This mode is an alternative to the FIFO interrupt mode of operation in which the status of the receiver and transmitter is automatically determined by sending interrupts to the MPU.

#### 24.3.4.6.4 FIFO DMA Mode Operation

Although the DMA operation includes four modes (DMA modes 0 through 3), the information in [Table 24-133, UART Hardware Requests](#), assumes that mode 1 is used. (Mode 2 and mode 3 are legacy modes that use only one DMA request for each module.)

In mode 2, the remaining DMA request is used for RX. In mode 3, the remaining DMA request is used for TX.

DMA requests in mode 2 and mode 3 use the `UARTi_DREQ_TX` signals (where  $i = 1$  to 10).

The `UARTi_DREQ_RX` signals are not used by the module in mode 2 and mode 3:

The DMA mode and signals usage can be selected as follows:

- When the `UARTi.UART_SCR[0]` `DMA_MODE_CTL` bit is set to 0, setting the `UARTi.UART_FCR[3]` `DMA_MODE` bit to 0 enables DMA mode 0. Setting the `UARTi.UART_FCR[3]` `DMA_MODE` bit to 1 enables DMA mode 1.
- When the `UARTi.UART_SCR[0]` `DMA_MODE_CTL` bit is set to 1, the `UARTi.UART_SCR[2:1]` `DMA_MODE_2` bit field determines DMA mode 0 to mode 3 based on the supplementary control register (SCR) description.

For example:

- If no DMA operation is desired, set the `UARTi.UART_SCR[0]` `DMA_MODE_CTL` bit to 1 and the `UARTi.UART_SCR[2:1]` `DMA_MODE_2` bit field to 0x0. (The `DMA_MODE` bit is discarded.)
- If DMA mode 1 is desired, set the `UARTi.UART_SCR[0]` `DMA_MODE_CTL` bit to 0 and the `UARTi.UART_FCR[3]` `DMA_MODE` bit to 1, or set the `UARTi.UART_SCR[0]` `DMA_MODE_CTL` bit to 1 and the `SCR[2:1]` `DMA_MODE_2` bit field to 01. (The `UARTi.UART_FCR[3]` `DMA_MODE` bit is discarded.)

If the FIFOs are disabled (the UARTi.UART\_FCR[0] FIFO\_EN bit is set to 0), the DMA occurs in single-character transfers.

When DMA mode 0 is programmed, the signals associated with DMA operation are not active.

Depending on UARTi.UART\_MDR3[2] SET\_DMA\_TX\_THRESHOLD, the threshold can be programmed different ways:

- SET\_TX\_DMA\_THRESHOLD = 1:

The threshold value will be the value of the TX\_DMA\_THRESHOLD register. If SET\_TX\_DMA\_THRESHOLD + TX trigger spaces 64, then the default method of threshold is used: threshold value = TX FIFO size.

- SET\_TX\_DMA\_THRESHOLD = 0:

The threshold value = TX FIFO size TX trigger space. The TX DMA line is asserted if the TX FIFO level is lower than the threshold. It remains asserted until TX trigger spaces number of bytes are written into the FIFO. The DMA line is then deasserted and the FIFO level is compared with the threshold value.

#### 24.3.4.6.4.1 DMA sequence to disable TX DMA

In order to disable TX DMA if it is not needed anymore (e.g. all transfers are done and UART idle mode is desired), the following sequence must be use

1. DMA mode 1 is set (both TX/RX DMA) by registers UARTi.UART\_SCR[0] = 0 and UARTi.UART\_FCR[3] = 1:

- A. Set the UARTi.UART\_SCR[2:1] DMA\_MODE\_2 bit fields to 01 (DMA mode 1)
- B. Set the UARTi.UART\_SCR[0] DMA\_MODE\_CTL bit to 1 (this setting of UARTi.UART\_SCR[0] DMA\_MODE-CTL will ignores UARTi.UART\_FCR[3] DMA\_MODE\_CTL bit )

---

**NOTE:** It is strongly suggested to do steps 'a' and 'b' in two separate write in order to avoid malfunction of the device.

- C. Set the UARTi.UART\_FCR[3] DMA\_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UARTi.UART\_SCR[0] DMA\_MODE\_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used. In IrDA modes RX can be forcibly disabled by setting UARTi.UART\_ACREG[5] DIS\_IR\_RX bit

---

**NOTE:** There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

- D. Set the UARTi.UART\_FCR[2:1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
  - E. Set the UARTi.UART\_SCR[2:1] DMA\_MODE\_2 bit field to 10 (DMA mode 2, RX only).
  - F. Set the UARTi.UART\_FCR[2:1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
  - G. Set the UARTi.UART\_SCR[2:1] DMA\_MODE\_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.
2. DMA mode 1 is set (both TX/RX DMA) by registers UARTi.UART\_FCR[3] = 0 and UARTi.UART\_SCR[0] = 1, UARTi.UART\_SCR[2:1] = 01. It is almost the same as above, but steps 'a', and 'b' can be skipped:
    - A. Set the UARTi.UART\_FCR[3] DMA\_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UARTi.UART\_SCR[0] DMA\_MODE\_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used. In IrDA modes RX can be forcibly disabled by setting UARTi.UART\_ACREG[5] DIS\_IR\_RX bit

**NOTE:** There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

- B. Set the UARTi.UART\_FCR[2:1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
  - C. Set the UARTi.UART\_SCR[2:1] DMA\_MODE\_2 bit field to 10 (DMA mode 2, RX only).
  - D. Set the UARTi.UART\_FCR[2:1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
  - E. Set the UARTi.UART\_SCR[2:1] DMA\_MODE\_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.
3. DMA mode 3 is set (TX DMA only) by registers UARTi.UART\_FCR[3] = 0 and UARTi.UART\_SCR[0] = 1, UARTi.UART\_SCR[2:1] = 11. It is the same as above:
    - A. Set the UARTi.UART\_FCR[3] DMA\_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UARTi.UART\_SCR[0] DMA\_MODE\_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used. In IrDA modes RX can be forcibly disabled by setting UARTi.UART\_ACREG[5] DIS\_IR\_RX bit

**NOTE:** There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

- B. Set the UARTi.UART\_FCR[2:1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
- C. Set the UARTi.UART\_SCR[2:1] DMA\_MODE\_2 bit field to 10 (DMA mode 2, RX only).
- D. Set the UARTi.UART\_FCR[2:1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
- E. Set the UARTi.UART\_SCR[2:1] DMA\_MODE\_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.

#### 24.3.4.6.4.2 DMA Transfers (DMA Mode 1, 2, or 3)

Figure 24-62 through Figure 24-65 show the supported DMA operations.

**Figure 24-62. Receive FIFO DMA Request Generation (32 Characters)**

uart-026

In receive mode, a DMA request is generated when the RX FIFO reaches its threshold level defined in the trigger level register (UARTi.UART\_TLR). This request is deasserted when the number of bytes defined by the threshold level is read by the device DMA controllers.

In transmit mode, a DMA request is automatically asserted when the TX FIFO is empty. This request is deasserted when the number of bytes defined by the number of spaces in the UARTi.UART\_TLR register is written by the device DMA controllers. If an insufficient number of characters is written, the DMA request stays active.

**Figure 24-63. Transmit FIFO DMA Request Generation (56 Spaces)**

uart-027

The DMA request is again asserted if the FIFO can receive the number of bytes defined by the UARTi.UART\_TLR register.

The threshold can be programmed in a number of ways. Figure 24-63 shows a DMA transfer operating with a space setting of 56 that can arise from using the auto settings in the UARTi.UART\_FCR[5:4] TX\_FIFO\_TRIG bit field or the UARTi.UART\_TLR[3:0] TX\_FIFO\_TRIG\_DMA bit field concatenated with the TX\_FIFO\_TRIG bit field.

The setting of 56 spaces in the UART/IrDA/CIR module must correlate with the settings of the device DMA controllers, so that the buffer does not overflow (program the DMA request size of the LH controller to equal the number of spaces in the UART/IrDA/CIR module).

Figure 24-64 shows an example with eight spaces to show the buffer level crossing the space threshold. The LH DMA controller settings must correspond to those of the UART/IrDA/CIR module.

Figure 24-64. Transmit FIFO DMA Request Generation (8 Spaces)

uart-028

The next example shows the setting of one space that uses the DMA for each transfer of one character to the transmit buffer (see Figure 24-65). The buffer is filled faster than the baud rate at which data is transmitted to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer.

On two occasions, the buffer holds the maximum amount of data words; shortly after this, the DMA is disabled to show the slower transmission of the data words to the TX pin. Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UARTi.UART\_DLL and UARTi.UART\_DLH registers.

The DMA settings must correspond to the system LH DMA controller settings to ensure correct operation of this logic.

Figure 24-65. Transmit FIFO DMA Request Generation (1 Space)

uart-029

The final example illustrates the setting of eight spaces but setting the TX DMA threshold directly by setting `UART_MDR3[1] NONDEFAULT_FREQ` bit and `UART_TX_DMA_THRESHOLD` register (see Figure 24-66). In the example, `UART_TX_DMA_THRESHOLD[5:0] TX_DMA_THRESHOLD = 3` and the trigger level is 8. The buffer is filled at a faster rate than the BAUD rate transmits data to the TX pin. The buffer is filled with 8 bytes and the DMA operations stop transferring data to the transmit buffer. When the buffer is emptied to the threshold level by transmission, the DMA operation activates again to fill the buffer with 8 bytes.

Eventually, the buffer will be emptied at the rate specified by the BAUD Rate settings of the `UART_DLL` and `UART_DLH` registers.

If the selected threshold level + trigger level exceeds max buffer size, then the original TX DMA threshold method is used to prevent TX overrun, regardless of the `UART_MDR3[1] NONDEFAULT_FREQ` value.

The DMA settings should correspond to the system Local Host DMA controller settings in order to ensure the correct operation of this logic.

**Figure 24-66. Transmit FIFO DMA Request Generation Using Direct TX DMA Threshold Programming. (Threshold = 3; Spaces = 8)**

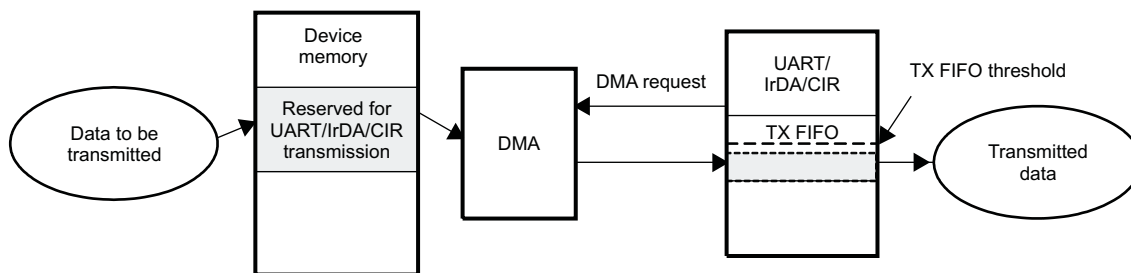

uart-036

#### 24.3.4.6.4.3 DMA Transmission

Figure 24-67 shows DMA transmission.

**Figure 24-67. DMA Transmission**

uart-030

1. Data to be transmitted are put in the device memory reserved for UART/IrDA/CIR transmission by the

**DMA:**

- a. Until the TX FIFO trigger level is not reached, a DMA request is generated
  - b. An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).
2. Data in the TX FIFO are automatically transmitted.
  3. The end of the transmission is signaled by the UARTi.UART\_THR empty (TX FIFO empty).

---

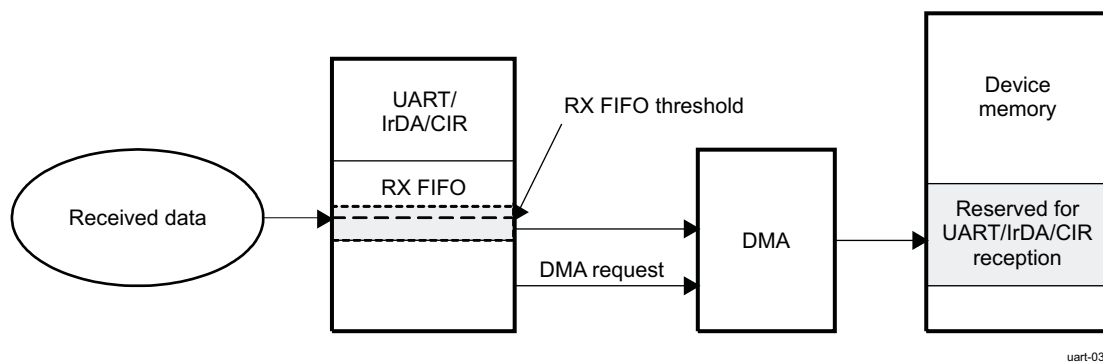

**NOTE:** In IrDA mode, the transmission does not end immediately after the TX FIFO empties, at which point the last data byte, the CRC field, and the stop flag still must be transmitted; thus, the end of transmission occurs a few milliseconds after the UARTi.UART\_THR register empties.

---

#### 24.3.4.6.4.4 DMA Reception

Figure 24-68 shows DMA reception.

**Figure 24-68. DMA Reception**

1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA:
  - a. At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
  - b. An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

#### 24.3.4.7 Mode Selection

##### 24.3.4.7.1 Register Access Modes

###### 24.3.4.7.1.1 Operational Mode and Configuration Modes

Register access depends on the register access mode, although register access modes are not correlated to functional mode selection. Three different modes are available:

- Operational mode
- Configuration mode A
- Configuration mode B

Operational mode is the selected mode when the function is active; serial data transfer can be performed in this mode.

Configuration mode A and configuration mode B are used during module initialization steps. These modes enable access to configuration registers, which are hidden in the operational mode. The modes are used when the module is inactive (no serial data transfer processed) and only for initialization or reconfiguration of the module.

The value of the UARTi.UART\_LCR register determines the register access mode (see [Table 24-140](#)).

**Table 24-140. UART/IrDA/CIR Register Access Mode Programming (Using UART\_LCR)**

Mode	Condition
Configuration mode A	UART_LCR[7] = 0x1 and UART_LCR[7:0] != 0xBF
Configuration mode B	UART_LCR[7] = 0x1 and UART_LCR[7:0] = 0xBF
Operational mode	UART_LCR[7] = 0x0

#### 24.3.4.7.1.2 Register Access Submode

In each access register mode (operational mode or configuration mode A/B), some register accesses are conditional on the programming of a submode (MSR\_SPR, TCR\_TLR, and XOFF). These registers are identified in [Section 24.3.6](#), *UART/IrDA/CIR Register Manual*.

[Table 24-141](#) through [Table 24-143](#) summarize the register access submodes.

**Table 24-141. Subconfiguration Mode A Summary**

Mode	Condition
MSR_SPR	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

**Table 24-142. Subconfiguration Mode B Summary**

Mode	Condition
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1
XOFF	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)

**Table 24-143. Suboperational Mode Summary**

Mode	Condition
MSR_SPR	UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

#### 24.3.4.7.1.3 Registers Available for the Register Access Modes

[Table 24-144](#) lists the names of the register bits in each access register mode. Gray shading indicates that the register does not depend on the register access mode (available in all modes).

**Table 24-144. UART/IrDA/CIR Register Access Mode Overview**

Address Offset	Registers					
	Configuration Mode A		Configuration Mode B		Operational Mode

#### 24.3.4.7.2 UART/IrDA (SIR, MIR, FIR)/CIR Mode Selection

To select a mode, set the UARTi.UART\_MDR1[2:0] MODE\_SELECT bit field (see Table 24-145).

**Table 24-145. UART Mode Selection**

Value	Mode
0x0:	UART 16x mode
0x1:	SIR mode (UART3 only)
0x2:	UART 16x auto-baud
0x3:	UART 13x mode
0x4:	MIR mode (UART3 only)
0x5:	FIR mode (UART3 only)

**Table 24-145. UART Mode Selection (continued)**

Value	Mode
0x6:	CIR mode (UART3 only)

MODE\_SELECT is effective when the module is in operational mode (see [Section 24.3.4.7.1, Register Access Modes](#)).

#### 24.3.4.7.2.1 Registers Available for the UART Function

Only the registers listed in [Table 24-146](#) are used for the UART function.

**Table 24-146. UART Mode Register Overview**

Address Offset	Registers <sup>(1) (2)</sup>

### 24.3.4.8 Protocol Formatting

#### 24.3.4.8.1 UART Mode

##### 24.3.4.8.1.1 UART Clock Generation: Baud Rate Generation

The UART function contains a programmable baud generator and a set of fixed divisors that divide the 48-MHz clock input down to the expected baud rate.

Figure 24-69 shows the baud rate generator and associated controls.

uart-032

#### CAUTION

Before initializing or modifying clock parameter controls (UARTi.UART\_DLH, UARTi.UART\_DLL), MODE\_SELECT = DISABLE (UARTi.UART\_MDR1[2:0]) must be set to 0x7. Failure to observe this rule can result in unpredictable module behavior.

##### 24.3.4.8.1.2 Choosing the Appropriate Divisor Value

Two divisor values are:

- UART 16x mode: Divisor value = Operating frequency / (16x baud rate)
- UART 13x mode: Divisor value = Operating frequency / (13x baud rate)

Table 24-149 and Table 24-150 describe the UART baud rate settings.

**Table 24-149. UART Baud Rate Settings (48-MHz Clock)**

#### 24.3.4.8.1.3 UART Data Formatting

The UART can use hardware flow control to manage transmission and reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals.

The UART is enhanced with the autobauding function. In control mode, autobauding lets the speed, the number of bits per character, and the parity selected be set automatically.

### 24.3.4.8.1.3.1 Frame Formatting

When autobauding is not used, frame format attributes must be defined in the UARTi.UART\_LCR register.

Character length is specified using the UARTi.UART\_LCR[1:0] CHAR\_LENGTH bit field.

The number of stop-bits is specified using the UARTi.UART\_LCR[2] NB\_STOP bit.

The parity bit is programmed using the UARTi.UART\_LCR[5:3] PARITY\_EN, PARITY\_TYPE\_1, and PARITY\_TYPE\_2 bit fields (see Table 24-151).

**Table 24-151. UART Parity Bit Encoding**

PARITY_EN	PARITY_TYPE_1	PARITY_TYPE_2	Parity
0	N/A	N/A	No parity
1	0	0	Odd parity
1	1	0	Even parity
1	0	1	Forced 1
1	1	1	Forced 0

### 24.3.4.8.1.3.2 Hardware Flow Control

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled and disabled independently by programming the UARTi.UART\_EFR[7:6] AUTO\_CTS\_EN and AUTO\_RTS\_EN bit fields, respectively.

With auto-CTS, uarti\_ctsn must be active before the module can transmit data.

Auto-RTS activates the uarti\_rtsn output only when there is enough room in the RX FIFO to receive data. It deactivates the uarti\_rtsn output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the UARTi.UART\_TCR register determine the levels at which uarti\_rtsn is activated and deactivated.

If auto-CTS and auto-RTS are enabled, data transmission does not occur unless the RX FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If auto-CTS and auto-RTS are not enabled, overrun errors occur if the transmit data rate exceeds the RX FIFO latency.

- Auto-RTS:

Auto-RTS data flow control originates in the receiver block. The RX FIFO trigger levels used in auto-RTS are stored in the UARTi.UART\_TCR register. uarti\_rtsn is active if the RX FIFO level is below the HALT trigger level in the UARTi.UART\_TCR[3:0] RX\_FIFO\_TRIG\_HALT bit field. When the RX FIFO HALT trigger level is reached, uarti\_rtsn is deasserted. The sending device (for example, another UART) can send an additional byte after the trigger level is reached because it may not recognize the deassertion of RTS until it begins sending the additional byte.

uarti\_rtsn is automatically reasserted when the RX FIFO reaches the RESUME trigger level programmed by the UARTi.UART\_TCR[7:4] RX\_FIFO\_TRIG\_START bit field. This reassertion requests the sending device to resume transmission.

In this case, uarti\_rtsn is an active-low signal.

- Auto-CTS:

The transmitter circuitry checks uarti\_ctsn before sending the next data byte. When uarti\_ctsn is active, the transmitter sends the next byte. To stop the transmitter from sending the next byte, uarti\_ctsn must be deasserted before the middle of the last stop-bit currently sent.

The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled, the uarti\_ctsn state changes do not have to trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO, and a receiver overrun error can result.

In this case, uarti\_ctsn is an active-low signal.

### 24.3.4.8.1.3.3 Software Flow Control

Software flow control is enabled through the enhanced feature register (UARTi.UART\_EFR) and the modem control register (UARTi.UART\_MCR). Different combinations of software flow control can be enabled by setting different combinations of the UARTi.UART\_EFR[3:0] bit field (see Table 24-152).

Two other enhanced features relate to software flow control:

- XON-any function (UARTi.UART\_MCR[5]): Operation resumes after receiving any character after the XOFF character is recognized. If special character detect is enabled and special character is received after XOFF1, it does not resume transmission. The special character is stored in the RX FIFO.

---

**NOTE:** The XON-any character is written into the RX FIFO even if it is a software flow character.

---

- Special character (UARTi.UART\_EFR[5]): Incoming data is compared to XOFF2. When the special character is detected, the XOFF interrupt (UARTi.UART\_IIR[4]) is set, but it does not halt transmission. The XOFF interrupt is cleared by a read of UARTi.UART\_IIR. The special character is transferred to the RX FIFO. Special character does not work with XON2, XOFF2, or sequential XOFFs.

**Table 24-152. UART\_EFR[3:0] Software Flow Control Options**

Bit 3	Bit 2	Bit 1	Bit 0	TX, RX Software Flow Controls
0	0	X	X	No transmit flow control
1	0	X	X	Transmit XON1, XOFF1
0	1	X	X	Transmit XON2, XOFF2
1	1	X	X	Transmit XON1, XON2: XOFF1, XOFF2 <sup>(1)</sup>
X	X	0	0	No receive flow control
X	X	1	0	Receiver compares XON1, XOFF1
X	X	0	1	Receiver compares XON2, XOFF2
X	X	1	1	Receiver compares XON1, XON2: XOFF1, XOFF2 <sup>(1)</sup>

<sup>(1)</sup> In these cases, the XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2.

XON1 is defined in the UARTi.UART\_XON1\_ADDR1[7:0] XON\_WORD1 bit field. XON2 is defined in the UARTi.UART\_XON2\_ADDR2[7:0] XON\_WORD2 bit field.

XOFF1 is defined in the UARTi.UART\_XOFF1[7:0] XOFF\_WORD1 bit field. XOFF2 is defined in the UARTi.UART\_XOFF2[7:0] XOFF\_WORD2 bit field.

#### 24.3.4.8.1.3.3.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases, XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission stops after transmission of the current character completes. Detection of XOFF also sets the UARTi.UART\_IIR[4] bit (if enabled by UARTi.UART\_IER[5]) and causes the interrupt line to go low.

To resume transmission, an XON1/2 character must be received (in certain cases, XON1 and XON2 must be received sequentially). When the correct XON characters are received, the UARTi.UART\_IIR[4] bit is cleared and the XOFF interrupt disappears.

---

**NOTE:** When a parity, framing, or break error occurs while receiving a software flow control character, this character is treated as normal data and is written to the RX FIFO.

---

When XON-any and special character detect are disabled and software flow control is enabled, no valid XON or XOFF characters are written to the RX FIFO. For example, when UARTi.UART\_EFR[1:0] = 0x2, if XON1 and XOFF1 characters are received, they are not written to the RX FIFO.

When pairs of software flow characters are programmed to be received sequentially (UARTi.UART\_EFR[1:0] = 0x3), the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

#### 24.3.4.8.1.3.3.2 Transmit (TX)

Two XOFF1 characters are transmitted when the RX FIFO passes the trigger level programmed by UARTi.UART\_TCR[3:0]. As soon as the RX FIFO reaches the trigger level programmed by UARTi.UART\_TCR[7:4], two XON1 characters are sent, so the data transfer recovers.

---

**NOTE:** If software flow control is disabled after an XOFF character is sent, the module transmits XON characters automatically to enable normal transmission.

---

The transmission of XOFF(s)/XON(s) follows the same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is 5, 6, or 7 characters, the 5, 6, or 7 LSBs of XOFF1/2 and XON1/2 are transmitted. The 5, 6, or 7 bits of a character are seldom transmitted, but this function is included to maintain compatibility with earlier designs.

It is assumed that software flow control and hardware flow control are never enabled simultaneously.

#### 24.3.4.8.1.3.4 Autobauding Modes

In autobauding mode, the UART can extract transfer characteristics (speed, length, and parity) from an "at" (AT) command (ASCII code). These characteristics are used to receive data after an AT and to send data.

The following AT commands are valid:

AT	DATA	<CR>
at	DATA	<CR>
A/		
a/		

A line break during the acquisition of the sequence AT is not recognized, and an echo function is not implemented in hardware.

A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final <CR> (0x0D), are saved to the RX FIFO. The autobaud state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved in the RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The UARTi.UART\_UASR register reflects the correct settings for the baud rate detected. Interrupt activity can continue in this fashion when a subsequent character is received. Therefore, it is recommended that the software enable the RHR interrupt when using the autobaud mode.

The following settings are detected in autobaud mode with a module clock of 48 MHz:

- Speed:
  - 115.2K baud
  - 57.6K baud
  - 38.4K baud
  - 28.8K baud
  - 19.2K baud
  - 14.4K baud
  - 9.6K baud
  - 4.8K baud
  - 2.4K baud
  - 1.2K baud

- Length: 7 or 8 bits
- Parity: Odd, even, or space

---

**NOTE:** The combination of 7-bit character plus space parity is not supported.

---

Autobauding mode is selected when the UARTi.UART\_MDR1[2:0] MODE\_SELECT bit field is set to 0x2. In UART autobauding mode, UARTi.UART\_DLL, UARTi.UART\_DLH, and UARTi.UART\_LCR[5:0] bit field settings are not used; instead, UASR is updated with the configuration detected by the autobauding logic.

#### UASR Autobauding Status Register Use

This register is used to set up transmission according to the characteristics of the previous reception instead of the UARTi.UART\_LCR, UARTi.UART\_DLL, and UARTi.UART\_DLH registers when the UART is in autobauding mode.

To reset the autobauding hardware (to start a new AT detection) or to set the UART in standard mode (no autobaud), the UARTi.UART\_MDR1[2:0] MODE\_SELECT bit field must be set to reset state (0x7) and then to the UART in autobauding mode (0x2) or to the UART in standard mode (0x0).

Use limitation:

- Only 7- and 8-bit characters (5- and 6-bit not supported)
- 7-bit character with space parity not supported
- Baud rate between 1200 and 115,200 bps (10 possibilities)

#### 24.3.4.8.1.3.5 Error Detection

When the UARTi.UART\_LSR register is read, the UARTi.UART\_LSR[4:2] bit field reflects the error bits (BI: break condition, FE: framing error, PE: parity error) of the character at the top of the RX FIFO (the next character to be read). Therefore, reading the UARTi.UART\_LSR register and then reading the UARTi.UART\_RHR register identifies errors in a character.

Reading the UARTi.UART\_RHR register updates the BI, FE, and PE bits (see [Table 24-135](#) for the UART mode interrupts).

The UARTi.UART\_LSR[7] RX\_FIFO\_STS bit is set when there is an error in the RX FIFO and is cleared only when no errors remain in the RX FIFO.

---

**NOTE:** Reading the UARTi.UART\_LSR register does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading the UARTi.UART\_RHR register.

---

Reading the UARTi.UART\_LSR register clears the OE bit if it is set (see [Table 24-135](#) for the UART mode interrupts).

#### 24.3.4.8.1.3.6 Overrun During Receive

Overrun during receive occurs if the RX state-machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the MPU with the UARTi.UART\_IIR[5:1] IT\_TYPE bit field set to 0x3 (receiver line status error) and discards the remaining portion of the frame.

Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received, the MPU must:

- Reset the RX FIFO.
- Read the UARTi.UART\_RESUME register, which clears the internal flag.

### 24.3.4.8.1.3.7 Time-Out and Break Conditions

#### 24.3.4.8.1.3.7.1 Time-Out Counter

An RX idle condition is detected when the receiver line (uarti\_rxd) is high for a time that equals 4x the programmed word length + 12 bits. uarti\_rxd is sampled midway through each bit.

For sleep mode, the counter is reset when there is activity on uarti\_rxd.

For the time-out interrupt, the counter counts only when there is data in the RX FIFO, and the count is reset when there is activity on uarti\_rxd or when the UARTi.UART\_RHR register is read.

#### 24.3.4.8.1.3.7.2 Break Condition

When a break condition occurs, uarti\_txd is pulled low. A break condition is activated by setting the UARTi.UART\_LCR[6] BREAK\_EN bit. The break condition is not aligned on word stream (a break condition can occur in the middle of a character). The only way to send a break condition on a full character is:

1. Reset the TX FIFO (if enabled).
2. Wait for the transmit shift register to empty (the UARTi.UART\_LSR[6] TX\_SR\_E bit is set to 1).
3. Take a guard time according to stop-bit definition.
4. Set the BREAK\_EN bit to 1.

The break condition is asserted while the BREAK\_EN bit is set to 1.

The time-out counter and break condition apply only to UART modem operation and not to IrDA/CIR mode operation.

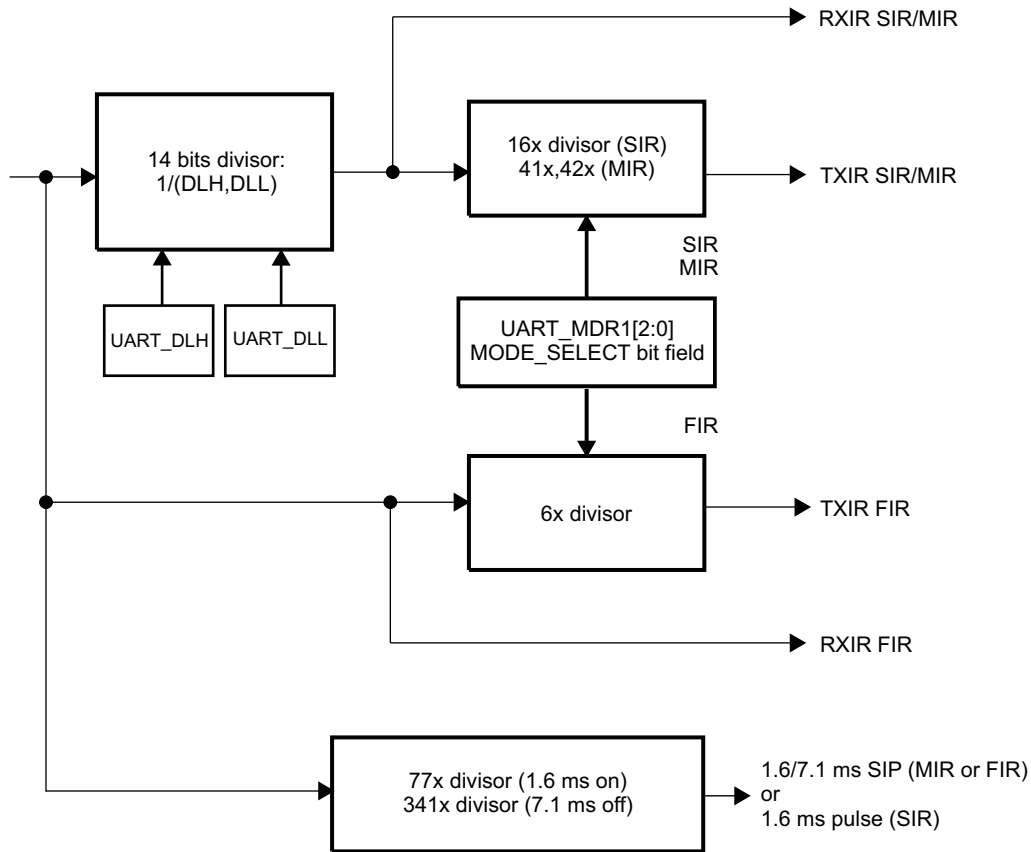

### 24.3.4.8.2 IrDA Mode (UART3 Only)

#### 24.3.4.8.2.1 IrDA Clock Generation: Baud Generator

The IrDA function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

[Figure 24-70](#) shows the baud rate generator and associated controls.

Figure 24-70. Baud Rate Generator

uart-033

**CAUTION**

Before initializing or modifying clock parameter controls (UARTi.UART\_DLH, UARTi.UART\_DLL), MODE\_SELECT=DISABLE (UARTi.UART\_MDR1[2:0]) must be set to 0x7. Failure to observe this rule can result in unpredictable module behavior.

**24.3.4.8.2.2 Choosing the Appropriate Divisor Value**

Three divisor values are:

- SIR mode: Divisor value = Operating frequency/(16x baud rate)
- MIR mode: Divisor value = Operating frequency/(41x/42x baud rate)
- FIR mode: Divisor value = None

Table 24-153 lists the IrDA baud rate settings.

**Table 24-153. IrDA Baud Rate Settings**

Baud Rate	IR Mode	Baud Multiple	Encoding	DLH, DLL (Decimal)	Actual Baud Rate	Error (%)	Source Jitter (%)	Pulse Duration
2.4 kbps	SIR	16x	3/16	1250	2.4 kbps	0	0	78.1 μs
9.6 kbps	SIR	16x	3/16	312	9.6153 kbps	+0.16	0	19.5 μs
19.2 kbps	SIR	16x	3/16	156	19.231 kbps	+0.16	0	9.75 μs
38.4 kbps	SIR	16x	3/16	78	38.462 kbps	+0.16	0	4.87 μs

**Table 24-153. IrDA Baud Rate Settings (continued)**

Baud Rate	IR Mode	Baud Multiple	Encoding	DLH, DLL (Decimal)	Actual Baud Rate	Error (%)	Source Jitter (%)	Pulse Duration
57.6 kbps	SIR	16x	3/16	52	57.692 kbps	+0.16	0	3.25 $\mu$ s
115.2 kbps	SIR	16x	3/16	26	115.38 kbps	+0.16	0	1.62 $\mu$ s
0.576 Mbps	MIR	41x/42x	1/4	2	0.5756 Mbps <sup>(1)</sup>	0	+1.63/-0.80	416 ns
1.152 Mbps	MIR	41x/42x	1/4	1	1.1511 Mbps <sup>(1)</sup>	0	+1.63/-0.80	208 ns
4 Mbps	FIR	6x	4 PPM	–	4 Mbps	0	0	125 ns

<sup>(1)</sup> Average value

**NOTE:** Baud rate error and source jitter table values do not include 48-MHz reference clock error and jitter.

#### 24.3.4.8.2.3 IrDA Data Formatting

The methods described in this section apply to all IrDA modes (SIR, MIR, and FIR).

##### 24.3.4.8.2.3.1 IR RX Polarity Control

The UART3.UART\_MDR2[6] IRRXINVERT bit provides the flexibility to invert the uart3\_rxd pin in the UART to ensure that the protocol at the output of the transceiver has the same polarity at module level. By default, the uart3\_rxd pin is inverted because most transceivers invert the IR receive pin.

##### 24.3.4.8.2.3.2 IrDA Reception Control

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

Operation of the uart3\_rxd input can be disabled by the UART3.UART\_ACREG[5] DIS\_IR\_RX bit.

##### 24.3.4.8.2.3.3 IR Address Checking

In all IR modes, when address checking is enabled, only frames intended for the device are written to the RX FIFO. This restriction avoids receiving frames not meant for this device in a multipoint infrared environment. It is possible to program two frame addresses that the UART IrDA receives, with the UART3.UART\_XON1\_ADDR1[7:0] XON\_WORD1 and UART3.UART\_XON2\_ADDR2[7:0] XON\_WORD2 bit fields.

Setting the UART\_EFR[0] bit to 1 selects address1 checking. Setting the UART\_EFR[1] bit to 1 selects address2 checking. Setting the UART\_EFR[1:0] bit field to 0 disables all address checking operations. If both bits are set, the incoming frame is checked for private and public addresses.

If address checking is disabled, all received frames write to the RX FIFO.

##### 24.3.4.8.2.3.4 Frame Closing

A transmission frame can be terminated in two ways:

- Frame-length method: Set the UART3.UART\_MDR1[7] FRAME\_END\_MODE bit to 0. The MPU writes the value of the frame length to the UART3.UART\_TXFLH and UART3.UART\_TXFLL registers. The device automatically attaches end flags to the frame when the number of bytes transmitted equals the value of the frame length.
- Set-EOT bit method: Set the FRAME\_END\_MODE bit to 1. The MPU writes 1 to the UART3.UART\_ACREG[0] EOT bit just before it writes the last byte to the TX FIFO. When the MPU writes the last byte to the TX FIFO, the device internally sets the tag bit for that character in the TX FIFO. As the TX state-machine reads data from the TX FIFO, it uses this tag-bit information to attach end flags and correctly terminate the frame.

#### 24.3.4.8.2.3.5 Store and Controlled Transmission

In store and controlled transmission (SCT) mode, the MPU starts writing data to the TX FIFO. Then, after writing a part of a frame (for a bigger frame) or an entire frame (a small frame; that is, a supervisory frame), the MPU writes 1 to the UART3.UART\_ACREG[2] SCTX\_EN bit (deferred TX start) to start transmission.

SCT mode is enabled by setting the UART3.UART\_MDR1[5] SCT bit to 1. This transmission method differs from normal mode, in which data transmission starts immediately after data is written to the TX FIFO. SCT mode is useful for sending short frames without TX underrun.

#### 24.3.4.8.2.3.6 Error Detection

When the UART3.UART\_LSR register is read, the UART3.UART\_LSR[4:2] bit field reflects the error bits [FL, CRC, ABORT] of the frame at the top of the STATUS FIFO (the next frame status to be read).

The error is triggered by an interrupt (for IrDA mode interrupts, see [Table 24-136](#)). The STATUS FIFO must be read until empty (a maximum of eight reads is required).

#### 24.3.4.8.2.3.7 Underrun During Transmission

Underrun during transmission occurs when the TX FIFO is empty before the end of the frame is transmitted. When underrun occurs, the device closes the frame with end flags but attaches an incorrect CRC value. The receiving device detects a CRC error and discards the frame; it can then ask for a retransmission.

Underrun also causes an internal flag to be set, which disables additional transmissions. Before the next frame can be transmitted, the MPU must:

- Reset the TX FIFO.
- Read the UART3.UART\_RESUME register, which clears the internal flag.

This function can be disabled by the UART3.UART\_ACREG[4] DIS\_TX\_UNDERRUN bit, compensated by the extension of the stop-bit in transmission if the TX FIFO is empty.

#### 24.3.4.8.2.3.8 Overrun During Receive

Overrun during receive for the IrDA mode has the same function as that for the UART mode (see [Section 24.3.4.8.1.3.6](#), *Overrun During Receive*).

#### 24.3.4.8.2.3.9 Status FIFO

In IrDA modes, a status FIFO records the received frame status. When a complete frame is received, the length of the frame and the error bits associated with the frame are written to the status FIFO.

Reading the UART3.UART\_SFREGH[3:0] MSB and UART3.UART\_SFREGL[3:0] (LSB) bit fields obtains the frame length. The frame error status is read in the UART3.UART\_SFLSR register. Reading the UART3.UART\_SFLSR register increments the status FIFO read pointer. Because the status FIFO is eight entries deep, it can hold the status of eight frames.

The MPU uses the frame-length information to locate the frame boundary in the received frame data. The MPU can screen bad frames using the error status information and can later request the sender to resend only the bad frames.

This status FIFO can be used effectively in DMA mode because the MPU must be interrupted only when the programmed status FIFO trigger level is reached, not each time a frame is received.

#### 24.3.4.8.2.4 SIR Mode Data Formatting

This section provides specific instructions for SIR mode programming.

##### 24.3.4.8.2.4.1 Abort Sequence

The transmitter can prematurely close a frame (abort) by sending the sequence 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

A transmission frame can be aborted by setting the UART3.UART\_ACREG[1] ABORT\_EN bit to 1. When this bit is set to 1, 0x7D and 0xC1 are transmitted and the frame is not terminated with CRC or stop flags.

When a 0x7D character followed immediately by a 0xC1 character is received without transparency, the receiver treats a frame as an aborted frame.

#### **CAUTION**

When the TX FIFO is not empty and the UART3.UART\_MDR1[5] SCT bit is set to 1, the UART IrDA starts a new transfer with data of a previous frame when the aborted frame is sent. Therefore, the TX FIFO must be reset before sending an aborted frame.

#### **24.3.4.8.2.4.2 Pulse Shaping**

SIR mode supports the 3/16 or the 1.6- $\mu$ s pulse duration methods. The UART3.UART\_ACREG[7] PULSE\_TYPE bit selects the pulse width method in the transmit mode.

#### **24.3.4.8.2.4.3 SIR Free Format Programming**

The SIR FF mode is selected by setting the module in the UART mode (UART3.UART\_MDR1[2:0] MODE\_SELECT = 0x0) and the UART3.UART\_MDR2[3] PULSE bit to 1 to allow pulse shaping.

Because the bit format stays the same, some UART mode configuration registers must be set at specific values:

- UART3.UART\_LCR[1:0] CHAR\_LENGTH bit field = 0x3 (8 data bits)
- UART3.UART\_LCR[2] NB\_STOP bit = 0x0 (1 stop-bit)
- UART3.UART\_LCR[3] PARITY\_EN bit = 0x0 (no parity)

The UART mode interrupts are used for the SIR FF mode, but many are not relevant (XOFF, RTS, CTS, modem status register, etc.).

#### **24.3.4.8.2.5 MIR and FIR Mode Data Formatting**

This section describes common instructions for FIR and MIR mode programming.

At the end of a frame reception, the MPU reads the line status register (UART3.UART\_LSR) to detect errors in the received frame.

When the UART3.UART\_MDR1[6] SIP\_MODE bit is set to 1, the TX state-machine always sends one SIP at the end of a transmission frame. However, when the SIP\_MODE bit is set to 0, SIP transmission depends on the UART3.UART\_ACREG[3] SEND\_SIP bit.

The MPU can set the SEND\_SIP bit at least once every 500 ms. The advantage of this approach over the default approach is that the TX state-machine does not have to send the SIP at the end of each frame, thus reducing the overhead required.

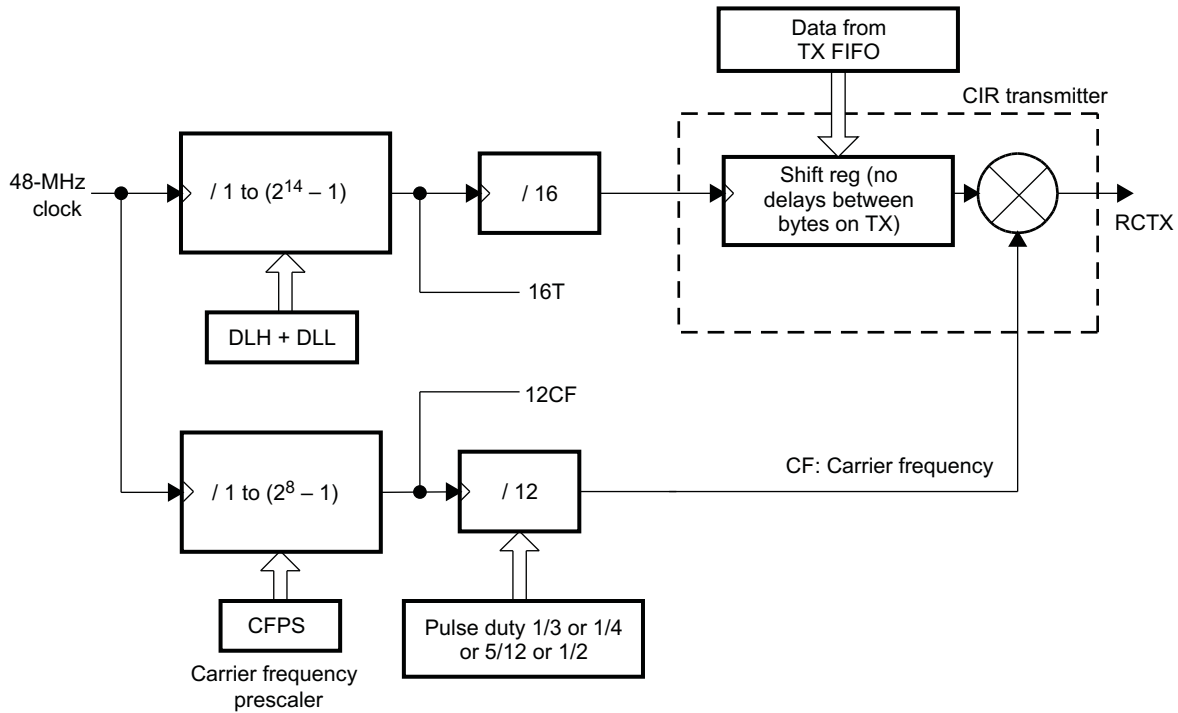

#### **24.3.4.8.3 CIR Mode (UART3 Only)**

##### **24.3.4.8.3.1 CIR Mode Clock Generation**

Depending on the encoding method (variable pulse distance/biphase), the MPU must develop a data structure that combines 1 and 0 with a  $t$  period to encode the complete frame to transmit. This can then be transmitted to the infrared output with a modulation method, as shown in [Figure 24-71](#).

Figure 24-71. CIR Mode Block Components

uart-034

Based on the requested modulation frequency, the UART3.UART\_CFPS register must be set with the correct dividing value to provide an accurate pulse frequency:

$$\text{Dividing value} = (\text{FCLK} / 12) / \text{MODfreq}$$

Where:

FCLK = System clock frequency (48 MHz)

12 = Real value of baud multiple

MODfreq = Effective frequency of the modulation (MHz)

Example: For a targeted modulation frequency of 36 kHz, the value of CFPS must be set to 0x7 (decimal), which provides a modulation frequency of 36.04 kHz.

**NOTE:** The UART3.UART\_CFPS register starts with a reset value of 105 (decimal), which translates to a frequency of 38.1 kHz.

The duty cycle of these pulses is user-defined by the pulse duty register bits in the UART3.UART\_MDR2 register. Table 24-154 shows the duty cycle.

Table 24-154. Duty Cycle

UART_MDR2[5:4]	Duty Cycle (High-Level)
00	1/4
01	1/3
10	5/12
11	1/2

### 24.3.4.8.3.2 CIR Data Formatting

The methods described in this section apply to all CIR modes.

#### 24.3.4.8.3.2.1 IR RX Polarity Control

The IR RX polarity control for CIR mode has the same function as that for IrDA mode (see [Section 24.3.4.8.2.3.1, IR RX Polarity Control](#)).

#### 24.3.4.8.3.2.2 CIR Transmission

In transmission, the MPU software must exercise an element of real-time control to transmit data packets, each of which must be emitted at a constant delay from the start-bits of each individual packet. Thus, when sending a series of packets, the packet-to-packet delay must respect a specific delay. Two methods can be used to control this delay:

- Filling the TX FIFO with a number of zero bits that are transmitted with a  $t$  period
- Using an external system timer to control the delay between each start-of-frame or between the end of a frame and the start of the next one. This can be performed by:
  - Controlling the start of the frame using the UART3.UART\_MDR1[5] SCT bit and the UART3.UART\_ACREG[2] SCTX\_EN bit, depending on the timer status
  - Using the UART3.UART\_IIR[5] TX\_STATUS\_IT interrupt bit to preload the next frame in the TX FIFO and to control the start of the timer (in case of control delay between the end of a frame and the start of the next frame)

### 24.3.5 UART/IrDA/CIR Basic Programming Model

This section describes the procedure for operating the UART with FIFO and DMA or interrupts. This three-part procedure ensures the quick start of the UART. It does not cover every UART feature.

The first programming model covers software reset of the UART. The second programming model describes FIFO and DMA configuration. The last programming model describes protocol, baud rate, and interrupt configuration.

**NOTE:** Each programming model can be used independently of the other two; for instance, reconfiguring the FIFOs and DMA settings only.

Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see [Section 24.3.4.7.1, Register Access Modes](#).

#### 24.3.5.1 Global Initialization

##### 24.3.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the UART/IrDA/CIR module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the UART/IrDA/CIR.

For more information, see [Section 24.3.3, UART/IrDA/CIR Integration](#).

**Table 24-155. Global Initialization of Surrounding Modules for UART/IrDA/CIR**

Surrounding Modules	Comments
PRCM	UART functional and interface clocks must be enabled. For more information, see <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Control module	Module-specific pad muxing must be set in the control module. For more information, see <a href="#">Chapter 18, Control Module</a> .
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see <a href="#">Section 18.4.6.4, IRQ_CROSSBAR Module Functional Description</a> , in <a href="#">Chapter 18, Control Module</a>
Interrupt controllers	Device INTCs must be configured to enable the interrupt request generation. For information about enabling interrupts, see <a href="#">Chapter 17, Interrupt Controllers</a> .
DMA_CROSSBAR	DMA_CROSSBAR configuration must be done to allow module DREQs to be mapped to certain device DMA line. For more information see <a href="#">Section 18.4.6.4, DMA_CROSSBAR Module Functional Description</a> , in <a href="#">Chapter 18, Control Module</a> .
DMA controllers	DMA controllers configuration must be done to enable the module DMA channel request. See <a href="#">Chapter 16, DMA Controllers</a>
Interconnects	For information about the L4 interconnect configuration, see <a href="#">Chapter 14, Interconnect</a> .

##### 24.3.5.1.2 UART/IrDA/CIR Module Global Initialization

The procedure in [Table 24-156](#) can be used to initialize UART when performing software reset.

**Table 24-156. UART/IrDA/CIR Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Perform a software reset.	UART_SYSC[1] SOFTRESET	1
Wait until reset is finished.	UART_SYSS[0] RESETDONE	=1

### 24.3.5.2 Mode selection

Table 24-157 describes how to set different register access mode.

**Table 24-157. Configure Register Access Mode**

Step	Register/Bit Field/Programming Model	Value
Set the register access mode A	UART_LCR[7] DIV_EN	1
	UART_LCR[7:0]	≠0xBF
Set the register access mode B	UART_LCR[7:0]	0xBF
Set the operational mode	UART_LCR[7] DIV_EN	0

### 24.3.5.3 Submode selection

This section describes how to set different register access submode.

**Table 24-158. Configure Register Access Submode TCR\_TLR**

Step	Register/Bit Field/Programming Model	Value
<b>Configure the submode TCR_TLR:</b>		
Configure mode B	see Table 24-157	
Enable writing to register bits UART_MCR[6:5]	UART_EFR[4] ENHANCED_EN	1
Configure mode A	see Table 24-157	0x1
Set the submode TCR_TLR	UART_MCR[6] TCR_TLR	1

**Table 24-159. Configure Register Access Submode MSR\_SPR**

Step	Register/Bit Field/Programming Model	Value
<b>First option to configure the submode MSR_SPR:</b>		
Configure mode B	see Table 24-157	
Set the submode MSR_SPR	UART_EFR[4] ENHANCED_EN	0
<b>Second option to configure the submode MSR_SPR:</b>		
Configure mode B	see Table 24-157	
Enable writing to register bits UART_MCR[6:5]	UART_EFR[4] ENHANCED_EN	1
Set the submode MSR_SPR	UART_MCR[6] TCR_TLR	0

**Table 24-160. Configure Register Access Submode XOFF**

Step	Register/Bit Field/Programming Model	Value
<b>Configure of the XOFF:</b>		
Configure B	see Table 24-157	
Set the submode XOFF	UART_EFR[4] ENHANCED_EN	0

### 24.3.5.4 Load FIFO trigger and DMA mode settings

#### 24.3.5.4.1 DMA mode Settings

To enable and configure DMA mode, perform the following steps:

**Table 24-161. DMA Mode Settings**

Step	Register/Bit Field/Programming Model	Value
Set the option of DMA mode configuration	UART_SCR[0] DMA_MODE_CTL	-
IF Configure DMA mode 0 and 1	UART_SCR[0] DMA_MODE_CTL	=0

**Table 24-161. DMA Mode Settings (continued)**

Step	Register/Bit Field/Programming Model	Value
Select the DMA mode, for more information see <a href="#">Section 24.3.4.6.4</a>	UART_FCR[3] DMA_MODE	-
IF Configure DMA mode from 0 to 3	UART_SCR[0] DMA_MODE_CTL	=1
Select the DMA mode, for more information see <a href="#">Section 24.3.4.6.4</a>	UART_SCR[2:1] DMA_MODE_2	-

#### 24.3.5.4.2 FIFO Trigger Settings

In this section is described configuration and settings of FIFO trigger level, which enable DMA and interrupt generation.

**Table 24-162. Load FIFO Triggers Defined by the FCR**

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see <a href="#">Table 24-158</a>	0x-
Set the desire RX FIFO trigger level	UART_FCR[5:4] TX_FIFO_TRIG	0x-
Set the desire TX FIFO trigger level	UART_FCR[7:6] RX_FIFO_TRIG	0x-

**Table 24-163. Load FIFO Triggers Defined by the TLR**

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see <a href="#">Table 24-158</a>	0x-
Set the desire RX FIFO trigger level	UART_TLR[7:4] RX_FIFO_TRIG_DMA	0x-
Set the desire TX FIFO trigger level	UART_TLR[3:0] TX_FIFO_TRIG_DMA	0x-

**Table 24-164. Load FIFO Triggers Defined by the Concatenated Value**

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see <a href="#">Table 24-158</a>	0x-
Set the register bit	UART_SCR[7] RX_TRIG_GRANU1	1
Set the desire RX FIFO trigger level	UART_TLR[7:4] RX_FIFO_TRIG_DMA UART_FCR[7:6] RX_FIFO_TRIG	0x-
Set the register bit	UART_SCR[6] TX_TRIG_GRANU1	1
Set the desire TX FIFO trigger level	UART_TLR[3:0] TX_FIFO_TRIG_DMA UART_FCR[5:4] TX_FIFO_TRIG	0x-

#### 24.3.5.5 Protocol, Baud rate and interrupt settings

##### 24.3.5.5.1 Baud rate settings

**Table 24-165. Baud Rate Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2:0] MODE_SELECT	0x7
Switch to register configuration mode B	see <a href="#">Table 24-157</a>	
Enable access to <a href="#">UART_IER[7:4]</a>	UART_EFR[4] ENHANCED_EN	1
Switch register operational mode	see <a href="#">Table 24-157</a>	
Disable sleep mode	UART_IER[4] SLEEP_MODE	0
Switch to register configuration mode A or B	see <a href="#">Table 24-157</a>	

**Table 24-165. Baud Rate Settings (continued)**

Step	Register/Bit Field/Programming Model	Value
Set the appropriate divisor value	UART_DLL[7:0] CLOCK_LSB	0x-
	UART_DLH[5:0] CLOCK_MSB	

#### 24.3.5.5.2 Interrupt settings

**Table 24-166. Interrupt Settings**

Step	Register/Bit Field/Programming Model	Value
Switch to register configuration mode B	see <a href="#">Table 24-157</a>	0x7
Enable access to UART_IER[7:4]	UART_EFR[4] ENHANCED_EN	1
Switch register operational mode	see <a href="#">Table 24-157</a>	
Set the desired interrupt configuration (0: Disable the interrupt; 1: Enable the interrupt)	UART_IER[7] CTS_IT	0x-
	UART_IER[6] RTS_IT	
	UART_IER[5] XOFF_IT	
	UART_IER[4] SLEEP_MODE	
	UART_IER[3] MODEM_STS_IT	
	UART_IER[2] LINE_STS_IT	
	UART_IER[1] THR_IT	
	UART_IER[0] RHR_IT	

#### 24.3.5.5.3 Protocol settings

Load the desired protocol formatting (parity, stop-bit, character length) and switch to register operational mode.

**Table 24-167. Protocol Settings**

Step	Register/Bit Field/Programming Model	Value
Load desired protocol formatting, see <a href="#">Section 24.3.4.8.1.3.1</a> , <i>Frame Formatting</i>	UART_LCR[5] PARITY_TYPE_2	0x-
	UART_LCR[4] PARITY_TYPE_1	
	UART_LCR[3] PARITY_EN	
	UART_LCR[2] NB_STOP	
	UART_LCR[1:0] PARITY_LENGTH	
Switch to register operational mode	UART_LCR[7] DIV_EN	0
	UART_LCR[6] BREAK_EN	

#### 24.3.5.5.4 UART/IrDA(SIR/MIR/FIR)/CIR

**Table 24-168. UART/IrDA/CIR Mode Selection**

Step	Register/Bit Field/Programming Model	Value
Load the desired UART mode, see <a href="#">Section 24.3.4.7.2</a> , <i>UART/IrDA (SIR, MIR, FIR)/CIR Mode Selection</i>	UART_MDR1[2:0] MODE_SELECT	0x-

### 24.3.5.6 Hardware and Software Flow Control Configuration

This section describes the programming steps to enable and configure hardware and software flow control. Hardware and software flow control cannot be used at the same time.

#### 24.3.5.6.1 Hardware Flow Control Configuration

**Table 24-169. Hardware Flow Control Configuration**

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see <a href="#">Table 24-158</a>	0x7
Load the start and halt trigger value.	<a href="#">UART_TCR[7:4] AUTO_RTS_START</a> <a href="#">UART_TCR[3:0] AUTO_RTS_HALT</a>	0x-
Enable or disable receive and transmit hardware flow control mode.	<a href="#">UART_EFR[7] AUTO_CTS_EN</a> <a href="#">UART_EFR[6] AUTO_RTS_EN</a>	0x-

#### 24.3.5.6.2 Software Flow Control Configuration

**Table 24-170. Software Flow Control Configuration**

Step	Register/Bit Field/Programming Model	Value
Set the register access submode XOFF	see <a href="#">Table 24-160</a>	
Load the software control characters	<a href="#">UART_XON1_ADDR1[7:0] XON_WORD1</a> <a href="#">UART_XON2_ADDR2[7:0] XON_WORD2</a> <a href="#">UART_XOFF1[7:0] XOFF_WORD1</a> <a href="#">UART_XOFF2[7:0] XOFF_WORD2</a>	0x-
Set the register access submode TCR_TLR	see <a href="#">Table 24-158</a>	
Enable or disable XON any function (0: Disable; 1: Enable).	<a href="#">UART_MCR[5] XON_EN</a>	--
Load start and halt trigger value for software flow control	<a href="#">UART_TCR[7:4] AUTO_RTS_START</a> <a href="#">UART_TCR[3:0] AUTO_RTS_HALT</a>	0x-
Enable or disable special character function (0: Disable; 1: Enable)	<a href="#">UART_EFR[5] SPEC_CHAR</a>	0x-
Set the software flow control mode	<a href="#">UART_EFR[3:0] SW_FLOW_CONTROL</a>	0x-

### 24.3.5.7 IrDA Programming Model (UART3 Only)

#### 24.3.5.7.1 SIR mode

##### 24.3.5.7.1.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with parity forced to 1, baud rate = 115.2 kbps, FIFOs disabled, 2 stop-bits, and 8-bit word length:

**Table 24-171. SIR Mode Receive Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	<a href="#">UART_MDR1[2:0] MODE_SELECT</a>	0x7
Grant access to the <a href="#">UART_DLL</a> and <a href="#">UART_DLH</a> registers	<a href="#">UART_LCR[7:0]</a>	0x80
Load the baud rate(115.2 Kbps)	<a href="#">UART_DLL[7:0] CLOCK_LSB</a> <a href="#">UART_DLH[5:0] CLOCK_MSB</a>	0x1A 0x00
Set SIR mode	<a href="#">UART_MDR1[2:0] MODE_SELECT</a>	0x1

**Table 24-171. SIR Mode Receive Settings (continued)**

Step	Register/Bit Field/Programming Model	Value
Disable access to the <a href="#">UART_DLL</a> and <a href="#">UART_DLH</a> registers	<a href="#">UART_LCR</a> [7:0]	0x00
Enable the <a href="#">UART_RHR</a> interrupt	<a href="#">UART_IER_IRDA</a> [0] RHR_IT	1

#### 24.3.5.7.1.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 6-byte frame with no parity, baud rate = 115.2 kbps, FIFOs disabled, 3/16 encoding, 2 stop-bits, and 7-bit word length:

**Table 24-172. SIR Mode Transmit Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	<a href="#">UART_MDR1</a> [2:0] MODE_SELECT	0x7
Grant access to the <a href="#">UART_DLL</a> and <a href="#">UART_DLH</a> registers	<a href="#">UART_LCR</a> [7:0]	0x80
Load the baud rate (115.2 Kbps)	<a href="#">UART_DLL</a> [7:0] CLOCK_LSB	0x1A
	<a href="#">UART_DLH</a> [5:0] CLOCK_MSB	0x00
Set SIR mode	<a href="#">UART_MDR1</a> [2:0] MODE_SELECT	0x1
Disable access to the <a href="#">UART_DLL</a> and <a href="#">UART_DLH</a> registers	<a href="#">UART_LCR</a> [7:0]	0x00
Force DTR output to active	<a href="#">UART_MCR</a> [0] DTR	1
Enable the THR interrupt	<a href="#">UART_IER_IRDA</a> [1] THR_IT	0x1
Set transmit frame length to 6 bytes	<a href="#">UART_TXFLL</a> [7:0] TXFLL	0x06
Set the seven starts of frame transmission	<a href="#">UART_EBLR</a> [7:0] EBLR	0x08
Set SIR pulse width to be 1.6 $\mu$ s	<a href="#">UART_ACREG</a> [7] PULSE_TYPE	1

#### 24.3.5.7.2 MIR mode

##### 24.3.5.7.2.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with no parity, baud rate = 1.152 Mbps, and FIFOs disabled.

**Table 24-173. MIR Mode Receive Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	<a href="#">UART_MDR1</a> [2:0] MODE_SELECT	0x7
Grant access to the <a href="#">UART_DLL</a> and <a href="#">UART_DLH</a> registers	<a href="#">UART_LCR</a> [7:0]	0x80
Load the baud rate (1.152bps)	<a href="#">UART_DLL</a> [7:0] CLOCK_LSB	0x01
	<a href="#">UART_DLH</a> [5:0] CLOCK_MSB	0x00
Set MIR mode	<a href="#">UART_MDR1</a> [2:0] MODE_SELECT	0x4
Disable access to the <a href="#">UART_DLL</a> and <a href="#">UART_DLH</a> registers	<a href="#">UART_LCR</a> [7:0]	0x00
Force outputs DTR and RTS to active	<a href="#">UART_MCR</a> [1:0]	0x3
Enable the <a href="#">UART_RHR</a> interrupt	<a href="#">UART_IER_IRDA</a> [0] RHR_IT	1

##### 24.3.5.7.2.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 60-byte frame with no parity, baud rate = 1.152 Mbps, and FIFOs disabled.

**Table 24-174. MIR Mode Transmit Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2:0] MODE_SELECT	0x7
Grant access to the <a href="#">UART_DLL</a> and <a href="#">UART_DLH</a> registers	UART_LCR[7:0]	0x80
Load the baud rate (115.2 kbps)	UART_DLL[7:0] CLOCK_LSB UART_DLH[5:0] CLOCK_MSB	0x01 0x00
Set SIR mode	UART_MDR1[2:0] MODE_SELECT	0x4
Disable access to the <a href="#">UART_DLL</a> and <a href="#">UART_DLH</a> registers	UART_LCR[7:0]	0x00
Force DTR output to active	UART_MCR[0] DTR	1
Enable the THR interrupt	UART_IER_IRDA[1] THR_IT	0x1
Set transmit frame length to 60 bytes	UART_TXFLL[7:0] TXFLL	0x3C
Set the eight additional starts of frame transmission	UART_EBLR[7:0] EBLR	0x08
SIP is sent at the end of transmission	UART_ACREG[3] SEND_SIP	1

### 24.3.5.7.3 FIR mode

#### 24.3.5.7.3.1 Receive

The following programming model explains how to program the module to receive the IrDA frame with no parity, baud rate = 4 Mbps, FIFOs enabled, 8-bit word length.

**Table 24-175. FIR Mode Receive Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2:0] MODE_SELECT	0x7
Grant access to the <a href="#">UART_DLL</a> and <a href="#">UART_DLH</a> registers	UART_LCR[7:0]	0x80
Enable access to change <a href="#">UART_FCR</a> [0]	UART_DLL[7:0] CLOCK_LSB UART_DLH[7:0] CLOCK_MSB	0x0
FIFO clear and enable	UART_FCR[2:0]	0x7
Set the FIFO trigger level	see <a href="#">Section 24.3.5.4, Load FIFO trigger and DMA mode settings</a>	
Set FIR mode	UART_MDR1[2:0] MODE_SELECT	0x5
Set frame length	UART_RXFLL[7:0] RXFLL	0xA
Disable access to the <a href="#">UART_DLL</a> and <a href="#">UART_DLH</a> registers	UART_LCR[7:0]	0x00
Enable the <a href="#">UART_RHR</a> interrupt	UART_IER_IRDA[0] RHR_IT	1

#### 24.3.5.7.3.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 4-byte frame with no parity, baud rate = 4 Mbps, FIFOs enabled, and 8-bit word length.

**Table 24-176. FIR Mode Transmit Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2:0] MODE_SELECT	0x7
Grant access to the <a href="#">UART_DLL</a> and <a href="#">UART_DLH</a> registers	UART_LCR[7:0]	0x80
Enable access to change <a href="#">UART_FCR</a> [0]	UART_DLL[7:0] CLOCK_LSB UART_DLH[5:0] CLOCK_MSB	0x0
FIFO clear and enable	UART_FCR[2:0]	0x7

**Table 24-176. FIR Mode Transmit Settings (continued)**

Step	Register/Bit Field/Programming Model	Value
Set the FIFO trigger level	see <a href="#">Section 24.3.5.4, Load FIFO trigger and DMA mode settings</a>	
Set FIR mode	<a href="#">UART_MDR1</a> [2:0] MODE_SELECT	0x1
Disable access to the <a href="#">UART_DLL</a> and <a href="#">UART_DLH</a> registers	<a href="#">UART_LCR</a> [7:0]	0x00
Set FIR mode and enable auto-SIP mode	<a href="#">UART_MDR1</a> [7:0]	0x45
Set frame length	<a href="#">UART_TXFLL</a> [7:0] TXFLL	0x4
	<a href="#">UART_TXFLH</a> [7:0] TXFLH	0x0
Force DTR output to active	<a href="#">UART_MCR</a> [0] DTR	1
Enable the THR interrupt	<a href="#">UART_IER_IRDA</a> [1] THR_IT	1
Set the eight additional starts of frame transmission	<a href="#">UART_EBLR</a> [7:0] EBLR	0x08
SIP is sent at the end of transmission	<a href="#">UART_ACREG</a> [3] SEND_SIP	1

## 24.3.6 UART/IrDA/CIR Register Manual

### 24.3.6.1 UART/IrDA/CIR Instance Summary

**Table 24-177. UART/IrDA/CIR Instance Summary**

Module Name	Module Base Address	Size
UART1	0x4806 A000	136 Bytes
UART2	0x4806 C000	136 Bytes
UART3	0x4802 0000	136 Bytes
UART4	0x4806 E000	136 Bytes
UART5	0x4806 6000	136 Bytes
UART6	0x4806 8000	136 Bytes
UART7	0x4842 0000	136 Bytes
UART8	0x4842 2000	136 Bytes
UART9	0x4842 4000	136 Bytes
UART10	0x4AE2 B000	136 Bytes

### 24.3.6.2 UART/IrDA/CIR Registers

#### 24.3.6.2.1 UART/IrDA/CIR Register Summary

**Table 24-178. UART/IrDA/CIR Registers Mapping Summary 1**

	<b>Instance</b>																																																																								
	UART1 UART2 UART3 UART4 UART5 UART6 UART7 UART8 UART9 UART10																																																																								
<b>Description</b>	The transmitter section consists of the transmit holding register (THR) and the transmit shift register. The THR is a 64-byte FIFO. The local host (LH) writes data to the THR. The data is placed in the transmit shift register where it is shifted out serially on the TX output. If the FIFO is disabled, location 0 of the FIFO stores the data.

<b>Description</b>	The receiver section consists of the receiver holding register (RHR) and the receiver shift register. The RHR is a 64-byte FIFO. The receiver shift register receives serial data from RX input. The data is converted to parallel data and moved to the RHR. If the FIFO is disabled, location 0 of the FIFO stores the single data character. <b>Note:</b> If an overflow occurs, the data in the RHR is not overwritten.		
<b>Type</b>	R

<b>Description</b>	Transmission control register  This register stores the RX FIFO threshold levels to start/stop transmission during hardware/software flow control. Notes: Trigger levels from 0 to 60 bytes are available with a granularity of 4. (Trigger level = 4 x [4-bit register value]) The programmer must ensure that <code>UART_TCR[3:0] &gt; UART_TCR[7:4]</code> when auto-RTS or software flow control is enabled to avoid a mis-operation of the device. In FIFO interrupt mode with flow control, the programmer must ensure that the trigger level to halt transmission is greater than or equal to the RX FIFO trigger level ( <code>UART_TLR[7:4]</code> or <code>UART_FCR[7:6]</code> ); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist because a DMA request is sent each time a byte is received.

<b>Description</b>	Mode definition register 1  The mode of operation can be programmed by writing to MDR1[2:0] and therefore the MDR1 must be programmed on startup after configuration of the configuration registers ( <a href="#">UART_DLL</a> , <a href="#">UART_DLH</a> , and <a href="#">UART_LCR</a> ). The value of MDR1[2:0] must not be changed again during normal operation. <b>Note:</b> If the module is disabled by setting the MODE_SELECT field to 111, interrupt requests can still be generated unless disabled through the interrupt enable register ( <a href="#">UART_IER</a> ). In this case, UART mode interrupts are visible. Reading the interrupt identification register ( <a href="#">UART_IIR</a> ) shows UART mode interrupt flags.

**Table 24-234. UART\_MDR2**

Address Offset	0x0000 0024	Instance	
Physical Address	<a href="#">0x4806 A024</a> <a href="#">0x4806 C024</a> <a href="#">0x4802 0024</a> <a href="#">0x4806 E024</a> <a href="#">0x4806 6024</a> <a href="#">0x4806 8024</a> <a href="#">0x4842 0024</a> <a href="#">0x4842 2024</a> <a href="#">0x4842 4024</a> <a href="#">0x4AE2 B024</a>		UART1 UART2 UART3 UART4 UART5 UART6 UART7 UART8 UART9 UART10
Description	Mode definition register 2  IR-IrDA and IR-CIR modes only. <a href="#">UART_MDR2[0]</a> describes the status of the interrupt in <a href="#">UART_IIR[5]</a> . The IRTX_UNDERRUN bit should be read after an <a href="#">UART_IIR[5] TX_STATUS_IT</a> interrupt. The bits [2:1] of this register set the trigger level for the frame status FIFO (8 entries) and must be programmed before the mode is programmed in <a href="#">UART_MDR1[2:0]</a> . <b>Note:</b> The <a href="#">UART_MDR2[6]</a> gives the flexibility to invert the RX pin in the UART to ensure that the protocol at the input of the transceiver module has the same polarity at module level. By default, the RX pin is inverted because most transceivers invert the IR receive pin.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																SET_TXIR_ALT	IRRXINVERT	CIR_PULSE_MODE	UART_PULSE	STS_FIFO_TRIG	IRTX_UNDERRUN										

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0. Write has no effect.	RW	0x000000
7	SET_TXIR_ALT	Provide alternate function for <a href="#">UART_MDR1</a> [4] (SET_TXIR).  0x0: Normal mode 0x1: Alternate mode for SET_TXIR	R	0
6	IRRXINVERT	IR mode only (IrDA and CIR). Invert RX pin in the module before the voting or sampling system logic of the infrared block. This does not affect the RX path in UART modem modes.  0x0: Inversion is performed. 0x1: No inversion is performed.	RW	0
5:4	CIR_PULSE_MODE	CIR pulse modulation definition. Defines high level of the pulse width associated with a digit:  0x0: Pulse width of 3 from 12 cycles 0x1: Pulse width of 4 from 12 cycles 0x2: Pulse width of 5 from 12 cycles 0x3: Pulse width of 6 from 12 cycles	RW	0x0
3	UART_PULSE	UART mode only. Allows pulse shaping in UART mode.  0x0: Normal UART mode 0x1: UART mode with a pulse shaping	RW	0
2:1	STS_FIFO_TRIG	IR-IrDA mode only. Frame status FIFO threshold select:  0x0: 1 entry 0x1: 4 entries 0x2: 7 entries 0x3: 8 entries	RW	0x0
0	IRTX_UNDERRUN	IrDA transmission status interrupt. When the <a href="#">UART_IIR</a> [5] interrupt occurs, the meaning of the interrupt is:  Read 0x0: The last bit of the frame transmitted successfully without error.  Read 0x1: An underrun occurred. The last bit of the frame was transmitted but with an underrun error. The bit is reset to 0 when the <a href="#">UART_RESUME</a> register is read.	R	0

**Table 24-254. UART\_UASR**

<b>Address Offset</b>	0x0000 0038		
<b>Physical Address</b>	0x4806 A038 0x4806 C038 0x4802 0038 0x4806 E038 0x4806 6038 0x4806 8038 0x4842 0038 0x4842 2038 0x4842 4038 0x4AE2 B038	<b>Instance</b>	UART1 UART2 UART3 UART4 UART5 UART6 UART7 UART8 UART9 UART10
<b>Description</b>	UART autobauding status register  UART autobauding mode only. This status register returns the speed, the number of bits by characters, and the type of the parity in UART autobauding mode. In autobauding mode, the input frequency of the UART modem must be fixed to 48 MHz. Any other module clock frequency results in incorrect baud rate recognition. <b>Note:</b> When the UART is in autobauding mode, this register, instead of the <a href="#">UART_LCR</a> , <a href="#">UART_DLL</a> , and <a href="#">UART_DLH</a> registers, is used to set up transmission according to the characteristics of the previous reception. To reset the autobauding hardware (to start a new AT detection), set <a href="#">UART_MDR1[2:0]</a> to 111 (reset value), then set <a href="#">UART_MDR1[2:1]</a> to 010 (UART in autobaud mode). To set the UART to standard mode (no autobaud), set <a href="#">UART_MDR1[2:1]</a> to 000.

<b>Description</b>	Auxiliary control register. IR-IrDA and IR-CIR modes only.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
RESERVED																																		
																PULSE_TYPE	SD_MOD	DIS_IR_RX	DIS_TX_UNDERRUN	SEND_SIP	SCTX_EN	ABORT_EN	EOT_EN											

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0. Write has no effect.	RW	0x000000
7	PULSE_TYPE	SIR pulse width select 0x0: 3/16 of baud-rate pulse width 0x1: 1.6 $\mu$ s	RW	0
6	SD_MOD	Primary output used to configure transceivers. Connected to the SD/MODE input pin of IrDA transceivers. 0x0: SD pin is set to high. 0x1: SD pin is set to low.	RW	0
5	DIS_IR_RX	0x0: Normal operation (RX input automatically disabled during transmit but enabled outside of transmit operation) 0x1: Disables RX input (permanent state - independent of transmit)	RW	0
4	DIS_TX_UNDERRUN	It is recommended to disable TX FIFO underrun capability by masking corresponding underrun interrupt. When disabling underrun by setting <a href="#">UART_ACREG[4]</a> = 1, garbage data is sent over TX line. 0x0: Long stop-bits cannot be transmitted; TX underrun is enabled. 0x1: Long stop-bits can be transmitted; TX underrun is disabled.	RW	0

Bits	Field Name	Description	Type	Reset
3	SEND_SIP	MIR/FIR modes only. Send serial infrared interaction pulse (SIP). If this bit is set during an MIR/FIR transmission, the SIP is sent at the end of it. This bit is cleared automatically at the end of the SIP transmission. 0x0: No action 0x1: Send SIP pulse.	RW	0
2	SCTX_EN	Store and controlled TX start. When <a href="#">UART_MDR1[5]</a> = 1 and the LH writes 1 to this bit, the TX state-machine starts frame transmission. This bit is self-clearing.	RW	0
1	ABORT_EN	Frame abort. The LH can intentionally abort transmission of a frame by writing 1 to this bit. Neither the end flag nor the CRC bits are appended to the frame. If TX FIFO is not empty and <a href="#">UART_MDR1[5]</a> = 1, UART IrDA starts a new transfer with data of the previous frame when the abort frame is sent. Therefore, TX FIFO must be reset before sending an abort frame.	RW	0
0	EOT_EN	EOT (end of transmission) bit. The LH writes 1 to this bit just before it writes the last byte to the TX FIFO in set-EOT bit frame closing method. This bit is cleared automatically when the LH writes to the THR (TX FIFO).	RW	0

<b>Description</b>	BOF length register		
	<p>IR-IrDA and IR-CIR modes only. In IR-IrDA SIR operation, this register specifies the number of BOF + xBOFs to transmit. Value set into this register must account for the BOF character; therefore, to send only one BOF with no XBOF, this register must be set to 1. To send one BOF with N XBOF, this register must be set to N + 1. The value 0 sends 1 BOF plus 255 XBOF. In IR-IrDA MIR mode, this register specifies the number of additional start flags (MIR protocol mandates a minimum of 2 start flags). In IR-CIR mode, this register specifies the number of consecutive 0s to be received before generating the RX_STOP interrupt (<a href="#">UART_IIR[2]</a>). All received 0s are stored in the RX FIFO. When the register is set to 0, this feature is deactivated and always in reception state, which can be disabled by setting the <a href="#">UART_ACREG[5]</a> to 1.</p> <p><b>Note:</b> If the RX_STOP interrupt occurs before a byte boundary, the remaining bits of the last byte are filled with 0s and passed into the RX FIFO.</p>

<b>Description</b>	Carrier frequency prescaler		
	Because the consumer IR works at modulation rates of 30 to 56.8 kHz, the 48-MHz clock must be prescaled before the clock can drive the IR logic. This register sets the divisor rate to give a range to accommodate the remote-control requirements in baud multiples of 12x. The value of the CFPS at reset is 0105 decimal, which equals 38.1 kHz output from starting conditions. The 48-MHz carrier is prescaled by the CFPS, which is then divided by the 12x baud multiple.

## 24.4 Multichannel Serial Peripheral Interface

This section describes the four Multichannel Serial Peripheral Interface (McSPI) modules for the device.

### 24.4.1 McSPI Overview

The SPI is a master/slave synchronous serial bus. There are four separate McSPI modules (McSPI1, McSPI2, McSPI3, and McSPI4) in the device (see [Figure 24-72](#)). All these four modules support up to four external devices (four chip selects) and are able to work as both master and slave.

**Figure 24-72. Multichannel SPI Modules**

The McSPI modules include the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of SPI word lengths, ranging from 4 to 32 bits
- Up to four master channels, or single channel in slave mode
- Master multichannel mode:
  - Full duplex/half duplex
  - Transmit-only/receive-only/transmit-and-receive modes
  - Flexible input/output (I/O) port controls per channel
  - Programmable clock granularity
  - SPI configuration per channel. This means, clock definition, polarity enabling and word width
- Single interrupt line for multiple interrupt source events
- Power management through wake-up capabilities
- Enable the addition of a programmable start-bit for SPI transfer per channel (start-bit mode)
- Supports start-bit write command
- Supports start-bit pause and break sequence
- Programmable timing control between chip select and external clock generation
- Built-in FIFO available for a single channel

## 24.4.2 McSPI Environment

### 24.4.2.1 Basic McSPI Pins for Master Mode

Figure 24-73 shows all of the McSPI interface signals in master mode.

Figure 24-73. McSPI Interface Signals in Master Mode

(1) Direction depends on bits IS, DPE1 and DPE0 in MCSPI\_CHxCONF

mcspi-006

Table 24-288 describes the McSPI I/O in master mode.

Table 24-288. McSPI I/O Description (Master Mode)

Device-Level Signal Name	Module Signal Name	I/O <sup>(1)</sup>	Description
spim_sclk	SPICLK	O	SPI <sub>m</sub> module serial clock output
spim_d[0]	SPIDAT[0]	O <sup>(2)</sup>	SPI Data I/O. Can be configured either as input or as output depending on MCSPI_CHxCONF[18] IS and MCSPI_CHxCONF[16] DPE0.
spim_d[1]	SPIDAT[1]	I <sup>(2)</sup>	SPI Data I/O. Can be configured either as input or as output depending on MCSPI_CHxCONF[18] IS and MCSPI_CHxCONF[17] DPE1.
spim_cs[i]	SPIEN[x]	O	SPI <sub>m</sub> module chip-select i output

<sup>(1)</sup> I = Input; O = Output

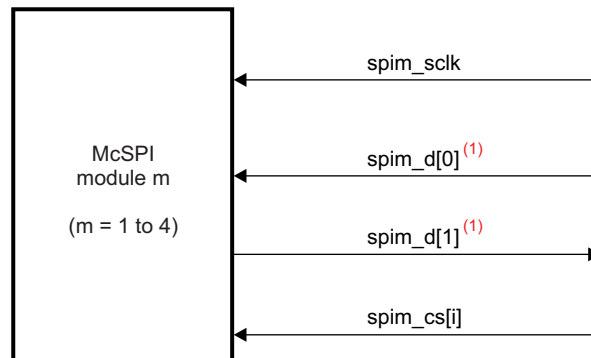

<sup>(2)</sup> Example configuration only.

**NOTE:** For the spim\_sclk signals to work properly, the INPUTENABLE bit of the appropriate CTRL\_CORE\_PAD\_x registers should be set to 0x1 because of retiming purposes.

### 24.4.2.2 Basic McSPI Pins for Slave Mode

Figure 24-74 shows all of the McSPI interface signals in slave mode.

**Figure 24-74. McSPI Interface Signals in Slave Mode**

<sup>(1)</sup> Direction depends on bits IS, DPE1 and DPE0 in MCSPI\_CHxCONF

mcspi-007

Table 24-289 describes the McSPI I/O in slave mode.

**Table 24-289. McSPI I/O Description (Slave Mode)**

Device-Level Signal Name	Module Signal Name	I/O <sup>(1)</sup>	Description
spim_sclk	SPICLK	I	McSPI <sub>m</sub> module serial clock input
spim_d[0]	SPIDAT[0]	I <sup>(2)</sup>	SPI Data I/O. Can be configured either as input or as output depending on MCSPI_CHxCONF[18] IS and MCSPI_CHxCONF[16] DPE0.
spim_d[1]	SPIDAT[1]	O <sup>(2)</sup>	SPI Data I/O. Can be configured either as input or as output depending on MCSPI_CHxCONF[18] IS and MCSPI_CHxCONF[17] DPE1.
spim_cs[i]	SPIEN[x]	I	McSPI <sub>m</sub> module chip-select i input. Can be selected through MCSPI_CH0CONF[22:21] SPIENSLV bit field

<sup>(1)</sup> I = Input; O = Output

<sup>(2)</sup> Example configuration only.

### 24.4.2.3 Multichannel SPI Protocol and Data Format

The synchronous SPI protocol allows a master device to initiate serial data transfers to a slave device. A slave select line (SPIEN[x]) allows selection of an individual slave SPI device. Slave devices that are not selected do not interfere with SPI bus activities.

McSPI offers the flexibility to modify the following parameters to adapt to the device features:

- **Word length**  
 McSPI supports any SPI word ranging from 4 bits to 32 bits long (the MCSPI\_CHxCONF[11:7] WL bit field).  
 SPI word length can be changed between transmissions to allow the master device to communicate with peripheral slaves that have different requirements.
- **SPI enable (SPIEN[x], for channel x of instance m)**  
 The polarity of the SPI enable signals is programmable (the MCSPI\_CHxCONF[6] EPOL bit). SPIEN[x] signals can be active high or low.  
 Assertion of the SPIEN[x] signals is programmable and can be done manually or automatically. The manual assertion mode is available in single master mode only. SPIEN[x] can be kept active between words with the MCSPI\_CHxCONF[20] FORCE bit.  
 Two consecutive words for two different slave devices can go along with active SPIEN[x] signals with different polarity.

- Programmable start-bit  
In start-bit mode a start-bit is added before the SPI word length to indicate how the next SPI word must be handled. The start-bit is enabled by setting the [MCSPI\\_CHxCONF\[23\]](#) SBE bit to 1. The [MCSPI\\_CHxCONF\[24\]](#) SBPOL bit defines the polarity of the start-bit.
- Programmable SPI clock
  - Bit rate  
In master mode, the baud rate of the SPI serial clock is programmable using the 48-MHz reference clock (from the power, reset, and clock management [PRCM] module). [Table 24-290](#) lists the SPICLK bit rates obtained for data transfer when programming the clock divider (the [MCSPI\\_CHxCONF\[5:2\]](#) CLKD bit field).

**Table 24-290. SPI Master Clock Rates**

Divider	Clock Rate
1	48 MHz <sup>(1)</sup>
2	24 MHz <sup>(1)</sup>
4	12 MHz
8	6 MHz
16	3 MHz
32	1.5 MHz
64	750 kHz
128	375 kHz
256	~187 kHz
512	~93.7 kHz
1024	~46.8 kHz
2048	~23.4 kHz
4096	~11.7 kHz

<sup>(1)</sup> These frequencies are not necessarily supported by all SPI modules. For more information, see the *Timing Requirements and Switching Characteristics* chapter in the device data manual.

- Polarity and phase  
The polarity (the [MCSPI\\_CHxCONF\[1\]](#) POL bit) and the phase (the [MCSPI\\_CHxCONF\[0\]](#) PHA bit) of the SPI serial clock (SPICLK) are configurable to offer four combinations. Software selects the right combination, depending on the device. See [Table 24-291](#) and [Figure 24-75](#).

**Table 24-291. Phase and Polarity Combinations**

Polarity (POL)	Phase (PHA)	SPI Mode	Description
0	0	Mode 0	SPICLK is inactive low and sampling occurs at the rising edge.
0	1	Mode 1	SPICLK is inactive low and sampling occurs at the falling edge.
1	0	Mode 2	SPICLK is inactive high and sampling occurs at the falling edge.
1	1	Mode 3	SPICLK is inactive high and sampling occurs at the rising edge.

**Figure 24-75. Phase and Polarity Combinations**

#### 24.4.2.3.1 Transfer Format

In master and slave modes, the McSPI drives the data lines when SPIEN[x] is asserted.

Each word is transmitted starting with the most-significant bit (MSB).

This section explains the two cases of data transmission determined by the clock phase (PHA) and the type of data transmission using a start-bit (SBE) called the start-bit mode:

- Transmission in mode 0 and mode 2 (PHA = 0)

When PHA = 0, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid one-half cycle of SPICLK after the assertion of SPIEN.

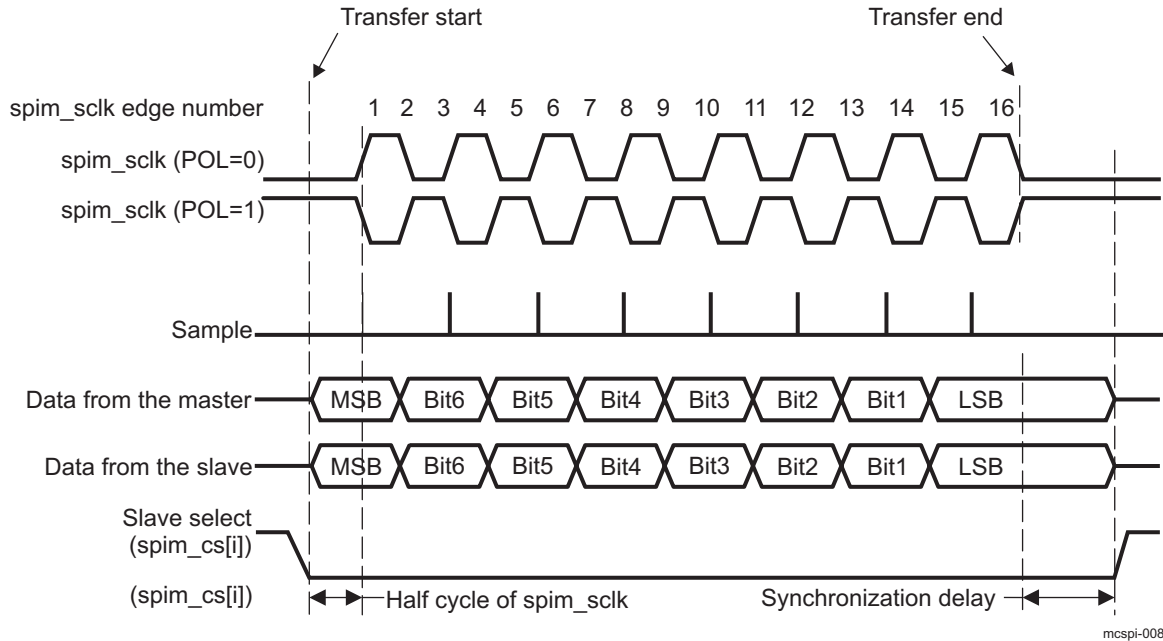

Therefore, the first edge of the SPICLK line is used by the master to sample the first data bit sent by the slave. On the same edge, the first data bit sent by the master is sampled by the slave.

On the next SPICLK edge, the received data bit is shifted into the receive shift register and a new data bit is transmitted on the serial data line.

This process continues for a number of pulses on the SPICLK line defined by the SPI word length programmed in the master device, with data being latched on odd-numbered edges and shifted on even-numbered edges. See [Figure 24-76](#).

**Figure 24-76. Full-Duplex Transfer Format With PHA = 0**

- Transmission in mode 1 and mode 3 (PHA = 1)

When PHA = 1, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid on the following SPICLK edge (one-half cycle later). This is the sampling edge for the master and slave. A synchronization delay is added between the activation of SPIEN[x] and the first SPICLK edge. The received data bit is shifted into the shift register on the third SPICLK edge.

This process continues for a number of pulses on the SPICLK line defined by the SPI word length programmed in the master device, with data being latched on even-numbered edges and shifted on odd-numbered edges.

**NOTE:** The minimum synchronization delay is one cycle of SPICLK, if the frequency of SPICLK equals the frequency of SPI<sub>m</sub>\_FCLK (McSPI<sub>m</sub> functional clock) in master mode. The minimum synchronization delay is one-half cycle of SPICLK, if the frequency of SPICLK is lower than the frequency of SPI<sub>m</sub>\_FCLK in the master and slave modes.

- Transmission with a start-bit (SBE = 1)

When the [MCSPI\\_CHxCONF\[23\]](#) SBE bit is set to 1, a start-bit is added before the MSB to indicate whether the next SPI word must be handled as a command or as data.

[Figure 24-77](#) shows an example of a data transfer with an extra start-bit.

**Figure 24-77. Extended SPI Transfer With a Start-Bit (SBE = 1)**

**24.4.2.4 SPI in Master Mode**

Figure 24-78 shows a case in master mode (full-duplex) where the McSPI module is connected with two slave devices.

**Figure 24-78. McSPI Master Mode (Full Duplex)**

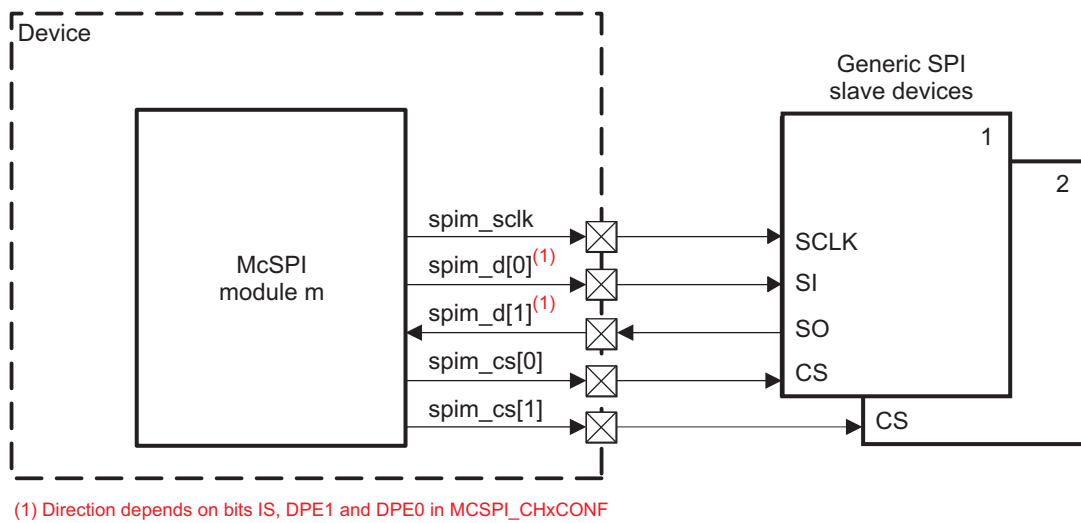

Figure 24-79 shows the master single mode, which can also be configured in receive-only mode.

Figure 24-79. McSPI Master Single Mode (Receive Only)

k = 0 or 1 depending on bits IS, DPE1 and DPE0 in MCSPI\_CHxCONF

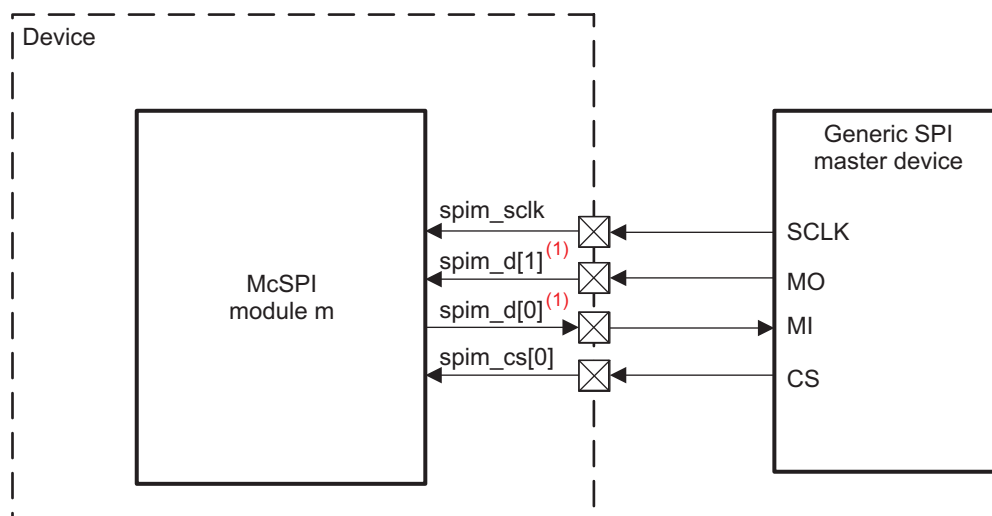

mcspi-003

### 24.4.2.5 SPI in Slave Mode

Figure 24-80 shows a case in slave mode (full-duplex).

**NOTE:** Only channel 0 can be configured as slave, but the chip-enable signal can be connected to any SPIEN[x] pin and then rerouted internally to channel 0 (the MCSPI\_CHxCONF[22:21] SPIENSLV bit field [where x = 0]). For more information, see Section 24.4.4.4, *Slave Mode*.

Figure 24-80. McSPI Slave Mode (Full Duplex)

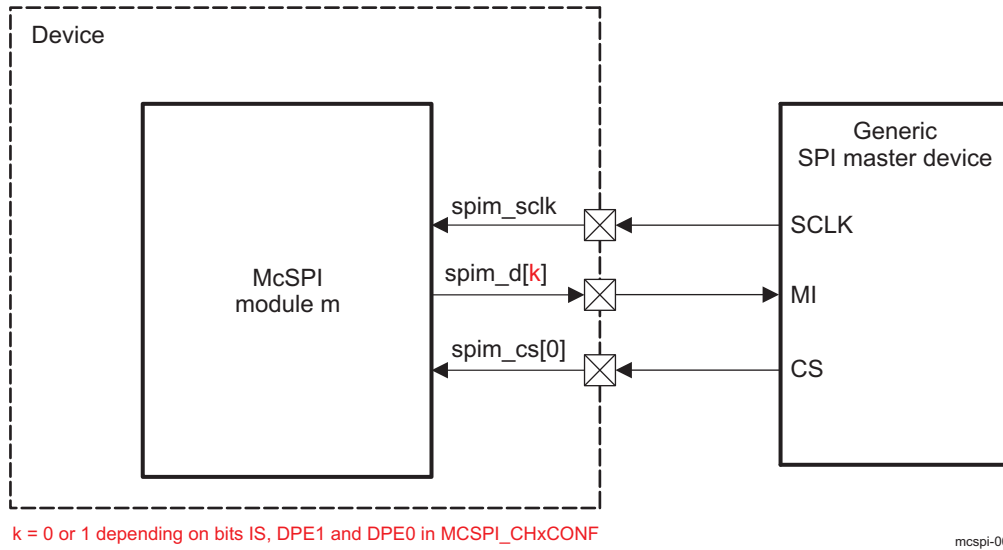

(1) Direction depends on bits IS, DPE1 and DPE0 in MCSPI\_CHxCONF

mcspi-004

Figure 24-81 shows the slave single mode, which can also be configured in transmit-only mode.

**Figure 24-81. McSPI Slave Single Mode (Transmit Only)**

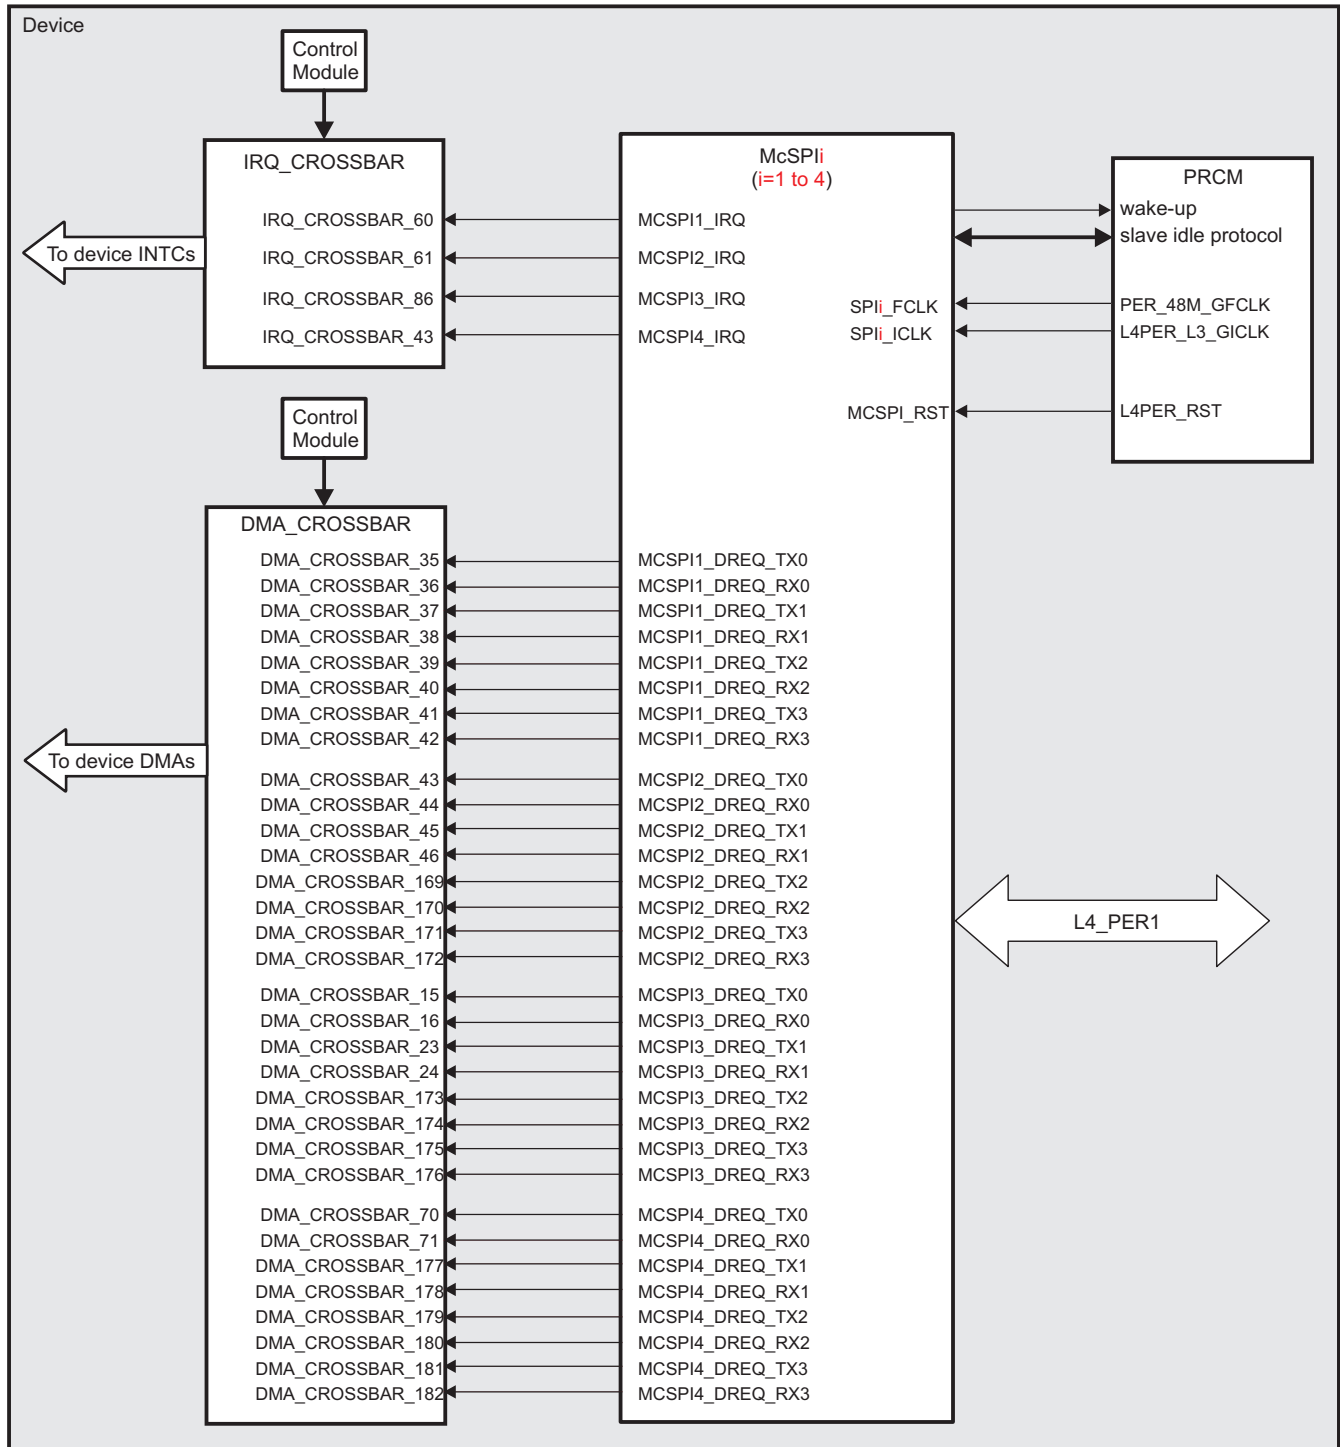

### 24.4.3 McSPI Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 24-82 shows McSPI integration.

Figure 24-82. McSPI Integration

mcspi-011

Table 24-292 through Table 24-294 summarize the integration of the module in the device.

**Table 24-292. McSPI Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect
McSPI1	PD_COREAON	L4_PER1

---

**NOTE:** The Default Mapping column in [Table 24-294 McSPI Hardware Requests](#) shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ\_CROSSBAR and DMA\_CROSSBAR modules, respectively. For more information about the IRQ\_CROSSBAR module, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#). For more information about the DMA\_CROSSBAR module, see [Section 18.4.6.5, DMA\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#).

---

---

**NOTE:** For more information about the device interrupt controllers, see [Chapter 17, Interrupt Controllers](#). For more information about the device DMA\_SYSTEM module, see [Section 16.1, System DMA](#). For more information about the device EDMA module, see [Section 16.2, Enhanced DMA](#).

---

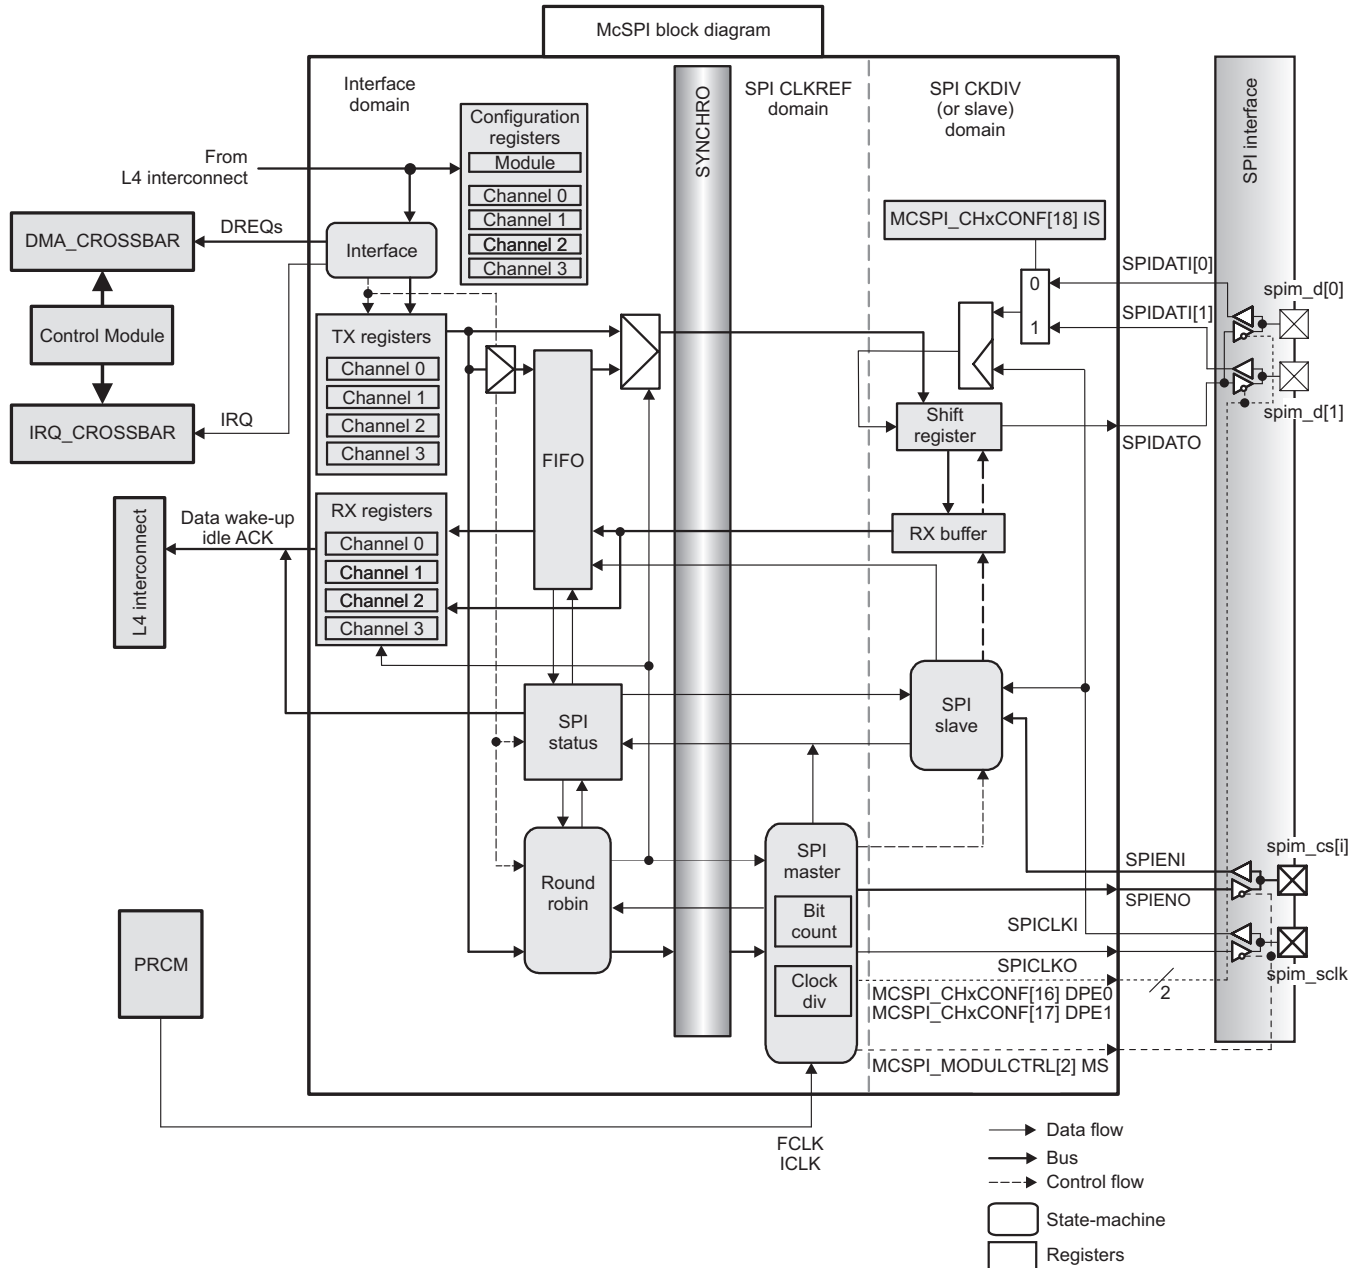

### 24.4.4 McSPI Functional Description

#### 24.4.4.1 McSPI Block Diagram

Figure 24-83 shows the McSPI module.

Figure 24-83. McSPI Block Diagram

mcspi-012

#### 24.4.4.2 Reset

The McSPI module can be reset either by hardware or by software reset. All configuration registers and all state machines are reset by the hardware reset signal (MCSPi\_RST). McSPI can be reset by software through the [MCSPI\\_SYSCONFIG\[1\] SOFTRESET](#) bit. This bit has the same impact on the module as the hardware reset signal. The only exception is that the [MCSPI\\_SYSCONFIG](#) register is not affected by that software reset.

### 24.4.4.3 Master Mode

#### 24.4.4.3.1 Master Mode Features

The McSPI master mode supports multichannel communication with up to four independent SPI communication channel contexts. The McSPI initiates a data transfer on the data lines (SPIDAT[0] and SPIDAT[1]) and generates clock (SPICLK) and control (SPIEN) signals.

Connected to multiple external devices, the McSPI exchanges data with one SPI device at a time through two main modes (available in slave mode):

- Two-data-pins interface mode (transmit-and-receive mode for full-duplex transmission)
- Single-data-pin interface mode (recommended for half-duplex transmission)

---

**NOTE:** There is a fixed chip select line allocation in multichannel master mode. Channel x SPIEN[x] is mapped to spim\_cs[i] pin.

---

Two DMA request events (read and write) allow synchronized accesses of the DMA controller with the activity of McSPI.

Three interrupt events can be used for data transmission and reception in master mode (for more information about interrupts, see [Section 24.4.4.7.1, Interrupt Events in Master Mode](#)).

#### 24.4.4.3.2 Master Transmit-and-Receive Mode (Full Duplex)

In full-duplex transmission, data is transmitted (shifted out serially on SPIDAT[0]) and received (shifted in serially on SPIDAT[1]) simultaneously on separate data lines.

The master transmit-and-receive mode is programmable per channel (the [MCSPI\\_CHxCONF\[13:12\]](#) TRM bit field).

Channel access to the shift registers for transmission/reception is based on the [MCSPI\\_TXx](#) transmitter register state, the [MCSPI\\_RXx](#) receiver register state, and round-robin arbitration.

Channels that meet the following rules are included in the round-robin list of active channels scheduled for transmission and/or reception. The arbiter skips channels that do not meet the rules and searches in the rotation for the next enabled channel.

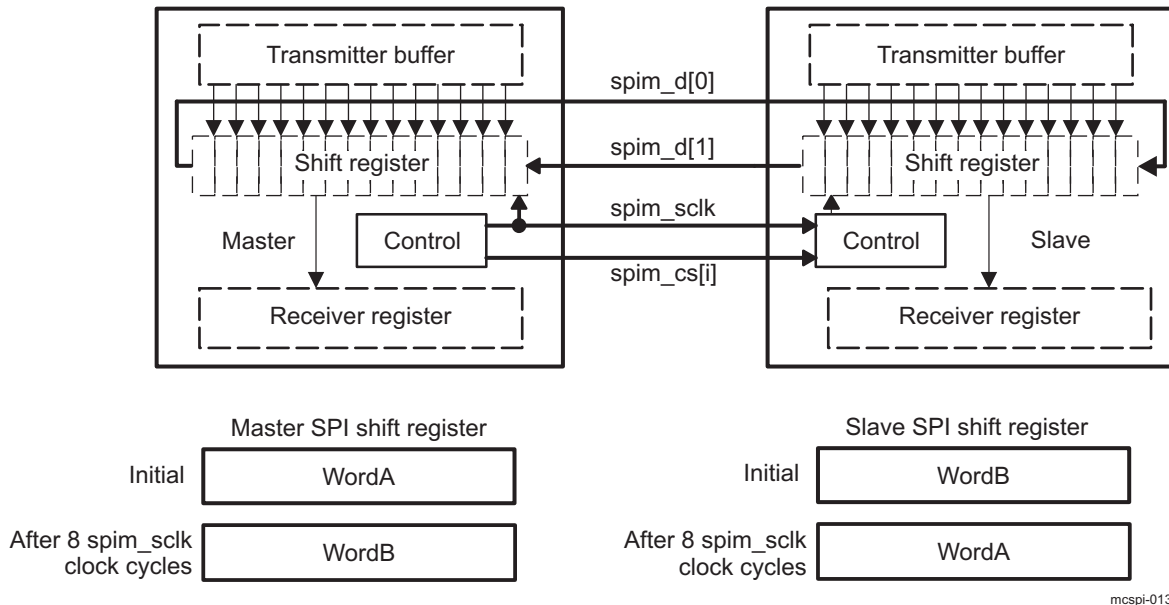

- **Rule 1:** Only enabled channels (the [MCSPI\\_CHxCTRL\[0\]](#) EN bit) can be scheduled for transmission and/or reception.
- **Rule 2:** If its [MCSPI\\_TXx](#) transmitter register is not empty (the [MCSPI\\_CHxSTAT\[1\]](#) TXS bit), an enabled channel can be scheduled when the shift register is assigned. If the [MCSPI\\_TXx](#) register is empty when the shift register is assigned, the TXx\_UNDERFLOW event is activated, and the next enabled channel with new data to transmit is scheduled (see also transmit-only mode).
- **Rule 3:** An enabled channel can be scheduled if its receive register is not full (the [MCSPI\\_CHxSTAT\[0\]](#) RXS bit) when the shift register is assigned (see also receive-only mode). Therefore, the [MCSPI\\_RXx](#) register cannot be overwritten. The SPI1.[MCSPI\\_IRQSTATUS\[3\]](#) RX0\_OVERFLOW bit is never set to this mode.

When SPI word transfer completes (the [MCSPI\\_CHxSTAT\[2\]](#) EOT bit is set), the updated [MCSPI\\_TXx](#) register of the next scheduled channel is loaded into the shift register. The serialization (transmit-and-receive) starts depending on the channel communication configuration. When serialization completes, the received data transfers to the channel receive register.

The serial clock (SPICLK) synchronizes shifting and sampling of the information on the two serial data lines (SPIDAT[0] and SPIDAT[1]). Each time a bit transfers out from the master, 1 bit transfers in from the slave.

[Figure 24-84](#) shows an example of a full-duplex system with a master device (McSPI module *m*) on the left and a slave device on the right. After eight cycles of the serial clock SPICLK, WordA transfers from the master to the slave. At the same time, WordB transfers from the slave to the master.

Figure 24-84. SPI Full-Duplex Transmission (Example)

### 24.4.4.3.3 Master Transmit-Only Mode (Half Duplex)

The master transmit-only mode prevents the microprocessor unit (MPU) from reading the `MCSPI_RXx` register (minimizing data movement) when only transmission is meaningful.

The master transmit-only mode is programmable per channel (the `MCSPI_CHxCONF[13:12]` TRM bit field). Transmission starts only after data is loaded into the `MCSPI_TXx` register.

Rule 1 and Rule 2, defined in Section 24.4.4.3.2, apply in this mode.

Rule 3, defined in Section 24.4.4.3.2, does not apply.

In master transmit-only mode, the `MCSPI_RXx` register state FULL does not prevent transmission and the `MCSPI_RXx` register is always overwritten with the new SPI word. This event is not significant when only transmission is meaningful. Thus, the `RX0_OVERFLOW` bit in the `MCSPI_IRQSTATUS` register is never set in this mode.

The hardware automatically disables the `RX_FULL` interrupt and the DMA read requests.

The transfer status is given by the `MCSPI_CHxSTAT[2]` EOT bit.

### 24.4.4.3.4 Master Receive-Only Mode (Half Duplex)

The master receive mode prevents the MPU from refilling the `MCSPI_TXx` register (minimizing data movement) when only reception is meaningful.

The master receive mode is programmable per channel (the `MCSPI_CHxCONF[13:12]` TRM bit field).

The master receive-only mode enables channel scheduling only on the empty state of the `MCSPI_RXx` register.

Rule 1 and Rule 3, defined in Section 24.4.4.3.2, apply in this mode.

Rule 2, defined in Section 24.4.4.3.2, does not apply.

In the master receive-only mode, software must write dummy data to the `MCSPI_TXx` register. Only one dummy write is enough to receive any number of words from the slave. Software must ensure that the `MCSPI_TXx` register is always full (the `TXx_EMPTY` bits of `MCSPI_IRQSTATUS`) when receiving. The content of the `MCSPI_TXx` register is always loaded into the shift register when the shift register is assigned. After writing the dummy data to the `MCSPI_TXx` register, the `TXx_EMPTY` and `TXx_UNDERFLOW` bits in the `MCSPI_IRQSTATUS` register are never set in receive-only mode.

The `MCSPI_CHxSTAT[2]` EOT bit gives the status of serialization. The `RXx_FULL` bits of the `MCSPI_IRQSTATUS` register are set when received data is loaded from the shift register to the corresponding `MCSPI_RXx` register. The `MCSPI_IRQSTATUS[3]` `RX0_OVERFLOW` bit is never set in this mode.

#### 24.4.4.3.5 Single-Channel Master Mode

When the McSPI is configured as a master device with a single enabled channel (`MCSPI_MODULCTRL[2]` `MS` = 0 and `MCSPI_MODULCTRL[0]` `SINGLE` = 1), the assertion of the `SPIEN[x]` signal is optional depending on device connected to the controller. In 3-pin mode (`MCSPI_MODULCTRL[1]` `PIN34` = 1) the controller starts transmitting data when a write to the `MCSPI_TXx` register or the FIFO is performed. In 4-pin mode (`MCSPI_MODULCTRL[1]` `PIN34` = 0) the assertion and de-assertion of `SPIEN[x]` is controlled by software using the `MCSPI_CHxCONF[20]` `FORCE` bit.

##### 24.4.4.3.5.1 Programming Tips When Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for the SPI word transfer to complete (wait until the `MCSPI_CHxSTAT[2]` EOT bit is set to 1) before disabling the current channel and enabling a different channel.
- Disable the current channel, and then enable the other channel.

##### 24.4.4.3.5.2 Force SPIEN[x] Mode

Continuous transfers are allowed manually by keeping the `SPIEN[x]` signal active for successive SPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the `SPIEN[x]` line. This mode is supported by all channels and any master sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the `SPIEN[x]` active mode is supported when:

- A single channel is used (with the `MCSPI_MODULCTRL[0]` `SINGLE` bit set to 1).
- Transfer parameters are loaded in the configuration register of the appropriate channel (`MCSPI_CHxCONF`).

The state of the `SPIEN[x]` signal is programmable:

- Writing 1 to the `MCSPI_CHxCONF[20]` `FORCE` bit drives the `SPIEN[x]` line high when the `MCSPI_CHxCONF[6]` `EPOL` bit is set to 0. `SPIEN[x]` is driven low when the `MCSPI_CHxCONF[6]` `EPOL` bit is set to 1.
- Writing 0 to the `MCSPI_CHxCONF[20]` `FORCE` bit drives the `SPIEN[x]` line low when the `MCSPI_CHxCONF[6]` `EPOL` bit is set to 0. `SPIEN[x]` is driven high when the `MCSPI_CHxCONF[6]` `EPOL` bit is set to 1.
- A single channel is enabled (the `MCSPI_CHxCTRL[0]` `EN` bit is set to 1). The first enabled channel activates the `SPIEN[x]` line.

When the channel is enabled, the `SPIEN[x]` signal activates with the programmed polarity. As in the multichannel master mode, the transfer start depends on the status of the `MCSPI_TXx` register (the `MCSPI_CHxSTAT[1]` `TXS` bit), the status of the `MCSPI_RXx` register (the `MCSPI_CHxSTAT[1]` `RXS` bit), and the defined mode (the `MCSPI_CHxCONF[13:12]` `TRM` bit field) of the channel enabled.

The `MCSPI_CHxSTAT[2]` EOT bit gives the transfer status of each SPI word. The `RXx_FULL` bit in the `MCSPI_IRQSTATUS` register is set when received data is loaded from the shift register to the `MCSPI_RXx` register.

A change in the configuration parameters is propagated directly on the SPI interface. If the `SPIEN[x]` signal is activated, ensure that the configuration is changed only between SPI words to avoid corrupting the current transfer.

---

**NOTE:** To avoid data corruption, `SPIEN` polarity and `SPICLK` phase and `SPICLK` polarity must not be modified when the `SPIEN[x]` signal is activated.

---

A delay between SPI words that requires the connected SPI slave device to switch from one configuration to another (for instance, from transmit-only to receive-only) must be handled by software.

At the end of the last SPI word, the channel must be deactivated (the `MCSPI_CHxCTRL[0] EN` bit set to 0) and `SPIEN[x]` can be forced to its INACTIVE state using the `MCSPI_CHxCONF[20] FORCE` bit.

Figure 24-85 and Figure 24-86 show successive transfers with `SPIEN[x]` maintained active low with a different configuration for each SPI word in single-data-pin and dual-data-pin interface modes, respectively.

**Figure 24-85. Continuous Transfers With `SPIEN[x]` Maintained Active (Single-Data-Pin Interface Mode)**

**Figure 24-86. Continuous Transfers With `SPIEN[x]` Maintained Active (Dual-Data-Pin Interface Mode)**

**NOTE:** The `SPIEN[x]` signal can be maintained active via software using the `MCSPI_CHxCONF[20] FORCE` bit only when the `MCSPI_MODULCTRL[0] SINGLE` bit is set to 0x1.

### 24.4.4.3.5.3 Turbo Mode

Turbo mode improves the throughput of the SPI interface when a single channel is enabled by allowing transfers until the shift register and the `MCSPI_RXx` register are full. Turbo mode is time saving when a transfer exceeds two words. This mode is programmable per channel (through the `SPI1.MCSPI_CHxCONF[9] TURBO` bit).

When several channels are enabled, the `TURBO` bit has no effect and the channel access to the shift registers remains as previously described.

In turbo mode, Rule 1 and Rule 2 apply, but Rule 3 does not (see Section 24.4.4.3.2, *Master Transmit-and-Receive Mode (Full Duplex)*). An enabled channel can be scheduled if its receive register is full (the `MCSPI_CHxSTAT[0] RXS` bit) when the shift-register is assigned until the shift register is full.

The `MCSPI_RXx` register cannot be overwritten in turbo mode. Consequently, the `MCSPI_IRQSTATUS[3] RX0_OVERFLOW` bit is never set in this mode.

### 24.4.4.3.6 Start-Bit Mode

In start-bit mode, an extended bit is added before the SPI word to indicate whether the next SPI word must be handled as a command or as data. This feature is available only in master mode. Start-bit mode cannot be used at the same time as turbo mode and/or force SPIEN[x] mode. In this case, only one channel can be used; round-robin arbitration is not possible.

This mode is programmable per channel by setting the [MCSPI\\_CHxCONF\[23\]](#) SBE bit to 1. The polarity of the extended bit is programmable per channel. When the [MCSPI\\_CHxCONF\[24\]](#) SBPOL bit is set to 0, the SPI word must be handled as a command. When the [MCSPI\\_CHxCONF\[24\]](#) SBPOL bit is set to 1, the SPI word must be handled as data. Moreover, start-bit polarity can be changed dynamically during start-bit transfer without disabling the channel for reconfiguration; in this case, users must configure the [MCSPI\\_CHxCONF\[24\]](#) SBPOL bit before writing the SPI word to be transmitted to the TX register.

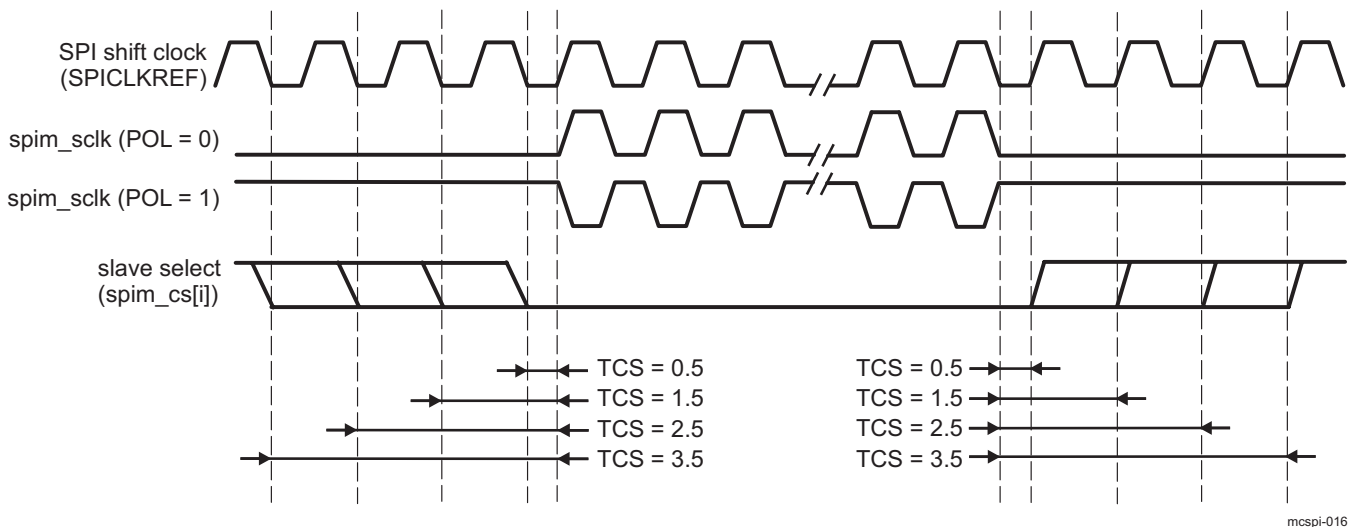

### 24.4.4.3.7 Chip-Select Timing Control

The chip-select (CS) timing control is available only in master mode with automatic CS generation (the [MCSPI\\_MODULCTRL\[0\]](#) SINGLE bit set to 0) to add a programmable delay between CS assertion and first clock edge, or CS removal and last clock edge. This option is available only in 4-pin mode when [MCSPI\\_MODULCTRL\[1\]](#) PIN34 set to 0.

This mode is programmable per channel through the [MCSPI\\_CHxCONF\[26:25\]](#) TCS0 bit field.

[Figure 24-87](#) shows the CS SPIEN timing controls.

**Figure 24-87. CS (SPIEN) Timing Controls**

mcspi-016

**NOTE:** Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between CS assertion and the first clock edge with PHA = 1 or between CS removal and the last clock edge with PHA = 0.

### 24.4.4.3.8 Programmable SPI Clock

In master mode, the baud rate of the SPI serial clock is programmable.

An internal reference clock, SPIm\_FCLK, is used as input of a programmable divider (the [MCSPI\\_CHxCONF\[5:2\]](#) CLKD bit field) to generate the bit rate of the serial output clock SPICLK. [Table 24-295](#) summarizes the supported divisor values.

**Table 24-295. SPI Master Clock Rates**

Divider	Clock Rate
1	48 MHz <sup>(1)</sup>
2	24 MHz <sup>(1)</sup>
4	12 MHz
8	6 MHz
16	3 MHz
32	1.5 MHz
64	750 kHz
128	375 kHz
256	~187 kHz
512	~93.7 kHz
1024	~46.8 kHz
2048	~23.4 kHz
4096	~11.7 kHz
8192 and higher: Division not supported	–

<sup>(1)</sup> These frequencies are not necessarily supported by all SPI modules. For more information, see the *Timing Requirements and Switching Characteristics* chapter in the device data manual.

#### 24.4.4.3.8.1 Clock Ratio Granularity

By default, the clock division ratio is defined by the [MCSPI\\_CHxCONF\[5:2\]](#) CLKD bit field with power-of-2 granularity leading to a clock division in the range 1 to 4096; in this case, the duty cycle is always 50 percent. With the [MCSPI\\_CHxCONF\[29\]](#) CLKG bit, clock division granularity can be changed to one clock cycle; in that case the [MCSPI\\_CHxCTRL\[15:8\]](#) EXTCLK bit field is concatenated with the [MCSPI\\_CHxCONF\[5:2\]](#) CLKD bit field to give a 12-bit-wide division ratio in the range 1 to 4096.

When granularity is one clock cycle (the CLKG bit set to 1), for the odd value of the clock ratio, the clock high level lasts one clock cycle more than the low level, depending on the [MCSPI\\_CHxCONF\[1\]](#) POL and [MCSPI\\_CHxCONF\[0\]](#) PHA bits (see [Table 24-296](#)).

**Table 24-296. CLKSPIO High/Low Time Computation**

Clock Ratio $F_{RATIO}$	CLKSPIO High Time	CLKSPIO Low Time
1	$T_{HIGH\_REF}$	$T_{LOW\_REF}$
Even $\geq 2$	$T\_ref \times (F_{RATIO}/2)$	$T\_ref \times (F_{RATIO}/2)$
Odd $\geq$ (POL = PHA)	$T\_ref \times (F_{RATIO} - 1)/2$	$T\_ref \times (F_{RATIO} + 1)/2$
Odd $\geq$ (POL $\neq$ PHA)	$T\_ref \times (F_{RATIO} + 1)/2$	$T\_ref \times (F_{RATIO} - 1)/2$

**NOTE:**  $F_{RATIO}$  = SPICLK frequency ( $F_{OUT}$ ) division ratio  
 $T_{HIGH}$  = SPICLK high time period  
 $T_{LOW}$  = SPICLK low time period  
 $T\_ref$  = FCLK period  
 $T_{HIGH\_REF}$  = FCLK high time period  
 $T_{LOW\_REF}$  = FCLK low time period

If the CLKG bit is set to 1;  $F_{RATIO}$  = EXTCLK concatenated with CLKD + 1.

For odd ratio values, the duty cycle is calculated as follows:

$$\text{Duty\_cycle} = (1 - 1/F_{RATIO})/2$$

[Table 24-297](#) shows examples of clock granularity with a clock source frequency of 48 MHz.

**Table 24-297. Clock Granularity Examples**

EXTCLK	CLKD	CLKG	F <sub>RATIO</sub>	PHA	POL	T <sub>HIGH</sub> (ns)	T <sub>LOW</sub> (ns)	T <sub>PERIOD</sub> (ns)	Duty Cycle	F <sub>OUT</sub> (MHz)
X	0	0	1	X	X	10.4	10.4	20.8	50–50	48
X	1	0	2	X	X	20.8	20.8	41.6	50–50	24
X	2	0	4	X	X	41.6	41.6	83.2	50–50	12
X	3	0	8	X	X	83.2	83.2	166.4	50–50	6
0	0	1	1	X	X	10.4	10.4	20.8	50–50	48
0	1	1	2	X	X	20.8	20.8	41.6	50–50	24
0	2	1	3	1	0	41.6	20.8	62.4	66–33	16
0	2	1	3	1	1	20.8	41.6	62.4	33–66	16
0	3	1	4	X	X	41.6	41.6	83.2	50–50	12
5	0	1	81	1	0	852.8	832	1684.8	50.6–49.4	0.592
5	7	1	88	X	X	915.2	915.2	1830.4	50–50	0.545

#### 24.4.4.4 Slave Mode

To select the McSPI slave mode, set the [MCSPI\\_MODULCTRL\[2\]](#) MS bit.

A McSPI slave device can be connected to up to four external SPI master devices but handles transactions with one SPI master device at a time.

In slave mode, the McSPI initiates data transfer on the data lines (SPIDAT[0] and SPIDAT[1]) when it is selected by an active control signal (SPIEN[x]) and receives an SPI clock (SPICLK) from the external SPI master device. Only channel 0 can be configured as a slave but through the [MCSPI\\_CH0CONF\[22:21\]](#) SPIENSLV bit field any of the SPIEN[x] signals can be used to select the McSPI module. In slave mode and when the [MCSPI\\_MODULCTRL\[1\]](#) PIN34 is set to 0x0 (default behavior), the McSPI uses the edge of SPIEN[x] to detect word length. For this reason, SPIEN[x] must become inactive between each word.

When the [MCSPI\\_MODULCTRL\[1\]](#) PIN34 is set to 0x0, the McSPI does not support SPIEN[x] active between SPI words. In this case, the McSPI uses the edge to detect word length.

When the [MCSPI\\_MODULCTRL\[1\]](#) PIN34 is set to 0x1, a multiword transfer can be performed without needing the external SPI master to deactivate SPIEN[x] between each word as in this case the McSPI module works in 3-pin slave mode and SPIEN[x] is not needed.

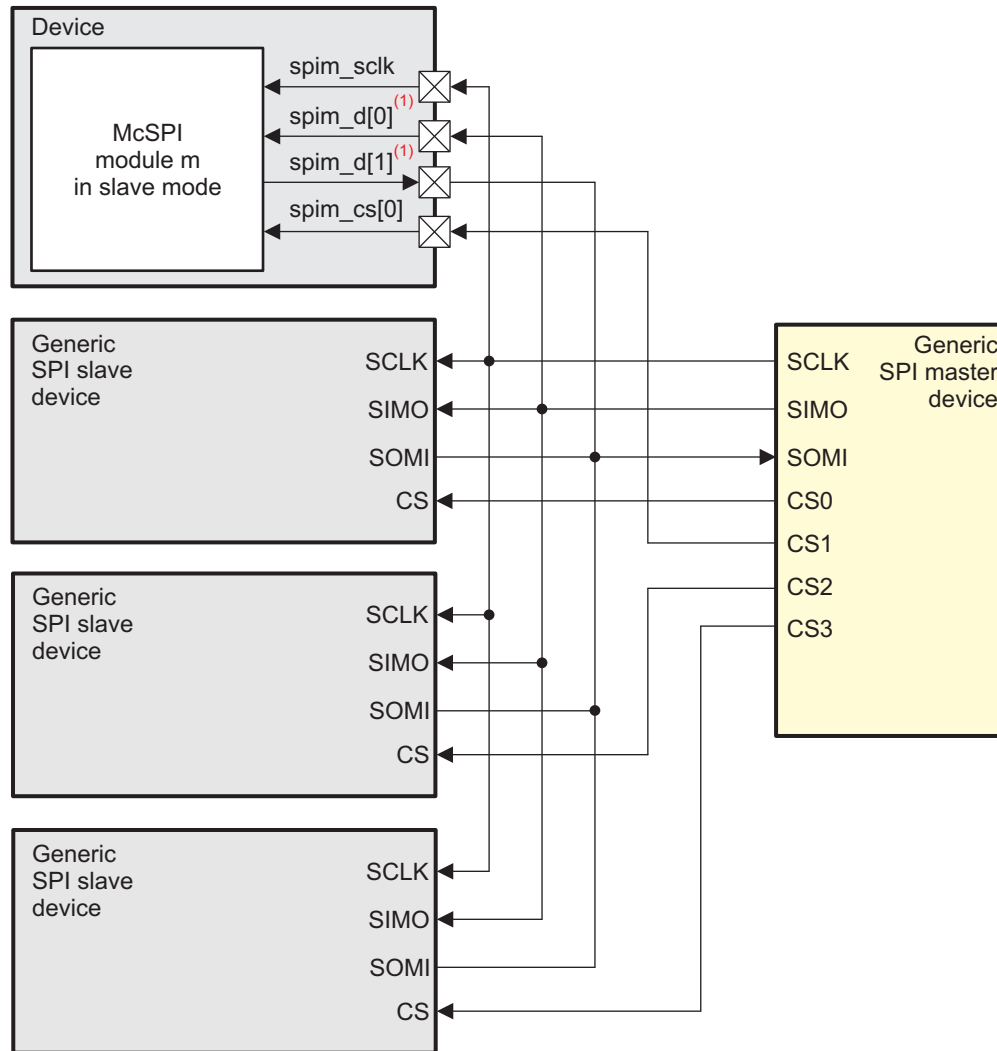

##### 24.4.4.4.1 Dedicated Resources

Only channel 0 can be enabled in slave mode. In this section, register names such as [SPI1.MCSPI\\_CHxCTRL](#) stand for [SPI1.MCSPI\\_CH0CTRL](#), where x = 0 (channel 0 control register).

[Figure 24-88](#) shows an example of four slaves wired on a single master device.

Figure 24-88. Example of McSPI Slave With One Master and Multiple Slave Devices on Channel 0

(1) Direction depends on bits IS, DPE1 and DPE0 in MCSPI\_CHxCONF

mcspi-017

Channel 0 in slave mode has the following resources:

- Its own channel enable, programmable with the [MCSPI\\_CHxCTRL\[0\] EN](#) bit (where x = 0). This channel must be enabled before transmission and reception.
- For this mode, the slave-select signal can be detected on any of the [SPIEN\[x\]](#) ports. This is programmable with the [MCSPI\\_CHxCONF\[22:21\] SPIENSLV](#) bit field (where x = 0).
- Its own transmitter register, [MCSPI\\_TXx](#) (where x = 0), on top of the common transmit shift register. If the [MCSPI\\_TXx](#) register is empty, the [MCSPI\\_CHxSTAT\[1\] TXS](#) bit (where x = 0) is set. If McSPI is selected by an external master (the active signal on the [SPIEN\[x\]](#) port assigned to channel 0), the [MCSPI\\_TXx](#) register content of channel 0 is always loaded into the shift register, whether its content is updated or not. The [MCSPI\\_TXx](#) register must be loaded before McSPI is selected by a master.
- Its own receiver register, [MCSPI\\_RXx](#) (where x = 0), on top of the common receive shift register. If the [MCSPI\\_RXx](#) register is full, the [MCSPI\\_CHxSTAT\[0\] RXS](#) bit (where x = 0) is set.

**NOTE:** The [MCSPI\\_TXx](#) and [MCSPI\\_RXx](#) registers of the other channels are not used. Reading from or writing to a channel register other than channel 0 has no effect.

- Its own communication configuration with the following parameters through the [MCSPI\\_CHxCONF](#) register (where x = 0):

- Transmit and receive modes, programmable with the TRM field
- Interface mode (two data pins or single data pin) and data pins assignment, both programmable with the IS and DPE bits. (The SPI modules are in slave mode after reset and must be properly configured for the modules to act in master mode.)
- SPI word length, programmable with the WL bits
- SPIEN[x] polarity, programmable with the EPOL bit
- SPICLK polarity, programmable with the POL bit
- SPICLK phase, programmable with the PHA bit

The SPICLK frequency of a transfer is controlled by the external SPI master connected to the McSPI slave device. The [MCSPI\\_CHxCONF\[5:2\] CLKD](#) bit field (where x = 0) is not used in slave mode.

---

**NOTE:** The configuration of the channel can be loaded in the [MCSPI\\_CHxCONF](#) register (where x = 0) only when the channel is disabled.

---

- Two DMA request events, read and write, synchronize read/write accesses of the DMA controller with the activity of McSPI. DMA requests are asserted using the [MCSPI\\_CHxCONF\[15\] DMAR](#) bit (where x = 0) for reading and the [MCSPI\\_CHxCONF\[14\] DMAW](#) bit (where x = 0) for writing.
- Four interrupt events (see [Section 24.4.4.7.2, Interrupt Events in Slave Mode](#))

#### 24.4.4.4.2 Slave Transmit-and-Receive Mode

The slave receive mode is programmable (set the [MCSPI\\_CHxCONF\[13:12\] TRM](#) bit field [where x = 0] to 0x0).

In slave transmit-and-receive mode, the [MCSPI\\_TXx](#) register must be loaded before McSPI is selected by an external SPI master device.

After a channel is enabled, transmission and reception proceed with interrupt and DMA request events.

The [MCSPI\\_TXx](#) register content is always loaded in the shift register whether it is updated or not. The event TXx\_UNDERFLOW is activated accordingly and does not prevent transmission.

When the SPI word transfer completes (the [MCSPI\\_CHxSTAT0\[2\] EOT](#) bit [where x = 0] is set to 1), the received data is transferred to the channel receive register.

To use McSPI as a slave transmit-only device, the RXx\_FULL and RX0\_OVERFLOW interrupts and DMA read requests must be disabled due to the state of the [MCSPI\\_RXx](#) register (see [Section 24.4.4.7.2, Interrupt Events in Slave Mode](#)).

#### 24.4.4.4.3 Slave Transmit-Only Mode

The slave transmit-only mode is programmable (set the [MCSPI\\_CHxCONF\[13:12\] TRM](#) bit field [where x = 0] to 0x2) and avoids the requirement for the MPU to read the [MCSPI\\_RXx](#) register (minimizing data movement) only when transmission is meaningful.

To use the McSPI as a slave transmit-only device, the RXx\_FULL and RX0\_OVERFLOW interrupts and DMA read requests must be disabled due to the state of the [MCSPI\\_RXx](#) register.

When the SPI word transfer completes, the [MCSPI\\_CHxSTAT\[2\] EOT](#) bit is set (where x = 0).

[Figure 24-89](#) shows a half-duplex system with a master device on the left and a transmit-only slave device on the right. Each time a bit transfers out from the slave, 1 bit transfers in the master. After eight cycles of the serial clock SPICLK, WordB transfers from the slave to the master.

Figure 24-89. SPI Half-Duplex Transmission (Transmit-Only Slave)

mcspi-031

#### 24.4.4.4.4 Slave Receive-Only Mode

The slave receive mode is programmable (set the `MCSPI_CHxCONF`[13:12] TRM bit field [where x = 0] to 0x1).

In receive-only mode, the `MCSPI_Tx` register must be loaded before the McSPI is selected by an external SPI master device. The `MCSPI_Tx` register content is always loaded into the shift register whether it is updated or not. The `Txx_UNDERFLOW` event is activated accordingly and does not prevent transmission.

When the SPI word transfer completes (the `MCSPI_CHxSTAT0`[2] EOT bit [where x = 0] is set to 1), the received data is transferred to the channel receive register.

To use the McSPI as a slave receive-only device, the `Txx_EMPTY` and `Txx_UNDERFLOW` interrupts and the DMA write requests must be disabled due to the state of the `MCSPI_Tx` register.

For a full-duplex transmission, the serial clock (SPICLK) synchronizes shifting and sampling of the information on the single serial data line. For full duplex, two data lines are required. If SPICLK synchronizes on a single serial data line, the data line should be half-duplex.

Figure 24-90 shows a half-duplex system with a master device on the left and a receive-only slave device on the right. Each time a bit transfers out from the master, 1 bit transfers in from the slave. After eight cycles of the serial clock SPICLK, WordA transfers from the master to the slave.

**Figure 24-90. SPI Half-Duplex Transmission (Receive-Only Slave)**

$k = 0$  or  $1$  depending on bits IS, DPE1 and DPE0 in MCSPI\_CHxCONF

mcspi-032

#### 24.4.4.5 3-Pin or 4-Pin Mode

Depending on targeted application the SPI interface can be configured to use 3 or 4 pins through the [MCSPI\\_MODULCTRL\[1\]](#) PIN34 bit. If this bit is set to 0, McSPI is in 4-pin mode using the SPICLK, SPIDAT[0], SPIDAT[1] and SPIEN[x] signals. If PIN34 is set to 1 the controller is in 3-pin mode and SPIEN[x] is not used. In this mode all options related to chip select management are useless (EPOL, FORCE and TCS0 bits of [MCSPI\\_CHxCONF](#)). 3-pin and 4-pin operation applies to both master and slave modes.

#### 24.4.4.6 FIFO Buffer Management

The McSPI controller has a built-in 128-byte buffer to unload the DMA or interrupt handler and improve data throughput.

This buffer can be used by only one channel at a time and is selected by setting the [MCSPI\\_CHxCONF\[28\]](#) FFER or [MCSPI\\_CHxCONF\[27\]](#) FFEW bit to 1. If several channels are selected and several FIFO enable bit fields are set to 1, the controller forces the buffer not to be used; the driver must set only one FIFO enable bit field.

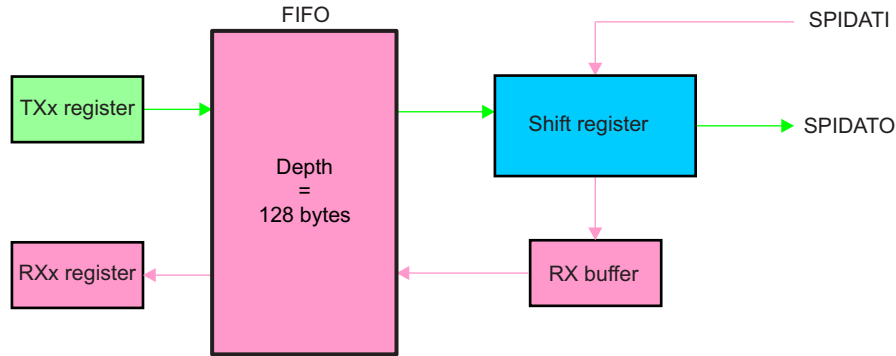

The buffer can be used in the following modes:

- Master or slave mode
- Transmit-only, receive-only, or transmit-and-receive mode
- Single channel or turbo mode, or normal round-robin mode. In round-robin mode the buffer is used by only one channel.

Every word length ( [MCSPI\\_CHxCONF\[11:7\]](#) WL) is supported.

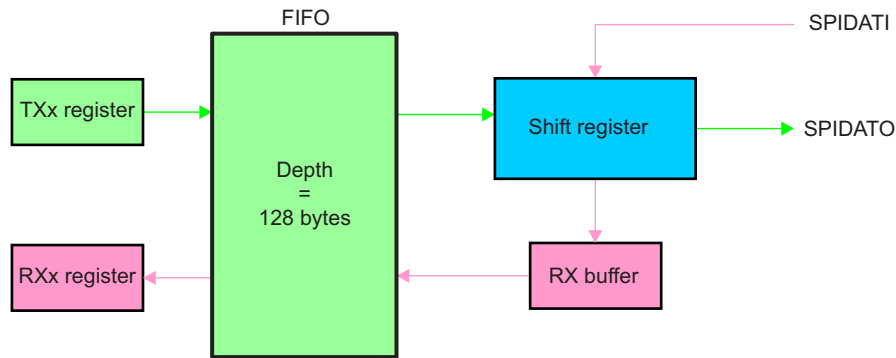

In transmit-and-receive mode, the buffer can be used in transmit (see [Figure 24-91](#)) or receive (see [Figure 24-92](#)) directions, or in both directions. If only one direction is chosen in transmit-and-receive mode, the full buffer is used for this direction. In both directions, the buffer is split into two halves, one for each direction (see [Figure 24-93](#)).

**Figure 24-91. Buffer Used in Transmit Direction Only**

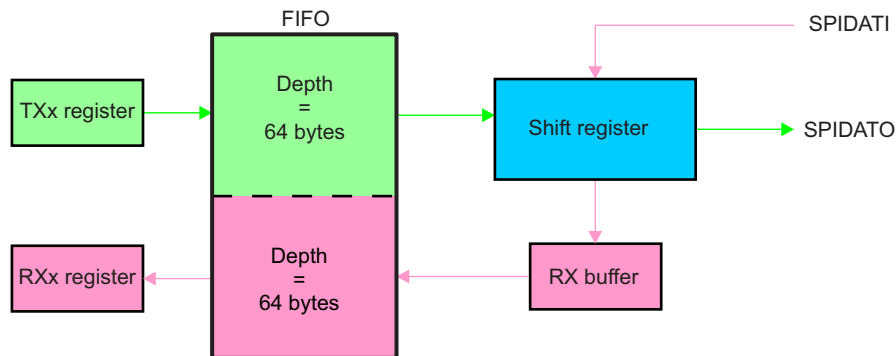

mcspi-102

**Figure 24-92. Buffer Used in Receive Direction Only**

mcspi-103

**Figure 24-93. Buffer Used for Transmit and Receive Directions**

mcspi-101

Two levels ( [MCSPI\\_XFERLEVEL\[5:0\]](#) AEL and [MCSPI\\_XFERLEVEL\[13:8\]](#) AFL) rule the buffer management. The granularity of these levels is 1 byte; it is not aligned with the SPI word length. The driver must set these values as a multiple of the SPI word length defined in [MCSPI\\_CHxCONF\[11:7\]](#) WL. [Table 24-298](#) lists the number of bytes written in the FIFO, depending on the word length.

**Table 24-298. FIFO Writes, Word Length Relationship**

	SPI Word Length (WL)		
	$3 \leq WL \leq 7$	$8 \leq WL \leq 15$	$16 \leq WL \leq 31$
Number of bytes written in the FIFO	1 byte	2 bytes	4 bytes

The FIFO buffer pointers are reset when the corresponding channel is enabled or the FIFO configuration changes.

**24.4.4.6.1 Buffer Almost Full**

The `MCSPI_XFERLEVEL[15:8]` AFL bit field is needed when the buffer is used to receive an SPI word from a slave (the `MCSPI_CHxCONF[28]` FFER bit must be set to 1). It defines the almost-full buffer status. See Figure 24-94.

When the FIFO pointer reaches this level, an interrupt or a DMA request is sent to the MPU to enable the system to read AFL + 1 bytes from the receive register.

**NOTE:** AFL + 1 must correspond to a multiple value of the `MCSPI_CHxCONF[11:7]` WL bit field.

When DMA is used, the request is deasserted after the first receive register read.

No new request is asserted again as long as the system has not performed the correct number of read accesses.

**NOTE:** The `MCSPI_IRQSTATUS` register bits are not available in DMA mode. In DMA mode, the `SPIm_DMA_RXx` request is asserted on the same conditions as the `MCSPI_IRQSTATUS` `RXx_FULL` flag.

**24.4.4.6.2 Buffer Almost Empty**

The `MCSPI_XFERLEVEL[7:0]` AEL bit field is needed when the buffer is used to transmit an SPI word to a slave (the `MCSPI_CHxCONF[27]` FFEW bit must be set to 1). It defines the almost-empty buffer status. See Figure 24-95.

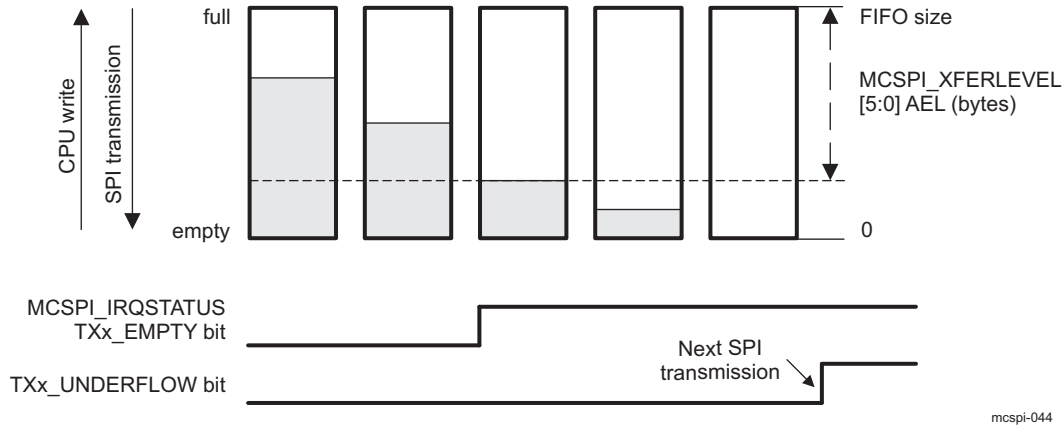

When the FIFO pointer does not reach this level, an interrupt or a DMA request is sent to the MPU to enable the system to write AEL + 1 bytes to the transmit register.

**NOTE:** AEL + 1 must correspond to a multiple value of the `MCSPI_CHxCONF[11:7]` WL bit field.

When DMA is used, the request is deasserted after the first transmit register write.

No new request is asserted again as long as the system has not performed the correct number of write accesses.

**Figure 24-95. Buffer Almost Empty Level (AEL)**

**NOTE:** The [MCSPi\\_IRQSTATUS](#) register bits are not available in DMA mode. In DMA mode, the [SPIm\\_DMA\\_TXx](#) request is asserted on the same conditions as the [MCSPi\\_IRQSTATUS TXx\\_EMPTY](#) flag.

#### 24.4.4.6.3 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user must previously configure in the [MCSPi\\_XFERLEVEL](#) register the AEL and AFL levels and especially the [MCSPi\\_XFERLEVEL\[31:16\]](#) WCNT bit field to define the number of SPI words to be transferred using the FIFO before enabling the channel.

This counter lets the controller stop the transfer correctly after a defined number of SPI word transfers. If WCNT is set to 0x0000, the counter is not used and the user must stop the transfer manually by disabling the channel; in this case, the user does not know how many SPI transfers have been done. For received words, software must poll the [CHxSTAT\[5\] RXFFE](#) bit and read the [MCSPi\\_RXx](#) receive register to empty the FIFO buffer.

When the end-of-word count interrupt is generated (the [MCSPi\\_IRQSTATUS\[17\] EOW](#) bit is set), the user can disable the channel and poll the [MCSPi\\_CHxSTAT\[5\] RXFFE](#) bit to know the last SPI words in the FIFO buffer and read them.

No new request is asserted as long as the system has not performed the correct number of write accesses.

#### 24.4.4.7 Interrupts

Each channel can issue interrupt events.

Each interrupt event has status bits in the [MCSPi\\_IRQSTATUS](#) register ([RXx\\_FULL](#), [TXx\\_UNDERFLOW](#), [TXx\\_EMPTY](#), etc.) (where x = 0, 3) that indicate whether service is required. Each status bit has an interrupt enable bit (a mask) in the [MCSPi\\_IRQENABLE](#) register ([RXx\\_FULL\\_ENABLE](#), [TXx\\_UNDERFLOW\\_ENABLE](#), [TXx\\_EMPTY\\_ENABLE](#), etc.).

When an interrupt occurs and a mask is later applied on it, the interrupt line is not asserted again, even if the interrupt source is not serviced.

The McSPI supports interrupt-driven and polling operations.

##### 24.4.4.7.1 Interrupt Events in Master Mode

In master mode, the interrupt events related to the state of the [MCSPi\\_TXx](#) register are [TXx\\_EMPTY](#) and [TXx\\_UNDERFLOW](#). The interrupt event related to the state of the [MCSPi\\_RXx](#) register is [RXx\\_FULL](#).

#### 24.4.4.7.1.1 TXx\_EMPTY

The TXx\_EMPTY event is activated when a channel is enabled and its MCSPI\_TXx register is empty (transient event). Enabling a channel automatically triggers this event, except in master receive-only mode (see Section 24.4.4.3.4, *Master Receive-Only Mode*). When the FIFO buffer is enabled (the MCSPI\_CHxCONF[27] FFEW bit is set to 1), the MCSPI\_IRQSTATUS TXx\_EMPTY bit is set as soon as there is enough space in the buffer to write a number of bytes defined by the MCSPI\_XFERLEVEL[5:0] AEL bit field.

The MCSPI\_TXx register must be loaded with data to remove the source of the interrupt; the MCSPI\_IRQSTATUS TXx\_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx\_EMPTY event is asserted as long as the MPU has not performed the number of writes into the MCSPI\_TXx register defined by the MCSPI\_XFERLEVEL[5:0] AEL bit field. The MPU must perform the correct number of writes.

#### 24.4.4.7.1.2 TXx\_UNDERFLOW

The event TXx\_UNDERFLOW is activated when the channel is enabled and if the MCSPI\_TXx register or the FIFO is empty (not updated with new data) when an external master device starts a data transfer with the McSPI (transmit and receive).

The TXx\_UNDERFLOW is a harmless warning in master mode.

To avoid having a TXx\_UNDERFLOW event at the beginning of a transmission, the TXx\_UNDERFLOW event is not activated when no data has been loaded into the MCSPI\_TXx register, because the channel is enabled. To avoid having a TXx\_UNDERFLOW event, the MCSPI\_TXx register must seldom be loaded.

The MCSPI\_IRQSTATUS TXx\_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

#### 24.4.4.7.1.3 RXx\_FULL

The RXx\_FULL event is activated when a channel is enabled and the MCSPI\_RXx register becomes filled (transient event). When the FIFO buffer is enabled (the MCSPI\_CHxCONF[28] FFER bit is set to 1), RXx\_FULL is asserted as soon as the number of bytes held in the FIFO to be read reaches the MCSPI\_XFERLEVEL[13:8] AFL threshold.

The MCSPI\_RXx register must be read to remove the source of the interrupt; the MCSPI\_IRQSTATUS RXx\_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx\_FULL event is asserted as long as the MPU has not performed AFL + 1 reads into MCSPI\_RXx. The MPU must perform the correct number of reads.

#### 24.4.4.7.1.4 End Of Word Count

The MCSPI\_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the MCSPI\_XFERLEVEL[31:16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the SPI transfer is halted on the channel using the FIFO buffer as soon as MCSPI\_XFERLEVEL[31:16] WCNT is not reloaded and the channel is not re-enabled.

The MCSPI\_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

#### **24.4.4.7.2 Interrupt Events in Slave Mode**

In slave mode, the interrupt events related to the state of the [MCSPI\\_TXx](#) register are TXx\_EMPTY and TXx\_UNDERFLOW. The interrupt events related to the state of the [MCSPI\\_RXx](#) are RXx\_FULL and RX0\_OVERFLOW (channels 1, 2, and 3 do not have a receiver overflow status bit). See the [MCSPI\\_IRQSTATUS](#) register.

##### **24.4.4.7.2.1 TXx\_EMPTY**

The TXx\_EMPTY event is activated when a channel is enabled and its [MCSPI\\_TXx](#) register is empty. Enabling the channel automatically raises this event. If the FIFO buffer is enabled (the [MCSPI\\_CHxCONF\[27\]](#) FFEW bit is set to 1), the TXx\_EMPTY event is asserted as soon as there is enough space in buffer to write a number of bytes defined by the [MCSPI\\_XFERLEVEL\[5:0\]](#) AEL bit field.

The [MCSPI\\_TXx](#) register must be loaded with data to remove the source of the interrupt; the [MCSPI\\_IRQSTATUS](#) TXx\_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx\_EMPTY event is asserted as long as the MPU has not performed the number of writes into the [MCSPI\\_TXx](#) register defined by [MCSPI\\_XFERLEVEL\[5:0\]](#) AEL bit field. The MPU must perform the correct number of writes.

##### **24.4.4.7.2.2 TXx\_UNDERFLOW**

The TXx\_UNDERFLOW event is activated when a channel is enabled and if the [MCSPI\\_TXx](#) register is empty (not updated with new data) when an external master device starts a data transfer with the McSPI (transmit and receive).

When FIFO is enabled, the data emitted while the underflow event is raised is not the last data written in the FIFO but the next data in the FIFO (an old transmitted value or a dummy data in the FIFO has been reset).

TXx\_UNDERFLOW indicates an error (data loss) in slave mode.

To avoid having a TXx\_UNDERFLOW event at the beginning of a transmission, the TXx\_UNDERFLOW event is not activated when no data has been loaded into the [MCSPI\\_TXx](#) register because the channel is enabled.

The [MCSPI\\_IRQSTATUS](#) TXx\_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

##### **24.4.4.7.2.3 RXx\_FULL**

The RXx\_FULL event is activated when a channel is enabled and the [MCSPI\\_RXx](#) register is being filled (transient event). When the FIFO buffer is enabled (the [MCSPI\\_CHxCONF\[28\]](#) FFER bit is set to 1), RXx\_FULL is asserted as soon as the number of bytes held in the buffer to read defined by the [MCSPI\\_XFERLEVEL\[13:8\]](#) AFL bit field.

The [MCSPI\\_RXx](#) register must be read to remove the source of the interrupt; the [MCSPI\\_IRQSTATUS](#) RXx\_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx\_FULL event is asserted as long as the MPU has not performed AFL + 1 reads into [MCSPI\\_RXx](#). The MPU must perform the correct number of reads.

##### **24.4.4.7.2.4 RX0\_OVERFLOW**

The RX0\_OVERFLOW event is activated in slave mode in transmit-and-receive mode or receive-only mode when a channel is enabled and the [MCSPI\\_RXx](#) register or FIFO is full when a new SPI word is received. The [MCSPI\\_RXx](#) register is always overwritten with the new SPI word. If the FIFO is enabled, data within the FIFO are overwritten; it must be considered as corrupted. The RX0\_OVERFLOW event should not appear in slave mode using the FIFO.

The RX0\_OVERFLOW event indicates an error (data loss) in slave mode.

The [MCSPI\\_IRQSTATUS](#)[3] `RX0_OVERFLOW` interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

#### 24.4.4.7.2.5 End Of Word Count

The [MCSPI\\_IRQSTATUS](#)[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the [MCSPI\\_XFERLEVEL](#)[31:16] `WCNT` bit field. If `WCNT` is set to `0x0000`, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the SPI transfer is halted on the channel using the FIFO buffer as soon as `WCNT` is not reloaded and the channel is not re-enabled.

The [MCSPI\\_IRQSTATUS](#)[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

#### 24.4.4.7.3 Interrupt-Driven Operation

An interrupt enable bit in the [MCSPI\\_IRQENABLE](#) register can be set to enable each event to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the MPU must:

1. Read the [MCSPI\\_IRQSTATUS](#) register to identify which event occurred.
2. Read the [MCSPI\\_RXx](#) register that corresponds to the event to remove the source of an `RXx_FULL` event or write into the [MCSPI\\_TXx](#) register that corresponds to the event to remove the source of a `TXx_EMPTY` event. No action is required to remove the source of the `WKS` (wake-up), `TXx_UNDERFLOW`, and `RX0_OVERFLOW` events.
3. Set the corresponding bit of the [MCSPI\\_IRQSTATUS](#) register to 1 to clear an interrupt status and then release the interrupt line.

The interrupt status bit must always be reset after channel enabling and before events are enabled as interrupt sources.

#### 24.4.4.7.4 Polling

When the interrupt capability of an event is disabled in the [MCSPI\\_IRQENABLE](#) register, the interrupt line is not asserted, but the status bits in the [MCSPI\\_IRQSTATUS](#) register can be polled by software to detect when the corresponding event occurs.

Once the expected event occurs:

- `RXx_FULL`: To remove the source of the event, the MPU must read the corresponding [MCSPI\\_RXx](#) register.
- `TXx_EMPTY`: To remove the source of the event, the MPU must write into the corresponding [MCSPI\\_TXx](#) register.
- `WKS` (wake-up), `TXx_UNDERFLOW`, and `RX0_OVERFLOW`: No action is required to remove the source of the event.

To clear an interrupt, set the corresponding status bit of the [MCSPI\\_IRQSTATUS](#) register to 1. This does not affect the interrupt line state.

#### 24.4.4.8 DMA Requests

Each McSPI channel, if enabled, can issue DMA requests. There are two DMA request lines per McSPI channel (one for read and one for write).

The DMA read request line is asserted when the McSPI channel is enabled and new data is available in the receive register of the McSPI channel. A DMA read request can be individually masked with the `SPI1.MCSPI_CHxCONF`[15] `DMAR` bit. The DMA read request line is deasserted when reading of the [MCSPI\\_RXx](#) register of the McSPI channel completes.

The DMA write request line is asserted when the McSPI channel is enabled and the [MCSPI\\_TXx](#) register of the McSPI channel is empty. A DMA write request can be individually masked with the [SPI1.MCSPI\\_CHxCONF\[14\]](#) DMAW bit. The DMA write request line is deasserted when loading of the [MCSPI\\_TXx](#) register of the channel completes.

#### 24.4.4.9 Power Saving Management

Power consumption can be optimized by switching off internal clocks (interface and functional clock) when there is no activity. The McSPI is compliant with the idle and wake-up system handshake protocol.

##### 24.4.4.9.1 Normal Mode

In normal mode, internal SPI module clocks are automatically switched off (autogated) when there is no activity in slave or master mode.

Autogating of the module interface clock and functional clock occurs when the following conditions are met:

- The [MCSPI\\_SYSCONFIG\[0\]](#) AUTOIDLE bit is set.
- In master mode, there is no data to transmit or receive in all channels.
- In slave mode, the McSPI is not selected by the external master and there are no register accesses.

Autogating of the module interface clock and functional clock stops when the following conditions are met:

- In master mode, an internal access occurs.
- In slave mode, an internal access occurs or the McSPI is selected by the external master.

##### 24.4.4.9.2 Idle Mode

At the PRCM module level, when all conditions are met to shut off the [PER\\_48M\\_GFCLK](#) or [L4PER\\_L3\\_GICLK](#) output clock, the PRCM module automatically launches a hardware handshake protocol to ensure that the McSPI is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the McSPI.

Although this handshake is completely hardware-oriented and out of software control, the method in which the McSPI module acknowledges the PRCM IDLE request is configurable through the [MCSPI\\_SYSCONFIG\[4:3\]](#) SIDLEMODE bit field.

The settings of the SIDLEMODE bit field and the related acknowledgment modes are:

- Force-idle mode (the [MCSPI\\_SYSCONFIG\[4:3\]](#) SIDLEMODE bit field is set to 0x0): The McSPI module acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully in this case because it does not prevent the loss of data when the clock is switched off.
- No-idle mode (the SIDLEMODE bit field is set to 0x1): The McSPI never acknowledges an IDLE request from the PRCM module and is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient to save power because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
- Smart-idle mode (the SIDLEMODE bit field is set to 0x2): The McSPI acknowledges the IDLE request, basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for efficient system power management.

When configured in smart-idle mode, the McSPI also offers an additional granularity on the [PER\\_48M\\_GFCLK](#) and [L4PER\\_L3\\_GICLK](#) gating. The [MCSPI\\_SYSCONFIG\[9:8\]](#) CLOCKACTIVITY bit field determines which clock shuts down (the [PER\\_48M\\_GFCLK](#), [L4PER\\_L3\\_GICLK](#), neither clock, or both clocks).

The setting of the CLOCKACTIVITY bit field is used internally to the McSPI to determine on which part of the module the conditions to acknowledge the PRCM IDLE request are tested. For example, if [PER\\_48M\\_GFCLK](#) is not shut down on a PRCM IDLE request, the McSPI considers only [L4PER\\_L3\\_GICLK](#) and the associated pending activities before acknowledging the request.

Some McSPI features are associated with L4PER\_L3\_GICLK and others with PER\_48M\_GFCLK. Using the CLOCKACTIVITY bit field with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if the McSPI acknowledges an IDLE request.

The settings of the CLOCKACTIVITY bit field and the associated features are:

- CLOCKACTIVITY set to 00: ICLK off and FCLK off, ICLK and FCLK are considered for generating the acknowledge. This setting also means that FCLK and ICLK are likely to be shut down on a PRCM IDLE request.
- CLOCKACTIVITY set to 01: ICLK on and FCLK off, ICLK is not shut down on a PRCM IDLE request; only FCLK is concerned.
- CLOCKACTIVITY set to 10: ICLK off and FCLK on, FCLK is not shut down on a PRCM IDLE request; only ICLK is concerned.
- CLOCKACTIVITY set to 11: ICLK on and FCLK on, none of the clocks are shut down. This means the McSPI can potentially acknowledge the IDLE request without checking the internal functions linked to its clocks.

#### CAUTION

The PRCM module does not have a hardware means of reading the CLOCKACTIVITY settings. Therefore, software must ensure consistent programming between CLOCKACTIVITY and the PER\_48M\_GFCLK and L4PER\_L3\_GICLK control bits in the PRCM module. If the McSPI is disabled in the CM\_FCLKEN and CM\_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the McSPI clocks. This can lead to unpredictable behavior.

#### 24.4.4.9.2.1 Wake-Up Event in Smart-Idle Mode

The module wake-up feature is enabled when the [MCSPI\\_SYSCONFIG\[2\]](#) ENAWAKEUP and [MCSPI\\_WAKEUPENABLE\[0\]](#) WKEN bits are set. Wake-up capability is relevant only when the module is configured in slave mode.

The module generates an asynchronous wake-up request to the system power manager to switch back the interface clock and the functional clock. A wakeup is requested when channel 0 is enabled and an asynchronous selection occurs on the mcs pim.csx port associated with channel 0 (see the definition for the [MCSPI\\_CHxCONF\[22:21\]](#) SPIENSLV bit field [where x = 0] in the register table description).

After the McSPI wake-up request, the system power manager must reactivate the interface clock:

- Before the beginning of the second SPI word serialization when the McSPI is in slave transmit-only mode or in slave transmit-and-receive mode
- Before the end of the second received SPI word in slave receive-only mode. To avoid data loss, the first received SPI word must be read from the [MCSPI\\_RXx](#) register (where x = 0) before the completion of the second SPI word serialization.

[Table 24-299](#) lists the supported cases in smart-idle mode.

**Table 24-299. Smart-Idle Mode and Wake-Up Capabilities**

Mode	Interface Clock	SPI Clock Ref	Functionality	Wake-Up Event
Master	Must be maintained	Must be maintained	Full functionality, but the module does not generate a new interrupt or DMA request until the system exits wake-up mode	No wake-up event
Slave	Can be switched off	Can be switched off	An SPI word can be transmitted and/or received, but the module does not generate any new interrupts or DMA requests until the system exits wake-up mode.	The module asynchronously sends a wake-up request if an event on the SPIEN[x] port associated with channel 0 is detected.

In wake-up mode, the interrupt and DMA request lines are no longer asserted.

Any access to the module in wake-up mode generates an error as long as the interface clock is alive.

#### 24.4.4.9.2.2 Transitions From Smart-Idle Mode to Normal Mode

The McSPI detects the end of the wake period through the idle and wake-up hardware handshake protocol.

The interrupt status register (the [MCSPI\\_IRQSTATUS](#)[16] WKS bit) is updated with the event causing the wakeup; the wake-up event at the origin of the transition to the normal mode is converted to its corresponding interrupt when enabled by the [MCSPI\\_IRQENABLE](#)[16] WKE bit or the DMA request.

Interrupts and wake-up events have independent enable and disable controls, accessible through the [MCSPI\\_IRQENABLE](#) and [MCSPI\\_WAKEUPENABLE](#) registers. Software must ensure the overall consistency.

The interrupt status register [MCSPI\\_IRQSTATUS](#) is updated with the event causing the wakeup; the wake-up event at the origin of the transition to normal mode is converted to its corresponding interrupt request or DMA request. The module is fully operational.

#### 24.4.4.9.2.3 Force-Idle Mode

Force-idle mode is enabled and exited as follows:

- Force-idle mode is enabled when the [MCSPI\\_SYSCONFIG](#)[4:3] SIDLEMODE bit field is set to 0x0.
  - In force-idle mode, the McSPI responds unconditionally to the IDLE request by deasserting unconditionally the interrupt and DMA request lines, if asserted. In addition, the wake-up capability is totally inhibited even if the [MCSPI\\_SYSCONFIG](#)[2] ENAWAKEUP and [MCSPI\\_WAKEUPENABLE](#)[0] WKEN bits are set.
  - The transition from normal mode to idle mode does not affect the interrupt event bits of the [MCSPI\\_IRQSTATUS](#) register.
  - In force-idle mode, because the module must be disabled, the interrupt and DMA request lines are likely deasserted. The interface clock and SPI clock provided to the McSPI can be switched off.
  - An IDLE request during an SPI data transfer can lead to an unexpected and unpredictable result. Software must avoid such a request.
- The module exits force-idle mode through the idle and wake-up hardware handshake protocol. The module is fully operational. The interrupt and DMA request lines are optionally asserted one clock cycle later.

## 24.4.5 McSPI Programming Guide

This section describes the low-level hardware programming sequences for the configuration and use of the McSPI module.

### 24.4.5.1 Global Initialization

#### 24.4.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the McSPI module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the McSPI. For further information, see [Section 24.4.3, McSPI Integration](#) and [Section 24.4.2, McSPI Environment](#).

[Table 24-300](#) lists the information on the global initialization of the surrounding modules.

**Table 24-300. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	MCSPI_FCLK functional clock must be enabled. See <a href="#">Section 3.1.1.1.2, Module-Level Clock Management</a> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
L4 Interconnect	For information about L4_PER1 interconnect configuration, see <a href="#">Section 14.3, L4 Interconnects</a> , in <a href="#">Chapter 14, Interconnect</a> .
DMA_CROSSBAR	DMA_CROSSBAR configuration must be done to allow module DREQs to be mapped to certain device DMA line. For more information see <a href="#">Section 18.4.6.5, DMA_CROSSBAR Module Functional Description</a> , in <a href="#">Chapter 18, Control Module</a> .
Device DMAs	Device DMA configuration must be done to enable the module DMA channel requests.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see <a href="#">Section 18.4.6.4, IRQ_CROSSBAR Module Functional Description</a> , in <a href="#">Chapter 18, Control Module</a> .
Device INTCs	Device INTCs must be configured to enable the interrupt request generation. For more information see <a href="#">Chapter 17 Interrupt Controllers</a> .

#### 24.4.5.1.2 McSPI Global Initialization

##### 24.4.5.1.2.1 Main Sequence – McSPI Global Initialization

The procedure in [Table 24-301](#) can be used to initialize McSPI when performing software reset.

**Table 24-301. McSPI Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Perform a software reset.	MCSPISYSCONFIG[1] SOFTRESET	1
Wait until reset is finished?	MCSPISYSSTATUS[0] RESETDONE	=1
Configure static settings (such as SPI master or slave) as required.	MCSPIMODULCTRL[8:0]	0x-
Write MCSPISYSCONFIG	MCSPISYSCONFIG	0x-

### 24.4.5.2 Operational Mode Configuration

#### 24.4.5.2.1 McSPI Operational Modes

The selection of the working mode is done with the [MCSPICHxCONF](#) register.

**Table 24-302. McSPI Receive Mode Initialization**

Step	Register/Bit Field/Programming Model	Value
Set receive mode for the channel.	<a href="#">MCSPI_CHxCONF</a> [13:12] TRM	0x1
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	<a href="#">MCSPI_CHxCONF</a>	0x-
Reset the status bits.	<a href="#">MCSPI_IRQSTATUS</a>	0x0

**Table 24-303. McSPI Transmit Mode Initialization**

Step	Register/Bit Field/Programming Model	Value
Set transmit mode for the channel.	<a href="#">MCSPI_CHxCONF</a> [13:12] TRM	0x2
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	<a href="#">MCSPI_CHxCONF</a>	0x-
Reset the status bits.	<a href="#">MCSPI_IRQSTATUS</a>	0x0

**Table 24-304. McSPI Transmit-and-Receive Mode Initialization**

Step	Register/Bit Field/Programming Model	Value
Set transmit and receive mode for the channel.	<a href="#">MCSPI_CHxCONF</a> [13:12] TRM	0x0
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	<a href="#">MCSPI_CHxCONF</a>	0x-
Reset the status bits.	<a href="#">MCSPI_IRQSTATUS</a>	0x0

#### 24.4.5.2.1.1 Common Transfer Sequence

McSPI module allows the transfer of one or several words, according to different modes:

- MASTER Normal, MASTER Turbo, SLAVE
- TRANSMIT–RECEIVE, TRANSMIT-ONLY, RECEIVE-ONLY
- Write and Read requests: Interrupts, DMA
- SPIEN[x] lines assertion/deassertion: automatic, manual

For all these sequences, the host process contains the main process and the interrupt routines.

The interrupt routines are called on the interrupt signals or by an internal call if the module is used in polling mode.

[Table 24-305](#) represents the main sequence which is common to all transfers.

In multi-channel master mode, the sequences of different channels can be run simultaneously.

**Table 24-305. Common Transfer Sequence (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Write <a href="#">MCSPI_IRQSTATUS</a> to reset channel status bits	<a href="#">MCSPI_IRQSTATUS</a> [channel x bits]	0b1111
Write <a href="#">MCSPI_IRQENABLE</a> to enable interrupts	<a href="#">MCSPI_IRQENABLE</a>	0x-
Write <a href="#">MCSPI_CHxCONF</a> to configure the channel	<a href="#">MCSPI_CHxCONF</a>	0x-
Start the channel	<a href="#">MCSPI_CHxCTRL</a> [0] EN	1
Wait for the first write request (TX empty or DMA write)		
Write the transmitter register with data	<a href="#">MCSPI_TXx</a>	0x-
Wait for the host event for end of transfer		
Stop the channel	<a href="#">MCSPI_CHxCTRL</a> [0] EN	0

### 24.4.5.2.1.2 End of Transfer Sequences

The end of transfer depends on the transfer mode. [Table 24-306](#) summarizes the type of end of transfer per transfer mode and gives a reference to the appropriate section for details.

**Table 24-306. End of Transfer Sequences**

		TRANSMIT-AND-RECEIVE		TRANSMIT-ONLY		RECEIVE-ONLY	
		INTERRUPT	DMA	INTERRUPT	DMA	INTERRUPT	DMA
<b>MASTER Normal</b>	End of transfer sequence	See <a href="#">Section 24.4.5.2.1.3</a>		See <a href="#">Section 24.4.5.2.1.4.1</a>	See <a href="#">Section 24.4.5.2.1.4.2</a>	See <a href="#">Section 24.4.5.2.1.5.1</a>	See <a href="#">Section 24.4.5.2.1.5.2</a>
	Minimum number of word	1	1	1	1	1	2
	DMA transfer size		N		N		N-1
<b>MASTER Turbo</b>	End of transfer sequence	See <a href="#">Section 24.4.5.2.1.3</a>		See <a href="#">Section 24.4.5.2.1.4.1</a>	See <a href="#">Section 24.4.5.2.1.4.2</a>	See <a href="#">Section 24.4.5.2.1.6.1</a>	See <a href="#">Section 24.4.5.2.1.6.2</a>
	Minimum number of word	1	1	1	1	2	3
	DMA transfer size		N		N		N-2
<b>SLAVE</b>	End of transfer sequence	See <a href="#">Section 24.4.5.2.1.3</a>		See <a href="#">Section 24.4.5.2.1.4.1</a>	See <a href="#">Section 24.4.5.2.1.4.2</a>	See <a href="#">Section 24.4.5.2.1.7</a>	
	Minimum number of word	1	1	1	1	1	1
	DMA transfer size		N		N	N	N

The transfer to execute has a size of N words.

The different sequences can be merged in one process to manage transfers of several types. The end of transfer sequences are described from the start of the channel.

In these sequences, some soft variables are used:

- write\_count = 0
- read\_count = 0
- channel\_enable = FALSE
- last\_transfer = FALSE
- last\_request = FALSE

They are initialized before starting the channel.

### 24.4.5.2.1.3 Transmit-and-Receive (Master and Slave)

If the requests are configured in DMA, write\_count and read\_count are assigned with 'N' when the DMA handlers have completed their 'N' OCP accesses.

**Table 24-307. Transmit-and-Receive (Master and Slave) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	<a href="#">MCSPI_CHxCTRL[0]</a> EN	1
Wait for write_count = N AND read_count = N		
Stop the channel	<a href="#">MCSPI_CHxCTRL[0]</a> EN	0

**Table 24-308. Transmit-and-Receive (Master and Slave) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read <a href="#">MCSPI_IRQSTATUS</a>	<a href="#">MCSPI_IRQSTATUS</a>	0x-
Write <a href="#">MCSPI_IRQSTATUS</a> to reset channel status bits	<a href="#">MCSPI_IRQSTATUS</a> [channel x bits]	0b1111
<b>IF: TXx_EMPTY</b>		
Write the transmitter register with data	<a href="#">MCSPI_TXx</a>	0x-
Increment write_count +1		
<b>IF: RXx_FULL</b>		
Read the receiver register	<a href="#">MCSPI_RXx</a>	0x-
Increment read_count +1		
<b>ENDIF</b>		

#### 24.4.5.2.1.4 Transmit-Only (Master and Slave)

##### 24.4.5.2.1.4.1 Based on Interrupt Requests

**Table 24-309. Transmit-Only With Interrupts (Master and Slave) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	<a href="#">MCSPI_CHxCTRL</a> [0] EN	1
Wait until last_transfer = TRUE		
Wait for end of transfer	<a href="#">MCSPI_CHxSTAT</a> [2] EOT	=1
Stop the channel	<a href="#">MCSPI_CHxCTRL</a> [0] EN	0

**Table 24-310. Transmit-Only With Interrupts (Master and Slave) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read <a href="#">MCSPI_IRQSTATUS</a>	<a href="#">MCSPI_IRQSTATUS</a>	0x-
Write <a href="#">MCSPI_IRQSTATUS</a> to reset channel status bits	<a href="#">MCSPI_IRQSTATUS</a> [channel x bits]	0b1111
<b>IF: TXx_EMPTY AND write_count &lt; N</b>		
Write the transmitter register with data	<a href="#">MCSPI_TXx</a>	0x-
Increment write_count +1		
<b>ELSEIF: write_count ≥ N</b>		
last_transfer = TRUE		
<b>ENDIF</b>		

##### 24.4.5.2.1.4.2 Based on DMA Write Requests

When the DMA handler has completed its 'N' OCP accesses, write\_count is assigned with 'N'.

**Table 24-311. Transmit-Only With DMA (Master and Slave) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	<a href="#">MCSPI_CHxCTRL</a> [0] EN	1
Wait until write_count = N		
Disable DMA write request	<a href="#">MCSPI_CHxCONF</a> [14] DMAW	0
Wait until last_transfer = TRUE		
Wait for end of transfer	<a href="#">MCSPI_CHxSTAT</a> [2] EOT	=1
Stop the channel	<a href="#">MCSPI_CHxCTRL</a> [0] EN	0

**Table 24-312. Transmit-Only With DMA (Master and Slave) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read <a href="#">MCSPI_IRQSTATUS</a>	<a href="#">MCSPI_IRQSTATUS</a>	0x-
Write <a href="#">MCSPI_IRQSTATUS</a> to reset channel status bits	<a href="#">MCSPI_IRQSTATUS</a> [channel x bits]	0b1111
<b>IF:</b> TXx_EMPTY AND write_count = N		
last_transfer = TRUE		
<b>ENDIF</b>		

#### 24.4.5.2.1.5 Master Normal Receive-Only

##### 24.4.5.2.1.5.1 Based on Interrupt Requests

**Table 24-313. Receive-Only With Interrupt (Master Normal) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	<a href="#">MCSPI_CHxCTRL</a> [0] EN	1
Wait until last_request = TRUE		
Stop the channel	<a href="#">MCSPI_CHxCTRL</a> [0] EN	0
Read the receiver register	<a href="#">MCSPI_RXx</a>	0x-
Increment read_count +1		

**Table 24-314. Receive-Only With Interrupt (Master Normal) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read <a href="#">MCSPI_IRQSTATUS</a>	<a href="#">MCSPI_IRQSTATUS</a>	0x-
Write <a href="#">MCSPI_IRQSTATUS</a> to reset channel status bits	<a href="#">MCSPI_IRQSTATUS</a> [channel x bits]	0b1111
<b>IF:</b> RXx_FULL AND read_count = N - 1		
last_request = TRUE		
<b>ELSEIF:</b> read_count ≠ N - 1		
Read the receiver register	<a href="#">MCSPI_RXx</a>	0x-
Increment read_count +1		
<b>ENDIF</b>		

##### 24.4.5.2.1.5.2 Based on DMA Read Requests

When the DMA handler has completed its 'N-1' OCP accesses, read\_count is assigned with 'N-1'.

**Table 24-315. Receive-Only With DMA (Master Normal) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	<a href="#">MCSPI_CHxCTRL</a> [0] EN	1
Wait until read_count = N - 1		
Disable DMA read request	<a href="#">MCSPI_CHxCONF</a> [15] DMAR	0
Wait until last_transfer = TRUE		
Stop the channel	<a href="#">MCSPI_CHxCTRL</a> [0] EN	0
Read the receiver register	<a href="#">MCSPI_RXx</a>	0x-
Increment read_count +1		

**Table 24-316. Receive-Only With DMA (Master Normal) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel x bits]	0b1111
<b>IF:</b> RXx_FULL		
Read the receiver register	MCSPI_RXx	0x-
Increment read_count +1		
<b>ENDIF</b>		

#### 24.4.5.2.1.8 Transfer Procedures With FIFO

These flows describe the transfer with FIFO.

The McSPI module allows the transfer of one or several words, according to different modes:

- MASTER Normal, MASTER Turbo, SLAVE
- TRANSMIT–RECEIVE, TRANSMIT-ONLY, RECEIVE-ONLY
- Write and Read requests: IRQ, DMA

For all these flows, the host process contains the main process and the interrupt routine. This routine is called on the IRQ signals or by an internal call if the module is used in polling mode.

For more information, see [Section 24.4.4.6, FIFO Buffer Management](#).

**Table 24-323. FIFO Mode Common Sequence (Master) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Write <a href="#">MCSPI_IRQSTATUS</a> to reset channel status bits	<a href="#">MCSPI_IRQSTATUS</a>	1
Write <a href="#">MCSPI_IRQENABLE</a> to enable interrupts	<a href="#">MCSPI_IRQENABLE</a>	1
Write <a href="#">MCSPI_CHxCONF</a> to configure the channel	<a href="#">MCSPI_CHxCONF</a>	0x-
Write <a href="#">MCSPI_XFERLEVEL</a>	<a href="#">MCSPI_XFERLEVEL</a>	0x-
Start the channel	<a href="#">MCSPI_CHxCTRL[0] EN</a>	1
<b>IF: Receive only</b>		
Wait for the write request (TX empty or DMA write)		
Write for the transmitter register with data	<a href="#">MCSPI_TXx</a>	0x-
<b>ENDIF</b>		
Wait for the host event for end of transfer		
Stop the channel	<a href="#">MCSPI_CHxCTRL[0] EN</a>	0

#### 24.4.5.2.1.8.1 Common Transfer Sequence in FIFO Mode

This flow describes the host sequence for a transfer of any type defined in [Section 24.4.5.2.1.8, Transfer Procedures With FIFO](#).

In multi-channel, only one channel can use the FIFO.

Before enabling the FIFO for a channel ([MCSPI\\_CHxCONF\[28\] FFER](#) and [MCSPI\\_CHxCONF\[27\] FFEW](#) bits), the host must check that the FIFO is not enabled for another channel, even if these channels are not used.

In transmit-and-receive mode, the FIFO can be enabled for write or read request only, without FIFO for the other request.

In Slave mode, the channel 0 only can be activated. The correct SPIEN line is chosen in [MCSPI\\_CHxCONF\[22:21\] SPIENSLV](#) bits (where x = 0).

The McSPI module can start the transfer only when the first write request has been released by writing the [MCSPI\\_TXx](#) register, even in receive-only mode (only one write request occurs in this case).

#### 24.4.5.2.1.8.2 End of Transfer Sequences in FIFO Mode

[Table 24-324](#) summarizes the type of end of transfer per transfer mode and gives a reference to the appropriate section for details.

**Table 24-324. End of Transfer Sequences in FIFO Mode**

Word count	TRANSMIT AND RECEIVE	TRANSMIT-ONLY	RECEIVE-ONLY
Yes	See <a href="#">Figure 24-96</a>	See <a href="#">Figure 24-98</a>	See <a href="#">Figure 24-99</a>
No	See <a href="#">Figure 24-97</a>	See <a href="#">Figure 24-98</a>	See <a href="#">Figure 24-100</a>

The end of transfer sequences are described from the start of the channel.

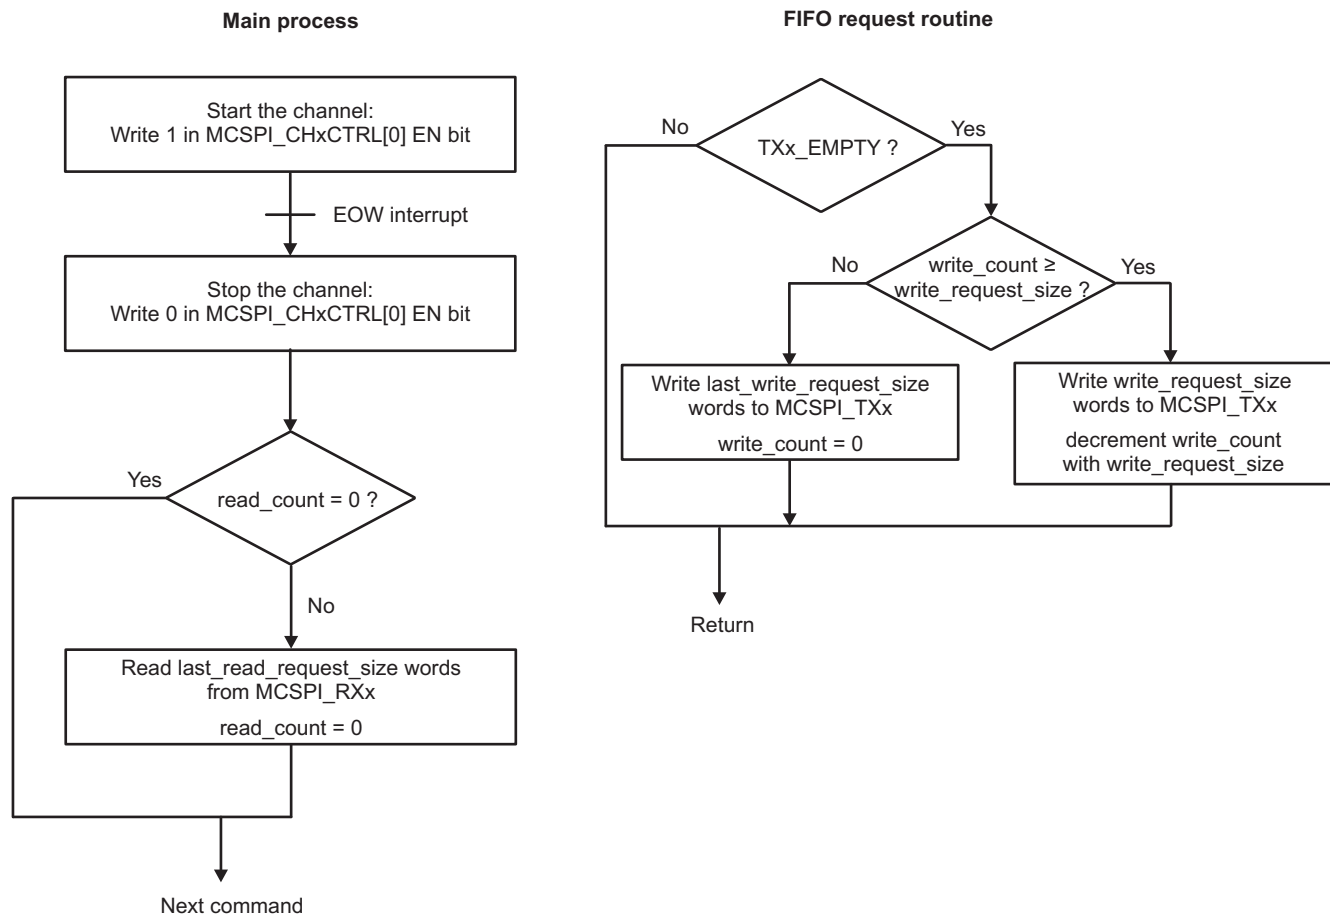

In these sequences, some soft variables are used:

- write\_count = N
- read\_count = N
- last\_request = FALSE

They are initialized before starting the channel.

#### 24.4.5.2.1.8.3 Transmit-and-Receive With Word Count

Figure 24-96 shows the flow of a transfer in transmit-and-receive mode, with word count.

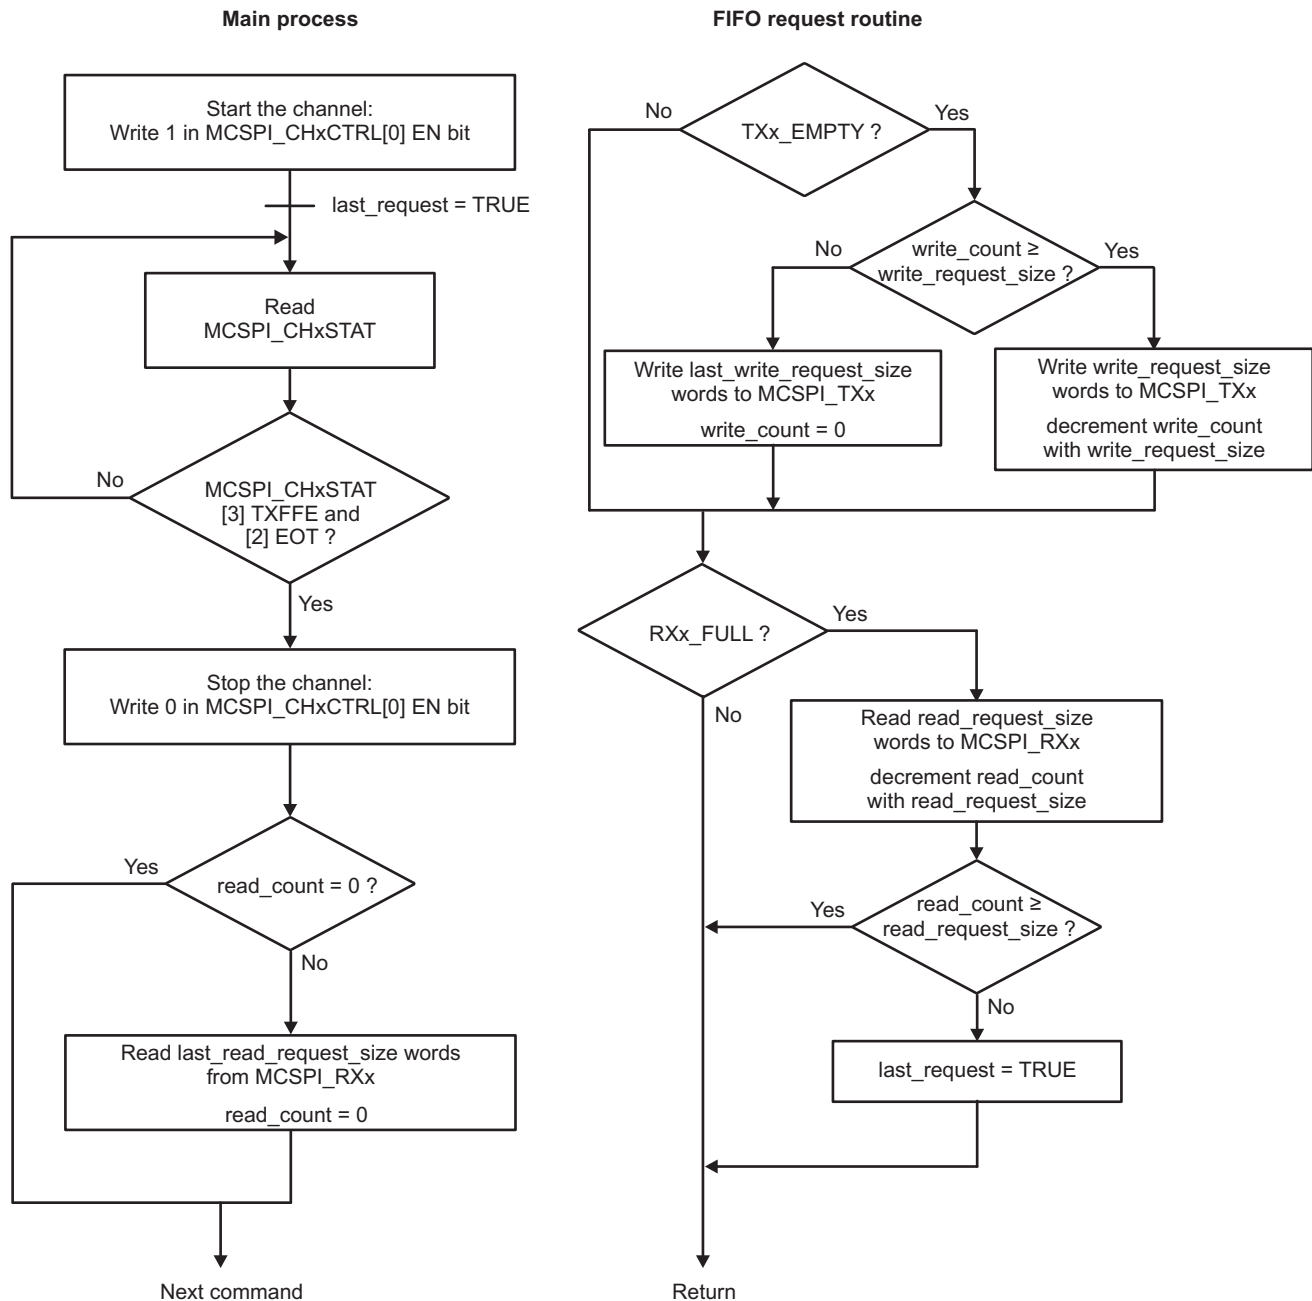

mcspi-045

**Figure 24-96. FIFO Mode Transmit-and-Receive With Word Count (Master)**

#### 24.4.5.2.1.8.4 Transmit-and-Receive Without Word Count

Figure 24-97 shows the flow of a transfer in transmit-and-receive mode, without word count.

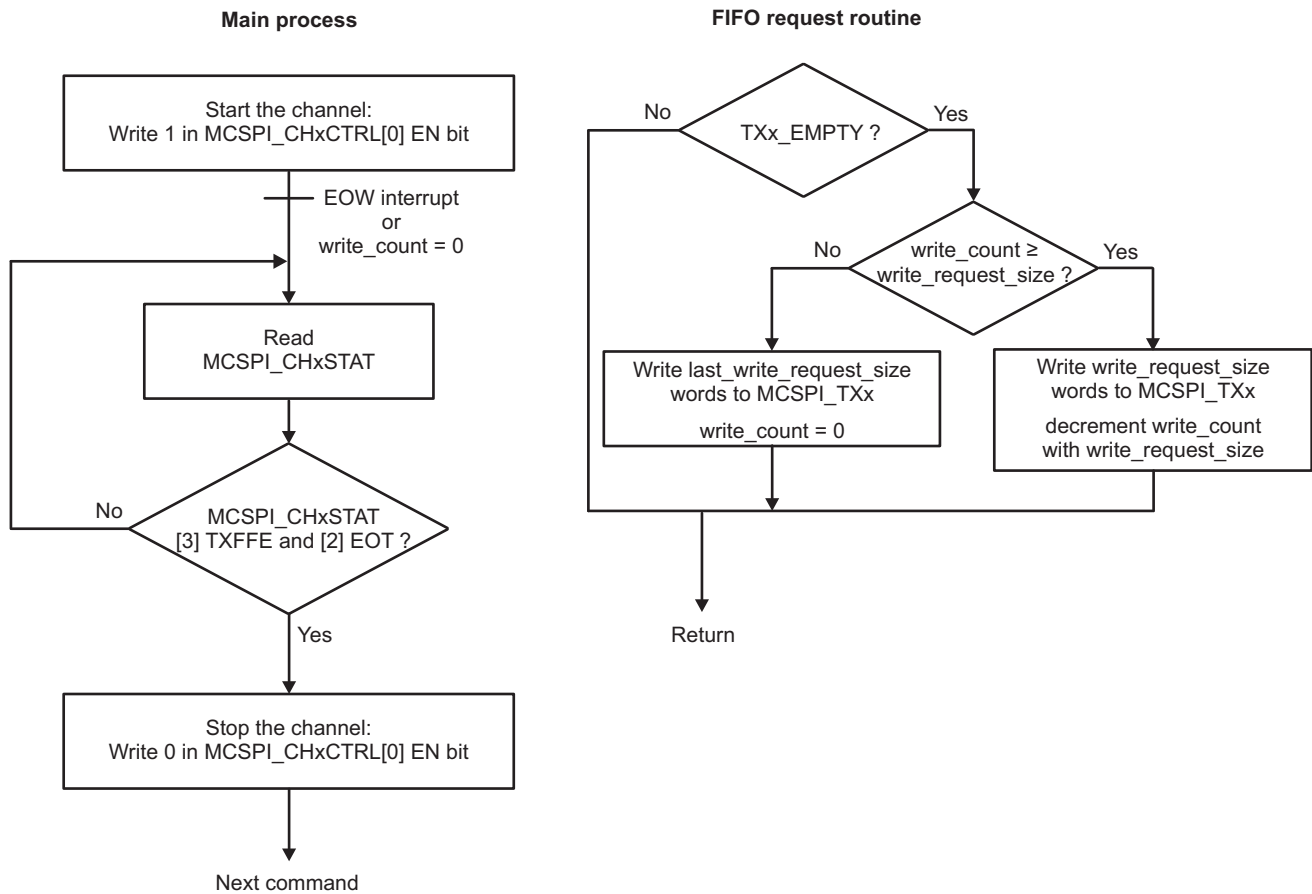

mcspi-046

Figure 24-97. FIFO Mode Transmit-and-Receive Without Word Count (Master)

24.4.5.2.1.8.5 Transmit-Only

Figure 24-98 shows the flow of a transfer in transmit-only mode, with or without word count. The difference between word count enabled or not is just on the condition after starting the channel:

- word count enable: wait for EOW interrupt
- word count disable: wait for write\_count = 0

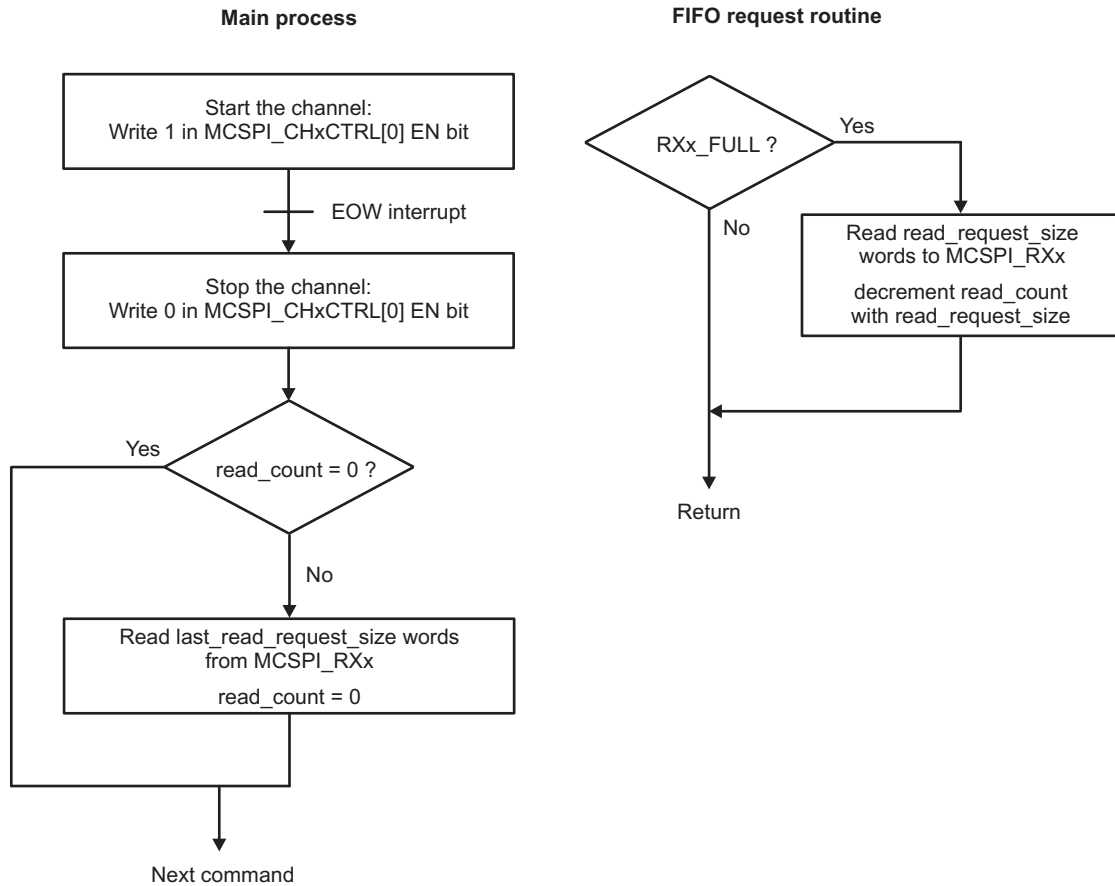

mcspi-047

Figure 24-98. FIFO Mode Transmit-Only (Master)

24.4.5.2.1.8.6 Receive-Only With Word Count

24.4.5.3 Common Transfer Procedures Without FIFO – Polling Method

24.4.5.3.1 Receive-Only Procedure – Polling Method

Table 24-325 lists the receive-only procedure using the polling method.

Table 24-325. Receive-Only Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode	See Table 24-302.	
Start the channel.	MCSPI_CHxCTRL[0] EN	1

**Table 24-325. Receive-Only Procedure – Polling Method (continued)**

Step	Register/Bit Field/Programming Model	Value
Wait for end-of-transfer.	<a href="#">MCSPI_CHxSTAT[2]</a> EOT	=1
Read the receiver register.	<a href="#">MCSPI_RXx</a>	0x-
Stop the channel if no more data is expected.	<a href="#">MCSPI_CHxCTRL[0]</a> EN	0

#### 24.4.5.3.2 Receive-Only Procedure – Interrupt Method

[Table 24-326](#) lists the receive-only procedure using the interrupt method.

**Table 24-326. Receive-Only Procedure – Interrupt Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See <a href="#">Table 24-302</a> .	
Start the channel.	<a href="#">MCSPI_CHxCTRL[0]</a> EN	1
Enable the interrupt for the receiver register.	<a href="#">MCSPI_IRQENABLE[2]</a> RX_FULL_ENABLE	1
Wait for interrupt.		
Read the status register.	<a href="#">MCSPI_IRQSTATUS[2]</a> RX_FULL	1
Disable the interrupt if no more data is expected.	<a href="#">MCSPI_IRQENABLE[2]</a> RX_FULL_ENABLE	0
Stop the channel if no more data is expected.	<a href="#">MCSPI_CHxCTRL[0]</a> EN	0
Read the receiver register.	<a href="#">MCSPI_RXx</a>	0x-

#### 24.4.5.3.3 Transmit-Only Procedure – Polling Method

[Table 24-327](#) lists the transmit-only procedure using the polling method.

**Table 24-327. Transmit-Only Procedure – Polling Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See <a href="#">Table 24-303</a>	
Start the channel.	<a href="#">MCSPI_CHxCTRL[0]</a> EN	1
Write the transmitter register with data.	<a href="#">MCSPI_TXx</a>	0x-
Wait until end of transfer?	<a href="#">MCSPI_CHxSTAT[2]</a> EOT	=1
Stop the channel.	<a href="#">MCSPI_CHxCTRL[0]</a> EN	0

#### 24.4.5.3.4 Transmit-and-Receive Procedure – Polling Method

[Table 24-327](#) lists the transmit-and-receive procedure using the polling method.

**Table 24-328. Transmit-and-Receive Procedure – Polling Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See <a href="#">Table 24-304</a> .	
Start the channel.	<a href="#">MCSPI_CHxCTRL[0]</a> EN	1
Write the transmitter register with data.	<a href="#">MCSPI_TXx</a>	0x-
Wait until transmit/receive word?	<a href="#">MCSPI_CHxSTAT[2]</a> EOT	=1
Stop the channel.	<a href="#">MCSPI_CHxCTRL[0]</a> EN	0
Read the receiver register.	<a href="#">MCSPI_TXx</a>	0x-

## 24.4.6 McSPI Register Manual

### 24.4.6.1 McSPI Instance Summary

**Table 24-329. McSPI Instance Summary**

Module Name	Base Address	Size
McSPI1	0x4809 8000	4 KiB
McSPI2	0x4809 A000	4 KiB
McSPI3	0x480B 8000	4 KiB
McSPI4	0x480B A000	4 KiB

### 24.4.6.2 McSPI Registers

#### 24.4.6.2.1 McSPI Register Summary

Table 24-330 lists the McSPI registers. Each register is 32 bits wide.

**Table 24-330. McSPI Register Summary**

Register	Type	Offset Address	McSPI1 Physical Address	McSPI2 Physical Address	McSPI3 Physical Address	McSPI4 Physical Address
<a href="#">MCSPI_HL_REV</a>	RW	0x00	0x4809 8000	0x4809 A000	0x480B 8000	0x480B A000

<b>Physical Address</b>	<a href="#">0x4809 8010</a> <a href="#">0x4809 A010</a> <a href="#">0x480B 8010</a> <a href="#">0x480B A010</a>	<b>Instance</b>	McSPI1 McSPI2 McSPI3 McSPI4
<b>Description</b>	Clock management configuration		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												IDLEMODE	FREEEMU	SOFTRESET	

Bits	Field Name	Description	Type	Reset
31:4	RESERVED		R	0x0000000
3:2	IDLEMODE	Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state.  0x0: Force-idle mode: local target's IDLE state follows (acknowledges) the system's IDLE requests unconditionally, that is, regardless of the module's internal requirements. Backup mode, for debug only.  0x1: No-idle mode: local target never enters IDLE state. Backup mode, for debug only.  0x2: Smart-idle mode: local target's IDLE state eventually follows (acknowledges) the system's IDLE requests, depending on the IP module's internal requirements. Module shall not generate (IRQ- or DMA-request-related) wake-up events.  0x3: Smart-idle wake-up-capable mode: local target's IDLE state eventually follows (acknowledges) the system's IDLE requests, depending on the module's internal requirements. Module may generate (IRQ- or DMA-request-related) wake-up events when in IDLE state. Mode is relevant only if the appropriate IP module "swake-up" output(s) is (are) implemented.	RW	0x2
1	FREEEMU	Sensitivity to emulation (debug) suspend input signal.  0x0: Module is sensitive to emulation suspend. 0x1: Module is not sensitive to emulation suspend.	RW	0

Bits	Field Name	Description	Type	Reset
0	SOFTRESET	Software reset. (Optional) Write 0x0: No action Read 0x0: Reset done, no pending action Read 0x1: Reset (software or other) ongoing Write 0x1: Initiate software reset	RW	0

<b>Address Offset</b>	0x110		
<b>Physical Address</b>	<a href="#">0x4809 8110</a> <a href="#">0x4809 A110</a> <a href="#">0x480B 8110</a> <a href="#">0x480B A110</a>	<b>Instance</b>	McSPI1 McSPI2 McSPI3 McSPI4
<b>Description</b>	This register allows controlling various parameters of the configuration interface and is not affected by software reset.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																CLOCKACTIVITY	RESERVED	SIDLEMODE	ENAWAKEUP	SOFTRESET	AUTOIDLE										

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Reads return 0	RW	0x000000
9:8	CLOCKACTIVITY	Clocks activity during wake-up mode period 0x0: Interface and functional clocks may be switched off. 0x1: Interface clock is maintained. Functional clock may be switched off. 0x2: Functional clock is maintained. Interface clock may be switched off. 0x3: Interface and functional clocks are maintained.	RW	0x0
7:5	RESERVED	Reads returns 0	RW	0x0
4:3	SIDLEMODE	Power management 0x0: If an IDLE request is detected, the McSPI acknowledges it unconditionally and goes in inactive mode. Interrupt, DMA requests and wake-up lines are unconditionally deasserted and the module wake-up capability is deactivated even if the [2] ENAWAKEUP bit is set. 0x1: If an IDLE request is detected, the request is ignored and the module does not switch to wake-up mode, and keeps on behaving normally. 0x2: If an IDLE request is detected, the module will switch to wake-up mode based on its internal activity, and the wake-up capability can be used if the bit [2] ENAWAKEUP is set. 0x3: Reserved - do not use.	RW	0x2
2	ENAWAKEUP	Wake-up feature control 0x0: Wake-up capability is disabled. 0x1: Wake-up capability is enabled.	RW	1
1	SOFTRESET	Software reset. During reads it always returns 0. 0x0: (write) Normal mode 0x1: (write) Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware.	RW	0
0	AUTOIDLE	Internal interface clock-gating strategy 0x0: Interface clock is free-running. 0x1: Automatic interface clock gating strategy is applied, based on the interface activity.	RW	1

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Reads returns 0.	RW	0x00000
11	SSB	Set status bit  0x0: No action. Writing 0 does not clear already set status bits. This bit must be cleared before trying to clear a status bit of the <a href="#">MCSPI_IRQSTATUS</a> register.  0x1: Force to 1 all status bits of <a href="#">MCSPI_IRQSTATUS</a> register. Writing 1 into this bit sets to 1 all status bits in the <a href="#">MCSPI_IRQSTATUS</a> register.	RW	0
10	SPIENDIR	Set the direction of the SPIEN[3:0] lines and SPICLK line.  0x0: Output (as in master mode)  0x1: Input (as in slave mode)	RW	0
9	SPIDATDIR1	Set the direction of the SPIDAT[1].  0x0: Output  0x1: Input	RW	0
8	SPIDATDIR0	Set the direction of the SPIDAT[0].  0x0: Output  0x1: Input	RW	0
7	WAKD	SWAKEUP output (signal data value of internal signal to system). The signal is driven high or low according to the value written into this bit.  0x0: The pin is driven low.  0x1: The pin is driven high.	RW	0
6	SPICLK	SPICLK line (signal data value) If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the CLKSPI line (high or low), and a write into this bit has no effect. If [10] SPIENDIR = 0 (output mode direction), the CLKSPI line is driven high or low according to the value written into this bit.	RW	0
5	SPIDAT_1	SPIDAT[1] line (signal data value) If [9] SPIDATDIR1 = 0 (output mode direction), the SPIDAT[1] line is driven high or low according to the value written into this bit. If [9] SPIDATDIR1 = 1 (input mode direction), this bit returns the value on the SPIDAT[1] line (high or low), and a write into this bit has no effect.	RW	0

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reads returns 0.	RW	0x000000
8	FDAA	<p>FIFO DMA address 256-bit aligned</p> <p>This bit is used when a FIFO is managed by the module and DMA connected to the controller provides only 256-bit aligned address. If this bit is set the enabled channel which uses the FIFO has its data managed through <a href="#">MCSPI_DAF TX</a> and <a href="#">MCSPI_DAF RX</a> registers instead of <a href="#">MCSPI_TXx</a> and <a href="#">MCSPI_RXx</a> registers.</p> <p>0x0: FIFO data managed by <a href="#">MCSPI_TXx</a> and <a href="#">MCSPI_RXx</a> registers.</p> <p>0x1: FIFO data managed by <a href="#">MCSPI_DAF TX</a> and <a href="#">MCSPI_DAF RX</a> registers.</p>	RW	0
7	MOA	<p>Multiple word interface access: this bit can only be used when a channel is enabled using a FIFO. It allows the system to perform multiple SPI word access for a single 32-bit interface word access. This is possible for WL &lt; 16.</p> <p>0x0: Multiple word access disabled</p> <p>0x1: Multiple word access enabled with FIFO</p>	RW	0
6:4	INITDLY	<p>Initial SPI delay for first transfer: this field is an option only available in SINGLE master mode. The controller waits for a delay to transmit the first SPI word after channel enabled and corresponding TX register filled. This delay is based on SPI output frequency clock. No clock output provided to the boundary and chip select is not active in 4-pin mode within this period.</p> <p>0x0: No delay for first spi transfer.</p> <p>0x1: The controller wait 4 SPI bus clock</p> <p>0x2: The controller wait 8 SPI bus clock</p> <p>0x3: The controller wait 16 SPI bus clock</p> <p>0x4: The controller wait 32 SPI bus clock</p>	RW	0x0
3	SYSTEM_TEST	<p>Enables the system test mode</p> <p>0x0: Functional mode</p> <p>0x1: System test mode (SYSTEST)</p>	RW	0
2	MS	<p>Master/slave</p> <p>0x0: Master - The module generates the SPICLK and SPIEN[3:0].</p> <p>0x1: Slave - The module receives the SPICLK and SPIEN[3:0].</p>	RW	1
1	PIN34	<p>Pin mode selection: This bit is used in master or slave mode to configure the SPI pin mode (3-pin or 4-pin). If asserted the controller only uses SIMO, SOMI, and SPICLK clock pin for SPI transfers.</p> <p>0x0: SPIEN is used as a chip-select.</p> <p>0x1: SPIEN is not used. In this mode all related options to chip-select have no meaning.</p>	RW	0
0	SINGLE	<p>Single channel/Multi Channel (master mode only)</p> <p>0x0: More than one channel will be used in master mode.</p> <p>0x1: Only one channel will be used in master mode. This bit must be set in Force SPIEN[x] mode.</p>	RW	0

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Read returns 0.	R	0x0
29	CLKG	Clock divider granularity this bit defines the granularity of channel clock divider: power of 2 or one clock cycle granularity. When this bit is set the register <a href="#">MCSPI_CHxCTRL[15:8]</a> EXTCLK must be configured to reach a maximum of 4096 clock divider ratio. Then the clock divider ratio is a concatenation of [5:2] CLKD and <a href="#">MCSPI_CHxCTRL[15:8]</a> EXTCLK values 0x0: Clock granularity of power of 2 0x1: One clock cycle granularity	RW	0
28	FFER	FIFO enabled for receive: Only one channel can have this bit field set. 0x0: The buffer is not used to receive data. 0x1: The buffer is used to receive data.	RW	0
27	FFEW	FIFO enabled for transmit: Only one channel can have this bit field set. 0x0: The buffer is not used to transmit data. 0x1: The buffer is used to transmit data.	RW	0
26:25	TCS0	Chip-select time control This 2-bit field defines the number of interface clock cycles between CS toggling and first or last edge of SPI clock. 0x0: 0.5 clock cycle 0x1: 1.5 clock cycles 0x2: 2.5 clock cycles 0x3: 3.5 clock cycles	RW	0x0

Bits	Field Name	Description	Type	Reset
24	SBPOL	Start-bit polarity 0x0: Start-bit polarity is held to 0 during SPI transfer. 0x1: Start-bit polarity is held to 1 during SPI transfer.	RW	0
23	SBE	Start-bit enable for SPI transfer 0x0: Default SPI transfer length as specified by WL bit field 0x1: Start bit D/CX added before SPI transfer. Polarity is defined by bit [24] SBPOL	RW	0
22:21	SPIENSLV	Channel 0 only and slave mode only: SPI slave select signal detection. Reserved bits for other cases. 0x0: Detection enabled only on SPIEN[0] 0x1: Detection enabled only on SPIEN[1] 0x2: Detection enabled only on SPIEN[2] 0x3: Detection enabled only on SPIEN[3]	RW	0x0
20	FORCE	Manual SPIEN assertion to keep SPIEN active between SPI words (single channel master mode only). 0x0: Writing 0 into this bit drives low the SPIEN line when [6] EPOL=0, and drives it high when [6] EPOL=1. 0x1: Writing 1 into this bit drives high the SPIEN line when [6] EPOL=0, and drives it low when [6] EPOL=1.	RW	0
19	TURBO	Turbo mode 0x0: Turbo is deactivated (recommended for single SPI word transfer). 0x1: Turbo is activated to maximize the throughput for multiple SPI words transfer.	RW	0
18	IS	Input Select 0x0: Data line 0 (SPIDAT[0]) selected for reception 0x1: Data line 1 (SPIDAT[1]) selected for reception	RW	1
17	DPE1	Transmission enable for data line 1 0x0: Data line 1 (SPIDAT[1]) selected for transmission 0x1: No transmission on Data Line1 (SPIDAT[1])	RW	1
16	DPE0	Transmission Enable for data line 0 0x0: Data Line0 (SPIDAT[0]) selected for transmission 0x1: No transmission on data line 0 (SPIDAT[0])	RW	0
15	DMAR	DMA read request The DMA read request line is asserted when the channel is enabled and a new data is available in the receive register of the channel. The DMA read request line is deasserted on read completion of the receive register of the channel. 0x0: DMA read request disabled 0x1: DMA read request enabled	RW	0
14	DMAW	DMA write request. The DMA write request line is asserted when The channel is enabled and the transmitter register of the channel is empty. The DMA write request line is deasserted on load completion of the transmitter register of the channel. 0x0: DMA write request disabled 0x1: DMA write request enabled	RW	0

Bits	Field Name	Description	Type	Reset

11:7	WL	SPI word length 0x0: Reserved 0x1: Reserved 0x2: Reserved 0x3: The SPI word is 4 bits long 0x4: The SPI word is 5 bits long 0x5: The SPI word is 6 bits long 0x6: The SPI word is 7 bits long 0x7: The SPI word is 8 bits long 0x8: The SPI word is 9 bits long 0x9: The SPI word is 10 bits long 0xA: The SPI word is 11 bits long 0xB: The SPI word is 12 bits long 0xC: The SPI word is 13 bits long 0xD: The SPI word is 14 bits long 0xE: The SPI word is 15 bits long 0xF: The SPI word is 16 bits long 0x10: The SPI word is 17 bits long 0x11: The SPI word is 18 bits long 0x12: The SPI word is 19 bits long 0x13: The SPI word is 20 bits long 0x14: The SPI word is 21 bits long 0x15: The SPI word is 22 bits long 0x16: The SPI word is 23 bits long 0x17: The SPI word is 24 bits long 0x18: The SPI word is 25 bits long 0x19: The SPI word is 26 bits long 0x1A: The SPI word is 27 bits long 0x1B: The SPI word is 28 bits long 0x1C: The SPI word is 29 bits long 0x1D: The SPI word is 30 bits long 0x1E: The SPI word is 31 bits long 0x1F: The SPI word is 32 bits long	RW	0x00
6	EPOL	SPIEN polarity 0x0: SPIEN is held high during the ACTIVE state. 0x1: SPIEN is held low during the ACTIVE state.	RW	0

Bits	Field Name	Description	Type	Reset
5:2	CLKD	<p>Frequency divider for SPICLK (only when the module is a Master SPI device). A programmable clock divider divides the SPI reference clock (FCLK) with a 4-bit value, and results in a new clock SPICLK available to shift-in and shift-out data. By default, the clock divider ratio has a power of 2 granularity when [29] CLKG is cleared. Otherwise, this field is the 4-LSB bit of a 12-bit register concatenated with clock divider extension <a href="#">MCSPI_CHxCTRL</a>[15:8] EXTCLK register. The value description below defines the clock ratio when [29] CLKG is set to 0.</p> <p>0x0: 1            0x1: 2            0x2: 4            0x3: 8            0x4: 16            0x5: 32            0x6: 64            0x7: 128            0x8: 256            0x9: 512            0xA: 1024            0xB: 2048            0xC: 4096            0xD: 8192            0xE: 16384            0xF: 32768</p>	RW	0x0
1	POL	<p>SPICLK polarity (see <a href="#">Section 24.4.2.3.1, Transfer Format</a>)</p> <p>0x0: SPICLK is held low during the INACTIVE state            0x1: SPICLK is held high during the INACTIVE state</p>	RW	0
0	PHA	<p>SPICLK phase (see <a href="#">Section 24.4.2.3.1, Transfer Format</a>)</p> <p>0x0: Data are latched on odd-numbered edges of SPICLK.            0x1: Data are latched on even-numbered edges of SPICLK.</p>	RW	0

## 24.5 Quad Serial Peripheral Interface

### 24.5.1 Quad Serial Peripheral Interface Overview

The quad serial peripheral interface (QSPI) module is a kind of SPI module that allows single, dual, or quad read access to external SPI devices. This module has a memory mapped register interface, which provides a direct interface for accessing data from external SPI devices and thus simplifying software requirements. The QSPI works as a master only.

The one QSPI in the device is primarily intended for fast booting from quad-SPI flash memories. [Figure 24-101](#) shows the QSPI module overview.

**Figure 24-101. QSPI Overview**

The QSPI supports the following features:

- General SPI features:
  - Programmable clock divider
  - Six pin interface
  - Programmable length (from 1 to 128 bits) of the words transferred
  - Programmable number (from 1 to 4096) of the words transferred
  - 4 external chip-select signals
  - Support for 3-, 4-, or 6-pin SPI interface
  - Optional interrupt generation on word or frame (number of words) completion
  - Programmable delay between chip select activation and output data from 0 to 3 QSPI clock cycles
  - Programmable signal polarities
  - Programmable active clock edge
  - Software-controllable interface allowing for any type of SPI transfer
  - Control through L3\_MAIN configuration port
- Serial flash interface (SFI) features:
  - Serial flash read/write interface
  - Additional registers for defining read and write commands to the external serial flash device
  - 1 to 4 address bytes
  - Fast read support, where fast read requires dummy bytes after address bytes; 0 to 3 dummy bytes can be configured.
  - Dual read support

- Quad read support
- Little-endian support (only for memory mapped registers used to configure QSPI controller and not SPI content accesses)
- Linear increment addressing mode only

The QSPI supports only dual and quad reads. Dual or quad writes are not supported. In addition, there is no "pass through" mode supported where the data present on the QSPI input is sent to its output.

---

**NOTE:** The QSPI module does not support cache line wrap mode.

---

## 24.5.2 QSPI Environment

Figure 24-102 shows a typical connection of the QSPI module to the external quad-SPI flash memory.

**Figure 24-102. QSPI Connected to an External Quad-SPI Flash Memory**

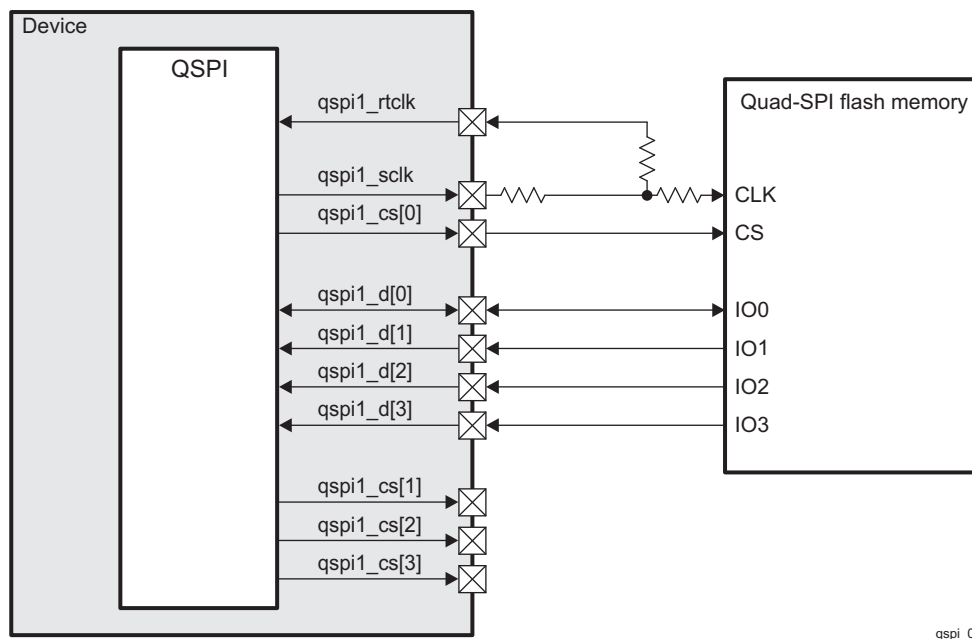

Table 24-369 lists and describes the QSPI I/O signals.

qspi\_002

**Table 24-369. QSPI I/O Signals**

QSPI Signal/Pad name	I/O <sup>(1)</sup>	Description					
		3-pin <sup>(2)</sup> SPI Read (Single Read)	3-pin <sup>(2)</sup> SPI Write (Single Write)	4-pin <sup>(2)</sup> SPI Read (Single Read)	4-pin <sup>(2)</sup> SPI Write (Single Write)	4-pin <sup>(2)</sup> SPI Read (Dual Read)	6-pin <sup>(2)</sup> SPI Read (Quad Read)

qspi1_d[2]	I	Not used	Not used	Not used	Not used	Not used	Used as SPI data input 2
qspi1_d[3]	I	Not used	Not used	Not used	Not used	Not used	Used as SPI data input 3
qspi1_sclk	O	Clock for the external SPI device					
qspi1_cs[0]	O	External SPI device chip-select 0					
qspi1_cs[1]	O	External SPI device chip-select 1					
qspi1_cs[2]	O	External SPI device chip-select 2					
qspi1_cs[3]	O	External SPI device chip-select 3					
qspi1_rtclk	I	The qspi1_sclk output must be connected to the qspi1_rtclk input, and is used for controlling the timing of the read return data when the QSPI module operates in Mode 0. In case Mode 3 is used, there is no need to connect the qspi1_sclk to the qspi1_rtclk.					

<sup>(1)</sup> I = Input; O = Output

<sup>(2)</sup> This is the pin count at the SPI flash memory side. The pin count at the device side is increased by one because of the qspi1\_rtclk signal. References to the pin count throughout this chapter consider the pin count at the SPI flash memory side.

---

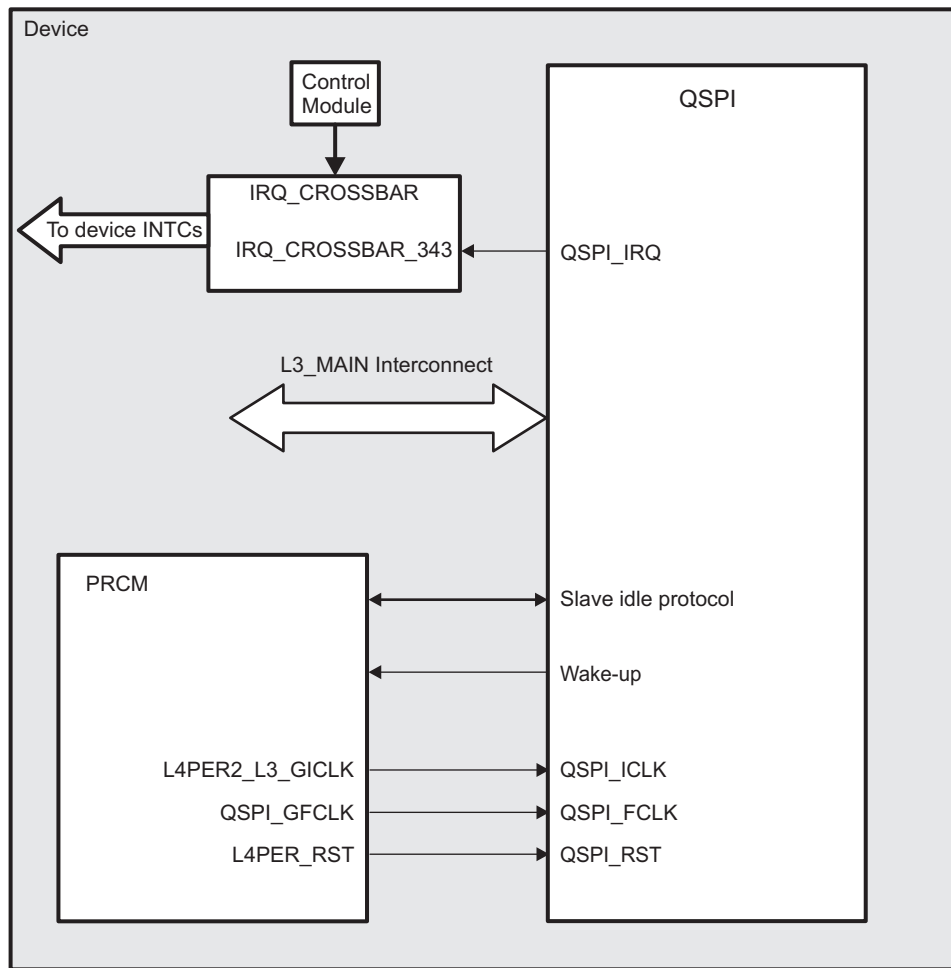

**NOTE:** In order to ensure proper timing, precise layout and routing requirements must be followed. For layout and routing requirements for all QSPI signals, see section “PCB Guidelines” of the device Data Manual.

---

### 24.5.3 QSPI Integration

Figure 24-103 shows the integration of the QSPI module in the device.

Figure 24-103. QSPI Integration

qspi\_003

Table 24-370 through Table 24-372 summarize the integration of the QSPI in the device.

Table 24-370. QSPI Integration Attributes

Module Instance	Attributes

**Table 24-372. QSPI Hardware Requests**

Module Instance	Source Signal Name	Interrupt Requests		Description
		Destination	Default Mapping	
		IRQ_CROSSBAR Input		
QSPI	QSPI_IRQ	IRQ_CROSSBAR_343	–	QSPI interrupt request

**NOTE:** The Default Mapping column in [Table 24-372](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device interrupt controller (INTC) through the IRQ\_CROSSBAR module. For more information about the IRQ\_CROSSBAR module, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#). For more information about the device INTCs, see [Chapter 17, Interrupt Controllers](#).

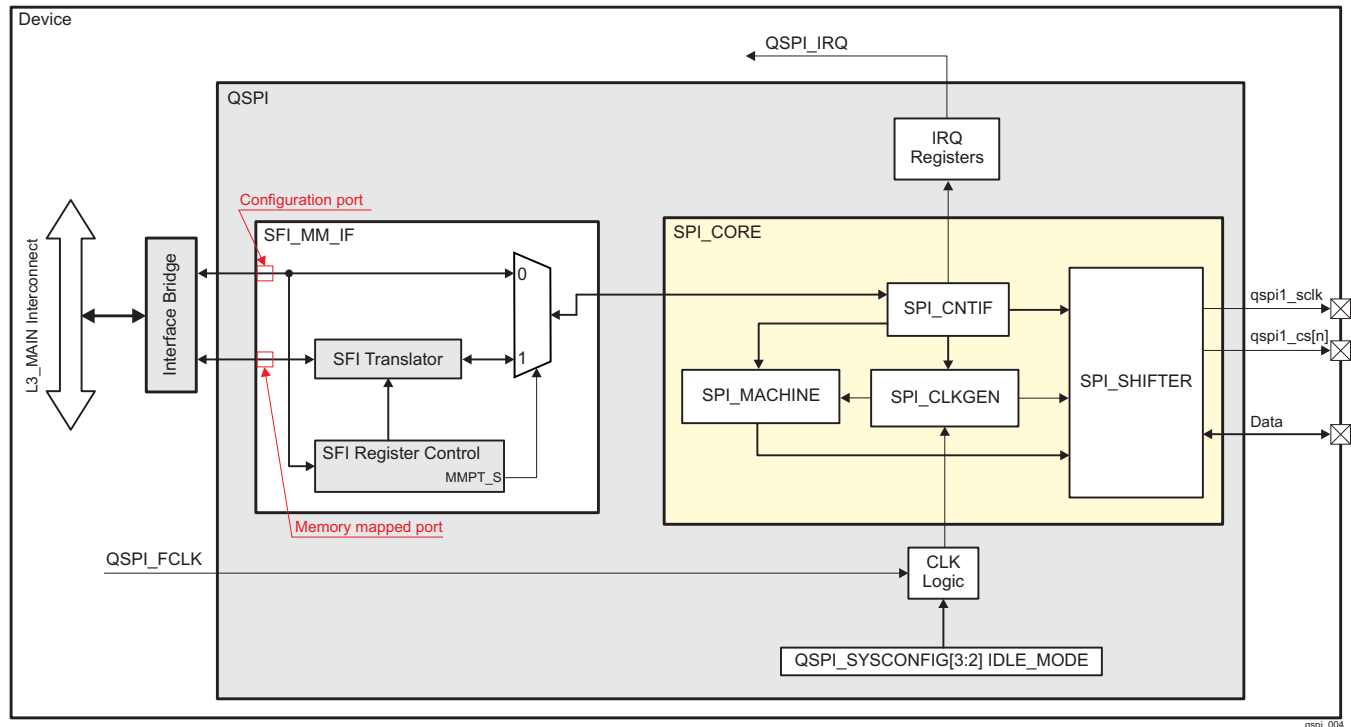

**NOTE:** For the description of the interrupt source, see [Section 24.5.4.3, QSPI Interrupt Requests](#).

## 24.5.4 QSPI Functional Description

### 24.5.4.1 QSPI Block Diagram

Initial device boot from external SPI flash memory can be accomplished through the QSPI module. The interface is a simple 4-wire SPI used for control or data transfers. The QSPI also supports a 3-wire SPI protocol where the qspi1\_d[0] signal is used as a bidirectional for reads and writes. In addition, a 6-wire mode can be used to support quad read devices. [Figure 24-104](#) shows the QSPI block diagram.

**Figure 24-104. QSPI Block Diagram**

The QSPI is composed of two blocks. The first one is the SFI memory-mapped interface (SFI\_MM\_IF) and the second one is the SPI core (SPI\_CORE). The SFI\_MM\_IF block is associated only with SPI flash memories and is used for specifying typical for the SPI flash memories settings (read or write command, number of address and dummy bytes, and so on) unlike the SPI\_CORE block, which is associated with the SPI interface itself and is used to configure typical SPI settings (chip-select polarity, serial clock inactive state, SPI clock mode, length of the words transferred, and so on).

The SFI\_MM\_IF comprises the following two subblocks:

- SFI register control
- SFI translator

The SPI\_CORE comprises the following four subblocks:

- SPI control interface (SPI\_CNTIF)
- SPI clock generator (SPI\_CLKGEN)
- SPI control state machine (SPI\_MACHINE)
- SPI data shifter (SPI\_SHIFTER)

In addition, an interface bridge connects the two ports (configuration port and memory-mapped port) of the SFI\_MM\_IF block to the L3\_MAIN interconnect. There are no software controls associated with this interface bridge.

The QSPI supports long transfers through a frame-style sequence. In its generic SPI use mode, a word can be defined up to 128 bits and multiple words can be transferred during a single access. For each word, a device initiator must read or write the new data and then tell the QSPI to continue the current operation. Using this sequence, a maximum of 4096 128-bit words can be transferred in a single SPI read or write operation. This allows great flexibility when connecting the QSPI to various types of devices.

As opposed to the generic SPI use mode, the communication with serial flash-type devices requires sending a byte command, followed by sending bytes of data. Commands can be sent through the SPI\_CORE block to communicate with a serial flash device; however, it is easier to do this using the SFI\_MM\_IF block because it is intended to ease the communication with serial flash devices. If the SPI\_CORE is used to communicate with a serial flash device, software must load the command into the SPI data transfer register with additional configuration fields, perform the byte transfer, then place the data to be sent (or configure for receive) along with additional configuration fields, and perform that transfer. Reads and writes to serial flash devices are more specific. First, the read or write command byte is sent, followed by 1 to 4 bytes of address (corresponding to the address to read/write), then followed by the data write/receive phase. Data is always sent byte oriented. When the address is loaded, data can be continuously read or written, and the address will automatically increment to each byte address internally to the serial flash device.

---

**NOTE:** The SFI\_MM\_IF block only allows reading and writing to an externally connected SPI flash device. The SFI\_MM\_IF block does not allow reads or writes to internal configuration and status registers of the SPI flash device. These registers must be accessed through the features of the SPI\_CORE block.

---

#### 24.5.4.1.1 SFI Register Control

The SFI register control block consists of the following five configuration registers:

- [QSPI\\_SPI\\_SETUP0\\_REG](#)
- [QSPI\\_SPI\\_SETUP1\\_REG](#)
- [QSPI\\_SPI\\_SETUP2\\_REG](#)
- [QSPI\\_SPI\\_SETUP3\\_REG](#)
- [QSPI\\_SPI\\_SWITCH\\_REG](#)

The first four registers let the user define the following:

- Byte command for a serial flash read specified by the QSPI\_SPI\_SETUP<sub>i</sub>\_REG[7:0] RCMD bit field
- Byte command for a serial flash write specified by the QSPI\_SPI\_SETUP<sub>i</sub>\_REG[23:16] WCMD bit field
- Number of address bytes required for the particular type of serial flash specified by the

QSPI\_SPI\_SETUP<sub>i</sub>\_REG[9:8] NUM\_A\_BYTES bit field

- Number of “dummy bytes” that may be needed to support the fast read mode function of some serial flash devices. The QSPI\_SPI\_SETUP<sub>i</sub>\_REG[11:10] NUM\_D\_BYTES bit field specifies the number of “dummy bits.” In addition, the QSPI\_SPI\_SETUP<sub>i</sub>\_REG[28:24] NUM\_D\_BITS bit field can also specify the number of “dummy bits.”
- Whether the read command is single (normal), dual, or quad read mode command. This is specified by the QSPI\_SPI\_SETUP<sub>i</sub>\_REG[13:12] READ\_TYPE bit field. (*i* is equal to 0, 1, 2 and 3 and means that the QSPI\_SPI\_SETUP<sub>i</sub>\_REG registers are associated with each of the four supported chip-selects [that is, four supported output SPI flash devices])

The QSPI\_SPI\_SWITCH\_REG register acts as a static switch which allows the configuration port (shown in [Figure 24-104](#)) to connect directly to the SPI\_CORE block, or allows the memory-mapped port (also shown in [Figure 24-104](#)) to connect to the SPI\_CORE block. This is done using the QSPI\_SPI\_SWITCH\_REG[0] MMPT\_S bit.

In addition, the QSPI\_SPI\_SWITCH\_REG[1] MM\_INT\_EN bit is used to enable or disable the word complete interrupt during operations using the memory-mapped port.

#### 24.5.4.1.2 SFI Translator

The SFI translator block represents an FSM which, based on the configuration information loaded into the SFI register control block, converts each input read/write sequence into an SPI\_CORE configuration sequence for access to the external serial flash memory.

A read sequence is converted into the following actions:

1. SPI chip-select goes active.
2. Read command byte is issued.
3. 1 to 4 address bytes, which correspond to the first address supplied, are issued.
4. 0 to 3 dummy bytes are issued, if “fast read” is supported.
5. Data bytes are read from the external SPI flash memory.
6. SPI chip-select goes inactive.

For linear addressing mode, action 5 is repeated until the byte count to be transferred reaches zero.

A write sequence is identical to a read sequence, except that a write sequence does not use dummy bytes.

Another important aspect with regard to writes is that a serial flash memory location can only be written to if the bits are erased in advance. Erased means the bits are set to 1. This means that writing only changes 1 contents to 0. It is not possible with this write to change the contents of a bit from 0 to 1. An erase command must be performed to do this operation. Erase commands cannot be executed on single byte locations. Depending on device types, there are page, block, and chip erase commands. To perform an erase command, the particular command must be sent over the SPI bus, and an internal register of the serial flash device must then be polled to determine when the erase completes. The erases must be done through the configuration port by software before performing any writes through the memory-mapped port. This means that writes are passed through to the serial flash device, but if the memory locations being modified are not properly erased before the write, the contents may not result in what was sent.

#### 24.5.4.1.3 SPI Control Interface

The SPI control interface contains configuration registers used to configure the SPI core functionality of the QSPI. This block maintains all configuration settings for the SPI core (that is, settings specific for the SPI interface itself but not for the SPI flash memories).

The registers defined for this block are:

- The QSPI\_PID register, which is read only and contains QSPI revision associated information
- The QSPI\_SPI\_CLOCK\_CNTRL\_REG register, which is used to control external SPI clock (qspi1\_sclk)
- The QSPI\_SPI\_DC\_REG register used to define the SPI clock mode and chip-select polarity for the four external SPI devices
- The QSPI\_SPI\_CMD\_REG register used to control the operation of the SPI command. This register is

also used to configure and transfer data.

- Four data registers used for reading the data received and for writing the data to be transferred. These registers are:
  - [QSPI\\_SPI\\_DATA\\_REG](#)
  - [QSPI\\_SPI\\_DATA\\_REG\\_1](#)
  - [QSPI\\_SPI\\_DATA\\_REG\\_2](#)
  - [QSPI\\_SPI\\_DATA\\_REG\\_3](#)
 These four registers compose a 128-bit shift register.
- The [QSPI\\_SPI\\_STATUS\\_REG](#) register, which contains status information

All of these registers can only be written if the QSPI is not busy. This means that they can be written if the [QSPI\\_SPI\\_STATUS\\_REG\[0\]](#) BUSY bit is 0x0. The QSPI becomes busy when a write to the [QSPI\\_SPI\\_CMD\\_REG\[18:16\]](#) CMD bit field is performed. Writing to this bit field starts an SPI transaction and sets the [QSPI\\_SPI\\_STATUS\\_REG\[0\]](#) BUSY bit to 0x1. The CMD bit field can be written again when the BUSY bit is 0x0. In addition, the start of the SPI transaction is synchronized to the qspi1\_sclk clock and clearing of the BUSY bit is synchronized to the QSPI\_FCLK clock.

The register group [QSPI\\_SPI\\_DATA\\_REG\\_3](#), [QSPI\\_SPI\\_DATA\\_REG\\_2](#), [QSPI\\_SPI\\_DATA\\_REG\\_1](#) and [QSPI\\_SPI\\_DATA\\_REG](#) is treated as a single 128-bit word for shifting data in and out. The [QSPI\\_SPI\\_DATA\\_REG\\_3](#) register is used for the most significant bits and the [QSPI\\_SPI\\_DATA\\_REG](#) is used for the least significant bits. This applies for both reads and writes. For example, after reading a 128-bit word (WLEN = 0x7F) the most significant bit of the data read, that is bit 127, will be located at [QSPI\\_SPI\\_DATA\\_REG\\_3\[31\]](#) position and the least significant bit, that is bit 0 of the data read, will be located at the [QSPI\\_SPI\\_DATA\\_REG\[0\]](#) position.

The data written to this register group should be right justified so that a data pre-shifting is not required. The [QSPI\\_SPI\\_CMD\\_REG\[25:19\]](#) WLEN bit field determines the location of the most significant bit and the bit position that will be shifted out first during a write. In order to shift out byte data the WLEN bit field should be set to 0x7 and the data byte should be written to the lower byte of the [QSPI\\_SPI\\_DATA\\_REG](#) register. By setting the word length to 0x7 the [QSPI\\_SPI\\_DATA\\_REG](#) register will look like a pseudo 8-bit shift register. When the user wants to write 40-bit long word the WLEN bit field should be set to 0x27, the 32 least significant bits of data should be written to the [QSPI\\_SPI\\_DATA\\_REG](#) and the rest 8 most significant bits of data should be written to the lower byte of the [QSPI\\_SPI\\_DATA\\_REG\\_1](#) register. By setting WLEN to 0x27 these two registers will look like a pseudo 40-bit shift register. When the word length is greater than 64 bits the [QSPI\\_SPI\\_DATA\\_REG\\_2](#) register is also used and the previously described logic applies. The [QSPI\\_SPI\\_DATA\\_REG\\_3](#) register is used together with the other three data registers when the word length is greater than 96 bits.

When dual or quad read mode is used the number of the words transferred must be even. This number is configured through the [QSPI\\_SPI\\_CMD\\_REG\[11:0\]](#) FLEN bit field.

---

**NOTE:** The QSPI module does not support a "pass through" mode where the data present on qspi1\_d[1] is sent to qspi1\_d[0], when 4-pin non-dual read mode is used. This means that setting the [QSPI\\_SPI\\_CMD\\_REG\[18:16\]](#) CMD bit field to 0x1 causes the QSPI only to read from an external device using the qspi1\_d[1] pad as an input and if a write to the same external device is desired, the CMD bit field should be set to 0x2, which causes the qspi1\_d[0] pad to be used as an output.

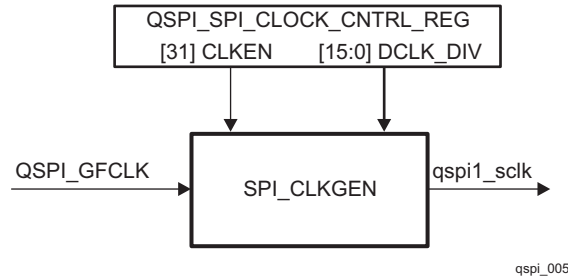

---

#### 24.5.4.1.4 SPI Clock Generator

The SPI clock generator uses the QSPI\_FCLK clock as an input, and generates the qspi1\_sclk, which is a divided version of the QSPI\_FCLK clock. The divide ratio is a 16-bit value configured through the [QSPI\\_SPI\\_CLOCK\\_CNTRL\\_REG\[15:0\]](#) DCLK\_DIV bit field and thus provides a division factor in a range from 1 to 65536. The QSPI\_FCLK clock is divided by the DCLK\_DIV value + 1 to provide the qspi1\_sclk clock. When DCLK\_DIV = 0x0 the QSPI\_FCLK clock equals the DCLK clock. The value in the DCLK\_DIV bit field applies only when the [QSPI\\_SPI\\_CLOCK\\_CNTRL\\_REG\[31\]](#) CLKEN bit is set to 0x1. [Figure 24-105](#) shows the SPI\_CLKGEN block.

If the CLKEN bit is 0x0 the command specified in the [QSPI\\_SPI\\_CMD\\_REG\[18:16\]](#) CMD bit field is not executed and the [QSPI\\_SPI\\_STATUS\\_REG\[0\]](#) BUSY bit is not set. The command is executed only if the CLKEN bit is 0x1 before write to the CMD bit field.

**Figure 24-105. SPI\_CLKGEN Block**

#### 24.5.4.1.5 SPI Control State-Machine

The SPI control state-machine (SPI\_MACHINE) manages the operation of the SPI\_CORE block. SPI\_MACHINE takes control and configuration information from the registers in the SPI\_CNTIF block as input and provides control information to the SPI data shifter. This information is used to control the SPI data port. The SPI\_MACHINE also generates status information, which is sent back to the SPI\_CNTIF block.

Writing a valid value to the [QSPI\\_SPI\\_CMD\\_REG\[18:16\]](#) CMD bit field sets immediately the [QSPI\\_SPI\\_STATUS\\_REG\[0\]](#) BUSY bit to 0x1, activates the corresponding [qspi1\\_cs\[n\]](#) (n = 0 to 3) and starts the SPI data transaction. The BUSY bit is cleared automatically when [QSPI\\_SPI\\_CMD\\_REG\[25:19\]](#) WLEN number of bits are shifted in or out. If the value of the [QSPI\\_SPI\\_STATUS\\_REG\[27:16\]](#) WDCNT bit field is different than 0x0 and WLEN number of bits are shifted already, the SPI\_MACHINE waits until another write to the CMD bit field is performed. If the command written to the CMD bit field is valid, then this increments the value of the WDCNT bit field from 0x0 and starts shifting data in or out again. This is repeated until the WDCNT bit field reaches the frame length ([QSPI\\_SPI\\_CMD\\_REG\[11:0\]](#) FLEN), that is, all words of the frame are shifted or till earlier frame termination occurs. While the SPI\_MACHINE is waiting for write to the CMD bit field the corresponding [qspi1\\_cs\[n\]](#) (n = 0 to 3) remains active and the BUSY flag is set to 0x0. In addition, the bit length for each word can be changed during a frame from 1 to 128 bits using the [QSPI\\_SPI\\_CMD\\_REG\[25:19\]](#) WLEN bit field.

The SPI\_MACHINE also provides a mechanism to terminate the frame earlier. This is done by writing an invalid command to the CMD bit field. An invalid command corresponds to the 0x0 and 0x4 (reserved) values of the CMD bit field. Writing one of these values when the the WDCNT bit field is not equal to 0x0 and when the BUSY flag is 0x0 terminates the frame earlier.

The corresponding [qspi1\\_cs\[n\]](#) (n = 0 to 3) becomes inactive when all words are shifted or when the frame terminates earlier.

#### 24.5.4.1.6 SPI Data Shifter

The SPI data shifter handles the capture and generation of the SPI interface signals. Based on control signals from the SPI\_MACHINE and SPI\_CNTIF blocks, data is shifted in or out on falling or rising edge of [qspi1\\_sclk](#) clock depending on the SPI clock mode selected. [Table 24-373](#) lists the four defined clock modes of operation for the QSPI.

**Table 24-373. SPI Clock Modes Definition**

Mode	Settings in the <a href="#">QSPI_SPI_DC_REG</a> Register		Description
	Value of the CKP bits	Value of the CKPH bits	
0	0	0	Data input captured on falling edge of <a href="#">qspi1_sclk</a> clock. Data output generated on falling edge of <a href="#">qspi1_sclk</a> clock
1	0	1	Data input captured on rising edge of <a href="#">qspi1_sclk</a> clock. Data output generated on rising edge of <a href="#">qspi1_sclk</a> clock

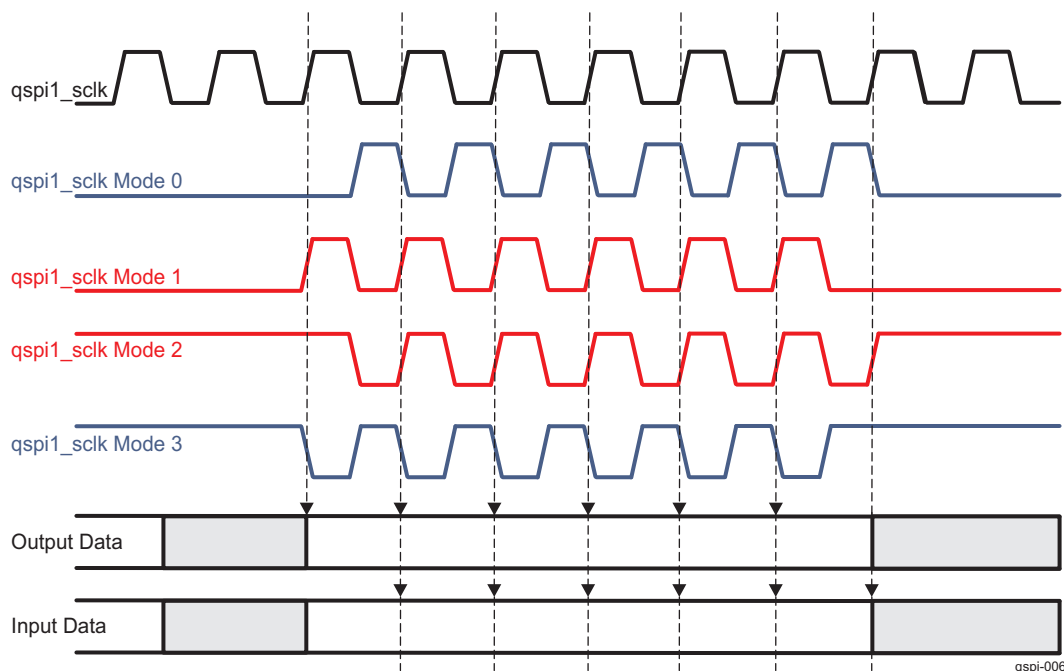

**Table 24-373. SPI Clock Modes Definition (continued)**

Mode	Settings in the <a href="#">QSPI_SPI_DC_REG</a> Register		Description
	Value of the CKP bits	Value of the CKPH bits	
2	1	0	Data input captured on rising edge of qspi1_sclk clock. Data output generated on rising edge of qspi1_sclk clock
3	1	1	Data input captured on falling edge of qspi1_sclk clock. Data output generated on falling edge of qspi1_sclk clock

**NOTE:** Mode 1 and Mode 2 are not supported and should not be used.

The CKPi and CKPHi (i = 0 to 3) bits of the [QSPI\\_SPI\\_DC\\_REG](#) register control the clock modes. Each of these 4 bits corresponds to an output chip select.

[Figure 24-106](#) shows all four clock modes. In addition, through the DDi (i = 0 to 3) bits of the [QSPI\\_SPI\\_DC\\_REG](#) register the data can be delayed from one to three qspi1\_sclk clock cycles after the corresponding qspi1\_cs[n] (n = 0 to 3) goes active. The active state of each chip-select can also be controlled through the CSPi (i = 0 to 3) bits of the [QSPI\\_SPI\\_DC\\_REG](#) register.

**Figure 24-106. SPI Clock Modes**

#### 24.5.4.2 QSPI Clock Configuration

The QSPI complies with the PRCM slave-idle protocol. The QSPI\_FCLK clock is gated based on the values loaded in the [QSPI\\_SYSCONFIG\[3:2\]](#) IDLE\_MODE bit field. Three modes are supported:

- Force-idle: The QSPI\_FCLK clock is gated unconditionally by the QSPI.
- No-idle: The QSPI\_FCLK clock is never gated by the QSPI.
- Smart-idle: The QSPI\_FCLK clock is gated by the QSPI, depending on its internal requirements.

#### 24.5.4.3 QSPI Interrupt Requests

The QSPI generates one interrupt request which is connected to the IRQ\_CROSSBAR module. This interrupt request, QSPI\_IRQ, is connected to the IRQ\_CROSSBAR\_343 input. The QSPI\_IRQ interrupt line can be activated by one of the interrupt events listed in [Table 24-374](#).

Figure 24-107 shows a logical representation of the QSPI interrupt generation scheme.

**Figure 24-107. Logical Representation of the QSPI Interrupt Generation Scheme**

**QSPI\_SPI\_STATUS\_REG[1] WC** and **QSPI\_SPI\_STATUS\_REG[2] FC** are status bits indicating whether word or frame transfer is complete. Setting the corresponding interrupt enable bit (**WIRQ** or **FIRQ**) in the **QSPI\_SPI\_CMD\_REG** register allows these events (**WC** and **FC**) to generate an interrupt. The **WC** and **FC** bits are reset every time the user writes to the **QSPI\_SPI\_CMD\_REG** register or reads the **QSPI\_SPI\_STATUS\_REG** register. This is done to keep control parameters from changing the interface protocol signals while a transfer is in progress. Additionally, the **QSPI\_SPI\_SWITCH\_REG[1] MM\_INT\_EN** bit is used to enable or disable the word complete interrupt during operations using the memory-mapped port.

When the **QSPI\_SPI\_CMD\_REG[14] WIRQ** and **QSPI\_SPI\_CMD\_REG[15] FIRQ** bits are set to 0x1 the following applies:

- The QSPI activates its interrupt line only if the interrupts are enabled by setting to 0x1 the corresponding bits in the **QSPI\_INTR\_ENABLE\_SET\_REG** register. These interrupts can be disabled by setting the corresponding bits in the **QSPI\_INTR\_ENABLE\_CLEAR\_REG** register to 0x1.
- After an interrupt has been serviced, software must clear the corresponding status flag. This is done by setting the corresponding bit in the **QSPI\_INTR\_STATUS\_ENABLED\_CLEAR** register to 0x1, which also clears the corresponding bit in the **QSPI\_INTR\_STATUS\_RAW\_SET** register. The status flags in the **QSPI\_INTR\_STATUS\_RAW\_SET** register are set even if the corresponding interrupt is disabled unlike those in the **QSPI\_INTR\_STATUS\_ENABLED\_CLEAR** register, which are set only if the corresponding interrupt is enabled.
- The QSPI also generates an interrupt if a certain bit in the **QSPI\_INTR\_STATUS\_RAW\_SET** register is set to 0x1 and the corresponding interrupt is enabled through the **QSPI\_INTR\_ENABLE\_SET\_REG** register. This feature is useful during user software debugging. In addition, even if interrupts are not enabled a corresponding raw flag in the **QSPI\_INTR\_STATUS\_RAW\_SET** register is set to 0x1 when an IRQ condition occurs.
- Even if interrupts are not enabled, a certain status bit in the **QSPI\_INTR\_STATUS\_RAW\_SET** register can also be cleared by setting to 0x1 the corresponding bit in the

[QSPI\\_INTR\\_STATUS\\_ENABLED\\_CLEAR](#) register.

It must be considered that the previously described scenario applies if the [QSPI\\_SPI\\_CMD\\_REG\[14\]](#) WIRQ and [QSPI\\_SPI\\_CMD\\_REG\[15\]](#) FIRQ bits are set to 0x1.

**NOTE:** The QSPI\_IRQ interrupt line is activated only if at least one of the following conditions is met:

- The word complete interrupt is enabled:
  - during operations using the memory-mapped port by setting to 0x1 both the [QSPI\\_SPI\\_SWITCH\\_REG\[1\]](#) MM\_INT\_EN and [QSPI\\_INTR\\_ENABLE\\_SET\\_REG\[1\]](#) WIRQ\_ENA\_SET bits.
  - during operations using the configuration port by setting to 0x1 both the [QSPI\\_SPI\\_CMD\\_REG\[14\]](#) WIRQ and [QSPI\\_INTR\\_ENABLE\\_SET\\_REG\[1\]](#) WIRQ\_ENA\_SET bits.
- The frame complete interrupt is enabled setting to 0x1 both the [QSPI\\_SPI\\_CMD\\_REG\[15\]](#) FIRQ and [QSPI\\_INTR\\_ENABLE\\_SET\\_REG\[0\]](#) FIRQ\_ENA\_SET bits.

The QSPI\_IRQ interrupt line is also activated when both the conditions are met.

[Table 24-374](#) lists the event flags and the corresponding mask bits of the sources which can cause interrupts.

**Table 24-374. QSPI Events**

Event Flag	Event Mask	Description
<a href="#">QSPI_INTR_STATUS_RAW_SET[1]</a> WIRQ_RAW	<a href="#">QSPI_INTR_ENABLE_SET_REG[1]</a> WIRQ_ENA_SET	Word complete interrupt event. Asserted each time after a word is transferred or received.
<a href="#">QSPI_INTR_STATUS_ENABLED_CLEAR[1]</a> WIRQ_ENA	<a href="#">QSPI_INTR_ENABLE_CLEAR_REG[1]</a> WIRQ_ENA_CLR

<a href="#">QSPI_INTR_STATUS_ENABLED_CLEAR[0]</a> FIRQ_ENA	<a href="#">QSPI_INTR_ENABLE_CLEAR_REG[0]</a> FIRQ_ENA_CLR	
<a href="#">QSPI_SPI_STATUS_REG[2]</a> FC	<a href="#">QSPI_SPI_CMD_REG[15]</a> FIRQ	

#### 24.5.4.4 QSPI Memory Regions

Two memory regions are associated with the QSPI. The first memory region is dedicated to the configuration port. Using this memory region, all internal registers can be programmed and serial transfers made from the four supported external SPI devices. The L3\_MAIN start address at which the configuration port is available is 0x4B30 0000. The second memory region is associated mainly with the memory-mapped port and is used for communication directly with one of the four supported external SPI devices. This memory region starts at 0x5C00 0000 and ends at 0x5FFF FFFF L3\_MAIN address.

The CTRL\_CORE\_CONTROL\_IO\_2[10:8] QSPI\_MEMMAPPED\_CS bit field provides a functionality for remapping the previously described address space which starts at 0x5C00 0000 L3\_MAIN address to one of the four supported chip selects or to the configuration registers. The CTRL\_CORE\_CONTROL\_IO\_2 register resides in the CTRL\_MODULE\_CORE.

It is important to keep in mind that the configuration port provides an access to all the QSPI registers listed in [Table 24-376](#). These are configuration registers and also four data registers. The configuration registers are used to configure typical SPI and serial flash memory settings and the four data registers are used for read and write operations. When communicating with an external SPI device (but not an SPI flash memory) the SPI\_CORE module should be used and the data exchanged is available through these four data registers, which can be accessed only through the configuration port. When a communication with an external SPI flash memory is desired, the memory-mapped port should be used.

In other words, to read from an external SPI flash memory, first configure the QSPI through the configuration port and then perform a read through the memory-mapped port.

## 24.5.5 QSPI Register Manual

## 24.6 Multichannel Audio Serial Port

This section describes the multichannel audio serial port (McASP).

### 24.6.1 McASP Overview

This section introduces the multichannel audio serial port (McASP) module and describes its main functions and connections in the device.

The McASP functions as a general-purpose audio serial port optimized to the requirements of various audio applications. The McASP module can operate in both transmit and receive modes. The McASP is useful for time-division multiplexed (TDM) stream, Inter-IC Sound (I2S) protocols reception and transmission as well as for an intercomponent digital audio interface transmission (DIT). The McASP has the flexibility to gluelessly connect to a Sony/Philips digital interface (S/PDIF) transmit physical layer component.

Although intercomponent digital audio interface reception (DIR) mode (i.e. S/PDIF stream receiving) is not natively supported by the McASP module, a specific TDM mode implementation for the McASP receivers allows an easy connection to external DIR components (for example, S/PDIF to I2S format converters).

The device have integrated eight McASP modules with:

- McASP1 and McASP2 supporting up to 16 channels with independent TX/RX clock/sync domain
- McASP3 through McASP8 modules supporting up to 4 channels with independent TX/RX clock/sync domain

[Figure 24-108](#) shows the McASP modules in the device.

Figure 24-108. McASP Modules Overview

mcasp-001

McASP module includes the following main features:

- Two modules (McASP1 and McASP2) supporting up to 16 channels each and independent TX/RX clock/sync domains.
- Six modules (McASP3, McASP4, McASP5, McASP6, McASP7, and McASP8) supporting up to 4 channels each and unified clock/sync domain.
- Independent serializer for each AXRx channel of each McASP<sub>x</sub> module.
- Idle request/acknowledge protocol
- A single 32-bit buffer per serializer for transmit and receive operations
- 2 x interconnect slave interface ports:
  - A configuration (CFG) port supplied with an internal L4-interconnect interface clock
  - A slave DMA data port synchronized with functional clock
- Two independent clock generator modules for transmit and receive.
  - Clocking flexibility allows the McASP to receive and transmit at different rates. For example, the McASP can receive data at 48 kHz but output up-sampled data at 96 kHz or 192 kHz.
- McASP module functional clock can be generated:
  - internally (master mode)
  - supplied over McASP serial interface (slave mode)
  - has a controllable functional clock divide ratio
- Independent transmit and receive modules, each includes:
  - Programmable clock and frame sync generator.
  - TDM streams from 2 to 32, and 384 time slots.
  - Support for time slot sizes of 8, 12, 16, 20, 24, 28, and 32 bits.
  - Data formatter for bit manipulation.
- Glueless connection to audio analog-to-digital converters (ADC), digital-to-analog converters (DAC), codec, digital audio interface receiver (DIR), and S/PDIF transmit physical layer components.
- Wide variety of I2S and similar bit-stream format.
- Integrated digital audio interface transmitter (DIT):
  - S/PDIF, IEC60958-1, AES-3 formats.
  - Enhanced channel status/user data RAM.
- 384-slot TDM with external digital audio interface receiver (DIR) device.
  - For DIR reception, an external DIR receiver integrated circuit should be used with I2S output format and connected to the McASP receive section.
- Support for 2x DMA requests (one per direction):
  - 1 level-sensitive transmit direct memory access (DMA) request common for all of the McASP serializers
  - 1 level-sensitive receive direct memory access (DMA) request common for all of the McASP serializers
  - All transmit DMA requests are mapped to the device DMA crossbar
- One transmit interrupt request common for all serializers
- One receive interrupt request common for all serializers
- Each of the Rx and Tx interrupts is propagated to different host processors via the device Interrupt Crossbar

---

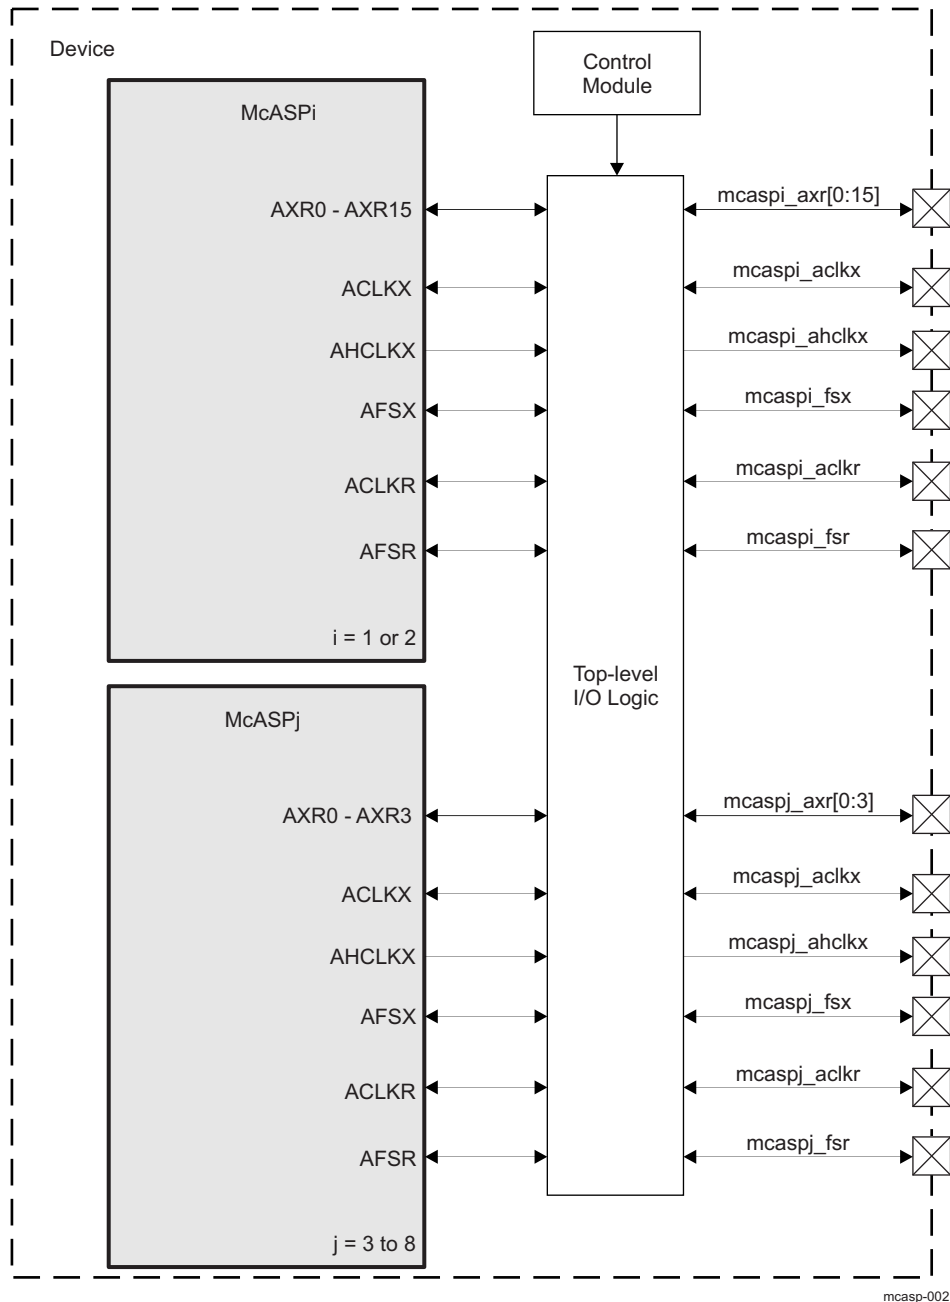

**NOTE:** Because a serializer receive and transmit channels data is shared on the same McASP data pin, user can choose to have either Tx or Rx function from a serializer, not both at the same time.

---

### 24.6.2 McASP Environment

This section describes the McASP application fields from an environment point of view (external connections), along with the McASP connectivity options. This section also lists all of the possible interfaces and describes the protocol and data format used in each case. Figure 24-109 shows the McASP modules in their environment in the device.

Figure 24-109. McASP Environment

#### 24.6.2.1 McASP Signals

Table 24-417 describes the McASP pins, their corresponding signal names at device level and specifies their links to functions.

**Table 24-417. McASP I/O Signals**

Module Pin Name	Device Level Signal Name	I/O <sup>(1)</sup>	Description	Module Pin Reset Value
<b>McASP1 module</b>				
AXR0	mcasp1_axr[0]	I/O	Audio transmit/receive data - channel 0	HiZ

AFSX	mcasp8_fsx	I/O	Transmit frame synchronization	HiZ
ACLKR	mcasp8_aclkr	I/O	Receive bit clock	HiZ
AFSR	mcasp8_fsr	I/O	Receive frame synchronization	HiZ

---

**NOTE:** For the `mcaspx_aclkx`, `mcaspx_ahclkx` and `mcaspx_aclkr` signals to work properly, the INPUTENABLE bit of the appropriate CTRL\_CORE\_PAD\_x registers should be set to 0x1 because of retiming purposes.

---

**NOTE:** The path from module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. For more information, refer to the [Section 18.4.6.1.1, Pad Configuration Registers](#), and [Section 18.5, Control Module Register Manual](#), in [Chapter 18, Control Module](#).

---

**NOTE:** A serializer AXR data pin is shared between the transmit and receive logic of that serializer. The direction of data is determined in the `MCASP_PDIR` and the function (Tx or Rx) is selected in the corresponding serializer control register `MCASP_XRSRCTLn`.

---

## 24.6.2.2 Protocols and Data Formats

### 24.6.2.2.1 Protocols Supported

The McASP supports a wide variety of protocols:

- Transmit section supports:
  - Wide variety of I2S and similar bit-stream formats.
  - TDM streams from 2 to 32 time slots.
  - S/PDIF, IEC60958-1, AES-3 formats.
- Receive section supports:
  - Wide variety of I2S and similar bit-stream formats.
  - TDM streams from 2 to 32 time slots.
  - TDM stream of 384 time slots specifically designed for easy interface to external digital interface receiver (DIR) device transmitting DIR frames to McASP using the I2S protocol (one time slot for each DIR subframe).

The transmit and receive sections of the module may be individually programmed to support the following options on the basic serial protocol:

- Programmable clock and frame sync polarity (rising or falling edge): ACLKR/X, AHCLKR/X, and AFSR/X.
- Slot length (number of bits per time slot): 8, 12, 16, 20, 24, 28, 32 bits supported.

- Word length (bits per word): 8, 12, 16, 20, 24, 28, 32 bits; always less than or equal to the time slot length.
- First-bit data delay: 0, 1, 2 bit clocks.
- Left/right alignment of word inside slot.
- Bit order: MSB first or LSB first.
- Bit mask/pad/rotate function.
  - Automatically aligns data internally in either Q31 or integer formats.
  - Automatically masks nonsignificant bits (sets to 0, 1, or extends value of another bit).

---

**NOTE:** In I2S mode, the transmit and receive sections can support simultaneous transfers on up to all serial data pins operating as 192 kHz stereo channels.

---

In DIT mode for McASP, additional features of the transmitters are:

- Transmit-only mode 384 time slots (subframe) per frame.
- Biphase encoded LVCMOS output
- Channel status RAM (384 bits).
- User data RAM (384 bits).
- Separate valid bit (V) for subframe A, B.
- Stereo Support Only (Mono means send data 2x via software)

In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to all serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for I2S mode, due to the need to generate Biphase Mark Encoded Data).

---

**NOTE:** The McASP does NOT natively support DIR-mode reception (i.e. receiving in the S/PDIF format). To allow this, the McASP can use a DIR-input to I2S-output converter implemented by an external device (i.e. external DIR component). To facilitate reception in this case, the TDM mode of McASP receivers logic is extended to support a non-standard 384-slot TDM stream.

---

---

**NOTE:** An external transceiver must be connected to the McASP port in the device to translate the electrical signals delivered by the McASP (1.2 V or 1.8 V LVCMOS levels) to the electrical levels of the S/PDIF standard.

---

#### 24.6.2.2.2 Definition of Terms

The serial bitstream transmitted or received by a McASP serializer is a long sequence of 1s and 0s on an audio transmit/receive pins AXRn. However, the sequence has a hierarchical organization that can be described in terms of frames of data, slots, words, and bits.

A basic synchronous serial interface consists of three important components: clock, frame sync, and data. [Figure 24-110](#) shows two of the three basic components: the clock signal (ACLKX/ACLKR) and the data signals AXRn. [Figure 24-110](#) does not specify whether the clock is for transmit (ACLKX) or receive (ACLKR) because the definitions of terms apply to both receive and transmit interfaces. In operation, each transmitter and receiver uses the signals ACLKX and ACLKR as serial clock, respectively. Optionally, a receiver can use ACLKX as the serial clock when a transmitter and receiver (not from the same serializer) of the McASP are configured to operate synchronously.

- Bit:

A bit is the smallest entity in the serial data stream. The beginning and end of each bit is marked by an edge of the serial clock. The duration of a bit is a serial clock period. A '1' is represented by a logic high on AXRn pins for the entire duration of the bit. A 0 is represented by a logic low on an AXRn pin for the entire duration of the bit.

- Word:

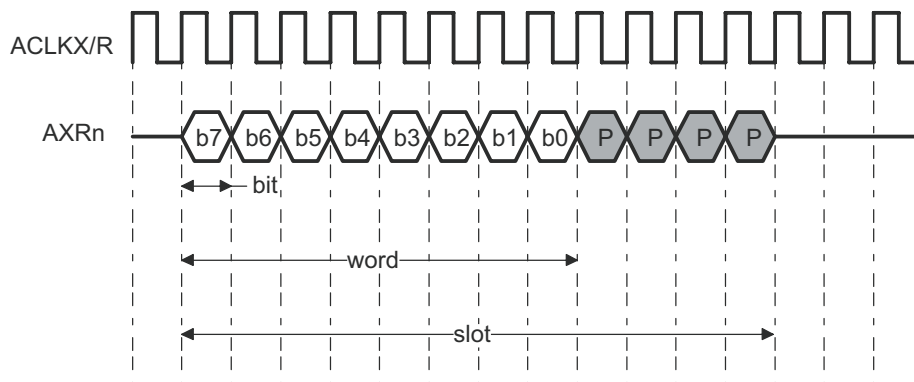

A word is a group of bits that make up the data being transferred between the McASP and the external device. Figure 24-110 shows an 8-bit word.

- Slot:

A slot consists of the bits that make up the word and can consist of additional bits used to pad the word to a convenient number of bits for the interface between the McASP and the external device. In Figure 24-110, the audio data consists of only 8 bits of useful data (8-bit word), but it is padded with four 0s (12-bit slot) to satisfy the desired protocol in interfacing to an external device. Within a slot, the bits can be shifted out of the McASP on an AXRn pin with either MSB or LSB first.

When the word size is smaller than the slot size, the word can be aligned to the left of the slot (beginning) or to the right of the slot (end). The additional bits in the slot not belonging to the word can be padded with 0, 1, or with one of the bits (typically, the MSB or LSB) from the data word, i.e. left-aligned words within a slot are terminated with padding bits and right-aligned words within a slot are preceded by padding bits to fit in the slot size. Figure 24-111 shows these options.

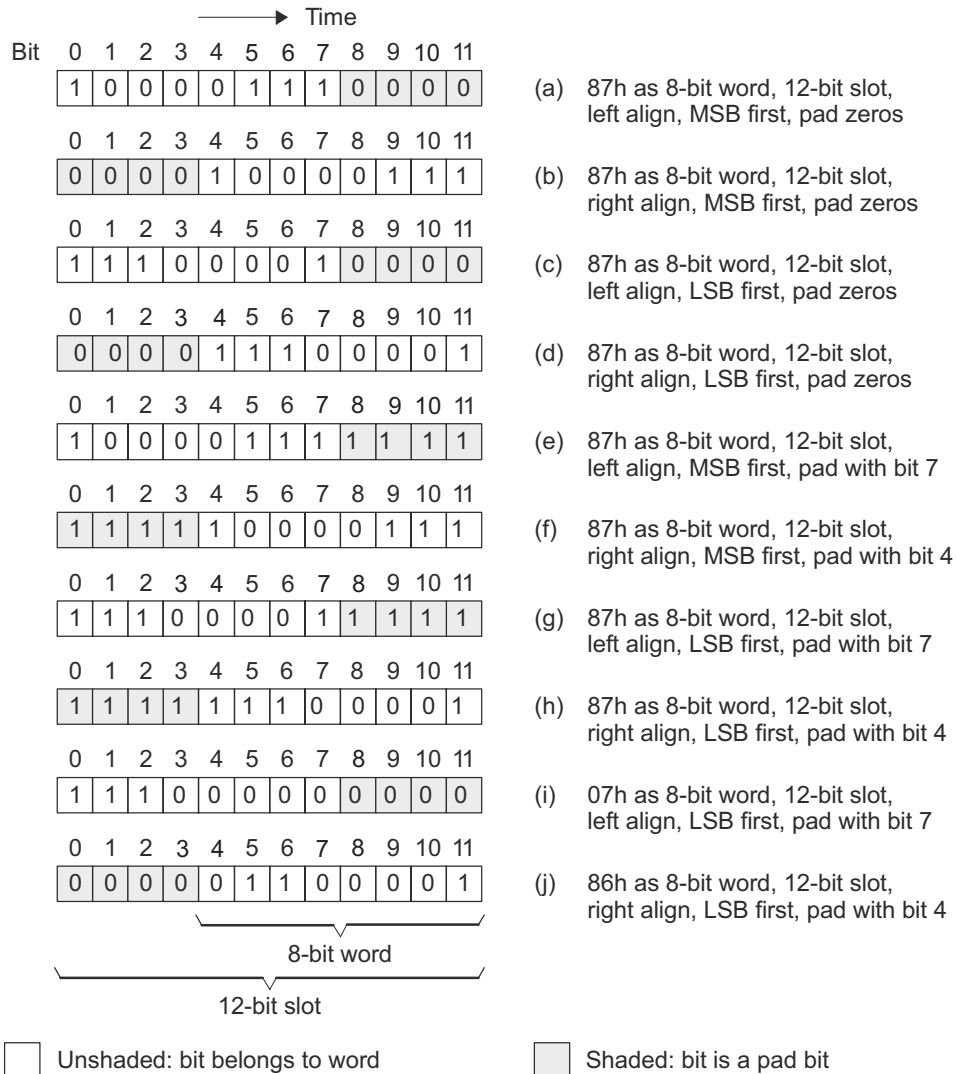

**Figure 24-110. Definition of Bit, Word, and Slot**

- (1) b7:b0 - bits. Bits b7 to b0 form a word.
- (2) P - pad bits. Bits b7 to b0, together with the 4 pad bits, form a slot.
- (3) In this example, the data is transmitted MSB first, left-aligned.

mcasp-003

**Figure 24-111. Bit Order and Word Alignment Within a Slot Examples**

• **Frame**

The third basic element of a synchronous serial interface is the frame synchronization signal, also referred to as frame sync in this chapter. A frame contains one or multiple slots, as determined by the desired protocol. Figure 24-112 shows an example frame of data and the frame definitions. In operation, the transmitter uses AFSX, and the receiver - AFSR signal. Figure 24-112 does NOT specify whether the frame sync (FS) is for transmit (AFSX) or receive (AFSR) because the definitions of terms apply to both receive and transmit interfaces. In operation, each transmitter/receiver uses AFSX/AFSR as a frame synchronization signal, respectively. Optionally, the receiver can use AFSX as the frame sync when the transmitter and receiver of the McASP are configured to operate synchronously. This example shows two slots in a frame (I2S format) and a frame-sync (FS) duration of a slot length.

This section shows only the generic definition of the frame sync. For more information about the frame-sync formats required for the transfer modes and protocols (TDM-mode and DIT-mode supported formats), see Section 24.6.2.2.3, TDM Format and Section 24.6.2.2.5, S/PDIF-Coding Format.

- NOTE:** All of the McASP serializers share the same, device pad accessible, clock and frame signals, as follows:
- AHCLKX, ACLKX, and AFSX for the transmitting section
  - ACLKR and AFSR for the receiving section

**Figure 24-112. Definition of Frame and Frame-Sync Width**

mcasp-005

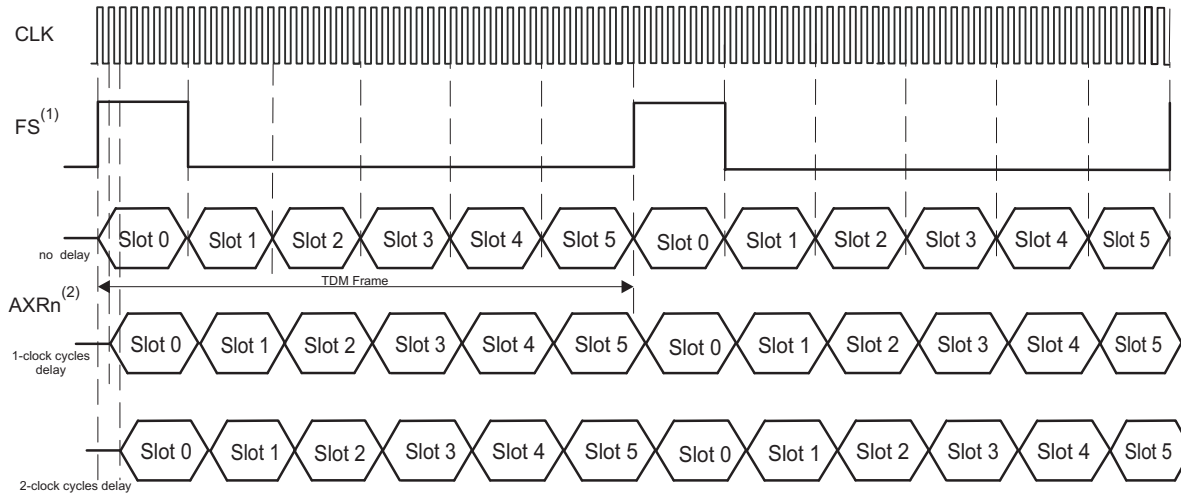

The following terms are used throughout this chapter:

- TDM: Time-division multiplexed. See [Section 24.6.2.2.3](#) for details on the TDM protocol
- I2S: Inter-Integrated Sound protocol, commonly used on audio interfaces. The McASP supports the I2S protocol as part of the TDM mode (when configured as a 2-slot frame).
- DIT: Digital audio interface transmit. The McASP supports transmitting in S/PDIF format on each AXRn data pin.
- DIR: Digital audio interface receive. The McASP does NOT natively support receiving in S/PDIF format on AXRn data pins and requires an external DIR-to-TDM or DIR-to-I2S converter chip for a DIR-frame reception.
- Slot or time slot: For DIT/DIR format, a McASP time slot corresponds to a DIT/DIR subframe.

### 24.6.2.2.3 TDM Format

The TDM format is used to transfer data between the host CPU and one or more analog-to-digital converter (ADC), digital-to-analog converter (DAC), or S/PDIF receiver (DIR) devices. An example for a 6-slot (channel) TDM transmission on one McASP data pin - AXRn is illustrated on [Figure 24-113](#).

**Figure 24-113. TDM Format - 6 channel example**

- (1) - Frame sync duration of 1 slot - length is shown. A single bit - duration of FS is also supported
- (2) - Slot 0 of AXRn stream is being offset with 0-, 1-, and 2- clock cycle delay from the frame sync, respectively.

mcasp-006

The TDM format uses three signals in a basic synchronous serial interface: data (AXRn), clock (CLK) and frame sync (FS). The data signal present on AXRn pin is fully synchronous to the serial clock (ACLKX or ACLKR). The data bits are grouped into words and slots (see also [Section 24.6.2.2.2](#)), the latter being also referred to as the "time-slots" or "channels" in TDM terminology. A frame consists of multiple time-slots. Each TDM frame is marked by the frame sync signal (AFSX or AFSR). The TDM transfer is continuous and periodic, with no delays between slots.

Within a certain frame, the last bit of slot N is followed immediately on the next serial clock with the first bit of the next slot N+1. On the boundary between two adjacent TDM-frames, the last bit of the last slot from the frame M, is followed immediately on the next clock cycle with the first bit of the first slot from the next frame M+1. For McASP, there is an option to offset the first bit of the first slot with a 0-, 1- or 2-cycle delay from the frame sync signal.

The frame sync - AFSX/AFSR only marks the beginning of slot 0 and start of a new frame. Since it does not determine the boundaries of a slot, there is a requirement for a connected transmitter and receiver to agree on the number of transferred bits per slot.

In a typical audio system involving McASP module, a single TDM data frame is transferred during each sample period  $T_s$  of a data converter. The user has following choices to implement multiple channels:

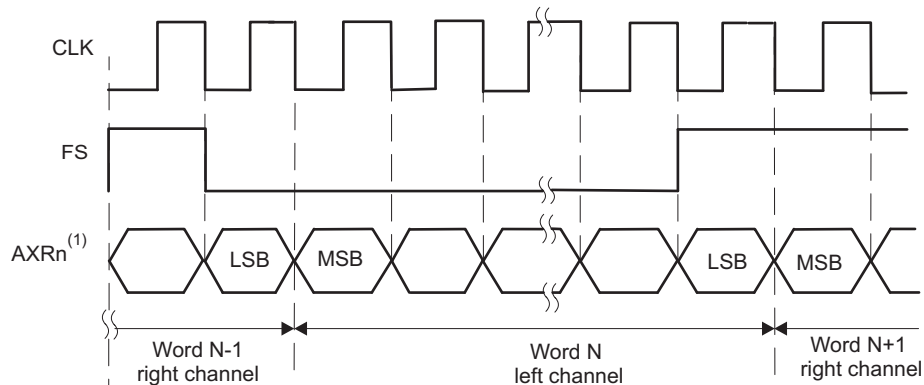

- Use more data slots (on a price of higher speed serial clock) per frame transmitted/received on just one of the available McASP data pins AXRn.
- Use less number of slots per TDM frame (requires a slower serial clock), making them available on several of the McASP pins AXRn.

#### 24.6.2.2.4 I2S Format

The TDM transfer mode of the McASP supports the I2S format when frame is configured to have 2 slots. I2S format is specifically designed to transfer a stereo channel (left and right) over a single data pin AXRn. "Slots" are also commonly referred to as "channels". The frame width duration in the I2S format equals size of a slot. The frame signal is also referred to as "word select" in the I2S format.

The I2S protocol is illustrated on [Figure 24-114](#).

Figure 24-114. I2S Format Overview

(1) - The example shows I2S data MSB-first transmission with 1-clock cycle delay between FS and data MSB

mcasp-036

#### 24.6.2.2.5 S/PDIF Coding Format

The McASP transmitter supports the S/PDIF format with 3.3V biphasemark encoded output. The S/PDIF format is supported by the DIT- transfer mode of the McASP. This section briefly discusses the S/PDIF coding format.

**NOTE:** The DIR- reception of S/PDIF format frames is NOT natively supported from the device McASP. For this purpose, an external DIR-to-TDM transfer mode adapter can be used between the remote device S/PDIF transmitter output and the McASP TDM-only compatible receiver input.

##### 24.6.2.2.5.1 Biphasemark Code

In S/PDIF format, the digital signal is coded using the biphasemark code (BMC). For each serializer transmitter  $n$ , the clock, frame, and data are embedded in only one signal - the data signal AXRn. In the BMC system, each data bit is encoded into two logical states (00, 01, 10, or 11) at the pin. These two logical states form a cell. The duration of the cell, which equals the duration of the data bit, is called a time interval. A logical 1 is represented by two transitions of the signal within a time interval, which corresponds to a cell with logical states 01 or 10. A logical 0 is represented by one transition within a time interval, which corresponds to a cell with logical states 00 or 11. In addition, the logical level at the start of a cell is inverted from the level at the end of the previous cell. Figure 24-115 and Table 24-418 show how data is encoded to the BMC format.

As shown in Figure 24-115, the clock frequency is twice the unencoded data bit rate. In addition, the clock is always programmed to  $128 \times f_s$ , where  $f_s$  is the sample rate (see Section 24.6.2.2.5.3, Frame Format, for details on how this clock rate is derived based on the S/PDIF format). The device receiving in S/PDIF format can recover the clock and frame information from the BMC signal.

**Table 24-418. Biphase-Mark Encoder**

Data (Unencoded)	Previous State at Pin AXRn	BMC-Encoded Cell Output at Pin AXRn
0	0	11
0	1	00
1	0	10
1	1	01

**24.6.2.2.5.2 S/PDIF Subframe Format**

Every audio sample transmitted in a subframe consists of 32 S/PDIF time intervals (or cells), numbered 0 to 31. Figure 24-116 shows a subframe.

- Time intervals 0–3 carry one of the three permitted preambles to signify the type of audio sample in the current subframe. The preamble is not encoded in BMC format, and therefore the preamble code can contain more than two consecutive 0 or 1 logical states in a row. See Table 24-419.
- Time intervals 4–27 carry the audio sample word in linear 2s-complement representation. The MSB is carried by time interval 27. When a 24-bit coding range is used, the LSB is in time interval 4. When a 20-bit coding range is used, time intervals 8-27 carry the audio sample word with the LSB in time interval 8. Time intervals 4–7 may be used for other applications and are designated auxiliary sample bits.
- If the source provides fewer bits than the interface allows (20 or 24), the unused LSBs are set to logical 0. For a nonlinear PCM audio application or a data application, the main data field can carry any other information.
- Time interval 28 carries the validity bit (V) associated with the main data field in the subframe.
- Time interval 29 carries the user data channel (U) associated with the main data field in the subframe.
- Time interval 30 carries the channel status information (C) associated with the main data field in the subframe. The channel status indicates if the data in the subframe is digital audio or some other type of data.
- Time interval 31 carries a parity bit (P) such that time intervals 4–31 carry an even number of 1s and an even number of 0s (even parity). As listed in Table 24-419, the preambles (time intervals 0–3) are also defined with even parity.

Figure 24-116. S/PDIF Subframe Format

As listed in Table 24-419, the McASP DIT generates only one polarity of preambles, and it assumes the previous logical state is 0. This is because the McASP assures an even-polarity encoding scheme when transmitting in DIT mode. If an underrun condition occurs, the DIT resynchronizes to the correct logic level on the AXRn pin before continuing with the next transmission.

Table 24-419. Preamble Codes

Preamble Code <sup>(1)</sup>	Previous Logical State	Logical States on pin AXRn <sup>(2)</sup>	Description
B (or Z)	0	1110 1000	Start of a block and subframe 1
M (or X)	0	1110 0010	Subframe 1
W (or Y)	0	1110 0100	Subframe 2

<sup>(1)</sup> Historically, preamble codes are referred to as B, M, and W. For use in professional applications, preambles are referred to as Z, X, and Y, respectively.

<sup>(2)</sup> The preamble is not BMC-encoded. Each logical state is synchronized to the serial clock. These eight logical states make up time slots (cells) 0 to 3 in the S/PDIF stream.

### 24.6.2.2.5.3 Frame Format

An S/PDIF frame is composed of two subframes (see Figure 24-117). For linear coded audio applications, the rate of frame transmission normally corresponds exactly to the source sampling frequency  $f_s$ . The S/PDIF format clock rate is therefore  $128 \times f_s$  ( $128 = 32$  cells per subframe  $\times 2$  clocks per cell  $\times 2$  subframes per sample). For example, for an S/PDIF stream at a 192-kHz sampling frequency, the serial clock is  $128 \times 192$  kHz = 24.58 MHz.

In 2-channel operation mode, the samples taken from both channels are transmitted by time multiplexing in consecutive subframes. Both subframes contain valid data (cell 28 validity bits for A- and B- channels, both set to '0'). The first subframe (left or A channel in stereophonic operation and primary channel in monophonic operation) normally starts with preamble M. However, the preamble of the first subframe changes to preamble B once every 192 frames to identify the start of the block structure used to organize the channel status information. The second subframe (right or B channel in stereophonic operation and secondary channel in monophonic operation) always starts with preamble W.

In single-channel operation mode in a professional application, the frame format is the same as in the 2-channel mode. Data is carried in the first subframe and may be duplicated in the second subframe. If the second subframe is not carrying duplicate data, cell 28 (validity bit) is set to logical 1.

Figure 24-117. S/PDIF Frame Format

### 24.6.3 McASP Integration

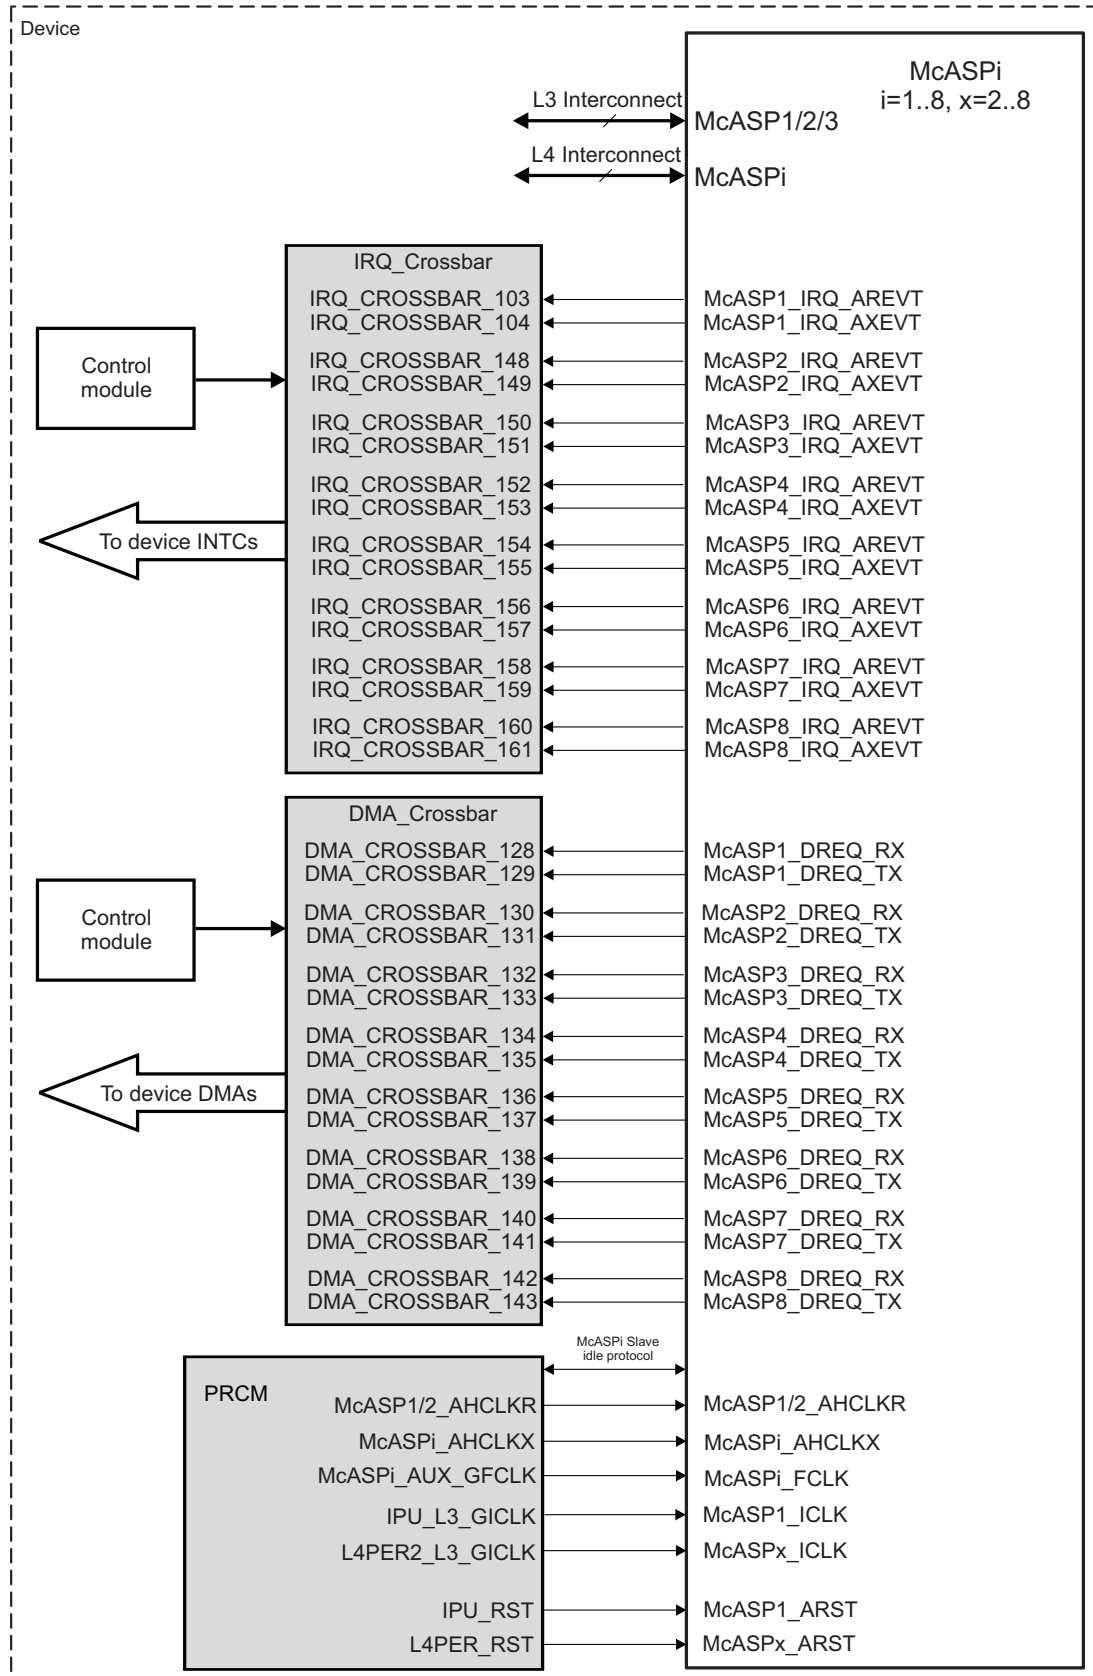

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

McASP module includes the following features:

- Slave idle protocol
- One DMA request for transmit event
- One DMA request for receive event
- One interrupt request (IRQ) for transmit
- One interrupt request (IRQ) for receive

[Figure 24-118](#) shows McASP integration.

Figure 24-118. McASP Integration

mcasp-011

**NOTE:** For more information about the slave idle protocol, see [Section 3.1.1.1.2, Module Level Clock Management of Chapter 3, Power, Reset, and Clock Management](#).

Table 24-420 through Table 24-422 summarize McASP integration in the device.

**Table 24-420. McASP Integration Attributes**

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
McASP1	PD_COREAON	No	L3_MAIN L4_PER2
McASP2	PD_COREAON	No	L3_MAIN L4_PER2
McASP3	PD_COREAON	No	L3_MAIN L4_PER2
McASP4	PD_COREAON	No	L4_PER2
McASP5	PD_COREAON	No	L4_PER2
McASP6	PD_COREAON	No	L4_PER2
McASP7	PD_COREAON	No	L4_PER2
McASP8	PD_COREAON	No	L4_PER2

**Table 24-421. McASP Clocks and Resets**

Module Instance	Destination Signal Name	Source Signal Name	Source	Clocks
				Description
McASP1	MCASP1_AHCLKR	MCASP1_AHCLKR	PRCM	McASP1 AHCLKR receive high-frequency master clock
	MCASP1_AHCLKX	MCASP1_AHCLKX		McASP1 AHCLKX transmit high-frequency master clock
	MCASP1_FCLK	MCASP1_AUX_GFCLK		McASP1 functional clock

	MCASP5_DREQ_TX	DMA_CROSSBAR_137	DMA_DSP1_DREQ_9 DMA_DSP2_DREQ_9	McASP5 module transmit event request
McASP6	MCASP6_DREQ_RX	DMA_CROSSBAR_138	DMA_DSP1_DREQ_10 DMA_DSP2_DREQ_10	McASP6 module receive event request
	MCASP6_DREQ_TX	DMA_CROSSBAR_139	DMA_DSP1_DREQ_11 DMA_DSP2_DREQ_11	McASP6 module transmit event request
McASP7	MCASP7_DREQ_RX	DMA_CROSSBAR_140	DMA_DSP1_DREQ_12 DMA_DSP2_DREQ_12	McASP7 module receive event request
	MCASP7_DREQ_TX	DMA_CROSSBAR_141	DMA_DSP1_DREQ_13 DMA_DSP2_DREQ_13	McASP7 module transmit event request
McASP8	MCASP8_DREQ_RX	DMA_CROSSBAR_142	DMA_DSP1_DREQ_14 DMA_DSP2_DREQ_14	McASP8 module receive event request
	MCASP8_DREQ_TX	DMA_CROSSBAR_143	DMA_DSP1_DREQ_15 DMA_DSP2_DREQ_15	McASP8 module transmit event request

**NOTE:** The **Default Mapping** column in [Table 24-422 McASP Hardware Requests](#) shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ\_CROSSBAR and DMA\_CROSSBAR modules, respectively. For more information about the IRQ\_CROSSBAR module, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#). For more information about the DMA\_CROSSBAR module, see [Section 18.4.6.5, DMA\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#). For more information about the device interrupt controllers, see [Chapter 17, Interrupt Controllers](#). For more information about the device DSP1\_EDMA and DSP2\_EDMA modules, see [Section 5.3.7, DSP Integrated EDMA Subsystem](#).

**NOTE:**

- For the description of the interrupt source, see [Section 24.6.4.12, McASP Events and Interrupt Requests](#).
  - For the description of the DMA source, see [Section 24.6.4.13, DMA Requests](#).
-

## **24.6.4 McASP Functional Description**

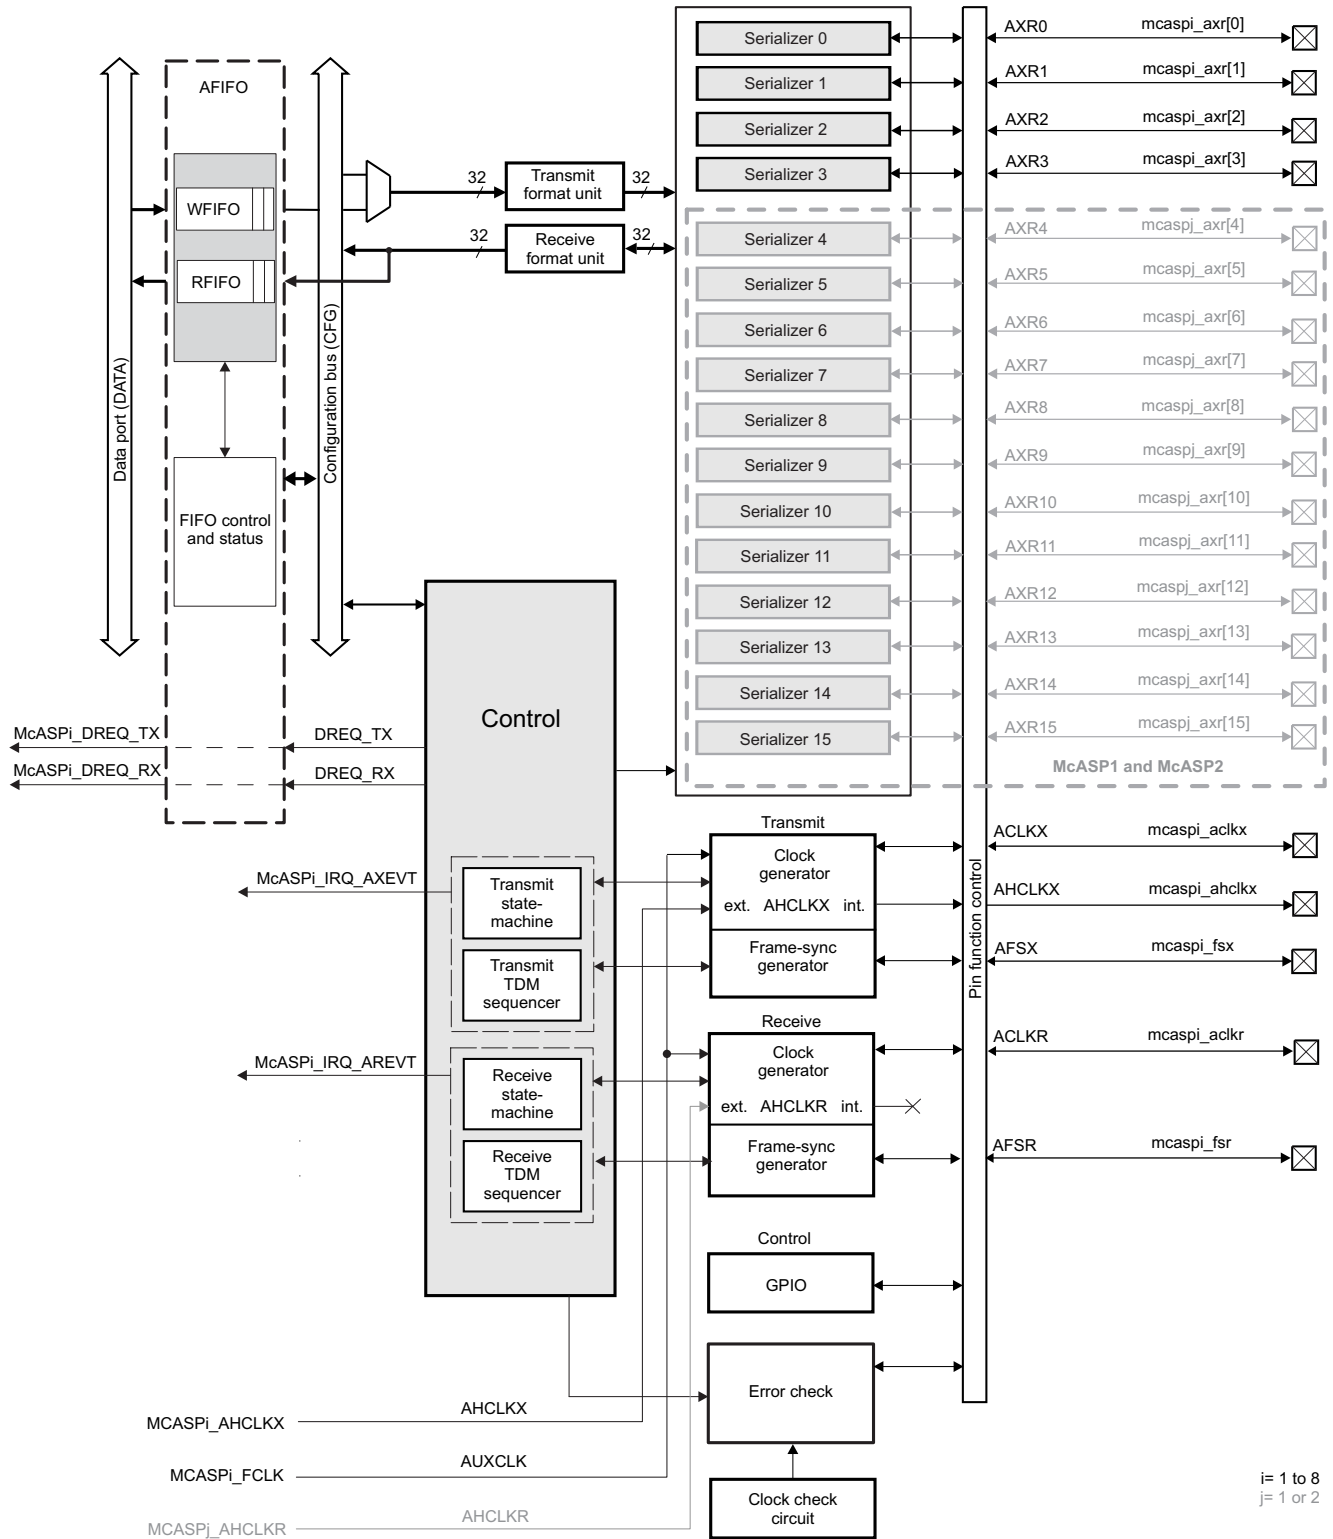

In the text throughout this section a single instance of McASP is described assuming that all modules are functionally identical. For module availability and integration differences, see [Section 24.6.2, McASP Environment](#), and [Section 24.6.3, McASP Integration](#)

### **24.6.4.1 McASP Block Diagram**

[Figure 24-119](#) shows the major blocks of the McASP module. McASP1 and McASP2 have 16 serializers each, and McASP<sub>n</sub> (n = 3 to 8) have 4 serializers each. The serializers share a clock and frame-sync generator, format unit, and error-checking logic independently for the receive and transmit part.

Figure 24-119. McASP Module Block Diagram

mcasp-012

**NOTE:** The internal and external clocks mentioned in this section are with respect to clock and frame-sync generator modules.

### 24.6.4.2 McASP Clock and Frame-Sync Configurations

There are three scenarios to provide clock source signals for the Tx part and four scenarios for the Rx part of the McASP serializers. The first three scenarios are identical between the Tx and Rx part of the McASP. They feature an asynchronous operation between receiver and transmitter channels using independent Tx/Rx bit rate clock sources (either internal or external).

In the first scenario, the transmit - XCLK and receive - RCLK serial clocks (clock at the bit rate) are generated internally by passing through a couple of clock dividers off the internal functional clock source (AUXCLK). In this case, the bit rate clock is generated internally and is driven out on the pin ACLKX for the Tx part and pin ACLKR for the Rx part, respectively. An internally generated high-frequency clock can be optionally driven out onto the AHCLKX pin for the Tx part to serve as a reference clock for other components in the system.

In the second scenario, an external for the device clock, is passed on the ACLKX (for the TX part) and ACLKR (for the RX part) pins which are configured as inputs. In this case the Rx- /Tx- high-speed clock logic is bypassed for the XCLK/RCLK generation.

In the third (mixed) scenario, an externally driven (master) high-frequency clock is applied on the AHCLKX (for the TX part) pin, which is configured as input. In this case the AHCLKX clock frequency can be divided down via programming the ACLKX associated divider to produce the necessary bit rate clock. The high-speed clock divider can NOT be used.

In the fourth clock generation scenario the bit rate clock for McASP receivers - RCLK is derived from the bit rate clock of the McASP transmitters - XCLK for a synchronous operation between transmitters and receivers. Hence, the whole receiver clock generator logic is bypassed.

A typical role of the McASP frame sync signal is to carry the left/right clock (LRCLK) signal when transmitting and receiving stereo data.

For an asynchronous operation, the AFSX (Tx part) and AFSR (Rx part) frame synchronization signals can be sourced internally or delivered externally independently for the Tx and Rx channels. During synchronous operation the receive frame sync - AFSR signal is derived from the transmit frame sync - AFSX signal. A synchronous and asynchronous mode applies to bit rate clock and frame sync signals at the same time.

#### 24.6.4.2.1 McASP Transmit Clock

The transmit high-speed and transmit clock configuration is controlled by the following registers:

- [MCASP\\_ACLKXCTL](#)
- [MCASP\\_AHCLKXCTL](#)

In case, the transmit bit clock, ACLKX, is generated internally, the [MCASP\\_ACLKXCTL](#)[5] CLKXM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the [MCASP\\_ACLKXCTL](#)[4:0] CLKXDIV bit field) from the source signal.

If the transmit high-frequency master clock, AHCLKX, is also sourced internally (that is first scenario described in [Section 24.6.4.2](#), the [MCASP\\_AHCLKXCTL](#)[15] HCLKXM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the [MCASP\\_AHCLKXCTL](#)[11:0] HCLKXDIV bit field) from the McASP internal clock source AUXCLK.

Internally, the McASP always shifts transmit data at the rising edge of the internal transmit clock - XCLK, (see [Figure 24-120](#)). The CLKXP mux determines if ACLKX needs to be inverted to become XCLK. If [MCASP\\_ACLKXCTL](#)[7] CLKXP = 0, the CLKXP mux directly passes ACLKX signal to XCLK. As a result, the McASP shifts transmit data at the rising edge of ACLKX. If [MCASP\\_ACLKXCTL](#)[7] CLKXP = 1, the CLKXP mux passes the inverted version of ACLKX to XCLK. As a result, the McASP shifts transmit data at the falling edge of ACLKX.

It can be seen in [Figure 24-120](#) that XCLK is propagated to the Rx clock logic, to allow an internally synchronous operation between McASP transmitters and receivers. This is used for example in the McASP loopback mode.

**NOTE:** The polarity of ACLKX can be controlled in [MCASP\\_ACLKXCTL\[7\]](#) CLKXP, regardless of ACLKX signal being internally or externally sourced.

In addition, there is an option to invert polarity of the AHCLKX master high speed clock via writing the [MCASP\\_AHCLKXCTL\[14\]](#) HCLKXP bit.

**NOTE:** In a similar way, the polarity of AHCLKX clock can be controlled in [MCASP\\_AHCLKXCTL\[14\]](#) HCLKXP, regardless of the AHCLKX signal being internally or externally sourced.

Figure 24-120 is the block diagram of the transmit clock generator.

**Figure 24-120. Transmit Clock Generator Block Diagram**

**NOTE:** In this device:

- ACLKX is mapped on the device ball `mcaspi_aclkx`, where  $i = 1$  to 8
- internal AHCLKX is mapped on the device ball `mcaspi_ahclkx`
- external AHCLKX is mapped on `MCASPi_AHCLKX` clock from the PRCM

For more on McASP integration, see [Section 24.6.2, McASP Environment](#), and [Section 24.6.3, McASP Integration](#).

#### 24.6.4.2.2 McASP Receive Clock

The McASP receive clock generator is built on a very similar to the transmit clock generator (but independent) circuit.

The receive clock configuration is controlled by the following registers:

- [MCASP\\_ACLKRCTL](#)
- [MCASP\\_AHCLKRCTL](#)

In case, the receive bit clock, ACLKR, is generated internally (but asynchronously to XCLK), the [MCASP\\_ACLKRCTL\[5\]](#) CLKRM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the [MCASP\\_ACLKRCTL\[4:0\]](#) CLKRDIV bit field) from the source signal.

If the receive high-frequency master clock, AHCLKR, is also sourced internally (that is, first scenario described in [Section 24.6.4.2](#)) and the [MCASP\\_AHCLKRCTL\[15\]](#) HCLKRM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the [MCASP\\_AHCLKRCTL\[11:0\]](#) HCLKRDIV bit field) from the McASP internal clock source AUXCLK.

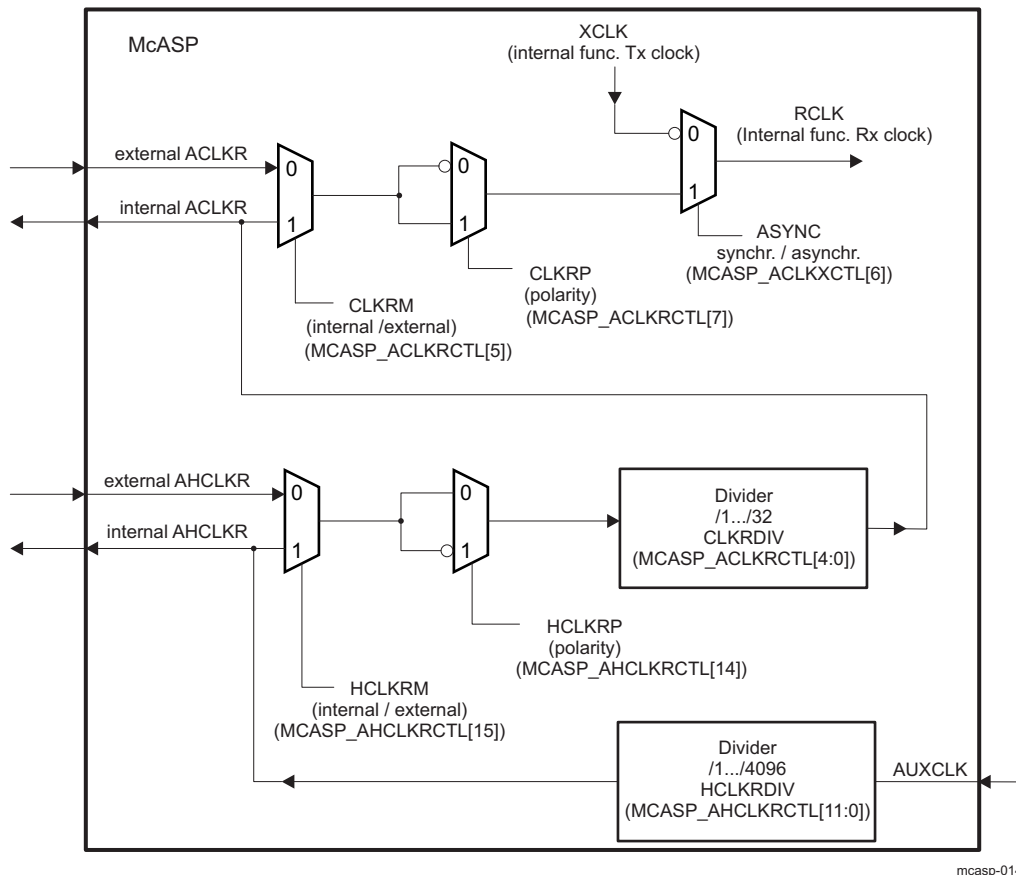

**NOTE:** The polarity of ACLKR can be controlled in [MCASP\\_ACLKRCTL\[7\]](#) CLKRP, regardless of ACLKR signal being internally or externally sourced.

In a similar way, the polarity of AHCLKR clock can be controlled in [MCASP\\_AHCLKRCTL\[14\]](#) HCLKRP, regardless of the AHCLKR signal being internally or externally sourced.

There is an option for the McASP receiver to be configured to operate synchronously to the ACLKX and AFSX signals. The XCLK output of the Tx Clock generator (see [Figure 24-120](#) and [Figure 24-121](#)) becomes source of the receive clock (RCLK output), when the [MCASP\\_ACLKXCTL\[6\]](#) ASYNC bit in the transmit clock control register is set to '0b0'. For more information, refer to [Section 24.6.4.2.4](#).

[Figure 24-121](#) is the block diagram of the receive clock generator.

**Figure 24-121. Receive Clock Generator Block Diagram**

mcasp-014

**NOTE:** In this device:

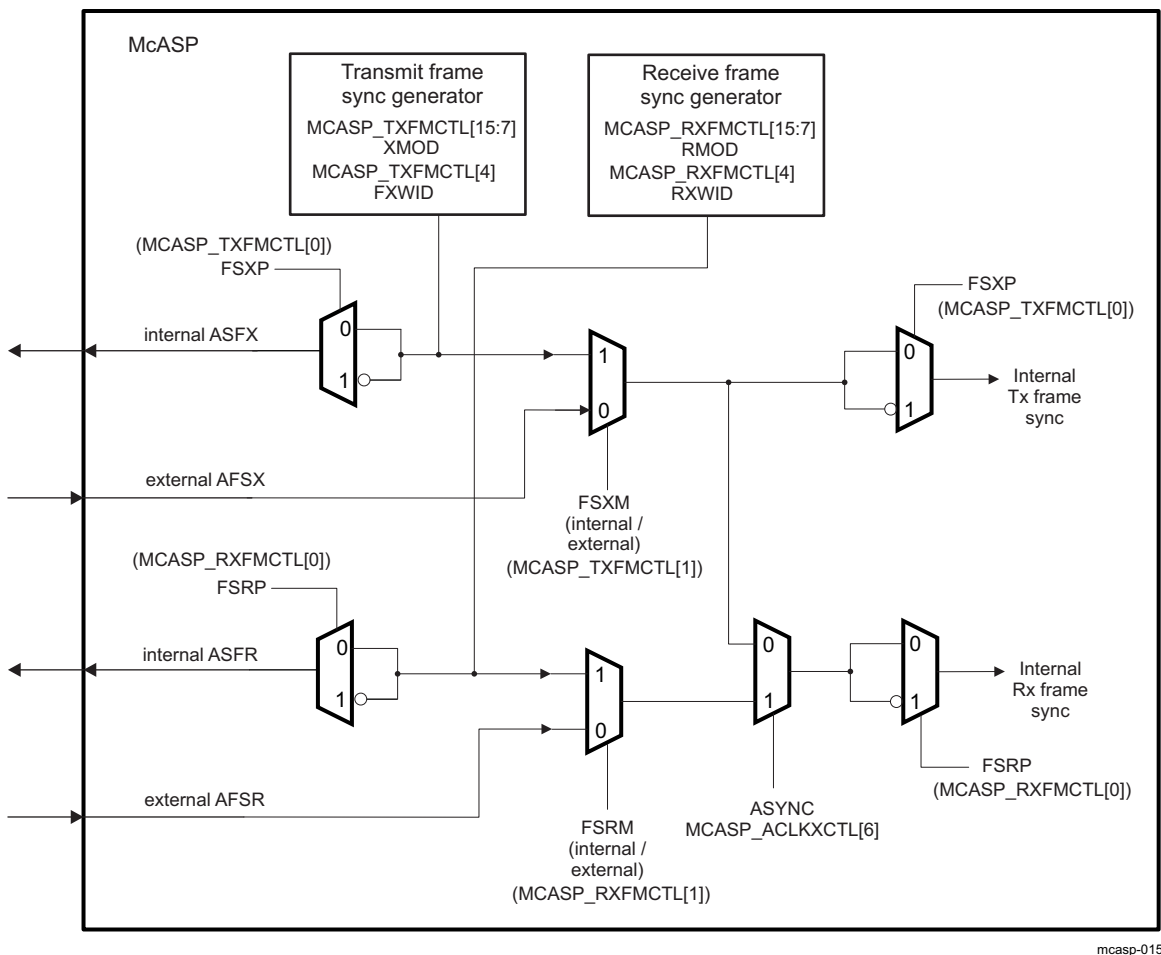

- ACLKR is mapped on the device ball mcaspi\_aclkr, where i = 1 to 8
- internal AHCLKR is tied-off
- external AHCLKR is mapped on PRCM MCASPi\_AHCLKR from PRCM for McASP1 and McASP2
- external AHCLKR is tied-off for McASP3 through McASP8

For more on McASP integration, see [Section 24.6.2, McASP Environment](#), and [Section 24.6.3, McASP Integration](#).

**24.6.4.2.3 Frame-Sync Generator**

There are two different modes for frame sync: burst and TDM. The McASP frame sync generator logic is illustrated in [Figure 24-122](#). I/O buffers are not part of the McASP module, and are not shown in the figure.

**Figure 24-122. Frame Sync Generator Block Diagram**

**NOTE:** For more on McASP integration, see [Section 24.6.2, McASP Environment](#), and [Section 24.6.3, McASP Integration](#).

**For the transmit logic**, following frame-sync generator configurations can be selected:

- Internally/externally generated frame-sync via configuring bit [MCASP\\_TXFMCTL\[1\]](#) FSXM
- Frame-sync polarity: Rising edge or falling edge via configuring bit [MCASP\\_TXFMCTL\[0\]](#) FSXP
- Frame-sync width: "single bit" or "single word" via configuring bit [MCASP\\_TXFMCTL\[4\]](#) FXWID

- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is defined in the bitfield [MCASP\\_TXFMCTL\[15:7\]](#) XMOD, as follows:
  - For DIT mode (384 slots) - [MCASP\\_TXFMCTL\[15:7\]](#) XMOD = 0x180
  - For I2S mode (2 TDM slots) - [MCASP\\_TXFMCTL\[15:7\]](#) XMOD = 0x2
  - For TDM mode (from 3 to 32 TDM slots) - [MCASP\\_TXFMCTL\[15:7\]](#) XMOD set in range 0x3 - 0x20
- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in [MCASP\\_TXFMT\[17:16\]](#) XDATDLY

**For the receive logic**, following frame-sync generator configurations can be selected:

- Internally/externally generated frame-sync via configuring bit [MCASP\\_RXFMCTL\[1\]](#) FSRM
- Frame-sync polarity: Rising edge or falling edge via configuring bit [MCASP\\_RXFMCTL\[0\]](#) FSRP
- Frame-sync width: "single bit" or "single word" via configuring bit [MCASP\\_RXFMCTL\[4\]](#) FRWID
- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is defined in the bitfield [MCASP\\_RXFMCTL\[15:7\]](#) RMOD, as follows:
  - For I2S mode (2 TDM slots) - [MCASP\\_RXFMCTL\[15:7\]](#) RMOD = 0x2
  - For TDM mode (from 3 to 32 TDM slots) - [MCASP\\_RXFMCTL\[15:7\]](#) RMOD set in range 0x3 - 0x20
  - For the special 384-slot TDM mode - [MCASP\\_RXFMCTL\[15:7\]](#) RMOD=0x180
- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in [MCASP\\_RXFMT\[17:16\]](#) RDATDLY
- Selecting the source (AFSX or AFSR) of receiver internal frame synchronization. This is done in the same bit - [MCASP\\_ACLKXCTL\[6\]](#) ASYNC, used to define the receiver internal clock source. For more details, refer to [Section 24.6.4.2.4](#).

Regardless of the AFSX/AFSR being internally generated or externally sourced, the polarity of AFSX/AFSR is determined by FSXP/FSRP, respectively, to be either rising or falling edge. If FSXP/FSRP = 0, the frame sync polarity is rising edge. If FSXP/FSRP = 1, the frame sync polarity is falling edge.

---

**NOTE:** Certain restrictions apply to the receive and transmit logic settings, when [MCASP\\_ACLKXCTL\[6\]](#) ASYNC is set to 0b0. They are described in [Section 24.6.4.2.4](#).

---

#### 24.6.4.2.4 Synchronous and Asynchronous Transmit and Receive Operations

##### Synchronous Transmit and Receive Operations -

When [MCASP\\_ACLKXCTL\[6\]](#) ASYNC is written to 0b0, the transmit and receive sections operate synchronously to the transmit section clock and transmit frame sync signals.

Though Rx section may have a different data format, it has to be configured to have the same slot size than the transmit section one. As shown on the [Figure 24-121](#), with the ASYNC bit set to 0b0, the RCLK becomes an inverted version of the transmit clock generator XCLK output.

When [MCASP\\_ACLKXCTL\[6\]](#) ASYNC = 0b0, both Rx and Tx sections use the same clock and frame sync signals. For this reason, they must be aligned on the following settings:

- [MCASP\\_TXDITCTL\[0\]](#) DITEN = 0 (that is, transmission in TDM mode is enabled)
- The total number of bits per frame must be the same (that is, RSSZ \* RMOD product value must equal XSSZ \* XMOD product value)
- The settings in [MCASP\\_ACLKRCTL](#) are NOT considered
- FSXM must match FSRM
- FXWID must match FRWID

For all other settings, the transmit and receive sections may be programmed independently.

##### Asynchronous Transmit and Receive Operations -

When [MCASP\\_ACLKXCTL\[6\]](#) ASYNC = 0b1, Tx and Rx operate independently from each other with separate clock and frame sync signals.

**NOTE:** Synchronous transmit and receive operations are allowed only in the McASP TDM (I2S) mode (i.e. when `MCASP_TXDITCTL[0] DITEN=0b0`).

### 24.6.4.3 Serializers

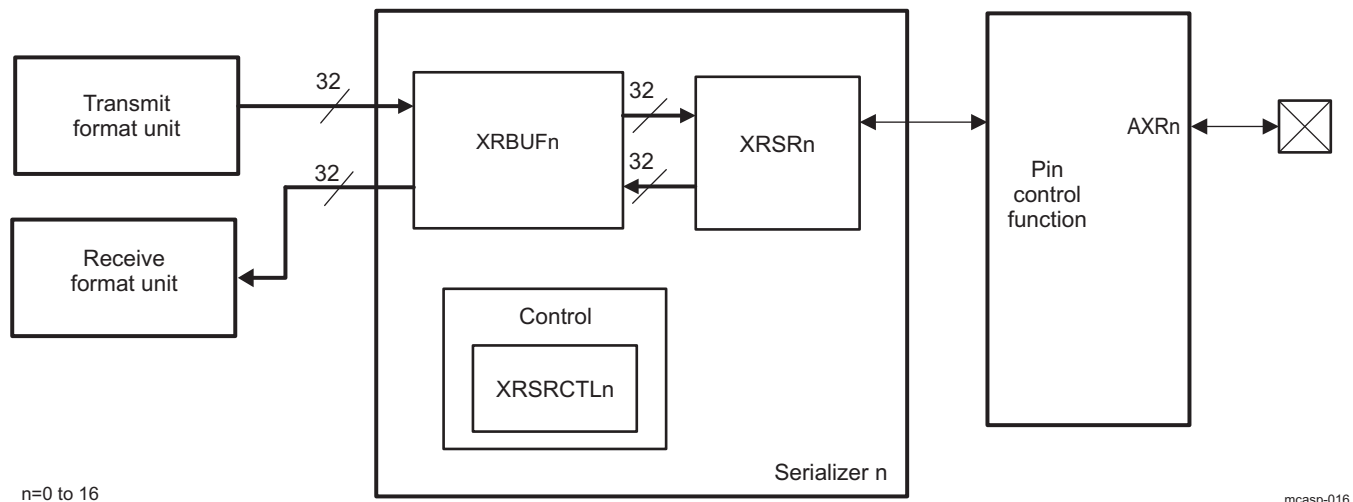

The McASP serializers shift serial data in (Rx) and out (Tx) of the McASP. A given serializer n consists of a shift register (XRSRn) with a single-entry data buffer XRBUFn used either for transmitting (write accessible in register `MCASP_TXBUFn`) or for receiving (read accessible in register `MCASP_RXBUFn`) data. In addition, each serializer has a dedicated control register (`MCASP_XRSRCTLn`) and a serial bidirectional data pin - AXRn. The register `MCASP_XRSRCTLn` allows n-th serializer to be configured as a transmitter, receiver, or as inactive. There are transmit and receive data formatting units to support data alignment options of the McASP which are shared between all Tx and Rx serializers, respectively.

A given serializer XRSRn shifter configured as a receiver in `MCASP_XRSRCTLn`, shifts in data through McASP corresponding device level bidirectional data pad AXRn. A given serializer XRSRn shifter configured as a transmitter in `MCASP_XRSRCTLn`, shifts out data on McASP corresponding device level bidirectional data pad AXRn.

The serializer is clocked from the transmit section clock (ACLKX signal) if configured to transmit or clocked from the receive section clock (ACLKR signal) if configured to receive. A serializer configured to transmit and receive operates in lockstep, which means that for McASP there are at most a couple of zones, one for transmit and one for receive.

Figure 24-123 is the serializer block diagram.

**Figure 24-123. Individual Serializer and Connections Within McASP**

**Transmission on the n-th serializer is performed as follows:**

The McASP is serviced by writing data into the register `MCASP_TXBUFn`, which is an alias of the serializer data buffer - XRBUFn for transmit function. The data automatically passes through the transmit format unit before reaching the XRBUFn register in the serializer. The data is then copied from the XRBUFn to XRSRn and shifted out from AXRn synchronously to the serial clock.

**Reception from the n-th serializer is performed as follows:**

The data is shifted into the McASP XRSRn serializer register through the AXRn pin, bit by bit. Once the entire slot becomes available within the XRSRn shift register, the data is copied into the serializer data buffer - XRBUFn, and can be accessed in the `MCASP_RXBUFn` register, which is an alias of the serializer data buffer - XRBUFn for receive function. When software reads the data from this register, the McASP passes the data through the receive format unit, hence it returns the formatted data.

**Serializer controls:**

A serializer n is configured as inactive via setting bitfield `MCASP_XRSRCTLn[1:0] SRMOD` to 0x0.

For a transmitting serializer, the [MCASP\\_XRSRCTLn\[3:2\]](#) DISMOD bitfield, defines the AXRn pin output state, during inactive slots (HIGH, LOW or Hi-Z).

Transmit function for the n-th serializer is selected via setting bitfield [MCASP\\_XRSRCTLn\[1:0\]](#) SRMOD to 0x1.

Receive function for the n-th serializer is selected via setting bitfield [MCASP\\_XRSRCTLn\[1:0\]](#) SRMOD to 0x2.

In the DIT-transmission mode (that is S/PDIF format data transmission): in addition to the data, the serializer shifts out other DIT-specific information accordingly (preamble, user data, etc.). For more information, see [Section 24.6.2.2.5](#)

#### 24.6.4.4 Format Units

The McASP has one transmit data formatting unit and one receive data formatting unit, shared between the device McASP serializers. These units automatically remap the data bits within the transmitted or received words between a natural format for the device processors (for example, a Q31 representation) and the required format for the external serial device (for example I2S format). During the remapping process, the format unit can also mask off certain bits.

Since all transmitters share the same data formatting unit, the McASP only supports one transmit format at a time. For example, the McASP does NOT transmit in "I2S format" on serializer 0, while transmitting "Left Justified" on serializer 1. Likewise, the receiver section of the McASP only supports one data format at a time, and this format applies to all receiving serializers.

---

**NOTE:** The McASP can transmit in one format while receiving in a completely different format.

---

The bit mask and pad stage of each of Tx and Rx format units includes a full 32-bit mask register, allowing selected individual bits to either pass through the stage unchanged, or be masked off. The bit mask and pad then pad the value of the masked off bits by inserting either a 0, a 1, or one of the original 32 bits as the pad value. The last option allows for sign-extension when the sign bit is selected to pad the remaining bits. The rotate right stage performs bitwise rotation by a multiple of 4 bits (between 0 and 28 bits), programmable by the [MCASP\\_RXFMT/MCASP\\_TXFMT](#) register. Note that this is a rotation process, not a shifting process, so bit 0 gets shifted back into bit 31 during the rotation. The bit order - reversal stage either passes all 32 bits directly through, or swaps them. This allows for either MSB or LSB first data formats. If bit order reversal is not enabled, then the McASP will naturally transmit and receive in an LSB first order. Finally, note that the RDATDLY/XDATDLY bits in the [MCASP\\_RXFMT/MCASP\\_TXFMT](#) also determine the data format. For example, the difference between I2S format and left-justified is determined by the delay between the frame sync edge and the first data bit of a given time slot. For I2S format, RDATDLY/XDATDLY should be set to a 1-bit delay, whereas for left-justified format, it should be set to a 0-bit delay. The combination of all the options in [MCASP\\_RXFMT/MCASP\\_TXFMT](#) means that the McASP supports a wide variety of data formats, both on the serial data lines, and in the device CPU data representation.

##### 24.6.4.4.1 Transmit Format Unit

The McASP transmit formatting unit consists of three stages :

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB-first or LSB-first)

[Figure 24-124](#) shows the transmit formatting unit.

The McASP transmitter supports serial formats of:

- Slot (or Time slot) size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size ≤ Slot size
- Alignment: when more bits/slot than bits/words, then:
  - Left aligned = word shifted first, remaining bits are pad
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot

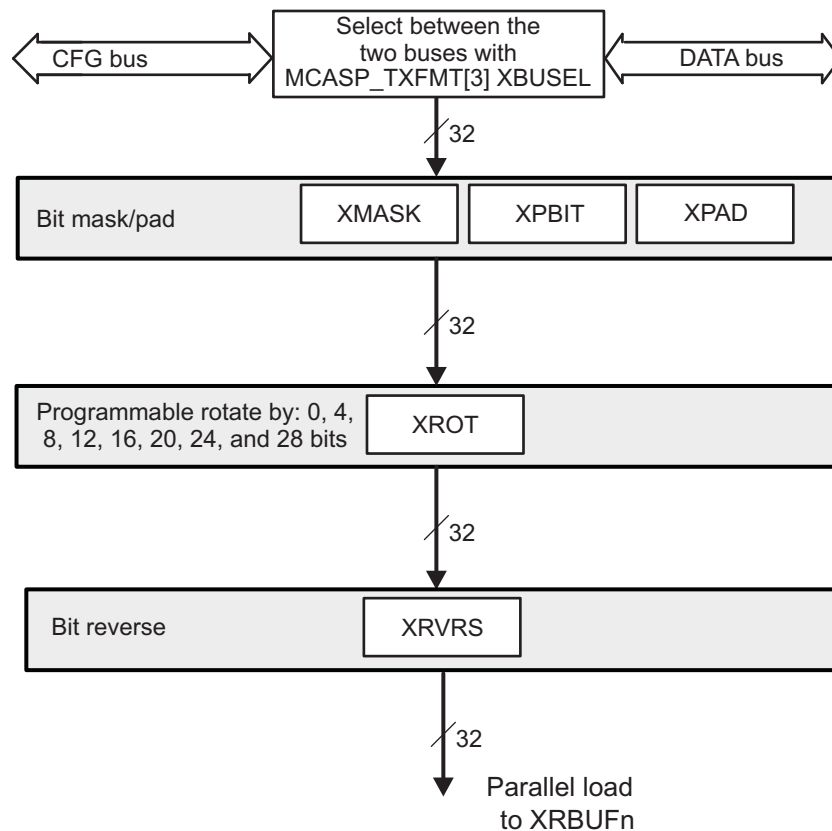

- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB
  - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the bitstream format register - `MCASP_TXFMT`:

- `XRVRS`: bit reverse (1) or no bit reverse (0)
- `XROT`: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- `XSSZ`: transmit slot size of 8, 12, 16, 20, 24, 28, or 32 bits

**Figure 24-124. Transmit Format Unit**

mcasp-017

As shown in [Figure 24-124](#), the data to the transmit format unit can come from the configuration port (CFG) or the data port (DATA). The selection is made through the `MCASP_TXFMT[3] XBUSEL` bit. According to port type selected, data transfer has different behaviour. For more details, refer to the [Section 24.6.4.10.1.3, Transfers Through the DATA Port](#), and [Section 24.6.4.10.1.4, Transfers Through the Configuration \(CFG\) Bus](#).

In the transmit format unit (TFU), the input data bits are first masked-off with the `MCASP_TXMASK[31:0] XMASK` contents. The masked data is then right-rotated to `MCASP_TXFMT[2:0] XROT` positions, to produce the output word for a TDM- or DIT- transmission.

The bit mask stage includes a full 32-bit mask register, allowing selected individual bits to pass through the stage unchanged or be masked off.

#### 24.6.4.4.1.1 TDM Mode Transmission Data Alignment Settings

The TDM-mode transmission settings are relevant for I2S-protocol and protocols using more than 2 TDM-slots.

`XSSZ` should always be programmed to match the slot size of the serial stream.

**NOTE:** Note that, TDM word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the XROT field.

The [Table 24-423](#) show the XRVRS and XROT fields for each serial format and for both integer and Q31 fractional internal representations.

The [Table 24-423](#) assumes that all slot size (SLOT in [Table 24-423](#)) and word size (WORD in [Table 24-423](#)) options are multiples of 4, since the transmit rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1.

The transmit bit mask/pad unit operates on data as an initial step of the transmit format unit, and the data is aligned in the same representation as it is written to the transmitter by the MPU or DSP (typically Q31 or integer).

**Table 24-423. McASP TFU TDM Mode Settings**

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_TXFMT bits	
			XROT <sup>(1)</sup>	XRVRS
MSB first <sup>(2)</sup>	Left aligned	Q31 fraction	0	1
MSB first	Right aligned	Q31 fraction	SLOT - WORD	1
LSB first	Left aligned	Q31 fraction	32 - WORD	0
LSB first	Right aligned	Q31 fraction	32 - SLOT	0
MSB first <sup>(2)</sup>	Left aligned	Integer	WORD	1
MSB first	Right aligned	Integer	SLOT	1
LSB first	Left aligned	Integer	0	0
LSB first	Right aligned	Integer	(32 - (SLOT - WORD)) % 32	0

<sup>(1)</sup> WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

<sup>(2)</sup> To transmit in I2S format, select MSB first, left aligned, and also select XDADLY = 01 (1 bit delay)

#### 24.6.4.4.1.2 DIT Mode Transmission Data Alignment Settings

In case of a DIT-mode (S/PDIF protocol ) transmission, while left-aligned Q31 data should be right-rotated to a multiple by 4 positions, no right-rotation is required for a right-aligned Q31 data. Because this is a rotation process, not a shifting process, bit 0 gets shifted back into bit 31 during the process.

The [MCASP\\_TXFMT\[17:16\]](#) XDADLY bit field must be set to a 0-bit delay (0x0 value).

For left-aligned Q31 data, the following transmit format unit settings process the data into right-aligned data, ready for transmission:

- [MCASP\\_TXFMT\[2:0\]](#) XROT =
  - 0x2 (rotate right by 8 bits) - for a 24-bit output audio data
  - 0x3 (rotate right by 12 bits) - for a 20-bit output audio data
  - 0x4 (rotate right by 16 bits) - for a 16-bit output audio data
- [MCASP\\_TXFMT\[15\]](#) XRVRS = 0x0 – Bit reversal is not enabled; the McASP naturally transmits and receives in a LSB-first order.
- [MCASP\\_TXMASK\[32\]](#) XMASK = 0xFFFFFFFF00 – 0xFFFF0000
- [MCASP\\_TXFMT\[14:13\]](#) XPAD = 0x0 (Pad extra bits with 0s.)

For right-aligned data, the following transmit format unit settings process the data into right-aligned audio data ready for transmission:

- [MCASP\\_TXFMT\[2:0\]](#) XROT = 0x0 (rotate right by 0 bits regardless of the audio word length)

- **MCASP\_TXFMT**[15] XRVR = 0x0 – Bit reversal is not enabled; the McASP naturally transmits and receives in a LSB-first order.
- **MCASP\_TXMASK**[32] XMASK = 0x00FFFFFF – 0x0000FFFF
- **MCASP\_TXFMT**[14:13] XPAD = 0x0 (Pad extra bits with 0s.)

The example settings provided in [Table 24-424](#) should be applied to McASP in cases of DIT-transmitting a Q31 data as a 24-bit, 20-bit and 16-bit left- or right- aligned audio word, respectively. Note that the listed settings let the McASP TFU preserve the most significant bits and cut only the LSBs of the original Q31 CPU data:

**Table 24-424. McASP TFU DIT-Mode Example Settings**

Output Audio Word Alignment	Audio Word Length	Right-rotation (multiple of 4-bit positions)	XMASK	XROT
LEFT	16	16	0xFFFF0000	0x4
LEFT	20	12	0xFFFF0000	0x3
LEFT	24	8	0xFFFF0000	0x2
RIGHT	16	0	0x0000FFFF	0x0
RIGHT	20	0	0x0000FFFF	0x0
RIGHT	24	0	0x0000FFFF	0x0

Assuming that a Q31 data word 0xFA5AFxxx (where x-marked nibbles of the data are applied as padding bits of the word) is generated by MPU on the McASP CFG (peripheral) port. To transmit a left-aligned 20-bit version of same word, preserving the MSBs, according to the [Table 24-424](#), the user must set XMASK=0xFFFF0000, and to select a right-rotation to 12 positions (XROT=0x3).

- After applying 0-s (XPAD=0) as masking-off bits at the first TFU stage, word is transformed to the word 0xFA5AF000.
- After a rotation by 12 positions to the right is performed in TFU, the 20-bit output word obtained is: 0x000FA5AF. Thus the word gets ready for transmission being mapped with its LS-bit as bit 8 and its MS-bit as bit 27 within a S/PDIF bitstream. This word is shifted in a LSB-to-MSB order (XRVR = 0x0) out of the XRSR register during a DIT-transmission.

Assuming that a right-aligned Q31 data word - 0x yyyyE4B4 is generated by software on the McASP CFG (peripheral) port (with the presumption that y-marked nibbles of the input data are applied as padding bits). To transmit a right-aligned 16-bit version of same word, preserving the MSBs, according to the table McASP TFU Example Settings, user is supposed to set XMASK=0x0000FFFF, and to select right-rotation to 0 positions (XROT=0x0).

- After masking-off with 0s at first TFU stage, word is transformed to 0x0000E4B4.
- Since no rotation is applied, the 16-bit output word obtained is actually the one obtained in the masking stage – 0x0000E4B4.

The above examples use internal representation in integer and Q31 notation, but other fractional notations are also possible.

#### 24.6.4.4.2 Receive Format Unit

The McASP receive formatting unit consists of three stages:

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB first or LSB first)

[Figure 24-125](#) shows the receive format unit (RFU).

**Figure 24-125. Receive Format Unit**

mcasp-018

The McASP receiver supports serial formats of:

- Slot or time slot size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size  $\leq$  Slot size
- Alignment when more bits are available per slot than bits per word within the slot, then:
  - Left aligned = word shifted first, remaining bits are pad
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB
  - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the receive bitstream format register - [MCASP\\_RXFMT](#):

- RRVRS: bit reverse (1) or no bit reverse (0)
- RROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- RSSZ: receive slot size of 8, 12, 16, 20, 24, 28, or 32 bits

As shown on [Figure 24-125](#), the data processed in the RFU can be output to host CPU through the configuration port (CFG) or the data port (DATA). The selection is made through the [MCASP\\_RXFMT\[3\] RBUSEL](#) bit. According to port type selected, data transfer has different behaviour. For more details, refer to the [Section 24.6.4.10.1.3, Transfers Through the DATA Port](#), and [Section 24.6.4.10.1.4, Transfers Through the Configuration \(CFG\) Bus](#).

#### 24.6.4.4.2.1 TDM Mode Reception Data Alignment Settings

RSSZ should always be programmed to match the slot size of the serial stream.

**NOTE:** Note that the word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the RROT field.

Table 24-425 shows the RRVRS and RROT fields for each serial format and for both integer and Q31 fractional internal representations.

**Table 24-425. McASP RFU Settings**

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_RXFMT bits	
			RROT <sup>(1)</sup>	RRVRS
MSB first <sup>(2)</sup>	Left aligned	Q31 fraction	SLOT	1
MSB first	Right aligned	Q31 fraction	WORD	1
LSB first	Left aligned	Q31 fraction	(32 - (SLOT - WORD)) % 32	0
LSB first	Right aligned	Q31 fraction	0	0
MSB first <sup>(2)</sup>	Left aligned	Integer	SLOT - WORD	1
MSB first	Right aligned	Integer	0	1
LSB first	Left aligned	Integer	32 - SLOT	0
LSB first	Right aligned	Integer	32 - WORD	0

<sup>(1)</sup> WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

<sup>(2)</sup> To receive in I2S format, select MSB first, left aligned, and also select RDATDLY = 01 (1 bit delay)

The Table 24-425 assumes that all slot size and word size options are multiples of 4; since the receive rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be received in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1. The receive bit mask/pad unit operates on data as the final step of the receive format unit (see Figure 24-125), and the data is aligned in the same representation as it is read from the receiver (typically Q31 or integer).

#### 24.6.4.5 State-Machines

The receive and transmit sections have independent state machines.

Each state-machine controls the interactions between the various units in the McASP Rx and Tx sections, respectively. In addition, each state-machine keeps track of error conditions and serial port status. No serial transfers can occur until the RX/TX state-machine is released from reset.

The transmit state-machine is controlled by the transmit bitstream format register (MCASP\_TXFMT) and it reports the McASP status and error conditions in the transmitter status register (MCASP\_TXSTAT).

Similarly, the receive state-machine is controlled by the receive bitstream format register (MCASP\_RXFMT) and it reports the McASP status and error conditions in the receiver status register (MCASP\_RXSTAT).

#### 24.6.4.6 TDM Sequencers

There are separate TDM sequencers for the transmit section and the receive section. Each TDM sequencer keeps track of the slot count. In addition, the TDM sequencer checks the bits of MCASP\_RXTDM/MCASP\_TXTDM and determines if the McASP should receive/transmit in that time slot.

There are two possibilities for a slot: The McASP either performs Rx/Tx operations during the time slot (transmit/receive bit is active), or the McASP skips Rx/Tx operations during the time slot (transmit/receive bit is inactive). In the latter case, no transfers between the XRBUF and XRSR registers in the serializer would occur during that time slot.

In addition, during time of inactive slots, the serializers programmed as transmitters place their data output pins - AXRn in a predetermined state - logic low, high, or high impedance (tri-stated) as programmed in each serializer control register `MCASP_XRSRCTLn[3:2]` DISMOD. Refer also to [Section 24.6.4.9.2.1, TDM Time Slots Generation and Processing](#), for details on how DMA event or interrupt generations are handled during inactive time slots in TDM mode.

**In case of a DIT-transmission (S/PDIF transfers):** the time division multiplexing (TDM) sequencer is used to count the 384 subframes (slots) in the DIT block. If currently transmitting slot 1, slot 2 (next value of the TDM slot counter) should be used during the encode phase to select the appropriate C, V, and U bit, because the data encoded and written to a `MCASP_TXBUFn` register during the current time slot (slot 1) is actually shifted out on the next time slot.

The transmit TDM sequencer is controlled by the `MCASP_TXTDM` register and reports the current transmit slot to the `MCASP_TXTDMSLOT[9:0]` XSLOT CNT bit field.

#### 24.6.4.7 McASP Software Reset

The McASP can be put into reset through the global transmit and receive control register (`MCASP_GBLCTL`). A valid serial clock must be supplied to the McASP to assert the software reset bits in the `MCASP_GBLCTL` register.

#### 24.6.4.8 McASP Power Management

[Table 24-426](#) describes power-management features available to the McASP.

**Table 24-426. Local Power-Management Features**

Feature	Registers	Description
Slave idle modes	<code>PWRIDLESYSCONFIG[1:0]</code> <code>IDLE_MODE</code>	Force-idle, no-idle, and smart-idle modes are available.

#### CAUTION

No wakeup schema is supported for the McASP. To ensure a correct behavior after enabling McASP at device PRCM level, the user software is strongly recommended to choose *No Idle* mode, setting `PWRIDLESYSCONFIG[1:0]` `IDLE_MODE` to 0x1. Before disabling McASP at device PRCM level, user software is strongly recommended to choose a *Smart-Idle* mode, setting `PWRIDLESYSCONFIG[1:0]` `IDLE_MODE` to 0x2.

#### 24.6.4.9 Transfer Modes

##### 24.6.4.9.1 Burst Transfer Mode

The McASP supports a burst transfer mode, which is useful for nonaudio data such as passing control information between two processors. Burst transfer mode uses a synchronous serial format similar to the TDM mode. The frame sync generation is not periodic or time-driven as in TDM mode, but data driven, and the frame sync is generated for each data word transferred.

When operating in burst frame sync mode (see [Figure 24-126](#)), as specified for transmit (`MCASP_TXFMCTL[15:7] = 0`) and receive (`MCASP_RXFMCTL[15:7]` RMOD = 0), one slot is shifted for each active edge of the frame sync signal that is recognized. Additional clocks after the slot and before the next frame sync edge are ignored.

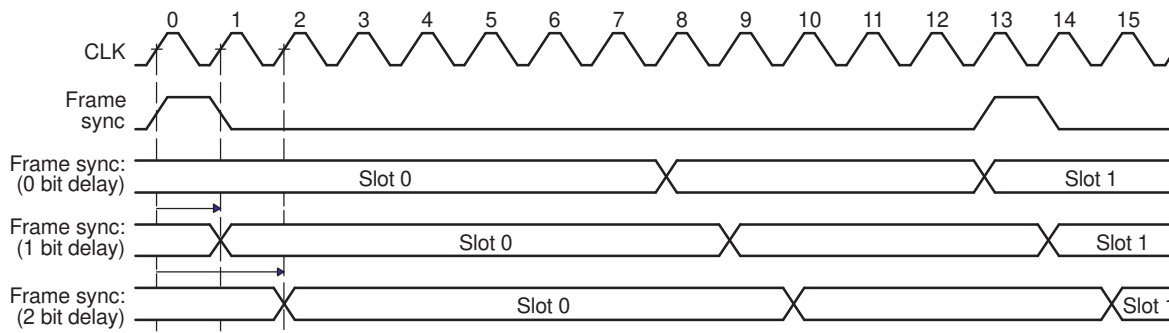

In burst frame sync mode, the frame sync delay may be specified as 0, 1, or 2 serial clock cycles. This is the delay between the frame sync active edge and the start of the slot. The frame sync signal lasts for a single bit clock duration (`MCASP_RXFMCTL[4]` FRWID = 0, `MCASP_TXFMCTL[4]` FXWID = 0).

For transmit, when generating the transmit frame sync internally, the frame sync begins when the previous transmission has completed and when all the XBUF<sub>n</sub> (for every serializer set to operate as a transmitter) has been updated with new data.

For receive, when generating the receive frame sync internally, frame sync begins when the previous transmission has completed and when all the RBUF<sub>n</sub> (for every serializer set to operate as a receiver) has been read.

**Figure 24-126. Burst Frame Sync Mode**

The control registers must be configured as follows for the burst transfer mode. The burst mode specific bit fields are in bold face:

- **MCASP\_PFUNC**: The clock, frame, data pins must be configured for McASP function.
- **MCASP\_PDIR**: The clock, frame, data pins must be configured to the direction desired.
- **MCASP\_PDOUT**, **MCASP\_PDIN**, **MCASP\_PDSET**, **MCASP\_PDCLR**: Not applicable. Leave at default.
- **MCASP\_GBLCTL**: Follow the initialization sequence in [Section 24.6.5.1.2, McASP Global Initialization](#), to configure this register.
- **MCASP\_AMUTE**: Not applicable. Leave at default.
- **MCASP\_LBCTL**: If loopback mode is desired, configure this register according to [Section 24.6.4.14 Loopback Modes](#), otherwise leave this register at default.
- **MCASP\_TXDITCTL**: DITEN must be left at default 0 to select non-DIT mode. Leave the register at default.
- **MCASP\_RXMASK/MCASP\_TXMASK**: Mask desired bits according to [Section 24.6.4.4, Format Units](#).
- **MCASP\_RXFMT/MCASP\_TXFMT**: Program all fields according to data format desired. See [Section 24.6.4.4, Format Units](#).
- **MCASP\_RXFMT/MCASP\_TXFMT**: Clear RMOD/XMOD bits to 0 to indicate burst mode. Clear FRWID/FXWID bits to 0 for single bit frame sync duration. Configure other fields as desired.
- **MCASP\_ACLKRCTL/MCASP\_ACLKXCTL**: Program all fields according to bit clock desired. See [Section 24.6.4.2, McASP Clock and Frame-Sync Configurations](#).
- **MCASP\_AHCLKRCTL/MCASP\_AHCLKXCTL**: Program all fields according to high-frequency clock desired. See [Section 24.6.4.2, McASP Clock and Frame-Sync Configurations](#).
- **MCASP\_RXTDM/MCASP\_TXTDM**: Program RTDMS0/XTDMS0 to 1 to indicate one active slot only. Leave other fields at default.
- **MCASP\_EVTCTLR/MCASP\_EVTCTLX**: Program all fields according to interrupts desired.
- **MCASP\_RXCLKCHK/MCASP\_TXCLKCHK**: Not applicable. Leave at default.
- **MCASP\_XRSRCTL<sub>n</sub>**: Program SRMOD to inactive/transmitter/receiver as desired. DISMOD is not applicable and should be left at default.
- **MCASP\_DITCSRA<sub>i</sub>**, **MCASP\_DITCSRB<sub>i</sub>**, **MCASP\_DITUDRA<sub>i</sub>**, **MCASP\_DITUDRB<sub>i</sub>**: Not applicable. Leave at default.

#### 24.6.4.9.2 Time-Division Multiplexed (TDM) Transfer Mode

The McASP time-division multiplexed (TDM) transfer mode supports the TDM format discussed in [Section 24.6.2.2.3](#).

Transmitting data in the TDM transfer mode requires a minimum set of pins:

- ACLKX - transmit bit clock
- AFSX - transmit frame sync (or commonly called left/right clock)
- One or more serial data pins, AXRn, whose serializers are configured to transmit

For more details on McASP transmitting serializers clock and frame sync options, refer to the [Section 24.6.4.2.1, Transmit Clock](#), and [Section 24.6.4.2.3, Frame-Sync Generator](#).

Similarly, to receive data in the TDM transfer mode requires a minimum set of pins:

- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)
- One or more serial data pins, AXRn, whose serializers are configured to receive

For more details on McASP receiving serializers clock and frame sync options, refer to [Section 24.6.4.2.2, Receive Clock](#), and [Section 24.6.4.2.3, Frame-Sync Generator](#).

The control registers must be configured as follows for the TDM mode. The TDM mode specific bit fields are highlighted in bold:

- **MCASP\_PFUNC**: The clock, frame, data pins must be configured for McASP function.
- **MCASP\_PDIR**: The clock, frame, data pins must be configured to the direction desired.
- **MCASP\_PDOUT**, **MCASP\_PDIN**, **MCASP\_PDSET**, **MCASP\_PDCLR**: Not applicable. Leave at default.
- **MCASP\_GBLCTL**: Follow the initialization sequence is described in the [Section 24.6.5.2, Operational Modes Configuration](#).
- **MCASP\_AMUTE**: Leave this register at default state.
- **MCASP\_LBCTL**: If loopback mode is desired, configure this register according to [Section 24.6.4.14](#), otherwise leave this register at default.
- **MCASP\_TXDITCTL**: DITEN must be left at default 0 to select TDM mode (transmitters only).
- **MCASP\_RXMASK/MCASP\_TXMASK**: Mask desired bits according to [Section 24.6.4.4, Format Units](#).
- **MCASP\_RXFMT/MCASP\_TXFMT**: Program all fields according to data format desired. See the [Section 24.6.4.4, Format Units](#).
- **MCASP\_RXFMCTL/MCASP\_TXFMCTL**: Set RMOD/XMOD bits to (0x2 - 0x20) for Rx/Tx (2- 32 slots) TDM mode. In addition, set RMOD to 0x180 if 384-slot TDM stream has to be received by McASP. Configure other fields as desired.
- **MCASP\_ACLKRCTL/MCASP\_ACLKXCTL**: Program all fields according to bit clock desired. For more information, refer to [Section 24.6.4.2](#).
- **MCASP\_AHCLKRCTL/MCASP\_AHCLKXCTL**: Program all fields according to high-frequency clock desired. For more details, refer to [Section 24.6.4.2](#).
- **MCASP\_RXTDM/MCASP\_TXTDM**: Program all fields according to the time slot characteristics desired.
- **MCASP\_EVTCTLX**: Program all fields according to transmit interrupts desired.
- **MCASP\_RXCLKCHK/MCASP\_TXCLKCHK**: Program all fields according to clock checking desired.
- **MCASP\_XRSRCTLn**: Program all fields according to serializer operation desired.

---

**NOTE:** The **MCASP\_DITCSRAi**, **MCASP\_DITCSRBi**, **MCASP\_DITUDRAi**, **MCASP\_DITUDRBi** (i=0 to 5) settings are NOT applicable in TDM transfer modes. They have to be kept at their default values.

---

#### 24.6.4.9.2.1 TDM Time Slots Generation and Processing

TDM mode on the McASP can extend to support multiprocessor applications, with up to 32 time slots per frame. For each of the time slots, the McASP may be configured to participate or to be inactive by configuring **MCASP\_TXTDM** and/or **MCASP\_RXTDM** registers.

The TDM sequencer (separate ones for transmit and receive) functions in this mode. The TDM sequencer counts the slots beginning with the frame sync. For each slot, the TDM sequencer checks the respective bit in either `MCASP_TXTDM` or `MCASP_RXTDM` to determine if the McASP transmits/receives in that time slot.

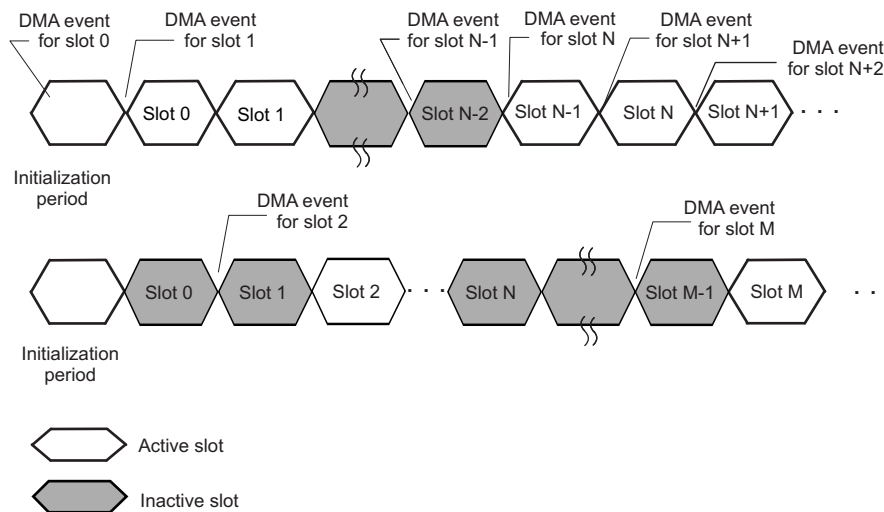

**NOTE:** If a `MCASP_TXTDM/MCASP_RXTDM` bit defines an active slot (number of slot matches the bit position), the McASP functions normally during that time slot; otherwise, the McASP is inactive during that time slot; no update to the buffer occurs, and no event is generated. McASP (transmit only) data pins are automatically set to a high-impedance state, 0, or 1 during that slot, as determined by bitfield `MCASP_XRSRCTLn[3:2] DISMOD`.

Figure 24-127 shows when the transmit DMA event - AXEVT is generated. See Section 24.6.4.10.1, *Data Ready Status and Event/Interrupt Generation* for details on data ready and the initialization period indication. The transmit DMA event for an active time slot (slot N) is generated during the previous time slot (slot N - 1), regardless of the previous time slot (slot N - 1) being active or inactive.

During an active transmit time slot (slot N), if the next time slot (slot N + 1) is configured to be active, the copy from `XRBUFn` to `XRSRn` generates the DMA event for time slot N + 1. If the next time slot (slot N + 1) is configured to be inactive, then the DMA event will be delayed to time slot M - 1. In this case, slot M is the next active time slot. The DMA event for time slot M is generated during the first bit time of slot M - 1.

The receive DMA event is generated after data is received in the buffer (looks back in time). If a time slot is disabled, then no data is copied to the buffer for that time slot and no DMA event is generated.

**Figure 24-127. Transmit DMA Event (AXEVT) Generation in TDM Time Slots**

mcasp-019

#### 24.6.4.9.2.2 Special 384-Slot TDM Mode for Connection to External DIR

The McASP receiver also supports a 384 time slot TDM mode (DIR mode), to support S/PDIF receiver ICs whose natural block (block corresponds to McASP frame) size is 384 samples. The receive TDM time slot register (`MCASP_RXTDM`) should be programmed to all 1s during reception of a DIR block. Other TDM functionalities (for example, inactive slots) are not supported (only the slot counter counts the 384 subframes in a block). To receive data in DIR mode, the following pins are typically needed:

- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)
- In this mode, AFSR should be connected to a DIR which outputs a start of block signal, instead of LRCLK
- One or more serial data pins, AXR<sub>n</sub>, whose serializers have been configured to receive
- For this special DIR mode, the control registers can be configured just as for TDM mode, except set

RMOD in [MCASP\\_RXFMCTL](#) to 384 (0x180) to receive 384 time slots

### 24.6.4.9.3 DIT Transfer Mode

The DIT transfer mode of the McASP also supports transmission of audio data in S/PDIF, AES-3, and IEC-60958 formats. These formats are designed to carry audio data between different systems through an optical or coaxial cable. The DIT mode applies only to a serializer configured as transmitter, not as receiver. For a description of the S/PDIF format, see [Section 24.6.2.2.5, S/PDIF Coding Format](#).

#### 24.6.4.9.3.1 Transmit DIT Encoding

When the McASP operates in DIT mode, the data transmitted is output as a biphasemark encoded bitstream, with preamble, channel status, user data, validity, and parity automatically stuffed into the bitstream by the McASP. The McASP includes separate validity bits for even/odd subframes and two 384-bit RAM modules to hold channel status and user data bits.

---

**NOTE:** The transmit TDM time slot register ([MCASP\\_TXTDM](#)) should be programmed to all 1s during DIT mode. TDM functionality is not supported in DIT mode, except that the TDM slot counter counts the DIT subframes.

---

To transmit data in DIT mode, the following pins are typically required:

- AHCLKX – transmit high-frequency master clock (The internal clock source can be used instead.)
- One serial data pin (AXRn) of a serializer n configured to transmit.

For DIT Mode Transmission Data Alignment Settings see [Section 24.6.4.4.1.2](#).

If the McASP is configured to transmit in the DIT mode on more than one serial data pin, the bit streams on all pins will be synchronized. In addition, although they will carry unique audio data, they will carry the same channel status, user data, and validity information.

The actual 24-bit audio data must always be in bit positions 23–0 after passing through the first three stages of the transmit format unit.

#### 24.6.4.9.3.2 Transmit DIT Clock and Frame-Sync Generation

The DIT transmitter works only in the following configuration:

- In the transmit frame control register ([MCASP\\_TXFMCTL](#)):
  - Internally generated transmit frame sync, FSXM = 1
  - Rising-edge frame sync, FSXP = 0
  - Bit-width frame sync, FXWID = 0
  - 384-slot TDM, XMOD = 1 1000 0000b
- In the transmit clock control register ([MCASP\\_ACLKXCTL](#)), ASYNC = 1
- In the transmit bitstream format register ([MCASP\\_TXFMT](#)), XSSZ = 1111 (32-bit slot size)

All combinations of AHCLKX and ACLKX are supported.

The following summarizes the register configurations required for DIT mode. DIT mode-specific bit fields are in bold face:

- [MCASP\\_PFUNC](#): The data pin - AXRn must be configured for McASP function. If AHCLKX is used, it must also be configured for McASP function. Other pins can be configured to function as GPIOs, if desired.
- [MCASP\\_PDIR](#): The data pin must be configured as output. If internal clock source AUXCLK is used as the reference clock, it may be output as the AHCLKX device level signal by configuring AHCLKX pin as an output.
- [MCASP\\_GBLCTL](#): Global initialization
- [MCASP\\_AMUTE](#): Leave this register at default state.
- [MCASP\\_TXDITCTL](#): The DITEN bit must be set to 0b1 to enable DIT mode. Configure other bits as

desired.

- **MCASP\_TXMASK**: Mask the desired bits, depending upon left-aligned or right-aligned internal data.
- **MCASP\_TXFMT**: XDATDLY = 0. XRVRs = 0. XPAD = 0. XSSZ = Fh (32-bit slot). XBUSEL = configured as desired. The XROT bit is configured, as described in the [Section 24.6.4.4.1.2](#).
- **MCASP\_TXFMCTL**: Configure the bits according to former discussions.
- **MCASP\_ACLKXCTL**: ASYNC = 1. Program the CLKXDIV bits to obtain the bit clock rate desired. CLKXM = 1.
- **MCASP\_AHCLKXCTL**: Program the HCLKXDIV bits to obtain the high-frequency bit clock rate desired.
- **MCASP\_TXTDM**: Set to FFFF FFFFh for all active slots for DIT transfers.
- **MCASP\_EVTCTLX**: Program all fields according to the interrupts desired.
- **MCASP\_TXCLKCHK**: Program all fields according to the clock checking desired.
- **MCASP\_XRSRCTLn**: Set SRMOD = 1 (transmitter) for the DIT pins.
- **MCASP\_DITCSRAi** and **MCASP\_DITCSRBi**: Program the channel status bits as desired.
- **MCASP\_DITUDRAi** and **MCASP\_DITUDRBi**: Program the user data bits as desired.

---

**NOTE:** In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to 2 serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for TDM (I2S) mode, due to the need to generate Biphase Mark Encoded Data - see [Section 24.6.2.2.5.1](#)).

---

#### 24.6.4.9.3.3 DIT Channel Status and User Data Register Files

The channel status registers (**MCASP\_DITCSRAi** and **MCASP\_DITCSRBi**) and user data registers (**MCASP\_DITUDRAi** and **MCASP\_DITUDRBi**) are not double-buffered. Typically, programmers use one of the synchronizing interrupts, such as the last slot, to create an event at a safe time so the register may be updated. In addition, the software reads the transmit TDM slot counter to determine which word of the register is being used.

It is a software requirement to avoid writing to the word of user data and channel status that are being used to encode the current time slot; otherwise, it is undetermined whether old or new data is used to encode the bitstream.

The DIT subframe format is defined in [Section 24.6.2.2.5.2](#), *S/PDIF Subframe Format*. The channel status information (C) and user data (U) are defined in the following DIT control registers:

- **MCASP\_DITCSRA0** to **MCASP\_DITCSRA5**: The 192 bits in these six registers contain the channel status information for the left channel within each frame.
- **MCASP\_DITCSR0** to **MCASP\_DITCSR5**: The 192 bits in these six registers contain the channel status information for the right channel within each frame.
- **MCASP\_DITUDRA0** to **MCASP\_DITUDRA5**: The 192 bits in these six registers contain the user data information for the left channel within each frame.
- **MCASP\_DITUDRB0** to **MCASP\_DITUDRB5**: The 192 bits in these six registers contain the user data information for the right channel within each frame.
- The S/PDIF block format is shown in [Figure 24-117](#). There are 192 frames within a block (frame 0 to frame 191). There are two subframes within each frame (subframes 1 and 2 for the left and right channels, respectively).

The channel status and user data information sent on each subframe is summarized in [Table 24-427](#).

**Table 24-427. Channel Status and User Data for Each DIT Block**

#### 24.6.4.10 Data Transmission and Reception

The McASP is serviced by writing data to the [MCASP\\_TXBUF<sub>n</sub>](#) registers for transmit operations, and by reading data from the [MCASP\\_RXBUF<sub>n</sub>](#) registers for receive operations. The McASP sets status flags and notifies the software whenever data is ready to be serviced. The [Section 24.6.4.10.1, Data Ready Status and Event/Interrupt Generation](#), discusses data-ready status in details.

The McASP transmit/receive XRBUF<sub>n</sub> buffer can be accessed through one of the two peripheral ports of the device:

- DATA port: This port is dedicated to DMA initiated data transfers on the device for McASP transmit (Tx) purposes.

- Configuration bus (CFG): The configuration bus- CFG port is used for peripheral configuration control and receive/transmit data transfers initiated by the host CPU in the device.

[Section 24.6.4.10.1.3](#), *Transfers Through the Data Port (DATA)*, and [Section 24.6.4.10.1.4](#), *Transfers Through the Configuration Bus (CFG)*, discuss how to perform transfers through the data port (DATA) and the configuration port (CFG), respectively.

A device CPU and DMA usages are discussed in [Section 24.6.4.10.1.5](#), *Using the device CPUs for McASP Servicing*, and [Section 24.6.4.10.1.6](#), *Using the DMA for McASP Servicing*, respectively.

McASP DATA port allows DMAs to access the McASP transmit buffer more efficiently on the L3\_MAIN-interconnect or L4\_PER2 interconnect, using burst transfers. The physical addresses to access these registers are listed in [Section 24.6.6.2.5](#).

## 24.6.4.10.1 Data Ready Status and Event/Interrupt Generation

### 24.6.4.10.1.1 Transmit Data Ready

The transmit data ready flag - XDATA in the [MCASP\\_TXSTAT](#) register reflects the data ready status of XRBUF<sub>n</sub> buffers for all of the active slot transmitting serializers. The XDATA flag is set whenever data is transferred from a transmitting serializer buffer - XRBUF<sub>n</sub> to its corresponding XRSR<sub>n</sub> shift register. Thus, the XDATA bit indicates the global event that some of the serializers data buffer - XRBUF<sub>n</sub> is emptied and ready to accept new data from the host (CPU or DMA). The transmit data ready event is individually indicated per serializer in its corresponding control register [MCASP\\_XRSRCTL<sub>n</sub>\[4\]](#) XRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Tx buffer must be serviced (written). When [MCASP\\_TXBUF<sub>n</sub>](#) is written to by the host, the [MCASP\\_XRSRCTL<sub>n</sub>\[4\]](#) XRDY is deasserted to 0b0. As XDATA global flag is an OR-event of all active serializers XRDY flags, it indicates to software the moment, when write service operation has to be initiated by the McASP host (XDATA=0b1). The XRDY flags have to be sequentially scanned by user software to determine which serializer [MCASP\\_TXBUF<sub>n</sub>](#) register has to be currently written. Once all requested [MCASP\\_TXBUF<sub>n</sub>](#) are written, the serializers control XRDY flags are cleared to 0b0. As a consequence, XDATA flag is deasserted to 0b0, to indicate to SW that write operation is completed for all serializers.

The global XDATA flag can be cleared when the [MCASP\\_TXSTAT\[5\]](#) XDATA bit is written to 0b1, or once [MCASP\\_TXBUF<sub>n</sub>](#) registers of all the serializers, that have previously raised their XRDY flags, are written with corresponding active slot data by the host.

Whenever XDATA is set, the AXEVT event is automatically generated on MCASPi\_DREQ\_TX line (if enabled in the [MCASP\\_XEVTCTL](#) register) to notify the DMA of the [MCASP\\_TXBUF<sub>n</sub>](#) empty status. An interrupt - MCASPi\_IRQ\_AXEVT can be also generated if the XDATA interrupt is enabled in the [MCASP\\_EVTCTLX](#) register (for details, see [Section 24.6.4.12.1](#), *Transmit Data Ready Interrupt*).

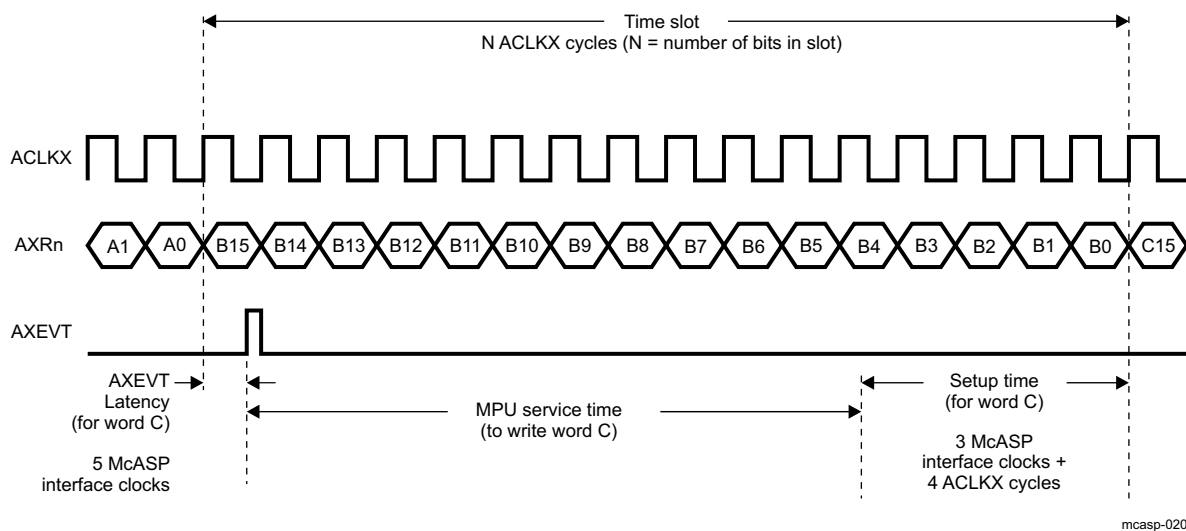

For DMA requests, the McASP does not require that [MCASP\\_TXSTAT](#) be read between DMA events. This means that, even if [MCASP\\_TXSTAT](#) already has the XDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

Because the serializer acts in lockstep, only one DMA event is generated to indicate that the transmit serializer is ready to be written to with new data.

[Figure 24-128](#) shows the timing details of when AXEVT is generated at the McASP boundary. In this example, as soon as the last bit (A0) of word A is transmitted, the McASP sets the XDATA flag and generates an AXEVT event. However, it takes up to five McASP interface clocks (AXEVT latency) before AXEVT is active at the McASP boundary. Upon AXEVT, the CPU can begin servicing the McASP by writing word C into the [MCASP\\_TXBUF<sub>n</sub>](#) (service time). The CPU must write word C into the [MCASP\\_TXBUF<sub>n</sub>](#) within the setup time required by the McASP (setup time).

The maximum service time (see [Figure 24-128](#)) can be calculated as:

$$\text{Service Time} = \text{Time Slot} - \text{AXEVT Latency} - \text{Setup Time}$$

**Figure 24-128. MPU Service Time Upon Transmit DMA Event (AXEVT)**

#### 24.6.4.10.1.2 Receive Data Ready

Similarly, the receive data ready flag - RDATA in the [MCASP\\_RXSTAT](#) register reflects the data ready status of XRBUF<sub>n</sub> buffers for all of the active slot receiving serializers. The RDATA flag is set whenever data is transferred from a receiving serializer shift register XRSR<sub>n</sub> to its corresponding XRBUF<sub>n</sub> data buffer. Thus, the RDATA bit indicates the global event that some of the receivers data buffer - RXBUF<sub>n</sub> already contains received data (i.e. a buffer is full) and is ready to transfer it to the host (MPU/DSP). The receive data ready event is individually indicated per serializer in its corresponding control register [MCASP\\_XRSRCTL<sub>n</sub>](#) [5] RRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Rx buffer must be serviced (read). When [MCASP\\_RXBUF<sub>n</sub>](#) is read from the host, the [MCASP\\_XRSRCTL<sub>n</sub>](#) [5] RRDY is deasserted to 0b0. As RDATA global flag is an OR-event of all active serializers RRDY flags, it indicates to software the moment, when read service operation has to be initiated by the McASP host (RDATA=0b1). The RRDY flags have to be sequentially scanned by user software to determine which serializer [MCASP\\_RXBUF<sub>n</sub>](#) register has to be currently read. Once all requested [MCASP\\_RXBUF<sub>n</sub>](#) are read, the serializers control RRDY flags are cleared to 0b0. As a consequence, RDATA flag is deasserted to 0b0, to indicate to SW that read operation is completed for all serializers.

The global RDATA flag can be cleared when the [MCASP\\_RXSTAT](#)[5] RDATA bit is written to 0b1, or once [MCASP\\_RXBUF<sub>n</sub>](#) registers of all the serializers, that have previously raised their RRDY flags, are read by the host.

Whenever RDATA is set, the AREVT event is automatically generated on MCASPi\_DREQ\_RX line (if enabled in the [MCASP\\_REVTCTL](#) register) to notify the DMA of the [MCASP\\_RXBUF<sub>n</sub>](#) full status. An interrupt - MCASPi\_IRQ\_AREVT can be also generated if the RDATA interrupt is enabled in the [MCASP\\_EVTCTLR](#) register (for details, see [Section 24.6.4.12.1, Receive Data Ready Interrupt](#)).

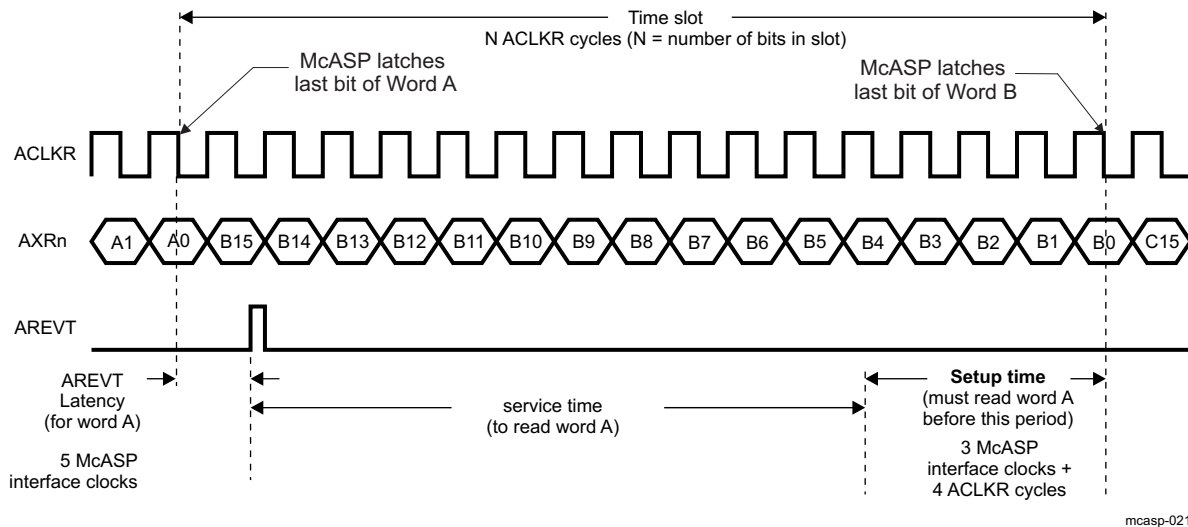

[Figure 24-129](#) shows the timing details of when AREVT event is generated at the McASP boundary. In this example, as soon as the last bit (bit A0) of Word A is received, the McASP sets the RDATA flag and generates an AREVT event. However, it takes up to five McASP interface clocks (AREVT Latency) before AREVT is active at the McASP boundary. Upon AREVT, the CPU can begin servicing the McASP by reading Word A from the [MCASP\\_RXBUF<sub>n</sub>](#) (service time). The CPU must read Word A from the [MCASP\\_RXBUF<sub>n</sub>](#) register no later than the setup time required by the McASP (Setup Time).

The maximum service time (see [Figure 24-129](#)) can be calculated as:

$$\text{Service Time} = \text{Time Slot} - \text{AREVT Latency} - \text{Setup Time}$$

Figure 24-129. CPU Service Time Upon Receive Event (AREVT)

mcasp-021

### 24.6.4.10.1.3 Transfers Through the Data Port (DATA)

#### CAUTION

To perform internal transfers through the DATA port, clear the XBUSEL/RBUSEL bit to 0b0 in the [MCASP\\_TXFMT/MCASP\\_RXFMT](#) register, respectively. Failure to do so may result in software malfunction.

**NOTE:** McASP1, McASP2, and McASP3, whose data ports are accessible directly via L3\_MAIN, do not support FIFO/constant addressing modes. Incrementing transfers must be used instead.

In a typical McASP transfer scenario, the DMA Controller write accesses the XRBUF<sub>n</sub> transmit buffer through the McASP data port (DATA) on L3\_MAIN Interconnect for McASP1/2/3 and on L4\_PER2 Interconnect for McASP4/5/6/7/8. CPU hosts can access both XRBUF<sub>n</sub> transmit and receive data buffers on their corresponding DATA port address via DATA port corresponding address. To perform transfers through the DATA port, simply have the DMA Controller write the McASP Tx buffer through Interconnect DATA port location. Refer to [Section 24.6.6.2.5](#). Although the transfer is passed through an integrated AFIFO transmit/receive buffer, the host (DMA or CPU) must follow the described below procedure to access the data buffers of each serializer, regardless the AFIFO is enabled or disabled. The AFIFO operation is described in [Section 24.6.4.11](#).

For accesses through the DATA port, the DMA/CPU services all the serializers through accessing only a single address. In addition, as can be seen in [Section 24.6.6.2.5](#), the same physical DATA port address is used regardless of a read or write access is performed. The McASP automatically cycles through the active slot transmitting/receiving serializers, internally generating the appropriate offsets.

**NOTE:** DATA port allows the DMA/CPU to automatically access only the data buffers. There is no way for DMA/CPU to access the McASP configuration registers addressing their corresponding McASP DATA port.

For transmit operations through the DATA port, the host must always write to the same transmit buffer DATA port address (which is same than the receive buffer DATA port address) to service all of the active slot transmitting serializers. Regardless of McASP serializer 0 being configured inactive or active, the user software must always configure the destination address to match the DATA port location of TXBUF buffer (See [Section 24.6.6.2.5](#)).

In addition, the DMA/CPU must write the buffers of all transmitting serializers in incremental (although not necessarily consecutive) order. For example, if only serializers 1 and 3 are set up as active transmitters, the DMA/CPU should write to the same transmit buffer DATA port address twice - first data for serializer 1 and second data for serializer 3 upon each transmit data ready event. This exact servicing order must be followed so that data appears in the appropriate serializers.

---

**NOTE:** For write transfers through McASP DATA port it is preferable to use DMA on corresponding Interconnect. This is because DMAs initiated traffic gets better advantage of the burst transfers supported by DATA port.

---

For receive operations through the DATA port, the DMA/CPU must always read from the same receive buffer DATA port address (which is same than the transmit buffer DATA port address) to service all of the active slot receiving serializers. Regardless of McASP serializer 0 being configured inactive or active, the user software must always configure the DMA/CPU source address to match the DATA port location of RXBUF buffer (See [Section 24.6.6.2.5](#)).

In addition, reads from the receive buffer for all active slot receiving serializers through the Rx DATA port return data in incremental (although not necessarily consecutive) order. For example, if serializers 0, 1 and 3 are set up as active receivers, the MPU should read from the same receive buffer DATA port address three times to obtain data for serializers 0, 1 and 3 in this exact order, upon each receive data ready event.

---

**NOTE:** To service a serializer for a transmit or receive operation through the McASP DATA port, the initiator always writes (preferably DMA) and reads from the same address (refer to [Section 24.6.6.2.5](#)), respectively.

---

See [Section 24.6.6.2.5, McASP\\_DATA Register Summary](#), for more details about XRBUF<sub>n</sub> buffer physical address corresponding to the McASP DATA port on:

- Main Interconnect (L3\_MAIN or L4\_PER2)

---

**NOTE:** When transmitting through the DATA port, the DMA/CPU must write data (at the same address) to each serializer configured as *active* (active slot selected in [MCASP\\_TXTDM](#)) and *transmit* (Tx enabled in [MCASP\\_XRSRCTLn](#)) within each time slot. Failure to do so results in a buffer underrun condition (see [Section 24.6.4.15.1, Buffer Underrun Error - Transmitter](#)). Similarly, when DMA/CPU receives, data must be read from each serializer configured as *active* (active slot selected in [MCASP\\_RXTDM](#)) and *receive* (Rx enabled in [MCASP\\_XRSRCTLn](#)) within each time slot. Failure to do so results in a buffer overrun condition (see [Section 24.6.4.15.2, Buffer Overrun Error - Receiver](#)).

---

#### 24.6.4.10.1.4 Transfers Through the Configuration Bus (CFG)

##### CAUTION

To perform internal transfers through the configuration bus, set the XBUSEL/RBUSEL bit to 1 in the [MCASP\\_TXFMT/MCASP\\_RXFMT](#) registers, respectively. Failure to do so may result in software malfunction.

---

**NOTE:** McASP1, McASP2, and McASP3, whose data ports are accessible directly via L3\_MAIN do not support FIFO/constant addressing modes. Incrementing transfers must be used instead.

---

In this method, the DMA/CPU accesses the XRBUF<sub>n</sub> transmit or receive buffer through corresponding configuration bus (CFG) address.

The exact XRBUF<sub>n</sub> transmit/receive buffer physical address for any particular serializer is determined by adding the transmit/receive buffer alias register offset for that particular serializer to the base address of McASP CFG port actual for L4\_PER2 accesses. The XRBUF<sub>n</sub> buffer of the n-th serializer configured as a transmitter is aliased - **MCASP\_TXBUF<sub>n</sub>** in the CFG port address space. For example, the XRBUF2 transmit buffer is mapped as the **MCASP\_TXBUF2** register. Similarly, the XRBUF<sub>n</sub> buffer of the n-th serializer configured as a receiver is aliased - **MCASP\_RXBUF<sub>n</sub>** in the CFG port address space. For example, the XRBUF3 receive buffer is mapped as the **MCASP\_RXBUF3** register.

Accessing the XRBUF through the DATA port (see [Section 24.6.4.10.1.3](#)) is different than CFG port accesses because the DATA port access demands the same physical address, regardless of transfer direction or current channel index, while accessing through the peripheral configuration port - CFG, the DMA/CPU must provide the exact **MCASP\_TXBUF<sub>n</sub>** or **MCASP\_RXBUF<sub>n</sub>** address upon accessing n-th serializer TX or RX buffer, respectively. For more details about **MCASP\_TXBUF<sub>n</sub>** and **MCASP\_RXBUF<sub>n</sub>** addresses corresponding to McASP CFG port, see [Section 24.6.6.2.1, MCASP\\_CFG Register Summary](#).

#### **24.6.4.10.1.5 Using a Device CPU for McASP Servicing**

The device CPUs can be used to service the McASP transmit channels through interrupts (upon MCASPi\_IRQ\_AXEVT and MCASPi\_IRQ\_AREVT interrupts). Because these interrupt events are connected to device IRQ\_CROSSBAR module, they could be software mapped to input IRQ lines of any device CPU. Another way to service the transmit and receive channels, a polling of the XDATA bit in the **MCASP\_TXSTAT** register and RDATA bit in the **MCASP\_RXSTAT** register can be performed by device CPUs, respectively. As discussed in [Section 24.6.4.10.1.3, Transfers Through the Data Port \(DATA\)](#), and [Section 24.6.4.10.1.4, Transfers Through the Configuration Bus \(CFG\)](#), the device CPUs can access McASP XRBUF serializer buffer through their corresponding DATA and CFG port locations.

To use the device CPUs to service the McASP through interrupts, the XDATA/RDATA bit must be enabled in the respective **MCASP\_EVTCTLX/MCASP\_EVTCTLR** registers, to generate interrupts MCASPi\_IRQ\_AXEVT/MCASPi\_IRQ\_AREVT to the device CPUs upon data ready

#### **24.6.4.10.1.6 Using the DMA for McASP Servicing**

The typical scenario is to use the DMA to service the McASP transmit and receive logic through the DATA port, although the DMA can also service the McASP through the configuration bus (CFG). The transfer passes through integrated AFIFO transmit/receive buffer. If AFIFO is enabled, DMA requests are collected and fed to a device DMA controller (see [Figure 24-119](#)). The data transfer is managed by the AFIFO according to generated transmit and receive events in the McASP and data is fed to transmit buffers and fetched from receive buffers as described in [Section 24.6.4.11](#). The generation of transmit and receive request is described below. After generation of transmit/receive DMA events from McASP module, these events are collected in AFIFO and on specific AFIFO conditions described in [Section 24.6.4.11](#) the requests (transmit or receive) are forwarded to a DMA controller via MCASPi\_DREQ\_TX and MCASPi\_DREQ\_RX outputs. If the AFIFO is disabled (default state) it is transparent for the McASP module and all request are directly sent to the DMA controller.

**Figure 24-130. DMA Transmit and Receive Event in an Audio Example – One Event**

mcasp-022

In transmit mode, the DMA event - AXEVT (MCASPi\_DREQ\_TX output), which is triggered upon each XDATA transition from 0 to 1, is used to service the McASP TXBUF<sub>n</sub> transmit buffers. In receive mode, the DMA event AREVT (MCASPi\_DREQ\_RX output) which is triggered upon each RDATA transition from 0 to 1, is used to service the McASP RXBUF<sub>n</sub> receive buffers.

Figure 24-130 is an example of an audio system with six audio channels (LF, RF, LS, RS, C and LFE) transmitted or received through the McASP signals - AXR0, AXR1 and AXR2. It shows the points at which events AXEVT/AREVT are triggered.

In Figure 24-130, a Tx DMA event AXEVT is triggered on each time slot. In the example, AXEVT is triggered for each of the transmit audio channel time slot (time slot for channels LF, LS, and C; and time slot for channels RF, RS, LFE). Transmit DMA events are generated automatically upon transmit data ready, provided that DMA TX requests generation is enabled in the MCASP\_XEVTCTL register. Similarly, Rx DMA event AREVT is triggered for each of the receive audio channel time slot. Receive DMA events are generated automatically upon receive data ready, provided that DMA RX requests generation is enabled in the MCASP\_REVTCTL register.

#### 24.6.4.11 McASP Audio FIFO (AFIFO)

The AFIFO contains two FIFOs: one Read FIFO (RFIFO), and one Write FIFO (WFIFO). The RFIFO and the WFIFO are the same size: 64 32-bit Words. To ensure backward compatibility with existing software, both the Read and Write FIFOs are disabled by default. See Figure 24-131 for a high-level block diagram of the AFIFO. The AFIFO may be enabled/disabled and configured via the WFIFOCTL and RFIFOCTL registers. Note that if the Read or Write FIFO is to be enabled, it must be enabled prior to initializing the receive/transmit section of the McASP.

Figure 24-131. McASP Audio FIFO (AFIFO) Block Diagram

mcasp-034

#### 24.6.4.11.1 AFIFO Data Transmission

When the Write FIFO is disabled, transmit DMA requests pass through directly from the McASP to the host/DMA controller. Whether the WFIFO is enabled or disabled, the McASP generates transmit DMA requests as needed; the AFIFO is “invisible” to the McASP. When the Write FIFO is enabled, transmit DMA requests from the McASP are sent to the AFIFO, which in turn generates transmit DMA requests to the host/DMA controller. If the Write FIFO is enabled, upon a transmit DMA request from the McASP, the WFIFO writes WNUMDMA 32-bit words to the McASP if and when there are at least WNUMDMA words in the Write FIFO. If there are not, the WFIFO waits until this condition has been satisfied. At that point, it writes WNUMDMA words to the McASP. (See description for [WFIFOCTL\[7:0\] WNUMDMA](#).) If the host CPU writes to the Write FIFO, independent of a transmit DMA request, the WFIFO will accept host writes until full. After this point, excess data will be discarded. Note that when the WFIFO is first enabled, it will immediately issue a transmit DMA request to the host. This is because it begins in an empty state, and is therefore ready to accept data.

#### 24.6.4.11.1.1 Transmit DMA Event Pacer

The AFIFO may be configured to delay making a transmit DMA request to the host until the Write FIFO has enough space for a specified number of words. In this situation, the number of transmit DMA requests to the host or DMA controller is reduced. If the Write FIFO has space to accept WNUMEVT 32-bit words, it generates a transmit DMA request to the host and then waits for a response. Once WNUMEVT words have been written to the FIFO, it checks again to see if there is space for WNUMEVT 32-bit words. If there is space, it generates another transmit DMA request to the host, and so on. In this fashion, the Write FIFO will attempt to stay filled. Note that if transmit DMA event pacing is desired, [WFIFOCTL\[15:8\]](#) WNUMEVT should be set to a non-zero integer multiple of the value in [WFIFOCTL\[7:0\]](#) WNUMDMA. If transmit DMA event pacing is not desired, then the value in [WFIFOCTL\[15:8\]](#) WNUMEVT should be set equal to the value in [WFIFOCTL\[7:0\]](#) WNUMDMA.

#### 24.6.4.11.2 AFIFO Data Reception

When the Read FIFO is disabled, receive DMA requests pass through directly from McASP to the host/DMA controller. Whether the RFIFO is enabled or disabled, the McASP generates receive DMA requests as needed; the AFIFO is “invisible” to the McASP. When the Read FIFO is enabled, receive DMA requests from the McASP are sent to the AFIFO, which in turn generates receive DMA requests to the host/DMA controller. If the Read FIFO is enabled and the McASP makes a receive DMA request, the RFIFO reads RNUMDMA 32-bit words from the McASP, if and when the RFIFO has space for RNUMDMA words. If it does not, the RFIFO waits until this condition has been satisfied; at that point, it reads RNUMDMA words from the McASP. (See description for [RFIFOCTL\[7:0\]](#) RNUMDMA.) If the host CPU reads the Read FIFO, independent of a receive DMA request, and the RFIFO at that time contains less than WNUMEVT words, those words will be read correctly, emptying the FIFO.

#### 24.6.4.11.2.1 Receive DMA Event Pacer

The AFIFO may be configured to delay making a receive DMA request to the host until the Read FIFO contains a specified number of words. In this situation, the number of receive DMA requests to the host or DMA controller is reduced. If the Read FIFO contains at least WNUMEVT 32-bit words, it generates a receive DMA request to the host and then waits for a response. Once WNUMEVT 32-bit words have been read from the RFIFO, the RFIFO checks again to see if it contains at least another WNUMEVT words. If it does, it generates another receive DMA request to the host, and so on. In this fashion, the Read FIFO will attempt to stay empty. Note that if receive DMA event pacing is desired, [RFIFOCTL\[15:8\]](#) RNUMEVT should be set to a non-zero integer multiple of the value in [RFIFOCTL\[7:0\]](#) RNUMDMA. If receive DMA event pacing is not desired, then the value in [RFIFOCTL\[15:8\]](#) RNUMEVT should be set equal to the value in [RFIFOCTL\[7:0\]](#) RNUMDMA.

#### 24.6.4.11.3 Arbitration Between Transmit and Receive DMA Requests

If both the WFIFO and the RFIFO are enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete. If only the WFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete. If only the RFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the receive DMA request. Once a transfer is in progress, it is allowed to complete.

#### 24.6.4.12 McASP Events and Interrupt Requests

[Table 24-428](#) lists all the transmit event flags. [Table 24-429](#) lists all the Receive event flags. Source of each of these TX/RX events can be a TX/RX channel from any McASPi serializer configured as transmitter or receiver respectively.

**Table 24-428. TX Events<sup>(1)</sup>**

Event Mask	Event Flag	Map to <sup>(2)</sup>	Description
<a href="#">MCASP_EVTCTLX[0]</a> XUNDRN	<a href="#">MCASP_TXSTAT[0]</a> XUNDRN	MCASPi_IRQ_AXEVT	Transmit buffer underrun

<sup>(1)</sup> Global events for all transmitting serializers in a single McASPi module.

<sup>(2)</sup> Every McASPi module generates separate IRQ event.

**Table 24-428. TX Events<sup>(1)</sup> (continued)**

Event Mask	Event Flag	Map to <sup>(2)</sup>	Description
MCASP_EVTCTLX[1] XSYNCERR	MCASP_TXSTAT[1] XSYNCERR	MCASPi_IRQ_AXEVT	Unexpected transmit frame sync
MCASP_EVTCTLX[2] XCKFAIL	MCASP_TXSTAT[2] XCKFAIL	MCASPi_IRQ_AXEVT	Transmit clock failure
MCASP_EVTCTLX[3] XDMAERR	MCASP_TXSTAT[7] XDMAERR	MCASPi_IRQ_AXEVT	DATA port transmit error
MCASP_EVTCTLX[4] XLAST	MCASP_TXSTAT[4] XLAST	MCASPi_IRQ_AXEVT	Transmit last slot interrupt
MCASP_EVTCTLX[5] XDATA	MCASP_TXSTAT[5] XDATA	MCASPi_IRQ_AXEVT	Transmit data-ready interrupt
MCASP_EVTCTLX[7] XSTAFRM	MCASP_TXSTAT[6] XSTAFRM	MCASPi_IRQ_AXEVT	Transmit start of frame interrupt
n.a.	MCASP_TXSTAT[8] XERR	n.a.	OR-event of all Tx-error events: (XDMAERR   XCKFAIL   XUNDRN   XSYNCERR ). It is cleared ONLY when all error flags are cleared
n.a.	MCASP_TXSTAT[3] XTDM SLOT	n.a.	Qualifies the current TDM slot as an odd or an even slot.

**Table 24-429. RX Events<sup>(1)</sup>**

Event Mask	Event Flag	Map to <sup>(2)</sup>	Description
MCASP_EVTCTLR[0] ROVRN	MCASP_RXSTAT[0] ROVRN	MCASPi_IRQ_AREVT	Receive buffer overrun
MCASP_EVTCTLR[1] RSYNCERR	MCASP_RXSTAT[1] RSYNCERR	MCASPi_IRQ_AREVT	Unexpected receive frame sync
MCASP_EVTCTLR[2] RCKFAIL	MCASP_RXSTAT[2] RCKFAIL	MCASPi_IRQ_AREVT	Receive clock failure
MCASP_EVTCTLR[3] RDMAERR	MCASP_RXSTAT[7] RDMAERR	MCASPi_IRQ_AREVT	DATA port receive error
MCASP_EVTCTLR[4] RLAST	MCASP_RXSTAT[4] RLAST	MCASPi_IRQ_AREVT	Receive last slot
MCASP_EVTCTLR[5] RDATA	MCASP_RXSTAT[5] RDATA	MCASPi_IRQ_AREVT	Receive data-ready
MCASP_EVTCTLR[7] RSTAFRM	MCASP_RXSTAT[6] RSTAFRM	MCASPi_IRQ_AREVT	Receive start of frame
n.a.	MCASP_RXSTAT[8] RERR	n.a.	OR-event of all Rx-error events: (RDMAERR   RCKFAIL   ROVRN   RSYNCERR ). RERR event is cleared once all error flags are cleared.
n.a.	MCASP_RXSTAT[3] RTDM SLOT	n.a.	Qualifies the current TDM slot as an odd or an even slot.

<sup>(1)</sup> Global events for all receiving serializers in a single McASPi module. These events and masks are available in same format for every McASPi module

<sup>(2)</sup> Every McASP module generates separate IRQ event.

Software has to read the [MCASP\\_TXSTAT/MCASP\\_RXSTAT](#) register to determine which event occurs at a global level for McASP Tx/Rx logic. In addition user software has to scan the XRDY/RRDY read-only flags in the [MCASP\\_XRSRCTLn](#) registers to determine which active serializer is the actual source of the event.

A Tx interrupt line (MCASPi\_IRQ\_AXEVT) is asserted (active high) when one of the [MCASP\\_TXSTAT](#) notified events occurs, provided that it is enabled in its corresponding [MCASP\\_EVTCTLX](#) bit. Similarly, a Rx interrupt line (MCASPi\_IRQ\_AREVT) is asserted (active high) when one of [MCASP\\_RXSTAT](#) notified events occurs, provided that it is enabled in its corresponding [MCASP\\_EVTCTLR](#) bit. See also [Section 24.6.4.12.4, Multiple Interrupts](#) and the [Section 24.6.4.10.1, Data Ready Status and Event/Interrupt Generation](#).

#### 24.6.4.12.1 Transmit Data Ready Event and Interrupt

The transmit data-ready interrupt (XDATA) is generated if XDATA is 1 in the [MCASP\\_TXSTAT](#) register and XDATA is enabled in [MCASP\\_EVTCTLX](#). The [Section 24.6.4.10.1, Data Ready Status and Event/Interrupt Generation](#), provides details on when XDATA is set in the [MCASP\\_TXSTAT](#) register.

A transmit-start-of-frame interrupt (XSTAFRM) is triggered by the recognition of a transmit frame sync.

A transmit-last-slot interrupt (XLAST) is a qualified version of the data-ready interrupt (XDATA). It has the same behavior than the data-ready interrupt, but is further qualified by having the data requested belonging to the last slot (the slot that just ended is the next-to-last TDM slot, the current slot is the last slot).

#### 24.6.4.12.2 Receive Data Ready Event and Interrupt

The receive data-ready interrupt (RDATA) is generated if RDATA is 1 in the [MCASP\\_RXSTAT](#) register and RDATA is enabled in [MCASP\\_EVTCTLR](#). The [Section 24.6.4.10.1, Data Ready Status and Event/Interrupt Generation](#), provides details on when RDATA flag is set in the [MCASP\\_RXSTAT](#) register.

A receiver start of frame (RSTAFRM) interrupt is triggered by the recognition of a receiver frame sync.

A receiver last slot (RLAST) interrupt is a qualified version of the data ready interrupt (RDATA). It has the same behavior as the data ready interrupt, but is further qualified by having the data in the buffer come from the last TDM time slot (the slot that just ended was last TDM slot).

#### 24.6.4.12.3 Error Interrupt

Upon detection, the following error conditions generate interrupt flags:

In the transmit status register ([MCASP\\_TXSTAT](#)):

- Transmit underrun (XUNDRN)
- Unexpected transmit frame sync (XSYNCERR)
- Transmit clock failure (XCKFAIL)
- Transmit DATA port error (XDMAERR)

Each interrupt source also has a corresponding enable bit in the transmit interrupt control register ([MCASP\\_EVTCTLX](#)). If the enable bit is set, an interrupt is requested when the interrupt flag is set in [MCASP\\_TXSTAT](#). If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

In the receive status register ([MCASP\\_RXSTAT](#)) :

- Receiver overrun (ROVRN)
- Unexpected receive frame sync (RSYNCERR)
- Receive clock failure (RCKFAIL)
- Receive DATA port error (RDMAERR)

Each interrupt source also has a corresponding enable bit in the receive interrupt control register ([MCASP\\_EVTCTLR](#)). If the enable bit is set, an interrupt is requested when the interrupt flag is set in [MCASP\\_RXSTAT](#). If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

#### 24.6.4.12.4 Multiple Interrupts

This only applies to interrupts and not to DMA requests. The following terms are defined:

- **Active Interrupt Request:** a flag in [MCASP\\_TXSTAT](#) is set and the interrupt is enabled in [MCASP\\_EVTCTLX](#).
- **Outstanding Interrupt Request:** An interrupt request has been issued on one of the McASP transmit interrupt port, but that request has not yet been serviced.
- **Serviced:** The CPUs write to [MCASP\\_TXSTAT](#) to clear one or more of the active interrupt request flags.

The first interrupt request to become active for the serializer with the interrupt flag set in [MCASP\\_TXSTAT/MCASP\\_RXSTAT](#) and the interrupt enabled in [MCASP\\_EVTCTLX/MCASP\\_EVTCTLR](#) generates a request on the McASP transmit or receive interrupt port.

If more than one interrupt request becomes active in the same cycle, a single interrupt request is generated on the McASP transmit or receive interrupt port. Subsequent interrupt requests that become active while the first interrupt request is outstanding do not immediately generate a new request pulse on the McASP transmit or receive interrupt port.

The interrupt is serviced with the CPU writing to [MCASP\\_TXSTAT/MCASP\\_RXSTAT](#). If any interrupt requests are active after the write, a new request is generated on the McASP transmit or receive interrupt port.

One outstanding interrupt request is allowed on each port, so a transmit and a receive interrupt request may both be outstanding at the same time.

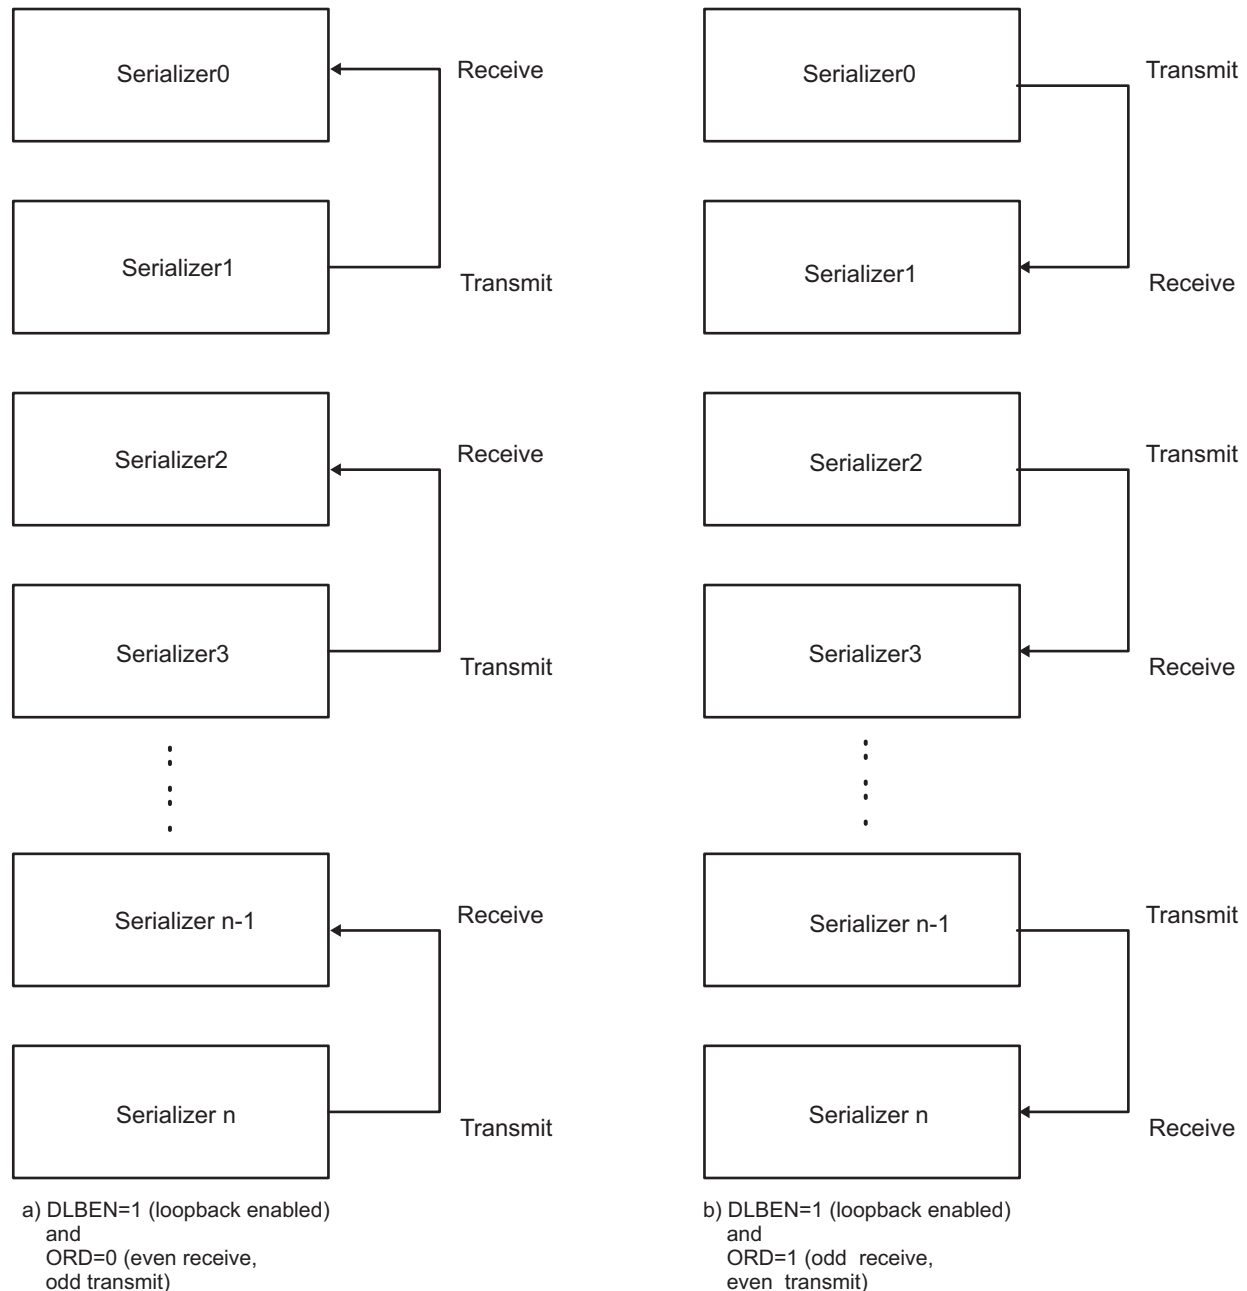

#### 24.6.4.13 DMA Requests

The McASP can generate one DMA request to the DMA\_CROSSBAR to transmit (MCASPi\_DREQ\_TX) or receive (MCASPi\_DREQ\_RX) data. A DMA request to transmit data is generated if the XDATDMA bit in the [MCASP\\_XEVTCTL](#) register is cleared. A DMA request to receive data is generated if the RDATDMA bit in the [MCASP\\_REVTCTL](#) register is cleared.

#### 24.6.4.14 Loopback Modes

The McASP features a digital loopback mode (DLB) that allows loopback test transfers in TDM mode between McASP transmitters and receivers within the same device. In loopback mode, the output of a transmit serializer is connected internally to the input of a receive serializer. Therefore, a receiver data can be checked against a transmitter data to ensure that the McASP settings are correct. Digital loopback mode applies to TDM mode only (2 to 32 slots in a frame). It does not apply to DIT mode (XMOD = 0x180) or burst mode (XMOD = 0).

[Figure 24-132](#) shows the basic logical connection of the serializers in loopback mode.

**Figure 24-132. McASP Serializers Operation in Loopback Mode**

mcasp-023

Two types of loopback connections are possible, selected by the ORD bit in the digital loopback control register - [MCASP\\_LBCTL](#) as follows:

- ORD = 0: Outputs of odd serializers are connected to inputs of even serializers. If this mode is selected, the odd serializers must be configured as transmitters and even serializers as receivers.
- ORD = 1: Outputs of even serializers are connected to inputs of odd serializers. If this mode is selected, the even serializers must be configured as transmitters and odd serializers as receivers.

User can choose in software (bit IOLBEN of the [MCASP\\_LBCTL](#)) between a McASP module internal loopback and a device I/O level loopback.

When a **McASP internal loopback** is selected ([MCASP\\_LBCTL\[4\]](#) IOLBEN=0b0 ), it is NOT necessary to configure [MCASP\\_PFUNC](#) and [MCASP\\_PDIR](#) registers for McASP pin settings. Nevertheless, data can be optionally made externally visible at the I/O pin of the transmit serializer, if the pin is configured as a McASP output pin by setting the corresponding [MCASP\\_PFUNC](#) bit to 0 (i.e. to function as McASP, not GPIO) and [MCASP\\_PDIR](#) bit to 1 (output).

When a **device I/O level loopback** is selected ([MCASP\\_LBCTL\[4\]](#) IOLBEN=0b1 ), the [MCASP\\_PFUNC](#) and [MCASP\\_PDIR](#) registers must be configured with the appropriate settings for all AXRn pins, according to ORD bit configuration.

In case of device I/O loopback, the connectivity is externally applied between device pads (i.e. reaching device I/O buffers ).

Hence, the corresponding padconfiguration registers must be appropriately configured in the device Control Module - CTRL\_MODULE\_CORE\_PAD. For more details, see [Section 18.4.6.1.1, Pad Configuration Registers](#), in [Chapter 18, Control Module](#).

When In loopback mode, the transmit clock and frame sync are used by both the transmit and receive sections of the McASP. The transmit and receive sections operate synchronously. This is achieved by setting the MODE bitfield of the [MCASP\\_LBCTL](#) register to 0x1 and the ASYNC bit of the [MCASP\\_ACLKXCTL](#) register to 0b0.

#### 24.6.4.14.1 Loopback Mode Configurations

This is a summary of the settings required for digital loopback mode for TDM format :

- The [MCASP\\_LBCTL\[0\]](#) DLBEN bit must be set to 0b1 to enable a loopback mode. It must be kept at 0b0 during normal McASP operation.
- The [MCASP\\_LBCTL\[4\]](#) IOLBEN bit must be set to select between internal (McASP local) loopback mode or device I/O level loopback mode.
- The [MCASP\\_LBCTL\[3:2\]](#) MODE bitfield must be set to 0x1 for both the transmit and receive sections to use the transmit clock and frame sync generator.
- The [MCASP\\_LBCTL\[1\]](#) ORD must be programmed appropriately to select odd or even serializers to be transmitters or receivers.
- The corresponding serializers must be configured accordingly.
- The bit - [MCASP\\_ACLKXCTL\[6\]](#) ASYNC must be cleared to 0b0 to ensure synchronous transmit and receive operations.
- The bitfields - [MCASP\\_RXFMCTL\[15:7\]](#) RMOD and [MCASP\\_TXFMCTL\[15:7\]](#) XMOD must be set within range (0x2- 0x20) to indicate TDM mode.

---

**NOTE:** Loopback mode does not apply to DIT or burst mode, because McASP receivers do NOT natively support DIR - reception.

---

#### 24.6.4.15 Error Reporting

The McASP includes error-checking capability for the serial protocol and data underrun. In addition, the McASP includes a timer that continually measures the high-frequency master clock every 32 AHCLKX clock cycles. The value of the timer can be read to get a measurement of the clock frequency and has a minimum and maximum range setting that can set an error flag if the master clock goes out of a specified range.

When one or more errors (software selectable) are detected, an interrupt can be generated if desired, based on one or more error sources.

##### 24.6.4.15.1 Buffer Underrun Error -Transmitter

A buffer underrun occurs when a serializer is instructed by the transmit state-machine to transfer data from XRBUF<sub>n</sub> buffer to XRSR<sub>n</sub> shift register, but the corresponding ([MCASP\\_TXBUF<sub>n</sub>](#) ) register has not yet been written with new data since the last time the transfer occurred. When this occurs, the transmit state-machine sets the XUNDRN flag.

An underrun is checked only once per time slot. The `MCASP_TXSTAT[0]` XUNDRN flag is set when an underrun condition occurs. Once set, the XUNDRN flag remains set until the host explicitly writes 1 to the XUNDRN bit to clear it.

In DIT mode, a pair of BMC zeros is shifted out when an underrun occurs (four bit times at 128 bfs). By shifting out a pair of zeros, a clock can be recovered on the receiver. To recover, reset the McASP and restart with the proper initialization.

In TDM mode, during an underrun case, a long stream of zeros are shifted out causing the DACs to mute. To recover, reset the McASP and start again with the proper initialization.

#### 24.6.4.15.2 Buffer Overrun Error-Receiver

A buffer overrun occurs when a serializer is instructed to transfer data from XRSRn shift register to XRBUFn receiver buffer, but the corresponding `MCASP_RXBUFn` register has not yet been read since the last time the transfer occurred. When this occurs, the receiver state machine sets the overrun flag - ROVRN. However, the individual serializer writes over the data in the XRBUFn buffer register (destroying the previous sample) and continues shifting.

An overrun is checked only once per time slot. The `MCASP_RXSTAT[0]` ROVRN flag is set when an overrun condition occurs. It is possible that an overrun occurs on one time slot but then the host catches up and does not cause an overrun on the following time slots. However, once the ROVRN flag is set, it remains set until the host explicitly writes a 1 to the ROVRN bit to clear the ROVRN bit.

#### 24.6.4.15.3 DATA Port Error - Transmitter

A transmit DATA port error, as indicated by the XDMAERR flag in the `MCASP_TXSTAT` register, occurs when the DMA or device CPU writes more words to the DATA port of the McASP than it should.

The `MCASP_TXSTAT[7]` XDMAERR=0b1 indicates that the DMA or device CPU wrote too many words to the McASP DATA port for a given transmit DMA event. Writing too few words results in a transmit underrun error setting XUNDRN in `MCASP_TXSTAT`.

While XDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or device CPU. The McASP transmitter and the DMA must be reinitialized to resynchronize them.

#### 24.6.4.15.4 DATA Port Error - Receiver

A receive DATA port error, as indicated by the RDMAERR flag in the `MCASP_RXSTAT` register, occurs when the DMA or device CPU reads more words from the DATA port of the McASP than it should.

The `MCASP_RXSTAT[7]` RDMAERR indicates that the DMA or device CPU read too many words from the McASP DATA port for a given receive AREVT event. Reading too few words results in a receiver overrun error setting ROVRN in `MCASP_RXSTAT`.

While RDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or device CPU. The McASP receiver and the DMA must be reinitialized to resynchronize them.

#### 24.6.4.15.5 Unexpected Frame Sync Error

An unexpected frame sync occurs in when:

- in burst mode and TDM mode, the next active edge of the frame sync occurs early such that the current slot will not be completed by the time the next slot is scheduled to begin.
- in TDM mode, an unexpected frame sync occurs also if the frame sync does NOT occur exactly during the correct bit clock (not a cycle earlier or later) and before slot 0.

When an unexpected frame sync occurs, there are two possible actions depending upon when the unexpected frame sync occurs:

1. **Early:** An early unexpected frame sync occurs when the McASP is in the process of completing the current frame and a new frame sync is detected (not including overlap that occurs due to a 1 or 2 bit frame sync delay). When an early unexpected frame sync occurs:

- Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
  - Current frame is not resynchronized. The number of bits in the current frame is completed. The next frame sync, which occurs after the current frame is completed, will be resynchronized.
2. **Late:** A late unexpected frame sync occurs when there is a gap or delay between the last bit of the previous frame and the first bit of the next frame. When a late unexpected frame sync occurs (as soon as the gap is detected):
- Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
  - Resynchronization occurs upon the arrival of the next frame sync.

Late frame sync is detected the same way in burst mode and TDM mode. However, in burst mode, late frame sync is not meaningful and its interrupt enable should not be set.

#### 24.6.4.15.6 Clock Failure Detection

##### 24.6.4.15.6.1 Clock Failure Check Startup

It is initially expected of the clock failure circuits to generate an error until at least one measurement is taken. Therefore, the clock failure interrupts, clock switch, and mute functions should not be enabled immediately, but only after a specific startup procedure.

To start the transmit clock failure check procedure:

1. Configure the transmit clock failure detect logic (XMIN, XMAX, XPS) in the transmit clock check control register ([MCASP\\_TXCLKCHK](#)).
2. Clear the transmit clock failure flag (XCKFAIL) in the transmit status register ([MCASP\\_TXSTAT](#)).
3. Wait until the first measurement is taken (> 32 AHCLKX clock periods).
4. Verify that no clock failure is detected.
5. Repeat Step 2 through Step 4 until the clock is running and is no longer issuing clock failure errors.
6. After the transmit clock is measured and falls within the acceptable range, the following can be enabled:
  1. The transmit clock failure interrupt enable bit (XCKFAIL) in the transmitter interrupt control register ([MCASP\\_EVTCTLX](#))

To start the receive clock failure check procedure:

1. Configure receive clock failure detect logic (RMIN, RMAX, RPS) in the receive clock check control register ([MCASP\\_RXCLKCHK](#)).
2. Clear receive clock failure flag (RCKFAIL) in the receive status register ([MCASP\\_RXSTAT](#)).
3. Wait until first measurement is taken (> 32 AHCLKR clock periods).
4. Verify no clock failure is detected.
5. Repeat steps 2–4 until clock is running and is no longer issuing clock failure errors.
6. After the receive clock is measured and falls within the acceptable range, the following may be enabled:
  1. the receive clock failure (RCKFAIL) interrupt enable bit in the receive interrupt control register ([MCASP\\_EVTCTLR](#))

##### 24.6.4.15.6.2 Transmit Clock Failure Check and Recovery

The transmit clock failure check circuit (see [Figure 24-133](#)) works off the internal McASP interface clock and the external high-frequency serial clock (AHCLKX). It continually counts the number of interface clocks for every 32 high-rate serial clock (AHCLKX) periods, and stores the count in XCNT of the transmit clock check control register ([MCASP\\_TXCLKCHK](#)) every 32 high-rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (XMIN), and automatically flags an interrupt (XCKFAIL in `MCASP_TXSTAT`) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is less than XMIN. The logic continually compares the current count (from the running interface clock counter) to the maximum allowable boundary (XMAX). This is so that if the external clock completely stops, the counter value is not copied to XCNT. An out-of-range maximum condition occurs when the count is greater than XMAX. The XMIN and XMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

For the transmit clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

If a clock failure is detected, the transmit clock failure flag (XCKFAIL) in `MCASP_TXSTAT` is set. This causes an interrupt if the transmit clock failure interrupt enable bit (XCKFAIL) in `MCASP_EVTCTLX` is set.

**Figure 24-133. Transmit Clock Failure Detection Circuit Block Diagram**

mcasp-024

### 24.6.4.15.6.3 Receive Clock Failure Check and Recovery

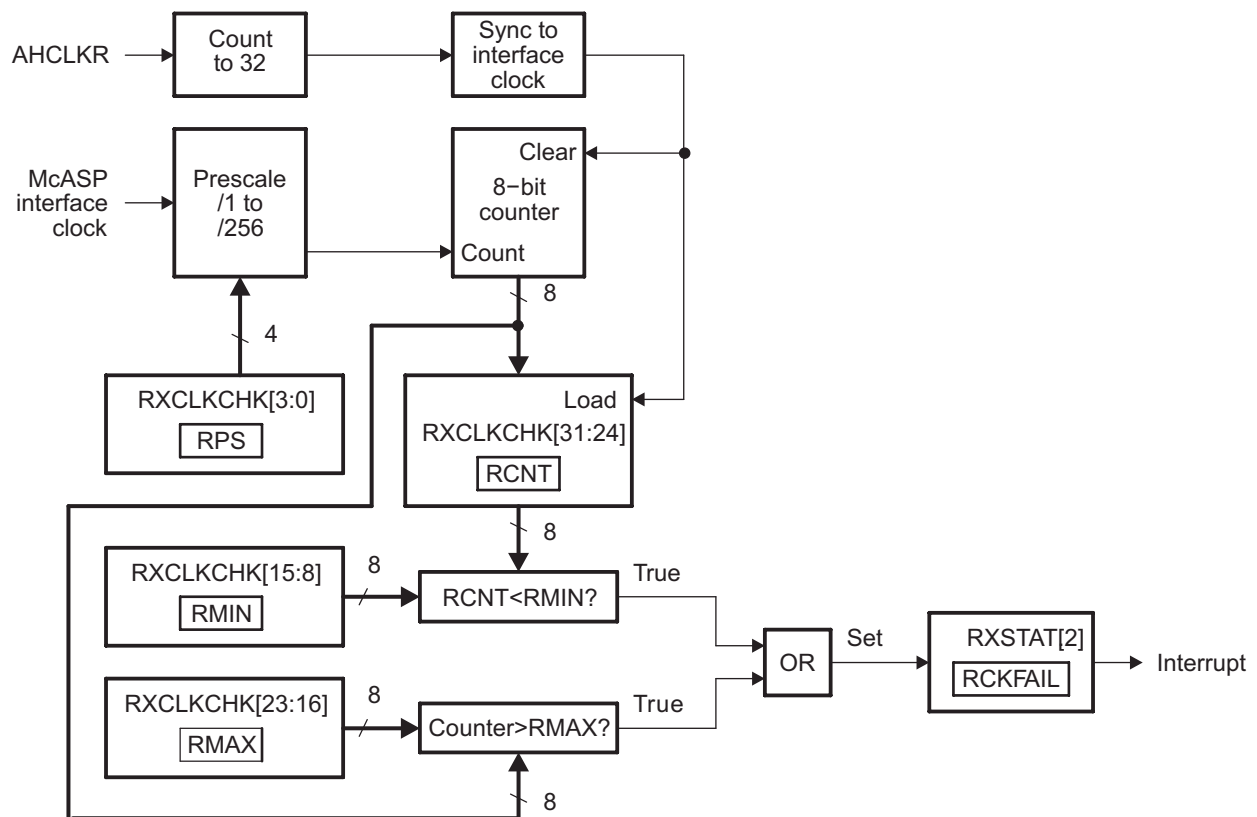

The receive clock failure check circuit (see [Figure 24-134](#)) works off both the internal McASP interface clock and the high-frequency serial clock (AHCLKR) coming from the device clock generator. It continually counts the number of interface clocks for every 32 high rate serial clock (AHCLKR) periods, and stores the count in RCNT of the receive clock check control register (`MCASP_RXCLKCHK`) every 32 high rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (RMIN) and automatically flags an event (RCKFAIL in `MCASP_RXSTAT`) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is smaller than RMIN. The logic continually compares the current count (from the running interface clock counter) against the maximum allowable boundary (RMAX). This is in case the external clock completely stops, so that the counter value is not copied to RCNT. An out-of-range maximum condition occurs when the count is greater than RMAX. Note that the RMIN and RMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate either that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

In order for the receive clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

**Figure 24-134. Receive Clock Failure Detection Circuit Block Diagram**

## 24.6.5 McASP Low-Level Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the McASP module.

### 24.6.5.1 Global Initialization

#### 24.6.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the McASP module is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the McASP (for more information, see [Section 24.6.3, McASP Integration](#), and [Section 24.6.2, McASP Environment](#)).

[Table 24-430](#), describes the global initialization of surrounding modules.

**Table 24-430. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	Module functional and interface clocks must be enabled. (See <a href="#">Section 3.6, Clock Management Functional Description</a> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .)
Control module	Module-specific pad muxing and other pad configurations must be set in the control module. (See <a href="#">Section 18.4.6.1.1, Pad Configuration Registers</a> , in <a href="#">Chapter 18, Control Module</a> ).
(Optional) IRQ_CROSSBAR	Interrupt crossbar configuration must be done to enable the interrupts from the McASP. For more details on IRQ_CROSSBAR module, see <a href="#">Section 18.4.6.4, IRQ_CROSSBAR Module Functional Description</a> , in <a href="#">Chapter 18, Control Module</a> .
(Optional) DMA_CROSSBAR	DMA configuration must be done to enable the McASP DMA data channel requests. For more information on DMA_CROSSBAR module configuration, see <a href="#">Section 18.4.6.5, DMA_CROSSBAR Module Functional Description</a> , in <a href="#">Chapter 18, Control Module</a> .
(Optional) L4_PER2 and L3_MAIN Interconnects	For more information about the interconnect configuration, see <a href="#">Section 14.2.1, L3_MAIN Interconnect Overview</a> in <a href="#">Section 14.2, L3 Interconnect</a> .

**NOTE:** The IRQ\_CROSSBAR and the DMA\_CROSSBAR configurations are required when the interrupt and DMA-based communication modes are used. Further initialization of the selected IRQ and DMA controllers of the host CPU must be done for full functionality of the McASP DMA and IRQ lines.

#### 24.6.5.1.2 McASP Global Initialization

##### 24.6.5.1.2.1 Main Sequence – McASP Global Initialization for DIT-Transmission

The procedure in [Table 24-431](#) initializes the McASP serializers transmitters to operate in DIT-mode (S/PDIF-transmission protocol) after a power-on reset (POR).

#### CAUTION

Before performing McASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the [MCASP\\_GBLCTL](#) register.

**Table 24-431. McASP Transmitters Global Initialization for DIT-Mode Operation**

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different McASP components.	MCASP_GBLCTL[12:8]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[12:8]	=0x00
3. Configure the local power management.	PWRIDLESYSCONFIG[1:0] IDLE_MODE	0x1
4. Configure the transmit format unit.	See Section 24.6.5.1.2.1.1.	
5. Configure the transmit frame sync generator.	See Section 24.6.5.1.2.1.2.	
6. Configure the transmit clock generator.	See Section 24.6.5.1.2.1.3.	
7. Configure the TDM sequencer—set all slots active.	MCASP_TXTDM[31:0] XTDMs	0xFFFF FFFF
8. Configure the desired n-th serializer (n=0 to 3) for transmit mode operation. <sup>(1)</sup>	MCASP_XRSRCTLn [1:0] SRMOD	0x1
9. Configure the McASP pins functionality.	See Section 24.6.5.1.2.1.4.	
10. Enable the McASP DIT - transmission mode.	MCASP_TXDITCTL[0] DITEN	0x1 <sup>(2)</sup>
11. Configure DIT-specific subframe fields.	See Table 24-436.	
12. Release from reset state the divider that outputs the AHCLKX clock. <sup>(3)</sup>	MCASP_GBLCTL[9] XHCLKRST	0x1
13. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[9] XHCLKRST	=0x1
14. Release from reset state the divider that outputs the ACLKX clock. <sup>(3)</sup>	MCASP_GBLCTL[8] XCLKRST	0x1
15. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[8] XCLKRST	=0x1

<sup>(1)</sup> For an unused serializer n, write MCASP\_XRSRCTLn [1:0] SRMOD=0x0 to disable it.

<sup>(2)</sup> This globally configures all active transmitters to operate in DIT-mode.

<sup>(3)</sup> During reset state the local McASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP\_AHCLKXCTL and MCASP\_ACLKXCT registers are ignored; hence, the transmission clock does not stop during the reset state of the dividers.

#### 24.6.5.1.2.1.1 Subsequence – Transmit Format Unit Configuration for DIT-Transmission

The procedure in Table 24-432 configures the transmit frame format unit of the McASP module for a DIT-transmission.

#### NOTE:

- The first transmit data bit always has a 0-bit delay.
- The bitstream is always transmitted in least-significant-bit (LSB)-first order.
- Pad value for extra bits in a certain slot is always 0.

**Table 24-432. Transmit Format Unit Configuration for DIT-Transmission**

Step	Register/Bit Field/Programming Model	Value
Configure the slot size to 32 bits.	MCASP_TXFMT[7:4] XSSZ	0xF
<b>IF:</b> the data to transmit is left- aligned	Software test condition	
Set data mask in the range 0xFFFF FF00 – 0xFFFF 0000.	MCASP_TXMASK[31:0] XMASK	0x- <sup>(1)</sup>
Rotate data right by a multiple-of-4- bit positions.	MCASP_TXFMT[2:0] XROT	0x- <sup>(1)</sup>
<b>ELSE</b>		
Set data mask in the range 0x00FF FFFF– 0x0000 FFFF.	MCASP_TXMASK[31:0] XMASK	0x- <sup>(1)</sup>
Rotate data right by 0-bit positions.	MCASP_TXFMT[2:0] XROT	0x0
<b>ENDIF</b>		

<sup>(1)</sup> Refer to Section 24.6.4.4.1, *Transmit Fromat Unit* and Section 24.6.4.4.1.2, *DIT-Mode Transmission Data Alignment Settings*.

**Table 24-432. Transmit Format Unit Configuration for DIT-Transmission (continued)**

Step	Register/Bit Field/Programming Model	Value
Select to write data to active serializers transmit buffers using peripheral (CFG) or DATA port	MCASP_TXFMT[3] XBUSEL	0x-

#### 24.6.5.1.2.1.2 Subsequence – Transmit Frame Synchronization Generator Configuration for DIT-Transmission

The procedure in [Table 24-433](#) configures the transmit frame synchronization generator of the McASP module.

**NOTE:** The frame synchronization signal is always rising-edge active and always has a single-bit width.

**Table 24-433. Transmit Frame-Synchronization Generator Configuration for DIT-Transmission**

Step	Register/Bit Field/Programming Model	Value
Select 384-slot size block.	MCASP_TXFMCTL[15:7] XMOD	0x180
Select internally-generated transmit frame sync.	MCASP_TXFMCTL[1] FSXM	0x1

#### 24.6.5.1.2.1.3 Subsequence – Transmit Clock Generator Configuration for DIT-Transmission

**NOTE:** By default, the ACLKX and AHCLKX clocks are generated only from the McASP internal clock source.

The procedure in [Table 24-434](#) configures the transmit clock generator of the McASP module.

**Table 24-434. Transmit Clock Generator Configuration in DIT-Mode**

Step	Register/Bit Field/Programming Model	Value
Set the divisor for the internally generated high frequency clock– AHCLKX.	MCASP_AHCLKXCTL[11:0] HCLKXDIV	0x-
Set the divisor for the internally generated transmission clock– ACLKX.	MCASP_ACLKXCTL[4:0] CLKXDIV	0x-
Configure the transmit clock failure detect logic.	See <a href="#">Section 24.6.4.15.6.1, Clock Failure Check Startup</a> .	

#### 24.6.5.1.2.1.4 Subsequence - McASP Pins Functional Configuration

The procedure in [Table 24-435](#) configures the McASP pins for McASP functionality.

**Table 24-435. McASP Pins Functional Configuration**

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have McASP functionality.	MCASP_PFUNC[31:0]	0x0
Configure the McASP pins as outputs:	MCASP_PDIR[28] AFSX;	0x1
AFSX	MCASP_PDIR[27] AHCLKX;	0x1
AHCLKX	MCASP_PDIR[26] ACLKX;	0x1
ACLKX	MCASP_PDIR [i] AXRi	0x1
Desired i-th McASP data pin AXRi is configured as an output for DIT-transmission.		

### 24.6.5.1.2.1.5 Subsequence – DIT-specific Subframe Fields Configuration

The procedure in [Table 24-436](#) configures the DIT-specific subframe fields as part of the S/PDIF format data.

**Table 24-436. DIT-Specific Subframe Fields Configuration**

Step	Register/Bit Field/Programming Model	Value
Configure the valid bit value for odd time slots.	<a href="#">MCASP_TXDITCTL</a> [3] VB	0x-
Configure the valid bit value for even time slots.	<a href="#">MCASP_TXDITCTL</a> [2] VA	0x-
Configure the user data bit for each subframe A and B in a 384-slot S/PDIF block.	<a href="#">MCASP_DITUDRAi</a> [31:0] DITUDRAi, where i = 0 to 5	0x-
	<a href="#">MCASP_DITUDRBi</a> [31:0] DITUDRBi, where i = 0 to 5	0x-
Configure the channel status bit for each subframe A and B in a 384-slot S/PDIF block.	<a href="#">MCASP_DITCSRAi</a> [31:0], where i = 0 to 5	0x-
	<a href="#">MCASP_DITCSRBi</a> [31:0], where i = 0 to 5	0x-

### 24.6.5.1.2.2 Main Sequence – McASP Global Initialization for TDM-Reception

The procedure in [Table 24-437](#) initializes a McASP serializer n receiver(s) to operate in TDM-mode (the only mode supported by McASP receivers) after a power-on reset (POR). This is used for I2S (2-slot TDM) and other TDM-based audio protocols reception.

#### CAUTION

Before performing McASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the [MCASP\\_GBLCTL](#) register.

**NOTE:** The McASP receivers support only TDM-frames (including 384-TDM frames) reception. DIT-frames reception (i.e. S/PDIF stream) can be implemented indirectly via an external DIR-chip converter with DIT-input and TDM (I2S)-compatible output connected to device McASP receiver input (TDM-only compatible).

**Table 24-437. McASP Receivers Global Initialization for TDM-Mode Operation**

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different McASP receive components.	<a href="#">MCASP_GBLCTL</a> [4:0]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	<a href="#">MCASP_GBLCTL</a> [4:0]	=0x00
3. Configure the local power management.	<a href="#">PWRIDLESYSCONFIG</a> [1:0] IDLE_MODE	0x1
4. Configure the receive format unit.	See <a href="#">Section 24.6.5.1.2.2.1</a> .	
5. Configure the receive frame sync generator.	See <a href="#">Section 24.6.5.1.2.2.2</a> .	
6. Configure the receive clock generator.	See <a href="#">Section 24.6.5.1.2.2.3</a> .	
7. Program all bits -RTDMSk (where k=0 to 31) according to the time slot characteristics desired (positions of active versus inactive slots within a frame).	<a href="#">MCASP_RXTDM</a> [ k ] RTDMSk , where k=0 to 31	0x-
8. Configure the desired n-th serializer for receive mode operation. <sup>(1)</sup>	<a href="#">MCASP_XRSRCTLn</a> [1:0] SRMOD	0x2
9. Configure the McASP pins functionality.	See <a href="#">Section 24.6.5.1.2.2.4</a> .	

<sup>(1)</sup> For an unused serializer n, write [MCASP\\_XRSRCTLn](#) [1:0] SRMOD=0x0 to disable it.

**Table 24-437. McASP Receivers Global Initialization for TDM-Mode Operation (continued)**

Step	Register/Bit Field/Programming Model	Value
10. Optional: Configure a McASP Rx channel for a loopback operation (TDM mode only) in <a href="#">MCASP_LBCTL</a> [31:0].	See <a href="#">Section 24.6.4.14.1, Loopback Mode Configurations</a> .	0x- <sup>(2)</sup>
11. Release from reset state the divider that outputs the AHCLKR clock. <sup>(3)</sup> See also <sup>(4)</sup> .	<a href="#">MCASP_GBLCTL</a> [1] RHCLKRST	0x1
12. Poll the bit to ensure that it is successfully latched in the register. See also <sup>(4)</sup> .	<a href="#">MCASP_GBLCTL</a> [1] RHCLKRST	=0x1
13. Release from reset state the divider that outputs the ACLKR clock. <sup>(3)</sup> See also <sup>(5)</sup> .	<a href="#">MCASP_GBLCTL</a> [0] RCLKRST	0x1
14. Poll the bit to ensure that it is successfully latched in the register. See also <sup>(5)</sup> .	<a href="#">MCASP_GBLCTL</a> [0] RCLKRST	=0x1

<sup>(2)</sup> In this case the receiver clock and frame sync are derived from the McASP transmitter logic, so [MCASP\\_ACLKXCTL](#)[6] ASYNC must be set to 0b0. Neither McASP internal receiver clock and frame sync generators, nor external clock and frame sync source are used.

<sup>(3)</sup> During reset state the local McASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the [MCASP\\_AHCLKRCTL](#) and [MCASP\\_ACLKRCTL](#) registers are ignored; hence, the reception clock does not stop during the reset state of the dividers.

<sup>(4)</sup> This step is necessary even if external high-frequency serial clocks are used.

<sup>(5)</sup> This step can be skipped if external serial clocks are used and they are running.

#### 24.6.5.1.2.2.1 Subsequence – Receive Format Unit Configuration in TDM Mode

The procedure in [Table 24-438](#) configures the receive frame format unit of the McASP module for TDM slots reception.

**Table 24-438. Receive Format Unit Configuration for TDM-Reception**

Step	Register/Bit Field/Programming Model	Value
Configure the desired TDM-slot size	<a href="#">MCASP_RXFMT</a> [7:4] RSSZ	0x- <sup>(1)</sup>
Set data mask out value (0x0000 0000 - 0xFFFF FFFF).	<a href="#">MCASP_RXMASK</a> [31:0] RMASK	0x- <sup>(2)</sup>
Select a padding value for masked-out bits.	<a href="#">MCASP_RXFMT</a> [14:13] RPAD	0x-
Specify position (0x0-0x1F) of the bit in corresponding register <a href="#">MCASP_RXBUF<sub>n</sub></a> which value to be used as a pad value in case <a href="#">MCASP_RXFMT</a> [14:13] RPAD=0x2.	<a href="#">MCASP_RXFMT</a> [12:8] RPBIT	0x-
Rotate data right by a multiple of 4- bit positions.	<a href="#">MCASP_RXFMT</a> [2:0] RROT	0x- <sup>(3)</sup>
Received stream bit order (LSB- or MSB-first ). Must be set to 0x1 for an I2S stream reception (MSB-first).	<a href="#">MCASP_RXFMT</a> [15] RRVRS	0x- <sup>(3)</sup>
Specify a delay between frame sync and first bit of data in number of bits. Must be set to 0x1 for an I2S stream reception.	<a href="#">MCASP_RXFMT</a> [17:16] RDATDLY	0x-
Select to read data from active serializers receive buffers using peripheral (CFG) or DATA port	<a href="#">MCASP_RXFMT</a> [3] RBUSEL	0x-

<sup>(1)</sup> Refer to [Section 24.6.4.4.2, Receive Format Unit](#), regarding options for received TDM-slot sizes.

<sup>(2)</sup> For more details on Rx masking value, refer to [Section 24.6.4.4.2.1, TDM - Mode Reception Data Alignment Settings](#)

<sup>(3)</sup> For more details on rotation and received TDM stream bit order, refer to [Section 24.6.4.4.2.1, TDM - Mode Reception Data Alignment Settings](#) and [Table 24-425, McASP RFU Settings](#).

### 24.6.5.1.2.2.2 Subsequence – Receive Frame Synchronization Generator Configuration in TDM Mode

The procedure in [Table 24-439](#) configures the transmit frame synchronization generator of the McASP module.

**NOTE:** The same bit - [MCASP\\_ACLKXCTL\[6\]](#) ASYNC which is used to determine if McASP receivers and transmitters work synchronously on the same clock, is also used to define if receiver frame sync is derived from the transmit frame sync generator, or generated independently in the receiver (either internally or externally sourced). Hence, the settings in below table [Table 24-439](#) have no effect, if [MCASP\\_ACLKXCTL\[6\]](#) ASYNC = 0.

**Table 24-439. Receive Frame-Synchronization Generator Configuration for TDM-Reception**

Step	Register/Bit Field/Programming Model	Value
Select number of TDM slots per frame. Must be set to 0x2, in case of an I2S-reception. For more details on frame-sync generator, refer to <a href="#">Section 24.6.4.2.3</a> .	<a href="#">MCASP_RXFMCTL[15:7]</a> RMOD	0x- <sup>(1)</sup>
Choose the receive frame sync width -single bit/single word. For more details on frame-sync generator, refer to <a href="#">Section 24.6.4.2.3</a> .	<a href="#">MCASP_RXFMCTL[4]</a> FRWID	0x-
Select start of received frame sync polarity - rising /falling edge. For more details on frame-sync generator, refer to <a href="#">Section 24.6.4.2.3</a> .	<a href="#">MCASP_RXFMCTL[0]</a> FSRP	0x-
<b>IF</b> receive frame sync - FS is internally generated	Software test condition	
Select internally- generated receive frame sync. For more details on frame-sync generator, refer to <a href="#">Section 24.6.4.2.3</a> .	<a href="#">MCASP_RXFMCTL[1]</a> FSRM	0b1
If McASP receiver is required to output internally generated frame, AFSR pin must be set as an output in step 9 of the sequence documented in the <a href="#">Table 24-437</a> . This must not be done in current step because the frame control register - <a href="#">MCASP_TXFMCTL</a> must be appropriately configured prior to AFSR pin outputting a frame to an external device.	<a href="#">MCASP_PDIR[31]</a> AFSR	0b1
<b>ELSE</b>		
Select externally- generated receive frame sync. For more details on frame-sync generator, refer to <a href="#">Section 24.6.4.2.3</a> .	<a href="#">MCASP_RXFMCTL[1]</a> FSRM	0b0
Setup the AFSR pin as input (device level: <code>mcaspi_fsr</code> )	<a href="#">MCASP_PDIR[31]</a> AFSR	0b0
<b>ENDIF</b>		
To generate McASP receive frame sync in receiver logic, select an asynchronous frame sync.	<a href="#">MCASP_ACLKXCTL[6]</a> ASYNC	0b1

<sup>(1)</sup> Must be set to 0x180 in case of 384-TDM slot frame reception from a DIR component I2S-output. For more details on TDM-frame settings, refer to [Section 24.6.4.9.2](#).

### 24.6.5.1.2.2.3 Subsequence – Receive Clock Generator Configuration

The procedure in [Table 24-440](#) configures the receive clock generator of the McASP module.

**NOTE:** The settings in below table [Table 24-440](#) have no effect, if [MCASP\\_ACLKXCTL\[6\]](#) ASYNC = 0 (i.e. receive clock is sourced from the inverted version of the transmit clock). For example, such is the case when McASP loopback mode is used.

**Table 24-440. Receive Clock Generator Configuration**

Step	Register/Bit Field/Programming Model	Value
To use the McASP receive clock generator, select an asynchronous receiver clock schema (ASYNC=1). Otherwise an inverted version of transmit clock XCLK is used (receiver synchronized with transmitter).	MCASP_ACLKXCTL[6] ASYNC	0b1
<b>IF</b> receive clock - RCLK is internally generated	Software test condition	
The high-speed receive clock - AHCLKR is internally generated based on AUXCLK		
Select an internally-generated high-frequency clock.	MCASP_AHCLKRCTL[15] HCLKRM	0b1
Select the internal high-speed clock source polarity: non-inverted or inverted.	MCASP_AHCLKRCTL[14] HCLKRP	0x-
Set the divisor for the internally generated high-frequency clock – AHCLKR in range (1 - 4096).	MCASP_AHCLKRCTL[11:0] HCLKRDIV	0x-
Select an internally-generated receive clock.	MCASP_ACLKRCTL[5] CLKRM	0b1
Receiver samples on rising/falling edge. Select Rx sampling on the rising edge if transmitter shifts out on falling edge, and vice versa.	MCASP_ACLKRCTL[7] CLKRP	0x-
Set the divisor for the internally generated receive clock– ACLKR in range (1 - 32).	MCASP_ACLKRCTL[4:0] CLKRDIV	0x-
Optional: If McASP receiver is required to output internally generated clock, ACLKR pin must be set as an output in step 9 of the sequence documented in the <a href="#">Table 24-437</a> . This must not be done in current step because the clock control register - MCASP_ACLKRCTL must be appropriately configured prior to ACLKR pin outputting a receive clock to an external device.	MCASP_PDIR[29] ACLKR	0b1
<b>ELSE</b>		
Select an externally-generated receive clock. Note that in this case the AHCLKR signal path and the CLKRDIV divider are NOT used.	MCASP_ACLKRCTL[5] CLKRM	0b0
Receiver samples on rising/falling edge. Select Rx sampling on the rising edge if transmitter shifts out on falling edge, and vice versa.	MCASP_ACLKRCTL[7] CLKRP	0x-
Setup an input direction for the ACLKR pin	MCASP_PDIR[29] ACLKR	0b0
<b>ENDIF</b>		
Configure the transmit clock failure detect logic.	See <a href="#">Section 24.6.4.15.6.1, Clock Failure Check Startup</a> .	

#### 24.6.5.1.2.2.4 Subsequence—McASP Receiver Pins Functional Configuration

The procedure in [Table 24-441](#) configures the McASP pins for McASP functionality.

**Table 24-441. McASP Receiver Pins Functional Configuration**

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have McASP functionality.	MCASP_PFUNC[31:0]	0x0
Configure the McASP pins direction: AFSR ACLKR Desired n-th McASP data pin AXRn is configured as an input for receiving.	MCASP_PDIR[31] AFSR; MCASP_PDIR[29] ACLKR; MCASP_PDIR[n] AXRn;	0x- <sup>(1)</sup> 0x- <sup>(2)</sup> 0x0

<sup>(1)</sup> See [Table 24-439](#).

<sup>(2)</sup> For more details on McASP clock configurations, refer to [Table 24-440](#).

### 24.6.5.1.2.3 Main Sequence – McASP Global Initialization for TDM -Transmission

The procedure in [Table 24-442](#) initializes a McASP serializer n transmitter(s) to operate in TDM-mode after a power-on reset (POR). This is used for I2S (2-slot TDM) and other TDM-based audio protocols transmission.

#### CAUTION

Before performing McASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the [MCASP\\_GBLCTL](#) register.

**Table 24-442. McASP Transmitters Global Initialization for TDM-Mode Operation**

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different McASP transmit components.	<a href="#">MCASP_GBLCTL</a> [12:8]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	<a href="#">MCASP_GBLCTL</a> [12:8]	=0x00
3. Configure the local power management.	<a href="#">PWRIDLESYSCONFIG</a> [1:0] IDLE_MODE	0x1
4. Configure the transmit format unit.	See <a href="#">Section 24.6.5.1.2.3.1</a> .	
5. Configure the transmit frame sync generator.	See <a href="#">Section 24.6.5.1.2.3.2</a> .	
6. Configure the transmit clock generator.	See <a href="#">Section 24.6.5.1.2.3.3</a> .	
7. Program all bits - XTDMSk, where k=0 to 31, according to the time slot characteristics desired (positions of active versus inactive slots within a frame).	<a href="#">MCASP_TXTDM</a> [ k ] XTDMSk, where k=0 to 31 <sup>(1)</sup>	0x-
8. Configure the desired n-th serializer for transmit mode operation. <sup>(2)</sup>	<a href="#">MCASP_XRSRCTLn</a> [1:0] SRMOD;	0x1
9. Setup all active transmitters to operate in TDM mode.	<a href="#">MCASP_TXDITCTL</a> [0] DITEN	0x0 <sup>(3)</sup>
10. Configure the McASP pins functionality.	See <a href="#">Section 24.6.5.1.2.3.4</a> .	
11. Optional: Configure a McASP Tx channel for loopback operation (TDM mode only) in <a href="#">MCASP_LBCTL</a> [31:0].	See <a href="#">Section 24.6.4.14.1</a> , <i>Loopback Mode Configurations</i> .	0x-
12. Release from reset state the divider that outputs the AHCLKR clock. See <sup>(4)</sup>	<a href="#">MCASP_GBLCTL</a> [9] XHCLKRST	0x1
13. Poll the bit to ensure that it is successfully latched in the register.	<a href="#">MCASP_GBLCTL</a> [9] XHCLKRST	=0x1
14. Release from reset state the divider that outputs the ACLKR clock. See <sup>(4)</sup>	<a href="#">MCASP_GBLCTL</a> [8] XCLKRST	0x1
15. Poll the bit to ensure that it is successfully latched in the register.	<a href="#">MCASP_GBLCTL</a> [8] XCLKRST	=0x1

<sup>(1)</sup> Appropriately program in bitfield [MCASP\\_XRSRCTLn](#) [3:2] DISMOD, the desired level (high-impedance state, 0, or 1) at AXRn output, during time of inactive slots. Note, that this setting does NOT apply when all slots are programmed to be active within a frame (in particular DIT-mode).

<sup>(2)</sup> For an unused serializer n, write [MCASP\\_XRSRCTLn](#) [1:0] SRMOD=0x0 to disable it.

<sup>(3)</sup> All active transmit channels operate either in TDM mode or in DIT mode depending on DITEN value. There is no option to choose Tx Mode between DIT and TDM separately per serializer transmitter.

<sup>(4)</sup> During reset state the local McASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the [MCASP\\_AHCLKX](#) and [MCASP\\_ACLKX](#) registers are ignored; hence, the transmission clock does not stop during the reset state of the dividers.

### 24.6.5.1.2.3.1 Subsequence – Transmit Format Unit Configuration in TDM Mode

The procedure in [Table 24-443](#) configures the transmit frame format unit of the McASP module for TDM slots transmission.

**Table 24-443. Transmit Format Unit Configuration for TDM-Transmission**

Step	Register/Bit Field/Programming Model	Value
Configure the desired TDM-slot size	MCASP_TXFMT[7:4] XSSZ	0x- <sup>(1)</sup>
Set data mask out value (0x0000 0000 - 0xFFFF FFFF).	MCASP_TXMASK[31:0] XMASK	0x- <sup>(2)</sup>
Select a padding value for masked-out bits.	MCASP_TXFMT[14:13] XPAD	0x-
Specify position (0x0-0x1F) of the bit in corresponding register MCASP_TXBUF <sub>n</sub> which value to be used as a pad value in case MCASP_TXFMT[14:13] XPAD=0x2.	MCASP_TXFMT[12:8] XPBIT	0x-
Rotate data right by a multiple of 4- bit positions.	MCASP_TXFMT[2:0] XROT	0x- <sup>(3)</sup>
transmitted stream bit order (LSB- or MSB-first ). Must be set to 0x1 for an I2S stream transmission (MSB-first).	MCASP_TXFMT[15] XRVR5	0x- <sup>(3)</sup>
Specify a delay between frame sync and first bit of data in number of bits. Must be set to 0x1 for an I2S stream transmission.	MCASP_TXFMT[17:16] XDATDLY	0x-
Select to write data to active serializers transmit buffers using peripheral (CFG) or DATA port	MCASP_TXFMT[3] XBUSEL	0x-

<sup>(1)</sup> Refer to [Section 24.6.4.4.1, Transmit Format Unit](#) , regarding options for transmitted TDM-slot sizes.

<sup>(2)</sup> For more details on Tx masking value, refer to [Section 24.6.4.4.1.1, TDM - Mode Transmission Data Alignment Settings](#)

<sup>(3)</sup> For more details on rotation and transmitd TDM stream bit order, refer to [Section 24.6.4.4.1.1, TDM - Mode Transmission Data Alignment Settings](#) and [Table 24-423, McASP TFU TDM Mode Settings](#).

**24.6.5.1.2.3.2 Subsequence – Transmit Frame Synchronization Generator Configuration in TDM Mode**

The procedure in [Table 24-444](#) configures the transmit frame synchronization generator of the McASP module.

**Table 24-444. Transmit Frame-Synchronization Generator Configuration for TDM-Transmission**

Step	Register/Bit Field/Programming Model	Value
Select number of TDM slots per frame (2 - 32). Must be set to 0x2, in case of an I2S-transmission. For more details on frame-sync generator, refer to <a href="#">Section 24.6.4.2.3</a> .	MCASP_TXFMCTL[15:7] XMOD	0x-
Choose the transmit frame sync width -single bit/single word. For more details on frame-sync generator, refer to <a href="#">Section 24.6.4.2.3</a> .	MCASP_TXFMCTL[4] FXWID	0x-
Select start of transmit frame sync polarity - rising /falling edge. For more details on frame-sync generator, refer to <a href="#">Section 24.6.4.2.3</a> .	MCASP_TXFMCTL[0] FSXP	0x-
<b>IF</b> transmit frame sync - FS is internally generated	Software test condition	
Select internally- generated transmit frame sync. For more details on frame-sync generator, refer to <a href="#">Section 24.6.4.2.3</a> .	MCASP_TXFMCTL[1] FSXM	0b1
If McASP transmitter is required to output internally generated frame, AFSX pin must be set as an output in step 10 of the sequence documented in the <a href="#">Table 24-442</a> . This must NOT be done in current step because the frame control register - MCASP_TXFMCTL must be appropriately configured prior to AFSX pin outputting a frame sync to an external device.	MCASP_PDIR[28] AFSX	0b1
<b>ELSE</b>		
Select externally- generated transmit frame sync. For more details on frame-sync generator, refer to <a href="#">Section 24.6.4.2.3</a> .	MCASP_TXFMCTL[1] FSXM	0b0
Setup the AFSX pin as input	MCASP_PDIR[28] AFSX	0b0

### 24.6.5.1.2.3.3 Subsequence – Transmit Clock Generator Configuration for TDM Cases

The procedure in [Table 24-445](#) configures the transmit clock generator of the McASP module.

**Table 24-445. Transmit Clock Generator Configuration for TDM Cases**

Step	Register/Bit Field/Programming Model	Value
<b>IF</b> transmit clock - XCLK is internally generated	Software test condition	
<b>IF</b> high-speed transmit clock - AHCLKX is internally generated based on AUXCLK	Software test condition	
Select an internally-generated high-frequency clock.	<a href="#">MCASP_AHCLKXCTL</a> [15] HCLKXM	0b1
Select the high-frequency clock source polarity: non-inverted or inverted.	<a href="#">MCASP_AHCLKXCTL</a> [14] HCLKXP	0x-
Set the divisor for the internally generated high-frequency clock – AHCLKX in range (1 - 4096).	<a href="#">MCASP_AHCLKXCTL</a> [11:0] HCLKXDIV	0x-
Optional: If McASP transmitter is required to output internally generated high-frequency clock, AHCLKX pin must be set as an output in step 10 of the sequence documented in the <a href="#">Table 24-442</a> . This must NOT be done in current step because the clock control register - <a href="#">MCASP_AHCLKXCTL</a> must be appropriately configured prior to AHCLKX pin outputting a high-speed clock to an external device.	<a href="#">MCASP_PDIR</a> [27] AHCLKX	0b1
<b>ELSE</b>		
Select an externally-generated high frequency clock (HCLKXDIV divider can not be used).	<a href="#">MCASP_AHCLKXCTL</a> [15] HCLKXM	0b0
Select the high-speed transmit clock source polarity: non-inverted or inverted.	<a href="#">MCASP_AHCLKXCTL</a> [14] HCLKXP	0x-
Setup an input direction for the AHCLKX pin	<a href="#">MCASP_PDIR</a> [27] AHCLKX	0b0
<b>ENDIF</b>		
Select an internally-generated transmit clock.	<a href="#">MCASP_ACLKXCTL</a> [5] CLKXM	0b1
Transmitter samples on rising/falling edge. Select Tx shifting out data on the rising edge if receiver samples on falling edge, and vice versa.	<a href="#">MCASP_ACLKXCTL</a> [7] CLKXP	0x-
Set the divisor for the internally generated transmit clock– ACLKX in range (1 - 32).	<a href="#">MCASP_ACLKXCTL</a> [4:0] CLKXDIV	0x-
Optional: If McASP transmitter is required to output internally generated clock, ACLKX pin) must be set as an output in step 10 of the sequence documented in the <a href="#">Table 24-442</a> . This must NOT be done in current step because the clock control register - <a href="#">MCASP_ACLKXCTL</a> must be appropriately configured prior to ACLKX pin outputting a transmit clock to an external device.	<a href="#">MCASP_PDIR</a> [26] ACLKX	0b1
<b>ELSE</b>		
Select an externally-generated transmit clock. Note that in this case the AHCLKX signal path and the CLKXDIV divider are NOT used.	<a href="#">MCASP_ACLKXCTL</a> [5] CLKXM	0b0
Transmitter samples on rising/falling edge. Select Tx shifting out data on the rising edge if receiver samples on falling edge, and vice versa.	<a href="#">MCASP_ACLKXCTL</a> [7] CLKXP	0x-
Setup an input direction for the ACLKX pin	<a href="#">MCASP_PDIR</a> [26] ACLKX	0b0
<b>ENDIF</b>		
Configure the transmit clock failure detect logic.	See <a href="#">Section 24.6.4.15.6.1</a> , <i>Clock Failure Check Startup</i> .	

### 24.6.5.1.2.3.4 Subsequence—McASP Transmit Pins Functional Configuration

The procedure in [Table 24-446](#) configures the McASP pins for McASP functionality.

**Table 24-446. McASP Transmit Pins Functional Configuration**

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have McASP functionality.	MCASP_PFUNC[31:0]	0x0
Configure the McASP pins direction: AFSX AHCLKX ACLKX Desired n-th McASP data pin AXRn is configured as an output for transmission.	MCASP_PDIR[28] AFSR; MCASP_PDIR[27] AHCLKR; MCASP_PDIR[26] ACLKR; MCASP_PDIR[n] AXRn	0x- <sup>(1)</sup> 0x- <sup>(2)</sup> 0x- <sup>(2)</sup> 0x1

<sup>(1)</sup> See [Table 24-444](#).

<sup>(2)</sup> For more details on McASP clock configurations, refer to [Table 24-440](#).

## 24.6.5.2 Operational Modes Configuration

### 24.6.5.2.1 McASP Transmission Modes

#### 24.6.5.2.1.1 Main Sequence – McASP DIT- /TDM- Polling Transmission Method

[Figure 24-135](#) shows the McASP DIT-/TDM- polling method.

---

**NOTE:**

- The McASP polling transmission model considers the MPU/DSP as the source of audio data for the McASP transmission buffer.
  - The transmit DMA request is disabled and the XDMAERR event is not analyzed.
-

Figure 24-135. McASP DIT- /TDM- Transmission Polling Method

mcasp-026

Table 24-447 summarizes the register call for the transmission DIT-/TDM- polling mode.

Table 24-447. Register Call Summary for Main Sequence – McASP DIT-/TDM- Transmission Polling Method

Register Name
MCASP_XEVTCTL
MCASP_TXSTAT
MCASP_GBLCTL
MCASP_TXTDM
MCASP_TXBUFn
MCASP_XRSRCTLn
MCASP_DITUDRAI (i=0 to 5)
MCASP_DITUDRBI (i=0 to 5)
MCASP_DITCSRAI (i=0 to 5)

**Table 24-447. Register Call Summary for Main Sequence – McASP DIT-/TDM- Transmission Polling Method (continued)**

Register Name
<a href="#">MCASP_DITCSRBi</a> (i=0 to 5)

[Table 24-448](#) summarizes the subprocess call for the DIT-/TDM- transmission polling mode.

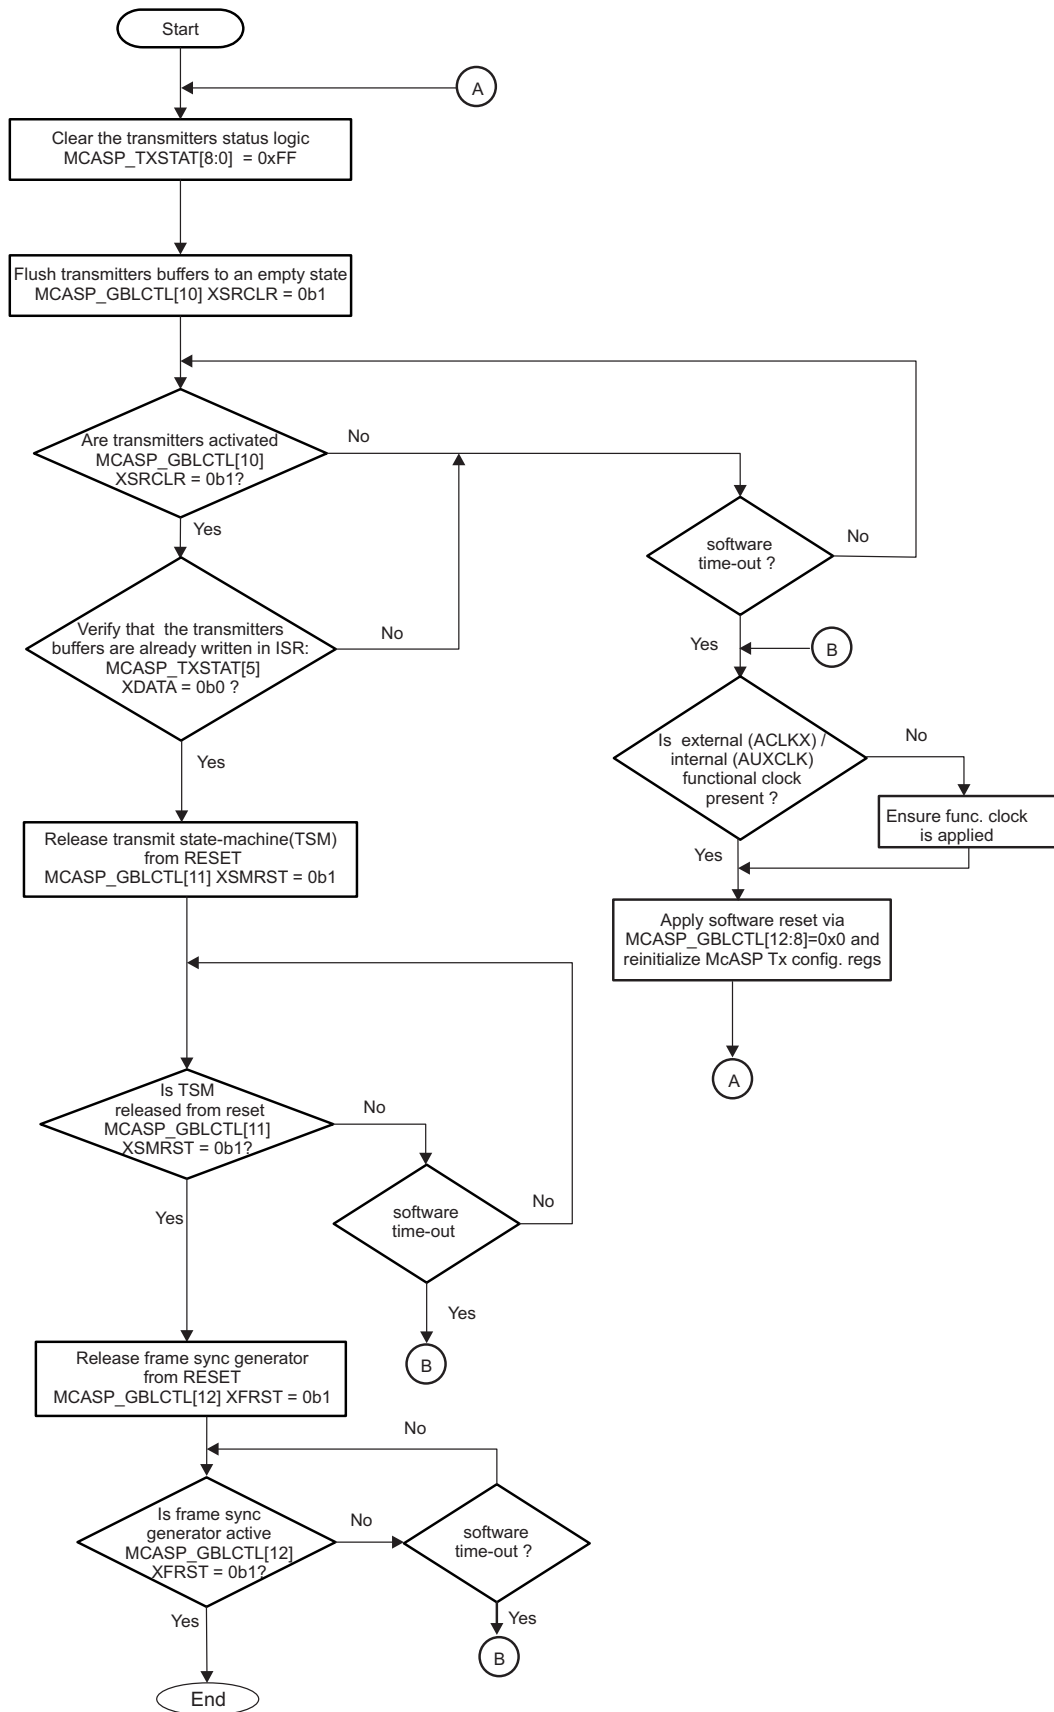

**Table 24-448. Subprocess Call Summary for Main Sequence – McASP DIT-/TDM- Transmission Polling Method**

Subprocess Name	Cross-Reference
Error handling	<a href="#">Figure 24-141</a>

#### **24.6.5.2.1.2 Main Sequence – McASP DIT- /TDM - Interrupt Transmission Method**

[Figure 24-136](#) shows the initial setup for interrupt-based transmission.

Figure 24-136. Subsequence – DIT-/TDM- Transmission Startup Procedure

mcasp-027

Table 24-449 shows the configuration of the McASP using an interrupt method for DIT-/TDM-transmission.

**Table 24-449. McASP DIT-/TDM- Interrupt Transmission Model**

Step	Register/Bit Field/Programming Model	Value
Disable Tx DMA requests generation.	MCASP_XEVTCTL[0] XDATDMA	0x1
Enable the data ready event transmit interrupt.	MCASP_EVTCTLX[5] XDATA	0x1
Optional: Enable the transmit error event interrupts.	MCASP_EVTCTLX[2] XCKFAIL MCASP_EVTCTLX[1] XSYNCERR MCASP_EVTCTLX[0] XUNDRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt (useful for DIT user data/ channel status next S/PDIF frame info update.)	MCASP_EVTCTLX [7] XSTAFRM MCASP_EVTCTLX[4] XLAST	0x1 0x1
<b>IF</b> write transfer is through the McASP DATA port (MCASP_TXFMT[3] XBUSEL is set to 0b0).	Software test condition (setting is done in step4 of the <i>McASP Transmitters Global Initialization</i> - see Table 24-431 )	
Enable the DATA port error based interrupt.	MCASP_EVTCTLX[3] XDMAERR	0x1
<b>ELSE</b>		
Disable the DATA port error based interrupt.	MCASP_EVTCTLX[3] XDMAERR	0x0
<b>ENDIF</b>		
DIT/TDM - Transmission Startup Procedure	See Figure 24-136.	

Table 24-450 summarizes the register call to initialize the McASP to transmit using interrupt events.

**Table 24-450. Register Call Summary for Subsequence – McASP DIT-/TDM- Transmission Startup Procedure**

Register Name	Register Name
MCASP_GBLCTL	MCASP_TXSTAT

### 24.6.5.2.1.3 Main Sequence –McASP DIT- /TDM - Mode DMA Transmission Method

Table 24-451 shows the configuration of the McASP using the DMA method for transmission. Possible interrupt error event servicing is also considered. Table 24-450 shows the initial setup for DMA - based transmission.

**NOTE:** Because of the DATA port burst access capability with the DMA method, it is strongly recommended that DMA transfers are initiated through the McASP DATA port.

**Table 24-451. McASP DMA Transmission Model with Interrupt Events Servicing**

Step	Register/Bit Field/Programming Model	Value
<b>Recommended:</b> Select DATA port to access the transmit buffers.	MCASP_TXFMT[3] XBUSEL	0x0
Enable the Tx DMA requests generation.	MCASP_XEVTCTL[0] XDATDMA	0x0
Enable the Tx DMA error event, because of McASP DATA port usage.	MCASP_EVTCTLX[3] XDMAERR	0x1
Optional: Enable the transmit error event interrupts.	MCASP_EVTCTLX[2] XCKFAIL MCASP_EVTCTLX[1] XSYNCERR MCASP_EVTCTLX[0] XUNDRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt.	MCASP_EVTCTLX [7] XSTAFRM MCASP_EVTCTLX[4] XLAST	0x1 0x1
Disable the data ready event transmit interrupt, as DMA is used to service this request.	MCASP_EVTCTLX[5] XDATA	0x0

**Table 24-451. McASP DMA Transmission Model with Interrupt Events Servicing (continued)**

Step	Register/Bit Field/Programming Model	Value
DMA startup transmission procedure. This procedure is identical than the one shown in <a href="#">Figure 24-136</a> . The only difference is that DMA automatically services all the AXEVT events raised by the McASP, and no CPU data processing intervention is required. The CPU is involved only in error handling shown in <a href="#">Figure 24-139</a> .	See <a href="#">Figure 24-136</a> .	

### 24.6.5.2.2 McASP Reception Modes

#### 24.6.5.2.2.1 Main Sequence – McASP Polling Reception Method

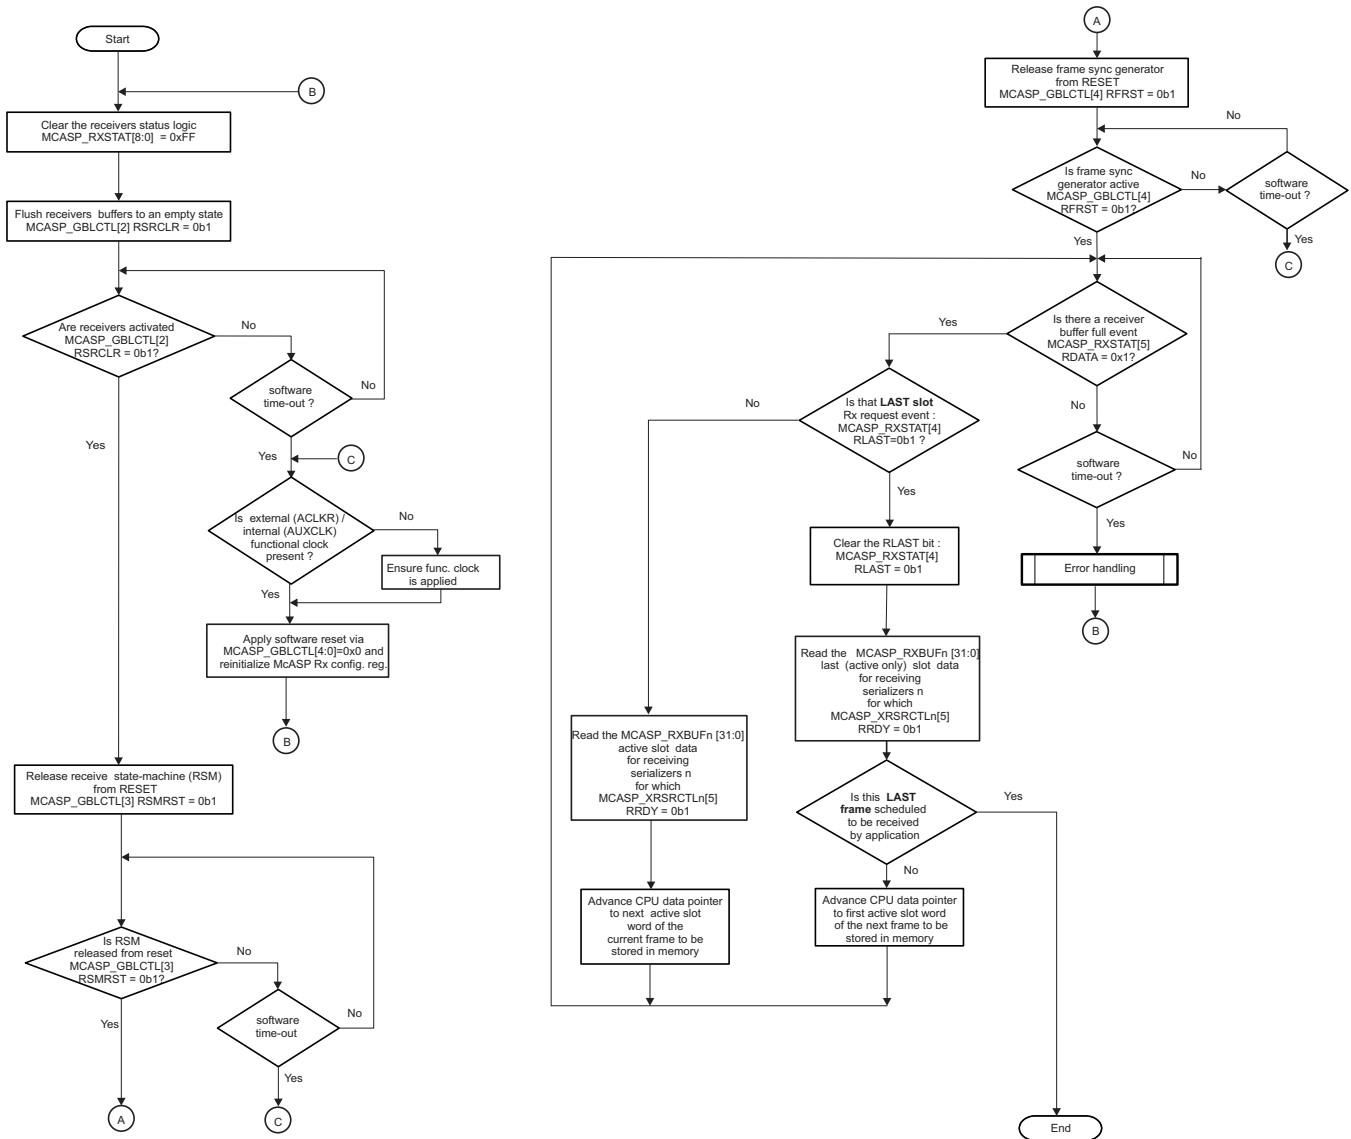

[Figure 24-137](#) shows the McASP polling reception method.

---

**NOTE:** The McASP polling reception model considers the device CPUs as the accessor of audio data from the McASP receive buffers.

---

Figure 24-137. McASP Polling Reception Method

mcasp-043

Table 24-452 summarizes the register call for the reception polling mode.

Table 24-452. Register Call Summary for Main Sequence – McASP Reception Polling Method

Register Name
MCASP_RXSTAT
MCASP_GBLCTL
MCASP_RXBUFn
MCASP_XRSRCTLn

Table 24-453 summarizes the subprocess call for the polling mode.

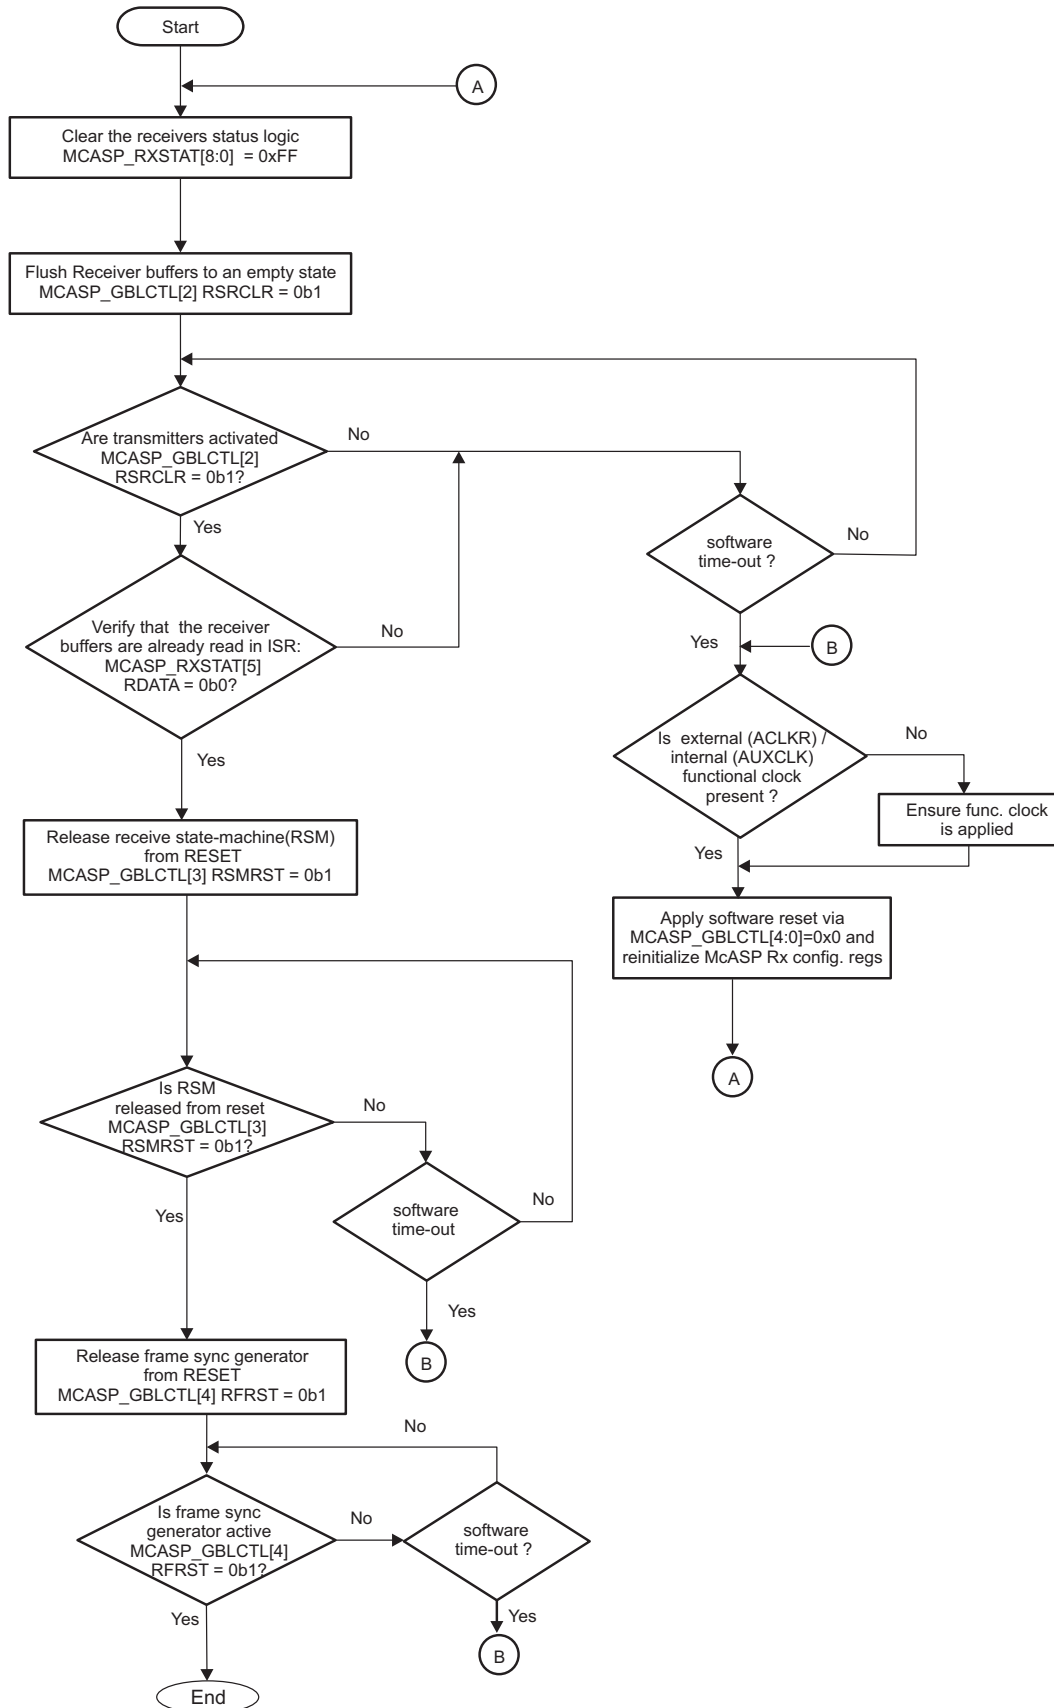

**Table 24-453. Subprocess Call Summary for Main Sequence – McASP Reception Polling Method**

Subprocess Name	Cross-Reference
Error handling	<a href="#">Figure 24-142</a>

#### **24.6.5.2.2.2 Main Sequence – McASP TDM - Interrupt Reception Method**

[Figure 24-138](#) shows the initial setup for interrupt-based reception.

Figure 24-138. Subsequence – TDM - Reception Startup Procedure

mcaspp-032

Table 24-454 shows the configuration of the McASP using an interrupt method for TDM- reception.

**Table 24-454. McASP TDM- Interrupt Reception Model**

Step	Register/Bit Field/Programming Model	Value
Disable Rx DMA requests generation.	MCASP_REVTCTL[0] RDATDMA	0x1
Enable the data ready event receive interrupt.	MCASP_EVTCTLR[5] RDATA	0x1
Optional: Enable the receive error event interrupts.	MCASP_EVTCTLR[2] RCKFAIL MCASP_EVTCTLR[1] RSYNCERR MCASP_EVTCTLR[0] ROVRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt	MCASP_EVTCTLR [7] RSTAFRM MCASP_EVTCTLR[4] RLAST	0x1 0x1
IF read transfer is through the McASP DATA port (MCASP_RXFMT[3] RBUSEL is set to 0b0).	Software test condition (setting is done in step4 of the <i>McASP Receivers Global Initialization for TDM-Mode Operation</i> - see Table 24-437 )	
Enable the DATA port error based interrupt.	MCASP_EVTCTLR[3] RDMAERR	0x1
<b>ELSE</b>		
Disable the DATA port error based interrupt.	MCASP_EVTCTLR[3] RDMAERR	0x0
<b>ENDIF</b>		
TDM - Transmission Startup Procedure	See Figure 24-138.	

Table 24-455 summarizes the register call to initialize the McASP to transmit using interrupt events.

**Table 24-455. Register Call Summary for Subsequence – McASP TDM- Reception Startup Procedure**

Register Name	Register Name
MCASP_GBLCTL	MCASP_RXSTAT

#### 24.6.5.2.2.3 Main Sequence – McASP TDM - Mode DMA Reception Method

Table 24-456 shows the configuration of the McASP using the DMA method for reception. Possible interrupt error event servicing is also considered. Table 24-450 shows the initial setup for DMA - based transmission.

---

**NOTE:** Because of the DATA port burst access capability with the DMA method, it is strongly recommended that DMA transfers are initiated through the McASP DATA port.

---

**Table 24-456. McASP DMA Reception Model with Interrupt Events Servicing**

Step	Register/Bit Field/Programming Model	Value
<b>Recommended:</b> Select DATA port to access the transmit buffers.	MCASP_RXFMT[3] RBUSEL	0x0
Enable the Rx DMA requests generation.	MCASP_REVTCTL[0] RDATDMA	0x0
Enable the Rx DMA error event, because of McASP DATA port usage.	MCASP_EVTCTLR[3] RDMAERR	0x1
Optional: Enable the receive error event interrupts.	MCASP_EVTCTLR[2] RCKFAIL MCASP_EVTCTLR[1] RSYNCERR MCASP_EVTCTLR[0] ROVRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt.	MCASP_EVTCTLR [7] RSTAFRM MCASP_EVTCTLR[4] RLAST	0x1 0x1
Disable the data ready event receive interrupt, as DMA is used to service this request.	MCASP_EVTCTLR[5] RDATA	0x0

**Table 24-456. McASP DMA Reception Model with Interrupt Events Servicing (continued)**

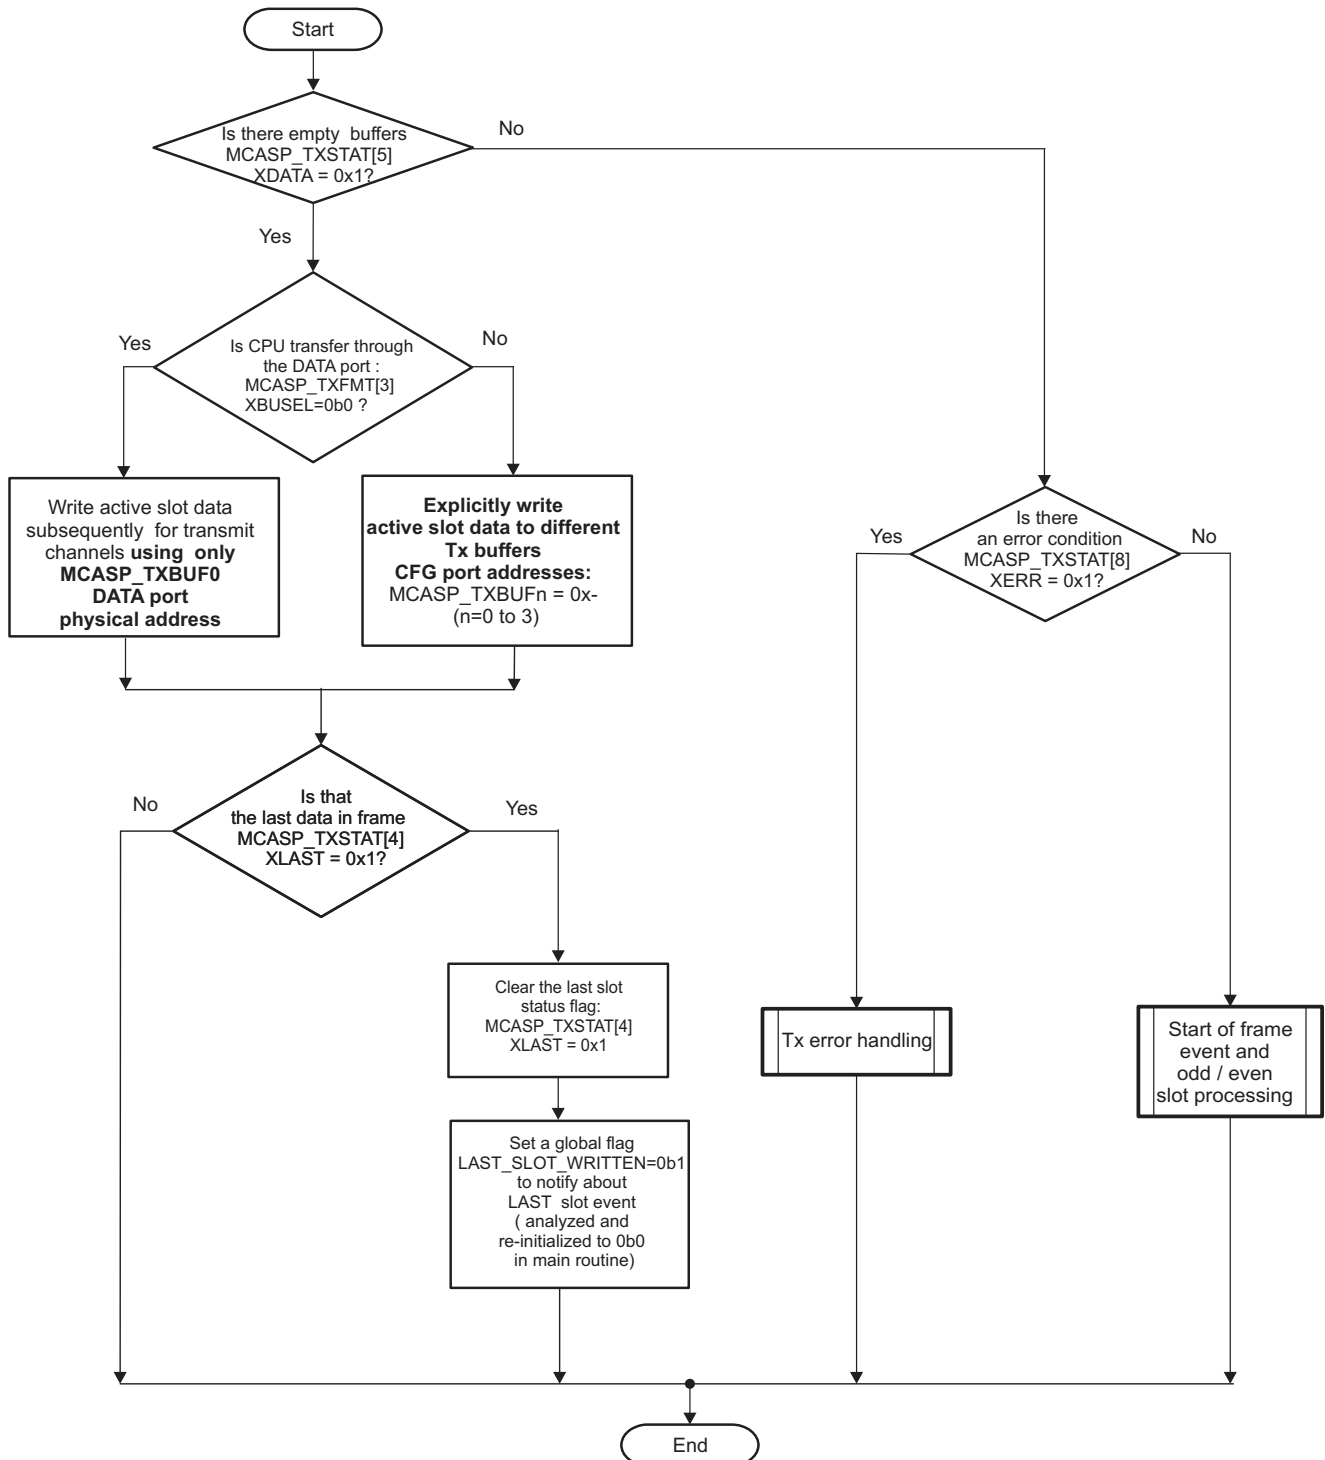

Step	Register/Bit Field/Programming Model	Value
DMA startup reception procedure. This procedure is identical than the one shown in <a href="#">Figure 24-138</a> . The only difference is that DMA automatically services all the AREVT events raised by the McASP, and no CPU data processing intervention is required. The CPU is involved only in error handling shown in <a href="#">Figure 24-140</a> .	See <a href="#">Figure 24-138</a> .	

### 24.6.5.2.3 McASP Event Servicing

#### 24.6.5.2.3.1 McASP DIT-/TDM- Transmit Interrupt Events Servicing

[Figure 24-139](#) shows the flow of DIT-/TDM- mode transmit interrupt events servicing for the McASP module.

Figure 24-139. McASP Transmit Interrupt Events Servicing

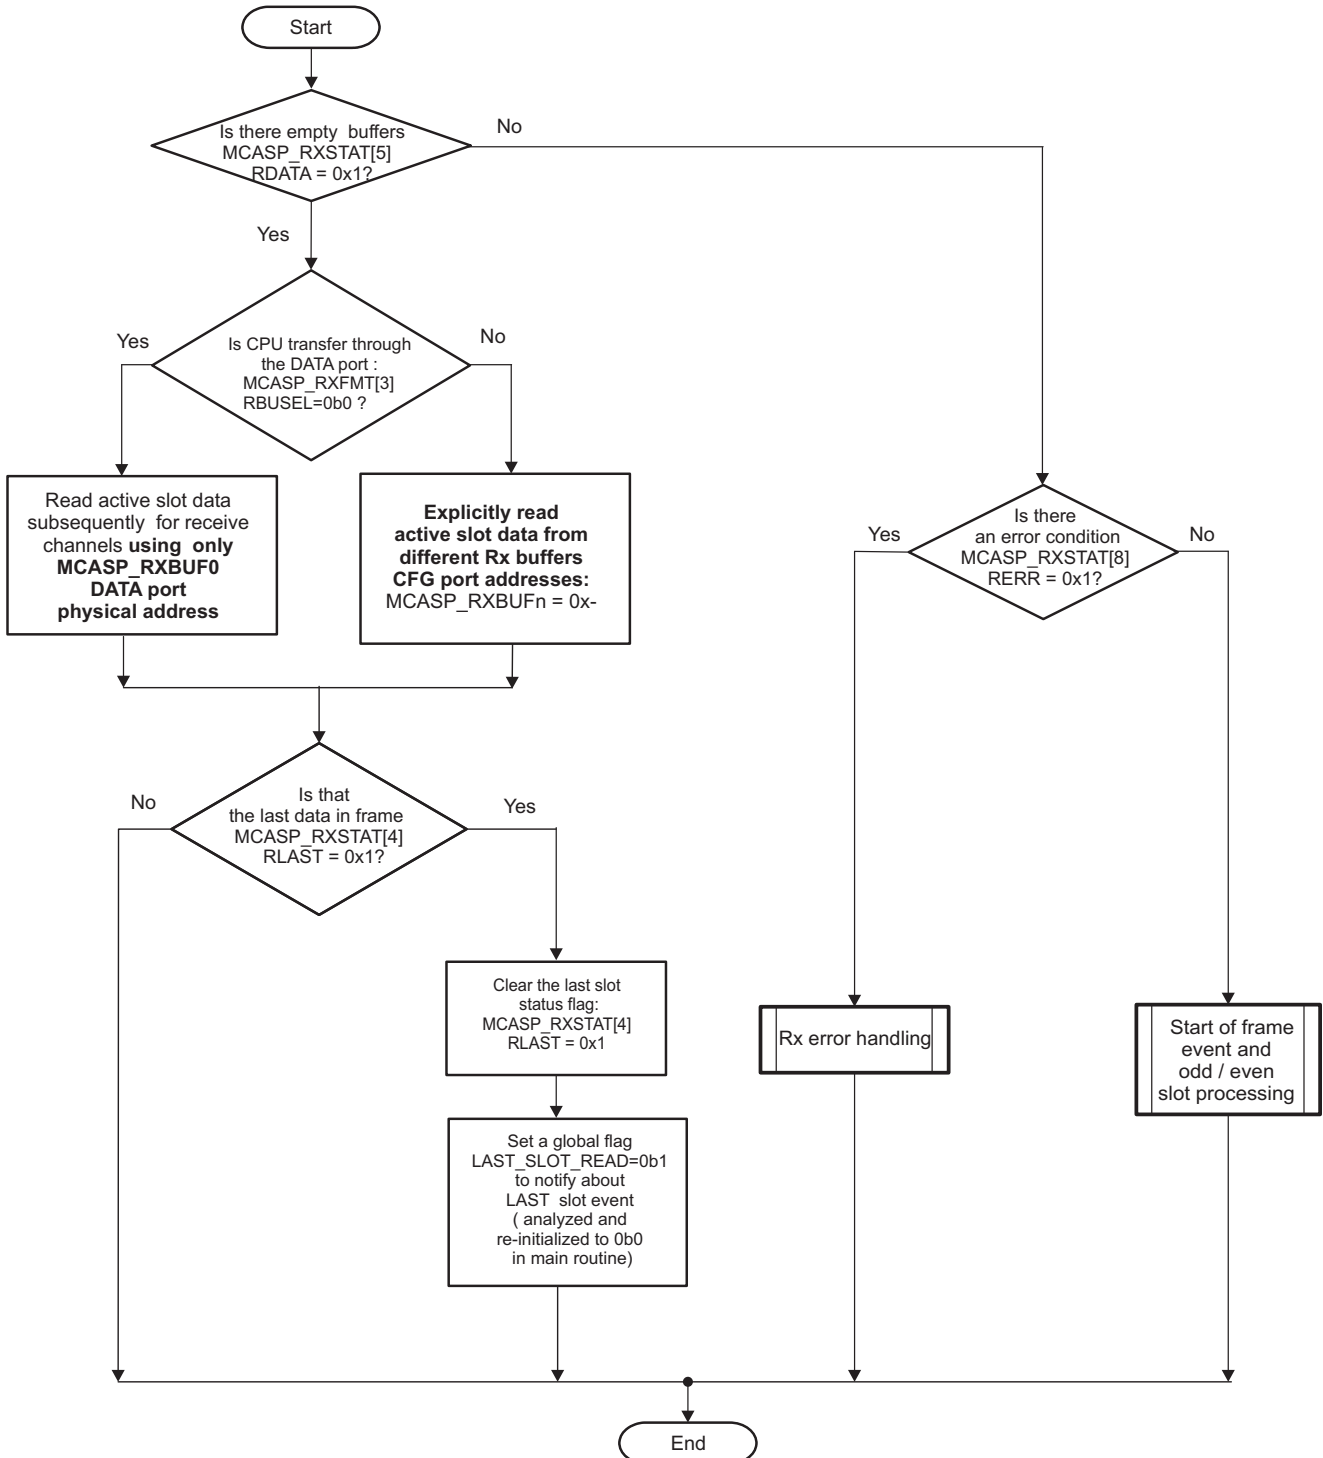

mcasp-029

24.6.5.2.3.2 McASP TDM- Receive Interrupt Events Servicing

Figure 24-140 shows the flow of DIT-/TDM- mode transmit interrupt events servicing for the McASP module.

Figure 24-140. McASP Receive Interrupt Events Servicing

mcasp-033

Table 24-457 lists the register call summary for the receive interrupt events servicing.

**Table 24-457. Register Call Summary for McASP Receive Interrupt Events Servicing**

Register Name	Register Name	Register Name
MCASP_RXSTAT	MCASP_RXBUFn	MCASP_RXFMT

Table 24-458 lists the subprocess call summary for receive interrupt events servicing.

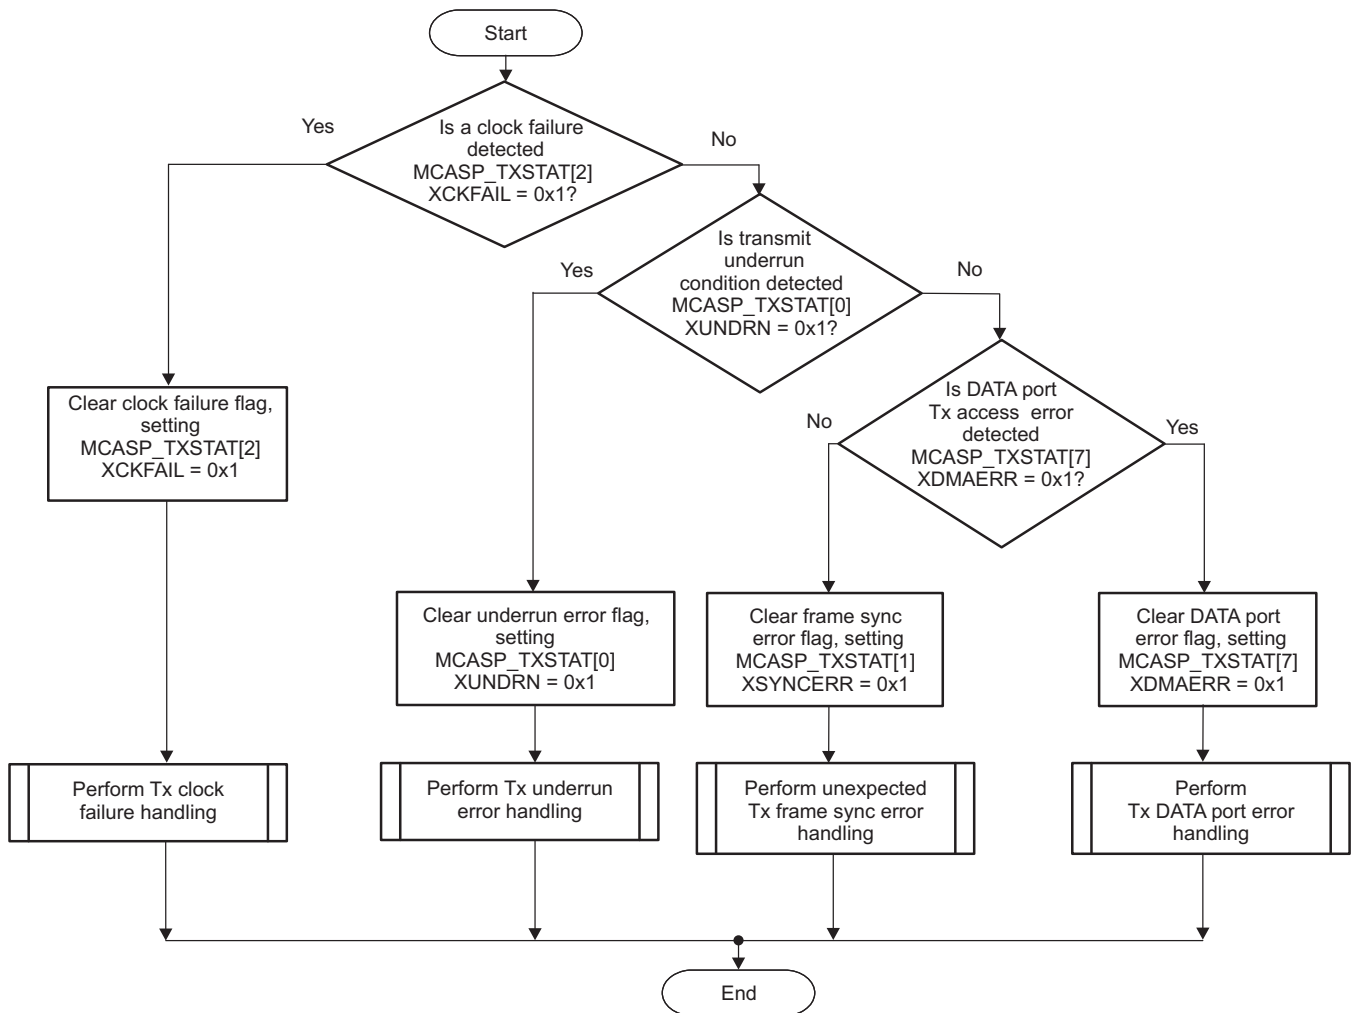

**Table 24-458. Subprocess Call Summary for Receive Interrupt Events Servicing**

Subprocess Name	Cross-Reference
McASP receive error handling	Figure 24-142
Start of frame handling	Section 24.6.4.12.2

**24.6.5.2.3.3 Subsequence – McASP DIT-/TDM -Modes Transmit Error Handling**

Figure 24-141 shows the transmit error handling schema for the McASP, which can be implemented as part of the Tx interrupt service routine or as part of the Tx polling sequence.

**Figure 24-141. McASP Transmit Error Handling**

mcasp-030

Table 24-459 lists the register call summary for the McASP transmit error handling.

**Table 24-459. Register Call Summary for McASP Transmit Error Handling**

Register Name
MCASP_TXSTAT

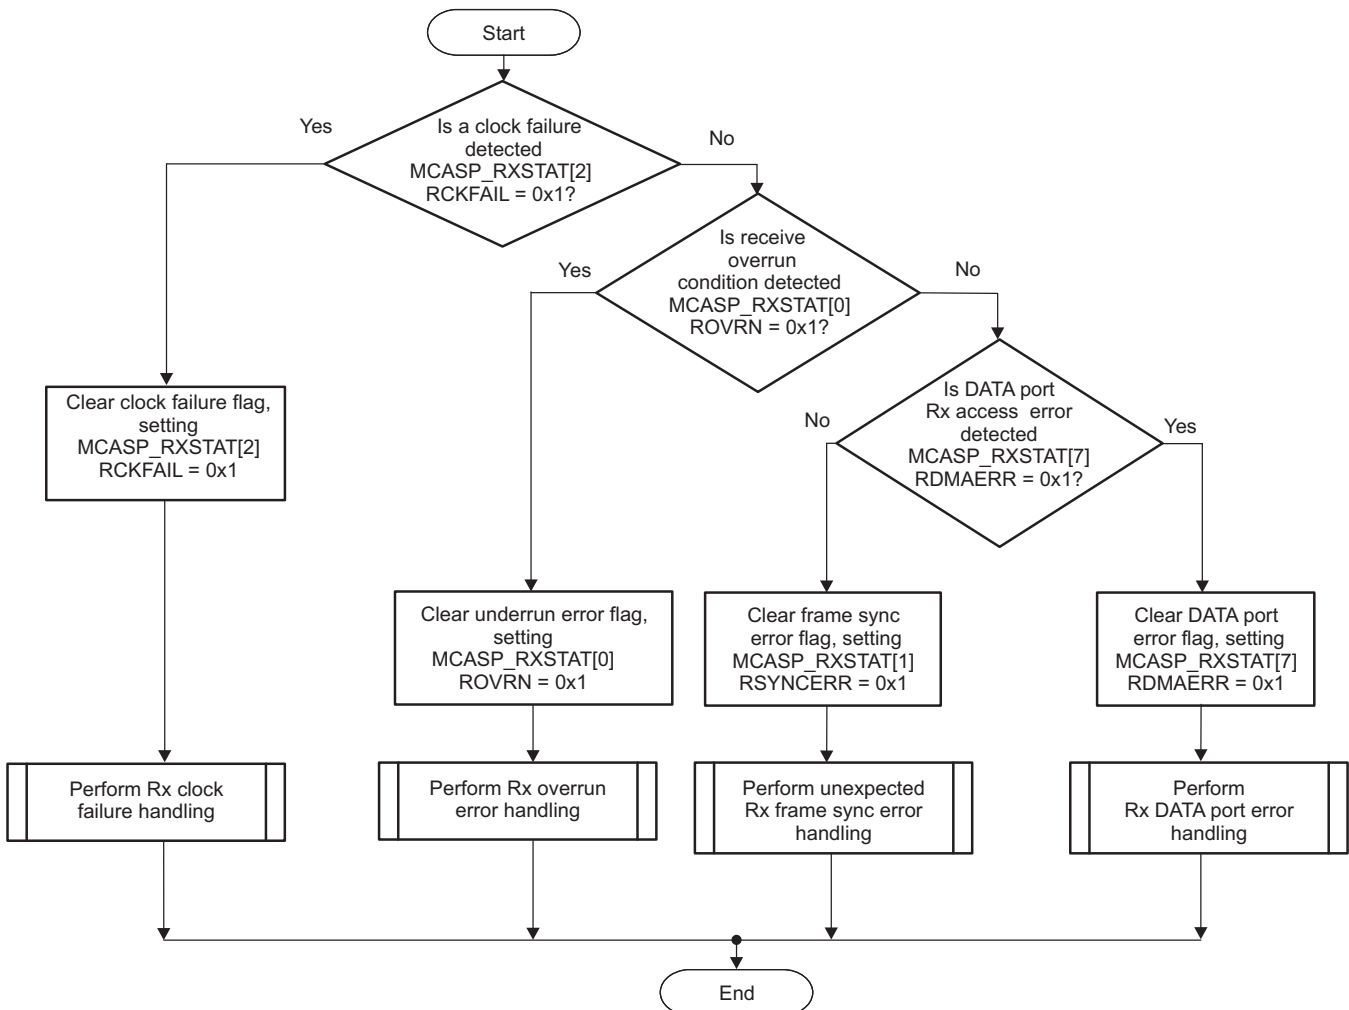

**NOTE:**

- For more information about transmit clock failure handling, see [Section 24.6.4.15.6.2, Transmit Clock Failure Check and Recovery](#).
- For more information about transmit buffer underrun handling, see [Section 24.6.4.15.1, Buffer Underrun Error -Transmitter](#).
- For more information about DATA port Tx error handling, see [Section 24.6.4.15.3, DATA Port Error - Transmitter](#).
- For more information about unexpected Tx frame sync error handling, see [Section 24.6.4.15.5, Unexpected Frame Sync Error](#).

**24.6.5.2.3.4 Subsequence – McASP Receive Error Handling**

Figure 24-142 shows the receive error handling schema for the McASP, which can ONLY be implemented as part of the Rx polling sequence.

**Figure 24-142. McASP Receive Error Handling**

mcasp-031

[Table 24-460](#) lists the register call summary for the McASP receive error handling.

**Table 24-460. Register Call Summary for McASP Receive Error Handling**

Register Name
<a href="#">MCASP_RXSTAT</a>

**NOTE:**

- For more information about receive clock failure handling, see [Section 24.6.4.15.6.3](#), *Receive Clock Failure Check and Recovery*.
- For more information about receive buffer overrun handling, see [Section 24.6.4.15.2](#), *Buffer Overrun Error - Receiver*.
- For more information about DATA port Rx error handling, see [Section 24.6.4.15.4](#), *DATA Port Error - Receiver*.
- For more information about unexpected Rx frame sync error handling, see [Section 24.6.4.15.5](#), *Unexpected Frame Sync Error*.

## 24.6.6 McASP Register Manual

### 24.6.6.1 McASP Instance Summary

Table 24-461 summarizes the McASP instances.

**Table 24-461. McASP Instance Summary**

Module Name	Base Address L3_MAIN Interconnect	Base Address L4_PER2 Interconnect	Size
MCASP1_CFG	-	0x4846 0000	4 KiB
MCASP2_CFG	-	0x4846 4000	4 KiB

**NOTE:** The address locations listed in [Table 24-462](#) to [Table 24-465](#), *MCASP\_CFG Register Mapping Summary*, are relevant for accessing:

- All McASP configuration registers
  - [MCASP\\_TXBUFn](#) registers
  - [MCASP\\_RXBUFn](#) registers
- through the McASP peripheral configuration (CFG) port.

The [MCASP\\_TXFMT](#)[3] XBUSEL bit must be set to 0b1, to allow CFG port write accesses to the McASP XRBUFn buffer. The [MCASP\\_RXFMT](#)[3] RBUSEL bit must be set to 0b1, to allow CFG port read accesses to the McASP XRBUFn buffer.

#### 24.6.6.2.2 MCASP\_CFG Register Description

The tables below describe the individual MCASP\_CFG register bits.

**NOTE:** For all of the below described registers the indexes n and N are applying to serializers (not slots).

Register descriptions cover the superset McASP (16 serializers and all signals pinned out). For the particular McASP instantiation, please refer to [Section 24.6.2](#), *McASP Environment*, and [Section 24.6.3](#), *McASP Integration*.

<b>Address Offset</b>	0x0000 0018		
<b>Physical Address</b>	<a href="#">0x4846 0018</a> <a href="#">0x4846 4018</a> <a href="#">0x4846 8018</a> <a href="#">0x4846 C018</a> <a href="#">0x4847 0018</a> <a href="#">0x4847 4018</a> <a href="#">0x4847 8018</a> <a href="#">0x4847 C018</a>	<b>Instance</b>	<a href="#">MCASP1_CFG_PER2_L4</a> <a href="#">MCASP2_CFG_PER2_L4</a> <a href="#">MCASP3_CFG_PER2_L4</a> <a href="#">MCASP4_CFG_PER2_L4</a> <a href="#">MCASP5_CFG_PER2_L4</a> <a href="#">MCASP6_CFG_PER2_L4</a> <a href="#">MCASP7_CFG_PER2_L4</a> <a href="#">MCASP8_CFG_PER2_L4</a>
<b>Description</b>	<p>Pin data output register - holds a value for data out at all times, and may be read back at all times. The value held by <a href="#">MCASP_PDOUT</a> is not affected by writing to <a href="#">MCASP_PDIR</a> and <a href="#">MCASP_PFUNC</a>. However, the data value in <a href="#">MCASP_PDOUT</a> is driven out onto the McASP pin only if the corresponding bit in <a href="#">MCASP_PFUNC</a> is set to 1 (GPIO function) and the corresponding bit in <a href="#">MCASP_PDIR</a> is set to 1 (output).</p> <p>When reading data, it returns the corresponding bit value in <a href="#">MCASP_PDOUT[n]</a>; it does not return the input from the I/O pin.</p> <p>When writing data, writes to the corresponding <a href="#">MCASP_PDOUT[n]</a> bit.</p> <p>PDOUT has these aliases or alternate addresses:</p> <ul style="list-style-type: none"> <li>• <a href="#">MCASP_PDSET</a> - when written to at this address, writing a 1 to a bit in <a href="#">MCASP_PDSET</a> sets the corresponding bit in <a href="#">MCASP_PDOUT</a> to 1; writing a 0 has no effect and keeps the bits in <a href="#">MCASP_PDOUT</a> unchanged.</li> <li>• <a href="#">MCASP_PDCLR</a> - when written to at this address, writing a 1 to a bit in <a href="#">MCASP_PDCLR</a> clears the corresponding bit in <a href="#">MCASP_PDOUT</a> to 0; writing a 0 has no effect and keeps the bits in <a href="#">MCASP_PDOUT</a> unchanged.</li> </ul> <p>There is only one set of data-out bits, <a href="#">MCASP_PDOUT[31:0]</a>. The other registers, <a href="#">MCASP_PDSET</a> and <a href="#">MCASP_PDCLR</a>, are just different addresses for the same control bits, with different behaviors during writes.</p> <p><b>Some register bits might not be functional for all McASP instances, due to corresponding McASP pin not being pinned out on a particular device part number. Refer to device-specific DM for more information on the supported McASP features.</b></p>

<b>Description</b>	The pin data set register is an alias of the pin data output register ( <a href="#">MCASP_PDOUT</a> ) for writes only. Writing a 1 to the <a href="#">MCASP_PDSET</a> bit sets the corresponding bit in <a href="#">MCASP_PDOUT</a> and, if <a href="#">MCASP_PFUNC</a> = 1 (GPIO function) and <a href="#">MCASP_PDIR</a> = 1 (output), drives a logic high on the pin. Some register bits might not be functional for all McASP instances, due to corresponding McASP pin not being pinned out on a particular device part number. Refer to device-specific DM for more information on the supported McASP features.

<b>Description</b>	Global transmit control register - provides initialization of the transmit and receive sections. The bit fields in <b>MCASP_GBLCTL</b> are synchronized and latched by the transmitter and receiver corresponding clocks - ACLKX (bits [12:8]) and ACLKR (bits [4:0]), respectively. Before programming <b>MCASP_GBLCTL</b> , ensure that the serial clocks are running. If the corresponding external serial clocks - ACLKX and ACLKR, are not yet running, select the internal serial clock source in AHCLKXCTL, AHCLKRCTL, ACLKXCTL and ACLKRCTL before programming the <b>MCASP_GBLCTL</b> . Also, after programming any bits in <b>MCASP_GBLCTL</b> , do not proceed until reading back from <b>MCASP_GBLCTL</b> and verifying that the bits in <b>MCASP_GBLCTL</b> are latched.		
<b>Type</b>	RW

RESERVED																			XFRST	XSMRST	XSRCLR	XHCLKRST	XCLKRST	RESERVED			RFRST	RSMRST	RSRCLR	RHCLKRST	RCLKRST

Bits	Field Name	Description	Type	Reset
31:13	RESERVED	Reserved	RW	0x00000
12	XFRST	Transmit frame-sync generator reset enable bit  0x0: The transmit frame-sync generator is reset. 0x1: The transmit frame-sync generator is active. When released from reset, the transmit frame-sync generator begins counting serial clocks and generating frame sync as programmed.	RW	0
11	XSMRST	Transmit state-machine reset enable bit  0x0: The transmit state-machine is held in reset. AXR[n] pin state: If <b>MCASP_PFUNC</b> [n] = 0 and <b>MCASP_PDIR</b> [n] = 1, the corresponding serializer [n] drives the AXR[n] pin to the state specified for inactive time slot. 0x1: The transmit state-machine is released from reset. When released from reset, the transmit state-machine immediately transfers data from XBUF[n] to XRSR[n]. The transmit state-machine sets the underrun flag (XUNDRN) in <b>MCASP_XSTAT</b> , if XBUF[n] have not been preloaded with data before reset is released. The transmit state-machine also immediately begins detecting frame sync and is ready to transmit. Transmission of TDM time slot begins at slot 0 after reset is released.	RW	0
10	XSRCLR	Transmit serializer clear enable bit. By clearing and then setting this bit, the transmit buffer is flushed to an empty state (XDATA = 1). If XSMRST = 1, XSRCLR = 1, XDATA = 1, and XBUF is not loaded with new data before the start of the next active time slot, an underrun occurs.  0x0: The transmit serializer is cleared. 0x1: The transmit serializer is active. When the transmit serializer is first taken out of reset (XSRCLR changes from 0 to 1), the transmit data ready bit (XDATA) in <b>MCASP_XSTAT</b> is set to indicate XBUF is ready to be written.	RW	0
9	XHCLKRST	Transmit high-frequency clock divider reset enable bit  0x0: The transmitter high-frequency clock divider is held in reset and passes through its input as divide-by-1. 0x1: The transmitter high-frequency clock divider is running.	RW	0

Bits	Field Name	Description	Type	Reset
8	XCLKRST	Transmit clock divider reset enable bit  0x0: The transmit clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input.  0x1: The transmit clock divider is running.	RW	0
7:5	RESERVED	Reserved	RW	0x0
4	RFRST	Receive frame sync generator reset enable bit.  0x0: Receive frame sync generator is reset.  0x1: Receive frame sync generator is active. When released from reset, the receive frame sync generator begins counting serial clocks and generating frame sync as programmed.	RW	0
3	RSMRST	Receive state machine reset enable bit.  0x0: Receive state machine is held in reset.  0x1: Receive state machine is released from reset. When released from reset, the receive state machine immediately begins detecting frame sync and is ready to receive. Receive TDM time slot begins at slot 0 after reset is released.	RW	0
2	RSRCLR	Receive serializer clear enable bit. By clearing then setting this bit, the receive buffer is flushed.  0x0: Receive serializers are cleared.  0x1: Receive serializers are active.	RW	0
1	RHCLKRST	Receive high-frequency clock divider reset enable bit.  0x0: Receive high-frequency clock divider is held in reset and passes through its input as divide-by-1.  0x1: Receive high-frequency clock divider is running.	RW	0
0	RCLKRST	Receive clock divider reset enable bit.  0x0: Receive clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input.  0x1: Receive clock divider is running.	RW	0

RCNT								RMAX								RMIN								RESERVED				RPS			

Bits	Field Name	Description	Type	Reset
31:24	RCNT	0x0 - 0xFF: Receive clock count value (from previous measurement). The clock circuit continually counts the number of interface clocks for every 32 receive high-frequency master clock (AHCLKR) signals, and stores the count in RCNT until the next measurement is taken.	R	0x00
23:16	RMAX	0x00-0xFF: Receive clock maximum boundary. This 8-bit unsigned value sets the maximum allowed boundary for the clock check counter after 32 receive high-frequency master clock (AHCLKR) signals have been received. If the current counter value is greater than RMAX after counting 32 AHCLKR signals, RCKFAIL in MCASP_RXSTAT is set. The comparison is performed using unsigned arithmetic.	RW	0x00
15:8	RMIN	0x00 - 0xFF: Receive clock minimum boundary. This 8-bit unsigned value sets the minimum allowed boundary for the clock check counter after 32 receive high-frequency master clock (AHCLKR) signals have been received. If RCNT is less than RMIN after counting 32 AHCLKR signals, RCKFAIL in RSTAT is set. The comparison is performed using unsigned arithmetic.	RW	0x00
7:4	RESERVED		RW	0x0
3:0	RPS	Receive clock check prescaler value. 0x0: McASP interface clock divided by 1 0x1: McASP interface clock divided by 2 0x2: McASP interface clock divided by 4 0x3: McASP interface clock divided by 8 0x4: McASP interface clock divided by 16 0x5: McASP interface clock divided by 32 0x6: McASP interface clock divided by 64 0x7: McASP interface clock divided by 128 0x8: McASP interface clock divided by 256 0x9 - 0xF: Reserved	RW	0x0

<b>Address Offset</b>	0x0000 00C0		
<b>Physical Address</b>	0x4846 00C0 0x4846 40C0 0x4846 80C0 0x4846 C0C0 0x4847 00C0 0x4847 40C0 0x4847 80C0 0x4847 C0C0	<b>Instance</b>	MCASP1_CFG_PER2_L4 MCASP2_CFG_PER2_L4 MCASP3_CFG_PER2_L4 MCASP4_CFG_PER2_L4 MCASP5_CFG_PER2_L4 MCASP6_CFG_PER2_L4 MCASP7_CFG_PER2_L4 MCASP8_CFG_PER2_L4
<b>Description</b>	Transmitter status register - If the McASP logic attempts to set an interrupt flag in the same cycle that the CPU writes to the flag to clear it, the McASP logic has priority and the flag remains set. This also causes the generation of a new interrupt request.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																XERR	XDMAERR	XSTAFRM	XDATA	XLAST	XTDMSLOT	XCKFAIL	XSYNCERR	XUNDRN							

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	RW	0x000000
8	XERR	XERR bit always returns a logic-OR of: XUNDRN   XSYNCERR   XCKFAIL   XDMAERR. Allows a single bit to be checked to determine if a transmitter error interrupt has occurred.  0x0: No errors have occurred. 0x1: An error has occurred.	RW	0
7	XDMAERR	Transmit DMA error flag. XDMAERR is set when the CPU or DMA writes more words to the DATA port of the McASP in a given time slot than it should. Causes a transmit interrupt (XINT) if this bit and XDMAERR in <a href="#">MCASP_EVTCTLX</a> are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect.  0x0: Transmit DMA error did not occur. 0x1: Transmit DMA error occurred.	RW	0
6	XSTAFRM	Transmit start of frame flag. Causes a transmit interrupt (XINT) if this bit and XSTAFRM in <a href="#">MCASP_EVTCTLX</a> are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect.  0x0: No new transmit frame sync (AFSX) is detected. 0x1: A new transmit frame sync (AFSX) is detected.	RW	0
5	XDATA	Transmit data ready flag. Causes a transmit interrupt (XINT) if this bit and XDATA in <a href="#">MCASP_EVTCTLX</a> are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect  0x0: XBUF[n] is written and is full  0x1: Data is copied from XBUF[n] to XRSR[n]. XBUF[n] is empty and ready to be written. XDATA is also set when the transmit serializers are taken out of reset. When XDATA is set, it always causes a DMA event (AXEVT).	RW	0
4	XLAST	Transmit last slot flag. XLAST, along with XDATA, are set if the current slot is the last slot in a frame. Causes a transmit interrupt (XINT) if this bit and XLAST in <a href="#">MCASP_EVTCTLX</a> are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect.  0x0: Current slot is not the last slot in a frame. 0x1: Current slot is the last slot in a frame. XDATA is also set.	RW	0
3	XTDMSLOT	Returns the LSB of XSLOT. Allows a single read of XSTAT to determine whether the current TDM time slot is even or odd.  read 0x0: Current TDM time slot is odd. read 0x1: Current TDM time slot is even.	R	0

Bits	Field Name	Description	Type	Reset
2	XCKFAIL	Transmit clock failure flag. XCKFAIL is set when the transmit clock failure detection circuit reports an error. Causes a transmit interrupt (XINT) if this bit and XCKFAIL in <a href="#">MCASP_EVTCTLX</a> are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: Transmit clock failure did not occur. 0x1: Transmit clock failure occurred	RW	0
1	XSYNCERR	Unexpected transmit frame-sync flag. XSYNCERR is set when a new transmit frame sync (AFSX) occurs before it is expected. Causes a transmit interrupt (XINT) if this bit and XSYNCERR in <a href="#">MCASP_EVTCTLX</a> are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: Unexpected transmit frame sync did not occur 0x1: Unexpected transmit frame sync occurred.	RW	0
0	XUNDRN	Transmitter underrun flag. XUNDRN is set when the transmit serializer is instructed to transfer data from XBUF[n] to XRSR[n], but XBUF[n] has not yet been serviced with new data since the last transfer. Causes a transmit interrupt (XINT) if this bit and XUNDRN in <a href="#">MCASP_EVTCTLX</a> are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: Transmitter underrun did not occur 0x1: Transmitter underrun occurred.	RW	0

RESERVED																							RRDY	XRDY	DISMOD	SRMOD					

Bits	Field Name	Description	Type	Reset
31:6	RESERVED	Reserved	RW	0x0000000
5	RRDY	Receive buffer ready bit. RRDY indicates the current receive buffer state. Always reads 0 when programmed as a transmitter or as inactive. If SRMOD bit is set to receive (2h), RRDY switches from 0 to 1 whenever data is transferred from XRSRn to RBUFn.  Read 0x0: Receive buffer (MCASP_RXBUFn) is empty.  Read 0x1: Receive buffer (MCASP_RXBUFn) contains data and needs to be read before the start of the next time slot or a receiver overrun occurs.	R	0
4	XRDY	Transmit buffer ready bit. XRDY indicates the current transmit buffer state. Always reads 0 when programmed as a receiver or as inactive. If SRMOD bit is set to transmit (1h), XRDY switches from 0 to 1 when XSRCLR in GBLCTL is switched from 0 to 1 to indicate an empty transmitter. XRDY remains set until XSRCLR is forced to 0, data is written to the corresponding transmit buffer, or SRMOD bit is changed to receive (2h) or inactive (0).  Read 0x0: The transmit buffer (MCASP_TXBUFn) contains data.  Read 0x1: The transmit buffer (MCASP_TXBUFn) is empty and needs to be written before the start of the next time slot or a transmit underrun occurs.	R	0
3:2	DISMOD	Serializer pin drive mode bit. Drive on pin when in inactive TDM slot of transmit mode or when serializer is inactive. This field only applies if the pin is configured as a McASP pin (PFUNC = 0).  0x0: Drive on pin is 3-state. 0x1: Reserved 0x2: Drive on pin is logic low. 0x3: Drive on pin is logic high.	RW	0x0
1:0	SRMOD	Serializer mode bit  0x0: The serializer is inactive 0x1: The serializer is operating in transmit mode. 0x2: The serializer is operating in receive mode. 0x3: Reserved	RW	0x0

**24.6.6.2.5 MCASP\_DAT Register Summary**

Table 24-566 to Table 24-569 summarize the MCASP\_DAT register mapping.

**Table 24-566. MCASP\_DAT Register Summary 1**

Register Name	Type	Register Width (Bits)	Address Offset	MCASP1_DAT L3_MAIN Physical Address
<a href="#">MCASP_RXBUF</a>	R	32	0x0000 0000 <sup>(1)</sup>	0x4580 0000
<a href="#">MCASP_TXBUF</a>	W	32	0x0000 0000 <sup>(1)</sup>	0x4580 0000

<sup>(1)</sup> 0x000 is just an example DATA port offset value. Actually, whatever the offset value is added to base address, it is ignored (don't care) when MPU/DSP performs accesses to XRBUFFn RX/TX buffers through the McASP DATA port.

**Table 24-567. MCASP\_DAT Register Summary 2**

Register Name	Type	Register Width (Bits)	Address Offset	MCASP2_DAT L3_MAIN Physical Address
MCASP_RXBUF	R	32	0x0000 0000 <sup>(1)</sup>	0x45C0 0000
MCASP_TXBUF	W	32	0x0000 0000 <sup>(1)</sup>	0x45C0 0000

<sup>(1)</sup> 0x000 is just an example DATA port offset value. Actually, whatever the offset value is added to base address, it is ignored (don't care) when MPU/DSP performs accesses to XRBUF<sub>n</sub> RX/TX buffers through the McASP DATA port.

**Table 24-568. MCASP\_DAT Register Summary 3**

Register Name	Type	Register Width (Bits)	Address Offset	MCASP3_DAT L3_MAIN Physical Address	MCASP4_DAT L4_PER2 Physical Address	MCASP5_DAT L4_PER2 Physical Address
MCASP_RXBUF	R	32	0x0000 0000 <sup>(1)</sup>	0x4600 0000	0x4843 6000	0x4843 A000
MCASP_TXBUF	W	32	0x0000 0000 <sup>(1)</sup>	0x4600 0000	0x4843 6000	0x4843 A000

<sup>(1)</sup> 0x000 is just an example DATA port offset value. Actually, whatever the offset value is added to base address, it is ignored (don't care) when MPU/DSP performs accesses to XRBUF<sub>n</sub> RX/TX buffers through the McASP DATA port.

**Table 24-569. MCASP\_DAT Register Summary 4**

Register Name	Type	Register Width (Bits)	Address Offset	MCASP6_DAT L4_PER2 Physical Address	MCASP7_DAT L4_PER2 Physical Address	MCASP8_DAT L4_PER2 Physical Address
MCASP_RXBUF	R	32	0x0000 0000 <sup>(1)</sup>	0x4844 C000	0x4845 0000	0x4845 4000
MCASP_TXBUF	W	32	0x0000 0000 <sup>(1)</sup>	0x4844 C000	0x4845 0000	0x4845 4000

<sup>(1)</sup> 0x000 is just an example DATA port offset value. Actually, whatever the offset value is added to base address, it is ignored (don't care) when MPU/DSP performs accesses to XRBUF<sub>n</sub> RX/TX buffers through the McASP DATA port.

---

**NOTE:** For [MCASP\\_RXBUF](#) and [MCASP\\_TXBUF](#) buffer accesses through the McASP DATA port, the destination physical address is always the same regardless of current channel index or transfer direction. The [MCASP\\_TXFMT\[3\]](#) XBUSEL bit must be set to 0b0, to allow write transfers through the DATA port. The [MCASP\\_RXFMT\[3\]](#) RBUSEL bit must be set to 0b0, to allow read transfers through the DATA port.

---

**NOTE:** The McASP DATA port is exclusively assigned for DMAs/device CPUs accesses to the McASP channels transmit and receive buffer registers. All other McASP module registers must be accessed through the McASP CFG (peripheral) port.

---

**NOTE:** McASP1, McASP2, and McASP3, whose data port are accessible directly via L3\_MAIN, do not support FIFO/constant addressing modes. Incrementing transfers must be used instead.

---

#### 24.6.6.2.6 MCASP\_DAT Register Description

**Table 24-570. MCASP\_RXBUF**

Address Offset	Physical Address	Instance
0x0000 0000	0x4580 0000	MCASP1_DAT_MAIN_L3
	0x45C0 0000	MCASP2_DAT_MAIN_L3
	0x4600 0000	MCASP3_DAT_MAIN_L3
	0x4843 6000	MCASP4_DAT_PER2_L4
	0x4843 A000	MCASP5_DAT_PER2_L4
	0x4844 C000	MCASP6_DAT_PER2_L4
	0x4845 0000	MCASP7_DAT_PER2_L4
	0x4845 4000	MCASP8_DAT_PER2_L4

**Table 24-570. MCASP\_RXBUF (continued)**

<b>Description</b>	Through the DATA port, the Host can service all serializers through a single address and the McASP automatically cycles through the appropriate serializers. For receive operations through the DATA port, the Host should read from the same RBUF DATA port address to service all of the active receive serializers upon each receive data ready event. To enable accesses from the Host to the McASP XRBUF registers through the DATA port, one must clear the RBUSEL bits to 0 in the respective <a href="#">MCASP_RXFMT</a> registers in the MCASP_CFG Memory Map.
<b>Type</b>	R

Bits	Field Name	Description	Type	Reset
31:0	RXBUF	Rx buffer data.	R	0x0000 0000

## 24.7 SuperSpeed USB DRD

This section describes the SuperSpeed (SS) USB 3.0 Dual-Role-Device (DRD) subsystem of the device.

---

**NOTE:** This chapter describes a module (subsystem) in the superset device. The available number of instances and supported set of features is device part number dependent. Refer to device *Data Manual*, for more information.

---

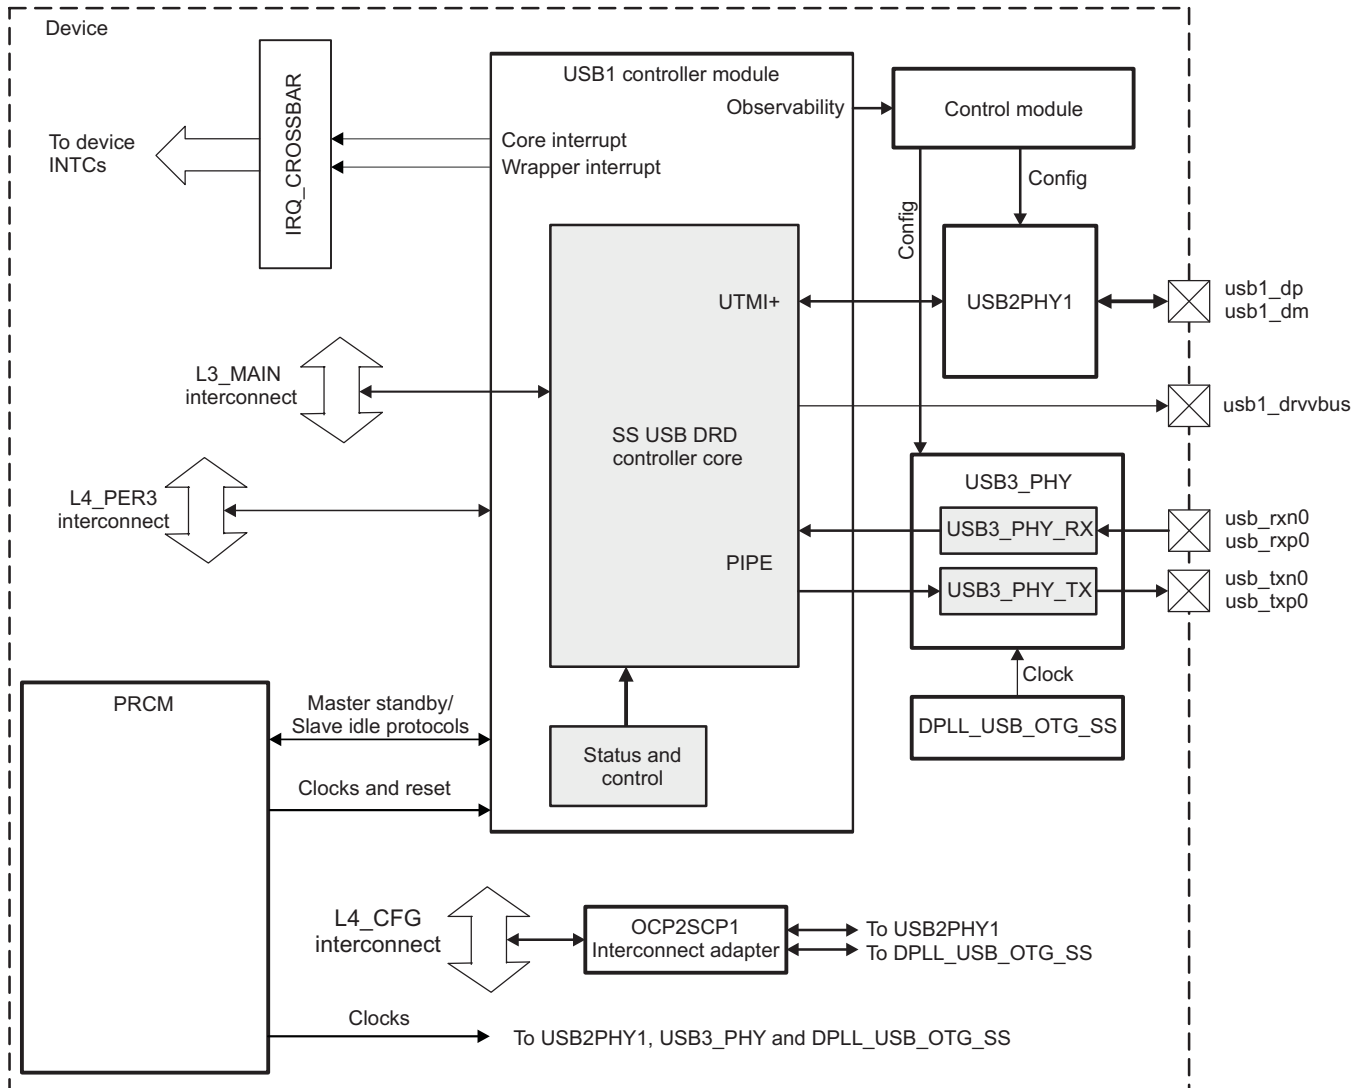

### 24.7.1 SuperSpeed USB DRD Subsystem Overview

SuperSpeed USB DRD Subsystem has four instances in the device providing the following functions:

- USB1: SuperSpeed (SS) USB 3.0 Dual-Role-Device (DRD) subsystem with integrated SS (USB3.0) PHY and HS/FS (USB2.0) PHY
- USB2: High-Speed (HS) USB 2.0 Dual-Role-Device (DRD) subsystem with integrated HS/FS PHY
- USB3: HS USB 2.0 Dual-Role-Device (DRD) subsystem with ULPI (SDR) interface to external HS/FS PHYs
- USB4: HS USB 2.0 Dual-Role-Device (DRD) subsystem with ULPI (SDR) interface to external HS/FS PHYs.

Figure 24-143 shows the USB1 subsystem overview.

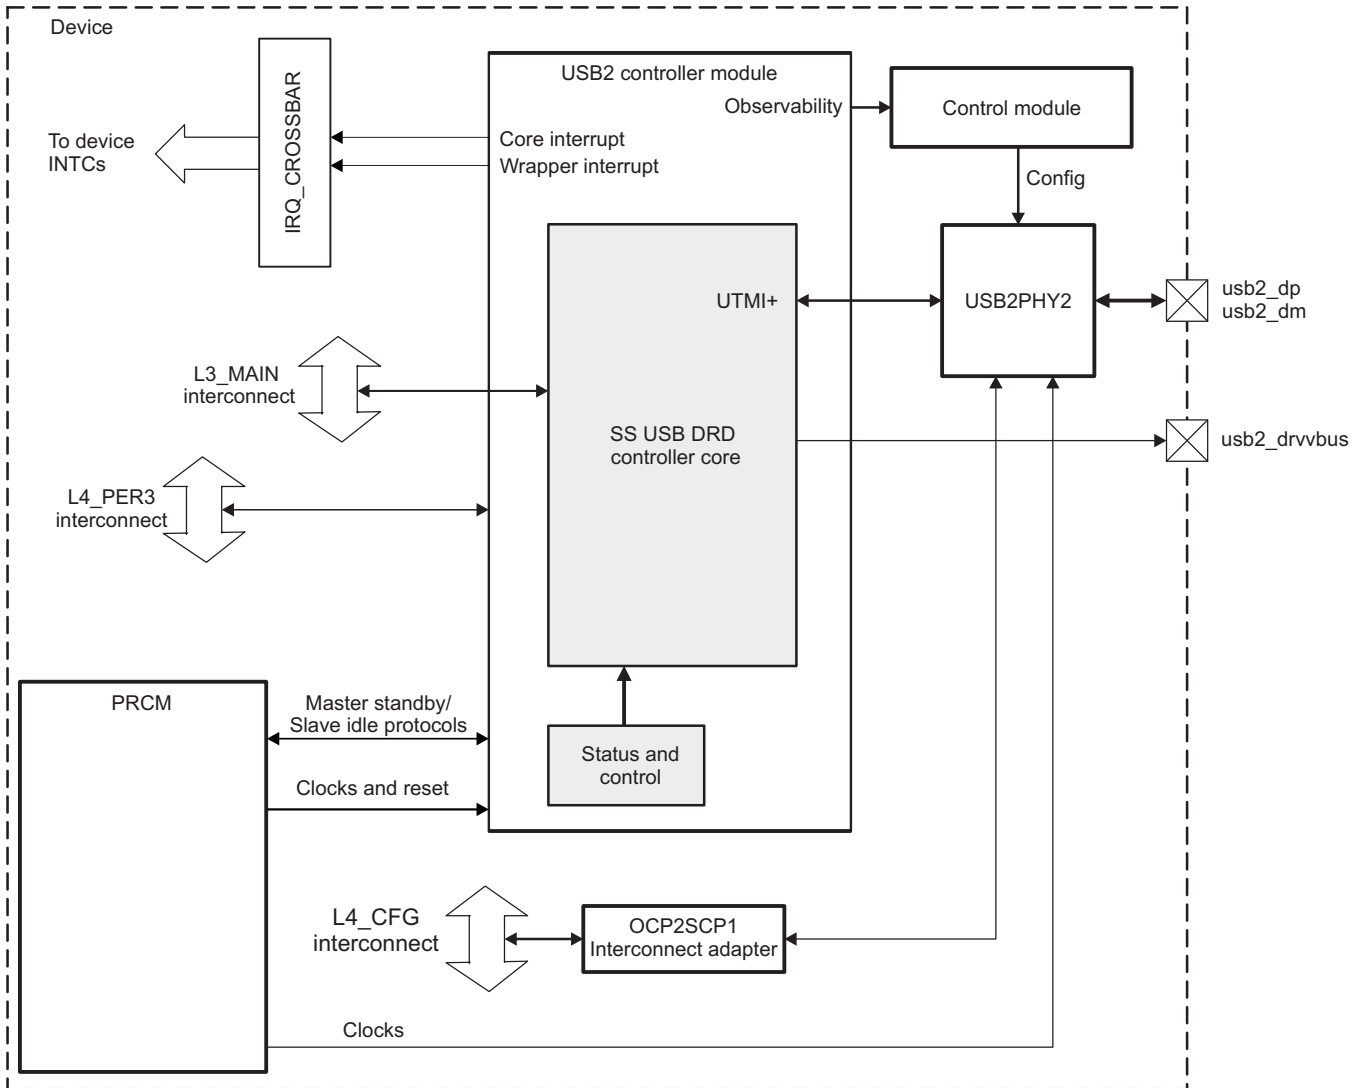

Figure 24-143. USB1 Highlight

usbss-011

Figure 24-144 shows the USB2 subsystem overview.

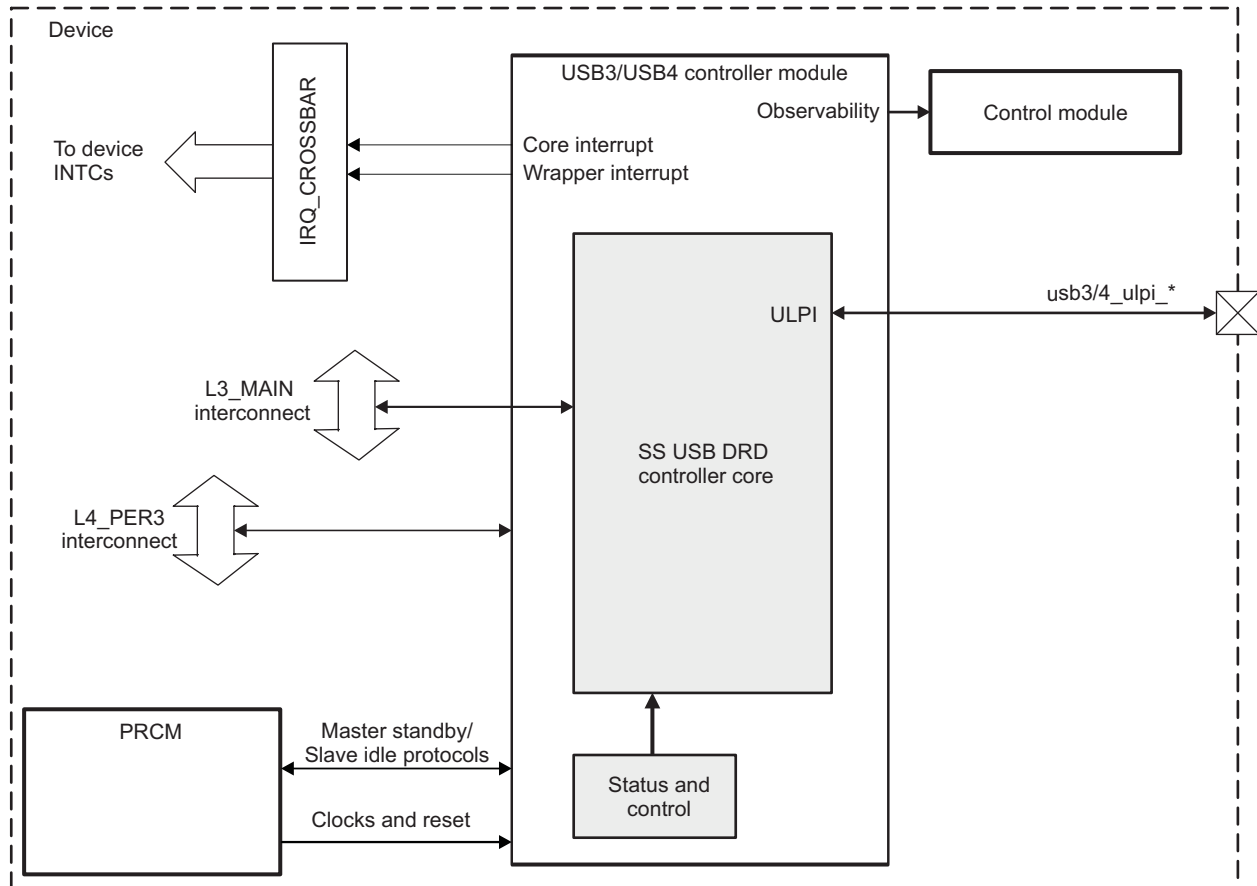

Figure 24-144. USB2 Highlight

usbss-012

Figure 24-145 shows the USB3 and USB4 subsystem overview.

**Figure 24-145. USB3 and USB4 Highlight**

usbss-013

### 24.7.1.1 Main Features

SuperSpeed USB DRD Subsystem has the following features:

- Dual-role-device (DRD) capability:
  - Supports USB Peripheral (or Device) mode at speeds SS (5Gbps)(USB1 only), HS (480 Mbps), and FS (12 Mbps)
  - Supports USB Host mode at speeds SS (5Gbps)(USB1 only), HS (480 Mbps), FS (12 Mbps), and LS (1.5 Mbps)
  - USB static peripheral operation
  - USB static host operation
  - Flexible stream allocation
  - Stream priority
  - External Buffer Control
- Each instance contains single xHCI controller with the following features:
  - Internal DMA controller
  - Descriptor caching and data prefetching
  - Interrupt moderation and blocking
  - Power management USB3.0 states for U0, U1, U2, and U3
  - Dynamic FIFO memory allocation for all endpoints
  - Supports all modes of transfers (control, bulk, interrupt, and isochronous)

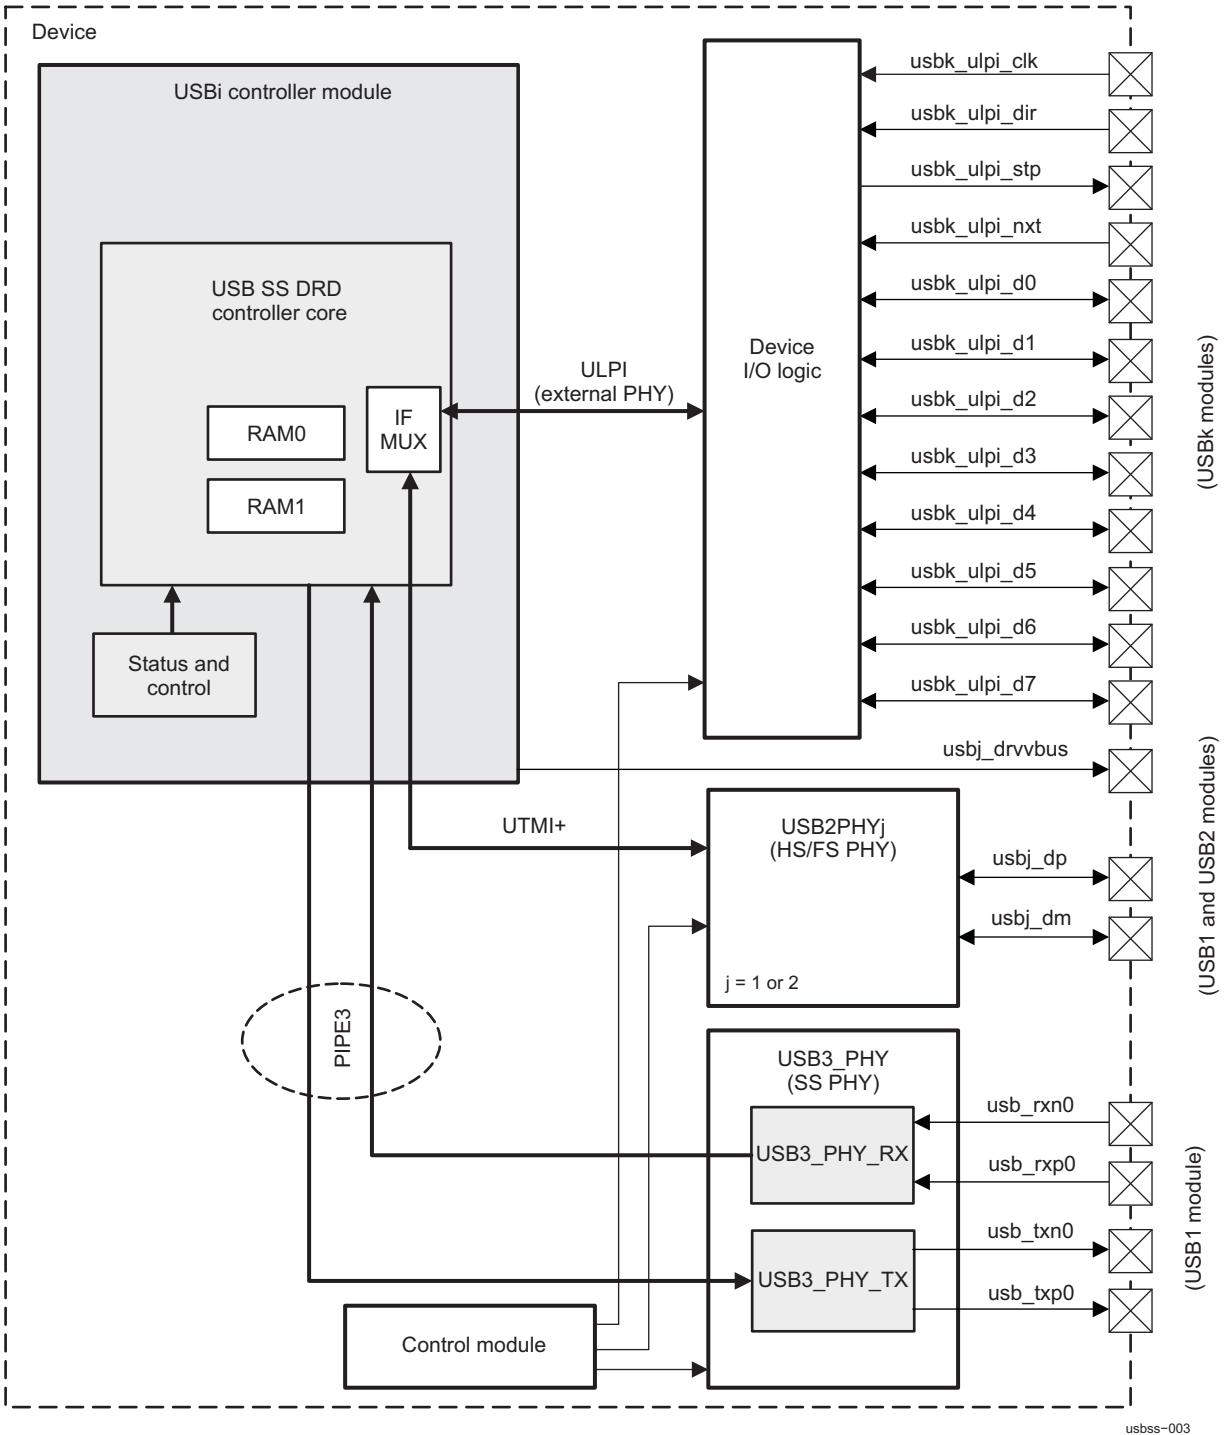

- Supports high bandwidth ISO mode
- Connects to an external charge pump for VBUS 5 V generation
- USB-HS PHY (USB2PHY1 and USB2PHY2 for USB1 and USB2, respectively): contain the USB functions, drivers, receivers, and pads for correct D+/D– signalling
- USB3\_PHY. The USB3\_PHY is embedded in the USB1 subsystem and contains:
  - USB3\_PHY\_RX deserializer to receive data at SuperSpeed mode
  - USB3\_PHY\_TX serializer to transmit data at SuperSpeed mode
  - Power sequencer that contains a power control state machine, generating the sequences to power up/down the USB3\_PHY\_RX/USB3\_PHY\_TX
  - Dedicated DPLL (DPLL\_USB\_OTG\_SS)

## 24.7.2 SuperSpeed USB DRD Subsystem Environment

### 24.7.2.1 SuperSpeed USB DRD Subsystem I/O Interfaces

Figure 24-146 describes the I/O signals of the SuperSpeed USB subsystem interfaces.

Figure 24-146. SuperSpeed USB Subsystem Environment

i = 1 to 4

k = 3 or 4

Table 24-574 through Table 24-577 describe the I/O signals of the SuperSpeed USB subsystem interfaces shown in Figure 24-146

**Table 24-574. USB1 Input/Output Description**

Module Pin	Device-Level Signal Name	I/O <sup>(1)</sup>	Description	Reset Value
<b>USB2PHY1</b>				
DRVVBUS	usb1_drvvbus	O	Drive-VBUS enable to external charge pump/power switch	0
DP	usb1_dp	I/O	USB2.0 half-duplex differential pair	HiZ
DM	usb1_dm	I/O		HiZ
<b>USB3_PHY</b>				
TX	usb_txn0	O	USB3.0 transmitter differential pair	HiZ
TY	usb_txp0	O		HiZ
RX	usb_rxn0	I	USB3.0 receiver differential pair	HiZ
RY	usb_rxp0	I		HiZ

<sup>(1)</sup> I = Input; O = Output; I/O = Bidirectional

**Table 24-575. USB2 Input/Output Description**

**Table 24-576. USB3 Input/Output Description**

Module Pin	Device-Level Signal Name	I/O	Description	Reset Value
<b>ULPI interface</b>				
ULPI_CLK	usb3_ulpi_clk	I	Clock input from external transceiver	HiZ
ULPI_DIR	usb3_ulpi_dir	I	Data direction control from external transceiver	HiZ
ULPI_STP	usb3_ulpi_stp	O	Output to external transceiver to stop data stream	1
ULPI_NXT	usb3_ulpi_nxt	I	Next signal control from external transceiver	HiZ
ULPI_DATA0	usb3_ulpi_d0	I/O	Data bit 0 to/from external transceiver	HiZ
ULPI_DATA1	usb3_ulpi_d1	I/O	Data bit 1 to/from external transceiver	HiZ
ULPI_DATA2	usb3_ulpi_d2	I/O	Data bit 2 to/from external transceiver	HiZ
ULPI_DATA3	usb3_ulpi_d3	I/O	Data bit 3 to/from external transceiver	HiZ
ULPI_DATA4	usb3_ulpi_d4	I/O	Data bit 4 to/from external transceiver	HiZ
ULPI_DATA5	usb3_ulpi_d5	I/O	Data bit 5 to/from external transceiver	HiZ
ULPI_DATA6	usb3_ulpi_d6	I/O	Data bit 6 to/from external transceiver	HiZ
ULPI_DATA7	usb3_ulpi_d7	I/O	Data bit 7 to/from external transceiver	HiZ

**Table 24-577. USB4 Input/Output Description**

Module Pin	Device-Level Signal Name	I/O	Description	Reset Value
<b>ULPI interface</b>				

**Table 24-577. USB4 Input/Output Description (continued)**

Module Pin	Device-Level Signal Name	I/O	Description	Reset Value
ULPI_CLK	usb4_ulpi_clk	I	Clock input from external transceiver	HiZ
ULPI_DIR	usb4_ulpi_dir	I	Data direction control from external transceiver	HiZ
ULPI_STP	usb4_ulpi_stp	O	Output to external transceiver to stop data stream	1
ULPI_NXT	usb4_ulpi_nxt	I	Next signal control from external transceiver	HiZ
ULPI_DATA0	usb4_ulpi_d0	I/O	Data bit 0 to/from external transceiver	HiZ
ULPI_DATA1	usb4_ulpi_d1	I/O	Data bit 1 to/from external transceiver	HiZ
ULPI_DATA2	usb4_ulpi_d2	I/O	Data bit 2 to/from external transceiver	HiZ
ULPI_DATA3	usb4_ulpi_d3	I/O	Data bit 3 to/from external transceiver	HiZ
ULPI_DATA4	usb4_ulpi_d4	I/O	Data bit 4 to/from external transceiver	HiZ
ULPI_DATA5	usb4_ulpi_d5	I/O	Data bit 5 to/from external transceiver	HiZ
ULPI_DATA6	usb4_ulpi_d6	I/O	Data bit 6 to/from external transceiver	HiZ
ULPI_DATA7	usb4_ulpi_d7	I/O	Data bit 7 to/from external transceiver	HiZ

---

**NOTE:** The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see [Section 18.4.6.1.1, Pad Configuration Registers](#) in [Chapter 18, Control Module](#).

---

## 24.7.2.2 SuperSpeed USB Subsystem Application

### 24.7.2.2.1 USB3.0 DRD Application

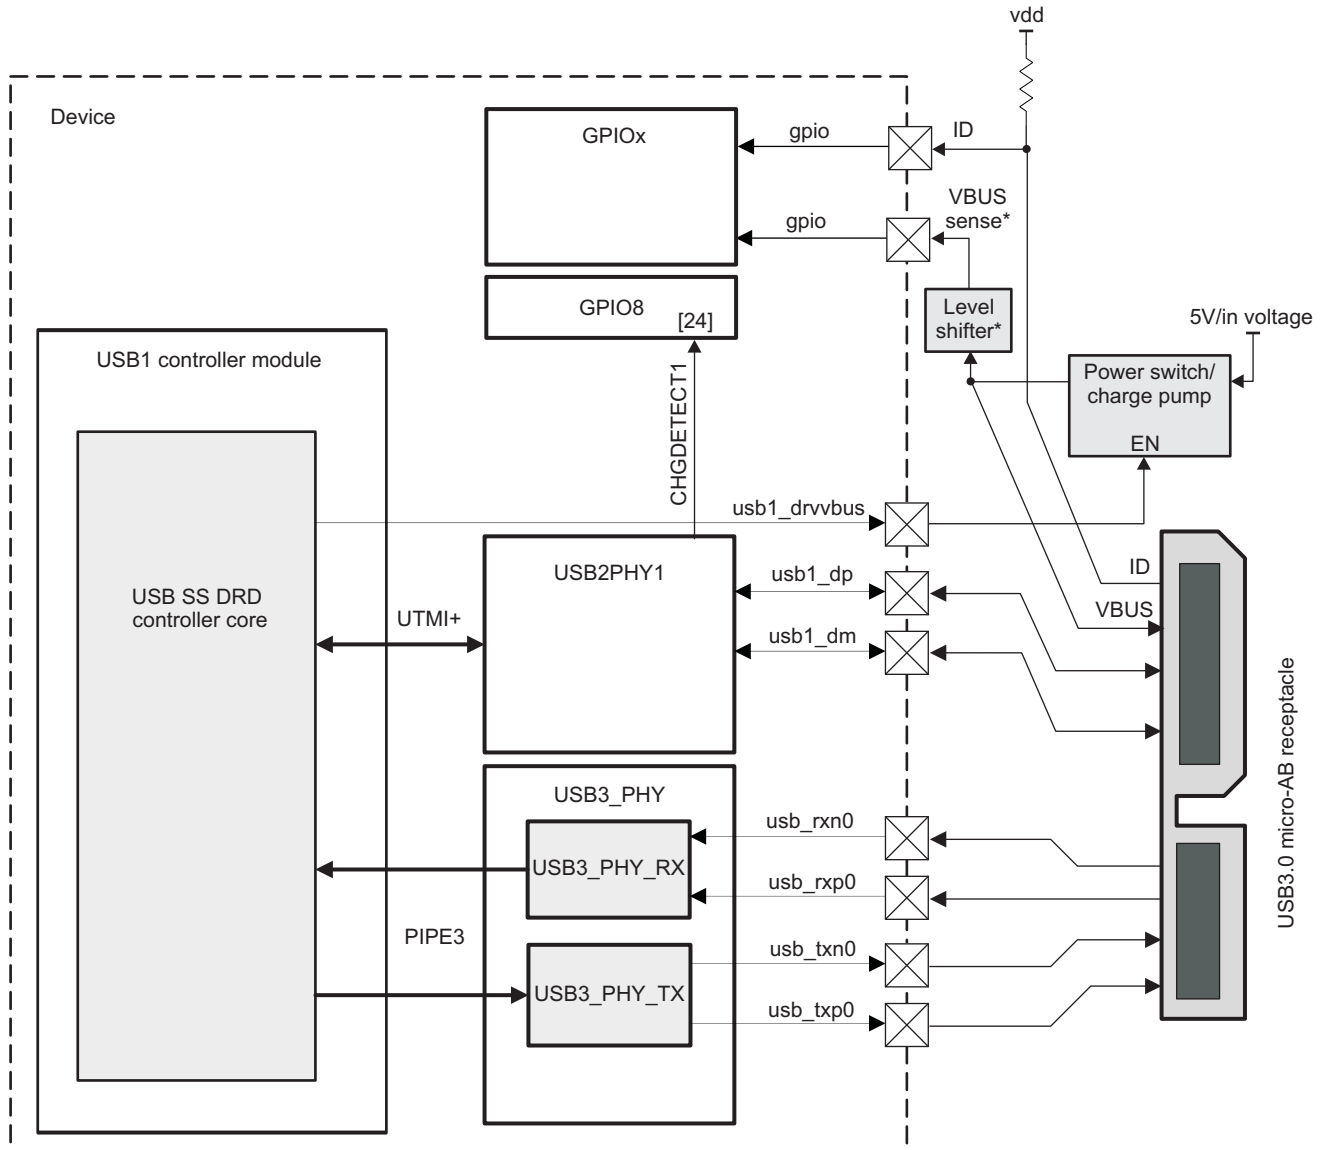

[Figure 24-147](#) shows a typical application using the SuperSpeed USB subsystem. The application represents a full-featured integration and allows all of the capabilities of the controller used.

VBUS sensing can be exported to the external Power-Management IC (PMIC) in case it supports this function. This would eliminate the need for additional components such as level shifters and comparators. In this case, software driver must be modified to be able to react on PMIC interrupts for VBUS-rise and VBUS-fall through the I2C1 interface.

Some PMICs support the VBUS\_DETECT output from the VBUS comparator to be muxed directly on their GPIO pin. In this case PMIC VBUS\_DETECT can be connected to a SoC GPIO pin, thus, this functionally is identical to [Figure 24-147](#).

See the respective PMIC datasheet for details.

Figure 24-147. SuperSpeed USB Controller Application: USB3.0 DRD

\* When PMIC supports this function, PMIC can be utilized instead of a GPIO. Consult your PMIC datasheet for details.

usbss-004

The USB3.0 micro-AB receptacle characterizes a USB3.0 DRD, and allows the following attachments:

- Micro-A-type plugs, to attach to a USB peripheral/hub upstream port (or to another DRD, as host)
- Micro-B-type plugs, to attach to a USB host/hub downstream port (or to another DRD, as peripheral)
- To USB3.0 devices: The USB3.0 micro plug covers all contacts of the receptacle.
- To USB2.0 devices: The USB2.0 micro plug occupies only the wider, USB2.0 half of the receptacle. SuperSpeed signal pairs remain floating.

24.7.2.2.2 USB2.0 DRD Internal PHY

Figure 24-148 shows a USB2.0-only integration in which the USB3.0 capability is not available. Similarly to Figure 24-147, VBUS sensing can be exported to the companion PMIC.

Figure 24-148. SuperSpeed USB Controller Application: USB2.0 DRD (Internal PHY)

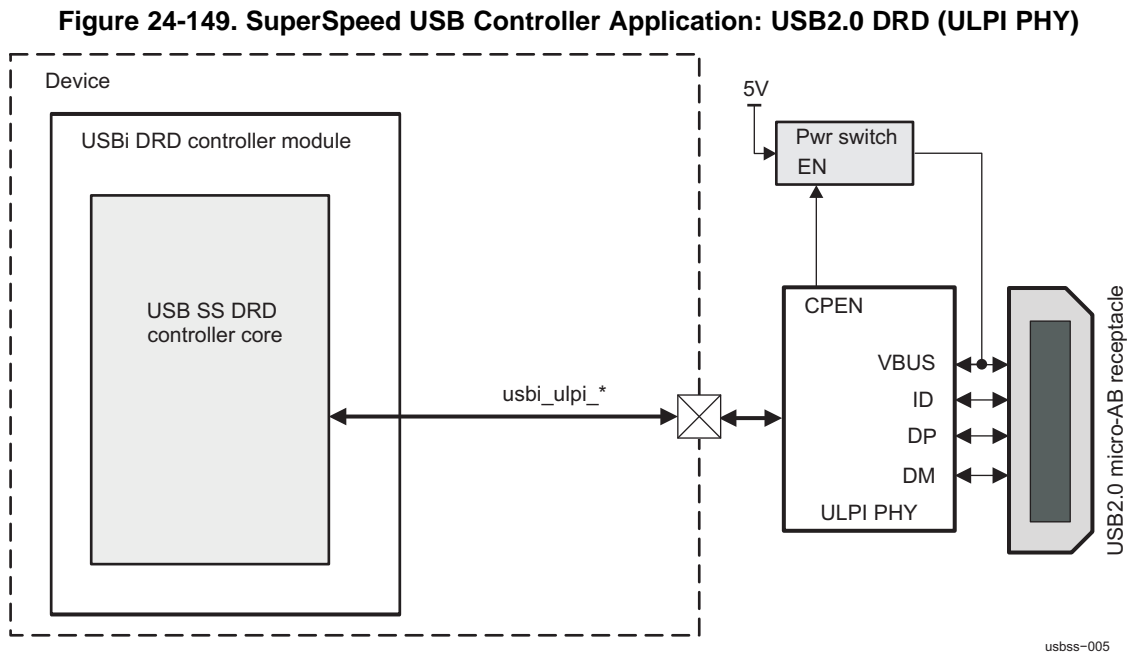

\* When PMIC supports this function, PMIC can be utilized instead of a GPIO. Consult your PMIC datasheet for details.

The USB2.0 micro-AB receptacle characterizes a USB2.0 DRD and accepts the following:

- Micro-A-type plugs, which attach to a USB peripheral/hub upstream port (or another DRD, as host)
- Micro-B-type plugs, which attach to a USB host/hub downstream port (or another DRD, as peripheral)
- USB2.0 devices only: The USB2.0 micro plug covers all contacts of the receptacle.
- USB3.0 devices: The USB3.0 micro plug is incompatible and the SuperSpeed signal pairs of the cable remain floating.

### 24.7.2.2.3 USB2.0 DRD External PHY

Figure 24-149 shows an external ULPI PHY IC is used instead of the on-chip UTMI PHY (USB2PHY). Seen from outside the system, both integrations are functionally equivalent. Internally, the functions of the ID and VBUS are taken over by the ULPI PHY. However, power on VBUS can be supplied by a VBUS switch with more power than the ULPI PHY is capable of.

i = 3 or 4

### 24.7.2.2.4 Host Mode

In always-host mode:

- ID pin can be omitted. Driver must be set explicitly to operate in host mode
- USB receptacle used must be type-A USB3.0 or USB2.0 respectively.

### 24.7.2.2.5 Device Mode

In always-device (peripheral) mode

- ID pin can be omitted. Driver must be set explicitly to operate in device mode
- VBUS power switch is not needed. USB devices never drive VBUS
- USB receptacle used must be type-B standard/micro USB3.0 or USB2.0 respectively.

## 24.7.3 SuperSpeed USB Subsystem Integration

The L3 (master) interconnect generates data traffic within the device. The L4 (slave) interconnect is a configuration port for register setting.

Figure 24-150 shows the SuperSpeed USB subsystem integration in the device.

Figure 24-150. SuperSpeed USB Subsystem Integration

usbss-002

i = 1 to 4

k = 3 or 4

Table 24-578 through Table 24-580 summarize the integration of the module in the device.

**Table 24-578. SuperSpeed USB Subsystem Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect
USB1	PD_L3INIT	L3_MAIN L4_PER3
USB2	PD_L3INIT	L3_MAIN L4_PER3
USB3	PD_L3INIT	L3_MAIN L4_PER3
USB4	PD_L3INIT	L3_MAIN L4_PER3
USB2PHY1	PD_L3INIT	L4_CFG
USB2PHY2	PD_L3INIT	L4_CFG
USB3_PHY	PD_L3INIT	L4_CFG

Table 24-579 lists the clocks provided to the SuperSpeed USB subsystem.

**Table 24-579. SuperSpeed USB Subsystem Clocks and Resets**

Module Instance	Destination Signal Name	Source Signal Name	Source	Clocks
				Description
USB1	USB1_FCLK	USB2PHY1_UTMI_CLK	USB2PHY1	60-MHz UTMI clock from PHY
	USB1_MICLK	L3INIT_L3_GICLK	PRCM	L3 interconnect clock, for the L3 master port interface <a href="#">Section 3.6.4.10, CD_L3INIT Clock Domain</a> in <a href="#">Chapter 3, Power, Reset and Clock Management</a> .
	USB1_SUSP_CLK	USB_OTG_SS_REF_CLK	PRCM	Suspend clock
USB2	USB2_FCLK	USB2PHY2_UTMI_CLK	USB2PHY2	60-MHz UTMI clock from PHY
	USB2_MICLK	L3INIT_L3_GICLK	PRCM	L3 interconnect clock, for the L3 master port interface.
	USB2_SUSP_CLK	USB_OTG_SS_REF_CLK	PRCM	Suspend clock
	USB2_125M_CLK	L3INIT_60M_FCLK	PRCM	125-MHz clock for the non-USB3.0 instances.
USB3	USB3_FCLK	OTG_60M_FCLK	usb3_ulpi_clk pad	60-MHz ULPI clock from PHY
	USB3_MICLK	L3INIT_L3_GICLK	PRCM	L3 interconnect clock, for the L3 master port interface .
	USB3_SUSP_CLK	USB_OTG_SS_REF_CLK	PRCM	Suspend clock
	USB3_125M_CLK	L3INIT_60M_FCLK	PRCM	125-MHz clock for the non-USB3.0 instances.
USB4	USB4_FCLK	OTG_60M_FCLK	usb4_ulpi_clk pad	60-MHz ULPI clock from PHY
	USB4_MICLK	L3INIT_L3_GICLK	PRCM	L3 interconnect clock, for the L3 master port interface .
	USB4_SUSP_CLK	USB_OTG_SS_REF_CLK	PRCM	Suspend clock
	USB4_125M_CLK	L3INIT_60M_FCLK	PRCM	125-MHz clock for the non-USB3.0 instances.
USB2PHY1	USB2PHY1_REF_CLK	L3INIT_960M_GFCLK	PRCM	Functional REF 960-MHz clock (from the DPPLL_USB, PRCM controlled)
	USB2PHY1_WKUP_CLK	FUNC_32K_CLK	PRCM	Wakeup 32-kHz functional clock

**Table 24-579. SuperSpeed USB Subsystem Clocks and Resets (continued)**

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
	USB2PHY1_TREF_CLK	USB_OTG_SS_REF_CLK	PRCM	Functional TREF clock derived from SYS_CLK1
USB2PHY2	USB2PHY2_REF_CLK	L3INIT_960M_GFCLK	PRCM	Functional REF 960-MHz clock (from the DPLL_USB, PRCM controlled)
	USB2PHY2_WKUP_CLK	FUNC_32K_CLK	PRCM	Wakeup 32-kHz functional clock
	USB2PHY2_TREF_CLK	USB_OTG_SS_REF_CLK	PRCM	Functional TREF clock derived from SYS_CLK1
USB3_PHY	USB3PHY_REF_CLK	USB_LFPS_TX_GFCLK	PRCM	Fixed-frequency USB3 transmitter REF functional clock
	DPLL_USBSS_REF_CLK	USB_OTG_SS_REF_CLK	PRCM	Functional DPLL REF clock derived from SYS_CLK1
	USB3PHY_WKUP_CLK	COREAON_32K_GFCLK	PRCM	Wakeup and debounce 32-kHz functional clock
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
USB1	USB1_RST	L3INIT_RET_RST	PRCM	USB1 controller module hardware retention reset
USB2	USB2_RST	L3INIT_RET_RST	PRCM	USB2 controller module hardware retention reset
USB3	USB3_RST	L3INIT_RET_RST	PRCM	USB3 controller module hardware retention reset
USB4	USB4_RST	L3INIT_RET_RST	PRCM	USB4 controller module hardware retention reset

Table 24-580 lists the interrupt lines that are driven out from the SuperSpeed USB controller modules.

**Table 24-580. SuperSpeed USB Subsystem Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	IRQ_CROSSBAR Input	Default Mapping	Description
USB1	USB1_IRQ_INTR0	IRQ_CROSSBAR_71	MPU_IRQ_76	USB1 main (core) interrupt request
	USB1_IRQ_INTR1	IRQ_CROSSBAR_72	MPU_IRQ_77 IPU1_IRQ_73 IPU2_IRQ_73	USB1 wrapper interrupt request
USB2	USB2_IRQ_INTR0	IRQ_CROSSBAR_73	MPU_IRQ_78 IPU1_IRQ_74 IPU2_IRQ_74	USB2 main (core) interrupt request
	USB2_IRQ_INTR1	IRQ_CROSSBAR_87	MPU_IRQ_92 IPU1_IRQ_76 IPU2_IRQ_76	USB2 wrapper interrupt request
USB3	USB3_IRQ_INTR0	IRQ_CROSSBAR_88	MPU_IRQ_93 IPU1_IRQ_77 IPU2_IRQ_77	USB3 main (core) interrupt request
	USB3_IRQ_INTR1	IRQ_CROSSBAR_344	-	USB3 wrapper interrupt request
USB4	USB4_IRQ_INTR0	IRQ_CROSSBAR_345	-	USB4 main (core) interrupt request
	USB4_IRQ_INTR1	IRQ_CROSSBAR_346	-	USB4 wrapper interrupt request

**NOTE:** The **Default Mapping** column in [Table 24-580](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ\_CROSSBAR module. For more information about the IRQ\_CROSSBAR module, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#).

For more information about the device interrupt controllers, see [Chapter 17, Interrupt Controllers](#).

---

## 24.8 SATA Controller

### 24.8.1 SATA Controller Overview

The SATA host controller handles data interactions between a local host system memory and a SATA mass storage device with minimal local host (LH) intervention.

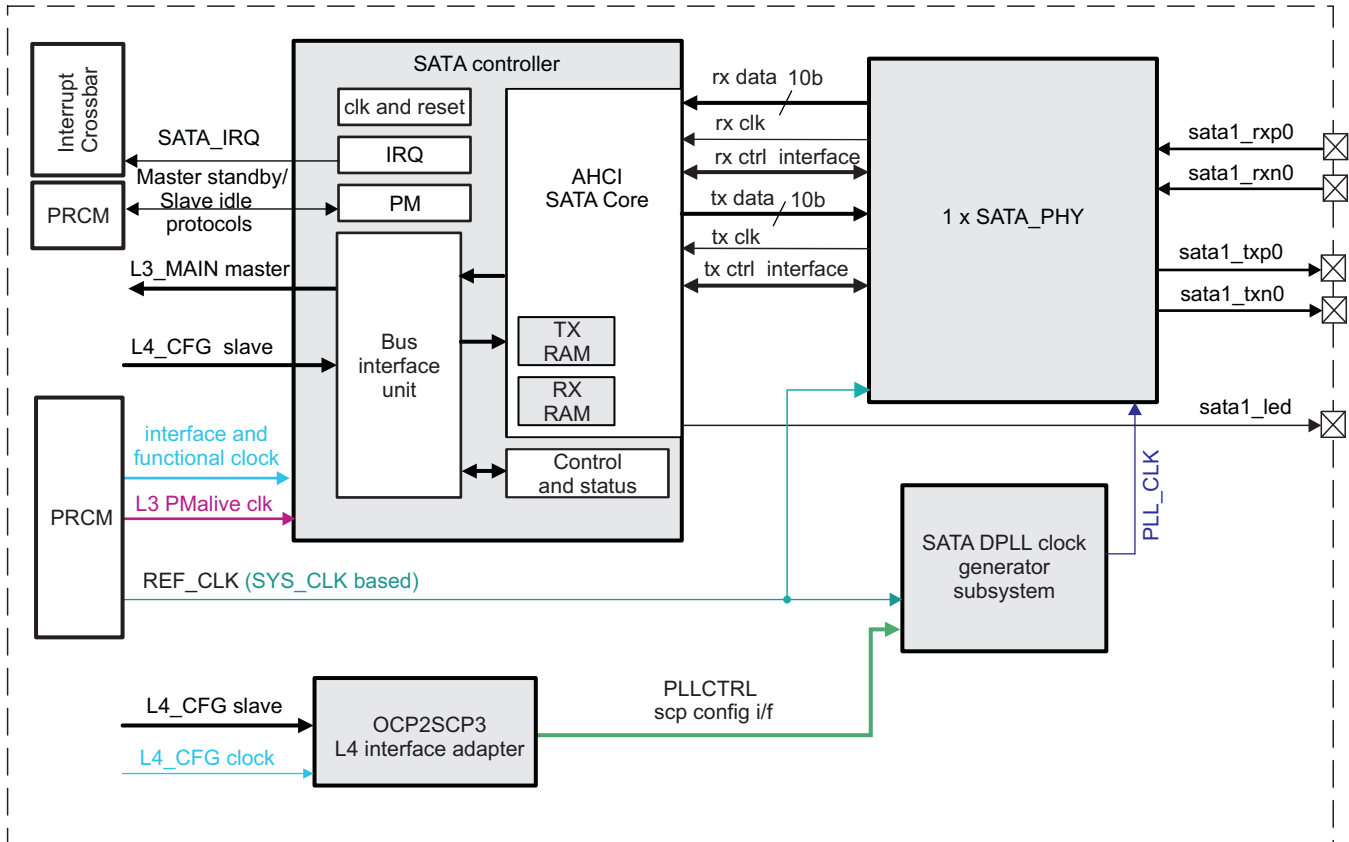

In contrast to the parallel 16-bit - ATA (PATA) interface, the SATA interface takes advantage of serial data transmission/reception over a differential pair of conductors. SATA uses the command set from the ATA/ATAPI-6 standard augmented with native command queuing (NCQ) commands optimized for the serialized interface.

The device has one embedded SATA host bus adapter (HBA) controller with a single port. The device SATA host subsystem is composed of several functional components (see [Figure 24-151](#)):

- The core component of the SATA host controller subsystem (signified as SATA controller on the [Figure 24-151](#)) implements the transport and link layers of the SATA interface protocol, i.e. all SATA media access control (MAC) functionalities.
- SATA\_PHY encompasses the physical layer (PHY) components - serializer, de-serializer, etc. which adapt the generated by the SATA controller MAC logic parallel 10-bit output data stream for serial electrical transmission and reception.
- DPLL\_SATA is a programmable (through registers of the integrated PLL controller - PLLCTRL\_SATA) DPLL clock source that provides a high-speed clock to the SATA\_PHY serializer/de-serializer components.
- An L4\_CFG interface adapter - OCP2SCP3, which enables accessing the PLLCTRL\_SATA registers via L4\_CFG interconnect accesses.

For details regarding the device SATA host subsystem components - SATA\_PHY, PLLCTRL\_SATA, DPLL\_SATA and interface adapter), see [Section 26.1.1, SATA PHY Subsystem Overview](#), in [Chapter 26, Shared PHY Component Subsystems](#).

[Figure 24-151](#) shows an overview of the device-embedded SATA host controller subsystem.

**Figure 24-151. SATA Host Controller Subsystem Overview**

sata1-001

### 24.8.1.1 SATA Controller

The SATA controller is the main functional component of the device-embedded SATA (Host Bus Adapter) HBA and is based on advanced host controller interface (AHCI) module. The SATA controller handles data transactions at the link and transport layers of the SATA interface using the advanced host controller interface (AHCI) mechanism. The SATA controller core engine is a generation 2-compliant host (supporting 3 Gbps transfer speed) with integrated DMA and FIFO RAM buffers.

The SATA controller AHCI-based interactions involve extensive DMA processing of both data and command transfers, reducing much of the user overhead associated with standard ATA task file register servicing. The SATA HBA port programmable DMA acts as a master on the device L3\_MAIN interconnect, which facilitates direct command/data transfers between host system memory and attached SATA storage devices.

The SATA controller has a slave configuration port accessible on the device L4\_CFG interconnect. This port provides the user with an appropriate register interface for HBA setup, control and status, interrupt settings, DMA configuration, etc.

#### 24.8.1.1.1 AHCI Mode Overview

The SATA core supports the AHCI hardware mechanism, which provides the user software with a suitable HBA register interface to manage SATA interface operations. Generally, the AHCI introduces a system memory structure that includes some generic control and status area and a list of command entries (which can have a depth from 1 up to 32 entries) assigned per HBA port. Each of the command list entries contains information necessary to program a SATA device and pointers to data transfer descriptors.

The AHCI mode of operation disregards the master/slave communication model. A certain SATA AHCI host controller port establishes a point-to-point connectivity with only a single SATA peripheral device at a time, which is always a master device.

#### 24.8.1.1.2 Native Command Queuing

The SATA AHCI engine supports NCQ and is capable of command queued protocol interactions with NCQ-compliant SATA mass storage devices. The NCQ commands generated by a SATA HBA port are loaded into command queues maintained at the peripheral device. The commands are stored in a queue and subsequently fetched and processed by peripheral device controller in sequences, which imply more native and highly-optimized for the device order of execution. The synchronization between an NCQ-aware SATA HBA and an NCQ-aware peripheral storage device involves implementation of the so called FPDMA queued command protocol, which ensures that HBA posts NCQ commands to the target SATA device in its demanded NCQ order.

#### 24.8.1.1.3 SATA Transport Layer Functionalities

The SATA controller handles all of the transport layer functions of the SATA protocol. During reception it receives a frame information structure (FIS) from its link layer through the RX FIFO, decodes the type, and routes it to the proper location through the port DMA. During transmission it transfers a FIS constructed by the port DMA to the link layer through the TX FIFO. It also passes link layer errors and checks for transport layer errors to pass up to the system. The transport layer also contains the TX and RX FIFOs. These FIFOs are used as asynchronous data buffers between the serial domain and the bus clock domain. The size of these FIFOs affects the subsystem ability to buffer data before flow control must be asserted. It also affects the maximum transaction size that can be programmed into the port DMA.

#### 24.8.1.1.4 SATA Link Layer Functionalities

The link layer maintains the link and supports all SATA link layer functionality, including:

- Out-of-band (OOB) transmit signaling
- Frame negotiation and arbitration
- Envelope framing/deframing
- Cyclic redundancy check (CRC) calculation (receive and transmit)
- 8b/10b encoding/decoding
- Flow control
- Frame acknowledgment and status
- Data width conversion
- Data scrambling/descrambling
- Primitive transmission
- Primitive detection and dropping
- Power management

#### 24.8.1.2 SATA Controller Features

This section describes the features supplied by the SATA controller module. The SATA controller complies with the following standards:

- *Serial ATA Standard* specification (revision 2.6)
- *Serial ATA Advanced Host Controller Interface* specification (revision 1.1). The device SATA host controller also complies with the *Serial ATA Advanced Host Controller Interface* specification (revision 1.3), excluding support for the port multiplier FIS-based switching feature.

The main features of the SATA host controller are:

- Serial ATA 1.5-Gbps and 3-Gbps speeds (SATA-1 and SATA-2)
- Integrated RxFIFO and TxFIFO RAM data buffers
- Support of all SATA power management features
- AHCI support of 64-bit addressing mode (see device limitation note below)
- HBA port associated Internal DMA engine
- Hardware-assisted NCQ for up to 32 entries

- Command completion coalescing (CCC) interrupts
- Support of port multiplier with command-based switching
- Activity LED generation

Additionally, link layer supports:

- 8b/10b encoding and decoding functionality
- RX elasticity buffer
- TX OOB sequence generation
- RX OOB sequence generation

The differences between the SATA host controller and a standard SATA host controller defined by the *Serial ATA Gold Standard* specification (v2.6) are:

- Staggered spin-up is not supported (only one HBA AHCI port embedded).
- Only one port is supported by the device-embedded SATA HBA from up to 32 possible, according to the standard.
- The SATA controller is AHCI-mode compliant only and does not support standard ATA legacy modes of operation.
- Cold presence detection signals are not available. The SATA controller targets support for permanently attached SATA drives only.

The following features are NOT supported by the SATA host subsystem:

- Far-end analog loopback
- Cold presence detect (CPD) signal is not available at the system level. As a consequence, the SATA device hot-plug operation is not supported.
- Mechanical presence switch signal is not available at system level.
- Message signaled interrupts
- PHY layer functionalities of SATA controller are not integrated. These are assigned to the SATA\_PHY transceiver integrated at the device level (outside SATA controller module itself).

The SATA controller master (DMA) interface features:

- 32-bit data
- 36 bits of the AHCI master address bus (byte-aligned addressing) implemented in the device. See device limitation note below.
- 1-bit tag-ID port, but the tag value is 1 on all accesses (that is, the feature is not used)
- Sequential burst support (16 x 32 bit – Dwords)

---

**NOTE:** Even though the SATA AHCI Controller supports 64-bit -addressing mode, only 36-lower bits of the 64-bit address bus are integrated (meaningful) in the device. This defines a 64-GiB AHCI master address space.

---

The SATA controller slave interface features:

- 32-bit data, 13-bit (byte-aligned) address
- Single access (no burst support)
- All accesses are expected to be 4 bytes wide, 32-bit aligned.

---

**NOTE:** Accesses smaller than 4 bytes wide (that is, byte enable patterns different from 4'b1111) are functional and do not generate an error. Misaligned addresses do not generate an error.

---

As can be seen in [Figure 24-151](#), the SATA Controller has all events merged to a single interrupt output - SATA\_IRQ, mapped to the device Interrupt Crossbar.

## 24.8.2 SATA Controller Environment

Apart from the SATA communication-dedicated electrical connections to the SATA\_PHY component, there is an additional SATA-defined-led drive generation signal that can be output at the device pad: `spi1_cs[1]`. For more information about this signal pad configuration register mapping, see [Section 18.4.6.1.1, Pad Configuration Registers](#) in [Chapter 18, Control Module](#). For more details regarding the behavior of activity LED generation, see [Section 24.8.4.10, Activity LED Generation Functionality](#).

**Table 24-581. SATA Controller I/O Signals**

Module Pin Name	Device Level Signal Name	I/O <sup>(1)</sup>	Description	Reset Value
TXP <sup>(2)</sup>	sata1_txp0	O	TXP output of the SATA PHY differential transmission line	0
TXN <sup>(2)</sup>	sata1_txn0	O	TXN output of the SATA PHY differential transmission line	0
RXP <sup>(2)</sup>	sata1_rxp0	I	RXP input of the SATA PHY differential reception line	Hi-Z
RXN <sup>(2)</sup>	sata1_rxn0	I	RXN input of the SATA PHY differential reception line	Hi-Z
ACT0_LED	sata1_led	O	HBA port activity LED indication	Hi-Z

<sup>(1)</sup> I = Input; O = Output

<sup>(2)</sup> These signals are part of the interface between SATA PHY serializer / de-serializer and the externally attached SATA storage device.

---

**NOTE:** The path from module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. For more information, refer to the sections [Section 18.4.6.1.1, Pad Configuration Registers](#), and [Section 18.5, Control Module Register Manual](#), in [Chapter 18, Control Module](#), for more information.

---

The [Figure 24-152](#) shows the SATA host controller subsystem environment summarizing the interface signals exported directly from SATA controller at the device boundary, as well as those exported after SATA\_PHY processing at the device boundary. For more information on the interface between the SATA controller and SATA\_PHY, see [Chapter 26, Shared PHY Component Subsystems](#).

Figure 24-152. SATA Subsystem Environment

sata1-002

### 24.8.3 SATA Controller Integration

This section describes the SATA AHCI host controller integration in the device, including information about clocks, resets, and hardware requests. [Figure 24-153](#) shows the SATA controller integration.

**Figure 24-153. SATA Controller Integration**

sata1-003

SATA controller integration includes these features:

- A single functional and interface clock (SATA\_FICLK, shared between the master and the slave interfaces)
- A functional always-on clock (SATA\_PMALIVE\_FCLK to support entrance into and exit from the SATA defined low-power modes)
- A single hardware nonretention reset input (SATA\_RST\_MAIN\_ARST\_N)
- Master standby and slave idle protocols with the power, reset, and clock management (PRCM) module
- A single interrupt request generation line (SATA\_IRQ, mapped to IRQ\_CROSSBAR\_49 line of IRQ CROSSBAR)
- No DMA or wakeup requests generation to surrounding modules
- L3\_MAIN master interface
- L4\_CFG-configuration slave interface

The SATA encoded symbol transmission/decoded symbol reception relies on two serial clocks, which are supplied indirectly from the DPLL\_SATA through the SATA\_PHY component.

**NOTE:** For more information about the slave idle protocol and the wakeup request, see [Section 3.1.1.1.2, Module-Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 24-582](#) through [Table 24-584](#) summarize the integration of the module in the device.

**Table 24-582. SATA Controller Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect
SATA	PD_L3INIT	L4_CFG L3_MAIN

**Table 24-583. SATA Controller Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SATA	SATA_FICLK	L3INIT_L3_GICLK	PRCM	SATA interface and functional clock
	SATA_PMALIVE_FCLK	L3INIT_48M_GFCLK	PRCM	Always-on SATA-specific, power-management support clock
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SATA	SATA_RST_MAIN_ARST_N	L3INIT_RST	PRCM	A nonretention hardware reset

**Table 24-584. SATA Controller Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	Destination IRQ_CROSSBAR Input	Default Mapping	Description
SATA	SATA_IRQ	IRQ_CROSSBAR_49	MPU_IRQ_54 DSP1_IRQ_80 DSP2_IRQ_80	SATA Controller IRQ line

**NOTE:** The “Default Mapping” column in [Table 24-584 SATA Controller Hardware Requests](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ\_CROSSBAR module. For more information about the IRQ\_CROSSBAR module, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#). For more information about the device interrupt controllers, see [Chapter 17, Interrupt Controllers](#).

**NOTE:**

- For a description of the interrupt source, see [Section 24.8.4.5, Interrupt Requests](#).

**NOTE:**

- The SATA HBA does not generate DMA and wakeup hardware requests to the surrounding modules integrated in the device

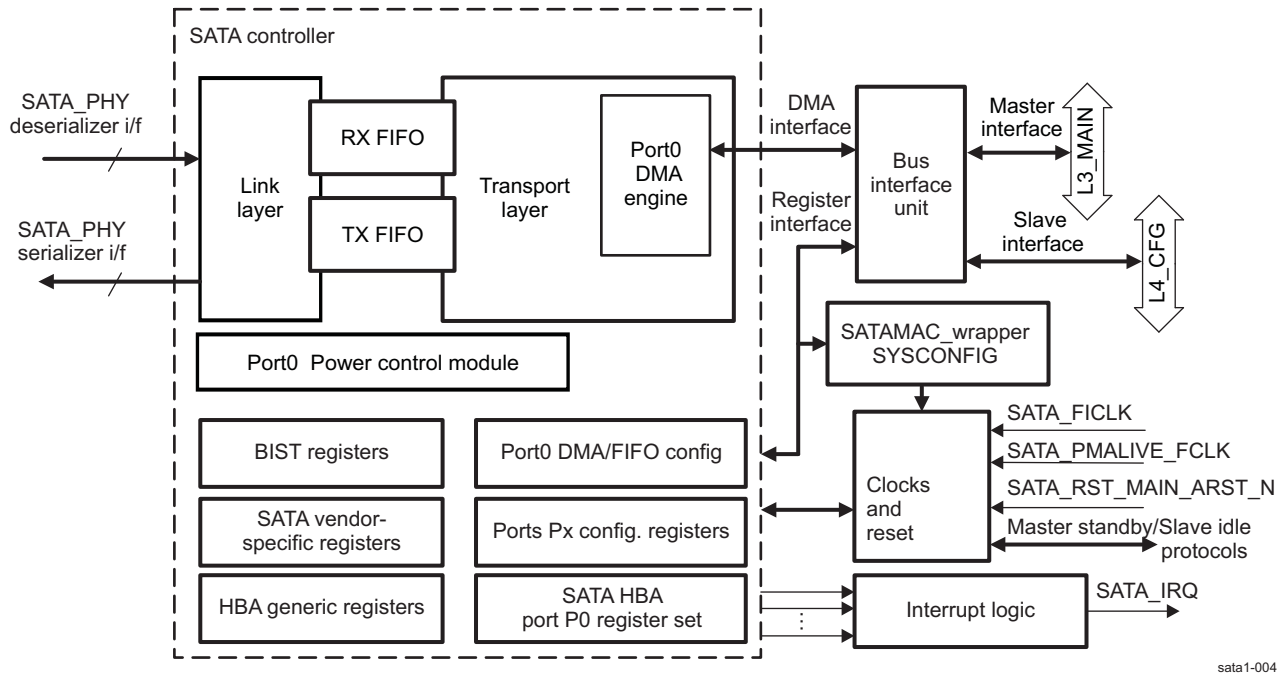

## 24.8.4 SATA Controller Functional Description

### 24.8.4.1 SATA Controller Block Diagram

Figure 24-154 shows a block diagram of the SATA host controller.

Figure 24-154. SATA Controller Functional Block Diagram

The SATA HBA port-associated DMA is a master on the device L3\_MAIN interconnect. For a write to the attached storage device, this port reads FISs from the host system memory and pushes them into the transmit FIFO. When frame Dwords are received at RxFIFO, this interface is used to write the data out to the dedicated host system memory area. For details about DMA features and operation, see [Section 24.8.4.8, DMA Port Configuration](#).

The SATA controller has a configuration slave interface used to read and write all system registers. The slave interface includes the following functions:

- Configuring the SATA AHCI core (and indirectly, to a certain extent, the SATA\_PHY physical component)
- Configuring the DMA for transmit and receive operations
- Initiating write transfers to the attached storage device
- Responding to interrupts and reads

Both the slave and master interface of the SATA host controller share the same functional and interface clock, that is, operate on the same frequency (see also [Section 24.8.3, SATA Controller Integration](#)).

A bus interface unit adapts the SATA controller master and slave buses to the corresponding L3\_MAIN and L4\_CFG device interconnects.

**NOTE:** The **SATA controller AHCI Core registers** are part of the instance signified as **DWC\_ahsata** inside the [Section 24.8.6.1, SATA Controller Instance Summary](#).

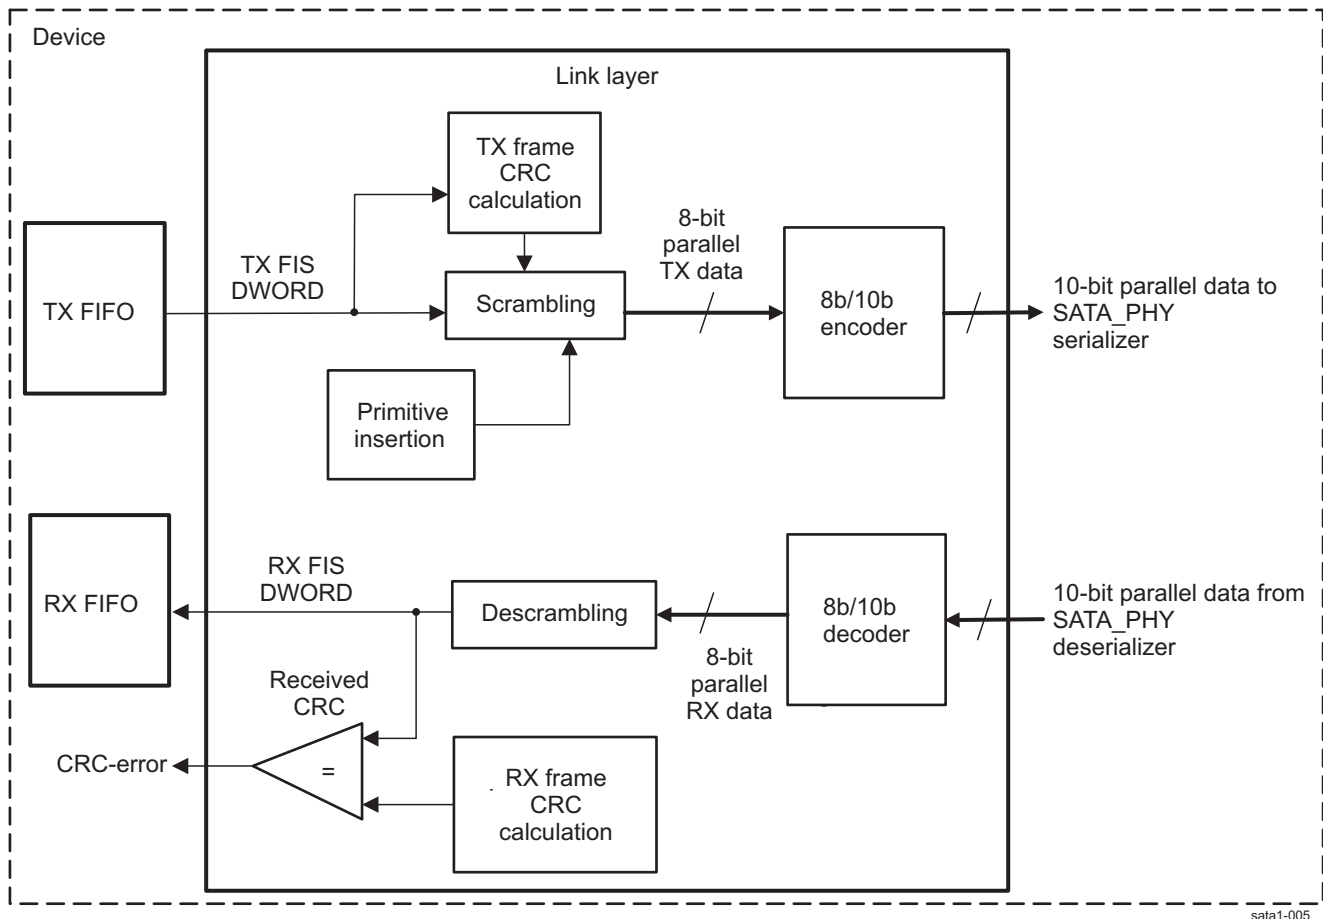

### 24.8.4.2 SATA Controller Link Layer Protocol and Data Format

One of the main tasks of the SATA HBA Link layer is to perform a parallel 8-bit FIS data to a 10-bit parallel code conversion (8b/10b encoding). The encoded stream, which is a sequence of 10-bit parallel-encoded characters, is subsequently passed to the SATA\_PHY serializer component to adapt to a serial 10-bit character transmission to the SATA peripheral device. For more details, see [Section 26.1.1](#), *SATA PHY Subsystem Overview*, and [Section 26.1.4](#), *SATA PHY Subsystem Functional Description*, in [Chapter 26](#), *Shared PHY Component Subsystems*.

One of the main tasks of the SATA HBA Link receiver is to perform a 8b/10b decoding, in which process the parallel 10-bit characters coming out from the SATA\_PHY de-serializer are decoded to parallel data or control bytes. The received symbols with invalid codes are rejected by the link layer and corresponding illegal reception errors are generated. For more details regarding the SATA\_PHY de-serializer, see [Section 26.1.1](#), *SATA PHY Subsystem Overview*, and [Section 26.1.4](#), *SATA PHY Subsystem Functional Description*, in [Chapter 26](#), *Shared PHY Component Subsystems*.

There are also other data process stages at the link layer, such as CRC calculation, scrambling/descrambling, primitive insertion/detection, etc. [Figure 24-155](#) shows the primary stages of link Dword data processing.

**Figure 24-155. Simplified Schema of Link Dword Processing**

sata1-005

#### 24.8.4.2.1 SATA 8b/10b Parallel Encoding/Decoding

The input to the link coder logic is a parallel (unencoded) data byte and an associated control variable: Z with two possible values (K, D). The Z value signifies the byte to be encoded either as a control character (K value) or a data character (D value). The data byte (ABCDEFGH, where A matches the least significant bit [LSB]) is divided into two asymmetric portions: a 5-bit one ABCDE (range: 0 to 31) and a 3-bit one FGH (range: 0 to 7).

The encoding process is performed in two stages. At the first stage, the 5-bit portion is converted to a 6-bit subblock (abcdei); at the second stage, the 3-bit portion is converted to a 4-bit subblock (fghj). An additional parameter called running disparity (rd) is taken into account during code calculation at both the character transmission and reception link sides. It introduces code correlation between adjacent bytes so that the current subblock code can depend on the code of the previous subblock and its associated rd output value. As a consequence, depending on the input rd parameter and the 8b/10b encoded value, the encoding/decoding lookup tables might have two different entries for the same byte.

The 10-bit parallel-encoded character is passed to the 10-bit data input of the SATA\_PHY serializer component, which further transmits it serially in a LSB to most significant bit (MSB) order (abcdeifghj). The receiver link receives and decodes the sequence in the same LSB to MSB order (abcdeifghj). While SATA encoder takes the full range of a data byte (0–255) encoding values, it uses only two values to encode control characters. For more information on the 8b/10b encoding/decoding process, see the SATA standard specification.

#### 24.8.4.2.2 SATA Stream Dword Components

The basic unit of SATA information is Dword – a double sized word (32 bits). An encoded Dword has a 40-bit length (4 x 10 bits), but, for simplicity, unencoded Dword lengths are considered here. Each Dword is serially transmitted or received by the SATA\_PHY components in LSB character to MSB character order.

- Primitives

The shortest meaningful component of the SATA stream is the primitive, which consists of a single Dword. Different types of primitive characters are inserted into the SATA stream to maintain synchronization between the host and the SATA peripheral device. Primitives convey real-time state information regarding the SATA communication channel itself. For example, the SATA link layer generates primitives to perform flow control, synchronize power management state transitions, frame enveloping, etc. The transport layer is not aware of the lower level primitive Dwords. They are subject to processing only to the link layer.

- Primitive handshakes

In some cases, the transmitter of a primitive can require that the receiver send an acknowledge Dword to confirm primitive reception, which is a primitive handshake.

The first byte of a primitive Dword is always a control character (or  $Z = K$ ) with two possible encodings. The remaining three data bytes ( $Z = D$ ) contain the function of the primitive. According to the SATA standard, the transmitter and the receiver are not required to match the number of primitives sent and received.

[Table 24-585](#) briefly summarizes the primitives used by SATA.

**Table 24-585. SATA Primitives Summary**

Primitive Name	Short Description
ALIGNp	Sent in pairs to PHY component to readjust its internal operations
CONTp	After CONTp insertion, previous primitives are repeated continuously until a different primitive is inserted
DMATp	terminates DMA data transmission
EOFp	End of frame
HOLDp	Inserted to hold data when transmitter doesn't have data ready to transmit
HOLDAp	Acknowledges a HOLDp primitive
PMACKp	Acknowledges a power management request
PMNAKp	A power management request denial
PMREQ_Pp	Power management request to PARTIAL state
PMREQ_Sp	Power management request to SLUMBER state
R_ERRp	Reception error occurred
R_IPp	Current node is receiving data
R_OKp	Reception without error
R_RDYp	Receiver is ready for reception

**Table 24-585. SATA Primitives Summary (continued)**

Primitive Name	Short Description
SOFP	Start of frame
SYNCP	Synchronization primitive
WTRMP	Transmitter inserts this primitive while waiting to get the reception status from receiver
XRDYP	Transmitter has data ready for transmission

- SATA data frames

SATA data frames incorporate data FISs constructed at the transport layer along with some primitives (see [Figure 24-156](#)). The maximum number of Dwords between SOFP to EOFp does not exceed 2064 Dwords, including the FIS type and CRC fields described here.

- Frame FIS components

The FIS (Frame Information Structure) contents of a frame incorporate the Dwords that correspond to SATA target data structures. FIS Dwords are output from transport layer Tx FIFO to the transmitter link 8b/10b encoder during transmission. In the case of reception, the FIS content is obtained at transport layer Rx FIFO after being successfully decoded by the receiver link logic. The commands and data embedded into Frame FISs are generated/interpreted at a higher transport level of the SATA controller and are user software-accessible in the host system memory.

- CRC

The CRC is the last Dword in a frame, immediately following the last FIS Dword of the frame and preceding the EOFp primitive. The 32-bit CRC calculation is performed only on the FIS Dwords of the frame contents, so that frame-inserted primitives such as HOLDp, CONTp, etc., are not taken into account. The CRC is aligned on a Dword boundary. CRC code computation expects an input of an even number of words and should be Dword-multiple. If an FIS block contains an odd number of words, the last FIS word is padded with 0s to a full Dword before the CRC is calculated.

- During transmission: The CRC Dword is calculated on original FIS contents, before scrambling and serial 8b/10b encoding are performed.
- During reception: The CRC Dword is calculated on the 8b/10b decoded and subsequently descrambled 8-bit FIS Dword contents. It is then compared to the CRC received from the source to perform error check analysis.

- Frame embedded primitives

The beginning of a frame is marked with a SOFP primitive, and the end is marked with an EOFp primitive. Some primitives, such as HOLDp and HOLDAp acknowledge, can be inserted into frames between data FISs.

- SATA data stream

As shown in [Figure 24-156](#), the SATA data stream is composed of frames carrying the target data/command contents combined with various primitives generated to maintain consistency of transfers over the SATA interface.

**Figure 24-156. SATA Data Stream Components**

sata1-006

### 24.8.4.2.3 Scrambling/Descrambling Processing

The contents of a frame are scrambled before being passed to the link 8b/10b encoder. Scrambling is performed on Dword quantities by XORing the data to be transmitted with the output of a linear feedback shift register (LFSR). All data words between the SOFp and EOFp are scrambled, including the CRC. [Figure 24-155](#) shows the basic flow.

The SATA controller (as defined by the SATA standard) performs scrambling/descrambling processing for EMI reduction purposes. Two scramblers are instantiated within the SATA controller: The first, the data payload scrambler, scrambles FIS data payload contents (including the calculated CRC Dword); the second, the repeated primitive suppression scrambler, scrambles only the repeated primitive stream contents.

The scrambling runs as follows: A certain data payload Dword located between SOFp and EOFp is XORed with the data payload scrambler output. The resulting scrambled Dword is submitted to the 8b/10b encoder for transmission.

On reception, the Dword is decoded using a 10b/8b decoder, the scrambler output is XORed with the resulting Dword, and the resulting Dword is presented to the link layer. It is then used for CRC computation. The CRC Dword is scrambled in the same way as data payload characters.

For details on the scrambling/descrambling feature, see the *SATA Standard Specification (rev.2.6)*.

### 24.8.4.3 Resets

#### 24.8.4.3.1 Hardware Reset

The module is reinitialized in hardware upon activation of PRCM.L3INIT\_RST reset signal ( for more information about hardware reset, see [Section 24.8.3](#), *SATA Controller Integration*).

For more information on the PRCM.L3INIT\_RST hardware reset signal, refer to [Section 3.5.5](#), *Reset Domains*, in [Chapter 3](#), *Power, Reset, and Clock Management*.

This reset normally occurs on device power up or during a system bus failure. All components of the SATA AHCI core are initialized, including the HBA port and generic registers. The bus interface unit (BIU) and SATA AHCI core wrapper components are also impacted.

#### 24.8.4.3.2 Software Initiated Resets

The SATA controller supports three levels of software reset, each of which has different impact over the SATA HBA hardware components and AHCI interface registers:

- Software reset (least intrusive)
- Port reset
- HBA reset (most intrusive)

---

**NOTE:** It is recommended that user software always starts with the least intrusive reset approach. Software chooses the next most intrusive reset only if the less intrusive reset does not succeed in clearing the condition.

---

##### 24.8.4.3.2.1 Software Reset

Software reset impacts only the attached to the HBA port SATA peripheral device, without affecting the established communication between physical layers or HBA engine.

To issue a software reset, the user must prepare two H2D register FISs into the emptied command list of the port. The first FIS must have bits SRST = 0b1 and C = 0b0. The first FIS corresponding command header bits C and R are set as follows: C = 0b1 and R = 0b1. The second FIS has bits SRST = 0b0 and C = 0b0. The second FIS corresponding command header bits C and R are set as follows: C = 0b0 and R = 0b0.

However, steps must be taken before issuing the software reset to the peripheral device attached to the port. For details on software reset, see the AHCI specification.

### 24.8.4.3.2.2 Port Reset

The port reset (also known as COMRESET) must be applied when the HBA port does not function properly after a software reset is issued to the port. The effect is that the SATA HBA port is reinitialized and communication between the phy layers of both the SATA host and the SATA target device is reestablished.

To trigger a COMRESET sequence on the SATA interface, user software must write 0x1 to the [SATA\\_PxSCTL\[3:0\]DET](#) bit field. The host receives a COMINIT signal sequence, indicating that the peripheral device has successfully reestablished communication. For more information on port reset, see the AHCI specification (revision 1.1).

---

**NOTE:** The port reset (COMRESET) method is the preferred AHCI mechanism for error recovery and should be used instead of the software reset.

---

### 24.8.4.3.2.3 HBA Reset

Software can globally reset the SATA controller, if a port reset does not clear the conditions successfully. On HBA reset, all SATA AHCI core interface registers are reset, **excluding those from the hardware initialization domain** - the [SATA\\_PxCLB](#), [SATA\\_PxCLBU](#), [SATA\\_PxFB](#) and [SATA\\_PxFBU](#) registers. All state machines that relate to data transfers and queuing return to IDLE state, and the port is reinitialized by sending COMRESET. The global reset is triggered when user software sets the [SATA\\_GHC\[0\]HR](#) = 0b1 bit. The HBA indicates that global reset is finished, deasserting the [SATA\\_GHC\[0\]HR](#) bit to 0b0 in hardware. Hence, user software must poll the HR bit to detect this condition. For more information, see the mentioned AHCI standard specification.

## 24.8.4.4 Power Management

The device SATA host controller subsystem power management can be identified at the following levels:

- SATA controller low power-management features (defined also in the SATA standard specification, revision 2.6)
- Master standby and idle slave protocols established between SATA controller and the device PRCM through a SATA AHCI core wrapper interface (signified as SATAMAC\_wrapper instance inside the [Section 24.8.6.1](#), *SATA Controller Instance Summary*).

This section describes the relationships that exist between both levels of SATA Controller power management.

### 24.8.4.4.1 SATA Specific Power Management

The SATA controller core supports both PARTIAL and SLUMBER low-power states, as described in the SATA standard specification (revision 2.6). These modes allow power savings by powering down part of SATA\_PHY and gating off the clocks to the link layer. The port power control module is used to enter and exit these modes, which can have the normal functional clocks gated off.

#### 24.8.4.4.1.1 PARTIAL Power Mode

In the PARTIAL power state, the SATA\_PHY component transmits electrical IDLE to the device and the receiver is left on to receive OOB signals. This mode can also be used to support near-end analog loopback, if a device is attached.

#### 24.8.4.4.1.2 Slumber Power Mode

In the SLUMBER power state, the transmitter is completely turned off. This allows for greater power savings but near-end analog loopback cannot be performed and there is a longer latency to exit the mode.

#### 24.8.4.4.1.3 Software Control over Low Power States

The user has manual control over low power states through the [SATA\\_PxCMD \[31:28\]ICC](#) register bit field. This works if the link is in IDLE state; otherwise, writes to this field are ignored.

#### 24.8.4.4.1.4 Aggressive Power Management

Low power modes can be initiated by software when there are no pending transactions, but the SATA AHCI core also supports aggressive power management. In this mode, the subsystem automatically initiates the PARTIAL or SLUMBER state when there are no inflight commands. This is useful for power savings, but the price is increased latency if a low-power mode is entered and a transfer request is made. Software enables aggressive link-layer power management by setting the [SATA\\_PxCMD\[26\]ALPE](#) bit to 0x1. The link aggressive power management state (PARTIAL or SLUMBER) is selected using the [SATA\\_PxCMD\[27\]ASP](#) bit.

#### 24.8.4.4.2 Master Standby and Slave Idle Management Protocols

The master standby and slave idle protocols are implemented between the PRCM and SATA controller, with mode settings located in the SATAMAC\_wrapper register ([SATA\\_SYSCONFIG](#)).

- The standard idle request/acknowledge handshake is associated with the L4\_CFG slave port. The default idle mode is smart-idle, as indicated by the power-on reset (POR) value: [SATA\\_SYSCONFIG\[3:2\]IDLEMODE = 0x2](#).

---

**NOTE:** No other mode is expected to be required in normal operation: no-idle and force-idle are used for debugging only. Because the module is not capable of asynchronous wakeup, the smart-idle/wakeup (IDLEMODE = 0x3) is strictly equivalent to smart-idle.

---

- The standby/wait handshake is associated with the L3\_MAIN master port. Software is responsible to keep the DMA operations and the standby status in sync.

The default standby mode is smart-standby, as indicated by the POR value: [SATA\\_SYSCONFIG\[5:4\]STANDBYMODE = 0x2](#). However, the SATA controller hardware does not provide any indication about DMA activity that could be used to drive the standby dynamically (that is, the smart mode): Smart-standby is therefore strictly equivalent to the force-standby mode (that is, the module remains in or goes to permanent standby).

The standby control procedures are therefore software-driven.

To exit standby:

1. Change the standby mode to no-standby by setting [SATA\\_SYSCONFIG\[5:4\] = 0x1](#).
2. Optional: Confirm the SATA controller standby status through the PRCM. For more information, see [Section 3.6.4.1.4, Clock Domain Module Attributes](#), in [Chapter 3, Power, Reset, and Clock Management](#).
3. Only then, enable the controller DMA (AHCI list processor). For more information, see the AHCI specification.

To enter standby:

1. Disable the controller DMA (AHCI list processor). For more information, see the AHCI specification.
2. Ensure all pending transactions have completed. For more information, see the AHCI specification.
3. Change the standby mode to smart-standby (or force-standby) by setting [SATA\\_SYSCONFIG\[5:4\] = 0x2](#).

#### CAUTION

The software is responsible to keep the DMA operations and the standby mode status in sync.

---

**NOTE:** Because the standby exit is software driven, it is by definition synchronous: the asynchronous wakeup is never activated, which means that the smart-standby and smart-standby/wakeup are equivalent (as well as force-standby).

---

**NOTE:** For more information on the SATA Controller master standby and slave idle management protocols with the device PRCM, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

#### 24.8.4.4.3 Clock Gating Synchronization

The bus clock can also be gated off in either the PARTIAL or SLUMBER state, if the software guarantees there is nothing in flight, the clock can be stopped and started without glitches, and the clock can be restarted quickly when activity is initiated from the device side.

The following steps outline the procedure to stop the clock:

1. Put the link in a low power state (either PARTIAL or SLUMBER)
  - SATA MAC link layer can enter low power either manually see [Section 24.8.4.4.1.3, Software Control over Low Power States](#)) or automatically (see [Section 24.8.4.4.1.4, Aggressive Power Management](#))
  - If there is no device attached (making it impossible to enter a low power state), the [SATA\\_SYSCONFIG\[16\] OVERRIDE0](#) override bit can be set to 0b1 to stop the interface/functional clock (SATA\_FICLK) and save power.
2. Initiate the clock stopping procedure.

#### CAUTION

If a SATA drive attached to the SATA HBA port has not entered a low power state (PARTIAL or SLUMBER), the user must not set the [SATA\\_SYSCONFIG\[16\]OVERRIDE0](#) bit; otherwise, the link layer can be ruined, resulting in indeterminate SATA controller behavior.

**Table 24-586. Local Power-Management Features**

Feature	Registers	Description
Slave idle modes	<a href="#">SATA_SYSCONFIG</a> [3:2]IDLEMODE bit field	The available modes are: Force-idle, no-idle, and smart-idle wakeup disabled modes are available.
Master standby modes	<a href="#">SATA_SYSCONFIG</a> [5:4]STANDBYMODE bit field	The available modes are: Force-standby, no-standby, smart-standby wakeup disabled
Clock-gate overriding mode	<a href="#">SATA_SYSCONFIG</a> [16]OVERRIDE0 bit field	Clock stopping override function. Should not be applied when attached to port SATA peripheral device has not entered a Low-power mode.

For more information on the L3INIT\_L3\_GICLK functional clock gating in the device PRCM, refer to [Section 3.1.1.1.4, Clock Domain-Level Clock Management](#), in the chapter, *Power, Reset and Clock Management*.

#### 24.8.4.5 Interrupt Requests

This section describes all of the conditions that can generate an interrupt. Each condition is subject to the masking capabilities described in [Section 24.8.4.5.4, Interrupt Condition Control](#).

##### 24.8.4.5.1 Interrupt Generation

Both level and pulse interrupts are available. Exercise care when using the pulse interrupt. Because of the synchronization and interrupt aggregation from the internal core, clearing one interrupt as another interrupt occurs can prevent a new pulse from being generated. A new pulse is generated only if the first interrupt is completely cleared (that is, the level interrupt goes away) before the new interrupt event occurs. Thus, an interrupt can occur after the register write is issued to clear the first interrupt but before the interrupt is fully cleared. In this case, a new pulse is not issued and the level interrupt remains asserted. After issuing the write to clear an interrupt, software must read the interrupt status registers to ensure that a new interrupt has not occurred.

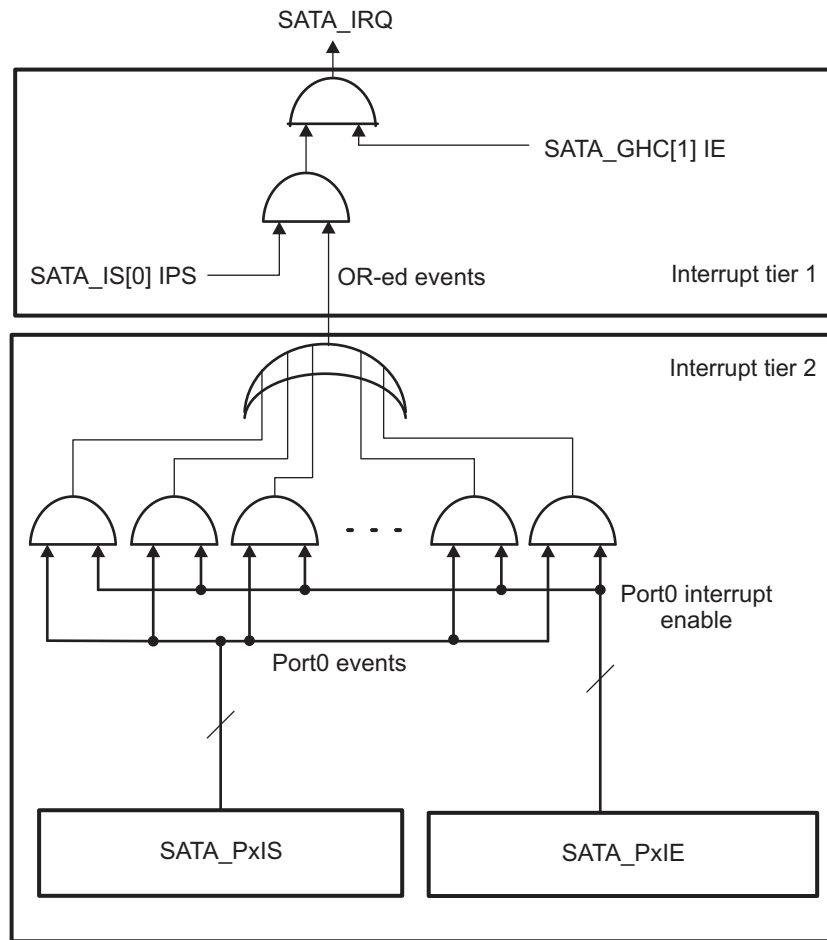

**24.8.4.5.2 Levels of Interrupt Control**

The AHCI directs that interrupts be indicated in a two-tier structure and thus associated with different HBA ports. Considering the device SATA HBA single-port implementation for the first tier, only the [SATA\\_IS\[0\]](#) IPS bit should be considered. It indicates if the only port available to the user (HBA port 0) has pending interrupts.

For the second tier, the [SATA\\_PxIS](#) register (where x = 0) indicates which specific interrupt condition(s) occurs to trigger an interrupt on port 0. In most cases, software writes 0x1 (Write One to Clear) to clear these bits, and then writes 0x1 to the [SATA\\_IS \[0\]](#)IPS bit to clear the interrupt. However, some interrupts in the [SATA\\_PxIS](#) register have alternate methods of being cleared (for details, see [Section 24.8.6.2.2, DWC\\_ahsata Register Description](#)). [Section 24.8.4.5.3, Interrupt Events Description](#), describes all interrupt generating conditions.

[Figure 24-157](#) shows the SATA controller two-tier interrupt propagation structure. Besides [SATA\\_IS\[0\]](#), which gates all interrupts at the port 0 level, the tier 1 interrupt is globally gated by the [SATA\\_GHC\[1\]](#) IE bit.

**Figure 24-157. SATA Controller Interrupt Propagation Schema**

sata1-007

**NOTE:** Regardless of the device SATA controller single HBA port implementation, user software must read/write the tier 1 [SATA\\_IS\[0\]](#) IPS register bit to process interrupts.

### 24.8.4.5.3 Interrupt Events Description

This section describes the different events that are reflected in the [SATA\\_PxIS](#) register and that cause SATA\_IRQ interrupt generation, if enabled, in the [SATA\\_PxIE](#) register. For more information regarding SATA\_IRQ handling at the IRQ CROSSBAR subsystem, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#).

#### 24.8.4.5.3.1 Task File Error Status

This event is registered whenever the [SATA\\_PxTFD\[7:0\]](#) STS bit field is updated by the device and the error bit [SATA\\_PxTFD\[0\]STS\\_ERR](#) is set. [SATA\\_PxTFD\[7:0\]](#) STS is updated when a new register FIS, PIO setup FIS, or set device bits FIS is received from the device.

#### 24.8.4.5.3.2 Host Bus Fatal Error

This event is registered whenever an error is received by the SATA controller internal DMA master port from the configuration slave port.

#### 24.8.4.5.3.3 Interface Fatal Error Status

This event is registered if an error is generated on the interface. The following conditions can cause this:

- SYNC escape during an H2D register or data FIS transmission
- One of the following errors during a data FIS transfer:
  - Protocol ([SATA\\_PSERR\[10\] ERR\\_P](#))
  - CRC ([SATA\\_PSERR\[21\] DIAG\\_C](#))
  - Handshake ([SATA\\_PSERR\[22\] DIAG\\_H](#))
  - SATA\_PHY not ready ([SATA\\_PSERR\[9\] ERR\\_C](#))
- Unknown FIS received with a good CRC, but length greater than 64 bytes
- Physical region descriptor (PRD) table byte count of 0

---

**NOTE:** This is a fatal error in which the DMA is in an error state until software clears the [SATA\\_PxCMD\[0\] ST](#) bit or resets the interface with a port or global reset. For more information about software-initiated resets, see [Section 24.8.4.3.2, Software Initiated Resets](#).

---

#### 24.8.4.5.3.4 Interface Non-Fatal Error Status

This event is registered on the following error conditions:

- One or more of the following errors are registered during a non-data FIS transfer:
  - Protocol ([SATA\\_PSERR\[10\] ERR\\_P](#))
  - CRC ([SATA\\_PSERR\[21\] DIAG\\_C](#))
  - Handshake ([SATA\\_PSERR\[22\] DIAG\\_H](#))
  - SATA\_PHY not ready ([SATA\\_PSERR\[9\] ERR\\_C](#))
- Command list underflow during a read operation when software builds a command table that has more total bytes than the transaction given to the device

---

**NOTE:** The conditions previously described are non-fatal and the SATA host controller continues to operate normally.

---

#### 24.8.4.5.3.5 Overflow Status

This event is registered if command list overflow is detected during read or write when software builds a command table with fewer total bytes than the transaction given to the device.

---

**NOTE:** This is a fatal error in which the DMA is in an error state until software clears the [SATA\\_PxCMD\[0\]](#) ST bit or resets the interface with a port or global reset. For more information about software-initiated resets, see [Section 24.8.4.3.2, Software Initiated Resets](#).

---

#### 24.8.4.5.3.6 *Incorrect Port Multiplier Status*

This event is registered when the SATA controller receives a FIS from a device with a PM field not matching what is expected. The [SATA\\_PxIS\[23\]](#) IPMS event corresponding bit can be set during device enumeration, but software should ignore it until enumeration is finished.

#### 24.8.4.5.3.7 *PHYReady Change Status*

This event is registered when the status of PHYReady changes. Its corresponding status bit ([SATA\\_PxIS\[22\]](#) PRCS) reflects the [SATA\\_PxSERR\[16\]](#)DIAG\_N bit.

#### 24.8.4.5.3.8 *Port Connect Change Status*

This event is registered when there was a change in the current connect status as reflected by the [SATA\\_PxSERR\[26\]](#)DIAG\_X bit.

#### 24.8.4.5.3.9 *Descriptor Processed*

This event is registered when a transaction completes. Its corresponding flag ([SATA\\_PxIS\[5\]](#) DPS) is set whenever a PRD with the I bit set transfers all of its data.

---

**NOTE:** The PRD interrupt is an opportunistic interrupt and should not be used to definitely indicate the end of a transfer. Two PRD interrupts can happen close in time so that the second interrupt is missed while the first PRD interrupt is being cleared.

---

When a PRD entry is exhausted, the HBA can be directed to generate an interrupt through the I bit in the PRD entry (although a PRD is not considered exhausted until all data FISs that transfer data pointed to by that PRD entry is complete). For example, if the data FIS is 8 KiB, and this is covered by three PRD entries, the data is not considered valid at the end of the first or second PRD because the CRC has not been checked, even though the data has been copied to memory or to the device. Therefore, if the I bit is set in the PRD entry, the HBA must hold onto it internally and not set PxIS.DPS until the data FIS is complete and the CRC is correct. Once correct, PxIS.DPS can be set and, if PxIE.DPE and GHC.IE are set, the HBA generates an interrupt.

Conversely, if the PRD entry is 16 KiB and two 8 KiB Data FISS are used to transfer all of the data pointed to by the PRD entry, the PRD interrupt associated with that PRD entry is not signaled until after the second data FIS transfer completes successfully.

#### 24.8.4.5.3.10 *Unknown FIS Interrupt*

This status event indicates that an unknown FIS is received and copied into system memory.

#### 24.8.4.5.3.11 *Set Device Bits Interrupt*

This status event indicates that a Set Device Bits FIS is received with the I bit set and copied to system memory.

#### 24.8.4.5.3.12 *DMA Setup FIS Interrupt*

This status event indicates that a DMA Setup FIS is received with the I bit set and copied into system memory.

#### 24.8.4.5.3.13 PIO Setup FIS Interrupt

This status event indicates that a PIO Setup FIS with the I bit set is copied into system memory and the data related to that FIS is transferred.

#### 24.8.4.5.3.14 Device to Host Register FIS Interrupt

This status event indicates that a D2H Register FIS is received with the I bit set and copied to system memory.

#### 24.8.4.5.4 Interrupt Condition Control

There are several ways for software to control the conditions causing a non - command completion coalescing (**non-CCC**) SATA\_IRQ interrupt assertion. The [SATA\\_GHC\[1\] IE](#) register bit serves as a global mask. If it is 0x0, all interrupts are masked. If it is 0x1, interrupts not masked by the [SATA\\_IS](#) (all interrupts for port 0) and [SATA\\_PxIE](#) registers can trigger an interrupt. The [SATA\\_PxIE](#) register matches the [SATA\\_PxIS](#) register bit for bit. If the corresponding bit in the [SATA\\_PxIE](#) register is set to 0x1, the interrupt is unmasked. If the corresponding is 0x0, the interrupt is masked off.

[Table 24-587](#) summarizes the SATA controller interrupt status bits and their corresponding interrupt enable bits at the second tier of the SATA controller interrupt generation schema.

**Table 24-587. Interrupt Events Summary**

Event Status Flag	Interrupt Event Mask	Mapped to Interrupt Output	Brief Interrupt Event Description
<a href="#">SATA_PxIS</a> [30]TFES	<a href="#">SATA_PxIE</a> [30]TFEE	SATA_IRQ	Task File Error
<a href="#">SATA_PxIS</a> [29]HBFS	<a href="#">SATA_PxIE</a> [29]HBFE	SATA_IRQ	Host Bus Fatal Error
<a href="#">SATA_PxIS</a> [27]IFS	<a href="#">SATA_PxIE</a> [27]IFE	SATA_IRQ	Interface Fatal Error
<a href="#">SATA_PxIS</a> [26]INFS	<a href="#">SATA_PxIE</a> [26]INFE	SATA_IRQ	Interface Non-Fatal Error
<a href="#">SATA_PxIS</a> [24]OFS	<a href="#">SATA_PxIE</a> [24]OFE	SATA_IRQ	Overflow
<a href="#">SATA_PxIS</a> [23]IPMS	<a href="#">SATA_PxIE</a> [23]IPME	SATA_IRQ	Incorrect Port Multiplier
<a href="#">SATA_PxIS</a> [22]PRCS	<a href="#">SATA_PxIE</a> [22]PRCE	SATA_IRQ	Phy Ready Change
<a href="#">SATA_PxIS</a> [6]PCS	<a href="#">SATA_PxIE</a> [6]PCE	SATA_IRQ	Port Connect Change
<a href="#">SATA_PxIS</a> [5]DPS	<a href="#">SATA_PxIE</a> [5]DPE	SATA_IRQ	Descriptor Processed
<a href="#">SATA_PxIS</a> [4]UFS	<a href="#">SATA_PxIE</a> [4]UFE	SATA_IRQ	Unknown FIS Received
<a href="#">SATA_PxIS</a> [3]SDBS	<a href="#">SATA_PxIE</a> [3]SDBE	SATA_IRQ	Set Device Bits FIS Received
<a href="#">SATA_PxIS</a> [2]DSS	<a href="#">SATA_PxIE</a> [2]DSE	SATA_IRQ	DMA Setup FIS Received
<a href="#">SATA_PxIS</a> [1]PSS	<a href="#">SATA_PxIE</a> [1]PSE	SATA_IRQ	PIO Setup FIS Received
<a href="#">SATA_PxIS</a> [0]DHRS	<a href="#">SATA_PxIE</a> [0]DHRE	SATA_IRQ	Device to Host Register FIS Received

**NOTE:** To ensure normal generation of the standard (single-event driven, non-CCC) interrupts described in [Table 24-587](#), the user must ensure that the CCC feature is disabled (that is, the [SATA\\_CCC\\_CTL](#)[0] EN bit is set to 0x0).

#### 24.8.4.5.5 Command Completion Coalescing Interrupts

The SATA controller supports CCC, which can be thought of as interrupt pacing. Instead of being generated for every command completed, an interrupt can be triggered based on a certain number of commands completed and/or a timer time-out. This significantly reduces the load on the CPU by not allowing software to receive an interrupt every time a command is processed. Software can thus queue many commands or wait for many received FISes and process them as a batch. All CCC functions are controlled by the [SATA\\_CCC\\_CTL](#), [SATA\\_CCC\\_PORTS](#), and [SATA\\_TIMER1MS](#) registers. Setting

[SATA\\_CCC\\_PORTS](#)[0]PRT = 0x1 makes the only available SATA controller HBA port 0 - CCC-aware. The [SATA\\_CCC\\_CTL](#) register can be used to program CCC logic to trigger an interrupt whenever a certain number of commands are complete and/or a timeout value (as specified by the TV field of [SATA\\_CCC\\_CTL](#) and [SATA\\_TIMER1MS](#) registers) occurs. For specific programming instructions, see the [SATA\\_CCC\\_CTL](#) description.

#### 24.8.4.5.1 CCC Interrupt Based on Expired Timeout Value

To trigger a CCC interrupt on a port after an elapsed timer value, the following programming sequence must be implemented by user software:

1. Software disables the CCC feature, clearing [SATA\\_CCC\\_CTL](#)[0] EN to 0b0.
2. Software sets [SATA\\_CCC\\_PORTS](#)[0] PRT = 0x1 to make HBA port 0 CCC-aware.
3. Software sets [SATA\\_CCC\\_CTL](#)[15:8] CC = 0x0, which provides that the expired timeout trigger condition is selected.
4. Software defines the 1-ms time-based unit by loading an appropriate number of interface/functional clock cycles into the 20-bit [SATA\\_TIMER1MS](#)[19:0] TIMV bit field. For example, its reset value of 0x186A0 (100 000 x SATA\_FICLK cycles) provides that a 1-ms timeout base will be generated if SATA\_FICLK = 100 MHz.
5. Software chooses the timeout value as the number of 1-ms intervals through the 16-bit [SATA\\_CCC\\_CTL](#)[31:16]TV bit field.
6. Software enables the CCC-interrupt feature, asserting [SATA\\_CCC\\_CTL](#)[0] EN bit to 0b1.

Assertion of bit [SATA\\_CCC\\_CTL](#)[0] EN to 0x1 is required to start the 1MS TIMER after the above described configuration steps are completed.

---

**NOTE:** On CCC event configuration, the CCC feature should be disabled (that is, [SATA\\_CCC\\_CTL](#)[0] EN should be kept at 0b0).

---

---

**NOTE:** Due to the single SATA controller HBA port integration, the source of the CCC interrupt, if enabled, is always HBA port 0. On a CCC interrupt, the [SATA\\_CCC\\_CTL](#)[7:3] INT read-only bit changes to 0x0 (its reset value is 0x1) . As a consequence, the STA\_IS[0] IPS bit is set to 0x1.

---

#### 24.8.4.5.2 CCC Interrupt Based on Completion Count

If the desired method to receive an interrupt is based on the completion of a certain number of commands, the following settings must be performed:

1. Software disables the CCC feature, clearing [SATA\\_CCC\\_CTL](#)[0] EN to 0b0.
2. Software sets [SATA\\_CCC\\_PORTS](#)[0] PRT = 0x1 to make HBA port 0 CCC-aware.
3. Software sets [SATA\\_CCC\\_CTL](#)[15:8] CC! = 0x0 to the desired number (1–255) of commands to be completed. The CC! = 0x0 provides that the count completion condition is selected.
4. Software enables the CCC-interrupt feature, asserting the [SATA\\_CCC\\_CTL](#)[0] EN bit to 0b1.

---

**NOTE:** On CCC event configuration , the CCC feature should be disabled (that is, [SATA\\_CCC\\_CTL](#)[0] EN should be kept at 0b0).

---

---

**NOTE:** Due to the single SATA controller HBA port integration, the source of the CCC interrupt, if enabled, is always HBA port 0. On a CCC interrupt, the [SATA\\_CCC\\_CTL](#) [7:3]INT read-only bit changes to 0x0 (its reset value is 0x1) . As a consequence, the STA\_IS[0] IPS bit is set to 0x1.

---

### 24.8.4.6 System Memory FIS Descriptors

The SATA AHCI mode supports a command list of from 1 up to 32 entries (command slots) assigned to HBA port 0, which should be allocated and built into host system memory by user software. After receiving command/data messages from the attached port 0 SATA mass-storage drive, the HBA extracts the FIS Dwords, sorts them out, and stores them into different areas of RX FIS-allocated host system memory.

#### 24.8.4.6.1 Command List Structure Basics

Each command list entry has an associated command header (CH) that takes 32 bytes in host system memory, from which only the first 4 Dwords (16 bytes) are used. The CH contains different fields that detail the direction of transfer (H2D or D2H), type of command (ATA/ATAPI), reset behavior, PM ID, byte count and byte length of the PRD table, etc.

A command list slot CH specifies the base address of the underlying command table and information about the associated command FIS length. The command table in system memory has three main areas:

- A 64-byte command FIS area in which the user loads the command-associated FIS contents
- An ATAPI area in which a 12- or 16-byte ATAPI command is loaded, if specified in the CH (through bit A)
- A PRD table area that allows up to 65535 data descriptor entries

An entry of a PRD table (that is, a scatter/gather list item) specifies descriptor parameters of a data block transfer handled by the HBA port DMA.

[Figure 24-158](#) shows the interrelations between the FIS-related structures that user software must allocate and build into the host system memory.

For details on command and data structures in host system memory, see the AHCI and SATA standard specifications.

Figure 24-158. Command List Descriptor Structures

After allocating the necessary portions for the CL, command slots underlying data descriptors, and received FISs into host system memory, the base addresses of these memory locations must be provided by user software to the HBA through the hardware init domain registers: **SATA\_PxCLB** (command list base address - lower bits), **SATA\_PxCLBU** (command list base address-upper bits), **SATA\_PxFB** (received FISs system memory area base address-lower bits) and **SATA\_PxFBU** (received FISs system memory area base address-upper bits) . Thus, the command and data DMA engines can access the transfer context programming structures.

**NOTE:** **SATA\_PxCLBU** / **SATA\_PxFBU** registers store the upper half of the native 64-bit AHCI addresses. Because only 36-lower bits of the AHCI 64-bit address bus are integrated in the device, actually only the 4-lower bits within **SATA\_PxCLBU** / **SATA\_PxFBU** are meaningful. **The remaining 28-bits must be always written to '0'-s in the descriptors ( **SATA\_PxCLBU**[31:4]=0x0 / **SATA\_PxFBU**[31:4]=0x0) .** Default value for the **SATA\_PxCLBU** / **SATA\_PxFBU** registers is 0x0, so that a 32-bit SW driver which never accesses them works seamlessly, by accessing only the 32-bit (lower half) addresses which reside in the **SATA\_PxCLB** / **SATA\_PxFB** registers.

#### 24.8.4.6.2 Supported Types of Commands

The following types commands are supported:

- Standard serial ATA nonqueued commands set.

As opposed to NCQ, these commands are serviced, acknowledged one by one after a successful completion. The nonqueued SATA CL entries can take advantage of the PRD prefetching option indicated by the P flag in the corresponding CH (for more information, see the SATA specification). The ATA legacy commands are not supported by the SATA AHCI core.

- **ATAPI commands**

ATAPI commands are supported by the SATA HBA engine. A request for an ATAPI command service is indicated by setting CH bit A to 0b1. The ATAPI command that the user builds into the ATAPI area of the command table can be 12 or 16 bytes in length and is indicated by the PIO Setup FIS sent by the SATA peripheral storage device requesting the ATAPI command. In addition, the SATA controller supports ATAPI active-LED generation (See [Section 24.8.4.10, Activity LED Generation Functionality](#)).

- **NCQ-commands**

NCQ-commands are supported by the SATA controller HBA engine, the execution of which can be greatly facilitated by the CCC interrupt feature (for more information, see [Section 24.8.4.5.5, Command Completion Coalescing Interrupts](#)). As described in [Section 24.8.1.1.2, Native Command Queuing](#), the NCQ commands have FPDMA queued command protocol mechanism, which implies that they are treated in a different way than standard SATA commands. The AHCI interface register set include specific registers, such as [SATA\\_PxSACT](#), etc., to make the HBA aware of the outstanding NCQ slots in a command list. As opposed to standard nonqueued commands, NCQ commands are acknowledged before their actual completion, which accelerates the CL servicing for NCQ slots. The queue tag of the command requested by the SATA peripheral device is indicated to the HBA port by the TAG field in a DMA Setup FIS that an attached SATA peripheral device sends to the SATA controller host. The HBA then uses the tag value to index the NCQ commands updated by user software in the command list. The NCQ command descriptors are not allowed to use the prefetching option in CH because their order of execution is determined by the SATA target device.

#### **24.8.4.6.3 Received FIS Structures**

After stream decoding and primitive removal by the link layer, the validated FIS Dwords are extracted from the Rx FIFO buffer by the transport layer DMA, and the original SATA storage drive FIS structures are recovered to a dedicated host system memory space. The DMA stores the received FISs into different memory areas based on FIS type. The unknown FIS reception is legal to HBA, as long as the length of the unknown FIS does not overrun the 64-byte size limit of the FIS descriptors. For details on received FISs memory area organization, see the AHCI and SATA standard specifications.

#### **24.8.4.6.4 FIS Descriptors Summary**

The FISs that encapsulate SATA target commands and data contents can be divided into:

- FISs transmitted from the host to an attached SATA peripheral device (H2D FISs)
- FISs sent by an attached SATA peripheral device to the host (D2H FISs)

The H2D FISs are constructed by user software into system memory. The H2D FIS types are:

- H2D Register FIS
- H2D DMA Setup FIS
- H2D Data FIS

The D2H FISs are constructed by the attached SATA peripheral device transport layer. The D2H FIS types are as follows:

- D2H Register FIS
- D2H DMA Setup FIS
- PIO Setup FIS
- DMA Activate FIS
- Set Device Bits FIS
- D2H Data FIS

For details on different type of FIS contents, see the SATA standard specification (revision 2.6).

## 24.8.4.7 Transport Layer FIS-Based Interactions

### 24.8.4.7.1 Software Processing of the Port Command List

After user software instantiates the CL structures in host system memory, it must maintain them appropriately. The command list is advanced when the BSY, DRQ, and ERR bits of a serial ATA device task file are cleared, which is communicated through a D2H register FIS to HBA port. The HBA port 0 hardware clears the corresponding to the *i*-th completed command: `SATA_PxCI [i] CI (SATA_PxCI [TAG] CI for NCQ)` bit to notify user software that the next command FIS can be advanced into the CL. The software then builds the command slot components: CH fields, command table, and associated PRD data descriptors in system memory. Software asserts the `SATA_PxCI[i+1] CI` (or `SATA_PxCI[TAG] CI` bit for an NCQ indicated command) to activate the prepared CL command, which is possible only when `SATA_PxCMD[0] ST = 0x1`. The nonqueued commands in the CL are processed in ascending order of slots (linear processing). The `SATA_PxCMD [12:8]CCS` read-only field indicates the CL index of the command currently being issued by the HBA port.

The processing of NCQ command slots invokes additional register update/check steps. Before setting the `SATA_PxCI[TAG] CI` bit to 0b1 and posting an active NCQ command to the SATA HBA port, software must indicate an NCQ outstanding command at the position defined by the SATA peripheral device queue TAG by setting `SATA_PxSACT[TAG] DS = 0x1`. After the queued command is posted, the peripheral SATA device sends a Set Device Bits FIS to the HBA port to clear the `SATA_PxSACT` bits corresponding to the successfully completed NCQ commands.

Command-list processing is initially triggered by software setting `SATA_PxCMD[0] ST = 0x1`, which requires certain conditions to be satisfied.

---

**NOTE:** There are some restrictions to setting `SATA_PxCMD[0] ST` to 0x1. For more information, see the AHCI specification (revision 1.1).

---

The SATA controller is capable of command list override (CLO) operation. CLO is activated by setting `SATA_PxCMD[3] CLO = 0b1`, which is expected only when `SATA_PxCMD[0] ST = 0x0` (that is, the command list is not processed by the HBA) to avoid HBA-indeterminate behavior. As a consequence of a CLO operation, the `SATA_PxTFD` register `STS_DRQ` and `STS_BSY` flags are cleared. For example, CLO is necessary when the DRQ and BSY flags cannot be cleared by HBA before issuing a software reset (because of some hang condition). For more information on CLO behavior, see the AHCI standard specification.

### 24.8.4.7.2 Handling the Received FIS Descriptors

The HBA DMA facilitates the reception of the D2H FISs into host system memory. The reception is enabled by the user setting `SATA_PxCMD[4] FRE` to 0b1. The software is allowed to change the `SATA_Px FB / SATA_Px FB U` contents and thus move the FIS reception area to different system memory locations, if `SATA_PxCMD[14] FR` is cleared, which occurs after software writes `SATA_PxCMD[4] FRE = 0b0`. In this case, further FIS reception is blocked when the internal Rx FIFO becomes full. Before setting `SATA_PxCMD[4] FRE` to 0x1, the user software must ensure that a valid address is programmed into the `SATA_Px FB / SATA_Px FB U` registers.

---

**NOTE:** The HBA port stores the unknown FISs (up to 64 bytes) in system memory but does not have a specified behavior to indicate an error condition on reception. The unknown FISs must be handled specifically by user software.

---

## 24.8.4.8 DMA Port Configuration

The SATA controller handles all data operations on its port with an internal DMA integrated in SATA AHCI core.

The SATA controller DMA transfers all information between system memory and the attached SATA peripheral device, as well as configuration and status FISs. The transmit and receive DMA data paths are independently programmable.

The burst size in both directions is fixed to 16 Dwords. The DMA issues transactions of this size or smaller (in Dword increments), depending on programmed transaction size.

---

**NOTE:** If the programmed transaction size is lower than 16-Dwords (burst size), then the DMA maxes out at transaction size.

---

The user can also separately program the transaction size for receive and transmit channels by setting the [SATA\\_PxDMACR\[7:4\]](#) RXTS and [SATA\\_PxDMACR\[3:0\]](#) TXTS bit fields. The transaction size is the minimum amount of data on which the DMA works. For example, if a FIS comes from the device to the host, the DMA does not begin transferring data into system memory until there is at least [SATA\\_PxDMACR\[7:4\]](#) RXTS number of Dwords in the receive FIFO. During transmit, the DMA reads data from system memory in [SATA\\_PxDMACR\[3:0\]](#) TXTS Dword increments to put into the transmit FIFO. Transactions can be broken up into multiple bursts of 16 Dword - size, crossing of a 1-KiB boundary (boundary between 1-KiB address blocks in memory), or end-of-frame. RXFIFO and TXFIFO transaction sizes are limited to maximum half the size of the integrated RXFIFO and TXFIFO buffers. For more information on maximum transaction sizes and RXFIFO/TXFIFO depths, see the [SATA\\_PxDMACR](#) and [SATA\\_PPARAMR](#) descriptions.

#### 24.8.4.9 Port Multiplier Operation

The SATA controller HBA port supports connection to a bunch of maximum 15 devices through a port multiplier (PM). The communication mechanism is based on PM command-based switching.

##### 24.8.4.9.1 Command-Based Switching Mode

In this mode of operation, user software must initiate transfers to different PM ports so that multiple commands are not outstanding to different devices connected to the PM extension ports.

##### 24.8.4.9.1.1 Port Multiplier NCQ and Non-NCQ Commands Generation

The PM port command servicing order depends on the type of commands in the CL:

- Non-queued command generation to PMs  
When processing commands that are non-queued, the HBA executes each command entry in its entirety before moving to the next entry in the command list. The next entry can include a command to a different PM device port. Because the HBA operates in the order of its command list, system software must not fill the list in sequential order with commands to a single device; otherwise, another device might get starved. For more information, see the AHCI standard specification.
- NCQ command generation to PMs  
Because the SATA controller supports command-based switching only, system software must only add NCQ commands to the command list that target a single port behind the PM, wait for the commands to finish ([SATA\\_PxSACT](#) bits all cleared), and then add commands for a different port. For more information, see the AHCI standard specification.

##### 24.8.4.9.2 Port Multiplier Enumeration

To enumerate PM devices, a software reset should be issued by SATA controller to the PM port #0xF (this is a point of connection for the PM or a single endpoint device). The software must prepare two H2D Register FISs into the host system memory for a software reset with the PM-port select (PMP) field set to 0xF. To ensure reliable PM device enumeration, software must also perform a CLO operation. For more information, see the AHCI standard specification.

##### 24.8.4.10 Activity LED Generation Functionality

The HBA port drives the device-level sata1\_led signal that is active on the following conditions (see also [Table 24-581](#)):

- If ([SATA\\_PxCI](#) [31:0]! = 0x0 or [SATA\\_PxSACT](#)[31:0]! = 0x0) and [SATA\\_PxCMD](#)[24] ATAPI = 0b0 (for active nonATAPI commands indication)
- If ([SATA\\_PxCI](#) [31:0]! = 0x0 or [SATA\\_PxSACT](#)[31:0]! = 0x0) and [SATA\\_PxCMD](#)[24] ATAPI = 0b1 and

[SATA\\_PxCMD](#)[25] DLAE = 0b1 (for active ATAPI commands indication)

When [SATA\\_PxCI](#) and [SATA\\_PxSACT](#) are cleared to 0x0, the LED on the sata1\_led signal-associated pad is driven off.

#### 24.8.4.11 Supported Types of SATA Transfers

SATA controller AHCI mode defines two types of transfers between the host system memory and a SATA peripheral device: DMA and PIO data transfers. Whether the transaction is of a DMA type or PIO type, the HBA fetches and stores data to memory, offloading the CPU. No register is implemented for direct user access to the data port.

PIO transfers specified by PIO Setup FISs are strongly discouraged because of their limited support of error indication. PIO commands use is limited to only few cases in which commands support only PIO mechanism, such as execution of the IDENTIFY DEVICE command and ATAPI command transfers in which the PACKET command is invoked. The SATA controller AHCI mechanism allows multiple DRQ blocks of data per PIO command.

##### 24.8.4.11.1 Supported Higher Level Protocols

The following DMA, PIO, FPDMA-queued, and ATAPI command/data protocols are supported by the SATA controller AHCI engine:

- Standard SATA command-related
  - Nondata command protocol
  - PIO write protocol
  - PIO read protocol
  - DMA write protocol
  - DMA read protocol
- NCQ command-related
  - Write FPDMA-queued protocol
  - Read FPDMA-queued protocol
- ATAPI PACKET command-related
  - PACKET Nondata command protocol
  - PACKET PIO read/write protocol
  - PACKET DMA read/write protocol

#### 24.8.4.12 SATA Controller AHCI Hardware Register Interface

[Table 24-588](#) summarizes the SATA host controller subsystem registers and divides them into functional categories.

**Table 24-588. Summary of SATA Host Subsystem Functional Registers**

Register	Functional Category	Brief Register Description
<a href="#">SATA_SYSCONFIG</a>	Device-level registers (wrapper of SATA AHCI core)	TI wrapper idle/standby power management configuration register
<a href="#">SATA_CDRLOCK</a> <sup>(1)</sup>		TI wrapper register which defines default delay of received data valid information.
<a href="#">SATA_IDR</a>	SATA vendor-specific (VS) register	TI high lander identification register

<sup>(1)</sup> Under normal conditions, the user is supposed to keep this register at its default (power-on-reset) value.

**Table 24-588. Summary of SATA Host Subsystem Functional Registers (continued)**

Register	Functional Category	Brief Register Description	
SATA_CAP	SATA controller generic registers	SATA HBA capabilities set 1	
SATA_CAP2		SATA HBA capabilities set 2	
SATA_VS		SATA HBA register showing supported AHCI specification revision	
SATA_GPARAM1R		SATA HBA global parameters set 1	
SATA_GPARAM2R		SATA HBA global parameters set 2	
SATA_GHC		SATA HBA global AHCI settings	
SATA_PPARAMR		SATA HBA ports-related registers	SATA HBA port x <sup>(2)</sup> parameter settings
SATA_PI	Enables SATA HBA port x <sup>(2)</sup> functionalities		
SATA_IS	Enables all SATA HBA port x <sup>(2)</sup> associated interrupts (first tier of interrupt schema)		
SATA_CCC_PORTS	Enables SATA CCC feature for the port x <sup>(2)</sup>		
SATA_CCC_CTL	CCC feature parameters control and status		
SATA_TIMER1MS	Time base for 1-ms unit of CCC timeout		
SATA_PxCLB	SATA HBA Port Px <sup>(2)</sup> SATA Specification- defined Functional Registers		CL base address (lower-half of AHCI 64-bit address)
SATA_PxCLBU			CL base address (upper-half of AHCI 64-bit address) <sup>(3)</sup>
SATA_PxFB			Received FISs base address (lower-half of AHCI 64-bit address)
SATA_PxFBU			Received FISs base address (upper-half of AHCI 64-bit address) <sup>(3)</sup>
SATA_PxIE		Port x <sup>(2)</sup> non-CCC interrupt enable	
SATA_PxIS		Port x <sup>(2)</sup> non-CCC interrupt event status	
SATA_PxCMD		Port x <sup>(2)</sup> command register	
SATA_PxTFD		Port x <sup>(2)</sup> task file data register	
SATA_PxSIG		Port x <sup>(2)</sup> associated SATA signature register	
SATA_PxSSTS		Port x <sup>(2)</sup> SStatus SATA register (See the SATA standard specification.)	
SATA_PxSCTL		Port x <sup>(2)</sup> SControl SATA register (See the SATA standard specification.)	
SATA_PxSERR		Port x <sup>(2)</sup> SError SATA register (See the SATA standard specification.)	
SATA_PxSACT		Port x <sup>(2)</sup> SActive SATA register (See SATA standard specification.)	
SATA_PxCI		Port x <sup>(2)</sup> command activation/completion indication register	
SATA_PxSNTF		Port x <sup>(2)</sup> SNotification register (See the SATA standard specification.)	
SATA_OOBR		OOB detection counters setup	
SATA_PxDMACR		Non-standard Port Px <sup>(2)</sup> Control register	Port x <sup>(2)</sup> associated DMA configuration register
SATA_TESTR		SATA HBA BIST related registers	Test/normal mode switching
SATA_BISTAFR			BIST FIS-activate register
SATA_BISTCR			BIST control register
SATA_BISTFCTR	BIST FIS count register		
SATA_BISTSR	BIST status register		
SATA_BISTDECR	BIST Dword error count register		

<sup>(2)</sup> x = 0, as only SATA HBA port 0 is implemented

<sup>(3)</sup> Only the 4-lower bits meaningful in the device, the others must be kept at '0'

## 24.8.5 SATA Controller Low Level Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the SATA host controller.

### 24.8.5.1 Global Initialization

#### 24.8.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements to initialize the surrounding modules when the SATA host controller is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the SATA host controller (for more information, see and ). [Table 24-589](#) describes the global initialization of surrounding modules.

**Table 24-589. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	Module functional and interface clocks must be enabled (see <a href="#">Section 3.1.1.1.2, Module-Level Clock Management</a> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> ).
Control Module	Module-specific pad muxing and other PHY power configurations must be set in the control module (see <a href="#">Section 18.4.6.1.1, Pad Configuration Registers</a> and <a href="#">Section 18.5, Control Module Register Manual</a> , in <a href="#">Chapter 18, Control Module</a> ).
IRQ_CROSSBAR	IRQ_CROSSBAR must be configured to enable the interrupt from the SATA controller (see <a href="#">Section 18.4.6.4, IRQ_CROSSBAR Module Functional Description</a> , in <a href="#">Chapter 18, Control Module</a> ).
L4_CFG and L3_MAIN interconnects	For more information about the interconnect configuration, see <a href="#">Section 14.2.3.2.1, L3_MAIN Interconnect Agents</a> and <a href="#">Section 14.3, L4 Interconnect</a> , in <a href="#">Chapter 14, Interconnect</a> .

**NOTE:** The MPU INTC configuration is required when using the interrupt communication mode.

#### 24.8.5.1.2 SATA Controller Global Initialization

##### 24.8.5.1.2.1 Main Sequence SATA Controller Global Initialization

[Table 24-590](#) describes the procedure to initialize the SATA host controller after a POR.

**Table 24-590. SATA Controller Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Configure the OCP2SCP3 adapter for PLLCTRL_SATA.	See <a href="#">Section 26.1.5, SATA PHY Subsystem Low - Level Programming Model</a> in <a href="#">Chapter 26, Shared PHY Component Subsystems</a> .	-
Configure the DPLL_SATA.	See <a href="#">Section 26.1.5, SATA PHY Subsystem Low - Level Programming Model</a> in <a href="#">Chapter 26, Shared PHY Component Subsystems</a> .	-
Configure the SATA_PHY.	See <a href="#">Section 26.1.5, SATA PHY Subsystem Low - Level Programming Model</a> in <a href="#">Chapter 26, Shared PHY Component Subsystems</a> .	-
Perform all firmware capability writes. (1)	See <a href="#">Section 24.8.5.1.2.2, SubSequence – Firmware Capability Writes</a> .	-
Set up all appropriate structures in memory per the AHCI standard specification.	See <a href="#">Section 24.8.4.6, System Memory FIS Descriptors</a> . See also the AHCI standard specification.	-

(1) This step has an effect only on hardware initialization.

**Table 24-590. SATA Controller Global Initialization (continued)**

Step	Register/Bit Field/Programming Model	Value
Write a valid CL memory base address to the <a href="#">SATA_PxCLB</a> register.	<a href="#">SATA_PxCLB</a> [31:10] CLB	CL Base address (lower-half)
	<a href="#">SATA_PxCLBU</a> [3:0] CLBU	CL Base address (upper-half) Only 4-lower bits meaningful in the device, other must be always written to '0'-s
Write a valid Rx FIS memory base address to the <a href="#">SATA_PxFB</a> register.	<a href="#">SATA_PxFB</a> [31:8] FB	Rx FIS Base address (lower-half)
	<a href="#">SATA_PxFBU</a> [3:0] FBU	Rx FIS Base address (upper-half) Only 4-lower bits meaningful in the device, other must be always written to '0'-s
Issue a software type of reset depending on the error condition.	See <a href="#">Section 24.8.4.3.2, Software Initiated Resets.</a>	-
Set the appropriate bits in the <a href="#">SATA_PxCMD</a> register.	See <a href="#">Section 24.8.4.7.1, Software Processing of the Port Command List.</a> See also the AHCI standard specification.	-
Program the <a href="#">SATA_PxSCTL</a> register to configure SATA interface capabilities.	See the AHCI standard specification.	-
Program the <a href="#">SATA_PxDMACR</a> register.	See <a href="#">Section 24.8.4.8, DMA Port Configuration.</a>	-
Enable the interrupts at port 0.	<a href="#">SATA_IS</a> [0] IPS	0x1
Enable the involved port 0 specific interrupts.	See <a href="#">Section 24.8.4.5.2, Levels of Interrupt Control,</a> and <a href="#">Section 24.8.4.5.4, Interrupt Condition Control.</a>	-
Enable the FIS reception in the <a href="#">SATA_PxCMD</a> register.	<a href="#">SATA_PxCMD</a> [4] FRE	0x1
Spin up the device (if required).	See the AHCI standard specification and the SATA standard specification.	-

**NOTE:** The SATA AHCI Controller always manipulates 64-bit memory pointers, and the master interface has 64-bit addresses, but the actual AHCI master interface integration in the device uses ONLY the 36-lower bits. In that case, even though the AHCI support indicates “64-bit” in the [SATA\\_CAP](#)[31] S64A, ONLY the 4-lower bits ([SATA\\_PxCLBU](#) [3:0] / [SATA\\_PxFBU](#) [3:0]) are meaningful in the device. **The upper 28 bits of the address, i.e. [SATA\\_PxCLBU](#) [31:4] / [SATA\\_PxFBU](#) [31:4], must be always SW-programmed to '0'.**

**NOTE:** Default value of the [SATA\\_PxCLBU](#) / [SATA\\_PxFBU](#) registers is 0x0, so that a 32-bit SW driver which never accesses them works seamlessly, by accessing only the 32-bit (lower half) addresses which reside in the [SATA\\_PxCLB](#) / [SATA\\_PxFB](#) registers.

#### 24.8.5.1.2.2 SubSequence – Firmware Capability Writes

[Table 24-591](#) lists the firmware capability write sequence by which SATA HBA initialization is performed.

**NOTE:** In the following sequence, SATA controller accesses hardware initialization domain registers that can be written only one time after POR.

**Table 24-591. Firmware Capability Writes**

Step	Register/Bit Field/Programming Model	Value
Disable the staggered spin-up support feature. <sup>(1)</sup>	<a href="#">SATA_CAP</a> [27] SSS	0x0

<sup>(1)</sup> It makes no sense to enable staggered spin-up because only one HBA port is used.

**Table 24-591. Firmware Capability Writes (continued)**

Step	Register/Bit Field/Programming Model	Value
Enable the SATA controller port 0.	<a href="#">SATA_PI[0]</a> PI	0x1
Disable the mechanical presence detect feature. <sup>(1)</sup>	<a href="#">SATA_CAP[28]</a> SMPS	0x0
Disable the external signal-only connector. <sup>(1)</sup>	<a href="#">SATA_PxCMD[22:21]</a> ESP	0x0
Disable the cold presence detect feature. <sup>(1)</sup>	<a href="#">SATA_PxCMD[20]</a> CPD	0x0
Disable support for the mechanical presence switch.	<a href="#">SATA_PxCMD[19]</a> MPSP	0x0
Disable the hot-plug-capable port feature.	<a href="#">SATA_PxCMD[18]</a> HPCP	0x0
<b>If PM is attached:</b>		
Set the <a href="#">SATA_PxCMD [17]</a> PMA bit to notify HBA that the PM is attached to HBA port 0.	<a href="#">SATA_PxCMD[17]</a> PMA	0x1
<b>ELSE</b>		
Clear the <a href="#">SATA_PxCMD[17]</a> PMA bit as a notification that a single-target SATA device is attached to port 0.	<a href="#">SATA_PxCMD[17]</a> PMA	0x0

### 24.8.5.1.3 Issue Command - Main Sequence

The procedure in [Table 24-592](#) prepares a command list entry and issues its corresponding command.

**Table 24-592. Prepare and Issue a Command**

Step	Register/Bit Field/Programming Model	Value
Build command header and command table into host system memory.	For details, see <a href="#">Section 24.8.4.6.1, Command List Structure Basics</a> .	-
Create the command corresponding PRD table.		
Queue the command to the command list.	See <a href="#">Section 24.8.4.7.1, Software Processing of the Port Command List</a> .	-
Set the <a href="#">SATA_PxCMD[0]</a> ST bit to direct the DMA to start processing the CL.	<a href="#">SATA_PxCMD[0]</a> ST	0x1 <sup>(1)</sup>
<b>IF a nonNCQ command is issued:</b>		
Set the corresponding <a href="#">SATA_PxCi.CI</a> bit to activate a command already prepared in the i-th slot of the CL.	<a href="#">SATA_PxCi[i]</a> CI	0x-
<b>ELSE</b>		
Indicate the NCQ slot positions through the <a href="#">SATA_PxSACT</a> register. For details on TAG tracking, see <a href="#">Section 24.8.4.7.1</a> .	<a href="#">SATA_PxSACT[TAG]</a> DS	0x-
Set the corresponding <a href="#">SATA_PxCi.CI</a> bit to activate the NCQ command already prepared in the i-th slot of the CL.	<a href="#">SATA_PxCi[TAG]</a> CI	0x-

<sup>(1)</sup> See the AHCI standard specification for important restrictions when PxCMD[0] ST can be software-asserted to 1.

### 24.8.5.1.4 Receive FIS—Main Sequence

The procedure in [Table 24-593](#) is used to handle a FIS reception.

**Table 24-593. FIS Reception**

Step	Register/Bit Field/Programming Model	Value
Read <a href="#">SATA_PxIS</a> to determine the type of FIS.	For more information, see <a href="#">Section 24.8.4.7.2, Handling the Received FIS Descriptors</a> .	-

## 24.8.6 SATA Controller Register Manual

### 24.8.6.1 SATA Controller Instance Summary

**Table 24-594. SATA Instance Summary**

Module Name	Module Base Address	Size (Bytes)
<a href="#">DWC_ahsata</a>	0x4A14 0000	4352
<a href="#">SATAMAC_wrapper</a>	0x4A14 1100	256

## 24.9 PCIe Controller

This section describes the features and functions of the device Peripheral Component Interconnect Express (PCIe) Controller which provides a high-speed glueless serial interconnect to peripherals utilizing high bandwidth applications.

### 24.9.1 PCIe Controller Subsystem Overview

The Peripheral Component Interconnect Express (PCIe) module is a multi-lane I/O interconnect that provides low pin-count, high reliability, and high-speed data transfer at rates of up to 5.0 Gbps per lane, per direction, for serial links on backplanes and printed wiring boards. It is a 3-rd Generation I/O Interconnect technology succeeding PCI and ISA bus that is designed to be used as a general-purpose serial I/O interconnect. It is also used as a bridge to other interconnects like SATA, USB2/3.0, GbE MAC, and so forth.

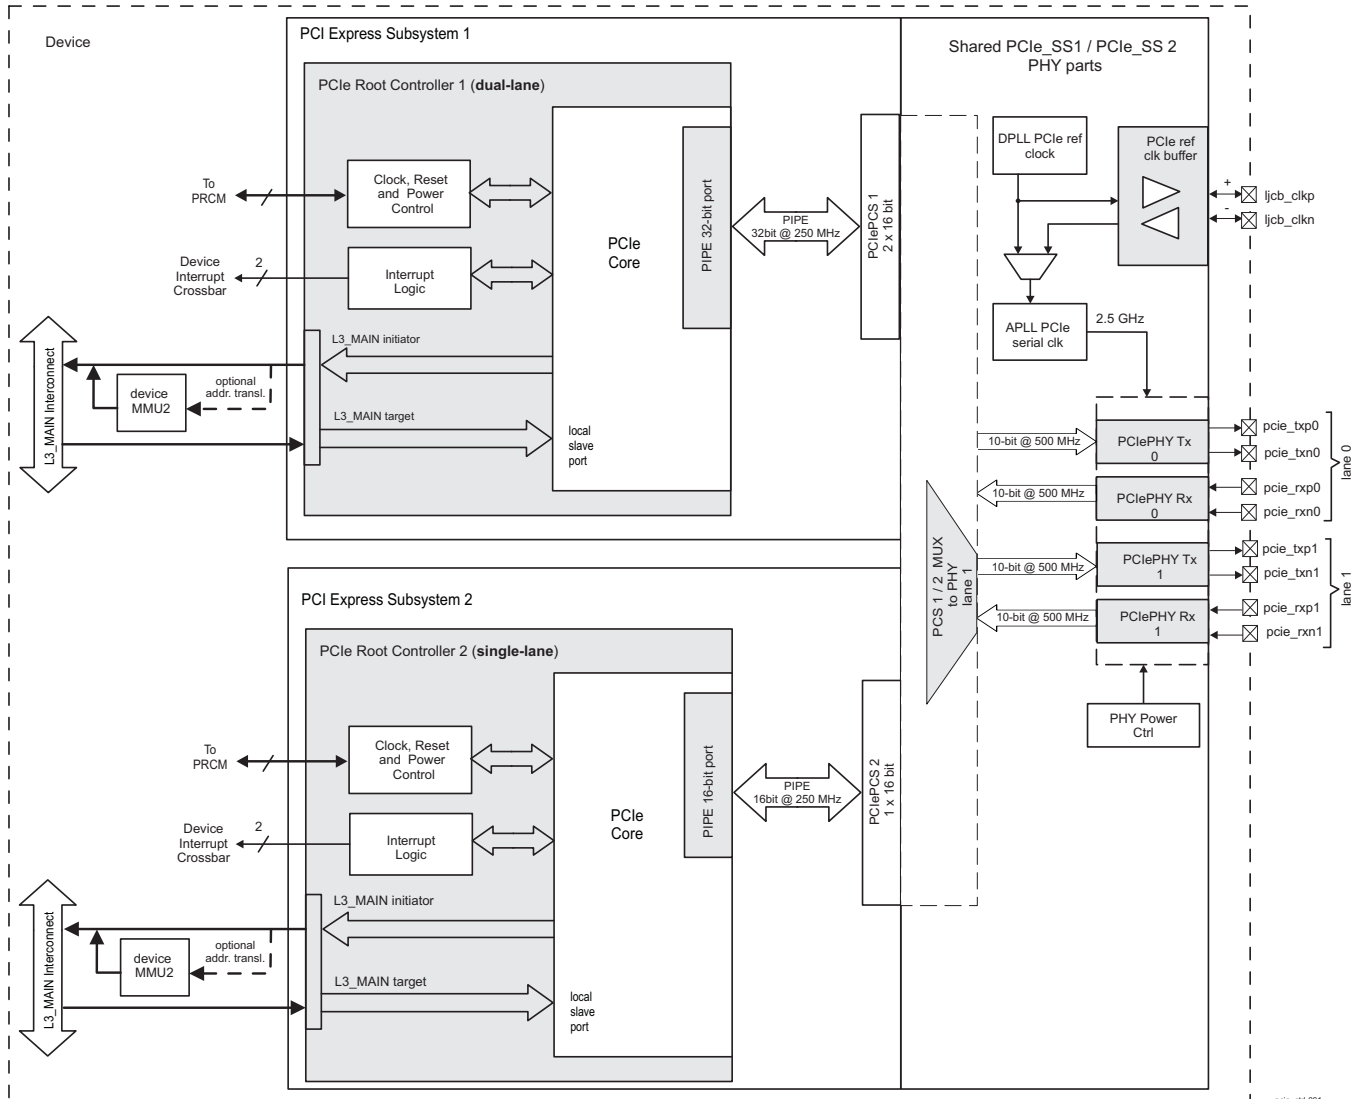

The device instantiates two PCIe subsystems (PCIe\_SS1 and PCIe\_SS2). The PCIe controller is capable to operate either in Root Complex (RC) or in End Point (EP) PCIe mode. The device PCIe\_SS1 controller supports up to two 16-bit data lanes on its PIPE port. The device PCIe\_SS2 controller supports only one 16-bit data lane on its PIPE port.

When the PCIe\_SS1 controller PIPE port is configured to operate in a single-lane mode, it operates on a single pair of PCIe PHY serializer and deserializer - PCIe1\_PHY\_TX/PCIe1\_PHY\_RX. When PCIe\_SS1 PIPE is configured to operate in dual-lane mode, it operates on two pairs of PCIe PHY serializer and deserializer - PCIe1\_PHY\_TX/PCIe1\_PHY\_RX and PCIe2\_PHY\_TX/PCIe2\_PHY\_RX, respectively. The single-lane PCIe\_SS2 controller PIPE port (if enabled) can operate only on the PCIe2\_PHY\_TX/PCIe2\_PHY\_RX pair. Hereby, if PCIe\_SS2 controller is used, the PCIe\_SS1 can operate only in a single-lane mode on the PCIe1\_PHY\_TX/PCIe1\_PHY\_RX. In addition, PCIe PHY subsystem encompasses a PCIe PCS (physical coding sublayer), a PCIe power management logic, APLL, a DPLL reference clock generator and an APLL clock low-jitter buffer. For more details on PCIe PHY subsystem, please refer to [Section 26.4, PCIe Shared Phy Subsystem](#).

- The PCIe Controller implements the transport and link layers of the PCIe interface protocol.
- PCIe PCS (a physical coding sublayer component) converts a 8-bit portion of parallel data over a PCIe lane to a 10-bit parallel data to adapt the process of serialization and deserialization in the TX/RX PHYs to various requirements. At the same time it transforms the transmission rate to maintain the PCIe Gen2 bandwidth (5 Gbps) on both sides (PCIe controller and PHY).
- A multiplexer logic which adds flexibility to connect a PCIe controller hardware mapped PCS logic output to a single (for the single-lane PCIe\_SS2 controller) or to a couple (for the 2-lane PCIe\_SS1 controller) of PHY ports at a time
- Physical layer (PHY) serializer/deserializer components with associated power control logic, building the so called PMA (physical media attachment) part of the PCIe\_PHY transceiver, as follows:
  - PCIe physical port 0 associated serializer (TX) - PCIe1\_PHY\_TX and deserializer (RX) - PCIe1\_PHY\_RX
  - PCIe physical port 1 associated serializer (TX) - PCIe2\_PHY\_TX and deserializer (RX) - PCIe2\_PHY\_RX
- DPLL\_PCIE\_REF is a DPLL clock source, controlled from the device PRCM, that provides a 100-MHz clock to the PCIe PHY serializer/deserializer components reference clock inputs.
- Both the PCIe\_SS1 and PCIe\_SS2 share the same APLL (APLLPCIe) which by default multiplies the DPLL\_PCIE\_REF (typically 100 MHz or 20 MHz) clock to 2.5 GHz.
- The APLLPCIe low-jitter buffer (ACSPCIE) and additional logic takes care to provide the PCIe APLL reference input clock.

[Figure 24-159](#) shows an overview of a device PCIe subsystem with its integrated components.

Figure 24-159. PCIe Controller Subsystem Overview

24.9.1.1 PCIe Controllers Key Features

This section describes the features supplied by the PCIe controller modules (including PCIe at device level). The PCIe\_SS1 and PCIe\_SS2 controllers comply with the following standards:

- PCI Local Bus Specification revision 3.0
- PCI Express Base 3.0 Specification, revision 1.0.

**At system level the device supports PCI express interface in the following configurations:**

- Each PCIe subsystem controller has support for PCIe Gen2 mode (5.0 Gbps per lane) and Gen1 mode (2.5 Gbps per lane).
- One PCIe (PCIe\_SS1) operates as Gen2 2-lanes supporting in either root-complex (RC) or end-point EP.
- Two PCIe (PCIe\_SS1 and PCIe\_SS2) operates Gen2 1-lane supporting either RC or EP with the possibility of one operating in Gen1 and one in Gen2.
- PCIe\_SS1 can be configured to operate in either 2-Lane (dual lane) or 1-Lane (single lane) mode, as follows:
  - Single Lane - lane 0 mapped to the PCIe port 0 of the device

- Flexible dual lane configuration - lanes 0 and 1 can be swapped on the two PCIe ports
- PCIe\_SS2 can only operate in 1-Lane mode, as follows:
  - Single Lane - lane 0 mapped to the device PCIe port 1
 When PCIe\_SS1 is configured to operate in dual-lane mode, PCIe\_SS2 is not available.

**The main features of a device PCIe controller are:**

- 16-bit operation at 250 MHz on PIPE interface (per 16-bit lane)
- One master port on the L3\_MAIN supporting 32-bit address and 64-bit data bus.
- PCIe\_SS1/PCIe\_SS2 master port dedicated MMU (device MMU2) on L3\_MAIN path, to which PCIe traffic can be optionally mapped.
- One slave port on the L3\_MAIN supporting 29-bit address and 64-bit data bus.
- Maximum outbound payload size of 64 Bytes (the L3 Interconnect PCIe1/2 target ports split bursts of size >64 Bytes to the into multiple 64 Byte bursts)
- Maximum inbound payload size of 256 Bytes (internally converted to 128 Byte - bursts)
- No remote read request size limit: implicit support for 4 KiB-size and greater
- Support of EP legacy mode
- Support of inbound I/O accesses in EP legacy mode
- PIPE interface features fixed-width (16-bit data per lane) and dynamic frequency to switch between PCIe Gen1 and Gen2.
- Ultra-low transmit and receive latency
- Automatic Lane reversal as specified in the PCI Express Base 3.0 Specification, revision 1.0 (transmit and receive)
- Polarity inversion on receive
- Single Virtual Channel (VC0) and Single Traffic Class (TC0)
- Single Function in End point mode
- Automatic credit management
- ECRC generation and checking
- All PCI Device Power Management D-states with the exception of D3<sub>cold</sub>/L2 state
- PCI Express Active State Power Management (ASPM) state L0s and L1 (with exceptions)
- PCI Express Link Power Management states except for L2 state
- PCI Express Advanced Error Reporting (AER)
- PCI Express messages for both transmit and receive
- Filtering for Posted, Non-Posted, and Completion traffic
- Configurable BAR filtering, I/O filtering, configuration filtering and completion lookup/timeout
- Access to configuration space registers and external application memory mapped registers through ECAM mechanism.
- Legacy PCI Interrupts reception (RC) and generation (EP)
- 2x hardware interrupts per PCIe\_SS1 and PCIe\_SS2 controller mapped via the device Interrupt Crossbar (IRQ\_CROSSBAR) to multiple device host (MPU, DSP, and so forth) interrupt controllers in the device
- MSIs generation and reception
- PCIe\_PHY Loopback in RC mode

## 24.9.2 PCIe Controller Environment

The below [Table 24-675](#) shows the device integrated PCI Express subsystem interface signals to external PCIe devices.

**Table 24-675. PCIe\_SS I/O Signals**

Device Level Signal Name	I/O <sup>(1)</sup>	Description	Reset Value
pcie_txp0	O	TX output of the PCIe port 0 PHY differential transmission line (positive by default) <a href="#">Section 24.9.3</a>	0
pcie_txn0	O	TX output of the PCIe port 0 PHY differential transmission line (negative by default) <a href="#">Section 24.9.3</a>	0
pcie_rxp0	I	RX input of the PCIe port 0 PHY differential reception line (positive by default) <a href="#">Figure 24-160</a>	HiZ
pcie_rxn0	I	RX input of the PCIe port 0 PHY differential reception line (negative by default) <a href="#">Figure 24-160</a>	HiZ
pcie_txp1	O	TX output of the PCIe port 0 PHY differential transmission line (positive by default) <a href="#">Section 24.9.3</a>	0
pcie_txn1	O	TX output of the PCIe port 0 PHY differential transmission line (negative by default) <a href="#">Section 24.9.3</a>	0
pcie_rxp1	I	RX input of the PCIe port 1 PHY differential reception line (positive by default) <a href="#">Figure 24-160</a>	HiZ
pcie_rxn1	I	RX input of the PCIe port 1 PHY differential reception line (negative by default) <a href="#">Figure 24-160</a>	HiZ
ljcb_clkp	I/O	Differential clock positive input or output	HiZ
ljcb_clkn	I/O	Differential clock negative input or output	HiZ

<sup>(1)</sup> I = Input; O = Output; I/O = Bidirectional

**Table 24-676. PCIe\_SS Port Configuration**

PCIE_B1C0_MODE_SEL <sup>(1)</sup>	PCIE_B0_B1_TSYNCEN <sup>(1)</sup>	Port 0	Port 1
0 (C0) (default)	0	PCS1 (MAC B) lane 0	PCS2 (MAC C) lane 0
1 (B1)	0	PCS1 (MAC B) lane 0	-
1 (B1)	1	PCS1 (MAC B) lane 0	PCS1 (MAC B) lane 1

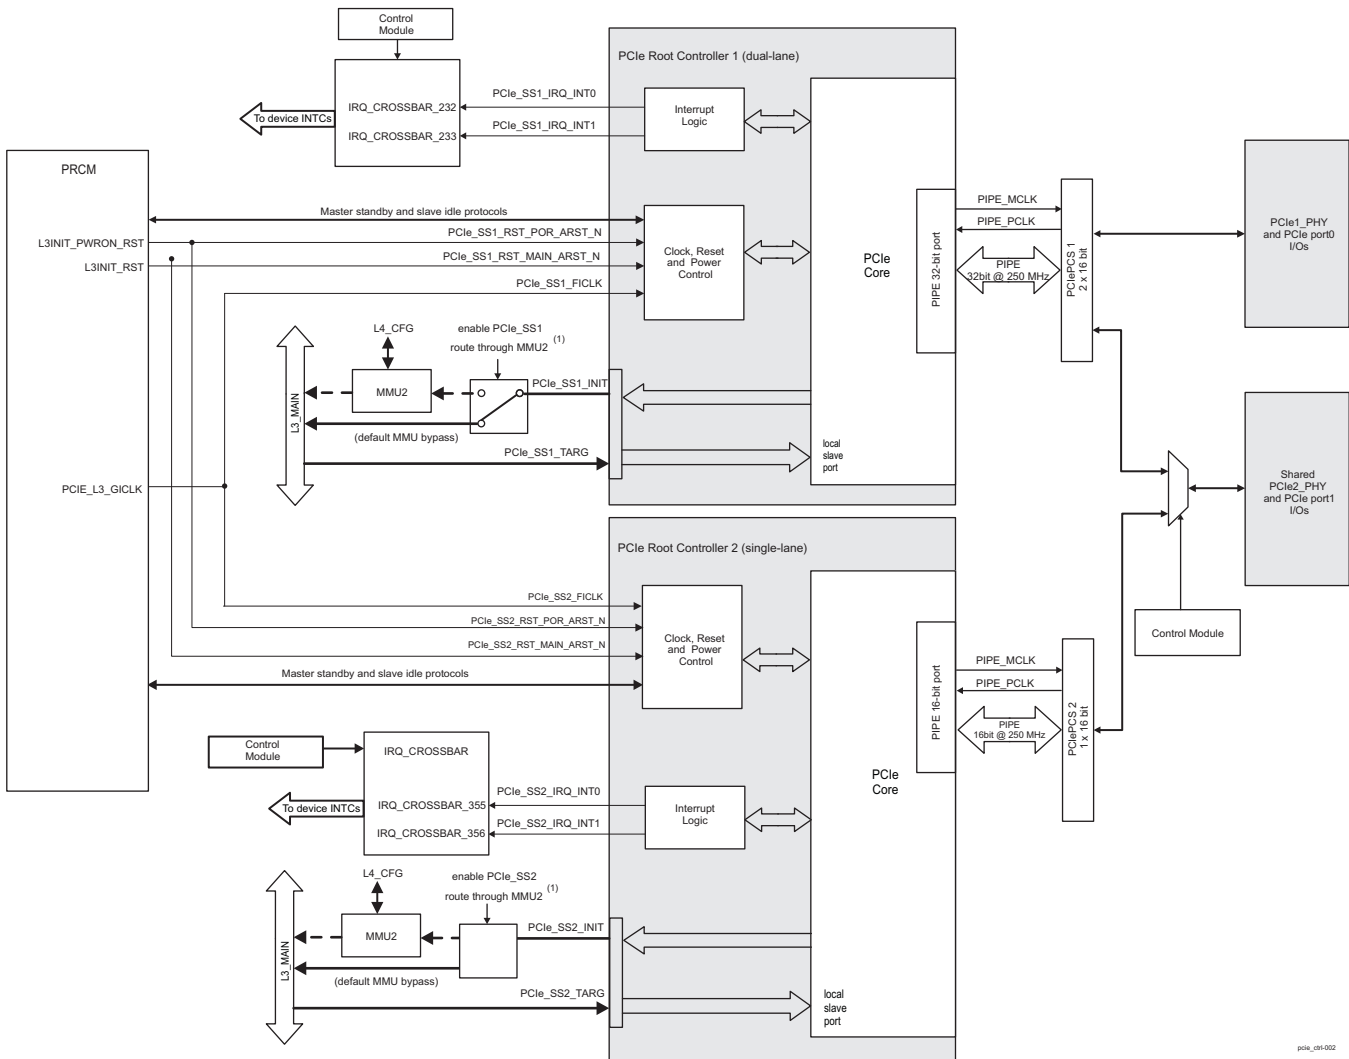

<sup>(1)</sup> See CTRL\_CORE\_PCIE\_CONTROL register in [Section 18.5, CTRL\\_MODULE\\_CORE Registers](#)

For more information on the interface between PCIe\_SS controller and PCIe\_PHY, see [Section 26.4.4.1, PCIe Shared PHY Subsystem Block Diagram](#), and [Section 26.4.4, PCIe Shared PHY Subsystem Functional Descriptions](#) in [Section 26.4, PCIe Shared PHY Subsystem](#).

### 24.9.3 PCIe Controllers Integration

This section describes the PCIe controllers integration in the device, including information about clocks, resets, and hardware requests. [Figure 24-160](#) shows the PCIe controllers integration.

**Figure 24-160. PCIe Controllers Integration**

**NOTE:** By default, the traffic from the PCIe\_SS1 and PCIe\_SS2 controller master (initiator) port - PCIe\_SS1\_INIT/PCIe\_SS2\_INIT to the L3\_MAIN interconnect, bypasses the device MMU2. Mapping the PCIe traffic from the PCIe master port to MMU2 on the L3\_MAIN path is enabled via a bit in the device Core Control Module. For more details, refer to the [Section 24.9.4.3.1.1](#).

PCIe controller integration includes these features:

- A single interface/functional clock (PCIe\_SS\_FICLK, shared between the master and the slave interfaces)
- A couple of functional clocks:
  - A PCIE controller clock input which receives the PIPE\_PCLK generated by the associated PCIe PHY PCS logic
  - A PCIE controller clock output PIPE\_MCLK which mirrors PIPE\_PCLK back to the PCIe PHY PCS component

- Two hardware non-retention resets - PCIe\_SS\_RST\_POR\_ARST\_N and PCIe\_SS\_RST\_MAIN\_ARST\_N by PRCM
- Master standby and slave idle protocols with the power, reset, and clock management (PRCM) module
- Two interrupt request lines (per each PCIe controller):
  - PCIe\_SS1\_IRQ\_INT0/PCIe\_SS2\_IRQ\_INT0 - a main interrupt line
  - PCIe\_SS1\_IRQ\_INT1/PCIe\_SS2\_IRQ\_INT1 - a MSI interrupt line
- No DMA requests generation to surrounding modules
- One 64-bit data/32-bit address master port on the L3\_MAIN interconnect (with an option to pass the PCIe initiator traffic to L3\_MAIN through device MMU2). For details, refer to the [Section 24.9.4.3](#).
- One 64-bit data/29-bit address slave port on the L3\_MAIN interconnect (No MMU included on the slave address path). For details, refer to the [Section 24.9.4.3](#).

For more details on the MMU2 integration in the device, refer to the [Section 20.2, MMU Integration](#) of the [Chapter 20, Memory Management Units](#).

**NOTE:** For more information about the slave idle protocol and the wakeup request, see [Section 3.1.1.1.2, Module-Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 24-677](#) through [Table 24-679](#) summarize the integration of the module in the device.

**Table 24-677. PCIe Controllers Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect
PCIe_SS1	PD_L3INIT	L3_MAIN
PCIe_SS2	PD_L3INIT	L3_MAIN

**Table 24-678. PCIe Controllers Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
PCIe_SS1	PCIe_SS1_FICLK	PCIE_L3_GICLK	PRCM	PCIe_SS1 root controller interface and functional clock (shared between slave and master ports)
PCIe_SS2	PCIe_SS2_FICLK	PCIE_L3_GICLK	PRCM	PCIe_SS2 root controller interface and functional clock (shared between slave and master ports)
Resets				
PCIe_SS1	PCIe_SS1_RST_POR_ARST_N	L3INIT_PWRON_RST	PRCM	A nonretention hardware power-on reset to the PCIe_SS1 controller
	PCIe_SS1_RST_MAIN_ARST_N	L3INIT_RST	PRCM	A nonretention hardware main reset to the PCIe_SS1 controller
PCIe_SS2	PCIe_SS2_RST_POR_ARST_N	L3INIT_PWRON_RST	PRCM	A non-retention hardware power-on reset to the PCIe_SS2 controller
	PCIe_SS2_RST_MAIN_ARST_N	L3INIT_RST	PRCM	A non-retention hardware main reset to the PCIe_SS2 controller

**Table 24-679. PCIe Controllers Hardware Requests**

Module Instance	IRQ Source Name	Interrupt Requests		
		IRQ_CROSSBAR Input	Default Mapping	Description
PCIe_SS1	PCIe_SS1_IRQ_INT0	IRQ_CROSSBAR_232	N/A	PCIe_SS1 controller main interrupt request.
	PCIe_SS1_IRQ_INT1	IRQ_CROSSBAR_233	N/A	PCIe_SS1 controller MSI interrupt request.
PCIe_SS2	PCIe_SS2_IRQ_INT0	IRQ_CROSSBAR_355	N/A	PCIe_SS2 controller main interrupt request
	PCIe_SS2_IRQ_INT1	IRQ_CROSSBAR_356	N/A	PCIe_SS2 controller MSI interrupt request.

---

**NOTE:** The **Default Mapping** column in [Table 24-679, PCIe Controller Hardware Requests](#) shows the default mapping of the IRQ sources listed in column **IRQ Source Name** to a certain interrupt line of one of the device interrupt controllers. These IRQ sources can also be mapped to other interrupt lines of each device interrupt controller through the IRQ\_CROSSBAR module. For more information about the IRQ\_CROSSBAR module, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#). For more information about the device interrupt controllers, see [Chapter 17, Interrupt Controllers](#).

---

**NOTE:** No DMA requests are generated by the PCIe controller to the surrounding modules.

---

For more details on interrupt request management at the PCIe subsystem local level, refer to the [Section 24.9.4.6, PCIe Controller Interrupt Requests](#).

## 24.9.4 PCIe SS Controller Functional Description

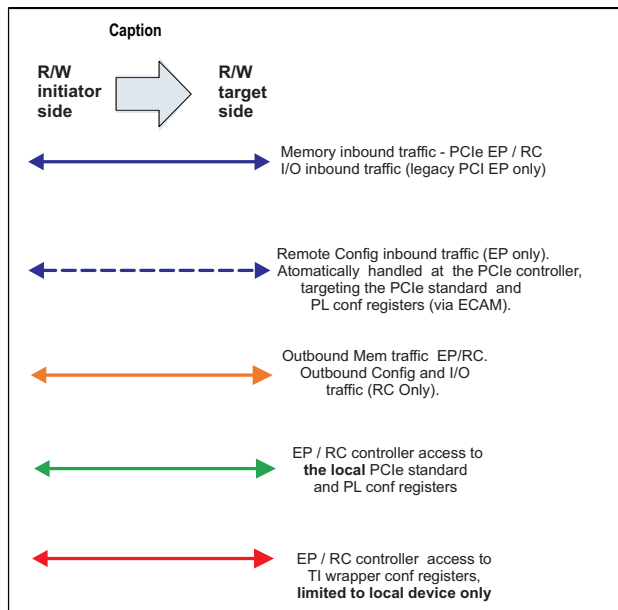

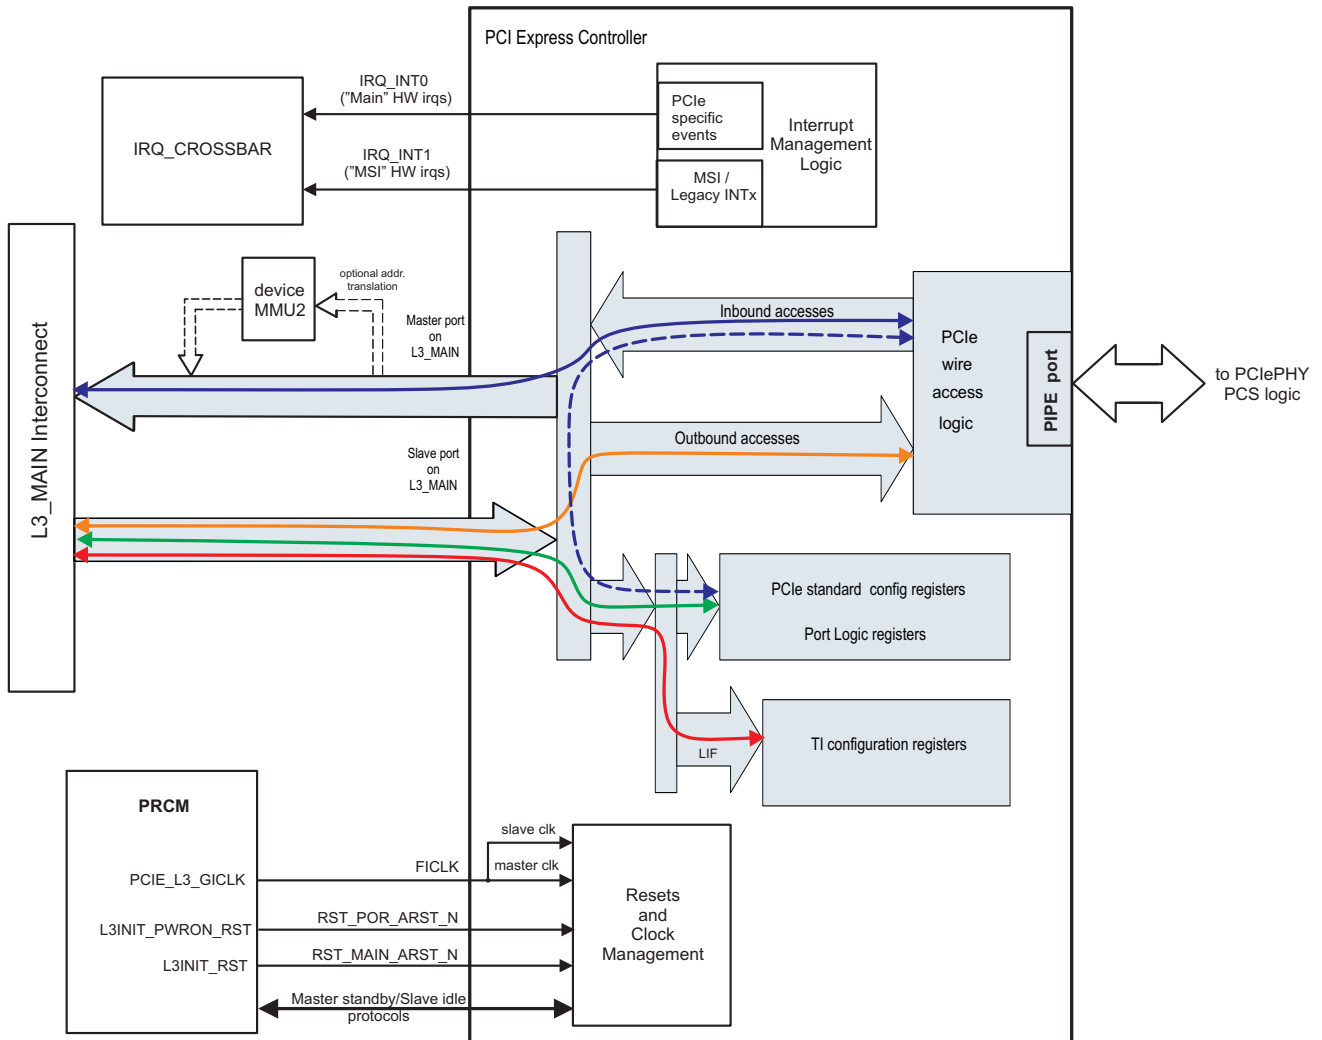

### 24.9.4.1 PCIe Controller Functional Block Diagram

This section describes how the overall PCI express functionality is implemented by the current controller, both as EP and as RC, and how each type of traffic is transmitted and received.

The PCI express interface allows memory-mapped read and write transactions to be performed across different partners of the same PCIe fabric. Locally the device local PCIe system is composed of the PCIe\_SS controller itself, device local hosts (such as MPU, DSP, and so forth), device DMAs (EDMA, and so forth) and device system memory (EMIFs SDRAM), connected to the PCIe controller via L3\_MAIN interconnect.

[Figure 24-161](#) summarizes the functional components of the PCIe\_SS controller, as well as the connectivity between PCIe\_SS and other components (MMU2, IRQ\_CROSBAR, PRCM, and so forth) within the device.

Figure 24-161. PCIe Controller Functional Block Diagram

pciectrl-003

### 24.9.4.2 PCIe Traffics

Most of the accesses (Memory-space) are typically flowing straight through the controller, from PCIe bus to L3\_MAIN or the other way. However, some transactions are accesses to the PCIe device's configuration registers:

- The source of those accesses is either the local running application, through the PCIe slave port, or a distant PCIe device on the bus, as an inbound transaction from the PCIe wire. Access may or may not be possible depending on the mode of operation (see also transfer descriptions on the [Figure 24-161](#)).
- The destination of those accesses is either the PCIe controller core, for the PCIe-standard configuration registers and the non-standard port logic (PL) registers, or the TI wrapper configuration registers accessed over the local interface (LIF).

[Figure 24-161](#) also gives a simplified view of the accesses allowed by device PCIe controller.

On the right hand side of the diagram is the PCIe\_PHY (PCS+PMA), itself connected to the PCIe wires. The same structure is expected in the link partner on the other side of the link. Each partner can initiate and complete transactions on the link, using a packet-based protocol. Each lane is a full-duplex serial channel, that is, packets can be exchanged in both directions simultaneously. When more than one lane is used, each packet is transmitted in parallel over all active lanes.

The bidirectional accesses, initiated from components on the PCIe bus (fabric) to/from the device local PCIe subsystem are identified as *Inbound traffic*, while the bidirectional accesses, initiated by device local PCIe system to/from the PCIe bus are identified as *Outbound traffic*.

Note that there are two ways to transmit data from the local PCIe system to a distant PCIe partner:

- **Outbound write accesses**, locally initiated by, for example, a local DMA accessing controller through the PCIe slave port, connected on L3\_MAIN, to push data towards a distant PCIe partner.
- **Inbound read accesses**, remotely initiated by, for example, a distant DMA through the PCIe wire, and issued on the PCIe master port, connected on L3\_MAIN, to fetch data from the local memory.

Likewise, there are two ways for the local PCIe system to receive data from a distant PCIe partner:

- **Outbound read accesses**, locally initiated by, for example, a local DMA accessing the PCIe slave port, connected on L3\_MAIN, to fetch data from a distant PCIe partner.
- **Inbound write accesses**, remotely initiated by, for example, a distant DMA through the PCIe wire, and issued on the PCIe master port towards the local system memory.

---

**NOTE:** Inbound PCIe I/O transfers are supported by the PCIe controller only in EP mode (typically for legacy PCI - EPs).

---

### 24.9.4.3 PCIe Controller Ports on L3\_MAIN Interconnect

The PCIe controller to L3\_MAIN connectivity is illustrated, on the left-hand side of the [Figure 24-161](#). Read/write accesses from external PCIe components to the device local system memory on L3\_MAIN are performed through the PCIe\_SS master (initiator) port - PCIe\_SS\_INIT. The addresses issued on this port are by default directly routed to the L3\_MAIN, but they can be optionally routed to and further translated by the device memory management unit - MMU2 before they reach the L3\_MAIN target. For more details on MMU port, refer to [Section 24.9.4.3.1.1](#).

On the other hand, the device local hosts (MPU, DSP, and so forth) initiate accesses to the PCIe controller local registers and PCIe bus remote devices via a PCIe\_SS slave (target) port - PCIe\_SS\_TARG on the L3\_MAIN. No MMU is included on the slave path. The slave interface has two uses: manage the local PCIe controller, and carry outbound PCIe traffic, that is initiated locally by PCIe hosts (MPU, DSP, DMAs, and so forth) within the device.

#### 24.9.4.3.1 PCIe Controller Master Port

The PCIe controller master port (using AXI protocol with an adapter to the device L3\_MAIN interconnect) has the following key features:

- 64-bit data, 32-bit address bus width
- Up to 16 simultaneous outstanding transactions, on up to 16 different IDs (4-bit ID port) total for read

and write ports together, as follows:

- Posted incoming PCIe transactions are all mapped to AXI ID 0, which ensures that they are executed in order. This includes all high-bandwidth writes, which are memory-type - posted.
- Non-posted incoming PCIe transactions are mapped to AXI ID 1 and above. This includes the high-bandwidth memory-type reads.
- uses the same clock source as the PCIe slave port, but potentially on a different divider ratio
- PCIe master port, does not use a disconnect interface, because unlike the PCIe slave port, it is expected to be always active when the PCIe controller has to initiate a transaction over the device L3\_MAIN.
- The PCIe controller maximum inbound payload size is 256 Bytes. The PCIe master port burst maximum length is 16 words (16 x 64-bit data words = 128 Bytes per burst). Hence a 256 Byte inbound data payload is converted by the PCIe master port to 2 max-sized bursts (128 Byte each) towards the device L3\_MAIN interconnect PCIe slave port which is 128 Byte-burst compatible.
- Only incremental bursts (INCR) are supported by the PCIe controller master port.
- Non-aligned bursts can be generated - bursts that are not aligned with their own size: a burst-aligned portion of  $2^N$ -bytes aligned burst starts on a byte address multiple of  $2^N$ , that is a byte address with the N LSBs at '0').

The PCIe memory space supports a 64-bit address mode but in the device PCIe controller, the AXI master port address size is restricted to 32 bits.

---

**NOTE:** A PCIe controller remains fully functional, and able to receive transactions from , for example, anywhere within the 64-bit PCIe memory space, as long as they are correctly remapped by the inbound address translation unit (ATU) to a 32-bit L3\_MAIN space address (device L3\_MAIN 4 GiB - memory space). The limitation is that the range addressable by the PCIe master is reduced, and that regions larger than  $2^{32}$  bytes (4GiB) total, cannot be mapped to the AXI master port on L3\_MAIN.

---

#### 24.9.4.3.1.1 PCIe Controller Master Port to MMU Routing

A standalone MMU2 module is included at the system level, primarily for use by the PCIe\_SS1 and PCIe\_SS2 controller. This provides several benefits including protection of the MPU host memory regions from corruption by PCIe\_SS1 and PCIe\_SS2 accidental accesses.

PCIe controller initiated (by remote side) traffic can be optionally routed through the MMU2 as controlled by a Control Core Module register bit. The PCIe\_SS1 and PCIe\_SS2 routing allows these sub-systems to be used to perform transfers.

---

**NOTE:** By default, the CTRL\_MODULE\_CORE instance located CTRL\_CORE\_CONTROL\_IO\_1[20] MMU2\_DISABLE bit is set to 0b0 and the MMU2 is functionally enabled. Despite this, the PCIe\_SS1 and PCIe\_SS2 controller traffic still bypasses this MMU. In order, for PCIe\_SS1 and PCIe\_SS2 master traffic to be routed through the MMU2, the CTRL\_MODULE\_CORE bits: CTRL\_CORE\_SMA\_software\_7[13] PCIE\_SS1\_MMU\_ROUTE\_ENABLE and CTRL\_CORE\_SMA\_software\_7[12] PCIE\_SS2\_MMU\_ROUTE\_ENABLE, must be set to 0b1 by user software.

---

Accesses are directed to the MMU2 by the L3\_MAIN switch fabric through the use of a 33-rd address bit. For the PCIe\_SS1 and PCIe\_SS2 master port, the value of the 33rd bit is actually defined by the above mentioned control module CTRL\_CORE\_SMA\_software\_7 register bits. For descriptions of the CTRL\_CORE\_SMA\_software\_7 register bitfields related to MMU2 route controls, refer to the [Section 18.5, Control Module Register Manual](#), in the chapter, *Control Module*.

For more information on device MMU2 functionality and register settings, refer to the [Section 20.3, MMU Functional Description](#) and [Section 20.5, MMU Register Manual](#), in the chapter, *Memory Management Units*, respectively.

### 24.9.4.3.2 PCIe Controller Slave Port

The PCIe controller slave port gives access to two internal targets: the local target, to manage the local controller, and the outbound window, which forwards accesses onto the PCIe wire.

The PCIe slave port (using AXI protocol with an adapter to the device L3\_MAIN interconnect) has the following key features:

- **64-bit data, 29-bit address** bus width
- Up to 16 simultaneous outstanding transactions, up to 16 different IDs (4-bit ID port).
- Uses the same clock source as the PCIe controller master port, but potentially on a different divider ratio.
- Supports L3\_MAIN disconnect protocol
- Exclusive and locked accesses are not supported for read and write port

PCIe Controller slave port purposes are:

- **Configuration and management of the PCIe controller:**
  - This low-bandwidth activity accesses the device PCIe controller local configuration/status registers, the Port Logic registers and the PCIe controller wrapper TI-specific registers.
  - The L3\_MAIN base address corresponding to the PCIe\_SS1 controller local configuration/status registers (DIF access targets) is 0x5100\_0000. For the PCIe\_SS2 controller local configuration/status registers (DIF access targets), the L3\_MAIN base address is 0x5180\_0000.
  - Bursts are not supported when accessing these registers.
- **Outbound PCIe traffic:**
  - This activity can consume the entire bandwidth available on the PCIe wires (up to 1 Gbyte/s in each direction for 2-lane, Gen2 operation), in concurrence with the AXI master ports' operation (that carries inbound PCIe traffic).
  - PCIe controller maximum outbound payload size is 64 Bytes (the L3 Interconnect PCIe1/2 target ports split bursts of size > 64 Bytes to the into multiple 64 Byte bursts). Only bursts of incremental type (INCR) are supported on the PCIe controller slave port.
  - Non-aligned bursts can be generated.
  - All outbound traffic activities are mapped within a device L3\_MAIN space region which is 256 MiB in size.
  - For the PCIe\_SS1 controller the PCIe outbound window is mapped within range 0x2000\_0000 - 0x2FFF\_FFFF of the device L3\_MAIN memory space. For the PCIe\_SS2 controller the PCIe outbound window is mapped within range 0x3000\_0000 - 0x3FFF\_FFFF (256 MiB) of the device L3\_MAIN memory space.

---

**NOTE:** The PCIe controller remains fully functional, and able to send transactions to, for example, anywhere within the 64-bit PCIe memory space, with the appropriate remapping of the 28-bit address by the outbound address translation unit (iATU). The limitation is that the total size of addressed PCIe regions (in config, memory, IO spaces) must be less than  $2^{28}$  bytes.

---

**NOTE:** Because only incremental burst mode is supported, the PCIe addresses can not be in a cacheable memory space. Subsequently, cache coherence protocol is not involved, and the PCIe controller is not expected to receive coherent PCIe TLPs (NS=0). For safety purpose, the PCIe controller coherent feature must be permanently disabled (and this applies for the device by default) by keeping `PCICTRL_TI_CONF_SYSCONFIG[16] MCOHERENT_EN` at value 0b0. In that case, inbound coherent PCIe TLPs ( that means with NS=0) proceed normally, but coherence will not be guaranteed by the device.

---

### 24.9.4.4 PCIe Controller Reset Management

The PCIe controller has two hardware reset inputs - a hardware **main** and **fundamental** resets which are asynchronous and active low.

In addition, a number of internal reset conditions can cause some sections of the controller to reset, depending on the power transitions and configuration. All reset conditions and categories are described below.

#### 24.9.4.4.1 PCIe Reset Types and Stickiness

Three types of reset conditions are defined by the PCI standard. Each reset condition listed below falls into one of these categories. The same reset condition can take different types depending on the usecase:

- Cold reset condition: upon device power-up.
- Warm reset condition: does not follow a device power-up.
- Hot reset condition: transmitted over the PCIe link.

A reset including the physical layer (PCIe\_PHY) is **called a fundamental reset**. According to the PCI Express Base 3.0 Specification, revision 1.0, it clears the programming registers non-sticky bits, and may clear or may not clear the sticky bits as well, depending on a Vaux power supply. If Vaux integrated in a PCIe subsystem, it is enabled via PM specific sticky bits - [PM\\_CSR\[8\]](#) PME\_EN and [DEV\\_CAS\[10\]](#) AUXPM\_EN register bits.

#### CAUTION

No Vaux power supply source is defined in hardware for the device integrated PCIe\_SS. Subsequently, all PCIe bits defined by the PCIe standard or device specific implementation as "sticky", are reset along with the "non-sticky" bits upon a PCIe fundamental reset assertion. Because it is mandatory to communicate the permanent Vaux absence to the device PCIe EP/RC controller, the EP/RC [DEV\\_CAS\[10\]](#) AUXPM\_EN (or [PM\\_CSR\[8\]](#) PM\_EN) and [PCIECTRL\\_TI\\_CONF\\_PM\\_CTRL \[11\]](#) AUX\_PWR\_DET bits have to be always software written '0' during initialization.

A **function-level reset (FLR)** impacts only one of the EP device's functions.

---

**NOTE:** The device PCIe controller supports only a single function, so it does not support FLR.

---

#### 24.9.4.4.2 PCIe Reset Conditions

##### 24.9.4.4.2.1 PCIe Main Reset

**Main hardware reset:** Assertion of the reset signal on the main hardware reset input of the PCIe subsystem unconditionally brings the entire PCIe controller back to its default state. The main HW reset impacts both non-sticky and sticky bits of the PCIe controller.

---

**NOTE:** The [PCIECTRL\\_TI\\_CONF\\_DEVICE\\_TYPE\[3:0\]](#) TYPE (RC/EP) bitfield and the remaining TI wrapper configuration registers ([PCIe\\_SS\\_TI\\_CONF](#)) are sensitive to main hardware reset only.

---

##### 24.9.4.4.2.1.1 PCIe Subsystem Cold Main Reset Source

The cold main reset has as a source - the device [PRCM.L3INIT\\_PWRON\\_RST](#) power-on reset. For more information on the PCIe controller hardware reset inputs see [Section 24.9.3, PCIe Controller Integration](#)).

The [L3INIT\\_PWRON\\_RST](#) assertion by PRCM resets all PCIe controller registers including the TI wrapper configuration registers (note that the PCIe device type in the [PCIECTRL\\_TI\\_CONF\\_DEVICE\\_TYPE](#) register is reset by default to "Root Complex").

For more information on the [PRCM.L3INIT\\_PWRON\\_RST](#) hardware reset, refer to [Section 3.5.5, Reset Domains](#), in [Chapter 3, Power, Reset, and Clock Management](#).

#### 24.9.4.4.2.1.2 PCIe Subsystem Warm Main Reset Sources

The warm main reset of the PCIe controller is sourced by the device PRCM L3INIT\_RST output. For more information on the PCIe controller hardware reset inputs see [Section 24.9.3, PCIe Controller Integration](#)). For more information on the PRCM.L3INIT\_RST hardware reset, refer to [Section 3.5.5, Reset Domains](#), in [Chapter 3, Power, Reset, and Clock Management](#).

The L3INIT\_RST main reset is triggered from different warm reset sources within the PD\_L3INIT power domain (global warm software reset, MPU watchdog reset, and so forth).

**Software triggered main reset to PCIe controller :** To the above group of PRCM warm main reset sources, there is also a software-triggered reset which can be asserted locally and independently to each of the PCIe\_SS1 and PCIe\_SS2 in the PD\_L3INIT domain. The main software reset is triggered via assertion of bit:

- RM\_PCIESS\_RSTCTRL[0] RST\_LOCAL\_PCIE1 for the device PCIe\_SS1 controller
- RM\_PCIESS\_RSTCTRL[1] RST\_LOCAL\_PCIE2 for the device PCIe\_SS2 controller

The software (warm) reset completion triggered through device PRCM is flagged in the *Write-one to Clear* PRCM register:

- RM\_PCIESS\_RSTST[0] RST\_LOCAL\_PCIE1 for the device PCIe\_SS1 controller
- RM\_PCIESS\_RSTST[1] RST\_LOCAL\_PCIE2 for the device PCIe\_SS2 controller

The user software running on PCIe controller is supposed to clear the reset status bit upon reset completion event via writing 0b1 to RM\_PCIESS\_RSTST[0] RST\_LOCAL\_PCIE1 and RM\_PCIESS\_RSTST[1] RST\_LOCAL\_PCIE2 bit in PRCM.

For more details on above PCIe controller software reset bits, refer to the [Section 3.12, PRCM Register Manual](#), in the [Chapter 3, Power, Reset and Clock Management](#)

---

**NOTE:** The warm main reset (including PCIe subsystem software reset) from PRCM impacts all PCIe core register bits (sticky and non-sticky) and the PCIe TI wrapper configuration registers (PCIe\_SS\_TI\_CONF). Note that the PCIe device type in the [PCIECTRL\\_TI\\_CONF\\_DEVICE\\_TYPE](#) register is reset by default to "Root Complex".

For more details on sticky/non-sticky bits behaviour refer to the PCI Express Base 3.0 Specification, revision 1.0.

---

#### 24.9.4.4.2.2 PCIe Standard Specific Resets to the PCIe Core Logic

**Fundamental hardware reset** - This reset impacts all non-sticky PCIe core bits. It is automatically triggered:

- upon a software initiated device type change in the [PCIECTRL\\_TI\\_CONF\\_DEVICE\\_TYPE\[3:0\]](#) TYPE (to RC/EP)
- upon exiting certain low-power modes
- upon PCIe controller's main power supply (Vmain) being powered-up or Vmain detected below a defined threshold by the PCIe RC. This is a cold fundamental reset.

---

**NOTE:** All (sticky and non-sticky bits) of the PCIe controller core are reset upon fundamental hardware reset assertion because of Vaux not implemented. Hereby all PCIe core registers have to be re-initialized from scratch after a PCIe fundamental reset.

---

**Hardware fundamental reset operation:** The hardware fundamental reset is an input to the PCIe core, to be controlled by the local PCIe software driver. Its impact is conditional: a fundamental reset clears the entire controller (including the PCIe\_PHY part), with the following exceptions:

- DEVICE\_TYPE register (unconditional) and all other PCIe\_SS\_TI\_CONF registers
- PCIe link PM FSM, if the module is out of "IDLE"

The fundamental reset is applied to PCIe core in the following two cases :

- After reprogramming the device type (to EP or RC) in the [PCIECTRL\\_TI\\_CONF\\_DEVICE\\_TYPE\[3:0\]](#)

TYPE bitfield, to latch in the new type and clear the programming registers. Remain out of idle and clear [PCIECTRL\\_TI\\_CONF\\_PM\\_CTRL\[11\]](#) AUX\_PWR\_DET to 0 beforehand, in order to reset also the sticky bits.

- L3 exit at initial power-up unless the restart is already initiated by the other side of the link

---

**NOTE:** The TYPE value ("EP", "legacy EP" or "RC") has to be read back by software until desired type-value is seen. This insures that the fundamental reset triggered by "TYPE" change has completed successfully. The user software must not change the [PCIECTRL\\_TI\\_CONF\\_DEVICE\\_TYPE\[3:0\]](#) TYPE register value during PCIe core operation.

---

**NOTE:** The fundamental hardware reset does not impact the [PCIECTRL\\_TI\\_CONF\\_DEVICE\\_TYPE\[3:0\]](#) TYPE (RC/EP) bitfield and the remaining TI wrapper configuration registers (PCIe\_SS\_TI\_CONF). These can be reset only by a PCIe main reset input assertion.

---

**PCIe link-down reset condition** - When the PCIe link has gone down and goes up again, namely transitions from D3cold/L3 back to D0, the PCIe core auto-applies this **internal fundamental reset** and reports it on IRQ event ([PCIECTRL\\_TI\\_CONF\\_IRQSTATUS\\_MAIN\[11\]](#) LINK\_REQ\_RST) after link-up.

**PCIe hot-reset condition** - As defined by the PCIe standard: reset condition propagated in-band (over the PCIe wire) from an upstream port to a downstream port, using the TS1 and TS2 OS (see the PCI Express Base 3.0 Specification, revision 1.0). Requires the link to be already powered and up. The hot reset causes the link to go down and up again, causing a link-down reset condition, and as such is a fundamental reset.

The hot reset sequence can be tracked in the LTSSM by the transition to "hot reset" state, then on to "detect" and the rest of the link-up sequence.

- When RC, a hot reset is generated by writing the bit "Secondary Bus Reset" of the PCIe standard "Bridge Control Register" - [BRIDGE\\_INT \[22\]](#) SEC\_BUS\_RST bit .
- When EP, a host reset is automatically processed by the controller hardware.

**PCIe soft reset condition** - As defined by the PCIe standard: When the D-state of a device is changed from D3<sub>hot</sub> to D0 by software, namely by the RC doing a remote CFG write to the EP ([EP](#)) [PM\\_CSR \[1:0\]](#) PWR\_STATE register, the EP device reacts depending on its DIF CS (local) setting of the no-soft-reset (NSR) bit ([EP](#)) [PM\\_CSR \[3\]](#) NSR:

- If bit NSR=0, the soft reset is applied, and the device transitions to the D0<sub>uninitialized</sub> state (see [Figure 24-162](#)). Non-sticky bits are reset.
- If bit NSR=1, the soft reset is inhibited, the device transitions directly to the D0<sub>active</sub> state (see [Figure 24-162](#)), no reset is applied. Full context is retained, including non-sticky bits.

---

**NOTE:** The soft reset is a hot reset. The soft reset is not a fundamental reset; that means that it does not reset the PHY, only the programming registers.

---

#### 24.9.4.5 PCIe Controller Power Management

This section is a brief summary of the supported power modes and power transitions, as well as the consequences (clock gating, power gating, resets, and so forth) on the PCIe controller.

##### 24.9.4.5.1 PCIe Protocol Power Management

The power state of a PCIe controller port is described by four different FSMs, each running at a different level of the protocol, each with its own independent state. The FSMs are covered in [Section 24.9.4.5.1.1](#) through .

[Table 24-680](#) summarizes the typical power stable state combinations, namely the combinations of states the controller can settle into, after a number of potential transitions and transient states, and assuming that the lowest power state possible is used.

The PCIe standard defined optional gating of the reference clock on PCIe\_PHY PLL input (and therefore of the PIPE clock) when in L1-state is not supported. As shown in the [Table 24-680](#), the PIPE clock is always running while link is in L1.

**Table 24-680. Power States Summary**

Device D-state	Link L-state	PHY LTSSM state	PIPE power down	PIPE clock <sup>(1)</sup>	Vmain	LP_CLK <sup>(2)</sup> (auxiliary clock)	Slave Idle	Master Standby
D0_uninitialized <sup>(3)</sup>	LDn	Detect	P1	OFF	don't care	ON	1	1
D0_uninitialized	L0	n/a	P0	ON	ON	ON	0	1
D0_active	L0	L0	P0	ON	ON	ON	0	0/1 <sup>(4)</sup>
D0_active	L0s	L0s	P0s	ON	ON	ON	0	0/1 <sup>(4)</sup>
D0_active	L1	L1	P1	ON	ON	ON	0	0/1 <sup>(4)</sup>
D1	L1	L1	P1	ON	ON	ON	0	1
D2	L1	L1	P1	ON	ON	ON	0	1
D3_hot	L1	L1	P1	ON	ON	ON	0	1
D3_cold	L3	n/a	P2	OFF	OFF	OFF	1	1

<sup>(1)</sup> The PIPE clock activity, as visible from the PCIe core boundary, implies the activity of the high-speed PLL it is derived from, which implies the activity of the reference clock on the PLL input.

<sup>(2)</sup> See [Section 24.9.4.5.2](#)

<sup>(3)</sup> Default controller state after reset. Not a real PCIe state.

<sup>(4)</sup> Master standby value depends on the PCI express application (MSE, ISE, and so forth)

#### 24.9.4.5.1.1 PCIe Device/function power state (D-state)

The function power state machine is the highest-level PM FSM in a PCIe device. The power state control bitfield is part of standard PCIe register bitfield- [\(EP\)PM\\_CSR/\(RC\)PM\\_CSR](#) [1:0] PWR\_STATE.

---

**NOTE:** A Vaux power source is not tied to the PCIe core, that is why the state D3\_cold with Vaux switched-on is unsupported by the PCIe PM FSM.

---

---

**NOTE:** The six available D-states are, by order of decreasing power: D0\_uninitialized (default), D0\_active, D1, D2, D3\_hot, D3\_cold. Note that the function power state Cfg field - is only 2 bit, encoding only 4 combinations: D0, D1, D2, D3. The difference between uninitialized and active (D0), and between hot and cold (D3) is implicit.

---

The eventual ("stable" or "quiescent") power state of a PCIe link (link state) is determined by the D-state of the downstream device. For the current controller, it means that the D-state determines the link state in EP type mode, but not in RC type mode.

Note also that the device may go through a number of transient link states before entering/after exiting its quiescent link state, so that a device, for example, in D3\_hot may be consuming maximum instantaneous power.

**D0\_uninitialized** is the function's default state, entered after powerup and/or reset. It is used by the RC software to enumerate the function (Cfg transactions). Mem and IO transaction are disabled. It can only be entered through a reset, partial or total. Together with D0\_active, it is the highest-power D-state.

**D0\_active** is the function's active state, where all Memory and I/O transactions take place. By definition, a function transitions from D0\_uninitialized to D0\_active after the RC software enables Memory and I/O transactions, either as completer ("Cfg" write 0b1 to memory space enable: MSE/IO space enable: ISE) or as requester ("Cfg" write 1 to bus master enable: BME). D0\_active can be exited to/entered from D1, D2, or D3\_hot by the RC software writing to the function's [\(EP\)PM\\_CSR](#)[1:0] PWR\_STATE power state. Together with D0\_uninitialized, it is the highest-power D-state.

**D1 and D2** are two optional states, with reduced power compared to D0. Both operate the same way, and have the same action on lower-level PM FSM, with D1 expected to have a faster wakeup and D2 a lower power. Both are supported by the current controller. D1 and D2 can be exited to/entered from D0\_active, D1, D2, or exited to D3\_hot, by the RC software writing to the function's (EP)PM\_CSR[1:0] PWR\_STATE power state bitfield. The current controller supports D1 and D2 but a fully compliant implementation also depends on the system providing the right combination of HW and software.

**D3\_hot** is a lower-power state (compared to D0, D1, D2). It can be entered from D0\_active, D1, or D2 by the RC software writing to the function's (EP)PM\_CSR[1:0] PWR\_STATE. Transition to D3\_hot is typically continued to D3\_cold and main power (VMAIN) shutdown. It can also be exited to D0 by the RC writing (0b00) to the (EP)PM\_CSR[1:0] PWR\_STATE. The state transition to either D0\_active or D0\_uninitialized depends on the NSR value written in the bit (EP)PM\_CSR[3] NSR (No\_Soft\_Reset bit) of 0b1 (that means - function is not reset) or 0b0 (that means - function is reset, link is restarted and must be reconfigured) respectively.

**D3\_cold** is the lowest-power state, defined by the VMAIN being turned off. It is typically entered from D3\_hot as shown in the figure below, but any turn-off request will actually place the function in that state. It can only be exited to D0\_uninitialized, by restoring VMAIN and after resetting the function, totally or partially (see link states below).

**Figure 24-162. PCIe D-state (function power state) FSM diagram**

pcie\_005

The Figure 24-162 shows the state transitions in the power state. NSR is the “No\_Soft\_Reset” bit in the function's (EP)PM\_CSR configuration register. NSR advertizes the ability of the device to go into D3\_hot while retaining its register settings (when 1), or conversely, the inability to do so and the reset of those setting upon D3\_hot exit (when 0).

NSR is read-only to the RC software over Cfg accesses, but it can be set by the EP's local software over DIF (CS access) prior to enumeration. The controller shall apply the NSR to itself accordingly.

Most function power state transitions are done explicitly by the RC-side software writing into the EP function's (EP) `PM_CSR[1:0]` `PWR_STATE`, over the PCIe wire. This is one of the two PM control mechanisms of PCIe, the other one being ASPM. The remaining function power state transitions are caused by resets.

The D-state of a device sets the link power state (L-state) for the PCIe link above. In other words, the L-state of a PCIe link (connecting an upstream device, closer to the RC, and a downstream device, closer to an EP) is set by the downstream device.

#### 24.9.4.5.1.2 PCIe Controller PIPE Powerstate (Powerdown Control)

The PIPE interfaces the MAC, or controller, above PIPE in the protocol hierarchy and the PHY, or transceiver, below PIPE. The current controller implementation has a PIPE interface at its boundary.

#### CAUTION

The physical layer as defined by the PCIe standard extends into the PCIe MAC layer, to include, for example, the LTSSM, so that “physical layer” and PHY do not coincide, with the latter included in the former.

The PIPE interface has its own power state, driven by the PCIe controller towards PCIe\_SS PHY on a 2-bit powerdown signal, depending on the PM state machines above. It has four states: P0, P0s, P1, P2:

- **P0 (pipe\_powerdown = 0b00):** active state, for high-speed (HS) data transmission and reception. Used for L0 link state.
- **P0s (pipe\_powerdown = 0b01):** active HS receiver, suspended transmitter. Used for L0s link state.
- **P1 (pipe\_powerdown = 0b10):** Suspended HS receiver and transmitter, but PIPE clock still running.
- **P2 (pipe\_powerdown = 0b11):** Suspended HS receiver and transmitter, PIPE clock stopped - asynchronous mode.

#### 24.9.4.5.2 PCIe Controller Clocks Management

##### 24.9.4.5.2.1 PCIe Clock Domains

The controller has two main clock domains: the L3\_MAIN bridge (ports) and the PCIe core.

The L3\_MAIN bridge runs on a single clock. That same clock is used to run both the PCIe controller master and slave ports. It can be divided, with independently ratios for master and slave. However, both sides are typically expected to run at the same speed, as both are capable of the same performance.

There is an auxiliary clock - LP\_CLK which is a PCIe\_SS internal low-power clock, used when pipe clock is stopped. It is assumed to be always available when the module is not idle.

The PCIe core runs on the PIPE clock whenever that clock is provided by the relevant PCIe\_PHY. When the PCIe link is in a low-power state and the PIPE clock is not available, the core splits in two sub-domains:

- Most of the core stops
- A small “auxiliary” part of the core (which includes the configuration registers) switches to a low-power clock LP\_CLK
- The two subdomains can still be considered synchronous despite their different clocking scheme, since they are either running on the same clock, or one of the subdomain clocks is stopped.

##### 24.9.4.5.2.2 PCIe Controller Idle/Standby Clock Management Interfaces

A PCIe controller has two clock management (CM) interfaces with device PRCM:

- A master port clock management interface based on master standby protocol with the device PRCM
- A slave port clock management interface based on slave idle protocol with the device PRCM

The PCIe wrapper logic located register [PCIECTRL\\_TI\\_CONF\\_SYSCONFIG\[3:2\] IDLEMODE](#) and [PCIECTRL\\_TI\\_CONF\\_SYSCONFIG\[5:4\] STANDBYMODE](#) bitfields are used to software configure the idle /standby CM behaviour locally for the PCIe\_SS controller. The [Table 24-681](#), shows the available CM options.

**Table 24-681. Local Power-Management Features**

Feature	Registers	Description
Slave idle modes	<a href="#">PCIECTRL_TI_CONF_SYSCONFIG</a> [3:2] IDLEMODE bit field	The available modes are: Force-Idle, No-Idle, wakeup-disabled Smart-Idle and wakeup-capable Smart-Idle.
Master standby modes	<a href="#">PCIECTRL_TI_CONF_SYSCONFIG</a> [5:4] STANDBYMODE bit field	The available modes are: Force-Standby, No-Standby, wakeup-disabled Smart-Standby and wakeup-capable Smart-Standby.

For more information on the PCIeSS functional clock gating in the device PRCM (clock PCIE\_L3\_GICLK), refer to [Section 3.1.1.1.4, Clock Domain-Level Clock Management](#), in the chapter, *Power, Reset and Clock Management*.

The relations between the PCIeSS master (standby)/slave (idle) behaviour to various PCIe protocol link power management features are covered in the [Section 24.9.4.5.2.2.1](#) and [Section 24.9.4.5.2.2.2](#), respectively.

#### 24.9.4.5.2.2.1 PCIe Controller Master Standby Behavior

As a master (initiator) on the device L3\_MAIN interconnect, the PCIe controller supports the standby protocol over the standard three signals: mstandby/mwait/mwakeup. The behavior of that interface can be configured in the PCIeSS controller wrapper (PCIe\_SS\_TI\_CONF) register - [PCIECTRL\\_TI\\_CONF\\_SYSCONFIG\[5:4\] STANDBYMODE](#) bitfield.

The standby protocol notifies the local system if inbound PCIe transactions are likely to be routed to the controller's master port.

---

**NOTE:** Note that CFG-type transactions are typically not part of the PCIe controller master port transfers: in RC mode they are only outbound, and in EP mode they are processed inside the controller.

---

**Automatic mode (default):** most operations are expected to take place in "smart-standby" mode. In that mode, the master standby interface is automatically managed by the PCIe status, featuring (Mstandby = 0) if (D-state=D0<sub>active</sub> and MSE=1 that is bit [\(RC\) STATUS\\_COMMAND\\_REGISTER/\(EP\) STATUS\\_COMMAND\\_REGISTER\[1\] MEM\\_SPACE\\_EN](#)) :

- D-state = D0<sub>active</sub> indicates that the link is up, that data can be exchanged. It's also a condition for memory-type transactions to take place.
- The Memory Space Enable bit [\(RC\) STATUS\\_COMMAND\\_REGISTER\[1\] MEM\\_SPACE\\_EN](#), indicating that the RC has enumerated the PCIe fabric and configured the memory space for operation, before EP writing the MSE bit in the local CFG register - [\(EP\) STATUS\\_COMMAND\\_REGISTER](#) via DIF CS access.

In automatic (smart-standby) mode, the standby is therefore controlled remotely by the RC software, which sets both the D-state and the MSE.

Note that the master does not go to standby during ASPM (so called active state power management) transitions to L0s or L1 on the link, as it remains in "D0<sub>active</sub>" during that time. Although the physical layer is partially or fully stopped during L0s and L1, the short restart time of a few microseconds does not justify a transition to standby by the master. In other words, the master goes or doesn't go to standby after a link layer transition to L1, depending on the cause, if a transition in "D-state" or "ASPM" occurred, respectively.

More generally, the link state is not directly correlated to the automatic standby state of the master:

- Master in standby (mstandby=1): link can be in L0 (link startup), L1 (D1, D2, D3hot), L3 (D3cold)
- Master out of standby (mstandby=0): link can be in L0, L0S/L1 (ASPM)

The "Mstandby" status depends on the possibility of transactions, not on actual transactions. The master may remain out of standby indefinitely without any transaction, and an incoming transaction shall not cause the master to exit standby. The latter is an error case which occurrence is prevented in hardware.

The mwait=0 handshake, eventually returned after the mstandby=0 transition, should prevent the master from issuing transactions until the system is ready. However, no back-pressure can actually be applied to the PCIe to prevent inbound accesses after, for example, MSE has been set. It is assumed that there will be sufficient time for the mwait to transition, that is typically for the system to reopen the path to its local memory, before the first inbound transaction is routed to the master.

When the PCIe local controller itself is in RC mode, note that the D-state may remain D0active even after the has gone down. It is therefore advised to use the clearing of the local MSE bit to set the master in standby. Alternatively, the RC can be placed in D3hot mode, or the standby can be forced (to mstandby = 1) by setting the standbymode to "force-standby". Whatever the method, the RC is aware of the state of the entire PCIe fabric, and is expected to put its master in standby in full knowledge of the situation.

For more information on the PCIe Controller Standby Management Protocol with the device PRCM, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

**Manual control, EP type:** When incoming transactions are not memory-type (e.g.: IO type), the master is capable of issuing transactions while the automatic out-of-standby conditions above are not met.

---

**NOTE:** In the EP, non-memory type transaction cases, it is the user software responsibility to manually force the master out of standby via setting the bit [PCIECTRL\\_TI\\_CONF\\_SYSCONFIG\[5:4\] STANDBYMODE = 0x1](#), that means - "No-Standby", before the first transaction, and to return it to automatic mode via setting [PCIECTRL\\_TI\\_CONF\\_SYSCONFIG\[5:4\] STANDBYMODE = 0x2](#), that means - "Smart-Standby" after the last transaction.

---

For instance, an EP shall have to monitor the ISE (IO space enable) bit and the link status, and set the [PCIECTRL\\_TI\\_CONF\\_SYSCONFIG \[5:4\] STANDBYMODE](#) bitfield accordingly if EP is configured to have an IO BAR.

#### 24.9.4.5.2.2 PCIe Controller Slave Idle/Disconnect Behavior

As a target of the device L3\_MAIN bus (with target being the PCIe controller slave port on L3\_MAIN respectively), the controller supports the "Idle" protocol. The behaviour of that interface can be configured in the PCIeSS controller wrapper register - [PCIECTRL\\_TI\\_CONF\\_SYSCONFIG\[3:2\] IDLEMODE](#) bitfield.

Additionally, the slave port clock management supports a disconnect protocol which is controlled automatically.

The idle transition of the PCIe controller is strictly synchronized to PIPE clock. The PRCM places the PCIe controller to an "Idle state" before PCIePCS generated PIPE clock is stopped due to some reason: g.h. PCIe PHY low power transition with gating local PLL clocks, the APLL\_PcIE clock or gating PCIeREF\_DPLL clock. The IDLE state is automatically maintained by PRCM during periods in which PIPE clock is stopped.

PCIe controller transitions to IDLE initiated by the system PRCM are strictly synchronized with the PCIe operational state. The PRCM allows the PCIe controller to be brought out of "IDLE" state, only if the generation of the PIPE clock is enabled by configuring the high-frequency PLL (source of the PIPE clock) and the 100 MHz PCIe reference clock scheme (source of the high-frequency clock). For more details on the PCIe PLL and PHY related clocks, refer to the [Section 26.4, PCIe Shared PHY Subsystem](#) in the chapter, *Shared PHY Component Subsystems*.

#### CAUTION

All accesses to the device PCIe controller on its slave port, namely to the local target configuration PL/PCIe standard/wrapper registers or to the PCIe bus, require the PIPE clock to be running. The presence of the PCIe interface clock - PCIE\_L3\_GICLK is not sufficient to perform such accesses.

#### 24.9.4.5.2.2.2.1 PCIe Controller Idle Sequence During D3cold/L3 State

When the link of a RC enters L3 mode, the PIPE interface must go to P2 mode for power saving. The PCIe controller maintains the PIPE interface in P1 mode (PIPE clock running) and the internal registers accessible until the system requests entry into "Idle", and only then transition to P2: it is the device PRCM responsibility to Idle the module ([PCIECTRL\\_TI\\_CONF\\_SYSCONFIG](#) [3:2] IDLEMODE set to 0x2 - *Smart Idle mode* should be selected), in order to reach a low-power state. Transitioning to "P2", stops the PIPE clock and makes the register inaccessible, which in turn corresponds to an "IDLED" and disconnected from L3\_MAIN PCIe slave port.

---

**NOTE:** The "L3" state can only be exited when the RC re-enabling the Vmain power supply, and reconfiguring all PCIe registers from scratch: In both EP and RC cases, the system should detect Vmain power assertion, apply a fundamental reset, then bring the module out of "IDLE" and restart the link normally. All registers are reset.

---

#### 24.9.4.6 PCIe Controller Interrupt Requests

In the rest of this section, and for clarity:

- **"Interrupts"** refer by default to the virtual interrupt lines emulated by the PCIe protocol using either the PCI legacy or PCIe Message-Signaled Interrupts (MSI) methods, and used for non-PCIe purposes by the system.
- **"Hardware interrupts"** refer to the actual interrupt signals coming out of the current PCIe controller, and used to manage various events of the PCIe protocol, including PCI interrupts.

Each PCIe controller has two **hardware interrupt lines** described in [Table 24-682](#) and [Table 24-684](#), which are level-sensitive. PCIe pulse interrupts are unsupported in the device.

**The main HW interrupt line** - PCIe\_SS1\_IRQ\_INT0/PCIe\_SS2\_IRQ\_INT0 receives all interrupt events related to the control of the PCIe operation, including power management and errors.

**The MSI HW interrupt line** - PCIe\_SS1\_IRQ\_INT1/PCIe\_SS2\_IRQ\_INT1 receives all interrupt events propagated by a remote EP over the PCIe interface, for specific (non-PCIe) applicative purposes, in conjunction with the PCIe transactions. This includes the legacy interrupts (INTx) as well as the Message Signaled Interrupts (MSI) proper, as defined by the PCIe standard.

---

**NOTE:** MSI-X is unsupported by PCIe controller.

---

The difference between the two hardware interrupt types - "main" and "MSI" is that the main interrupt events are used by the PCIe interface, whereas the MSI interrupt uses the PCIe interface.

---

**NOTE:** Incoming MSI events only exist in RC mode when MSI events are received over the PCIe wire. In EP mode, other mechanisms allow controller to generate (transmit) of the same type of interrupt events onto the PCIe bus.

---

The main interrupt events are further divided into PCI management and error events. The MSI interrupts are divided into legacy and MSI proper. Each of these four categories of events is described in [Section 24.9.4.6.1](#) and [Section 24.9.4.6.2.2](#).

#### 24.9.4.6.1 PCIe Controller Main Hardware Management

##### 24.9.4.6.1.1 PCIe Management Interrupt Events

The events described here trigger the main interrupt line. Each status bit is set to one by a specific PCIe event, and must be cleared by the local SW.

**CFG\_MSE\_EVT:** (EP mode) PCIe controller's Memory Space Enable (MSE) config bit has been set by the RC software - written to 1 by a configuration write. This notifies the local EP that incoming memory-type PCIe transactions may now target the local function, over the AXI master port.

**CFG\_BME\_EVT:** (EP mode) PCIe controller's Bus Master Enable (BME) config bit has been set by the RC software - written to 1 by a configuration write. This allows the local EP to initiate (outgoing) PCIe transactions, over the AXI slave's outbound window.

**LINK\_UP\_EVT:** Link layer has successfully booted and reached L0active state. Data can be transmitted and received over the PCIe wire.

**LINK\_REQ\_RST:** Link-down reset was triggered (by link-down condition). Non-sticky bits have been reset.

**PM\_PME:** (RC mode) PCIe controller has received a power management event PM message on its PCIe downstream port, requesting wakeup.

**PME\_TO\_ACK:** (RC mode) PCIe controller has received a Turn-Off Acknowledge PM message on its PCIe downstream port, acknowledging a previously transmitted turnoff message (PME\_Turn\_Off).

**PME\_TURN\_OFF:** (EP mode) PCIe controller has received a Turn-Off PM message on its PCIe upstream port, requesting an acknowledge (PME\_TO\_Ack) and the transition of the link to L2/L3

#### 24.9.4.6.1.2 PCIe Error Interrupt Events

The events described here trigger the main interrupt line.

**ERR\_COR:** (RC mode) Correctable Error message received on PCIe downstream port.

**ERR\_NONFATAL:** (RC mode) Uncorrectable Error message received on PCIe downstream port.

**ERR\_FATAL:** (RC mode) Fatal Error message received on PCIe downstream port.

**ERR\_SYS:** (RC mode) Either of the three error messages above (correctable, non-fatal, fatal) was reported and enabled in the root control register.

**ERR\_ECRC:** End-to-end CRC error detected.

**ERR\_AXI:** AXI slave error caused by response table overflow. This error is not supposed to happen.

#### 24.9.4.6.1.3 Summary of PCIe Controller Main Hardware Interrupt Events

Table 24-682 describes the events, related to control of the PCIe interface operation itself, including power management, reset and error handling, that trigger the "main" hardware interrupt line.

**Table 24-682. PCIe Main Hardware Interrupt Events Summary**

Event Status and Clear	Interrupt Enable	Interrupt Disable	Mapping	Description
PCIECTRL_TI_CONF_IRQSTA TUS_MAIN[14] CFG_MSE_EVT	PCIECTRL_TI_CONF_IRQEN ABLE_SET_MAIN[14] CFG_MSE_EVT_EN	PCIECTRL_TI_CONF_IRQEN ABLE_CLR_MAIN[14] CFG_MSE_EVT_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	CFG "Memory Space Enable" change event

**Table 24-682. PCIe Main Hardware Interrupt Events Summary (continued)**

Event Status and Clear	Interrupt Enable	Interrupt Disable	Mapping	Description
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[4] ERR_AXI	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[4] ERR_AXI_EN	PCIECTRL_TI_CONF_IRQCLR_MAIN[4] ERR_AXI_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"AXI tag lookup fatal error" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[3] ERR_COR	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[3] ERR_CORR_EN	PCIECTRL_TI_CONF_IRQCLR_MAIN[3] ERR_CORR_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Correctable Error" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[2] ERR_NONFATAL	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[2] ERR_NONFATAL_EN	PCIECTRL_TI_CONF_IRQCLR_MAIN[2] ERR_NONFATAL_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Non-Fatal Error" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[1] ERR_FATAL	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[1] ERR_FATAL_EN	PCIECTRL_TI_CONF_IRQCLR_MAIN[1] ERR_FATAL_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Fatal Error" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[0] ERR_SYS	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[0] ERR_SYS_EN	PCIECTRL_TI_CONF_IRQCLR_MAIN[0] ERR_SYS_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"System Error" event

**NOTE:** While the [PCIECTRL\\_TI\\_CONF\\_IRQSTATUS\\_MAIN](#) register is updated only if corresponding interrupt is enabled in the [PCIECTRL\\_TI\\_CONF\\_IRQENABLE\\_SET\\_MAIN](#) register, the [PCIECTRL\\_TI\\_CONF\\_IRQSTATUS\\_RAW\\_MAIN](#) register always provides the Legacy/MSI event status regardless of an interrupt being enabled or disabled in the [PCIECTRL\\_TI\\_CONF\\_IRQENABLE\\_SET\\_MAIN](#) register.

#### 24.9.4.6.2 PCIe Controller Legacy and MSI Virtual Interrupts Management

The PCIe protocol uses TLPs to create "virtual" interrupt lines across the PCIe fabric. Interrupts do not constitute a separate transaction type like Mem, Cfg, I/O, and so forth, but reuse the existing types.

##### 24.9.4.6.2.1 Legacy PCI Interrupts (INTx)

Legacy PCI interrupts are supported over PCIe by dedicated message codes (posted-write in Msg space) that flag the assertion or deassertion of one of four "virtual" interrupt lines (or pins): INTA, INTB, INTC, INTD. They can only be sent by EPs, and routed to/received by the RC.

PCIe controller supports single-function mode and can send only INTA when configured as EP.

**NOTE:** Use of legacy PCI interrupt is exclusive with use of MSI (defined in [Section 24.9.4.6.2.1.2](#)). MSI should be the preferred method whenever possible.

##### 24.9.4.6.2.1.1 Legacy PCI Interrupt Events Overview

Legacy INTx (with x= A/B/C/D) are interrupt events inherited from PCI, where each was implemented on a physical bus wire. The RC can allocate each line to a given EP function, which is then allowed to assert/deassert that line (and only that line). PCI legacy interrupt events are mapped on the MSI interrupt line of PCIe controller. For more details, refer to [Section 24.9.4.6.2.1.2](#) and [Section 24.9.4.6.2.1.3](#).

The controller HW shall both set and clear the IRQ status bit according to the assert and deassert messages received over the PCIe wire, respectively. In other words, the legacy interrupt status bit do not need to be cleared by the local software after processing.

Typical legacy interrupt service routine (ISR) on the RC-configured PCIe controller is:

- Remote EP function transmits an "assert INTx" message. Value of x (within A/B/C/D) was previously assigned by the RC software using configuration accesses.
- "assert INTx" message is routed up the PCIe topology to the RC (local controller)
- [PCIECTRL\\_TI\\_CONF\\_IRQSTATUS\\_MSI](#) status bit INTx goes to 1
- MSI interrupt line is asserted
- software reads [PCIECTRL\\_TI\\_CONF\\_IRQSTATUS\\_MSI](#) status register. The asserted bit (A,B,C,D)

allows to determine the EP function that generated the event.

- software accesses this EP function over PCIe to process the interrupt: ad-hoc service routine
- As a result of the processing, remote EP function transmits the “deassert INTx” message
- software clears the [PCIECTRL\\_TI\\_CONF\\_IRQSTATUS\\_MSI](#) status bit INTx to 0.
- MSI interrupt line is deasserted, assuming there is no other asserted event.

#### 24.9.4.6.2.1.2 Legacy PCI Interrupt Transmission (EP mode only)

Writing 0b1 to TI wrapper register [PCIECTRL\\_TI\\_CONF\\_INTX\\_ASSERT\[0\]](#) ASSERT\_F0 bit sends an ASSERT message on the “interrupt pin” specified in the config header space.

Writing 0b1 to TI wrapper register [PCIECTRL\\_TI\\_CONF\\_INTX\\_DEASSERT\[0\]](#) DEASSERT\_F0 bit will send a DEASSERT message on the “interrupt pin” specified in the config header space.

A status of the virtual “interrupt line” is available by reading out either bitfield.

---

**NOTE:** This status is just a local record of the last message sent, it is not the result of any feedback from the PCIe fabric, since messages are posted, no response is generated. For that reason, the PCIe protocol does not guarantee the coherence between assertion and deassertion INTx messages, that means that it’s up to the application to ensure that the INTx assertion has been seen by the RC before sending the deassertion, and vice versa.

---

#### CAUTION

The operations above should only be used when in EP mode, and will produce undefined results if applied to an RC-configured controller.

#### 24.9.4.6.2.1.3 Legacy PCI Interrupt Reception (RC mode only)

The reception of either of the 8 INTx message codes (ASSERT/DEASSERT of INTA/B/C/D) shall assert/deassert the corresponding HW interrupt event in status register:

- [PCIECTRL\\_TI\\_CONF\\_IRQSTATUS\\_MSI\[0\]](#) INTA
- [PCIECTRL\\_TI\\_CONF\\_IRQSTATUS\\_MSI\[1\]](#) INTB
- [PCIECTRL\\_TI\\_CONF\\_IRQSTATUS\\_MSI\[2\]](#) INTC
- [PCIECTRL\\_TI\\_CONF\\_IRQSTATUS\\_MSI\[3\]](#) INTD

This implies that the status of an asserted event does not need to be cleared locally (by software writing 1 to the [PCIECTRL\\_TI\\_CONF\\_IRQENABLE\\_CLR\\_MSI\[n\]](#) INTx\_EN bit, where n=0 to 3 and x=A, B, C, D, respectively) as it is expected to be cleared remotely over PCIe, by the EP function.

---

**NOTE:** The RC does not keep track of the INTx requester, even though the information is available in the incoming TLP’s RequesterID: each legacy interrupt is expected to be used by only one EP function, known a priori by the RC.

---

When messages are posted, there is no response generated by the RC.

INTx messages can only be received (and the corresponding HW interrupts asserted) when in RC mode.

---

**NOTE:** The HW interrupts have to be maintained disabled when in EP mode.

---

#### 24.9.4.6.2.2 PCIe Controller Message Signaled Interrupts (MSI)

Message Signal Interrupts are the preferred option to map interrupt over PCIe. It allows up to 32 interrupt vectors/events to be triggered by each EP function. MSI interrupts are implemented memory-space (posted) writes, 1-DWORD long. They should only be sent by EPs to the RC.

---

**NOTE:** While legacy PCI interrupts are mapped onto PCIe messages (Msg), the Message Signaled Interrupts are mapped onto PCIe memory writes (MWr), not onto messages.

Use of MSI is exclusive with use of legacy PCI interrupts (defined above).

---

An MSI is a memory (posted) write done by an EP to a mailbox in the RC. The data size is always 32 bit, the address and the data are programmed by the RC during PCIe enumeration, into the EP function's MSI capability descriptor (in the EP function's PCI config space).

Like legacy PCI interrupts, MSI does not pass any status information to the RC, other than the interrupt vector (event) itself: the data payload of the write access is used exclusively to identify the interrupt's requester and its vector. The exchange of status information is outside the scope of MSI.

---

**NOTE:** Unlike the legacy PCI interrupts, MSI does not emulate an interrupt "level" that is either high or low, gets asserted or deasserted. Each MSI interrupt vector corresponds to a univocal event, that does not get "cleared" later on.

---

---

**NOTE:** The device integrated PCIe controller does not support extended MSI-X message signaled interrupts.

---

#### 24.9.4.6.2.2.1 PCIe Specific MSI Interrupt Event Overview

MSI are interrupts designed specifically for PCIe, unlike the legacy PCI events seen in the [Section 24.9.4.6.2.1](#). They are mapped on the MSI interrupt line of PCIe controller, using a single status bit in the [PCIECTRL\\_TI\\_CONF\\_IRQSTATUS\\_MSI](#) register. The "MSI controller" decodes and records each received MSI write as a specific "vector" coming from a specific EP function. Each application assigns a dedicated meaning to a given vector. Each function can use up to 32 vectors, as configured by the RC. MSI vectors can only be "asserted" by the EP function, unlike PCI legacy events that can be asserted and deasserted. In other words, the local software has to "clear" the asserted vector before it can be reused.

The [PCIECTRL\\_TI\\_CONF\\_IRQSTATUS\\_MSI](#) status bit MSI must remain set as long as a vector is still set. Once the last vector has been cleared, the MSI bit must be cleared by software.

See also [Section 24.9.4.6.2.2.3](#).

Typical MSI interrupt service routine on the RC-configured PCIe controller:

1. Software reads [PCIECTRL\\_TI\\_CONF\\_IRQSTATUS\\_MSI](#) status register, and identifies an (unspecified) MSI event, as opposed to a PCI legacy event.
2. Software clears [PCIECTRL\\_TI\\_CONF\\_IRQSTATUS\\_MSI\[4\]](#) MSI.
3. Software reads [PCIECTRL\\_PL\\_MSI\\_CTRL\\_INT\\_STATUS\\_N](#) and identifies EP functions that raised MSI.
4. Software clears [PCIECTRL\\_PL\\_MSI\\_CTRL\\_INT\\_STATUS\\_N](#) status bit.
5. Software calls the EP function specific interrupt handlers for each of the vectors.
6. Repeat steps 3 to 5 until [PCIECTRL\\_PL\\_MSI\\_CTRL\\_INT\\_STATUS\\_N](#) reads 0.
7. Exit MSI IRQ handler, only if [PCIECTRL\\_PL\\_MSI\\_CTRL\\_INT\\_STATUS\\_N](#) is 0.

#### 24.9.4.6.2.2.2 PCIe Controller MSI Transmission Methods (EP mode)

There are two methods for MSI transmission: hardware and software. MSI transmission applies only to EP configured local PCIe system.

#### 24.9.4.6.2.2.2.1 PCIe Controller MSI transmission, hardware method

The device PCIe controller (EP) transmits an MSI by writing 0b1 to the TI config wrapper register [PCIECTRL\\_TI\\_CONF\\_MSI\\_XMT\[0\]](#) MSI\_REQ\_GRANT bit. The other fields indicate function number, TC, vector, for the MSI. The address, data (potentially modulated by the vector) are automatically extracted from the EP function's MSI capability descriptor, previously programmed by the remote RC during enumeration.

For status, [PCIECTRL\\_TI\\_CONF\\_MSI\\_XMT\[0\]](#) MSI\_REQ\_GRANT can be polled. The bit remains HIGH (0b1) following a request (write to 0b1) and goes back LOW (0b0) once the MSI transmit request has been granted.

---

**NOTE:** Bit [PCIECTRL\\_TI\\_CONF\\_MSI\\_XMT\[0\]](#) MSI\_REQ\_GRANT reflects only the PCIe local status, that is a confirmation that the MSI has been transmitted. Since the MSI is a posted write, there is no way for the EP to ensure that it has been correctly received by the RC.

---

#### 24.9.4.6.2.2.2.2 PCIe Controller MSI transmission, software method

Alternatively, an MSI can also be sent as a SW-composed memory write (MWr). MSI address and data shall be taken from the local EP function's MSI capability descriptor, where they were programmed by the RC at enumeration, along with the "multiple message enabling". If more than one vector is enabled, MSI data can be modulated accordingly. Furthermore, the transaction shall match the mandatory characteristics of an MSI MWr access, as follows :

- Header attribute bits ATTR = 2'b00 (no snoop = 0, relaxed ordering = 0)
- 1 DWORD long
- First byte enable: 0b0000
- Last byte enable: 0b0011 (16 bits of data)

Such a SW-generated MSI can be scheduled at the end of a series of memory transactions (MRd/MWr), with the PCI transaction ordering rules guaranteeing that the MSI will not overtake the other transactions.

#### 24.9.4.6.2.2.3 PCIe Controller MSI Reception (RC mode)

Unlike legacy PCI interrupts, MSI must be configured by the RC in each function before use. Depending on its reception capacities, the RC can enable between 1 and 32 vectors (individual events) per MSI-enabled EP function.

The current RC implementation supports MSI reception for up to 8 different EP functions, with up to the protocol's maximum (32) vectors a piece, all mapped to a single MSI address. MSI reception is handled by the "MSI controller" though non-standard "port logic" (PL) registers (mapped in the PCI config space): For more details see the PCIe controller port logic associated [PCIECTRL\\_PL\\_MSI\\_CTRL\\_x](#) registers in the [Section 24.9.7.5.1](#).

The reception of MSI implicitly requires the MSI mailbox address (in PCI memory space) to be routed to the RC: refer to [Section 24.9.4.7, PCIe Controller Address Spaces and Address Translation](#) for that. The MSI address (32-bit or 64-bit) is programmed in dedicated PCIe PL registers.

The MSI message data (MWr DWORD) is encoded as follows for the current RC. This encoding shall be used by the RC to configure the remote EP discovered at enumeration.

**Table 24-683. MSI Message Data Encoding (RC)**

Bit range	Size	Value	Comment
31:16	16	0x0000	Reserved as per PCI standard
15:8	8	0x00	Unused, always zero
7:5	3	0 to 7	Identifier of EP function in MSI controller (8 possible values)
4:0	5	0 to 31	Interrupt vector for the EP (32 possible values)

An inbound access recognized as MSI is terminated inside the controller, and does not appear on the PCIe controller's master port like other inbound memory writes in the same range.

### 24.9.4.6.3 PCIe Controller MSI Hardware Interrupt Events

Table 24-684 describes the events, related to non-PCIe interrupts (PCI legacy and PCIe MSI interrupts), which trigger the "MSI" hardware interrupt line.

**Table 24-684. MSI Hardware Interrupt Events Summary**

Event Status and Clear <sup>(1)</sup>	Interrupt Enable Bit	Interrupt Disable Bit	Mapping	Description
PCIECTRL_TI_CONF_IRQSTATUS_MSI[0] INTA	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI[0] INTA_EN	PCIECTRL_TI_CONF_IRQCLR_MSI[0] INTA_EN	PCIe_SS1_IRQ_INT1 PCIe_SS2_IRQ_INT1	Legacy interrupt caused by EP sending inband ASSERT/DEASSERT event on virtually emulated by PCIe pin INTA.
PCIECTRL_TI_CONF_IRQSTATUS_MSI[1] INTB	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI[1] INTB_EN	PCIECTRL_TI_CONF_IRQCLR_MSI[1] INTB_EN	PCIe_SS1_IRQ_INT1 PCIe_SS2_IRQ_INT1	Typically set and cleared by the remote EP, without local software intervention.
PCIECTRL_TI_CONF_IRQSTATUS_MSI[2] INTC	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI[2] INTC_EN	PCIECTRL_TI_CONF_IRQCLR_MSI[2] INTC_EN	PCIe_SS1_IRQ_INT1 PCIe_SS2_IRQ_INT1	MSI interrupt status. It is cleared by clearing all vectors in the MSI controller (PL) registers.
PCIECTRL_TI_CONF_IRQSTATUS_MSI[3] INTD	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI[3] INTD_EN	PCIECTRL_TI_CONF_IRQCLR_MSI[3] INTD_EN	PCIe_SS1_IRQ_INT1 PCIe_SS2_IRQ_INT1	
PCIECTRL_TI_CONF_IRQSTATUS_MSI[4] MSI	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI[4] MSI_EN	PCIECTRL_TI_CONF_IRQCLR_MSI[4] MSI_EN	PCIe_SS1_IRQ_INT1 PCIe_SS2_IRQ_INT1	

<sup>(1)</sup> The MSI hardware interrupts have to be maintained disabled when in EP mode.

**NOTE:** While the [PCIECTRL\\_TI\\_CONF\\_IRQSTATUS\\_MSI](#) register is updated only if corresponding interrupt is enabled in the [PCIECTRL\\_TI\\_CONF\\_IRQENABLE\\_SET\\_MSI](#) register, the [PCIECTRL\\_TI\\_CONF\\_IRQSTATUS\\_RAW\\_MSI](#) register always provides the Legacy/MSI event status regardless of an interrupt being enabled or disabled in the [PCIECTRL\\_TI\\_CONF\\_IRQENABLE\\_SET\\_MSI](#) register.

### 24.9.4.7 PCIe Controller Address Spaces and Address Translation

The PCIe controller acts as a general-purpose bridge between the device local PCIe system and the PCIe fabric. Both are address-based mappings, and the bridging requires address translation between the different spaces.

The [Table 24-685](#) lists the memory-mapped spaces interconnected by each of the PCIe\_SS1 and PCIe\_SS2 controllers. For each address space (row), the local PCIe subsystem (including the PCIe core) provides “entry points” (4th column) to inject transactions into the specified space, and “exit points” (5th column) to receive transactions from the specified space.

**Table 24-685. PCIe\_SS Address Space Map**

Space name	Address width	Size (bytes)	Entry point	Exit point	Comments
Device L3_MAIN memory space visible through PCIe controller's master port	32-bit	4 GiB	iATU IBR output	device system RAM, miscellaneous modules	Accessed over PCIe controller initiator (master) port; Includes the outbound window below.
PCIe_SS controller outbound window in device	28-bit	256 MiB	Device CPU hosts (MPU, DSPs, and so forth) of PCIe subsystem on device L3_MAIN interconnect	iATU OBR input	Mapped within PCIe controller target (slave) port, the outbound window is itself remapped within the device L3_MAIN memory space (256 MiB sized region).
PCIe memory space	32-bit/64-bit <sup>(1)</sup>	4 GiB/16 EiB	ATU OBR output (mem mode)	ATU IBR input (mem mode)	Contains all memory BARs

<sup>(1)</sup> Regarding the PCIe address space shared between all devices identified on the PCIe fabric, the local PCIe controller OBR iATU output generates a 32-bit address (it addresses a total of 4 GiB external PCIe space), while the IBR iATU input receives accesses from within a total of 16 ExaBytes of external PCIe space (a 64-bit address).

**Table 24-685. PCIe\_SS Address Space Map (continued)**

Space name	Address width	Size (bytes)	Entry point	Exit point	Comments
PCIe I/O space	32-bit	4 GiB	ATU OBR output (I/O mode)	ATU IBR input (I/O mode)	Contains all I/O BARs
PCIe config space (ECAM)	28-bit	256 MiB	ATU OBR output (configuration mode)	Configuration registers inside PCIe controller	Contains the PCIe-standard configuration spaces for EP functions (a 4 KiB- descriptor per function).

By definition, an iATU (Address Translation Unit) has an input (the space the access originates from) and an output (the space the access is headed for), with the required address translation taking place in the middle. An iATU inbound region (IBR) routes from PCIe (input) to device L3\_MAIN space (output), an iATU outbound region (OBR) routes from the L3\_MAIN space (input) to the PCIe (output).

[Table 24-686](#) summarizes the action of the different ATU regions. It contains the same information as the table above, organized differently. Note that inbound regions are not required to managed incoming configuration accesses, which are completed automatically by the PCIe controller hardware.

PCIe controller core outbound and inbound ATUs define:

- 16 outbound iATU regions
- 4 inbound iATU regions

**Table 24-686. Address Translation Unit Region Access Summary**

ATU region direction	ATU region type	Source space	Destination space
Outbound (OBR)	Memory	PCIe controller outbound window	PCIe memory space
Inbound (IBR)	Memory	PCIe memory space	Device PCIe subsystem space
Outbound (OBR)	I/O	PCIe controller outbound window	PCIe I/O space
Inbound (IBR)	I/O	PCIe I/O space	Device PCIe subsystem space
Outbound (OBR)	Configuration	PCIe controller outbound window	PCIe Cfg space

In a read/write access to an iATU outbound region (input), which is mapped in the PCIe controller target's 256 MiB-wide outbound window, do not confuse:

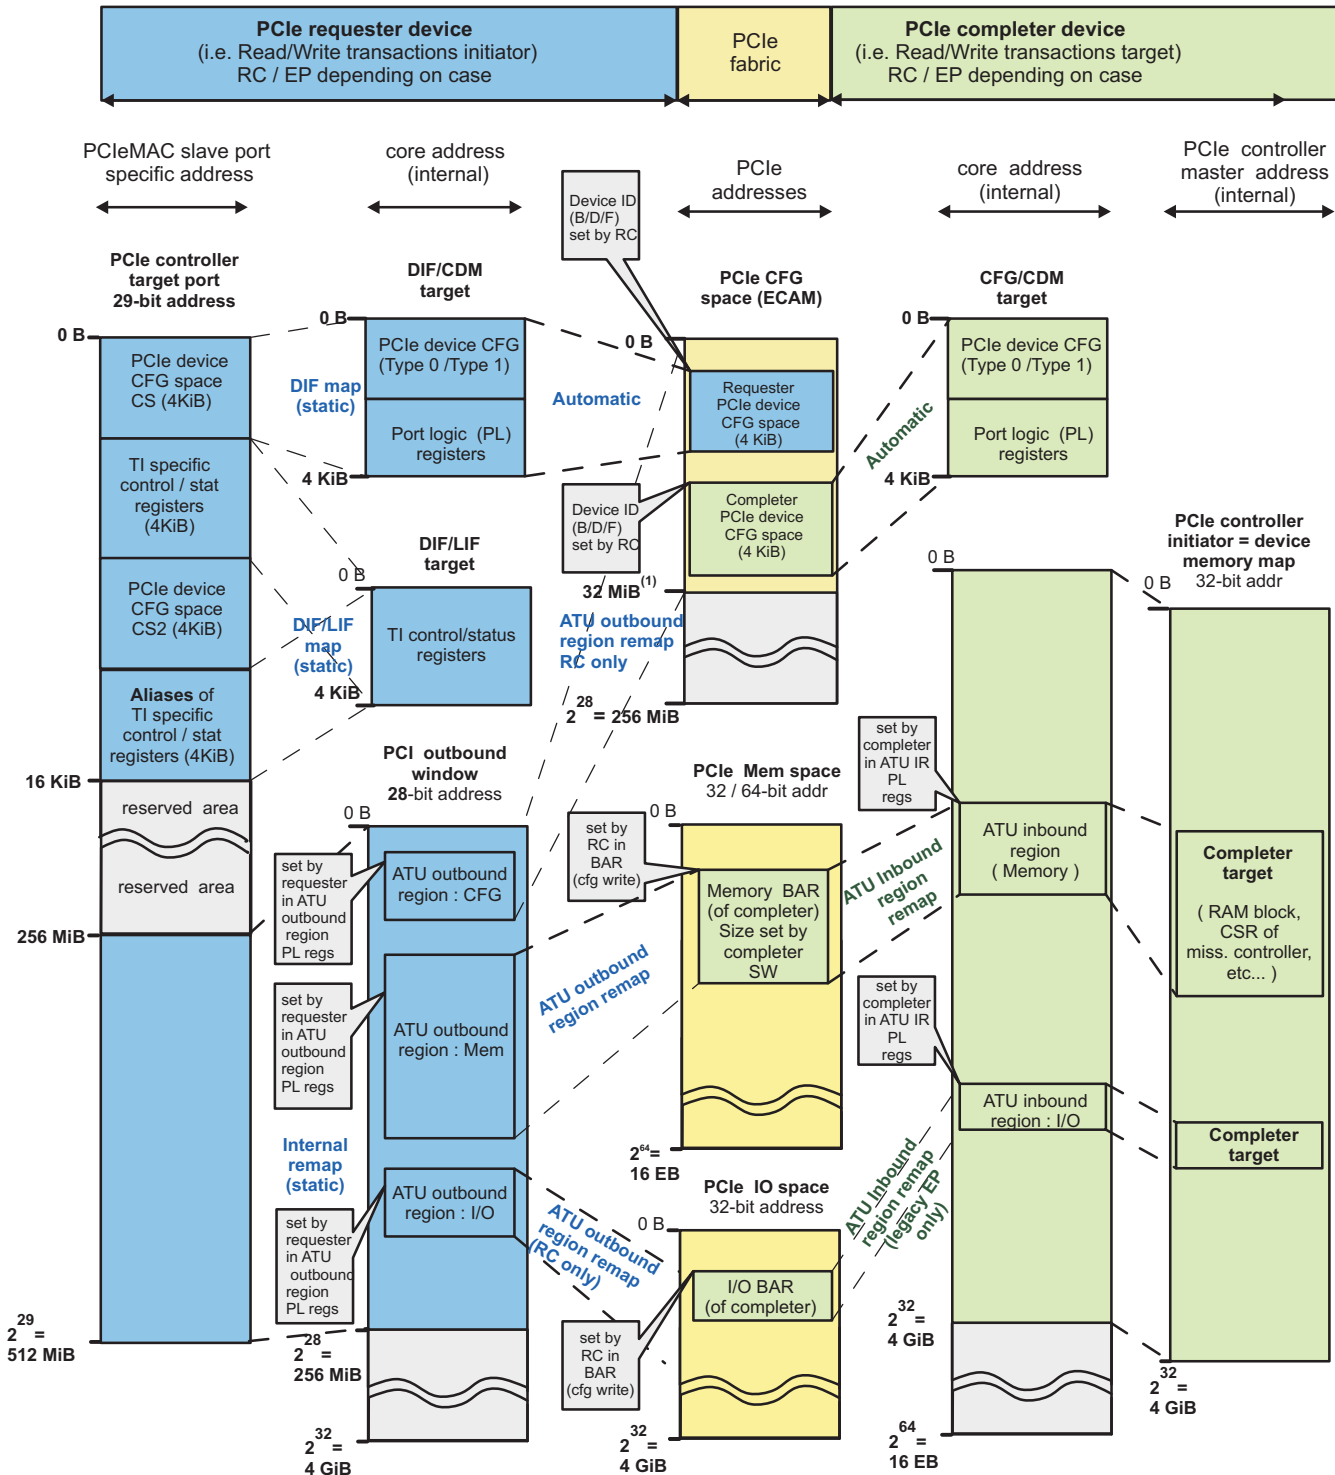

- Physical address accessed in the device L3\_MAIN address space - 4 GiB
- Physical address within the PCIe\_SS1/PCIe\_SS2 controller target (slave) port:
  - PCIe outbound window - Cfg ; Memory and I/O space accessible within (0x2000\_0000 - 0x2FFF\_FFFF)/(0x3000\_0000 - 0x3FFF\_FFFF)
  - PCIe controller local configuration/status registers accessible within (0x5100\_0000 - 0x517F\_FFFF)/(0x5180\_0000 - 0x51FF\_FFFF)
- Address offset within the outbound window (0 - 256 MiB)

#### CAUTION

In the calculation of an ATU outbound region translation, the input is the address offset within the outbound window, ranging from 0x0000\_0000 (0 bytes) to 0x0FFF\_FFFC (256 MiB – 4 Bytes), they are the third and last address type in the list above.

PCI express is an interconnect that propagates read/write accesses from/to systems beyond the local device PCIe subsystem. The figure below shows such a link, where the transaction initiator (PCIe requester device, on the left) and the transaction target (PCIe completer device, on the right) are two instances of the PCIe controller subsystem, connected over the PCI express fabric (in the middle). The physical routing of the transaction over the PCIe topology (through switches) is implicit and transparent for addresses. A simplified chain of address translation is represented for each PCIe transaction type (Configuration, Memory or IO).

Figure 24-163. PCIe Core to PCIe Core Address Mapping and Translation

Note(1): The EP PCIe CFG space (EP function descriptors) occupies 32 MiB of the whole 256 MiB Outbound window. This because only a single EP function (#0) is implemented out of 8 possible. pcie\_ctrl-004

**NOTE:** There is a difference between requester/completer and RC/EP relationships, an EP device can be either the requester or the completer in a memory transaction.

### 24.9.4.8 PCIe Traffic Requesting and Responding

The PCIe wire can carry several types of packet-based traffic. The current chapter details how the current controller can be requester and completer of each type:

- **Requester:** initiates and transmits an outbound request, receives a response if required by (non-posted) request type.
- **Completer:** receives and processes an inbound request, generates and transmits a response if required by (non-posted) request type.

#### 24.9.4.8.1 PCIe Memory-type (Mem) Traffic Management

The bulk of PCIe traffic is expected to take place in the memory (MEM) space, making use of large TLP/large L3\_MAIN interface bursts.

Before PCI activity starts, one or several BAR of each device (EP function or RC) shall be initialized in Memory mode, as described in the [Section 24.9.4.9.3, Base Address Registers \(BAR\) Initialization](#).

The following fields shall be set, using (CS) access (they are RO over PCI) :

- BARn[0]= "space decoder" shall be set to 0 = MEM space. This is the default setting for all BAR.
- BARn[2:1] = "type" shall be configured to either 32 or 64-bit. In the latter case, BARn+1 above shall contain the 32-bit upper part of the BAR base address.
- BARn[3] = "prefetchable" (P)

The BAR shall be enabled, using (CS2) access to BARn[0]:

- Write 1: BARn is enabled, can be configured by the RC writing to the MSBits of the BARn base address field.
- Write 0: BARn is disabled: register is read-only and return 0 over PCIe.

As part of the standard enumeration process, the RC then maps all the Memory BARs it finds (while discovering the connected EP functions) into the memory address space (32 or 64-bit address), using Cfg accesses over the PCIe wire. Optionally, the RC can also configure its own two BAR, over the DIF interface.

Once that process is complete, memory requests can take place point-to-point, that means that the requests can be initiated by any device (EP or RC) towards any other device function.

#### 24.9.4.8.1.1 PCIe Memory Requesting

An ATU outbound region can then be programmed to remap the desired parts of the memory space (which correspond to BARs on other devices) into the local controller target's outbound window, accessed through the L3\_MAIN slave port.

Alternatively, the iATU can be bypassed, and the outgoing access forwarded to the PCIe wire without address translation. In that *pass-through* mode, the PCIe address is equal to the 28 LSBits of the PCIe controller target address, that is, the address offset within the 256 MiB-wide outbound window. This gives access to the lowest 256 MiB of the PCIe memory space, from 0x0 to 0x0FFF\_FFFC.

The forwarded PCIe TLPs shall have the following (hardcoded) header field values:

- TYPE = 0 = MRd/ MWr (Memory read or write)
- EP (poisoned bit) = 0 (not poisoned)
- ATTR (Attributes) = 2b01:
  - ATTR[1] = RO (relaxed ordering) = 0
  - ATTR[0] = NS (no snoop) = 1
- TC (traffic class) = 0

Initiators in the device local PCIe subsystem (typically CPUs or DMA) can then access memory space by initiating read/write accesses on the controller's slave port over L3\_MAIN, either to the range of an enabled ATU outbound region, for the translated mode (with all TLP fields configurable), or outside any enabled ATU outbound region, for the pass-through mode (with the TLP fields hardcoded as explained above).

#### **24.9.4.8.1.2 PCIe Memory Responding**

An ATU inbound region can be programmed in BAR matching mode to remap (part or all of) each memory BAR to the controller's inbound window (this means to translate their address to the memory space of the device chip), and issue them on the PCIe controller's master port towards L3\_MAIN. BAR matching mode is expected to be the most common method for an EP. In that mode, the ATU can be set up before enumeration - before the BAR's actual range (offset) is configured by the remote RC.

Alternatively, the ATU inbound region can be programmed in address matching mode. In that case, any access routed to the device (EP or RC) and matching the range specified in the ATU is remapped to the controller's inbound window (this means to translate their address to the memory space of the device), and issued on the master port towards L3\_MAIN.

Address matching is the preferred method for an RC, which would route any access outside its base/limit range, as defined in its PCIe standard (Type-1) configuration space, and independently of any BAR so that BAR matching is not possible. In that case, only space not already taken up by a BAR can be used. Note the setup of an address matching iATU inbound region can only be done after enumeration, that is, after the RC has discovered and mapped all enabled Memory BAR of all EP functions to their address.

Finally, in case an incoming access does not match any enabled ATU inbound region (BAR or address matching), the transaction is just passed through untranslated, that is, with the address unchanged and the TLP attributes stripped off. This is not expected to be commonly used.

Incoming memory requests (to the local EP's Memory BAR) shall then cause the master port on L3\_MAIN to access a given address range of the local system (potentially the entire 32-bit address range).

#### **24.9.4.8.2 PCIe Configuration Type (Cfg) Traffic Management**

Configuration (Cfg) traffic is not symmetrical: it can only be requested by the RC, and completed (in the case of PCIe controller) by the EP. It is used by the RC for the enumeration of the fabric: EP, functions, switches.

---

**NOTE:** The RC cannot use configuration traffic over the PCIe wire to access its own 4 KiB configuration space. To do that, it uses DIF accesses (CS) with bit [PCIECTRL\\_PL\\_DBI\\_RO\\_WR\\_EN\[0\]](#) CX\_DBI\_RO\_WR\_EN = 0b0.

---

##### **24.9.4.8.2.1 RC Self-configuration (RC Only)**

Like any other device on the PCIe fabric, the RC has its own 4-KiB configuration space, where RC local configuration registers are stored.

---

**NOTE:** Since the RC configuration registers are programmed by the RC itself, no remote access over the PCIe wire (Cfg TLP) is required. Local DIF accesses (CS) are used instead.

---

However, some register fields normally defined as read-only by the PCI standard are actually programmable over DIF (see [Section 24.9.4.9.2](#)), which may cause a standard software driver to fail. In that case, the CS-writability of those fields has to be disabled by reprogramming the located in the PCIe controller port logic bit [PCIECTRL\\_PL\\_DBI\\_RO\\_WR\\_EN\[0\]](#) CX\_DBI\_RO\_WR\_EN to 0b0. Note that this is normally done after CS-writable fields have been configured by the non-standard initialization "firmware", thus making the RC's configuration space PCI compliant.

The [Section 24.9.4.8.2.2](#) and [Section 24.9.4.8.2.3](#) only covers configuration of an EP function by an RC, using actual Configuration TLPs (transport layer packets).

##### **24.9.4.8.2.2 Configuration Requests over PCIe (RC Only)**

After coming out of reset, the PCI fabric is enumerated by the RC through configuration (Cfg) transactions to the switches and EP present in the topology. The enumeration process is covered by the PCI and PCIe standards - for more details refer to the PCI Express Base 3.0 Specification, revision 1.0.

Configuration transactions are created by an outbound ATU region set up to translate the PCIe controller slave port accesses into Cfg TLP on the PCIe wire.

- The L3\_MAIN interconnect port (read or write) determines the TLP type (CfgRd/CfgWr)
- The data is passed unchanged from the L3\_MAIN interconnect to the PCI world (write) and reciprocally (read)
- The entire PCI configuration space can be mapped as a standard, contiguous block, as specified in the **Enhanced Configuration Access Mechanism (ECAM)**. The ATU maps this 256 MiB block at a programmable base address within the controller slave port's 256 MiB "outbound window", using the ATU "Cfg shift" feature.
- The other parameters are programmed beforehand in the ATU's configuration registers (IATU\_\*)

The (28-bit) address offset within the 256 MiB ECAM block is the concatenation of :

- **Cfg register address** (Offset[11:0] = 12-bit = 4 KiB configuration space per EP function)
- **Function number** (Offset[14:12] = 3 bit = 8 functions per PCIe EP )
- **Device number** (Offset[19:15] = 5 bit = 32 devices per bus, always 0 for PCIe controller itself)
- **Bus number** (Offset[27:20] = 8-bit = 256 busses in the PCIe fabric)
- Total for ECAM: 8 + 5 + 3 + 12 = 28-bit offset, or 256 x 32 x 8 x 4 KiB = 256 MiB

---

**NOTE:** The device PCIe controller itself supports only one function in EP mode. On the PCIe fabric, however when in RC mode, the PCIe controller may need to configure up to 8 functions per EP (potentially for all 65536 EPs). Hence the ECAM config. space visible to RC is 256 MiB in size.

---

A Cfg read access to the Vendor ID register is used by the RC to detect the presence of a function. If that specific read (address 0x000 in the 4-KiB PCI config space) fails with an UR PCIe response (Unsupported Request: no function present), the PCIe controller shall return a correct response to L3\_MAIN with data 0xFFFF. This indicates the absence of the function to the application, without triggering an error on L3\_MAIN.

#### 24.9.4.8.2.3 Configuration Responding over PCIe (EP Only)

As an EP, the device only expects to receive (and never transmit) configuration transactions, and expects those to be CFG0 and not CFG1.

Incoming Cfg accesses with the appropriate Target ID are automatically routed to the targeted EP function's 4-KiB PCI configuration space, which contains both the PCI standard registers (header, descriptors, extended descriptors, and so forth) and the PL registers. The request read/write complete automatically, with no transaction appearing on the PCIe controller master port. Since Cfg accesses are non-posted, each incoming request shall generate a response.

---

**NOTE:** An ATU inbound region is also capable of processing incoming Cfg transactions, and translating them into read/write accesses on the master port towards L3\_MAIN. However, this method is not expected to be used, and automatic completion –described above– is expected to be used instead.

---

#### 24.9.4.8.3 PCIe I/O-type (IO) traffic management

I/O traffic is not symmetrical: it can only be requested by the RC, and responded to by the EP. It is a mostly deprecated feature of PCI, and could be replaced by Memory traffic. However, it is still required by the standard for a PCIe RC. It is supported by the current controller in both RC (requester) and **legacy EP mode (completer)**.

##### 24.9.4.8.3.1 PCIe I/O requesting (RC only)

As part of the standard enumeration process, the RC maps all the I/O BARs it finds (while discovering the connected EP functions) into the 4 GiB I/O address space (32-bit address).

An ATU outbound region shall then be programmed to map a zone of the I/O space into the controller target's outbound window, accessed through the slave port.

Initiators in the RC host (typically a local CPU) can then access I/O space by initiating (1 DWORD) read/write accesses to the ATU region's range on the controller's slave port on L3\_MAIN.

---

**NOTE:** There is NO specific hardware mechanism to notify the RC that it is allowed to issue I/O requests, since that configuration decision comes from the RC in the first place.

---

#### 24.9.4.8.3.2 PCIe IO BAR initialization before enumeration (EP only)

Before PCI enumeration, each BAR can be initialized/enabled individually for IO space, using the DIF access (CS or CS2). The size of an enabled IO BAR (that is, the number of writable bits in the base address) is fixed to 256 bytes, that is, a mask of 0xFF that is, the writable BAR base address range for the RC is BARn[31:8], while BARn[7:0] is read-only.

In (CS) access, the BARn[0] "space decoder" field becomes RW and shall be written to 1 = IO space

In (CS2) access, BARn[0] becomes a write-only BAR enable :

- Write '1': BARn is enabled, can be configured by the RC writing to the MSBits of the BARn base address field.
- Write '0': BARn is disabled: register is read-only and return 0x0 over PCIe.

#### 24.9.4.8.3.3 PCIe I/O responding (PCI legacy EP only)

I/O support is permitted only for the "legacy EP" type, that is, EP's side it is required that [PCIECTRL\\_TI\\_CONF\\_DEVICE\\_TYPE](#)[3:0] TYPE has been preliminary set to 0x1 by EP's local software. Before PCI activity starts, one or several BAR of the EP function shall be enabled in I/O mode, to get enumerated by the RC as per the PCI standard.

An iATU (internal address translation unit) inbound region can be programmed in **BAR matching mode** to map the BAR to the controller's inbound window (that is, translate their address to the memory space of the SoC), and issue them on the PCIe master port towards device L3\_MAIN.

BAR matching mode is expected to be the most common method for an EP. In that mode, the iATU can be set up before enumeration, that is, before the BAR's actual range (offset) is configured by the remote RC.

Alternatively, the ATU inbound region could be programmed in address matching mode. However, a valid I/O access coming into an EP is necessarily within a BAR, so BAR matching should be used. Additionally, BAR matching can be configured before enumeration, that is, before the RC has mapped the I/O BAR to their actual address.

Incoming I/O requests to the local EP's IO BAR shall then cause the PCIe master port to access a given address range of the local system (potentially the entire 32-bit address range), in 32-bit read/write accesses.

#### 24.9.4.8.4 PCIe Message-type (Msg) traffic management

Most messages are generated and received automatically by logic in the controller HW, and do not require any specific intervention from the user.

The application can transmitted the following power management messages by writing to the TI configuration wrapper instance [PCIECTRL\\_TI\\_CONF\\_PM\\_CTRL](#) register:

- [PCIECTRL\\_TI\\_CONF\\_PM\\_CTRL](#) [0]PME\_TURN\_OFF: (power management event, turn off) request from RC to turn off, broadcasted downstream.
- [PCIECTRL\\_TI\\_CONF\\_PM\\_CTRL](#)[1] PM\_PME: (power management event): request from EP to wake up, routed upstream towards RC.

No dedicated logic exists in the controller to support vendor-defined messages.

The ATU is capable of generating (outgoing) messages, and receiving (incoming) ones, by translating them from read/write accesses on the PCIe controller slave port, or to read/write accesses on the PCIe controller master port, respectively. However, this functionality is not required for standard PCI operation.

### 24.9.4.9 PCIe Programming Register Interface

PCI is an memory-mapped, dynamically reconfigurable interconnect protocol, so that the same physical register may be accessed in several different ways. The current chapter targets to describe only the statically-mapped programming registers of the local PCIe controller, accessed over the local AXI slave.

They are composed of:

- **PCIe-standard configuration registers:** by definition accessible over the PCIe wire through the PCIe configuration (and extended configuration - ECAM) space. Those registers are different depending on the selected mode (Type-0: EP or Type1: RC).
- **Port Logic (PL) registers:** non-standard user-accessible registers for additional PCIe functionality. They are also accessible over PCIe wire, in the configuration (ECAM) space.
- **TI-specific control and status registers:** more non-standard registers, accessible only locally. These are associated with the PCIe controller wrapper level functional control and status.

#### 24.9.4.9.1 PCIe Register Access

The [Table 24-687](#) summarizes how the resources of the local controller can be accessed. Note that the rightmost column represent accesses to the PCIe controller hosts system memory.

**Table 24-687. Summary of Access Types related to PCIe Controller Local Resources**

Access	PCIe standard configuration registers	Port Logic (PL) registers	TI-specific registers	System memory available to PCIe
Local DIF access (over PCIe controller target (slave) port, from device host CPUs and DMAs)	Yes <sup>(1)</sup> (CS or CS2)	Yes	Yes	No
Remote PCIe config (Cfg) transaction (over PCIe wire)	EP: Yes <sup>(1)</sup> RC: No <sup>(2)</sup>	EP: Yes RC: No <sup>(2)</sup>	No	No
Remote PCIe Memory transaction (over PCIe wire)	No	No	No	Yes (iATU)
Remote PCIe IO transaction (over PCIe wire)	No	No	No	EP: Yes (iATU) RC: No <sup>(3)</sup>

<sup>(1)</sup> 1. Read and writes to PCIe standard configuration registers (in PCIe config space, address 0x0 to 0x700) will give different results depending on the access method (DIF CS/CS2, PCIe): see .

<sup>(2)</sup> 2. PCIe Cfg transactions can only be issued by the RC (to an EP): A RC cannot receive one.

<sup>(3)</sup> 3. PCIe IO transactions can only be issued by the RC (to an EP): A RC cannot receive one.

#### 24.9.4.9.2 Double Mapping of the PCIe Local Control Registers

Each local programming register is mapped twice inside the controller’s local target, with an offset of 0x1000 (4 KiB) between the two mappings.

**The "low" mapping is the Data Interface (DIF) chip-select (CS) access.** In DIF CS mode, some fields that are read-only (RO) over PCI become writable if PL bit `PCICTRL_PL_DBI_RO_WR_EN[0]` `CX_DBI_RO_WR_EN=0b1` (default). This access is used by the local host (e.g. BIOS) for the initialization of the PCI device, prior to PCI protocol startup (LTSSM enable). Fields and registers that are CS-sensitive are labeled (CS) in the [Section 24.9.7](#).

**The "high" mapping is the Data Interface (DIF) chip-select-2 (CS2) access.** In DIF CS2 mode, some fields that are read-only (RO) over PCI or in DIF CS mode, become writable if PL bitfield `PCICTRL_PL_DBI_RO_WR_EN[0]` `CX_DBI_RO_WR_EN=0b1` (default). This access is also used by the local host for further initialization of the PCI device. Fields and registers that are CS2-sensitive are labeled (CS2) in the tables below.

- NOTE:** The following important notes on accesses must be considered by user for device PCIe controller:
- If PCIe\_SS\_PL\_CONF instance located bitfield [PCIECTRL\\_PL\\_DBI\\_RO\\_WR\\_EN\[0\]](#) CX\_DBI\_RO\_WR\_EN is cleared to 0b0, the "CS and CS2-sensitive" fields become read-only (RO) again, that is, they revert to the behaviour defined in the PCI/PCIe standards.
  - The standard PCI configuration registers (header, descriptors, extended descriptors) are the only ones that can change their behaviour in CS and CS2 access.
  - The port logic (PL) registers and the PCIe controller wrapper TI configuration registers are not affected by the CS: for those, the two mappings have the same properties, that is, they are perfect aliases
  - For an RC, which by definition cannot access its own (locally stored) configuration registers over the PCIe wire, the DIF access is the only alternative. The PCIe controller must present a PCI-standard-compliant type-1 configuration space to the RC software driver, that is, with none of the read-only bits actually writable, as follows:
    - the DIF CS access should be used
    - PL bitfield [PCIECTRL\\_PL\\_DBI\\_RO\\_WR\\_EN\[0\]](#) CX\_DBI\_RO\_WR\_EN should be cleared to 0b0 (after a pre-initialization, if required)

### 24.9.4.9.3 Base Address Registers (BAR) Initialization

The 6 base address registers ((EP) BAR0 through (EP) BAR5) supported in EP mode (Type0), get discovered and configured by the RC during PCI enumeration, as per the PCIe standard. Via the PCIe ECAM (enhanced configuration access) mechanism the RC maps a remote EP function's BAR registers in 64-bit PCIe memory space and software run on RC access them as the [PCIECTRL\\_EP\\_PCIEWIRE\\_BAR0](#) through [PCIECTRL\\_EP\\_PCIEWIRE\\_BAR5](#) registers. Note that the configuration space of the RC (Type1 registers) also contains two BARs ((RC) BAR0 and (RC) BAR1), but they are not expected to be used.

Before enumeration, BARs can be initialized by the local software, using DIF access (CS or CS2), to modify the properties seen by the RC at enumeration. The following can be configured in each BAR: enabling, IO or memory type, size (mask width). Even BAR numbers (0,2,4) can also be paired with the BAR number above (1,3,5) to create a single, 64-bit address (memory).

- NOTE:** If PCIe\_SS\_PL\_CONF instance located register [PCIECTRL\\_PL\\_DBI\\_RO\\_WR\\_EN\[0\]](#) CX\_DBI\_RO\_WR\_EN bit is cleared, most BAR fields become read-only again, behaving like in over-the-wire PCI Cfg writes by the RC. Only the BAR base address (MSbits) is still writable. The size/mask, type, and enabling become read-only.

**Table 24-688. PCIe Default BAR Configuration**

	Enabled <sup>(1)</sup>	Space <sup>(2)</sup> BARn[0]	Type <sup>(2)</sup> BARn[2:1]	Prefetch <sup>(2)</sup> BARn[3]	Mem Size <sup>(1)</sup> (M-bit mask)	I/O Size (M-bit mask)
<a href="#">(EP) BAR0</a>	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	1 MiB (20-bit)	256 Bytes (8-bit)
<a href="#">(EP) BAR1</a>	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	64 KiB (16-bit)	256 Bytes (8-bit)
<a href="#">(EP) BAR2</a>	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	1 MiB (20-bit)	256 Bytes (8-bit)
<a href="#">(EP) BAR3</a>	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	64 KiB (16-bit)	256 Bytes (8-bit)
<a href="#">(EP) BAR4</a>	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	4 KiB (12-bit)	256 Bytes (8-bit)
<a href="#">(EP) BAR5</a>	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	64 KiB (16-bit)	256 Bytes (8-bit)

<sup>(1)</sup> reprogrammable with DIF (CS2) access

<sup>(2)</sup> reprogrammable with DIF (CS) access

The [Table 24-689](#) and [Table 24-690](#) describe how a memory and IO BAR can be accessed, respectively. A single address of the PCIe config space is accessed for a given BAR, with each line of the table showing a different mode: read vs. write; PCIe Cfg access vs. DIF (CS) access vs. DIF (CS2) access.

"M" is the width of the BAR mask in bits, with 2<sup>M</sup> the BAR size in bytes. Bits M and above are writable by the RC over the PCIe wire to set the BAR base address, as follows:

- The value of M for a Memory BAR varies from 4 ( $2^4=16$  Byte = minimum size) to 32 ( $2^{32} = 4$  GiB for a 32-bit BAR, potentially more for a 64-bit BAR) depending on the BAR and on the configuration.
- The current implementation forces M=8 for an I/O BAR, that is, an IO BAR has a fixed size of  $2^8=256$  bytes, the maximum allowed by the PCIe protocol.

**Table 24-689. BARn Register Access Methods (Mem BAR)**

Method	BAR[31:M] <sup>(1)</sup>	BAR[M-1:4]	BAR[3]	BAR[2:1]	BAR[0]
PCI read	Base address readout	Read returns zero	Read out "Prefetchable"	Read out "Type"	Read out 0 "space decoder" <sup>(2)</sup>
PCI write	Base address write	No effect (masked = R/O)	No effect	No effect	No effect
CS read	Base address readout	Read returns zero (masked)	Read out "Prefetchable"	Read out "Type"	Read out 0 "space decoder" <sup>(2)</sup>
CS write	Base address write	No effect (masked = R/O)	Write "Prefetchable"	Write "Type"	Write "space decoder" <sup>(2)</sup>
CS2 read	Base address readout	Read returns zero (masked)	Read out "Prefetchable"	Read out "Type"	Read out 0 "space decoder" <sup>(2)</sup>
CS2 write	Write 0 to unmask (Sets M)	Write 1 to mask (Sets M)	Write 1	Write 1	Write "BAR enable"

<sup>(1)</sup> For M=32, the BAR mask is 32-bit wide, the BAR size is 4 GiB and the column disappears.

<sup>(2)</sup> Space decoder is Memory = 0 in this table.

**Table 24-690. BARn Register Access Methods (IO BAR)**

Method	BAR[31:8]	BAR[7:2]	BAR[1]	BAR[0]
PCI read	Base address readout	Read returns zero	Read out 0 (reserved bit)	Read out 1 "space decoder" <sup>(1)</sup>
PCI write	Base address write	No effect (masked = R/O)	No effect	No effect
CS read	Base address readout	Read returns zero (masked)	Read out 0 (reserved bit)	Read out 1 "space decoder" <sup>(1)</sup>
CS write	Base address write	No effect (masked = R/O)	Write 0 No effect	Write "space decoder" <sup>(1)</sup>
CS2 read	Base address readout	Read returns zero (masked)	Read out 0 (reserved)	Read out 1 "space decoder" <sup>(1)</sup>
CS2 write	Write 0. No effect in fixed-sized I/O BAR	Write 1. No effect in fixed-sized I/O BAR	Write 0 No effect	Write "BAR enable"

<sup>(1)</sup> Space decoder is I/O = 1 in this table.

## 24.9.5 PCIe Controller Low Level Programming Model

### 24.9.5.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the PCIe\_SS1 and PCIe\_SS2 controllers are used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the PCIe\_SS (for more information, see PCIe Controllers Integration and PCIe Controllers Environment). [Table 24-691](#) describes the global initialization of the surrounding modules.

**Table 24-691. Global Initialization of the PCIe Surrounding Modules**

Surrounding Modules	Comments
PRCM	Module functional and interface clocks must be enabled. (See <a href="#">Section 3.6, Clock Management Functional Description</a> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .)
Control Module	Module configuration must be done in control module. See <a href="#">Section 18.5, CTRL_MODULE_CORE Registers</a> and <a href="#">Table 24-676, PCIe Port Configuration</a>
(Optional) IRQ_CROSSBAR	Interrupt crossbar configuration must be done to map the interrupts from the PCIe Controllers to a certain device processor INTC via the IRQ_CROSSBAR module. For more details on IRQ_CROSSBAR programming, see <a href="#">Section 18.4.6.4, IRQ_CROSSBAR Module Functional Description</a> , in <a href="#">Chapter 18, Control Module</a> .
(Optional) A local INTC	The local interrupt controller must be configured to enable the interrupt once IRQ output is mapped on INTC via the IRQ_CROSSBAR. See <a href="#">Chapter 17, Interrupt Controllers</a> .
L4 and L3_MAIN interconnects	For more information about the interconnect configuration, see <a href="#">Section 14.2.3.2.1, L3_MAIN Interconnect Agents</a> , and <a href="#">Section 14.3.1, L4 Interconnect Overview</a> , in <a href="#">Chapter 14, Interconnects</a> .
(Optional) Device MMU2	For more information on the configuration for routing the PCIe_SS1,2 master port traffic through the device MMU2, see <a href="#">Section 24.9.4.3.1.1</a> , as well as <a href="#">Chapter 20, Memory Management Units</a> .

**NOTE:** The interrupt configuration is required when using interrupt communication mode.

### 24.9.5.2 Main Sequence of PCIe Controllers Initialization

**NOTE:** This section aims to describe only the basic steps that must be followed by PCIe application software in order for a PCIe RC or EP type device to initialize, establish PCIe connectivity and interact with devices on the PCIe fabric. For this reason, it focuses on settings of the PCIe controllers wrapper registers (and not on PCI/PCIe standard and non-standard (PL) registers), through which PCIe application interacts with PCIe devices.

**Table 24-692. Main Sequence PCIe Controller Global Initialization**

RC and/or EP Initialization Step <sup>(1)</sup>	Register/Bit Field/Programming Model	Value
1. Initialize the DPLL_PClE_REF (clock source, dividers, power dependencies) in PRCM	Refer to <a href="#">Section 26.4.5</a>	
2. Assert a local software main reset to the PCIe_SS1,2 controllers	PRCM.RM_PCISS_RSTCTRL[0] RST_LOCAL_PCIE1 PRCM.RM_PCISS_RSTCTRL[1] RST_LOCAL_PCIE2	0b1
3. Poll main reset completion status for the PCIe_SS1,2 controllers	PRCM.RM_PCISS_RSTST[0] RST_LOCAL_PCIE1 PRCM.RM_PCISS_RSTST[1] RST_LOCAL_PCIE2	=0b1
4. Perform tuning of the PCIe PHY	Refer to <a href="#">Section 26.4.5</a>	
<b>IF:</b> required operation mode for PCIe controller is "RC"	Software Test Condition	

<sup>(1)</sup> Unless a step is not marked as "[EP Only]" or "[RC Only]", the initialization step should be considered as applicable in both EP and RC modes of PCIe controller.

**Table 24-692. Main Sequence PCIe Controller Global Initialization (continued)**

RC and/or EP Initialization Step <sup>(1)</sup>	Register/Bit Field/Programming Model	Value
5. Select RC type	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	0x4 (default)
6. Poll to insure a fundamental reset has completed	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	=0x4
7. Make sure LTSSM_EN is kept by RC's software at value 0b0	PCIECTRL_TI_CONF_DEVICE_CMD[0] LTSSM_EN	0b0
8. Initialize RC PCIe controller's core registers.	See <a href="#">Table 24-694</a>	
9. Clear the IRQ main status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MAIN[31:0]	0xFFFFFFFF
10. First time enable PCIe main interrupts. Depends on which PCIe protocol events and error events will be handled by application.	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN [14:0]	0x-
11. Clear the IRQ msi status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MSI[31:0]	0xFFFFFFFF
12. [optional step] Enable INTx (x=A,B,C,D) interrupts reception (generated from legacy EPs to RC) but disable MSI interrupts reception at the same time. OR Enable the MSI interrupts reception (MSI interrupts are generated to RC from PCIe EPs only) but disable the INTx interrupts reception at the same time	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI [3:0] INTx_EN	0x-
	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI [4] MSI_EN	0b1
	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI [4] MSI_EN	0b1
	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI [3:0] INTx_EN	0xF
<b>ELSE IF:</b> required operation mode for PCIe controller is "PCIe EP"		
5. Select "PCIe EP" type	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	0x0
6. Poll to insure fundamental reset has completed	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	=0x0
7. Make sure LTSSM_EN is kept by EP's software at value 0b0	PCIECTRL_TI_CONF_DEVICE_CMD[0] LTSSM_EN	0b0
8. Initialize EP PCIe controller's core registers	See <a href="#">Table 24-693</a>	
9. Clear the IRQ main status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MAIN[31:0]	0xFFFFFFFF
10. First time enable -PCIe main interrupts. Depends on which PCIe protocol events and error events will be handled by application.	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN [14:0]	0x-
11. Clear the IRQ msi status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MSI[31:0]	0xFFFFFFFF
12. Disable both INTx (x=A,B,C,D) and MSI interrupts reception.	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI [4:0]	0x1F
<b>ELSE:</b>		
5. Select "PCI Legacy EP" type	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	0x1
6. Poll to insure fundamental reset has completed	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	=0x1
7. Make sure LTSSM_EN is kept by EP's software at value 0b0	PCIECTRL_TI_CONF_DEVICE_CMD[0] LTSSM_EN	0b0
8. Initialize EP controller local registers via DIF CS/CS2 accesses	See <a href="#">Table 24-693</a>	
9. Clear the IRQ main status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MAIN[31:0]	0xFFFFFFFF
10. First time enable PCIe main interrupts. Depends on which PCIe protocol events and error events will be handled by application.	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN [14:0]	0x-
11. Clear the IRQ main status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MSI[31:0]	0xFFFFFFFF
12. Disable both INTx (x=A,B,C,D) and MSI interrupts reception	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI [4:0]	0x1F
<b>ENDIF</b>		

**Table 24-692. Main Sequence PCIe Controller Global Initialization (continued)**

RC and/or EP Initialization Step <sup>(1)</sup>	Register/Bit Field/Programming Model	Value
13. PCIe (RC/EP) controller enables the link. It is supposed that all active EPs attached on the PCIe fabric synchronously enable their LTSSM engine with the RC.	<a href="#">PCIECTRL_TI_CONF_DEVICE_CMD</a> [0] LTSSM_EN	0b1
14. Local CPU polls until the PCIe Controller link is up (that is, brought into L0- power state)	<a href="#">PCIECTRL_TI_CONF_PHY_CS</a> [16] LINK_UP	=0b1
15. If <a href="#">PCIECTRL_TI_CONF_IRQSTATUS_MAIN</a> [3] LINK_UP_EVT has been enabled in step (10), this means it should be cleared	<a href="#">PCIECTRL_TI_CONF_IRQSTATUS_MAIN</a> [12] LINK_UP_EVT	0b1
16. RC host starts link training sequence, negotiation with EPs, enumeration of the EPs, and initializes the descriptors per each of the discovered EP functions. Example: RC initializes the MSI message vectors table per each of the EPs. RC maps the EPs global PCIe Memory per each EP function appropriately initializing the BARn registers MSB part.		
17. [RC only] <b>IF:</b> an EP is a requester, the RC remotely enables its BME bit via an ECAM access to the EP's command /status register.	PCIe_SS1_EP_CFG_PClc. <a href="#">PCIECTRL_EP_PCIEWIRE_STATUS_COMMAND_REGISTER</a> [2] BUSMASTER_EN	0b1
18. [RC only] <b>IF:</b> an EP is a completer, the RC remotely enables its MSE (for Mem transfers) or ISE bits (for legacy I/O transfers) via an ECAM access to the EP's command/status register.	PCIe_SS1_EP_CFG_PClc. <a href="#">PCIECTRL_EP_PCIEWIRE_STATUS_COMMAND_REGISTER</a> [1] MEM_SPACE_EN OR PCIe_SS1_EP_CFG_PClc. <a href="#">PCIECTRL_EP_PCIEWIRE_STATUS_COMMAND_REGISTER</a> [0] IO_SPACE_EN	0b1
19. [EP only] Before EP's application generates a request (that is, requester EP), the EP application must insure that its local BME_EVT status has already been asserted to 0b1 by the RC host controller.  The EP must locally clear the BME interrupt, writing BME_EVT_MSG flag to 0b1 (Wr1toClr).	<a href="#">PCIECTRL_TI_CONF_IRQSTATUS_MAIN</a> [13] BME_EVT_MSG OR <a href="#">PCIECTRL_TI_CONF_IRQSTATUS_RAW_MAIN</a> [13] BME_EVT_MSG	=0b1
20. [RC only] Before RC application initiates a request to a completer EP function with a <i>Memory type BAR</i> , the RC must check that EP's MEM_SPACE_EN flag has already been asserted by the RC host. This is done via an ECAM remote access by RC to EP's command/status register. [EP Only] The EP's CPU is notified about remote MEM_SPACE_EN flag assertion in a dedicated bit that can be enabled to generate an interrupt. The interrupt flag is cleared via writing to 0b1 (Wr1toClr).	PCIe_SS1,2_EP_CFG_PClc. <a href="#">PCIECTRL_EP_PCIEWIRE_STATUS_COMMAND_REGISTER</a> [1] MEM_SPACE_EN	=0b1
	The EP application may receive an interrupt (if enabled – see step 10) indicated in the <a href="#">PCIECTRL_TI_CONF_IRQSTATUS_MAIN</a> [14] MSE_EVT_MSG. Or poll this in <a href="#">PCIECTRL_TI_CONF_IRQSTATUS_RAW_MAIN</a> [14] MSE_EVT_MSG.	0b1
20. [RC only] Before RC application initiates a request to a completer EP function with an <i>I/O type BAR</i> , the RC must check that EP's IO_SPACE_EN flag has already been asserted by the RC host. This is done via an ECAM remote read access by RC to EP's command/status register.	PCIe_SS1,2_EP_CFG_PClc. <a href="#">PCIECTRL_EP_PCIEWIRE_STATUS_COMMAND_REGISTER</a> [0] IO_SPACE_EN	=0b1
[EP Only] Unlike Mem type EPs, there is no interrupt event to notify the EP about its ISE flag being asserted by the RC. So, to be aware of an incoming transaction, I/O legacy EP must poll local IO_SPACE_EN flag until its asserted by RC to 0b1.	<a href="#">PCIECTRL_EP_DBICS_STATUS_COMMAND_REGISTER</a> [0] IO_SPACE_EN	=0b1
[EP Only] 21. IF IO_SPACE_EN bit has been set to '1' for a legacy EP, user must force the legacy EP master port out-of-standby (before first transaction). There is no automatical standby generation for I/O transfers.	<a href="#">PCIECTRL_TI_CONF_SYSCONFIG</a> [5:4] STANDBYMODE	0x1

**Table 24-693. Local EP (Type 0) PCIe Standard and Port Logic Registers Initialization Subsequence**

8.1 Initialize PCI standard configuration header registers via corresponding DIF CS/CS2 accesses. Example: BAR MASK0 – BAR MASK5 (that must be entirely initialized by the EP, and LSB part of the BAR0 – BAR5 registers)	For more details on these settings, refer to the <i>PCI Express Base 3.0 Specification, revision 1.0</i>
8.2 Initialize the RC PCIe capability registers via corresponding DIF CS/CS2 accesses.	For more details on these settings, refer to the <i>PCI Express Base 3.0 Specification, revision 1.0</i>
8.3 Initialize the RC PCIe Port Logic registers. Example: iATU settings of internal local address ranges, link settings – link powers, timings, and so forth	

**Table 24-694. RC (Type 1) PCIe Standard and Port Logic Registers Initialization Subsequence**

RC must enable write operation to be able to configure its own PCIe standard and PL registers.	<a href="#">PCIECTRL_PL_DBI_RO_WR_EN[0]</a> CX_DBI_RO_WR_EN	0b1
8. 1 Initialize RC PCI standard configuration header registers via corresponding DIF CS/CS2 accesses. (Example: RC BAR 0,1 and BAR MASK0,1 registers.)	For more details on these settings, refer to the <i>PCI Express Base 3.0 Specification, revision 1.0</i>	
8.2 Initialize the RC PCIe capability registers via corresponding DIF CS/CS2 accesses.	For more details on these settings, refer to the <i>PCI Express Base 3.0 Specification, revision 1.0</i>	
8.3 Initialize the RC PCIe Port Logic registers. Example: iATU settings of internal local address ranges, link settings – link power, timings, and so forth Prepare the MSI vectors, Setup of the MSI, others.		
Disable write operation in RC PCIe standard and PL registers.	<a href="#">PCIECTRL_PL_DBI_RO_WR_EN[0]</a> CX_DBI_RO_WR_EN	0b0

**NOTE:** When the PCIe\_SS1 controller is configured to operate in two lane mode, by default lane 0 is mapped to the PCIe1\_PHY (device PCIe PHY port 0), and lane 1 is mapped to the PCIe2\_PHY (device PCIe PHY port 1). The PCIe\_SS1\_TI\_CONF wrapper located software control - [PCIECTRL\\_TI\\_CONF\\_PHY\\_CS\[0\]](#) REVERSE\_LANES allows user software to swap mapping of the PCIe\_SS1 controller lane 0 and lane 1 on the two device PCIe PHY ports (swapping the RX and TX paths simultaneously with polarity of an individual lane unchanged). Note that the identical control is not functional in the PCIe\_SS2\_TI\_CONF, because the PCIe\_SS2 can operate in a single lane mode only, and (if selected) its lane 0 is always mapped to the PCIe PHY port 1 (that is, PCIe2\_PHY).

## 24.9.6 PCIe Standard Registers vs PCIe Subsystem Hardware Registers Mapping

The below tables provide the PCIe/PCI standard logical registers versus PCIe controller hardware registers mapping in the device.

**Table 24-695. PCIe Type-0 (EP) Configuration Standard Capability Registers vs PCIe Controller Hardware Registers Mapping**

PCIe Standard Register Name	PCIe_SS1_EP_CFG_PClE and PCIe_SS2_EP_CFG_PClE Corresponding Register <sup>(1)</sup>	PCIe_SS1_EP_CFG_DBICS and PCIe_SS2_EP_CFG_DBICS Corresponding Register <sup>(2)</sup>	PCIe_SS1_EP_CFG_DBICS2 and PCIe_SS2_EP_CFG_DBICS2 Corresponding Register <sup>(3)</sup>

## 24.9.7 PCIe Controller Register Manual

### 24.9.7.1 PCIe Controller Instance Summary

**Table 24-699. PCIe\_SS1 Instance Summary**

Module Name	Module Base Address	Size
<a href="#">PCIe_SS1_EP_CFG_PCIE</a>	ECAM_Param_Base_Addr <sup>(1)</sup> + 0x2000 0000	4 KiB
<a href="#">PCIe_SS1_EP_CFG_DBICS</a>	0x5100 0000	128 Bytes
<a href="#">PCIe_SS1_RC_CFG_DBICS</a>	0x5100 0000	128 Bytes
<a href="#">PCIe_SS1_PL_CONF</a>	0x5100 0700	500 Bytes
<a href="#">PCIe_SS1_EP_CFG_DBICS2</a>	0x5100 1000	128 Bytes
<a href="#">PCIe_SS1_RC_CFG_DBICS2</a>	0x5100 1000	128 Bytes
<a href="#">PCIe_SS1_TI_CONF</a>	0x5100 2000	332 Bytes

<sup>(1)</sup> ECAM\_Param\_Base\_Addr = 0x0000\_0000 to 0x0FFF\_F000

**Table 24-700. PCIe\_SS2 Instance Summary**

Module Name	Module Base Address	Size
<a href="#">PCIe_SS2_EP_CFG_PCIE</a>	ECAM_Param_Base_Addr <sup>(1)</sup> + 0x3000 0000	4 KiB
<a href="#">PCIe_SS2_EP_CFG_DBICS</a>	0x5180 0000	128 Bytes
<a href="#">PCIe_SS2_RC_CFG_DBICS</a>	0x5180 0000	128 Bytes
<a href="#">PCIe_SS2_PL_CONF</a>	0x5180 0700	500 Bytes
<a href="#">PCIe_SS2_EP_CFG_DBICS2</a>	0x5180 1000	128 Bytes
<a href="#">PCIe_SS2_RC_CFG_DBICS2</a>	0x5180 1000	128 Bytes
<a href="#">PCIe_SS2_TI_CONF</a>	0x5180 2000	332 Bytes

<sup>(1)</sup> ECAM\_Param\_Base\_Addr = 0x0000\_0000 to 0x0FFF\_F000

**NOTE:** The *ECAM\_Param\_Base\_Addr* variable is the 16-bit **base address** (this address is 4 KiB-aligned with value in the range: 0x0000\_0000 - 0x0FFF\_F000) of the relevant EP function descriptor (relevant EP's function PCIe standard and PL configuration registers) **in a contiguous 256-MiB ECAM space** (0x0000\_0000 - 0x0FFF\_FFFF). For more information on the PCIe ECAM configuration space mapping mechanism, refer to the section *PCI Express Enhanced Configuration Access Mechanism (ECAM)*, in the *PCI Express Base 3.0 Specification, Revision 1.0*.

For information on the EP's function PL register offsets and descriptions, refer to the [Section 24.9.7.5](#).

### 24.9.7.2 PCIe\_SS\_EP\_CFG\_PCIe Registers

**NOTE:** This section describes the PCIe EP mode (PCIe type-0) standard configuration registers as they are accessed over PCIe wire logic and not via DIF CS/CS2 accesses. These register names are prefixed with "PCIECTRL\_EP\_PCIEWIRE".

#### 24.9.7.2.1 PCIe\_SS\_EP\_CFG\_PCIe Register Summary

**Table 24-701. PCIe\_SS1\_EP\_CFG\_PCIe Registers Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	PCIe_SS1_EP_CFG_PCIe Physical Address
<a href="#">PCIECTRL_EP_PCIEWIRE_DEVICE_VENDORID</a>	R	32	0x0	ECAM_Param_Base_Addr <sup>(1)</sup> + 0x2000 0000

**NOTE:** The *ECAM\_Param\_Base\_Addr* variable is the 16-bit base address (this address is 4 KiB-aligned with value in the range: 0x0000\_0000 - 0x0FFF\_F000) of the relevant EP function descriptor (relevant EP's function PCIe standard and PL configuration registers) in a contiguous 256-MiB ECAM space (0x0000\_0000 - 0x0FFF\_FFFF). For more information on the PCIe ECAM configuration space mapping mechanism, refer to the section *PCI Express Enhanced Configuration Access Mechanism (ECAM)*, in the *PCI Express Base 3.0 Specification, Revision 1.0*.

For information on the EP's function PL register offsets and descriptions, refer to [Section 24.9.7.5](#).

### 24.9.7.3 PCIe\_SS\_EP\_CFG\_DBICS Registers

**NOTE:** This section describes the PCIe EP mode (PCIe type-0) standard configuration registers as they are locally accessed within the DIF CS space. These register names are prefixed with "PCIECTRL\_EP\_DBICS".

#### 24.9.7.3.1 PCIe\_SS\_EP\_CFG\_DBICS Register Summary

**Table 24-755. PCIe\_SS1\_EP\_CFG\_DBICS Registers Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	PCIe_SS1_EP_CFG_DBICS Physical Address
PCIECTRL_EP_DBICS_DEVICE_VENDORID	RW	32	0x0	0x5100 0000

### 24.9.7.4 PCIe\_SS\_RC\_CFG\_DBICS Registers

**NOTE:** This section describes the PCIe RC mode (PCIe type-1) standard configuration registers as they are locally accessed within the DIF CS space. These register names are prefixed with "PCIECTRL\_RC\_DBICS".

#### 24.9.7.4.1 PCIe\_SS\_RC\_CFG\_DBICS Register Summary

**Table 24-817. PCIe\_SS1\_RC\_CFG\_DBICS Registers Mapping Summary**

### 24.9.7.5 PCIe\_SS\_PL\_CONF Registers

**NOTE:** The [Section 24.9.7.5.1](#) lists the implementation-specific (that is, not PCIe-standard) “port logic” - PL registers, mapped in the 4-KiB PCIe configuration space along with the PCIe-standard registers already described. Unlike the standard registers, port logic (PL) registers are not affected by the device type (Type-0/EP vs. Type-1/RC).

**NOTE:** Besides at the (DIF CS space) physical addresses listed in below tables, the PCIe PL configuration registers are also locally accessible (aliased) at the (DIF CS2 space) base address 0x5100\_1700 (PCIe\_SS1) and 0x5180\_1700 (PCIe\_SS2), without any difference in PL registers behaviour between CS and CS2 spaces. There is also no difference in PL registers behaviour between PCIe wire remote accesses and local (DIF CS,CS2) accesses.

#### 24.9.7.5.1 PCIe\_SS\_PL\_CONF Register Summary

<b>Address Offset</b>	0x0000 0000	<b>Instance</b>	PCIe_SS1_PL_CONF PCIe_SS2_PL_CONF
<b>Physical Address</b>	0x5100 0700 0x5180 0700		
<b>Description</b>	Ack Latency and Replay Timer Register		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REPLAY_TIME_LIMIT																ACK_LATENCY_TIME_LIMIT															

Bits	Field Name	Description	Type	Reset
31:16	REPLAY_TIME_LIMIT	The replay timer expires when it reaches this limit; The core initiates a replay upon reception of a Nak or when the replay timer expires; The default value depends on number of bytes (NB) per cycle, which is defined by the maximum core base frequency of the device PCIe core, corresponding to 250 MHz for PCIe-Gen2 (5 Gbps) operation. The default is then updated based on the Negotiated Link Width and Max_Payload_Size; Note: If operating at 5 Gb/s, then the rounded-up value of an additional (153/CX_NB) cycles is added, where CX_NB correspond to the number of PCIePCS 8-bit input symbols per single 16-bit lane, that is, CX_NB=2. This means at 5Gbps, 77 extra cycles should be considered for the replay time limit. This is for additional internal processing for received TLPs and transmitted DLLPs.	RW	0xc0
15:0	ACK_LATENCY_TIME_LIMIT	The Ack/Nak latency timer expires when it reaches this limit; The default value depends on number of bytes (NB) per cycle, which is defined by the maximum core base frequency of the device PCIe core, corresponding to 250 MHz for PCIe-Gen2 (5 Gbps) operation. The default is then updated based on the Negotiated Link Width and Max_Payload_Size. Note: If operating at 5 Gb/s, then the rounded-up value of an additional (51 /CX_NB) cycles is added, where CX_NB correspond to the number of PCIePCS 8-bit input symbols per single 16-bit lane, that is, CX_NB=2. This means at 5Gbps, 26 extra cycles should be considered for the acknowledge latency time limit. This is for additional internal processing for received TLPs and transmitted DLLPs.	RW	0x40

### 24.9.7.7 PCIe\_SS\_RC\_CFG\_DBICS2 Registers

**NOTE:** This section describes the PCIe RC mode (PCIe type-1) standard configuration registers as they are locally accessed within the DIF CS2 space. These register names are prefixed with "PCIECTRL\_RC\_DBICS2".

#### 24.9.7.7.1 PCIe\_SS\_RC\_CFG\_DBICS2 Register Summary

**Table 24-1015. PCIe\_SS1\_RC\_CFG\_DBI\_CS2 Registers Mapping Summary**

Bits	Field Name	Description	Type	Reset
31	DETECT_PARERR	Detected Parity Error	RW	0x0
30	SIGNAL_SYSERR	Signaled System Error	RW	0x0
29	RCVD_MASTERABORT	Received Master Abort	RW	0x0
28	RCVD_TRGTABORT	Received Target Abort	RW	0x0
27	SIGNAL_TRGTABORT	Signaled Target Abort	RW	0x0
26:25	DEVSEL_TIME	DevSel Timing, Harsdwired to 0 for PCIeExpress	R	0x0
24	MASTERDATA_PARERR	Master Data Parity Error	RW	0x0
23	FAST_B2B	Back to Back Capable, Harsdwired to 0 for PCIeExpress	R	0x0
22	RESERVED	Reserved	R	0x0
21	C66MHZ_CAP	66MHz Capable, Harsdwired to 0 for PCIeExpress	R	0x0
20	CAP_LIST	Capabilities List Hardwired to 1	R	0x1
19	INTX_STATUS	INTx Status	R	0x0
18:11	RESERVED		R	0x0
10	INTX_ASSER_DIS	INTx Assertion Disable	RW	0x0
9	FAST_BBEN	Bit hardwired to 0 for PCIeExpress	R	0x0
8	SERR_EN	SERR Enable	RW	0x0
7	IDSEL_CTRL	Bit hardwired to 0 for PCIeExpress	R	0x0
6	PARITYERRRESP	Parity Error Response	RW	0x0
5	VGA_SNOOP	Not Applicable forPCI Express; Bit hardwired to 0 for PCIeExpress	R	0x0
4	MEMWR_INVA	Not Applicable for PCI Express; Bit hardwired to 0 for PCIeExpress	R	0x0
3	SPEC_CYCLE_EN	Not Applicable for PCI Express; Bit hardwired to 0 for PCIeExpress	R	0x0
2	BUSMASTER_EN	Bus Master Enable (BME)	RW	0x0
1	MEM_SPACE_EN	Memory Space Enable (MSE)	RW	0x0
0	IO_SPACE_EN	IO Space Enable (ISE)	RW	0x0

## 24.9.7.8 PCIe\_SS\_TI\_CONF Registers

### 24.9.7.8.1 PCIe\_SS\_TI\_CONF Register Summary

**NOTE:** Though the PCIe controller wrapper TI configuration registers are also accessible (aliased) at base address 0x5100\_3000 (PCIe\_SS1) and 0x5180\_3000 (PCIe\_SS2), the preferable base addresses to access them are the ones used in above table, that is, 0x5100\_2000 and 0x5180\_2000. These registers are visible only within the device L3\_MAIN space.

**Table 24-1075. PCIe\_SS1\_TI\_CONF Registers Mapping Summary**

## 24.10 DCAN

This chapter describes the controller area network modules (DCAN) in the device.

### 24.10.1 DCAN Overview

The Controller Area Network (CAN) is a serial communications protocol which efficiently supports distributed real-time applications. CAN has high immunity to electrical interference and the ability to self-diagnose and repair data errors. In a CAN network, many short messages are broadcast to the entire network, which provides for data consistency in every node of the system.

The device supports two DCAN modules, referred to as DCAN1 and DCAN2, connecting to the CAN network through external (for the device) transceivers. The DCAN modules support bit rates up to 1 Mbit/s and are compliant to the CAN 2.0B protocol specification

Figure 24-164 shows the DCAN1 module highlights.

Figure 24-164. DCAN1 Overview

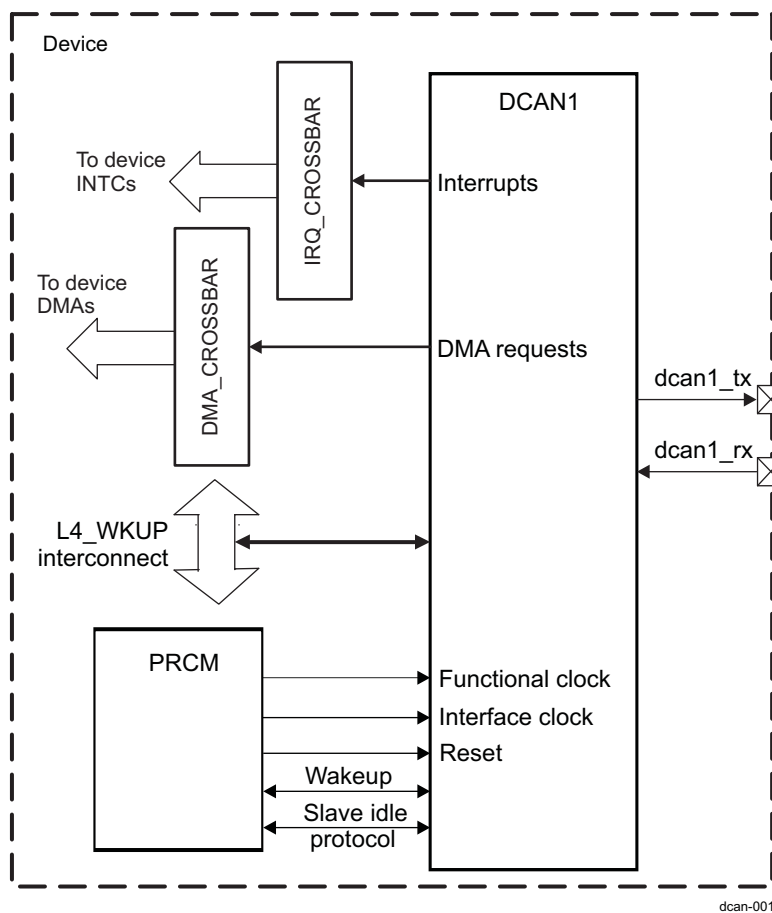

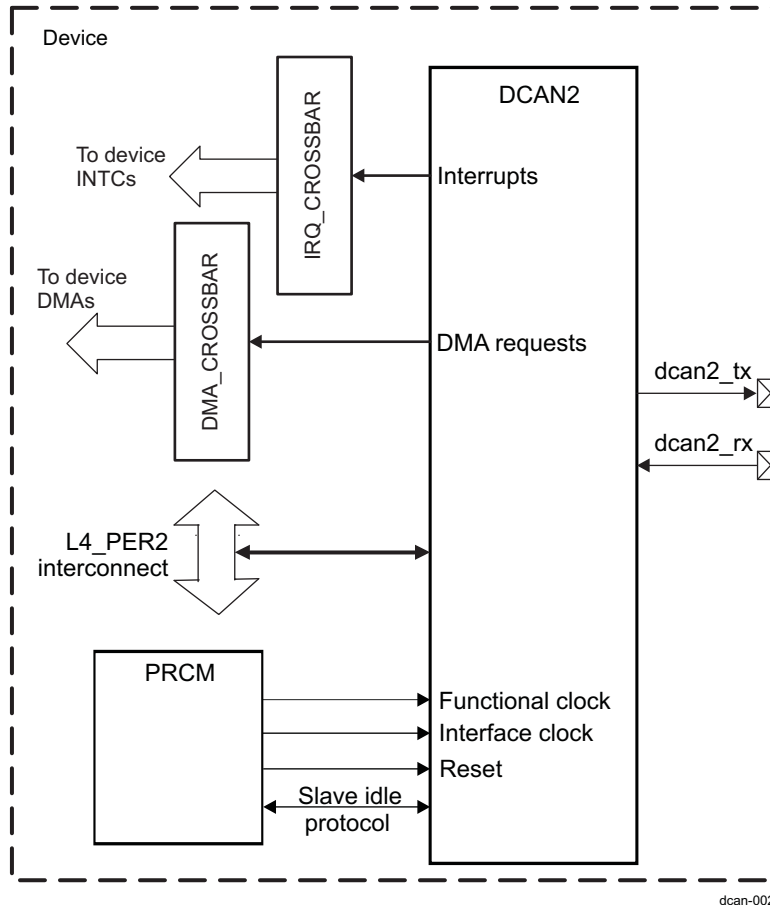

Figure 24-165 shows the DCAN2 module highlights .

**Figure 24-165. DCAN2 Overview**

### 24.10.1.1 Features

The DCAN module implements the following features:

- Support for CAN protocol version 2.0 part A, B
- Bit rates up to 1 Mbit/s
- 64 message objects in a dedicated message RAM
- Individual identifier mask for each message object
- Programmable FIFO mode for message objects
- Programmable loop-back modes for self-test operation
- Suspend mode for debug support
- Automatic bus on after Bus-Off state by a programmable 32-bit timer
- Message RAM parity check mechanism
- Direct access to message RAM during test mode
- Support for two interrupt lines: Level 0 and Level 1, plus separate parity error interrupt line
- Local power down and wakeup support
- Automatic message RAM initialization
- Support for DMA access

### 24.10.2 DCAN Environment

CAN network physical layer consists of two-wire differential bus, usually twisted pair, and provides high level of interference immunity. External CAN transceiver IC is needed to access a CAN bus by the DCAN.

Figure 24-166 shows an overview of a typical DCAN application.

Figure 24-166. DCAN Typical Application

Table 24-1119 describes the external signals of the DCAN1 module.

Table 24-1119. DCAN2 I/O Description

Module Signal	Device Signal	I/O <sup>(1)</sup>	Description	Value at Reset
CAN_RX	dcan2_rx	I	Serial data input from external CAN transceiver	HiZ
CAN_TX	dcan2_tx	O	Serial data output to external CAN transceiver	1

<sup>(1)</sup> I = Input; O = Output

Table 24-1120 describes the external signals of the DCAN2 module.

Table 24-1120. DCAN1 I/O Description

Module Signal	Device Signal	I/O <sup>(1)</sup>	Description	Value at Reset
CAN_RX	dcan1_rx	I	Serial data input from external CAN transceiver	HiZ
CAN_TX	dcan1_tx	O	Serial data output to external CAN transceiver	1

<sup>(1)</sup> I = Input; O = Output

**NOTE:** The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see [Section 18.4.6.1.1, Pad Configuration Registers of Chapter 18, Control Module](#).

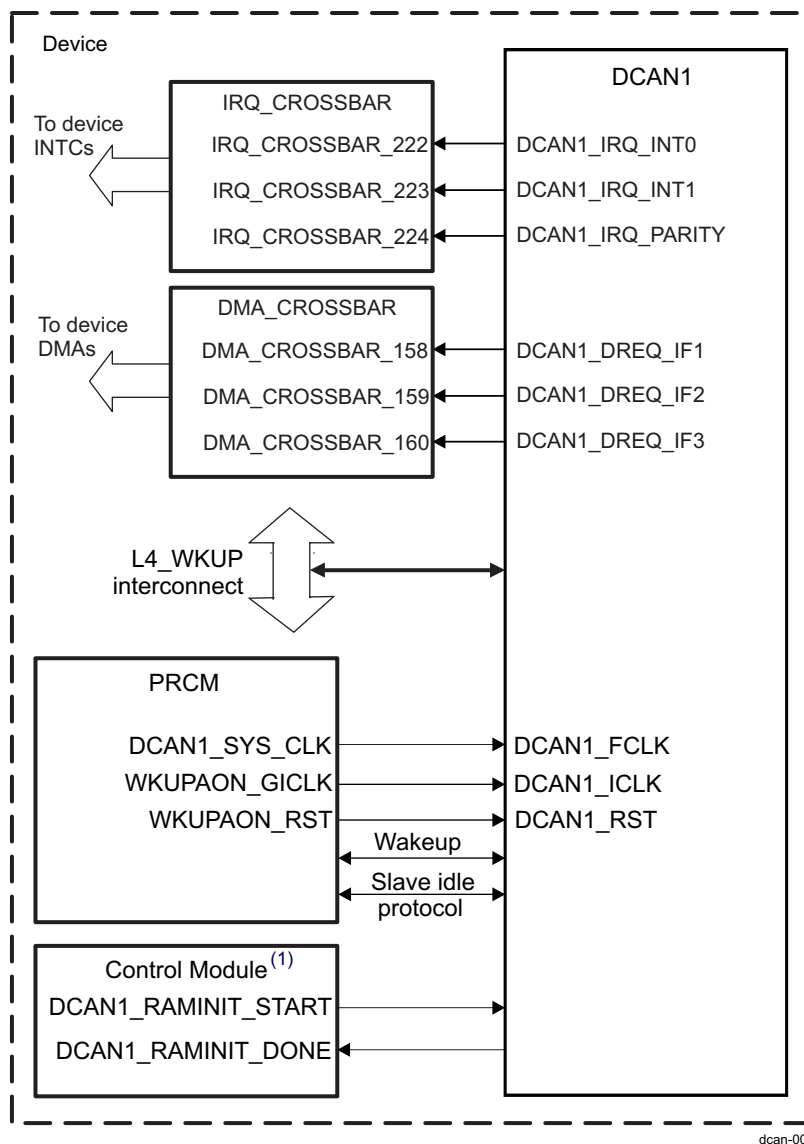

### 24.10.2.1 CAN Network Basics

- CAN bus is a 2-wire differential bus using NRZ encoding and has two states:
  - Recessive state (logic 1)
  - Dominant state (logic 0)
- The network is multimaster. When two or more nodes attempt to transmit at the same time, a non-destructive arbitration technique guarantees messages are sent in order of priority and no messages are lost
- The message transmission is multicast. Data messages transmitted are identifier based, not address based
- Content of message is labeled by the identifier that is unique throughout the network (for example, rpm, temperature, position, pressure, etc.)
- All nodes on network receive the message and each performs an acceptance test on the identifier. If message is relevant, it is processed, otherwise it is ignored
- The unique identifier also determines the priority of the message (the lower the numerical value of the identifier, the higher the priority is)
- Data is transmitted and received using message frames, consisting of:
  - Arbitration field
  - Control field
  - Data field (0 ÷ 8 bytes)
  - CRC field
  - ACK field.

### 24.10.3 DCAN Integration

Figure 24-167 shows the integration of the DCAN1 module in the device.

Figure 24-167. DCAN1 Integration

<sup>(1)</sup> For more information on DCAN RAM Initialization see [Section 24.10.4.12.1.3, DCAN RAM Hardware Initialization](#)

Figure 24-168 shows the integration of the DCAN2 module in the device .

Figure 24-168. DCAN2 Integration

dcan-005

(1) For more information on DCAN RAM Initialization see [Section 24.10.4.12.1.3](#), *DCAN RAM Hardware Initialization*

[Table 24-1121](#) through [Table 24-1123](#) summarize the integration of the DCAN modules in the device.

Table 24-1121. DCAN Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect

**Table 24-1123. DCAN Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	IRQ_CROSSBAR Input	Default Mapping	Description
DCAN1	DCAN1_IRQ_INT0	IRQ_CROSSBAR_222	-	Error, Status, and Message Objects interrupt
	DCAN1_IRQ_INT1	IRQ_CROSSBAR_223	-	Message Objects interrupt
	DCAN1_IRQ_PARITY	IRQ_CROSSBAR_224	-	Parity error interrupt
DCAN2	DCAN2_IRQ_INT0	IRQ_CROSSBAR_225	-	Error, Status, and Message Objects interrupt
	DCAN2_IRQ_INT1	IRQ_CROSSBAR_226	-	Message Objects interrupt
	DCAN2_IRQ_PARITY	IRQ_CROSSBAR_227	-	Parity error interrupt
DMA Requests				
Module Instance	Source Signal Name	DMA_CROSSBAR Input	Default Mapping	Description
DCAN1	DCAN1_DREQ_IF1	DMA_CROSSBAR_158	-	DMA request for IF1 register set
	DCAN1_DREQ_IF2	DMA_CROSSBAR_159	-	DMA request for IF2 register set
	DCAN1_DREQ_IF3	DMA_CROSSBAR_160	-	DMA request for IF3 register set
DCAN2	DCAN2_DREQ_IF1	DMA_CROSSBAR_161	-	DMA request for IF1 register set
	DCAN2_DREQ_IF2	DMA_CROSSBAR_162	-	DMA request for IF2 register set
	DCAN2_DREQ_IF3	DMA_CROSSBAR_163	-	DMA request for IF3 register set

**NOTE:** DCAN has no default IRQ mappings through the IRQ\_CROSSBAR. For DCAN, the IRQ\_CROSSBAR module must be configured prior to unmask interrupts in the interrupt controller(s).  
For more information about the IRQ\_CROSSBAR module, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#).  
For more information about the device interrupt controllers, see [Chapter 17, Interrupt Controllers](#).

**NOTE:** For more information about the DMA\_CROSSBAR module, see [Section 18.4.6.5, DMA\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#).

**NOTE:** For the description of the interrupt source, see [Section 24.10.4.2, Interrupt Functionality](#).

### 24.10.4 DCAN Functional Description

The DCAN module performs CAN protocol communication according to ISO 11898-1. The bit rate can be programmed to values up to 1 Mbit/s. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

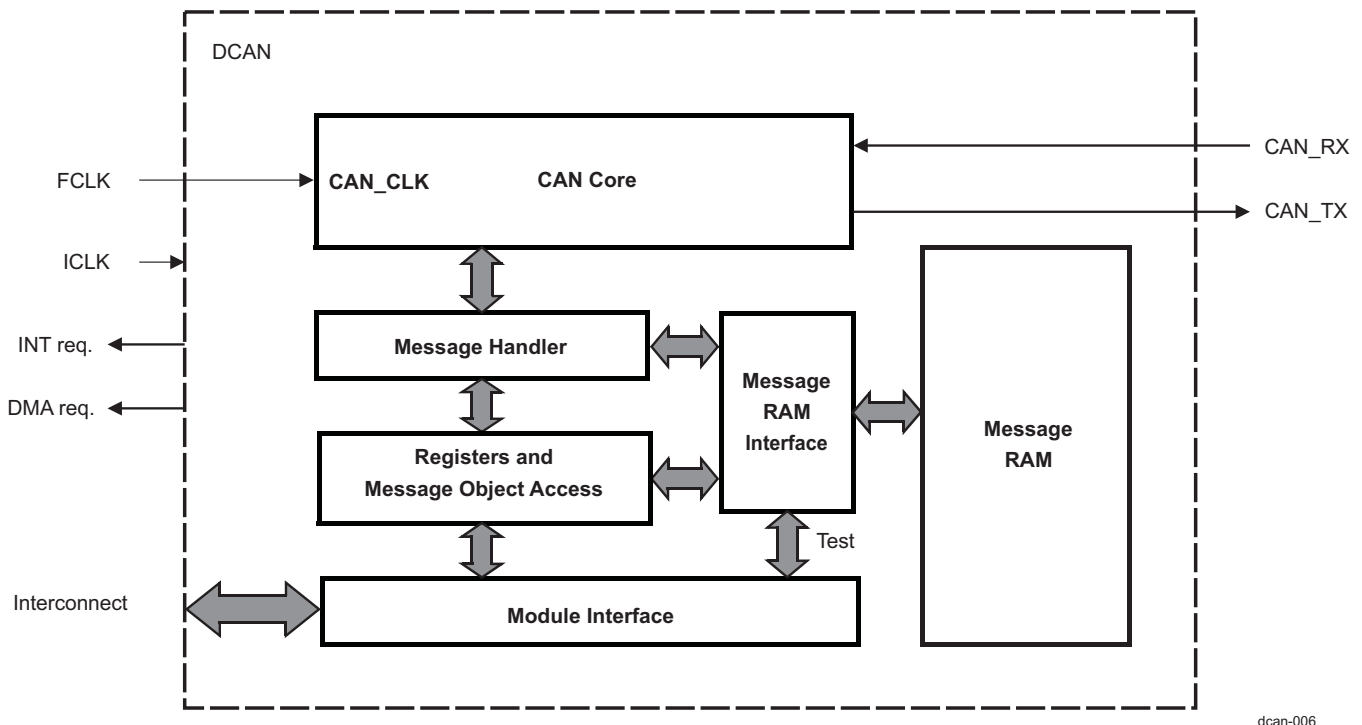

For communication on a CAN network, individual message objects can be configured. The message objects and identifier masks are stored in the message RAM.

All functions concerning the handling of messages are implemented in the message handler. Those functions are acceptance filtering, the transfer of messages between the CAN core and the message RAM, and the handling of transmission requests, as well as the generation of interrupts or DMA requests.

The register set of the DCAN module can be accessed directly via the module interface. These registers are used to control and configure the CAN core and the message handler, and to access the message RAM.

Figure 24-169 shows the DCAN block diagram and its features are described below.

**Figure 24-169. DCAN Block Diagram**

dcan-006

**CAN Core:** The CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1 protocol functions.

**Message Handler:** The message handler is a state machine that controls the data transfer between the single-ported message RAM and the CAN core's Rx/Tx shift register. It also handles acceptance filtering and the interrupt/DMA request generation as programmed in the control registers.

**Message RAM:** The DCAN enables a storage of 64 CAN messages.

**Message RAM Interface:** Three interface register sets control the MPU read and write accesses to the message RAM. There are two interface registers sets for read and write access, IF1 and IF2, and one interface register set for read access only, IF3. Additional information can be found in [Section 24.10.4.8.12, Reading From a FIFO Buffer](#).

The interface registers have the same word-length as the message RAM.

**Registers and Message Object Access:** Data consistency is ensured by indirect accesses to the message objects. During normal operation, all software and DMA accesses to the message RAM are done through interface registers. In a dedicated test mode, the message RAM is memory mapped and can be directly accessed by either MPU or DMA.

**Module Interface:** The DCAN module registers are accessed by the user software through a 32-bit peripheral bus interface.

**Clocking:** Two clocks are provided to the DCAN module: the peripheral synchronous clock (interface clock [ICLK]) and the peripheral asynchronous clock (functional clock [FCLK]) .

#### 24.10.4.1 Module Clocking Requirements

Two clocks are provided to the DCAN module:

- the peripheral synchronous clock (ICLK) as the general module clock source
- and the peripheral asynchronous clock (FCLK) provided to the CAN core for generating the CAN bit timing.

**NOTE:** ICLK must always be higher or equal to FCLK, in order to achieve a stable functionality of the DCAN. Here, also the frequency shift of the modulated ICLK has to be considered:

$$f_{0, ICLK}(OCP) \pm \Delta f_{FM, ICLK}(OCP) \geq f_{FCLK}$$

For more information on how to configure the relevant clock source registers, see [Chapter 3, PRCM](#) and the device data manual.

#### 24.10.4.2 Interrupt Functionality

Interrupts can be generated on two interrupt lines: INT0 and INT1. These lines can be enabled by setting the [DCAN\\_CTL\[1\] IE0](#) and [\[17\] IE1](#) bits, respectively. The interrupts are level triggered at the chip level.

The DCAN provides three groups of interrupt sources: message object interrupts, status change interrupts, and error interrupts (see [Figure 24-170, Error and Status Change Interrupts](#) and [Figure 24-171, Message Objects Interrupts](#)).

The source of an interrupt can be determined by the interrupt identifiers [DCAN\\_INT\[15:0\] INT0ID/\[23:16\] INT1ID](#). When no interrupt is pending, the register will hold the value zero.

Each interrupt line remains active until the dedicated field in the interrupt register [DCAN\\_INT\[15:0\] INT0ID/\[23:16\] INT1ID](#) again reach zero (this means the cause of the interrupt is reset), or until IE0/IE1 are reset.

The value 0x8000 in the INT0ID field indicates that an interrupt is pending because the CAN core has updated (not necessarily changed) the Error and Status register ([DCAN\\_ES](#)). This interrupt has the highest priority. The software can update (reset) the status bits [\[9\] WAKEUPPND](#), [\[4\] RXOK](#), [\[3\] TXOK](#) and [\[2:0\] LEC](#) by reading [DCAN\\_ES](#), but a write access of the software will never generate or reset an interrupt.

Values between 1 and the number of the last message object indicates that the source of the interrupt is one of the message objects, INT0ID resp. INT1ID will point to the pending message interrupt with the highest priority. The Message Object 1 has the highest priority; the last message object has the lowest priority.

An interrupt service routine that reads the message that is the source of the interrupt may read the message and reset the message object's IntPnd at the same time ([DCAN\\_IF1CMD/DCAN\\_IF2CMD\[19\] CLRINTPND](#) bit). When IntPnd is cleared, [DCAN\\_INT](#) will point to the next message object with a pending interrupt.

##### 24.10.4.2.1 Message Object Interrupts

Message object interrupts are generated by events from the message objects. They are controlled by the flags IntPnd, TxIE and RxIE that are described in [Section 24.10.4.11.1, Structure of Message Objects](#).

Message object interrupts can be routed to either INT0 or INT1 line, controlled by the interrupt multiplexer registers (DCAN\_INTMUX12 to DCAN\_INTMUX78).

#### 24.10.4.2.2 Status Change Interrupts

The events WAKEUPPND, RXOK, TXOK and LEC in the error and status register (DCAN\_ES) belong to the status change interrupts. The status change interrupt group can be enabled by DCAN\_CTL[2] SIE bit.

If SIE is set, a status change interrupt will be generated at each CAN frame, independent of bus errors or valid CAN communication, and also independent of the message RAM configuration.

Status change interrupts can only be routed to interrupt line INT0, which has to be enabled by setting DCAN\_CTL[1] IE0 = 1.

---

**NOTE:** Reading DCAN\_ES will clear the WAKEUPPND flag. If in global power-down mode, the WAKEUPPND flag is cleared by such a read access before the DCAN module has been waken up by the system, the DCAN may re-assert the WAKEUPPND flag, and a second interrupt may occur.

---

#### 24.10.4.2.3 Error Interrupts

The events PER, BOFF and EWARN, monitored in the DCAN\_ES register belong to the error interrupts. The error interrupt group can be enabled by setting bit DCAN\_CTL[3] EIE = 1.

Error interrupts can only be routed to interrupt line INT0, which has to be enabled by setting DCAN\_CTL[1] IE0 = 1.

**Figure 24-170. Error and Status Change Interrupts**

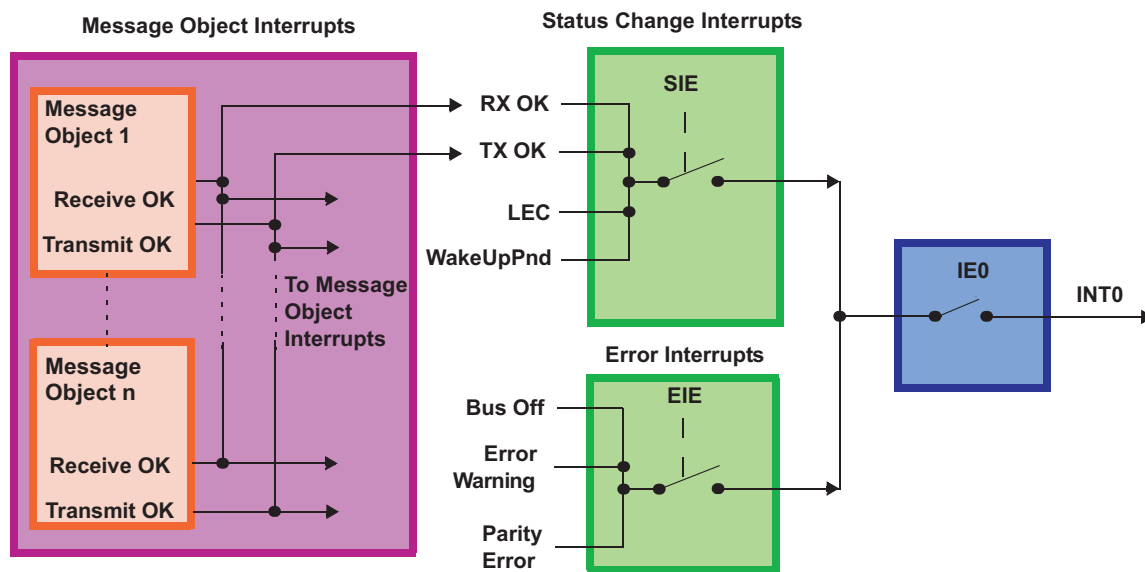

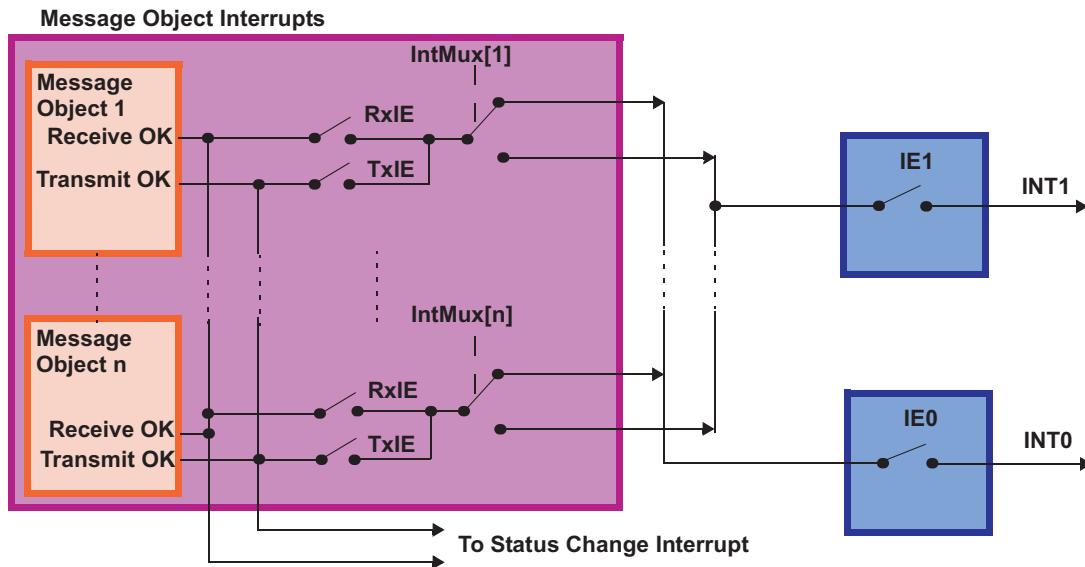

Figure 24-171. Message Objects Interrupts

#### 24.10.4.3 DMA Functionality

The DCAN provides three DMA request lines, each indicating new data in one of the three interface register sets IF1, IF2 and IF3.

The update of IF1 and IF2 registers will be initiated by a write access to the IF1 respective IF2 Command Registers ([DCAN\\_IF1CMD](#), [DCAN\\_IF2CMD](#)).

The IF3 registers content can be automatically updated on reception of CAN messages in message objects which are programmed for automatic IF3 update, see [Section 24.10.4.10.2, IF3 Register Set](#).

When a DCAN internal IFx (x = 1 to 3) update is complete, a DMA request will be activated and stays active until the first access to one of the relevant IFx registers. The DMA functionality has to be enabled by setting bit [18] DE0/[19] DE1/[20] DE3 in [DCAN\\_CTL](#).

#### 24.10.4.4 Local Power-Down Mode

The DCAN supports a local power-down mode, which can be controlled within the DCAN registers.

##### 24.10.4.4.1 Entering Local Power-Down Mode

The local power-down mode is requested by setting the [DCAN\\_CTL\[24\] PDR](#) bit (=1).

The DCAN then finishes all transmit requests of the message objects. When all requests are done, DCAN waits until a bus idle state is recognized. Then it will automatically set the [DCAN\\_CTL\[0\] INIT](#) bit to prevent any further CAN transfers, and it will also set the [DCAN\\_ES\[10\] PDA](#) bit. With setting the PDA bit, the DCAN module indicates that the local power-down mode has been entered.

During local power-down mode, the internal clocks of the DCAN module are turned off, but there is a wakeup logic (see [Section 24.10.4.4.2, Wakeup From Local Power Down](#)) that can be active, if enabled. Also, the actual contents of the control registers can be read back.

---

**NOTE:** In local low-power mode, the software must not clear the INIT bit while PDR is set. If there are any messages in the message RAM which are configured as transmit messages and the application resets the INIT bit, these messages may get sent.

---

##### 24.10.4.4.2 Wakeup From Local Power Down

There are two ways to wake up the DCAN from local power-down mode:

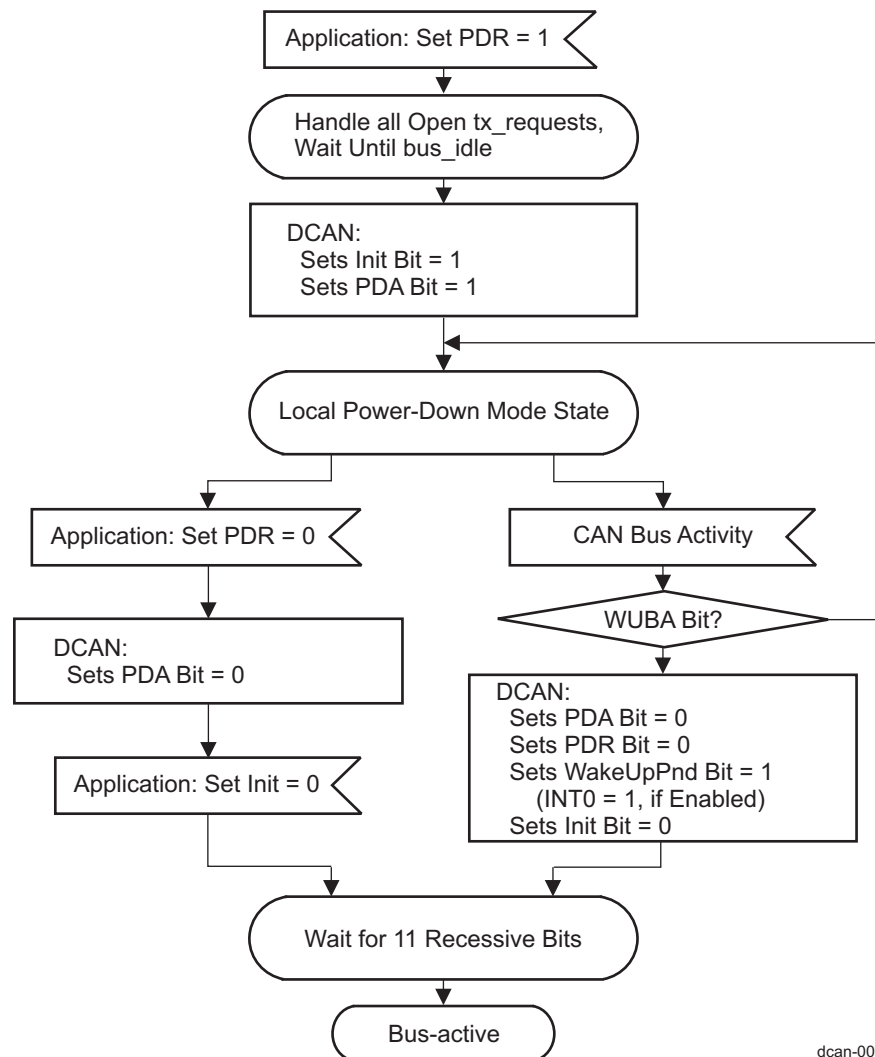

- The application could wake up the DCAN module manually by clearing the `DCAN_CTL[24]` PDR bit and then clearing the `DCAN_CTL[0]` INIT.
- Alternatively, a CAN bus activity detection circuit can be activated by setting the wakeup on bus activity bit (`DCAN_CTL[25]` WUBA). If this circuit is active, on occurrence of a dominant CAN bus level, the DCAN will automatically start the wakeup sequence. It will clear the `DCAN_CTL[24]` PDR bit and also clear the `DCAN_ES[10]` PDA bit. The `DCAN_ES[10]` WAKEUPPND bit will be set. If status interrupts are enabled, also an interrupt will be generated. Finally the `DCAN_CTL[0]` INIT bit will be cleared.

After the INIT bit has been cleared, the module waits until it detects 11 consecutive recessive bits on the CAN\_RX pin and then goes bus-active again.

**NOTE:** The CAN transceiver circuit has to stay active in order to detect any CAN bus activity while the DCAN is in local power down mode. The first CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power-down and automatic wake-up mode, is lost.

Figure 24-172 shows a flow diagram about entering and leaving local power-down mode.

**Figure 24-172. Local Power-Down Mode Flow Diagram**

dcan-009

### 24.10.4.5 Parity Check Mechanism

The DCAN provides a parity check mechanism to ensure data integrity of message RAM data. For each word (32 bits) in message RAM, one parity bit will be calculated. The formation of the different words is according to the message RAM representation in RDA mode, see [Section 24.10.4.11.4, Message RAM Representation in Direct Access Mode](#).

Parity information is stored in the message RAM on write accesses and will be checked against the stored parity bit from message RAM on read accesses.

The Parity check functionality can be enabled or disabled by [DCAN\\_CTL\[13:10\]](#) PMD bit field.

In case of disabled parity check, the parity bits in message RAM will be left unchanged on write access to data area and no check will be done on read access.

If parity checking is enabled, parity bits will be automatically generated and checked by the DCAN. The parity bits could be read in debug/suspend mode (see [Section 24.10.4.11.3, Message RAM Representation in Debug/Suspend Mode](#)) or in RDA mode (see [Section 24.10.4.11.4, Message RAM Representation in Direct Access Mode](#)). However, direct write access to the parity bits is only possible in this two modes with parity check disabled.

A parity bit will be set, if the modulo-2-sum of the data bits is 1. This definition is equivalent to: The parity bit will be set, if the number of 1 bits in the data is odd.

---

**NOTE:** DCAN is configured to even parity by the design.

---

#### 24.10.4.5.1 Behavior on Parity Error

On any read access to message RAM (e.g., during start of a CAN frame transmission), the parity of the message object will be checked. If a parity error is detected, the [DCAN\\_ES\[8\]](#) PER bit will be set. If error interrupts are enabled, an interrupt would also be generated. In order to avoid the transmission of invalid data over the CAN bus, the `MsgVal` bit of the message object will be reset to 0.

The message object data can be read by the software, independently of parity errors. Thus, the software has to ensure that the read data is valid, for example, by immediately checking the parity error code register ([DCAN\\_PERR](#)) on parity error interrupt.

---

**NOTE:** During RAM initialization, no parity check is done, but if the PMD bit is set, the parity bits will be generated.

---

#### 24.10.4.5.2 Parity Testing

Testing the parity mechanism can be done by enabling the bit `RamDirectAccess` ([DCAN\\_TEST\[9\]](#) RDA) and manually writing the parity bits directly to the dedicated RAM locations. With this, data and parity bits could be checked when reading directly from RAM.

---

**NOTE:** If parity check is disabled, the software has to ensure correct parity bit handling in order to prevent parity errors later on when parity check is enabled.

---

### 24.10.4.6 Debug/Suspend Mode

The module supports the usage of an external debug unit by providing functions like pausing DCAN activities and making message RAM content accessible via interconnect interface.

Before entering debug/suspend mode, the DCAN will either wait until a started transmission or reception will be finished and bus idle state is recognized, or immediately interrupt a current transmission or reception. This is depending on bit [DCAN\\_CTL\[8\]](#) IDS in the CAN control register.

Afterwards, the DCAN enters debug/suspend mode, indicated by [DCAN\\_CTL \[16\]](#) INITDBG flag.

During debug/suspend mode, all DCAN registers can be accessed. Reading reserved bits will return '0'. Writing to reserved bits will have no effect.

Also, the message RAM will be memory mapped. This allows the external debug unit to read the message RAM. For the memory organization, see [Section 24.10.4.11.3, Message RAM Representation in Debug/Suspend Mode](#).

---

**NOTE:** During debug/suspend mode, the message RAM cannot be accessed via the IFx register sets.

---

---

**NOTE:** Writing to control registers in debug/suspend mode may influence the CAN state machine and further message handling.

---

For debug support, the auto clear functionality of the following DCAN registers is disabled:

- [DCAN\\_ES](#) register (clear of status flags by read)
- [DCAN\\_IF1CMD/DCAN\\_IF2CMD](#) command registers (clear of [14] DMAACTIVE flag by read/write)

#### 24.10.4.7 Configuration of Message Objects Description

The whole message RAM should be configured before the end of the initialization, however it is also possible to change the configuration of message objects during CAN communication.

The CAN software driver must offer subroutines that:

- Transfer a complete message structure into a message object. (Configuration)
- Transfer the data bytes of a message into a message object and set TxRqst and NewDat. (Start a new transmission)
- Get the data bytes of a message from a message object and clear NewDat (and IntPnd). (Read received data)
- Get the complete message from a message object and clear NewDat (and IntPnd). (Read a received message, including identifier, from a message object with UMask = '1')

Parameters of the subroutines are the Message Number and a pointer to a complete message structure or to the data bytes of a message structure.

Two examples of assigning the IFx interface register sets to these subroutines are shown here:

In the first method, the tasks of the application program that may access the module are divided into two groups. Each group is restricted to the use of one of the interface register sets. The tasks of one group may interrupt tasks of the other group, but not of the same group.

In the second method, which may be a special case of the first method, there are only two tasks in the application program that access the module. A Read\_Message task that uses IF2 or IF3 to get received messages from the message RAM and a Write\_Message task that uses IF1 to write messages to be transmitted (or to be configured) into the message RAM. Both tasks may interrupt each other.

##### 24.10.4.7.1 Configuration of a Transmit Object for Data Frames

[Table 24-1124](#) shows how a transmit object can be initialized.

**Table 24-1124. Initialization of a Transmit Object**

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	0	appl.	0	appl.	0

The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of the outgoing message. If an 11-bit identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored.

The data length and data itself (DLC[3:0] and Data0-7) are given by the application. TxRqst and RmtEn should not be set before the data is valid.

If the TXIE bit is set, the IntPnd bit will be set after a successful transmission of the message object.

If the RmtEn bit is set, a matching received remote frame will cause the TxRqst bit to be set; the remote frame will autonomously be answered by a data frame.

The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask='1') to allow groups of remote frames with similar identifiers to set the TxRqst bit. The Dir bit should not be masked. For details, see [Section 24.10.4.8.8, Reception of Remote Frames](#).

Identifier masking must be disabled (UMask = '0') if no remote frames are allowed to set the TxRqst bit (RmtEn = '0').

#### 24.10.4.7.2 Configuration of a Transmit Object for Remote Frames

It is not necessary to configure transmit objects for the transmission of remote frames. Setting TxRqst for a receive object causes the transmission of a remote frame with the same identifier as the data frame for which this receive object is configured.

#### 24.10.4.7.3 Configuration of a Single Receive Object for Data Frames

[Table 24-1125](#) shows how a receive object for data frames can be initialized.

**Table 24-1125. Initialization of a single Receive Object for Data Frames**

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	0	0	0	appl.	0	0	0	0

The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of accepted received messages. If an 11-bit Identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a data frame with an 11-bit Identifier is received, ID[17:0] is set to '0'.

The data length code (DLC[3:0]) is given by the application. When the message handler stores a data frame in the message object, it will store the received data length code and eight data bytes. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by non specified values.

The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask = '1') to allow groups of data frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. If some bits of the mask bits are set to "don't care," the corresponding bits of the arbitration register ([DCAN\\_IF1ARB](#), [DCAN\\_IF2ARB](#), [DCAN\\_IF3ARB](#)) will be overwritten by the bits of the stored data frame.

If the RxIE bit is set, the IntPnd bit will be set when a received data frame is accepted and stored in the message object.

If the TxRqst bit is set, the transmission of a remote frame with the same identifier as actually stored in the arbitration bits will be triggered. The content of the arbitration bits may change if the mask bits are used (UMask = '1') for acceptance filtering.

#### 24.10.4.7.4 Configuration of a Single Receive Object for Remote Frames

[Table 24-1126](#) shows how a receive object for remote frames can be initialized.

**Table 24-1126. Initialization of a Single Receive Object for Remote Frames**

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	appl.	0	0	0	0

A receive object for remote frames may be used to monitor remote frames on the CAN bus. The remote frame stored in the receive object will not trigger the transmission of a data frame. Receive objects for remote frames may be expanded to a FIFO buffer (see [Section 24.10.4.7.5, Configuration of a FIFO Buffer](#)).

UMask must be set to '1.' The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be set to "must-match" or to "don't care," to allow groups of remote frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. For details, see [Section 24.10.4.8.8, Reception of Remote Frames](#).

The arbitration bits (ID[28:0] and Xtd bit) may be given by the application. They define the identifier and type of accepted received remote frames. If some bits of the mask bits are set to "don't care," the corresponding bits of the arbitration bits will be overwritten by the bits of the stored remote frame. If an 11-bit Identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a remote frame with an 11-bit Identifier is received, ID[17:0] will be set to '0.'

The data length code (DLC[3:0]) may be given by the application. When the message handler stores a remote frame in the message object, it will store the received data length code. The data bytes of the message object will remain unchanged.

If the RxIE bit is set, the IntPnd bit will be set when a received remote frame is accepted and stored in the message object.

#### 24.10.4.7.5 Configuration of a FIFO Buffer

With the exception of the EoB bit, the configuration of receive objects belonging to a FIFO buffer is the same as the configuration of a single receive object.

To concatenate multiple message objects to a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest number will be the first message object of the FIFO buffer. The EoB bit of all message objects of a FIFO buffer except the last one have to be programmed to zero. The EoB bits of the last message object of a FIFO Buffer is set to one, configuring it as the end of the block.

#### 24.10.4.8 Message Handling

When initialization is finished, the DCAN module synchronizes itself to the traffic on the CAN bus. It does acceptance filtering on received messages and stores those frames that are accepted into the designated message objects. The application has to update the data of the messages to be transmitted and to enable and request their transmission. The transmission is requested automatically when a matching remote frame is received.

The application may read messages which are received and accepted. Messages that are not read before the next messages is accepted for the same message object will be overwritten.

Messages may be read interrupt-driven or after polling of NewDat.

##### 24.10.4.8.1 Message Handler Overview

The message handler state machine controls the data transfer between the Rx/Tx shift register of the CAN core and the message RAM. It performs the following tasks:

- Data transfer from message RAM to CAN core (messages to be transmitted)
- Data transfer from CAN core to the message RAM (received messages)
- Data transfer from CAN core to the acceptance filtering unit
- Scanning of message RAM for a matching message object (acceptance filtering)
- Scanning the same message object after being changed by IF1/IF2 registers when priority is the same

or higher as the message the object found by last scanning

- Handling of TxRqst flags
- Handling of interrupt flags

The message handler registers contains status flags of all message objects grouped into the following topics:

- Transmission Request Flags
- New Data Flags
- Interrupt Pending Flags
- Message Valid Registers

Instead of collecting above listed status information of each message object via IFx registers separately, these message handler registers provides a fast and easy way to get an overview, for example, about all pending transmission requests.

All message handler registers are read-only.

#### **24.10.4.8.2 Receive/Transmit Priority**

The receive/transmit priority for the message objects is attached to the message number, not to the CAN identifier. Message object 1 has the highest priority, while the last implemented message object has the lowest priority. If more than one transmission request is pending, they are serviced due to the priority of the corresponding message object so messages with the highest priority, for example, can be placed in the message objects with the lowest numbers.

The acceptance filtering for received data frames or remote frames is also done in ascending order of message objects, so a frame that has been accepted by a message object cannot be accepted by another message object with a higher message number. The last message object may be configured to accept any data frame or remote frame that was not accepted by any other message object, for nodes that need to log the complete message traffic on the CAN bus.

#### **24.10.4.8.3 Transmission of Messages in Event Driven CAN Communication**

If the shift register of the CAN core is ready for loading and if there is no data transfer between the IFx registers and message RAM, the MSGVAL bits in the Message Valid register ([DCAN\\_MSGVAL12](#) to [DCAN\\_MSGVAL78](#)) and the TXRQST bits in the transmission request register ([DCAN\\_TXRQ12](#) to [DCAN\\_TXRQ78](#)) are evaluated. The valid message object with the highest priority pending transmission request is loaded into the shift register by the message handler and the transmission is started. The message object's NewDat bit is reset.

After a successful transmission and if no new data was written to the message object (NewDat = '0') since the start of the transmission, the TxRqst bit will be reset. If TxIE is set, IntPnd will be set after a successful transmission. If the DCAN has lost the arbitration or if an error occurred during the transmission, the message will be retransmitted as soon as the CAN bus is free again. If meanwhile the transmission of a message with higher priority has been requested, the messages will be transmitted in the order of their priority.

If automatic retransmission mode is disabled by setting the [DCAN\\_CTL\[5\]](#) DAR bit, the behavior of bits TXRQST and NEWDAT in the [DCAN\\_IF1CMD/DCAN\\_IF2CMD](#) register of the interface register set is as follows:

- When a transmission starts, the TxRqst bit of the respective interface register set is reset, while bit NewDat remains set.
- When the transmission has been successfully completed, the NewDat bit is reset.

When a transmission failed (lost arbitration or error), bit NewDat remains set. To restart the transmission, the application has to set TxRqst again.

Received remote frames do not require a receive object. They will automatically trigger the transmission of a data frame, if in the matching transmit object the RmtEn bit is set.

#### 24.10.4.8.4 Updating a Transmit Object

The software may update the data bytes of a transmit object any time via the IF1/IF2 interface registers, neither MSGVAL, nor TXRQST have to be reset before the update.

Even if only a part of the data bytes are to be updated, all four bytes in the corresponding IF1/IF2 Data A register (DCAN\_IF1DATA/DCAN\_IF2DATA) or IF1/IF2 Data B register (DCAN\_IF1DATB/DCAN\_IF2DATB) have to be valid before the content of that register is transferred to the message object. Either the software has to write all four bytes into the IF1/IF2 data register or the message object is transferred to the IF1/IF2 data register before the software writes the new data bytes.

When only the data bytes are updated, first 0x87 can be written to bits [23:16] of the IF1/IF2 Command register (DCAN\_IF1CMD/DCAN\_IF2CMD) and then the number of the message object is written to bits [7:0] MESSAGE\_NUMBER of the command register, concurrently updating the data bytes and setting TXRQST with NEWDAT.

To prevent the reset of TxRqst at the end of a transmission that may already be in progress while the data is updated, NewDat has to be set together with TxRqst in event driven CAN communication. For details, see [Section 24.10.4.8.3, Transmission of Messages in Event Driven CAN Communication](#).

When NewDat is set together with TxRqst, NewDat will be reset as soon as the new transmission has started.

#### 24.10.4.8.5 Changing a Transmit Object

If the number of implemented message objects is not sufficient to be used as permanent message objects only, the transmit objects may be managed dynamically. The software can write the whole message (arbitration, control, and data) into the interface register. The bits [23:16] of the command register (DCAN\_IF1CMD/DCAN\_IF2CMD) can be set to 0xB7 for the transfer of the whole message object content into the message object. Neither Dir, nor TxRqst have to be reset before this operation.

If a previously requested transmission of this message object is not completed but already in progress, it will be continued; however, it will not be repeated if it is disturbed.

To only update the data bytes of a message to be transmitted, bits [23:16] of the command register (DCAN\_IF1CMD/ DCAN\_IF2CMD) should be set to 0x87.

---

**NOTE:** After the update of the transmit object, the interface register set will contain a copy of the actual contents of the object, including the part that had not been updated.

---

#### 24.10.4.8.6 Acceptance Filtering of Received Messages

When the arbitration and control bits (Identifier + IDE + RTR + DLC) of an incoming message are completely shifted into the shift register of the CAN core, the message handler starts the scan of the message RAM for a matching valid message object:

- The acceptance filtering unit is loaded with the arbitration bits from the CAN core shift register.
- Then the arbitration and mask bits (including MsgVal, UMask, NewDat, and EoB) of message object 1 are loaded into the acceptance filtering unit and are compared with the arbitration bits from the shift register. This is repeated for all following message objects until a matching message object is found, or until the end of the message RAM is reached.
- If a match occurs, the scanning is stopped and the message handler proceeds depending on the type of the frame (data frame or remote frame) received.

#### 24.10.4.8.7 Reception of Data Frames

The message handler stores the message from the CAN core shift register into the respective message object in the message RAM. Not only the data bytes, but all arbitration bits and the data length code are stored into the corresponding message object. This ensures that the data bytes stay associated to the identifier even if arbitration mask registers are used.

The NewDat bit is set to indicate that new data (not yet seen by the software) has been received. The software should reset the NewDat bit when it reads the message object. If at the time of the reception the NewDat bit was already set, MsgLst is set to indicate that the previous data (supposedly not seen by the software) is lost. If the RxIE bit is set, the IntPnd bit is set, causing the [DCAN\\_INT](#) to point to this message object.

The TxRqst bit of this message object is reset to prevent the transmission of a remote frame, while the requested data frame has just been received.

#### 24.10.4.8.8 Reception of Remote Frames

When a remote frame is received, three different configurations of the matching message object have to be considered:

- Dir = '1' (direction = transmit), RmtEn = '1', UMask = '1' or '0'  
The TxRqst bit of this message object is set at the reception of a matching remote frame. The rest of the message object remains unchanged.
- Dir = '1' (direction = transmit), RmtEn = '0', UMask = '0'  
The remote frame is ignored, this message object remains unchanged.
- Dir = '1' (direction = transmit), RmtEn = '0', UMask = '1'  
The remote frame is treated similar to a received data frame. At the reception of a matching Remote Frame, the TxRqst bit of this message object is reset. The arbitration and control bits (Identifier + IDE + RTR + DLC) from the shift register are stored in the message object in the message RAM and the NewDat bit of this message object is set. The data bytes of the message object remain unchanged.

#### 24.10.4.8.9 Reading Received Messages

The software may read a received message any time via the IFx interface register. The data consistency is guaranteed by the message handler state machine. Typically the software will write first 0x7F to bits [23:16] and then the number of the message object to bits [7:0] MESSAGE\_NUMBER of the command register ([DCAN\\_IF1CMD/ DCAN\\_IF2CMD](#)). That combination will transfer the entire received message from the message RAM into the interface register set. Additionally, the bits NewDat and IntPnd are cleared in the message RAM (not in the interface register set). The values of these bits in the message control register ([DCAN\\_IF1MCTL/DCAN\\_IF2MCTL/DCAN\\_IF3MCTL](#)) always reflect the status before resetting the bits. If the message object uses masks for acceptance filtering, the arbitration bits show which of the different matching messages has been received.

The actual value of NewDat shows whether a new message has been received since last time when this message object was read. The actual value of MsgLst shows whether more than one message has been received since the last time when this message object was read. MsgLst will not be automatically reset.

#### 24.10.4.8.10 Requesting New Data for a Receive Object

By means of a remote frame, the software may request another CAN node to provide new data for a receive object. Setting the TxRqst bit of a receive object will cause the transmission of a remote frame with the identifier of the receive object. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the TxRqst bit is automatically reset. Setting the TxRqst bit without changing the contents of a message object requires the value 0x84 in bits [23:16] of the command register ([DCAN\\_IF1CMD/ DCAN\\_IF2CMD](#)).

#### 24.10.4.8.11 Storing Received Messages in FIFO Buffers

Several message objects may be grouped to form one or more FIFO buffers. Each FIFO buffer configured to store received messages with a particular (group of) identifier(s). arbitration and mask registers of the FIFO buffer's message objects are identical. The end of buffer (EoB) bits of all but the last of the FIFO buffer's message objects are '0'; in the last one the EoB bit is '1.'

Received messages with identifiers matching to a FIFO buffer are stored into a message object of this FIFO buffer, starting with the message object with the lowest message number. When a message is stored into a message object of a FIFO buffer, the NewDat bit of this message object is set. By setting NewDat while EoB is '0', the message object is locked for further write accesses by the message handler until the software has cleared the NewDat bit.

Messages are stored into a FIFO buffer until the last message object of this FIFO buffer is reached. If none of the preceding message objects is released by writing NewDat to '0,' all further messages for this FIFO buffer will be written into the last message object of the FIFO buffer (EoB = '1') and therefore overwrite previous messages in this message object.

#### **24.10.4.8.12 Reading From a FIFO Buffer**

Several messages may be accumulated in a set of message objects which are concatenated to form a FIFO buffer before the application program is required (in order to avoid the loss of data) to empty the buffer.

A FIFO buffer of length N will store N-1, plus the last received message since last time it was cleared.

A FIFO buffer is cleared by reading and resetting the NewDat bits of all its message objects, starting at the FIFO Object with the lowest message number. This should be done in a subroutine following the example shown in [Figure 24-173](#).

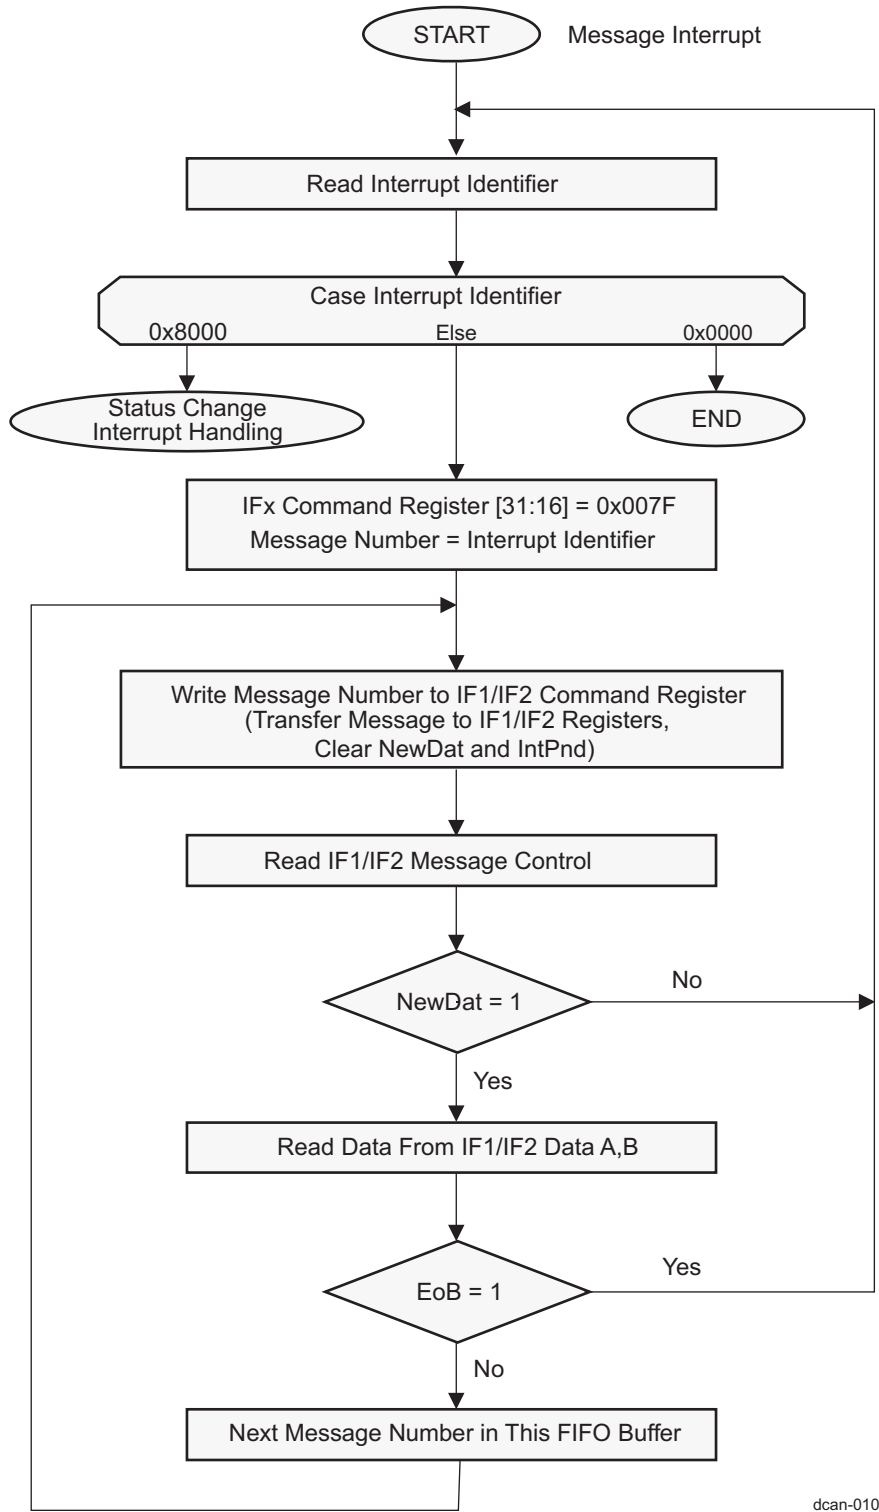

---

**NOTE:** All message objects of a FIFO buffer needs to be read and cleared before the next batch of messages can be stored. Otherwise, true FIFO functionality can not be guaranteed, since the message objects of a partly read buffer will be re-filled according to the normal (descending) priority.

---

Reading from a FIFO buffer message object and resetting its NewDat bit is handled the same way as reading from a single message object.

**Figure 24-173. Software Handling of a FIFO Buffer (Interrupt Driven)**

dcan-010

#### 24.10.4.9 CAN Bit Timing

The DCAN supports bit rates between < 1 kBit/s and 1000 kBit/s.

Each member of the CAN network has its own clock generator, typically derived from a crystal oscillator. The bit timing parameters can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes' oscillator periods ( $f_{osc}$ ) may be different.

The frequencies of these oscillators are not absolutely stable. Small variations are caused by changes in temperature or voltage and by deteriorating components. As long as the variations remain inside a specific oscillator tolerance range ( $df$ ), the CAN nodes are able to compensate for the different bit rates by resynchronizing to the bit stream.

In many cases, the CAN bit synchronization will amend a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive.

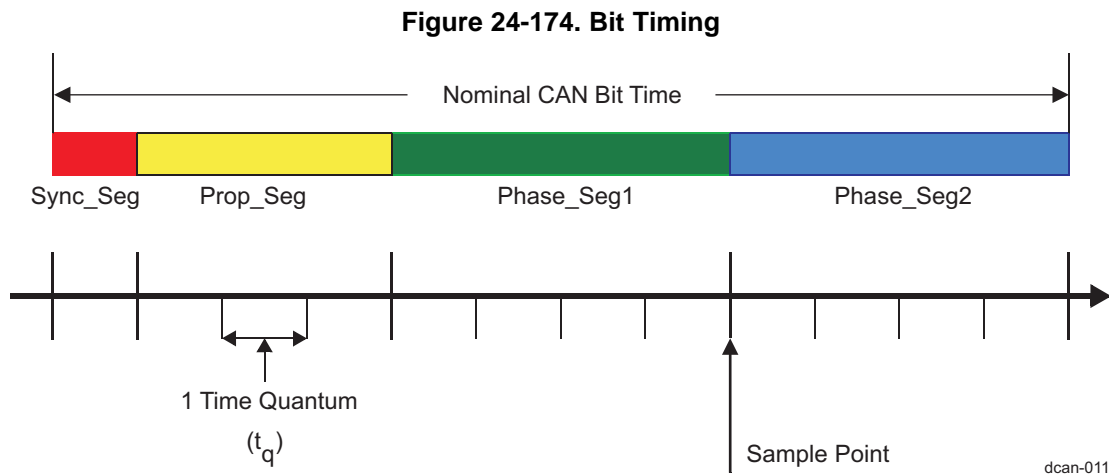

The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly.

#### 24.10.4.9.1 Bit Time and Bit Rate

According to the CAN specification, the bit time is divided into four segments (see [Figure 24-174](#)):

- Synchronization segment (Sync\_Seg)
- Propagation time segment (Prop\_Seg)
- Phase buffer segment 1 (Phase\_Seg1)
- Phase buffer segment 2 (Phase\_Seg2)

Each segment consists of a specific number of time quanta. The length of one time quantum ( $t_q$ ), which is the basic time unit of the bit time, is given by the FCLK and the baud rate prescalers (BRPE and BRP). With these two baud rate prescalers combined, divider values from 1 to 1024 can be programmed:

$$t_q = \text{Baud Rate Prescaler} / \text{FCLK}$$

Apart from the fixed length of the synchronization segment, these numbers are programmable. [Table 24-1127](#) describes the minimum programmable ranges required by the CAN protocol.

A given bit rate may be met by different bit time configurations.

**Table 24-1127. Parameters of the CAN Bit Time**

Parameter	Range	Remark
Sync_Seg	1 $t_q$ (fixed)	Synchronization of bus input to FCLK
Prop_Seg	[1 ... 8] $t_q$	Compensates for the physical delay times
Phase_Seg1	[1 ... 8] $t_q$	May be lengthened temporarily by synchronization

**Table 24-1127. Parameters of the CAN Bit Time (continued)**

Parameter	Range	Remark
Phase_Seg2	[1 ... 8] $t_q$	May be shortened temporarily by synchronization
Synchronization Jump Width (SJW)	[1 ... 4] $t_q$	May not be longer than either Phase Buffer Segment

**NOTE:** For proper functionality of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

**24.10.4.9.1.1 Synchronization Segment**

The synchronization segment (Sync\_Seg) is the part of the bit time where edges of the CAN bus level are expected to occur. If an edge occurs outside of Sync\_Seg, its distance to the Sync\_Seg is called the phase error of this edge.

**24.10.4.9.1.2 Propagation Time Segment**

This part of the bit time is used to compensate physical delay times within the CAN network. These delay times consist of the signal propagation time on the bus and the internal delay time of the CAN nodes.

Any CAN node synchronized to the bit stream on the CAN bus can be out of phase with the transmitter of the bit stream, caused by the signal propagation time between the two nodes. The CAN protocol's nondestructive bitwise arbitration and the dominant acknowledge bit provided by receivers of CAN messages require that a CAN node transmitting a bit stream must also be able to receive dominant bits transmitted by other CAN nodes that are synchronized to that bit stream. The example in Figure 24-175 shows the phase shift and propagation times between two CAN nodes.

**Figure 24-175. The Propagation Time Segment**

$$\text{Delay A\_to\_B} \geq \text{node output delay(A)} + \text{bus line delay(A/E/B)} + \text{node input delay(B)}$$

$$\text{Prop\_Seg} \geq \text{Delay A\_to\_B} + \text{Delay B\_to\_A}$$

$$\text{Prop\_Seg} \geq 2 \cdot [\text{max}(\text{node output delay} + \text{bus line delay} + \text{node input delay})]$$

dcan-012

In this example, both nodes A and B are transmitters performing an arbitration for the CAN bus. The node A has sent its start of frame bit less than one bit time earlier than node B, therefore node B has synchronized itself to the received edge from recessive to dominant. Since node B has received this edge delay(A\_to\_B) after it has been transmitted, node B's bit timing segments are shifted with regard to node A. Node B sends an identifier with higher priority and so it will win the arbitration at a specific identifier bit when it transmits a dominant bit while node A transmits a recessive bit. The dominant bit transmitted by node B will arrive at node A after the delay (B\_to\_A).

Due to oscillator tolerances, the actual position of node A's sample point can be anywhere inside the nominal range of node A's Phase Buffer Segments, so the bit transmitted by node B must arrive at node A before the start of Phase\_Seg1. This condition defines the length of Prop\_Seg.

If the edge from recessive to dominant transmitted by node B would arrive at node A after the start of Phase\_Seg1, it could happen that node A samples a recessive bit instead of a dominant bit, resulting in a bit error and the destruction of the current frame by an error flag.

This error only occurs when two nodes arbitrate for the CAN bus which have oscillators of opposite ends of the tolerance range and are separated by a long bus line; this is an example of a minor error in the bit timing configuration (Prop\_Seg too short) that causes sporadic bus errors.

Some CAN implementations provide an optional 3-Sample Mode. The DCAN does not. In this mode, the CAN bus input signal passes a digital low-pass filter, using three samples and a majority logic to determine the valid bit value. This results in an additional input delay of  $1 t_p$ , requiring a longer Prop\_Seg.

#### 24.10.4.9.1.3 Phase Buffer Segments and Synchronization

The phase buffer segments (Phase\_Seg1 and Phase\_Seg2) and the synchronization jump width (SJW) are used to compensate for the oscillator tolerance.

The phase buffer segments surround the sample point and may be lengthened or shortened by synchronization.

The synchronization jump width (SJW) defines how far the resynchronizing mechanism may move the sample point inside the limits defined by the phase buffer segments to compensate for edge phase errors.

Synchronizations occur on edges from recessive to dominant. Their purpose is to control the distance between edges and sample points.

Edges are detected by sampling the actual bus level in each time quantum and comparing it with the bus level at the previous sample point. A synchronization may be done only if a recessive bit was sampled at the previous sample point and if the actual time quantum's bus level is dominant.

An edge is synchronous if it occurs inside of Sync\_Seg; otherwise, its distance to the Sync\_Seg is the edge phase error, measured in time quanta. If the edge occurs before Sync\_Seg, the phase error is negative, else it is positive.

Two types of synchronization exist: hard synchronization and resynchronizing. A hard synchronization is done once at the start of a frame; inside a frame, only resynchronization is possible.

- **Hard Synchronization**

After a hard synchronization, the bit time is restarted with the end of Sync\_Seg, regardless of the edge phase error. Thus hard synchronization forces the edge which has caused the hard synchronization, to lie within the synchronization segment of the restarted bit time.

- **Bit Resynchronizations**

Resynchronization leads to a shortening or lengthening of the Bit time such that the position of the sample point is shifted with regard to the edge.

When the phase error of the edge which causes resynchronization is positive, Phase\_Seg1 is lengthened. If the magnitude of the phase error is less than SJW, Phase\_Seg1 is lengthened by the magnitude of the phase error, else it is lengthened by SJW.

When the phase error of the edge which causes Resynchronization is negative, Phase\_Seg2 is shortened. If the magnitude of the phase error is less than SJW, Phase\_Seg2 is shortened by the magnitude of the phase error, else it is shortened by SJW.

If the magnitude of the phase error of the edge is less than or equal to the programmed value of SJW, the results of hard synchronization and resynchronization are the same. If the magnitude of the phase error is larger than SJW, the resynchronization cannot compensate the phase error completely, and an error of (phase error - SJW) remains.

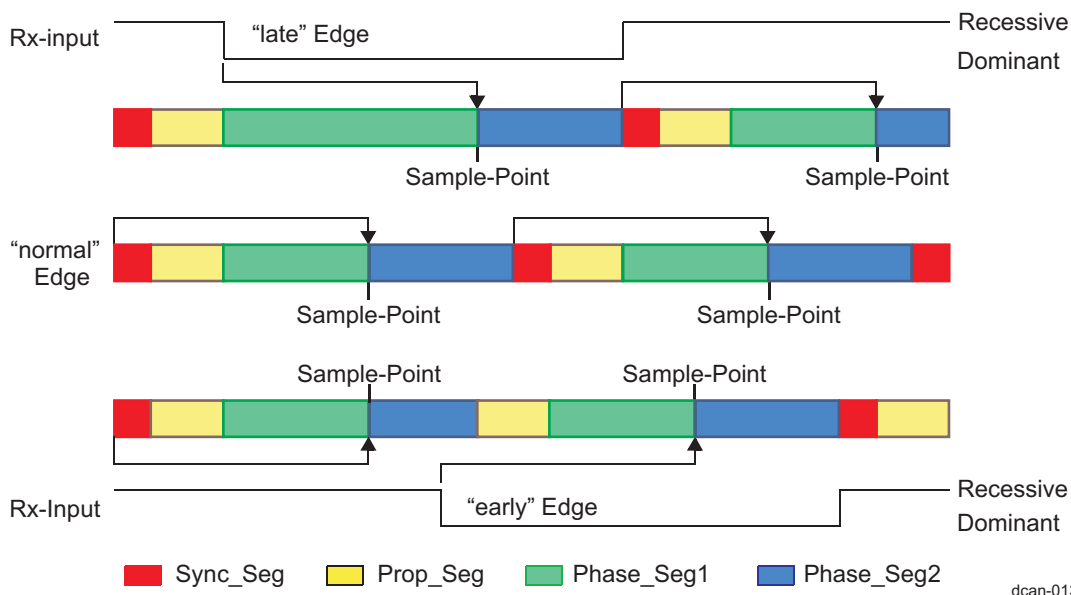

Only one synchronization may be done between two sample points. The synchronizations maintain a minimum distance between edges and sample points, giving the bus level time to stabilize and filtering out spikes that are shorter than (Prop\_Seg + Phase\_Seg1).

Apart from noise spikes, most synchronizations are caused by arbitration. All nodes synchronize “hard” on the edge transmitted by the “leading” transceiver that started transmitting first, but due to propagation delay times, they cannot become ideally synchronized. The leading transmitter does not necessarily win the arbitration; therefore, the receivers have to synchronize themselves to different transmitters that subsequently take the lead and that are differently synchronized to the previously leading transmitter. The same happens at the acknowledge field, where the transmitter and some of the receivers will have to synchronize to that receiver that takes the lead in the transmission of the dominant acknowledge bit.

Synchronizations after the end of the arbitration will be caused by oscillator tolerance, when the differences in the oscillator’s clock periods of transmitter and receivers sum up during the time between synchronizations (at most ten bits). These summarized differences may not be longer than the SJW, limiting the oscillator’s tolerance range.

Figure 24-176 shows how the phase buffer segments are used to compensate for phase errors. There are three drawings of each two consecutive bit timings. The upper drawing shows the synchronization on a “late” edge, the lower drawing shows the synchronization on an “early” edge, and the middle drawing is the reference without synchronization.

**Figure 24-176. Synchronization on Late and Early Edges**

In the first example, an edge from recessive to dominant occurs at the end of Prop\_Seg. The edge is "late" since it occurs after the Sync\_Seg. Reacting to the late edge, Phase\_Seg1 is lengthened so that the distance from the edge to the sample point is the same as it would have been from the Sync\_Seg to the sample point if no edge had occurred. The phase error of this late edge is less than SJW, so it is fully compensated and the edge from dominant to recessive at the end of the bit, which is one nominal bit time long, occurs in the Sync\_Seg.

In the second example, an edge from recessive to dominant occurs during Phase\_Seg2. The edge is "early" since it occurs before a Sync\_Seg. Reacting to the early edge, Phase\_Seg2 is shortened and Sync\_Seg is omitted, so that the distance from the edge to the sample point is the same as it would have been from a Sync\_Seg to the sample point if no edge had occurred. As in the previous example, the magnitude of this early edge’s phase error is less than SJW, so it is fully compensated.

The phase buffer segments are lengthened or shortened temporarily only; at the next bit time, the segments return to their nominal programmed values.

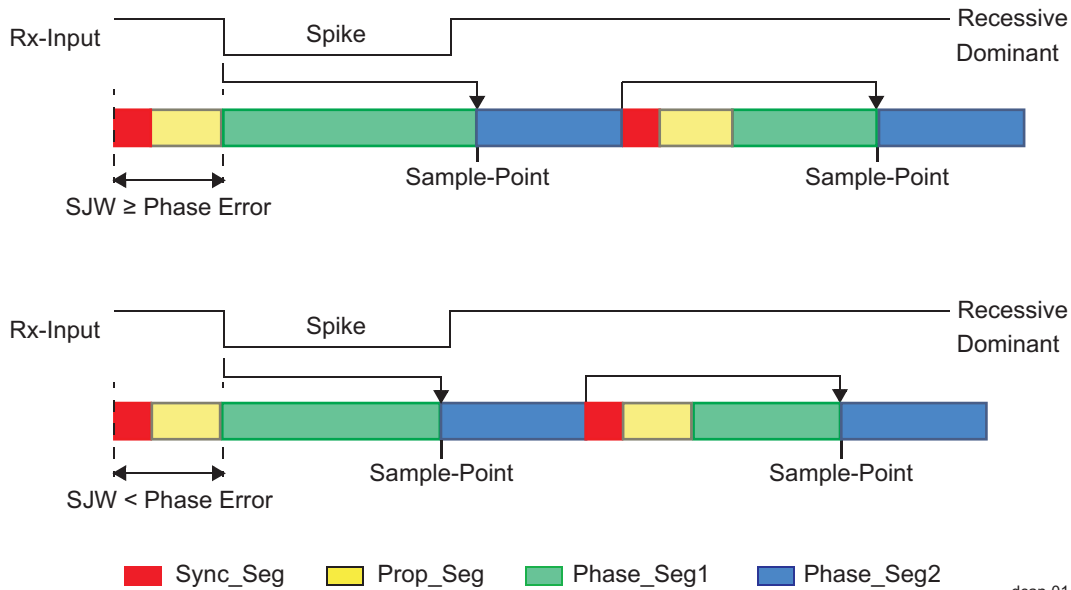

In these examples, the bit timing is seen from the point of view of the CAN implementation’s state machine, where the bit time starts and ends at the sample points. The state machine omits Sync\_Seg when synchronizing on an early edge because it cannot subsequently redefine that time quantum of Phase\_Seg2 where the edge occurs to be the Sync\_Seg.

Figure 24-177 shows how short dominant noise spikes are filtered by synchronizations. In both examples, the spike starts at the end of Prop\_Seg and has the length of (Prop\_Seg + Phase\_Seg1).

In the first example, the synchronization jump width is greater than or equal to the phase error of the spike's edge from recessive to dominant. Therefore the sample point is shifted after the end of the spike; a recessive bus level is sampled.

In the second example, SJW is shorter than the phase error, so the sample point cannot be shifted far enough; the dominant spike is sampled as actual bus level.

**Figure 24-177. Filtering of Short Dominant Spikes**

#### 24.10.4.9.1.4 Oscillator Tolerance Range

With the introduction of CAN protocol version 1.2, the option to synchronize on edges from dominant to recessive became obsolete. Only edges from recessive to dominant are considered for synchronization. The protocol update to version 2.0 (A and B) had no influence on the oscillator tolerance.

The tolerance range  $df$  for an oscillator's frequency  $f_{osc}$  around the nominal frequency  $f_{nom}$  with:

$$(1 - df) \cdot f_{nom} \leq f_{osc} \leq (1 + df) \cdot f_{nom}$$

dcan-e015

depends on the proportions of Phase\_Seg1, Phase\_Seg2, SJW, and the bit time. The maximum tolerance  $df$  is defined by two conditions (both shall be met):

$$I: df \leq \frac{\min(TSeg1, TSeg2)}{2x(13x(bit\_time - TSeg2))}$$

$$II: df \leq \frac{SJW}{20xbit\_time}$$

dcan-e016

It has to be considered that SJW may not be larger than the smaller of the phase buffer segments and that the propagation time segment limits that part of the bit time that may be used for the phase buffer segments.

The combination Prop\_Seg = 1 and Phase\_Seg1 = Phase\_Seg2 = SJW = 4 allows the largest possible oscillator tolerance of 1.58%. This combination with a propagation time segment of only 10% of the bit time is not suitable for short bit times; it can be used for bit rates of up to 125 kBit/s (bit time = 8 μs) with a bus length of 40 m.

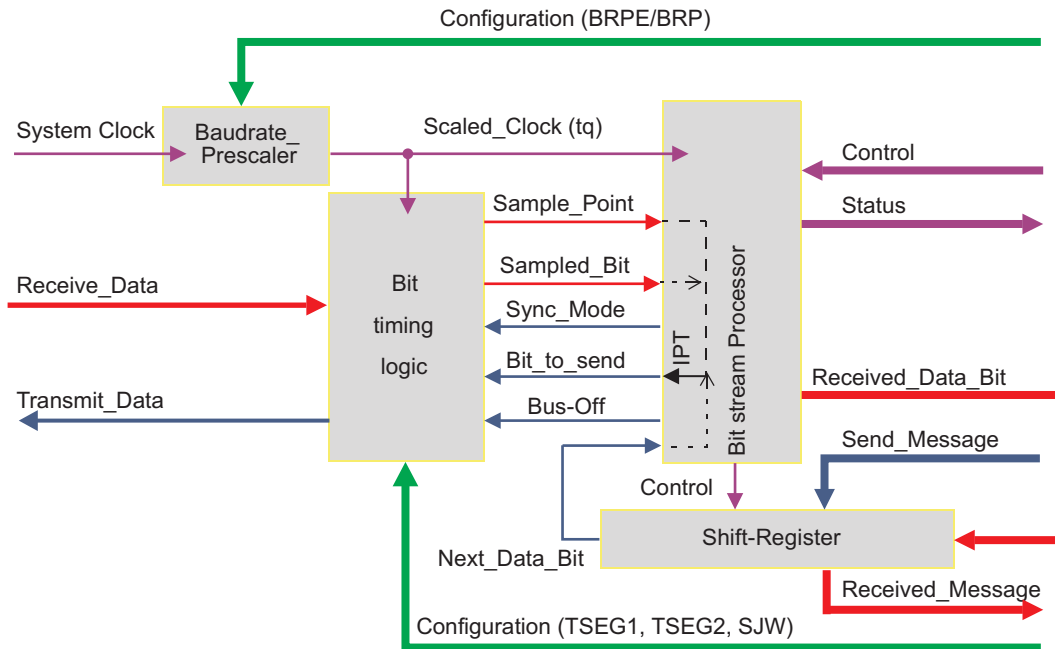

#### 24.10.4.9.2 DCAN Bit Timing Registers

In the DCAN, the bit timing configuration is programmed in [DCAN\\_BTR\[14:0\]](#), additionally a baud rate prescaler extension of four bits ([DCAN\\_BTR\[19:16\] BRPE](#)) is provided.

- The sum of Prop\_Seg and Phase\_Seg1 is set in [11:8] TSEG1
- Phase\_Seg2 in [14:12] TSEG2
- SynchronizationJumpWidth in [7:6] SJW
- and baud rate prescaler [5:0] BRP (plus [19:16] BRPE)

Figure 24-178 shows the CAN protocol controller.

**Figure 24-178. Structure of the CAN Core's CAN Protocol Controller**

dcan-017

In [DCAN\\_BTR](#) register, the components TSEG1, TSEG2, SJW and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1...n], values in the range of [0...n-1] are programmed. That way, e.g., SJW (functional range of [1...4]) is represented by only two bits.

Therefore, the length of the bit time is (programmed values)  $[TSEG1 + TSEG2 + 3] t_q$  or (functional values)  $[Sync\_Seg + Prop\_Seg + Phase\_Seg1 + Phase\_Seg2] t_q$ .

The data in the bit timing register ([DCAN\\_BTR](#)) is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by BRPE/BRP) defines the length of the time quantum (the basic time unit of the bit time); the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the sample point, and occasional synchronizations are controlled by the bit timing state machine, which is evaluated once each time quantum. The rest of the CAN protocol controller, the bit stream processor (BSP) state machine, is evaluated once each bit time, at the sample point.

The shift register serializes the messages to be sent and parallelizes received messages. Its loading and shifting is controlled by the BSP. The BSP translates messages into frames and vice versa. It generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. It is evaluated at the sample point and processes the sampled bus input bit. The time after the sample point that is needed to calculate the next bit to be sent (e.g., data bit, CRC bit, stuff bit, error flag, or idle) is called the information processing time (IPT), which is  $0 t_q$  for the DCAN.

Generally, the IPT is CAN controller-specific, but may not be longer than  $2 t_q$ . The IPC length is the lower limit of the programmed length of Phase\_Seg2. In case of a synchronization, Phase\_Seg2 may be shortened to a value less than IPT, which does not affect bus timing.

**24.10.4.9.2.1 Calculation of the Bit Timing Parameters**

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting bit time (1 / Bit rate) must be an integer multiple of the CAN clock period.

The bit time may consist of 8 to 25 time quanta. The length of the time quantum  $t_q$  is defined by the baud rate prescaler with  $t_q = (\text{Baud Rate Prescaler}) / \text{FCLK}$ . Several combinations may lead to the desired bit time, allowing iterations of the following steps.

First part of the bit time to be defined is the Prop\_Seg. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandible CAN bus systems. The resulting time for Prop\_Seg is converted into time quanta (rounded up to the nearest integer multiple of  $t_q$ ).

The Sync\_Seg is 1  $t_q$  long (fixed), leaving (bit time – Prop\_Seg – 1)  $t_q$  for the two Phase Buffer Segments. If the number of remaining  $t_q$  is even, the Phase Buffer Segments have the same length, Phase\_Seg2 = Phase\_Seg1, else Phase\_Seg2 = Phase\_Seg1 + 1.

The minimum nominal length of Phase\_Seg2 has to be regarded as well. Phase\_Seg2 may not be shorter than any CAN controller’s Information Processing Time in the network, which is device dependent and can be in the range of [0...2]  $t_q$ .

The length of the synchronization jump width is set to its maximum value, which is the minimum of four (4) and Phase\_Seg1.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formulas given in [Table 24-1128](#).

If more than one configurations are possible to reach a certain Bit rate, it is recommended to choose the configuration which allows the highest oscillator tolerance range.

CAN nodes with different clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system’s oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies’ stability has to be increased in order to find a protocol compliant configuration of the CAN bit timing.

The resulting configuration is written into the bit timing register ([DCAN\\_BTR](#)):

- [14:12] TSEG2 = Phase\_Seg2 - 1
- [11:8] TSEG1 = Phase\_Seg1+ Prop\_Seg - 1
- [7:6] SJW = SynchronizationJumpWidth - 1
- [5:0] BRP = Prescaler - 1

**24.10.4.9.2.2 Example for Bit Timing Calculation**

In this example, the frequency of FCLK is 20 MHz, BRP is 2, the bit rate is 500 KBit/s.

**Table 24-1128. Example For Bit Timing**

Parameter	Formula	Value	$t_q$
bit time (500 KBit/s)	1/bit rate, consists of $t_{\text{Sync\_Seg}} + t_{\text{TSeg1}} + t_{\text{TSeg2}}$	2000 ns	20
delay of bus driver		280 ns	-
delay of receiver circuit		29 ns	-
delay of bus line (16 m)	$16 \times 5.5 \text{ ns/m}$	88 ns	-
$t_q$	BRP/FCLK	100 ns	1
$t_{\text{Sync\_Seg}}$	$1 \times t_q$ (fixed)	100 ns	1
$t_{\text{Prop\_Seg}}$	INT ( $2 \times \text{delays} + 1$ ) = $8 \times t_q$	800 ns	8
$t_{\text{Seg1}}$	$t_{\text{Prop\_Seg}} + t_{\text{Phase\_Seg1}}$	1400 ns	14

**Table 24-1128. Example For Bit Timing (continued)**

Parameter	Formula	Value	$t_q$
$t_{Seg2}$	bit time - ( $t_{Sync\_Seg} + t_{Seg1}$ )	500 ns	5
$t_{SJWmax}$	MIN ( $4 \times t_q, t_{Phase\_Seg1}$ )	400 ns	4

In this example, the bit timing register [DCAN\\_BTR](#) is programmed to:

- BRP = 2 - 1 = 1
- BRPE = 0
- TSEG1 = 14 - 1 = 13 (0xC)
- TSEG2 = 5 - 1 = 4
- SJW = 4 - 1 = 3

#### 24.10.4.10 Message Interface Register Sets

The interface register sets control the software read and write accesses to the message RAM. There are two interface registers sets for read/write access, IF1 and IF2 and one interface register set for read access only, IF3.

Due to the structure of the message RAM, it is not possible to change single bits or bytes of a message object. Instead, always a complete message object in the message RAM is accessed. Therefore the data transfer from the IF1/IF2 registers to the message RAM requires the message handler to perform a read-modify-write cycle: First those parts of the message object that are not to be changed are read from the message RAM into the interface register set, and after the update the whole content of the interface register set is written into the message object.

After the partial write of a message object, those parts of the interface register set that are not selected in [DCAN\\_IF1CMD/DCAN\\_IF2CMD](#), will be set to the actual contents of the selected message object.

After the partial read of a message object, those parts of the interface register set that are not selected in [DCAN\\_IF1CMD/DCAN\\_IF2CMD](#), will be left unchanged.

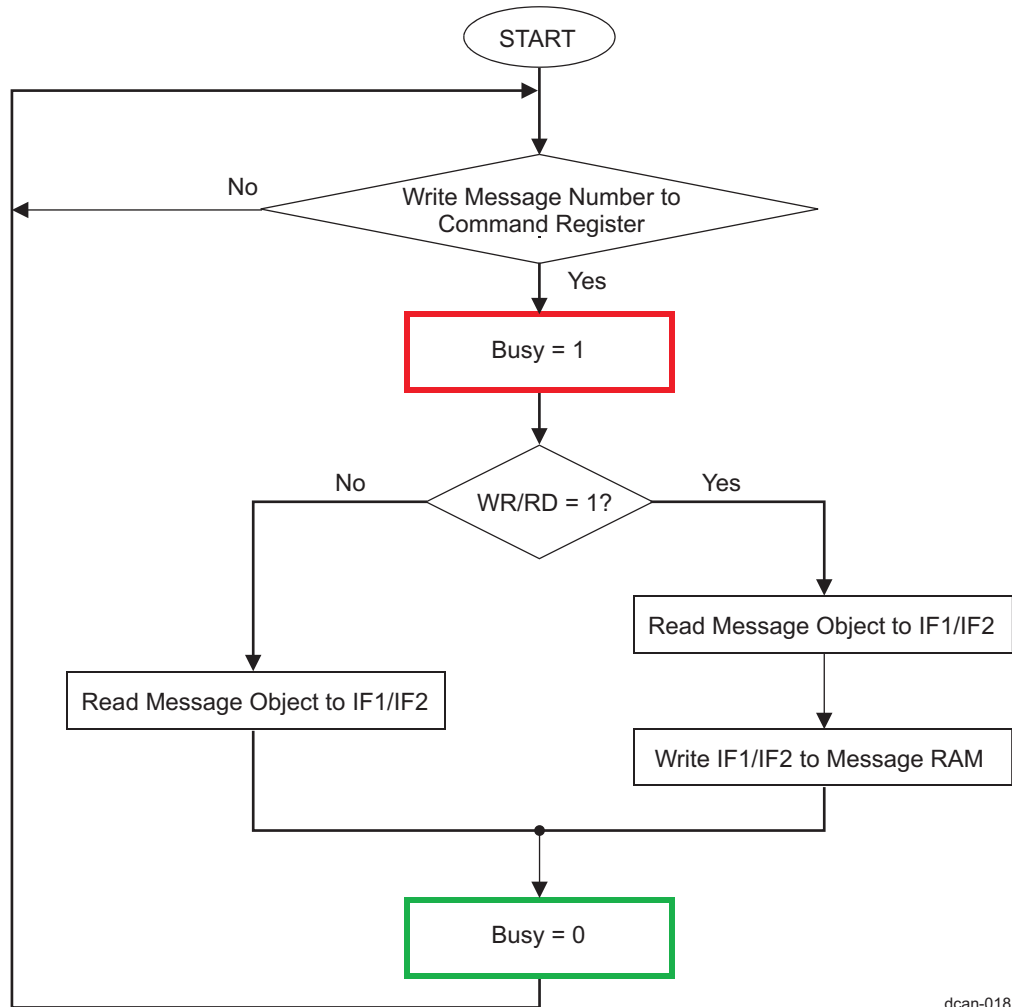

By buffering the data to be transferred, the interface register sets avoid conflicts between concurrent software accesses to the message RAM and CAN message reception and transmission. A complete message object (see [Section 24.10.4.11.1, Structure of Message Objects](#)) or parts of the message object may be transferred between the message RAM and the IF1/IF2 register set (see [Section 24.10.5, DCAN Register Manual](#)) in one single transfer. This transfer, performed in parallel on all selected parts of the message object, guarantees the data consistency of the CAN message.

##### 24.10.4.10.1 Message Interface Register Sets 1 and 2

The IF1 and IF2 register sets control the data transfer to and from the message object. [DCAN\\_IF1CMD/DCAN\\_IF2CMD](#) address the desired message object in the message RAM and specifies whether a complete message object or only parts should be transferred. The data transfer is initiated by writing the message number to the bits [7:0] MESSAGE\_NUMBER.

When the software initiates a data transfer between the IF1/IF2 registers and message RAM, the message handler sets the [15] BUSY bit in respective [DCAN\\_IF1CMD/DCAN\\_IF2CMD](#) to 1. After the transfer has completed, the BUSY bit is set back to 0 (see [Figure 24-179](#)).

**Figure 24-179. Data Transfer Between IF1/IF2 Registers and Message RAM**

dcan-018

#### 24.10.4.10.2 IF3 Register Set

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by software. The intention of this feature of IF3 is to provide an interface for the DMA to read packets efficiently. The automatic update functionality can be programmed for each message object ([DCAN\\_IF3UPD12](#) to [DCAN\\_IF3UPD78](#)).

All valid message objects in message RAM which are configured for automatic update, will be checked for active NewDat flags. If such a message object is found, it will be transferred to the IF3 register (if no previous DMA transfers are ongoing), controlled by IF3 Observation register ([DCAN\\_IF3OBS](#)). If more than one NewDat flag is active, the message object with the lowest number has the highest priority for automatic IF3 update.

The NewDat bit in the message object will be reset by a transfer to IF3.

If DCAN internal IF3 update is complete, a DMA request is generated. The DMA request stays active until first read access to one of the IF3 registers. The DMA functionality has to be enabled by setting bit [DCAN\\_CTL\[20\] DE3 = 1](#).

---

**NOTE:** The IF3 register set cannot be used for transferring data into message objects.

---

### 24.10.4.11 Message RAM

The DCAN message RAM contains message objects and parity bits for the message objects. There are up to 64 message objects in the message RAM.

During normal operation, accesses to the message RAM are performed via the interface register sets, and the software cannot directly access the message RAM.

The interface register sets IF1 and IF2 provide indirect read/write access from the software to the message RAM. The IF1 and IF2 register sets can buffer control and user data to be transferred to and from the message objects.

The third interface register set IF3 can be configured to automatically receive control and user data from the message RAM when a message object has been updated after reception of a CAN message. The software does not need to initiate the transfer from message RAM to IF3 register set.

The message handler avoids potential conflicts between concurrent accesses to message RAM and CAN frame reception/transmission.

There are two modes where the message RAM can be directly accessed by the software:

- Debug/Suspend mode (see [Section 24.10.4.11.3](#), *Message RAM Representation in Debug/Suspend Mode*)
- RAM Direct Access (RDA) mode (see [Section 24.10.4.11.4](#), *Message RAM Representation in Direct Access Mode*)

#### CAUTION

Writes to the DCAN RAM must not be done while it is in low-power mode. If such writes occur, the behavior is undefined and RAM content is corrupted. It has to be ensured in software that the low-power mode is removed from the DCAN RAM before writing to it.

#### 24.10.4.11.1 Structure of Message Objects

[Table 24-1129](#) shows the structure of a message object.

The highlighted fields are those parts of the message object which are represented in dedicated registers. For example, the transmit request flags of all message objects are represented in centralized transmit request registers.

**Table 24-1129. Structure of a Message Object**

UMask	Msk[28:0]	MXtd	MDir	EoB	unused	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
MsgVal	ID[28:0]	Xtd	Dir	DLC[3:0]	Data 0	Data 1	Data 2	Data 3	Data 4	Data 5	Data 6	Data 7

**Table 24-1130. Message Object Field Descriptions**

Field Name	Value	Description
MsgVal		Message valid
	0	The message object is ignored by the message handler.
	1	The message object is to be used by the message handler.
<p>Note: This bit may be kept at level '1' even when the identifier bits ID[28:0], the control bits Xtd, Dir, or the data length code are changed. It should be reset if the Messages Object is no longer required. The software must reset the MsgVal bit of all unused Messages Objects during the initialization before it resets the INIT bit in the <a href="#">DCAN_CTL</a> register.</p>		

**Table 24-1130. Message Object Field Descriptions (continued)**

Field Name	Value	Description
UMask		Use acceptance mask
	0	Mask bits (Msk[28:0], MXtd and MDir) are ignored and not used for acceptance filtering.
	1	Mask bits are used for acceptance filtering.  Note: If the UMask bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one.
ID[28:0]		Message identifier
	ID[28:0]	29-bit ("extended") identifier bits
	ID[28:18]	11-bit ("standard") identifier bits
Msk[28:0]		Identifier mask
	0	The corresponding bit in the message identifier is not used for acceptance filtering (don't care).
	1	The corresponding bit in the message identifier is used for acceptance filtering.
Xtd		Mask extended identifier
	0	The extended identifier bit (IDE) has no effect on the acceptance filtering.
	1	The extended identifier bit (IDE) is used for acceptance filtering.  Note: When 11-bit ("standard") Identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered.
Dir		Message direction
	0	Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, the message is stored in this message object.
	1	Direction = transmit: On TxRqst, a data frame is transmitted. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = one).
MDir		Mask message direction
	0	The message direction bit (Dir) has no effect on the acceptance filtering.
	1	The message direction bit (Dir) is used for acceptance filtering.
EOB		End of block
	0	The message object is part of a FIFO Buffer block and is not the last message object of this FIFO Buffer block.
	1	The message object is a single message object or the last message object in a FIFO Buffer Block.  Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one.
NewDat		New data
	0	No new data has been written into the data bytes of this message object by the message handler since the last time when this flag was cleared by the software.
	1	The message handler or the software has written new data into the data bytes of this message object.
MsgLst		Message lost (only valid for message objects with direction = receive)
	0	No message was lost since the last time when this bit was reset by the software.
	1	The message handler stored a new message into this message object when NewDat was still set, so the previous message has been overwritten.
RxIE		Receive interrupt enable
	0	IntPnd will not be triggered after the successful reception of a frame.
	1	IntPnd will be triggered after the successful reception of a frame.
TxIE		Transmit interrupt enable
	0	IntPnd will not be triggered after the successful transmission of a frame.
	1	IntPnd will be triggered after the successful transmission of a frame.
IntPnd		Interrupt pending
	0	This message object is not the source of an interrupt.
	1	This message object is the source of an interrupt. The interrupt Identifier in the interrupt register (DCAN_INT) will point to this message object if there is no other interrupt source with higher priority.

**Table 24-1130. Message Object Field Descriptions (continued)**

Field Name	Value	Description
RmtEn		Remote enable
	0	At the reception of a remote frame, TxRqst is not changed.
	1	At the reception of a remote frame, TxRqst is set.
TxRqst		Transmit request
	0	This message object is not waiting for a transmission.
	1	The transmission of this message object is requested and is not yet done.
DLC[3:0]		Data length code
	0 - 8	Data frame has 0 - 8 data bytes.
	9 - 15	Data frame has 8 data bytes.
		Note: The data length code of a message object must be defined to the same value as in the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.
Data 0		1st data byte of a CAN data frame
Data 1		2nd data byte of a CAN data frame
Data 2		3rd data byte of a CAN data frame
Data 3		4th data byte of a CAN data frame
Data 4		5th data byte of a CAN data frame
Data 5		6th data byte of a CAN data frame
Data 6		7th data byte of a CAN data frame
Data 7		8th data byte of a CAN data frame
		Note: Byte Data 0 is the first data byte shifted into the shift register of the CAN core during a reception, byte Data 7 is the last. When the message handler stores a data frame, it will write all the eight data bytes into a message object. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by undefined values.

#### 24.10.4.11.2 Addressing Message Objects in RAM

The starting location of a particular message object in RAM is:  
 Message RAM base address + (message object number) × 0x20

That is, message object 1 starts at offset 0x0020; message object 2 starts at offset 0x0040, etc.

**NOTE:** Because 0 is not a valid message object number, at offset 0x0000 is not located message object 0, but the last implemented: 64.

The base address for DCAN1 RAM is 0x4AE3 D000 and DCAN2 RAM is 0x4848 1000.

Message object number 1 has the highest priority.

**Table 24-1131. Message RAM Addressing in Debug/Suspend and RDA Modes**

Message Object Number	Offset	Word Number	Debug/Suspend Mode, see Section 24.10.4.11.3	RDA Mode, see Section 24.10.4.11.4
64 (last implemented)	0x0000	1	Parity	Data Bytes 4-7
	0x0004	2	MXtd,MDir,Mask	Data Bytes 0-3
	0x0008	3	Xtd,Dir,ID	ID[27:0],DLC
	0x000C	4	Ctrl	Mask,Xtd,Dir,ID[28]

### 24.10.4.11.3 Message RAM Representation in Debug/Suspend Mode

In debug/suspend mode, the message RAM will be memory mapped. This allows the external debug unit to access the message RAM.

**NOTE:** During debug/suspend mode, the message RAM cannot be accessed via the IFx register sets.

**Table 24-1132. Message RAM Representation in Debug/Suspend Mode**

#### 24.10.4.11.4 Message RAM Representation in Direct Access Mode

When the [DCAN\\_TEST](#)[9] RDA bit is set while the DCAN module is in test mode ([DCAN\\_CTL](#)[7] TEST = 1), the software has direct access to the message RAM. Due to the 32-bit bus structure, the RAM is split into word lines to support this feature. The software has access to one word line at a time only.

In RAM direct access mode, the RAM is represented by a continuous memory space within the address frame of the DCAN module, starting at the message RAM base address.

Note: During direct access mode, the message RAM cannot be accessed via the IFx register sets.

Any read or write to the RAM addresses for RAM Direct Access during normal operation mode (TEST bit or RDA bit not set) will be ignored.

**Table 24-1133. Message RAM Representation in RAM Direct Access Mode**

#### 24.10.4.12 CAN Operation

After device reset, the `DCAN_CTL[0] INIT` is set and all CAN protocol functions are disabled. The CAN module must be initialized before operating it. Figure 24-180 illustrates the basic initialization flow for the CAN module.

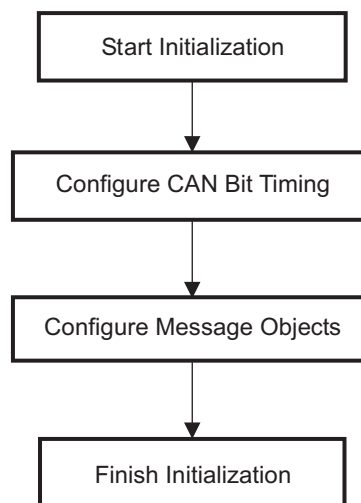

##### 24.10.4.12.1 CAN Module Initialization

A general CAN module initialization would mean the following two critical steps:

- Configuration of the CAN bit timing
- Configuration of message objects

To initialize the CAN controller, the software has to set up the CAN bit timing and those message objects that have to be used for CAN communication. Message objects that are not needed, can be deactivated.

**Figure 24-180. CAN Module General Initialization Flow**

dcan-019

**24.10.4.12.1.1 Configuration of CAN Bit Timing**

The CAN module must be in initialization mode to configure the CAN bit timing.

For CAN bit timing software configuration flow, see [Figure 24-181](#), *CAN Bit-Timing Configuration*.

**Step 1:** Enter *initialization mode* (DCAN\_CTL[0] INIT = 1).

While the INIT bit is set, the message transfer from and to the CAN bus is stopped, and the status of the CAN\_TX output is recessive (high).

The CAN error counters are not updated. Setting the INIT bit does not change any other configuration register.

Also, note that the CAN module is in initialization mode on device reset and during Bus-Off.

**Figure 24-181. CAN Bit-Timing Configuration**

**Step 2:** Set the Configure Change Enable bit (DCAN\_CTL[6] CCE = 1).

The access to the Bit Timing register (DCAN\_BTR) for the configuration of the bit timing is enabled when both INIT = 1 and CCE = 1.

**Step 3:** Wait for the INIT bit to get set (=1). This would make sure that the module has entered Initialization mode.

**Step 4:** Write the bit timing values into DCAN\_BTR. See [Section 24.10.4.9.2](#), *DCAN Bit Timing Registers* for the values calculation for a given bit timing.

**Step 5:** Clear the CCE and INIT bits (=0).

**Step 6:** Wait for the INIT bit to clear (=0). This would ensure that the module has come out of Initialization mode.

Following these steps, the module comes to operation by synchronizing itself to the CAN bus, provided the [DCAN\\_BTR](#) is configured as per the CAN bus baud rate, although the message objects have to be configured before carrying out any communication.

---

**NOTE:** The module will not come out of the Initialization mode if any incorrect [DCAN\\_BTR](#) values are written in step 4.

---

---

**NOTE:** The required message objects should be configured as transmit or receive objects before the start of data transfer as explained in [Section 24.10.4.12.1, CAN Module Initialization](#).

---

#### 24.10.4.12.1.2 Configuration of Message Objects

The message objects can be configured only through the interface registers; the software does not have direct access to the message object (message RAM) . Familiarize yourself with the interface register set (IFx) usage (see [Section 24.10.4.10, Message Interface Register Sets](#)) and the message object structure (see [Section 24.10.4.11, Message RAM](#)) before configuring the message objects.

For more information regarding the procedure to configure the message objects, see [Section 24.10.4.7, Configuration of Message Objects Description](#). All the message objects should be configured to particular identifiers or set to not valid before the message transfer is started. It is possible to change the configuration of message objects during normal operation (that is between data transfers).

---

**NOTE:** The message objects initialization is independent of the bit-timing configuration.

---

#### 24.10.4.12.1.3 DCAN RAM Hardware Initialization

The memory hardware initialization for the DCAN module is enabled in the device control module. Setting `RAMINIT_START` to 1, causes RAM initialization with zeros and sets parity bits accordingly. Software must wait for the `RAMINIT_DONE` bit to be set to ensure successful RAM initialization.

For more details on `CTRL_CORE_CONTROL_IO_2` register, see [Section 18.5, Control Module Register Manual](#).

#### 24.10.4.12.2 CAN Message Transfer (Normal Operation)

Once the DCAN is initialized and `DCAN_CTL[0] INIT` bit is reset (=0), the CAN core synchronizes itself to the CAN bus and is ready for message transfer as per the configured message objects.

The software may enable the interrupt lines (`DCAN_CTL[1] IE0` and `[17] IE1 = 1`) at the same time when it clears `[0] INIT` and `[6] CCE = 0`. The status interrupts `[3] EIE` and `[2] SIE` may be enabled (=1) simultaneously.

The CAN communication can be carried out in any of the following two modes: interrupt and polling.

The `DCAN_INT` register points to those message objects with `IntPnd = 1`. It is updated even if the interrupt lines to the host processor are disabled (`DCAN_CTL[1] IE0` and `[17] IE1 = 0`).

The software may poll all MessageObject's `NewDat` and `TxRqst` bits in parallel from the `DCAN_NWDAT_X` and the `DCAN_TXRQ_X` registers respectively. Polling can be made easier if all transmit objects are grouped at the low numbers and all receive objects are grouped at the high numbers.

Received messages are stored into their appropriate message objects if they pass acceptance filtering.

The whole message (including all arbitration bits, DLC and up to eight data bytes) is stored into the message object. As a consequence (e.g., when the identifier mask is used), the arbitration bits which are masked to "don't care" may change in the message object when a received message is stored.

The software may read or write each message at any time via the interface registers, as the message handler guarantees data consistency in case of concurrent accesses.

If a permanent message object (arbitration and control bits set up during configuration and leaving unchanged for multiple CAN transfers) exists for the message, it is possible to only update the data bytes.

If several transmit messages should be assigned to one message object, the whole message object has to be configured before the transmission of this message is requested.

The transmission of multiple message objects may be requested at the same time. They are subsequently transmitted, according to their internal priority.

Messages may be updated or set to not valid at any time, even if a requested transmission is still pending. However, the data bytes will be discarded if a message is updated before a pending transmission has started.

Depending on the configuration of the message object, a transmission may be automatically requested by the reception of a remote frame with a matching identifier.

#### 24.10.4.12.2.1 Automatic Retransmission

According to the CAN Specification (ISO11898), the DCAN provides a mechanism to automatically retransmit frames which have lost arbitration or have been disturbed by errors during transmission. The frame transmission service will not be confirmed to the user before the transmission is successfully completed.

By default, this automatic retransmission is enabled. It can be disabled by setting bit disable automatic retransmission ( [DCAN\\_CTL\[5\] DAR = 1](#)). Further details to this mode are provided in [Section 24.10.4.8.3, Transmission of Messages in Event Driven CAN Communication](#).

#### 24.10.4.12.2.2 Auto-Bus-On

By default, after the DCAN has entered Bus-Off state, the software can start a Bus-Off-Recovery sequence by resetting the [DCAN\\_CTL\[0\] INIT](#) bit to 0. If this is not done, the module will stay in Bus-Off state.

The DCAN provides an automatic Auto-Bus-On feature which is enabled by bit [DCAN\\_CTL\[9\] ABO](#). If set, the DCAN will automatically start the Bus-Off-Recovery sequence. The sequence can be delayed by a user-defined number of interface clock cycles which can be defined in the Auto-Bus-On Time register ([DCAN\\_ABOTR](#)).

---

**NOTE:** If the DCAN goes to Bus-Off state due to a massive occurrence of CAN bus errors, it stops all bus activities and automatically sets the INIT bit. Once the INIT bit has been reset by the software or due to the Auto-Bus-On feature, the device will wait for 129 occurrences of bus Idle (equal to 129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus-Off recovery sequence, the error counters will be reset.

---

#### 24.10.4.12.3 Test Modes

The DCAN module provides several test modes which are mainly intended for production tests or self test.

For all test modes, the [DCAN\\_CTL\[7\] TEST](#) bit needs to be set to 1. This enables write access to the test register ([DCAN\\_TEST](#)).

---

**NOTE:** It must be ensured by software that all message transfers are completed before entering test mode.

---

#### 24.10.4.12.3.1 Silent Mode

The silent mode may be used to analyze the traffic on the CAN bus without affecting it by sending dominant bits (e.g., acknowledge bit, overload flag, active error flag). The DCAN is still able to receive valid data frames and valid remote frames, but it will not send any dominant bits. However, these are internally routed to the CAN core.

Figure 24-182 shows the connection of signals CAN\_TX and CAN\_RX to the CAN core in silent mode. Silent mode can be activated by setting the DCAN\_TEST[3] SILENT bit to 1. In ISO 11898-1, the silent mode is called the bus monitoring mode.

**Figure 24-182. CAN Core in Silent Mode**

**24.10.4.12.3.2 Loopback Mode**

The loopback mode is mainly intended for hardware self-test functions. In this mode, the CAN core uses internal feedback from Tx output to Rx input. Transmitted messages are treated as received messages, and can be stored into message objects if they pass acceptance filtering. The actual value of the CAN\_RX input pin is disregarded by the CAN core. Transmitted messages can still be monitored at the CAN\_TX pin.

In order to be independent from external stimulation, the CAN core ignores acknowledge sampled in the acknowledge slot of a data/remote frame.

Figure 24-183 shows the connection of signals CAN\_TX and CAN\_RX to the CAN core in loopback mode. Loopback mode can be activated by setting bit DCAN\_TEST[4] LBACK to 1.

---

**NOTE:** In loopback mode, the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN core are disregarded. For including these into the testing, see Section 24.10.4.12.3.3, *External Loopback Mode*.

---

**Figure 24-183. CAN Core in Loopback Mode**

### 24.10.4.12.3.3 External Loopback Mode

The external loopback mode is similar to the loopback mode; however, it includes the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN core. When external loopback mode is selected, the input of the CAN core is connected to the input buffer of the Tx pin.

With this configuration, the Tx pin IO circuit can be tested.

External loopback mode can be activated by setting bit `DCAN_TEST[8] EXL` to 1.

Figure 24-184 shows the connection of signals `CAN_TX` and `CAN_RX` to the CAN core in external loopback mode.

---

**NOTE:** When loopback mode is active (LBACK bit set), the EXL bit will be ignored.

---

**Figure 24-184. CAN Core in External Loopback Mode**

### 24.10.4.12.3.4 Loopback Mode Combined With Silent Mode

It is also possible to combine loopback mode and silent mode by setting bits `DCAN_TEST[4] LBACK` and `[3] SILENT` at the same time. This mode can be used for a "Hot Selftest", that is, the DCAN hardware can be tested without affecting the CAN network. In this mode, the `CAN_RX` pin is disconnected from the CAN core and no dominant bits will be sent on the `CAN_TX` pin.

Figure 24-185 shows the connection of the signals `CAN_TX` and `CAN_RX` to the CAN core in case of the combination of loopback mode with silent mode.

**Figure 24-185. CAN Core in Loop Back Combined With Silent Mode**

#### 24.10.4.12.3.5 Software Control of CAN\_TX Pin

Four output functions are available for the CAN transmit pin CAN\_TX. In addition to its default function (serial data output), the CAN\_TX pin can drive constant dominant or recessive values, or it can drive the CAN sample point signal to monitor the CAN core's bit timing.

Combined with the readable value of the CAN\_RX pin, this function can be used to check the physical layer of the CAN bus.

The output mode of pin CAN\_TX is selected by programming the [DCAN\\_TEST\[6:5\] TX](#):

- 0x0: Normal operation, CAN\_TX is controlled by the DCAN core
- 0x1: Sample point can be monitored at CAN\_TX pin
- 0x2: CAN\_TX pin drives a dominant value
- 0x3: CAN\_TX pin drives a recessive value.

---

**NOTE:** The software control for the CAN\_TX pin interferes with CAN protocol functions. For CAN message transfer or any of the test modes (loopback mode, external loopback mode or silent mode), the CAN\_TX pin should operate in its default functionality.

---

#### 24.10.4.13 GPIO Support

The CAN\_RX and CAN\_TX pins of the DCAN module can be used as general purpose IO pins, if CAN functionality is not needed. This function is controlled by the CAN TX IO control register ([DCAN\\_TIOC](#)) and the CAN RX IO control register ([DCAN\\_RIOC](#)).

## 24.10.5 DCAN Register Manual

### 24.10.5.1 DCAN Instance Summary

**Table 24-1134. DCAN Instance Summary**

Module Name	Base Address	Size
DCAN1	0x4AE3 C000	8 KiB
DCAN2	0x4848 0000	8 KiB

### 24.10.5.2 DCAN Registers

**NOTE:** After device reset, the registers of the DCAN hold the values shown in the register descriptions.

Additionally, the Bus-Off state is reset and the CAN\_TX pin is set to recessive (HIGH). The INIT bit in the [DCAN\\_CTL](#) is set to enable the software initialization. The DCAN will not influence the CAN bus until the software resets INIT to 0.

#### 24.10.5.2.1 DCAN Register Summary

### 24.10.5.2.2 DCAN Register Description

**Table 24-1136. DCAN\_CTL**

<b>Address Offset</b>	0x0000 0000		
<b>Physical Address</b>	0x4AE3 C000 0x4848 0000	<b>Instance</b>	DCAN1 DCAN2
<b>Description</b>	DCAN control register <b>NOTE:</b> The Bus-Off recovery sequence (refer to CAN specification) cannot be shortened by setting or resetting INIT bit. If the module goes Bus-Off, it will automatically set the INIT bit and stop all bus activities. When the INIT bit is cleared by the application again, the module will then wait for 129 occurrences of Bus Idle (129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the bus-off recovery sequence, the error counters will be reset. After the INIT bit is reset, each time when a sequence of 11 recessive bits is monitored, a Bit0 error code is written to <a href="#">DCAN_ES</a> , enabling the software to check whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
RESERVED								RESERVED		DE3	DE2	DE1	IE1	INITDBG	SWR	RESERVED	PMD						ABO	IDS	TEST	CCE	DAR	RESERVED	EIE	SIE	IE0	INIT

Bits	Field Name	Description	Type	Reset
31:26	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x00
25	WUBA	Automatic wake up on bus activity when in local power-down mode. Note: The CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power down and automatic wake-up mode, will be lost.  0: No detection of a dominant CAN bus level while in local power-down mode.  1: Detection of a dominant CAN bus level while in local power-down mode is enabled. On occurrence of a dominant CAN bus level, the wake up sequence is started (Additional information can be found in <i>Local Power-Down Mode</i> ).	RW	0
24	PDR	Request for local low power-down mode  0: No application request for local low power-down mode. If the application has cleared this bit while DCAN in local power-down mode, also the INIT bit has to be cleared.  1: Local power-down mode has been requested by application. The DCAN will acknowledge the local power-down mode by setting bit PDA in the <a href="#">DCAN_ES</a> register. The local clocks will be turned off by DCAN internal logic (Additional information can be found in <i>Local Power-Down Mode</i> ).	RW	0
23:21	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x0
20	DE3	Enable DMA request line for IF3. Note: A pending DMA request for IF3 remains active until first access to one of the IF3 registers.  0: Disabled 1: Enabled	RW	0
19	DE2	Enable DMA request line for IF2. Note: A pending DMA request for IF2 remains active until first access to one of the IF2 registers.  0: Disabled 1: Enabled	RW	0

Bits	Field Name	Description	Type	Reset
18	DE1	Enable DMA request line for IF1. Note: A pending DMA request for IF1 remains active until first access to one of the IF1 registers.  0: Disabled 1: Enabled	RW	0
17	IE1	Interrupt line 1 enable  0: Disabled - Module interrupt INT1 is always low. 1: Enabled - interrupts will assert line INT1 to one; line remains active until pending interrupts are processed.	RW	0
16	INITDBG	Internal init state while debug access  0: Not in debug mode, or debug mode requested but not entered. 1: Debug mode requested and internally entered; the DCAN is ready for debug accesses.	RW	0
15	SWR	Software reset enable. Note: To execute software reset, the following procedure is necessary:  1. Set INIT bit to shut down CAN communication. 2. Set SWR (this) bit additionally to INIT bit.  0: Normal Operation 1: Module is forced to reset state. This bit will automatically get cleared after execution of software reset after one OCP clock cycle.	RW	0
14	RESERVED	This bit is always read as 0. Writes have no effect.	R	0
13:10	PMD	Parityon/off  0x5: function disabled Others: function enabled	RW	0x5
9	ABO	Auto-Bus-On enable  0: The Auto-Bus-On feature is disabled 1: The Auto-Bus-On feature is enabled	RW	0
8	IDS	Interruption debug support enable  0: When Debug/Suspend mode is requested, DCAN will wait for a started transmission or reception to be completed before entering Debug/Suspend mode 1: When Debug/Suspend mode is requested, DCAN will interrupt any transmission or reception, and enter Debug/Suspend mode immediately.	RW	0
7	TEST	Test mode enable  0: Normal Operation 1: Test Mode	RW	0
6	CCE	Configuration change enable  0: The software has no write access to the configuration registers. 1: The software has write access to the configuration registers (when INIT bit is set).	RW	0
5	DAR	Disable automatic retransmission  0: Automatic retransmission of not successful messages enabled. 1: Automatic retransmission disabled.	RW	0
4	RESERVED	This bit is always read as 0. Writes have no effect.	R	0
3	EIE	Error interrupt enable  0: Disabled - PER, BOFF and EWARN bits can not generate an interrupt. 1: Enabled - PER, BOFF and EWARN bits can generate an interrupt at INTO line and affect the interrupt register.	RW	0

Bits	Field Name	Description	Type	Reset
2	SIE	Status change interrupt enable 0: Disabled - WAKEUPPND, RXOK, TXOK and LEC bits can not generate an interrupt. 1: Enabled - WAKEUPPND, RXOK, TXOK and LEC can generate an interrupt at INT0 line and affect the interrupt register.	RW	0
1	IE0	Interrupt line 0 enable 0: Disabled - Module interrupt INT0 is always low. 1: Enabled - interrupts will assert line INT0 to one; line remains active until pending interrupts are processed.	RW	0
0	INIT	Initialization 0: Normal operation 1: Initialization mode is entered	RW	1

**Table 24-1138. DCAN\_ES**

<b>Address Offset</b>	0x0000 0004	<b>Instance</b>	DCAN1 DCAN2
<b>Physical Address</b>	0x4AE3 C004 0x4848 0004		
<b>Description</b>	<p>Error and Status Register</p> <p>Interrupts are generated by bits PER, BOFF and EWARN (if EIE bit in <a href="#">DCAN_CTL</a> is 1) and by bits WAKEUPPND, RXOK, TXOK, and LEC (if SIE bit in <a href="#">DCAN_CTL</a> is 1). A change of bit EPASS will not generate an interrupt.</p> <p>Reading the <a href="#">DCAN_ES</a> clears the WAKEUPPND, PER, RXOK and TXOK bits and set the LEC to value '7.' Additionally, the status interrupt value (0x8000) in the <a href="#">DCAN_INT</a> will be replaced by the next lower priority interrupt value.</p> <p>For debug support, the auto clear functionality of <a href="#">DCAN_ES</a> (clear of status flags by read) is disabled when in debug/suspend mode.</p>		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0						
RESERVED																						PDA	WAKEUPPND	PER	BOFF	EWARN	EPASS	RXOK	TXOK								LEC

Bits	Field Name	Description	Type	Reset
31:11	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x00 0000
10	PDA	Local power-down mode acknowledge  0: DCAN is not in local power-down mode. 1: Application request for setting DCAN to local power-down mode was successful. DCAN is in local power-down mode.	R	0
9	WAKEUPPND	Wake up pending. This bit can be used by the software to identify the DCAN as the source to wake up the system. This bit will be reset if <a href="#">DCAN_ES</a> is read.  0: No Wake Up is requested by DCAN. 1: DCAN has initiated a wake up of the system due to dominant CAN bus while module power down.	R	0
8	PER	Parity error detected. This bit will be reset if <a href="#">DCAN_ES</a> register is read.  Read 0: No parity error has been detected since last read access. Read 1: The parity check mechanism has detected a parity error in the Message RAM. Write 0: No effect Write 1: End of interrupt (EOI) for parity error on <a href="#">DCAN_PARITY</a> interrupt line	RW	0
7	BOFF	Bus-Off state  0: The CAN module is not bus-off state. 1: The CAN module is in bus-off state.	R	0
6	EWARN	Warning state  0: Both error counters are below the error warning limit of 96. 1: At least one of the error counters has reached the error warning limit of 96.	R	0
5	EPASS	Error passive state  0: On CAN Bus error, the DCAN could send active error frames. 1: The CAN core is in the error passive state as defined in the CAN Specification.	R	0

Bits	Field Name	Description	Type	Reset
4	RXOK	<p>Received a message successfully. This bit will be reset if <a href="#">DCAN_ES</a> register is read.</p> <p>0: No message has been successfully received since the last time when this bit was read by the software. This bit is never reset by DCAN internal events.</p> <p>1: A message has been successfully received since the last time when this bit was reset by a read access of the software (independent of the result of acceptance filtering).</p>	R	0
3	TXOK	<p>Transmitted a message successfully. This bit will be reset if <a href="#">DCAN_ES</a> register is read.</p> <p>0: No message has been successfully transmitted since the last time when this bit was read by the software. This bit is never reset by DCAN internal events.</p> <p>1: A message has been successfully transmitted (error free and acknowledged by at least one other node) since the last time when this bit was reset by a read access of the software.</p>	R	0
2:0	LEC	<p>Last error code. The LEC field indicates the type of the last error on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error.</p> <p>0x0: No error</p> <p>0x1: Stuff error: More than five equal bits in a row have been detected in a part of a received message where this is not allowed.</p> <p>0x2: Form error: A fixed format part of a received frame has the wrong format.</p> <p>0x3: Ack error: The message this CAN core transmitted was not acknowledged by another node.</p> <p>0x4: Bit1 error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant.</p> <p>0x5: Bit0 error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (logical value '0'), but the monitored bus level was recessive. During Bus-Off recovery, this status is set each time a sequence of 11 recessive bits has been monitored. This enables the software to monitor the proceeding of the Bus-Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed).</p> <p>0x6: CRC error: In a received message, the CRC check sum was incorrect. (CRC received for an incoming message does not match the calculated CRC for the received data).</p> <p>0x7: No CAN bus event was detected since the last time the software read <a href="#">DCAN_ES</a>. Any read access to <a href="#">DCAN_ES</a> re-initializes the LEC to value '7.'</p>	R	0x7

<b>Address Offset</b>	0x0000 0100		
<b>Physical Address</b>	0x4AE3 C100 0x4848 0100	<b>Instance</b>	DCAN1 DCAN2
<b>Description</b>	IF1 Command Register The IF1 Command Register ( <a href="#">DCAN_IF1CMD</a> ) configure and initiate the transfer between the IF1 register set and the message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the software writes the message number to bits [7:0] MESSAGE_NUMBER. With this write operation, the BUSY bit is automatically set to 1 to indicate that a transfer is in progress. After 4 to 14 OCP clock cycles, the transfer between the interface register and the message RAM will be completed and the BUSY bit is cleared. The maximum number of cycles is needed when the message transfer concurs with a CAN message transmission, acceptance filtering, or message storage. If the software writes to both <a href="#">DCAN_IF1CMD/DCAN_IF2CMD</a> consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed. While BUSY bit is one, IF1/IF2 register sets are write protected. For debug support, the auto clear functionality of the IF1/IF2 command registers (clear of DMAACTIVE flag by r/w) is disabled during Debug/Suspend mode. If an invalid Message Number is written to bits [7:0] MESSAGE_NUMBER, the message handler may access an implemented (valid) message object instead.		
<b>Type</b>	RW

<b>Address Offset</b>	0x0000 0120		
<b>Physical Address</b>	0x4AE3 C120 0x4848 0120	<b>Instance</b>	DCAN1 DCAN2
<b>Description</b>	<p>IF2 Command Register</p> <p>The IF2 Command Register (<a href="#">DCAN_IF2CMD</a>) configure and initiate the transfer between the IF2 register set and the message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the software writes the message number to bits [7:0] MESSAGE_NUMBER. With this write operation, the BUSY bit is automatically set to 1 to indicate that a transfer is in progress. After 4 to 14 OCP clock cycles, the transfer between the interface register and the message RAM will be completed and the BUSY bit is cleared. The maximum number of cycles is needed when the message transfer concurs with a CAN message transmission, acceptance filtering, or message storage. If the software writes to both <a href="#">DCAN_IF1CMD/DCAN_IF2CMD</a> consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed.</p> <p>While BUSY bit is one, IF1/IF2 register sets are write protected.</p> <p>For debug support, the auto clear functionality of the IF1/IF2 command registers (clear of DMAACTIVE flag by r/w) is disabled during Debug/Suspend mode.</p> <p>If an invalid Message Number is written to bits [7:0] MESSAGE_NUMBER, the message handler may access an implemented (valid) message object instead.</p>

<b>Physical Address</b>	0x4AE3 C140 0x4848 0140	<b>Instance</b>	DCAN1 DCAN2
<b>Description</b>	<p>IF3 Observation Register</p> <p>The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by software (Additional information can be found in <a href="#">Section 24.10.4.11.1 Structure of Message Objects</a>). The observation flags (Bits [4:0]) are used to determine, which data sections of the IF3 interface register set have to be read in order to complete a DMA read cycle. After all marked data sections are read, the DCAN is enabled to update the IF3 interface register set with new data. Any access order of single bytes or half-words is supported. When using byte or half-word accesses, a data section is marked as completed, if all bytes are read.</p> <p>NOTE: If IF3 Update Enable is used and no Observation flag is set, the corresponding message objects will be copied to IF3 without activating the DMA request line and without waiting for DMA read accesses.</p> <p>A write access to this register aborts a pending DMA cycle by resetting the DMA line and enables updating of IF3 interface register set with new data. To avoid data inconsistency, the DMA controller should be disabled before reconfiguring IF3 observation register. The status of the current read-cycle can be observed via status flags (Bits [12:8]).</p>

## 24.11 Gigabit Ethernet Switch (GMAC\_SW)

This chapter describes the three-port gigabit switch ethernet subsystem in the device.

### 24.11.1 GMAC\_SW Overview

The three-port gigabit ethernet switch subsystem (GMAC\_SW) provides ethernet packet communication and can be configured as an ethernet switch. It provides the gigabit media independent interface (G/MII) in MII mode, reduced gigabit media independent interface (RGMII), reduced media independent interface (RMII), and the management data input output (MDIO) for physical layer device (PHY) management.

Figure 24-186 shows the GMAC\_SW subsystem overview.

**Figure 24-186. GMAC\_SW Overview**

#### 24.11.1.1 Features

The GMAC\_SW subsystem provides the following features:

- Two Ethernet ports (port 1 and port 2) with selectable RGMII, RMII, and G/MII (in MII mode only) interfaces plus internal Communications Port Programming Interface (CPPI 3.1) on port 0
- Synchronous 10/100/1000 Mbit operation
- Wire rate switching (802.1d)
- Non-blocking switch fabric
- Flexible logical FIFO-based packet buffer structure
- Four priority level Quality Of Service (QOS) support (802.1p)
- CPPI 3.1 compliant DMA controllers

- Support for Audio/Video Bridging (P802.1Qav/D6.0)
- Support for IEEE 1588 Clock Synchronization (2008 Annex D and Annex F)
  - Timing FIFO and time stamping logic embedded in the subsystem
- Device Level Ring (DLR) Support
- Energy Efficient Ethernet (EEE) support (802.3az)
- Flow Control Support (802.3x)
- Address Lookup Engine (ALE)
  - 1024 total address entries plus VLANs
  - Wire rate lookup
  - Host controlled time-based aging
  - Multiple spanning tree support (spanning tree per VLAN)
  - L2 address lock and L2 filtering support
  - MAC authentication (802.1x)
  - Receive-based or destination-based multicast and broadcast rate limits
  - MAC address blocking
  - Source port locking
  - OUI (Vendor ID) host accept/deny feature
  - Remapping of priority level of VLAN or ports
- VLAN support
  - 802.1Q compliant
    - Auto add port VLAN for untagged frames on ingress
    - Auto VLAN removal on egress and auto pad to minimum frame size
- Ethernet Statistics:
  - EtherStats and 802.3Stats Remote network Monitoring (RMON) statistics gathering (shared)
  - Programmable statistics interrupt mask when a statistic is above one half its 32-bit value
- Flow Control Support (802.3x)
- Digital loopback and FIFO loopback modes supported
- Maximum frame size 2016 bytes (2020 with VLAN)
- 8k (2048 × 32) internal CPPI buffer descriptor memory
- Management Data Input/Output (MDIO) module for PHY Management
- Programmable interrupt control with selected interrupt pacing
- Emulation support
- Programmable Transmit Inter Packet Gap (IPG)
- Reset isolation (switch function remains active even in case of all device resets except for POR pin reset and ICEPICK cold reset)
- Full duplex mode supported in 10/100/1000 Mbps. Half-duplex mode supported only in 10/100 Mbps.
- IEEE 802.3 gigabit Ethernet conformant

---

**NOTE:** G/MII interface is functional in MII mode only.

## 24.11.2 GMAC\_SW Environment

### 24.11.2.1 G/MII Interface

G/MII Interface can operate only in MII Mode.

- In MII Mode (100/10 Mbps): GMAC\_SW operates in full-duplex and half-duplex.

The pin connections of the G/MII Interface is shown in Figure 24-187. The detailed description of the signals are listed in the following tables.

Figure 24-187. MII Interface Typical Application

Table 24-1250. MII I/O Description

Signal	Device Pin(s)	I/O <sup>(1)</sup>	Description
MT_CLK	mii0_txclk mii1_txclk	I	The transmit clock is a continuous clock that provides the timing reference for transmit operations. The MTXD and MTXEN signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
MTXD[3:0]	mii0_txd[3:0] mii1_txd[3:0]	O	The transmit data pins are a collection of 4 data signals MTXD[3:0] comprising 4 bits of data. MTXD0 is the least-significant bit (LSB). The signals are synchronized by MT_CLK and valid only when MTXEN is asserted.
MTXEN	mii0_txen mii1_txen	O	The transmit enable signal indicates that the MTXD pins are generating 4bit data for use by the PHY. It is driven synchronously by MT_CLK.
MTXER	mii0_txer mii1_txer	O	Transmit data error. Used only for EEE to request PHY for low power transition.
MCOL	mii0_col mii1_col	I	In half-duplex operation, the MCOL pin is asserted by the PHY when it detects a collision on the network. It remains asserted while the collision condition persists. This signal is not necessarily synchronous to MT_CLK nor MR_CLK. In full-duplex operation, the MCOL pin is used for hardware transmit flow control. Asserting the MCOL pin will stop packet transmissions; packets in the process of being transmitted when MCOL is asserted will complete transmission. The MCOL pin should be held low if hardware transmit flow control is not used.

<sup>(1)</sup> I = Input; O = Output

**Table 24-1250. MII I/O Description (continued)**

Signal	Device Pin(s)	I/O <sup>(1)</sup>	Description
MCRS	mii0_crs mii1_crs	I	In half-duplex operation, the MCRS pin is asserted by the PHY when the network is not idle in either transmit or receive. The pin is de-asserted when both transmit and receive are idle. This signal is not necessarily synchronous to MT_CLK nor MR_CLK. In full-duplex operation, the MCRS pin should be held low.
MR_CLK	mii0_rxclk mii1_rxclk	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The MRXD, MRXDV, and MRXER signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
MRXD	mii0_rxd[0:3] mii1_rxd[0:3]	I	The receive data pins are a collection of 4 data signals comprising 4 bits of data. MRXD0 is the least-significant bit (LSB). The signals are synchronized by MR_CLK and valid only when MRXDV is asserted.
MRXDV	mii0_rxdv mii1_rxdv	I	The receive data valid signal indicates that the MRXD pins are generating nibble data for use by the GMAC_SW. It is driven synchronously to MR_CLK.
MRXER	mii0_rxer mii1_rxer	I	Receive Data Error input
MDIO_MDCLK	mdio_mclk	O	Management data clock. The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO_D pin.
MDIO_D	mdio_d	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

**24.11.2.2 RMII Interface**

Figure 24-188 shows a device with integrated GMAC\_SW and MDIO interfaced via a RMII connection in a typical system. The individual CPSW and MDIO signals for the RMII interface are summarized in Table 24-1251.

For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

**Figure 24-188. RMII Interface Typical Application**

**Table 24-1251. RMI I/O Description**

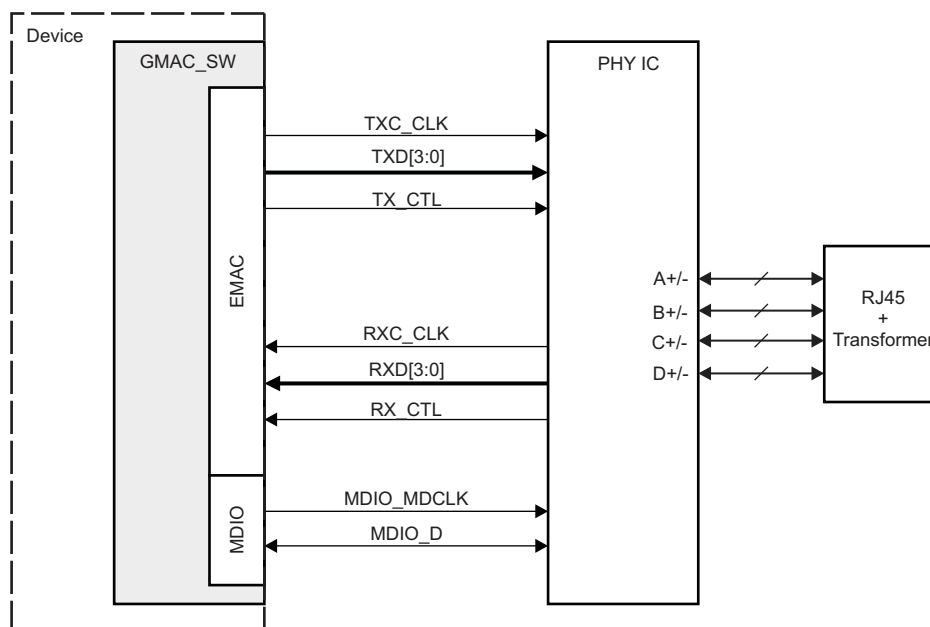

Signal	Device Pin(s)	I/O <sup>(1)</sup>	Description
TXD[1:0]	rmii0_txd[1:0] rmii1_txd[1:0]	O	Transmit data . The transmit data pins are a collection of 2 bits of data. TXD0 is the least-significant bit (LSB). The signals are synchronized by RMI1_MHZ_50_CLK and valid only when TXEN is asserted.
TXEN	rmii0_txen rmii1_txen	O	Transmit enable. The transmit enable signal indicates that the RMI1_TXD pins are generating data for use by the PHY. RMI1_TXEN is synchronous to RMI1_MHZ_50_CLK
RMI10_MHZ_50_CLK K	RMI1_MHZ_50_CLK	I/O	RMI1 reference clock.
RMI11_MHZ_50_CLK K			The reference clock is used to synchronize all RMI1 signals. RMI1_MHZ_50_CLK must be continuous and fixed at 50 MHz.
RXD[1:0]	rmii0_rxd[1:0] rmii1_rxd[1:0]	I	Receive data. The receive data pins are a collection of 2 bits of data. RXD0 is the least-significant bit (LSB). The signals are synchronized by RMI1_MHZ_50_CLK and valid only when CRS_DV is asserted and RXER is de-asserted.
CRS_DV	rmii0_crs rmii1_crs	I	Carrier sense/receive data valid. Multiplexed signal between carrier sense and receive data valid.
RXER	rmii0_rxer rmii1_rxer	I	Receive error. The receive error signal is asserted to indicate that an error was detected in the received frame.
MDIO_MDCLK	mdio_mclk	O	Management data clock (MDIO_MCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO_D pin.
MDIO_D	mdio_d	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

<sup>(1)</sup> I = Input; O = Output

**24.11.2.3 RGMII Interface**

Figure 24-189 shows a device with integrated CPSW and MDIO interfaced via a RGMII connection in a typical system. The individual CPSW and MDIO signals for the RGMII interface are summarized in Table 24-1252.

**Figure 24-189. RGMII Interface Typical Application**

**Table 24-1252. RGMII I/O Description**

Signal	Device Pin(s)	I/O <sup>(1)</sup>	Description
TXD[3:0]	rgmii0_txd[3:0] rgmii1_txd[3:0]	O	The transmit data pins are a collection of 4 bits of data. TXD0 is the least-significant bit (LSB). The signals are valid only when TX_CTL is asserted.
TX_CTL	rgmii0_rxctl rgmii1_rxctl	O	Transmit Control/enable. The transmit enable signal indicates that the TXD pins are generating data for use by the PHY.
TXC_CLK	rgmii0_txc rgmii1_txc	O	The transmit reference clock. The clock is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, and 125 MHz at 1000 Mbps of operation.
RXD[3:0]	rgmii0_rxd[3:0] rgmii1_rxd[3:0]	I	The receive data pins are a collection of 4 bits of data. RXD0 is the least-significant bit (LSB). The signals are valid only when RX_CTL is asserted.
RX_CTL	rgmii0_rxctl rgmii1_rxctl	I	The receive data valid/control signal indicates that the RXD pins are nibble data for use by the GMAC_SW.
RXC_CLK	rgmii0_rxc rgmii1_rxc	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, 125 MHz at 1000 Mbps of operation.
MDIO_MDCLK	mdio_mclk	O	Management data clock (MDIO_MCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin.
MDIO_D	mdio_d	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

<sup>(1)</sup> I = Input; O = Output

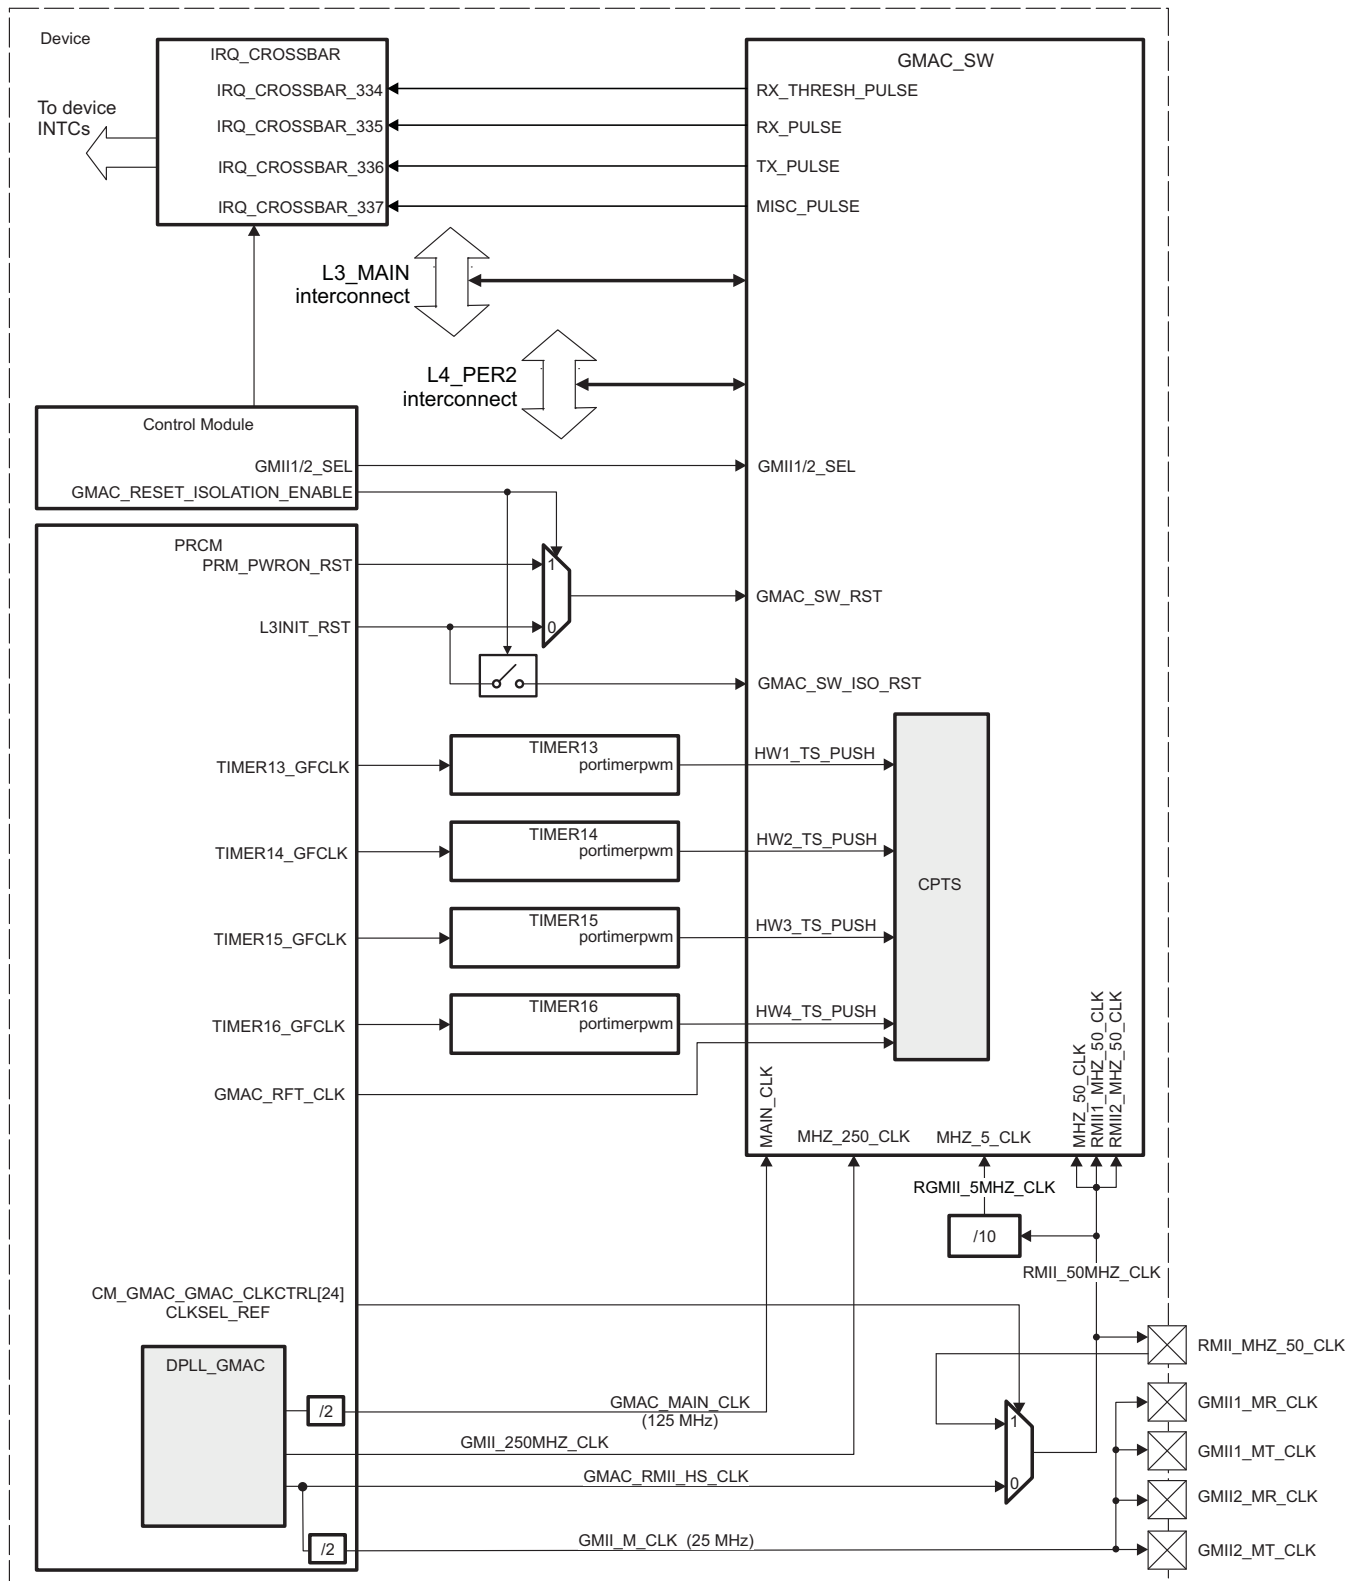

**NOTE:** The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see [Section 18.4.6.1.1, Pad Configuration Registers](#) in [Chapter 18, Control Module](#).

### 24.11.3 GMAC\_SW Integration

Figure 24-190 shows the integration of the GMAC\_SW module in the device.

Figure 24-190. GMAC\_SW Integration

gmacsw-005

**NOTE:** The device provides the option to receive or output the RMIIC reference clock (RMII\_50MHZ\_CLK) from/to external pin as shown in [Figure 24-190](#). See the RMII\_CLK\_SETTING register bit in the [Section 18.5 Control Module Register Manual](#), and CLKSEL\_REF in [Section 3.12, PRCM Register Manual](#) to configure the clocking option of RMII.

See [Chapter 3, PRCM](#) for details about power, clock and reset options for GMAC\_SW.

[Table 24-1253](#) through [Table 24-1255](#) summarize the integration of the GMAC\_SW module in the device.

**Table 24-1253. GMAC\_SW Integration Attributes**

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
GMAC_SW	PD_COREAON	Yes	L3_MAIN L4_PER2

**Table 24-1255. GMAC\_SW Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	IRQ_CROSSBAR Input	Default Mapping	Description
GMAC_SW	RX_THRESH_PULSE	IRQ_CROSSBAR_334	-	Receive threshold interrupt

**Table 24-1255. GMAC\_SW Hardware Requests (continued)**

RX_PULSE	IRQ_CROSSBAR_335	-	Receive packet completion interrupt
TX_PULSE	IRQ_CROSSBAR_336	-	Transmit packet completion interrupt
MISC_PULSE	IRQ_CROSSBAR_337	-	Miscellaneous interrupt (SPF2_PEND, SPF1_PEND, EVNT_PEND, STAT_PEND, HOST_PEND, MDIO_LINKINT, MDIO_USERINT)

---

**NOTE:** GMAC\_SW has no default IRQ mappings through the IRQ\_CROSSBAR. For GMAC\_SW, the IRQ\_CROSSBAR module must be configured prior to unmask interrupts in the interrupt controller(s).  
 For more information about the IRQ\_CROSSBAR module, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#).  
 For more information about the device interrupt controllers, see [Chapter 17, Interrupt Controllers](#).

---

---

**NOTE:** For the description of the interrupt source, see [Section 24.11.4.5, Interrupt Functionality](#).

---

### 24.11.4 GMAC\_SW Functional Description

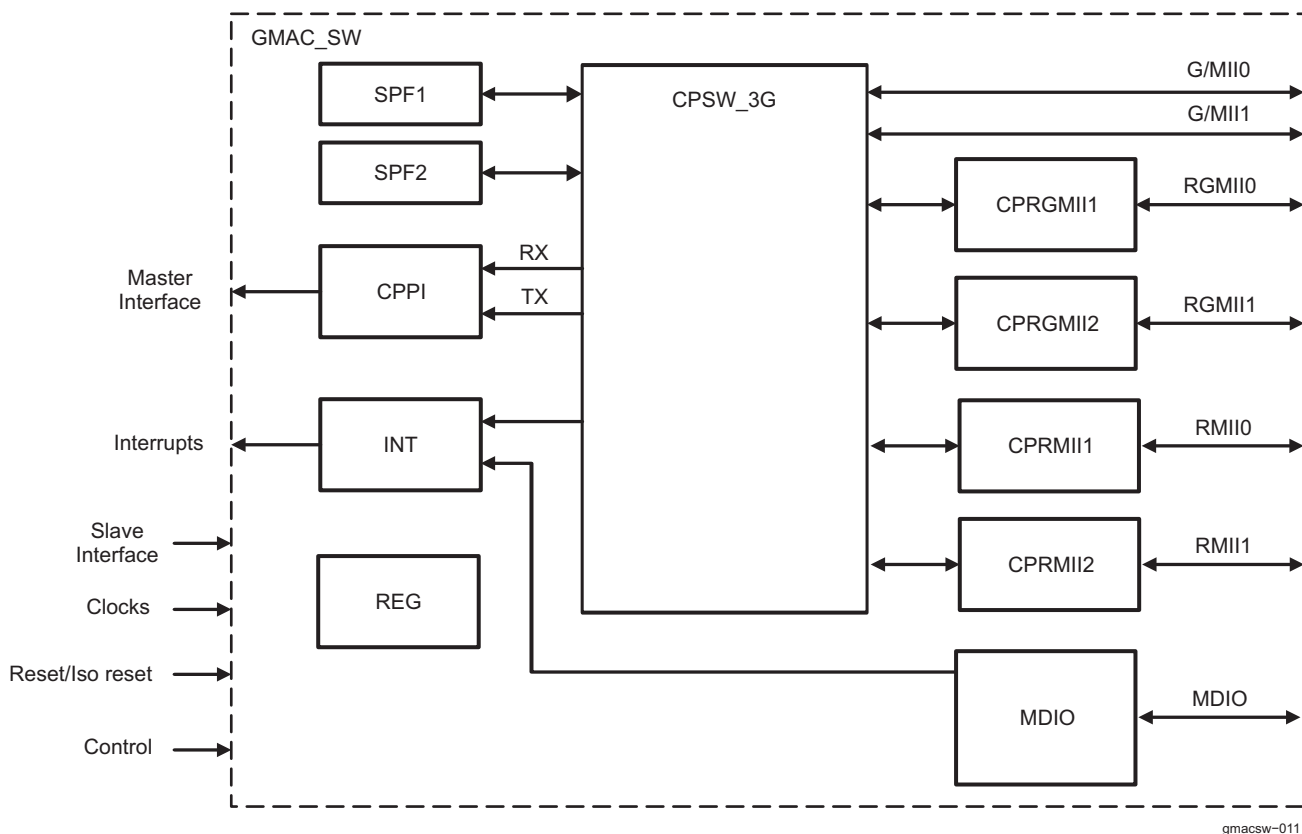

The 3-port switch (GMAC\_SW) Ethernet subsystem modules are compliant to the IEEE Std 802.3 Specification. GMAC\_SW is shown in [Figure 24-191](#).

#### 24.11.4.1 Functional Block Diagram

The GMAC\_SW subsystem consists of:

- CPSW\_3G which contains two G/MII interfaces
- Two RGMII interface modules
- Two RMII interface modules
- One MDIO interface module
- One Interrupt Controller module
- One CPPI interface
- Local CPPI memory of size 8 KiB
- Two Static Packet Filters

**Figure 24-191. GMAC\_SW Top Level Block Diagram**

#### 24.11.4.2 GMAC\_SW Ports

Ethernet Subsystem has three Ports. Port 0 is the Host port (internal to the Subsystem). Ports 1 and 2 are the external ports connected to G/MII, RGMII, or RMII interfaces as per the interface selected.

Naming conventions followed in this chapter:

- Port0 is referred to the Host Port
- Port1 is referred to the interfaces GMII0/RGMII0/RMII0
- Port2 is referred to the interfaces GMII1/RGMII1/RMII1

#### 24.11.4.2.1 Interface Mode Selection

The 3-port switch (GMAC\_SW) Ethernet Subsystem has two 10/100/1000 Ethernet ports with selectable MII, RMII, and RGMII interfaces.

The interface mode is selected by configuring the MII mode selection register bitfields (GMII1\_SEL and GMII2\_SEL) in the control module. See [Section 18.5, Control Module Register Manual](#) for details.

See device data manual for configuring the pin mux mode as per the interface selected.

#### 24.11.4.3 Clocking

##### 24.11.4.3.1 Subsystem Clocking

GMAC\_SW clocking summary is shown in [Section 24.11.3, GMAC\\_SW Integration](#).

##### 24.11.4.3.2 Interface Clocking

Data is transmitted and received with respect to the reference clocks of the interface pins.

###### 24.11.4.3.2.1 G/MII Interface Clocking

GMII1\_MR\_CLK, GMII1\_MT\_CLK, GMII2\_MR\_CLK, GMII2\_MT\_CLK frequencies are fixed by the 802.3 specification.

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps

###### 24.11.4.3.2.2 RGMII Interface Clocking

RGMII\_RXC, RGMII\_TXC frequencies are:

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps
- 125 MHz at 1000 Mbps

###### 24.11.4.3.2.3 RMII Interface Clocking

RMII interface clock RMII\_50MHZ\_CLK frequency is:

- 50 MHz at 10 Mbps
- 50 MHz at 100 Mbps

See the RMII\_CLK\_SETTING bit in the device Control Module and CLKSEL\_REF in PRCM to configure the clocking option of RMII (external pin or PRCM).

###### 24.11.4.3.2.4 MDIO Clocking

The MDIO clock is based on a divide-down of the interface (MAIN\_CLK) clock, running at 125 MHz. The application software or driver must control the divide-down value.

See the [MDIO\\_CONTROL](#) register for configuring the Clock Divider (CLKDIV) value.

#### 24.11.4.4 Software IDLE

The submodule software idle register bits enable CPSW\_3G operation to be completely or partially suspended by software control. There are three CPSW\_3G submodules that contain software idle register bits (CPGMAC\_SL1, CPGMAC\_SL2, and CPDMA). Each of the three submodules may be individually commanded to enter the idle state. The idle state is entered at packet boundaries, and no further packet operations will occur on an idled submodule until the idle command is removed. The CPSW\_3G module

enters the idle state when all three submodules are commanded to enter and have entered the idle state. Idle status is determined by reading or polling the three submodule idle bits. The CPSW\_3G is in the idle state when all three submodules are in the idle state. The [CPSW\\_SOFT\\_IDLE\[0\]](#) SOFT\_IDLE bit may be set if desired after the submodules are in the idle state. The CPSW SOFT\_IDLE bit causes packets to not be transferred from one FIFO to another FIFO internal to the switch.

#### 24.11.4.5 Interrupt Functionality

GMAC\_SW Ethernet Subsystem has four Interrupt outputs:

- RX\_PULSE - Receive Interrupt
- TX\_PULSE - Transmit Interrupt
- RX\_THRESH\_PULSE - Receive Threshold Interrupt
- MISC\_PULSE - Miscellaneous Interrupt.

##### 24.11.4.5.1 Receive Packet Completion Pulse Interrupt (RX\_PULSE)

The RX\_PULSE interrupt is a pulse interrupt selected from the GMAC\_SW RX\_PEND[7:0] interrupts. The receive DMA controller has eight channels with each channel having a corresponding (RX\_PEND[7:0]).

The following steps will enable the receive packet completion interrupt:

1. Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the [CPDMA\\_RX\\_INTMASK\\_SET](#) register.
2. The receive completion interrupt(s) to be routed to RX\_PULSE is selected by setting one or more bits in the receive interrupt enable register ([WR\\_CO\\_RX\\_EN](#)). The masked interrupt status can be read in the address location of RX\_STAT bit in the [WR\\_CO\\_RX\\_STAT](#) register.

When the GMAC\_SW completes a packet reception, the subsystem issues an interrupt to the host processor by writing the packet's last buffer descriptor address to the appropriate channel queue's receive completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the software processes one or more packets from the buffer chain and then acknowledges one or more interrupt(s) by writing the address of the last buffer descriptor processed to the queue's associated receive completion pointer (RX\_n\_CP) in the receive DMA state RAM.

Upon reception of an interrupt, software should perform the following:

1. Read the [WR\\_CO\\_RX\\_STAT\[7:0\]](#) RX\_STAT bit address location to determine which channel(s) caused the interrupt.
2. Process received packets for the interrupting channel(s).
3. Write the GMAC\_SW completion pointer(s) (RX\_n\_CP). The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the subsystem (address of last buffer descriptor used by the subsystem). If the two values are not equal (which means that the GMAC\_SW has received more packets than the software has processed), the receive packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the system has received), the pending interrupt is de-asserted. The value that the GMAC\_SW is expecting is found by reading the receive channel *n* completion pointer register (RX\_n\_CP).
4. Write the value 1h to the [CPDMA\\_EOI\\_VECTOR](#) register.

To disable the interrupt:

1. The eight channel interrupts may be individually disabled by writing to 1 the appropriate bit in the [CPDMA\\_RX\\_INTMASK\\_CLEAR](#) register.
2. The receive completion pulse interrupt could be disabled by clearing to 0 all the bits in the [WR\\_CO\\_RX\\_EN](#) register.

The software could still poll for the [CPDMA\\_RX\\_INTSTAT\\_RAW](#) and [CPDMA\\_RX\\_INTSTAT\\_MASKED](#) registers if the corresponding interrupts are enabled.

#### **24.11.4.5.2 Transmit Packet Completion Pulse Interrupt (TX\_PULSE)**

The TX\_PULSE interrupt is a pulse interrupt selected from the GMAC\_SW TX\_PEND[7:0] interrupts. The transmit DMA controller has eight channels with each channel having a corresponding (TX\_PEND[7:0]).

To enable the transmit packet completion interrupt:

1. Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the [CPDMA\\_TX\\_INTMASK\\_SET](#) register.
2. The transmit completion interrupt(s) to be routed to TX\_PULSE is selected by setting one or more bits in the transmit interrupt enable register [WR\\_C0\\_TX\\_EN](#). The masked interrupt status can be read in the address location of TX\_STAT bit in the [WR\\_C0\\_TX\\_STAT](#) register.

When the GMAC\_SW completes the transmission of a packet, the GMAC\_SW subsystem issues an interrupt to the host processor by writing the packet's last buffer descriptor address to the appropriate channel queue's transmit completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon reception of an interrupt, software should perform the following:

1. Read the TX\_STAT bit address location to determine which channel(s) caused the interrupt
2. Process received packets for the interrupting channel(s).
3. Write the GMAC\_SW completion pointer(s) (TX *n*\_CP). The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the GMAC\_SW (address of last buffer descriptor used by the GMAC\_SW). If the two values are not equal (which means that the GMAC\_SW has transmitted more packets than the software has processed), the transmit packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the subsystem has transferred), the pending interrupt is cleared. The value that the GMAC\_SW is expecting is found by reading the transmit channel *n*completion pointer register (TX *n*\_CP).
4. Write the 2h to the [CPDMA\\_EOI\\_VECTOR](#) register.

To disable the interrupt:

1. The eight channel interrupts may be individually disabled by writing to 1 the appropriate bit in the [CPDMA\\_TX\\_INTMASK\\_CLEAR](#) register.
2. The receive completion pulse interrupt could be disabled by clearing to 0 all the bits in the [WR\\_C0\\_TX\\_EN](#) register.

The software could still poll for the [CPDMA\\_TX\\_INTSTAT\\_RAW](#) and [CPDMA\\_TX\\_INTSTAT\\_MASKED](#) registers, if the corresponding interrupts are enabled.

#### **24.11.4.5.3 Receive Threshold Pulse Interrupt (RX\_THRESH\_PULSE)**

The RX\_THRESH\_PULSE interrupt is an immediate (non-paced) pulse interrupt selected from the CPSW\_3G RX\_THRESH\_PEND[7:0] interrupts. The receive DMA controller has eight channels with each channel having a corresponding threshold pulse interrupt (RX\_THRESH\_PEND[7:0]).

To enable the receive threshold pulse Interrupt:

1. Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the [CPDMA\\_RX\\_INTMASK\\_SET](#) register.
2. The receive threshold interrupt(s) to be routed to RX\_THRESH\_PULSE is selected by setting one or more bits in the receive threshold interrupt enable register [WR\\_C0\\_RX\\_THRESH\\_EN](#). The masked interrupt status can be read in the address location of RX\_THRESH\_STAT bit in the [WR\\_C0\\_RX\\_THRESH\\_STAT](#) register.

The RX\_THRESH\_PULSE is asserted when enabled when the channel's associated free buffer count RX *n*\_FREEBUFFER is less than or equal to the corresponding RX *n*\_PENDTHRESH register.

Upon reception of an interrupt, software should perform the following:

1. Read the RX\_THRESH\_STAT bit address location to determine which channel(s) caused the interrupt.
2. Process the received packets in order to add more buffers to any channel that is below the threshold value.

3. Write the CPSW\_3G completion pointer(s).
4. Write the value 0h to the [CPDMA\\_EOI\\_VECTOR](#) register.

The threshold pulse interrupt is an immediate interrupt intended to indicate that software should immediately process packets to preclude an overrun condition from occurring for the particular channels.

To disable the interrupt:

1. The eight channel receive threshold interrupts may be individually disabled by writing to 1 the appropriate bit in the [CPDMA\\_RX\\_INTMASK\\_CLEAR](#) register.
2. The receive threshold pulse interrupt could be disabled by clearing to 0 the corresponding bits in the [WR\\_C0\\_RX\\_THRESH\\_EN](#) register.

The software could still poll for the [CPDMA\\_RX\\_INTSTAT\\_RAW](#) and [CPDMA\\_RX\\_INTSTAT\\_MASKED](#) registers, if the corresponding interrupts are enabled.

#### 24.11.4.5.4 Miscellaneous Pulse Interrupt (MISC\_PULSE)

The MISC\_PULSE interrupt is an immediate pulse interrupt selected from the miscellaneous interrupts (SPF2\_PEND, SPF1\_PEND, EVNT\_PEND, STAT\_PEND, HOST\_PEND, MDIO\_LINKINT, MDIO\_USERINT).

The miscellaneous interrupt(s) is selected by setting one or more bits in the miscellaneous interrupt enable register ([WR\\_C0\\_MISC\\_EN](#)).

Upon reception of an interrupt, software should perform the following:

- Read the MISC\_STAT bit address location to determine the source of the interrupt.
- Process the interrupt.
- Write the value 3h to the [CPDMA\\_EOI\\_VECTOR](#) register.

---

**NOTE:** The [WR\\_C0\\_MISC\\_STAT](#) register's [MDIO\\_LINKINT](#) and [MDIO\\_USERINT](#) bitfields represent the Port0/Phy0 status. [MDIO\\_LINKINT\[1\]](#) and [MDIO\\_USERINT\[1\]](#) are not provided in [WR\\_C0\\_MISC\\_STAT](#) register. As such, MDIO Link and User interrupts can only be generated for Port0. For Port1, software must poll the status, visible in the [MDIO\\_LINKINTMASKED](#) or [MDIO\\_USERINTMASKED](#) registers.

---

##### 24.11.4.5.4.1 EVNT\_PEND(CPTS\_PEND) Interrupt

See [Section 24.11.4.10, Common Platform Time Sync \(CPTS\)](#) for more details on this interrupt.

##### 24.11.4.5.4.2 Statistics Interrupt

The statistics level interrupt (STAT\_PEND) will be asserted, if enabled when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is cleared by writing to decrement all statistics values greater than 8000 0000h (such that their new values are less than 8000 0000h). The raw and masked statistics interrupt status may be read by reading the [CPDMA\\_TX\\_INTSTAT\\_RAW](#) and [CPDMA\\_TX\\_INTSTAT\\_MASKED](#) registers, respectively.

The Statistics interrupt is enabled by setting to 1 the [STAT\\_INT\\_MASK](#) bit in the [CPDMA\\_DMA\\_INTMASK\\_SET](#) register

##### 24.11.4.5.4.3 Host Error interrupt

The host error interrupt (HOST\_PEND) will be asserted, if enabled when a host error is detected during transmit or receive CPDMA transactions. The host error interrupt is intended for software debug, and is cleared by a warm reset or a system reset. The raw and masked host interrupt status can be read by reading the [CPDMA\\_DMA\\_INTSTAT\\_RAW](#) and [CPDMA\\_DMA\\_INTSTAT\\_MASKED](#) registers, respectively.

The transmit host error conditions are:

- SOP error

- OWNERSHIP bit not set in SOP buffer
- next buffer descriptor pointer without EOP cleared to 0
- buffer pointer cleared to 0
- buffer length cleared to 0
- packet length error

The receive host error conditions are:

- OWNERSHIP bit not set in input buffer
- Zero buffer pointer
- Zero buffer Length on non-SOP descriptor
- SOP buffer length not greater than offset

The HOST\_PEND is enabled by setting to 1 the HOST\_ERR\_INTMASK in the [CPDMA\\_DMA\\_INTMASK\\_SET](#) register. The host error interrupt is disabled by setting to 1 the appropriate bit in the [CPDMA\\_DMA\\_INTMASK\\_CLEAR](#) register.

#### 24.11.4.5.4.4 MDIO Interrupts

[MDIO\\_LINKINT](#) is set if there is a change in the link state of the PHY corresponding to the address in the PHYADR\_MON field of the MDIO\_USERPHYSEL $n$  register and the corresponding LINKINT\_ENABLE bit is set. The [MDIO\\_LINKINT](#) event is also captured in the [MDIO\\_LINKINTMASKED](#) register. When the GO bit in the MDIO\_USERACCESS $n$  register transitions from 1 to 0, indicating the completion of a user access, and the corresponding USERINTMASKSET bit in the [MDIO\\_USERINTMASKSET](#) register is set, the MDIO\_USERINT signal is asserted. The MDIO\_USERINT event is also captured in the [MDIO\\_USERINTMASKED](#) register.

#### 24.11.4.5.5 Interrupt Pacing

RX\_PULSE and TX\_PULSE interrupts can be paced. The RX\_THRESH\_PULSE and MISC\_PULSE interrupts are not paced. The Interrupt pacing feature limits the number of interrupts that occur during a given period of time. For heavily loaded systems in which interrupts can occur at a very high rate (for example, 148,800 packets per second for Ethernet), the performance benefit is significant due to minimizing the overhead associated with servicing each interrupt. Interrupt pacing increases the processor cache hit ratio by minimizing the number of times that large interrupt service routines are moved to and from the processor instruction cache.

Each RX\_PULSE and TX\_PULSE interrupt contains an interrupt pacing sub-block (six total). Each sub-block is disabled by default allowing the selected interrupt inputs to pass through unaffected. The interrupt pacing module counts the number of interrupts that occur over a 1 ms interval of time. At the end of each 1 ms interval, the current number of interrupts is compared with a target number of interrupts (specified by the associated maximum number of interrupts register). Based on the results of the comparison, the length of time during which interrupts are blocked is dynamically adjusted. The 1 ms interval is derived from a 4  $\mu$ s pulse that is created from a prescale counter whose value is set in the INT\_PRESCALE field in the [WR\\_INT\\_CONTROL](#) register. The INT\_PRESCALE value should be written with the number of ICLK periods in 4  $\mu$ s. The pacing timer determines the interval during which interrupts are blocked and decrements every 4  $\mu$ s. It is reloaded each time a zero count is reached. The value loaded into the pacing timer is calculated by hardware every 1 ms according to the following algorithm:

```
if (intr_count > 2*intr_max)
    pace_timer = 255;
else if (intr_count > 1.5*intr_max)
    pace_timer = last_pace_timer*2 + 1;
else if (intr_count > 1.0*intr_max)
    pace_timer = last_pace_timer + 1;
else if (intr_count > 0.5*intr_max)
    pace_timer = last_pace_timer - 1;
else if (intr_count != 0)
    pace_timer = last_pace_timer/2;
else
    pace_timer = 0;
```

If the rate of interrupt inputs is much less than the target interrupt rate specified in the associated maximum interrupts register, then the interrupt is not blocked. If the interrupt rate is greater than the target rate, the interrupt will be "paced" at the rate specified in the interrupt maximum register. The [WR\\_C0\\_RX\\_IMAX/WR\\_C0\\_TX\\_IMAX](#) register should be written with a value between 2 and 63 inclusive, indicating the target number of interrupts per millisecond.

#### 24.11.4.6 Reset Isolation

Reset isolation for the GMAC\_SW allows the switch function to remain active in during all device resets except for POR pin reset and ICEPICK COLD reset. Packet traffic to/from the GMAC\_SW host will be flushed/dropped, but the ethernet switch will remain operational for all traffic between external devices on the switch even though the device is undergoing a device reset. Pin mux configuration for ethernet related I/O and reference clocks needed by the GMAC\_SW to be active is controlled by a protected control module bit.

##### 24.11.4.6.1 Reset Isolation Functional Description

The device has two modes of operation concerning the reset of the GMAC\_SW Ethernet switch. The mode is controlled by the GMAC\_RESET\_ISOLATION\_ENABLE bit in the Control Module. This bit defaults to 0. Any modification of this bit first requires writing an unlock pattern to lock register in device control module. After modification, the bit should again be locked by writing appropriate value to the lock register. Writes to the GMAC\_RESET\_ISOLATION\_ENABLE bit and to the lock register must all be supervisor mode writes.

##### GMAC\_RESET\_ISOLATION\_ENABLE = 0 (disabled)

1. This is the default state of the bit after control module reset.
2. Upon any device level resets, the entire GMAC\_SW, DPLL\_GMAC, L3/L4 interconnect, control module (including all pin mux control and the GMAC\_RESET\_ISOLATION\_ENABLE bit itself) are immediately reset.

##### GMAC\_RESET\_ISOLATION\_ENABLE = 1 (enabled)

1. This mode is selected when the GMAC\_RESET\_ISOLATION\_ENABLE bit is set to 1 by software.
2. Upon any device reset source other than porz pin or ICEPICK cold (that is, this includes software global cold, any watchdog reset, warm resetn pin, ICEPICK warm, software global warm or security violation), the following is true:
  1. The CPSW\_3GSS\_R is put into "isolate" mode and non-switch related portions of the subsystem are reset.
  2. The 50 MHz and 125 MHz reference clocks to the GMAC\_SW Ethernet Subsystem remain active throughout the entire reset condition.
  3. The control for pin multiplexing for all of the signals maintain their current configuration throughout the entire reset condition.
  4. The reset-isolated logic inside GMAC\_SW Ethernet Subsystem maintains the switch functionality
3. Upon any cold reset sources, the entire GMAC\_SW Ethernet Subsystem, DPLL\_GMAC, control module (including all pin mux control and the GMAC\_RESET\_ISOLATION\_ENABLE bit itself) are reset.

For more details on the register configuration, see the Control Module CTRL\_CORE\_CONTROL\_IO\_2 register in [Section 18.5, Control Module Register Manual](#).

#### 24.11.4.7 Software Reset

The CPSW\_3G software reset register ([CPSW\\_SOFT\\_RESET](#)), CPSW\_3GSS software reset register ([WR\\_SOFT\\_RESET](#)) and the three submodule software reset registers enable the CPSW\_3GSS to be reset by software.

There are three CPSW\_3G submodules that contain software reset registers (CPGMAC\_SL1, CPGMAC\_SL2 ([SL\\_SOFT\\_RESET](#)), and CPDMA ([CPDMA\\_SOFT\\_RESET](#))). Each of the three submodules may be individually commanded to be reset by software.

For the CPDMA, the reset state is entered at packet boundaries, at which time the CPDMA reset occurs. The CPGMAC\_SL soft reset is immediate. Submodule reset status is determined by reading or polling the submodule reset bit. If the submodule reset bit is read as a one, then the reset process has not yet completed. The submodule soft reset process could take up to 2ms each. The reset has completed if the submodule reset bit is read as a zero.

After all three submodules (in any order) have been reset and a read of each submodule reset bit indicates that the reset process is complete, the CPSW\_3G software reset register bit may be written to complete the CPSW\_3G module software reset operation. The CPSW\_3G software reset bit controls the reset of the FIFO's, the statistics submodule, and the address lookup engine (ALE). The CPSW\_3G software reset is immediate and will be indicated by reading a zero from the soft reset bit.

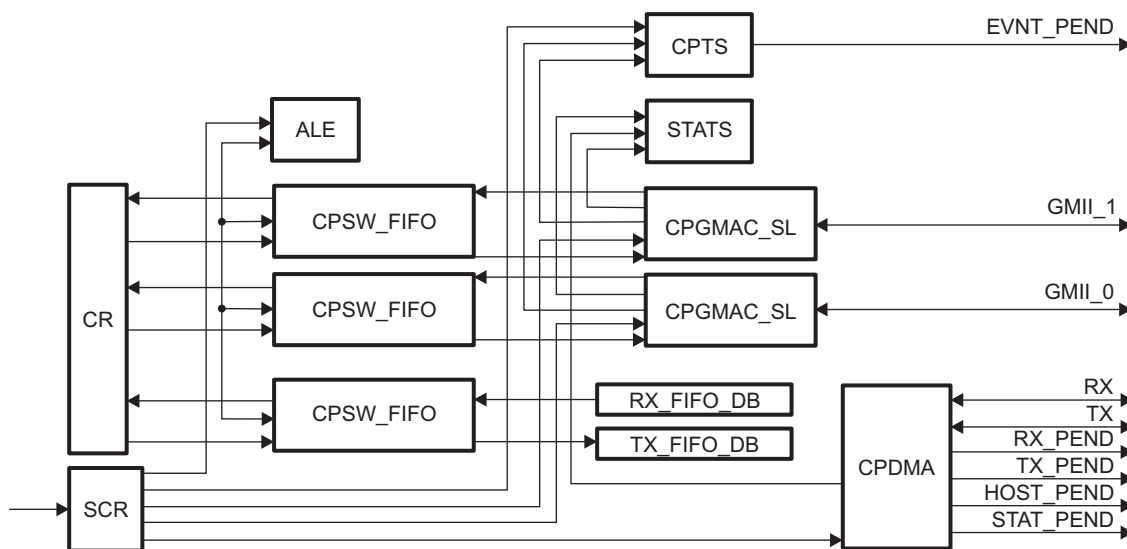

The CPSW\_3GSS software reset bit controls the reset of the INT, REGS, and CPPI. The CPSW\_3GSS software reset is immediate and will be indicated by reading a zero from the soft reset bit.

#### 24.11.4.8 CPSW\_3G

The CPSW\_3G G/MII interfaces are compliant to the IEEE Std 802.3 Specification.

The CPSW\_3G contains two CPGMAC\_SL interfaces (ports 1 and 2), one CPPI interface Host Port (port 0), Common Platform Time Sync (CPTS), ALE Engine and CPDMA. A top-level block diagram of the CPSW\_3G is shown in [Figure 24-192](#).

**Figure 24-192. CPSW\_3G Block Diagram**

##### 24.11.4.8.1 CPDMA RX and TX Interfaces

The CPDMA submodule is a CPPI compliant packet DMA transfer controller. The CPPI interface is port 0.

##### 24.11.4.8.1.1 Functional Operation

After reset, initialization, and configuration the host may initiate transmit operations. Transmit operations are initiated by host writes to the appropriate transmit channel head descriptor pointer contained in the STATERAM block. The transmit DMA controller then fetches the first packet in the packet chain from memory in accordance with CPPI protocol. The DMA controller writes the packet into the external transmit FIFO in 64-byte bursts (maximum).

Receive operations are initiated by host writes to the appropriate receive channel head descriptor pointer after host initialization and configuration. The receive DMA controller writes the receive packet data to external memory in accordance with CPPI protocol. For a detailed description of buffer descriptors, see [Section 24.11.4.11, CPPI Buffer Descriptors](#).

#### 24.11.4.8.1.2 Receive DMA Interface

The receive DMA is an eight channel CPPI compliant interface. Each channel has a single queue for frame reception.

##### 24.11.4.8.1.2.1 Receive DMA Host Configuration

To configure the RX DMA for operation the software must perform the following:

1. Initialize the receive addresses.
2. Initialize the RX\_HDP registers to 0.
3. Enable the desired receive interrupts in the [CPDMA\\_RX\\_INTMASK\\_SET](#) register.
4. Write the [CPDMA\\_RX\\_BUFFER\\_OFFSET](#) register value.
5. Setup the receive channel(s) buffer descriptors in host memory as required by CPPI
6. Enable the RX DMA controller by setting the RX\_EN bit in the [CPDMA\\_RX\\_CONTROL](#) register.

##### 24.11.4.8.1.2.2 Receive Channel Teardown

The host commands a receive channel teardown by writing the channel number to the [CPDMA\\_RX\\_TEARDOWN](#) register. When a teardown command is issued to an enabled receive channel the following will occur:

- Any current frame in reception will complete normally.
- The `teardown_complete` bit will be set in the next buffer descriptor in the chain (if there is one).
- The channel head descriptor pointer will be cleared to 0.
- A receive interrupt for the channel will be issued to the host.
- The software should acknowledge a teardown interrupt with a FFFF FFFCh Acknowledge value.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by a set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a FFFF FFFCh acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be FFFF FFFCh if the interrupt was due to a teardown command.

#### 24.11.4.8.1.3 Transmit DMA Interface

The transmit DMA is an eight channel CPPI compliant interface. Priority between the eight queues may be either fixed or round robin as selected by the TX\_PTYPE bit in the [CPDMA\\_DMACONTROL](#) register. If the priority type is fixed, then channel 7 has the highest priority and channel 0 has the lowest priority. Round robin priority proceeds from channel 0 to channel 7.

##### 24.11.4.8.1.3.1 Transmit DMA Host Configuration

To configure the TX DMA for operation the software must do the following:

1. Initialize the TX\_HDP registers to 0.
2. Enable the desired transmit interrupts in the [CPDMA\\_TX\\_INTMASK\\_SET](#) register.
3. Setup the transmit channel(s) buffer descriptors in host memory as defined in CPPI.
4. Configure and enable the transmit operation as desired in the [CPDMA\\_TX\\_CONTROL](#) register.
5. Write the appropriate TX\_HDP registers with the appropriate values to start transmit operations.

##### 24.11.4.8.1.3.2 Transmit Channel Teardown

The host commands a transmit channel teardown by writing the channel number to the [CPDMA\\_TX\\_TEARDOWN](#) register. When a teardown command is issued to an enabled transmit channel the following will occur:

- Any frame currently in transmission will complete normally

- The teardown complete bit will be set in the next sop buffer descriptor (if there is one).
- The channel head descriptor pointer will be cleared to 0.
- An interrupt will be issued to inform the host of the channel teardown.
- The software should acknowledge a teardown interrupt with a FFFF FFFCh acknowledge value

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a FFFF FFFCh acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be FFFF FFFCh if the interrupt was due to a teardown command.

#### 24.11.4.8.1.4 Transmit Rate Limiting

Transmit operations can be configured to rate limit the transmit data for each transmit priority. Rate limiting is enabled for a channel when the TX\_RLIM bit associated with that channel is set in the [CPDMA\\_DMACONTROL](#) register. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then TX\_RLIM should be set to 11000000b with the MSB corresponding to channel 7. When any channels are configured to be rate-limiting, the priority type must be fixed for transmit. Round-robin priority type is not allowed when rate-limiting. Each of the eight transmit priorities has an associated register to control the rate at which the priority is allowed to send data (TX\_PRI(0..7)\_RATE) when the channel is rate-limiting. Each priority has a send count (PRI(0..7)\_SEND\_CNT) and an idle count (PRI(0..7)\_IDLE\_CNT). The transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is allowed to send is controlled by the equation:

$$\text{Priority Transfer rate in Mbit/s} = ((\text{PRI\_IDLE\_CNT}/(\text{PRI\_IDLE\_CNT} + \text{PRI\_SEND\_CNT})) \times \text{frequency} \times 32$$

Where *frequency* is the CPDMA interface clock (MAIN\_CLK) frequency.

#### 24.11.4.8.1.5 Command IDLE

The CMD\_IDLE bit in the [CPDMA\\_DMACONTROL](#) register allows CPDMA operation to be suspended. When the idle state is commanded, the CPDMA will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the tx cell FIFO will be transmitted. For receive, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Commanded idle is similar in operation to emulation control and clock stop.

#### 24.11.4.8.2 Address Lookup Engine (ALE)

The address lookup engine (ALE) processes all received packets to determine which port(s) if any that the packet should be forwarded to. The ALE uses the incoming packet received port number, destination address, source address, length/type, and VLAN information to determine how the packet should be forwarded. The ALE outputs the port mask to the switch fabric that indicates the port(s) the packet should be forwarded to. The ALE is enabled when the ENABLE\_ALE bit in the [ALE\\_CONTROL](#) register is set. All packets are dropped when the ENABLE\_ALE bit is cleared to 0.

In normal operation, the CPGMAC\_SL modules are configured to issue an abort, instead of an end of packet, at the end of a packet that contains an error (runt, frag, oversize, jabber, crc, alignment, code etc.) or at the end of a mac control packet. However, when the [SL\\_MACCONTROL](#) configuration bit(s) RX\_CEF\_EN, RX\_CSF\_EN, or RX\_CMF\_EN are set, error frames, short frames or mac control frames have a normal end of packet instead of an abort at the end of the packet. When the ALE receives a packet that contains errors (due to a set header error bit), or a mac control frame and does not receive an abort, the packet will be forwarded only to the host port (port 0). No ALE learning occurs on packets with errors or mac control frames. Learning is based on source address and lookup is based on destination address.

The ALE may be configured to operate in bypass mode by setting the ALE\_BYPASS bit in the [ALE\\_CONTROL](#) register. When in bypass mode, all CPGMAC\_SL received packets are forwarded only to the host port (port 0). Packets from the two ports can be on separate RX DMA channels by configuring the [P0\\_CPDMA\\_RX\\_CH\\_MAP](#) register. In bypass mode, the ALE processes host port transmit packets the same as in normal mode. In general, packets would be directed by the host in bypass mode.

The ALE may be configured to operate in OUI deny mode by setting the ENABLE\_OUI\_DENY bit in the [ALE\\_CONTROL](#) register. When in OUI deny mode, a packet with a non-matching OUI source address will be dropped unless the destination address matches a multicast table entry with the super bit set. Broadcast packets will be dropped unless the broadcast address is entered into the table with the super bit set. Unicast packets will be dropped unless the unicast address is in the table with block and secure both set (supervisory unicast packet).

Multicast supervisory packets are designated by the super bit in the table entry. Unicast supervisory packets are indicated when block and secure are both set. Supervisory packets are not dropped due to rate limiting, OUI, or VLAN processing.

#### 24.11.4.8.2.1 Address Table Entry

The ALE table contains 1024 entries. Each table entry represents a free entry, an address, a VLAN, an address/VLAN pair, or an OUI address. Software should ensure that there are not double address entries in the table. The double entry used would be indeterminate. Reserved table bits must be written with zeroes.

Source Address learning occurs for packets with a unicast, multicast or broadcast destination address and a unicast or multicast (including broadcast) source address. Multicast source addresses have the group bit (bit 40) cleared before ALE processing begins, changing the multicast source address to a unicast source address. A multicast address of all ones is the broadcast address which may be added to the table. A learned unicast source address is added to the table with the following control bits:

**Table 24-1256. Learned Address Control Bits**

Bit(s)	Value
unicast_type	11
Block	0
Secure	0

If a received packet has a source address that is equal to the destination address then the following occurs:

- The address is learned if the address is not found in the table.
- The address is updated if the address is found.
- The packet is dropped.

#### Table Entry Type

00 - Free Entry

01 - Address Entry : unicast or multicast determined by destination **address bit 40**.

10 - VLAN entry

11 - VLAN Address Entry : unicast or multicast determined by **address bit 40**.

#### 24.11.4.8.2.1.1 Free Table Entry

**Table 24-1257. Free (Unused) Address Table Entry Bit Values**

71:62	61:60	59:0
Reserved	ENTRY_TYPE(00)	Reserved

### 24.11.4.8.2.1.2 Multicast Address Table Entry

**Table 24-1258. Multicast Address Table Entry Bit Values**

71:69	68:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_MASK	SUPER	Reserved	MCAST_FWD_S TATE	ENTRY_TYPE( 01)	Reserved	MULTICAST_A DDRESS

#### Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

#### Port Mask(2:0) (PORT\_MASK)

This 3-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

#### Multicast Forward State (MCAST\_FWD\_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT\_MASK has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

#### Table Entry Type (ENTRY\_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

#### Packet Address (MULTICAST\_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

### 24.11.4.8.2.1.3 VLAN/Multicast Address Table Entry

**Table 24-1259. VLAN/Multicast Address Table Entry Bit Values**

71:69	68:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_MASK	SUPER	Reserved	MCAST_FWD_S TATE	ENTRY_TYPE( 11)	VLAN_ID	MULTICAST_A DDRESS

#### Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

#### Port Mask(2:0) (PORT\_MASK)

This 3-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

#### **Multicast Forward State (MCAST\_FWD\_STATE)**

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT\_MASK has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

#### **Table Entry Type (ENTRY\_TYPE)**

Address entry type. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

#### **VLAN ID (VLAN\_ID)**

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

#### **Packet Address (MULTICAST\_ADDRESS)**

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

### **24.11.4.8.2.1.4 Unicast Address Table Entry**

**Table 24-1260. Unicast Address Table Entry Bit Values**

71:68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_NUMBER	BLOCK	SECURE	UNICAST_TYPE (00) or (X1)	ENTRY_TYPE(01)	Reserved	UNICAST_ADDRESS

#### **Port Number (PORT\_NUMBER)**

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).

#### **Block (BLOCK)**

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

#### **Secure (SECURE)**

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port\_number.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

#### Unicast Type (UNICAST\_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

#### Table Entry Type (ENTRY\_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

#### Packet Address (UNICAST\_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

### 24.11.4.8.2.1.5 OUI Unicast Address Table Entry

**Table 24-1261. OUI Unicast Address Table Entry Bit Values**

71:64	63:62	61:60	59:48	47:24	23:0
Reserved	UNICAST_TYPE(10)	ENTRY_TYPE(01)	Reserved	UNICAST_OUI	Reserved

#### Unicast Type (UNICAST\_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

#### Table Entry Type (ENTRY\_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

#### Packet Address (UNICAST\_OUI)

For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup.

### 24.11.4.8.2.1.6 VLAN/Unicast Address Table Entry

**Table 24-1262. Unicast Address Table Entry Bit Values**

71:68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_NUMBER	BLOCK	SECURE	UNICAST_TYPE (00) or (X1)	ENTRY_TYPE (11)	VLAN_ID	UNICAST_ADDRESS

### Port Number (PORT\_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. [Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).]

### Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

### Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry PORT\_NUMBER.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

### Unicast Type (UNICAST\_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

### Table Entry Type (ENTRY\_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

### VLAN ID (VLAN\_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

### Packet Address (UNICAST\_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

#### 24.11.4.8.2.1.7 VLAN Table Entry

**Table 24-1263. VLAN Table Entry**

71:62	61:60	59:48	47:27	26:24	23:19	18:16	15:11	10:8	7:3	2:0
Reserved	ENTRY_TY PE(10)	VLAN_ID	Reserved	FORCE_UN TAGGED_E GRESS	Reserved	REG_MCAS T_FLOOD_ MASK	Reserved	UNREG_M CAST_FLO OD_MASK	Reserved	VLAN_MEM BER_LIST

**Table Entry Type (ENTRY\_TYPE)**

10: VLAN entry

**VLAN ID (VLAN\_ID)**

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

**Force Untagged Packet Egress (FORCE\_UNTAGGED\_EGRESS)**

This field causes the packet VLAN tag to be removed on egress (except on port 0).

**Registered Multicast Flood Mask (REG\_MCAST\_FLOOD\_MASK)**

Mask [port 2-1-0] used for multicast when the multicast address is found.

**Unregistered Multicast Flood Mask (UNREG\_MCAST\_FLOOD\_MASK)**

Mask [port 2-1-0] used for multicast when the multicast address is not found.

**VLAN Member List (VLAN\_MEMBER\_LIST)**

This 3-bit field indicates which port(s) are members of the associated VLAN.

**24.11.4.8.2.2 Packet Forwarding Processes**

There are four processes that an incoming received packet may go through to determine packet forwarding. The processes are Ingress Filtering, VLAN\_Aware Lookup, VLAN\_Unaware Lookup, and Egress.

Packet processing begins in the Ingress Filtering process. Each port has an associated packet forwarding state that can be one of four values (Disabled, Blocked, Learning, or Forwarding). The default state for all ports is Disabled. The host sets the packet forwarding state for each port.

In the packet ingress process (receive packet process), there is a forward state test for unicast destination addresses and a forward state test for multicast addresses. The multicast forward state test indicates the port states required for the receiving port in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state for the packet to be forwarded for transmission. The mcast\_fwd\_state indicates the required port state for the receiving port as indicated in the preceding table. The unicast forward state test indicates the port state required for the receiving port in order to forward the unicast packet. The transmit port must be in the Forwarding state in order to forward the packet. The block and secure bits determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state. The transmit port must be in the Forwarding state regardless. The forward state test used in the ingress process is determined by the destination address packet type (multicast/unicast).

In general, packets received with errors are dropped by the address lookup engine without learning, updating, or touching the address. The error condition and the abort are indicated by the CPGMAC\_SL to the ALE. Packets with errors may be passed to the host (not aborted) by a CPGMAC\_SL port, if the port has the RX\_CMF\_EN, RX\_CEF\_EN, or RX\_CSF\_EN bit(s) set. Error packets that are passed to the host by the CPGMAC\_SL are considered to be bypass packets by the ALE and are sent only to the host. Error packets do not learn, update, or touch addresses regardless of whether they are aborted or sent to the host. Packets with errors received by the host are forwarded as normal.

The following control bits are in the [SL\\_MACCONTROL](#) register:

- [22] RX\_CEF\_EN - enables frames that are fragments, long, jabber, CRC, code, and alignment errors to be forwarded
- [23] RX\_CSF\_EN - enables short frames to be forwarded
- [24] RX\_CMF\_EN - enables MAC control frames to be forwarded.

**24.11.4.8.2.3 Learning Process**

The learning process is applied to each receive packet that is not aborted. The learning process is a concurrent process with the packet forwarding process.

#### 24.11.4.8.2.4 VLAN Aware Mode

The CPSW\_3G is in VLAN aware mode when the VLAN\_AWARE bit is set in the [CPSW\\_CONTROL](#) register. In VLAN aware mode, ports 0 receive packets (out of the CPSW\_3G) may or may not be VLAN encapsulated depending on the RX\_VLAN\_ENCAP bit in the [CPSW\\_CONTROL](#) register. Port 0 receive packet data is never modified. VLAN is not removed regardless of the force untagged egress bit for Port 0. VLAN encapsulated receive packets have a 32-bit VLAN header encapsulation word added to the packet data. VLAN encapsulated packets are specified by a set rx\_vlan\_encap bit in the packet buffer descriptor.

Port 0 transmit packets are never VLAN encapsulated (encapsulation is not allowed).

In VLAN aware mode, transmitted packet data is changed depending on the packet type (pkt\_type), packet priority (pkt\_pri), and VLAN information.

#### 24.11.4.8.2.5 VLAN Unaware Mode

The CPSW\_3G is in VLAN unaware mode when the VLAN\_AWARE bit is cleared to 0 in the [CPSW\\_CONTROL](#) register. Port 0 receive packets (out of the CPSW\_3G) may or may not be VLAN encapsulated depending on the RX\_VLAN\_ENCAP bit in the [CPSW\\_CONTROL](#) register. Port 0 transmit packets are never VLAN encapsulated.

#### 24.11.4.8.3 Packet Priority Handling

Packets are received on three ports, two are CPGMAC\_SL Ethernet ports and the third port is the CPPI host port. Received packets have a received packet priority (0 to 7, with 7 being the highest priority).

The received packet priority is the port priority for untagged packets, and the actual packet priority for priority tagged and VLAN tagged packets. The received packet priority is mapped through the receive ports associated packet priority to header packet priority mapping register to obtain the header packet priority (the CPDMA RX and TX nomenclature is reversed from the CPGMAC\_SL nomenclature).

The header packet priority is mapped through the header priority to switch priority mapping register to obtain the hardware switch priority (0 to 3, with 3 being the highest priority). The header packet priority is then used as the actual transmit packet priority if the VLAN information is to be sent on egress.

#### 24.11.4.8.4 FIFO Memory Control

Each of the three CPSW\_3G ports has an identical associated FIFO. Each FIFO contains a single logical receive queue and four logical transmit queues (priority 0 through 3). Each FIFO memory contains 20,480 bytes (20k) total organized as 2560 by 64-bit words contained in a single memory instance. The FIFO memory is used for the associated port transmit and receive queues. The TX\_MAX\_BLKs field in the FIFOs associated Px\_MAX\_BLKs register determines the maximum number of 1k FIFO memory blocks to be allocated to the four logical transmit queues (transmit total). The RX\_MAX\_BLKs field in the FIFO's associated Px\_MAX\_BLKs register determines the maximum number of 1k memory blocks to be allocated to the logical receive queue. The TX\_MAX\_BLKs value plus the RX\_MAX\_BLKs value must sum to 20 (the total number of blocks in the FIFO). If the sum were less than 20, then some memory blocks would be unused. The default is 17 (decimal) transmit blocks and three receive blocks. The FIFOs follow the naming convention of the Ethernet ports. Host Port is Port0 and External Ports are Port1 and Port2.

#### 24.11.4.8.5 FIFO Transmit Queue Control

There are four transmit queues in each transmit FIFO. Software has some flexibility in determining how packets are loaded into the queues and on how packet priorities are selected for transmission (how packets are removed and transmitted from queues). All ports on the switch have identical FIFO's. For the purposes of the below the transmit FIFO is switch egress even though the port 0 transmit FIFO is connected to the CPDMA receive (also switch egress). The CPDMA nomenclature is reversed from the CPGMAC\_SL nomenclature due to legacy reasons.

#### **24.11.4.8.5.1 Normal Priority Mode**

When operating in normal mode, lower priority frames are dropped before higher priority frames. The intention is to give preference to higher priority frames. Priority 3 is the highest priority and is allowed to fill the FIFO. Priority 2 will drop packets if the packet is going to take space in the last 2k available. Priority 1 will drop packets if the packet is going to take space in the last 4k available. Priority 0 will drop packets if the packet is going to take space in the last 6k available. If fewer than 4 priorities are to be implemented then the priorities should be mapped such that the highest priorities are used. For example, if two priorities are going to be used then all packets should be mapped to priorities 3 and 2 and priorities 1 and 0 should be unused. Priority escalation may be used in normal priority mode if desired. Normal priority mode is configured as described below:

- Select normal priority mode by setting TX\_IN\_SEL = 00 for all ports (default value in P0/1/2\_TX\_IN\_CTL)
- Configure priority mapping to use only the highest priorities if less than 4 priorities are used. Refer to [Section 24.11.4.8.3, Packet Priority Handling](#).

#### **24.11.4.8.5.2 Dual MAC Mode**

When operating in dual MAC mode the intention is to transfer packets between ports 0 and 1 and ports 0 and 2, but not between ports 1 and 2. Each CPGMAC\_SL appears as a single MAC with no bridging between MAC's. Each CPGMAC\_SL has at least one unique (not the same) mac address.

Dual MAC mode is configured as described below:

- Set the ALE\_VLAN\_AWARE bit in the [ALE\\_CONTROL](#) register. This bit configures the ALE to process in VLAN aware mode. The CPSW\_3G VLAN aware bit (VLAN\_AWARE in [CPSW\\_CONTROL](#)) determines how packets VLAN's are processed on CPGMAC\_SL egress and does not affect how the ALE processes packets or the packet destination. The CPSW\_3G VLAN aware bit may be set or not as required (must be set, if VLAN's are to exit the switch).
- Configure the Port 1 to Port 0 VLAN
  - Add a VLAN Table Entry with ports 0 and 1 as members (clear the flood masks).
  - Add a VLAN/Unicast Address Table Entry with the Port1/0 VLAN and a port number of 0. Packets received on port 1 with this unicast address will be sent only to port 0 (egress). If multiple mac addresses are desired for this port then multiple entries of this type may be configured.
- Configure the Port 2 to Port 0 VLAN
  - Add a VLAN Table Entry with ports 0 and 2 as members (clear the flood masks).
  - Add a VLAN/Unicast Address Table Entry with the Port2/0 VLAN and a port number of 0. Packets received on port 2 with this unicast address will be sent only to port 0 (egress). If multiple mac addresses are desired for this port then multiple entries of this type may be configured.
- Packets from the host (port 0) to ports 1 and 2 should be directed. If directed packets are not desired then VLAN with addresses can be added for both destination ports.
- Select the dual mac mode on the port 0 FIFO by setting TX\_IN\_SEL = 01 in [P0\\_TX\\_IN\\_CTL](#). The intention of this mode is to allow packets from both ethernet ports to be written into the FIFO without one port starving the other port.
- The priority levels may be configured such that packets received on port 1 egress on one CPDMA RX channel while packets received on port 2 egress on a different CPDMA RX channel.

#### **24.11.4.8.5.3 Rate Limit Mode**

Rate-limit mode is intended to allow some CPDMA transmit (switch ingress) channels and some CPGMAC\_SL FIFO priorities (switch egress) to be rate-limited. Non rate-limited traffic (bulk traffic) is allowed on non rate-limited channels and FIFO priorities. The bulk traffic does not impact the rate-limited traffic. Rate-limited traffic must be configured to be sent to rate-limited queues (via packet priority handling). The allocated rates for rate-limited traffic must not be oversubscribed. For example, if port 1 is sending 15% rate limited traffic to port 2 priority 3, and port 0 is also sending 10% rate-limited traffic to

port 2 priority 3, then the port 2 priority 3 egress rate must be configured to be 25% plus a percent or two for margin. The switch must be configured to allow some percentage of non rate-limited traffic. Non rate-limited traffic must be configured to be sent to non rate-limited queues. No packets from the host should be dropped, but non rate-limited traffic received on an ethernet port can be dropped. Rate-limited mode is configured as shown below:

1. Set TX\_IN\_SEL = 10 in P1/2\_TX\_IN\_CTL to enable ports 1 and 2 transmit FIFO inputs to be configured for rate-limiting queues. Enabling a queue to be rate-limiting with this field affects only the packet being loaded into the FIFO, it does not configure the transmit for queue shaping.
2. Configure the number of rate-limited queues for port 1 and 2 transmit FIFO's by setting the TX\_RATE\_EN field in P1/2\_TX\_IN\_CTL. Rate limited queues must be the highest number. For example, if there are two rate limited queues then 1100 would be written to this field for priorities 3 and 2. This field enables the FIFO to allow rate-limited traffic into rate-limited queues while discriminating against non rate-limited queues.
3. Set P1\_PRIN\_SHAPE\_EN and P2\_PRIN\_SHAPE\_EN in the CPSW\_PTYPE register. These bits determine which queues actually shape the output data stream. In general, the same priorities that are set in TX\_RATE\_EN are set in these bits as well, but the FIFO input and output enable bits are separate to allow rate-limiting from the host to non shaped channels if desired. When queue shaping is not enabled for a queue then packets are selected for egress based on priority. When queue shaping is enabled then packets are selected for egress based on queue percentages. If shaping is required on a single queue then it must be priority 3 (priorities 2, 1 and 0 are strict priority). If shaping is required on two queues then it must be on priorities 2 and 3 (priorities 1 and 0 are strict priority). If shaping is required on three queues then it must be on priorities 3, 2, and 1 (priority 0 would then get the leftovers). Priority shaping follows the requirements in the IEEE P802.1Qav/D6.0 specification. Priority shaping is not compatible with priority escalation (escalation must be disabled).
4. PO\_TX\_IN\_CTL[17:16] TX\_IN\_SEL should be set to 00, so Port 0 egress (CPDMA RX) is not rate-limited.
5. The CPDMA is configured for rate-limited transmit (switch ingress) channels by setting the highest bits of the TX\_RLIM field in the CPDMA\_DMACONTROL register. If there are two rate-limited channels, then TX\_RLIM = 11000000 (the rate limited channels must be the highest priorities). Also, the TX\_PTYPE bit in the CPDMA\_DMACONTROL register must be set (fixed priority mode). Rate-limited channels must go to rate-limited FIFO queues, and the FIFO queue rate must not be oversubscribed.

#### 24.11.4.8.6 Audio Video Bridging

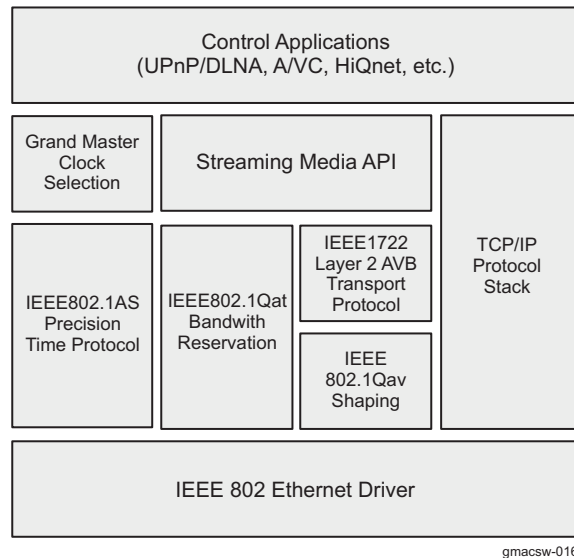

Audio Video Bridging is an ongoing project of IEEE 802.1 concerned with enabling low-latency streaming of time-sensitive audiovisual data over networks. Devices are designated as talkers (transmitters), bridges, or listeners (receivers). It is suggested that the maximum latency could be 2 ms over 7 hops for Class A devices and 20 ms over 7 hops for Class B devices. A hop is essentially a single local area network stage in the journey of a packet. Every time a bridge is encountered between one network section and another a hop is involved. One of the performance goals is that AVB streams will not use more than 75 percent of a link's bandwidth, leaving the remaining capacity for non-AVB streams.

The goal of developing AVB is simply--extend Ethernet's data-networking capabilities to the realm of reliable real-time audio/video networking.

An "Audio Video Bridging" network is one that implements a set of protocols being developed by the IEEE 802.1 Audio/Video Bridging Task Group. There are four primary differences between the proposed Audio Video Bridging architecture and existing 802 architectures (from now on the term "AVB" will be used instead of "Audio Video Bridging"):

1. Precise synchronization - IEEE 802.1AS: "*Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks*". "a.k.a Precision Time Protocol (PTP).
2. Traffic shaping for media streams - IEEE 802.1Qav: "*Virtual Bridged Local Area Networks: Forwarding and Queuing for Time-Sensitive Streams*."
3. Admission controls - IEEE 802.1Qat: "*Virtual Bridged Local Area Networks - Amendment 9: Stream Reservation Protocol (SRP)*."
4. Identification of non-participating devices - IEEE 802.1BA: "Audio/Video Bridging (AVB) Systems"

**Figure 24-193. The Network Static with AVB**

The following sections describe the media transport protocols that work within the AVB framework.

**24.11.4.8.6.1 IEEE 802.1AS: Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks (Precision Time Protocol (PTP))**

The protocol defined by 802.1AS automatically selects a device to be the master clock, and then distributes this clock throughout the bridged LAN / IP subnet to all other network devices using link-specific transmit/receive time-stamping. However, we only use a two-step solution only on transmit. That is, we do not modify a packet with the timestamp on the way out. The timestamp packet is sent out and then a separate message with the timestamp is sent by the host afterward. Receive can be one or two step.

---

**NOTE:** The 802.1AS-distributed clock is not used as a media clock. Rather, the shared 802.1AS clock reference is used to regenerate the media clock at the listener/renderer. Such a reference removes the need to force the latency of the network to be constant, or compute long running averages in order to estimate the actual media rate of the transmitter in the presence of substantial network jitter. IEEE 802.1AS is based on the ratified IEEE 1588 standard.

---

Based on IEEE 1588:2002, PTP devices exchange standard Ethernet messages that synchronize network nodes to a common time reference by defining clock master selection and negotiation algorithms, link delay measurement and compensation, and clock rate matching and adjustment mechanisms.

Designed as a simplified profile of IEEE 1588, a primary difference between 1588 and IEEE 802.1AS is that PTP is a layer 2--in other words, a non-IP routable protocol. Like IEEE 1588, PTP defines an automatic method for negotiating the network clock master, the Best Master Clock Algorithm (BMCA). PTP nodes can be assigned one of eight priority levels, presumably based on clock quality. BMCA defines the underlying negotiation and signaling mechanism whose purpose is to identify the AVB LAN Grandmaster. Once a Grandmaster has been selected, synchronization automatically begins.

At the core of 802.1AS synchronization is time-stamping. In short, during PTP message ingress/egress from the 802.1AS-capable MAC, the PTP Ether type triggers the sampling of the value of a local real-time counter (RTC). Slave nodes compare the value of their RTC against the PTP Grandmaster and, by use of link delay measurement and compensation techniques, match their RTC value to the time of the AVB LAN PTP domain. After network time throughout the AVB LAN has converged, periodic SYNC and FOLLOW\_UP messages provide the information that enables the PTP rate matching adjustment algorithms. The result is all PTP nodes are then synchronized to the same "Wall Clock" time. PTP assures 1- $\mu$ s accuracy over seven network hops.

**Figure 24-194. AVB Network & PTP Clock Entities**

The media transport protocols that work within the AVB framework are:

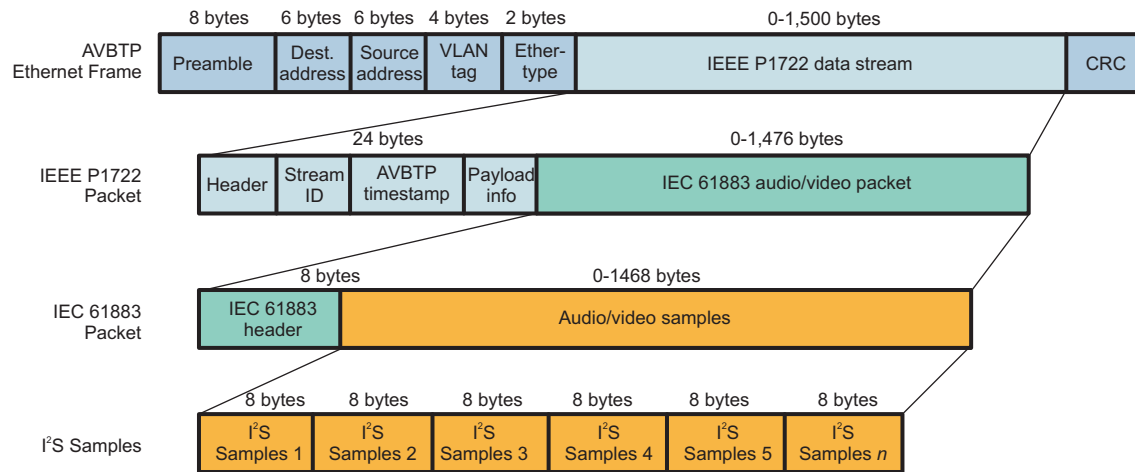

**24.11.4.8.6.1.1 IEEE 1722: "Layer 2 Transport Protocol for Time-Sensitive Streams"**

AVBTP or 1722 sits above the IEEE 802.1 AVB plumbing and below the application layer. It acts as the conduit between an Ethernet MAC and a streaming application. AVBTP abstracts the underlying network transmission channel to enable the virtual connection of distributed audio and video CODECs over reliable Ethernet networks. A complete AVBTP Ethernet packet is shown in [Figure 24-195](#) and illustrates how IEC 61883-6 AM824 uncompressed audio samples are encapsulated in an Ethernet frame.

Figure 24-195. IEEE 1722 Packets

IEEE 1722 Packet Construction

1722 or AVBTP Presentation Time and Synchronization:

Synchronization in an AVB network starts with the Precision Time Protocol but ends with synchronized media clocks. PTP is responsible for synchronizing all nodes in an AVB network to identical wall clock time; not for synchronizing media clocks. In other words, PTP does not actually transport synchronized media clocks but instead provides a low-level building block crucial for managing a distributed media synchronization system.

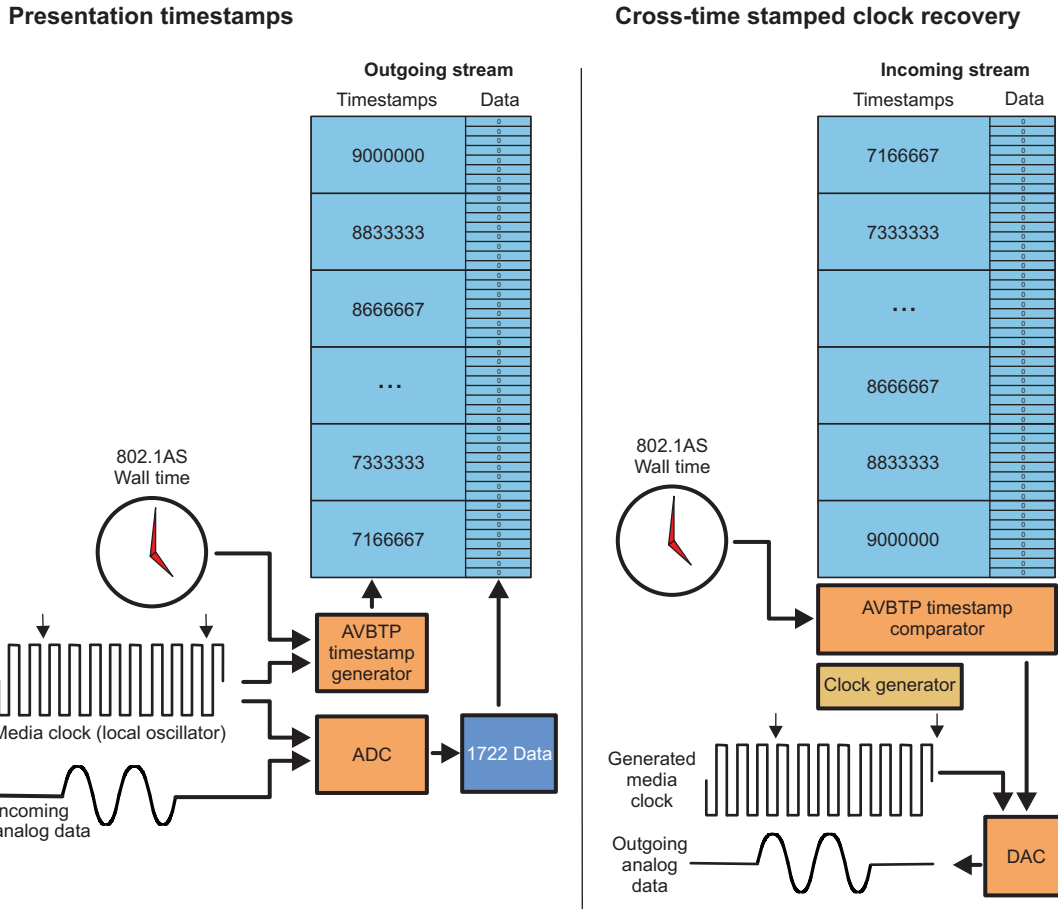

A crucial benefit of this approach is coexistence of multiple, independent media clock domains on an AVB network. Unrelated audio and video streams can simultaneously exist in the same LAN.

AVBTP assumes that AVB node media clocks are clocked by free-running oscillators. It is also assumed that the node's internal concept of wall clock time has been synchronized to the PTP Grandmaster. AVBTP media clock sources embed "AVBTP Presentation Timestamps" in AVBTP streaming packets. Figure 24-196 illustrates the relationship between PTP network time and AVBTP Presentation Timestamps.

24.11.4.8.6.1.2 IEEE 1733: Extends RTCP for RTP Streaming over AVB-supported Networks

This standard specifies the protocol, data encapsulations, connection management and presentation time procedures used to ensure interoperability between audio and video based end stations that use standard networking services provided by all IEEE 802 networks meeting QoS requirements for time-sensitive applications by leveraging the Real-time Transport Protocol (RTP) family of protocols and IEEE 802.1 Audio/Video Bridging (AVB) protocols.

**Figure 24-196. Cross Time Stamping and Presentation Timestamps**

**24.11.4.8.6.2 IEEE 802.1Qav: "Virtual Bridged Local Area Networks: Forwarding and Queuing for Time-Sensitive Streams"**

This standard allows bridges to provide guarantees for time-sensitive (that is, bounded latency and delivery variation), loss-sensitive real-time audio video (AV) data transmission (AV traffic). It specifies per priority ingress metering, priority regeneration, and timing-aware queue draining algorithms. This standard uses the timing derived from IEEE 802.1AS. Virtual Local Area Network (VLAN) tag encoded priority values are allocated, in aggregate, to segregate frames among controlled and non-controlled queues, allowing simultaneous support of both AV traffic and other bridged traffic over and between wired and wireless Local Area Networks (LANs).

Such a guarantee in bandwidth is provided by two functional entities:

- A registration protocol, which registers the service and its maximum network utilization with a device or switch (IEEE 802.1Qat: "Virtual Bridged Local Area Networks - Amendment 9: Stream Reservation Protocol (SRP)")
- A hardware bandwidth management service.
  - Receive policing and
  - Transmit rate control.

**End Station Behavior**

In order for an end station to successfully participate in the transmission and reception of time-sensitive streams, it is necessary for their behavior to be compatible with the operation of the forwarding and queuing mechanisms employed in bridges.

The requirements for end stations that participate as "talkers" i.e., sources of time-sensitive streams are different from the requirements that apply to "listeners", the destination station(s) for the streams.

**Talker Behavior**

In order for Talker-originated data streams to make use of the credit-based shaper behavior in Bridges, it is a requirement for a Talker to use the priorities that the Bridges in the network recognize as being associated with SR classes exclusively for transmitting stream data.

It is also necessary for the Talker and the Bridges in the path to the Listener(s), to have a common view of the bandwidth required in order to transmit the Talker's streams, and for that bandwidth to be reserved along the path to the Listener(s). This latter requirement can be met by means of stream reservation mechanisms, such as defined in SRP, or by other management means.

End stations that are Talkers shall exhibit transmission behavior for frames that are part of "time-sensitive streams" that is consistent with the operation of the credit-based shaper algorithm, both in terms of the way they transmit frames that are part of an individual data stream, and in terms of the way they transmit stream data frames from a Port.

In effect, the queuing model for a Talker Port (and a Listener port), and for given priorities, can be considered to look like [Figure 24-197](#).

**Listener Behavior**

The primary requirement for a listener station is that it is capable of buffering the amount of data that could be transmitted for a stream during a time period equivalent to the accumulated maximum jitter that could be experienced by stream data frames in transmission between Talker and Listener.

From the point of view of the specification of the forwarding and queuing requirements for time-sensitive streams, it is assumed that the listener will assess the buffering required for a stream as part of the stream bandwidth reservation mechanisms employed by the implementation.

The credit-based shaper's operation details are beyond the scope of this document.

**Figure 24-197. AV Stream Queuing/Policing**

**24.11.4.8.6.2.1 Configuring the Device for 802.1Qav Operation:**

There is no dedicated register-set to be configured for the time-sensitive stream handling. The list of functional features of CPSW\_3G that will have to be configured are:

- DESCRIPTORS and CHANNEL CONFIGURATIONS:
  - CPPI TX and RX descriptors
  - VLAN and Priority tags

**Table 24-1264. Example of TX Configuration**

TX DMA CHANNEL	Packet Priority	Switch Queue Priority
7	7	3
6	5	2
5	3	1
4	1	0

**Table 24-1265. Example of RX Configuration**

RX DMA CHANNEL	Packet Priority	Switch Queue Priority
0	7	0
0	5	0
0	3	0
0	1	0

- ALE Configuration:
  - ALE in VLAN-ware mode, Non-ALE in bypass mode.

**Table 24-1266. Example of Rate-limit Configurations**

Register	Value	Description
<a href="#">CPSW_PTYPE</a>	0x0006 0000	For Port1 -- 2 highest priority channels.
<a href="#">P1_TX_IN_CTL[ 23:20] TX_RATE_EN</a>	0b1100	2 highest priority channels are rate limited
<a href="#">P1_TX_IN_CTL[17:16] TX_IN_SEL</a>	0b10	Rate limit mode
<a href="#">P1_SEND_PERCENT</a>	0x14 3E00	20% PRI7, 62% PRI5
<a href="#">CPDMA_DMACONTROL</a>	0xC001	Chan7, Chan6 are Rate Limited. Round-robin selection of DMA channel.
<a href="#">CPDMA_TX_PRI7_RATE</a>	0x1 0013	200 Mbps
<a href="#">CPDMA_TX_PRI6_RATE</a>	0x1 0005	~600 Mbps

#### 24.11.4.8.7 Ethernet MAC Sliver (CPGMAC\_SL)

The CPGMAC\_SL peripheral shall be compliant to the IEEE Std 802.3 Specification. Half-duplex mode is supported in 10/100 Mbps mode, but not in 1000 Mbps (gigabit) mode.

Features:

- Synchronous 10/100/1000 Mbit operation
- G/MII Interface
- Hardware Error handling including CRC
- Full-Duplex Gigabit operation (half-duplex gigabit is not supported)
- EtherStats and 802.3Stats RMON statistics gathering support for external statistics collection module
- Transmit CRC generation selectable on a per channel basis
- Emulation Support
- VLAN Aware Mode Support
- Hardware flow control

- Programmable Inter Packet Gap (IPG).

#### **24.11.4.8.7.1 G/MII Media Independent Interface**

The following sections cover operation of the Media Independent Interface in 10/100/1000 Mbps modes. An IEEE 802.3 compliant Ethernet MAC controls the interface.

##### **24.11.4.8.7.1.1 Data Reception**

###### **24.11.4.8.7.1.1.1 Receive Control**

Data received from the PHY is interpreted and output. Interpretation involves detection and removal of the preamble and start of frame delimiter, extraction of the address and frame length, data handling, error checking and reporting, cyclic redundancy checking (CRC), and statistics control signal generation.

###### **24.11.4.8.7.1.1.2 Receive Inter-Frame Interval**

The 802.3 required inter-packet gap (IPG) is 24 GMII clocks (96 bit times) for 10/100 Mbit modes, and 12 GMII clocks (96 bit times) for 1000 Mbit mode. However, the MAC can tolerate a reduced IPG (2 GMII clocks in 10/100 mode and 5 GMII clocks in 1000 mode) with a correct preamble and start frame delimiter.

This interval between frames must comprise (in the following order):

- An Inter-Packet Gap (IPG).
- A seven octet preamble (all octets 0x55).
- A one octet start frame delimiter (0x5D).

###### **24.11.4.8.7.1.2 Data Transmission**

The Gigabit Ethernet Mac Sliver (GMII) passes data to the PHY when enabled. Data is synchronized to the transmit clock rate. The smallest frame that can be sent is two bytes of data with four bytes of CRC (6 byte frame).

###### **24.11.4.8.7.1.2.1 Transmit Control**

A jam sequence is output if a collision is detected on a transmit packet. If the collision was late (after the first 64 bytes have been transmitted) the collision is ignored. If the collision is not late, the controller will back off before retrying the frame transmission. When operating in full duplex mode the carrier sense (CRS) and collision sensing modes are disabled.

###### **24.11.4.8.7.1.2.2 CRC Insertion**

The MAC generates and appends a 32-bit Ethernet CRC onto the transmitted data, if the transmit packet header PASS\_CRC bit is 0. For the CPMAC\_SL generated CRC case, a CRC at the end of the input packet data is not allowed.

If the header word PASS\_CRC bit is set, then the last four bytes of the TX data are transmitted as the frame CRC. The four CRC data bytes should be the last four bytes of the frame and should be included in the packet byte count value. The MAC performs no error checking on the outgoing CRC when the PASS\_CRC bit is set.

###### **24.11.4.8.7.1.2.3 MTXER**

The MTXER signal is only used for EEE. If an underflow condition occurs on a transmitted frame, the frame CRC will be inverted to indicate the error to the network. Underflow is a hardware error.

#### **24.11.4.8.7.1.2.4 Adaptive Performance Optimization (APO)**

The Ethernet MAC port incorporates Adaptive Performance Optimization (APO) logic that may be enabled by setting the TX\_PACE bit in the [SL\\_MACCONTROL](#) register. Transmission pacing to enhance performance is enabled when set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions) thereby increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision or excessive collision) the pacing counter is decremented by one, down to zero.

With pacing enabled, a new frame is permitted to immediately (after one IPG) attempt transmission only if the pacing counter is zero. If the pacing counter is non zero, the frame is delayed by the pacing delay, a delay of approximately four inter-packet gap delays. APO only affects the IPG preceding the first attempt at transmitting a frame. It does not affect the back-off algorithm for re-transmitted frames.

#### **24.11.4.8.7.1.2.5 Inter-Packet-Gap Enforcement**

The measurement reference for the IPG of 96 bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision, and MCRS is de-asserted within approximately 48 bit times of MTXEN being de-asserted, then 96 bit times is measured from MTXEN. If the frame suffered a collision, or if MCRS is not de-asserted until more than approximately 48 bit times after MTXEN is de-asserted, then 96 bit times (approximately, but not less) is measured from MCRS.

The transmit IPG can be shortened by eight bit times when enabled and triggered. The TX\_SHORT\_GAP\_EN bit in the [SL\\_MACCONTROL](#) register enables the TX\_SHORT\_GAP input to determine whether the transmit IPG is shorted by eight bit times.

#### **24.11.4.8.7.1.2.6 Back Off**

The Gigabit Ethernet Mac Sliver (GMII) implements the 802.3 binary exponential back-off algorithm.

#### **24.11.4.8.7.1.2.7 Programmable Transmit Inter-Packet Gap**

The transmit inter-packet gap (IPG) is programmable through the [SL\\_TX\\_GAP](#) register. The default value is decimal 12. The transmit IPG may be increased to the maximum value of 1FFh. Increasing the IPG is not compatible with transmit pacing. The short gap feature will override the increased gap value, so the short gap feature may not be compatible with an increased IPG.

#### **24.11.4.8.7.1.2.8 Speed, Duplex and Pause Frame Support Negotiation**

The CPMAC\_SL can operate in half duplex or full duplex in 10/100 Mbit modes, and can operate in full duplex only in 1000 Mbit mode. Pause frame support is included in 10/100/1000 Mbit modes as configured by the host.

#### **24.11.4.8.7.2 RMII Interface**

The CPRMII peripheral is compliant to the RMII specification document.

##### **24.11.4.8.7.2.1 Features**

- Source Synchronous 10/100 Mbit operation
- Full and Half Duplex support

##### **24.11.4.8.7.2.2 RMII Receive (RX)**

The CPRMII receive (RX) interface converts the input data from the external RMII PHY (or switch) into the required MII (CPGMAC) signals. The carrier sense and collision signals are determined from the RMII input data stream and transmit inputs as defined in the RMII specification.

An asserted RMRXER on any di-bit in the received packet will cause an MRXER assertion to the CPGMAC during the packet. In 10Mbps mode, the error is not required to be duplicated on 10 successive clocks. Any di-bit which has an asserted RMII\_RXER during any of the 10 replications of the data will cause the error to be propagated.

Any received packet that ends with an improper nibble boundary aligned RMCERSDV toggle will issue an MRXER during the packet to the CPGMAC. Also, a change in speed or duplex mode during packet operations will cause packet corruption.

The CPRMII can accept receive packets with shortened preambles, but 0x55 followed by a 0x5D is the shortest preamble that will be recognized (1 preamble byte with the start of frame byte). At least one byte of preamble with the start of frame indicator is required to begin a packet. An asserted RMCERSDV without at least a single correct preamble byte followed by the start of frame indicator will be ignored.

#### **24.11.4.8.7.2.3 RMII Transmit (TX)**

The CPRMII transmit (TX) interface converts the GMAC\_SW MII input data into the RMII transmit format. The data is then output to the external RMII PHY.

The GMAC\_SW does not source the transmit error (MII TXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be de-asserted at all times and is not an input into the CPRMII module. Zeroes are output on RMTXD[1:0] for each clock that RMTXEN is de-asserted.

#### **24.11.4.8.7.3 RGMII Interface**

The CPRGMII peripheral is compliant to the RGMII specification document.

##### **24.11.4.8.7.3.1 RGMII Features**

- Supports 1000/100/10 Mbps speed
- In SR1.1, Internal TXC delay on transmit is always enabled
- In SR2.x, Internal TXC delay on transmit can be enabled or disabled using bits [26] RGMII2\_ID\_MODE\_N and [25] RGMII1\_ID\_MODE\_N of the [CTRL\\_CORE\\_SMA\\_SW\\_1](#) register.
- MII mode is not supported

##### **24.11.4.8.7.3.2 RGMII Receive (RX)**

The CPRGMII receive (RX) interface converts the source synchronous DDR input data from the external RGMII PHY into the required G/MII (CPGMAC) signals.

##### **24.11.4.8.7.3.3 In-Band Mode of Operation**

The CPRGMII is operating in the in-band mode of operation when the EXT\_EN bit of the [SL\\_MACCONTROL](#) register is set to 1. The link status, duplexity, and speed are determined from the RGMII input data stream RXD[3:0] when RX\_CTL is deasserted, as defined in the RGMII specification. The PHY might need to be configured beforehand to output in-band data. The in-band data is indicated as shown in [Table 24-1267](#).

**Table 24-1267. In-Band Data**

RXD3	RXD[2:1]		RXD0
Duplex status:	Link Speed:	RXC_CLK Speed:	Link Status:
0: half-duplex	00: 10-Mbps mode	2.5 MHz	0: Link is down
1: full-duplex	01: 100-Mbps mode	25 MHz	1: Link is up
	10: 1000-Mbps mode	125 MHz	
	11: reserved	reserved	

#### 24.11.4.8.7.3.4 Forced Mode of Operation

The CPRGMII is operating in the forced mode of operation when the EXT\_EN bit of the [SL\\_MACCONTROL](#) register is set to 0. In the forced mode of operation, the in-band data is ignored if present. The link status is forced high, and the duplexity and speed are determined from the [SL\\_MACCONTROL\[0\]](#) FULLDUPLEX and [7] GIG bits. If GIG = 1, then operation is gigabit mode. If the GIG is 0, the operation is 100 Mbps mode.

#### 24.11.4.8.7.3.5 RGMII Transmit (TX)

The CPRGMII transmit (TX) interface converts the CPGMAC G/MII input data into the DDR RGMII format. The DDR data is then output to the external PHY.

The CPGMAC does not source the transmit error (TXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be de-asserted at all times and is not an input into the CPRGMII module.

The TXD[7:0] data bus uses only the lower nibble. The CPRGMII will output the lower nibble twice in 10/100 mode to avoid unnecessary signal switching.

Packets will be precluded from transmission through the CPRGMII module for 4096 transmit clocks after the rising edge of RGMII\_LINK. Packet transmission will begin on the first TX\_CTL rising edge after the 4096 transmit clock count has expired.

#### 24.11.4.8.7.4 Frame Classification

Received frames are proper (good) frames if they are between 64 and RX\_MAXLEN in length (inclusive) and contain no errors (code/align/CRC).

Received frames are long frames if their frame count exceeds the value in the [SL\\_RX\\_MAXLEN](#) register. The [SL\\_RX\\_MAXLEN](#) register reset (default) value is 1518 (decimal). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames if their frame count is less than 64 bytes. Short frames that contain no errors are undersized frames. Short frames with CRC, code, or alignment errors are fragment frames.

A received long packet will always contain RX\_MAXLEN number of bytes transferred to memory (if RX\_CEF\_EN = 1). An example with RX\_MAXLEN = 1518 is:

- If the frame length is 1518, then the packet is not a long packet and there will be 1518 bytes transferred to memory.
- If the frame length is 1519, there will be 1518 bytes transferred to memory. The last three bytes will be the first three CRC bytes.
- If the frame length is 1520, there will be 1518 bytes transferred to memory. The last two bytes will be the first two CRC bytes.
- If the frame length is 1521, there will be 1518 bytes transferred to memory. The last byte will be the first CRC byte.

If the frame length is 1522, there will be 1518 bytes transferred to memory. The last byte will be the last data byte.

#### 24.11.4.8.8 Embedded Memories

**Table 24-1268. Embedded Memories**

Memory Type Description	Number of Instances	
Single-port 2560 × 64 RAM	3	(Packet FIFO's)
Single-port 64-word × 1152-bit RAM	1	(ALE)
Single-port 2048-word × 32-bit RAM	1	(CPPI)

#### 24.11.4.8.9 Flow Control

There are two types of switch flow control: CPPI port flow control and Ethernet port flow control. The CPPI and Ethernet port naming conventions for data flow into and out of the switch are reversed. For the CPPI port (port 0), transmit operations move packets from external memory into the switch and then out to either or both Ethernet transmit ports (ports 1 and 2). CPPI receive operations move packets that were received on either or both Ethernet receive ports to external memory.

##### 24.11.4.8.9.1 CPPI Port Flow Control

The CPPI port has flow control available for transmit (switch ingress). CPPI receive operations (switch egress) do not require flow control. CPPI Transmit flow control is initiated when enabled and triggered. CPPI transmit flow control is enabled by setting the P0\_FLOW\_EN bit in the [CPSW\\_FLOW\\_CONTROL](#) register. CPPI transmit flow control is enabled by default on reset because host packets should not be dropped in any mode of operation.

##### 24.11.4.8.9.2 Ethernet Port Flow Control

The Ethernet ports have flow control available for transmit and receive. Transmit flow control stops the Ethernet port from transmitting packets to the wire (switch egress) in response to a received pause frame. Transmit flow control does not depend on FIFO usage.

The ethernet ports have flow control available for receive operations (packet ingress). Ethernet port receive flow control is initiated when enabled and triggered. Packets received on an ethernet port can be sent to the other ethernet port or the CPPI port (or both). Each destination port can trigger the receive ethernet port flow control. An ethernet destination port triggers another ethernet receive flow control when the destination port is full.

When a packet is received on an ethernet port interface with enabled flow control the below occurs:

- The packet will be sent to all ports that currently have room to take the entire packet.
- The packet will be retried until successful to all ports that indicate they don't have room for the packet.

The flow control trigger to the CPGMAC\_SL will be asserted until the packet has been sent, and there is room in the logical receive FIFO for packet runout from another flow control trigger (RX\_PKT\_CNT = 0). Ethernet port receive flow control is disabled by default on reset. Ethernet port receive flow control requires that the RX\_FLOW\_EN bit in the associated CPGMAC\_SL be set to 1. When receive flow control is enabled on a port, the port's associated FIFO block allocation must be adjusted. The port RX allocation must increase from the default three blocks to accommodate the flow control runout. A corresponding decrease in the TX block allocation is required. If a sending port ignores a pause frame then packets may overrun on receive (and be dropped) but will not be dropped on transmit. If flow control is disabled for G/MII ports, then any packets that are dropped are dropped on transmit and not on receive.

##### 24.11.4.8.9.2.1 Receive Flow Control

When enabled and triggered, receive flow control is initiated to limit the CPGMAC\_SL from further frame reception. Half-duplex mode receive flow control is collision based while full duplex mode issues 802.3X pause frames. In either case, receive flow control prevents frame reception by issuing the flow control appropriate for the current mode of operation. Receive flow control is enabled by the RX\_FLOW\_EN bit in the [SL\\_MACCONTROL](#) register. Receive flow control is triggered (when enabled) when the RX\_FLOW\_TRIGGER input is asserted. The CPGMAC\_SL is configured for collision or IEEE 802.3X flow control via the FULLDUPLEX bit in the [SL\\_MACCONTROL](#) register.

#### 24.11.4.8.9.2.1 Collision Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the port is operating in half-duplex mode (FULLDUPLEX is cleared in [SL\\_MACCONTROL](#)). When receive flow control is enabled and triggered, the port will generate collisions for received frames. The jam sequence transmitted will be the twelve byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3 (hex). The jam sequence will begin no later than approximately as the source address starts to be received. Note that these forced collisions will not be limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm. Receive flow control does not depend on the value of the incoming frame destination address. A collision will be generated for any incoming packet, regardless of the destination address.

#### 24.11.4.8.9.2.2 IEEE 802.3X Based Receive Flow Control

IEEE 802.3x based receive flow control provides a means of preventing frame reception when the port is operating in full-duplex mode (FULLDUPLEX is set in [SL\\_MACCONTROL](#)). When receive flow control is enabled and triggered, the port will transmit a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The CPGMAC\_SL will transmit a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle, or following the completion of the frame currently being transmitted). The pause frame will contain the maximum possible value for the pause time (FFFFh). The MAC will count the receive pause frame time (decrements FF00h down to 0) and retransmit an outgoing pause frame if the count reaches zero. When the flow control request is removed, the MAC will transmit a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval will be received normally (provided the RX FIFO is not full).

Pause frames will be transmitted if enabled and triggered regardless of whether or not the port is observing the pause time period from an incoming pause frame.

The CPGMAC\_SL will transmit pause frames as:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01.
- The 48-bit source address - from SL\_SA[47:0] input.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause time value FF.FF. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request will have a pause time value of 00.00.
- Zero padding to 64-byte data length (The CPGMAC\_SL will transmit only 64 byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

If RX\_FLOW\_EN is cleared to 0 while the pause time is nonzero, then the pause time will be cleared to 0 and a zero count pause frame will be sent.

#### 24.11.4.8.9.2.2 Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the CPGMAC\_SL from transmitting any further frames. Incoming pause frames are only acted upon when the FULLDUPLEX and TX\_FLOW\_EN bits in the [SL\\_MACCONTROL](#) register are set. Pause frames are not acted upon in half-duplex mode. Pause frame action will be taken if enabled, but normally the frame will be filtered and not transferred to memory. MAC control frames will be transferred to memory if the RX\_CMF\_EN (copy MAC frames) bit in the [SL\\_MACCONTROL](#) register is set. The TX\_FLOW\_EN and FULLDUPLEX bits effect whether or not MAC control frames are acted upon, but they have no effect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC Control Frames with an opcode field = 0001h. Incoming pause frames will only be acted upon by the port if:

- TX\_FLOW\_EN is set in [SL\\_MACCONTROL](#) register, and
- the frame's length is 64 to [SL\\_RX\\_MAXLEN](#) bytes inclusive, and
- the frame contains no CRC error or align/code errors.

The pause time value from valid frames will be extracted from the two bytes following the opcode. The pause time will be loaded into the port's transmit pause timer and the transmit pause time period will begin.

If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- if the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer will immediately expire, or
- if the new pause time value is zero then the transmit pause timer will immediately expire, else
- the port transmit pause timer will immediately be set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame will be discarded).

If TX\_FLOW\_EN in [SL\\_MACCONTROL](#) register is cleared, then the pause-timer will immediately expire.

The port will not start the transmission of a new data frame any sooner than 512-bit times after a pause frame with a non-zero pause time has finished being received (MRXDV going inactive). No transmission will begin until the pause timer has expired (the port may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received will be completed and unaffected.

Incoming pause frames consist of the below:

- A 48-bit destination address equal to:
  - The reserved multicast destination address 01.80.C2.00.00.01
  - , or the CPGMAC\_SL SL\_SA [47:0] input.
- The 48-bit source address of the transmitting device.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause\_time. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 bytes. The standard allows pause frames longer than 64 bytes to be discarded or interpreted as valid pause frames. The CPGMAC\_SL will recognize any pause frame between 64 bytes and RX\_MAXLEN bytes in length.

#### **24.11.4.8.10 Short Gap**

The port 1 (and port 2) transmit inter-packet gap (IPG) may be shortened by eight bit times when enabled and triggered. The TX\_SHORT\_GAP\_EN bit in the [SL\\_MACCONTROL](#) register enables the gap to be shortened when triggered. The condition is triggered when the port 1 (port 2) transmit FIFO has a user defined number of FIFO blocks used. The port 1 transmit FIFO blocks used determines if the port 1 gap is shortened, and the port 2 transmit FIFO blocks used determines if the port 2 gap is shortened. The [CPSW\\_GAP\\_THRESH](#) register value determines the port 1 short gap threshold, and the [CPSW\\_GAP\\_THRESH](#) register value determines the port 2 short gap threshold.

#### **24.11.4.8.11 Switch Latency**

The CPSW\_3G is a store and forward switch. The switch latency is defined as the amount of time between the end of packet reception of the received packet to the start of the output packet transmit.

**Table 24-1269. Switch Latency**

Mode	Latency
Gig (1000)	880 ns
100	1.3 $\mu$ s
10	6.5 $\mu$ s

#### 24.11.4.8.12 Emulation Control

The emulation control input (EMUSUSP) and submodule emulation control registers allow CPSW\_3G operation to be completely or partially suspended. There are three CPSW\_3G submodules that contain emulation control registers (CPGMAC\_SL1, CPGMAC\_SL2, and CPDMA). The submodule emulation control registers must be accessed to facilitate CPSW\_3G emulation control. The CPSW\_3G module enters the emulation suspend state if all three submodules are configured for emulation suspend and the emulation suspend input is asserted. A partial emulation suspend state is entered if one or two submodules is configured for emulation suspend and the emulation suspend input is asserted. Emulation suspend occurs at packet boundaries. The emulation control feature is implemented for compatibility with other peripherals.

##### CPGMAC\_SL Emulation Control

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE bits in the [SL\\_EMCONTROL](#) register) allow CPGMAC\_SL operation to be suspended. When the emulation suspend state is entered, the CPGMAC\_SL will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For receive, frames that are detected by the CPGMAC\_SL after the suspend state is entered are ignored. Emulation control is implemented for compatibility with other peripherals.

##### CPDMA Emulation Control

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE bits in the [CPDMA\\_EMCONTROL](#) register) allow CPDMA operation to be suspended. When the emulation suspend state is entered, the CPDMA will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the tx cell FIFO will be transmitted. For receive, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Emulation control is implemented for compatibility with other peripherals.

[Table 24-1270](#) shows the operations of the emulation control input and register bits.

**Table 24-1270. Emulation Control Input**

EMUSUSP	SOFT	FREE	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

#### 24.11.4.8.13 FIFO Loopback

FIFO loopback mode is entered when the FIFO\_LOOPBACK bit in the [CPSW\\_CONTROL](#) register is set. FIFO loopback mode causes packets received on a port to be turned around and transmitted back on the same port. Port 0 receive is fixed on channel 0 in FIFO loopback mode. The RXSOFOVERRUN statistic is incremented for each packet sent in FIFO loopback mode. Packets sent in with errors are returned with errors (they are not dropped). FIFO loopback is intended as a simple mechanism for test purposes. FIFO loopback should be performed in full duplex mode only.

#### 24.11.4.8.14 Device Level Ring (DLR) Support

Device Level Ring (DLR) support is enabled by setting the DLR\_EN bit in the [CPSW\\_CONTROL](#) register. When enabled, incoming received DLR packets are detected and sent to queue 3 (highest priority) of the egress port(s). If the host port is the egress port for a DLR packet then the packet is sent on the CPDMA Rx channel selected by the P0\_DLR\_CPDMA\_CH field in the [P0\\_CONTROL](#) register. The supervisor node MAC address feature is supported with the dlr\_unicast bit in the unicast address table entry. When set, the dlr\_unicast bit causes a packet with the matching destination address to be flooded to the vlan\_member\_list minus the receive port and minus the host port (the port\_number field in the unicast address table entry is a don't care). Matching dlr\_unicast packets are flooded regardless of whether the packet is a DLR packet or not. The EN\_P0\_UNI\_FLOOD bit in the [ALE\\_CONTROL](#) register has no effect on DLR unicast packets. Packets are determined to be DLR packets as shown below:

1. DLR is enabled (DLR\_EN is set in the [CPSW\\_CONTROL](#)).
2. One of the sequences below are true.
  1. The first packet ltype matches [CPSW\\_VLAN\\_LTYPE](#)[15:0] VLAN\_LTYPE1 and Px\_CONTROL[20] Px\_VLAN\_LTYPE1\_EN is set and the second packet ltype matches [CPSW\\_DLR\\_LTYPE](#)[15:0] DLR\_LTYPE.
  2. The first packet ltype matches [CPSW\\_VLAN\\_LTYPE](#)[31:16] VLAN\_LTYPE2 and Px\_CONTROL[21] Px\_VLAN\_LTYPE2\_EN is set and the second packet ltype matches [CPSW\\_DLR\\_LTYPE](#)[15:0] DLR\_LTYPE.
  3. The first packet ltype matches [CPSW\\_VLAN\\_LTYPE](#)[15:0] VLAN\_LTYPE1 and Px\_CONTROL[20] Px\_VLAN\_LTYPE1\_EN is set and the second packet ltype matches [CPSW\\_VLAN\\_LTYPE](#)[31:16] VLAN\_LTYPE2 and Px\_CONTROL[21] Px\_VLAN\_LTYPE2\_EN is set and the third packet ltype matches [CPSW\\_DLR\\_LTYPE](#)[15:0] DLR\_LTYPE.

#### 24.11.4.8.15 Energy Efficient Ethernet Support (802.3az)

---

**NOTE:** CM\_GMAC\_CLKSTCTRL[1:0]CLKTRCTRL bit field must not be programmed for SW\_SLEEP or HW\_AUTO.

---

Energy Efficient Ethernet (EEE) allows the PRCM to turn off the module clock during inactive periods as determined by network and host traffic. The module can then be awakened by host queued transmit packet(s) or by a port's external Ethernet PHY. EEE operations are configured as shown below:

1. The 10-bit EEE clock pre-scale value is written to the [CPSW\\_EEE\\_PRESCALE](#) register. The pre-scaler is used to clock all EEE-related counters
2. The port Idle to LPI count values (Px\_IDLE2LPI) are written with the desired values
3. The port LPI to Wake count values (Px\_LPI2WAKE) are written with the desired values
4. The EEE\_EN bit is set in the switch [CPSW\\_CONTROL](#) register
5. Set the [WR\\_CONTROL](#)[8] SS\_EEE\_EN bit to enable energy efficient operations at subsystem level.

EEE operation can begin after configuration. The host allows (through PRCM) the CPSW\_3G to enter a low power state by asserting the CLKSTOP\_REQ signal. There are no requirements on host queues or traffic in order for the host to assert or de-assert CLKSTOP\_REQ to the CPSW\_3G.

Each ethernet port has a transmit and a receive LPI (low power indicate) state. The receive LPI state is entered when the port's corresponding PHY indicates the LPI state via the CPSW\_3G GMII interface. The PHY indicates LPI by asserting MRXER with a MRXD[7:0] value of 0x01 while MRXDV is deasserted (inter-packet gap). The Ethernet transmit port indicates LPI after the Px\_IDLE2LPI value has been counted (the transmit port has gone idle for the configured amount of time). If another packet is received for transmit during the count then the count is restarted. When the transmit port has been idle for the Idle to LPI time, the transmit port enters the LPI state and indicates LPI to the associated PHY. The LPI is indicated to the external PHY by an asserted MTXER with a MTXD[7:0] while MTXEN is deasserted (inter-packet gap). The CPDMA LPI state includes transmit and receive. The CPDMA LPI state is entered when the CPDMA transmit and receive have both been idle for the Idle to LPI time ([P0\\_IDLE2LPI](#)). The Idle to LPI time value for all ports must be large relative to the switch latency to ensure that the count is not able to complete between successive packets.

**NOTE:** The procedure above is described for the GMII interfaces at the CPSW\_3G boundary. External PHY signaling has the following conditions:

- GMII interface is used only in MII mode. Therefore, only MRXD[3:0] and MTXD[3:0] are pinned out
- RGMII is a DDR interface. TXEN and TXER are the sampled values of TX\_CTL at the rising and the falling TXC\_CLK edges, respectively. RXDV and RXER are the sampled values of RX\_CTL at the rising and the falling RXC\_CLK edges, respectively
- In RMII mode, EEE is not supported.

When all transmit and receive ports are in the LPI state (CPSW LPI state), the CLKSTOP\_ACK signal is asserted, and the PRCM is allowed to stop the module clock. When CLKSTOP\_ACK is asserted, the clock may be turned on and off as desired by the host. The host is allowed to restart the clock, perform slave read/write operations to the CPSW\_3G memory address space, and then turn off the clock again while CLKSTOP\_ACK is asserted.

The software can remove and disable from re-entering the CPSW LPI state by restarting the module clock and then de-asserting CLKSTOP\_REQ. The host may queue transmit packets at any time including without regard to the CPSW\_3G LPI state (the clock must be restarted in order to write the CPSW\_3G slave address space as described above). Host writes to transmit head descriptor pointers will cause the CLKSTOP\_WAKEUP signal to be asserted if the CPSW\_3G is in the low power state (if CLKSTOP\_ACK is asserted).

The external Ethernet PHY's can also wakeup the PRCM by removing the Ethernet receive LPI indication. If the module is in the CPSW Idle state with CLKSTOP\_ACK asserted and the receive LPI indication is removed, the CLKSTOP\_WAKEUP signal will be asynchronously asserted. On wakeup, the PRCM restarts the clock and de-asserts the CLKSTOP\_REQ signal. The CLKSTOP\_WAKEUP signal will be synchronously deasserted with CLKSTOP\_ACK. Upon the deassertion of CLKSTOP\_REQ, the Ethernet ports will count the P<sub>x</sub>\_LPI2WAKE time for each port at which time the port is available for transmit. Upon the de-assertion of CLKSTOP\_REQ, the CPDMA transmit will count the [P0\\_LPI2WAKE](#) count at which time the CPDMA will begin to send any packets that the host has queued (switch ingress). The wait time on CPDMA transmit is included to preclude the host from filling up the Ethernet port transmit FIFO's while the Ethernet ports are in the LPI to wake time. There is no LPI to wake time on CPDMA receive (switch egress).

#### 24.11.4.8.16 CPSW\_3G Network Statistics

The CPSW\_3G has a set of statistics that record events associated with frame traffic on selected switch ports. The statistics values are cleared to zero 38 clocks after the rising edge of GMAC\_RST. When one or more port enable (P<sub>n</sub>\_STAT\_EN) bits in the [CPSW\\_STAT\\_PORT\\_EN](#) register are set, all statistics registers are write to decrement. The value written will be subtracted from the register value with the result being stored in the register. If a value greater than the statistics value is written, then zero will be written to the register (writing 0xFFFF FFFF clears a statistics location). When all port enable bits are cleared to zero, all statistics registers are read/write (normal write direct, so writing 0x0000 0000 clears a statistics location). All write accesses must be 32-bit accesses. In the below statistics descriptions, "the port" refers to any enabled port (with a corresponding set P<sub>n</sub>\_STAT\_EN bit).

The statistics interrupt (STAT\_PEND) will be issued if enabled when any statistics value is greater than or equal to 0x8000 0000. The statistics interrupt is removed by writing to decrement any statistics value greater than 0x8000 0000. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from 0xFFFF FFFF to 0x0000 0000.

See [Section 24.11.6.5](#), *STATS Registers* for description of every network statistic.

[Table 24-1271](#) and [Table 24-1272](#) summarize network statistics.

**Table 24-1271. Rx Statistics Summary**

Rx Statistic	Frame /Oct	Rx/Rx +Tx	Frame Type					Frame Size (bytes)								Event				
			MAC control		Data <sup>(1)</sup>			<64	64	65-127	128-255	256-511	512-1023	1024-rx_maxlen	>rx_maxlen	Flow Coll. <sup>(2)</sup>	CRC Error	Align/Code	Overrun	Addr. Disc.

Rx Octets	O	R	(y	y	y	y	y)	n	(y	y	y	y	y	y)	n	-	n	n	-	n
Net Octets	O	R+T	(y	y	y	y	y)	(y	y	y	y	y	y	y)	y)	-	-	-	-	-

(1) The multicast, broadcast and unicast columns in the table refer to non-MAC Control/non-pause frames (i.e. data frames).  
(2) Flow coll. are half-duplex collisions forced by the MAC to achieve flow-control. A collision will be forced during the first 8 bytes so should not show in frame fragments. Some of the '-'s in this column might in reality be 'n's.  
(3) The non-pause column refers to all MAC control frames (for example, frames with length/type=88.08) with opcodes other than 0x0001. The pauseframe column refers to MAC frames with the opcode=0x0001.  
(4) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.  
(5) "-" indicates conditions which are ignored in the formations of the statistic.  
(6) "%" If either a MAC control frame or pause frame has a multicast or broadcast destination address then the appropriate statistics will be updated.  
(7) "y^" Frame fragments are not counted if less than 8 bytes.  
(8) The rx\_overruns stat is for RX\_MOF\_OVERRUNS and RX\_SOF\_OVERRUNS added together.  
(9) Statistics marked "R+T" are formed by summing the Rx and Tx statistics, each of which is formed independently.

**Table 24-1272. Tx Statistics Summary**

Tx Statistic <sup>(1)</sup>	Frame/Octet	Tx/Rx+Tx	Frame Type					Frame Size (bytes)							Event													
			MAC control <sup>(2)</sup>		Data			64	65-127	128-255	256-511	512-1023	1024-1535	>1535	CRC Error	Collision Type					No Carrier	Queued	Deferred	Underrun				
			Pause-MAC	Any-CPU	Multicast	Broadcast	Unicast									Flow <sup>(3)</sup>	1	2-15	16	Late								
Good Tx Frames	F	T	(y) <sup>(4)</sup>	y	y	y	y	(y	y	y	y	y	y	(y	y	y	y	- <sup>(5)</sup>	-	-	-	n	n	n	-	-	n	
Broadcast Tx Frames	F	T	n	(%  <sup>(6)</sup>	n	y	n	(y	y	y	y	y	y	y	y	y	y	-	-	-	-	n	n	n	-	-	n	
Multicast Tx Frames	F	T	(y	%	y	n	n	(y	y	y	y	y	y	y	y	y	y	-	-	-	-	n	n	n	-	-	n

Collisions	F	T	n	(y	y	y	y	(y	y	y	y	y	y	y	y	y	y	-	(+ <sup>(7)</sup>	+	+	+	+	+	n	-	-	-
Single Collision Tx Frames	F	T	n	(y	y	y	y	(y	y	y	y	y	y	y	y	y	y	-	-	y	n	n	n	n	-	-	-	
Multiple Collision Tx Frames	F	T	n	(y	y	y	y	(y	y	y	y	y	y	y	y	y	y	-	-	n	y	n	n	n	-	-	-	
Excessive Collisions	F	T	n	(y	y	y	y	(y	y	y	y	y	y	y	y	y	y	-	-	n	n	y	n	n	-	-	-	
Late Collisions	F	T	n	(y	y	y	y	n	(y	y	y	y	y	y	y	y	y	-	-	-	-	-	y	-	-	-	-	
Deferred Tx Frames	F	T	n	(y	y	y	y	(y	y	y	y	y	y	y	y	y	y	-	-	n	n	n	n	n	-	y	n	
Carrier Sense Errors	F	T	(y	y	y	y	y	(y	y	y	y	y	y	y	y	y	y	-	-	-	-	-	-	y	-	-	-	
64octet Frames	F	R+T <sup>(8)</sup>	(y	y	y	y	y	y	n	n	n	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-		
65-127octet Frames	F	R+T	(y	y	y	y	y	n	y	n	n	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-		
128-255octet Frames	F	R+T	(y	y	y	y	y	n	n	y	n	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-		

<sup>(1)</sup> When the transmit Tx FIFO is drained due to the MAC being disabled or link being lost, then the frames being purged will not appear in the Tx statistics.

<sup>(2)</sup> Pause (MAC) frames are issued in the MAC as perfect (no CRC error) 64 byte frames in full duplex only, so they cannot collide.

<sup>(3)</sup> The flow collision type is for half-duplex collisions forced by the MAC to achieve flow control. Some of the '-'s in this column might in reality be 'n's. To prevent double-counting, Net Octets are unaffected by the jam sequence – the 'received' bytes, however, are counted. (See [Table 24-1271](#).)

<sup>(4)</sup> "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.

<sup>(5)</sup> "-" indicates conditions which are ignored in the formations of the statistic.

<sup>(6)</sup> "%" If a CPU sourced MAC control frame has a multicast or broadcast destination address then the appropriate statistics will be updated.

<sup>(7)</sup> "+" indicates collisions which are "summed" (i.e. every collision is counted in the Collisions statistic). Jam sequences used for halfduplex flow control are also counted.

<sup>(8)</sup> Statistics marked "R+T" are formed by summing the Rx and Tx statistics, each of which is formed independently.

**Table 24-1272. Tx Statistics Summary (continued)**

Tx Statistic <sup>(1)</sup>	Frame/Octet	Tx/Rx+Tx	Frame Type					Frame Size (bytes)							Event									
			MAC control <sup>(2)</sup>			Data		64	65-127	128-255	256-511	512-1023	1024-1535	>1535	CRC Error	Collision Type					No Carrier	Queued	Deferred	Underrun
			Pause-MAC	Any-CPU	Multicast	Broadcast	Unicast									Flow <sup>(3)</sup>	1	2-15	16	Late				
256-511octet Frames	F	R+T	(y	y	y	y	y)	n	n	n	y	n	n	n	-	-	-	-	n	n	n	-	-	-

<sup>(9)</sup> "\$" Every byte written on the wire during each retry attempt is also counted in addition to frames which experience no collisions or carrier loss.

## **24.11.4.9 Static Packet Filter (SPF)**

### **24.11.4.9.1 SPF Overview**

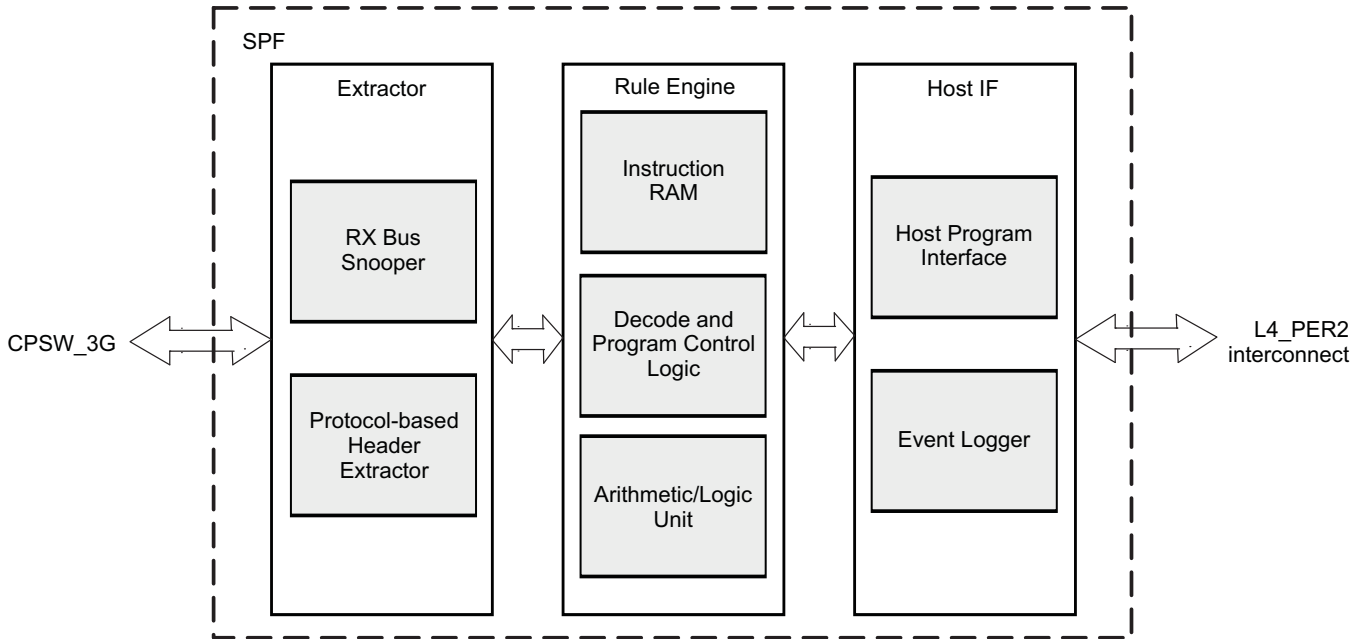

The Static Packet Filter (SPF) provides protection against some of the most common forms of Denial of Service (DoS) attacks that exploit the Layer 3 and Layer 4 functions of the network stack running on a system. The DoS attacks that are mitigated by the SPF module are:

- ARP Flood
- Fraggle
- Illegal Fragment Offset
- Illegal TCP Options
- Jolt2
- Jolt
- Land
- Micro Fragment
- Null Scan
- Ping Flood
- Short ICMP Packet
- Smurf
- SSPing
- SYN Fragment
- TCP SYN Flood
- Xmas Scan

### **24.11.4.9.2 SPF Functional Description**

#### **24.11.4.9.2.1 SPF Block Diagram**

[Figure 24-198](#) shows the block diagram of the Static Packet Filter module. There are three main components of the static packet filter – packet header extractor to decode packet formats, rule engine to check for malformed protocol header fields and a host interface to provide control and configuration access to a host processor and to keep a log of filtered packets in system memory.

**Figure 24-198. SPF Block Diagram**

The packet parser interfaces to the three-port Ethernet switch (CPSW\_3G). The CPSW\_3G signals are snooped for receive traffic and the packet contents are provided to the packet header extractor. The parser can decode various network packet formats and determine the location of the header corresponding to each of the specified protocols and store the values in internal registers. The packet parser can decode VLAN, PPPoE, IP, TCP, UDP and ICMP frame formats and determine the location of each protocol header in a frame. The location of each of these headers is used by the rule engine for performing checks against preprogrammed conditions.

The rule engine monitors information in the header fields and upon detection of an abnormal combination of values in these packet header fields, issues an instruction to drop the packet to the external RFIFO interface. The rule engine can also monitor the receive rate of a particular class of packets and can limit the number of packets that actually pass through the system. The operation of rule engine is programmable and that gives flexibility to perform a range of different checks on the contents of packet to determine whether or not it should be accepted.

The event logger captures the activity in the packet filter. In addition, based upon the settings programmed by the host software, the event logger writes detailed information about any frames that have been dropped thus far. This information is written to a part of the system memory as configured by the host software.

#### 24.11.4.9.2.2 Interrupts

The Static Packet Filter has one interrupt that is used to inform the host about excessive number of logged packet drops. The addresses of the instructions (or drop codes) in the instruction memory that cause packet to be dropped are associated with a threshold. When the threshold is met, the packet drop is logged. Each time a packet drop is logged, it is counted. When the number of logged records reaches the value specified by the `SPF_INTCNT` register, the host is interrupted. The threshold settings can be controlled by host software to limit the frequency of interrupts. Writing a zero to `SPF_INTCNT` disables the interrupt in this scenario. Whenever interrupt is enabled and is triggered, it can be cleared by writing one to either Raw register or Masked register.

Interrupts are controlled by the following registers:

1. Raw register `SPF_INT_RAW`: Holds the Raw state of interrupt, that is, without mask. The hardware interrupt is latched in this register and is only cleared when a one is written to either Raw register or Masked register. Writing a zero has no effect on this register.
2. Masked register `SPF_INT_MASKED`: This is the actual interrupt given to the system. It is the result of

bitwise AND operation of Raw and Mask registers. Once the interrupt is sensed by the system, this register should be cleared by writing one to this register or to Raw register during ISR execution. Writing zero has no effect on this register

3. Mask set register [SPF\\_MASK\\_SET](#): Writing one to this register enables the interrupt. By default, the interrupt is disabled and needs to be enabled by writing a one to this register. Writing a zero has no effect on this register. Writing to this register also set clear register.
4. Mask clear register [SPF\\_MASK\\_CLR](#): Writing one to this register disables interrupt. Writing a zero has no effect on this register.

#### 24.11.4.9.2.3 Protocol Header Extractor

The extractor module has a protocol aware state machine. It decodes the header field in the current protocol header to determine the encapsulating protocol type and extracts various parameters used for software logging. The extractor module also provides the offset to octets in the packet, where Layer 3 and Layer 4 protocol headers start, to the rule engine. These protocol headers correspond to the location of IP and TCP/UDP/ICMP headers from the beginning of the packet.

Ethernet packets with VLAN, PPPoE, IP, IP Options, and ICMP/TCP/UDP protocol are supported by the extractor. When unknown protocols are detected, the extractor skips any additional packet processing. Some examples of how packet parsing is done by the Extractor are given below.

- Ethernet – VLAN - PPPoE – IP – IP Options –TCP/UDP/ICMP – Payload
- Ethernet – VLAN – PPPoE – IP – IP options – Unknown – Payload
- Ethernet – VLAN – PPPoE – IP – TCP/UDP/ICMP – Payload
- Ethernet – VLAN – PPPoE – IP – Unknown – Payload
- Ethernet – VLAN – PPPoE – Fragmented IP – Unknown – Payload
- Ethernet – VLAN – IP – IP Options –TCP/UDP/ICMP – Payload
- Ethernet – VLAN – IP – IP options – Unknown – Payload
- Ethernet – VLAN – IP – TCP/UDP/ICMP – Payload
- Ethernet – VLAN – IP – Unknown – Payload
- Ethernet – VLAN – Fragmented IP – Unknown – Payload
- Ethernet – IP – IP Options –TCP/UDP/ICMP – Payload
- Ethernet – IP – IP options – Unknown – Payload
- Ethernet – IP – TCP/UDP/ICMP – Payload
- Ethernet – IP – Unknown – Payload
- Ethernet – Fragmented IP – Unknown – Payload
- Ethernet – Unknown

The flow of Extractor state machine flow is as follows.

1. Wait for start of packet and proceed to step 2 if start of packet detected.
2. Read Ethernet header Length/Type field (at offset 13). Go to step 3 if next header is VLAN, to step 4 if it is PPP header, to step 5 if it is IP header and to step 8 otherwise.
3. Allow VLAN header to pass and read the Length/Type field. Go to step 4 if next header is PPP, to step 5 if it is IP header and to step 8 otherwise.
4. Read the protocol type in PPP header. Go to step 5 if protocol is IP and to step 8 for unknown protocol
5. Extract source IP address and destination IP address from the IP header. Determine if the packet has IP options or if the packet is fragmented. Go to step 6 if the packet has IP options and to step 8 if the packet is fragmented. If there are no options and the next protocol header is TCP/UDP, go to step 7. Otherwise, skip processing and go to step 8 because the packet has unrecognized protocol header
6. Skip IP options and determines the next protocol header. Go to step 7 if next header is TCP/UDP/ICMP. In case the packet contains an IP fragment or if the protocol in the next header is unknown, skip processing and go to step 8.
7. The packet has TCP/UDP/ICMP header. Extract TCP/UDP source and destination port numbers for logging or ICMP type and code fields and go to step 8.

8. Wait for end of frame and go to step 1 at end of frame.

In case the packet is aborted (indicated by address 0x10 on VBUSP with request and write ready asserted), the extractor state machine flushes its current state, goes back to the idle state and waits for next packet.

The Extractor provides information to rule engine about location of Layer 3 and Layer 4 protocols. When this information is provided to rule engine, the Base Register 1 and Base register 2 are loaded with Layer 3 start offset and Layer 4 start offset respectively. Until the extractor completes decoding of these protocol headers and sends the offset values to rule engine, the rule engine does not execute any instruction that operates on fields in these protocol headers.

Extractor module extracts IP protocol, Source IP address, Destination IP address, TCP/UDP source port, TCP/UDP destination port and ICMP type/code from incoming packet and provides this information to the Host logger module for software reporting. In case IP header or TCP/UDP header does not contain the extractable fields then the corresponding field is logged as zero.

In case packet has unknown Layer 4 protocol or IP packet is fragmented such that the packet does not contain TCP/UDP/ICMP header then TCP/UDP source/destination ports or ICMP type/code fields are logged as zeros.

#### 24.11.4.9.2.4 Programmable Rule Engine

The rule engine is a micro-coded machine that is programmed by the host software. The rule engine is programmed to evaluate various expressions involving the header fields of different protocols that the incoming packet belongs to. These expressions are coded into the instructions that are stored in an internal RAM and are used to check whether a packet is mal-formed or is potentially a DoS attack packet. The rule engine executes the instructions for each incoming packet and makes a decision about accepting or rejecting the packet.

Since each packet can have multiple distinct protocol headers, the location of the headers can be different from packet to packet. The rule engine gets information about the location of the protocol headers from the packet header extractor. The packet header extractor can decode several different protocol types. The octet number at which a particular protocol header is stored is loaded into SPF Base Registers. An application may require SPF to filter packets based on protocols that are not decoded by the extractor. In such cases, SPF allows bypassing the header extractor and then the rule engine can be programmed to analyze packets and figure out the location of each header.

The Rule Engine instructions are programmed before the SPF module is enabled. The instructions cannot be overwritten while the rule engine is processing packets. To modify the contents of code RAM during operation, SPF must be disabled temporarily and then new instructions can be loaded.

Once SPF is enabled, the rule engine starts to fetch instructions one at a time. For each instruction, the operands are obtained from either the packet octets that are being received, from internal registers or from the immediate values inside the instruction itself. If the octet that is needed for execution has not yet been received, then the execution stalls until the required octet is received. In case the operand specified in the instruction refers to a packet octet that has already gone by and is not available in the packet buffer, then the execution stalls until the end of packet. An instruction is executed only when all the required operands are available. Based on the instruction execution results, the packet may immediately be dropped or the results of the evaluated expressions may be stored for future use. In addition, the current instruction can also cause the rule engine to skip a specified number of instructions (immediately following the current instruction) and resume from another location in the instruction RAM.

The rule engine operates on multiple operands and performs multiple tasks in each clock cycle. In each cycle, it can perform one arithmetic and/or logical operation on two pairs of operands. The operands are masked with a 32-bit mask that is generated from the information provided in the instruction. The mask allows for operations that involve variable sized operands. Each operation generates a 32-bit number and a flag bit. The 32-bit number is typically either the sum or the output of bit-wise logical operation. The flag is a single bit result of a comparison operation. The result of each operation can be saved in the internal registers if a specified condition is satisfied. Similarly, depending on the result of the operation, the rule

engine can jump to another location in the instruction memory. The program can instruct the rule engine to either perform two save operations, two conditional jumps or one jump and one save. The conditions must be mutually exclusive to prevent unspecified operation. In addition to providing an alternate path for execution, the instruction can cause the rule engine to accept or reject the current packet and exit from the program until the next packet is received.

When the execution of an instruction does not result in a decision to accept or reject the packet, the rule engine progresses to the next instruction. Instructions are executed until a final decision is made. If a packet is aborted in the middle at the network interface, the rule engine aborts execution and clears all base registers, program counter, octet counter and packet buffer. It is then ready to process next packet.

From a hardware perspective, the rule engine contains a buffer to store packet octets, several internal registers for temporary storage, instruction decoding logic and control circuitry. A description of each of the hardware resources in the rule engine follows.

#### **24.11.4.9.2.4.1 Internal Registers**

Several different types of registers are provided in the rule engine. The description of each of these is provided below.

- **Base Registers (B0-B4):** There are four hardware base registers (B1-B4) that store the location of various protocol headers. The B0 register is not a hardware register and it always means a reference to the first octet in a packet. Each base register is eight bits wide and is used to reference octets in a packet. The base registers can point to any octet in the packet upto 255 octets. These registers are readable and writable by the rule engine. In addition, base registers B1 and B2 are loaded with data provided by the extractor when the rule engine is not running in extractor bypass mode (`SPF_CONTROL[2] SPF_EXT_BYPASS`). The rule engine can write to base registers irrespective of whether extractor bypass is enabled. When an operand needs to use contents of B1-B4 registers, the instruction only executes if the specified base register was loaded at least once after the beginning of current packet. If the specified base register was not loaded during the current packet, then the operand referenced by this base register cannot be extracted from the packet and will cause the rule engine to stall.
- **Constant Registers (C0-C7):** The rule engine can refer to any of eight 32-bit constant values. These are programmed by the host (`SPF_CONSTj`,  $j = 0$  to 7) and the rule engine only has read access to these registers. Each of these registers can be changed at any time by the host software. However, changing the value of these registers is not recommended as unpredictable behavior may occur if contents are changed while the rule engine is executing instructions that use the C0-C7 values.
- **General Purpose 32-bit registers (R0-R7):** There are eight 32-bit registers that can be read/written by the rule engine. These are general purpose registers and can be used as temporary storage. In addition, when the rule engine is required to provide logging information, R4-R7 are used to store information that will be written to memory.
- **Rate limit registers (L0-L3):** Four 8-bit rate limit registers are used by rule engine to count specific types of packets that are to be rate limited. These registers are counters that are loaded with programmed threshold values (`SPF_RATELIMIi`,  $i = 0$  to 3) at the end of time interval determined by the clock pre-scaler (`SPF_PRESCALE`).
- **General Purpose 1-bit registers (T0-T3):** Four 1-bit registers are provided to store comparison results by the rule engine. These registers can be used to store 1-bit output from ALUs. In addition, the logical OR and logical AND of the flags can also be stored in T0-T3 registers. The 32-bit ALU results may also be stored in T0-T3 registers but only the LSB will be stored.

The rule engine instructions refer to these internal registers during execution. More details about instruction encoding are in subsequent sections.

#### **24.11.4.9.2.4.2 Packet Buffer**

When the rule engine is processing a packet, it stored a snapshot of latest 32 octets in an internal buffer. This buffer allows evaluation of expressions on packet octets even after the packet octets have gone by on the external receive VBUSP network interface.

At the start of packet, the first eight octets received are loaded into the first eight locations of the packet buffer. When the next eight octets arrive, these are loaded into the first eight locations and the existing octets are moved to the following eight locations. This process is continued until the packet buffer is full. When packet buffer is full and additional octets arrive, the oldest eight octets are shifted out and are no longer available to the rule engine. Thus, the packet buffer provides a snapshot of most recent octets received.

When the rule engine encounters instructions that reference packet octets which have not yet been received then the rule engine stalls until the required octets are available. Similarly, instructions which require octets that have already been shifted out of the packet buffer will cause rule engine to stall. And since these octets will never be available, the rule engine will not execute any further instructions for the current packet. It will return to the first instruction when the packet ends.

**Figure 24-199. Packet Octets as Stored in the Packet Buffer**

RFIFO VBUSP	63:56	55:48	47:40	39:32	31:24	23:16	15:8	7:0

gmacsw-025

The contents of a packet, when used as one or more operands in an instruction, are always fetched from the packet buffer. The Base registers (B0-B4) in conjunction with an offset and bits are used to specify which octets are to be used as operands.

#### 24.11.4.9.2.5 Intrusion Event Logger

The activity of the static packet filter is logged by the intrusion event logger. Based on the configuration, the event logger writes specific fields of the incoming packet that violate a particular rule to the system memory for software diagnostics.

The logging module allows controlling the frequency at which events are logged to the memory. A set of nine counters are provided and, of these, eight can be mapped to any address of the rule engine's instruction RAM using map registers. This mapping logically associates the log information with the instruction that caused the packet to be dropped. The 9th counter is not associated with any particular instruction and it can be used to count the packets that were dropped at instructions not mapped to any of the other eight counters.

For each of the nine counters, there is a register to store the minimum number of attacks that must be detected before any information is logged to memory. Only when this threshold is met and logging is enabled, the host interface module writes log data in system memory. The memory area used to log is specified by the host in the [SPF\\_LOG\\_BEGIN](#) address and [SPF\\_LOG\\_END](#) address registers.

The event logger continues to write data to memory until it runs out of space and the log overwrite is disabled. With each update of the log, the [SPF\\_LOG\\_HWPTR](#) is updated. This information can be used by the host to determine how much data has been logged. The software in turn keeps the [SPF\\_LOG\\_SWPTR](#) updated to inform the SPF about the next address from where information will be read by the host software. It is required that software program correct value of [SPF\\_LOG\\_END](#) address to enable hardware to determine roll-over location. The SPF considers all space before the [SPF\\_LOG\\_SWPTR](#) as available for logging. In case [SPF\\_CONTROL\[9\]](#) [SPF\\_LOGOW\\_EN](#) control bit is set, SPF ignores [SPF\\_LOG\\_SWPTR](#) and logs data irrespective of software read log status. Note that the memory space allocated for logging is a multiple of four 32-bit words and end address [SPF\\_LOG\\_END](#) should be loaded with byte address of the next byte following the last log entry. For example if 16 bytes space is allocated for SPF logging from address 0x1400\_0000, then [SPF\\_LOG\\_BEGIN](#) should be 0x1400\_0000 and [SPF\\_LOG\\_END](#) should be 0x1400\_0010.

The host software must set [SPF\\_CONTROL\[8\]](#) [SPF\\_LOG\\_EN](#) bit to activate logging. The setting of [SPF\\_LOG\\_EN](#) bit has no effect on the threshold based counters and they are always active. In addition to the log counters, SPF has one master drop count register ([SPF\\_DROPCNT](#)) which tracks the total number of packets dropped thus far. This counter does not roll over and must be cleared for re-run by the host processor once it reaches the maximum value.

The format in which packet information is written in the memory by the event logger is shown in [Table 24-1273](#) and [Table 24-1274](#).

**Table 24-1273. Format for TCP/UDP Packets**

Drop Code	-	-	Protocol
Source IP Address			
Destination IP Address			
Source TCP/UDP Port		Destination TCP/UDP Port	

**Table 24-1274. Format for ICMP Packets**

Drop Code	-	-	Protocol
Source IP Address			
Destination IP Address			
Type	Code	Checksum	

Each entry logged to memory has a drop code associated with it. The drop code is the address in instruction memory that actually triggered the drop. Up to eight drop codes can be monitored in this manner. In addition to drop code, the protocol, IP addresses and source/destination ports associated with the dropped packet are recorded.

Log data can be supplied by either Extractor module or by Rule engine. The [SPF\\_CONTROL\[3\]](#) [SPF\\_RULE\\_LOG](#) bit must be set to use log data from Rule Engine and cleared to use data supplied by the Extractor.

When logging is done through the Rule Engine, contents of internal registers R4-R7 are written to memory. The format of packet information stored can be programmed in the rule engine except for the drop code field which is static and cannot be changed. The format in which rule engine information is written in the memory by the event logger is shown in [Table 24-1275](#).

**Table 24-1275. Rule Engine Format**

Drop Code	Register 4[23:0]
	Register 5[31:0]
	Register 6[31:0]

**Table 24-1275. Rule Engine Format (continued)**

Register 7[31:0]
------------------

The rule engine programming must ensure that these registers contain all required information that is to be recorded before the packet drop instruction is executed. As soon as the drop instruction is executed, the logging module starts to send data from the registers R4, R5, R6 and R7 to the system memory and is not possible to modify the contents of these registers.

#### 24.11.4.9.2.6 Rate Limiter

The static packet filter provides a way to limit the rate of specific types of incoming packets. The SPF module provides four rate limit registers (L0-L3) that are used in conjunction with a clock prescaler (**SPF\_PRESCALE**) and rule engine instructions. The clock prescaler is a clock divider and every count down to zero and the subsequent roll-over indicates end of a time interval. At every such event, each of the four rate limit registers is loaded with a preset value (**SPF\_RATELIM<sub>i</sub>**,  $i = 0$  to 3) that is programmable by the host processor. When packets are received, the rule engine can identify packets of particular types and execute a limit operation. The limit operation specifies a condition (described in [Table 24-1293](#)) and a limit register. If the condition evaluates to true, the packet is dropped if the rate limit register is zero. If it is non-zero, then the rate limit register is decremented by one.

Thus, by using the prescaler and the limit registers, it is possible to control the rate of specific type of packets. By controlling the value of prescale counter (common to all rate limit registers) and the rate limit thresholds, the granularity of the rate can be modified. A lower value of prescale counter will cause frequent reloads of the rate limit registers and will allow rate control over small time intervals. Keeping the prescale counter at extremely small values may cause the rate limiter to be ineffective because the limit registers will be reloaded too frequently to count down to zero. Conversely, a higher value of prescale counter will cause less frequent reloads of the rate limit registers and the rate control will be over longer time intervals. The reload value of each 8-bit rate limit register and the prescale register are programmed by the host processor before SPF is enabled. A reload value of 0xFF can be used to disable any of the rate limiters at run-time without changing the firmware. Both the prescale and limit registers can be modified during run-time.

#### 24.11.4.9.2.7 Rule Engine Instruction Set Architecture

##### 24.11.4.9.2.7.1 Instruction Format

The design supports 64 deep instruction memory. Each of the instructions is 78 bit wide and is stored in a RAM internal to the SPF module. Each instruction can have up to four operands, two arithmetic/logical operations and two conditional jump/save actions based on the outcome of the operations.

The operand field is 52 bits wide and it can have up to four operands. The arithmetic and logical operation codes are four bits each. The operation codes are nine bits each.

**Table 24-1276. Instruction Format**

Bits	Field Name	Description
77:26	OPERAND	Up to four operands are specified in this field. The source of the operands can be the packet that is being received at the network interface, one of the internal register values or an 8/16/32 bit operand specified within the instruction.
25:22	FUNCTION0	This field specifies a single or dual operand Arithmetic/Logic Function. This function is applied to one or both of first two operands specified in the instruction.
21:18	FUNCTION1	This field also specifies a single or dual operand Arithmetic/Logic Function. This function is applied to one or both of the third and fourth operands specified in the instruction.

**Table 24-1276. Instruction Format (continued)**

Bits	Field Name	Description
17:9	OPERATION0	<p>A Save/Jump/Limit/Nop operation is specified in this function.</p> <p>Save operation code includes the source and destination information. The save source is the output of functions and the destination is one of the internal registers where data should be saved.</p> <p>Jump operation code has information about a condition and a destination. The jump occurs when the condition, which is based on the result of function0 and function1, is true. The Jump destination controls the flow of instruction execution.</p> <p>Jump to location 1 results in the packet being dropped. Rule engine goes back to initial instruction and waits for next packet. The event logger writes information to memory.</p> <p>Jump to location zero results in the packet being accepted. The rule engine goes back to initial instruction and waits for next packet.</p> <p>Limit operation code has information about a condition and a rate limit register. The Limit operation either causes the packet to be dropped or results in the specified rate limit register to be decremented by one.</p>
8:0	OPERATION1	This field specifies a second save/jump operation. The format for this field is same as for Operation0.

#### 24.11.4.9.2.7.2 Operand Field

The operand field specifies up to four operands. Each operand is obtained from the incoming packet data, from an internal register or as an immediate value specified in the instruction itself. In addition, there is a bit mask associated with each operand. The mask values are encoded in the instruction itself and the mask for each operand is applied before it is used by the Arithmetic and Logic Unit.

The operands are input to the two 32-bit Arithmetic and Logic units. For all calculations, a mask is used with each operand. The mask is a 32-bit number that is generated from a 5-bit code provided in the instruction or from an immediate value in the instruction. The 5-bit mask code specifies how many bits (from the LSB side) will be input to the ALU. An immediate mask must be used when the mask is not a continuous sequence of 1's. Whenever an immediate mask value is specified, the mask value specified by the 'Bits' fields is ignored.

Each operand is at least 13-bits long and the encoding for each operand types is shown in [Table 24-1277](#) to [Table 24-1284](#).

**Table 24-1277. Packet Data Operand**

<b>Description</b>	This type of operand is derived from the packet itself. The encoding specifies a number of bits (up to 32) to be extracted from a location in the packet indicated by the selected base register and offset. The format of 13-bit operand code is shown below. Internally, a 32-bit number is obtained from the packet. Then, a mask is created from the bits[4:0] field and bitwise ANDed with the 32- bits extracted from the packet.												
	12	11	10	9	8	7	6	5	4	3	2	1	0
	Base[2:0]			Offset[4:0]					Bits[4:0]				
Bits	Field Name	Description											
12:10	Base[2:0]	The Base field selects one of the Base registers B0, B1, B2, B3 or B4. The operand comprises of (Bits+1) bits extracted from the packet. The offset from where the operand octets are extracted is determined by the sum of the value of specified base register (Base 0 to Base 4) and the specified offset. Base 0 is start of packet.											
9:5	Offset[4:0]	The value of the selected base register plus the specified offset is the octet location in the packet from where the specified number of bits will be picked.											
4:0	Bits[4:0]	The number of bits to be used as operand is specified by Bits+1. When Bits[4:0] is zero, only one bit is used as operand. When Bits[4:0] is 31, then 32 bits are used as operand.											

**Table 24-1278. Constant Operand**

<b>Description</b>		One of the eight constants programmed by the host software can be used as operand. The bits field specifies the mask to be applied to the selected 32-bit constant.											
12	11	10	9	8	7	6	5	4	3	2	1	0	
1	0	1	0	0	C[2:0]			Bits[4:0]					
<b>Bits</b>	<b>Field Name</b>	<b>Description</b>											
7:5	C[2:0]	This field selects one of the constants (C0-C7).											
4:0	Bits[4:0]	The number of bits to be used as operand is specified by Bits+1. When Bits[4:0] is zero, the least significant bit is used as operand. When Bits[4:0] is 2, then two LSBs are used as operand and so on.											

**Table 24-1279. 32-bit Register Operand**

<b>Description</b>		One of eight 32-bit registers is used as operand and bits[4:0] field specifies the bitmask to be applied to that register.											
12	11	10	9	8	7	6	5	4	3	2	1	0	
1	0	1	0	1	R[2:0]			Bits[4:0]					
<b>Bits</b>	<b>Field Name</b>	<b>Description</b>											
7:5	R[2:0]	This field selects one of the 32-bits registers (R0-R7).											
4:0	Bits[4:0]	The number of bits to be used as operand is specified by Bits+1. When Bits[4:0] is zero, the least significant bit is used as operand. When Bits[4:0] is 2, then two LSBs are used as operand and so on.											

**Table 24-1280. 1-bit Register Operand**

<b>Description</b>		One of the four 1-bit registers is used as operand.											
12	11	10	9	8	7	6	5	4	3	2	1	0	
1	0	1	1	0	0	T[1:0]		0	0	0	0	0	
<b>Bits</b>	<b>Field Name</b>	<b>Description</b>											
6:5	T[1:0]	This field selects one of the four 1-bits registers (T0-T3).											

**Table 24-1281. Base Register Operand**

<b>Description</b>		One of the base registers is used. The 2-bit codes are 00, 01, 10 and 11 for B1 to B4 respectively.											
12	11	10	9	8	7	6	5	4	3	2	1	0	
1	0	1	1	1	1	B[1:0]		0	0	Bits[2:0]			
<b>Bits</b>	<b>Field Name</b>	<b>Description</b>											
6:5	B[1:0]	This field selects one of the four base registers (B1-B4). Note that B0 is a virtual register which is always zero and specifies the start of packet.											
2:0	Bits[2:0]	The number of bits to be used as operand is specified by Bits+1. When Bits[4:0] is zero, the least significant bit is used as operand. When Bits[4:0] is 2, then two LSBs are used as operand and so on.											

When the operand field is all-ones it does not specify any operand and is considered zero.

The tables below list the combinations in which operands may be programmed in an instruction. In this list, Pkt/Reg operand is an operand consisting of octets from the packet or the contents of one of the internal registers; mask specifies the value that is used as a mask instead of the mask generated from the Bits field in the instruction; immediate operand (immediate[7:0], immediate[15:0] and immediate[31:0]) is an 8/16/32 bit number that is used as an operand. The format of Pkt/Reg operand is as shown previously. The decoding of operands for each ALU is dependent upon the type of operation specified in the ALU and the format of the operand field. When there are four operands in the operand field, the first and second operands are used in ALU0 and the rest by ALU1. When ALU0 needs only one operand, then the remaining operands are fed to ALU1. The order of decoding operands is designed to first provide operands to ALU0 from the more significant side of operand field and then to ALU1. If the number of operands specified in instruction does not match with the number of operands required by the ALUs, unspecified behavior can occur. For an instruction to execute, both ALUs must have valid data. If any of the ALUs uses a packet data operand which is not yet available then the rule engine stalls until data is available. During the stall phase, the instruction is decoded every cycle and all required operands must be available simultaneously for the instruction to be executed. In addition, if an instruction refers to packet octets that are no longer available, the rule engine stalls until the end of packet.

Pkt/Reg Operand[12:0]	1101 Mask[15:0] 01 Immediate[15:0]		
Pkt / Reg / Imm[7:0] Operand[12:0]	11110 Immediate[31:0] 11		
11110 Immediate[31:0] 11			Pkt / Reg / Imm[7:0] Operand[12:0]

**Table 24-1289. Operand Field With One Operand**

Pkt / Reg / Imm[7:0] Operand[12:0]	Reserved	Reserved	Reserved
Pkt/Reg Operand[12:0]	11000 Mask[7:0]	Reserved	Reserved
Pkt/Reg Operand[12:0]	11001 Mask[15:0] 11111		Reserved
11101 Immediate[15:0] 11111		Reserved	Reserved
11110 Immediate[31:0] 11			Reserved

The formats in which operands are specified in the operand field have certain restrictions:

- a mask cannot follow an immediate value
- a mask cannot follow a previous mask
- a reserved field should have all following fields reserved as well
- the first field cannot be a mask

### 24.11.4.9.2.7.3 Arithmetic/Logical Function Field

There can be two codes for arithmetic and logical functions in each instruction. Each of the operations can involve one or two operands.

The location of each function field in an instruction is listed in [Table 24-1290](#).

**Table 24-1290. Arithmetic/Logical Instruction Field**

Bits	Description
23:20	Single or Dual operand Arithmetic/Logic Function (function 0)
19:16	Single or Dual operand Arithmetic/Logic Function (function 1)

The bit codes for each arithmetic/logic function that can be performed on the operands of an instruction are listed in [Table 24-1291](#).

**Table 24-1291. Arithmetic/Logical Operation Codes**

Code	Description	Operands Required	32-bit result	1-bit flag result
0x0	Less Than	2	0	Set if true
0x1	Less Than Equal To	2	0	Set if true
0x2	Greater Than	2	0	Set if true
0x3	Greater Than Equal To	2	0	Set if true
0x4	Equal to Zero	1	0	Set if true
0x5	Not Equal to Zero	1	0	Set if true
0x6	Equal to One	1	0	Set if true
0x7	Not Equal to One	1	0	Set if true
0x8	Equal	2	0	Set if true
0x9	Not Equal	2	0	Set if true
0xA	Add	2	Sum	Set if overflow
0xB	Subtract	2	Difference	Set if output is negative
0xC	Bitwise AND	2	Bitwise AND	0
0xD	Bitwise OR	2	Bitwise OR	0
0xE	Result is same as Operand	1	Same as operand	0
0xF	No Function (NOF)	0	0	0

The ALU0 and ALU1 are assigned function0 and function1 respectively. In case only one function is to be performed in an instruction, function0 field should be used to do that. An instruction with no function for ALU0 and a valid function for ALU1 will result in unspecified behavior.

The output of each function is in the form of a 32-bit number and a single bit value. The single bit value is either the carry bit from an add/subtract operation or the Boolean result from a comparison function. The single bit output from each function is referred as the flag0 or flag1 result. The 32-bit number is the outcome of arithmetic or a bitwise logical operation and it is referred to as the word0 or word1 result.

### 24.11.4.9.2.7.4 Operation Field

The operation field specifies a limit, save or a jump operation. All of these operations involve two arguments that are specified within the instruction.

In case of limit operation, one of the arguments is a condition and the other argument is a limit register. In case of save operation, one of the arguments is source data and the other argument is a destination where the data will be saved. In jump operation, the first argument is a condition that must be true for the jump to occur and the second argument is a destination to which the program control will be moved to. The destination argument in a jump operation also specifies specific destinations that lead to the current packet being immediately rejected or accepted.

The location of operation field in an instruction is shown in [Table 24-1292](#).

**Table 24-1292. Operation Fields**

Bits	Description
17:9	Limit/Save/Jump Operation (operation 0) For limit operation, [17:16] is the operation field, [15:13] is the condition field and [12:9] is a limit register. For save operation, [17:16] is the operation field, [15:13] is the source field, and [12:9] is the destination field. For jump operation, [17:16] is the operation field, [15:13] is the condition field, and [12:9] is the destination field
8:0	Limit/Save/Jump Operation (operation 1) For limit operation, [8:7] is the operation field, [6:4] is the condition field and [3:0] is a limit register. For save operation, [8:7] is the operation field, [6:4] is the source field, and [3:0] is the destination field. For jump operation, [8:7] is the operation field, [6:4] is the condition field, and [3:0] is the destination field.

**Table 24-1293. Limit Operation**

<b>Description</b>	In a limit operation, the condition argument specifies a condition that must be true for the specified limit register to be decremented if non-zero or the packet to be dropped if the limit register is zero.
--------------------	--

8	7	6	5	4	3	2	1	0
0	0	Condition Code			Limit Register			

Bits	Field Name	Description
6:4	Condition Code	It is a 3-bit code that specifies the condition that must be true for the operation to be executed. 0x0: Single bit flag (flag0 from function 0) 0x1: Single bit flag (flag1 from function 1) 0x2: Logical OR of flags (flag0   flag1) 0x3: Logical NOR of flags (!(flag0   flag1)) 0x4: Logical AND of flags (flag0 & flag1) 0x5: Logical NAND of flags (!(flag0 & flag1)) 0x6: XOR of flags (flag0 ^ flag1) 0x7: Unconditional Decrement/Limit
3:0	Limit Register	It is a 4-bit code that specifies the limit register that is to be decremented or checked for zero value. 0x0: Rate limit register L0 0x1: Rate limit register L1 0x2: Rate limit register L2 0x3: Rate limit register L3 0x4-0xF: Reserved

**Table 24-1294. Save Operation**

<b>Description</b>	The arguments for a save operation include a code for source data and a code for the destination. The source is either a single bit data or a 32-bit word. The single bit data is either a flag from the functions or a logical OR/AND of the flags. The 32-bit word is the result of the ALU arithmetic/logical functions.
--------------------	---

8	7	6	5	4	3	2	1	0
0	1	Source Data Code			Destination Register Code			

Bits	Field Name	Description
6:4	Source Data Code	It is a 3-bit code that specifies the source data which is to be save in another register 0x0: Single bit flag (flag0 from function 0) 0x1: Single bit flag (flag1 from function 1) 0x2: Logical OR of flags (flag0   flag1) 0x3: Logical AND of flags (flag0 & flag1) 0x4: Output of function (word0) 0x5: Output of function (word1) 0x6-0x7: Reserved
3:0	Destination Register Code	It is a 4-bit code that specified the register in which source data is to be stored 0x0-0x3: Single Bit register (T0-T3) 0x4-0x7: Base Register (B1-B3) 0x8-0xF: 32-bit Register (R0-R7)

For some instructions, the rule engine extracts the operand from the current packet. To determine the packet bits to be used as operands, it refers to one or more base registers. Whenever an instruction causes a change in value of any of the base registers, it cause the rule engine to wait for one clock cycle before executing the next instruction. The rule engine is a pipelined processor and change in the value of a base register causes the prefetched operand values to become stale and these need to be fetched again. The clock cycle inserted allows rule-engine to fetch the data again before the instruction using this data is executed. Only the instructions that use packet data will be delayed by a clock cycle if the previous instruction caused a change in the base register that is referenced in the current instruction.

**Table 24-1295. Jump Operation**

<b>Description</b>	For jump operation, one of the operands is a condition that must evaluate to true for the jump operation to occur. The other operand is the destination to which the program counter will move to if the jump operation is executed. The condition in a jump operation is either one of the flags from the output of the arithmetic/logic unit or a logical AND/OR of the flags.							
8	7	6	5	4	3	2	1	0
1	0	Condition Code			Destination Code			

Bits	Field Name	Description
6:4	Condition Code	Condition Code 0x0: Single bit flag (flag0 from function 0) 0x1: Single bit flag (flag1 from function 1) 0x2: Logical OR of flags (flag0   flag1) 0x3: Logical NOR of flags (!(flag0   flag1)) 0x4: Logical AND of flags (flag0 & flag1) 0x5: Logical NAND of flags (!(flag0 & flag1)) 0x6: XOR of flags (flag0 ^ flag1) 0x7: Unconditional Jump
3:0	Destination Code	Destination Code 0x0: Accept packet, return to instruction zero and wait for the next packet. 0x1: Reject packet and return to instruction zero. 0x2-0xF: Go to instruction at offset +2 ...+15

The jump operation results in a change of program execution flow. The jump destination determines the next instruction that will be executed by the rule engine. The destination is only specified as a positive offset to the current value of the program counter. The program counter can result in the rule engine skipping a given number of instructions instead of executing the next instruction. In addition, the destination field can instruct the rule engine to immediately reject or accept the current packet without any further checks. The rule engine then goes back to the first instruction and waits for a new packet to arrive before it executes any further instructions.

The rule engine is a pipelined processor. When it executes a jump operation, there is a delay of one clock cycle before the next instruction is executed.

The operations specified in the two operation fields are independent of each other. However, it is possible that conflicting operations are specified in the operation fields of an instruction. When conflicting operations are specified and conditions of both operations evaluate to true; then the execution flow is determined as described below:

1. If one of the ALUs has a limit/jump operation that will cause the packet to be dropped, then the packet will be dropped irrespective of what the other ALU indicates.
2. If case 1 above is false and one of the ALUs has a jump operation that will cause the packet to be accepted, then the packet will be accepted and the rule engine will return to idle state.
3. If case 1 and 2 above are false and one of the ALUs has a jump to offset with the respective condition true, the jump will be executed. If there is conflicting jump to offset information in the two ALUs, ALU0 is given priority.

**Table 24-1296. No Operation**

Description		If there is no Save, Jump or Limit operation specified in the operation field, it is interpreted as a no operation. There is no change in execution flow, no change in any register values or rate limit registers when a no operation is encountered.							
8	7	6	5	4	3	2	1	0	
1	1	Reserved			Reserved				

It is expected that the rule engine will be programmed such that a decision to accept or discard the current packet is made before all instructions have executed. If the rule engine reaches the last instruction and it does not result in a decision to accept/reject the packet, then the execution flow does not stop and all instructions from the first instruction are executed again until the end of packet is reached.

### 24.11.4.9.3 Programming Guide

#### 24.11.4.9.3.1 Initialization Routine

The packet filter must be initialized in order for it to operate as specified. A typical order in which the module can be initialized is shown below:

1. Initialize the firmware by programming the internal memory and verify it (SPF\_INSTR\_W2, SPF\_INSTR\_W1, SPF\_INSTR\_W0, [SPF\\_INSTR\\_CTL](#))
2. Allocate memory for logs written by SPF and initialized the log space parameters ([SPF\\_LOG\\_BEGIN](#), [SPF\\_LOG\\_END](#), SPF\_SW\_PTR)
3. Program the log map registers to associate drop codes with the log thresholds. ([SPF\\_LOG\\_MAP0](#), [SPF\\_LOG\\_MAP1](#))
4. Program log thresholds ([SPF\\_LOG\\_THRESHk](#), where k = 0 to 8)
5. Program constant registers if required by the firmware ([SPF\\_CONSTj](#), where j = 0 to 7)
6. Program clock prescale counters and rate limit registers if required by the firmware ([SPF\\_PRESCALE](#), [SPF\\_RATELIMI](#), where i = 0 to 3)
7. Program the interrupt frequency control register and interrupt mask register to setup interrupts ([SPF\\_INTCNT](#), [SPF\\_MASK\\_SET](#))
8. Program the control registers to enable SPF filter and logger ([SPF\\_CONTROL](#)).

#### 24.11.4.9.3.2 Interrupt Service Routine

The interrupt service routine in SPF should be designed to process the data logs generated by SPF. It should trigger a higher layer application software that can analyze the data logs and determine if any remedial measures are required based on the information in the logs. At the minimum, the interrupt service routine must reprogram the software pointer for the logging machine to be able to continue logging.

The typical tasks performed following an interrupt are listed in the pseudo code below.

```
SPF_ISR {
  read log hardware pointer
  read log software pointer
  determine how many log entries are to be read
  read each log entry starting with the software pointer
  update software pointer to reflect the next unread entry
  clear interrupt
}
```

#### 24.11.4.9.3.3 Rule Engine Example Program

Here is an example of how the rule engine can be programmed to detect packets that resemble Denial of Service traffic. The pseudo code is shown below.

```
IDLE:
  jump to ICMP if start_of_packet
```

```

ICMP:
if (protocol==ICMP)
limit_ICMP
if (fragmented packet)
drop and jump to IDLE
accept and jump to IDLE
else
jump to IP
IP:
if (source_ip==dest_ip)
drop and jump to IDLE
if (fragmented and (fragment_offset+ip_size)>2^16)
drop and jump to IDLE
accept the packet and jump to IDLE
    
```

#### 24.11.4.10 Common Platform Time Sync (CPTS)

The Common Platform Time Sync (CPTS) module is used to facilitate host control of time sync operations. It enables compliance with the IEEE 1588-2008 standard for a precision clock synchronization protocol.

##### 24.11.4.10.1 CPTS Architecture

Figure 24-200 shows the architecture of the CPTS module inside the GMAC\_SW Ethernet Subsystem. Time stamp values for every packet transmitted or received on either port of the GMAC\_SW are recorded. At the same time, each packet is decoded to determine if it is a valid time sync event. If so, an event is loaded into the Event FIFO for processing containing the recorded time stamp value when the packet was transmitted or received.

In addition, both hardware (HWx\_TS\_PUSH) and software (TS\_PUSH) can be used to read the current time stamp value through the Event FIFO

**Figure 24-200. CPTS Block Diagram**

The reference clock used for the time stamp (CPTS\_RFT\_CLK) can be derived from several sources. See [Chapter 3, PRCM](#) for more details.

##### 24.11.4.10.2 CPTS Initialization

The CPTS module should be configured as:

1. Reset the CPTS module.
2. Clear the CPTS\_EN bit in the [CPTS\\_CONTROL](#) register.
3. Write the CLKSEL\_RFT value in the CM\_GMAC\_GMAC\_CLKCTRL register in the PRCM with the desired reference clock selection.
4. Set the CPTS\_EN bit in the [CPTS\\_CONTROL](#) register.

5. If using interrupts and not polling, enable the interrupt by setting the TS\_PEND\_EN bit in the [CPTS\\_INT\\_ENABLE](#) register.

#### **24.11.4.10.3 Time Stamp Value**

The time stamp value is a 32-bit value that increments on each CPTS\_RFT\_CLK rising edge when CPTS\_EN is set to 1. When CPTS\_EN is cleared to 0, the time stamp value is reset to 0.

If more than 32-bits of time stamp are required by the application, the host software must maintain the necessary number of upper bits. The upper time stamp value should be incremented by the host when the rollover event is detected.

For test purposes, the time stamp can be written via the time stamp load function ([CPTS\\_TS\\_LOAD\\_VAL](#) and [CPTS\\_TS\\_LOAD\\_EN](#) registers).

#### **24.11.4.10.4 Event FIFO**

All time sync events are push onto the Event FIFO. There are 16 locations in the event FIFO with no overrun indication supported. Software must service the event FIFO in a timely manner to prevent FIFO overrun.

#### **24.11.4.10.5 Time Sync Events**

Time Sync events are 64-bit values that are pushed onto the event FIFO and read in two 32-bit reads. Two 32-bit registers, [CPTS\\_EVENT\\_HIGH](#) and [CPTS\\_EVENT\\_LOW](#) hold the data of a time sync event. There are five types of sync events:

- Time stamp push event
- Time stamp counter rollover event
- Time stamp counter half-rollover event
- Ethernet receive event
- Ethernet transmit event

##### **24.11.4.10.5.1 Time Stamp Push Event**

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the TS\_PUSH bit of the [CPTS\\_TS\\_PUSH](#) register. The time stamp value is returned in the event, along with a time stamp push event code. Software should not push a second time stamp event on to the FIFO until the first time stamp value has been read from the event FIFO.

##### **24.11.4.10.5.2 Time Stamp Counter Rollover Event**

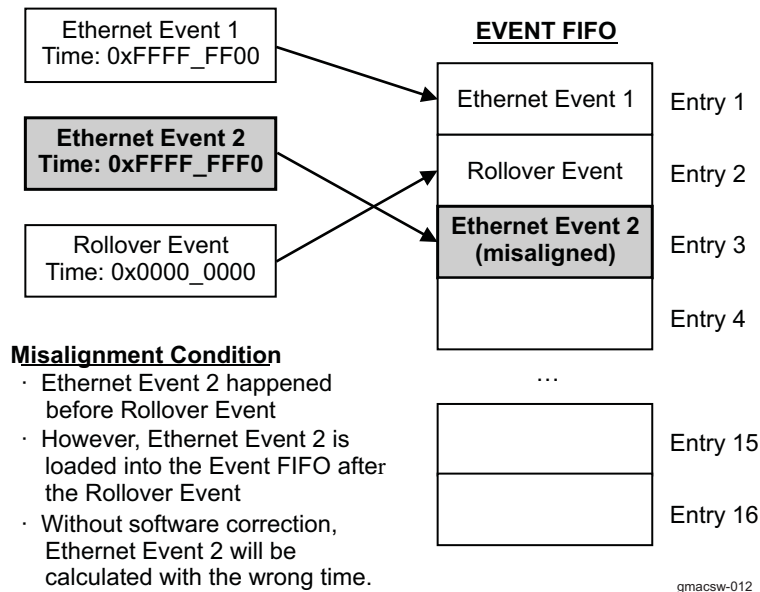

The CPTS module contains a 32-bit time stamp value. The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from FFFF FFFFh to 0000 0000h, and the software maintained upper count value should be incremented.

##### **24.11.4.10.5.3 Time Stamp Counter Half-rollover Event**

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value has incremented from 7FFF FFFFh to 8000 0000h. The half-rollover event is included to enable software to correct a misaligned event condition. The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value, such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. [Figure 24-201](#) shows a misalignment condition.

Host software must detect and correct for misaligned event conditions. For every event after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the time stamp value is low (0000 0000h through 7FFF FFFFh), then the event time stamp was taken after the rollover and no correction is required. If the value is high (8000 0000h through FFFF FFFFh), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event. The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

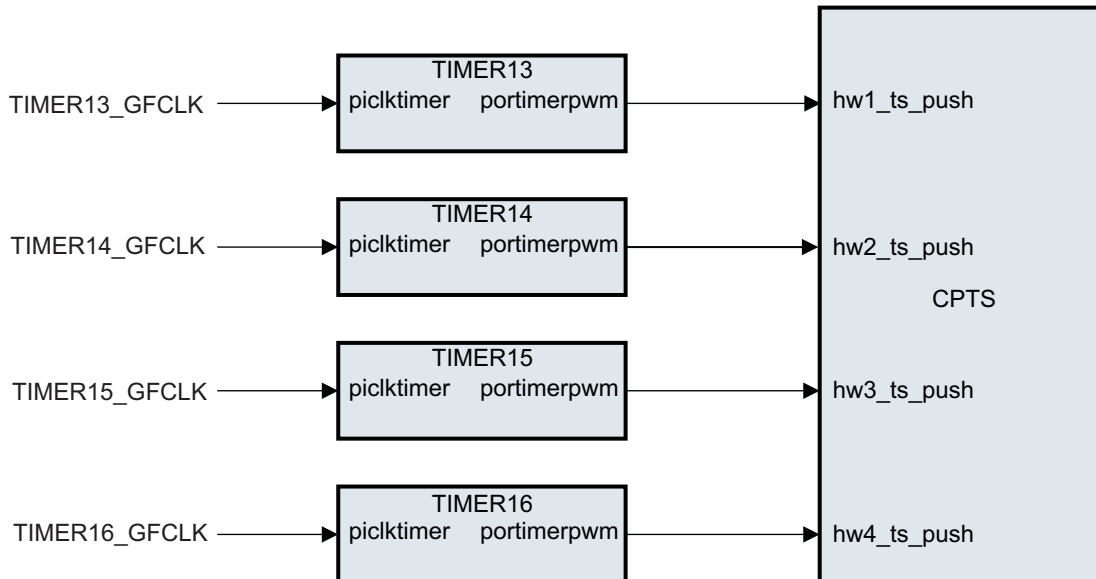

**Figure 24-201. Event FIFO Misalignment Condition**

#### 24.11.4.10.5.4 Hardware Time Stamp Push Event

There are four hardware time stamp inputs (HW1/4\_TS\_PUSH) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each hardware time stamp input is internally connected to the PORTIMERPWM output of each timer as shown in [Figure 24-202](#).

Figure 24-202. HW1/4\_TSP\_PUSH Connection

The event is loaded into the event FIFO on the rising edge of the timer, and the PORT\_NUMBER field in the [CPTS\\_EVENT\\_HIGH](#) register indicates the hardware time stamp input that caused the event.

Each hardware time stamp input must be asserted for at least 10 periods of the selected RCLK clock. Each input can be enabled or disabled by setting the respective bits in the [CPTS\\_CONTROL](#) register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

#### 24.11.4.10.5.5 Ethernet Port Events

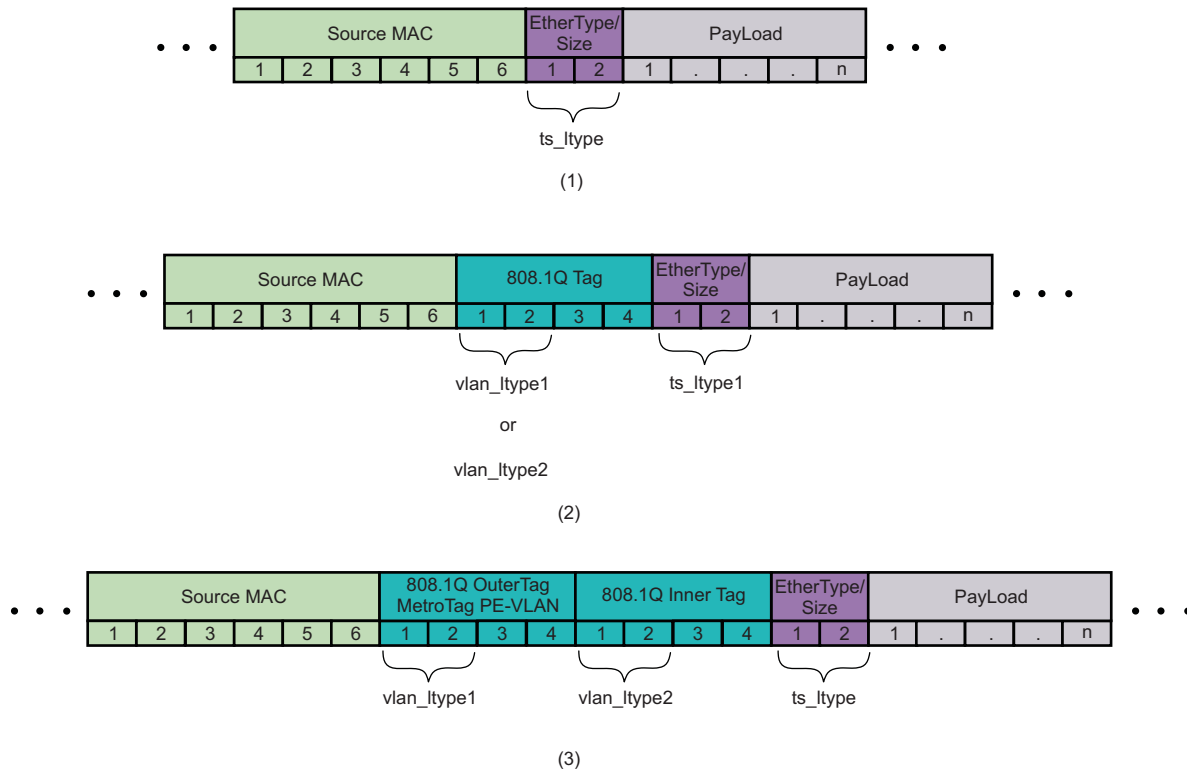

Packets transmitted or received on each Ethernet port can generate Ethernet Transmit Events or Ethernet Receive Events, respectively. The CPTS hardware will decode each packet to determine if it is a valid CPTS time sync event.

According to the IEEE 802.3 Ethernet standard, each Ethernet frame contains a 2-octet EtherType field to indicate which protocol is encapsulated in the Payload field, as shown in [Figure 24-203](#). For standard time sync packets, this will contain the EtherType for the Precision Time Protocol (IEEE 1588), which is defined as 0x88F7. The CPTS hardware will compare this field to the TS\_LTYPE1 field or the TS\_LTYPE2 field (depending on which enable bit was set) in the [CPSW\\_TS\\_LTYPE](#) register, which should also be programmed to 88F7h.

When a virtual LAN is used, an additional 4-octet 802.1Q tag is inserted in the Ethernet frame before the EtherType field, as shown in [Figure 24-203](#). To indicate to the CPTS hardware that a virtual LAN is in use, the Pn\_TS\_VLAN\_LTYPE1\_EN (or Pn\_TS\_VLAN\_LTYPE2\_EN) enable bit must be set in the Pn\_CONTROL register. The EtherType for the 802.1Q tag is defined as 0x8100, and the CPTS hardware will compare this value to the VLAN\_LTYPE1 (or VLAN\_LTYPE2 depending on which enable bit was set) field in the [CPSW\\_VLAN\\_LTYPE](#) register, which should also be programmed to 0x8100.

When two stacked VLANs are used, two additional 4-octet 801.Q tags are inserted in the Ethernet frame before the EtherType field, as shown in [Figure 24-203](#). In this case, both VLAN\_LTYPE1 and VLAN\_LTYPE2 must be enabled. The outer tag must match the value of the VLAN\_LTYPE1 field, and the inner tag must match the value of the VLAN\_LTYPE2 field.

**Figure 24-203. Partial Ethernet-II Frames Showing Register Mapping of EtherTypes for a Simple Frame (1), a Single 1Q Tag Added (2), and Two 1Q Tags Added (3)**

To enable transmit/receive event packets on a given Ethernet port, perform the following steps, where `n` is the port number:

1. Set the [1] `Pn_TS_TX_EN` or the [0] `Pn_TS_RX_EN` bit in the `Pn_CONTROL` register to enable transmit/receive event packets
2. Configure the register fields as follows:
  1. Set the `Pn_CONTROL[2] Pn_TS_LTYPE1_EN` or [3] `Pn_TS_LTYPE2_EN` bit to 1
  2. Set the `CPSW_TS_LTYPE[15:0] TS_LTYPE1` or [31:16] `TS_LTYPE2` (depending on which enable bit was set in 2(a)) field to 88F7h, which corresponds to the Precision Time Protocol (IEEE 1588) EtherType.
  3. Set the `Pn_TS_SEQ_MTYPE[21:16] Pn_TS_SEQ_ID_OFFSET` field to 1Eh, which is the sequence ID offset in the common message header given in the IEEE 1588 specification.
3. To enable support for VLAN tagging (IEEE 802.1Q):
  1. Set the [20] `Pn_TS_VLAN_LTYPE1_EN` or [21] `Pn_TS_VLAN_LTYPE2_EN` bit in the `Pn_CONTROL` register.
  2. Set the `CPSW_VLAN_LTYPE[15:0] VLAN_LTYPE1` or [31:16] `VLAN_LTYPE2` field (matching what was used in step 3a) to 8100h, which corresponds to the VLAN-tagged frame (IEEE 802.1Q) EtherType.
4. To enable support for up to two stacked VLANs (IEEE 802.1ad):
  1. Set the `Pn_TS_VLAN_LTYPE1_EN` and `Pn_TS_VLAN_LTYPE2_EN` bits in the `Pn_CONTROL` register.
  2. Set the `VLAN_LTYPE1` field in the `CPSW_VLAN_LTYPE` register to match the EtherType of the outer tag.
  3. Set the `VLAN_LTYPE2` field in the `CPSW_VLAN_LTYPE` register to 8100h, which corresponds to the VLAN-tagged frame (IEEE 802.1Q) EtherType of the inner tag.
5. Set the `Pn_TS_SEQ_MTYPE[15:0] Pn_TS_MSG_TYPE_EN` field to choose which types of time stamp messages will push events onto the Event FIFO. Table 9-20 lists the message types defined in the

IEEE 1588-2008 specification. [Table 24-1297](#) lists the message types defined in the IEEE 1588-2008 specification.

**Table 24-1297. Values of Message Type Field**

Message Type	Value (hex)
Sync	0
Delay_Req	1
Pdelay_Req	2
Pdelay_Resp	3
Reserved	4-7
Follow_Up	8
Delay_Resp	9
Pdelay_Resp_Follow_Up	A
Announce	B
Signaling	C
Management	D
Reserved	E-F

Once a transmitted or received packet is determined to be a valid time sync packet, the Ethernet Transmit Event or Ethernet Receive Event is loaded onto the Event FIFO. The [CPTS\\_EVENT\\_HIGH](#) register contains the Message Type and Sequence ID values from the original time sync packet. The [CPTS\\_EVENT\\_LOW](#) register contains the time stamp value when the packet arrived at the corresponding port.

#### 24.11.4.10.6 CPTS Interrupt Handling

When an event is push onto the Event FIFO, an interrupt can be generated to indicate to software that a time sync event occurred. The following steps should be taken to process time sync events using interrupts:

1. Enable the TS\_PEND interrupt by setting the TS\_PEND\_EN bit of the [CPTS\\_INT\\_ENABLE](#) register.
2. Upon interrupt, read the [CPTS\\_EVENT\\_LOW](#) and [CPTS\\_EVENT\\_HIGH](#) registers values.
3. Set the EVENT\_POP field (bit 0) of the [CPTS\\_EVENT\\_POP](#) register to pop the previously read value off of the event FIFO.
4. Process the interrupt as required by the application software.

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

1. Enable the TS\_PEND interrupt by setting the TS\_PEND\_EN bit of the [CPTS\\_INT\\_ENABLE](#) register.
2. Upon interrupt, read the [CPTS\\_EVENT\\_LOW](#) and [CPTS\\_EVENT\\_HIGH](#) registers values.
3. Set the EVENT\_POP bit of the [CPTS\\_EVENT\\_POP](#) register to pop the previously read value off of the event FIFO.
4. Wait for an amount of time greater than four CPTS\_RFT\_CLK periods plus four MAIN\_CLK periods.
5. Read the TS\_PEND\_RAW bit in the [CPTS\\_INTSTAT\\_RAW](#) register to determine if another valid event is in the event FIFO. If it is asserted, go to step 2; otherwise, go to step 6.
6. Process the interrupt(s) as required by the application software.

Software also has the option of disabling the interrupt and polling the TS\_PEND\_RAW bit of the [CPTS\\_INTSTAT\\_RAW](#) register to determine if a valid event is on the event FIFO.

#### 24.11.4.11 CPPI Buffer Descriptors

The buffer descriptor is a central part of the GMAC\_SW Ethernet Subsystem and is how the application software describes Ethernet packets to be sent and empty buffers to be filled with incoming packet data.

Host Software sends and receives network frames via the CPPI compliant host interface. The host interface includes module registers and host memory data structures. The host memory data structures are buffer descriptors and data buffers. Buffer descriptors are data structures that contain information about a single data buffer. Buffer descriptors may be linked together to describe frames or queues of frames for transmission of data and free buffer queues available for received data.

**NOTE:** The 8K bytes of Ethernet Subsystem CPPI RAM begin at address 0x4848 6000 and end at 0x4848 7FFF from the GMAC\_SW perspective. The buffer descriptors programmed to access the CPPI RAM memory should use this address range.

**24.11.4.11.1 TX Buffer Descriptors**

A TX buffer descriptor (Table 24-1298) is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

**Table 24-1298. TX Buffer Descriptor Format**

**24.11.4.11.1.1 CPPI TX Data Word 0**

**Next Descriptor Pointer**

The next descriptor pointer points to the 32-bit word aligned memory address of the next buffer descriptor in the transmit queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is zero, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC. The value of pNext should never be altered once the descriptor is in an active transmit queue, unless its current value is NULL. If the pNext pointer is initially NULL, and more packets need to be queued for transmit, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the transmitter will halt on the transmit channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC

**24.11.4.11.1.2 CPPI TX Data Word 1**

**Buffer Pointer**

The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the `buffer_pointer`. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

#### 24.11.4.11.1.3 CPPI TX Data Word 2

##### Buffer Offset

Indicates how many unused bytes are at the start of the buffer. A value of 0000h indicates that no unused bytes are at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 000Fh (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The host sets the `Buffer_Offset` value (which may be zero to the buffer length minus 1). Valid only on SOP.

##### Buffer Length

Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the `Buffer_Length` field. The host sets the `Buffer_Length`. The `Buffer_Length` must be greater than zero.

#### 24.11.4.11.1.4 CPPI TX Data Word 3

##### Packet Length

Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the `Buffer_Length` fields should equal the `Packet_Length`. Valid only on SOP. The packet length must be greater than zero. The packet data will be truncated to the packet length if the packet length is shorter than the sum of the packet buffer descriptor buffer lengths. A host error occurs if the packet length is greater than the sum of the packet buffer descriptor buffer lengths.

##### Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

0 - Not start of packet buffer.

1 - Start of packet buffer.

##### End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

0 - Not end of packet buffer.

1 - End of packet buffer.

##### Ownership (OWNER) Flag

When set this flag indicates that all the descriptors for the given packet (from SOP to EOP) are currently owned by the EMAC. This flag is set by the software application on the SOP packet descriptor before adding the descriptor to the transmit descriptor queue. For a single fragment packet, the SOP, EOP, and OWNER flags are all set. The OWNER flag is cleared by the EMAC once it is finished with all the descriptors for the given packet. Note that this flag is valid on SOP descriptors only.

0 - The packet is owned by the host

1 - The packet is owned by the port

##### End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the transmit queue for a given transmit channel, and that the transmitter has halted. This flag is initially cleared by the software application prior to adding the descriptor to the transmit queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet (the EOP flag is set), and there are no more descriptors in the transmit list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC transmitter for the corresponding channel has halted. This is useful when the application appends additional packet descriptors to a transmit queue list that is already owned by the EMAC. Note that this flag is valid on EOP descriptors only.

0 - The TX queue has more packets to transfer.

1 - The Descriptor buffer is the last buffer in the last packet in the queue.

#### **Teardown Complete (TDOWNCMPLT) Flag**

This flag is used when a transmit queue is being torn down, or aborted, instead of allowing it to be transmitted. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the SOP descriptor of each packet as it is aborted from transmission. Note that this flag is valid on SOP descriptors only. Also note that only the first packet in an unsent list has the TDOWNCMPLT flag set. Subsequent descriptors are not processed by the EMAC.

0 - The port has not completed the teardown process.

1 - The port has completed the commanded teardown process.

#### **Pass CRC (PASSCRC) Flag**

This flag is set by the software application in the SOP packet descriptor before it adds the descriptor to the transmit queue. Setting this bit indicates to the EMAC that the 4 byte Ethernet CRC is already present in the packet data, and that the EMAC should not generate its own version of the CRC. When the CRC flag is cleared, the EMAC generates and appends the 4-byte CRC. The buffer length and packet length fields do not include the CRC bytes. When the CRC flag is set, the 4-byte CRC is supplied by the software application and is already appended to the end of the packet data. The buffer length and packet length fields include the CRC bytes, as they are part of the valid packet data. Note that this flag is valid on SOP descriptors only.

0 - The CRC is not included with the packet data and packet length.

1 - The CRC is included with the packet data and packet length.

#### **TO\_PORT**

Port number to send the directed packet to. This field is set by the host. This field is valid on SOP. Directed packets go to the directed port, but an ALE lookup is performed to determine untagged egress in VLAN\_AWARE mode.

1 - Send the packet to port 1 if TO\_PORT\_EN is asserted.

2 - Send the packet to port 2 if TO\_PORT\_EN is asserted.

#### **TO\_PORT\_ENABLE**

Indicates when set that the packet is a directed packet to be sent to the TO\_PORT field port number. This field is set by the host. The packet is sent to one port only (index not mask). This bit is valid on SOP.

0 - not a directed packet

1 - directed packet

#### **24.11.4.11.2 RX Buffer Descriptors**

A RX buffer descriptor ([Table 24-1299](#)) is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

**Table 24-1299. RX Buffer Descriptor Format**

#### 24.11.4.11.2.1 CPPI RX Data Word 0

##### Next Descriptor Pointer

The 32-bit word aligned memory address of the next buffer descriptor in the RX queue. This is the mechanism used to reference the next buffer descriptor from the current buffer descriptor. If the value of this pointer is zero then the current buffer is the last buffer in the queue. The host sets the Next\_Descriptor\_Pointer.

#### 24.11.4.11.2.2 CPPI RX Data Word 1

##### Buffer Pointer

The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the Buffer\_Pointer.

#### 24.11.4.11.2.3 CPPI RX Data Word 2

##### Buffer Offset

Indicates how many unused bytes are at the start of the buffer. A value of 0000h indicates that there are no unused bytes at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 000Fh (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The port writes the Buffer\_Offset with the value from the CPDMA\_RX\_BUFFER\_OFFSET register value. The host initializes the Buffer\_Offset to zero for free buffers. The Buffer\_Length must be greater than the CPDMARX\_BUFFER\_OFFSET register value. The buffer offset is valid only on SOP.

##### Buffer Length

Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host initializes the Buffer\_Length, but the port may overwrite the host initiated value with the actual buffer length value on SOP and/or EOP buffer descriptors. SOP buffer length values will be overwritten if the packet size is less than the size of the buffer or if the offset is nonzero. EOP buffer length values will be overwritten if the entire buffer is not filled up with data. The Buffer\_Length must be greater than zero.

#### 24.11.4.11.2.4 CPPI RX Data Word 3

##### Packet Length

Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the Buffer\_Length fields should equal the Packet\_Length. Valid only on SOP.

**Start of Packet (SOP) Flag**

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on SOP descriptors.

**End of Packet (EOP) Flag**

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on EOP descriptors.

**Ownership (OWNER) Flag**

When set, this flag indicates that the descriptor is currently owned by the EMAC. This flag is set by the software application before adding the descriptor to the receive descriptor queue. This flag is cleared by the EMAC once it is finished with a given set of descriptors, associated with a received packet. The flag is updated by the EMAC on SOP descriptor only. So when the application identifies that the OWNER flag is cleared on an SOP descriptor, it may assume that all descriptors up to and including the first with the EOP flag set have been released by the EMAC. (Note that in the case of single buffer packets, the same descriptor will have both the SOP and EOP flags set.)

**End of Queue (EOQ) Flag**

When set, this flag indicates that the descriptor in question was the last descriptor in the receive queue for a given receive channel, and that the corresponding receiver channel has halted. This flag is initially cleared by the software application prior to adding the descriptor to the receive queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet received (also sets the EOP flag), and there are no more descriptors in the receive list (next descriptor pointer is NULL). The software application can use this bit to detect when the EMAC receiver for the corresponding channel has halted. This is useful when the application appends additional free buffer descriptors to an active receive queue. Note that this flag is valid on EOP descriptors only.

**Teardown Complete (TDOWNCMPLT) Flag**

This flag is used when a receive queue is being torn down, or aborted, instead of being filled with received data. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the descriptor of the first free buffer when the tear down occurs. No additional queue processing is performed.

**Pass CRC (PASSCRC) Flag**

This flag is set by the EMAC in the SOP buffer descriptor if the received packet includes the 4-byte CRC. This flag should be cleared by the software application before submitting the descriptor to the receive queue.

**Long (Jabber) Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is a jabber frame and was not discarded because the RX\_CEF\_EN bit was set in the [SL\\_MACCONTROL](#) register. Jabber frames are frames that exceed the RXMAXLEN in length, and have CRC, code, or alignment errors.

**Short (Fragment) Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is only a packet fragment and was not discarded because the RX\_CSF\_EN bit was set in the [SL\\_MACCONTROL](#) register.

**Control Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an EMAC control frame and was not discarded because the RX\_CMF\_EN bit was set in the [SL\\_MACCONTROL](#) register.

**Overrun Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet was aborted due to a receive overrun.

#### **Packet Error (PKT\_ERR) Flag**

Packet Contained Error on Ingress:

00 - no error

01 - CRC error on ingress

10 - Code error on ingress

11 - Align error on ingress

#### **VLAN Encapsulated Packet (RX\_VLAN\_ENCAP)**

Indicates when set that the packet data contains a 32-bit VLAN header word that is included in the packet byte count. This field is set by the port to be the value of the [CPSW\\_CONTROL](#) register RX\_VLAN\_ENCAP bit.

#### **FROM\_PORT**

Indicates the port number that the packet was received on (ingress to the switch).

### **24.11.4.12 MDIO**

The MII Management interface module implements the 802.3 serial management interface to interrogate and control two Ethernet PHYs simultaneously using a shared two-wire bus. Two user access registers ([MDIO\\_USERACCESS0/MDIO\\_USERACCESS1](#)) control and monitor up to two PHYs simultaneously.

#### **24.11.4.12.1 MDIO Frame Formats**

[Table 24-1300](#) shows the read format and [Table 24-1301](#) shows the write format of the 32-bit MII Management interface frames.

**Table 24-1300. MDIO Read Frame Format**

Pre-amble	Start Delimiter	Operation Code	PHY Address	Register Address	Turnaround	Data
FFFF FFFFh	01	10	AAAAA	RRRRR	Z0	DDDD.DDDD.DDDD.DDDD

**Table 24-1301. MDIO Write Frame Format**

Pre-amble	Start Delimiter	Operation Code	PHY Address	Register Address	Turnaround	Data
FFFF FFFFh	01	01	AAAAA	RRRRR	10	DDDD.DDDD.DDDD.DDDD

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY's pull-up resistor will pull the MDIO line to a logic 1. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic 1 bits on the MDIO line with 32 corresponding cycles on MDCLK to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on MDIO with 32 corresponding MDCLK cycles before it responds to any other transaction.

#### **Preamble**

The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a 1. This sequence provides the PHY a pattern to use to establish synchronization.

#### **Start Delimiter**

The preamble is followed by the start delimiter which is indicated by a 01 pattern. The pattern assures transitions from the default logic 1 state to logic 0, and back to logic 1.

### Operation Code

The operation code for a read is 10, while the operation code for a write is a 01.

### PHY Address

The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSB of the PHY address.

### Register Address

The Register address is 5 bits allowing 32 registers to be addressed within each PHY. Refer to the 10/100 PHY address map for addresses of individual registers.

### Turnaround

An idle bit time during which no device actively drives the MDIO signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall drive a zero bit onto MDIO for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

### Data

The Data field is 16 bits. The first bit transmitted and received is the MSB of the data word.

#### 24.11.4.12.2 MDIO Functional Description

The MII Management I/F will remain idle until enabled by setting the ENABLE bit in the [MDIO\\_CONTROL](#) register. The MII Management I/F will then continuously poll the link status from within the Generic Status Register of all possible 32 PHY addresses in turn recording the results in the [MDIO\\_LINK](#) register. The LINKSEL bit in the [MDIO\\_USERPHYSEL0/1](#) register determines the status input that is used. A change in the link status of the two PHYs being monitored will set the appropriate bit in the [MDIO\\_LINKINTRAW](#) register and the [MDIO\\_LINKINTMASKED](#) register, if enabled by the LINKINT\_ENABLE bit in the [MDIO\\_USERPHYSEL0/1](#) register.

The [MDIO\\_ALIVE](#) register is updated by the MII Management I/F module if the PHY acknowledged the read of the generic status register. In addition, any PHY register read transactions initiated by the host also cause the [MDIO\\_ALIVE](#) register to be updated.

At any time, the host can define a transaction for the MII Management interface module to undertake using the DATA, PHYADR, REGADR, and WRITE fields in a [MDIO\\_USERACCESS0/1](#) register. When the host sets the GO bit in this register, the MII Management interface module will begin the transaction without any further intervention from the host. Upon completion, the MII Management interface will clear the GO bit and set the USERINTRAW bit in the [MDIO\\_USERINTRAW](#) register corresponding to the [MDIO\\_USERACCESS0/1](#) register being used. The corresponding bit in the [MDIO\\_USERINTMASKED](#) register may also be set depending on the mask setting in the [MDIO\\_USERINTMASKSET](#) and [MDIO\\_USERINTMASKCLR](#) registers. A round-robin arbitration scheme is used to schedule transactions that may be queued by the host in different [MDIO\\_USERACCESS0/1](#) registers. The host should check the status of the GO bit in the [MDIO\\_USERACCESS0/1](#) register before initiating a new transaction to ensure that the previous transaction has completed. The host can use the ACK bit in the [MDIO\\_USERACCESS0/1](#) register to determine the status of a read transaction.

It is necessary for software to use the MII Management interface module to setup the auto-negotiation parameters of each PHY attached to a MAC port, retrieve the negotiation results, and setup the [SL\\_MACCONTROL](#) register in the corresponding MAC.

#### 24.11.5 GMAC\_SW Programming Guide

##### 24.11.5.1 Transmit Operation

After reset, the host must write zeroes to all TX DMA State head descriptor pointers. The TX port may then be enabled. To initiate packet transmission the host constructs transmit queues in memory (one or more packets for transmission) and then writes the appropriate TX DMA state head descriptor pointers. For each buffer added to a transmit queue, the host must initialize the TX buffer descriptor values as follows:

1. Write the Next Descriptor Pointer with the 32-bit aligned address of the next descriptor in the queue (zero if last descriptor)
2. Write the Buffer Pointer with the byte aligned address of the buffer data
3. Write the Buffer Length with the number of bytes in the buffer
4. Write the Buffer Offset with the number of bytes in the offset to the data (nonzero with SOP only)
5. Set the SOP, EOP, and Ownership bits as appropriate
6. Clear the End Of Queue bit

The port begins TX packet transmission on a given channel when the host writes the channel's TX queue head descriptor pointer with the address of the first buffer descriptor in the queue (nonzero value). Each channel may have one or more queues, so each channel may have one or more head descriptor pointers. The first buffer descriptor for each TX packet must have the Start of Packet (SOP) bit and the Ownership bit set to one by the host. The last buffer descriptor for each TX packet must have the End of Packet (EOP) bit set to one by the host. The port will transmit packets until all queued packets have been transmitted and the queue(s) are empty. When each packet transmission is complete, the port will clear the Ownership bit in the packet's SOP buffer descriptor and issue an interrupt to the host by writing the packet's last buffer descriptor address to the queue's TX DMA State Completion Pointer. The interrupt is generated by the write, regardless of the value written. When the last packet in a queue has been transmitted, the port sets the End Of Queue bit in the EOP buffer descriptor, clears the Ownership bit in the SOP Descriptor, zeroes the appropriate DMA state head descriptor pointer, and then issues a TX interrupt to the host by writing to the queue's associated TX completion pointer (address of the last buffer descriptor processed by the port). The port issues a maskable level interrupt (which may then be routed through external interrupt control logic to the host).

On interrupt from the port, the host processes the buffer queue, detecting transmitted packets by the status of the Ownership bit in the SOP buffer descriptor. If the Ownership bit is cleared to zero, then the packet has been transmitted and the host may reclaim the buffers associated with the packet. The host continues queue processing until the end of the queue or until a SOP buffer descriptor is read that contains a set Ownership bit indicating that the packet transmission is not complete. The host determines that all packets in the queue have been transmitted when the last packet in the queue has a cleared Ownership bit in the SOP buffer descriptor, the End of Queue bit is set in the last packet EOP buffer descriptor, and the Next Descriptor Pointer of the last packet EOP buffer descriptor is zero. The host acknowledges an interrupt by writing the address of the last buffer descriptor to the queue's associated TX Completion Pointer in the TX DMA State. If the host written buffer address value is different from the buffer address written by the port, then the level interrupt remains asserted. If the host written buffer address value is equal to the port written value, then the level interrupt is de-asserted. The port write to the completion pointer actually stores the value in the state register (RAM). The host written value is actually not written to the register location. The host written value is compared to the register contents (which was written by the port) and if the two values are equal, the interrupt is removed, otherwise the interrupt remains asserted. The host may process multiple packets previous to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

A mis-queued packet condition may occur when the host adds a packet to a queue for transmission as the port finishes transmitting the previous last packet in the queue. The mis-queued packet is detected by the host when queue processing detects a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and a nonzero Next Descriptor Pointer in the EOP buffer descriptor. A mis-queued packet means that the port read the last EOP buffer descriptor before the host added the new last packet to the queue, so the port determined queue empty just before the last packet was added. The host corrects the mis-queued packet condition by initiating a new packet transfer for the mis-queued packet by writing the mis-queued packet's SOP buffer descriptor address to the appropriate DMA State TX Queue head Descriptor Pointer.

The host may add packets to the tail end of an active TX queue at any time by writing the Next Descriptor Pointer to the current last descriptor in the queue. If a TX queue is empty (inactive), the host may initiate packet transmission at any time by writing the appropriate TX DMA State head descriptor pointer. The host software should always check for and reinitiate transmission for mis-queued packets during queue processing on interrupt from the port. In order to preclude software underrun, the host should avoid adding buffers to an active queue for any TX packet that is not complete and ready for transmission.

The port determines that a packet is the last packet in the queue by detecting the End of Packet bit set with a zero Next Descriptor Pointer in the packet buffer descriptor. If the End of Packet bit is set and the Next Descriptor Pointer is nonzero, then the queue still contains one or more packets to be transmitted. If the EOP bit is set with a zero Next Descriptor Pointer, then the port will set the EOQ bit in the packet's EOP buffer descriptor and then zero the appropriate head descriptor pointer previous to interrupting the port (by writing the completion pointer) when the packet transmission is complete.

**Figure 24-204. TX Queue Head Descriptor**

### 24.11.5.2 Receive Operation

After reset, the host must write zeroes to all RX DMA State head descriptor pointers. The RX port may then be enabled. To initiate packet reception, the host constructs receive queues in memory and then writes the appropriate RX DMA state head descriptor pointer. For each RX buffer descriptor added to the queue, the host must initialize the RX buffer descriptor values as follows:

1. Write the Next Descriptor Pointer with the 32-bit aligned address of the next descriptor in the queue (zero if last descriptor)
2. Write the Buffer Pointer with the byte aligned address of the buffer data
3. Clear the Offset field
4. Write the Buffer Length with the number of bytes in the buffer
5. Clear the SOP, EOP, and EOQ bits
6. Set the Ownership bit

The host enables packet reception on a given channel by writing the address of the first buffer descriptor in the queue (nonzero value) to the channel's head descriptor pointer in the channel's RX DMA state. When packet reception begins on a given channel, the port fills each RX buffer with data in order starting with the first buffer and proceeding through the RX queue. If the Buffer Offset in the RX DMA State is nonzero, then the port will begin writing data after the offset number of bytes in the SOP buffer. The port performs the following operations at the end of each packet reception:

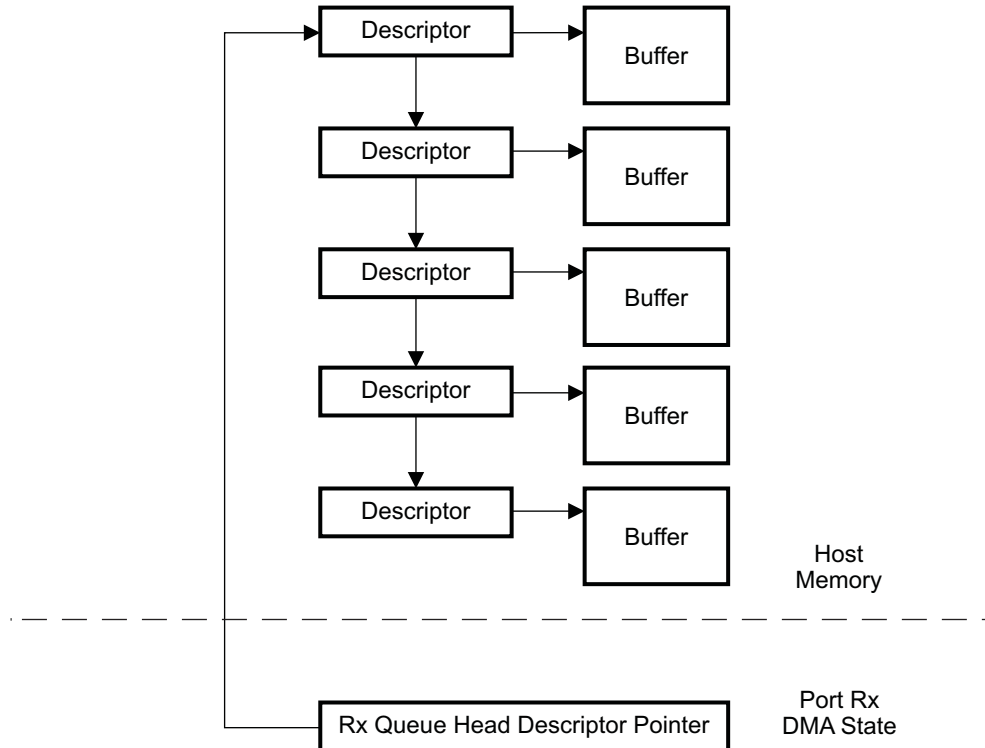

1. Overwrite the buffer length in the packet's EOP buffer descriptor with the number of bytes actually received in the packet's last buffer. The host initialized value is the buffer size. The overwritten value

will be less than or equal to the host initialized value.

2. Set the EOP bit in the packet's EOP buffer descriptor.
3. Set the EOQ bit in the packet's EOP buffer descriptor if the current packet is the last packet in the queue.
4. Overwrite the packet's SOP buffer descriptor Buffer Offset with the RX DMA state value (the host initialized the buffer descriptor Buffer Offset value to zero). All non SOP buffer descriptors must have a zero Buffer Offset initialized by the host.
5. Overwrite the packet's SOP buffer descriptor buffer length with the number of valid data bytes in the buffer. If the buffer is filled up, the buffer length will be the buffer size minus buffer offset.
6. Set the SOP bit in the packet's SOP buffer descriptor.
7. Write the SOP buffer descriptor Packet Length field.
8. Clear the Ownership bit in the packet's SOP buffer descriptor.
9. Issue an RX host interrupt by writing the address of the packet's last buffer descriptor to the queue's RX DMA State Completion Pointer. The interrupt is generated by the write to the RX DMA State Completion Pointer address location, regardless of the value written.

On interrupt the host processes the RX buffer queue detecting received packets by the status of the Ownership bit in each packet's SOP buffer descriptor. If the Ownership bit is cleared then the packet has been completely received and is available to be processed by the host. The host may continue RX queue processing until the end of the queue or until a buffer descriptor is read that contains a set Ownership bit indicating that the next packet's reception is not complete. The host determines that the RX queue is empty when the last packet in the queue has a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and the Next Descriptor Pointer in the EOP buffer descriptor is zero.

A mis-queued buffer may occur when the host adds buffers to a queue as the port finishes the reception of the previous last packet in the queue. The mis-queued buffer is detected by the host when queue processing detects a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and a nonzero Next Descriptor Pointer in the EOP buffer descriptor. A mis-queued buffer means that the port read the last EOP buffer descriptor before the host added buffer descriptor(s) to the queue, so the port determined queue empty just before the host added more buffer descriptor(s). In the transmit case, the packet transmission is delayed by the time required for the host to determine the condition and reinitiate the transaction, but the packet is not actually lost. In the receive case, receive overrun condition may occur in the mis-queued buffer case. If a new packet reception is begun during the time that the port has determined the end of queue condition, then the received packet will overrun (start of packet overrun). If the mis-queued buffer occurs during the middle of a packet reception then middle of packet overrun may occur. If the mis-queued buffer occurs after the last packet has completed, and is corrected before the next packet reception begins, then overrun will not occur. The host acts on the mis-queued buffer condition by writing the added buffer descriptor address to the appropriate RX DMA State Head Descriptor Pointer.

**Figure 24-205. RX Queue Head Descriptor**

### 24.11.5.3 MDIO Software Interface

#### 24.11.5.3.1 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO Control register ([MDIO\\_CONTROL](#)).
2. Enable the MDIO module by setting the ENABLE bit in [MDIO\\_CONTROL](#).
3. The MDIO PHY alive status register ([MDIO\\_ALIVE](#)) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register ([MDIO\\_LINK](#)) can determine whether this PHY already has a link.
4. Setup the appropriate PHY addresses in the MDIO user PHY select register ([MDIO\\_USERPHYSEL0/1](#)), and set the LINKINTENB bit to enable a link change event interrupt if desirable.
5. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register ([MDIO\\_USERINTMASKSET](#)) to use the MDIO user access register ([MDIO\\_USERACCESS0/1](#)). Since only one PHY is used in this device, the application software can use one [MDIO\\_USERACCESS0/1](#) to trigger a completion interrupt; the other [MDIO\\_USERACCESS0/1](#) is not setup.

#### 24.11.5.3.2 Writing Data To a PHY Register

The MDIO module includes a user access register ([MDIO\\_USERACCESS0/1](#)) to directly access a specified PHY device. To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register ([MDIO\\_USERACCESS0/1](#)) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in [MDIO\\_USERACCESS0/1](#) corresponding to the PHY and PHY register you want to write.

3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in [MDIO\\_USERACCESS0/1](#) for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register ([MDIO\\_USERINTRAW](#)) corresponding to [MDIO\\_USERACCESS0/1](#) used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register ([MDIO\\_USERINTMASKSET](#)), then the bit is also set in the MDIO user command complete interrupt register ([MDIO\\_USERINTMASKED](#)) and an interrupt is triggered on the host processor.

#### **24.11.5.3.3 Reading Data From a PHY Register**

The MDIO module includes a user access register ([MDIO\\_USERACCESS0/1](#)) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register ([MDIO\\_USERACCESSn](#)) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in [MDIO\\_USERACCESS0/1](#) corresponding to the PHY and PHY register you want to read.
3. The read data value is available in the DATA bits in [MDIO\\_USERACCESS0/1](#) after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in [MDIO\\_USERACCESS0/1](#). After the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register ([MDIO\\_USERINTRAW](#)) corresponding to [MDIO\\_USERACCESS0/1](#) used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register ([MDIO\\_USERINTMASKSET](#)), then the bit is also set in the MDIO user command complete interrupt register ([MDIO\\_USERINTMASKED](#)) and an interrupt is triggered on the host processor.

#### **24.11.5.4 Initialization and Configuration of CPSW**

To configure the GMAC\_SW Ethernet Subsystem for operation, the host must perform the following:

1. Select the Interface (G/MII, RGMII, RMII) Mode
2. Configure pads (PIN muxing), as per the interface selected.
3. Enable the GMAC\_SW Ethernet Subsystem Clocks
4. Configure the PRCM registers [CM\\_GMAC\\_CLKSTCTRL](#) and [CM\\_GMAC\\_GMAC\\_CLKCTRL](#) to enable power and clocks to GMAC\_SW Ethernet Subsystem.
5. Apply Soft Reset to GMAC\_SW Subsystem, [CPSW\\_3G](#), [CPGMAC\\_SL1/2](#), and [CPDMA](#)
6. Initialize the HDPs (Header Description Pointer) and CPs (Completion Pointer) to NULL
7. Configure the Interrupts
8. Configure the [CPSW\\_CONTROL](#) register
9. Configure the [CPSW\\_STAT\\_PORT\\_EN](#) register
10. Configure the ALE
11. Configure the MDIO
12. Configure the CPDMA receive DMA controller
13. Configure the CPDMA transmit DMA controller
14. Configure the CPPI TX and RX Descriptors
15. Configure [CPGMAC\\_SL1](#) and [CPGMAC\\_SL2](#), as per the desired mode of operations.
16. Start up RX and TX DMA (Write to HDP of RX and TX)
17. Wait for the completion of Transfer (HDP cleared to 0)

## 24.11.6 GMAC\_SW Register Manual

### 24.11.6.1 GMAC\_SW Instance Summary

**Table 24-1302. GMAC\_SW Instance Summary**

Module Name	Module Base Address	Size
SS	0x4848 4000	80 Bytes
PORT	0x4848 4100	1792 Bytes
CPDMA	0x4848 4800	256 Bytes
STATS	0x4848 4900	128 Bytes
STATERAM	0x4848 4A00	288 Bytes
CPTS	0x4848 4C00	240 Bytes
ALE	0x4848 4D00	88 Bytes
SL1	0x4848 4D80	64 Bytes
SL2	0x4848 4DC0	64 Bytes
MDIO	0x4848 5000	192 Bytes
WR	0x4848 5200	352 Bytes
SPF1	0x4848 5C00	512 Bytes
SPF2	0x4848 5E00	512 Bytes

**NOTE:** CPPI RAM address space starts at 0x4848 6000 and is 8 KiB deep. For details about CPPI RAM, see [Section 24.11.4.11, CPPI Buffer Descriptors.](#)

### 24.11.6.2 SS Registers

#### 24.11.6.2.1 SS Register Summary

RESERVED																EEE_PRESCALE															

Bits	Field Name	Description	Type	Reset
31:12	RESERVED		R	0x0
11:0	EEE_PRESCALE	Energy Efficient Ethernet Pre-scale count load value – This value is loaded into the EEE pre-scale counter each time the pre-scale count decrements to zero. The EEE counters are enabled to decrement each time the pre-scale counter reaches zero (and the EEE counters are enabled to count time). If this value is zero then the EEE counters decrement on every clock. If this value is 0x001 then the counters decrement on every other clock (and so on).	RW	0x0

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		R	0x0
8:4	P1_TX_MAX_BLKs	Transmit FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical transmit priority queues. 0x11 is the recommended value of P1_TX_MAX_BLKs unless the port is in fullduplex flow control mode. In flow control mode, the P1_RX_MAX_BLKs will need to increase in order to accept the required run out in fullduplex mode. This value will need to decrease by the amount of increase in P1_RX_MAX_BLKs. 0xE is the minimum value for P1_TX_MAX_BLKs.	RW	0x11
3:0	P1_RX_MAX_BLKs	Receive FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical receive queue. This value must be greater than or equal to 0x3. It should be increased In fullduplex flow control mode to 0x5 or 0x6 depending on the required runout space. The P1_TX_MAX_BLKs value must be decreased by the amount of increase in P1_RX_MAX_BLKs. 0x6 is the maximum value for P1_RX_MAX_BLKs.	RW	0x3

RESERVED																SOFT_RESET															

Bits	Field Name	Description	Type	Reset
31:1	RESERVED		R	0x0
0	SOFT_RESET	Software reset - Writing a one to this bit causes the CPDMA logic to be reset. Software reset occurs when the RX and TX DMA Controllers are in an idle state to avoid locking up the VBUSP bus. After writing a one to this bit, it may be polled to determine if the reset has occurred. If a one is read, the reset has not yet occurred. If a zero is read then reset has occurred.	RW	0x0

RESERVED																TX_RLIM												RESERVED	RX_CEF	CMD_IDLE	RX_OFFLEN_BLOCK	RX_OWNERSHIP	TX_PTYPE

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:8	TX_RLIM	Transmit Rate Limit Channel Bus 00000000 - no rate-limited channels 10000000 - channel 7 is rate-limited 11000000 - channels 7 downto 6 are rate-limited 11100000 - channels 7 downto 5 are rate-limited 11110000 - channels 7 downto 4 are rate-limited 11111000 - channels 7 downto 3 are rate-limited 11111100 - channels 7 downto 2 are rate-limited 11111110 - channels 7 downto 1 are rate-limited 11111111 - channels 7 downto 0 are rate-limited all others invalid - this bus must be set MSB towards LSB. TX_PTYPE must be set if any TX_RLIM bit is set for fixed priority.	RW	0x0
7:5	RESERVED		R	0x0
4	RX_CEF	RX Copy Error Frames Enable - Enables DMA overrun frames to be transferred to memory (up to the point of overrun). The overrun error bit will be set in the frame EOP buffer descriptor. Overrun frame data will be filtered when RX_CEF is not set. Frames coming from the receive FIFO with other error bits set are not effected by this bit. 0 - Frames containing overrun errors are filtered. 1 - Frames containing overrun errors are transferred to memory.	RW	0x0
3	CMD_IDLE	Command Idle 0 - Idle not commanded 1 - Idle Commanded (read IDLE in <a href="#">CPDMA_DMASTATUS</a> )	RW	0x0
2	RX_OFFLEN_BLOCK	Receive Offset/Length word write block. 0 - Do not block the DMA writes to the receive buffer descriptor offset/buffer length word. The offset/buffer length word is written as specified in CPPI 3.0. 1 - Block all CPDMA DMA controller writes to the receive buffer descriptor offset/buffer length words during CPPI packet processing. when this bit is set, the CPDMA will never write the third word to any receive buffer descriptor.	RW	0x0
1	RX_OWNERSHIP	Receive Ownership Write Bit Value. 0 - The CPDMA writes the receive ownership bit to zero at the end of packet processing as specified in CPPI 3.0. 1 - The CPDMA writes the receive ownership bit to one at the end of packet processing. Users who do not use the ownership mechanism can use this mode to preclude the necessity of software having to set this bit each time the buffer descriptor is used.	RW	0x0
0	TX_PTYPE	Transmit Queue Priority Type 0 - The queue uses a round robin scheme to select the next channel for transmission. 1 - The queue uses a fixed (channel 7 highest priority) priority scheme to select the next channel for transmission	RW	0x0

RESERVED																RX_BUFFER_OFFSET															

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:0	RX_BUFFER_OFFSET	Receive Buffer Offset Value - The RX_BUFFER_OFFSET will be written by the port into each frame SOP buffer descriptor buffer_offset field. The frame data will begin after the rx_buffer_offset value of bytes. A value of 0x0000 indicates that there are no unused bytes at the beginning of the data and that valid data begins on the first byte of the buffer. A value of 0x000F (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. This value is used for all channels.	RW	0x0

<b>Address Offset</b>	0x0000 0040	<b>Instance</b>	STATS
<b>Physical Address</b>	0x4848 4940		
<b>Description</b>	This statistic indicates the number of IEEE 802.3X pause frames transmitted by the port. Pause frames cannot underrun or contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect upon the statistic. Pause frames sent by software will not be included in this count. Since pause frames are only transmitted in full duplex carrier loss and collisions have no effect upon this statistic. Transmitted pause frames are always 64 byte multicast frames so will appear in the <a href="#">MULTICAST_TX_FRAMES</a> and <a href="#">RX_TX_64_OCTET_FRAMES</a> statistics.
