRi](#):
  - Read and write port addressing modes, DMA [DMA4\\_CCRi\[13:12\]](#) and [DMA4\\_CCRi\[15:14\]](#) bit field
  - Priority bit for both read and write ports, DMA [DMA4\\_CCRi\[6\]](#) and [DMA4\\_CCRi\[26\]](#) bits
  - DMA request number (set to 0 for a software-triggered transfer) and DMA register bit fields [DMA4\\_CCRi\[4:0\] = 0](#) and [DMA4\\_CCRi\[20:19\] = 0](#)
- [DMA4\\_CSEIi](#), [DMA4\\_CSFi](#), [DMA4\\_CDEIi](#), and [DMA4\\_CDFIi](#): Source and destination element and frame indexes (depending on addressing mode)

2. Start the transfer through the enable bit in the channel [DMA4\\_CCRi](#) register and DMA [DMA4\\_CCRi\[7\]](#) bit

The following example performs a DMA transfer on channel 10 of a 240\*160 picture from RAM to RAM (0x80C00000 to 0x80F00000):

```
UWORD32 RegVal = 0;
DMA4_t *DMA4;
DMA4 = (DMA4_t
        *)malloc(sizeof(DMA4_t));

/* Init. parameters
   */
DMA4->DataType = 0x2; //
    DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0; //
    DMA4_CSDPi[8:7]
DMA4->WritePortAccessType = 0; //
    DMA4_CSDPi[15:14]
DMA4->SourceEndiansim = 0; //
    DMA4_CSDPi[21]
DMA4->DestinationEndianism = 0; //
```

```

        DMA4_CSDPi[19]
DMA4->WriteMode = 0; //
        DMA4_CSDPi[17:16]
DMA4->SourcePacked = 0; //
        DMA4_CSDPi[6]
DMA4->DestinationPacked = 0; //
        DMA4_CSDPi[13]
DMA4->NumberOfElementPerFrame = 240; //
        DMA4_CENi
DMA4->NumberOfFramePerTransferBlock = 160; //
        DMA4_CFNi
DMA4->SourceStartAddress = 0x80C00000; //
        DMA4_CSSAi
DMA4->DestinationStartAddress = 0x80F00000; //
        DMA4_CDSAi
DMA4->SourceElementIndex = 1; //
        DMA4_CSEIi
DMA4->SourceFrameIndex = 1; //
        DMA4_CSFii
DMA4->DestinationElementIndex = 1; //
        DMA4_CDEIi
DMA4->DestinationFrameIndex = 1; //
        DMA4_CDFii
DMA4->ReadPortAccessMode = 1; //
        DMA4_CCRi[13:12]
DMA4->WritePortAccessMode = 1; //
        DMA4_CCRi[15:14]
DMA4->ReadPriority = 0; //
        DMA4_CCRi[6]
DMA4->WritePriority = 0; //
        DMA4_CCRi[23]
DMA4->ReadRequestNumber = 0; //
        DMA4_CCRi[4:0]
DMA4->WriteRequestNumber = 0; //
        DMA4_CCRi[20:19]

/* 1) Configure the transfer
   parameters in the logical DMA registers
   */
/*-----*/

/*
   a) Set the data type CSDP[1:0], the Read/Write Port access type
   CSDP[8:7]/[15:14], the Source/dest endianism CSDP[21]/CSDP[19], write
   mode CSDP[17:16], source/dest packed or non-packed
   CSDP[6]/CSDP[13]*/

// Read CSDP
RegVal =
    DMA4_CSDP_CH10;

// Build reg

DMA4_CSEI_CH10 = DMA4->SourceElementIndex;

/* g)-
   Set the source frame index CSFI[15:0]*/
DMA4_CSFI_CH10 =
        DMA4->SourceFrameIndex ;

/* h)- Set the destination element
   index CDEI[15:0]*/

```

```

DMA4_CDEI_CH10 =
    DMA4->DestinationElementIndex;

/* i)- Set the destination
   frame index CDFI[31:0]*/

DMA4_CDFI_CH10 =
    DMA4->DestinationFrameIndex;

/* 2) Start the DMA transfer by
   Setting the enable bit CCR[7]=1 */

/*-----*/

//write enable bit
DMA4_CCR_CH10 |= 1 << 7; /* start */

```

### 16.1.5.3 Hardware-Synchronized Transfer

To monitor a hardware synchronized DMA transfer, initialize the [DMA4\\_CDACi](#) register before the software enable.

To configure an LCh to synchronize by element, packet, frame, or block, the frame synchronization [DMA4\\_CCRi\[5\]](#) FS bit and the block synchronization [DMA4\\_CCRi\[18\]](#) BS bit must be programmed. For all the following synchronized transfers (element, packet, and frame or block-synchronized transfers), the user must first set the [DMA4\\_CCRi\[24\]](#) SEL\_SRC\_DST\_SYNC bit to 1 when the source triggers on the DMA request and set it the [DMA4\\_CCRi\[24\]](#) SEL\_SRC\_DST\_SYNC bit to 0 when the destination triggers on the DMA request.

---

**NOTE:** The user must take care when setting the [DMA4\\_CCRi\[23\]](#) PREFETCH bit it is in conjunction with [DMA4\\_CCRi\[24\]](#) SEL\_SRC\_DST\_SYNC bit.

---

- To configure an LCh to transfer one element per DMA request:
  1. Set the number of DMA request associated with the current LCH in the [DMA4\\_CCRi\[20:19\]](#) SYNCHRO\_CONTROL\_UPPER and [DMA4\\_CCRi\[4:0\]](#) SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the [DMA4\\_CSDPi\[1:0\]](#) DATA\_TYPE bit field.
  3. Set the Read Port access type (single or burst access) in the [DMA4\\_CSDPi\[8:7\]](#) SRC\_BURST\_EN bit field.
  4. Set the Write Port access type (single or burst access) in the [DMA4\\_CSDPi\[15:14\]](#) DST\_BURST\_EN bit field.
  5. Set the Read Port addressing mode in the [DMA4\\_CCRi\[13:12\]](#) SRC\_AMODE bit field.
  6. Set the Write Port addressing mode in the [DMA4\\_CCRi\[15:14\]](#) DST\_AMODE bit field.
  7. Set the Read start address in the [DMA4\\_CSSAi\[31:0\]](#) SRC\_START\_ADRS bit field.
  8. Set the Write start address in the [DMA4\\_CDSAi\[31:0\]](#) DST\_START\_ADRS bit field.
  9. Set both FS and BS to 0 in [DMA4\\_CCRi\[5\]](#) FS and [DMA4\\_CCRi\[18\]](#) BS.
  10. Set to 1 the channel enable bit [DMA4\\_CCRi\[7\]](#) EN.
- To configure an LCh to transfer one frame per DMA request:
  1. Set the number of DMA request associated to the current LCH in the [DMA4\\_CCRi\[20:19\]](#) SYNCHRO\_CONTROL\_UPPER and [DMA4\\_CCRi\[4:0\]](#) SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the [DMA4\\_CSDPi\[1:0\]](#) DATA\_TYPE bit field.
  3. Set the number of element per frame in the [DMA4\\_CENi\[23:0\]](#) CHANNEL\_ELMNT\_NBR bit field.
  4. Set the Read Port access type (single or burst access) in the [DMA4\\_CSDPi\[8:7\]](#) SRC\_BURST\_EN bit field.

5. Set the Write Port access type (single or burst access) in the [DMA4\\_CSDPi\[15:14\]](#) DST\_BURST\_EN bit field.
  6. Set the Read Port addressing mode in the [DMA4\\_CCRi\[13:12\]](#) SRC\_AMODE bit field.
  7. Set the Write Port addressing mode in the [DMA4\\_CCRi\[15:14\]](#) DST\_AMODE bit field.
  8. Set the Read start address in the [DMA4\\_CSSAi\[31:0\]](#) SRC\_START\_ADRS bit field.
  9. Set the Write start address in the [DMA4\\_CDSAi\[31:0\]](#) DST\_START\_ADRS bit field.
  10. Set FS to 1 and BS to 0, respectively, in [DMA4\\_CCRi\[5\]](#) FS and [DMA4\\_CCRi\[18\]](#) BS.
  11. Set to 1 the channel enable bit [DMA4\\_CCRi\[7\]](#) EN.
- To configure an LCh to transfer one block per DMA request:
    1. Set the number of DMA request associated to the current LCH in the [DMA4\\_CCRi\[20:19\]](#) SYNCHRO\_CONTROL\_UPPER and [DMA4\\_CCRi\[4:0\]](#) SYNCHRO bit field.
    2. Set the data type, also referenced as element size (ES), in the [DMA4\\_CSDPi\[1:0\]](#) DATA\_TYPE bit field.
    3. Set the number of element per frame in the [DMA4\\_CENi\[23:0\]](#) CHANNEL\_ELMNT\_NBR bit field.
    4. Set in the [DMA4\\_CFNi\[15:0\]](#) CHANNEL\_FRAME\_NBR bit field the number of frame (transfers), to take place before the LCH gets disabled.
    5. Set the Read Port access type (single or burst access) in the [DMA4\\_CSDPi\[8:7\]](#) SRC\_BURST\_EN bit field.
    6. Set the Write Port access type (single or burst access) in the [DMA4\\_CSDPi\[15:14\]](#) DST\_BURST\_EN bit field.
    7. Set the Read Port addressing mode in the [DMA4\\_CCRi\[13:12\]](#) SRC\_AMODE bit field.
    8. Set the Write Port addressing mode in the [DMA4\\_CCRi\[15:14\]](#) DST\_AMODE bit field.
    9. Set the Read start address in the [DMA4\\_CSSAi\[31:0\]](#) SRC\_START\_ADRS bit field.
    10. Set the Write start address in the [DMA4\\_CDSAi\[31:0\]](#) DST\_START\_ADRS bit field.
    11. Set FS to 0 and BS to 1, respectively, in [DMA4\\_CCRi\[5\]](#) FS and [DMA4\\_CCRi\[18\]](#) BS.
    12. Set to 1 the channel enable bit [DMA4\\_CCRi\[7\]](#) EN.
  - To configure an LCh to transfer one packet per DMA request:
    1. Set the number of DMA request associated to the current LCH in the [DMA4\\_CCRi\[20:19\]](#) SYNCHRO\_CONTROL\_UPPER and [DMA4\\_CCRi\[4:0\]](#) SYNCHRO bit field.
    2. Set the data type, also referenced as element size (ES), in the [DMA4\\_CSDPi\[1:0\]](#) DATA\_TYPE bit field.
    3. Set the number of elements per packet to transfer: If the packet requestor is in the source, set [DMA4\\_CCRi\[24\]](#) SEL\_SRC\_DST\_SYNC to 1 and set the packet element number in the [DMA4\\_CSFli](#) register and set the addressing mode of source to constant addressing in [DMA4\\_CCRi\[13:12\]](#) SRC\_AMODE bit field; else, if the packet requestor is in the destination, set the [DMA4\\_CCRi\[24\]](#) SEL\_SRC\_DST\_SYNC to 0 and set the packet element number in the [DMA4\\_CDFli](#) register and set the addressing mode of destination to constant addressing in [DMA4\\_CCRi\[15:14\]](#) DST\_AMODE bit field.
    4. Set the number of elements per frame in the [DMA4\\_CENi\[23:0\]](#) CHANNEL\_ELMNT\_NBR bit field.
    5. Set in the [DMA4\\_CFNi\[15:0\]](#) CHANNEL\_FRAME\_NBR bit field the number of frames (transfers), to take place before the LCH gets disabled.
    6. Set the element number in the packet in the [DMA4\\_CSFli\[15:0\]](#) PKT\_ELNT\_NBR, if constant addressing or post-incremented addressing modes are used in the source side. However, the number of element in the packet is set in the [DMA4\\_CDFli\[15:0\]](#) PKT\_ELNT\_NBR if constant addressing mode is used in the destination side.
    7. Set the Read Port access type (single or burst access) in the [DMA4\\_CSDPi\[8:7\]](#) SRC\_BURST\_EN bit field.
    8. Set the Write Port access type (single or burst access) in the [DMA4\\_CSDPi\[15:14\]](#) DST\_BURST\_EN bit field.
    9. Set the Read Port addressing mode in the [DMA4\\_CCRi\[13:12\]](#) SRC\_AMODE bit field.

10. Set the Write Port addressing mode in the [DMA4\\_CCRi\[15:14\]](#) DST\_AMODE bit field.
11. Set the Read start address in the [DMA4\\_CSSAi\[31:0\]](#) SRC\_START\_ADRS bit field.
12. Set the Write start address in the [DMA4\\_CDSAi\[31:0\]](#) DST\_START\_ADRS bit field.
13. Set FS to 1 and BS to 1, respectively, in [DMA4\\_CCRi\[5\]](#) FS and [DMA4\\_CCRi\[18\]](#) BS.
14. Set to 1 the channel enable bit [DMA4\\_CCRi\[7\]](#) EN.

---

**NOTE:** It is possible to stop a transfer by disabling the channel by resetting the [DMA4\\_CCRi\[7\]](#) ENABLE bit.

---

#### 16.1.5.4 Synchronized Transfer Monitoring Using CDAC

The [DMA4\\_CDACi](#) register is writable and non-initialized (value undefined). It can be initialized to monitor a transfer by applying the following programming model:

1. Write 0 in the [DMA4\\_CDACi](#) register.
2. Enable the channel.
3. If a time-out occurs, read [DMA4\\_CDACi](#) register.
4. If [DMA4\\_CDACi](#) != 0 (it is the value configured in [DMA4\\_CDACi](#)):

This indicates that the corresponding transfer has started. The user can then rely on [DMA4\\_CCENi](#) and [DMA4\\_CCFNi](#) element and frame counters.

Otherwise, if [DMA4\\_CDACi](#) = 0 (it is the value configured in the [DMA4\\_CDACi](#)):

This indicates that the corresponding transfer did not start.

#### 16.1.5.5 Concurrent Software and Hardware Synchronization

This section describes thread allocation only; it does not describe the entire transfer. Because synchronized transfers are latency critical, you must allocate a thread at least on the synchronized target side.

Even for multiple concurrent channels, thread reservation ensures that when a hardware DMA request arrives, the read/write scheduler finds available thread(s) to initiate a channel schedule and issue a read/write transaction.

Consider six concurrent channels:

- Channels 0, 1, 2, and 3 are dedicated to memory-memory transfer; they are software triggered and not synchronized.
- Channel 4 is dedicated to memory-peripheral transfer, hardware triggered, and synchronized on the write side.
- Channel 5 is dedicated to peripheral-memory transfer, hardware triggered, and synchronized on the read side.

To perform thread reservation:

1. Allow thread reservation for priority channel 4 and channel 5:  
Reserve one thread (Read ThreadID 0) on the read port and one thread (Write ThreadID 0) on the write port: set the [DMA4\\_GCR\[13:12\]](#) HI\_THREAD\_RESERVED bit field to 0x1.
2. Specify channel priority:  
Channel 4 is a write high priority channel: set [DMA4\\_CCRi\[26\]](#) WRITE\_PRIORITY = 1.  
Channel 5 is a read high priority channel: set [DMA4\\_CCRi\[6\]](#) READ\_PRIORITY = 1.

#### 16.1.5.6 Chained Transfer

A chained DMA transfer can be programmed as follows:

1. Configure the transfer parameters for each logical DMA channel in the chain as in step 1 for either the synchronized or non-synchronized transfers described in [Section 16.1.5.5, Concurrent Software and Hardware Synchronization](#).

2. For each channel in the chain, configure the `DMA4_CLNK_CTRLi` register as follows:
  - Next logical DMA channel number (for a looping chained transfer link last channel to first channel number), in the `DMA4_CLNK_CTRLi[4:0]` NEXTLCH\_ID bit field.
  - Include the logical channel to the chain and enable link by setting the `DMA4_CLNK_CTRLi[15]` ENABLE\_LNK bit.
  - For a non-looping chain, the last logical channel in the chain must have the `DMA4_CLNK_CTRLi[15]` ENABLE\_LNK bit set to 0 to indicate the end of the chain.
3. Enable the transfer through the enable bit in the first logical channel `DMA4_CCRi[7]` ENABLE bit. All other channels in the chain must be disabled. Each channel is enabled automatically in turn when the previous logical channel transfer completes. A non-synchronized transfer starts immediately; a hardware-synchronized transfer starts when the DMA request line corresponding to the first DMA channel in the chain is asserted.

To stop a looping chained transfer, disable the `DMA4_CLNK_CTRLi[15]` ENABLE\_LNK bit (by setting it to 0x0), of the final channel transfer.

In the RAM-to-RAM copy example, to copy in loop, it is possible to link channel 10 on itself. The following line can be added in the channel configuration:

```
/* g) Set link for loop */
DMA4_CLNK_CTRL_CH10 =
    0x0000800A;
```

### 16.1.5.7 90-Degree Clockwise Image Rotation

The 90-degree clockwise image rotation example described in [Section 16.1.4.5, Addressing Modes](#), can be programmed as follows:

1. Configure the transfer parameters in the logical DMA channel registers:
  - `DMA4_CSDPi`:
    - Transfer ES = 32-bit (32 bpp), `DMA4_CSDPi[1:0]` DATA\_TYPE bit field
    - Read and write port access types = maximum burst size supported by memory device, `DMA4_CSDPi[8:7]` SRC\_BURST\_EN and `DMA4_CSDPi[15:14]` DST\_BURST\_EN bit fields
    - Source and destination endianness, `DMA4_CSDPi[21]` SRC\_ENDIAN and `DMA4_CSDPi[19]` DST\_ENDIAN bits
    - Write mode = posted with last element nonposted, `DMA4_CSDPi[17:16]` WRITE\_MODE bit field
    - Source and destination packed = Yes (although destination writes do not benefit because EI1), `DMA4_CSDPi[6]` SRC\_PACKED and `DMA4_CSDPi[13]` DST\_PACKED bits
  - `DMA4_CENi`: EN = 240
  - `DMA4_CFNi`: FN per transfer block = 160
  - `DMA4_CSSAi`: Source start address = 0x100000
  - `DMA4_CDSAi`: destination start address = 0x20013E
  - `DMA4_CCRi`:
    - Read and write port addressing modes = double-index addressing mode for both or post-increment addressing on source and double-index addressing on destination, `DMA4_CCRi[13:12]` SRC\_AMODE and `DMA4_CCRi[15:14]` DST\_AMODE bit fields
    - Low or high priority, `DMA4_CCRi[6]` READ\_PRIORITY bit
    - DMA request number = 0 (for software-triggered transfer), `DMA4_CCRi[4:0]` SYNCHRO\_CONTROL and `DMA4_CCRi[20:19]` SYNCHRO\_CONTROL\_UPPER bit fields
  - `DMA4_CSEIi`: Source EI = 1
  - `DMA4_CSFii`: Source frame index = 1
  - `DMA4_CDEIi`: destination EI = 637
  - `DMA4_CDFii`: destination frame index = 152967
2. Start the transfer through the enable bit in the channel `DMA4_CCRi` register.

The following parameters are used to perform this rotation from 0x80C00000 RAM address to 0x80F00000, with the same code used in [Section 16.1.5.2, Software-Triggered \(Nonsynchronized\) Transfer](#).

```

/* Init. parameters */
DMA4->DataType = 0x2; //
    DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0x3; // DMA4_CSDPi[8:7]

DMA4->WritePortAccessType = 0x3; // DMA4_CSDPi[15:14]

DMA4->SourceEndiansim = 0; // DMA4_CSDPi[21]

DMA4->DestinationEndianism = 0; // DMA4_CSDPi[19]

DMA4->WriteMode = 0x2; // DMA4_CSDPi[17:16]
DMA4->SourcePacked
    = 0x1; // DMA4_CSDPi[6]
DMA4->DestinationPacked = 0x1; //
    DMA4_CSDPi[13]
DMA4->NumberOfElementPerFrame = 240; // DMA4_CENi

DMA4->NumberOfFramePerTransferBlock = 160; // DMA4_CFNi

DMA4->SourceStartAddress = 0x80C00000; // DMA4_CSSAi

DMA4->DestinationStartAddress = 0x80F00000; // DMA4_CDSAi

DMA4->SourceElementIndex = 1; // DMA4_CSEIi

DMA4->SourceFrameIndex = 1; // DMA4_CSFII

DMA4->DestinationElementIndex = 637; // DMA4_CDEIi

DMA4->DestinationFrameIndex = -152967; // DMA4_CDFII

DMA4->ReadPortAccessMode = 0x3; // DMA4_CCRi[13:12]

DMA4->WritePortAccessMode = 0x3; // DMA4_CCRi[15:14]

DMA4->ReadPriority = 0; // DMA4_CCRi[6]
DMA4->WritePriority =
    0; // DMA4_CCRi[23]
DMA4->ReadRequestNumber = 0; // DMA4_CCRi[4:0]

DMA4->WriteRequestNumber = 0; // DMA4_CCRi[20:19]

```

### 16.1.5.8 Graphic Operations

- Transparent copy:
  1. Set the [DMA4\\_CCRi\[17\]](#) TRANSPARENT\_COPY\_ENABLE bit to 1
  2. Set the [DMA4\\_CCRi\[16\]](#) CONST\_FILL\_ENABLE bit to 0
  3. Set the value of the key color in the [DMA4\\_COLORi\[15:0\]](#) COLOR\_KEY bit field

To perform this graphic operation, the following lines can be added to the example of [Section 16.1.5.2, Software-Triggered \(Nonsynchronized\) Transfer](#).

```

DMA4_CCR_CH10 &= ~(0x1 << 16);
DMA4_CCR_CH10 |= 0x1 << 17;

DMA4_COLOR_CH10 = 0x00000003;

```

- Solid Color fill:
  1. Set the [DMA4\\_CCRi\[16\]](#) CONST\_FILL\_ENABLE bit to 1
  2. Set the [DMA4\\_CCRi\[17\]](#) TRANSPARENT\_COPY\_ENABLE bit to 0

3. Set the value of key the color in the `DMA4_COLORi[15:0]` `SOLID_COLOR` bit field

To perform this graphic operation, the following lines can be added to the example of [Section 16.1.5.2, Software-Triggered \(Nonsynchronized\) Transfer](#).

```
DMA4_CCR_CH10 &= ~(0x1 << 17);
DMA4_CCR_CH10 |= 0x1 << 16;

DMA4_COLOR_CH10 = 0x00000003;
```

### 16.1.5.9 Linked-List Programming Guidelines

- With the exception of the `DMA4_CCRi[7]` `ENABLE` bit and the `DMA4_CDPi[7]` `PAUSE_LINK_LIST` bit during a linked-list transfer (descriptor load phase or data load phase), avoid programming any register through the configuration port.
- Before enabling any linked-list transfer, ensure that all global registers and all registers in the descriptor are initialized. Some static channel registers (registers that are not updated by the descriptor to be loaded) must also be initialized correctly:
  - For type 2, the following registers must be initialized with consistent values:
    - All global registers
    - `DMA4_CCRi`
    - `DMA4_CSDPi`
    - `DMA4_CLNK_CTRLi`
  - For type 3, the following registers must be initialized with consistent values:
    - All global registers
    - `DMA4_CCRi`
    - `DMA4_CSDPi`
    - `DMA4_CLNK_CTRLi`
    - `DMA4_CICRi`
    - `DMA4_CFNi`
- In case of a linked list with descriptor types 2 and 3, the content of the `DMA4_CCRi` register must not change during super-block life.
- The `PAUSE_LINK_LIST` bit must not be set in the initialization phase.

## 16.1.6 DMA\_SYSTEM Register Manual

### 16.1.6.1 DMA\_SYSTEM Instance Summary

**Table 16-19. DMA\_SYSTEM Instance Summary**

Module Name	Base Address	Size
DMA_SYSTEM	0x4A05 6000	4 KiB

### 16.1.6.2 DMA\_SYSTEM Registers

#### 16.1.6.2.1 DMA\_SYSTEM Register Summary

Index *i* represents the logical channel number (where  $i = 0$  to 31). The offset address for some registers is calculated from the channel *c* number. For example, the DMA4\_CCR10 (channel 10) register has an offset address of  $10 \times 0x60 = 0x3C0$ , and thus a physical address of  $0x4A05\ 6080 + 0x3C0 = 0x4A05\ 6440$ .

Index *j* represents the interrupt line number (where  $j = 0$  to 3). The offset address for some registers is calculated from the channel *c* number. For example, the DMA4\_IRQSTATUS\_L3 (line 3) register has an offset address of  $3 \times 0x4 = 0xC$ , and thus a physical address of  $0x4A05\ 6008 + 0xC = 0x4A05\ 6014$ .

**Table 16-20. DMA\_SYSTEM Registers Mapping Summary**

### 16.1.6.2.2 DMA\_SYSTEM Register Description

**NOTE:** Some registers have no reset value (marked with -) because of hardware implementation in memory. Software must ensure the correct programming of these registers, if needed.

Shadow registers are used to read run-time registers such as CCEN, CCFN, CDAC, and CSAC. Typically, when accessed in 8-bit or 16-bit access for two consecutive accesses, the value of the previous registers can change. A shadow register holds the entire value to let the next access recover the remaining 24 or 16 bits.

For non-32-bit transactions, start reading or writing from the LSByte first to enable the register update. There is no issue for 32-bit read-write transactions.

**Table 16-39. DMA4\_GCR**

<b>Address Offset</b>	0x0000 0078	<b>Instance</b>	DMA_SYSTEM
<b>Physical Address</b>	0x4A05 6078		
<b>Description</b>	FIFO sharing between high and low priority channel. The Maximum per channel FIFO depth is bounded by the low and high channel FIFO budget. The high respectively low priority channels maximum burst size must be less than the min (high respectively low priority channel FIFO budget, per channel maximum FIFO depth)		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								ARBITRATION_RATE								RESERVED				MAX_CHANNEL_FIFO_DEPTH											
CHANNEL_ID_GATE																HI_LO_FIFO_BUDGET				HI_THREAD_RESERVED											

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x00
24	CHANNEL_ID_GATE	Gates the Channel ID bus monitoring on both Read and Write ports 0x0: Gates the Channel ID qualifiers on both Read and Write Ports 0x1: Does not gate the Channel ID qualifiers on both Read and Write Ports	RW	0x0
23:16	ARBITRATION_RATE	Arbitration switching rate between prioritized and regular channel queues	RW	0x01
15:14	HI_LO_FIFO_BUDGET	Allow to have a separate Global FIFO budget for high and low priority channels. For Hi priority Channel: (Per_channel_Maximum FIFO depth + 1) x Number of active High priority Channel =< High Budget FIFO For Low priority channel: (Per_channel_Maximum FIFO depth + 1) x Number of active Low priority Channel =< Low Budget FIFO  0x0: no fixed budget for neither higher nor lower priority channel 0x1: 75% of FIFO for low priority and 25% for high priority channels 0x2: 25% of FIFO for low priority and 75% for high priority channels 0x3: 50% of FIFO for low priority and 50% for high priority channels	RW	0x0
13:12	HI_THREAD_RESERVED	Allow thread reservation for high priority channel on both read and write ports.  0x0: No ThreadID is reserved on the Read Port for high priority channels. No ThreadID is reserved on the Write Port for high priority channels. 0x1: Read Port ThreadID 0 is reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels. 0x2: Read port ThreadID 0 and ThreadID 1 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels. 0x3: Read PortThreadID 0, ThreadID 1 and ThreadID 2 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels.	RW	0x0

Bits	Field Name	Description	Type	Reset
11:8	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x0
7:0	MAX_CHANNEL_FIFO_DEPTH	Maximum FIFO depth allocated to one logical channel. Maximum FIFO depth can not be 0x0. It should be at least 0x1 or greater. Note that If channel limit is less than destination burst size enough data will not be accumulated in the data FIFO and it will never be sent out on the WR port. The burst size should be less than the FIFO limit specified in this bit field.	RW	0x10

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x0
29:27	RESERVED	Reserved for non-GP devices	RW	0x0
26	WRITE_PRIORITY	Channel priority on the Write side  0x0: Channel has low priority on the write side during the arbitration process. 0x1: Channel has high priority on write sided during the arbitration process.	RW	0

Bits	Field Name	Description	Type	Reset
25	BUFFERING_DISABLE	This bit allows to disable the default buffering functionality when transfer is source synchronized.  0x0: Buffering is enabled across element/packet when source is synchronized to element, packet, frame or blocks.  0x1: Buffering is disabled across element/packet when source is synchronized to element, packet, frame or blocks.	RW	-
24	SEL_SRC_DST_SYNC	Specifies that element, packet, frame or block transfer (depending on CCR.bs and CCR.fs) is triggered by the source or the destination on the DMA request  0x0: Transfer is triggered by the destination. If synch on packet the packet element number is specified in the CDFI register.  0x1: Transfer is triggered by the source. If synchronized on packet the packet element number is specified in the CSFI register.	RW	-
23	PREFETCH	Enables the prefetch mode  0x0: Prefetch mode is disabled. When Sel_Src_Dst_Sync=1 transfers are buffered and pipelined between DMA requests.  0x1: Prefetch mode is enabled. Prefetch mode is active only when destination is synchronized. It is software user responsibility not to have at the same time Prefetch=1 when Sel_Src_Dst_Sync=1. This mode is not supported.	RW	0
22	SUPERVISOR	Enables the supervisor mode  0x0: Supervisor mode is disabled.  0x1: Supervisor mode is enabled.	RW	0
21	RESERVED	Reserved for non-GP devices	RW	0
20:19	SYNCHRO_CONTROL_UPPER	Channel Synchronization control upper (used in conjunction with the 5 bits of synchro channel <a href="#">DMA4_CCRi[4:0]</a> ) Used in conjunction, as 2 MSB, with the 5 bits of the synchro channel bit field.	RW	0b00
18	BS	Block synchronization This bit used in conjunction with the fs to see how the DMA request is serviced in a synchronized transfer.	RW	-
17	TRANSPARENT_COPY_ENABLE	Transparent copy enable  0x0: Transparent copy mode is disabled.  0x1: Transparent copy mode is enabled.	RW	-
16	CONST_FILL_ENABLE	Constant fill enable  0x0: Constant fill mode is disabled.  0x1: Constant fill mode is enabled.	RW	0
15:14	DST_AMODE	Selects the addressing mode on the Write Port of a channel.  0x0: Constant address mode  0x1: Post-incremented address mode  0x2: Single index address mode  0x3: Double index address mode	RW	0bxx
13:12	SRC_AMODE	Selects the addressing mode on the Read Port of a channel.  0x0: Constant address mode  0x1: Post-incremented address mode  0x2: Single index address mode  0x3: Double index address mode	RW	0bxx
11	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0

Bits	Field Name	Description	Type	Reset
10	WR_ACTIVE	Indicates if the channel write context is active or not Read 0x0: Channel is not active on the write port. Read 0x1: Channel is currently active on the write port.	R	0
9	RD_ACTIVE	Indicates if the channel read context is active or not Read 0x0: Channel is not active on the read port. Read 0x1: Channel is currently active on the read port.	R	0
8	SUSPEND_SENSITIVE	Logical channel suspend enable bit 0x0: The channel ignores the MSuspend even if EMUFree is set to 0. 0x1: If EMUFree is set to 0 and MSuspend comes in then all current OCP services (single transaction or burst transaction as specified in the corresponding CSDP register) have to be completed before stopping processing any more transactions.	RW	0
7	ENABLE	Logical channel enable. It is SW responsibility to clear the CSR register and the IRQSTATUS bit for the different interrupt lines before enabling the channel. 0x0: The logical channel is disabled. 0x1: The logical channel is enabled.	RW	0
6	READ_PRIORITY	Channel priority on the read side 0x0: Channel has low priority on the read side during the arbitration process. 0x1: Channel has high priority on read sided during the arbitration process.	RW	0
5	FS	Frame synchronization This bit used in conjunction with the BS to see how the DMA request is serviced in a synchronized transfer FS = 0 and BS = 0: An element is transferred once a DMA request is made. FS = 0 and BS = 1: An entire block is transferred once a DMA request is made. FS = 1 and BS = 0: An entire frame is transferred once a DMA request is made. FS = 1 and BS = 1: A packet is transferred once a DMA request is made. All these different transfers can be interleaved on the port with other DMA requests.	RW	-
4:0	SYNCHRO_CONTROL	Channel synchronization control This bit field used in conjunction with the second_level_synchro_control_upper (as 2 MSB) 0000000 : Is reserved for non synchronized LCH transfer xxxxxxx (from 1 to 127)There are 127 possible DMA request to assign to any LCH. <b>Note:</b> The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, DMA4_CCR[4:0] SYNCHRO_CONTROL must be set to 0x2 (DMA request number + 1).	RW	0b00000

## 16.2 Enhanced DMA

This chapter describes the Enhanced Direct Memory Access (EDMA) controller.

### 16.2.1 EDMA Module Overview

The enhanced direct memory access module, also called EDMA, performs high-performance data transfers between two slave points, memories and peripheral devices without microprocessor unit (MPU) or digital signal processor (DSP) support during transfer. EDMA transfer is programmed through a logical EDMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

The EDMA can also perform transfers between external memories and between Device subsystems internal memories, with some performance loss caused by resource sharing between the read and write ports.

EDMA controller is based on two major principal blocks:

- EDMA third-party channel controller (EDMA\_TPCC)
- EDMA third-party transfer controller (EDMA\_TPTC)

The **TPCC** is a high flexible Channel Controller. It serves as an user interface and an event interface for the EDMA controller. The EDMA\_TPCC serves to prioritize incoming software requests or events from peripherals and submits transfer requests (TRs) to the transfer controller.

The **TPTC** performs read and write transfers by EDMA ports to the slave peripherals as programmed in the "Active" and "Pending" set of the registers. The transfer controllers are responsible for data movement and issue read/write commands to the source and destination addresses that are programmed for a given transfer in the EDMA\_TPCC.

The SoC integrates the following EDMA instances:

- One system-level EDMA
- One DSP internal EDMA (per DSP)
- One EVE internal EDMA (per EVE)

Each of these EDMA modules consists of:

- One TPCC instance
- Two TPTC instances

---

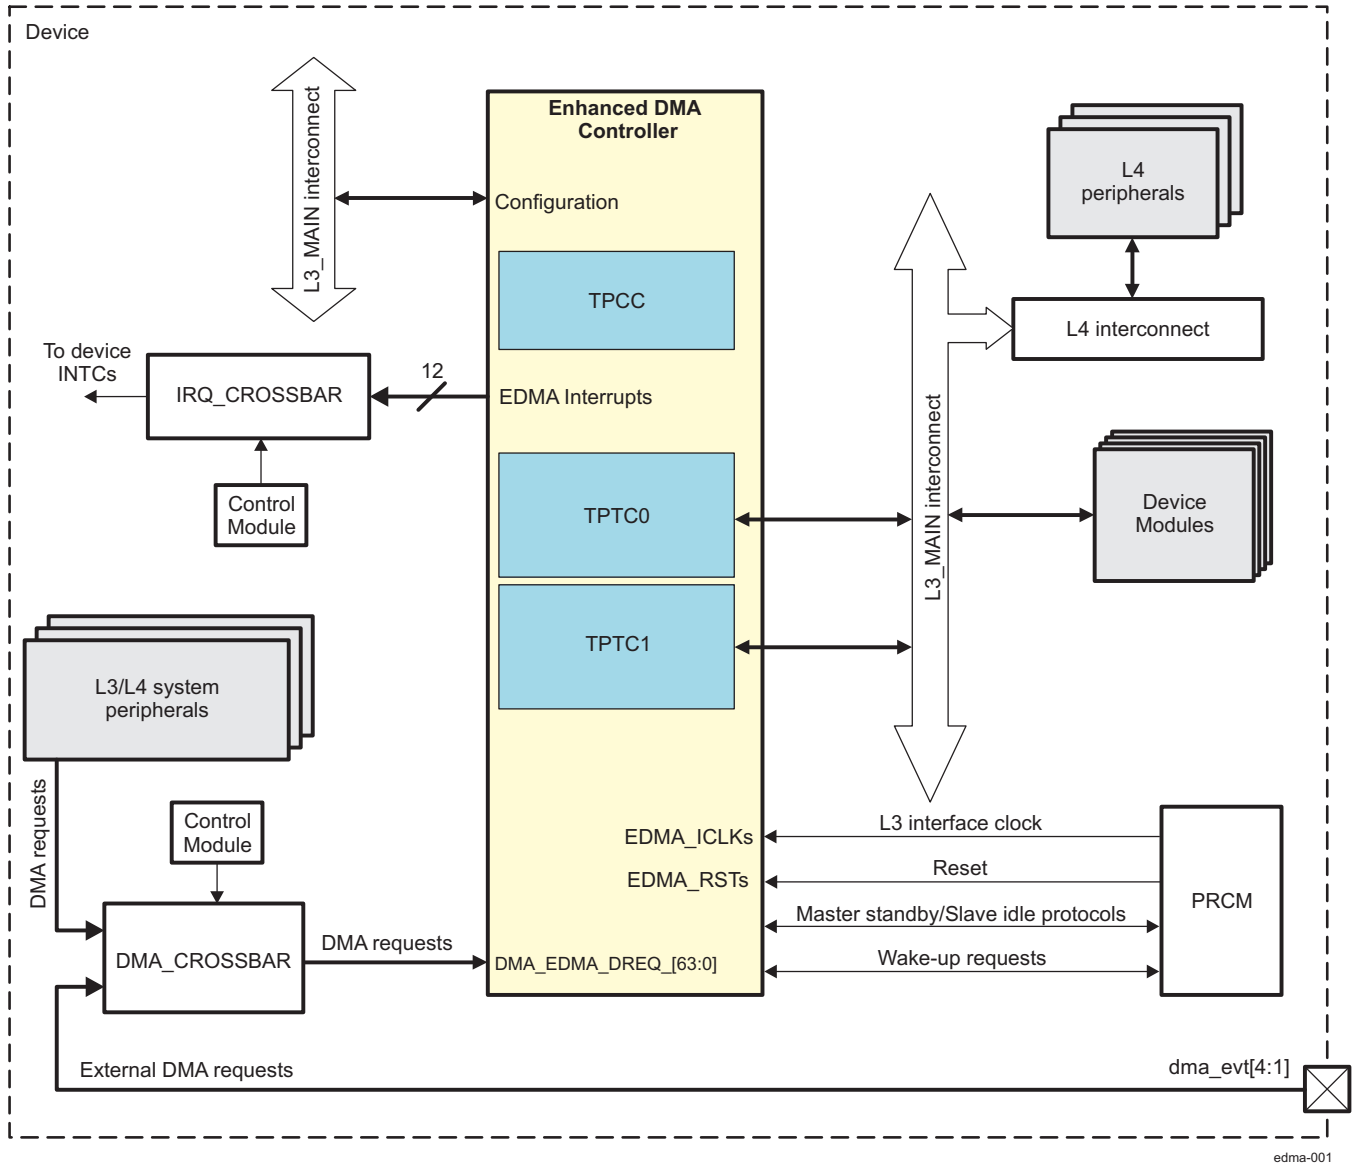

**NOTE:** All EDMA modules in the SoC are functionally identical. Note that some of the configuration parameters may be different for the various EDMA instances (see [Section 16.2.1.2, EDMA Controllers Configuration](#)).

This chapter is mostly focused on describing the system-level EDMA module (in terms of configuration and integration in the SoC). For details on DSPx\_EDMA / EVEx\_EDMA integration, see their respective chapters.

---

[Figure 16-12](#) shows an overview of the EDMA module.

Figure 16-12. EDMA module Overview

The device CPUs can configure the EDMA controller blocks through the L3\_MAIN interconnect.

### 16.2.1.1 EDMA Features

The **EDMA\_TPCC** channel controller has following features:

- Fully orthogonal transfer description:
  - Three transfer dimensions.
  - A-synchronized transfers: one-dimension serviced per event.
  - AB-synchronized transfers: two-dimensions serviced per event.
  - Independent indexes on source and destination.
  - Chaining feature allows a 3-D transfer based on a single event.
- Flexible transfer definition:
  - Increment or FIFO transfer addressing modes.
  - Linking mechanism allows automatic PaRAM set update.

- Chaining allows multiple transfers to execute with one event.
- Interrupt generation for the following:
  - Transfer completion.
  - Error conditions.
- Debug visibility:
  - Queue water marking/threshold.
  - Error and status recording to facilitate debug.
- 64 DMA request channels:
  - Event synchronization.
  - Manual synchronization (CPU(s) write to event set registers [EDMA\\_TPCC\\_ESR](#) and [EDMA\\_TPCC\\_ESRH](#)).
  - Chain synchronization (completion of one transfer triggers another transfer).
- Eight QDMA channels:
  - QDMA channels trigger automatically upon writing to a parameter RAM (PaRAM) set entry.
  - Support for programmable QDMA channel to PaRAM mapping.
- 512 PaRAM sets:
  - Each PaRAM set can be used for a DMA channel, QDMA channel, or link set.
- Two transfer controllers/event queues.
- 16 event entries per event queue.
- Memory protection support:
  - Proxy memory protection for TR submission.
  - Active memory protection for accesses to PaRAM and registers.

The **EDMA\_TPTC** transfer controller has the following features:

- Two transfer controllers (TC).
- 128-bit wide read and write ports per TC.
- Up to four in-flight transfer requests (TRs).
- Programmable priority level.
- Supports two-dimensional transfers with independent indexes on source and destination (EDMA\_TPCC manages the 3rd dimension).
- Support for increment or constant addressing mode transfers.
- Interrupt and error support.
- Memory-Mapped Register (MMR) bit fields are fixed position in 32-bit MMR regardless of endianness.

EDMA controller uses the shared MMU1 module for transferring to and from DSP module. This provides several benefits including:

- Protection of Host CPU memory regions from accidental corruption by EDMA TPTCs.
- Direct allocation of buffers in user space without the need for translation between CPU and DSP applications utilizing EDMA TPTCs.

Accesses by the EDMA TPTCs (both TPTC0 and TPTC1) may optionally be routed through the MMU1.

The TPTC0 and TPTC1 routing allows EDMA transfer controller to be used to perform transfers using only the virtual addresses of the associated buffers.

For more information about MMU1 module refer to [Chapter 20 Memory Management Units](#).

### 16.2.1.2 EDMA Controllers Configuration

[Table 16-83](#) summarizes the configuration for each of the EDMA channel controllers present on the SoC.

**Table 16-83. EDMA Channel Controllers Configuration**

Parameter	SYS_EDMA CC Configuration	DSPx_EDMA CC Configuration	EVEx_EDMA CC Configuration
Number of DMA channels (NUM_DMACH)	64	64	16
Number of QDMA channels (NUM_QDMACH)	8	8	8
Number of interrupt channels (NUM_INTCH)	64	64	16
Number of PaRAM set entries (NUM_PARAMENTRY)	512	128	128
Number of event queues (NUM_EVQUE)	2	2	2
Number of transfer controllers (NUM_TC)	2	2	2
Memory protection existence (MPEXIST)	Yes	Yes	Yes
Number of memory protection and shadow regions (NUM_REGIONS)	8	8	8
Channel mapping existence (CHMAPEXIST)	Yes	Yes	Yes

Table 16-84 summarizes the configuration of each of the EDMA transfer controllers present on the SoC.

**Table 16-84. EDMA Transfer Controllers Configuration**

Parameter	SYS_EDMA TC0 / TC1 Configuration	DSPx_EDMA TC0 / TC1 Configuration	EVEx_EDMA TC0 / TC1 Configuration
Data FIFO size (FIFOSIZE)	1024 bytes	2048 bytes	2048 bytes
Bus width (BUSBYTE)	16 bytes	16 bytes	16 bytes
Number of destination FIFO register sets (DSTREGDEPTH)	4 entries	4 entries	4 entries
Default burst size (DBS)	Defined by CTRL_CORE_CONTROL_ IO_1 register	Defined by DSP_SYS_BUS_CONFIG register	Defined by EVE_BUS_CONFIG register

### 16.2.2 EDMA Controller Environment

The EDMA controller supports external DMA requests through the dma\_evt[4:1] pins (see [Table 16-85](#)). A logical channel can be configured to respond to an external synchronization request.

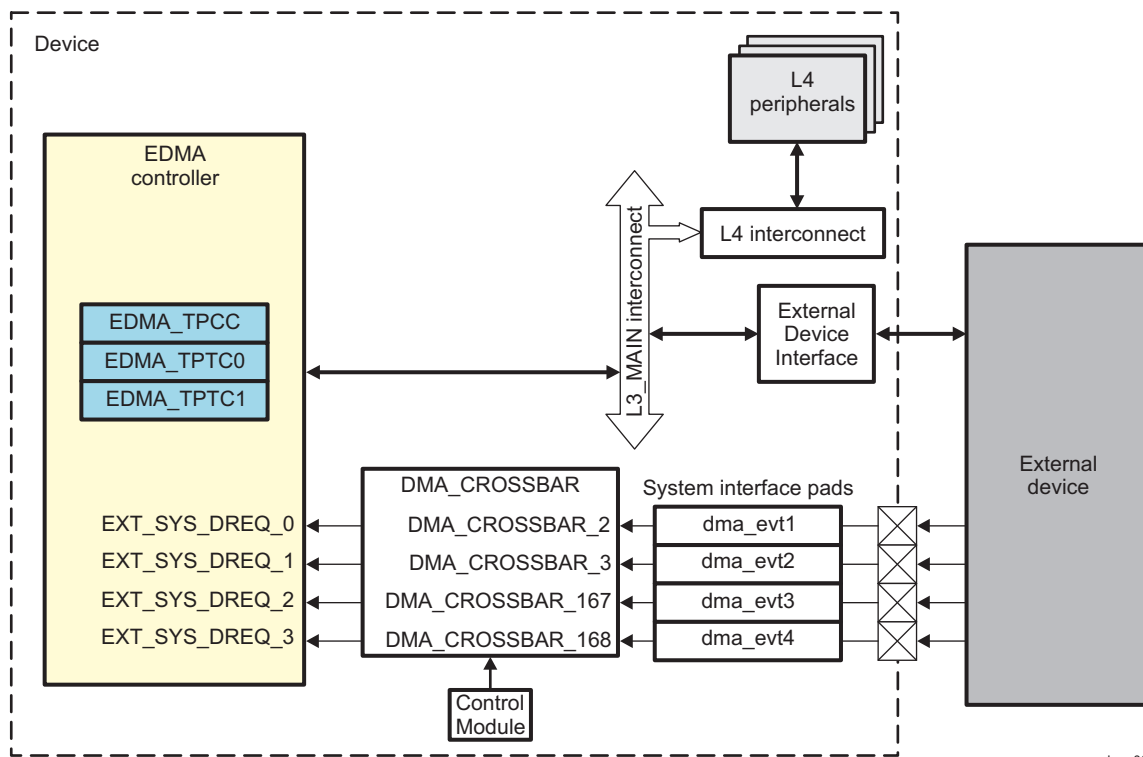

**Table 16-85. External EDMA Request Signals**

Pin Name	DMA_CROSSBAR Input	Signal Name	I/O <sup>(1)</sup>	Description	Module Reset Value
dma_evt1	DMA_CROSSBAR_2	EXT_SYS_DREQ_0	I	External DMA request 0 (system expansion)	Z
dma_evt2	DMA_CROSSBAR_3	EXT_SYS_DREQ_1	I	External DMA request 1 (system expansion)	Z
dma_evt3	DMA_CROSSBAR_167	EXT_SYS_DREQ_2	I	External DMA request 2 (system expansion)	Z
dma_evt4	DMA_CROSSBAR_168	EXT_SYS_DREQ_3	I	External DMA request 3 (system expansion)	Z

<sup>(1)</sup> I = Input, O = Output

[Figure 16-13](#) shows an example of how to use the external hardware DMA request pins in the EDMA environment.

**Figure 16-13. Example of External DMA Requests Use**

edma-005

An external device can use the external DMA request pins to start a logical channel transfer. The transfer can be a memory-to-memory transfer in which the source memory is in the external device.

By default, the external DMA request signals are not available on external pins after a cold reset. For more information about multiplexing out the two signal lines to pins, refer to [Chapter 18, Control Module](#).

All 64 DMA request lines are transition sensitive.

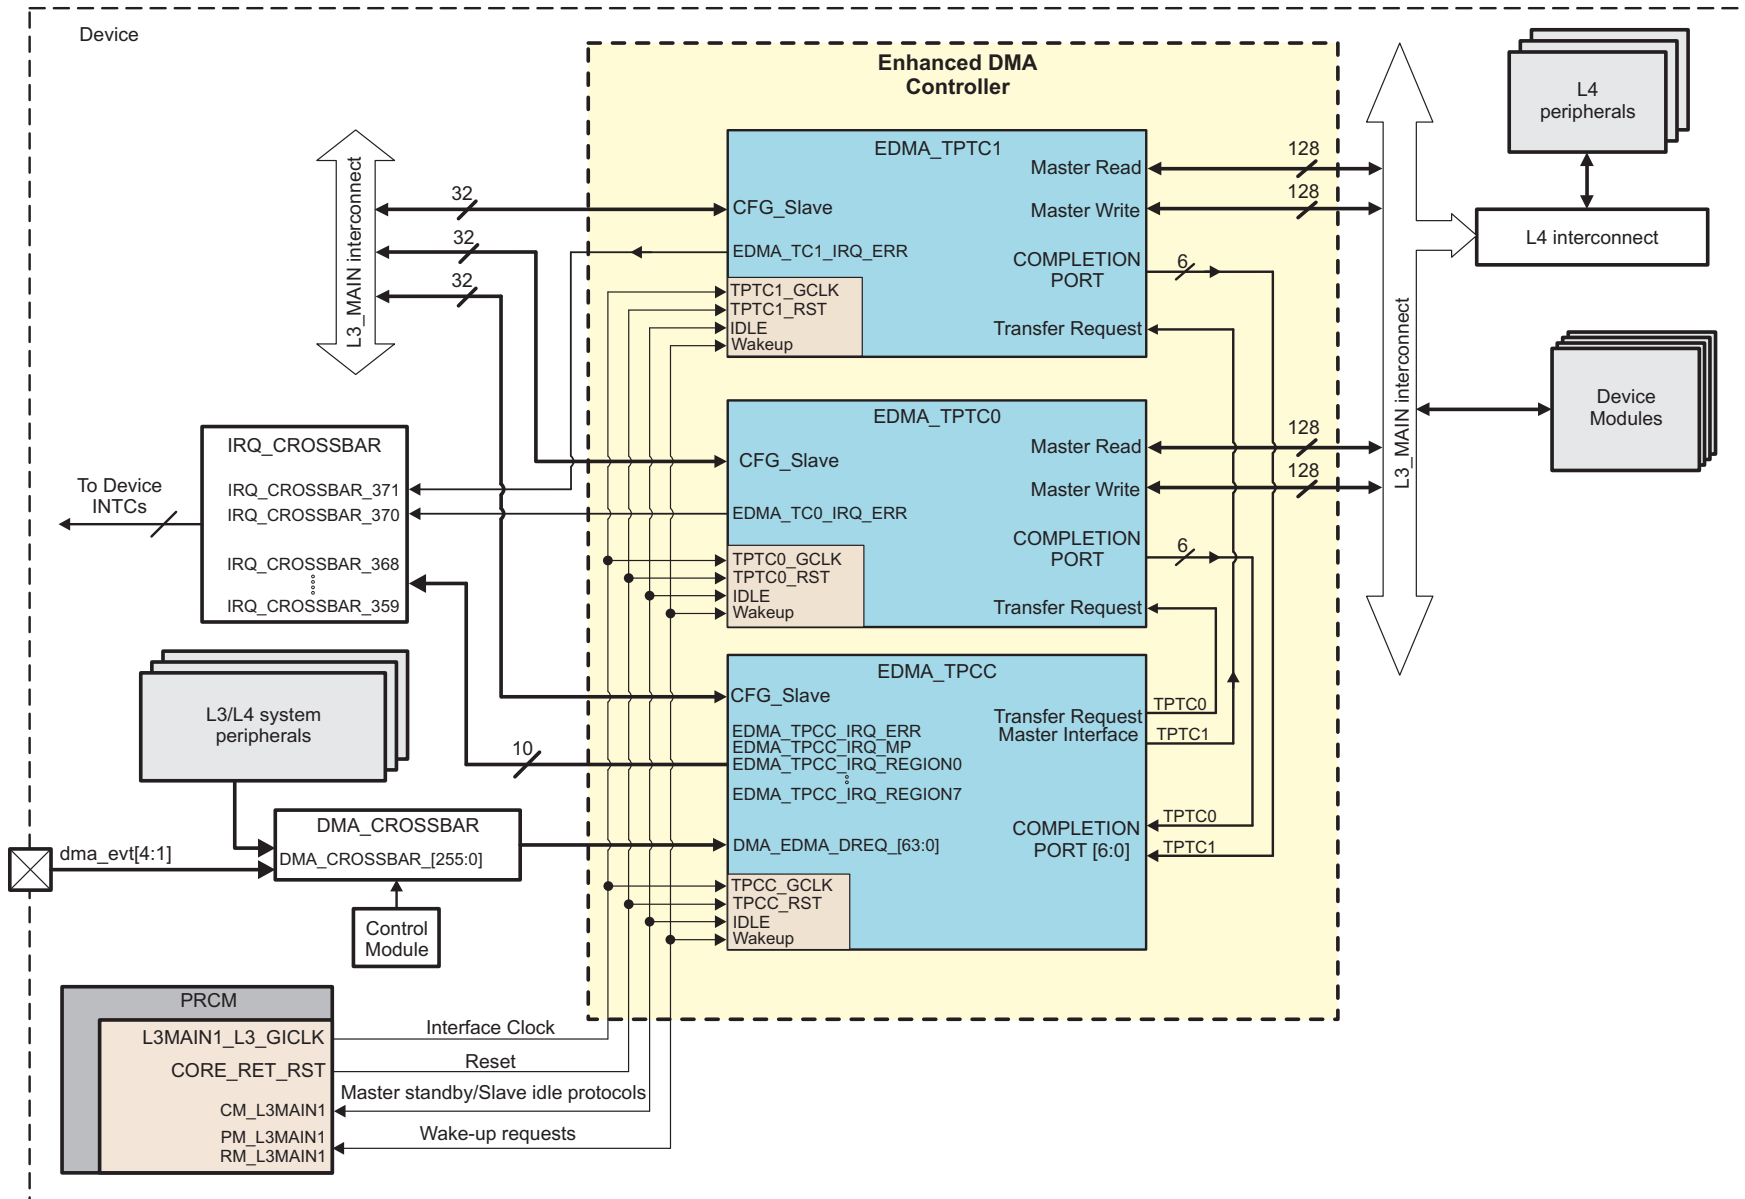

### 16.2.3 EDMA Controller Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

[Figure 16-14](#) shows the EDMA controller integration.

Figure 16-14. EDMA Controller Integration

edma-002

Table 16-86 through Table 16-88 summarize the integration of the module in the device.

**Table 16-86. EDMA Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect
EDMA_TPCC	PD_COREAON	L3_MAIN
EDMA_TPTC0		
EDMA_TPTC1		

**Table 16-87. EDMA Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
EDMA_TPCC	EDMA_TPCC_GCLK	L3MAIN1_L3_GICKL	PRCM	Interface clock. It supports the configuration port. For information about PRCM clock gating and management, see <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
EDMA_TPTC0	EDMA_TPTC0_GCLK			
EDMA_TPTC1	EDMA_TPTC1_GCLK			
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
EDMA_TPCC	EDMA_TPCC_RST	CORE_RET_RST	PRCM	Hardware retention reset. It initializes all internal logic of the EDMA controller modules, all global registers, and some of the per-channel registers, implemented in flip-flops. However, all remaining per-channel registers are memory-based, and, therefore, are not reset (have undefined values). Thus, when programming a channel for the first time, all bits that have undefined reset values must be configured before enabling the channel. For information about PRCM reset sources and distribution, see <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
EDMA_TPTC0	EDMA_TPTC0_RST			
EDMA_TPTC1	EDMA_TPTC1_RST			

**Table 16-88. EDMA Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	Destination IRQ_CROSSBAR INPUT	Default mapping	Description
EDMA_TPCC	EDMA_TPCC_IRQ_ERR	IRQ_CROSSBAR_359	-	TPCC error interrupt. This IRQ source signal is not mapped by default to any device INTC. For more information about INTC refer to <a href="#">Chapter 17 Interrupt Controllers</a> .
	EDMA_TPCC_IRQ_MP	IRQ_CROSSBAR_360	-	TPCC memory protection interrupt. This IRQ source signal is not mapped by default to any device INTC.

**Table 16-88. EDMA Hardware Requests (continued)**

EDMA_TPCC_IRQ_REGION0	IRQ_CROSSBAR_361	-	TPCC Region 0 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
EDMA_TPCC_IRQ_REGION1	IRQ_CROSSBAR_362	-	TPCC Region 1 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
EDMA_TPCC_IRQ_REGION2	IRQ_CROSSBAR_363	-	TPCC Region 2 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
EDMA_TPCC_IRQ_REGION3	IRQ_CROSSBAR_364	-	TPCC Region 3 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
EDMA_TPCC_IRQ_REGION4	IRQ_CROSSBAR_365	-	TPCC Region 4 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
EDMA_TPCC_IRQ_REGION5	IRQ_CROSSBAR_366	-	TPCC Region 5 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
EDMA_TPCC_IRQ_REGION6	IRQ_CROSSBAR_367	-	TPCC Region 6 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
EDMA_TPCC_IRQ_REGION7	IRQ_CROSSBAR_368	-	TPCC Region 7 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
EDMA_TPTC0	EDMA_TC0_IRQ_ERR	IRQ_CROSSBAR_370	-	TPTC0 error interrupt. This IRQ source signal is not mapped by default to any device INTC.
EDMA_TPTC1	EDMA_TC1_IRQ_ERR	IRQ_CROSSBAR_371	-	TPTC1 error interrupt. This IRQ source signal is not mapped by default to any device INTC.

**NOTE:** The “**Default Mapping**” column in [Table 16-88 EDMA Hardware Requests](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ\_CROSSBAR or DMA\_CROSSBAR modules.

For more information about the IRQ\_CROSSBAR and DMA\_CROSSBAR modules, see sections: [Section 18.4.6.4 IRQ\\_CROSSBAR Module Functional Description](#) and [Section 18.4.6.5 DMA\\_CROSSBAR Module Functional Description](#), in [Chapter 18 Control Module](#). For more information about the device interrupt controllers, see [Chapter 17 Interrupt Controllers](#).

**NOTE:** For a description of the interrupt source, see [Section 16.2.4.9, EDMA interrupts](#).

### 16.2.3.1 EDMA Requests to the EDMA Controller

[Table 16-89](#) lists the default DMA sources for the EDMA controller. In addition, the EDMA inputs (DMA\_EDMA\_DREQ\_[63:0]) can alternatively be sourced through the associated DMA\_CROSSBAR from one of the 256 multiplexed device DMA sources listed in [Table 16-6](#). The CTRL\_CORE\_DMA\_EDMA\_DREQ\_y\_z registers (where y and z are indexes of EDMA input lines) in the Control Module are used to select between the default DMA sources and the multiplexed DMA sources.

**Table 16-89. EDMA Default Request Mapping**

DMA Request Line	DMA_CROSSBAR Instance Number	DMA_CROSSBAR Configuration Register	DMA_CROSSBAR Default Input Index	Default DMA Source Name	Default DMA Source Description
DMA_EDMA_DREQ_0	1	<a href="#">CTRL_CORE_DMA_EDMA_DREQ_0_1</a> [7:0]	1	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_1	2	<a href="#">CTRL_CORE_DMA_EDMA_DREQ_0_1</a> [23:16]	2	EXT_SYS_DREQ_0	External DMA request 0 (system expansion)
DMA_EDMA_DREQ_2	3	<a href="#">CTRL_CORE_DMA_EDMA_DREQ_2_3</a> [7:0]	3	EXT_SYS_DREQ_1	External DMA request 1 (system expansion)
DMA_EDMA_DREQ_3	4	<a href="#">CTRL_CORE_DMA_EDMA_DREQ_2_3</a> [23:16]	4	GPMC_DREQ	GPMC data transmit request from prefetch engine
DMA_EDMA_DREQ_4	5	<a href="#">CTRL_CORE_DMA_EDMA_DREQ_4_5</a> [7:0]	5	Reserved	Reserved by default but can be remapped to a valid DMA source

## 16.2.4 EDMA Controller Functional Description

This chapter discusses the architecture of the EDMA controller.

### 16.2.4.1 Block Diagram

Figure 16-15 shows the functional block diagram of the EDMA controller.

**Figure 16-15. EDMA Controller Block Diagram**

#### 16.2.4.1.1 Third-Party Channel Controller

The TPCC is the EDMA transfer scheduler responsible for scheduling, arbitrating, and issuing user programmed transfers to the two TPTCs.

Figure 16-16 shows a functional block diagram of the EDMA channel controller (EDMA\_TPCC).

The main blocks of the EDMA\_TPCC are as follows:

- **Parameter RAM (PaRAM):** The PaRAM maintains parameter sets for channel and reload parameter sets. The PaRAM must be written with the transfer context for the desired channels and link parameter sets. EDMA\_TPCC processes and sets based on a trigger event and submits a transfer request (TR) to the transfer controllers.
- **EDMA event and interrupt processing registers:** Allows mapping of events to parameter sets, enable/disable events, enable/disable interrupt conditions, and clearing interrupts.
- **Completion detection:** The completion detect block detects completion of transfers by the EDMA\_TPTCs or slave peripherals. The completion of transfers can be used optionally to chain trigger new transfers or to assert interrupts.
- **Event queues:** Event queues form the interface between the event detection logic and the transfer request submission logic.
- **Memory protection registers:** Memory protection registers define the accesses (privilege level and requestor(s)) that are allowed to access the DMA channel shadow region view(s) and regions of PaRAM.

Other functions include the following:

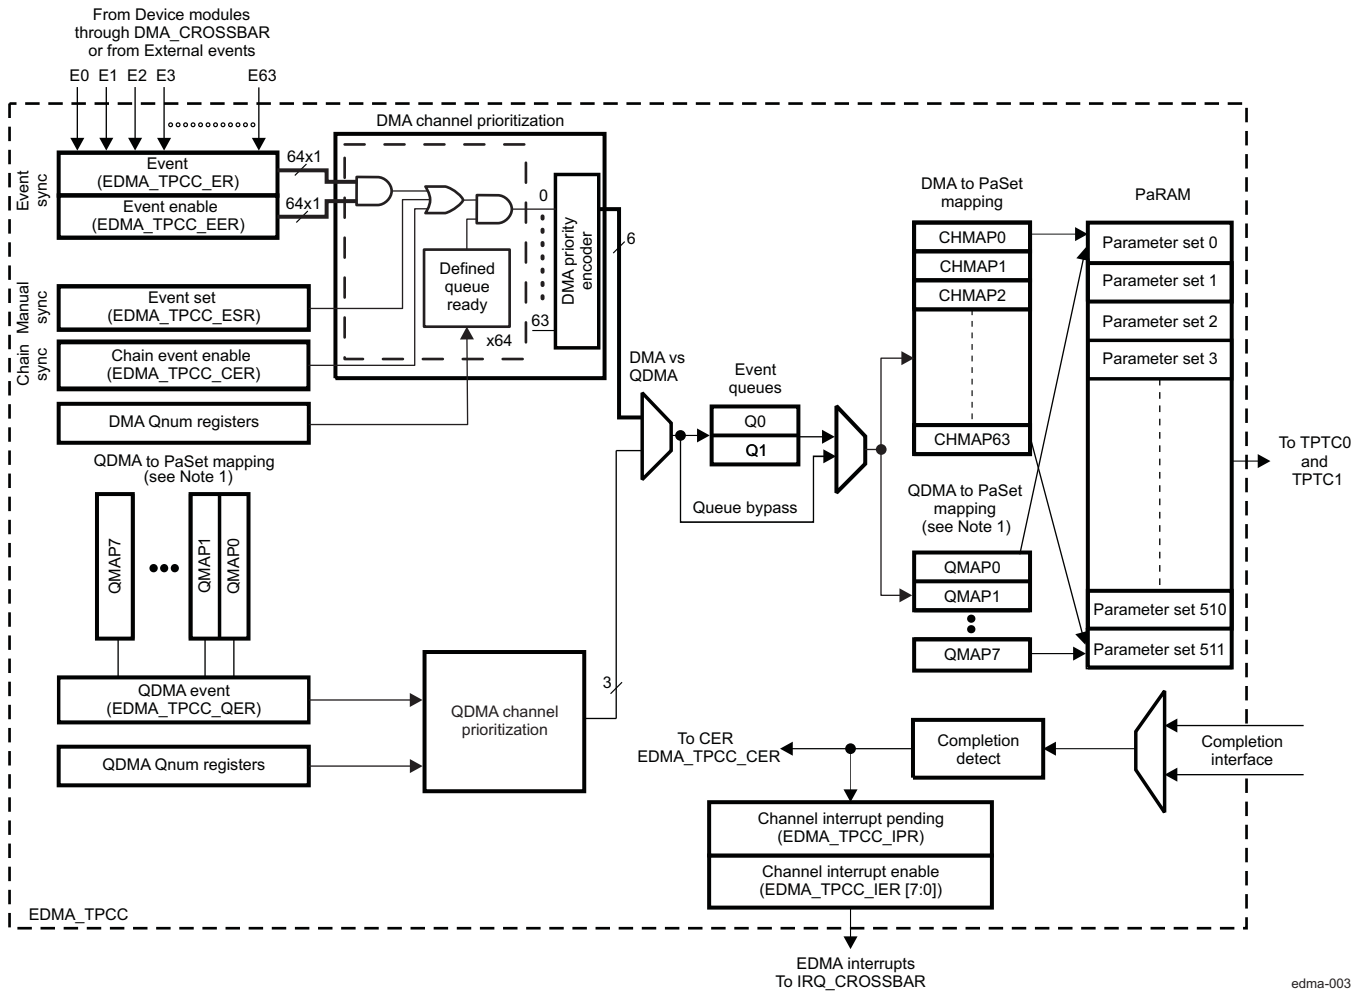

- **Region registers:** Region registers allow DMA resources (DMA channels and interrupts) to be assigned to unique regions that different EDMA programmers own (for example, MPU or DSPs).
- **Debug registers:** Debug registers allow debug visibility by providing registers to read the queue status, controller status, and missed event status.

The EDMA\_TPCC includes two channel types: DMA channels (64 channels) and QDMA channels (8 channels).

Each channel is associated with a given event queue/transfer controller and with a given PaPARAM set. The main difference between a DMA channel and a QDMA channel is the method that the system uses to trigger transfers.

Figure 16-16 is a block diagram of the EDMA\_TPCC.

Figure 16-16. EDMA Channel Controller Block Diagram

(1) Although it is depicted twice in Figure 16-16, there is only one physical register set for the QDMA to PaPARAM set mapping block.

The EDMA\_TPCC supports up to 64 DMA channels and up to 8 QDMA channels. These channels are identical, except for how they are triggered:

- DMA channels are triggered by external events (such as McSPI modules TX event and McSPI modules RX event) by the event set registers [EDMA\\_TPCC\\_ESR](#) and [EDMA\\_TPCC\\_ESRH](#), or through chaining register [EDMA\\_TPCC\\_CER](#).
- QDMA channels are triggered automatically (auto-triggered) by the CPU. QDMAs allow a minimum number of linear writes to be issued to the TPCC to force a series of transfers to occur.

The TPCC arbitrates among pending DMA and QDMA events with a fixed [64:1] and [8:1] priority encoder for these events, respectively (a low channel number corresponds to a high priority).

edma-003

DMA events are always higher priority than QDMA events. The higher-priority event is placed in the event queue to await submission to the transfer controllers, which occurs at the earliest opportunity. Each event queue is serviced in FIFO order, with a maximum of 16 queued events per event queue. If more than one TPTC is ready to be programmed with a transmission request (TR), the event queues are serviced with fixed priority: Q0 is higher than Q1. When an event is ready to be queued and the event queue and the TC channel are empty, the event bypasses the event queue and goes directly to the PaRAM processing logic for submission to the appropriate TC. If the transfer request TR bus or PaPARAM processing are busy, the bypass path is not used. The bypass is not used to dequeue for a higher-priority event.

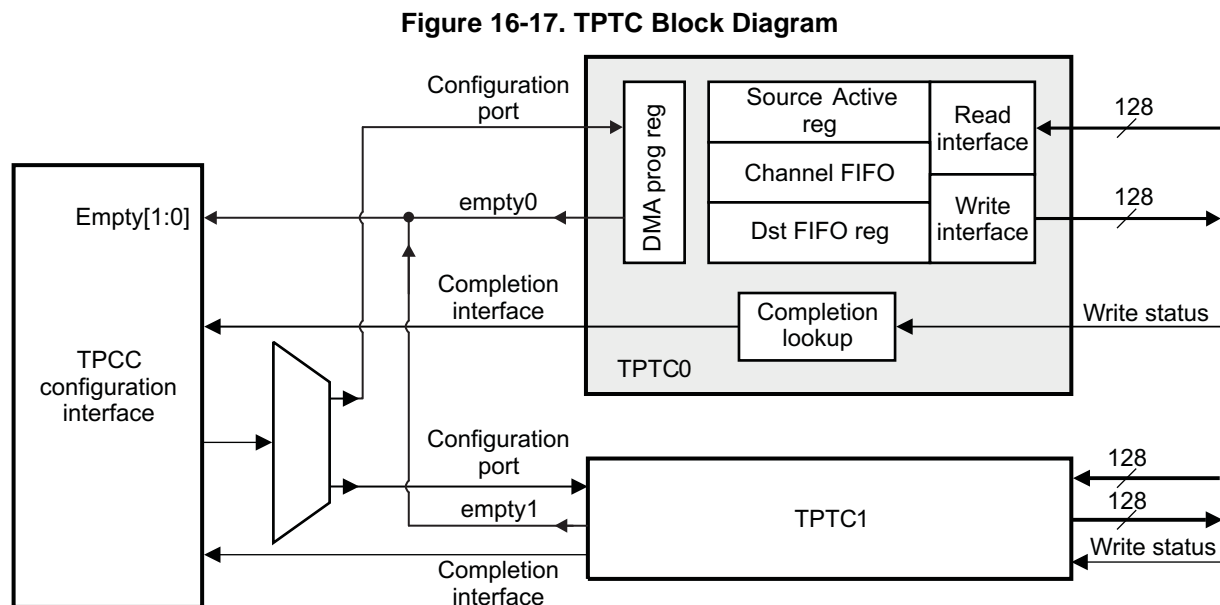

Events are extracted from the event queue when the EDMA\_TPTC is available for a new TR to be programmed into the EDMA\_TPTC (signaled with the empty signal, indicating an empty program register set). As an event is extracted from the event queue, the associated PaPARAM entry is processed and submitted to the TPTC as a TR. The TPCC updates the appropriate counts and addresses in the PaPARAM entry in anticipation of the next trigger event for that PaPARAM entry.

The EDMA\_TPCC also has an error detection logic that causes an error interrupt generation on various error conditions (for example: missed events [EDMA\\_TPCC\\_EMR](#) and [EDMA\\_TPCC\\_EMRH](#) registers, exceeding event queue thresholds in [EDMA\\_TPCC\\_CCERR](#) register, etc.).

### 16.2.4.1.2 Third-Party Transfer Controller

The TPTC module is the EDMA transfer engine that generates transfers as programmed in dedicated working registers, using two dedicated master ports: a read-only port and a write-only port.

[Figure 16-17](#) shows a functional block diagram and of the EDMA transfer controller (EDMA\_TPTC) and its connection to the EDMA\_TPCC.

**NOTE:** The port data bus width of the instances of the TPTC is fixed at 128 bits.

Two instances of the EDMA\_TPTC generate concurrent traffic on the L3\_MAIN interconnect. Each TC controller consists of the following components:

- **DMA Program Register Set:** Stores the context for the DMA transfer that is loaded into the active register set when the current active register set completes. The CPU or TPCC programs the Program Register Set, not the active register set. For typical standalone operation, the CPU programs the Program Register while the TC services the Active register set. The Program Register set includes ownership control such that CPU software and the EDMA stay synchronized relative to one another.
- **Source Active Register Set :** Stores the context (src/dst/cnt/etc) for the DMA Transfer Request (TR) in progress in the Read Controller. The Active register set is split into independent Source and

Destination, because the source interconnect controller and the distant interconnect controller operate independently of one another.

- Destination FIFO Register Set: Stores the context (src/dst/cnt/etc) for the DMA Transfer Request (TR) in progress, or pending, in the Write Controller. The pending register must allow the source controller to begin processing a new TR while the distant register set processes the previous TR.
- Channel FIFO: Temporary holding buffer for in-flight data. The read return data of the source peripheral is stored in the Data FIFO, and then is written to the destination peripheral by the write command/data bus.
- Read Controller/Interconnect Read Interface: The Interconnect read interface issues optimally sized read commands to the source peripheral, based on a burst size of 128 bytes and available landing space in the channel FIFO.
- Write controller/Interconnect Write interface: The local interconnect write interface issues optimally sized write commands to the destination peripheral, based on a burst size of 128 bytes and available data in the channel FIFO.
- Completion interface: sends completion codes to the EDMA\_TPCC when a transfer completes and generates interrupts and chained events in the TPCC module.
- Configuration port: Slave interface that provides read/write access to program registers and read access to all memory-mapped TPTC registers.

When one EDMA\_TPTC module is idle and receive its first TR, DMA program register set receives the TR, where it transitions to the DMA source active set and the destination FIFO register set immediately. The second TR (if pending from EDMA\_TPCC) is loaded into the DMA program set, ensuring it can start as soon as possible when the active transfer completes. As soon as the current active set is exhausted, the TR is loaded from the DMA program register set into the DMA source active register set as well as to the appropriate entry in the destination FIFO register set.

The read controller issues read commands controlled by the rules of command fragmentation and optimization. These are issued only when the data FIFO has space available for the data read. When sufficient data is in the data FIFO, the write controller starts issuing a write command again following the rules for command fragmentation and optimization.

Depending on the number of entries, the read controller can process up to two or four transfer requests ahead of the destination subject to the amount of free data FIFO.

#### 16.2.4.2 Types of EDMA controller Transfers

An EDMA transfer is always defined in terms of three dimensions. [Figure 16-18](#) shows the three dimensions used by EDMA controller transfers. These three dimensions are defined as:

- 1st Dimension or Array (A): The 1st dimension in a transfer consists of [EDMA\\_TPCC\\_ABCNT\\_n\[15:0\]](#) ACNT contiguous bytes.
- 2nd Dimension or Frame (B): The 2nd dimension in a transfer consists of [EDMA\\_TPCC\\_ABCNT\\_n\[31:16\]](#) BCNT arrays of ACNT bytes. Each array transfer in the 2nd dimension is separated from each other by an index programmed using bit-fields [EDMA\\_TPCC\\_BIDX\\_n\[15:0\]](#) SBIDX or [EDMA\\_TPCC\\_BIDX\\_n\[31:16\]](#) DBIDX.
- 3rd Dimension or Block (C): The 3rd dimension in a transfer consists of CCNT frames of BCNT arrays of ACNT bytes. The Count for 3rd Dimension is defined in register [EDMA\\_TPCC\\_CCNT\\_n\[15:0\]](#) CCNT. Each transfer in the 3rd dimension is separated from the previous by an index programmed using [EDMA\\_TPCC\\_CIDX\\_n\[15:0\]](#) SCIDX or [EDMA\\_TPCC\\_CIDX\\_n\[31:16\]](#) DCIDX.

---

**NOTE:** The reference point for the index depends on the synchronization type. The amount of data transferred upon receipt of a trigger/synchronization event is controlled by the synchronization types ([EDMA\\_TPCC\\_OPT\\_n\[2\]](#) SYNCDIM bit). For these three dimensions, only two synchronization types are supported: A-synchronized transfers and AB-synchronized transfers.

---

**Figure 16-18. Definition of ACNT, BCNT, and CCNT**

edma-007

**16.2.4.2.1 A-Synchronized Transfers**

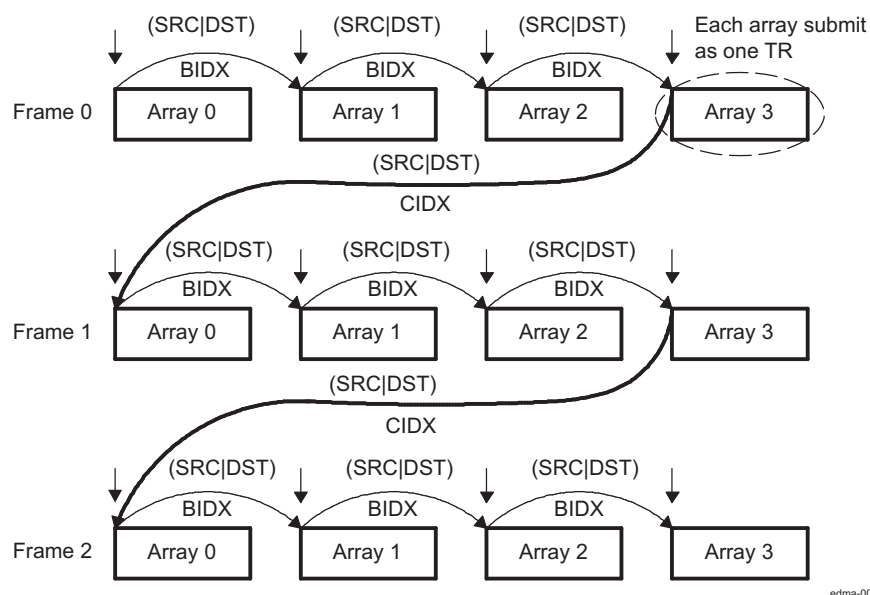

In an A-synchronized transfer, each EDMA sync event initiates the transfer of the 1st dimension of [EDMA\\_TPCC\\_ABCNT\\_n\[15:0\]](#) ACNT bytes, or one array of ACNT bytes. Each event/TR packet conveys the transfer information for one array only. Thus, BCNT × CCNT events are needed to completely service a PaRAM set.

Arrays are always separated by [EDMA\\_TPCC\\_BIDX\\_n\[15:0\]](#) SBIDX and [EDMA\\_TPCC\\_BIDX\\_n\[31:16\]](#) DBIDX, as shown in [Figure 16-19](#), where the start address of Array N is equal to the start address of Array N – 1 plus source (SRC) or destination (DST) in [EDMA\\_TPCC\\_BIDX\\_n](#) register.

Frames are always separated by [EDMA\\_TPCC\\_CIDX\\_n\[15:0\]](#) SCIDX and [EDMA\\_TPCC\\_CIDX\\_n\[31:16\]](#) DCIDX. For A-synchronized transfers, after the frame is exhausted, the address is updated by adding SRCCIDX/DSTCIDX to the beginning address of the last array in the frame. As in [Figure 16-19](#), SRCCIDX / DSTCIDX is the difference between the start of Frame 0 Array 3 to the start of Frame 1 Array 0.

[Figure 16-19](#) shows an A-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of n (ACNT) bytes. In this example, a total of 12 sync events (BCNT × CCNT) exhaust a PaRAM set. See [Figure 16-19](#) for details on parameter set updates.

**Figure 16-19. A-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)**

edma-008

### 16.2.4.2.2 AB-Synchronized Transfers

In a AB-synchronized transfer, each EDMA sync event initiates the transfer of 2 dimensions or one frame. Each event/TR packet conveys information for one entire frame of BCNT\_n arrays of ACNT\_n bytes. Thus, EDMA\_TPCC\_CCNT\_n events are needed to completely service a PaRAM set.

Arrays are always separated by EDMA\_TPCC\_BIDX\_n[15:0] SBIDX and EDMA\_TPCC\_BIDX\_n[31:16] DBIDX as shown in Figure 16-20. Frames are always separated by SRCCIDX and DSTCIDX.

Note that for AB-synchronized transfers, after a TR for the frame is submitted, the address update is to add EDMA\_TPCC\_CIDX\_n[15:0] SCIDX / EDMA\_TPCC\_CIDX\_n[31:16] DCIDX to the beginning address of the beginning array in the frame. This is different from A-synchronized transfers where the address is updated by adding SRCCIDX/DSTCIDX to the start address of the last array in the frame. See Section 16.2.4.3.6 Parameter Set Updates for details on parameter set updates.

Figure 16-20 shows an AB-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of n (ACNT) bytes. In this example, a total of 3 sync events (CCNT) exhaust a PaRAM set; that is, a total of 3 transfers of 4 arrays each completes the transfer.

Figure 16-20. AB-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)

**NOTE:** ABC-synchronized transfers are not directly supported. It can be logically achieved by chaining between multiple AB-synchronized transfers.

**NOTE:** VCP does not support Const/FIFO mode DMA transfers. The EDMA should be configured for AB-Synchronized transfer with ACNT = 8, BCNT = number of elements.

### 16.2.4.3 Parameter RAM (PaRAM)

The EDMA controller is a RAM-based architecture. The transfer context (source/destination addresses, count, indexes, etc.) for DMA or QDMA channels is programmed in a parameter RAM table in EDMA\_TPCC. The PaRAM table is segmented into multiple PaRAM sets. Each PaRAM set includes eight four-byte PaRAM set entries (32-bytes total per PaRAM set), which includes typical DMA transfer parameters such as source address, destination address, transfer counts, indexes, options, etc.

The PaRAM structure supports flexible ping-pong, circular buffering, channel chaining, and auto-reloading (linking).

The contents of the PaRAM include the following:

- 512 PaRAM sets
- 64 channels that are direct mapped and can be used as link or QDMA sets if not used for DMA channels
- 64 channels remain for link or QDMA sets

By default, all channels map to PaRAM set to 0, they should be remapped before use by [EDMA\\_TPCC\\_DCHMAPN\\_m](#) and [EDMA\\_TPCC\\_QCHMAPN\\_j](#) registers.

**Table 16-90. EDMA Parameter RAM Contents**

PaRAM Set Number	Base Address	Parameters <sup>(1)</sup>
0	EDMA Base Address + 4000h to EDMA Base Address + 401Fh	PaRAM set 0
1	EDMA Base Address + 4020h to EDMA Base Address + 403Fh	PaRAM set 1
2	EDMA Base Address + 4040h to EDMA Base Address + 405Fh	PaRAM set 2
3	EDMA Base Address + 4060h to EDMA Base Address + 407Fh	PaRAM set 3
4	EDMA Base Address + 4080h to EDMA Base Address + 409Fh	PaRAM set 4
5	EDMA Base Address + 40A0h to EDMA Base Address + 40BFh	PaRAM set 5
6	EDMA Base Address + 40C0h to EDMA Base Address + 40DFh	PaRAM set 6
7	EDMA Base Address + 40E0h to EDMA Base Address + 40FFh	PaRAM set 7
8	EDMA Base Address + 4100h to EDMA Base Address + 411Fh	PaRAM set 8
9	EDMA Base Address + 4120h to EDMA Base Address + 413Fh	PaRAM set 9
...	...	...
63	EDMA Base Address + 47E0h to EDMA Base Address + 47FFh	PaRAM set 63
64	EDMA Base Address + 4800h to EDMA Base Address + 481Fh	PaRAM set 64
65	EDMA Base Address + 4820h to EDMA Base Address + 483Fh	PaRAM set 65
...	...	...
510	EDMA Base Address + 7FC0h to EDMA Base Address + 7FDFh	PaRAM set 510
511	EDMA Base Address + 7FE0h to EDMA Base Address + 7FFFh	PaRAM set 511

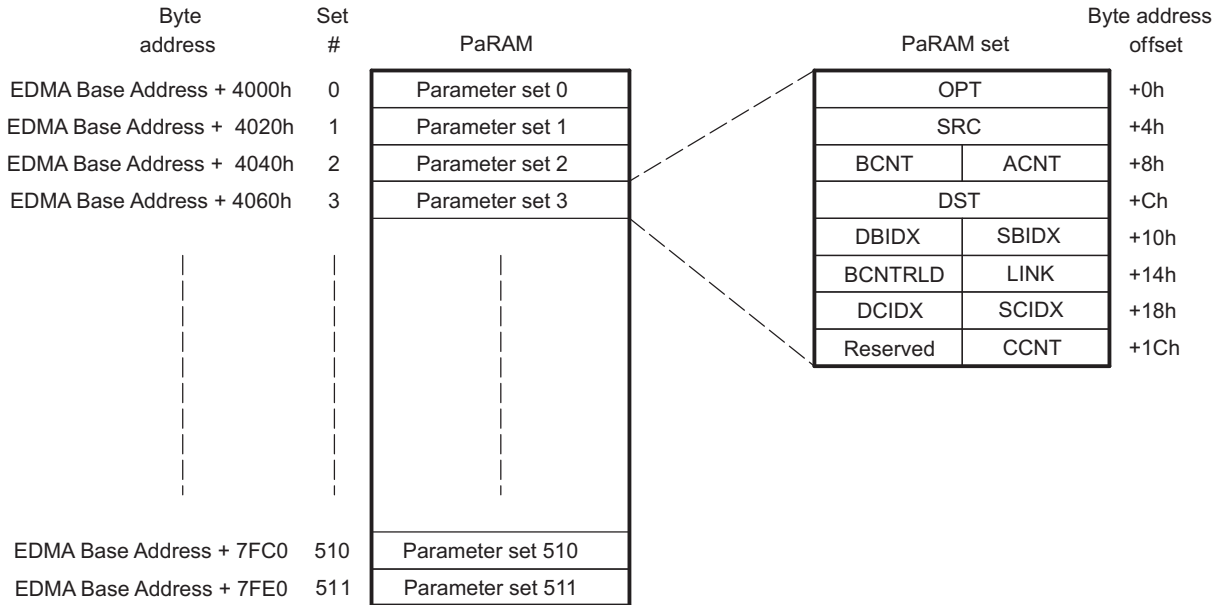

<sup>(1)</sup> The device has 8 QDMA channels that can be mapped to any parameter set number from 0 to 511.

#### 16.2.4.3.1 PaRAM

Each parameter set of PaRAM is organized into eight 32-bit words or 32 bytes, as shown in [Figure 16-21](#) and described in [Table 16-91](#). Each PaRAM set consists of 16-bit and 32-bit parameters.

**Figure 16-21. PaRAM Set**

edma-010

**Table 16-91. EDMA Channel Parameter Description**

Offset Address (bytes)	Acronym	Parameter	Description
0h	OPT	Channel Options <a href="#">EDMA_TPCC_OPT_n</a> register	Transfer configuration options
4h	SRC	Channel Source Address <a href="#">EDMA_TPCC_SRC_n</a> register	The byte address from which data is transferred
8h <sup>(1)</sup>	ACNT	Count for 1st Dimension <a href="#">EDMA_TPCC_ABCNT_n[15:0]</a> ACNT bit-field.	Unsigned value specifying the number of contiguous bytes within an array (first dimension of the transfer). Valid values range from 1 to 65 535.
	BCNT	Count for 2nd Dimension <a href="#">EDMA_TPCC_ABCNT_n[31:16]</a> BCNT bit-field.	Unsigned value specifying the number of arrays in a frame, where an array is ACNT bytes. Valid values range from 1 to 65 535.
Ch	DST	Channel Destination Address <a href="#">EDMA_TPCC_DST_n</a> register	The byte address to which data is transferred
10h <sup>(1)</sup>	SBIDX	Source BCNT Index <a href="#">EDMA_TPCC_BIDX_n[15:0]</a> SBIDX bit-field.	Signed value specifying the byte address offset between source arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
	DBIDX	Destination BCNT Index <a href="#">EDMA_TPCC_BIDX_n[31:16]</a> DBIDX bit-field.	Signed value specifying the byte address offset between destination arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
14h <sup>(1)</sup>	LINK	Link Address <a href="#">EDMA_TPCC_LNK_n[15:0]</a> LINK bit-field	The PaRAM address containing the PaRAM set to be linked (copied from) when the current PaRAM set is exhausted. A value of FFFFh specifies a null link.
	BCNTRL	BCNT Reload <a href="#">EDMA_TPCC_LNK_n[31:16]</a> BCNTRL bit-field	The count value used to reload BCNT when BCNT decrements to 0 (TR is submitted for the last array in 2nd dimension). Only relevant in A-synchronized transfers.
18h <sup>(1)</sup>	SCIDX	Source CCNT index. <a href="#">EDMA_TPCC_CIDX_n[15:0]</a> SCIDX bit-field.	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767.  A-synchronized transfers: The byte address offset from the beginning of the last source array in a frame to the beginning of the first source array in the next frame.  AB-synchronized transfers: The byte address offset from the beginning of the first source array in a frame to the beginning of the first source array in the next frame.
	DCIDX	Destination CCNT index. <a href="#">EDMA_TPCC_CIDX_n[31:16]</a> DCIDX bit-field.	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767.  A-synchronized transfers: The byte address offset from the beginning of the last destination array in a frame to the beginning of the first destination array in the next frame.  AB-synchronized transfers: The byte address offset from the beginning of the first destination array in a frame to the beginning of the first destination array in the next frame.
1Ch	CCNT	Count for 3rd Dimension. <a href="#">EDMA_TPCC_CCNT_n[15:0]</a> CCNT bit-field.	Unsigned value specifying the number of frames in a block, where a frame is BCNT arrays of ACNT bytes. Valid values range from 1 to 65 535.
	Reserved	Reserved	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

<sup>(1)</sup> If OPT, SRC, or DST is the trigger word for a QDMA transfer, then a 32-bit access to that field is required. Furthermore, it is recommended to perform only 32-bit accesses on the parameter RAM for best code compatibility. For example, switching the endianness of the processor will swap addresses of the 16-bit fields, but 32-bit accesses avoid the issue entirely.

### 16.2.4.3.2 EDMA Channel PaRAM Set Entry Fields

#### 16.2.4.3.2.1 Channel Options Parameter (OPT)

For detailed information about the channel options parameter, see the [EDMA\\_TPCC\\_OPT\\_n](#) register description in [Section 16.2.7.2.2.1, EDMA\\_TPCC Register Description](#).

#### 16.2.4.3.2.2 Channel Source Address (SRC)

The 32-bit source address parameter specifies the starting byte address of the source. For SAM in increment mode, there are no alignment restrictions imposed by EDMA. For SAM in constant addressing mode, it must program the source address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). If this rule is not observed, the EDMA\_TPTC returns an error. Refer to [Section 16.2.4.12.3 Error Generation](#) for additional details.

#### 16.2.4.3.2.3 Channel Destination Address (DST)

The 32-bit destination address parameter specifies the starting byte address of the destination. For DAM in increment mode, there are no alignment restrictions imposed by EDMA. For DAM in constant addressing mode, it must program the destination address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). If this rule is not observed, the EDMA\_TPTC returns an error. Refer to [Section 16.2.4.12.3 Error Generation](#) for additional details.

#### 16.2.4.3.2.4 Count for 1st Dimension (ACNT)

[EDMA\\_TPCC\\_ABCNT\\_n\[15:0\]](#) ACNT represents the number of bytes within the 1st dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65 535. Therefore, the maximum number of bytes in an array is 65 535 bytes (64K – 1 bytes). ACNT must be greater than or equal to 1 for a TR to be submitted to EDMA\_TPTC. A transfer with ACNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in [EDMA\\_TPCC\\_OPT\\_n](#).

Refer to [Section 16.2.4.3.5 Dummy Versus Null Transfer Comparison](#) and [Section 16.2.4.5.3 Dummy or Null Completion](#) for details on dummy/null completion conditions.

#### 16.2.4.3.2.5 Count for 2nd Dimension (BCNT)

[EDMA\\_TPCC\\_ABCNT\\_n\[15:0\]](#) BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT are between 1 and 65 535. Therefore, the maximum number of arrays in a frame is 65 535 (64K – 1 arrays). A transfer with BCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in [EDMA\\_TPCC\\_OPT\\_n](#).

Refer to [Section 16.2.4.3.5 Dummy Versus Null Transfer Comparison](#) and [Section 16.2.4.5.3 Dummy or Null Completion](#) for details on dummy/null completion conditions.

#### 16.2.4.3.2.6 Count for 3rd Dimension (CCNT)

[EDMA\\_TPCC\\_CCNT\\_n\[15:0\]](#) CCNT is a 16-bit unsigned value that specifies the number of frames in a block. Valid values for CCNT are between 1 and 65 535. Therefore, the maximum number of frames in a block is 65 535 (64K – 1 frames). A transfer with CCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in [EDMA\\_TPCC\\_OPT\\_n](#).

A CCNT value of 0 is considered either a null or dummy transfer.

Refer to [Section 16.2.4.3.5 Dummy Versus Null Transfer Comparison](#) and [Section 16.2.4.5.3 Dummy or Null Completion](#) for details on dummy/null completion conditions.

#### 16.2.4.3.2.7 BCNT Reload (BCNTRLD)

[EDMA\\_TPCC\\_LNK\\_n\[31:16\]](#) BCNTRLD is a 16-bit unsigned value used to reload the [EDMA\\_TPCC\\_ABCNT\\_n\[15:0\]](#) BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-synchronized transfers. In this case, the EDMA\_TPCC decrements the BCNT value by 1 on each TR submission. When BCNT reaches 0, the EDMA\_TPCC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value.

For AB-synchronized transfers, the EDMA\_TPCC submits the BCNT in the TR and the EDMA\_TPTC decrements BCNT appropriately. For AB-synchronized transfers, BCNTRLD is not used.

#### 16.2.4.3.2.8 Source B Index (SBIDX)

[EDMA\\_TPCC\\_BIDX\\_n\[15:0\]](#) SBIDX is a 16-bit signed value (2s complement) used for source address modification between each array in the 2nd dimension. Valid values for [EDMA\\_TPCC\\_BIDX\\_n\[15:0\]](#) SBIDX are between  $-32\,768$  and  $32\,767$ . It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-synchronized and AB-synchronized transfers. Some examples:

- [EDMA\\_TPCC\\_BIDX\\_n\[15:0\]](#) SBIDX = 0000h (0): no address offset from the beginning of an array to the beginning of the next array. All arrays are fixed to the same beginning address.
- [EDMA\\_TPCC\\_BIDX\\_n\[15:0\]](#) SBIDX = 0003h (+3): the address offset from the beginning of an array to the beginning of the next array in a frame is 3 bytes. For example, if the current array begins at address 1000h, the next array begins at 1003h.
- [EDMA\\_TPCC\\_BIDX\\_n\[15:0\]](#) SBIDX = FFFFh (−1): the address offset from the beginning of an array to the beginning of the next array in a frame is −1 byte. For example, if the current array begins at address 5054h, the next array begins at 5053h.

#### 16.2.4.3.2.9 Destination B Index (DBIDX)

[EDMA\\_TPCC\\_BIDX\\_n\[31:16\]](#) DBIDX is a 16-bit signed value (2s complement) used for destination address modification between each array in the 2nd dimension. Valid values for [EDMA\\_TPCC\\_BIDX\\_n\[31:16\]](#) DBIDX are between  $-32\,768$  and  $32\,767$ . It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-synchronized and AB-synchronized transfers. Refer to [Section 16.2.4.3.2.8 Source B Index \(SBIDX\)](#) for examples.

#### 16.2.4.3.2.10 Source C Index (SCIDX)

[EDMA\\_TPCC\\_CIDX\\_n\[15:0\]](#) SCIDX is a 16-bit signed value (2s complement) used for source address modification in the 3rd dimension. Valid values for [EDMA\\_TPCC\\_CIDX\\_n\[15:0\]](#) SCIDX are between  $-32\,768$  and  $32\,767$ . It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-synchronized and AB-synchronized transfers.

---

**NOTE:** When SCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame ([Figure 16-19](#)), while the current array in an AB-synchronized transfer is the first array in the frame ([Figure 16-20](#)).

---

#### 16.2.4.3.2.11 Destination C Index (DCIDX)

[EDMA\\_TPCC\\_CIDX\\_n\[31:16\]](#) DCIDX is a 16-bit signed value (2s complement) used for destination address modification in the 3rd dimension. Valid values are between  $-32\,768$  and  $32\,767$ . It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array TR in the next frame. It applies to both A-synchronized and AB-synchronized transfers.

**NOTE:** When DCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 16-19), while the current array in a AB-synchronized transfer is the first array in the frame (Figure 16-20).

#### 16.2.4.3.2.12 Link Address (LINK)

The EDMA\_TPCC provides a mechanism, called linking, to reload the current PaRAM set upon its natural termination (that is, after the count fields are decremented to 0) with a new PaRAM set. The 16-bit parameter `EDMA_TPCC_LNK_n[15:0]` LINK specifies the byte address offset in the PaRAM from which the EDMA\_TPCC loads/reloads the next PaRAM set during linking.

It must program the link address to point to a valid aligned 32-byte PaRAM set. The 5 LSBs of the LINK field should be cleared to 0.

The EDMA\_TPCC ignores the upper 2 bits of the LINK entry, allowing the flexibility of programming the link address as either an absolute/literal byte address or use the PaRAM-base-relative offset address. Therefore, if it use the literal address with a range from 4000h to 7FFFh, it will be treated as a PaRAM-base-relative value of 0000h to 3FFFh.

It should check that the programmed value in the `EDMA_TPCC_LNK_n[15:0]` LINK field is correctly, so that link update is requested from a PaRAM address that falls in the range of the available PaRAM addresses on the device.

Value of FFFFh in `EDMA_TPCC_LNK_n[15:0]` LINK bit-field is referred to as a NULL link that should cause the EDMA\_TPCC to perform an internal write of 0 to all entries of the current PaRAM set, except for the `EDMA_TPCC_LNK_n[15:0]` LINK field is set to FFFFh. Also, see Section 16.2.4.5 *Completion of a DMA Transfer* for details on terminating a transfer.

#### 16.2.4.3.3 Null PaRAM Set

A null PaRAM set is defined as a PaRAM set where all count fields (`EDMA_TPCC_ABCNT_n[15:0]` ACNT, `EDMA_TPCC_ABCNT_n[31:16]` BCNT, and `EDMA_TPCC_CCNT_n[15:0]` CCNT) are cleared to 0. If a PaRAM set associated with a channel is a NULL set, then when serviced by the EDMA\_TPCC, the bit corresponding to the channel is set in the associated event missed register (`EDMA_TPCC_EMR`, `EDMA_TPCC_EMRH`, or `EDMA_TPCC_QEMR`). This bit remains set in the associated secondary event register (`EDMA_TPCC_SER`, `EDMA_TPCC_SERH`, or `EDMA_TPCC_QSER`).

*This implies that any future events on the same channel are ignored by the EDMA\_TPCC and it is required to clear the bit in `EDMA_TPCC_SER`, `EDMA_TPCC_SERH`, or `EDMA_TPCC_QSER` for the channel.* This is considered an error condition, since events are not expected on a channel that is configured as a null transfer.

#### 16.2.4.3.4 Dummy PaRAM Set

A dummy PaRAM set is defined as a PaRAM set where at least one of the count fields (`EDMA_TPCC_ABCNT_n[15:0]` ACNT, `EDMA_TPCC_ABCNT_n[31:16]` BCNT, or `EDMA_TPCC_CCNT_n[15:0]` CCNT) is cleared to 0 and at least one of the count fields is nonzero.

If a PaRAM set associated with a channel is a dummy set, then when serviced by the EDMA\_TPCC, it will not set the bit corresponding to the channel (DMA/QDMA) in the event missed register (`EDMA_TPCC_EMR`, `EDMA_TPCC_EMRH`, or `EDMA_TPCC_QEMR`) and the secondary event register (`EDMA_TPCC_SER`, `EDMA_TPCC_SERH`, or `EDMA_TPCC_QSER`) bit gets cleared similar to a normal transfer. Future events on that channel are serviced. A dummy transfer is a legal transfer of 0 bytes.

#### 16.2.4.3.5 Dummy Versus Null Transfer Comparison

There are some differences in the way the EDMA\_TPCC logic treats a dummy versus a null transfer request. A null transfer request is an error condition, but a dummy transfer is a legal transfer of 0 bytes. A null transfer causes an error bit ( $E_n$ ) in `EDMA_TPCC_EMR` to get set and the  $E_n$  bit in `EDMA_TPCC_SER` remains set, essentially preventing any further transfers on that channel without clearing the associated error registers.

Table 16-92 summarizes the conditions and effects of null and dummy transfer requests.

**Table 16-92. Dummy and Null Transfer Request**

Feature	Null TR	Dummy TR
EDMA_TPCC_EMR / EDMA_TPCC_EMRH / EDMA_TPCC_QEMR is set	Yes	No
EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER remains set	Yes	No
Link update (STATIC = 0 in EDMA_TPCC_OPT_n)	Yes	Yes
EDMA_TPCC_QER is set	Yes	Yes
EDMA_TPCC_IPR / EDMA_TPCC_IPRH, EDMA_TPCC_CER / EDMA_TPCC_CERH is set using early completion	Yes	Yes

**16.2.4.3.6 Parameter Set Updates**

When a TR is submitted for a given DMA/QDMA channel and its corresponding PaRAM set, the EDMA\_TPCC is responsible for updating the PaRAM set in anticipation of the next trigger event. For events that are not final, this includes address and count updates; for final events, this includes the link update.

The specific PaRAM set entries that are updated depend on the channel’s synchronization type (A-synchronized or B-synchronized) and the current state of the PaRAM set. A B-update refers to the decrementing of EDMA\_TPCC\_ABCNT\_n[31:16] BCNT in the case of A-synchronized transfers after the submission of successive TRs. A C-update refers to the decrementing of CCNT in the case of A-synchronized transfers after BCNT TRs for EDMA\_TPCC\_ABCNT\_n[15:0] ACNT byte transfers have submitted. For AB-synchronized transfers, a C-update refers to the decrementing of EDMA\_TPCC\_CCNT\_n[15:0] CCNT after submission of every transfer request.

Refer to Table 16-93 for details and conditions on the parameter updates. A link update occurs when the PaPARAM set is exhausted, as described in Section 16.2.4.3.7 Linking Transfers.

After the TR is read from the PaPARAM (and is in process of being submitted to EDMA\_TPTC), the following fields are updated if needed:

- A-synchronized: BCNT, CCNT, SRC, DST.
- AB-synchronized: CCNT, SRC, DST.

The following fields are not updated (except for during linking, where all fields are overwritten by the link PaPARAM set):

- A-synchronized: EDMA\_TPCC\_ABCNT\_n[15:0] ACNT, EDMA\_TPCC\_LNK\_n[31:16] BCNTRLD, EDMA\_TPCC\_BIDX\_n[15:0] SBIDX, EDMA\_TPCC\_BIDX\_n[31:16] DBIDX, EDMA\_TPCC\_CIDX\_n[15:0] SCIDX, EDMA\_TPCC\_CIDX\_n[31:16] DCIDX, EDMA\_TPCC\_OPT\_n, EDMA\_TPCC\_LNK\_n[15:0]LINK.
- AB-synchronized: EDMA\_TPCC\_ABCNT\_n[15:0] ACNT, EDMA\_TPCC\_ABCNT\_n[31:16] BCNT, EDMA\_TPCC\_LNK\_n[31:16] BCNTRLD, EDMA\_TPCC\_BIDX\_n[15:0] SBIDX, EDMA\_TPCC\_BIDX\_n[31:16] DBIDX, EDMA\_TPCC\_CIDX\_n[15:0] SCIDX, EDMA\_TPCC\_CIDX\_n[31:16] DCIDX, EDMA\_TPCC\_OPT\_n, EDMA\_TPCC\_LNK\_n[15:0]LINK.

**NOTE:** PaPARAM updates only pertain to the information that is needed to properly submit the next transfer request to the EDMA\_TPTC. Updates that occur while data is moved within a transfer request are tracked within the transfer controller, and is detailed in Section 16.2.4.12 EDMA Transfer Controller (EDMA\_TPTC). For A-synchronized transfers, the EDMA\_TPCC always submits a TRP for EDMA\_TPCC\_ABCNT\_n[15:0] ACNT bytes (EDMA\_TPCC\_ABCNT\_n[31:16] BCNT = 1 and EDMA\_TPCC\_CCNT\_n[15:0] CCNT = 1). For AB-synchronized transfers, the EDMA\_TPCC always submits a TRP for EDMA\_TPCC\_ABCNT\_n[15:0] ACNT bytes of BCNT arrays (EDMA\_TPCC\_CCNT\_n[15:0] CCNT = 1). The EDMA\_TPTC is responsible for updating source and destination addresses within the array based on EDMA\_TPCC\_ABCNT\_n[15:0] ACNT and EDMA\_TPCC\_OPT\_n[10:8] FWID. For AB-synchronized transfers, the EDMA\_TPTC is also responsible to update source and destination addresses between arrays based on EDMA\_TPCC\_BIDX\_n[15:0] SBIDX and EDMA\_TPCC\_BIDX\_n[31:16] DBIDX.

Table 16-93 shows the details of parameter updates that occur within EDMA\_TPCC for A-synchronized and AB-synchronized transfers.

**Table 16-93. Parameter Updates in EDMA\_TPCC (for Non-Null, Non-Dummy PaRAM Set)**

	A-Synchronized Transfer			AB-Synchronized Transfer		
	B-Update	C-Update	Link Update	B-Update	C-Update	Link Update
<b>Condition:</b>	BCNT > 1	BCNT == 1 && CCNT > 1	BCNT == 1 && CCNT == 1	N/A	EDMA_TPCC_C CNT_n[15:0] CCNT > 1	EDMA_TPCC_CCNT_n[15:0] CCNT == 1
SRC	+= SBIDX	+= SCIDX	= Link.EDMA_TPCC_SRC_n	in EDMA_TP TC	+= SCIDX	= Link.EDMA_TPCC_SRC_n
DST	+= DBIDX	+= DCIDX	= Link.EDMA_TPCC_DST_n	in EDMA_TP TC	+= DCIDX	= Link.EDMA_TPCC_DST_n
ACNT	None	None	= Link.EDMA_TPCC_ABCNT_n[15:0] ACNT	None	None	= Link.EDMA_TPCC_ABCNT_n[15:0] ACNT
BCNT	-- 1	= BCNTRLD	= Link.EDMA_TPCC_ABCNT_n[31:16] BCNT	in EDMA_TP TC	N/A	= Link.EDMA_TPCC_ABCNT_n[31:16] BCNT
CCNT	None	-- 1	= Link.EDMA_TPCC_CCNT_n[15:0] CCNT	in EDMA_TP TC	--1	= Link.EDMA_TPCC_CCNT_n[15:0] CCNT
SBIDX	None	None	= Link.EDMA_TPCC_BIDX_n[15:0] SBIDX	in EDMA_TP TC	None	= Link.EDMA_TPCC_BIDX_n[15:0] SBIDX
DBIDX	None	None	= Link.EDMA_TPCC_BIDX_n[31:16] DBIDX	None	None	= Link.EDMA_TPCC_BIDX_n[31:16] DBIDX
SCIDX	None	None	= Link.EDMA_TPCC_BIDX_n[15:0] SBIDX	in EDMA_TP TC	None	= Link.EDMA_TPCC_BIDX_n[15:0] SBIDX
DCIDX	None	None	= Link.EDMA_TPCC_BIDX_n[31:16] DBIDX	None	None	= Link.EDMA_TPCC_BIDX_n[31:16] DBIDX
LINK	None	None	= Link.EDMA_TPCC_LNK_n[15:0] LINK	None	None	= Link.EDMA_TPCC_LNK_n[15:0] LINK
BCNTRLD	None	None	= Link.EDMA_TPCC_LNK_n[31:16] BCNTRLD	None	None	= Link.EDMA_TPCC_LNK_n[31:16] BCNTRLD
OPT <sup>(1)</sup>	None	None	= LINK.EDMA_TPCC_OPT_n	None	None	= LINK.EDMA_TPCC_OPT_n

<sup>(1)</sup> In all cases, no updates occur if EDMA\_TPCC\_OPT\_n[3] STATIC == 1 for the current PaRAM set.

**NOTE:** The EDMA\_TPCC includes no special hardware to detect when an indexed address update calculation overflows/underflows. The address update will wrap across boundaries as programmed by the user. It should ensure that no transfer is allowed to cross internal port boundaries between peripherals. A single TR must target a single source/destination slave endpoint.

### 16.2.4.3.7 Linking Transfers

The EDMA\_TPCC provides a mechanism known as linking, which allows the entire PaRAM set to be reloaded from a location within the PaRAM memory map (for both DMA and QDMA channels). Linking is especially useful for maintaining ping-pong buffers, circular buffering, and repetitive/continuous transfers with no CPU intervention. Upon completion of a transfer, the current transfer parameters are reloaded with the parameter set pointed to by the 16-bit link address field of the current parameter set. Linking only occurs when the [EDMA\\_TPCC\\_OPT\\_n\[3\]](#) STATIC bit is cleared.

---

**NOTE:** It should always link a transfer (EDMA or QDMA) to another useful transfer. If it must terminate a transfer, then link the transfer to a NULL parameter set. Refer to [Section 16.2.4.3.3 Null PaRAM Set](#).

---

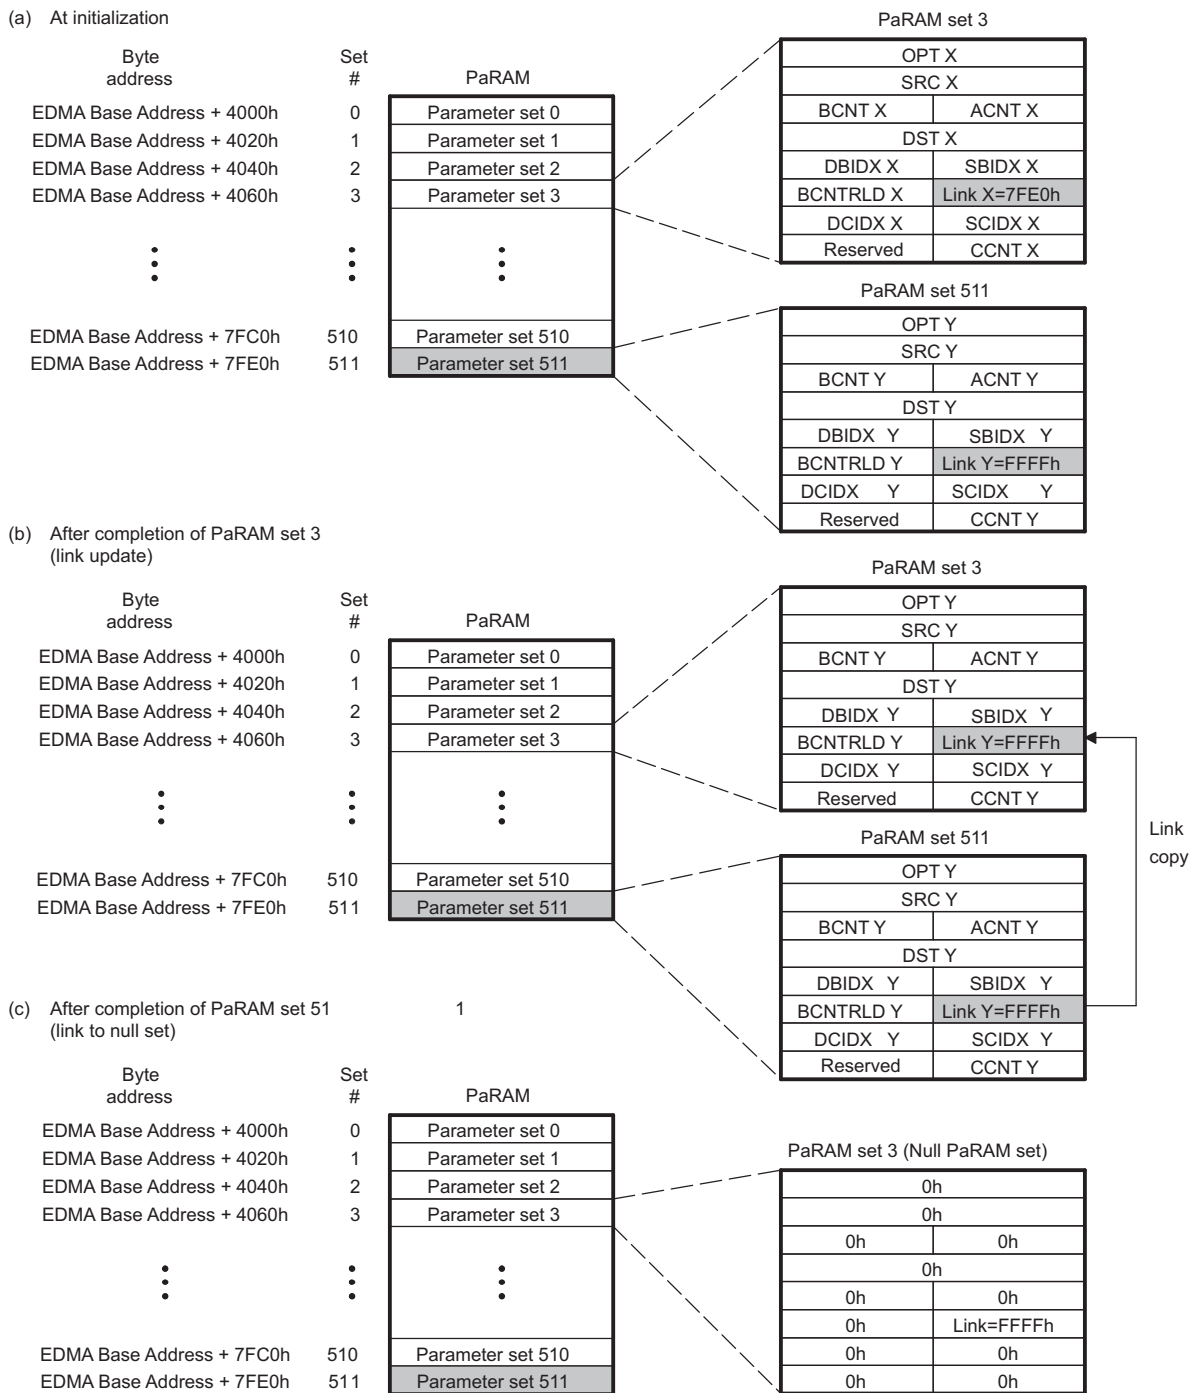

The link update occurs after the current PaRAM set event parameters have been exhausted. An event's parameters are exhausted when the EDMA channel controller has submitted all of the transfers that are associated with the PaRAM set.

A link update occurs for null and dummy transfers depending on the state of the [EDMA\\_TPCC\\_OPT\\_n\[3\]](#) STATIC bit and the [EDMA\\_TPCC\\_LNK\\_n\[15:0\]](#) LINK field. In both cases (null or dummy), if the value of [EDMA\\_TPCC\\_LNK\\_n\[15:0\]](#) LINK is FFFFh, then a null PaRAM set (with all 0s and [EDMA\\_TPCC\\_LNK\\_n\[15:0\]](#) LINK set to FFFFh) is written to the current PaRAM set. Similarly, if [EDMA\\_TPCC\\_LNK\\_n\[15:0\]](#) LINK is set to a value other than FFFFh, then the appropriate PaRAM location that [EDMA\\_TPCC\\_LNK\\_n\[15:0\]](#) LINK points to is copied to the current PaRAM set.

Once the channel completion conditions are met for an event, the transfer parameters that are located at the link address are loaded into the current DMA or QDMA channel's associated parameter set. This indicates that the EDMA\_TPCC reads the entire set (eight words) from the PaRAM set specified by [EDMA\\_TPCC\\_LNK\\_n\[15:0\]](#) LINK and writes all eight words to the PaRAM set that is associated with the current channel. [Figure 16-22](#) shows an example of a linked transfer.

Figure 16-22. Linked Transfer

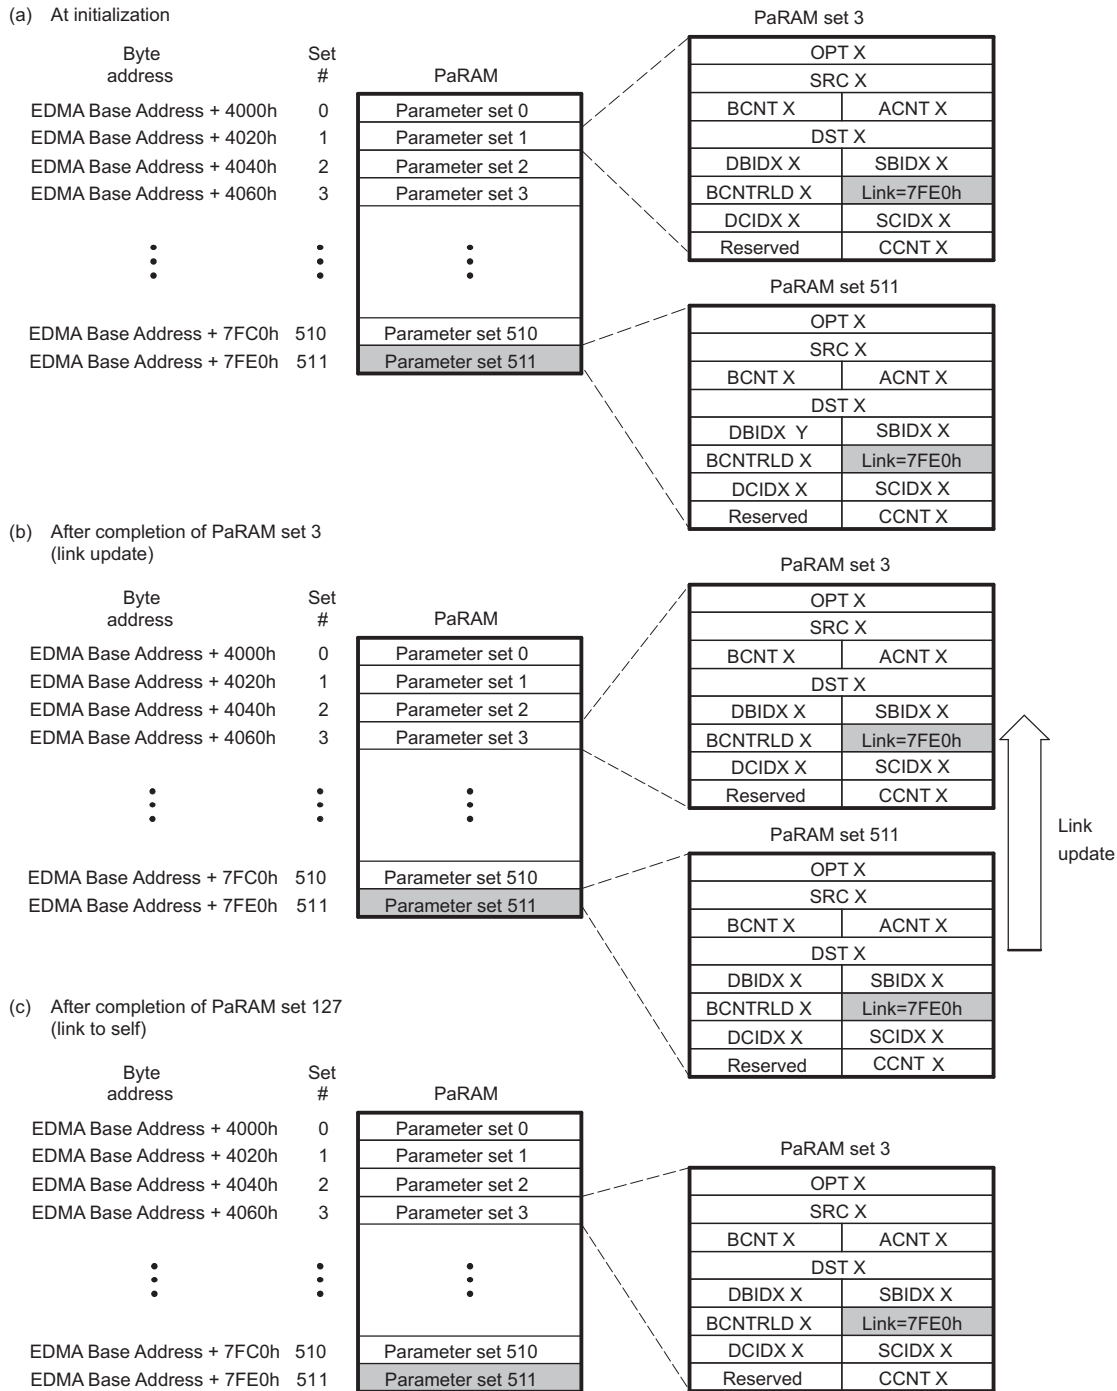

edma-011

Any PaRAM set in the PaRAM can be used as a link/reload parameter set. The PaRAM sets associated with peripheral synchronization events (refer to [Section 16.2.4.6 Event, Channel, and PaRAM Mapping](#)) only use for linking if the corresponding events are disabled.

If a PaRAM set location is defined as a QDMA channel PaRAM set (by [EDMA\\_TPCC\\_QCHMAPN\\_j](#) register), then copying the link PaRAM set into the current QDMA channel PaRAM set is recognized as a trigger event. It is latched in [EDMA\\_TPCC\\_QER](#) because a write to the trigger word was performed. This feature is used to create a linked list of transfers using a single QDMA channel and multiple PaRAM sets. Refer to [Section 16.2.4.2 QDMA Channels](#).

Linking to itself replicates the behavior of auto-initialization, thus facilitating the use of circular buffering and repetitive transfers. After an EDMA channel exhausts its current PaRAM set, it reloads all of the parameter set entries from another PaRAM set, which is initialized with values that are identical to the original PaRAM set. Figure 16-23 shows an example of a linked to self transfer. Here, the PaRAM set 511 has the link field pointing to the address of parameter set 511 (linked to self).

**Figure 16-23. Link-to-Self Transfer**

edma-012

**NOTE:** If the in `EDMA_TPCC_OPT_n[3]` STATIC bit is set for a PaRAM set, then link updates are not performed.

### 16.2.4.3.8 Constant Addressing Mode Transfers/Alignment Issues

If either `EDMA_TPCC_OPT_n[0]` SAM or `EDMA_TPCC_OPT_n[1]` DAM is set (constant addressing mode), then the source or destination address must be aligned to a 256-bit aligned address, respectively, and the corresponding `EDMA_TPCC_BIDX_n` is an even multiple of 32 bytes (256 bits). The EDMA\_TPCC does not recognize errors here, but the EDMA\_TPTC asserts an error if this is not true. Refer to [Section 16.2.4.12.3 Error Generation](#).

---

**NOTE:** The constant addressing (CONST) mode has limited applicability. The EDMA is configured for the constant addressing mode (`EDMA_TPCC_OPT_n[0]` SAM / `EDMA_TPCC_OPT_n[1]` DAM = 1) only if the transfer source or destination (on-chip memory, off-chip memory controllers, slave peripherals) support the constant addressing mode. If the constant addressing mode is not supported, the similar logical transfer can be achieved using the increment (INCR) mode (`EDMA_TPCC_OPT_n[0]` SAM / `EDMA_TPCC_OPT_n[1]` DAM = 0) by appropriately programming the count and indices values.

---

### 16.2.4.3.9 Element Size

The EDMA controller does not use element-size and element-indexing. Instead, all transfers are defined in terms of all three dimensions: `EDMA_TPCC_ABCNT_n[15:0]` ACNT, `EDMA_TPCC_ABCNT_n[31:16]` BCNT, and `EDMA_TPCC_CCNT_n[15:0]` CCNT. An element-indexed transfer is logically achieved by programming `EDMA_TPCC_ABCNT_n[15:0]` ACNT to the size of the element and `EDMA_TPCC_ABCNT_n[31:16]` BCNT to the number of elements that need to be transferred. For example: If there are 16-bit audio data and 256 audio samples that must be transferred to a serial port, therefore the `EDMA_TPCC_ABCNT_n[15:0]` ACNT = 2 (2 bytes) and `EDMA_TPCC_ABCNT_n[31:16]` BCNT = 256.

### 16.2.4.4 Initiating a DMA Transfer

There are multiple ways to initiate a programmed data transfer using the EDMA\_TPCC channel controller. Transfers on DMA channels are initiated by three sources.

They are listed as follows:

- **Event-triggered transfer request** (this is the typical usage of EDMA controller): A peripheral, system, or externally-generated event triggers a transfer request.
- **Manually-triggered transfer request:** The CPU manually triggers a transfer by writing a 1 to the corresponding bit in the event set registers (`EDMA_TPCC_ESR` / `EDMA_TPCC_ESRH`).
- **Chain-triggered transfer request:** A transfer is triggered on the completion of another transfer or sub-transfer.

Transfers on QDMA channels are initiated by two sources. They are as follows:

- **Auto-triggered transfer request:** Writing to the programmed trigger word triggers a transfer.
- **Link-triggered transfer requests:** Writing to the trigger word triggers the transfer when linking occurs.

#### 16.2.4.4.1 DMA Channel

##### 16.2.4.4.1.1 Event-Triggered Transfer Request

When an event is asserted from a peripheral or device pins, it gets latched in the corresponding bit of the event register (`EDMA_TPCC_ER[31:0]`  $En = 1$ ). For more information about peripheral events to EDMA events mapping, refer to *the device data manual*.

If the corresponding event in the event enable register (`EDMA_TPCC_EER`) is enabled (`EDMA_TPCC_EER[31:0]`  $En = 1$ ), then the EDMA\_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

If the PaRAM set is valid (not a NULL set), then a transfer request packet (TRP) is submitted to the EDMA\_TPTC and the `EDMA_TPCC_ER[31:0]`  $En$  bit is cleared. At this point, a new event can be safely received by the EDMA\_TPCC.

If the PaRAM set associated with the channel is a NULL set (see [Section 16.2.4.3.3 Null PaRAM Set](#)), then no transfer request (TR) is submitted and the corresponding [EDMA\\_TPCC\\_ER\[31:0\]](#)  $E_n$  bit is cleared and simultaneously the corresponding channel bit is set in the event miss register ([EDMA\\_TPCC\\_EMR\[31:0\]](#)  $E_n = 1$ ) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include cleaning the event missed error before re-triggering the DMA channel.

When an event is received, the corresponding event bit in the event register is set ([EDMA\\_TPCC\\_ER\[31:0\]](#)  $E_n = 1$ ), regardless of the state of [EDMA\\_TPCC\\_EER\[31:0\]](#)  $E_n$ . If the event is disabled when an external event is received ([EDMA\\_TPCC\\_ER\[31:0\]](#)  $E_n = 1$  and [EDMA\\_TPCC\\_EER\[31:0\]](#)  $E_n = 0$ ), the [EDMA\\_TPCC\\_ER\[31:0\]](#)  $E_n$  bit remains set. If the event is subsequently enabled ([EDMA\\_TPCC\\_EER\[31:0\]](#)  $E_n = 1$ ), then the pending event is processed by the EDMA\_TPCC and the TR is processed/submitted, after which the [EDMA\\_TPCC\\_ER\[31:0\]](#)  $E_n$  bit is cleared.

If an event is being processed (prioritized or is in the event queue) and another sync event is received for the same channel prior to the original being cleared ([EDMA\\_TPCC\\_ER\[31:0\]](#)  $E_n \neq 0$ ), then the second event is registered as a missed event in the corresponding bit of the event missed register ([EDMA\\_TPCC\\_EMR\[31:0\]](#)  $E_n = 1$ ).

#### 16.2.4.4.1.2 Manually-Triggered Transfer Request

The CPU or any peripheral device module initiates a DMA transfer by writing to the event set register [EDMA\\_TPCC\\_ESR](#). Writing a 1 to an event bit in the [EDMA\\_TPCC\\_ESR](#) results in the event being prioritized/queued in the appropriate event queue, regardless of the state of the [EDMA\\_TPCC\\_EER\[31:0\]](#)  $E_n$  bit. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA\_TPTC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see [Section 16.2.4.3.3 Null PaRAM Set](#)), then no transfer request (TR) is submitted and the corresponding [EDMA\\_TPCC\\_ER\[31:0\]](#)  $E_n$  bit is cleared and simultaneously the corresponding channel bit is set in the event miss register [EDMA\\_TPCC\\_EMR\[31:0\]](#)  $E_n = 1$  to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include clearing the event missed error before re-triggering the DMA channel.

If an event is being processed (prioritized or is in the event queue) and the same channel is manually set by a write to the corresponding channel bit of the event set register [EDMA\\_TPCC\\_ESR\[31:0\]](#)  $E_n = 1$  prior to the original being cleared [EDMA\\_TPCC\\_ESR\[31:0\]](#)  $E_n = 0$ , then the second event is registered as a missed event in the corresponding bit of the event missed register [EDMA\\_TPCC\\_EMR\[31:0\]](#)  $E_n = 1$ .

#### 16.2.4.4.1.3 Chain-Triggered Transfer Request

Chaining is a mechanism by which the completion of one transfer automatically sets the event for another channel. When a chained completion code is detected, the value of which is dictated by the transfer completion code [EDMA\\_TPCC\\_OPT\\_n\[17:12\]](#) TCC of the PaRAM set associated with the channel, it results in the corresponding bit in the chained event register [EDMA\\_TPCC\\_CER](#) to be set ([EDMA\\_TPCC\\_CER\[31:0\]](#)  $E[\text{TCC}] = 1$ ).

Once a bit is set in [EDMA\\_TPCC\\_CER](#), the EDMA\_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA\_TPTC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see [Section 16.2.4.3.3 Null PaRAM Set](#)), then no transfer request (TR) is submitted and the corresponding [EDMA\\_TPCC\\_CER\[31:0\]](#)  $E_n$  bit is cleared and simultaneously the corresponding channel bit is set in the event miss register [EDMA\\_TPCC\\_EMR\[31:0\]](#)  $E_n = 1$  to indicate that the event was discarded due to a null TR being serviced. In this case, the error condition must be cleared before the DMA channel can be re-triggered. Good programming practices might include clearing the event missed error before re-triggering the DMA channel.

If a chaining event is being processed (prioritized or queued) and another chained event is received for the same channel prior to the original being cleared ([EDMA\\_TPCC\\_CER\[31:0\]](#)  $E_n \neq 0$ ), then the second chained event is registered as a missed event in the corresponding channel bit of the event missed register [EDMA\\_TPCC\\_EMR\[31:0\]](#)  $E_n = 1$ .

---

**NOTE:** Chained event registers [EDMA\\_TPCC\\_CER](#), event registers [EDMA\\_TPCC\\_ER](#), and event set registers [EDMA\\_TPCC\\_ESR](#) operate independently. An event  $E_n$  can be triggered by any of the trigger sources (event-triggered, manually-triggered, or chain-triggered).

---

## 16.2.4.4.2 QDMA Channels

### 16.2.4.4.2.1 Auto-triggered and Link-Triggered Transfer Request

QDMA-based transfer requests are issued when a QDMA event gets latched in the QDMA event register [EDMA\\_TPCC\\_QER\[31:0\]](#)  $E_n = 1$ . A bit corresponding to a QDMA channel is set in the QDMA event register [EDMA\\_TPCC\\_QER](#) when the following occurs:

- A CPU (or any device module) write occurs to a PaRAM address that is defined as a QDMA channel trigger word (programmed in the QDMA channel mapping register [EDMA\\_TPCC\\_QCHMAPN\\_j](#) for the particular QDMA channel and the QDMA channel is enabled via the QDMA event enable register [EDMA\\_TPCC\\_QEER\[31:0\]](#)  $E_n = 1$ .
- EDMA\_TPCC performs a link update on a PaRAM set address that is configured as a QDMA channel matches [EDMA\\_TPCC\\_QCHMAPN\\_j](#) settings and the corresponding channel is enabled via the QDMA event enable register [EDMA\\_TPCC\\_QEER\[31:0\]](#)  $E_n = 1$ .

Once a bit is set in [EDMA\\_TPCC\\_QER](#), the EDMA\_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA\_TPTC and the channel can be triggered again.

If a bit is already set in [EDMA\\_TPCC\\_QER\[31:0\]](#)  $E_n = 1$  and a second QDMA event for the same QDMA channel occurs prior to the original being cleared, the second QDMA event gets captured in the QDMA event miss register [EDMA\\_TPCC\\_QEMR\[7:0\]](#)  $E_n = 1$ .

### 16.2.4.4.3 Comparison Between DMA and QDMA Channels

The primary difference between DMA and QDMA channels is the event/channel synchronization.

QDMA events are either auto-triggered or link triggered. Auto-triggering allows QDMA channels to be triggered by CPU(s) with a minimum number of linear writes to PaRAM. Link triggering allows a linked list of transfers to be executed, using a single QDMA PaRAM set and multiple link PaRAM sets.

A QDMA transfer is triggered when a CPU (or other device modules) writes to the trigger word of the QDMA channel parameter set (auto-triggered) or when the EDMA\_TPCC performs a link update on a PaRAM set that has been mapped to a QDMA channel (link triggered).

---

**NOTE:** The CPUs triggered (manually triggered) DMA channels, in addition to writing to the PaRAM set, it is required to write to the event set register [EDMA\\_TPCC\\_ESR](#) to kick-off the transfer.

---

QDMA channels are typically for cases where a single event accomplishes a complete transfer since the CPU (or other device modules) must reprogram some portion of the QDMA PaRAM set in order to re-trigger the channel. QDMA transfers are programmed with `EDMA_TPCC_ABCNT_n[31:0]` BCNT = 1 and `EDMA_TPCC_CCNT_n[15:0]` CCNT = 1 for A-synchronized transfers, and `EDMA_TPCC_CCNT_n[15:0]` CCNT = 1 for AB-synchronized transfers.

Additionally, since linking is also supported (if `EDMA_TPCC_OPT_n[3]` STATIC = 0) for QDMA transfers, it allows to initiate a linked list of QDMAs, so when `EDMA_TPCC` copies over a link PaRAM set (including the write to the trigger word), the current PaRAM set mapped to the QDMA channel automatically recognizes as a valid QDMA event and initiate another set of transfers as specified by the linked set.

#### 16.2.4.5 Completion of a DMA Transfer

A parameter set for a given channel is complete when the required number of transfer requests is submitted (based on receiving the number of synchronization events). The expected number of TRs for a non-null/non-dummy transfer is shown in [Table 16-94](#) for both synchronization types along with state of the PaRAM set prior to the final TR being submitted. When the counts (`EDMA_TPCC_ABCNT_n[31:0]` BCNT and/or `EDMA_TPCC_CCNT_n[15:0]` CCNT) are this value, the next TR results in:

- Final chaining or interrupt codes sent by the transfer controllers (instead of intermediate).
- Link updates (linking to either null or another valid link set).

**Table 16-94. Expected Number of Transfers for Non-Null Transfer**

Sync Mode	Counts at time 0	Total # Transfers	Counts prior to final TR
A-synchronized	ACNT BCNT CCNT	(BCNT × CCNT ) TRs of ACNT bytes each	<code>EDMA_TPCC_ABCNT_n[31:0]</code> BCNT == 1 && <code>EDMA_TPCC_CCNT_n[15:0]</code> CCNT == 1
AB-synchronized	ACNT BCNT CCNT	CCNT TRs for ACNT × BCNT bytes each	<code>EDMA_TPCC_CCNT_n[15:0]</code> CCNT == 1

The PaRAM OPT field must program with a specific transfer completion code TCC or `EDMA_TPCC_OPT_n[17:12]` TCC along with the other `EDMA_TPCC_OPT_n` fields ([22] TCCHEN, [20] TCINTEN, [23] ITCCHEN, and [21] ITCINTEN bits) to indicate whether the completion code is to be used for generating a chained event or/and for generating an interrupt upon completion of a transfer.

The specific `EDMA_TPCC_OPT_n[17:12]` TCC value (6-bit binary value) programmed dictates which of the 64-bits in the chain event register `EDMA_TPCC_CER` [TCC] and/or interrupt pending register `EDMA_TPCC_IPR` [TCC] is set.

It can selectively program whether the transfer controller sends back completion codes on completion of the final transfer request (TR) of a parameter set `EDMA_TPCC_OPT_n[22]` TCCHEN or `EDMA_TPCC_OPT_n[20]` TCINTEN, for all but the final transfer request (TR) of a parameter set `EDMA_TPCC_OPT_n[23]` ITCCHEN or `EDMA_TPCC_OPT_n[21]` ITCINTEN), or for all TRs of a parameter set (both). Refer to [Section 16.2.4.8 Chaining EDMA Channels](#) for details on chaining (intermediate/final chaining) and [Section 16.2.4.9 EDMA Interrupts](#) for details on intermediate/final interrupt completion.

A completion detection interface exists between the EDMA channel controller and transfer controller(s). This interface sends back information from the transfer controller to the channel controller to indicate that a specific transfer is completed. Completion of a transfer is used for generating chained events and/or generating interrupts to the CPU(s).

All DMA/QDMA PaRAM sets must also specify a link address value. For repetitive transfers such as ping-pong buffers, the link address value must point to another predefined PaRAM set. Alternatively, a non-repetitive transfer must set the link address value to the null link value. The null link value is defined as FFFFh. Refer to [Section 16.2.4.3.7 Linking Transfers](#) for more details.

**NOTE:** Any incoming events that are mapped to a null PaRAM set results in an error condition. The error condition must clear before the corresponding channel is used again. Refer to [Section 16.2.4.3.5 Dummy Versus Null Transfer Comparison](#).

There are three ways the EDMA\_TPCC gets updated/informed about a transfer completion: normal completion, early completion, and dummy/null completion. This applies to both chained events and completion interrupt generation.

#### 16.2.4.5.1 Normal Completion

In normal completion mode [EDMA\\_TPCC\\_OPT\\_n\[11\]](#) TCCMODE = 0, the transfer or sub-transfer is considered to be complete when the EDMA channel controller receives the completion codes from the EDMA transfer controller. In this mode, the completion code to the channel controller is posted by the transfer controller after it receives a signal from the destination peripheral. Normal completion is typically used to generate an interrupt to inform the CPU that a set of data is ready for processing.

#### 16.2.4.5.2 Early Completion

In early completion mode [EDMA\\_TPCC\\_OPT\\_n\[11\]](#) TCCMODE = 1, the transfer is considered to be complete when the EDMA channel controller submits the transfer request (TR) to the EDMA transfer controller. In this mode, the channel controller generates the completion code internally. Early completion is typically useful for chaining, as it allows subsequent transfers to be chained-triggered while the previous transfer is still in progress within the transfer controller, maximizing the overall throughput of the set of the transfers.

#### 16.2.4.5.3 Dummy or Null Completion

This is a variation of early completion. Dummy or null completion is associated with a dummy set [Section 16.2.4.3.4](#) or null set [Section 16.2.4.3.3](#). In both cases, the EDMA channel controller does not submit the associated transfer request to the EDMA transfer controller(s). However, if the set (dummy/null) has the OPT field programmed to return completion code (intermediate/final interrupt/chaining completion), then it sets the appropriate bits in the interrupt pending registers [EDMA\\_TPCC\\_IPR](#) and [EDMA\\_TPCC\\_IPRH](#) or chained event register [EDMA\\_TPCC\\_CER](#) and [EDMA\\_TPCC\\_CERH](#). The internal early completion path is used by the channel controller to return the completion codes internally (that is, EDMA\_TPCC generates the completion code).

#### 16.2.4.6 Event, Channel, and PaRAM Mapping

Several of the 64 DMA channels are tied to a specific hardware event, thus allowing events from device peripherals or external hardware (via the `dma_evt[4:1]` pins) to trigger transfers. A DMA channel typically requests a data transfer when it receives its event (apart from manually-triggered, chain-triggered, and other transfers). The amount of data transferred per synchronization event depends on the channel's configuration ([EDMA\\_TPCC\\_ABCNT\\_n\[15:0\]](#) ACNT, [EDMA\\_TPCC\\_ABCNT\\_n\[31:16\]](#) BCNT, [EDMA\\_TPCC\\_CCNT\\_n\[15:0\]](#) CCNT, etc.) and the synchronization type (A-synchronized or AB-synchronized).

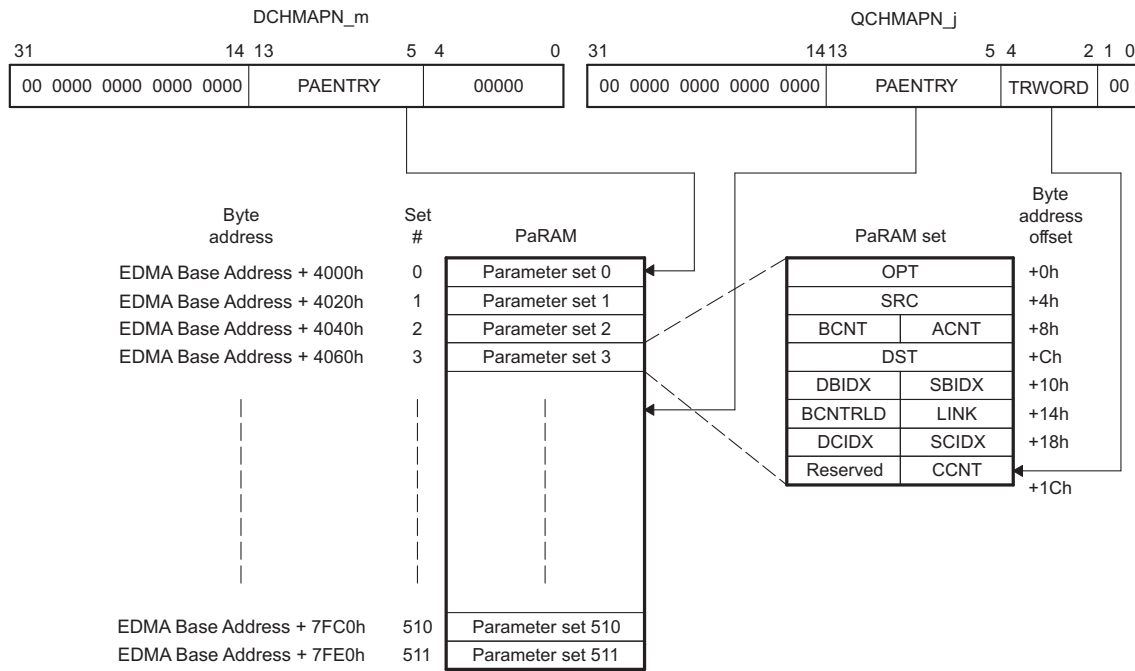

The association of an event to a channel is fixed within the EDMA Channel Controller, that is, each DMA channel has one specific event associated with it. The EDMA event crossbar can be used to select which level events (of which there are more than 64) are mapped to the 64 input events to the EDMA Channel Controller. The default mapping and event crossbar mapping are defined in [Section 16.2.3.1, EDMA Requests to the EDMA Controller](#). The event crossbar mapping is controlled by the device Control Modules registers refer to [Section 18.4.6.4 IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18 Control Module](#).

In an application, if a channel does not use the associated synchronization event or if it does not have an associated synchronization event (unused), that channel can be used for manually-triggered or chained-triggered transfers, for linking/reloading, or as a QDMA channel.

### 16.2.4.6.1 DMA Channel to PaRAM Mapping

The mapping between the DMA channel numbers and the PaRAM sets is programmable (see Table 16-90). The DMA channel mapping registers `EDMA_TPCC_DCHMAPN_m` in the `EDMA_TPCC` provide programmability that allows the DMA channels to be mapped to any of the PaRAM sets in the PaRAM memory map. Figure 16-24 illustrates the use of `EDMA_TPCC_DCHMAPN_m`. There is one `EDMA_TPCC_DCHMAPN_m` register per channel.

**Figure 16-24. DMA Channel and QDMA Channel to PaRAM Mapping**

edma-013

### 16.2.4.6.2 QDMA Channel to PaRAM Mapping

The mapping between the QDMA channels and the PaRAM sets is programmable. The QDMA channel mapping register `EDMA_TPCC_QCHMAPN_j` in the `EDMA_TPCC` allows to map the QDMA channels to any of the PaRAM sets in the PaRAM memory map. Figure 16-25 illustrates the use of `EDMA_TPCC_QCHMAPN_j`.

`EDMA_TPCC_QCHMAPN_j[4:2]` TRWORD bit-field allows to program the trigger word in the PaRAM set for the QDMA channel. A trigger word is one of the eight words in the PaRAM set. For a QDMA transfer to occur, a valid TR synchronization event for `EDMA_TPCC` is a write to the trigger word in the PaRAM set pointed to by `EDMA_TPCC_QCHMAPN_j` for a particular QDMA channel. By default, QDMA channels are mapped to PaRAM set 0.

It must appropriately re-map PaRAM set 0 before use.

Figure 16-25. QDMA Channel to PaRAM Mapping

### 16.2.4.7 EDMA Channel Controller Regions

The EDMA channel controller divides its address space into eight regions. Individual channel resources are assigned to a specific region, where each region is typically assigned to a specific device module uses the EDMA controller.

Application software can use regions or to ignore them altogether. It can be used active memory protection in conjunction with regions so that only a specific device module which uses the EDMA (for example, privilege identification) or privilege level (for example, user vs. supervisor) is allowed access to a given region, and thus to a given DMA or QDMA channel. This allows robust system-level DMA code where each EDMA initiator only modifies the state of the assigned resources. Memory protection is described in [Section 16.2.4.10 Memory Protection](#).

#### 16.2.4.7.1 Region Overview

The EDMA channel controller memory-mapped registers are divided in three main categories:

1. Global registers
2. Global region channel registers
3. Shadow region channel registers

The global registers are located at a single/fixed location in the EDMA\_TPCC memory map. These registers control EDMA resource mapping and provide debug visibility and error tracking information.

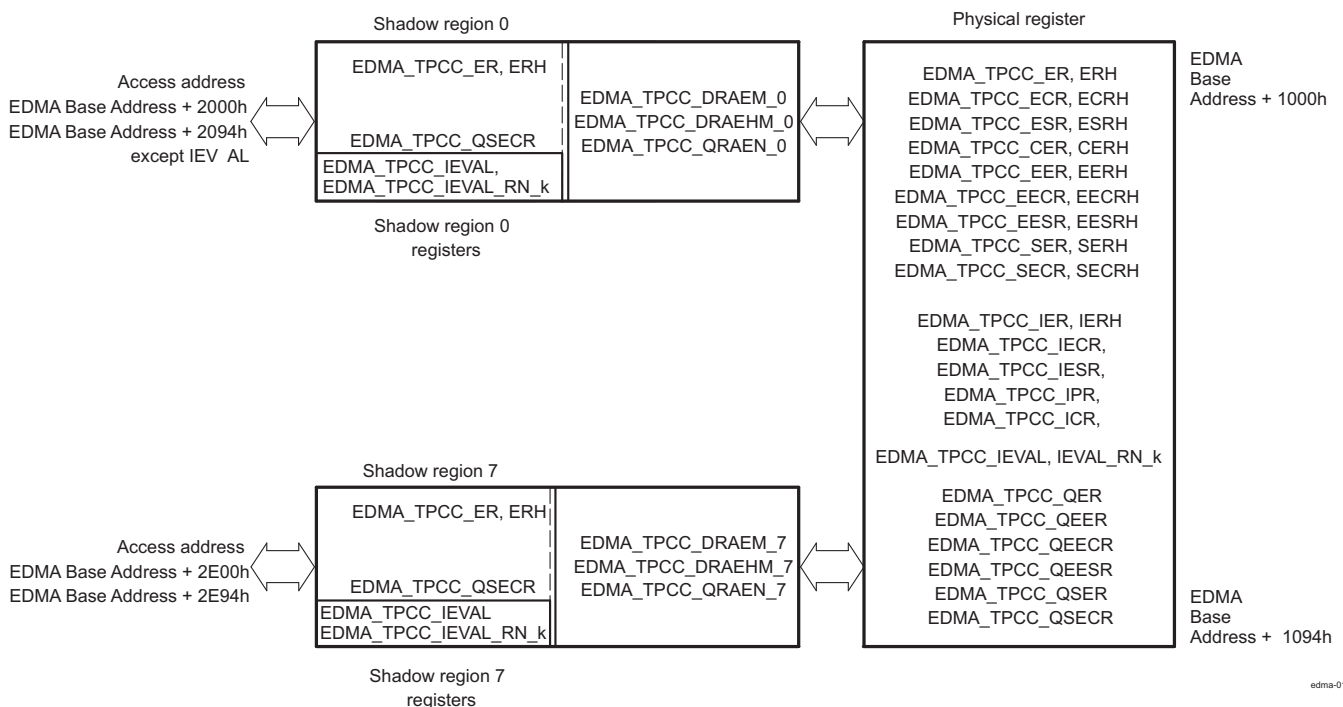

The channel registers (including DMA, QDMA, and interrupt registers) are accessible via the global channel region address range, or in the shadow *n* channel region address range(s). For example, the event enable register [EDMA\\_TPCC\\_EER](#) is visible at the global address of EDMA Base Address + 1020h or region addresses of EDMA Base Address + 2020h for region 0, EDMA Base Address + 2220h for region 1, ... EDMA Base Address + 2E20h for region 7.

The DMA region access enable registers [EDMA\\_TPCC\\_DRAEM\\_k](#) and the QDMA region access enable registers [EDMA\\_TPCC\\_QRAEN\\_k](#) control the underlying control register bits that are accessible via the shadow region address space (except for [EDMA\\_TPCC\\_IEVAL](#) and [EDMA\\_TPCC\\_IEVAL\\_RN\\_k](#) registers). [Table 16-95](#) lists the registers in the shadow region memory map. Refer to [EDMA\\_TPCC](#) register summary [Table 16-111](#) for the complete global and shadow region memory maps.

**Figure 16-26. Shadow Region Registers**

edma-015

### 16.2.4.7.2 Channel Controller Regions

There are eight EDMA shadow regions (and associated memory maps). Associated with each shadow region are a set of registers defining which channels and interrupt completion codes belong to that region. These registers are user-programmed per region to assign ownership of the DMA/QDMA channels to a region.

- [EDMA\\_TPCC\\_DRAEM\\_k](#) and [EDMA\\_TPCC\\_DRAEHM\\_k](#): One register pair exists for each of the shadow regions. The number of bits in each register pair matches the number of DMA channels (64 DMA channels). These registers need to be programmed to assign ownership of DMA channels and interrupt (or [EDMA\\_TPCC\\_OPT\\_n\[17:12\]](#) TCC codes) to the respective region. Accesses to DMA and interrupt registers via the shadow region address view are filtered through the DRAEM/DRAEHM pair. A value of 1 in the corresponding [EDMA\\_TPCC\\_DRAEM\\_k\[31:0\]](#) / [EDMA\\_TPCC\\_DRAEHM\\_k\[31:0\]](#) bit implies that the corresponding DMA interrupt channel is accessible; a value of 0 in the corresponding [EDMA\\_TPCC\\_DRAEM\\_k\[31:0\]](#) / [EDMA\\_TPCC\\_DRAEHM\\_k\[31:0\]](#) bit forces writes to be discarded and returns a value of 0 for reads.
- [EDMA\\_TPCC\\_QRAEN\\_k](#): One register exists for every region. The number of bits in each register matches the number of QDMA channels (4 QDMA channels). These registers must be programmed to assign ownership of QDMA channels to the respective region. To enable a channel in a shadow region using shadow region 0 [EDMA\\_TPCC\\_QEER](#), the corresponding bits in QRAE must be set or writing into [EDMA\\_TPCC\\_QEESR](#) there will be no the desired effect.
- [EDMA\\_TPCC\\_MPPAN\\_k](#) and [EDMA\\_TPCC\\_MPPAG](#): One register exists for every region. This register defines the privilege level, requestor, and types of accesses allowed to a region's memory-mapped registers.

It is typical for an application to have a unique assignment of QDMA/DMA channels (and, therefore, a given bit position) to a given region.

The use of shadow regions allows restricted access to EDMA resources (DMA channels, QDMA channels, TCC, interrupts) by tasks in a system by setting or clearing bits in the [EDMA\\_TPCC\\_DRAEM\\_k](#) / [EDMA\\_TPCC\\_QRAEN\\_k](#) registers.

If exclusive access to any given channel / TCC code is required for a region, then only that region's [EDMA\\_TPCC\\_DRAEM\\_k](#) / [EDMA\\_TPCC\\_QRAEN\\_k](#) have the associated bit set.

#### Example 16-1. Resource Pool Division Across Two Regions

This example illustrates a resource pool division across two regions, assuming region 0 must be allocated 16 DMA channels (0-15) and 1 QDMA channel (0) and 32 TCC codes (0-15 and 48-63).

Region 1 needs to be allocated 16 DMA channels (16-32) and the remaining 7 QDMA channels (1-7) and TCC codes (16-47).

[EDMA\\_TPCC\\_DRAEM\\_k](#) should be equal to the OR of the bits that are required for the DMA channels and the TCC codes:

```
Region 0: DRAEHM, DRAEM = 0xFFFF0000, 0x0000FFFF QRAEN = 0x0000001
Region 1: DRAEHM, DRAEM = 0x0000FFFF, 0xFFFF0000 QRAEN = 0x00000FE
```

### 16.2.4.7.3 Region Interrupts

In addition to the EDMA\_TPCC global completion interrupt, there is an additional completion interrupt line that is associated with every shadow region. Along with the interrupt enable register [EDMA\\_TPCC\\_IER](#), DRAEM acts as a secondary interrupt enable for the respective shadow region interrupts. Refer to [Table 16-88 Hardware Request](#) for more information about EDMA Interrupts.

### 16.2.4.8 Chaining EDMA Channels

The channel chaining capability for the EDMA allows the completion of an EDMA channel transfer to trigger another EDMA channel transfer. The purpose is to allow the ability to chain several events through one event occurrence.

Chaining is different from linking ([Section 16.2.4.3.7 Linking Transfers](#)). The EDMA link feature reloads the current channel parameter set with the linked parameter set. The EDMA chaining feature does not modify or update any channel parameter set. It provides a synchronization event to the chained channel (see [Section 16.2.4.4.1.3 Chain-Triggered Transfer Request](#)).

Chaining is achieved at either final transfer completion or intermediate transfer completion, or both, of the current channel. Consider a channel  $m$  (DMA/QDMA) required to chain to channel  $n$ . Channel number  $n$  (0-63) needs to be programmed into the `EDMA_TPCC_OPT_n[17:12]` TCC bit-field of channel  $m$  channel options parameter (OPT) set.

- If final transfer completion chaining `EDMA_TPCC_OPT_n[22] TCCHEN = 1` is enabled, the chain-triggered event occurs after the submission of the last transfer request of channel  $m$  is either submitted or completed (depending on early or normal completion).
- If intermediate transfer completion chaining `EDMA_TPCC_OPT_n[23] ITCCHEN = 1` is enabled, the chain-triggered event occurs after every transfer request, except the last of channel  $m$  is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion chaining (`EDMA_TPCC_OPT_n[22] TCCHEN = 1` and `EDMA_TPCC_OPT_n[23] ITCCHEN = 1`) are enabled, then the chain-trigger event occurs after every transfer request is submitted or completed (depending on early or normal completion).

[Table 16-96](#) illustrates the number of chain event triggers occurring in different synchronized scenarios. Consider channel 31 programmed with `EDMA_TPCC_ABCNT_n[15:0] ACNT = 3`, `EDMA_TPCC_ABCNT_n[31:16] BCNT = 4`, `EDMA_TPCC_CCNT_n[15:0] CCNT = 5`, and `EDMA_TPCC_OPT_n[17:12] TCC = 30`.

**Table 16-96. Chain Event Triggers**

Options	(Number of chained event triggers on channel 30)	
	A-Synchronized	AB-Synchronized
<code>EDMA_TPCC_OPT_n[22] TCCHEN = 1</code> , <code>EDMA_TPCC_OPT_n[23] ITCCHEN = 0</code>	1 (Owing to the last TR)	1 (Owing to the last TR)
<code>EDMA_TPCC_OPT_n[22] TCCHEN = 0</code> , <code>EDMA_TPCC_OPT_n[23] ITCCHEN = 1</code>	19 (Owing to all but the last TR)	4 (Owing to all but the last TR)
<code>EDMA_TPCC_OPT_n[22] TCCHEN = 1</code> , <code>EDMA_TPCC_OPT_n[23] ITCCHEN = 1</code>	20 (Owing to a total of 20 TRs)	5 (Owing to a total of 5 TRs)

### 16.2.4.9 EDMA Interrupts

The EDMA interrupts are divided into 2 categories: transfer completion interrupts and error interrupts.

There are nine region interrupts, eight shadow regions and one global region. The transfer completion interrupts are listed in [Table 16-97](#). The transfer completion interrupts and the error interrupts from the transfer controllers are all routed to the device interrupt controllers INTCs through the inputs of the `IRQ_CROSSBAR` module.

**Table 16-97. EDMA Transfer Completion Interrupts**

Name	Description
<code>EDMA_TPCC_INT0</code>	EDMA_TPCC Transfer Completion Interrupt Shadow Region 0
<code>EDMA_TPCC_INT1</code>	EDMA_TPCC Transfer Completion Interrupt Shadow Region 1
<code>EDMA_TPCC_INT2</code>	EDMA_TPCC Transfer Completion Interrupt Shadow Region 2
<code>EDMA_TPCC_INT3</code>	EDMA_TPCC Transfer Completion Interrupt Shadow Region 3
<code>EDMA_TPCC_INT4</code>	EDMA_TPCC Transfer Completion Interrupt Shadow Region 4
<code>EDMA_TPCC_INT5</code>	EDMA_TPCC Transfer Completion Interrupt Shadow Region 5
<code>EDMA_TPCC_INT6</code>	EDMA_TPCC Transfer Completion Interrupt Shadow Region 6
<code>EDMA_TPCC_INT7</code>	EDMA_TPCC Transfer Completion Interrupt Shadow Region 7

**Table 16-98. EDMA Error Interrupts**

Name	Description
EDMA_TPCC_ERRINT	EDMA_TPCC Error Interrupt
EDMA_TPCC_MPINT	EDMA_TPCC Memory Protection Interrupt
EDMA_TC0_ERRINT	TC0 Error Interrupt
EDMA_TC1_ERRINT	TC1 Error Interrupt

#### 16.2.4.9.1 Transfer Completion Interrupts

The EDMA\_TPCC is responsible for generating transfer completion interrupts to the CPU(s) (and other EDMA masters). The EDMA generates a single completion interrupt per shadow region, as well as one for the global region on behalf of all 64 channels. The various control registers and bit fields facilitate EDMA interrupt generation.

The software architecture must either use the global interrupt or the shadow interrupts, but not both.

The transfer completion code [EDMA\\_TPCC\\_OPT\\_n\[17:12\]](#) TCC value is directly mapped to the bits of the interrupt pending register [EDMA\\_TPCC\\_IPR](#) / [EDMA\\_TPCC\\_IPRH](#).

For example, if [EDMA\\_TPCC\\_OPT\\_n\[17:12\]](#) TCC = 10 0001b, [EDMA\\_TPCC\\_IPRH\[1\]](#) is set after transfer completion, and results in interrupt generation to the CPU(s) if the completion interrupt is enabled for the CPU. See [Section 16.2.4.9.1.1 Enabling Transfer Completion Interrupts](#) for details about enabling EDMA transfer completion interrupts.

When a completion code is returned (as a result of early or normal completions), the corresponding bit in [EDMA\\_TPCC\\_IPR](#) / [EDMA\\_TPCC\\_IPRH](#) registers is set if transfer completion interrupt (final/intermediate) is enabled in the channel options parameter (OPT) for a PaRAM set associated with the transfer.

**Table 16-99. Transfer Complete Code (TCC) to EDMA\_TPCC Interrupt Mapping**

TCC values in <a href="#">EDMA_TPCC_OPT_n[17:12]</a> TCC ( <a href="#">EDMA_TPCC_OPT_n[20]</a> TCINTEN / <a href="#">EDMA_TPCC_OPT_n[21]</a> ITCINTEN = 1)		EDMA_TPCC_IPR Bit Set	TCC values in <a href="#">EDMA_TPCC_OPT_n[17:12]</a> TCC ( <a href="#">EDMA_TPCC_OPT_n[20]</a> TCINTEN / <a href="#">EDMA_TPCC_OPT_n[21]</a> ITCINTEN = 1)		EDMA_TPCC_IPRH Bit Set <sup>(1)</sup>
0		<a href="#">EDMA_TPCC_IPR[0]</a>	20h		<a href="#">EDMA_TPCC_IPR[32]</a> / <a href="#">EDMA_TPCC_IPRH[0]</a>
1		<a href="#">EDMA_TPCC_IPR[1]</a>	21h		<a href="#">EDMA_TPCC_IPR[33]</a> / <a href="#">EDMA_TPCC_IPRH[1]</a>
2h		<a href="#">EDMA_TPCC_IPR[2]</a>	22h		<a href="#">EDMA_TPCC_IPR[34]</a> / <a href="#">EDMA_TPCC_IPRH[2]</a>
3h		<a href="#">EDMA_TPCC_IPR[3]</a>	23h		<a href="#">EDMA_TPCC_IPR[35]</a> / <a href="#">EDMA_TPCC_IPRH[3]</a>
4h		<a href="#">EDMA_TPCC_IPR[4]</a>	24h		<a href="#">EDMA_TPCC_IPR[36]</a> / <a href="#">EDMA_TPCC_IPRH[4]</a>
...		...	...		...
1Eh		<a href="#">EDMA_TPCC_IPR[30]</a>	3Eh		<a href="#">EDMA_TPCC_IPR[62]</a> / <a href="#">EDMA_TPCC_IPRH[30]</a>
1Fh		<a href="#">EDMA_TPCC_IPR[31]</a>	3Fh		<a href="#">EDMA_TPCC_IPR[63]</a> / <a href="#">EDMA_TPCC_IPRH[31]</a>

<sup>(1)</sup> Bit fields [EDMA\\_TPCC\\_IPR](#) [32-63] correspond to bits 0 to 31 in [EDMA\\_TPCC\\_IPRH](#), respectively.

The transfer completion code (TCC) can program to any value for a DMA/QDMA channel. A direct relation between the channel number and the transfer completion code value does not need to exist. This allows multiple channels having the same transfer completion code value to cause a CPU to execute the same interrupt service routine (ISR) for different channels.

If the channel is used in the context of a shadow region and it intends for the shadow region interrupt to be asserted, then ensure that the bit corresponding to the TCC code is enabled in [EDMA\\_TPCC\\_IER](#) / [EDMA\\_TPCC\\_IERH](#) and in the corresponding shadow region's DMA region access registers ([EDMA\\_TPCC\\_DRAEM\\_k](#) / [EDMA\\_TPCC\\_DRAEHM\\_k](#)).

Interrupt generation can be enabled at either final transfer completion or intermediate transfer completion, or both. Consider channel *m* as an example.

- If the final transfer interrupt ([EDMA\\_TPCC\\_OPT\\_n\[20\]](#) TCINTEN = 1) is enabled, the interrupt occurs after the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).
- If the intermediate transfer interrupt ([EDMA\\_TPCC\\_OPT\\_n\[21\]](#) ITCINTEN = 1) is enabled, the interrupt occurs after every transfer request, except the last TR of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion interrupts ([EDMA\\_TPCC\\_OPT\\_n\[20\]](#) TCINTEN = 1, and [EDMA\\_TPCC\\_OPT\\_n\[21\]](#) ITCINTEN = 1) are enabled, then the interrupt occurs after every transfer request is submitted or completed (depending on early or normal completion).

Table 16-100 shows the number of interrupts that occur in different synchronized scenarios. Consider channel 31, programmed with [ABCNT\\_n\[15:0\]](#) ACNT = 3, [EDMA\\_TPCC\\_ABCNT\\_n\[31:16\]](#) BCNT = 4, [EDMA\\_TPCC\\_CCNT\\_n\[15:0\]](#) CCNT = 5, and [EDMA\\_TPCC\\_OPT\\_n\[17:12\]](#) TCC = 30.

**Table 16-100. Number of Interrupts**

Options	A-Synchronized	AB-Synchronized
<a href="#">EDMA_TPCC_OPT_n[20]</a> TCINTEN = 1, <a href="#">EDMA_TPCC_OPT_n[21]</a> ITCINTEN = 0	1 (Last TR)	1 (Last TR)
<a href="#">EDMA_TPCC_OPT_n[20]</a> TCINTEN = 0, <a href="#">EDMA_TPCC_OPT_n[21]</a> ITCINTEN = 1	19 (All but the last TR)	4 (All but the last TR)
<a href="#">EDMA_TPCC_OPT_n[20]</a> TCINTEN = 1, <a href="#">EDMA_TPCC_OPT_n[21]</a> ITCINTEN = 1	20 (All TRs)	5 (All TRs)

#### 16.2.4.9.1.1 Enabling Transfer Completion Interrupts

For the EDMA channel controller to assert a transfer completion to the external environment, the interrupts must be enabled in the EDMA\_TPCC. This is in addition to setting up the [EDMA\\_TPCC\\_OPT\\_n\[20\]](#) TCINTEN and [EDMA\\_TPCC\\_OPT\\_n\[21\]](#) ITCINTEN bits of the associated PaRAM set.

The EDMA channel controller has interrupt enable registers [EDMA\\_TPCC\\_IER](#) / [EDMA\\_TPCC\\_IERH](#) and each bit location in [EDMA\\_TPCC\\_IER](#) / [EDMA\\_TPCC\\_IERH](#) serves as a primary enable for the corresponding interrupt pending registers [EDMA\\_TPCC\\_IPR](#) / [EDMA\\_TPCC\\_IPRH](#).

All of the interrupt registers ([EDMA\\_TPCC\\_IER](#), [EDMA\\_TPCC\\_IESR](#), [EDMA\\_TPCC\\_IECR](#), and [EDMA\\_TPCC\\_IPR](#)) are either manipulated from the global DMA channel region, or by the DMA channel shadow regions. The shadow regions provide a view to the same set of physical registers that are in the global region.

The EDMA channel controller has a hierarchical completion interrupt scheme that uses a single set of interrupt pending registers [EDMA\\_TPCC\\_IPR](#) / [EDMA\\_TPCC\\_IPRH](#) and single set of interrupt enable registers [EDMA\\_TPCC\\_IER](#) / [EDMA\\_TPCC\\_IERH](#). The programmable DMA region access enable registers [EDMA\\_TPCC\\_DRAEM\\_k](#) / [EDMA\\_TPCC\\_DRAEHM\\_k](#) provides a second level of interrupt masking. The global region interrupt output is gated based on the enable mask that is provided by [EDMA\\_TPCC\\_IER](#) / [EDMA\\_TPCC\\_IERH](#), see [Figure 16-27](#)

The region interrupt outputs are gated by [EDMA\\_TPCC\\_IER](#) and the specific [EDMA\\_TPCC\\_DRAEM\\_k](#) / [EDMA\\_TPCC\\_DRAEHM\\_k](#) associated with the region.

[Figure 16-27](#) shows the Interrupt diagram of the EDMA controller.

Figure 16-27. Interrupt Diagram

edma-016

The EDMA\_TPCC generates the transfer completion interrupts that are associated with each shadow region, the following conditions must be true:

- EDMA\_TPCC\_INT0: (EDMA\_TPCC\_IPRH[31] E63 & EDMA\_TPCC\_IERH[31] E63 & EDMA\_TPCC\_DRAEHM\_k.DRAEHM\_0[31] E63) | (EDMA\_TPCC\_IPR[0] E0 & EDMA\_TPCC\_IER[0] E0 & EDMA\_TPCC\_DRAEM\_k.DRAEM\_0[0] E0) | (EDMA\_TPCC\_IPR[1] E1 & EDMA\_TPCC\_IER[1] E1 & EDMA\_TPCC\_DRAEM\_k.DRAEM\_0[1] E1) | ... | (EDMA\_TPCC\_IPRH[31] E63 & EDMA\_TPCC\_IERH[31] E63 & EDMA\_TPCC\_DRAEHM\_k.DRAEHM\_0[31] E63)
- EDMA\_TPCC\_INT1: (EDMA\_TPCC\_IPRH[31] E63 & EDMA\_TPCC\_IERH[31] E63 & EDMA\_TPCC\_DRAEHM\_k.DRAEHM\_1[31] E63) | (EDMA\_TPCC\_IPR[0] E0 & EDMA\_TPCC\_IER[0] E0 & EDMA\_TPCC\_DRAEM\_k.DRAEM\_1[0] E0) | (EDMA\_TPCC\_IPR[1] E1 & EDMA\_TPCC\_IER[1] E1 & EDMA\_TPCC\_DRAEM\_k.DRAEM\_1[1] E1) | ... | (EDMA\_TPCC\_IPRH[31] E63 & EDMA\_TPCC\_IERH[31] E63 & EDMA\_TPCC\_DRAEHM\_k.DRAEHM\_1[31] E63)
- EDMA\_TPCC\_INT2: (EDMA\_TPCC\_IPRH[31] E63 & EDMA\_TPCC\_IERH[31] E63 & EDMA\_TPCC\_DRAEHM\_k.DRAEHM\_2[31] E63) | (EDMA\_TPCC\_IPR[0] E0 & EDMA\_TPCC\_IER[0] E0 & EDMA\_TPCC\_DRAEM\_k.DRAEM\_2[0] E0) | (EDMA\_TPCC\_IPR[1] E1 & EDMA\_TPCC\_IER[1] E1 & EDMA\_TPCC\_DRAEM\_k.DRAEM\_2[1] E1) | ... | (EDMA\_TPCC\_IPRH[31] E63 & EDMA\_TPCC\_IERH[31] E63 & EDMA\_TPCC\_DRAEHM\_k.DRAEHM\_2[31] E63)....
- Up to EDMA\_TPCC\_INT7: (EDMA\_TPCC\_IPRH[31] E63 & EDMA\_TPCC\_IERH[31] E63 & EDMA\_TPCC\_DRAEHM\_k.DRAEHM\_7[31] E63) | (EDMA\_TPCC\_IPR[0] E0 & EDMA\_TPCC\_IER[0] E0 & EDMA\_TPCC\_DRAEM\_k.DRAEM\_7[0] E0) | (EDMA\_TPCC\_IPR[1] E1 & EDMA\_TPCC\_IER[1] E1 & EDMA\_TPCC\_DRAEM\_k.DRAEM\_7[1] E1) | ... | (EDMA\_TPCC\_IPRH[31] E63 & EDMA\_TPCC\_IERH[31] E63 & EDMA\_TPCC\_DRAEHM\_k.DRAEHM\_7[31] E63)

**NOTE:** The [EDMA\\_TPCC\\_DRAEM\\_k](#) / [EDMA\\_TPCC\\_DRAEHM\\_k](#) for all regions are expected to be set up at system initialization and to remain static for an extended period of time. The interrupt enable registers are used for dynamic enable/disable of individual interrupts.

Because there is no relation between the [EDMA\\_TPCC\\_OPT\\_n\[17:12\]](#) TCC value and the DMA/QDMA channel, it is possible, the DMA channel 0 to have the [EDMA\\_TPCC\\_OPT\\_n\[17:12\]](#) TCC = 63 in its associated PaRAM set. This mean that if a transfer completion interrupt is enabled ([EDMA\\_TPCC\\_OPT\\_n\[20\]](#) TCINTEN or [EDMA\\_TPCC\\_OPT\\_n\[21\]](#) ITCINTEN is set), then based on the TCC value, [EDMA\\_TPCC\\_IPRH\[31\]](#) E63 is set up on completion. For proper channel operations and interrupt generation using the shadow region map - program the [EDMA\\_TPCC\\_DRAEM\\_k](#) / [EDMA\\_TPCC\\_DRAEHM\\_k](#) that is associated with the shadow region to have read/write access to both bit 0 (corresponding to channel 0) and bit 63 (corresponding to [EDMA\\_TPCC\\_IPRH](#) bit that is set upon completion).

#### 16.2.4.9.1.2 Clearing Transfer Completion Interrupts

Transfer completion interrupts that are latched to the interrupt pending registers ( [EDMA\\_TPCC\\_IPR](#) / [EDMA\\_TPCC\\_IPRH](#) ) are cleared by writing a 1 to the corresponding bit in the interrupt pending clear register ( [EDMA\\_TPCC\\_ICR](#) / [EDMA\\_TPCC\\_ICRH](#) ). For example, a write of 1 to [EDMA\\_TPCC\\_ICR\[0\]](#) E0 clears a pending interrupt in [EDMA\\_TPCC\\_IPR\[0\]](#) E0.

If an incoming transfer completion code TCC ([EDMA\\_TPCC\\_OPT\\_n\[17:12\]](#) TCC) gets latched to a bit in [EDMA\\_TPCC\\_IPR](#) / [EDMA\\_TPCC\\_IPRH](#), then additional bits that get set due to a subsequent transfer completion does not result in asserting the [EDMA\\_TPCC](#) completion interrupt. In order for the completion interrupt to be pulsed, the required transition is from a state where no enabled interrupts are set to a state where at least one enabled interrupt is set.

#### 16.2.4.9.2 EDMA Interrupt Servicing

Upon completion of a transfer (early or normal completion), the EDMA channel controller sets the appropriate bit in the interrupt pending registers ( [EDMA\\_TPCC\\_IPR](#) / [EDMA\\_TPCC\\_IPRH](#) ), as the transfer completion codes specify. If the completion interrupts are appropriately enabled, then the CPU enters the interrupt service routine (ISR) when the completion interrupt is asserted.

After servicing the interrupt, the ISR should clear the corresponding bit in [EDMA\\_TPCC\\_IPR/EDMA\\_TPCC\\_IPRH](#), thereby enabling recognition of future interrupts. The [EDMA\\_TPCC](#) only asserts additional completion interrupts when all [EDMA\\_TPCC\\_IPR](#) / [EDMA\\_TPCC\\_IPRH](#) bits clear.

When one interrupt is serviced many other transfer completions may result in additional bits being set in [EDMA\\_TPCC\\_IPR](#) / [EDMA\\_TPCC\\_IPRH](#), thereby resulting in additional interrupts. Each of the bits in [EDMA\\_TPCC\\_IPR](#) / [EDMA\\_TPCC\\_IPRH](#) may need different types of service therefore, the ISR must check all pending interrupts and continue until all of the posted interrupts are serviced appropriately.

Examples of pseudo code for a CPU interrupt service routine for an [EDMA\\_TPCC](#) completion interrupt are shown in [Example 16-2](#) and [Example 16-3](#).

The ISR routine in [Example 16-2](#) is more exhaustive and incurs a higher latency.

#### Example 16-2. Interrupt Servicing

The pseudo code:

1. Reads the interrupt pending register [EDMA\\_TPCC\\_IPR](#) / [EDMA\\_TPCC\\_IPRH](#).
2. Performs the operations needed.
3. Writes to the interrupt pending clear register [EDMA\\_TPCC\\_ICR](#) / [EDMA\\_TPCC\\_ICRH](#) to clear the corresponding [EDMA\\_TPCC\\_IPR](#) / [EDMA\\_TPCC\\_IPRH](#) bit(s).
4. Reads [EDMA\\_TPCC\\_IPR](#) / [EDMA\\_TPCC\\_IPRH](#) again:
  - a. If [EDMA\\_TPCC\\_IPR](#) / [EDMA\\_TPCC\\_IPRH](#) is not equal to 0, repeat from step 2 (implies occurrence of new event between step 2 to step 4).

**Example 16-2. Interrupt Servicing (continued)**

- b. If `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH` is equal to 0, assure that all of the enabled interrupts are inactive.

---

**NOTE:** An event may occur during step 4 while the `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH` bits are read as 0 and the application is still in the interrupt service routine. If this happens, a new interrupt is recorded in the device interrupt controller and a new interrupt generates as soon as the application exits in the interrupt service routine.

---

[Example 16-3](#) is less rigorous, with less burden on the software in polling for set interrupt bits, but can occasionally cause a race condition as mentioned above.

**Example 16-3. Interrupt Servicing**

If any enabled and pending (possibly lower priority) interrupts are left, force the interrupt logic to reassert the interrupt pulse by setting the `EDMA_TPCC_IEVAL[0]` EVAL bit in the interrupt evaluation register.

The pseudo code is as follows:

1. Enters ISR.
2. Reads `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH`.
3. For the condition that is set in `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH`:
  - a. Service interrupt as the application requires.
  - b. Clear the bit for serviced conditions (others may still be set, and other transfers may have resulted in returning the TCC to `EDMA_TPCC` after step 2).
4. Reads `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH` prior to exiting the ISR:
  - a. If `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH` is equal to 0, then exit the ISR.
  - b. If `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH` is not equal to 0, then set `EDMA_TPCC_IEVAL` so that upon exit of ISR, a new interrupt triggers if any enabled interrupts are still pending.

**16.2.4.9.3 Interrupt Evaluation Operations**

The `EDMA_TPCC` has interrupt evaluate registers `EDMA_TPCC_IEVAL` that exist in the global region and in each shadow region. The registers in the shadow region are the only registers in the DMA channel shadow region memory map that are not affected by the settings for the DMA region access enable registers `EDMA_TPCC_DRAEM_k` / `EDMA_TPCC_DRAEHM_k`. Writing a 1 to the `EDMA_TPCC_IEVAL[0]` EVAL bit in the registers that are associated with a particular shadow region results in pulsing the associated region interrupt (global or shadow), if any enabled interrupt (via `EDMA_TPCC_IER` / `EDMA_TPCC_IERH`) is still pending `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH`. This register assures that the CPU does not miss the interrupts (or the EDMA master associated with the shadow region) if the software architecture chooses not to use all interrupts. Refer to [Example 16-3](#) about the use of `EDMA_TPCC_IEVAL` in the EDMA interrupt service routine (ISR).

Similarly an error evaluation register `EDMA_TPCC_EEVAL` exists in the global region. Writing a 1 to the `EDMA_TPCC_EEVAL[0]` EVAL bit causes the pulsing of the error interrupt if any pending errors are in `EDMA_TPCC_EMR` / `EDMA_TPCC_EMRH`, `EDMA_TPCC_QEMR`, or `EDMA_TPCC_CCERR`. See [Section 16.2.4.9.4 Error Interrupts](#) for additional information regarding error interrupts.

---

**NOTE:** While using `EDMA_TPCC_IEVAL` for shadow region completion interrupts, check that the `EDMA_TPCC_IEVAL` operated upon is from that particular shadow region memory map.

---

#### 16.2.4.9.4 Error Interrupts

The EDMA\_TPCC error registers provide the capability to differentiate error conditions (event missed, threshold exceed, etc.). Additionally, setting the error bits in these registers results in asserting the EDMA\_TPCC error interrupt. If the EDMA\_TPCC error interrupt is enabled in the device interrupt controller(s), then it allows the CPU(s) to handle the error conditions.

The EDMA\_TPCC has a single error interrupt (EDMA\_TPCC\_ERRINT) that is asserted for all EDMA\_TPCC error conditions. There are four conditions that cause the error interrupt:

- DMA missed events: for all 64 DMA channels. DMA missed events are latched in the event missed registers [EDMA\\_TPCC\\_EMR](#) / [EDMA\\_TPCC\\_EMRH](#).
- QDMA missed events: for all 8 QDMA channels. QDMA missed events are latched in the QDMA event missed register [EDMA\\_TPCC\\_QEMR](#).
- Threshold exceed: for all event queues. These are latched in EDMA\_TPCC error register [EDMA\\_TPCC\\_CCERR](#).
- TCC error: for outstanding transfer requests that are expected to return completion code [EDMA\\_TPCC\\_OPT\\_n\[22\]](#) TCCHEN or [EDMA\\_TPCC\\_OPT\\_n\[23\]](#) TCINTEN bit is set to 1, exceeding the maximum limit of 63. This is also latched in the EDMA\_TPCC error register [EDMA\\_TPCC\\_CCERR](#).

[Figure 16-28](#) illustrates the EDMA\_TPCC error interrupt generation operation.

If any of the bits are set in the error registers due to any error condition, the EDMA\_TPCC\_ERRINT is always asserted, as there are no enables for masking these error events. Similar to transfer completion interrupts (EDMA\_TPCC\_INT), the error interrupt also only pulses when the error interrupt condition transitions from no errors being set to at least one error being set. If additional error events are latched prior to the original error bits clearing, the EDMA\_TPCC does not generate additional interrupt.

To reduce the burden on the software, there is an error evaluate register [EDMA\\_TPCC\\_EEVAL](#) that allows re-evaluation of pending set error events/bits, similar to the interrupt evaluate register [EDMA\\_TPCC\\_IEVAL](#). Unlike the [EDMA\\_TPCC\\_IEVAL](#) functionality, the [EDMA\\_TPCC\\_EEVAL](#) register must be written with '1' after any error interrupts are serviced (even when all pending errors are cleared) in order for subsequent errors to trigger a new interrupt.

---

**NOTE:** It is good practice to enable the error interrupt in the device interrupt controller and to associate an interrupt service routine with it to address the various error conditions appropriately. Doing so puts less burden on the software (polling for error status), it provides a good debug mechanism for unexpected error conditions.

---

### 16.2.4.10 Memory Protection

The EDMA channel controller supports two kinds of memory protection: active and proxy.

#### 16.2.4.10.1 Active Memory Protection

Active memory protection is a feature that allows or prevents read and write accesses to the EDMA\_TPCC registers. Active memory protection is achieved by a set of memory protection permissions attribute [EDMA\\_TPCC\\_MPPAN\\_k](#) registers.

The EDMA\_TPCC register map is divided into three categories:

- a global region.
- a global channel region.
- eight shadow regions.

Each shadow region consists of the respective shadow region registers and the associated PaRAM. For more detailed information regarding the contents of a shadow region, refer to [Table 16-111 EDMA\\_TPCC Registers Mapping Summary](#).

Each of the eight shadow regions has an associated [EDMA\\_TPCC\\_MPPAN\\_k](#) registers that defines the specific requestor(s) and types of requests that are allowed to the regions resources.

The global channel region is also protected with a memory-mapped register [EDMA\\_TPCC\\_MPPAG](#). The [EDMA\\_TPCC\\_MPPAG](#) applies to the global region and to the global channel region, except the other [EDMA\\_TPCC\\_MPPAN\\_k](#) registers themselves.

[Table 16-101](#) shows the accesses that are allowed or not allowed to the [EDMA\\_TPCC\\_MPPAG](#) and [EDMA\\_TPCC\\_MPPAN\\_k](#). The active memory protection uses the [EDMA\\_TPCC\\_OPT\\_n\[31\]](#) PRIV and [EDMA\\_TPCC\\_OPT\\_n\[27:24\]](#) PRIVID attributes of the EDMA peripheral modules. The [EDMA\\_TPCC\\_OPT\\_n\[31\]](#) PRIV is the privilege level (i.e., user vs. supervisor).

The [EDMA\\_TPCC\\_OPT\\_n\[27:24\]](#) PRIVID refers to a privilege ID with a number that is associated with an EDMA peripheral modules.

**Table 16-101. Allowed Accesses**

Access	Supervisor	User
Read	Yes	Yes
Write	Yes	No

[Table 16-102](#) describes the [EDMA\\_TPCC\\_MPPAN\\_k](#) register mapping for the shadow regions (which includes shadow region registers and PaRAM addresses).

The region-based [EDMA\\_TPCC\\_MPPAN\\_k](#) registers are used to protect accesses to the DMA shadow regions and the associated region PaRAM. Because there are eight regions, there are eight [EDMA\\_TPCC\\_MPPAN\\_k](#) region registers (MPPAN[0-7]).

**Table 16-102. MPPA Registers to Region Assignment**

Register	Registers Protect	Address Range	PaRAM Protect <sup>(1)</sup>	Address Range
<a href="#">EDMA_TPCC_MPPAG</a>	Global Range	0000h-1FFCh	N/A	N/A
<a href="#">EDMA_TPCC_MPPAN_k</a> . <a href="#">MPPAN_0</a>	DMA Shadow 0	2000h-21FCh	1st octant	4000h-47FCh
<a href="#">MPPAN_1</a>	DMA Shadow 1	2200h-23FCh	2nd octant	4800h-4FFCh
<a href="#">MPPAN_2</a>	DMA Shadow 2	2400h-25FCh	3rd octant	5000h-57FCh
<a href="#">MPPAN_3</a>	DMA Shadow 3	2600h-27FCh	4th octant	5800h-5FFCh
<a href="#">MPPAN_4</a>	DMA Shadow 4	2800h-29FCh	5th octant	6000h-67FCh
<a href="#">MPPAN_5</a>	DMA Shadow 5	2A00h-2BFCh	6th octant	6800h-6FFCh
<a href="#">MPPAN_6</a>	DMA Shadow 6	2C00h-2DFCh	7th octant	7000h-77FCh
<a href="#">MPPAN_7</a>	DMA Shadow 7	2E00h-2FFCh	8th octant	7800h-7FFCh

<sup>(1)</sup> The PARAM region is divided into 8 regions referred to as an octant.

**Example Access denied.**

Write access to shadow region 7's event enable set register [EDMA\\_TPCC\\_EESR](#):

1. The original value of the event enable register [EDMA\\_TPCC\\_EER](#) at address offset 0x1020 is 0x0.
2. The [EDMA\\_TPCC\\_MPPAN\\_k](#). [EDMA\\_TPCC\\_MPPAN\\_7](#)[7] NS is set to prevent user level accesses ([EDMA\\_TPCC\\_MPPAN\\_k](#). [EDMA\\_TPCC\\_MPPAN\\_7](#)[1] UW = 0, [EDMA\\_TPCC\\_MPPAN\\_k](#). [EDMA\\_TPCC\\_MPPAN\\_7](#)[2] UR = 0), but it allows supervisor level accesses ([EDMA\\_TPCC\\_MPPAN\\_k](#). [EDMA\\_TPCC\\_MPPAN\\_7](#)[4] SW = 1, [EDMA\\_TPCC\\_MPPAN\\_k](#). [EDMA\\_TPCC\\_MPPAN\\_7](#)[5] SR = 1) with a privilege ID of 0. ([EDMA\\_TPCC\\_MPPAN\\_k](#). [EDMA\\_TPCC\\_MPPAN\\_7](#)[10] AID0 = 1).
3. EDMA peripheral modules with a privilege ID of 0 attempts to perform a user-level write of a value of 0xFF00FF00 to shadow region 7's event enable set register [EDMA\\_TPCC\\_EESR](#) at address offset 0x2E30.

---

**NOTE:** The [EDMA\\_TPCC\\_EER](#) is a read-only register and the only way that write to it is by writing to the [EDMA\\_TPCC\\_EESR](#). There is only one physical register for [EDMA\\_TPCC\\_EER](#), [EDMA\\_TPCC\\_EESR](#), etc. and that the shadow regions only provide to the same physical set.

---

4. Since the [EDMA\\_TPCC\\_MPPAN\\_k](#). [EDMA\\_TPCC\\_MPPAN\\_7](#)[1] UW = 0, though the privilege ID of the write access is set to 0, the access is not allowed and the [EDMA\\_TPCC\\_EER](#) is not written too.

**Table 16-103. Example Access Denied**

Register	Value	Description
<a href="#">EDMA_TPCC_EER</a> (offset 0x1020)	0x0000 0000	Value in <a href="#">EDMA_TPCC_EER</a> to begin with.
<a href="#">EDMA_TPCC_EESR</a> (offset 0x2E30)	0xFF00 FF00 ↓	Value attempted to be written to shadow region 7's <a href="#">EDMA_TPCC_EESR</a> . This is done by an EDMA connected device module with a privilege level of User and Privilege ID of 0.
<a href="#">EDMA_TPCC_MPPAN_k</a> (offset 0x082C)	0x0000 04B0  X	Memory Protection Filter <a href="#">EDMA_TPCC_MPPAN_k</a> [10] AID0 = 1, <a href="#">EDMA_TPCC_MPPAN_k</a> [1] UW = 0, <a href="#">EDMA_TPCC_MPPAN_k</a> [2] UR = 0, <a href="#">EDMA_TPCC_MPPAN_k</a> [4] SW = 1, <a href="#">EDMA_TPCC_MPPAN_k</a> [5] SR = 1.  Access Denied
<a href="#">EDMA_TPCC_EER</a> (offset 0x1020)	0x0000 0000	Final value of <a href="#">EDMA_TPCC_EER</a>

**Example Access Allowed**

Write access to shadow region 7's event enable set register [EDMA\\_TPCC\\_EESR](#):

1. The original value of the event enable register [EDMA\\_TPCC\\_EER](#) at address offset 0x1020 is 0x0.
2. The [EDMA\\_TPCC\\_MPPAN\\_k](#). [EDMA\\_TPCC\\_MPPAN\\_7](#) is set to allow user-level accesses ([EDMA\\_TPCC\\_MPPAN\\_k](#). [EDMA\\_TPCC\\_MPPAN\\_7](#)[1] UW = 1, [EDMA\\_TPCC\\_MPPAN\\_k](#). [EDMA\\_TPCC\\_MPPAN\\_7](#)[2] UR = 1) and supervisor-level accesses ([EDMA\\_TPCC\\_MPPAN\\_k](#). [EDMA\\_TPCC\\_MPPAN\\_7](#)[4] SW = 1, [EDMA\\_TPCC\\_MPPAN\\_k](#). [EDMA\\_TPCC\\_MPPAN\\_7](#)[5] SR = 1) with a privilege ID of 0. ([EDMA\\_TPCC\\_MPPAN\\_k](#). [EDMA\\_TPCC\\_MPPAN\\_7](#)[10] AID0 = 1).
3. EDMA peripheral modules with a privilege ID of 0, attempts to perform a user-level write of a value of 0xABCD0123 to shadow region 7's event enable set register [EDMA\\_TPCC\\_EESR](#) at address offset 0x2E30.

---

**NOTE:** The [EDMA\\_TPCC\\_EER](#) is a read-only register and the only way that write to it is by writing to the [EDMA\\_TPCC\\_EESR](#). There is only one physical register for [EDMA\\_TPCC\\_EER](#), [EDMA\\_TPCC\\_EESR](#), etc. and that the shadow regions only provide to the same physical set.

---

4. Since the [EDMA\\_TPCC\\_MPPAN\\_k](#). [EDMA\\_TPCC\\_MPPAN\\_7](#)[1] UW = 1 and [EDMA\\_TPCC\\_MPPAN\\_k](#). [MPPAN\\_7](#)[10] AID0 = 1, the user-level write access is allowed.
5. The accesse to shadow region registers are masked by their respective [EDMA\\_TPCC\\_DRAEM\\_k](#)

register. In this example, the [EDMA\\_TPCC\\_DRAEM\\_k](#). EDMA\_TPCC\_DRAEM\_7 is set of 0x9FF00FC2.

6. The value finally written to [EDMA\\_TPCC\\_EER](#) is 0x8BC00102.

**Table 16-104. Example Access Allowed**

Register	Value	Description
<a href="#">EDMA_TPCC_EER</a> (offset 0x1020)	0x0000 0000	Value in EER to begin with.
<a href="#">EDMA_TPCC_EESR</a> (offset 0x2E30)	0xFF00 FF00	Value attempted to be written to shadow region 7's EESR. This is done by an EDMA peripheral module with a privilege level of User and Privilege ID of 0.
<a href="#">EDMA_TPCC_MPPAN_k</a> , <a href="#">EDMA_TPCC_MPPAN_7</a> (offset 0x082C)	0x0000 04B3	Memory Protection Filter <a href="#">EDMA_TPCC_MPPAN_k</a> [10] AID = 1, <a href="#">EDMA_TPCC_MPPAN_k</a> . <a href="#">EDMA_TPCC_MPPAN_7</a> [1] UW = 1, <a href="#">EDMA_TPCC_MPPAN_k</a> . <a href="#">EDMA_TPCC_MPPAN_7</a> [2] UR = 1, <a href="#">EDMA_TPCC_MPPAN_k</a> . <a href="#">EDMA_TPCC_MPPAN_7</a> [4] SW = 1, <a href="#">EDMA_TPCC_MPPAN_k</a> . <a href="#">EDMA_TPCC_MPPAN_7</a> [5] SR = 1.
	√ ↓	Access allowed.
<a href="#">EDMA_TPCC_DRAEM_k</a> , <a href="#">EDMA_TPCC_DRAEM_7</a> (offset 0x0378)	0x9FF0 0FC2	DMA Region Access Enable Filter
<a href="#">EDMA_TPCC_EESR</a> (offset 0x2E30)	0x8BC0 0102	Value written to shadow region 7's EESR. This is done by an EDMA peripheral module with a privilege level of User and a Privilege ID of 0.
<a href="#">EDMA_TPCC_EER</a> (offset 0x1020)	0xBC0 0102	Final value of EER.

#### 16.2.4.10.2 Proxy Memory Protection

Proxy memory protection allows an EDMA transfer programmed by a given peripheral module connected to EDMA, to have its permissions travel with the transfer through the EDMA\_TPTC. The permissions travel along with the read transactions to the source and the write transactions to the destination endpoints. The [EDMA\\_TPCC\\_OPT\\_n](#)[31] PRIV bit and [EDMA\\_TPCC\\_OPT\\_n](#)[27:24] PRIVID bit is set with the peripheral module's PRIV value and PRIVID values, respectively, when any part of the PaRAM set is written.

The [EDMA\\_TPCC\\_OPT\\_n](#)[31] PRIV is the privilege level (i.e., user vs. supervisor). The [EDMA\\_TPCC\\_OPT\\_n](#)[27:24] PRIVID refers to a privilege ID with a number that is associated with an peripheral module connected to EDMA.

These options are part of the TR that are submitted to the transfer controller. The transfer controller uses the above values on their respective read and write command bus so that the target endpoints can perform memory protection checks based on these values.

Consider a parameter set that is programmed by a CPU in user privilege level for a simple transfer with the source buffer on an L2 page and the destination buffer on an L1D page. The [EDMA\\_TPCC\\_OPT\\_n](#)[31] PRIV is 0 for user-level and the CPU has a [EDMA\\_TPCC\\_OPT\\_n](#)[27:24] PRIVID to 0.

The PaRAM set is shown in [Figure 16-29](#).

**Figure 16-29. PaRAM Set Content for Proxy Memory Protection Example**

(a) EDMA Parameters

Parameter Contents		Parameter	
0010 0007h		Channel Options Parameter (OPT)	
009F 0000h		Channel Source Address (SRC)	
0001h	0004h	Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
00F0 7800h		Channel Destination Address (DST)	
0001h	0001h	Destination BCNT Index (DBIDX)	Source BCNT Index (SBIDX)
0000h	FFFFh	BCNT Reload (BCNTRLD)	Link Address (LINK)
0001h	1000h	Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
0000h	0001h	Reserved	Count for 3rd Dimension (CCNT)

**Figure 16-30. Channel Options Parameter (OPT) Example**

(b) Channel Options Parameter (OPT<sub>n</sub>) Content

edma-018

The [EDMA\\_TPCC\\_OPT\\_n\[31\]](#) PRIV and [EDMA\\_TPCC\\_OPT\\_n\[27:24\]](#) PRIVID information travels along with the read and write requests that are issued to the source and destination memories.

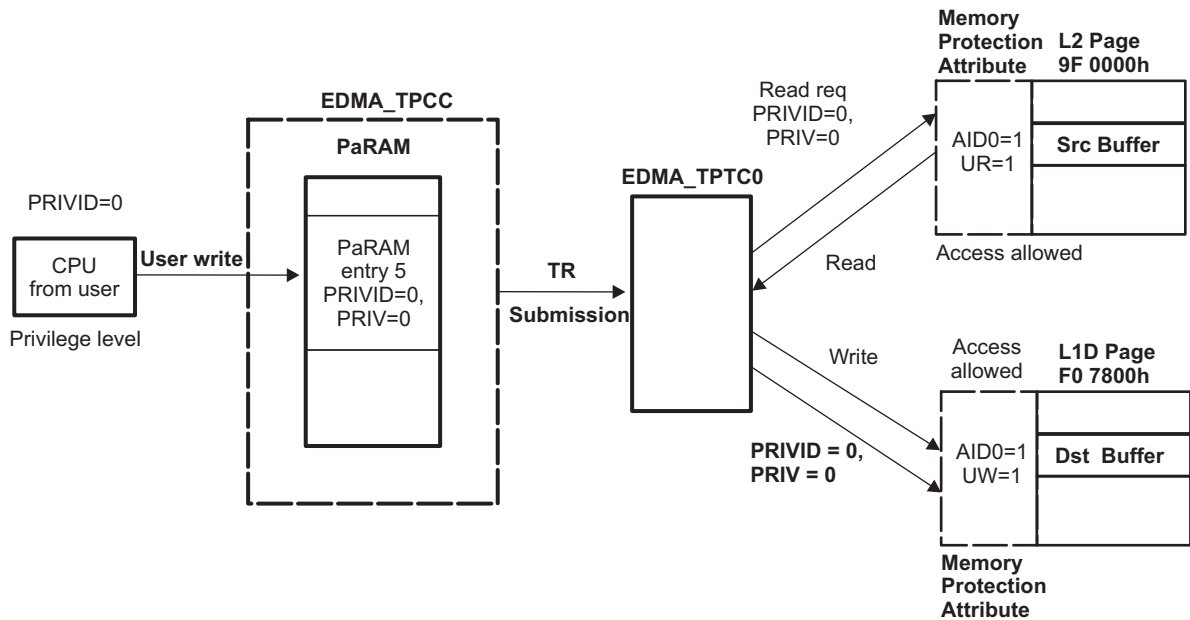

For example, if the access attributes that are associated with the L2 page with the source buffer only allow supervisor read, write accesses [EDMA\\_TPCC\\_MPPAN\\_k\[4\]](#) SW and [EDMA\\_TPCC\\_MPPAN\\_k\[5\]](#) SR, the user-level read request above is refused. Similarly, if the access attributes that are associated with the L1D page with the destination buffer only allow supervisor read and write accesses ([EDMA\\_TPCC\\_MPPAN\\_k\[4\]](#) SW, [EDMA\\_TPCC\\_MPPAN\\_k\[5\]](#) SR), the user-level write request above is refused. For the transfer to succeed, the source and destination pages must have user-read and user-write permissions, respectively, along with allowing accesses from a PRIVID = 0.

Because the privilege level and privilege identification travel with the read and write requests, EDMA acts as a proxy.

[Figure 16-31](#) illustrates the propagation of [EDMA\\_TPCC\\_OPT\\_n\[31\]](#) PRIV and [EDMA\\_TPCC\\_OPT\\_n\[27:24\]](#) PRIVID at the boundaries of all the interacting entities (CPU, EDMA\_TPCC, EDMA\_TPTCs, and slave memories).

edma-019

### 16.2.4.11 Event Queue(s)

Event queues are a part of the EDMA channel controller. Event queues form the interface between the event detection logic in the EDMA\_TPCC and the transfer request (TR) submission logic of the EDMA\_TPCC. Each queue is 16 entries deep. Each event queue can queue a maximum of 16 events. If there are more than 16 events, then the events that cannot find a place in the event queue remain set in the associated event register and the CPU does not stall.

There are two event queues for the device: Queue0, Queue1. Events in Queue0 result in submission of its associated transfer requests (TRs) to TC0. The transfer requests that are associated with events in Queue1 are submitted to TC1.

An event that wins prioritization against other DMA and/or QDMA pending events is placed at the tail of the appropriate event queue. Each event queue is serviced in FIFO order. Once the event reaches the head of its queue and the corresponding transfer controller is ready to receive another TR, the event is de-queued and the PaRAM set corresponding to the de-queued event is processed and submitted as a transfer request packet (TRP) to the associated EDMA transfer controller.

Queue0 has highest priority and Queue1 has the lowest priority, if Queue0 and Queue1 both have at least one event entry and if both TC0 and TC1 can accept transfer requests, then the event in Queue0 is de-queued first and its associated PaRAM set is processed and submitted as a transfer request (TR) to TC0.

Refer to [Section 16.2.4.11.4](#) for system-level performance considerations. All of the event entries in all of the event queues are software readable (not writeable) by accessing the event entry registers [EDMA\\_TPCC\\_Q0E\\_p](#) and [EDMA\\_TPCC\\_Q1E\\_p](#). Each event entry register characterizes the queued event in terms of the type of event (manual, event, chained or auto-triggered) and the event number. Refer to [Section 16.2.7.2.2.1 EDMA\\_TPCC Register Description](#) for Q0E\_p / Q1E\_p descriptions of the bit fields.

#### 16.2.4.11.1 DMA/QDMA Channel to Event Queue Mapping

Each of the 64 DMA channels and eight QDMA channels are programmed independently to map to a specific queue, using the DMA queue number register [EDMA\\_TPCC\\_DMAQNUMN\\_k](#) and the QDMA queue number register [EDMA\\_TPCC\\_QDMAQNUM](#). The mapping of DMA/QDMA channels is critical to achieving the desired performance level for the EDMA and most importantly, in meeting real-time deadlines. Refer to [Section 16.2.4.11.4 System-level Performance Considerations](#).

**NOTE:** If an event is ready to be queued and both the event queue and the EDMA transfer controller that is associated to the event queue are empty, then the event bypasses the event queue, and moves the PaRAM processing logic, and eventually to the transfer request submission logic for submission to the EDMA\_TPTC. In this case, the event is not logged in the event queue status registers.

#### 16.2.4.11.2 Queue RAM Debug Visibility

There are two event queues and each queue has 16 entries. These 16 entries are managed in a circular FIFO. There is a queue status register `EDMA_TPCC_QSTATN_i` associated with each queue. These along with all of the 16 entries per queue can be read via registers `EDMA_TPCC_QSTATN_i` and `Q0E_p / Q1E_p`, respectively.

These registers provide user visibility.

The event queue entry register (`QxEy Q0E_p / Q1E_p`) uniquely identifies the specific event type (event-triggered, manually-triggered, chain-triggered, and QDMA events) along with the event number (for all DMA/QDMA event channels) that are in the queue or have been de-queued (passed through the queue).

Each of the 16 entries in the event queue are read using the `EDMA_TPCC` memory-mapped register. To see the history of the last 16 TRs that have been processed by the EDMA on a given queue, read the event queue registers. This provides user/software visibility and is helpful for debugging real-time issues (typically post-mortem), involving multiple events and event sources.

The queue status register (`QSTATn EDMA_TPCC_QSTATN_i`) includes fields for the start pointer `EDMA_TPCC_QSTATN_i[3:0] STRTPTR` which provides the offset to the head entry of an event. It also includes a field called `EDMA_TPCC_QSTATN_i[12:8] NUMVAL` that provides the total number of valid entries residing in the event queue at a given instance of time. The `EDMA_TPCC_QSTATN_i[3:0] STRTPTR` is used to index appropriately into the 16 event entries. `EDMA_TPCC_QSTATN_i[12:8] NUMVAL` number of entries starting from `ST RTPTR` are indicative of events still queued in the respective queue. The remaining entry must be read to determine what's already de-queued and submitted to the associated transfer controller.

#### 16.2.4.11.3 Queue Resource Tracking

The `EDMA_TPCC` event queue includes watermarking/threshold logic that allows to keep track of maximum usage of all event queues. This is useful for debugging real-time deadline violations that may result from head-of-line blocking on a given EDMA event queue.

The maximum number of events are programmed that the queue up in an event queue by programming the threshold value (between 0 to 15) in the queue watermark threshold A register `EDMA_TPCC_QWMTHRA`. The maximum queue usage is recorded actively in the watermark `EDMA_TPCC_QSTATN_i[20:16] WM` field of the queue status register, that keeps getting updated based on a comparison of number of valid entries, which is also visible in the `EDMA_TPCC_QSTATN_i[12:8] NUMVAL` bit and the maximum number of entries.

If the queue usage is exceeded, this status is visible in the `EDMA_TPCC` registers: the `QTHRXCdn` bits in the channel controller error register `EDMA_TPCC_CCERR[7:0]` and the `EDMA_TPCC_QSTATN_i[24] THRXCD` bit, where  $n$  stands for the event queue number. Any bits that are set in `EDMA_TPCC_CCERR` also generate an `EDMA_TPCC` error interrupt.

#### 16.2.4.11.4 Performance Considerations

The main system bus infrastructure (L3) arbitrates bus requests from all of the masters (TCs, CPU(S), and other bus masters) to the shared slave resources (peripherals and memories).

The priorities of transfer requests (read and write commands) from the EDMA transfer controllers with respect to other masters within the device `IRQ_CROSSBAR` are programmed using the Control Module registers. The `EDMA_TPCC_QUEPRI` register has no affect.

Therefore, the priority of unloading queues has a secondary affect compared to the priority of the transfers as they are executed by the `EDMA_TPTC` (dictated by the priority set using the Control Module registers, refer to [Section 18.5 Control Module Register Manual](#) in [Chapter 18 Control Module](#) chapter).

### 16.2.4.12 EDMA Transfer Controller (EDMA\_TPTC)

The EDMA channel controller is the user-interface of the EDMA and the EDMA transfer controller (EDMA\_TPTC) is the data movement engine of the EDMA controller. The EDMA\_TPCC submits transfer requests (TR) to the EDMA\_TPTC and the EDMA\_TPTC performs the data transfers dictated by the TR, so the EDMA\_TPTC is a slave to the EDMA\_TPCC.

#### 16.2.4.12.1 Architecture Details

##### 16.2.4.12.1.1 Command Fragmentation

The TC read and write controllers in conjunction with the source and destination register sets are responsible for issuing optimally-sized reads and writes to the slave endpoints. An optimally-sized command is defined by the transfer controller default burst size (DBS), which is defined in [Section 16.2.4.12.5 EDMA\\_TPTC Configuration](#).

The EDMA\_TPTC attempts to issue the largest possible command size as limited by the DBS value or the [EDMA\\_TPCC\\_ABCNT\\_n\[15:0\]](#) ACNT and [EDMA\\_TPCC\\_ABCNT\\_n\[31:16\]](#) BCNT value of the TR. EDMA\_TPTC obeys the following rules:

- The read/write controllers always issue commands less than or equal to the DBS value.
- The first command of a 1D transfer command always aligns the address of subsequent commands to the DBS value.

[Table 16-105](#) lists the TR segmentation rules that are followed by the EDMA\_TPTC. In summary, if the [EDMA\\_TPCC\\_ABCNT\\_n\[15:0\]](#) ACNT value is larger than the DBS value, then the EDMA\_TPTC breaks the [EDMA\\_TPCC\\_ABCNT\\_n\[15:0\]](#) ACNT array into DBS-sized commands to the source/destination addresses. Each [EDMA\\_TPCC\\_ABCNT\\_n\[31:16\]](#) BCNT number of arrays are then serviced in succession.

For BCNT arrays of ACNT bytes (that is, a 2D transfer), if the [EDMA\\_TPCC\\_ABCNT\\_n\[15:0\]](#) ACNT value is less than or equal to the DBS value, then the TR may be optimized into a 1D-transfer in order to maximize efficiency. The optimization takes place if the EDMA\_TPTC recognizes that the 2D-transfer is organized as a single dimension ([EDMA\\_TPCC\\_ABCNT\\_n\[15:0\]](#) ACNT == [EDMA\\_TPCC\\_BIDX\\_n](#)) and the ACNT value is a power of 2.

[Table 16-105](#) lists conditions in which the optimizations are performed.

**Table 16-105. Read/Write Command Optimization Rules**

ACNT ≤ DBS	ACNT is power of 2	BIDX = ACNT	BCNT ≤ 1023	SAM/DAM = Increment	Description
Yes	Yes	Yes	Yes	Yes	Optimized
No	x	x	x	x	Not Optimized
x	No	x	x	x	Not Optimized
x	x	No	x	x	Not Optimized
x	x	x	No	x	Not Optimized
x	x	x	x	No	Not Optimized

##### 16.2.4.12.1.2 TR Pipelining

TR pipelining refers to the ability of the source active set to proceed ahead of the destination active set. Essentially, the reads for a given TR may already be in progress while the writes of a previous TR may not have completed.

The number of outstanding TRs is limited by the number of destination FIFO register entries.

TR pipelining is useful for maintaining throughput on back-to-back small TRs. It minimizes the startup overhead because reads start in the background of a previous TR writes.

**Example 16-4. Command Fragmentation (DBS = 64)**

The pseudo code:

1. [EDMA\\_TPTCn\\_PCNT\[15:0\]](#) ACNT = 8, [EDMA\\_TPTCn\\_PCNT\[31:16\]](#) BCNT = 8, [EDMA\\_TPTCn\\_PBDX\[15:0\]](#) SBIDX = 8, [EDMA\\_TPTCn\\_PBDX\[31:16\]](#) DBIDX = 10, [EDMA\\_TPTCn\\_PSRC\[31:0\]](#) SADDR = 64, [EDMA\\_TPTCn\\_SADST\[31:0\]](#) DADDR = 191

Read Controller: This is optimized from a 2D-transfer to a 1D-transfer such that the read side is equivalent to [EDMA\\_TPTCn\\_PCNT\[15:0\]](#) ACNT = 64, [EDMA\\_TPTCn\\_PCNT\[31:16\]](#) BCNT = 1.

Cmd0 = 64 byte

Write Controller: Because DBIDX != ACNT, it is not optimized.

Cmd0 = 8 byte, Cmd1 = 8 byte, Cmd2 = 8 byte, Cmd3 = 8 byte, Cmd4 = 8 byte, Cmd5 = 8 byte, Cmd6 = 8 byte, Cmd7 = 8 byte.

2. [EDMA\\_TPTCn\\_PCNT\[15:0\]](#) ACNT=128, [EDMA\\_TPTCn\\_PCNT\[31:16\]](#) BCNT = 1, [EDMA\\_TPTCn\\_PSRC\[31:0\]](#) SADDR = 63, [EDMA\\_TPTCn\\_SADST\[31:0\]](#) DADDR = 513

Read Controller: Read address is not aligned.

Cmd0 = 1 byte, (now the SADDR is aligned to 64 for the next command)

Cmd1 = 64 bytes

Cmd2 = 63 bytes

Write Controller: The write address is also not aligned.

Cmd0 = 63 bytes, (now the DADDR is aligned to 64 for the next command)

Cmd1 = 64 bytes

Cmd2 = 1 byte

**16.2.4.12.1.3 Performance Tuning**

By default, reads are as issued as fast as possible. In some cases, the reads issued by the EDMA\_TPTC could fill the available command buffering for a slave, delaying other (potentially higher priority) masters from successfully submitting commands to that slave. The rate at which read commands are issued by the EDMA\_TPTC is controlled by the [EDMA\\_TPTCn\\_RDRATE](#) register. The [EDMA\\_TPTCn\\_RDRATE](#) register defines the number of cycles that the EDMA\_TPTC read controller waits before issuing subsequent commands for a given TR, thus minimizing the chance of the EDMA\_TPTC consuming all available slave resources. The [EDMA\\_TPTCn\\_RDRATE\[2:0\]](#) RDRATE value must be set to a relatively small value if the transfer controller is targeted for high priority transfers and to a higher value if the transfer controller is targeted for low priority transfers.

In contrast, the Write Interface does not have any performance turning knobs because writes always have an interval between commands as write commands are submitted along with the associated write data.

**16.2.4.12.2 Memory Protection**

The transfer controller plays an important role in handling proxy memory protection. There are two access properties associated with a transfer: for instance, the privilege id (system-wide identification assigned to a master) of the master initiating the transfer, and the privilege level (user versus supervisor) used to program the transfer. This information is maintained in the PaRAM set when it is programmed in the channel controller. When a TR is submitted to the transfer controller, this information is made available to the EDMA\_TPTC and used by the EDMA\_TPTC while issuing read and write commands. The read or write commands have the same privilege identification, and privilege level as that programmed in the EDMA transfer in the channel controller.

**16.2.4.12.3 Error Generation**

Errors are generated if enabled under three conditions:

- EDMA\_TPTC detection of an error signaled by the source or destination address.
- Attempt to read or write to an invalid address in the configuration memory map.

- Detection of a constant addressing mode TR violating the constant addressing mode transfer rules (the source/destination addresses and source/destination indexes must be aligned to 32 bytes).

Either or all error types may be disabled. If an error bit is set and enabled, the error interrupt for the concerned transfer controller is generated.

#### 16.2.4.12.4 Debug Features

The DMA program register set, DMA source active register set, and the destination FIFO register set are used to derive a brief history of TRs serviced through the transfer controller.

Additionally, the EDMA\_TPTC status register [EDMA\\_TPTCn\\_TCSTAT](#) has dedicated bit fields to indicate the ongoing activity within different parts of the transfer controller:

- The [EDMA\\_TPTCn\\_TCSTAT\[1\]](#) SRCACTV bit indicates whether the source active set is active.
- The [EDMA\\_TPTCn\\_TCSTAT\[6:4\]](#) DSTACTV bit indicates the number of TRs resident in the destination register active set at a given instance.
- The [EDMA\\_TPTCn\\_TCSTAT\[0\]](#) PROGBUSY bit indicates whether a valid TR is present in the DMA program set.

---

**NOTE:** If the TRs are in progression, it must realize that there is a chance that the values read from the EDMA\_TPTC status registers will be inconsistent since the EDMA\_TPTC changes the values of these registers due to ongoing activities.

It is recommended that to ensure no additional submission of TRs to the EDMA\_TPTC in order to facilitate ease of debug.

---

##### 16.2.4.12.4.1 Destination FIFO Register Pointer

The destination FIFO register pointer is implemented as a circular buffer with the start pointer being [EDMA\\_TPTCn\\_TCSTAT\[12:11\]](#) DFSTRTPTR and a buffer depth of usually 2 or 4. The EDMA\_TPTC maintains two important status details in [EDMA\\_TPTCn\\_TCSTAT](#) that are used during advanced debugging, if necessary. The [EDMA\\_TPTCn\\_TCSTAT\[12:11\]](#) DFSTRTPTR is a start pointer, the index to the head of the destination FIFO register. The [EDMA\\_TPTCn\\_TCSTAT\[6:4\]](#) DSTACTV is a counter for the number of valid (occupied) entries. These registers are used to get a brief history of transfers.

Examples of some register field values and their interpretation:

- [EDMA\\_TPTCn\\_TCSTAT\[12:11\]](#) DFSTRTPTR = 0x0 and [EDMA\\_TPTCn\\_TCSTAT\[6:4\]](#) DSTACTV = 0x0 implies that no TRs are stored in the destination FIFO register.
- [EDMA\\_TPTCn\\_TCSTAT\[12:11\]](#) DFSTRTPTR = 0x1 and [EDMA\\_TPTCn\\_TCSTAT\[6:4\]](#) DSTACTV = 0x2 implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 1 and the second pending TR is read from the destination FIFO register entry 2.
- [EDMA\\_TPTCn\\_TCSTAT\[12:11\]](#) DFSTRTPTR = 0x3 and [EDMA\\_TPTCn\\_TCSTAT\[6:4\]](#) DSTACTV = 0x2 implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 3 and the second pending TR is read from the destination FIFO register entry 0.

##### 16.2.4.12.5 EDMA\_TPTC Configuration

[Table 16-106](#) provides the configuration of the individual EDMA transfer controllers present on the device. The DBS for each transfer controller is defined by Control Module register ([CTRL\\_CORE\\_CONTROL\\_IO\\_1](#)) settings.

**Table 16-106. EDMA Transfer Controller Configurations**

Name	TC0	TC1
<a href="#">EDMA_TPTCn_TCCFG[2:0]</a> FIFOSIZE	1024 bytes	1024 bytes
<a href="#">EDMA_TPTCn_TCCFG[5:4]</a> BUSWIDTH	16 bytes	16 bytes
<a href="#">EDMA_TPTCn_TCCFG[9:8]</a> DSTREGDEPTH	4 entries	4 entries

**Table 16-106. EDMA Transfer Controller Configurations (continued)**

Name	TC0	TC1
DBS	Defined by <a href="#">CTRL_CORE_CONTROL_IO_1[9:8]</a> TC0_DEFAULT_BURST_SIZE	Defined by <a href="#">CTRL_CORE_CONTROL_IO_1[13:12]</a> TC1_DEFAULT_BURST_SIZE

### 16.2.4.13 Event Dataflow

This section summarizes the data flow of a single event, from the time the event is latched to the channel controller to the time the transfer completion code is returned. The following steps list the sequence of EDMA\_TPCC activity:

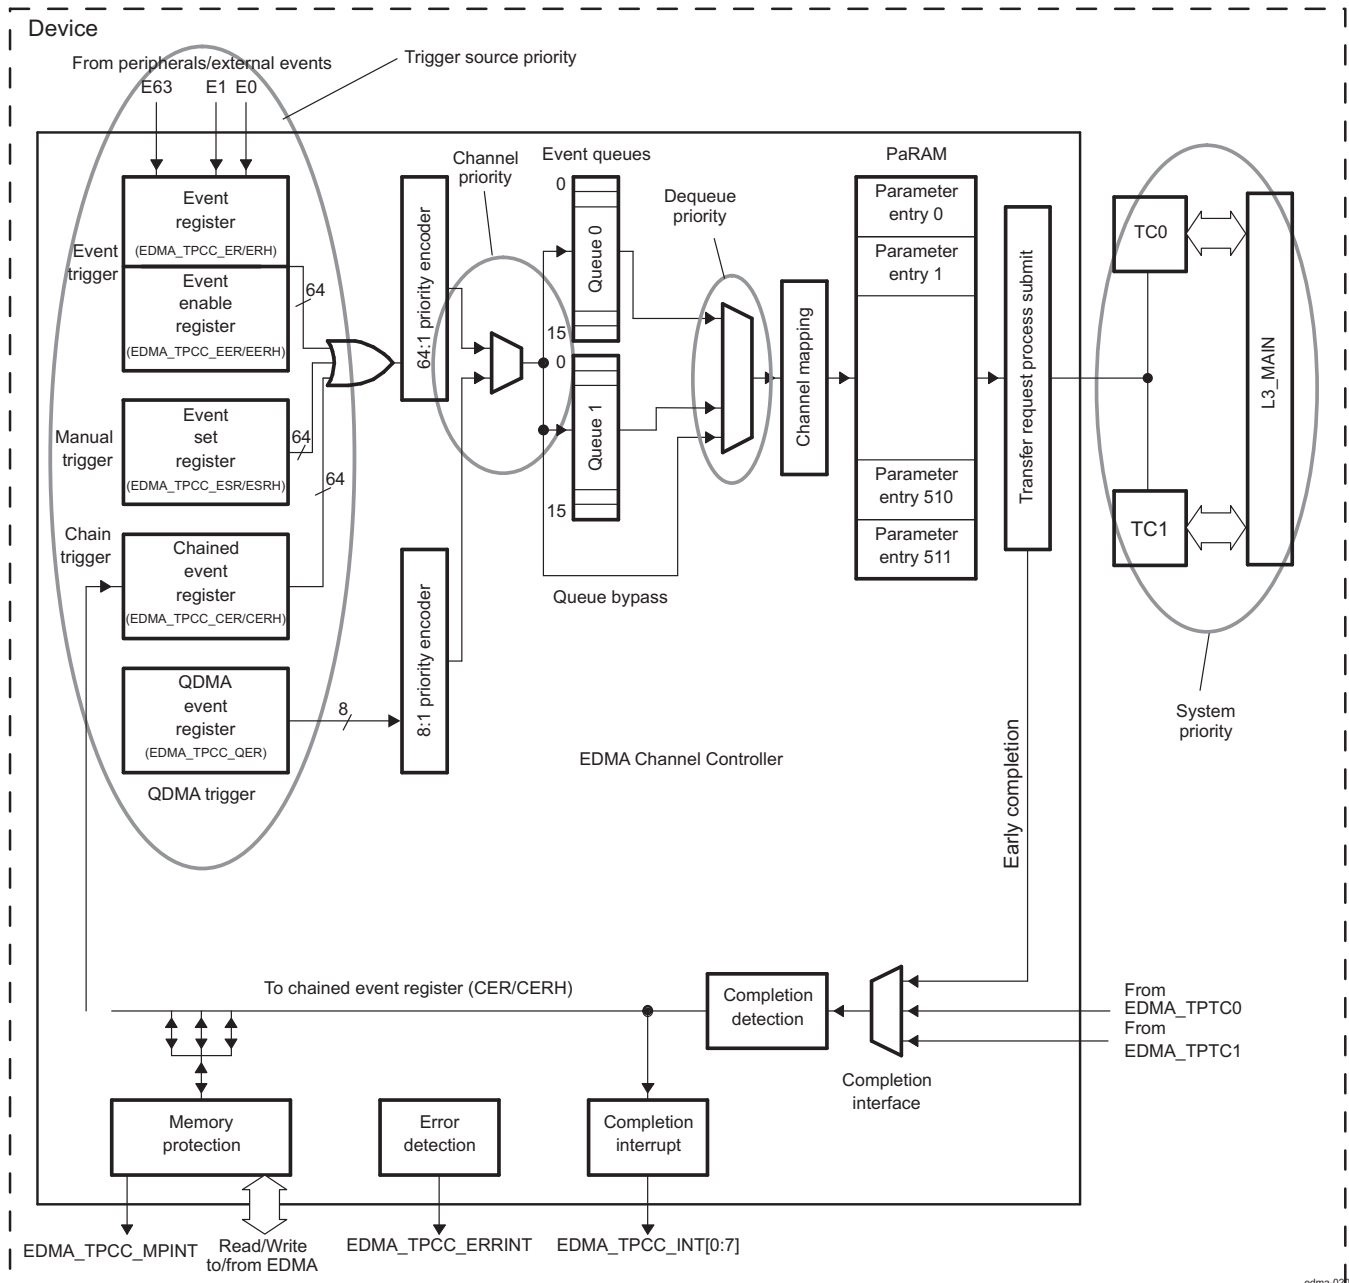

1. Event is asserted from an external source (peripheral or external interrupt). This also is similar for a manually-triggered, chained-triggered, or QDMA-triggered event. The event is latched into the [EDMA\\_TPCC\\_ER\[31:0\]En](#) / [EDMA\\_TPCC\\_ERH\[31:0\] En](#) (or [EDMA\\_TPCC\\_CER\[31:0\] En](#) / [EDMA\\_TPCC\\_CERH\[31:0\] En](#), [EDMA\\_TPCC\\_ESR\[31:0\] En](#) / [EDMA\\_TPCC\\_ESRH\[31:0\] En](#), [EDMA\\_TPCC\\_QER\[7:0\] En](#)) bit.
2. Once an event is prioritized and queued into the appropriate event queue, the [EDMA\\_TPCC\\_SER\[31:0\] En](#) \ [EDMA\\_TPCC\\_SERH\[31:0\] En](#) (or [EDMA\\_TPCC\\_QSER\[7:0\] En](#)) bit is set to inform the event prioritization / processing logic to disregard this event since it is already in the queue. Alternatively, if the transfer controller and the event queue are empty, then the event bypasses the queue.
3. The EDMA\_TPCC processing and the submission logic evaluates the appropriate PaRAM set and determines whether it is a non-null and non-dummy transfer request (TR).
4. The EDMA\_TPCC clears the [EDMA\\_TPCC\\_ER\[31:0\] En](#) / [EDMA\\_TPCC\\_ERH\[31:0\] En](#) (or [EDMA\\_TPCC\\_CER\[31:0\] En](#) / [EDMA\\_TPCC\\_CERH\[31:0\] En](#), [EDMA\\_TPCC\\_ESR\[31:0\]En](#) / [EDMA\\_TPCC\\_ESRH\[31:0\] En](#), [EDMA\\_TPCC\\_QER\[31:0\] En](#)) bit and the [EDMA\\_TPCC\\_SER\[31:0\] En](#) / [EDMA\\_TPCC\\_SERH\[31:0\] En](#) bit as soon as it determines the TR is non-null. In the case of a null set, the [EDMA\\_TPCC\\_SER\[31:0\] En](#) / [EDMA\\_TPCC\\_SERH\[31:0\] En](#) bit remains set. It submits the non-null/non-dummy TR to the associated transfer controller. If the TR was programmed for early completion, the EDMA\_TPCC immediately sets the interrupt pending register ([EDMA\\_TPCC\\_IPR\[31:0\] I\[TCC\]](#) / [EDMA\\_TPCC\\_IPRH\[31:0\] I\[TCC\]](#) - 32).
5. If the TR was programmed for normal completion, the EDMA\_TPCC sets the interrupt pending register ([EDMA\\_TPCC\\_IPR\[31:0\] I\[TCC\]](#) / [EDMA\\_TPCC\\_IPRH\[31:0\] I\[TCC\]](#)) when the EDMA\_TPTC informs the EDMA\_TPCC about completion of the transfer (returns transfer completion codes).
6. The EDMA\_TPCC programs the associated EDMA\_TPTC's Program Register Set with the TR.
7. The TR is then passed to the Source Active set and the DST FIFO Register Set, if both the register sets are available.
8. The Read Controller processes the TR by issuing read commands to the source slave endpoint. The Read Data lands in the Data FIFO of the EDMA\_TPTC<sub>n</sub>.
9. As soon as sufficient data is available, the Write Controller begins processing the TR by issuing write commands to the destination slave endpoint.
10. This continues until the TR completes and the EDMA\_TPTC<sub>n</sub> then signals completion status to the EDMA\_TPCC.

### 16.2.4.14 EDMA controller Prioritization

The EDMA controller has many implementation rules to deal with concurrent events/channels, transfers, etc. The following subsections detail various arbitration details whenever there might be occurrence of concurrent activity. [Figure 16-32](#) shows the different places EDMA priorities come into play.

Figure 16-32. EDMA Prioritization

#### 16.2.4.14.1 Channel Priority

The EDMA event registers [EDMA\\_TPCC\\_ER](#) and [EDMA\\_TPCC\\_ERH](#) capture up to 64 events, the QDMA event register [EDMA\\_TPCC\\_QER](#) captures QDMA events for all QDMA channels therefore, it is possible for events to occur simultaneously on the DMA/QDMA event inputs. For events arriving simultaneously, the event associated with the lowest channel number is prioritized for submission to the event queues (for DMA events, channel 0 has the highest priority and channel 63 has the lowest priority, for QDMA events, channel 0 has the highest priority and channel 7 has the lowest priority). This mechanism only sorts simultaneous events for submission to the event queues.

If a DMA and QDMA event occurs simultaneously, the DMA event always has prioritization against the QDMA event for submission to the event queues.

#### 16.2.4.14.2 Trigger Source Priority

If a EDMA channel is associated with more than one trigger source (event trigger, manual trigger, and chain trigger), and if multiple events are set simultaneously for the same channel ( $EDMA\_TPCC\_ER[31:0] E_n = 1$ ,  $EDMA\_TPCC\_ESR[31:0] E_n = 1$ ,  $EDMA\_TPCC\_CER[31:0] E_n = 1$ ), then the EDMA\_TPCC always services these events in the following priority order: event trigger (via  $EDMA\_TPCC\_ER$ ) is higher priority than chain trigger (via  $EDMA\_TPCC\_CER$ ) and chain trigger is higher priority than manual trigger (via  $EDMA\_TPCC\_ESR$ ).

This implies that if for channel 0, both  $EDMA\_TPCC\_ER[0] E_0 = 1$  and  $EDMA\_TPCC\_CER[0] E_0 = 1$  at the same time, then the  $EDMA\_TPCC\_ER[0] E_0$  event is always queued before the  $EDMA\_TPCC\_CER[0] E_0$  event.

#### 16.2.4.14.3 Dequeue Priority

The priority of the associated transfer request (TR) is further mitigated by which event queue is being used for event submission (dictated by  $EDMA\_TPCC\_DMAQNUMN_k$  and  $EDMA\_TPCC\_QDMAQNUM$ ). For submission of a TR to the transfer request, events need to be de-queued from the event queues. Queue 0 has the highest dequeue priority and queue 1 the lowest.

### 16.2.4.15 EDMA Power, Reset and Clock Management

#### 16.2.4.15.1 Clock and Power Management

The EDMA channel controller and transfer controller are clocked from L3MIAN1\_L3\_GICLK interface clock. The EDMA system runs at the L3 clock frequency.

The Auto clock gating for the EDMA\_TPCC module is controlled by the  $EDMA\_TPCC\_CLKGDIS[0]$  CLKGDIS bit at the module level.

The L3MIAN1\_L3\_GICLK interface clock to EDMA controller's modules are controlled by the following registers in the PRCM module:

- PRCM.CM\_L3MAIN1\_TPCC\_CLKCTRL - manages EDMA\_TPCC module clock.
- PRCM.CM\_L3MAIN1\_TPTC1\_CLKCTRL - manages EDMA\_TPTC0 module clock.
- PRCM.CM\_L3MAIN1\_TPTC2\_CLKCTRL - manages EDMA\_TPTC1 module clock.

EDMA\_TPCC and EDMA\_TPTC0 and EDMA\_TPTC1 modules have wakeup dependances to several device modules. The wakeup dependency based on EDMA modules service requests are controlled by registers in PRCM module:

- PRCM.PM\_L3MAIN1\_TPCC\_WKDEP - controls wakeup dependency based on TPCC service requests.
- PRCM.PM\_L3MAIN1\_TPTC1\_WKDEP - controls wakeup dependency based on TPTC0 service requests.
- PRCM.PM\_L3MAIN1\_TPTC2\_WKDEP - controls wakeup dependency based on TPTC1 service requests.

The EDMA\_TPCC, EDMA\_TPTC0 and EDMA\_TPTC1 can be placed in reduced-power modes to conserve power during periods of low activity. The power management of the peripheral is controlled by the PRCM module. The PRCM acts as a master controller for power management for all peripherals on the device.

The EDMA controller can be idled on receiving a clock stop request from the PRCM. The requests to EDMA\_TPCC and EDMA\_TPTC0 and EDMA\_TPTC1 are separate. In general, it should be verified that there are no pending activities in the EDMA controller

---

**NOTE:** When EDMA controller modules no longer require the interface clock, software can disable it at the PRCM level by configuring the MODULEMODE bit field (PRCM.CM\_L3MAIN1\_TPCC\_CLKCTRL[1:0], PRCM.CM\_L3MAIN1\_TPTC1\_CLKCTRL[1:0], PRCM.CM\_L3MAIN1\_TPTC2\_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At the PRCM level, when all the conditions to shut off the L3MIAN1\_L3\_GICLK clock are met the PRCM module automatically launches a hardware handshake protocol to ensure EDMA modules are ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the EDMA modules. For more information, refer to [Chapter 3, Power, Reset, and Clock Management](#).

---

#### 16.2.4.15.2 Reset Considerations

A hardware resets the EDMA (EDMA\_TPCC, EDMA\_TPTC0 and EDMA\_TPTC1) and the EDMA configuration registers. The PaRAM memory contents are undefined after device reset and it should not rely on parameters to be reset to a known state. The PaRAM entry must be initialized to a desired value before it is used. The EDMA modules are reset by CORE\_RET\_RST reset signal from PRCM.

#### 16.2.4.16 Emulation Considerations

During debug when using the emulator, the CPU(s) may be halted on an execute packet boundary for single-stepping, benchmarking, profiling, or other debug purposes. During an emulation halt, the EDMA channel controller and transfer controller operations continue. Events continue to be latched and processed and transfer requests continue to be submitted and serviced.

Since EDMA is involved in servicing multiple master and slave peripherals, it is not feasible to have an independent behavior of the EDMA for emulation halts. EDMA functionality would be coupled with the peripherals it is servicing, which might have different behavior during emulation halts.

### 16.2.5.2 Subframe Extraction Example

The EDMA can efficiently extract a small frame of data from a larger frame of data. By performing a 2D-to-1D transfer, the EDMA retrieves a portion of data for the CPU to process. In this example, a 640 × 480-pixel frame of video data is stored in external memory. Each pixel is represented by a 16-bit halfword. The CPU extracts a 16 × 12-pixel subframe of the image for processing. To facilitate more efficient processing time by the CPU, the EDMA places the subframe in internal L2 SRAM. Figure 16-35 shows the transfer of a subframe from external memory to L2.

The same PaRAM entry options are used for QDMA channels, as well as DMA channels. The EDMA\_TPCC\_OPT\_n[3] STATIC bit is set to prevent linking. For successive transfers, only changed parameters need to be programmed before triggering the channel.

Figure 16-36 shows the parameters for Subframe Extraction transfer.

### 16.2.5.3 Data Sorting Example

Many applications require the use of multiple data arrays, it is often desirable to have the arrays arranged such that the first elements of each array are adjacent, the second elements are adjacent, and so on. Often this is not how the data is presented to the device. Either data is transferred via a peripheral with the data arrays arriving one after the other or the arrays are located in memory with each array occupying a portion of contiguous memory spaces. For these instances, the EDMA can reorganize the data into the desired format.

To determine the parameter set values, the following need to be considered:

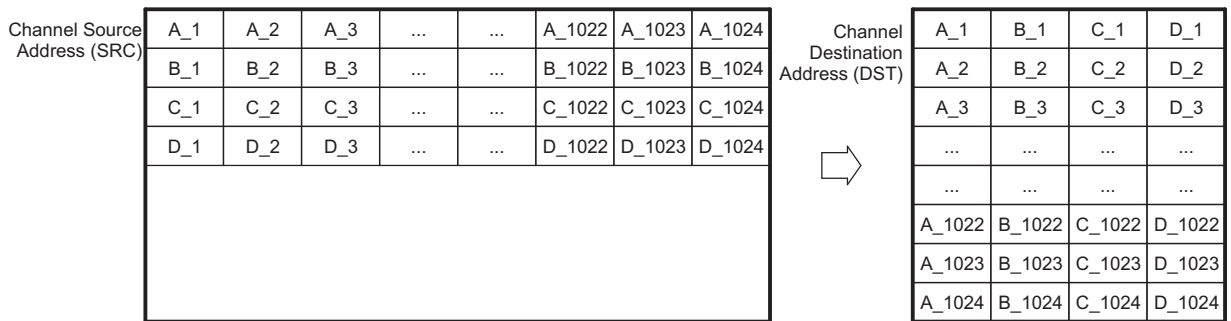

- ACNT - Program this to be the size in bytes of an element.
- BCNT - Program this to be the number of elements in a frame.
- CCNT - Program this to be the number of frames.
- SBIDX - Program this to be the size of the element or ACNT.
- DBIDX - CCNT x ACNT
- SCIDX - ACNT x BCNT
- DCIDX - ACNT

The synchronization type needs to be AB-synchronized and the `EDMA_TPCC_OPT_n[3]` STATIC bit is 0 to allow updates to the parameter set. It is advised to use normal EDMA channels for sorting.

It is not possible to sort this with a single trigger event. Instead, the channel can be programmed to be chained to itself. After BCNT elements get sorted, intermediate chaining could be used to trigger the channel again causing the transfer of the next BCNT elements and so on. Figure 16-38 shows the parameter set programming for this transfer, assuming channel 0 and an element size of 4 bytes.

Figure 16-37 shows the Data Sorting transfer

### 16.2.5.4 Peripheral Servicing Example

The EDMA channel controller also services peripherals in the background of CPU operation, without requiring any CPU intervention. Through proper initialization of the EDMA channels, they can be configured to continuously service on-chip and off-chip peripherals throughout the device operation. Each event available to the EDMA has its own dedicated channel, and all channels operate simultaneously. The only requirements are to use the proper channel for a particular transfer and to enable the channel event in the event enable register `EDMA_TPCC_EER`. When programming an EDMA channel to service a peripheral, it is necessary to know how data is to be presented to the processor. Data is always provided with some kind of synchronization event as either one element per event (non-bursting) or multiple elements per event (bursting).

#### 16.2.5.4.1 Non-bursting Peripherals

Non-bursting peripherals include the on-chip multichannel audio serial port (McASP) and many external devices, such as codecs. Regardless of the peripheral, the EDMA channel configuration is the same.

The McASP transmit and receive data streams are treated independently by the EDMA. The transmit and receive data streams can have completely different counts, data sizes, and formats.

To transfer the incoming data stream to its proper location in DDR memory, the EDMA channel must be set up for a 1D-to-1D transfer with A-synchronization. Because an event (AREVT) is generated for every word as it arrives, it is necessary to have the EDMA issue the transfer request for each element individually. Figure 16-40 shows the parameters for this transfer. The source address of the EDMA channel is set to the data port address (DAT) for McASP, and the destination address is set to the start of the data block in DDR. Because the address of serializer buffer is fixed, the source B index is cleared to 0 (no modification) and the destination B index is set to 0x2 (increment).

Based on the premise that serial data is typically a high priority, the EDMA channel should be programmed to be on queue 0.

Figure 16-39 shows servicing incoming McASP data.

### 16.2.5.4.2 Bursting Peripherals

Higher bandwidth applications require that multiple data elements be presented to the processor core for every synchronization event. This frame of data can either be from multiple sources that are working simultaneously or from a single high-throughput peripheral that streams data to/from the processor.

In this example, a port is receiving a video frame from a camera and presenting it to the DSP one array at a time. The video image is 640 × 480 pixels, with each pixel represented by a 16-bit element. The image is to be stored in external memory.

To transfer data from an external peripheral to an external buffer one array at a time based on EVT<sub>n</sub>, channel *n* must be configured. Due to the nature of the data (a video frame made up of arrays of pixels) the destination is essentially a 2D entity. Figure 16-42 shows the parameters to service the incoming data with a 1D-to-2D transfer using AB-synchronization. The source address is set to the location of the video framer peripheral, and the destination address is set to the start of the data buffer. Because the input address is static, the EDMA\_TPCC\_BDIX<sub>n</sub>[15:0] SBIDX is 0 (no modification to the source address). The destination is made up of arrays of contiguous, linear elements; therefore, the EDMA\_TPCC\_BIDX<sub>n</sub>[31:16] DBIDX is set to pixel size, 2 bytes. EDMA\_TPCC\_ABCNT<sub>n</sub>[15:0] ANCT is equal to the pixel size, 2 bytes. EDMA\_TPCC\_ABCNT<sub>n</sub>[31:16] BCNT is set to the number of pixels in an array, 640. EDMA\_TPCC\_CCNT<sub>n</sub>[15:0] CCNT is equal to the total number of arrays in the block, 480. EDMA\_TPCC\_CIDX<sub>n</sub>[15:0] SCIDX is 0 because the source address undergoes no increment. The EDMA\_TPCC\_CIDX<sub>n</sub>[31:16] DCIDX is equal to the difference between the starting addresses of each array. Because one pixel is 16 bits (2 bytes), EDMA\_TPCC\_CIDX<sub>n</sub>[31:16] DCIDX is equal to 640 × 2.

Figure 16-41 shows Bursting Peripherals Transfer.

### 16.2.5.4.3 Continuous Operation

Configuring an EDMA channel to receive a single frame of data is useful, and is applicable to some systems. A majority of the time, however, data is going to be continuously transmitted and received throughout the entire operation of the processor. In this case, it is necessary to implement some form of linking such that the EDMA channels continuously reload the necessary parameter sets. In this example, McASP is configured to transmit and receive data on a T1 array. To simplify the example, only two channels are active for both transmit and receive data streams. Each channel receives packets of 128 elements. The packets are transferred from the serial port to internal memory and from internal memory to the serial port, as shown in Figure 16-43.

The McASP generates AREVT for every element received and generates AXEVT for every element transmitted. To service the data streams, the DMA channels associated with the McASP must be setup for 1D-to-1D transfers with A-synchronization.

Figure 16-44 shows the parameter entries for the channel for these transfers. To service the McASP continuously throughout DSP operation, the channels must be linked to a duplicate PaRAM set in the PaRAM. After all frames have been transferred, the EDMA channels reload and continue.

Figure 16-45 shows the reload parameters for the channel.

Figure 16-43. Servicing Continuous McASP Data Example

edma-026

#### 16.2.5.4.3.1 Receive Channel

EDMA channel 15 services the incoming data stream of McASP. The source address is set to that of the receive serializer buffer, and the destination address is set to the first element of the data block. Because there are two data channels being serviced, A and B, they are to be located separately within the L2 SRAM.

To facilitate continuous operation, a copy of the PaRAM set for the channel is placed in PaRAM set 64. The LINK option is set and the link address is provided in the PaRAM set. Upon exhausting the channel 15 parameter set, the parameters located at the link address are loaded into the channel 15 parameter set and operation continues. This function continues throughout device operation until halted by the CPU.

#### 16.2.5.4.3.2 Transmit Channel

EDMA channel 12 services the outgoing data stream of McASP. In this case the destination address needs no update, hence, the parameter set changes accordingly. Linking is also used to allow continuous operation by the EDMA channel, with duplicate PaRAM set entries at PaRAM set 65.

### 16.2.5.4.4 Ping-Pong Buffering

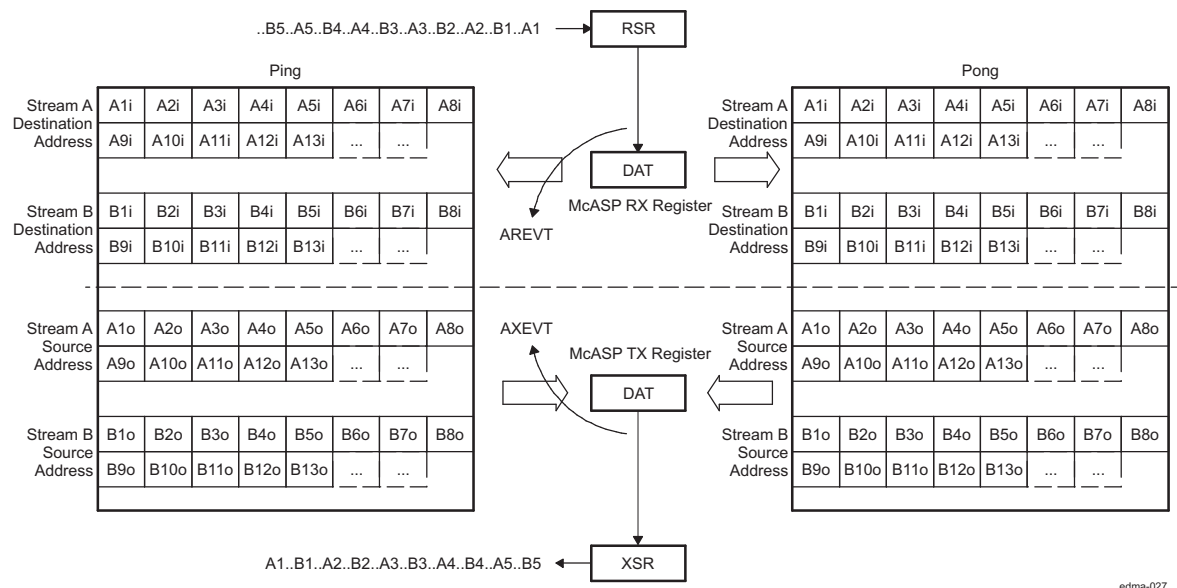

Although the previous configuration allows the EDMA to service a peripheral continuously, it presents a number of restrictions to the CPU. Because the input and output buffers are continuously being filled/emptied, the CPU must match the pace of the EDMA very closely to process the data. The EDMA receive data must always be placed in memory before the CPU accesses it, and the CPU must provide the output data before the EDMA transfers it. Though not impossible, this is an unnecessary challenge. It is particularly difficult in a 2-level cache scheme.

Ping-pong buffering is a simple technique that allows the CPU activity to be distanced from the EDMA activity. This means that there are multiple (usually two) sets of data buffers for all incoming and outgoing data streams. While the EDMA transfers the data into and out of the ping buffers, the CPU manipulates the data in the pong buffers. When both CPU and EDMA activity completes, they switch. The EDMA then writes over the old input data and transfers the new output data. Figure 16-46 shows the ping-pong scheme for this example.

To change the continuous operation example, such that a ping-pong buffering scheme is used, the EDMA channels need only a moderate change. Instead of one parameter set, there are two; one for transferring data to/from the ping buffers and one for transferring data to/from the pong buffers. As soon as one transfer completes, the channel loads the PaPARAM set for the other and the data transfers continue. Figure 16-47 shows the EDMA channel configuration required.

Each channel has two parameter sets, ping and pong. The EDMA channel is initially loaded with the ping parameters (Figure 16-47). The link address for the ping set is set to the PaPARAM offset of the pong parameter set (Figure 16-48). The link address for the pong set is set to the PaPARAM offset of the ping parameter set (Figure 16-49). The channel options, count values, and index values are all identical between the ping and pong parameters for each channel. The only differences are the link address provided and the address of the data buffer.

Figure 16-46. Ping-Pong Buffering for McASP Data Example

#### 16.2.5.4.4.1 Synchronization with the CPU

To utilize the ping-pong buffering technique, the system must signal the CPU when to begin to access the new data set. After the CPU finishes processing an input buffer (ping), it waits for the EDMA to complete before switching to the alternate (pong) buffer. In this example, both channels provide their channel numbers as their report word and set the EDMA\_TPCC\_OPT\_n[20] TCINTEN bit to generate an interrupt after completion. When channel 15 fills an input buffer, the E15 bit in the interrupt pending register

[EDMA\\_TPCC\\_IPR](#) is set; when channel 12 empties an output buffer, the E12 bit in [EDMA\\_TPCC\\_IPR](#) is set. The CPU must manually clear these bits. With the channel parameters set, the CPU polls [EDMA\\_TPCC\\_IPR](#) to determine when to switch. The EDMA and CPU could alternatively be configured such that the channel completion interrupts the CPU. By doing this, the CPU could service a background task while waiting for the EDMA to complete.

### 16.2.5.4.5 Transfer Chaining Examples

The following examples explain the intermediate transfer complete chaining function.

#### 16.2.5.4.5.1 Servicing Input/Output FIFOs with a Single Event

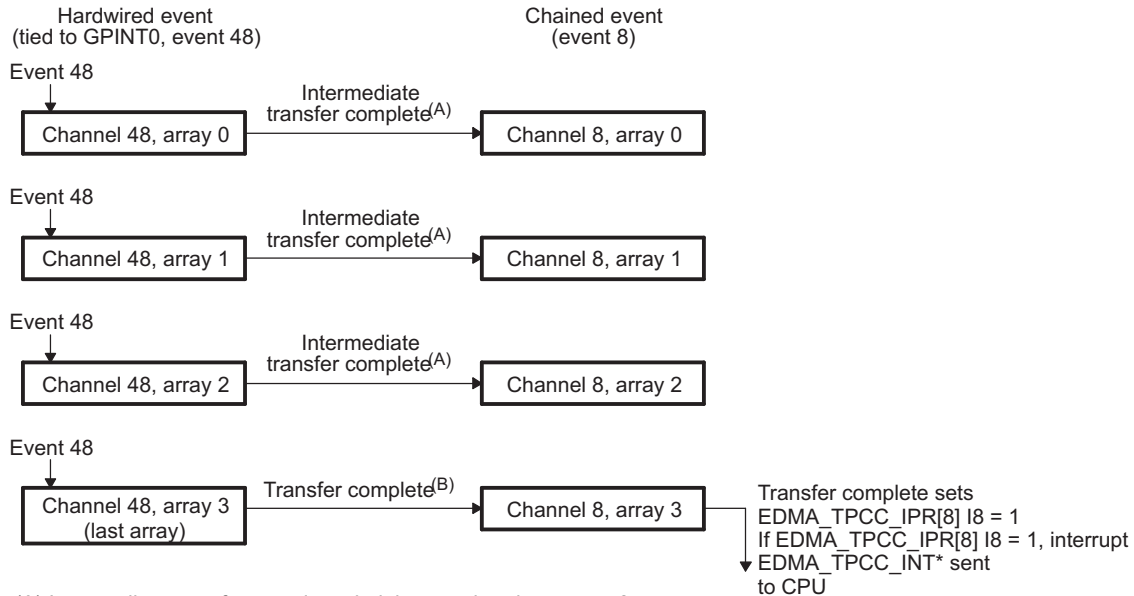

Many systems require the use of a pair of external FIFOs that must be serviced at the same rate. One FIFO buffers data input, and the other buffers data output. The EDMA channels that service these FIFOs can be set up for AB-synchronized transfers. While each FIFO is serviced with a different set of parameters, both can be signaled from a single event.

For example, an external interrupt pin can be tied to the status flags of one of the FIFOs. When this event arrives, the EDMA needs to perform servicing for both the input and output streams. Without the intermediate transfer complete chaining feature this would require two events, and thus two external interrupt pins. The intermediate transfer complete chaining feature allows the use of a single external event (for example, a GPIO event). [Figure 16-50](#) shows the EDMA setup and illustration for this example.

A GPIO event (in this case, GPINT0) triggers an array transfer. Upon completion of each intermediate array transfer of channel 48, intermediate transfer complete chaining sets the E8 bit (specified by TCC of 8) in the chained event register [EDMA\\_TPCC\\_CER](#) and provides a synchronization event to channel 8. Upon completion of the last array transfer of channel 48, transfer complete chaining—not intermediate transfer complete chaining—sets the E8 bit in [EDMA\\_TPCC\\_CER](#) (specified by [EDMA\\_TPCC\\_OPT\\_n\[11\]](#) TCCMODE: TCC) and provides a synchronization event to channel 8. The completion of channel 8 sets the I8 bit (specified by [EDMA\\_TPCC\\_OPT\\_n\[11\]](#) TCCMODE: TCC) in the interrupt pending register [EDMA\\_TPCC\\_IPR](#), which can generate an interrupt to the CPU, if the I8 bit in the interrupt enable register [EDMA\\_TPCC\\_IER](#) is set.

[Figure 16-50](#) shows the Intermediate Transfer Completion Chaining Example.

**Figure 16-50. Intermediate Transfer Completion Chaining Example**

Notes: (A) Intermediate transfer complete chaining synchronizes event 8  
EDMA\_TPCC\_OPT\_n[23] ITCCHEN = 1, TCC = 01000b, and sets EDMA\_TPCC\_CER[8] E8 = 1  
(B) Transfer complete chaining synchronizes event 8  
EDMA\_TPCC\_OPT\_n[22] TCCHEN = 1, EDMA\_TPCC\_OPT\_n[17:12] TCC = 01000b and sets EDMA\_TPCC\_CER[8] E8 = 1

Setup

Channel 48 parameters for chaining

- Enable transfer complete chaining:  
EDMA\_TPCC\_OPT\_n[22] TCCHEN = 1  
EDMA\_TPCC\_OPT\_n[17:12] TCC = 01000b
- Enable intermediate transfer complete chaining:  
EDMA\_TPCC\_OPT\_n[23] ITCCHEN = 1  
EDMA\_TPCC\_OPT\_n[17:12] TCC = 01000b

Channel 8 parameters for chaining

- Enable transfer complete chaining:  
EDMA\_TPCC\_OPT\_n[20] TCINTEN = 1  
EDMA\_TPCC\_OPT\_n[17:12] TCC = 01000b
- Disable intermediate transfer complete chaining:  
EDMA\_TPCC\_OPT\_n[23] ITCCHEN = 0

Event enable register (EDMA\_TPCC\_EER)

- Enable channel 48  
EDMA\_TPCC\_EERH[16] E48 = 1

edma-028

**16.2.5.4.5.2 Breaking Up Large Transfers with Intermediate Chaining**

Another feature of intermediate transfer chaining EDMA\_TPCC\_OPT\_n[23] ITCCHEN is for breaking up large transfers. A large transfer may lock out other transfers of the same priority level for the duration of the transfer. For example, a large transfer on queue 0 from the internal memory to the external memory using the EMIF may starve other EDMA transfers on the same queue. In addition, this large high-priority transfer may prevent the EMIF for a long duration to service other lower priority transfers. When a large transfer is considered to be high priority, it should be split into multiple smaller transfers. Figure 16-51 shows the EDMA setup and illustration of an example single large block transfer.

**Figure 16-51. Single Large Block Transfer Example**

The intermediate transfer chaining enable `EDMA_TPCC_OPT_n[23] ITCCHEN` provides a method to break up a large transfer into smaller transfers. For example, to move a single large block of memory (16K bytes), the EDMA performs an A-synchronized transfer. The element count is set to a reasonable value, where reasonable derives from the amount of time it would take to move this smaller amount of data. Assume 1 Kbyte is a reasonable small transfer in this example. The EDMA is set up to transfer 16 arrays of 1 Kbyte elements, for a total of 16K byte elements. The `EDMA_TPCC_OPT_n[17:12] TCC` field in the channel options parameter (OPT) is set to the same value as the channel number and `EDMA_TPCC_OPT_n[23] ITCCHEN` are set. In this example, EDMA channel 25 is used and `EDMA_TPCC_OPT_n[17:12] TCC` is also set to 25. The `EDMA_TPCC_OPT_n[20] TCINTEN` may also be set to trigger interrupt 25 when the last 1 Kbyte array is transferred. The CPU starts the EDMA transfer by writing to the appropriate bit of the event set register `EDMA_TPCC_ESR[25] E25`. The EDMA transfers the first 1 Kbyte array. Upon completion of the first array, intermediate transfer complete code chaining generates a synchronization event to channel 25, a value specified by the `EDMA_TPCC_OPT_n[17:12] TCC` field. This intermediate transfer completion chaining event causes EDMA channel 25 to transfer the next 1 Kbyte array. This process continues until the transfer parameters are exhausted, at which point the EDMA has completed the 16K byte transfer. This method breaks up a large transfer into smaller packets, thus providing natural time slices in the transfer such that other events may be processed. Figure 16-52 shows the EDMA setup and illustration of the broken up smaller packet transfers.

**Figure 16-52. Smaller Packet Data Transfers Example**

### 16.2.5.5 Setting Up an EDMA Transfer

The following list provides a quick guide for the typical steps involved in setting up a transfer.

**Step 1.** Initiating a DMA/QDMA channel

1. Determine the type of channel (QDMA or DMA) to be used.
2. Channel mapping
  - i. If using a QDMA channel, program the [EDMA\\_TPCC\\_QCHMAPN\\_j](#) with the parameter set number to which the channel maps and the trigger word.
  - ii. If using a DMA channel, program the [EDMA\\_TPCC\\_DCHMAPN\\_m](#) with the parameter set number to which the channel maps.
3. If the channel is being used in the context of a shadow region, ensure the [EDMA\\_TPCC\\_DRAEM\\_k](#) / [EDMA\\_TPCC\\_DRAEHM\\_k](#) for the region is properly set up to allow read write accesses to bits in the event registers and interrupt registers in the Shadow region memory map. The subsequent steps in this process should be done using the respective shadow region registers. (Shadow region descriptions and usage are provided in [Section 16.2.4.7.1.](#))
4. Determine the type of triggering used.
  - i. If external events are used for triggering (DMA channels), enable the respective event in [EDMA\\_TPCC\\_EER](#) / [EDMA\\_TPCC\\_EERH](#) by writing into [EDMA\\_TPCC\\_EESR](#) / [EDMA\\_TPCC\\_EESRH](#).
  - ii. If QDMA Channel is used, enable the channel in [EDMA\\_TPCC\\_QEER](#) by writing into [EDMA\\_TPCC\\_QEESR](#).
5. Queue setup
  - i. If a QDMA channel is used, set up the [EDMA\\_TPCC\\_QDMAQNUM](#) to map the channel to the respective event queue.
  - ii. If a DMA channel is used, set up the [EDMA\\_TPCC\\_DMAQNUMN\\_k](#) to map the event to the respective event queue.

**Step 2.** Parameter set setup

1. Program the PaPARAM set number associated with the channel. Note that

---

**NOTE:** If it is a QDMA channel, the PaPARAM entry that is configured as trigger word is written to last. Alternatively, enable the QDMA channel (step 1-b-ii above) just before the write to the trigger word.

---

**Step 3.** Interrupt setup

1. Enable the interrupt in the [EDMA\\_TPCC\\_IER](#) / [EDMA\\_TPCC\\_IERH](#) by writing into [EDMA\\_TPCC\\_IESR](#) / [EDMA\\_TPCC\\_IESRH](#).
2. Ensure that the EDMA\_TPCC completion interrupt (either the global or the shadow region interrupt) is enabled properly in the device interrupt controller.
3. Ensure the EDMA\_TPCC completion interrupt (this refers to either the Global interrupt or the shadow region interrupt) is enabled properly in the Device Interrupt controller.
4. Set up the interrupt controller properly to receive the expected EDMA interrupt.

**Step 4.** Initiate transfer

1. This step is highly dependent on the event trigger source:
  - i. If the source is an external event coming from a peripheral, the peripheral will be enabled to start generating relevant EDMA events that can be latched to the [EDMA\\_TPCC\\_ER](#) transfer.
  - ii. For QDMA events, writes to the trigger word (step 2-a above) will initiate the transfer.
  - iii. Manually triggered transfers will be initiated by writes to the Event Set Registers [EDMA\\_TPCC\\_ESR](#) / [EDMA\\_TPCC\\_ESRH](#).
  - iv. Chained-trigger events initiate when a previous transfer returns a transfer completion code equal to the chained channel number.

**Step 5. Wait for completion**

1. If the interrupts are enabled as mentioned in step 3 above, then the EDMA\_TPCC will generate a completion interrupt to the CPU whenever transfer completion results in setting the corresponding bits in the interrupt pending register [EDMA\\_TPCC\\_IPR](#) / [EDMA\\_TPCC\\_IPRH](#). The set bits must be cleared in the [EDMA\\_TPCC\\_IPR](#) / [EDMA\\_TPCC\\_IPRH](#) by writing to corresponding bit in [EDMA\\_TPCC\\_ICR](#) / [EDMA\\_TPCC\\_ICRH](#).
2. If polling for completion (interrupts not enabled in the device controller), then the application code can wait on the expected bits to be set in the [EDMA\\_TPCC\\_IPR](#) / [EDMA\\_TPCC\\_IPRH](#). Again, the set bits in the [EDMA\\_TPCC\\_IPR](#) / [EDMA\\_TPCC\\_IPRH](#) must be manually cleared via [EDMA\\_TPCC\\_ICR](#) / [EDMA\\_TPCC\\_ICRH](#) before the next set of transfers is performed for the same transfer completion code values.

## 16.2.6 EDMA Debug Checklist and Programming Tips

This section lists some tips to keep in mind while debugging applications using the EDMA controller.

### 16.2.6.1 EDMA Debug Checklist

Table 16-107 provides some common issues and their probable causes and resolutions.

**Table 16-107. Debug Checklist**

Issue	Description/Solution
<p>The transfer associated with the channel does not happen. The channel does not get serviced.</p>	<p>The EDMA_TPCC may not service a transfer request, even though the associated PaRAM set is programmed appropriately. Check for the following:</p> <ol style="list-style-type: none"> <li>1) Verify that events are enabled, i.e., if an external/peripheral event is latched in Event Registers <a href="#">EDMA_TPCC_ER</a> / <a href="#">EDMA_TPCC_ERH</a>, check that the event is enabled in the Event Enable Registers <a href="#">EDMA_TPCC_EER</a> / <a href="#">EDMA_TPCC_EERH</a>. Similarly, for QDMA channels, check that QDMA events are appropriately enabled in the QDMA Event Enable Register <a href="#">EDMA_TPCC_QEER</a>.</li> <li>2) Verify that the DMA or QDMA Secondary Event Register <a href="#">EDMA_TPCC_SER</a> / <a href="#">EDMA_TPCC_SERH</a> / <a href="#">EDMA_TPCC_QSER</a> bits corresponding to the particular event or channel are not set.</li> </ol>
<p>The Secondary Event Registers bits are set, not allowing additional transfers to occur on a channel.</p>	<p>It is possible that a trigger event was received when the parameter set associated with the channel/event was a NULL set for a previous transfer on the channel. This is typical in two cases:</p> <ol style="list-style-type: none"> <li>1) QDMA channels: Typically if the parameter set is non-static and expected to be terminated by a NULL set (i.e., <a href="#">EDMA_TPCC_OPT_n[3]</a> STATIC = 0x0, <a href="#">EDMA_TPCC_LNK_n[15:0]</a> LINK = 0xFFFF), the parameter set is updated with a NULL set after submission of the last TR. Because QDMA channels are auto-triggered, this update caused the generation of an event. An event generated for a NULL set causes an error condition and results in setting the bits corresponding to the QDMA channel in the <a href="#">EDMA_TPCC_QEMR</a> and <a href="#">EDMA_TPCC_QSER</a>. This will disable further prioritization of the channel.</li> <li>2) DMA channels used in a continuous mode: The peripheral may be set up to continuously generate infinite events (for instance, in case of McASP, every time the data shifts out from the DXR register, it generates an XEVT). The parameter set may be programmed to expect only a finite number of events and to be terminated by a NULL link. After the expected number of events, the parameter set is reloaded with a NULL parameter set. Because the peripheral will generate additional events, an error condition is set in the <a href="#">EDMA_TPCC_SER[31:0]</a> En and <a href="#">EDMA_TPCC_EMR[31:0]</a> En set, preventing further event prioritization.</li> </ol> <p>Check the number of events received is limited to the expected number of events for which the parameter set is programmed, or check the bits corresponding to particular channel or event are not set in the Secondary event registers (<a href="#">EDMA_TPCC_SER</a> / <a href="#">EDMA_TPCC_SERH</a> / <a href="#">EDMA_TPCC_QSER</a>) and Event Missed Registers (<a href="#">EDMA_TPCC_EMR</a> / <a href="#">EDMA_TPCC_EMRH</a> / <a href="#">EDMA_TPCC_QEMR</a>) before trying to perform subsequent transfers for the event/channel.</p>
<p>Completion interrupts are not asserted, or no further interrupts are received after the first completion interrupt.</p>	<p>Check the following:</p> <ol style="list-style-type: none"> <li>1) The interrupt generation is enabled in the <a href="#">EDMA_TPCC_OPT_n</a> of the associated PaRAM set (<a href="#">EDMA_TPCC_OPT_n[20]</a> TCINTEN = 0x1 and/or <a href="#">EDMA_TPCC_OPT_n[20]</a> ITCINTEN = 0x1).</li> <li>2) The interrupts are enabled in the EDMA Channel Controller, via the Interrupt Enable Registers ( <a href="#">EDMA_TPCC_IER</a> / <a href="#">EDMA_TPCC_IERH</a> ).</li> <li>3) The corresponding interrupts are enabled in the device interrupt controller.</li> <li>4) The set interrupts are cleared in the interrupt pending registers ( <a href="#">EDMA_TPCC_IPR</a> / <a href="#">EDMA_TPCC_IPRH</a> ) before exiting the transfer completion interrupt service routine (ISR). See <a href="#">Section 16.2.4.9.1.2 Clearing Transfer Completion Interrupts</a> for details on writing EDMA ISRs.</li> <li>5) If working with shadow region interrupts, make sure that the DMA Region Access registers ( <a href="#">EDMA_TPCC_DRAEM_k</a> / <a href="#">EDMA_TPCC_DRAEHM_k</a> ) are set up properly, because the <a href="#">EDMA_TPCC_DRAEM_k</a> / <a href="#">EDMA_TPCC_DRAEHM_k</a> registers act as secondary enables for shadow region completion interrupts, along with the <a href="#">EDMA_TPCC_IER</a> / <a href="#">EDMA_TPCC_IERH</a> registers.</li> </ol> <p>If working with shadow region interrupts, make sure that the bits corresponding to the transfer completion code <a href="#">EDMA_TPCC_OPT_n[17:12]</a> TCC value are also enabled in the <a href="#">EDMA_TPCC_DRAEM_k</a> / <a href="#">EDMA_TPCC_DRAEHM_k</a> registers. For instance, if the PaRAM set associated with Channel 0 returns a completion code of 63 <a href="#">EDMA_TPCC_OPT_n[17:12]</a> TCC = 63, ensure that <a href="#">EDMA_TPCC_DRAEHM_k[31]</a> E63 is also set for a shadow region completion interrupt because the interrupt pending register bit set will be <a href="#">EDMA_TPCC_IPRH[31]</a> I63 (not <a href="#">EDMA_TPCC_IPR[0]</a> I0).</p>

### 16.2.6.2 EDMA Programming Tips

1. For several registers, the setting and clearing of bits needs to be done via separate dedicated registers.  
 For example, the Event Register ([EDMA\\_TPCC\\_ER](#) / [EDMA\\_TPCC\\_ERH](#)) can only be cleared by writing a 1 to the corresponding bits in the Event Clear Registers ([EDMA\\_TPCC\\_ECR](#) / [EDMA\\_TPCC\\_ECRH](#)). Similarly, the Event Enable Register ([EDMA\\_TPCC\\_EER](#) / [EDMA\\_TPCC\\_EERH](#)) bits can only be set with writing of 0x1 to the Event Enable Set Registers ([EDMA\\_TPCC\\_EESR](#) / [EDMA\\_TPCC\\_EESRH](#)) and cleared with writing of 0x1 to the corresponding bits in the Event Enable Clear Register ([EDMA\\_TPCC\\_EECR](#) / [EDMA\\_TPCC\\_EECRH](#)).
2. Writes to the shadow region memory maps are governed by region access registers ([EDMA\\_TPCC\\_DRAEM\\_k](#) / [EDMA\\_TPCC\\_DRAEHM\\_k](#) / [EDMA\\_TPCC\\_QRAEN\\_k](#)). If the appropriate channels are not enabled in these registers, read/write access to the shadow region memory map is not enabled.
3. When working with shadow region completion interrupts, ensure that the DMA Region Access Registers ([EDMA\\_TPCC\\_DRAEM\\_k](#) / [EDMA\\_TPCC\\_DRAEHM\\_k](#)) for every region are set in a mutually exclusive way (unless it is a requirement for an application). If there is an overlap in the allocated channels and transfer completion codes (setting of Interrupt Pending Register bits) in the region resource allocation, it results in multiple shadow region completion interrupts.  
 For example, if [EDMA\\_TPCC\\_DRAEM\\_k.DRAEM\\_0\[0\]](#) E0 and [EDMA\\_TPCC\\_DRAEM\\_k.DRAEM\\_1\[0\]](#) E0 are both set, then on completion of a transfer that returns a TCC = 0x0, they will generate both shadow region 0 and 1 completion interrupts.
4. While programming a non-dummy parameter set, ensure the [EDMA\\_TPCC\\_CCNT\\_n\[15:0\]](#) CCNT is not left to zero.
5. Enable the EDMA\_TPCC error interrupt in the device controller and attach an interrupt service routine (ISR) to ensure that error conditions are not missed in an application and are appropriately addressed with the ISR.
6. Depending on the application, it can want to break large transfers into smaller transfers and use self-chaining to prevent starvation of other events in an event queue.
7. In applications where a large transfer is broken into sets of small transfers using chaining or other methods, it chooses to use the early chaining option to reduce the time between the sets of transfers and increase the throughput.  
 However, keep in mind that with early completion, all data might have not been received at the end point when completion is reported because the EDMA\_TPCC internally signals completion when the TR is submitted to the EDMA\_TPTC, potentially before any data has been transferred.
8. The event queue entries can be observed to determine the last few events if there is a system failure (provided the entries were not bypassed).

## 16.2.7 EDMA Register Manual

### 16.2.7.1 EDMA Instance Summary

Table 16-108 shows the L3\_MAIN base address and address space for the EDMA module instances.

**Table 16-108. EDMA Instance Summary**

Module Name	Base Address (L3_MAIN Access)	Size
SYS_EDMA_TPCC	0x4330 0000	1 MB
SYS_EDMA_TPTC0	0x4340 0000	1 MB
SYS_EDMA_TPTC1	0x4350 0000	1 MB
DSP1_EDMA_TPCC	0x40D1 0000	32 KB
DSP1_EDMA_TPTC0	0x40D0 5000	4 KB
DSP1_EDMA_TPTC1	0x40D0 6000	4 KB
DSP2_EDMA_TPCC	0x4151 0000	32 KB
DSP2_EDMA_TPTC0	0x4150 5000	4 KB
DSP2_EDMA_TPTC1	0x4150 6000	4 KB
EVE1_EDMA_TPCC	0x420A 0000	32 KB
EVE2_EDMA_TPCC	0x421A 0000	32 KB
EVE1_EDMA_TPTC0	0x4208 6000	4 KB
EVE2_EDMA_TPTC0	0x4218 6000	4 KB
EVE1_EDMA_TPTC1	0x4208 7000	4 KB
EVE2_EDMA_TPTC1	0x4218 7000	4 KB

Table 16-109 lists the base addresses for DSP internal (private) access to its embedded TPCC / TPTC modules.

**Table 16-109. DSP Private Access EDMA Instance Summary**

Module Name	Base Address	Size
DSP_EDMA_TPCC	0x01D1 0000	32 KB
DSP_EDMA_TPTC0	0x01D0 5000	4 KB
DSP_EDMA_TPTC1	0x01D0 6000	4 KB

Table 16-110 lists the base addresses for EVE internal (private) access to its embedded TPCC / TPTC modules.

**Table 16-110. EVE EDMA Instance Summary (Private Access)**

Module Name	Base Address (EVE Private Access)	Size
EVE_EDMA_TPCC	0x400A 0000	32 KB
EVE_EDMA_TPTC0	0x4008 6000	4 KB
EVE_EDMA_TPTC1	0x4008 7000	4 KB

### 16.2.7.2 EDMA Registers

#### 16.2.7.2.1 EDMA Register Summary

Table 16-111 through Table 16-121 summarize the EDMA\_TPCC, EDMA\_TPTC0 and EDMA\_TPTC1 registers.

**NOTE:** All EDMA modules in the SoC are functionally identical. Note that some of the configuration parameters may be different for the various EDMA instances (see [Section 16.2.1.2, EDMA Controllers Configuration](#)).

**Table 16-111. System EDMA\_TPCC Registers Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	SYS_EDMA_TPCC Physical Address (L3_MAIN Access)

<b>Description</b>	QDMA Secondary Event Clear Register The secondary event clear register is used to clear the status of the <a href="#">EDMA_TPCC_QSER</a> and <a href="#">EDMA_TPCC_QER</a> register (note that this is slightly different than the <a href="#">EDMA_TPCC_SER</a> operation, which does not clear the <a href="#">EDMA_TPCC_ER</a> .En register). CPU write of '1' to the <a href="#">EDMA_TPCC_QSECR</a> .En bit clears the <a href="#">EDMA_TPCC_QSER</a> .En and <a href="#">EDMA_TPCC_QER</a> .En register fields. CPU write of '0' has no effect..

BCNT												ACNT																			

Bits	Field Name	Description	Type	Reset
31:16	BCNT	<p>BCNT: Count for 2nd Dimension: BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT can be anywhere between 1 and 65535. Therefore, the maximum number of arrays in a frame is 65535 (64K-1 arrays). BCNT=1 means 1 array in the frame, and BCNT=0 means 0 arrays in the frame. In normal mode, a BCNT of '0' is considered as either a Null or Dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. If the <a href="#">EDMA_TPCC_OPT_n.WIMODE</a> bit is set, then the programmed BCNT value will be incremented by '1' before submission to TC. I.e., 0 means 1, 1 means 2, 2 means 3, ..., 0xFFFF means 0xFFFF. A value of 0xFFFF is an illegal value that will be treated as a Null TR.</p>	RW	0x0
15:0	ACNT	<p>ACNT: number of bytes in 1st dimension: ACNT represents the number of bytes within the first dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65535. Therefore, the maximum number of bytes in an array is 65535 bytes (64K-1 bytes). ACNT must be greater than or equal to '1' for a TR to be submitted to TC. An ACNT of '0' is considered as either a null or dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. If the <a href="#">EDMA_TPCC_OPT_n.WIMODE</a> bit is set then the ACNT field represents a word count. The CC must internally multiply by 4 to translate the word count to a byte count prior to submission to the TC. The 2 MSBs of the 16-bit ACNT are reserved and should always be written as 'b00' by the user. If user writes a value other than 0, it will still be treated as 0 since the multiply-by-4 operation (to translate between a word count and a byte count) will drop the 2 msbits. For dummy and null transfer definition, the ACNT definition will disregard the 2 msbits. I.e., a programmed ACNT value of 0x8000 in WI-mode will be treated as 0 byte transfer, resulting in null or dummy operation dependent on the state of BCNT and CCNT.</p>	RW	0x0

Bits	Field Name	Description	Type	Reset
31:16	DBIDX	Destination 2nd Dimension Index: DBIDX is a 16-bit signed value (2's complement) used for destination address modification in between each array in the 2nd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-Sync and AB-Sync transfers.	RW	0x0

Bits	Field Name	Description	Type	Reset
15:0	SBIDX	Source 2nd Dimension Index: SBIDX is a 16-bit signed value (2's complement) used for source address modification in between each array in the 2nd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-sync and AB-sync transfers.	RW	0x0

<b>Description</b>	Link and Reload parameters		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCNTRLD																LINK															

Bits	Field Name	Description	Type	Reset
31:16	BCNTRLD	BCNT Reload: BCNTRLD is a 16-bit unsigned value used to reload the BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-Sync'ed transfers. In this case, the CC decrements the BCNT value by one on each TR submission. When BCNT (conceptually) reaches zero, then the CC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value. For AB-synchronized transfers, the CC submits the BCNT in the TR and therefore the TC is responsible to keep track of BCNT, not thus BCNTRLD is a don't care field.	RW	0x0

Bits	Field Name	Description	Type	Reset
15:0	LINK	<p>Link Address:</p> <p>The CC provides a mechanism to reload the current PaRAM Entry upon its natural termination (i.e., after count fields are decremented to '0') with a new PaRAM Entry. This is called 'linking'. The 16-bit parameter LINK specifies the byte address offset in the PaRAM from which the CC loads/reloads the next PaRAM entry in the link. The CC should disregard the value in the upper 2 bits of the LINK field as well as the lower 5-bits of the LINK field. The upper two bits are ignored such that the user can program either the 'literal' byte address of the LINK parameter or the 'PaRAM base-relative' address of the link field. Therefore, if the user uses the literal address with a range from 0x4000 to 0x7FFF, it will be treated as a PaRAM-base-relative value of 0x0000 to 0x3FFF. The lower-5 bits are ignored and treated as 'b00000, thereby guaranteeing that all Link pointers point to a 32-byte aligned PaRAM entry. In the latter case (5-lsbs), behavior is undefined for the user (i.e., don't have to test it). In the former case (2 msbs), user should be able to take advantage of this feature (i.e., do have to test it). If a Link Update is requested to a PaRAM address that is beyond the actual range of implemented PaRAM, then the Link will be treated as a Null Link and all 0s plus 0xFFFF will be written to the current entry location. A LINK value of 0xFFFF is referred to as a NULL link which should cause the CC to write 0x0 to all entries of the current PaRAM Entry except for the LINK field which is set to 0xFFFF. The Priv/Privid state is overwritten to 0x0 when linking. MSBs and LSBS should not be masked when comparing against the 0xFFFF value. I.e., a value of 0x3FFE is a non-NULL PaRAM link field.</p>	RW	0x0

DCIDX																SCIDX															

Bits	Field Name	Description	Type	Reset
31:16	DCIDX	Destination Frame Index: DCIDX is a 16-bit signed value (2's complement) used for destination address modification for the 3rd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array in the next frame. It applies to both A-sync and AB-sync transfers. Note that when DCIDX is applied, the current array in an A-sync transfer is the last array in the frame, while the current array in a ABsync transfer is the first array in the frame.	RW	0x0
15:0	SCIDX	Source Frame Index: SCIDX is a 16-bit signed value (2's complement) used for source address modification for the 3rd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-sync and AB-sync transfers. Note that when SCIDX is applied, the current array in an A-sync transfer is the last array in the frame, while the current array in a AB-sync transfer is the first array in the frame.	RW	0x0

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCNT																ACNT															

Bits	Field Name	Description	Type	Reset
31:16	BCNT	B-Dimension count: Number of arrays to be transferred, where each array is ACNT in length. Count Remaining for Source Active Register Set. Represents the amount of data remaining to be read. Initial value is copied from <a href="#">EDMA_TPTCn_PCNT</a> . TC decrements ACNT and BCNT as necessary after each read command is issued. Final value should be 0 when TR is complete.	R	0x0
15:0	ACNT	A-Dimension count: Number of bytes to be transferred in first dimension. Count Remaining for Source Active Register Set. Represents the amount of data remaining to be read. Initial value is copied from <a href="#">EDMA_TPTCn_PCNT</a> . TC decrements ACNT and BCNT as necessary after each read command is issued. Final value should be 0 when TR is complete.	R	0x0

## ***Interrupt Controllers***

---

---

This chapter describes the interrupt controllers (INTCs) in the device.

<b>Topic</b>	<b>Page</b>
<b>17.1 Interrupt Controllers Overview .....</b>	<b>4326</b>
<b>17.2 Interrupt Controllers Environment .....</b>	<b>4328</b>
<b>17.3 Interrupt Controllers Integration .....</b>	<b>4330</b>
<b>17.4 Interrupt Controllers Functional Description .....</b>	<b>4368</b>

## 17.1 Interrupt Controllers Overview

The device has a large number of interrupts to service the needs of its many peripherals and subsystems. The MPU, DSP (x2), IPU (x2), and EVE (x2) subsystems are capable of servicing these interrupts via their integrated interrupt controllers. In addition, each processor's interrupt controller is preceded by an Interrupt Controller Crossbar (IRQ\_CROSSBAR) that provides flexibility in mapping the device interrupts to processor interrupt inputs. For more information about IRQ crossbar, see [Chapter 18, Control Module](#).

### Dual Cortex®-A15 MPU Subsystem Interrupt Controller (MPU\_INTC)

The MPU\_INTC module (also called Generalized Interrupt Controller [GIC]) is a single functional unit that is integrated in the Arm® Cortex-A15 multiprocessor core (MPCore) alongside Cortex-A15 processors. It provides:

- 160 hardware interrupt inputs
- Generation of interrupts by software
- Prioritization of interrupts
- Masking of any interrupts
- Distribution of the interrupts to the target Cortex-A15 processor(s)
- Tracking the status of interrupts

Each Cortex-A15 processor supports three main groups of interrupt sources, with each interrupt source having a unique ID:

- *Software Generated Interrupts (SGIs)*: SGIs are generated by writing to the Cortex-A15 Software Generated Interrupt Register (GICD\_SGIR). A maximum of 16 SGIs (ID0–ID15) can be generated for each CPU interface. An SGI has edge-triggered properties. The software triggering of the interrupt is equivalent to the edge transition of the interrupt signal on a peripheral input.
- *Private Peripheral Interrupts (PPIs)*: A PPI is an interrupt generated by a peripheral that is specific to a single processor. Although interrupts ID16–ID31 are dedicated to PPIs in general, only seven PPIs are actually used for each CPU interface (ID25–ID31). Interrupts ID16–ID24 are reserved (not used).
- *Shared Peripheral Interrupts (SPIs)*: SPIs are triggered by events generated on associated interrupt input lines. In this device, the GIC is configured to support 160 SPIs corresponding to its external IRQS[159:0] signals. SPIs start at ID32 and their mapping is presented in [Section 17.3.1](#).

For detailed information about this module and description of SGIs and PPIs, see the Arm *Cortex-A15 MPCore Technical Reference Manual* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).

### C66x DSP Subsystem Interrupt Controller (DSPx\_INTC, where x = 1, 2)

There are two Digital Signal Processing (DSP) subsystems in the device - DSP1, and DSP2. Each DSP subsystem integrates an interrupt controller - DSPx\_INTC, which interfaces the system events to the C66x core interrupt and exceptions inputs. It combines up to 128 interrupts into 12 prioritized interrupts presented to the C66x CPU.

For detailed information about this module, see [Chapter 5, DSP Subsystem](#).

### Dual Cortex-M4 IPU Subsystem Interrupt Controller (IPUx\_Cx\_INTC, where x = 1, 2)

There are two Image Processing Unit (IPU) subsystems in the device - IPU1, and IPU2. Each IPU subsystem integrates two Arm Cortex-M4 cores.

A Nested Vectored Interrupt Controller (NVIC) is integrated within each Cortex-M4. The interrupt mapping is the same (per IPU) for the two cores to facilitate parallel processing. The NVIC supports:

- 64 external interrupts (in addition to 16 Cortex-M4 internal interrupts), which are dynamically prioritized with 16 levels of priority defined for each core
- Low-latency exception and interrupt handling
- Prioritization and handling of exceptions
- Control of the local power management
- Debug accesses to the processor core

For detailed information about this module, refer to Arm *Cortex-M4 Technical Reference Manual* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).

**NOTE:** IPUx\_Cx\_INTc is a unified name for the following interrupt controllers:

- IPU1\_C0\_INTc - NVIC in first Cortex-M4 core of IPU1
- IPU1\_C1\_INTc - NVIC in second Cortex-M4 core of IPU1
- IPU2\_C0\_INTc - NVIC in first Cortex-M4 core of IPU2
- IPU2\_C1\_INTc - NVIC in second Cortex-M4 core of IPU2

**EVE Subsystem Interrupt Controller (EVE<sub>x</sub>\_INTc, where x = 1 to 2)**

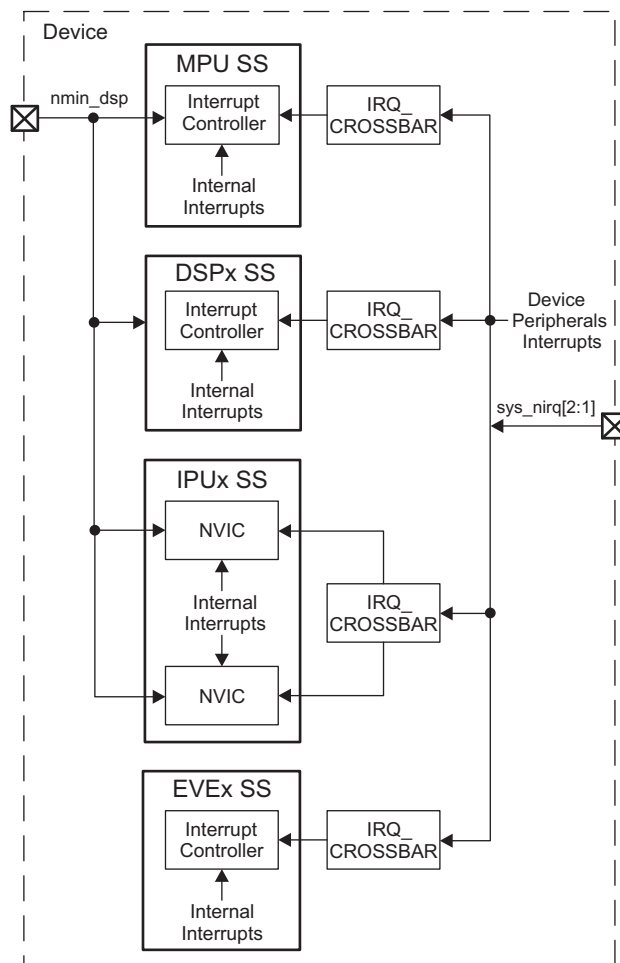

There are two Embedded Video Engine (EVE) subsystems in the device - EVE1, and EVE2. Each EVE subsystem integrates an interrupt controller - EVE<sub>x</sub>\_INTc, which handles incoming interrupts, merging them with internal interrupt sources to drive ARP32's interrupt inputs. It also allows ARP32 to generate outgoing interrupts or events to synchronize with other system processors and EDMA.

The EVE<sub>x</sub>\_INTc supports up to 32 active-high level interrupt inputs. Its architecture allows both hardware and software prioritization.

For detailed information about this module, see [Section 8.1, Embedded Vision Engine](#).

[Figure 17-1](#) shows the top-level block diagram of the interrupt controllers in this device.

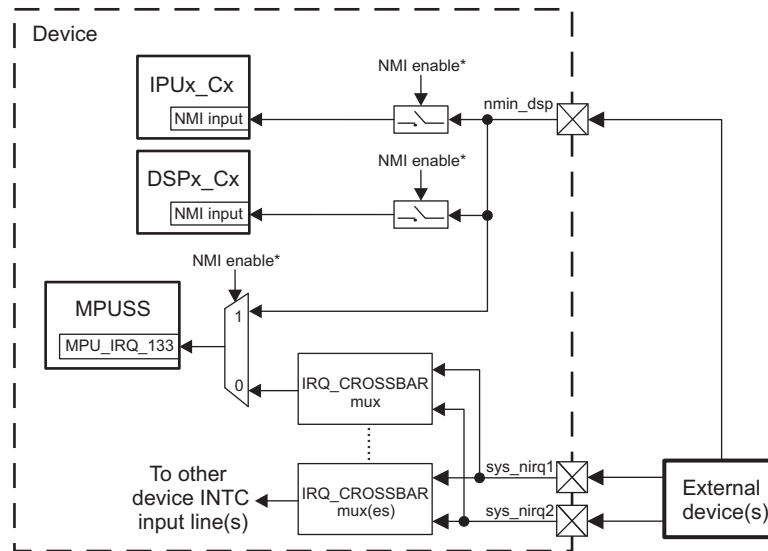

**Figure 17-1. Interrupt Controllers in the Device**

## 17.2 Interrupt Controllers Environment

Figure 17-2 shows the relationship between the device INTCs and external interrupts.

**Figure 17-2. Interrupts From External Devices**

\* NMI enable is done via corresponding bit field in the `CTRL_CORE_NMI_DESTINATION_x` register (x=1,2)

Table 17-1 describes the signals that can be used by external devices to generate interrupts to the device INTCs.

**Table 17-1. Interrupts From External Devices**

Device Pin	I/O <sup>(1)</sup>	Description
<code>sys_nirq1</code>	I	External devices can use these pins to generate a system wake-up interrupt event to any device INTC. The user must take care to configure the corresponding <code>IRQ_CROSSBAR</code> properly (via Control Module).
<code>sys_nirq2</code>	I	

<sup>(1)</sup> I = Input, O = Output

**Table 17-1. Interrupts From External Devices (continued)**

Device Pin	I/O <sup>(1)</sup>	Description
nmin_dsp	I	<p>External device can use this pin to generate a non-maskable interrupt (NMI) event to the following device processors:</p> <ul style="list-style-type: none"> <li>- IPU1_C0, IPU1_C1. Upon enable (via Control Module), the NMI is routed directly to the NMI input of Cortex M4 core. Note that NMI can be enabled separately for IPU1_C0 and IPU1_C1.</li> <li>- IPU2_C0, IPU2_C1. Upon enable (via Control Module), the NMI is routed directly to the NMI input of Cortex M4 core. Note that NMI can be enabled separately for IPU2_C0 and IPU2_C1.</li> <li>- DSP1, DSP2. Upon enable (via Control Module), the NMI is routed directly to the NMI input of C66x CPU.</li> </ul> <p>The signal from the <b>nmin_dsp</b> pin can also be mapped to the MPU_INTC (MPU_IRQ_133 input) but it would be treated by Cortex-A15 as a general interrupt and not as a non-maskable interrupt. The Cortex-A15 processor does not provide NMI input.</p> <p>The Control Module registers CTRL_CORE_NMI_DESTINATION_1 and CTRL_CORE_NMI_DESTINATION_2 are used to route the <b>NMI</b> signal to the corresponding device processor subsystems as follows:</p> <ul style="list-style-type: none"> <li>• Writing 0x1 to CTRL_CORE_NMI_DESTINATION_1[23:16] IPU2_C1 enables NMI mapping to IPU2_C1;</li> <li>• Writing 0x1 to CTRL_CORE_NMI_DESTINATION_1[15:8] IPU2_C0 enables NMI mapping to IPU2_C0;</li> <li>• Writing 0x1 to CTRL_CORE_NMI_DESTINATION_1[7:0] IPU1_C1 enables NMI mapping to IPU1_C1;</li> <li>• Writing 0x1 to CTRL_CORE_NMI_DESTINATION_2[31:24] IPU1_C0 enables NMI mapping to IPU1_C0;</li> <li>• Writing 0x1 to CTRL_CORE_NMI_DESTINATION_2[23:16] DSP2 enables NMI mapping to DSP2;</li> <li>• Writing 0x1 to CTRL_CORE_NMI_DESTINATION_2[15:8] DSP1 enables NMI mapping to DSP1;</li> <li>• Writing 0x1 to CTRL_CORE_NMI_DESTINATION_2[7:0] MPU enables NMI mapping to MPU_IRQ_133 interrupt line of MPU_INTC; writing 0x0 to this bit field disables the NMI mapping and IRQ_CROSSBAR mux is mapped to MPU_IRQ_133 instead.</li> </ul> <p>For more information about CTRL_CORE_NMI_DESTINATION_1 and CTRL_CORE_NMI_DESTINATION_2 registers, see <a href="#">Chapter 18, Control Module</a>.</p>

---

**NOTE:** External devices can also use the GPIO modules to generate an interrupt to the device INTCs. For more information, see [Chapter 27, General-Purpose Interface](#).

---

## 17.3 Interrupt Controllers Integration

Table 17-2 through Table 17-8 present the default interrupt mapping of the device INTCs. The mapping of device interrupts to IRQ\_CROSSBAR inputs is presented in Table 17-9.

---

**NOTE:** All device interrupts (external to the MPU, DSP [x2], IPU [x2], and EVE [x2] subsystems) are active-high, level-sensitive.

---

### CAUTION

A single interrupt source can be physically mapped to multiple INTCs. With multiple-mapped interrupts, it is strongly recommended to unmask each interrupt source in only one INTC at a time.

### 17.3.1 Interrupt Requests to MPU\_INTC

Table 17-2 lists the default interrupt sources for the MPU\_INTC. In addition, interrupts MPU\_IRQ\_4, MPU\_IRQ\_[130:7], MPU\_IRQ\_[138:133], and MPU\_IRQ\_[159:141] can alternatively be sourced through the MPU's IRQ\_CROSSBAR from one of the 420 multiplexed device interrupts listed in Table 17-9. The CTRL\_CORE\_MPU\_IRQ\_y\_z registers (where y and z are indexes of INTC input lines) in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

---

**NOTE:** The interrupts listed in Table 17-2 are also called Shared Peripheral Interrupts (SPIs) in Arm Cortex-A15 terminology. That is, the MPU\_IRQ\_[159:0] interrupt inputs correspond to the **IRQS[N:0]** GIC signals (N = 159 for this device), described in the *Arm Cortex-A15 MPCore Processor Technical Reference Manual*.

The association between the Shared Peripheral Interrupts (MPU\_IRQ\_0 – MPU\_IRQ\_159) and the GIC inputs (ID32 – ID191) is shown in the first column of this table.

---

**Table 17-2. MPU\_INTC Default Interrupt Mapping**

IRQ Input Line (GIC ID Number) <sup>(1)</sup>	IRQ CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
MPU_IRQ_0 (ID32)	N/A	N/A	N/A	MPU_CLUSTER_IRQ_INTERR	Illegal writes to interrupt controller memory map region
MPU_IRQ_1 (ID33)	N/A	N/A	N/A	CS_CTI_MPU_C0_IRQ	TRIGOUT[6] of Cross Trigger Interface 0 (CTI0)
MPU_IRQ_2 (ID34)	N/A	N/A	N/A	CS_CTI_MPU_C1_IRQ	TRIGOUT[6] of Cross Trigger Interface 1 (CTI1)
MPU_IRQ_3 (ID35)	N/A	N/A	N/A	MPU_CLUSTER_IRQ_AXIERR	Error indication for AXI write transactions with a BRESP error condition
MPU_IRQ_4 (ID36)	1	CTRL_CORE_MPU_IRQ_4_7[8:0]	1	ELM_IRQ	Error location process completion interrupt
MPU_IRQ_5 (ID37)	N/A	N/A	N/A	WD_TIMER_MPU_C0_IRQ_WARN	MPU_WD_TIMER channel 0 warning interrupt
MPU_IRQ_6 (ID38)	N/A	N/A	N/A	WD_TIMER_MPU_C1_IRQ_WARN	MPU_WD_TIMER channel 1 warning interrupt
MPU_IRQ_7 (ID39)	2	CTRL_CORE_MPU_IRQ_4_7[24:16]	2	EXT_SYS_IRQ_1	External interrupt (active low) via sys_nirq1 pin
MPU_IRQ_8 (ID40)	3	CTRL_CORE_MPU_IRQ_8_9[8:0]	3	CTRL_MODULE_CORE_IRQ_SEC_EVTS	Combined firewall error interrupt. For more information, see <a href="#">Section 18.4.6.14.3</a> .
MPU_IRQ_9 (ID41)	4	CTRL_CORE_MPU_IRQ_8_9[24:16]	4	L3_MAIN_IRQ_DBG_ERR	L3_MAIN debug error
MPU_IRQ_10 (ID42)	5	CTRL_CORE_MPU_IRQ_10_11[8:0] (not functional)	5	L3_MAIN_IRQ_APP_ERR	L3_MAIN application or non-attributable error <sup>(2)</sup>
MPU_IRQ_11 (ID43)	6	CTRL_CORE_MPU_IRQ_10_11[24:16]	6	PRM_IRQ_MPU	PRCM interrupt to MPU
MPU_IRQ_12 (ID44)	7	CTRL_CORE_MPU_IRQ_12_13[8:0]	7	DMA_SYSTEM_IRQ_0	System DMA interrupt 0
MPU_IRQ_13 (ID45)	8	CTRL_CORE_MPU_IRQ_12_13[24:16]	8	DMA_SYSTEM_IRQ_1	System DMA interrupt 1
MPU_IRQ_14 (ID46)	9	CTRL_CORE_MPU_IRQ_14_15[8:0]	9	DMA_SYSTEM_IRQ_2	System DMA interrupt 2
MPU_IRQ_15 (ID47)	10	CTRL_CORE_MPU_IRQ_14_15[24:16]	10	DMA_SYSTEM_IRQ_3	System DMA interrupt 3
MPU_IRQ_16 (ID48)	11	CTRL_CORE_MPU_IRQ_16_17[8:0]	11	L3_MAIN_IRQ_STAT_ALARM	L3_MAIN statistic collector alarm interrupt
MPU_IRQ_17 (ID49)	12	CTRL_CORE_MPU_IRQ_16_17[24:16]	12	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_18 (ID50)	13	CTRL_CORE_MPU_IRQ_18_19[8:0]	13	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_19 (ID51)	14	CTRL_CORE_MPU_IRQ_18_19[24:16]	14	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_20 (ID52)	15	CTRL_CORE_MPU_IRQ_20_21[8:0]	15	GPMC_IRQ	GPMC interrupt
MPU_IRQ_21 (ID53)	16	CTRL_CORE_MPU_IRQ_20_21[24:16]	16	GPU_IRQ	GPU interrupt
MPU_IRQ_22 (ID54)	17	CTRL_CORE_MPU_IRQ_22_23[8:0]	17	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_23 (ID55)	18	CTRL_CORE_MPU_IRQ_22_23[24:16]	18	Reserved	Reserved by default but can be remapped to a valid interrupt source

<sup>(1)</sup> This column shows the association between the Shared Peripheral Interrupts (MPU\_IRQ\_0 – MPU\_IRQ\_159) and the GIC inputs (ID32 – ID191).

<sup>(2)</sup> The L3\_MAIN\_IRQ\_APP\_ERR interrupt is directly mapped to the MPU\_IRQ\_10 line, bypassing the crossbar instance dedicated to this line. No other interrupt source can be mapped to MPU\_IRQ\_10.

**Table 17-2. MPU\_INTC Default Interrupt Mapping (continued)**

IRQ Input Line (GIC ID Number) <sup>(1)</sup>	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
MPU_IRQ_24 (ID56)	19	CTRL_CORE_MPU_IRQ_24_25[8:0]	19	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_25 (ID57)	20	CTRL_CORE_MPU_IRQ_24_25[24:16]	20	DISPC_IRQ	Display controller interrupt

**Table 17-2. MPU\_INTC Default Interrupt Mapping (continued)**

IRQ Input Line (GIC ID Number) <sup>(1)</sup>	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
MPU_IRQ_159 (ID191)	152	CTRL_CORE_MPU_IRQ_158_159[24:16]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source

**NOTE:** The "IRQ\_CROSSBAR Default Input Index" column of [Table 17-2](#) shows which input of the corresponding IRQ\_CROSSBAR instance is mapped to its output (and then routed to the corresponding MPU\_INTC input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL\_CORE\_MPU\_IRQ\_y\_z register bit fields that are used to control the mapping of device interrupts to MPU\_INTC inputs. For example, the MPU\_IRQ\_4\_7[8:0] bit field is used to configure which device interrupt would be mapped to the MPU\_IRQ\_4 line. The reset value of this bit field is 0x1, meaning that ELM\_IRQ would be mapped to MPU\_IRQ\_4 by default because it is connected to the IRQ\_CROSSBAR\_1 input.

'N/A' in this column means that the corresponding interrupt is internal to the MPU subsystem. There is no IRQ\_CROSSBAR dedicated to the associated MPU\_INTC input line and therefore, the user cannot change its default mapping.

### 17.3.2 Interrupt Requests to DSP1\_INTC

[Table 17-3](#) lists the default interrupt sources for the DSP1\_INTC. In addition, interrupts DSP1\_IRQ\_32 through DSP1\_IRQ\_95 can alternatively be sourced through the DSP1's IRQ\_CROSSBAR from one of the 420 multiplexed device interrupts listed in [Table 17-9](#). The CTRL\_CORE\_DSP1\_IRQ\_y\_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

**Table 17-3. DSP1\_INTC Default Interrupt Mapping**

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
DSP1_IRQ_0	N/A	N/A	N/A	CGEM_IRQ_0	CGEM Internal Interrupt
DSP1_IRQ_1	N/A	N/A	N/A	CGEM_IRQ_1	CGEM Internal Interrupt

DSP1_IRQ_121	N/A	N/A	N/A	CGEM_IRQ_41	CGEM Internal Interrupt
DSP1_IRQ_122	N/A	N/A	N/A	CGEM_IRQ_42	CGEM Internal Interrupt

**Table 17-3. DSP1\_INTC Default Interrupt Mapping (continued)**

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
DSP1_IRQ_123	N/A	N/A	N/A	CGEM_IRQ_43	CGEM Internal Interrupt
DSP1_IRQ_124	N/A	N/A	N/A	CGEM_IRQ_44	CGEM Internal Interrupt
DSP1_IRQ_125	N/A	N/A	N/A	CGEM_IRQ_45	CGEM Internal Interrupt
DSP1_IRQ_126	N/A	N/A	N/A	CGEM_IRQ_46	CGEM Internal Interrupt
DSP1_IRQ_127	N/A	N/A	N/A	CGEM_IRQ_47	CGEM Internal Interrupt

**NOTE:** The "IRQ\_CROSSBAR Default Input Index" column of [Table 17-3](#) shows which input of the corresponding IRQ\_CROSSBAR instance is mapped to its output (and then routed to the corresponding DSP1\_INTC input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL\_CORE\_DSP1\_IRQ\_y\_z register bit fields that are used to control the mapping of device interrupts to DSP1\_INTC inputs. For example, the DSP1\_IRQ\_32\_33[8:0] bit field is used to configure which device interrupt would be mapped to the DSP1\_IRQ\_32 line. The reset value of this bit field is 0x1, meaning that ELM\_IRQ would be mapped to DSP1\_IRQ\_32 by default because it is connected to the IRQ\_CROSSBAR\_1 input.

'N/A' in this column means that the corresponding interrupt is internal to the DSP1 subsystem. There is no IRQ\_CROSSBAR dedicated to the associated DSP1\_INTC input line and therefore, the user cannot change its default mapping.

### 17.3.3 Interrupt Requests to DSP2\_INTC

[Table 17-4](#) lists the default interrupt sources for the DSP2\_INTC. In addition, interrupts DSP2\_IRQ\_32 through DSP2\_IRQ\_95 can alternatively be sourced through the DSP2's IRQ\_CROSSBAR from one of the 420 multiplexed device interrupts listed in [Table 17-9](#). The CTRL\_CORE\_DSP2\_IRQ\_y\_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

**Table 17-4. DSP2\_INTC Default Interrupt Mapping**

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
DSP2_IRQ_0	N/A	N/A	N/A	CGEM_IRQ_0	CGEM Internal Interrupt

DSP2_IRQ_127	N/A	N/A	N/A	CGEM_IRQ_47	CGEM Internal Interrupt

**NOTE:** The "IRQ\_CROSSBAR Default Input Index" column of [Table 17-4](#) shows which input of the corresponding IRQ\_CROSSBAR instance is mapped to its output (and then routed to the corresponding DSP2\_INTC input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL\_CORE\_DSP2\_IRQ\_y\_z register bit fields that are used to control the mapping of device interrupts to DSP2\_INTC inputs. For example, the DSP2\_IRQ\_32\_33[8:0] bit field is used to configure which device interrupt would be mapped to the DSP2\_IRQ\_32 line. The reset value of this bit field is 0x1, meaning that ELM\_IRQ would be mapped to DSP2\_IRQ\_32 by default because it is connected to the IRQ\_CROSSBAR\_1 input.

'N/A' in this column means that the corresponding interrupt is internal to the DSP2 subsystem. There is no IRQ\_CROSSBAR dedicated to the associated DSP2\_INTC input line and therefore, the user cannot change its default mapping.

### 17.3.4 Interrupt Requests to IPU1\_Cx\_INTC

[Table 17-5](#) lists the default interrupt sources for the IPU1\_Cx\_INTC. In addition, device interrupts IPU1\_IRQ\_23 through IPU1\_IRQ\_79 can alternatively be sourced through the IPU1's IRQ\_CROSSBAR from one of the 420 multiplexed device interrupts listed in [Table 17-9](#). The CTRL\_CORE\_IPU1\_IRQ\_y\_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

**Table 17-5. IPU1\_Cx\_INTC Default Interrupt Mapping**

IRQ Input Line <sup>(1)</sup>	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
IPU1_IRQ_0	N/A	N/A	N/A	Reserved	MSP initial value in exception vector table
IPU1_IRQ_1	N/A	N/A	N/A	RESET_IRQ	Reset
IPU1_IRQ_2	N/A	N/A	N/A	NMI_IRQ	External NMI input (interrupt from <b>nmin_dsp</b> device pad)

<sup>(1)</sup> This column shows the number of the corresponding exception type.

**Table 17-5. IPU1\_Cx\_INTC Default Interrupt Mapping (continued)**

IRQ Input Line <sup>(1)</sup>	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
IPU1_IRQ_3	N/A	N/A	N/A	HARD_FAULT_IRQ	All fault conditions, if the fault handle is not enabled
IPU1_IRQ_4	N/A	N/A	N/A	MEM_MANAGE_FAULT_IRQ	Memory management fault; access to illegal locations
IPU1_IRQ_5	N/A	N/A	N/A	BUS_FAULT_IRQ	Bus error (on AHB intf)
IPU1_IRQ_6	N/A	N/A	N/A	USAGE_FAULT_IRQ	Program error

IPU1_IRQ_78	56	<a href="#">CTRL_CORE_IPU1_IRQ_77_78</a> [24:16]	62	Reserved	Reserved by default but can be remapped to a valid interrupt source
IPU1_IRQ_79	57	<a href="#">CTRL_CORE_IPU1_IRQ_79_80</a> [8:0]	63	Reserved	Reserved by default but can be remapped to a valid interrupt source

**NOTE:** Exceptions/interrupts IPU1\_IRQ\_[15:0] are all internal to the Cortex-M4 core.

Exceptions/interrupts IPU1\_IRQ\_[79:16] are all external to the Cortex-M4 core – that is, the first Cortex-M4 external interrupt is mapped to IPU1\_IRQ\_16 (exception #16), and the last (sixty-fourth) Cortex-M4 external interrupt is mapped to IPU1\_IRQ\_79 (exception #79).

For more information about Cortex-M4 exception types, refer to Arm *Cortex®-M4 Devices Generic User Guide* (available at <http://infocenter.arm.com/help/index.jsp>).

**NOTE:** The "IRQ\_CROSSBAR Default Input Index" column of [Table 17-5](#) shows which input of the corresponding IRQ\_CROSSBAR instance is mapped to its output (and then routed to the corresponding IPU1\_Cx\_INTC input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL\_CORE\_IPU1\_IRQ\_y\_z register bit fields that are used to control the mapping of device interrupts to IPU1\_Cx\_INTC inputs. For example, the IPU1\_IRQ\_23\_24[8:0] bit field is used to configure which device interrupt would be mapped to the IPU1\_IRQ\_23 line. The reset value of this bit field is 0x14, meaning that DISPC\_IRQ would be mapped to IPU1\_IRQ\_23 by default because it is connected to the IRQ\_CROSSBAR\_20 input.

'N/A' in this column means that the corresponding interrupt is internal to the IPU1 subsystem. There is no IRQ\_CROSSBAR dedicated to the associated IPU1\_Cx\_INTC input line and therefore, the user cannot change its default mapping.

The CTRL\_CORE\_IPU1\_IRQ\_y\_z registers control the IRQ\_CROSSBAR settings for both NVICs in the IPU1 subsystem. That is, it is not possible to map different interrupts to the same interrupt input of the NVICs in IPU1.

### 17.3.5 Interrupt Requests to IPU2\_Cx\_INTC

[Table 17-6](#) lists the default interrupt sources for the IPU2\_Cx\_INTC. In addition, device interrupts IPU2\_IRQ\_23 through IPU2\_IRQ\_79 can alternatively be sourced through the IPU2's IRQ\_CROSSBAR from one of the 420 multiplexed device interrupts listed in [Table 17-9](#). The CTRL\_CORE\_IPU2\_IRQ\_y\_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

**Table 17-6. IPU2\_Cx\_INTC Default Interrupt Mapping**

IRQ Input Line <sup>(1)</sup>	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
IPU2_IRQ_0	N/A	N/A	N/A	Reserved	MSP initial value in exception vector table
IPU2_IRQ_1	N/A	N/A	N/A	RESET_IRQ	Reset
IPU2_IRQ_2	N/A	N/A	N/A	NMI_IRQ	External NMI input (interrupt from <b>nmin_dsp</b> device pad)
IPU2_IRQ_3	N/A	N/A	N/A	HARD_FAULT_IRQ	All fault conditions, if the fault handle is not enabled
IPU2_IRQ_4	N/A	N/A	N/A	MEM_MANAGE_FAULT_IRQ	Memory management fault; access to illegal locations
IPU2_IRQ_5	N/A	N/A	N/A	BUS_FAULT_IRQ	Bus error (on AHB intf)
IPU2_IRQ_6	N/A	N/A	N/A	USAGE_FAULT_IRQ	Program error

<sup>(1)</sup> This column shows the number of the corresponding exception type.

**Table 17-6. IPU2\_Cx\_INTC Default Interrupt Mapping (continued)**

IRQ Input Line <sup>(1)</sup>	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description

IPU2_IRQ_70	48	CTRL_CORE_IPU2_IRQ_69_70[24:16]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
IPU2_IRQ_71	49	CTRL_CORE_IPU2_IRQ_71_72[8:0]	119	Reserved	Reserved by default but can be remapped to a valid interrupt source
IPU2_IRQ_72	50	CTRL_CORE_IPU2_IRQ_71_72[24:16]	118	Reserved	Reserved by default but can be remapped to a valid interrupt source
IPU2_IRQ_73	51	CTRL_CORE_IPU2_IRQ_73_74[8:0]	72	USB1_IRQ_INTR1	USB1 interrupt 1
IPU2_IRQ_74	52	CTRL_CORE_IPU2_IRQ_73_74[24:16]	73	USB2_IRQ_INTR0	USB2 interrupt 0
IPU2_IRQ_75	53	CTRL_CORE_IPU2_IRQ_75_76[8:0]	117	Reserved	Reserved by default but can be remapped to a valid interrupt source
IPU2_IRQ_76	54	CTRL_CORE_IPU2_IRQ_75_76[24:16]	87	USB2_IRQ_INTR1	USB2 interrupt 1
IPU2_IRQ_77	55	CTRL_CORE_IPU2_IRQ_77_78[8:0]	88	USB3_IRQ_INTR0	USB3 interrupt 0
IPU2_IRQ_78	56	CTRL_CORE_IPU2_IRQ_77_78[24:16]	62	Reserved	Reserved by default but can be remapped to a valid interrupt source
IPU2_IRQ_79	57	CTRL_CORE_IPU2_IRQ_79_80[8:0]	63	Reserved	Reserved by default but can be remapped to a valid interrupt source

**NOTE:** Exceptions/interrupts IPU2\_IRQ\_[15:0] are all internal to the Cortex-M4 core.

Exceptions/interrupts IPU2\_IRQ\_[79:16] are all external to the Cortex-M4 core – that is, the first Cortex-M4 external interrupt is mapped to IPU2\_IRQ\_16 (exception #16), and the last (sixty-fourth) Cortex-M4 external interrupt is mapped to IPU2\_IRQ\_79 (exception #79).

For more information about Cortex-M4 exception types, refer to Arm *Cortex®-M4 Devices Generic User Guide* (available at <http://infocenter.arm.com/help/index.jsp>).

**NOTE:** The "IRQ\_CROSSBAR Default Input Index" column of [Table 17-6](#) shows which input of the corresponding IRQ\_CROSSBAR instance is mapped to its output (and then routed to the corresponding IPU2\_Cx\_INTC input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL\_CORE\_IPU2\_IRQ\_y\_z register bit fields that are used to control the mapping of device interrupts to IPU2\_Cx\_INTC inputs. For example, the IPU2\_IRQ\_23\_24[8:0] bit field is used to configure which device interrupt would be mapped to the IPU2\_IRQ\_23 line. The reset value of this bit field is 0x14, meaning that DISPC\_IRQ would be mapped to IPU2\_IRQ\_23 by default because it is connected to the IRQ\_CROSSBAR\_20 input.

'N/A' in this column means that the corresponding interrupt is internal to the IPU2 subsystem. There is no IRQ\_CROSSBAR dedicated to the associated IPU2\_Cx\_INTC input line and therefore, the user cannot change its default mapping.

The CTRL\_CORE\_IPU2\_IRQ\_y\_z registers control the IRQ\_CROSSBAR settings for both NVICs in the IPU2 subsystem. That is, it is not possible to map different interrupts to the same interrupt input of the NVICs in IPU2.

### 17.3.6 Interrupt Requests to EVE1\_INTC1

[Table 17-7](#) lists the default interrupt sources for the EVE1\_INTC1. In addition, device interrupts EVE1\_IRQ\_0 through EVE1\_IRQ\_7 can alternatively be sourced through the EVE1's IRQ\_CROSSBAR from one of the 420 multiplexed device interrupts listed in [Table 17-9](#). The CTRL\_CORE\_EVE1\_IRQ\_y\_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

**Table 17-7. EVE1\_INTC1 Default Interrupt Mapping**

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
EVE1_IRQ_0	1	<a href="#">CTRL_CORE_EVE1_IRQ_0_1</a> [8:0]	1	ELM_IRQ	Error location process completion interrupt
EVE1_IRQ_1	2	<a href="#">CTRL_CORE_EVE1_IRQ_0_1</a> [24:16]	2	EXT_SYS_IRQ_1	External interrupt (active low) via sys_nirq1 pin

EVE1_IRQ_31	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source

**NOTE:** The "IRQ\_CROSSBAR Default Input Index" column of [Table 17-7](#) shows which input of the corresponding IRQ\_CROSSBAR instance is mapped to its output (and then routed to the corresponding EVE1\_INTC input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL\_CORE\_EVE1\_IRQ\_y\_z register bit fields that are used to control the mapping of device interrupts to EVE1\_INTC inputs. For example, the EVE1\_IRQ\_0\_1[8:0] bit field is used to configure which device interrupt would be mapped to the EVE1\_IRQ\_0 line. The reset value of this bit field is 0x1, meaning that ELM\_IRQ would be mapped to EVE1\_IRQ\_0 by default because it is connected to the IRQ\_CROSSBAR\_1 input.

'N/A' in this column means that the corresponding interrupt is internal to the EVE1 subsystem. There is no IRQ\_CROSSBAR dedicated to the associated EVE1\_INTC input line and therefore, the user cannot change its default mapping.

### 17.3.7 Interrupt Requests to EVE2\_INTC1

[Table 17-8](#) lists the default interrupt sources for the EVE2\_INTC1. In addition, device interrupts EVE2\_IRQ\_0 through EVE2\_IRQ\_7 can alternatively be sourced through the EVE2's IRQ\_CROSSBAR from one of the 420 multiplexed device interrupts listed in [Table 17-9](#). The CTRL\_CORE\_EVE2\_IRQ\_y\_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

**Table 17-8. EVE2\_INTC1 Default Interrupt Mapping**

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
EVE2_IRQ_0	1	<a href="#">CTRL_CORE_EVE2_IRQ_0_1[8:0]</a>	1	ELM_IRQ	Error location process completion interrupt
EVE2_IRQ_1	2	<a href="#">CTRL_CORE_EVE2_IRQ_0_1[24:16]</a>	2	EXT_SYS_IRQ_1	External interrupt (active low) via sys_nirq1 pin
EVE2_IRQ_2	3	<a href="#">CTRL_CORE_EVE2_IRQ_2_3[8:0]</a>	3	CTRL_MODULE_CORE_IRQ_SEC_EVTS	Combined firewall error interrupt. For more information, see <a href="#">Section 18.4.6.14.3</a> .
EVE2_IRQ_3	4	<a href="#">CTRL_CORE_EVE2_IRQ_2_3[24:16]</a>	4	L3_MAIN_IRQ_DBG_ERR	L3_MAIN debug error
EVE2_IRQ_4	5	<a href="#">CTRL_CORE_EVE2_IRQ_4_5[8:0]</a>	5	L3_MAIN_IRQ_APP_ERR	L3_MAIN application or non-attributable error
EVE2_IRQ_5	6	<a href="#">CTRL_CORE_EVE2_IRQ_4_5[24:16]</a>	6	PRM_IRQ_MPU	PRCM interrupt to MPU
EVE2_IRQ_6	7	<a href="#">CTRL_CORE_EVE2_IRQ_6_7[8:0]</a>	7	DMA_SYSTEM_IRQ_0	System DMA interrupt 0
EVE2_IRQ_7	8	<a href="#">CTRL_CORE_EVE2_IRQ_6_7[24:16]</a>	8	DMA_SYSTEM_IRQ_1	System DMA interrupt 1
EVE2_IRQ_8	N/A	N/A	N/A	EVE1_GP1	EVE1 GP1 interrupt
EVE2_IRQ_9	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE2_IRQ_10	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE2_IRQ_11	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE2_IRQ_12	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE2_IRQ_13	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE2_IRQ_14	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE2_IRQ_15	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source

**Table 17-8. EVE2\_INTC1 Default Interrupt Mapping (continued)**

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
EVE2_IRQ_16	N/A	N/A	N/A	EVE1_MBX2_INT1	EVE1 Mailbox 2 Interrupt 1
EVE2_IRQ_17	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE2_IRQ_18	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE2_IRQ_19	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source

EVE2_IRQ_21	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE2_IRQ_22	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE2_IRQ_23	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE2_IRQ_24	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE2_IRQ_25	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE2_IRQ_26	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE2_IRQ_27	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE2_IRQ_28	N/A	N/A	N/A	EVE2_MBX2_INT0	EVE2 Mailbox 2 Interrupt 0
EVE2_IRQ_29	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE2_IRQ_30	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE2_IRQ_31	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source

**NOTE:** The "IRQ\_CROSSBAR Default Input Index" column of [Table 17-8](#) shows which input of the corresponding IRQ\_CROSSBAR instance is mapped to its output (and then routed to the corresponding EVE2\_INTC input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL\_CORE\_EVE2\_IRQ\_y\_z register bit fields that are used to control the mapping of device interrupts to EVE2\_INTC inputs. For example, the EVE2\_IRQ\_0\_1[8:0] bit field is used to configure which device interrupt would be mapped to the EVE2\_IRQ\_0 line. The reset value of this bit field is 0x1, meaning that ELM\_IRQ would be mapped to EVE2\_IRQ\_0 by default because it is connected to the IRQ\_CROSSBAR\_1 input.

'N/A' in this column means that the corresponding interrupt is internal to the EVE2 subsystem. There is no IRQ\_CROSSBAR dedicated to the associated EVE2\_INTC input line and therefore, the user cannot change its default mapping.

### 17.3.8 Mapping of Device Interrupts to IRQ\_CROSSBAR Inputs

[Table 17-9](#) shows the individual connection between all module IRQs and all IRQ\_CROSSBAR inputs.

**Table 17-9. Connection of Device IRQs to IRQ\_CROSSBAR Inputs**

IRQ_CROSSBAR Input	Interrupt Name	Interrupt Source	Description
IRQ_CROSSBAR_0	Reserved	Reserved	Reserved
IRQ_CROSSBAR_1	ELM_IRQ	ELM	Error location process completion interrupt
IRQ_CROSSBAR_2	EXT_SYS_IRQ_1	External system	External interrupt (active low) via sys_nirq1 pin
IRQ_CROSSBAR_3	CTRL_MODULE_CORE_IRQ_SEC_EVTS	CTRL_MODULE_CORE	Combined firewall error interrupt. For more information, see <a href="#">Section 18.4.6.14.3</a>
IRQ_CROSSBAR_4	L3_MAIN_IRQ_DBG_ERR	L3_MAIN	L3_MAIN debug error
IRQ_CROSSBAR_5	L3_MAIN_IRQ_APP_ERR	L3_MAIN	L3_MAIN application or non-attributable error
IRQ_CROSSBAR_6	PRM_IRQ_MPU	PRM	PRCM interrupt to MPU
IRQ_CROSSBAR_7	DMA_SYSTEM_IRQ_0	DMA_SYSTEM	System DMA interrupt 0
IRQ_CROSSBAR_8	DMA_SYSTEM_IRQ_1	DMA_SYSTEM	System DMA interrupt 1
IRQ_CROSSBAR_9	DMA_SYSTEM_IRQ_2	DMA_SYSTEM	System DMA interrupt 2
IRQ_CROSSBAR_10	DMA_SYSTEM_IRQ_3	DMA_SYSTEM	System DMA interrupt 3
IRQ_CROSSBAR_11	L3_MAIN_IRQ_STAT_ALARM	L3_MAIN	L3_MAIN statistic collector alarm interrupt
IRQ_CROSSBAR_12	Reserved	Reserved	Reserved
IRQ_CROSSBAR_13	Reserved	Reserved	Reserved
IRQ_CROSSBAR_14	Reserved	Reserved	Reserved
IRQ_CROSSBAR_15	GPMC_IRQ	GPMC	GPMC interrupt
IRQ_CROSSBAR_16	GPU_IRQ	GPU	GPU interrupt
IRQ_CROSSBAR_17	Reserved	Reserved	Reserved
IRQ_CROSSBAR_18	Reserved	Reserved	Reserved
IRQ_CROSSBAR_19	Reserved	Reserved	Reserved

## 18.1 Control Module Overview

The control module allows software control of the various operation modes supported by the device. It is composed of two submodules. The CTRL\_MODULE\_CORE submodule which resides in the COREAON power domain and the CTRL\_MODULE\_WKUP submodule which resides in the WKUPAON power domain. These two submodules represent a set of registers which are used to control the device I/O ports and also various kinds of settings related to the different device operation modes and also to its internal modules.

The CTRL\_MODULE\_CORE submodule has registers for the following features:

- Pad configuration with following controls:
  - Pad I/O multiplexing
  - Pad pullup and pulldown configuration
  - Pad wake-up detection enabling
  - Pad wake-up event status
  - Pad input buffer enable
  - Pad slew rate control
- Device thermal management control and status registers
- PBIAS cell and MMC1 I/O cells control
- IRQ\_CROSSBAR and DMA\_CROSSBAR control
- Control the priority of initiator accesses to the external SDRAM
- Control the priority of initiators connected to L3\_MAIN interconnect
- Memory region lock registers
- Mapping of the device non-maskable interrupt (NMI) to respective cores
- Controls for the DDR2/DDR3 I/O Cells
- Controls for the DDR2/DDR3 associated vref-generation cells
- AVS Class 0 associated registers
- ABB associated registers
- PCIe related registers
- Standard eFuse logic
- Other miscellaneous functions:
  - Status of the system boot settings
  - DSP1 and DSP2 reset vector address
  - Settings associated with USB, SATA, and HDMI PHYs
  - DSS PLLs multiplexing and enabling
  - Force MPU write nonposted transactions
  - Firewalls error status
  - Settings related to different peripheral modules
  - Others

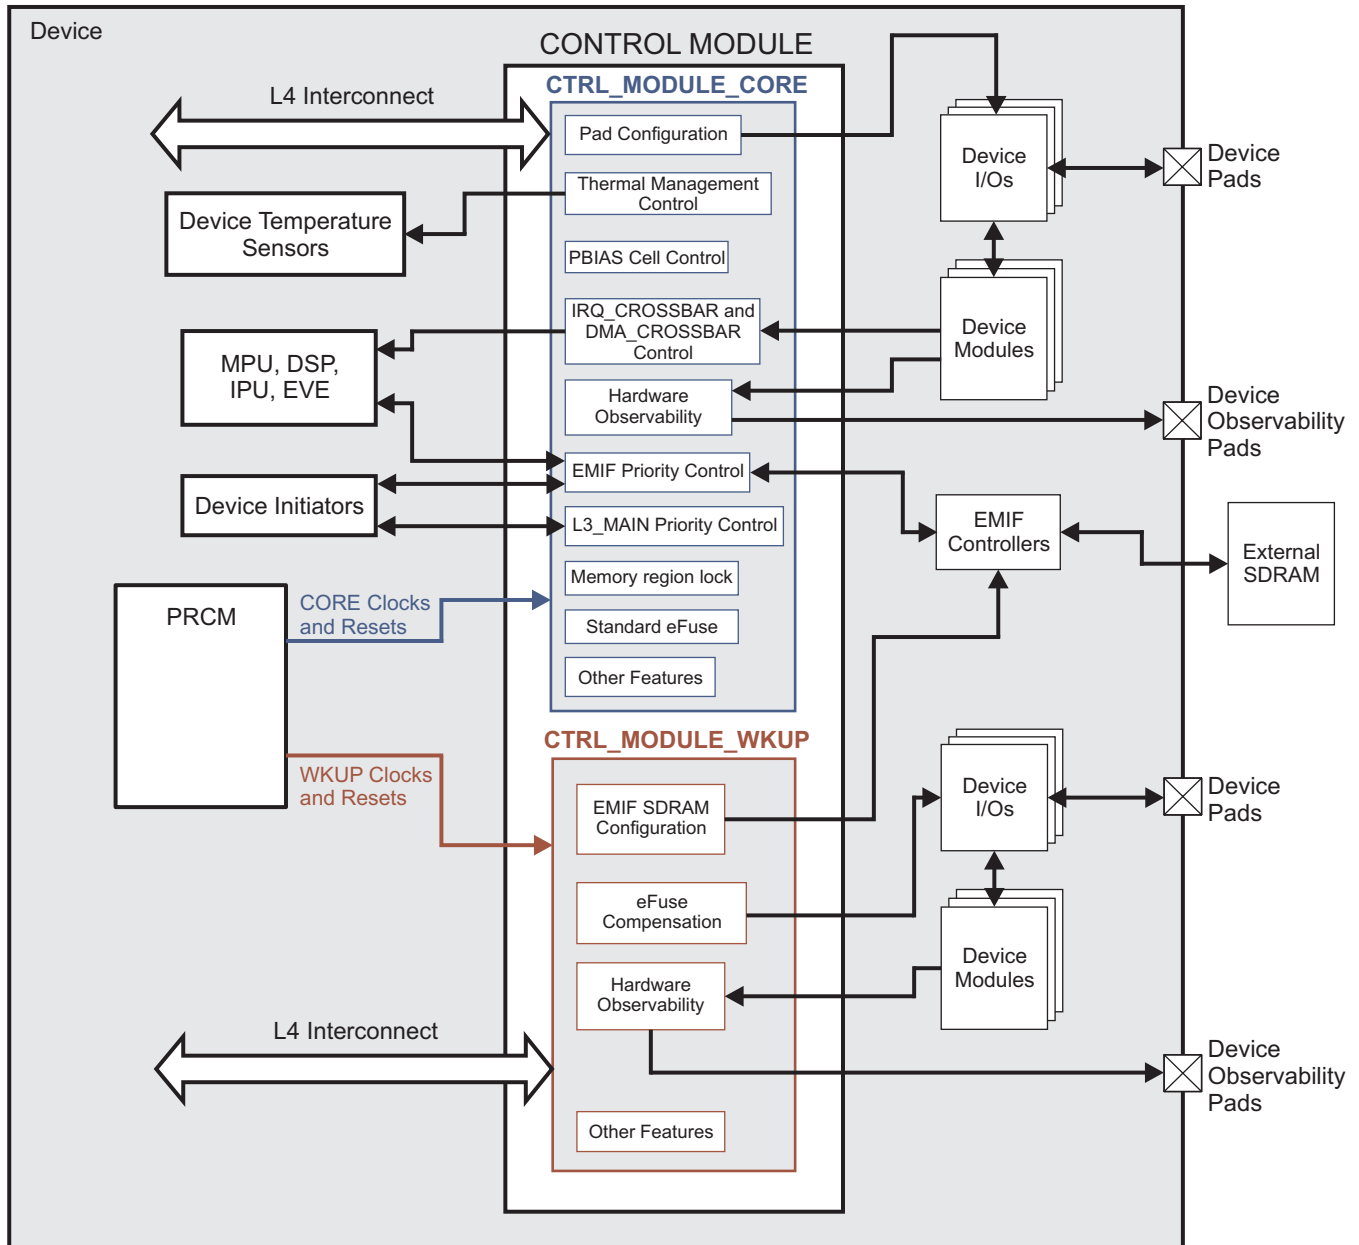

The CTRL\_MODULE\_WKUP submodule has registers for the following features:

- Basic EMIF configuration settings
- XTAL Oscillator control
- Efuse I/O compensation
- Other functions

[Figure 18-1](#) represents an overview block diagram of the control module.

Figure 18-1. Control Module Overview Block Diagram

ctrlmod-001

## 18.2 Control Module Environment

One of the control module functions is to control the multiplexing of certain signals from the device internal modules. Using the correct pad configuration settings, the control module maps these observability lines to the device boundary and a set of user selected internal module signals are available to be observed on the device pads. In addition, there are also two lines intended for observation of any of the device interrupt requests connected to the inputs of the IRQ\_CROSSBAR module and two lines intended for observation of any of the DMA requests connected to the inputs of the DMA\_CROSSBAR module. For more information, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#) and [Section 18.4.6.5, DMA\\_CROSSBAR Module Functional Description](#).

An external non-maskable interrupt signal is also present. Using the appropriate registers the NMI can be mapped to different device cores. For more information, see [Section 18.4.6.9, NMI Mapping to respective cores](#).

Figure 18-2 is an overview of the control module environment.

**Figure 18-2. Control Module Environment**

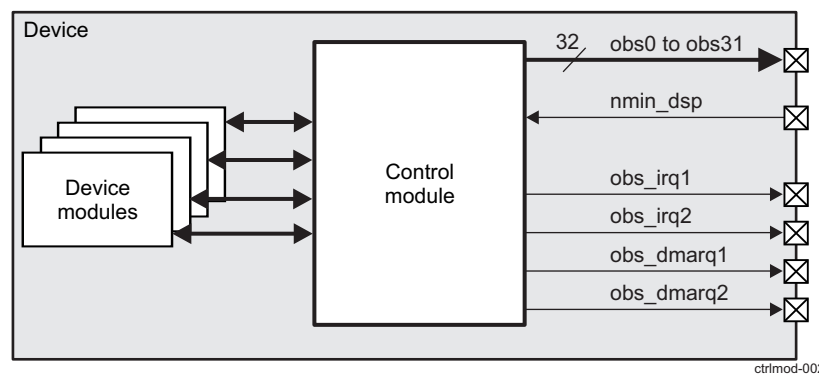

Table 18-1 shows the NMI input signal and observability outputs used to observe different signals of the device modules.

**Table 18-1. Control Module I/O Description**

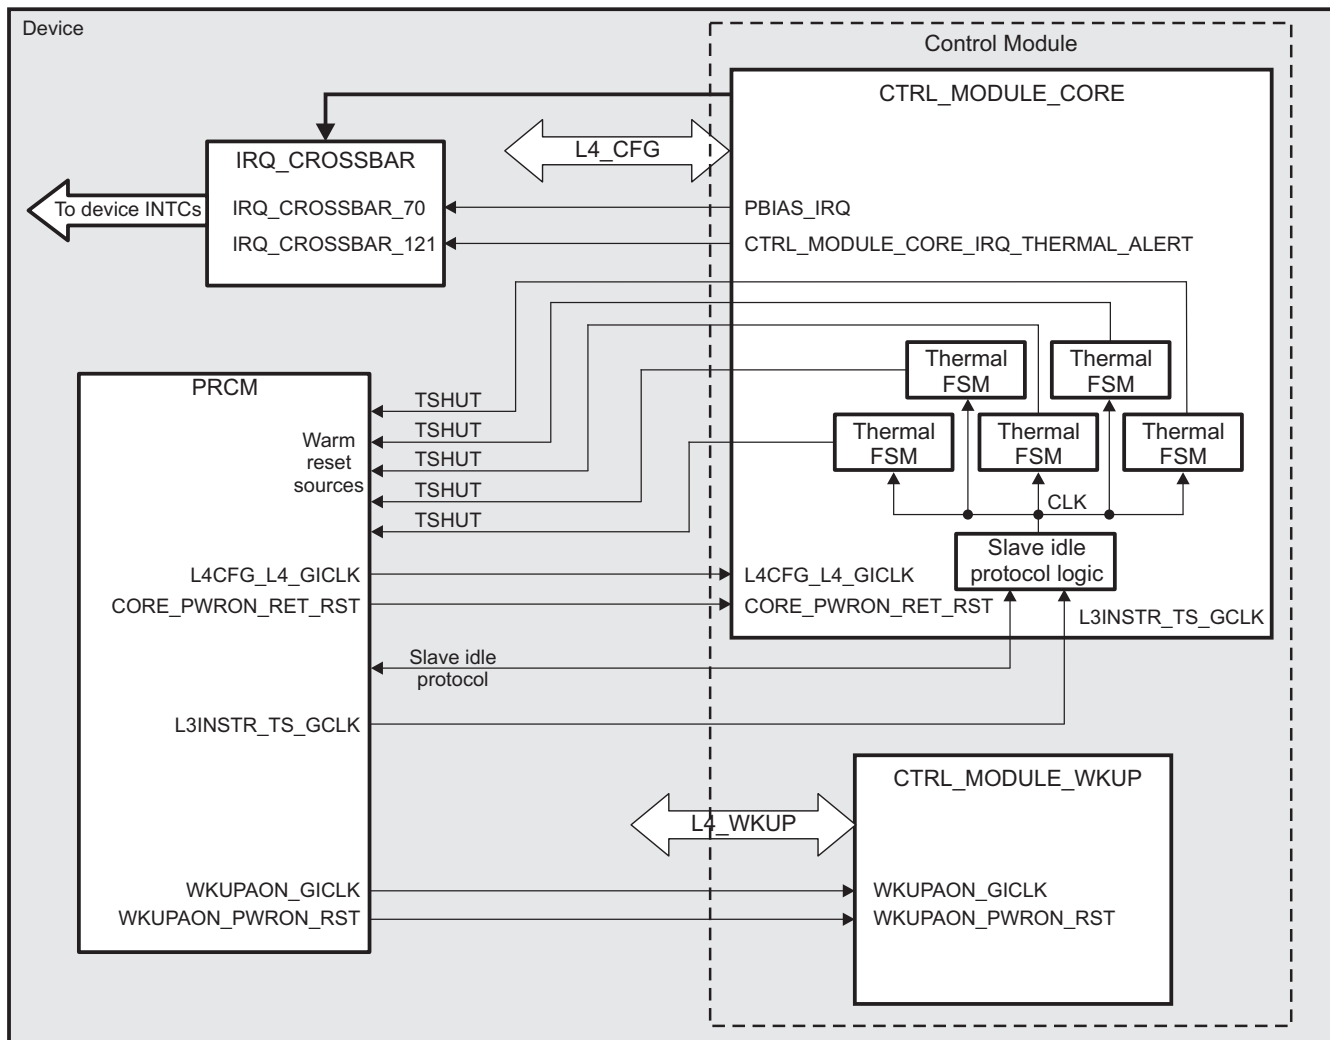

Signal	I/O <sup>(1)</sup>	Description
obs[31:0]	O	32 internal hardware observability signals
nmin_dsp	I	External non-maskable interrupt signal
obs_irq1	O	Two signals intended for IRQ observation
obs_irq2	O	
obs_dmarq1	O	Two signals intended for DREQ observation
obs_dmarq2	O	

<sup>(1)</sup> I = Input; O = Output; I/O = Bidirectional

### 18.3 Control Module Integration

Figure 18-3 shows the integration of the control module in the device.

Figure 18-3. Control Module Integration

ctrlmod-003

Table 18-2 through Table 18-4 summarize the integration of the Control Module in the device.

Table 18-2. Control Module Integration Attributes

Submodule	Attributes	
	Power Domain	Interconnect
CTRL_MODULE_CORE	PD_COREAON	L4_CFG
CTRL_MODULE_WKUP	PD_WKUPAON	L4_WKUP

Table 18-3. Control Module Clocks and Resets

Clocks				
Submodule	Destination Signal Name	Source Signal Name	Source	Description

**Table 18-3. Control Module Clocks and Resets (continued)**

CTRL_MODULE_CORE	L4CFG_L4_GICKL	L4CFG_L4_GICKL	PRCM	Interface clock to the CTRL_MODULE_CORE submodule
	L3INSTR_TS_GCLK	L3INSTR_TS_GCLK	PRCM	Common functional clock for the five thermal FSMs instantiated in the CTRL_MODULE_CORE submodule
CTRL_MODULE_WKUP	WKUPAON_GICKL	WKUPAON_GICKL	PRCM	Interface clock to the CTRL_MODULE_WKUP submodule
<b>Resets</b>				
CTRL_MODULE_CORE	CORE_PWRON_RST	CORE_PWRON_RST	PRCM	Internal power-on reset (POR) affecting the CTRL_MODULE_CORE submodule
CTRL_MODULE_WKUP	WKUPAON_PWRON_RST	WKUPAON_PWRON_RST	PRCM	Internal POR affecting the CTRL_MODULE_WKUP submodule

**Table 18-4. Control Module Hardware Requests**

Submodule	Source Signal Name	Interrupt Requests		Description
		Destination IRQ_CROSSBAR Input	Default Mapping	
CTRL_MODULE_CORE	PBIAS_IRQ	IRQ_CROSSBAR_70	MPU_IRQ_75	Interrupt signal generated by the PBIAS cell when the MMC1 I/Os supply voltage is not equal to the bias voltage generated by the PBIAS cell
	CTRL_MODULE_CORE_IRQ_THERMAL_ALERT	IRQ_CROSSBAR_121	MPU_IRQ_126	Thermal alert interrupt signal generated when one of the five thermal sensors goes over the temperature threshold value

**NOTE:** The “Default Mapping” column in [Table 18-4 Control Module Hardware Requests](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ\_CROSSBAR module.

For more information about the IRQ\_CROSSBAR module, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#).

For more information about the device interrupt controllers, see [Chapter 17, Interrupt Controllers](#).

The integration of the control module is the following:

- No wake-up request generation
- No DMA request generation
- No master standby protocol with the PRCM
- Slave idle protocol, between the CTRL\_MODULE\_CORE submodule and the PRCM, related only to the L3INSTR\_TS\_GCLK
- One interrupt request to the IRQ\_CROSSBAR module
- Five (thermal shutdown) TSHUT signals used as PRCM warm reset sources
- Two clocks and one reset signal to the CTRL\_MODULE\_CORE submodule
- One clock and one reset signal to the CTRL\_MODULE\_WKUP submodule

## 18.4 Control Module Functional Description

### 18.4.1 Control Module Clock Configuration

There is no software control over the L4CFG\_L4\_GICKL and WKUPAON\_GICKL clocks neither in the control module nor in the PRCM module. The L4CFG\_L4\_GICKL clock is automatically gated when there is no access to the CTRL\_MODULE\_CORE registers and the WKUPAON\_GICKL is automatically gated when there is no access to the CTRL\_MODULE\_WKUP registers. There are clock activity status bits for these two clocks in the PRCM module.

The L3INSTR\_TS\_GCLK is controlled by the CTRL\_CORE\_BANDGAP\_MASK\_1[31:30] SIDLEMODE bit field. For more information, see [Section 18.4.6.2.5](#).

The L3INSTR\_TS\_GCLK has also the following software controls located in the PRCM module:

- Status: see [Chapter 3, Power, Reset, and Clock Management](#)
- Divider ratio: see [Chapter 3, Power, Reset, and Clock Management](#)

### 18.4.2 Control Module Resets

The control module is not sensitive to software reset. It does not respond to global warm reset too. The control module is reset only by the internal POR (global cold reset).

Despite the previously stated that control module is not sensitive to global warm reset all CTRL\_CORE\_PAD\_x registers are exception of this rule and are sensitive to global warm reset. All other control module registers are sensitive only to global cold reset.

The PRCM provides the CORE\_PWRON\_RET\_RST POR signal to the CTRL\_MODULE\_CORE and the WKUPAON\_PWRON\_RST POR signal to the CTRL\_MODULE\_WKUP. For more information, see [Section 3.5.5, Reset Domains](#), in [Chapter 3, Power, Reset, and Clock Management](#).

### 18.4.3 Control Module Power Management

#### 18.4.3.1 Power Management Protocols

The control module, which is slave on the L4 interconnect, does not support master standby or slave idle protocols for handshaking with the PRCM. Only the five thermal FSMs support slave idle protocol used to control their common functional clock, that is the L3INSTR\_TS\_GCLK clock.

### 18.4.4 Hardware Requests

The control module does not generate DMA and wake-up requests. The CTRL\_MODULE\_CORE submodule generates only two IRQs to the IRQ\_CROSSBAR module. The first one is the PBIAS\_IRQ and the second one is the CTRL\_MODULE\_CORE\_IRQ\_THERMAL\_ALERT. For more information, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#).

### 18.4.5 Control Module Initialization

The control module responds to the internal POR. During device initialization, only modules used at boot time are associated with the pads. Other module inputs are internally tied and output buffers are turned off. After POR, software must set the pad configuration registers to appropriate values according to the desired device configuration.

The CTRL\_CORE\_BOOTSTRAP[15:0] bit field reflects the state of the sysboot[15:0] pads captured at POR in the PRCM module.

### 18.4.6 Functional Description Of The Various Register Types In CTRL\_MODULE\_CORE Submodule

The following sections describe in detail the purpose of the various kinds of registers and register groups which reside in the CTRL\_MODULE\_CORE submodule.

### 18.4.6.1 Pad Configuration

#### 18.4.6.1.1 Pad Configuration Registers

The pad configuration registers are used to configure most of the device pads. Each pad configuration register is associated only with one pad. The name of each register is formed by the corresponding pad name and the prefix "CTRL\_CORE\_PAD\_". Almost all pad configuration registers have same bits. In some of these registers certain bits cannot be present. Figure 18-4 shows the general case in which all the pad configuration register bits are present. Table 18-5 describes these bits.

After POR, software must set the pad configuration registers to appropriate values depending on the desired device configuration. Configuration of the pad configuration registers is normally done as part of the IO delay recalibration sequence described in Section 18.4.6.1.8, *IO Delay Recalibration*.

**Figure 18-4. Pad Configuration Register Bits**

ctrlmod-005

**Table 18-5. Description Of The Pad Configuration Register Bits**

Bit/Bit Field	Bit Meaning		Description
	0b0	0b1	
WAKEUPEVENT	Wake-up event is not detected	Wake-up event is detected	Wake-up event status for a given pad. Indicates whenever the pad state is changed (0->1 or 1->0). In addition, when a wake-up event from a given I/O cell is received, the PRCM will wake up the MPU by switching-on its power domain and clocks and then generating an interrupt.
WAKEUPENABLE	Disable I/O wake-up function	Enable I/O wake-up function	Enables wake-up detection on input
SLEWCONTROL	Fast slew is selected	Slow slew is selected	Selects the slew rate for a given pad. The slew rate should be set to the value specified in the device Data Manual for a given mode of operation.
INPUTENABLE <sup>(1)</sup>	Receive mode is disabled. The pad is configured in output mode only.	Receive mode is enabled. The pad is configured in bidirectional mode.	Enables the input buffer of a given I/O
PULLTYPESELECT	Weak pull-down resistor is selected	Weak pull-up resistor is selected	Weak pull-up or weak pull-down resistor selection for a given pad
PULLUDENABLE	Weak pull-up/pull-down resistor is enabled	Weak pull-up/pull-down resistor is disabled	Enables weak pull-up/pull-down feature of a given pad
MODESELECT	Default IO Timing Mode is used	A Virtual or Manual IO Timing Mode is used.	Selects between the Default IO Timing Mode and a Virtual or Manual IO Timing Mode. Refer to the device Data Manual for definition of the required settings for a given mode of operation. When this bit is 0b1, a Virtual IO Timing Mode can be selected via the DELAYMODE field of this register, as described in Section 18.4.6.1.5, <i>Virtual IO Timing Modes</i> . Manual IO Timing Modes are selected via the procedure described in Section 18.4.6.1.6, <i>Manual IO Timing Modes</i> .

<sup>(1)</sup> To enable/disable the input buffers of the mmc1\_\* pads the ACTIVE bits of the corresponding CTRL\_CORE\_PAD\_x registers are used. These registers have ACTIVE bits instead of INPUTENABLE bits.

**Table 18-5. Description Of The Pad Configuration Register Bits (continued)**

Bit/Bit Field	Bit Meaning		Description
	0b0	0b1	
DELAYMODE	This bit field selects the Virtual Timing Mode used when the MODESELECT bit is set to 0b1. See <a href="#">Section 18.4.6.1.5, Virtual IO Timing Modes</a> for details.		
MUXMODE	This bit field selects the desired Multiplexing Mode for the pad. See section “ <i>Multiplexing Characteristics</i> ” of the Data Manual for a list of available functions for each pad.		

---

**NOTE:** The default SLEWCONTROL settings in each pad configuration register must be used to guarantee timings, unless specific instructions otherwise are given in the individual timing sub-sections of the device Data Manual. The only exception is when the MUXMODE is configured to select a vout\*\_\* signal. In this case the corresponding SLEWCONTROL bit is recommended to be set to slow slew instead of the default fast slew. FAST slew setting is allowed, but results in faster edge rates on the VOUTn bus, higher power/ground noise, and higher EMI emissions compared to SLOW slew rate.

---

**NOTE:** It must be taken into account that when an external pull resistor is desired, the internal pull resistors must be disabled by software because they are enabled by default.

---

**NOTE:** GPIO pins can directly snoop device pads even if those are configured in the other modes. For GPIO output user needs to set pad mux.

---

The following signals require CTRL\_CORE\_PAD\_x to be programmed with INPUTENABLE=1 for retiming purposes:

- mmc2\_clk, mmc3\_clk, and mmc4\_clk
- gpmc\_clk
- i2cj\_scl where j=1-5
- spim\_sclk where m=1-4
- mcaspi\_aclcx, mcaspi\_ahclkx and mcaspi\_aclkr signals where i=1-8

#### 18.4.6.1.1.1 Permanent PU/PD disabling (SR 2.0 only)

This section applies only to SR2.0.

The internal pull resistors of pads gpmc\_a[27:24, 22:19] can be permanently disabled by pulling sysboot15 high during power-on-reset deassertion. When sysboot15 = 1, the corresponding PULLUDENABLE bit does not apply anymore. In this case it is a don't care bit whatever value set. This functionality is intended to be used when mmc2\_dat\* signals are configured on the gpmc\_a[27:24, 22:19] pads. In this case, if sysboot15 = 1, external pull-up resistors with values as per JEDEC eMMC specification (JESD84-B451) must be connected to these pads. If gpmc\_a[27:24, 22:19] are connected to non-multiplexed NOR flash used for booting and sysboot15 = 1, external pull-down resistors are mandatory on these pads otherwise boot is not possible. During NOR flash run-time accesses the external pull-down resistors are not needed.

#### 18.4.6.1.2 Pull Selection

There is no automatic gating control to ensure that internal weak pull-up or pull-down resistors on a pad are disconnected whenever pad is configured as output. If a pad is always configured in output mode, it is recommended for user software to disable any internal pull resistor tied to it to avoid unnecessary consumption.

[Table 18-6](#) describes the software controls available for pad internal pull-up and pull-down resistors in the control module pad configuration registers.

**Table 18-6. Pull Selection**

PULL		Pad Behavior
PULLTYPESELECT	PULLUDENABLE	
0	1	Pull-down selected but not activated
0	0	Pull-down selected and activated
1	1	Pull-up selected but not activated
1	0	Pull-up selected and activated

### 18.4.6.1.3 Pad multiplexing

Many of the Device pads support pad multiplexing. This means that their function can be independently chosen from two or more options. The selection of functions available on each pad is enumerated in the “*Multiplexing Characteristics*” section of the Data Manual. The desired function is selected via the MUXMODE field of the associated pad configuration register.

By default, the MUXMODE field of most device pads is set to 0xF, which means the pads are in Hi-Z. Only MUXMODE values which correspond to defined functions should be used.

---

**NOTE:** When setting the MUXMODE of any mmc1\_\* pad, the following register fields should also be programmed:

- [CTRL\\_CORE\\_CONTROL\\_PBIAS\[27\]](#) SDCARD\_BIAS\_PWRDNZ = 1
  - [CTRL\\_CORE\\_CONTROL\\_PBIAS\[26\]](#) SDCARD\_IO\_PWRDNZ = 1
  - If MUXMODE=0 is not selected, configure [CTRL\\_CORE\\_CONTROL\\_PBIAS\[21\]](#) SDCARD\_BIAS\_VMODE
    - Clear to 0 if vddshv8 = 1.8V
    - Set to 1 if vddshv8 = 3.3V
- 

### 18.4.6.1.4 IOSETs

An IO signal may have multiplexing options across two or more device pads. In many cases, the user is allowed to select any combination of IO signal multiplexing options to use for an interface. But in some cases, specific combinations of multiplexing options must be selected to guarantee the Timing and Switching Characteristics in the *Data Manual*. These specific combinations are called IOSETs, and they generally represent layout-friendly groups of pads that are pinned-out in close proximity to each other. IOSETs are defined in the Data Manual for interfaces that require them.

### 18.4.6.1.5 Virtual IO Timing Modes

When operating a pad in certain modes, a Virtual IO Timing Mode must be selected to ensure that IO timings are met. The modes requiring Virtual IO Timing Modes are described in *Virtual Functions Mapping* tables within the “*Timing Requirements and Switching Characteristics*” section of the Data Manual. These tables list each pad associated with a specific Virtual IO Timing Mode, along with the DELAYMODE setting required for that pad.

To select a Virtual IO Timing Mode, both the MODESELECT field of each associated pad configuration register must be set to 0b1 and DELAYMODE field of each associated pad configuration register must be set to match the *Virtual Function Mapping* tables in the Data Manual.

Selection of all Virtual IO Timings Modes should be done as part of the IO Delay Recalibration Sequence described in [Section 18.4.6.1.8, IO Delay Recalibration](#).

### 18.4.6.1.6 Manual IO Timing Modes

When operating a pad in certain modes, a Manual IO Timing Mode must be configured to ensure that IO timings are met. The modes requiring Manual IO Timing Modes are described in *Manual Functions Mapping* tables within the “*Timing Requirements and Switching Characteristics*” section of the Data Manual. These tables list each pad associated with a specific Manual IO Timing Mode, along with the required A\_DELAY and G\_DELAY values that should be used to calculate the correct values to be set in the CFG\_x\_IN, CFG\_x\_OEN, and CFG\_x\_OUT registers associated with that pad. For more information regarding these registers, see [Section 18.7, IODELAYCONFIG Module Register Manual](#)

To select a Manual IO Timing Mode, the MODESELECT field of each associated pad configuration register must be set to 0b1 and the associated CFG\_x\_IN, CFG\_x\_OEN, and CFG\_x\_OUT registers should be set via the following sequence:

1. Compute CDPE and FPDE based on the following equations using values from the IODELAYCONFIG module registers (the register values must be converted to decimal before calculating):

$$CDPE = \frac{10 * (CONFIG\_REG\_3[15:0] \text{ COARSE\_REF\_COUNT} * CONFIG\_REG\_2[15:0] \text{ REFCLK\_PERIOD})}{2 * (CONFIG\_REG\_3[31:16] \text{ COARSE\_DELAY\_COUNT} * 88)}$$

$$FDPE = \frac{10 * (CONFIG\_REG\_4[15:0] \text{ FINE\_REF\_COUNT} * CONFIG\_REG\_2[15:0] \text{ REFCLK\_PERIOD})}{2 * (CONFIG\_REG\_4[31:16] \text{ FINE\_DELAY\_COUNT} * 264)}$$

ctrlmod-014

2. For each pad that requires a Manual IO Timing Mode, perform the following setups to calculate the values required to be programmed into each of the associated CFG\_x\_IN, CFG\_x\_OEN, and CFG\_x\_OUT IODELAYCONFIG module registers:

- a. Calculate the Coarse Values and Fine Values corresponding to the A\_DELAY and G\_DELAY values listed in the Data Manual for the associated Manual IO Timing Mode as follows:

$$G\_DELAY\_COARSE = \text{floor}\left(\frac{G\_DELAY}{920}\right)$$

$$G\_DELAY\_FINE = \frac{\text{floor}(G\_DELAY \bmod 920) * 10}{60}$$

$$A\_DELAY\_COARSE = \text{floor}\left(\frac{A\_DELAY}{CDPE}\right)$$

$$A\_DELAY\_FINE = \frac{\text{floor}(A\_DELAY \bmod CDPE) * 10}{FDPE}$$

ctrlmod-015

- b. Calculate the required number of Coarse Elements and Fine Elements:

$$COARSE\_ELEMENTS = G\_DELAY\_COARSE + A\_DELAY\_COARSE$$

$$FINE\_ELEMENTS = \frac{G\_DELAY\_FINE + A\_DELAY\_FINE}{10}$$

ctrlmod-016

- c. If FINE\_ELEMENTS > 22, recalculate COARSE\_ELEMENTS and FINE\_ELEMENTS as follows:

$$COARSE\_ELEMENTS = \frac{\text{TOTAL\_DELAY}}{CDPE}$$

$$FINE\_ELEMENTS = \frac{\text{TOTAL\_DELAY} \bmod CDPE}{FDPE}$$

$$\text{Where } \text{TOTAL\_DELAY} = (\text{Original } COARSE\_ELEMENTS * CDPE) + (\text{Original } FINE\_ELEMENTS * FDPE)$$

ctrlmod-017

- d. Convert COARSE\_ELEMENTS and FINE\_ELEMENTS to 5-bit binary values  
COARSE\_ELEMENTS\_5b and FINE\_ELEMENTS\_5b
- e. Write associated CFG\_x register with 0x29400 + COARSE\_ELEMENTS\_5b << 5 +

## FINE\_ELEMETs\_5b

Selection of all Manual IO Timing Modes should be done as part of the IO Delay Recalibration Sequence described in [Section 18.4.6.1.8, IO Delay Recalibration](#).

### 18.4.6.1.7 Isolation Requirements

When reprogramming the MUXMODE, DELAYMODE, and MODESELECT fields of a pad configuration register or the CFG\_x\_IN, CFG\_x\_OEN, and CFG\_x\_OUT registers in the IODELAYCONFIG Module, there is potential for a glitch on the corresponding IO. Therefore, the device IOs should be isolated when writing to any of these fields. Isolating the IOs forces them to tri-state output with internal pulls holding their previous levels. De-isolating the IOs returns their control to the selected peripheral modules.

---

**NOTE:** While the IOs are Isolated, code must execute only from internal RAM and the isolated IO interfaces should not be actively used.

---

Isolation is a global event that affects all LVCMOS IOs except for the following:

- JTAG IOs
- on\_off
- rstoutn

Isolation/De-isolation of the device IOs is accomplished via the following sequences:

#### Isolation Sequence:

1. Ensure that the [CTRL\\_CORE\\_CONTROL\\_PBIAS\[27\]](#) SDCARD\_BIAS\_PWRDNZ and [CTRL\\_CORE\\_CONTROL\\_PBIAS\[26\]](#) SDCARD\_IO\_PWRDNZ bits are set to 1
2. Write 1 to the PRM\_IO\_PMCTRL[0] ISOCLK\_OVERRIDE bit
3. Poll the PRM\_IO\_PMCTRL[1] ISOCLK\_STATUS bit until it reads 1
4. Write 1 to the [CTRL\\_CORE\\_SMA\\_SW\\_0\[2\]](#) ISOLATE bit
5. Read the [CTRL\\_CORE\\_SMA\\_SW\\_0\[2\]](#) ISOLATE bit for timing purposes only
6. Write the PRM\_IO\_PMCTRL[0] ISOCLK\_OVERRIDE bit to 0
7. Poll the PRM\_IO\_PMCTRL[1] ISOCLK\_STATUS bit until it reads 0

#### De-isolation Sequence:

1. Write 1 to the PRM\_IO\_PMCTRL[0] ISOCLK\_OVERRIDE bit
2. Poll the PRM\_IO\_PMCTRL[1] ISOCLK\_STATUS bit until it reads 1
3. Write 0 to the [CTRL\\_CORE\\_SMA\\_SW\\_0\[2\]](#) ISOLATE bit
4. Read the [CTRL\\_CORE\\_SMA\\_SW\\_0\[2\]](#) ISOLATE bit for timing purposes only
5. Write the PRM\_IO\_PMCTRL[0] ISOCLK\_OVERRIDE bit to 0
6. Poll the PRM\_IO\_PMCTRL[1] ISOCLK\_STATUS bit until it reads 0

Configuration of the pad configuration registers is normally done as part of the IO Delay Recalibration Sequence described in [Section 18.4.6.1.8, IO Delay Recalibration](#), which references the above Isolation/De-isolation sequences.

### 18.4.6.1.8 IO Delay Recalibration

After adjusting the AVS voltage for VDD\_CORE\_L voltage domain, an IO Delay Recalibration Sequence must be followed to ensure device IO timings are met. The IO Delay Recalibration Sequence is as follows:

#### IO Delay Recalibration Sequence:

1. Complete the AVS voltage change on the VDD\_CORE\_L voltage domain and ensure voltage has stabilized to the new AVS target voltage
2. Unlock the registers used by this sequence as follows:
  - a. Write 0x2FF1AC2B to register [CTRL\\_CORE\\_MMR\\_LOCK\\_1](#) of the Control Module
  - b. Write 0x6F361E05 to register [CTRL\\_CORE\\_MMR\\_LOCK\\_5](#) of the Control Module

- c. Write 0x0000AAAA to register [CONFIG\\_REG\\_8](#) of the IODELAYCONFIG Module
3. Perform IO Delay Calibration
  - a. Write register field [CONFIG\\_REG\\_2\[15:0\]](#) REFCLK\_PERIOD of the IODELAYCONFIG Module with the L4\_ICLK clock period in ps divided by 10 (or, equivalently, L3\_ICLK clock period in ps divided by 5), then rounded down to the closest integer
    - i. L4\_ICLK = 133MHz requires a value of 0x2EF
  - b. Write 1 to register field [CONFIG\\_REG\\_0\[0\]](#) CALIBRATION\_START of the IODELAYCONFIG module to initiate the calibration.
  - c. Poll register field [CONFIG\\_REG\\_0\[0\]](#) CALIBRATION\_START for 0, indicating calibration is complete.
4. Isolate the device IOs via the Isolation Sequence described in [Section 18.4.6.1.7 Isolation Requirements](#)
5. Update the delay mechanism for each IO with new calibrated values:
  - a. Write 1 to register field [CONFIG\\_REG\\_0\[1\]](#) ROM\_READ of the IODELAYCONFIG module to initiate a reload of calibrated delay values for all IOs.
  - b. Poll register field [CONFIG\\_REG\\_0\[1\]](#) ROM\_READ for 0, indicating reload is complete.
6. Configure the pad configuration register (CTRL\_CORE\_PAD\_x) for each IO with the desired MUXMODE, DELAYMODE, and MODESELECT settings.
7. Configure all required Manual IO Timing Modes as described in [Section 18.4.6.1.6, Manual IO Timing Modes](#)
8. De-isolate the device IOs via the de-isolation sequence described in [Section 18.4.6.1.7 Isolation Requirements](#)
9. Relock the registers used by this sequence:
  - a. Write 0x1A1C8144 to register [CTRL\\_CORE\\_MMR\\_LOCK\\_1](#)
  - b. Write 0x143F832C to register [CTRL\\_CORE\\_MMR\\_LOCK\\_5](#)
  - c. Write 0x0000AAAB to register [CONFIG\\_REG\\_8](#)

#### 18.4.6.2 Thermal Management Related Registers

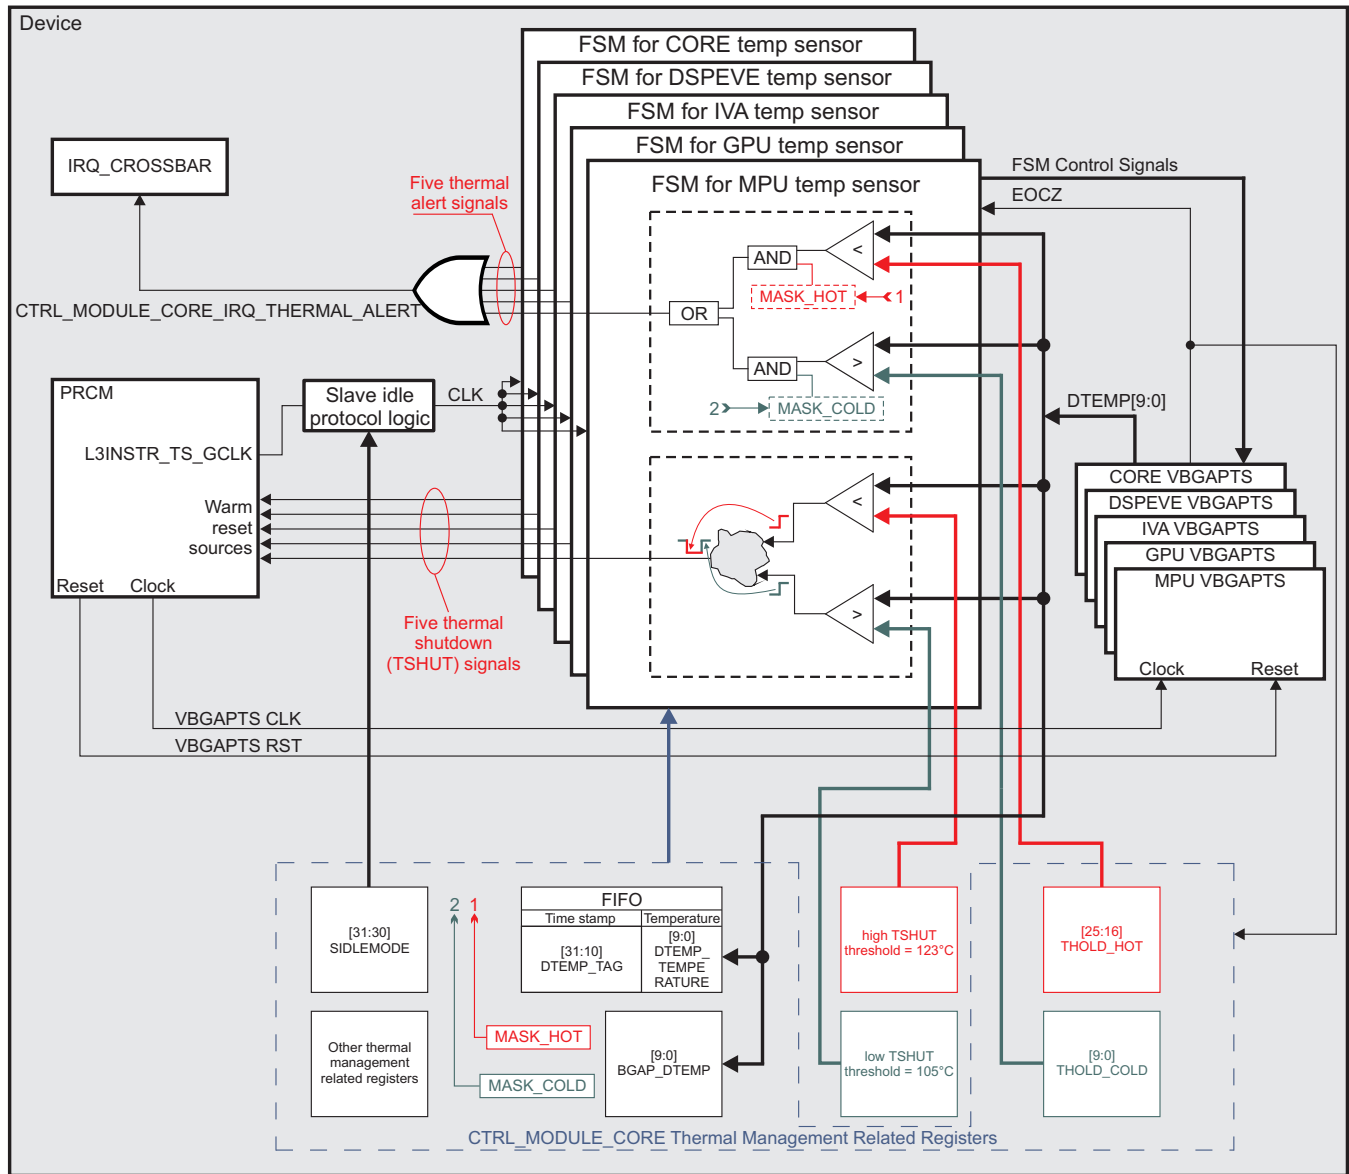

There are five temperature sensors on the device die. Each sensor is associated only with one voltage domain and is also a part of a VBGAPTS cell. This cell has a 10-bit ADC. The ADC converts the temperature values into digital output values proportional to the temperature measured. Each VBGAPTS cell is controlled by a dedicated FSM referred to as thermal FSM. The registers associated with each FSM reside in the CTRL\_MODULE\_CORE submodule. All FSMs are clocked by the L3INSTR\_TS\_GCLK clock. The PRCM module controls this clock through the slave idle protocol.

The device thermal management related registers can be split into the following classes:

- Temperature sensors control registers
- Registers for the thermal alert comparators
- Temperature timestamp registers
- Other registers used for:
  - controlling the FIFOs
  - controlling the clock provided to the five FSMs

[Figure 18-5](#) shows the block diagram of the device thermal management.

Figure 18-5. Thermal Management Functional Block Diagram

ctrlmod-006

Table 18-7 describes the signals related to the device thermal management logic.

Table 18-7. Thermal Management Signals Description

Signal	I/O <sup>(1)</sup>	Description
EOCZ	O	End of conversion signal. When low, this signal indicates that the value of DTEMP[9:0] is valid.
DTEMP[9:0]	O	Temperature data from the temperature sensor. This value is valid when EOCZ is low.
VBGAPTS CLK	I	Functional clock from the WKUPAON power domain used by the temperature sensor during temperature conversion.
THERMAL ALERT	O	The five thermal alert outputs from each thermal FSM are ORed and then mapped as an interrupt request to the IRQ_CROSSBAR module. Software uses this interrupt to implement the device thermal management policy.
TSHUT	O	Each of the five thermal shutdown signals is mapped to the PRCM and is used as a warm reset signal. These overheat protection signals are high during normal operation and go low during thermal shutdown event.

<sup>(1)</sup> I = Input; O = Output

The ADC values which correspond to the current temperature are listed in [Table 18-10](#).

#### **18.4.6.2.1 Temperature Sensors Control Registers**

Each VBGAPTS cell works in continuous conversion mode controlled by the corresponding FSM. This means that the temperature is measured at regular time intervals. The start of temperature measurement is initiated automatically by each FSM after it goes out of reset state. To control the main delay between two measurements the [CTRL\\_CORE\\_BANDGAP\\_MASK\\_1\[29:27\]](#) COUNTER\_DELAY bit field is used. After this delay expires the five FSMs automatically start a temperature conversion.

The conversion is complete when the [CTRL\\_CORE\\_TEMP\\_SENSOR\\_x\[10\]](#) BGAP\_EOCZ\_x status bits are set to 0x0. After this the valid temperature is written automatically by each FSM in the [CTRL\\_CORE\\_TEMP\\_SENSOR\\_x\[9:0\]](#) BGAP\_DTEMP\_x bit fields, and then software is able to read it from the corresponding register. After writing the valid temperature values the five FSMs wait one clock cycle and start another conversion cycle.

For details regarding the [CTRL\\_CORE\\_TEMP\\_SENSOR\\_x](#) registers, see [Table 18-9](#).

#### **18.4.6.2.2 Registers For The Thermal Alert Comparators**

There is a comparator block responsible for the thermal alert function of the [CTRL\\_MODULE\\_CORE](#) thermal management logic. This comparator block is composed of two comparators. One dedicated to low temperature threshold and the other one to high temperature threshold. Because of the five temperature sensors there are also five comparator blocks. Software can configure the low temperature threshold through the [CTRL\\_CORE\\_BANDGAP\\_THRESHOLD\\_x\[9:0\]](#) THOLD\_COLD\_x bit fields and high temperature threshold through the [CTRL\\_CORE\\_BANDGAP\\_THRESHOLD\\_x\[25:16\]](#) THOLD\_HOT\_x bit fields. The values which have to be loaded in these bit fields are the same as those listed in [Table 18-10](#). For example, to set the high temperature threshold value to 120°C, the THOLD\_HOT field must be loaded with value of 931 (0x3A3).

The thermal alert logic provides also a capability to mask the outputs of the comparators associated with low and high temperature thresholds. The low temperature threshold comparator outputs are masked by setting to 0x0 the corresponding [MASK\\_COLD\\_x](#) bits in the [CTRL\\_CORE\\_BANDGAP\\_MASK\\_1](#) and [CTRL\\_CORE\\_BANDGAP\\_MASK\\_2](#) registers. The high temperature threshold comparator outputs are masked by setting to 0x0 the corresponding [MASK\\_HOT\\_x](#) bits in [CTRL\\_CORE\\_BANDGAP\\_MASK\\_1](#) and [CTRL\\_CORE\\_BANDGAP\\_MASK\\_2](#) registers.

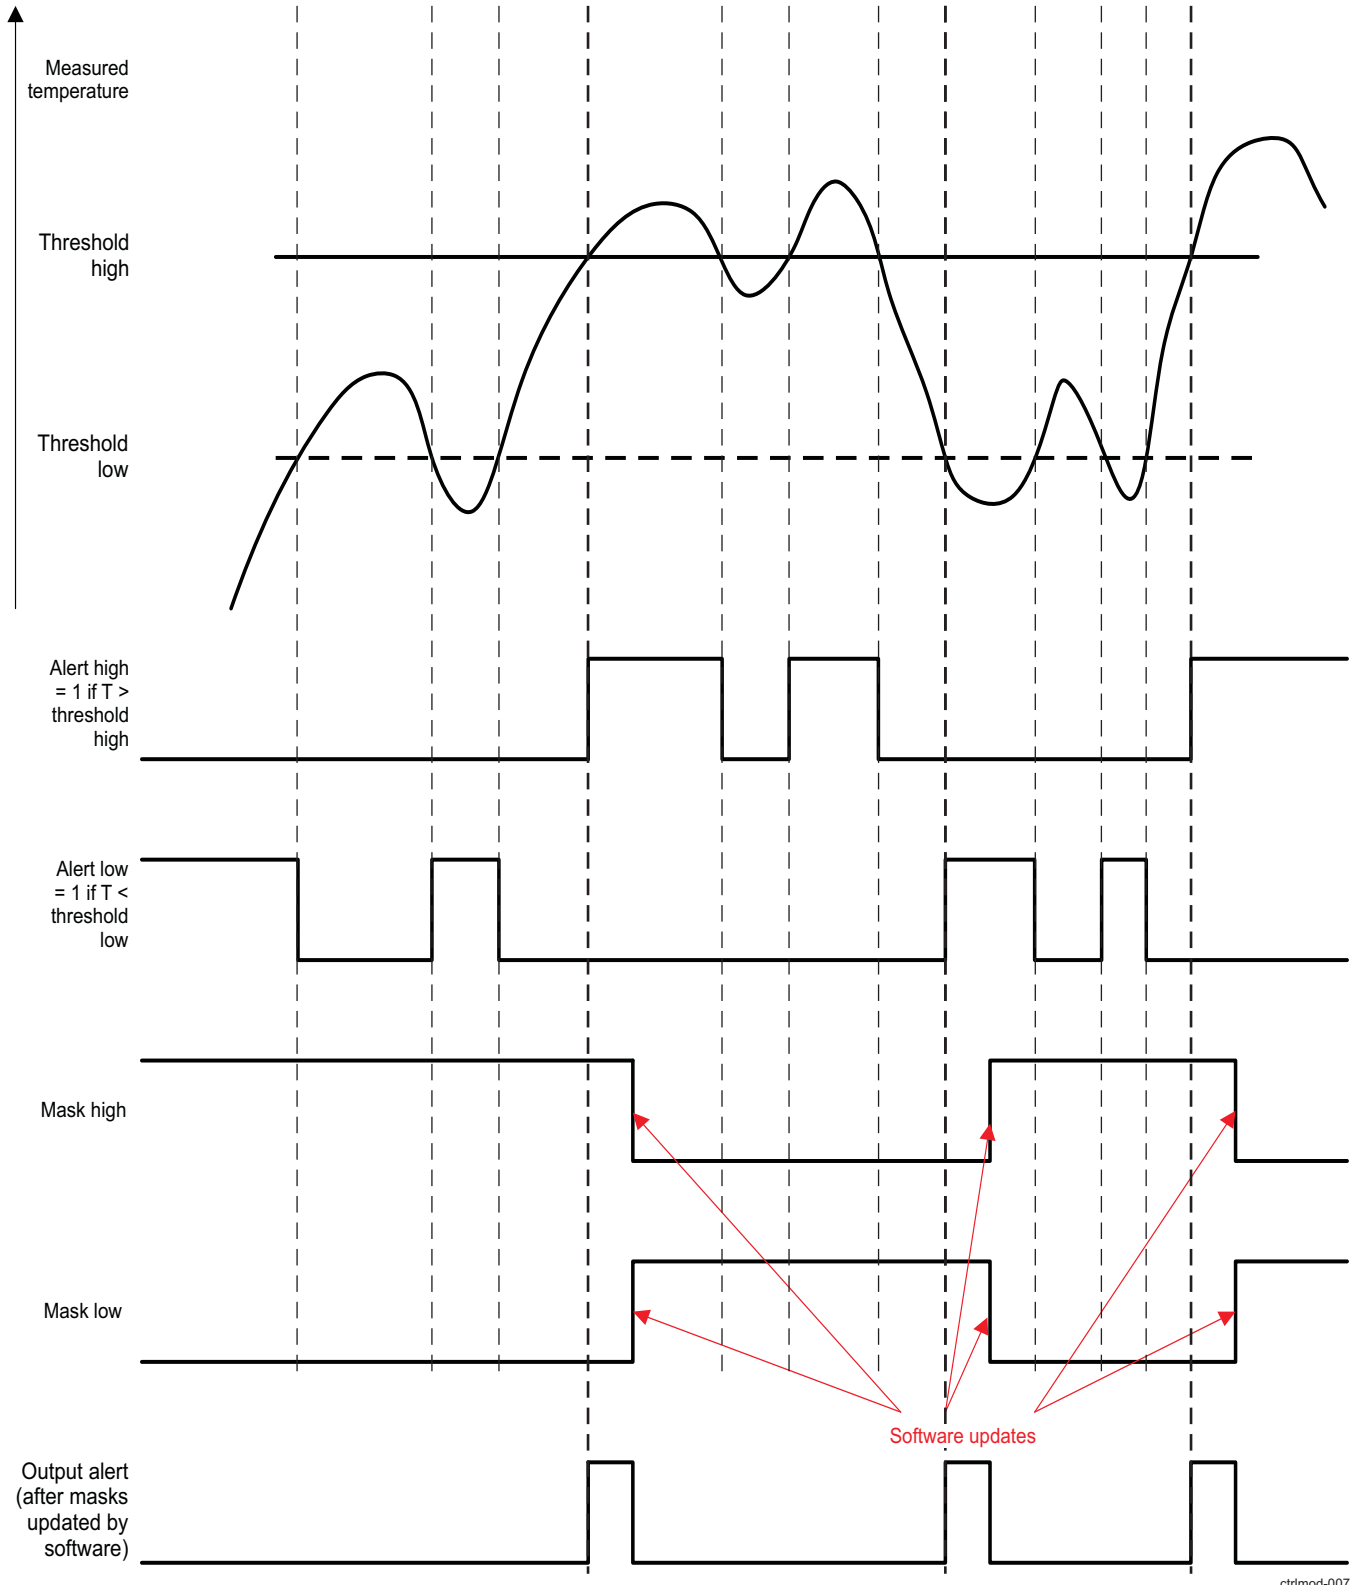

The masked low and high temperature threshold outputs are ORed once and as a result a single thermal alert signal is produced. As there are five temperature sensors there are also five thermal alert output signals produced. These five signals are then ORed (see [Figure 18-5](#)) in the [CTRL\\_MODULE\\_CORE\\_IRQ\\_THERMAL\\_ALERT](#) signal, which delivers an interrupt to the [IRQ\\_CROSSBAR\\_121](#) input line of the [IRQ\\_CROSSBAR](#) module. Software can use this interrupt to implement the device thermal management policy. The [CTRL\\_MODULE\\_CORE\\_IRQ\\_THERMAL\\_ALERT](#) signal is also routed to the [CTRL\\_CORE\\_BANDGAP\\_STATUS\\_1\[31\]](#) ALERT bit. Value of 0x1 indicates that the [CTRL\\_MODULE\\_CORE\\_IRQ\\_THERMAL\\_ALERT](#) signal is asserted.

The non masked (raw) comparator outputs are available for reading through the corresponding bits in the [CTRL\\_CORE\\_BANDGAP\\_STATUS\\_1](#) and [CTRL\\_CORE\\_BANDGAP\\_STATUS\\_2](#) registers. The low temperature threshold comparator outputs are read through the [COLD\\_x](#) bits and the high temperature threshold comparator outputs through the [HOT\\_x](#) bits.

[Figure 18-6](#) shows the behavior of the thermal alert logic.

For details regarding the [CTRL\\_CORE\\_BANDGAP\\_THRESHOLD\\_x](#) registers, see [Table 18-9](#).

Figure 18-6. Behavior Of The Thermal Alert Logic

ctrlmod-007

### 18.4.6.2.3 Thermal Shutdown Comparators

There is also a comparator block responsible for the thermal shutdown (TSHUT) function of the CTRL\_MODULE\_CORE thermal management logic. This comparator block is also composed of two comparators. One dedicated to low TSHUT threshold and the other one to high TSHUT threshold. Because of the five temperature sensors there are also five comparator blocks. The comparator outputs for the low and high TSHUT thresholds of each comparator block are connected to a logic which then generates a single TSHUT signal. All five TSHUT signals are tied to the PRCM and used as warm reset sources. For details, see [Figure 18-5](#).

The values of the five low and high TSHUT thresholds are fixed and can be neither overridden nor read by software. The value for the high TSHUT threshold is 123°C (assuming ±2°C temperature sensor accuracy), and the low TSHUT threshold is 105°C.

When the high TSHUT threshold is reached, the TSHUT output is activated. To deactivate each TSHUT output, the temperature must go below the value of each low TSHUT threshold.

Each of the five TSHUT signals is used as an overheat protection.

[Figure 18-7](#) shows the behavior of the TSHUT logic.

**Figure 18-7. Behavior Of The Thermal Shutdown Logic**

ctrlmod-008

### 18.4.6.2.4 Temperature Timestamp Registers

Each time one of the CTRL\_CORE\_TEMP\_SENSOR\_x[9:0] BGAP\_DTEMP\_x bit fields is updated with new temperature value, this value is also automatically stored into a 5-level deep FIFO and a timestamp is registered too. There are five FIFOs used to store a brief history for the last few temperature measurements and are also dedicated to temperature timestamping feature. Each FIFO has two fields. The first one is 10 bits wide, 5 levels deep, and is intended to store the temperature values for the last five measurements. The second field is 22 bits wide, 5 levels deep, and acts like a counter for the number of temperature measurements. Each FIFO is composed of the following registers:

- CTRL\_CORE\_DTEMP\_x\_0

- CTRL\_CORE\_DTEMP\_x\_1
- CTRL\_CORE\_DTEMP\_x\_2
- CTRL\_CORE\_DTEMP\_x\_3
- CTRL\_CORE\_DTEMP\_x\_4

Table 18-8 shows a generic description of the five FIFOs.

For details regarding the five CTRL\_CORE\_DTEMP\_x registers, see Table 18-9.

**Table 18-8. FIFOs Generic Description**

FIFO Levels	Second FIFO Field (22 Bits) – Timestamp Bits [31:10]	Description	First FIFO field (10 Bits) – Temperature Bits [9:0]	Description
Level 1	DTEMP_TAG_x_0	Indicates the number of temperature measurements	DTEMP_TEMPERATURE_x_0	Indicates the last measured temperature value (the most recent sample)
Level 2	DTEMP_TAG_x_1	Indicates the number of temperature measurements minus one (DTEMP_TEMPERATURE_x_0 – 1)	DTEMP_TEMPERATURE_x_1	Indicates the penultimate measured temperature value
Level 3	DTEMP_TAG_x_2	Indicates the number of temperature measurements minus two (DTEMP_TEMPERATURE_x_0 – 2)	DTEMP_TEMPERATURE_x_2	Indicates temperature value measured before DTEMP_TEMPERATURE_x_1
Level 4	DTEMP_TAG_x_3	Indicates the number of temperature measurements minus three (DTEMP_TEMPERATURE_x_0 – 3)	DTEMP_TEMPERATURE_x_3	Indicates temperature value measured before DTEMP_TEMPERATURE_x_2
Level 5	DTEMP_TAG_x_4	Indicates the number of temperature measurements minus four (DTEMP_TEMPERATURE_x_0 – 4)	DTEMP_TEMPERATURE_x_4	Indicates temperature value measured before DTEMP_TEMPERATURE_x_3 (the oldest sample)

**NOTE:** DTEMP\_TAG\_x\_4 increments its value with one after each fifth temperature measurement.

DTEMP\_TAG\_x\_3 increments its value with one after each fourth temperature measurement.

DTEMP\_TAG\_x\_2 increments its value with one after each third temperature measurement.

DTEMP\_TAG\_x\_1 increments its value with one after each second temperature measurement.

DTEMP\_TAG\_x\_0 increments its value with one after each temperature measurement.

#### 18.4.6.2.5 Other Thermal Management Related Registers

- **Controlling the FIFOs:**

Software can stop a certain FIFO to update with new temperature and timestamp values when setting to 0x1 one of the FREEZE\_x bits in the CTRL\_CORE\_BANDGAP\_MASK\_1 and CTRL\_CORE\_BANDGAP\_MASK\_2 registers. These 5 bits are automatically cleared by hardware after the FIFOs are cleared.

Each FIFO is cleared by setting to 0x1 one of the CLEAR\_x bits in the CTRL\_CORE\_BANDGAP\_MASK\_1 and CTRL\_CORE\_BANDGAP\_MASK\_2 registers. These 5 bits are also automatically set by hardware to 0x0 after the FIFOs clearing procedure completes.

- **Controlling the clock provided to the five FSMs:**

The five FSMs comply with the PRCM slave idle protocol. They share common functional clock (L3INSTR\_TS\_GCLK), which is automatically gated by PRCM depending on the value of the [CTRL\\_CORE\\_BANDGAP\\_MASK\\_1](#)[31:30] SIDLEMODE bit field. L3INSTR\_TS\_GCLK clock is also enabled automatically by the PRCM module.

#### 18.4.6.2.6 Summary of the Thermal Management Related Registers

[Table 18-9](#) summarizes all the thermal management related registers.

**Table 18-9. Summary of the Thermal Management Related Registers**

#### 18.4.6.2.7 ADC Values Versus Temperature

Table 18-10 provides all the valid ADC values which correspond to the temperature measured which is read from the CTRL\_CORE\_TEMP\_SENSOR\_x[9:0] BGAP\_DTEMP\_x bit fields. Table 18-10 also provides the values for the low and high temperature thresholds which are configurable through the CTRL\_CORE\_BANDGAP\_THRESHOLD\_x[9:0] THOLD\_COLD\_x and CTRL\_CORE\_BANDGAP\_THRESHOLD\_x[25:16] THOLD\_HOT\_x bit fields.

**Table 18-10. ADC Values Versus Temperature**

ADC Code	Temperature		ADC Code	Temperature		ADC Code	Temperature		ADC Code	Temperature	
	From	To		From	To		From	To		From	To
0-539	Outside region of operation		641	0.8	1.2	743	43.4	44	845	85.2	85.6
540	-40	-40	642	1.2	1.6	744	44	44.4	846	85.6	86
541	-40	-40	643	1.6	2	745	44.4	44.8	847	86	86.4
542	-40	-40	644	2	2.4	746	44.8	45.2	848	86.4	86.8

**Table 18-10. ADC Values Versus Temperature (continued)**

ADC Code	Temperature		ADC Code	Temperature		ADC Code	Temperature		ADC Code	Temperature	
543	-40	-40	645	2.4	2.8	747	45.2	45.6	849	86.8	87.2

**18.4.6.3 PBIAS Cell And MMC1 I/O Cells Control Registers**

The PBIAS cell is associated with device MMC1 interface and used together with the MMC1 I/O cells. Its purpose is to provide bias voltage to the MMC1 I/O cells. Without this bias voltage these I/O cells can not function properly.

The PBIAS cell is controlled by software using the [CTRL\\_CORE\\_CONTROL\\_PBIAS](#) register. The [CTRL\\_CORE\\_CONTROL\\_HYST\\_1](#) register is used for hysteresis and drive strength control of the MMC1 I/O cells.

[Figure 18-8](#) shows the PBIAS cell with the control bits and connections between it, the control module and the MMC1 I/O cells.

**Figure 18-8. PBIAS Cell And Its Connections**

ctrimod-009

Table 18-11 describes PBIAS cell and MMC1 I/O cells control bits.

**Table 18-11. Control Bits For the PBIAS and MMC1 I/O Cells**

Control bits for PBIAS cell and MMC1 I/O cells	Reset Value	Description
<a href="#">CTRL_CORE_CONTROL_PBIAS</a> [27] SDCARD_BIAS_PWRDNZ	0x0	This bit turns ON and OFF the PBIAS cell. Software must keep it to 0x0 whenever the PBIAS cell supply voltage is ramping up/down or changing. Thus the PBIAS cell is protected. This bit should be set to 0x1 only after the PBIAS cell supply voltage is stable. This action power up the PBIAS cell.
<a href="#">CTRL_CORE_CONTROL_PBIAS</a> [26] SDCARD_IO_PWRDNZ	0x0	This bit turns ON and OFF the MMC1 I/O cells. Software must keep it to 0x0 whenever the MMC1 IOs supply voltage is ramping up/down or changing. Thus the MMC1 I/O cells are protected. When this bit is set to 0x0, the MMC1 pads are floating. This bit should be set to 0x1 only after the MMC1 IOs supply voltage is stable. This action powers up the MMC1 I/O cells.
<a href="#">CTRL_CORE_CONTROL_PBIAS</a> [25] SDCARD_BIAS_HIZ_MODE	0x0	When this bit is set to 0x1, the PBIAS cell output is in high impedance state and the SDCARD_BIAS_VMODE_ERROR bit sets automatically to 0x1. When SDCARD_BIAS_HIZ_MODE is set to 0x0, the PBIAS cell is in normal operation mode.
<a href="#">CTRL_CORE_CONTROL_PBIAS</a> [24] SDCARD_BIAS_SUPPLY_HI_OUT	0x0	This is status bit indicating whether the MMC1 I/O cells supply voltage is equal to 1,8V or 3,3V.
<a href="#">CTRL_CORE_CONTROL_PBIAS</a> [23] SDCARD_BIAS_VMODE_ERROR	0x0	Status bit which indicates, during PBIAS cell normal operation mode, whether the voltage defined by the SDCARD_BIAS_VMODE bit is equal to the MMC1 IOs supply voltage or not. If not, this bit is automatically set to 0x1 4µs after the voltage detection. It is also mapped to the IRQ_CROSSBAR_70 input line and is used as an interrupt source. If both voltage values are not equal an interrupt is generated.
<a href="#">CTRL_CORE_CONTROL_PBIAS</a> [21] SDCARD_BIAS_VMODE	0x1	By controlling this bit software tells the PBIAS cell whether the MMC1 I/O cells supply voltage is equal to 1,8V or 3,3V. Its reset value indicates that the MMC1 IOs voltage level is 3,3V.
<a href="#">CTRL_CORE_CONTROL_HYST_1</a> [31] SDCARD_HYST	0x1	Hysteresis enabling/disabling for the MMC1 IOs input buffer.
<a href="#">CTRL_CORE_CONTROL_HYST_1</a> [30:29] SDCARD_IC	0x0	Impedance control (drive strength) for the MMC1 IOs output buffer.

When the MMC1 signals are not used, that is MUXMODE different than 0x0 selected, the PBIAS cell must also be configured for proper work of the other interface signals multiplexed on the MMC1 I/O cells. For example, if MUXMODE = 0xE (gpio6\_21 to gpio6\_26 signals selected) the PBIAS cell and MMC1 I/O cells must be configured. This means that both the cells must be powered and the appropriate PBIAS cell control bits must also be configured.

The MMC1 interface pads are the following:

- mmc1\_clk
- mmc1\_cmd
- mmc1\_dat[3:0]
- mmc1\_sdcd
- mmc1\_sdpw

All of these pads except the mmc1\_sdcd and mmc1\_sdpw pads are associated with the PBIAS cell and the [CTRL\\_CORE\\_CONTROL\\_PBIAS](#) register and are also controlled by the [CTRL\\_CORE\\_CONTROL\\_HYST\\_1](#) register.

The PBIAS cell and the MMC1 I/O cells are powered externally through the vddshv8 ball.

The PBIAS cell must be programmed according to the MMC1 I/O cells supply voltage. For details, see [Table 18-12](#).

**Table 18-12. PBIAS Cell Voltage Configuration<sup>(1)</sup>**

<b>CTRL_CORE_CONTROL_PBIAS[21] SDCARD_BIAS_VMODE Bit Configuration</b>	<b>PBIAS Cell and MMC1 I/O Cells Supply Voltage</b>	<b>Type of Operation</b>
1.8V (0x0)	1.8V	Normal 1.8V operation
1.8V (0x0)	3.3V	Damaging configuration <sup>(2)</sup>
3.3V (0x1)	1.8V	Damaging configuration <sup>(2)</sup>
3.3V (0x1)	3.3V	Normal 3.3V operation

<sup>(1)</sup> For damaging configuration, hardware system protection is provided to prevent deterioration of the associated MMC1 I/Os.

<sup>(2)</sup> These modes must not be used.

Table 18-13 summarizes the generation of the CTRL\_CORE\_CONTROL\_PBIAS[23] SDCARD\_BIAS\_VMODE\_ERROR status flag, which depends on the various combinations of bits in the CTRL\_CORE\_CONTROL\_PBIAS register. When this flag sets to 0x1, it is recommended the MMC1 I/O cells to be powered down by setting to 0x0 the CTRL\_CORE\_CONTROL\_PBIAS[26] SDCARD\_IO\_PWRDNZ bit.

**Table 18-13. PBIAS Cell Error Signal Truth Table**

<b>Programmed Voltage Level (SDCARD_BIAS_VMODE) E)</b>	<b>SDCARD_BIAS_SUPP LY_HI_OUT</b>	<b>SDCARD_BIAS_HIZ_M ODE</b>	<b>PWRDNZ Bits</b>	<b>SDCARD_BIAS_VMOD E_ERROR</b>
0	0	X	0	0
0	0	0	1	0
0	1	0	1	1
X	X	1	1	1
1	0	X	0	0
1	0	0	1	1
1	1	0	1	0

SDCARD\_BIAS\_VMODE\_ERROR = 0x1 shows that the programmed voltage level is not the same as the voltage indicated by the SDCARD\_BIAS\_SUPPLY\_HI\_OUT bit or high impedance mode is selected.

SDCARD\_BIAS\_VMODE\_ERROR = 0x0 shows that the programmed voltage level is the same as the voltage indicated by the SDCARD\_BIAS\_SUPPLY\_HI\_OUT bit or it is not considered because SDCARD\_PWRDNZ = 0x0.

#### 18.4.6.4 IRQ\_CROSSBAR Module Functional Description

There is an IRQ\_CROSSBAR module in the device, which is controlled by registers in the CTRL\_MODULE\_CORE submodule. The IRQ\_CROSSBAR is able to map any of its input signals to any of its outputs. This module is associated with the device interrupt sources. The IRQs from all the device modules are connected to the IRQ\_CROSSBAR inputs. Each module IRQ is connected only to one crossbar input. Each output of the IRQ\_CROSSBAR module is connected only to one interrupt line of certain interrupt controller (INTC). Thus, the device IRQs are mapped to the device INTCs through the IRQ\_CROSSBAR. Some of these IRQs are mapped by default to certain interrupt lines of one of the device INTCs, but there are IRQs which are not mapped by default to any interrupt line of any device INTC. All IRQs, connected to the IRQ\_CROSSBAR inputs, can be remapped to other interrupt lines of the different device INTCs through the CTRL\_CORE\_X\_IRQ\_B\_A registers. Each of these registers has a structure described in Table 18-14.

**Table 18-14. Generic Description of the CTRL\_CORE\_X\_IRQ\_B\_A IRQ\_CROSSBAR Control Registers**

<b>Bits</b>	<b>Field Name</b>	<b>Description</b>	<b>Type</b>	<b>Note</b>
31:25	RESERVED		R	

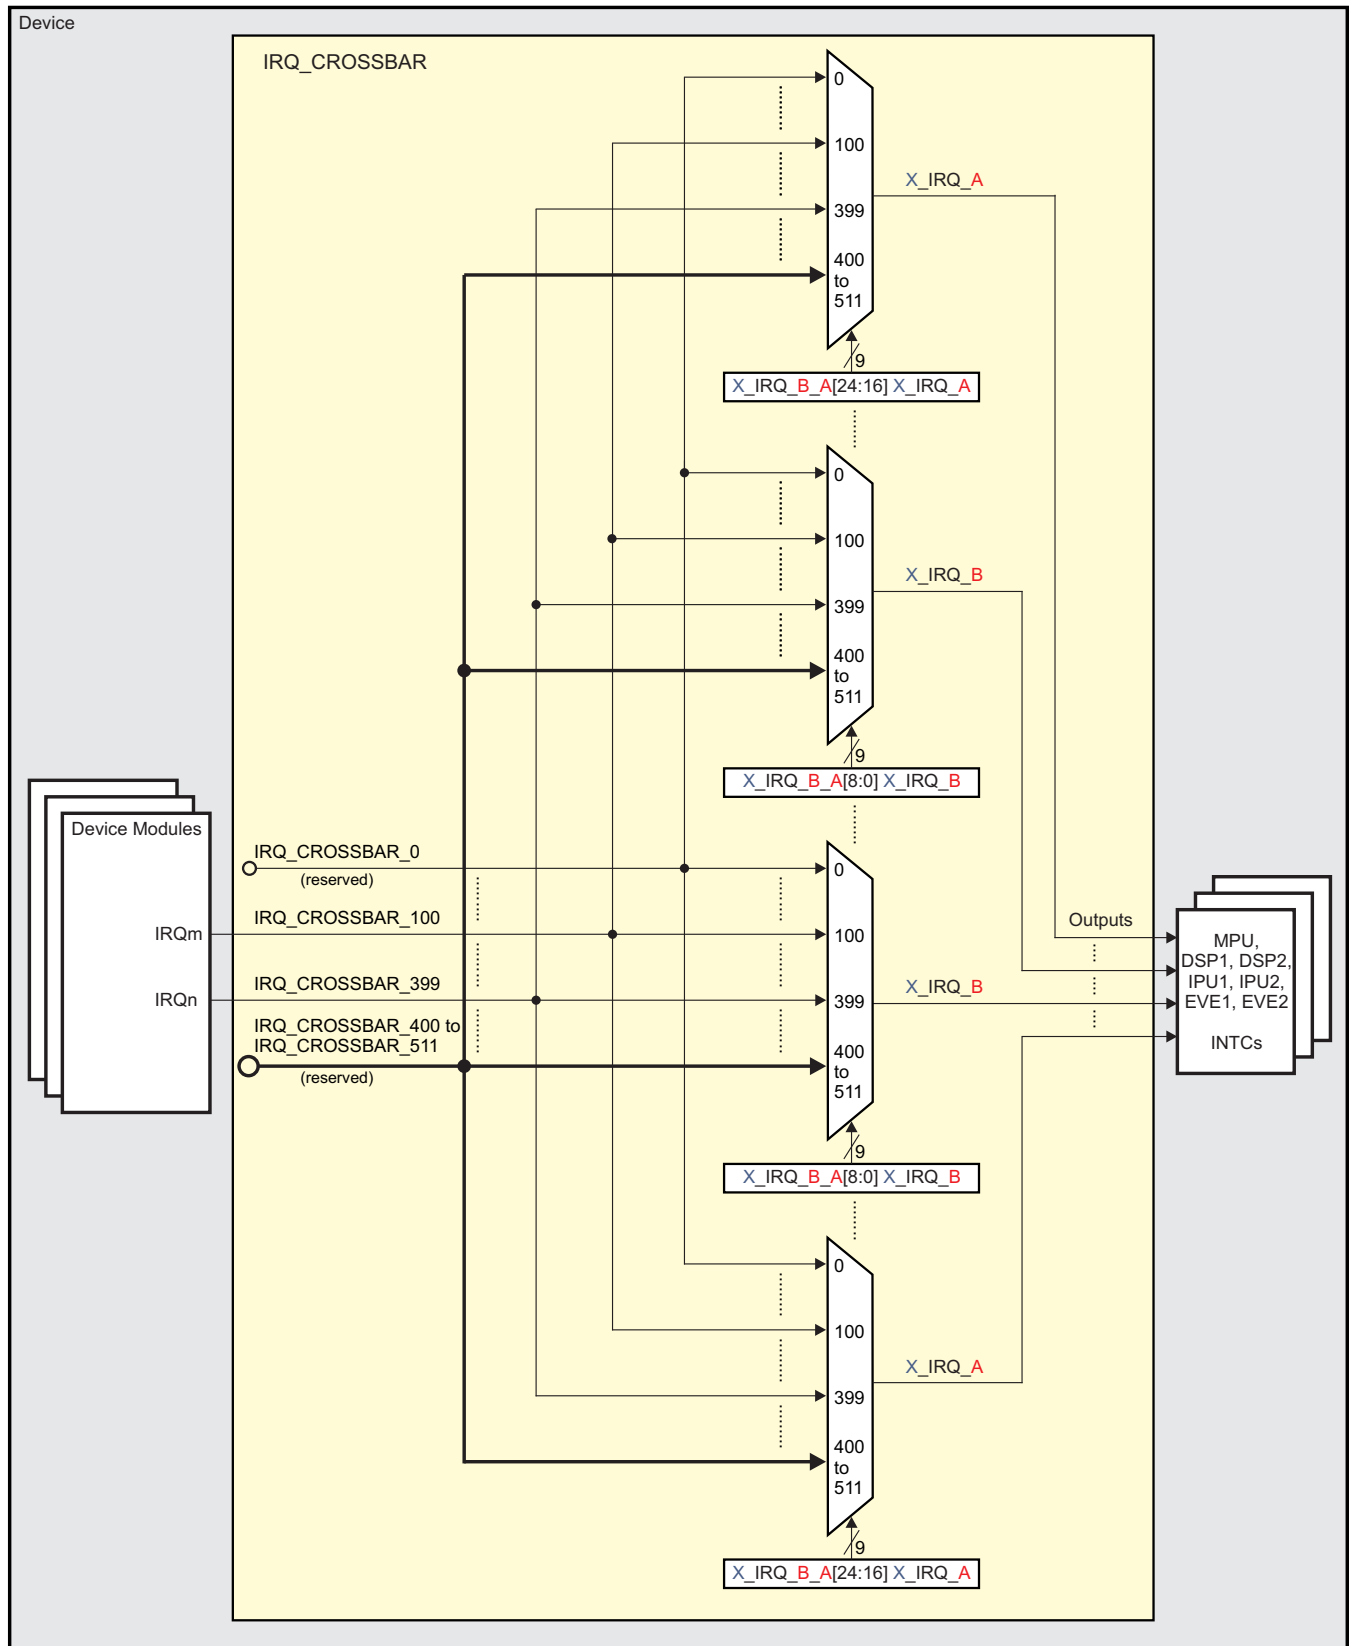

**Table 18-14. Generic Description of the CTRL\_CORE\_X\_IRQ\_B\_A IRQ\_CROSSBAR Control Registers (continued)**

Bits	Field Name	Description	Type	Note
24:16	X_IRQ_A	Selects an interrupt source signal for the X_IRQ_A INTC line 0x0: Reserved 0x1: Maps IRQ_CROSSBAR input 1 to X_IRQ_A INTC line 0x2: Maps IRQ_CROSSBAR input 2 to X_IRQ_A INTC line 0x-: ..... 0x64: Maps IRQ_CROSSBAR input 100 to X_IRQ_A INTC line 0x-: .....  0x190 to 0x1FF: Reserved	RW	X is summarization. 8:0	X_IRQ_B	Selects an interrupt source signal for the X_IRQ_B INTC line 0x0: Reserved 0x1: Maps IRQ_CROSSBAR input 1 to X_IRQ_B INTC line 0x2: Maps IRQ_CROSSBAR input 2 to X_IRQ_B INTC line 0x-: ..... 0x64: Maps IRQ_CROSSBAR input 100 to X_IRQ_B INTC line 0x-: ..... 0x190 to 0x1FF: Reserved	RW	B is summarization. It shows the number of the line for the corresponding INTC. B is equal to 0, 1, 2, ..., and so on, depending on the count of the INTC lines controlled by the IRQ_CROSSBAR module.

Figure 18-9 represents the way in which the IRQ\_CROSSBAR module works. It shows the device modules and their IRQs connected to the IRQ\_CROSSBAR inputs, the structure of the cross-bar and its outputs connected to the device INTCs.

Figure 18-9. IRQ\_CROSSBAR Module Functional Diagram

ctrlmod-010

Each IRQ\_CROSSBAR control register has two 9-bit fields. Each 9-bit field is associated only with one interrupt line. Through this 9-bit field any of the IRQs connected to the IRQ\_CROSSBAR inputs can be mapped to the INTC line associated with this 9-bit field. For example, the register [CTRL\\_CORE\\_MPU\\_IRQ\\_74\\_75](#) is associated with MPU\_IRQ\_74 and MPU\_IRQ\_75. The 9-bit field [CTRL\\_CORE\\_MPU\\_IRQ\\_74\\_75\[24:16\]](#) MPU\_IRQ\_75 is associated only with MPU\_IRQ\_75 interrupt line of the MPU INTC. Setting this bit field to any other value different than its reset value will map another module IRQ to the MPU\_IRQ\_75 interrupt line. The default (reset) value of this bit field is 0x46 which corresponds to the IRQ\_CROSSBAR\_70 input. The PBIAS\_IRQ is connected to this cross-bar input. Setting another register to 0x46 will cause the PBIAS\_IRQ to be mapped to another INTC line. For example, if the [CTRL\\_CORE\\_DSP1\\_IRQ\\_40\\_41\[8:0\]](#) DSP1\_IRQ\_40 is set to 0x46 the PBIAS\_IRQ will be mapped to the DSP1\_IRQ\_40 interrupt line. The same logic also applies to the other interrupt lines of the device INTCs.

In addition, not all of the interrupt lines of a given INTC are controlled by the IRQ\_CROSSBAR registers. This means, that there are interrupt lines which are not connected to any IRQ\_CROSSBAR output and thus only one IRQ is connected to these interrupt lines. In the most common case these lines are used by interrupt sources internal or specific for the corresponding module, which has an INTC.

[Table 18-15](#) shows which lines of each INTC are associated with the IRQ\_CROSSBAR control registers. The rest of the INTC lines (not listed in the table) cannot be controlled by the cross-bar registers.

**Table 18-15. Interrupt Lines Associated With The IRQ\_CROSSBAR Control Registers**

MPU INTC Lines	DSP INTC Lines	IPU INTC Lines	EVE INTC Lines
MPU_IRQ_4, MPU_IRQ_7 to MPU_IRQ_130, MPU_IRQ_133 to MPU_IRQ_159	DSP1_IRQ_32 to DSP1_IRQ_95, DSP2_IRQ_32 to DSP2_IRQ_95	IPU1_IRQ_23 to IPU1_IRQ_79, IPU2_IRQ_23 to IPU2_IRQ_79	EVE1_IRQ_0 to EVE1_IRQ_7, EVE2_IRQ_0 to EVE2_IRQ_7

The individual connection between all module IRQs and all IRQ\_CROSSBAR inputs is shown in [Section 17.3.8, Mapping of Device Interrupts to IRQ\\_CROSSBAR Inputs](#) of [Chapter 17, Interrupt Controllers](#).

In addition, the [CTRL\\_CORE\\_OVS\\_IRQ\\_IO\\_MUX](#) register is used to select for observation on two external pads any IRQ connected to the IRQ\_CROSSBAR inputs. Using the [CTRL\\_CORE\\_OVS\\_IRQ\\_IO\\_MUX\[17:9\]](#) OVS\_IRQ\_IO\_MUX\_2 bit field all IRQs can be mapped to the obs\_irq2 signal. The [CTRL\\_CORE\\_OVS\\_IRQ\\_IO\\_MUX\[8:0\]](#) OVS\_IRQ\_IO\_MUX\_1 bit field maps all IRQs to the obs\_irq1 signal. For example, setting the [CTRL\\_CORE\\_OVS\\_IRQ\\_IO\\_MUX\[8:0\]](#) OVS\_IRQ\_IO\_MUX\_1 to 0x18 maps the GPIO1\_IRQ\_1 to the obs\_irq1 line and thus this IRQ can be observed.

#### 18.4.6.5 DMA\_CROSSBAR Module Functional Description

There is a DMA\_CROSSBAR module in the device, which is controlled by registers in the CTRL\_MODULE\_CORE submodule. The DMA\_CROSSBAR is able to map any of its input signals to any of its outputs. This module is associated with the device DMA request source signals. The DREQs from all the device modules are connected to the DMA\_CROSSBAR inputs. Each DREQ signal is connected only to one DMA cross-bar input. Each output of the DMA\_CROSSBAR module is connected only to one input line of the device DMA modules. The DMAs associated with the DMA\_CROSSBAR are the following:

- DMA\_SYSTEM
- DMA\_EDMA
- DMA\_DSP1\_EDMA
- DMA\_DSP2\_EDMA

All DREQs, connected to the DMA\_CROSSBAR inputs, can be remapped to other lines of the these DMA modules through the [CTRL\\_CORE\\_DMA\\_X\\_DREQ\\_B\\_A](#) registers. Each of these registers has a structure described in [Table 18-16](#).

**Table 18-16. Generic Description of the CTRL\_CORE\_DMA\_X\_DREQ\_B\_A DMA\_CROSSBAR Control Registers**

Bits	Field Name	Description	Type	Note
31:24	RESERVED		R	
23:16	DMA_X_DREQ_A_IRQ_A	Selects a DMA request source signal for the DMA_X_DREQ_A_IRQ_A DMA line 0x0: Reserved 0x1: Reserved 0x2: Maps DMA_CROSSBAR input 2 to DMA_X_DREQ_A_IRQ_A DMA line 0x3: Maps DMA_CROSSBAR input 3 to DMA_X_DREQ_A_IRQ_A DMA line 0x-: ..... 0x32: Maps DMA_CROSSBAR input 50 to DMA_X_DREQ_A_IRQ_A DMA line 0x-: .....  0xCC to 0xFF: Reserved	RW	X is summarization. It is equal to: <ul style="list-style-type: none"> <li>• SYSTEM</li> <li>• EDMA</li> <li>• DSP1_EDMA</li> <li>• DSP2_EDMA</li> </ul> X shows to which DMA all inputs of the DMA_CROSSBAR module can be mapped. A is also summarization. It shows the number of the DREQ line for the corresponding DMA module. A is equal to 0, 1, 2, ..., and so on, depending on the count of the DMA lines controlled by the DMA_CROSSBAR module. For more details, see <a href="#">Table 18-17</a> .
15:8	RESERVED		R	
7:0	DMA_X_DREQ_B_IRQ_B	Selects a DMA request source signal for the DMA_X_DREQ_B_IRQ_B DMA line 0x0: Reserved 0x1: Reserved 0x2: Maps DMA_CROSSBAR input 2 to DMA_X_DREQ_B_IRQ_B DMA line 0x3: Maps DMA_CROSSBAR input 3 to DMA_X_DREQ_B_IRQ_B DMA line 0x-: ..... 0x32: Maps DMA_CROSSBAR input 50 to DMA_X_DREQ_B_IRQ_B DMA line 0x-: ..... 0xCC to 0xFF: Reserved	RW	B is also summarization. It shows the number of the DREQ line for the corresponding DMA module. B is equal to 0, 1, 2, ..., and so on, depending on the count of the DMA lines controlled by the DMA_CROSSBAR module. For more details, see <a href="#">Table 18-17</a> .

[Figure 18-10](#) represents the way in which the DMA\_CROSSBAR module works. It shows the device modules and their DREQs connected to the DMA\_CROSSBAR inputs, the structure of the cross-bar and its outputs connected to the device DMA modules.

Figure 18-10. DMA\_CROSSBAR Module Functional Diagram

ctrlmod-011

Each DMA\_CROSSBAR control register has two 8-bit fields. Each 8-bit field is associated only with one line of certain DMA module. Through this 8-bit field any of the DREQs connected to the DMA\_CROSSBAR inputs can be mapped to the DMA line associated with this 8-bit field. For example, the register [CTRL\\_CORE\\_DMA\\_EDMA\\_DREQ\\_62\\_63](#) is associated with DMA\_EDMA\_DREQ\_62 and DMA\_EDMA\_DREQ\_63 lines. The 8-bit field [CTRL\\_CORE\\_DMA\\_EDMA\\_DREQ\\_62\\_63\[7:0\]](#) DMA\_EDMA\_DREQ\_62\_IRQ\_62 is associated only with DMA\_EDMA\_DREQ\_62 line of the DMA\_EDMA module. Setting this bit field to any other value different than its reset value will map another DREQ from the device modules to the DMA\_EDMA\_DREQ\_62 line. The default (reset) value of this bit field is 0x3F which corresponds to the DMA\_CROSSBAR\_63 input. The UART5\_DREQ\_TX is connected to this crossbar input. Setting another register to 0x3F will cause the UART5\_DREQ\_TX to be mapped to another DMA line. For example, if the [CTRL\\_CORE\\_DMA\\_EDMA\\_DREQ\\_30\\_31\[23:16\]](#) DMA\_EDMA\_DREQ\_31\_IRQ\_31 is set to 0x3F the UART5\_DREQ\_TX will be mapped to the DMA\_EDMA\_DREQ\_31 line. The same logic also applies to the other lines of the device DMAs.

[Table 18-17](#) shows which lines of each DMA are associated with the DMA\_CROSSBAR control registers. The rest of the lines (not listed in the table) cannot be controlled by the cross-bar registers.

**Table 18-17. DREQ Lines Associated With The DMA\_CROSSBAR Control Registers**

DMA_SYSTEM DREQ Lines	DMA_EDMA DREQ Lines	DMA_DSP1_EDMA DREQ Lines	DMA_DSP2_EDMA DREQ Lines
DMA_SYSTEM_DREQ_0 to DMA_SYSTEM_DREQ_126	DMA_EDMA_DREQ_0 to DMA_EDMA_DREQ_63	DMA_DSP1_DREQ_0 to DMA_DSP1_DREQ_19	DMA_DSP2_DREQ_0 to DMA_DSP2_DREQ_19

The individual connection between all module DREQs and all DMA\_CROSSBAR inputs is shown in [Section 16.1.3.2, Mapping of DMA Requests to DMA\\_CROSSBAR Inputs](#) of [Section 16.1, System DMA](#).

In addition, the [CTRL\\_CORE\\_OVS\\_DMARQ\\_IO\\_MUX](#) register is used to select for observation on two external pads any DREQ connected to the DMA\_CROSSBAR inputs. Using the [CTRL\\_CORE\\_OVS\\_DMARQ\\_IO\\_MUX\[15:8\]](#) OVS\_DMARQ\_IO\_MUX\_2 bit field all DREQs can be mapped to the obs\_dmarq2 signal. The [CTRL\\_CORE\\_OVS\\_DMARQ\\_IO\\_MUX\[7:0\]](#) OVS\_DMARQ\_IO\_MUX\_1 bit field maps all DREQs to the obs\_dmarq1 signal. For example, setting the [CTRL\\_CORE\\_OVS\\_DMARQ\\_IO\\_MUX\[7:0\]](#) OVS\_DMARQ\_IO\_MUX\_1 to 0x6 maps the DISPC\_DREQ to the obs\_dmarq1 line and thus this DREQ can be observed.

#### 18.4.6.6 SDRAM Initiator Priority Registers

The [CTRL\\_CORE\\_EMIF\\_INITIATOR\\_PRIORITY\\_1](#) to [CTRL\\_CORE\\_EMIF\\_INITIATOR\\_PRIORITY\\_6](#) registers are intended to control the priority of each initiator accessing the two EMIFs. Each 3-bit field in these registers is associated only with one initiator. Setting this bit field to 0x0 means that the corresponding initiator has a highest priority over the others and setting it to 0x7 is for lowest priority. This feature is useful in case of concurrent access to the external SDRAM from several initiators.

---

**NOTE:** The priorities configured through the [CTRL\\_CORE\\_EMIF\\_INITIATOR\\_PRIORITY\\_1](#) to [CTRL\\_CORE\\_EMIF\\_INITIATOR\\_PRIORITY\\_6](#) registers have affect only at the L3 switch levels and are always overridden at DMM level by the priorities configured through the DMM\_PEG\_PRIO\_k registers.

---

#### 18.4.6.7 L3\_MAIN Initiator Priority Registers

The [CTRL\\_CORE\\_L3\\_INITIATOR\\_PRESSURE\\_1](#) to [CTRL\\_CORE\\_L3\\_INITIATOR\\_PRESSURE\\_6](#) registers are used for controlling the priority of certain initiators on the L3\_MAIN. Each 2-bit field in these registers is associated only with one initiator. Setting this bit field to 0x3 means that the traffic of this initiator has highest priority over the other traffics. A value of 0x0 is for lowest priority. Through these registers a dynamic priority escalation for the following L3\_MAIN initiators is provided:

- MPU
- DSP1
- DSP2
- IPU1

- IPU2
- GPU P1
- GPU P2
- SATA
- MMC1
- MMC2
- USB1
- USB2
- USB3
- USB4

#### 18.4.6.8 Memory Region Lock Registers

There are five registers used to lock different memory regions of CTRL\_MODULE\_CORE memory mapped space. A memory region is locked, means that all write accesses to this region are ignored. Writing a value unique for each register will lock certain memory region and writing another unique value results in unlocking of the same region. These five registers can lock the entire memory space of the CTRL\_MODULE\_CORE submodule. [Table 18-18](#) gives more details.

**Table 18-18. Memory Region Lock Registers**

Register	Memory Space to Lock	Groups of Registers Associated With This Memory Region	Lock/Unlock (register reset value)
<a href="#">CTRL_CORE_MMR_LOCK_1</a>	Region from 0x0000 0100 to 0x0000 079F	Thermal management related registers, EMIF initiator priority, L3_MAIN initiator pressure (priority), standard eFuse and other registers	locked
<a href="#">CTRL_CORE_MMR_LOCK_2</a>	Region from 0x0000 07A0 to 0x0000 0D9F	IRQ_CROSSBAR and DMA_CROSSBAR registers	locked
<a href="#">CTRL_CORE_MMR_LOCK_3</a>	Region from 0x0000 0DA0 to 0x0000 0FFF	A few registers associated with device I/Os	locked
<a href="#">CTRL_CORE_MMR_LOCK_4</a>	Region from 0x0000 1000 to 0x0000 13FF	Reserved range	locked
<a href="#">CTRL_CORE_MMR_LOCK_5</a>	Region from 0x0000 1400 to 0x0000 1FFF	Mainly pad configuration registers	locked

---

**NOTE:** By default the entire CTRL\_MODULE\_CORE memory space is locked but the ROM code unlocks it by writing corresponding unlock values to all CTRL\_CORE\_MMR\_LOCK\_x registers.

---

#### 18.4.6.9 NMI Mapping To Respective Cores

Two registers [CTRL\\_CORE\\_NMI\\_DESTINATION\\_1](#) and [CTRL\\_CORE\\_NMI\\_DESTINATION\\_2](#) are intended to map the external non-maskable interrupt (NMI) to certain of the device host processors. Writing 0x1 into a bit field of these registers enables the NMI to be mapped to the corresponding processor associated with this bit field. Writing 0x0 disables the NMI mapping to this processor.

#### 18.4.6.10 Software Controls for the DDR2/DDR3 I/O Cells

There are two types of I/O cells associated with the DDR2/DDR3 interface. These are single-ended and differential I/O cells.

These I/O cells have the following software controls which reside in registers of the CTRL\_MODULE\_CORE:

- Output impedance controls - I[2:0]

- Slew rate controls - SR[2:0]
- Weak driver controls - WD[1:0]

The I and SR controls apply when the I/Os operate as outputs. The WD controls apply when the I/Os operate as both inputs or outputs.

The bits I[2:0] are used for programming the desired impedance value of the output buffer. [Table 18-19](#) describes the I[2:0] controls which are valid for pull-up and pull-down outputs.

**Table 18-19. Output Impedance Controls - I[2:0]**

I[2]	I[1]	I[0]	Drive Setting Name	Output Impedance
0	0	0	Imp80	80 Ohms
0	0	1	Imp60	60 Ohms
0	1	0	Imp48	48 Ohms
0	1	1	Imp40	40 Ohms
1	0	0	Imp34	34 Ohms
1	0	1	Reserved	Reserved
1	1	0	Reserved	Reserved
1	1	1	Reserved	Reserved

To achieve optimal noise/speed trade-off the slew rate of the output signal can also be programmed using the slew rate control bits SR[2:0] shown in [Table 18-20](#). These SR settings do not affect the DC drive strength of the output buffer. They only control its turn-on time.

**Table 18-20. Slew Rate Controls - SR[2:0]**

SR[2]	SR[1]	SR[0]	Turn-On Time Level	Note
0	0	0	fastest	All 8 values are valid.
...	...	...		
...	...	...		
1	1	1	slowest	

Weak pull-up, pull-down or keeper option for device DDR2/3 pads is enabled through the WD[1:0] bits. The weak pull-up or pull-down option is used to define the pad state (high or low) when no signal is driving the pad. The weak keeper option is used to maintain the previous output value when nothing is driving the pad. [Table 18-21](#) describes the WD controls. They are used for avoiding floating pads on the DDR2/DDR3 interface.

**Table 18-21. Weak Driver Controls - WD[1:0]**

WD[1]	WD[0]	Single-Ended Operation	Differential Pair Operation	
			padp	padn
0	0	Pull logic disabled	Pull logic disabled	Pull logic disabled
0	1	Weak pullup enabled	Weak pullup enabled	Weak pulldown enabled
1	0	Weak pulldown enabled	Weak pulldown enabled	Weak pullup enabled
1	1	Weak keeper enabled	Weak keeper enabled	Weak keeper enabled

**NOTE:** To avoid unnecessary power consumption, software must overwrite the Weak Driver (WD) reset values by setting them to 0x0.

It must be taken into account that the I, SR and WD software controls apply for several pads combined in groups, and not for a single pad. For example, writing 0x1 to the [CTRL\\_CORE\\_CONTROL\\_DDRCACH1\\_0\[17:16\]](#) DDR3CH1\_PART5A\_WD bit field enables the weak pull-up resistors for all 16 pads in the PART5A group. These are the ddr1\_a[15:0] pads. [Table 18-22](#) shows the I, SR and WD controls for the different DDR2/DDR3 pad groups.

**Table 18-22. Software Group Controls for the DDR2/DDR3 Pads**

DDR2/DDR3 Interface I/O Group Controls	Group Name	Pads in a Group

#### 18.4.6.11 Reference Voltage for the Device DDR2/DDR3 Receivers

The device DDR2/DDR3 input buffers work in so-called Vref-based receiver mode. In this mode, the buffers act like differential comparators with positive terminal connected to a device pad which receives signals from DDR2/DDR3 memory and negative terminal connected to a source of reference voltage.

To work properly, a reference voltage must be provided to the device DDR2/DDR3 input buffers. There are two Vref-generation cells per memory channel in the device intended to supply this internal reference voltage.

Figure 18-11 shows the Vref-generation cells in the device.

Figure 18-11. Vref-Generation Cells and Their Controls

Both the Vref-generation cells associated with EMIF1 are powered through the vdds\_ddr1 ball. Both the Vref-generation cells associated with EMIF2 are powered through the vdds\_ddr2 ball. For more information, see the device data manual.

The control bits for the Vref-generation cells reside in the CTRL\_CORE\_CONTROL\_DDRIO\_0 and CTRL\_CORE\_CONTROL\_DDRIO\_1 registers. There are VREF\_x\_TAP[1:0] control bits which set the output drive capability of the Vref cells. Table 18-23 lists the possible options for selection of load current sourced from the output of each Vref-generation cell.

Table 18-23. Vref Cell Load Current Selection

VREF_x_TAP1	VREF_x_TAP0	Description
0	0	2- $\mu$ A load current
0	1	4- $\mu$ A load current
1	0	8- $\mu$ A load current
1	1	32- $\mu$ A load current

According to the noise environment, the user can choose to filter the supplied reference voltage. Two coupling capacitors internal to each Vref-generation cell are available and configurable through the VREF\_x\_CCAP[1:0] control bits in the CTRL\_CORE\_CONTROL\_DDRIO\_0 and CTRL\_CORE\_CONTROL\_DDRIO\_1 registers, as specified in Table 18-24.

**Table 18-24. Vref Cell Coupling Capacitor Selection**

VREF_x_CCAP1	VREF_x_CCAP0	Capacitor
0	0	No capacitor connected.
0	1	One capacitor connected between Vbias and ground. <sup>(1)</sup>
1	0	One capacitor connected between Vbias and Vdds. <sup>(2)</sup>
1	1	One capacitor connected between Vbias and ground and one capacitor connected between Vbias and Vdds.

<sup>(1)</sup> Vbias is the output of the Vref-generation cell which provides the reference voltage.

<sup>(2)</sup> Vdds is the power supply voltage of the Vref-generation cell.

The Vref-generation cells can be enabled by setting to 0x1 the VREF\_x\_EN bits in the [CTRL\\_CORE\\_CONTROL\\_DDRIO\\_0](#) and [CTRL\\_CORE\\_CONTROL\\_DDRIO\\_1](#) registers. These cells can be disabled (for leakage improvement and when not in use) by clearing the same VREF\_x\_EN bits.

[Table 18-25](#) shows the Vref-generation cells control bits and the DDR2/DDR3 pads used as receivers to which the corresponding Vref cell supplies reference voltage.

**Table 18-25. Controls for the Vref-Generation Cells Versus DDR2/DDR3 Receiver Pads**

#### 18.4.6.12 AVS Class 0 Associated Registers

AVS Class 0 attempts to normalize the power consumption across all devices by lowering the operating voltage of certain voltage rails. This procedure of lowering the voltage should be performed in the boot loader after ROM code. The new voltage to be set for each AVS Class 0 supported voltage rail should be read from the eFuse using dedicated registers. Then the power supply output voltage is adjusted to this new voltage value.

The following voltage rails support AVS Class 0:

- vdd\_iva
- vdd\_dspeve
- vdd
- vdd\_gpu
- vdd\_mpu

**NOTE:** For descriptions of the voltage rails previously listed see the "Power Supply Signal Descriptions" table in the device Data Manual.

Table 18-26 shows all registers associated with AVS Class 0. The corresponding AVS Class 0 voltage value can be read from the 12 LSbits of each of the listed registers. They contain the voltage value in hex format. To find the actual value in mV a conversion from hex to decimal value is needed. For example, if the value read from [CTRL\\_CORE\\_STD\\_FUSE\\_OPP\\_VMIN\\_MPU\\_2](#)[11:0] STD\_FUSE\_OPP\_VMIN\_MPU\_2 is 0x041F, then this corresponds to 1055 mV.

**Table 18-26. Registers Associated With AVS Class 0 Voltage**

Physical Address	Bit Field Containing the AVS Class 0 Voltage Value	Voltage Rail	Supported OPP
0x4A00 25CC	<a href="#">CTRL_CORE_STD_FUSE_OPP_VMIN_IVA_2</a> [11:0] STD_FUSE_OPP_VMIN_IVA_2	vdd_iva	OPP_NOM

0x4A00 3B24	<a href="#">CTRL_CORE_STD_FUSE_OPP_VMIN_MPU_3</a> [11:0] STD_FUSE_OPP_VMIN_MPU_3		OPP_OD
0x4A00 3B28	<a href="#">CTRL_CORE_STD_FUSE_OPP_VMIN_MPU_4</a> [11:0] STD_FUSE_OPP_VMIN_MPU_4		OPP_HIGH
0x4A00 3B2C	<a href="#">CTRL_CORE_STD_FUSE_OPP_VMIN_MPU_5</a> [11:0] STD_FUSE_OPP_VMIN_MPU_5		OPP_PLUS

Some of the OPPs listed in [Table 18-26](#) may not be supported for some devices. In these cases the voltage values in the corresponding AVS Class 0 registers can be disregarded.

---

**NOTE:** For more information about the supported OPPs, see the "*Operating Performance Points*" section of the device Data Manual.

---

In some cases, the AVS Class 0 voltage that is read from the CTRL\_CORE\_STD\_FUSE\_OPP\_VMIN\_xxx\_y registers has a value between two incremental voltage steps of the power supply. If such a case occurs, the higher voltage value should be selected.

If several AVS Class 0 supported voltage rails are combined with each other, then all corresponding registers should be read and the highest value should be selected. The power supply of the combined rails should be changed to this highest voltage value.

---

**NOTE:** For a list of the supported voltage rail combinations, see the device Data Manual.

---

[Figure 18-12](#) shows a general example of how AVS Class 0 should be performed.

Figure 18-12. AVS Class 0 Procedure

### 18.4.6.13 ABB Associated Registers

When ABB is needed the following registers should be used:

- [CTRL\\_CORE\\_LDOVBB\\_DSPEVE\\_VOLTAGE\\_CTRL](#)
- [CTRL\\_CORE\\_LDOVBB\\_IVA\\_VOLTAGE\\_CTRL](#)
- [CTRL\\_WKUP\\_LDOVBB\\_GPU\\_VOLTAGE\\_CTRL](#)
- [CTRL\\_WKUP\\_LDOVBB\\_MPU\\_VOLTAGE\\_CTRL](#)
- The CTRL\_CORE\_STD\_FUSE\_OPP\_VMIN\_xxx\_y registers depending on the OPP. There are different values for each OPP stored in each one of these registers.

The ABB LDO target value can be read from CTRL\_CORE\_STD\_FUSE\_OPP\_VMIN\_xxx\_y[24:20] VSETABB bits, if CTRL\_CORE\_STD\_FUSE\_OPP\_VMIN\_xxx\_y[25] ABBEN is set to 0x1. Then this value should be written to bits FBB\_VSET\_OUT (bits [4:0]) of registers CTRL\_CORE/WKUP\_LDOVBB\_x\_VOLTAGE\_CTRL. The ABB LDO target value applies when CTRL\_CORE/WKUP\_LDOVBB\_x\_VOLTAGE\_CTRL[10] FBB\_MUX\_CTRL is set to 0x1, that is, FBB\_VSET\_OUT is used as a target bias voltage. When ABB is bypassed (not used) the FBB\_VSET\_OUT bits should be loaded with 0x0 and FBB\_MUX\_CTRL should be set to 0x0.

It must be taken into account that the ABB LDO target value depends on the OPP. For example, concerning the MPU voltage domain:

- in case of OPP\_NOM the value from CTRL\_CORE\_STD\_FUSE\_OPP\_VMIN\_MPU\_2[24:20] VSETABB should be used.
- in case of OPP\_OD the value from CTRL\_CORE\_STD\_FUSE\_OPP\_VMIN\_MPU\_3[24:20] VSETABB should be used.

---

**NOTE:** Before enabling the ABB LDO in FBB mode the FBB\_VSET\_OUT and FBB\_MUX\_CTRL bits must be programmed. The FBB\_VSET\_OUT bits must be loaded with a value which corresponds to the relevant OPP.

---

For more details regarding ABB see [Section 3.8.3.4 ABB LDO Programming sequence](#).

#### 18.4.6.14 Registers For Other Miscellaneous Functions

##### 18.4.6.14.1 System Boot Status Settings

The CTRL\_CORE\_BOOTSTRAP register is a status register which indicates the state of the sysboot0 to sysboot15 input signals. Their purpose is to select the boot interface, the device source clock configuration and also other boot related settings.

---

**NOTE:** For proper device operation, sysboot14 must be tied to vss. For SR1.1, sysboot15 must be tied to vdd, but for SR2.0 it is configurable. For more information, see [Section 18.4.6.1.1.1, Permanent PU/PD disabling \(SR 2.0 only\)](#) in [Chapter 18, Control Module](#).

---

##### 18.4.6.14.2 Force MPU Write Nonposted Transactions

The control module provides a way for software to force all writes from the MPU subsystem to the L3\_MAIN to be nonposted regardless of the attributes of the transactions coming from the MPU. This is done by setting to 0x1 the CTRL\_CORE\_MPU\_FORCEWRNP[0] MPU\_FORCEWRNP bit. This bit must not be changed until the transfer completes.

##### 18.4.6.14.3 Firewall Error Status Registers

There are four status registers which show when there is a firewall error. The CTRL\_CORE\_SEC\_ERR\_STATUS\_FUNC\_1 and CTRL\_CORE\_SEC\_ERR\_STATUS\_FUNC\_2 registers are used in device normal operation mode. The x\_FW\_ERROR bits from these two registers are combined into a single interrupt signal sent to the IRQ\_CROSSBAR module as shown in [Figure 18-13](#). The CTRL\_CORE\_SEC\_ERR\_STATUS\_DEBUG\_1 and CTRL\_CORE\_SEC\_ERR\_STATUS\_DEBUG\_2 registers are used when the device is in debug mode. These two registers have bits same as in the CTRL\_CORE\_SEC\_ERR\_STATUS\_FUNC\_1 and CTRL\_CORE\_SEC\_ERR\_STATUS\_FUNC\_2 registers.

All bits in these registers are cleared when the ERROR\_LOG\_k and L4\_IA\_ERROR\_LOG\_L registers are cleared.

Figure 18-13. Combined Firewall Error Interrupt

**18.4.6.14.4 Settings Related To Different Peripheral Modules**

The [CTRL\\_CORE\\_CONTROL\\_IO\\_1](#) and [CTRL\\_CORE\\_CONTROL\\_IO\\_2](#) registers have controls for specific settings of several device peripheral modules.

**18.4.7 Functional Description Of The Various Register Types In CTRL\_MODULE\_WKUP Submodule**

The following sections describe in detail the purpose of the various kinds of registers and register groups which reside in the CTRL\_MODULE\_WKUP submodule.

**18.4.7.1 Registers For Basic EMIF Configuration**

The [CTRL\\_WKUP\\_SECURE\\_EMIF1\\_SDRAM\\_CONFIG](#) and [CTRL\\_WKUP\\_SECURE\\_EMIF2\\_SDRAM\\_CONFIG](#) registers have bits which determine the basic settings of the two EMIF controllers. These are, for example, settings like CAS write latency, SDRAM drive strength, SDRAM termination resistor values, SDRAM type and others.

The [CTRL\\_WKUP\\_SECURE\\_EMIF1\\_SDRAM\\_CONFIG](#) bit field values are exported upon POR to the EMIF1.EMIF\_SDRAM\_CONFIG register.

The [CTRL\\_WKUP\\_SECURE\\_EMIF2\\_SDRAM\\_CONFIG](#) bit field values are exported upon POR to the EMIF2.EMIF\_SDRAM\_CONFIG register.

The [CTRL\\_WKUP\\_EMIF1\\_SDRAM\\_CONFIG\\_EXT](#) and [CTRL\\_WKUP\\_EMIF2\\_SDRAM\\_CONFIG\\_EXT](#) registers are associated with DDR PHY controls, ODT values for device DDR I/Os, some leveling related parameters and others.

<b>Description</b>	Control VBGAPTS temperature sensor and thermal comparator shutdown register		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																BGAP_TMPSOFF_CORE		BGAP_EOCZ_CORE		BGAP_DTEMP_CORE											

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Reserved	R	0x0
11	BGAP_TMPSOFF_CORE	This bit indicates the temperature sensor state. 0x0: temperature sensor is ON 0x1: temperature sensor is OFF <b>NOTE:</b> Software doesn't take care of this bit to get the temperature data. Only the BGAP_EOCZ_CORE bit is needed.	R	0x1
10	BGAP_EOCZ_CORE	ADC End of Conversion. Active low, when BGAP_DTEMP_CORE is valid.	R	0x0
9:0	BGAP_DTEMP_CORE	Temperature data from the ADC. Valid if EOCZ is low.	R	0x0

Bits	Field Name	Description	Type	Reset
31	RESERVED		R	0x0
30	USB2PHY_AUTORESUME_EN	Auto resume enable 0x0: disable autoresume 0x1: enable autoresume	RW	0x0
29	USB2PHY_DISCHGDET	Disable charger detect 0x0: charger detect function enabled 0x1: charger detect function disabled	RW	0x1
28	USB2PHY_PD	Power down the entire USB2_PHY2 (data, common module and UTMI). 0x0: Normal operation 0x1: Power down the USB2_PHY2	RW	0x0
27:21	RESERVED		R	0x0
20	USB2PHY_CHG_DET_DM_COMP	Output of the comparator on DM during the resistor host detect protocol. 0x0: DM line is below 0.75V to 0.95V 0x1: DM line is above 0.75V to 0.95V	R	0x0
19	USB2PHY_CHG_DET_DP_COMP	Output of the comparator on DP during the resistor host detect protocol 0x0: DP line is below 0.75V to 0.95V 0x1: DP line is above 0.75V to 0.95V	R	0x0
18	USB2PHY_DATADET	Output of the charger detect comparator 0x0: DM line is below 0.25V to 0.4V 0x1: DM line is above 0.25V to 0.4V	R	0x0
17	USB2PHY_CHGDETDONE	Status indicates that charger detection protocol is over 0x0: charger detection protocol is not over 0x1: charger detection protocol is over	R	0x0
16	USB2PHY_CHGDETECTED	Output of the charger detection protocol 0x0: charger not detected 0x1: charger detected	R	0x0
15	USB2PHY_RESETDONEMCLK	OCP reset status 0x0: OCP domain is in reset 0x1: OCP domain is out of reset	R	0x0
14	USB2PHY_UTMIRESETDONE	UTMI FSM reset status 0x0: UTMI FSMs are in reset 0x1: UTMI FSMs are out of reset	R	0x0
13	USBDPLL_FREQLOCK	Status from USB DPLL	R	0x0
12	USB2PHY_RESETDONETCLK	resetdonetclk status from USB2_PHY2	R	0x0
11	USB2PHY_GPIOMODE	GPIO mode 0x0: USB mode enabled 0x1: GPIO mode enabled	RW	0x0
10	USB2PHY_CHG_DET_EXT_CTL	Charge detect external control 0x0: charger detect internal state machine used 0x1: charge detect statemachine is bypassed	RW	0x0
9	USB2PHY_RDM_PD_CHGDET_EN	DM Pull down control 0x0: PD disabled 0x1: PD enabled	RW	0x0

Bits	Field Name	Description	Type	Reset
8	USB2PHY_RDP_PU_CHGDET_EN	DP Pull up control 0x0: PU disabled 0x1: PU enabled	RW	0x0
7	USB2PHY_CHG_VSRC_EN	VSRC enable on DP line: Host charger case 0x0: disable VSRC drive on DP 0x1: drives VSRC 600mV on DP line	RW	0x0
6	USB2PHY_CHG_ISINK_EN	ISINK enable on DM line: Host charger case 0x0: disable the ISINK on DM 0x1: enables the ISINK (100µA) on DM line	RW	0x0
5	USB2PHY_SINKONDP	When '1' current sink is connected to DP instead of DM 0x0: Default value 0x1: enables the ISINK on DP instead of DM	RW	0x0
4	USB2PHY_SRCONDM	When '1' voltage source is connected to DP instead of DM 0x0: Default value 0x1: enable the VSRC on DM instead of DP	RW	0x0
3	USB2PHY_RESTARTCHGDET	restartchgdet: '1' for 1 msec cause the CD_START to reset 0x0: Default value 0x1: a high pulse of 1 msec causes the charger detect to restart on negative edge of restartchgdet	RW	0x0
2	USB2PHY_MCPCPUEN	MCPC Pull up enable 0x0: disable the MCPC pull up 0x1: enable the 4.7K to 10K pull up on receive line DP when datapolarity is 0 and DM when datapolarity is 1	RW	0x0
1	USB2PHY_MCPCMODEEN	MCPC Mode enable 0x0: disable MCPC mode 0x1: enable MCPC mode	RW	0x0
0	USB2PHY_DATAPOLARITYN	Data polarity 0x0: DP functionality is on DP and DM functionality is on DM 0x1: DP functionality is on DM and DM functionality is on DP	RW	0x0
