Bits	Field Name	Description	Type	Reset
31:28	RESERVED		R	0x0
27	CLKACTIVITY_L4PER_32K_GFCLK	This field indicates the state of the L4PER_32K_FCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
26	CLKACTIVITY_UART5_GFCLK	This field indicates the state of the UART5_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
25	RESERVED		R	0x0
24	CLKACTIVITY_GPIO_GFCLK	This field indicates the state of the GPIO_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
23	CLKACTIVITY_MMC4_GFCLK	This field indicates the state of the MMC4_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0

Bits	Field Name	Description	Type	Reset
22	CLKACTIVITY_MMC3_GFCLK	This field indicates the state of the MMC3_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
21	CLKACTIVITY_PER_96M_GFCLK	This field indicates the state of the PER_96M_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
20	CLKACTIVITY_PER_48M_GFCLK	This field indicates the state of the PER_48M_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
19	CLKACTIVITY_PER_12M_GFCLK	This field indicates the state of the PER_12M_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
18	CLKACTIVITY_UART4_GFCLK	This field indicates the state of the UART4_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
17	CLKACTIVITY_UART3_GFCLK	This field indicates the state of the UART3_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
16	CLKACTIVITY_UART2_GFCLK	This field indicates the state of the UART2_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
15	CLKACTIVITY_UART1_GFCLK	This field indicates the state of the UART1_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
14	CLKACTIVITY_TIMER9_GFCLK	This field indicates the state of the DMT9_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
13	CLKACTIVITY_TIMER4_GFCLK	This field indicates the state of the DMT4_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
12	CLKACTIVITY_TIMER3_GFCLK	This field indicates the state of the DMT3_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0

Bits	Field Name	Description	Type	Reset
11	CLKACTIVITY_TIMER2_GFCLK	This field indicates the state of the DMT2_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
10	CLKACTIVITY_TIMER11_GFCLK	This field indicates the state of the DMT11_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
9	CLKACTIVITY_TIMER10_GFCLK	This field indicates the state of the DMT10_GFCLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
8	CLKACTIVITY_L4PER_L3_GICLK	This field indicates the state of the L4PER_L3_GICLK clock in the domain. [warm reset insensitive] 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
7:2	RESERVED		R	0x0
1:0	CLKTRCTRL	Controls the clock state transition of the L4PER clock domain. 0x0: NO_SLEEP: Sleep transition cannot be initiated. Wakeup transition may however occur. 0x1: SW_SLEEP: Start a software forced sleep transition on the domain. 0x2: SW_WKUP: Start a software forced wake-up transition on the domain. 0x3: HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions.	RW	0x0

#### 3.12.26.2 CAM\_PRM Register Description

**Table 3-1168. PM\_CAM\_PWRSTCTRL**

<b>Address Offset</b>	0x0000 0000	<b>Instance</b>	CAM_PRM
<b>Physical Address</b>	<a href="#">0x4AE0 7000</a>		
<b>Description</b>	This register controls the CAM power state to reach upon a domain sleep transition		
<b>Type</b>	RW		

Bits	Field Name	Description	Type	Reset
31:18	RESERVED		R	0x0
17:16	VIP_BANK_ONSTATE	VIP_BANK memory state when domain is ON. 0x3: Memory bank is on when the domain is ON.	R	0x3
15:5	RESERVED		R	0x0

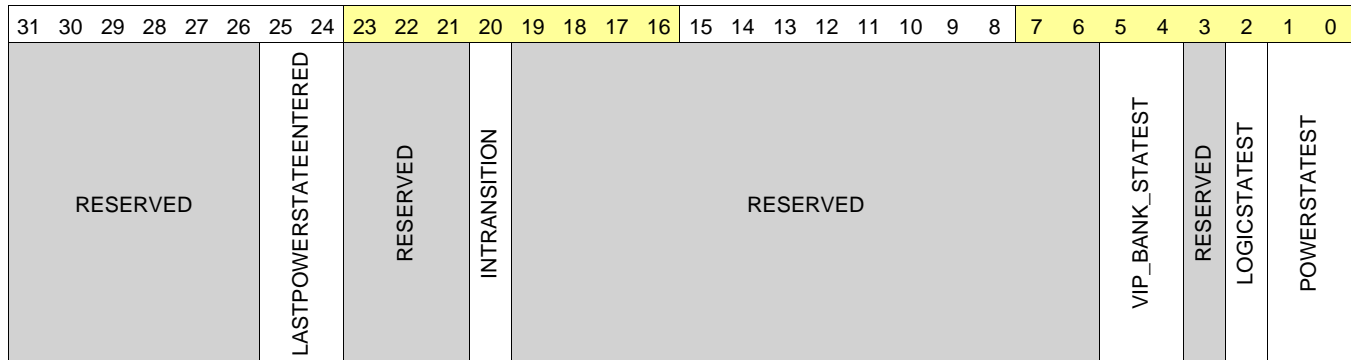

Bits	Field Name	Description	Type	Reset
4	LOWPOWERSTATECHANGE	Power state change request when domain has already performed a sleep transition. Allows going into deeper low power state without waking up the power domain.  0x0: Do not request a low power state change.  0x1: Request a low power state change. This bit is automatically cleared when the power state is effectively changed or when power state is ON.	RW	0x0
3:2	RESERVED		R	0x0
1:0	POWERSTATE	Power state control  0x0: OFF state	RW	0x0

#### 3.12.29.2 CUSTEFUSE\_PRM Register Description

**Table 3-1391. PM\_CUSTEFUSE\_PWRSTCTRL**

<b>Address Offset</b>	0x0000 0000	<b>Instance</b>	CUSTEFUSE_PRM
<b>Physical Address</b>	<a href="#">0x4AE0 7600</a>		
<b>Description</b>	This register controls the CUSTEFUSE power state to reach upon a domain sleep transition		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																LOWPOWERSTATECHANGE	RESERVED		POWERSTATE												

Bits	Field Name	Description	Type	Reset
31:5	RESERVED		R	0x0
4	LOWPOWERSTATECHANGE	Power state change request when domain has already performed a sleep transition. Allows going into deeper low power state without waking up the power domain.  0x0: Do not request a low power state change.  0x1: Request a low power state change. This bit is automatically cleared when the power state is effectively changed or when power state is ON.	RW	0x0
3:2	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
1:0	POWERSTATE	Power state control 0x0: OFF state 0x1: Reserved 0x2: Reserved 0x3: ON State	RW	0x0

<b>Address Offset</b>	0x0000 0020	<b>Instance</b>	DEVICE_PRM
<b>Physical Address</b>	0x4AE0 7D20		
<b>Description</b>	This register allows controlling power management features of the IOs.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																GLOBAL_WUEN	RESERVED						WUCLK_STATUS	WUCLK_CTRL	RESERVED	IO_ON_STATUS	ISOOVR_EXTEND	RESERVED	ISOCLK_STATUS	ISOCLK_OVERRIDE	

Bits	Field Name	Description	Type	Reset
31:17	RESERVED		R	0x0
16	GLOBAL_WUEN	Global IO wakeup enable. This is a gating condition to all individual IO WUEN coming from control module. Gating is done in the Spinner logic.  0x0: All individual IO WUEN are gated in the Spinner logic (overriden to 0). 0x1: All individual IO WUEN from control module are going to IOs.	RW	0x0
15:10	RESERVED		R	0x0
9	WUCLK_STATUS	Gives value of WUCLKOUT signal coming back from IO pad ring.	R	0x0
8	WUCLK_CTRL	Direct control on WUCLKIN signal to IO pad ring.  0x0: WUCLKIN signal is driven to 0. IO wakeup daisy chain is functional as well as IO whose wakeup feature is enabled. 0x1: WUCLKIN signal is driven to 1. IO wakeup daisy chain is reset and is latching current pad states and WUEN inputs.	RW	0x0
7:6	RESERVED		R	0x0
5	IO_ON_STATUS	Gives the functional status of the IO ring.  0x0: Part or all of the IOs are not in the ON state, that is are in isolation state. 0x1: All IOs are in the ON state.	R	0x1
4	ISOOVR_EXTEND	Control non-EMIF IO isolation extension upon a device wakeup from OFF mode.  0x0: Non-EMIF IO isolation is not extended. 'EMIF_ON' IO transition happens as soon as automatic restore is completed. 0x1: Non-EMIF IO isolation is extended. 'EMIF_ON' IO transition is stalled.	RW	0x0
3:2	RESERVED		R	0x0
1	ISOCLK_STATUS	Gives value of ISOCLKOUT signal coming back from IO pad ring.	R	0x0

Bits	Field Name	Description	Type	Reset
0	ISOCLK_OVERRIDE	Override control on ISOCLKIN signal to IO pad ring. Used at boot time when it is needed to change the mode of an IO from 1.8V default mode to 1.2V mode. When not overridden, this signal is controlled by hardware only. 0x0: ISOCLKIN signal is not overridden. 0x1: ISOCLKIN signal is overridden to active value ('1').	RW	0x0

RESERVED																								AIPOFF	ENFUNC5	ENFUNC4	ENFUNC3	ENFUNC2	ENFUNC1	ABBOFF_SLEEP	ABBOFF_ACT	ENABLE_RTA

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		R	0x0
8	AIPOFF	Override on AIPOFF input of SRAM LDO. 0x0: AIPOFF signal is not overridden 0x1: AIPOFF signal is overridden to '1'. Corresponding SRAM LDO is disabled and in HZ mode.	RW	0x0
7	ENFUNC5	ENFUNC5 input of SRAM LDO. 0x0: Active to retention is a one step transfer 0x1: Active to retention is a two steps transfer	RW	0x0
6	ENFUNC4	ENFUNC4 input of SRAM LDO. 0x0: One external clock is supplied 0x1: No external clock is supplied	RW	0x0
5	ENFUNC3	ENFUNC3 input of SRAM LDO. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this. 0x0: Sub regulation is disabled 0x1: Sub regulation is enabled	RW	0x0
4	ENFUNC2	ENFUNC2 input of SRAM LDO. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this. 0x0: External cap is used 0x1: External cap is not used	RW	0x0
3	ENFUNC1	ENFUNC1 input of SRAM LDO. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this. 0x0: Short circuit protection is disabled 0x1: Short circuit protection is enabled	RW	0x0

Bits	Field Name	Description	Type	Reset
2	ABBOFF_SLEEP	Determines whether SRAMNWA is supplied by VDDS or VDDAR during deep-sleep. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this.  0x0: SRAMNWA supplied with VDDS 0x1: SRAMNWA supplied with VDDAR	RW	0x0
1	ABBOFF_ACT	Determines whether SRAMNWA is supplied by VDDS or VDDAR during active mode. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this.  0x0: SRAMNWA supplied with VDDS 0x1: SRAMNWA supplied with VDDAR	RW	0x0
0	ENABLE_RTA	Control for HD memory RTA feature. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this.  0x0: HD memory RTA feature is disabled 0x1: HD memory RTA feature is enabled	RW	0x0

#### 3.12.32.2 DSP2\_PRM Register Description

**Table 3-1470. PM\_DSP2\_PWRSTCTRL**

<b>Address Offset</b>	0x0000 0000	<b>Instance</b>	DSP2_PRM
<b>Physical Address</b>	<a href="#">0x4AE0 7B00</a>		
<b>Description</b>	This register controls the DSP power state to reach upon a domain sleep transition		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								DSP2_EDMA_ONSTATE			DSP2_L2_ONSTATE			DSP2_L1_ONSTATE			RESERVED								LOWPOWERSTATECHANGE	RESERVED		POWERSTATE			

Bits	Field Name	Description	Type	Reset
31:22	RESERVED		R	0x0
21:20	DSP2_EDMA_ONSTATE	DSP_EDMA state when domain is ON. 0x3: Memory bank is on when the domain is ON.	R	0x3
19:18	DSP2_L2_ONSTATE	DSP_L2 state when domain is ON. 0x3: Memory bank is on when the domain is ON.	R	0x3
17:16	DSP2_L1_ONSTATE	DSP_L1 state when domain is ON. 0x3: Memory bank is on when the domain is ON.	R	0x3
15:5	RESERVED		R	0x0
4	LOWPOWERSTATECHANGE	Power state change request when domain has already performed a sleep transition. Allows going into deeper low power state without waking up the power domain. 0x0: Do not request a low power state change. 0x1: Request a low power state change. This bit is automatically cleared when the power state is effectively changed or when power state is ON.	RW	0x0
3:2	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
1:0	POWERSTATE	Power state control 0x0: OFF state 0x1: Reserved 0x2: Reserved 0x3: ON State	RW	0x3

### 3.12.34 EMU\_CM Registers

#### 3.12.34.1 EMU\_CM Register Summary

**Table 3-1493. EMU\_CM Registers Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	EMU_CM Physical Address L4_WKUP Interconnect
<a href="#">CM_EMU_CLKSTCTRL</a>	RW	32	0x0000 0000	0x4AE0 7A00
<a href="#">CM_EMU_DEBUGSS_CLKCTRL</a>	R	32	0x0000 0004	0x4AE0 7A04
<a href="#">CM_EMU_DYNAMICDEP</a>	RW	32	0x0000 0008	0x4AE0 7A08
<a href="#">CM_EMU_MPU_EMU_DBG_CLKCTRL</a>	R	32	0x0000 000C	0x4AE0 7A0C

#### 3.12.34.2 EMU\_CM Register Description

**Table 3-1494. CM\_EMU\_CLKSTCTRL**

<b>Address Offset</b>	0x0000 0000	<b>Instance</b>	EMU_CM
<b>Physical Address</b>	<a href="#">0x4AE0 7A00</a>		
<b>Description</b>	This register enables the EMU domain power state transition. It controls the HW supervised domain power state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain. [warm reset insensitive]		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																CLKACTIVITY_EMU_SYS_CLK	RESERVED						CLKTRCTRL								

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		R	0x0
8	CLKACTIVITY_EMU_SYS_CLK	This field indicates the state of the EMU_SYS_CLK clock in the domain. 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
7:2	RESERVED		R	0x0
1:0	CLKTRCTRL	Controls the clock state transition of the EMU clock domain. 0x0: Reserved 0x1: Reserved 0x2: SW_WKUP: Start a software forced wake-up transition on the domain. 0x3: HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions.	RW	0x2

### 3.12.44 MPU\_PRM Registers

#### 3.12.44.1 MPU\_PRM Register Summary

**Table 3-1877. MPU\_PRM Registers Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	MPU_PRM Physical Address L4_WKUP Interconnect
<a href="#">PM_MPU_PWRSTCTRL</a>	RW	32	0x0000 0000	0x4AE0 6300
<a href="#">PM_MPU_PWRSTST</a>	RW	32	0x0000 0004	0x4AE0 6304
<a href="#">RM_MPU_MPU_CONTEXT</a>	RW	32	0x0000 0024	0x4AE0 6324

**3.12.44.2 MPU\_PRM Register Description**
**Table 3-1878. PM\_MPU\_PWRSTCTRL**

<b>Address Offset</b>	0x0000 0000	<b>Instance</b>	MPU_PRM
<b>Physical Address</b>	0x4AE0 6300		
<b>Description</b>	This register controls the MPU domain power state to reach upon a domain sleep transition. If the value programmed in this register correspond to a lower power state than the one programmed in MPU-SS for CPU0 and/or CPU1, then value of this register is overwritten in PRCM logic to limit the power state to enter. Note: Even if value of this register is overwritten in PRCM logic, value of this register remains unchanged. - If user programs MPU power domain to go to CSWRET, then he can not program L2\$ to OFF mode. Note: Only the MPU Subsystem supports memory retention. MPU subsystem does not support OFF state. Only CPU1 supports FORCED_OFF state with no subsequent recovery to ON/active state - this is very application specific and may not be available in all TI standard software offerings.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

29	ABB_DSPEVE_DONE_ST	DSPEVE ABB mode change completion status. This status is set for both automatic transition upon a voltage transition, and OPP change (when OPP_CHANGE bit is cleared by hardware in PRM_ABBLDO_MM_CTRL register). It is cleared by SW.  0x0: No interrupt 0x1: Interrupt is pending	RW	0x0
28	ABB_GPU_DONE_ST	GPU ABB mode change completion status. This status is set for both automatic transition upon a voltage transition, and OPP change (when OPP_CHANGE bit is cleared by hardware in PRM_ABBLDO_MM_CTRL register). It is cleared by SW.  0x0: No interrupt 0x1: Interrupt is pending	RW	0x0
27:13	RESERVED		R	0x0
12	DPLL_EVE_RECAL_ST	EVE DPLL recalibration interrupt status.  0x0: No interrupt 0x1: Interrupt is pending	RW	0x0
11	DPLL_DSP_RECAL_ST	DSP DPLL recalibration interrupt status.  0x0: No interrupt 0x1: Interrupt is pending	RW	0x0
10	FORCEWKUP_ST	IPU domain software supervised wakeup transition completed event interrupt status.  0x0: No interrupt 0x1: Interrupt is pending	RW	0x0
9	IO_ST	IO pad event interrupt status.  0x0: No interrupt 0x1: Interrupt is pending	RW	0x0
8	RESERVED		R	0x0
7	DPLL_DDR_RECAL_ST	DDR DPLL recalibration interrupt status.  0x0: No interrupt 0x1: Interrupt is pending	RW	0x0
6	DPLL_GPU_RECAL_ST	GPU DPLL recalibration interrupt status.  0x0: No interrupt 0x1: Interrupt is pending	RW	0x0
5	DPLL_GMAC_RECAL_ST	GMAC DPLL recalibration interrupt status.  0x0: No interrupt 0x1: Interrupt is pending	RW	0x0
4	DPLL_ABE_RECAL_ST	ABE DPLL recalibration interrupt status.  0x0: No interrupt 0x1: Interrupt is pending	RW	0x0
3	DPLL_PER_RECAL_ST	PER DPLL recalibration interrupt status.  0x0: No interrupt 0x1: Interrupt is pending	RW	0x0

Bits	Field Name	Description	Type	Reset
2	DPLL_IVA_RECAL_ST	IVA DPLL recalibration interrupt status. 0x0: No interrupt 0x1: Interrupt is pending	RW	0x0
1	DPLL_MPU_RECAL_ST	MPU DPLL recalibration interrupt status. 0x0: No interrupt 0x1: Interrupt is pending	RW	0x0
0	DPLL_CORE_RECAL_ST	CORE DPLL recalibration interrupt status. 0x0: No interrupt 0x1: Interrupt is pending	RW	0x0

### 3.12.48.2 WKUPAON\_CM Register Description

**Table 3-1946. CM\_WKUPAON\_CLKSTCTRL**

<b>Address Offset</b>	0x0000 0000	<b>Instance</b>	WKUPAON_CM
<b>Physical Address</b>	0x4AE0 7800		
<b>Description</b>	This register enables the domain power state transition. It controls the HW supervised domain power state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								RESERVED	CLKACTIVITY_UART10_GFCLK	CLKACTIVITY_TIMER1_GFCLK	CLKACTIVITY_DCAN1_SYS_CLK	CLKACTIVITY_SYS_CLK_ALL	CLKACTIVITY_SYS_CLK_FUNC	RESERVED	CLKACTIVITY_WKUPAON_GICLK	CLKACTIVITY_WKUPAON_SYS_GFCLK	RESERVED	CLKACTIVITY_ABE_LP_CLK	CLKACTIVITY_SYS_CLK	RESERVED								CLKTRCTRL			

Bits	Field Name	Description	Type	Reset
31:20	RESERVED		R	0x0
19	RESERVED		R	0x0
18	CLKACTIVITY_UART10_GFCLK	This field indicates the state of the UART10_GFCLK clock in the domain. [warm reset insensitive]  0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
17	CLKACTIVITY_TIMER1_GFCLK	This field indicates the state of the TIMER1_GFCLK clock in the domain. [warm reset insensitive]  0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
16	CLKACTIVITY_DCAN1_SYS_CLK	This field indicates the state of the DCAN1_SYS_CLK clock in the domain. [warm reset insensitive]  0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
15	CLKACTIVITY_SYS_CLK_ALL	This field indicates the state of the SYS_CLK running at SCRMM level because of any SCRMM clock request. [warm reset insensitive]  0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
14	CLKACTIVITY_SYS_CLK_FUNC	This field indicates the state of the functional SYS_CLK clocks in the domain (this exclude activity of EMU_GCLK clock). [warm reset insensitive]  0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0

Bits	Field Name	Description	Type	Reset
13	RESERVED		R	0x0
12	CLKACTIVITY_WKUPAON_GICLK	This field indicates the state of the WKUPAON_GICLK clock in the domain. [warm reset insensitive]  0x0: Corresponding clock is definitely gated  0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
11	CLKACTIVITY_WKUPAON_SYS_GFCLK	This field indicates the state of the WKUPAON_SYS_GFCLK clock in the domain. [warm reset insensitive]  0x0: Corresponding clock is definitely gated  0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
10	RESERVED		R	0x0
9	CLKACTIVITY_ABE_LP_CLK	This field indicates the state of the ABE_LP_CLK clock in the domain. [warm reset insensitive]  0x0: Corresponding clock is definitely gated  0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
8	CLKACTIVITY_SYS_CLK	This field indicates the state of the SYS_CLK clock in the domain(it includes profiling, EMU_SYS_GCLK and all functional SYS_CLK. [warm reset insensitive]  0x0: Corresponding clock is definitely gated  0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
7:2	RESERVED		R	0x0
1:0	CLKTRCTRL	Controls the clock state transition of the WKUPAON clock domain.  0x0: NO_SLEEP: Sleep transition cannot be initiated. Wakeup transition may however occur.  0x1: Reserved  0x2: SW_WKUP: Start a software forced wake-up transition on the domain.  0x3: HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions.	RW	0x0

## 4.1 Dual Cortex-A15 MPU Subsystem Overview

### 4.1.1 Introduction

The dual Cortex®-A15 microprocessor unit (MPU) subsystem serves the applications processing role by running the high-level operating system (HLOS) and application code. The MPU subsystem is based on the symmetric multiprocessor (SMP) architecture, and thus it delivers high performance and optimal power management, debug, and emulation capabilities.

The MPU subsystem incorporates two Cortex-A15 MPU cores (MPU\_C0 and MPU\_C1), individual level 1 (L1) caches, level 2 (L2) cache (MPU\_L2CACHE) shared between them, and various other shared peripherals. To aid software development, the processor cores can be kept cache-coherent with each other and with the L2 cache.

The MPU subsystem provides a high-performance computing platform with high peak-computing performance and low memory latency, while also supporting a configuration to shut off one core and run the other at low voltage and low frequency to achieve low-power operation.

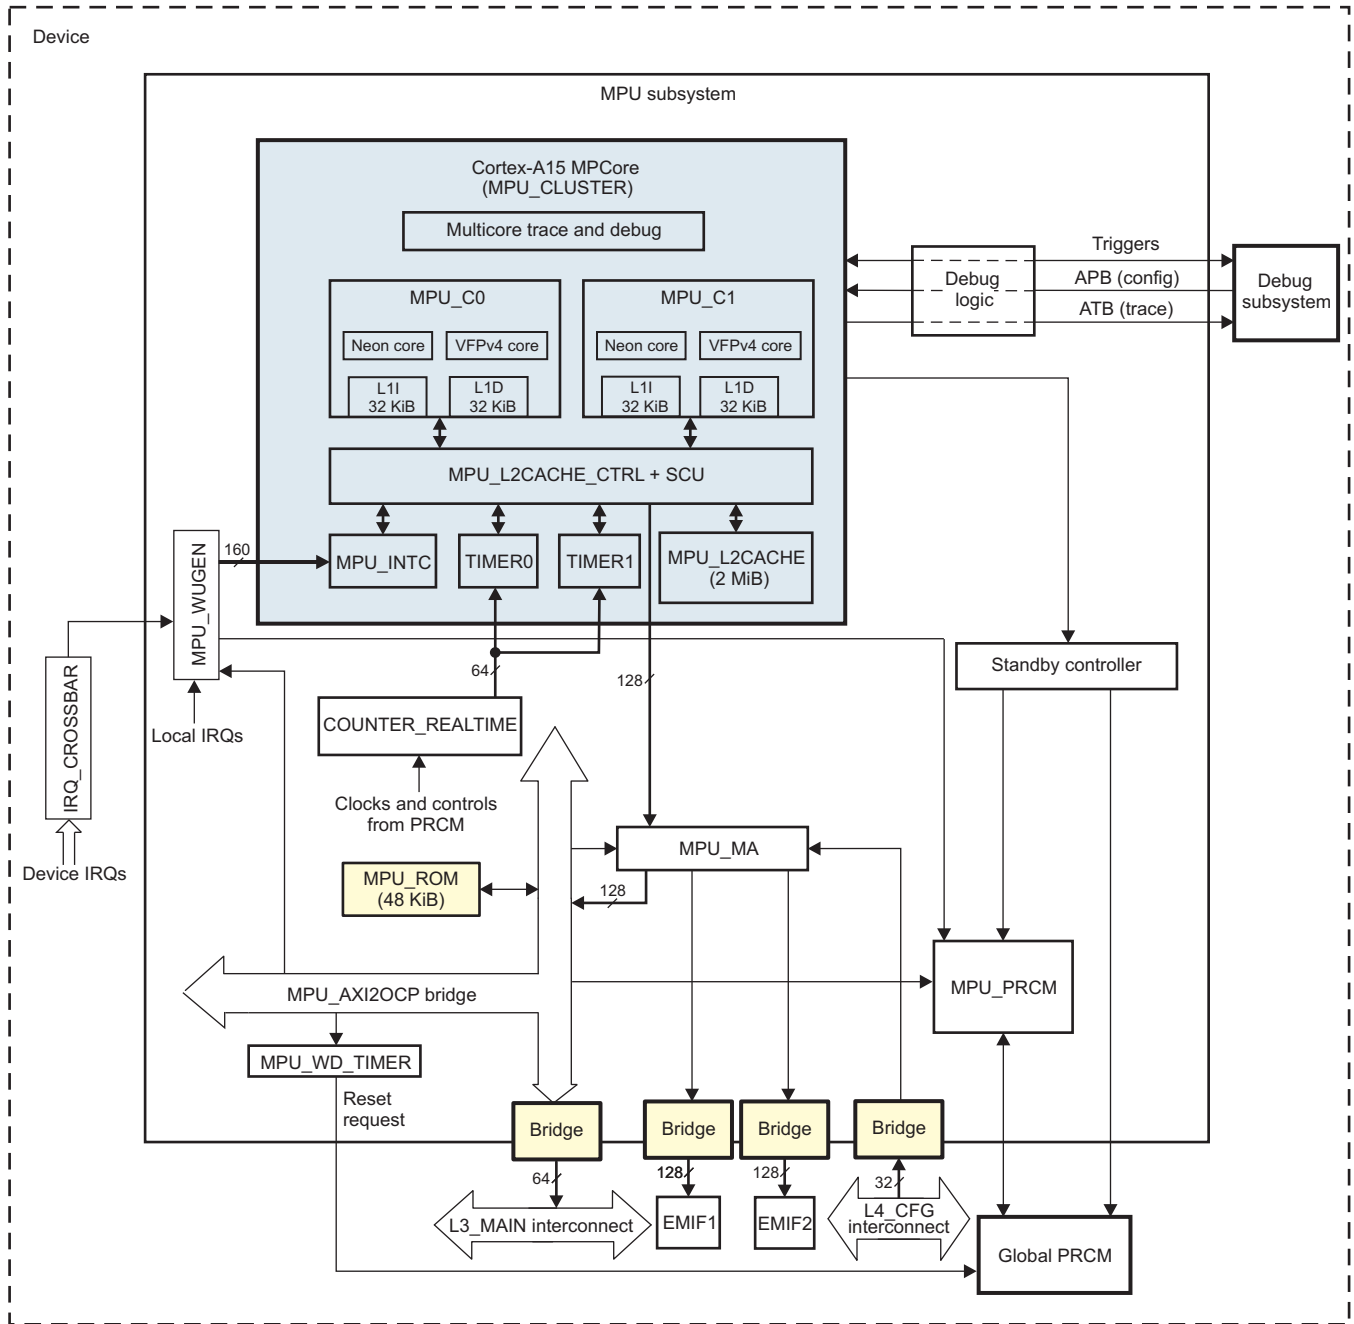

---

**NOTE:** Only MPU\_C1 can be put in off (FORCED\_OFF) power state. The lowest power state of MPU\_C0 is CSWR.

---

Figure 4-1 is a high-level block diagram of the MPU subsystem.

Figure 4-1. MPU Subsystem Overview

### 4.1.2 Features

The MPU subsystem integrates the following:

- Arm®Cortex-A15 MPCore (MPU\_CLUSTER)
  - Two Cortex-A15 MPU cores (revision r2p2, SMP architecture), each of them having the following features:
    - Superscalar, dynamic multi-issue technology
      - Out-of-order (OoO) instruction dispatch and completion
      - Dynamic branch prediction with branch target buffer (BTB), global history buffer (GHB), and 48-entry return stack
      - Continuous fetch and decoding of three instructions per clock cycle
      - Dispatch of up to four instructions and completion of eight instructions per clock cycle
      - Provides optimal performance from binaries compiled for previous Arm processors
      - Five execution units handle simple instructions, branch instructions, Neon™ and floating point instructions, multiply instructions, and load and store instructions.
      - Simple instructions take two cycles from dispatch, while complex instructions take up to 11 cycles.
      - Can issue two simple instructions in a cycle
      - Can issue a load and a store instruction in the same cycle
    - Integrated Neon processing engine to include the Arm Neon Advanced SIMD (single instruction, multiple data) support for accelerated media and signal processing computation
    - Includes VFPv4-compatible hardware to support single- and double-precision add, subtract, divide, multiply and accumulate, and square root operations
    - Extensive support to accelerate virtualization using a hypervisor
    - 32-KiB L1 instruction (L1I) and 32-KiB L1 data (L1D) cache:
      - 64-byte line size
      - 2-way set associative
    - Memory management unit (MMU):
      - Two-level translation lookaside buffer (TLB) organization
        - First level is an 32-entry, fully associative micro-TLB implemented for each of instruction fetch, load, and store.
        - Second level is a unified, 4-way associative, 512-entry main TLB
      - Supports hardware TLB table-walk for backward-compatible and new 64-bit entry page table formats
      - New page table format can produce 40-bit physical addresses
      - Two-stage translation where first stage is HLOS-controlled and the second level may be controlled by a hypervisor. Second stage always uses the new page table format
  - Integrated L2 cache (MPU\_L2CACHE) and snoop control unit (SCU):
    - 2-MiB of unified (instructions and data) cache organized as 16 ways of 2048 sets of 64-byte lines
    - Redundant L1 data (cache) tags to perform snoop filtering (L1 instruction cache tags are not duplicated)
    - Operates at Cortex-A15 MPU core clock rate
    - Integrated L2 cache controller (MPU\_L2CACHE\_CTRL):
      - Sixteen 64-byte line buffers that handle evictions, line fills and snoop transfers
      - One 128-bit AMBA4 Coherent Bus (AXI4-ACE) port
      - Auto-prefetch buffer for up to 16 streams per core and detecting forward and backward strides
    - L1 cache coherency between the MPU cores is maintained by the L2 cache controller, which

also serves as a snoop controller.

- SCU ensures memory coherency between the two MPU cores
- Generalized interrupt controller (GIC, also referred to as MPU\_INTC): An interrupt controller supplied by Arm. The single GIC in the MPU\_CLUSTER routes interrupts to each of the MPU cores. The GIC supports:
  - Number of shared peripheral interrupts (SPI): 160
  - Number of software generated interrupts (SGI): 16
  - Number of CPU interfaces: 2
  - Virtual CPU interface for virtualization support. This allows the majority of guest operating system (OS) interactions with the GIC to be handled in hardware, but with physical interrupts still requiring hypervisor intervention to assign them to the appropriate virtual machine.
- Integrated timer counter and one timer block per MPU core
- Arm CoreSight™ debug and trace modules. For more information, see [Chapter 33, On-Chip Debug Support](#).
- MPU\_AXI2OCP bridge (local interconnect):
  - Connected to Memory Adapter (MPU\_MA), which routes the non-EMIF address space transactions to MPU\_AXI2OCP
  - Single request multiple data (SRMD) protocol on L3\_MAIN port
  - Multiple targets:
    - 64-bit port to the L3\_MAIN interconnect. Interface frequency is 1/4 or 1/8 of core frequency
    - MPU\_ROM
    - Internal MPU subsystem peripheral targets, including Memory Adapter LISA Section Manager (MA\_LSM), wake-up generator (MPU\_WUGEN), watchdog timer (MPU\_WD\_TIMER), and local PRCM module (MPU\_PRCM) configuration
    - Internal AXI target, CoreSight System Trace Module (CS\_STM)
- Memory adapter (MPU\_MA): Helps decrease the latency of accesses between the MPU\_L2CACHE and the two EMIFs (EMIF0 and EMIF1) by providing a direct path between the MPU subsystem and the EMIFs:
  - Connected to 128-bit AMBA4 interface of MPU\_CLUSTER
  - Direct 128-bit interface to each of EMIF0 and EMIF1
  - Interface speed between MPU\_CLUSTER and MPU\_MA is at half-speed of MPU\_CLUSTER internal core frequency
  - Quarter-speed interface to EMIF
  - Performs interleaving functions to optimize EMIF interface bandwidth
  - Uses firewall logic to check access rights of incoming addresses
- Local PRCM (MPU\_PRCM):
  - Handles MPU\_C0 and MPU\_C1 power domains
  - Supports SR3-APG (SmartReflex3 Automatic Power Gating) power management technology inside the MPU\_CLUSTER
  - MPU subsystem has six power domains
- Wake-up generator (MPU\_WUGEN)
  - Responsible for waking up the MPU cores
  - Used by the ROM code and OS during SMP boot
- Standby controller: Handles the power transitions inside the MPU subsystem
- Realtime (master) counter (COUNTER\_REALTIME): Produces the count used by the private timer peripherals in the MPU\_CLUSTER
- Watchdog timer (MPU\_WD\_TIMER): Used to generate a chip-level watchdog reset request to global PRCM
- On-chip ROM (MPU\_ROM): Both MPU\_C0 and MPU\_C1 can boot from this memory. The MPU\_ROM

size is 48-KiB, and the address range is from 0x4003 8000 to 0x4004 3FFF. For more information, see [Chapter 32, Initialization](#).

- Interfaces:
  - 128-bit interface to each of EMIF0 and EMIF1
  - 64-bit master port to the L3\_MAIN interconnect
  - 32-bit slave port from the L4\_CFG\_EMU interconnect (debug subsystem) for configuration of the MPU subsystem debug modules
  - 32-bit slave port from the L4\_CFG interconnect for memory adapter firewall (MPU\_MA\_NTTP\_FW) configuration
  - 32-bit ATB output for transmitting debug and trace data
  - 160 peripheral interrupt inputs

## 4.2 Dual Cortex-A15 MPU Subsystem Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 4-2 shows the MPU subsystem integration.

Figure 4-2. MPU Subsystem Integration

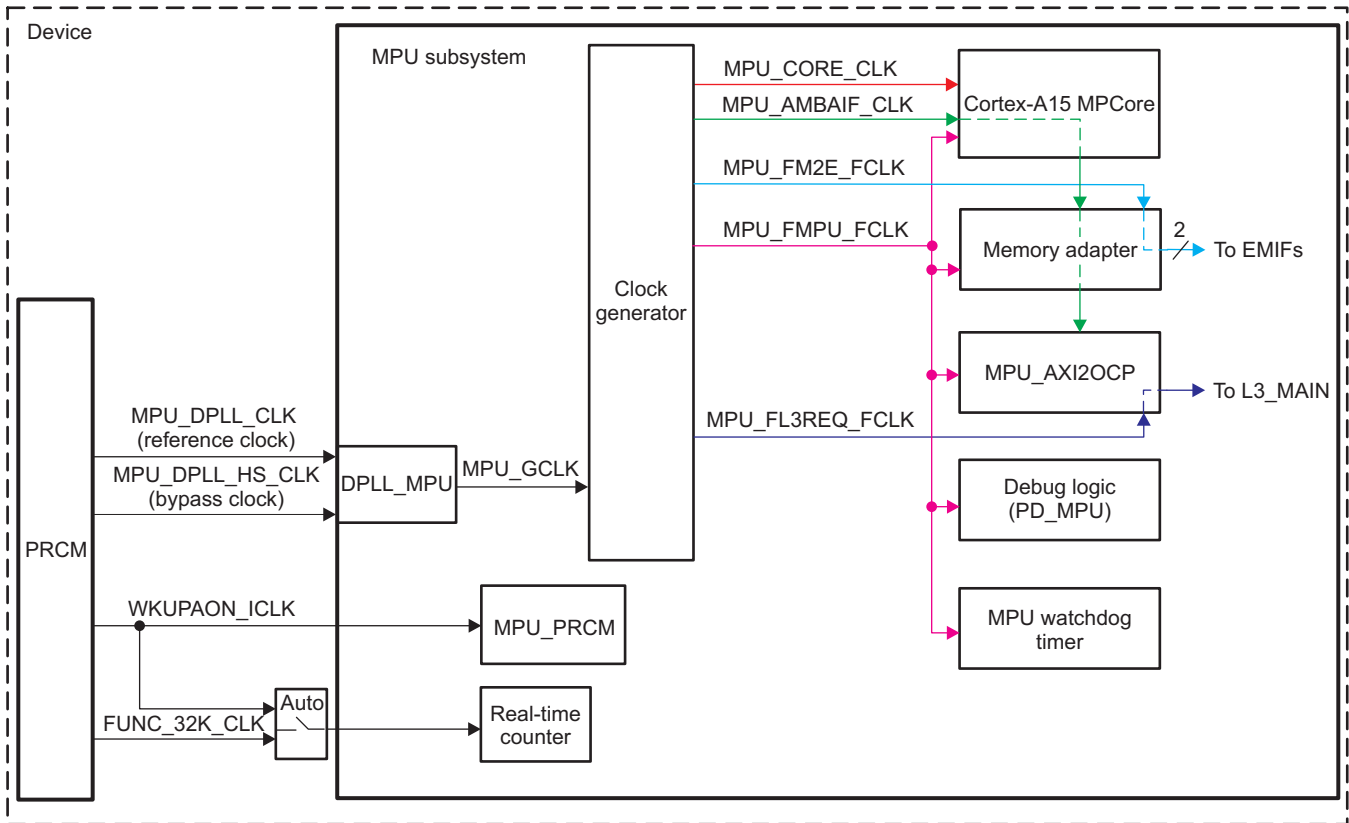

**NOTE:** For more information about:

- Clock distribution inside MPU subsystem, see [Section 4.2.1, Clock Distribution](#).
- Reset distribution inside MPU subsystem, see [Section 4.2.2, Reset Distribution](#).
- MPU\_INTC default interrupt mapping, and IRQ\_CROSSBAR mapping, see [Chapter 17, Interrupt Controllers](#).
- MPU watchdog timer reset request, see [Section 4.3.6, MPU Watchdog Timer](#).
- MPU trace and cross-triggering with Debug Subsystem, see [Chapter 33, On-Chip Debug Support](#).
- Master standby protocol and wakeup request, see [Section 3.1.1.1.2, Module-Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

### 4.2.1 Clock Distribution

The Cortex-A15 MPU clock generator is fed by the MPU digital phase-locked loop (DPLL), which can be gated off by the global power, reset, and clock management (PRCM) module when system power domain is in a low-power state. There is a global clock gating for each MPU core. Because of the DPLL\_MPU, the MPU subsystem is asynchronous from the rest of the device.

Figure 4-3 shows the MPU subsystem clocking scheme.

**Figure 4-3. MPU Subsystem Clocking Scheme**

The clock generator generates the following clocks from the DPLL\_MPU output clock (MPU\_GCLK):

- MPU\_CORE\_CLK
- MPU\_AMBAIF\_CLK
- MPU\_FMPU\_FCLK
- MPU\_FL3REQ\_FCLK
- MPU\_FM2E\_FCLK

MPU\_CORE\_CLK is directly derived (no hardware dividing) from the DPLL\_MPU output clock (that is, MPU\_CORE\_CLK = MPU\_GCLK). The other clocks are derived via dividers.

Table 4-1 shows the supported frequency values for MPU subsystem clocks at different OPPs.

**Table 4-1. MPU Subsystem Clocks Frequency Value Versus OPP**

Clocks (Derived From DPLL_MPU)	OPP_LOW	OPP_NOM	OPP_OD	OPP_HIGH	OPP_PLUS
MPU_CORE_CLK (f)	See <sup>(1)</sup>	See <sup>(1)</sup>	See <sup>(1)</sup>	See <sup>(1)</sup>	See <sup>(1)</sup>
MPU_AMBAIF_CLK	f/2	f/2	f/2	f/2	f/2
MPU_FMPU_FCLK	f/4	f/4	f/4	f/4	f/4
MPU_FL3REQ_FCLK	f/4	f/4	f/4	f/8	f/8
MPU_FM2E_FCLK	f/4	f/4	f/4	f/4	f/4

<sup>(1)</sup> See device *Data Manual* for information about frequency value

Some of the OPPs listed in [Table 4-1](#) may not be supported for some devices.

**NOTE:** For more information about the supported OPPs, see the "Operating Performance Points" section of the device Data Manual.

**NOTE:** For more information about the DPLL\_MPU, see [Section 3.6.3.7, DPLL\\_MPU Description](#), in [Chapter 3, Power, Reset, and Clock Management](#).

The two MPU cores cannot be clocked at different frequencies.

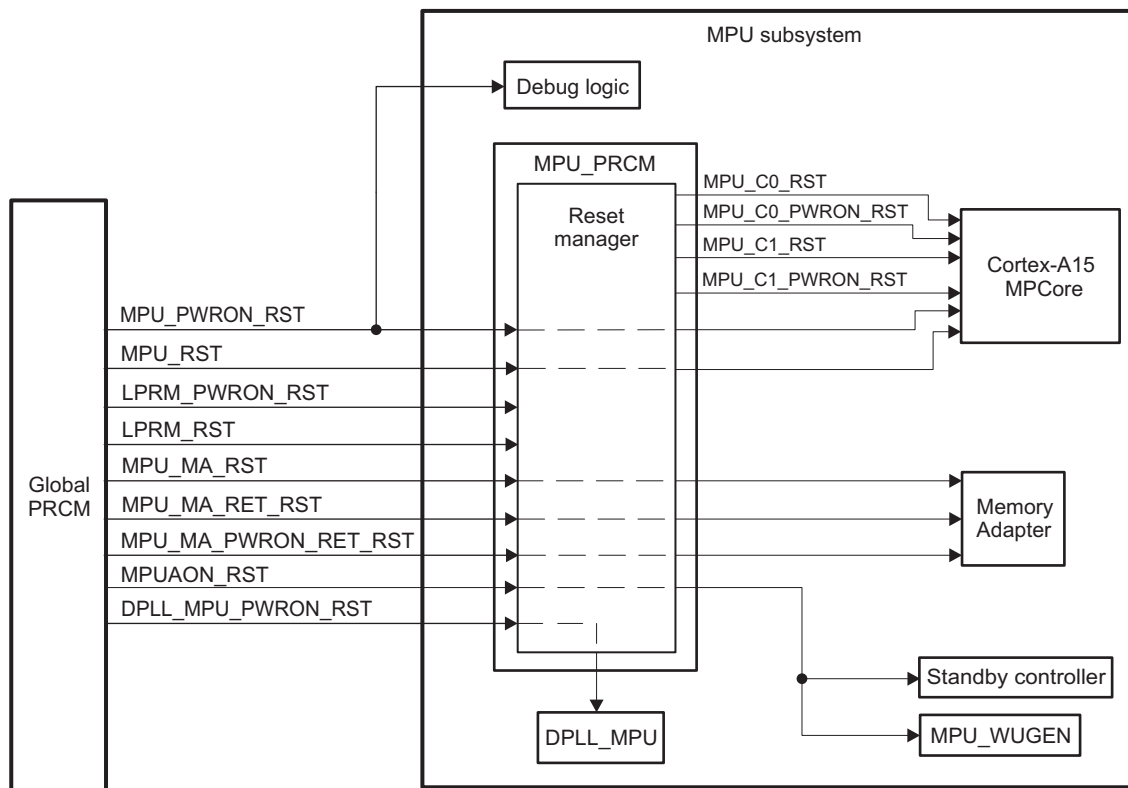

The realtime counter (COUNTER\_REALTIME) is clocked by either WKUPAON\_ICLK or FUNC\_32K\_CLK clocks, provided by the global PRCM module. By default, WKUPAON\_ICLK is used as a COUNTER\_REALTIME clock. When the MPU subsystem goes to standby mode, the counter automatically switches to a low-power mode using the FUNC\_32K\_CLK (SYS\_CLK1/610).

### 4.2.2 Reset Distribution

Resets to the MPU subsystem are provided by the global PRCM module and controlled by the local MPU\_PRCM module.

[Figure 4-4](#) shows the reset scheme of the MPU subsystem.

**Figure 4-4. MPU Subsystem Reset Scheme**

All external resets that are input to the local PRCM signals are active low. All external reset input signals are driven by the global PRCM. Four internal reset signals are generated by the local PRCM module.

The LPRM\_PWRON\_RST reset signal is a global cold reset for the wake-up logic and resets the wake-up domain logic (the PSCON modules) in the local PRCM module. A cold reset is typically asserted when power is initially applied to the system. The user can check whether this reset event has occurred by reading the [PRM\\_RSTST\[0\] GLOBAL\\_COLD\\_RST](#) bit.

The LPRM\_RST reset signal is a global warm reset that resets the wake-up domain logic (the PSCON modules) in the local PRCM module. Warm reset is typically used to reset a system that has been operating for some time. The user can check whether this reset event has occurred by reading the [PRM\\_RSTST\[1\] GLOBAL\\_WARM\\_RST](#) bit.

The DPLL\_MPU\_PWRON\_RST reset signal resets the DPLL\_MPU.

The MPUAON\_RST reset signal resets the MPU always-on domain: the standby controller and the MPU\_WUGEN. The user can check whether the reset has occurred by reading the [WKG\\_CONTROL\\_0\[15\] DOMAIN\\_RST](#) bit for MPU\_C0 and the [WKG\\_CONTROL\\_1\[15\] DOMAIN\\_RST](#) bit for MPU\_C1.

The MPU\_MA has three incoming reset signals:

- MPU\_MA\_RST
- MPU\_MA\_RET\_RST
- MPU\_MA\_PWRON\_RET\_RST

The local PRCM module provides two reset signals for each CPU:

- The MPU\_C0\_RST and MPU\_C1\_RST reset signals are warm reset events. These reset signals initialize most of the Arm MPU cores, except the debug logic (breakpoints and watchpoints are retained during this reset). The user can check whether these reset events have occurred by reading the [RM\\_CPUX\\_RSTCTRL\[0\] RST](#) bit.
- The MPU\_C0\_PWRON\_RST and MPU\_C1\_PWRON\_RST reset signals are cold and debug reset events.

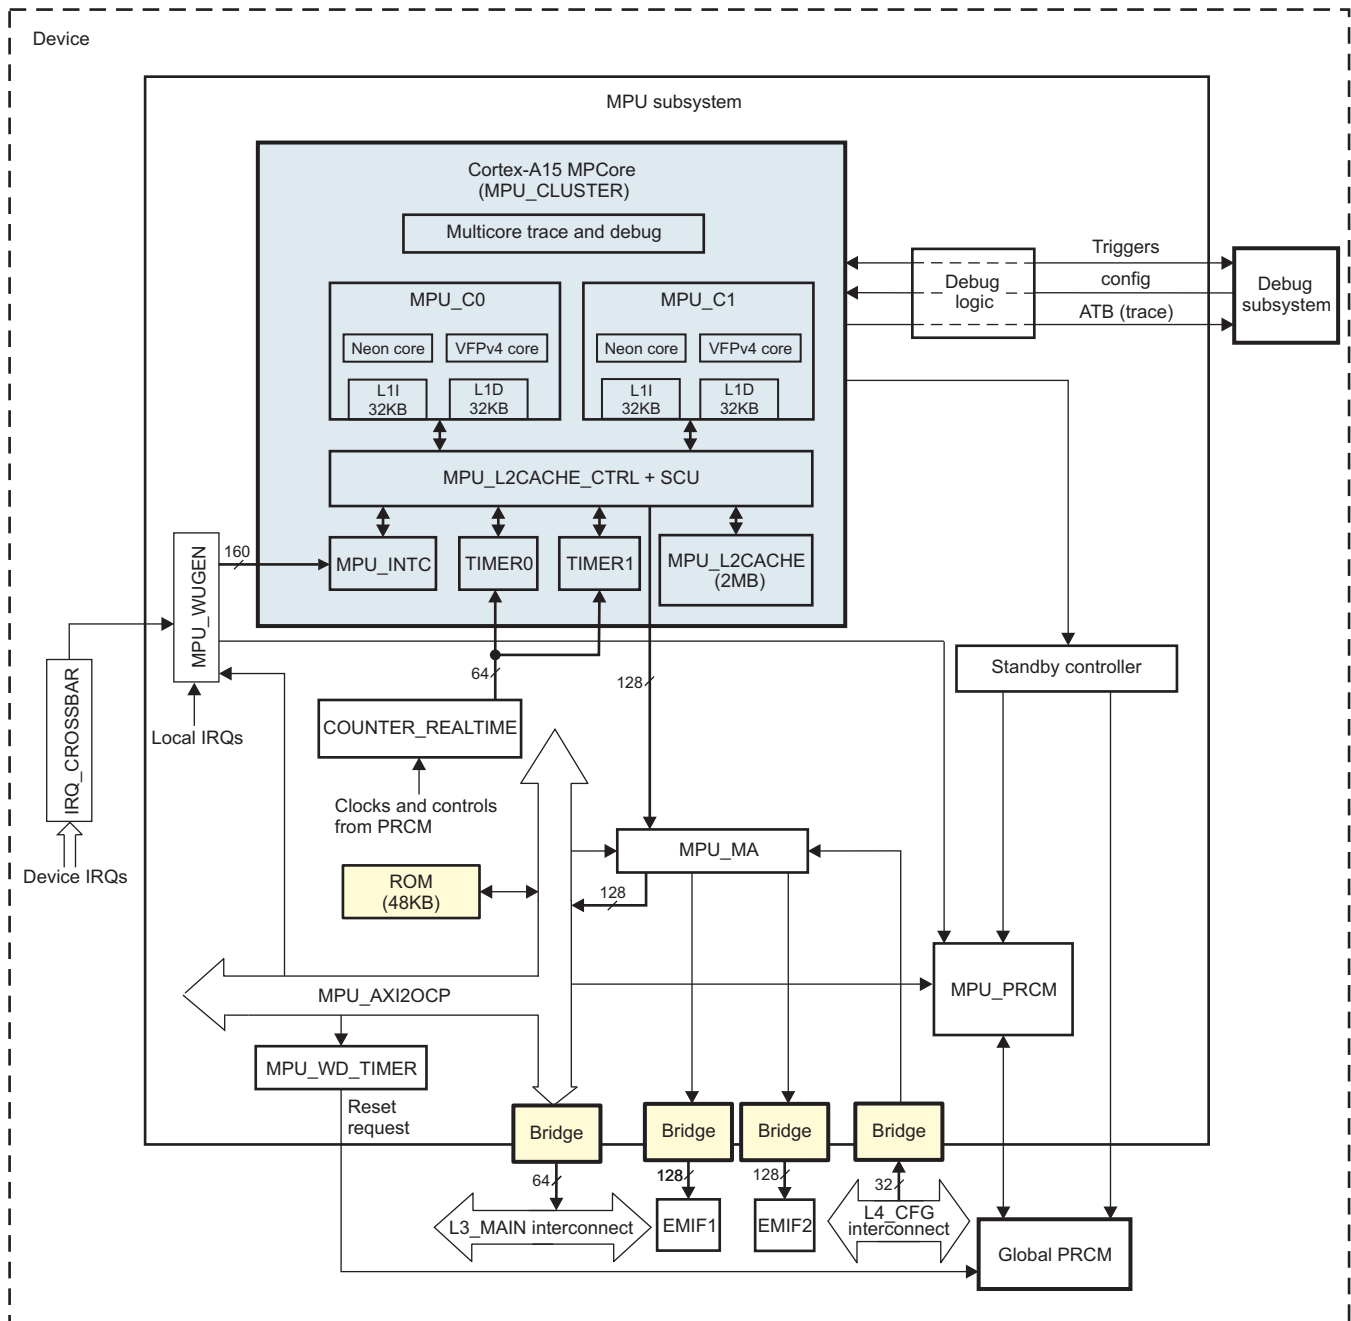

For more information about clocks, resets, and power domains, and the MPU\_PWRON\_RST and MPU\_RST reset signals, see [Chapter 3, Power, Reset, and Clock Management](#).

### 4.3 Dual Cortex-A15 MPU Subsystem Functional Description

#### 4.3.1 MPU Subsystem Block Diagram

Figure 4-5 shows the block diagram of the MPU subsystem.

Figure 4-5. MPU Subsystem Block Diagram

#### 4.3.2 Cortex-A15 MPCore (MPU\_CLUSTER)

The MPU\_CLUSTER consists of:

- Two CPUs (dual-core configuration), including:
  - Arm version 7 ISA: Standard Arm instruction set plus Thumb®-2, Jazelle® RCT, and Jazelle DBX Java™ accelerator

- Neon SIMD coprocessor and VFPv4
- 12-stage in-order MPU core pipeline
- 128-bit-wide instruction fetch allows fetching up to four instructions/cycle
- 32 KiB/32 KiB instruction and data cache for each MPU core
- Complex Execution Unit (FPU) per MPU core
- 32-entry fully-associative micro-TLB each for instruction and data per MPU core
- 512-entry 4-way set-associative unified TLB per MPU core
- Unified L2 cache control including tags
- Interrupt controller (MPU\_INTC)
  - Supports 160 hardware interrupts. For more information about interrupt mapping, see [Chapter 17, Interrupt Controllers](#).
- One timer and watchdog timer per MPU core
- Internal APB bridge that connects to the APB port of each MPU core

The major interfaces of the MPU\_CLUSTER are:

- Single AXI master supporting 128-bit interface
- System coherency supported through the AXI4 ACE interface
- An ATB port (for processor trace)
- An APB port
- Interrupt request lines

---

**NOTE:** The following hardware restrictions/limitations are applied to the Cortex-A15 MPCore in this device:

- Not implemented features:
  - ACP port to support hardware coherency with external master
  - ECC/parity support for the L1 or L2 caches
- Supported ACE configurations:
  - **AXI3** mode (default). In this configuration, barrier transactions are not issued on the AMBA4 interface.
  - **ACE non-coherent, no L3** mode. In this configuration, barrier transactions are issued on the AMBA4 interface.

For more information about AMBA4 interface configuration, see [Section 4.3.8, MPU Subsystem AMBA Interface Configuration](#).

---

For more information about Cortex-A15 MPCore, see the *Arm Cortex-A15 MPCore Technical Reference Manual* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).

#### 4.3.2.1 MPU L2 Cache Memory System

The MPU subsystem implements an L2 memory system. This memory system consists of an L2 cache (MPU\_L2CACHE) and associated L2 cache controller (MPU\_L2CACHE\_CTRL). The MPU L2 cache controller runs at full-CPU speed and is configured to have one 128-bit master port. The L2 cache controller is configurable via CP15 registers and is tightly coupled to the L1 memory system. The MPU L2 memory system supports Arm Instruction Set Architecture (v7).

MPU L2 supports hardware cache coherency, but is used in a limited way in the device. Because the rest of the system does not support coherency with the MPU L2 cache, software coherence is required.

The L2 cache size on the MPU subsystem is 2 MiB. The cache is configured as 16-way set associative, with 64-B line size. The L2 cache controller performs critical word-first-refilling with a random or pseudo-random cache replacement policy.

The L2 includes logic to support cache event monitoring. The events being monitored are routed to the hardware debug (MPUHWDBGOUT[31:0]) port. The mapping of these events to the MPUHWDBGOUT[31:0] port is described in the *Control Module* chapter.

The L2 can be configured to generate interrupts on error conditions or event counter overflow/increment. The L2 interrupt (MPU\_CLUSTER\_IRQ\_AXIERR) is mapped to interrupt line MPU\_IRQ\_3. When an interrupt occurs, software may look at corresponding interrupt register to determine the source of the interrupt.

#### **4.3.2.1.1 MPU L2 Cache Architecture**

The main features of the MPU\_L2CACHE are:

- 2048-KiB 16-way set-associative unified instruction/data cache
- 9-stage L2 pipeline
- L2 hit latency of 12 cycles
- Fixed line length of 64-bytes (16 words)
- L1 inclusive
- Physically indexed and tagged
- 16-way set-associative (maximum)
- Bank partitions to support streaming Neon loads and simultaneous (two) L2 requests
- Exclusive-D L2 cache fill policy
- Global-random replacement strategy
- Four dirty bits per cache line to minimize traffic to L3
- Low-leakage sleep mode (retention until accessed)
- Cache redundancy and repair

#### **4.3.2.1.2 MPU L2 Cache Controller**

The main features of the MPU\_L2CACHE\_CTRL are:

- Single 128-bit AXI4 master port interface
- Tightly coupled L2/SCU for better L2 hit latency
- Nonblocking: Supports hit-under-miss and miss-under-miss for Neon requests
- Performs critical data first refilling
- Supports the following cache modes:
  - Write-through, read allocate
  - Write-back, read allocate, and write allocate
- Supports write-combining to two independently tagged quad-words
- 12 × 128-bit write buffers to buffer subblock writes (per MPU core)
- 12 × 128-bit ACP write buffer (shared across MPU cores)
- 16-entry × 512-bit victim buffers (shared across MPU cores)
- Separate 128-bit interfaces to the I-side and the D-side:
  - Four beat (128-bit) transfers to refill L1 from L2 (or 128-bit AXI)
  - Eight beat (64-bit) transfers to refill L1 from AXI
- 128-bit subblock write and copy-back interface on the D-side
- Outstanding transactions on the AXI4 master port:
  - 16 read
  - 16 write
- Performs hardware table walk using the L2 unified TLB

**NOTE:** The Cortex-A15 processor memory system treats all write-through (WT) accesses as 'write-through, no-allocate'. This means that no cache line from any write-through page allocates in any L1 data or L2 cache. This implies that write-through lines are implemented as non-cacheable in Cortex-A15. Memory requests for write-through cache lines are not looked-up in the L1D or L2, and are sent directly to the AXI master interface. Not caching WT lines was done primarily to avoid back-and-forth L1/L2 snoop invalidations and increasing interconnect traffic when more than one CPU attempts to write to the same WT line. Coherency traffic is greatly reduced in an MP configuration when WT data is treated as 'write-through, no-allocate'.

For non-cacheable and WT memory, all Cortex-A15 memory read requests are 64 bytes. A15 over-reads and then allows forwarding of the data to multiple load instructions. If there is only a single load request for that line, there is no latency hit (since Cortex-A15 does critical word first) although there is potentially an increase in bus power. If there are multiple hits due to consecutive loads of data within the same line, there is a possibility of significant performance gains.

### 4.3.3 MPU\_AXI2OCP

MPU\_AXI2OCP provides a protocol bridge between buses and also serves as a small local interconnect to:

- Handle traffic to the L3\_MAIN interconnect
- Configure local configuration registers in the MPU subsystem

Main features of MPU\_AXI2OCP:

- Connects to the L3\_MAIN interconnect through a 64-bit port. The interface frequency is configurable between one fourth (default value) and one eighth of the MPU\_DPLL\_CLK clock signal frequency. This is programmable in the global PRCM register CM\_MPU\_MPU\_CLKCTRL[25:24] CLKSEL\_EMIF\_DIV\_MODE bit. For CM\_MPU\_MPU\_CLKCTRL register description, see [Chapter 3, Power, Reset, and Clock Management](#)
- Connects to the CS\_STM module through a 32-bit AXI interface (for software instrumentation)
- Connection to the following modules for register configuration:
  - MPU\_MA
  - MPU\_PRCM
  - MPU\_WUGEN
  - MPU\_WD\_TIMER
- Contains internal configuration register related to the MPU\_MA function ([MA\\_PRIORITY](#))
- Supports memory barrier instruction
- Supports single-request-multiple-data (data handshaking) burst mode to pipeline requests
- Supports multiple outstanding requests
- Supports posted and nonposted write transactions, based on the attributes of the transactions coming from the Cortex-A15 processor. Software can override all writes from the MPU\_AXI2OCP to the L3\_MAIN interconnect to be nonposted, regardless of the attributes of the transactions coming from the Arm Cortex-A15 processor, by setting the Control Module register CTRL\_CORE\_MPU\_FORCEWRNP[0] MPU\_FORCEWRNP bit to 0x1. This bit must not be changed until the transfer completes. For CTRL\_CORE\_MPU\_FORCEWRNP register description, see [Chapter 18, Control Module](#).

## 4.3.4 Memory Adapter

### 4.3.4.1 MPU\_MA Overview

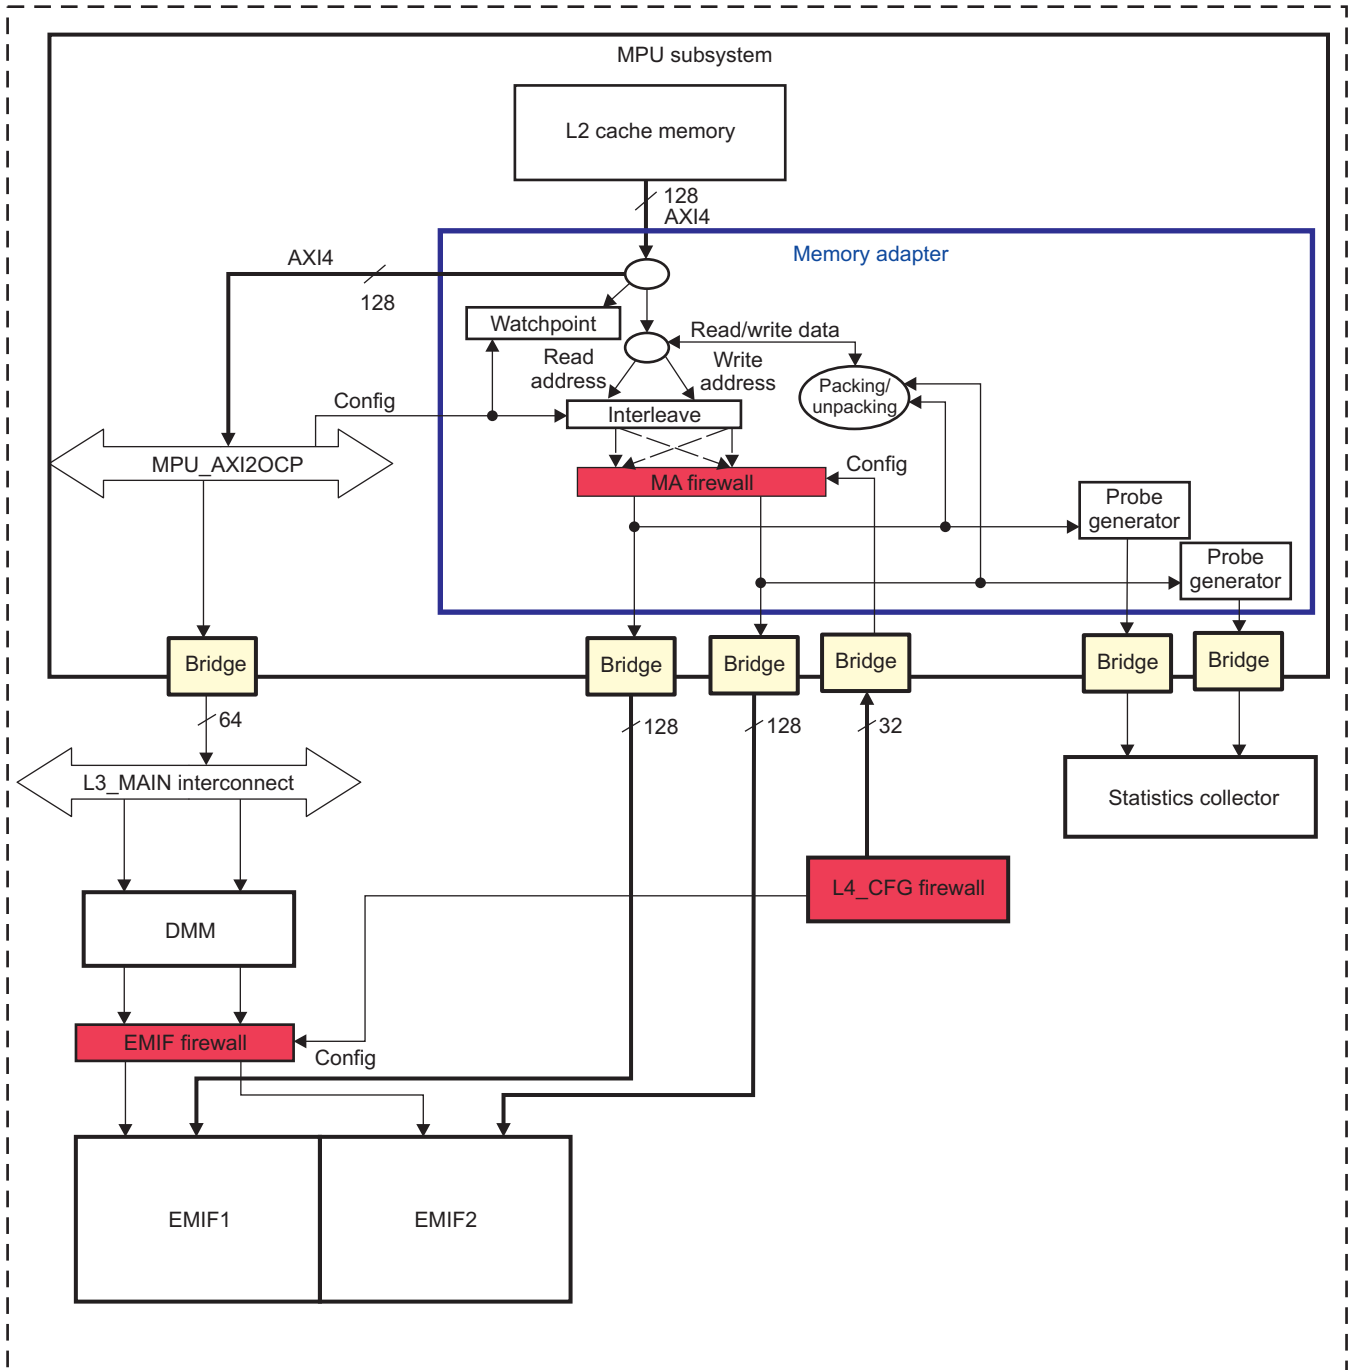

To decrease the latency of accesses between the MPU L2 cache, and the two EMIF modules, a direct path between the MPU subsystem and the EMIFs is created. This direct path is supported by a memory adapter (MPU\_MA) module. The MPU\_MA splits the incoming (from L2 cache) AXI4 traffic into MPU\_AXI2OCP and EMIF accesses. The MPU\_AXI2OCP accesses are sent to the memory adapter A2O ports. The EMIF accesses are optionally interleaved between the two EMIF ports. Mandatory firewall checks are performed on all accesses to the EMIFs.

The main features of the MPU\_MA are:

- Splits accesses between the MPU\_AXI2OCP and the EMIF
- Input from L2 cache and output to MPU\_AXI2OCP is AMBA4-compatible and runs at half the Cortex-A15 CPU frequency
- Supported read response interleaving on A2O port
- Parallel processing of reads and writes
- Support for narrow bursts
- Supports 4 × 128-bit line fills and eviction with critical word first
- Supports barrier instructions on normal read and write channels
- Direct 128-bit interfaces to each of EMIF1 and EMIF2:
  - Single request multiple data
  - No write response on posted writes
- Performs interleaving functions to load-balance the activities across the two EMIFs
- Uses firewall logic to check access rights of incoming addresses. The firewall on both EMIFs supports:
  - Configurable number of regions with fixed priority
  - Access support for up to eight execution domains
  - Busy indicator during reconfiguration
- Blocked read and write access to the EMIF for all accesses failing authorization checks
- Burst wrap for single cache line fills
- Supports boot from EMIF space
- Supports 8 GiB of memory. 6GiB accessible only by the MPU (MPU-only memory) and 2GiB shared among the system. Only 4 GiB are physically available on this device. 2GiB accessible only by the MPU and 2 GiB shared among the system.
- MA\_LSM supports programmable interleaving for 2 GiB of shared memory:
  - Programmable multizone DRAM mapping and interleaving configuration
  - Supports four prioritized sections for defining configuration regions within the external memory
  - Supports interleaving at 128-, 256-, and 512-byte boundaries
- Fixed interleaving for extended 6 GiB of MPU-only memory
- Supports standard disconnect and idle protocols for independent powering down of the MPU\_MA and both EMIFs (the EMIF must be powered down or up as a pair)
- Probe interface for performance monitoring of the EMIF ports
- 11 outstanding reads and 16 outstanding writes
- Supports exclusive accesses used for MPU internal synchronization
- Provides watchpoint capability on AXI bus. For more information, see [Section 4.3.4.7](#).

Figure 4-6 shows the integration of the MPU\_MA in the device.

Figure 4-6. MPU\_MA Overview

#### 4.3.4.2 AXI Input Interface

The AXI input is driven from the single external port of the L2 cache. The incoming accesses are directed to the MPU\_AXI2OCP module through the A2O port or begin their processing for a potential EMIF access. The routing of accesses is based on the AXI address and the EMIF boot input (pi\_emifboot).

Table 4-2 lists the AXI access memory mapping. If the accesses are targeted for the MPU\_AXI2OCP, then they are registered and sent to the A2O port without any alterations in its attributes (size, ID, etc.). The reserved space in the lower order memory area is a result of providing 8 GiB of continuous space for all the nonaliased regions.

The EMIF memory space is broken into eight 1-GiB sections, which are denoted *emif(a)* through *emif(h)*. This partitioning helps to specify the aliasing of several memory ranges. It also aids in the discussion of how the MPU memory space is mapped into the physical EMIF space.

---

**NOTE:** Although the MPU has 8-GiB EMIF dedicated memory space, only 4 GiB are used. 4 GiB is the total of physically available SDRAM for this device.

---

It is expected that the OS uses either the lower 2-GiB space and the lower aliased address of *emif(a)* and (b), or the continuous 8-GiB space and the upper aliasing of the *emif(a)* and (b) for all EMIF accesses.

**Table 4-2. AXI Access Memory Mapping**

Region Name	Start Address	End Address	Interleaving	MPU_MA Action
Boot space	0x00 0000 0000	0x00 000F FFFF	Default	Sent to Firewall/EMIF, if <i>pi_emifboot</i> = 1
			N/A	Sent to A20 port, if <i>pi_emifboot</i> = 0
Non-emif	0x00 0010 0000	0x00 7FFF FFFF	N/A	Sent to A20 port
Emif(a)	0x00 8000 0000	0x00 BFFF FFFF	Programmable	Aliased to address range 0x02 8000 0000–0x02 FFFF FFFF
Emif(b)	0x00 C000 0000	0x00 FFFF FFFF	Programmable	
Reserved	0x01 0000 0000	0x01 FFFF FFFF	N/A	DECERR returned
Emif(c)	0x02 0000 0000	0x02 3FFF FFFF	Fixed	Sent to Firewall/EMIF
Emif(d)	0x02 4000 0000	0x02 7FFF FFFF	Fixed	Sent to Firewall/EMIF
Emif(a)	0x02 8000 0000	0x02 BFFF FFFF	Programmable	Sent to Firewall/EMIF
Emif(b)	0x02 C000 0000	0x02 FFFF FFFF	Programmable	Sent to Firewall/EMIF
Emif(g)	0x03 0000 0000	0x03 3FFF FFFF	Fixed	Sent to Firewall/EMIF
Emif(h)	0x03 4000 0000	0x03 7FFF FFFF	Fixed	Sent to Firewall/EMIF
Emif(e)	0x03 8000 0000	0x03 BFFF FFFF	Fixed	Sent to Firewall/EMIF
Emif(f)	0x03 C000 0000	0x03 FFFF FFFF	Fixed	Sent to Firewall/EMIF
Reserved	0x04 0000 0000	0xFF FFFF FFFF	N/A	DECERR returned

#### 4.3.4.3 Interleaving

To load-balance the activities across the two EMIFs, interleaving is used. For the lower 2-GiB address space, which is shared between the system and the MPU, a wide range of interleaving options are provided using the *MA\_LISA\_MAP\_i* registers. Because the EMIF memories are accessible by the MPU subsystem through *MPU\_MA* and by the *L3\_MAIN* interconnect through the DMM, the same interleaving scheme must be used in both paths. To ensure compatibility, the interleaving function is implemented by a scaled down version of the LISA Section Manager (LSM), which implements the interleaving function in the DMM.

The high-order memory space, which is accessible only from the MPU subsystem, uses a simple fixed-interleaving scheme, which can be disabled. Heavy use in high memory space under noninterleaved configuration affects the balancing of the system access in lower-order memory.

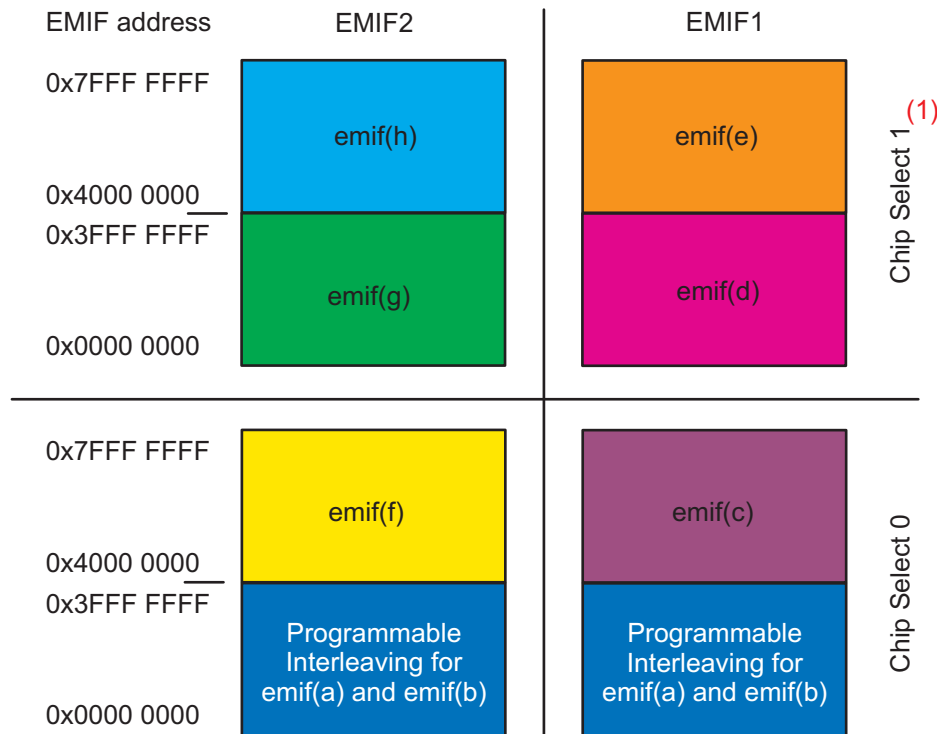

##### 4.3.4.3.1 High-Order Fixed Interleaving Model

The memory address ranges *emif(c)* through *emif(h)* can be interleaved between the two EMIFs by setting the *MA\_PRIORITY*[8] *HIMEM\_INTERLEAVE\_UN* bit to 0x1. If enabled, this high-order interleaving occurs on a fixed 256-byte boundary, unlike *emif(a)* and *emif(b)* programmable interleaving which can be configured to 128-, 256-, and 512-byte boundary through the *MA\_LISA\_MAP\_i*[19:18] *SDRC\_INTL* bit field and is enabled through the *MA\_LISA\_MAP\_i* [9:8] *SDRC\_MAP* bit field.

Figure 4-7 and Figure 4-8 show how sections emif(a) through emif(h) are mapped into the EMIF1 and EMIF2 address spaces. The MA\_LISA\_MAP\_i registers can be programmed to allow emif(a) and emif(b) address ranges to be remapped anywhere in EMIF1 or EMIF2 address spaces. Restricting EMIF1 and EMIF2 address spaces to the locations 0x0000 0000–0x7FFF FFFF allows the fully programmable emif(a) and emif(b) regions to co-exist with the fixed interleaving regions (emif(c) through emif(h)) without overlap. Although it is not recommended, the user can program the interleaver to map the emif(a) and emif(b) address ranges to the EMIF 0x8000 0000–0xFFFF FFFF location. If this is done, then additional address aliasing exists between emif sections (a/b) and sections (c) through (h).

**NOTE:** In fixed interleaving, memory address space 0 is always used.

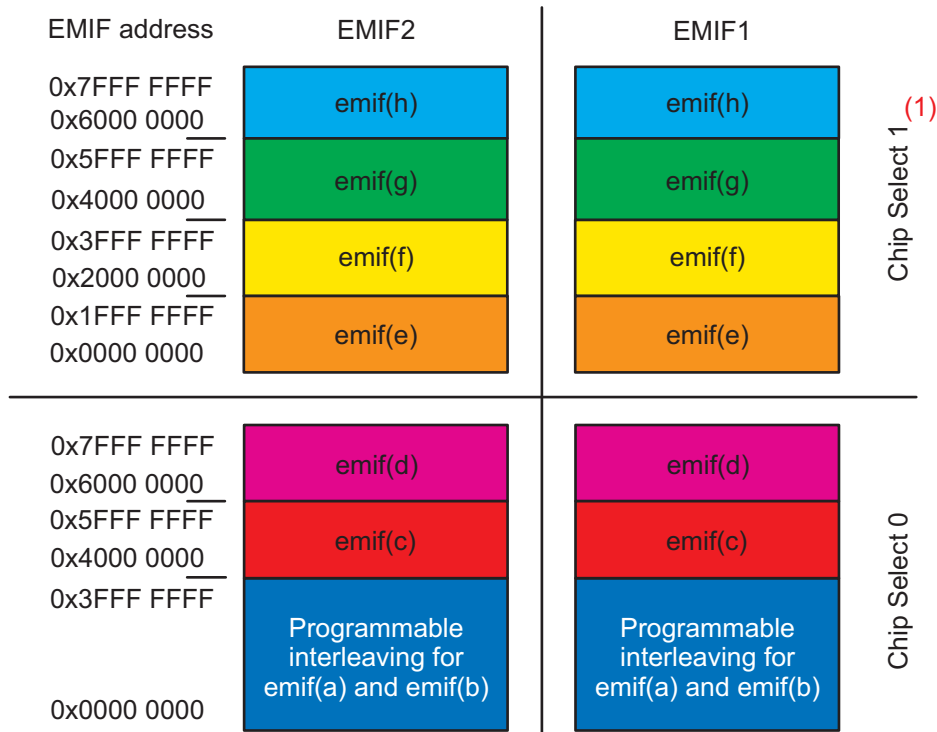

**Figure 4-7. Fixed MPU-to-EMIF Address Mapping Without High-Order Interleaving**

(1) Chip select 1 is not supported on this device

mpu\_a15-007

**Figure 4-8. Fixed MPU-to-EMIF Address Mapping With High-Order Interleaving**

(1) Chip select 1 is not supported on this device

mpu\_a15-008

#### 4.3.4.3.2 Lower 2-GiB Programmable Interleaving Model

For more information about the lower 2-GiB programmable interleaving model of the MA\_LSM, see the *Dynamic Mapping*, and *Address Mapping* sections in [Section 15.2, Dynamic Memory Manager](#). When reading, replace DMM with MA\_LSM.

**NOTE:** The MA\_LSM is associated with the lower 2GiB shared memory space, that is, emif(a) and emif(b). In this case there is programmable interleaving (128B, 256B and 512B) and programmable MPU-to-EMIF address mapping configured through the MA\_LISA\_MAP\_i registers.

The MA\_LSM is NOT associated with the 6GiB of MPU-only memory, that is, Emif(c) through Emif(h). In this case there is fixed interleaving (256B only) and fixed MPU-to-EMIF address mapping which cannot be programmed using the MA\_LISA\_MAP\_i registers because MA\_LSM is not used with address ranges greater than 2GiB. The fixed MPU-to-EMIF address mapping is shown in [Figure 4-7](#) and [Figure 4-8](#).

#### 4.3.4.3.3 Local Interconnect and Synchronization Agent (LISA) Section Manager

The LSM module in the MPU\_MA contains one set of registers and two ports. Each port can handle one address translation, provide the interface size, and determine the EMIF mapping. The two ports process read and write addresses simultaneously. The MA\_LSM supports four sections.

#### 4.3.4.3.4 MA\_LSM Registers

[Table 4-3](#) lists the DMM registers that are duplicated locally in the MPU\_MA. These registers have the same names except that DMM is replaced by MPU\_MA. Software must keep the content of these registers equal to the content of their counterparts in the DMM.

**Table 4-3. MPU\_MA Registers Duplicated From the DMM Register Map**

Register	Type	Width (Bits)	Base Address
MA_LISA_LOCK	RW	32	0x482A F01C
MA_LISA_MAP_i (where i = 0 to 3)	RW	32	0x482A F040–0x482A F04C

For descriptions of the registers, see [Section 15.2, Dynamic Memory Manager](#). The only differences are the following reset values of the MA\_LISA\_MAP\_0 register:

- MA\_LISA\_MAP\_0[22:20] SYS\_SIZE = 0x1 (32-MiB section)
- MA\_LISA\_MAP\_0[17:16] SDRG\_ADDRSPC = 0x1
- MA\_LISA\_MAP\_0[9:8] SDRG\_MAP = 0x1

The configuration of the MPU\_MA must be programmed by the Cortex-A15 MPU to match the configuration of the DMM during boot. The registers must be locked after initial programming to avoid corruption by application software. When the SM configuration registers are being programmed, there are no interlocks or safeguards to prevent accesses from being processed at the same time. The MA\_LISA\_LOCK and MA\_LISA\_MAP\_i registers are retained during power down of retention mode.

If an access is made to a region marked as having unused address space or an unmapped SDRG map, no access is made to the EMIF and an error is returned. If an access is made to a region marked as accesses-SDRG-internal-registers, no access occurs to the EMIF and an error is returned. This is because the internal registers are not accessible from this port.

If an access is made to a region that is not mapped to any LISA section, or selects a section with one of the following programmations, then no access is made to the EMIF and an error is returned on the AXI port:

- SDRG\_MAP field equal to UNMAPPED
- SDRG\_ADDRSPC field equal to UNUSED

#### 4.3.4.3.5 Posted and Nonposted Writes

On posted writes, a response is returned after all write data is accepted by the MPU\_MA and one of the following occurs:

- The request is canceled, because of an interleaving error.
- The request is pushed into the firewall FIFO.

On nonposted writes, a response is not returned until after all write data is accepted by the MPU\_MA and one of the following occurs:

- The request is canceled, because of an interleaving error.
- The request has a firewall violation.
- The associated response is received from the EMIF (access is completed in the EMIF).

When the FORCEWRNP[0] MPUFORCEWRNP bit is set to 0x1, all writes are forced to be converted to nonposted writes (prevents posted writes).

#### 4.3.4.3.6 Errors

If the region is marked as unmapped, or targets EMIF internal registers or reserved space, access is blocked and an error response is returned. Such an error occurs on the first half of a potential split access and aborts the entire access at that time. DECERR errors ultimately generate Arm aborts. See the Arm Fault Status Register for more information.

To avoid undefined results, the following program rules must be followed:

- A section cannot be mapped as interleaving (MA\_LISA\_MAP\_i[9:8] SDRG\_MAP = 0x3), and the MA\_LISA\_MAP\_i[19:18] SDRG\_INTL bit field must be equal to 0x0.
- If the section maps to a single EMIF (MA\_LISA\_MAP\_i[9:8] SDRG\_MAP = 0x1 or 0x2), the MA\_LISA\_MAP\_i[7:0] SDRG\_ADDR bit field must be aligned to the MA\_LISA\_MAP\_i[22:20] SYS\_SIZE bit field (that is, the lower SDRG\_ADDR bits must be 0).

- If the section maps to both EMIFs (MA\_LISA\_MAP\_i[9:8] SDRC\_MAP = 0x3), the MA\_LISA\_MAP\_i[7:0] SDRC\_ADDR bit field must be aligned to MA\_LISA\_MAP\_i[22:20] SYS\_SIZE – 1, because the addressable space for each EMIF is half.
- If the section maps to both EMIFs (MA\_LISA\_MAP\_i[9:8] SDRC\_MAP = 0x3), the MA\_LISA\_MAP\_i[22:20] SYS\_SIZE bit field cannot be 0.

#### 4.3.4.4 Statistics Collector Probe Ports

To enable performance monitoring by the debug subsystem, a subset of interconnect signals must be monitored and sent to a statistics collector in the CORE domain. For more information about the statistics collector, see [Chapter 33, On-Chip Debug Support](#) chapter.

#### 4.3.4.5 MPU\_MA Firewall

A firewall (MA\_MPU\_NTTP\_FW) exists between the interleaving logic and each EMIF port. The firewall checks the address and access qualifiers against the permission attributes for the highest priority region to which the address belongs. If the access fails to get permission, a violation occurs and the fw\_func\_error or fw\_debug\_error output is asserted. The failing access is blocked and a slave error response is returned on the MPU\_MA port for read and nonposted accesses. For more information about the MPU\_MA firewall, see [Chapter 14, Interconnect](#).

#### 4.3.4.6 MPU\_MA Power and Reset Management

The MA\_LSM supports only smart-idle mode.

#### 4.3.4.7 MPU\_MA Watchpoint

The MPU\_MA implements a Watchpoint unit (MPU\_MA\_WP) attached to its AXI input interface and thus allowing the user to track certain AXI transactions. The MPU\_MA\_WP can be programmed to generate a trigger when a specified AXI transaction (or a chain of AXI transactions) satisfies a set of user-defined attributes. Upon triggering (that is, upon transaction match), additional information about the target transaction is captured in dedicated log registers.

##### 4.3.4.7.1 Watchpoint Types

The MPU\_MA\_WP supports three types of watchpoints:

- Data watchpoint
- Memory barrier watchpoint
- Chained watchpoint (combination of data watchpoint and memory barrier)

Two types of chaining are supported based on the configuration of the [DBG\\_HWWP0\\_CHAIN\\_CNTL\[1\] CHAIN\\_TYPE](#) bit:

- Data watchpoint match *followed* by memory barrier match
- Data watchpoint match *preceded* by memory barrier match

Chaining is enabled by setting the [DBG\\_HWWP0\\_CHAIN\\_CNTL\[0\] CHAIN\\_WP\\_EN](#) bit to '1'. Note that both the data watchpoint and the memory barrier must also be subsequently enabled (by setting the [DBG\\_HWWP0\\_MAIN\\_CNTL\[0\] WP\\_EN](#) and [DBG\\_HWWP0\\_MEM\\_CNTL\[0\] MEM\\_BAR\\_WP\\_EN](#) bits, respectively) for chaining to work. To avoid race conditions and partial matches, no chained match may occur until the complete chain of watchpoints has been fully enabled.

##### 4.3.4.7.2 Transaction Filtering Options

The following filtering options can be specified for a **data watchpoint match** condition (via the [DBG\\_HWWP0\\_MAIN\\_CNTL](#) and [DBG\\_HWWP0\\_AUX\\_CNTL](#) registers):

- Address within or outside a specific range
- Various access types:
  - Read or Write (non-posted/posted/either) or any (no preference)

- Supervisor or User or any (no preference)
- Data or Instruction or any (no preference)
- MPU\_MA target: AXI2OCP bridge or EMIF or any (no preference)
- Initiator: CPU0 or CPU1 or unknown source (ACP, FEQ, etc.) or any (no preference)

The following filtering options can be specified for a **memory barrier match** condition (via the [DBG\\_HWWP0\\_MEM\\_CNTL](#) register):

- Type of memory barrier instruction: DSB or DMB or any (no preference)
- Type of memory barrier access: Read or Write or any (no preference)

#### 4.3.4.7.3 Transaction Match Effects

The following information concerns transaction attributes logging depending on the transaction match:

- **Data watchpoint match:** When a data watchpoint matches, the following transaction attributes are logged irrespective of the target of the transaction (not all attributes may be applicable for all targets):
  - 40-bit AXI physical address of the transaction
    - Related log registers: [DBG\\_HWWP0\\_HG\\_ADDR0\\_LOG](#) and [DBG\\_HWWP0\\_LW\\_ADDR0\\_LOG](#)
  - 128-bit data associated to the *n*-th beat of the burst transaction, where *n* is configured by the user (before enabling the watchpoint) in the [DBG\\_HWWP0\\_MAIN\\_CNTL](#)[23:20] BEAT\_SEL bit field
    - Related log registers: [DBG\\_HWWP0\\_DATA0\\_LOG](#), [DBG\\_HWWP0\\_DATA1\\_LOG](#), [DBG\\_HWWP2\\_DATA0\\_LOG](#), and [DBG\\_HWWP3\\_DATA0\\_LOG](#)
  - Byte Enable: Specifies the 16 data byte enables associated with the up to 128-bit data captured
    - Related log register: [DBG\\_HWWP0\\_DATA\\_TRANS\\_ATTR0\\_LOG](#)[15:0] BYTE\_EN
  - Initiator Info: Specifies which initiator generated the transaction
    - Related log register: [DBG\\_HWWP0\\_TRANS\\_ATTR0\\_LOG](#)[22:20] INIT\_INFO
  - Response Info: Specifies whether the response indicates transaction success or failure
    - Related log register: [DBG\\_HWWP0\\_TRANS\\_ATTR0\\_LOG](#)[25:24] RESP\_INFO
  - Target Info: Specifies the target of the access
    - Related log register: [DBG\\_HWWP0\\_TRANS\\_ATTR0\\_LOG](#)[18:16] TARGET\_INFO
  - Transaction Type: Specifies the type of the transaction which matches
    - Related log register: [DBG\\_HWWP0\\_TRANS\\_ATTR0\\_LOG](#)[12:10] TRANS\_TYPE
  - Burst Length (1..63)
    - Related log register: [DBG\\_HWWP0\\_TRANS\\_ATTR0\\_LOG](#)[9:4] BURST\_LENGTH
  - Burst Type: Specifies the type of the burst (only relevant if Burst Length > 1)
    - Related log register: [DBG\\_HWWP0\\_TRANS\\_ATTR0\\_LOG](#)[2:0] BURST\_TYPE
  - Additional attributes, such as:
    - Data/Instruction access ([DBG\\_HWWP0\\_TRANS\\_ATTR1\\_LOG](#)[2] DATA)
    - Supervisor/User access ([DBG\\_HWWP0\\_TRANS\\_ATTR1\\_LOG](#)[1] SUPERVISOR)
- **Memory barrier watchpoint match:** When a memory barrier watchpoint matches, transaction attributes logged are those of the transaction immediately following the memory barrier
- **Chained watchpoint match:** When a chained watchpoint matches (which implies that both memory barrier and data watchpoint have matched), transaction attributes logged are those of the transaction of the matching data watchpoint

#### 4.3.4.7.4 Trigger Generation

The user can configure the MPU\_MA\_WP unit to generate a trigger upon watchpoint match. The MPU\_MA\_WP has a single trigger output (MA\_WP\_TRIGGER) which is mapped to the CTITRIGIN[6] input of the CS\_CTI\_S module and is shared by the following trigger sources:

- **Data watchpoint trigger:** Upon data watchpoint match, the [DBG\\_HWWP0\\_MAIN\\_CNTL](#)[31] TRIG bit is set (if trigger generation is enabled). This status bit is cleared upon 0->1 transition of the

[DBG\\_HWWP0\\_MAIN\\_CNTL\[0\]](#) WP\_EN bit

- **Memory barrier watchpoint trigger:** Upon memory barrier match, the [DBG\\_HWWP0\\_MEM\\_CNTL\[31\]](#) MEM\_BAR\_TRIG bit is set (if trigger generation is enabled). This status bit is cleared upon 0->1 transition of the [DBG\\_HWWP0\\_MEM\\_CNTL\[0\]](#) MEM\_BAR\_WP\_EN bit
- **Chained watchpoint trigger:** Upon chained watchpoint match, the [DBG\\_HWWP0\\_CHAIN\\_CNTL\[31\]](#) CHAIN\_WP\_TRIG bit is set (if trigger generation is enabled). This status bit is cleared upon 0->1 transition of the [DBG\\_HWWP0\\_CHAIN\\_CNTL\[0\]](#) CHAIN\_WP\_EN bit

Note that the MPU\_MA\_WP module supports only a global enable (by setting the [TRIG\\_CTRL\[0\]](#) TRIG\_EN bit) for all three sources listed above. It is SW responsibility to identify the source of the trigger generation by checking the corresponding trigger status bits.

#### 4.3.4.7.5 Programming Options Summary

Below is a summary of the MPU\_MA\_WP programmable options:

- Match on a data watchpoint only:
  - Configure the [DBG\\_HWWP0\\_MAIN\\_CNTL](#) register
  - Configure the [DBG\\_HWWP0\\_AUX\\_CNTL](#) register
  - Set the [DBG\\_HWWP0\\_MAIN\\_CNTL\[0\]](#) WP\_EN bit to enable data watchpoint
- Match on a memory barrier only:
  - Configure the [DBG\\_HWWP0\\_MEM\\_CNTL](#) register
  - Set the [DBG\\_HWWP0\\_MEM\\_CNTL\[0\]](#) MEM\_BAR\_WP\_EN bit to enable memory barrier
- Match on a data watchpoint chained with a memory barrier:
  - Configure the [DBG\\_HWWP0\\_CHAIN\\_CNTL\[1\]](#) CHAIN\_TYPE bit to chain data watchpoint *before* memory barrier or data watchpoint *after* memory barrier.
  - Set the [DBG\\_HWWP0\\_CHAIN\\_CNTL\[0\]](#) CHAIN\_WP\_EN bit to enable the chain (but both the memory and data watchpoints must also be subsequently enabled)
  - Configure the [DBG\\_HWWP0\\_MAIN\\_CNTL](#) register
  - Configure the [DBG\\_HWWP0\\_AUX\\_CNTL](#) register
  - Set the [DBG\\_HWWP0\\_MAIN\\_CNTL\[0\]](#) WP\_EN bit to enable data watchpoint
  - Configure the [DBG\\_HWWP0\\_MEM\\_CNTL](#) register
  - Set the [DBG\\_HWWP0\\_MEM\\_CNTL\[0\]](#) MEM\_BAR\_WP\_EN bit to enable memory barrier

### 4.3.5 Realtime Counter (Master Counter)

#### 4.3.5.1 Counter Operation

The real-time counter (COUNTER\_REALTIME) is a free-running counter which produces the count used by the private timer peripherals in the MPU\_CLUSTER. For this reason, it is also called Master Counter.

COUNTER\_REALTIME supports two modes of operation:

- **Active (FUNC):** This is the normal mode in which the counter runs
- **Sleep / Low-Power (LP):** The counter automatically switches to this mode when the MPU subsystem goes to standby mode

COUNTER\_REALTIME has two clock inputs:

- **32K (slow) clock:** This is the FUNC\_32K\_CLK (SYSCLK1/610) clock
- **System (fast) clock:** This is the WKUPAON\_ICLK clock (coming from the global PRCM). The two sources for this clock are:
  - SYS\_CLK1: Main system clock of the SoC. Supported frequencies are: 19.2, 20, and 27 MHz
  - ABE\_LP\_CLK: Clock derived from DPLL\_ABE, used in some low-power use cases; runs at 12.288 MHz (DPLL cascading)

COUNTER\_REALTIME implements two internal counters: a 40-bit coarse counter, and a 48-bit system counter.

The coarse counter is driven by the FUNC\_32K\_CLK clock. The coarse counter is the only one running in LP mode (the system counter is off in LP mode) and it is also used in FUNC mode as a timebase reference for the system counter. During active mode, the coarse counter value is multiplied by 375/2. This effectively shifts left the base counter value. This initial value is output to the CPUs and is also fed back into the circuit.

The system clock is running in parallel to the 32K clock and it drives the active mode circuit of COUNTER\_REALTIME, which includes the following basic blocks:

- 48-bit system counter
- 12-bit fractional incrementor. It has the following input parameters:
  - Numerator (N) for SYS mode: [PRM\\_FRAC\\_INCREMENTER\\_NUMERATOR](#) [11:0] SYS\_MODE\_NUMERATOR
  - Numerator for ABE\_LP mode: [PRM\\_FRAC\\_INCREMENTER\\_NUMERATOR](#) [27:16] ABE\_LP\_MODE\_NUMERATOR
  - Common Denominator (D): [PRM\\_FRAC\\_INCREMENTER\\_DENOMINATOR\\_RELOAD](#) [11:0] DENOMINATOR
- Fine alignment circuit

At each system clock rising edge, the system counter value is compared to the shifted ( $\times 375/2$ ) coarse counter value and based on this comparison, the system counter is either incremented or unchanged.

---

**NOTE:** COUNTER\_REALTIME is designed for a count rate of 6.144 million counts per second ( $32768\text{Hz} \times 375/2$ ). Since the SoC does not use a true  $32768\text{Hz}$  source (instead uses  $\text{SYS\_CLK1}/610$ , which is  $\sim 32787\text{Hz}$  for  $20\text{MHz SYS\_CLK1}$ ), the resulting timer rate is not 6.144 and timer drift can accumulate. To minimize error in active mode, the adjustable fine increment rate **MUST** equal the fixed coarse increment rate.

---

[Table 4-4](#) shows suggested COUNTER\_REALTIME increment values.

**Table 4-4. COUNTER\_REALTIME Increment Values**

COUNTER_REALTIME Clock Mode	COUNTER_REALTIME Clock Name	COUNTER_REALTIME Fast Source Rate (Hz)	Numerator (N) for Fast Source	Denominator (D) for Fast Source	COUNTER_REALTIME Fine Rate (Hz)	COUNTER_REALTIME 32K Source Rate (Hz)	COUNTER_REALTIME Fixed Coarse Rate (Hz)
			Target 32K*(375/2)		(Sys clock)*(N/D)	(SYSCLK1/610)	32K*(375/2)
System (SYS)	SYS_CLK1	19,200,000	75	244	5,901,639.3	31,475	5,901,639.3
		20,000,000	75	244	6,147,541.0	32,787	6,147,541.0
		27,000,000	75	244	8,299,180.3	44,262	8,299,180.3
ABE Low-Power (ABE_LP)	ABE_LP_CLK	12,288,000	1875	3904	5,901,639.3	31,475	5,901,639.3
			868	1735	6,147,541.2	32,787	6,147,541.0
			955	1414	8,299,179.6	44,262	8,299,180.3
Low-Power (LP)	FUNC_32K_CLK	NA	NA	NA	NA	31,475	5,901,639.3
		NA	NA	NA	NA	32,787	6,147,541.0
		NA	NA	NA	NA	44,262	8,299,180.3

#### 4.3.5.2 Frequency Change Procedure

The change between the system clock (SYS\_CLK1) and the ABE low-power clock (ABE\_LP\_CLK) is performed within global PRCM. A software-controllable bit (CM\_CLKSEL\_WKUPAON[0] CLKSEL) controls this change. A glitch-free clock multiplexer produces the resulting clock (WKUPAON\_ICLK), which is used as the functional clock of the master counter. The CM\_CLKSEL\_WKUPAON[0] CLKSEL bit is exported from global PRCM to the master counter to control simultaneously the mode (SYS or ABE\_LP).

The transition from SYS to ABE\_LP mode (DPLL cascading entry) is done under software control as follows:

- DPLL\_ABE must be locked before (under software control, global PRCM register CM\_CLKMODE\_DPLL\_ABE[2:0] DPLL\_EN = 0x7).
- Software writes 1 in the global PRCM register CM\_CLKSEL\_WKUPAON[0] CLKSEL bit to choose DPLL\_ABE clock.

The transition from ABE\_LP to SYS mode (DPLL cascading exit) is done under software control as follows:

- Software writes 0 in the global PRCM register CM\_CLKSEL\_WKUPAON[0] CLKSEL bit to choose SYS CLK.
- DPLL\_ABE may be unlocked after.

Transition from FUNC (ABE\_LP or SYS) to LP mode is done by hardware upon MPU subsystem standby entry sequence.

Transition from LP to FUNC (ABE\_LP or SYS) mode is done by hardware upon MPU subsystem standby exit sequence.

The frequency change involves some uncertainty on the counter due to a glitch-free clock MUX in global PRCM. In order not to accumulate them, a free-running coarse counter on the FUNC\_32K\_CLK clock holds the reference count, used for realignment when necessary. To load and reload the reference count value (x375/2) from the coarse counter, the user must write 1 in the [PRM\\_FRAC\\_INCREMENTER\\_DENUMERATOR\\_RELOAD\[16\] RELOAD](#) bit (but it must be 0 prior to that).

Once configured (at first boot time), the counter is running in all modes without any action required by software.

### 4.3.6 MPU Watchdog Timer

The MPU watchdog timer (MPU\_WD\_TIMER) implements two channels, one per MPU core (MPU\_WD\_TIMER\_C0 and MPU\_WD\_TIMER\_C1, respectively; an unified name MPU\_WD\_TIMER\_Cx is used hereafter in the chapter). The MPU\_WD\_TIMER operates on MPU subsystem clock (MPU\_DPLL\_CLK).

Each MPU\_WD\_TIMER\_Cx channel implements:

- A 32-bit decrementing counter which has a period set by the value loaded into the counter (via the [WDT\\_LOAD\\_REGISTER\\_i\[31:0\]](#) NEWCOUNT bit field) and the prescaler ratio (set via the [WDT\\_PRESCALER\\_REGISTER\\_i\[9:0\]](#) PRESCALER bit field). The period is calculated as follows:  $T_{\text{MPU\_WD\_TIMER\_Cx}} = (\text{PRESCALER} + 1) \times (\text{NEWCOUNT} + 1) / f(\text{MPU\_DPLL\_CLK})$ .
- Two interrupt output signals (WARN, INTR)
- One reset request output (MPUSSRST)

The counter starts decrementing when the [WDT\\_CONTROL\\_REGISTER\\_i\[0\]](#) ENABLE bit is set to 0x1. The current count value can be monitored by reading the [WDT\\_COUNT\\_REGISTER\\_i\[31:0\]](#) CURRENTCOUNT bit field. When the counter reaches zero, a timeout condition occurs. In the timeout condition, the counter stops counting and:

- MPU\_WD\_TIMER\_Cx\_IRQ interrupt is generated to the MPU\_INTC, if enabled by setting the [WDT\\_CONTROL\\_REGISTER\\_i\[1\]](#) INTREN bit to 0x1.
- Reset request is generated to the global PRCM, if enabled by setting the [WDT\\_CONTROL\\_REGISTER\\_i\[3\]](#) MPUSSRSTEN bit to 0x1.

---

**NOTE:** If the MPU core corresponding to the MPU\_WD\_TIMER\_Cx channel is in debug state, the counter does not decrement until the MPU core returns to non-debug state. Debug state is inferred by monitoring the DBGACK signal corresponding to this core.

---

Additionally, the user can also setup a warning condition which can be used to signal an interrupt that gives software a notice when the MPU\_WD\_TIMER\_Cx is getting close to a timeout. The threshold value is set in the [WDT\\_WARNING\\_REGISTER\\_i\[31:0\]](#) WARNING\_WATERMARK bit field. The current count value is then compared to the threshold (warning watermark) level value and when  $\text{CURRENTCOUNT} = \text{WARNING\_WATERMARK}$ , a warning interrupt (MPU\_WD\_TIMER\_Cx\_IRQ\_WARN) is generated to the MPU\_INTC (if enabled by setting the [WDT\\_CONTROL\\_REGISTER\\_i\[1\]](#) WARNEN bit to 0x1).

The mapping of the four MPU\_WD\_TIMER interrupts is as follows:

- MPU\_WD\_TIMER\_C0\_IRQ\_WARN mapped to MPU\_IRQ\_5
- MPU\_WD\_TIMER\_C1\_IRQ\_WARN mapped to MPU\_IRQ\_6
- MPU\_WD\_TIMER\_C0\_IRQ mapped to MPU\_IRQ\_139
- MPU\_WD\_TIMER\_C1\_IRQ mapped to MPU\_IRQ\_140

The user can also poll the following status bits:

- [WDT\\_RESET\\_STATUS\\_REGISTER\\_i\[0\]](#) TO, to know when the timeout condition has occurred. This bit might also be used to figure out which MPU\_WD\_TIMER\_Cx signalled a reset request.
- [WDT\\_RESET\\_STATUS\\_REGISTER\\_i\[1\]](#) WARN, to know when the warning condition has occurred.

The following programming guidelines should be taken into account:

- The [WDT\\_PRESCALER\\_REGISTER\\_i](#) register should be written (if needed) before the [WDT\\_LOAD\\_REGISTER\\_i](#) register is written. This is

because when the [WDT\\_LOAD\\_REGISTER\\_i](#) register is written, the [WDT\\_COUNT\\_REGISTER\\_i](#) register is immediately updated with this value and at the same time, the PRESCALER value is sampled to be used by the decrement logic which controls the [WDT\\_COUNT\\_REGISTER\\_i](#) register.

- The [WDT\\_WARNING\\_REGISTER\\_i](#) and [WDT\\_LOAD\\_REGISTER\\_i](#) registers should be written before the MPU\_WD\_TIMER\_Cx is enabled ([WDT\\_CONTROL\\_REGISTER\\_i\[0\] ENABLE = 0x1](#)). Otherwise, interrupts and reset request may be asserted immediately depending on the state of these registers. For example, after reset these registers have '0' and if the [WDT\\_CONTROL\\_REGISTER](#) register is configured to enable the corresponding interrupts and reset request, and then MPU\_WD\_TIMER\_Cx is enabled, interrupts and reset request are immediately asserted.

The suggested programming order is as follows:

1. Set the warning watermark level ([WDT\\_WARNING\\_REGISTER\\_i](#)), if needed
2. Set the prescaler ratio ([WDT\\_PRESCALER\\_REGISTER\\_i\[9:0\] PRESCALER](#))
3. Set the new count value ([WDT\\_LOAD\\_REGISTER\\_i](#))
4. Enable corresponding interrupts and reset request in [WDT\\_CONTROL\\_REGISTER\\_i](#), if needed
5. Enable MPU\_WD\_TIMER\_Cx ([WDT\\_CONTROL\\_REGISTER\\_i\[0\] ENABLE = 0x1](#))

---

**NOTE:** When the MPU cores are going to low power state, the MPU\_WD\_TIMER may need to be disabled. If it is not disabled, then the MPU\_WD\_TIMER may timeout (since the MPU core is not refreshing the timeout counters) and will generate MPUSS reset request which will reset the MPU domain, including both MPU cores.

---

### 4.3.7 MPU Subsystem Power Management

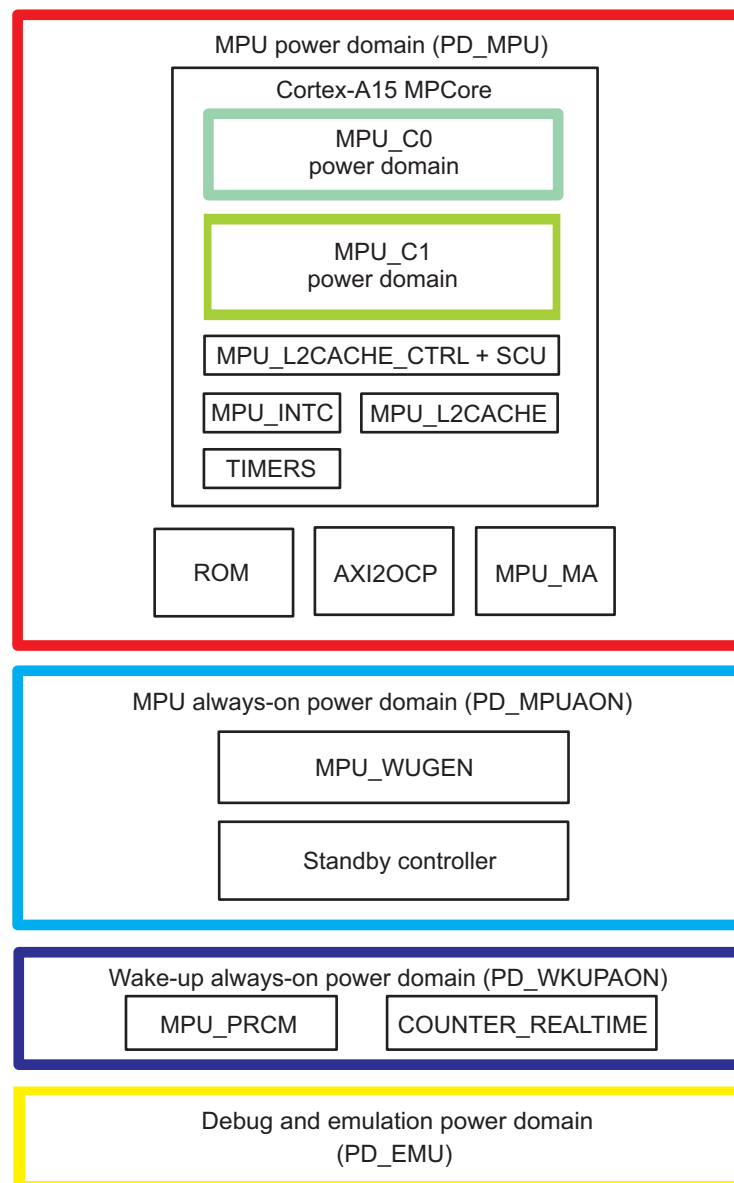

The MPU subsystem implements a local PRCM (MPU\_PRCM) module to handle the local Cortex-A15 CPU power domains, along with the corresponding L1 cache. The MPU\_PRCM module includes two power-management control (PSCON) modules to control the power chains for MPU\_C0 and MPU\_C1. The [PRM\\_PSCON\\_COUNT](#) register is used for that control purpose.

In addition to the standard power-management technique supported in the device, the MPU subsystem also employs an SR3-APG (SmartReflex3 automatic power gating) power-management technology to reduce leakage. This technology allows for full logic and memories retention on MPU\_C0 and MPU\_C1 and is controlled by the MPU\_PRCM. The SR3-APG power-management can be enabled by setting the [PRM\\_PSCON\\_COUNT\[24\] HG\\_EN](#) bit. For more information about how to enable SR3-APG fast-wakeup, see [Section 4.3.7.6, SR3-APG Technology Fail-Safe Mode](#).

#### 4.3.7.1 Power Domains

The MPU subsystem is divided into six power domains controlled by the local or global PRCM module, as shown in [Figure 4-9](#).

**Figure 4-9. MPU Subsystem Power Domains Overview**

**NOTE:** The MPU debug and trace modules are implemented in various power domains. For more information, see [Chapter 33, On-Chip Debug Support](#).

---

The device-level power domains are directly aligned with voltage domains and thus can be represented as a cross-reference to the different voltage domains.

For information about the physical power domains (PD\_MPU, PD\_MPUAON, PD\_WKUPAON, and PD\_EMU) and the related voltage domains, see [Chapter 3, Power, Reset, and Clock Management](#).

#### 4.3.7.2 Power States of MPU\_Cx

MPU\_Cx (where x = 0 or 1) changes power states only when the StandbyWFI signal is asserted. There is no signal coming from the MPU cores, or the MPU\_CLUSTER to define in which power state MPU\_Cx can go. Software must program such information by writing to the PM\_CPUx\_PWRSTCTRL[1:0] POWERSTATE bit field before executing the WFI instruction. [Table 4-5](#) provides the software requirements before executing the WFI instruction, and the condition to return to RUN mode.

**Table 4-5. MPU\_Cx State Transitions**

Low-Power State	Software Sequence Before Executing WFI	Wakeup (Transition Back to Run Mode)
<b>WFI/ON</b> Logic ON L1\$ ON	Execute a Data Synchronization Barrier (DSB) instruction.	Managed locally to MPU_Cx upon one of the following sources: <ul style="list-style-type: none"> <li>• An interrupt, masked or unmasked (important: masked does not mean disabled)</li> <li>• An imprecise data abort, regardless of the value of the CPSRA bit</li> <li>• A debug request generated by writing 1 to the HALTING DEBUG MODE bit of the Cortex-A15 DBGSCR register, or the assertion of the Cortex-A15 EDBGRRQ pin</li> <li>• Global device cold or warm reset source</li> </ul>
<b>WFI/INACT</b> Logic ON L1\$ ON	Execute a DSB instruction.	Managed locally by MPU_PRCM upon following source: <ul style="list-style-type: none"> <li>• An interrupt, enabled at MPU_WUGEN level</li> <li>• A forced wakeup (sw_wkup)</li> <li>• A full debug wake-up request sequence: ForceActive from the DAP_PC, a debug request (as explained previously), assert block reset, wait for processor to halt and clear the block reset</li> <li>• Global device cold or warm reset source</li> </ul>
<b>WFI/RETENTION</b> Logic RET L1\$ ON L1\$ peripheral OFF	<ol style="list-style-type: none"> <li>1. Set the PM_CPUx_PWRSTCTRL[1:0] POWERSTATE bit field to 0x1 (RETENTION state).</li> <li>2. Execute a DSB instruction.</li> </ol>	Managed locally by MPU_PRCM upon following source: <ul style="list-style-type: none"> <li>• An interrupt, enabled at MPU_WUGEN level</li> <li>• A forced wakeup (sw_wkup)</li> <li>• A full debug wake-up request sequence: ForceActive from the DAP_PC, a debug request (as explained previously), assert block reset, wait for processor to halt and clear the block reset</li> <li>• Global device cold or warm reset source</li> </ul> MPU_PRCM does not need to reset MPU_Cx.
<b>WFI/FORCED_OFF<sup>(1)</sup></b> Logic OFF L1\$ OFF	<ol style="list-style-type: none"> <li>1. Save MPU_INTC configuration for MPU_C1 interrupts.</li> <li>2. Disable SGI and PPI toward MPU_C1 in MPU_INTC.</li> <li>3. Save all Arm registers, including CPSR and SPSR.</li> <li>4. Save all CP15 registers.</li> <li>5. Save all debug-related states.</li> <li>6. Set the PM_CPU1_PWRSTCTRL[1:0] POWERSTATE bit field to 0x0 (OFF state).</li> <li>7. Set the PM_CPU1_PWRSTCTRL[7] FORCED_OFF bit to 0x1.</li> <li>8. Clear the C-bit in the SCTLR to prevent further data cache allocation.</li> <li>9. Clean/invalidate L1\$ content on an as-needed basis.</li> <li>10. Clear SMP bit to take CPU out of coherency.</li> <li>11. Execute an ISB instruction to ensure that all of the above CP15 register changes have been committed.</li> <li>12. Execute a DSB instruction.</li> </ol>	Managed locally by MPU_PRCM upon following source: <ul style="list-style-type: none"> <li>• A forced wakeup (sw_wkup)</li> <li>• A full debug wake-up request sequence (as previously mentioned). Block reset is not supported.</li> <li>• Global device cold or warm reset source</li> </ul> MPU_PRCM must reset MPU_C1 to make it reboot and restore its context, including MPU_INTC.

<sup>(1)</sup> Applies to MPU\_C1 only.

**NOTE:** For the description of the Cortex-A15 CPU registers and the DSB/ISB instructions, see the *Arm Cortex-A15 Technical Reference Manual* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).

The RETENTION low-power state is not natively supported by the MPU\_CLUSTER. This mode is implemented with SR3-APG power-management technology. The MPU subsystem power-management hardware is designed to ensure that the system does not have an L1 cache coherency problem when putting both MPU cores in retention mode. In this mode, the MPU\_Cx logic is in full retention with all memory content preserved by keeping the array of memories fully powered and the logic of the memory peripherals shut down. In slow wake-up mode, memories are put into retention to prevent more leakage.

In FORCED\_OFF and RETENTION low-power states, the standby controller gates the clock to the MPU\_CLUSTER by deasserting the CLKEN signal before signaling the MPU\_PRCM to perform a power transition. In these low-power states, the MPU core can be wakened only by the MPU\_PRCM. A number of important actions must be performed by software before entering such a state.

FORCED\_OFF mode applies only to MPU\_C1. In this mode, it is critically important for software to clear the SMP bit of the targeted MPU core to take that MPU core out of coherency and to prevent TLB, BTB, or instruction cache maintenance operations from other MPU core in the cluster being issued to this MPU core. The SMP bit is part of the Auxiliary Control Register (ACTLR); there is one ACTLR per MPU core. The ACTLR is a CP15 register. For more information about this register, see the *Arm Cortex-A15 Technical Reference Manual* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).

A wakeup from FORCED\_OFF low-power state must always happen through a MPU core (MPU\_C1) reset so that the MPU core (MPU\_C1) restores its state to the same level as before the power transition before handling the wake-up event itself (the interrupt). A wakeup from RETENTION low-power state does not need to happen through a MPU core reset because MPU core logics are fully retained.

**NOTE:** The private peripheral interrupts (PPIs) cannot wake up an MPU core in INACT, RETENTION, or FORCED\_OFF low-power state. Software-generated interrupts (SGI) cannot wake up an MPU core in the same low-power state. However, it is possible to work around the issue by applying the following method:

- When MPU\_Cx wants to send an SGI to MPU\_Cy (that is, the other MPU core), it must first systematically set the CM\_CPUy\_CLKSTCTRL[1:0] CLKTRCTRL bit field to 0x2 (software-forced wake-up transition),
- The MPU\_Cy corresponding ISR must write back the CM\_CPUy\_CLKSTCTRL[1:0] CLKTRCTRL bit field to 0x3 (HW\_AUTO, automatic transition).

Table 4-6 gives details of the power state of the supported MPU\_Cx and the corresponding values of the MPU\_PRCM register.

**Table 4-6. MPU\_Cx Supported Power States**

Hardware Conditions		MPU_Cx Programming Model		Resulting MPU_Cx State			
StandbyWFI StandbyWFE	State of L2/Other MPU core	MPU_PRCM Power State PM_CPUx_PWRS TCTRL[1:0] POWERSTATE	MPU_PRCM Clock Transition Control CM_CPUx_CLKST CTRL[1:0] CLKTRCTRL	Logic	L1 Cache	Arm Cortex-A15 Internal Clock	Power State at MPU_PRCM
MPU_Cx running	Any	Any	Any	ON	ON	ON	ON
MPU_Cx in WFE	Any	Any	Any	ON	ON	OFF	ON
MPU_Cx in WFI	Any	Any	NO_SLEEP/SW_W KUP	ON	ON	OFF	ON
MPU_Cx in WFI	Any	ON	HW_AUTO	ON	ON	OFF	ON

**Table 4-6. MPU\_Cx Supported Power States (continued)**

Hardware Conditions		MPU_Cx Programming Model		Resulting MPU_Cx State			
StandbyWFI StandbyWFE	State of L2/Other MPU core	MPU_PRCM Power State PM_CPUx_PWRS TCTRL[1:0] POWERSTATE	MPU_PRCM Clock Transition Control CM_CPUx_CLKST CTRL[1:0] CLKTRCTRL	Logic	L1 Cache	Arm Cortex-A15 Internal Clock	Power State at MPU_PRCM
MPU_C1 in WFI	Any	FORCED_OFF <sup>(1)</sup>	HW_AUTO	OFF	OFF	OFF	OFF
MPU_Cx in WFI	!= (IDLE/WFI /WFI)	Any	HW_AUTO	ON	ON	OFF	ON
MPU_Cx in WFI	IDLE/WFI/ WFI	INACT	HW_AUTO	ON	ON	OFF	INACT
MPU_Cx in WFI	IDLE/WFI/ WFI	RETENTION	HW_AUTO	SR3-APG/ ON <sup>(2)</sup>	ON/RETENTI ON <sup>(3)</sup>	OFF	CSWRET

- <sup>(1)</sup> FORCED\_OFF mode applies only to MPU\_C1. See [Table 4-5](#) for the guidelines about how to enter FORCED\_OFF mode.
- <sup>(2)</sup> If [PRM\\_PSCON\\_COUNT\[24\]](#) HG\_EN = 1, MPU core logic is put in SR3-APG state. If not, MPU core logic is kept ON.
- <sup>(3)</sup> L1\$ state depends on the values of the [PRM\\_PSCON\\_COUNT\[25\]](#) HG\_RAMPUP and [PRM\\_PSCON\\_COUNT\[24\]](#) HG\_EN bits. When CPU PD is in the CSWRET state, if HG\_ENABLE = 0x1 and HG\_RAMPUP = 0x1, then L1\$ memory is in ON state, else L1\$ memory is in the RETENTION state. For more information, see [Section 4.3.7.6, SR3-APG Technology Fail-Safe Mode](#).

The PM\_CPUx\_PWRSTCTRL register is static over any power transition. That is, software programs it before executing the WFI instruction and does not change it until MPU\_Cx is again in running mode. In other words, when MPU\_Cx reaches a low-power state, it cannot move to another low-power state. It must be woken up to reach another low-power state. To wake up MPU\_Cx, the user must:

1. Execute a forced wake-up transition to the MPU\_Cx: CM\_CPUx\_CLKSTCTRL[1:0] CLKTRCTRL = 0x2.
2. The MPU\_Cx interrupt handler must write back the automatic hardware transition: CM\_CPUx\_CLKSTCTRL[1:0] CLKTRCTRL = 0x3.

[Table 4-7](#) shows the available MPU\_Cx power states in single and coherency mode. For coherency, software must ensure that both MPU cores are in the same power state.

**Table 4-7. Available MPU\_Cx Power States in Single and Coherency Mode**

MPU_C0 Power State	MPU_C1 Power State	Mode
Running/ON or WFI/ON	Running/ON or WFI/ON	SMP mode (coherent mode)
WFI/INACT	WFI/INACT	
WFI/CSWRET	WFI/CSWRET	
Running/ON or WFI/ON	FORCED_OFF	Single mode (MPU_C1 is out of coherency)
WFI/INACT	FORCED_OFF	
WFI/CSWRET	FORCED_OFF	

### 4.3.7.3 Power States of MPU Subsystem

The MPU subsystem power domain (PD\_MPU) must be at a higher or equal power state (a state that consumes more power) than the higher of the two MPU cores. For example, it is illegal for the MPU subsystem power state to be RETENTION, while the power state of one or both of the MPU cores is ON.

Software must ensure that only legal power states are programmed. When an illegal state is entered, the behavior of the hardware is unpredictable.

[Table 4-8](#) lists the MPU subsystem legal power states.

**Table 4-8. MPU Subsystem Legal Power States**

Hardware Conditions		MPU/System Programming Model				Resulting MPU/System State			
MPU_Cx States	State of L2	PRCM Power State PM_MPU_PW RSTCTRL[1:0] POWERSTATE	PRCM Logic Retention State PM_MPU_P WRSTCTRL[2] LOGICRETSTATE	PRCM L2 Memory Retention State PM_MPU_PW RSTCTRL[9] MPU_L2_RET STATE	PRCM Clock Transition Control CM_MPU_CL KSTCTRL[1:0] CLKTRCTRL	Logic	L2 Cache	DPLL Clock	Power State (at PRCM)
At least one is ON	Any	Any	Any	Any	Any	ON	ON	ON	ON
Any	!= (IDLE / WFI)	Any	Any	Any	Any	ON	ON	ON	ON
Power state of both MPU cores is less than or equal to INACT	IDLE / WFI	Any	Any	Any	NO_SLEEP/SW_WKUP	ON	ON	ON	ON
	IDLE / WFI	ON	Any	Any	HW_AUTO	ON	ON	ON	ON
	IDLE / WFI	INACT	Any	Any	HW_AUTO	ON	ON	OFF	INACT
Power state of both MPU cores is less than or equal to CSWRET	IDLE / WFI	RETENTION	CSWRET	RETENTION	HW_AUTO	ON	RETENTION	OFF	CSWRET
	IDLE / WFI	RETENTION	CSWRET	OFF	HW_AUTO	ON	OFF	OFF	CSWRET

**NOTE:** All the transitions presented in [Table 4-8](#), except for the first line, are handled by the MPU\_PRCM and the global PRCM.

Once the MPU subsystem reaches a low-power state (INACT, CSWRET), it cannot move to another low-power state. It must be woken up to reach another low-power state.

#### 4.3.7.4 MPU\_WUGEN

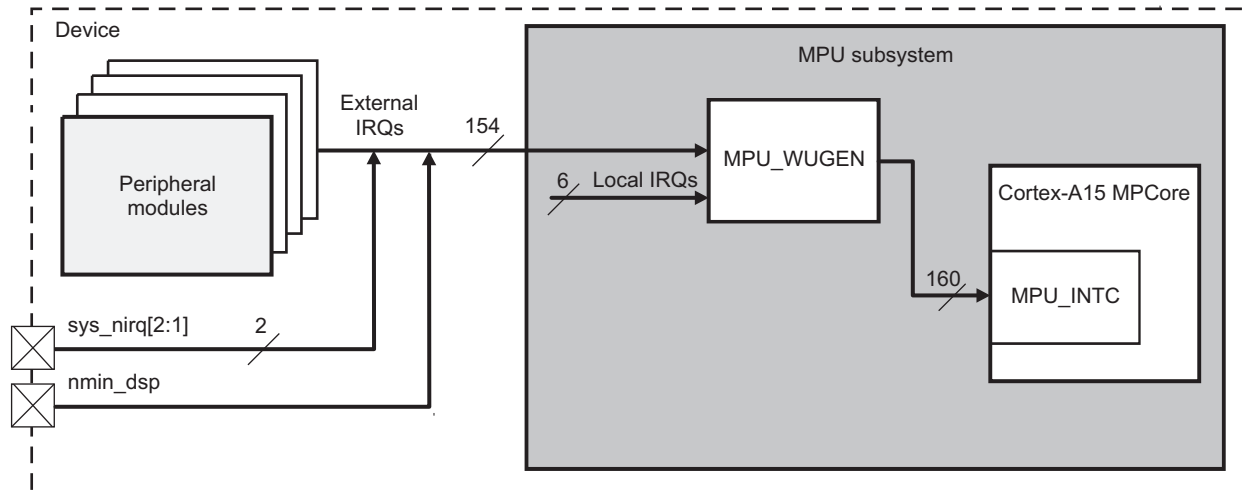

The MPU\_WUGEN belongs to the MPU always-on power domain (PD\_MPUAON) and is responsible for generating wake-up events from the incoming interrupts (external and local to the MPU subsystem) according to the MPU\_WUGEN 160-bit enable field (from WKG\_ENB\_A\_x to WKG\_ENB\_E\_x for MPU\_Cx, where x = 0 or 1), which defines the interrupt that wakes up the MPU cores.

All interrupts are enabled after reset, except MPU\_IRQ\_8. The Cortex-A15 MPU can access the MPU\_WUGEN internal configuration registers through the MPU\_AXI2OCP.

Software must program interrupt enabling and disabling coherently in the MPU\_INTC and in the MPU\_WUGEN enable registers. That is, a given interrupt for a given MPU core is either enabled at both MPU\_INTC and MPU\_WUGEN, or disabled at both; no combination is allowed.

MPU\_WUGEN includes two registers ([AUX\\_CORE\\_BOOT\\_0](#) and [AUX\\_CORE\\_BOOT\\_1](#)) which can be used by the ROM code and OS during SMP boot. The [AUX\\_CORE\\_BOOT\\_0](#) register is intended to indicate boot status to MPU\_C1, the second core (also known as aux core); the [AUX\\_CORE\\_BOOT\\_1](#) register can be used to store execution start address of the MPU\_C1. For more information, see [Section 32.3.4, Startup and Configuration](#), in [Chapter 32, Initialization](#).

[Figure 4-10](#) is a functional overview of the MPU\_WUGEN in the MPU subsystem.

**Figure 4-10. MPU\_WUGEN Overview**

#### 4.3.7.5 Power Transition Sequence

At power-on-reset (POR), or global warm reset, both MPU cores are powered on. Software can determine the appropriate power mode for both MPU cores and program the MPU\_PRCM accordingly.

There are three types of power transitions:

- Power transitions that do not involve the local or global PRCM module
  - MPU\_Cx transition to WFE/ON - corresponds to line 2 of [Table 4-6](#)
  - MPU\_Cx transition to WFI/ON - corresponds to lines 3, 4, and 6 of [Table 4-6](#)
- Power transitions handled by the local PRCM module
  - MPU\_C1 transition to WFI/FORCED\_OFF - corresponds to line 5 of [Table 4-6](#). Requires software to program MPU\_PRCM with FORCED\_OFF mode.
  - MPU\_Cx transition to WFI/INACT, or WFI/RET - corresponds to line 7, 8 and 9 of [Table 4-6](#). Requires software to program the MPU\_PRCM with INACT/RET mode.
- Power transitions handled by the local and global PRCM modules

#### 4.3.7.6 SR3-APG Technology Fail-Safe Mode

The SR3-APG power-management technology implements a fast power ramp-up technology. To take advantage of the fast ramp-up feature in SR3-APG, software must first enable it by setting the [PRM\\_PSCON\\_COUNT\[25\] HG\\_RAMPUP](#) bit to 1.

A fail-safe mechanism is put in place to revert back to the standard power ramp-up time by setting the [PRM\\_PSCON\\_COUNT\[25\] HG\\_RAMPUP](#) bit to 0.

The slow ramp-up time can be set through the [PRM\\_PSCON\\_COUNT\[23:16\] HG\\_PONOUT\\_2\\_PGDOODIN\\_TIME](#) bit field when the HG weak chain is used (in other words, the [PRM\\_PSCON\\_COUNT\[25\] HG\\_RAMPUP](#) bit is set to 0x0).

This applies only when SR3-APG is enabled ([PRM\\_PSCON\\_COUNT\[24\] HG\\_EN](#) = 1).

The L1 cache memory state depends on the values of the [PRM\\_PSCON\\_COUNT\[25\] HG\\_RAMPUP](#) and [PRM\\_PSCON\\_COUNT\[24\] HG\\_EN](#) bits. When CPU PD is in CSWRET state and HG\_ENABLE and HG\_RAMPUP are set to 0x1, L1 cache is in the ON state.

If SR3-APG is disabled ([PRM\\_PSCON\\_COUNT\[24\] HG\\_EN](#) = 0), the L1 cache array can be put in RETENTION during CSWRET regardless of the [PRM\\_PSCON\\_COUNT\[25\] HG\\_RAMPUP](#) bit.

### 4.3.8 MPU Subsystem AMBA Interface Configuration

There are some inputs at the MPU core (MPU\_Cx) boundary which can be tied off to disable certain kind of transactions appearing on the AMBA4 interface:

- SYSBARDISABLE (SBD): This controls whether:
  - Barriers are handled internal to MPU core (SBD = 1), or
  - Barriers are issued on the AMBA4 interface (SBD = 0).
- BROADCASTINNER (BI), BROADCASTOUTER (BO), BROADCASTMAINTENANCE (BCM): These control whether external snoops are issued on AMBA4 interface or not:
  - BI=BO=BCM=0: No external snoops issued.
  - BI=BO=BCM=1: External snoops can be issued. Not supported in the device.

For detailed description on these inputs, see the Arm *Cortex-A15 Technical Reference Manual* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).

To give flexibility and mitigate risk, a programmable register ([AMBA\\_IF\\_MODE](#)) is added to control the tie-off value of these MPU\_Cx inputs. Once this register is programmed, MPU power domain has to go through OSWRET transition for the programmed values in bits [AMBA\\_IF\\_MODE](#) [3:0] to take effect. This is because the MPU\_Cx non-cpu logic latches the value on the corresponding inputs when it is coming out of reset.

These are the only legal combinations of [BI, BO, BCM, SBD] allowed:

- BI, BO, BCM, SBD = 0001 – Corresponds to **AXI3** mode. Barriers not issued on AMBA4 interface. External snoops not issued. This is the default mode.
- BI, BO, BCM, SBD = 0000 – Corresponds to **ACE non-coherent, no L3** mode. Barriers issued on AMBA4 interface. External snoops not issued.

The ROM code provides specific API for configuring the [AMBA\\_IF\\_MODE](#) register. For more information, see section *Wakeup Generator*, in [Chapter 32, Initialization](#).

## 4.4 Dual Cortex-A15 MPU Subsystem Register Manual

### 4.4.1 Dual Cortex-A15 MPU Subsystem Instance Summary

**Table 4-9. Dual Cortex-A15 MPU Subsystem Instance Summary**

Module Name	Base Address	Size
MPU_CS_STM	0x4700 0000	16 MiB
MPU_INTC	0x4821 0000	32 KiB
MPU_PRCM_OCP_SOCKET	0x4824 3000	512 bytes
MPU_PRCM_DEVICE	0x4824 3200	512 bytes
MPU_PRCM_PRM_C0	0x4824 3400	512 bytes
MPU_PRCM_CM_C0	0x4824 3600	512 bytes
MPU_PRCM_PRM_C1	0x4824 3800	512 bytes
MPU_PRCM_CM_C1	0x4824 3A00	512 bytes
MPU_WUGEN	0x4828 1000	4 KiB
Reserved	0x4829 0000	12 KiB
MPU_WD_TIMER	0x482A 0000	4 KiB
MPU_AXI2OCP_MISC	0x482A 2000	4 KiB
MPU_MA_LSM	0x482A F000	256 bytes
MPU_MA_WP	0x482A F200	256 bytes

#### 4.4.2 MPU\_CS\_STM Registers

For information about the MPU\_CS\_STM registers and their description, see the Arm *CoreSight STM Technical Reference Manual* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).

#### 4.4.3 MPU\_INTC Registers

For information about the MPU\_INTC registers and their description, see the Arm *Cortex-A15 MPCore Technical Reference Manual* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).

<b>Address Offset</b>	0x0000 0000	<b>Instance</b>	MPU_WUGEN
<b>Physical Address</b>	0x4828 1000		
<b>Description</b>	Wake-up generator control and status register for MPU_C0		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
RESERVED																DOMAINRESET	MPU_WARM_RESET	MPU_COLD_RESET	RESERVED	EVENTO	STANDBYWFE	STANDBYWFI	RESERVED									

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved	R	0x00000
15	DOMAINRESET	MPU always-on power domain (PD_MPUAON) reset status bit. It shows if the reset occurred previously. 0x0: no reset occur 0x1: reset occur	R	0x0
14	MPU_WARM_RESET	This bit is set when the MPU_WARM_RESET signal is asserted. 0x0: MPU_WARM_RESET reset signal has not been asserted 0x1: MPU_WARM_RESET reset request has been asserted	RW	0x0
13	MPU_COLD_RESET	This bit is set when the MPU_COLD_RESET signal is asserted. 0x0: MPU_COLD_RESET reset signal has not been asserted 0x1: MPU_COLD_RESET reset request has been asserted	RW	0x0
12:11	RESERVED	Reserved	R	0x0
10	EVENTO	EVENTO status bit. The event output signal is active, when one SEV instruction is executed. This bit is set when a rising edge of EVENTO from CPU is detected. 0x0: Rising edge of EVENTO is not detected 0x1: Rising edge of EVENTO is detected	RW	0x0
9	STANDBYWFE	This bit gives software the visibility to track whether WFE mode have been entered. 0x0: WFE mode has not been entered 0x1: WFE mode has been entered	RW	0x0
8	STANDBYWFI	This bit gives software the visibility to track whether WFI mode have been entered. 0x0: WFI mode has not been entered 0x1: WFI mode has been entered	RW	0x0
7:0	RESERVED	Reserved	R	0x0

<b>Address Offset</b>	0x0000 0400	<b>Instance</b>	MPU_WUGEN
<b>Physical Address</b>	0x4828 1400		
<b>Description</b>	Wake-up generator control and status register for MPU_C1		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								DOMAINRESET	MPU_WARM_RESET	MPU_COLD_RESET	RESERVED	EVENTO	STANDBYWFE	STANDBYWF1	RESERVED																

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved	R	0x00000
15	DOMAINRESET	MPU always-on power domain (PD_MPUAON) reset status bit. It shows if the reset occurred previously. 0x0: No reset occurred. 0x1: Reset occurred.	R	0x0
14	MPU_WARM_RESET	This bit is set when the MPU_WARM_RESET signal is asserted. 0x0: MPU_WARM_RESET reset signal has not been asserted. 0x1: MPU_WARM_RESET reset request has been asserted.	RW	0x0
13	MPU_COLD_RESET	This bit is set when the MPU_COLD_RESET signal is asserted. 0x0: MPU_COLD_RESET reset signal has not been asserted. 0x1: MPU_COLD_RESET reset request has been asserted.	RW	0x0
12:11	RESERVED	Reserved	R	0x0
10	EVENTO	EVENTO status bit. The event output signal is active, when one SEV instruction is executed. This bit is set when a rising edge of EVENTO from CPU is detected. 0x0: Rising edge of EVENTO is not detected. 0x1: Rising edge of EVENTO is detected.	RW	0x0
9	STANDBYWFE	This bit gives software the visibility to track whether WFE mode have been entered. 0x0: WFE mode has not been entered. 0x1: WFE mode has been entered.	RW	0x0
8	STANDBYWFI	This bit gives software the visibility to track whether WFI mode have been entered. 0x0: WFI mode has not been entered. 0x1: WFI mode has been entered.	RW	0x0
7:0	RESERVED	Reserved	R	0x0

**Table 4-81. AUX\_CORE\_BOOT\_1**

<b>Address Offset</b>	0x804	<b>Instance</b>	MPU_WUGEN
<b>Physical Address</b>	0x4828 1804		
<b>Description</b>	This register is used by the ROM code and OS during SMP boot. It is intended to store the execution start address of MPU_C1. When needed, the SMP OS (executing on MPU_C0) stores the execution start address of MPU_C1 in <a href="#">AUX_CORE_BOOT_1</a> , and then wakes up MPU_C1 by executing a SEV command. When MPU_C1 receives an event (caused by the SEV command), it executes the event handler in the ROM Code, which eventually branches to the address stored in <a href="#">AUX_CORE_BOOT_1</a> .		
<b>Type</b>	RW

Dual Cortex-A15 MPU Subsystem Functional Description

- [MPU Watchdog Timer: \[0\]\[1\]\[2\]\[3\]\[4\]](#)

Dual Cortex-A15 MPU Subsystem Register Manual

- [MPU\\_WD\\_TIMER Register Summary: \[5\]](#)
- [MPU\\_WD\\_TIMER Register Description: \[6\]](#)

**Table 4-94. WDT\_COUNT\_REGISTER\_i**

<b>Address Offset</b>	0x0000 0004 + (0x20 * i)	<b>Index</b>	i = 0 to 1
<b>Physical Address</b>	0x482A 0004 + (0x20 * i)	<b>Instance</b>	MPU_WD_TIMER
<b>Description</b>	This register is a 32-bit decrementing counter. The decrement rate is programmed in the <a href="#">WDT_PRESCALER_REGISTER_i</a> . The <a href="#">WDT_COUNT_REGISTER_i</a> can be read to get the current count. It decrements if the MPU_WD_TIMER_Cx is enabled ( <a href="#">WDT_CONTROL_REGISTER_i[0] ENABLE = 0x1</a> ). If the processor related to the corresponding watchdog channel is in debug state, the counter does not decrement until the processor returns to non-debug state. The <a href="#">WDT_COUNT_REGISTER_i</a> decrements down to zero and stops. The only way to update the <a href="#">WDT_COUNT_REGISTER_i</a> is to write to the <a href="#">WDT_LOAD_REGISTER_i</a> . If a software failure prevents the <a href="#">WDT_COUNT_REGISTER_i</a> from being refreshed, the <a href="#">WDT_COUNT_REGISTER_i</a> reaches zero, the watchdog timeout status flag is set and all interrupt requests or reset requests enabled in the <a href="#">WDT_CONTROL_REGISTER_i</a> are signalled. If a reset request is enabled, the global PRCM is then responsible for resetting the MPUSS. Debug state is inferred by monitoring the DBGACK signal corresponding to this core. This register is reset by warm reset of the corresponding MPU core.		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CURRENTCOUNT																															

Bits	Field Name	Description	Type	Reset
31:0	CURRENTCOUNT	Current count of the MPU_WD_TIMER.	R	0x0000 0000

**Table 4-96. WDT\_WARNING\_REGISTER\_i**

<b>Address Offset</b>	0x0000 0008 + (0x20 * i)	<b>Index</b>	i = 0 to 1
<b>Physical Address</b>	0x482A 0008 + (0x20 * i)	<b>Instance</b>	MPU_WD_TIMER
<b>Description</b>	The <a href="#">WDT_COUNT_REGISTER_i</a> is compared to the <a href="#">WDT_WARNING_REGISTER_i</a> . If <a href="#">WDT_COUNT_REGISTER_i</a> is less than or equal to the <a href="#">WDT_WARNING_REGISTER_i</a> and <a href="#">WDT_CONTROL_REGISTER_i[8]</a> WARNEN = 0b1, a warning interrupt is signalled to the MPU_INTC. The warning condition can be used to signal an interrupt that gives software a notice that the MPU_WD_TIMER_Cx is getting close to a timeout, when a more serious action should be taken.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

<b>Physical Address</b>	0x482A 0010 + (0x20 * i)	<b>Instance</b>	MPU_WD_TIMER
<b>Description</b>	This register controls the behavior of the MPU_WD_TIMER_Cx. This register is reset by warm reset of the corresponding MPU core.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																WARNEN	RESERVED				MPUSSRSTEN	RESERVED	INTREN	ENABLE							

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved. Ignored on writes. Reads return 0s.	R	0x00 0000
8	WARNEN	Warning Interrupt Enable. If this bit is set and the warning watermark test is true, a warning interrupt is generated to the MPU_INTC.	RW	0
7:4	RESERVED	Reserved. Ignored on writes. Reads return 0s.	R	0x0
3	MPUSSRSTEN	MPUSS Reset Enable. If this field is 0b1 when the timer reaches zero, a request is sent to the global PRCM to begin a global warm reset.	RW	0
2	RESERVED	Reserved. Ignored on writes. Reads return 0s.	R	0
1	INTREN	Interrupt Enable. If this field is 0b1 when the timer reaches zero, an interrupt request is sent to the MPU_INTC.	RW	0
0	ENABLE	Enable for MPU_WD_TIMER_Cx. 0: MPU_WD_TIMER_Cx is disabled. It will not count down and it will not generate a reset request. All MPU_WD_TIMER_Cx registers may be accessed. 1: MPU_WD_TIMER_Cx is enabled. It will count down and generate a reset request if it reaches 0. This bit is reset by warm or power-on reset.	RW	0

<b>Address Offset</b>	0x0000 0014 + (0x20 * i)	<b>Index</b>	i = 0 to 1
<b>Physical Address</b>	0x482A 0014 + (0x20 * i)	<b>Instance</b>	MPU_WD_TIMER
<b>Description</b>	The TO bit indicated that this MPU_WD_TIMER_Cx has timed out. This might be used to figure out which MPU_WD_TIMER_Cx signalled a reset. This register is not reset by warm reset, but only by cold reset.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																WARN	TO														

Bits	Field Name	Description	Type	Reset
31:2	RESERVED	Reserved. Ignored on writes. Reads return 0s.	R	0x0000 0000
1	WARN	Warning. Indicates that the count has passed the warning watermark level while the <a href="#">WDT_CONTROL_REGISTER_i[8]</a> WARNEN bit was set. Write a '1' to this bit to reset it.	RW W1toClr	0
0	TO	Timeout. Indicates the <a href="#">WDT_COUNT_REGISTER_i</a> has reached zero (timed out) and the signalling enabled in the <a href="#">WDT_CONTROL_REGISTER_i</a> has occurred. Can be used to determine which MPU_WD_TIMER_Cx instance caused a reset. Write a '1' to this bit to reset it.	RW W1toClr	0

### 4.4.13 MPU\_MA\_LSM Registers

#### 4.4.13.1 MPU\_MA\_LSM Register Summary

**Table 4-107. MPU\_MA\_LSM Register Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	MPU_MA_LSM Physical Address
RESERVED	R	32	0x0000 0010	0x482A F010
MA_LISA_LOCK	RW	32	0x0000 001C	0x482A F01C
MA_LISA_MAP_i <sup>(1)</sup>	RW	32	0x0000 0040 + (0x4 * i)	0x482A F040 + (0x4 * i)

<sup>(1)</sup> i = 0 to 3

#### 4.4.13.2 MPU\_MA\_LSM Register Description

For the description of the MPU\_MA\_LSM registers, see [Section 15.2, Dynamic Memory Manager](#), where MA\_LISA\_LOCK corresponds to the DMM\_LISA\_LOCK register description, and MA\_LISA\_MAP\_i corresponds to the DMM\_LISA\_MAP\_i register description.

### 4.4.14 MPU\_MA\_WP Registers

#### 4.4.14.1 MPU\_MA\_WP Register Summary

**Table 4-108. MPU\_MA\_WP Registers Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	MPU_MA_WP Physical Address
<a href="#">DBG_HWWP_CAP</a>	R	32	0x0000 0000	0x482A F200
<a href="#">TRIG_CTRL</a>	RW	32	0x0000 0004	0x482A F204
<a href="#">DBG_HWWP0_LW_ADDR0</a>	RW	32	0x0000 0008	0x482A F208
<a href="#">DBG_HWWP0_HG_ADDR0</a>	RW	32	0x0000 000C	0x482A F20C
<a href="#">DBG_HWWP0_MAIN_CNTL</a>	RW	32	0x0000 0010	0x482A F210
<a href="#">DBG_HWWP0_AUX_CNTL</a>	RW	32	0x0000 0014	0x482A F214
<a href="#">DBG_HWWP0_MEM_CNTL</a>	RW	32	0x0000 0018	0x482A F218
<a href="#">DBG_HWWP0_CHAIN_CNTL</a>	RW	32	0x0000 001C	0x482A F21C
<a href="#">DBG_HWWP0_LW_ADDR0_LOG</a>	R	32	0x0000 0020	0x482A F220
<a href="#">DBG_HWWP0_HG_ADDR0_LOG</a>	R	32	0x0000 0024	0x482A F224
<a href="#">DBG_HWWP0_DATA0_LOG</a>	R	32	0x0000 0028	0x482A F228

**Table 4-108. MPU\_MA\_WP Registers Mapping Summary (continued)**

Register Name	Type	Register Width (Bits)	Address Offset	MPU_MA_WP Physical Address
<a href="#">DBG_HWWP0_DATA1_LOG</a>	R	32	0x0000 002C	0x482A F22C
<a href="#">DBG_HWWP0_DATA2_LOG</a>	R	32	0x0000 0030	0x482A F230
<a href="#">DBG_HWWP0_DATA3_LOG</a>	R	32	0x0000 0034	0x482A F234
<a href="#">DBG_HWWP0_TRANS_ATTR0_LOG</a>	R	32	0x0000 0038	0x482A F238
<a href="#">DBG_HWWP0_TRANS_ATTR1_LOG</a>	R	32	0x0000 003C	0x482A F23C
<a href="#">DBG_HWWP0_DATA_TRANS_ATTR0_LOG</a>	R	32	0x0000 0040	0x482A F240

**NOTE:** The user is required to set all trigger options and match criteria *before* enabling the watchpoint via setting the [DBG\\_HWWP0\\_MAIN\\_CNTL\[0\]](#) WP\_EN bit. To change any match options or to re-enable the trigger, the WP\_EN must first be cleared. The \_LOG registers should normally be read only after the [DBG\\_HWWP0\\_MAIN\\_CNTL\[31\]](#) TRIG bit is verified to be '1'.

#### 4.4.14.2 MPU\_MA\_WP Register Description

## **DSP Subsystems**

---

---

This chapter describes the features and functions of the device integrated digital processing subsystems.

**NOTE:** Devices may include up to two identical instances of DSP subsystem (DSP1 and DSP2). Refer to the device *Data Manual* for number of DSP instances on a specific device. This chapter describes the two DSP device superset. For devices with a single DSP, the information on DSP2 can be ignored.

Topic	Page
<b>5.1 DSP Subsystems Overview .....</b>	<b>1541</b>
<b>5.2 DSP Subsystem Integration .....</b>	<b>1546</b>
<b>5.3 DSP Subsystems Functional Description .....</b>	<b>1552</b>
<b>5.4 DSP Subsystem Register Manual .....</b>	<b>1589</b>

## 5.1 DSP Subsystems Overview

The device includes two identical instances (DSP1 and DSP2) of a digital signal processor (DSP) subsystem, based on the TI's standard TMS320C66x DSP CorePac core.

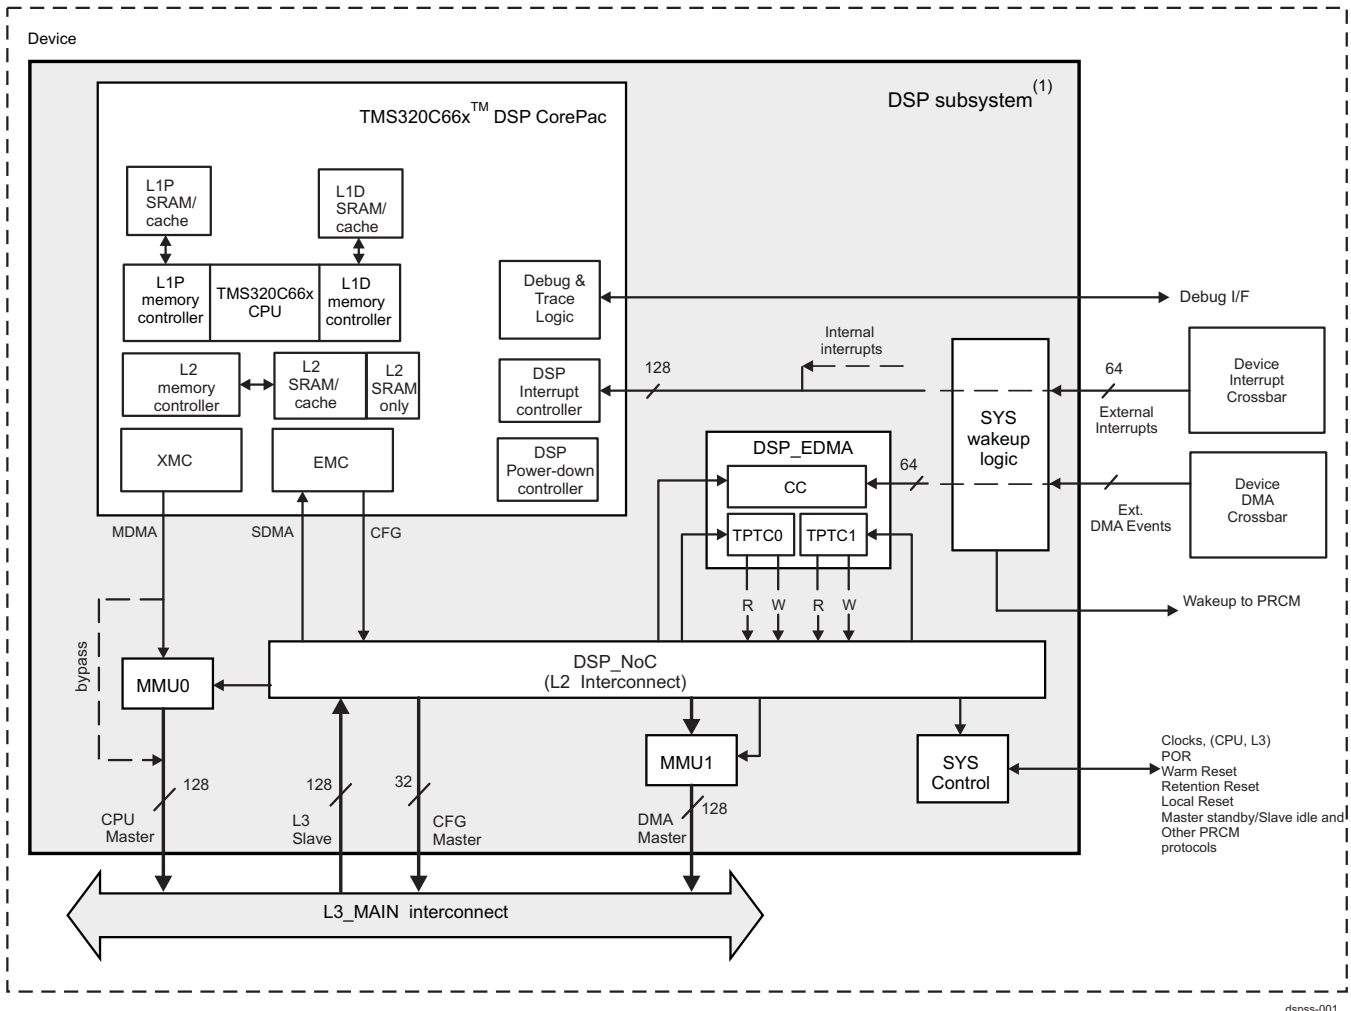

The TMS320C66x DSP core enhances the TMS320C674x core, which merges the C674x floating point and the C64x+ fixed-point instruction set architectures. The C66x DSP is object-code compatible with the C64x+/C674x DSPs.

For more information on the TMS320C66x core CPU, see the *TMS320C66x DSP CPU and Instruction Set Reference Guide*, ([SPRUGH7](#)).

Each of the two DSP subsystems integrated in the device includes the following components:

- A TMS320C66x CorePac DSP core that encompasses :
  - L1 program-dedicated (L1P) cacheable memory
  - L1 data-dedicated (L1D) cacheable memory
  - L2 (program and data) cacheable memory
  - Extended Memory Controller (XMC)
  - External Memory Controller (EMC)
  - DSP CorePac located interrupt controller (INTC)
  - DSP CorePac located power-down controller (PDC)
- Dedicated enhanced data memory access engine - EDMA, to transfer data from/to memories and peripherals external to the DSP subsystems and to local DSP memory (most commonly L2 SRAM). The external DMA requests are passed through DSP system level (SYS) wakeup logic, and collected from the DSP1 / DSP2 dedicated outputs of the device DMA Events Crossbar for each of the two subsystems.
- A level 2 (L2) interconnect network (DSP NoC) to allow connectivity between different modules of the subsystem or the remainder of the device via the device L3\_MAIN interconnect.
- Two memory management units (on EDMA L2 interconnect and DSP MDMA paths) for accessing the device L3\_MAIN interconnect address space
- Dedicated system control logic (DSP\_SYSTEM) responsible for power management, clock generation, and connection to the device power, reset, and clock management (PRCM) module

[Figure 5-1](#) is the DSP subsystem top-level architecture.

**Figure 5-1. DSP Subsystem Highlight**

dspss-001

**NOTE:** (1) : This diagram shows a single DSP instance. Each device may have **one or two identical DSP instances**, refer to corresponding *device Data Manual* for the specific device support.

### 5.1.1 DSP Subsystems Key Features

The TMS320C66x Instruction Set Architecture (ISA) is the latest for the C6000 family. As with its predecessors (C64x, C64x+ and C674x), the C66x is an advanced VLIW architecture with 8 functional units (two multiplier units and six arithmetic logic units) that operate in parallel. The C66x CPU has a total of 64 general-purpose 32-bit registers.

Some features of the DSP C6000 family devices are :

- Advanced VLIW CPU with eight functional units (two multipliers and six ALUs) which:
  - Executes up to eight instructions per cycle for up to ten times the performance of typical DSPs
  - Allows designers to develop highly effective RISC-like code for fast development time
- Instruction packing
  - Gives code size equivalence for eight instructions executed serially or in parallel
  - Reduces code size, program fetches, and power consumption
- Conditional execution of most instructions

- Reduces costly branching
- Increases parallelism for higher sustained performance
- Efficient code execution on independent functional units
  - Industry's most efficient C compiler on DSP benchmark suite
  - Industry's first assembly optimizer for fast development and improved parallelization
- 8-/16-/32-bit/64-bit data support, providing efficient memory support for a variety of applications
- 40-bit arithmetic options which add extra precision for vocoders and other computationally intensive applications
- Saturation and normalization to provide support for key arithmetic operations
- Field manipulation and instruction extract, set, clear, and bit counting support common operation found in control and data manipulation applications.

The C66x CPU has the following additional features :

- Each multiplier can perform two 16 × 16-bit or four 8 × 8 bit multiplies every clock cycle.
- Quad 8-bit and dual 16-bit instruction set extensions with data flow support
- Support for non-aligned 32-bit (word) and 64-bit (double word) memory accesses
- Special communication-specific instructions have been added to address common operations in error-correcting codes.
- Bit count and rotate hardware extends support for bit-level algorithms.
- Compact instructions: Common instructions (AND, ADD, LD, MPY) have 16-bit versions to reduce code size.
- Protected mode operation: A two-level system of privileged program execution to support higher-capability operating systems and system features such as memory protection.
- Exceptions support for error detection and program redirection to provide robust code execution
- Hardware support for modulo loop operation to reduce code size and allow interrupts during fully-pipelined code
- Each multiplier can perform 32 × 32 bit multiplies
- Additional instructions to support complex multiplies allowing up to eight 16-bit multiply/add/subtracts per clock cycle

The TMS320C66x has the following key improvements to the ISA :

- 4x Multiply Accumulate improvement for both fixed and floating point
- Improvement of the floating point arithmetic
- Enhancement of the vector processing capability for fixed and floating point
- Addition of domain-specific instructions for complex arithmetic and matrix operations

**On the C66x ISA, the vector processing capability is improved by extending the width of the SIMD instructions.** The C674x DSP supports 2-way SIMD operations for 16-bit data and 4-way SIMD operations for 8-bit data. C66x enhances this capabilities with the addition of SIMD instructions for 32-bit data allowing operation on 128-bit vectors. For example the QMPY32 instruction is able to perform the element to element multiplication between two vectors of four 32-bit data each.

C66x ISA includes a set of specific instructions to handle complex arithmetic and matrix operations.

- **TMS320C66x DSP CorePac memory components :**
  - A 32-KiB L1 program memory (L1P) configurable as cache and / or SRAM:
    - When configured as a cache, the L1P is a 1-way set-associative cache with a 32-byte cache line
    - The DSP CorePac L1P memory controller provides bandwidth management, memory protection, and power-down functions
    - The L1P is capable of cache block and global coherence operations
    - The L1P controller has an Error Detection (ED) mechanism, including necessary SRAM
    - The L1P memory can be fully configured as a cache or SRAM

- Page size for L1P memory is 2KB
- A 32-KiB L1 data memory (L1D) configurable as cache and / or SRAM:
  - When configured as a cache, the L1D is a 2-way set-associative cache with a 64-byte cache line
  - The DSP CorePac L1D memory controller provides bandwidth management, memory protection, and power-down functions
  - The L1D memory can be fully configured as a cache or SRAM
  - No support for error correction or detection
  - Page size for L1D memory is 2KB
- A 288-KiB (program and data) L2 memory, only part of which is cacheable:
  - When configured as a cache, the L2 memory is a 4-way set associative cache with a 128-byte cache line
  - Only 256 KiB of L2 memory can be configured as cache or SRAM
  - 32 KiB of the L2 memory is always mapped as SRAM
  - The L2 memory controller has an Error Correction Code (ECC) and ED mechanism, including necessary SRAM
  - The L2 memory controller supports hardware prefetching and also provides bandwidth management, memory protection, and power-down functions.
  - Page size for L2 memory is 16KB
- The **External Memory Controller (EMC)** is a bridge from the C66x CorePac to the rest of the DSP subsystem and device. It has :
  - a 32-bit configuration port (CFG) providing access to local subsystem resources (like DSP\_EDMA, DSP\_SYSTEM, etc) or to L3\_MAIN resources accessible via the CFG address range.
  - a 128-bit slave-DMA port (SDMA) which provides accesses of system masters outside the DSP subsystem to resources inside the DSP subsystem or C66x DSP CorePac memories, i.e. when the DSP subsystem is the slave in a transaction.
- The Extended Memory Controller (XMC) processes requests from the L2 Cache Controller (which are a result of CPU instruction fetches, load/store commands, cache operations) to device resources via the C66x DSP CorePac 128-bit master DMA (MDMA) port :
  - Memory protection for addresses outside C66x DSP CorePac generated over device L3\_MAIN on the MDMA port
  - Prefetch, multi-in-flight requests
- A DSP local **Interrupt Controller (INTC)** in the DSP C66x CorePac, interfaces the system events to the DSP C66x core CPU interrupt and exceptions inputs. Each DSP subsystem C66x CorePac interrupt controller supports up to 128 system events of which 64 interrupts are external to DSP subsystems, collected from the DSP1 /DSP2 dedicated outputs of the device Interrupt Crossbar.
- **Local Enhanced Direct Memory Access (EDMA) controller features:**
  - Channel controller (CC) : 64-channel, 128 PaRAM, 2 Queues
  - 2 x Third-party Transfer Controllers (TPTC0 and TPTC1):
    - Each TC has a 128-bit read port and a 128-bit write port
    - 2KiB FIFOs on each TPTC
  - 1-dimensional/2-dimensional (1D/2D) addressing
  - Chaining capability
- **DSP subsystems integrated MMUs:**
  - Two MMUs are integrated:
    - The MMU0 is located between DSP MDMA master port and the device L3\_MAIN interconnect and can be optionally bypassed
    - The MMU1 is located between the EDMA master port and the device L3\_MAIN interconnect
- A DSP local **Power-Down Controller (PDC)** is responsible to power-down various parts of the DSP C66x CorePac, or the entire DSP C66x CorePac.

- The DSP subsystems **System Control logic** provides:
  - Slave idle and master standby protocols with device PRCM for powerdown
  - OCP Disconnect handshake for init and target busses
  - Asynchronous reset
  - Power-down modes :
    - "Clockstop" mode featuring wake-up on interrupt event. The DMA event wake-up is managed in software.
- The device DSP subsystems are supplied by a PRCM DPLL, but each DSP1/2 **has integrated its own PLL module** outside the C66x CorePac for clock gating and division.
- **Each of the two device DSP subsystems has following port instances** to connect to remaining part of the device. See also [Figure 5-1](#):
  - A 128-bit initiator (DSP MDMA master) port for MDMA/Cache requests
  - A 128-bit initiator (DSP EDMA master) port for EDMA requests
  - A 32-bit initiator (DSP CFG master) port for configuration requests
  - A 128-bit target (DSP slave) port for requests to DSP memories and various peripherals
- **C66x DSP subsystems (DSPSS) safety aspects :**
  - Above mentioned memory ECC/ED mechanisms
  - MMUs enable mapping of only the necessary application space to the processor
  - Memory Protection Units internal to the DSPSS ( in L1P,L1D and L2 memory controllers ) and external to DSPSS (firewalls) to help define legal accesses and raise exceptions on illegal accesses
  - Exceptions: Memory errors, various DSP errors, MMU errors and some system errors are detected and cause exceptions. The exceptions could be handled by the DSP or by a designated safety processor at the chip level. Note that it may not be possible for the safety processor to completely handle some exceptions

**Unsupported features on the C66x DSP core for the device are:**

- The Extended Memory Controller MPAX (memory protection and address extension) 36-bit addressing is NOT supported

**Known DSP subsystem powermode restrictions for the device are:**

- "Full logic / RAM retention" mode featuring wake-up on both interrupt or DMA event (logic in "always on" domain). Only OFF mode is supported by DSP subsystem, **requiring full boot.**

## 5.2 DSP Subsystem Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 5-2 shows the integration of the DSP subsystem.

Figure 5-2. DSP Subsystem Integration

**NOTE:** For more information about the slave idle protocol and the wake-up request, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 5-1 through Table 5-3 summarize the integration of the module in the device.

Table 5-1. DSP Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
DSP1	PD_DSP1	L3_MAIN
DSP2	PD_DSP2	L3_MAIN

**Table 5-2. DSP Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description

	DSP2_LRST	DSP2_LRST	PRCM module	
	DSP2_LRST_DONE <sup>(1)</sup>	DSP2_LRST_DONE	DSP2	

<sup>(1)</sup> Destination of this local reset monitoring signal is the PRCM

**NOTE:** For information about PRCM clock gating and management, see [Section 3.7.2, PD\\_DSP1 Description](#) and [Section 3.7.3, PD\\_DSP2 Description](#) in [Chapter 3, Power, Reset, and Clock Management](#).

The DSP1 / DSP2 generates a number of interrupt requests (IRQs) mapped via the device IRQ\_CROSBAR to other device interrupt controllers (outside DSP subsystem). They are described in [Table 5-3](#).

**Table 5-3. DSP Hardware Requests**

Module Instance	Source Signal Name	Interrupt Requests		Description
		Destination IRQ_CROSSBAR Input	Default Mapping	
DSP1	DSP1_IRQ_MMU0	IRQ_CROSSBAR_23	MPU_IRQ_28 DSP1_IRQ_54 DSP2_IRQ_54	Interrupt from the DSP1 subsystem local MMU0 (DSP1_MMU0CFG).
	DSP1_IRQ_MMU1	IRQ_CROSSBAR_145	-	DSP1 subsystem local MMU1 (DSP1_MMUCFG1) interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP1_IRQ_TPCC_ERR	IRQ_CROSSBAR_317	-	DSP1 subsystem aggregated ("OR-ed") error interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP1_IRQ_TPCC_GLOBAL	IRQ_CROSSBAR_318	-	DSP1 subsystem EDMA channel controller global interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP1_IRQ_TPCC_REGION0	IRQ_CROSSBAR_319	-	DSP1 subsystem EDMA channel controller REGION0 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP1_IRQ_TPCC_REGION1	IRQ_CROSSBAR_320	-	DSP1 subsystem EDMA channel controller REGION1 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP1_IRQ_TPCC_REGION2	IRQ_CROSSBAR_321	-	DSP1 subsystem EDMA channel controller REGION2 interrupt. This IRQ source signal is not mapped by default to any device INTC.

**Table 5-3. DSP Hardware Requests (continued)**

DSP1_IRQ_TPCC_REGION3	IRQ_CROSSBAR_322	-	DSP1 subsystem EDMA channel controller REGION3 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
DSP1_IRQ_TPCC_REGION4	IRQ_CROSSBAR_323	-	DSP1 subsystem EDMA channel controller REGION4 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
DSP1_IRQ_TPCC_REGION5	IRQ_CROSSBAR_324	-	DSP1 subsystem EDMA channel controller REGION5 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
DSP1_IRQ_TPCC_REGION6	IRQ_CROSSBAR_375	-	DSP1 subsystem EDMA channel controller REGION6 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
DSP1_IRQ_TPCC_REGION7	IRQ_CROSSBAR_376	-	DSP1 subsystem EDMA channel controller REGION7 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
DSP2	DSP2_IRQ_MMU0	IRQ_CROSSBAR_146	-	DSP2 subsystem local MMU0 (DSP2_MMU0CFG) interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP2_IRQ_MMU1	IRQ_CROSSBAR_147	-	DSP2 subsystem local MMU1 (DSP2_MMUCFG1) interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP2_IRQ_TPCC_ERR	IRQ_CROSSBAR_325	-	DSP2 subsystem aggregated ("OR-ed") error interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP2_IRQ_TPCC_GLOBAL	IRQ_CROSSBAR_326	-	DSP2 subsystem EDMA channel controller global interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP2_IRQ_TPCC_REGION0	IRQ_CROSSBAR_327	-	DSP2 subsystem EDMA channel controller REGION0 interrupt. This IRQ source signal is not mapped by default to any device INTC.

**Table 5-3. DSP Hardware Requests (continued)**

DSP2_IRQ_TPCC_REGION1	IRQ_CROSSBAR_328	-	DSP2 subsystem EDMA channel controller REGION1 interrupt. This IRQ source signal is not mapped by default to any device INTC.
DSP2_IRQ_TPCC_REGION2	IRQ_CROSSBAR_329	-	DSP2 subsystem EDMA channel controller REGION2 interrupt. This IRQ source signal is not mapped by default to any device INTC.
DSP2_IRQ_TPCC_REGION3	IRQ_CROSSBAR_330	-	DSP2 subsystem EDMA channel controller REGION3 interrupt. This IRQ source signal is not mapped by default to any device INTC.
DSP2_IRQ_TPCC_REGION4	IRQ_CROSSBAR_331	-	DSP2 subsystem EDMA channel controller REGION4 interrupt. This IRQ source signal is not mapped by default to any device INTC.
DSP2_IRQ_TPCC_REGION5	IRQ_CROSSBAR_332	-	DSP2 subsystem EDMA channel controller REGION5 interrupt. This IRQ source signal is not mapped by default to any device INTC.
DSP2_IRQ_TPCC_REGION6	IRQ_CROSSBAR_377	-	DSP2 subsystem EDMA channel controller REGION6 interrupt. This IRQ source signal is not mapped by default to any device INTC.
DSP2_IRQ_TPCC_REGION7	IRQ_CROSSBAR_378	-	DSP2 subsystem EDMA channel controller REGION7 interrupt. This IRQ source signal is not mapped by default to any device INTC.

---

**NOTE:** The DSP1 / DSP2 does NOT generate any DMA requests towards other device DMA controllers outside DSP1 / DSP2 (EDMA, DMA\_SYSTEM, etc.).

---

---

**NOTE:** The “**Default Mapping**” column in [Table 5-3, DSP Hardware Requests](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ\_CROSSBAR module. For more information about the IRQ\_CROSSBAR module, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#). For more information about the device interrupt controllers, see [Chapter 17, Interrupt Controllers](#).

---

**NOTE:**

- For a description of the interrupt source controls at DSP subsystem level, see [Section 5.3.4, DSP Interrupt Requests](#).
-

**DSP1/DSP2 subsystem external interrupt sources:** The default interrupt sources mapped by the device IRQ\_CROSSBAR to the DSP1 / DSP2 interrupt controller lines are described in the [Chapter 17, Interrupt Controllers](#). The programmable muxing of various external interrupt sources to the DSP1\_INTC.DSP1\_IRQ\_x and DSP2\_INTC.DSP2\_IRQ\_x input lines (where x=32 to 95) is covered in the [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), of the [Chapter 18, Control Module](#).

**DSP1/DSP2 subsystem internal interrupt sources:** The mapping of DSP subsystem internal IRQ sources to DSP1\_IRQ\_x / DSP2\_IRQ\_x lines (where x=0 to 31 and x=96 to 127 for DSP subsystem internal event sources) is described in the [Section 5.3.4, DSP Interrupt Requests](#).

**DSP1/DSP2 subsystem external DMA request sources:** The [Table 5-6](#) and [Table 5-7](#) lists the default DSP1 and DSP2 external DMA request sources, respectively, routed via the device DMA\_CROSSBAR to the DSP1\_EDMA / DSP2\_EDMA channel controller inputs (DMA\_DSP1\_DREQ\_i / DMA\_DSP2\_DREQ\_i).

## 5.3 DSP Subsystems Functional Description

### 5.3.1 DSP Subsystems Block Diagram

Each of the device two DSP subsystems - DSP1 and DSP2 is composed of a DSP C66x CorePac coupled with several other submodules that enable its integration in the device architecture. Device DSP subsystem provides :

- a 128-bit master data port (MDMA) on device L3\_MAIN with a dedicated DSP subsystem local MMU (MMU0) on the path.
- a 32-bit master configuration port (CFG) on device L3\_MAIN through which DSP host configures various device located peripherals (external to the DSP subsystem).
- a 128-bit slave DMA port (SDMA) on device L3\_MAIN which allows external initiators (masters) to DSP to manipulate some portion of its config / status registers (those which are mapped in the L3\_MAIN space) in the device
- a 128-bit master EDMA port - which allows the DSP\_EDMA traffic controllers to initiate transfers on L3\_MAIN.

The C66x DSP subsystem is illustrated in the [Figure 5-1](#).

## 5.3.2 DSP Subsystem Components

### 5.3.2.1 C66x DSP Subsystem Introduction

The key component of the C66x DSP subsystem is built on the TI's high performance TMS320C66x DSP CorePac which consists of a single TMS320C66x CPU (DSP\_C0) processor along with a level 1 (L1P and L1D) cacheable SRAM and a level 2 (L2) cacheable SRAM memories interfaced via associated local L1P, L1D and L2 memory controllers, respectively. A DSP C66x CorePac includes also some other internal peripheral components, see [Section 5.3.2.2.3](#) for details.

This chapter provides an overview of the DSP subsystem and the following considerations associated with it :

- DSP C66x CorePac Core and L1 / L2 Memories
- DSP System control and configuration :
  - clock management
  - wake-up event generation
  - interrupt masking
- DSP Booting
- DSP subsystem internal memory and external memory (L3\_MAIN) space views
- DSP INTC interrupts mapping, event combining and exception generation
- DMA requests mapping to EDMA channels and EDMA traffic routing
- Others

For more information on the TMS320C66x DSP CorePac, refer to the *TMS320C66x DSP CorePac User Guide*, ( [SPRUGW0C](#)), the *TMS320C66x DSP Cache User Guide*, ( [SPRUGY8](#)) and the *TMS320C66x DSP CPU and Instruction Set Reference Guide*, ( [SPRUGH7](#)).

### 5.3.2.2 DSP TMS320C66x CorePac

The TMS320C66x DSP CorePac is illustrated on [Figure 5-1](#). It consists of a single DSP C66x CPU (DSP\_C0) processor tightly coupled with level 1 - L1P (program), L1D (data) cacheable SRAM memories and level 2 (L2) cacheable SRAM memories. The C66x CorePac integrated memories are interfaced via associated local L1P, L1D and L2 memory controllers, respectively.

Additionally, the DSP C66x CorePac contains the following internal peripherals:

- an interrupt controller (DSP\_INTC) to service DSP C66x CorePac internal and external interrupt events
- a power-down controller (DSP\_PDC)
- an external memory controller - DSP\_EMCC
- an extended memory controller - DSP\_XMC\_CTRL
- a bandwidth manager - BWM with local controls to the L1P-, L1D- and L2-memories
- an internal direct memory access controller - IDMA

The C66x CorePac DSP also instantiates Debug and Trace logic, part of which is implemented in the DSP core C66x CPU. For more details, refer to the [Chapter 33, On-Chip Debug Support](#).

#### 5.3.2.2.1 DSP TMS320C66x CorePac CPU

The DSP C66x CorePac CPU includes following key components :

- A program fetch unit
- 16-/32-bit instruction dispatch unit, advanced instruction packing
- Instruction decode unit
- Two data paths, each with four functional units
- 64 x 32-bit general purpose registers
- Control logic and associated registers
- An internal interrupt and exception controller
- Test, emulation logic
- Internal DMA (IDMA) for transfers between internal memories

For more information on the TMS320C66x central processing unit, see the *TMS320C66x DSP CPU and Instruction Set Reference Guide*, ([SPRUGH7](#)).

#### 5.3.2.2.2 DSP TMS320C66x CorePac Internal Memory Controllers and Memories

The TMS320C66x DSP CorePac implements a two-level internal cache-based memory architecture.

##### 5.3.2.2.2.1 Level 1 Memories

Level 1 memory (L1) is split into separate program memory (L1P memory) and data memory (L1D memory). Each of the memories can be split into static RAM (normal addressable on-chip memory) and cache.

**L1P memory** is dedicated to TMS320C66x CPU program words storage and is interfaced via a dedicated L1P memory controller in the DSP C66x CorePac. User can choose to initialize one part of the L1P memory as cache and the other as SRAM. The entire 32 KiB memory is cacheable. The L1P features a dynamically configurable cache size (4 KiB, 8 KiB, 16 KiB and 32 KiB) defined via L1P controller configuration register - L1PCFG[2:0] L1PMODE bitfield. **Note that, the L1P controller maps the cache space by starting at the top of the L1P memory map (i.e. from most significant address) and working downwards. The L1P mapped SRAM size is 32 KiB minus the configured cache size.**

---

**NOTE:** The L1P cache / SRAM is ONLY read-accessible by the C66x CPU processor. The DSP C66x CorePac external DMAs (SDMA and EDMA) and internal DMA (IDMA) are the only initiators which can write to the L1P memory. The CPU may however write access and modify certain L1P cache/SRAM controller registers if such access is allowed for the register.

---

**NOTE:** In the device integrated DSP, at reset, the entire 32 KiB- L1P memory is initialized as a cache (reset value of L1PMODE=0x7).

For more information on the L1P cache/SRAM memories, refer to the *TMS320C66x DSP Cache User Guide*, ( [SPRUGY8](#)).

**L1D memory** is used for level 1 CPU data storage and is interfaced via a dedicated L1D memory controller in the DSP C66x CorePac. User can choose to initialize one part of the L1D memory as cache and the other as SRAM. The entire 32 KiB memory is cacheable. The L1D features a dynamically configurable cache size (4 KiB, 8 KiB, 16 KiB and 32 KiB) defined via L1D configuration register - L1DCFG[2:0] L1DMODE bitfield. **Note that, the L1D controller maps the cache space by starting at the top of the L1D memory map (i.e. from most significant address) and working downwards. The L1D mapped SRAM size is 32 KiB minus the configured cache size.**

**NOTE:** In the device integrated DSP, at reset, the entire 32 KiB- L1D memory is initialized as a cache ( i.e. reset value of L1DMODE = 0x7).

For more information on the L1D cache/SRAM memories, refer to the *TMS320C66x DSP Cache User Guide*, ( [SPRUGY8](#)).

#### 5.3.2.2.2 Level 2 Memory

**The L2 memory** can also be split into L2 RAM (normal addressable on-chip memory) and L2-cache for caching external to the DSP meagmodule memory locations. The on-chip integrated L2 memory total size is 288 KiB. The L2 memory is shared between data and program word sources within and outside the DSP C66x CorePac. The L2 memory is divided into two physical 128 bit-wide banks, accesses to which are interleaved on address LSB. Each of the two L2 banks is further split into 4 subbanks.

**NOTE:** Only 256 KiB of the L2 memory are cacheable in the device DSP. The remaining 32 KiB are always mapped as static RAM.

The L2 memory features a dynamically configurable cache size (32 KiB, 64 KiB, 128 KiB and 256 KiB) defined via L2 configuration register - L2CFG[2:0] L2MODE bitfield. The additional (to the 32KiB fixed SRAM L2) SRAM available is 256-KiB minus the cache size.

**L2 memory controller is responsible for MDMA bus error events reporting. The DSP C66x CorePac MDMA bus error event is exported outside the C66x DSP CorePac in the subsystem, and can be enabled to trigger the ERRINT\_IRQ aggregated interrupt output.** See also corresponding "MDMAERREVT" event in the [Table 5-5](#).

**NOTE:** The MDMA bus error event is not exported outside DSP subsystem. However it is merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT\_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT\_IRQ generation and associated event registers at DSP\_SYSTEM level, refer to the [Section 5.3.4.2.2](#).

#### 5.3.2.2.3 DSP C66x CorePac Internal Peripherals

The DSP C66x CorePac includes the following internal peripherals:

- DSP interrupt controller (DSP\_INTC)
- DSP power-down controller (DSP\_PDC)
- Bandwidth manager (DSP\_BWM)
- Memory Protection Hardware
- Internal DMA (DSP\_IDMA) controller

- External Memory Controller (DSP\_EMC)
- Extended Memory Controller (DSP\_XMC\_CTRL) including prefetch buffer logic
- Error Detection logic for the L1P memory
- Error Detection and Correction (ECC) logic for the L2 memory

This section briefly describes the DSP\_INTC, DSP\_PDC, DSP\_BWM, DSP\_IDMA, DSP\_EMC, DSP\_XMC\_CTRL controller, L1P Error detection and L2 ECC logic. For more information on the TMS320C66x DSP CorePac, see the *TMS320C66x DSP CorePac User Guide*, ( [SPRUGW0C](#)).

#### 5.3.2.2.3.1 DSP C66x CorePac Interrupt Controller (DSP INTC)

The DSP C66x CorePac includes an interrupt controller (DSP\_INTC) and can receive a total of 128 system events as inputs. They include DSP-generated events and chip-level events.

In addition to these 128 events, a non-maskable (NMI) event (see the [Section 5.3.4.1.1](#)) and reset events are mapped to the DSP\_INTC as well, and are routed straight through to the DSP CPU core.

For more details on the DSP\_INTC functionalities and its corresponding control / status registers (part of the DSP\_ICFG local configuration space), refer to the section *Interrupt Controller* within the *TMS320C66x DSP CorePac User Guide*, ( [SPRUGW0C](#)).

For more details on input interrupt mappings and associated IRQ wake-up events, refer to the [Section 5.3.4.1](#).

For more information about the device DSP\_INTC, see [Chapter 17, Interrupt Controllers](#). For more information on chip level IRQ mapping via the device IRQ\_CROSSBAR module, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#).

#### 5.3.2.2.3.2 DSP C66x CorePac Power-Down Controller (DSP PDC)

The DSP C66x CorePac includes a power-down controller (PDC). The PDC can power-down all of the following components of the DSP C66x CorePac and internal memories of the DSP subsystem:

- C66x CPU
- L1P Memory
- L2 Memory
- Cache controllers
- Entire TMS320C66x DSP CorePac

Refer to the *Power-Down Controller* in the *TMS320C66x DSP CorePac User Guide*, ( [SPRUGW0C](#)) for detailed descriptions of the DSP C66x CorePac components power-down control.

#### 5.3.2.2.3.3 DSP C66x CorePac Bandwidth Manager (BWM)

The DSP C66x CorePac implements a bandwidth manager (BWM) to assure that some requestors do NOT block resources in the C66x CorePac DSP for extended periods of time.

Refer to the *Bandwidth Management Architecture* in the *TMS320C66x DSP CorePac User Guide*, ( [SPRUGW0C](#)) for detailed descriptions of the DSP C66x CorePac components power-down control.

#### 5.3.2.2.3.4 DSP C66x CorePac Memory Protection Hardware

The C66x Core Pac memory protection architecture introduces in the DSP a combination of DSP privilege levels and a memory system permission structure. This provides several benefits to the system, as follows:

**The DSP C66x CorePac MP events are exported outside the DSP C66x CorePac in DSP subsystem, and can be enabled to trigger the ERRINT\_IRQ aggregated interrupt output. See also corresponding memory protection fault events listed in the [Table 5-5](#).**

---

**NOTE:** The memory protection exception events are not exported outside DSP subsystem. However they are merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT\_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT\_IRQ generation and associated event registers at DSP\_SYSTEM level, refer to the [Section 5.3.4.2.2](#).

---

**NOTE:** IDMA, DMA or System initiators should not issue read/write requests to regions of DSP L1P, L1D, or L2 memory configured as cache. In such cases the corresponding MPPA register should be set to 0x0 to disallow external read/write accesses.

---

Refer to the section *Memory Protection* in the *TMS320C66x DSP CorePac User Guide*, ( [SPRUGW0C](#)) for detailed descriptions of the DSP C66x CorePac components power-down control.

#### 5.3.2.2.3.5 DSP C66x CorePac Internal DMA (IDMA) Controller

The IDMA controller performs fast block transfers between any two memory locations local to the DSP C66x CorePac. Local memory locations are defined as those in Level 1 program (L1P), Level 1 data (L1D), and Level 2 (L2) memories, or in the external peripheral configuration (CFG) port.

The IDMA configuration / status registers themselves are part of the DSP\_ICFG and are visible only to C66x CPU.

---

**NOTE:** The IDMA cannot transfer data to or from the internal DSP memory-mapped register space (DSP\_ICFG).

The IDMA exception is mapped to the system level ERRINT\_IRQ interrupt event. For more details, refer to the [Section 5.3.4.2.2](#) and the [Table 5-5](#).

---

**The DSP C66x CorePac IDMA error event is exported outside the DSP C66x CorePac in the subsystem, and can be enabled to trigger the ERRINT\_IRQ aggregated interrupt output.** See also corresponding "EMC\_IDMAERR" event in the [Table 5-5](#).

---

**NOTE:** The IDMA exception error event is not exported outside DSP subsystem. However it is merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT\_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT\_IRQ generation and associated event registers at DSP\_SYSTEM level, refer to the [Section 5.3.4.2.2](#).

---

The IDMA is fully described in the section *Internal Direct Memory Access (IDMA) Controller* of the *TMS320C66x DSP CorePac User Guide*, ( [SPRUGW0C](#)).

#### 5.3.2.2.3.6 DSP C66x CorePac External Memory Controller

The DSP C66x CorePac has an embedded External Memory Controller which acts as a bridge between the DSP C66x CorePac CPU and the remaining part of DSP subsystem. It implements two ports interfacing the DSP C66x CorePac environment:

- An external peripheral 32-bit CFG port which acts as an (DSP CPU cfg) initiator on the DSP\_NoC L2 interconnect. It is the root source of all C66x CPU external configuration traffic (**excluding the DSP\_ICFG traffic which takes place only within the DSP C66x CorePac**) towards the subsystem.
- An SDMA slave port which is a target on the L2 DSP\_NoC interconnect. It generally accepts traffic initiated on DSP\_NoC by the:
  - DSP\_EDMA\_TC0 and DSP\_EDMA\_TC1
  - DSP external slave port on the L3\_MAIN

In summary:

- The CPU CFG port provides access to the memory-mapped registers which control various peripherals

and resources within the DSP subsystem, such as the MMUs, DSP\_EDMA controllers, DSP system control and wakeup logic, DSP NoC itself, DSP external peripherals, etc.

- The DSP system masters found outside the DSP C66x CorePac such as the DSP\_EDMA controllers (TC0 and TC1) or L3\_MAIN masters (device MPU, IPU1, IPU2, etc.) access the SDMA slave port to reach resources inside the DSP C66x CorePac. In respect to the SDMA port, the DSP C66x CorePac is the slave in the transaction.

The DSP\_EMC controller adds following functionalities to the DSP C66x CorePac:

- Reporting errors related to the C66x CPU external peripheral configuration bus (associated registers)

---

**NOTE:** Regarding PrivID versus AID mapping functionality of the EMC, the C66x DSP CorePac is able to distinguish ONLY "local" vs "external" requests. The device integrated C66x DSP CorePac has the SDMA PrivID input tied-off to a value of 0x0. On DSP C66x CorePac SDMA port, this means that no distinguishing can be made between external requests which come over DSP\_NoC interconnect from local DSP\_EDMA and those coming from other initiators accessing DSP via the device L3\_MAIN interconnect.

**This limits the functionality of the internal memory protection registers.**

---

**The DSP C66x CorePac EMC error event is exported outside the DSP C66x CorePac in the subsystem, and is capable to trigger the ERRINT\_IRQ aggregated interrupt output.** See also corresponding **EMC\_BUSERR** event in the [Table 5-5](#).

---

**NOTE:** The EMC configuration bus error event is not exported outside DSP subsystem. However it is merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT\_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT\_IRQ generation and associated event registers at DSP\_SYSTEM level, refer to the [Section 5.3.4.2.2](#).

---

For various DSP\_NoC initiator vs target mappings, refer to the [Table 5-8](#).

Note that, there are DSP\_NoC pressure (Mflag bus) controls in DSP\_SYSTEM logic related to the C66x CPU CFG and DSP\_NoC SDMA init traffic. They are described in the [Section 5.3.8.3](#).

The EMC functionalities / registers are fully described in the section *External Memory Controller (EMC)* of the *TMS320C66x DSP CorePac User Guide*, ([SPRUGW0C](#)).

### 5.3.2.2.3.7 DSP C66x CorePac Extended Memory Controller

The DSP C66x CorePac located extended memory controller (DSP\_XMC\_CTRL) implements a local DMA master port (MDMA) which provides the primary path for C66x CPU and cache requests to the device level memories such as (DDR or L3 SRAM) and peripheral / memory mapped register space. Via some additional logic, including DSP\_SYSTEM controls and a local DSP MMU - DSP\_MMU0 on the path (with option to bypass), C66x local MDMA port is mapped to the DSP subsystem CPU master port (i.e. MDMA master port of the DSP CPU on L3\_MAIN). The DSP C66x Corepac MDMA port is mapped to the DSP Subsystem CPU Master Port (with DSP\_MMU0 involved or not involved) to allow fast accesses (DSP\_NoC not involved) to the external SDRAM (via the L3\_MAIN and DMM) or to L3 SRAM (via the L3\_MAIN).

The memory protection settings in MPAX defines types of the memory accesses permitted on various address ranges within DSP C66x CorePac 32-bit address map.

The DSP\_XMC\_CTRL also instantiates program and data prefetch buffer logic to reduce time during servicing read requests from the L1D, L1P and L2 memory controllers. The aim is to buffer program and data fetches from external L3\_MAIN memory locations. While the program prefetch buffer is organized as 4 entry x 32 byte, the data prefetch buffer is organized in 8 slots, with 128 bytes per slot. The DSP\_XMC\_CTRL prefetch reduces the penalty associated with accesses to the L3\_MAIN SDRAM upon L1P, L1D and L2-cache read-misses.

---

**NOTE:** the DSP\_XMC\_CTRL registers are part of the DSP\_ICFG space, hence they are not accessible outside the DSP C66x CorePac (visible only to the C66x CPU).

---

In summary the DSP\_XMC\_CTRL provides :

- a master path from the DSP C66x CorePac level 2 cache / SRAM memory to device memory such as SDRAM or L3 SRAM or peripheral / MMR address space.
- memory protection on external address ranges related to L3\_MAIN RAMs (via MPAX unit) :
  - 16 user-defined address ranges (MPAX segments) can be used to divide external memory space
- Address translation
- Data and Program prefetch buffer logic
- 12- address candidate buffer that acts as a "stream detection filter"

---

**NOTE:** The device DSP subsystem does NOT use the DSP C66x CorePac multicore shared memory controller (MSMC) port to add more static RAM within subsystem boundaries, i.e. no additional SRAM is available in the DSP except for the L1P, L1D and L2 memories. Only the DSP\_XMC\_CTRL controller MDMA port on the L3\_MAIN interconnect is used to extend DSP available RAM memory via a direct or DSP\_MMU0 translated access to the device EMIF DDR memories and OCMC RAMs.

---

---

**NOTE:** **Only the memory protection function of the DSP\_XMC\_CTRL MPAX unit is intergated** and used in the device DSP subsystem. The MDMA port 32-bit to 36-bit address extension function is NOT used in the device DSP because L3\_MAIN address bus width is 32-bit. The DSP\_MMU0 does NOT perform an address size (32b -> 36b) extension as well.

---

The XMC functionalities / registers are fully described in the section *Extended Memory Controller (XMC)* of the *TMS320C66x DSP CorePac User Guide*, ([SPRUGW0C](#)).

### 5.3.2.2.3.7.1 XMC MDMA Accesses at DSP System Level

#### 5.3.2.2.3.7.1.1 DSP System MPAX Logic

The default configuration of MPAX registers provides a 32-bit view of system memory on L3\_MAIN.

In summary, each MPAX segment (mentioned above) is programmed with a starting virtual base address, segment sizes from 4 GiB down to 4 KiB, replacement address (i.e., physical address); and permission attributes. Provided that DSP\_MMU0 can be used to perform address translation, in most cases the replacement address will equal the base address (i.e., virtual == physical from DSP C66x CorePac perspective).

The system level implementation of MPAX logic allows the C66x CPU to change permission without being required to flush the cache.

The C66x CPU subsystem relies on the MPAXn.PERM field to properly configure the permissions for remote address ranges. The MDMA.rperm[6:0] signals are tie-off to a fixed value of 0x7F on the DSP C66x CorePac boundary.

#### 5.3.2.2.3.7.1.2 MDMA Non-Post Override Control

The C66x corepac submits writes denoted as either "cacheable" or non-cacheable. Write accesses that are non-cacheable will be submitted as interconnect (L3\_MAIN) non-posted writes; whereas write accesses that are cacheable are submitted as interconnect posted writes. An exception for the cache writes to L3\_MAIN is that in the case of a cache block write-back operation (when actual cache evict busrts are actually issued towards L3\_MAIN connected memory), a non-posted write is submitted.

---

**NOTE:** In order to provide a safety net for interconnects that may do aggressive reordering, a memory-mapped register SW control is provided - [DSP\\_SYS\\_BUS\\_CONFIG\[24\]](#) `NOPOSTOVERRIDE`. When set, this results in all write commands being issued as non-posted. This bit defaults to set, and thus the default behavior is for non-posted writes to be used exclusively.

---

#### 5.3.2.2.3.8 L1P Memory Error Detection Logic

The L1P memory detection logic (no correction is implemented) uses a 4-bit parity per 256-bit location (1-bit parity per 64-bit line quadrant).

The L1P error detection logic features:

- L1P error detection command, status and address controls (registers)
- L1P\_ED error detection exception / interrupt to the DSP\_INTC upon DMA / IDMA access
- a direct exception event to C66x CPU (DSP\_INTC not involved) upon parity error during a program fetch from L1P-cache
- L1P-cache error recovery

**The L1P parity error detection event is exported outside the DSP C66x CorePac in the subsystem, and can be enabled to trigger the ERRINT\_IRQ aggregated interrupt output.** See also corresponding "PMC\_ED" event in the [Table 5-5](#).

---

**NOTE:** The L1P error detection event is not exported outside DSP subsystem. However it is merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT\_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT\_IRQ generation and associated event registers at DSP\_SYSTEM level, refer to the [Section 5.3.4.2.2](#).

---

For more details on L1P error detection logic, refer to the section *L1P Error Detection*, of the *TMS320C66x DSP CorePac User Guide*, ([SPRUGW0C](#)).

#### 5.3.2.2.3.9 L2 Memory Error Detection and Correction Logic

The L2 Memory error detection and correction logic (ECC) implements a distance-3 "detect 2, correct 1" Hamming code based error correction / detection algorithm. A 12-bit hamming code per 256-bit is used.

The L2 error detection and correction logic features:

- L2 error detection command, status and address controls (registers)
- L2 EDC enable
- L2 error detection event counter
- 2x L2 EDC exception / interrupts mapped to the DSP\_INTC :
  - L2\_ED1 = "error corrected" event
  - L2\_ED2 = "error-not-corrected" event

**The two L2 memory error correction events are exported outside the DSP C66x CorePac in the subsystem, and can be enabled to trigger the ERRINT\_IRQ aggregated interrupt output.** See also corresponding "UMC\_ED1" and "UMC\_ED2" events in the [Table 5-5](#).

---

**NOTE:** The L2 error detection events are not exported outside DSP subsystem. However they are merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT\_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT\_IRQ generation and associated event registers at DSP\_SYSTEM level, refer to the [Section 5.3.4.2.2](#).

---

For more details on L2 error detection and correction logic, refer to the section *L2 Error Detection and Correction* of the *TMS320C66x DSP CorePac User Guide*, ([SPRUGW0C](#)).

### 5.3.2.3 DSP Debug and Trace Support

The DSP subsystem offers full support for the native DSP C66x CorePac debug features. This includes Advanced Event Triggering (AET) and Trace.

#### 5.3.2.3.1 DSP Advanced Event Triggering (AET)

AET capability can be used to debug complex problems as well as understand performance characteristics of user applications. AET provides the following capabilities:

- **Hardware Program Breakpoints:** specify addresses or address ranges that can generate events such as halting the processor or triggering the trace capture.
- **Data Watchpoints:** specify data variable addresses, address ranges, or data values that can generate events such as halting the processor or triggering the trace capture.
- **Counters:** count the occurrence of an event or cycles for performance monitoring.
- **State Sequencing:** allows combinations of hardware program breakpoints and data watchpoints to precisely generate events for complex sequences.

#### 5.3.2.3.2 DSP Trace Support

Trace is a debug technology that provides a detailed, historical account of application code execution, timing, and data accesses. Trace collects, compresses, and exports debug information for analysis. Trace works in real-time and does not impact the execution of the system. Trace is supported via Code Composer Studio.

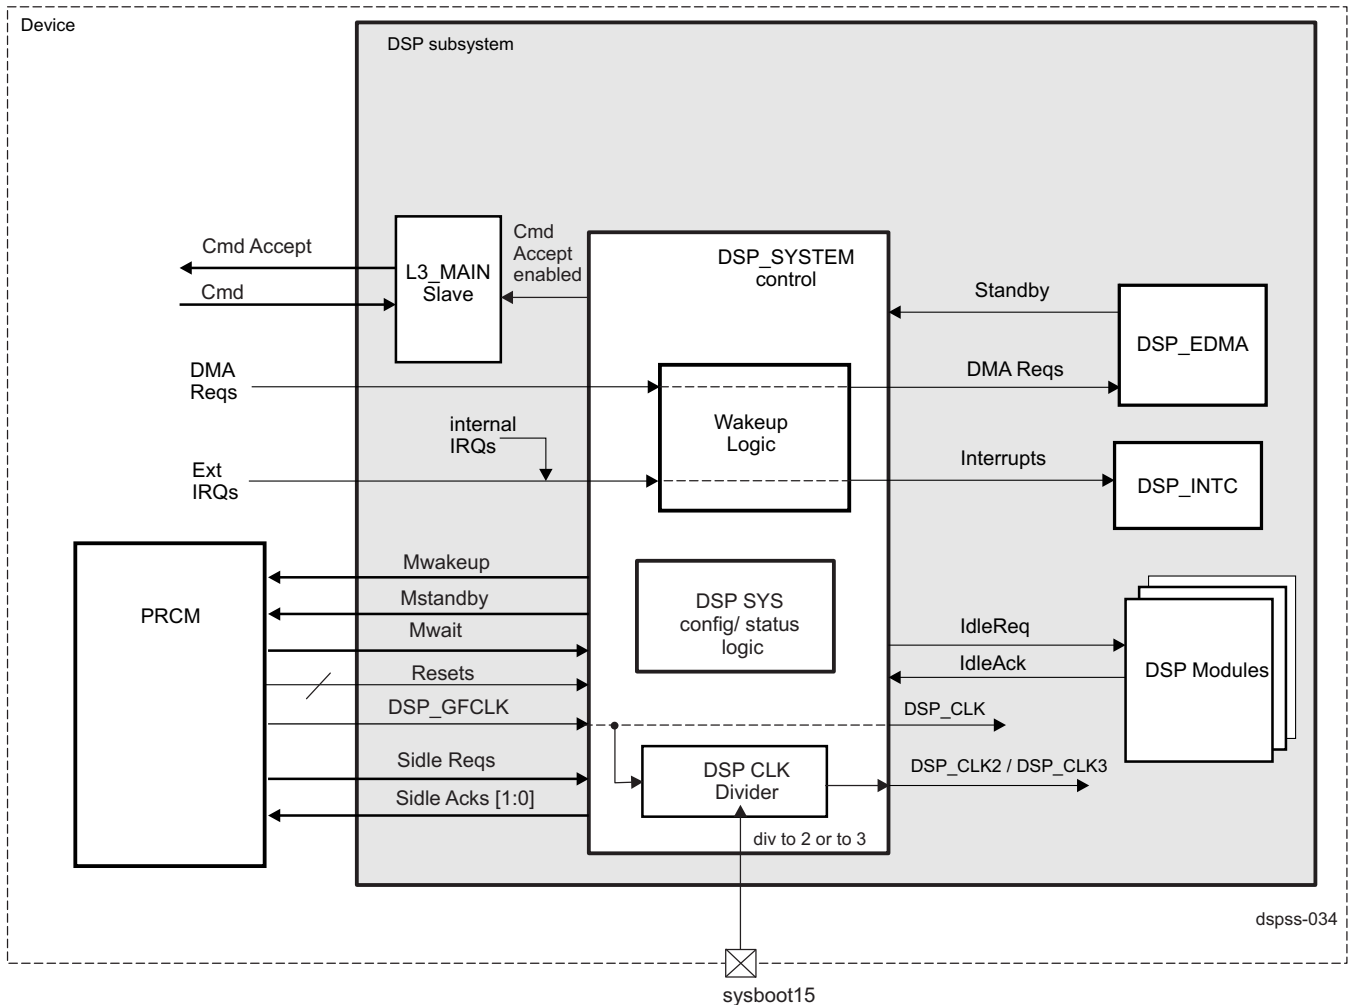

See also the [Chapter 33, On-Chip Debug Support](#).

### 5.3.3 DSP System Control Logic

The DSP\_SYSTEM module controls the following functions:

- Generation of the divided clocks (DSP\_CLK2 or DSP\_CLK3) to all components of the DSP subsystem
- Synchronization of the DSP divided clocks
- PRCM module power handshaking
- Reset input resynchronization of the active-to-inactive transition to the CD1\_CLK clock
- DSP subsystem top level configuration registers and its access from the DSP core.

[Figure 5-3](#) highlights the DSP\_SYSTEM and its connectivities to the surrounding blocks within the subsystem and in the device.

**Figure 5-3. DSP\_SYSTEM Block Diagram**

### 5.3.3.1 DSP System Clocks

The DSP1 and DSP2 subsystems inputs a primary non-divided clock (DSP1\_FICLK / DSP2\_FICLK) and based on it (DSP\_CLK1), internally generates either **a divided by 2 clock** (DSP\_CLK2) or **a divided by 3 clock** (DSP\_CLK3). The divided clock determines the operation rate of the DSP subsystem logic and bus interfaces. The division is defined upon device boot time through signal level externally applied on the device **sysboot15** input. The actual bit configuration is latched upon power-on reset in Control Module register CTRL\_CORE\_BOOTSTRAP[15] SYS\_BOOT\_15\_CLOCK\_DIVIDER boot status bit. For more details, refer to the [Section 18.4.6.14.1, System Boot Status Settings](#) of the chapter, *Control Module*.

**NOTE:** Only DSP\_CLK3 clock is supported on this SoC. Upon boot time, sysboot15 set at '1' selects a DSP\_CLK3 divided clock version for the DSP subsystem logic and bus interfaces. For SR1.1, sysboot15 must be tied to vdd to select DSP\_CLK3, but for SR2.0 it is configurable. For more information, see [Section 18.4.6.1.1.1, Permanent PU/PD disabling \(SR 2.0 only\)](#) in [Chapter 18, Control Module](#).

The clock operating mode setting (DSP\_CLK2 or DSP\_CLK3) must be static just before and continually after reset deassertion. This signal will also drive the configuration to the DSP C66x CorePac for the XMC\_MDMA\_CLK, EMC\_SDMA\_CLK, and EMC\_CFG\_CLK configurations.

The DSPSS1 / DSPSS2 subsystem input clock frequency (DSP\_CLK1) corresponds to the PRCM DSP1\_GFCLK / DSP2\_GFCLK frequency that is configured in the device PRCM registers.

---

**NOTE:** For valid DSP\_CLK1 (and hence for DSP\_CLK3 = DSP\_CLK1 / 3) frequency range, see the Operating Performance Points section of the device Data Manual.

---

The [Section 5.3.2](#) also shows the distribution of the different DSP subsystems blocks within the two DSP local clock domains CD0\_CLK (running on DSP\_CLK frequency) and CD1\_CLK (running on DSP\_CLK2 or DSP\_CLK3 frequency).

### 5.3.3.2 DSP Hardware Resets

The DSP uses the same reset sources than those mapped to the DSP C66x CorePac; i.e. DSP C66x CorePac reset inputs will be pinned out as DSP system reset inputs.

The [Table 5-4](#) summarizes the DSP hardware reset inputs and their functional descriptions.

**Table 5-4. Summary of the DSP1 and DSP2 Hardware Resets**

DSP1 reset input	DSP1 reset "done" output to PRCM	Description
DSP1_PWR_RST	-	This is power-on reset signal used inside DSP1 to reset mainly the emulation logic. It resets the entire DSP1 logic.
DSP1_RST	-	Reset signal used to reset all logic inside DSP1 except Emulation logic.
DSP1_LRST	-	Reset applied ONLY to the C66x CPU inside DSP1
-	DSP1_LRST_DONE	Indicates completion of the DSP1 local C66x CPU reset to device PRCM
DSP2 reset input	DSP2 reset "done" output to PRCM	Description
DSP2_PWR_RST	-	This is power-on reset signal used inside DSP2 to reset mainly the emulation logic. It resets the entire DSP2 logic.
DSP2_RST	-	Reset signal used to reset all logic inside DSP2 except Emulation logic.
DSP2_LRST	-	Reset applied ONLY to the C66x CPU inside DSP2
-	DSP2_LRST_DONE	Indicates completion of the DSP2 local C66x CPU reset to device PRCM

See also the [Section 5.2](#) for more information on the PRCM reset sources to DSP reset inputs connectivity.

Refer to the [Section 3.5.6.6](#), *DSP1 Subsystem Power-on Reset Sequence* and the [Section 3.5.6.8](#), *DSP2 Subsystem Power-on Reset Sequence* in the chapter, *Power, Reset and Clock Managment* for more details on the DSP1 and DSP2 power-on reset sequence, respectively.

---

**NOTE:** In the case of DSP1 / DSP2 recovery from the "Powerdown-grid off", a full power-on-reset sequence is required before re-booting and resuming functional operation.

---

---

**The DSP host (device MPU) software must ensure that the PRCM functional clock DSP1\_GFCLK / DSP2\_GFCLK is enabled to the DSP1 / DSP2, respectively, prior to starting the DSP1 / DSP2 power-on reset sequence.**

---

### 5.3.3.3 DSP Software Resets

During a software reset on the DSP, all resets described in [Table 5-4](#) are asserted, except for the power-on DSP\_PWRON\_RST signal which remains de-asserted in this case.

The DSP subsystem does NOT implement any local software reset controls. The software reset assertion and DSP\_LRST completion monitoring is done in PRCM located registers (part of the DSP1\_PRM / DSP2\_PRM address space).

Refer to the [Section 3.5.6.7](#), *DSP1 Subsystem Software Warm Reset Sequence* and the [Section 3.5.6.9](#), *DSP2 Subsystem Software Warm Reset Sequence* in the chapter, *Power, Reset and Clock Manangement* for more details on the DSP1 and DSP2 software reset sequence and related software controls, respectively.

### 5.3.3.4 DSP Power Management

The supported power-down modes are:

- Slave idle and master standby protocols for powerdown
- "Disconnect from interconnect" handshake for init and target busses
- Clock Stop mode - wakeup on interrupt or DMA event
- Grid OFF mode : No power supply is switched-on

---

**NOTE:** Powerdown-retention mode is NOT supported by DSP subsystem. **The DSP recovery from the Powerdown-grid OFF mode requires full boot.**

---

The DSP C66x CorePac natively supports "CLKSTOP/Static Powerdown" and "POWERDOWN (Grid off)" modes of operation. Once the device PRCM restores clocks and power supply, then the DSP C66x CorePac can exit static-powerdown.

The DSP\_SYSTEM wakeup logic is implemented in the "always-on" clock / power supply domain. This logic monitors new interrupts / events and will drive the IDLE wakeup request when a new interrupt / event occurs.

#### 5.3.3.4.1 DSP System Powerdown Protocols

For each of the powerdown modes – Static or Powerdown-Grid Off, the device PRCM will control whether clocks are gated, or whether supplies are reduced or removed.

---

**NOTE:** In the case of "Powerdown-grid off", a full power-on-reset sequence is required before re-booting and resuming functional operation.

---

In the static powerdown modes - the DSP recognizes new level interrupts while in a clock-gated state (and drive wakeup request). During this powerdown mode all internal state will be retained, including DSP C66x CorePac, interconnect, EDMA, memories, etc.

The following protocols are implemented with PRCM:

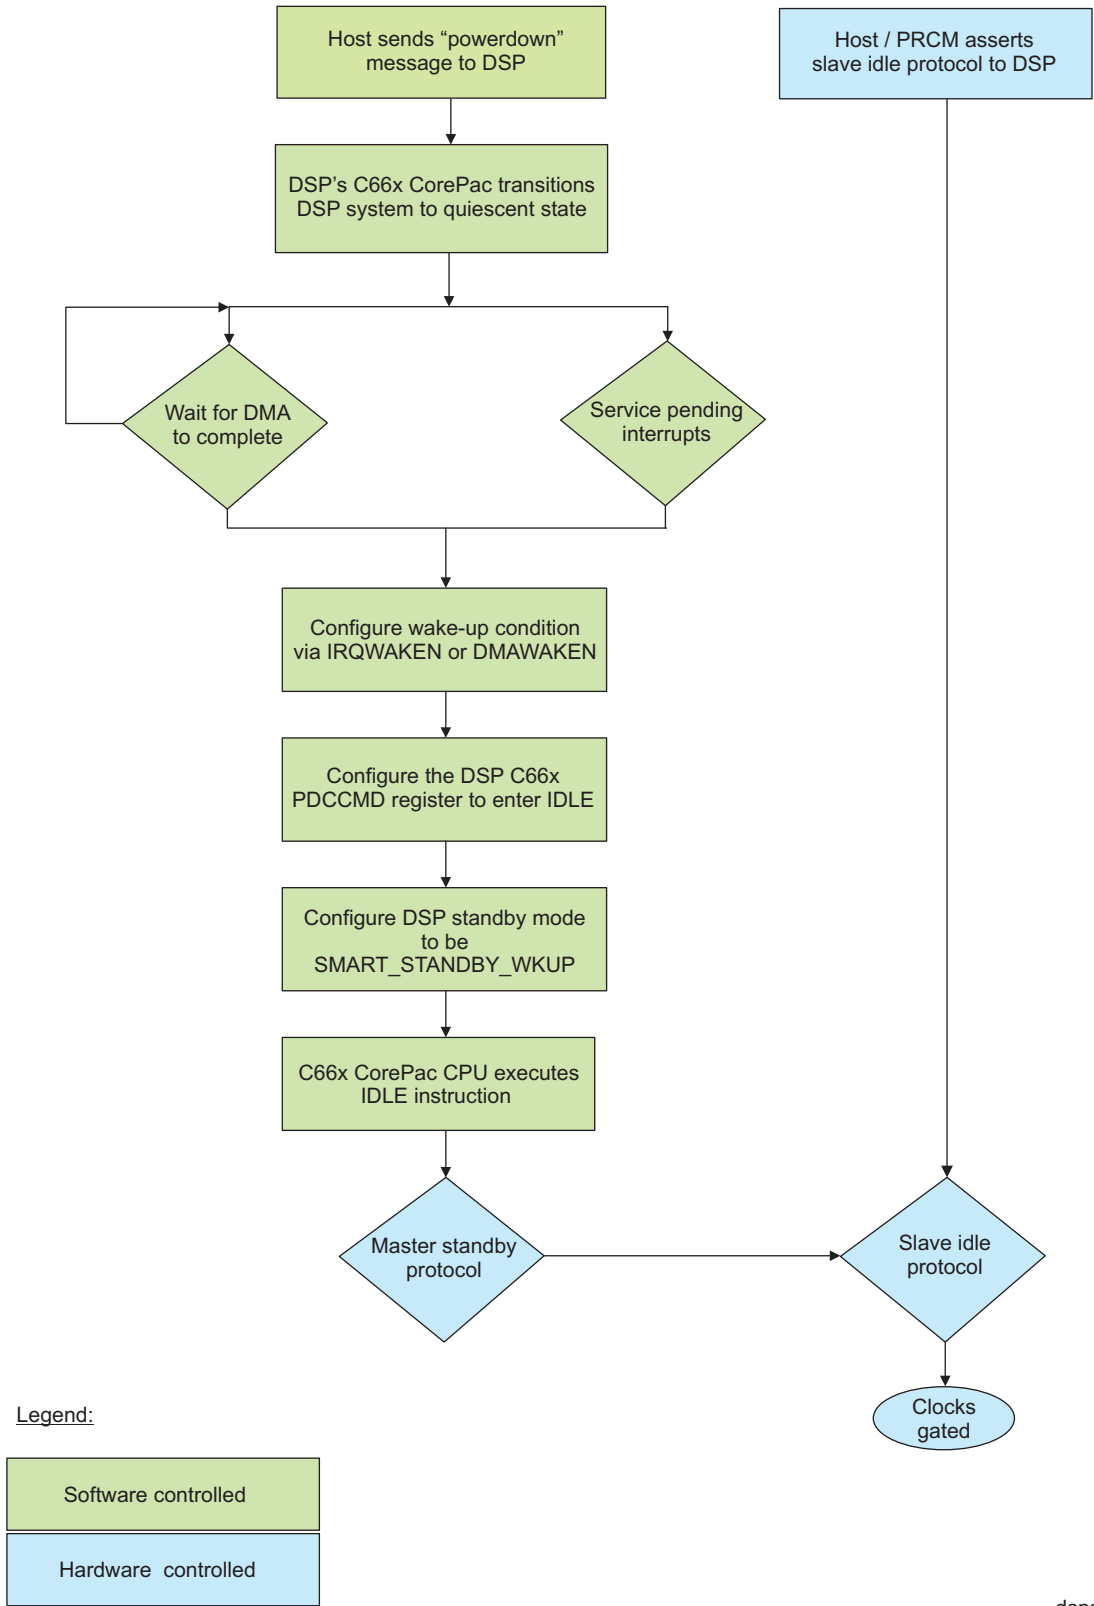

- Slave idle protocol with device PRCM for powerdown (wake-up capable)
- Master standby protocol with device PRCM for powerdown
- Interconnect disconnect for master and slave ports

The Master standby and slave idle protocols behaviour is controlled in the [DSP\\_SYS\\_SYSCONFIG](#) register.

#### 5.3.3.4.2 DSP Software and Hardware Power Down Sequence Overview

Figure 5-4 highlights the high level flow-chart for entry into any of the DSP powerdown modes. The system host (typically) first informs the DSP that it should enter a powerdown mode. The host (g.h. device MPU) sends a software message (normally via system level mailbox+interrupt). In parallel, the PRCM (via host or DSP programming) will hardware assert an SIdleReq request to the DSP via the IDLE Protocol connection. At the next stage, the C66x CPU, in general, performs any software bookkeeping necessary to transition the DSP subsystem to a quiescent state. This may include : waiting for outstanding DMA transfers to complete, waiting for outstanding DMA transfers to complete, etc. The C66x processor should finally execute the IDLE instruction when it is ready to be powered-down. Assuming the [DSP\\_SYS\\_SYSCONFIG\[5:4\]](#) STANDBYMODE is enabled, then the hardware will transition to an idle state and notify to the system the intention to enter powerdown state to the system via the master standby and slave idle protocols. After IDLE and MSTANDBY handshake is completed, the DSP clocks are optionally gated; and supply rails are optionally reduced or turned off.

Figure 5-4. Extended Duration Sleep Software and Hardware Sequence

dspss-042

---

**NOTE:** The PM\_DSPx\_PWRSTCTRL[1:0] POWERSTATE bit field in device PRCM must be set to 0x3 (ON state) prior to performing the sequence shown in [Figure 5-4](#) for the transition to be successful.

---

### 5.3.3.4.3 DSP IDLE Wakeup

In order to facilitate auto-wakeup of DSP C66x, the IDLE protocol's wakeup capability is used. Wakeup operation is enabled if [DSP\\_SYS\\_SYSCONFIG\[3:2\] IDLEMODE](#) is set to 0x3.

In this mode, while in IDLE state, if an external input interrupt source is asserted (if enabled via the [DSP\\_SYS\\_IRQWAKEEN0 / DSP\\_SYS\\_IRQWAKEEN1](#) mask) or if an external DMA event source is asserted (if enabled via the [DSP\\_SYS\\_DMAWAKEEN0 / DSP\\_SYS\\_DMAWAKEEN1](#) mask) or if the DSP subsystem NMI input is asserted (**note that there is no wake enable mask for the non-maskable interrupt**) then the Mwakeup signal is asserted to the PRCM which is expected to observe the Mwakeup. Upon such assertion the PRCM enables the clocks, exiting the "Standby" and "Idle" states. at this point the C66x CPU is able to branch to the pending interrupt service routine. The Mwakeup is deasserted when all IRQ or DMA requests enabled in the [DSP\\_SYS\\_IRQWAKEEN0/1](#) and [DSP\\_SYS\\_DMAWAKEEN0/1](#) are deasserted.

The Wakeup logic controlling assertion of the Mwakeup request is completely asynchronous because in IDLE mode the clock may not be present. It relies on level sensitive interrupts.

---

**NOTE:** The DSP\_EDMA must be manually removed from IDLE / Standby state. During that time, it is possible that the EDMA input event is no longer pending and may not have been recognized/latched as an EVENT to the EDMA. In that case, the user SW can enable the DSP\_EDMA\_WAKE\_INT (in associated [DSP\\_SYS\\_EDMAWAKE0\\_IRQENABLE\\_SET](#) register ) to recognize in the ([DSP\\_SYS\\_EDMAWAKE0\\_IRQSTATUS\\_RAW / DSP\\_SYS\\_EDMAWAKE0\\_IRQSTATUS](#) ) which specific EDMA event was asserted and caused the wakeup condition. The DSP software can then trigger the corresponding DSP\_EDMA channel manually (by setting the ESR) or by servicing the interrupt/event manually via reads and writes. For more details, refer to the [Section 5.3.5.1](#).

---

### 5.3.3.4.4 DSP SYSTEM IRQWAKEEN registers

The [DSP\\_SYS\\_IRQWAKEEN0 / DSP\\_SYS\\_IRQWAKEEN1](#) masking bits must be appropriately set for any valid interrupt mapped from device IRQ\_CROSSBAR to the DSP subsystem boundary, to enable its path (passing through the DSP\_SYSTEM wakeup logic) to the DSP local interrupt controller - DSP\_INTC.

#### CAUTION

In order for a given interrupt to be serviced by the DSP (even when the Idle Instruction is NOT being executed), the Interrupt must be enabled in the corresponding [DSP\\_SYS\\_IRQWAKEEN0](#) or [DSP\\_SYS\\_IRQWAKEEN1](#) register.

### 5.3.3.4.5 DSP Automatic Power Transition

This section provides register details for configuring the DSP1 subsystem in automatic power transition mode. The same should be considered for DSP2 in corresponding PRCM and DSP2 related registers.

The DSP1 module is supposed to be configured to automatic management in PRCM.DSP1\_CM\_CORE\_AON via setting the register CM\_DSP1\_DSP1\_CLKCTRL[1:0] MODULEMODE bitfield to 0x1. The DSP1 clock domain is supposed to be configured in automatic "HW\_AUTO" transition (setting bitfield CM\_DSP1\_CLKSTCTRL[1:0] CLKTRCTRL=0x3).

The power state (controls are in the PRCM.DSP1\_PRM instance) to reach upon a sleep transition is configured in the PM\_DSP1\_PWRSTCTRL[1:0]POWERSTATE bitfield.

### 5.3.4 DSP Interrupt Requests

The DSP subsystem relies on the DSP C66x CorePac local interrupt controller - DSP\_INTC for mapping the various input interrupts to the C66x CPU, that are :

- generated outside the DSP, by the device intergated modules and subsystems
- generated within the DSP subsystems but outside the DSP C66x CorePac
- generated by different components within the DSP C66x CorePac

In addition, a non-maskable input interrupt, direct mapped on a C66x processor NMI input is implemented. It is mapped via a register that resides within the device Control Module. Both the maskable interrupts and the non-maskable interrupts are synchronized internally.

Part of the DSP subsystem module generated interrupts which are output as follows:

- DSP\_EDMA interrupts
- DSP\_MMU0 and DSP\_MMU1 interrupts
- Error interrupts

Figure 5-5 shows how are the interrupt sources organized. To manage and expand the interrupt capabilities of the DSP C66x CorePac (internal and external interrupt requests), the DSP subsystem includes two levels of interrupt control :

- The DSP C66x CorePac local Interrupt controller - DSP\_INTC
- The System control logic - DSP\_SYSTEM

Figure 5-5. DSP Subsystem Interrupt Management

dsps-006

### 5.3.4.1 DSP Input Interrupts

In summary, the DSP\_INTC accepts up to 124 event inputs, and flexibly maps those down to 12 interrupt inputs to the DSP. The mapping can be 1:1 (input:output), or can use the event combiner to map multiple interrupts (within a 32-bit group) to one of the DSP interrupt inputs. In general, many of the 124 interrupt controller inputs are collected within the DSP C66x CorePac, and are NOT available at the DSP C66x CorePac boundaries.

**The C66x CPU dropped event is exported outside the C66x CorePac in DSP subsystem, and can be enabled to trigger the ERRINT\_IRQ aggregated interrupt output.** See also corresponding "INTERR" event listed in the [Table 5-5](#).

---

**NOTE:** The dropped CPU event is not exported outside DSP subsystem. However it is merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT\_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT\_IRQ generation and associated event registers at DSP\_SYSTEM level, refer to the [Section 5.3.4.2.2](#).

---

Part of the input interrupts, generated by DSP peripherals that are located outside the DSP C66x CorePac - DSP\_EDMA (DSP\_EDMA\_CC, DSP\_EDMA\_TC0, DSP\_EDMA\_TC1), DSP\_MMU0, DSP\_MMU1 and DSP\_NoC, are also mapped to outputs at the DSP subsystem boundary, such that they can be exported to system hosts (MPU, etc.) via the device IRQ\_CROSSBAR.

Of particular interest, MMUs (DSP\_MMU0 and DSP\_MMU1) interrupts will typically be serviced by the device MPU instead of by the local DSP core.

Any interrupt input at DSP subsystem boundaries (i.e. excluding the DSP subsystem internal IRQ sources that reside in and outside the DSP C66x CorePac) can be used to wake-up the DSP subsystem from an IDLE state. This is described in the [Section 5.3.3.4.3](#) and is controlled by the DSP\_SYSTEM logic register [DSP\\_SYS\\_SYSCONFIG \[3:2\] IDLEMODE](#) bitfield along with the [DSP\\_SYS\\_IRQWAKEEN0 / DSP\\_SYS\\_IRQWAKEEN1](#) registers.

#### CAUTION

The [DSP\\_SYS\\_IRQWAKEEN0 / DSP\\_SYS\\_IRQWAKEEN1](#) bits **MUST** be enabled for externally mapped interrupts (DSP\_INTC[95:32]) to be serviced by the DSP regardless of the DSP power state (IDLE or non-IDLE).

The DSP C66x CorePac DSP\_INTC registers are NOT readable by any entity other than the C66x CPU, because they are part of the DSP\_ICFG C66x CorePac internal configuration space (see also the [Section 5.3.10](#)). Hereby, only the C66x itself is able to service these interrupt events. The only way for these interrupts to be cleared is for the DSP CPU to clear the state in the EVTFLAGi (where i=0 to 3) register, or via reset assertion.

---

**NOTE:** For cases where the DSP maps an interrupt directly, the DSP is not strictly required to clear the EVTFLAGi register. User software must take the extra step of clearing the EVTFLAGi to cause the corresponding output interrupt to be cleared and re-asserted upon a new input event assertion.

---

#### 5.3.4.1.1 DSP Non-maskable Interrupt Input

The device DSP also supports a non-maskable interrupt (NMI) directly mapped to the NMI input of the C66x CPU. This line is also mapped to the NMEVT input of the DSP local INTC, and can be used as an exception signal, too. At system level, the NMI interrupt mapping to the DSP\_INTC is controlled via the **device core Control Module** register as follows:

- CTRL\_CORE\_NMI\_DESTINATION\_2 [15:8] DSP1 = 0x1 enables the DSP1 to receive the NMI coming from the device **nmin\_dsp** input.
- CTRL\_CORE\_NMI\_DESTINATION\_2 [23:26] DSP2 = 0x1 enables the DSP2 to receive the NMI

coming from the device `nmin_dsp` input.

For more details on the NMI receive enable bit mapping, refer to the [Section 18.5, Control Module Register Manual](#) in the chapter, *Control Module*.

### 5.3.4.2 DSP Event and Interrupt Generation Outputs

#### 5.3.4.2.1 DSP MDMA and DSP EDMA Mflag Event Outputs

The Mflag events generated by DSP subsystem EVTOUT bus are represented in the [Figure 5-5](#).

A couple of the DSP EVTOUT bus outputs - EVTOUT[31] and EVTOUT[30] are used for generation of MFLAGs dedicated to the DSP MDMA and EDMA ports, respectively. DSP MFLAGs are connected directly to DMM and EMIF. The DSP MFLAGs participate in the DMM Emergency and EMIF MFLAG prioritization schemes. At the L3 Level Bandwidth regulators connected to the DSP MDMA and EDMA ports can be used to control DSP traffic versus other device traffic.

The device DSP subsystem is able to generate the 2 output Mflag events via the following DSP\_SYSTEM module located registers :

- [DSP\\_SYS\\_EVTOUT\\_SET\[31:30\]](#)
- [DSP\\_SYS\\_EVTOUT\\_CLR\[31:30\]](#)

The current state of the outputs can be detected by reading any of these "pseudo" register bits.

---

**NOTE:** Only EVTOUT[31:30] outputs are implemented in the device, hence only bits [31:30] of the mentioned DSP\_SYS\_EVTOUT\_x registers are used.

---

The [DSP\\_SYS\\_EVTOUT\\_SET](#) register unconditionally drives the corresponding output event to '1'. The [DSP\\_SYS\\_EVTOUT\\_CLR](#) register unconditionally drives the corresponding output event to a '0'.

#### 5.3.4.2.2 DSP Aggregated Error Interrupt Output

The aggregated error interrupt of the DSP subsystem is shown in the [Figure 5-5](#).

The subset of those events that correspond to: **DSP C66x CorePac generated error events**, **DSP\_EDMA error interrupts** and **L2 DSP\_NoC interconnect error interrupt**, is reduced by an OR-schematic to a single ERRINT\_IRQ output interrupt which is made available on DSP subsystem boundary. It is expected that one of the DSP system hosts monitors the interrupts/error conditions in safety conscious systems.

[Figure 5-6](#) shows a functional representation of the DSP error interrupt "OR"-reduction logic. In summary, there exists an **unmasked status** ([DSP\\_SYS\\_ERRINT\\_IRQSTATUS\\_RAW](#)) register, two complementary enable bit-vector registers ([DSP\\_SYS\\_ERRINT\\_IRQENABLE\\_SET](#) / [DSP\\_SYS\\_ERRINT\\_IRQENABLE\\_CLR](#)), and a masked status register ([DSP\\_SYS\\_ERRINT\\_IRQSTATUS](#)). The ERRINT event is asserted when any enabled error interrupt input is asserted.

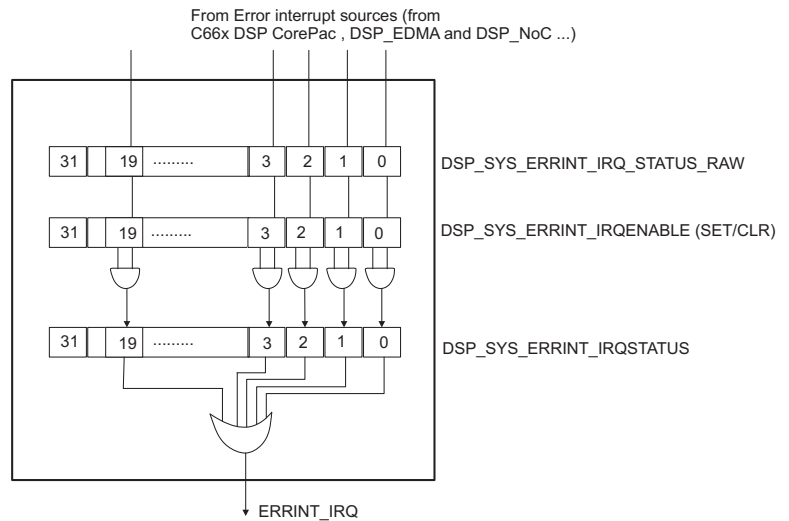

---

**NOTE:** The ERRINT\_IRQ output can be programmatically mapped as the DSPi\_IRQ\_TPCC\_ERR (where i=1 to 2) interrupt to all device (dsp hosts) interrupt controllers via the device IRQ\_CROSSBAR. For more information on the IRQ\_CROSSBAR module, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#). For more information about the device interrupt controllers, see [Chapter 17, Interrupt Controllers](#).

---

Figure 5-6. ERRINT Diagram

dsps-043

The Table 5-5 details the mapping of error event output sources to the bit positions within the following DSP error event related registers :

- [DSP\\_SYS\\_ERRINT\\_IRQSTATUS\\_RAW](#)
- [DSP\\_SYS\\_ERRINT\\_IRQSTATUS](#)
- [DSP\\_SYS\\_ERRINT\\_IRQENABLE\\_SET](#)
- [DSP\\_SYS\\_ERRINT\\_IRQENABLE\\_CLR](#)

Following functional descriptions are valid for the above registers :

- **IRQ status raw register** - This register provides a per-event raw interrupt status vector. The Raw status is set even if the corresponding event is not enabled. Software can write '1' to set the (raw) status for debug purposes.
- **IRQ status register** - This register provides a per-event enabled interrupt status vector. The Enabled status is set if the corresponding event is enabled and the raw status is set. Software can write 1 to clear the (raw) status after the interrupt has been serviced. The clear takes effect even if the interrupt is not enabled.
- **IRQ enable register** - This register provides a per-event interrupt enable bit vector. Software can write 1 to set (i.e., enable the corresponding interrupt). Reads of this register return the actual state of the enable register (and is the same as reading the corresponding "IRQ Clear" - register)
- **IRQ clear register** - This register provides a per-event interrupt enable bit vector. Software can write 1 to clear (i.e., disable the corresponding interrupt). Reads of this register return the actual state of the enable register (and is the same as reading the corresponding "IRQ Set" register)

**NOTE:** A [DSP\\_SYS\\_ERRINT\\_IRQSTATUS\\_RAW](#) bit is set even if the corresponding event is NOT enabled in the [DSP\\_SYS\\_ERRINT\\_IRQENABLE\\_SET](#).

Table 5-5. DSP ERRINT Interrupt Mapping

Interrupt Number	Name	Description
0	tpcc_errint_level	DSP EDMA CC error interrupt
1	tptc_errint0_level	DSP EDMA TC0 error interrupt
2	tptc_errint1_level	DSP EDMA TC1 error interrupt
3	noc_errint_level	DSP L2 Interconnect (DSP_NoC) error interrupt

**Table 5-5. DSP ERRINT Interrupt Mapping (continued)**

Interrupt Number	Name	Description
4	INTERR	DSP C66x CorePac Dropped CPU Interrupt event
5	EMC_IDMAERR	DSP C66x CorePac Invalid IDMA Parameters
6	MDMAERREVT	DSP C66x CorePac VbusM Error Event
7	PMC_ED	DSP C66x CorePac Single bit error detected during DMA read
8	UMC_ED1	DSP C66x CorePac Corrected bit error detected
9	UMC_ED2	DSP C66x CorePac Uncorrected bit error detected
10	SYS_CMPA	DSP C66x CorePac CPU memory protection fault
11	PMC_CMPA	DSP C66x CorePac CPU memory protection fault
12	PMC_DMPA	DSP C66x CorePac DMA memory protection fault
13	DMC_CMPA	DSP C66x CorePac CPU memory protection fault
14	DMC_DMPA	DSP C66x CorePac DMA memory protection fault
15	UMC_CMPA	DSP C66x CorePac CPU memory protection fault
16	UMC_DMPA	DSP C66x CorePac DMA memory protection fault
17	EMC_CMPA	DSP C66x CorePac CPU memory protection fault
18	EMC_BUSERR	DSP C66x CorePac Bus Error Interrupt
19	Reserved	-
20	Reserved	-
21	Reserved	-
22	Reserved	-

Note that neither of the events, listed in [Table 5-5](#), is exported as a separate hardware interrupt off the DSP boundary.

#### 5.3.4.2.3 Non-DSP C66x CorePac Generated Peripheral Interrupt Outputs

The non-DSP C66x CorePac interrupts generated by peripherals within the DSP subsystem are also summarized in the [Figure 5-5](#).

Besides the aggregated error event ERRINT\_IRQ interrupts – DSPi\_IRQ\_TPCC\_ERR (where i=1 to 2), interrupts (see also [Figure 5-5](#)) **generated individually by DSPSS peripherals located outside the DSP C66x CorePac**, are mapped as separate IRQ outputs at DSP boundaries. They are sourced by the DSP\_EDMA\_CC, DSP\_EDMA\_TC0, DSP\_EDMA\_TC1, DSP\_MMU0, DSP\_MMU1 and DSP\_NoC and exported to other host INTCs via the device IRQ\_CROSSBAR. Refer to the [Section 5.2](#), for more information on these DSP interrupt outputs mapping.

#### 5.3.5 DSP DMA Requests

The DSP\_EDMA\_CC (channel controller) supports 64 hardware event inputs, that can be used to synchronize the 64 DMA channels. These event inputs are provided at the DSP subsystem boundary via the device DMA\_CROSSBAR and can be mapped to sources within the device.

The DSP subsystem receives DMA requests from certain peripherals, such as the McASP modules. The DMA requests path through the DSP logic is shown in [Figure 5-7](#).

Similar to the interrupts received at DSP subsystem boundary, the DSP EDMA requests are first routed through the wakeup generation logic of the DSP\_SYSTEM module, hence, each DMA request received by the DSP subsystem can wakeup the system from DSP low power modes (including wakeup from DSP OFF mode). To enable the DMA requests mapped via the DMA\_CROSSBAR to **DSP\_EDMA\_CC [19:0]** inputs, corresponding bits in range [19:0] of the register **DSP\_SYS\_DMAWAKEEN0** must be enabled in software.

#### CAUTION

The DMA request corresponding **DSP\_SYS\_DMAWAKEEN0** / **DSP\_SYS\_DMAWAKEEN1** MUST be enabled, for the DMA requests to be serviced by the DSP regardless of the DSP being in IDLE or active state.

Figure 5-7. DSP DMA Requests

Table 5-6 and Table 5-7 list the default DMA sources for the DSP1\_EDMA and DSP2\_EDMA controllers. In addition, DSP1\_EDMA / DSP2\_EDMA inputs (DMA\_DSP1\_DREQ\_[19:0] / DMA\_DSP2\_DREQ\_[19:0]) can alternatively be sourced through the associated DMA\_CROSSBAR from one of the 256 multiplexed device DMA sources listed in Table 16-6. The CTRL\_CORE\_DMA\_DSP1\_DREQ\_y\_z / CTRL\_CORE\_DMA\_DSP2\_DREQ\_y\_z registers (where y and z are indexes of DSP1\_EDMA / DSP2\_EDMA input lines) in the Control Module are used to select between the default DMA sources and the multiplexed DMA sources.

For more details on the device DMA\_CROSSBAR multiplexing registers structure, refer to Section 18.4.6.5, DMA\_CROSSBAR Module Functional Description of chapter, Control Module.

**Table 5-6. DSP1\_EDMA Default Request Mapping**

DMA Request Line	DMA_CROSSBAR Instance Number	DMA_CROSSBAR Configuration Register	DMA_CROSSBAR Default Input Index	Default DMA Source Name	Default DMA Source Description
DMA_DSP1_DREQ_0	1	CTRL_CORE_DMA_DSP1_DREQ_0_1[7:0]	128	McASP1_DREQ_RX	McASP1 receive event
DMA_DSP1_DREQ_1	2	CTRL_CORE_DMA_DSP1_DREQ_0_1[23:16]	129	McASP1_DREQ_TX	McASP1 transmit event
DMA_DSP1_DREQ_2	3	CTRL_CORE_DMA_DSP1_DREQ_2_3[7:0]	130	McASP2_DREQ_RX	McASP2 receive event

DMA_DSP2_DREQ_20 - DMA_DSP2_DREQ_63	N/A	N/A	N/A	Reserved	Reserved

<sup>(1)</sup> VCP does not support Const/FIFO mode DMA transfers. The DSP2\_EDMA should be configured for AB-Synchronized transfer with ACNT = 8, BCNT = number of elements.

### 5.3.5.1 DSP EDMA Wakeup Interrupt

This section provides description of the registers used for the **EDMA wakeup interrupt** functionality, including the EDMA\_WAKE\_INT IRQ status and enable fields. The EDMA Wakeup Interrupt allows incoming EDMA events to be latched and an interrupt sent to the DSP (if enabled). This interrupt is generated in the DSP\_SYSTEM as a single "OR-ed" output of all external DMA requests latched in DSP subsystem. This output is further synchronized to DSP\_FCLK and mapped as the EDMA\_WAKE\_INT event to the DSP\_IRQ\_31 input of the C66x DSP CorePac DSP\_INTC. The C66x CPU is expected to service the interrupt by triggering the corresponding EDMA channel manually, or by servicing the request via normal reads and writes (instead of using the EDMA). This functionality is required since the EDMA is not capable of following the smart wakeup protocol.

---

**NOTE:** The [DSP\\_SYS\\_DMAWAKEEN0](#) / [DSP\\_SYS\\_DMAWAKEEN1](#) registers are used for enabling the assertion of the 'Mwakeup' asynchronous wakeup request to the device PRCM upon DMA requests reception. The interrupt functionality of the registers: [DSP\\_SYS\\_EDMAWAKE0\\_x](#) covered in this subsection is specifically for generating **an wake interrupt** to the DSP. In most cases, the enable mask for the two sets of registers should be set to the same value.

---

The EDMAWAKE0 registers corresponding to the EDMA Events 19 thru 0 (msbit to lsb) are as follows:

- [DSP\\_SYS\\_EDMAWAKE0\\_IRQSTATUS\\_RAW](#)[19:0]
- [DSP\\_SYS\\_EDMAWAKE0\\_IRQSTATUS](#)[19:0]
- [DSP\\_SYS\\_EDMAWAKE0\\_IRQENABLE\\_SET](#)[19:0]
- [DSP\\_SYS\\_EDMAWAKE0\\_IRQENABLE\\_CLR](#)[19:0]

Following functional descriptions are valid for the above registers :

- **IRQ status raw register** - This register provides a per-event raw interrupt status vector. The Raw status is set even if the corresponding event is not enabled. Software can write '1' to set the (raw) status for debug purposes.
- **IRQ status register** - This register provides a per-event enabled interrupt status vector. The Enabled status is set if the corresponding event is enabled and the raw status is set. Software can write 1 to clear the (raw) status after the interrupt has been serviced. The clear takes effect even if the interrupt is not enabled.
- **IRQ enable register** - This register provides a per-event interrupt enable bit vector. Software can write 1 to set (i.e., enable the corresponding interrupt). Reads of this register return the actual state of the enable register (and is the same as reading the corresponding "IRQ Clear" - register)
- **IRQ clear register** - This register provides a per-event interrupt enable bit vector. Software can write 1 to clear (i.e., disable the corresponding interrupt). Reads of this register return the actual state of the enable register (and is the same as reading the corresponding "IRQ Set" register)

---

**NOTE:** A [DSP\\_SYS\\_EDMAWAKE0\\_IRQSTATUS\\_RAW](#) bit is set even if the corresponding event is NOT enabled in the [DSP\\_SYS\\_EDMAWAKE0\\_IRQENABLE\\_SET](#)[19:0].

---

### 5.3.6 DSP Intergated Memory Management Units

#### 5.3.6.1 DSP MMUs Overview

A standalone memory management unit (DSP\_MMU0) is included within the DSP1 (DSP1\_MMU0) and DSP2 (DSP2\_MMU0) subsystems boundaries. The DSP\_MMU0 is integrated on the C66x CPU MDMA path to the device L3\_MAIN interconnect. This provides several benefits including protection of the system memories from corruption by DSP1 and DSP2 accidental accesses.

A standalone memory management unit (DSP\_MMU1) is included within the DSP1 (DSP1\_MMU1) and DSP2 (DSP2\_MMU1) subsystems boundaries. The DSP\_MMU1 is integrated on the EDMA data path which starts from the L2 DSP\_NoC interconnect and leaves the DSP subsystem on the DSP EDMA master port. This provides several benefits including protection of the device L3\_MAIN memory space from corruption by DSP1 and DSP2 DMA (DSP1\_EDMA and DSP2\_EDMA, respectively ) accidental accesses.

Both DSP MMUs generate interrupts which are internally mapped to the DSP C66x CorePac DSP\_INTC and output to the device IRQ\_CROSSBAR. See also the [Section 5.2](#) and [Section 5.3.4](#).

#### CAUTION

**In the case of a page fault**, a DSP C66x CorePac CPU is unable to service it's own DSP\_MMU0 and DSP\_MMU1 interrupts . The device MPU (Cortex-A15) is expected to manage any TLB patches as necessary.

Both DSP MMUs (on MDMA and EDMA paths respectively) have identical functionalities.

- 32-bit input and output address width (to match L3\_MAIN address width)
- 32 TLB cache entries
- 32 + 1 tags
- 128-bit data bus for MDMA and EDMA

### 5.3.6.2 Routing MDMA Traffic through DSP MMU0

DSP C66x CPU traffic initiated on the DSP MDMA port can be optionally routed through the DSP\_MMU0 on the 32-bit MDMA address path. This is controlled in two levels :

- **global** by the DSP\_SYSTEM register [DSP\\_SYS\\_MMU\\_CONFIG \[0\]](#) MMU0\_EN bit. This bit acts as a mux-select : setting it to 0b1 enables requests to use the DSP\_MMU0; clearing this bit to 0b0 disables MMU table lookup and causes accesses to use the non-translated address (MMU bypass). By default the DSP\_MMU0 is disabled in DSP\_SYSTEM and MDMA port traffic bypasses the DSP\_MMU0.
- **local** by MMU enable control in a dedicated DSP\_MMU0 memory mapped register. It is used to enable the MMU functionality after the page tables are programmed for MMU operation. For details, refer to the [Chapter 20, Memory Management Units](#).

---

**NOTE:** For the DSP\_MMU0 to operate, SW should enable it both at the DSP\_SYSTEM global level and DSP\_MMU0 local register level.

When enabling the DSP\_MMU0, software must take care that no transactions are in flight through that MMU. This is typically handled by issuing a DSP "MFENCE" instruction operation. Note that the local enable bit inside the DSP\_MMU0 must be configured as normal (refer to the [Chapter 20, Memory Management Units](#).)

For more information on the MFENCE operation, refer to the section, *C66x CPU Instruction Set of the TMS320C66x DSP CPU and Instruction Set* ).

---

In addition, the DSP\_MMU0 traffic can be aborted in case of a lockup via the [DSP\\_SYS\\_MMU\\_CONFIG \[8\]](#) MMU0\_ABORT bit. In other words, this bit can be used to clear a hang condition that may occur if the DSP\_MMU0 encounters a page fault that cannot be serviced.

For more information on device DSP\_MMU0 functionality and register settings, refer to the [Section 20.3, MMU Functional Description](#) and [Section 20.5, MMU Register Manual](#), in the chapter, *Memory Management Units*, respectively.

### 5.3.6.3 Routing EDMA Traffic through DSP MMU1

The DSP\_EDMA traffics initiated on the DSP EDMA master port can be optionally routed through the DSP\_MMU1 on the EDMA address path. This is controlled in two levels :

- **global** by the DSP\_SYSTEM register [DSP\\_SYS\\_MMU\\_CONFIG \[4\]](#) MMU1\_EN bit. This bit acts as a

mux-select : setting it to 0b1 enables requests to use the DSP\_MMU1; clearing this bit to 0b0 disables MMU table lookup and causes accesses to use the non-translated address (MMU bypass). By default the DSP\_MMU1 is disabled in DSP\_SYSTEM and EDMA traffic bypasses the DSP\_MMU1.

- **local** by MMU enable control in a dedicated DSP\_MMU1 memory mapped register. It is used to enable the MMU functionality after the page tables are programmed for MMU operation. For details, refer to the [Section 20.5, MMU Register Manual](#), in the [Chapter 20, Memory Management Units](#).

---

**NOTE:** For the DSP\_MMU1 to operate, SW should enable it both at the DSP\_SYSTEM global level and DSP\_MMU1 local register level.

When enabling the DSP\_MMU1, software must take care that no transactions are in flight through that MMU. This is typically handled by disabling any EDMA transactions prior to enabling the MMU. Note that the local enable bit inside the DSP\_MMU1 must be configured as normal (refer to the [Chapter 20, Memory Management Units](#).)

For more information on the MFENCE operation, refer to the section, *C66x CPU Instruction Set of the TMS320C66x DSP CPU and Instruction Set*).

---

In addition, the DSP\_MMU1 traffic can be aborted in case of a lockup via the [DSP\\_SYS\\_MMU\\_CONFIG \[12\] MMU1\\_ABORT](#) bit. In other words, this bit can be used to clear a hang condition that may occur if the DSP\_MMU1 encounters a page fault that cannot be serviced.

For more information on device DSP\_MMU1 functionality and settings, refer to the [Section 20.3, MMU Functional Description](#) and the [Section 20.5, MMU Register Manual](#), in the chapter, *Memory Management Units*, respectively.

### 5.3.7 DSP Integrated EDMA Subsystem

This section represents an overview of the DSP integrated EDMA functionalities, as well as the subsystem level and device related register controls. For more details on the EDMA functionalities and programming registers, refer to the [Section 16.2, Enhanced DMA](#).

#### 5.3.7.1 DSP EDMA Overview

The enhanced-DMA subsystem which is part of the DSP1 (DSP1\_EDMA) and the DSP2 (DSP2\_EDMA) subsystems is the primary DMA engine for transfers between system memory (DDR and/or L3\_MAIN SRAM) and DSP internal memories (L1s and L2).

The Channel Controller - DSP\_EDMA\_CC serves as the “user interface” of the DSP\_EDMA. The two Transfer Controllers - DSP\_EDMA\_TC0 and DSP\_EDMA\_TC1 serve as the data transfer engines of the DSP\_EDMA. The C66x CPU typically programs the Channel Controller, which in turn submits Transfer Requests (TR) to the appropriate Transfer Controller. Interrupts are posted in the DSP\_EDMA\_CC upon transfer completion (if requested), and signaled to the C66x. The EDMA TC completion interrupt is not supported/connected.

The DSP\_EDMA is primarily used to perform block transfers between DSP C66x CorePac memories (mostly L2 memory) and system memory (mostly DDR or L3 SRAM).

The DSP\_EDMA is configured with 2 Queues (in the CC). Two DSP\_EDMA traffic controllers (TC) offer high performance and preemptability of transfers. For typical use cases, it is expected that low latency/small payload transfers ) use Queue0/TC0 and high bandwidth/large payload transfers (e.g., DDR on L3\_MAIN or DSP local L2 SRAM) will use Queue1/TC1.

#### **DSP\_EDMA\_CC configuration in the device features :**

- 64x EDMA channels
- 8x QDMA channels
- 64x interrupt channels
- 128x PaRAM entries
- 2x Event Queues
- 2x Traffic controllers

- memory protection support
- channel mapping capability
- 8x memory protected and Shadow Regions

#### DSP\_EDMA\_TC0/TC1 configuration in the device features :

- 2048 Byte FIFO support
- multitag support
- 16-bit data bus
- 4-level destination register depth
- 7-bit address for internal FIFOs
- 16 IDs for Read commands
- 16 IDs for Write commands

---

**NOTE:** The device DSP integrated EDMA controller instances (DSP\_EDMA\_CC, DSP\_EDMA\_TC0 and DSP\_EDMA\_TC1) are functionally identical with the device EDMA controller instances (EDMA\_TPCC, EDMA\_TPTC0 and EDMA\_TPTC1). The only difference is that the DSP\_EDMA instances are located at different physical addresses.

For more details on the DSP\_EDMA\_CC, DSP\_EDMA\_TC0 and DSP\_EDMA\_TC1 controllers functionalities, refer to [Section 16.2.4, EDMA Controller Functional Description](#), in [Section 16.2, Enhanced DMA](#).

The DSP\_EDMA instances, their corresponding registers summary and descriptions are covered in the [Section 16.2.7, EDMA Register Manual](#) of the [Section 16.2, Enhanced DMA](#).

---

### 5.3.7.2 DSP System and Device Level Settings of DSP EDMA

**DSP\_EDMA traffic TC0 and TC1 controllers "Active" or "Idle" status:** can be monitored in DSP\_SYSTEM located :

- [DSP\\_SYS\\_STAT\[1\]](#) TC0\_STAT bit
- [DSP\\_SYS\\_STAT\[2\]](#) TC1\_STAT bit

The **default** burst size for both the DSP\_EDMA\_TC0 and DSP\_EDMA\_TC1 can be defined in DSP\_SYSTEM register. This is achieved via programming :

- [DSP\\_SYS\\_BUS\\_CONFIG \[1:0\]](#) TC0\_DBS
- [DSP\\_SYS\\_BUS\\_CONFIG \[5:4\]](#) TC1\_DBS

There are also other DSP\_EDMA controls associated with DSP\_NoC interconnect pressure settings. For more details, refer to the [Section 5.3.8](#).

**The 3 error events associated with the DSP\_EDMA\_CC, DSP\_EDMA\_TC0 and DSP\_EDMA\_TC1 are exported outside the DSP C66x CorePac in the subsystem, and are able to trigger the ERRINT\_IRQ aggregated interrupt output.** See also corresponding "tpcc\_errint\_level", "tptc\_errint0\_level" and "tptc\_errint1\_level" events, respectively in the [Table 5-5](#).

---

**NOTE:** The DSP\_EDMA\_CC, DSP\_EDMA\_TC0 and DSP\_EDMA\_TC1 events are NOT exported outside DSP subsystem. However they are merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT\_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT\_IRQ generation and associated event registers at DSP\_SYSTEM level, refer to the [Section 5.3.4.2.2](#).

---

The DSP\_SYSTEM logic is assigned to route the external DMA requests to the EDMA hardware request inputs. Additionally, EDMA events can conditionally wake-up the DSP system from a low power mode, via software enabling DSP\_SYSTEM MWakeup handshake with the device PRCM. This mechanism is described in the [Section 5.3.5](#).

The programmable muxing of various external DMA request sources to the DSP EDMA. DMA\_DSP1\_DREQ\_x and DMA\_DSP2\_DREQ\_x input lines (where x=0 to 19) is covered in the [Section 18.4.6.5, DMA\\_CROSSBAR Module Functional Description](#), of the [Chapter 18, Control Module](#).

**DSP1/DSP2 subsystem external DMA request sources** : For the default DSP1 / DSP2 external DMA request sources, routed via the device DMA\_CROSSBAR to the DSP1\_EDMA / DSP2\_EDMA channel controller inputs (DMA\_DSP1\_DREQ\_i / DMA\_DSP2\_DREQ\_i), respectively, refer to the [Section 5.3.5](#).

### 5.3.8 DSP L2 interconnect Network

A 128-bit level 2 (L2) Interconnect from Arteris - FlexNoC® is instantiated in the DSP subsystem, outside the DSP C66x CorePac. It is signified as "DSP\_NoC" throughout this chapter.

---

**NOTE:** The C66x master MDMA data does NOT flow through the DSP\_NoC.

---

**The system and local initiators on DSP\_NoC are as follows :**

- local C66x CPU 32-bit CFG master port which traffic is split via DSP\_NoC fabric into several configuration target traffics inside and outside the DSP subsystem.
- SDMA initiator port on DSP\_NoC which conveys accesses towards DSP Memories and memory-mapped registers initiated outside the DSP subsystem via the L3\_MAIN interconnect.
- EDMA traffic controllers - TC0 read / write initiator ports
- EDMA traffic controllers - TC1 read / write initiator ports

---

**NOTE:** The DSP\_ICFG space is not visible to SDMA initiators (DSP\_EDMA or DSP hosts on L3\_MAIN ) with CFG traffic.

---

**The targets on the DSP\_NoC are as follows :**

- DSP C66x CorePac SDMA port
- Internal CFG targets on the DSP\_NoC :
  - DSP\_MMU0 Cfg
  - DSP\_MMU1 Cfg
  - DSP\_SYSTEM Cfg
  - DSP\_EDMA\_CC Cfg
  - DSP\_EDMA\_TC0 Cfg
  - DSP\_EDMA\_TC1 Cfg
- 32-bit CFG port on L3\_MAIN (it acts as master on the L3\_MAIN)
- EDMA Target port which conveys EDMA bidi transfers outside the DSP (through or bypassing DSP\_MMU1).

The [Table 5-8](#) summarizes the interconnections which can be established between DSP initiators and targets over the L2 DSP\_NoC in the device. In this table HW implemented interconnections are marked with an asterics.

**Table 5-8. DSP\_NoC Defined Connectivities**

		DSP_NoC Initiators			
		DSP C66x CorePac CFG init	EDMA_TC0 init	EDMA_TC1 init	SDMA init (mapped to SDMA port on L3_MAIN)
<b>DSP_NoC Targets</b>	DSP C66x CorePac SDMA (slave) port	n.a.	*	*	*
	DSP_MMU0 Cfg	*	n.a.	n.a.	*
	DSP_MMU1 Cfg	*	n.a.	n.a.	*
	DSP_SYSTEM Cfg	*	n.a.	n.a.	*
	DSP_EDMA_CC Cfg	*	n.a.	n.a.	*
	DSP_EDMA_TC0 Cfg	*	n.a.	n.a.	*
	DSP_EDMA_TC1 Cfg	*	n.a.	n.a.	*
	DSP_NoC Cfg	*	n.a.	n.a.	*
	Cfg port (Cfg Init on L3_MAIN)	*	n.a.	n.a.	n.a.
	Master DMA port ( DSP DMA init on L3_MAIN)	n.a.	*	*	n.a.

**A DSP\_NoC error event (combination of several local to the interconnect events) is exported outside the DSP C66x CorePac in the subsystem, and can be enabled to trigger the ERRINT\_IRQ aggregated interrupt output.** See also corresponding "noc\_errint\_level" event in the [Table 5-5](#).

---

**NOTE:** The DSP\_NoC event is NOT exported outside DSP subsystem. However it is merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT\_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT\_IRQ generation and associated event registers at DSP\_SYSTEM level, refer to the [Section 5.3.4.2.2](#).

---

### 5.3.8.1 DSP Public Firewall Settings

The DSP1 and DSP2 L2 Interconnect (DSP1\_NoC and DSP2\_NoC, respectively) implements two firewalls – dsp firewall0 (DSP\_FW0) is used to protect DSP\_MMU0's configuration space (which includes the TLB) and dsp firewall1 is used to protect DSP\_MMU1's configuration space (which includes the TLB). Access permission is based on the privilege level, domain, ConnID, and access types of a request.

The default value of 0xFFFF\_FFFF in the MRM region 0 permission registers:

- [L3\\_DSPSS\\_INIT\\_OCP\\_MMU0\\_CTRL\\_TARG\\_OCP\\_FW\\_503000\\_MRM\\_PERMISSION\\_REGION\\_LO\\_W\\_0](#)
- [L3\\_DSPSS\\_INIT\\_OCP\\_MMU0\\_CTRL\\_TARG\\_OCP\\_FW\\_503000\\_MRM\\_PERMISSION\\_REGION\\_HIG\\_H\\_0](#)
- [L3\\_DSPSS\\_INIT\\_OCP\\_MMU1\\_CTRL\\_TARG\\_OCP\\_FW\\_504000\\_MRM\\_PERMISSION\\_REGION\\_LO\\_W\\_0](#)
- [L3\\_DSPSS\\_INIT\\_OCP\\_MMU1\\_CTRL\\_TARG\\_OCP\\_FW\\_504000\\_MRM\\_PERMISSION\\_REGION\\_HIG\\_H\\_0](#)

permits any requestor to access the DSP\_MMU0 and DSP\_MMU1 configuration space.

For more information on the access region definitions, public privilege access, public user access and initiator permission settings, which are identical between DSP\_NoC firewalls and L3\_MAIN interconnect firewalls, refer to the [Section 14.2.3.7.3, L3\\_MAIN Firewall Functionality](#), in the, [Section 14.2, L3\\_MAIN Interconnect](#).

There are also several other DSP\_NoC registers - [L3\\_DSPSS\\_INIT\\_OCP\\_MMU0\\_CTRL\\_TARG\\_OCP\\_FW\\_503000\\_LOGICAL\\_ADDR\\_ERRLOG\\_0](#), [L3\\_DSPSS\\_INIT\\_OCP\\_MMU0\\_CTRL\\_TARG\\_OCP\\_FW\\_503000\\_REGUPDATE\\_CONTROL](#) used for error handling, firewall reset and other purposes. These are functionally identical with the corresponding L3\_MAIN interconnect registers, described in the [Section 14.2.3.8, L3\\_MAIN Interconnect Error Handling](#), in the [Section 14.2, L3\\_MAIN Interconnect](#).

The various firewall access control registers are part of the C66x CPU local accessible - DSP\_FW\_L2\_NOC\_CFG address space, and L3\_MAIN initiators accessible DSP1/2\_FW\_L2\_NOC\_CFG configuration space. The corresponding MMU0 and MMU1 configuration space firewall registers ( DSP\_FW0 starting at offset **0x0000\_0000** , and DSP\_FW1 starting at offset **0x0000\_1000** ) are summarized and described in the [Section 5.4.4](#).

### 5.3.8.2 DSP NoC Flag Mux and Error Log Registers

The DSP\_NoC registers (starting at offset  $\geq$  0x0000\_4000) are used for error logging and flag muxing purposes. The status information stored in there can be used for example to resolve issues related to DSP\_NoC access conflicts, for debug purposes, etc.

For more information, refer to the , *Flag Muxing*, in the [Section 14.2, L3\\_MAIN Interconnect](#).

### 5.3.8.3 DSP NoC Arbitration

A pressure based arbitration is implemented for the DSP\_NoC interconnect.

A DSP\_NoC local MFlag mechanism is used but it is SW controlled in the DSP\_SYSTEM configuration space.

This is done via the register [DSP\\_SYS\\_BUS\\_CONFIG](#) bitfields :

- TC0\_L2PRES - for DSP\_EDMA\_TC0 pressure control
- TC1\_L2PRES - for DSP\_EDMA\_TC1 pressure control
- CFG\_L2PRES - for the DSP C66x CorePac 32-bit CFG pressure control
- SDMA\_L2PRES - for pressure control of the DSP system and L3\_MAIN accesses targetting the DSP C66x CorePac SDMA slave port

The pressure for each port is signaled on a MFlag[1:0] bus and conveys a value of 0 (lowest), 1 (medium), or 3 (highest). A value of 0x2 is reserved/undefined.

---

**NOTE:** The default pressure level for all ports is 0x0 and is recommended for most systems. This results in round-robin arbitration across active requests.

---

### 5.3.9 DSP Boot Configuration

DSP1 subsystem boot vector input which defines the 22-bit DSP1 Boot Address is mapped to the device core control module register CTRL\_CORE\_CONTROL\_DSP1\_RST\_VECT[21:0] DSP1\_RST\_VECT bitfield. DSP2 subsystem boot vector input which defines the 22-bit DSP2 Boot Address is mapped to the device core control module register CTRL\_CORE\_CONTROL\_DSP2\_RST\_VECT[21:0] DSP2\_RST\_VECT bitfield. In general, the device MPU (Cortex-A15) host loads code to a given address location in the device system memory, sets the DSP1\_RST\_VECT / DSP2\_RST\_VECT bitfield to the address value, and then release the DSP1 / DSP2 from reset. At that point, the DSP1 / DSP2 will begin fetching code from that location.

---

**NOTE:** If the values of the control core module CTRL\_CORE\_CONTROL\_DSP1\_RST\_VECT[21:0] / CTRL\_CORE\_CONTROL\_DSP2\_RST\_VECT [21:0] register change, the values will be taken into account by DSP upon the next reset.

---

---

**NOTE:** Upon device boot time (a power-on reset applied), the device "sysboot15" input latched in the Control Module bootstrap register defines the value of DSP functional clock divider (2 or 3). For more details, refer to the [Section 5.3.3.1](#)

---

### 5.3.10 DSP Internal and External Memory Views

#### 5.3.10.1 C66x CPU View of the Address Space

The **C66x CPU View** represents the view from the DSP, which result from program fetches, or load / store instructions. Accesses to DSP memories (L1P, L1D, L2) and to DSP Internal configuration space ( DSP\_ICFG ) are intercepted within the DSP C66x CorePac (whether using local or global addresses).

The DSP C66x CorePac CFG (C66x CPU 32-bit master port) interface is strictly for non-cacheable loads and stores, and is intended to be used for I/O space or memory mapped registers (MMR) space. DSP C66x CorePac CFG accesses are routed / arbitrated by the DSP\_NoC L2 interconnect. DSP C66x CorePac CFG accesses are mapped between 0x01C0\_0000 and 0x0FFF\_FFFF.

---

**NOTE:** The DSP C66x CorePac CFG initiator interface is strictly for non-cacheable loads and stores within MMR and I/O spaces.

---

DSP configuration accesses to **external to DSP subsystem** peripherals can be issued on either the DSP subsystem CFG Master port which is mapped to the device L3\_MAIN or DSP 32-bit CFG "system" interface is connected to the chip level L3\_MAIN interconnect and used to access L3\_MAIN addresses that are mapped between 0x01C0\_0000 and 0x0FFF\_FFFF.

**DSP accesses (to non-DSP memories like SDRAM on L3\_MAIN) for addresses above 0x1000\_0000 are handled via the DSP (XMC) MDMA 128-bit master interface and are routed to the DSP subsystem MDMA Initiator port either through DSP\_MMU0 or bypassing MMU.**

**NOTE:** In some cases, L3\_MAIN peripherals may be mapped to both the MDMA bus and the CFG bus. In that case, there may be a latency advantage of using the CFG address for those peripherals

Table 5-9 shows the DSP C66x CPU memory view of the various DSP C66x CorePac internal and external resources.

**Table 5-9. C66x CPU View Map**

C66x CPU View (DSP C66x CorePac Internal only, MDMA or CFG init ports) <sup>(1)</sup>		Size	DSP Memory Region	Function
Start Address	End Address			
0x0080_0000	0x0084_7FFF	288 KiB	DSP_L2	DSP L2 SRAM (local)

0x0200_0000	0x020F_FFFF	1 MiB	EVE1	DSP configuration traffic to the EVE1 (mapped on the DSP CFG interface)
0x0210_0000	0x021F_FFFF	1 MiB	EVE2	DSP configuration traffic to the EVE2 (mapped on the DSP CFG interface)
0x0220_0000	0x023F_FFFF	2 MiB	Reserved	Reserved
0x0330_0000	0x033F_FFFF	1 MiB	EDMA_TPCC	DSP configuration traffic to the EDMA_TPCC (mapped on the DSP CFG interface)
0x0340_0000	0x034F_FFFF	1 MiB	EDMA_TC0	DSP configuration traffic to the EDMA_TC0 (mapped on the DSP CFG interface)
0x0350_0000	0x035F_FFFF	1 MiB	EDMA_TC1	DSP configuration traffic to the EDMA_TC1 (mapped on the DSP CFG interface)
0x0800_0000	0x0800_FFFF	64 KiB	DSP_XMC_CTRL MMRs	DSP internal MMRs for XMC controller (non-cache)
0x0802_0000	0x080F_FFFF	896 KiB	MDMA non-cache	MDMA initiator (non-cache) to L3_MAIN (DSP_MMU0)
0x0810_0000	0x0BBF_FFFF	59 MiB		
0x1000_0000	0x10FF_FFFF	16 MiB	DSP1 L1P, L1D and L2 memories	An image of DSP1 C66x CorePac internal space - only L1P, L1D and L2 memories (global) <sup>(3)</sup>

<sup>(1)</sup> Only the C66x CPU view of device implemented functional memory regions are shown. The remaining regions are reserved.

<sup>(2)</sup> The internal configuration space registers are visible ONLY to the C66x CPU (DSP\_C0) within the DSP C66x CorePac, i.e. they are NOT visible to initiators outside the DSP C66x CorePac.

<sup>(3)</sup> The DSP1 CPU sees an image of its own memories in the 0x1000\_0000 - 0x10FF\_FFFF address range (the same mapped also at lower addresses 0x0080\_0000 - 0x00F0\_7FFF). On the other side, DSP2 CPU addresses, generated in the same range (with DSP2\_MMU0 involved), are mapped to the DSP2 MDMA port (cached transfers to/from L3\_MAIN connected system memories).

**Table 5-9. C66x CPU View Map (continued)**

C66x CPU View (DSP C66x CorePac Internal only, MDMA or CFG init ports ) <sup>(1)</sup>		Size	DSP Memory Region	Function
Start Address	End Address			
0x1000_0000	0x10FF_FFFF	16 MiB	DSP2 MDMA (cached)	DSP2 MDMA initiator (cached) to L3_MAIN (through DSP2_MMU0)
0x1100_0000	0x11FF_FFFF	16 MiB	DSP2 L1P, L1D and L2 memories	An image of DSP2 C66x CorePac internal space - only L1P, L1D and L2 memories (global) <sup>(4)</sup>
			DSP1 MDMA (cached)	MDMA initiator (cached) to L3_MAIN (through DSP1_MMU0)
0x1200_0000	0x1FFF_FFFF	224 MiB	MDMA (cached)	DSP1 and DSP2 MDMA initiator (cached) to L3_MAIN (through DSP1_MMU0 / DSP2_MMU0, respectively )
0x2000_0000	0xFFFF_FFFF	3584 MiB	MDMA (cached)	DSP1 and DSP2 MDMA initiator (cached) to L3_MAIN (through DSP1_MMU0 / DSP2_MMU0, respectively )

<sup>(4)</sup> The DSP2 CPU sees an image of its own memories in the 0x1100\_0000 - 0x11FF\_FFFF address range (the same mapped also at lower addresses 0x0080\_0000 - 0x00F0\_7FFF). On the other side, DSP1 CPU addresses, generated in the same range (with DSP1\_MMU0 involved), are mapped to the DSP1 MDMA port (cached transfers to / from L3\_MAIN connected system memories).

Refer to the [Section 2.2, L3\\_MAIN Memory Space Mapping](#), in the chapter, *Memory Mapping*, for the addresses of the L3\_MAIN space memory-mapped registers. Refer to the [Section 2.7, DSP Subsystem Memory Space Mapping](#) in the same chapter for a description of the DSP1 and DSP2 internal memory, additional memory, and peripherals that the DSP1 and DSP2 have access to.

### 5.3.10.2 DSP\_EDMA View of the Address Space

EDMA is able to initiate internal accesses directly to the DSP memories via the DSP C66x CorePac SDMA bus. The access is conducted to the DSP C66x CorePac internal memories over the L2 DSP\_NoC interconnect.

[Table 5-10](#) shows the DSP integrated EDMA controller memory view of the various DSP C66x CorePac internal and external resources.

**Table 5-10. DSP EDMA Controller View Map**

DSP_EDMA Controller View (EDMA master internal / external port )		Size	DSP Memory Region	Function
Start Address	End Address			
0x0080_0000	0x0084_7FFF	288 KiB	DSP_L2	DSP L2 SRAM (local)
0x00E0_0000	0x00E0_7FFF	32 KiB	DSP_L1P	DSP L1P SRAM (local)
0x00F0_0000	0x00F0_7FFF	32KiB	DSP_L1D	DSP L1D SRAM (local)
0x0802_0000	0x0BBF_FFFF	59 MiB	EDMA to L3_MAIN	EDMA initiator (DSP_MMU1)
0x1000_0000	0x10FF_FFFF	16 MiB	DSP L1/L2	An image of DSP C66x CorePac internal space - only L1P, L1D and L2 memories (global) <sup>(1)</sup>
0x2000_0000	0xFFFF_FFFF	3584 MiB	DMA OCP	L3_MAIN interconnect memory via MMU1 / DMA OCP Initiator

<sup>(1)</sup> The internal configuration space registers DSP\_ICFG are visible ONLY to the C66x CPU (DSP\_C0) within the DSP C66x CorePac , i.e. they are NOT visible to the DSP\_EDMA.

Access from EDMA to external resources on L3\_MAIN are routed via DSP subsystem **EDMA initiator port**. **Note that these accesses are transferred through the DSP\_MMU1 memory management unit.**

**NOTE:** The DSP\_EDMA can NOT access the DSP\_ICFG ( DSP C66x CorePac internal) addresses.

With the DSP\_MMU1 disabled, the subset of the memory map used for DSP\_EDMA internal accesses will NOT be visible. Thus only addresses which equal 0x2000\_0000 and above will be considered as valid 32-bit addresses ( i.e. L3\_MAIN space accesses only).

Refer to the [Section 2.2, L3\\_MAIN Memory Space Mapping](#), in the chapter, *Memory Mapping*, for the addresses of the L3\_MAIN space memory-mapped registers. Refer to the [Section 2.7, DSP Subsystem Memory Space Mapping](#) in the same chapter for a description of the DSP1 and DSP2 internal memory, additional memory, and peripherals that the DSP1 and DSP2 have access to.

### 5.3.10.3 L3\_MAIN View of the DSP Address Space

System initiated accesses (i.e. external-to-DSP accesses over device L3\_MAIN) to DSP are issued over the DSP SDMA target port.

**NOTE:** The MSB-bits of the address are truncated to only provide an 8 MiB view of the memory map within the DSP subsystem. Notice that the relative offsets of the DSP CFG space is different for the OCP SDMA target port relative to the DSP internal initiators.

The SDMA target bus is able to access internal subsystem address space (such as DSP\_EDMA, DSP\_MMU0, DSP\_MMU1, etc.), or the DSP local memory address space. The SDMA target bus **is NOT able to access the DSP ICFG space (such as DSP\_INTC, DSP\_BWM, etc)** or the other initiator ports on the DSP subsystem boundary (i.e., accesses cannot go through DSPSS to get to the DSP\_EDMA initiator port, L3\_MAIN CFG initiator port ).

The DSP slave DMA port memory map - [Table 5-11](#) shows an 8 MiB window (23-bit address) both from the SDMA Target bus (0x0000\_0000 through 0x007F\_FFFF), as well as the EDMA (0x0080\_0000 through 0x00FF\_FFFF). The DSP C66x CorePac internally views itself as a 16 MiB window where 0x0000\_0000 through 0x007F\_FFFF is reserved, L2 SRAM starts at 0x0080\_0000, L1P SRAM starts at 0x00E0\_0000, and L1D SRAM starts at 0x00F0\_0000).

**Table 5-11. SDMA Target Port Memory Map**

System L3_MAIN View <sup>(1)</sup>		Size	DSP Memory Region	Function
Start Address	End Address			
0x0000_0000	0x0004_7FFF	288 KiB	DSP_L2	DSP L2 SRAM (local)
0x0050_0000	0x0050_0FFF	4 KiB	DSP_SYSTEM	DSP SYSTEM MMR Block
0x0050_1000	0x0050_1FFF	4 KiB	DSP_MMU0CFG	DSP MMU0 configuration / regs
0x0050_2000	0x0050_2FFF	4 KiB	DSP_MMU1CFG	DSP MMU1 configuration / regs
0x0050_5000	0x0050_5FFF	4 KiB	DSP_EDMA_TC0	DSP EDMA Transfer Controller 0
0x0050_6000	0x0050_6FFF	4 KiB	DSP_EDMA_TC1	DSP EDMA Transfer Controller 1
0x0050_7000	0x0050_7FFF	4 KiB	DSP_NoC	DSP L2 Interconnect registers
0x0051_0000	0x0051_7FFF	32 KiB	DSP_EDMA_CC	DSP EDMA Channel Controller
0x0060_0000	0x0060_7FFF	32 KiB	DSP_L1P	DSP L1P SRAM (local)
0x0070_0000	0x0070_7FFF	32 KiB	DSP_L1D	DSP L1D SRAM (local)

<sup>(1)</sup> Only system (L3\_MAIN) view over functionally used regions are shown. The remaining regions are reserved.

Refer to the [Section 2.2, L3\\_MAIN Memory Space Mapping](#), in the chapter, *Memory Mapping*, for the addresses of the L3\_MAIN space memory-mapped registers. Refer to the [Section 2.7, DSP Subsystem Memory Space Mapping](#) in the same chapter for a description of the DSP1 and DSP2 internal memory, additional memory, and peripherals that the DSP1 and DSP2 have access to.

## 5.4 DSP Subsystem Register Manual

This section describes the DSP Subsystem instances registers.

### 5.4.1 DSP Subsystem Instance Summary

**Table 5-12. DSP Subsystem Instance Summary**

Module Name	Module Base Address	Size
<a href="#">DSP_ICFG</a>	0x0180 0000 <sup>(1)</sup>	4 KiB
<a href="#">DSP_SYSTEM</a>	0x01D0 0000 <sup>(1)</sup>	256 Bytes
<a href="#">DSP_FW_L2_NOC_CFG</a>	0x01D0 3000 <sup>(1)</sup>	8576 Bytes
<a href="#">DSP1_SYSTEM</a>	0x40D0 0000	256 Bytes
<a href="#">DSP1_FW_L2_NOC_CFG</a>	0x40D0 3000	8576 Bytes
<a href="#">DSP2_SYSTEM</a>	0x4150 0000	256 Bytes
<a href="#">DSP2_FW_L2_NOC_CFG</a>	0x4150 3000	8576 Bytes

<sup>(1)</sup> The registers of DSP subsystem instances prefixed only with DSP in the name, and NOT DSP1 or DSP2, are NOT visible on the device L3\_MAIN. They are visible only within the DSP\_ICFG internal configuration space hence accessible only by the DSP C66x CPU.

**NOTE:** For more details on the DSP\_MMU0 and DSP\_MMU1 registers, as well as their :

- DSP\_MMU0CFG and DSP\_MMU1CFG physical addresses accesible only by DSP\_C0 CPU core in the DSP subsystem
- DSP1\_MMU0CFG and DSP1\_MMU1CFG physical addresses visible on L3\_MAIN
- DSP2\_MMU0CFG and DSP2\_MMU1CFG physical addresses visible on L3\_MAIN

refer to [Section 20.5, MMU Register Manual](#), in [Chapter 20, Memory Management Units](#).

**NOTE:** For more details on the DSP\_EDMA\_CC, DSP\_EDMA\_TC0 and DSP\_EDMA\_TC1 registers, as well as their :

- DSP1\_EDMA\_CC, DSP1\_EDMA\_TC0 and DSP1\_EDMA\_TC1 physical addresses visible on L3\_MAIN
- DSP2\_EDMA\_CC, DSP2\_EDMA\_TC0 and DSP2\_EDMA\_TC1 physical addresses visible on L3\_MAIN

refer to [Section 16.2.7, EDMA Register Manual](#), in [Section 16.2, Enhanced DMA](#).

#### CAUTION

The L1P, L1D and L2 memory controller registers mapped in the L3\_MAIN are limited to 32-bit data access; 16- and 8-bit access are not allowed and can corrupt register content.

## 5.4.2 DSP\_ICFG Registers

### 5.4.2.1 DSP\_ICFG Register Summary

**NOTE:** The DSP\_ICFG addresses are visible only within the DSP core internal configuration space.

**Table 5-13. DSP\_ICFG Registers Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	DSP_ICFG Physical Address	Register Reset Value <sup>(1)</sup>
EVTFLAG0	R	32	0x0000 0000	0x0180 0000	0x0000 0000

### 5.4.2.2 DSP\_ICFG Register Description

For bitfield descriptions of all registers which reside within the DSP\_ICFG configuration address space, refer to the *TMS320C66x DSP CorePac User Guide*, ([SPRUGW0C](#)).

### 5.4.3 DSP\_SYSTEM Registers

#### 5.4.3.1 DSP\_SYSTEM Register Summary

**NOTE:** While the DSP1\_SYSTEM and DSP2\_SYSTEM addresses are part of the device L3\_MAIN memory space, the **DSP\_SYSTEM** addresses are visible only within the DSP\_ICFG internal configuration space (visible only to C66x CPU and debug logic).

**Table 5-14. DSP\_SYSTEM and DSP1\_SYSTEM Registers Mapping Summary**

**Table 5-30. DSP\_SYS\_IRQWAKEEN0**

<b>Address Offset</b>	0x0000 0020	<b>Instance</b>	DSP_SYSTEM
<b>Physical Address</b>	0x01D0 0020 0x40D0 0020 0x4150 0020		DSP1_SYSTEM DSP2_SYSTEM
<b>Description</b>	The register provides a global interrupt wakeup enable bit vector that defines which input interrupts are used to cause a wake from powerdown state (via the slave idle protocol). IRQWAKEEN0 is for interrupt inputs 63 thru 32, and IRQWAKEEN1 is for interrupt inputs 95 thru 64. Internal interrupts cannot cause a wake condition since in this state there is no guaranteed clock and all sub-modules should be in idle state. Software can write 1 to set and 0 to clear the corresponding bit (i.e., enable the corresponding interrupt for wakeup). Reads of this register return the actual state of the enable register.

#### 5.4.4 DSP\_FW\_L2\_NOC\_CFG Registers

This section covers the DSPSS level defined public firewall (DSP\_MMU0, DSP\_MMU1) and L2 interconnect (DSP\_NoC) functional registers.

##### 5.4.4.1 DSP\_FW\_L2\_NOC\_CFG Register Summary

**NOTE:** While the DSP1\_FW\_L2\_NOC\_CFG and DSP2\_FW\_L2\_NOC\_CFG addresses are part of the device L3\_MAIN memory space, **the DSP\_FW\_L2\_NOC\_CFG addresses are visible only within the DSP\_ICFG internal configuration space (visible only to C66x CPU and debug logic).**

**Table 5-70. DSP\_FW\_L2\_NOC\_CFG and DSP1\_FW\_L2\_NOC\_CFG Registers Mapping Summary**

## IVA Subsystem

---

---

---

---

**NOTE:** The IVA-HD subsystem is a set of video encoder and decoder hardware accelerators. The list of supported codecs can be found in the software development kit (SDK) documentation.

The IVA-HD subsystem availability is device part number dependent. Refer to device *Data Manual*, for more information.

---

## Dual Cortex-M4 IPU Subsystem

---

---

This chapter describes the dual Cortex-M4 image processor unit (IPU) subsystem.

Topic	Page
7.1 Dual Cortex-M4 IPU Subsystem Overview .....	1634
7.2 Dual Cortex-M4 IPU Subsystem Integration.....	1637
7.3 Dual Cortex-M4 IPU Subsystem Functional Description.....	1642
7.4 Dual Cortex-M4 IPU Subsystem Register Manual .....	1655

## 7.1 Dual Cortex-M4 IPU Subsystem Overview

### 7.1.1 Introduction

The device instantiates two dual Cortex®-M4 image processor unit (IPU) subsystems available for general purpose usage.

---

**NOTE:** The two IPU subsystems are identical from functional point of view. Thus, a unified name **IPUx** shall be used throughout the chapter for simplification.

---

Each IPU subsystem contains two Arm® Cortex-M4 processors (IPUx\_C0 and IPUx\_C1) that share a common level 1 (L1) cache (called unicache [IPUx\_UNICACHE]). The two Cortex-M4 cores are completely homogeneous to one another. Any task possible using one Cortex-M4 core is also possible using the other Cortex-M4 core. It is software responsibility to distribute the various tasks between each Cortex-M4 core for optimal performance.

The integrated interrupt handling of the IPUx subsystem allows it to function as an efficient control unit.

[Figure 7-1](#) is a high-level block diagram of the IPUx subsystem.

Figure 7-1. IPUx Subsystem Overview

### 7.1.2 Features

Each IPU subsystem integrates the following:

- Two Arm Cortex-M4 microprocessors (IPUx\_C0 and IPUx\_C1):
  - Armv7-M and Thumb®-2 instruction set architecture (ISA)
  - Armv6 SIMD and digital signal processor (DSP) extensions
  - Single-cycle MAC
  - Integrated nested vector interrupt controller (NVIC) (also called IPUx\_Cx\_INTC, where x = 0, 1)
  - Integrated bus matrix
  - Registers:
    - Thirteen general-purpose 32-bit registers
    - Link register (LR)
    - Program counter (PC)
    - Program status register, xPSR
    - Two banked SP registers
  - Integrated power management
  - Extensive debug capabilities
- Unicache interface:
  - Instruction and data interface
  - Supports paralleled accesses
- Level 2 (L2) master interface (MIF) splitter for access to memory or configuration port
- Configuration port: Used for unicache maintenance and unicache memory management unit (IPUx\_UNICACHE\_MMU) configuration
- Unicache:
  - 32 KiB divided into 16 banks
  - 4-way
  - Cache configuration lock/freeze/preload
  - Internal MMU:
    - 16-entry region-based address translation
    - Read/write control and access type control
    - Execute Never (XN) MMU protection policy
    - Little-endian format
- Subsystem counter timer module (IPUx\_UNICACHE\_SCTM, or just SCTM)
- On-chip ROM (IPUx\_ROM) and banked RAM (IPUx\_RAM) memory
- Emulation/debug: Emulation feature embedded in Cortex-M4
- L2 MMU (IPUx\_MMU): 32 entries with table walking logic
- Wake-up generator (IPUx\_WUGEN): Generates wake-up request from external interrupts
- Power management:
  - Local power-management control: Configurable through the IPUx\_WUGEN registers.
  - Three sleep modes supported, controlled by the local power-management module.
  - IPUx is clock-gated in all sleep modes.
  - IPUx\_Cx\_INTC interrupt interface stays awake.

## 7.2 Dual Cortex-M4 IPU Subsystem Integration

Figure 7-2 and Figure 7-3 show the integration of IPU1 and IPU2 in the device.

Figure 7-2. IPU1 Subsystem Integration

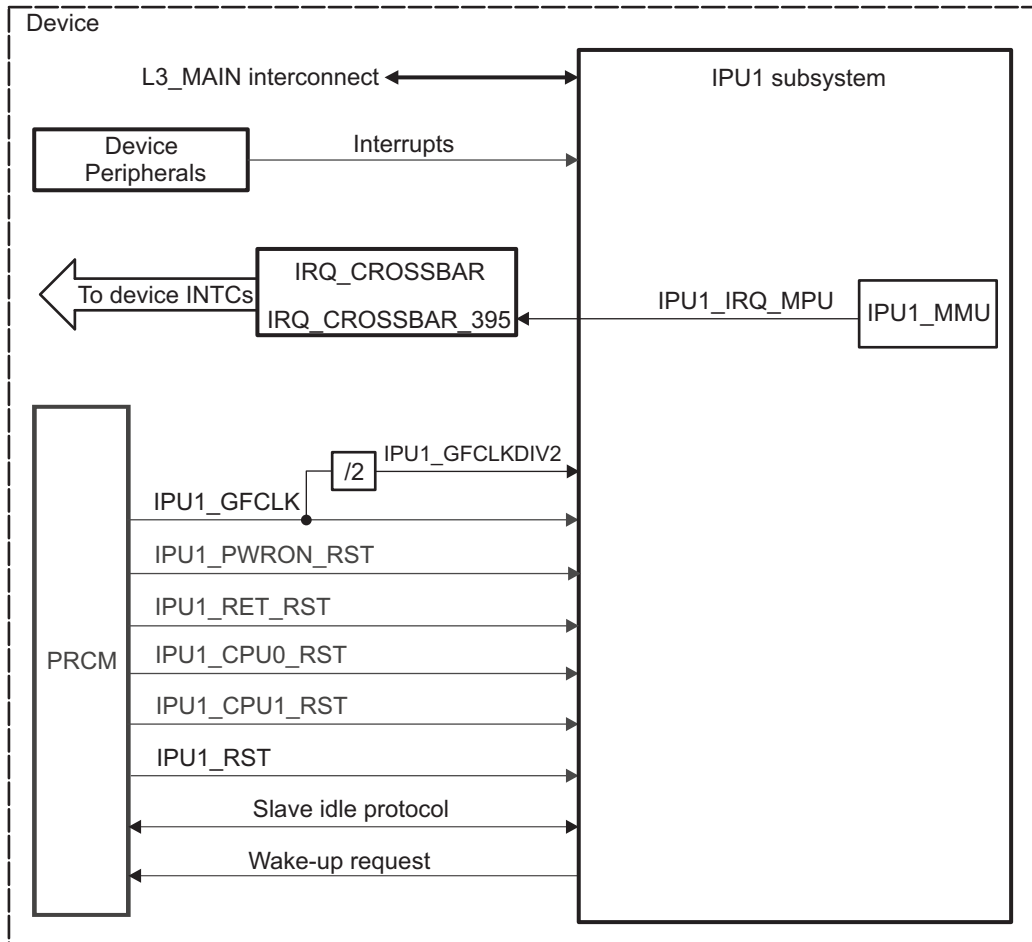

Figure 7-3. IPU2 Subsystem Integration

Table 7-1 through Table 7-3 summarize the integration of the module in the device.

Table 7-1. IPUx Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
IPU1	PD_IPU	L3_MAIN
IPU2	PD_CORE	L3_MAIN

Table 7-2. IPUx Hardware Requests

Module Instance	Interrupt Name (Source)	Interrupt Requests		
		IRQ_CROSSBAR Input (Destination)	Default Mapping	Description
IPU1	IPU1_IRQ_MPU	IRQ_CROSSBAR_395	MPU_IRQ_100	IPU1_MMU fault interrupt.
IPU2	IPU2_IRQ_MPU	IRQ_CROSSBAR_396	–	IPU2_MMU fault interrupt. This interrupt is not mapped by default to any device INTC.

**Table 7-3. IPUx Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
IPU1	IPU1_GFCLK	IPU1_GFCLK	PRCM module	IPU1 interface and functional clock(s). See <a href="#">Section 7.2.1.1</a> for details.
	IPU1_GFCLKDIV2	IPU1_GFCLK		
IPU2	IPU2_GFCLK	IPU2_GFCLK	PRCM module	IPU2 interface and functional clock(s). See <a href="#">Section 7.2.1.1</a> for details.
	IPU2_GFCLKDIV2	IPU2_GFCLK		
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
IPU1	IPU1_PWRON_RST	IPU1_PWRON_RST	PRCM module	Power-on reset, used to reset the whole IPU1 subsystem
	IPU1_RET_RST	IPU1_RET_RST	PRCM module	Retention reset to few retention logic inside the IPU1_UNICACHE
	IPU1_CPU0_RST	IPU1_CPU0_RST	PRCM module	Reset signal to IPU1_C0
	IPU1_CPU1_RST	IPU1_CPU1_RST	PRCM module	Reset signal to IPU1_C1
	IPU1_RST	IPU1_RST	PRCM module	Reset signal to the IPU1_UNICACHE and the IPU1_MMU
IPU2	IPU2_PWRON_RST	IPU2_PWRON_RST	PRCM module	Power-on reset, used to reset the whole IPU2 subsystem
	IPU2_RET_RST	IPU2_RET_RST	PRCM module	Retention reset to few retention logic inside the IPU2_UNICACHE
	IPU2_CPU0_RST	IPU2_CPU0_RST	PRCM module	Reset signal to IPU2_C0
	IPU2_CPU1_RST	IPU2_CPU1_RST	PRCM module	Reset signal to IPU2_C1
	IPU2_RST	IPU2_RST	PRCM module	Reset signal to the IPU2_UNICACHE and the IPU2_MMU

**NOTE:** The “**Default Mapping**” column in [Table 7-2](#) shows the default mapping of module IRQ source signal. This IRQ source signal can also be mapped to other lines of each device Interrupt controller through the IRQ\_CROSSBAR module.

For more information about the IRQ\_CROSSBAR module, see [Chapter 18, Control Module](#).

For more information about the device interrupt controllers, see [Chapter 17, Interrupt Controllers](#).

For more information about clocks, resets, and power domains, see [Chapter 3, Power, Reset, and Clock Management](#).

## 7.2.1 Dual Cortex-M4 IPU Subsystem Clock and Reset Distribution

### 7.2.1.1 Clock Distribution

The IPUx subsystem has two clock inputs:

- **IPUx\_GFCLK:** Main source clock for IPUx; feeds most of IPUx internal modules:
  - IPUx Unicache & MMU, L2 MIF & MPORT (all running on (1x) IPUx\_GFCLK)
  - Cortex-M4 cores, IPUx\_RAM, IPUx\_ROM (all running on (1/2x) IPUx\_GFCLK via internal divider)
- **IPUx\_GFCLKDIV2:** This is IPUx\_GFCLK externally divided by two; feeds IPUx L2 MMU

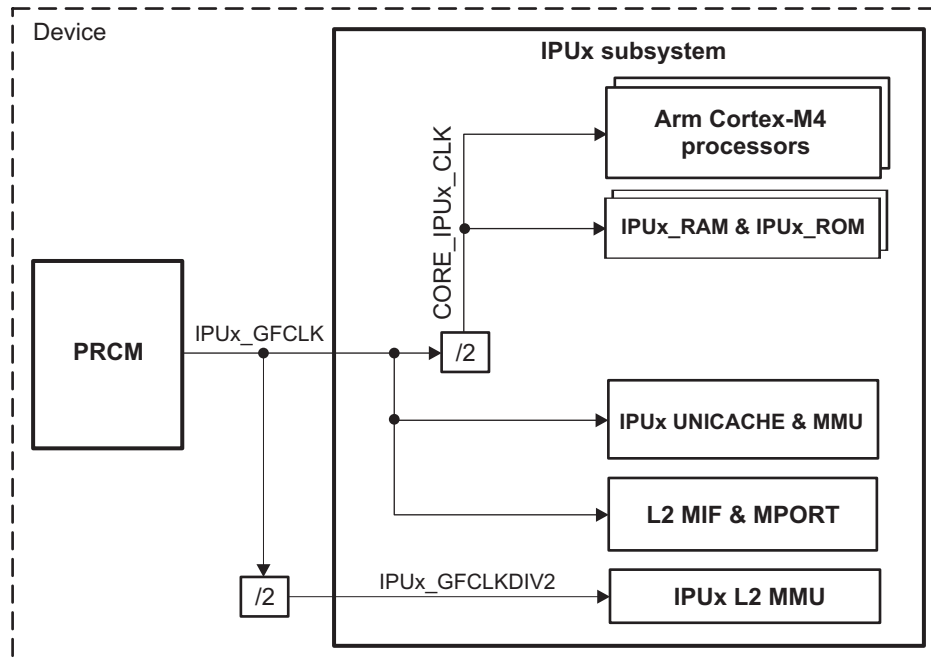

The IPUx\_GFCLK itself can be derived from either:

- CORE\_IPUx\_ISS\_BOOST\_CLK – main clock for IPUx from DPLL\_CORE, or
- DPLL\_ABE\_X2\_CLK – alternative clock from DPLL\_DDR

For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

Figure 7-4 shows the clocking scheme of the IPUx subsystem.

**Figure 7-4. IPUx Subsystem Clocking Scheme**

### 7.2.1.2 Reset Distribution

Three reset signals controlled by the power, reset, and clock management (PRCM) module let the two Arm Cortex-M4 processors and the rest of the IPUx subsystem be reset independently. These three reset signals are: IPUx\_CPU0\_RST, IPUx\_CPU1\_RST, and IPUx\_RST. The Arm Cortex-M4 processors must come out of reset one at a time:

- At IPUx\_CPU0\_RST, IPUx\_C0 comes out of reset, but IPUx\_C1 is held in reset.
- IPUx\_C0 controls the reset for IPUx\_C1 (through the PRCM RM\_IPUx\_RSTCTRL[1] RST2 bit).

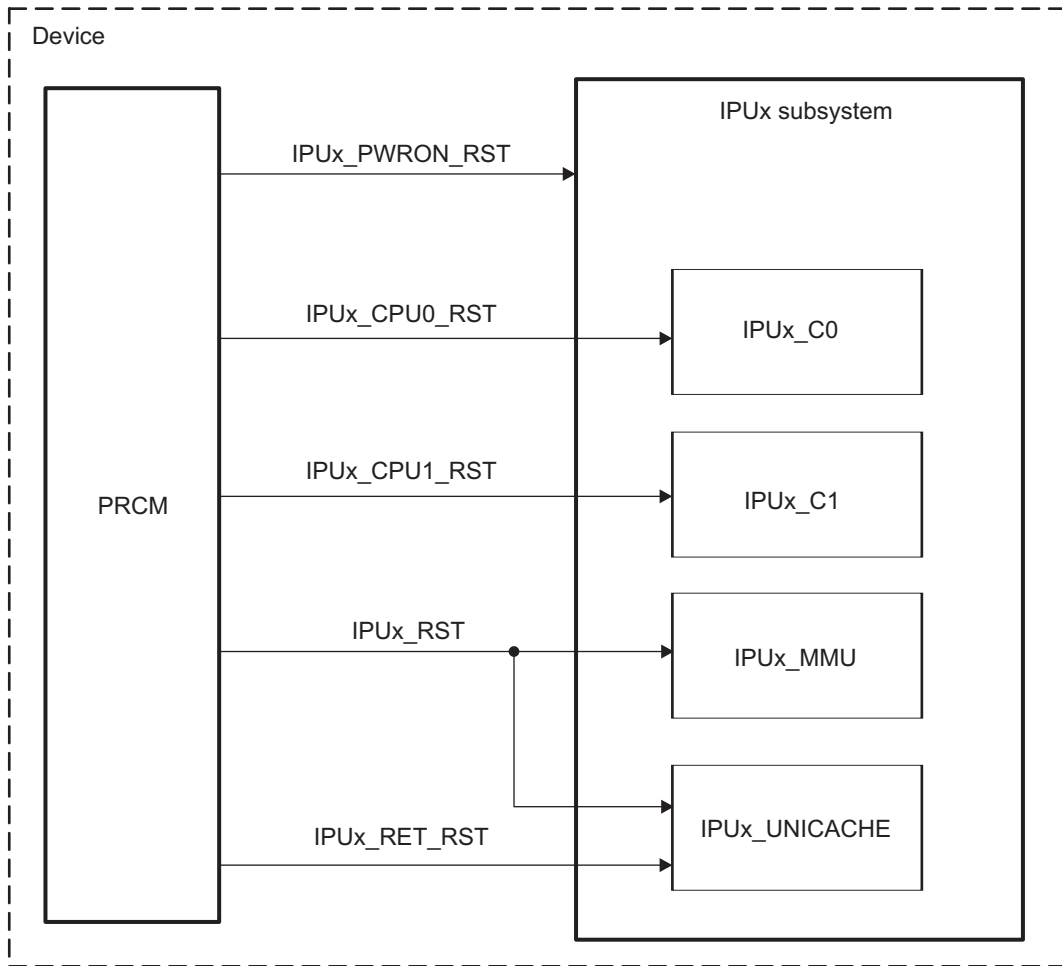

Because IPUx\_C0 controls the reset for IPUx\_C1 (through the PRCM registers), the code running on IPUx\_C0 decides the mode of operation, whether it is:

- Mode 1: One Arm Cortex-M4 processor is running, and the other processor is held on reset.
- Mode 2: The two Arm Cortex-M4 processors are running.

This decision of which mode to use is driven by the use case. If the software partitioning and performance requirement for a use case requires two Cortex-M4 processors to run simultaneously, the user must go to mode 2. If IPUx\_C1 is not required for a particular use case, the user can remain in mode 1.

Figure 7-5 shows the reset scheme of the IPUx subsystem.

Figure 7-5. IPUx Subsystem Reset Scheme

## 7.3 Dual Cortex-M4 IPU Subsystem Functional Description

### 7.3.1 IPUx Subsystem Block Diagram

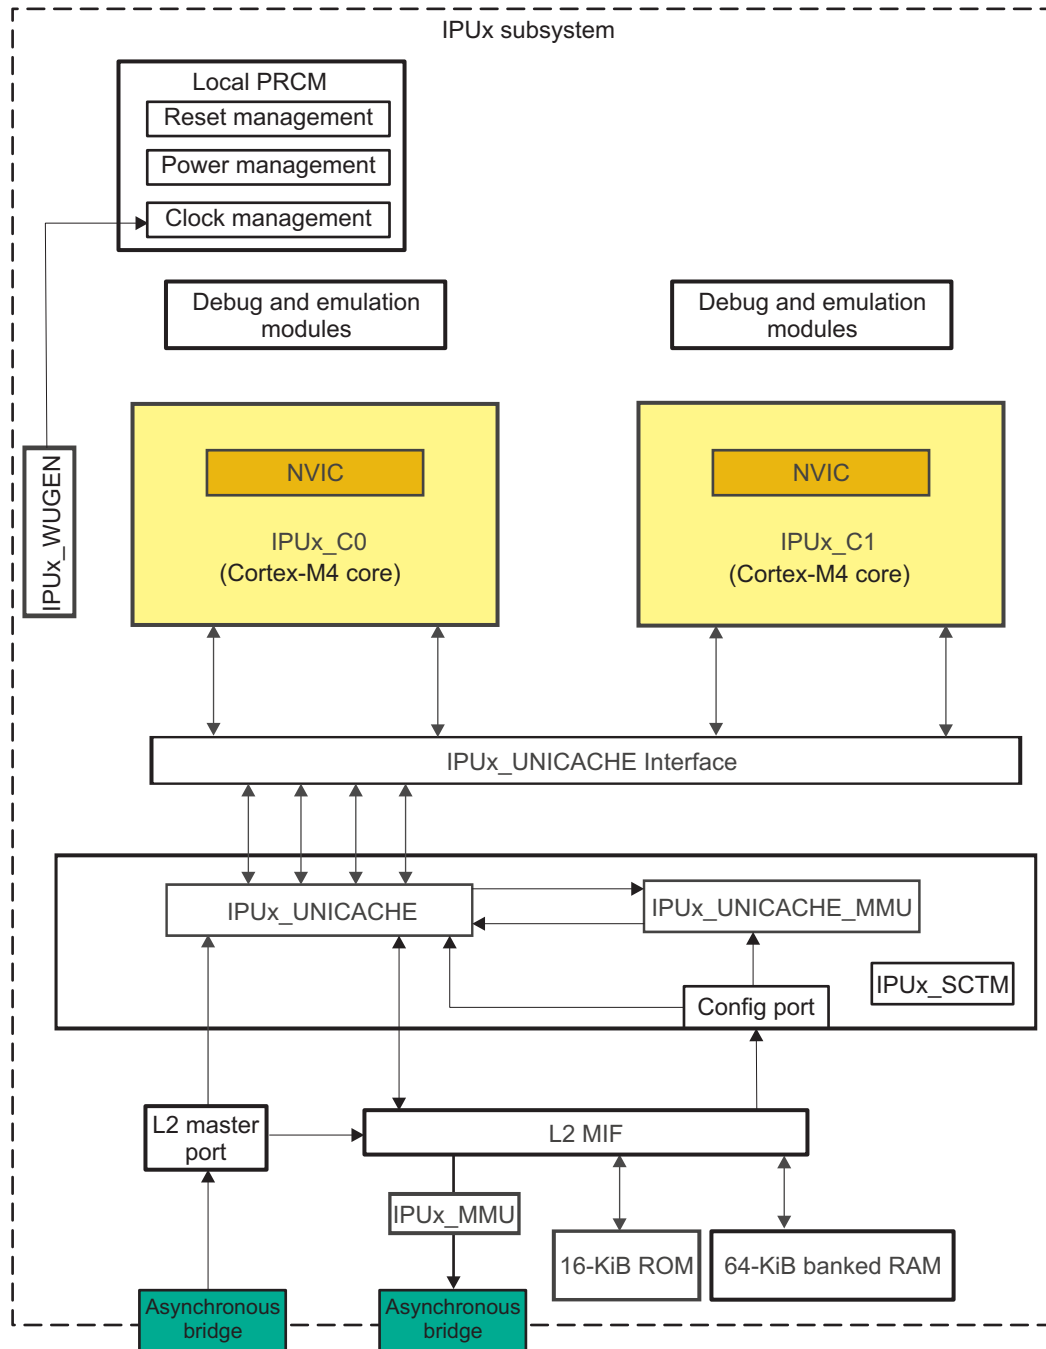

The IPUx subsystem integrates the following group of submodules:

- Two Arm Cortex-M4 processors: Two cores (r0p1 revision), IPUx\_C0 and IPUx\_C1. For a description of the Arm Cortex-M4 processor, see the *Arm Cortex-M4 Technical Reference Manual*, available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp).
- Interrupt controller (IPUx\_Cx\_INTC): To facilitate parallel processing, the interrupt mapping is the same for the two cores. Each Cortex-M4 processor receives the same interrupts, except for a few internal interrupts. Every IRQ line is shared between the two Arm processors. By properly configuring the IPUx\_Cx\_INTC registers inside each Arm processor, it can be ensured that the shared IRQ is taken by only one of the Arm processors (for more information, see [Chapter 17, Interrupt Controllers](#)).
- IPUx\_UNICACHE interface: The cache interface converts the data between the different protocols in the subsystem. Four ports are required to support the four buses from the Arm Cortex-M4 processors (two for each processor). The instruction and data connections from each Arm Cortex-M4 are multiplexed, but the Arm Cortex-M4 prevents conflicts on this connection. Default cache policies are provided through the sideband signals and are not used to access the cache. Cacheability is provided through the MMU inside the cache.
- IPUx\_UNICACHE: Allows basic maintenance operations, which are performed through a dedicated interface: preload, lock, clean (write out dirty lines, but do not invalidate directly), and invalidate.
- IPUx\_UNICACHE\_MMU: Serves the role of an attribute MMU (AMMU) for the unicache. It provides the multi-access cache with region-based address translation, read/write control, access type control, and multilevel cache maintenance. Access to the IPUx\_UNICACHE\_MMU is done only under privilege mode. The IPUx\_UNICACHE\_MMU can be programmed by the dual Cortex-A15 microprocessor unit (MPU) subsystem through the IPUx subsystem slave port.
- IPUx\_UNICACHE\_SCTM: Embedded in the IPUx\_UNICACHE
- Interconnect configuration port: Cache maintenance and MMU configuration are done through an interconnect slave port. Accesses must be performed to a noncacheable area that must be defined within the IPUx\_UNICACHE\_MMU. Interconnect accesses are generated from the L2 MIF.
- IPUx\_MMU: Provides address translation for all the accesses done from the IPUx subsystem to the level 3 (L3\_MAIN) interconnect. The IPUx\_MMU can be programmed by the MPU subsystem through the IPUx subsystem slave port.
- L3\_MAIN interconnect port: Allows access to the system memories and peripherals. For the address mapping of the modules in the IPUx subsystem, see [Chapter 2, Memory Mapping](#).
- On-chip IPUx\_ROM and banked IPUx\_RAM memory. The IPUx\_ROM memory is used for boot/initialization purposes. For more information about the initialization of the device, see [Chapter 32, Initialization](#).

[Figure 7-6](#) is a block diagram of the IPUx subsystem.

Figure 7-6. IPUx Subsystem Block Diagram

## 7.3.2 Power Management

### 7.3.2.1 Local Power Management

The user can configure the local power management through the [STANDBY\\_CORE\\_SYSCONFIG](#), [IDLE\\_CORE\\_SYSCONFIG](#), and [WUGEN\\_IRQ\\_EN](#) registers. The user can:

- Configure the different standby modes (the default is smart wake-up standby mode) through the [STANDBY\\_CORE\\_SYSCONFIG\[1:0\]](#) STANDBYMODE bit field
- Configure the different idle modes (the default is smart wake-up idle mode) through the [IDLE\\_CORE\\_SYSCONFIG\[1:0\]](#) IDLEMODE bit field

- Control which interrupts will cause a wakeup by appropriately configuring the [WUGEN\\_MEVT0](#) and [WUGEN\\_MEVT1](#) registers (the default is ALL\_MASKED)

The IPUx subsystem provides three sleep modes:

- On mode: Sleep on exit (wait for the interrupt service routine [ISR] to complete)
- Sleep mode: Wait for interrupt to wake up the processor
- Deep-sleep mode: Long duration sleep; phase-locked loop (PLL) can be stopped

During sleep mode, the system clock can be stopped, but the free-running clock input must still be running to allow the processor to be wakened by an interrupt or an event. The sleep modes are invoked by wait for interrupt (WFI) or wait for event (WFE) instructions. The processor clock is automatically stopped, waiting for an interrupt or an event. Deep-sleep mode also stops the processor clock, but this can also be supported by the PRCM module. A combined signal is generated from the two Cortex-M4 processors in deep-sleep mode to initiate another power state and let the PRCM module handle the next power states. At this time, software must ensure that all IPUx\_UNICACHE background operations (for example, maintenance) are complete.

[Table 7-4](#) describes local clock gating.

**Table 7-4. Local Clock Gating**

Cortex-M4 CPU Mode	IPUx_C1 On	IPUx_C1 Sleep	IPUx_C1 Deep Sleep
IPUx_C0 On	On	Functional clock 2 stopped locally	Functional clock 2 stopped locally
IPUx_C0 Sleep	Functional clock 1 stopped locally	Functional clock 1 and clock 2 stopped locally	Functional clock 1 and clock 2 stopped locally
IPUx_C0 Deep Sleep	Functional clock 1 stopped locally	Functional clock 1 and clock 2 stopped locally	Standby request to power-management module

---

**NOTE:** For information about source clock gating and for a description of the sleep/wake-up transitions, see [Chapter 3, Power, Reset, and Clock Management](#).

---

### 7.3.2.2 Power Domains

The IPUx subsystem is divided into two power domains (PD\_IPU and PD\_COREAON), which are controlled by the PRCM module.

The PD\_IPU power domain is the main power domain and includes all the IPUx subsystem components (two Arm Cortex-M4 processors, IPUx\_UNICACHE, IPUx\_ROM and IPUx\_RAM memories, and emulation\debug modules) except the IPUx\_WUGEN.

The PD\_COREAON power domain is an always-on power domain. The PD\_COREAON power domain contains the IPUx\_WUGEN, which generates a wake-up request from external interrupts. By this separate PD\_COREAON power domain, the wake-up request can be generated even when the PD\_IPU power domain is in OFF or RET state.

For information about the PD\_IPU and PD\_COREAON power domains, see [Chapter 3, Power, Reset, and Clock Management](#).

### 7.3.2.3 Voltage Domain

The IPUx subsystem is located within the CORE voltage domain (VD\_CORE). All IPU logic (Cortex-M4 cores, IPUx\_UNICACHE/MMU, IPUx\_WUGEN, etc...) is fed by VD\_CORE. All IPU memory arrays are fed by on-chip memory (SRAM) LDO dedicated to the CORE domain – SLDO\_CORE.

For information about VD\_CORE and SLDO\_CORE, see [Chapter 3, Power, Reset, and Clock Management](#).

### 7.3.2.4 Power States and Modes

[Table 7-5](#) lists the different power modes and the expected states for each power domain.

**Table 7-5. IPUx Subsystem Power Modes**

	Functional Domain	Activity			Power Status	
		Core		IPUx subsystem	PD_DSP Power Domain	PD_COREAON Power Domain
	Modules included	IPUx_C0	IPUx_C1	IPUx_WUGEN		
Power modes	Active	Active	Active	Active	ON	ON
	IPUx_C0 idle	Idle	Active	Active	ON	ON
	IPUx_C1 idle	Active	Idle	Active	ON	ON
	Core standby	Idle	Idle	Active	ON	ON
	Full idle	Idle	Idle	Idle	ON	ON
	CSWR	Idle	Idle	Idle	ON/LOWV	ON/LOWV
	OSWR	Idle	Idle	Idle	RET	ON
	Power off	Idle	Idle	Idle	OFF	OFF

Table 7-6 lists the power mode transitions in the IPUx subsystem.

**Table 7-6. Power Mode Transitions**

	Active	IPUx_C0 Idle	IPUx_C1 Idle	Standby	Full-Idle	Retention	Power Off
Active		WFE/WFI instruction	WFE/WFI instruction				
IPUx_C0 idle	Events/interrupts			Deep sleep			
IPUx_C1 idle	Events/interrupts			Deep sleep			
Standby	Wake-up IRQ				L1/L2/ IPUx_WUGEN functional domain idle		
Full idle	Wake-up IRQ			Wake-up (through interconnect)		PRCM module	PRCM module
CSWR/OSWR					PRCM module or wakeup		PRCM module
Power off					PRCM module or wakeup	PRCM module	

The different power modes and their features are:

- Active mode: All function domains are operative.
- IPUx\_C0 and IPUx\_C1 idle mode:
  - Only the CPU core is idled (when running WFE/WFI instructions).
  - Only one Cortex-M4 core can be in this mode. Interrupts or events can waken the core.
  - Can go into sleep or deep-sleep mode. Potentially, both cores can be in sleep mode.
  - When both cores are in deep-sleep mode, a standby request is sent to the PRCM module.
  - Software must ensure that all IPUx\_UNICACHE background operations (for example, maintenance) are complete before the PRCM module asserts an IdleReq.
- Core standby mode
  - Both cores in the CORE functional domain are in idle mode (an interrupt cannot wake up either of the cores).
  - The PRCM module must have acknowledged its acceptance by an MWait signal.
  - After this handshake, all power management is under the control of the PRCM module.
- Full-idle mode:
  - The IPUx subsystem functional domain is also idled.

- After coming to this mode, power states can be moved deeper.
- Retention mode:
  - The voltage of the logic supply is lowered to reduce static power consumption by leakage current. The logic power switch in the PD\_IPU power domain is still closed (ON); thus, all logic states are retained.
  - L1 and/or L2 memories can go independently into retention depending on the settings done at the PRCM level.
- Power off mode:
  - The voltage source is shut down. The logic states, including the retention logic, are lost.
  - The IPUx\_WUGEN is not operating and only the PRCM module can trigger the IPUx subsystem wakeup.
  - Reset must be applied to the IPUx subsystem to restart the two Arm Cortex-M4 processors and the memory subsystem.

### 7.3.2.5 Wake-Up Generator (IPUx\_WUGEN)

The IPUx\_WUGEN in the IPUx subsystem enables efficient power management. The IPUx\_WUGEN generates a wake-up signal to the PRCM module to enable the IPUx subsystem to recover its functional clocks, which are gated by the PRCM module when at least one request is active. The IPUx\_WUGEN can be configured in standby mode or idle mode through the [STANDBY\\_CORE\\_SYSCONFIG\[1:0\]](#) STANDBYMODE and [IDLE\\_CORE\\_SYSCONFIG\[1:0\]](#) IDLEMODE bit fields.

#### 7.3.2.5.1 IPUx\_WUGEN Main Features

The IPUx\_WUGEN allows:

- Gating of the IPUx subsystem clock dynamically, thus reducing power consumption
- Simplifying of dependencies in the PRCM module

[Figure 7-7](#) is an overview of the IPUx\_WUGEN.

Figure 7-7. IPUx\_WUGEN Overview

The wake-up signal to the PRCM module requests the IPUx subsystem functional clock (IPUx\_GFCLK). The wake-up signal to the Arm Cortex-M4 processors indicates to them that at least one enabled request is active.

### 7.3.3 IPUx\_UNICACHE

Table 7-7 describes the IPUx\_UNICACHE configuration in the IPUx subsystem platform.

Table 7-7. IPUx\_UNICACHE Configuration

Parameter	Value
Way	4
Size	32 KiB
Bank elements	32 bits
Bank number	16
Slave interface data size	32 bits
Master interface data size	64 bits
Line size	256 bits
MMU lookup	Included
Number of slaves	4
Number of masters	1
Number of fill/prefetch buffers	Four prefetch buffers
Slave types	IPUx_UNICACHE interface

IPUx\_UNICACHE allows basic maintenance operations, which are performed through a dedicated interface:

1. Preload
2. Lock
3. Clean
4. Invalidate

Maintenance of the cache is performed between the start and end addresses. This allows for direct control of memory regions. All maintenance operations occur in the background and can generate an interrupt when they complete. Such operations are protected by software semaphore, because only one operation at a time can be performed. The maintenance operations can also be performed using MMU small entries.

### 7.3.4 IPUx\_UNICACHE\_MMU

The IPUx\_UNICACHE\_MMU serves the role of an attribute MMU (AMMU) for the unicache. It provides the multi-access cache with region-based address translation, read/write control, access type control, and multi-level cache maintenance. [Table 7-8](#) describes the IPUx\_UNICACHE\_MMU configuration in the device.

**Table 7-8. IPUx\_UNICACHE\_MMU Configuration**

Parameter	Values
Number of large pages	4 entries
Size of large pages	512 MiB or 32 MiB (configurable)
Number of medium pages	2 entries
Size of medium pages	256 KiB or 128 KiB (configurable)
Number of small pages	10 entries
Size of small pages	16 KiB or 4 KiB (configurable)
Number of patch pages	Not included
Size of line pages	256-bit
Number of comparison interfaces	4
Number of comparator sets	1
Write pipeline data comparison	Disabled
Number of IPUx_UNICACHE maintenance interfaces	3
Size of entry address	32-bit

As can be seen in [Table 7-8](#), IPUx\_UNICACHE\_MMU supports different page sizes: large, medium, and small. The number of large pages, number of medium pages, etc., is defined at design time. The size of the pages is configurable in the following IPUx\_UNICACHE\_MMU registers:

- [CACHE\\_MMU\\_LARGE\\_POLICY\\_i\[1\]](#) SIZE
- [CACHE\\_MMU\\_MED\\_POLICY\\_j\[1\]](#) SIZE
- [CACHE\\_MMU\\_SMALL\\_POLICY\\_k\[1\]](#) SIZE

The different MMU page sizes can be used to create smaller policies within a larger region.

The logical source address is configured in:

- [CACHE\\_MMU\\_LARGE\\_ADDR\\_i\[31:25\]](#) ADDRESS
- [CACHE\\_MMU\\_MED\\_ADDR\\_j\[31:17\]](#) ADDRESS
- [CACHE\\_MMU\\_SMALL\\_ADDR\\_k\[31:12\]](#) ADDRESS

The logical source translated address is configured in:

- [CACHE\\_MMU\\_LARGE\\_XLTE\\_i\[31:25\]](#) ADDRESS
- [CACHE\\_MMU\\_MED\\_XLTE\\_j\[31:17\]](#) ADDRESS
- [CACHE\\_MMU\\_SMALL\\_XLTE\\_k\[31:12\]](#) ADDRESS

When the SIZE bit is set to 0, all the bits in the ADDRESS bit field of the corresponding logical source address and logical source translated address can be used.

When the SIZE bit is set to 1, the ADDRESS bit field of the corresponding logical source address and logical source translated address must be programmed only with addresses that can address the size of a second possible page.

### 7.3.5 IPUx\_UNICACHE\_SCTM

The Subsystem Counter Timer Module (SCTM) is a generic profile counter and timer module that provides the following functions:

- Counter functions:
  - Input events counting
  - Two counter modes:
    - Event counting
    - Duration counting
  - Counter chaining
- Timer functions:
  - Periodic intervals generation
  - Two timer modes:
    - Run-once mode
    - Restart mode
  - Events and/or interrupt generation

The SCTM has eight counters (two of which have timer functions). There are input events going into the SCTM and interrupt events going to the IPU INTC. For more information about the counter configuration and the SCTM input events, see [Section 33.7.2, IPU Subsystem Performance Monitoring](#), in [Chapter 33, On-Chip Debug Support](#). For more information about the mapping of the SCTM interrupt event signals to IPU INTC inputs, see [Section 17.3.4, Interrupt Requests to IPU1\\_Cx\\_INTC](#), in [Chapter 17, Interrupt Controllers](#).

Figure 7-8 shows the SCTM block diagram.

Figure 7-8. SCTM Block Diagram

#### 7.3.5.1 Counter Functions

##### 7.3.5.1.1 Input Events

Signals from within the subsystem are routed to the SCTM and used to control the counters and timers in the module. The routing of the input events from the module boundary to an individual counter is accomplished through an input event multiplexer and is controlled by the [CACHE\\_SCTM\\_CTCR\\_WT\\_i\[20:16\] INPSEL](#) and [CACHE\\_SCTM\\_CTCR\\_WOT\\_j\[20:16\] INPSEL](#) bit fields.

---

**NOTE:** For more information about input events to the module boundary, see [Section 33.7.2.2, Cache Events](#), in [Chapter 33, On-Chip Debug Support](#).

---

### 7.3.5.1.2 Counters

There are individual 32-bit counters in the SCTM. The counters count when the input event signals are asserted.

#### 7.3.5.1.2.1 Counting Modes

The counters in the SCTM support two mutually exclusive counting modes:

- Event mode: The counter increments each time a rising edge is detected on the designated input event signal.
- Duration mode: The counter continually increments when the event input is asserted.

#### 7.3.5.1.2.2 Counter Overflow

When the counter reaches the terminal value (0xFFFFFFFF) it wraps and continues to increment. This is considered a timer overflow condition. The [CACHE\\_SCTM\\_CTCR\\_WT\\_i\[6\] OVRFLW](#) and [CACHE\\_SCTM\\_CTCR\\_WOT\\_j\[6\] OVRFLW](#) bits indicate that overflow has occurred. The overflow bit can be cleared by reading it. When chained, only the high-order counter overflows.

#### 7.3.5.1.2.3 Counters and Processor State

The counters can be configured to alter their behavior based on the state of the CPU. The [CACHE\\_SCTM\\_CTCR\\_WT\\_i\[4\] FREE](#) and [CACHE\\_SCTM\\_CTCR\\_WOT\\_j\[4\] FREE](#) bits determine whether the counter will continue to operate when the processor enters debug halt state. When the FREE bit is set to 0, the counter stops incrementing while the debug halt input from the CPU is asserted. Normal operation resumes when the processor exits the debug halt state and the debug halt input is deasserted. When the FREE bit is set to 1, the state of the debug halt input is not used to control counter operation.

The [CACHE\\_SCTM\\_CTCR\\_WT\\_i\[5\] IDLE](#) and [CACHE\\_SCTM\\_CTCR\\_WOT\\_j\[5\] IDLE](#) bits determine whether the counter will continue to operate when the processor enters idle state (the processor is no longer executing instructions and is waiting for a wake-up event). When the IDLE bit is set to 0, the counter stops incrementing while the idle input from the CPU is asserted. Normal operation resumes when the processor exits the idle state and the idle input is deasserted. When the IDLE bit is set to 1, the state of the idle input is not used to control counter operation.

#### 7.3.5.1.2.4 Chaining Counters

The individual 32-bit counters in the SCTM can be chained with an adjacent counter to form a 64-bit counter. Counters chained to a counter across an even-odd index boundary with the even counter contain the least-significant 32 bits of the 64-bit pairing. For example, counters 1 and 0 can be paired and counter 1 will contain bits 63:32 and counter 0 will contain bits 31:0. The high-order counter increments by 1 each time the low-order counter wraps.

Counters are chained by setting the [CACHE\\_SCTM\\_CTCR\\_WT\\_i\[2\] CHAIN](#) or [CACHE\\_SCTM\\_CTCR\\_WOT\\_j\[2\] CHAIN](#) bit for both counters. When chained, the counter control for both counters is taken from the [CACHE\\_SCTM\\_CTCR\\_WT\\_i](#) or [CACHE\\_SCTM\\_CTCR\\_WOT\\_j](#) register of the low-order counter. Other than the CHAIN bit, all other bits in the high-order [CACHE\\_SCTM\\_CTCR\\_WT\\_i](#) or [CACHE\\_SCTM\\_CTCR\\_WOT\\_j](#) register are ignored.

Chained counters can function only in counter mode. Timer mode is not supported.

The [CACHE\\_SCTM\\_CTCR\\_WT\\_i\[7\] CHNSDW](#) and [CACHE\\_SCTM\\_CTCR\\_WOT\\_j\[7\] CHNSDW](#) bits are used to indicate that a counter can provide atomics accessed when chained. These bits are valid only for counters with even indexes (the lower half of a 64-bit counter pair). When these bits are set, the counter can shadow the value of the lower half of the chained counter value at the same time the upper half of the counter is read. The shadowed value (not the current value) is returned when the value of the low-order

counter is read. Therefore, when a chained counter has atomic read capability, an atomic counter value can be obtained simply by reading the high-order counter first, followed by the low-order counter. This order must always be observed to prevent reading stale counter values from the low-order counter. When counters are functioning independently, the shadow feature is deactivated and a read of the counter always returns the current value.

#### **7.3.5.1.2.5 Enabling and Disabling Counters**

After the counter is correctly configured, it can be started by setting the [CACHE\\_SCTM\\_CTCR\\_WT\\_i\[0\]](#) ENBL or [CACHE\\_SCTM\\_CTCR\\_WOT\\_j\[0\]](#) ENBL bit. At this point, the counter begins incrementing under the control of the configured event input. The counter can be disabled (counting stops) at any time by clearing the ENBL bit. Counters can be enabled and disabled dynamically during application flow.

Counters can also be enabled and disabled as groups through the [CACHE\\_SCTM\\_CTGNBL](#) register. This register provides control of the individual counter-enable in groups. This allows an application to enable or disable groups of counters in lockstep by setting corresponding bits to 1 (bit number corresponds to counter number).

#### **7.3.5.1.2.6 Resetting Counters**

The counters can be reset to their initial value (0x00000000) by writing 1 to the [CACHE\\_SCTM\\_CTCR\\_WT\\_i\[1\]](#) RESET or [CACHE\\_SCTM\\_CTCR\\_WOT\\_j\[1\]](#) RESET bit. If the counter is chained, the high-order and low-order counters are reset when the RESET bit is written for the low-order counter.

Counters can also be reset as groups through the [CACHE\\_SCTM\\_CTGRST](#) registers. These registers provide control of the individual counter reset in groups. This allows an application to reset groups of counters in lockstep.

### **7.3.5.2 Timer Functions**

Counters 0 and 1 in the SCTM can function as timers. When operating as timers, interrupts and/or debug input events are generated when the value of the counter reaches a designated interval.

#### **7.3.5.2.1 Periodic Intervals**

The interval for a timer is contained in the [CACHE\\_SCTM\\_TINTVLR\\_i](#) register. There is a [CACHE\\_SCTM\\_TINTVLR\\_i](#) register for every timer-capable counter in the SCTM. Timers are initialized to 0. When the corresponding [CACHE\\_SCTM\\_CTCNTR\\_k](#) increments and matches the values designated in [CACHE\\_SCTM\\_TINTVLR\\_i](#), the timer is considered to be triggered and events configured in [CACHE\\_SCTM\\_CTCR\\_WT\\_i](#) are generated.

Timers can function in one of two mutually exclusive modes:

- Run-once mode: The timer stops after the first interval match and is not re-enabled until the timer is reset to the initial value (0) by setting the [CACHE\\_SCTM\\_CTCR\\_WT\\_i\[1\]](#) RESET bit to 1.
- Restart mode: The timer automatically resets to the initial value (0) each time the designated interval is reached.

The [CACHE\\_SCTM\\_CTCR\\_WT\\_i\[10\]](#) RESTART bit is used to configure the timer mode.

#### **7.3.5.2.2 Event Generation**

Timers can generate interrupts and debug events. Interrupts are routed from the module boundary to the interrupt controller(s) in the subsystem. Debug events are routed as triggers to debug logic within the subsystem.

The generation of the interrupts is controlled by the [CACHE\\_SCTM\\_CTCR\\_WT\\_i\[8\]](#) INT bit. The generation of debug events is controlled by the [CACHE\\_SCTM\\_CTCR\\_WT\\_i\[9\]](#) DBG bit. The INT and DBG bits can be set simultaneously and both signals are generated on interval match.

If neither INT nor DBG is set, the timer function is disabled and the counter functions as a regular counter.

### 7.3.6 IPUx\_MMU

An additional MMU provides address translation for the accesses done from the IPUx subsystem to the L3\_MAIN interconnect. The main characteristics of this MMU are:

- 32 entries
- Compatible with Armv6 architecture MMU translation tables (protection bits not used)
- Page-based or access-based endianness conversion
- Two-level descriptor hierarchy
- One intermediate page table
- Four page sizes (16 MiB, 1 MiB, 64 KiB, 4 KiB)
- Page table alignment on 128-byte boundary for Arm11® compatibility

The configuration of the MMU can be done from one of the Cortex-M4 cores or from the L3\_MAIN interconnect slave port. The accesses done to configure the MMU cannot be part of a burst access.

For more information about the IPUx\_MMU, see [Chapter 20, Memory Management Units](#).

#### 7.3.6.1 IPUx\_MMU Behavior on Page-Fault in IPUx Subsystem

**Table 7-9. IPUx\_MMU Behavior on Page-Fault**

Application		Debug	
Table-Walker Enabled	Table-Walker Disabled	Table-Walker Enabled	Table-Walker Disabled
Use Table-Walker to find translation. Update TLB cache if successful, set TRANSLATIONFAULT bit and interrupt if not. The following bits are used for the purpose: MMU_IRQENABLE[1] TRANSLATIONFAULT and MMU_IRQSTATUS[1] TRANSLATIONFAULT.	Set TLBMISS bit and interrupt and stall. The following registers are used for the purpose: MMU_IRQENABLE[0] TLBMISS and MMU_IRQSTATUS[0] TLBMISS.	Use Table-Walker to find translation. Update TLB cache if successful (only if the MMU_CNTL[3] EMUTLBUPDATE bit is set), generate in-band bus error if not.	Set EMUMISS bit and interrupt and stall. The following bits are used for the purpose: MMU_IRQENABLE[2] EMUMISS and MMU_IRQSTATUS[2] EMUMISS.

The MMU fault interrupt line is connected to both Cortex-M4 cores (at IPUx\_IRQ\_16 interrupt line) and is also propagated outside of the IPUx subsystem and connected to an IRQ\_CROSSBAR input (IRQ\_CROSSBAR\_395 for the IPU1 MMU interrupt, IRQ\_CROSSBAR\_396 for the IPU2 MMU interrupt). The user can route this interrupt to any device host processor by programming properly the corresponding Control Module registers. The host processor (typically, a Cortex-A15) receives the MMU fault and must clean up the fault to resume the execution of the code (or reset IPUx subsystem). It is not possible for one of the Cortex-M4 CPUs to clean up the fault caused by the other Cortex-M4 CPU. This is because both the slave port of the IPUx\_MMU (which is stalled) and the configuration port of IPUx\_MMU are connected (through a splitter) to the same IPUx\_UNICACHE master port.

The default behavior of the IPUx\_MMU previously described can be overridden by setting the MMU\_GP\_REG[0] BUS\_ERR\_BACK\_EN bit to 1. Once this bit is set, all MMU faults (including TLB miss) return a bus error to the IPUx subsystem (interrupt event XLATE\_MMU\_FAULT). This allows the end user to quickly establish the cause of the MMU fault by having appropriate code in the ISR.

### 7.3.7 Interprocessor Communication (IPC)

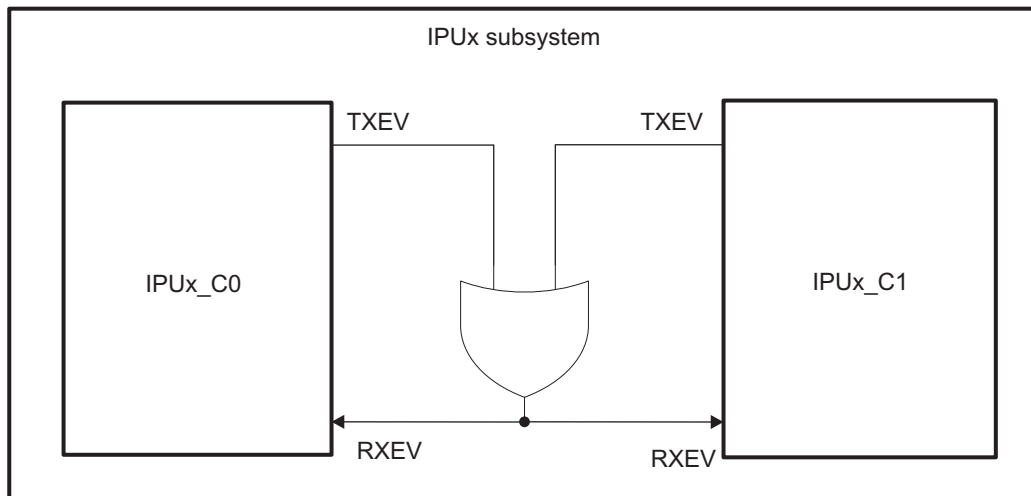

#### 7.3.7.1 Use of WFE and SEV

The IPUx subsystem provides a multiprocessor communication interface for synchronizing tasks. The Arm processors have one output signal, TXEV (transmit event), for sending events and one input signal, RXEV (receive event), for receiving events. [Figure 7-9](#) shows how TXEV and RXEV are connected in the IPUx subsystem.

When a WFE instruction is executed, the processor enters into sleep mode waiting for an event and continues instruction execution when an external event is received. With an SEV (send event) instruction, one processor can wake up the other processor, which is in sleep mode.

The WFE and SEV instructions can help reduce the number of iterations around a lock acquire loop (a spinlock), and thereby reduce power consumption. The basic mechanism involves an observer that is in a spinlock executing a WFE instruction, which suspends execution on that observer until an asynchronous exception or an explicit event (sent by an observer using the SEV instruction) is seen by that observer. The observer that holds the lock uses the SEV instruction to send an event after a lock is released.

**Figure 7-9. Event Communication Connection in IPUx Subsystem**

### 7.3.7.2 Use of Interrupt for IPC

Each Cortex-M4 core can interrupt the other Cortex-M4 core by setting up an interrupt register ([CORTEXM4\\_CTRL\\_REG](#)). This register is used to trigger the corresponding 'per core' HWSEM\_M4\_IRQ interrupt (interrupt number 19). Because the priority level for that interrupt can be defined, it is possible to choose the task level at which the interrupt will run. For example, if IPUx\_C0 was active and IPUx\_C1 was idle (WFI state), when IPUx\_C0 completes its task it sets the bit for IPUx\_C1 in the control register ([CORTEXM4\\_CTRL\\_REG\[16\] INT\\_CORTEX\\_2](#)) and goes into sleep mode. IPUx\_C1 wakes up seeing this interrupt, and starts running its task. After the completion of its task, IPUx\_C1 sets the interrupt for IPUx\_C0 ([CORTEXM4\\_CTRL\\_REG\[0\] INT\\_CORTEX\\_1](#)), and then goes into WFI state. This kind of handshake ensures that if IPUx\_C0 and IPUx\_C1 are accessing the same resources (memory, registers etc.), only one of the CPUs at a time is active.

### 7.3.7.3 Use of the Bit-Band Feature for Semaphore Operations

The two Cortex-M4 cores share the same memory system, and it is possible to use the bit-band feature to carry semaphore operations. Because the bit-band alias writes are locked read-modify-write transfers, provided that all tasks changed only the lock bit representing themselves, the lock bits of other tasks are not lost, even if two tasks try to write to the same memory location at the same time.

Each Cortex-M4 core supports two bit-band regions.

Bit-band 1 applies to the virtual address space 0x2000 0000–0x200F FFFF (1 MiB). This virtual address space can be mapped to any physical address and bit-banding will apply to that region. It is recommended that the user map the L2 IPUx\_RAM (64 KiB) to this virtual space and use it only for bit-banding operations. If required, the user can define other available small and medium pages over and above the L2 IPUx\_RAM virtual space and further extend the use of the bit-band feature.

Bit-band 2 applies to the virtual address space 0x4000 0000–0x400F FFFF (1 MiB). The first 16 KiB of this space (0x4000 0000–0x4000 3FFF) are already reserved for small (one page) pages and cannot be remapped by software. The bit-band alias that corresponds to this 16-KiB region (0x4200 0000–0x4207 FFFF) must also be treated as reserved and no access should be made. The rest of bit-band 2 can be used by appropriately defining the available small and medium pages. In this device, because it is likely that during normal AMMU programming all of L3\_MAIN is mapped to this region, it is highly recommended that the user use only bit-band 1 for all purposes and bit-band 2 only if it is necessary.

#### 7.3.7.4 Private Memory Space

Each Arm Cortex-M4 processor has its own memory space, inaccessible by the other processor. In the private memory space are the IPUx\_Cx\_INTC and RW table registers: [CORTEXM4\\_RW\\_PID1](#) and [CORTEXM4\\_RW\\_PID2](#). [CORTEXM4\\_RW\\_PID1](#) and [CORTEXM4\\_RW\\_PID2](#) are accessible only by the respective Cortex-M4 cores ([CORTEXM4\\_RW\\_PID1](#) is accessible only by IPUx\_C0, while [CORTEXM4\\_RW\\_PID2](#) is accessible only by IPUx\_C1). These registers are not accessible from the Cortex-A15 MPU. Because they are not shared, they do not require the bit-band feature (semaphore) to read and write to them.

### 7.3.8 IPU Boot Options

The IPU boot location is controlled via two Control Module registers:

- [CTRL\\_CORE\\_CORTEX\\_M4\\_MMUADDRTRANSLTR](#)[19:0] [CORTEX\\_M4\\_MMUADDRTRANSLTR](#): Used to set the physical translated address for IPU AMMU
- [CTRL\\_CORE\\_CORTEX\\_M4\\_MMUADDRLOGICTR](#)[19:0] [CORTEX\\_M4\\_MMUADDRLOGICTR](#): Used to set the logical source address for IPU AMMU

By default, two AMMU pages are enabled:

- Small page-0: Translates the 16KB address range from [CORTEX\\_M4\\_MMUADDRLOGICTR](#) to ([CORTEX\\_M4\\_MMUADDRLOGICTR](#) + 0x3FFF). If [CORTEX\\_M4\\_MMUADDRLOGICTR](#) is set to 0x00000, page-0 will control the boot location. If the boot location needs to be mapped to the L2 RAM (0x5502\_0000), then [CORTEX\\_M4\\_MMUADDRTRANSLTR](#) needs to be set to 0x55020. This page is set as non-cacheable at reset.
- Small page-1: Loaded with the physical address of the IPU AMMU configuration registers (0x5508\_0000 - 0x5508\_0FFF), which is mapped to the virtual address range from 0x4000\_0000 to 0x4000\_0FFF. This page is also set as non-cacheable at reset.

---

**NOTE:** Small page-1 is by default 4KB. Software has to modify it to 16KB to cover L2MMU/WUGEN masks.

---

For IPU to boot from any location in L3:

1. Provide boot address through [CORTEX\\_M4\\_MMUADDRTRANSLTR](#) to AMMU page-0 ([CORTEX\\_M4\\_MMUADDRLOGICTR](#) set to 0x00000). Keep L2 MMU disabled (or enable L2 MMU but keep the same translation for 0x0; otherwise there will be L2-MMU page-walks / page-faults).
2. Set [CORTEX\\_M4\\_MMUADDRTRANSLTR](#) to 0x00000 (or any value). Host CPU re-programs AMMU page to map 0x0 virtual address to a physical L2 RAM / L3 location. Only after the programming is complete, Cortex-M4 reset is released. L2 MMU as described above.
3. Set [CORTEX\\_M4\\_MMUADDRTRANSLTR](#) to 0x00000 (no translation). Host CPU programs L2 MMU to do the address translation for 0x0.

For IPU to boot from L2 RAM:

1. This must be done through AMMU page-0. Use either (1) or (2) as described above.

## 7.4 Dual Cortex-M4 IPU Subsystem Register Manual

### 7.4.1 IPUx Subsystem Instance Summary

Table 7-10 and Table 7-11 summarize the IPU1 and IPU2 subsystem instances, respectively.

**Table 7-10. IPU1 Subsystem Instance Summary**

Module Name	Base Address (IPU Private Access)	Base Address (L3_MAIN Interconnect)	Size
IPU1_UNICACHE_CFG	0x5508 0000	N/A	256 B
IPU1_UNICACHE_SCTM	0x5508 0400	N/A	1 KiB
IPU1_UNICACHE_MMU (AMMU)	0x5508 0800	0x5888 0800	2 KiB

<b>Description</b>	These registers contain the control and status settings for a single counter in the module. There will be a CTCR for every counter in the module (WT: with timer)		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
RESERVED								INPSEL								RESERVED								RESTART	DBG	INT	CHNSDW	OVRFLW	IDLE	FREE	DURMODE	CHAIN	RESET	ENBL

Bits	Field Name	Description	Type	Reset
31:21	RESERVED	Reserved.	R	0x000
20:16	INPSEL	Counter Timer input selection 0: Constantly asserted input that results in a free-running counter/timer 1-31: Index of event input signal selected	RW	0x00
15:11	RESERVED	Reserved.	R	0x00
10	RESTART	Restart the timer after an interval match 0: The timer stops after the first interval match. It must be manually reset by software before it starts counting again (run-once timer mode). 1: The timer immediately resets to 0 and begins incrementing again based on the current input configuration (restart timer mode).	RW	0
9	DBG	Signal debug logic on interval match 0: No debug event is generated. 1: Upon interval match, generates a debug event on the corresponding debug output event signal	RW	0
8	INT	Generate interrupt on interval match 0: No interrupt is generated. 1: Upon interval match, generates an interrupt on the corresponding interrupt output event signal	RW	0
7	CHNSDW	Counter has a shadow register for chain reads. 0: The read of the corresponding counter register returns the current value. 1: Read of the high-order counter register, simultaneously loads the current value of the 32 LSBs into a shadow register. The read of the counter register that corresponds to this counter returns the value of the shadow register. This is applicable only when the counter is chained.	R	0
6	OVRFLW	Counter has wrapped since it was last read 0: The counter has not wrapped since the last read. 1: The counter has wrapped since the last read.	R	0
5	IDLE	Counter ignores processor IDLE state 0: The counter does not increment during IDLE state. 1: The counter continues to function during IDLE state; applicable if IDLEMODE = 1.	RW	0
4	FREE	Counter ignores processor debug halt state	RW	0

Bits	Field Name	Description	Type	Reset
		0: The counter does not increment (decrement) during the debug halt state. 1: The counter continues to function during debug halt state.		
3	DURMODE	Counter is in duration or occurrence mode  0: The counter operates in event mode. The counter increments by 1 each time a rising edge is seen on the designated input event signal. 1: The counter operates in duration mode. The counter increments every time a clock cycle is seen and the corresponding input event signal is asserted.	RW	0
2	CHAIN	Counter is chained to an adjacent counter  0: The counter is not chained. 1: Reserved	RW	0
1	RESET	Counter reset control  0: No effect 1: The corresponding counter is reset to the initial value and the OVERFLW bit is cleared. It continues to function if it is still enabled.	RW	0
0	ENBL	Counter enable control  0: The counter does not increment. 1: The counter increments as configured.	RW	0

## ***Embedded Vision Engine***

---

---

This chapter describes the Embedded Vision Engine (EVE) for the device.

---

**NOTE:** Devices may include up to two identical instances of EVE subsystem (EVE1 and EVE2). Refer to the device *Data Manual* for the number of EVE instances on a specific device. This chapter describes the two EVE device superset. For devices without EVE subsystem integrated, the information can be ignored.

---

Topic	Page
<b>8.1 Embedded Vision Engine (EVE) Subsystem .....</b>	<b>1686</b>
<b>8.2 ARP32 CPU and Instruction Set .....</b>	<b>1839</b>
<b>8.3 VCOP CPU and Instruction Set .....</b>	<b>2031</b>

## 8.1 Embedded Vision Engine (EVE) Subsystem

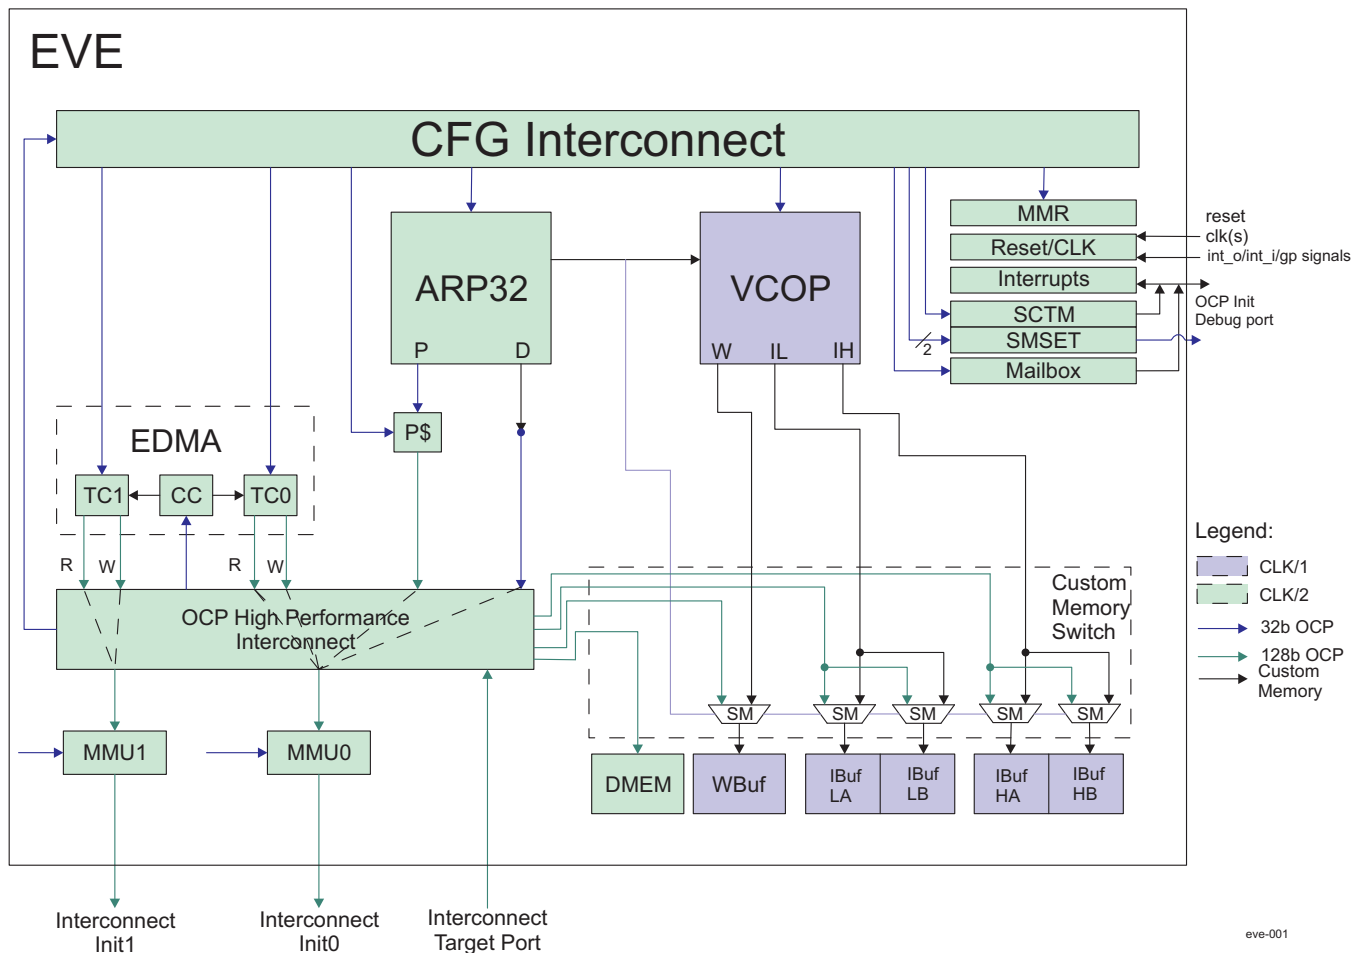

### 8.1.1 EVE Overview

The Embedded Vision Engine (EVE) module is a programmable imaging and vision processing engine, intended for use in devices that serve customer electronics imaging and vision applications. Its programmability meets late-in-development or post-silicon processing requirements, and lets third parties or customers add differentiating features in imaging and vision products.

The device includes two instantiations of the EVE engine. A single EVE module consists of an ARP32 scalar core, a vector coprocessor (VCOP) vector core, and an Enhanced DMA (EDMA3) controller.

Figure 8-1 is a high-level block diagram of the EVE module.

Figure 8-1. EVE Overview

The ARP32 scalar core is the subsystem controller. It coordinates internal EVE interaction, as well as interaction with other components in the system on chip (SoC), like host processor and the DSP. The VCOP is a SIMD engine with built-in loop control and address generation.

The EDMA block is the local DMA. It is used for transferring data between system memories (typically SDRAM and/or L3 SRAM) and internal EVE memories.

Module interconnect is conceptually broken into two parts: A high-performance interconnect and a configuration interconnect. The high-performance interconnect serves as primary high bandwidth (partial) crossbar connection between the EDMA, ARP32, DMA, OCP initiator/target buses and EVE memories. The configuration interconnect provides connectivity to the various memory-mapped registers (MMR) within the EVE module.

The custom memory switch provides a statically muxed low-latency and high-bandwidth connection between the VCOP and the internal EVE memories. The custom memory switch also provides any accesses from the high-performance interconnect and EVE memories.

The interrupt controller (INTC) handles incoming interrupts, merging them with internal interrupt sources to drive the interrupt inputs of the ARP32 .

The MMR block includes control and status bits for general EVE functions that do not reside in other blocks, including reset and clock controller registers and memory static mux ownership.

The SCTM block includes debug logic that supports the counting and timing of various EVE level events, namely VCOP stall counts, VCOP access counts, ARP32 cache miss counts, and so on. The SMSET block provides software message tracing, as well as event tracking.

The reset-clock controller handles subsystem reset and power-management functions.

The EVE engine includes the following main features:

- Two 128-bit interconnect initiator ports used for:
  - Paging between system-level memory (L3 SRAM/DDR) and EVE memory (primarily IBUF, WBUF)
  - ARP32 program fetches to system memory (through program cache)
  - ARP32 load or store requests to system memory
  - ARP32 program cache-related read requests, including prefetch/preload requests
- 128-bit interconnect target port used for system-level host or DMA access to EVE memory or MMR space
- Scalar core (ARP32) with the following features:
  - 32KB program cache (direct mapped and prefetch)
  - 32KB data memory (DMEM)
- Vector core (VCOP):
  - 32KB working buffer (WBUF)
  - 16KB image buffer low copy A (IBUFLA)
  - 16KB image buffer low copy B (IBUFLB)
  - 16KB image buffer high copy A (IBUFHA)
  - 16KB image buffer high copy B (IBUFHB)
- EDMA channel controller (EDMACC): 128 PaRAM entries, 2 Queues
- EDMA transfer controllers: two instances, 2k FIFO each
- Memory Management Units (MMUs):
  - 32-entry TLB per MMU
  - Page walking with hardware
  - EDMA accesses and ARP32 program or data accesses to system memory space
  - Can limit EVE accesses to desired subset of system addresses
- Configuration interconnect for MMR and debug accesses
- High-performance interconnect for high throughput and high concurrency data transfers between connected endpoints
- Multiple interrupts for interrupt mapping, DMA event mapping, and interprocessor handshaking
- Support for Idle and Standby handshake for clock gating
- No support for retention and memory array off modes
- Error detection on all memories:
  - Single bit error detect on DMEM, WBUF, IBUFLA, IBUFLB, IBUFHA, and IBUFHB
  - Double bit error detect on program cache
- Invalid instruction detection in the two processor units (ARP32 and VCOP)
- Debug support
  - Subsystem Counter Timer Module (SCTM) for counting and measuring of VCOP, EVE program

- cache, and EDMA performance-related state
- Software Messaging System Event Trace (SMSET) for trace of software messages and hardware events
- ARP32 debug support: State visibility, breakpoint, run control, cross-triggering
- VCOP debug support: State visibility and run control
- Interprocessor communication: Internal Mailbox for DSP/EVE communication

### 8.1.1.1 EVE Memories

Table 8-1 lists the memories inside the EVE subsystem. See Section 8.1.3.3, *Internal Memory Overview*, for an overview of each memory and its organization, see Section 8.1.3.16, *Memory Map*, for the subsystem memory mapping.

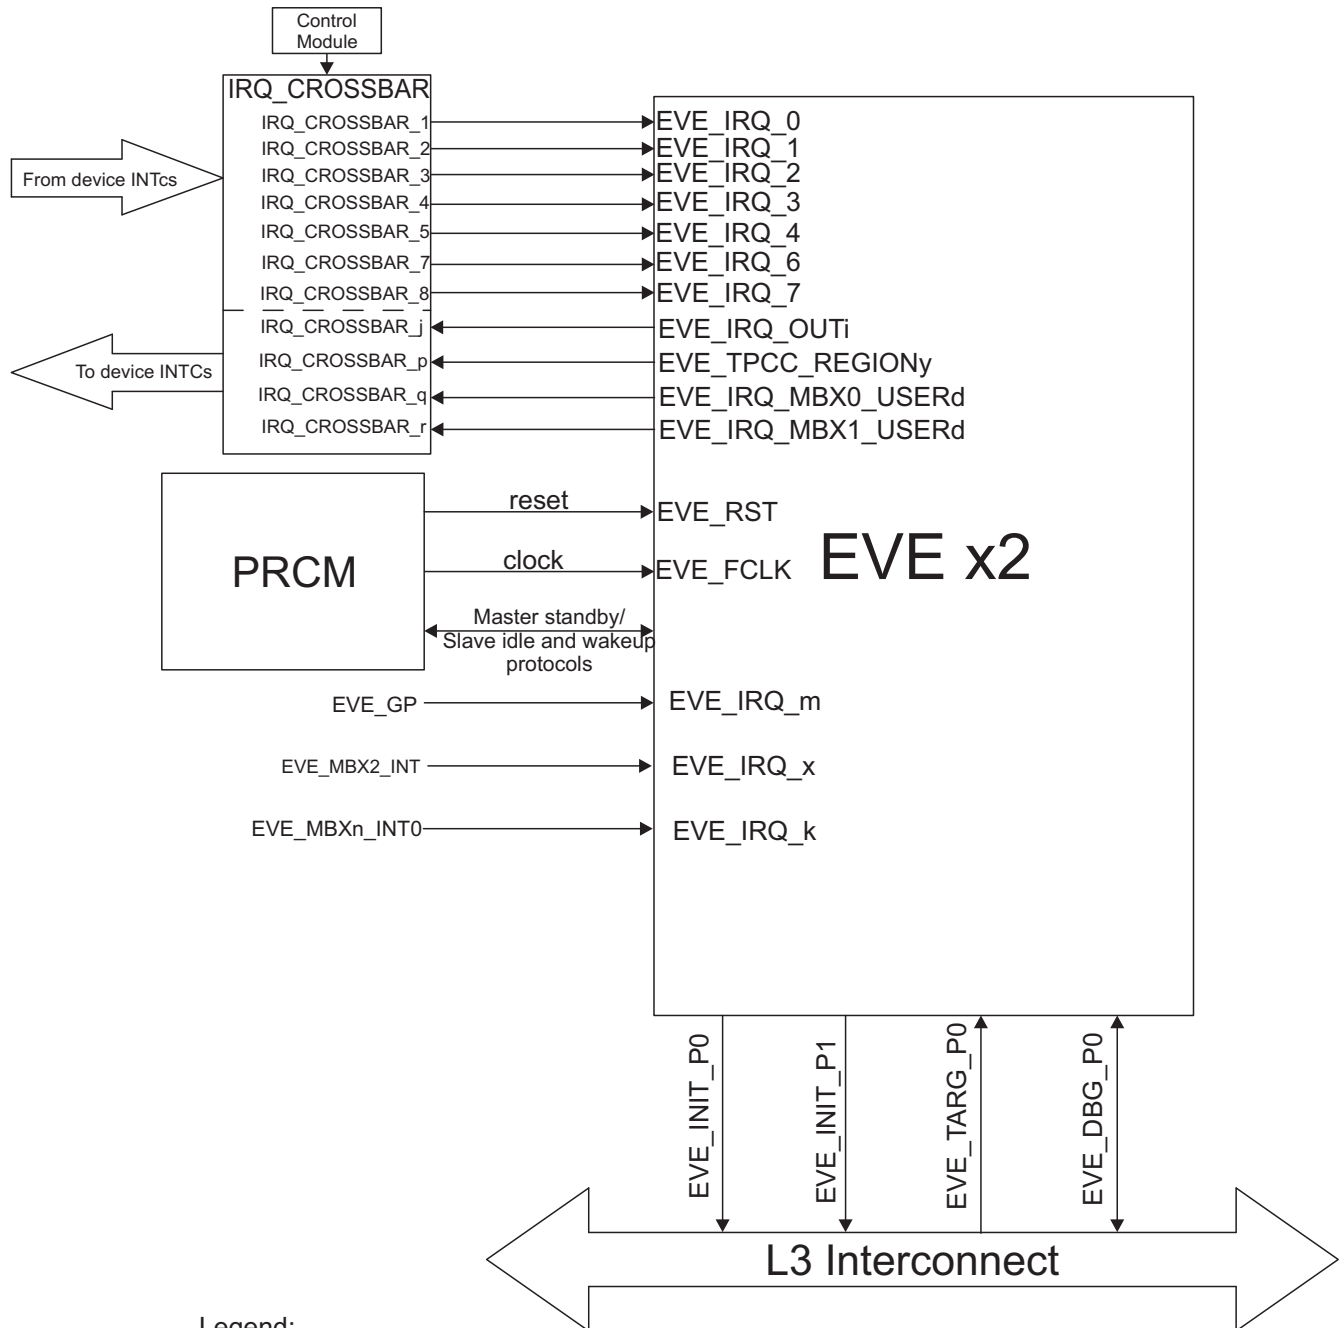

**Table 8-1. EVE Subsystem Memory Blocks**

Memory	Organization	Size	Function
PMEM	1024 × 256	32KB	ARP32 program cache
DMEM	2048 × 128	32KB	ARP32 data memory
WBUF	8 × 1024 × 32	32KB	VCOP working buffer
IBUFLA	8 × 512 × 32	16KB	Image buffer low copy A
IBUFLB	8 × 512 × 32	16KB	Image buffer low copy B
IBUFHA	8 × 512 × 32	16KB	Image buffer high copy A
IBUFHB	8 × 512 × 32	16KB	Image buffer high copy B

### 8.1.2 EVE Integration

Figure 8-2 shows the EVE integration inside the device. EVE includes a number of mailboxes, interrupts, DMA events, and general-purpose I/Os (GPIOs) to facilitate handshaking between the EVE modules and also between other initiators or targets such as DSP, MPU, IPU, VIP, VPE and the PRCM module.

Figure 8-2. EVE Integration

Legend:

- i = 0, 1, 2, 3
- j = 168 to 171 for EVE1
- j = 172 to 175 for EVE2
- k = 28, 29, 30
- m = 8 for EVE1, 9 for EVE2
- d = 1 to 3;
- y = 1 to 4
- x = 16 for EVE1, 17 for EVE2
- n = 2, 3, 4
- p = 281 to 283 for EVE1
- p = 290 to 292 for EVE2
- q = 284 to 289 for EVE1; 293 to 298 for EVE2

**NOTE:** Figure 8-2 is an overview of the EVE integration; for detailed explanation of the interrupt, mailbox, and general-purpose signals coming out or going in each EVE subsystem, see Figure 8-3 and Figure 8-4.

Table 8-2 through Table 8-4 summarize the integration of the EVE subsystem in the device.

**Table 8-2. EVE Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect
EVE1	PD_EVE1	L3_MAIN
EVE2	PD_EVE2	L3_MAIN

**Table 8-3. EVE Clocks and Resets**

Module Instance	Destination Signal Name	Source Signal Name	Source	Description

**Table 8-4. EVE Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	Destination IRQ_CROSSBAR Input	Default Mapping	Description
EVE1	ELM_IRQ	IRQ_CROSSBAR_1	EVE1_IRQ_0	Error location process completion
	EXT_SYS_IRQ_1	IRQ_CROSSBAR_2	EVE1_IRQ_1	External interrupt (active low)
	CTRL_MODULE_CORE_IRQ_SEC_EVTS	IRQ_CROSSBAR_3	EVE1_IRQ_2	Firewall out-band error
	L3_MAIN_IRQ_DBG_ERR	IRQ_CROSSBAR_4	EVE1_IRQ_3	Interconnect debug error
	L3_MAIN_IRQ_APP_ERR	IRQ_CROSSBAR_5	EVE1_IRQ_4	Interconnect application or non-attributes errors on L3
	PRM_IRQ_MPU	IRQ_CROSSBAR_6	EVE1_IRQ_5	PRCM module interrupt
	DMA_SYSTEM_IRQ_0	IRQ_CROSSBAR_7	EVE1_IRQ_6	SDMA interrupt to EVE1
	DMA_SYSTEM_IRQ_1	IRQ_CROSSBAR_8	EVE1_IRQ_7	SDMA interrupt to EVE1
	EVE2_GP8	N/A	EVE1_IRQ_9	EVE general-purpose interrupt
	EVE2_MBX2_INT1	N/A	EVE1_IRQ_17	EVE mailbox interrupt
	MAILBOX2_INTERRUPT0	N/A	EVE1_IRQ_28	Mailbox 2 interrupt 0
	RESERVED	N/A	EVE1_IRQ_29	Reserved
	RESERVED	N/A	EVE1_IRQ_30	Reserved
	EVE1_IRQ_OUT0	IRQ_CROSSBAR_168	N/A	EVE interrupt output
EVE1_IRQ_OUT1	IRQ_CROSSBAR_169	N/A	EVE interrupt output

		EVE2_IRQ_MBX0_USER3	IRQ_CROSSBAR_295	N/A	EVE Mailbox 0 user 3

**Table 8-4. EVE Hardware Requests (continued)**

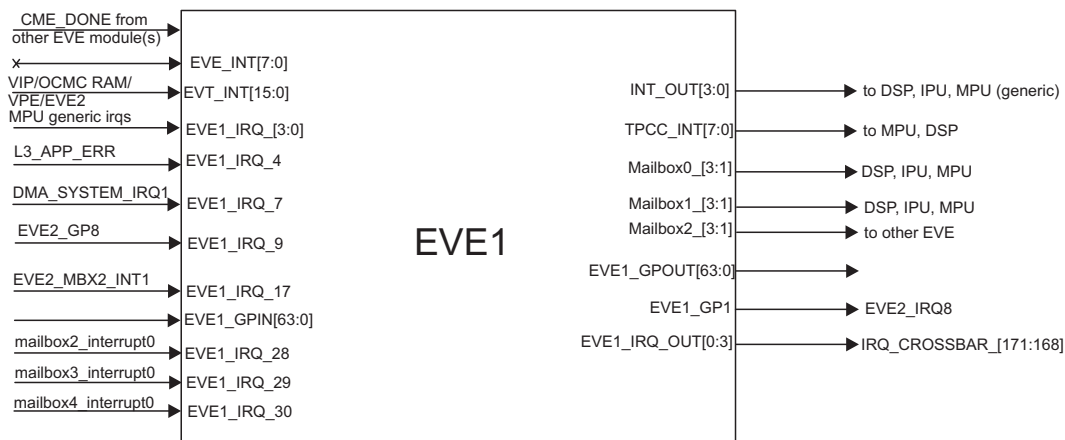

Interrupt Requests				
	EVE2_IRQ_MBX1_US ER1	IRQ_CROSSBAR_296	N/A	EVE Mailbox 1 user 1
	EVE2_IRQ_MBX1_US ER2	IRQ_CROSSBAR_297	N/A	EVE Mailbox 1 user 2
	EVE2_IRQ_MBX1_US ER3	IRQ_CROSSBAR_298	N/A	EVE Mailbox 1 user 3
No DMA Requests				

**NOTE:** The **Default Mapping** column in [Table 8-4](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device INTC through the IRQ\_CROSSBAR module.  
 For more information about the IRQ\_CROSSBAR module, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#).

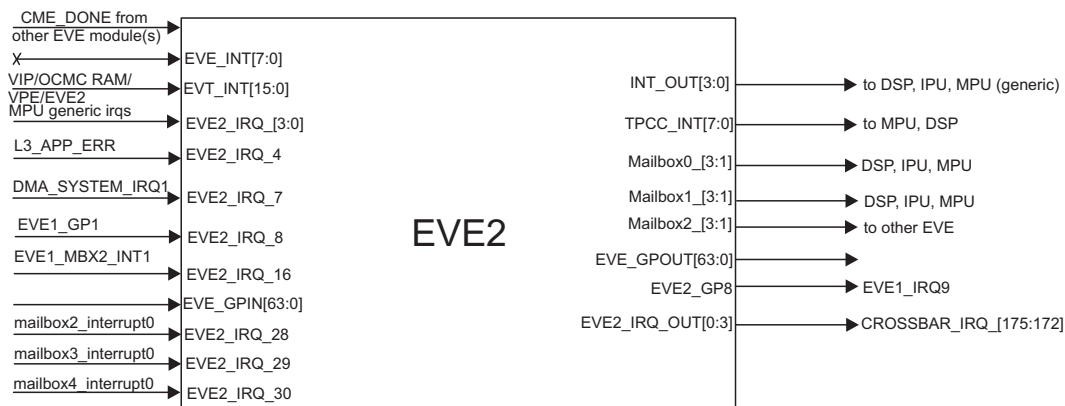

**8.1.2.1 Multi-EVE Recommended Connections**

[Figure 8-3](#) and [Figure 8-4](#) show the interrupts, general purpose signals, and DMA requests for each EVE instance.

**Figure 8-3. EVE1 Signals**

**Figure 8-4. EVE2 Signals**

**EVE INT[7:0] Usage:**

EVE\_INT[7:0] are not connected to any chip-level or inter-EVE interrupt. These interrupts can be tied to any chip-level mailboxes or any other interrupts that are intended as wake-up interrupts.

### TPCC Interrupts Usage:

TPCC interrupts are used as region-based interrupts. The transfers for different processors are divided into separate regions and on completion of a transfer the associated TPCC\_INT interrupts the corresponding processor. Region 0 interrupt is reserved for the internal ARP32 processor. Region 1 is routed to the main processor unit (MPU) of the system. Region 2 is routed to DSP1, region 3 to DSP2, and region 4 to IPU.

### GPIO Usage:

There are total of 64 general-purpose outputs (GPOs) and 64 general-purpose inputs (GPIs) in each EVE instance. The GPOs of each EVE are connected to the GPIs of all other EVEs, as shown in [Figure 8-3](#) and [Figure 8-4](#). The EVEs communicate their internal processing/task status to the other EVEs with these GPIO signals.

In addition, for each EVE instance, one GPO pin is connected to a DMA event of every EVE. This connection facilitates direct triggering of DMA from the targeted EVE. The EVE that is triggering the DMA transfer to another EVE must be aware of the status of the other EVE in order to safely initiate the DMA transfer. This should be managed in software if desired. For more information about general-purpose signals uses, see [Section 8.1.3.6, General-Purpose Inputs/Outputs](#).

## 8.1.3 EVE Functional Description

### 8.1.3.1 EVE Connection ID (ConnID) Mapping

The ConnID value is used for error reporting in the memory switch error register ([EVE\\_MSW\\_ERR\[24:16\] CONNID](#)). Table 1-5 lists the EVE internal initiators and their assigned 9-bit ConnID values.

**Table 8-5. EVE Internal ConnID Mapping**

Initiator	CONNID Value
System initiators (through OCP target bus)	0 to FFh
ARP32	100h
VCOP	101h
EDMA TC0	102h
EDMA TC1	103h

### 8.1.3.2 EVE Processors Overview

#### 8.1.3.2.1 Scalar Core (ARP32)

The scalar core (ARP32) executes conventional RISC instructions. The scalar core is based on the ARP32 processor, which contains the following five functional units:

- The L-unit performs the logical, shift, rotation, extraction, reverse, clear, set, and equal operations.
- The S-unit performs the move operations.
- The D-unit performs arithmetic operations that include compare less than and greater than instructions, address calculation for load and store instructions, PC calculations for branch instructions and stack pointer increment/decrement for PUSH/POP and CALL/RETURN instructions.
- The M-unit performs multiplication.
- The DIV-unit is used for bit serial divide logic.

The ARP32 includes 32-bit program fetch and 32-bit data access bus. For additional information about ARP32 core see [Section 8.2, ARP32 CPU and Instruction Set](#).

### 8.1.3.2.2 VCOP

The VCOP is an SIMD engine with built-in loop control and address generation. The VCOP is programmed in array of 2D block processing level. The vector core has the following resources:

- 4 nested for loops, with loop variables i1, i2, i3, and i4
- 8 address generators, each capable of 4-dimensional addressing; address pattern is  $base + i1*const1 + i2*const2 + i3*const3 + i4*const4$
- 16-entry vector register file, each entry is 8-way SIMD × 40-bit signed (sign-extended or zero-padded from 8/16/32-bit signed/unused memory data, or zero-padded from operation upon register data)
- Two general-purpose functional units, each N-way SIMD, N = 2, 4, 8, 16, 32
- Table lookup unit supporting up to N parallel histogram operations
- 8 load units
- 8 store units
- Flat versus Aliased view of EVE memory

In addition, the VCOP supports the following functions:

- Generic compute
- Table lookup
- Histogram and weighted histogram

For additional information about VCOP, see [Section 8.3, VCOP CPU and Instruction Set](#).

### 8.1.3.2.3 Scalar-Vector Interaction

The ARP32 scalar and vector cores share one program memory, but can execute in parallel on separate threads. The scalar core has sole control of the program memory, so all vector instructions are accessed by the scalar core. When a vector instruction is recognized as such it is relayed through the scalar-vector interface to the vector core for execution.

### 8.1.3.3 Internal Memory Overview

This section provides a functional overview for each of the memory endpoints listed in [Table 8-6](#).

**Table 8-6. Internal Memory Blocks**

Memory	Organization	Size	Function
PMEM	1024 × 256	32KB	ARP32 program cache
DMEM	2048 × 128	32KB	ARP32 data memory
WBUF	8 × 1024 × 32	32KB	VCOP working buffer
IBUFLA	8 × 512 × 32	16KB	Image buffer low copy A
IBUFLB	8 × 512 × 32	16KB	Image buffer low copy B
IBUFHA	8 × 512 × 32	16KB	Image buffer high copy A
IBUFHB	8 × 512 × 32	16KB	Image buffer high copy B

**NOTE:** EVE internal memories, PMEM, DMEM, WBUFs and IBUFs, are visible in the SoC. Device host processors like Cortex-A15, Cortex-M4, and DSP access the EVE memories through its OCP ports. For EVE memory mapping, see [Table 8-26](#). For information about the address space of EVE subsystem modules and memories from device point of view, see [Chapter 2, Memory Mapping](#).

### 8.1.3.3.1 Program Cache/Memory

For detailed explanation of the program cache operation, see [Section 8.1.3.4, Program Cache Architecture](#).

### 8.1.3.3.2 ARP32 Data Memory (DMEM)

The ARP32 data memory is logically organized as four banks of 32-bit memories. It is the primary location for storing run-time variables and stack for the software execution environment for the ARP32 core. This memory is byte addressable, and is accessed with byte granularity by all valid initiators. DMEM is accessed at peak rate of up to 4B/cycle by the ARP32 core, or up to 16B/cycle by the system components (EVE EDMA, DMA target bus). The vector core cannot access this memory.

The arbitration between the ARP32 and DMA/System accesses to DMEM is done on round-robin scheme. That is a continuous stream of requests from two (or more) initiator ports results in each requestor gaining access on alternating burst boundaries, therefore DMA/System accesses to DMEM should be minimized in order to avoid impacting the ARP32 performance. Only a single access (ARP32 or DMA/System access) occurs in a single cycle.

### 8.1.3.3.3 WBUF

VCOP WBUF is the primary location for VCOP look-up tables (LUTs) and other relatively long-lived data buffers. This memory is byte addressable. On a time-slot basis (as controlled by the ARP32 core) WBUF ownership is assigned to either the system (ARP32, EDMA, DMA target bus) or the VCOP.

WBUF is accessible by VCOP, ARP32, and system components (EDMA, DMA target bus) depending on the programmed ownership. The primary master of working buffer is the VCOP.

As shown in [Figure 8-5](#), VCOP can access each of the eight banks of memory independently, giving a total of 256-bits per cycle. ARP32 core can access up to 32-bits per cycle in a given bank and EDMA (and other system components) can access up to 128-bits per cycle of contiguous banks of memory within a 128-bit aligned window (this is a case when there are no independent bank accesses, and single access does not cross 128-bit boundary).

Figure 8-5. WBUF Bank Organization

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																																
63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32																																
Bank 7								Bank 6								Bank 5								Bank 4								Bank 3								Bank 2								Bank 1								Bank 0							
32767	32766	32765	32764	32763	32762	32761	32760	32759	32758	32757	32756	32755	32754	32753	32752	32751	32750	32749	32748	32747	32746	32745	32744	32743	32742	32741	32740	32739	32738	32737	32736																																

EDMA versus system accesses (through OCP target bus) are arbitrated dynamically, on OCP bus boundaries, with round-robin policy within the OCP high performance Interconnect. EDMA/System versus ARP32 accesses are arbitrated at dataphase boundaries.

The master that owns the WBUF is pseudostatically defined in the [EVE\\_MSW\\_CTL\[16\]](#) WBUF bit. When [EVE\\_MSW\\_CTL\[16\]](#) WBUF = 0x0 the static mux (SM) provides a connection from the OCP high-performance interconnect (EDMA, ARP32 or external-to-EVE initiated access) to the WBUF memory, and VCOP accesses are not allowed. Otherwise, ([EVE\\_MSW\\_CTL\[16\]](#) WBUF = 0x1) SM provides a connection from VCOP to the WBUF memory and system accesses are not allowed.

In case VCOP or system initiators access the WBUF address location while WBUF is not owned, an error is captured in the EVE memory switch error register ([EVE\\_MSW\\_ERR](#)) and EVE memory switch error the address register ([EVE\\_MSW\\_ERRADDR](#)) and the corresponding flag in [EVE\\_MSW\\_ERR\\_IRQSTATUS\\_RAW](#) register is set. Debug accesses do not set the error registers or interrupt, but result in OCP ERR response.

### 8.1.3.3.4 Image Buffers—IBUFLA, IBUFLB, IBUFHA, and IBUFHB

EVE image buffers are the primary location for the time-slot based data buffers. These buffers are built to facilitate ping-pong ownership and accesses by the EDMA and the VCOP. On a time-slot bases (as controlled by the ARP32 core), each of the respective image buffers can be assigned ownership to either the System (ARP32, EDMA, OCP target bus) or the VCOP.

IBUFLx and IBUFHx (x = A, B) are typically used as output buffers, and as such VCOP can concurrently access up to eight banks of memory in the VCOP-owned IBUFLA and IBUFLB banks and up to eight banks of memory in one of the VCOP owned IBUFHA and IBUFHB (see [Figure 8-6](#)). ARP32 accesses 32-bits per cycle in one of the system-owned IBUF banks.

**Figure 8-6. IBUF Bank Organization**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Bank 7				Bank 6				Bank 5				Bank 4				Bank 3				Bank 2				Bank 1				Bank 0			
16383	16382	16381	16380	16379	16378	16377	16376	16375	16374	16373	16372	16371	16370	16369	16368	16367	16366	16365	16364	16363	16362	16361	16360	16359	16358	16357	16356	16355	16354	16353	16352

EDMA (and other EVE system components) access up to 128 bits per cycle of contiguous banks of memory (in case there are no independent bank accesses) within a 128-bit window (a single access does not cross 128-bit boundary) for each system-owned corresponding IBUF bank. For example, if all banks are system owned, EDMA TC0 (or any other EVE system resource) accesses IBUFL at 128-bits per cycle in parallel with EDMA TC1 accessing IBUFH at 128-bits per cycle, giving a total throughput of 256-bits per cycle.

EDMA versus system versus ARP32 accesses are arbitrated dynamically on OCP burst boundaries. The arbitration is done with round-robin policy inside the EVE high-performance interconnect.

The ownership of each IBUF is pseudostatically controlled by the [EVE\\_MSW\\_CTL \[12\]](#)IBUFHB, [EVE\\_MSW\\_CTL \[8\]](#)IBUFLB, [EVE\\_MSW\\_CTL \[4\]](#)IBUFHA, [EVE\\_MSW\\_CTL \[0\]](#)IBUFLA bits. Ownership is also internally changed by ARP32 custom instruction or through writes to the memory-mapped address.

By setting [EVE\\_MSW\\_CTL \[12/8/4/0\]](#)IBUF = 0x1 the ownership of the IBUF memory is granted to VCOP, otherwise ([EVE\\_MSW\\_CTL](#):IBUF = 0x0) the memory is owned by the EVE system resources. If IBUF is system owned, then the SM provides a connection from the EVE high-performance interconnect (for EDMA, ARP32, or external-to-EVE initiated access) to the corresponding IBUF memory, and VCOP accesses are not allowed. If IBUF is VCOP owned, the static mux provides a connection from VCOP to the IBUF memory, and system accesses are not allowed.

Ownership of each of the four IBUF regions (IBUFLA, IBUFLB, IBUFHA, and IBUFHB) is independently programmable with no restrictions. Aliased versus nonaliased mode is controlled by setting the [EVE\\_MEMMAP](#) register. In nonaliased mode it is possible for the VCOP core to own all four IBUFs, or for the system resources to own all four IBUFs or any combination. In aliased mode VCOP owns only one of the IBUFHx regions and one of the IBUFLx regions (x = A, B) because both A and B copies of the IBUFs are mapped to the same address.

In case VCOP or system initiators access the WBUF address location while IBUF is not owned, an error is captured in EVE memory switch error register ([EVE\\_MSW\\_ERR](#)) and EVE memory switch error address register ([EVE\\_MSW\\_ERRADDR](#)) and the corresponding flag in the [EVE\\_MSW\\_ERR\\_IRQSTATUS\\_RAW](#) register is set. Debug accesses do not cause the error registers or interrupt to be set, but result in OCP ERR response.

[Figure 8-7](#) shows the typical ownership patterns that offer different amounts of memory/bandwidth to VCOP (V) versus system (S) accesses.

Figure 8-7. VCOP Versus System Memory Ownership Examples

### 8.1.3.3.5 Memory Switch Error Registers

The memory switch error registers capture the first occurrence of an error caused by a functional access. Software must service the error and clear the MMR to capture subsequent errors. The registers capture the identity of the specific requester through the OCP ConnID (see Table 8-5) field and the specific address that is requested.

The MSBs of the address is always 0x400, which matches the internal (local) address view. For system accesses, this does not necessarily match the system view base address. For IBUFL and IBUFH, the physical address offset is captured even in aliased mode (for example, IBUFLB address at 0x4007 0000 is used in both aliased and nonaliased mode).

Unlike the parity/error detect registers, that provide unique error registers per memory type, the memory switch error registers capture errors regardless of which specific memory is accessed.

Debug accesses do not cause the error or interrupt registers to be set, but result in OCP error response.

The memory switch error registers are:

- [EVE\\_MSW\\_ERR](#)— indicates whether the error is system-, EDMA-, VCOP-, or ARP32-initiated buffer ownership error and captures the corresponding ConnID
- [EVE\\_MSW\\_ERRADDR](#)— Captures the physical address of memory switch error

Associated error interrupts are mapped on:

- [EVE\\_MSW\\_ERR\\_IRQSTATUS\\_RAW](#) - indicates error interrupt
- [EVE\\_MSW\\_ERR\\_IRQSTATUS](#) - indicates error interrupt if event is enabled
- [EVE\\_MSW\\_ERR\\_IRQENABLE\\_SET](#) - enables the corresponding error interrupt
- [EVE\\_MSW\\_ERR\\_IRQENABLE\\_CLR](#) - disables the corresponding error interrupt

### 8.1.3.3.6 Memory Error Detection

EVE supports parity-based error detection for all internal data memories (including DMEM, WBUF, IBUFLA, IBUFLB, IBUFHA, and IBUFHB) on the minimum access size granularity of 8 bits (that is, there is 1 bit of parity per byte of memory). EVE subsystem also implements double bit error detection for program cache SRAM through a distance 3, 10-bit Hamming code. The 10-bit Hamming code is also applied to the tag and address for a particular cache line.

When parity is enabled, write accesses to any memory cause the parity/encoding bit(s) to be calculated for the specific write data (along with tag and address value for program cache) and written to the corresponding encoding location. For all read accesses from any data memory, the parity bit is read and compared against previously calculated parity for the current pattern in the memory. For program cache, only ARP32 program fetches perform stored versus expected encoding comparison (accesses through program cache OCP debug target port do not result in code calculation). If a mismatch occurs the error details are recorded in parity error MMR (different for each memory - IBUF, WBUF, DMEM) and the associated interrupt is asserted. At the same time, an OCP error response is generated.

The registers that capture program cache-related parity errors, ARP32 DMEM-related parity errors, WBUF-related parity errors, and IBUF-related parity errors are:

- [EVE\\_PMEM\\_ED\\_CTL](#)– Enables and disables error PMEM detection logic. Also lets the user invert error detection logic.
- [EVE\\_PMEM\\_ED\\_STAT](#)–Status register for the detected PMEM error
- [EVE\\_PMEM\\_EDADDR](#)– Physical address of parity error
- [EVE\\_DMEM\\_ED\\_CTL](#)– Enables/Disables DMEM error detection logic. Also lets the user invert error detection logic.
- [EVE\\_DMEM\\_ED\\_STAT](#)– Status register for the detected DMEM error
- [EVE\\_DMEM\\_EDADDR](#)– Physical address of parity error
- [EVE\\_DMEM\\_EDADDR\\_BO](#)– Address byte offset for parity error
- [EVE\\_WBUF\\_ED\\_CTL](#)– Enables/Disables WBUF error detection logic. Also lets the user invert error detection logic.
- [EVE\\_WBUF\\_ED\\_STAT](#)– Status register for the detected WBUF error
- [EVE\\_WBUF\\_EDADDR](#)– Physical address of parity error
- [EVE\\_WBUF\\_EDADDR\\_BO](#)– Address byte offset for parity error
- [EVE\\_IBUF\\_ED\\_CTL](#)– Enables/Disables IBUF error detection logic. Also lets the user invert error detection logic.
- [EVE\\_IBUF\\_ED\\_STAT](#)– Status register for the detected IBUF error
- [EVE\\_IBUF\\_EDADDR](#)– Physical address of parity error
- [EVE\\_IBUF\\_EDADDR\\_BO](#)– Address byte offset for parity error

Data returned to the requestor is not modified even in the case of error. The requestor consumes the data potentially causing execution or propagation of bad code and/or data. For a description of the recovery mechanism, see [Section 8.1.3.3.6.4, Parity Error Recovery](#).

Each MMR captures the first occurrence of an error. Software then services the error and clears the MMR to capture subsequent errors (generation of OCP error responses continue if additional errors are detected). The parity error MMRs include bit fields to describe which initiator generated the memory access and the specific byte address. Debug accesses do not cause the error or interrupt registers to be set, but result in OCP error response.

Error interrupts are routed to both ARP32 and as EVE outputs to the device level host. ARP32 services interrupts caused by VCOP, EDMA, or OCP target accesses. However, for errors caused by ARP32 accesses, the ARP32 core is unable to service interrupt, and either the DSP or device local CPU detects and services those errors. This detect and service action is described in [Section 8.1.3.10.1, EVE Interrupt Sources – Memory Switch and Parity Error Interrupts](#).

#### 8.1.3.3.6.1 Captured Address – EDADDR and EDADDR\_BO

The EDADDR registers ([EVE\\_PMEM\\_EDADDR](#), [EVE\\_DMEM\\_EDADDR](#), [EVE\\_WBUF\\_EDADDR](#), and [EVE\\_IBUF\\_EDADDR](#)) capture the memory width aligned address for the faulting address. A byte offset bit array for the corresponding memory ([EVE\\_PMEM\\_EDADDR\\_BO](#), [EVE\\_DMEM\\_EDADDR\\_BO](#), [EVE\\_WBUF\\_EDADDR\\_BO](#), and [EVE\\_IBUF\\_EDADDR\\_BO](#)) is used to indicate which specific bytes relative to the aligned address is at fault. For most requestors this gives an accurate view of the specific byte for which parity error was detected.

For VCOP, because independent word addresses are generated to the eight banks of IBUF and WBUF, the BANK0 address is latched in the EDADDR register even if that bank is not at fault. In the case of linear addressing, BANK0 + byte\_offset mask gives an accurate view. In the case of table-base loads (each bank uses a different address) the reported BANK0 address and the byte offset are used to post-mortem determine which specific address have the error.

The MSBs of the address are always 0x400, which matches the internal (local) address view. For system accesses this does not necessarily match the system view base address. For IBUFs the physical address offset is captured in both aliased and nonaliased mode (for example, IBUFLB address at 0x4007 is used in both aliased and nonaliased modes).

**NOTE:** EDADDR\_BO does not exist for PMEM memory. PMEM only supports Hamming code-based error detection. PMEM does not support parity per 8-bit detection (unlike the data memories).

### 8.1.3.3.6.2 Modes of Operation

The EVE error detection includes two basic modes of operation by setting the EN bit in the EVE\_<MEMORY>\_ED\_CTRL ([EVE\\_PMEM\\_ED\\_CTRL](#), [EVE\\_DMED\\_ED\\_CTRL](#), [EVE\\_WBUF\\_ED\\_CTRL](#) and [EVE\\_IBUF\\_ED\\_CTRL](#)) register, as listed in [Table 8-7](#).

**Table 8-7. Error Detection Modes**

Mode	Description
EN	Error detection logic is enabled. Writes update parity. Reads check parity.
DIS	Error detection logic is disabled and can be clock gated. Writes do not modify parity. Reads do not check parity.

**NOTE:** No parity valid bit exists in addition to a parity state bit. After an existing reset, the ED logic is in disabled state. In this mode the parity RAMs are clock gated to minimize power consumption (though state must be retained). When transitioning to enable state, the underlying SRAM + Parity is in a state that may result in parity mismatch.

For ARP32 program cache, the program cache automatically goes through an Invalidate All sequence; during this time the ARP32 program cache fetch path is stalled. After all lines are invalidated, any subsequent ARP32 request is serviced as cache miss. The newly fetched cacheline is written to PMEM along with valid hamming code bits, and subsequent cache hits check the parity for each instruction fetch. For debug and configuration accesses, the parity and encoding bits are not checked. Debug software uses the tag state to produce an appropriate visual for debug purposes.

For data memory (DMEM, WBUF, and IBUF), it is possible (though not recommended for functional and nontest software) for ARP32, VCOP, or DMA to read a memory location for which the parity bit is not set. After enabling EVE\_<DMEM, WBUF, or IBUF>\_ED\_CTRL for the corresponding memory, software must initialize all of the memory, which results in setting a valid parity bit. After this, any parity mismatch results in error signaling, as summarized in the previous sections.

### 8.1.3.3.6.3 Parity Error Testability

For the software to test their parity error interrupt service routine (ISRs), parity errors can be forced to occur. The EVE subsystem does this by providing an INVERT mode of operation per memory endpoint (by setting the INV bit in the EVE\_<PMEM, DMEM, WBUF, or IBUF>\_ED\_CTRL register). When INVERT mode is set (EVE\_<MEMORY>\_ED\_CTRL[1] INV = 0x1), and parity is enabled, all read accesses to the corresponding memory return the inverse value of the stored parity bit before the parity check comparison. As a result a parity error is latched and reported through an interrupt, as described in [Section 8.1.3.3.5, Memory Switch Error Registers](#). For program memory, the INV bit causes the encoding calculation to return the inverted value for pass or fail.

For testing the ARP32 parity error ISR, these registers can be set asynchronously by the host processor or system EDMA controller. This setting mimics the random nature of radiation-induced soft error.

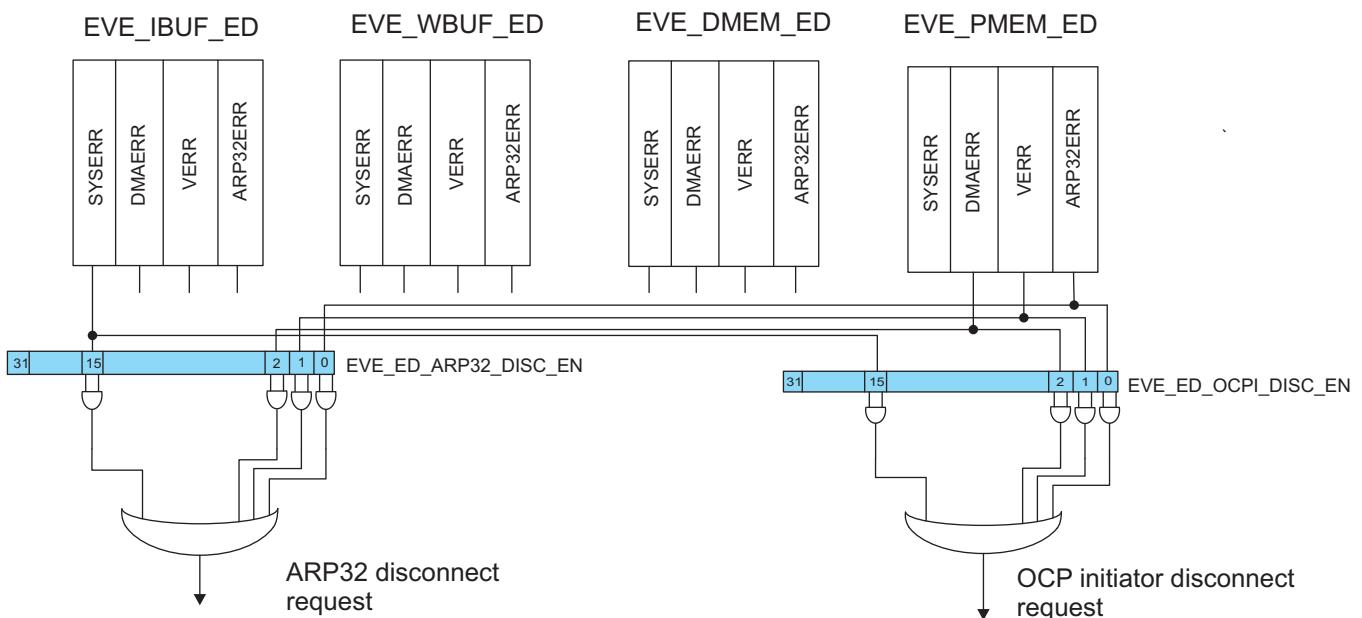

Parity or Hamming errors can be injected to a specific address after the initialization sequence. Parity or error detection is placed in disable mode (EVE\_<MEMORY>\_ED\_CTRL[0] EN = 0x0), and software can write an incorrect value to the desired address. Writes during disable mode do not modify the parity bit or encoding bits, thus the stored parity or encoding bits are considered incorrect. The memory then can be enabled. Any subsequent read access to that memory location results in a parity error mismatch.

#### 8.1.3.3.6.4 Parity Error Recovery

When a parity error occurs, the faulty data is consumed by the requester. VCOP may fetch and process bad data from IBUF or WBUF. ARP32 may try to execute a faulty instruction from the program cache, or read a faulty pointer from DMEM. To avoid these problems, the subsystem parity error interrupt scheme notifies ARP32 or the host of any parity errors (see [Section 8.1.3.10.1, EVE Interrupt Sources – Memory Switch and Parity Error Interrupts](#)).

To minimize corruption of the system, and to let the system host query the error detection registers, a user selectable parity error disconnect scheme is provided. This mechanism lets the user disconnect the ARP32 from the neighboring EVE system, and/or disconnect the OCP initiator port from the device interconnect. Each of these disconnects can be manually initiated by setting the [EVE\\_DISC\\_CONFIG](#) register, or [EVE\\_DISC\\_CONFIG](#) can be initiated when a specific parity error is detected based on requestor and memory. The disconnect sequence is enabled in the [EVE\\_ED\\_OCPI\\_DISC\\_EN](#) and [EVE\\_ED\\_ARP32\\_DISC\\_EN](#) registers. [Figure 8-8](#) shows an overview of the disconnection request.

**Figure 8-8. Parity Error ARP32/OCP Disconnect**

#### 8.1.3.3.7 VCOP System Error Halt Conditions

VCOP has several internal error conditions that force the core to halt execution and freeze its internal state so that ARP32 or debugger can inspect the state of the VCOP. The vector core also provides an error interrupt that causes VCOP to halt based on detection of EVE-level errors. These are mapped to the VCOP memory switch error source status ([EVE\\_MSW\\_ERR\[1\] VERR](#)) and VCOP parity error source status ([EVE\\_WBUF\\_ED\\_STAT\[1\] VERR](#) or [EVE\\_IBUF\\_ED\\_STAT\[1\] VERR](#)). By default the halt signals are enabled. Halt signal generation can be modified by writing to the [EVE\\_VCOP\\_HALT\\_CONFIG\[1\] MSW\\_EN](#) and [EVE\\_VCOP\\_HALT\\_CONFIG\[0\] ED\\_EN](#) bits.

In addition, the [EVE\\_VCOP\\_HALT\\_CONFIG\[2\] FORCE\\_ABORT](#) bit is used to directly force the vector core to halt based on any unforeseen error condition. The error is detected by ARP32 through a watchdog timer at which point ARP32 sets the [FORCE\\_ABORT](#) signal to halt or abort the current loop occurring in the VCOP core.

#### 8.1.3.4 Program Cache Architecture

The main features of ARP32 program cache are:

- 32-KB direct mapped cache
- 32-B line size
- Hit throughput: 32-bits per cycle, 100% throughput

- Read-only (from ARP32 perspective), all accesses are cacheable
- Read and write by debug OCP port
- Software directed preload
- Demand based prefetch
- Software directed invalidate
  - Global
  - Range based
- Debug support:
  - Single register one-line invalidate (for breakpoint support)
  - Tags memory mapped
  - SRAM memory mapped
  - Cache miss signaling to SCTM
- Hamming code based error detection: 10-bits per 256-bit location + tag + address

Program cache is a direct-mapped cache, therefore software controls the linking of the functions in external memory to minimize conflict misses. The program cache supports error detection encoding and can correct two errors per 256 bits of program code.

### 8.1.3.4.1 Basic Operation

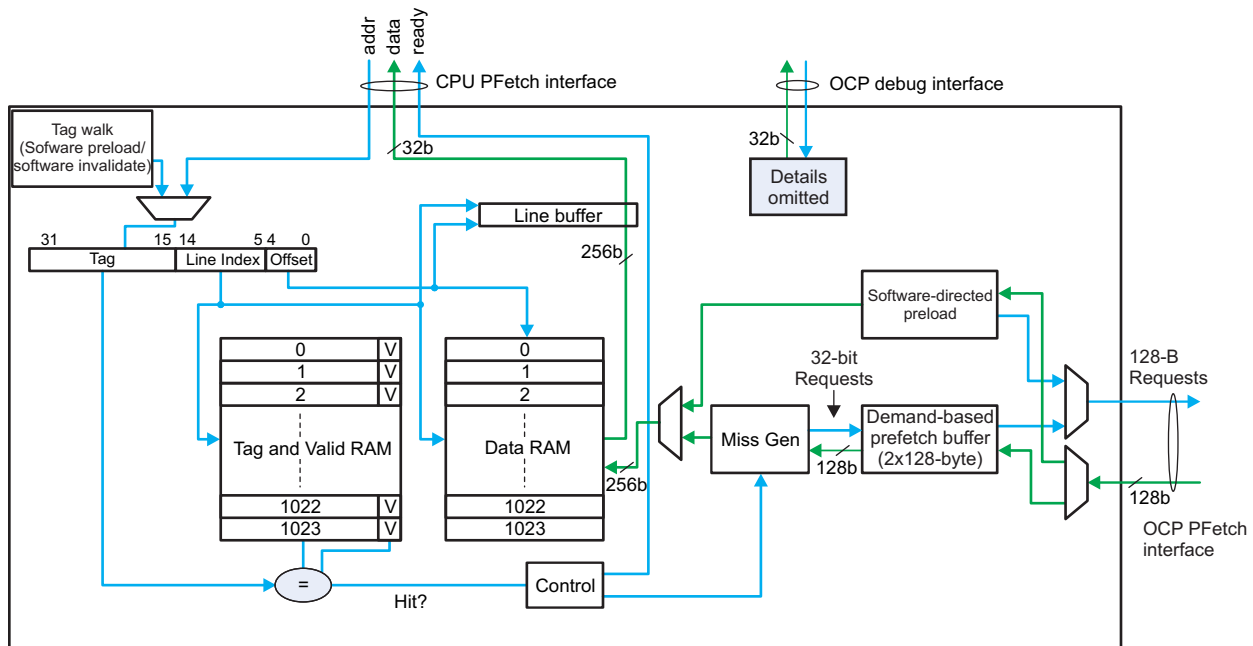

The program cache is always enabled and treats all ARP32 accesses as cacheable.

For cache hits the interface between ARP32 and program cache can handle back-to-back requests with 0 cycle latency to provide full throughput and program execution for the ARP32. For cache misses, the cache controller stalls ARP32, and internally submits a 32-bit OCP request (through the demand-based prefetch (DBP) block). After the 32-bit cacheline returns, the program cache returns the appropriate data to the ARP32 and starts the CPU.

For CPU-generated miss requests (not software-direct preload), the DBP block snoops the internal request and either services the request directly or schedules a miss+prefetch operation to the system.

Figure 8-9 shows the program cache block diagram.

Figure 8-9. EVE Program Cache Architecture

### 8.1.3.4.2 Line Buffer

The program cache includes a software and performance transparent 256-bit line buffer. The line buffer minimizes accesses to the underlying cache/SRAM in the case of back-to-back hits to the same line; doing so minimizes power consumption. The line buffer is allocated on any program cache access to a new line. As long as subsequent program fetches are to the same line, the data returns to ARP32 directly from the line buffer.

### 8.1.3.4.3 Software Direct Preload

Software Direct Preload SDP allows preloading of a range of system memory into the program cache. Software sets the preload base address register ([EVE\\_PC\\_PBAR](#)), along with a preload byte counter ([EVE\\_PC\\_PBC](#)) register (maximum = 0x8000). Hardware will issue a cache line fill request to the system for the associated line for the programmed address range. When the data is returned for each line, it is written into the cache (32-bits per write, to minimize program stalls) and the tag is marked as valid for the new address. This process is repeated for every cache line in the requested range. When the operation completes, the [EVE\\_PC\\_PBC](#) register is set to 0.

---

**NOTE:** Software must verify that the previous operation is completed before issuing another SDP operation.

---

Functional ARP32 requests are given a lower priority relative to software preload requests. The normal operation of the software preload results in many idle cycles while preload requests are in flight through the system. During that time ARP32 CPU accesses that result in cache hits proceed unhindered. If a CPU cache miss occurs while SDP operation is active, the two operations proceed in parallel.

The start address can be any arbitrary byte address, whereas the preload operation occurs on cache lines (32-bit aligned). Thus, the range preloaded is effectively rounded down to the nearest cache-line address relative to the start address, and rounded up to include the entire cache line relative to the end address.

Preload requests operate in parallel with the DBP block and do not use the buffering provided by the DBP block. Instead, the returned data for software direct preload is written directly to the program cache as highest priority, thus minimizing the required buffering and minimizing the impact on the system.

### 8.1.3.4.4 User Coherence Operation

The memory spaces cached in ARP32 program cache are not always coherent with the external memory. For example, if the copy of the code in external memory is modified, it is possible that the copy of the code that is cached in L1P is out of date with respect to the corresponding location contents in system memory. This may happen, for example, if software is implemented using code overlays. The application controlling such paging should take the appropriate steps to invalidate a cache that is rendered incoherent.

In addition, the ARP32 breakpoint methodology involves emulation and debug software inserting a breakpoint instruction in the program image in system memory (by replacing a valid instruction). Thus, there is a mechanism to update the cache to reflect the newly inserted breakpoint instruction. This is accomplished with the same software or hardware mechanism.

To allow for such software-directed invalidate, the cache controller supports three methods to invalidate the content of the cache:

- Global invalidate
- Range-based invalidate
- Single-address invalidate

#### 8.1.3.4.4.1 Global Invalidate

The program cache clear register must be set ([EVE\\_PC\\_INV\[0\]](#) | = 0x1) to invalidate all the lines in the program cache. This is done by resetting all valid bits. Because EVE implements the valid bits with memory, the operation takes approximately a number of cycles equal to the number of tags. During invalidate-all operation, any CPU fetches are stalled until the invalidate-all operation completes, resulting in subsequent misses in the program cache.

#### 8.1.3.4.4.2 Range-Based Invalidate

The program cache controller supports a programmable invalidate mechanism, with which the starting address and the number of words to invalidate can be specified to start an invalidation sequence. The programming model for the invalidation mechanism consist of two memory mapped registers: the start address register ([EVE\\_PC\\_IBAR\[31:0\] ADDR](#)) that holds the start address and the byte count register ([EVE\\_PC\\_IBC\[15:0\] BC](#)) that holds the number of bytes to be invalidated.

The invalidate operation begins immediately with the writing into [EVE\\_PC\\_IBC\[15:0\] BC](#) (maximum = 0x8000). The application first sets the [EVE\\_PC\\_IBAR\[31:0\] ADDR](#) bit field and then the byte count register to ensure correct operation. The operation involves cycling through addresses starting from the value of [EVE\\_PC\\_IBAR\[31:0\] ADDR](#) in increments of the cache line size, doing tag lookups to check if the line exists in the cache. If the line exists in cache, the corresponding valid bit is reset. The

[EVE\\_PC\\_IBC\[15:0\] BC](#) bit field is reset to 0 when the invalidate completes. As the byte count register is readable, a check for 0 provides a synchronization event for the application to execute from the region being invalidated or before issuing another range-based invalidate.

---

**NOTE:** [EVE\\_PC\\_IBAR\[31:0\] ADDR](#) can be any arbitrary byte address; whereas the invalidate operation occurs on cache-lines (that is, 32-bit aligned). Thus the range invalidated is effectively rounded down to the nearest cache-line address relative to the start address, and rounded up to include the entire cache line relative to the end address.

---

As in the global invalidate case, any CPU program fetches issued during the invalidate-range operation are stalled until the invalidation completes.

#### 8.1.3.4.4.3 Single-Address Invalidate – For Breakpoint Operation

Because ARP32 supports breakpoint insertion, a single register version of the range-based invalidate is provided through the invalidate single address register ([EVE\\_PC\\_ISAR](#)). This is distinct from the previously defined range based invalidate, though the underlying hardware mechanism is the same. It is legal for the range-based invalidate and single-address invalidate to occur at the same time. Both commands must complete, though the order of completion is not explicitly defined.

Emulation software replaces the appropriate instruction in system memory with the breakpoint instruction. To ensure that future ARP32 execution of that line of code is fetched from system memory (as opposed to directly serviced from the cache), emulation software writes the address to [EVE\\_PC\\_ISAR\[31:0\] ADDR](#).

The invalidate operation begins immediately on writing into the [EVE\\_PC\\_ISAR](#) register. The hardware operation involves checking the tag for the specified address. If the line exists in the cache, the corresponding valid bit is reset. Upon completion, the [EVE\\_PC\\_ISAR\[31:0\] ADDR](#) bit field is set to 0, thus informing the emulation software driver that the command is complete.

Operation is undefined if the application of emulation software tries to write to this register before the previous command completes.

#### 8.1.3.4.5 Demand-Based Prefetch

The DBP block is used to improve performance for straight line cache misses, by snooping the program cache miss/software preload requests and issuing larger/pipelined burst requests to the system. The DBP block includes a 256-byte buffer that is logically composed of two 128-byte buffers.

When EVE is reset, the buffers are reset to an idle/empty state and DBP defaults to enabled ([EVE\\_BUS\\_CONFIG\[4\] DBP\\_ENABLE = 0x1](#)). When a new cache-line request is detected, the DBP initiates 128-byte burst to the system for the current 128-byte aligned range, and another 128-byte burst for the next 128-byte aligned range. DBP requests never cross the 128-byte boundary. Depending on the alignment of the new cache request, for initial requests with  $LSB = 0$ , 128-byte request is issued; for  $LSB = 0x20$ , a 96-byte burst is issued; for  $LSB = 0x40$  a 64-byte burst is issued; and for  $LSB = 0x60$ , a 32-byte burst is issued. This last case does not allocate space in the prefetch buffer.

Any subsequent cache miss requests that match addresses for the previously prefetched data are returned directly from the prefetch buffer. When a cache request is received for address with LSB = 0x60 (last 32 bytes of a 128-byte aligned buffer), then that 128-byte buffer segment is marked invalid and the next sequential 128 bytes of data is prefetched. The prefetch buffer is always 256 bytes ahead of the program cache miss requests, and operates in ping-pong fashion with each of the 128-bytes buffer segments.

Example:

1. Buffer 0 holds addresses from 0x0 through 0x7F and buffer 1 holds addresses 0x80 through 0xFF. If the next miss request is to any location in buffer 1 (for example 0xA0), then buffer 0 is invalidated and prefetches range 0x100 through 0x17F.
2. Buffer 0 holds addresses from 0x0 through 0x7F and buffer 1 holds addresses 0x80 through 0xFF. If the next miss request is to the final quadrant of buffer 1 (0xE0), then return data from 0xE0 is returned. Both buffer 1 and buffer 0 are invalidated and addresses 0x100 and 0x180 are prefetched.

When a discontinuous cache-line request is received (that is, the request is not allocated [or in flight] in the prefetch buffer), then the entire prefetch buffer is invalidated, and the sequence begins from the start.

The prefetch buffer is invalidated when any user coherence operation is initiated.

DBP is disabled by clearing the [EVE\\_BUS\\_CONFIG\[4\]](#) DBP\_ENABLE bit. When disabled, all cache miss requests bypass the DBP buffers and are issued to the system as 32-byte demand cache misses.

### 8.1.3.4.6 Debug Support

#### 8.1.3.4.6.1 Read/Write Accessibility through OCP Debug Target Port

The OCP debug target port into the program cache provides full read and write of the cache SRAM contents, both for the data as well as tag contents, including parity/ecc and valid bits.

Writability is provided for memory self-test and parity error injection. ARP32 is in halted (for example in IDLE or debug halt) or reset state while write accesses are issued to program cache SRAM or tags. This is not intended as a code-preload feature. As such, if writes are performed to the tag value, 0 must be written to the valid bit before ARP32 can resume operation.

Relative to the EVE level base address, the data RAM resides at address 0x0 through 0x7FFF. The tag + ECC + valid bits reside at word-aligned addresses in the range of 0x8000 through 0x8FFF (base relative).

**Table 8-. EVE Tag Visibility**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAG																Reserved						HC					V				

Bit	Name	Description
31:15	TAG	Tag. When valid bit = 1, this bit represents the 17 MSBs of the cached address. Reads return tag; writes have no effect. Read access when LB = 0.
14:11	Reserved	Reserved. Read return 0s.
10:1	HC	Hamming code. Written by hardware based on computed Hamming code value calculated based on tag, address, and program cache data contents for this line. Read and compared by hardware to recalculated value when cache-line hit occurs. Reads return Hamming code; writes have no effect. Read accesses when LB = 0.
0	V	Valid bit. Set to 1 by hardware when tag + data line is valid/allocated. Cleared to 0 by hardware when tag + data line is invalid. Reads return valid bit; writes have no effect. Read access when LB = 0.

#### 8.1.3.4.6.2 Breakpoint Support

Breakpoints are supported through the single-address invalidate operation summarized in [Section 8.1.3.4.4.3, Single-Address Invalidate – For Breakpoint Operation](#). The emulation software replaces a functional instruction in system memory with the breakpoint opcode, and then invalidates that address in program cache through the range-based invalidate operation.

### 8.1.3.4.6.3 Cache Profiling

The program cache provides several output signals to the EVE SCTM block for the purpose of profiling and debugging cache performance issues.

**Table 8-9** lists the cache profiling signals. The Type column of the table is either pulse or duration. The pulse signals are driven active one cycle for each occurrence. A sequence of consecutive active cycles represent multiple occurrences. It is possible that the duration signal stays active for multiple cycles on a given occurrence. These are stall signals that determine the total number of cycles in the stalled state. The SCTM Mode column describes the counter mode that is programmable in the SCTM module for a given counter. The SCTM Mode column is either event or duration. Event signals result in incrementing the counter once per low-to-high transition on a given input. As such, the event mode is not overly useful for cache profiling. The duration mode measures the number of cycles during which a given signal is active. This is the mode used for most Cache profiling. In the case of counting pulses, this reports the total number of occurrences of a given state/signal (that is, cache hits). In the case of counting duration, this reports the total time in a given state.

**Table 8-9. Cache Profiling Signal List**

Name	Type	SCTM Mode	Description
cache_miss_count	Pulse	Duration	Per cache miss request occurrence
cache_hit_count	Pulse	Duration	Per cache hit request occurrence
line_buffer_hit_count	Pulse	Duration	Line buffer hit occurrence
cache_miss_stall	Duration	Duration (or event)	Driven high for the duration of a cache miss. Used by SCTM to measure the time the ARP32 is stalled due to a cache miss.
prefetch_compulsory_count	Pulse	Duration	Pulse on each or every compulsory DBP request to the system (that is, for the first 128-bit request after a buffer flush, or from IDLE state).
prefetch_lookahead_count	Pulse	Duration	Pulse on each or every lookahead DBP request to the system (that is, for the second 128-bit request after a flush).
prefetch_hit_count	Pulse	Duration	Pulse on each or every cache request that hits an already requested prefetch cache line, whether resident in the prefetch buffer or already requested but still in flight, and thus does not generate an additional prefetch request.
prefetch_line_count	Pulse	Duration	Pulse on every 32-bit cacheline that is requested/allocated into the prefetch buffer (including those that bypass the buffer due to starting at address 0x60). The difference between prefetch_line_count and prefetch_hit_count is equivalent to a prefetch_flush_line_count.
prefetch_discard_stall	Duration	Duration (or event)	Represents the amount of time that previously issued prefetch requests data is in flight (and is discarded) while a new compulsory prefetch request begins.

### 8.1.3.4.7 Error Detection

For a description of the error detection mechanism, see [Section 8.1.3.3.6, Memory Error Detection](#).

### 8.1.3.5 EDMA

**NOTE:** The device EVE integrated EDMA controller instance (EDMA3\_0\_CC0) which is functionally identical with the device EDMA controller instances (EDMA\_TPCC, EDMA\_TPTC0 and EDMA\_TPTC1). The only difference is that the EDMA3\_0\_CC0 instance is located at different physical addresses.

EDMA is a DMA engine for transfers between the system memory (DDR and L3 SRAM) and EVE internal memories. For more detailed description of EDMA controller, see [Section 16.2, Enhanced DMA](#), in [Chapter 16 Enhanced DMA](#).

**Figure 8-10** is a high-level overview figure of the EDMA controller embedded in the EVE subsystem. The figure shows two major components:

- The Channel Controller (EDMACC or CC), which serves as the user interface of EDMA
- The Transfer Controllers (EDMATC or TC), which serve as the data transfer engine of EDMA

The ARP32 submits requests to the channel controller, which in turn submits transfer requests (TRs) to the appropriate transfer controller. Interrupts are posted in the EDMA CC upon transfer completion (if requested) and signaled to ARP32 core.

The EDMA is configured with two queues (in the CC) and two TC instances. The two TC instances offer maximum performance and concurrency for the case where simultaneous transfers occur between two different system-level endpoints, and two different EVE internal memories. For typical use cases, it is expected that transfers involving EMIF or DDR and L3 SRAM are mapped to two different TCs (TC0 for EMIF-related requests and TC1 for L3 SRAM related requests). For example, EMIF or DDR to IBUFL in parallel with IBUFH to L3 SRAM can be processed with maximum performance.

Table 8-10 shows the specific EDMA configuration for the available resources on EVE.

Figure 8-10. EDMA Block Diagram

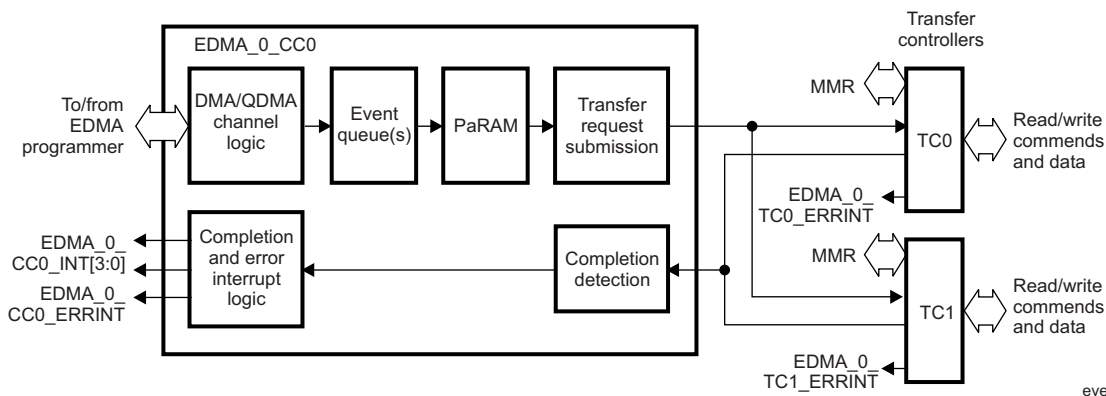

Table 8-10. EDMA Configuration

Name	Description	Configuration
NUM_DMACH	Number of EDMA channels	16
NUM_QDMACH	Number of QDMA channels	8
NUM_INTCH	Number of interrupt channels	16
NUM_PARAMETERY	Number of PaRAM entries	128
NUM_EVQUE	Number of event queues	2
NUM_TC	Number of TPTC interfaces	2
MPEXIST	Memory protection exists	No
NUM_REGIONS	Number of MP and shadow regions	8
CHMAPEXIST	Channel mapping exists	Yes

### 8.1.3.5.1 DMA Channel Events

The EDMA input events/signals are driven by the evt\_int[15:0] input signals. Those input interrupts are also connected to INTC1 of the EVE. A subset of these event inputs is mapped to ECM start events. Software must enable individual input interrupts as either events or ARP32 interrupts.

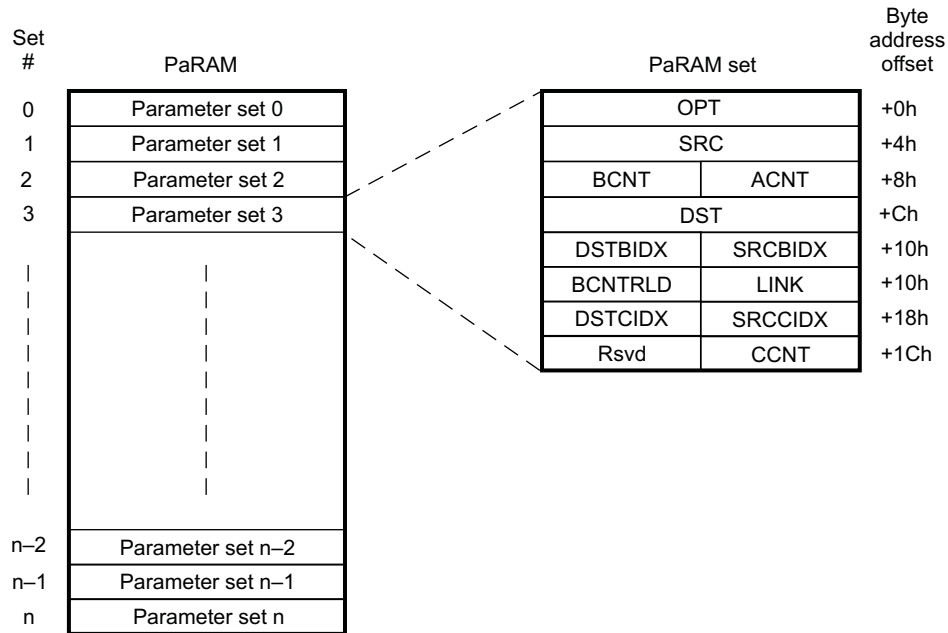

The EDMA channels can also be used under software control. In this case the DMA channels are triggered by writes to the event set register, or through internal chaining feature.

### 8.1.3.5.2 DMA Parameter Set

Figure 8-11 shows the layout of parameter RAM sets as a sequence of 128 entries which are adjacent in memory, and a detailed look into the contents of each parameter RAM.

**Figure 8-11. Structure of Parameter RAM Sets and Contents**

Note: *n* is the number of PaRAM sets supported in the EDMACC for a specific device.

**Table 8-11. Fields in Parameter RAM**

Acronym	Parameter
OPT	Channel Options
SRC	Channel Source Address
ACNT	Count for 1st Dimension
BCNT	Count for 2nd Dimension
DST	Channel Destination Address
SRCBIDX	Source BCNT Index
DSTBIDX	Destination BCNT Index
LINK	Link Address
BCNTRLD	BCNT Reload
SRCCIDX	Source CCNT Index
DSTCCIDX	Destination CCNT Index
CCNT	Count for 3rd Dimension
RSVD	Reserved

For a detailed explanation of the configuration of DMA PARAM set, see the *EVE Programmers Guide*, available through a TI representative.

### 8.1.3.5.3 Channel Controller

This section reviews various hardware resources of the channel controller that are programmed from the ARP32 controller of the EVE subsystem.

**Parameter set:** A parameter set is the program memory of the channel controller that describes the attributes of a transfer. Each parameter set describes one data transfer from a source address to a destination address. A parameter set is a group of eight contiguous 32-bit words and has an address that is aligned on a 256-bit boundary. There are 64 of these parameter sets, allowing the description of 64 transfers ahead of time. Individual parameter sets are used to describe isolated transfers, or they are linked together to describe a group of related transfers.

There are two types of DMA channels in the channel controller (CC) interface:

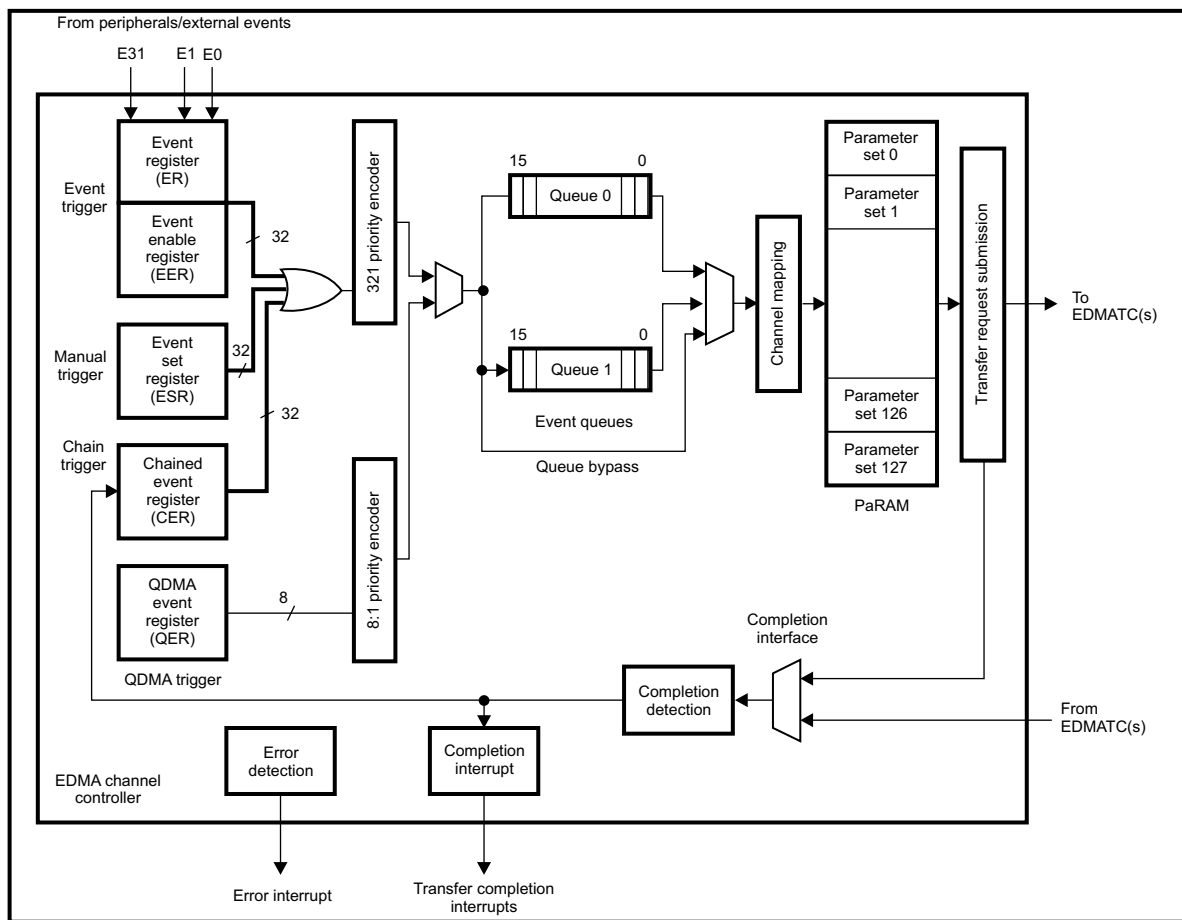

- **EDMA channel:** a data transfer channel that takes a parameter set as an input and requires that an event is triggered by a write to the corresponding event of the event set register (ESR), or by detecting assertion of a hardware event (Event Triggered), or by chain triggering. Software can designate a specific event as the trigger event by programming the mapping between the parameter set and the event in the DCHMAP register, and by mapping a DMA channel to a specific hardware event queue in the DMAQNUM register. EVE has 16 EDMA channels that must be assigned to 1 of 16 events of the ESR register, and mapped to 1 of 2 TC queues using DMAQNUM registers.
- **QDMA channel:** a data transfer channel that is similar to an EDMA channel, but is automatically triggered by the write to a specific word of parameter set (typically the eighth word). Eight QDMA channels are mapped to one of the two TC queues using the QDMAQNUM register.

An EDMA channel is used to describe a regular sequence of data transfers, in which the amount of data sent or received, and source and destination data address increments between successive transfers does not vary dynamically, but by regular amounts. A QDMA channel is used when it is needed to program in new values for the source and destination addresses. The amount of data to transferred varies from one transfer to another, and for other dynamic situations.

**EVENT queue:** data transfer events are different physical DMA channels (ESR writes for EDMA channels and parameter set trigger word writes for QDMA channels) and are detected simultaneously. The events are queued based on a fixed priority arbitration scheme; the EDMA channels are higher-priority events than the QDMA channels. Among the two groups of channels, the lowest-numbered channel is the highest priority.

Figure 8-12 shows the block diagram of the channel controller.

**Figure 8-12. Channel Controller Block Diagram**

eve-016

### 8.1.3.5.4 EVE-Level Bus Width and Throughput

Table 8-12 shows the EVE-level effective bus width and the resulting peak bandwidth. In general, the effective bus width is the minimum of the bus width values between a given initiator and given target. For example, the DMEM port is effectively 4 bytes wide when accessed by ARP32 and is effectively 16 bytes wide when accessed by DMA. Similarly, VCOP memories are 4 bytes, 32 bytes and 16 bytes wide when accessed by ARP32, VCOP, and TCn, respectively.

**Table 8-12. EVE-Level Effective Bus Width**

		INITIATORS									
		ARP32		VCOP			TC0		TC1		OCP Target Port
		Program	Data	WBUF	IBUFL	IBUFH	Read	Write	Read	Write	
TARGETS	Program cache hit	4									
	Program cache OCP Target		4				4	4	4	4	4
	DMEM		4				16	16	16	16	16
	WBUF		4	32			16	16	16	16	16
	IBUFL		4		32		16	16	16	16	16

	OCP Init1								16	16	

#### 8.1.3.5.4.1 Concurrent Transfer Requirements

The two OCP ports are independent from one another to allow full bandwidth and nonblock requests, when EVE TC0 accesses one system-level memory at the same time as EVE TC1 accesses a different system-level memory and both internally access two different IBUF memories. The overall throughput is limited to only 128 bits per cycle in the case when the two TCs are accessing:

- The same system-level memory (EMIF, L3 SRAM)
- The same internal memory buffer

### 8.1.3.6 General-Purpose Inputs/Outputs

The general-purpose input signal state can be read directly through [EVE\\_GPINO](#) (for inputs 31:0) and [EVE\\_GPIN1](#) (for inputs 63:32). These registers/GPIN signals are also mapped to the ARP32 INTC2 and INTC3 registers respectively.

The GPIs are used to convey state information (readable in the GPIN registers), or they are enabled as interrupts through the corresponding [ARP32\\_INTn\\_IRQENABLE\\_SET](#) register. A rising edge on the GP input is latched as a new interrupt in the corresponding [ARP32\\_INTn\\_IRQSTATUS](#) register.

The EVE subsystem also provides 64 GPOs. These outputs are manipulated by [EVE\\_GPOUTm](#), [EVE\\_GPOUTm\\_SET](#), [EVE\\_GPOUTm\\_CLR](#), and [EVE\\_GPOUTm\\_PULSE](#). The EVE\_GPOUT0 register group controls eve\_gpout[31:0] signals and the EVE\_GPOUT1 register group controls eve\_gpout[63:32] signals. The current state of the output is detected by reading any of the [EVE\\_GPOUTm](#), [EVE\\_GPOUTm\\_SET](#), [EVE\\_GPOUTm\\_CLR](#), or [EVE\\_GPOUTm\\_PULSE](#) registers. The 64 GPOs are used to drive interrupts or state information to other EVEs in a multi-EVE system.

The GPOUTn register can be explicitly set with the corresponding write data word. Byte or halfword writes are permitted in this case (though support may depend on the specific initiator). A read-modify-write sequence can be required if different tasks own different bits within the GPOUT bank. In this case, access for the read-modify-write sequence must be assured. The [EVE\\_GPOUTm\\_SET](#) register unconditionally drives the corresponding output event to 1. GPIOm\_CLR unconditionally drives the corresponding output event to 0. The [EVE\\_GPOUTm\\_PULSE](#) register unconditionally drives the output to one for four cycles, then deasserts the signal to 0. If the signal is 1, then the [EVE\\_GPOUTm\\_PULSE](#) simply deasserts the output signal. Software must ensure the output is low before using the [EVE\\_GPOUTm\\_PULSE](#) feature.

There are several GPOUT signals connected to arbitration/pressure bits (MFlag bits) in the device.

For EVE1 port 1 and EVE1 port 2 (EVE1 TC0 and EVE1 TC1) MFlag is driven by eve1\_gpout[63] and eve1\_gpout[62] respectively; eve1\_gpout[63] is connected to DMM\_P1 and EMIF and eve1\_gpout[62] is connected to DMM\_P2 and EMIF.

EVE2 MFlag is driven by eve2\_gpout[63] and eve2\_gpout[62] for EVE2\_P1 and EVE2\_P2 respectively; gpout[63] is connected to DMM\_P2 and EMIF and gpout[62] is connected to DMM\_P1 and EMIF.

EVE signals are described in [Figure 8-3](#) through [Figure 8-4](#).

EVE MFlag signals are not used inside L3\_MAIN. Within the device main interconnect bandwidth regulators are used to control pressure/arbitration of EVE traffic.

### 8.1.3.7 CME Signaling

The credit management engine (CME) protocol is a credit-based data transfer scheme. A central agent asserts a START signal to a DMA engine or host processor. This signal indicates that a fixed-size data buffer is available to be read or written. Then the DMA engine or host processor is responsible for asserting a DONE signal back to the CME when the data buffer is read or written. The Central Agent uses this information to update its credit accounting (there is a consumer end and producer end for any buffer that is managed by CME). The EVE subsystem generically supports START and DONE signaling, and software must service the request accordingly.

#### **CME START signal:**

In a multi-EVE system the CME START signals are broadcast to the eve\_evt\_int[n:0] input signals of each EVE. These signals are mapped on both EDMA events or ARP32 interrupts. Software enables the appropriate event or input in the appropriate EVE, based on the overall system goals.

For a given EVE, a START signal must either be used to trigger an EDMA transfer directly for a known or agreed quantity of data, or it must trigger an ARP32 interrupt, which then manually sets up an EDMA transfer as necessary.

#### **CME DONE signal:**

EVE provides eight CME DONE signals that can be triggered from multiple internal conditions or sources. For any EVE in the system, the DONE output signals are driven either based on any one of the eight EDMA region interrupt outputs, or based on the [EVE\\_CME\\_DONE\\_GPOUT](#) register.

The EDMA region interrupt outputs are statically allocated in the device or host. As such, it is desirable to connect higher-numbered "done" bits to the CME to avoid resource allocation issues. The basic logic is essentially a mux select for each respective bit (see [Figure 8-13](#)). The selection is done through the [EVE\\_CME\\_DONE\\_SEL\[31:0\]](#) register.

Figure 8-13. CME Done Logic

CME registers in the EVE subsystem are:

- [EVE\\_CME\\_DONE\\_GPOUT](#)
- [EVE\\_CME\\_DONE\\_GPOUT\\_SET](#)
- [EVE\\_CME\\_DONE\\_GPOUT\\_CLR](#)
- [EVE\\_CME\\_DONE\\_GPOUT\\_PULSE](#)
- [EVE\\_CME\\_DONE\\_SEL](#)
- [EVE\\_CME\\_DONE\\_EN](#)

The DONE GPOUT registers are used to directly drive the state of the internal CME DONE output signals. The [EVE\\_CME\\_DONE\\_SEL](#) register sets whether the EVE output signals are driven from the EDMA region interrupts, the DONE GPOUT internal value, or a pass through from the eve\_passthru signals.

---

**NOTE:** The device does not support hardware CME.

---

### 8.1.3.8 Multi-EVE and VIP Usage Models

#### 8.1.3.8.1 Data Partitioning

In this usage model, the data received from the VIP is partitioned between EVEs.

Figure 8-14 shows data partitioning usage model. In this case VIP<sub>x</sub> is the producer, and EVE1 and EVE2 are consumers. Also at the other end, EVE1 and EVE2 are producers, while VIP<sub>x+1</sub> is the consumer.

Figure 8-14. Data Partitioning

The CME issues producer start to VIPx, and VIPx returns done when it is done. The CME then broadcasts a consumer START to all the EVEs and combines the consumer DONE it receives from all the EVEs.

The CME issues producer start to EVEs and combines the producer done from all of them before it issues a consumer START to VIPx+1. VIPx+1 indicates a consumer DONE when it is done.

### 8.1.3.8.2 Task Partitioning

In this usage model, task is partitioned between the EVEs.

Figure 8-15 shows the task partitioning usage model.

In this case EVE1 is consumer for VIPx, EVE2 is the consumer for EVE1, and VIPx+1 is the consumer for EVE2.

The CME issues producer start to VIPx, and VIPx returns done when it is done. The CME then indicates a consumer start to EVE1 and receives the consumer done EVE1.

EVEs can use the following methods to communicate the START and DONE signaling between them:

1. **Mailbox:** Each EVE indicates START and DONE to the respective EVE using the Send Remote and Receive Local method. This method gives the most flexible time relationship for the task partitioning, but also adds most load on ARP32
2. **GPIOs:** In this case, each EVE uses GPIOs to communicate Start and Done to each EVE. This method adds the complexity of determining change of state of GPIOs to make sure a change of state is correctly determined.
3. **EDMA events:** Each EVE can trigger an EDMA and indicate DONE directly by using EDMA events and GPOuts for DONE functionality. The event trigger is completely hardware-based handshaking that does not include the ARP32 in the scheme. The DONE generation involves ARP32 as GPOut is used for this functionality. This scheme can only be used where there is deterministic timing relationship between each event and the processing needs in each EVE. In this case, the EVE triggering the EDMA uses its GPOUT signal connected to the INTC1 of the corresponding EVE to trigger the EDMA.

The last EVE in the usage model communicates with VIPx using the standard CME protocol.

For recommended Multi-EVE Interrupts/Events/Mailboxes/GPIOs recommended connections see [Section 8.1.2.1](#).

### 8.1.3.9 Memory Management Unit

There are two MMUs. Each of the two EDMA TCs is mapped to a different MMU. One of the MMUs is also shared with ARP32 program and data accesses. The ARP32 program cache and data accesses share an MMU to provide a convenient mechanism whereby ARP32 debug accesses have a single and consistent view of the system, which is equivalent to ARP32 software view. For the EDMA paths, the two MMUs provide maximum concurrency for each TC and its respective accesses to system memory. See [Table 8-13](#) for MMU Configurations

**Table 8-13. MMU Configuration**

Name	Description	Configuration
MMU_Entries_Number	The number of entries in the TLB cache	32 entries
MMU_Command_Bypass	Bypass command register	2 cycle latency
MMU_Response_Bypass	Bypass response register(depends on clock speed versus technology)	2 cycle latency
MMU_LRU_Enable	LRU algorithm for TLB endry replacement	Disabled

**Table 8-13. MMU Configuration (continued)**

Name	Description	Configuration
MMU_RRB_Enable	Determines if Generic RRB module is instantiated (Zero only for DSPSS)	Present
LOG_DATA_WIDTH	data width configuration	128-bit data bus

Each MMU allows multiple EVEs to have the same software even when the EVEs are communicating with each other. This can be accomplished by using virtual addresses for each EVE address space. The predominant use of multiple EVEs occurs when adjacent EVEs communicate with each other and send or receive data from adjacent neighbors. In this case, it is suggested that a consistent right neighbor and left neighbor address is defined with MMU for the EVEs. Keeping the right neighbor and left neighbor address the same across different platforms and devices helps with software reuse strategy.

The suggested address mapping for the left neighbor is 0x4100 0000, and for the right neighbor is 0x4200 0000, where the left neighbor for EVE<sub>n</sub> is EVE<sub>n-1</sub> and the right neighbor for EVE<sub>n</sub> is EVE<sub>n+1</sub>. For EVE<sub>1</sub>, the left neighbor is the last EVE implemented in the SoC, and for the last EVE in the SoC, EVE<sub>1</sub> is the right neighbor.

For more information about MMU configuration, see [Chapter 20, Memory Management Unit](#).

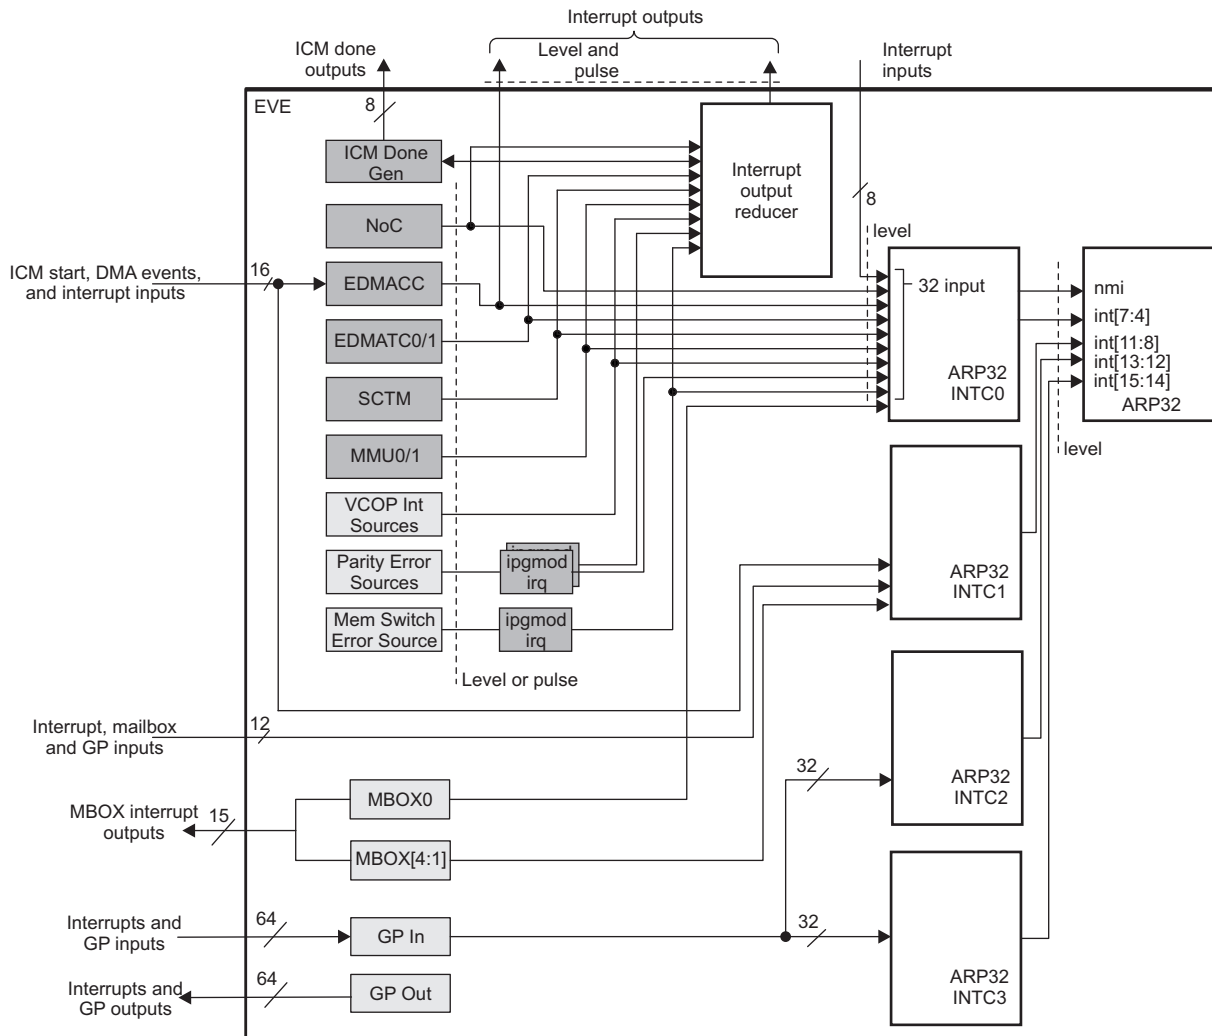

### 8.1.3.10 Interrupt Control

Each standard block (Interconnect, EDMA, SCTM) provides active high interrupts directly to the ARP32 INTC. In some cases, the submodule IP generated interrupts are mapped as outputs on the EVE boundary.

EVE interrupts (parity error interrupts and memory switch error interrupts) are summarized in [Section 8.1.3.10.1, EVE Interrupt Sources – Memory Switch and Parity Error Interrupts](#). EVE accepts active-high input interrupts from the system and maps them to system-level mailbox interrupts.

[Figure 8-16](#) is an overview of EVE interrupt topology.

Figure 8-16. EVE Interrupt Block Diagram

### 8.1.3.10.1 EVE Interrupt Sources – Memory Switch and Parity Error Interrupts

Figure 8-17 illustrates the mapping of EVE memory switch errors to a single interrupt output (EVE\_MSW\_ERR\_INT). Figure 8-18 shows the mapping of EVE parity and error detect error interrupt outputs (EVE\_ED\_LCL\_IRQ and EVE\_ED\_OUT\_IRQ).

The errors are captured in the appropriate functional error bit field along with the additional error details (such as ConnID and specific address). Error status interrupts are readable in the [EVE\\_MSW\\_ERR\\_IRQSTATUS\\_RAW](#) registers. Software enables (or disables) interrupt generation for that source by writing to the appropriate bit in the interrupt enable set or clear register. When any enabled [EVE\\_MSW\\_ERR\\_IRQSTATUS\\_RAW](#) bit is set, then an interrupt is generated to the ARP32 INTC on the corresponding IRQ output (enabling of IRQSTATUS\_RAW event is done through [EVE\\_MSW\\_ERR\\_IRQENABLE\\_SET\[3:0\]ENABLE](#) and [EVE\\_MSW\\_ERR\\_IRQENABLE\\_CLR\[3:0\]ENABLE](#) registers).

When the interrupt is served, software clears the interrupt status register fields and the source error register (through the `EVE_MSW_ERR` register or the `EVE_<MEM>_ED` register). New interrupt is latched into the `EVE_MSW_ERR_IRQSTATUS` register only after the register is cleared and new error occurs on the corresponding source error bit or signal. The appropriate bit in the `EVE_MSW_ERR_IRQSTATUS_RAW` register must be set on a low-to-high transition of the corresponding source error bit or signal. The `EVE_MSW_ERR_IRQSTATUS` register is routed to EVE-level interrupt output (active-high level and pulse signals are output) and as an active-high level interrupt to the ARP32 INTC.

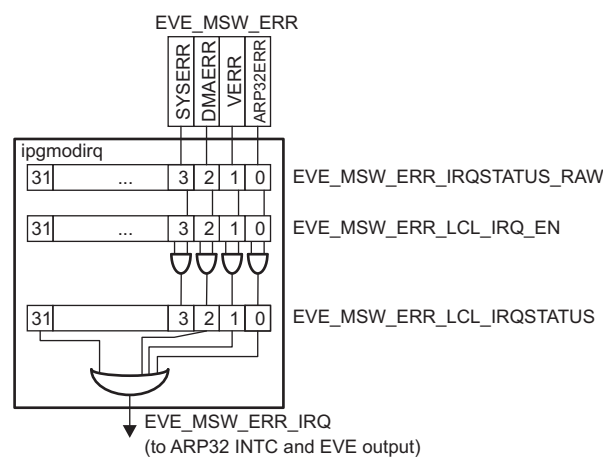

Two interrupts are provided for EVE parity or error detect interrupt. The first is the local version (`EVE_ED_LCL_IRQ`) provided as an active-high level interrupt to the ARP32 INTC. The second is an output version (`EVE_ED_OUT_IRQ`) provided as an output on the EVE boundary as both active-high level and pulse version. This lets software selectively control which parity error sources are serviced by the ARP32, and which parity error sources are serviced by the external host. Typically, ARP32 services parity error interrupts generated by VCOP, EDMA, or system accesses and the system host services parity error interrupts generated by ARP32 accesses. The following registers control the detection and servicing of those interrupts (`EVE_ED_LCL_IRQ` and `EVE_ED_OUT_IRQ`):

- `EVE_ED_LCL_IRQSTATUS_RAW`
- `EVE_ED_LCL_IRQSTATUS`
- `EVE_ED_LCL_IRQENABLE_SET`
- `EVE_ED_LCL_IRQENABLE_CLR`
- `EVE_ED_OUT_IRQSTATUS_RAW`
- `EVE_ED_OUT_IRQSTATUS`
- `EVE_ED_OUT_IRQENABLE_SET`
- `EVE_ED_OUT_IRQENABLE_CLR`

The mechanism for detecting LCL and OUT interrupts is the same as the sequence described for the memory switch error interrupts. Any interrupt condition is captured in the `IRQSTATUS_RAW` registers (`EVE_ED_LCL_IRQSTATUS_RAW`[31:0] `EVENT` and `EVE_ED_OUT_IRQSTATUS_RAW`[32:0] `EVENT`), but only after enabling the appropriate `IRQSTATUS_RAW` bits (through `EVE_ED_LCL_IRQENABLE_SET`[3:0] `ENABLE` and `EVE_ED_LCL_IRQENABLE_SET`[3:0] `ENABLE` bit fields) the event is outputted for further processing (to the EVE parity or error detect error interrupts).

See [Table 8-14](#), [Figure 8-18](#), and [Figure 8-18](#) for more information.

### 8.1.3.10.2 ARP32 INTC

The EVE subsystem instantiates four INTC subblocks. Each ARP32 INTC supports up to 32 active-high level interrupt inputs, and outputs up to five active-high level interrupt outputs. NTC0 maps to NMI and INT[7:4]; INTC1 maps to INT[11:8]; INTC2 maps to INT[13:12]; and INTC3 maps to INT[15:14].

The [ARP32\\_INTn\\_IRQSTATUS\\_RAW](#) or [ARP32\\_NMI\\_IRQSTATUS\\_RAW](#) register is set when the input signal transitions from a low-to-high state. Software clears the [ARP32\\_INTn\\_IRQSTATUS\\_RAW](#) or [ARP32\\_NMI\\_IRQSTATUS\\_RAW](#) register by writing 1 into the appropriate bit position. To latch a new level interrupt, software must first clear the source so that a new low-to-high transition is generated on the INTC input. This is compatible with both level and source interrupt sources.

Upon clearing any bit in a given [ARP32\\_\[INTn\(j\)\]NMI\]\\_IRQSTATUS\\_RAW](#) register, if any enabled interrupts are still set, that is [ARP32\\_\[INTn\(j\)\]NMI\]](#) output signal pulse is low for two clock cycles and is about to transition back to high state. This results in resetting the ARP32 IFR and thus triggers a new ISR, protecting against race conditions. Any new interrupts must occur after the initial read of the [ARP32\\_INTn\\_IRQSTATUS](#) or [ARP32\\_NMI\\_IRQSTATUS](#) state.

Upon entering an ISR, software must first read from the [EVE\\_INTk\\_OUT\\_IRQSTATUS](#) register, which may show multiple enabled interrupts pending. Software clears the state of those enabled interrupts that are set (by writing 1 to [EVE\\_INTk\\_OUT\\_IRQENABLE\\_CLR](#) and [IRQSTATUS](#) bit) and that are dispatched for servicing. Software determines which interrupt source to service first through whatever scheme is convenient. Upon servicing the selected interrupt, software clears the original source interrupt status.

Figure 8-19 shows the INTC for ARP32.

Figure 8-19. EVE INTC for ARP32

Table 8-16, Table 8-17, Table 8-18, and Table 8-19 summarize the ARP32 interrupt mapping.

Table 8-16. EVE ARP32 Interrupt Event Mapping Group0/INTC0

Interrupt	Name	Description	Source
0	eve_int00 <sup>(1)</sup>	Mapping to Mailbox 0	EVE input
1	eve_int01 <sup>(1)</sup>	Mapping to Mailbox 1	EVE input
2	eve_int02 <sup>(1)</sup>	Mapping to Mailbox 2	EVE input
3	eve_int03 <sup>(1)</sup>	Reserved	EVE input
4	eve_int04 <sup>(1)</sup>	Reserved	EVE input
5	eve_int05 <sup>(1)</sup>	Reserved	EVE input
6	eve_int06 <sup>(1)</sup>	Reserved	EVE input
7	eve_int07 <sup>(1)</sup>	Reserved	EVE input
8	tpcc_intg	EDMA CC global interrupt	EDMA CC

<sup>(1)</sup> eve\_int[7:0] are available only to the ARP32 interrupt controller. They are unavailable and reserved to the output interrupt reducer.

**Table 8-16. EVE ARP32 Interrupt Event Mapping Group0/INTC0 (continued)**

Interrupt	Name	Description	Source
9	tpcc_int0	EDMA CC region 0 interrupt	EDMA CC
10	tpcc_int1	EDMA CC region 1 interrupt	EDMA CC
11	tpcc_int2	EDMA CC region 2 interrupt	EDMA CC
12	tpcc_int3	EDMA CC region 3 interrupt	EDMA CC
13	tpcc_int4	EDMA CC region 4 interrupt	EDMA CC
14	tpcc_int5	EDMA CC region 5 interrupt	EDMA CC
15	tpcc_int6	EDMA CC region 6 interrupt	EDMA CC
16	tpcc_int7	EDMA CC region 7 interrupt	EDMA CC
17	SCTM_TIMEVNTINT0	SCTM timer interrupt 0	SCTM
18	SCTM_TIMEVNTINT1	SCTM timer interrupt 1	SCTM
19	vcop_done <sup>(2)</sup>	VCOP done	VCOP
20	vcop_err_intn	VCOP error	VCOP
21	mmu0_int	MMU0 interrupt	MMU0
22	mmu1_int	MMU1 interrupt	MMU1
23	tpcc_errint	EDMA CC error interrupt	EDMA CC
24	tptc_errint0	EDMA TC0 error interrupt	EDMA TC0
25	tptc_errint1	EDMA TC1 error interrupt	EDMA TC1
26	noc_errint	Interconnect error interrupt	Interconnect
27	EVE_MSW_ERR_INT	Buffer error interrupt	EVE top
28	EVE_ED_LCL_ERR_INT or EVE_ED_OUT_ERR_INT <sup>(3)</sup>	Parity error interrupt	EVE top
29	mailbox0_interrupt0	Mailbox 0 interrupt 0	Mailbox 0
30	mailbox1_interrupt0	Mailbox 1 interrupt 0	Mailbox 1
31	Reserved	Reserved	Reserved

<sup>(2)</sup> Vcop\_done will deassert when new instructions are issued. Using the interrupt service routine, the interrupt is cleared in ARP32 INTC. Clearing of the actual source is with the functional mechanism of sending new instructions.

<sup>(3)</sup> EVE\_ED\_LCL\_ERR\_INT (EVE\_ED\_LCL\_IRQSTATUS\_RAW, EVE\_ED\_LCL\_IRQSTATUS) is used by the ARP32 INTC and EVE\_ED\_OUT\_ERR\_INT (EVE\_ED\_OUT\_IRQSTATUS\_RAW, EVE\_ED\_OUT\_IRQSTATUS) is used for the output interrupts reducer.

**Table 8-17. EVE ARP32 Interrupt Event Mapping Group1/INTC1**

### 8.1.3.10.3 Output Interrupt Reduction

EVE provides four output interrupts based on the same approach shown previously for the ARP32 INTC. The EDMA region interrupts, as well as the four output interrupts, are provided at the EVE boundary as shown in [Figure 8-16](#).

For more information about the IRQ\_CROSSBAR module, see [Section 18.4.6.4, IRQ\\_CROSSBAR Module Functional Description](#), in [Chapter 18, Control Module](#).

[Table 8-16](#) shows the interrupt mapping for the output interrupt reducer.

### 8.1.3.10.4 End of Interrupt Mapping

End of interrupt (EOI) is a feature used for software handshake with pulsed interrupts.

EOI MMR functionality is provided for EVE-generated interrupts that are mapped as outputs to the system. This feature is necessary when the external system uses the pulsed version of a given interrupt. Because all interrupts inside EVE are level interrupts, the EOI feature is not required for those interrupts.

---

**NOTE:** The EVE subsystem does not condition interrupts for internal submodules (EDMA, interconnect, MMU, or SCTM). Those interrupts are mapped directly as outputs to the system and no EOI functionality is provided for them.

---

[Table 8-20](#) lists the EOI mapping for the required interrupts.

**Table 8-20. EVE EOI Mapping**

EVE MMR Value	EVE Interrupt Overview
1	eve_int0_out
2	eve_int1_out
3	eve_int2_out
4	eve_int3_out

### 8.1.3.11 Interprocessor Communication

This kind of communication is managed through mailboxes. The mailbox function supports 2-way communication between a maximum of four users. This function relies on internal submodules, each supporting 1-way communication between one user referred to as the sender and another user referred to as the receiver. Software allocates the mailbox submodule to the communication between two users. EVE includes internal mailbox to support synchronization and messages passing between EVE-, ARP32-, and system-level hosts.

#### 8.1.3.11.1 Mailbox Configuration

The mailbox submodule includes support for four users and, therefore, provides four interrupt outputs. MAILBOX\_Interrupt0 is mapped to the EVE INTC and MAILBOX\_Interrupt[3:1] are mapped to three external host processors.

Six submailboxes are provided, allowing bidirectional communication between the ARP32 and the three external hosts:

- MAILBOX\_MESSAGE0: HOST0 to EVE
- MAILBOX\_MESSAGE1: HOST1 to EVE
- MAILBOX\_MESSAGE2: HOST2 to EVE
- MAILBOX\_MESSAGE3: EVE to HOST0
- MAILBOX\_MESSAGE4: EVE to HOST1
- MAILBOX\_MESSAGE5: EVE to HOST2

In the case of EVE-to-EVE communication, a send-remote-receive-local scheme is used, and thus software can leave MESSAGE[5:3] unused.

The listed allocation in this section is just an example. For more information about the Mailbox module, see [Chapter 19, Mailbox](#).

#### 8.1.3.11.1 Mailbox 0 – EVE to DSP1, DSP2 and MPU

Mailbox 0 is dedicated to bidirectional communication between local EVE, two DSPs (DSP1 & DSP2), and a host MPU. In this mailbox, 6 out of 16, submailboxes are used, 3 for senders and 3 for receivers. Additional mailboxes are available, if needed, to separate message traffic based on type or content between each sender and receiver pair (see [Table 8-21](#)).

**Table 8-21. EVE to DSP1, DSP2 and MPU Mapping**

		Receiver			
		EVE <sub>n</sub>	DSP1	DSP2	MPU
Sender	EVE <sub>n</sub>	-	En_M0	En_M0	En_M0
	DSP1	En_M0	-	-	-
	DSP2	En_M0	-	-	-
	MPU	En_M0	-	-	-

#### 8.1.3.11.2 Mailbox 1 – EVE to Other Hosts

Mailbox 1 is dedicated to bidirectional communication with other system-level hosts (such as additional MPU cores). The actual usage and mapping varies on the different devices.

In a multicore system, additional mailbox modules are included to support generic and lower-frequency, higher-latency communication. This mailbox is used by host that needs tightly coupled interaction with the local EVE.

This mailbox has a similar usage as mailbox 0. Six submailboxes are used, three for senders and three for receivers (see [Table 8-22](#)).

**Table 8-22. EVE to Other Hosts Mapping**

		Receiver			
		EVE <sub>n</sub>	Host X	Host Y	Host Z
Sender	EVE <sub>n</sub>	-	En_M1	En_M1	En_M1
	Host X	En_M1	-	-	-
	Host Y	En_M1	-	-	-
	Host Z	En_M1	-	-	-

#### 8.1.3.11.3 Mailbox 2 – EVE to EVE in a 2x EVE System

In a system with 2x EVEs, Mailbox2 in each EVE is reserved for "receive" messages from other EVEs. [Table 8-23](#) shows the connection between different EVEs. Since EVE implements send remote, receive local methodology for mailboxes, each EVE receives messages locally, in its own mailbox, from other EVEs. While it sends messages to other EVEs to their mailboxes respectively. This reduces the latency incurred in accessing the mailboxes.

**Table 8-23. EVE to EVE Mapping**

		Receive Local	
		EVE1	EVE2
Sender	EVE1	-	E1_M2
	EVE2	E0_M2	-

### 8.1.3.12 Powerdown

The EVE subsystem supports two methods of power-minimization and clock gating:

- Active mode power minimization
- Extended duration sleep

#### 8.1.3.12.1 Extended Duration Sleep

Extended duration sleep is an explicitly requested powerdown mode handshaking with the device-level PRCM. As a result, the EVE input clocks are gated. The EVE subsystem is able to latch new interrupts and wake-up requests while in this clock gated state. Internal state is retained, including ARP32 registers, ARP32 data SRAM and program cache contents, VCOP state, EDMA registers, PaRAM, EVE level registers, and so forth.

Since the EVE subsystem has only one logical clock domain (even though divided clocks are used) the PRCM only gates clocks to the EVE subsystem after all of the appropriate handshakes (that is IDLE, STANDBY, and OCP Disconnect) are concluded and the EVE subsystem is in a completely IDLE, STANDBY, and DISCONNECTED state.

##### 8.1.3.12.1.1 Sequence Overview

To enter extended duration sleep mode, the system host first signals the EVE subsystem (through systemlevel mailbox and interrupt) that it is entering this mode. In parallel, the PRCM asserts an SIdleReq request to the EVE subsystem. ARP32 performs any software book-keeping necessary to transition the EVE subsystem to a quiescent state. This can include:

- Waiting for outstanding DMA transfers to complete
- Waiting for VCOP to finish the current task
- Servicing pending interrupts

If the [EVE\\_SYSCONFIG\[5:4\]](#) STANDBYMODE bit field is set accordingly, then the EVE hardware transitions to IDLE state and signals the desire to enter powerdown state to the device through the STANDBY and Idle protocols. After handshakes are completed internal EVE clocks are gated.

[Figure 8-20](#) depicts the extended duration sleep software/hardware sequence.

Figure 8-20. Extended Duration Sleep Software/Hardware Sequence

### 8.1.3.12.1.2 Idle Protocol Overview

EVE IDLE protocol is associated with the EVE OCP target port. The configuration of the IDLE state is done by setting the `EVE_SYSCONFIG[3:2]` IDLEMODE bit field.

When the EVE subsystem is configured in Smart-Idle or in Smart-Idle-Wakeup, the following sequence must be performed upon an IDLE request from the PRCM:

- Acknowledge the receipt of the request by going into sleeptrans state.
- Wait for MStandby state.
- Disconnect all OCP target ports using the OCP disconnect protocol.
- Gate EVE internal clocks.
- Acknowledge the IDLE request by going into IDLE state.

Externally generated OCP requests (through DMA OCP target bus) to EVE memory space are gated only after the MStandby state is entered. This is required because explicit messaging with either the MPU or the DMA may be necessary before ARP32 software can reach a state that allows entrance to MStandby.

### 8.1.3.12.1.3 Mstandby Protocol Overview

MSTANDBY protocol is initiated based on ARP32 executing idle instruction provided the other internal EVE masters are in idle state (assuming in Smart-Standby mode).

ARP32 software must wait until all internal operations are finished, before executing idle instruction.

The standby sequence follows:

1. ARP32 software waits for all activity to stop.
2. ARP32 issues IDLE instruction and all EVE submodules are in IDLE state.
3. Using the OCP disconnect protocol, deactivate all OCP initiator ports.

4. Assert the MStandby signal.

#### 8.1.3.12.1.4 IDLE Wakeup

To facilitate auto-idle wakeup of the EVE subsystem, the wakeup capability of the idle protocol is used. A wake-up operation is executed when SYSCONFIG[3:2] IDLEMODE = 3h (SmartIdle-Wakeup).

In this mode, while in IDLE state, if an external input interrupt source that is enabled through the [ARP32\\_IRQWAKEEN](#) mask is active, then the SWakeup signal is asserted to the system. The device is expected to monitor the SWakeup request and enable clocks and exit the STANDBY and IDLE states. At this point, ARP32 can branch to the pending ISR.

The SWakeup signal is deasserted when all interrupt signals that are enabled in the IRQWAKEEN register are deasserted.

The logic controlling the assertion of SWakeup is completely asynchronous and does not rely on any input clock.

[ARP32\\_IRQWAKEEN](#) is not replicated per NMI, INTx. Any interrupt enabled in the [ARP32\\_IRQWAKEEN](#) mask must be enabled in one of the corresponding ARP32\_INT\_IRQENABLE registers.

#### 8.1.3.13 Hardware-Assisted Software Self-Test – MISRs

To facilitate software self-test, MISRs are instantiated on address and data buses at key points in the system, such as ARP32 interfaces and the interconnect-WBUF interface. ARP32 is covered because it is the key control engine. WBUF coverage is provided as a convenient central destination that is used to indirectly provide coverage for a majority of EVE logic.

The MISRs monitor the address and data buses and calculate a signature based on the address or data pattern on a valid address or data phases. The signature registers reset to 0. A different speed value can be manually written through software to each signature register: [MISR0\\_A](#), [MISR0\\_D](#), [MISR1\\_A](#), [MISR1\\_D](#), and [MISR2\\_Dk](#). Based on a known memory access data pattern, the MISR signature can be predicted or calculated and used as a reference for subsequent tests that occur at boot time or during runtime in a safety critical application.

The MISR calculation is a shift-register/XOR tree calculation using classical CRC algorithms.

The MISR calculation is initiated by setting the [MISR\\_CTL](#)[2:0] ENABLE bit field:

- bit 0: enable MISR 0 – ARP32 PMEM path
- bit 1: enable MISR 1 – ARP32 DMEM path
- bit 2: enable MISR2 – Interconnect WBUF path

The [MISR\\_CLEAR](#)[2:0] CLEAR register clears the MISR 0 and MISR 1 calculations for the corresponding path.

[Table 8-24](#) describes the location and width of the various MISRs in the system and is shown as thick blue lines in the block diagram in [Figure 8-1](#).

**Table 8-24. MISR Mapping**

		Address	Read Data	Write Data	Bus Width	MISR algorithm
<a href="#">MISR0_A</a>	ARP32/PMEM	x			32	CRC-32
<a href="#">MISR0_D</a>	ARP32/PMEM		x		32	CRC-32
<a href="#">MISR1_A</a>	ARP32/DMEM	x			32	CRC-32
<a href="#">MISR1_D</a>	ARP32/DMEM			x	32	CRC-32
<a href="#">MISR2_Dk</a> (k = 0:3)	Interconnect/WBU F			x	128	CRC-32 (*4)

### **8.1.3.13.1 Mapping of MISRs to Different Width Buses**

For WBUF data MISR, four instances of CRC-32 MISRs are instantiated in parallel to populate the width of the data bus. For ARP32 interfaces, a single instance of CRC-32 MISR is instantiated on each interface.

Each write data bus MISR ([MISR1\\_D](#) and [MISR2\\_Dk](#)) is activated based on the byte-enable pattern for the corresponding 32-bit word of memory. If any single byte-enable signal (of the 4 for the 4-bytes in the word) is active, then that MISR is updated. Byte-enables that are active use the corresponding data bus value. To avoid "don't care" signals from corrupting the MISR calculation, byte-enables that are inactive use a value of 0 on the input to the 32-bit MISR.

### **8.1.3.13.2 Detection of Valid Address and Data Cycles**

For each MISR in the EVE subsystem, the update cycle occurs for functional accesses, once per read or write request or address phase for address based MISRs, and once per data phase for data-bus based MISRs. If a phase is extended due to "not ready" condition on the target, then the MISR is not updated on that cycle. MISR is updated only on the cycle where the REQUEST and READY signals are active.

### **8.1.3.13.3 Creating a Unique Signature – Software Self-Test Implications**

To create tests that produce a unique signature, software must take care to ensure that the order of transactions (and resulting data/address phases) to a given MISR are consistent. Varying time between transactions does not affect the signature, because it is not updated on idle or not-ready cycles.

For cases that use a single initiator to access a given MISR, crossing asynchronous boundaries is acceptable. This is always true for ARP MISRs, but not necessarily for the WBUF MISRs.

For example if TC0 reads the OCP initiator bus and writes to WBUF MISR, the result is a consistent signature. And when TC0 reads EMIF address space (which is asynchronous) and writes to WBUF, while TC1 is also writing to WBUF results in different order of transactions.

For cases where all transactions/interactions are synchronous, using multiple initiators results in a consistent signature.

### **8.1.3.13.4 Multipass Tests Using WBUF MISR**

The WBUF MISR is used to indirectly provide coverage for a majority of EVE logic. The EVE-level EDMA can be used to perform memcopy operation between a given source memory range and a WBUF memory address range and thus the WBUF MISR. The source buffer contains known values that are either the interim results of a VCOP self-test, or simply initialized to a known data pattern to provide interconnect level coverage. This is repeated for the necessary paths in the EVE subsystem to provide indirect coverage for those paths.

It is possible to reserve a portion of WBUF memory for the write data accesses during the self-test operation. The necessary reserved address space can be minimized by using EDMA constant mode transfers, which require a minimum of 32 bits of reserved space.

### **8.1.3.14 Error Recovery – ARP32 and OCP Disconnect**

To prevent runaway code from corrupting the remainder of the system, and provide a clean reset/recovery mechanism, the EVE subsystem provides a mechanism to disconnect ARP32 from the remainder of the EVE subsystem, and to disconnect L3 initiator buses from the remainder of the device.

When ARP32 or OCP initiator buses are disconnected, the MPU or debugger can detect the EVE MMRs and memories through the interconnect target bus.

When the ARP32 and OCP buses are disconnected, a full reset and reboot cycle are issued in order to resume normal ARP32<->EVE operation. This is required in order to avoid any asynchronous timing paths due to asynchronous reset assertion to ARP32.

### 8.1.3.14.1 ARP32 Disconnect

ARP32 disconnect occurs when a specific parity error is detected and is enabled in the corresponding [EVE\\_ED\\_ARP32\\_DISC\\_EN](#) register. A disconnect request can also be issued by setting the [EVE\\_DISC\\_CONFIG\[0\]](#) ARP32\_DISC bit to 1.

When the ARP32 core is in the process of disconnecting (waiting on in-flight request and response) the [EVE\\_STAT\[17:16\]](#) ARP32\_DISC\_STATUS bit field is set to 0x1, meaning "attempting to disconnect". When ARP32 is disconnected on both the program and data interfaces, then this bit field is set to 0x0 (disconnected).

---

**NOTE:** Software must wait for disconnected state before issuing a reset to the ARP32 core. This status ensures the neighboring system is not in a corrupted state

---

### 8.1.3.14.2 OCP Initiator Disconnect

The OCP initiator disconnect request occurs based on a specific parity error that is enabled in the corresponding [EVE\\_ED\\_OCPI\\_DISC\\_EN](#) register, or when the [EVE\\_DISC\\_CONFIG\[4\]](#) OCPI\_DISC bit is set to 0x1.

When a disconnect request is issued both OCP initiator buses are disconnected. The disconnect logic forces the OCP initiator buses to stall at a clean boundary, such that EVE reset can be issued without violating the OCP protocol detected by the neighboring L3 interconnect. The disconnect logic also tries to fence any new requests, by allowing the current request handshake to complete, but gating any new OCP requests to the system. When the previously issued requests have received all responses, the interface is drained; at this point, the OCP disconnect protocol enters the M\_OFF state.

When the OCP initiators are disconnecting, waiting on in-flight request/responses to complete, the [EVE\\_STAT\[21:20\]](#) OCPI\_DISC\_STATUS read value is 0x1 or "attempting to disconnect". Otherwise, when both initiators are disconnected, then the bit field contains the value 0, meaning that initiators are disconnected. In order to guarantee that the neighboring system is not left in a corrupted state, software must wait for disconnected state before issuing a reset to EVE

---

**NOTE:** Any requests into the OCP target bus must be stopped.

---

### 8.1.3.15 Lock and Unlock Feature

The EVE subsystem provides a Lock/Unlock mechanism that helps to prevent unintended access to the various control registers of the EVE control module, or EVE subcomponents. Ten lock and unlock registers are defined, where each register is used to lock and unlock access to a specific area of the memory map. [Table 8-25](#) summarizes the logical groupings.

**Table 8-25. Lock Register Mapping**

Register Name	Mapping	Locked Registers
MMR_LOCK0	EVE memory configuration and standard EVE registers	<a href="#">EVE_REVISION</a> , <a href="#">EVE_HWINFO</a> , <a href="#">EVE_SYSCONFIG</a> , <a href="#">EVE_STAT</a> , <a href="#">EVE_DISC_CONFIG</a> , <a href="#">EVE_BUS_CONFIG</a> , <a href="#">EVE_VCOP_HALT_CONFIG</a> , <a href="#">EVE_MMU_CONFIG</a>

<sup>(2)</sup> i = 4 to 7 and 8 to 15

<sup>(3)</sup> k = 0 to 3

### 8.1.3.16 EVE Memory Map

For ARP32/EDMA view, the entire 32-bit address space is defined. Accesses to addresses less than 0x4000 0000 and greater than or equal to 0x4010 0000 are used to generate accesses to the external system. These accesses are managed through the MMU module. Accesses to addresses 0x4000 0000 to 0x400F FFFF that are generated directly by ARP32/EDMA are used to access the internal EVE address space. The MMU initiator is only able to access external-to-EVE address space, thus EVE logically remaps a virtual address (address generated by ARP32/EDMA below 0x4000 0000 and above 0x4010 0000) to any 32-bit physical address in the system, such that addresses mapped to 0x4000 0000 still occur. In other words, the EVE address space coexists with the same address space mapped for a different function at system memory through the MMU translation.

EDMA views a compressed/aliased version of the VCOP memories. This is dependent on the [EVE\\_MEMMAP\[4\] LCL\\_EDMA\\_ALIAS](#) bit.

VCOP address space is limited to the VCOP memories. The VCOP memory map depends on the setting of the [EVE\\_MEMMAP\[0\] VCOP\\_ALIAS](#) bit.

The system address space represents accesses to the external system through the OCP target bus. At the system level, this memory range is mapped to a fixed base address. [Table 8-26](#) lists the address that represents the offset relative to that base address.

[Table 8-26](#) shows the EVE subsystem memory map, with separate columns to show the ARP32/EDMA, VCOP, and SYS views.

**Table 8-26. EVE Subsystem Memory Map**

ARP32/EDMA View		VCOP View		SYS View		Size	Region	Function
Start Address	End Address	Start Address	End Address	Start Address	End Address			
0h	3FFF FFFFh					1024MB	MMU0/MMU1	System Memory through MMU

**Table 8-26. EVE Subsystem Memory Map (continued)**

ARP32/EDMA View		VCOP View		SYS View		Size	Region	Function
Start Address	End Address	Start Address	End Address	Start Address	End Address			
4000 0000h	4001 FFFFh			0	1 FFFFh	128KB	Reserved	–
4002 0000h	4002 7FFFh			2 0000h	2 7FFFh	32KB	DMEM	Data memory

4010 0000h	FFFF FFFFh					3071MB	MMU0/MMU1	System memory through MMU

### 8.1.3.16.1 VCOP and Local EDMA: IBUF Memory Map Aliasing

To facilitate ping-pong buffer management, EVE allows the local EDMA and VCOP view of IBUFLA versus IBUFLB, and IBUFHA versus IBUFHB memories to be aliased into the same address ranges. ARP32 and System accesses (through OCP target port) always use the unique/256-KB address map for IBUF memory accesses.

Having a VCOP accesses and `EVE_MEMMAP[0] VCOP_ALIAS = 0x1` limits VCOP data memory view to 128KB, with A and B sets aliased to the same address range, depending on the MMR ownership bits (`EVE_MSW_CTL`). When `EVE_MEMMAP[0]VCOP_ALIAS = 0x0`, VCOP uses the full 256 KB address. The `EVE_MEMMAP[0]VCOP_ALIAS` bit has no effect on how other initiators (ARP32, EDMA or SYS) see the VCOP memories. The VCOP view truth table is shown in [Table 8-27](#). If IBUFLA/IBUFHA is set (while VCOP owned), then the memory switch points to the IBUFHA/IBUFLA memory and IBUFHB/IBUFLB is a "don't care". If VCOP accesses address that is shown in gray in [Table 8-27](#), that is reported as an error.

Having local EDMA accesses, when `EVE_MEMMAP[4] LCL_EDMA_ALIAS = 0x1`, limits local EDMA data memory view to 128KB, with A and B sets aliased to the same address range, dependent on the MMR ownership bits (`EVE_MSW_CTL`). When `EVE_MEMMAP[4] LCL_EDMA_ALIAS = 0x0`, EDMA uses the full 256-KB address. The `EVE_MEMMAP[4] LCL_EDMA_ALIAS` bit has no effect on how other initiators detect the VCOP memories. [Table 8-28](#) is the local EDMA truth table. If `IBUFHA` or `IBUFLA` is cleared (while EDMA/system owned), then the memory switch points to the `IBUFHA` or `IBUFLA` memory and `IBUFHB/LB` bit is a don't care bit. If ARP32, EDMA, or system accesses an address shown in gray, then that is reported as an error.

---

**NOTE:** The ALIAS and ownership register are modified when the system is initialized, or between major modes of operation when no memory transactions are ongoing. If the mode changes while accesses are in progress, then a given address may change from valid to reserved (or viceversa), or a given address can change from one memory to another.

---

**NOTE:** ARP32 and system accesses (including the system EDMA) always view the expanded 256-KB unique addresses for access to IBUF memories.

When a memory switch error is detected, the physical address is captured. `IBUFLB` address is `0x40007 0000` even if in aliased mode.

---

### 8.1.3.16.2 ARP32 Write Model – Avoiding Race Conditions

ARP32 uses posted writes exclusively. This implies that writes are "fire-and-forget" and that writes on a given path complete some variable number of cycles after being issued by ARP32. If ARP32 issues a write followed by either a read or write to the same endpoint, then those accesses complete in order. However, if ARP32 issues a write to a given endpoint target (for example `MSW_CTL`) and then issues a read or write to a different endpoint target (for example `IBUF`), then the `IBUF` access may occur before the `MSW_CTL` write. To assure that a write has landed, that ARP32 must issues a read to the same address range.

In case of memory switch ownership or aliasing modifications, software must ensure that the mode change is established. This is done by reading back the value of the ownership or alias registers.

**Table 8-27. VCOP IBUF Aliasing Truth Table**

EVE_MEMMAP: VCOP_ALIAS Bit	EVE_MSW_CTL Bit				VCOP Address			
	IBUFLA	IBUFHA	IBUFLB	IBUFHB	10000h	14000h	30000h	34000h

### 8.1.3.17 Debug Support

The SCTM and SMSET modules facilitate application and kernel-level performance tuning, as well as general debug. The EVE subsystem minimizes debug intrusion.

#### 8.1.3.17.1 ARP32 Debug Support

The EVE subsystem provides the entire IcePick™ and cross-triggering interfaces at the EVE boundary for use at the system level. EVE ARP32 configuration supports two hardware watchpoints. There are no hardware breakpoints.

The ARP32 core supports the following debug features:

- A 32-bit OCP slave port as the debug interface
- Memory-mapped registers showing and controlling debug status of the core
- Ownership mechanism for managing use of all debug features by application code or debug software
- View of CPU resources (program memory, data memory, CPU architectural register, CPU control registers)
- Real-time debug access to CPU resources, if the CPU does not need to be halted to make a debug access
- Unlimited number of simultaneous software breakpoints using the BKPT instruction supported by the core
- Limited number of simultaneous hardware watchpoint (HWWP) units
- Run control:
  - Halting cpu at SWBP, HWBP, HWWP, incoming external Trigger
  - Single stepping in processor - instruction by instruction
  - Resuming CPU from halted state
- Cross triggering:
  - Halting the CPU on an incoming external trigger
  - Sending a trigger pulse out when the CPU halts as a result of SWBP, HWBP, HWWP trigger/match
  - Sending a trigger pulse out when HWBP, HWWP match is detected, even if the CPU is not configured to halt
- Debug control and status registers:
  - Shows the status of debug access, CPU core execution status
  - Shows miscellaneous status like RESET and IDLE state

### 8.1.3.17.2 SCTM

The SCTM provides general-purpose counters and timers. It also allows counting and measuring of specific internal EVE signals (for example, stall signals). The general-purpose counter/timer functionality is used by both BIOS software and application software. The signal-measuring functions are typically used for performance-related debug. See [Section 8.1.6](#) for more details concerning SCTM.

#### 8.1.3.17.2.1 SCTM Configuration

[Table 8-29](#) shows the SCTM configuration for EVE. The SCTM module is configured for eight 32-bit counters, two of which can be configured as timers. Timers are counters that include a threshold MMR value and an interrupt. The interrupt is pulsed when the counter reaches the programmed threshold. It is possible for any two even and odd counter pairs to be chained (through MMR) to operate as a 64-bit counter. The SCTM configuration in EVE supports the atomic read feature on counter[3:0] pair and counter[5:6] pair.

**Table 8-29. SCTM Configuration in EVE**

Generic	SCTM Feature/Parameter Details	Value	Number on Device
CTM_NUMINPT	Number of event input signals supported	0 to 127	31
CTM_NUMCNTR	Number of counters in the module	1 to 32	8
CTM_NUMTIMR	Number of timers	0 to 8	2
CTM_TIMINTPOLARITY	Timer interrupt polarity	0 = Active low 1 = Active high	1
CTM_TIMINTWIDTH	Timer interrupt pulse width	1 or more	2
CTM_NUMSTM	Number of counters for STM export	0 to 32	0
CTM_CCMAVAIL	CCM frame export available	0 = No 1 = Yes	0
CTM_NUMDBGSGL	Number of debug event signals	0 to 8	0

**Table 8-29. SCTM Configuration in EVE (continued)**

Generic	SCTM Feature/Parameter Details	Value	Number on Device
CTM_ASYNCIDLEREQ	Whether IDLE request is asynchronous signal	0 = No 1 = Yes	0
CTM_CNTR_CHAINSHADOW	Atomicity feature for even-indexed counters	One per counter. 0 = No chain shadow feature 1 = Chain shadow feature in counter chain mode	Counter numbers 2 and 4 have the chaining feature.

**8.1.3.17.2.2 SCTM Resources Reserved for BIOS**

Timer 0 (and associated interrupt) is exclusively reserved for BIOS software for driving the BIOS tick.

Timer 1 (and associated interrupt) is free to be used by application software.

BIOS also requires a 64-bit free-running counter with low-latency accessibility that is used during application logging. This is provided through the ARP32 free-running 64-bit counter.

**8.1.3.17.2.3 SCTM Event Mapping**

The SCTM events include low-level stall and duration signals sourced by various components of EVE, mainly program cache-related signals and VCOP-related signals. Table 8-30 summarized the event mapping. Event inputs start numbering at 1, because event0 is reserved and SCTM internally uses the functional clock as event0.

For more details on the functionality of each signal listed in the table, see *EVE Programmer's Guide*. Contact your TI representative for instructions how to access this document.

The SCTM module operates at half the clock rate (EVE<sub>Ex</sub>\_GFCLK), CLK2 = 0.5 × CLK1. The event sources include CLK2 and CLK1 signals. The CLK2 relative signals are connected directly to SCTM. The CLK1 relative signals are conditioned by EVE-level logic to scale from CLK1 to CLK2. Because these signals are Duration type signals, EVE logic asserts a CLK2 pulse for every two CLK1 pulses detected. This results in, at most, 1 CLK1 cycle of inaccuracy in the CLK2 duration reported by the SCTM.

The SCTM allows measurement of active-high signals. The Type column represents the functional characteristics of the source signals, which can be Pulse, Duration or Edge. The SCTM Mode column describes the typical mode for the SCTM counter when used with a particular signal. The options are event or duration mode. The pulse signals are driven active one cycle for each occurrence, a sequence of consecutive active cycles represents multiple occurrences. For a type of signal where the duration implies the number of occurrences in particular state (for example, the number of cache hits) the duration mode of SCTM is used. The Duration type represents a signal that may stay active for multiple cycles on a given occurrence. These are stall signals, where software tried to determine the number of cycles in the stalled state. Duration mode indicates the time stalled. Event mode indicates the number of unique occurrences of stalls. Event is useful in this case since there is always a deassertion between occurrences. The Edge type goes active for undefined periods of time but must go inactive before the next occurrence. Event mode of the SCTM is used for these signals.

**Table 8-30. SCTM Events**

SCTM Event	Name	Source	Type	SCTM Mode	Clock
1	cache_miss_count	ARP32_Pcache	Pulse	Duration	CLK2
2	cache_hit_count	ARP32_Pcache	Pulse	Duration	CLK2
3	cache_miss_stall	ARP32_Pcache	Duration	Duration or Event	CLK2
4	prefetch_compulsory_count	ARP32_Pcache	Pulse	Duration	CLK2
5	Prefetch_lookahead_count	ARP32_Pcache	Pulse	Duration	CLK2
6	prefetch_hit_count	ARP32_Pcache	Pulse	Duration	CLK2
7	line_buffer_hit_count	ARP32_Pcache	Pulse	Duration	CLK2
8	Prefetch_line_count	ARP32_Pcache	Pulse	Duration	CLK2

**Table 8-30. SCTM Events (continued)**

SCTM Event	Name	Source	Type	SCTM Mode	Clock
9	prefetch_discard_stall	ARP32_Pcache	Duration	Duration or event	CLK2
10	tpcc_aet	EDMA	Duration	Duration or event	CLK2
11	arp32_int4	INTC	Duration	Duration or event	CLK2
12	arp32_int5	INTC	Duration	Duration or event	CLK2
13	arp32_int6	INTC	Duration	Duration or event	CLK2
14	arp32_int7	INTC	Duration	Duration or event	CLK2
15	vcop_busy	VCOP	Pulse	Duration	CLK2
16	vcop_idle_and_done	VCOP	Pulse	Duration	CLK2
17	vcop_wait_for_arp32	VCOP	Pulse	Duration	CLK2
18	vcop_arp32_awaits	VCOP	Pulse	Duration	CLK2
19	vcop_overhead	VCOP	Pulse	Duration	CLK1
20	vcop_ld_stall_by_st	VCOP	Pulse	Duration	CLK1
21	vcop_op_stall_by_ldst	VCOP	Pulse	Duration	CLK1
22	vcop_op_stall_by_dependency	VCOP	Pulse	Duration	CLK1
23	vcop_rd_ibuf1	VCOP	Pulse	Duration	CLK1
24	vcop_rd_ibufh	VCOP	Pulse	Duration	CLK1
25	vcop_rd_wbuf	VCOP	Pulse	Duration	CLK1
26	vcop_wr_ibuf1	VCOP	Pulse	Duration	CLK1
27	vcop_wr_ibufh	VCOP	Pulse	Duration	CLK1
28	vcop_wr_wbuf	VCOP	Pulse	Duration	CLK1
29	vcop_loop_start	VCOP	Edge	Event	CLK2
30	vcop_done	VCOP	Edge	Event	CLK2
31	arp32_nmi	INTC	Duration	Duration or event	CLK2
32	arp32_int8	INTC	Duration	Duration of event	CLK2
33	arp32_int9	INTC	Duration	Duration of event	CLK2
34	arp32_int10	INTC	Duration	Duration of event	CLK2
35	arp32_int11	INTC	Duration	Duration of event	CLK2
36	arp32_int12	INTC	Duration	Duration of event	CLK2
37	arp32_int13	INTC	Duration	Duration of event	CLK2
38	arp32_int14	INTC	Duration	Duration of event	CLK2
39	arp32_int15	INTC	Duration	Duration of event	CLK2

#### 8.1.3.17.2.4 SCTM Halt and Idle Modes

The SCTM module has a method for enabling and disabling counters based on whether the CPU is in debug-halt (SUSPEND) state or idle state (IDLE). This state information is provided from the ARP32 CPU to the SCTM module through the SUSPEND and IDLE inputs.

#### 8.1.3.17.3 SMSET

The SMSET allows tracing of key EVE subsystem events, as well as software messages from the ARP32 CPU. SMSET accepts software messages through its OCP target port, and accepts key system events through the system event input. These messages or events are queued locally in SMSET and written to the chip-level software trace module through the SMSET and EVE OCP debug initiator port. The system trace macrocell (STM) then traces these messages along with trace content with other chip-level agents. For details, see [Chapter 33, On-Chip Debug Support](#).

### 8.1.3.17.3.1 SMSET Configuration

Table 8-31 summarizes the SMSET configuration in EVEN. The SMSET module is configured to support both event and software message tracing, and supports cross-triggering. System events (that are not storable and can overflow) include a 4-deep buffer; and software events (that can be stalled and never overflow) support a 2-deep buffer.

**Table 8-31. SMSET Configuration in EVE**

Generic	SCTM Feature/Parameter Details	Value	In EVE Subsystem	Number on Device
NB_EVENTS	Number of system events	1 to 255	52	9
SW_MESSAGE	Software messages support	0 to 1	1	1
TRIG_MIN_WIDTH	Minimum trigger input pulse (L4 cycles)	1 to 8	2	2
EVENTS_BUF_DEPTH	System events buffer depth	1 to 16	4	4
SW_BUF_DEPTH	Software message buffer depth	0 to 16	2	2

### 8.1.3.17.3.2 SMSET Event Mapping

The SMSET events include higher-level start and end task events. Table 8-32 summarize the event mapping. Refer to the *EVE Programmer's Guide* for details on the functionality of each signal listed. Contact your TI representative for instructions how to access the *EVE Programmer's Guide*.

The SMSET module operates at the CLK2 rate.

The SMSET traces events on either a high-to-low transition or low-to-high transition, but not both. Thus, the EDMAs tpcc\_aet signal is not directly compatible with SMSET tracing. The tpcc\_aet is an active-high signal that is used to measure the duration of a specific EDMA transfer. The tpcc\_aet signal is programmed (in EDMA CC MMRs) to go high when a specific trigger is detected and to go low when a specific completion code is received. EVE logic implements custom tpcc\_aet\_start and tpcc\_aet\_end signals. The tpcc\_aet\_start signal pulses high (for one cycle) when tpcc\_aet transitions to high, and the tpcc\_aet\_end signal pulses high (for one cycle) when tpcc\_aet transitions to low.

The Type column in Table 8-32 lists the functional characteristics of the source signal (Pulse, Duration, or Edge).

The Pulse signals are expected to be driven active one cycle for each occurrence. A sequence of consecutive active cycles represent multiple occurrences. Duration mode of SCTM makes sense for this type of signal where the duration implies the number of occurrences in a particular state (for example, the number of cache hits).

The Duration type represents a signal that may stay active for multiple cycles on a given occurrence. These are typically stall signals where the user is trying to determine the number of cycles in the stalled state. Duration mode indicates the total time stalled. Event mode will indicate the number of unique occurrences of stalls. "Event" is useful in this case because there will always be a deassertion between occurrences.

An Edge signal goes active for undefined period of time but is goes inactive before the next occurrence. Event mode of the SCTM must be used for these signals.

**Table 8-32. List of SMSET Events**

SMSET Event	Name	Source	Type	SMSET Mode	Clock
0	tpcc_aet_start	EDMA	Pulse	Duration	CLK2
1	tpcc_aet_stop	EDMA	Pulse	Duration	CLK2
2	arp32_int4	INTC	Duration	Duration or event	CLK2
3	arp32_int5	INTC	Duration	Duration or event	CLK2
4	arp32_int6	INTC	Duration	Duration or event	CLK2
5	arp32_int7	INTC	Duration	Duration or event	CLK2

**Table 8-32. List of SMSET Events (continued)**

SMSET Event	Name	Source	Type	SMSET Mode	Clock
6	vcop_loop_start	VCOP	Edge	Event	CLK2
7	vcop_done	VCOP	Edge	Event	CLK2
8	arp32_nmi	INTC	Duration	Duration or event	CLK2
9	arp32_int8	INTC	Duration	Duration or event	CLK2
10	arp32_int9	INTC	Duration	Duration or event	CLK2
11	arp32_int10	INTC	Duration	Duration or event	CLK2
12	arp32_int11	INTC	Duration	Duration or event	CLK2
13	arp32_int12	INTC	Duration	Duration or event	CLK2
14	arp32_int13	INTC	Duration	Duration or event	CLK2
15	arp32_int14	INTC	Duration	Duration or event	CLK2
16	arp32_int15	INTC	Duration	Duration or event	CLK2

### 8.1.3.18 EVE L2\_FNOC Interconnect

A level 2 (L2) Interconnect from Arteris - FlexNoC® is instantiated in the EVE subsystem.

#### 8.1.3.18.1 EVE L2\_FNOC Flag Mux and Error Log Registers

The EVE\_L2\_FNOC flagmux and error log registers are used for error logging and flag muxing purposes. The status information stored in them can be used to resolve issues related to EVE\_NoC access conflicts, debugging, and so forth. The related registers are described in [Section 8.1.5.3 EVE L2\\_FNOC Register Summary and Description](#). For more information on flag muxing and error logging, see [Section 14.2.3.8 L3\\_MAIN Interconnect Error Handling](#) in [Section 14.2 L3\\_MAIN Interconnect](#).

## 8.1.4 EVE Programming Model

### 8.1.4.1 Boot

The EVE boot process follows:

1. EVEn\_RST and EVEn\_CPU\_RST (n = 1, 2) are asserted for a minimum of 16 cycles.
2. Host processor (through PRCM) deasserts eve\_rst\_n (eve\_arp32vcop\_rst\_n remains asserted). This lets the system access EVE-level memories/MMRs through the OCP target bus while ARP32 remains in reset.
3. Host processor initializes EVE state:
  - a. Enable parity generation for EVE memories: clear DMEM, WBUF, IBUF memories to initialize parity state (optional and can be handled at runtime by ARP32).
  - b. Load ARP32 code and data into desired memories:
    - i. Code is typically in EMIF/DDR memory, but can be any valid chip-level memory.
    - ii. Data is typically in EVE DMEM, but can also be in EMIF/DDR or other chip level memory
  - c. Initialize MMU TLB and related page tables: A translation must exist for address 0h because ARP32 boot vector is always at 0h (for MMU programming model see [Chapter 20, Memory Management Unit](#)).
  - d. Load VCOP memories: Ownership defaults to non-VCOP so no extra steps are required (optional and can be handled at runtime by ARP32).
  - e. Initialize EDMA, INTC (optional and can be handled at runtime by ARP32).
4. Host processor (through PRCM) deasserts eve\_arp32vcop\_rst\_n
5. ARP32 initializes EVE state, for steps not handled by host processor:
  - a. Configure EDMA.
  - b. Configure interrupt controller: Enable all error-related interrupts.

- c. Enable parity on all memories: Scrub memories to initialize parity state.
  - d. Initialize VCOP working buffers.
6. ARP32 manages ping-pong processing:
- a. Page in input buffers through EDMA.
  - b. Assign memory ownership of I/O buffers to VCOP or EDMA/SYS.
  - c. Page out output buffers through EDMA.
  - d. Initialize VCOP program.
  - e. Wait for VCOP completion, EDMA input paging completion, and EDMA output paging completion.

#### 8.1.4.2 Task Change and Program Cache Prefetch

The ARP32 switches tasks in a number of ways. In this context, a task represents a unit of program flow that typically executes for many ping-pong time slices and represents a code section that is typically 16k to 32k long.

##### 8.1.4.2.1 Simple or Unoptimized Branch to New Task

In the simplest case, the ARP32 branches to the new code section. The existence of program cache provides reasonable performance, especially if the new task program code is cache friendly and is executed a number of times before the next task switch occurs.

### 8.1.4.2.2 Prefetch, Wait, then Branch to New Task

To optimize the task switch efficiency, use the software-directed preload operation. In this case:

- Complete with the current task.
- Execute a Software directed preload command (as described in [Section 8.1.3.4.3](#), Software Direct Preload).
- Wait for preload completion.
- Branch to the new address.

Given that the cache view and system view of the program address are still the same, there are no additional overhead and constraints.

### 8.1.4.2.3 Hidden Prefetch

If any two tasks are small enough to fit in program cache, software uses SDP to fetch the contents of the next tasks into program cache while operating on the current task. If that program cache is direct mapped, extra care must be taken to ensure that any two tasks do not reside in the same modulo-32k range of memory.

### 8.1.4.3 Interrupts

The following pseudocode describes a typical and simple workflow for ARP32 to service pending interrupts. This flow is not the only possible sequence and is not meant to represent a mandated software sequence:

1. ARP32 enables and maps interrupts:
  - a. Enable ARP32 global interrupt enable (ARP32.CSR.GIE).
  - b. Enable ARP32 nonmaskable interrupts (ARP32.IER.NMIE).
  - c. Enable ARP32 interrupt inputs (ARP32.IER[n]).
  - d. Map EVE-level interrupts to the appropriate ARP32 interrupt input (ARP32\_INTn\_IRQENABLE\_SET).
2. When interrupt is asserted, ARP32 branches into interrupt vector code:
  - a. ARP32 hardware clears the GIE bit, new interrupts are ignored
  - b. ARP32 software reads ARP32\_INTn\_IRQSTATUS
  - c. Clear to be serviced interrupts in ARP32\_INTn\_IRQSTATUS (by issuing write of 1)
  - d. For each pending interrupt in ARP32\_INTn\_IRQSTATUS:
    - i. ARP32 software reads IP interrupt status (<IP\_INT>\_IRQSTATUS)
    - ii. For each pending interrupt in <IP\_INT>\_IRQSTATUS:
      1. May not be necessary for pulsed or timer type interrupts.
      2. Perform functional operations necessary to service interrupt.
      3. Clear IP source interrupt status (by setting correct bit in <IP\_INT>\_IRQSTATUS to 1).
      4. Ideally, only exit loop after <IP\_INT>\_IRQSTATUS is all 0s.
    - iii. Only exit loop after <IP\_INT>\_IRQSTATUS is all 0s
  - e. ARP32 software returns from interrupt through BIRP (branch interrupt return pointer) instruction: ARP32 hardware sets the GIE bit (by copy of SCSR to CSR, new interrupts are enabled) and clears IFRn.

For ARP32 register and state details (especially for CSR, GIE, and SCSR functionalities), see the *ARP32 CPU and Instruction Set Reference Guide*.

#### 8.1.4.4 Safety Considerations

This section highlights the known hardware that must be enabled in a safety-conscious system, and specific software techniques that increases the level of safety of EVE.

##### 8.1.4.4.1 Memory Error Detection

Memory error detection provides hardware to detect single-bit errors in data memories (DMEM, WBUF, and IBUF) and detect double-bit errors in program memories. This hardware can capable detect stuck-at faults, as well as radiation-induced soft errors.

- For data memories, to avoid false error signaling, memories must be initialized with known values before reading those memories. See [Section 8.1.3.3.6, Memory Error Detection](#).
- All sources of error detection error interrupts must be enabled. See [Section 8.1.3.3.6, Memory Error Detection](#), and [Section 8.1.3.10.1, EVE Interrupt Sources – Memory Switch and Parity Error Interrupts](#).
- Software must be tested at development time to ensure robust response to random errors. See [Section 8.1.3.3.6.3, Parity Error Testability](#).
- Software must be tested at runtime to ensure hardware is properly operating. See [Section 8.1.3.3.6.3, Parity Error Testability](#).

##### 8.1.4.4.2 MMU

The MMU is configured to minimize the view of system memory that ARP32 and EDMA are allowed to access. This prevents either coding bugs or faulty hardware from impacting other critical areas of the system, such as the system host code and data sections. For detailed explanation of the MMU and its programming, see [Chapter 20, Memory Management Unit \(MMU\)](#).

##### 8.1.4.4.3 Firewall

The system firewall is used to prevent access by unintended system initiators from accidentally modifying EVE memory; or accesses from intended system initiators to unintended EVE memory. For firewall configuration see [Section 14.2, Interconnect](#).

##### 8.1.4.4.4 Interconnect

The EVE detects accesses to reserved locations in the memory-map and informs the system.

##### 8.1.4.4.5 Application Stability/Sequencing

The Mailbox module or the local EVE SMSET module can be leveraged to report either heartbeat or sequence messages to the system host. By sending deterministic messages, the host ARM verifies that EVE is still active and following a reasonable path of code execution.

##### 8.1.4.4.6 Interrupt Servicing

ISRs are implemented to count the expected number of interrupts (for example, EDMA, mailbox, timer) and check for extra or missing interrupts where possible. For example, if the [ARP32\\_INTn\\_IRQSTATUS\[31:0\] EVENT](#) bit field is set, then at least one of the source registers is set as well. Or, if an EDMA interrupt is received, then at least one of the CIPR bits is set. For EDMA interrupts, software tracks DMAs submitted versus DMAs completed.

### 8.1.5 EVE Subsystem Register Manual

#### 8.1.5.1 EVE Instance Summary

[Table 8-33](#) lists EVE instances.

**Table 8-33. EVE Instance Summary**

Module Name	Base Address	Size
EVE1	0x4200 0000	4KiB
EVE1_DSP <sup>(1)</sup>	0x0200 0000	4KiB
EVE2	0x4210 0000	4KiB
EVE2_DSP <sup>(1)</sup>	0x0210 0000	4KiB
EVE1_L2_FNOC <sup>(2)</sup>	0x0208 A000	1024 Bytes
EVE2_L2_FNOC	0x4218 A000	1024 Bytes

<sup>(1)</sup> Address space is NOT visible on L3\_MAIN for the device. It is visible only within the DSP\_ICFG internal configuration space, hence accessible only by the DSP C66x CPU.

<sup>(2)</sup> Address space is NOT visible on L3\_MAIN for the device.

### 8.1.5.2 EVE Register Summary and Description

#### 8.1.5.2.1 EVE Register Summary

Table 8-34 summarizes the EVE registers.

**Table 8-34. EVE Register Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	EVE1 Physical Address L3 Interconnect	EVE1_DSP Physical Address DSP private	EVE2 Physical Address L3 Interconnect	EVE2_DSP Physical Address DSP private

RESERVED																STANDBYMODE		IDLEMODE		FREEEMU		SOFTRESET									

Bits	Field Name	Description	Type	Reset
31:6	RESERVED	Reserved. Read returns 0s	RW	0x0000
5:4	STANDBYMODE	00: Force-Standby mode: This mode is a backup mode intended to be used only if the smart-idle mode is bugged. When in this mode / the SAF asserts with minimal hardware condition the status saying : I am in standby:. It is the responsibility of the software to ensure that the SAF is in a correct quiet state before programming this mode. Additionally when in this mode / the SAF is not allowed to generate wakeup reques . 01: No-Standby: This mode is a backup mode intended to be used only if the smart-idle mode is bugged. When in this mode / the SAF never asserts the status declaring that the system is in standby. 10: Smart-Standby: default. EVE generates the standby status based upon all hardware internal status / namely after having performed all hardware operations necessary to be in a correct quiet state. Additionally when in this mode / the SAF is not allowed to generate wakeup request. 11: Smart-Standby-Wkup: Same as Smart-Standby. (EVE generates the standby status based upon all hardware internal status / namely after having performed all hardware operations necessary to be in a correct quiet state ) . . Additionally when in this mode / the SAF is allowed to generate wakeup request	RW	0x0
3:2	IDLEMODE	00: Force-idle: This mode is a backup mode intended to be used only if the smart-idle mode is bugged. When in this mode the IAF acknowledges a request to go idle from the power manager with minimal hardware condition. It is the responsibility of the software to ensure that the IAF are in a correct quiet state before requesting a force-idle transition. Additionaly when in this mode the IAF is not allowed to generate any wakeup request. 01: No-idle: When in this mode the IAF disregards any request to go idle from the power manager. 10: Smart-idle: default mode. default. When in this mode / the IAF acknowledges a request to go idle from the power manager after having performed all hardware operations necessary to be in a correct quiet state. Additionally when in this mode / the IAF is not allowed to generate any wakeup reques 11: SmartIdleWkup : When in this mode / the IAF acknowledges a request to go idle from the power manager after having performed all hardware operations necessary for the IAF to be in a correct quiet state. Additionally when in this mode / the IAF is allowed to generate wakeup request	RW	0x0

## 8.1.6 Subsystem Counter Timer Module

### 8.1.6.1 Introduction

#### 8.1.6.1.1 Overview

As the complexity of SoC architectures increases, system and subsystem optimization requires increased visibility into the frequency and duration of events within the system. One way to address these profiling requirements is to embed dedicated event or profile counters in all functional modules with profiling requirements. While this can address the fundamental requirements, there are several disadvantages to this approach:

- System architects must determine the detailed profiling requirements very early in the specification process.
- These dedicated profiling resources are generally quite similar across functional blocks so the redundant function introduces gate/area penalties in each functional module.
- Embedded profiling resources are harder to optimize out of subsequent system revisions when profiling requirements may be less prevalent.
- The embedded resources may have different configuration and control interfaces and this increases the difficulty of providing unified profiling data from all modules in a subsystem.

This section defines the functional specification for a generic counter timer module that can be instantiated within the processor subsystem and that also functions as a centralized profiling module for the entire subsystem. This module maps a large number of system and subsystem event signals to a smaller number of counter resources. Some of the counter resources in the module can be configured for timer functionality where system and/or debug events can be generated when designated intervals are matched.

In the EVE subsystem eight 32-bit counters are instantiated. Two of those eight counters can be configured as timers.

The generic centralized counter timer approach provides several advantages:

- Unified programmers view of all profiling resources within the subsystem
- Accessible by debug tools and application
- Parameterized synthesis for full configurability of the number of event inputs and counter resources
- A more flexible solution that lets designers tailor gate count to customer profiling requirements
- Standard configuration and control interfaces encourage reuse across subsystem modules within a complex SoC.
- In addition to profiling functions, resources in this module can be used to address normal application counter/timer functions, such as OS timers.

#### 8.1.6.1.2 Top-Level Requirements

The SCTM has the following top-level functional requirements:

- Counter timer resources:
  - A maximum of 32 counters can be instantiated in a single SCTM.
  - A maximum of eight of the counters can be instantiated with timer (event generation) functionality in addition to the base counter function.
- System event signal inputs:
  - A maximum of 127 event signal inputs can be supported by the SCTM.
  - Any of the system event signal inputs can be routed to any of the counter timer resources in the SCTM.
- Counter functionality:
  - The module contains a collection of 32-bit counters that can be chained to an adjacent counter for 64-bit capability.
  - The counters can be configured to operate with any one of the event signal inputs.

- The counters can be configured to operate in a free-running mode that counts the total number of clock cycles.
- The counters can operate in duration mode that counts the total duration in cycles that the assigned input signal is asserted.
- The counters can operate in event mode that counts the total number of times the assigned event signal is asserted.
- The counters can be configured to continue to run or to temporarily stop when the CPU enters the debug halt state.
- The counters can be configured to continue to run or to temporarily stop when the CPU enters the IDLE state.
- Timer functionality:
  - Timers have all the functionality of counters.
  - Timers have a 32-bit interval match register.
  - Timers can be configured to generate an interrupt event when the counter matches the interval register.
  - Timers can be configured to generate a debug event when the counter matches the interval register.
  - The timers can be configured to run to the interval register once or to reinitialize each time the interval counter is matched.
- System Trace Interface:
  - The counter state dump can be configured as periodic or may be generated under application control.

### 8.1.6.1.3 Configuration

Table 8-266 lists the configuration of the SCTM in EVE.

**Table 8-266. SCTM Configuration**

Generic	SCTM Feature/Parameter Details	Value	Number on Device
CTM_NUMINPT	Number of event input signals supported	0 to 127	31
CTM_NUMCNTR	Number of counters in the module	1 to 32	8
CTM_NUMTIMR	Number of timers	0 to 8	2
CTM_TIMINTPOLARITY	Timer interrupt polarity	0 = Active low 1 = Active high	1
CTM_TIMINTWIDTH	Timer interrupt pulse width	1 or more	2
CTM_NUMSTM	Number of counters for STM export	0-32	0
CTM_CCMAVAIL	CCM frame export available	0 = No 1 = Yes	0
CTM_NUMDBGSGL	Number of debug event signals	0-8	0
CTM_ASYNCIDLEREQ	Whether IDLE request is asynchronous signal	0 = No 1 = Yes	0
CTM_CNTR_CHAINSHADOW	Atomicity feature for even-indexed counters	One per counter. 0 = No chain shadow feature 1 = Chain shadow feature in counter chain mode	Counter numbers 2 and 4 have the chaining feature.

### 8.1.6.1.4 Block Diagram

Figure 8-21 represents a block diagram for the Counter Timer Module.

Figure 8-21. SCTM Block Diagram

### 8.1.6.2 Functional Description

The SCTM is a generic profile counter and timer module that can integrate these functions into a single module in a subsystem.

#### 8.1.6.2.1 Configuration Interface

The SCTM has an OCP 2.1-compliant slave interface for configuring and controlling the module. For a detailed description of the register file and the individual registers, see [Section 8.1.6.4](#), SCTM Register Manual. The configuration interface has the following basic functional requirements:

- Any unimplemented configuration memory space:
  - Generates a bus error on application read or write
  - Generates a bus error on debug read
  - Returns 0s and no bus error on debug read
- Any write to a read only register (application or debug) generates a bus error.

### 8.1.6.2.2 Counter Function

#### 8.1.6.2.2.1 Input Events

Any signal of interest from within the subsystem can be routed to this module and used to control the counters and timers in the module. The routing of the input events from the module boundary to an individual counter is accomplished through an input event multiplexer and is controlled by the INPSEL bit field in the CTCR\_WT\_j or CTCR\_WOT\_j register.

The SCTM supports a maximum of 127 input events. The details of the input events for a particular device are detailed in a device-specific appendix to this specification. Application and debug software can determine the number of counters in the SCTM by reading the NUMINPT field in the [SCTM\\_CTCNTL](#) register.

#### 8.1.6.2.2.2 Counters

The individual 32-bit counters in the SCTM count when the input event signals are asserted. The SCTM supports a maximum of 32 counters. The counter configuration for a particular device is detailed in a device-specific appendix to this specification. Application and debug software can determine the number of counters in the SCTM by reading the NUMCNTR field in the [SCTM\\_CTCNTL](#) register.

#### 8.1.6.2.2.3 Counting Mode

Counters function in one of two mutually exclusive counting modes:

- Event mode – The counter increments each time a rising edge is detected on the designated input event signal.
- Duration mode – The counter continually increments when the event input is asserted.

The DURMOD bit in the SCTM\_CTCR\_WT\_j or SCTM\_CTCR\_WOT\_j register controls operating mode of the counter.

#### 8.1.6.2.2.4 Counter Overflow

When the counter reaches the terminal value (FFFF FFFFh) it wraps and continues to increment. This condition is considered a timer overflow condition and the OVRFLW bit in the SCTM\_CTCR\_WT\_j or SCTM\_CTCR\_WOT\_j register indicates that overflow has occurred. The overflow bit can be cleared by reading the SCTM\_CTCR\_WT\_j or SCTM\_CTCR\_WOT\_j register. When chained, only the high-order counter (bits 63:32) can overflow.

#### 8.1.6.2.2.5 Counters and Processor State

The counters can be configured to alter their behavior based on the state of the CPU in the subsystem supported by the SCTM. The FREE bit in the SCTM\_CTCR\_WT\_j or SCTM\_CTCR\_WOT\_j register determines if the counter continues to operate when the processor enters the debug-halt state. When this bit is 0 (the default), the counter stops incrementing while the debug-halt input from the CPU is asserted. Normal operation resumes when the processor exits the debug halt state and the debug-halt input is deasserted. When the FREE bit is 1, the state of the debug-halt input is not used to control counter operation.

The IDLE bit in the SCTM\_CTCR\_WT\_j or SCTM\_CTCR\_WOT\_j register determines if the counter continues to operate when the processor enters the IDLE state (the processor is no longer executing instructions and is waiting for a wakeup event). When this bit is 0 (the default), the counter stops incrementing while the IDLE state input from the CPU is asserted. Normal operation resumes when the processor exits the idle state and the idle state INPUT is deasserted. When the IDLE bit is 1, the state of the idle input does not control counter operation.

Not all subsystems may contain a processor or the subsystem processor may not support debug halt and/or idle modes. In this case, the processor state inputs to the SCTM are tied to the inactive value.

When there are multiple CPUs in a subsystem, the processor state inputs can be sourced from a single processor, or they can be the logical OR of the processor state signals from all CPUs in the subsystem.

### 8.1.6.2.2.6 Chaining Counters

The individual 32-bit counters in the SCTM can be chained with an adjacent counter to form a 64-bit counter. Counters can be chained to a counter across an even-odd index boundary with the even counter containing the least-significant 32-bits of the 64-bit pairing. For example, when counters 1 and 0 are paired, counter 1 contains bits 63:32 and counter 0 contains bits 31:00. The higher-order counter increments by 1 each time the lower order counter wraps.

Counters are chained by setting the CHAIN bit in the SCTM\_CTCR\_WT\_j or SCTM\_CTCR\_WOT\_j register for both of the counters. When chained, the counter control for both counters is taken from the lower-order SCTM\_CTCR\_WT\_j or SCTM\_CTCR\_WOT\_j register. Other than CHAIN, all the other bits in the higher-order SCTM\_CTCR\_WT\_j or SCTM\_CTCR\_WOT\_j register are ignored.

Chained counters can function in counter mode only. Timer mode is not supported.

#### 8.1.6.2.2.6.1 Reading Chained Counters

Some applications may require atomic reads of the 64 bits of a chained counter pair. An SCTM instance can be configured at synthesis time to provide an atomic read capability for one or more 64-bit counter pairs. When this capability is present, the designated counter pair provides atomic access when the correct read sequence is performed.

So when a chained counter has atomic read capability, an atomic counter value can be obtained by first reading the high-order counter followed by the low-order counter. Always observe this ordering, to prevent reading stale counter values from the low-order counter.

The shadow feature for chained counters is active only when the low-order counter is chained to a high-order counter. When functioning independently, the shadow feature is deactivated and a read of the counter always returns the current value.

To prevent sync errors introduced by the debugger, only application accesses activate the shadow feature. Debug qualified accesses always return the current value of the low-order counter, regardless of configuration.

#### 8.1.6.2.2.7 Enabling and Disabling Counters

After the counter is correctly configured, the counter can be started by setting the ENBL bit in the corresponding SCTM\_CTCR\_WT\_j or SCTM\_CTCR\_WOT\_j register. At this point, the counter begins incrementing under the control of the configured event input. The counter can be disabled (counting stops) at any time by clearing ENBL. Counters can be enabled and disabled dynamically during application flow.

Counters can also be enabled and disabled as groups through the [SCTM\\_CTGNBL0](#) registers. These registers provide control of the individual counter enables in groups of 32. This allows an application to enable or disable groups of counter in lockstep.

#### 8.1.6.2.2.8 Resetting Counters

The counters can be reset to their initial value (0000 0000h) by setting the RESET bit in the SCTM\_CTCR\_WT\_j or SCTM\_CTCR\_WOT\_j register to 1. If the counter is chained, both the high-order and low-order counters are reset when the RESET bit is set in the CTCR<sub>n</sub> for the low-order counter.

Counters can also be reset as groups through the SCTM\_CTGRSTL0 register. These registers provide control of the individual counter reset in groups of 32. This control lets an application reset groups of counters in lockstep.

### 8.1.6.2.3 Timer Function

A subset of the counters modules in the SCTM can function as timers. When operating as timers, interrupts and/or debug input events are generated when the counter value reaches a designated interval. The counters with timer capabilities always occupy the lowest indexed counters in the SCTM. A maximum of eight counters can function as timers in SCTM v1. The actual number for a particular implementation of the SCTM is configured at synthesis time. The number of timers in a particular device is detailed in a device-specific appendix to this specification. Application and debug software can determine the total number of counters with timer capabilities reading the NUMTIMR field in the [SCTM\\_CTCNTL](#) register.

### 8.1.6.2.3.1 Periodic Intervals

The interval for a timer is contained in the `SCTM_TINTVLR_j` register. There is a `SCTM_TINTVLR_j` register for every timer capable counter in the SCTM. Timers are initialized to 0. When the corresponding `CTCNTRn` increments and matches the values designated in `SCTM_TINTVLR_j`, the timer is considered to be triggered and events configured in `SCTM_CTCR_WT_j` or `SCTM_CTCR_WOT_j` are generated.

Timers can function in one of two mutually exclusive modes:

- Run once mode – The timer stops after the first interval match and is not re-enabled until the timer is reset to the initial value (0) by setting the RESET bit in the `SCTM_CTCR_WT_j` and `SCTM_CTCR_WOT_j` register to 1.
- Restart mode – The timer automatically resets to the initial value (0) each time the designated interval is reached.

### 8.1.6.2.3.2 Event Generation

Timers are able to generate both interrupts and debug events. Interrupts are routed from the module boundary to INTC in the subsystem. Debug events are routed as triggers to debug logic within the subsystem. It is assumed that these debug trigger events are merged with other debug resources and used to control debug activity like CPU control or trace.

The generation of the interrupts is controlled by the INT bit in the `SCTM_CTCR_WT_j` or `SCTM_CTCR_WOT_j` register. The generation of debug events is controlled by the DBG in the `CTCRn`. Both INT and DBG can be set simultaneously and both signals are generated on interval match.

For debug events, the pulse width is one cycle and the active polarity is high (a high going pulse of one cycle). For interrupts, the polarity and duration of the pulse are synthesizable options that can be tailored to the requirements of the INTC in the subsystem.

If neither the INT nor the DBG bit is set, the timer function is disabled and the counter functions as a regular counter.

The SCTM events include low-level stall and duration signals sourced by various components of the EVE subsystem. The primary categories include program cache-related signals and VCOP-related signals. [Table 8-267](#) summarized the event mapping. Event inputs start numbering at 1, because event0 is reserved and the SCTM internally uses the functional clock as event 0.

The SCTM module operates at the CLK2 rate (nominally 250 to 300 MHz). The event sources include CLK2 and CLK1 ( $CLK1 = 2 \times CLK2$ ) signals. The CLK2 relative signals are connected directly to the SCTM. The CLK1 relative signals are conditioned by EVE level logic to scale from CLK1 to CLK2. Because these are duration type signals, EVE logic asserts a CLK2 pulse for every two CLK1 pulses detected. This results in, at most, one CLK1 cycle of inaccuracy in the CLK2 duration reported by SCTM.

**Table 8-267. List of SCTM Events**

SCTM Event	Name	Source	Type	SCTM Mode	Clock
1	cache_miss_count	ARP32_Pcache	Pulse	Duration	CLK2

### 8.1.6.2.3.3 Watchdog Timer Function

A normally configured timer supports a software watchdog capability in which software can continually reset the timer by writing to the SCTM\_CTCR\_j[1] RESET bit or to the corresponding bit in the [SCTM\\_CTGRST0](#) register before the interval expires (and the interrupt is generated).

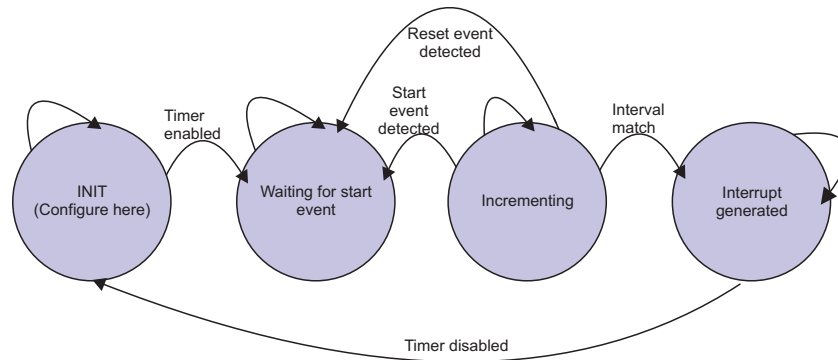

The timers also support a hardware watchdog function where selected input events can start and reset the timers without software interaction.

When hardware watchdog mode is enabled, the SCTM\_CTCR\_WT/WOT\_j[23:16] INPSEL bit field selects the event that starts a WD timer. Once the input event is selected, the timer increments using the functional clock. If it reaches the interval match value before being reset, the interrupt is generated.

The WD timer is reset when an input event is detected. This resets the counter to 0. The counter does not restart until another input event is detected. The state-machine shown in [Figure 8-22](#) illustrated the functional operation of the timer when configured for hardware watchdog mode.

Some important notes about WD timer mode operation:

- The INPSEL field selects the WD start event. This is always a rising edge event.
- The DURMODE bit is overridden. Once started, the timer continues to increment using the functional clock.

**Figure 8-22. Watchdog Operation**

### 8.1.6.2.4 System Trace Integration

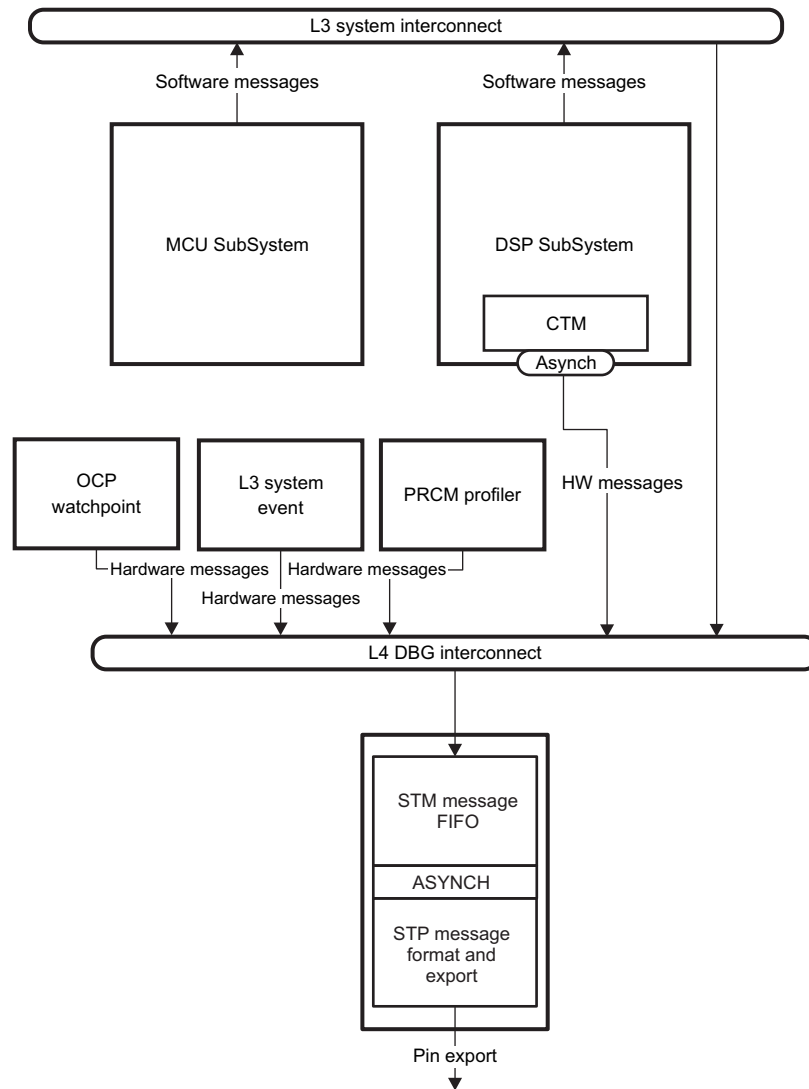

#### 8.1.6.2.4.1 Overview

Many devices have system-level trace capabilities. This capability is generally implemented in a top-level module called the STM. The STM collects software and hardware messages (the trace data) from various other system modules and subsystems through a dedicated STM bus (OCP compliant). The STM then formats these high-level trace messages into streams of MIPI® system trace protocol (STP) compliant messages. The STP messages are then transmitted to a dedicated STP receiver over a narrow (generally four pins), high-speed export interface.

The SCTM has an optional mode that provides an STM OCP interface and a mode where the state of the counters can be transferred through the STM.

Figure 8-23 shows a typical STM system configuration with the SCTM as a hardware master. The hardware master messages from the SCTM STM bus enter the L4 debug interconnect through an asynchronous bridge. Other system-level hardware masters are also writing messages to the STM through this interconnect. Software messages from applications running on the MCU or DSP to reach the STM message buffer through a bridge from L3 interconnect to the L4 interconnect. The STM orders and formats the high-level hardware and software messages into STP protocol messages and exports them to an off-chip trace receiver.

Figure 8-23. Typical STM System Integration

#### 8.1.6.2.4.2 STM Configuration

Because the STM function of the SCTM is an optional feature, the NUMSTM bit in the SCTM\_CTCNTL register is read to determine if any counters are available for STM export:

- If the value in NUMSTM is 0, there is no STM capability in the module.
- If the value is greater than 0 ( $N \leq$  the total counters in the module), then the first N counters can also be designated for STM export.

The STM capability of the SCTM is enabled by setting the ENBL bit in the [SCTM\\_CTSTMCNTL](#) register to 1.

#### 8.1.6.2.4.2.1 Periodic Counter State Export

The general operating mode of the SCTM STM function is to periodically export a message frame that provides a snapshot of the state of each counter designated for inclusion in the STM counter state message. The length of the snapshot interval is controlled by a programmable counter. The interval for this counter is determined by the value in the SCTM\_CTSTMINTVL<sub>i</sub> register. A periodic counter is reloaded with this value. The counter decrements using the functional clock of the SCTM. When the counter decrements to 0, a snapshot of all the designated counters is taken for STM export and the counter is reloaded using the value in CTSTMINTVL. If the value in CTSTMINTVL is 0, periodic message export is disabled.

Because an entire snapshot of data must be captured when an interval expires, the SCTM must have temporary storage for all the counter values that are designated for export.

#### 8.1.6.2.4.2.2 Application Control of Counter State Export

Application software can also independently trigger the export of a CSM frame bsetting the CSMXPORT bit in the CTSTMCNTL register to 1.

- When the bit is set to 1, a snapshot is captured and a CSM frame is exported.
- Software-triggered export is available only when periodic export is not active; writing 1 when periodic export is active has no effect.
- The SW bit in the CSM header designates that this frame is generated by software.

#### 8.1.6.2.4.2.3 Application Control of the Counter Configuration Export

The STM system also supports an optional counter configuration message (CCM). The capability for generating this message is a synthesizable option. If the module has been synthesized to support CCM, the SCTM\_CTSTMCNTL[3] CCMAVAIL bit is asserted.

Export of the CCM message frame is only triggered by setting the CCMXPORT bit in the CTSTMCNTL register to 1.

- When 1 is written, a snapshot is captured and a CCM frame is exported.
- Software-triggered export is available only when periodic export is not active; writing 1 when periodic export is active has no effect.

### 8.1.6.3 Use Case Examples

This section contains high-level examples of the programming sequences for common SCTM user scenarios. The following examples assume that the counter timer module is already enabled by setting the ENBL bit in the SCTM\_CT CNTL register to 1. The examples also assume that the CTCR<sub>n</sub>:ENBL bit is cleared before any configuration writes other than RESET.

#### 8.1.6.3.1 Counter Enable

##### 8.1.6.3.1.1 Enabling a Single Counter

Perform the following procedure to enable a single counter:

1. Reset the counter by setting the SCTM\_CTCR\_WOT<sub>j</sub>[1] RESET bit to 1.
2. Select which signal drives the counter function by writing the correct index to the SCTM\_CTCR\_WOT<sub>j</sub>[23:16]INPSEL bit field
3. Configure the sampling scheme to be used by the counter (edge/level) by writing to the SCTM\_CTCR\_WOT<sub>j</sub> [3]DURMODE bit (if required).
4. Set the behavior for system state by writing to the SCTM\_CTCR\_WOT<sub>j</sub>[5]IDLE and SCTM\_CTCR\_WOT<sub>j</sub>[4] FREE bits (if required).
5. Start the counter function by setting the SCTM\_CTCR\_WOT<sub>j</sub>[0] ENBL bit to 1.

#### **8.1.6.3.1.2 Reading a Single Counter**

Perform the following procedure to read a single counter:

1. Read the value of the counter through the CTCNTR\_k register.
2. Read the corresponding SCTM\_CTCR\_WOT\_j[6] OVRFLW bit to determine if the counter has wrapped since the last read of the registers.
3. (Optional) The counter can then be reset by setting the SCTM\_CTCR\_WOT\_j[1] RESET bit to 1.

#### **8.1.6.3.1.3 Enabling a Group of Counters Simultaneously**

Perform the following procedure to enable a group of counters:

1. For each counter in the group:
  - a. Enable access to the SCTM by setting the [SCTM\\_CTCNTL\[0\] ENBL](#) bit to 1.
  - b. Select which signal drives the counter function by writing the correct index to the [SCTM\\_CTCR\\_WOT\\_j \[23:16\] INPSEL](#) bit field.
  - c. Configure the sampling scheme to be used by the counter (edge/level) by writing to the [SCTM\\_CTCR\\_WOT\\_j \[3\] DURMODE](#) bit (if required).
  - d. Set the behavior for system state by writing to the [SCTM\\_CTCR\\_WOT\\_j \[5\] IDLE](#) and [\[4\]FREE](#) bits (if required).
2. Start all counters in lockstep by writing to the CTGNBL0 register for all counters that are set to 1 in the group.

#### **8.1.6.3.1.4 Reading a Group of Counters Simultaneously**

Perform the following procedure to read a group of counters:

1. Read the [SCTM\\_CTGNBL0](#) register and save.
2. Clear the corresponding enable bit of each counter in the group to 0.
3. Write back the [SCTM\\_CTGNBL0](#) register content.
4. For each counter in the group:
  - a. Read the value of the counter through the [SCTM\\_CTCNTR\\_k](#) register.
  - b. Read the corresponding [SCTM\\_CTCR\\_WOT\\_j\[6\] OVRFLW](#) bit to determine if the counter has wrapped since the last read of the [SCTM\\_CTCR\\_WOT\\_j](#) register.
5. (Optional) Resume the group count by writing back the saved value of the [SCTM\\_CTGNBL0](#) register.

#### **8.1.6.3.1.5 Configuring a Chained Counter**

Perform the following procedure to configure a chained counter:

1. Select the counter pair to be used for chaining (N and N + 1).
2. Set the [SCTM\\_CTCR\\_WOT\\_j \[2\]CHAIN](#) bit of counter N + 1 to 1.
3. For the [SCTM\\_CTCR\\_WOT\\_j](#) register for counter N in the counter pair:
  - a. Select which signal drives the counter function by writing the correct index to the [SCTM\\_CTCR\\_WOT\\_j\[23:16\]INPSEL](#) bit field.
  - b. Configure the sampling scheme to be used by the counter (edge/level) by writing to the [SCTM\\_CTCR\\_WOT\\_j \[3\]DURMODE](#) bit (if required).
  - c. Set the behavior for system state by writing to the [SCTM\\_CTCR\\_WOT\\_j \[5\]IDLE](#) and [SCTM\\_CTCR\\_WOT\\_j \[4\]FREE](#) bits (if required).
  - d. Start the counter function by setting the [SCTM\\_CTCR\\_WOT\\_j\[0\] ENBL](#) bit to 1.

#### **8.1.6.3.2 Timer Enable**

This example assumes interrupt generation capabilities. Perform the following procedure to enable the timer:

1. Disable interrupts globally using the CPU INTM mask or some other global interrupt masking in the

target subsystem.

2. Select which signal drives the counter function by writing the correct index to the `SCTM_CTCR_WT_j[23:16]` INPSEL bit field.
3. Configure the sampling scheme to be used by the counter (edge/level) by writing to the `SCTM_CTCR_WT_j[3]` DURMODE bit (if required).
4. Set the behavior for system state by writing to the `SCTM_CTCR_WT_j [5]IDLE` and `[4] FREE` bits (if required).
5. If the timer function is continuous, set the `SCTM_CTCR_j[10]` RESTART bit to 1.
6. Set the `SCTM_CTCR_WT_j[8]` INT bit to 1.
7. Set the interval match value in the corresponding `SCTM_TINTVLR_j` register.
8. Enable the corresponding interrupt in the subsystem INTC.
9. Enable interrupts globally.
10. Start the counter function by setting the `SCTM_CTCR_WT_j[0]` ENBL bit to 1.

#### 8.1.6.3.3 Periodic STM Export Enable

Perform the following procedure to enable periodic STM export:

1. Configure, but do not enable, all the counters required for export per [Section 8.1.6.3.1](#), Counter Enable.
2. Enable the STM configuration capability by setting the `SCTM_CTSTMCNTL[0]` ENBL bit to 1.
3. Disable periodic export by writing 0000 0000h to the `SCTM_CTSTMINTVL` register.
4. (Optional) Change the hardware master ID by writing the new value to the `SCTM_CTSTMMSTID[6:0]` MASTID bit.
5. Tag which counters are selected for export by setting the corresponding bits.
6. Set the total number of counters tagged for export through a write to the `SCTM_CTSTMCNTL[11:6]` NUMEXPORT bit.
7. (Optional) To include overflow information in the CSM message, set the `SCTM_CTSTMCNTL[1]` SENDOVR bit to 1.
8. (Optional) To send a counter configuration message (CCM), set the `SCTM_CTSTMCNTL[4]` CCMEXPORT bit to 1.
  - a. This feature is only available if the `SCTM_CTSTMCNTL[3]CCMAVAIL` bit reads as 1.
  - b. Test for completion of the CCM export through the `SCTM_CTSTMCNTL[5]` XPORTACT bit.
9. Enable periodic export by writing the interval value to the `SCTM_CTSTMINTVL` register.
10. Enable the counters per [Section 8.1.6.3.1](#), *Counter Enable*.

#### 8.1.6.3.4 Disabling the SCTM

Perform the following procedure to disable the SCTM:

1. When periodic STM export is enabled:
  - a. Disable periodic export by writing 0000 0000h to the `SCTM_CTSTMINTVL` register.
  - b. Test for completion of the CCM export through the `SCTM_CTSTMCNTL[5]` XPORTACT bit.
  - c. Disable the STM function by writing 0 to the `SCTM_CTSTMCNTL[0]`ENBL bit.
2. Disable all counters by setting the `SCTM_CTGNBL0` register to 0000 0000h.
3. Disable the SCTM by setting the `SCTM_CTCNTL[0]` ENBL bit to 0.

## 8.1.7 Software Message and System Event Trace

### 8.1.7.1 Introduction

#### 8.1.7.1.1 Overview

The SMSET is a trace module used for monitoring key system events and transferring software messages. SMSET is performing arbitration between hardware messages and software messages written to the trace receiver through STM by the host processor. SMSET module provides various debug features such as: monitor system events, enable/disable event detection, Start/Stop event monitoring upon external trigger, time sampling, generating hardware message upon system event or every sampling window boundary and interleaving of hardware and software messages.

#### 8.1.7.1.2 Configuration

[Table 8-296](#) lists the configuration of the SMSET in the EVE subsystem.

**Table 8-296. SMSET Configuration**

Generic	SMSET Feature	Number on Device
NB_EVENTS	Number of system events	9
SW_MESSAGE	Software messages support	1
TRIG_MIN_WIDTH	Minimum trigger input pulse (L4 cycles)	2
EVENTS_BUF_DEPTH	System events buffer depth	4
SW_BUF_DEPTH	Software message buffer depth	2

#### 8.1.7.1.3 Block Diagram

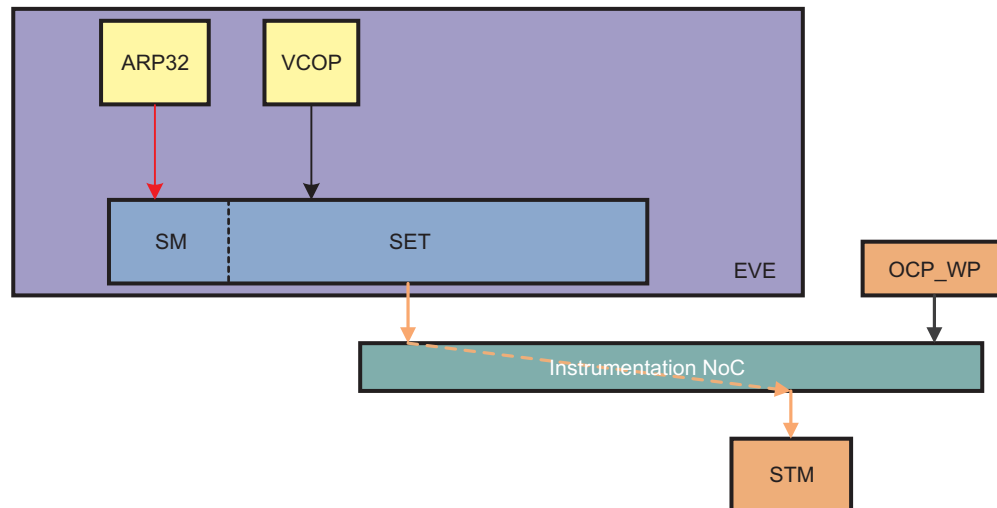

The block diagram shown in [Figure 8-24](#) is a generic example to show the main concept of SMSET. Software messages are initiated by processors. Basically, a processor is writing a message to the trace receiver through STM. SMSET is performing arbitration between hardware messages and software messages.

Software messages and system event messages can be interleaved. Software messages do not require a sequence of write accesses; therefore, the SMSET is can switch to the system event detection as soon as the event is detected.

In case of conflicting accesses between software message and detection of system events, the SMSET can switch to the system event detection as soon as the event is detected. Software messages are never lost. Therefore, an SMSET buffer allows absorbing instrumentation accesses peaks, which prevents stalling the processor originating the message.

In case of a platform implementing several SMSET instances, the priority is arbitrated by the instrumentation NoC at SoC level.

It is possible to program the sampling window size to exchange STM bandwidth for time-stamping accuracy. All the events detected within the sampling window are considered close enough and packed in the same message as concurrent events and therefore reported in the trace log with the same time stamp. In case a selected event has been captured but not yet written to the STM queue, the system event trace module shall not wait for the sampling window boundary to write the pending packet to the STM. This results in two separate messages reporting the first and second pulse of the selected event. System events are considered synchronous to the SMSET functional clock. The sampling window size granularity is one SMSET cycle. The size ranges from 1 to 256 cycles.

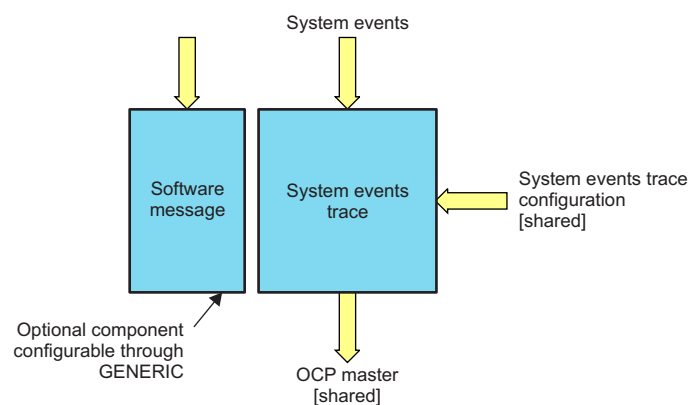

**Figure 8-24. SMSET Block Diagram**

## 8.1.7.2 Functional Description

### 8.1.7.2.1 Connectivity

The SMSET component is interfaced to the following:

- Configuration OCP slave port to configure the SMSET parameters
- System events [x N] for monitoring
- Processors supporting software messages (through OCP interface)
- Instrumentation OCP master port to write hardware and software messages into the STM queue

**Figure 8-25. SMSET Interfaces**

### 8.1.7.2.2 SMSET Event Mapping

The SMSET events include higher-level start and end task events. [Table 8-297](#) summarize the event mapping.

The SMSET module operates at the CLK2 rate.

SMSET traces events on either a high-to-low transition or low-to-high transition, but not both. Thus, the EDMA's `tpcc_aet` signal is not directly compatible with SMSET tracing. The `tpcc_aet` is an active high signal that can be used to measure the duration of a specific edma transfer. The `tpcc_aet` signal can be programmed (in EDMA CC MMRs) to go high when a specific trigger is detected, and go low when a specific completion code is received. EVE logic will implement a custom `tpcc_aet_start` and `tpcc_aet_end` signals. The `tpcc_aet_start` signal will pulse high (for one cycle) when `tpcc_aet` transitions to high, and `tpcc_aet_end` signal will pulse high (for one cycle) when `tpcc_aet_end` signal when `tpcc_aet` transitions to low.

[Table 8-297](#) details the various profiling signals.

The “pulse” signals are expected to be driven active one cycle for each occurrence. A sequence of consecutive active cycles represent multiple occurrences. “Duration” mode of the SMSET makes sense for this type of signal where the duration implies the number of occupancies in a particular state (for example the number of cache hits)

The “duration” type represents a signal that may stay active for multiple cycles on a given occurrence. These are typically stall signals where the user is attempting to determine the total number of cycles in the “stalled” state. “Duration” mode will indicate the total time stalled. “Event” mode will indicate the number of unique occurrences of stalls. “Event” is useful in this case since there will always be a deassertion between occurrences.

“Edge” type goes active for undefined period of time but is guaranteed to go inactive before the next occurrence. “Event” mode of the SCTM should be used for these signals.

**Table 8-297. List of SMSET Events**

SMSET Event	Name	Source	Type	SMSET Mode	Clock
0	<code>tpcc_aet_start</code>	EDMA	Pulse	Duration	CLK2
1	<code>tpcc_aet_stop</code>	EDMA	Pulse	Duration	CLK2
2	<code>arp32_int4</code>	INTC	Duration	Duration or event	CLK2
3	<code>arp32_int5</code>	INTC	Duration	Duration or event	CLK2
4	<code>arp32_int6</code>	INTC	Duration	Duration or event	CLK2
5	<code>arp32_int7</code>	INTC	Duration	Duration or event	CLK2
6	<code>vcop_loop_start</code>	VCOP	Edge	Event	CLK2
7	<code>vcop_done</code>	VCOP	Edge	Event	CLK2
8	<code>arp32_nmi</code>	INTC	Duration	Duration or event	CLK2
9	<code>arp32_int8</code>	INTC	Duration	Duration or event	CLK2

11	<code>arp32_int10</code>	INTC	Duration	Duration or event	CLK2
12	<code>arp32_int11</code>	INTC	Duration	Duration or event	CLK2
13	<code>arp32_int12</code>	INTC	Duration	Duration or event	CLK2
14	<code>arp32_int13</code>	INTC	Duration	Duration or event	CLK2
15	<code>arp32_int14</code>	INTC	Duration	Duration or event	CLK2
16	<code>arp32_int15</code>	INTC	Duration	Duration or event	CLK2

### 8.1.7.2.3 Software Messages

A GENERIC shall specify if software messages generated to STM through SMSET is supported. Software messages are initiated by processors. Basically a processor is writing a message to the trace receiver through STM. SMSET is just performing arbitration between hardware messages and software messages. Most of the subsystems cannot afford to have two OCP master ports for debug purpose. Interleaving is done in SMSET module.

#### 8.1.7.2.4 SMSET Master Port

The SMSET master port is connected to an instrumentation OCP master port to export hardware and software messages through the STM module. The write accesses to STM are arbitrated at the instrumentation OCP interconnect level.

The SMSET master port supports burst transactions to reduce trace export surplus on the PTI interface; this surplus is due to instrumentation flows interleaving at instrumentation NoC level.

##### 8.1.7.2.4.1 OCP Disconnect

The SMSET is supporting disconnect protocol on its master OCP interface, to make sure that software message transactions always complete. If software messages are initiated, while the instrumentation interconnect is disconnected, the access completes with a DVA response, and written data are lost.

##### 8.1.7.2.5 SMSET Debug Features

The SMSET component provides the following system debug capabilities:

- Monitor events.
- Enable and disable event detection.
- Start event monitoring upon external trigger.
- Stop event monitoring upon external trigger.
- Time stamping.
- Generate hardware message upon system event.
- Generate hardware message every sampling window boundary.
- Interleave hardware messages and software messages.
- Program SMSET from debugger.
- Program SMSET from application.

##### 8.1.7.2.6 Component Ownership

Some of the SMSET resources are owned either by the application or by the debugger. The ownership is required to configure or program SMSET. In other words, ownership determines if write access is granted to the SMSET control registers. The SMSET resource ownership is exclusive. Hence, simultaneous use of SMSET resources by both the debugger and the application is not permitted. However, the debugger can forcibly seize ownership of SMSET resources.

---

**NOTE:** A read access does not require ownership; therefore, either the debugger or the application can read any SMSET registers with or without ownership.

---

##### 8.1.7.2.6.1 Ownership State

The ownership has three basic states:

- AVAILABLE: The unit has not been claimed.
- CLAIMED: The unit has been claimed.
- ENABLED: The unit is enabled by the owning party.

##### 8.1.7.2.6.1.1 Available State

An SMSET is set to the AVAILABLE state when one of two conditions occurs:

- The state is available when power-on reset (POR) is asserted.
- The state is available if the SMSET is owned by the debugger and the emulator is disconnected.

**NOTE:** A warm reset has no effect on the operation of SMSET. An emulator disconnect has no effect when the application owns the unit.

#### 8.1.7.2.6.1.2 Claimed State

An SMSET is in the CLAIMED state when either the debugger or the application has claimed it. The CLAIMED state provides exclusive access to the owner. The other party is not permitted write access to the unit until the owning party releases the claim. Once a unit is claimed, only the owner can write to the other resources controlled by the claim.

The debugger, however, is allowed to forcibly seize control of a unit, if it is already claimed by the application, by setting the DEBUGGEROVERRIDE bit to 1 in the SMSET configuration register (CFG).

#### 8.1.7.2.6.1.3 Enabled State

An SMSET enters the ENABLED state when it is activated. The owner can continue writing to the other resources while SMSET is enabled.

#### 8.1.7.2.6.2 Ownership Commands

Ownership of the SMSET resources is managed through the OWNERSHIP bit in the SMSET configuration register (CFG). [Table 8-298](#) lists the ownership commands.

**Table 8-298. Ownership Commands**

OWNERSHIP Bits	Meaning	Description
00	Release ownership	Release ownership of system events trace. The Release command is accepted only from the owner.
01	Claim ownership	Claim access to system events trace. The claim command is successful only if the unit is available, or the requester is the debugger and the DEBUGGEROVERRIDE bit is high.
10	Enable unit	Activate system events trace for use. The enable command is accepted only from the owner.
11	No Operation	The NOP command does not affect ownership or claim state.

#### 8.1.7.2.6.3 Claim Reset

When a resource is owned by the debugger, the resource is released if the debugger is disconnected. Debugger disconnection is accomplished by asserting PIDCON = 0.

If a resource is owned by the application and the processor enters the debug state, the resource continues to belong to the application. The SMSET is not sensitive to debug state.

If SMSET ownership is released while there are still data in the SMSET FIFO, the master port continues to export data to the STM until the FIFO is drained.

### 8.1.7.3 Use Case Examples

#### 8.1.7.3.1 Procedure to Enable System Event Capture

Perform the following procedure to enable system event capture:

1. Claim the ownership by setting the OWNERSHIP bit in the SMSET configuration register ([SMSET\\_CFG](#)) to 01b.
2. Check the ownership and the current owner by reading the OWNERSHIP bit in the SMSET configuration register ([SMSET\\_CFG](#)).
3. Set the appropriate sampling window size value in the system event sampling window register ([SMSET\\_SESW](#)).
4. Enable the events needed to be detected by setting the appropriate bits in the programming of the

system event detection enable registers ([SMSET\\_SEDEN\\_i](#)) to 1.

5. Select the polarity of the event detection by writing the appropriate value to the EventPolarity bit in the SMSET configuration register ([SMSET\\_CFG](#)).
6. Select the message event generation by writing the appropriate value to the MessageEventGeneration bit in the SMSET configuration register ([SMSET\\_CFG](#)).
7. Enable system event capture by setting the SystemEventCapture bit in the SMSET configuration register ([SMSET\\_CFG](#)) to 1.

#### 8.1.7.3.2 Procedure to Start and Stop System Event Capture from External Trigger Detection

Perform the following procedure to start and stop system event capture from external trigger detection:

1. Claim the ownership by setting the OWNERSHIP bit in the SMSET configuration register ([SMSET\\_CFG](#)) to 1.
2. Check the ownership and the current owner by reading the OWNERSHIP bit in the SMSET configuration register ([SMSET\\_CFG](#)).
3. Set the appropriate sampling window size value in the system event sampling window register ([SMSET\\_SESW](#)).
4. Enable the events to be detected by setting the appropriate bits in the programming of the system event detection enable registers ([SMSET\\_SEDEN\\_i](#)) to 1.
5. Select the polarity of the event detection by writing the appropriate value to the EventPolarity bit in the SMSET configuration register ([SMSET\\_CFG](#)).
6. Select the message event generation by writing the appropriate value to the MessageEventGeneration bit in the SMSET configuration register ([SMSET\\_CFG](#)).
7. Enable capturing system events from external trigger detection by setting the StopCapturingSystemEvents bit in the SMSET configuration register to 1.
8. Enable capturing system events from external trigger detection by setting the StartCapturingSystemEvents bit in the SMSET configuration register to 1.
9. Enable system event capture by writing a 1 to the SystemEventCapture bit in the SMSET configuration register.

#### 8.1.7.3.3 Procedure to Disable System Event Capture

Perform the following procedure to disable system event capture:

1. Disable system event capture by setting the SystemEventCapture bit in the SMSET configuration register ([SMSET\\_CFG](#)) to 0.
2. Release the ownership by setting the OWNERSHIP bit in the SMSET configuration register ([SMSET\\_CFG](#)) to 0.
3. Check the ownership by reading the OWNERSHIP bit in the SMSET configuration register ([SMSET\\_CFG](#)). It must be available (OWNERSHIP = 0).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
OWNERSHIP								RESERVED								CAPTUREEN		RESERVED	EVENTLEVEL	EVENTMSG	STOP	START	RESERVED										
DEBUGGEROVERRIDE		CURRENTOWNER																															

Bits	Field Name	Description	Type	Reset
31:30	OWNERSHIP	Read to get current ownership status. The claim status encoding is (0=Available, 1=Claimed, 2=Enabled, 3=Reserved);Send command to modify ownership state: 00= Release ownership, 01 = Claim ownership, 10 = Enable unit, 11 = No operation	RW	0x0
29	DEBUGGEROVERRIDE	Reading from the DebuggerOverride bit returns a 1.	RW	0x1
28	CURRENTOWNER	This value reflects the SMSET ownership when the register is in a non-Available state.	R	0x0
27:8	RESERVED		R	0x0
7	CAPTUREEN	When high the sytem event capture is enabled	RW	0x0
6:5	RESERVED		R	0x0
4	EVENTLEVEL	This applies to all selected events: 0x0: low level event detection 0x1: high level evnet detection	RW	0x1
3	EVENTMSG	essage generated based on: 0x0: sampling window 0x1: event detection	RW	0x0
2	STOP	Stop capturing system events from external trigger detection [EMU1 HIGH to LOW]	RW	0x0
1	START	Start capturing system events from external trigger detection [EMU0 HIGH to LOW]	RW	0x0
0	RESERVED		R	0x0

## 8.2 ARP32 CPU and Instruction Set

### 8.2.1 Overview

ARP32 refers to a family of customizable, embedded processors targeted for deeply embedded control applications that require high-performance at very-low system cost (die size) and dynamic power-consumption. Example of applications that can benefit using the ARP32 includes embedded video processing engine, computer vision, and video analytics processing engine.

Figure 8-26 illustrates the overlapping nature of the ARP32 CPU and feature set in different application contexts.

**Figure 8-26. ARP32 Versions and ISA/Feature Space**

## 8.2.2 Features

The main features of the ARP32 processor include:

- Single issue RISC processor with Harvard memory architecture
- Highly efficient integer pipeline delivering high performance at low area and power cost
- Provides customization of instruction set to provide acceleration of a target application
- Supported by fully optimizing C/C++ compiler including intrinsic-driven usage of special custom instructions

It is recommended that ARP32 CPU users only use C/C++ language with the supported TI compiler and tools; assembly level programming is highly discouraged and may break future compatibility with the ARP32 processor family or its variants.

## 8.2.3 Block Diagram

Figure 8-27 shows the ARP32 core interfaces.

**Figure 8-27. ARP32 CPU Block Diagram**

## 8.2.4 Architecture

### 8.2.4.1 Interface Description

Table 8-313 provides the basic description of the interface signals of the core. The data and instruction memory interface implements a simple request-ready based handshake sufficient to directly interface TIs compiled SRAM memories.

There is no architectural clock-gating implemented within the ARP32 core. The clock control logic is implemented outside the ARP32 core assisted by signals driven by the CPU core via the **IDLE** instruction.

**Table 8-313. Interface Signals**

Signal	Direction	Width	Description
<b>Clock, Reset</b>			
cpu_fclk	In	1	Functional clock input
cpu_porz_i	In	1	Power On reset (active low)
cpu_resetz_i	In	1	Functional reset (active low)
cpu_standby_o	Out	1	CPU standby status (active high)

**Table 8-313. Interface Signals (continued)**

Signal	Direction	Width	Description
<b>Data Interface</b>			
cpu_dmem_enz_o	Out	1	Data memory request, active low
cpu_dmem_dbg_o	Out	1	Debug access qualifier for Data memory request
cpu_dmem_wrz_o	Out	1	Data memory write enable, active low (0: write, 1:read)
cpu_dmem_bez[3:0]	Out	4	Data memory byte enables, active low
cpu_dmem_addr_o[31:2]	Out	30	Data memory address (carries a word address)
cpu_dmem_wdata_o[31:0]	Out	32	Data memory write data
cpu_dmem_rdata_i[31:0]	In	32	Data memory read data
cpu_dmem_rdy_i	In	1	Data memory ready, active high
cpu_dmem_err_i	In	1	Data memory access error, active high, valid along with cpu_dmem_rdy_i
<b>Instruction Interface</b>			
cpu_imem_enz_o	Out	1	Instruction memory request, active low
cpu_imem_dbg_o	Out	1	Debug access qualifier for Instruction memory request
cpu_imem_addr_o[31:2]	Out	30	Instruction memory address (carries a word address)
cpu_imem_rdata_i[31:0]	In	32	Instruction memory read data
cpu_imem_rdy_i	In	1	Instruction memory ready, active high
cpu_imem_err_i	In	1	Instruction memory access error, active high, valid along with cpu_imem_rdy_i
<b>Interrupt Interface</b>			
cpu_nmi_i	In	1	Non-maskable interrupt, active high
cpu_int4_i	In	1	Maskable interrupt 4, active high
cpu_int5_i	In	1	Maskable interrupt 5, active high
cpu_int6_i	In	1	Maskable interrupt 6, active high
cpu_int7_i	In	1	Maskable interrupt 7, active high
cpu_int8_i	In	1	Maskable interrupt 8, active high
cpu_int9_i	In	1	Maskable interrupt 9, active high
cpu_int10_i	In	1	Maskable interrupt 10, active high
cpu_int11_i	In	1	Maskable interrupt 11, active high
cpu_int12_i	In	1	Maskable interrupt 12, active high
cpu_int13_i	In	1	Maskable interrupt 13, active high
cpu_int14_i	In	1	Maskable interrupt 14, active high
cpu_int15_i	In	1	Maskable interrupt 15, active high
cpu_iack_o	Out	1	Interrupt acknowledge, active high
cpu_inum_o	Out	4	Identifier of acknowledged interrupt

#### 8.2.4.1.1 Data Memory Interface

- The address sent out to data memory is always a word address. Access sizes smaller than word size are supported via byte enables.
- The CPU core asserts the memory request signal (active low, `cpu_dmem_enz_o`) along with corresponding address (`cpu_dmem_addr_o`) and read/write qualifier (active low, `cpu_dmem_wrz_o`) until a ready (active high, `cpu_dmem_rdy_i`) is received from the memory sub-system.
- For a zero-wait state access, the ready is expected next cycle to the request. Ready must be de-asserted to extend the access cycle for a higher wait state memory subsystem.
- For read accesses, the CPU samples the read data bus (`cpu_dmem_rdata_i[31:0]`) when ready is asserted. For write accesses, ready indicates write completion whereas read data bus is a don't care.
- For writes accesses, appropriate byte enables (active low, `cpu_dmem_bez[3:0]`) are asserted in request phase. This is the only way for the memory sub-system to identify access size of a write access. Byte steering is done by the core, hence the memory sub-system can use the ANY lanes of write data bus for easy selections/multiplexing of write data - for byte writes, the write data is duplicated on all four byte lanes of write data bus whereas for halfword writes, the write data is duplicated on both the halfword lanes of write data bus.
- For read accesses, access size is always 32b - the memory sub-system always returns 32b at the requested word address. CPU core selects the appropriate bytes based on access size and access address.

#### 8.2.4.1.2 Instruction Memory Interface

- The address sent out to the instruction memory is always a word address, access size is always a word (32 bits) and writes are not supported. Hence, byte enables and read/write qualifiers are not present for the instruction memory interface.
- The CPU core asserts the memory request signal (active low, `cpu_imem_enz_o`) along with the corresponding address (`cpu_imem_addr_o`) until a ready (active high, `cpu_imem_rdy_i`) is received from the memory subsystem.
- For a zero-wait state access, the ready is expected the next cycle to the request. Ready must be de-asserted to extend the access cycle for a higher wait state memory subsystem.
- The CPU samples the read data bus (`cpu_imem_rdata_i[31:0]`) when ready is asserted.

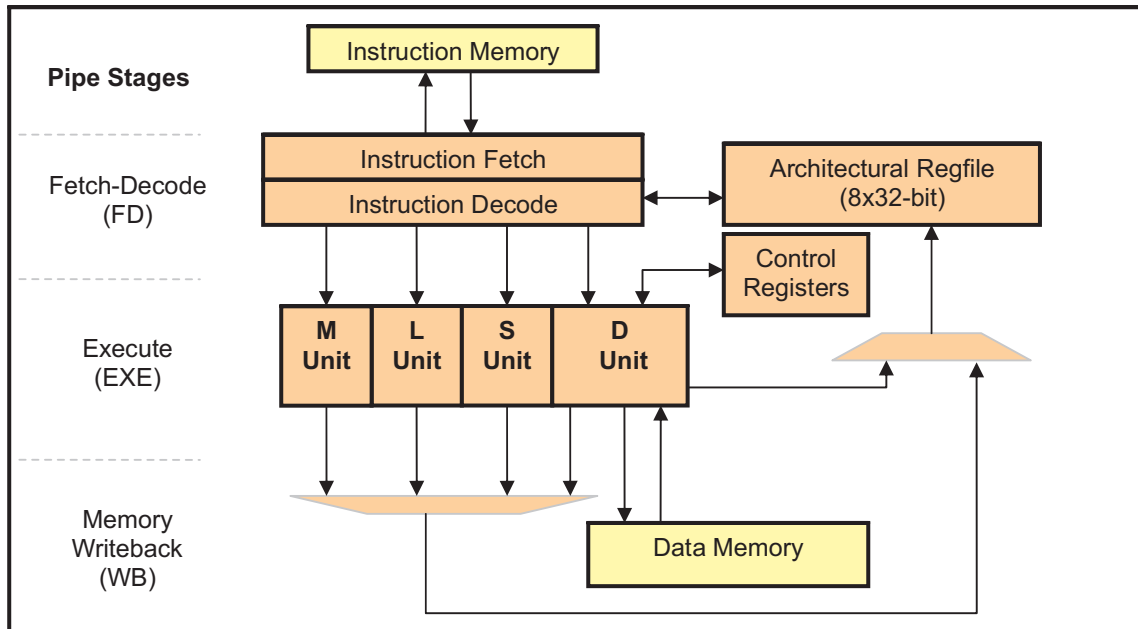

## 8.2.4.2 Pipeline

### 8.2.4.2.1 Overview

The ARP32 CPU implements a three-deep pipeline (see [Figure 8-28](#)): merged fetch-decode (FD), Execute (EXE), and Writeback (WB). The fetch-decode and writeback stages are overlapped.

**Figure 8-28. ARP32 CPU Pipeline**

### 8.2.4.2.2 Pipeline Operation

The first stage (FetchDecode/FD) of the pipe operates directly on the instruction memory read data input. This stage consists of the following:

- Instructions are decoded to determine
  - size of the instruction (32 bit/16 bit)
  - source operand, destination operand (in architectural and control register file)
  - if it is a blocking multi-execute cycle instruction
- Source operands are read from architectural register file

In the second stage (Execute/EXE) of the pipe:

- All arithmetic/data processing instructions are executed.
- For a single execute cycle instruction, the results are available at the end of this stage and are written back to architectural register file and control register file (if required).
- Instructions requiring data memory access (load, store, call, return etc) compute the access address in this cycle and place the memory access request on data memory bus (along with all other qualifiers). For write accesses, write data is also provided in this stage.

In the last stage (MemoryWriteback/WB) of the pipe:

- All instructions having data memory access request issued in EXE stage waits for the read data (for read accesses) or write completion notification (for write accesses) via the data memory 'ready' signal.
- If memory subsystem asserts the ready signal, the read data is updated to architectural register file

**NOTE:** The Writeback stage is really outside the processor core and is used for load/store instructions only. All other instructions complete at EXE stage updating the result. Hence, in some sense the pipe depth of the ARP32 processor is really 2 (Fetch-Decode, Execute).

Consider the following example code sequence in [Example 8-1](#). [Table 8-314](#) shows how the instructions flows through the pipe, highlighting the fact that only load/store instructions use the WB stage (others complete/retire at EXE).

**Example 8-1. ARP32 CPU Pipeline Operation**

```

MVK  0x100, R0      ; (I1) Move 0x100 into R0
MVKH 0x02000000, R0 ; (I2) Move 0x0200 into R0[31:16]
ADD  100, R0, R0    ; (I3) Add 100 to R0
LDW  *+R2(0), R3   ; (I4) Load a word to R3
ADD  4, R2, R2      ; (I5) Increment R2 to next word address
STW  R3, *+R4(0)   ; (I6) Store R3 to address pointed by R4
ADD  4, R4, R4      ; (I7) Increment R4 to next word address
    
```

**Table 8-314. ARP32 CPU Pipeline Operation**

Cycle	1	2	3	4	5	6	7	8	9
FD	MVK (I1)	MVKH (I2)	ADD (I3)	LDW (I4)	ADD (I5)	STW (I6)	ADD (I7)		
EXE		MVK (I1)	MVKH (I2)	ADD (I3)	LDW (I4)	ADD (I5)	STW (I6)	ADD (I7)	
WB						LDW (I4)		STW (I6)	

**8.2.4.2.3 Pipeline Interlocks**

The pipeline is fully interlocked – the CPU stalls in case of source operand registers have pending loads. Data bypassing for read-after-write dependency is implemented at the end of EXE and WB stages to increase instructions-per-cycle (IPC).

The load data has a single-cycle load use penalty since the load data is written back to register file at WB stage. In the following example, the ADD instruction stalls for a cycle to allow load to complete:

```

LDW  *+R0(0), R0    ; Load a word into R0
ADD  4, R0, R0      ; Increment R0 to the next word address
MVK  100, R1        ; Move a value 100 into R1
    
```

Since the CPU allows a nondependent instruction to continue executing, this stall is avoided, if the MVK (no dependency on the load data) instruction is placed in the load delay slot – the CPU executes all three instructions without a stall.

```

LDW  *+R0(0), R0    ; Load a word into R0
MVK  100, R1        ; Move a value 100 into R1
ADD  4, R0, R0      ; Increment R0 to the next word address
    
```

### 8.2.4.3 Data Format

The ARP32 CPU is an integer machine supporting three different data width/formats: byte, halfword, and word. A byte is 8 bits, a halfword is 16 bits, and a word is 32 bits – they directly map to native C data types: char, short, and int, respectively.

Each type is aligned with the corresponding size, that is, byte aligned to byte boundary, halfword aligned to 2-byte boundary, word aligned to 4-byte boundary. It is the compiler/toolchain and the programmers responsibility to maintain the access alignment all the time (for global and/or local variables).

The ARP32 core does not support unaligned access. If an unaligned access is attempted by software (via an appropriate instruction), the CPU ignores the lower 2 bits of the data memory (byte) address, thus forcing an alignment to the (truncated, floored) word address.

### 8.2.4.4 Endian Support

The ARP32 CPU supports only little-endian byte ordering in the memory subsystem (see [Figure 8-29](#)). A word loaded from the memory is loaded into a CPU register as follows:

- a byte or half word at address A is the least significant byte or half word within the word at that address
- a byte at address A is the least significant byte within the half word at that address

**Figure 8-29. ARP32 CPU Little Endianness**

	31	24 23	16 15	8 7	0
Word at address A	Byte [Addr + 3]	Byte [Addr + 2]	Byte [Addr + 1]	Byte [Addr + 0]	
Halfword at address A			Byte [Addr + 1]	Byte [Addr + 0]	

### 8.2.4.5 Architectural Register File

The ARP32 CPU contains an 8-entry, 32-bit architectural register file named R0-R7.

The architectural registers are read (for source operands) at the end of Fetch-decode (2 dedicated read ports available at fetch-decode for this) and written back at the end of execute stage (1 dedicated write port available at EXE for this). Additionally, for load instructions, the memory read data is written back to architectural register file at the end of writeback stage (1 dedicated write port available at WB for this) and for store instructions, the architectural register file is read (for write data) at the execute stage (via a dedicated read port available in EXE phase).

The register file contains logic to detect matching of write address in the execute stage and two read addresses in the decode stage for bypassing of result data to read data buses. The read data is flopped in the register file and routed to the execution unit in the execute stage.

### 8.2.4.6 CPU Control Registers

The control register file (CREG) contains registers that control or report status for the ARP32 CPU. [Table 8-315](#) lists the control registers contained in the control register file.

Control registers are accessed via **MVC**, **MVCH** instructions – this is the only mechanism for moving the contents of registers between the architectural register file and the control register file. Control registers are addressable via 5 bits in the *creg* field of the **MVC/MVCH** instructions. All control registers are defined as 32 bits – **MVC** + **MVCH** pair should be used to move immediate values to any control registers.

The following instructions are available in the **MVC/MVCH** family:

- **MVC** *ucst16, creg*
- **MVC** *areg, creg*
- **MVC** *creg, areg*
- **MVCH** *ucst16, creg*

**Table 8-315. Control Registers**

Acronym	Register Name	Section
CSR	Control Status Register	<a href="#">Section 8.2.4.6.1</a>
IER	Interrupt Enable Register	<a href="#">Section 8.2.4.6.2</a>

ICR	Interrupt Clear Register	<a href="#">Section 8.2.4.6.5</a>
NRP	Nonmaskable Interrupt Return Pointer Register	<a href="#">Section 8.2.4.6.6</a>
IRP	Interrupt Return Pointer Register	<a href="#">Section 8.2.4.6.7</a>
SP	Stack Pointer Register	<a href="#">Section 8.2.4.6.8</a>
GDP	Global Data Pointer Register	<a href="#">Section 8.2.4.6.9</a>
LR	Link Register	<a href="#">Section 8.2.4.6.10</a>
LSA0	Loop 0 Start Address Register	<a href="#">Section 8.2.4.6.11</a>
LEA0	Loop 0 End Address Register	<a href="#">Section 8.2.4.6.12</a>
LCNT0	Loop 0 Iteration Count Register	<a href="#">Section 8.2.4.6.13</a>
LSA1	Loop 1 Start Address Register	<a href="#">Section 8.2.4.6.14</a>
LEA1	Loop 1 End Address Register	<a href="#">Section 8.2.4.6.15</a>
LCNT1	Loop 1 Iteration Count Register	<a href="#">Section 8.2.4.6.16</a>
LCNT0RLD	Loop 0 Iteration Count Reload Value Register	<a href="#">Section 8.2.4.6.17</a>
SCSR	Shadow Control Status Register	<a href="#">Section 8.2.4.6.18</a>
NMISCSR	NMI Shadow Control Status Register	<a href="#">Section 8.2.4.6.19</a>
CPUID	CPU ID Register	<a href="#">Section 8.2.4.6.20</a>
DPC	Decode Program Counter	<a href="#">Section 8.2.4.6.21</a>
TSCH	Time-Stamp Counter (high 32 bits) Register	<a href="#">Section 8.2.4.6.22</a>
TACL	Time-Stamp Counter (low 32 bits) Register	<a href="#">Section 8.2.4.6.22</a>

Direct modification of the CREG entries is limited to a few special case instructions. For example, some forms of the **ADD** and **SUB** instructions directly modify the stack pointer (SP) to improve code execution performance.

A read of a control register (by **MVC** *creg*, *areg*) can be immediately followed by any other instruction using the same *areg* without causing a stall – the read data is forwarded to the next instruction in the pipeline. The following example illustrates the behavior:

```
// Read from IRP and push it stack
MVC  IRP, R0          ; Read IRP and place it in R0
STRF R0, R0          ; No stall, content of IRP is pushed to stack
```

A write to a control register is also bypassed to another instruction immediately following it and using the same *creg*. The following example illustrates the behavior:

```
// Update SP before a register push
MVC  5000, SP        ; Update SP to 5000
STRF R0, R0          ; No stall, R0 is pushed @5000
```

However, a write to a control register (by **MVC** *areg*, *creg*) has one exposed effective delay slot for an immediately following read from the same control register (by **MVC** *creg*, *areg*). The following examples illustrate the behavior:

```
// Write to LCNT0 and read it back
MVC  2000, LCNT0     ; Update LCNT0 again
NOP                                     ; without this NOP the next MVC will read UNPREDICTABLE value
MVC  LCNT0, R0       ; R0=2000
```

### 8.2.4.6.1 Control Status Register (CSR)

The control status register (CSR) contains control and status bits. The CSR is shown in [Figure 8-30](#) and described in [Table 8-316](#).

The condition code bits GT, LT, and EQ are not required to be one-hot. They may be set in any combinations using the **MVC** instruction or by combinations of **CMP** and instructions that update the EQ bit. However, execution of compare instructions enforces a one-hot condition for GT/LT/EQ.

Having more than one bit set does not affect conditional branch execution, as each branch compares only the respective condition bits, that is, the **BGE** instruction uses the CSR[4] and CSR[2] bits to determine if the branch is taken. The remaining condition bits have no effect on the **BGE** instruction.

**Figure 8-30. Control Status Register (CSR)**

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

**Table 8-316. Control Status Register (CSR) Field Descriptions**

Bit	Field	Value	Description
31-14	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
13	DBZ	0-1	Divide-By-Zero. Status indicating if a Divide-By-Zero condition occurred since last time it was cleared. Once set, software <b>MUST</b> clear this bit. It is set only if the DBZE bit is set.
12	DBZE	0-1	Divide-By-Zero exception enable. When set to 1, CPU takes an UNDEF interrupt when a divide-by-zero condition is detected by <b>DIV</b> , <b>DIVU</b> , <b>MOD</b> , or <b>MODU</b> instructions. By default this bit is disabled.
11-8	INUM	0 1h 2h 3h 4h 5h 6h 7h 8h 9h Ah Bh Ch Dh Eh Fh	Interrupt Number. Indicates the interrupt ID of the last taken interrupt.
7	V	0-1	Overflow bit. Arithmetic operations that results in overflow or borrow set this bit. See individual instruction descriptions for instructions that modify the V bit.
6	SAT	0-1	Saturation bit. Arithmetic operations whose results have been saturated set this bit. See individual instruction descriptions for instructions that modify the SAT bit.
5	C	0-1	Carry bit. Arithmetic operations that results in carry out or borrow set this bit. See individual instruction descriptions for instructions that modify the C bit.

**Table 8-316. Control Status Register (CSR) Field Descriptions (continued)**

Bit	Field	Value	Description
4	GT	0-1	Greater-than bit. This bit is set or cleared based on the result of a <b>CMP</b> instruction. (GT = 1 if Rx > Ry; else GT = 0). See individual instruction descriptions for instructions that modify the GT bit.
3	LT	0-1	Less-than bit. This bit is set or cleared based on the result of a <b>CMP</b> instruction. (LT = 1 if Rx < Ry; else LT = 0). See individual instruction descriptions for instructions that modify the LT bit.
2	EQ	0-1	Equal bit. This bit is set to 1 if the result of an instruction execution results in a zero result or the result of a <b>CMP</b> instruction returns equality (EQ = 1 if Rx == Ry; else EQ = 0). See individual instruction descriptions for instructions that modify the EQ bit.
1	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
0	GIE	0 1	Global interrupt enable. Disables all interrupts, except the reset interrupt and NMI (nonmaskable interrupt). Enables all interrupts.

#### 8.2.4.6.2 Interrupt Enable Register (IER)

The interrupt enable register (IER) enables and disables individual interrupts. The IER is shown in [Figure 8-31](#) and described in [Table 8-317](#).

**Figure 8-31. Interrupt Enable Register (IER)**

**Table 8-317. Interrupt Enable Register (IER) Field Descriptions**

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
15-4	IE <sub>n</sub>	0 1	Interrupt enable. An interrupt triggers interrupt processing only if the corresponding bit is set to 1. Interrupt is disabled. Interrupt is enabled.
3-2	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
1	NMIE	0 1	Nonmaskable interrupt enable. An interrupt triggers interrupt processing only if the bit is set to 1. The NMIE bit is cleared at reset. After reset, software must set the NMIE bit to enable the NMI and to allow INT15-INT4 to be enabled by the GIE bit in CSR and the corresponding IER bit. The NMIE bit cannot be cleared manually; a write of 0 has no effect. The NMIE bit is also cleared by the occurrence of an NMI. All nonreset interrupts are disabled. All nonreset interrupts are enabled.
0	Reserved	1	Reserved. The reserved bit location is always read as 1. A value written to this field has no effect.

### 8.2.4.6.3 Interrupt Flag Register (IFR)

The interrupt flag register (IFR) contains the status of the maskable interrupts (INT15-INT4) and the NMI interrupt. Each corresponding bit in the IFR is set to 1 when that interrupt occurs; otherwise, the bits are cleared to 0. The IFR is shown in [Figure 8-32](#) and described in [Table 8-318](#).

The update to IFR via a write to the interrupt set register (ISR)/interrupt clear register (ICR) has one effective delay slot; IFR cannot be set/cleared using one **MVC** instruction (a write to ISR/ICR) and read the corresponding changed value of IFR via a very next **MVC** instruction. Software should use a **NOP** after a write to ISR/ICR, if the changed value has to be read immediately.

```
MVC  0x10, ISR      ; Set IFR[4]
NOP                                     ; a NOP to fill the delay slot
MVC  IFR, R0       ; R0 would contain 0x10
```

**Figure 8-32. Interrupt Flag Register (IFR)**

LEGEND: R = Readable by the **MVC** instruction; -n = value after reset

**Table 8-318. Interrupt Flag Register (IFR) Field Descriptions**

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
15-4	IF $n$	0 1	Interrupt flag. Indicates the status of the corresponding maskable interrupt. An interrupt flag may be manually set by setting the corresponding bit (IS $n$ ) in the interrupt set register (ISR) or manually cleared by setting the corresponding bit (IC $n$ ) in the interrupt clear register (ICR). 0 Interrupt has not occurred. 1 Interrupt has occurred.
3-2	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
1	NMIF	0 1	Nonmaskable interrupt flag. 0 Interrupt has not occurred. 1 Interrupt has occurred.
0	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.

#### 8.2.4.6.4 Interrupt Set Register (ISR)

The interrupt set register (ISR) allows to manually set the maskable interrupts (INT15-INT4) in the interrupt flag register (IFR). Writing a 1 to any of the bits in ISR causes the corresponding interrupt flag (IF $n$ ) to be set in IFR. Writing a 0 to any bit in ISR has no effect. It is not possible to set any bit in ISR to affect NMI or reset. The ISR is shown in [Figure 8-33](#) and described in [Table 8-319](#).

**NOTE:** Any write to ISR (by the **MVC** instruction) effectively has one delay slot because the results cannot be read (by the **MVC** instruction) in IFR until two cycles after the write to ISR.

Any write to the interrupt clear register (ICR) is ignored by a simultaneous write to the same bit in ISR.

**Figure 8-33. Interrupt Set Register (ISR)**

LEGEND: R = Read only; W = Writeable by the **MVC** instruction; - $n$  = value after reset

**Table 8-319. Interrupt Set Register (ISR) Field Descriptions**

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
15-4	IS $n$	0	Interrupt set. Corresponding interrupt flag (IF $n$ ) in IFR is not set.
		1	Corresponding interrupt flag (IF $n$ ) in IFR is set.
3-0	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.

### 8.2.4.6.5 Interrupt Clear Register (ICR)

The interrupt clear register (ICR) allows to manually clear the maskable interrupts (INT15-INT4) in the interrupt flag register (IFR). Writing a 1 to any of the bits in ICR causes the corresponding interrupt flag (IF $n$ ) to be cleared in IFR. Writing a 0 to any bit in ICR has no effect. Incoming interrupts have priority and override any write to ICR. It is not possible to set any bit in ICR to affect NMI or reset. The ISR is shown in Figure 8-34 and described in Table 8-320.

**NOTE:** Any write to ICR (by the **MVC** instruction) effectively has one delay slot because the results cannot be read (by the **MVC** instruction) in IFR until two cycles after the write to ICR.

Any write to ICR is ignored by a simultaneous write to the same bit in the interrupt set register (ISR).

**Figure 8-34. Interrupt Clear Register (ICR)**

LEGEND: R = Read only; W = Writeable by the **MVC** instruction; - $n$  = value after reset

**Table 8-320. Interrupt Clear Register (ICR) Field Descriptions**

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
15-4	IC $n$	0	Interrupt clear. Corresponding interrupt flag (IF $n$ ) in IFR is not cleared.
		1	Corresponding interrupt flag (IF $n$ ) in IFR is cleared.
3-0	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.

### 8.2.4.6.6 Nonmaskable Interrupt (NMI) Return Pointer Register (NRP)

The NMI return pointer register (NRP) contains the return pointer that directs the CPU to the proper location to continue program execution after NMI processing. A branch using the address in NRP (**BNRP**) in your interrupt service routine returns to the program flow when NMI servicing is complete. The NRP is shown in [Figure 8-35](#) and described in [Table 8-321](#).

**Figure 8-35. NMI Return Pointer Register (NRP)**

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -x = value is indeterminate after reset

**Table 8-321. NMI Return Pointer Register (NRP) Field Descriptions**

Bit	Field	Value	Description
31	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
30-0	Return Address	0-7FFF FFFFh	Contains the return address. It is written by the CPU while taking an NMI. It is read by the CPU to execute the <b>BNRP</b> instruction.

### 8.2.4.6.7 Interrupt Return Pointer Register (IRP)

The interrupt return pointer register (IRP) contains the return pointer that directs the CPU to the proper location to continue program execution after processing a maskable interrupt (INT15-INT4, SWI, or UNDEF). A branch using the address in IRP (**BIRP**) in your interrupt service routine returns to the program flow when interrupt servicing is complete. The IRP is shown in [Figure 8-36](#) and described in [Table 8-322](#).

**Figure 8-36. Interrupt Return Pointer Register (IRP)**

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -x = value is indeterminate after reset

**Table 8-322. Interrupt Return Pointer Register (IRP) Field Descriptions**

Bit	Field	Value	Description
31	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
30-0	Return Address	0-7FFF FFFFh	Contains the return address. It is written by the CPU while taking an interrupt. It is read by the CPU to execute the <b>BIRP</b> instruction.

**8.2.4.6.8 Stack Pointer Register (SP)**

The stack pointer register (SP) may be directly updated by software using the **MVC** instruction. The SP points to the top of the stack and always contains a byte address. The programmer is responsible for ensuring the correct alignment of the SP. See [Section 8.2.4.14](#) for more details on stack pointer convention that must be followed. The SP is shown in [Figure 8-37](#).

**Figure 8-37. Stack Pointer Register (SP)**

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

**8.2.4.6.9 Global Data Pointer Register (GDP)**

The GDP may be directly updated by software using the **MVC/MVCH** instruction. The GDP points to the start of the global data section (.bss section) and always contains a byte address. The programmer is responsible for ensuring that the convention described in [Section 8.2.4.15](#) is maintained. The GDP is shown in [Figure 8-38](#).

**Figure 8-38. Global Data Pointer Register (GDP)**

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

**8.2.4.6.10 Link Register (LR)**

The link register (LR) contains the return address (a halfword address) for a **RET** instruction. A **CALL** instruction saves the last return address into the stack and updates LR with the return address. A **RET** instruction uses the current value of LR as the target address and restores the last return address into LR from the stack. The LR is shown in [Figure 8-39](#) and described in [Table 8-323](#).

**Figure 8-39. Link Register (LR)**

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

**Table 8-323. Link Register (LR) Field Descriptions**

Bit	Field	Value	Description
31	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
30-0	Return Address	0-7FFF FFFFh	Contains the return address (a halfword address) for a <b>RET</b> instruction.

### 8.2.4.6.11 Loop 0 Start Address Register (LSA0)

The loop 0 start address register (LSA0) contains the start address (byte address) of Loop 0. Note that Loop 0 is the inner loop. The LSA0 is shown in [Figure 8-40](#) and described in [Table 8-324](#).

See [Section 8.2.4.17](#) for more details on hardware loop mechanism and usage of this register.

**Figure 8-40. Loop 0 Start Address Register (LSA0)**

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

**Table 8-324. Loop 0 Start Address Register (LSA0) Field Descriptions**

Bit	Field	Value	Description
31-0	LSA0	0-FFFF FFFFh	Start address of Loop 0 (byte address).

### 8.2.4.6.12 Loop 0 End Address Register (LEA0)

The loop 0 end address register (LEA0) contains the end address (byte address) of Loop 0. Note that Loop 0 is the inner loop. The LEA0 is shown in [Figure 8-41](#) and described in [Table 8-325](#).

See [Section 8.2.4.17](#) for more details on hardware loop mechanism and usage of this register.

**Figure 8-41. Loop 0 End Address Register (LEA0)**

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

**Table 8-325. Loop 0 End Address Register (LEA0) Field Descriptions**

Bit	Field	Value	Description
31-0	LEA0	0-FFFF FFFFh	End address of Loop 0 (byte address).

**8.2.4.6.13 Loop 0 Iteration Count Register (LCNT0)**

The loop 0 iteration count register (LCNT0) contains the iteration count of Loop 0. Note that Loop 0 is the inner loop. The LCNT0 is shown in [Figure 8-42](#) and described in [Table 8-326](#).

See [Section 8.2.4.17](#) for more details on hardware loop mechanism and usage of this register.

**Figure 8-42. Loop 0 Iteration Count Register (LCNT0)**

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

**Table 8-326. Loop 0 Iteration Count Register (LCNT0) Field Descriptions**

Bit	Field	Value	Description
31-0	LCNT0	0-FFFF FFFFh	Iteration count of Loop 0.

#### 8.2.4.6.14 Loop 1 Start Address Register (LSA1)

The loop 1 start address register (LSA1) contains the start address (byte address) of Loop 1. Note that Loop 1 is the outer loop. The LSA1 is shown in [Figure 8-43](#) and described in [Table 8-327](#).

See [Section 8.2.4.17](#) for more details on hardware loop mechanism and usage of this register.

**Figure 8-43. Loop 1 Start Address Register (LSA1)**

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

**Table 8-327. Loop 1 Start Address Register (LSA1) Field Descriptions**

Bit	Field	Value	Description
31-0	LSA1	0-FFFF FFFFh	Start address of Loop 1 (byte address).

#### 8.2.4.6.15 Loop 1 End Address Register (LEA1)

The loop 1 end address register (LEA1) contains the end address (byte address) of Loop 1. Note that Loop 1 is the outer loop. The LEA1 is shown in [Figure 8-44](#) and described in [Table 8-328](#).

See [Section 8.2.4.17](#) for more details on hardware loop mechanism and usage of this register.

**Figure 8-44. Loop 1 End Address Register (LEA1)**

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

**Table 8-328. Loop 1 End Address Register (LEA1) Field Descriptions**

Bit	Field	Value	Description
31-0	LEA1	0-FFFF FFFFh	End address of Loop 1 (byte address).

**8.2.4.6.16 Loop 1 Iteration Count Register (LCNT1)**

The loop 1 iteration count register (LCNT1) contains the iteration count of Loop 1. Note that Loop 1 is the outer loop. The LCNT1 is shown in [Figure 8-45](#) and described in [Table 8-329](#).

See [Section 8.2.4.17](#) for more details on hardware loop mechanism and usage of this register.

**Figure 8-45. Loop 1 Iteration Count Register (LCNT1)**

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

**Table 8-329. Loop 1 Iteration Count Register (LCNT1) Field Descriptions**

Bit	Field	Value	Description
31-0	LCNT1	0-FFFF FFFFh	Iteration count of Loop 1.

**8.2.4.6.17 Loop 0 Iteration Count Reload Value Register (LCNT0RLD)**

The loop 0 iteration count reload value register (LCNT0RLD) contains the value that the loop 0 iteration count register (LCNT0) is reloaded during the outer loop rewind. LCNT0RLD is automatically updated by hardware when a write to LCNT0 is performed (via **MVC** instruction), thus LCNT0RLD does not need to be explicitly programmed during a loop setup. The LCNT0RLD is shown in [Figure 8-46](#) and described in [Table 8-330](#).

See [Section 8.2.4.17](#) for more details on hardware loop mechanism and usage of this register.

**Figure 8-46. Loop 0 Iteration Count Reload Value Register (LCNT0RLD)**

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

**Table 8-330. Loop 0 Iteration Count Reload Value Register (LCNT0RLD) Field Descriptions**

Bit	Field	Value	Description
31-0	LCNT0RLD	0-FFFF FFFFh	Reload value of the loop 0 iteration count register (LCNT0).

### 8.2.4.6.18 Shadow Control Status Register (SCSR)

The shadow control status register (SCSR) contains a copy of the control status register (CSR) (of background code) in the interrupt context (except for an NMI). The SCSR is shown in [Figure 8-47](#) and described in [Table 8-331](#).

On acceptance of an interrupt (except for an NMI), the current state of the control status register (CSR) is copied to SCSR. On execution of a **BIRP** instruction, SCSR is copied back to CSR. SCSR facilitates fast interrupt response. A write to SCSR has no effect on machine operation.

**Figure 8-47. Shadow Control Status Register (SCSR)**

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

**Table 8-331. Shadow Control Status Register (SCSR) Field Descriptions**

Bit	Field	Value	Description
31-14	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
13	DBZ	0-1	Shadow copy of CSR:DBZ bit.
12	DBZE	0-1	Shadow copy of CSR:DBZE bit.
11-8	INUM	0-Fh	Shadow copy of CSR:INUM field.
7	V	0-1	Shadow copy of CSR:V bit.
6	SAT	0-1	Shadow copy of CSR:SAT bit.
5	C	0-1	Shadow copy of CSR:C bit.
4	GT	0-1	Shadow copy of CSR:GT bit.
3	LT	0-1	Shadow copy of CSR:LT bit.
2	EQ	0-1	Shadow copy of CSR:EQ bit.
1	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
0	GIE	0-1	Shadow copy of CSR:GIE bit.

### 8.2.4.6.19 NMI Shadow Control Status Register (NMISCSR)

The NMI shadow control status register (NMISCSR) contains a copy of the control status register (CSR) (of background code) in the nonmaskable interrupt context. The NMISCSR is shown in Figure 8-48 and described in Table 8-332.

On acceptance of an NMI, the current state of the control status register (CSR) is copied to NMISCSR. On execution of a **BNRP** instruction, NMISCSR is copied back to CSR. NMISCSR facilitates correct servicing of an NMI even in a nested context. A write to NMISCSR has no effect on machine operation.

**Figure 8-48. NMI Shadow Control Status Register (NMISCSR)**

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

**Table 8-332. NMI Shadow Control Status Register (NMISCSR) Field Descriptions**

Bit	Field	Value	Description
31-14	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
13	DBZ	0-1	Shadow copy of CSR:DBZ bit.
12	DBZE	0-1	Shadow copy of CSR:DBZE bit.
11-8	INUM	0-Fh	Shadow copy of CSR:INUM field.
7	V	0-1	Shadow copy of CSR:V bit.
6	SAT	0-1	Shadow copy of CSR:SAT bit.
5	C	0-1	Shadow copy of CSR:C bit.
4	GT	0-1	Shadow copy of CSR:GT bit.
3	LT	0-1	Shadow copy of CSR:LT bit.
2	EQ	0-1	Shadow copy of CSR:EQ bit.
1	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
0	GIE	0-1	Shadow copy of CSR:GIE bit.

### 8.2.4.6.20 CPU Identification Register (CPUID)

The CPU identification register (CPUID) contains the major and minor version ID. The CPUID is shown in [Figure 8-49](#) and described in [Table 8-333](#).

**Figure 8-49. CPU Identification Register (CPUID)**

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset; -x = value is indeterminate after reset

**Table 8-333. CPU Identification Register (CPUID) Field Descriptions**

Bit	Field	Value	Description
31-20	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
19-16	CPUNUM	0-Fh	Reflects the value on the t_cpunum_i[3:0] input port. The input port is sampled on reset release and kept constant – it is not sampled continuously.
15-12	Y_MINOR	0-Fh	Minor revision.
11-0	X_MAJOR	0-FFFh	Major revision.

**8.2.4.6.21 Decode Program Counter Register (DPC)**

The decode program counter register (DPC) contains the halfword address of the next instruction to be executed (or instruction currently at DEC stage of the pipe). The DPC is shown in [Figure 8-50](#) and described in [Table 8-334](#).

The DPC is a read-only register provided for debug purposes only. A read of DPC while the CPU is halted at a debug event shows the PC of the next instruction to be executed (after the CPU is resumed from a halted state). The debugger can use DPC to determine the halt location. Reading DPC from the debugger while the CPU is running has limited or no use.

An **MVC** instruction with DPC as write address is ignored by the CPU, no errors are generated.

A read of DPC via the **MVC** instruction returns the address of the **MVC** instruction itself. For example, in the following assembly instruction sequence, the read of DPC via the **MVC** instruction returns 0x101 in R1:

```
0x100   ADDD 1, R0, R0
0x101   MVC DPC, R1 ; R1 gets 0x101
```

**Figure 8-50. Decode Program Counter Register (DPC)**

LEGEND: R = Read only; -n = value after reset

**Table 8-334. Decode Program Counter Register (DPC) Field Descriptions**

Bit	Field	Value	Description
31	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
30-0	Decode Program Counter	0-7FFF FFFFh	Contains the address of the next instruction to be executed.

**8.2.4.6.22 Time Stamp Counter Registers (TSCL and TSCH)**

The CPU contains a free running 64-bit counter that advances each CPU clock under normal operation. The counter is accessed as two 32-bit read-only control registers, TSCL ([Figure 8-51](#)) and TSCH ([Figure 8-52](#)).

**Figure 8-51. Time Stamp Counter Register - Low Half (TSCL)**

LEGEND: R = Readable by the **MVC** instruction; -n = value after reset

**Figure 8-52. Time Stamp Counter Register - High Half (TSCH)**

LEGEND: R = Readable by the **MVC** instruction; -n = value after reset

### 8.2.4.6.22.1 Initialization

The counter is cleared to 0 after reset, and counting is disabled. Subsequently, any write to TSCL initializes the counter to 0 (the write data is ignored) and enables the counter. A write to TSCH is completely ignored, without any side effect of enabling the time stamp counter (like that with TSCL). The counter remains enabled until the next CPU functional reset. Once enabled, there is no way to disable the counter or reinitialize the counter to 0.

### 8.2.4.6.22.2 Enabling Counting

The counter is enabled by writing to TSCL. The value written is ignored. Counting begins in the cycle after the **MVC** instruction executes. If executed with the count disabled, the following code sequence shows the timing of the count starting (assuming no stalls occur in the three cycles shown).

```
MVC  0, TSCL           ; Start the counter
MVC  TSCL, R0          ; R0 = 0
MVC  TSCL, R1          ; R1 = 1
```

### 8.2.4.6.22.3 Disabling Counting

Once enabled, counting cannot be disabled under program control. Counting is disabled in the following cases:

- After exiting the reset state.
- When the CPU is fully powered down.

### 8.2.4.6.22.4 Reading the Counter

Reading the full 64-bit count takes two sequential **MVC** instructions. A read from TSCL causes the upper 32 bits of the current count (the value of the counter when the corresponding **MVC** instruction is at Fetch/DEC stage) to be copied into TSCH. In normal operation, only this snapshot of the upper half of the 64-bit count is available to the programmer. The value read will always be the value copied at the cycle of the last **MVC TSCL, reg** instruction. If it is read with no TSCL reads having taken place since reset, then the reset value of 0 is read.

When reading the full 64-bit value, it must be ensured that no interrupts are serviced between the two **MVC** instructions if an ISR is allowed to make use of the time stamp counter. There is no way for an ISR to restore the previous value of TSCH (snapshot) if it reads TSCL, since a new snapshot is performed.

The following example shows the correct and recommended way of obtaining the full 64-bit value of the time stamp counter:

```
// Disable interrupts
MVC  CSR, R7           ; Get CSR into R7
CLR  0, 0, R7, R7     ; Clear R7[0]
MVC  R7, CSR          ; Copy R7 back to CSR (clears GIE)

// Read Counter
MVC  TSCL, R0          ; read lower 32b into R0
MVC  TSCH, R1          ; read upper 32b into R1

// Enable interrupts
MVC  CSR, R7           ; Get CSR into R7
SET  0, 0, R7, R7     ; Set R7[0]
MVC  R7, CSR          ; Copy R7 back to CSR (sets GIE)
```

### 8.2.4.7 CPU Shadow Registers

The ARP32 CPU implements a shadow copy for the following registers:

- All architectural registers: R0-R7
- Loop control registers: LSA $n$ , LEA $n$ , LCNT $n$

The shadow registers are used to save-off the main registers during an interrupt processing. When an interrupt is taken, the main registers are copied onto the corresponding shadow register by the CPU along with saving the interrupt return address in IRP/NRP. The original registers are restored back upon a return from interrupt – as a result of a **BIRP** or **BNRP** instruction execution.

As a result of this, as long as interrupts are not allowed to be nested, interrupt handler routines in the ARP32 CPU do not need to save of any registers on the stack, this significantly reduces the interrupt processing latency.

Table 8-335 provides the list of the shadow registers in the ARP32 CPU.

**Table 8-335. CPU Shadow Registers**

Acronym	Register Name	Description
SR0	Shadow R0	Shadow copy of R0
SR1	Shadow R1	Shadow copy of R1
SR2	Shadow R2	Shadow copy of R2
SR3	Shadow R3	Shadow copy of R3
SR4	Shadow R4	Shadow copy of R4
SR5	Shadow R5	Shadow copy of R5
SR6	Shadow R6	Shadow copy of R6
SR7	Shadow R7	Shadow copy of R7
SLSA0	Shadow Loop 0 Start Address	Shadow copy of LSA0
SLEA0	Shadow Loop 0 End Address	Shadow copy of LEA0
SLCNT0	Shadow Loop 0 Iteration Count	Shadow copy of LCNT0
SLSA1	Shadow Loop 1 Start Address	Shadow copy of LSA1
SLEA1	Shadow Loop 1 End Address	Shadow copy of LEA1
SLCNT1	Shadow Loop 1 Iteration Count	Shadow copy of LCNT1
SLCNT0RLD	Shadow Loop 0 Iteration Count Reload	Shadow copy of LCNT0RLD

Shadow registers are access via the **MVS** instruction:

- **MVS sreg, areg** - Read shadow register into an architectural register
- **MVS areg, sreg** - Write shadow register from an architectural register

The **MVS** instruction is executed by the S unit. Any write to the shadow registers (via a **MVS areg, sreg** instruction) has two exposed delay slots - a subsequent read from the same *sreg* (via a **MVS areg, sreg** instruction) must be separated by at least two instructions. Otherwise, the old value of *sreg* is read.

The read result (of a **MVS sreg, areg** instruction) is bypassed appropriately to a subsequent instruction using the same *areg* – there is no delay slot or stall in this case.

The following examples illustrate the behavior:

```
// Update SR0 and then read back (assume SR0 = 0x100, R0 = 0x200)
MVS  R0, SR0      ; Move R0 to SR0
NOP                               ; NOP to fill delay slot #1
MVS  SR0, R7      ; Move SR0 to R7, R7 = 0x100 (old value)

// Update SR0 and then read back (assume SR0 = 0x100, R0 = 0x200)
MVS  R0, SR0      ; Move R0 to SR0
NOP                               ; NOP to fill delay slot #1
NOP                               ; NOP to fill delay slot #2
MVS  SR0, R7      ; Move SR0 to R7, R7 = 0x200 (new value)
```

### 8.2.4.8 Functional Units

The ARP32 CPU contains the following main functional units:

- **L-Unit:** Performs all logical operations (AND/OR/XOR/NOT/shift and minimum/maximum), some bit level operations like bit rotation, signed/unsigned bit extraction, bit reversal, bit clear, bit set operations, left most bit detection, and saturation operation.
- **S-Unit:** Performs the move operations.
- **D-Unit:** Performs arithmetic operations that include compare less/greater than instructions, address calculation for load/store instructions, PC calculations for branch instructions, and stack pointer increment/decrement for **PUSH/POP** and **CALL/RETURN** instructions.
- **M-Unit:** Performs multiplication, division, and modulo operations.

### 8.2.4.9 Instruction Fetch

The ARP32 ISA has instructions that are either 16 bit or 32 bit; the mix being chosen to achieve optimal code size without sacrificing the performance (of the amount of actual work done per instruction per cycle).

The ARP32 CPU allows 16/32-bit instructions to be mixed freely without any overhead or switching between instruction decoding mode. The program counter (PC) always points to a halfword address aligned with an instruction boundary. However, the program fetch is always aligned with a word boundary. The ARP32 CPU always requests a 32-bit word from a word-aligned address over its 32-bit wide program interface. Internally, the CPU maintains a 16 bit single entry fetch buffer (FetchBuffer[15:0]) to store an unused instruction word or part of an instruction word.

This allows a simpler program memory subsystem design and allows area, power efficient implementation of tightly coupled program memory subsystem without incurring any overhead on code density.

Since instructions in the ARP32 CPU are either 16 bit or 32 bit and they are freely mixable, any 32-bit word fetched from the program memory (FetchWord[31:0]) may have the following cases:

- **The FetchWord contains two 16-bit instructions:** the first instruction (FetchWord[15:0]) is sent to the instruction decoder and the second instruction (FetchWord[31:16]) is stored in the FetchBuffer. The stored instruction is then sent to the instruction decoder at the next decode cycle. No program request is sent for a cycle (as the fetch buffer already contains the next instruction to be executed) unless there is a branch.
- **The FetchWord contains one 32-bit instruction:** the entire FetchWord is sent to the instruction decoder and the FetchBuffer is invalidated.
- **The FetchWord contains one 16-bit instruction and the lower halfword of the next 32-bit instruction:** the valid 16-bit instruction (in FetchWord[15:0]) is sent to the instruction decoder and the lower halfword of the next 32-bit instruction is stored in the FetchBuffer. A second fetch must be performed to fetch the upper halfword of the 32-bit instruction before it is decoded. The request for this second fetch is sent in the current cycle. When the corresponding FetchWord is available (for example, at the next cycle), its lower halfword constitutes the full 32-bit instruction word and is sent to the instruction decoder. The unused upper halfword of the current FetchWord is stored back to the FetchBuffer again.

Thus, for a sequential program with an arbitrary mix of 16-bit and 32-bit instructions, the instruction is executed without a single cycle of stall (due to unavailability of a whole instruction word for decoding) in the pipeline. However, if the target address of a program discontinuity (due to branch, call, return interrupt) is not word aligned and there exists a 32-bit instruction at the target address, a single 32-bit aligned fetch is not sufficient to fetch a full 32-bit instruction word. In this case, there is a stall/bubble cycle in the CPU pipeline. The fetch engine of the CPU issues an additional instruction fetch request at the next cycle to fulfill the required 32-bit instruction fetch and the CPU pipeline continues normally.

### 8.2.4.10 Alignment of 32-bit Instructions

The fetch engine of the ARP32 CPU supports 16-bit and 32-bit instructions to be aligned at any halfword boundary. For a sequential execution, CPU fetches and executes from such instruction stream without incurring any stall cycles. However, if a program discontinuity target contains an unaligned 32-bit instruction, the CPU stalls for a cycle.

---

**NOTE:** The following requirements are for efficient code generation, not functionally correct code generation. The ARP32 CPU supports having a 32-bit instruction at an unaligned discontinuity target – with the associated stall overhead. There are cases where this cannot be avoided – for example, an interrupt return to an unaligned 32-bit instruction.

---

This requires that for the most efficient programming of the ARP32 CPU, all programs contain 32-bit instructions to be aligned on a 32-bit boundary in the program memory. For the ARP32 C/C++ compiler/toolchain, this means that a 32-bit alignment is maintained for the following cases:

- All assembly level basic blocks that start with a 32-bit instruction
- All functions that start with a 32-bit instruction
- All HLA loop rewind targets (content of  $LSA_n$  registers) that contains a 32-bit instruction

If the previous conditions are met, the following most frequent cases where a program discontinuity happens, do not incur any additional stalls:

- Use of branch/call immediate instructions (**Bcc** *scst9*, **Bcc** *scst16*, or **CALL** *scst22*) for general program flow control
- Use of register call (**CALL** *src1*) for long calls to labels or function calls using function pointers
- Use of HLA for loop constructs and corresponding branch

### 8.2.4.11 Instruction Execution in Branch Delay Slot

The ARP32 CPU allows one delay slot for the following control flow instructions:

- branch (**Bcc** *scst9*, **Bcc** *scst16*, or **Bcc** *dst*)
- call (**CALL** *scst22* or **CALL** *src1*)
- return (**RET**)

There is no delay slot for SWI.

An instruction is placed in a branch delay slot as long as the restrictions mentioned in [Section 8.2.5.3](#) are maintained.

### 8.2.4.12 Address Space

The ARP32 CPU uses the convention that both instruction and data memory is byte addressable. The ARP32 CPU is capable of supporting full 32-bit instruction and data memory address space.

The ARP32 core is a pure Harvard architecture, separate instruction and data bus access the program and data memory space. However, while integrating the core, it is possible to unify the program and data space to make it a unified (modified Harvard) memory architecture.

### 8.2.4.13 Program Counter Convention

In the ARP32 CPU, the PC (program counter register) always contains halfword addresses. Correspondingly, all PC related registers (IRP, NRP) also contain a halfword address. The PC conventions used in pseudo code and other program snippets presume this convention,  $PC = PC + 1$  indicates advancement of the PC by 1 entry, with each entry containing 2 bytes.

However, since program fetch is always of word size and word aligned, a word address is sent over the instruction fetch address bus (`cpu_imem_addr_of[31:2]`).

This convention is used in most of the cases in the ISA where a PC related operation is implied. However, there are some use cases where an absolute byte address is needed to reference a location in program memory. Based on these considerations, the following rules/conventions are applied to PC related instructions and operations; the ARP32 compiler/toolchain and assembly code must maintain the following rules/conventions:

- For immediate branch instructions (**Bcc** *scst9* or **Bcc** *scst16*), the branch offset is treated as halfword offsets. This offset is directly added to the PC to calculate effective branch address (see immediate branch instructions).
- For immediate call instructions (**CALL** *scst22*), the call address is treated as PC relative halfword offset. This offset is directly added to the PC to calculate effective call address (see immediate call instructions).
- For register branch or call instructions (**Bcc** *src1* or **CALL** *src1*), the register content is treated as the absolute byte address of the branch/call destination. This address is first converted to a halfword address and then loaded to the PC.
- For set loop address instruction (**SLA** *ucst16, creg*), the immediate offset is treated as a PC relative halfword offset. This offset is directly added to the PC to calculate effective branch address (see immediate branch instructions).
- While setting up address in loop address registers (*LSAn*, *LEAn*) using the **MVC/MVCH** instructions (immediate or register forms), the value set in the loop address register is the absolute halfword address (of loop start/end instruction).
- A call instruction (**CALL** *src1* or **CALL** *scst22*) saves off a return address to the stack that is a halfword address. A corresponding return instruction (**RET**) loads this address directly onto the PC to return to the correct location.
- An interrupt saves off a return address to the IRP/NRP register that is a halfword address. A corresponding return instruction (**BIRP** or **BNRP**) loads this address directly onto the PC to return to the correct location.
- Interrupt Service Table (IST) entries are treated as a halfword address to the interrupt handler routine.

The PC is an architectural register, that is, it contains machine state, but is not directly accessible through the instruction set. Instruction execution has an effect on the PC, but the current PC value can not be read or written explicitly.

### 8.2.4.14 Stack Pointer Convention

The ARP32 CPU has a 32-bit stack pointer register (SP) and its content is always assumed to be a byte address. Any address computation using the SP value considers content of the SP as a byte address while computing an effective address of a byte/halfword/word access.

The ARP32 CPU is a descending stack machine. The ARP32 CPU programming model requires that the programmer and/or the compiler/toolchain maintain the following conventions:

- Stack pointer (SP) is initialized to a high address, it reduces to a lower address as it proceeds through function calls during program execution.
- Stack pointer (SP) must be always aligned to a 4-byte word address. It is software responsibility to keep the SP always aligned to 4-byte word address when allocating/de-allocating stack – there is no hardware support to do this alignment automatically. Since the ARP32 CPU does not support unaligned access, a stack pointer value not aligned to 4-byte boundary may result in access to unaligned addresses and thus produce unexpected result.
- In all cases where the CPU itself modifies the SP (call, return, **LDRF/STRF**), it always increments/decrements it by 4 (word aligned).

- Stack pointer (SP) always points to the next free location where an entry is stacked. For pushing anything onto stack, the CPU writes to the location the SP is currently pointing to and then post-decrements the SP. Similarly, while popping anything from the stack, the CPU pre-decrements the SP and then reads from the location (pre-decremented) the SP points to. For example:
  - Every **CALL** saves the return address to the location the SP is currently pointing to and then post-decrements the SP.
  - Every **RET** pre-decrements the SP and then loads the return address from the location updated SP points to.
- To allocate stack in a function (in the function prolog), reduce the SP by an amount equal to local stack frame size.
- Local variables, input arguments to functions and spilled variables all are accessed via the SP relative positive offset load/store instructions.
- To de-allocate stack in a function (in the function epilog), increase the SP by an amount equal to local stack frame size.

The ARP32 core does not save any context on stack during interrupt processing. The same stack layout and convention is applied to the interrupt handler function/procedure – except for additional register save requirements.

#### 8.2.4.15 Global Data Pointer Convention

Global data pointer register (GDP) contains a byte address of the start of global data section. It is computed by the linker and assigned to a linker symbol that the boot routine must be used to initialize GDP.

#### 8.2.4.16 Conditional Execution

On the ARP32 CPU, conditional execution is available only by using conditional branches.

Most data processing instructions and all compare instructions update the condition flags in control status register: CSR[2]EQ, CSR[3]LT, CSR[4]GT. Some instructions update all flags and some instructions only update a subset. See the instruction descriptions for the flags they affect. Instructions update the status bit relevant to it; other status bits are left unchanged.

Conditional branch instructions are executed, based on the condition flags set in another instruction, either:

- immediately after the instruction that updated the flags
- after any number of intervening instructions that have not updated the flags

See conditional branch instruction for more details.

#### 8.2.4.17 Hardware Loop Acceleration

##### 8.2.4.17.1 Overview

The ARP32 CPU implements a hardware loop assist (HLA) function to reduce cycles in critical inner loops that are typically spent in loop control operations such as loop index increment, decrement, compare, branch operations. Using an HLA mechanism, a zero-overhead rewind to the top of the loop is achieved for up to two levels of nested loops. The structure and operation of the HLA is conformable for easy mapping of loop constructs (for, while, do, etc.) available in C/C++.

Up to two levels of nested loops are supported. Additional levels of nesting are possible through standard software techniques.

In a two level nested loop construct, the inner most level is termed as Loop 0, while the outer level is termed Loop 1. For a single-level nested loop, only Loop 0 is used. Control registers associated with Loop 0 and Loop 1 control the operation of each level.

### 8.2.4.17.2 Loop Registers

HLA operation is setup and controlled by six control registers listed in [Table 8-336](#). Note that LSA $n$  and LEA $n$  registers contain/reflect the byte address.

**Table 8-336. Hardware Loop Control Registers**

Acronym	Register Name	Description
LSA0	Loop 0 Start Address Register	Contains the Start Address of Loop 0
LEA0	Loop 0 End Address Register	Contains the End Address of Loop 0
LCNT0	Loop 0 Iteration Count Register	Contains the Iteration Count of Loop 0
LSA1	Loop 1 Start Address Register	Contains the Start Address of Loop 1
LEA1	Loop 1 End Address Register	Contains the End Address of Loop 1
LCNT1	Loop 1 Iteration Count Register	Contains the Iteration Count of Loop 1
LCNT0RLD	Loop 0 Iteration Count Reload Value Register	Contains the LCNT0 reload value during outer loop rewind

### 8.2.4.17.3 Loop Setup Instructions

Loop control registers are accessed via the **MVC/MVCH** instructions like any other control registers.

To simplify and optimize loop setup in the most frequent compiler generated use cases, a separate instruction called set loop address (**SLA** *ucst16, creg*) is provided. The **SLA** instruction takes a PC-relative immediate positive halfword offset (*ucst16*) and writes the byte address of the location indicated by the PC + *ucst16* value to the LSA $n$  and LEA $n$  registers.

Loop setup occurs in the following order:

- For a single-level loop (only Loop 0):
  1. Setup LSA0
  2. Setup LEA0
  3. Setup LCNT0
- For a two-level loop (Loop 0 and Loop 1):
  1. Setup LSA1
  2. Setup LEA1
  3. Setup LCNT1
  4. Setup LSA0
  5. Setup LEA0
  6. Setup LCNT0

HLA is not assured to work if the above order is not maintained.

### 8.2.4.17.4 Loop Operation

The loop setup process for each level of nesting consists of the following (in the specified order):

1. Setup loop start address register (LSA $n$ ) with the byte address of the first instruction in the corresponding loop.
2. Setup loop end address register (LEA $n$ ) with the byte address of the last instruction in the corresponding loop.
3. Setup loop iteration count register (LCNT $n$ ) with the intended loop iteration count.

A loop becomes active as soon as a value greater than 1 is programmed in LCNT $n$ . The LSA $n$  and LEA $n$  registers are written when the corresponding **MVC/SLA** instruction is executed but the values are not used by the processor (for detecting loop rewind condition) until the corresponding loop becomes active.

When a loop becomes active ( $LCNTn > 1$ ), the PC of the instruction at DEC phase is checked with the LEAn register. If they match, the CPU takes a zero-cycle overhead branch to the top of the loop provided by the LSA<sub>n</sub> registers. The program fetch request to LSA<sub>n</sub> is placed when the last instruction of a loop is at DEC. Thus there is no delay slot for the loop rewind branch, neither any stall or null cycle.

For  $LCNTn = x$ , the loop rewinds  $x - 1$  times, effectively the loop body executes total  $x$  times ( $x - 1$  rewinds and the last fall through pass). For  $LCNTn = 1$ , the loop body executes once (zero rewind). For  $LCNTn = 0$ , the loop is not considered active – the CPU just linearly executes – however, as a result, the loop body executes once (linear fall through). Note that  $LCNTn = 0$  does not mean loop body would not be executed.

During operation, the  $LCNTn$  registers are directly updated (decremented) with the remaining iteration count. The loop counters are updated along with the corresponding rewind-branch. At any time  $LCNTn$  is read to determine how many iterations of the corresponding loop are still to be executed. When each level completes, the corresponding  $LCNTn$  registers become zero, the LSA<sub>n</sub>/LEA<sub>n</sub> registers are left unchanged. Note that for  $LCNTn = 1$ , the loop body executes once and the loop counter is decremented when the last instruction of the corresponding loop is executed.

The  $LCNT0RLD$  register is updated automatically by the CPU whenever a value is written to  $LCNT0$  (for example, during loop setup). For a two-level nested loop, once the inner most level iteration completes and the CPU rewinds to the top of the outer loop, the  $LCNT0$  is reloaded with the content of  $LCNT0RLD$ . Note that even if  $LCNT0RLD$  is a programmer visible control register, it acts as a shadow register of  $LCNT0$  (updated on any write to  $LCNT0$ ) and must not be explicitly written during a loop setup.

There are no restrictions in embedding an HLA construct or instruction sequence, consisting of one or two levels of nested loops, into a larger level of nested loop implemented by normal software techniques.

Figure 8-53. Loop Operation

#### 8.2.4.17.5 Call and Branch within Loop Context

Branches (**Bcc scst9**, **Bcc scst16**, or **Bcc dst**) within the loop are allowed, provided the conditions explicitly mentioned in [Section 8.2.5.3.2](#) are met.

Calls (**CALL scst22** or **CALL dst**) within the loop are generally not supported as the loop registers are not explicitly saved off when a CALL is executed within the loop context. However, software uses **CALL** instructions if the call tree does not contain any HLA usage within the caller code.

#### 8.2.4.17.6 Dynamic Changes to Loop Iteration Count

A write to the LCNTn register within the loop body (of either of the loops) is used to dynamically change the iteration count, including pre-maturely terminating the corresponding level. Such a write to LCNTn instruction must be executed at least 2 instructions before the last (ending) instruction of the corresponding loop (x).

It is also possible to skip inner loop dynamically (per iteration of the outer loop) by simply branching across the inner loop within the outer loop context. It is not necessary to explicitly set the inner loop count to 0/1 (loop inactive values). Similarly, a branch out of the outer loop context is possible without setting the outer loop count to inactive values. This relies on the fact that even if the inner or outer loop count has not been set to an inactive value, a loop rewind does not happen unless the loop end PC (LEAn) is encountered.

These features (dynamically changing the loop iteration count, skipping inner/outer loop via branches) are used by the compiler to implement constructs such as last/continue/break and alike.

#### 8.2.4.17.7 Interrupt Processing During HLA

Interrupts are not taken while the last instruction of a loop level is at DEC. Interrupts are taken after the loop rewind happens. The return address saved off during the interrupt processing points to the loop rewind address (LSAn). Consequently, a return from interrupt returns to the last rewind address (LSAn).

When taking an interrupt (irrespective if an HLA is active), the CPU saves off the six loop registers in the corresponding shadow registers. They are restored when interrupts are returned via the **BIRP/BNRP** instructions.

#### 8.2.4.17.8 HLA Usage in Interrupt Context

Since loop context is fully saved by hardware while taking an interrupt, HLA is used within an ISR context freely without requiring any additional context save. For allowing nested interrupts, the shadow copies of HLA registers must be saved off to the stack explicitly along with other shadow registers. This helps achieve very-low interrupt latency in the ARP32 CPU under a single-level-nested-interrupt use model.

#### 8.2.4.17.9 HLA Usage Restrictions

There are certain restrictions on HLA usage, see [Section 8.2.5.3.2](#).

## 8.2.4.17.10 HLA Mapping Examples

### 8.2.4.17.10.1 Loops With Single Level of Nesting

#### Example 8-2. C memset-like Loop, Single Level, Minimum Instructions

Pseudo C code:

```
int i, myarray[100];
for (i=0; i< 100; i++) {
    myarray[i] = 1;
}
```

**Table 8-337. Example 1 of Generated Assembly Code (relevant instructions only)**

Byte Address	Instruction	Comment
0x100	MVKS 1, R0	Write data
0x102	SLA 6, LSA0	First instr of loop0 is at #6 halfword offset LSA0 = 0x102 + hex(6 x 2) = 0x10E
0x106	SLA 5, LEA0	Last instr of loop0 is at #5 halfword offset LEA0 = 0x106 + hex(5 x 2) = 0x110
0x10A	MVC 100, LCNT0	iter count = 100
0x10E	STW R0, *++R1(1)	First instr of Loop 0
0x110	NOP	Last instr of Loop 0 (padding needed)

**Table 8-338. Example 2 of Generated Assembly Code (relevant instructions only)**

Byte Address	Instruction	Comment
0x100	MVKS 1, R0	Write data
0x102	SLA 6, LSA0	First instr of loop0 is at #6 halfword offset LSA0 = 0x102 + hex(6 x 2) = 0x10E
0x106	SLA 5, LEA0	Last instr of loop0 is at #5 halfword offset LEA0 = 0x106 + hex(5 x 2) = 0x110
0x10A	MVC 100, LCNT0	iter count = 100
0x10E	STW R0, *+R1(0)	First instr of Loop 0
0x110	ADD 4, R1, R1	Last instr of Loop 0 (padding needed)

**Example 8-3. C memcpy-like Loop, Single Level, Minimum Instructions**

Pseudo C code:

```

void MyMemcpyByWord (void *ptr1, void *ptr2, int size){
    int ii, dbwSize = size>>2;
    unsigned int *dst = ptr1;
    unsigned int *src = ptr2;
    for (ii=0 ; ii< dbwSize ; ii++)
        dst[ii] = src[ii];
}
  
```

**Table 8-339. Example 1 of Generated Assembly Code (relevant instructions only)**

Byte Address	Instruction	Comment
0x100	SLA 5, LSA0	First instr of loop0 is at #5 halfword offset LSA0 = 0x100 + hex(5 x 2) = 0x10A
0x104	SLA 4, LEA0	Last instr of loop0 is at #4 halfword offset LEA0 = 0x104 + hex(4 x 2) = 0x10C
0x108	MVC R1, LCNT0	iter count = "size" (passed via R1)
0x10A	LDW *++R2(1), R3	Load word from source (Loop 0, instr 1)
0x10C	STW R3, *++R4(1)	Store word to dest (Loop 0, instr 2)

**Table 8-340. Example 2 of Generated Assembly Code (relevant instructions only)**

Byte Address	Instruction	Comment
0x100	SLA 5, LSA0	First instr of loop0 is at #5 halfword offset LSA0 = 0x100 + hex(5 x 2) = 0x10A
0x104	SLA 6, LEA0	Last instr of loop0 is at #6 halfword offset LEA0 = 0x104 + hex(6 x 2) = 0x110
0x108	MVC R1, LCNT0	iter count = "size" (passed via R1)
0x10A	LDW *+R2(0), R3	Load word from source (Loop 0, instr 1)
0x10C	ADD 4, R2, R2	Increment src pointer
0x10E	STW R3, *+R4(0)	Store word to dest
0x110	ADD 4, R4, R4	Increment dest pointer (Loop 0, instr 4)

### 8.2.4.17.10.2 Loops With Two Levels of Nesting

#### Example 8-4. Two-level Nesting, Both Loops Ending at Same Instruction

Pseudo C code:

```

For (i=0; i<20; i++) {
    Instruction1    // size 16b
    Instruction2    // size 32b
    Instruction3    // size 32b
    Instruction4    // size 16b
    For (j=0; j<10; j++) {
        Instruction5 // size 16b
        Instruction6 // size 32b
        Instruction7 // size 16b
    }
}
    
```

**Table 8-341. Example of Generated Assembly Code (relevant instructions only)**

Byte Address	Instruction	Comment
0x100	SLA 18, LSA1	First instr of loop1 is at #18 halfword offset LSA1 = 0x100 + hex(18 x 2) = 0x124
0x104	SLA 19, LEA1	Last instr of loop0 is at #19 halfword offset LEA0 = 0x104 + hex(19 x 2) = 0x12A
0x108	MVC 20, LCNT1	iter count (=20) of loop1
0x10C	SLA 6, LSA0	First instr of loop0 is at #6 halfword offset LSA1 = 0x10C + hex(6 x 2) = 0x118
0x110	SLA 9, LEA0	First instr of loop0 is at #9 halfword offset LEA0 = 0x110 + hex(9 x 2) = 0x122
0x114	MVC 10, LCNT0	iter count (=10) of loop0
0x118	Instruction1	Loop1 start
0x11A	Instruction2	
0x11E	Instruction3	
0x122	Instruction4	
0x124	Instruction5	Loop0 start
0x126	Instruction6	
0x12A	Instruction7	Loop0 end, Loop1 end

**Example 8-5. Two-level Nesting, Different Ending Instructions for Two Levels**

Pseudo C code:

```

For (i=0; i<20; i++) {
    Instruction1    // size 16b
    Instruction2    // size 32b
    Instruction3    // size 32b
    Instruction4    // size 16b
    For (j=0; j<10; j++) {
        Instruction5 // size 16b
        Instruction6 // size 32b
        Instruction7 // size 16b
    }
    Instruction8    // size 32b
    Instruction9    // size 32b
    Instruction10   // size 16b
}
    
```

**Table 8-342. Example of Generated Assembly Code (relevant instructions only)**

Byte Address	Instruction	Comment
0x100	SLA 18, LSA1	First instr of loop1 is at #18 halfword offset LSA1 = 0x100 + hex(18 x 2) = 0x124
0x104	SLA 19, LEA1	Last instr of loop1 is at #19 halfword offset LEA0 = 0x104 + hex(19 x 2) = 0x12A
0x108	MVC 20, LCNT1	iter count (=20) of loop1
0x10C	SLA 6, LSA0	First instr of loop0 is at #6 halfword offset LSA1 = 0x10C + hex(6 x 2) = 0x118

## 8.2.4.18 Interrupts

### 8.2.4.18.1 Overview

The ARP32 CPU supports various types of interrupts that include: reset, a non-maskable interrupt (NMI), 12 maskable interrupts (INT15-INT4), an undefined instruction interrupt (UNDEF), and a software interrupt (SWI). The following registers control the CPU behavior on receipt of an interrupt:

- Control Status Register (CSR)
- Interrupt Enable Register (IER)
- Interrupt Flag Register (IFR)
- Interrupt Set Register (ISR)
- Interrupt Clear Register (ICR)
- Nonmaskable Interrupt Return Pointer Register (NRP)
- Interrupt Return Pointer Register (IRP)

The SWI and UNDEF interrupts are special cases that do not have an associated input pin. The SWI interrupt mechanism is activated by decoding of the **SWI** instruction. The UNDEF interrupt is activated by detection of an undefined instruction.

On acknowledge of an enabled interrupt, the ARP32 CPU loads the contents of the interrupt service table entry associated with the interrupt into the PC.

Each interrupt type is discussed in the following sections; [Table 8-343](#) summarizes the ARP32 CPU interrupts.

**Table 8-343. Interrupt Summary**

Interrupt Name	Vector Address (byte)	Input Pin	Enable Control	Interrupt Return Pointer Register	Interrupt Return Instruction to be Used	Context Save and Restore Actions	
						By Hardware	By Software
Reset	00h	cpu_reset_i	Always Enabled	NA	NA	NA	NA
NMI	04h	cpu_nmi_i	IER:NMIE	NRP	BNRP	CSR to NMISCSR	R0-R7 to Stack, LSA <sub>n</sub> to Stack, LEA <sub>n</sub> to Stack, LCNT <sub>n</sub> to Stack
SWI	08h	None	Always Enabled	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA <sub>n</sub> to SLSA <sub>n</sub> , LEA <sub>n</sub> to SLEA <sub>n</sub> , LCNT <sub>n</sub> to SLCNT <sub>n</sub>	None
UNDEF	0Ch	None	Always Enabled	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA <sub>n</sub> to SLSA <sub>n</sub> , LEA <sub>n</sub> to SLEA <sub>n</sub> , LCNT <sub>n</sub> to SLCNT <sub>n</sub>	None
INT4	10h	cpu_int4_i	CSR:GIE; IER:NMIE; IER:IE4	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA <sub>n</sub> to SLSA <sub>n</sub> , LEA <sub>n</sub> to SLEA <sub>n</sub> , LCNT <sub>n</sub> to SLCNT <sub>n</sub>	None
INT5	14h	cpu_int5_i	CSR:GIE; IER:NMIE; IER:IE5	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA <sub>n</sub> to SLSA <sub>n</sub> , LEA <sub>n</sub> to SLEA <sub>n</sub> , LCNT <sub>n</sub> to SLCNT <sub>n</sub>	None
INT6	18h	cpu_int6_i	CSR:GIE; IER:NMIE; IER:IE6	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA <sub>n</sub> to SLSA <sub>n</sub> , LEA <sub>n</sub> to SLEA <sub>n</sub> , LCNT <sub>n</sub> to SLCNT <sub>n</sub>	None

**Table 8-343. Interrupt Summary (continued)**

Interrupt Name	Vector Address (byte)	Input Pin	Enable Control	Interrupt Return Pointer Register	Interrupt Return Instruction to be Used	Context Save and Restore Actions	
						By Hardware	By Software
INT7	1Ch	cpu_int7_i	CSR:GIE; IER:NMIE; IER:IE7	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA <sub>n</sub> to SLSA <sub>n</sub> , LEA <sub>n</sub> to SLEA <sub>n</sub> , LCNT <sub>n</sub> to SLCNT <sub>n</sub>	None
INT8	20h	cpu_int8_i	CSR:GIE; IER:NMIE; IER:IE8	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA <sub>n</sub> to SLSA <sub>n</sub> , LEA <sub>n</sub> to SLEA <sub>n</sub> , LCNT <sub>n</sub> to SLCNT <sub>n</sub>	None
INT9	24h	cpu_int9_i	CSR:GIE; IER:NMIE; IER:IE9	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA <sub>n</sub> to SLSA <sub>n</sub> , LEA <sub>n</sub> to SLEA <sub>n</sub> , LCNT <sub>n</sub> to SLCNT <sub>n</sub>	None
INT10	28h	cpu_int10_i	CSR:GIE; IER:NMIE; IER:IE10	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA <sub>n</sub> to SLSA <sub>n</sub> , LEA <sub>n</sub> to SLEA <sub>n</sub> , LCNT <sub>n</sub> to SLCNT <sub>n</sub>	None
INT11	2Ch	cpu_int11_i	CSR:GIE; IER:NMIE; IER:IE11	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA <sub>n</sub> to SLSA <sub>n</sub> , LEA <sub>n</sub> to SLEA <sub>n</sub> , LCNT <sub>n</sub> to SLCNT <sub>n</sub>	None
INT12	30h	cpu_int12_i	CSR:GIE; IER:NMIE; IER:IE12	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA <sub>n</sub> to SLSA <sub>n</sub> , LEA <sub>n</sub> to SLEA <sub>n</sub> , LCNT <sub>n</sub> to SLCNT <sub>n</sub>	None
INT13	34h	cpu_int13_i	CSR:GIE; IER:NMIE; IER:IE13	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA <sub>n</sub> to SLSA <sub>n</sub> , LEA <sub>n</sub> to SLEA <sub>n</sub> , LCNT <sub>n</sub> to SLCNT <sub>n</sub>	None
INT14	38h	cpu_int14_i	CSR:GIE; IER:NMIE; IER:IE14	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA <sub>n</sub> to SLSA <sub>n</sub> , LEA <sub>n</sub> to SLEA <sub>n</sub> , LCNT <sub>n</sub> to SLCNT <sub>n</sub>	None
INT15	3Ch	cpu_int15_i	CSR:GIE; IER:NMIE; IER:IE15	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA <sub>n</sub> to SLSA <sub>n</sub> , LEA <sub>n</sub> to SLEA <sub>n</sub> , LCNT <sub>n</sub> to SLCNT <sub>n</sub>	None

### 8.2.4.18.2 Interrupt Processing

Figure 8-54 provides an illustration of different actions and events of interest during an interrupt processing. In this case, both INT4 and INT5 were asserted simultaneously, INT4 was selected as the winner and was taken after few cycles when all enable conditions (CSR[0]GIE, IER[1]NMIE, IER[n]) were met.

Note that the CPU entity signals/registers are shown in **bold** font; internal (and sometimes just conceptual) signals are shown in normal font.

The conceptual signal “Interrupt Accept” shows when a particular interrupt (in this case, INT4) is accepted to be taken next. This is generated by considering that all set bits of IFR, the interrupt priority, the enable conditions, and a safe cycle boundary within the CPU, where accepting an interrupt is safe.

The conceptual signal “Interrupt Taken” shows when a particular interrupt (in this case, INT4) is actually taken. The actions corresponding to an interrupt processing (IST access, context save, etc.) starts to take place within the CPU after this condition is achieved.

The delay between ‘Interrupt Accept’ and ‘Interrupt Taken’ is due to pending memory transaction on CPU instruction and data interfaces. The CPU waits for all outstanding instruction and data memory requests to be serviced before starting interrupt context save or IST access process.

Figure 8-54. Interrupt Processing

### 8.2.4.18.3 Interrupt Acknowledgment

The ARP32 CPU interrupts are sensitive to rising edge detected on the input interrupt pins (detected synchronously detected on the rising edge of the input clock). All interrupt pins are active high, with the exception of reset, which is active low and asynchronous.

The `cpu_iack_o` output signal is asserted high for a single cycle to indicate (to hardware external to the CPU core) that the CPU has begun processing an interrupt. The `cpu_inum_o` signal indicates the number of the interrupt that is being processed. The value driven on `cpu_inum_o` signal is also captured in the INUM field of the control status register (CSR).

Note that `cpu_jack_o` and `cpu_inum_o` are asserted for all interrupts (including reset). [Table 8-344](#) summarizes the `cpu_inum_o` values.

**Table 8-344. `cpu_inum_o` Values**

<code>cpu_inum_o[3:0]</code>	Interrupt
0h	Reset
1h	NMI
2h	SWI
3h	UNDEF
4h	INT4
5h	INT5
6h	INT6
7h	INT7
8h	INT8
9h	INT9
Ah	INT10
Bh	INT11
Ch	INT12
Dh	INT12
Eh	INT14
Fh	INT15

#### 8.2.4.18.4 Interrupt Priorities

When two interrupts happen at the same time, they are serviced by the ARP32 in order of their priority. The priority level for each interrupt is listed in [Table 8-345](#)

**Table 8-345. Interrupt Priorities**

Priority	Interrupt
Highest	Reset
	NMI
	SWI
	INT4
	INT5
	INT6
	INT7
	INT8
	INT9
	INT10
	INT11
	INT12
	INT13
	INT14
	INT15
Lowest	UNDEF

### 8.2.4.18.5 Interrupt Service Table (IST)

Each entry of the interrupt service table (IST) contains a byte address that points to the beginning of the interrupt service routine for that interrupt. When the ARP32 CPU accepts an interrupt, the contents of the associated IST entry is read (IST[n]), converted to the corresponding halfword address, and then loaded into the PC creating an effective branch.

The starting address of the IST is always the address 00h in the instruction memory; the IST can not be relocated. The addresses (byte address) of each entry is shown in [Table 8-346](#).

IST entries are byte address(s) of the interrupt handler (interrupt service routine) functions. Since 4 bytes are allocated for each IST entry, the interrupt handlers are placed anywhere in the 32-bit program memory space and the ARP32 CPU directly branches to that address. This reduces interrupt latency significantly since an instruction need not be fetched/decoded/executed from an IST location, nor an intermediate routine/call/branch needs to be processed for a branch to relatively large distance.

In fact, the IST is an “array of pointers (each entry 32 bits) to interrupt handler functions in C/C++” placed at the instruction memory address 0, which is remapped to a physical address by using the memory management unit (MMU0) that services program cache requests.

**Table 8-346. Interrupt Service Table (IST)**

Byte Address	IST Entry
00h	Reset
04h	NMI
08h	SWI
0Ch	UNDEF
10h	INT4
14h	INT5
18h	INT6
1Ch	INT7
20h	INT8
24h	INT9
28h	INT10
2Ch	INT11
30h	INT12
34h	INT13
38h	INT14
3Ch	INT15

### 8.2.4.18.6 Interrupt Flags

The ARP32 CPU maintains the pending status of all non-reset external interrupts (NMI, INT15-INT4) in the corresponding bit in the interrupt flag register (IFR). A 1 indicates the corresponding interrupt is pending, reading a 0 indicates the corresponding interrupt is not pending (either is being processed or it has not occurred).

When a rising edge is detected on the input pins of external interrupts (NMI, INT15-INT4), the corresponding bits in IFR are set unconditionally in the next CPU clock cycle. When the CPU actually takes a particular interrupt, the corresponding IFR bit is cleared by the CPU. Thus at any point, reading IFR using the **MVC** instruction shows which input external interrupts is asserted or is not yet processed by the CPU (or in pending state).

The CPU checks the status of IFR bits to understand that an interrupt is asserted, and starts processing this interrupt. Processing of an interrupt involves checking for all associated enable conditions, prioritization between simultaneously asserted interrupts and actions to perform interrupt service table look up to finally achieve a branch to the interrupt service routine of the corresponding interrupt. The exact behavior and actions taken on each kind of interrupts are described in [Section 8.2.4.18.7](#).

It is possible to set one or more interrupt flags of maskable interrupts in IFR - by writing to the corresponding bit in the interrupt set register (ISR) - creating the same effect of an external interrupt assertion. This makes it possible for the software to raise a maskable interrupt. The following examples illustrate this:

#### Example 8-6. Setting Interrupt Flag

```
MVC  0x10, ISR      ; Set IFR[4] to raise INT4
```

#### Example 8-7. Setting Interrupt Flag

```
MVC  IFR, R0        ; Get current state
SET  5,5, R0, R0    ; Set R0:bit[5]
MVC  R0,  ISR       ; Set IFR[5] without changing other bits
```

---

**NOTE:** Setting of IFR by an external interrupt assertion has a higher priority than writing or clearing the IFR bits via the **MVC** instruction.

---

### 8.2.4.18.7 Interrupt Behavior

All maskable (INT15-INT4) and non-maskable (NMI) interrupt processing is triggered by the corresponding interrupt flag bit in the interrupt flag register (IFR). For SWI and UNDEF, a direct instruction decode (or non-decode) triggers interrupt processing. Once an interrupt is triggered, the CPU checks the corresponding enabling conditions (if any), does a priority resolution among simultaneously asserted interrupts, and then starts processing the interrupt.

The details of conditions for processing each type of interrupts and the actions taken by the CPU during and returning from the interrupts are described in the following subsections.

#### 8.2.4.18.7.1 Reset Interrupt

Reset is the highest priority interrupt and is used to initialize the CPU to a known state. The reset interrupt is unique in a number of ways:

- `cpu_resetz_i` is an active-low signal and is treated asynchronously. All other interrupts are active-high signals, or activated via the instruction decoder.
- `cpu_resetz_i` must be held low for 4 clock cycles before it goes high again to reinitialize the CPU properly.
- `cpu_resetz_i` is not affected by branches or pending loads or any enable bits or any other condition applicable for processing other interrupts. The current instruction execution is aborted and the CPU registers are returned to their default state.
- Reset uses interrupt semantics, that is, loading of the IST table entry; however, it is not required to issue a **BIRP** instruction to exit reset processing.

#### 8.2.4.18.7.2 Non-maskable Interrupt (NMI)

NMI is the second-highest priority interrupt and is generally used to alert the CPU of a serious hardware problem. For an NMI to be detected (and processed) by the ARP32 CPU, the non-maskable interrupt enable (NMIE) bit in the interrupt enable register (IER) must be set to 1. The NMIE bit is cleared to 0 at reset to prevent an NMI being taken prematurely (before system initialization). The NMI bit is set (to enable NMI) by software only after the system has been properly initialized and is ready to accept NMIs. The NMIE bit is also cleared at the occurrence of an NMI to prevent another NMI from being processed; it may be set again in the interrupt set register (ISR), to allow nested NMIs, by software after the CPU state has been saved properly in the previous NMI ISR. While the NMIE bit is cleared, all maskable interrupts (INT15-INT4) are also disabled.

When the NMIF bit is set, (as a result of an NMI assertion via `cpu_nmi_i` input pin), assuming the previous conditions are met, the ARP32 CPU is said to accept the interrupt and performs the following actions to process the NMI:

- CPU stops fetching further instruction from instruction memory
- CPU execute pipe is allowed to drain
  - Any load/store instructions (including **LDRF**, **STRF**, **CALL**, **RET**) currently executing are allowed to complete
  - Any instruction in the branch/call/return delay slot is allowed to complete
- The CSR[11:8]INUM field is updated with the NMI interrupt ID.
- The CSR content is copied to the NMISCSR.
- The IER[1]NMIE bit is cleared.
- The CSR[0]GIE bit is cleared.
- The IFR[1]NMIF bit in the IFR is cleared.
- The PC value of the next instruction to execute (after completion of the interrupt service routine) is stored to the NRP register. This is the interrupt return address.
- The `cpu_iack_o` is asserted for a cycle along with the corresponding interrupt ID on `cpu_inum_o`.
- An instruction fetch request to NMI IST location is sent and eventually the NMI IST entry is loaded into the PC. As a result, the CPU begins executing the NMI interrupt service routine.

To exit an NMI service routine, the **BNRP** instruction must be used. Execution of the **BNRP** instruction causes:

- The NMISCSR content is copied to the CSR.
- The PC loaded with the contents of the NRP.
- IER[1]NMIE bit is set.

#### **8.2.4.18.7.3 SWI Interrupt**

The **SWI** instruction is used to trigger the software interrupt. Software interrupts are always enabled. The SWI interrupt does not have a corresponding entry in the IFR, ICR, ISR, or IER, and it is not affected by the state of the CSR:GIE or IER[1]NMIE bits. An SWI does not have any delay slot. Decoding of SWI causes the following actions to be taken by the ARP32 CPU:

- The CSR:INUM field is updated with the SWI interrupt ID.
- The CSR content is copied to the SCSR.
- All architectural registers (R0-R7) and HLA registers (LSAn, LEAn, and LCNTn) are saved to the corresponding shadow registers.
- The CSR[0]GIE bit is cleared.
- The address of the next instruction (interrupt return address) to be stored to the IRP register.
- The `cpu_iack_o` is asserted for a cycle along with the corresponding interrupt ID on `cpu_inum_o`.
- An instruction fetch request to SWI IST location is sent and eventually the SWI IST entry is loaded into the PC. As a result, the CPU begins executing the SWI ISR.

To exit a SWI service routine, the **BIRP** instruction must be used. Execution of the **BIRP** instruction causes:

- The SCSR content is copied to the CSR.
- All architectural registers (R0-R7) and HLA registers (LSAn, LEAn, and LCNTn) are restored from the corresponding shadow registers.
- The PC loaded with the contents of the IRP.

#### 8.2.4.18.7.4 Maskable Interrupts

The ARP32 CPU supports 12 maskable interrupts (INT15-INT4). For a maskable interrupt to be detected (and processed) by the ARP32 CPU:

- The global (maskable) interrupt enable (GIE) bit in the control status register (CSR) must be set to 1. The GIE bit is cleared to 0 at reset to prevent a maskable interrupt being taken prematurely (before system initialization). The GIE bit is set (to enable maskable interrupts) only after the system has been properly initialized and is ready to accept interrupts. The GIE bit is also cleared at the occurrence of an interrupt (NMI, INT15-INT4, SWI, and UNDEF) to prevent another interrupt from being processed; it may be set again in the ISR (to enable nested maskable interrupts) by software after the CPU state has been saved off properly.
- The IER:NMIE bit must be set.
- The corresponding enable bit in the interrupt enable register (IER) must also be set. IER bits allow enabling/disabling single maskable interrupt at a time.

When any of the IFR flag bits (IFR[15-4]) of maskable interrupts are set, (as a result of an maskable interrupt assertion via `cpu_int[15-4]_i` input pins), assuming the previous conditions are met, the ARP32 CPU accepts the highest priority interrupt and performs the following actions to process the interrupt:

- CPU stops fetching further instruction from instruction memory
- CPU execute pipe is allowed to drain
  - Any load/store instructions (including **LDRF**, **STRF**, **CALL**, **RET**) currently executing are allowed to complete
  - Any instruction in the branch/call/return delay slot is allowed to complete
- The CSR[11:8]INUM field is updated with the corresponding maskable interrupt ID.
- The CSR content is copied to the SCSR.
- All architectural registers (R0-R7) and HLA registers (LSAn, LEAn, and LCNTn) are saved to the corresponding shadow registers.
- The CSR[0]GIE bit is cleared.
- The associated bit in the IFR is cleared.
- The PC value of the next instruction to execute (after completion of the interrupt service routine) is stored to the IRP register. This is the interrupt return address.
- The `cpu_iack_o` is asserted for a cycle along with the corresponding interrupt ID on `cpu_inum_o`.
- An instruction fetch request to the corresponding IST location is sent and eventually the IST entry is loaded into the PC. As a result, the CPU begins executing the corresponding interrupt service routine.

To exit a maskable service routine, the **BIRP** instruction must be used. Execution of the **BIRP** instruction causes:

- The SCSR content is copied to the CSR.
- All architectural registers (R0-R7) and HLA registers (LSAn, LEAn, and LCNTn) are restored from the corresponding shadow registers.
- The PC loaded with the contents of the IRP.

#### 8.2.4.18.7.5 UNDEF Interrupt

An UNDEF interrupt is triggered by either of the following conditions:

- The CPU decodes an undefined/unsupported instruction, an unmapped primary opcode in instruction word 7:0. This normally happen as a result of instruction memory getting corrupted. Note that not all kinds of invalid opcodes are detected by the CPU; for example, invalid fields other than the primary opcode of a valid instruction.
- The CPU executes a **DIV/DIVU/MOD/MODU** instruction where the divisor operand (`src1`) is 0.

An UNDEF interrupt causes the UNDEF IST entry to be loaded into the PC. UNDEF interrupts are always enabled, it does not have a corresponding entry in the IFR, ICR, ISR, or IER, and is unaffected by the state of the CSR[0]GIE or IER[1]NMIE bits.

The ARP32 CPU treats an UNDEF as an irrecoverable exception. It is not possible to correctly return from an UNDEF interrupt. The only way to recover from an UNDEF interrupt is to reset the CPU.

For example, when UNDEF is caused by an invalid instruction decode, the size of (undecoded) instruction under consideration is not determined unambiguously (since the ARP32 CPU supports freely mixable 16-bit and 32-bit instructions) and hence a recoverable return address is not saved to the IRP while taking an UNDEF interrupt.

The purpose of the UNDEF interrupt is to provide just the basic detection and diagnostic mechanism when such an irrecoverable fault occurs in the system. It is software responsibility to design such an UNDEF handler such that within the UNDEF handler context (without requiring to return from the UNDEF interrupt service routine), it can do diagnostic check(s), if any, and inform the external world (for example, a host CPU) that an irrecoverable fault/exception has happened within the ARP32 CPU that cannot be handled.

It is possible an **IDLE** instruction to be used in the UNDEF interrupt service routine to hold the processor in the UNDEF service routine, for debug purposes, and avoid returning to an incorrect instruction boundary (because of incorrect return address saved to IRP/NRP) causing further UNDEF(s).

Also a manipulation of the IRP to return to some known address (after clearing all machine state correctly, for example, CSR, SCSR), for example the C entry point ( `__cinit_00`) with the expectation that the CPU practically re-executes from reset with all ISA initialization done freshly by the boot code at the entry point. However, it is still just a workaround considering that the root cause of instruction memory corrupt remains uncorrected.

When an undefined instruction is decoded by the ARP32 CPU it performs the following action:

- The CSR[11:8]INUM field is updated with the UNDEF interrupt ID.
- The CSR content is copied to the SCSR.
- All architectural registers (R0-R7) and HLA registers (LSAn, LEAn, and LCNTn) are saved to the corresponding shadow registers.
- The CSR[0]GIE bit is cleared.
- The address of the next instruction (interrupt return address) to be stored to the IRP register.
- The `cpu_iack_o` is asserted for a cycle along with the corresponding interrupt ID on `cpu_inum_o`.
- An instruction fetch request to the UNDEF IST location is sent and eventually the UNDEF IST entry is loaded into the PC. As a result, the CPU begins executing the UNDEF interrupt service routine.

To exit an UNDEF service routine, the **BIRP** instruction is used. Execution of the **BIRP** instruction causes:

- The SCSR content is copied to the CSR.
- All architectural registers (R0-R7) and HLA registers (LSAn, LEAn, and LCNTn) are restored from the corresponding shadow registers.
- The PC loaded with the contents of the IRP.

However, it is not assured to result in successfully returning to a correct instruction boundary. More UNDEF may follow immediately.

#### 8.2.4.18.8 Interrupt Context Save and Restore

The ARP32 CPU supports extensive automatic context save and restore during interrupt processing to reduce the effective interrupt latency significantly.

While processing all maskable interrupts (INT15-INT4), SWI and UNDEF, the ARP32 CPU saves off all key registers into shadow registers and during an interrupt return, via the **BIRP** instruction, restores them back:

- The Control Status Register (CSR) is saved to Shadow Control Status Register (SCSR)
- All architectural registers (R0-R7) are saved to corresponding shadow registers (SR0-SR7)
- The HLA setup registers (LSAn, LEAn, LCNTn, LCNT0RLD) are saved to the corresponding shadow registers (SLSAn, SLEAn, SLCNTn, SLCNT0RLD)

Both saving and restoring happens in a single cycle in parallel to interrupt vector fetch or the return branch execution. Also, as long as interrupt nesting is not enabled, there is absolutely no need of any additional context save (or restore) by the software at the start (or end) of the interrupt service routine. Hence, these interrupts have extremely low effective latency and are considered fast.

While processing the non-maskable interrupt (NMI), however, the CPU does not do extensive context save and restore. Only the CSR register is saved off to NMISCSR and during an NMI return, via the **BNRP** instruction, CSR is restored back. So, at the beginning of an NMI ISR, the software ensures to save off the complete CPU state to stack and restore them back before issuing a **BNRP** instruction (to accomplish a return from NMI):

- All architectural registers (R0-R7)
- The HLA setup registers (LSAn, LEAn, LCNTn, LCNT0RLD)

Thus, the interrupt behavior of the ARP32 CPU makes all maskable interrupts (INT15-INT4), SWI, and UNDEF as fast, and non-maskable interrupt (NMI) as just correct. The maskable interrupts (INT15-INT4) are used as the functional interrupt(s) of the system and the NMI are used to handle/service System Error, Exception scenarios (for example, a bus fault on program or data access).

The following example illustrates the process of context save and restore within an NMI service routine. In this example, the `NMIHandler()` is the actual software NMI handler function and a single unified stack across background and interrupt handler code is intended.

`__NonMaskableInterruptHandlerWrapper:`

```

; Save off Arch regs first
STRF  R7, R0

; Save off HLA regs
MVC   LSA0,  R0
MVC   LEA0,  R1
MVC   LCNT0, R2
MVC   LSA1,  R3
MVC   LEA1,  R4
MVC   LCNT1, R5
MVC   LCNT0RLD, R6
STRF  R6, R0

; Now call the actual handler function
CALL  NMIHandler
NOP

; Restore HLA regs
LDRF  R0, R6
MVC   R0, LSA0
MVC   R1, LEA0
MVC   R2, LCNT0
MVC   R3, LSA1
MVC   R4, LEA1
MVC   R5, LCNT1
MVC   R6, LCNT0RLD

; Restore Arch regs
LDRF  R0, R7

; Return from NMI ISR
BNRP
NOP
  
```

Note that in the example, during context restore, a write to LCNT0 also gets written to LCNT0RLD. Hence, the LCNT0RLD register is restored after LCNT0 is restored.

### 8.2.4.18.9 Nested Interrupts

When an interrupt (INT15–INT4, SWI, and UNDEF) is taken, the CSR[0]GIE bit is cleared by the hardware and subsequently the GIE bit is restored on interrupt return via the **BIRP** instruction. Thus all maskable interrupts (INT15–INT4) are disabled within the interrupt service routine of maskable interrupts.

Also, when an NMI is taken, the IER[1]NMIE bit is cleared by the hardware and subsequently the IER[1]NMIE bit is restored on interrupt return via the **BNRP** instruction. Thus NMI and all maskable interrupts (INT15–INT4) are disabled within the NMI service routine.

So in general, nesting of interrupts (except the case of NMI within a maskable interrupt routine) is disabled. However, under software control, it is possible that the ARP32 CPU is configured to take fully nested interrupts.

The ARP32 CPU offers two programming models with respect to usage of interrupts in a nested or non-nested manner.

#### 8.2.4.18.9.1 Non-nested Interrupt Model

In this programming model, the CSR[0]GIE (or IER[1]NMIE) bit is not enabled within interrupts service routine of maskable interrupts (INT15–INT4), SWI, or UNDEF interrupt (or NMI). Hence, maskable interrupts (INT15–INT4), SWI, and UNDEF are not nested. However, an NMI is taken as a nested interrupt within a maskable interrupt (INT15–INT4), SWI, or UNDEF.

While adopting this programming model, the following points must be noted:

- It is the software responsibility to not use an **SWI** instruction within an ISR context. Otherwise, SWI corrupts the shadow registers and results in an unpredictable behavior.
- An UNDEF interrupts may be taken. UNDEF interrupts are irrecoverable exception and cannot be recovered from (see [Section 8.2.4.18.7.5](#))
- NMI service routine follows the procedure described in [Section 8.2.4.18.8](#). An NMIE must not be enabled within an NMI service routine as nesting of NMI itself is not supported.

Note that this programming model offers fast response time to system events via the maskable interrupt lines (INT15–INT4) by fully exploiting the extensive automatic context save/restore feature of the ARP32 CPU (see [Section 8.2.4.18.8](#)).

#### 8.2.4.18.9.2 Nested Interrupt Model

In this programming model, the CSR[0]GIE bit is enabled within the interrupts service routine of maskable interrupts (INT15–INT4), SWI, or UNDEF interrupt. Hence, it is possible that maskable interrupts are nested. An NMI can always be taken with all other non-NMI interrupts.

Before enabling the CSR[0]GIE bit (in ISR), the software must ensure proper context save of all CPU registers onto the stack:

- Architectural registers (R0-R7)
- Shadow registers (SR0-SR7)
- Key control registers: SCSR, IRP/NRP
- Optional control register: SP, IER

While adopting this programming model, the following points must be noted:

- The SP needs to be saved, if a separate stack for the interrupt service routine is required
- IER needs to be saved, if a different interrupt mask is expected within an ISR
- Once the GIE bit is enabled, even the current interrupt (the once being serviced) becomes enabled to be re-entered. If reentrant behavior is not intended, IER must be appropriately modified after saving it off to the stack.
- NMI service routine must follow the procedure described in [Section 8.2.4.18.8](#). An NMIE must not be enabled within an NMI service routine as nesting of NMI itself is not supported. All maskable interrupts (INT15–INT4) and NMI remain disabled within an NMI service routine.

The following example illustrates the process of context save and restore within a maskable interrupt service routine. In this example, it is assumed that the `InterruptHandler()` is the actual software interrupt handler function and a single unified stack across background and interrupt handler code is intended.

`__NonMaskableInterruptHandlerWrapper:`

```

; Save off Arch regs first
STRF  R7, R0

; Save off HLA shadow regs
MVS  SLSA0, R0
MVS  SLEA0, R1
MVS  SLCNT0, R2
MVS  SLSA1, R3
MVS  SLEA1, R4
MVS  SLCNT1, R5
MVS  SLCNT0RLD, R6
STRF  R6, R0

; Save off SCSR, IRP
MVC  SCSR, R0
MVC  IRP, R1
STRF  R1, R0

; Now call the actual handler function
CALL  InterruptHandler
NOP

; Restore SCSR, IRP
LDRF  R0, R1
MVC  R0, SCSR
MVC  R1, IRP

; Restore HLA shadow regs
LDRF  R0, R6
MVS  R0, SLSA0
MVS  R1, SLEA0
MVS  R2, SLCNT0
MVS  R3, SLSA1

MVS  R0, SR6
MVS  R0, SR7

; Return from NMI ISR
BIRP
NOP

```

### 8.2.4.18.10 Non-nested Interrupt Latency

This section describes the best and worst case interrupt latencies in the non-nested interrupt programming model (described in [Section 8.2.4.18.9.1](#)).

#### 8.2.4.18.10.1 Best Case Interrupt Latency

In the best case (and the most frequent case), the ARP32 CPU takes an interrupt as soon as (very next cycle) it is signaled at its boundary via the `cpu_int[15-4]_i` or `cpu_nmi_i` input ports. In this case, the ARP32 CPU takes as little as 5 cycles (from the cycle when the IFR bit gets set) to start executing the first instruction of the ISR:

- **Cycle 0:** `cpu_int[15-4]_i` or `cpu_nmi_i` assertion
- **Cycle 1:** corresponding IFR bit is set, interrupt enable conditions checked, interrupt priorities resolved, a winner interrupt is selected to be taken
- **Cycle 2:** `cpu_iack_o`, `cpu_inum_o` are asserted, program read request is sent to the corresponding IST address associate with the interrupt being serviced
- **Cycle 3:** program read data (IST content) is received and is loaded to PC
- **Cycle 4:** program read request is sent to the first instruction of the ISR routine
- **Cycle 5:** first instruction of the ISR routine is decoded
- **Cycle 6:** first instruction of the ISR routine is executed

Note that the ARP32 CPU saves off all architectural registers and other required CPU registers while taking the interrupt (in cycle 1) and as a result the ISR routine does not need to have any instructions to save off the machine state. The ISR routine directly starts executing code related to actual actions to be taken to service the interrupt.

#### 8.2.4.18.10.2 Worst Case Interrupt Latency

Under certain cases, the ARP32 CPU blocks taking an interrupt, thus introducing variable interrupt latency. The following are the worst cases:

- When a load/store multiple (**LDRF**, **STRF**) instruction is at the EXE stage of the CPU pipeline and an interrupt is asserted. The interrupt is not taken until the **LDRF/STRF** instruction is completed, which takes several (variable) cycles.

In compiler-generated code, **LDRF/STRF** is normally used as a function context save/restore across function calls; a maximum of three save-on-entry (SOE) registers as per the ARP32 CPU EABI function calling convention. Thus, three load/stores would need to finish before the CPU takes an interrupt. Moreover, if the stack pointer points to a wait-stated memory, this register save/restore takes even longer. Also, the program fetch request to the IST is stalled if the corresponding memory region is not zero-wait state, thus, increasing interrupt latency further.

- When a blocking, multicycle execute (**DIV/DIVU/MOD/MODU**) instruction is at the EXE stage of the CPU pipeline and an interrupt is asserted. The interrupt is not taken until the instruction at EXE is completed, which takes 13 (fixed) cycles.

## 8.2.5 Instruction Set

This section provides a description of the instruction set. Unless otherwise explicitly mentioned, all instructions are a single execute cycle instruction. All instructions that are multicycle execute are mentioned explicitly.

### 8.2.5.1 Instruction Operation and Execution Notations

[Table 8-347](#) explains the symbols used in the instruction Pseudo Code descriptions.

All immediate values are unsigned (zero-extended) or signed (sign-extended) to match the relevant associated operand size. For example, zero (or sign) extended to 32 bits for operations with architectural registers (32 bit in size), zero-extended to 32 bits for operation with SP (32 bits in size), and zero-extended to the width of the PC for operations with the PC.

Although the instruction set architecture (ISA) does not contain a writable program counter (PC) register, in the description of some instructions (especially in the pseudo code), a conceptual register, PC, has been used. This is to simplify the description and does not imply existence of such a physical register.

**Table 8-347. Instruction Pseudo Code Notations**

Symbol	Meaning
AND	bitwise AND
areg	architectural register (R0-R7)
baseR	base address register
creg	control register
dst	destination operand
GDP	global data pointer register
lmb0(x)	leftmost 0 bit search of x
lmb1(x)	leftmost 1 bit search of x
lsbn	n least-significant bits (for example, lsb32)
opn	field within opcode that specifies a unique instruction
OR	bitwise OR
PC	program counter
sat	saturate
SP	stack pointer register
src1	source operand 1
src2	source operand 2
sreg	shadow register
ucstn	n-bit unsigned immediate constant field (for example, ucst6)
XOR	bitwise exclusive-OR
+	addition
-	subtraction
x	multiplication
/	division
%	modulo
~	logical inverse
++	increment by 1
==	equal to
>	greater than
>=	greater than or equal to
<	less than
<=	less than or equal to
<<	shift left
>>	shift right
&&	logical AND

### 8.2.5.2 Instruction Syntax and Opcode Notations

Table 8-348 defines the syntaxes and opcode fields used in the instruction descriptions.

**Table 8-348. Instruction Syntax and Opcode Notations**

Symbol	Meaning
<i>areg</i>	architectural register (R0-R7)
<i>baseR</i>	base address register
<i>cc</i>	condition code (LT, GT, EQ, LE, GE, NE)
<i>creg</i>	control register
<i>dst</i>	destination
GDP	global data pointer register
<i>opn</i>	opfield; field within opcode that specifies a unique instruction
<i>scstn</i>	n-bit signed constant field
<i>sreg</i>	shadow register
SP	stack pointer register
<i>src1</i>	source 1
<i>src2</i>	source 2
<i>ucstn</i>	n-bit unsigned constant field
x	don't care

### 8.2.5.3 Instruction Scheduling Restrictions

The ARP32 CPU architecture places the following restrictions on instruction scheduling that must be maintained. Whereas the compiler maintains these restrictions while generating assembly code for C/C++ programs, it is the responsibility of the programmer to maintain the restrictions for codes written directly in assembly.

#### 8.2.5.3.1 Restrictions Applicable to a Branch Delay Slot

The following restrictions are applicable for an instruction in the delay slot of a branch (**Bcc** *scst9*, **Bcc** *scst16*, or **Bcc** *dst*), call (**CALL** *scst22* or **CALL** *src1*), and return (**RET**) instruction:

- 32-bit instructions are not allowed
- Another branch/call/return is not allowed
- **IDLE** instruction is not allowed
- **SWI** instruction is not allowed
- **LDRF/STRF** instructions with more than one register operand

Also, a branch delay slot cannot be the target of any branch/call/return.

#### 8.2.5.3.2 Restrictions on Loops Using Hardware Loop Assist (HLA)

Loops setup using the HLA mechanism (Section 8.2.4.17) are required to maintain the following restrictions:

- Minimum number of instructions in Loop 0 is 2
- Branches (**Bcc/CALL/RET** + the delay slot instruction) cannot be placed at the end of a loop. This makes the loop rewind and branch target unambiguous.
- Last two instruction of any level cannot be a multi-slot load/store multiple (**LDRF/STRF**)
- Software cannot branch (**Bcc/CALL/RET**) to the last instruction of any loop, that is, the last instruction of any loop cannot be a branch target.

### 8.2.5.3.3 Restrictions on Other Types of Control Flow Instructions

The following restrictions are applicable for other types of control flow instructions:

- **SWI** instruction must be followed by a **NOP**
- **BIRP/BNRP** instructions must be followed by a **NOP**

### 8.2.5.3.4 Restrictions for Write Data Bypass to Control Register Reads

The following restrictions are applicable for write data bypass to control register reads:

- An **MVC** instruction that writes to a control register (**MVC areg, creg**; **MVC ucst16, creg**; or **MVCH ucst16, creg**), must not be followed by an **MVC** instruction (**MVC creg, areg**) that reads the same control register.
- An **SLA** instruction that writes to a control register (**SLA ucst16, LSA<sub>n</sub>** or **SLA ucst16, LEA<sub>n</sub>**) must not be followed by an **MVC** instruction (**MVC creg, areg**) that reads the same control register.
- An **SLA** instruction that writes to a control register (**SLA ucst16, LSA<sub>n</sub>** or **SLA ucst16, LEA<sub>n</sub>**) must not be followed by an **MVCH** instruction (**MVCH creg, areg**) that reads the same control register.

### 8.2.5.3.5 Restrictions for Write Data Bypass to Shadow Register Reads

The following restriction is applicable for write data bypass to shadow register reads:

- There are at least two instructions separating an **MVS** instruction writing to a shadow register (**MVS areg, sreg**) and another **MVS** instruction reading the same shadow register (**MVS sreg, areg**).

### 8.2.5.3.6 Restrictions for Link Register Update

The following restriction is applicable for link register update:

- Link registers cannot be read or written in the delay slot of a call (**CALL scst22** or **CALL src1**) and return (**RET**) instruction.

## 8.2.5.4 Instruction Set Encoding

The ARP32 ISA comprises of a mix of 16-bit and 32-bit instructions. An instruction packet is defined as a 32-bit field for a 32-bit instruction and a 16-bit field for a 16-bit instruction. The instruction decoder is sent an instruction packet every cycle.

## 8.2.5.5 Instruction Descriptions

Table 8-349 lists the instructions for the ARP32 CPU.

**Table 8-349. Instruction Summary**

Instruction	Description	Size
<a href="#">ABS src2, dst</a>	Absolute value of a register	16-bit
<a href="#">ADD ucst16, src2, dst</a>	Add 16-bit unsigned constant to a register	32-bit
<a href="#">ADD ucst16, SP</a>	Add 16-bit unsigned constant to stack pointer, result to stack pointer	32-bit
<a href="#">ADD ucst16, SP, dst</a>	Add 16-bit unsigned constant to stack pointer, result to register	32-bit
<a href="#">ADD ucst3, src2, dst</a>	Add 3-bit unsigned constant to a register	16-bit
<a href="#">ADD src1, src2, dst</a>	Signed addition of two register values	16-bit
<a href="#">AND ucst16, src2, dst</a>	Bitwise AND 16-bit unsigned constant with a register	32-bit
<a href="#">AND src1, src2, dst</a>	Bitwise AND two registers	16-bit
<a href="#">B dst</a>	Indirect unconditional branch using a register	16-bit
<a href="#">BEQ dst</a>	Indirect conditional branch using a register	16-bit
<a href="#">BGE dst</a>	Indirect conditional branch using a register	16-bit
<a href="#">BGT dst</a>	Indirect conditional branch using a register	16-bit
<a href="#">BLE dst</a>	Indirect conditional branch using a register	16-bit

**Table 8-349. Instruction Summary (continued)**

Instruction	Description	Size
BLT dst	Indirect conditional branch using a register	16-bit
BNE dst	Indirect conditional branch using a register	16-bit
B scst9	Direct unconditional branch using a 9-bit signed constant offset	16-bit
BEQ scst9	Direct conditional branch using a 9-bit signed constant offset	16-bit
BGE scst9	Direct conditional branch using a 9-bit signed constant offset	16-bit
BGT scst9	Direct conditional branch using a 9-bit signed constant offset	16-bit
BLE scst9	Direct conditional branch using a 9-bit signed constant offset	16-bit
BLT scst9	Direct conditional branch using a 9-bit signed constant offset	16-bit
BNE scst9	Direct conditional branch using a 9-bit signed constant offset	16-bit
B scst16	Direct unconditional branch using a 16-bit signed constant offset	32-bit
BEQ scst16	Direct conditional branch using a 16-bit signed constant offset	32-bit
BGE scst16	Direct conditional branch using a 16-bit signed constant offset	32-bit
BGT scst16	Direct conditional branch using a 16-bit signed constant offset	32-bit
BLE scst16	Direct conditional branch using a 16-bit signed constant offset	32-bit
BLT scst16	Direct conditional branch using a 16-bit signed constant offset	32-bit
BNE scst16	Direct conditional branch using a 16-bit signed constant offset	32-bit
BIRP	Unconditional branch to interrupt return pointer	16-bit
BKPT	Software breakpoint	16-bit
BNRP	Unconditional branch to NMI return pointer	16-bit
CALL src1	Unconditional call using a register	16-bit
CALL scst22	Unconditional call using a 22-bit signed constant offset	32-bit
CLR ucst5_1, ucst5_2, src2, dst	Clear bit field bounded by two immediate values	32-bit
CLR src1, src2, dst	Clear bit field bounded by two register values	32-bit
CMP scst16, src2	Compare for equality, less than, greater than, 16-bit signed constant to a register	32-bit
CMP scst3, src2	Compare for equality, less than, greater than, 3-bit signed constant to a register	16-bit
CMP src1, src2	Signed compare for equality, less than, greater than, two register values	16-bit
CMPU ucst16, src2	Compare for equality, less than, greater than, 16-bit unsigned constant to a register	32-bit
CMPU ucst3, src2	Compare for equality, less than, greater than, 3-bit unsigned constant to a register	16-bit
CMPU src1, src2	Unsigned compare for equality, less than, greater than, two register values	16-bit
DIV src1, src2, dst	Signed division of two register values	32-bit
DIVU src1, src2, dst	Unsigned division of two register values	32-bit
EXT ucst5_1, ucst5_2, src2, dst	Extract and sign-extend a bit field bounded by two immediate values	32-bit
EXT src1, src2, dst	Extract and sign-extend a bit field bounded by two register values	32-bit
EXTU ucst5_1, ucst5_2, src2, dst	Extract and zero-extend a bit field bounded by two immediate values	32-bit
EXTU src1, src2, dst	Extract and zero-extend a bit field bounded by two register values	32-bit
IDLE	Idle until interrupt or reset	16-bit
LDB *+baseR[ucst3], dst	Load signed byte from memory with a 3-bit unsigned constant offset	16-bit
LDB *+baseR[ucst16], dst	Load signed byte from memory with a 16-bit unsigned constant offset	32-bit
LDB *+baseR[src1], dst	Load signed byte from memory with a register offset	16-bit
LDB *baseR++[ucst3], dst	Load signed byte from memory, postincrement memory with a 3-bit unsigned constant offset	16-bit
LDB *baseR++[src1], dst	Load signed byte from memory, postincrement memory with a register offset	16-bit

**Table 8-349. Instruction Summary (continued)**

Instruction	Description	Size
LDB *+SP[ucst6], dst	Load signed byte from memory with a SP-relative 6-bit unsigned constant offset	16-bit
LDB *+SP[ucst19], dst	Load signed byte from memory with a SP-relative 19-bit unsigned constant offset	32-bit
LDB *+GDP[ucst19], dst	Load signed byte from memory with a GDP-relative 19-bit unsigned constant offset	32-bit
LDBU *+baseR[ucst3], dst	Load unsigned byte from memory with a 3-bit unsigned constant offset	16-bit
LDBU *+baseR[ucst16], dst	Load unsigned byte from memory with a 16-bit unsigned constant offset	32-bit
LDBU *+baseR[src1], dst	Load unsigned byte from memory with a register offset	16-bit
LDBU *baseR++[ucst3], dst	Load unsigned byte from memory, postincrement memory with a 3-bit unsigned constant offset	16-bit
LDBU *baseR++[src1], dst	Load unsigned byte from memory, postincrement memory with a register offset	16-bit
LDBU *+SP[ucst6], dst	Load unsigned byte from memory with a SP-relative 6-bit unsigned constant offset	16-bit
LDBU *+SP[ucst19], dst	Load unsigned byte from memory with a SP-relative 19-bit unsigned constant offset	32-bit
LDBU *+GDP[ucst19], dst	Load unsigned byte from memory with a GDP-relative 19-bit unsigned constant offset	32-bit
LDH *+baseR[ucst3], dst	Load signed halfword from memory with a 3-bit unsigned constant offset	16-bit
LDH *+baseR[ucst16], dst	Load signed halfword from memory with a 16-bit unsigned constant offset	32-bit
LDH *+baseR[src1], dst	Load signed halfword from memory with a register offset	16-bit
LDH *baseR++[ucst3], dst	Load signed halfword from memory, postincrement memory with a 3-bit unsigned constant offset	16-bit
LDH *baseR++[src1], dst	Load signed halfword from memory, postincrement memory with a register offset	16-bit
LDH *+SP[ucst6], dst	Load signed halfword from memory with a SP-relative 6-bit unsigned constant offset	16-bit
LDH *+SP[ucst19], dst	Load signed halfword from memory with a SP-relative 19-bit unsigned constant offset	32-bit
LDH *+GDP[ucst19], dst	Load signed halfword from memory with a GDP-relative 19-bit unsigned constant offset	32-bit
LDHU *+baseR[ucst3], dst	Load unsigned halfword from memory with a 3-bit unsigned constant offset	16-bit
LDHU *+baseR[ucst16], dst	Load unsigned halfword from memory with a 16-bit unsigned constant offset	32-bit
LDHU *+baseR[src1], dst	Load unsigned halfword from memory with a register offset	16-bit
LDHU *baseR++[ucst3], dst	Load unsigned halfword from memory, postincrement memory with a 3-bit unsigned constant offset	16-bit
LDHU *baseR++[src1], dst	Load unsigned halfword from memory, postincrement memory with a register offset	16-bit
LDHU *+SP[ucst6], dst	Load unsigned halfword from memory with a SP-relative 6-bit unsigned constant offset	16-bit
LDHU *+SP[ucst19], dst	Load unsigned halfword from memory with a SP-relative 19-bit unsigned constant offset	32-bit
LDHU *+GDP[ucst19], dst	Load unsigned halfword from memory with a GDP-relative 19-bit unsigned constant offset	32-bit
LDW *+baseR[ucst3], dst	Load word from memory with a 3-bit unsigned constant offset	16-bit
LDW *+baseR[ucst16], dst	Load word from memory with a 16-bit unsigned constant offset	32-bit
LDW *+baseR[src1], dst	Load word from memory with a register offset	16-bit
LDW *baseR++[ucst3], dst	Load word from memory, postincrement memory with a 3-bit unsigned constant offset	16-bit

**Table 8-349. Instruction Summary (continued)**

Instruction	Description	Size
LDW *baseR++[src1], dst	Load word from memory, postincrement memory with a register offset	16-bit
LDW *+SP[ucst6], dst	Load word from memory with a SP-relative 6-bit unsigned constant offset	16-bit
LDW *+SP[ucst19], dst	Load word from memory with a SP-relative 19-bit unsigned constant offset	32-bit
LDW *+GDP[ucst19], dst	Load word from memory with a GDP-relative 19-bit unsigned constant offset	32-bit
LDRF op1, op2	Load register file from stack pointer	16-bit
LMBD ucst3, src2, dst	Left most bit detection	32-bit
MAX src1, src2, dst	Maximum of two signed register values	32-bit
MAXU src1, src2, dst	Maximum of two unsigned register values	32-bit
MIN src1, src2, dst	Minimum of two signed register values	32-bit
MINU src1, src2, dst	Minimum of two unsigned register values	32-bit
MOD src1, src2, dst	Signed modulo ( $32 \% 32 = 32$ )	32-bit
MODU src1, src2, dst	Unsigned modulo ( $32 \% 32 = 32$ )	32-bit
MPY src1, src2, dst	Signed multiplication of two register values ( $32\text{-bit} \times 32\text{-bit} = 32\text{-bit}$ )	32-bit
MPYU src1, src2, dst	Unsigned multiplication of two register values ( $32\text{-bit} \times 32\text{-bit} = 32\text{-bit}$ )	32-bit
MV src1, dst	Move register to register	16-bit
MVC areg, creg	Move architectural register to control register	16-bit
MVC creg, areg	Move control register to architectural register	16-bit
MVC ucst16, creg	Move 16-bit unsigned constant to control register	32-bit
MVCH ucst16, creg	Move 16-bit unsigned constant to upper bits of control register	32-bit
MVK ucst16, dst	Move 16-bit unsigned constant to register	32-bit
MVKH ucst16, dst	Move 16-bit unsigned constant to upper bits of register	32-bit
MVKLS scst16, dst	Move 16-bit signed constant to register	32-bit
MVKS scst6, dst	Move 6-bit signed constant to register	16-bit
MVS areg, sreg	Move architectural register to shadow register	16-bit
MVS sreg, areg	Move shadow register to architectural register	16-bit
NEG src2, dst	Negation	16-bit
NOP	No operation	16-bit
NOT src2, dst	Bitwise NOT	16-bit
OR ucst16, src2, dst	Bitwise OR 16-bit unsigned constant with a register	32-bit
OR src1, src2, dst	Bitwise OR two registers	16-bit
RET	Return from subroutine	16-bit
REV src1, src2, dst	Reverse a bit field bounded by two register values	32-bit
ROT src1, src2, dst	Rotate right	32-bit
ROTC src1, src2, dst	Rotate right through carry bit	32-bit
SADD src1, src2, dst	Signed addition of two register values with saturation	16-bit
SATN ucst3, src2, dst	Saturation to signed/unsigned <i>n</i> -bit value with sign/zero extend	32-bit
SET ucst5_1, ucst5_2, src2, dst	Set bit field bounded by two immediate values	32-bit
SET src1, src2, dst	Set bit field bounded by two register values	32-bit
SHL ucst5, src2, dst	Logical shift left by 5-bit unsigned constant	32-bit
SHL src1, src2, dst	Logical shift left by register value	16-bit
SHRA ucst5, src2, dst	Arithmetic shift right by 5-bit unsigned constant	32-bit
SHRA src1, src2, dst	Arithmetic shift right by register value	16-bit
SHRU ucst5, src2, dst	Logical shift right by 5-bit unsigned constant	32-bit
SHRU src1, src2, dst	Logical shift right by register value	16-bit
SLA ucst16, creg	Set loop address	32-bit

**Table 8-349. Instruction Summary (continued)**

Instruction	Description	Size
SSUB src1, src2, dst	Subtraction of two register values with saturation	16-bit
STB dst, *+baseR[ucst3]	Store byte to memory with a 3-bit unsigned constant offset	16-bit
STB dst, *+baseR[ucst16]	Store byte to memory with a 16-bit unsigned constant offset	32-bit
STB dst, *+baseR[src1]	Store byte to memory with a register offset	16-bit
STB dst, *baseR++[ucst3]	Store byte to memory, postincrement memory with a 3-bit unsigned constant offset	16-bit
STB dst, *baseR++[src1]	Store byte to memory, postincrement memory with a register offset	16-bit
STB dst, *+SP[ucst6]	Store byte to memory with a SP-relative 6-bit unsigned constant offset	16-bit
STB dst, *+SP[ucst19]	Store byte to memory with a SP-relative 19-bit unsigned constant offset	32-bit
STB dst, *+GDP[ucst19]	Store byte to memory with a GDP-relative 19-bit unsigned constant offset	32-bit
STH dst, *+baseR[ucst3]	Store halfword to memory with a 3-bit unsigned constant offset	16-bit
STH dst, *+baseR[ucst16]	Store halfword to memory with a 16-bit unsigned constant offset	32-bit
STH dst, *+baseR[src1]	Store halfword to memory with a register offset	16-bit
STH dst, *baseR++[ucst3]	Store halfword to memory, postincrement memory with a 3-bit unsigned constant offset	16-bit
STH dst, *baseR++[src1]	Store halfword to memory, postincrement memory with a register offset	16-bit
STH dst, *+SP[ucst6]	Store halfword to memory with a SP-relative 6-bit unsigned constant offset	16-bit
STH dst, *+SP[ucst19]	Store halfword to memory with a SP-relative 19-bit unsigned constant offset	32-bit
STH dst, *+GDP[ucst19]	Store halfword to memory with a GDP-relative 19-bit unsigned constant offset	32-bit
STW dst, *+baseR[ucst3]	Store word to memory with a 3-bit unsigned constant offset	16-bit
STW dst, *+baseR[ucst16]	Store word to memory with a 16-bit unsigned constant offset	32-bit
STW dst, *+baseR[src1]	Store word to memory with a register offset	16-bit
STW dst, *baseR++[ucst3]	Store word to memory, postincrement memory with a 3-bit unsigned constant offset	16-bit
STW dst, *baseR++[src1]	Store word to memory, postincrement memory with a register offset	16-bit
STW dst, *+SP[ucst6]	Store word to memory with a SP-relative 6-bit unsigned constant offset	16-bit
STW dst, *+SP[ucst19]	Store word to memory with a SP-relative 19-bit unsigned constant offset	32-bit
STW dst, *+GDP[ucst19]	Store word to memory with a GDP-relative 19-bit unsigned constant offset	32-bit
STHI ucst16, *+baseR[ucst6]	Store 16-bit halfword to memory with a 6-bit unsigned constant offset	32-bit
STRF op1, op2	Store register file to stack pointer	16-bit
SUB ucst16, src2, dst	Subtract 16-bit unsigned constant from a register	32-bit
SUB ucst16, SP	Subtract 16-bit unsigned constant from stack pointer, result to stack pointer	32-bit
SUB ucst16, SP, dst	Subtract 16-bit unsigned constant from stack pointer, result to register	32-bit
SUB ucst3, src2, dst	Subtract 3-bit unsigned constant from a register	16-bit
SUB src1, src2, dst	Signed subtraction of two register values	16-bit
SWI	Software interrupt	16-bit
XOR ucst16, src2, dst	Bitwise XOR 16-bit unsigned constant with a register	32-bit
XOR src1, src2, dst	Bitwise XOR two registers	16-bit

**ABS** *Absolute Value*

**Syntax** **ABS** *src2, dst*  
 Functional unit = L

**Opcode** 16 bit

**Description** The absolute value of *src2* is placed in *dst*. Note that *src2* is considered a signed 32-bit value.

**Condition Codes** CSR[2]EQ = (*dst* == 0)

**Pseudo Code** `dst = (src2 < 0)? -src2:src2`

**ADD** *Add 16-Bit Unsigned Constant to Register*
**Syntax** **ADD** *ucst16, src2, dst*

Functional unit = D

**Opcode** 32 bit

**Description** Addition of a 16-bit unsigned constant (*ucst16*) with *src2* and store result to *dst*.

**Condition Codes** CSR[2]EQ = (dst == 0)

CSR[5]C = {carry out} from (dst + {zero extend}ucst16)

CSR[7]V = {overflow} from (dst + {zero extend}ucst16)

Note that the carry (CSR:C) and overflow (CSR:V) bits are relevant to unsigned and signed operations, respectively. Appropriate bits are checked depending on if the operands are represented (or, interpreted) as unsigned or signed numbers.

**Pseudo Code**  $dst = src2 + \{zero\ extend\}ucst16$

**ADD** *Add 16-Bit Unsigned Constant to Stack Pointer, Result to Stack Pointer*

---

**Syntax** **ADD** *ucst16*, SP  
 Functional unit = D

**Opcode** 32 bit

**Description** Addition of a 16-bit unsigned constant (*ucst16*) with the stack pointer (SP) and store result to SP.

**Condition Codes** None

**Pseudo Code**  $SP = SP + ucst16$

**AND** *Bitwise AND 16-Bit Unsigned Constant with Register*

**Syntax** **AND** *ucst16, src2, dst*  
 Functional unit = L

**Opcode** 32 bit

**Description** Bitwise AND of a zero-extended 16-bit unsigned constant (*ucst16*) with *src2* and store result to *dst*.

**Condition Codes** CSR:EQ = (*dst* == 0)

**Pseudo Code** *dst* = *src2* AND {zero extend}*ucst16*

**B(cc)**                      *Direct Branch Using a 9-Bit Signed Constant Offset*

**Syntax**                      **B(cc)** *scst9*  
Functional unit = D

**Opcode**                      16 bit

<b>Syntax</b>	<b>Opcode</b>
<b>B</b> <i>scst9</i>	100 1010
<b>BLT</b> <i>scst9</i>	100 1011
<b>BGT</b> <i>scst9</i>	100 1110
<b>BEQ</b> <i>scst9</i>	100 1100
<b>BLE</b> <i>scst9</i>	100 1111
<b>BGE</b> <i>scst9</i>	101 0000
<b>BNE</b> <i>scst9</i>	100 1101

**Description**                      Performs a branch to the effective address formed by the signed addition of *scst9* with the current PC value. The offset is considered as a halfword offset. Note that the PC always contains a halfword address.

This instruction has one delay slot. See [Section 8.2.5.3.1](#) for restrictions on scheduling an instruction in this delay slot.

For conditional branches, if the associated conditional (cc) bit is set in the control status register (CSR), the branch is taken; otherwise, the PC is incremented by 1. Valid values for **cc** are:

- <blank> = unconditional
- LT = CSR[3]LT bit is set to 1
- GT = CSR[4]GT bit is set to 1
- EQ = CSR[2]EQ bit is set to 1
- LE = CSR[3]LT and CSR:EQ bits are set to 1
- GE = CSR[4]GT and CSR:EQ bits are set to 1
- NE = CSR[2]EQ bit is cleared to 0

**Condition Codes**                      None

**Pseudo Code**                      if (cond)                      PC = (PC + *scst9*)  
else                              PC = PC + 1

**B(cc)** *Direct Branch Using a 16-Bit Signed Constant Offset*

**Syntax** **B(cc)** *scst16*  
Functional unit = D

**Opcode** 32 bit

Syntax	Opcode
<b>B</b> <i>scst16</i>	00 1000 1001
<b>BLT</b> <i>scst16</i>	01 0000 1001
<b>BGT</b> <i>scst16</i>	10 1000 1001
<b>BEQ</b> <i>scst16</i>	01 1000 1001
<b>BLE</b> <i>scst16</i>	11 0000 1001
<b>BGE</b> <i>scst16</i>	11 1000 1001
<b>BNE</b> <i>scst16</i>	10 0000 1001

**Description** Performs a branch to the effective address formed by the signed addition of *scst16* with the current PC value. The offset is considered as a halfword offset. Note that the PC always contains a halfword address.

This instruction has one delay slot. See [Section 8.2.5.3.1](#) for restrictions on scheduling an instruction in this delay slot.

For conditional branches, if the associated conditional (cc) bit is set in the control status register (CSR), the branch is taken; otherwise, the PC is incremented by 1. Valid values for **cc** are:

- <blank> = unconditional
- LT = CSR[3]LT bit is set to 1
- GT = CSR[4]GT bit is set to 1

- LE = CSR[3]LT and CSR:EQ bits are set to 1
- GE = CSR[4]GT and CSR:EQ bits are set to 1
- NE = CSR[2]EQ bit is cleared to 0

**Condition Codes** None

**Pseudo Code**

```

if (cond)    PC = (PC + scst16)
else        PC = PC + 1

```

**BIRP**                      ***Branch Using an Interrupt Return Pointer***

**Syntax**                      **BIRP**  
Functional unit = D

**Opcode**                      16 bit

**Description**                      Performs an unconditional branch to the address in the interrupt return pointer register (IRP). The content of IRP is treated as a halfword address. The shadow control status register (SCSR) content is copied back to the control status register (CSR) as a result of this instruction.

This instruction has one delay slot. Only a NOP instruction is supported in a BIRP delay slot.

**Condition Codes**                      For context restore: CSR = SCSR

**Pseudo Code**                      PC = \*IRP  
CSR = SCSR, Rn = SRn, LSA<sub>n</sub> = SLSA<sub>n</sub>, LEA<sub>n</sub> = SLEA<sub>n</sub>, LCNT<sub>n</sub> = SLCNT<sub>n</sub>

**BKPT**                      *Software Breakpoint*

---

**Syntax**                      **BKPT**  
 Functional unit = S

**Opcode**                      16 bit

**Description**                      The **BKPT** instruction is equivalent to a single instruction endless loop. The ARP32 CPU re-fetches this same instruction again until released through the debug interface.

**Condition Codes**                      None

**Pseudo Code**                      None

**BNRP**                      ***Branch Using NMI Return Pointer***

**Syntax**                      **BNRP**  
                                     Functional unit = D

**Opcode**                      16 bit

**Description**                      Performs an unconditional branch to the address in the nonmaskable interrupt return pointer register (NRP). The content of NRP is treated as a halfword address. The IER1 is set to 1 upon executing this instruction. The shadow control status register (SCSR) content is copied back to the control status register (CSR) as a result of this instruction.

This instruction has one delay slot. Only a NOP instruction is supported in a BNRP delay slot.

**Condition Codes**                      For context restore: CSR = NMISCSR

**Pseudo Code**                      PC = \*NRP  
     CSR = NMISCSR

**CLR** *Clear Bit Field Bounded by Two Register Values*
**Syntax** CLR *src1, src2, dst*

Functional unit = L

**Opcode** 32 bit

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	13	12	10	9	7	6	0								
x	x	x	x	x	x	x	x	x	x	x	1	0	0	0	1	<i>dst</i>			<i>src2</i>			<i>src1</i>			0	0	0	0	1	0	0
											3			3			3			<i>opcode</i>											

**Description**

For  $src1[9:5] \geq src1[4:0]$ , the field in *src2* as specified by *src1[4:0]* to *src1[9:5]* is cleared to all 0s and the resulting value of *src2* is written to *dst*. *src2* is left unchanged. *src1[4:0]* is the LSB of the field and *src1[9:5]* is the MSB of the field. In other words, *src1[4:0]* and *src1[9:5]* represent the beginning and ending bits, respectively, of the field to be cleared to all 0s. The LSB location of *src2* is bit 0 and the MSB location of *src2* is bit 31.

Valid values of *src1[9:5]* and *src1[4:0]* are:

- $0 \leq src1[9:5] \leq 31$ ;  $0 \leq src1[4:0] \leq 31$
- $src1[9:5] \geq src1[4:0]$

For  $src1[9:5] < src1[4:0]$ , the result is undefined.

In the following example, *src1[4:0]* is 15 and *src1[9:5]* is 23.

**Condition Codes** CSR[2]EQ = (*dst* == 0)

**Pseudo Code**

```
dst = src2
for( i = 0; i < 32; i++) {
    if ( i >= src1[4:0] && i <= src1[9:5]) dst[i] = 0;
};
```

---

**CMP**                      **Compare for Equality, Less Than, Greater Than, 3-Bit Signed Constant to Register**

---

**Syntax**                      **CMP** *scst3*, *src2*  
 Functional unit = D

**Opcode**                      16 bit

**Description**                      Compares *src2* to a sign-extended 3-bit constant (*scst3*). The condition bits CSR:EQ, CSR:LT, and CSR:GT are updated based on the comparison.

**Condition Codes**                      CSR[2]EQ = (*src2* == {sign extend}(*scst3*))  
 CSR[3]LT = (*src2* < {sign extend}(*scst3*))  
 CSR[4]GT = (*src2* > {sign extend}(*scst3*))

**Pseudo Code**                      See Condition Codes

---

**CMP**                      ***Signed Compare for Equality, Less Than, Greater Than, Two Register Values***

---

**Syntax**                      **CMP** *src1, src2*  
 Functional unit = D

**Opcode**                      16 bit

**Description**                      Compares *src2* to *src1*. The condition bits CSR:EQ, CSR:LT, and CSR:GT are updated based on the comparison.

**Condition Codes**                      CSR[2]EQ = (*src2* == *src1*)  
 CSR[3]LT = (*src2* < *src1*)  
 CSR[4]GT = (*src2* > *src1*)

**Pseudo Code**                      See Condition Codes

---

**CMPU**                      **Compare for Equality, Less Than, Greater Than, 16-Bit Unsigned Constant to Register**

---

**Syntax**                      **CMPU** *ucst16*, *src2*  
 Functional unit = D

**Opcode**                      32 bit

**Description**                      Compares *src2* to a zero-extended 16-bit constant (*ucst16*). The condition bits CSR:EQ, CSR:LT, and CSR:GT are updated based on the comparison. This is an unsigned comparison.

**Condition Codes**                      CSR[2]EQ = (*src2* == {zero extend}(*ucst16*))  
 CSR[3]LT = (*src2* < {zero extend}(*ucst16*))  
 CSR[4]GT = (*src2* > {zero extend}(*ucst16*))

**Pseudo Code**                      See Condition Codes

**CMPU** *Compare for Equality, Less Than, Greater Than, 3-Bit Unsigned Constant to Register*

**Syntax** **CMPU** *ucst3, src2*  
Functional unit = D

**Opcode** 16 bit

**Description** Compares *src2* to a zero-extended 3-bit constant (*ucst3*). The condition bits CSR:EQ, CSR:LT, and CSR:GT are updated based on the comparison. This is an unsigned comparison.

**Condition Codes**

CSR[2]EQ = (*src2* == {zero extend}(*ucst3*))

CSR[3]LT = (*src2* < {zero extend}(*ucst3*))

CSR[4]GT = (*src2* > {zero extend}(*ucst3*))

**Pseudo Code** See Condition Codes

---

**CMPU**                      ***Unsigned Compare for Equality, Less Than, Greater Than, Two Register Values***

---

**Syntax**                      **CMPU** *src1, src2*  
 Functional unit = D

**Opcode**                      16 bit

**Description**                      Compares *src2* to *src1*. The condition bits CSR:EQ, CSR:LT, and CSR:GT are updated based on the comparison. This is an unsigned comparison.

**Condition Codes**                      CSR[2]EQ = (*src2* == *src1*)  
 CSR[3]LT = (*src2* < *src1*)  
 CSR[4]GT = (*src2* > *src1*)

**Pseudo Code**                      See Condition Codes

**DIV** *Signed Division of Two Register Values*

**Syntax** `DIV src1, src2, dst`  
 Functional unit = M

**Opcode** 32 bit

**Description** Signed division of *src1* and *src2* and store result to *dst*. Divide by 0 raises UNDEF interrupt, *dst* is written with 0, CSR:EQ gets set.

Using **DIV** (integer division) and **SHRA** (arithmetic right shift) does not produce the same result for negative numbers. The quotient of **DIV** is rounded towards zero, whereas the quotient of **SHRA** is rounded towards negative infinity. For example, using the **DIV** instruction:  $-9/4 = -2$ , whereas using the **SHRA** instruction:  $-9/4 = -3$ .

**Condition Codes** CSR:EQ = (dst == 0)

**Pseudo Code** `dst = src2 / src1`

**Cycles** 14 execute cycles. This is a blocking multi-execute cycle instruction.

**DIVU**                      ***Unsigned Division of Two Register Values***
**Syntax**                      **DIVU** *src1, src2, dst*

Functional unit = M

**Opcode**                      32 bit

**Description**                      Unsigned division of *src1* and *src2* and store result to *dst*. Divide by 0 raises UNDEF interrupt, *dst* is written with 0, CSR:EQ gets set.

**Condition Codes**                      CSR[2]EQ = (*dst* == 0)

**Pseudo Code**                      *dst* = *src2* / *src1*
**Cycles**                      14 execute cycles. This is a blocking multi-execute cycle instruction.

**EXTU** *Extract and Zero-Extend a Bit Field Bounded by Two Immediate Values*
**Syntax** `EXTU ucst5_1, ucst5_2, src2, dst`

Functional unit = L

**Opcode** 32 bit

**Description**

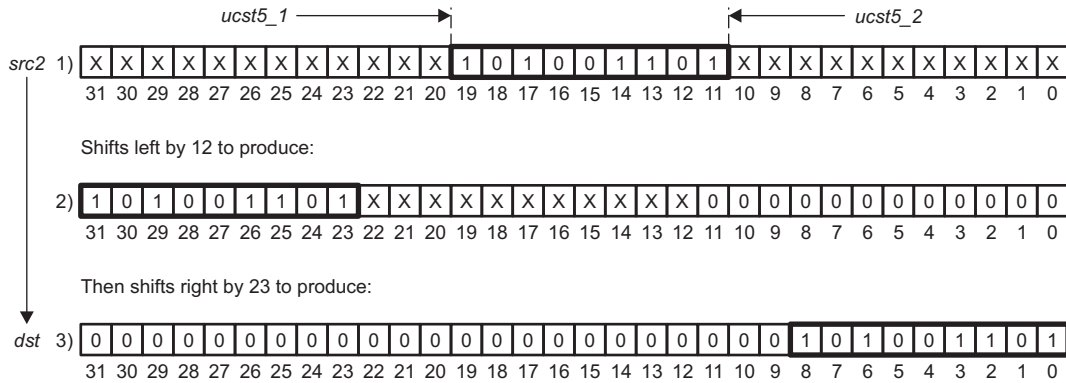

For  $ucst5\_1 \geq ucst5\_2$ , the field in *src2* as specified by *ucst5\_2* to *ucst5\_1* is extracted and zero-extended to 32 bits and is written to *dst*. *src2* is left unchanged. *ucst5\_2* is the LSB of the field and *ucst5\_1* is the MSB of the field to be extracted. In other words, *ucst5\_2* and *ucst5\_1* represent the beginning and ending bits, respectively, of the field to be extracted. The LSB location of *src2* is bit 0 and the MSB location of *src2* is bit 31.

Valid values of *ucst5\_1* and *ucst5\_2* are:

- $0 \leq ucst5\_1 \leq 31; 0 \leq ucst5\_2 \leq 31$
- $ucst5\_1 \geq ucst5\_2$

For  $ucst5\_1 < ucst5\_2$ , the result is undefined.

In the following example, *ucst5\_2* is 11 and *ucst5\_1* is 19.

**Condition Codes** CSR[2]EQ = (dst == 0)

**Pseudo Code**

```

tmpdst = 0; j = 0;
for( i = 0; i < 32; i++) {
    if ( i >= ucst5_2 && i <= ucst5_1) tmpdst[j++] = src2[i];
};
dst = tmpdst ;
    
```

**IDLE** *Idle Until Interrupt or Reset*

---

**Syntax** **IDLE**  
Functional unit = S

**Opcode** 16 bit

15	14	13	12	11	10	9										0
x	x	x	x	x	x	1	1	0	1	1	1	1	1	1	1	1

*opcode*

**Description** The **IDLE** instruction causes the CPU to wait for all pending instruction and data memory transactions to complete and then go to an idle state. The idle state is the equivalent of an endless loop. Termination of this loop occurs on an interrupt or reset. However, the CPU does not actually continue fetch/executing any actual instructions. On acceptance of an interrupt, PC + 1 is stored into the interrupt return pointer register (IRP), subsequent instruction execution after return from the interrupt begins at the instruction following the **IDLE** instruction.

For more details on usage of IDLE instruction, see [Section 8.2.6.3](#).

**Condition Codes** None

**Pseudo Code** None

---

**LDB(U)**                      **Load Byte from Memory with a 3-Bit Unsigned Constant Offset**

---

**Syntax**                      **LDB** *\*+baseR[ucst3], dst*  
or  
**LDBU** *\*+baseR[ucst3], dst*  
Functional unit = D

**Opcode**                      16 bit

Syntax	Opcode	Load Type
<b>LDB</b> <i>*+baseR[ucst3], dst</i>	101 1010	Load byte (sign-extended)
<b>LDBU</b> <i>*+baseR[ucst3], dst</i>	101 1000	Load byte unsigned (zero-extended)

**Description**                      Loads a byte (signed or unsigned) from memory (effective address) to *dst*. The memory address is formed from a base address register (*baseR*) and an offset (number of bytes) that is a 3-bit unsigned constant (*ucst3*). If an offset is not given, the assembler assigns an offset of zero. There must be brackets, [ ], around the specified offset, if using the optional offset parameter.

The square brackets, [ ], indicate that the *ucst3* is scaled by a left-shift of 0 bits. After scaling, *ucst3* is added to *baseR*. The result of the calculation is the effective address to be accessed in memory and the content loaded into *dst*.

The content is loaded into the 8 LSBs of *dst*. For the **LDB** instruction, the upper 24 bits of *dst* are sign-extended; for the **LDBU** instruction, the upper 24 bits of *dst* are zero-extended.

**Condition Codes**                      None

**Pseudo Code**                      *dst = \*(baseR[ucst3])*

**LDB(U)** *Load Byte from Memory with a 16-Bit Unsigned Constant Offset*

**Syntax** **LDB** *\*+baseR[ucst16], dst*  
or

<b>LDB</b> <i>*+SP[ucst6], dst</i>	110 1001	Load byte (sign-extended)
<b>LDBU</b> <i>*+SP[ucst6], dst</i>	110 0111	Load byte unsigned (zero-extended)

**Description**                      Loads a byte (signed or unsigned) from memory (effective address) to *dst*. The memory address is formed from the stack pointer (SP) and an offset (number of bytes) that is a 6-bit unsigned constant (*ucst6*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [ ], must surround the specified offset, if using the optional offset parameter.

The square brackets, [ ], indicate that the *ucst6* is scaled by a left-shift of 0 bits. After scaling, *ucst6* is added to SP. The result of the calculation is the effective address to be accessed in memory and the content loaded into *dst*.

The content is loaded into the 8 LSBs of *dst*. For the **LDB** instruction, the upper 24 bits of *dst* are sign-extended; for the **LDBU** instruction, the upper 24 bits of *dst* are zero-extended.

**Condition Codes**                      None

**Pseudo Code**                      *dst = \*(SP[ucst6])*

<b>LDBU</b> <i>*+SP[ucst19], dst</i>	00 0000 0111	Load byte unsigned (zero-extended)

**Description**

Loads a byte (signed or unsigned) from memory (effective address) to *dst*. The memory address is formed from the stack pointer (SP) and an offset (number of bytes) that is a 19-bit unsigned constant (*ucst19*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [ ], must surround the specified offset, if using the optional offset parameter.

The square brackets, [ ], indicate that the *ucst19* is scaled by a left-shift of 0 bits. After scaling, *ucst19* is added to SP. The result of the calculation is the effective address to be accessed in memory and the content loaded into *dst*.

The content is loaded into the 8 LSBs of *dst*. For the **LDB** instruction, the upper 24 bits of *dst* are sign-extended; for the **LDBU** instruction, the upper 24 bits of *dst* are zero-extended.

 Functional unit = S

**Opcode**                      16 bit

**Description**                      The content of the control register (*creg*) is moved to the architectural register (*areg*).

**Condition Codes**                      None

**Pseudo Code**                      *areg = creg*

**MVC**                      *Move 16-Bit Unsigned Constant to Control Register*

---

**Syntax**                      **MVC** *ucst16, creg*  
 Functional unit = S

**Opcode**                      32 bit

**Description**                      A 16-bit unsigned constant (*ucst16*) is moved to the control register (*creg*).

**Condition Codes**                      None

**Pseudo Code**                      `creg = {zero extend}ucst16`

**MVCH** *Move 16-Bit Unsigned Constant to Upper Bits of Control Register*
**Syntax** **MVCH** *ucst16, creg*

Functional unit = S

**Opcode** 32 bit

**Description** A 16-bit unsigned constant (*ucst16*) is moved to the upper halfword (bits 31-16) of the control register (*creg*). The lower halfword (bits 15-0) of *creg* is left unchanged.

**Condition Codes** None

**Pseudo Code** `creg[31:16] = ucst16`

**MVK**                      ***Move 16-Bit Unsigned Constant to Register***

---

**Syntax**                      **MVK** *ucst16, dst*  
 Functional unit = S

**Opcode**                      32 bit

**Description**                      A 16-bit unsigned constant (*ucst16*) is moved to *dst*.

**Condition Codes**                      CSR:EQ = (*dst* == 0)

**Pseudo Code**                      *dst* = {zero extend}*ucst16*

**MVKH**                      ***Move 16-Bit Unsigned Constant to Upper Bits of Register***

**Syntax**                      **MVKH** *ucst16, dst*  
                                     Functional unit = S

**Opcode**                      32 bit

**Description**                      A 16-bit unsigned constant (*ucst16*) is moved to the upper halfword (bits 31-16) of *dst*. The lower halfword (bits 15-0) of *dst* is left unchanged.

**Condition Codes**                      CSR:EQ = (*dst* == 0)

**Pseudo Code**                      *dst*[31:16] = *ucst16*

**MVKS**                      ***Move 6-Bit Signed Constant to Register***

**Syntax**                      **MVKS** *scst6*, *dst*  
                                     Functional unit = S

**Opcode**                      16 bit

**Description**                      A 6-bit signed constant (*scst6*) is sign extended and is moved to *dst*.

**Condition Codes**                      CSR:EQ = (*dst* == 0)

**Pseudo Code**                      *dst* = {sign extend}*scst6*

**MVS**                      ***Move Architectural Register to Shadow Register***

**Syntax**                      **MVS** *areg, sreg*  
 Functional unit = S

**Opcode**                      16 bit

**Description**                      The content of the architectural register (*areg*) is moved to the shadow register (*sreg*). This instruction has two exposed delay slots, the data written cannot be read back until the third cycle from the cycle when this instruction enters the EXE phase.

**Condition Codes**                      None

**Pseudo Code**                      *sreg* = *areg*

**MVS**                      ***Move Shadow Register to Architectural Register***

**Syntax**                      **MVS** *sreg, areg*  
 Functional unit = S

**Opcode**                      16 bit

**Description**                      The content of the shadow register (*sreg*) is moved to the architectural register (*areg*).

**Condition Codes**                      None

**Pseudo Code**                      *areg = sreg*

**NEG**                      *Negation*

**Syntax**                      **NEG** *src2, dst*  
 Functional unit = L

**Opcode**                      16 bit

**Description**                      *src2* is subtracted from zero and the result is stored in *dst*.

**Condition Codes**                      CSR[2]EQ = (*dst* == 0)

**Pseudo Code**                      *dst* = 0 - *src2*

**NOP**                      ***No Operation***

**Syntax**                      **NOP**  
                                     Functional unit = None

**Opcode**                      16 bit

**Description**                      No operation.

**Condition Codes**                      None

**Pseudo Code**                      None

**NOT** *Bitwise NOT*

---

**Syntax** **NOT** *src2, dst*  
 Functional unit = L

**Opcode** 16 bit

**Description** Performs a bitwise inversion of *src2* and stores the result in *dst*.

**Condition Codes** CSR[2]EQ = (*dst* == 0)

**Pseudo Code** *dst* = ~*src2*

**OR** *Bitwise OR 16-Bit Unsigned Constant with Register*

**Syntax** **OR** *ucst16, src2, dst*  
Functional unit = L

**Opcode** 32 bit

**Description** Bitwise OR of a zero-extended 16-bit unsigned constant (*ucst16*) with *src2* and store result to *dst*.

**Condition Codes** CSR[2]EQ = (dst == 0)

**Pseudo Code** `dst = src2 OR {zero extend}ucst16`

**OR** *Bitwise OR Two Registers*

**Syntax** **OR** *src1, src2, dst*  
 Functional unit = L

**Opcode** 16 bit

**Description** Bitwise OR of *src1* with *src2* and store result to *dst*.

**Condition Codes** CSR[2]EQ = (*dst* == 0)

**Pseudo Code** *dst* = *src2* OR *src1*

**RET**                      ***Return from Subroutine***

**Syntax**                      **RET**  
                                     Functional unit = D

**Opcode**                      16 bit

**Description**                      Load the link register (LR) into the program counter (PC), increment the stack pointer (SP), then load the contents of the memory location pointed to by SP into LR. The content of LR and the content of the memory location pointed to by SP in this case is treated as an absolute halfword address.

This instruction has one delay slot. See [Section 8.2.5.3.1](#) for restrictions on scheduling an instruction in this delay slot.

**Condition Codes**                      None

**Pseudo Code**                      `PC = LR; SP += 4; LR = *(SP)`

**REV** *Reverse a Bit Field Bounded by Two Register Values*
**Syntax** **REV** *src1, src2, dst*

Functional unit = L

**Opcode** 32 bit

31	30	29	28	27	26	25	24	23	22	21	20	16	15	13	12	10	9	7	6	0											
x	x	x	x	x	x	x	x	x	x	x	1	0	1	0	0	<i>dst</i>			<i>src2</i>			<i>src1</i>			0	0	0	0	1	0	0
												3			3			3			<i>opcode</i>										

**Description**

For  $src1[9:5] \geq src1[4:0]$ , the field in *src2* as specified by  $src1[4:0]$  to  $src1[9:5]$  is bit reversed. The reversed bits are merged with the remaining (unchanged) bits in *dst* and are stored in *dst*. *src2* is left unchanged.  $src1[4:0]$  is the LSB of the field and  $src1[9:5]$  is the MSB of the field to be bit reversed. In other words,  $src1[4:0]$  and  $src1[9:5]$  represent the beginning and ending bits, respectively, of the field to be bit reversed. The LSB location of *src2* is bit 0 and the MSB location of *src2* is bit 31.

Valid values of  $src1[9:5]$  and  $src1[4:0]$  are:

- $0 \leq src1[9:5] \leq 31$ ;  $0 \leq src1[4:0] \leq 31$
- $src1[9:5] \geq src1[4:0]$

For  $src1[9:5] < src1[4:0]$ , the result is undefined.

In the following example,  $src1[4:0]$  is 11 and  $src1[9:5]$  is 19.

**Condition Codes** CSR[2]EQ = (*dst* == 0)

**Pseudo Code**

```

dst = src2
pntr = src1[9:5];
for( i = 0; i < 32; i++) {
    if ( i >= src1[4:0] && i <= src1[9:5]){
        dst[i] = dst[pntr]
        --pntr;
    } else
        dst[i] = dst[i];
}

```

**ROT Rotate Right**

**Syntax**                    **ROT** *src1, src2, dst*  
 Functional unit = L

**Opcode**                    32 bit

31	30	29	28	27	26	25	24	23	22	21	20			16	15			13	12			10	9		7	6			0		
x	x	x	x	x	x	x	x	x	x	x	1	0	1	0	1	<i>dst</i>			<i>src2</i>			<i>src1</i>			0	0	0	0	1	0	0
												3			3			3			<i>opcode</i>										

**Description**                    *src1[4:0]* contains the number of bit positions that *src2* is to be rotated right. The new MSB value is defined by the previous LSB value of *src2*. The result is stored in *dst*. A *src1[4:0] = 0*, results in the **MV** *src1, dst* instruction.

In the following example, *src1[4:0]* is 9.

**Condition Codes**                    CSR[2]EQ = (*dst* == 0)

**Pseudo Code**

```

dst = src2
for( i = 1; i < src1; i++) {
  dst = { dst[0], dst[32-2: 1] };
}

```

**ROTC** *Rotate Right Through Carry Bit*

**Syntax** **ROTC** *src1, src2, dst*

Functional unit = L

**Opcode** 32 bit

**Description**

*src1[4:0]* contains the number of bit positions that *src2* is to be rotated right through the Carry bit (CSR[5]C). The new MSB value is defined by the current SAT bit in the control status register (CSR). The rotated LSB of *src2* is moved to CSR[5]C. The result is stored in *dst*. A *src1[4:0] = 0*, results in the **MV** *src1, dst* instruction.

In the following example, *src1[4:0]* is 9.

**Condition Codes** CSR[2]EQ = (*dst* == 0)  
 CSR[5]C: see the Pseudo Code

```

Pseudo Code
tmp = src2
for( i = 1; i < src1; i++) {
    tmp = { CSR[C], tmp[32-2: 1] };
    CSR[C] = tmp[0] ;
}
dst = tmp;
  
```

**SADD**                      *Signed Addition of Two Register Values with Saturation*

**Syntax**                    **SADD** *src1, src2, dst*  
 Functional unit = D

**Opcode**                    16 bit

**Description**             Signed addition of *src1* with *src2* with result saturation and stored to *dst*. If a saturate occurs, the SAT bit in the control status register (CSR) is set after *dst* is written.

**Condition Codes**        CSR[2]EQ = (*dst* == 0)  
 CSR[5]SAT = satP OR satN

**Pseudo Code**            *tmp* = *src2* + *src1*  
 satP = *tmp* > 2<sup>31</sup> - 1  
 satN = *tmp* < -2<sup>31</sup>  
*dst* = satP ? (2<sup>31</sup> - 1)        : (satN ? -2<sup>31</sup> : *tmp*)

**SET** *Set Bit Field Bounded by Two Immediate Values*
**Syntax** `SET ucst5_1, ucst5_2, src2, dst`

Functional unit = L

**Opcode** 32 bit

31	30	29	28	27	26	25				21	20				16	15			13	12			10	9										0			
x	x	x	x	x	x		ucst5_1					ucst5_2					dst			src2			1	1	0	0	0	0	0	0	0	0	0	0	0	0	0
						5					5					3			3			opcode															

**Description**

For  $ucst5\_1 \geq ucst5\_2$ , the field in *src2* as specified by *ucst5\_2* to *ucst5\_1* is set to all 1s and the resulting value of *src2* is written to *dst*. *src2* is left unchanged. *ucst5\_2* is the LSB of the field and *ucst5\_1* is the MSB of the field. In other words, *ucst5\_2* and *ucst5\_1* represent the beginning and ending bits, respectively, of the field to be set to all 1s. The LSB location of *src2* is bit 0 and the MSB location of *src2* is bit 31.

Valid values of *ucst5\_1* and *ucst5\_2* are:

- $0 \leq ucst5\_1 \leq 31$ ;  $0 \leq ucst5\_2 \leq 31$
- $ucst5\_1 \geq ucst5\_2$

For  $ucst5\_1 < ucst5\_2$ , the result is undefined.

In the following example, *ucst5\_2* is 15 and *ucst5\_1* is 23.

**Condition Codes** CSR[2]EQ = (dst == 0)

**Pseudo Code**

```
dst = src2
for( i = 0; i < 32; i++) {
    if ( i >= ucst5_2 && i <= ucst5_2) dst[i] = 1;
};
```

**SET** *Set Bit Field Bounded by Two Register Values*

**Syntax** **SET** *src1, src2, dst*

Functional unit = L

**Opcode** 32 bit

**Description** For  $src1[9:5] \geq src1[4:0]$ , the field in *src2* as specified by  $src1[4:0]$  to  $src1[9:5]$  is set to all 1s and the resulting value of *src2* is written to *dst*. *src2* is left unchanged.  $src1[4:0]$  is the LSB of the field and  $src1[9:5]$  is the MSB of the field. In other words,  $src1[4:0]$  and  $src1[9:5]$  represent the beginning and ending bits, respectively, of the field to be set to all 1s. The LSB location of *src2* is bit 0 and the MSB location of *src2* is bit 31.

Valid values of  $src1[9:5]$  and  $src1[4:0]$  are:

- $0 \leq src1[9:5] \leq 31$ ;  $0 \leq src1[4:0] \leq 31$
- $src1[9:5] \geq src1[4:0]$

For  $src1[9:5] < src1[4:0]$ , the result is undefined.

In the following example,  $src1[4:0]$  is 15 and  $src1[9:5]$  is 23.

**Condition Codes** CSR[2]EQ = (dst == 0)

**Pseudo Code**

```
dst = src2
for( i = 0; i < 32; i++) {
    if ( i >= src1[4:0] && i <= src1[9:5]) dst[i] = 1;
};
```

**SHL**                      ***Logical Shift Left by 5-Bit Unsigned Constant***

**Syntax**                      **SHL** *ucst5, src2, dst*  
Functional unit = L

**Opcode**                      32 bit

**Description**                      *src2* is left shifted by a 5-bit unsigned constant (*ucst5*) and the result is stored to *dst*.  
The shift in value is 0.

**Condition Codes**                      CSR[2] EQ = (*dst* == 0)

**Pseudo Code**                      *dst* = *src2* << *ucst5*

**SHL** *Logical Shift Left by Register Value*

---

**Syntax** **SHL** *src1, src2, dst*  
 Functional unit = L

**Opcode** 16 bit

**Description** *src2* is left shifted by an unsigned value (*src1*) and the result is stored to *dst*. The shift in value is 0. If the *src1* value is greater than 31, *dst* is cleared to 0.

**Condition Codes** CSR[2] EQ = (*dst* == 0)

**Pseudo Code**  $dst = (src1 > 31) ? 0 : (src2 \ll src1)$

**SHRA** *Arithmetic Shift Right by 5-Bit Unsigned Constant*
**Syntax** **SHRA** *ucst5, src2, dst*

Functional unit = L

**Opcode** 32 bit

**Description** *src2* is right shifted by a 5-bit unsigned constant (*ucst5*) and the result is stored to *dst*. The shift in value is the sign bit (bit 31) of *src2*.

Using **DIV** (integer division) and **SHRA** (arithmetic right shift) does not produce the same result for negative numbers. The quotient of **DIV** is rounded towards zero, whereas the quotient of **SHRA** is rounded towards negative infinity. For example, using the **DIV** instruction:  $-9/4 = -2$ , whereas using the **SHRA** instruction:  $-9/4 = -3$ .

**Condition Codes** CSR[2] EQ = (*dst* == 0)

**Pseudo Code**  $dst = \{sign\ extend\} \{src2 \gg ucst5\}$

**SHRA** *Arithmetic Shift Right by Register Value*

**Syntax** **SHRA** *src1, src2, dst*  
Functional unit = L

**Opcode** 16 bit

**Description** *src2* is right shifted by an unsigned value (*src1*) and the result is stored to *dst*. The shift in value is the sign bit (bit 31) of *src2*. If the *src1* value is greater than 31, *dst* is -1.  
Using **DIV** (integer division) and **SHRA** (arithmetic right shift) does not produce the same result for negative numbers. The quotient of **DIV** is rounded towards zero, whereas the quotient of **SHRA** is rounded towards negative infinity. For example, using the **DIV** instruction:  $-9/4 = -2$ , whereas using the **SHRA** instruction:  $-9/4 = -3$ .

**Condition Codes** CSR[2] EQ = (*dst* == 0)

**Pseudo Code**  $dst = (src1 > 31) ? \text{FFFF FFFFh} : \{\text{sign extend}\}\{src2 \gg src1\}$

**SHRU**                      ***Logical Shift Right by 5-Bit Unsigned Constant***
**Syntax**                      **SHRU** *ucst5, src2, dst*

Functional unit = L

**Opcode**                      32 bit

**Description**                      *src2* is right shifted by a 5-bit unsigned constant (*ucst5*) and the zero-extended result is stored to *dst*.

**Condition Codes**                      CSR[2] EQ = (*dst* == 0)

**Pseudo Code**                      *dst* = {zero extend}{*src2* >> *ucst5*}

**SHRU** *Logical Shift Right by Register Value*

---

**Syntax** **SHRU** *src1, src2, dst*  
 Functional unit = L

**Opcode** 16 bit

**Description** *src2* is right shifted by an unsigned value (*src1*) and the result is stored to *dst*. The shift in value is 0. If the *src1* value is greater than 31, *dst* is cleared to 0.

**Condition Codes** CSR[2] EQ = (*dst* == 0)

**Pseudo Code**  $dst = (src1 > 31) ? 0 : \{zero\ extend\}\{src2 \gg src1\}$

**SLA**                      ***Set Loop Address***

**Syntax**                      **SLA** *ucst16, creg*  
 Functional unit = S

**Opcode**                      32 bit

**Description**                      Sets up loop bound address using a program counter (PC)-relative immediate positive offset. A zero-extended 16-bit unsigned immediate value (*ucst16*) is added to the PC of the instruction and is written to *creg*. Note that the offset is treated as a halfword offset. The only allowed *creg* registers for this instruction are: LSA0, LEA0, LSA1, and LEA1.

**Condition Codes**                      None

**Pseudo Code**                       $creg = PC + \{\text{zero extend}\}ucst16$

**SSUB**                      ***Subtraction of Two Register Values with Saturation***

**Syntax**                      **SSUB** *src1, src2, dst*  
 Functional unit = D

**Opcode**                      16 bit

**Description**                      *src1* is subtracted from *src2* with result saturation and stored to *dst*. If a saturate occurs, the SAT bit in the control status register (CSR) is set after *dst* is written.

**Condition Codes**                      CSR[2] EQ = (*dst* == 0)  
 CSR[6] SAT = satP OR satN

**Pseudo Code**                      `tmp = src2 - src1`  
    `satP = tmp > 231 - 1`  
    `satN = tmp < -231`  
    `dst = satP ? (231 - 1) : (satN ? -231 : tmp)`

**STB** *Store Byte to Memory with a 3-Bit Unsigned Constant Offset*

**Syntax** **STB** *dst*, *\*,+baseR[ucst3]*  
Functional unit = D

**Opcode** 16 bit

**Description** The 8 LSBs (byte) of *dst* are stored to memory (effective address). The memory address is formed from a base address register (*baseR*) and an offset (number of bytes) that is a 3-bit unsigned constant (*ucst3*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [ ], must surround the specified offset, if using the optional offset parameter.

The square brackets, [ ], indicate that the *ucst3* is scaled by a left-shift of 0 bits. After scaling, *ucst3* is added to *baseR*. The result of the calculation is the effective address in memory that contains the content from *dst*.

**Condition Codes** None

**Pseudo Code**  $*(baseR[ucst3]) = *dst$

**STB**                                  **Store Byte to Memory with a 16-Bit Unsigned Constant Offset**

**Syntax**                                  **STB** *dst*, **\****baseR*[*ucst16*]  
 Functional unit = D

**Opcode**                                  32 bit

**Description**                                  The 8 LSBs (byte) of *dst* are stored to memory (effective address). The memory address is formed from a base address register (*baseR*) and an offset (number of bytes) that is a 16-bit unsigned constant (*ucst16*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [ ], must surround the specified offset, if using the optional offset parameter.

The square brackets, [ ], indicate that the *ucst16* is scaled by a left-shift of 0 bits. After scaling, *ucst16* is added to *baseR*. The result of the calculation is the effective address in memory that contains the content from *dst*.

**Condition Codes**                                  None

**Pseudo Code**                                  **\***(*baseR*[*ucst16*]) = *\*dst*

**STB** *Store Byte to Memory with a Register Offset*

---

**Syntax** **STB** *dst*, *\*+baseR[src1]*  
Functional unit = D

**Opcode** 16 bit

**Description** The 8 LSBs (byte) of *dst* are stored to memory (effective address). The memory address is formed from a base address register (*baseR*) and an offset (number of bytes) that is a register (*src1*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [ ], must surround the specified offset, if using the optional offset parameter.

The square brackets, [ ], indicate that the *src1* is scaled by a left-shift of 0 bits. After scaling, *src1* is added to *baseR*. The result of the calculation is the effective address in memory that contains the content from *dst*.

**Condition Codes** None

**Pseudo Code**  $*(baseR[src1]) = *dst$

**STB** *Store Byte to Memory, Postincrement with a 3-Bit Unsigned Constant Offset*

**Syntax** **STB** *dst, \*baseR++[ucst3]*

Functional unit = D

**Opcode** 16 bit

**Description** The 8 LSBs (byte) of *dst* are stored to memory (effective address). The memory address is the value of the base address register (*baseR*). After accessing, an offset (number of bytes) that is a 3-bit unsigned constant (*ucst3*) is added to *baseR* at the end of the EXE phase. Brackets, [ ], must surround the specified offset, if using the optional offset parameter.

**Condition Codes** None

**Pseudo Code**  $*(baseR++[ucst3]) = *dst$

---

**STB** *Store Byte to Memory with a GDP-Relative 19-Bit Unsigned Constant Offset*
**Syntax** **STB** *dst*, \*+GDP[*ucst19*]

Functional unit = D

**Opcode** 32 bit

**Description** The 8 LSBs (byte) of *dst* are stored to memory (effective address). The memory address is formed from the global data pointer register (GDP) and an offset (number of bytes) that is a 19-bit unsigned constant (*ucst19*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [ ], must surround the specified offset, if using the optional offset parameter.

The square brackets, [ ], indicate that the *ucst19* is scaled by a left-shift of 0 bits. After scaling, *ucst19* is added to GDP. The result of the calculation is the effective address in memory that contains the content from *dst*.

**Condition Codes** None

**Pseudo Code** \*(GDP[*ucst19*]) = \**dst*

---

**STH**                      **Store Halfword to Memory with a 3-Bit Unsigned Constant Offset**

---

**Syntax**                      **STH** *dst*, **+***baseR*[*ucst3*]

Functional unit = D

**Opcode**                      16 bit

**Description**                      The 16 LSBs (halfword) of *dst* are stored to memory (effective address). The memory address is formed from a base address register (*baseR*) and an offset (number of halfwords) that is a 3-bit unsigned constant (*ucst3*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [ ], must surround the specified offset, if using the optional offset parameter.

The square brackets, [ ], indicate that the *ucst3* is scaled by a left-shift of 1 bit. After scaling, *ucst3* is added to *baseR*. The result of the calculation is the effective address in memory that contains the content from *dst*.

Halfword addresses must be aligned on halfword (LSB is 0) boundaries.

**Condition Codes**                      None

**Pseudo Code**                       $*(baseR[ucst3]) = *dst$

**STH** *Store Halfword to Memory with a 16-Bit Unsigned Constant Offset*

**Syntax** **STH** *dst*, *\*+baseR[ucst16]*  
 Functional unit = D

**Opcode** 32 bit

**Description** The 16 LSBs (halfword) of *dst* are stored to memory (effective address). The memory address is formed from a base address register (*baseR*) and an offset (number of halfwords) that is a 16-bit unsigned constant (*ucst16*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [ ], must surround the specified offset, if using the optional offset parameter.

The square brackets, [ ], indicate that the *ucst16* is scaled by a left-shift of 1 bit. After scaling, *ucst16* is added to *baseR*. The result of the calculation is the effective address in memory that contains the content from *dst*.

Halfword addresses must be aligned on halfword (LSB is 0) boundaries.

**Condition Codes** None

**Pseudo Code**  $*(baseR[ucst16]) = *dst$

**STH** *Store Halfword to Memory with a Register Offset*

**Syntax**                    **STH** *dst*, *\*,+baseR[src1]*  
Functional unit = D

**Opcode**                    16 bit

**Description**                    The 16 LSBs (halfword) of *dst* are stored to memory (effective address). The memory address is formed from a base address register (*baseR*) and an offset (number of halfwords) that is a register (*src1*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [ ], must surround the specified offset, if using the optional offset parameter.

The square brackets, [ ], indicate that the *src1* is scaled by a left-shift of 1 bit. After scaling, *src1* is added to *baseR*. The result of the calculation is the effective address in memory that contains the content from *dst*.

Halfword addresses must be aligned on halfword (LSB is 0) boundaries.

**Condition Codes**                    None

**Pseudo Code**                    *\*(baseR[src1]) = \*dst*

**STH** *Store Halfword to Memory, Postincrement with a 3-Bit Unsigned Constant Offset*

**Syntax**            **STH** *dst*, *\*baseR++[ucst3]*

Functional unit = D

**Opcode**            16 bit

**Description**            The 16 LSBs (halfword) of *dst* are stored to memory (effective address). The memory address is the value of the base address register (*baseR*). After accessing, an offset (number of halfwords) that is a 3-bit unsigned constant (*ucst3*) is added to *baseR* at the end of the EXE phase. You must type the brackets, [ ], around the specified offset, if you use the optional offset parameter.

Halfword addresses must be aligned on halfword (LSB is 0) boundaries.

**Condition Codes**            None

**Pseudo Code**             $*(baseR++[ucst3]) = *dst$

**STH** *Store Halfword to Memory, Postincrement with a Register Offset*

**Syntax** **STH** *dst*, \**baseR*++[*src1*]

Functional unit = D

**Opcode** 16 bit

**Description** The 16 LSBs (halfword) of *dst* are stored to memory (effective address). The memory address is the value of the base address register (*baseR*). After accessing, an offset (number of halfwords) that is a register (*src1*) is added to *baseR* at the end of the EXE phase. You must type the brackets, [ ], around the specified offset, if you use the optional offset parameter.

Halfword addresses must be aligned on halfword (LSB is 0) boundaries.

**Condition Codes** None

**Pseudo Code** \*(*baseR*++[*src1*]) = \**dst*

**STH** *Store Halfword to Memory with a SP-Relative 6-Bit Unsigned Constant Offset*
**Syntax** `STH dst, *+SP[ucst6]`

Functional unit = D

**Opcode** 16 bit

**Description** The 16 LSBs (byte) of *dst* are stored to memory (effective address). The memory address is formed from the stack pointer (SP) and an offset (number of halfwords) that is a 6-bit unsigned constant (*ucst6*). If an offset is not given, the assembler assigns an offset of zero. You must type the brackets, [ ], around the specified offset, if you use the optional offset parameter.

The square brackets, [ ], indicate that the *ucst6* is scaled by a left-shift of 1 bit. After scaling, *ucst6* is added to SP. The result of the calculation is the effective address in memory that contains the content from *dst*.

Halfword addresses must be aligned on halfword (LSB is 0) boundaries.

**Condition Codes** None

**Pseudo Code** `*(SP[ucst6]) = *dst`

---

**STH** *Store Halfword to Memory with a SP-Relative 19-Bit Unsigned Constant Offset*

---

**Syntax** **STH** *dst*, **\*+SP**[*ucst19*]

Functional unit = D

**Opcode** 32 bit

**Description** The 16 LSBs (byte) of *dst* are stored to memory (effective address). The memory address is formed from the stack pointer (SP) and an offset (number of halfwords) that is a 19-bit unsigned constant (*ucst19*). **STW** *Store Word to Memory with a GDP-Relative 19-Bit Unsigned Constant Offset*
**Syntax** **STW** *dst, \*+GDP[ucst19]*

Functional unit = D

**Opcode** 32 bit

**Description**

The entire content (word) of *dst* is stored to memory (effective address). The memory address is formed from the global data pointer register (GDP) and an offset (number of words) that is a 19-bit unsigned constant (*ucst19*). If an offset is not given, the assembler assigns an offset of zero. You must type the brackets, [ ], around the specified offset, if you use the optional offset parameter.

The square brackets, [ ], indicate that the *ucst19* is scaled by a left-shift of 2 bits. After scaling, *ucst19* is added to GDP. The result of the calculation is the effective address in memory that contains the content from *dst*.

Word addresses must be aligned on word (two LSBs are 0) boundaries.

**Condition Codes** None

**Pseudo Code**  $*(GDP[ucst19]) = *dst$

**STHI** *Store 16-Bit Halfword to Memory with a 6-Bit Unsigned Constant Offset*
**Syntax** *STHI ucst16, \*+baseR[ucst6]*

Functional unit = S

**Opcode** 32 bit

**Description** The 16-bit unsigned constant (*ucst16*) is stored to memory (effective address). The memory address is formed from a base address register (*baseR*) and an offset (number of halfwords) that is a 6-bit unsigned constant (*ucst6*). If an offset is not given, the assembler assigns an offset of zero. You must type the brackets, [ ], around the specified offset, if you use the optional offset parameter.

The square brackets, [ ], indicate that the *ucst6* is scaled by a left-shift of 1 bit. After scaling, *ucst6* is added to *baseR*. The result of the calculation is the effective address in memory that contains *ucst16*.

Halfword addresses must be aligned on halfword (LSB is 0) boundaries.

**Condition Codes** None

**Pseudo Code** `*(baseR[ucst6]) = ucst16`

**STRF** *Store Register File to Stack Pointer*

**Syntax** **STRF** *op1*, *op2*  
 Functional unit = D

**Opcode** 16 bit

**Description** The current base register file is stored to the starting address specified by the postdecremented value of the stack pointer (SP). *op1* specifies the ending register (last register stored) and *op2* specifies the beginning register (first register stored). All registers between *op1* and *op2* are stored inclusive. The registers are stored in order from lowest register (*op2*) to highest register (*op1*).

Valid values of *op1* and *op2* are:  $op1 \geq op2$

For  $op1 < op2$ , results in unspecified behavior.

**Condition Codes** None

**Pseudo Code**

```
for ( i = op2; i <= op1 ; i++) {
    *(SP) = Ri;
    SP -= 4;
}
```

**SUB**                      **Subtract 16-Bit Unsigned Constant from Stack Pointer, Result to Stack Pointer**

---

**Syntax**                      **SUB** *ucst16*, SP  
 Functional unit = D

**Opcode**                      32 bit

**Description**                      Subtract a 16-bit unsigned constant (*ucst16*) from the stack pointer (SP) and store result to SP.

**Condition Codes**                      None

**Pseudo Code**                       $SP = SP - ucst16$

**SUB** *Subtract 16-Bit Unsigned Constant from Stack Pointer, Result to Register*
**Syntax** **SUB** *ucst16*, **SP**, *dst*

Functional unit = D
