13.3 L4 Interconnects

This section details the device L4 interconnects.

13.3.1 L4 Interconnect Overview

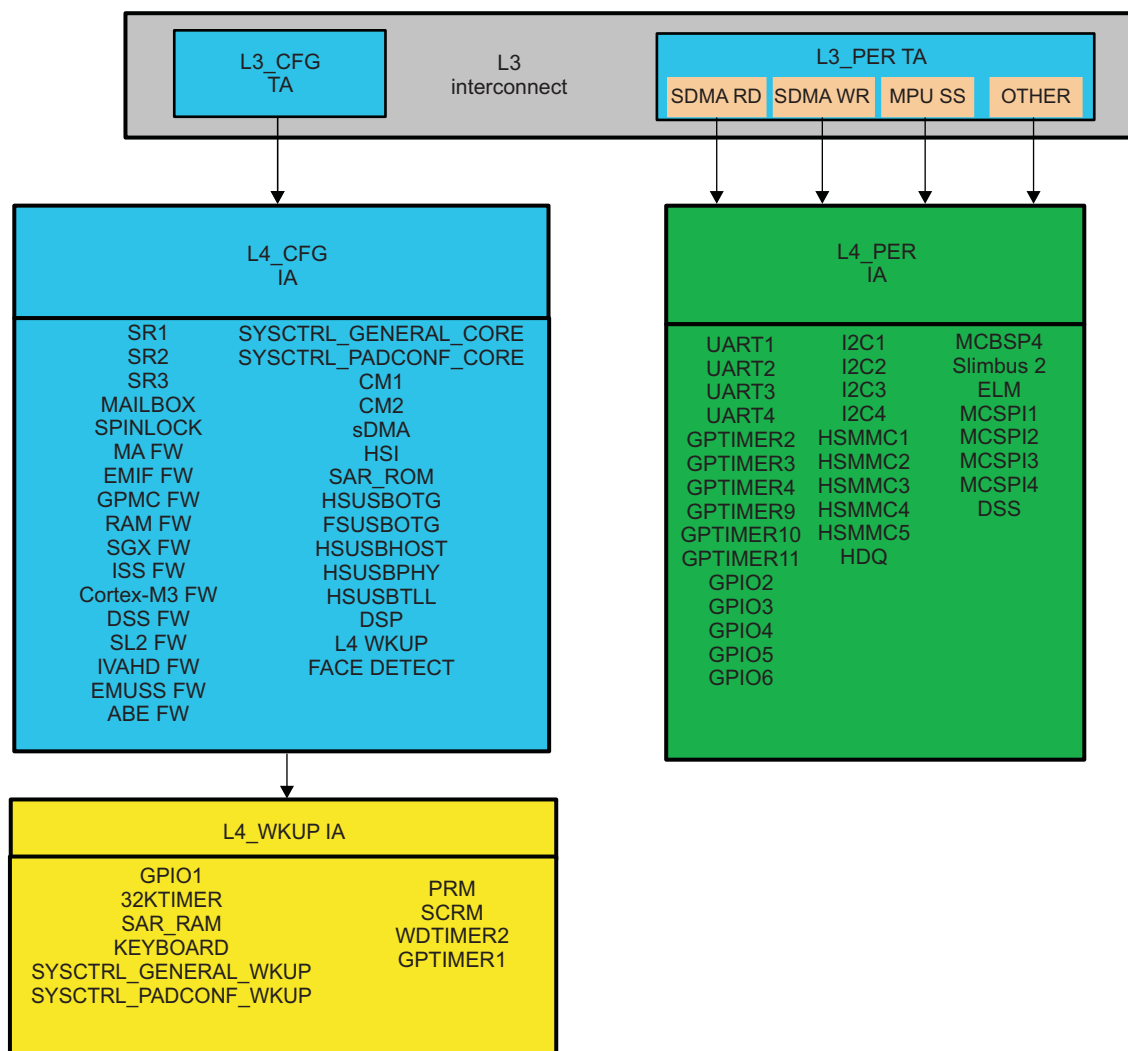

The device uses three separate L4 interconnect structures to connect peripheral modules. All L4s handle transfers with peripherals but are located in distinct power domains.

Figure 13-9 is an overview of the L4 interconnects and the peripherals attached to them.

The L4 interconnect is composed of the following interconnects:

- L4_CFG: Includes the majority of the configuration interface for L3 system modules and peripheral interconnect
- L4_PER: Includes the main peripherals that require sDMA access
- L4_WKUP: Includes peripherals attached to the WKUP power domain

Figure 13-9. L4 Interconnect Overview

icnt-013

The main features of the L4 interconnects are:

- From one to four 32-bit initiator ports for each L4 interconnect instance.
- 8-, 16-, or 32-bit data, single, or burst transactions
- Little endian

- Nonblocking architecture with fair arbitration between threads
- Target interfaces: Fully synchronous or divided synchronous
- L4_CFG and L4_PER frequency equal half of L3 frequency
- Protection logic that provides user-configurable access control to targets by each initiator
- Implementation of RFFs to support low-voltage dynamic power switching

13.3.2 L4 Interconnect Integration

Table 13-278 and Table 13-279 summarize the integration of the module in the device.

Table 13-278. Integration Attributes

Module Instance	Attributes
	Power Domain
L4_PER	PD_L4_PER
L4_CFG	PD_CORE
L4_WKUP	PD_WKUP

13.3.3 L4 Interconnect Functional Description

13.3.3.1 Module Distribution

IAs and TAs provide the interface to connect the different modules to their associated interconnect.

Table 13-280 through Table 13-285 list all the modules and subsystems with their associated agents. The agents are listed for each L4 interconnect domain.

13.3.3.1.1 L4_PER Interconnect Agents

The L4_PER interconnect handles transfers only to peripherals in the PER power domain. Table 13-280 lists the PER TAs.

Table 13-280. L4 PER TAs

Module Target Name	Description
PER_TA_UART1	UART port 1 module
PER_TA_UART2	UART port 2 module
PER_TA_UART3	UARTport 3 module
PER_TA_UART4	UART port 4 module
PER_TA_GPTIMER2	GPTIMER2 module
PER_TA_GPTIMER3	GPTIMER3 module
PER_TA_GPTIMER4	GPTIMER4 module
PER_TA_GPTIMER9	GPTIMER9 module
PER_TA_GPTIMER10	GPTIMER10 module
PER_TA_GPTIMER11	GPTIMER11 module
PER_TA_DSS	Display subsystem configuration module
PER_TA_GPIO2	General-purpose input/output 2 (GPIO2) module
PER_TA_GPIO3	GPIO3 module
PER_TA_GPIO4	GPIO4 module
PER_TA_GPIO5	GPIO5 module
PER_TA_GPIO6	GPIO6 module
PER_TA_I2C1	I2C1 module
PER_TA_I2C2	Multimaster I2C2 module
PER_TA_I2C3	Multimaster I2C3 module
PER_TA_I2C4	Multimaster I2C4 module
PER_TA_SLIMBUS2	Silmbus 2 module
PER_TA_ELM	Error location module
PER_TA_MCBSP4	McBSP4 module
PER_TA_MCSPI1	McSPI1 module
PER_TA_MCSPI2	MCSP12 module
PER_TA_MCSPI3	MCSP13 module
PER_TA_MCSPI4	MCSP14 module
PER_TA_HSMMC1	MMC controller 1 module
PER_TA_HSMMC2	MMC controller 2 module
PER_TA_HSMMC3	MMC controller 3 module
PER_TA_HSMMC4	MMC controller 4 module
PER_TA_HSMMC5	MMC controller 5 module
PER_TA_HDQ	Single-wire serial link low-rate module

Four ports communicate between the L3 interconnect and the L4_PER interconnect to allow the L3 initiators to access the L4_PER targets. [Table 13-281](#) lists the L4_PER initiator TAs.

For the list of initiators authorized to access the L4 peripheral peripherals, see [Section 13.2.3.2.2, Connectivity Matrix](#).

Table 13-281. L4_PER IAs

Module Initiator Name	Description
PER_IA_0	L3 system direct memory access (sDMA) RD interconnect port
PER_IA_1	L3 sDMA WR interconnect port
PER_IA_2	L3 MPU subsystem interconnect port
PER_IA_3	L3 others interconnect port

13.3.3.1.2 L4_CFG Interconnect Agents

The L4_CFG interconnect handles only transfers to peripherals in the core power domain. [Table 13-282](#) lists the TAs.

Table 13-282. L4_CFG TAs

Module Target Name	Description
CFG_TA_SYSCTRL_GENERAL_CORE	System control general core module
CFG_TA_SYSCTRL_PADCONF_CORE	System control padconf core module
CFG_TA_CM1	Clock manager 1 module
CFG_TA_CM2	Clock manager 1 module
CFG_TA_SDMA	sDMA module
CFG_TA_HSI	HS SSI module
CFG_TA_SAR_ROM	Save-and-restore ROM
CFG_TA_HSUSBOTG	HS USB OTG module
CFG_TA_FSUSBHOST	FS USB OTG module
CFG_TA_HSUSBHOST	HS USB host module
CFG_TA_HSUSBPHY	HS USB PHY module
CFG_TA_HSUSBTLL	USB TTL module
CFG_TA_DSP	DSP subsystem
CFG_TA_SR1	SmartReflex1 module
CFG_TA_SR2	SmartReflex2 module
CFG_TA_SR3	SmartReflex3 module
CFG_TA_MAILBOX	Mailbox module
CFG_TA_SPINLOCK	Spinlock module
CFG_TA_FACEDETECT	Face detect module
CFG_TA_MAFW	Memory Adapter firewall
CFG_TA_EMIFFW	EMIF firewall
CFG_TA_GPMCFW	GPMC firewall
CFG_TA_OCMRAMFW	RAM firewall
CFG_TA_SGXFw	SGX firewall
CFG_TA_ISSFw	ISS firewall
CFG_TA_CORTEXM3FW	Cortex-M3 firewall
CFG_TA_DSSFw	Display subsystem (DSS) firewall
CFG_TA_SL2FW	SL2 firewall
CFG_TA_IVAHDFW	IVA-HD firewall
CFG_TA_EMUSSFw	EMU subsystem firewall
CFG_TA_ABEFW	ABE firewall

Table 13-282. L4_CFG TAs (continued)

Module Target Name	Description
CFG_TA_L4WKUP	L4_WKUP connection

A unique port, CFG_IA_0, communicates between the L3 interconnect and the L4_CFG interconnect to allow the L3 initiators to access the L4_CFG targets (see [Table 13-283](#)).

For the list of initiators authorized to access the L4_CFG peripherals, see [Section 13.2.3.2.2, Connectivity Matrix](#).

Table 13-283. L4_CFG IAs

Module Initiator Name	Description
CFG_IA_0	L3 interconnect port

13.3.3.1.3 L4_WKUP Interconnect Agents

The L4-WKUP interconnect handles transfers only to peripherals in the WKUP power domain. [Table 13-284](#) lists the TAs. [Table 13-285](#) lists the L4 WKUP initiator agents.

Table 13-284. L4_WKUP TAs

Module Target Name	Description
WKUP_TA_GPIO1	GPIO1 module
WKUP_TA_32KTIMER	32-kHz timer module
WKUP_TA_SAR_RAM	Save-and-restore RAM
WKUP_TA_KEYBOARD	Keyboard module
WKUP_TA_SYSCTRL_GENERAL_WKUP	System control general WKUP module
WKUP_TA_SYSCTRL_PADCONF_WKUP	System control padconf WKUP module
WKUP_TA_PRM	Power reset management module
WKUP_TA_SCRM	System clock and reset management module
WKUP_TA_WDTIMER2	WDTIMER2 module
WKUP_TA_GPTIMER1	GPTIMER1 module

Table 13-285. L4_WKUP IAs

Module Initiator Name	Description
WKUP_IA_0	L4_CFG interconnect port

13.3.3.2 Power Management

As part of the system-wide power-management scheme, the L4 interconnects go into IDLE state after receiving a request from the PRCM module after all commands are serviced. This function is handled by hardware. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

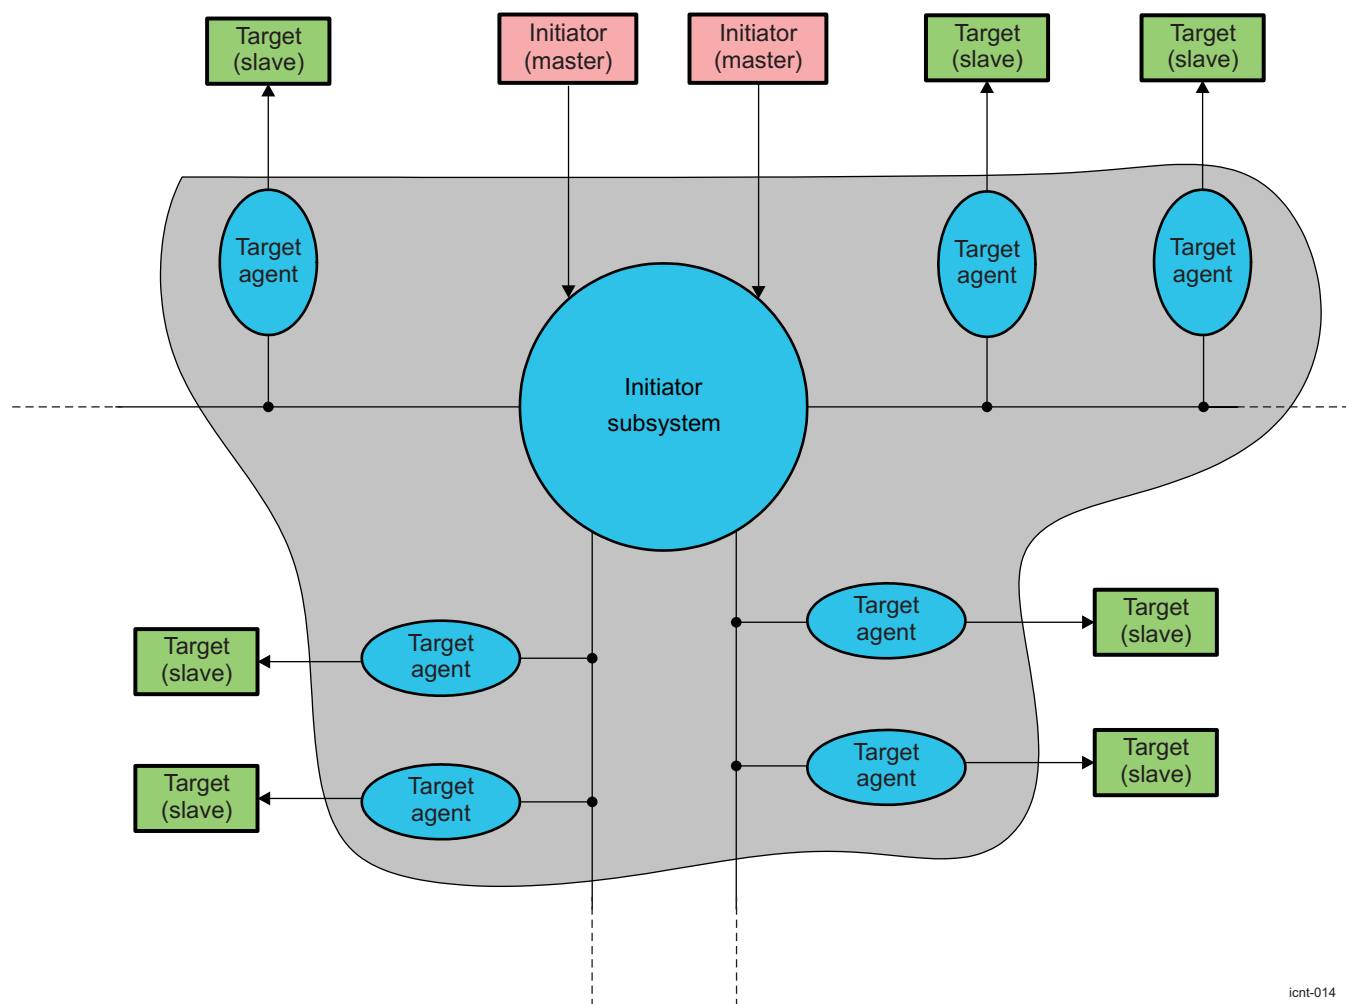

To reduce power consumption, each L4 interconnect automatically performs internal clock autogating. This is managed by hardware; no software configurations or settings are required.

Retention is performed on all software-accessible registers at IAs, TAs, and firewalls. This process prevents reconfiguration after a clock domain switches off. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

13.3.3.3 L4 Firewalls

Figure 13-10 is an internal view of the L4 interconnects in the overall interconnect. This architecture, with one initiator subsystem centralizing all initiator master requests and distributing them to all target modules (peripherals), enables the L4 interconnect firewall functions to be centralized at the L4 initiator subsystem level. The L4 firewall filters the accesses based on the configurable protection groups defined in the L4 address protection (AP) registers. Each module or TA is assigned to a protection group. The configuration is also defined in the L4 AP and is programmable on a module-per-module basis.

Figure 13-10. L4 Initiator-Target Connectivity

icnt-014

NOTE: As Figure 13-10 shows, targets are attached to branches. Branches do not impact the function of the L4 interconnect but are present to simplify timing closure and reduce active power consumption.

Because of the large address spaces and the number of peripherals connected to an L4 interconnect, two parameters are used to set up access permission:

- Programmable groups for initiators
 - Eight protection groups for L4_PER and L4_CFG interconnect
- Segments divided into regions of 4KB
 - 100 regions for the L4_PER interconnect
 - 104 regions for the L4_CFG interconnect

NOTE:

- Regions and segments are present for the L4_WKUP interconnect but cannot be programmed.
- L4_WKUP protection is done through the L4_CFG interconnect.

Protection group members are TAs with the same protection settings. A region is programmed to allow access to a unique selectable protection group. For better protection, different regions are grouped into protection group regions and associated with a protection group member.

All L4 interconnect information, such as numbers of protection groups, regions, and segments, is available in the [L4_LA_INITIATOR_INFO_L](#) register.

13.3.3.3.1 Protection Group

A protection group is defined by its initiators and REQ_INFO is allowed. Two registers define these two settings:

- The CONNID_BIT_VECTOR field [L4_AP_PROT_GROUP_MEMBERS_k_L](#) is a 1-bit vector that defines which initiator belongs to a group. A protection group is accessible by an initiator when the bit position corresponding to its ConnID is set to 1 in the CONNID_BIT_VECTOR field. [Table 13-286](#) lists all the ConnID available at the L4 levels.
- The ENABLE field [L4_AP_PROT_GROUP_ROLES_k_L](#) lists all possible REQ_INFO combinations associated with the [L4_AP_PROT_GROUP_MEMBERS_k_L](#) register. Setting a Req bit in this register determines the initiators type of access. For more information, see [Section 13.2.3.7.3, L3 Firewall Functionality](#). Two REQ_INFOS are used in L4 interconnects: MReqDebug and MReqSupervisor.

NOTE: Permissions are identical for read and write accesses in L4 interconnect.

k indicates the protection group number.

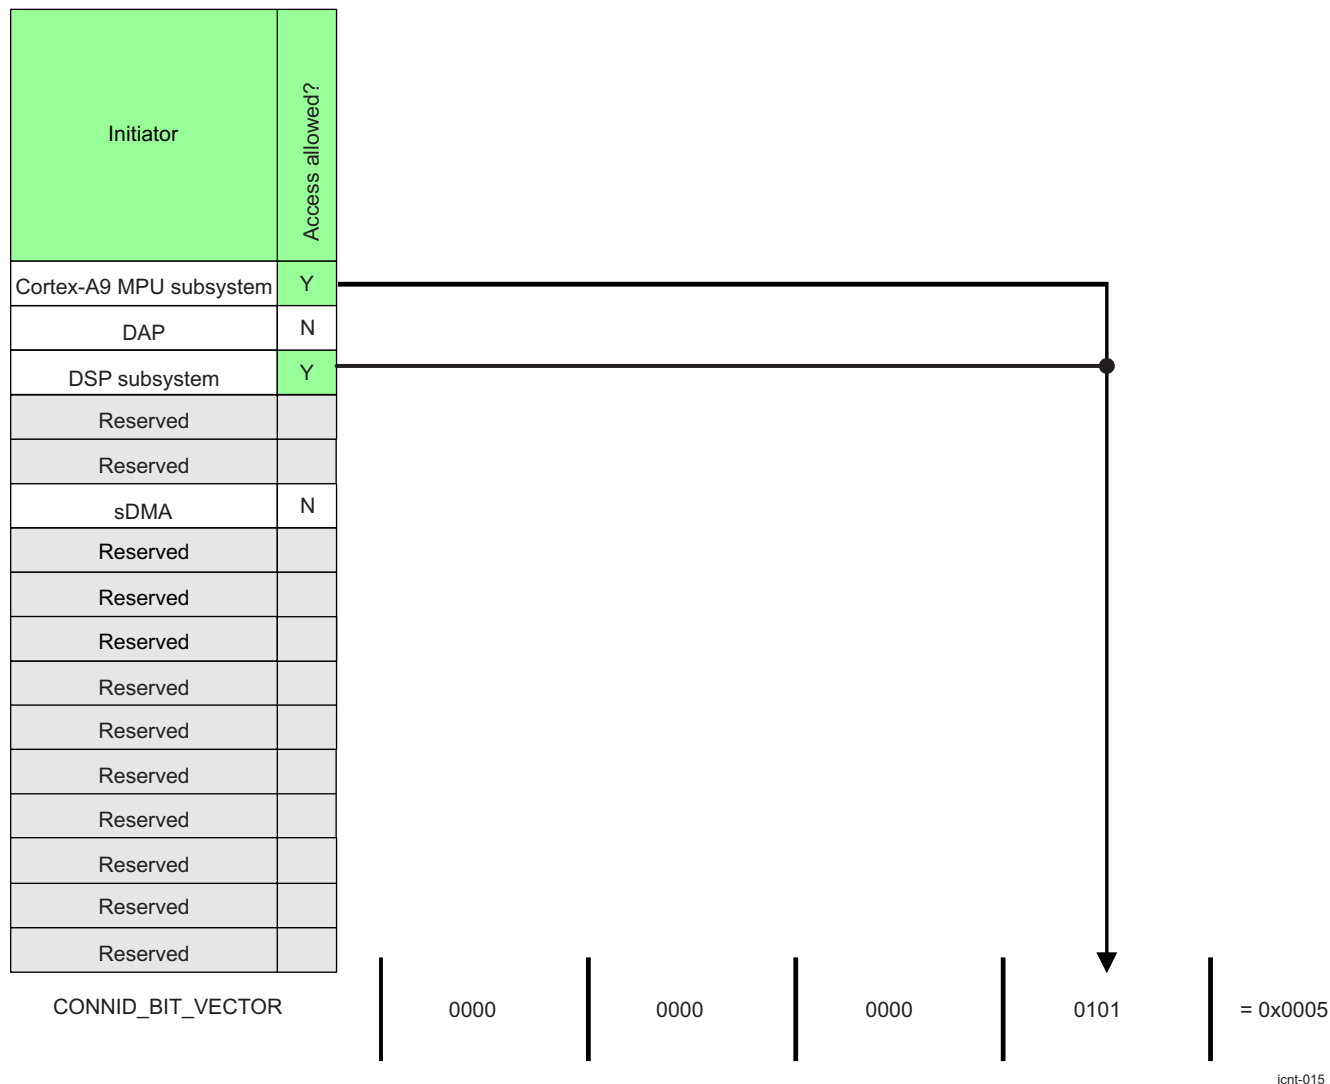

L indicates the region number.

Table 13-286. L4 ConnID Definition

ConnID	Initiator
0	Cortex™-A9 MPU subsystem
1	DAP
2	DSP subsystem
3	Reserved
4	Reserved
5	sDMA
6	Reserved
7	Reserved
8	Reserved
9	Reserved
A	Reserved
B	Reserved
C	Reserved
D	Reserved
E	Reserved
F	Reserved

Figure 13-11 is an example of CONNID_BIT_VECTOR.

Figure 13-11. Example of CONNID_BIT_VECTOR L4_AP_PROT_GROUP_MEMBERS_k

Setting bits 0 and 2 in the PROT_GROUP_ID_1 register defines a group initiator that can access targets in protection group 1, and includes the following:

- Cortex-A9 MPU subsystem
- DSP subsystem

Protection group 1 can be applied to multiple protection regions with no limitation. Each protection region that is configured with protection group 1 enables permission access only to the two initiators.

The L4_AP_REGION_I_H PROT_GROUP_ID field determines the region to which the protection group member is attached.

The values of some CONNID_BIT_VECTOR and ENABLE fields are exported by the SCM at reset or are user writable (see Table 13-409 for more information).

Table 13-287 and Table 13-288 list the default configuration of the various groups for each L4 interconnect. For each group, some modules/regions are associated with it with default initiator members.

Table 13-287. L4_PER Firewall Default Configuration

Group	Default Modules Associated With Group	Register	Modifiability	Default Value
Group 0 AP registers		L4_AP_PROT_GROUP_ROL ES_0_L	No	0xFFFF FFFF (all)
		L4_AP_PROT_GROUP_MEM BERS_0_L	No	0xFFFF (all)

		L4_AP_PROT_GROUP_MEM BERS_7_L	Yes	0xFFFF (all)

13.3.3.2 Segments and Regions

The protection mechanism for L4 interconnects is based on a hierarchical segmentation, as shown in [Figure 13-12](#). By default, some regions are attached to specific protection group members. This specificity lets users set up the permission access to certain types of modules requiring the same access protection without managing region allocation.

Figure 13-12. L4 Segmentation

All interconnect address spaces are covered by regions. Table 13-289 through Table 13-291 list the module mapping with their addresses, region numbers, and default protection group allocated to them.

NOTE: Module refers to the configuration registers of the module.

TA refers to the interconnect configuration registers of the TA associated with the module.

13.3.3.3 L4 Firewall Address and Protection Register Settings

Table 13-292 lists the settings of the AP registers relative to an L4 interconnect firewall. These values are computed based on the physical implementation of each L4 interconnect.

Table 13-292. L4 Firewall Register Description Overview

Register Type	Register Name	Bits	Field	Description
Segment	L4_AP_SEGMENT_i_L ⁽¹⁾	23:0	BASE	Segment base address
	L4_AP_SEGMENT_i_H ⁽¹⁾	4:0	SIZE	Segment size equals to 2 ^{SIZE}
Protection groups	L4_AP_PROT_GROUP_MEMBERS_k_L ⁽²⁾	15:0	CONNID_BIT_VECTOR	For L4ConnID, see Table 13-286 .
	L4_AP_PROT_GROUP_ROLES_k_L ⁽²⁾	31:0	ENABLE	See Section 13.2.3.7.3 for REQ_INFO description ⁽³⁾
Region setting	L4_AP_REGION_l_L ⁽⁴⁾	23:0	BASE	Defines the base address of region with respect to its segment base address
	L4_AP_REGION_l_H ⁽⁴⁾	27:24	SEGMENT_ID	Segment ID number of the region
		22:20	PROT_GROUP_ID	Protection group member attached to the region
		19:17	BYTE_DATA_WIDTH_EXP	Determines the number of byte in an access
		5:1	SIZE	Size of the region equals to 2 ^{SIZE}
	0	ENABLE	Enables the region protection	

⁽¹⁾ i = 0 to 1 for PER_AP
i = 0 to 6 for CFG_AP

⁽²⁾ k = 0 to 7 for PER_AP
k = 0 to 7 for CFG_AP

⁽³⁾ For L interconnects, only MReqDebug and MReqSupervisor are available.

⁽⁴⁾ l = 0 to 96 for PER_AP
l = 0 to 113 for CFG_AP

13.3.3.4 L4 Error Detection and Reporting

13.3.3.4.1 IA and TA Error Detection and Logging

The L4 interconnect provides mechanisms for handling internally detected errors or errors reported by modules attached to the L4 target ports.

NOTE: L4_IA denotes the IA for all L4 interconnects: L4_PER, L4_CFG, and L4_WKUP.

L4_TA denotes the TA for all L4 interconnects: L4_PER, L4_CFG, and L4_WKUP.

The L4 interconnects handle four types of errors:

- No target core found or address hole, detected and logged at IA
- Unsupported command, detected and logged at IA
- Protection violation, detected and logged at IA (see [Section 13.3.3.3](#), *L4 Firewalls*)
- Target does not service a request before a time-out expires. The error is detected and logged at TA (see [Section 13.3.3.4.2](#), *Time-Out*).

[Table 13-293](#) lists the value of the L4_IA_ERROR_LOG_L[25:24] CODE bit field stored when an error occurs.

Table 13-293. L4 CODE Bit Field Definition

CODE (bits 1:0)	Error Type	REQ_INFO	Secondary	ConnID	CMD
0	No error				
1	Unsupported command	x	x	x	x
2	Address hole	x	x	x	x
3	Protection violation	x		x	x

- **No target core found/address hole:** This error indicates that a request was addressed to a hole in the L4 address map. When this error occurs, an in-band error response is returned to the L3 level. The error is also logged into the [L4_IA_AGENT_STATUS_L\[27\] INBAND_ERROR](#) bit. Additionally, an address hole error code is logged to the [L4_IA_ERROR_LOG_L\[25:24\] CODE](#) bit field.
- **Unsupported command:** This error indicates that the command type of the request is not supported by the accessed target register. The error is logged into the [L4_IA_AGENT_STATUS_L\[27\] INBAND_ERROR](#) bit. An unsupported command error code is written to the [L4_IA_ERROR_LOG_L\[25:24\] CODE](#) bit field for the initiator interface.
- **Protection violation:** This error indicates that a request is not issued from an allowed initiator member or is issued with the inappropriate ReqInfo qualifiers associated with the target region. This error is reported using an in-band error and is written to the [L4_IA_AGENT_STATUS_L\[27\] INBAND_ERROR](#) bit. A protection violation error code is saved into the [L4_IA_ERROR_LOG_L\[25:24\] CODE](#) bit field for the same initiator interface. A protection violation is also logged in the [L4_IA_AGENT_STATUS_L\[31\] PROT_ERROR_SECONDARY](#) or [\[30\] PROT_ERROR_PRIMARY](#) bit when in debug or applicative mode, respectively.

The [L4_IA_ERROR_LOG_L\[30\] SECONDARY](#) bit indicates whether the error occurred in application or debug.

The [L4_IA_ERROR_LOG_H\[15:0\] REQ_INFO](#) bit field returns the type access (REQ_INFO qualifier) that caused the error.

The [L4_IA_ERROR_LOG_L\[11:8\] CONNID](#) bit field returns the ID of the initiator that caused the error.

The [L4_IA_ERROR_LOG_ADDR_L\[31:0\]](#) register logs the address for error conditions.

A [L4_IA_ERROR_LOG_L\[31\] MULTI](#) bit is asserted when multiple errors are detected. In this case, the error code corresponds to the first error that occurs.

13.3.3.4.2 Time-Out

A time-out mechanism can be enabled at the interconnect level and on a per-target basis. If the mechanism is enabled for a TA and interconnect and commands are not accepted or responses are not returned within the expected delay, the L4 interconnect generates an error event.

NOTE: The time-out mechanism is not available on the L4_WKUP interconnect, but L4_WKUP timeouts are detected in CFG_TA_L4WKUP of the L4_CFG interconnect.

The error is logged in the [L4_TA_AGENT_STATUS_L\[8\] REQ_TIMEOUT](#) bit. The affected TA enters an error state that causes it to send an error response to any new request targeted at it. To recover from this state, the TA must be reset by the system software. The time-out is counted starting from the moment a command is presented to the target, regardless of the target response to this command.

The L4 interconnect implements a centralized time-base circuit that broadcasts a set of four periodic pulse signals to all connected TAs. The time-base circuit offers four possible sets of four time-base signals. Selection is done by programming the [L4_LA_NETWORK_CONTROL_L\[10:8\] TIMEOUT_BASE](#) bit field.

The selected time-base signals are available at any TA. Each TA can be programmed to refer to one of these four time-base signals, using the [L4_TA_AGENT_CONTROL_L\[10:8\] REQ_TIMEOUT](#) bit field. These four signals are referred to as 1X time-base, 4X time-base, 16X time-base, and 64X time-base.

[Table 13-294](#) lists all values in number of L4 clock cycles.

Table 13-294. L4 Time-Out Link and TA Programming

L4_TA_AGENT_CONTROL_L REQ_TIMEOUT[2:0]					
L4_LA_NETWORK_CONTROL_L TIMEOUT_BASE[2:0]	0	1	2	3	4
0	All L4 time-out features are disabled.				

Table 13-294. L4 Time-Out Link and TA Programming (continued)

		L4_TA_AGENT_CONTROL_L REQ_TIMEOUT[2:0]			
L4_LA_NETWORK_CONTROL_L TIMEOUT_BASE[2:0]	0	1	2	3	4
1	Locally disabled	64	256	1024	4096
2		256	1024	4096	16,384
3		1024	4096	16,384	65,536
4		4096	16,384	65,536	262,144

The default reset value is 0x2 for REQ_TIMEOUT and 0x4 for TIMEOUT_BASE, implying 16,384 clock cycles.

A time-out condition is detected when the command acceptance or the response is not received after a delay of from one to three time-base periods.

Example:

- L4 frequency = 65 MHz
- TIMEOUT_BASE = 4 in the [L4_LA_NETWORK_CONTROL_L](#) register
- REQ_TIMEOUT = 2 in the [L4_TA_AGENT_CONTROL_L](#) for TA A
- REQ_TIMEOUT = 4 in the [L4_TA_AGENT_CONTROL_L](#) for TA B

At agent A, the time-base unit is 16,384 cycles. A time-out is issued when a request to the attached module is not accepted, or no response is sent after a delay of 252 μ s to 756 μ s.

At agent B, the time-base unit is 262,144 cycles. A time-out is issued when a request to the attached module is not accepted or no response is sent after a delay of 4 ms to 12 ms.

On detection of a time-out condition, the TA logs the error in the [L4_TA_AGENT_STATUS_L\[8\]](#) REQ_TIMEOUT bit, and it also reports the error to the IA, which forward it to the L3 interconnects.

After the time-out is detected and logged, the behavior of the attached module is ignored. A new request targeting the module arriving at the timed-out TA receives an error response. If the request is addressed to the agent internal registers, it is processed normally.

To recover from a time-out error, software is assumed to first reset the faulty module and then the TA using the [L4_TA_AGENT_CONTROL_L\[0\]](#) OCP_RESET bit.

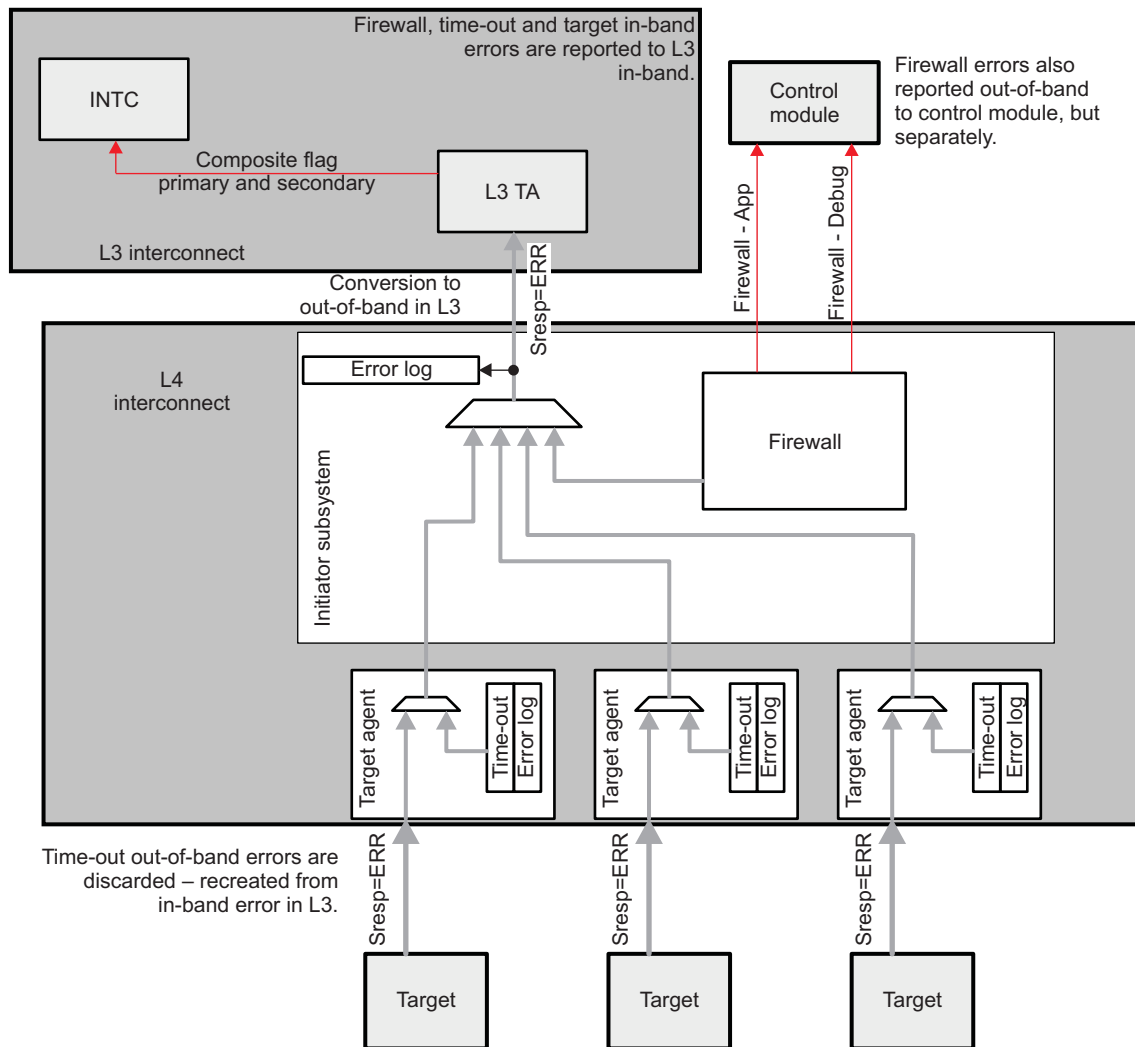

13.3.3.4.3 Error Reporting

[Figure 13-13](#) shows the error-reporting scheme used in the L4 interconnects. All L4 in-band errors are reported to their respective L3 TA, where errors are converted in an out-of band error signal (the L3 applicative and debug composite flags) going to the L3 Interrupt controllers.

Two levels of mask are present to report the error at INTC level:

- At the applicative and debug composite flag, to enable interrupt reporting, the following bits must be set:
 - L4 CFG in [L3_CLK1_FLAG_MASK_0\[3\]](#) and [L3_CLK1_FLAG_STATUS_1\[3\]](#)
 - L4 PER in [L3_CLK2_FLAG_MASK_0\[17\]\[16\]\[15\]\[6\]](#) and [L3_CLK2_FLAG_STATUS_1\[17\]\[16\]\[15\]\[6\]](#)
- At the L3 TA level, see [Section 13.2, L3 Interconnect](#).

Figure 13-13. L4 Error Reporting

icnt-017

13.3.3.4.4 Error Recovery

Writing 1 to the `L4_TA_AGENT_CONTROL_L[0] OCP_RESET` bit initiates the software reset period. Software reset must be asserted for at least 16 cycles of the target module interface clock, which can be a divided clock with respect to the L4 clock.

During the software reset period:

- Requests sent to the target module receive error responses. Therefore, if the faulty request is part of a DMA transfer, it is necessary to stop the DMA to prevent unwanted errors.
- Requests sent to the TA register block are processed as usual.
- The `L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT` status bit is cleared.

Writing 0 to the `L4_TA_AGENT_CONTROL_L[0] OCP_RESET` bit terminates the software reset period.

The attached module must then be reset to complete the recovery.

13.3.3.4.5 Firewall Error Logging in the Control Module

When a protection violation occurs, an interrupt is sent to the INTCs (if enabled). An in-band error is sent back to L3 IA and an out-band error can also be logged in the CONTROL.CONTROL_SEC_ERR_STATUS register in the system control module (SCM). These out-band errors are enabled/disabled at the L4 IA level by setting the L4_IA_AGENT_CONTROL_L[31][30] PROT_ERROR_SECONDARY_REP or PROT_ERROR_PRIMARY_REP bit to 1 for debug and application mode, respectively.

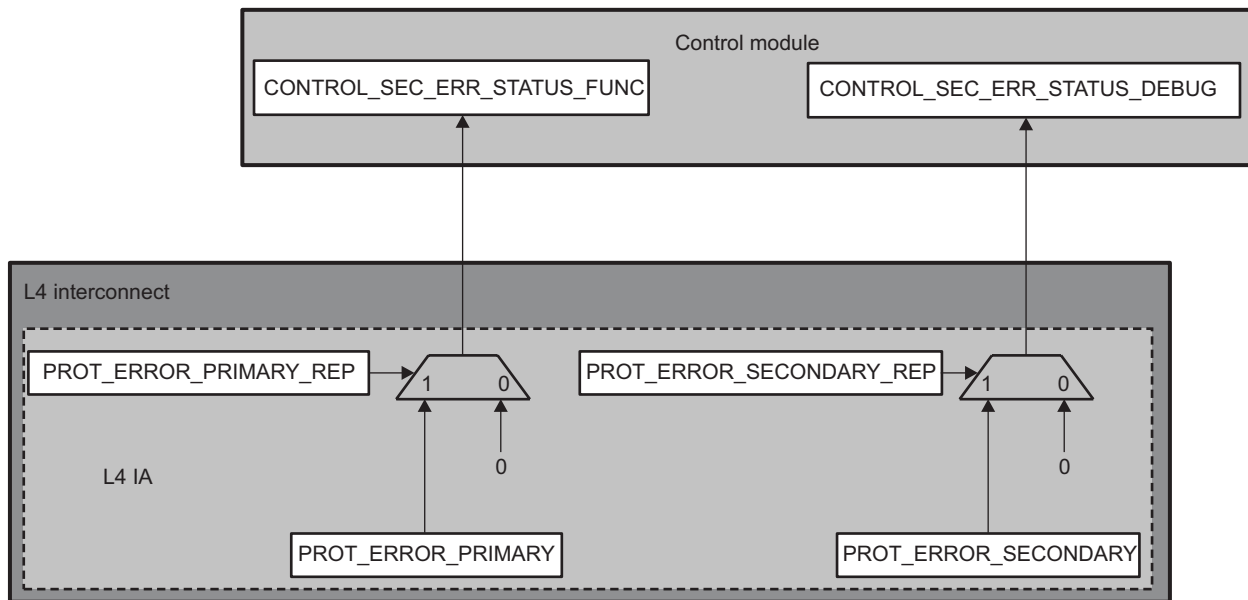

At the control module level, two logging registers are used, depending on the mode:

- In application mode or primary error reporting:
 - CONTROL.CONTROL_SEC_ERR_STATUS_FUNC[16] = L4_CFG protection violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_FUNC[17] = L4_PER protection violation
- In debug mode or secondary error reporting:
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG[16] = L4_CFG protection violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG[17] = L4_PER protection violation

NOTE: The CONTROL.CONTROL_SEC_ERR_STATUS_XXX registers are only readable.

Figure 13-14 shows the global protection error reporting to at the control module.

Figure 13-14. Protection Violation Out-of-Band Error Reporting

13.3.4 L4 Interconnect Programming Guide

13.3.4.1 L4 Interconnect Low-level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the L4 interconnect module.

13.3.4.1.1 Global Initialization

13.3.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the L4 interconnect module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the L4 interconnect. For more information, see [Section 13.3.2, L4 Interconnect Integration](#).

Table 13-295. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	For more information about the configuration of the module, see Chapter 3, Power, Reset, and Clock Management .
Control module	For more information about the configuration of the module, see Chapter 18, Control Module .
MPU INTC	The MPU INTC must be configured to enable the interrupts from L4 interconnect module. See Chapter 17 Interrupt Controllers .
sDMA	For more information about the configuration of the sDMA, see Chapter 16, sDMA .
L3 interconnect	For more information about the interconnect configuration, see Chapter 13, Interconnect .

13.3.4.1.2 Operational Modes Configuration

13.3.4.1.2.1 L4 Interconnect Error Analysis Mode

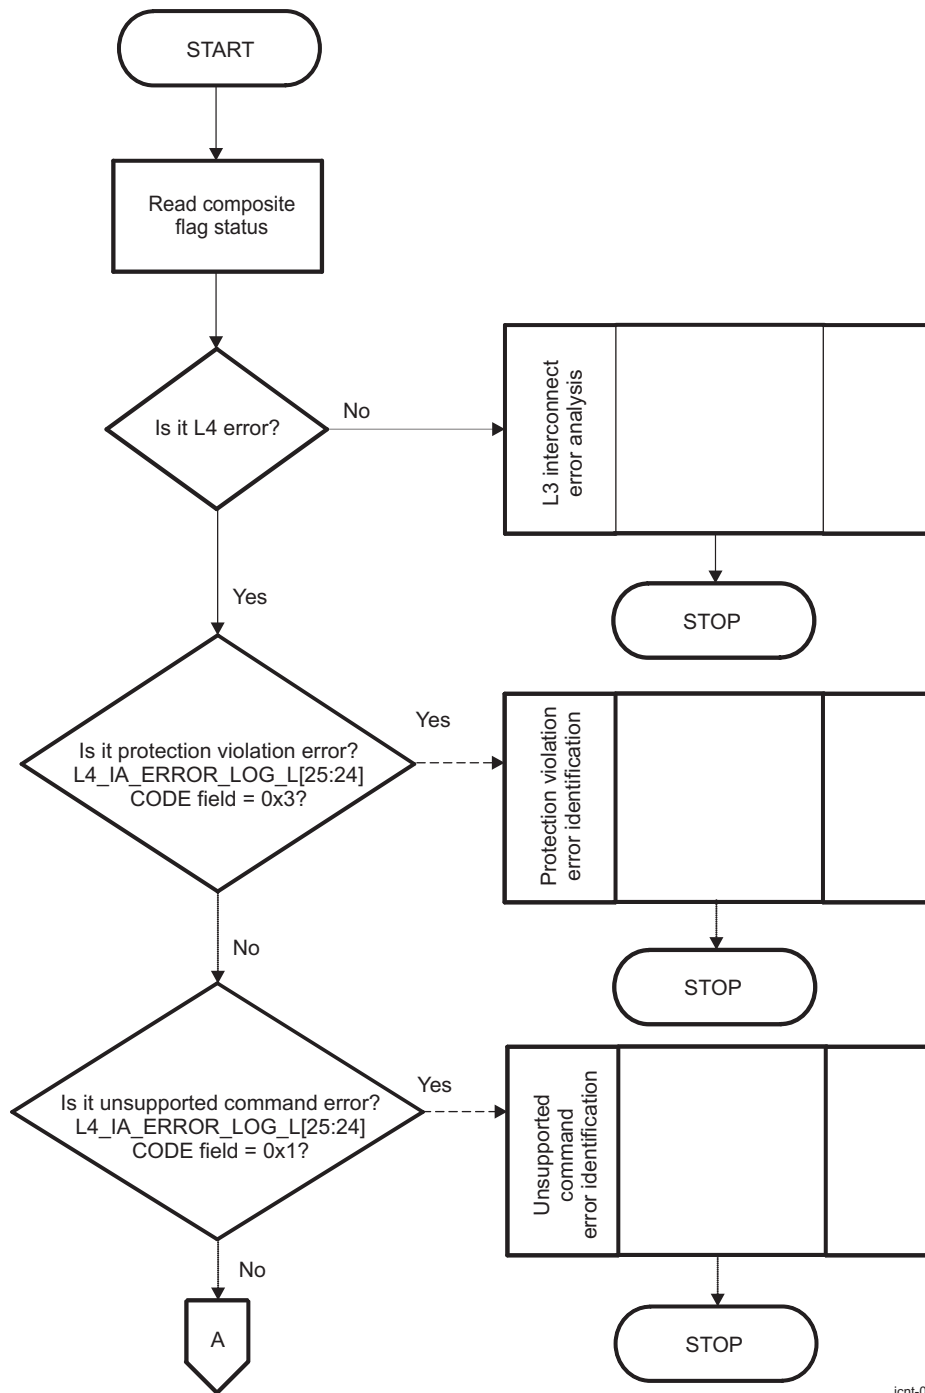

13.3.4.1.2.1.1 Main Sequence: L4 Interconnect Error Analysis Mode

The information required to analyze an error source is logged in several registers. The number of registers to access depends on the error source.

[Figure 13-15](#) and [Figure 13-16](#) show the software sequence required in most cases.

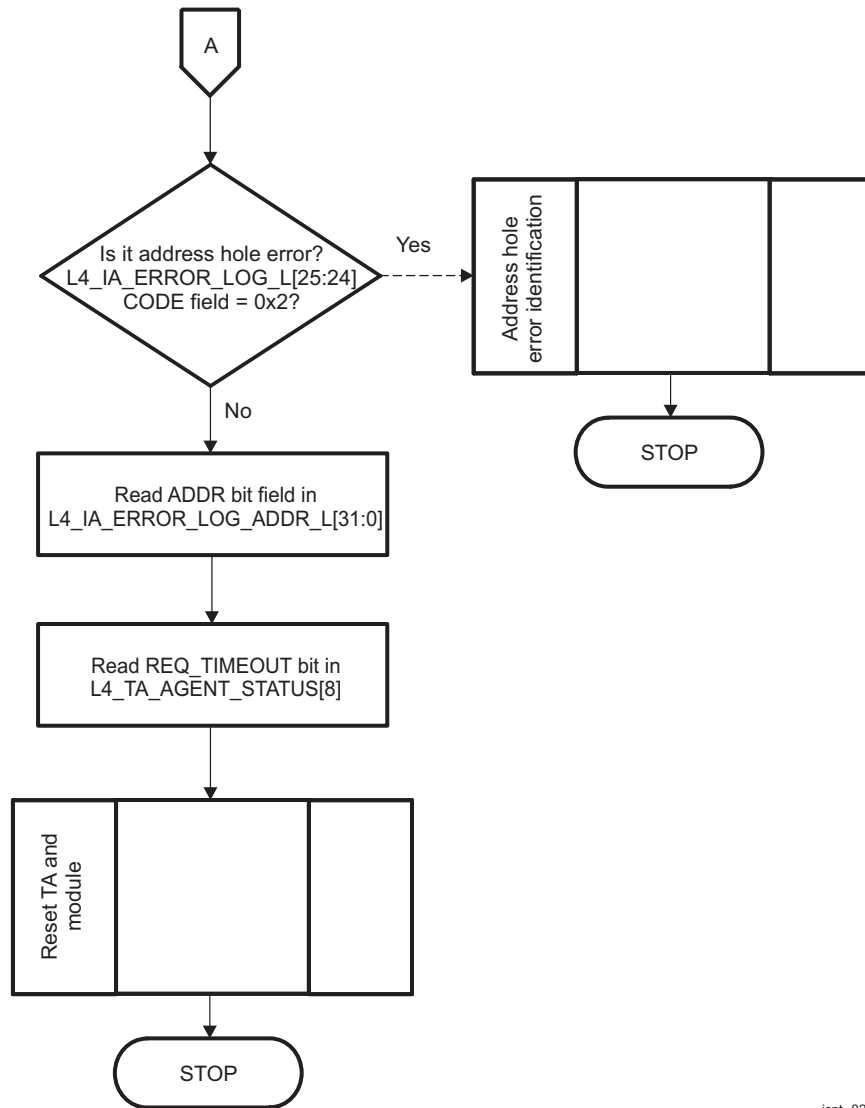

[Table 13-296](#) and [Table 13-297](#) show the main sequence for error analysis mode and its subprocess call summary, respectively.

Figure 13-15. Typical Error Analysis Sequence

icnt-019

Figure 13-16. Typical Error Analysis Sequence

Table 13-297. Subprocess Call Summary for Main Sequence – Error Analysis Mode

Subprocess	Cross-Reference
L3 interconnect error analysis	Section 13.2.3.8, L3 Interconnect Error Handling
L4 interconnect protection violation error identification	Section 13.3.4.1.2.1.2, Subsequence: L4 Interconnect Protection Violation Error Identification
L4 interconnect unsupported command/address hole error identification	Section 13.3.4.1.2.1.3, Subsequence: L4 Interconnect Unsupported Command/Address Hole Error Identification
L4 interconnect reset TA and module	Section 13.3.4.1.2.1.4, Subsequence: L4 Interconnect Reset TA and Module

13.3.4.1.2.1.2 Subsequence: L4 Interconnect Protection Violation Error Identification

This procedure describes the protection violation error identification (see [Table 13-298](#)).

Table 13-298. Protection Violation Error Identification

Step	Register/Bit Field/Programming Model	Value
Read multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	
Read initiator ID.	L4_IA_ERROR_LOG_L[11:8] CONNID	
Read command that cause the error.	L4_IA_ERROR_LOG_L[2:0] CMD	
Read address of request that caused the error.	L4_IA_ERROR_LOG_ADDR_L[31:0] ADDR	
IF: Is it a primary error?	L4_IA_AGENT_STATUS_L[30] PROT_ERROR_PRIMARY	=0x1
Read status bits.	CONTROL.CONTROL_SEC_ERR_STATUS_FUNC[17:16]	
Write 1 to clear status bits.	CONTROL.CONTROL_SEC_ERR_STATUS_FUNC[17:16]	0x3
Write 1 to clear IA status bit.	L4_IA_AGENT_STATUS_L[30] PROT_ERROR_PRIMARY	0x1
ELSE		
Read status bits.	CONTROL.CONTROL_SEC_ERR_STATUS_DEB_UG[17:16]	
Write 1 to clear status bits.	CONTROL.CONTROL_SEC_ERR_STATUS_DEB_UG[17:16]	0x3
Write 1 to clear IA status bit	L4_IA_AGENT_STATUS_L[31] PROT_ERROR_SECONDARY	0x1
ENDIF		
Write 1 to clear multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	0x1
Write 1 to clear in-band error status.	L4_IA_AGENT_STATUS_L[24] INBAND_ERROR	0x1

13.3.4.1.2.1.3 Subsequence: L4 Interconnect Unsupported Command/Address Hole Error Identification

This procedure describes the identification of unsupported command/address hole error (see [Table 13-299](#)).

Table 13-299. Unsupported Command/Address Hole Error Identification

Step	Register/Bit Field/Programming Model	Value
Read multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	
Read initiator ID.	L4_IA_ERROR_LOG_L[11:8] CONNID	
Read command that caused the error.	L4_IA_ERROR_LOG_L[2:0] CMD	
Read address of request that caused the error.	L4_IA_ERROR_LOG_ADDR_L[31:0] ADDR	
Read secondary status.	L4_IA_ERROR_LOG_L[30] SECONDARY	
Write 1 to clear secondary status.	L4_IA_ERROR_LOG_L[30] SECONDARY	0x1
Write 1 to clear multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	0x1
Write 1 to clear inband error status.	L4_IA_AGENT_STATUS_L[24] INBAND_ERROR	0x1

13.3.4.1.2.1.4 Subsequence: L4 Interconnect Reset TA and Module

This procedure resets the TA and module (see [Table 13-300](#)).

Table 13-300. Reset TA and Module

Step	Register/Bit Field/Programming Model	Value
Reset TA.	L4_TA_AGENT_CONTROL_L[0] OCP_RESET	0x1
Wait until target module clock = 16 cycles.		

Table 13-300. Reset TA and Module (continued)

Step	Register/Bit Field/Programming Model	Value
Write 0 to clear TA time - out status.	L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT	0x0
Write 0 to clear TA reset.	L4_TA_AGENT_CONTROL_L[0] OCP_RESET	0x0
Reset the attached module. ⁽¹⁾		

⁽¹⁾ For more information, see the respective module chapter.

13.3.4.1.2.2 L4 Interconnect Time-Out Configuration Mode

13.3.4.1.2.2.1 Main Sequence: L4 Interconnect Time-Out Configuration Mode

This procedure describes the time-out configuration sequence (see [Table 13-301](#)).

Table 13-301. Time-Out Configuration

Step	Register/Bit Field/Programming Model	Value
Disable time-out.	L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE	0x0
Clear TA time-out error status. ⁽¹⁾	L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT	0x1
Set time-out at TA level. ⁽¹⁾	L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT	xxx
Set time-out base.	L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE	xxx

⁽¹⁾ Must be done for each TA.

13.3.4.1.2.3 L4 Interconnect Firewall Configuration Mode

13.3.4.1.2.3.1 Main Sequence: L4 Interconnect Firewall Configuration Mode

This procedure describes the firewall configuration sequence (see [Table 13-302](#)).

Table 13-302. Firewall Configuration

Step	Register/Bit Field/Programming Model	Value
Define the members of protection group k. ⁽¹⁾	L4_AP_PROT_GROUP_MEMBERS_k_L[15:0] CONNID_BIT_VECTOR	xxx
Define the access type of a protection group k. ⁽¹⁾	L4_AP_PROT_GROUP_ROLES_k_L[15:0] ENABLE	xx
Set region affiliation to protection group. ⁽²⁾	L4_AP_REGION_I_L[22:20] PROT_GROUP_ID	xxx

⁽¹⁾ Must be done for each protection group.

⁽²⁾ Must be done for each region.

13.3.5 L4 Interconnects Register Manual

Table 13-303 through Table 13-305 list all L4 register blocks for IA, TA, AP, and LA. Each module instance is shown with the module register mapping and bit and bit field definitions.

Table 13-370. L4_TA_AGENT_CONTROL_L

Address Offset	0x0000 0020
Physical Address	See Table 13-331 to Table 13-343.
Description	Enable error reporting
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								SERROR_REP	RESERVED														REQ_TIMEOUT	RESERVED						OCP_RESET	

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Read returns 0.	R	0x00
24	SERROR_REP	Enable logging of error	R	0x0
23:11	RESERVED	Read returns 0.	UNDEFI NED_TY PE_STRI NG	
10:8	REQ_TIMEOUT	Time-out Bound. Values are: 0 - No time-out 1 - 1x base cycles. 2 - 4x base cycles. 3 - 16x base cycles. 4 - 64x base cycles.	RW	0x2
7:1	RESERVED	Read returns 0.	R	0x00
0	OCP_RESET	The OCP_RESET field controls the OCP reset signal to the attached core. Setting this bit clears any pending transfers and resets the OCP interface. The bit must be cleared to deassert the OCP reset signal. When the software reset feature is available on a target agent, the target agent OCP must also have a reset signal directed to the target core.	RW	0

Table 13-395. L4_LA_NETWORK_CONTROL_H

Address Offset	0x0000 0024
Physical Address	0x4800 0824 0x4A00 0824 0x4A30 0824
Description	Control interconnect global power control
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								CLOCK_GATE_DISABLE	RESERVED		THREAD0_PRI	RESERVED								EXT_CLOCK	RESERVED										

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Read returns 0.	R	0x00
24	CLOCK_GATE_DISABLE	When set to 1 this field disables all clock gating.	RW	0
23:21	RESERVED	Read returns 0.	R	0x0
20	THREAD0_PRI	Sets thread priority. If the field is set to 0, the default, all initiator threads are treated the same. Setting the THREAD0_PRI field to 1 assigns a higher arbitration priority to thread 0 of the first initiator OCP interface. To avoid starvation, arbitration is imposed by the initiator subsystem. When multiple requests from different initiator threads are dispatched to targets simultaneously, the oldest request is dispatched first. If thread 0 is assigned a higher priority, a request on thread 0 always wins arbitration. Assigning thread 0 of the first initiator OCP the highest priority on a request or response can result in the starvation of other threads.	R	1
19:9	RESERVED	Read returns 0.	R	0x000
8	EXT_CLOCK	When set to 1, the ext_clk_off_i signal on the initiator subsystem instructs the entire L4 to shut off.	R	1

Bits	Field Name	Description	Type	Reset
7:0	RESERVED	Read returns 0.	R	0x00

Table 13-419. L4_AP_REGION_I_H

Address Offset	0x304 + (0x08*)	Index	I = 0 to 99 for CORE_AP
Physical address	0x4800 0304 + (0x08*) 0x4A00 0304 + (0x08*)		
Description	Define the size, protection group and segment ID of the region		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								Reserved	PROT_GROUP_ID				BYTE_DATA_WIDTH_EXP				Reserved								SIZE				ENABLE		

Bits	Field Name	Description	Type	Reset
31:28	Reserved	Read returns 0	R	0x0
27:24	SEGMENT_ID	The segment associated to the region.	R	See Table 13-421 and Table 13-422 .

Bits	Field Name	Description	Type	Reset
23	Reserved	Read returns 0.	R	0
22:20	PROT_GROUP_ID	The protection group associated to the region.	RW	See Table 13-421 and Table 13-422 .
19:17	BYTE_DATA_WIDTH_EXP	The target data byte width is $2^{(\text{BYTE_DATA_WIDTH_EXP})}$ bytes.	R	See Table 13-421 and Table 13-422 .
16:6	Reserved	Read returns 0.	R	0x0
5:1	SIZE	Define the size of the region in bytes. 2^{SIZE} equals the region.	R	See Table 13-421 and Table 13-422 .
0	ENABLE	0x0: Disable the region, no access allows 0x1: Enable the region, with access as define in registers	R	0x1

Memory Subsystem

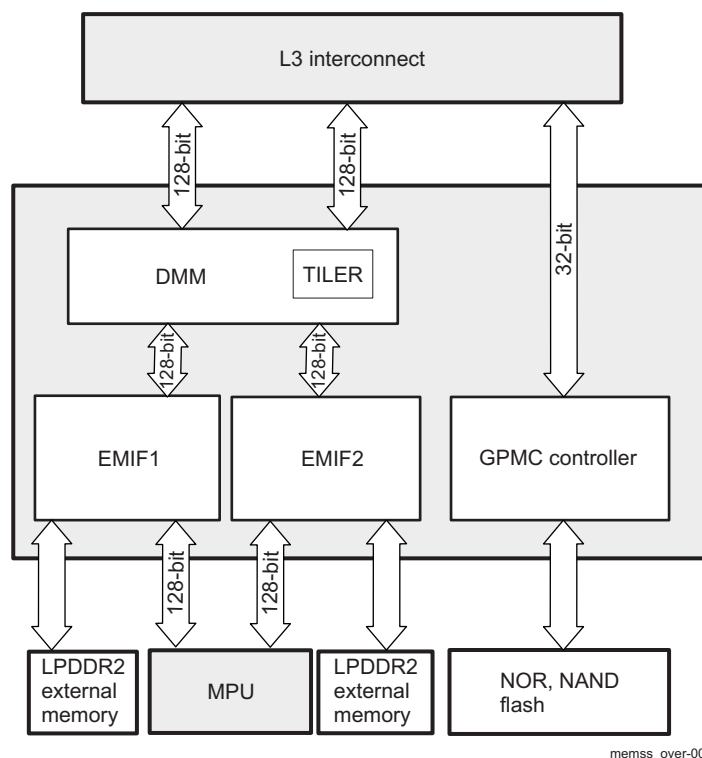

This chapter introduces the memory subsystem of the device.

Topic	Page
15.1 Memory Subsystem Overview	3252
15.2 Dynamic Memory Manager	3257
15.3 EMIF Controller.....	3338
15.4 General-Purpose Memory Controller	3410
15.5 Error Location Module.....	3550
15.6 On-Chip Memory (OCM) Subsystem	3577

15.1 Memory Subsystem Overview

Figure 15-1 shows a functional diagram of all memory subsystems in the device.

Figure 15-1. Memory Subsystem Functional Diagram

15.1.1 DMM Overview

The dynamic memory manager (DMM) module is typically located immediately in front of the synchronous dynamic random access memory (SDRAM) controller (SDRC), as shown in Figure 15-1.

In a broad sense, the DMM manages various aspects of memory accesses such as:

- Initiator-indexed priority generation
- Multizone SDRAM interleaving configuration
- Block object transfer optimization – tiling
- Centralized low-latency page translation – MMU-like feature

The dynamic qualifier for memory management highlights the software configurability, and hence the runtime nature, of the four aspects of memory management handled by the DMM.

15.1.1.1 DMM Features

From a functional perspective, the role of the DMM is to:

- Add initiator-based priority to any incoming requests
- Perform to/from tiling conversions of tiled requests
- Make on-the-fly basic transforms, such as quadrant rotations and mirroring
- Optionally, provide a low-latency page-based translation to handle memory fragmentation – MMU
- Distribute the traffic on all attached memory controllers according to the interleaving configuration

The main features of the DMM are:

- Programmable multizone DRAM mapping and interleaving configuration
- Programmable initiator-based request priority extension

- Multichannel memory transfer optimization
- Single SDRAM page request generation
- Low-latency interconnect port
- Page-grained address translation to manage memory fragmentation
- Automatic synchronized reloading of the address translation table

15.1.2 TILER Overview

The tiling and isometric lightweight engine for rotation (TILER) is a submodule of the DMM (see [Figure 15-1](#)) and is therefore described in [Section 15.2, Dynamic Memory Manager](#).

The TILER is intended to improve bidimensional (tiled) block transfer efficiency. It is, therefore, a module aimed at:

- Primarily, efficient handling of 2-dimension (2D) data mapped in tiles, such as video or graphics macroblocks
- Optionally, managing the memory fragmentation and zero-copy physical frame-buffer swapping through a page-grained translation
- Making isometric (distance preserving) transforms, such as 90-, 180-, or 270-degree rotations, with a horizontal or vertical reflection

The lightweight qualifier of this engine highlights its limited support of isometric transforms, as:

- Rotation performs only basic quadrant rotations by some multiple of 90 degrees.
- Reflection is limited to horizontal and vertical flip.
- Translation is restricted to a 4-KB page granularity.

Written differently, the functionality of the TILER is to map a 2D virtually addressed interconnect request into one or more physically addressed interconnect requests by:

- Transforming the virtual address, data, and byte-enable to match the requested 0-, 90-, 180-, or 270-degree orientation in a tiled 2D addressing space
- Optionally, translating the oriented tiled address by a page-specific vector to manage memory fragmentation and physical object aliasing

15.1.2.1 TILER Features

The main features of the TILER are:

- Efficiency improvement of 2D block access on SDRAMs
- Optimized interlaced access on tiled frames
- 2D virtual-to-physical address translation of SDRAM bidimensional objects to handle rotation
- Page-grained address translation to manage memory fragmentation and physical buffer aliasing
- Unlimited number of 2D tiled objects supported in any (0, 90, 180, or 270 degrees) orientation
- Full bandwidth use by minimizing the size of raster-based initiator buffers
- Optimization of multichannel memory transfers
- Interconnect request granularity balance (in X and Y directions)

15.1.3 EMIF Overview

The extended memory interface (EMIF) module is typically located near the DMM module, as shown in [Figure 15-1](#).

The EMIF provides connectivity between the device and LPDDR2-type memory. It manages data bus read/write accesses between external memories, the microprocessor unit (MPU), and the direct memory access (DMA) controller. It acts as the primary interface between SDRAM and all functional blocks, such as the ARM®, IVA-HD, imaging subsystem (ISS), GFX, and DMA controllers.

15.1.3.1 Main Features

The EMIF has the following capabilities:

- Supports JEDEC standard-compliant LPDDR2-SDRAM (S2 and S4) devices
- 2-GB SDRAM address range over two chip selects (CSs) (configurable with the DMM; see [Section 15.2, Dynamic Memory Manager](#), for more information)
- Supports two independent CSs, with their corresponding register sets, and independent page tracking
- Both CSs must have the same memory type and size.
- Flexible address muxing scheme that permits choosing different bank-mapping allocation by configuring the bank, column, and row-address decoding ordering
- 16- or 32-bit data path to external SDRAM
- Supports LPDDR2 devices with 1, 2, 4, or 8 internal banks
- Supports the following data bus widths:
 - 128-bit level 3 (L3) interconnect data bus width
 - 16- and 32-bit SDRAM data bus width
- Supports the following CAS latencies: 3, 4, 5, 6, 7, and 8
- Supports 256-, 512-, 1024-, and 2048-word page sizes
- Supports the following burst lengths: 8
- Supports sequential burst type
- SDRAM auto-initialization from reset or configuration change
- Supports bank interleaving across both CSs if same memory type
- Supports self-refresh and precharge power-down modes for low power (per CS, manual entry/exit self-refresh, and deep power-down modes)
- Supports deep power-down mode for low power
- Supports partial array self-refresh and temperature-controlled self-refresh modes for low power. Temperature-controlled self-refresh is supported only for mobile SDRAM having an on-chip temperature sensor.
- Supports prioritized refresh
- Programmable SDRAM refresh rate and backlog counter
- Supports ZQ calibration
- Supports temperature monitoring

15.1.4 GPMC Overview

The general-purpose memory controller (GPMC) is a unified memory controller dedicated to interfacing external memory devices:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (available only in nonmuxed mode) burst NOR flash devices
- NAND flash
- Pseudo-SRAM devices

15.1.4.1 GPMC Features

The GPMC is the external memory controller of the device. The GPMC data access engine provides a flexible programming model for communication with all standard memories. The GPMC supports various accesses:

- Asynchronous read/write access
- Asynchronous read page access (4, 8, and 16 Word16)
- Synchronous read/write access
- Synchronous read/write burst access without wrap capability (4, 8, and 16 Word16)

- Synchronous read/write burst access with wrap capability (4, 8, and 16 Word16)
- Address/data-multiplexed access
- Little- and big-endian access

The GPMC can communicate with a wide range of external devices:

- External asynchronous or synchronous 8-bit wide memory or device (nonburst device)
- External asynchronous or synchronous 16-bit wide memory or device
- External 16-bit nonmultiplexed device with limited address range (2KB)
- External 16-bit address/data-multiplexed NOR flash device
- External 8-bit and 16-bit NAND flash device
- External 16-bit pseudo-SRAM (pSRAM) device

The main features of the GPMC are:

- 8- or 16-bit-wide data path to external memory device
- Supports up to eight CS regions of programmable size and programmable base addresses in a total address space of 1GB
- Supports transactions controlled by a firewall
- On-the-fly error code detection using the Bose-Chaudhuri-Hocquenghem (BCH) ($t = 4, 8, \text{ or } 16$) or Hamming code to improve the reliability of NAND with a minimum effect on software (NAND flash with 512-byte page size or greater)
- Fully pipelined operation for optimal memory bandwidth use
- External device clock provided from the L3 clock divided by 1, 2, 3, or 4
- Supports programmable autclock gating when no access is detected
- Independent and programmable control signal timing parameters for setup and hold time on a per-chip basis. Parameters are set according to the memory device timing parameters, with a timing granularity of one L3 clock cycle.
- Flexible internal access time control (WAIT state) and flexible handshake mode using external WAIT pin monitoring
- Support bus keeping
- Support bus turnaround
- Prefetch and write posting engine associated with system DMA (sDMA) to achieve full performance from the AND device with minimum effect on NOR/SRAM concurrent access

NOTE: Page mode is available only in nonmultiplexed mode.

15.1.5 ELM Overview

NAND flash memories are dense and nonvolatile, but error-prone. Whenever NAND flash memories are read from, some level of error correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as bare NAND, the correction process is delegated to the memory controller.

The error location module (ELM) must be used in conjunction with the GPMC. The GPMC probes data read from an external NAND flash and uses them to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare area data field, with a maximum block size of 1023 bytes. Computation is based on the BCH algorithm. The ELM extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a configuration parameter. Error correction levels of 4, 8, and 16 bits are supported. The ELM relies on a static definition of the generator polynomial for each error correction level that corresponds to the generator polynomials defined in the GPMC. A larger number of errors can be detected, but the ELM cannot correct them all. The offending block is then tagged as uncorrectable.

When the error location process completes, an interrupt is triggered to inform a central processing unit (CPU) that its status can be checked. The error locations for the NAND page can be retrieved from the module through register accesses.

15.1.5.1 ELM Features

The ELM features:

- 4, 8, and 16 bits per 512-byte block error location based on BCH algorithm
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation when error location process completes:
 - When the full page has been processed in page mode
 - For each syndrome polynomial in continuous mode

15.1.6 OCM Overview

The on-chip memory (OCM) subsystem consists of the following OCM controllers: one connected to an on-chip ROM (SAR ROM), one connected to an on-chip RAM (SAR RAM), and one connected to an on-chip SRAM (L3 SRAM). Each memory controller has its own dedicated interface to the L3 interconnect.

15.1.6.1 SAR ROM

This on-chip ROM contains 4KB of memory and a linked list of descriptors used by sDMA during the restore context operation (when the device transitions from off to on mode).

The device-embedded SAR ROM has the following characteristics:

- 4-KB ROM
- 32-bit access per cycle
- Support for single- and burst-access transactions

15.1.6.2 SAR RAM

The on-chip SAR RAM contains 8KB and is mapped as four blocks with irregular region sizes. This memory content is preserved when the device goes into off mode (as long as the wake-up voltage domain remains supplied). It is used as context-saving memory to be written by software so that sDMA restores its saved content when the device transitions from off to on mode.

The device-embedded SAR RAM has the following characteristics:

- Support for single-access transactions
 - Operates at full L4-PER interconnect clock frequency
 - 32-bit access per cycle

15.1.6.3 L3 OCM_RAM

The on-chip L3 OCM_RAM contains 56KB of RAM, and partitioning is defined by the L3 firewall logic. The device-embedded L3 OCM_RAM has the following characteristics:

- Support for single and burst access transactions:
 - Operates at full L3 interconnect clock frequency
 - Fully pipelined, one 32-bit access per cycle
- Restricted access support

15.2 Dynamic Memory Manager

15.2.1 DMM Overview

This section describes the dynamic memory manager (DMM) and its tiling and isometric lightweight engine for rotation (TILER) submodule.

The DMM is introduced in [Section 15.1, Memory Subsystem Overview](#) in [Chapter 15, Memory Subsystem](#).

The function of the DMM is to:

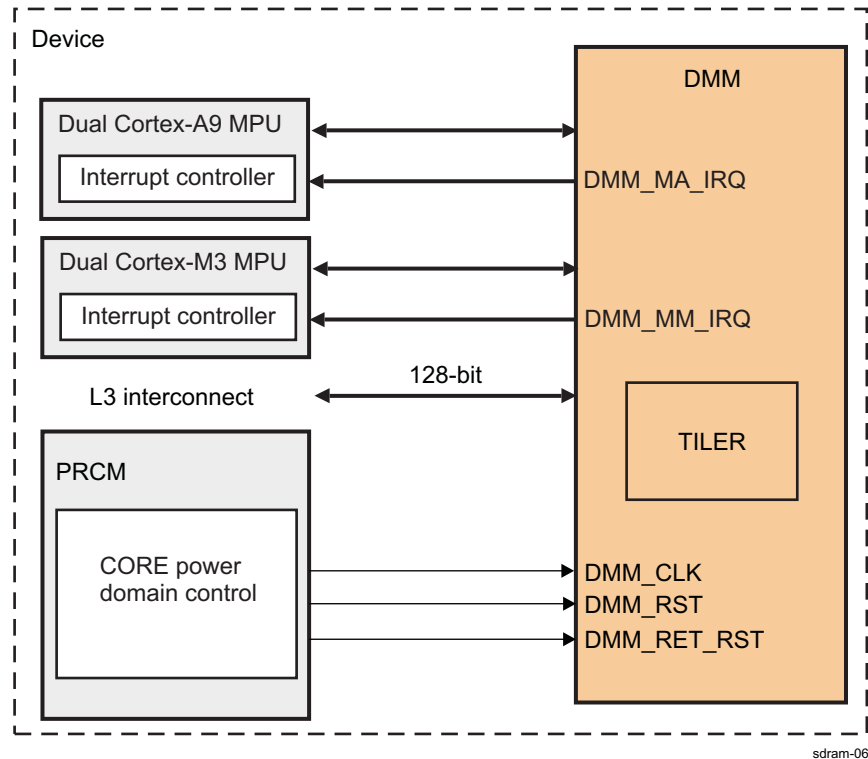

- Add initiator-based priority to any incoming requests
- Perform to-and-from tiling conversions of tiled requests
- Make on-the-fly basic transforms, such as quadrant rotations and mirroring
- Optionally provide a low-latency page-based translation to handle memory fragmentation – memory management unit (MMU)
- Distribute the traffic on all attached memory controllers according to the interleaving configuration

The TILER is also introduced in [Section 15.1, Memory Subsystem Overview](#) in [Chapter 15, Memory Subsystem](#).

The functions of the TILER are:

- Primary handling efficiently 2-dimensional (2D) data mapped in tiles, such as video or graphics macroblocks
- Optionally managing the memory fragmentation and zero-copy physical frame buffers swapping through a page-grained translation
- Allowing optimized interlaced accesses on tiled frames
- Making (distance preserving) transforms, such as 90-, 180-, or 270-degree rotations, with a horizontal or vertical reflection
- Interleaving the memory accesses among the two memory controllers (also called EMIF). For more information, see [Section 15.3, EMIF Controller](#).

[Figure 15-2](#) is an overview of the DMM and TILER in the device.

Figure 15-2. DMM and Tiler Overview

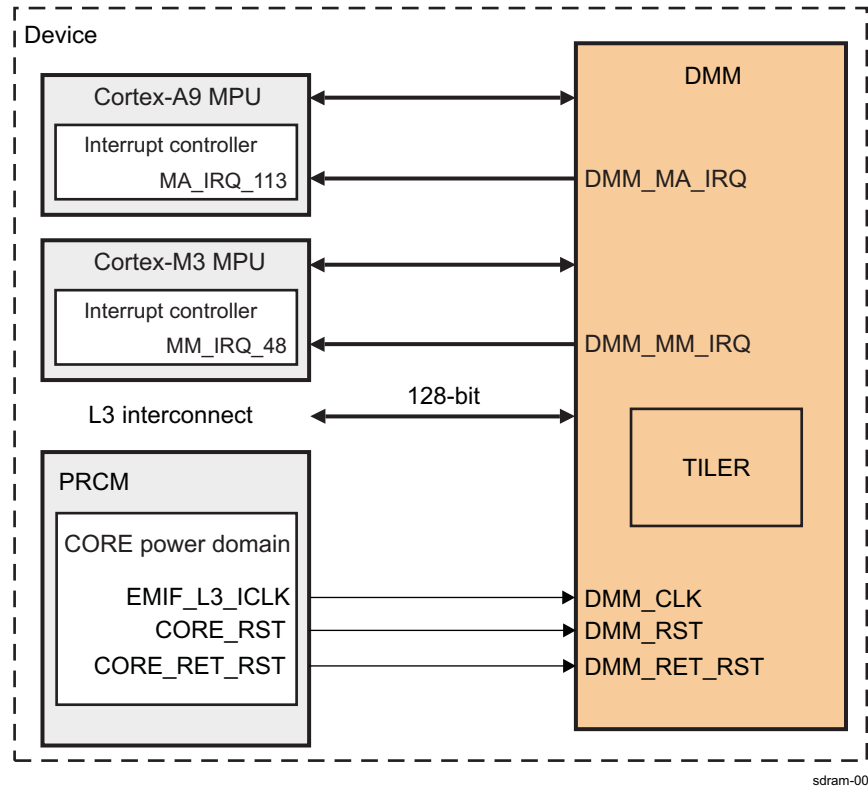

15.2.2 DMM Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

- IDLE hardware handshake (the DMM supports only smart-idle mode)
- No STANDBY hardware handshake
- No wake-up request
- No system direct memory access (sDMA) requests
- One interrupt line for interrupt request (IRQ)
- One functional clock

Figure 15-3 shows the integration of DMM in the device.

Figure 15-3. DMM Integration

NOTE: For more information about the IDLE hardware handshake, see [Chapter 3, Power, Reset, and Clock Management](#).

Table 15-1 through Table 15-3 summarize the integration of DMM in the device.

Table 15-1. DMM Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
DMM	PD_CORE	No	N/A

	DMM_PEG_HWINFO[6:0] PRIO_CNT	0x10	16 priority entries

15.2.3 DMM Functional Description

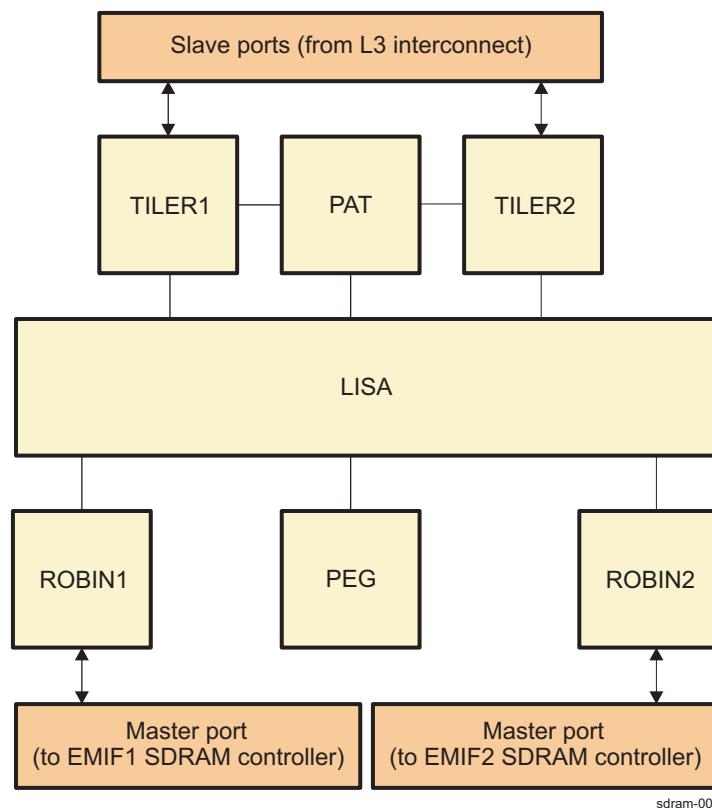

15.2.3.1 DMM Block Diagram

Figure 15-4 shows the DMM macro architecture. The DMM consists of six blocks:

- Two TILERS, each with its own interconnect slave port for converting requests back and forth between the input virtual addressing mode and the output physical tiled addressing mode. The tiling conversions of requests, write data, and responses is performed entirely in the TILER blocks.
- Two reordering buffer and initiator nodes (ROBINs), each with its own interconnect master port to initiate requests to the SDRC and allow tiled data, tiled response, and split response reconstruction. The ROBIN block manages only the reordering buffer and performs data reordering due to the orientation.
- A physical address translator (PAT) for managing the memory fragmentation
- A priority extension generator (PEG) to generate priorities required by the SDRC; these priorities are not used in the DMM.
- A local interconnect and synchronization agent (LISA) to synchronize all DMM subsystems and provide access to their configuration registers

Figure 15-4 is a block diagram of the DMM.

Figure 15-4. DMM Block Diagram

CAUTION

The interconnect must ensure that virtually addressed requests target only a TILER port.

15.2.3.2 DMM Clock Configuration

Table 15-5 describes the DMM clocks.

Table 15-5. DMM Clocks

Signal	I/O ⁽¹⁾	Description
DMM_CLK	I	Functional and interface clock

⁽¹⁾ I = Input; O = Output

The DMM is concerned with SDRC management and is in the MEMIF clock domain among the SDRCs. The DMM is a fully synchronous module, which uses the clock and clock-enable signals provided in the MEMIF clock domain to generate its interface and functional clocks.

To configure DMM_CLK control and settings, see [Table 15-2](#).

15.2.3.3 DMM Power Management

DMM power is supplied by the CORE power domain, and DMM power management complies with system power-management guidelines.

[Table 15-6](#) describes the power-management features available for the DMM module.

Table 15-6. DMM Local Power-Management Features

Feature	Registers	Description
Clock auto gating	N/A	Feature not available
Slave idle modes	DMM_SYSCONFIG [3:2] SIDLEMODE bit field	Only smart-idle wake-up mode is available.
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	N/A	Feature not available

Some of the DMM module registers are affected by the save-and-restore (SAR) mechanism. For more information about SAR, see [Chapter 3, Power, Reset, and Clock Management](#).

15.2.3.4 DMM Interrupt Requests

Errors in PAT area refill registers are reported through the [DMM_PAT_STATUS_i](#)[15:10] ERROR bit field (see [Table 15-7](#)).

Table 15-7. DMM Hardware Status Features

Feature	Type	Register	Description
PAT error flags	Read-only	DMM_PAT_STATUS_i [15:10] ERROR (i = 0 to 3)	Unexpected update of the PAT area refill registers

[Table 15-8](#) lists the event flags, and their masks, that can cause module interrupts.

Table 15-8. Events

Interrupt	Event Flag	Event Mask
ERR_LUT_MISS3	DMM_PAT_IRQSTATUS [31] EVENT0 DMM_PAT_IRQSTATUS_RAW [31] EVENT0	DMM_PAT_IRQENABLE_SET [31] EVENT0 DMM_PAT_IRQENABLE_CLR [31] EVENT0
ERR_UPD_DATA3	DMM_PAT_IRQSTATUS [30] EVENT0 DMM_PAT_IRQSTATUS_RAW [30] EVENT0	DMM_PAT_IRQENABLE_SET [30] EVENT0 DMM_PAT_IRQENABLE_CLR [30] EVENT0

15.2.3.5 DMM

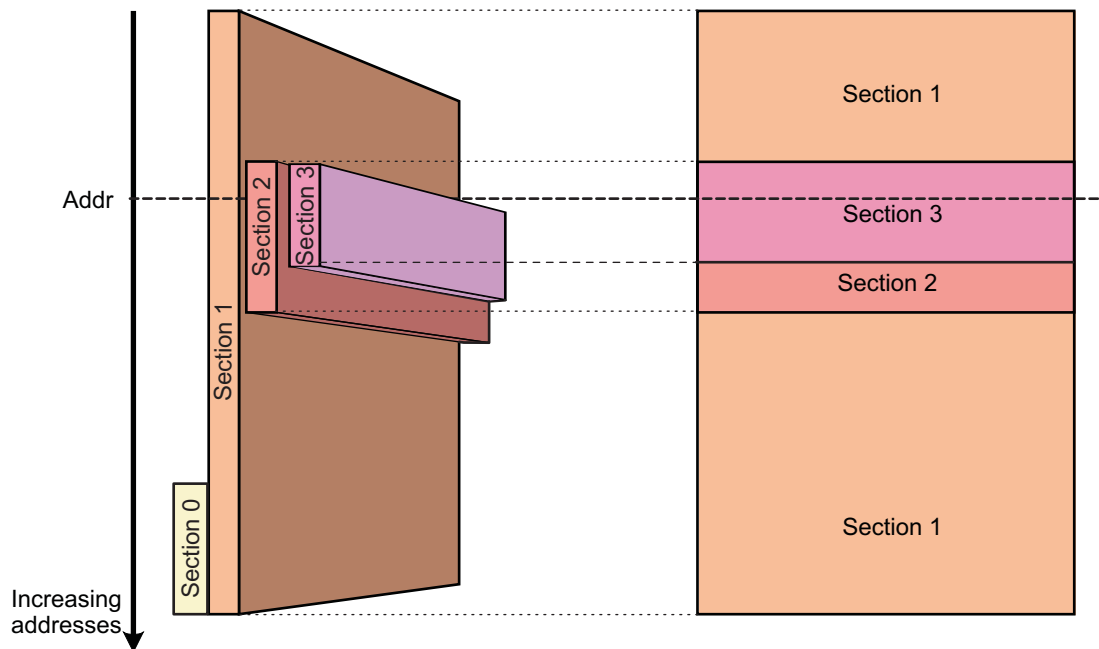

15.2.3.5.1 DMM Concepts

The DMM introduces the concepts of dynamic mapping and DMM atomic units.

15.2.3.5.1.1 Dynamic Mapping

The DMM manages its internal memory space as an ordered set of up to four sections. [Figure 15-5](#) shows the DMM sections and memory mapping.

Figure 15-5. DMM Sections and Memory Mapping

sdram_004

In the DMM, a section is:

- A segment of 16MiB to 2GiB, which is power-of-two in size and aligned to that size in the system map
- An area with a constant interleaving scheme: constant interleaving granularity on a constant set of SDRC (EMIF) targets
- Given a priority equal to its index: the higher the index, the higher the priority

NOTE: Whenever a request hits more than one DMM section, it follows the interleaving scheme of the section having the highest index.

The interleaving configuration of the DMM, its section-based dynamic memory mapping, is shown on the right in [Figure 15-5](#). In this example, a request at the system address Addr follows the interleaving scheme of section 3, although it hits sections 1, 2, and 3. Similarly, the DMM configuration given in this example prevents any request from using the interleaving scheme of section 0, because section 0 is fully masked by section 1, which has a higher priority.

Each of the four sections is configured through a [DMM_LISA_MAP_i](#) register, where $i = 0$ to 3.

NOTE: The DMM and SDRC registers ([Table 15-89](#) and EMIF registers; see [Section 15.3](#), *EMIF Controller*) are declared in two extra static DMM sections of the highest priority so that they cannot be masked by any standard programmable DMM section.

NOTE: The DMM atomic size is:

- 1kiB in noninterleaved sections
- Equal to the interleaving granularity (128, 256, or 512 bytes) in interleaved sections

15.2.3.5.1.2 Address Mapping

The address mapping inside the DMM is configurable through up to four sections. A DMM section description fits in a single register (DMM_LISA_MAP_i). Each section is defined based on:

- Its system address: The base address of the decoding range for the section
- Its size: The encoding is the number of bits used in the upper 8 bits of the incoming system address
- Its physical address: The base address of the memory range access in the external memory controller
- Its address space: The address space used on the external (for the DMM) memory controller when hitting this section. For details, see [Section 15.3.4.1.1, L3 Interface](#).
- The target memory controller. A section may hit a single or pair of controllers.
- Its interleaving definition

The address decoding is priority-based. In case of overlapping sections, only the highest-order one is hit. Register memory spaces have priority over regular memory sections. In case of four sections, the priority order is therefore:

1. Registers
2. DMM_LISA_MAP_3
3. DMM_LISA_MAP_2
4. DMM_LISA_MAP_1
5. DMM_LISA_MAP_0

All register-related addresses are reserved and fixed in the overall address mapping:

- DMM registers: 0x4E00_0000 to 0x4FFF_FFFF
- EMIF1 registers: 0x4C00_0000 to 0x4CFF_FFFF
- EMIF2 registers: 0x4D00_0000 to 0x4DFF_FFFF

There is no overlapping between register sections.

NOTE: Section decoding happens after PAT address translation in the case of TILER. In non-bypass mode, the system address considered for TILER accesses is the virtual address computed based on the PAT translation tables.

The [DMM_LISA_LOCK](#) register is used to lock the configuration once set. If written to 1, the LOCK bit prevents further writes to all [DMM_LISA_MAP_i](#) registers. The LOCK bit cannot be written back to 0. A reset is required to reprogram the sections.

15.2.3.5.1.3 Address Translation

The PAT engine of the DMM is composed of a 32-k entry physical address translation vector table and one or two refill engines. The refill engine is a specialized DMA for refilling the content of the PAT table.

The address translation mechanism is available only when the incoming request hits a page mode or tiled mode container; that is, when the incoming address targets the TILER or its aliased view in the system addressing space. Otherwise, the PAT logic is bypassed so that the resulting physical address corresponds to the input address.

The PAT engine supports multiple address translation schemes, called views, which can be bound to one or more initiators through a view mapping mechanism.

15.2.3.5.1.3.1 PAT View Mappings

The PAT engine can have up to 16 groups of initiators that share a set of four PAT views. The connection from an initiator to a PAT view is made through the DMM_PAT_VIEW register. Given that each PAT view index is coded on 4 bits, the DMM_PAT_VIEW register is a 64-bit register split into two 32-bit registers (DMM_PAT_VIEW0 for the first eight PAT view indexes and DMM_PAT_VIEW1 for the last eight PAT view indexes).

The PAT view index that corresponds to the initiator having the value i as the 4 most-significant bits (MSBs) of its L3 ConnID uses the view referenced in entry i of the DMM_PAT_VIEW. For example, the initiator 0xC4 uses the thirteenth view index of the DMM_PAT_VIEW register, the fifth view index in the DMM_PAT_VIEW1 register.

The PAT view index of the initiator i is found in the V_i field. The W_i field is aimed at writing the corresponding V_i . When writing to the DMM_PAT_VIEW registers, the only V_i view indexes that are updated are those having their corresponding W_i bit, and byte enable, set. The W_i bits are always read as 0. For instance, to set the PAT view indexes V_3 and V_7 to 2 and 1, respectively, the DMM_PAT_VIEW0 register must be written with 5000 6000h.

15.2.3.5.1.3.2 PAT View Map Base Address

The PAT view map base address defines the base address of all PAT translated addresses.

Bit [31] of all PAT translated addresses is set to BASE_ADDR. For example, if the DMM_PAT_VIEW_MAP_BASE register is set to 8000 0000h, all PAT translated addresses will have bit [31] set to 1 so that the translated addresses range from 8000 0000h to FFFF FFFFh. All reserved bits of this DMM PAT base address register are read to 0.

15.2.3.5.1.3.3 PAT Views

A PAT view defines the kind of physical address translation to perform for each mode accesses (page, 8-bit, 16-bit and 32-bit). Each mode of each PAT view can be configured to use a container-grained translation or page-mode translation.

15.2.3.5.1.3.3.1 PAT Direct Access Translation

The container-grained translation is named the direct access. In this mode, the translation vector is given directly by the CONT_x bit field that corresponds to the accessed mode.

- A page mode access uses the vector contained in the DMM_PAT_VIEW_MAP_i[27:24] CONT_PAGE bit field.
- A 32-bit mode access uses the vector contained in the DMM_PAT_VIEW_MAP_i[19:16] CONT_32 bit field.
- A 16-bit mode access uses the vector contained in the DMM_PAT_VIEW_MAP_i[11:8] CONT_16 bit field.
- An 8-bit mode access uses the vector contained in the DMM_PAT_VIEW_MAP_i[3:0] CONT_8 bit field.

See Figure 15-6.

Figure 15-6. PAT Direct Access Translation

15.2.3.5.1.3.3.2 PAT Indirect Access Translation

The page-grained translation is named the indirect access. In this mode the translation vector is found in the internal 32-k entry physical address translation vector table at the index given by bits [26:12] of the input virtual address, and the `DMM_PAT_VIEW_MAP_i` `CONT_x` bit field references the internal physical address translation table to use. Because the DMM uses only one such table, in this mode the `CONT_x` bit field must be written as 0. See [Figure 15-7](#).

Figure 15-7. PAT Indirect Access Translation

Each entry of the PAT lookup table (LUT) is a 19-bit vector that replaces bits [30:12] of the input virtual address. The PAT index aimed at selecting the vector in the table consists of bits [26:12] of the input virtual address.

15.2.3.5.1.3.3.3 PAT View Configuration

There are four different views in a DMM, each with its own `DMM_PAT_VIEW_MAP_i` register for defining the kind of address translation to perform.

The PAT view type of each mode is selected by the `ACCESS_x` bit field in the `DMM_PAT_VIEW_MAP_i` register, `i` being the index of the considered view. When this field is set to 1, the indirect access scheme is used; otherwise, the PAT performs the address translation in a direct way with the corresponding `CONT_x` vector.

When configuring a mode in a view to use the indirect access, the corresponding `CONT_x` bit field must be filled with 0.

15.2.3.5.1.3.3.4 PAT Address Translation LUT

The PAT LUT has the same geometry as the DMM container. It has 128 lines of 256 entries of 19-bit each. See [Figure 15-8](#).

Figure 15-8. Physical Address Translation Table

$E_{0,0}$	$E_{1,0}$	$E_{2,0}$	$E_{3,0}$	$E_{4,0}$	$E_{251,0}$	$E_{252,0}$	$E_{253,0}$	$E_{254,0}$	$E_{255,0}$
$E_{0,1}$	$E_{1,1}$	$E_{2,1}$	$E_{3,1}$	$E_{4,1}$	$E_{251,1}$	$E_{252,1}$	$E_{253,1}$	$E_{254,1}$	$E_{255,1}$
$E_{0,2}$	$E_{1,2}$	$E_{2,2}$	$E_{251,126}$	$E_{4,2}$	$E_{251,2}$	$E_{254,2}$	$E_{253,2}$	$E_{254,2}$	$E_{255,2}$
$E_{0,125}$	$E_{1,125}$	$E_{2,125}$	$E_{3,125}$	$E_{4,127}$	$E_{251,125}$	$E_{252,125}$	$E_{253,125}$	$E_{254,125}$	$E_{255,125}$
$E_{0,126}$	$E_{1,126}$	$E_{2,126}$	$E_{3,126}$	$E_{4,126}$	$E_{251,126}$	$E_{6,126}$	$E_{253,126}$	$E_{254,126}$	$E_{255,126}$
$E_{0,127}$	$E_{1,127}$	$E_{2,127}$	$E_{3,127}$	$E_{4,127}$	$E_{251,127}$	$E_{6,127}$	$E_{253,127}$	$E_{254,127}$	$E_{255,127}$

$E_{x,y}$ 4-KB page entry

sdram-074

Each entry of the PAT address corresponds to the page in the DMM container that has the same location. The entry (74, 42) in the table corresponds to the page (74, 42) in any DMM container.

15.2.3.5.1.3.3.5 Direct Access to the PAT Table Vectors

The PAT table is typically refilled with specialized DMA called refill engines. Some direct read and write access to the content of this table is granted when disabling the use of one or the other refill engine by writing 1 in the MODE $_i$ field of the [DMM_PAT_CONFIG](#) register that corresponds to the refill engine i to disable.

In this mode, often called the debug mode, the data read in or written to the [DMM_PAT_DATA \$_i\$](#) register corresponds to the vector in the PAT table, whose index is in the X0 and Y0 fields of the [DMM_PAT_AREA \$_i\$](#) register.

15.2.3.5.1.3.3.6 Automatic Refill Through the Refill Engines

See [Section 15.2.4.1](#), PAT Use Cases.

15.2.3.5.2 DMM Transaction Flows

15.2.3.5.2.1 Nontiled Transaction Flow

Each nontiled interconnect transaction that reaches the DMM on a TILER port is subject to the same processing.

The TILER blocks consider separated request, data, and response paths. An overview of each path follows and more detailed information is in [Section 15.2.3.5.3](#), DMM Internal Macro-Architecture.

On the request path, the flow consists of:

- Allocating a TILER response context for the timely generation of the appropriate responses
- Splitting 2D requests in a collection of 1D requests – TILER ports
- Splitting requests at DMM unit boundaries; the split granularity is provided by the LISA mapping registers
- Allocating an available buffer in the appropriate ROBIN, for both read and write requests
- In case of a write request, allocating and updating a TILER write context to direct the incoming write data into the relevant reordering buffer

- Generating the initiator-indexed priority extension by use of the PEG block

On the write data path, the flow consists of forwarding incoming data to the relevant reordering buffer in accordance with the corresponding TILER write context.

On the response path, responses are returned when:

- At least one response has entered each related buffer, in case of read requests
- All related responses have returned from the SDRC, in case of write requests
- AND no other previous pending response with the same tag exists

15.2.3.5.2.2 Tiled Transaction Flow

Similarly, each tiled interconnect transaction that reaches the DMM is subject to the same processing.

The TILER blocks consider separated request, data, and response paths. An overview of each path follows, and more detailed information is in [Section 15.2.3.5.3, DMM Internal Macro-Architecture](#).

On the request path, the processing phase consists of:

- Decoding the address to qualify whether the request targets the TILER or the memory directly
- Transforming TILER-specific requests to their natural representation; the address, width, and height are modified accordingly

On the request path, the generation phase consists of:

- Allocating a TILER response context for the timely generation of the appropriate responses
- Splitting malformed: The request stride differs from the container stride and from the double of this container stride – tiled 2D requests in a collection of 1D requests
- Splitting tiled requests at tile boundaries
- Performing the page-based address translation by use of the PAT block
- Allocating an available buffer in the appropriate ROBIN, for read and write requests
- In case of a write request, allocating and updating a TILER write context to direct the incoming write data into the relevant reordering buffer
- Generating the initiator-indexed priority extension by use of the PEG block

On the data path, any incoming data is transformed in accordance with the corresponding TILER write context and sent to the appropriate reordering buffer.

On the response path, responses are returned when:

- A minimal number of responses have entered the corresponding buffers, in case of read requests
- All related responses have returned from the SDRCs, in case of write requests
- No other previous pending response with the same tag exists

15.2.3.5.3 DMM Internal Macro-Architecture

This section describes the DMM internal macro-architecture, specifically:

- Input request decoding
- PAT and synchronized translation table reloading
- Output request and response generation
- Memory mapping in the system addressing space, including interleaving
- Tag management
- Priority handling
- Contexts
- Maximum allowed burst size
- Reconstruction buffer dimensioning

15.2.3.5.3.1 LISA Description

The LISA is a full crossbar aimed at setting priorities, managing tag, and mapping memory.

The interconnect routes are:

- TILER requests on the ROBIN initiator nodes
- TILER write data on the ROBIN write buffers
- ROBIN read data to the relevant TILER initiators

The LISA block registers are [DMM_LISA_MAP_i](#) (where $i = 0$ to 3) and [DMM_LISA_LOCK](#).

When two ROBINS are in use, the two ports are interleaved at a programmable boundary from 128 bytes or more (configurable with the [DMM_LISA_MAP_i\[19:18\]](#) SDRC_INTL bit field).

15.2.3.5.3.2 PAT Description

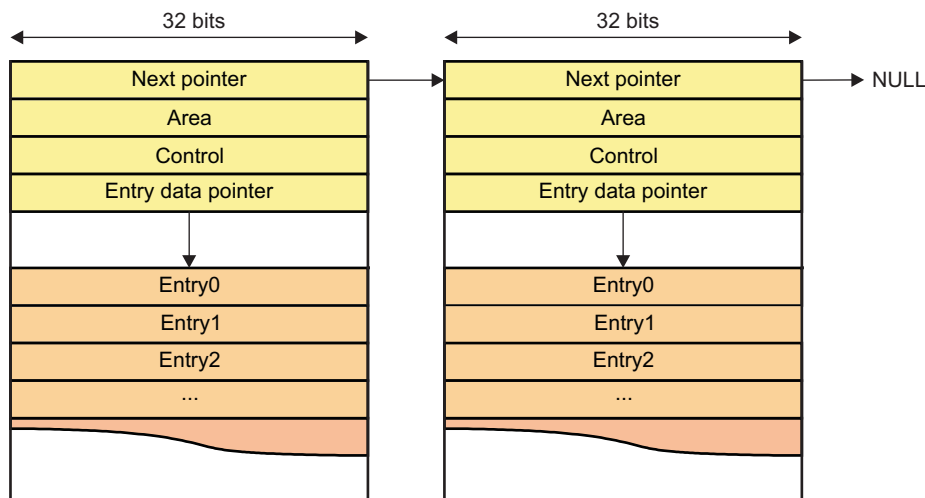

The PAT block maps physical pages to each TILER container page. The internal address translation memories used in the PAT block are designed with RFFs. It consists of:

- A memory-based LUT which has the same geometry as the container pages
- A refill engine for modifying entries in a given area of the internal LUT

A PAT descriptor is a singly-linked list node (see [Figure 15-9](#)) that contains:

- A description of the LUT area to reload
- A description of how to reload the defined LUT area
- A pointer to the location where the corresponding LUT entries are stored

Figure 15-9. PAT Descriptors

sdram-065

PAT descriptors are chained and processed until a NULL pointer is encountered. The PAT bank allocation scheme allows the updating of four consecutive entries of a line in a single cycle regardless of the refilling orientation.

The PAT descriptor structure directly maps the following registers (where $i = 0$ to 3):

- [DMM_PAT_DESCR_i](#)
- [DMM_PAT_AREA_i](#)
- [DMM_PAT_CTRL_i](#)
- [DMM_PAT_DATA_i](#)

The PAT refill engine can be started by:

- Filling manually all the necessary registers:
 - [DMM_PAT_AREA_i](#) with the (x_0, y_0) (x_1, y_1) area definition

- [DMM_PAT_DATA_i](#) with the physical address of the corresponding area entry table
- [DMM_PAT_CTRL_i\[6:4\]](#) DIRECTION bit field with the relevant (S, Y, X) direction of the area refill
- [DMM_PAT_CTRL_i\[0\]](#) START bit with 1
- Writing the physical address of a memory-mapped PAT descriptor in [DMM_PAT_DESCR_i](#), which updates:
 - [DMM_PAT_AREA_i](#) with the area value of the descriptor
 - [DMM_PAT_DATA_i](#) with the data value of the descriptor
 - [DMM_PAT_CTRL_i](#) with the control value of the descriptor
 - [DMM_PAT_DESCR_i](#) with the next value of the descriptor
- The data part of the PAT refill starts only when the [DMM_PAT_CTRL_i\[0\]](#) START bit is asserted.

The [DMM_PAT_STATUS_i](#) register can be used to see whether the process has completed without errors.

15.2.3.5.3.3 PEG Description

The PEG is a dynamic software-programmable, initiator-ConnID-indexed table of priorities. Its role is to change on the fly the priority of an initiator. The mapping of each initiator to the table (split into eight registers) is based on its 6-MSB group ConnID (see [Table 28-20, ConnID Mapping \(Debug View\)](#), in [Chapter 28, On-Chip Debug Support](#)).

When an interconnect request enters the DMM, its priority is extracted from the PEG LUT and set in its MReqInfo field.

The 64 priority entries are software-programmable with eight DMM_PEG_PRIO registers ([DMM_PEG_PRIO_k](#)).

These eight registers are each split into eight 4-bit fields, each field mapping an entry of the LUT with:

- The 3-bit priority coded on the 3 least-significant bits (LSBs): P_x field. A priority of 0 defines the highest priority and a priority of 7 defines the lowest priority. At reset, all priorities are set to 4. The priority of a request with ConnID equal to y is written in (8.k + x) P field, where k is the number of the priority register (k = 0 to 7) and x is the number of the P field in the corresponding register (x = 0 to 7). For example, if the ConnID is 0x16, its priority is written in the third priority register (where k = 2), in the P6 bit field ([26:24]), because x = 6.

Table 15-9. ConnIDs Vs PEG Priority Register Fields

RegisterField	P0	P1	P2	P3	P4	P5	P6	P7
DMM_PEG_PRIO_0	0	1	2	3	4	5	6	7
DMM_PEG_PRIO_1	8	9	10(0xA)	11(0xB)	12(0xC)	13(0xD)	14(0xE)	15(0xF)
DMM_PEG_PRIO_2	16(0x10)	17(0x11)	18(0x12)	19(0x13)	20(0x14)	21(0x15)	22(0x16)	23(0x17)
DMM_PEG_PRIO_3	24(0x18)	25(0x19)	26(0x1A)	27(0x1B)	28(0x1C)	29(0x1D)	30(0x1E)	31(0x1F)
DMM_PEG_PRIO_4	32(0x20)	33(0x21)	34(0x22)	35(0x23)	36(0x24)	37(0x25)	38(0x26)	39(0x27)
DMM_PEG_PRIO_5	40(0x28)	41(0x29)	42(0x2A)	43(0x2B)	44(0x2C)	45(0x2D)	46(0x2E)	47(0x2F)
DMM_PEG_PRIO_6	48(0x30)	49(0x31)	50(0x32)	51(0x33)	52(0x34)	53(0x35)	54(0x36)	55(0x37)
DMM_PEG_PRIO_7	56(0x38)	57(0x39)	58(0x3A)	59(0x3B)	60(0x3C)	61(0x3D)	62(0x3E)	63(0x3F)

- A \overline{W} field-specific active-low local write enable bit, always read as 0, on the most-significant bit (MSB). The role of the \overline{W} bit is to allow the modification of a single entry without requiring a read-modify-write sequence. Because its \overline{W} bits are always read as 0, writing back the modified register updates all priority fields of the register.

Although this priority information is generated before entering the LISA block, it is not used internally in the local interconnect arbitration but is forwarded to the EMIF as an MReqInfo, where it indicates the command priority.

It is also possible to give a priority for the internal PAT engine through the [DMM_PEG_PRIO_PAT](#) register.

15.2.3.5.3.4 **ROBIN Description**

The ROBIN is a block that provides some working buffering for converting data and responses to-and-from between raster and tiled organizations, and a master port to connect to the SDRC.

The ROBIN block:

- Forwards requests
- Writes data and buffers responses
- Keeps write data ordering
- Performs intraword tiling and orientation transforms
- Handles tags

15.2.3.5.3.5 **TILER Description**

The main function of the TILER is request conversion caused by tiling.

The TILER block:

- Decodes the address to qualify whether the request targets the TILER or the memory directly
- Converts TILER-specific requests to their natural representation; address, width, and height are modified accordingly
- Allocates an internal response context for the timely generation of appropriate responses
- Splits tiled requests at tile boundaries and not-tiled requests at DMM atomic section boundaries
- Requests the page-based address translation
- Requests buffer allocation in the appropriate ROBIN
- In case of a write request, allocates and updates an internal write context to direct the incoming write data into the relevant reordering buffer

The interdependent tiling and isometric transform concepts introduced in the TILER are described in the following section.

15.2.3.6 **TILER**

15.2.3.6.1 **TILER Concepts**

This section describes the concepts behind the TILER transforms, through a top-down approach starting from the main object container.

15.2.3.6.1.1 **TILER Rationale**

This section is a synthesis of all TILER concepts, giving one rule per TILER structure level.

[Figure 15-10](#) shows the TILER address space structure for tiled modes.

Figure 15-10. TILER Address Space Structure for Tiled Modes

sdram-005_public

15.2.3.6.1.1.1 The TILER is a 4-GB Virtual Address Space Composed of Eight Views

There is one view for each of the eight possible ways of scanning a frame-buffer:

- From left to right then from top to bottom

- From right to left then from top to bottom
- From left to right then from bottom to top
- From right to left then from bottom to top
- From top to bottom then from left to right
- From top to bottom then from right to left
- From bottom to top then from left to right
- From bottom to top then from right to left

15.2.3.6.1.1.2 A View is a 512-MB Virtual Address Space Composed of Four Containers

There is one container per element size to allow correct access patterns in any of the eight possible orientations. The container is the entity where all objects of a given element type are allocated.

The element is the entity of maximum size (8, 16, 32 bits or page-sized), which is invariant in any orientation.

15.2.3.6.1.1.3 A Container is a 128-MB Virtual Address Space

A container is composed of an array of 128 lines of 256 pages of 4 KB each.

The page defines the granularity of physical memory allocation through a PAT unit – MMU.

15.2.3.6.1.1.4 A Page is a 4-KB Virtual Address Space

A page is composed of two lines. Each line consists of two tiles.

15.2.3.6.1.1.5 A Tile is a 1-KB Address Space

The tile is designed to offer bidimensional data locality in a single SDRAM page. In this respect, it is sized to 1 KB; that is, to the size of the smallest SDRAM page.

15.2.3.6.1.2 TILER Modes

The TILER supports three major modes, bypass, page, and tiled. Each mode has a specific output request generation.

15.2.3.6.1.2.1 Bypass Mode

This mode is transparent from the TILER perspective. However, from the DMM perspective:

- 2D block bursts are broken down on a line basis in a set of incremental bursts.
- Incremental bursts, including those issued by a 2D block burst breakdown, are split at the DMM atomic unit of the section hit by the burst at:
 - The interleaving granularity of the section (128, 256, or 512 bytes) in interleaved sections
 - 1-KB boundary in noninterleaved sections

15.2.3.6.1.2.2 Page Mode

This mode uses the DMM address translation mechanism for nontiled accesses. In this respect it is similar to bypass mode:

- 2D block bursts are broken down on a line basis in a set of incremental bursts.
- Incremental bursts, including those issued by a 2D block burst breakdown, are split at:
 - The interleaving granularity of the section (128, 256, or 512 bytes) in interleaved sections
 - 1-KB boundary in noninterleaved sections

15.2.3.6.1.2.3 Tiled Mode

Tiled mode has two major breakdown algorithms:

- One for well-formed 2D block requests that conform to the orientation, mode, and stride listed in [Table 15-10](#)
- One for 1D incremental requests and ill-formed 2D block requests

Table 15-10. Well-Formed Tiled Mode 2D Block Requests

Orientation			Mode		Stride	Description
S	\bar{Y}	\bar{X}	M1	M0	(bytes)	
0	x	x	0	0	16,384	Plain access to an 8-bit progressive frame in 0 or 180 degrees
					32,768	Field access to an 8-bit interlaced frame 0 or 180 degrees
			0	1	32,768	Plain access to a 16-bit progressive frame in 0 or 180 degrees
					65,536	Field access to a 16-bit interlaced frame 0 or 180 degrees
			1	0	32,768	Plain access to a 32-bit progressive frame in 0 or 180 degrees
					65,536	Field access to a 32-bit interlaced frame 0 or 180 degrees
1	x	x	0	0	8192	Plain access to an 8-bit progressive frame in 90 or 270 degrees
					16,384	Field access to an 8-bit interlaced frame 90 or 270 degrees
			0	1	8192	Plain access to a 16-bit progressive frame in 90 or 270 degrees
					16,384	Field access to a 16-bit interlaced frame 90 or 270 degrees
			1	0	16,384	Plain access to a 32-bit progressive frame in 90 or 270 degrees
					32,768	Field access to a 32-bit interlaced frame 90 or 270 degrees

Similar to the bypass and page modes, ill-formed 2D block requests are broken down on a line basis in a set of incremental bursts. In tiled mode, however, these incremental virtual bursts do not translate to 1D physical burst requests.

15.2.3.6.1.3 Object Container Definition

The object container is the unique addressable entry point of the TILER. It is a 128-MB virtual address space, where all objects of a same kind and orientation are allocated.

Four main types of containers are present in the TILER, each referred by a mode:

- 8-bit element mode, for efficiently accessing bidimensional arrays of 8-bit data
- 16-bit element mode, for efficiently accessing bidimensional arrays of 16-bit data
- 32-bit element mode, for efficiently accessing bidimensional arrays of 32-bit data
- Page mode, for efficient 1D accesses

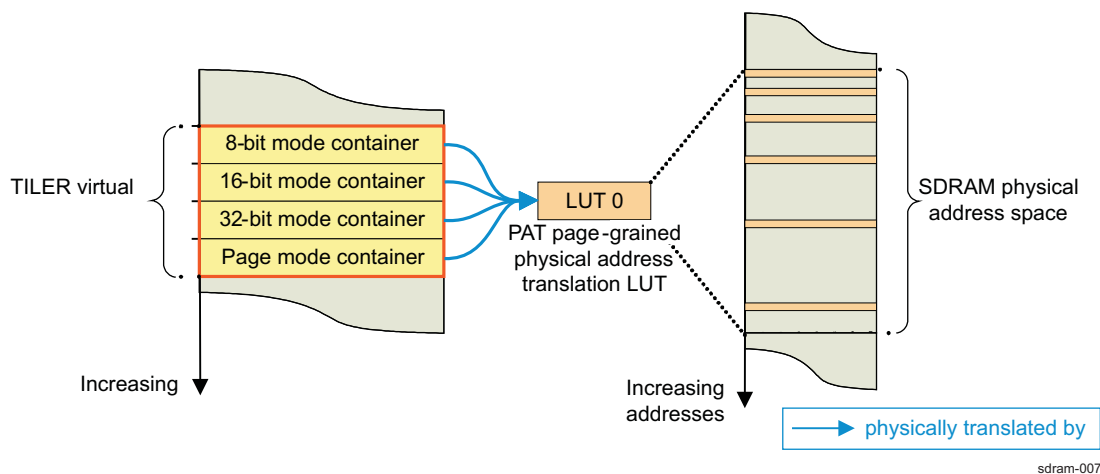

[Figure 15-11](#) shows the TILER object containers and views.

Figure 15-11. TILER Object Containers and Views

The 512-MB virtual address space composed of four 128-MB object containers of different modes is called a view. Because eight orientations are available per mode, the TILER actually manages 32 kinds of containers.

The physical memory footprint of a 512-MB TILER view is directly subject to the nature of the PAT unit.

A unique PAT LUT is instantiated in the DMM. This table is shared by all TILER modes. Hence, each of the four modes cannot be given its own private page-grained PAT LUT. A maximum of 128MB of objects among all TILER modes can be managed as shown in Figure 15-12.

Figure 15-12. TILER Memory Footprint With PAT and Shared Physical Address Translation LUT

Although each of the four modes has its own separate virtual 128-MB object container, these containers are all mapped to the same piecewise 128-MB physical address space, and are then not physically separated. Consequently, a memory-related system constraint is that no more than 128-MB of objects can be available simultaneously in a TILER view.

NOTE: Software must ensure that any object allocated in a mode does not physically overlap with any other object, even in another mode.

15.2.3.6.1.4 Page Definition

A TILER page defines the granularity of object allocation in virtual TILER containers.

Because the subpage structure is mode-specific, the page is the smallest granularity common to all modes, making it the granularity to consider in the TILER resource manager for object allocation.

15.2.3.6.1.4.1 Container Geometry With 4-KB Pages

Because the size of the page is 4 KB, any 128-MB object container is a set of 32,768 pages, organized in an array of 256 columns and 128 rows, as shown in Figure 15-13.

Figure 15-13. Object Container Geometry With 4-KB Pages

This array of pages is mapped to the system address space, as shown in Figure 15-14.

Figure 15-14. TILER Page Mapping When Using 4-KB Pages

In any 128-MB object container, the 4-KB page $P_{x,y}$ at column x (where $0 \leq x < 256$) and row y (where $0 \leq y < 128$), is found at an offset of $4096 \cdot (x + 256 \cdot y)$ bytes from the base address of the related object container.

Similarly, the page $P_{x,y}$ at column x (where $0 \leq x < 256$) and row y (where $0 \leq y < 128$), is translated by the LUT entry $E_{x+256 \cdot y}$ found at the index $x + 256 \cdot y$.

15.2.3.6.1.4.2 Container Geometry and Page Mapping Summary

The TILER has a page size of 4096 bytes. The page $P_{x,y}$:

- Has $\max_x = 256$ and $\max_y = 128$
- Is found at an offset of $4096 \cdot (x + \max_x \cdot y)$ bytes from the base address of the related object container

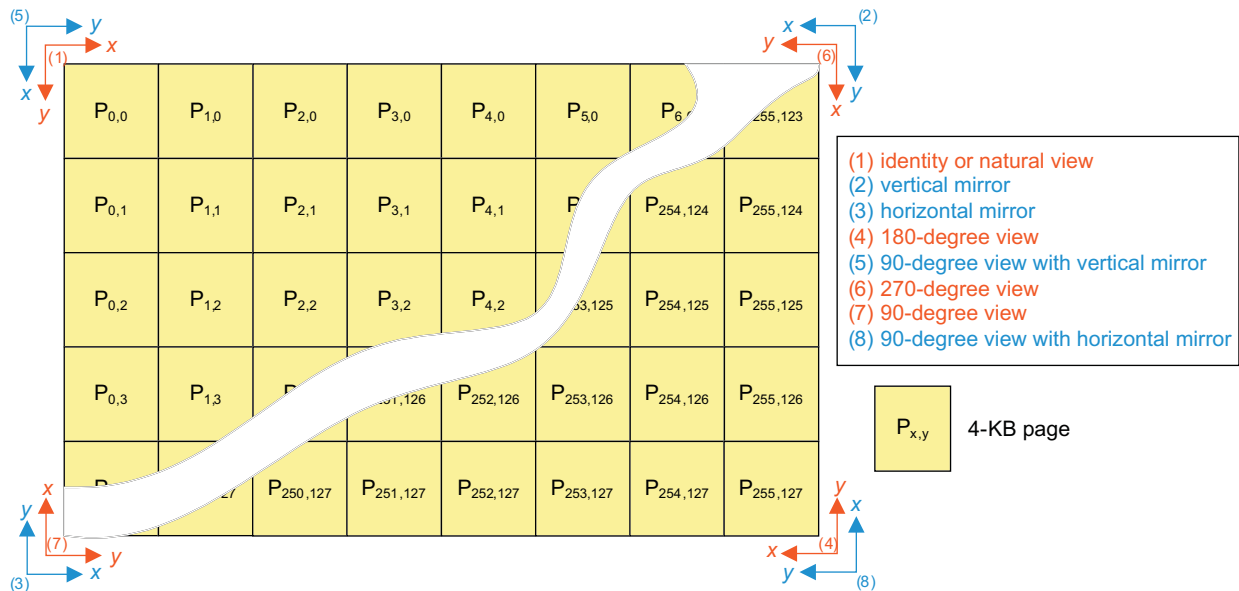

- Is translated by the entry at the index $(x + \max_x, y)$ of the LUT

15.2.3.6.1.5 Orientation

This section describes the eight on-the-fly orientation-related isometric transforms, which correspond to all available changes of orthonormal basis in the bidimensional space of the TILER container.

Figure 15-15 shows isometric transforms in the TILER container

Figure 15-15. Isometric Transforms in the TILER Container

sdram-010

Mathematically speaking, all these transforms correspond to the composition of a 0-, 90-, 180-, or 270-degree rotation with an optional reflection. The nature of this orientation is based on the three following binary parameters:

- X to change the direction of the x axis of the TILER container
- Y to change the direction of the y axis of the TILER container
- S to swap the modified x and y axis

Hereafter in this document the term orientation refers to any composition of a "quadrant" rotation with an optional horizontal (flip-flop) or vertical mirroring.

15.2.3.6.1.6 Tile Definition

A tile is a subdivision of a page that is aimed at:

- Representing a 2D block to better balance accesses in both directions
- Ensuring that any tiled access that fits within a tile is made atomic in the SDRG and fits in a single SDRAM memory page
- Minimizing the number of SDRAM page openings per 2D block transfer

The tile is defined as a 1-KB 2D block, and a 4-KB page as an array of two lines of two tiles each.

When the considered page is in an interleaved DMM section, it is necessary that:

- The DMM memory interleaving size of tiled accesses is set to 1 KB (a tile size) so that any tiled request that fits within a tile, fits in a single SDRAM memory page.
- Any request that spans two or four tiles is distributed on a maximum number of SDRGs.

15.2.3.6.1.7 TILER Virtual Addressing

The TILER can be virtually accessed in four different modes: 8-, 16-, 32-bit, and page modes. Each mode defines the element granularity to apply isometric transforms, as summarized in [Table 15-11](#).

Table 15-11. Coding and Description of TILER Modes

Mode	Name	Granularity (Element Size)
0	8-bit tiled mode	8 bits
1	16-bit tiled mode	16 bits
2	32-bit tiled mode	32 bits
3	Page mode	4096 bytes

For instance, making a vertical mirror of a 16-byte horizontal line that contains the word 000102030405060708090A0B0C0D0E0Fh, leads to:

- 0F0E0D0C0B0A09080706050403020100h in 8-bit tiled mode
- 0E0F0C0D0A0B08090607040502030001h in 16-bit tiled mode
- 0C0D0E0F08090A0B0405060700010203h in 32-bit tiled mode
- 000102030405060708090A0B0C0D0E0Fh in page mode – unchanged because the element granularity is 4KB

Besides, because each of the eight orientations is available for any of the four modes, the TILER has 32 addressing possibilities (see [Table 15-12](#)).

Table 15-12. Coding and Description of TILER Orientations

S	Y	X	Description	Alternate description
0	0	0	0-degree view	Natural view
0	0	1	0-degree view with vertical mirror	180-degree view with horizontal mirror
0	1	0	0-degree view with horizontal mirror	180-degree view with vertical mirror
0	1	1	180-degree view	
1	0	0	90-degree view with vertical mirror	270-degree view with horizontal mirror
1	0	1	270-degree view	
1	1	0	90-degree view	
1	1	1	90-degree view with horizontal mirror	270-degree view with vertical mirror

15.2.3.6.1.7.1 Page Mode Virtual Addressing and Characteristics

When used in page mode, the 128-MB TILER space is seen as an orientation-specific sequence of 32,768 pages of 4 KB each. The access sequence inside a page is left unchanged.

Therefore, in page mode, the TILER is accessed similarly to any 128-MB memory, with a 27-bit byte-based address.

NOTE: From here forward, the address is noted as *a* (see [Figure 15-16](#)).

Figure 15-16. Page Mode Virtual Addressing

s dram-027

15.2.3.6.1.7.2 Tiled Mode Virtual Addressing and Characteristics

When used in tiled mode, the 128-MB TILER space is seen as a giant frame-buffer, the container. The addressing and characteristics of this giant frame-buffer depend on:

- The tiled mode, which defines the considered atomic element size
- The orientation, which potentially swaps its x and y axis, and hence the container geometry

Table 15-13 summarizes the container characteristics in tiled mode.

Table 15-13. Tiled Mode Container Characteristics

Orientation S	Y	X	Element Size (Bits)	Width (Elements)	Height (Elements)	Stride (Bytes)	
						Progressive	Interlaced
0	x	x	8	16,384	8192	16,384	32,768
			16	16,384	4096	32,768	65,536
			32	8192	4096	32,768	65,536
1	x	x	8	8192	16,384	8192	16,384
			16	4096	16,384	8192	16,384
			32	4096	8192	16,384	32,768

As a result, the coordinate (x_0, y_0) of a pixel in an oriented view is translated in a virtual address, as shown in Figure 15-17 and Figure 15-18.

Figure 15-17. Tiled Mode Addressing in 0- or 180-Degree Orientation (S = 0)

Figure 15-18. Tiled Mode Addressing in 90- or 270-Degree Orientation (S = 1)

15.2.3.6.1.7.3 Element Ordering in the TILER Container

This section describes how elements (8-, 16-, or 32-bit data or a 4-KB page) are ordered in the container. In other words, this section describes how the path of incrementing virtual addresses is mapped in the container.

Regardless of the mode, and hence the element size, the sequence for ordering the elements in their related container is strictly similar and depends only on the related orientation. In other words:

- Mode is concerned with element granularity.
- Orientation is concerned with change of orthonormal basis for ordering the elements in the mode-specific container.

A corollary to the previous statements is that in a given mode the internal structure of an element is unchanged regardless of the orientation. In page mode for instance, the offset of a word inside a page is invariant by orientation; the content of a page is always accessed in the same manner.

In the following sections, the natural container orthonormal basis is referenced as:

$$(\vec{x}_N, \vec{y}_N)$$

sdram-030

and the oriented orthonormal basis is referenced as:

$$(\vec{x}_O, \vec{y}_O)$$

sdram-031

15.2.3.6.1.7.3.1 Natural View or 0-Degree View (Orientation 0)

This orientation defined by $S = 0$, $\bar{Y} = 0$, and $\bar{X} = 0$ means that the operated change of basis is:

$$\begin{cases} \vec{x}_O = \vec{x}_N \\ \vec{y}_O = \vec{y}_N \end{cases}$$

sdram-032

In any TILER mode, the elements are ordered from left to right and then from top to bottom in their container, as shown in Figure 15-19 and Figure 15-20.

Figure 15-19. Tiled Mode Ordering of Elements in Natural View

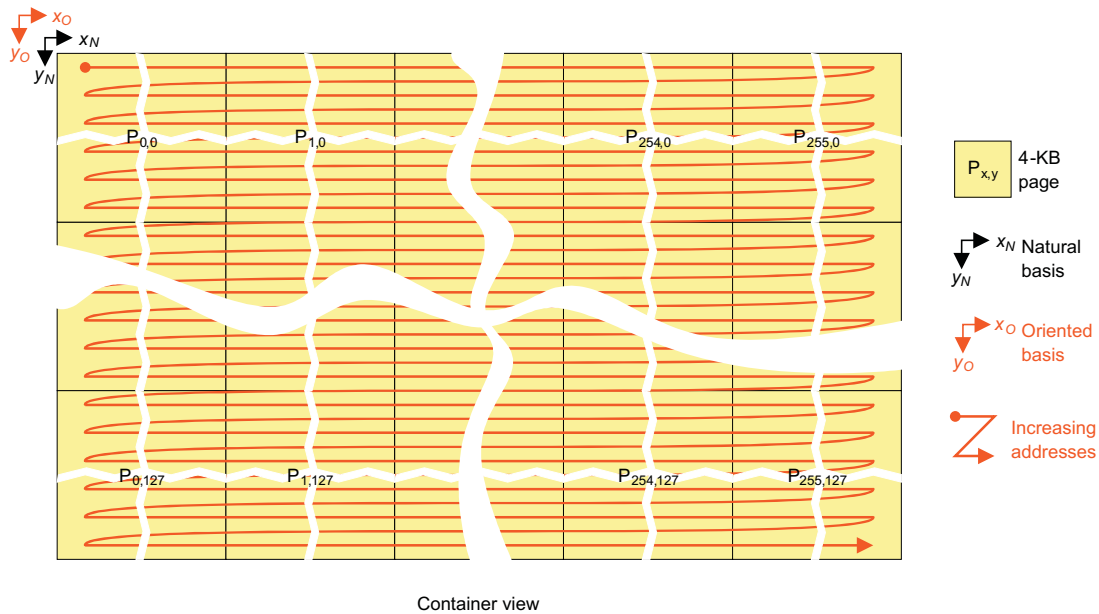

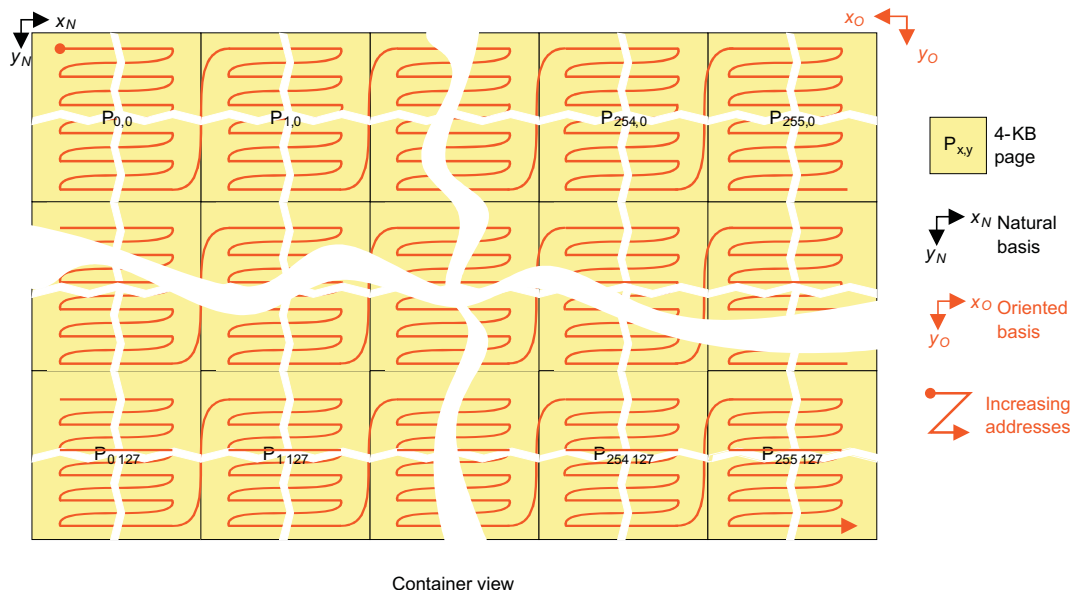

Figure 15-20. Page Mode Ordering of Elements in Natural View

15.2.3.6.1.7.3.2 0-Degree View With Vertical Mirror or 180-Degree View With Horizontal Mirror (Orientation 1)

This orientation defined by $S = 0$, $\bar{Y} = 0$, and $\bar{X} = 1$ and means that the operated change of basis is:

$$\begin{cases} \bar{x}_O = -\bar{x}_N \\ \bar{y}_O = \bar{y}_N \end{cases}$$

sdram-035

In any TILER mode, the elements are then ordered from right to left and then from top to bottom in their container, as shown in Figure 15-21 and Figure 15-22.

Figure 15-21. Tiled Mode Ordering of Elements in 0-Degree View With Vertical Mirror

Figure 15-22. Page Mode Ordering of Elements in 0-Degree View With Vertical Mirror

15.2.3.6.1.7.3.3 0-Degree View With Horizontal Mirror or 180-Degree View With Vertical Mirror (Orientation 2)

This orientation defined by $S = 0$, $\bar{Y} = 1$, and $\bar{X} = 0$ and means that the operated change of basis is:

$$\begin{cases} \bar{x}_O = \bar{x}_N \\ \bar{y}_O = -\bar{y}_N \end{cases}$$

sdram-038

In any TILER mode, the elements are ordered from left to right and then from bottom to top in their container, as shown in Figure 15-23 and Figure 15-24.

Figure 15-23. Tiled Mode Ordering of Elements in 0-Degree View With Horizontal Mirror

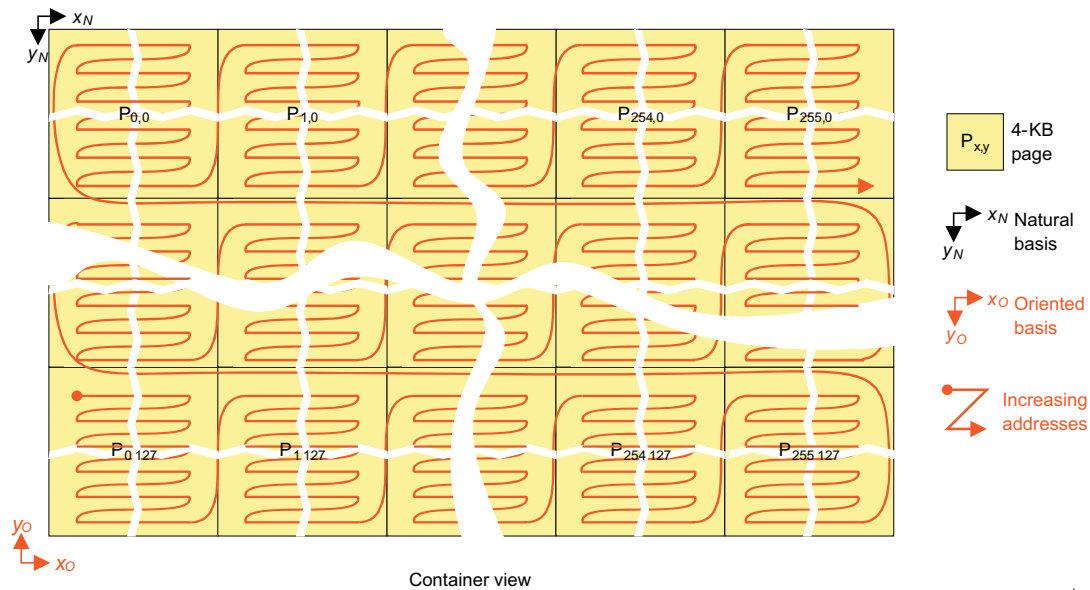

Figure 15-24. Page Mode Ordering of Elements in 0-Degree View With Horizontal Mirror

15.2.3.6.1.7.3.4 180-Degree View (Orientation 3)

This orientation defined by $S = 0$, $\bar{Y} = 1$, and $\bar{X} = 1$ and means that the operated change of basis is:

$$\begin{cases} \vec{x}_O = -\vec{x}_N \\ \vec{y}_O = -\vec{y}_N \end{cases}$$

sdram-041

In any TILER mode, the elements are ordered from right to left and then from bottom to top in their container, as shown in [Figure 15-25](#) and [Figure 15-26](#).

Figure 15-25. Tiled Mode Ordering of Elements in 180-Degree View

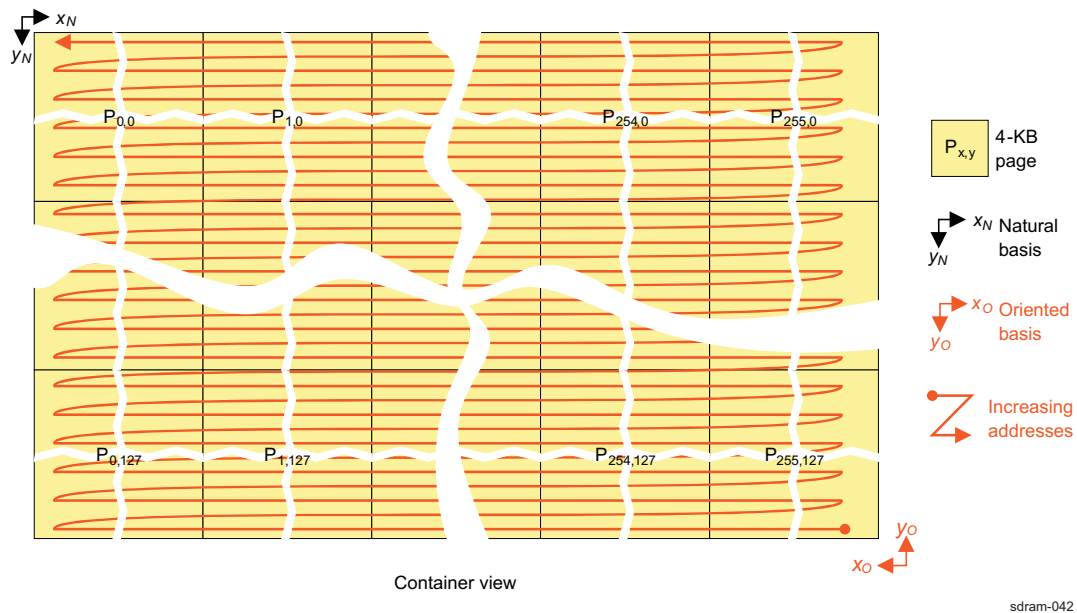

Figure 15-26. Page Mode Ordering of Elements in 180-Degree View

15.2.3.6.1.7.3.5 90-Degree View With Vertical Mirror or 270-Degree View With Horizontal Mirror (Orientation 4)

This orientation defined by $S = 1$, $\bar{Y} = 0$, and $\bar{X} = 0$ and means that the operated change of basis is:

$$\begin{cases} \bar{x}_O = \bar{y}_N \\ \bar{y}_O = \bar{x}_N \end{cases}$$

sdram-044

In any TILER mode, the elements are ordered from top to bottom and then from left to right in their container, as shown in Figure 15-27 and Figure 15-28.

Figure 15-27. Tiled Mode Ordering of Elements in 90-Degree View With Vertical Mirror

Figure 15-28. Page Mode Ordering of Elements in 90-Degree View With Vertical Mirror

15.2.3.6.1.7.3.6 270-Degree View (Orientation 5)

This orientation defined by $S = 1$, $\bar{Y} = 0$, and $\bar{X} = 1$ and means that the operated change of basis is:

$$\begin{cases} \bar{x}_O = \bar{y}_N \\ \bar{y}_O = -\bar{x}_N \end{cases}$$

sdram-047

In any TILER mode, the elements are ordered from top to bottom and then from right to left in their container, as shown in [Figure 15-29](#) and [Figure 15-30](#).

Figure 15-29. Tiled Mode Ordering of Elements in 270-Degree View

Figure 15-30. Page Mode Ordering of Elements in 270-Degree View

15.2.3.6.1.7.3.7 90-Degree View (Orientation 6)

This orientation defined by $S = 1$, $\bar{Y} = 1$, and $\bar{X} = 0$ and means that the operated change of basis is:

$$\begin{cases} \vec{x}_O = -\vec{y}_N \\ \vec{y}_O = \vec{x}_N \end{cases}$$

sdram-050

In any TILER mode, the elements are ordered from bottom to top and then from left to right in their container, as shown in Figure 15-31 and Figure 15-32.

Figure 15-31. Tiled Mode Ordering of Elements in 90-Degree View

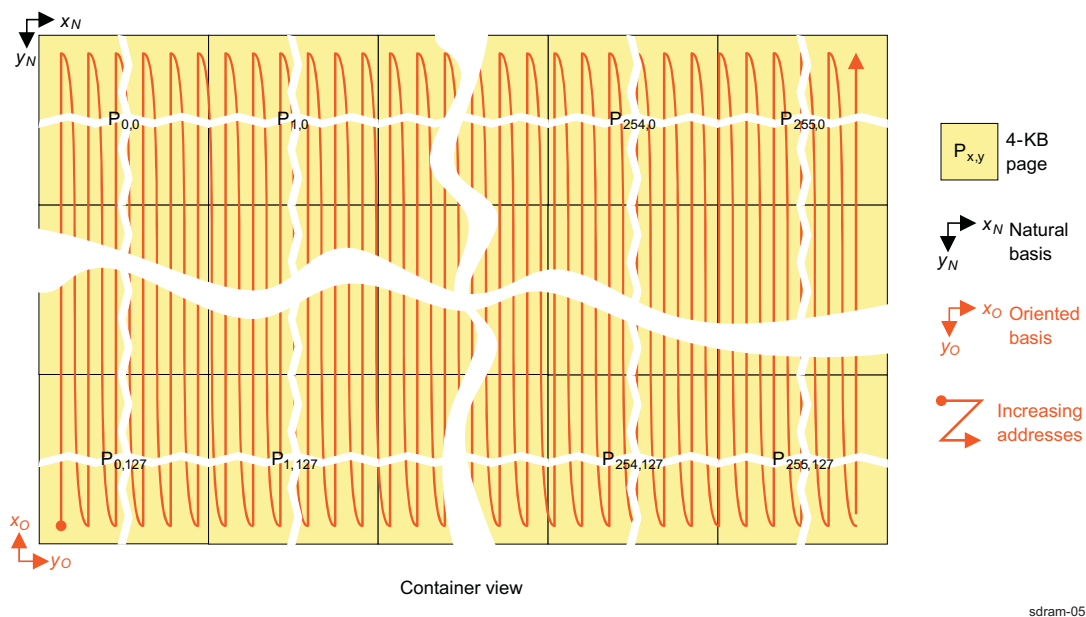

Figure 15-32. Page Mode Ordering of Elements in 90-Degree View

s dram-052

15.2.3.6.1.7.3.8 90-Degree View With Horizontal Mirror or 270-Degree View With Vertical Mirror (Orientation 7)

This orientation defined by $S = 1$, $\bar{Y} = 1$, and $\bar{X} = 1$ and means that the operated change of basis is:

$$\begin{cases} \bar{x}_O = -\bar{y}_N \\ \bar{y}_O = -\bar{x}_N \end{cases}$$

s dram-053

In any TILER mode, the elements are ordered from bottom to top and then from right to left in their container, as shown in [Figure 15-33](#) and [Figure 15-34](#).

Figure 15-33. Tiled Mode Ordering of Elements in 90-Degree View With Horizontal Mirror

s dram-054

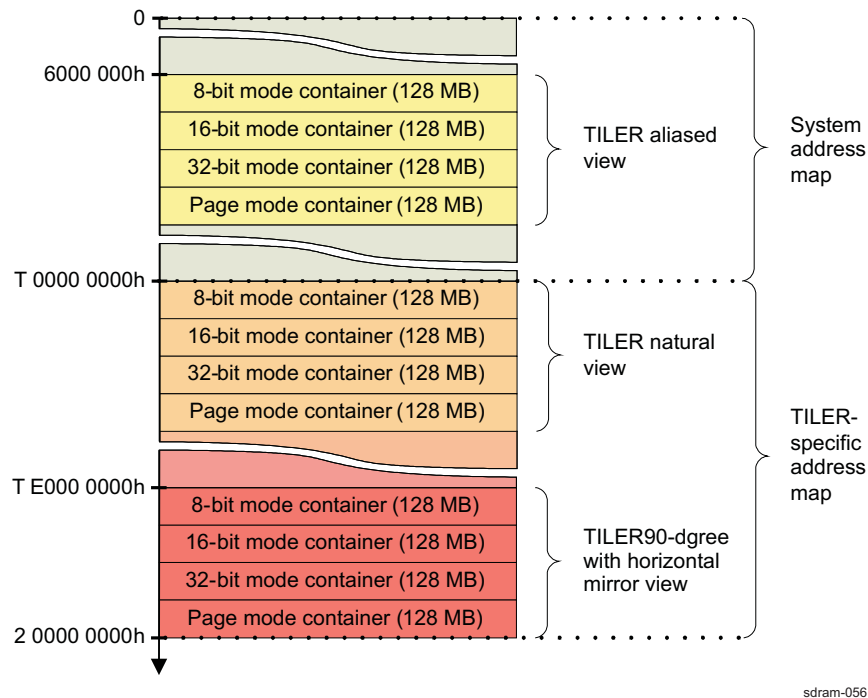

Figure 15-34. Page Mode Ordering of Elements in 90-Degree View With Horizontal Mirror

15.2.3.6.2 TILER Macro-Architecture

The TILER requires a 4-GB addressing space to map its 128-MB physical container in four modes and eight orientations. Because its addressing space alone fills the 4-GB global system address map, the TILER addressing space cannot enter as-is into the system address map. Besides, putting in place a register-based mechanism per initiator to specify the orientation of the following accesses and then reducing the TILER addressing space to a single 512-MB view is not an option; this is because most of the bandwidth-hungry initiators require simultaneous accesses to the TILER container in different views.

As a result, 32 bits are not enough to address all these requests, because the TILER port must convey not only virtually addressed requests to the "oriented" TILER containers but also physically addressed requests to the attached SDRs. A thirty-third address bit is necessary to distinguish the two separated address maps, as shown in Figure 15-35.

Figure 15-35. TILER Port Address Map

Still, having separated systems and TILER-specific address maps is not sufficient. In a system many existing and external IP blocks still rely on a 32-bit address and would then be limited to one or the other 4-GB addressing space. To overcome this limitation, one 512-MB view is aliased in the system address map as (see [Table 15-14](#) and [Figure 15-36](#)).

Table 15-14. TILER Aliased View in the L3 Interconnect Mapping

Start Address (hex)	End Address (hex)	Size
0x6000_0000	0x7FFF_FFFF	512 MB

From all incoming requests, TILER requests are filtered as having an address that fits one of the following:

- The address format in the TILER-specific address map given in [Table 15-15](#), or
- The address format of the aliased view in the system address map given in [Table 15-16](#); other requests are forwarded directly to the SDRC in TILER bypass mode.

Table 15-15. Address Format in the TILER-Specific Address Map

32	31	30	29	28	27	26 ... 4	3 ... 0
T	Orientation			Mode		Virtual address	
1	S	Y	X	M1	M0	A26 ... A4	0

Table 15-16. Address Format of the TILER Aliased View in the System Address Map

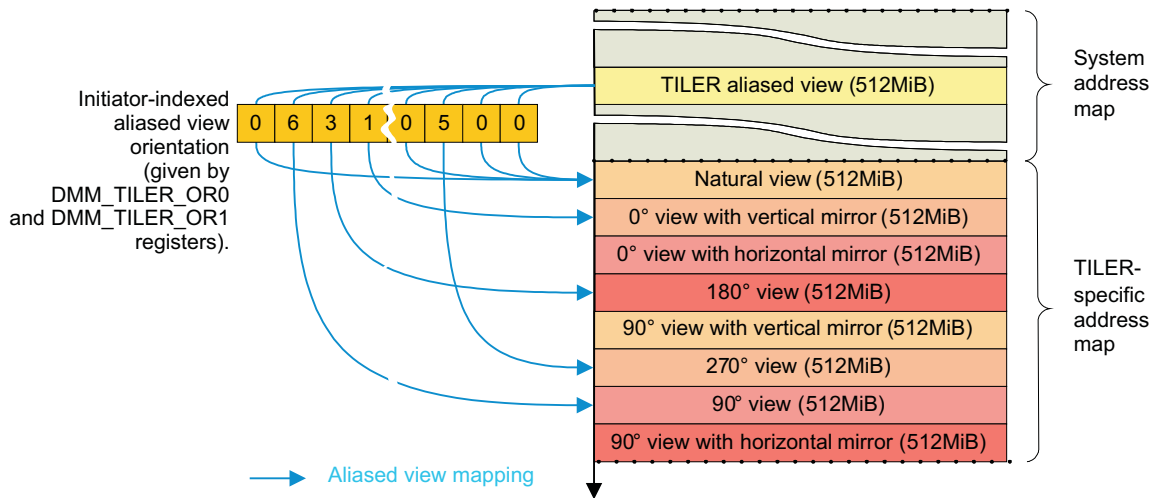

32	31	30	29	28	27	26 ... 4	3 ... 0
T	TILER aliasing			Mode		Virtual address	
0	0	1	1	M1	M0	A26 ... A4	0

In these address formats:

- The thirty-third bit, noted T, is aimed at distinguishing the standard 4-GiB system address map from the 4-GiB TILER-specific address map.
- The orientation bits, noted S, \bar{Y} , and \bar{X} , define the request orientation, as specified in Table 15-12.
- The mode bits, noted M1 and M0, define the request mode, as specified in Table 15-11.
- The remaining 27 bits, noted A0 to A26, define the mode and orientation specific virtual address, as defined in Figure 15-16, Figure 15-17, and Figure 15-18.

The orientation of the aliased TILER view is extracted from an initiator-indexed LUT, as shown in Figure 15-36.

Figure 15-36. TILER Aliased View Orientation

sdram-057

As shown in Figure 15-36, an internal initiator-indexed LUT stores the current orientation of the aliased view for each initiator.

When an interconnect request hits the TILER aliased view in the system address map, the request initiator orientation is extracted from the LUT and the request address is translated according to this orientation: the T bit is set and bits [31:29] are replaced with the orientation.

Regarding the dimensioning of this LUT, given that initiators simultaneously accessing multiple views use the TILER-specific address map, and many initiators do not need to access any view or can be restricted to accessing only the natural view, only a limited number of initiators are likely to dynamically modify the orientation of its aliased TILER view.

The orientation LUT is limited to 16 entries. These 16 orientation entries are mapped on the two 32-bit [DMM_TILER_OR0](#) and [DMM_TILER_OR1](#) registers.

The first eight entries of the LUT are mapped in the [DMM_TILER_OR0](#) register, and the last eight entries are mapped in the [DMM_TILER_OR1](#) register. Therefore, given an index x, the orientation related to this index is given in the ORx field.

Each of these registers is split into eight 4-bit fields, each field mapping an entry of the LUT with:

- An S, \bar{Y} , \bar{X} orientation code on the 3 LSBs
- An \bar{W} field-specific active-low local write-enable bit, always read as 0, on the MSB.

The registers fields that correspond to initiators that do not need any dynamic configuration of their aliased view orientation must be specified as reserved fields, and only written with zeros.

The \bar{W} bit allows the modification of a single entry without requiring a read-modify-write sequence. This approach is then more accommodating:

- In a system where multiple initiators can modify their own fields in the registers
- With initiators unable to make the read-modify-write sequence, such as DMA

Still, the \overline{W} bit is active-low to keep the compatibility with the usual read-modify-write sequence. When reading an aliased view orientation register, because all its \overline{W} bits are read as 0, if these bits are untouched by the modification—as they should be—writing back the modified register updates all orientation fields of the register.

15.2.3.6.3 TILER Guidelines for Initiators

15.2.3.6.3.1 Buffered Raster-Based Initiators

15.2.3.6.3.1.1 Buffer Size

The necessary minimum buffer size depends on the SDRAM prefetch size and on initiator support in terms of the following:

- Element size
- Orientation
- Maximum number of elements per line in all supported element sizes and orientations

Let N be the maximum number of elements per line for a given mode (element size) and orientation, P be the SDRAM memory prefetch size in bytes, and max be the function returning the maximum of the two parameters. The minimum necessary line buffer size to handle all resolutions in a given mode and orientation is listed in [Table 15-17](#).

Table 15-17. Minimum Buffer Size to Efficiently Handle Lines of up to N Elements

	0- or 180- Degree Orientation (S = 0)	90- or 270-Degree Orientation (S = 1)
8-bit mode	4 x N bytes	$max(4, P/4) \times N$ bytes
16-bit mode	None	$max(8, P/2) \times N$ bytes
32-bit mode	None	$max(8, P/2) \times N$ bytes

This minimal buffer size can be reached only with an advanced FIFO management scheme. The standard ping-pong buffer requires twice this buffer size.

NOTE: Given their nature, field accesses to an interlaced frame-buffer require buffers twice as small as in the standard progressive case.

For instance, an initiator that must handle only a single progressive frame-buffer in any orientation of:

- Up to 1920 × 1080 in YUV4:2:0
- Up to 1600 × 1200 in 16-bit RGB565
- Up to 800 × 600 in 32-bit ARGB

requires a line buffer of at least 15,360 bytes because:

- $4 \times 1920 + 4 \times 2960 = 15,360$ bytes required for a 3-plane YUV4:2:0 frame of 1920 × 1080
- $4 \times 1920 + 8 \times 960 = 15,360$ bytes required for a 2-plane YUV4:2:0 frame of 1920 × 1080
- $8 \times 1600 = 12,800$ bytes required for a 16-bit RGB565 frame of 1600 × 1200
- $8 \times 800 = 6400$ bytes required for a 32-bit ARGB frame of 800 × 600

and a line buffer of at least 30,720 bytes when using a simple ping-pong buffer scheme.

15.2.3.6.3.1.2 Performance

[Table 15-18](#) gives the ratio of effective data to transferred data at the external memory interface for buffered raster-based initiators in each mode and orientation, when using an up-to-32-bit DDR, lpDDR, or lpDDR2 SDRAM, or an up-to-16-bit DDR2 memory.

Table 15-18. Memory Data Payload for Buffered Raster-Based Initiators on Up-to-32-Bit DDR, lpDDR, or lpDDR2

	0- or 180-Degree Orientation (S = 0)		90- or 270-Degree Orientation (S = 1)	
	Progressive	Interlaced	Progressive	Interlaced
8-bit mode	100%	100%	100%	50%
16-bit mode	100%	100%	100%	50%
32-bit mode	100%	100%	100%	50%
Page mode	100%	N/A	100%	100%

When using 32-bit DDR, lpDDR, or lpDDR2 SDRAMs, or 16-bit DDR, DDR2, lpDDR, or lpDDR2 memories, whenever all previous guidelines are fulfilled, there is no penalty for these initiators to access a tiled object in any orientation, except for accesses to an interlaced frame in 90- or 270-degree orientation where the memory bandwidth is twice the requested bandwidth.

When using up-to-32-bit DDR, lpDDR, lpDDR2, or up-to-16-bit DDR2 SDRAMs, all accesses, except interlaced accesses in a 90- or 270-degree orientation, are equally efficient and offer the full possible memory bandwidth.

Because of its progressive nature, page mode does not introduce any performance hit.

[Table 15-19](#) lists the ratio of effective data-to-transferred data at the external memory interface for the buffered raster-based initiators in each mode and orientation when using a 32-bit DDR2 or DDR3 memory.

Table 15-19. Memory Data Payload for Buffered Raster-Based Initiators on 32-Bit DDR2 or DDR3

	0- or 180-Degree Orientation (S = 0)		90- or 270-Degree Orientation (S = 1)	
	Progressive	Interlaced	Progressive	Interlaced
8-bit mode	100%	50%	100%	50%
16-bit mode	100%	50%	100%	50%
32-bit mode	100%	50%	100%	50%
Page mode	100%	N/A	100%	100%

When using 32-bit DDR2 or DDR3 SDRAMs, whenever all previous guidelines are fulfilled, there is no penalty for these initiators to access a tiled object in any orientation, except for accesses to an interlaced frame in any orientation where the memory bandwidth is twice the requested bandwidth.

When using DDR2 or DDR3 SDRAMs, all accesses, except interlaced accesses, are equally efficient and offer the full possible memory bandwidth.

Similarly, page mode does not introduce any performance hit.

15.2.4 DMM Use Cases and Tips

15.2.4.1 PAT Use Cases

Five ways to use PAT are:

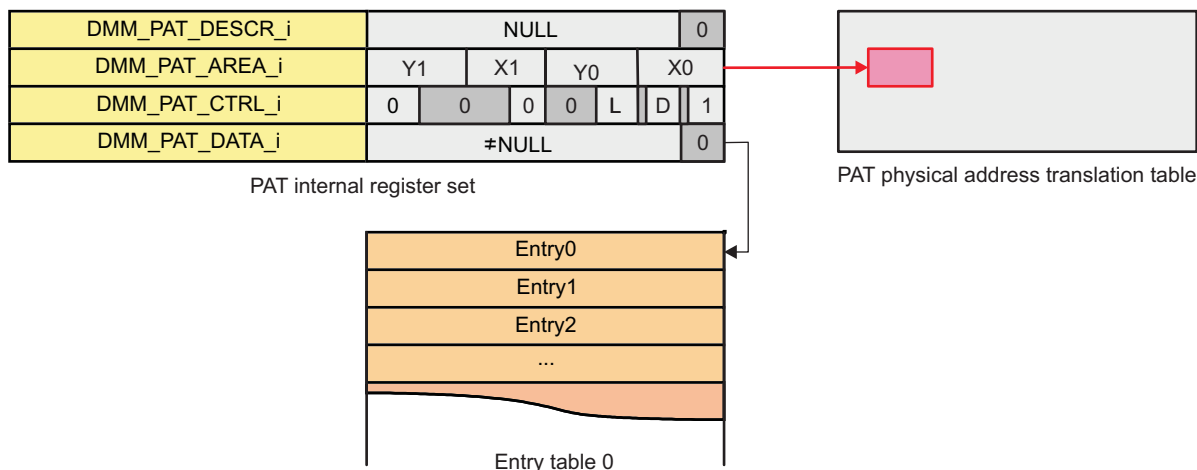

- Simple manual area refill
- Single auto-configured area refill
- Chained auto-configured area refill
- Synchronized auto-configured area refill
- Cyclic synchronized auto-configured area refill

15.2.4.1.1 Simple Manual Area Refill

The following must be performed to create a 16-byte aligned memory-mapped entry table containing all entries of the defined area (see [Figure 15-37](#)):

1. Write the [DMM_PAT_AREA_i](#) register with the relevant (x0, y0) (x1, y1) area definition.
2. Write the [DMM_PAT_DATA_i](#) register with the physical address of the created entry table.
3. Write the [DMM_PAT_CTRL_i](#) register with the requested refill direction and assert the [DMM_PAT_CTRL_i\[0\]](#) START bit with the requested refill direction D and with the LUT ID L if multiple LUTs are present in the system.
4. The refill is done when the [DMM_PAT_STATUS_i\[3\]](#) DONE bit is set.
5. A new refill can be initiated when the [DMM_PAT_STATUS_i\[0\]](#) READY bit is set.

Figure 15-37. Simple Manual Area Refill Scheme

sdram-067

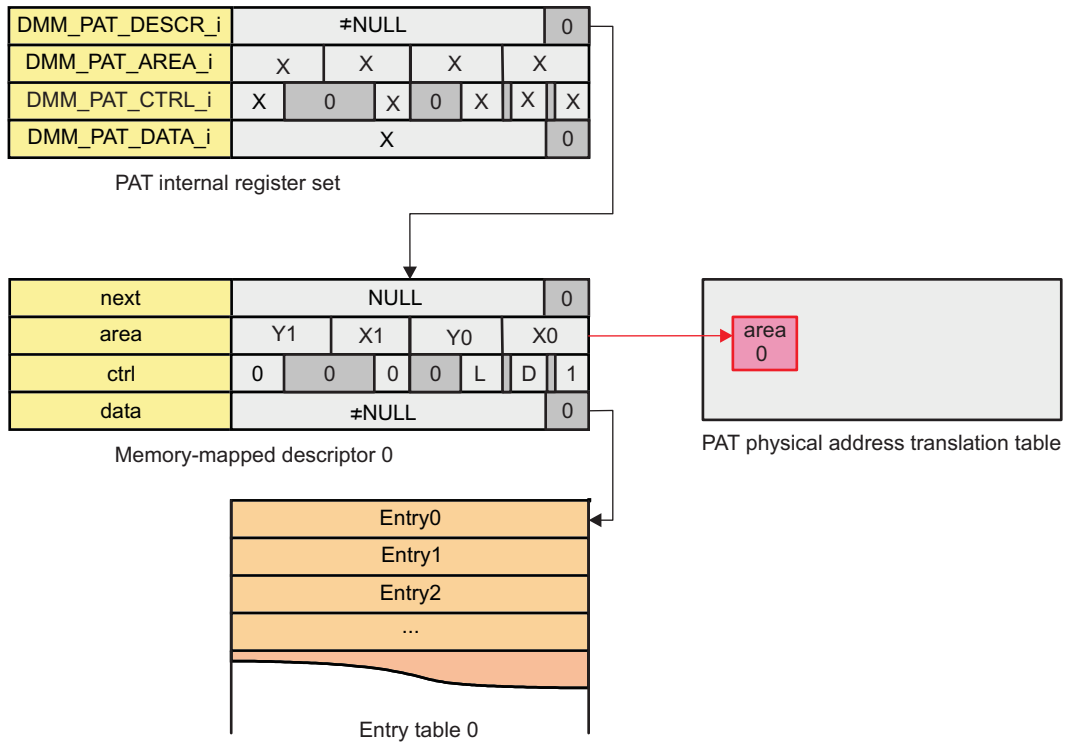

15.2.4.1.2 Single Auto-Configured Area Refill

The following must be performed to create a 16-byte aligned memory-mapped entry table containing all entries of the defined area (see [Figure 15-38](#)):

1. Create a 16-byte aligned memory-mapped descriptor structure where:
 - The next field is set to NULL.
 - The area field is set with the relevant (x0, y0) (x1, y1) area definition.
 - The ctrl field is set with the requested direction D, with the requested LUT ID L if multiple LUTs are present in the system, and the START bit is asserted to start refilling as soon as this descriptor enters the PAT refill engine.
 - The data field is set to the physical address of the created entry table.
2. Write the [DMM_PAT_DESCR_i](#) register with the physical address of the created descriptor.
3. The refill is done when the [DMM_PAT_STATUS_i\[3\]](#) DONE bit is set.

4. A new refill can be initiated when the `DMM_PAT_STATUS_i[0]` READY bit is set.

Figure 15-38. Single Auto-Configured Area Refill Scheme

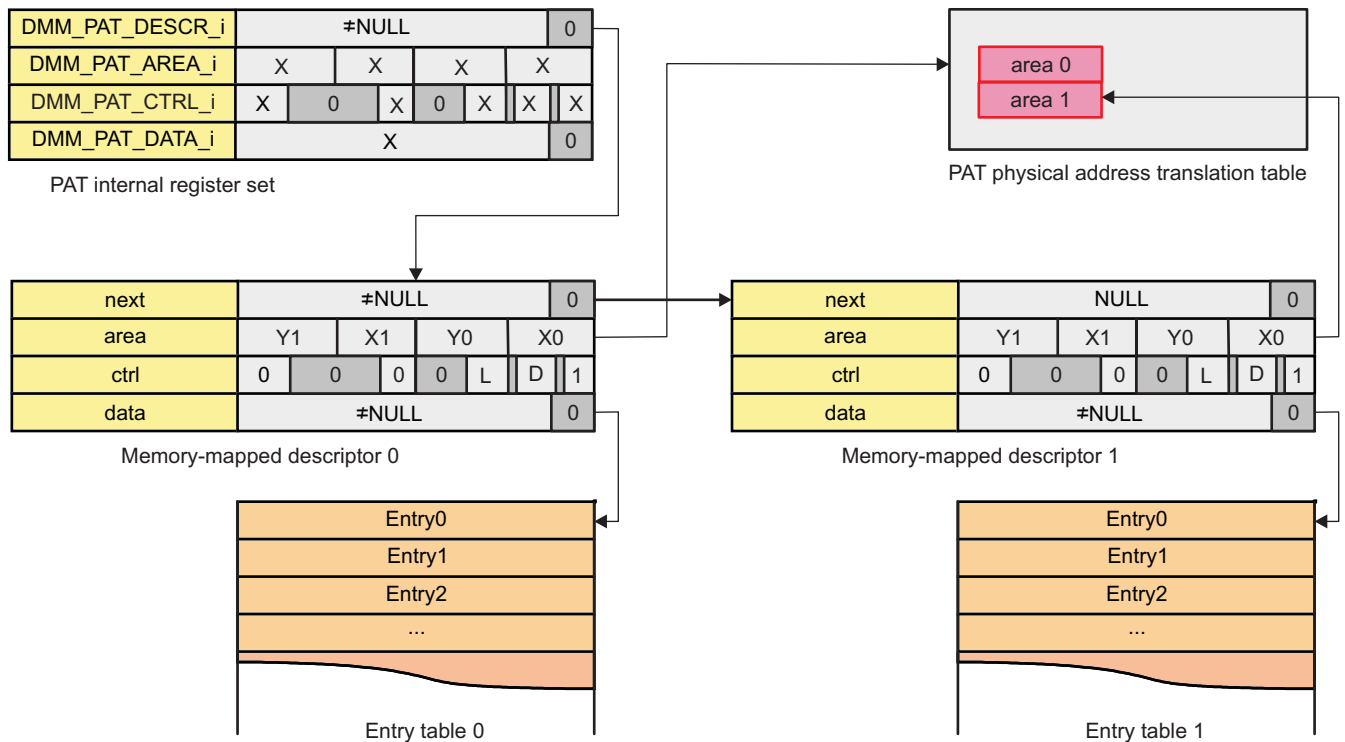

sdram-068

15.2.4.1.3 Chained Auto-Configured Area Refill

The following must be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area (see Figure 15-39):

1. Create one 16-byte aligned memory-mapped descriptor structure per area where:
 - The next field is set to the physical address of the next descriptor or NULL for the last one.
 - The area field is set with the relevant (x0, y0) (x1, y1) area definition.
 - The ctrl field is set with the requested direction D, with the requested LUT ID L if multiple LUTs are present in the system, and the START bit is asserted to start refilling as soon as the previous area refill is done.
 - The data field is set to the physical address of the corresponding entry table.
2. Write the `DMM_PAT_DESCR_i` register with the physical address of the first created descriptor.
3. Each area refill is done when the `DMM_PAT_STATUS_i[3]` DONE bit is set.
4. All area refills are done when the `DMM_PAT_STATUS_i[0]` READY bit is set.
5. A new refill can be initiated when the `DMM_PAT_STATUS_i[0]` READY bit is set.

Figure 15-39. Chained Auto-Configured Area Refill Scheme

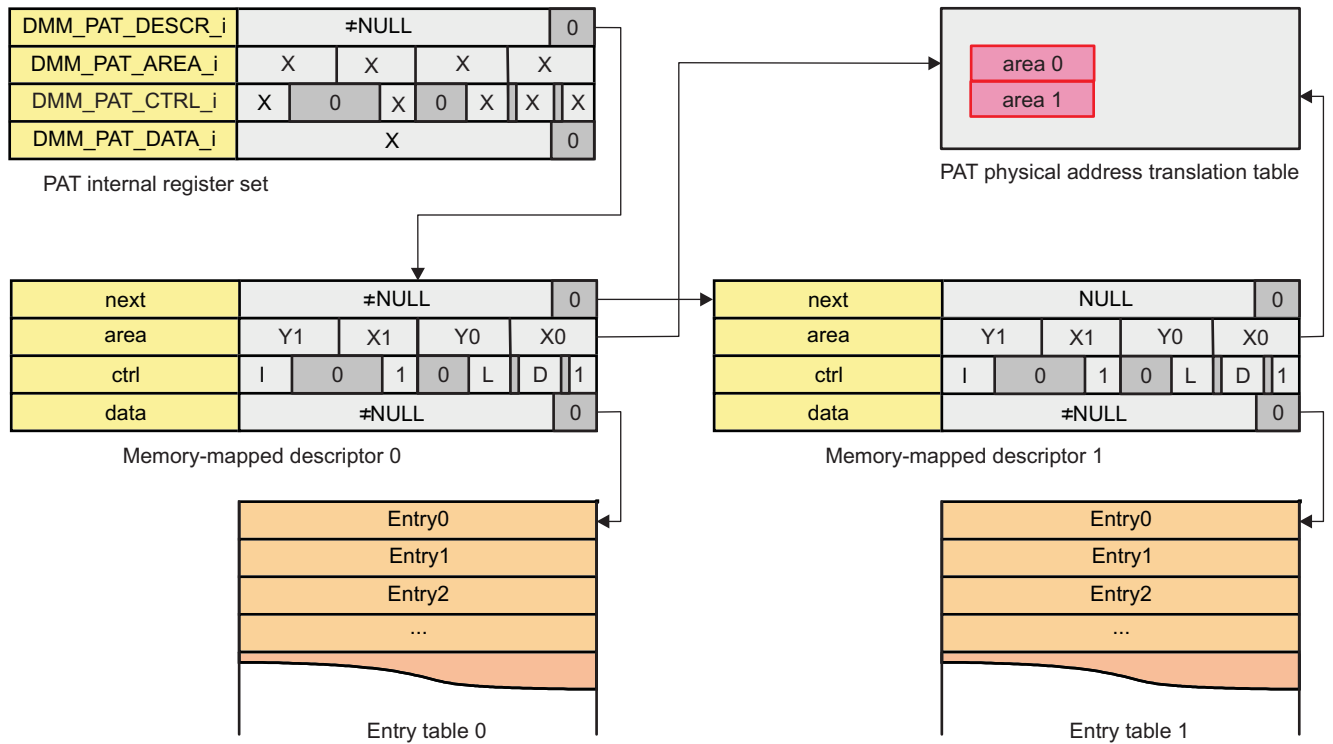

sdram-069

15.2.4.1.4 Synchronized Auto-Configured Area Refill

The following must be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area (see Figure 15-40):

1. Create one 16-byte aligned memory-mapped descriptor structure per area where:
 - The next field is set to the physical address of the next descriptor or NULL for the last one.
 - The area field is set with the relevant (x0, y0) (x1, y1) area definition.
 - The ctrl field is set with the synchronizing initiator identifier I, the SYNC bit is asserted, the requested direction D and the requested LUT ID L if multiple LUTs are present in the system, and the START bit is asserted to start refilling as soon as the previous area refill is done and initiator I has made one access in the previous area.
 - The data field is set to the physical address of the corresponding entry table.
2. Write the `DMM_PAT_DESCR_i` register with the physical address of the first created descriptor.
3. Each area refill is done when the `DMM_PAT_STATUS_i[3]` DONE bit is set.
4. All area refills are done when the `DMM_PAT_STATUS_i[0]` READY bit is set.
5. A new refill can be initiated when the `DMM_PAT_STATUS_i[0]` READY bit is set.

Figure 15-40. Synchronized Auto-Configured Area Refill Scheme

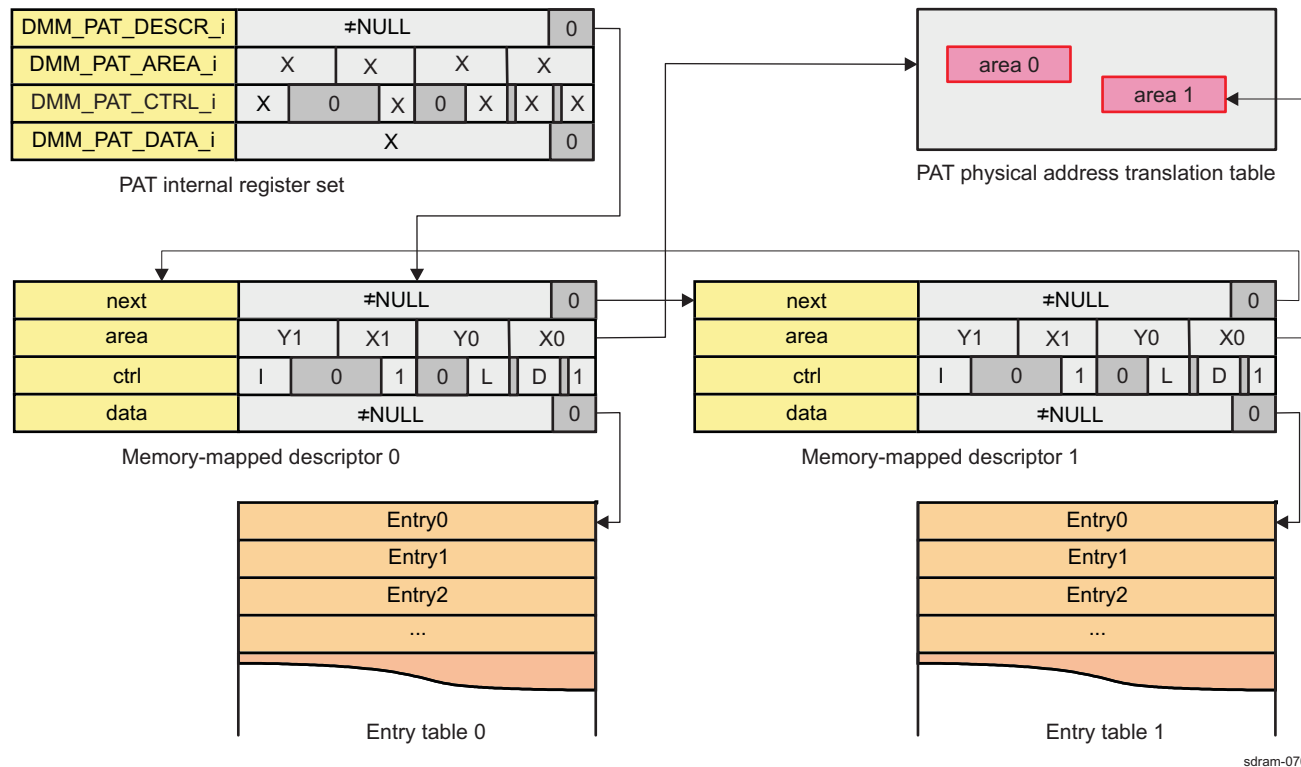

sdr-am-071

15.2.4.1.5 Cyclic Synchronized Auto-Configured Area Refill

The following must be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area (see Figure 15-41):

1. Create one 16-byte aligned memory-mapped descriptor structure per area where:
 - The next field is set to the physical address of the next descriptor in the circular list.
 - The area field is set with the relevant (x0, y0) (x1, y1) area definition.
 - The control field is set with the synchronizing initiator identifier I, the SYNC bit asserted, the requested direction D and requested LUT ID L if multiple LUTs are present in the system, and the START bit is asserted to start refilling as soon as the previous area refill is done and initiator I has made one access in the previous area.
 - The data field is set to the physical address of the corresponding entry table.
2. Write the DMM_PAT_DESCR_i register with the physical address of the initial descriptor.
3. Each area refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. A new refill can be initiated by writing any value to the DMM_PAT_DESCR_i register to abort the current one.

Figure 15-41. Cyclic Synchronized Auto-Configured Area Refill Scheme

sdram-070

NOTE: Never use circular lists of descriptors where all descriptors have the `DMM_PAT_CTRL_i[0]` START bit set and there is no synchronization. This leads to an endless continuous refill.

15.2.4.2 Addressing Management with LISA

15.2.4.2.1 Case 1: Use of One Memory Controller

In this example, assume there is 1 GB of external memory evenly spread onto two address spaces. The address range for address space 0 must start at offset `0x2000_0000` (see [Table 15-20](#)).

Table 15-20. Address Definition

Address Range	Memory Controller	Memory Controller Address Space ⁽¹⁾	Memory Controller Address Range
0x8000_0000 to 0x9FFF_FFFF	EMIF1	0x1	0x0000_0000 to 0x1FFF_FFFF
0xA000_0000 to 0xBFFF_FFFF	EMIF1	0x0	0x2000_0000 to 0x3FFF_FFFF

⁽¹⁾ For memory controller address spaces, see [Section 15.3.4.1.1, L3 Interface](#).

This configuration requires two nonoverlapping sections to be set. They can be defined in any order because there is no concern with priority in this case (see [Table 15-21](#)):

Table 15-21. Configuration

Bit Field	Section 0 (DMM_LISA_MAP_0)	Section 1 (DMM_LISA_MAP_1)
[31:24] SYS_ADDR	0x80	0xA0
[22:20] SYS_SIZE	0x5	0x5
[19:18] SDRC_INTL	0x0 (not applicable)	0x0 (not applicable)

Table 15-21. Configuration (continued)

Bit Field	Section 0 (DMM_LISA_MAP_0)	Section 1 (DMM_LISA_MAP_1)
[17:16] SDRC_ADDRSPC	0x1	0x0
[8] SDRC_MAP	0x1 (only one controller)	0x1 (only one controller)
[7:0] SDRC_ADDR	0x00	0x20

To check whether an address hits a section, use the 8 upper address bits of the address and mask them with the hit mask: $2^8 - 2^{\text{SYS_SIZE}}$. If the result is equal to SYS_ADDR, the section is hit.

To define the physical address to be issued to the memory controller, use the 8 upper address bits of the system address, mask them with the address mask: $2^{\text{SYS_SIZE}} - 1$, and OR them with SDRC_ADDR. This gives the resulting 8 upper physical address bits. All lower address bits are forwarded unchanged.

Request to address 0x99AE_37F0:

- Upper address bits: 0x99
- Hit mask: $2^8 - 2^5 = 0xE0$
- Masked upper address bits: 0x80, that is, hits section 0
- Address mask: $2^5 - 1 = 0x1F$
- Masked upper address bits: 0x19
- OR with SDRC_ADDR: 0x19
- Physical address: 0x19AE_37F0

This request is forwarded to address 0x19AE_37F0, address space 1 of the memory controller.

Request to address 0xB7FF_0340:

- Upper address bits: 0xB7
- Hit mask: $2^8 - 2^5 = 0xE0$
- Masked upper address bits: 0xA0, that is, hits section 1
- Address mask: $2^5 - 1 = 0x1F$
- Masked upper address bits: 0x17
- OR with SDRC_ADDR: 0x57
- Physical address: 0x57FF_0340

This request is forwarded to address 0x57FF_0340, address space 0 of the memory controller.

15.2.4.2.2 Case 2: Use of Two Memory Controllers

In the case of 512 MB interleaved at 128-byte boundaries and 256 MB noninterleaved on the second memory controller, one address space per memory controller, the following results are achieved (see [Table 15-22](#)):

Table 15-22. Address Definition

Address Range	Memory Controller	Memory Controller Address Space ⁽¹⁾	Memory Controller Address Range
0x8000_0000 to 0x9FFF_FFFF	EMIF1 and EMIF2, interleaved at 128-byte boundaries	0x0 on both controllers	0x0000_0000 to 0x0FFF_FFFF on both controllers
0xA000_0000 to 0xAFFF_FFFF	EMIF2 only	0x0	0x1000_0000 to 0x1FFF_FFFF

⁽¹⁾ For memory controller address spaces, see [Section 15.3.4.1.1, L3 Interface](#).

Two sections are used to map such a configuration, see [Table 15-23](#):

Table 15-23. Configuration

Bit Field	Section 0 (DMM_LISA_MAP_0)	Section 1 (DMM_LISA_MAP_1)
[31:24] SYS_ADDR	0x80	0xA0
[22:20] SYS_SIZE	0x5	0x4
[19:18] SDRC_INTL	0x1	0x0 (not applicable)
[17:16] SDRC_ADDRSPC	0x0	0x0
[8] SDRC_MAP	0x3	0x2
[7:0] SDRC_ADDR	0x00	0x10

Detecting a section hit is the same for the interleaved case as for the single controller case: to check whether an address hits a section, use the 8 upper address bits of the address and mask them with the hit mask: $28 - 2^{\text{SYS_SIZE}}$. If the result is equal to SYS_ADDR, the section is hit.

The physical address generation is modified for the interleaved case. In case of 256-byte interleaving, the first chunk of 256 bytes is mapped to the first controller, the second chunk to the second controller, and so on. This results in system address bit 8 to be decoded as the controller indicator, 0 for the first controller, and 1 for the second controller (system address bit 7 is used for interleaving at the 128-byte boundary, and bit 9 for 512 bytes). This bit is not included in the computed physical address, meaning the upper system address bits [31:9] are shifted to bits [30:8] when generating the physical address.

The rest of the address generation is handled the same as for the single controller case: to define the physical address to be issued to the memory controller, use the 8 upper address bits of the system address, mask them with the address mask: $2^{\text{SYS_SIZE}} - 1$, and OR them with SDRC_ADDR. This gives the resulting 8 upper physical address bits. All lower address bits are forwarded unchanged.

Request to address 0x99AE_37F0:

- Upper address bits: 0x99
- Hit mask: $2^8 - 2^5 = 0xE0$
- Masked upper address bits: 0x80, that is, hits section 0
- Address mask: $2^5 - 1 = 0x1F$
- Masked upper address bits: 0x19
- Full masked address: 0x19AE_37F0
- Bit 7 is 1, that is, targets the second memory controller
- Full masked shifted address (suppressing bit 7): 0x0CD7_1BF0 (see [Section 15.2.4.2.2.1](#))
- OR upper physical address bits with SDRC_ADDR: 0x0CD7_1BF0
- Physical address: 0x0CD7_1BF0

This request is forwarded to address 0x0CD7_1BF0, address space 0, of the second memory controller.

15.2.4.2.2.1 Address Upper Bits Shifting

Table 15-24 describes shifting the address upper bits.

Table 15-24. Address Upper Bits Shifting

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Address After Interleaving																																
0	0	0	0	1	1	0	0	1	1	0	1	0	1	1	1	0	0	0	1	1	0	1	1	1	1	1	1	1	0	0	0	0

15.2.5 DMM Basic Programming Model

The programming model section:

- Describes how objects can be addressed in all TILER modes and orientations
- Explains how the physical containers and PAT LUT can be shared between different modes
- Does not give an exhaustive description of the TILER and DMM registers, because these are described in [Section 15.2.3.5, DMM](#), and [Section 15.2.3.6, TILER](#).

15.2.5.1 Global Initialization

This section identifies the requirements for initializing the surrounding modules when the DMM is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the DMM (see [Table 15-25](#)).

Table 15-25. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. See Chapter 3, Power, Reset, and Clock Management .
Dual Cortex - M3 microprocessor unit (MPU)	Cortex-M3 interrupt controller (INTC) configuration must be done to enable the interrupts from the DMM. See Chapter 17, Interrupt Controllers .
Dual Cortex - A9 MPU	Cortex-A9 INTC configuration must be done to enable interrupts from the DMM. See Chapter 17, Interrupt Controllers .
L3 interconnect	Data interface

15.2.5.2 DMM Module Global Initialization

This procedure in [Table 15-26](#) initializes the DMM after a power-on reset (POR).

Table 15-26. DMM Global Initialization

Step	Register/Bit Field/Programming Model	Value
Configure the DMM for smart-idle power management mode.	DMM_SYSCONFIG [3:2] IDLE_MODE	0x2

15.2.5.3 DMM Operational Modes Configuration

15.2.5.3.1 Different Operational Modes

The TILER can be virtually accessed in four different modes: 8-, 16-, 32-bit, and page modes. Each mode defines the element granularity to apply isometric transforms (see [Table 15-27](#)).

Table 15-27. Coding and Description of TILER Modes

Mode	Name	Granularity (Element Size)
0	8-bit tiled mode	8 bits
1	16-bit tiled mode	16 bits
2	32-bit tiled mode	32 bits
3	Page mode	4096 bytes

15.2.5.3.2 Configuration Settings and LUT Refill

The procedure in [Table 15-28](#) provides the configuration settings and LUT refill.

Table 15-28. Configuration Settings and LUT Refill

Step	Register/Bit Field/Programming Model	Value
PAT configuration refill Engine 0	DMM_PAT_CONFIG[0] MODE0	xxx
PAT configuration refill Engine 1	DMM_PAT_CONFIG[1] MODE1	xxx
Set DMM PAT view register value for each initiator.	DMM_PAT_VIEW0 Vx DMM_PAT_VIEW1 Vx	xxx
Set DMM PAT write enable for the initiators.	DMM_PAT_VIEW0 Wx DMM_PAT_VIEW1 Wx	xxx
Choosing container type and access method	DMM_PAT_VIEW_MAP_i	xxx
Define the base address of all view mappings.	DMM_PAT_VIEW_MAP_BASE[31] BASE_ADDR	xxx
Set area definition for DMM physical address translator.	DMM_PAT_AREA_i	xxx
Set physical address of the current table refill entry data or entry data when in manual mode.	DMM_PAT_DATA_i[31:4] ADDR	xxx
Define the direction of this PAT table refill (S Y X), different from 0x011.	DMM_PAT_CTRL_i[6:4] DIRECTION	xxx
Start a PAT table refill.	DMM_PAT_CTRL_i[0] START	0x1

15.2.5.3.3 Interleaving Settings

The procedure in [Table 15-29](#) provides the interleaving settings.

Table 15-29. Interleaving Settings

Step	Register/Bit Field/Programming Model	Value
Set DMM system section address MSB.	DMM_LISA_MAP_i[31:24] SYS_ADDR	xxx
Set DMM system section size.	DMM_LISA_MAP_i[22:20] SYS_SIZE	xxx
Set SDRC interleaving mode.	DMM_LISA_MAP_i[19:18] SDRC_INTL	xxx
Set SDRC address space.	DMM_LISA_MAP_i[17:16] SDRC_ADDRSPC	xxx
Set SDRC mapping.	DMM_LISA_MAP_i[9:8] SDRC_MAP	xxx
Set SDRC address MSB.	DMM_LISA_MAP_i[7:0] SDRC_ADDR	xxx
Enable/disable DMM memory mapping lock.	DMM_LISA_LOCK[0] LOCK	xxx

15.2.5.3.4 Aliased Tiled View Orientation Settings and LUT Refill

The procedure in [Table 15-30](#) provides the settings for aliased tiled view and LUT refill.

Table 15-30. Aliased Tiled View Orientation Settings and LUT Refill

Step	Register/Bit Field/Programming Model	Value
Set DMM TILER orientation for each initiator.	DMM_TILER_OR0 ORx DMM_TILER_OR1 ORx	xxx
Set DMM TILER write enable for the initiators.	DMM_TILER_OR0 Wx DMM_TILER_OR1 Wx	xxx
Define the base address of all view mappings.	DMM_PAT_VIEW_MAP_BASE[31] BASE_ADDR	xxx
DMM PAT initiator for synchronization	DMM_PAT_CTRL_i[31:28] INITIATOR	xxx
Set DMM PAT table reload synchronization.	DMM_PAT_CTRL_i[16] SYNC	xxx
Set DMM PAT LUT index.	DMM_PAT_CTRL_i[9:8] LUT_ID	xxx
Define the direction of this PAT table refill (S Y X).	DMM_PAT_CTRL_i[6:4] DIRECTION	xxx
Start a PAT table refill.	DMM_PAT_CTRL_i[0] START	0x1

15.2.5.3.5 Priority Settings

The procedure in [Table 15-31](#) provides the sequence to set priorities.

Table 15-31. Priority Settings

Step	Register/Bit Field/Programming Model	Value
Set priority for each initiator.	DMM_PEG_PRIO_k Px	xxx
Set write enable for P_PAT field.	DMM_PEG_PRIO_PAT [4] W_PAT	xxx
Set priority for PAT engine.	DMM_PEG_PRIO_PAT [2:0] P_PAT	xxx

15.2.5.3.6 Error Handling

The procedure in [Table 15-32](#) provides the sequence for error handling.

Table 15-32. Error Handling

Step	Register/Bit Field/Programming Model	Value
Enable interrupt for selected type of error.	DMM_PAT_IRQENABLE_SET [15:9] DMM_PAT_IRQENABLE_SET [7:0]	xxx
When interrupt occurs		
Disable type of error to handle.	DMM_PAT_IRQENABLE_CLR [15:9] DMM_PAT_IRQENABLE_CLR [7:0]	xxx
Check error status.	DMM_PAT_IRQSTATUS [15:9] DMM_PAT_IRQSTATUS [7:0]	xxx

15.2.5.3.7 PAT Programming Model

The PAT maps the tiled data anywhere in the 4-GB physical address range, with a PAGE granularity. (The TILER page is the granularity of physical memory allocation in the TILER container. Each page is 4kiB).

A PAT view defines the kind of PAT to perform for each page, 8-, 16-, and 32-bit mode access. Each mode in each PAT view can be programmed in two different modes: direct translation and indirect translation.

15.2.5.3.7.1 PAT in Direct Translation Mode

In this mode, the PAT performs a translation of the 128-MB virtual container as a whole in the physical address space (that is, in the SDRAM). This mode is used only for debug or in case of a DMM without a PAT.

15.2.5.3.7.2 PAT in Indirect Translation Mode

This is the most commonly used mode. In this mode, the PAT performs a translation of each 4-KB page individually. In this way the 128-MB virtual address space can be scattered in the whole 2GB of the physical address space. This is achieved by using a 32,678-word LUT that converts each page index (32,768 possible values) into 19 address bits that represent this page address in the physical memory. The main characteristic of this mode is there is no constraint on the use of the physical memory except that it uses a multiple of 4-KB areas located at 4-KB boundaries in the physical memory. In this mode, the translation vector is in the internal 32-k entry PAT vector table at the index given by bits [26:12] of the input virtual address, and CONT_x = 0.

Programming sequence:

1. Set the [DMM_PAT_VIEW0](#) register (or [DMM_PAT_VIEW1](#), depending on the L3 CONN_ID of the initiator that is to perform the tiled accesses) with the appropriate value. For example, if the L3 CONN_ID equals 0, then the [DMM_PAT_VIEW0](#) register must be programmed with the value 0x0000_0001 (PAT view 1 selected for initiator 0).
2. Set [DMM_PAT_VIEW_MAP_BASE](#)[31] = 0x8000_0000 (must always be programmed at 1 to select the upper 2GB of the physical address space that corresponds to the external memory).

- Set all 16-bit tiled accesses in indirect translation mode by setting at least the field ACCESS_16 to 1 (DMM_PAT_VIEW_MAP_1 = 0x0000_8000), program DMM_PAT_VIEW_MAP_1 at 0x8080_8080.

15.2.5.4 Addressing an Object in Tiled Mode

This section describes how a frame-buffer with a top-left pixel at (x0,y0) in the natural view container and a bottom right pixel at (x1,y1) in the natural view container is addressed in any tiled mode and orientation.

15.2.5.4.1 Frame-Buffer Addressing

NOTE: In this section, the (x,y) coordinates are given in pixel units.

Given an (S, \bar{Y} , \bar{X}) orientation, the (x,y) coordinates of the first pixel of the frame in the oriented view (where W = the width and H = the height in pixels of the container in the considered frame mode) is:

(x,y) = (x_{or}, y_{or}) when S, (y_{or}, x_{or}) otherwise
with:

x_{or} = x₀ when \bar{X} , W-1-x₁ otherwise
y_{or} = y₀ when \bar{Y} , H-1-y₁ otherwise

Given a (M₁, M₀) TILER mode where M₁ ≠ 0 or M₀ ≠ 0, the size in bytes of a pixel is 2^{2M₁+M₀}.

Therefore, given an (S, \bar{Y} , \bar{X}) orientation and a n(M₁, M₀) TILER mode where M₁ ≠ 0 or M₀ ≠ 0, the byte offset of the base address of the considered oriented frame in its container is:

base_address((x₀, y₀), (x₁, y₁), (S, \bar{Y} , \bar{X}), (M₁, M₀)) = (y_{or}W + x_{or}) P₅ when S, (x_{or}H + y_{or}) P₅ otherwise
with:

x_{or} = x₀ when \bar{X} , W-1-x₁ otherwise
y_{or} = y₀ when \bar{Y} , H-1-y₁ otherwise
P₅ = 2^{2M₁+M₀}

In its natural orientation, the TILER container consists of 8192 lines of 16,384 pixels of 8 bits, or 4096 lines of 16,384 pixels of 16 bits, or 4096 lines of 8192 pixels of 32 bits.

Figure 15-42. Example of 8-Bit Frame-Buffer Addressing in any Orientation

sdram-075

This frame-buffer address generation is independent from the page size. For instance, the 8-bit frame-buffer shown in Figure 15-42 that ranges from the top-left pixel at (16, 32) to the bottom-right pixel at (223, 159) in the natural orientation view, corresponds to the 29-bit view address offsets and full 33-bit TILER addresses given in Table 15-33.

Table 15-33. 29-Bit View Address Offset and 33-Bit Full TILER Address for an 8-Bit Frame-Buffer

S	Y	X	x _{or}	y _{or}	29-Bit Address Offset in View	Full 33-Bit TILER Address
0	0	0	16	32	00080010h	100080010h
0	0	1	16,160	32	00083F20h	120083F20h
0	1	0	16	8032	07D80010h	147D80010h
0	1	1	16,160	8032	07D83F20h	167D83F20h
1	0	0	16	32	00020020h	180020020h
1	0	1	16,160	32	07E40020h	1A7E40020h
1	1	0	16	8032	00021F60h	1C0021F60h
1	1	1	16,160	8032	07E41F60h	1E7E41F60h

In this example the TILER is addressed in 8-bit mode, which translates to addresses with all mode bits (bits 27 and 28) cleared in the 29-bit address offset in view and in the full 33-bit TILER address.

15.2.5.4.2 TILER Page Mapping

Let:

- c (c = 0, 1, or 2) be the TILER page configuration (0 for 4-KB pages, 1 for 16-KB pages, and 2 for 64-KB pages)
- (x₀, y₀) be the top-left pixel and (x₁, y₁) be the bottom-right pixel of a frame in its natural orientation
- W be the width and H the height in pixels of the container in the considered frame mode

The top-left page coordinates (P_{x0}, P_{y0}) and bottom-right page coordinates (P_{x1}, P_{y1}) that correspond to the frame are given by: P_{x0} = (64·x₀·2^{2-c}) / W, P_{y0} = (32·y₀·2^{2-c}) / H, P_{x1} = (64·x₁·2^{2-c}) / W and P_{y1} = (32·y₁·2^{2-c}) / H.

In its natural orientation, the TILER container consists of 8192 lines of 16,384 pixels of 8 bits, or 4096 lines of 16,384 pixels of 16 bits, or 4096 lines of 8192 pixels of 32 bits.

NOTE: The page area type has the same structure as the [DMM_PAT_AREA_i](#) registers. For instance, the 8-bit frame-buffer described in [Figure 15-42](#) and ranging from the top-left pixel at (16, 32) to the bottom-right pixel at (223, 159) in the natural orientation view, is mapped from the top-left page at P0,0 to the bottom-right page P3,2.

15.2.5.5 Addressing an Object in Page Mode

In page mode, the orientation modifies only the sequence of accessed pages, not their content. In this respect the orientation must be seen as a way to optimize the one-dimensional (1D) object allocation in a TILER container by allowing a 1D object spanning multiple pages to map a set of adjacent pages in any direction. For instance, a 1.25-MB object, mapped on 320 pages of 4-KB can be allocated in a TILER container in any of the eight orientations (see [Section 15.2.3.6.1.7.3, Element Ordering in the TILER Container](#)).

The initial page can be chosen freely among all pages. In this respect, the address offset of a page in a TILER container is expressed as:

Let:

- c (c = 0, 1 or 2) be the TILER page configuration (0 for 4-KB pages, 1 for 16-KB pages, and 2 for 64-KB pages)
- (S, Y, X) be the orientation of the considered 1D object in page mode
- (P_x, P_y) be the coordinate of the initial page in the natural orientation view

The byte offset of the base address of the considered initial page in its oriented container is:

base_address((P_x, P_y), (S, Y, X)) = 4096·(64·y_{or}·2^{2-c} + x_{or})·2^{2-c} when S, 4096·(32·x_{or}·2^{2-c} + y_{or})·2^{2-c} otherwise

with:

x_{or} = P_x when X, 64·2^{2-c} - 1 - P_x otherwise

y_{or} = P_y when Y, 32·2^{2-c} - 1 - P_y otherwise

For instance, a 1D object starting from the page P32,63 in the natural orientation view on a DMM using 4-KB pages, corresponds to the 29-bit view address offsets and full 33-bit TILER addresses given in [Table 15-34](#).

Table 15-34. 29-Bit View Address Offset and 33-Bit Full TILER Address for a 1D Object

S	Y	X	x _{or}	y _{or}	29-Bit Address Offset in View	Full 33-Bit TILER Address
0	0	0	32	63	1BF20000h	11BF20000h
0	0	1	223	63	1BFDF000h	13BFDF000h
0	1	0	32	64	1C020000h	15C020000h
0	1	1	223	64	1C0DF000h	17C0DF000h
1	0	0	32	63	1903F000h	19903F000h
1	0	1	223	63	1EFBF000h	1BEFBF000h
1	1	0	32	64	19040000h	1D9040000h
1	1	1	223	64	1EFC0000h	1FEFC0000h

In this example the TILER is addressed in page mode, which translates to addresses with mode bits (bits 27 and 28) set in the 29-bit address offset in view and full 33-bit TILER address.

15.2.5.6 Sharing Containers Between Different Modes

When allocating objects in TILER containers, take care to ensure that no two objects physically overlap.

In this respect, and to ease the object allocation and deallocation, it is strongly advised to share a TILER page only for different objects that do both of the following:

- Belong to the same mode
- Have the same lifetime (that is, are allocated and deallocated simultaneously)

Two objects of different modes can physically overlap if:

- One physical page is mapped twice in two different locations of the DMM LUT.
- The two objects share the DMM LUT and the intersection of their two page set is not empty.

These two issues can be easily avoided by allocating a physical page only once in the DMM LUT.

The second issue is a bit more difficult, especially if the allocation of objects in the various TILER containers must be dynamic. Managing the fragmentation within a flat memory model in a space-constrained system is not straightforward, and is the main reason for the existence of MMUs in most current processors, which adds yet another constraint to the problem (the y dimension, which makes it even more difficult).

Returning to the CPU-analogy, the memory fragmentation issue has been mostly solved by using a virtual memory space larger than the actual physical memory space and a virtual-to-physical translation system. This allows contiguous virtual memory allocation when sufficient physical memory is available and the larger contiguous physical buffer is smaller than the requested memory allocation.

Similarly, the DMM answer to this object allocation in the TILER containers is two-fold:

- The DMM must have sufficient virtual address space in all modes to permit a static allocation of a pool of virtual buffers in all TILER modes for all TILER-aware initiators.
- Each TILER-aware initiator must dynamically manage its own pool of virtual buffers.

15.2.6 DMM Register Manual

This section provides information about the DMM registers. [Table 15-35](#) describes the DMM instance.

15.2.6.1 DMM Instance Summary

15.3 EMIF Controller

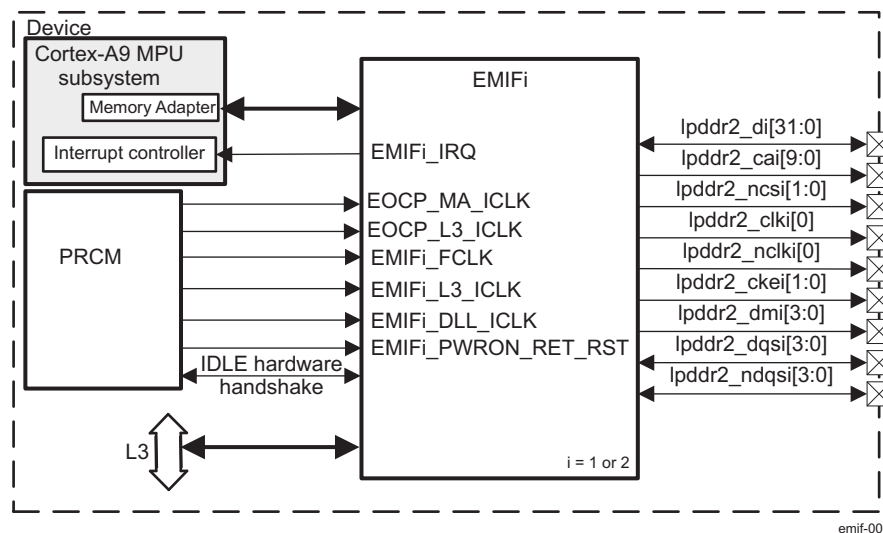

This section describes the features and functions of the external memory interface (EMIF) module of the device.

15.3.1 EMIF Module Overview

The EMIF module provides connectivity between the device and the LPDDR2-type memories and manages data bus read/write accesses between external memories, the microprocessor unit (MPU), and the direct memory access (DMA) controller.

The device includes two EMIF controllers. [Figure 15-43](#) is an overview of the EMIF module.

Figure 15-43. EMIF Module Overview

15.3.1.1 EMIF Module Main Features

The EMIF module supports the following features:

- JEDEC standard-compliant LPDDR2-SDRAM (S2 and S4) devices
- 2-GB SDRAM address ranges over two chip-selects (CSs) (1GB per CS) (configurable with the dynamic memory manager (DMM) module; see [Section 15.2, Dynamic Memory Manager](#), for more information)
- Two independent CSs with their corresponding register sets and independent page tracking
- Both CSs must have the same memory type and size.
- Flexible address muxing scheme, which permits the choosing of different bank mapping allocation by configuring the decoding order of the bank, column, and row address
- 16- or 32-bit data path to external SDRAM
- LPDDR2 devices with one, two, four, or eight internal banks
- Data bus widths:
 - 128-bit L3 interconnect data bus width
 - 16- and 32-bit SDRAM data bus widths
- CAS latencies: 3, 4, 5, 6, 7, and 8
- 256-, 512-, 1024-, and 2048-word page sizes
- Burst lengths: 8
- Sequential burst type
- SDRAM auto initialization from reset or configuration change
- Bank interleaving across both CSs if the same memory type

- Self-refresh and precharge power-down modes for low power (per CS, manual entry/exit self-refresh and deep power-down modes)
- Deep power-down mode for low power
- Partial array self-refresh and temperature-controlled self-refresh modes for low power. Temperature-controlled self-refresh is supported only for mobile SDRAM having on-chip temperature sensor.
- Prioritized refresh
- Programmable SDRAM refresh rate and backlog counter
- Output impedance (ZQ) calibration
- Active power-down
- Temperature monitoring

15.3.1.2 Not Supported Features

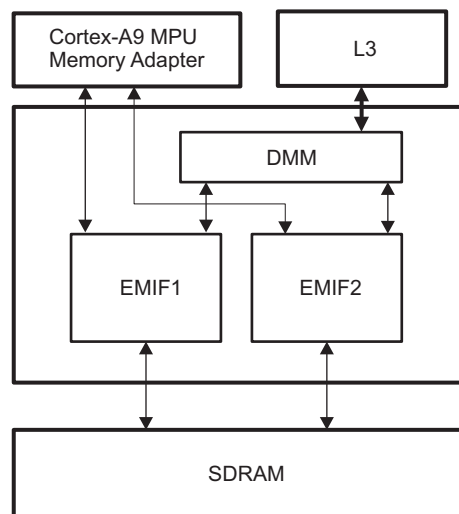

The EMIF module does not support:

- Interleave burst type
- Auto precharge
- Per-bank refreshes for LPDDR2-SDRAM

15.3.1.3 EMIF Overall Architecture

Figure 15-44 shows the EMIF connection with the surrounding modules.

Figure 15-44. EMIF Overall Architecture

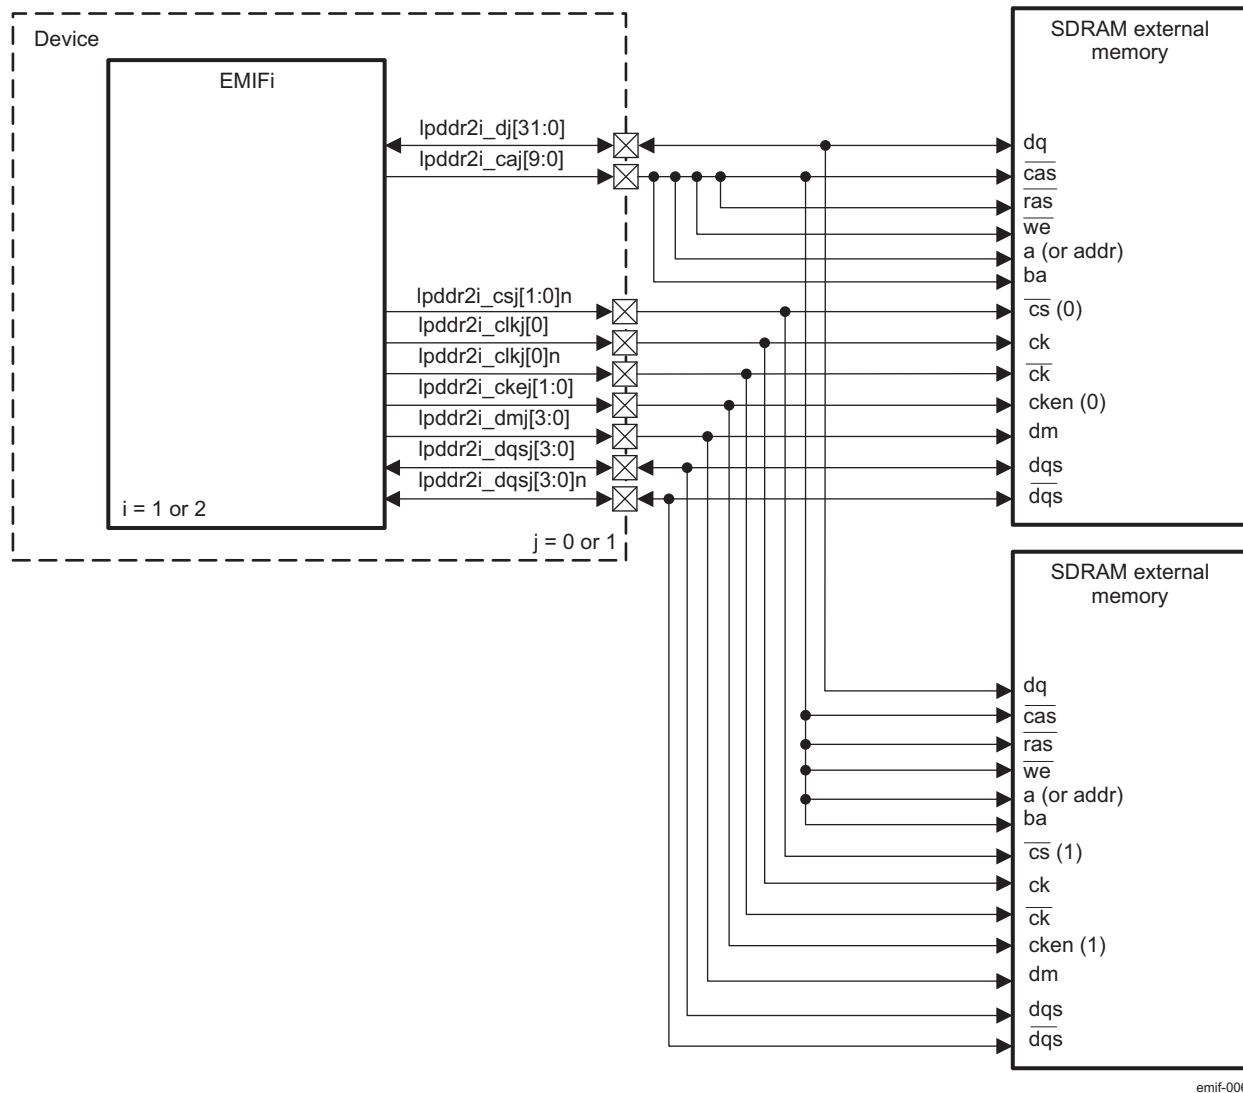

emif-007

15.3.2 EMIF Environment

This section describes the EMIF application fields from an environment point of view (external connections).

Figure 15-45 shows the EMIF generic configuration.

Figure 15-45. EMIF Generic Configuration

emif-006

15.3.2.1 EMIF Signals

Table 15-93 describes the module signals and specifies their links to functions.

Table 15-93. I/O Signals

Signal	I/O ⁽¹⁾	Description
EMIF1		
lpddr21_dq[31:0]	I/O	Data bus
lpddr21_ca[9:0]	O	Double-data rate (DDR) command/address
lpddr21_ncs[1:0]	O	Chip selects 1–0 (active low)
lpddr21_clk	O	Clock
lpddr21_nclk	O	Clock invert
lpddr21_cke[1:0]	O	Clock enables 1–0
lpddr21_dm[3:0]	I/O	Data mask
lpddr21_dqs[3:0]	I/O	Data strobe
lpddr21_ndqs[3:0]	I/O	Data strobe invert

⁽¹⁾ I = Input; O = Output

Table 15-93. I/O Signals (continued)

Signal	I/O ⁽¹⁾	Description
EMIF2		
lpddr22_dq[31:0]	I/O	Data bus
lpddr22_ca[9:0]	O	DDR command/address
lpddr22_ncs[1:0]	O	Chip selects 1–0 (active low)
lpddr22_clk	O	Clock
lpddr22_nclk	O	Clock invert
lpddr22_cke[1:0]	O	Clock enables 1–0
lpddr22_dm[3:0]	I/O	Data mask
lpddr22_dqs[3:0]	I/O	Data strobe
lpddr22_ndqs[3:0]	I/O	Data strobe invert

The CKE memory pin is dynamically driven by the SDRAM controller (SDRC) according to the memory interface activity. Each CS has its own CKE pin so that each CS can be controlled independently in terms of power-down, deep power-down, and self-refresh modes.

Each LPDDR2 channel (that is, each EMIF controller) can be connected to two external LPDDR2 memories. For more information, see [Section 15.2, Dynamic Memory Manager](#).

15.3.3 EMIF Integration

This section describes the integration of the module in the device, and includes information about clocks, resets, and hardware requests.

Figure 15-46 shows the integration of the EMIF1 module in the device.

Figure 15-46. EMIF1 Integration

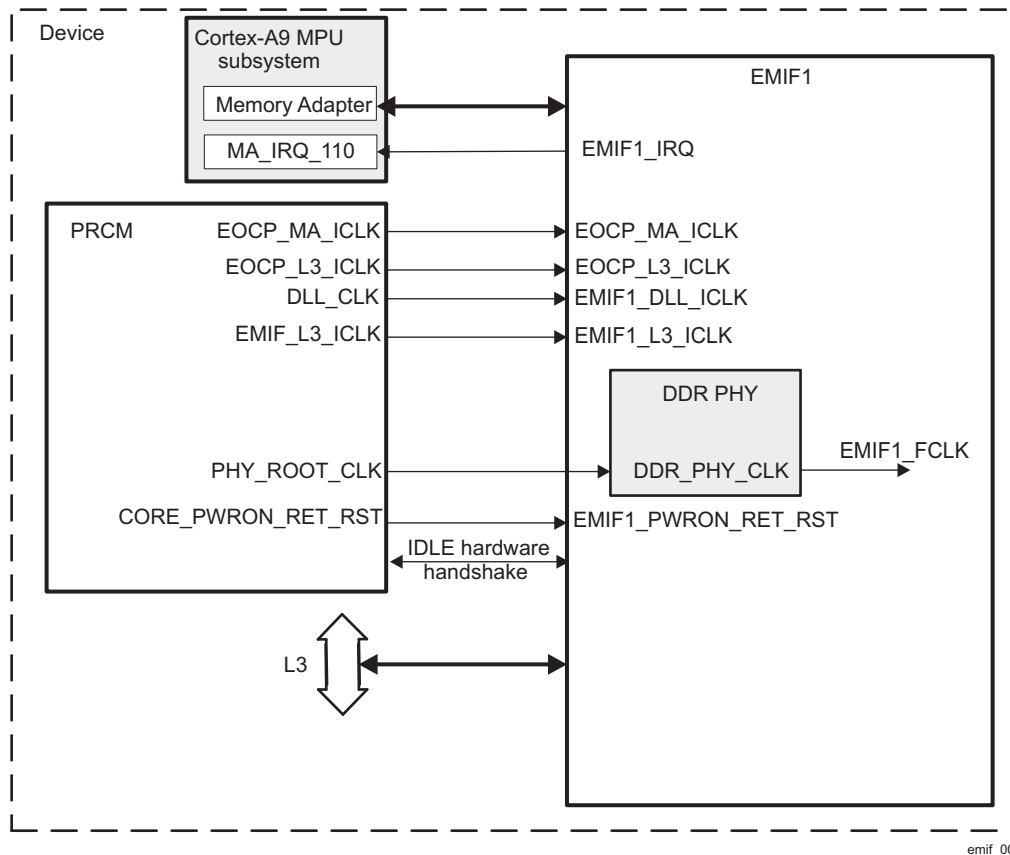

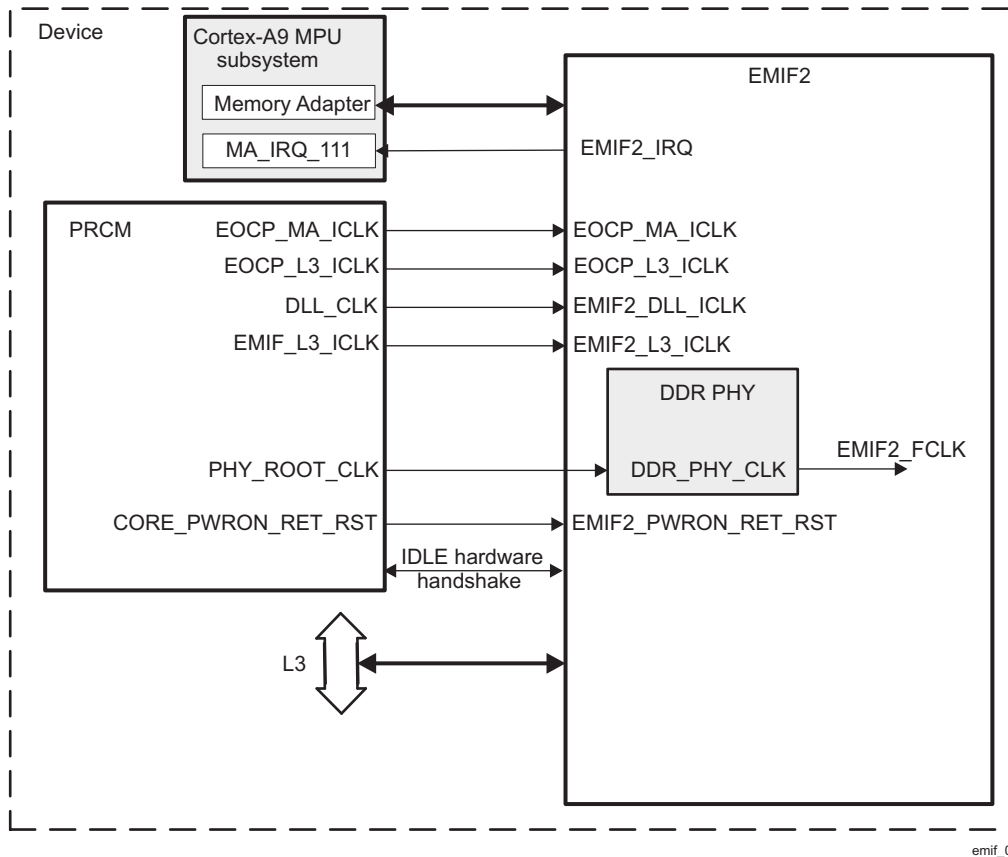

Figure 15-47 shows the integration of the EMIF2 module in the device.

Figure 15-47. EMIF2 Integration

emif_004

NOTE: DDR_PHY_CLK is equal to PHY_ROOT_CLK divided by 2. EMIFi_FCLK is equal to DDR_PHY_CLK divided by 2.

For more information about the EMIF clocking scheme, see [Chapter 3, Power, Reset, and Clock Management](#).

NOTE: For more information about the IDLE hardware handshake, see [Chapter 3, Power, Reset, and Clock Management](#).

Table 15-94 through Table 15-96 summarize the integration of the module in the device.

Table 15-94. Integration Attributes

Module Instance	Attributes

No DMA Requests				

NOTE: For the description of the interrupt source, see [Section 15.3.4.5, Interrupt Requests](#).

15.3.4 EMIF Functional Description

15.3.4.1 Block Diagram

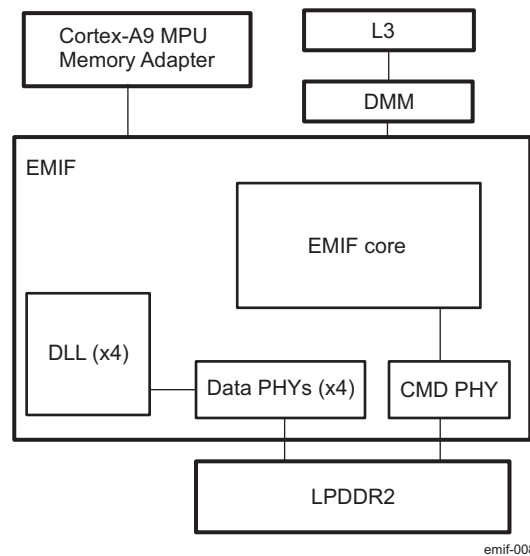

The EMIF is an L3 bus peripheral that provides an interface to the LPDDR2 memories.

Figure 15-48 shows the interconnection between the EMIF module and the other modules.

Digital locked loops (DLLs) are used to delay the input DQS signals during reads so that these strobe signals can be used to latch incoming data on the DQ pins, as required by the LPDDR2 standard.

Physical layers (PHYS) are hard macros that convert single-data rate (SDR) signals to DDR signals.

Figure 15-48. EMIF Block Diagram

15.3.4.1.1 L3 Interface

The EMIF supports three local interfaces: one connects to the system interconnect, one to a low-latency master, and one comes from the MPU half of the EMIF-to-MPU connection. These interfaces are used to request all external memory device accesses, to access the EMIF registers, and to transfer all data to and from the EMIF controller. Table 15-97 shows the MAddrSpace mapping to different chip-selects. A third interface arranges the connection between the EMIF and the MPU. It is separated to the MPU half of the EMIF-to-MPU L3 Interface and the EMIF half of the EMIF-to-MPU L3 Interface.

Table 15-97. MAddrSpace Mapping to Chip-Selects

MAddrSpace ⁽¹⁾	Chip-Select	Description	Exclusions
0x0	ICS[1:0]	SDRAM(s)	
0x1	CS1	Reserved for LPDDR2-NVM	
0x2	N/A	Reserved	Not visible to the MA port
0x3	N/A	Internal registers	Not visible to the MA port

⁽¹⁾ See DMM_LISA_MAP_i [17:16] SDRC_ADDRSPC register in Section 15.2, Dynamic Memory Manager.

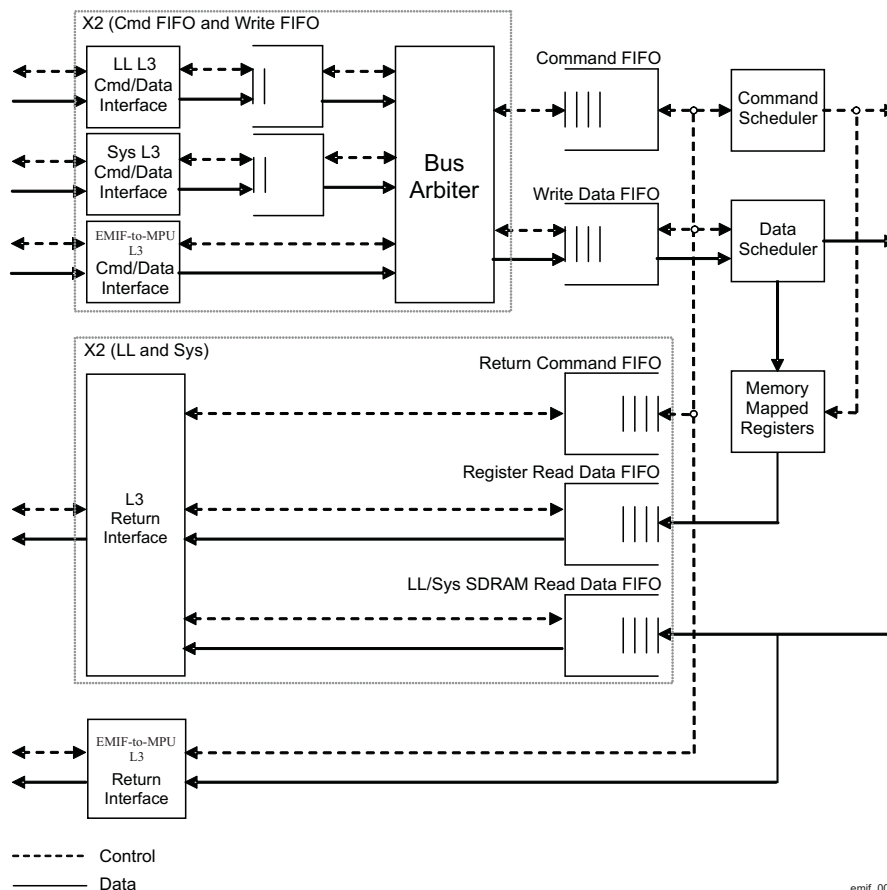

15.3.4.1.2 FIFO Description

The EMIF module contains the following FIFOs:

- Command FIFO
- Write data FIFO
- Return command FIFO
- Two read data FIFOs

Figure 15-49 shows the overall architecture of the EMIF module.

Figure 15-49. FIFO Block Diagram

Because the system (128-bit) L3 interface is the main interface, it has a higher allocation of FIFO slots than the low-latency (64-bit) L3 interface. Table 15-98 lists the allocation of the entries.

Table 15-98. FIFO Allocation

Parameter	System L3 Interface Entries	Low-Latency L3 Interface Entries	MPU Half of the EMIF-to-MPU L3 Interface Entries
Pre Command FIFO	5	5	3
Command FIFO	Programmable ⁽¹⁾	Programmable ⁽¹⁾	Programmable ⁽¹⁾
Pre Write FIFO	8	8	8
Write Data FIFO	Up to 19+8	Up to 19 + 8	Up to 19 + 8
Return Command FIFO	22	17	13
SDRAM Read Data FIFO	22	17	20
Register Read Data FIFO	2	2	0

⁽¹⁾ The total number of entries in the command FIFO is 10.

The command FIFO is shared between the three L3 interfaces, whereas there are three different FIFOs for every other type, one dedicated to each L3 interface.

The command FIFO stores all the commands coming in on the L3 command interface. The allocation of entries in the command FIFO is programmable per L3 interface using the [EMIF_L3_CONFIG\[27:24\]](#) REG_SYS_THRESH_MAX, [EMIF_L3_CONFIG\[19:16\]](#) REG_LL_THRESH_MAX, and [EMIF_L3_CONFIG\[23:20\]](#) REG_MPU_TRESH_MAX bit fields.

If the addition of the [EMIF_L3_CONFIG\[27:24\] REG_SYS_THRESH_MAX](#) and [EMIF_L3_CONFIG\[19:16\] REG_LL_THRESH_MAX](#) bit fields is greater than the number of entries in the command FIFO, the allocation depends on the traffic on the interfaces. For example, if both fields are programmed to 7, then either of the interfaces can use seven entries in the command FIFO if the other interface is idle. If both interfaces have traffic, then the EMIF starts to gradually allocate entries to both interfaces until it settles down to seven entries for the low-latency interface and three entries for the system interface, because the low-latency interface has higher priority. If the low-latency interface has no traffic, the system interface can use seven entries.

The allocation also depends on the traffic on the interfaces, if the [EMIF_L3_CONFIG\[27:24\] REG_SYS_THRESH_MAX](#) and [EMIF_L3_CONFIG\[19:16\] REG_LL_THRESH_MAX](#) bit fields are programmed to be equal to or greater than the number of entries in the command FIFO. For example, if both fields are programmed to 10, then the low-latency port can use all the entries if there is no traffic on the system interface. However, if there is no traffic on the low-latency interface, the system interface can use all but one entry. This is because the low-latency interface has higher priority than the system interface. The only way for the system interface to use all command FIFO entries is to set the [EMIF_L3_CONFIG\[19:16\] REG_LL_THRESH_MAX](#) bit field to 0. Writing 0 reserves no space for the associated interface. If the value is set to 0 and a request is seen for that interface, the command FIFO assumes a value of 1 for that interface.

The write data FIFO stores the write data for all the write transactions coming in on the L3 write data interface. The write FIFO is shared for all the ports. A similar token mechanism is used to allocate the write FIFO with the following exceptions. All ports are given a minimum of four tokens, which ensures that each has ensured access to three write FIFO locations. Any one port can only use up to 19 of the 25 write FIFO locations. Because there is an 8-word pre-FIFO, each port can have up to 27 backlogged writes.

The return command FIFO stores all the return transactions that are to be issued to the L3 return interface. These include the write status return and the read data return commands.

Two read data FIFOs store the read data to be sent to the L3 return interface. One read data FIFO stores read data from the memory mapped registers. The other read data FIFO stores read data from external memory.

A write command is executed only when four L3 words of the corresponding data is received in the write data FIFO, or when it is the last data, and if there is space in the return command FIFO. The EMIF schedules a read-only if the results can fit into the return command FIFO and the corresponding read data FIFOs.

15.3.4.1.3 MPU Port Restrictions

The EMIF MPU port is defined only to process memory requests. All register accesses are processed through the system or LL ports of the EMIF. The EMIF MPU port does not support 2D or register requests required or provided by the system and LL interfaces. The port priority is as follows:

1. LL port (highest priority)
2. System or MPU, depending on the MPriority field of the MReqInfo bus

The EMIF considers an address that matches and requires coherency if the arriving address rounded down to the nearest 1-K block matches any address in the FIFO rounded down to the nearest 1-K block plus or minus 1-K block. This ensures that any address within a burst will be coherent with any address within any other burst. This ensures that any address within 1024 bytes will be coherent. It is possible to be coherent up to 2048 bytes apart depending on the address. To maintain coherency two rules must be followed:

- Rule A: Any command arriving on any interface (MPU, system, or LL) that matches an address in the cFIFO is executed after the command in the cFIFO.
- Rule B: Any command arriving within a 10-cycle window of another, from the different interfaces that do not match any address in the cFIFO but may match command addresses arriving on a different interface, can be executed in any order.

15.3.4.1.4 Arbitration

The EMIF looks at all the commands stored in the command FIFO to schedule commands to the external memory. All commands with the same MConnID on a particular L3 interface complete in order. The EMIF does not ensure ordering between commands with different MConnIDs or between commands from two L3 interfaces. For more information about L3 interconnect terms (MConnID, MCMD, MADDR, etc.) see [Section 13.2, L3 Interconnect](#).

However, the EMIF does maintain data coherency. Therefore, the EMIF blocks a command, regardless of priority or the L3 interface, if that command is to the same block address (2048 bytes) as an older command that is not complete. Thus, the EMIF may have one pending read or write for each MConnID. Among all pending reads, the EMIF selects all reads that have their corresponding SDRAM banks already open. Similarly, among all pending writes, the EMIF selects all writes that have their corresponding SDRAM banks already open. Accesses to memory mapped registers are treated as accesses that have open banks.

As a result of this reordering, the EMIF may now have several pending reads and writes that have their corresponding banks open. The EMIF then selects the highest priority read from pending reads, and the highest priority write from pending writes. Commands from the low-latency L3 interface have a higher priority over the commands from the system L3 interface. If two or more commands have the highest priority, the EMIF selects the oldest command. As a result, the EMIF may now have the next read and a write command. If the return command FIFO and the read data FIFO have space and the external bus conflict is resolved, the EMIF performs the final read command before the final write command. If the return command FIFO has space but the read data FIFO is full, the EMIF performs the final write command before the final read command. Resolution of external bus conflict means all the SDRAM command-to-command counters are satisfied and the read-to-write or write-to-read turnaround time is met.

The EMIF does not support tag interleaving. In other words, for an L3 interface, the EMIF completes executing an L3 command before it switches to another command. The EMIF can, however, interleave execution between commands from two L3 interfaces.

The data coherency inside the EMIF is ensured only in a single level of L3 infrastructure. For example, if a write from a secondary L3 bus segment is blocked by a bridge element, the read from a tertiary bus can still beat the write to the EMIF. In such a case, to confirm that a write from master A has landed before a read from master B is performed, master A must wait for the write status from the EMIF before indicating to master B that the data is ready to be read. If master A does not use the L3 wait status, it must do the following:

1. Perform the required write.
2. Perform a dummy write to the [EMIF_MOD_ID_REV](#) register.
3. Perform a dummy read to the [EMIF_MOD_ID_REV](#) register.
4. Indicate to master B that the data is ready to be read after completion of read in Step 3. The completion of read in Step 3 ensures that the previous writes were done.

Apart from reads and writes, the EMIF must also open and close SDRAM banks and maintain the refresh counts for an SDRAM. The priority of SDRAM commands with respect to refresh levels are:

1. SDRAM refresh request when refresh-must level is reached (highest priority)
2. L3 request for a read without a higher priority write
3. SDRAM refresh request when refresh-need level is reached
4. L3 request for a write
5. SDRAM activate commands
6. SDRAM deactivate commands
7. SDRAM deep power-down request
8. SDRAM refresh request when refresh-may level is reached
9. SDRAM self-refresh or SDRAM power-down request (lowest priority)

While performing the previous scheduling algorithm, the EMIF may encounter two conditions:

- A continuous stream of high-priority commands can block lower priority commands.
- A continuous stream of SDRAM commands to a row in an open bank can block commands to another

row in the same bank.

In addition to this scheduling, the highest priority condition is a reset command. If this condition occurs, the EMIF abandons what it is doing and begins its start-up sequence. In this case, commands and data stored in the FIFOs are lost. The EMIF also starts its start-up sequence whenever the [EMIF_SDRAM_CONFIG](#) register is written and the [EMIF_SDRAM_REF_CTRL](#)[31] [REG_INITREF_DIS](#) bit is set to 0. In this case, commands and data stored in the FIFOs are not lost. The EMIF ensures that in-flight read or write transactions to the SDRAM are complete before starting the initialization sequence.

All the accesses to an SDRAM are pipelined to maximize use of the external bus. All of these are done while fulfilling the access timing requirements of an SDRAM.

15.3.4.2 Clock Management

The EMIF can gate EMIF_FCLK. There is an internal mechanism that can stop EMIF_FCLK automatically.

EMIF_FCLK can be stopped only after the SDRAM is put into self-refresh mode and the power-idle protocol on the L3 bus completes.

The EMIF waits for the DLL lock before performing any memory access.

The EMIF_FCLK frequency can be changed only after putting the external SDRAM in self-refresh mode.

EMIFi_FCLK frequency is equal to half of the DDR_PHY_CLK frequency. DDR_PHY_CLK is equal to half of the PHY_ROOT_CLK frequency.

15.3.4.3 Software Reset

The EMIF does not support a software reset.

The EMIF supports global warm reset mode, during which the EMIF keeps the SDRAM content. Upon a request from the PRCM module indicating a need to enter global warm reset mode, the EMIF does the following:

1. Completes the ongoing access and then puts the SDRAM in self-refresh mode
2. Clears all its FIFO contents and deasserts the sys_SCmdAccept and sys_SDataAccept ports

When the global warm reset must terminate:

1. The PRCM block deasserts its request signal to the EMIF.
2. The EMIF exits self-refresh mode when it receives host accesses from the MPU to the external memory.

15.3.4.4 System Power Management

15.3.4.4.1 Read Idle Window

The [EMIF_READ_IDLE_CTRL](#) register can force idle time between consecutive reads to allow the DDR PHY to recalibrate the DLL delays during gradual voltage and frequency change.

The [EMIF_READ_IDLE_CTRL](#)[8:0] [REG_READ_IDLE_INTERVAL](#) bit field determines the maximum interval $((\text{REG_READ_IDLE_INTERVAL} + 1) * 64 \text{ EMIF_FCLK clock cycles})$ between read idle detections or force read idle time. A value of 0 disables the read idle function.

The [EMIF_READ_IDLE_CTRL](#)[19:16] [REG_READ_IDLE_LEN](#) bit field determines the minimum size of idle window for the read idle detection and the force read idle time. The EMIF introduces idle time only if it does not see at least $(\text{REG_READ_IDLE_LEN} + 1) * 2$ number of idle EMIF_FCLK cycles in [REG_READ_IDLE_INTERVAL](#). Any command other than a read command is considered idle for this purpose. Force read idle occurs when the data bus is busy transferring read data and the read idle interval expires without seeing a read idle length pause in the reads.

15.3.4.4.2 LPDDR2-SDRAM Power-Down Mode

The EMIF supports power-down mode for low power. The EMIF automatically puts the SDRAM into power-down mode after it is idle for [EMIF_PWR_MGMT_CTRL\[15:12\] REG_PD_TIM](#) number of EMIF_FCLK cycles and the [EMIF_PWR_MGMT_CTRL\[10:8\] REG_LP_MODE](#) bit field is set to 0x4. In power-down mode, the EMIF does not stop the clocks to the SDRAM. The EMIF maintains [lpddr2i_cke\[j\] \[1:0\]](#) (where $i = 1$ or 2 and $j = 0$ or 1) low to maintain the power-down mode.

When the SDRAM is in power-down mode, the EMIF services register accesses normally.

If the LPDDR2-SDRAM is in power-down mode and one of the following occurs, the EMIF brings SDRAM out of power-down mode:

1. [EMIF_PWR_MGMT_CTRL\[10:8\] REG_LP_MODE](#) bit field is changed from 0x4 to some other value.
2. An SDRAM access is requested.
3. The refresh-must level is reached.

For LPDDR2-SDRAM, the EMIF module:

1. Drives [lpddr2i_cke\[j\] \[1:0\]](#) (where $i = 1$ or 2 and $j = 0$ or 1) high
2. Waits for [EMIF_SDRAM_TIM_2\[30:28\] REG_T_XP + 1](#) cycles
3. Enters its idle mode and can issue any commands

15.3.4.4.3 LPDDR2-SDRAM Deep Power-Down Mode

For ultimate power savings, the EMIF supports deep power-down mode for LPDDR2-SDRAM.

The SDRAM can be forced into deep power-down mode through software by setting the [EMIF_PWR_MGMT_CTRL\[11\] REG_DPD_EN](#) bit to 0x1. In this case the EMIF continues normal operation until all SDRAM access requests are serviced. At this point the EMIF issues a deep power-down command. The EMIF then maintains [lpddr2i_cke\[j\] \[1:0\]](#) (where $i = 1$ or 2 and $j = 0$ or 1) low to maintain deep power-down mode. In deep power-down mode, the EMIF automatically stops the clocks to the SDRAM.

Setting the [EMIF_PWR_MGMT_CTRL\[11\] REG_DPD_EN](#) bit to 1 overrides the setting of the [EMIF_PWR_MGMT_CTRL\[10:8\] REG_LP_MODE](#) bit field. Therefore, if the SDRAM is in self-refresh or power-down mode, and the [EMIF_PWR_MGMT_CTRL\[11\] REG_DPD_EN](#) bit is set to 1, the EMIF exits those modes and goes into deep power-down mode.

When the SDRAM is in deep power-down mode, the EMIF services register accesses normally.

If the [EMIF_PWR_MGMT_CTRL\[11\] REG_DPD_EN](#) bit is set to 0x0, the EMIF brings the SDRAM out of deep power-down mode.

For LPDDR2-SDRAM, the EMIF controller:

1. Drives [lpddr2i_cke\[j\] \[1:0\]](#) (where $i = 1$ or 2 and $j = 0$ or 1) high
2. Issues a RESET command to LPDDR2 (MRW)
3. Enters its idle mode and can issue any commands
4. Software must perform initialization, as specified in [Section 15.3.4.12, LPDDR2-SDRAM Initialization](#).

15.3.4.4.4 LPDDR2-SDRAM Self-Refresh Mode

The EMIF supports self-refresh mode for low power. The EMIF automatically puts the SDRAM into self-refresh mode after the EMIF is idle for [EMIF_PWR_MGMT_CTRL\[3:0\] REG_CS_TIM](#) number of EMIF_FCLK cycles and the [EMIF_PWR_MGMT_CTRL\[10:8\] REG_LP_MODE](#) bit field is set to 0x2. In self-refresh mode, the EMIF automatically stops the clocks to the SDRAM. The EMIF maintains [lpddr2i_cke\[j\] \[1:0\]](#) (where $i = 1$ or 2 and $j = 0$ or 1) low to maintain self-refresh mode.

When the SDRAM is in self-refresh mode, the EMIF services register accesses normally.

If the LPDDR2-SDRAM is in self-refresh mode and one of the following occurs, the EMIF brings SDRAM out of self-refresh mode:

1. The [EMIF_PWR_MGMT_CTRL\[10:8\] REG_LP_MODE](#) bit field is changed from 0x2 to some other value.

2. An SDRAM access is requested.
3. [EMIF_SDRAM_TIM_2\[2:0\]](#) REG_T_CKE + 1 cycles have elapsed since the SELF-REFRESH command was issued.

For LPDDR2-SDRAM, the EMIF:

1. Enables clocks
2. Drives `lpddr2i_cke[j][1:0]` ($i = 1$ or 2 and $j = 0$ or 1) high
3. Waits for [EMIF_SDRAM_TIM_2\[24:16\]](#) REG_T_XSNR + 1 cycles
4. Starts an auto-refresh cycle in the next cycle
5. Enters its idle mode and can issue any commands

15.3.4.4.5 Save and Restore

The EMIF supports the save-and-restore mechanism to switch off power to the EMIF.

For more information about the off-mode sequence and restoration of power to the EMIF sequence, see [Chapter 3, Power, Reset, and Clock Management](#).

15.3.4.4.6 Retention Mode

EMIF supports full-retention mode.

15.3.4.5 Interrupt Requests

The EMIF sources two interrupts: one for the system L3 interface and the other for the low-latency L3 interface. The pulse and level interrupt signals for a particular interface are sourced from the same raw interrupt internal to the module.

The EMIF sets the [EMIF_IRQSTATUS_RAW_SYS\[0\]](#) REG_RAW_SYS/EMIF_IRQSTATUS_RAW_LL[0] REG_RAW_LL bit (depending on which interface sent the command having an error) to 1, if an access request to an unsupported MAddrSpace is received. If such an error occurs, it is due to bad programming of the DMM. For more information about addressing, see [Section 15.2, Dynamic Memory Manager](#).

The interrupts can be cleared by writing 1 to the corresponding bits in the [EMIF_IRQSTATUS_RAW_SYS/EMIF_IRQSTATUS_RAW_LL](#) or the [EMIF_IRQSTATUS_SYS/EMIF_IRQSTATUS_LL](#) registers.

[Table 15-99](#) lists the event flags and their mask that can cause module interrupts.

Table 15-99. Events

Event Flag	Event Mask	Description
EMIF_IRQSTATUS_RAW_SYS[1] REG_TA_SYS / EMIF_IRQSTATUS_SYS[1] REG_TA_SYS	EMIF_IRQENABLE_SET_SYS[1] REG_EN_TA_SYS / EMIF_IRQENABLE_CLR_SYS[1] REG_EN_TA_SYS	System L3 interrupt for SDRAM temperature alert
EMIF_IRQSTATUS_RAW_LL[1] REG_TA_LL / EMIF_IRQSTATUS_LL[1] REG_TA_LL	EMIF_IRQENABLE_SET_LL[1] REG_EN_TA_LL / EMIF_IRQENABLE_CLR_LL[1] REG_EN_TA_LL	Low-latency L3 interrupt for SDRAM temperature alert
EMIF_IRQSTATUS_RAW_SYS[0] REG_ERR_SYS / EMIF_IRQSTATUS_SYS[0] REG_ERR_SYS	EMIF_IRQENABLE_SET_SYS[0] REG_EN_ERR_SYS / EMIF_IRQENABLE_CLR_SYS[0] REG_EN_ERR_SYS	System L3 interrupt for command or address error
EMIF_IRQSTATUS_RAW_LL[0] REG_ERR_LL / EMIF_IRQSTATUS_LL[0] REG_ERR_LL	EMIF_IRQENABLE_SET_LL[0] REG_EN_ERR_LL / EMIF_IRQENABLE_CLR_LL[0] REG_EN_ERR_LL	Low-latency L3 interrupt for command or address error

15.3.4.6 SDRAM Output Impedance Calibration

The EMIF supports automatic output impedance calibration. The ZQ calibration can be enabled per CS by setting the [EMIF_ZQ_CONFIG\[31\]](#) REG_ZQ_CS1EN and [EMIF_ZQ_CONFIG\[30\]](#) REG_ZQ_CS0EN bits. The EMIF supports three types of ZQ calibration commands:

- ZQINIT: ZQ calibration command during initialization
- ZQCS: ZQ calibration short command
- ZQCL: ZQ calibration long command

The EMIF issues a ZQCS command each time the [EMIF_ZQ_CONFIG\[15:0\]](#) REG_ZQ_REFINTERVAL bit field expires. In other words, the REG_ZQ_REFINTERVAL defines the interval between ZQCS commands. When a ZQCS command is issued, the EMIF waits and blocks any other command for ([EMIF_SDRAM_TIM_3\[20:15\]](#) REG_ZQ_ZQCS + 1) number of DDR clock cycles.

If the [EMIF_ZQ_CONFIG\[28\]](#) REG_ZQ_SFEXITEN bit field is set to 1, the EMIF issues a ZQCL command every time it exits self-refresh, active power-down, and precharge power-down modes. When a ZQCL command is issued, the EMIF waits and blocks any other command for ([EMIF_ZQ_CONFIG\[17:16\]](#) REG_ZQ_ZQCL_MULT + 1) × ([EMIF_SDRAM_TIM_3\[20:15\]](#) REG_ZQ_ZQCS + 1) number of DDR clock cycles.

If a separate calibration resistor is used per device, the ZQ calibration can be performed simultaneously over both CSs. To enable ZQ calibration to be performed simultaneously over both CSs, the [EMIF_ZQ_CONFIG\[27\]](#) REG_ZQ_DUALCALEN bit must be set to 1. If REG_ZQ_DUALCALEN is set to 0, the EMIF performs ZQ calibration per CS serially.

15.3.4.7 SDRAM Temperature Monitoring

The EMIF supports automatic temperature monitoring to facilitate the software update of the refresh rate according to the temperature changes of the LPDDR2. Temperature monitoring can be enabled per CS by setting the [EMIF_TEMP_ALERT_CONFIG\[31\]](#) REG_TA_CS1EN and [EMIF_TEMP_ALERT_CONFIG\[30\]](#) REG_TA_CS0EN bits.

The EMIF polls the temperature of the LPDDR2 (issues an MRR command to Mode Register 4) every time the [EMIF_TEMP_ALERT_CONFIG\[21:0\]](#) REG_TA_REFINTERVAL bit field expires. In other words, REG_TA_REFINTERVAL defines the interval between temperature alert polls. If the EMIF sees a 1 on bit 7 of the read data value from the MRR, which indicates the temperature has changed, the [EMIF_IRQSTATUS_SYS\[1\]](#) REG_TA_SYS bit (for L3 interconnect) or [EMIF_IRQSTATUS_LL\[1\]](#) REG_TA_LL bit (for low-latency L3) is set and the module sends an interrupt on the system and low-latency interrupt lines, respectively. When the interrupt is received, software updates the [EMIF_SDRAM_REF_CTRL\[15:0\]](#) REG_REFRESH_RATE bit field to the required value as per the temperature change.

If the [EMIF_TEMP_ALERT_CONFIG\[28\]](#) REG_TA_SFEXITEN bit is set to 1, the EMIF polls for temperature change every time it exits self-refresh, active power-down, and precharge power-down modes.

Because the EMIF is performing an MRR, it needs information about how the LPDDR2 is connected. The [EMIF_TEMP_ALERT_CONFIG\[27:26\]](#) REG_TA_DEVWDT and [EMIF_TEMP_ALERT_CONFIG\[25:24\]](#) REG_TA_DEVCNT bit fields provide the necessary information to the EMIF for MRR data compare. For example, if REG_TA_DEVWDT is set to 0, which indicates 8-bit devices are used, and if REG_TA_DEVCNT is set to 2, which indicates four devices are used to form a 32-bit bus, the mask used for checking is 4'b1111; that is, the EMIF expects data on each byte lane on a 32-bit bus.

15.3.4.8 SDRAM Refresh Scheduling

The EMIF uses two counters to schedule AUTO REFRESH commands: a 13-bit decrementing refresh interval counter and a 4-bit refresh backlog counter. The interval counter is used to define the rate at which connected SDRAM devices are refreshed. It is loaded with the value of the [EMIF_SDRAM_REF_CTRL\[15:0\]](#) REG_REFRESH_RATE bit field at reset (only the 13 LSBs are taken). The interval counter decrements by 1 each cycle until it reaches 0, at which point it reloads from the [EMIF_SDRAM_REF_CTRL\[15:0\]](#) REG_REFRESH_RATE bit field and restarts decrementing. The counter also reloads and restarts decrementing whenever the [EMIF_SDRAM_REF_CTRL\[15:0\]](#) REG_REFRESH_RATE bit field is updated.

The refresh backlog counter records the number of outstanding AUTO REFRESH commands the EMIF has. The backlog counter increments by 1 each time the interval counter reloads (unless it has reached its maximum value of 15). The backlog counter decrements by 1 each time the EMIF issues an AUTO REFRESH command (unless it is already 0). For the range of values that the backlog counter can take, there are four levels of urgency with which the EMIF must perform an auto refresh cycle (in which it issues AUTO REFRESH commands):

1. Refresh-may level is reached when the backlog count is greater than 0, which indicates there is a refresh backlog; therefore, if the EMIF is not busy and none of the SDRAM banks are open, the EMIF must perform an auto refresh cycle.
2. Refresh-release level is reached when the backlog count is greater than 4, which indicates the refresh backlog is getting bigger; therefore, if the EMIF is not busy it must perform an auto refresh cycle even if any of the banks are open.
3. Refresh-need level is reached when the backlog count is greater than 5, which indicates the refresh backlog is getting bigger and the EMIF must raise the priority of performing an auto refresh cycle above that of servicing new memory write requests. The EMIF starts servicing new memory accesses after the refresh-release level is cleared.
4. Refresh-must level is reached when the backlog count is greater than 7, which indicates the refresh backlog is becoming excessive and the EMIF must perform an auto refresh cycle before servicing any new memory access requests. The EMIF starts servicing new memory accesses after the refresh-release level is cleared.

The refresh counters do not operate when SDRAM is in self-refresh mode.

The EMIF issues AUTO REFRESH commands within auto refresh cycles. An auto refresh cycle consists of issuing an AUTO REFRESH command and waiting T_RFC (see [EMIF_SDRAM_TIM_3](#)) cycles before rechecking the refresh levels. If the refresh-release level is not reached, the EMIF starts another auto refresh cycle; otherwise, it returns to idle mode where it can issue any command. The EMIF ensures that no more than eight AUTO REFRESH commands are issued in any rolling tREFBW (= 4 * 8 * tRFC) window.

15.3.4.8.1 Performance Counters Description

The [EMIF_PERF_CNT_1](#) and [EMIF_PERF_CNT_2](#) registers can be used to monitor or calculate the EMIF bandwidth and efficiency. These counters can count events such as total SDRAM accesses, SDRAM activates, reads, writes, etc. Each counter counts events independent of the other counters. In addition to the ability to count events, the counters can also filter the events from a particular master or address space. The events to be counted and the filter enabling can be configured using the [EMIF_PERF_CNT_CFG](#) register. The filter value to be used can be configured using the [EMIF_PERF_CNT_SEL](#) register. Each counter can be configured independently.

[Table 15-100](#) lists all the events that can be counted and whether a filter can be applied to a particular event. A filter can be applied to an event if the following bits for Performance Counter 1 and Performance Counter 2 can be set equal to 0x1 for that event:

- Performance Counter 1: [EMIF_PERF_CNT_CFG](#)[15] REG_CNTR1_MCONNID_EN and [EMIF_PERF_CNT_CFG](#)[14] REG_CNTR1_REGION_EN
- Performance Counter 2: [EMIF_PERF_CNT_CFG](#)[31] REG_CNTR2_MCONNID_EN and [EMIF_PERF_CNT_CFG](#)[30] REG_CNTR2_REGION_EN

[Table 15-100](#) shows the possible filter configurations for the two performance counters. These filter configurations can be used in conjunction with a L3 master ID and/or external chip-select to obtain performance statistics for a particular L3 master and/or external chip-select.

Table 15-100. Performance Counter Filter Configuration

CNTRn_CFG ⁽¹⁾	CNTRn_REGION_EN ⁽¹⁾	CNTRn_MCONNID_EN ⁽¹⁾	Description
0x0 ⁽²⁾	0x0	0x0 or 0x1	Count total SDRAM accesses

⁽¹⁾ n = 1 or 2

⁽²⁾ When MReqDebug is set to a 1 for a particular L3 command, the performance counters will not be incremented for that command.

Table 15-100. Performance Counter Filter Configuration (continued)

CNTRn_CFG ⁽¹⁾	CNTRn_REGION_EN ⁽¹⁾	CNTRn_MCONNID_EN ⁽¹⁾	Description
0x1 ⁽²⁾	0x0	0x0 or 0x1	Count total SDRAM activates
0x2 ⁽²⁾	0x0 or 0x1	0x0 or 0x1	Count total L3 reads. CPU cache based operations are 32 bytes. DMA burst is 128 bytes.
0x3 ⁽²⁾	0x0 or 0x1	0x0 or 0x1	Count total L3 writes. CPU cache based operations are 32 bytes. DMA burst is 128 bytes.
0x4	0x0	0x0	Count number of EMIF FCLK clock cycles L3 Command FIFO is full
0x5	0x0	0x0	Count number of EMIF FCLK clock cycles L3 Write Data FIFO is full
0x6	0x0	0x0	Count number of EMIF FCLK clock cycles L3 Read Data FIFO is full
0x7	0x0	0x0	Count number of EMIF FCLK clock cycles L3 Return Command FIFO is full
0x8	0x0 or 0x1	0x0 or 0x1	Count number of priority elevations
0x9	0x0	0x0	Count number of EMIF FCLK clock cycles that a command was pending
0xA ⁽³⁾	0x0	0x0	Count number of EMIF FCLK clock cycles for which the memory data bus was transferring data.
0xA ⁽³⁾	0x0	0x1	Count number of L3 commands for which the memory data bus was transferring data.
0xB to 0xF	0x0	0x0	Reserved for future use.

⁽³⁾ When MReqDebug is set to a 1 for a particular L3 command, the performance counters will not be incremented for that command.

When CNTRn_CFG = 0xA and CNTRn_MCONNID_EN=0x1, the following guidelines must apply:

- Count of 1 implies OCP command up to 32 bytes for all the initiators except for Cortex-A9 MPU
- Count of 1 implies OCP command up to 16 bytes for Cortex-A9 MPU when all the other initiators are not generating traffic on SDRAM.
- When ConnID is set to a value other than 0x00, the performance counter reflects the traffic generated by the initiator that is associated with that ConnID. In case of ConnID=0x00 (MPU), the performance counter reflects combined traffic by all active initiators. Therefore, if there are multiple initiators generating traffic, the traffic generated by the MPU must be calculated using this formula:

$$\text{Actual MPU Count} = \text{Count value} - \sum_{i=0}^{\text{all_initiators-MPU}} \text{Count}_i$$

where i is different initiators and Count_i is the Count value for each of those initiators. Then:

- Actual MPU count of 1 implies OCP command up to 16 bytes for Cortex-A9 MPU
- Bandwidth for all other initiators except MPU is Count × 32 bytes
- Bandwidth calculation for MPU is MPU Count × 16 bytes

15.3.4.8.2 Performance Counters General Examples

15.3.4.8.2.1 PERF_CNT_1 General Example for Counting Write Accesses

The Performance Counter 1 register must count all write accesses from the dual Cortex-M3 MPU subsystem:

- To enable counting writes, the [EMIF_PERF_CNT_CFG\[3:0\]](#) REG_CNTR1_CFG bit field must be set to 0x3.
- The [EMIF_PERF_CNT_SEL\[15:8\]](#) REG_MCONNID1 bit field must be set to 0x44. The values

programmed into the REG_MCONNIDx bit fields are those in [Table 28-20](#), in [Chapter 28, On-Chip Debug Support](#), left-shifted by 2 bits.

- To enable filtering, the [EMIF_PERF_CNT_CFG\[15\]](#) REG_CNTR1_MCONNID_EN bit must be set to 0x1.

With this configuration, Counter 1 counts every write made to the EMIF from master 0x44 to any address space. This does not include accesses from other masters and does not include commands other than writes.

15.3.4.8.2.2 *PERF_CNT_2 General Example for Counting Total Access*

The Performance Counter 2 register must count total accesses to SDRAM regardless of the masters or address space.

- To enable counting all SDRAM accesses, the [EMIF_PERF_CNT_CFG\[19:16\]](#) REG_CNTR2_CFG bit field must be set to 0x0.
- To disable filtering, the [EMIF_PERF_CNT_CFG\[31\]](#) REG_CNTR2_MCONNID_EN and the [EMIF_PERF_CNT_CFG\[30\]](#) REG_CNTR2_REGION_EN bits must be set to 0x0.

With this configuration, Counter 2 counts every access made to the EMIF. This includes all accesses from all masters and to any address space.

15.3.4.8.2.3 *PERF_CNT_3 General Example for Counting all Read Accesses*

The Performance Counter 1 register must count all read accesses from the dual Cortex-M3 MPU subsystem to address space 0x0.

- To enable counting reads, the [EMIF_PERF_CNT_CFG\[3:0\]](#) REG_CNTR1_CFG bit field must be set to 0x2.
- The [EMIF_PERF_CNT_SEL\[15:8\]](#) REG_MCONNID1 and [EMIF_PERF_CNT_SEL\[1:0\]](#) REG_REGION_SEL1 bit fields must be set to 0x44 and 0x0, respectively.
- To enable filtering, the [EMIF_PERF_CNT_CFG\[15\]](#) REG_CNTR1_MCONNID_EN and [EMIF_PERF_CNT_CFG\[14\]](#) REG_CNTR1_REGION_EN bits must be set to 0x1.

With this configuration, Counter 1 counts every read made to the EMIF from master 0x44 to address space 0x0. This does not include accesses from other masters or accesses to other address space and does not include commands other than reads.

15.3.4.9 *EMIF Access Cycles*

By default, the EMIF keeps the SDRAM CSs active. To direct a command to one of the SDRAMs, the EMIF deasserts the CS to the other SDRAMs for the duration of the command. If the [EMIF_SDRAM_CONFIG\[3\]](#) REG_EBANK bit in the SDRAM configuration register is set to 0, CS1 is always driven high except during initialization and for REFRESH, POWER DOWN, SELF-REFRESH, and DEEP POWER-DOWN commands.

The EMIF always performs burst accesses to the SDRAM. Multiple SDRAM bursts may be needed to service a single L3 burst request. [Table 15-101](#) through [Table 15-105](#) show a few examples of how EMIF accesses SDRAM for a linear incrementing transaction type. T0, T1, etc. are clock cycles. R0 is read starting at column 0, R8 is read starting at column 8, and R16 is read starting at column 16. D0-1 is the data from column 0 and 1, D2-3 is the data from column 2 and 3, and so on.

Table 15-101. 64-Byte Linear Read Starting at Address 0x0

Table 15-105. 64-Byte Linear Read Starting at Address 0x18

T0	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10	T11	T12	T13
R6		R8					R16						
				D6-7	Unused	D8-9	D10-11	D12-13	D14-15	D16-17	D18-19	D20-21	Unused

The EMIF uses the unused data phases in the preceding figures by issuing successive read commands if there are reads to open banks pending in the command FIFO.

The write data conversion from SDR to DDR is done outside the EMIF.

15.3.4.9.1 SDRAM Read

A read access to an SDRAM is initiated with a READ command. The EMIF provides the internal bank address and the column address on `pad_ca_o` with the READ command. The EMIF registers the first read data from `lpddr2i_dj` (where $i = 1$ or 2 and $j = 0$ or 1) after $(\text{read_latency} + 3)$ DDR clock cycles. Read latency is programmed in the [EMIF_DDR_PHY_CTRL_1](#) register.

15.3.4.9.2 SDRAM Write

A write access to an SDRAM is initiated with a WRITE command. The EMIF provides the internal bank address and the column address on `pad_ca_o` with the WRITE command.

The EMIF delays the write data by the appropriate write latency minus 1. Subsequent data words are provided on `lpddr2i_dj` (where $i = 1$ or 2 and $j = 0$ or 1) along with the appropriate data mask on `lpddr2i_dmj` (where $i = 1$ or 2 and $j = 0$ or 1) on each successive clock cycle. The DDR PHY then adds one more clock cycle delay to the write data to appropriately center the write data to the outgoing DQS.

15.3.4.10 Turnaround Time

[Table 15-106](#) lists the turnaround time the EMIF introduces on the data bus for various back-to-back accesses. The EMIF takes advantage of the CAS latencies and packs the commands as close as possible on the control bus to introduce the following turnaround time on the data bus.

Table 15-106. Turnaround Time

Previous Access	Next Access	Turnaround Time (Number of DDR Clock Cycles)
SDRAM read	SDRAM read to the same CS	0

Table 15-106. Turnaround Time (continued)

Previous Access	Next Access	Turnaround Time (Number of DDR Clock Cycles)
SDRAM read	SDRAM read to a different CS	2
SDRAM read	SDRAM write	2
SDRAM write	SDRAM write	0
SDRAM write	SDRAM read	2

15.3.4.11 SDRAM Address Mapping

The EMIF interleaves the internal banks for SDRAM connected to both CSs (see [Table 15-107](#) for the SDRAM addressing space), according to the DMM (for more information, see [Section 15.2, Dynamic Memory Manager](#)). From the system point of view, the external SDRAM is seen as one block of SDRAM. If two external 64-MB devices are used, a 128-MB memory block is observed. If two external 32-MB devices are used, a 64-MB block is observed.

Table 15-107. SDRAM Addressing Space

Module Name	Base Address	Size
EMIF1 EMIF2-CS0-SDRAM ⁽¹⁾	0x8000 0000	0 to 1GB, programmable in DMM (see Section 15.2, Dynamic Memory Manager)
EMIF1 EMIF2-CS1-SDRAM ⁽²⁾	0xC000 0000	0 to 1GB, programmable in DMM (see Section 15.2, Dynamic Memory Manager)

⁽¹⁾ The addressing space is interleaved on two LPDDR memory controllers (EMIF1, EMIF2), each activating their CS0 line. These CSs can address 64, 128, 256, 512, 1024, or 2048MBs. Interleaving occurs at 128-byte granularity. EMIF1-CS0 base address is always 0x8000 0000 at reset, and occupies a 1-GB address space at reset (interleaving disabled at reset).

⁽²⁾ The addressing space is interleaved on two LPDDR memory controllers (EMIF1, EMIF2), each activating its CS1 line. These CSs are programmable to 64, 128, 256, 512, or 1024MBs. Interleaving occurs at 128-byte granularity. EMIF1-CS1 and EMIF2-CS1 are disabled at reset. Their base address is programmable to achieve a continuous address space with the respective CS0, regardless of the programmed address range. EMIF1-CS1 is disabled if the EMIF1-CS0 memory density is set to 2048MB (2GB) when interleaving is disabled, or if the EMIF1-CS0 + EMIF2-CS0 memory density is set to 1024MB (1GB) when interleaving is enabled.

When addressing SDRAM, if the [EMIF_SDRAM_CONFIG\[28:27\] REG_IBANK_POS](#) bit field is set to 0, the EMIF uses the following three bit fields to determine the mapping from the source address to the SDRAM row, column, bank, and CS:

- [EMIF_SDRAM_CONFIG\[6:4\] REG_IBANK](#)
- [EMIF_SDRAM_CONFIG\[3\] REG_EBANK](#)
- [EMIF_SDRAM_CONFIG\[2:0\] REG_PAGESIZE](#)

If the [EMIF_SDRAM_CONFIG\[28:27\] REG_IBANK_POS](#) bit field is set to 1, 2, or 3, the EMIF uses the following four bit fields to determine the mapping from the source address to the SDRAM row, column, bank, and CS:

- [EMIF_SDRAM_CONFIG\[6:4\] REG_IBANK](#)
- [EMIF_SDRAM_CONFIG\[3\] REG_EBANK](#)
- [EMIF_SDRAM_CONFIG\[2:0\] REG_PAGESIZE](#)
- [EMIF_SDRAM_CONFIG\[9:7\] REG_ROWSIZE](#)

In all cases the EMIF considers its SDRAM address space to be a single logical block, regardless of the number of physical devices or whether the devices are mapped across one or two EMIF CSs.

For [EMIF_SDRAM_CONFIG\[28:27\] REG_IBANK_POS = 0](#), [Table 15-108](#) and [Table 15-109](#) list which source address bits (MAddr) map to the SDRAM row, column, bank, and CS bits for all combinations of [REG_IBANK](#), [REG_EBANK](#), and [REG_PAGESIZE](#).

For [EMIF_SDRAM_CONFIG\[28:27\] REG_IBANK_POS != 0](#), [Table 15-111](#) and [Table 15-112](#) show which source address bits (MAddr) map to the SDRAM row, column, bank, and CS bits for all combinations of [REG_IBANK](#), [REG_EBANK](#), [REG_PAGESIZE](#), and [REG_ROWSIZE](#).

The tables also list the maximum size of the resulting SDRAM space.

Table 15-108. L3 Address to SDRAM Address Mapping for 16-Bit SDRAM (EMIF_SDRAM_CONFIG[28:27] REG_IBANK_POS = 0)

Reach (MBytes)	[3] REG_EBANK	[6:4] REG_IBANK	[2:0] REG_PAGESIZE	MAddr													[8:1]

For **EMIF_SDRAM_CONFIG**[28:27] **REG_IBANK_POS** = 0, the effect of the address-mapping scheme is that as the source address increments across SDRAM page boundaries, the EMIF moves onto the same page in the next bank in the current device (**lpddr2i_cs1**[0]n, where i = 1 or 2). This movement along the banks of the current device continues until the page is accessed in all banks in the current device. The EMIF then proceeds to the same page in the next device (if **EMIF_SDRAM_CONFIG**[3] **REG_EBANK** = 1, **lpddr2i_cs1**[1]n, where i = 1 or 2) and proceeds through the same page in all its banks before moving to the next page in the first device (**lpddr2i_cs1**[0]n, where i = 1 or 2). The EMIF exploits this movement across internal banks and CSs while remaining on the same page to maximize the number of open SDRAM banks within the overall SDRAM space.

Thus, the EMIF can keep a maximum of 16 banks (eight internal banks across two CSs) open at a time, and can interleave among all of them.

Table 15-110 through **Table 15-112** list the L3 address to SDRAM address mapping. In each case, there are x bits for bank, followed by y bits for row, followed by z bits for CS, followed by s bits for bank, and t bits for col in **MAddr**[31:N] (x, y, z, s, and t are given depending on the value of the **EMIF_SDRAM_CONFIG** bit field).

Table 15-110. L3 Address to SDRAM Address Mapping for **EMIF_SDRAM_CONFIG[28:27] **REG_IBANK_POS** = 1 and **EMIF_SDRAM_CONFIG_2**[27] **REG_EBANK_POS** = 0**

MAddr [31:N]				
Bank Address	Row Address	Chip-Select	Bank Address	Column Address
Number of bits defined by	Number of bits defined by	Number of bits defined by	Number of bits defined by	Number of bits defined by
EMIF_SDRAM_CONFIG [6] REG_IBANK	EMIF_SDRAM_CONFIG [9:7] REG_ROWSIZE	EMIF_SDRAM_CONFIG [3] REG_EBANK	EMIF_SDRAM_CONFIG [5:3] REG_IBANK	EMIF_SDRAM_CONFIG [2:0] REG_PAGESIZE
= 0: 0 bit	= 0: 9 bits	= 0: 0 bit	= 0: 0 bit	= 0: 8 bits
= 1: 0 bit	= 1: 10 bits	= 1: 1 bit	= 1: 1 bit	= 1: 9 bits
	= 2: 11 bits		= 2: 2 bits	= 2: 10 bits
	= 3: 12 bits		= 3: 2 bits	= 3: 11 bits
	= 4: 13 bits			
	= 5: 14 bits			
	= 6: 15 bits			
	= 7: 16 bits			

NOTE: N = 1 for 16-bit SDRAM, and N = 2 for 32-bit SDRAM.

The REG_IBANK bit field is listed twice because it gives the number of bank bits depending on their place in the MAddr.

For EMIF_SDRAM_CONFIG[28:27] REG_IBANK_POS = 1, the EMIF interleaves banks the same as for EMIF_SDRAM_CONFIG[28:27] REG_IBANK_POS = 0, but the interleaving of banks within a device (per CS) is limited to four banks. Thus, the EMIF can keep a maximum of 16 banks (eight internal banks across two CSs) open at a time, but can interleave among only 8 of them.

Table 15-111. L3 Address to SDRAM Address Mapping for EMIF_SDRAM_CONFIG[28:27] REG_IBANK_POS = 2 and EMIF_SDRAM_CONFIG_2[27] REG_EBANK_POS = 0

MAddr[31:N]

= 0: 0 bit	= 0: 9 bits	= 0: 0 bit	= 0: 0 bit	= 0: 8 bits
= 1: 0 bit	= 1: 10 bits	= 1: 1 bit	= 1: 1 bit	= 1: 9 bits
= 2: 1 bit	= 2: 11 bits			= 2: 10 bits
= 3: 2 bits	= 3: 12 bits			= 3: 11 bits
	= 4: 13 bits			
	= 5: 14 bits			
	= 6: 15 bits			
	= 7: 16 bits			

NOTE: N = 1 for 16-bit SDRAM, and N = 2 for 32-bit SDRAM.

For [EMIF_SDRAM_CONFIG\[28:27\]](#) REG_IBANK_POS = 2, the EMIF interleaves banks the same as for [EMIF_SDRAM_CONFIG\[28:27\]](#) REG_IBANK_POS = 0, but the interleaving of banks within a device (per CS) is limited to two banks. Thus, the EMIF can keep a maximum of 16 banks (eight internal banks across two CSs) open at a time, but can interleave among only 4 of them.

**Table 15-112. L3 Address to SDRAM Address Mapping for EMIF_SDRAM_CONFIG[28:27]
REG_IBANK_POS = 3 and EMIF_SDRAM_CONFIG_2[27] REG_EBANK_POS = 0**

MAddr[31:N]			
Bank Address	Row Address	Chip-Select	Column Address
Number of bits defined by EMIF_SDRAM_CONFIG[6:4] REG_IBANK	Number of bits defined by EMIF_SDRAM_CONFIG[9:7] REG_ROWSIZE	Number of bits defined by EMIF_SDRAM_CONFIG[3] REG_EBANK	Number of bits defined by EMIF_SDRAM_CONFIG[2:0] REG_PAGESIZE
= 0: 0 bit	= 0: 9 bits	= 0: 0 bit	= 0: 8 bits
= 1: 1 bit	= 1: 10 bits	= 1: 1 bit	= 1: 9 bits
= 2: 2 bits	= 2: 11 bits		= 2: 10 bits
= 3: 3 bits	= 3: 12 bits		= 3: 11 bits
	= 4: 13 bits		
	= 5: 14 bits		
	= 6: 15 bits		
	= 7: 16 bits		

NOTE: N = 1 for 16-bit SDRAM, and N = 2 for 32-bit SDRAM.

For [EMIF_SDRAM_CONFIG\[28:27\]](#) REG_IBANK_POS = 3, the EMIF cannot interleave banks within a device (per CS). However, it can interleave banks between the two CSs. Thus, the EMIF can keep a maximum of 16 banks (eight internal banks across two CSs) open at a time, but can interleave among only 2 of them.

Because the EMIF interleave among a fewer number of banks when [EMIF_SDRAM_CONFIG\[28:27\]](#) REG_IBANK_POS != 0, these cases are lower in performance than the [EMIF_SDRAM_CONFIG\[28:27\]](#) REG_IBANK_POS = 0 case. Thus, these cases are recommended to be used only with partial array self-refresh where performance can be traded off for power savings.

Table 15-113. L3 Address to SDRAM Address Mapping for [EMIF_SDRAM_CONFIG\[28:27\]](#) REG_IBANK_POS = 1 and [EMIF_SDRAM_CONFIG_2\[27\]](#) REG_EBANK_POS = 1

= 0: 0 bit	= 0: 0 bit	= 0: 9 bits	= 0: 0 bit	= 0: 8 bits
= 1: 1 bit	= 1: 0 bit	= 1: 10 bits	= 1: 1 bit	= 1: 9 bits
	= 2: 1 bit	= 2: 11 bits	= 2: 1 bit	= 2: 10 bits
	= 3: 2 bits	= 3: 12 bits	= 3: 1 bit	= 3: 11 bits
		= 4: 13 bits		
		= 5: 14 bits		
		= 6: 15 bits		
		= 7: 16 bits		

NOTE: N = 1 for 16-bit SDRAM, and N = 2 for 32-bit SDRAM.

The interleaving of banks within a device (per chip-select) is limited to two banks. The EMIF cannot interleave banks between the two chip-selects. Thus, the EMIF can keep a maximum of 16 banks (8 internal banks across two chip-selects) open at a time, but can interleave among only 2 of them.

Table 15-115. L3 Address to SDRAM Address Mapping for EMIF_SDRAM_CONFIG[28:27] REG_IBANK_POS = 3 and EMIF_SDRAM_CONFIG_2[27] REG_EBANK_POS = 1

MAddr[31:N]			
Chip-Select	Bank Address	Row Address	Column Address
Number of bits defined by EMIF_SDRAM_CONFIG [3] REG_EBANK	Number of bits defined by EMIF_SDRAM_CONFIG [6:4] REG_IBANK	Number of bits defined by EMIF_SDRAM_CONFIG [9:7] REG_ROWSIZE	Number of bits defined by EMIF_SDRAM_CONFIG [2:0] REG_PAGESIZE
= 0: 0 bit	= 0: 0 bit	= 0: 9 bits	= 0: 8 bits
= 1: 1 bit	= 1: 1 bit	= 1: 10 bits	= 1: 9 bits
	= 2: 2 bits	= 2: 11 bits	= 2: 10 bits
	= 3: 3 bits	= 3: 12 bits	= 3: 11 bits
		= 4: 13 bits	
		= 5: 14 bits	
		= 6: 15 bits	
		= 7: 16 bits	

NOTE: N = 1 for 16-bit SDRAM, and N = 2 for 32-bit SDRAM.

The EMIF cannot interleave banks within a device (per chip-select) or between the two chip-selects. Thus, the EMIF can keep a maximum of 16 banks (8 internal banks across two chip-selects) open at a time, but cannot interleave among them.

Because the EMIF interleaves among fewer banks when REG_IBANK_POS != 0 or REG_EBANK_POS = 1, these cases are lower in performance than the REG_IBANK_POS = 0 case. Thus, these cases are recommended to be used only along with partial array self-refresh, where performance can be traded for power savings.

15.3.4.12 LPDDR2 SDRAM Initialization

When coming out of reset if the [EMIF_SDRAM_CONFIG](#)[31:29] REG_SDRAM_TYPE bit field is equal to 4 or 5, the EMIF performs an LPDDR2 initialization sequence as follows:

1. Drives `lpddr2i_cke[j][1:0]` (where $i = 1$ or 2 and $j = 0$ or 1) high and starts to issue NOP commands continuously.
2. After 16 SDRAM refresh rate intervals, issues a PRECHARGE-ALL command. The SDRAM refresh rate is defined in the [EMIF_SDRAM_REF_CTRL](#)[15:0] REG_REFRESH_RATE bit field.
3. Issues a RESET command.
4. Software initializes LPDDR2 using the [EMIF_LPDDR2_MODE_REG_CFG](#) and [EMIF_LPDDR2_MODE_REG_DATA](#) registers. Software must enable refreshes by writing 1 in the [EMIF_LPDDR2_MODE_REG_CFG](#)[30] REG_REFRESH_EN bit during the last MRW command.

The EMIF also performs the initialization sequence whenever the [EMIF_SDRAM_CONFIG](#) register is written and the LPDDR2 initialization was not performed previously because the [SDRAM_REF_CTRL](#)[31] REG_INITREF_DIS bit was set to 0. Once the EMIF performs initialization, rewriting the SDRAM configuration register does not cause reinitialization.

NOTE: The values of the different bit fields in the [EMIF_SDRAM_CONFIG](#) and [EMIF_SDRAM_CONFIG_2](#) registers are set by the control module at reset. These values must be modified by the configuration header feature in the ROM code or by the initial boot image running from an external XIP booting memory or internal RAM (see [Section 27.4.8, Image Format](#)). They must not be modified during run time, because they reflect the used hardware LPDDR2 SDRAM configurations.

The EMIF does not perform any transactions until the LPDDR2 initialization sequence completes.

When the EMIF comes out of reset, the delay time in Step 2 resulting from the 16 refresh rate intervals + 8 cycles is approximately $16 \times$ [EMIF_SDRAM_REF_CTRL](#)[15:0] REG_REFRESH_RATE / input frequency.

15.3.5 EMIF Programming Guide

15.3.5.1 EMIF Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the EMIF module.

The following programming sequences are double, because there are two EMIF modules (EMIF1 and EMIF2) with the same register mapping but different register addresses.

15.3.5.1.1 Global Initialization

Table 15-116. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. See Chapter 3, Power, Reset, and Clock Management .
Interrupt submodule of the MPU	The interrupt requests from the EMIF must be enabled (unmasked). See Chapter 17, Interrupt Controllers .
DMM	The EMIF is a slave to the DMM. The DMM must be enabled and configured for communication with LPDDR2 memories. See Section 15.2, Dynamic Memory Manager .

15.3.5.1.1.1 EMIF Module Global Initialization

This procedure initializes the EMIF after a power-on reset (POR). The unused bits in all registers must be written with zeros. The values of the shadow registers are loaded in their corresponding registers when a frequency update sequence is performed.

NOTE: The values of the different bit fields in the [EMIF_SDRAM_CONFIG](#) and [EMIF_SDRAM_CONFIG_2](#) registers are set by the control module at reset. These values must be modified by the configuration header feature in the ROM code or by the initial boot image running from an external XIP booting memory or internal RAM (see [Section 27.4.8, Image Format](#)). They must not be modified during run time, because they reflect the used hardware LPDDR2 SDRAM configurations.

Table 15-117. EMIF Global Initialization

Step	Register/ Bit Field / Programming Model	Value
Assign the external bank address bits from lower or higher OCP address as shown in Table 15-110 , Table 15-111 , Table 15-112 , Table 15-113 , Table 15-114 , and Table 15-115 .	EMIF_SDRAM_CONFIG_2 [27] REG_EBANK_POS	0x-
Select the SDRAM type (S2 or S4)	EMIF_SDRAM_CONFIG [31:29] REG_SDRAM_TYPE	0x-
Assign internal bank address bits from L3 address as shown in Table 15-108 , Table 15-109 , Table 15-110 , Table 15-111 , Table 15-112 , Table 15-113 , Table 15-114 , and Table 15-115 .	EMIF_SDRAM_CONFIG [28:27] REG_IBANK_POS	0x-
Enable/disable DLL.	EMIF_SDRAM_CONFIG [20] REG_DDR_DISABLE_DLL	0x-
Choose between 32-bit or 16-bit wide SDRAM data bus.	EMIF_SDRAM_CONFIG [15:14] REG_NARROW_MODE	0x-
Define CAS latency when accessing connected SDRAM devices.	EMIF_SDRAM_CONFIG [13:10] REG_CL	0x-
Define the number of row address bits of connected SDRAM device.	EMIF_SDRAM_CONFIG [9:7] REG_ROWSIZE	0x-
Define the number of banks inside connected SDRAM device.	EMIF_SDRAM_CONFIG [6:4] REG_IBANK	0x-

Table 15-117. EMIF Global Initialization (continued)

Step	Register/ Bit Field / Programming Model	Value
Define whether SDRAM accesses use 1 or 2 chip-select lines.	EMIF_SDRAM_CONFIG[3] REG_EBANK	0x-
Define the internal page size of connected SDRAM device.	EMIF_SDRAM_CONFIG[2:0] REG_PAGESIZE	0x-
Configure the DDR PHY physical layer to the SDRAM (Read Latency for the read data from SDRAM in number of DDR clock cycles)	EMIF_DDR_PHY_CTRL_1 ⁽¹⁾	0x-----
Write the Shadow register of the EMIF_DDR_PHY_CTRL_1 with the same value.	EMIF_DDR_PHY_CTRL_1_SHDW ⁽¹⁾	EMIF_DDR_PHY_CTRL_1
Initialize MR LPDDR2 registers.	External LPDDR2 initialization, see Table 15-120	
Configure the DDR PHY physical layer to the SDRAM parameters.	EMIF_DDR_PHY_CTRL_2	0x-----
Define timings and clock parameters	EMIF Timing Initialization, see Table 15-119	
Configure the SDRAM Output Impedance Calibration parameters	EMIF Output Impedance Calibration Mode, see Table 15-121	
Configure the Temperature Alert parameters	EMIF Temperature Monitoring Mode, see Table 15-130	
(Optional) Configure the performance counter configuration Register	EMIF_PERF_CNT_CFG	0x-00--00-
(Optional) Configure the performance counter master region select register	EMIF_PERF_CNT_SEL	0x--0---0-
(Optional) Configure the System, Low-Latency L3 and MPU Interface threshold maxima.	EMIF_L3_CONFIG	0x0-0-00--
Clear all eventual previous indications of treated interrupts.	EMIF_IRQSTATUS_SYS, EMIF_IRQSTATUS_LL	0x-
(Optional) Enable system L3 interrupt for command or address error.	EMIF_IRQENABLE_SET_SYS[0] REG_EN_ERR_SYS	0x1
(Optional) Enable low-latency L3 interrupt for command or address error.	EMIF_IRQENABLE_SET_LL[0] REG_EN_ERR_LL	0x1

⁽¹⁾ Values loaded in these registers depend on OPP.

15.3.5.1.1.2 Subsequence – EMIF Timing Initialization

Table 15-119. Subsequence – EMIF Timing Initialization

Step	Register/ Bit Field / Programming Model	Value
Determine the minimum required size of the Read Idle window to be detected or generated.	EMIF_READ_IDLE_CTRL[19:16] REG_READ_IDLE_LEN	0x-
Determine the maximum interval between successive read idle events.	EMIF_READ_IDLE_CTRL[8:0] REG_READ_IDLE_INTERVAL	0x---
Write the Shadow register of the EMIF_READ_IDLE_CTRL with the same value.	EMIF_READ_IDLE_CTRL_SHDW	EMIF_READ_IDLE_CTRL
Define the minimum number of DDR clock cycles from Precharge to Activate or Refresh, minus one.	EMIF_SDRAM_TIM_1[28:25]REG_T_RP	0x-
Define minimum number of DDR clock cycles from Activate to Read or Write, minus one.	EMIF_SDRAM_TIM_1[24:21] REG_T_RCD	0x-

Table 15-119. Subsequence – EMIF Timing Initialization (continued)

Step	Register/ Bit Field / Programming Model	Value
Define minimum number of DDR clock cycles from last Write transfer to Precharge, minus one.	EMIF_SDRAM_TIM_1[20:17] REG_T_WR	0x-
Define minimum number of DDR clock cycles from Activate to Precharge, minus one.	EMIF_SDRAM_TIM_1[16:12] REG_T_RAS	0x--
Define Minimum number of DDR clock cycles from Activate to Activate, minus one.	EMIF_SDRAM_TIM_1[11:6]REG_T_RC	0x--
Define Minimum number of DDR clock cycles from Activate to Activate for a different bank, minus one.	EMIF_SDRAM_TIM_1[5:3]REG_T_RRD	0x-
Define Minimum number of DDR clock cycles from last Write to Read, minus one.	EMIF_SDRAM_TIM_1[2:0] REG_T_WTR	0x-
Write the Shadow register of the EMIF_SDRAM_TIM_1 ⁽¹⁾ .	EMIF_SDRAM_TIM_1_SHDW ⁽¹⁾	0x-----
Define minimum number of DDR clock cycles from Powerdown exit to any command other than a Read, minus one.	EMIF_SDRAM_TIM_2[30:28] REG_T_XP	0x-
Define minimum number of DDR clock cycles from Self-Refresh exit to any command other than a Read command, minus one.	EMIF_SDRAM_TIM_2[24:16] REG_T_XSNR	0x---
Define minimum number of DDR clock cycles from Self-Refresh exit to a Read command, minus one.	EMIF_SDRAM_TIM_2[15:6] REG_T_XSRD	0x---
Define minimum number of DDR clock cycles for the last read command to a Precharge command, minus one.	EMIF_SDRAM_TIM_2[5:3] REG_T_RTP	0x-
Write the Shadow register of the EMIF_SDRAM_TIM_2 ⁽²⁾ .	EMIF_SDRAM_TIM_2_SHDW ⁽²⁾	0x-----
Define minimum number of DDR clock cycles for which LPDDR2 must remain in Self Refresh, minus one.	EMIF_SDRAM_TIM_3[23:21] REG_T_CKESR	0x-
Define number of DDR clock cycles for a ZQCS command duration, minus one.	EMIF_SDRAM_TIM_3[20:15] REG_ZQ_ZQCS	0x--
Define number of DDR clock cycles related to the tDQSCKmax timing parameter. For a 400MHz DDR clock and tDQSCKMAX=5.5 ns, the recommended setting is 0x2.	EMIF_SDRAM_TIM_3[14:13] REG_T_TDQSCCKMAX	0x2
Define minimum number of DDR clock cycles from Refresh or Load Mode to Refresh or Activate, minus one.	EMIF_SDRAM_TIM_3[12:4] REG_T_RFC	0x---
Define maximum number of EMIF_SDRAM_REF_CTRL [15:0] REG_REFRESH_RATE intervals from Activate to Precharge command.	EMIF_SDRAM_TIM_3[3:0] REG_T_RAS_MAX	0x-
Write the Shadow register of the EMIF_SDRAM_TIM_3 ⁽²⁾ .	EMIF_SDRAM_TIM_3_SHDW ⁽²⁾	0x-----
Define the rate at which the connected SDRAM devices are refreshed.	EMIF_SDRAM_REF_CTRL[15:0] REG_REFRESH_RATE	0x----
Write the Shadow register of the EMIF_SDRAM_REF_CTRL with the same value.	EMIF_SDRAM_REF_CTRL_SHDW	EMIF_SDRAM_REF_CTRL

⁽¹⁾ Values loaded in these registers depend on OPP.

⁽²⁾ Values loaded in these registers depend on OPP.

15.3.5.1.1.3 Subsequence - External LPDDR2 Initialization

Table 15-120. Subsequence - External LPDDR2 Initialization

Step	LPDDR2 mode registers (MR)	Value
Wait until MR0[0]=0 (MR0[0] = 0 indicates that memory auto – initialization is completed).	MR0[0]	=0
Issue ZQINIT calibration command.	MR10	0xFF
Configure BT, BL, WC.	MR1	0x--
Configure the memory latency settings (RL and WL).	MR2 ⁽¹⁾	0x--
Unmask memory banks.	MR16	0x--
Unmask memory segments.	MR17	0x--

⁽¹⁾ Memory latency settings (RL and WL) depend on OPP.

15.3.5.1.2 Operational Modes Configuration

15.3.5.1.2.1 EMIF Output Impedance Calibration Mode

Table 15-121. EMIF Output Impedance Calibration Mode

Step	Register/Bit Field/Programming Model	Value
IF : Calibration per CS		
Determine on which chip select CS1 or CS0 the calibration is enabled.	EMIF_ZQ_CONFIG[31:30] REG_ZQ_CS1/0EN	0x-
ELSE : (Calibration on both the CS0 and CS1)		
Enable automatic output impedance calibration for both the chip selects simultaneously.	EMIF_ZQ_CONFIG[29] REG_ZQ_DUALCALEN	0x1
ENDIF		
Define the interval (number of refresh periods) between ZQCS commands.	EMIF_ZQ_CONFIG[15:0] REG_ZQ_REFINTERVAL	0x----
Define the number of ZQCL durations that build the ZQINIT duration.	EMIF_ZQ_CONFIG[19:18] REG_ZQ_ZQINIT_MULT	0x-
Define the number of ZQCS intervals that build the ZQCL duration.	EMIF_ZQ_CONFIG[17:16] REG_ZQ_ZQCL_MULT	0x-
Enable the issuing of ZQ-Long command on self-refresh, active power-down, and precharge power-down exit.	EMIF_ZQ_CONFIG[28] REG_ZQ_SFEXITEN	0x1

15.3.5.1.2.2 EMIF MR Read

Table 15-122. EMIF MR Read

Step	Register/Bit Field/Programming Model	Value
Choose CS0 or CS1 to issue the mode register read command.	EMIF_LPDDR2_MODE_REG_CFG[31] REG_CS	0x-
Write the mode register (MR) address.	EMIF_LPDDR2_MODE_REG_CFG[7:0] REG_ADDRESS	0x--
Initiate read command by reading the register.	EMIF_LPDDR2_MODE_REG_DATA[7:0]	

15.3.5.1.2.3 EMIF MR Write

Table 15-123. EMIF MR Write

Step	Register/Bit Field/Programming Model	Value
Choose CS0 or CS1 to issue mode register write command.	EMIF_LPDDR2_MODE_REG_CFG[31] REG_CS	0x-
Write the mode register (MR) address.	EMIF_LPDDR2_MODE_REG_CFG[7:0] REG_ADDRESS	0x----
Supply the data byte to be written and initiate write command by writing the register.	EMIF_LPDDR2_MODE_REG_DATA[7:0] REG_VALUE_0	0x–

15.3.5.1.2.4 EMIF SDRAM Self-Refresh

Table 15-124. EMIF SDRAM Self-Refresh Entering

Step	Register/Bit Field/Programming Model	Value
Define the number of DDR clock cycles after which the EMIF puts the external SDRAM in Self Refresh mode, when EMIF is idle.	EMIF_PWR_MGMT_CTRL[7:4] REG_SR_TIM	0x-
Enable self-refresh mode.	EMIF_PWR_MGMT_CTRL[10:8] REG_LP_MODE	0x2
Write the shadow register of EMIF_PWR_MGMT_CTRL.	EMIF_PWR_MGMT_CTRL_SHDW	0x-

Table 15-125. EMIF SDRAM Self-Refresh Exiting

Step	Register/ Bit Field / Programming Model	Value
Change REG_LP_MODE bitfield from 0x2 to any value.	EMIF_PWR_MGMT_CTRL[10:8] REG_LP_MODE	0x-
Write the shadow register of EMIF_PWR_MGMT_CTRL.	EMIF_PWR_MGMT_CTRL_SHDW	0x-----

15.3.5.1.2.5 EMIF LPDDR2 SDRAM Power-Down Mode

Table 15-126. EMIF SDRAM Power-Down Mode

Step	Register/Bit Field/Programming Model	Value
Define the number of DDR clock cycles after which the EMIF puts the external SDRAM in Power Down mode, when EMIF is idle.	EMIF_PWR_MGMT_CTRL[15:12] REG_PD_TIM	0x-
Enable (enter) power-down mode.	EMIF_PWR_MGMT_CTRL[10:8] REG_LP_MODE	0x4
Write the shadow register of EMIF_PWR_MGMT_CTRL.	EMIF_PWR_MGMT_CTRL_SHDW	0x-----

Table 15-127. EMIF SDRAM Power-Down Mode Exiting

Step	Register/ Bit Field / Programming Model	Value
Change REG_LP_MODE bitfield from 0x4 to any value.	EMIF_PWR_MGMT_CTRL[10:8] REG_LP_MODE	0x-
Write the shadow register of EMIF_PWR_MGMT_CTRL.	EMIF_PWR_MGMT_CTRL_SHDW	0x-----

15.3.5.1.2.6 EMIF LPDDR2-SDRAM Deep Power-Down Mode

Table 15-128. EMIF LPDDR2-SDRAM Deep Power-Down Mode Entering

Step	Register/Bit Field/Programming Model	Value
Define the number of DDR clock cycles after which the EMIF puts the external SDRAM in Power saving mode, when EMIF is idle.	EMIF_PWR_MGMT_CTRL[3:0] REG_CS_TIM	0x-
Enable (enter) deep power-down mode.	EMIF_PWR_MGMT_CTRL[11] REG_DPD_EN	0x1
Write the shadow register of EMIF_PWR_MGMT_CTRL.	EMIF_PWR_MGMT_CTRL_SHDW	0x-----

Table 15-129. EMIF LPDDR2-SDRAM Deep Power-Down Mode Exiting

Step	Register/ Bit Field / Programming Model	Value
Clear REG_DPD_EN bit.	EMIF_PWR_MGMT_CTRL[11] REG_DPD_EN	0
Write the shadow register of EMIF_PWR_MGMT_CTRL.	EMIF_PWR_MGMT_CTRL_SHDW	0x-----

NOTE: After Deep Power-Down exit Software must perform initialization, as specified in [Table 15-120](#).

15.3.5.1.2.7 EMIF Temperature Monitoring Mode

Table 15-130. EMIF Temperature Monitoring Mode

Step	Register/Bit Field/Programming Model	Value
Determine whether CS1 or CS0 is used for temperature alert polling.	EMIF_TEMP_ALERT_CONFIG[31:30] REG_TA_CS1/0EN	0x-
Define the interval (number of refresh periods) between temperature alert polls.	EMIF_TEMP_ALERT_CONFIG[21:0] REG_TA_REFINTERVAL	0x-----
Define how wide the physical memory device is.	EMIF_TEMP_ALERT_CONFIG[27:26] REG_TA_DEVWDT	0x-
Define which external byte lanes contain a device for temperature monitoring (which devices to be polled).	EMIF_TEMP_ALERT_CONFIG[25:24] REG_TA_DEVCNT	0x-
(Optional) Enable the issuing of a temperature alert poll on self-refresh exit (poll for temperature change every time EMIF exits self-refresh, active power-down, and precharge power-down modes).	EMIF_TEMP_ALERT_CONFIG[28] REG_TA_SFEXITEN	0x1
Enable system L3 interrupt for SDRAM temperature alert.	EMIF_IRQENABLE_SET_SYS[1] REG_EN_TA_SYS	0x1
Enable low-latency L3 interrupt for SDRAM temperature alert.	EMIF_IRQENABLE_SET_LL[1] REG_EN_TA_LL	0x1

15.3.5.1.3 EMIF Events Servicing

15.3.5.1.3.1 Interrupt Servicing

This section describes event servicing (interrupt treatment) of the EMIF module.

The following Interrupt mechanism is double, because there are two EMIF modules with different register addresses and two Interrupt lines, EMIF1_IRQ and EMIF2_IRQ.

Table 15-131. EMIF Event Servicing

Step	Register/ Bit Field / Programming Model	Value
Read the status registers:	EMIF_IRQSTATUS_SYS, EMIF_IRQSTATUS_LL	
IF:	EMIF_IRQSTATUS_SYS[0]	=1

Table 15-131. EMIF Event Servicing (continued)

Step	Register/ Bit Field / Programming Model	Value
Read the Error Log register and determine the Addressing mode, Command type and the Connection ID of the first errored transaction.	EMIF_L3_ERR_LOG	
Clear corresponding status flag	EMIF_IRQSTATUS_SYS[0] REG_ERR_SYS	0x1
ELSE IF :	EMIF_IRQSTATUS_SYS[1]	=1
Update the REFRESH_RATE to the required value as per the temperature change.	EMIF_SDRAM_REF_CTRL[15:0] REG_REFRESH_RATE	0x----
Clear corresponding status flag	EMIF_IRQSTATUS_SYS[1] REG_TA_SYS	0x1
ELSE IF:	EMIF_IRQSTATUS_LL[0]	=1
Read the error log register and determine the addressing mode, command type, and connection ID of the first errored transaction.	EMIF_L3_ERR_LOG	
Clear corresponding status flag	EMIF_IRQSTATUS_LL[0] REG_ERR_LL	0x1
ELSE IF:	EMIF_IRQSTATUS_LL[1]	=1
Update the REFRESH_RATE to the required value as per the temperature change.	EMIF_SDRAM_REF_CTRL[15:0] REG_REFRESH_RATE	0x----
Clear corresponding status flag	EMIF_IRQSTATUS_LL[1] REG_TA_LL	0x1
ENDIF		
Disable interrupts if needed	EMIF_IRQENABLE_CLR_SYS[0] REG_EN_ERR_SYS or EMIF_IRQENABLE_CLR_LL[0] REG_EN_ERR_LL	0x1

15.3.6 EMIF Register Manual

Table 15-132 lists the EMIF instance.

15.3.6.1 EMIF Instance Summary

Table 15-132. EMIF Instance Summary

Module Name	Base Address	Size
EMIF1	0x4C00 0000	16MB
EMIF2	0x4D00 0000	16MB

15.3.6.2 EMIF Registers

Table 15-133 summarizes the EMIF register mapping.

15.3.6.2.1 EMIF Register Summary

Table 15-133. EMIF Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	EMIF1 L3 Physical Address	EMIF2 L3 Physical Address

EMIF_DDR_PHY_CTRL_1_SHDW	RW	32	0x0000 00E8	0x4C00 00E8	0x4D00 00E8

NOTE: The values of the different bit fields in the [EMIF_SDRAM_CONFIG](#) and [EMIF_SDRAM_CONFIG2](#) registers are set by the control module at reset. These values must be modified by the configuration header feature in the ROM code or by the initial boot image running from an external XIP booting memory or internal RAM (see [Section 27.4.8, Image Format](#)). They must not be modified during run time, because they reflect the used hardware LPDDR2 SDRAM configurations.

15.3.6.2.2 EMIF Register Description

[Table 15-134](#) through describe the individual EMIF registers.

Table 15-134. EMIF_MOD_ID_REV

Address Offset	0x0000 0000	Instance	EMIF1 EMIF2
Physical Address	0x4C00 0000 0x4D00 0000		
Description	Revision number register		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																															

Bits	Field Name	Description	Type	Reset
31:0	RESERVED	Reserved for future use	R	0x---- (1)

(1) TI internal data

Table 15-136. EMIF_STATUS

Address Offset	0x0000 0004	Instance	EMIF1 EMIF2
Physical Address	0x4C00 0004 0x4D00 0004		
Description	SDRAM Status Register (STATUS)		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REG_BE	REG_DUAL_CLK_MODE	REG_FAST_INIT	RESERVED														REG_PHY_DLL_READY	RESERVED													

Bits	Field Name	Description	Type	Reset
31	REG_BE	Big endian mode select for 8 and 16-bit devices, set to 1 for big endian or 0 for little endian operation.	R	0
30	REG_DUAL_CLK_MODE	Dual Clock mode. Defines whether the L3_clk and EMIF_FCLK clock are asynchronous. L3_clk and EMIF_FCLK clock are asynchronous, if set to 1.	R	1
29	REG_FAST_INIT	Fast Init. Defines whether the EMIF fast initialization mode has been enabled. Fast initialization is enabled if set to 1.	R	0
28:3	RESERVED	Reserved	R	0x0000000
2	REG_PHY_DLL_READY	DDR PHY Ready. Reflects the value on the phy_ready port (active high) that defines whether the DDR PHY is ready for normal operation. The DDR PHY is ready for normal operation, if set to 1.	R	1
1:0	RESERVED	Reserved	R	0x0

Table 15-138. EMIF_SDRAM_CONFIG

Address Offset	0x0000 0008	Instance	EMIF1 EMIF2
Physical Address	0x4C00 0008 0x4D00 0008		
Description	SDRAM Config Register. A write to this register will cause the EMIF to start the SDRAM initialization sequence if it was not performed previously because EMIF_SDRAM_REF_CTRL[31] REG_INITREF_DIS was a zero.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0					
REG_SDRAM_TYPE			REG_IBANK_POS			RESERVED			REG_DDR2_DDQS	RESERVED			REG_DDR_DISABLE_DLL			RESERVED			REG_NARROW_MODE			REG_CL			REG_ROWSIZE			REG_IBANK			REG_EBANK			REG_PAGESIZE		

Bits	Field Name	Description	Type	Reset
31:29	REG_SDRAM_TYPE	SDRAM Type selection. Set to 4 for LPDDR2-S4, Set to 5 for LPDDR2-S2 All other value are reserved.	RW	0x- ⁽¹⁾
28:27	REG_IBANK_POS	Internal bank position. Set to 0 to assign internal bank address bits from L3 address as shown in Table 15-108 and Table 15-109 . Set to 1, 2, or 3 to assign internal bank address bits from L3 address as shown in Table 15-110 , Table 15-111 , and Table 15-112 .	RW	0x- ⁽¹⁾
26:24	RESERVED	RESERVED	RW	0x0
23	REG_DDR2_DDQS	DDR2 differential DQS enable. Set to 0 for single-ended DQS. Set to 1 for differential DQS. This bit is only for DDR2 mode, because the device supports LPDDR2; this bit is don't care.	RW	0x- ⁽¹⁾
22:21	RESERVED	RESERVED	RW	0x- ⁽¹⁾
20	REG_DDR_DISABLE_DLL	Disable DLL select. Set to 1 to disable DLL inside SDRAM.	RW	0x- ⁽¹⁾
19:16	RESERVED	RESERVED	RW	0x0
15:14	REG_NARROW_MODE	SDRAM data bus width. Set to 0 for 32-bit and set to 1 for 16-bit. All other values are reserved.	RW	0x- ⁽¹⁾
13:10	REG_CL	CAS Latency (referred to as read latency (RL) in some SDRAM specs). The value of this field defines the CAS latency to be used when accessing connected SDRAM devices. Value of 3, 4, 5, 6, 7, and 8 (CAS latency of 3, 4, 5, 6, 7, and 8) are supported for LPDDR2-SDRAM. All other values are reserved. Also program the EMIF_DDR_PHY_CTRL_1[3:0] REG_READ_LATENCY	RW	0x- ⁽¹⁾
9:7	REG_ROWSIZE	Row Size. Defines the number of row address bits of connected SDRAM devices. Set to 0 for 9 row bits, Set to 1 for 10 row bits, Set to 2 for 11 row bits, Set to 3 for 12 row bits, Set to 4 for 13 row bits, Set to 5 for 14 row bits, Set to 6 for 15 row bits, Set to 7 for 16 row bits. This field is only used when EMIF_SDRAM_CONFIG[28:27] REG_IBANK_POS field is set to 1, 2, or 3 or REG_EBANK_POS field in EMIF_SDRAM_CONFIG_2 register is set to 1.	RW	0x- ⁽¹⁾

⁽¹⁾ Value loaded by the control module at reset (see [Section 18.6.4](#), [SYSCTRL_GENERAL_WKUP Register Summary](#)).

Bits	Field Name	Description	Type	Reset
6:4	REG_IBANK	Internal Bank setup. Defines number of banks inside connected SDRAM devices. Set to 0 for 1 bank, Set to 1 for 2 banks, Set to 2 for 4 banks, Set to 3 for 8 banks. All other values are reserved.	RW	0x- ⁽¹⁾
3	REG_EBANK	External chip select setup. Defines whether SDRAM accesses will use 1 or 2 chip select lines. Set to 0 to use pad_cs_o_n[0] only. Set to 1 to use pad_cs_o_n[1:0]. This bit will automatically be set to 0 if EMIF_SDRAM_CONFIG_2[30] REG_CS1NVMEN field is set to 1.	RW	0x- ⁽¹⁾
2:0	REG_PAGESIZE	Page Size. Defines the internal page size of connected SDRAM devices. Set to 0 for 256-word page (8 column bits), Set to 1 for 512-word page (9 column bits), Set to 2 for 1024-word page (10 column bits), Set to 3 for 2048-word page (11 column bits). All other values are reserved.	RW	0x- ⁽¹⁾

Table 15-154. EMIF_SDRAM_TIM_3

Address Offset	0x0000 0028	Instance	EMIF1 EMIF2
Physical Address	0x4C00 0028 0x4D00 0028		
Description	SDRAM Timing 3 Register. If this register is byte written, care must be taken that all the fields are written before performing any accesses to the SDRAM.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								REG_T_CKESR	REG_ZQ_ZQCS				REG_T_TDQSKMAX	REG_T_RFC				REG_T_RAS_MAX													

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	Reserved	R	0x0
23:21	REG_T_CKESR	Minimum number of DDR clock cycles for which LPDDR2 must remain in Self Refresh, minus one.	RW	0x2
20:15	REG_ZQ_ZQCS	Number of DDR clock cycles for a ZQCS command, minus one.	RW	0x08
14:13	REG_T_TDQSKMAX	Number of DDR clock cycles that satisfy the tDQSKmax timing parameter minus one. For a 400MHz DDR clock and tDQSKMAX=5.5 ns, the recommended setting is 2.5 ns x 3 clks = 7.5 ns. 3 clks - 1 = 0x2.	RW	0x1
12:4	REG_T_RFC	Minimum number of DDR clock cycles from Refresh or Load Mode to Refresh or Activate, minus one.	RW	0x115
3:0	REG_T_RAS_MAX	Maximum number of reg_refresh_rate intervals from Activate to Precharge command. This field must be equal to ((tRASmax / tREFI)-1) rounded down to the next lower integer. Value for REG_T_RAS_MAX can be calculated as follows: If tRASmax = 120 us and tREFI = 15.7 us, then REG_T_RAS_MAX = ((120/15.7)-1) = 6.64. Round down to the next lower integer. Therefore, the programmed value must be 6.	RW	0x1

15:12	REG_PD_TIM	Power Mangement timer for Power-Down. The EMIF will put the external SDRAM in Power-Down mode after the EMIF is idle for these number of DDR clock cycles and if reg_lp_mode field is set to 4. Set to 0 to immediately enter Power-Down mode. Set to 1 for 16 clocks, set to 2 for 32 clocks, set to 3 for 64 clocks, set to 4 for 128 clocks, set to 5 for 256 clocks, set to 6 for 512 clocks, set to 7 for 1024 clocks, set to 8 for 2048 clocks, set to 9 for 4096 clocks, set to 10 for 8192 clocks, set to 11 for 16384 clocks, set to 12 for 32768 clocks, set to 13 for 65536 clocks, set to 14 for 131072 clocks, and set to 15 for 262144 clocks.	RW	0x0
11	REG_DPD_EN	Deep Power Down enable. Set to 0 for normal operation. Set to 1 to enter deep power-down mode. This mode will override the reg_lp_mode field setting.	RW	0
10:8	REG_LP_MODE	Automatic Power Management enable Set to 1: Reserved Set to 2: Self-refresh mode Set to 4: Power-down mode All other values will disable automatic power management.	RW	0x0

Bits	Field Name	Description	Type	Reset
7:4	REG_SR_TIM	Power Mangement timer for Self Refresh. The EMIF will put the external SDRAM in Self Refresh mode after the EMIF is idle for these number of DDR clock cycles and if reg_lp_mode field is set to 2. Set to 0 to immediately enter Self Refresh mode. Set to 1 for 16 clocks, set to 2 for 32 clocks, set to 3 for 64 clocks, set to 4 for 128 clocks, set to 5 for 256 clocks, set to 6 for 512 clocks, set to 7 for 1024 clocks, set to 8 for 2048 clocks, set to 9 for 4096 clocks, set to 10 for 8192 clocks, set to 11 for 16384 clocks, set to 12 for 32768 clocks, set to 13 for 65536 clocks, set to 14 for 131072 clocks, and set to 15 for 262144 clocks.	RW	0x0
3:0	REG_CS_TIM	Power Mangement timer for Clock Stop. The EMIF will put the external SDRAM in Clock Stop mode after the EMIF is idle for these number of DDR clock cycles and if reg_lp_mode field is set to 1. Set to 0 to immediately enter Clock Stop mode. Set to 1 for 16 clocks, set to 2 for 32 clocks, set to 3 for 64 clocks, set to 4 for 128 clocks, set to 5 for 256 clocks, set to 6 for 512 clocks, set to 7 for 1024 clocks, set to 8 for 2048 clocks, set to 9 for 4096 clocks, set to 10 for 8192 clocks, set to 11 for 16384 clocks, set to 12 for 32768 clocks, set to 13 for 65536 clocks, set to 14 for 131072 clocks, and set to 15 for 262144 clocks.	RW	0x0

RESERVED				REG_SYS_THRESH_MAX				REG_MPU_THRESH_MAX				REG_LL_THRESH_MAX				RESERVED							RESERVED								

Bits	Field Name	Description	Type	Reset
31:28	RESERVED	Reserved for future use.	R	0x0
27:24	REG_SYS_THRESH_MAX	System L3 Threshold Maximum. The number of commands the system interface can consume in the command FIFO. The value is used to determine when to stop future request, writing a zero will reserve no space for the associated interface. In the event the value is set to zero and a request is seen for that interface, the command FIFO will assume a value of 1. Since the low-latency interface has effectively a higher priority, the only way for the system interface to use all command FIFO entries is to set the REG_LL_THRESH_MAX to zero.	RW	0x7

Bits	Field Name	Description	Type	Reset
23:20	REG_MPU_THRESH_MAX	MPU Interface Threshold Maximum. The number of commands the MPU interface can consume in the command FIFO. The value is used to determine when to stop future request, writing a zero will reserve no space for the associated interface. In the event the value is set to zero and a request is seen for that interface, the command FIFO will assume a value of 1.	RW	0x7
19:16	REG_LL_THRESH_MAX	Low-latency L3 Threshold Maximum. The number of commands the low latency interface can consume in the command FIFO. The value is used to determine when to stop future request, writing a zero will reserve no space for the associated interface. In the event the value is set to zero and a request is seen for that interface, the command FIFO will assume a value of 1.	RW	0x7
15:8	RESERVED	Reserved for future use.	R	0x0
7:0	RESERVED	Although this field is reserved, it is still read writable. Values written have no effect on operation of the EMIF4D3.	RW	0xFF

Table 15-212. EMIF_DDR_PHY_CTRL_1

Address Offset	0x0000 00E4	Instance	EMIF1 EMIF2
Physical Address	0x4C00 00E4 0x4D00 00E4		
Description	DDR PHY Control 1 Register. This register is used to control the DDR PHY. The bit field definitions are DDR PHY specific.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																
DLL_MASTER_SENSITIVITY								REG_PHY_FREEZE_DELAY_CODE_POSTAMBLE								REG_PHY_FREEZE_DELAY_CODE_PREAMBLE								REG_DLL_MASTER_SW_CODE_CTRL								REG_DLL_SLAVE_DLY_CTRL								REG_READ_LATENCY							

Bits	Field Name	Description	Type	Reset
31:30	DLL_MASTER_SENSITIVITY	This field defines the level of sensitivity of the DLL master: the lower the value, the more sensitive the DLL is to PVT variation. The recommended setting is 0x2.	RW	0x0
29:26	REG_PHY_FREEZE_DELAY_CODE_POSTAMBLE	Postamble time respected by the DATA PHY freezing the DLL slave code after reads. Use the TI-validated value of 0x1.	RW	0x0
25:22	REG_PHY_FREEZE_DELAY_CODE_PREAMBLE	Preamble time respected by the DATA PHY before freezing the DLL slave code during reads. Use the TI-validated value of 0x2.	RW	0x0
21:12	REG_DLL_MASTER_SW_CODE_CTRL	DLL delay code when in software override mode, typically at OPP_BOOT. Keep at maximum delay (0x1FF) for this case. Override mode is controlled through DLL_OVERRIDE register fields in PRCM.	RW	0x1FF
11:4	REG_DLL_SLAVE_DLY_CTRL	DLL slave delay ratio control. For the typical SDRAM frequency of 400 MHz and DLL reference clock frequency of 100 MHz, this number must be set to 0x40 (1/4-th of 0xFF). 0x40: DLL ratio of 4 0x80: DLL ratio of 2 0xFF: DLL ratio of 1	RW	0xFF

Bits	Field Name	Description	Type	Reset
3:0	REG_READ_LATENCY	This field defines the read latency for the read data from SDRAM in number of DDR clock cycles. The REG_READ_LATENCY must be set to EMIF_SDRAM_CONFIG[13:10] REG_CL + EMIF_SDRAM_TIM_3 [14:13] REG_T_TDQSCKMAX. The write latency (WL) is tied to the RL. See the LPDDR2 SDRAM standard.	RW	0x0

15.4 General-Purpose Memory Controller

15.4.1 GPMC Overview

The general-purpose memory controller (GPMC) is a unified memory controller dedicated to interfacing external memory devices:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (only available in non-muxed mode) burst NOR flash devices
- NAND Flash
- Pseudo-SRAM devices

15.4.2 GPMC Environment

This section describes the GPMC application fields from an environment point of view (external connections). It describes GPMC connectivity options, and gives three possible interfaces.

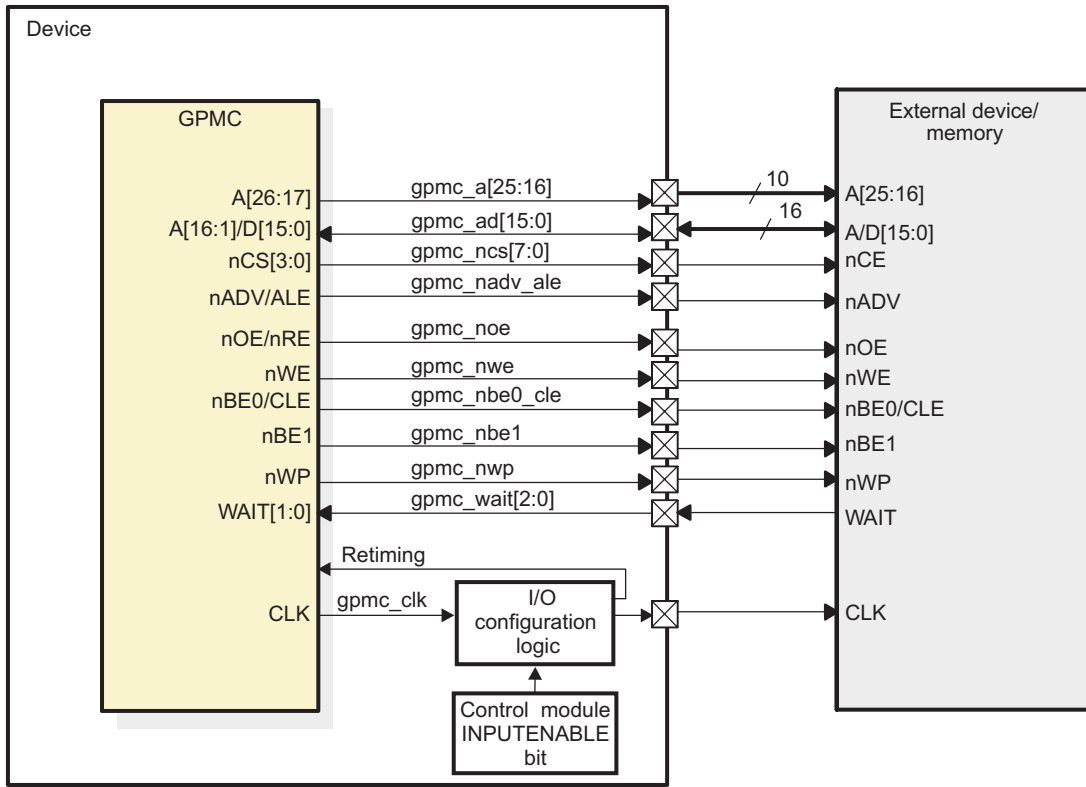

15.4.2.1 GPMC Modes

This section shows three GPMC external connections options:

- [Figure 15-50](#) shows a connection between the GPMC and a 16-bit synchronous address/data-multiplexed (or AAD-multiplexed, but this protocol use less address pins) external memory device ([Figure 15-50](#)).
- [Figure 15-50](#) shows a connection between the GPMC and a 16-bit synchronous nonmultiplexed external memory device ([Figure 15-51](#)).
- [Figure 15-52](#) shows a connection between the GPMC and a 16-bit NAND device ([Figure 15-52](#)).

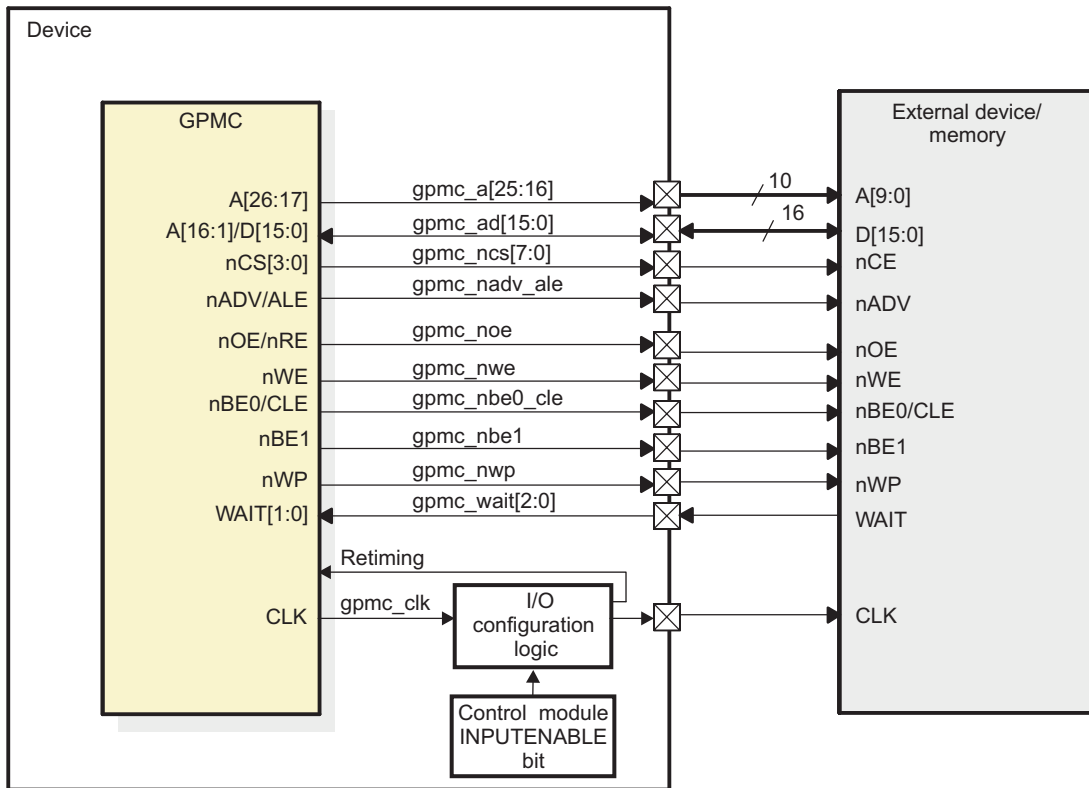

NOTE: The device does not provide the A0 byte address line required for random-byte addressable 8-bit wide device interfacing (for multiplexed and nonmultiplexed protocol). Hence, an 8-bit device must be connected to the D[7:0] / gpmc_ad[7:0] data bus (rather than D[15:8] / gpmc_ad[15:8]) of the GPMC controller. This limits the use of 8-bit wide device interfacing to byte-alias access.

Figure 15-50. GPMC to 16-Bit Address/Data-Multiplexed Memory

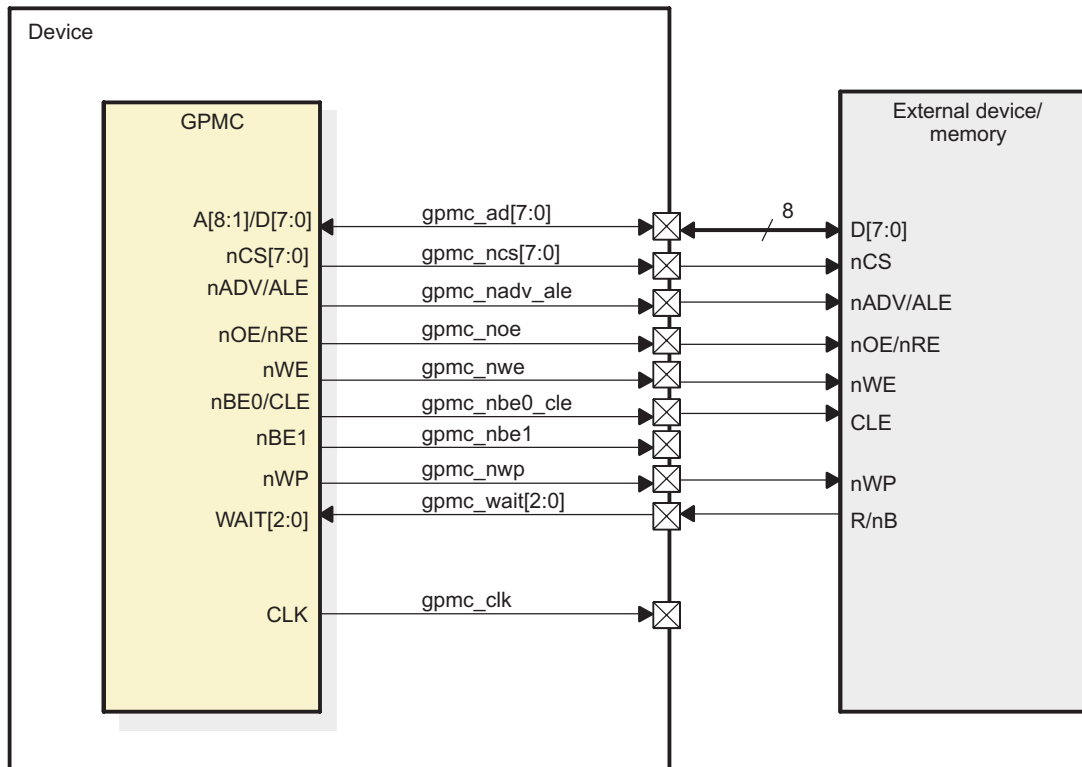

gpmc-002

Figure 15-51. GPMC to 16-Bit Nonmultiplexed Memory

gpmc-045

Figure 15-52. GPMC to 8-Bit NAND Device

gpmc-003

15.4.2.2 GPMC Signals

Table 15-216 lists the GPMC subsystem I/O pins.

Table 15-216. GPMC I/O Description

Pin Name	I/O	Description
gpmc_a[25:16]	O	Address
gpmc_ad[15:0]	I/O	Data
gpmc_ncs[7:0]	O	Chip-selects (active low)
gpmc_clk	O ⁽¹⁾	Clock generated for the external memory or device
gpmc_nadv_ale	O	Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories.
gpmc_noe_nre	O	Output enable (active low). Also used as read enable (active low) for NAND protocol memories.
gpmc_nwe	O	Write enable (active low)
gpmc_nbe0_cle	O	Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories.
gpmc_nbe1	O	Upper-byte enable (active low).
gpmc_nwp	O	Write protect (active low)
gpmc_wait[2:0]	I	External wait signal for NOR and NAND protocol memories. The wait signals can be mapped on any of the chip-select.
gpmc_io_dir	O	gpmc_ad[15:0] signal direction control: Low during transmit (for write access: data OUT from GPMC to memory), High during receive (for read access: data IN from memory to GPMC)

⁽¹⁾ This output signal is also used as retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).

Table 15-217 shows the use of address and data GPMC controller pins based on the type of external device.

Table 15-217. GPMC Pin Multiplexing Options

GPMC Pin	Multiplexed Address Data 16-Bit Device	Nonmultiplexed Address Data 16-Bit Device With LIMITED-ADDRESS Bit Enabled	16-Bit NAND Device	8-Bit NAND Device

gpmc_ad[13]	A14/D13	D13	D13	Not used
gpmc_ad[12]	A13/D12	D12	D12	Not used
gpmc_ad[11]	A12/D11	D11	D11	Not used
gpmc_ad[10]	A11/D10	D10	D10	Not used
gpmc_ad[9]	A10/D9	D9	D9	Not used
gpmc_ad[8]	A9/D8	D8	D8	Not used
gpmc_ad[7]	A8/D7	D7	D7	D7
gpmc_ad[6]	A7/D6	D6	D6	D6
gpmc_ad[5]	A6/D5	D5	D5	D5
gpmc_ad[4]	A5/D4	D4	D4	D4
gpmc_ad[3]	A4/D3	D3	D3	D3
gpmc_ad[2]	A3/D2	D2	D2	D2
gpmc_ad[1]	A2/D1	D1	D1	D1
gpmc_ad[0]	A1/D0	D0	D0	D0

When using non-multiplexed memories, it is recommended to enable [GPMC_CONFIG\[1\] LIMITEDADDRESS](#). This bit forces A[26:11] to 1 on the GPMC I/O side. Thus, only 2Kbytes of memory address space is accessible regardless of the memory size.

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 0x00.

Address mapping supports address/data-multiplexed 16-bit wide devices:

- The NOR flash memory controller still supports non-multiplexed address and data memory devices.
- Multiplexing mode can be selected through the [GPMC_CONFIG1_i\[9:8\] MUXADDDATA](#) bit field (i = 0 to 7).
- Asynchronous page mode is not supported for multiplexed address and data devices.

NOTE: The numbering for A (address) is starting from 1 instead of 0 such as D (data) because the A0 signal is handled within the GPMC but is not driven to any pad. The signal is only relevant to 8-bit accesses and this configuration is not recommended. If such a memory or device is connected, only every second word in the memory is accessible, that is, each 16-bit aligned 8-bit word is mapped but not the non-16-bit aligned ones. Any access to a non-aligned one will actually result in accessing the associated aligned one, at address A1 instead of address A.

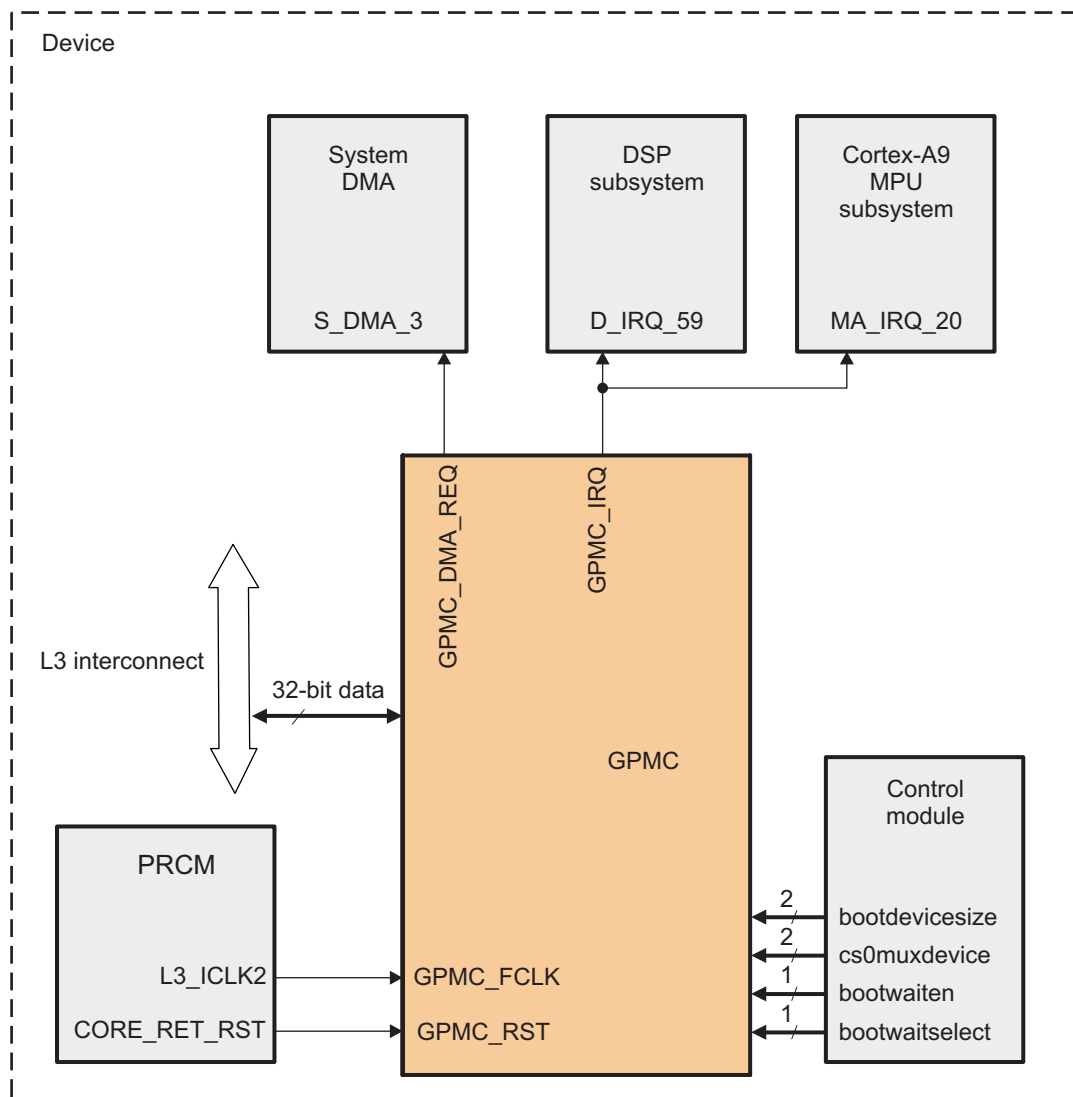

15.4.3 GPMC Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

- No STANDBY hardware handshake
- No wake-up request
- One system direct memory access (sDMA) request
- One interrupt request to the Cortex-A9 MPU Interrupt Controller (MA_IRQ) and to DSP subsystem (D_IRQ)
- One clock for functional and interface domains

Figure 15-53 shows GPMC integration.

Figure 15-53. GPMC Integration

gpmc-004

Table 15-218, Table 15-219 and Table 15-220 summarize the integration of the module in the device.

Table 15-218. GPMC Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-up Capability	Interconnect
GPMC	PD_CORE	No	L3

NOTE:

- For information about operation performance point (OPP) configuration description, see [Section 3.1.1.1.2, Module Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

Table 15-219. GPMC Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
GPMC	GPMC_FCLK	L3_ICLK2	PRCM	Functional clock
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
GPMC	GPMC_RST	CORE_RET_RST	PRCM	GPMC reset

NOTE: For clock description, see [Section 15.4.4.2, GPMC Clock Configuration](#).

Table 15-220. GPMC Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
GPMC	GPMC_IRQ	D_IRQ_59	DSP	GPMC interrupt to DSP subsystem
	GPMC_IRQ	MA_IRQ_20	Cortex-A9	GPMC interrupt to Cortex-A9 MPU subsystem
DMA Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
GPMC	GPMC_DMA_REQ	S_DMA_3	sDMA	GPMC request from Prefetch Engine to sDMA

NOTE:

- For interrupt source description, see [Section 15.4.4.5, GPMC Interrupt Requests](#).
- For DMA source description, see [Section 15.4.4.6, GPMC DMA Requests](#).

15.4.4 GPMC Functional Description

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the eight configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and the data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, 16-bit word, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single synchronous or single asynchronous read or write mode.
- To simulate a programmable internal-wait state, an external wait pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

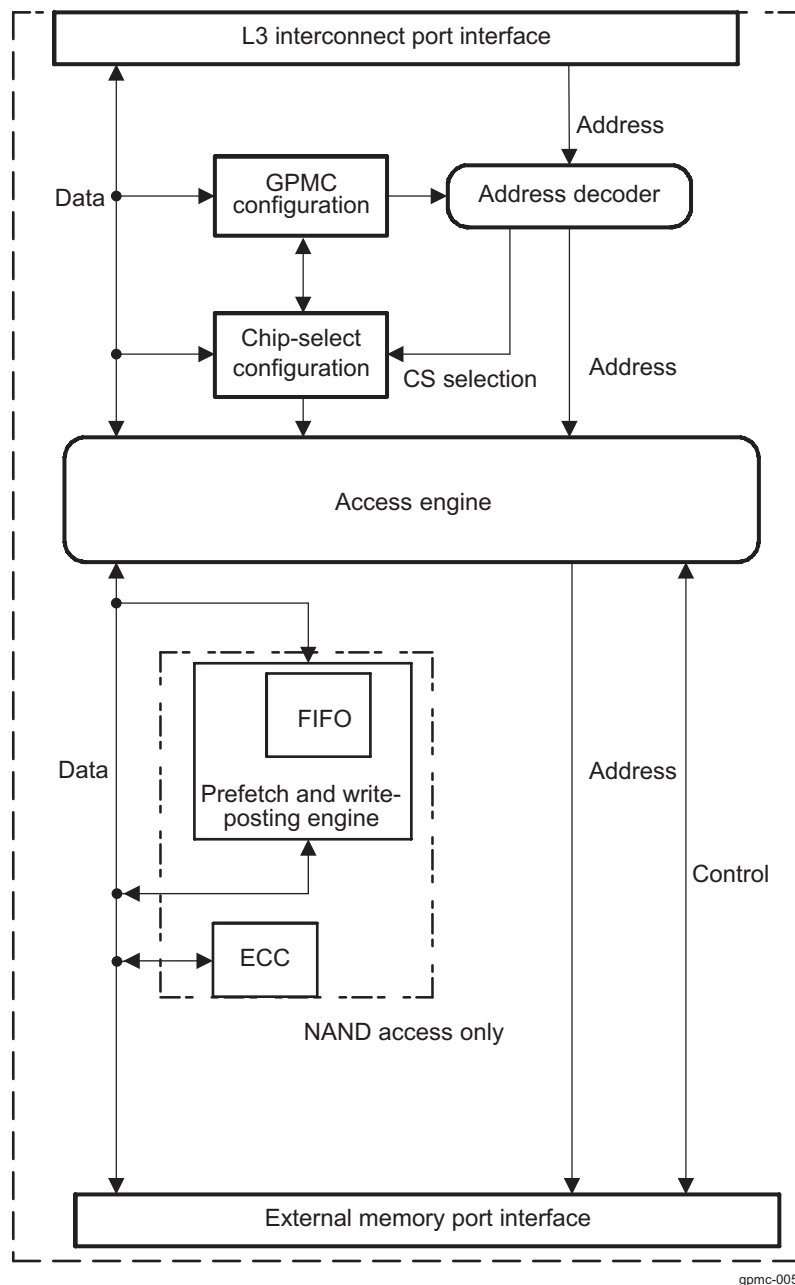

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC_FCLK) is used as a time reference to specify the following:

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

15.4.4.1 GPMC Block Diagram

Figure 15-54 shows the GPMC functional block diagram. The GPMC consists of six blocks:

- L3 interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

Figure 15-54. GPMC Block Diagram

The GPMC can access various external devices through the L3 Interconnect. The flexible programming model allows a wide range of attached device types and access schemes.

Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC is able to generate all control signals timing depending on the attached device and access type.

Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate device type control signals timing.

15.4.4.2 GPMC Clock Configuration

Table 15-221 describes the GPMC clocks.

Table 15-221. GPMC Clocks

Signal	I/O ⁽¹⁾	Description
GPMC_FCLK	I	Functional and interface clock
gpmc_clk	O	External clock provided to synchronous external memory devices.

⁽¹⁾ I = Input; O = Output

The gpmc_clk is generated by the GPMC from the internal GPMC_FCLK clock. The source of the GPMC_FCLK is described in [Table 15-219](#). The gpmc_clk is configured via the [GPMC_CONFIG1_i\[1:0\]](#) GPMCFCLKDIVIDER field (for i = 0 to 7) as shown in [Table 15-222](#).

Table 15-222. gpmc_clk Configuration

Source Clock	GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER	gpmc_clk Generated Clock Provided to External Memory Device
GPMC_FCLK	00	GPMC_FCLK
	01	GPMC_FCLK/2
	10	GPMC_FCLK/3
	11	GPMC_FCLK/4

15.4.4.3 GPMC Software Reset

The GPMC can be reset by software through the [GPMC_SYSCONFIG\[1\]](#) SOFTRESET bit. Setting the bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Hardware and software resets initialize all GPMC registers and the finite state-machine (FSM) immediately and unconditionally. The [GPMC_SYSSTATUS\[0\]](#) RESETDONE bit indicates that the software reset is complete when its value is 1. The software must ensure that the software reset completes before doing GPMC operations.

15.4.4.4 GPMC Power Management

GPMC power is supplied by the CORE power domain, and GPMC power management complies with system power-management guidelines.

[Table 15-223](#) describes power-management features available for the GPMC module.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.6, Clock Management Functional Description](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 15-223. GPMC Local Power Management Features

Feature	Registers	Description
Clock Auto Gating	GPMC_SYSCONFIG[0] AUTOIDLE bit	This bit allows a local power optimization inside the module, by gating the GPMC_FCLK clock upon the internal activity.
Slave Idle Modes	GPMC_SYSCONFIG[4:3] SIDLEMODE bit field	Force-idle, No-idle and Smart-idle wakeup modes are available
Clock Activity	N/A	Feature not available
Master Standby Modes	N/A	Feature not available
Global Wake-up Enable	N/A	Feature not available
Wake-up Sources Enable	N/A	Feature not available

15.4.4.5 GPMC Interrupt Requests

The GPMC generates one interrupt event as shown in [Figure 15-53](#) :

- The interrupt request goes from GPMC (GPMC_IRQ) to the Cortex-A9 MPU subsystem : MA_IRQ_20 and to the DSP subsystem : D_IRQ_59.

[Table 15-224](#) lists the event flags, and their mask, that can cause module interrupts.

Table 15-224. GPMC Interrupt Events

Event Flag	Event Mask	Sensitivity	Map to	Description
GPMC_IRQSTATUS [10] WAIT2EDGE DETECTIONSTATUS	GPMC_IRQENABLE [10] WAIT2EDGE DETECTIONENABLE	Edge	D_IRQ_59 and MA_IRQ_20	Wait2 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait2 signal. The rising or falling edge detection of Wait2 is selected through GPMC_CONFIG [10] WAIT2PINPOLARITY
GPMC_IRQSTATUS [9] WAIT1EDGE DETECTIONSTATUS	GPMC_IRQENABLE [9] WAIT1EDGE DETECTIONENABLE	Edge	D_IRQ_59 and MA_IRQ_20	Wait1 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait1 signal. The rising or falling edge detection of Wait1 is selected through GPMC_CONFIG [9] WAIT1PINPOLARITY
GPMC_IRQSTATUS [8] WAIT0EDGE DETECTIONSTATUS	GPMC_IRQENABLE [8] WAIT0EDGE DETECTIONENABLE	Edge	D_IRQ_59 and MA_IRQ_20	Wait0 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait0 signal. The rising or falling edge detection of Wait0 is selected through GPMC_CONFIG [8] WAIT0PINPOLARITY
GPMC_IRQSTATUS [1] TERMINAL COUNTSTATUS	GPMC_IRQENABLE [1] TERMINAL COUNTENABLE	Level	D_IRQ_59 and MA_IRQ_20	Terminal count event: Triggered on prefetch process completion, that is when the number of currently remaining data to be requested reaches zero
GPMC_IRQSTATUS [0] FIFOEVENTSTATUS	GPMC_IRQENABLE [0] FIFOEVENTENABLE	Level	D_IRQ_59 and MA_IRQ_20	FIFO event interrupt: Indicates FIFO levels availability for in Write-Posting mode and prefetch mode. GPMC_PREFETCH_CONFIG1 [2] DMAMODE shall be set to 0.

15.4.4.6 GPMC DMA Requests

The GPMC generates one DMA event as shown in [Figure 15-53](#) :

- From GPMC (GPMC_DMA_REQ) to the system DMA (sDMA) : S_DMA_3.

15.4.4.7 L3 Interconnect Interface

The GPMC L3 interconnect interface is a pipelined interface including an 16 x 32-bit word write buffer.

Any system host can issue external access requests through the GPMC.

The device system can issue the following requests through this interface:

- One 8-bit / 16-bit / 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 x 32, 4 x 32, 8 x 32 or 16 x 32 with the burst base address aligned on the total burst size are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line, for specific event control.

It is recommended to program the ATTACHEDDEVICEPAGELENGTH field ([GPMC_CONFIG1_i\[24:23\]](#)) according to the effective attached device page length and to enable WRAPBURST bit ([GPMC_CONFIG1_i\[31\]](#)) if the attached device supports wrapping burst.

However, it is possible to emulate wrapping burst on a non-wrapping memory by providing relevant addresses within the page or splitting transactions. Bursts larger than the memory page length are chopped into multiple bursts transactions. Due to the alignment requirements, a page boundary is never crossed.

15.4.4.8 GPMC Address and Data Bus

The current application supports GPMC connection to NAND devices and to address/data-multiplexed memories or devices. Connection to address/data-nonmultiplexed memories or devices is supported with a limited address range of 2 Kbytes.

Depending on the GPMC configuration of each chip-select, address and data bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

- When the [GPMC_CONFIG\[1\] LIMITEDADDRESS](#) bit is set to 1, A26-A11 are not modified during an external memory access. This limits the memory address space to 2K-byte regardless of the memory size.
- For address/data-multiplexed and AAD-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit wide NOR devices do not use GPMC I/O: `gpmc_ad[15:8]` for data (they are used for address if needed).
- 16-bit wide NAND devices do not use GPMC I/O: `gpmc_a[25:16]`.
- 8-bit wide NAND devices do not use GPMC I/O: `gpmc_a[25:16]` and GPMC I/O: `gpmc_ad[15:8]`.

CAUTION

Before accessing a chip-select configured with a nonmultiplexed protocol, set the LIMITEDADDRESS bit control.

15.4.4.8.1 GPMC I/O Configuration Setting

NOTE: In this section and next sections, the *i* in `GPMC_CONFIGx_i` stands for the GPMC chip-select *i* where *i* = 0 to 7.

To select a NAND device, program the following register fields:

- [GPMC_CONFIG1_i\[11:10\]](#) DEVICETYPE field = 0b10
- [GPMC_CONFIG1_i\[9:8\]](#) MUXADDDATA bit = 0b00

To select an address/data-multiplexed device, program the following register fields:

- [GPMC_CONFIG1_i\[11:10\]](#) DEVICETYPE field = 0b00
- [GPMC_CONFIG1_i\[9:8\]](#) MUXADDDATA bit = 0b10

To select an address/address/data-multiplexed device, program the following register fields:

- [GPMC_CONFIG1_i\[11:10\]](#) DEVICETYPE field = 0b00
- [GPMC_CONFIG1_i\[9:8\]](#) MUXADDDATA bit = 0b01

To select an address/data-nonmultiplexed device (limited to a 2K-byte address range), program the following register fields:

- [GPMC_CONFIG1_i\[11:10\]](#) DEVICETYPE field = 0b00
- [GPMC_CONFIG1_i\[9:8\]](#) MUXADDDATA bit = 0b00
- [GPMC_CONFIG\[1\] LIMITEDADDRESS](#) bit = 1

NOTE: The [GPMC_CONFIG1\[1\]](#) LIMITEDADDRESS bit only applies to address/data-nonmultiplexed devices; it has no effect on other device types (NAND, address/data-multiplexed).

15.4.4.8.2 GPMC CS0 Default Configuration at IC Reset

To ensure a correct external boot with a GPMC access from IC reset time on CS0, several external pins are sampled:

- The sys_boot[4:0] pins (device boundary) define the sequence of interfaces and devices to use for booting.
- The sys_boot[5] pin defines which group of booting sequences is preferred: memory booting (sys_boot[5] = 0) or peripheral booting (sys_boot[5] = 1).
- Additional pins are used to configure reset values in the [GPMC_CONFIG1_i](#) register (where i = 0) as detailed below and in [Table 15-225](#):
 - The *bootdevicesize* input pin (at the GPMC boundary) defines the size of the attached device on chip-select 0 and is used to configure the [GPMC_CONFIG1_i\[13:12\]](#) DEVICESIZE bits (where i = 0). The BOOT_DEVICE_TYPE signal is propagated from the system control module (SCM). Its value is fixed for the device at 0x1 at IC reset, which means that only 16-bit memories are supported for booting.
 - The *cs0muxdevice* input pin (at the GPMC boundary) selects whether the attached device to chip-select 0 is an address/data-multiplexed device or not. The input pin is used to configure the [GPMC_CONFIG1_i\[9:8\]](#) MUXADDDATA bit (where i = 0). The CS0_MUX_DEVICE signal is propagated from the SCM. Its value is fixed for the device at 0x2 at IC reset, which means that only address/data-multiplexed memories are supported for booting (that is, in a standalone way from memories connected to CS0).
 - The *bootwaiten* input pin (at the GPMC boundary) enables the monitoring on chip-select 0 of the WAIT pin at IC reset release time for read accesses. The input pin is used to configure the [GPMC_CONFIG1_i\[22\]](#) WAITREADMONITORING bit (where i = 0). The BOOT_WAIT_ENABLE signal is propagated from the system control module (SCM). When sys_boot[5:0] = 0b11 1111, the BOOT_WAIT_ENABLE signal is activated, causing the wait pin to be monitored for read accesses.
 - The *bootwaitselect* input pin selects the WAIT signal at IC reset release time between WAIT0 input pin, WAIT1 input pin or WAIT2 input pin. At IC reset release time, these three pins have different polarity.

Table 15-225. Boot Control Interface Input Signals Description

Signal Name	Width	Description
<i>bootdevicesize</i>	2	Size of the device attached on CS0 0b00: 8-bit 0b01: 16-bit 0b10: Reserved 0b11: Reserved
<i>cs0muxdevice</i>	2	Multiplexing mode of the device on CS0 0b00: Nonmultiplexed device on CS0 0b01: AAD-multiplexed device on CS0 (address-address-data) 0b10: Address/Data-multiplexed device on CS0 0b11: Reserved
<i>bootwaiten</i>	1	Wait monitoring on CS0 at IC reset release time for read accesses 0: Wait pin is not monitored 1: Wait pin is monitored
<i>bootwaitselect</i>	1	Selection of the wait pin 0: WAIT0 input pin 1: WAIT1 input pin 2: WAIT2 input pin

CAUTION

Using the internal boot code, the entire CS0 configuration can be modified before the first CS0 access. This modification of internal boot code is necessary for two external devices:

- NAND device attached to CS0
- Nonmultiplexed 2 Kbytes address range device attached to CS0

At reset time, the IC may boot from the internal ROM.

Reset values of the timing control parameters are defined to cope with direct boot on address and data multiplexed NOR Flash device, on non-multiplexed NOR Flash device or on any asynchronous device with large timing margins assuming a low GPMC_FCLK frequency (for example, 19.2Mhz) at boot time.

For a multiplexed access, the address 16 low-order bits are presented onto gpmc_ad[15:0] while the high-order bits are presented both onto gpmc_a[26:16]. If the external chip interface to the memories uses a 16-bit data bus, the high-order address bits are sampled on the address bus.

The reset values of timing parameters used at boot time are:

- CSONTIME = 1
- CSRDOFFTIME = 16
- ADVONTIME = 4
- ADVRDOFFTIME = 5
- OEONTIME = 6
- OEOFFTIME = 16
- RDACCESSTIME = 15
- RDCYCLETIME = 17

For an AAD-multiplexed access, all address bits are passed onto the data bus using two nADV rising edge. The first rising edge latches the address MSB down to bit 17 while the second rising edge latches address bits 16 down to 1. This configuration is only used for 16-bit memories.

The reset values of these timing parameters used at boot time are:

- ADVAADMUXONTIME = 1
- ADVAADMUXRDOFFTIME = 2
- OEAADMUXONTIME = 1
- OEAADMUXRDOFFTIME = 3

15.4.4.9 Address Decoder and Chip-Select Configuration

Addresses are decoded accordingly with the address request of the chip-select and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and eight sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file should be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated). [Section 15.4.7, GPMC Register Manual](#) provides the GPMC register locations. For the map of GPMC memory locations, see [Chapter 2, Memory Mapping](#).

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

15.4.4.9.1 Chip-Select Base Address and Region Size

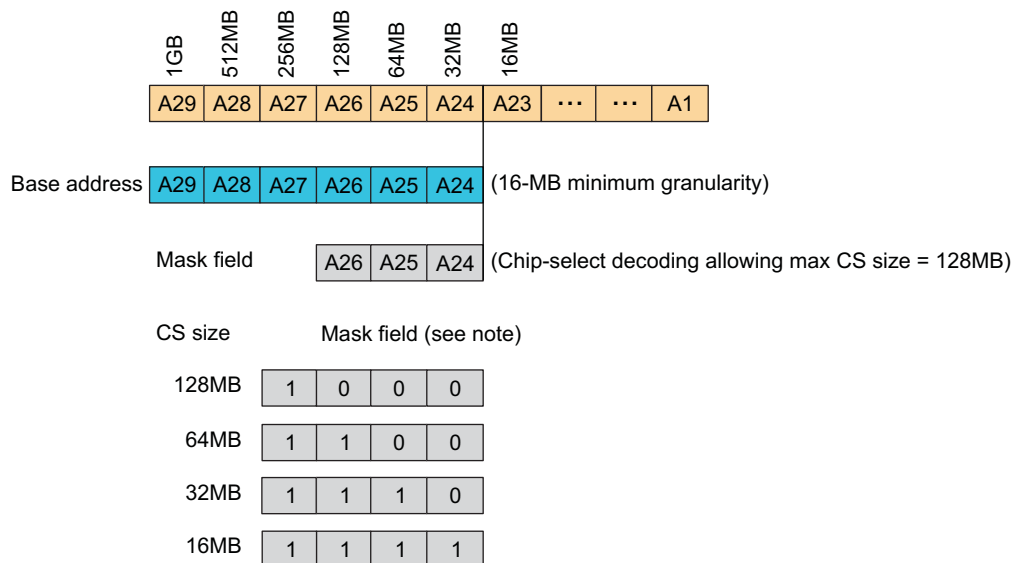

Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 1 Gbyte contiguous address space. For details, see [Chapter 2, Memory Mapping](#).

The GPMC 1G byte address space can be divided into a maximum of eight chip-select regions with programmable base address and programmable CS size. The CS size is programmable from 16M bytes to 128M bytes (must be a power-of-2) and is defined by the mask field. Attached memory smaller than the programmed CS region size is accessed through the entire CS region (aliasing).

Each chip-select has a 6-bit base address encoding and a 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-2 address value. During access decoding, the register base address value is used for address comparison with the address-bit line mapping as described in [Figure 15-55](#) (with A0 as the device system byte-address line). Base address is programmed through the `GPMC_CONFIG7_i[5:0]` BASEADDRESS bit field
- The register mask is used to exclude some address lines from the decoding. A register mask bit field set to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The register mask value must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the `GPMC_CONFIG7_i[11:8]` MASKADDRESS bit field.

Figure 15-55. Chip-Select Address Mapping and Decoding Mask

gpmc-006

Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the `GPMC_CONFIG7_i[6]` CSVALID bit (where i stands for the GPMC chip-select value, $i = 0$ to 7). In addition, a chip-select configuration can only be disabled if there is no ongoing access to that chip-select. This requires activity monitoring of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of chip-selects overlapping, an error is generated and no access will occur on either chip-select.

Chip-select 0 is the only chip-select region enabled after either a power-up or a GPMC reset.

CAUTION

Although the GPMC interface can drive up to 4 chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers, to allow the slowest device to maintain the total load on the lines.

15.4.4.9.2 Access Protocol

15.4.4.9.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the [GPMC_CONFIG1_i\[11:10\]](#) DEVICETYPE parameter (where i = 0 to 7) for:

- Random-access synchronous or asynchronous memory like NOR flash, SRAM
- NAND flash asynchronous devices

NOTE: For more information about the NAND flash GPMC basic programming model and NAND support, see [Section 15.4.4.13](#), *NAND Device Basic Programming Model*, and [Section 15.4.4.13.1](#), *NAND Memory Device in Byte or Word 16 Stream Mode*.

15.4.4.9.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the [GPMC_CONFIG1_i\[13:12\]](#) DEVICESIZE field (i = 0 to 7) to interface with a 16-bit wide device or an 8-bit wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to both the external device data-bus width and little-endian data organization.

NOTE: The device does not provide the A0 byte address line required for random-byte addressable 8-bit wide device interfacing (for both multiplexed and nonmultiplexed protocol). It limits the use of 8-bit wide device interfacing to byte-alias accesses. This limitation is not applicable to NAND device interfacing (8-bit wide or 16-bit wide devices).

15.4.4.9.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 0b00), an address- and data-multiplexing protocol can be selected through the [GPMC_CONFIG1_i\[9:8\]](#) MUXADDDATA bit field (i = 0 to 7). The nADV signal must be used as the external device address latch control signal. For the associated chip-select configuration, nADV assertion and deassertion time and nOE assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device. See [Section 15.4.3](#), *GPMC Integration*.

NOTE: This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data multiplexing protocol. See [Section 15.4.4.13](#), *NAND Device Basic Programming Model*.

15.4.4.9.3 External Signals

15.4.4.9.3.1 WAIT Pin Monitoring Control

GPMC access time can be dynamically controlled using an external gpmc_wait pin when the external device access time is not deterministic and cannot be defined and controlled only using the GPMC internal RDACCESSTIME, WRACCESSTIME and PAGEBURSTACCESSTIME wait state generator.

The GPMC features three input wait pins: gpmc_wait2, gpmc_wait1 and gpmc_wait0. These pins allow control of external devices with different wait-pin polarity. They also allow the overlap of wait-pin assertion from different devices without affecting access to devices for which the wait pin is not asserted.

- The [GPMC_CONFIG1_i\[17:16\]](#) WAITPINSELECT field (i = 0 to 7) selects which input gpmc_wait pin is used for the device attached to the corresponding chip-select.
- The polarity of the wait pin is defined through the WAITxPINPOLARITY bit of the [GPMC_CONFIG](#) register. A wait pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When WAIT is inactive, data is valid.

The GPMC access engine can be configured per CS to monitor the wait pin of the external memory device or not, based on the access type: read or write.

- The [GPMC_CONFIG1_i\[22\]](#) WAITREADMONITORING bit defines whether the wait pin should be monitored during read accesses or not.
- The [GPMC_CONFIG1_i\[21\]](#) WAITWRITEMONITORING bit defines whether the wait pin should be monitored during write accesses or not.

The GPMC access engine can be configured to monitor the wait pin of the external memory device asynchronously or synchronously with the GPMC_CLK clock, depending on the access type: synchronous or asynchronous (the [GPMC_CONFIG1_i\[29\]](#) READTYPE and [GPMC_CONFIG1_i\[27\]](#) WRITETYPE bits).

15.4.4.9.3.1.1 Wait Monitoring During an Asynchronous Read Access

When wait-pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with wait-pin monitoring enabled, the wait pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through wait-pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a WAIT invalid timing window and is set to such a value that the wait pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait-monitoring pipelining is also applicable to multiple accesses (access within a page).

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

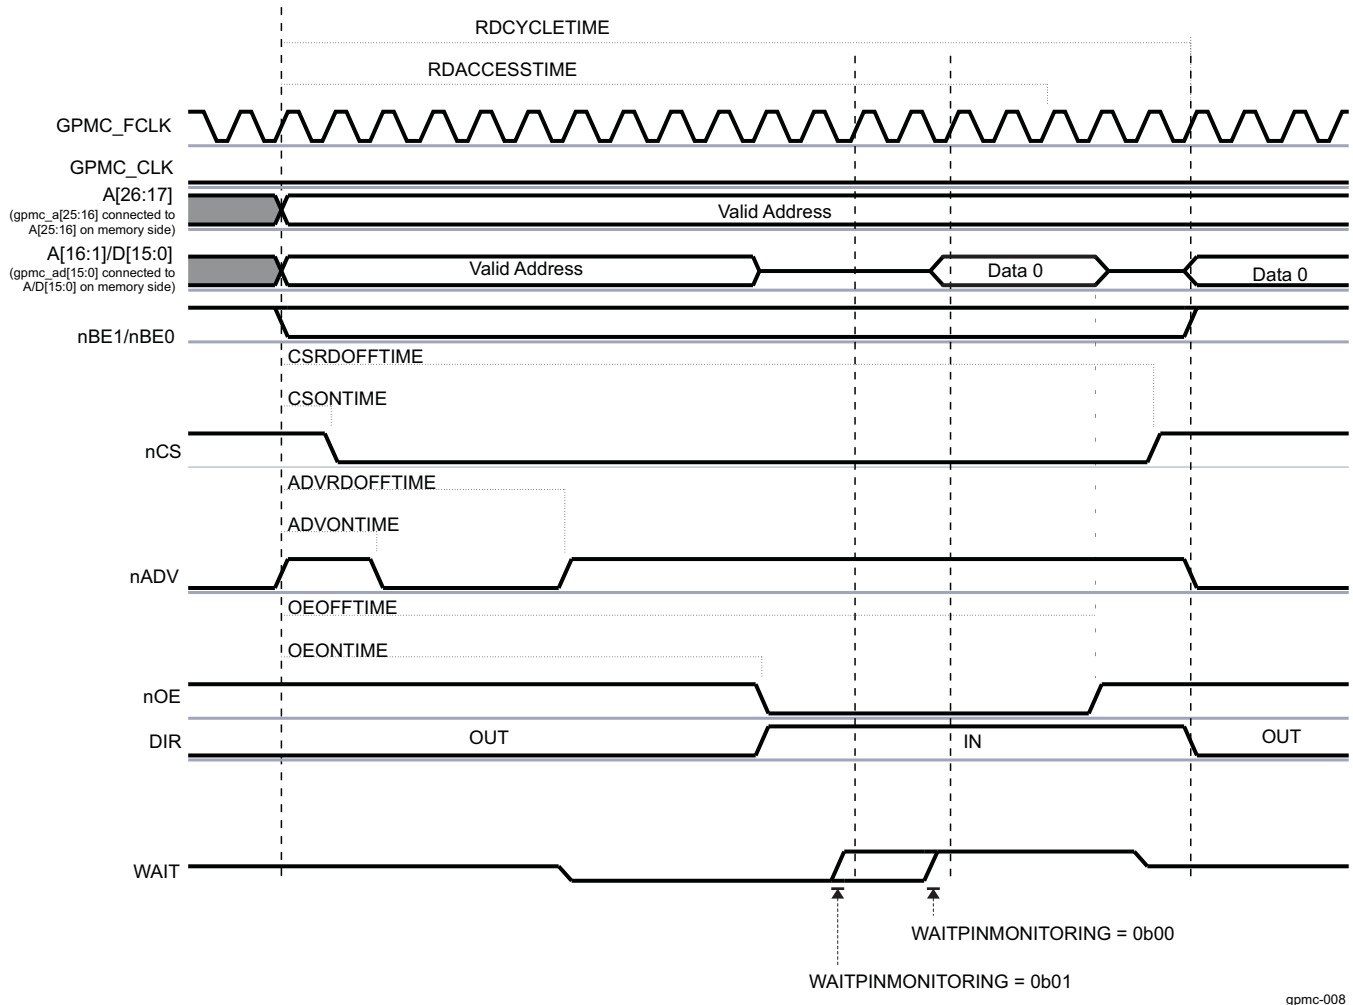

When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the [GPMC_CONFIG1_i\[19:18\]](#) WAITMONITORINGTIME field (i = 0 to 7).

NOTE:

- The WAITMONITORINGTIME parameter does not delay the wait-pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and no GPMC_CLK clock is provided to the external device. Still, GPMCFCLKDIVIDER is used as a divider for the GPMC clock, so it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 15-56 shows wait behavior during an asynchronous single read access.

Figure 15-56. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)

NOTE: The WAIT signal is active low. `GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME = 0b00, or 0b01.`

15.4.4.9.3.1.2 Wait Monitoring During an Asynchronous Write Access

When wait-pin monitoring is enabled for write accesses (`GPMC_CONFIG1_i[21] WAITWRITEMONITORING` bit = 0x1), the WAIT-invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the wait pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- WAIT monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus

is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.

- WAIT monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the `GPMC_CONFIG1_i[19:18]` WAITMONITORINGTIME fields ($i = 0$ to 7).

NOTE:

- The WAITMONITORINGTIME parameter does not delay the wait-pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and even though no clock is provided to the external device. Still, `GPMC_CONFIG1_i[1:0]` GPMCFCLKDIVIDER is used as a divider for the GPMC clock and so it must be programmed to define the correct WAITMONITORINGTIME delay.

15.4.4.9.3.1.3 Wait Monitoring During a Synchronous Read Access

During synchronous accesses with wait-pin monitoring enabled, the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle it is captured in. Alternatively, it can be sampled one or two GPMC_CLK cycles ahead of the clock cycle it applies to. This pipelining is applicable to the entire burst access, and to all data phase in the burst access. This WAIT pipelining depth is programmed in the `GPMC_CONFIG1_i[19:18]` WAITMONITORINGTIME field (where $i = 0$ to 7), and is expressed as a number of GPMC_CLK clock cycles.

In synchronous mode, when wait-pin monitoring is enabled (`GPMC_CONFIG1_i[22]` WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the WAIT deasserted-state detection.

Depending on the programmed WAITMONITORINGTIME value, the wait pin should be at a valid level, either asserted or deasserted:

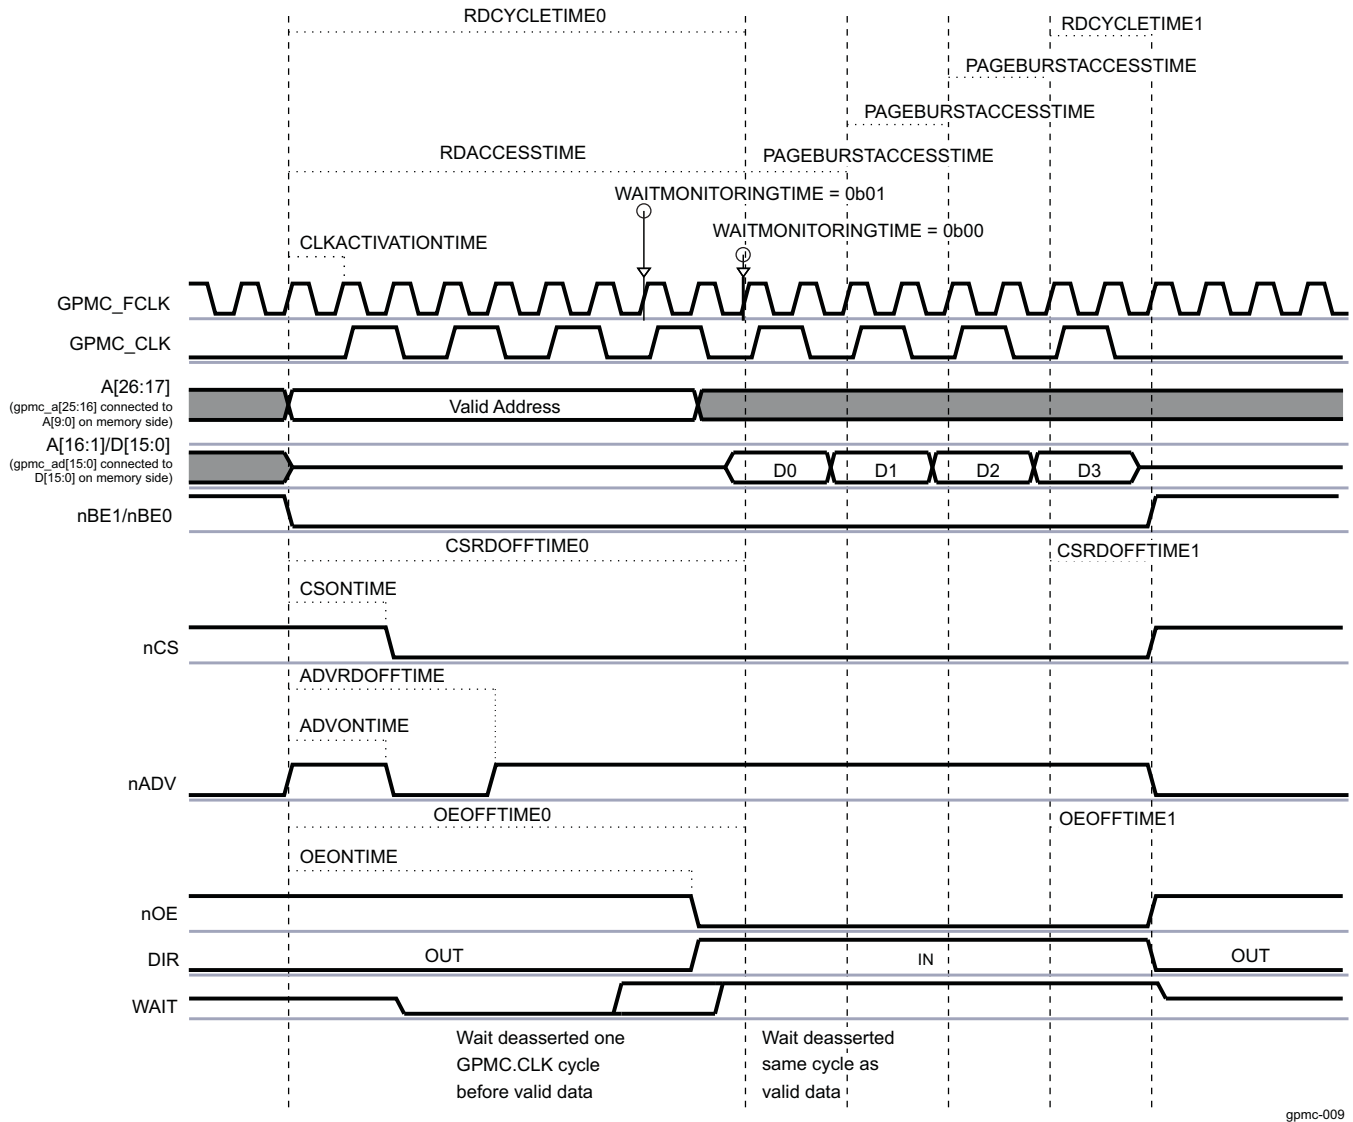

- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 (at RDACCESSTIME completion)
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME not equal to 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-inactive state. The Wait pipelining depth programming applies to the whole burst access.

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), WAIT monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), WAIT monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 15-57 shows wait behavior during a synchronous read burst access.

Figure 15-57. Wait Behavior During a Synchronous Read Burst Access

gpmc-009

NOTE: The WAIT signal is active low. WAITMONITORINGTIME = 00, 01.

15.4.4.9.3.1.4 Wait Monitoring During a Synchronous Write Access

During synchronous accesses with wait-pin monitoring enabled (the WAITWRITEMONITORING bit), the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

If enabled, external wait-pin monitoring can be used in combination with WRACCESSTIME to delay the effective memory device GPMC_CLK capture edge.

Wait-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME not equal to 0.

Wait-monitoring pipelining definition applies to whole burst accesses:

- WAIT monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as active indicates that the data

bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.

- WAIT monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

NOTE: Wait monitoring is supported for all configurations except for `GPMC_CONFIG1_i[19:18]` `WAITMONITORINGTIME = 0x0` (where `i = 0` to `7`) for write bursts with a clock divider of `1` or `2` (`GPMC_CONFIG1_i[1:0]` `GPMCFCLKDIVIDER` field equal to `0x0` or `0x1` respectively).

15.4.4.9.3.1.5 WAIT with NAND Device

For details about the use of the wait pin for communication with a NAND flash external device, see [Section 15.4.4.13.2, NAND Device-Ready Pin](#).

15.4.4.9.3.1.6 Idle Cycle Control Between Successive Accesses

15.4.4.9.3.1.6.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device must be delayed (in other words, control the nCS/nOE de-assertion to data bus in high-impedance delay).

The bus turnaround is a time-out counter starting after nCS or nOE de-assertion time, whichever occurs first, and delays the next access start-cycle time. The counter is programmed through the `GPMC_CONFIG6_i[3:0]` `BUSTURNAROUND` bit field (where `i = 0` to `7`).

After a read access to a chip-select with a non zero `BUSTURNAROUND`, the next access is delayed until the `BUSTURNAROUND` delay completes, if the next access is one of the following:

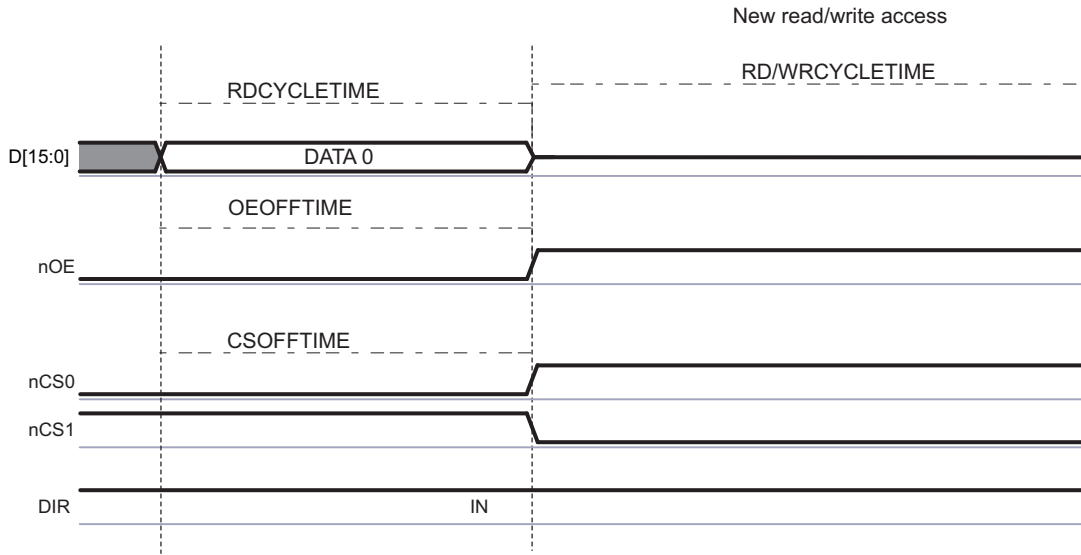

- A write access to any chip-select (same or different from the chip-select data was read from)
- A read access to a different chip-select from the chip-select data was read access from
- A read or write access to a chip-select associated with an address/data-multiplexed device

NOTE: Bus keeping starts after bus turnaround completion so that DIR changes from IN to OUT after bus turnaround. The bus will not have enough time to go into high-impedance even though it could be driven with the same value before bus turnaround timing.

`BUSTURNAROUND` delay runs in parallel with `GPMC_CONFIG6_i[3:0]` `CYCLE2CYCLEDELAY` delays. It should be noted that `BUSTURNAROUND` is a timing parameter for the ending chip-select access while `CYCLE2CYCLEDELAY` is a timing parameter for the following chip-select access. The effective minimum delay between successive accesses is driven by these delay timing parameters and by the access type of the following access. See [Figure 15-58](#) to [Figure 15-60](#).

Another way to prevent bus contention is to define an earlier nCS or nOE deassertion time for slow devices or to extend the value of `RDCYCLETIME`. Doing this prevents bus contention, but affects all accesses of this specific chip-select.

Figure 15-58. Read to Read for an Address-Data Multiplexed Device, on Different CS, without Bus Turnaround (nCS0 attached to a fast device)

gpmc-049

Figure 15-59. Read to Read / Write for an Address-Data Multiplexed Device, on Different CS, with Bus Turnaround

gpmc-050

Figure 15-60. Read to Read / Write for a Address-Data or AAD-multiplexed device, on the Same CS, with Bus Turnaround

15.4.4.9.3.1.6.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMECSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The [GPMC_CONFIG6_i\[7\]](#) CYCLE2CYCLESAMECSEN bit ($i = 0$ to 7) enables insertion of a minimum number of GPMC_FCLK cycles, defined by the [GPMC_CONFIG6_i\[11:8\]](#) CYCLE2CYCLEDELAY field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMECSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDOFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during 32-bit word or burst accesses split into successive single accesses when the single-access mode is used ([GPMC_CONFIG1_i\[30\]](#) READMULTIPLE = 0 or [GPMC_CONFIG1_i\[28\]](#) WRITEMULTIPLE = 0).

All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC.CLK) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC.CLK at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC.FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

15.4.4.9.3.1.6.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (nCS, nADV/ALE, nBE0/CLE, nOE/RE, nWE) assertion and de-assertion timing parameters and on the IC timing parameters, some control signals assertion times may overlap between the successive accesses to different CS. Similarly, some control signals (WE, OE/RE) may not respect required transition times.

To work around the overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If [GPMC_CONFIG6_i\[6\]](#) CYCLE2CYCLEDIFFCSEN is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC_FCLK cycles.

NOTE: CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN should be set in [GPMC_CONFIG6_i](#) registers to respectively get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. It should be noted that BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, since bus turnaround does not apply to all access types. See [Section 15.4.4.9.3.1.6.1, Bus Turnaround \(BUSTURNAROUND\)](#) for more details on bus turnaround.

[Table 15-226](#) describes the configuration required for idle cycle insertion.

Table 15-226. Idle Cycle Insertion Configuration

1st Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	= 0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Different	Nonmuxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	R/W	Any	Muxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	W	Any	Any	0	0	BUSTURNAROUND cycles are inserted.
W	> 0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	= 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	= 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.
R/W	> 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).
R/W	> 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

15.4.4.9.3.1.7 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the [GPMC_CONFIG1_i\[4\]](#) TIMEPARAGRANULARITY bit (where i stands for the GPMC chip-select value, i = 0 to 7). Increasing all access timing parameters allows support of slow devices.

15.4.4.9.3.2 *gpmc_io_dir Pin*

The `gpmc_io_dir` pin is used to control I/O direction on the GPMC data bus `gpmc_ad[15:0]`. Depending on top-level pad multiplexing, this signal can be output and used externally to the device, if required.

The `gpmc_io_dir` pin is low during transmit (OUT) and high during receive (IN).

For write accesses, the `gpmc_io_dir` pin stays OUT from start-cycle time to end-cycle time.

For read accesses, the `gpmc_io_dir` pin goes from OUT to IN at `nOE` assertion time and stays IN until:

- BUSTURNAROUND is enabled:
 - The `gpmc_io_dir` pin goes from IN to OUT at end-cycle time plus programmable bus turnaround time.
- BUSTURNAROUND is disabled:
 - After an asynchronous read access, the `gpmc_io_dir` pin goes from IN to OUT at `RDACCESSTIME + 1 GPMC_FCLK` cycle or when `RDCYCLETIME` completes, whichever occurs last.
 - After a synchronous read access, the `gpmc_io_dir` pin goes from IN to OUT at `RDACCESSTIME + 2 GPMC_FCLK` cycles or when `RDCYCLETIME` completes, whichever occurs last.

Because of the bus-keeping feature of the GPMC, after a read or write access and with no other accesses pending, the default value of the `gpmc_io_dir` pin is OUT (see [Section 15.4.4.10.10, Bus Keeping Support](#)).

In nonmultiplexed devices, the `gpmc_io_dir` pin stays IN between two successive read accesses to prevent unnecessary toggling (nonmultiplexed 16-bit wide devices support is limited to 2 Kbytes).

15.4.4.9.3.3 *Reset*

No reset signal is sent to the external memory device by the GPMC. For more information about external-device reset, see [Chapter 3, Power, Reset, and Clock Management](#).

The PRCM module provides an input pin, `global_rst_n`, to the GPMC:

- The `global_rst_n` pin is activated during device warm reset and cold reset.
- The `global_rst_n` pin initializes the internal state-machine and the internal configuration registers.

15.4.4.9.3.4 *Write Protect Signal (nWP)*

When connected to the attached memory device, the write protect signal can enable or disable the lockdown function of the attached memory.

The `gpmc_nwp` output pin value is controlled through the `GPMC_CONFIG[4]` WRITEPROTECT bit, which is common to all CS.

15.4.4.9.3.5 *Byte Enable (nBE1/nBE0)*

Byte enable signals (`nBE1/nBE0`) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

15.4.4.9.4 *Error Handling*

When an error occurs in the GPMC, the error information is stored in the `GPMC_ERR_TYPE` register and the address of the illegal access is stored in the `GPMC_ERR_ADDRESS` register. The GPMC only keeps the first error abort information until the `GPMC_ERR_TYPE` register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the `GPMC_ERR_TYPE[0]` ERRORVALID bit.

- ERRORNOTSUPPADD occurs when an incoming system request address decoding does not match

any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1 Kbyte.

- **ERRORNOTSUPPMCMD** occurs when an unsupported command request is decoded at the L3 interconnect interface.
- **ERRORTIMEOUT**: A time-out mechanism prevents the system from hanging. The start value of the 9-bit time-out counter is defined in the [GPMC_TIMEOUT_CONTROL](#) register and enabled with the [GPMC_TIMEOUT_CONTROL\[0\] TIMEOUTENABLE](#) bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. True abort to the MPU or interrupt generation is handled at interconnect level.

15.4.4.10 Timing Setting

The GPMC offers the maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For more information on GPMC_CLK and GPMC_FCLK see [Section 15.4.4.10.6, GPMC_CLK](#).

NOTE: In the following sections, the start access time refer to the time at which the access begins.

15.4.4.10.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME / WRCYCLETIME)

The [GPMC_CONFIG5_i\[4:0\] RDCYCLETIME](#) and [GPMC_CONFIG5_i\[12:8\] WRCYCLETIME](#) fields ($i = 0$ to 7) define the address bus and byte enables valid times for read and write accesses. To ensure a correct duty cycle of GPMC_CLK between accesses, RDCYCLETIME and WRCYCLETIME are expressed in GPMC_FCLK cycles and must be multiples of the GPMC_CLK cycle. RDCYCLETIME and WRCYCLETIME bit fields can be set with a granularity of 1 or 2 through [GPMC_CONFIG1_i\[4\] TIMEPARAGRANULARITY](#).

When either RDCYCLETIME or WRCYCLETIME completes, if they are not already deasserted, all control signals (nCS, nADV/ALE, nOE/RE, nWE, and BE0/CLE) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitches. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

NOTE: All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC.CLK) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC.CLK at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC.FCLK cycles.

If no inactive cycles are required between successive accesses to the same or to a different chip-select ([GPMC_CONFIG6_i\[7\] CYCLE2CYCLESAMECSSEN = 0](#) or [GPMC_CONFIG6_i\[6\] CYCLE2CYCLEDIFFCSSEN = 0](#), where $i = 0$ to 7), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals (nCS, nADV/ALE, nBE0/CLE, nWE, and nOE/RE) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses, that is, [CYCLE2CYCLESAMECSSEN = 1](#) or [CYCLE2CYCLEDIFFCSSEN = 1](#), the control signals are forced to their respective default reset values for the number of GPMC_FCLK cycles defined in [CYCLE2CYCLEDELAY](#).

15.4.4.10.2 nCS: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME /

CSWROFFTIME / CSEXTRADELAY)

The [GPMC_CONFIG2_i\[3:0\]](#) CSONTIME field (where $i = 0$ to 7) defines the nCS signal-assertion time relative to the start access time. It is common for read and write accesses.

[GPMC_CONFIG2_i\[12:8\]](#) CSRDOFFTIME (read access) and [GPMC_CONFIG2_i\[20:16\]](#) CSWROFFTIME (write access) bit fields define the nCS signal deassertion time relative to start access time.

CSONTIME, CSRDOFFTIME and CSWROFFTIME parameters are applicable to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte enable hold time after chip-select deassertion.

nCS signal transitions as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the [GPMC_CONFIG2_i\[7\]](#) CSEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on the nCS assertion and deassertion time to guarantee proper setup and hold time relative to GPMC_CLK. CSEXTRADELAY is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, CSEXTRADELAY applies to all parameters controlling nCS transitions.

The CSEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the nCS signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

15.4.4.10.3 nADV/ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME / ADVEXTRADELAY/ADVAADMUXONTIME/ADVAADMUXRDOFFTIME/ADVAADMUXWROFFTIME)

The [GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME field (where $i = 0$ to 7) defines the nADV/ALE signal-assertion time relative to start access time. It is common to read and write accesses.

[GPMC_CONFIG3_i\[12:8\]](#) ADVRDOFFTIME (read access) and [GPMC_CONFIG3_i\[20:16\]](#) ADVWROFFTIME (write access) bit fields define the nADV/ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte enable valid setup time control before nADV/ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte enable valid hold time control after nADV/ALE de-assertion. ADVRDOFFTIME and ADVWROFFTIME are applicable to both synchronous and asynchronous modes.

nADV/ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the [GPMC_CONFIG3_i\[7\]](#) ADVEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on nADV/ALE assertion and deassertion time to guarantee proper setup and hold time relative to GPMC_CLK. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, ADVEXTRADELAY applies to all parameters controlling nADV/ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than nADV/ALE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

[GPMC_CONFIG3_i\[6:4\]](#) ADVAADMUXONTIME, [GPMC_CONFIG3_i\[26:24\]](#) ADVAADMUXRDOFFTIME, and [GPMC_CONFIG3_i\[30:28\]](#) ADVAADMUXWROFFTIME parameters have the same functions as ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME, but apply to the first address phase in the AAD-multiplexed protocol. It is the user responsibility to make sure ADVAADMUXxxOFFTIME is programmed to a value lower than or equal to ADVxxOFFTIME. Functionality in AAD-mux mode is undefined if the settings do not comply with this requirement. ADVAADMUXxxOFFTIME can be programmed to the same value as ADVONTIME if no high nADV pulse is needed between the two AAD-mux address phases, which is the typical case in synchronous mode. In this configuration, nADV is kept low until it reaches the correct ADVxxOFFTIME.

See [Section 15.4.4.13, NAND Access Description](#) for more details on ADVONTIME, ADVRD OFFTIME, ADVWROFFTIME, and ADVAADMUXRD OFFTIME, ADVAADMUXWROFFTIME usage for CLE and ALE (Command / Address Latch Enable) usage for a NAND Flash interface.

15.4.4.10.4 nOE/nRE: Output Enable / Read Enable Signal Control Assertion / Deassertion Time (OEONTIME / OEOFFTIME / OEEXTRADELAY / OEAADMUXONTIME / OEAADMUXOFFTIME)

The [GPMC_CONFIG4_i\[3:0\]](#) OEONTIME field (where i = 0 to 7) defines the nOE/nRE signal assertion time relative to start access time. It is applicable only to read accesses.

The [GPMC_CONFIG4_i\[12:8\]](#) OEOFFTIME field defines the nOE/nRE signal deassertion time relative to start access time. It is applicable only to read accesses. nOE/nRE is not asserted during a write cycle.

OEONTIME, OEOFFTIME, OEAADMUXONTIME and OEAADMUXOFFTIME parameters are applicable to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before nOE/nRE assertion. OEOFFTIME can be used to control an address and byte enable valid hold time control after nOE/nRE assertion.

OEAADMUXONTIME and OEAADMUXOFFTIME parameters have the same functions as OEONTIME and OEOFFTIME, but apply to the first OE assertion in the AAD-multiplexed protocol for a read phase, or to the only OE assertion for a write phase. It is the user responsibility to make sure OEAADMUXOFFTIME is programmed to a value lower than OEONTIME. Functionality in AAD-mux mode is undefined if the settings do not comply with this requirement. OEAADMUXOFFTIME shall never be equal to OEONTIME because the AAD-mux protocol requires a second address phase with the nOE signal deasserted before nOE can be asserted again to define a read command.

The nOE/RE signal transitions as controlled through OEONTIME, OEOFFTIME, OEAADMUXONTIME and OEAADMUXOFFTIME can be delayed by half a GPMC_FCLK period by enabling the [GPMC_CONFIG4_i\[7\]](#) OEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on nOE/RE assertion and deassertion time to guaranty proper setup and hold time relative to GPMC_CLK. If enabled, OEEXTRADELAY applies to all parameters controlling nOE/nRE transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than nOE/RE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

NOTE: When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until nOE assertion time.

15.4.4.10.5 nWE: Write Enable Signal Control Assertion / Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)

The [GPMC_CONFIG4_i\[19:16\]](#) WEONTIME field (where i = 0 to 7) defines the nWE signal-assertion time relative to start access time. The [GPMC_CONFIG4_i\[28:24\]](#) WEOFFTIME field defines the nWE signal-deassertion time relative to start access time. These bit fields only apply to write accesses. nWE is not asserted during a read cycle.

WEONTIME can be used to control an address and byte enable valid setup time control before nWE assertion. WEOFFTIME can be used to control an address and byte enable valid hold time control after nWE assertion.

nWE signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by half a GPMC_FCLK period by enabling the [GPMC_CONFIG4_i\[23\]](#) WEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on nWE assertion and deassertion time to guaranty proper setup and hold time relative to GPMC_CLK. If enabled, WEEXTRADELAY applies to all parameters controlling nWE transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the nWE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

15.4.4.10.6 GPMC_CLK

GPMC_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC_CLK clock frequency is the GPMC_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the [GPMC_CONFIG1_i\[1:0\]](#) GPMCFCLKDIVIDER bit field (where $i = 0$ to 7), with a guaranteed 50-percent duty cycle.
- The GPMC_CLK clock is only activated when the access in progress is defined as synchronous (read or write access).
- The [GPMC_CONFIG1_i\[26:25\]](#) CLKACTIVATIONTIME field ($i = 0$ to 7) defines the number of GPMC_FCLK cycles from start access time to GPMC_CLK activation.
- The GPMC_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC_CLK clock is kept low when access is defined as asynchronous.

CAUTION

When cycle time completes, the GPMC_CLK may be high because of the GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC_CLK clock within the 50-percent required duty cycle, it is the user's responsibility to extend the RDCYCLETIME or WRCYCLETIME value.

NOTE: To ensure a correct external clock cycle, the following rules must be applied:

- $(RDCYCLETIME \text{ CLKACTIVATIONTIME})$ must be a multiple of $(GPMCFCLKDIVIDER + 1)$.
- The PAGEBURSTACCESSTIME value must be a multiple of $(GPMCFCLKDIVIDER + 1)$.

15.4.4.10.7 GPMC_CLK and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC_CLK edge can be controlled in the following ways:

- For the GPMC_CLK signal, the [GPMC_CONFIG1_i\[26:25\]](#) CLKACTIVATIONTIME field ($i = 0$ to 7) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC_CLK allows setup and hold control of control-signal assertion and deassertion times.
- When GPMC_CLK runs at the GPMC_FCLK frequency so that GPMC_CLK edge and control-signal transitions refer to the same GPMC_FCLK edge, the control-signal transitions can be delayed by half of a GPMC_FCLK period to provide minimum setup and hold times. This half-GPMC_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEEXTRADELAY, or WEEXTRADELAY parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC_FCLK cycle.

15.4.4.10.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read access time and write access time durations can be programmed independently through [GPMC_CONFIG5_i\[20:16\]](#) RDACCESSTIME and [GPMC_CONFIG6_i\[28:24\]](#) WRACCESSTIME ($i = 0$ to 7). This allows nOE and GPMC data capture timing parameters to be independent of nWE and memory device data capture timing parameters. RDACCESSTIME and WRACCESSTIME bit fields can be set with a granularity of 1 or 2 through [GPMC_CONFIG1_i\[4\]](#) TIMEPARAGRANULARITY.

15.4.4.10.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, [GPMC_CONFIG5_i\[20:16\]](#) RDACCESSTIME field ($i = 0$ to 7) defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge corresponding to the GPMC_CLK rising edge used for the first data capture.

GPMC_CLK which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. GPMC_CONFIG5_i[4:0] RDCYCLETIME must be greater than RDACCESSTIME in order to let the GPMC latch the last return data using the internally retimed GPMC_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access in both asynchronous mode and synchronous mode. For details about wait monitoring, see [Section 15.4.4.9.3.1, Chip-Select Base Address and Region Size](#).

15.4.4.10.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC_CONFIG6_i[28:24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a WAIT invalid timing window, and must be set to a correct value so that the gpmc_wait pin is at a valid state two GPMC_CLK cycles before WRACCESSTIME completes. For details about wait monitoring, see [Section 15.4.4.9.3.1, Chip-Select Base Address and Region Size](#).

In synchronous write mode, for single or burst accesses, WRACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data capture GPMC_CLK edge for a synchronous write access. For details about wait monitoring, see [Section 15.4.4.9.3.1, Chip-Select Base Address and Region Size](#).

15.4.4.10.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME bit field (i = 0 to 7) can be set with a granularity of 1 or 2 through GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY.

15.4.4.10.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data capture GPMC_FCLK edge on read access. For details about wait monitoring, see [Section 15.4.4.9.3.1, Chip-Select Base Address and Region Size](#).

15.4.4.10.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory-device data capture GPMC_CLK edge in synchronous write mode. For details about wait monitoring, see [Section 15.4.4.9.3.1, Chip-Select Base Address and Region Size](#).

15.4.4.10.10 Bus Keeping Support

At the end-cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completion time to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

15.4.4.11 NOR Access Description

For each chip-select configuration, the read access can be specified as either asynchronous or synchronous access through the [GPMC_CONFIG1_i\[29\]](#) READTYPE bit ($i = 0$ to 7). For each chip-select configuration, the write access can be specified as either synchronous or asynchronous access through the [GPMC_CONFIG1_i\[27\]](#) WRITETYPE bit ($i = 0$ to 7).

Asynchronous and synchronous read and write access time and related control signals are controlled through timing parameters that refer to GPMC_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface (GPMC_CLK) to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For details about asynchronous and synchronous access, see the descriptions of GPMC_CLK, RdAccessTime, WrAccessTime, and wait-pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

NOTE: The address bus and nBE[1:0] are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

15.4.4.11.1 Asynchronous Access Description

This section describes:

- Asynchronous single-read operation on an address/data multiplexed device
- Asynchronous single write operation on an address/data-multiplexed device
- Asynchronous single read operation on an AAD-multiplexed device
- Asynchronous single write operation on an AAD-multiplexed device
- Asynchronous multiple (page) read operation on a non-multiplexed device

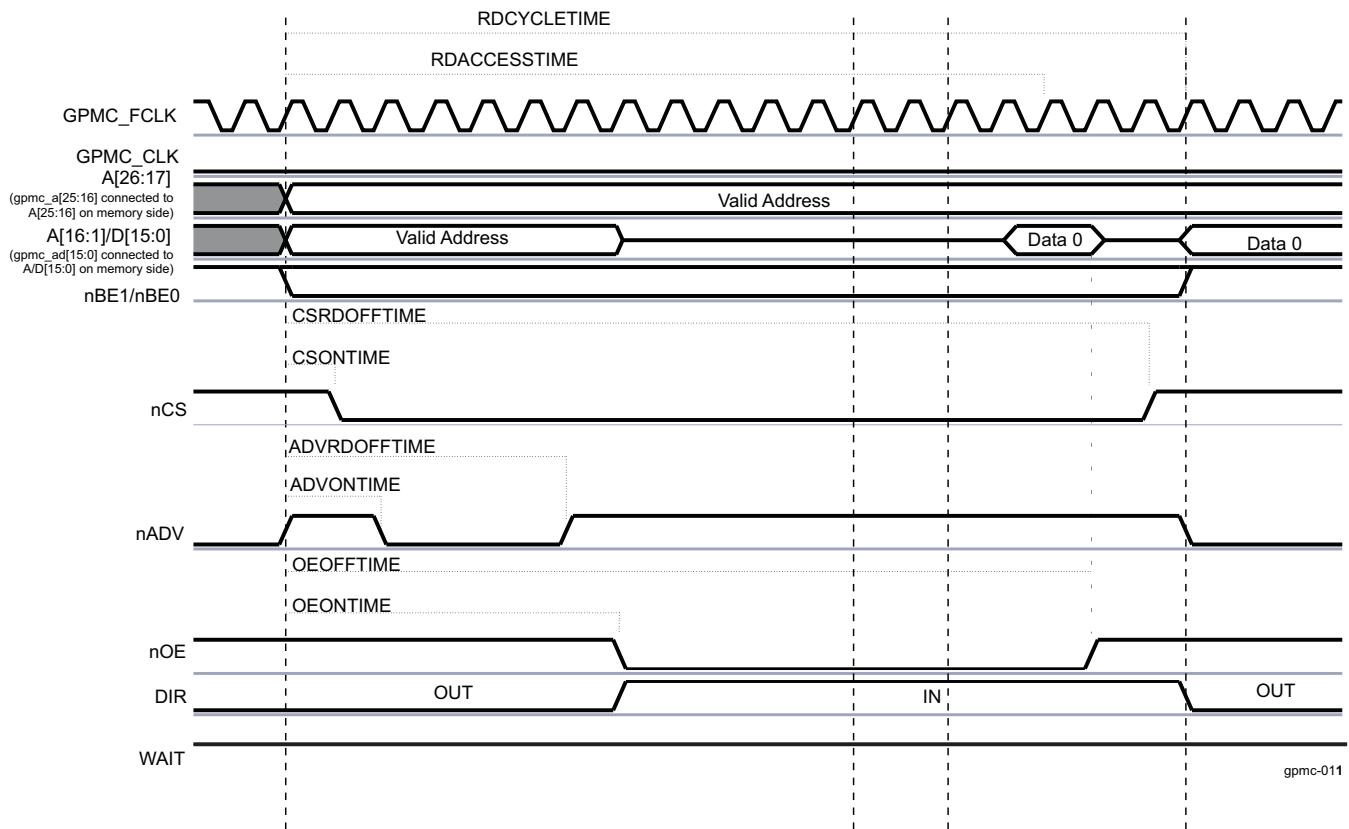

In asynchronous operations GPMC_CLK is not provided outside the GPMC and is kept low.

15.4.4.11.1.1 Access on Address/Data Multiplexed Devices

15.4.4.11.1.1.1 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

Figure 15-61 shows an asynchronous single read operation on an address/data-multiplexed device.

Figure 15-61. Asynchronous Single Read on an Address/Data-Multiplexed Device

See Section 15.4.5.6.1, *GPMC Timing Parameters Formulas* for formulas to calculate timing parameters.

Table 15-258 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For details, see Section 15.4.4.9.2.3, *Address/Data-Multiplexing Interface*.

Address bits (A[16:1] from a GPMC perspective, A[15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits gpmc_a[25:16] are placed on the address bus. The address phase ends at nOE assertion, when the DIR signal goes from OUT to IN.

- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CS ONTIME field. It controls the address setup time to nCS assertion.
 - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12:8] CS RD OFFTIME field. It controls the address hold time from nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADV ONTIME field.
 - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADV RD OFFTIME field.
- Output enable signal nOE:
 - nOE assertion indicates a read cycle.
 - nOE assertion time is controlled by the GPMC_CONFIG4_i[3:0] OE ONTIME field.

- nOE deassertion time is controlled by the [GPMC_CONFIG4_i\[12:8\]](#) OEOFFTIME field.
- Read data is latched when RDACCESSTIME completes. Access time is defined in the [GPMC_CONFIG5_i\[20:16\]](#) RDACCESSTIME field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that nOE is asserted.
- The end of the access is defined by the [GPMC_CONFIG5_i\[4:0\]](#) RDCYCLETIME parameter.

In the GPMC, when a 16-bit wide device is attached to the controller, a 32-bit word write access is split into two 16-bit word write accesses. For more information about GPMC access size and type adaptation, see [Section 15.4.4.11.5, System Burst Versus External Device Burst Support](#).

Between two successive accesses, if an nCS pulse is needed:

- The [GPMC_CONFIG6_i\[11:8\]](#) CYCLE2CYCLEDELAY field can be programmed with [GPMC_CONFIG6_i\[7\]](#) CYCLE2CYCLESAMECSEN enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

Figure 15-62. Two Asynchronous Single Read Accesses on an Address/Data Multiplexed Device (32-bit read split into 2 x 16-bit read)

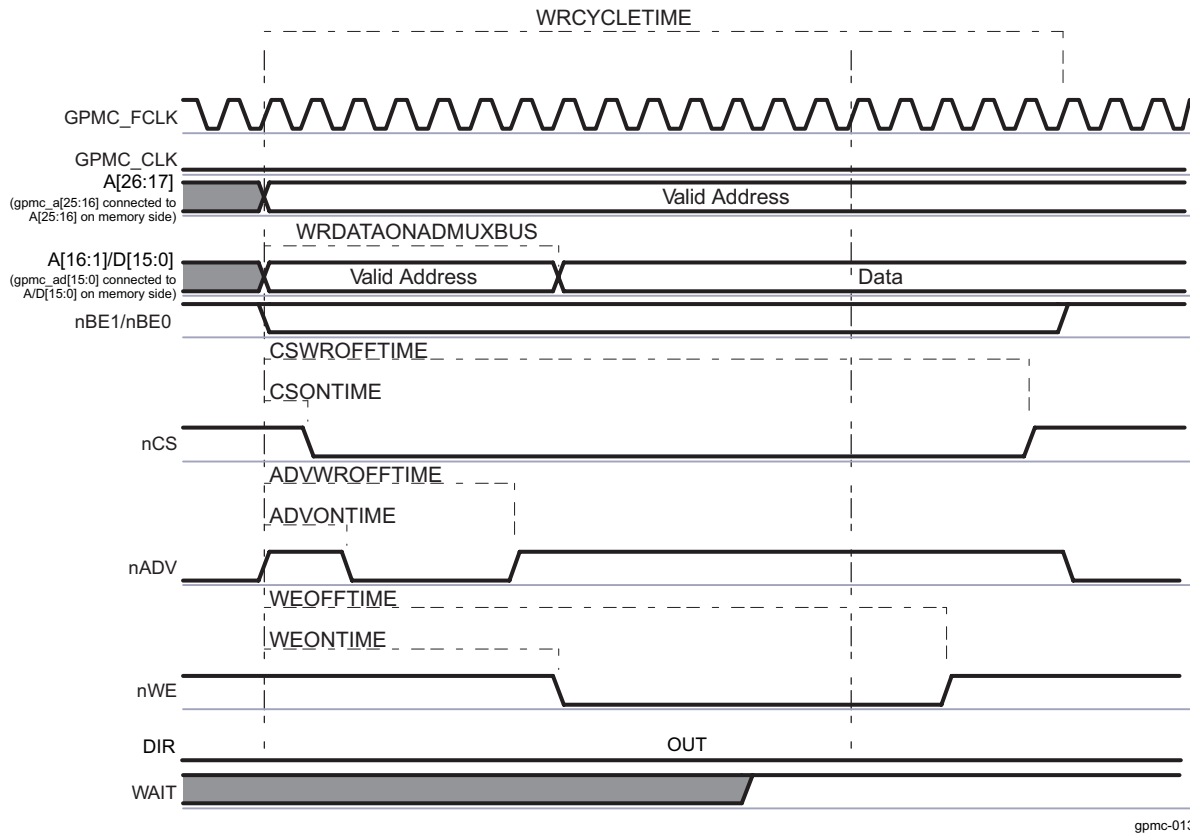

gpmc-044

15.4.4.11.1.2 Asynchronous Single Write Operation on an Address/Data-Multiplexed Device

Figure 15-63 shows an asynchronous single write operation on an address/data-multiplexed device.

Figure 15-63. Asynchronous Single Write on an Address/Data-Multiplexed Device

gpmc-013

See [Section 15.4.5.6.1, GPMC Timing Parameters Formulas](#) for formulas to calculate timing parameters.

[Table 15-258](#) lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the address bus until nWE assertion time. For more information, see [Section 15.4.4.9.2.3, Address/Data-Multiplexing Interface](#).

The nCS, and nADV signals are controlled in the same way as for asynchronous single read operation on an address/data-multiplexed device.

- Write enable signal nWE:
 - nWE assertion indicates a write cycle.
 - nWE assertion time is controlled by the [GPMC_CONFIG4_i\[19:16\] WEONTIME](#) field.
 - nWE deassertion time is controlled by the [GPMC_CONFIG4_i\[28:24\] WEOFFTIME](#) field.
- Direction signal DIR: DIR signal is OUT during the entire access.
- The end of the access is defined by the [GPMC_CONFIG5_i\[12:8\] WRCYCLETIME](#) parameter.

Address bits A[16:1] (GPMC point of view) are placed on the address/data bus at the start of cycle time, and the remaining address bits A[26:17] are placed on the address bus.

Data is driven on the address/data bus at a [GPMC_CONFIG6_i\[19:16\] WRDATAONADMUXBUS](#) time.

NOTE: Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See [Section 15.4.4.10.10](#), *Bus Keeping Support*.

15.4.4.11.1.1.3 Asynchronous Multiple (Page) Write Operation on an Address/Data-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for address/data-multiplexed devices.

If `GPMC_CONFIG1_i[28]` `WRITEMULTIPLE` is enabled (0x1) with `GPMC_CONFIG1_i[27]` `WRITETYPE` as asynchronous (0x0), the GPMC processes single asynchronous accesses.

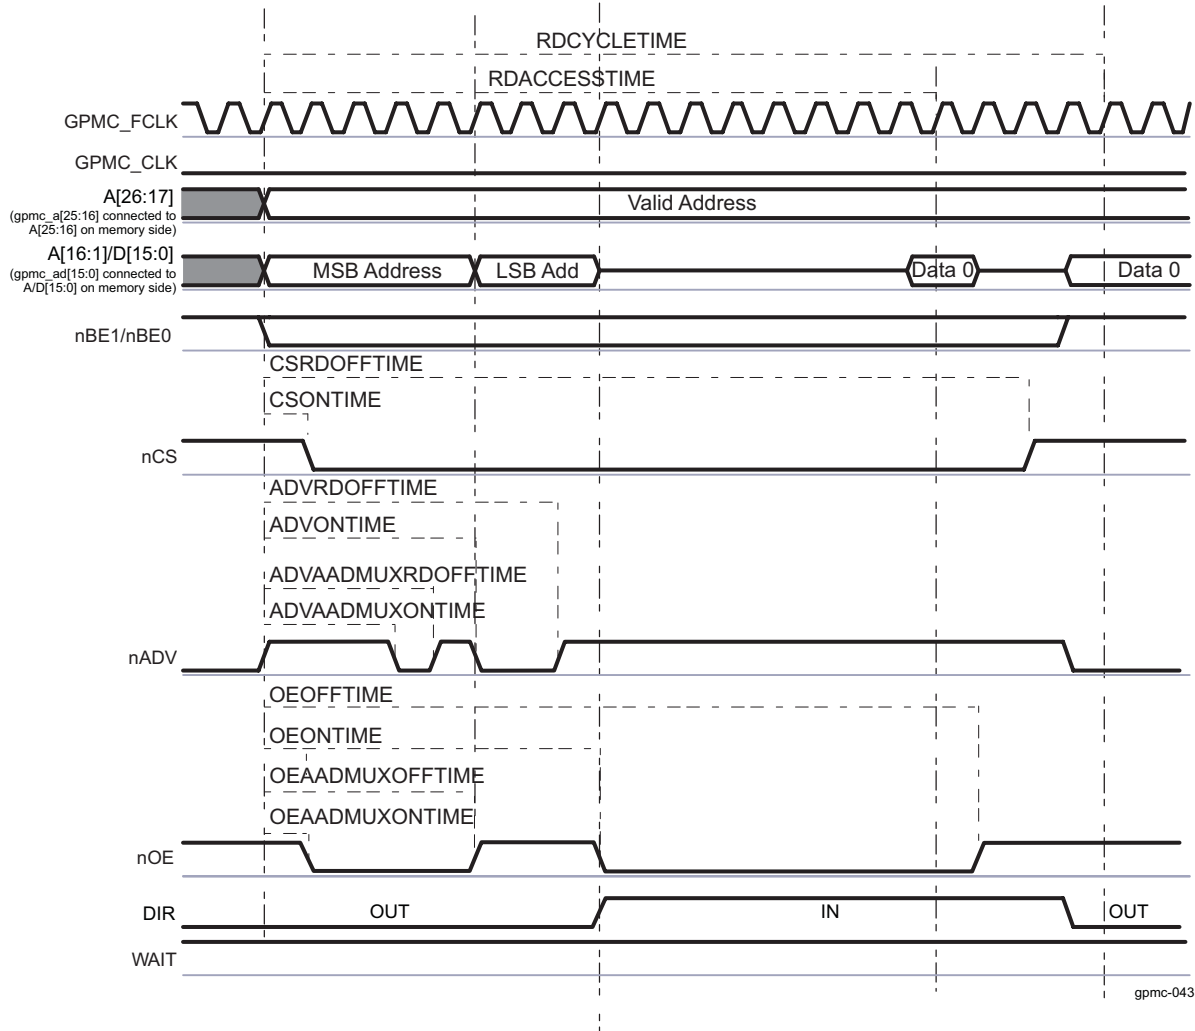

For accesses on non-multiplexed devices refer to [Section 15.4.4.11.3](#), *Asynchronous and Synchronous Accesses in Nonmultiplexed Mode*.

15.4.4.11.1.2 Access on Address/Address/Data Multiplexed Devices

15.4.4.11.1.2.1 Asynchronous Single Read Operation on an AAD-Multiplexed Device

Figure 15-64 shows an asynchronous single read operation on an AAD-multiplexed device.

Figure 15-64. Asynchronous Single Read on an AAD-Multiplexed Device

See Section 15.4.5.6.1, *GPMC Timing Parameters Formulas* for formulas to calculate timing parameters.

Table 15-258 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode.

When the GPMC generates a read access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The first address phase ends at the first nOE deassertion time. The second phase for LSB address is qualified with nOE driven high. The second address phase ends at the second nOE assertion time, when the DIR signal goes from OUT to IN.

The nCS, and DIR signals are controlled in the same way as for asynchronous single read operation on an address/data-multiplexed device.

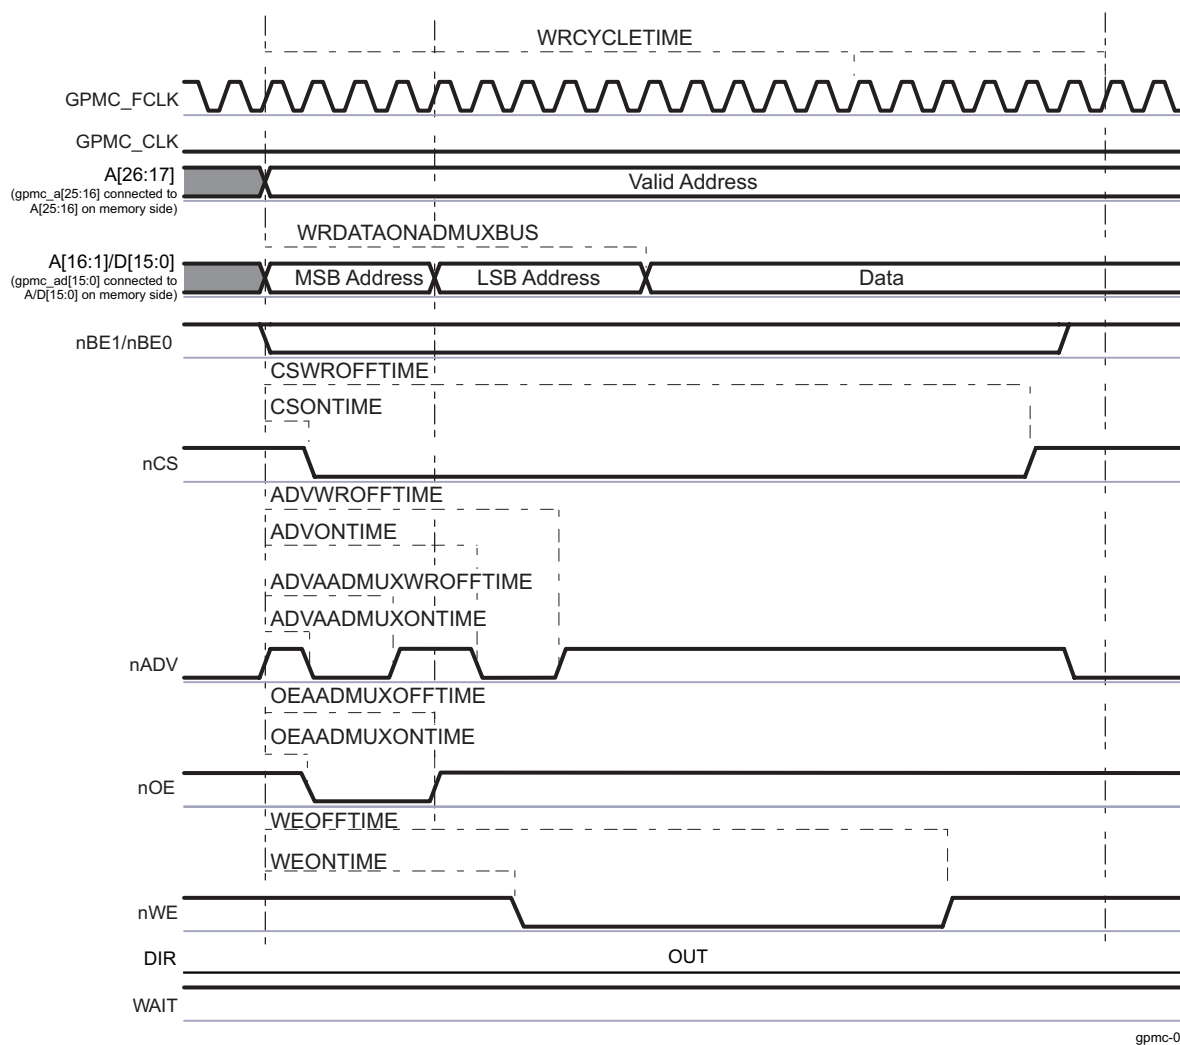

- Address valid signal nADV. nADV is asserted and deasserted twice during a read transaction:
 - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME field.
 - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME field.

- nADV second assertion time is controlled by the `GPMC_CONFIG3_i[3:0]` ADVONTIME field.
- nADV second deassertion time is controlled by the `GPMC_CONFIG3_i[12:8]` ADVRDOFFTIME field.
- Output Enable signal nOE. nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
 - nOE first assertion time is controlled by the `GPMC_CONFIG4_i[6:4]` OEAADMUXONTIME field.
 - nOE first deassertion time is controlled by the `GPMC_CONFIG3_i[15:13]` OEAADMUXOFFTIME field.
 - nOE second assertion time is controlled by the `GPMC_CONFIG4_i[3:0]` OEONTIME field.
 - nOE second deassertion time is controlled by the `GPMC_CONFIG4_i[12:8]` OEOFFTIME field.

15.4.4.11.1.2.2 Asynchronous Single Write Operation on an AAD-Multiplexed Device

Figure 15-65 shows an asynchronous single write operation on an AAD-multiplexed device.

Figure 15-65. Asynchronous Single Write on an AAD-Multiplexed Device

See [Section 15.4.5.6.1, GPMC Timing Parameters Formulas](#) for formulas to calculate timing parameters.

[Table 15-258](#) lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, nWE, and DIR signals are controlled in the same way as for asynchronous single write operation on an address/data-multiplexed device. See [Table 15-249](#).

- Address valid signal nADV is asserted and deasserted twice during a write transaction:
 - nADV first assertion time is controlled by the [GPMC_CONFIG3_i\[6:4\]](#) ADVAADMUXONTIME field.
 - nADV first deassertion time is controlled by the [GPMC_CONFIG3_i\[30:28\]](#) ADVAADMUXWROFFTIME field.
 - nADV second assertion time is controlled by the [GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME field.
 - nADV second deassertion time is controlled by the [GPMC_CONFIG3_i\[20:16\]](#) ADVWROFFTIME field.
- Output Enable signal nOE is asserted during the address phase of a write transaction:
 - nOE assertion time is controlled by the [GPMC_CONFIG4_i\[6:4\]](#) OEAADMUXONTIME field.
 - nOE deassertion time is controlled by the [GPMC_CONFIG3_i\[15:13\]](#) OEAADMUXOFFTIME field.

The address bits for the first address phase are driven onto the data bus until nOE deassertion. Data is driven onto the address/data bus at the clock edge defined by the [GPMC_CONFIG6_i\[19:16\]](#) WRDATAONADMUXBUS parameter.

15.4.4.11.1.2.3 Asynchronous Multiple (Page) Read Operation on an AAD-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for AAD-multiplexed devices.

If [GPMC_CONFIG1_i\[28\]](#) WRITEMULTIPLE is enabled (0x1) with [GPMC_CONFIG1_i\[27\]](#) WRITETYPE as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on non-multiplexed devices refer to [Section 15.4.4.11.3, Asynchronous and Synchronous Accessed in Nonmultiplexed Mode](#).

15.4.4.11.2 Synchronous Access Description

This section details read and write synchronous accesses on address/data multiplexed. All information in this section can be applied to any type of memory - non-multiplexed, address and data multiplexed or AAD-multiplexed - with a difference limited to the address phase. For accesses on non-multiplexed devices refer to [Section 15.4.4.11.3, Asynchronous and Synchronous Accessed in Nonmultiplexed Mode](#).

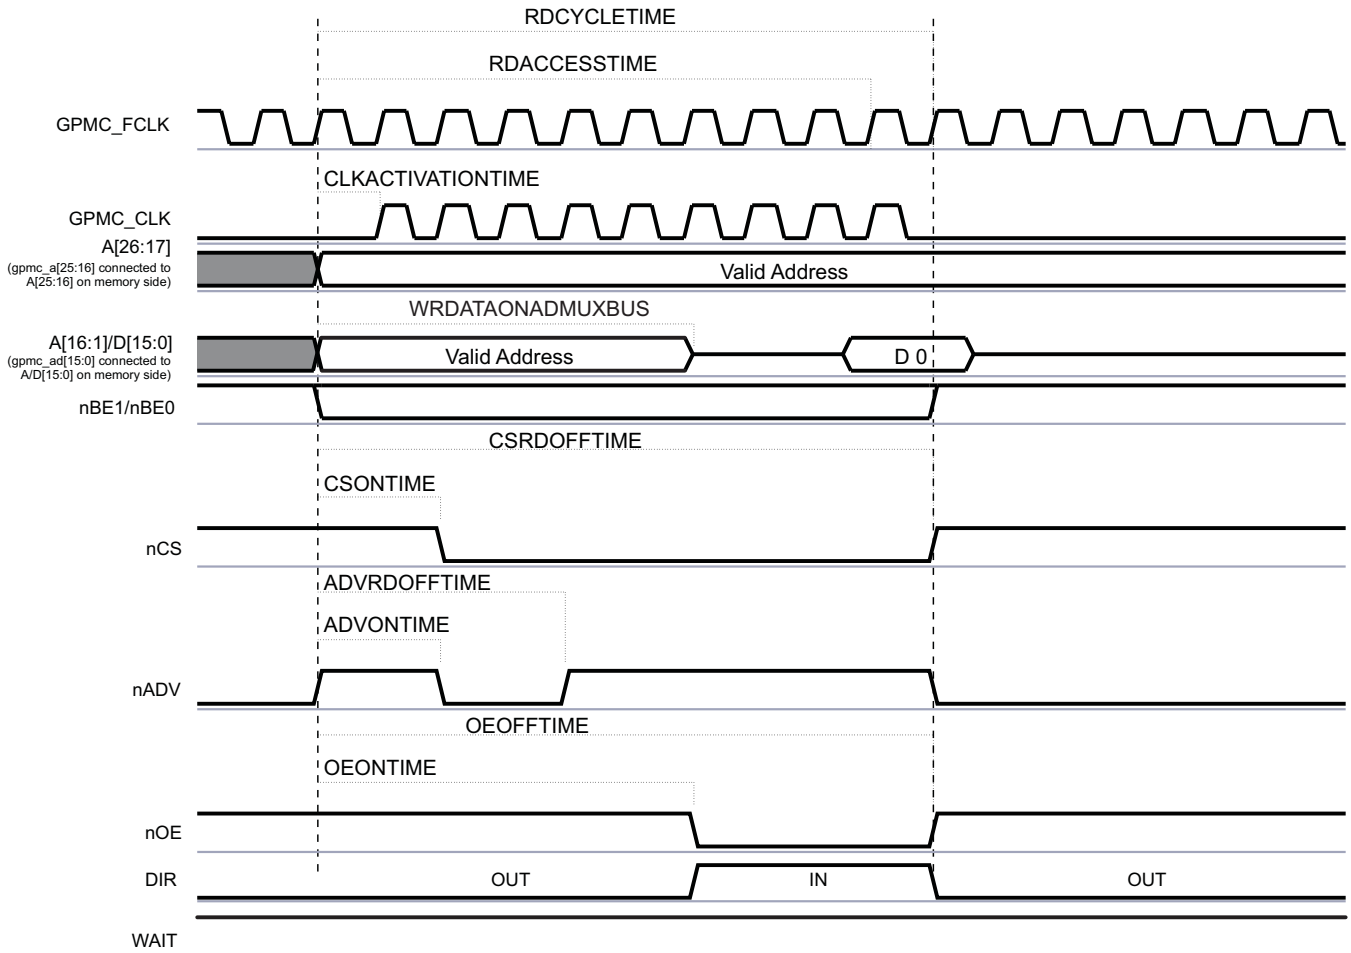

In synchronous operations:

- The GPMC_CLK clock is provided outside the GPMC when accessing the memory device.
- The GPMC_CLK clock is derived from the GPMC_FCLK clock using the [GPMC_CONFIG1_i\[1:0\]](#) GPMCFCLKDIVIDER field. In the following section i stands for the chip-select number, i = 0 to 7.
- The [GPMC_CONFIG1_i\[26:25\]](#) CLKACTIVATIONTIME field specifies that the GPMC_CLK is provided outside the GPMC 0, 1, or 2 GPMC_FCLK cycles after start access time until RDCYCLETIME or WRCYCLETIME completion.

15.4.4.11.2.1 Synchronous Single Read

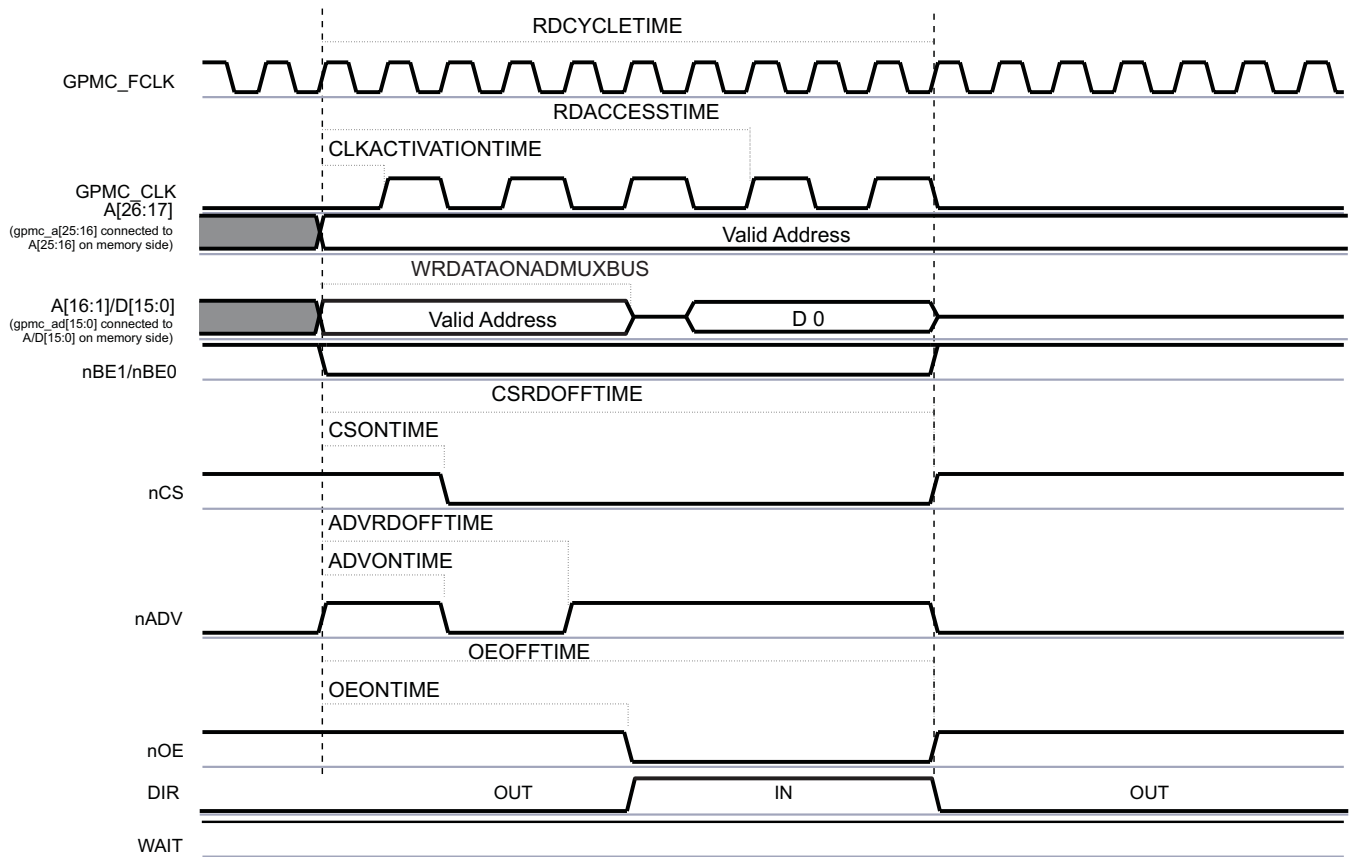

[Figure 15-66](#) and [Figure 15-67](#) show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

Figure 15-66. Synchronous Single Read (GPMCFCLKDIVIDER = 0)

gpmc-015

Figure 15-67. Synchronous Single Read (GPMCFCLKDIVIDER = 1)

gpmc-016

See Section 15.4.5.6.1, *GPMC Timing Parameters Formulas* for formulas to calculate timing parameters.

Table 15-258 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For details, see Section 15.4.4.9.2.3, *Address/Data-Multiplexing Interface*.

- Chip-select signal nCS:
 - nCS assertion time is controlled by the `GPMC_CONFIG2_i[3:0]` CSONTIME field and ensures address setup time to nCS assertion.
 - nCS deassertion time is controlled by the `GPMC_CONFIG2_i[12:8]` CSRDOFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the `GPMC_CONFIG3_i[3:0]` ADVONTIME field.
 - nADV deassertion time is controlled by the `GPMC_CONFIG3_i[12:8]` ADVRDOFFTIME field.
- Output enable signal nOE:
 - nOE assertion indicates a read cycle.
 - nOE assertion time is controlled by the `GPMC_CONFIG4_i[3:0]` OEONTIME field.
 - nOE deassertion time is controlled by the `GPMC_CONFIG4_i[12:8]` OEOFFTIME field.
- Initial latency for the first read data is controlled by `GPMC_CONFIG5_i[20:16]` RDACCESSTIME or by monitoring the WAIT signal.
- Total access time (`GPMC_CONFIG5_i[4:0]` RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus time from RDACCESSTIME to CSRDOFFTIME.
- Direction signal DIR: DIR goes from OUT to IN at the same time as nOE assertion.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, and DIR signals are controlled in the same way as for synchronous single read operation on an address/data-multiplexed device.

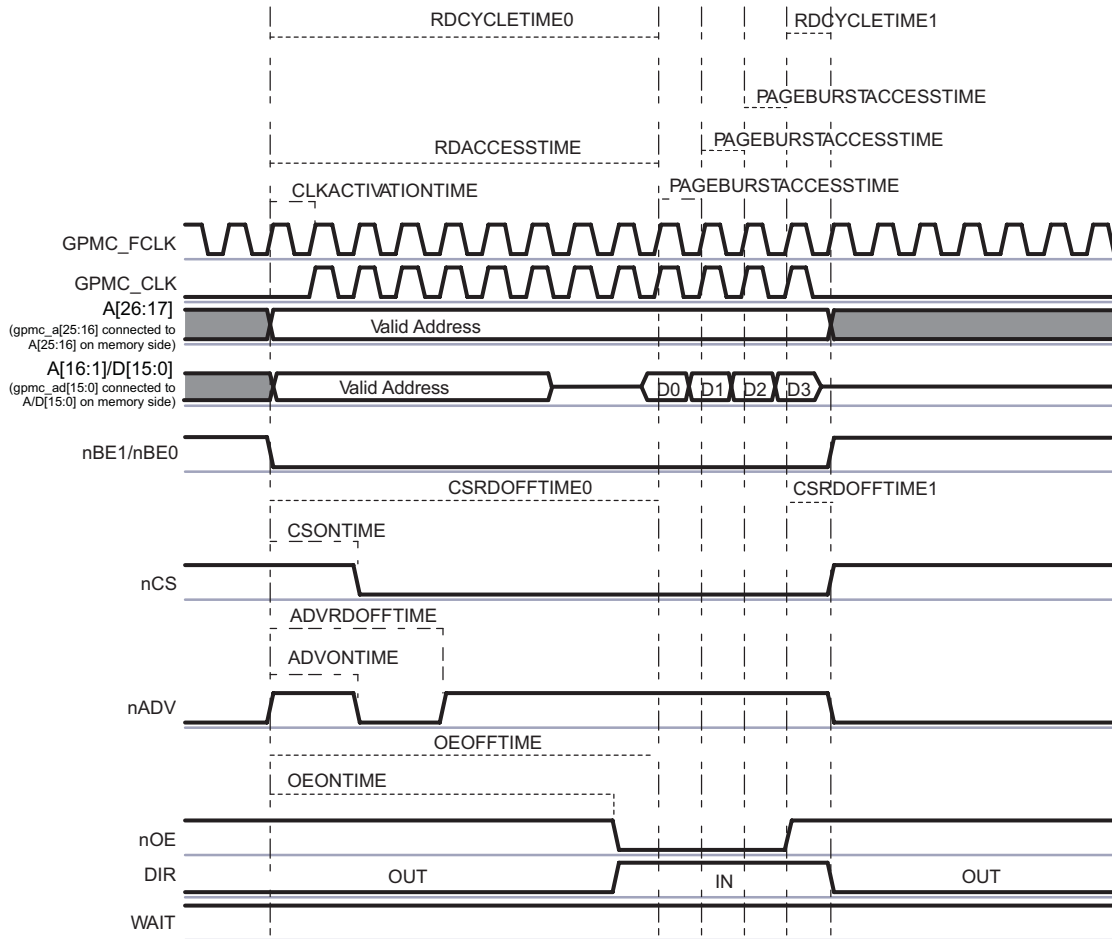

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
 - nADV first assertion time is controlled by the [GPMC_CONFIG3_i\[6:4\]](#) ADVAADMUXONTIME field.
 - nADV first deassertion time is controlled by the [GPMC_CONFIG3_i\[26:24\]](#) ADVAADMUXRDOFFTIME field.
 - nADV second assertion time is controlled by the [GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME field.
 - nADV second deassertion time is controlled by the [GPMC_CONFIG3_i\[12:8\]](#) ADVRDOFFTIME field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
 - nOE first assertion time is controlled by the [GPMC_CONFIG4_i\[6:4\]](#) OEAADMUXONTIME field.
 - nOE first deassertion time is controlled by the [GPMC_CONFIG3_i\[15:13\]](#) OEAADMUXOFFTIME field.
 - nOE second assertion time is controlled by the [GPMC_CONFIG4_i\[3:0\]](#) OEONTIME field.
 - nOE second deassertion time is controlled by the [GPMC_CONFIG4_i\[12:8\]](#) OEOFFTIME field.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 15.4.4.10.10](#), *Bus Keeping Support*.

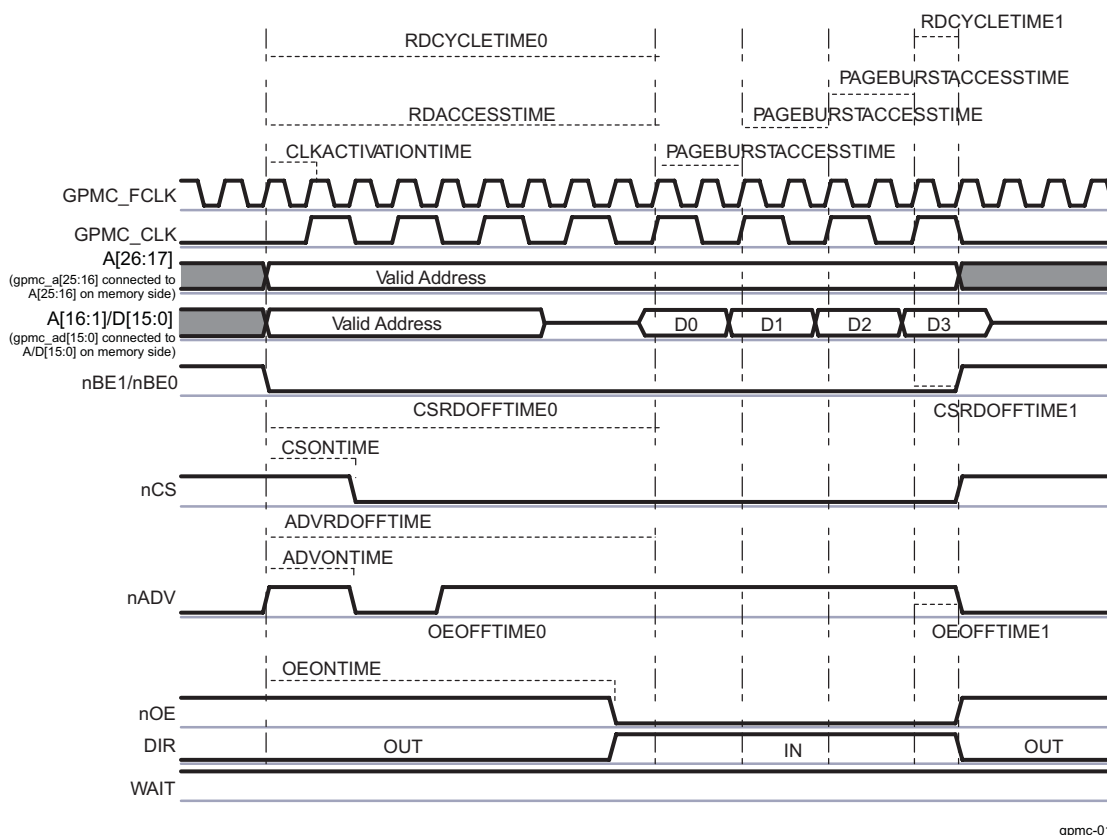

15.4.4.11.2.2 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst With Wraparound Capability)

[Figure 15-68](#) and [Figure 15-69](#) show a synchronous multiple read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

Figure 15-68. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)

gpmc-018

Figure 15-69. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)

When `GPMC_CONFIG5_i[20:16]` `RDACCESSTIME` completes, control-signal timings are frozen during the multiple data transactions, corresponding to `GPMC_CONFIG5_i[27:24]` `PAGEBURSTACCESSTIME` multiplied by the number of remaining data transactions.

The `nCS`, `nADV`, `nOE` and `DIR` signals are controlled in the same way as for synchronous single read operation. See [Table 15-244](#).

Initial latency for the first read data is controlled by `RDACCESSTIME` or by monitoring the `WAIT` signal. Successive read data are provided by the memory device each one or two `GPMC_CLK` cycles. The `PAGEBURSTACCESSTIME` parameter must be set accordingly with `GPMC_CONFIG1_i[1:0]` `GPMCFCLKDIVIDER` and the memory-device internal configuration. Depending on the device page length, the GPMC checks device page crossing during a new burst request and purposely insert initial latency (of `RDACCESSTIME`) when required.

Total access time `GPMC_CONFIG5_i[4:0]` `RDCYCLETIME` corresponds to `RDACCESSTIME` plus the address hold time from `nCS` deassertion. In [Figure 15-69](#), `RDCYCLETIME` programmed value equals to `RDCYCLETIME0` + `RDCYCLETIME1`.

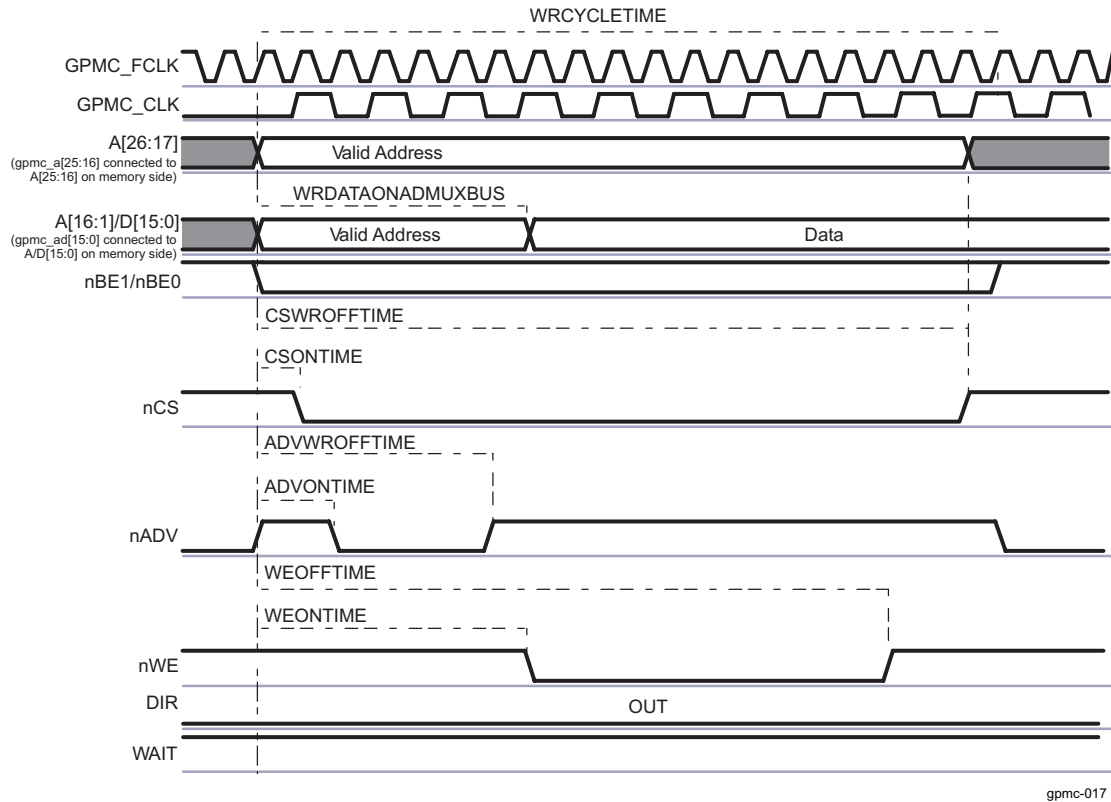

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 15.4.4.10.10, Bus Keeping Support](#).

Burst wraparound is enabled through the `GPMC_CONFIG1_i[31]` `WRAPBURST` bit and allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary through `GPMC_CONFIG1_i[24:23]` `ATTACHEDDEVICEPAGELENGTH`.

15.4.4.11.2.3 Synchronous Single Write

Burst write mode is used for synchronous single or burst accesses.

Figure 15-70. Synchronous Single Write on an Address/Data-Multiplexed Device

When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus (with address bits A[16:1]) until `GPMC_CONFIG6_i[19:16]` WRDATAONADMUXBUS time. First data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

15.4.4.11.2.4 Synchronous Multiple (Burst) Write

Synchronous burst write mode provides synchronous single or consecutive accesses.

Figure 15-71 shows a synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

Figure 15-71. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode

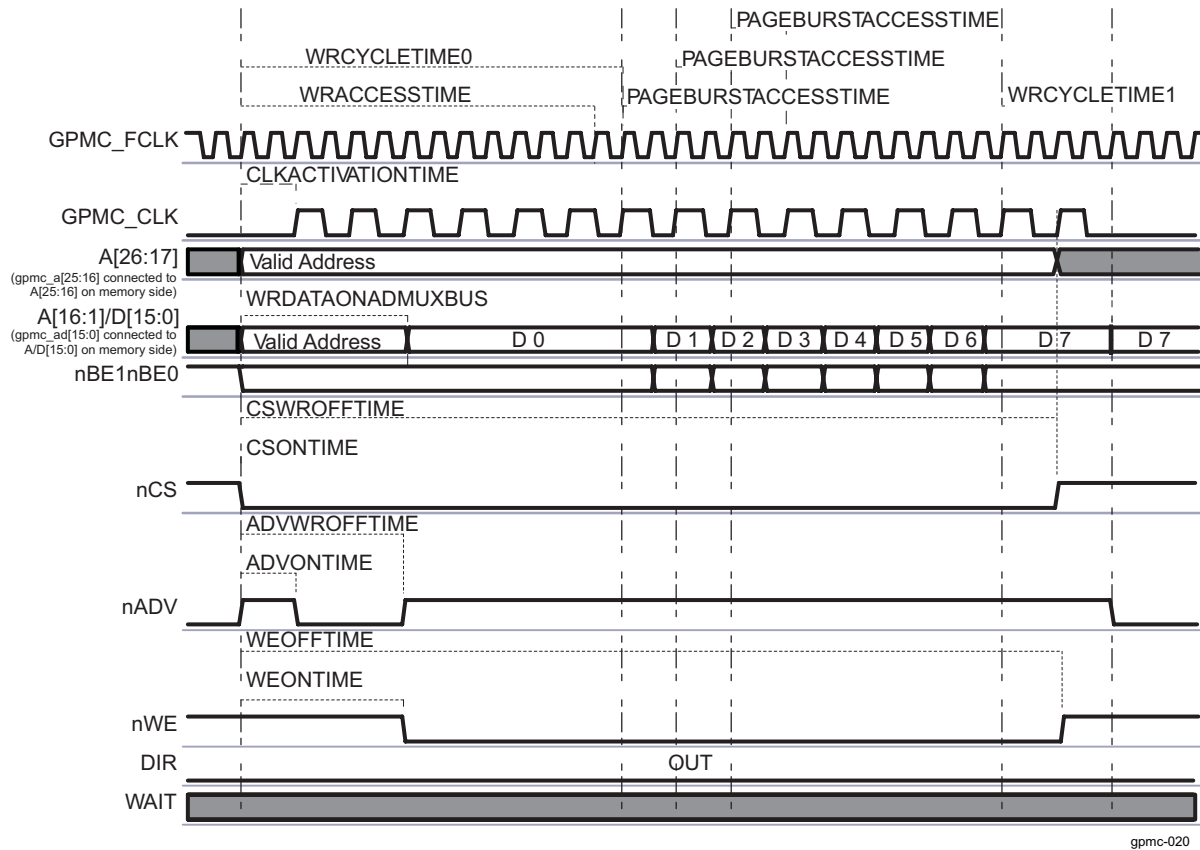

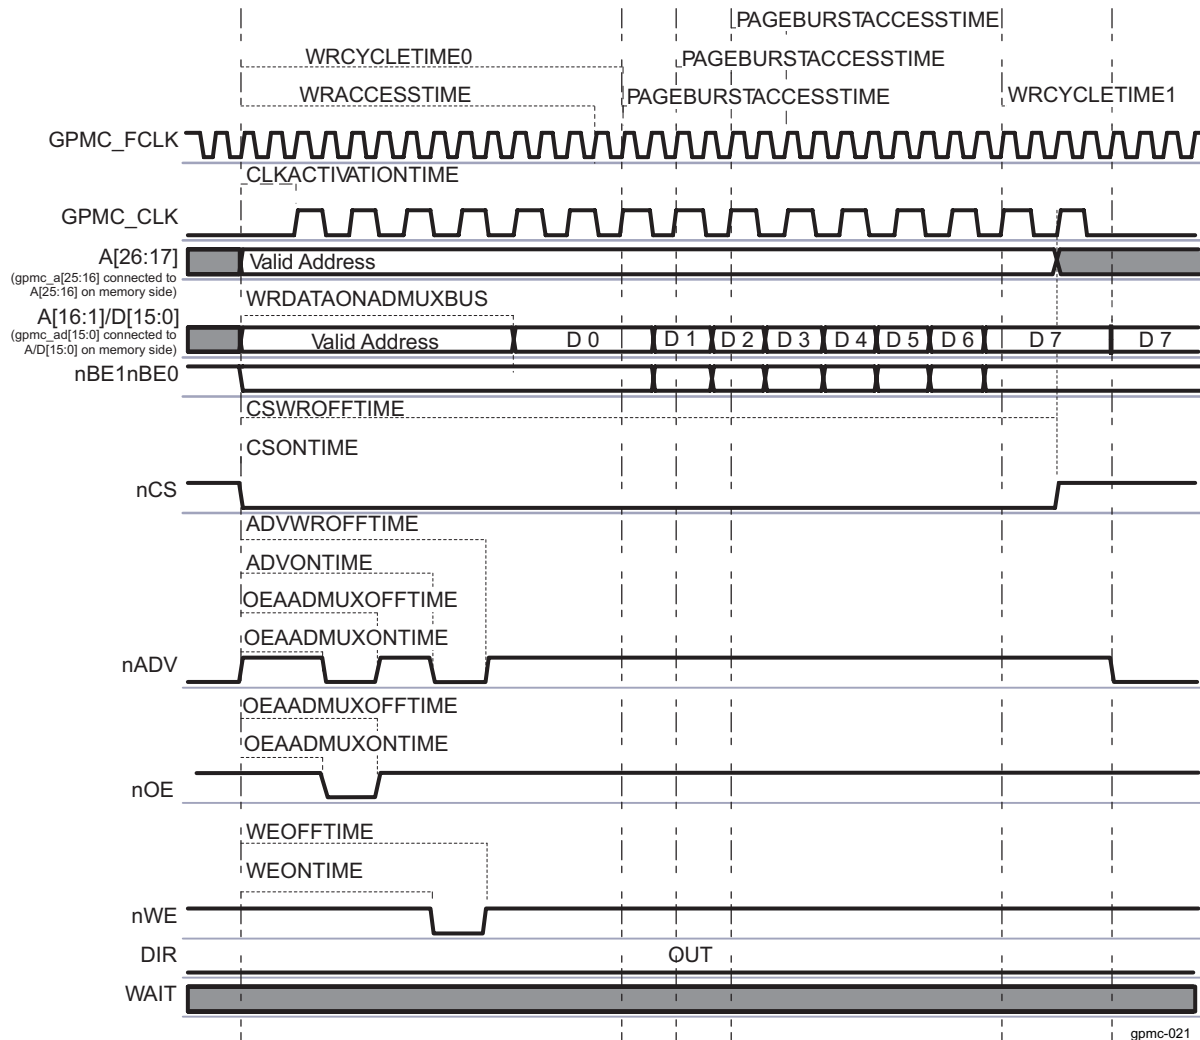

Figure 15-72 shows the same synchronous burst write access when the chip-select is configured in address/address/data-multiplexed (AAD-multiplexed) mode.

Figure 15-72. Synchronous Multiple Write (Burst Write) in Address/Address/Data-Multiplexed Mode

The first data of the burst is driven on the A/D bus at [GPMC_CONFIG6_i\[19:16\]](#) WRDATAONADMUXBUS.

When WRACCESTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the [GPMC_CONFIG5_i\[27:24\]](#) PAGEBURSTACCESTIME multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For details, see [Section 15.4.4.9.2.3, Address/Data-Multiplexing Interface](#).

- Chip-select signal nCS:
 - nCS assertion time is controlled by the [GPMC_CONFIG2_i\[3:0\]](#) CSONTIME field (i = 0 to 7) and ensures address setup time to nCS assertion.
 - nCS deassertion time controlled by the [GPMC_CONFIG2_i\[20:16\]](#) CSWROFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the [GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME field.
 - nADV deassertion time is controlled by the [GPMC_CONFIG3_i\[20:16\]](#) ADVWROFFTIME field.
- Write enable signal nWE:
 - nWE assertion indicates a read cycle.
 - nWE assertion time is controlled by the [GPMC_CONFIG4_i\[19:16\]](#) WEONTIME field.

- nWE deassertion time is controlled by the [GPMC_CONFIG4_i\[28:24\]](#) WEOFFTIME field.

NOTE: The nWE falling edge must not be used to control the time when the burst first data is driven in the address/data bus because some new devices require the nWE signal at low during the address phase.

- Direction signal DIR is OUT during the entire access.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, and DIR signals are controlled as detailed above.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
 - nADV first assertion time is controlled by the [GPMC_CONFIG3_i\[6:4\]](#) ADVAADMUXONTIME field.
 - nADV first deassertion time is controlled by the [GPMC_CONFIG3_i\[26:24\]](#) ADVAADMUXRDOFFTIME field.
 - nADV second assertion time is controlled by the [GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME field.
 - nADV second deassertion time is controlled by the [GPMC_CONFIG3_i\[12:8\]](#) ADVRDOFFTIME field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
 - nOE first assertion time is controlled by the [GPMC_CONFIG4_i\[6:4\]](#) OEAADMUXONTIME field.
 - nOE first deassertion time is controlled by the [GPMC_CONFIG4_i\[15:13\]](#) OEAADMUXOFFTIME field.
 - nOE second assertion time is controlled by the [GPMC_CONFIG4_i\[3:0\]](#) OEONTIME field.
 - nOE second deassertion time is controlled by the [GPMC_CONFIG4_i\[12:8\]](#) OEOFFTIME field.

First write data is driven by the GPMC at [GPMC_CONFIG6_i\[19:16\]](#) WRDATAONADMUXBUS, when in address/data mux configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during [GPMC_CONFIG5_i\[27:24\]](#) PAGEBURSTACCESSTIME GPMC_FCLK cycles. The last data of the synchronous burst write is driven until [GPMC_CONFIG5_i\[12:8\]](#) WRCYCLETIME completes.

- WRACCESSTIME is defined in the [GPMC_CONFIG6_i\[28:24\]](#) register.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time [GPMC_CONFIG5_i\[12:8\]](#) WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from nCS deassertion. In [Figure 15-71](#), the WRCYCLETIME programmed value equals WRCYCLETIME0 + WRCYCLETIME1. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See [Section 15.4.4.10.10, Bus Keeping Support](#).

15.4.4.11.3 Asynchronous and Synchronous Accesses in Nonmultiplexed Mode

Page mode is only available in non-muxed mode. The non-muxed mode is described in this section even though its use is very limited (address space limited to 2 KBytes).

- Asynchronous single read operation on a nonmultiplexed device
- Asynchronous single write operation on a nonmultiplexed device
- Asynchronous multiple (page mode) read operation on a nonmultiplexed device
- Synchronous operations on a nonmultiplexed device

15.4.4.11.3.1 Asynchronous Single Read Operation on a Nonmultiplexed Device

[Figure 15-73](#) shows an asynchronous single read operation on a nonmultiplexed device.

Figure 15-73. Asynchronous Single Read on an Address/Data-Nonmultiplexed Device

The 10-bit address is driven onto the address bus A[10:1] and the 16-bit data is driven onto the data bus D[15:0].

Read data is latched at [GPMC_CONFIG1_5\[20:16\]](#) RDACCESSTIME completion time. The end of the access is defined by the [GPMC_CONFIG1_5\[4:0\]](#) RDCYCLETIME parameter.

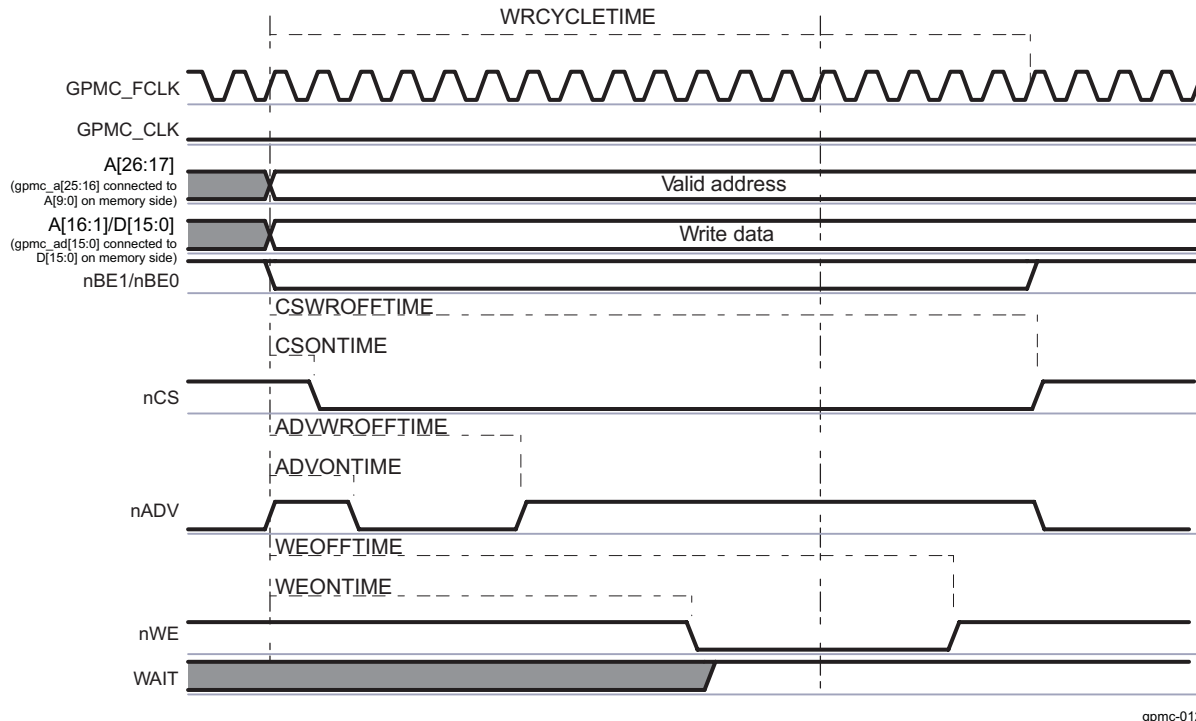

Set [GPMC_CONFIG\[1\]](#) LIMITEDADDRESS to 0x1 (A26-A11 are not modified during an external memory access).

nCS, nADV, nOE and DIR signals are controlled in the same way as address/data multiplexed accesses, see [Table 15-249](#).

gpmc-010

15.4.4.11.3.2 Asynchronous Single Write Operation on a Nonmultiplexed Device

[Figure 15-74](#) shows an asynchronous single write operation on a nonmultiplexed device.

Figure 15-74. Asynchronous Single Write on an Address/Data-Nonmultiplexed Device

The 10-bit address is driven onto the address bus A[10:1] and the 16-bit data is driven onto the data bus D[15:0].

Set **GPMC_CONFIG[1] LIMITEDADDRESS** to 0x1 (A26-A11 are not modified during an external memory access).

nCS, nADV, nWE and DIR signals are controlled in the same way as address/data multiplexed accesses, see [Table 15-249](#).

15.4.4.11.3.3 Asynchronous Multiple (Page Mode) Read Operation on a Nonmultiplexed Device

[Figure 15-75](#) shows an asynchronous multiple read operation on a Nonmultiplexed Device, in which two word32 host read accesses to the GPMC are split into one multiple (page mode of 4 word16) read access to the attached device.

Figure 15-75. Asynchronous Multiple (Page Mode) Read

gpmc-014

NOTE: The WAIT signal is active low.

nCS, nADV, nOE and DIR signals are controlled in the same way as address/data multiplexed accesses, see [Table 15-249](#).

When RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at [GPMC_CONFIG5_i\[20:16\]](#) RDACCESSTIME completion time (i = 0 to 7). The end of the access is defined by the [GPMC_CONFIG5_i\[4:0\]](#) RDCYCLETIME parameter.

Set [GPMC_CONFIG\[1\]](#) LIMITEDADDRESS to 0x1 (A26-A11 are not modified during an external memory access).

During consecutive accesses, the GPMC increments the address after each data read completes.

Delay between successive read data in the page is controlled by the [GPMC_CONFIG5_i\[27:24\]](#) PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Note that page crossing is only possible with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time starting from the nCS deassertion.

- The read cycle time is defined in the [GPMC_CONFIG5_i\[4:0\]](#) RDCYCLETIME field.
- In [Figure 15-75](#), the RDCYCLETIME programmed value equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

15.4.4.11.3.4 Synchronous Operations on a Nonmultiplexed Device

All information for this section is equivalent to similar operations for address/data- or AAD-multiplexed accesses. The only difference resides in the address phase. See [Section 15.4.5.3, GPMC Configuration in NOR Mode](#).

15.4.4.11.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The [GPMC_CONFIG1_i\[30\]](#) READMULTIPLE and [GPMC_CONFIG1_i\[28\]](#) WRITMULTIPLE bits ($i = 0$ to 7) are associated with the READTYPE and WRITETYPE parameters.

NOTE:

- Asynchronous write page mode is not supported.
 - 8-bit wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
 - Not applicable to NAND device interfacing.
-

15.4.4.11.5 System Burst Versus External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte enable controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two words, four words, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length burst. The maximum length that can be issued is defined per CS by the [GPMC_CONFIG1_i\[24:23\]](#) ATTACHEDDEVICEPAGELENGTH field ($i = 0$ to 7). When the ATTACHEDDEVICEPAGELENGTH value is less than the system burst request length (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the ATTACHEDDEVICEPAGELENGTH field value must correspond to the maximum-length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the [GPMC_CONFIG1_i\[31\]](#) WRAPBURST bit ($i = 0$ to 7) must be set to 1. Similarly DEVICESPAGELENGTH is set to 4 and 8 for memories supporting respectively 4 and 8 Word16-length-wrapping burst.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the ATTACHEDDEVICEPAGELENGTH value.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed burst length mode and a continuous burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the `GPMC_CONFIG1_i[24:23]` `ATTACHEDDEVICEPAGELENGTH` field is set accordingly to 4 or 8 words.

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-words boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the `ATTACHEDDEVICEPAGELENGTH` value. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait states between data accesses. If the memory does not behave this way (nonzero wait state burstable memory), wait-pin monitoring must be enabled to dynamically control data-access completion within the burst.

NOTE: When the system burst request length is less than the `ATTACHEDDEVICEPAGELENGTH` value, the GPMC proceeds with the required accesses.

15.4.4.12 pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The `GPMC_CONFIG1_i[11:10]` `DEVICETYPE` field ($i = 0$ to 7) must be set to 0b00.

The pSRAM devices uses the NOR protocol. It support the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR Flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can either automatically schedule autorefresh operations, which force the GPMC to use its `WAIT` signal capability when read or write operations occur during an internal self-refresh operation, or pSRAM devices automatically include the autorefresh operation in the access time. These devices do not require additional `WAIT` signal capability or a minimum `nCS` high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

15.4.4.13 NAND Access Description

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to *chip enable don't care* NAND devices since the chip-select allocated to the NAND device has to be deasserted if accesses to other chip-selects are requested.

15.4.4.13.1 NAND Memory Device in Byte or 16-bit Word Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data-stream-oriented (byte or 16-bit word).

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as Address Latch Enable (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as Command Latch Enable (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

15.4.4.13.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The [GPMC_CONFIG7_i](#) register (where $i = 0$ to 7) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16 Mbytes, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND Flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

CAUTION

To allow correct command, address, and data-access controls, the [GPMC_CONFIG1_i](#) register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters shown in [Table 15-227](#). Failure to comply with these settings corrupts the NAND interface protocol.

Table 15-227. Chip-Select Configuration for NAND Interfacing

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i [31] ⁽¹⁾	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i [30]	0	Single access
READTYPE	GPMC_CONFIG1_i [29]	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i [28]	0	Single access
WRITETYPE	GPMC_CONFIG1_i [27]	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i [26:25]	0b00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i [24:23]	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i [22]	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i [21]	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i [19:18]	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT	GPMC_CONFIG1_i [17:16]		Select which wait is monitored by edge detectors
DEVICESIZE	GPMC_CONFIG1_i [13:12]	0b00 or 0b01	8- or 16-bit interface
DEVICETYPE	GPMC_CONFIG1_i [11:10]	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1_i [9:8]	0b00	Nonmultiplexed mode

⁽¹⁾ $i = 0$ to 7

Table 15-227. Chip-Select Configuration for NAND Interfacing (continued)

Bit Field	Register	Value	Comments
TIMEPARAGRANULARITY	GPMC_CONFIG1_i[4]	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	GPMC_CONFIG1_i[1:0]	Don't care	Asynchronous mode

The [GPMC_CONFIG1_i](#) to [GPMC_CONFIG4_i](#) register (where $i = 0$ to 7) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

15.4.4.13.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The MPU software driver is responsible for issuing the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the [GPMC_NAND_COMMAND_i](#) and [GPMC_NAND_ADDRESS_i](#) register locations ($i = 0$ to 7) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the [GPMC_NAND_COMMAND_i](#) register location and to the [GPMC_NAND_ADDRESS_i](#) register location must be posted for faster operations ($i = 0$ to 7). The [GPMC_CONFIG\[0\]](#) NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An [GPMC_STATUS\[0\]](#) EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

[GPMC_NAND_COMMAND_i](#) and [GPMC_NAND_ADDRESS_i](#) ($i = 0$ to 7) are 32-bit word locations, which means any 32-bit word or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32-bit word or 16-bit word access to these registers, but it must account for the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to [GPMC_NAND_COMMAND_i](#) and [GPMC_NAND_ADDRESS_i](#) can be used, and any of the four byte locations of the registers are valid.

The same applies to a [GPMC_NAND_COMMAND_i](#) and a [GPMC_NAND_ADDRESS_i](#) ($i = 0$ to 7) 32-bit word write access to a 16-bit wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid.

15.4.4.13.1.3 Command Latch Cycle

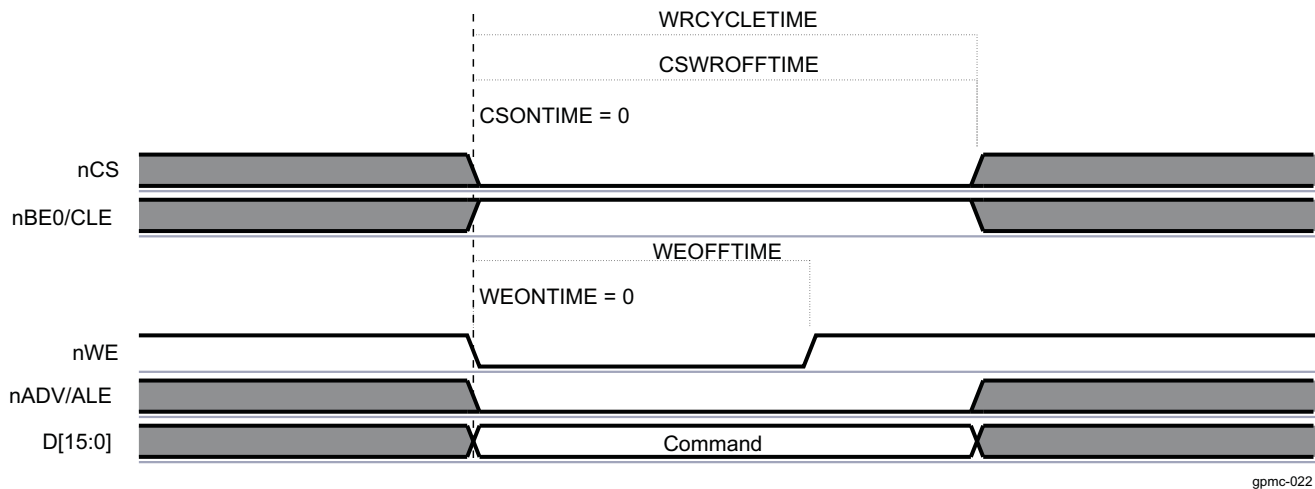

Writing data at the [GPMC_NAND_COMMAND_i](#) location ($i = 0$ to 7) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.

- ALE and nRE (nOE) are maintained inactive.

Figure 15-76 shows the NAND command latch cycle.

Figure 15-76. NAND Command Latch Cycle

NOTE: CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

NAND Flash memories do not use byte enable signals at all.

gpmc-022

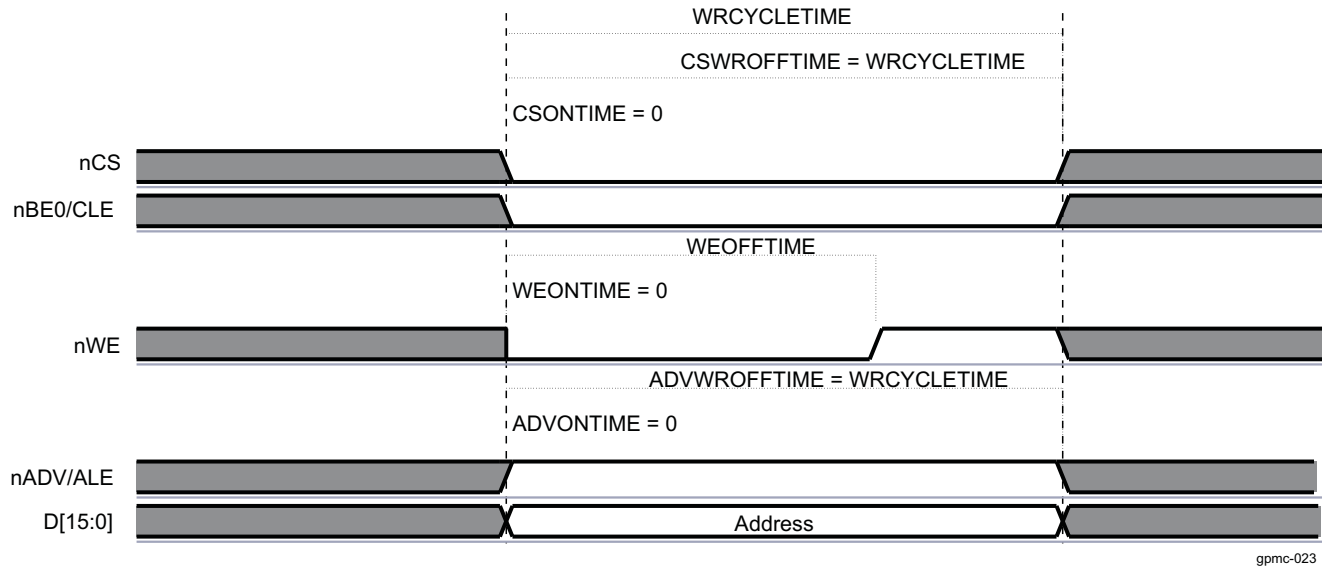

15.4.4.13.1.4 Address Latch Cycle

Writing data at the [GPMC_NAND_ADDRESS_i](#) location ($i = 0$ to 7) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 15-77 shows the NAND address latch cycle.

Figure 15-77. NAND Address Latch Cycle

gpmc-023

NOTE: ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

15.4.4.13.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

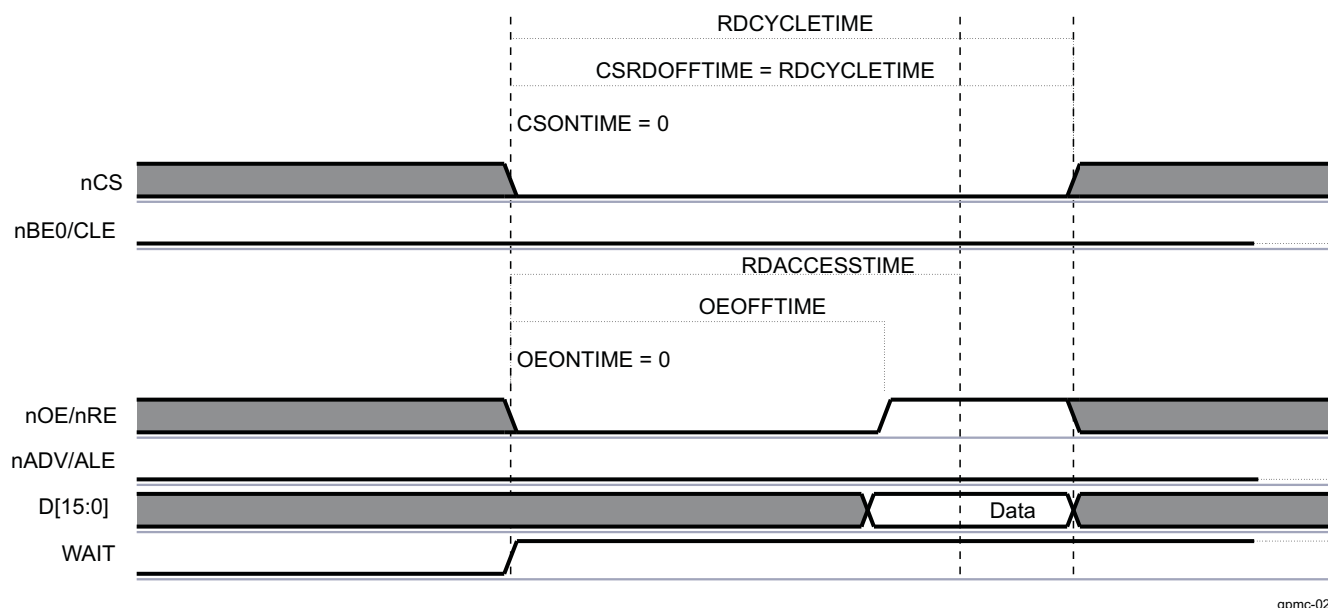

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the [GPMC_NAND_DATA_i](#) location ($i = 0$ to 7) mapped in the chip-select-associated control register region. [GPMC_NAND_DATA_i](#) is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Reading data from the [GPMC_NAND_DATA_i](#) location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, the RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device IC timing parameters.

ALE, CLE, and nWE are maintained inactive.

[Figure 15-78](#) shows the NAND data read cycle.

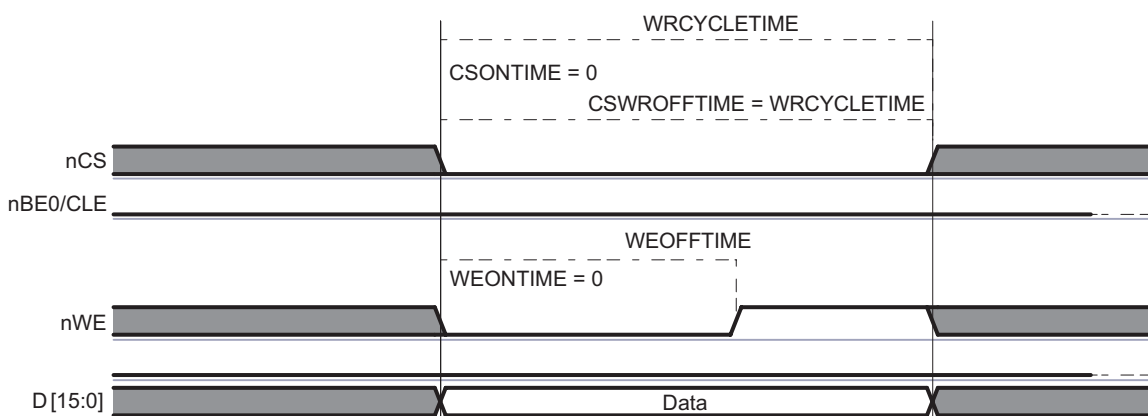

Figure 15-78. NAND Data Read Cycle

gpmc-024

Writing data to the [GPMC_NAND_DATA_i](#) location or to any location in the associated chip-select memory region activates an asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and nRE (nOE) are maintained inactive.

Figure 15-79 shows the NAND data write cycle.

Figure 15-79. NAND Data Write Cycle

gpmc-025

15.4.4.13.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by nCS-to-data-valid timing and has faster nRE-to-data-valid timing. Successive accesses with nCS deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that nCS always stays low between two accesses to the same chip-select. Moreover, an nCS deassertion time between the same chip-select NAND accesses is likely to be required as follows: the nCS deassertion requires programming CYCLETIME and RDACCESSTIME according to the nCS-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSRDOFFTIME, CSWROFFTIME, ADVRDOFFTIME, ADVWROFFTIME, OEOFFTIME, and WEOFFTIME on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses. For more information about optimal prefetch engine access, see [Section 15.4.4.13.4, Prefetch and Write-Posting Engine](#).

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, CYCLE2CYCLESAMEECSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high to data bus in tristate mode. This requires a bus turnaround setting (BUSTURNAROUND = 1), so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND Flash are not affected by the programmed bus turnaround delay.

15.4.4.13.1.7 Read and Write Access Size Adaptation

15.4.4.13.1.7.1 8-bit wide NAND Device

Host 16-bit word and 32-bit word read and write access requests to a chip-select associated with an 8-bit wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the chip-select is associated with an 8-bit wide NAND device.

15.4.4.13.1.7.2 16-bit wide NAND Device

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit wide NAND device should be avoided, especially when ECC calculation is enabled. 8-bit or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

15.4.4.13.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the WAIT GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 micro second) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

NOTE: If a read access to a NAND flash is done using the wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the [GPMC_CONFIG1_i\[21\]](#) WAITWRITEMONITORING and [GPMC_CONFIG1_i\[22\]](#) WAITREADMONITORING bits to 0, where $i = 0$ to 7), and use one of the following methods instead:

- Use software to poll the WAITnSTATUS bit ($n = 0$ to 3) of the [GPMC_STATUS](#) register.
- Configure an interrupt that is generated on the WAIT signal change (through the [GPMC_IRQENABLE](#) register bits[11:8]).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed WAIT bit in the [GPMC_STATUS](#) register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

15.4.4.13.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the [GPMC_STATUS](#) WAITxSTATUS bit ($x = 0$ or 1). The software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

15.4.4.13.2.2 Ready Pin Monitored by Hardware Interrupt

Each gpmc_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the [GPMC_CONFIG](#) WAITxPINPOLARITY bits ($x = 0$ or 1) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit ($x = 0$ or 3) of the [GPMC_IRQSTATUS](#) register according to the gpmc_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the [GPMC_IRQENABLE](#) register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the [GPMC_IRQSTATUS](#) register is set.

The WAITMONITORINGTIME field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the [GPMC_IRQSTATUS](#) register according to the gpmc_wait pin used for the NAND device ready signal monitoring.

15.4.4.13.3 ECC Calculator

The General Purpose Memory Controller includes an Error Code Correction (ECC) calculator circuitry that enables on the fly ECC calculation during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the [GPMC_ECC_CONFIG\[16\]](#) ECCALGORITHM bit:

1. Hamming code for 1-bit error code correction on 8- or 16-bit NAND Flash organized with page size greater than 512 bytes
2. BCH (Bose-Chaudhuri-Hocquenghem) code for 4- to 16-bit error correction

The GPMC does not directly handle the error code correction itself. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (row and column) bit parity accumulation. This parity accumulation is either accomplished on the programmed number of bytes or 16-bit words read from the memory device, or written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the [GPMC_ECC_CONFIG\[3:1\]](#) ECCCS bit field. Even if two CS use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

15.4.4.13.3.1 Hamming Code

All references to Error Code Correction (ECC) in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a two-dimensional (row and column) bit parity accumulation known as Hamming Code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and it is the software NAND driver responsibility to read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time and parallel computations on different chip-selects are not possible. Since it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. It is the software responsibility to make sure only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is completed.

15.4.4.13.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers ([GPMC_ECCj_RESULT](#), $j = 1$ to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially; one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The [GPMC_ECCj_RESULT](#) register value is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

The [GPMC_ECC_CONTROL\[3:0\]](#) ECCPOINTER field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The [GPMC_ECCj_RESULT](#) register value ($j = 1$ to 9) can be considered valid when ECCPOINTER equals $j + 1$. When [GPMC_ECCj_RESULT](#) (where $j = 9$) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The [GPMC_ECC_CONTROL\[8\]](#) ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each [GPMC_ECCj_RESULT](#) register, $j = 1$ to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSISE bits (j = 1 to 9) in the [GPMC_ECC_SIZE_CONFIG](#) register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in [GPMC_ECCj_RESULT](#)).

The ECCSIZE0 and ECCSIZE1 fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2 Kbyte data page 8-bit wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine [GPMC_ECCj_RESULT](#) registers (j= 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1:8]RESULTSISE bits are set to 0, and the ECC9RESULTSISE bit is set to 1.

15.4.4.13.3.1.2 ECC Enabling

The [GPMC_ECC_CONFIG](#)[3:1] ECCCS field selects the allocated chip-select. The [GPMC_ECC_CONFIG](#)[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The ECCPOINTER, ECCCLEAR, ECCSIZE, ECCjRESULTSISE (where j = 1 to 9), ECC16B, and ECCCS fields must not be changed or cleared while an ECC computation is in progress.

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

[Table 15-228](#) describes the ECC enable settings.

Table 15-228. ECC Enable Settings

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0-3	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0/1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0-7	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CONTROL	0-7	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	0x00-0xFF	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	0x00-0xFF	Defines ECCSIZE0
ECCjRESULTSISE (j from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

15.4.4.13.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word 16 streams. The parity accumulation is split into row and column accumulations, as shown in [Figure 15-80](#) and [Figure 15-81](#). The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream

P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream

P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream
 P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream
 Each column parity bit is XORed with the previous accumulated value.

Figure 15-80. Hamming Code Accumulation Algorithm (1/2)

gpmc-026

For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

$$P8e = \text{row0 XOR row2 XOR row4 XOR ... XOR row254}$$

$$P8o = \text{row1 XOR row3 XOR row5 XOR ... XOR row255}$$

$$P16e = \text{row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253}$$

$$P16o = \text{row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255}$$

Figure 15-81. Hamming Code Accumulation Algorithm (2/2)

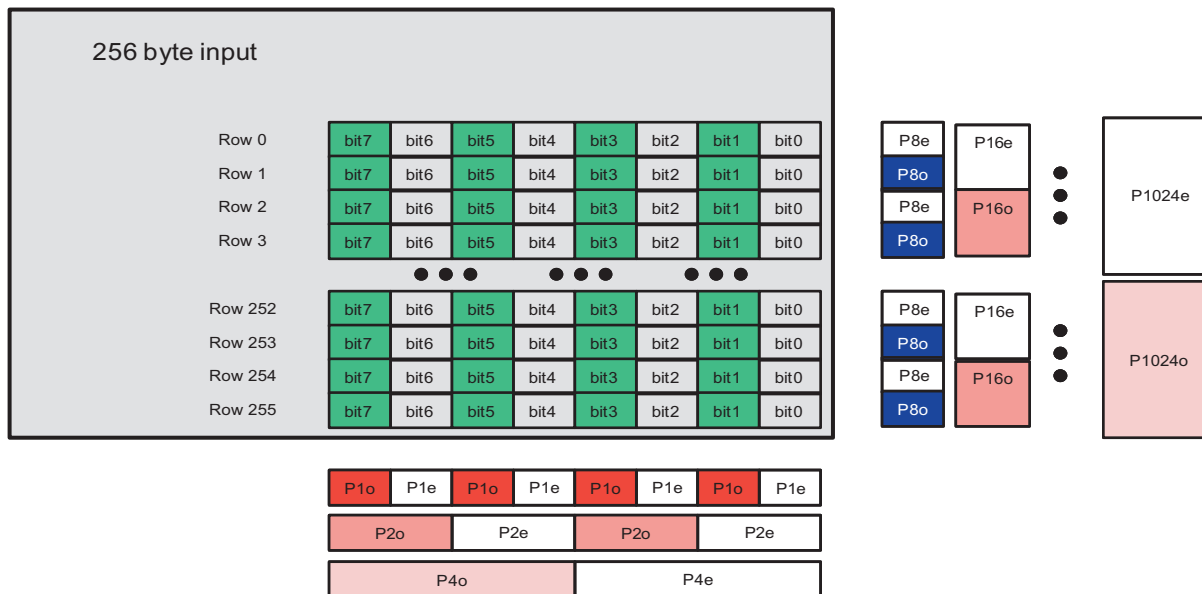

gpmc-027

Unused parity bits in the result registers are set to 0.

Figure 15-82 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

Figure 15-82. ECC Computation for a 256-Byte Data Stream (Read or Write)

gpmc-028

Figure 15-83 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

Figure 15-83. ECC Computation for a 512-Byte Data Stream (Read or Write)

gpmc-029

For a 2 Kbytes page, four 512 bytes ECC calculations plus one for the spare area are required. Results are stored in the [GPMC_ECCj_RESULT](#) registers (j = 1 to 9).

15.4.4.13.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, one bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). The software must correct the corresponding bit.
- If only one bit in the parity result is 1, it is an ECC error and the read data is correct.

15.4.4.13.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit based ECC computation is used for 8-bit wide NAND device interfacing.

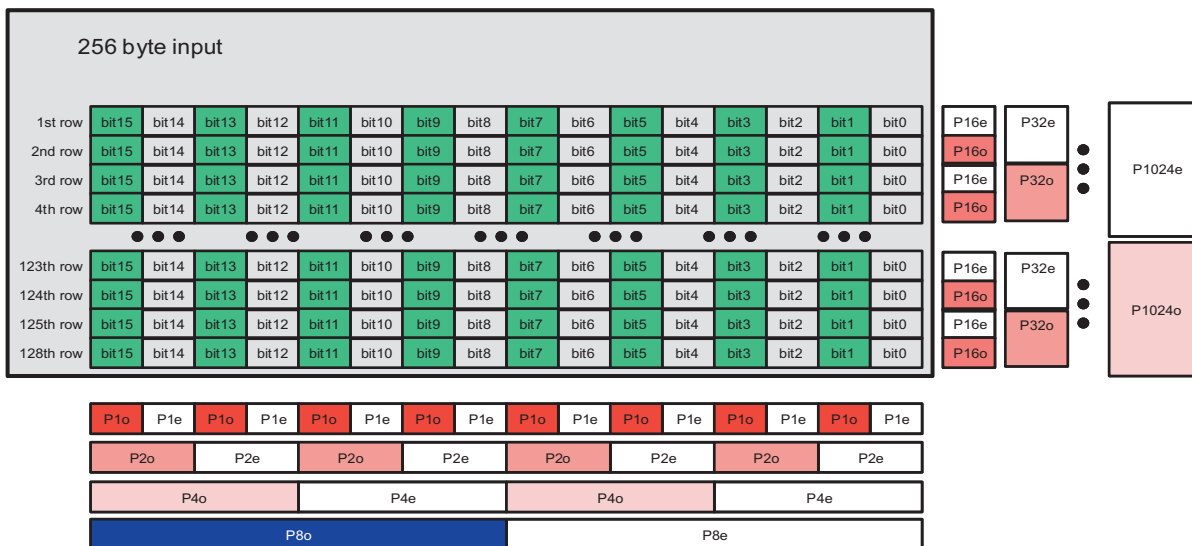

The 8-bit based ECC computation can be used for 16-bit wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit wide NAND devices. In this case, the 16-bit wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the least significant bit (LSB) of the 16-bit wide data is ordered first in the byte stream used for 8-bit based ECC computation.

15.4.4.13.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on a 16-bit word is used for 16-bit wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit wide NAND device, and the [GPMC_ECC_CONFIG\[7\]](#) ECC16B bit must be set to 0 when interfacing an 8-bit wide NAND device.

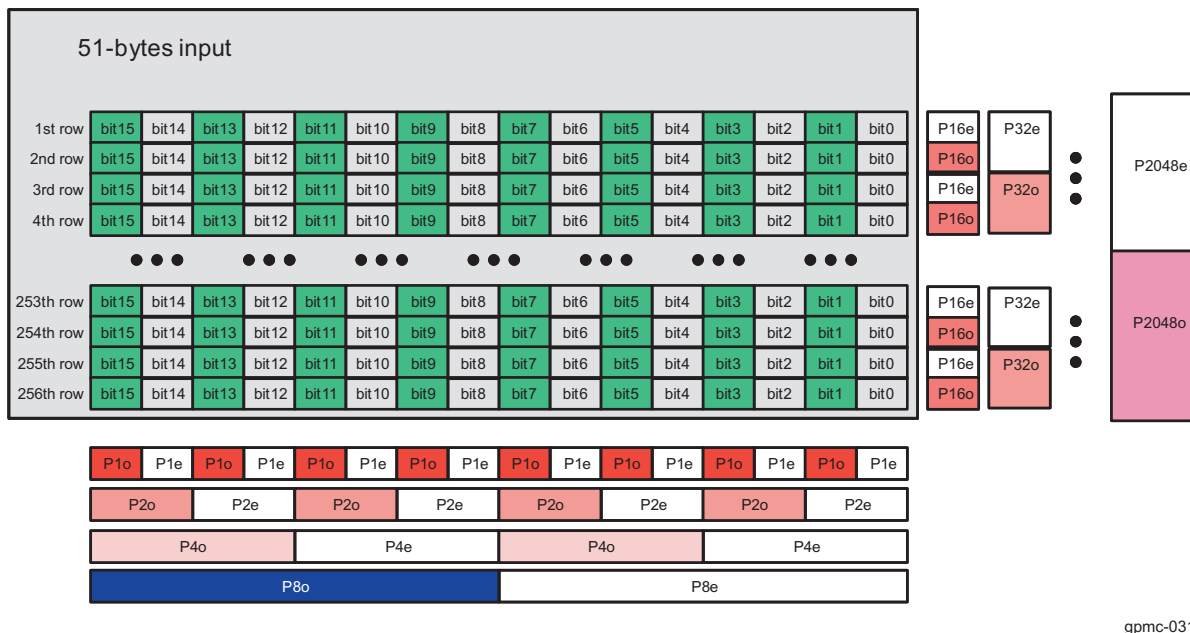

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit based ECC while there are computed on columns for a 16-bit based ECC. [Figure 15-84](#) and [Figure 15-85](#) show a 128 Word 16 ECC computation scheme and a 256 16-bit word ECC computation scheme.

Figure 15-84. 128 Word16 ECC Computation

gpmc-030

Figure 15-85. 256 Word16 ECC Computation

15.4.4.13.3.2 BCH Code (Bose-Chaudhuri-Hocquenghem)

All references to Error Code Correction (ECC) in this subsection refer to the 4- to 16-bit error correction BCH code.

15.4.4.13.3.2.1 Requirements

- Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, then some spare bytes, including the BCH ECC (and other information). The NAND IC can cache a full page, including spares, for read and write accesses. Typical page write sequence:
 - Sequential write to NAND cache of main data + spare data, for a page. ECC is calculated on the fly. Calculated ECC may be inserted on the fly in the spares, or replaced by dummy accesses.
 - When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
 - NAND writes its cache line (page) to the array.
 Typical page read sequence:
 - Sequential read of a page. ECC is calculated on the fly.
 - ECC module buffers status determines the presence of errors.
- Accesses to several memories may be interleaved by the GPMC, but only one of those memories can be a NAND using the BCH engine at a time; in other words, only one BCH calculation (for example, for a single page) can be on-going at any time. Note also that the sequential nature of NAND accesses guarantees that the data is always written / read out in the same order. BCH-relevant accesses are selected by the GPMCs chip-select.
- Each page may hold up to 4 Kbytes of data, spare bytes not included. This means up to 8 x 512-byte BCH messages. Since all the data is written / read out first, followed by the BCH ECC, this means that the BCH engine must be able to hold 8 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time. The BCH module has the capacity to store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.
- NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least 4

cycles of the GPMCs internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least 4 clock cycles after optimization when using the BCH calculator.

- The spare area is assumed to be large enough to hold the BCH ECC, that is, to have at least a message of 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (maximum codeword is 1023-byte long, ECC included, which leaves a lot of space to cover some spares bytes).

15.4.4.13.3.2.2 Memory-Mapping of the BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message $M(x)$. In our standard case, 512 bytes of data (that is, 2^{12} bits = 4096 bits) are seen as a polynomial of degree $2^{12} - 1 = 4095$, with parameters ranging from M0 to M4095. For 512 bytes of data, 52 bits are required for 4-bit error correction, and 104 bits are required for 8-bit error correction and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial $R(x)$ of degree 103 (or 51, depending on the selected mode). The complete codeword $C(x)$ is the concatenation of $M(x)$ and $R(x)$ as shown in [Table 15-229](#).

Table 15-229. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)

	Message $M(x)$			ECC $R(x)$		
Bit number	M4095	...	M0	R103	...	R0

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message $M(x)$ of degree $((512 + 3) * 8) - 1 = 4119$, for a total of $3+13 = 16$ spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in [GPMC_BCH_RESULT0_i](#), [GPMC_BCH_RESULT1_i](#), [GPMC_BCH_RESULT2_i](#), and [GPMC_BCH_RESULT3_i](#) (where $i = 0$ to 7).

15.4.4.13.3.2.2.1 Memory-Mapping of the Data Message

The data message mapping shall follow the following rules:

- Bit endianness within a byte is little-endian, that is, the bytes LS bit is also the lowest-degree polynomial parameter: a byte b7-b0 (with b0 the LS bit) represents a segment of polynomial $b7 * x^{(7+i)} + b6 * x^{(6+i)} + \dots + b0 * x^i$
- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the NANDs 16-bit words is big endian. This means that the same message mapped in 8- and 16-bit memories has the same content at the same byte address.

NOTE: The BCH module has no visibility over actual addresses. The most important point is the sequence of data word the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, and this produces the mapping patterns described below.

The following tables represent the mapping of the same 512-byte vector (typically a BCH message) in the NANDs memory space. Note that the byte 'address' is only an offset modulo 512 (0x200), since the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are respectively the bits M0 and $M(2^{12}-1)$ of the codeword mapping given above. In both cases the data vectors are aligned, that is, their boundaries coincide with the RAMs data word boundaries.

Table 15-230. Aligned Message Byte Mapping in 8-bit NAND

Byte offset	8-bit word
0x000	(msb) Byte 511 (0x1FF)
0x001	Byte 510 (0x1FE)
...	...
0x1FF	Byte 0 (0x0) (lsb)

Table 15-231. Aligned Message Byte Mapping in 16-bit NAND

Byte offset	16-bit words MSB	16-bit words LSB
0x000	Byte 510 (0x1FE)	(msb) Byte 511 (0x1FF)
0x002	Byte 508 (0x1FC)	Byte 509 (0x1FD)
...
0x1FE	Byte 0 (0x0)	(lsb) Byte 1 (0x1)

The following tables show the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on another sectors ECC).

Table 15-232. Aligned Nibble Mapping of Message in 8-bit NAND

Byte offset	8-bit word	
	4-bit most significant Nibble	4-bit less significant Nibble
1	(msb) Nibble S-1	Nibble S-2

$(S+3)/2 - 2$			Nibble 0 (lsb)	

Note that many other cases exist than the ones represented above, for example, where the message does not start on a word boundary.

15.4.4.13.3.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. It is up to the software to fetch those 13 bytes (or 6 bytes) from the modules interface, then store them to the NANDs spare area (page write) or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is a softwarecontrolled operation.

However, it is advised to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error as been detected. The creation of this codeword should be made as straightforward as possible.

There are cases where the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on-the-fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on-the-fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

15.4.4.13.3.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections, as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described below. To get a better understanding and see the real-life read and write sequences implemented with each mode, see [Section 15.4.4.13.3.2.3, Supported NAND Page Mappings and ECC Schemes](#).

For each mode:

- a sequence describes the mode in pseudo-language, with for each section the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0 and size1.
- a checksum condition is given. If the checksum condition is not respected for a given mode, the modules behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Note that wrapping modes 8, 9, 10, and 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for t = 4 ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

15.4.4.13.3.2.4 Manual Mode (0x0)

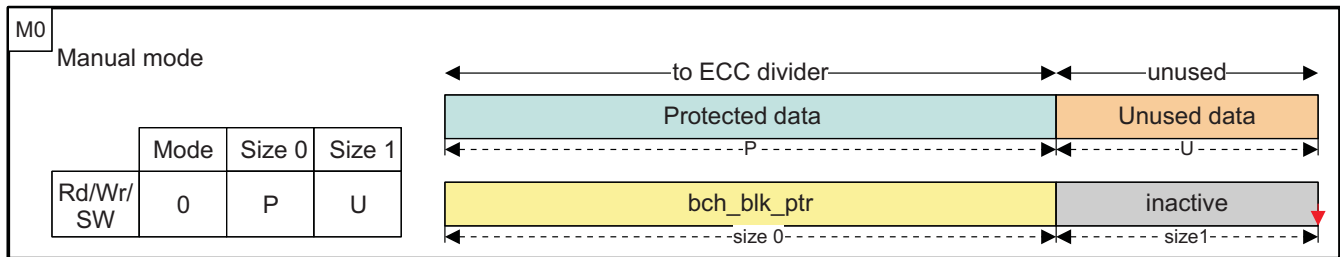

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port must be made, containing the appropriate data. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles need to be skipped, a number of unused nibbles must be programmed in `GPMC_ECC_SIZE_CONFIG[29:22] ECCSIZE1`. (In the same example: 5 nibbles to process + 3 to discard = 8 nibbles = exactly 2 x 16-bit accesses. Software must set:

- `GPMC_ECC_SIZE_CONFIG[19:12] ECCSIZE0 = 0x5`
- `GPMC_ECC_SIZE_CONFIG[29:22] ECCSIZE1 = 0x3`

NOTE: In the following figures size and size0 are the same parameter.

Figure 15-86. Manual Mode Sequence and Mapping

gpmc-032

Section processing sequence:

- One time with buffer
 - size0 nibbles of data, processing ON
 - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

In the following sections, S is the number of sectors in the page.

15.4.4.13.3.2.2.5 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S × (size0 + size1)

15.4.4.13.3.2.2.6 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
 - 1 nibble pad spare, processing OFF
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S × (size0 + 1 + size1)

15.4.4.13.3.2.2.7 Mode 0x2

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = $S \times (\text{size0} + \text{size1})$

15.4.4.13.3.2.2.8 Mode 0x3

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = $\text{size0} + (S \times \text{size1})$

15.4.4.13.3.2.2.9 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = $\text{size0} + (S \times \text{size1})$

15.4.4.13.3.2.2.10 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = $\text{size0} + (S \times (1 + \text{size1}))$

15.4.4.13.3.2.2.11 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time (no buffer used)
 - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = $\text{size0} + (S \times \text{size1})$

15.4.4.13.3.2.2.12 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time (no buffer used)
 - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S × (1+size1))

15.4.4.13.3.2.2.13 Mode 0x5

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S × (size0 + size1)

15.4.4.13.3.2.2.14 Mode 0xB (11)

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S × (size0 + 1 + size1)

15.4.4.13.3.2.2.15 Mode 0x6

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S × (size0 + size1)

15.4.4.13.3.2.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply throughout the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC)

are defined as explained in [Section 15.4.4.13.3.2.2.1](#), *Memory-Mapping of the Data Message*.

Each one of the following sections shows a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In [Figure 15-87](#) to [Figure 15-89](#), tables on the left summarize the mode, size0, size1 parameters to program for respectively write and read processing of a page, with the given mapping, where :

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC itself (in nibbles)
- S is the number of Sectors per page (2 in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. Note that the processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1kByte + spares, that is, $S = 2$ sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can only happen in the codeword that was actually written to the NAND, and not in the mathematical codeword of $n = 2^{13} - 1 = 8191$ bits. That codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, on the programmed sizes and on the sector number (all sizes in nibbles):

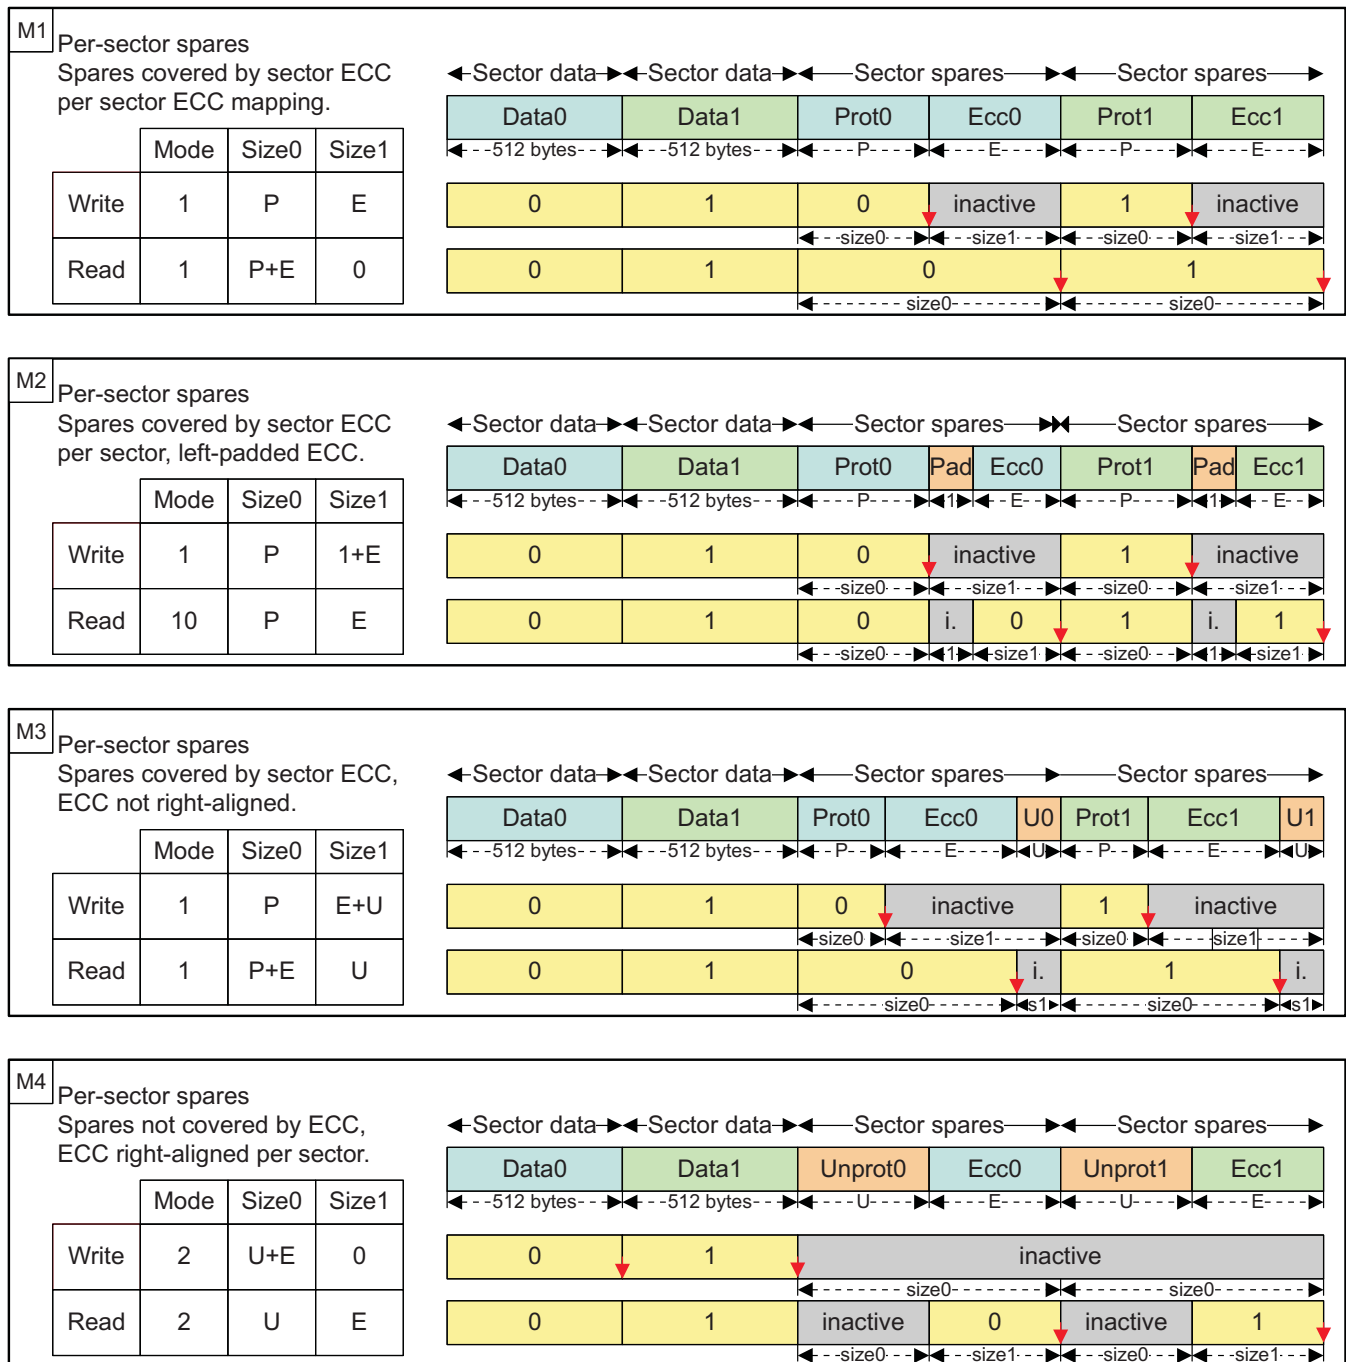

- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
 - all sectors: $(512) + P + E$
- Spares pooled and protected by sector 0 (below: see M5-M6):
 - sector 0 codeword: $(512) + P + E$
 - other sectors: $(512) + E$
- Unprotected spares (below: see M4-M7-M8-M11-M12):
 - all codewords $(512) + E$

15.4.4.13.3.2.3.1 Per-Sector Spare Mappings

In these schemes, each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of :

- ECC, which must be located after the data it protects
- other data, which may or may not be protected by the sectors ECC

Figure 15-87. NAND Page Mapping and ECC: Per-Sector Schemes

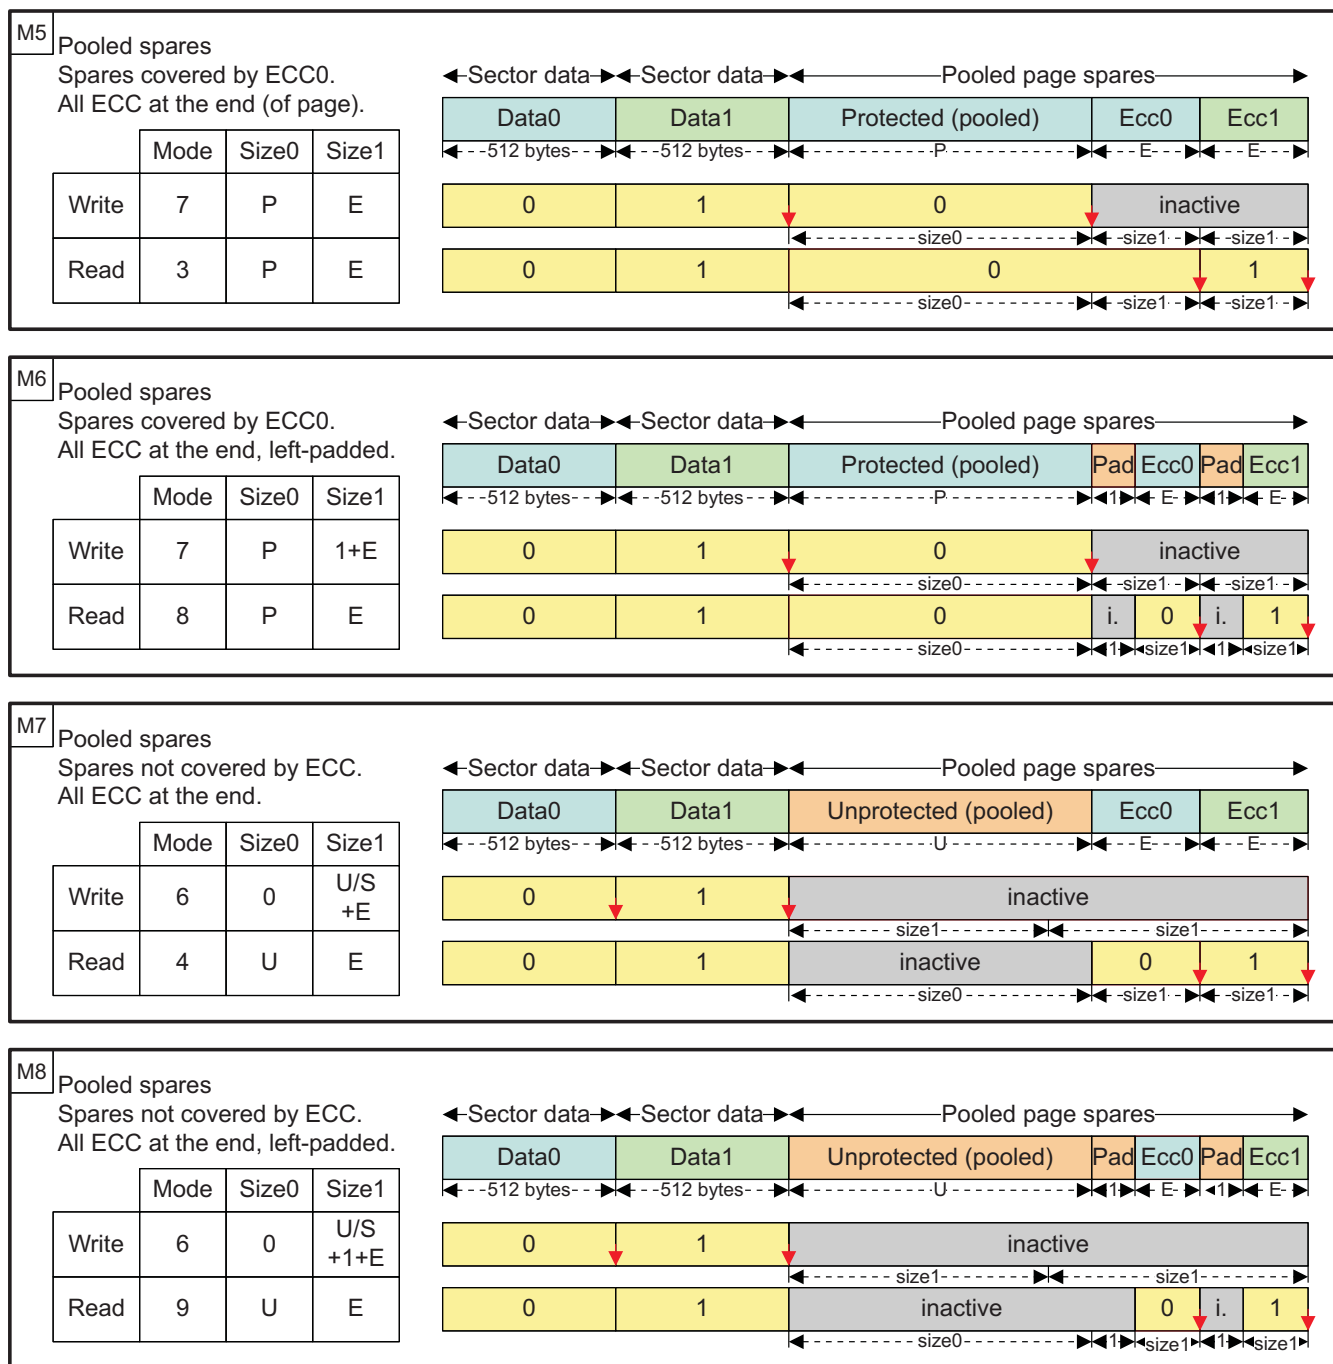

gpmc-033

15.4.4.13.3.2.3.2 Pooled Spare Mapping

In the schemes below, the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.
- The non-ECC spare data may or may not be covered by the ECC of sector 0

Figure 15-88. NAND Page Mapping and ECC: Pooled Spare Schemes

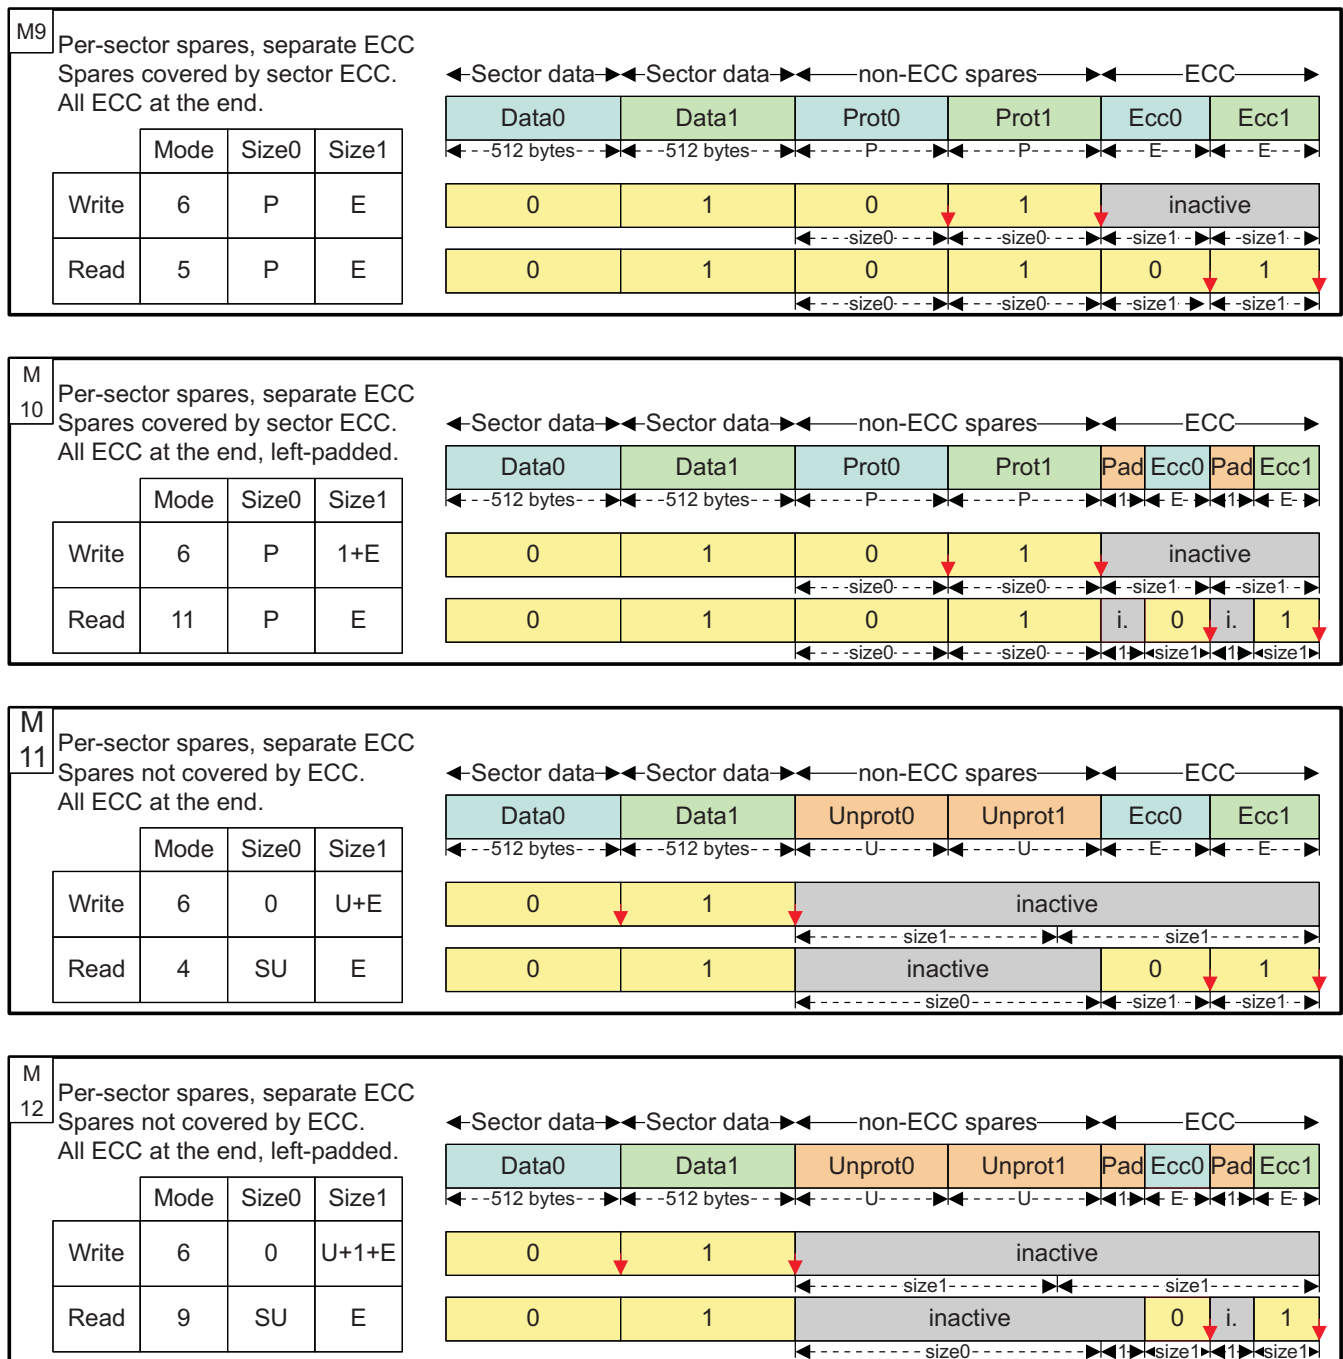

gpmc-034

15.4.4.13.3.2.3.3 Per-Sector Spare Mapping, with ECC Separated at the End of the Page

In these schemes, each 512-byte sector of the main area is associated with 2 sections of the spare area.

- ECC section, all aligned at the end of the page
- other data section, aligned before the ECCs, each of which may or may not be protected by its sectors ECC

Figure 15-89. NAND Page Mapping and ECC: Per-Sector Schemes, with Separate ECC

gpmc_035

15.4.4.13.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the MPU system frequency; such NAND read or write accesses issued by the processor will impact the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the L3 interface; as a default the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64 bytes (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled either by the MPU through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or the sDMA through DMA request synchronization, with a programmable request byte size in both prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. In consequence, it is limited to NAND data-stream access. The engine relies on the MPU NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, the engine data reads and writes sequencing is solely based on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the [GPMC_PREFETCH_CONFIG1\[23\] PFPWENROUNDROBIN](#) bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the [GPMC_PREFETCH_CONFIG1\[19:16\] PFPWEIGHTEDPRIO](#) field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

NOTE: The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

15.4.4.13.4.1 General Facts About the Engine Configuration

The engine can be configured only if the [GPMC_PREFETCH_CONTROL\[0\] STARTENGINE](#) bit is deasserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the [GPMC_PREFETCH_CONFIG1\[26:24\] ENGINECSSELECTOR](#) field.

In both prefetch and write-posting modes, the engine respectively uses byte or 16-bit word access requests for an 8- or 16-bit-wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT fields must be programmed accordingly as a number of bytes.

When the [GPMC_PREFETCH_CONFIG1\[7\]](#) ENABLEENGINE bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the [GPMC_NAND_COMMAND_i](#), [GPMC_NAND_ADDRESS_i](#), and [GPMC_NAND_DATA_i](#) registers (where i = 0 to 7).

The FIFO entry on the L3 interconnect port can be accessed with byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32 bits wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The [GPMC_PREFETCH_STATUS\[30:24\]](#) FIFOPointer field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots which can be written in write-posting mode. The [GPMC_PREFETCH_STATUS\[13:0\]](#) COUNTVALUE field monitors the number of remaining bytes to be read or written by the engine according to the TRANSFERCOUNT value. The FIFOPointer and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPointer equals 0, that is, the FIFO is empty, a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPointer equals 0, that is, the FIFO is full, a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

15.4.4.13.4.2 Prefetch Mode

The prefetch mode is selected when the [GPMC_PREFETCH_CONFIG1\[0\]](#) ACCESSMODE bit is cleared.

The MPU NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the [GPMC_PREFETCH_CONTROL\[0\]](#) STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (that is, reset, configured, and enabled) before the prefetch engine is started, so that the ECC is correctly computed on all data read by the prefetch engine.

When the [GPMC_PREFETCH_CONFIG1\[3\]](#) SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it only sets the STARTENGINE bit when the NAND device is in a ready state, meaning data is valid for prefetching.

When the SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active to inactive wait signal transition is detected. The transition detector must be cleared before any transition detection; see [Section 15.4.4.13.2.2, Ready Pin Monitored by Hardware Interrupt](#). The [GPMC_PREFETCH_CONFIG1\[5:4\]](#) WAITPINSELECTOR field selects which gpmc_wait pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit field before NAND address phase completion when in synchronized mode. The prefetch engine will start when an active to inactive wait signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by [GPMC_PREFETCH_CONFIG2\[13:0\]](#) TRANSFERCOUNT field.

Table 15-238. Prefetch Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Prefetch engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active.

Table 15-238. Prefetch Mode Configuration (continued)

Bit Field	Register	Value	Comments
ACCESSMODE	GPMC_PREFETCH_CONFIG1 [0]	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1 [14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2 [13:0]		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1 [3]	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1 [17:16]	0 to 1	Selects wait pin edge detector (if GPMC_PREFETCH_CONFIG1 [3] SYNCHROMODE = 0x1)
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1 [27]	0/1	See Section 15.4.4.13.4.6, Optimizing NAND Access Using the Prefetch and Write-Posting Engine .
CYCLOPTIMIZATION	GPMC_PREFETCH_CONFIG1 [30:28]		Number of clock cycle removed to timing parameters
ENABLEENGINE	GPMC_PREFETCH_CONFIG1 [7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL [0]	1	Starts the prefetch engine

15.4.4.13.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by the MPU or by an sDMA channel.

In MPU draining mode, the FIFO status can be monitored through the [GPMC_PREFETCH_STATUS](#)[30:24] FIFOPINTER field or through the [GPMC_PREFETCH_STATUS](#)[16] FIFOTHRESHOLDSTATUS bit. The FIFOPINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the [GPMC_IRQENABLE](#)[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the [GPMC_IRQSTATUS](#)[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must read all the available bytes, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the [GPMC_PREFETCH_STATUS](#)[13:0] COUNTVALUE field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the [GPMC_IRQENABLE](#)[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the [GPMC_IRQSTATUS](#)[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is only valid when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the [GPMC_PREFETCH_CONFIG1\[2\]](#) DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel owning this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

15.4.4.13.4.4 Write-Posting Mode

The write-posting mode is selected when the [GPMC_PREFETCH_CONFIG1\[0\]](#) ACCESSMODE bit is set.

The MPU NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the [GPMC_PREFETCH_CONTROL\[0\]](#) STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are properly calculated on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the [GPMC_PREFETCH_CONFIG1\[3\]](#) SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed [GPMC_PREFETCH_CONFIG2\[13:0\]](#) TRANSFERCOUNT accesses have been completed.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must only be issued when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

Table 15-239. Write-Posting Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Write-posting engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active

Table 15-239. Write-Posting Mode Configuration (continued)

Bit Field	Register	Value	Comments
ACCESSMODE	GPMC_PREFETCH_CONFIG1 [0]	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1 [14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2 [13:0]		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1 [3]	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1 [27]	0/1	See Section 15.4.4.13.4.6, Optimizing NAND Access Using the Prefetch and Write-Posting Engine .
CYCLOPTIMIZATION	GPMC_PREFETCH_CONFIG1 [30:28]		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1 [7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL [0]	1	Starts the prefetch engine

15.4.4.13.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by the MPU or by an sDMA channel.

In MPU filling mode, the FIFO status can be monitored through the [FIFOPOINTER](#) or through the [GPMC_PREFETCH_STATUS](#)[16] [FIFOTHRESHOLDSTATUS](#) bit. [FIFOPOINTER](#) indicates the current number of available free byte places in the FIFO, and the [FIFOTHRESHOLDSTATUS](#) bit, when set, indicates that at least [FIFOTHRESHOLD](#) free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the [GPMC_IRQENABLE](#)[0] [FIFOEVENTENABLE](#) bit is set. When the interrupt is fired, the [GPMC_IRQSTATUS](#)[0] [FIFOEVENTSTATUS](#) bit is set. To clear the interrupt, the MPU must write enough bytes to fill the FIFO, or enough bytes to get below the programmed threshold, and the [FIFOEVENTSTATUS](#) bit must be cleared to get further interrupt events. The [FIFOEVENTSTATUS](#) bit must always be cleared prior to asserting the [FIFOEVENTENABLE](#) bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the [STARTENGINE](#) bit.

The posting completion can be monitored through the [GPMC_PREFETCH_STATUS](#)[13:0] [COUNTVALUE](#) field. [COUNTVALUE](#) indicates the current number of remaining data to be written based on the [TRANSFERCOUNT](#) value. An interrupt is issued by the GPMC when the write-posting process completes (that is, [COUNTVALUE](#) equal to 0) if the [GPMC_IRQENABLE](#)[1] [TERMINALCOUNTEVENTENABLE](#) bit is set. When the interrupt is fired, the [GPMC_IRQSTATUS](#)[1] [TERMINALCOUNTSTATUS](#) bit is set. To clear the interrupt, the MPU must clear the [TERMINALCOUNTSTATUS](#) bit. The [TERMINALCOUNTSTATUS](#) bit must always be cleared prior to asserting the [TERMINALCOUNTEVENTENABLE](#) bit to clear any out-of-date logged interrupt event.

NOTE: The [COUNTVALUE](#) value is only valid if the write-posting engine is active and started, and an interrupt is only issued when [COUNTVALUE](#) reaches 0, that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the [DMAMode](#) bit field in the [GPMC_PREFETCH_CONFIG1](#)[2] [DMAMODE](#) bit must be set so that the GPMC issues a DMA hardware request when at least [FIFOTHRESHOLD](#) bytes-free places are available in the FIFO. The DMA channel owning this DMA request must be programmed so that a number of bytes equal to the value programmed in the [FIFOTHRESHOLD](#) bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request has been completed.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, the DMA or the MPU fill the FIFO with no consideration to the associated byte enables. Any byte stored in the FIFO is written into the memory device.

15.4.4.13.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates the CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and MPU accesses to a NAND memory device (through the defined chip-select memory region or through the [GPMC_NAND_DATA_i](#) location, i = 0 to 7) are never optimized.

The [GPMC_PREFETCH_CONFIG1](#)[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the [GPMC_PREFETCH_CONFIG1](#)[30:28] CYCLEOPTIMIZATION field defines the number of GPMC_FCLK cycles to be suppressed from the RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSOFFTIME, ADVOFFTIME, OEOFFTIME, and WEOFFTIME timing parameters.

[Figure 15-90](#) highlights that, in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the [GPMC_PREFETCH_CONFIG1](#)[30:28] CYCLEOPTIMIZATION field.

Figure 15-90. NAND Read Cycle Optimization Timing Description

gpmc-036

15.4.4.13.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected to.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the [GPMC_PREFETCH_CONFIG1\[23\]](#) PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the [GPMC_PREFETCH_CONFIG1\[19:16\]](#) PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

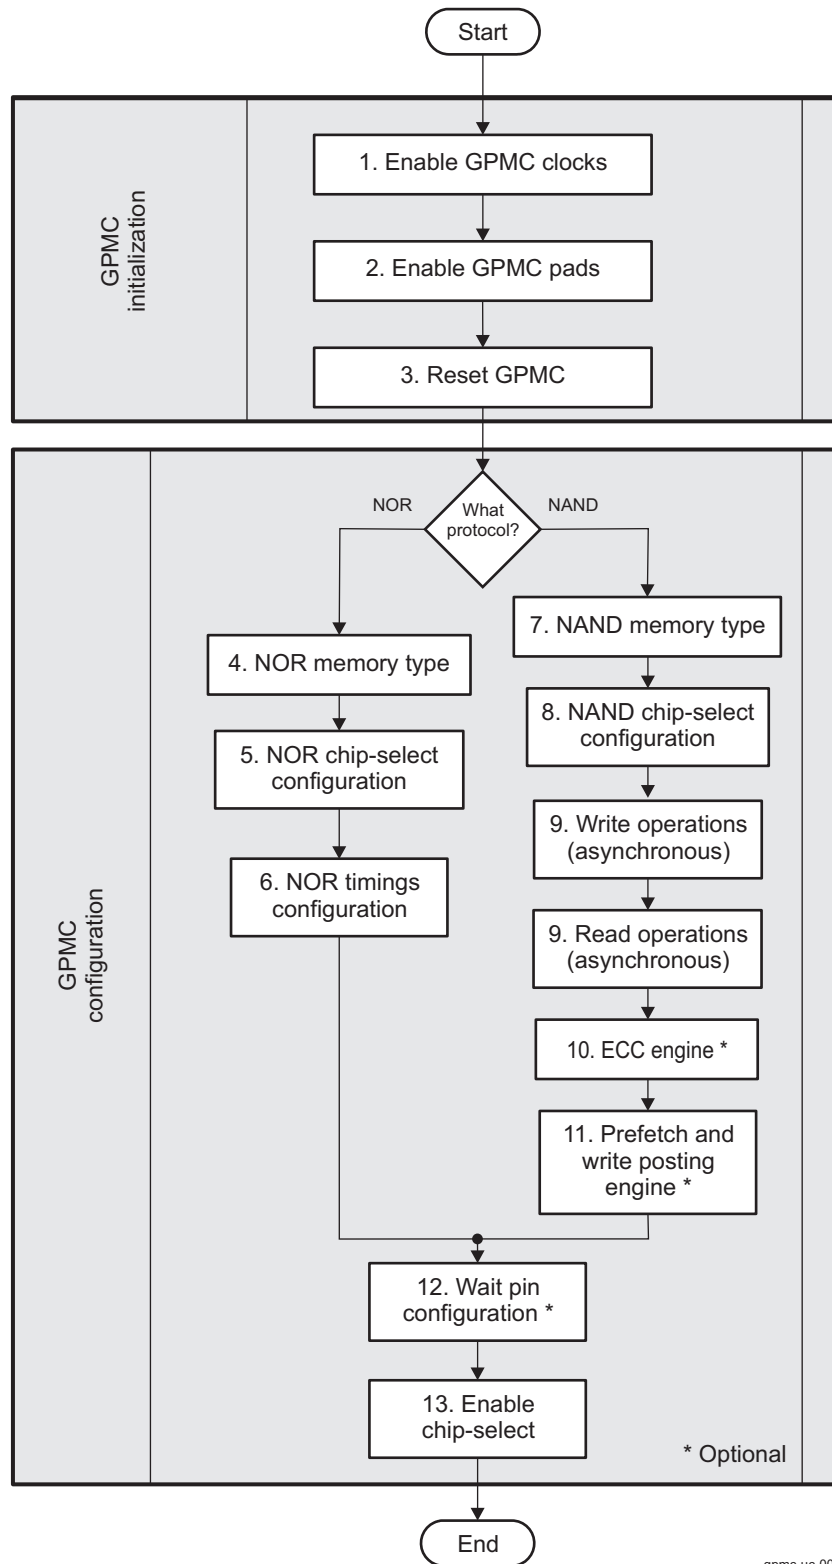

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 0x2. Considering the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

15.4.5 GPMC Basic Programming Model

15.4.5.1 GPMC High-Level Programming Model Overview

The goal of the basic high-level programming model is to introduce a top down approach to users that need to configure the GPMC module.

[Figure 15-91](#), [Table 15-240](#), [Table 15-241](#) and [Table 15-242](#) show a programming model top level diagram for the GPMC, and the description of each step. Each block of the diagram is detailed in one of the following subsections through a set of registers to configure.

Figure 15-91. Programming Model Top Level Diagram

gpmc-uc-001

Table 15-240. GPMC Initialization

Step	Description
Enable GPMC clocks	Module interface and functional clocks must be enabled. See Chapter 3, Power, Reset, and Clock Management .
Enable GPMC pads	Module-specific pad muxing and configuration must be set in the control module. See Chapter 18, Control Module .
Reset GPMC	See Table 15-243

Table 15-241. GPMC Configuration in NOR Mode

Step	Description
NOR Memory Type	See Table 15-244
NOR Chip-Select Configuration	See Table 15-245
NOR Timings Configuration	See Table 15-246
Wait Pin Configuration	See Table 15-254
Enable Chip-Select	See Table 15-255

Table 15-242. GPMC Configuration in NAND Mode

Step	Description
NAND Memory Type	See Table 15-249
NAND Chip-Select Configuration	See Table 15-250
Write Operations (Asynchronous)	See Table 15-251
Read Operations (Asynchronous)	See Table 15-251
ECC Engine	See Table 15-252
Prefetch and Write-Posting Engine	See Table 15-253
Wait Pin Configuration	See Table 15-254
Enable Chip-Select	See Table 15-255

15.4.5.2 GPMC Initialization

[Table 15-271](#) describes the settings required to prepare the GPMC, that is enabling its clock, its pads, and proceeding to a GPMC reset.

Table 15-243. Reset GPMC

Sub-process Name	Register / Bit Field	Value
Start a software reset	GPMC_SYSCONFIG[1] SOFTRESET	0x1
Wait until	GPMC_SYSSTATUS[0] RESETDONE =	0x1

15.4.5.3 GPMC Configuration in NOR Mode

This section gives a generic configuration for parameters related to the NOR memory connected to the GPMC.

Table 15-244. NOR Memory Type

Sub-process Name	Register / Bit Field	Value
Set the NOR protocol	GPMC_CONFIG1_i[11:10] DEVICETYPE	0x0
Set a device size	GPMC_CONFIG1_i[13:12] DEVICESIZE	x
Select an address and data multiplexing protocol	GPMC_CONFIG1_i[9] MUXADDDATA	x
Set the attached device page length	GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH	x

Table 15-244. NOR Memory Type (continued)

Sub-process Name	Register / Bit Field	Value
Set the wrapping burst capabilities	GPMC_CONFIG1_i[31] WRAPBURST	x
Select a timing signals latencies factor	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Select an output clock frequency ⁽¹⁾	GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER	x
Choose an output clock activation time ⁽¹⁾	GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME	x
Set a single or multiple access for read operations ⁽¹⁾	GPMC_CONFIG1_i[30] READMULTIPLE	x
Set a synchronous or asynchronous mode for read operations	GPMC_CONFIG1_i[29] READTYPE	x
Set a single or multiple access for write operations	GPMC_CONFIG1_i[28] WRITEMULTIPLE	x
Set a synchronous or asynchronous mode for write operations	GPMC_CONFIG1_i[27] WRITETYPE	x

⁽¹⁾ Only applies to synchronous configurations (or non-multiplexed async for the multiple access one).

Table 15-245. NOR Chip-Select Configuration

Sub-process Name	Register / Bit Field	Value
Select the chip-select base address	GPMC_CONFIG7_i[5:0] BASEADDRESS	x
Select the chip-select mask address	GPMC_CONFIG7_i[11:8] MASKADDRESS	x

Table 15-246. NOR Timings Configuration

Sub-process Name	Register / Bit Field	Value
Configure adequate timing parameters in various memory modes	See Section 15.4.5.6, GPMC Timing Parameters	

Table 15-247. Wait Pin Configuration

Sub-process Name	Register / Bit Field	Value
Enable or disable wait pin monitoring for read operations	GPMC_CONFIG1_i[22] WAITREADMONITORING	x
Enable or disable wait pin monitoring for write operations	GPMC_CONFIG1_i[21] WAITWRITEMONITORING	x
Select a wait pin monitoring time	GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME	x
Choose the input wait pin for the chip-select	GPMC_CONFIG1_i[17:16] WAITPINSELECT	x

Table 15-248. Enable Chip-Select

Sub-process Name	Register / Bit Field	Value
When all parameters are configured, enable the chip-select	GPMC_CONFIG7_i[6] CSVALID	x

15.4.5.4 GPMC Configuration in NAND Mode

This section gives a generic configuration for parameters related to the NAND memory connected to the GPMC.

Table 15-249. NAND Memory Type

Sub-process Name	Register / Bit Field	Value
Set the NAND protocol	GPMC_CONFIG1_i[11:10] DEVICETYPE	0x2
Set a device size	GPMC_CONFIG1_i[13:12] DEVICESIZE	x
Set the address and data multiplexing protocol to non-multiplexed attached device	GPMC_CONFIG1_i[9] MUXADDDATA	0x0
Select a timing signals latencies factor	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x

Table 15-249. NAND Memory Type (continued)

Sub-process Name	Register / Bit Field	Value
Set a synchronous or asynchronous mode and a single or multiple access for read and write operations	See Section 15.4.5.5 , <i>Set Memory Access</i>	x

Table 15-250. NAND Chip-Select Configuration

Sub-process Name	Register / Bit Field	Value
Select the chip-select base address	GPMC_CONFIG7_i[5:0] BASEADDRESS	x
Select the chip-select minimum granularity (16M bytes)	GPMC_CONFIG7_i[11:8] MASKADDRESS	x

Table 15-251. Asynchronous Read and Write Operations

Sub-process Name	Register / Bit Field	Value
Configure adequate timing parameters in asynchronous modes	See Section 15.4.5.6 , <i>GPMC Timing Parameters</i>	

Table 15-252. ECC Engine

Sub-process Name	Register / Bit Field	Value
Select the ECC result register where the first ECC computation is stored (Only applies to Hamming)	GPMC_ECC_CONTROL[3:0] ECCPOINTER	x ⁽¹⁾
Clear all ECC result registers	GPMC_ECC_CONTROL[8] ECCCLEAR	Write '1' to clear.
Define ECCSIZE0 and ECCSIZE1	GPMC_ECC_SIZE_CONFIG[19:12] ECCSIZE0 and [29:22] ECCSIZE1	x ⁽²⁾
Select the size of each of the 9 result registers (size specified by ECCSIZE0 or ECCSIZE1)	GPMC_ECC_SIZE_CONFIG[j-1] ECCjRESULTSIZ where j = 1 to 9	x
Select the chip-select where ECC is computed	GPMC_ECC_CONFIG[3:1] ECCCS	x
Select the Hamming code or BCH code ECC algorithm in use	GPMC_ECC_CONFIG[16] ECCALGORITHM	x
Select word size for ECC calculation	GPMC_ECC_CONFIG[7] ECC16B	x
If the BCH code is used, Set an error correction capability and Select a number of sectors to process	GPMC_ECC_CONFIG[13:12] ECCBCHTSEL and GPMC_ECC_CONFIG[6:4] ECCTOPSECTOR	x
Enable the ECC computation	GPMC_ECC_CONFIG[0] ECCENABLE	0x1

⁽¹⁾ This parameter depends on the numbers of sectors in a page.

⁽²⁾ Depends on the size of each sector in the NAND page.

Table 15-253. Prefetch and Write-Posting Engine

Sub-process Name	Register / Bit Field	Value
Disable the engine before configuration	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x0
Select the chip-select associated with a NAND device where the prefetch engine is active	GPMC_PREFETCH_CONFIG1[26:24] ENGINECSSELECTOR	x
Select access direction through prefetch engine, read or write.	GPMC_PREFETCH_CONFIG1[0] ACCESSMODE	x
Select the threshold used to issue a DMA request	GPMC_PREFETCH_CONFIG1[14:8] FIFOTHRESHOLD	x
Select either DMA synchronized mode or software manual mode.	GPMC_PREFETCH_CONFIG1[2] DMAMODE	x
Select if the engine immediately starts accessing the memory upon STARTENGINE assertion or if hardware synchronization based on a WAIT signal is used.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which wait pin edge detector should start the engine in synchronized mode	GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR	x

Table 15-253. Prefetch and Write-Posting Engine (continued)

Sub-process Name	Register / Bit Field	Value
Enter a number of clock cycles removed to timing parameters (For all back-to-back accesses to the NAND flash but not the first one)	GPMC_PREFETCH_CONFIG1[30:28] CYCLOPTIMIZATION	x
Enable the prefetch postwrite engine	GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE	0x1
Select the number of bytes to be read or written by the engine to the selected chip-select	GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT	x
Start the prefetch engine	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x1

Table 15-254. Wait Pin Configuration

Sub-process Name	Register / Bit Field	Value
Selects when the engine starts the access to CS	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which wait pin edge detector should start the engine in synchronized mode	GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR	x

Table 15-255. Enable Chip-Select

Sub-process Name	Register / Bit Field	Value
When all parameters are configured, enable the chip-select	GPMC_CONFIG7_[6] CSVALID	x

15.4.5.5 Set Memory Access

This section details the bit field to configure to set the GPMC in various memory modes.

Table 15-256. Mode Parameters Check List Table

Register	Bit	Bit field name	Asynchronous				Synchronous			
			Single Read Access	Single Write Access	Multiple Read (Page) Access	Multiple Write (Page) Access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access
GPMC_CONFIG1_i	30	READMULTIPLE	0x0	-	0x1 ⁽¹⁾	N/S	0x0	-	0x1	-
GPMC_CONFIG1_i	29	READTYPE	0x0	-	0x0 ⁽¹⁾	N/S	0x1	-	0x1	-
GPMC_CONFIG1_i	28	WRITEMULTIPLE	-	0x0	- ⁽¹⁾	N/S	-	0x0	-	0x1
GPMC_CONFIG1_i	27	WRITETYPE	-	0x0	- ⁽¹⁾	N/S	-	0x1	-	0x1

⁽¹⁾ Multiple read is not supported in address/data- and AAD-multiplexed modes. Multiple read is supported in Nonmultiplexed mode.

Table 15-257. Access Type Parameters Check List Table

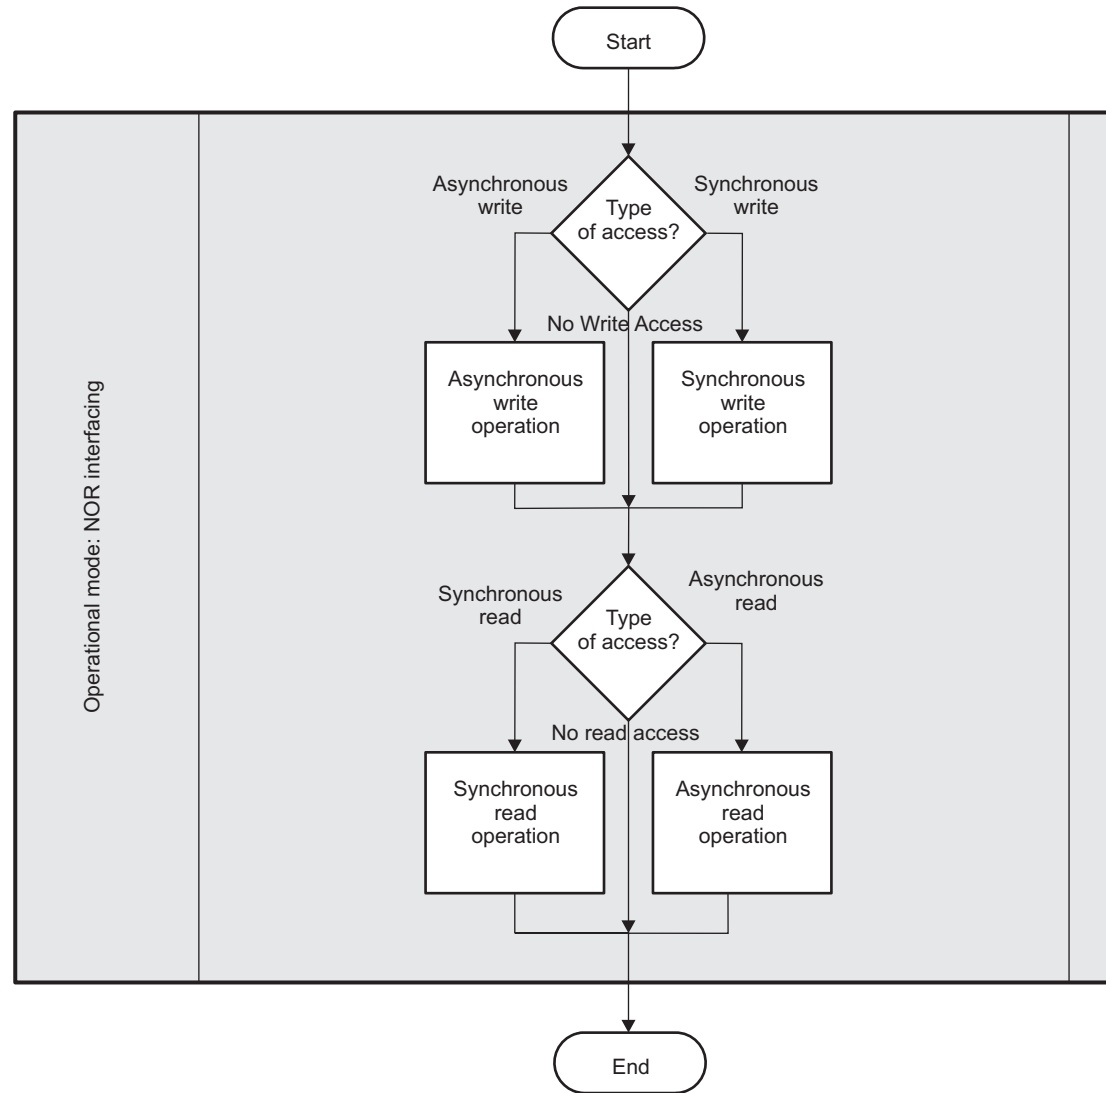

Register	Bit	Bit field name	Access Type		
			Non-mux	Address /Data Mux	AAD-mux
GPMC_CONFIG1_i	9:8	MUXADDDATA	0x0	0x2	0x1
GPMC_CONFIG	1	LIMITEDADDRESS ⁽¹⁾	0x1	0x0	0x0

⁽¹⁾ This parameter applies to all chip-selects. There is no per-CS configuration for this parameter.

15.4.5.6 GPMC Timing Parameters

Figure 15-92 shows a programming model diagram for the NOR interfacing timing parameters.

Figure 15-92. NOR Interfacing Timing Parameters Diagram

gpmc-uc-002

Table 15-258 lists bit fields to configure adequate timing parameter in various memory modes.

Table 15-258. Timing Parameters

Register	Bit	Bit field name	Asynchronous			Synchronous				Access Type		
			Single Read Access	Single Write Access	Multiple Read (Page) access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access	Non-multiplexed	Address/Data-multiplexed	AAD-multiplexed
GPMC_CONFIG1_i	9	MUXADDDATA	y	y	y	y	y	y	y	y	y	y

15.4.5.6.1 GPMC Timing Parameters Formulas

This section intends to help the user to calculate the GPMC timing bit fields values. Formulas are not listed exhaustively.

The section details:

- NAND Flash Interface Timing Parameters Formulas
- Synchronous NOR Flash Timing Parameters Formulas
- Asynchronous NOR Flash Timing Parameters Formulas

15.4.5.6.1.1 NAND Flash Interface Timing Parameters Formulas

This section lists formulas to use in order to calculate NAND timing parameters. This is the case when `GPMC_CONFIG1_j[11:10] DEVICETYPE = 0x2`. [Table 15-259](#) details NAND timing parameters.

Table 15-259. NAND Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - gpmc_nwe valid time
B	ns	Delay time - gpmc_ncs valid to gpmc_nwe valid
C	ns	Delay time - gpmc_nbe0_cle/gpmc_nadv_ale high to gpmc_nwe valid
D	ns	Delay time - gpmc_ad[15:0] valid to gpmc_nwe valid
E	ns	Delay time - gpmc_nwe invalid to gpmc_ad[15:0] invalid
F	ns	Delay time - gpmc_nwe invalid to gpmc_nbe0_cle/gpmc_nadv_ale invalid
G	ns	Delay time - gpmc_nwe invalid to gpmc_ncs invalid
H	ns	Cycle time - Write cycle time
I	ns	Delay time - gpmc_ncs valid to gpmc_noe valid
J	ns	Setup time - gpmc_ad[15:0] valid to gpmc_noe invalid
K	ns	Pulse duration - gpmc_noe valid time
L	ns	Cycle time - Read cycle time
M	ns	Delay time - gpmc_noe invalid to gpmc_ncs invalid

The configuration parameters are calculated through the following formulas.

$$A = (\text{WEOffTime} - \text{WEOnTime}) * (\text{TimeParaGranularity} + 1) * \text{GPMC_FCLK period}$$

$$B = ((\text{WEOnTime} - \text{CSONTime}) * (\text{TimeParaGranularity} + 1) + 0.5 * (\text{WEEExtraDelay} - \text{CSEExtraDelay})) * \text{GPMC_FCLK period}$$

$$C = ((\text{WEOnTime} - \text{ADVOnTime}) * (\text{TimeParaGranularity} + 1) + 0.5 * (\text{WEEExtraDelay} - \text{ADVExtraDelay})) * \text{GPMC_FCLK period}$$

$$D = (\text{WEOnTime} * (\text{TimeParaGranularity} + 1) + 0.5 * \text{WEEExtraDelay}) * \text{GPMC_FCLK period}$$

$$E = (\text{WrCycleTime} - \text{WEOffTime} * (\text{TimeParaGranularity} + 1) - 0.5 * \text{WEEExtraDelay}) * \text{GPMC_FCLK period}$$

$$F = (\text{ADVWrOffTime} - \text{WEOffTime} * (\text{TimeParaGranularity} + 1) + 0.5 * (\text{ADVExtraDelay} - \text{WEEExtraDelay})) * \text{GPMC_FCLK period}$$

$$G = (\text{CSWrOffTime} - \text{WEOffTime} * (\text{TimeParaGranularity} + 1) + 0.5 * (\text{CSEExtraDelay} - \text{WEEExtraDelay})) * \text{GPMC_FCLK period}$$

$$H = \text{WrCycleTime} * (1 + \text{TimeParaGranularity}) * \text{GPMC_FCLK period}$$

$$I = ((\text{OEOnTime} - \text{CSONTime}) * (\text{TimeParaGranularity} + 1) + 0.5 * (\text{OEEExtraDelay} - \text{CSEExtraDelay})) * \text{GPMC_FCLK period}$$

$$J = ((\text{AccessTime} - \text{OEOffTime}) * (\text{TimeParaGranularity} + 1) - 0.5 * \text{OEEExtraDelay}) * \text{GPMC_FCLK period}$$

$$K = (\text{OEOffTime} - \text{OEOnTime}) * (1 + \text{TimeParaGranularity}) * \text{GPMC_FCLK period}$$

$$L = \text{RdCycleTime} * (1 + \text{TimeParaGranularity}) * \text{GPMC_FCLK period}$$

$$M = (CSRdOffTime - OEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSExtraDelay - OEEExtraDelay) * GPMC_FCLK \text{ period}$$

Figure 15-93 shows a command latch cycle timing simplified example where formulas are associated with signal waves.

Figure 15-93. NAND Command Latch Cycle Timing Simplified Example

gpmc-048

15.4.5.6.1.2 Synchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to use in order to calculate synchronous NOR timing parameters. This is the case when `GPMC_CONFIG1_[11:10] DEVICETYPE = 0x0` and when `READTYPE` or `WRITETYPE` are set to synchronous mode.

Table 15-260. Synchronous NOR Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - gpmc_ncs low
B	ns	Delay time - address bus valid to gpmc_clk first edge Delay time - gpmc_nbe0_cle/gpmc_nbe1 valid to gpmc_clk first edge
C	ns	Pulse duration - gpmc_nbe0_cle/gpmc_nbe1 low
D	ns	Delay time - gpmc_clk rising edge to gpmc_nbe0_cle/gpmc_nbe1 invalid Delay time - gpmc_clk rising edge to gpmc_nadv_ale invalid
E	ns	Delay time - gpmc_clk rising edge to gpmc_ncs invalid Delay time - gpmc_clk rising edge to gpmc_noe invalid
F	ns	Delay time - gpmc_clk rising edge to gpmc_ncs transition
G	ns	Delay time - gpmc_clk rising edge to gpmc_nadv_ale transition
H	ns	Delay time - gpmc_clk rising edge to gpmc_noe transition
I	ns	Delay time - gpmc_clk rising edge to gpmc_nwe transition
J	ns	Delay time - gpmc_clk rising edge to gpmc_ad data bus transition Delay time - gpmc_clk rising edge to gpmc_nbe0_cle/gpmc_nbe1 transition
K	ns	Pulse duration - gpmc_nadv_ale low
L	ns	Delay time - gpmc_wait invalid to first data latching gpmc_clk edge

The configuration parameters are calculated through the following formulas.

1. For single read accesses:
 - A = (CSRDOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
 - C = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
 - D = (RDCYCLETIME - ACCESSTIME) * GPMC_FCLK period
 - E = (CSRDOFFTIME - ACCESSTIME) * GPMC_FCLK period
2. For burst read accesses (where n is the page burst access number):
 - A = (CSRDOFFTIME - CSONTIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
 - C = (RDCYCLETIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
 - D = (RDCYCLETIME - (ACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period
 - E = (CSRDOFFTIME - (ACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period
3. For burst write accesses (where n is the page burst access number):
 - A = (CSWROFFTIME - CSONTIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
 - C = (WRCYCLETIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
 - D = (WRCYCLETIME - (ACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period
 - E = (CSWROFFTIME - (ACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period
4. For all accesses:
 - For nCS falling edge (CS activated):
 - Case where [GPMC_CONFIG1_j\[1:0\]](#) GPMCFCLKDIVIDER = 0x0:
 - F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
 - Case where GPMCFCLKDIVIDER = 0x1:
 - F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSONTIME are odd) or (CLKACTIVATIONTIME and CSONTIME are even)
 - F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.
 - Case where GPMCFCLKDIVIDER = 0x2:
 - F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME) is a multiple of 3
 - F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

15.4.5.6.1.3 Asynchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to use in order to calculate asynchronous NOR timing parameters. This is the case when GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to asynchronous mode.

Table 15-261. Asynchronous NOR Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - gpmc_ncs low
B	ns	Delay time - gpmc_ncs valid to gpmc_nadv_ale invalid
C	ns	Delay time - gpmc_ncs valid to gpmc_noe invalid (single read)
D	ns	Pulse duration - address bus valid - 2nd, 3rd and 4th accesses
E	ns	Delay time - gpmc_ncs valid to gpmc_nwe valid
F	ns	Delay time - gpmc_ncs valid to gpmc_nwe invalid
G	ns	Address invalid duration between 2 successive R/W accesses
H	ns	Setup time - read data valid before gpmc_noe high
I	ns	Delay time - gpmc_ncs valid to gpmc_noe invalid (burst read)
J	ns	Delay time - address bus valid to gpmc_ncs valid
		Delay time - data bus valid to gpmc_ncs valid
		Delay time - gpmc_nbe0_cle/gpmc_nbe1 valid to gpmc_ncs valid
K	ns	Delay time - gpmc_ncs valid to gpmc_nadv_ale valid

Table 15-261. Asynchronous NOR Formulas Description Table (continued)

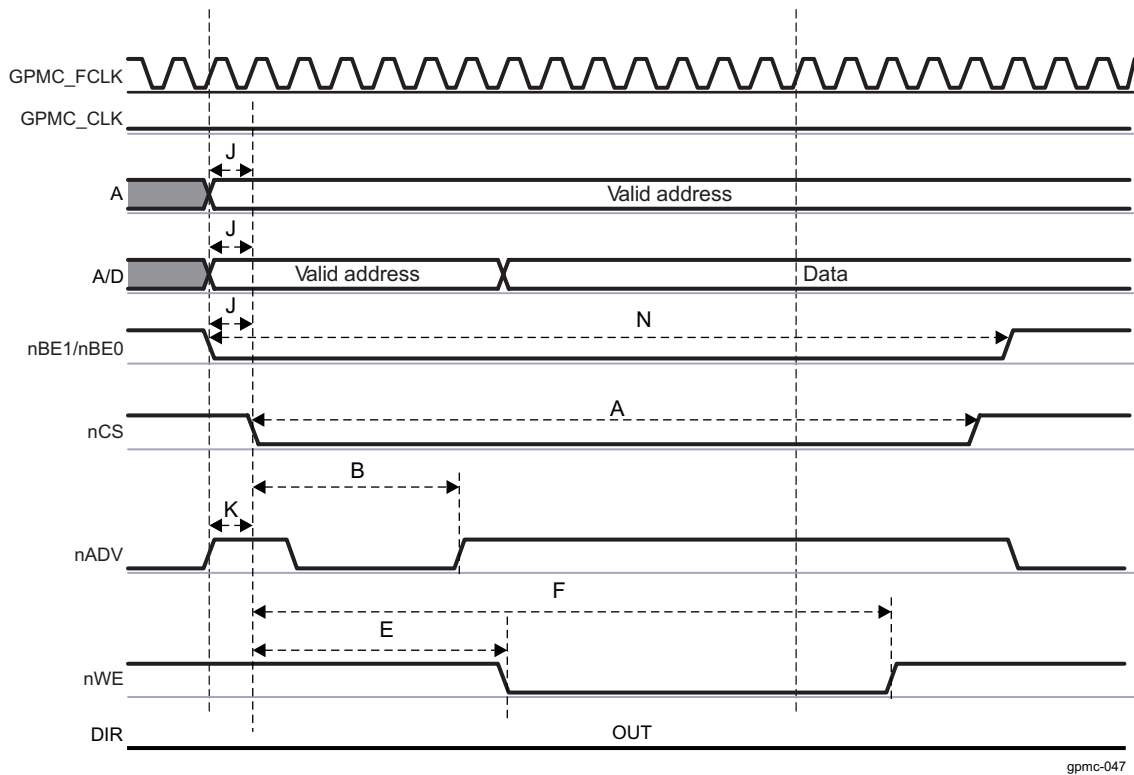

Configuration Parameter	Unit	Description
L	ns	Delay time - gpmc_ncs valid to gpmc_noe valid
M	ns	Delay time - gpmc_ncs valid to first data latching edge
N	ns	Pulse duration - gpmc_nbe0_cle/gpmc_nbe1 valid time
O	ns	Delay time - gpmc_ncs valid to gpmc_nadv_ale valid

The configuration parameters are calculated through the following formulas. Note that these formulas are not exhaustive.

- gpmc_ncs low pulse:
For single read: $A = (\text{CSRDOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$
For burst read: $A = (\text{CSRDOFFTIME} - \text{CSONTIME} + (\text{N} - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$, where N = page burst access number
For single write: $A = (\text{CSWROFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$
For burst write: $A = (\text{CSWROFFTIME} - \text{CSONTIME} + (\text{N} - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$, where N = page burst access number
- gpmc_ncs valid to gpmc_nadv_ale invalid delay:
For reading: $B = ((\text{ADVRDOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
For writing: $B = ((\text{ADVWROFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $C = ((\text{OEOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{OEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $D = \text{PAGEBURSTACCESSTIME} * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$
- $E = ((\text{WEONTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{WEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $F = ((\text{WEOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{WEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $G = \text{CYCLE2CYCLEDELAY} * \text{GPMC_FCLK period}$
- $H = ((\text{OEOFFTIME} - \text{ACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * \text{OEEXTRADELAY}) * \text{GPMC_FCLK period}$
- $I = ((\text{OEOFFTIME} + (\text{N} - 1) * \text{PAGEBURSTACCESSTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{OEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$, where N = page burst access number
- $J = (\text{CSONTIME} * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * \text{CSEXTRADELAY}) * \text{GPMC_FCLK period}$
- $K = ((\text{ADVONTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $L = ((\text{OEONTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{OEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $M = ((\text{ACCESSTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) - 0.5 * \text{CSEXTRADELAY}) * \text{GPMC_FCLK period}$
- gpmc_nbe0_cle/gpmc_nbe1 pulse:
For single read: $N = \text{RDCYCLETIME} * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$
For burst read: $N = (\text{RDCYCLETIME} + (\text{N} - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$, where N = page burst access number
For burst write: $N = (\text{WRCYCLETIME} + (\text{N} - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$, where N = page burst access number
- $O = ((\text{WRCYCLETIME} + (\text{N} - 1) * \text{PAGEBURSTACCESSTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$

Figure 15-95 shows an asynchronous NOR single write simplified example where formulas are associated with signal waves.

Figure 15-95. Asynchronous NOR Single Write Simplified Example

NOTE: Write multiple access is not supported in asynchronous mode. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

15.4.6 GPMC Use Cases And Tips

15.4.6.1 How to Set GPMC Timing Parameters for Typical Accesses

15.4.6.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8-bit or 16-bit-width memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples show how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104 MHz clock frequency
- Read access time: 80 ns

15.4.6.1.2 Typical GPMC Setup

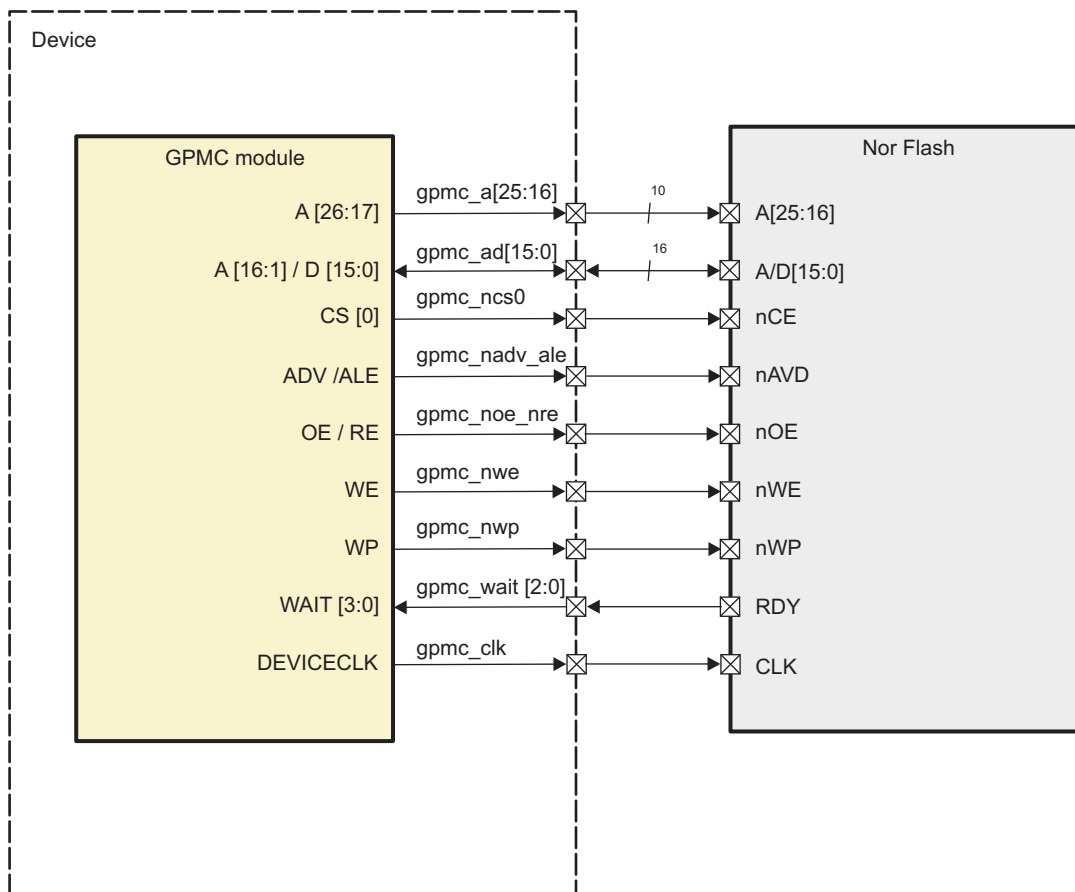

Table 15-262 lists some of the I/Os of the GPMC module.

Table 15-262. GPMC Signals

Signal Name	I/O	Description
GPMC_FCLK	Internal	Functional and interface clock. Acts as the time reference.
gpmc_clk	O	External clock provided to the external device for synchronous operations
gpmc_a[25:16]	O	Address
gpmc_ad[15: 0]	I/O	Data-multiplexed with addresses A[16:1] on memory side
gpmc_ncsx	O	Chip-select (where x = 0, or 1)
gpmc_nadv_ale	O	Address valid enable
gpmc_noe_nre	O	Output enable (read access only)
gpmc_nwe	O	Write enable (write access only)
gpmc_wait[2:0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

Figure 15-96 shows the typical connection between the GPMC module and an attached NOR Flash memory.

Figure 15-96. GPMC Connection to an External NOR Flash Memory

gpmc-037

The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

15.4.6.1.2.1 GPMC Configuration for Synchronous Burst Read Access

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 15-263 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 15-264 shows how to calculate timings for the GPMC using the memory parameters.

Figure 15-97 shows the synchronous burst read access.

Table 15-263. Useful Timing Parameters on the Memory Side

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	nCS setup time to clock	0
tACS	Address setup time to clock	3
tiACC	Synchronous access time	80

Table 15-263. Useful Timing Parameters on the Memory Side (continued)

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tBACC	Burst access time valid clock to output delay	5,2
tCEZ	Chip-select to High-Z	7
tOEZ	Output enable to High-Z	7
tAVC	nADV setup time	6
tAVD	nAVD pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read Access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle ($T = 9,615$ ns). The read access time between 2 bursts of data is tBACC = 5,2 ns. Therefore, data setup time is a clock period - tBACC = 4,415 ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read Access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

Table 15-264. Calculating GPMC Timing Parameters

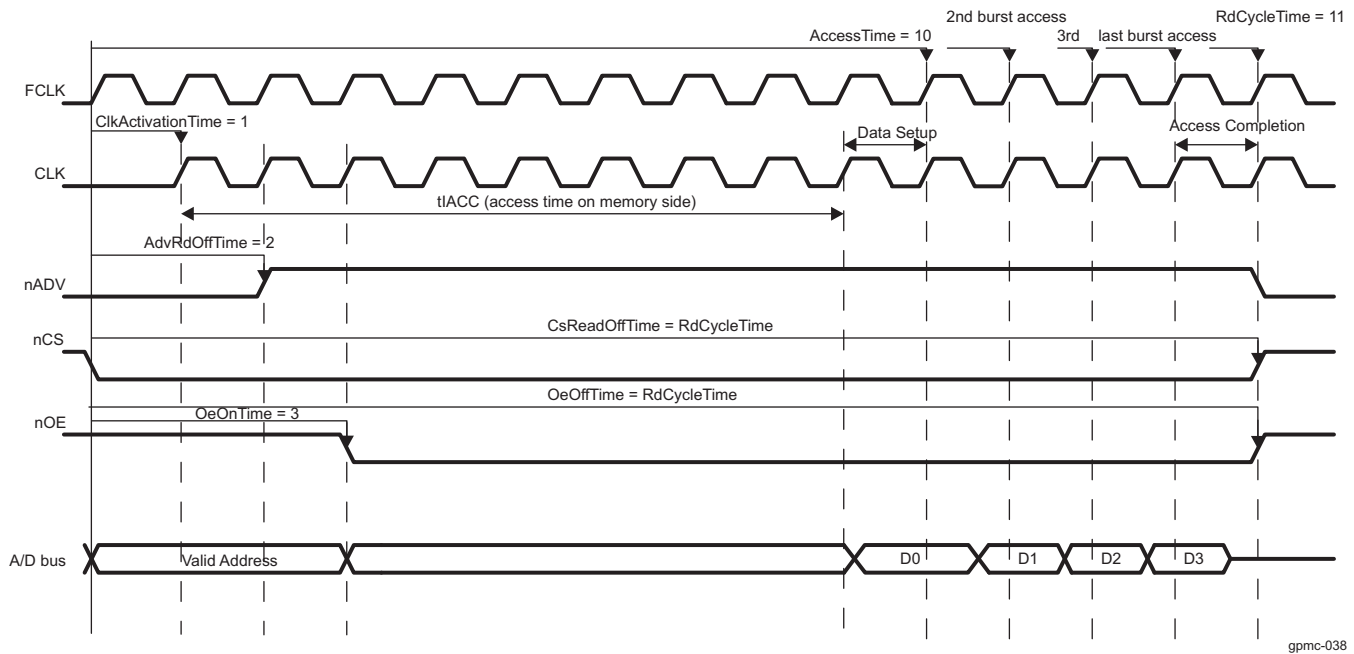

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
GPMC FCLK Divider	-	-	-	GPMCFCLKDIVIDER = 0x0
ClkActivation Time	min (tCES, tACS)	3	1	CLKACTIVATIONTIME = 0x1
RdAccessTime	roundmax (ClkActivationTime + tIACC + DataSetupTime)	94,03: (9,615 + 80 + 4,415)	10 : roundmax (94,03 / 9,615)	ACCESSTIME = 0x0A
PageBurst AccessTime	roundmax (tBACC)	roundmax (5,2)	1	PAGEBURSTACCESSTIME = 0x1
RdCycleTime	AccessTime + max (tCEZ, tOEZ)	101, 03: (94, 03 + 7)	11	RDCYCLETIME = 0x0B
CsOnTime	tCES	0	0	CSONTIME = 0x0
CsReadOffTime	RdCycleTime	-	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAVC ⁽¹⁾	0	0	ADVONTIME = 0x0
AdvRdOffTime	tAVD + tAVC ⁽²⁾	12	2	ADVRDOFFTIME = 0x02
OeOnTime ⁽³⁾	(ClkActivationTime + tACH) < OeOnTime (ClkActivationTime + tIACC)	-	3 for instance.	OEONTIME = 0x3
OeOffTime	RdCycleTime	-	11	OEOFFTIME = 0x0B

⁽¹⁾ The external clock provided to the NOR flash is not yet available.

⁽²⁾ AdvRdOffTime - AdvOnTime = tAVD; thus, AdvRdOffTime = tAVD + AdvOnTime = tAVD + tAVC.

⁽³⁾ OeOnTime must guarantee that addresses are available. It must not exceed the availability of the first burst of data.

Figure 15-97. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)

gpmc-038

15.4.6.1.2.2 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 15-265 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 15-266 shows how to calculate timings for the GPMC using the memory parameters.

Figure 15-98 shows the asynchronous read access.

Table 15-265. AC Characteristics for Asynchronous Read Access

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from nCS low	80
tAAVDS	Address setup time to rising edge of nADV	3
tAVDP	nADV low time	6
tCAS	nCS setup time to nADV	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Z	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

$$RdCycleTime = RdAccessTime + AccessCompletion = RdAccessTime + 1 \text{ clock cycle} + tOEZ:$$

- First, on the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 15-265: the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus. The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.
- To read the data correctly, the GPMC must be configure to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
- There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS

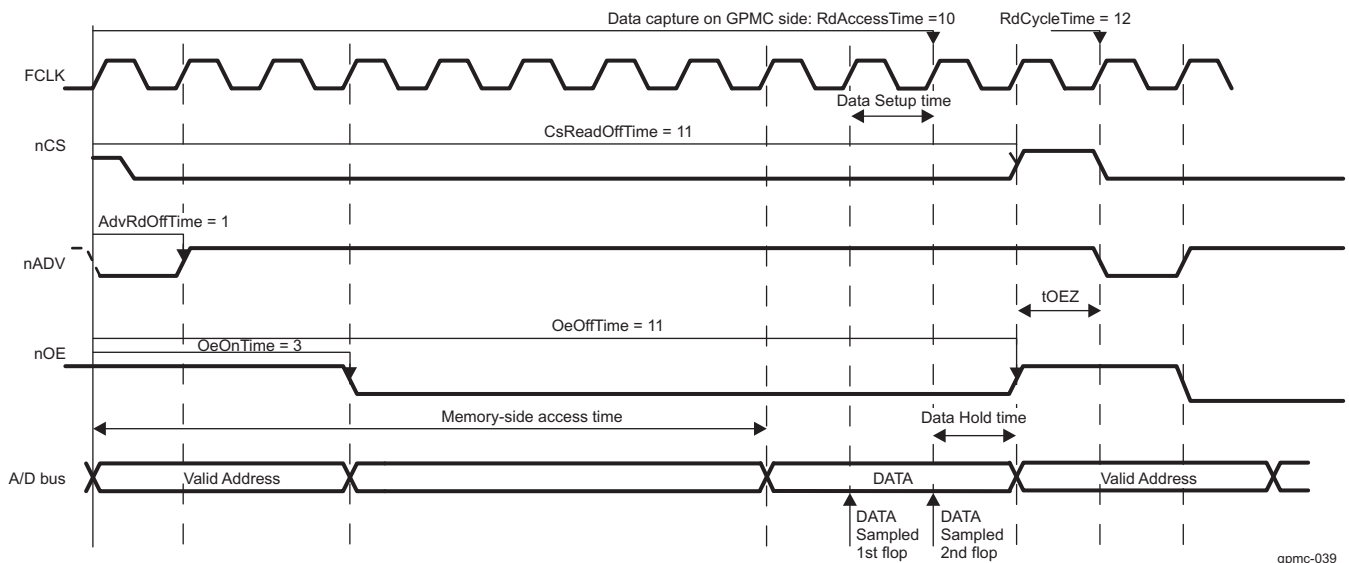

deassertion while reading the data). This data hold time is 1 clock cycle (that is, AccessTime + 1).

- To complete the access, nOE/nCS signals are driven to High-Z. AccessTime + 1 + tOEZ is the read cycle time.
- Addresses can now be relatched and a new read cycle begun.

Table 15-266. GPMC Timing Parameters for Asynchronous Read Access

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime		n/a (asynchronous mode)		
AccessTime	round max (tCE)	80	10	ACCESSTIME = 0x0A
PageBurstAccess Time	n/a (single access)			
RdCycleTime	AccessTime + 1 cycle + tOEZ	96, 615	12	RDCYCLETIME = 0x0C
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsReadOffTime	AccessTime + 1 cycle	89, 615	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAAVDS	3	1	ADVONTIME = 0x1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 0x01
OeOnTime	OeOnTime >= AdvRdOffTime (multiplexed mode)	-	3 for instance	OEONTIME = 0x3
OeOffTime	AccessTime + 1 cycle	89, 615	11	OEOFFTIME = 0x0B

Figure 15-98. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)

15.4.6.1.2.3 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9, 615 ns).

Table 15-268 shows how to calculate timings for the GPMC using the memory parameters.

Table 15-267 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 15-99 shows the synchronous burst write access.

Table 15-267. AC Characteristics for Asynchronous Single Write (Memory Side)

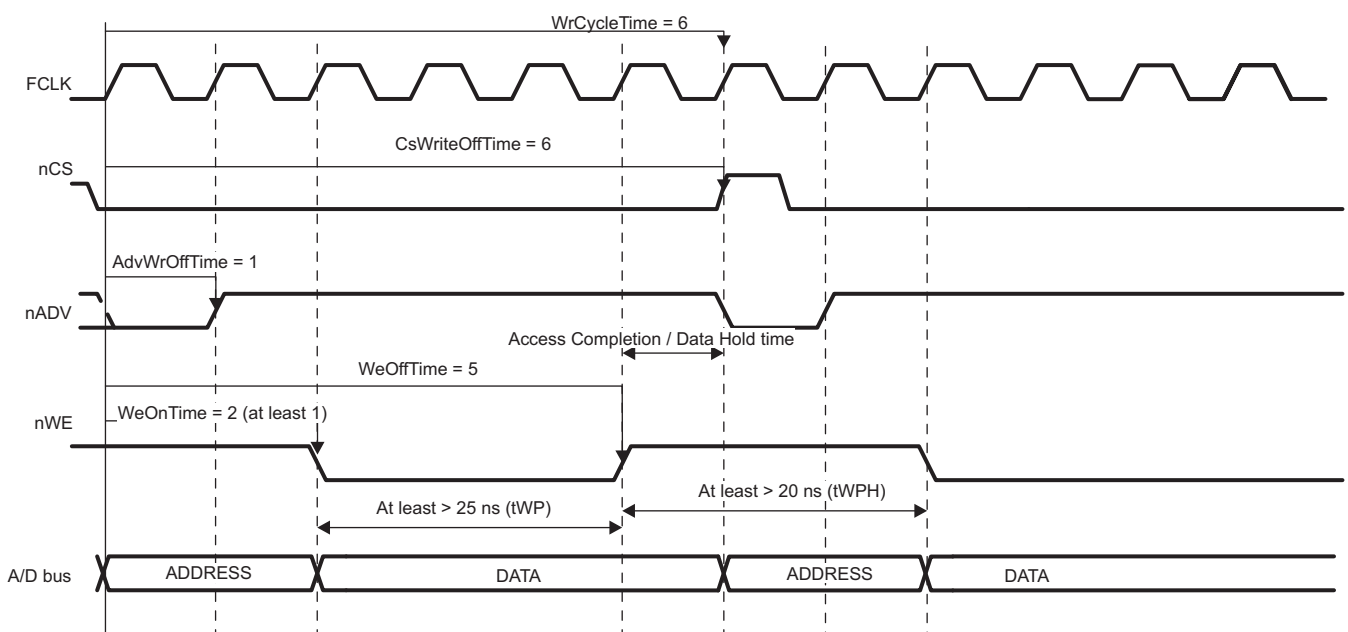

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60
tAVDP	nADV low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	nCS setup time to nWE	3
tCAS	nCS setup time to nADV	0
tAVSC	nADV setup time	3

For asynchronous single write access, write cycle time is $WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1$. For the AccessCompletion, the GPMC requires 1 cycle of data hold time (nCS deassertion).

Table 15-268. GPMC Timing parameters for Asynchronous Single Write

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Registers Configuration
ClkActivationTime		n/a (asynchronous mode)		
AccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime		n/a (single access)		
WrCycleTime	$WeOffTime + AccessCompletion$	57, 615	6	WRCYCLETIME = 0x06
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsWrOffTime	$WeOffTime + 1$	57, 615	6	CSWROFFTIME = 0x06
AdvOnTime	tAVSC	3	1	ADVONTIME = 0x1
AdvWrOffTime	$tAVSC + tAVDP$	9	1	ADVWROFFTIME = 0x01
WeOnTime	tCS	3	1	WEONTIME = 0x1
WeOffTime	$tCS + tWP + tWPH$	48	5	WEOFFTIME = 0x05

15.4.6.2 How to choose a suitable memory to use with the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

15.4.6.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or device, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit width asynchronous or synchronous memory or device (8-bit: non burst device only)
- 16-bit address and data multiplexed NOR flash devices (pSRAM, OneNAND™, ...)
- 8- and 16-bit NAND flash device

NOTE: Non-multiplexed NOR flash devices are supported by the GPMC but their usage is highly limited. As only ten address pins are available on the GPMC interface, the maximum device size supported is 2KB.

15.4.6.2.1.1 Memory Pin Multiplexing

This section highlights the interfacing differences of the GPMC supported memories.

Table 15-269. Supported memories interfaces

Function	16-bit Address/Data muxed pSRAM or NOR Flash ⁽¹⁾	OneNAND	16-bit NAND	8-bit NAND

15.4.6.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device, that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Thanks to its high density NAND is best suited to devices requiring high capacity data storage, such as pictures, music, or data files. NAND non-volatility, makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 15-270 summarizes the NAND interface signals level applied to external device or memories.

Table 15-270. NAND Interface Bus Operations Summary

Bus operation	CLE	ALE	nCE	nWE ⁽¹⁾	nRE ⁽¹⁾	nWP
Read (cmd input)	H	L	L	RE	H	x
Read (add input)	L	H	L	RE	H	x
Write (cmd input)	H	L	L	RE	H	H
Write (add input)	L	H	L	RE	H	H
Data input	L	L	L	RE	H	H
Data output	L	L	L	H	FE	x
Busy (during read)	x	x	H ⁽²⁾	H ⁽²⁾	H ⁽²⁾	x
Busy (during program)	x	x	x	x	x	H
Busy (during erase)	x	x	x	x	x	H
Write protect	x	x	x	x	x	L
Stand-by	x	x	H	x	x	H/L ⁽³⁾

⁽¹⁾ RE stands for rising edge, FE stands for falling edge

⁽²⁾ Can be either nCE high, or WE and nRE high.

⁽³⁾ nWP should be biased to CMOS high or CMOS low for standby

15.4.6.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND which is a sequential access device, NOR is directly addressable, that is, is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities it has slow write and erase functions compared to NAND architecture.

Table 15-271 summarizes the NOR interface signals level applied to external device or memories.

Table 15-271. NOR Interface Bus Operations Summary

Bus operation	CLK	nADV	nCS	nOE	nWE	WAIT	DQ[15:0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

15.4.6.2.1.4 Other Technologies

Other supported device type interact with the GPMC through the NOR interface protocol.

OneNAND™ is a high density and low-power memory device. OneNAND™ is based on single- or multi-level-cell NAND core with SRAM and logic, and interfaces as a synchronous NOR Flash, plus has synchronous write capability. It reads faster than conventional NAND and write faster than conventional NOR flash. Hence, it is appropriate for both mass storage and code storage.

pSRAM stands for pseudo-static random access memory. pSRAM is a low-power memory device for mobile applications. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR Flash, plus has synchronous write capability.

15.4.6.2.1.5 Supported Protocols

The GPMC supports the following interface protocols when communicating with external memory or external devices:

- Asynchronous read/write access
- Asynchronous read page access (4-8-16 Word16)
- Synchronous read/write access
- Synchronous read burst access without wrap capability (4-8-16 Word16)
- Synchronous read burst access with wrap capability (4-8-16 Word16)

15.4.6.2.2 GPMC Features and Settings

This section lists GPMC features and settings:

- Supported device type: up to four NAND or NOR protocol external memories or devices
- Operating Voltage: 1.8V;
- Maximum GPMC addressing capability: 1 GByte divided into eight chip-selects
- Maximum supported memory size: 256 MBytes (must be a power-of-2)
- Minimum supported memory size: 16 MBytes (must be a power-of-2). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8- and 16-bit wide
- Burst and page access: burst of 4-8-16 Word16
- Supports bus keeping
- Supports bus turn around

15.4.7 GPMC Register Manual

This section provides information about the GPMC instance in this product. [Table 15-273](#) provides a summary of the GPMC registers. The remaining parts of this section describe the registers within the module instance.

15.4.7.1 GPMC Register Summary

15.4.7.2 GPMC Register Descriptions

NOTE: All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except to [GPMC_NAND_DATA_i](#) register, are little endian. If the [GPMC_NAND_DATA_i](#) register location is accessed, the endianness is access-dependent.

In the whole section *i* corresponds to the chip-select number, *i* = 0 to 7.

15.5 Error Location Module

15.5.1 Error Location Module Overview

Non-managed NAND flash memories can be dense and nonvolatile in their own nature, but error-prone. When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as *bare NANDs*, the correction process is delegated to the memory controller.

The general-purpose memory controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-Chaudhuri-Hocquenghem (BCH) algorithm. The error-location module (ELM) extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM relies on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as *uncorrectable* in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

When the error-location process completes, an interrupt is triggered to inform the central processing unit (CPU) that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

15.5.1.1 ELM Features

The ELM has the following features:

- 4, 8, and 16 bits per 512-byte block error-location based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
 - When the full page has been processed in page mode
 - For each syndrome polynomial in continuous mode

15.5.2 ELM Integration

The ELM extracts error addresses from generated syndrome polynomials.

The ELM is used with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND flash page and stored in GPMC registers are passed to the ELM. The microprocessor unit (MPU) can then correct the data block by flipping the bits to which the ELM error-location outputs point.

Figure 15-100 shows the integration of the ELM subsystem in the device.

Figure 15-100. ELM Integration

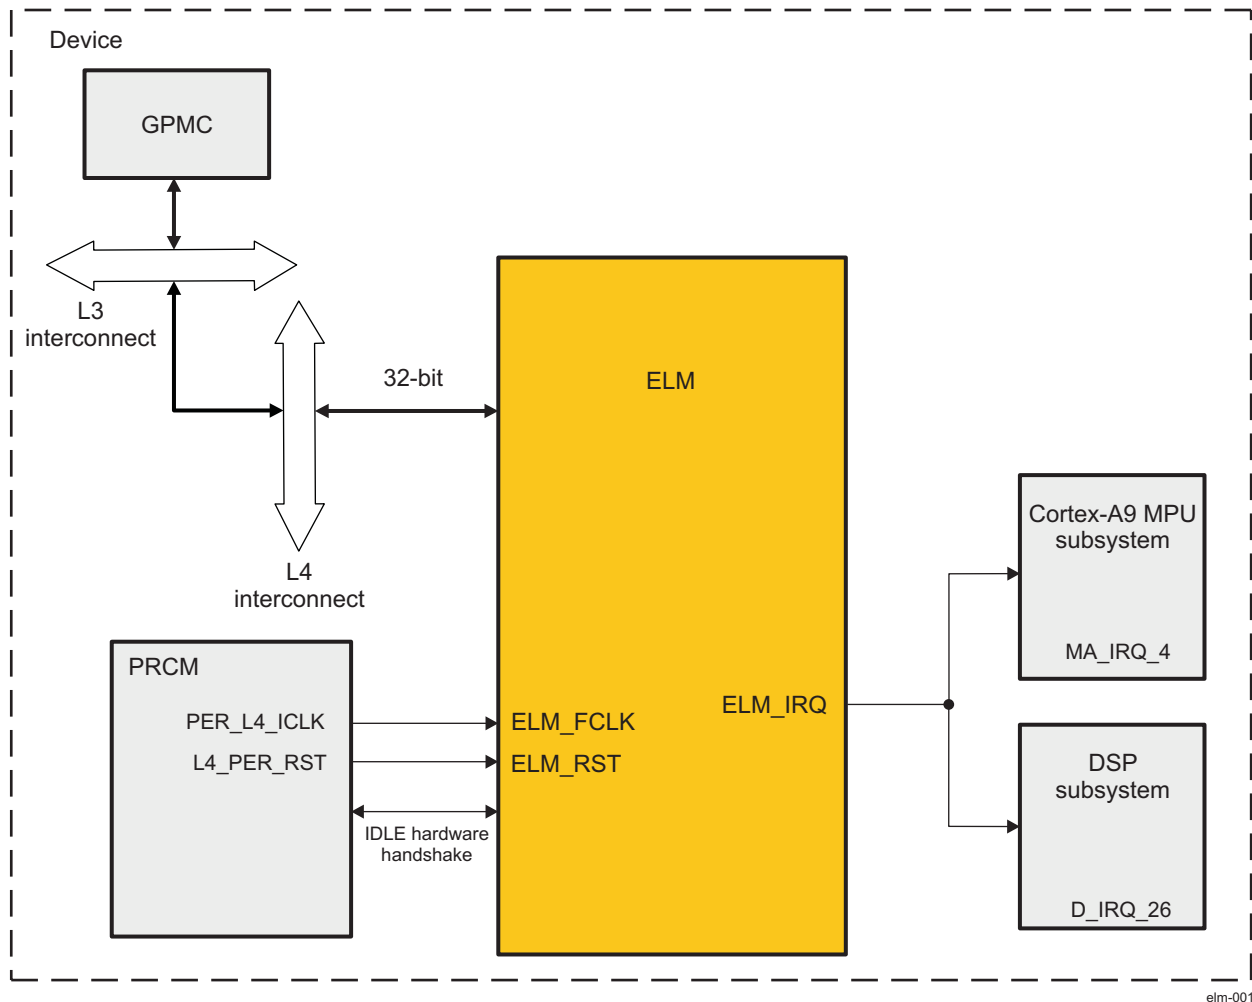

Table 15-346. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect

Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
ELM	ELM_RST	L4_PER_RST	PRCM	Power domain hardware reset For information about PRCM reset sources and distribution, see Section 3.5.4, Reset Domains in Chapter 3, Power, Reset, and Clock Management .

Table 15-348. Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
ELM	ELM_IRQ	MA_IRQ_4	Cortex-A9	BCH error-location module interrupt For information about Cortex-A9 interrupt control, see Section 17.3.2, Interrupt Requests to Cortex-A9 MPU INTC .
		D_IRQ_26	DSP	BCH error-location module interrupt For information about DSP interrupt control, see Section 5.3.7, Interrupts Requests .

15.5.3 ELM Functional Description

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

15.5.3.1 ELM Software Reset

To perform a software reset, write a 1 to the [ELM_SYSCONFIG\[1\] SOFTRESET](#) bit. The [ELM_SYSSTATUS\[0\] RESETDONE](#) bit indicates that the software reset is complete when its value is 1. When the software reset completes, the [ELM_SYSCONFIG\[1\] SOFTRESET](#) bit is automatically reset.

15.5.3.2 ELM Power Management

[Table 15-349](#) describes the power-management features available to the ELM module.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see the [Section 3.6.8, CD_L4_PER Clock Domain](#) in [Chapter 3, Power, Reset, and Clock Management](#).
- For a general description of `EnaWakeUp`, `IdleMode`, `ClockActivity`, and `StandbyMode` features, see [Section 3.6 Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#)

Table 15-349. Local Power Management Features

Feature	Registers	Description
Clock autogating	ELM_SYSCONFIG [0] AUTOGATING bit	This bit allows a local power optimization inside the module by gating the ELM_FCLK clock upon the interface activity.
Slave idle modes	ELM_SYSCONFIG [4:3] SIDLEMODE bit field	Force-idle, No-idle, and Smart-idle modes are available.
Clock activity	ELM_SYSCONFIG [8] CLOCKACTIVITY bit	The clock can be switched-off or maintained during the wake-up period.
Master Standby modes	N/A	
Global Wake-up Enable	N/A	
Wake-up Sources Enable	N/A	

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the ELM CLOCKACTIVITY and ELM clock PRCM control bits. For a description of the ClockActivity feature, see [Chapter 3, Power, Reset, and Clock Management](#).

15.5.3.3 ELM Interrupt Requests

[Table 15-350](#) lists the event flags, and their masks, that can cause module interrupts.

Table 15-350. Events

Event Flag	Event Mask	Map to	Description
ELM_IRQSTATUS [8] PAGE_VALID	ELM_IRQENABLE [8] PAGE_MASK	ELM_IRQ	Page interrupt
ELM_IRQSTATUS [7] LOC_VALID_7	ELM_IRQENABLE [7] LOCATION_MASK_7	ELM_IRQ	Error-location interrupt for syndrome polynomial 7
ELM_IRQSTATUS [6] LOC_VALID_6	ELM_IRQENABLE [6] LOCATION_MASK_6	ELM_IRQ	Error-location interrupt for syndrome polynomial 6
ELM_IRQSTATUS [5] LOC_VALID_5	ELM_IRQENABLE [5] LOCATION_MASK_5	ELM_IRQ	Error-location interrupt for syndrome polynomial 5
ELM_IRQSTATUS [4] LOC_VALID_4	ELM_IRQENABLE [4] LOCATION_MASK_4	ELM_IRQ	Error-location interrupt for syndrome polynomial 4
ELM_IRQSTATUS [3] LOC_VALID_3	ELM_IRQENABLE [3] LOCATION_MASK_3	ELM_IRQ	Error-location interrupt for syndrome polynomial 3
ELM_IRQSTATUS [2] LOC_VALID_2	ELM_IRQENABLE [2] LOCATION_MASK_2	ELM_IRQ	Error-location interrupt for syndrome polynomial 2
ELM_IRQSTATUS [1] LOC_VALID_1	ELM_IRQENABLE [1] LOCATION_MASK_1	ELM_IRQ	Error-location interrupt for syndrome polynomial 1
ELM_IRQSTATUS [0] LOC_VALID_0	ELM_IRQENABLE [0] LOCATION_MASK_0	ELM_IRQ	Error-location interrupt for syndrome polynomial 0

15.5.3.4 Processing Initialization

[ELM_LOCATION_CONFIG](#) global setting parameters must be set before using the error-location engine. The [ELM_LOCATION_CONFIG](#)[1:0] ECC_BCH_LEVEL bit defines the error-correction level used (4-,8-, or 16-bit error-correction). The [ELM_LOCATION_CONFIG](#)[26:16] ECC_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

The CPU can choose to use the ELM in continuous mode or page mode. If all [ELM_PAGE_CTRL](#)[i] SECTOR_i bits are reset (i is the syndrome polynomial number, i = 0 to 7), continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently – results for a syndrome can be retrieved and acknowledged at any time, whatever the status of the other seven processing contexts.
- Page mode: Syndrome polynomials are grouped into atomic entities – only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all [ELM_IRQENABLE\[i\]](#) LOCATION_MASK_i bits (i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the [ELM_IRQENABLE\[8\]](#) PAGE_MASK bit must be set to 1 when in page mode.

The CPU initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: [ELM_SYNDROME_FRAGMENT_0_i](#) to [ELM_SYNDROME_FRAGMENT_6_i](#). The first six registers can be written in any order, but [ELM_SYNDROME_FRAGMENT_6_i](#) must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the [ELM_SYNDROME_FRAGMENT_6_i\[16\]](#) SYNDROME_VALID bit).

As soon as one validity bit is asserted ([ELM_SYNDROME_FRAGMENT_6_i\[16\]](#) SYNDROME_VALID = 0x1, with i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated [ELM_LOCATION_STATUS_i](#) and [ELM_ERROR_LOCATION_0_i](#) to [ELM_ERROR_LOCATION_15_i](#) registers are not reset (i = 0 to 7). The software must not consider them until the corresponding [ELM_IRQSTATUS\[i\]](#) LOC_VALID_i bit is set.

15.5.3.5 Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the [ELM_LOCATION_STATUS_i\[8\]](#) ECC_CORRECTABLE bit is set to 1 and the [ELM_LOCATION_STATUS_i\[4:0\]](#) ECC_NB_ERRORS bit field is set to 0x0.
- Too many errors are detected; that is, when the [ELM_LOCATION_STATUS_i\[8\]](#) ECC_CORRECTABLE bit is set to 0 while the [ELM_LOCATION_STATUS_i\[4:0\]](#) ECC_NB_ERRORS bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if ECC_CORRECTABLE is 0.

If the engine completes early, the associated error-location registers [ELM_ERROR_LOCATION_0_i](#) to [ELM_ERROR_LOCATION_15_i](#) are not updated (i = 0 to 7).

In all other cases, the engine goes through the entire error-location process. Each time an error-location is found, it is logged in the associated ECC_ERROR_LOCATION bit field. The first error detected is logged in the [ELM_ERROR_LOCATION_0_i\[12:0\]](#) ECC_ERROR_LOCATION bit field; the second in the [ELM_ERROR_LOCATION_1_i\[12:0\]](#) ECC_ERROR_LOCATION bit field, and so on.

Table 15-351. ELM_LOCATION_STATUS_i Value Decoding Table

ECC_CORRECTABLE Value	ECC_NB_ERRORS Value	Status	Number of Errors Detected	Action Required
1	0	OK	0	None
1	≠ 0	OK	ECC_NB_ERRORS	Correct the data buffer read based on the ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i results.
0	Any	Failed	Unknown	Software-dependant

15.5.3.6 Processing Completion

When the processing for a given syndrome polynomial completes, its [ELM_SYNDROME_FRAGMENT_6_i\[16\]](#) SYNDROME_VALID bit is reset. It must not be set again until the exit status registers, [ELM_LOCATION_STATUS_i](#) ($i = 0$ to 7), for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding [ELM_IRQSTATUS\[i\]](#) LOC_VALID_i bit is set ($i = 0$ to 7). The processing-exit status is available from the associated [ELM_LOCATION_STATUS_i](#) register, and error locations are stored in order in the ECC_ERROR_LOCATION fields. The software must only read valid error-location registers based on the number of errors detected and located.

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the [ELM_SYNDROME_FRAGMENT_6_i\[16\]](#) SYNDROME_VALID validity bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in [ELM_PAGE_CTRL](#) are reset), an interrupt is triggered whenever a [ELM_IRQSTATUS\[i\]](#) LOC_VALID_i bit is asserted. The CPU must read the [ELM_IRQSTATUS](#) register to determine which polynomial is processed and retrieve the exit status and error locations ([ELM_LOCATION_STATUS_i](#) and [ELM_ERROR_LOCATION_0_i](#) to [ELM_ERROR_LOCATION_15_i](#)). When done, the CPU must clear the corresponding [ELM_IRQSTATUS\[i\]](#) LOC_VALID_i bit by writing it to 1. Other status bits must be written to 0 so that other interrupts are not unintentionally cleared. When using this mode, the [ELM_IRQSTATUS\[8\]](#) PAGE_VALID interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the [ELM_IRQENABLE\[i\]](#) LOCATION_MASK_i bits are cleared. A page is defined using the [ELM_PAGE_CTRL](#) register. Each SECTOR_i bit set means the corresponding polynomial i is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the [ELM_IRQSTATUS\[i\]](#) LOC_VALID_i bit fields. The module triggers an [ELM_IRQSTATUS\[8\]](#) PAGE_VALID interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the [ELM_IRQSTATUS](#) register must be cleared by using a single atomic-write access.

NOTE: Do not modify page setting parameters in the [ELM_PAGE_CTRL](#) register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the [ELM_PAGE_CTRL\[i\]](#) SECTOR_i bit fields ($i = 0$ to 7) are processed as usual, but are essentially ignored. The CPU must manually poll the [ELM_IRQSTATUS](#) bits to check for their status.

15.5.4 ELM Basic Programming Model

15.5.4.1 ELM Low Level Programming Model

15.5.4.1.1 Processing Initialization

Table 15-352. ELM Processing Initialization

Step	Register/ Bit Field / Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1

Defines the error-correction level used	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	Set value
Defines the maximum buffer length	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	Set value
Sets the ELM in continuous mode or page mode	ELM_PAGE_CTRL	Set value
If continuous mode is used	All ELM_PAGE_CTRL[i] SECTOR_i ($i = 0$ to 7)	0x0
Enables interrupt for syndrome polynomial i	ELM_IRQENABLE[i] LOCATION_MASK_i	0x1

Table 15-352. ELM Processing Initialization (continued)

Step	Register/ Bit Field / Programming Model	Value
else (page mode is used)	One syndrome polynomial <i>i</i> is set ELM_PAGE_CTRL[i] SECTOR_ <i>i</i> (<i>i</i> = 0 to 7)	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	All ELM_IRQENABLE[i] LOCATION_MASK_ <i>i</i> = 0x0 and ELM_IRQENABLE[8] PAGE_MASK = 0x1	Set value
endif		Set value
Set the input syndrome polynomial <i>i</i> .	ELM_SYNDROME_FRAGMENT_0_i	Set value
	ELM_SYNDROME_FRAGMENT_1_i	Set value
	ELM_SYNDROME_FRAGMENT_5_i	Set value
	ELM_SYNDROME_FRAGMENT_6_i	Set value
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID	0x1

15.5.4.1.2 Read Results

The engine goes through the entire error-location process and results can be read. [Table 15-353](#) and [Table 15-354](#) describe the processing completion for continuous and page modes, respectively.

Table 15-353. ELM Processing Completion for Continuous Mode

Step	Register/ Bit Field / Programming Model	Value
Wait until process is complete for syndrome polynomial <i>i</i> : Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Read for which <i>i</i> the error-location process is complete.	ELM_IRQSTATUS[i] LOC_VALID_ <i>i</i>	0x1
if the process fails (too many errors)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependant.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial <i>i</i> of the ECC_NB_ERRORS first registers. It is the software responsibility to correct errors in the data buffer.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
endif		
Clear the corresponding <i>i</i> interrupt.	ELM_IRQSTATUS[i] LOC_VALID_ <i>i</i>	0x1

A new syndrome polynomial can be processed after the end of processing ([ELM_SYNDROME_FRAGMENT_6_i\[16\]](#) SYNDROME_VALID = 0x0) and after the exit status register check ([ELM_LOCATION_STATUS_i](#)).

Table 15-354. ELM Processing Completion for Page Mode

Step	Register/ Bit Field / Programming Model	Value
Wait until process is complete for syndrome polynomial <i>i</i> : Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
Repeat the following actions the necessary number of times. That is, once for each valid defined block in the page.		

Table 15-354. ELM Processing Completion for Page Mode (continued)

Step	Register/ Bit Field / Programming Model	Value
Read the process exit status.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	
if the process fails (too many errors)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependant.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
endif		
End Repeat		
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed ([ELM_IRQSTATUS\[i\]](#) LOC_VALID_i = 0x1 for all syndrome polynomials i used in the page).

15.5.4.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM module is programmed for an 8-bit error-correction capability in continuous mode. After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a non-zero polynomial syndrome is reported from the GPMC (Polynomial syndrome 0 is used in the ELM):

- P = 0x0A16ABE115E44F767BFB0D0980

Table 15-355. Use Case: Continuous Mode

Step	Register/ Bit Field / Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG[4:3] SIDLEMODE	0x2
Defines the error-correction level used: 8 bits	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	0x1
Defines the maximum buffer length: 528 bytes (2x528 = 1056)	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	0x420
Sets the ELM in continuous mode	ELM_PAGE_CTRL	0
Enables interrupt for syndrome polynomial 0	ELM_IRQENABLE[0] LOCATION_MASK_0	0x1
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (i=0)	0xFB0D0980
	ELM_SYNDROME_FRAGMENT_1_i (i=0)	0xE44F767B
	ELM_SYNDROME_FRAGMENT_2_i (i=0)	0x16ABE115
	ELM_SYNDROME_FRAGMENT_3_i (i=0)	0x0000000A
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (i=0)	0x1
Wait until process is complete for syndrome polynomial 0: IRQ_ELM is generated or poll the status register.		
Read that error-location process is complete for syndrome polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1
Read the process exit status: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (i=0)	0x1

Table 15-355. Use Case: Continuous Mode (continued)

Step	Register/ Bit Field / Programming Model	Value
Read the number of errors: Four errors detected.	ELM_LOCATION_STATUS_j[4:0] ECC_NB_ERRORS (i=0)	0x4
Read the error-location bit addresses for syndrome polynomial 0 of the 4 first registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452.	ELM_ERROR_LOCATION_0_j (i=0)	0x1AF
	ELM_ERROR_LOCATION_1_j (i=0)	0x426
	ELM_ERROR_LOCATION_2_j (i=0)	0x775
	ELM_ERROR_LOCATION_3_j (i=0)	0xD7C
Clear the corresponding interrupt for polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in [Table 15-356](#) are given in decimal format.

Table 15-356. 16-bit NAND Sector Buffer Address Map

NAND Memory Address	Message bit addresses in the memory word															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	4215	4214	4213	4212	4211	4210	4209	4208	4223	4222	4221	4220	4219	4218	4217	4216
1	4175	4174	4173	4172	4171	4170	4169	4168	4183	4182	4181	4180	4179	4178	4177	4176
...																
47	3463	3462	3461	3460	3459	3458	3457	3456	3471	3470	3469	3468	3467	3466	3465	3464

49	3431	3430	3429	3428	3427	3426	3425	3424	3439	3438	3437	3436	3435	3434	3433	3432
50	3415	3414	3413	3412	3411	3410	3409	3408	3423	3422	3421	3420	3419	3418	3417	3416
...																
255	135	134	133	132	131	130	129	128	143	142	141	140	139	138	137	136
256	119	118	117	116	115	114	113	112	127	126	125	124	123	122	121	120
257	103	102	101	100	99	98	97	96	111	110	109	108	107	106	105	104
258	87	86	85	84	83	82	81	80	95	94	93	92	91	90	89	88
259	71	70	69	68	67	66	65	64	79	78	77	76	75	74	73	72
260	55	54	53	52	51	50	49	48	63	62	61	60	59	58	57	56
261	39	38	37	36	35	34	33	32	47	46	45	44	43	42	41	40
262	23	22	21	20	19	18	17	16	31	30	29	28	27	26	25	24
263	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and to flip this bit. The same process must be repeated for all detected errors.

15.5.4.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for an 16-bit error-correction capability in page mode. After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (Polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF
- P1 = 0xBAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EB

- P2 = 0x69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189
- P3 = 0x0

Table 15-362. ELM_SYSCONFIG

Address Offset	0x0000 0010	Instance	ELM
Physical Address	0x4807 8010		
Description	This register allows controlling various parameters of the OCP interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																CLOCKACTIVITYOCP	RESERVED			SIDLEMODE		RESERVED	SOFTRESET	AUTOGATING							

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	R	0x000000
8	CLOCKACTIVITYOCP	OCP Clock activity when module is in IDLE mode (during wake up mode period) 0x0: OCP Clock can be switch-off 0x1: OCP Clock is maintained during wake up period	RW	0
7:5	RESERVED	Reserved	R	0x0
4:3	SIDLEMODE	Slave interface power management (IDLE req/ack control) 0x0: FORCE Idle. IDLE request is acknowledged unconditionally and immediately (Default <i>Dumb</i> mode for safety) 0x1: NO idle. IDLE request is never acknowledged. 0x2: SMART Idle. The acknowledgment to an IDLE request is given based on the internal activity. 0x3: Reserved - do not use	RW	0x2
2	RESERVED	Reserved	R	0
1	SOFTRESET	Module software reset This bit is automatically reset by hardware (During reads, it always returns 0.) It has same effect as the OCP hardware reset. 0x0: Normal mode 0x1: Start soft reset sequence.	RW	0
0	AUTOGATING	Internal OCP clock gating strategy (no module visible impact other than saving power) 0x0: OCP clock is free-running 0x1: Automatic internal OCP clock gating strategy is applied based on the OCP interface activity.	RW	1

15.6 On-Chip Memory (OCM) Subsystem

15.6.1 OCM Subsystem Overview

There are three on-chip memories in the device.

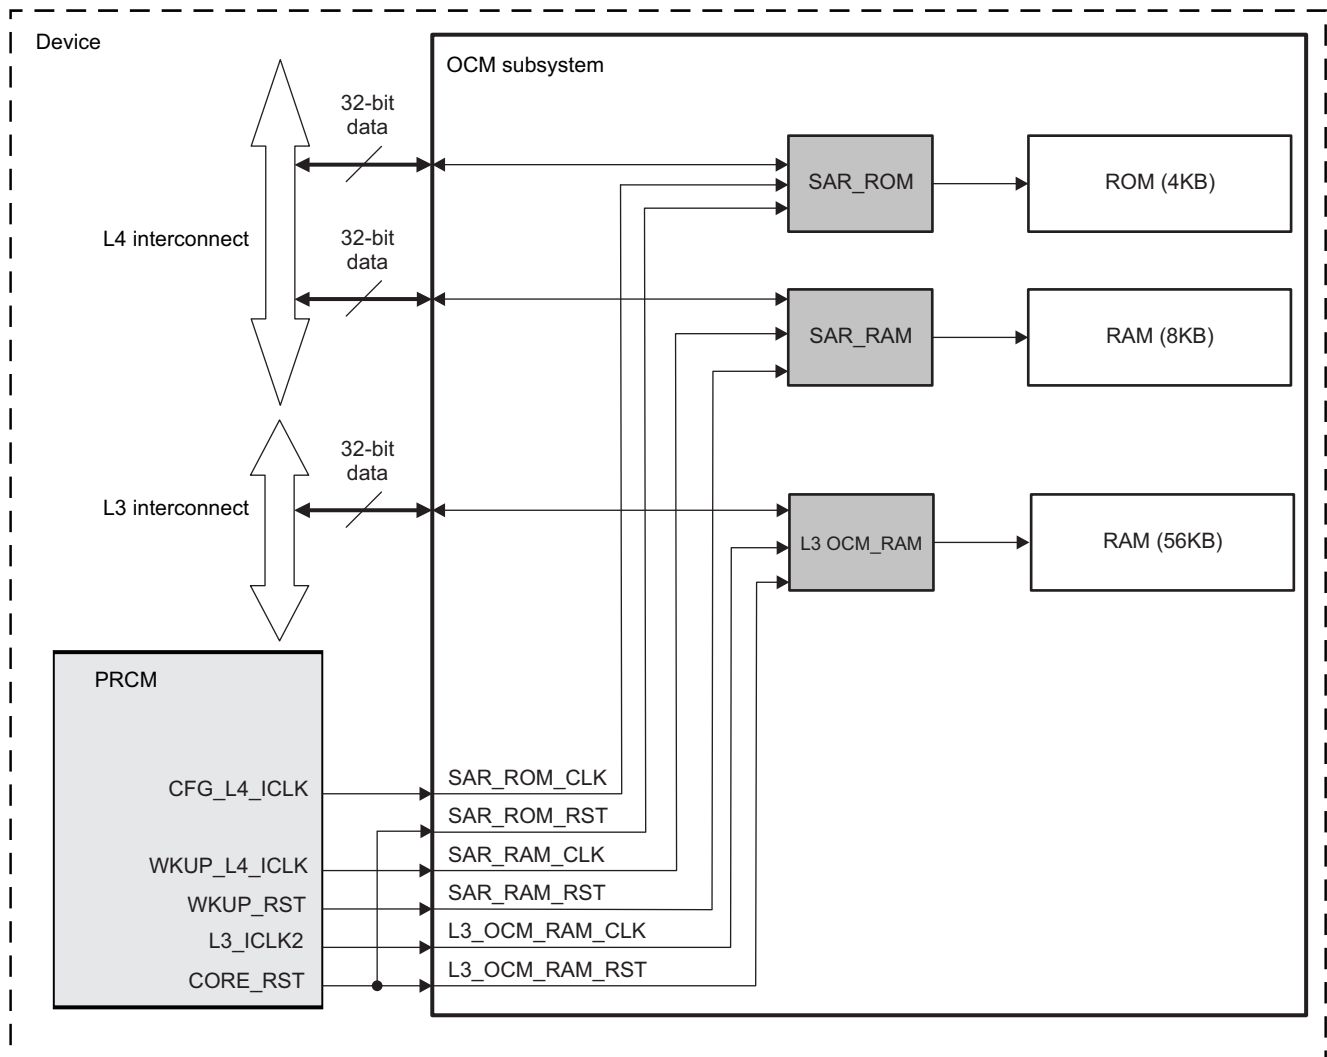

- A 4K-byte SAR read-only memory (ROM)
- A 8K-byte SAR random-access memory (RAM)
- A 56K-byte L3 static random-access memory (L3 OCM_RAM)

There are other on-chip memories located inside other subsystems (Cortex-A9 MPU, DSP IVA-HD, ABE, Cortex-M3 MPU) that are not described in the following sections. Refer to each subsystem chapter for more details.

15.6.2 OCM Subsystem Integration

[Figure 15-101](#) shows the integration of the OCM subsystem to the device.

Figure 15-101. OCM Subsystem Integration to the Device

15.6.3 OCM Subsystem Functional Description

15.6.3.1 SAR ROM

This on-chip ROM contains 4K bytes of memory and a linked list of descriptors used by the system DMA (sDMA) during the restore context operation (when device transitions from OFF to ON modes).

The device-embedded SAR ROM has the following characteristics:

- 4K-bytes ROM
- 32-bit access per cycle
- Support for single and burst access transactions

The memory space of the embedded ROM starts at 0x4A05 E000 and ends at 0x4A05 FFFF (8K bytes are reserved, but only 4K bytes are used).

15.6.3.2 SAR RAM

The on-chip SAR RAM contains 8K bytes and is mapped as 4 blocks with irregular region sizes. This memory content is preserved when the device goes into OFF mode (as long as the wake-up voltage domain remains supplied). It is used as context-saving memory to be written by the software, so that the sDMA restores its saved content when the device transitions from OFF to ON mode. Locations not used by the sDMA can be used as a scratch-pad memory by the software. It is mapped on the wake-up voltage domain.

The device-embedded SAR RAM has the following characteristics:

- Support for single-access transactions

- Operates at full L4-PER interconnect clock frequency
- 32-bit access per cycle

The SAR RAM space is at the following location:

- SAR space 1 (4KB): Starts at 0x4A32 6000 and ends at 0x4A32 6FFF
- SAR space 2 (1KB): Starts at 0x4A32 7000 and ends at 0x4A32 73FF
- SAR space 3 (2KB): Starts at 0x4A32 8000 and ends at 0x4A32 87FF
- SAR space 4 (1KB): Starts at 0x4A32 9000 and ends at 0x4A32 93FF

15.6.3.3 L3 OCM_RAM

The on-chip L3 OCM_RAM contains 56K bytes of RAM, partitioning is defined by the L3 firewall logic.

The device-embedded L3 OCM_RAM has the following characteristics:

- Support for single and burst access transactions:
 - Operates at full L3 interconnect clock frequency
 - Fully pipelined, one 32-bit access per cycle
- Restricted access support based on:
 - A region-based partitioning (refer to L3 firewall description)
 - The module owner of the access, with respect to its read and write permissions to that region
 - The transaction attributes of the access, with respect to the region permission properties. See [Section 13.2, L3 Interconnect](#) for details.

The memory space of the embedded RAM starts at 0x4030 0000 and ends at 0x4030 DFFF.

SDMA

This chapter describes the system direct memory access (SDMA) module.

Topic	Page
16.1 SDMA Module Overview	3582
16.2 SDMA Controller Environment.....	3584
16.3 SDMA Module Integration	3586
16.4 SDMA Functional Description.....	3591
16.5 SDMA Basic Programming Model	3625
16.6 SDMA Register Manual	3633

16.1 SDMA Module Overview

The system direct memory access (SDMA) module, also called DMA4, performs high-performance data transfers between memories and peripheral devices without microprocessor unit (MPU) or digital signal processor (DSP) support during transfer. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

The DMA controller includes the following main features:

- Data transfer support in either direction between:
 - Memory and memory
 - Memory and peripheral device
- 32 logical DMA channels supporting:
 - Multiple concurrent transfers
 - Independent transfer profile for each channel
 - 8-bit, 16-bit, or 32-bit data element transfer size
 - Software-triggered or hardware-synchronized transfers
 - Flexible source and destination address generation
 - Burst read and write
 - Chained multiple-channel transfers
 - Endianism conversion
 - Draining
 - Linked-list support for descriptor types 1, 2, and 3
- First-come, first-serve DMA scheduling with fixed priority
- Up to 127 DMA requests
- Constant fill
- Transparent copy
- Four programmable interrupt request output lines
- FIFO depth: 256 × 64-bit
- Data buffering
- FIFO budget allocation
- Power-management support
- Auto-idle power-saving support
- Implementation of retention flip-flops (RFFs) to support dynamic power switching (DPS) between system power modes without MPU involvement. For more information about DPS, see [Section 3.1.2.3](#), *Dynamic Power Switching*, in [Chapter 3](#), *Power, Reset and Clock Management*.

Figure 16-1 shows an overview of the SDMA module.

Figure 16-1. SDMA Overview

The SDMA module has three ports: one read, one write, and one configuration port, and provides multiple logical channel support. A dynamically allocated FIFO queue memory pool provides buffering between the read and write ports, which are multithreaded (two threads for the write port and four threads for the read port); this means that each transaction is flagged by a thread ID (0, 1, 2, or 3) in the request direction and in the response direction. This allows the read port to have four outstanding requests at a time. The write port has two threads budget available.

The MPU (or DSP) configures the SDMA through the L4-CFG interconnect.

16.2 SDMA Controller Environment

The SDMA controller supports external DMA requests through the `sys_ndmareq[3:0]` pins (see [Table 16-1](#)). A logical channel can be configured to respond to an external synchronization request.

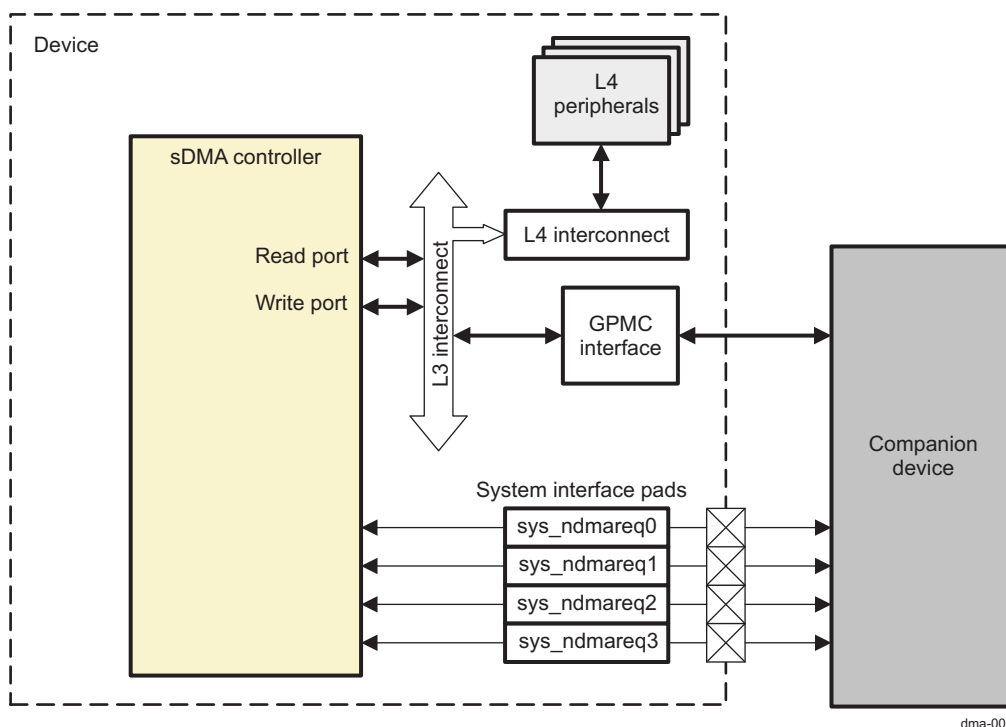

Table 16-1. External SDMA Request Signals

Signal Name	I/O ⁽¹⁾	Description	Reset Value
<code>sys_ndmareq0</code>	I	External DMA request 0 (system expansion)	Z
<code>sys_ndmareq1</code>	I	External DMA request 1 (system expansion)	Z
<code>sys_ndmareq2</code>	I	External DMA request 2 (system expansion)	Z
<code>sys_ndmareq3</code>	I	External DMA request 3 (system expansion)	Z

⁽¹⁾ I = Input; O = Output; I/O = Bidirectional

[Figure 16-2](#) shows an example of how to use the external hardware DMA request pins in the SDMA environment.

Figure 16-2. Example of External DMA Requests Use

An external device can use the external DMA request pins to start a logical channel transfer over the general-purpose memory controller (GPMC) interface. The transfer can be a memory-to-memory transfer in which the source memory is in the external device.

By default, the external DMA request signals are not available on external pins after a cold reset. For more information about multiplexing out the four signal lines to pins, see [Chapter 18, Control Module](#).

All 127 DMA request lines are transition-sensitive.

For a transition-sensitive DMA request (see [Figure 16-3](#)), the line must be maintained low (asserted) until the first DMA access is complete, after which the line must be maintained high (deasserted) for greater than one clock cycle (`DMA_L3_ICLK`):

- When the deassertion time is less than one clock cycle, the SDMA may not detect the deassertion.
- When the channel is enabled one cycle after a DMA request is disabled, the channel detects the DMA request and starts the corresponding transfer.
- When the channel is enabled two cycles after the DMA request is disabled, the channel does not

detect the DMA request.

Figure 16-3. Transition-Sensitive DMA Request Scheme

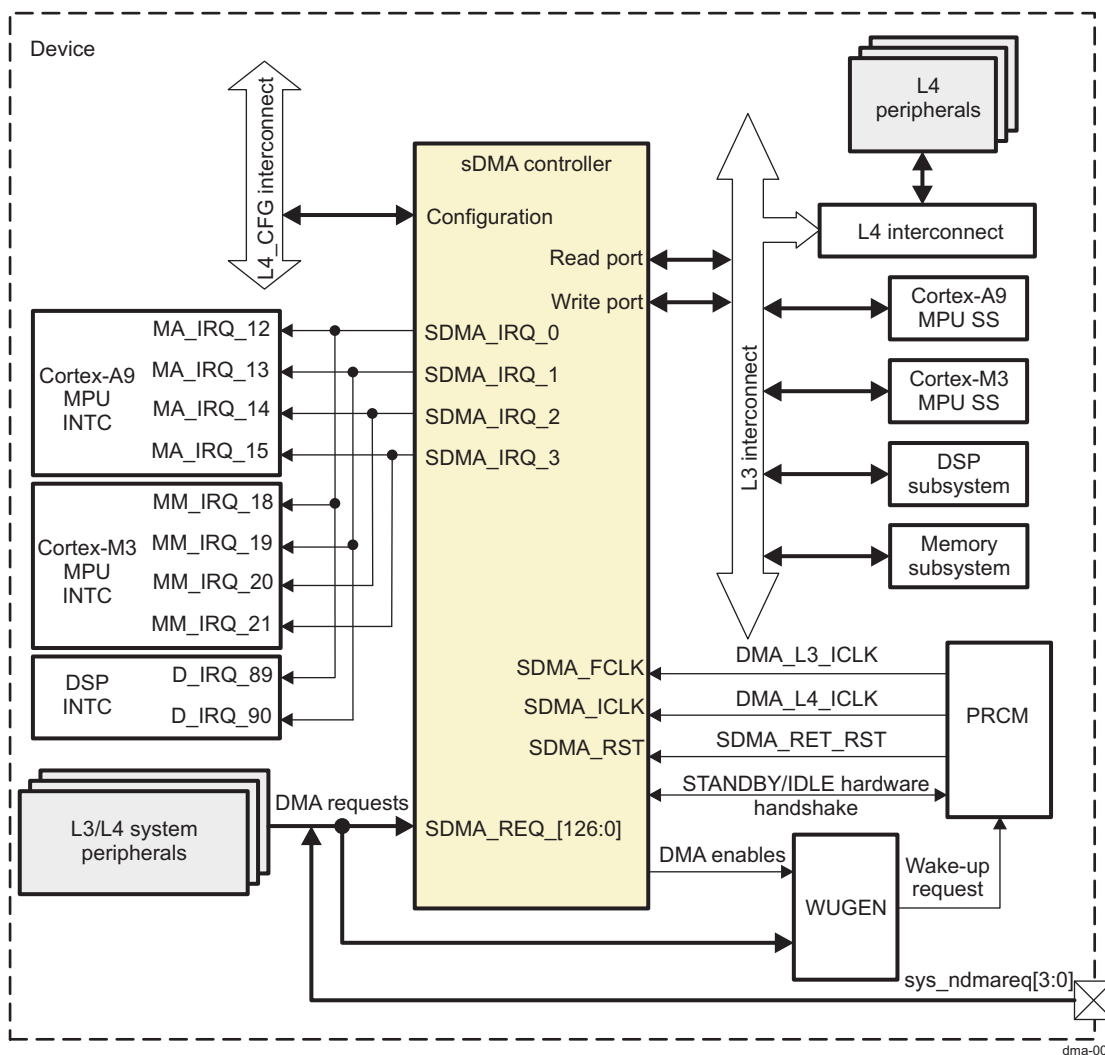

16.3 SDMA Module Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 16-4 shows the SDMA controller integration.

Figure 16-4. SDMA Controller Integration

NOTE: For more information about the wake-up generator (WUGEN), the STANDBY/IDLE hardware handshake, and the wake-up request, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 16-2 through Table 16-4 summarize the integration of the module in the device.

Table 16-2. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
SDMA	PD_CORE	L3 and L4-CFG

Table 16-3. Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SDMA	SDMA_FCLK	DMA_L3_ICLK	PRCM	Functional clock for all internal logic and for the two master read and write ports. For information about the power, reset, and clock management (PRCM) clock gating and management, see Chapter 3, Power, Reset, and Clock Management .
	SDMA_ICLK	DMA_L4_ICLK		Interface clock. It supports the configuration port. For information about PRCM clock gating and management, see Chapter 3, Power, Reset, and Clock Management .
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SDMA	SDMA_RST	SDMA_RET_RST	PRCM	Hardware reset. It initializes all internal logic of the SDMA module, all global registers, and some of the per-channel registers, implemented in flip-flops. However, all remaining per-channel registers are memory-based, and, therefore, are not reset (have undefined values). Thus, when programming a channel for the first time, all bits that have undefined reset values must be configured before enabling the channel. For information about PRCM reset sources and distribution, see Chapter 3, Power, Reset, and Clock Management .

Table 16-4. Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
SDMA	SDMA_IRQ_0	MA_IRQ_12	Cortex™-A9 MPU INTC	SDMA interrupt request 0. For information about the Cortex-A9 MPU INTC, see Section 17.3.2 .
	SDMA_IRQ_1	MA_IRQ_13	Cortex-A9 MPU INTC	SDMA interrupt request 1
	SDMA_IRQ_2	MA_IRQ_14	Cortex-A9 MPU INTC	SDMA interrupt request 2
	SDMA_IRQ_3	MA_IRQ_15	Cortex-A9 MPU INTC	SDMA interrupt request 3
	SDMA_IRQ_0	MM_IRQ_18	Cortex™-M3 MPU INTC	SDMA interrupt request 0. For information about the Cortex-M3 MPU INTC, see Section 17.3.3 .
	SDMA_IRQ_1	MM_IRQ_19	Cortex-M3 MPU INTC	SDMA interrupt request 1
	SDMA_IRQ_2	MM_IRQ_20	Cortex-M3 MPU INTC	SDMA interrupt request 2
	SDMA_IRQ_3	MM_IRQ_21	Cortex-M3 MPU INTC	SDMA interrupt request 3
	SDMA_IRQ_0	D_IRQ_89	DSP INTC	SDMA interrupt request 0. For information about the DSP INTC, see Section 5.3.7 .
	SDMA_IRQ_1	D_IRQ_90	DSP INTC	SDMA interrupt request 1

NOTE: For a description of the interrupt source, see [Section 16.4.2, SDMA Controller Interrupt Requests](#).

16.3.1 DMA Requests to the SDMA Controller

Table 16-5 lists the SDMA controller request mapping.

Table 16-5. SDMA Controller Request Mapping

DMA Request Line	Source	Description
S_DMA_0	Reserved	Reserved
S_DMA_1	sys_dma_req0	External DMA request 0 (system expansion)

16.4 SDMA Functional Description

The SDMA module provides high-performance data transfers between memories and peripheral devices with low processor use. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

Figure 16-5 shows the SDMA controller top-level block diagram.

Figure 16-5. SDMA Controller Top-Level Block Diagram

dma-005

16.4.1 SDMA Controller Power Management

Table 16-6 describes power-management features available for the SDMA controller.

NOTE:

- For information about source clock gating and sleep/wake-up transitions, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- For a description of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 16-6. Local Power-Management Features

Feature	Registers	Description
Clock auto gating	DMA4_OCP_SYSCONFIG [0] AUTOIDLE bit	This bit allows local power optimization inside the module by gating the SDMA_ICLK clock upon the interface activity.
Slave idle modes	DMA4_OCP_SYSCONFIG [4:3] SIDLEMODE bit field	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	DMA4_OCP_SYSCONFIG [9:8] CLOCKACTIVITY bit field	For configuration details, see Table 16-7 .
Master standby modes	DMA4_OCP_SYSCONFIG [13:12] MIDLEMODE bit field	Force-standby, no-standby, and smart-standby modes are available.
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	N/A	Feature not available

Table 16-7. Clock Activity Settings

SDMA_CLOCKACTIVITY Values	Clock State When Module is in IDLE State	
	SDMA_ICLK	SDMA_FCLK
00	Off	Off
10	Off	On
01	On	Off
11	On	On

CAUTION

Because the PRCM module cannot read CLOCKACTIVITY settings through hardware, software must ensure consistent programming between the SDMA_CLOCKACTIVITY and SDMA clock PRCM control bits. For a description of the ClockActivity feature, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

16.4.2 SDMA Controller Interrupt Requests

DMA4 has four interrupt lines (L_j, where j = 0, 1, 2, 3). Each logical channel can request an interrupt over any line. The attachment of a channel interrupt event to one of these four external lines is programmable. Software determines whether it attaches a channel interrupt to a single IRQ line or to multiple IRQ lines.

There are two different registers per interrupt line:

- The [DMA4_IRQSTATUS_Lj](#) CH_31_0_Lj field shows the status of the different sources of interrupt. If the [DMA4_IRQENABLE_Lj](#) bit is 1, channel *i* is the source of interrupt in line *j*. In contrast to the [DMA4_CSRi](#) registers, the [DMA4_IRQSTATUS_Lj](#) registers are updated regardless of the corresponding bits in the [DMA4_IRQENABLE_Lj](#) registers.
- The [DMA4_IRQENABLE_Lj](#) CH_31_0_Lj_EN field masks/unmasks the channel interrupt. If the [DMA4_IRQENABLE_Lj](#) bit is set to 0, channel interrupt *i* of the line *j* is masked.

Each logical channel can generate a number of different interrupt events when enabled (that is, set to 1) in the [DMA4_CICRi](#) register. Each status bit is updated in the [DMA4_CSRi](#) register only when the corresponding enable bit is enabled in the [DMA4_CICRi](#) register.

To determine an interrupt source when an interrupt rises on an interrupt line L_j:

- Identify the channel (LCH_{*i*}) generating the interrupt.
Read [DMA4_IRQSTATUS_Lj.LCHi](#) (LCH₀ to LCH₃₁). If LCH_{*i*} = 1, channel *i* is the originator of the interrupt.
- Identify the interrupt event.

Read the LCHi [DMA4_CSRi](#). For example, if the drop event (the [DMA4_CSRi\[1\]](#) DROP bit) is 1, a request collision will occur.

The interrupt event status bit in the [DMA4_CSRi](#) register is immediately reset after it is written to 1.

The interrupt status bit in the [DMA4_IRQSTATUS_Lj](#) register is cleared after it is written to 1.

16.4.2.1 Interrupt Generation

The SDMA module has four interrupt request output lines, [SDMA_IRQ_0](#) to [SDMA_IRQ_3](#). One or more logical channels can be programmed to generate an interrupt request on any of these lines when any one of the maskable DMA events listed in [Table 16-8](#) occurs.

Table 16-8. Logical DMA Channel Events

Event	Description
End of packet	A packet transfer completed.
End of block	A block transfer completed.
End of frame	A frame transfer completed.
End of super block	A super block transfer completed.
Half of frame	Half of the current frame transferred.
Start of last frame	The first element of the last frame transferred.
Transaction error	A transaction error is returned by the interconnect in either the read or write port.
Address error	An attempt was made to perform a DMA access to an address not aligned on an ES boundary. Condition to occur: if DMA4_CEN[23:0] CHANNEL_ELMNT_NBR = 0x000000 or DMA4_CFN[15:0] CHANNEL_FRAME_NBR = 0x0000 or DMA4_CSDP[1:0] DATA_TYPE = 0x3.
Supervisor transaction error	An error occurred, for example, when an unauthorized initiator (that is not a supervisor) tries to use a supervisor transfer.
Drain end	Drain is completed (DMA4_CCRi[10] WR_ACTIVE becomes 0).
Drop error	A drop event interrupt is generated when a DMA request is being serviced while a second one is asserted and a third one arrives before the second DMA request is serviced.

The logical DMA channels that generate an interrupt on a particular IRQ output are specified through the [DMA4_IRQENABLE_Lj](#) register (where *j* is the IRQ number: 0, 1, 2, or 3). The events that generate an interrupt for a particular channel can be configured through the channel [DMA4_CICRi](#) register.

When an interrupt is detected, the logical DMA channel generating the event can first be identified by reading the [DMA4_IRQSTATUS_Lj](#) register. The event causing the interrupt then can be identified by reading the interrupt status via the relevant DMA channel [DMA4_CSRi](#) register.

16.4.3 Logical Channel Transfer Overview

As [Figure 16-5](#) shows, the SDMA module has one read port and one write port operating independently of one another. Buffering is provided between the read and write ports through a FIFO queue memory pool that is shared dynamically between the active logical channels.

- Logical channel synchronization

A logical channel is described as hardware-synchronized when the DMA transfers are triggered by DMA requests from a hardware device. Alternatively, a logical channel is described as nonsynchronized when the DMA transfer is triggered by software.

- Logical channel activation

A logical channel becomes active as follows:

- For hardware-synchronized transfers, when the logical channel is enabled and the hardware DMA request line is asserted
- For software-triggered (nonsynchronized) transfers, as soon as software enables the logical channel

- Logical channel transfer composition

A DMA transfer is divided automatically into a number of transactions. Depending on the logical

channel context configured, the transfer size, start address alignment, addressing mode, and configured maximum burst size, each transaction can be a single access or a burst of accesses.

- Logical channel scheduling

When several logical channels are active at the same time, schedulers manage the read and write ports. The scheduling of logical channel transfers is similar for both read and write ports. When a logical channel becomes active, it is added to the tail of a scheduling queue. If more than one logical channel becomes active at the same time, the one with the lower number is queued first. This mechanism provides a first-come, first-serve scheduling scheme between the concurrently active logical channels.

In addition, each read and write port has a high-priority queue and a low-priority queue. The priority bits (WRITE_PRIORITY and READ_PRIORITY) in the logical channel `DMA4_CCRi` register determine whether a logical channel is queued as high or low priority. A software-configurable 8-bit priority counter gives weighting to the priority write queue. For every N (1 to 255) schedules from the priority write queue, one is scheduled from the regular write queue. A channel that is scheduled goes to the end of the queue after it completes its turn on the port. The relative weighting of the scheduling of the high-priority queue to the low priority queue is programmable from 1:1 to 1:256 through the DMA global channel register using the `DMA4_GCR[23:16] ARBITRATION_RATE` bit field.

NOTE: The `DMA4_GCR[23:16] ARBITRATION_RATE` bit field does not depend on the `DMA4_GCR[13:12] HI_THREAD_RESERVED` bit field. The `ARBITRATION_RATE` bit field depends on the `DMA4_CCRi[26] WRITE_PRIORITY` bit and the `DMA4_CCRi[6] READ_PRIORITY` bit.

- Read/write port access scheduling policy

When either the read or write port becomes available, the port access scheduler selects the next logical channel for which to perform a DMA transaction from either the high- or low-priority queue.

When the current DMA transaction (single or burst access) is complete and the full DMA transfer is not finished, the logical channel returns to the tail of the queue. Because the port access scheduling is on a per-transaction basis, a logical channel can be queued repeatedly this way several times during its block transfer.

The SDMA module can have up to four outstanding read transactions and two outstanding write transactions in the system interconnect; four read and two write thread IDs exist. For an arbitration cycle to occur, these two conditions must be met:

- At least one channel is requesting
- At least one free thread ID is available

On an arbitration cycle, the scheduler grants the highest priority channel that has an active request, allocates the thread ID, and tags this thread as busy. At a given time, a channel cannot be allocated for more than one thread ID.

NOTE: If more than one channel is active, each channel is given a thread ID for the current service only, not for the whole channel transfer.

When only one channel is enabled, only one thread is allocated for the channel. In such a situation the channel can have maximum of four outstanding commands (without getting the responses) without rescheduling the channel at the end of each transaction. Each command can be either single access (8-bit, 16-bit or 32-bit) or burst access ($2 \times M$, $4 \times M$, $8 \times M$ or $16 \times M$, where M can be 8, 16, or 32 bits).

When nonburst alignment is at the beginning of the transfer, the channel is rescheduled for each smaller access until burst-aligned. When the end of the transfer is not burst-aligned, the channel is rescheduled for each of the remaining smaller accesses.

For a logical channel transfer completion, when the last access is written to the destination, the logical channel becomes inactive. If enabled, an interrupt request is generated (see [Section 16.4.2.1, Interrupt Generation](#)).

16.4.4 FIFO Queue Memory Pool

A FIFO queue memory pool provides buffering between the read and write ports. The hardware allocates the space dynamically to a number of FIFO queues, and each queue is associated with an active logical channel.

To avoid a memory pool overflow, if there are fewer entries in the FIFO queue memory pool than are required for the maximum configured source burst size of the next logical channel to be scheduled, the logical channel is returned to the tail of the queue, and the port access scheduler continues to search the queue until it finds a logical channel that can be scheduled.

The maximum FIFO depth that can be allocated to each individual logical channel can be limited globally through the [DMA4_GCR\[7:0\] MAX_CHANNEL_FIFO_DEPTH](#) bit field. This value should be configured to allow a fair allocation of the memory pool between the active channels.

A logical channel is scheduled if it has not yet reached its allocation limit, even if the access to be performed will exceed this limit. This means that the effective number of entries used by a particular logical channel is limited to the configured maximum entries per channel + channel maximum configured burst size (in words) 1.

16.4.5 Addressing Modes

A DMA transfer block consists of a number of frames (FN). Each frame consists of a number of elements (EN), and each element can have a size of 8, 16, or 32 bits (ES), as follows:

$$\text{transfer block size} = \text{FN} \times \text{EN} \times \text{ES}$$

The FN, EN, and ES are common for the source and destination. However, the way in which the data is represented (addressing profile/mode) is independently programmable for the source and destination devices, using one of these four addressing modes:

- Constant: The address remains the same for consecutive element accesses.
- Post-increment: The address increases by the ES, even across consecutive frames.
- Single-index: The address increases by the ES plus the element index (EI) value minus 1 (even across consecutive frames).
- Double-index: The address increases by the ES plus the EI value minus 1 within a frame. When a full frame is transferred, the address increases by the ES plus the frame index (FI) value minus 1.

The ES, EI, and FI values are expressed in bytes. The EI and FI values can be positive or negative.

When calculating the EI and FI values, it is critical to note that, after an element is accessed, the logical channel address pointer equals the address of the last byte (highest address) of the accessed element. The correct value for the EI or FI must be such that, when added to the logical channel address pointer, it results in the address of the first byte (lowest address) of the next element to be accessed.

The EI and FI values must be configured so that the address of each element in the transfer is aligned on an ES boundary.

Consequently, the single-index addressing mode with EI = 1 or double-index addressing mode with EI = 1 and FI = 1 is equivalent to post-increment addressing.

NOTE: The source and destination start addresses must also be aligned on an ES boundary.

When the address of an element to be accessed is not aligned on an ES boundary, the transfer is stopped and a misaligned address error interrupt occurs, if enabled (see [Section 16.4.2.1, Interrupt Generation](#)).

The [DMA4_CFNi](#) register configures the FN in a block.

The [DMA4_CENi](#) register configures the EN.

The [DMA4_CSDPi](#) register configures the ES.

The [DMA4_CSSAi](#) and [DMA4_CDSAi](#) registers configure the source and destination start addresses.

The [DMA4_CCRi](#) register configures the source and destination addressing modes.

The [DMA4_CSEIi](#), [DMA4_CSFIi](#), [DMA4_CDEIi](#), and [DMA4_CDFIi](#) registers configure the source EI, source FI, destination EI, and destination FI, respectively.

The addressing profiles are expressed as equations as follows:

Equation 1. Constant addressing:

$$A(n + 1) = A(n)$$

Note: Constant addressing mode with DMA4 to/from DDR memory is not supported on the OMAP4460 device.
To fill DDR memory with a single value, the constant fill feature of DMA4 must be used instead of a constant addressing mode transfer.

Equation 2. Post-increment addressing:

$$A(n + 1) = A(n) + ES$$

Equation 3. Single-indexed addressing:

$$A(n + 1) = A(n) + ES + (EI - 1)$$

Equation 4. Double-indexed addressing:

When not at the end of a frame or transfer (that is, when the element counter $\neq 0$):

$$A(n + 1) = A(n) + ES + (EI - 1)$$

When at the end of a frame but not at the end of the transfer (that is, when the element counter = 0 and the frame counter $\neq 0$):

$$A(n + 1) = A(n) + ES + (FI - 1)$$

Calculate the element and frame index as follows:

Equation 5. Element index

$$EI = [(Stride - EI - 1) * ES] + 1$$

Equation 6. Frame index

$$FI = [(Stride - FI - 1) * ES] + 1$$

where:

$A(n)$: Byte address of the element n within the transfer.

ES is in bytes, ES{1, 2, 4}.

EI is in bytes, specified in a configuration register, 32768 EI 32767.

Stride EI: The difference in the number of elements between the start of the current element n to the start of next element, $n+1$.

Element counter: A counter that is (re)initiated with the number of elements per frame or per transfer. Decreased by 1 for each element transferred. The initial value is configured in the register DMA channel element number, [DMA4_CENi](#).

FI is in bytes, specified in a configuration register, 2147483648 FI 2147483647.

Stride FI: The difference in the number of elements between the start of the last element of the current frame and the beginning of the first element of the next frame.

Frame counter: A counter that is (re)initiated with the FN per transfer. Decreased by 1 for each frame transferred. The initial value is configured in the register DMA channel frame number, [DMA4_CFNi](#).

[Figure 16-6](#) shows how a stride EI and FI are defined. When handling complex configurations, using strides can make it easier to calculate EI and FI because you can calculate in elements instead of bytes. (This approach is used in the 90-degree clockwise image rotation example shown in [Figure 16-10](#).) The double-index addressing example shown in [Figure 16-6](#) uses ES = 4, EN = 2, EI = 5, FI = 5, and FN = 2.

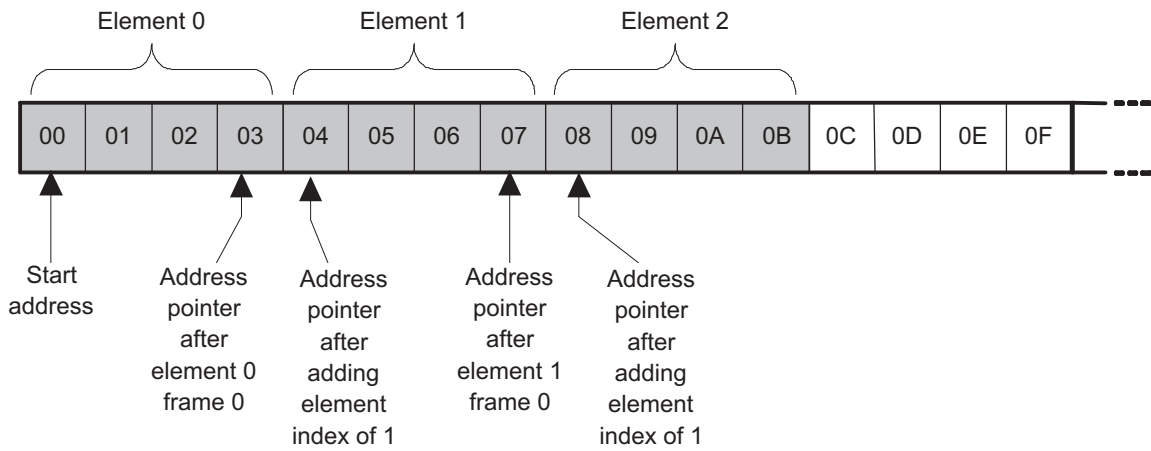

[Figure 16-6](#) through [Figure 16-9](#) show examples of addressing mode configurations. [Table 16-9](#) lists parameter values for the examples.

Figure 16-6. Example Showing Double-Index Addressing, Elements, Frames, and Strides

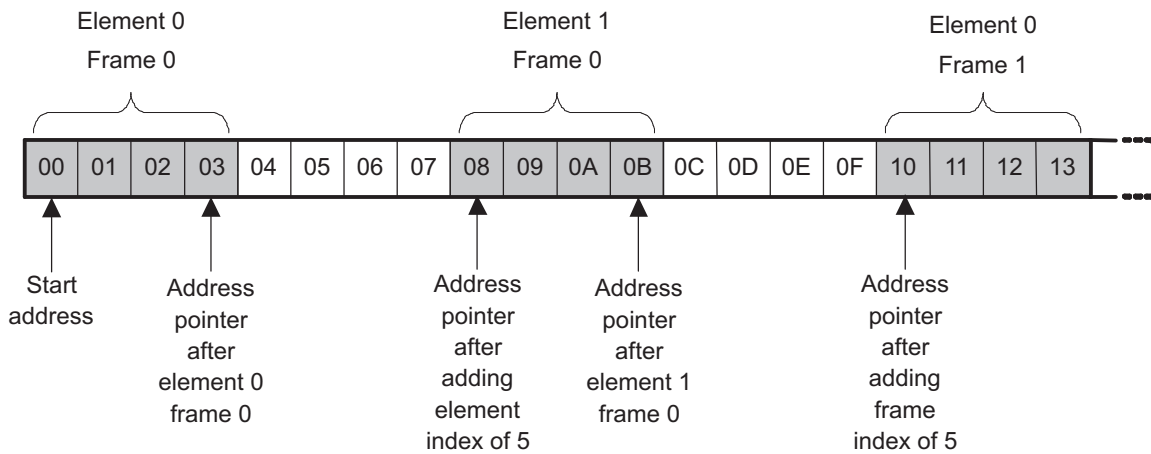

dma-011

Figure 16-7. Addressing Mode Example (a)

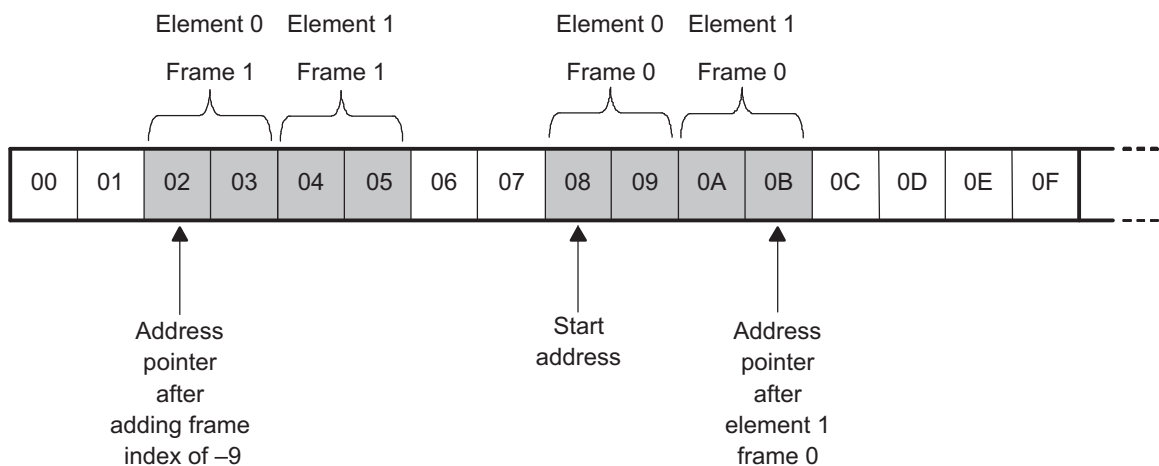

dma-010

Figure 16-8. Addressing Mode Example (b)

dma-009

Figure 16-9. Addressing Mode Example (c)

dma-008

Table 16-9. Parameter Values for Addressing Mode Examples (a), (b), and (c)

Parameter	Example (a)	Example (b)	Example (c)
Addressing mode	Single index (or post-increment)	Double index	Double index
Start address	0	0	8
ES	4 (32-bit)	4 (32-bit)	2 (16-bit)
EN	3	2	2
EI	1	5	1
FN	1	2	2
Frame index	N/A	5	-9

Double indexing can occur on source (read) or destination (write). Equations for rotation of xx degrees on destination are obtained by taking equations for rotation of $(360 - xx)$ degrees on source, and swapping the width (x) and height (y) of the image in them. The opposite is also true. Table 16-10 lists the equations for 90-, 180-, and 270-degree rotations.

Table 16-10. Equations for Rotation

		90° Rotation	180° Rotation	270° Rotation
Double indexing on destination (write)	Base address	$ES*(y-1)$	$ES*(x*y-1)$	$ES*y*(x-1)$
	EI	$ES*(y-1) + 1$	$1-2*ES$	$1-ES*(y + 1)$
	FI	$1 ES*[(x-1)*y + 2]$	$1-2*ES$	$1+ES*(x-1)*y$
Double indexing on source (read)	Base address	$ES*x*(y-1)$	$ES*(x*y-1)$	$ES*(x-1)$
	EI	$1-ES*(x + 1)$	$1-2*ES$	$ES*(x-1) + 1$
	FI	$1+ES*(y-1)*x$	$1-2*ES$	$1 ES*[(y-1)*x + 2]$

Table 16-11 and Figure 16-10 show the configuration required to perform a 90-degree clockwise rotation of a 240 x 160 pixel, 32-bit image. The EI, frame size, and FI values are configured so that the image is rotated line-by-line starting at the left end of the top line.

NOTE: The FI value for the destination is negative so that the first pixel of each subsequent line of the source image is written to the correct location at the destination.

Equation 5 and Equation 6 calculate the destination, FI and EI. The example assumes that the image lines are stored at consecutive addresses in memory, meaning that both EI and FI on the source side are 1.

Rotations:

Section 16.5.7, *90-Degree Clockwise Image Rotation*, describes how to program an example of a 90-degree clockwise image rotation.

Observe that:

- One pixel = one element
- One line = one DMA frame
- Pixel size = element size = ES

Table 16-11. Example Parameter Values for a 90-Degree Clockwise Image Rotation

Parameter	Source Value	Destination Value
Bits per pixel	32	32
ES	4	4
Image width	SW	SH
Image height	SH	SW
Stride elements (stride EI)	1 element	SH
Stride frames (stride FI)	1 element	$-(SW-1)*SH + 1 = 38,241$ elements
Start address	0x100000	$0x200000 + (SH - 1) \times ES = 0x20027C$
EN	SW	SW
EI	$[(Stride EI - 1) * ES] + 1 = 1$	$[(Stride EI - 1) * ES] + 1 = 637$
FN	SH	SH
FI	$[(Stride FI - 1) * ES] + 1 = 1$	$[(Stride FI - 1) * ES] + 1 = 152,967$

Figure 16-10. Example of a 90-Degree Clockwise Image Rotation

16.4.6 Packed Accesses

To pack data means to group data to match the bus size, thus optimizing a transfer. When the logical channel ES is less than the DMA module read/write port size, and the addressing profile supports it (post-increment mode or single- or double-index mode with EI = 1), the number of elements to transfer in each read/write port access can be maximized by specifying that the source or destination is packed through the channel DMA4_CSDPi register. Thus:

- For a read/write port size of 32 bits, the source or destination can be configured as packed for transfer

ESs of 8 bits (four elements per access) and 16 bits (two elements per access).

- For a read/write port size of 64 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (eight elements per access), 16 bits (four elements per access), and 32 bits (two elements per access).

Depending on the start address and transfer length, the first or last packed access can be only partially filled. This is indicated to the source or destination using the byte-enable signals.

16.4.7 Burst Transactions

Transfer performance can be improved so that the source or destination and addressing profile supports it. This can be achieved by configuring the logical channel to perform burst transactions consisting of multiple instead of single accesses. The channel can be programmed to use burst sizes equal to 16, 32, or 64 bytes through the [DMA4_CSDPi](#) register, with the read burst size programmable independently of the write burst size. Typically, the optimal burst size is 64 bytes (16 accesses for a 32-bit read/write port size or 8 accesses for a 64-bit read/write port size).

To obtain the maximum benefit from burst transactions, the source and destination start addresses must be aligned with the burst size. If this is not the case, the start of the transfer can consist of a number of smaller (single or burst) transactions until the first burst size boundary is reached.

Similarly, if the end of the transfer is not aligned on a burst size boundary, the final part of the transfer can consist of a number of smaller transactions.

NOTE: If post-incrementing is used, data must be packed to DMA data-port width, to use burst.

16.4.8 Endianism Conversion

The source and destination are each specified as little-endian or big-endian through the [DMA4_CSDPi](#) register for the particular logical channel. If the endianism of the source and destination differ, and if the logical channel ES is less than the SDMA module read/write port size, an endianism conversion is applied to the data before it is written to the destination.

When transferring data between a source and a destination with different endianism, it is important to specify an ES that equals the type of data being transferred to preserve the correct data image at the destination.

In the system, endianism conversion can be performed in more than one place. It is possible to instruct the source and/or destination to lock the endianism (that is, to not perform a conversion) through the logical DMA channel [DMA4_CSDPi](#) register.

NOTE: Because the device is little-endian by construction, the SDMA endianism registers must never be set to big-endian.

If SDMA is used to execute endian conversion by the setting source and destination to different endianism values, it is important to consider that the L3 interconnect also executes endian conversion if the SDMA and the source or destination have a different data bus width.

16.4.9 Transfer Synchronization

A logical channel can be programmed for software-triggered or hardware synchronized transfers.

16.4.9.1 Software Synchronization

A transfer is software-triggered when the logical channel is set up and started by software. To specify a software-triggered transfer, set the channel DMA [DMA4_CCRi\[4:0\]](#) and [DMA4_CCRi\[20:19\]](#) bit fields to 0. The transfer starts as soon as the DMA [DMA4_CCRi\[7\]](#) bit is set (when it enters the scheduling process).

16.4.9.2 Hardware Synchronization

A transfer is hardware-synchronized if the logical channel activation is driven by hardware requests from the source or destination target. A hardware-synchronized transfer is specified by configuring the DMA request line number in the channel `DMA4_CCRi` register to a value that corresponds to the DMA request line from the source or destination that generates the DMA requests. The DMA request numbers to be configured are specified in the DMA request mapping (see [Table 16-8](#)).

Specify the DMA request number in the `DMA4_CCRi[4:0]` SYNCHRO_CONTROL and `DMA4_CCRi[20:19]` SYNCHRO_CONTROL_UPPER bit fields. After the `DMA4_CCRi[7]` ENABLE bit is set, the logical channel becomes enabled but not activated (it does not enter the scheduling process), which means that channel registers are not updated until the first DMA request is received.

NOTE: The channel synchronization control registers are 1-based. For example, to enable the `S_DMA_1` request, the `DMA4_CCRi[4:0]` SYNCHRO_CONTROL bit field must be set to `0x2` (DMA request number + 1).

NOTE: A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared among several chained logical channels.

For hardware synchronization, the amount of data to be transferred for each assertion of the DMA request line is configured through the frame synchronization (FS) and block synchronization (BS) bits in the logical channel `DMA4_CCRi` register and the `DMA4_CCRi[5]` FS and `DMA4_CCRi[18]` BS bits, respectively.

The amount of data can be any of the following:

- A single element transfer: A complete element defined by data type. For example, 8/16/32 bits are transferred in response to a DMA request.
- A full frame: A complete frame of several elements is transferred in response to a DMA request.
- A full block (a full channel transfer): A complete block of several frames is transferred in response to a DMA request.
- A full packet (a full channel transfer): A complete packet of several elements is transferred in response to a DMA request.

Packets allow the size of each part of the full DMA transfer to be configured independently of the organization of the data to be transferred (typically a number of elements). This can be useful when the source or destination has a buffer (such as a FIFO queue) with a size unrelated to the frame size of the transfer. The packet size then can be set to the size of the buffer.

Packet transfer must be used only where the source or destination is addressed in constant addressing mode, because FI registers are reused to specify the packet size.

To support the burst mode, the logical channel must also be configured in target-port packed access mode.

The packet size is configured based on the `DMA4_CCRi[24]` SEL_SRC_DST_SYNC bit through either the channel `DMA4_CDFIi` register (source synchronized) or the `DMA4_CSFII` register (destination synchronized).

When the logical channel transfer block is not an exact multiple of the packet size, the final packet consists of the remaining elements in the transfer, using burst or single accesses to complete the block transfer.

The maximum transfer size, regardless of the packet size, is always as follows:

$$\text{Block_size} = \text{Number_of_Frame_in_Block} * \text{Number_of_Element_in_Frame} * \text{Element_Size}$$

- Synchronized at the source

The DMA module optimizes the transfer with respect to the number and size of burst transactions for the given source and destination addressing profiles and configured maximum burst sizes. When writing to the destination is slower than reading from the source, data is buffered in the channel FIFO queue. If the transfer is packet-synchronized at the source, the end-of-packet interrupt is disabled (see [Section 16.4.13, Reprogramming an Active Channel](#)).

For a source synchronized transfer, buffering can be enabled or disabled by setting the [DMA4_CCRi\[25\] BUFFERING_DISABLE](#) bit. For a packet source synchronization with buffering disabled and the packed/burst across the packet boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the packet transfer size. However, for a packet source synchronized transfer with buffering enabled and with the packed/burst across the packet boundary, the DMA module waits for the next DMA request(s) to read enough data to issue an atomic packed/burst write transaction (assuming that the address is packed/burst aligned).

NOTE: Buffering is not performed between frames, even if it is enabled. If the packed/burst is across the frame boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the frame transfer size.

- Synchronized at the destination

The performance of a hardware-synchronized transfer can be improved by using the prefetch mode, enabled through the channel [DMA4_CCRi\[23\] PREFETCH](#) bit. Data is prefetched on the read port side before the DMA request received and buffered in the FIFO queue. Up to a full transfer block can be prefetched, although this can be limited by the specified maximum channel FIFO queue depth (see [Section 16.4.4, FIFO Queue Memory Pool](#)).

Buffering disable is not allowed for a destination-synchronized transfer.

NOTE: Behavior is undefined when prefetch is enabled and a transfer is synchronized to the source.

Regardless of whether buffering is enabled, the last transaction in the frame or in the block is write nonposted (WNP) even if the write mode is specified as write last nonposted (WLNP; the [DMA4_CSDPi\[17:16\] WRITE_MODE](#) bit field = 0x2). However, in a packet synchronization mode, the last transaction of each packet in the transfer is WNP only if the buffering disable is on (even if the write mode is specified as WLNP).

Regardless of whether buffering is enabled, the packet interrupt is not generated in the packet source synchronized mode.

CAUTION

The [DMA4_CCRi\[25\] BUFFERING_DISABLE](#) bit must be filled with an allowed value, as specified in [Table 16-12](#).

Table 16-12. Buffering Disable

	BUFFERING_DISABLE (0: Buffering enable, 1: Buffering disable)	
Destination synchronized	0	Allowed
	1	Not allowed
Source synchronized	0	Allowed
	1	Allowed

- Synchronized transfer monitoring using CDAC ([DMA4_CDACi](#)):
Context is restored only when the channel becomes active on a DMA request (not at software enable). The channel is software-enabled first, and then a DMA request is asserted followed by the first context restore.
The CDAC register is writable; thus, the CDAC can be initialized to monitor the transfer and determine whether the transfer is started (for more information, see [Section 16.5.4, Synchronized Transfer Monitoring Using CDAC](#)).

NOTE: For 16-bit transactions, start reading from or writing to the LSByte first to enable the register update. This is not an issue for 32-bit read-write transactions.

16.4.10 Thread Budget Allocation

When several concurrent channels are latency critical and hardware synchronized, a specific latency cannot be ensured until the target is served. This situation occurs when the number of concurrent channels is greater than the number of available threads.

NOTE: Four threads are available on the read port, and two threads are available on the write port.

For a hardware-synchronized transfer (memory to peripheral), a minimum bandwidth for a latency-critical transfer must be ensured to avoid collisions between two hardware requests.

Because it is latency critical, the software user is responsible for the following:

- Programming the synchronized channel as a high-priority channel
- Reserving one or several threads for high-priority channels

The proposed implementation is as follows (see [Section 16.5.5, Concurrent Software and Hardware Synchronization](#)):

Prevent the regular channel queue from exceeding more than a programmable (3, 2, or 1) number of threads on the read port and no more than one thread on the write port. This number can be set in the global register [DMA4_GCR\[13:12\]](#).

The thread reservation is programmable for maximum use of thread resources for concurrent, low-priority channel transfer. Programmability can also allow a partial throughput control by limiting in software the number of concurrent outstanding requests that break the pipelining.

Depending on the [DMA4_GCR \[13:12\]](#) value, the following threadID on the read/write ports are allocated for a high-priority channel:

Read port priority thread reservation:

- [DMA4_GCR\[13:12\]](#) => 0x0 = No ThreadID is reserved for high-priority channels.
- [DMA4_GCR\[13:12\]](#) => 0x1 = Read ThreadID 0 is reserved for high-priority channels.
- [DMA4_GCR\[13:12\]](#) => 0x2 = Read ThreadID 0 and Read ThreadID 1 are reserved for high-priority channels.
- [DMA4_GCR\[13:12\]](#) => 0x3 = Read ThreadID 0, Read ThreadID 1, and Read ThreadID 2 are reserved for high-priority channels.

Write port priority thread reservation:

- [DMA4_GCR\[13:12\]](#) => 0x0 = No ThreadID is reserved for high-priority channels
- [DMA4_GCR\[13:12\]](#) => 0x1 = Write ThreadID 0 is reserved for high-priority channels.
- [DMA4_GCR\[13:12\]](#) => 0x2 = Write ThreadID 0 is reserved for high-priority channels.
- [DMA4_GCR\[13:12\]](#) => 0x3 = Write ThreadID 0 is reserved for high-priority channels.

Regardless of whether the enabled channels are high priority, only the setting of the [DMA4_GCR\[13:12\]](#) value forces the thread reservation to these values. Set the appropriate value to avoid losing threads using only regular channels.

To have an independent read and write priority context, a per-channel bit ([DMA4_CCRI\[26\]](#)) is added for write priority, and the previous priority bit becomes read priority bit ([DMA4_CCRI\[6\]](#)).

NOTE: The device has one priority bit per logical channel, not one priority bit per port.

16.4.11 FIFO Budget Allocation

To avoid fully occupying the FIFO with a high-priority transfer while low-priority channels wait in the arbitration queue, two separate FIFO budgets are specified: one for high-priority channels and one for low-priority channels. This is defined in the [DMA4_GCR](#) register, allowing the user to share the FIFO budget between the low- and high-priority channels. The amount of the FIFO allocated by the low- and high-priority channels is fixed by the value set in the [DMA4_GCR\[15:14\] HI_LO_FIFO_BUDGET](#) field. The maximum channel FIFO depth is limited by the [HI_LO_FIFO_BUDGET](#) field as follows:

If the channel is low priority:

- When [HI_LO_FIFO_BUDGET](#) = 0x1, then low priority cannot exceed 75 percent of the total FIFO.
- When [HI_LO_FIFO_BUDGET](#) = 0x2, then low priority cannot exceed 25 percent of the total FIFO.
- When [HI_LO_FIFO_BUDGET](#) = 0x3, then low priority cannot exceed 50 percent of the total FIFO.

If channel is high priority

- When [HI_LO_FIFO_BUDGET](#) = 0x1, then high priority cannot exceed 25 percent of the total FIFO.
- When [HI_LO_FIFO_BUDGET](#) = 0x2, then high priority cannot exceed 75 percent of the total FIFO.
- When [HI_LO_FIFO_BUDGET](#) = 0x3, then high priority cannot exceed 50 percent of the total FIFO.

The user must perform the following equation:

- For a high-priority channel: $(\text{Per_Channel_Maximum FIFO Depth} + 1) \times \text{Number of High Channel} \leq \text{High Budget FIFO}$
- For a low-priority channel: $(\text{Per_Channel_Maximum FIFO Depth} + 1) \times \text{Number of Low Channel} \leq \text{Low Budget FIFO}$

NOTE: Ensure that *Number of High Channel* means *Number of Active High-Priority Channel* and that *Number of Low Channel* means *Number of Active Low-Priority Channel*.

16.4.12 Chained Logical Channel Transfers

Chaining multiple logical channels permits transfers consisting of multiple parts to be executed without repeated software intervention. This results in better performance than the alternative of software setting up and starting each transfer separately. Each part of a chained transfer can have the data addressed in a different manner that permits the programming of a variety of complex transfers. For example:

- Interlaced video data with one logical channel configured to transfer the even lines and another logical channel configured to transfer the odd lines
- Protocol headers with a separate DMA4 channel configured to transfer each field in the header

Channels can be chained through each channel [DMA4_CLNK_CTRLi](#) register. When the transfer for the first channel completes, the next channel in the chain is enabled. The number of channels in the chain that are configured for hardware-synchronized transfers is flexible (although typically it may be all, none, or simply the first one). The DMA request line number must be set to 0 to specify that any or all of the channels in a chain are software-triggered or nonsynchronized.

The last channel in a chain can be chained to the first channel to create a continuously looping chain. The continuously looping transfer can be stopped on the fly at a specific channel by disabling the [DMA4_CLNK_CTRLi\[15\] ENABLE_LNK](#) bit. The looping transfer stops after the specified channel transfer is complete.

NOTE: A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared between several chained logical channels.

For more information about the programming model, see [Section 16.5, SDMA Basic Programming Model](#).

16.4.13 Reprogramming an Active Channel

A currently active logical DMA channel can be disabled through the `DMA4_CCRi[7]` ENABLE bit. When an ongoing transaction is complete and the read-active and write-active bits in the `DMA4_CCRi` register (`DMA4_CCRi[9]` RD_ACTIVE and `DMA4_CCRi[10]` WR_ACTIVE) are reset, the channel can be reprogrammed for a new transfer.

16.4.14 Packet Synchronization

A packet transfer notion is related to the behavior of some peripherals, which have certain buffering capability and requires to transfer the buffer content once an element number threshold is reached (a hardware DMA request is generated). To associate a frame synchronization to each DMA request is possible, but this limits the maximum transfer size. Indeed the maximum transfer size is proportional to the FIFO depth of the peripheral:

$$\text{maximum_transfer_size} = \text{peripheral_FIFO_depth} \times \text{number_of_frame_in_block}$$

The packet synchronization allows to dissociate the transfer size from the FIFO depth of the peripheral. Only Constant addressing mode is allowed on a read port or a write port if source target or destination target is packet synchronized respectively.

Example:

Consider a camera interface with a FIFO_depth of 128 words and a FIFO_element_number_threshold of 128, and a picture to transfer with a size 320 lines by 240 columns. If frame synchronization is associated with each DMA request then the maximum transfer size that can be performed is 128×2^{16} words. In this case, a frame is 128-word long, which does not fit the size of a line, and it is not possible to generate an interrupt at the end of line. However, by introducing the packet transfer notion, which is related to the peripheral FIFO behavior/structure, the maximum transfer size ($\text{maximum_transfer_size} = 2^{24} \times 2^{16}$ words) is independent of both peripheral_FIFO_depth and FIFO_element_number_threshold. This allows a long-enough transfer within one channel context and rotation operation on a large image format.

The main features of DMA Packet transfer are as follows:

- **DMA Packet_Data_Size** for each DMA Request: The Peripheral_element_number_threshold (the number of elements in a packet) shares the `DMA4_CSFl` and `DMA4_CDFli` configuration registers. If the peripheral is the source target, the addressing mode is constant, and the `DMA4_CSFl[15:0]` bit field is used to specify the packet data size in the `DMA4_CSFl` register. The user must set the `DMA4_CCRi[24]` SEL_SRC_DST_SYNC bit to 1. If the peripheral is the destination target, the addressing mode is constant, the `DMA4_CDFli[15:0]`, is used to specify the packet data size (PKT_ELNT_NBR), and the bit field [31:16] is unused. To specify the packet data size in the `DMA4_CDFli` register, the user must set the `DMA4_CCRi[24]` SEL_SRC_DST_SYNC bit to 0.

NOTE: The packet size can be a submultiple or non-submultiple of a frame size. If DMA Packet_Data_Size is aligned on the DMA channel block data size boundary, then DMA transfers the last data in the channel block boundary and stops at the block boundary for the last packet DMA Request. If the Packet_Data_size is not aligned on the block boundary, the remaining data smaller than a packet size are transferred using burst or single accesses to complete the block.

- **DMA Packet_Data_Transfer** does not affect DMA channel capabilities in term of packing and bursting. The packet synchronization mode is active when `DMA4_CCRi[5]` FS = `DMA4_CCRi[18]` BS = 1. Then:
 - If `DMA4_CCRi[24]` SEL_SRC_DST_SYNC = 0, the `DMA4_CDFli[15:0]` bit field gives the number of elements in the packet and the `DMA4_CDFli[31:16]` bit field is unused for the packet size.
 - If `DMA4_CCRi[24]` SEL_SRC_DST_SYNC = 1, the `DMA4_CSFl[15:0]` bit field gives the number of element in the packet and the `DMA4_CSFl[31:16]` bit field is unused for the packet size.

NOTE: The maximum transfer size, regardless of the packet size, is always:

$$\text{Block_size} = \text{Number_of_Frame_in_Block} \times \text{Number_of_Element_in_Frame} \times \text{Element_Size}.$$

If DMA channel packet/burst access is across the packet boundary, the DMA hardware automatically splits this packing/burst access into multiple smaller accesses that are aligned on the packet boundary. Otherwise, the DMA transfers data as a usual packing/burst access.

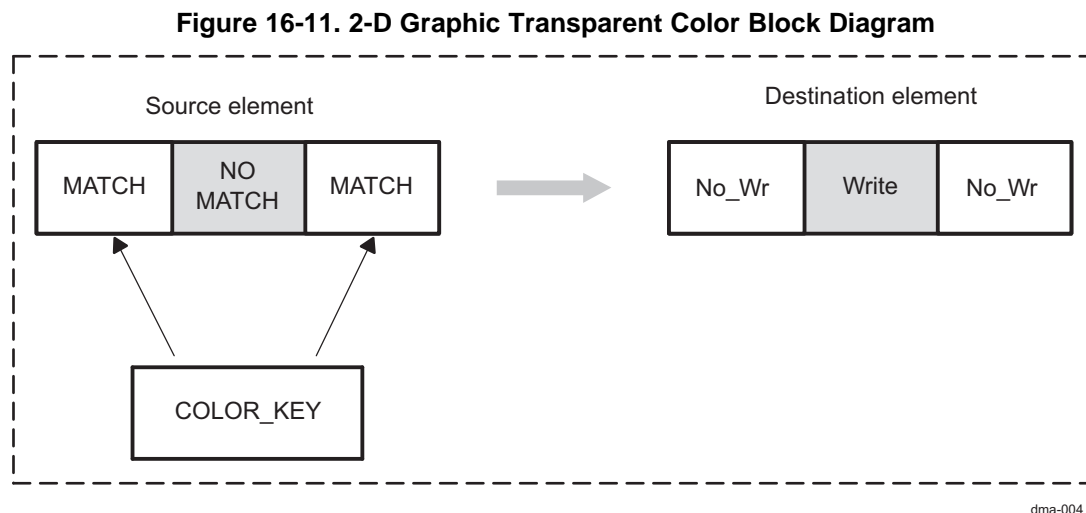

16.4.15 Graphics Acceleration Support

The SDMA supports two graphic acceleration features: transparent copy and constant fill.

Only one of these features can be enabled at a time through the [DMA4_CCRi](#) register for the particular logical DMA channel.

The transparent copy feature enables specification of a particular color through the [DMA4_COLORi](#) register so that when it is recognized in the data from the source, it is not copied to the corresponding location in the destination but instead leaves the data in the corresponding location in the destination as it is.

Figure 16-11 shows the 2-D graphic transparent color block diagram.

The constant fill feature provides the ability to specify a particular color through the [DMA4_COLORi](#) register for every specified location in the destination. In this case, the transfer consists only of writing to the destination without reading from a source.

Both features support 8, 16, and 24 bpp, depending on what is specified as the DMA transfer ES through the [DMA4_CSDPi](#) register. An ES of 32 bits corresponds to 24 bpp. During a 32-bit (24 bpp) transfer, the 8 most-significant bits (MSBs) ([31:24]) are 0. Both features are compatible with packed and burst transactions.

16.4.16 Supervisor Modes

A logical DMA channel can be configured to operate in supervisor mode through the [DMA4_CCRi](#)[22] SUPERVISOR bit. This must be done using supervisor access. Once a channel is configured in supervisor mode, the channel configuration is protected from nonsupervisor accesses. All DMA transactions on a supervisor channel are supervisor transactions.

16.4.17 Posted and Nonposted Writes

A logical channel can be configured in its [DMA4_CSDPi](#)[17:16] bits to use one of three write access handshake modes for the destination:

- Nonposted write: Each write must complete before transfer can continue or complete.

- Posted write: Transfer continues without waiting for each write to complete (may improve performance with slow devices).
- Posted with final write nonposted: Transfer continues without waiting for each write to complete, but final write completes before transfer can complete.

16.4.18 Disabling a Channel During Transfer

When a channel is disabled during a transfer, the channel undergoes an abort, unless it is hardware-source-synchronized with buffering enabled ([DMA4_CCRi\[25\] BUFFERING_DISABLE = 0](#)). If this is the case, the FIFO is drained to prevent the loss of data. For more information about this feature, see [Section 16.4.19, FIFO Draining Mechanism](#).

16.4.19 FIFO Draining Mechanism

When a source-synchronized channel is disabled during a transfer, the current hardware request (element/packet/frame/block) service completes and the channel [DMA4_CCRi\[9\] RD_ACTIVE](#) bit is set to 0, which means the channel is not active on the read port. The remaining data in the corresponding disabled channel FIFO is drained onto the write port and transferred to the programmed destination as in normal transfer.

At the end of the draining the [DMA4_CCRi\[10\] WR_ACTIVE](#) bit is set to 0 (channel is no longer active on the write port) and if the [DMA4_CICRi\[12\] DRAIN_END_IE](#) is set to 1, the [DMA4_CSRI\[12\] DRAIN_END](#) status bit is updated and an interrupt is generated.

Once a channel is disabled during a transfer, it must wait for the [DMA4_CCRi\[9\] RD_ACTIVE](#) and [DMA4_CCRi\[10\] WR_ACTIVE](#) bits to become 0 before being reenabled for a new transfer. The FIFO drain for a channel occurs only in the following cases:

- If the channel is a source synchronized channel and [DMA4_CCRi\[25\] BUFFERING_DISABLE = 0](#) and
- If the channel is not a solid fill channel and
- If the channel is not a transparent and copy channel and
- If the channel is a hardware, synchronized channel

NOTE: For a self-linked or chain-linked channel, the user must disable the [DMA4_CLNK_CTRLi\[15\] ENABLE_LINK](#) bit before disabling the channel.

In all other cases, the channel undergoes an abort.

16.4.20 Linked List

16.4.20.1 Overview

The SDMA supports the logical transfer-descriptor loader feature. A transfer descriptor represents a set of values that maps to a set of logical channel configuration registers.

A logical channel transfer descriptor can be loaded by DMA from memories, and then successive transfer descriptors can be autonomously loaded based on a linked-list scheme. This enables DMA4 scatter-gather transfers with minimum MPU support by removing successive channel configuration processing and associated interrupt handling overheads. It also optimizes DMA4 channel resources by enabling efficient transfer serialization on a single logical channel versus concurrent (multiple) logical channel use.

Different types of transfer descriptors are supported (full or partial logical channel configuration registers are set). This optimizes the memory size required for storing a long linked list, because parameter changes are limited to only a few logical channel configuration registers.

16.4.20.2 Link-List Transfer Profile

A linked-list transfer can be seen as a super-block transfer (where the block is composed of FN frames and each frame includes EN elements). The block size (FN x EN x ES) can be changed in the linked list by loading an updated transfer descriptor.

The end of the super block is signaled in the last descriptor associated with the last block. Generally, for a given link-list transfer, the logical channel is set at the beginning of the transfer and the logical channel configurations for the subsequent blocks are slightly changed. Thus, the descriptor can be limited to an update of only few parameters, such as FN or EN. This assumes that the content of unmodified registers is preserved when a new descriptor is loaded.

A transfer descriptor is composed of a set of channel configuration register values with the addition of the next-descriptor pointer register ([DMA4_CNDPi](#)) and a channel-descriptor parameter register ([DMA4_CDPi](#)). The next-descriptor pointer is the 32-bit address pointer from where the next transfer descriptor is to be loaded. The next-descriptor pointer is mapped depending on the descriptor type (1, 2, or 3).

16.4.20.3 Descriptors

A transfer descriptor is a set of values that maps to a set of logical channel configuration registers. The descriptor contains the parameters associated with a transfer profile (transfer size, source or destination addresses, etc). Four different types of transfer descriptors are supported to optimize the memory size required to store a long linked list and to minimize MPU use to create and maintain the descriptor list.

A transfer descriptor is a list of 32-bit values. A descriptor must be 32-bit aligned in memory. Only the 30 least-significant bits (LSBs) of the next-descriptor address pointer are updated from the descriptor, and the DMA4 forces the 2 LSBs to 0 on generation of the pointer address. The descriptor size is variable, depending on the descriptor type and the `Nxt_Dv` and `Nxt_Sv` bit fields.

Transfer descriptor bit mapping is the same as DMA4 logical-channel configuration register bit mapping, with the following exceptions:

- `Src_Element_index` and `Dst_Element_index` are concatenated in the same 32-bit location.
- [DMA4_CICRi](#) (interrupt event mask)
- CFN (frame number)
- Bit fields:
 - P: Corresponds to the `PAUSE_LINK_LIST` bit:
 - When set to 1 in the descriptor, the channel is suspended when the descriptor load completes.
 - The user must not set the `PAUSE_LINK_LIST` bit through the configuration port. Otherwise, behavior is undefined.
 - When set to 0 (through the configuration port) after pause, the linked-list channel resumes its transfer (descriptor load or data load).
 - B: Corresponds to the end-of-block enable bit (`BLOCK_IE`) of the [DMA4_CICRi](#) register; valid only for type 3. This value is don't care for descriptor types 1 and 2, where [DMA4_CICRi](#) is fully specified.
 - `Nxt_Dv`, `Nxt_Sv`: Mapped in the [DMA4_CDPi](#) register. They indicate one of the following possibilities:
 - Next descriptor contains an updated destination or source address.
 - Next descriptor does not update the source or destination address, but increments the last source or destination address (from the end of the last transfer).
 - The next source address and/or destination address are the last valid ones in the configuration memory. This means that the corresponding location in the configuration memory is not updated (assuming that they were initialized at least once in the past). This is also called wrapping addressing.
 - `Next_Descriptor_Type`: Specifies the next descriptor type that corresponds to the `NEXT_DESCRIPTOR_TYPE` bit field in the [DMA4_CDPi](#) register

16.4.20.4.5 Pause a Linked List

When the channel is suspended, it remains enabled.

The pause behaves differently, depending on the transfer mode:

- Normal transfer mode: If the user sets the [DMA4_CDPi\[7\] PAUSE_LINK_LIST](#) bit to 1, the channel completes the current read and write transactions and then suspends the channel. The channel can be resumed by setting the channel [DMA4_CDPi\[7\] PAUSE_LINK_LIST](#) bit to 0.
- Linked-list type 1, 2, or 3 mode: The user must not set the [DMA4_CDPi\[7\] PAUSE_LINK_LIST](#) bit through the configuration port; otherwise, transfer behavior is undefined.

A [PAUSE_LINK_LIST](#) bit (P) is set to 1 in the descriptor.

- The channel is suspended after the descriptor load, translation, and configuration memory update are complete.
- The linked list can be resumed by resetting the [DMA4_CDPi\[7\] PAUSE_LINK_LIST](#) bit (through the configuration port).

16.4.20.4.6 Stop a Linked List (Abort or Drain)

The channel can be stopped for a drain or an abort. These cases are exclusive.

16.4.20.4.6.1 Drain

- Drain conditions:

A channel is a drain candidate if it is a hardware-source-synchronized transfer with [DMA4_CCRi\[25\] BUFFERING_DISABLE](#) = 0 and should not be doing any of the graphics operation (transparent copy or solid-color fill).

- Drain trigger:

A drain candidate channel is drained if it is disabled ([DMA4_CCRi\[7\] ENABLE](#) = 0) or if it receives a transaction error on the read port.

- Drain behavior with a type 1, 2, or 3 descriptor. Drain trigger can occur in two situations:
 - During descriptor loading: Any ongoing current transaction is complete and the channel is aborted.
 - During data loading: The read is completed at the boundary of the request (element/frame/packet/block boundary), the FIFO is drained to the destination, and then a [DRAIN_END](#) interrupt can be asserted.

16.4.20.4.6.2 Abort

- Abort condition:

A channel is an abort candidate if it is software-synchronized, hardware-destination-synchronized, solid color-fill, transparent-color fill, or hardware-source-synchronized with [DMA4_CCRi\[25\] BUFFERING_DISABLE](#) = 1.

- Abort trigger:

A channel is an abort candidate if it is disabled ([DMA4_CCRi\[7\] ENABLE](#) = 0), if it receives a transaction error on the read or write port, or if there is a [MISALIGNMENT_ERROR](#).

- Abort behavior with a type 1, 2, or 3 descriptor:

If an abort trigger occurs, the channel aborts immediately after completion of current read/write transactions and then the FIFO is cleaned up.

In type 1, 2, or 3, if an abort trigger or drain trigger occurs during the descriptor load phase, the channel aborts.

16.4.20.4.7 Status Bit Behavior

This section describes the behavior of the [DMA4_CSRi\[6\] SYNC](#), [DMA4_CCRi\[9\] RD_ACTIVE](#) and [DMA4_CCRi\[10\] WR_ACTIVE](#) status bits:

- For a hardware-synchronized channel in linked-list mode, the [DMA4_CSRi\[6\] SYNC](#) bit becomes active ([DMA4_CSRi\[6\] SYNC](#) = 1) when the first data load transaction is scheduled and remains active

until the last data load transaction in the block (not super block) is descheduled (`DMA4_CSRI[6] SYNC = 0`). The SYNC bit is not active during the descriptor load phase.

- The `DMA4_CCRi[9] RD_ACTIVE` bit is active during the data load phase and the descriptor load phase. It becomes active when the first read transaction is scheduled. It becomes inactive:
 - When (during the descriptor load phase) the last descriptor write request is descheduled
 - When (during the data load phase) the last read transaction in the block (not super block) is descheduled for software-synchronized transfer or destination-synchronized transfer with prefetch enabled
 - When (during the data load phase) the last read transaction in the request (element/frame/packet/block sync) is descheduled for hardware-source-synchronized transfer or hardware-destination-synchronized transfer without prefetch
- The `DMA4_CCRi[10] WR_ACTIVE` bit is active only during the data load phase. It becomes active when the first write transaction is scheduled and becomes inactive:
 - Until the last write transaction in the block (not super block) is descheduled and the FIFO is cleaned up for software-synchronized transfer
 - Until the last write transaction in the request (element/frame/packet/block sync) is descheduled and the FIFO is cleaned up for hardware-source-synchronized transfer (with `DMA4_CCRi[25] BUFFERING_DISABLE = 0`) or hardware-destination-synchronized transfer.

16.4.20.4.8 *Linked-List Channel Linking*

Channel linking for inter- and intra-super blocks is supported for type 1, 2, and 3 descriptors.

Assume that CHx and CHz are linked-list channels using generic descriptors. If CHx is composed of N descriptors and CHz is composed of M descriptors, then in nonfast mode:

CHx: CHx[Data1]-> CHx[DES1] -> . -> CHx[DESN]->CHx[DataN + 1]

CHz: CHz[Data1]-> CHz[DES1] -> . -> CHz[DESM]->CHz[DataM + 1]

It is possible to link CHx to CHz or CHx to itself after the completion of the CHx transfer (end of super block). To do this, the user must set the `DMA4_CLNK_CTRLi[15] ENABLE_LNK` bit to 1 and the `DMA4_CLNK_CTRLi[4:0] NEXTLCH_ID` bit to z (or to x for self linking) through the last descriptor using a type 1 descriptor. The sequence is:

CHx: CHx[Data1]-> CHx[DES1] -> . -> CHx[DESN]->CHx[DataN+1] -> CHz: CHz[Data1]-> CHz[DES1] -> . -> CHz[DESM]->CHz[DataM+1]

It is also possible to link CHx to CHz during the CHx transfer and before the end of super block. The user must set the `DMA4_CLNK_CTRLi[15] ENABLE_LNK` bit to 1 and the `DMA4_CLNK_CTRLi[4:0] NEXTLCH_ID` bit to z through descriptor p (CHx[DESp]) using a type 1 descriptor. The sequence is:

CHx: CHx[Data1]-> CHx[DES1] ->. -> CHx[DESp]->CHx[Data(p + 1)] -> CHz[Data1]-> CHz[DES1] -> .

The user must continue the linking until channels CHx and CHz complete their super-block transfers; otherwise, the channels remain enabled.

NOTE: In channel linking, the head of a chain can be in fast mode or nonfast mode. All channels that are not in the head of the chain can be in nonfast mode only. In self-linking, the channel cannot be in fast mode.

NOTE: If channel CHx links to CHz in the middle of the superblock transfer (remember link bit can be set through Type-1 descriptor load), CHx is disabled after the corresponding data load and enables the channel CHz.

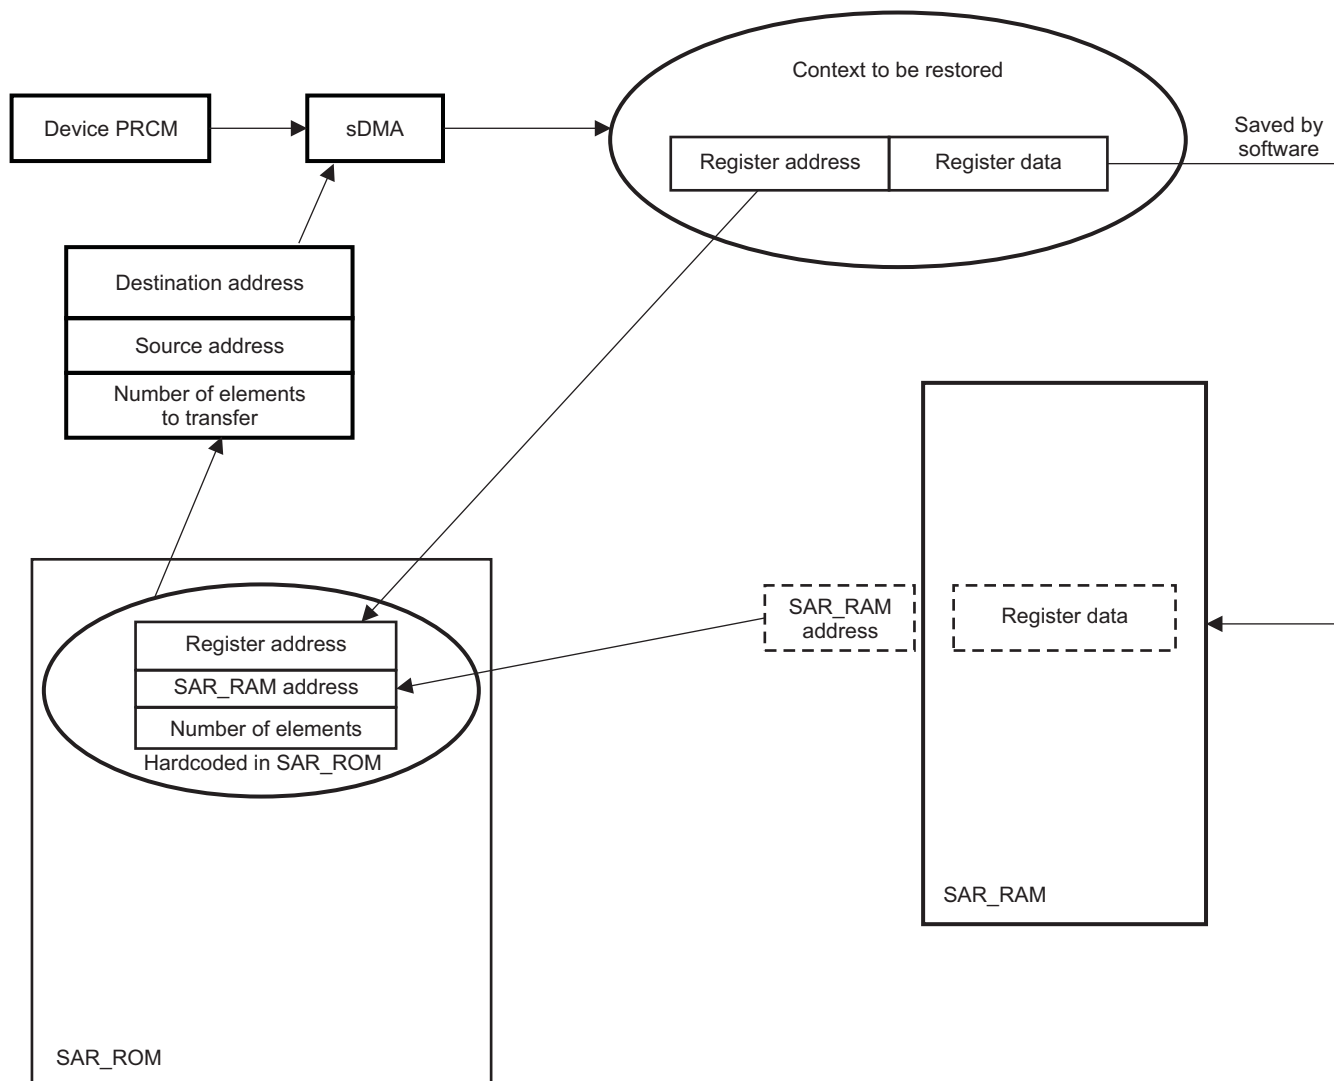

16.4.21 Auto-Restore Feature

The auto-restore feature is introduced mainly to accelerate the restore process, which otherwise is complex and time and resource consuming. In many system applications, it is required that the modem wake up and use only a few modules to wake up, without the intervention of the main MPU (Cortex-A9 MPU). The MPU still may be in off mode; however, some modules may need to come out of off mode. The SDMA can be used to restore the register contents of these modules. The auto-restore feature consists in saving the register data into a memory (SAR RAM in the WKUP domain) that remains powered even during off mode, and then in automatically retrieving data when returning from off mode.

The restore feature is enabled by default and cannot be disabled.

Figure 16-12 is an overview of the save-and-restore mechanism using SAR RAM and SAR ROM.

Figure 16-12. Overview of Save-and-Restore Mechanism Using SAR RAM and SAR ROM

dma-014

16.4.21.1 Save Process

The save process is done entirely by software; the SDMA module normally is not involved. Software must save the data to be restored in a dedicated location in SAR RAM. To reduce the save sequence execution time, the SDMA can be used with linked-list descriptors. These save descriptors are symmetrical with regards to descriptors in the SAR ROM.

The register content to be saved can be the register value before going into off mode or a value that is required on wake up. This means that the restored register value can differ from the last value of the register before going into off mode.

The following registers are affected:

- CM1 and CM2 configuration
Bits 0 of the CM_SHADOW_FREQ_CONFIG1 register and the CM_SHADOW_FREQ_CONFIG2 register are self-clearing and must be set at restore time. Thus, these data must always be overwritten in the SAR RAM.
- Because USBHOSTHS and USBTLL restore requires a particular sequencing, software must overwrite data read from the following registers implied in phase2a and phase 2b:
 - CM_L3INIT_HSUSBHOST_CLKCTRL_RESTORE
 - CM_L3INIT_HSUSBTLL_CLKCTRL_RESTORE
 - CM_SDMA_STATICDEP_RESTORE

The USBHOSTHS and USBTLL modules must be put in a particular mode when saving (and restoring) their context. In the case of context saving, software must:

- Configure the L3INIT clock domain to SW_WKUP to ensure module transitions
- Disable both modules
- Assert the SAR_MODE pins
- Enable back both modules. Optional clocks must be kept gated
- Save both modules context
- Disable both modules
- Deassert SAR_MODE pins
- At this point, software may enable back both modules and get the L3INIT clock domain out from SW_WKUP state.

16.4.21.2 Restore Process

As explained earlier, every time modem wakes up, the MPU must not necessarily wake up. This needs an automated way of restore. For example, when mobile is in roaming, and not in active use, it needs to change base stations. For this task, the MPU need not wake up, only a few peripherals/subsystems need to be in ON mode. Before executing any task, we need to restore their register contents.

16.4.21.2.1 PRCM and SDMA interaction During Restore Phase

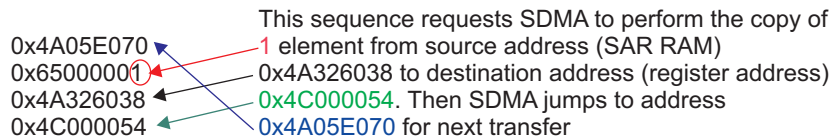

Restore is performed during three phases. At the end of each phase, the SDMA stops and waits for the PRCM to perform the next phase transfer. For more information, see [Section 3.9.3.2, Device Off Mode Wake-Up Sequences](#), in [Chapter 3, Power, Reset, and Clock Management](#).

16.4.21.2.2 SDMA Descriptors Description

The restore phase is done automatically by the SDMA. The SDMA gets the register address (destination address), number of elements to transfer, and the address of the data to transfer (Source address) from SAR ROM. As mentioned previously, the register data is stored in the SAR RAM.

The SAR ROM contains two types of descriptors the DMA-4 should use:

- Type-1 descriptors:
Type-1 descriptors (48 bytes) are used at the beginning of each phase. In addition to the source and destination address and number of elements, these descriptors contain the required data that initializes the SDMA. [Table 16-13](#) shows the Type-1 descriptor structure.
- Type-3 descriptors with source and destination address update:
Type-3 descriptors (16 bytes) are used for subsequent SDMA transfers and mainly contain the source and destination address and number of elements. [Table 16-16](#) shows the Type-3 descriptor structure. [Figure 16-13](#) is an example of SAR ROM code (Type-3 descriptor).

Figure 16-13. Type-3 SAR ROM Code Example

dma-015

Figure 16-14 is an example of last DMA transfer (Type-3 descriptor). To indicate to the DMA that this is the last transfer, the next descriptor address must be set to 0xFFFFFFF0, as shown in the figure.

Figure 16-14. Type-3 SAR ROM Last Transfer Example

dma-016

16.4.21.3 SAR RAM

The SAR RAM contains the data that needs to be maintained during off mode. The SAR RAM is split into three banks (see Table 16-18).

Table 16-18. SAR RAM Allocation

Access Mode	Bank	Address Range
Public	1 (SAR_RAM_1)	0x4A32_6000–0x4A32_6FFF (4KB)
Public, for I/O pad	2 (SAR_RAM_2)	0x4A32_7000–0x4A32_73FF (1KB)
Public	3 (SAR_RAM_3)	0x4A32_8000–0x4A32_87FF (2KB)

16.4.21.4 SAR ROM

The SAR ROM contains the list of registers that need to be saved before off mode and then restored after off mode, and where the register data is stored in SAR RAM. The SAR ROM start address is 0x4A05_E000.

When exiting off mode, PRCM automatically redirects the SDMA to address:

- 0x4A05_E000 for phase 1 (in SAR ROM)
- 0x4A05_E030 for phase 2a (in SAR ROM)
- 0x4A05_E060 for phase 2b (in SAR ROM)

The SAR ROM is built so that SDMA performs all the transfers for each phase. At the end of each phase, the SDMA stops. The PRCM module then requests to perform the next phase transfer, depending on the wake-up source.

Remarks:

- Phase 1 is always to happen; the restore mechanism is enabled by default and cannot be disabled.
- Phase 2 (2a and 2b) is to happen depending on the wake-up source from off mode. Therefore, it is mandatory to fill the SAR RAM locations used for USB restore correctly, even if USB is not used, because the restore sequence will happen.
- The USB host restore is to be performed before the USB TLL restore.

NOTE: Some consecutive address registers cannot be saved/restored with burst. This is the case for:

- CLK1_DSS_BW_REGULATOR.L3_BW_R_BANDWIDTH and CLK1_DSS_BW_REGULATOR.L3_BW_R_WATERMARK registers
- CLK2_XXX_BW_REGULATOR.L3_BW_R_BANDWIDTH and CLK2_XXX_BW_REGULATOR.L3_BW_R_WATERMARK registers, where XXX = ISS, IVAHD, and SGX.

To avoid the failure of an SDMA transfer, the transfer of the previous registers is performed using a single SDMA transfer.

16.4.21.5 SAR RAM Memory Allocation Reserved for Save and Restore

The memory size of the SAR RAM reserved for the save-and-restore mechanism is:

- 57 percent (2344 bytes) reserved for the SAR mechanism from SAR_RAM_1. The whole SAR_RAM_1 size is 4KB.
- 40 percent (408 bytes) reserved for the SAR mechanism from SAR_RAM_2. The whole SAR_RAM_2 size is 1KB.
- 51 percent (1052 bytes) reserved for the SAR mechanism from SAR_RAM_3. The whole SAR_RAM_3 size is 2KB.

The free part of the SAR RAM can be used by the user software to store any data that needs to be in always-on memory.

16.4.21.6 Register Mapping in SAR RAM

Table 16-19 describes the SAR_RAM_1 memory mapping.

Table 16-19. SAR_RAM_1 Memory Mapping

16.5 SDMA Basic Programming Model

16.5.1 Setup Configuration

After a hardware reset, program all fields in the logical channel registers to default values for any channels used, because most fields are undefined following reset.

Before programming any DMA transfers, the priority arbitration rate and the maximum FIFO depth must be configured through the [DMA4_GCR](#) register, and any required interrupts must be enabled through the [DMA4_IRQENABLE_Lj](#) registers and the logical channel [DMA4_CICRi](#) registers.

Software clears the [DMA4_CSRi](#) register and the IRQSTATUS bit for the different interrupt lines before enabling the channel.

16.5.2 Software-Triggered (Nonsynchronized) Transfer

To program a software-triggered DMA transfer:

1. Configure the transfer parameters in the logical DMA channel registers:

- [DMA4_CSDPi](#):
 - Transfer ES (8, 16, or 32 bits) in the DMA [DMA4_CSDPi\[1:0\]](#) bit field.
 - Read and write port access types (single/burst), DMA [DMA4_CSDPi\[8:7\]](#) and [DMA4_CSDPi\[15:14\]](#) bit fields
 - Source and destination endianness, DMA [DMA4_CSDPi\[21\]](#) and [DMA4_CSDPi\[19\]](#) bits
 - Write mode (posted or nonposted) and DMA [DMA4_CSDPi\[17:16\]](#) bit field
 - Source or destination packed or nonpacked (if the ES is less than the read/write port size), DMA [DMA4_CSDPi\[6\]](#) and [DMA4_CSDPi\[13\]](#) bits
- [DMA4_CENi](#): EN
- [DMA4_CFNi](#): FN per transfer block
- [DMA4_CSSAi](#) and [DMA4_CDSAi](#): Source and destination start address (aligned with transfer ES)
- [DMA4_CCRi](#):
 - Read and write port addressing modes, DMA [DMA4_CCRi\[13:12\]](#) and [DMA4_CCRi\[15:14\]](#) bit field
 - Priority bit for both read and write ports, DMA [DMA4_CCRi\[6\]](#) and [DMA4_CCRi\[26\]](#) bits
 - DMA request number (set to 0 for a software-triggered transfer) and DMA register bit fields [DMA4_CCRi\[4:0\] = 0](#) and [DMA4_CCRi\[20:19\] = 0](#)
- [DMA4_CSEIi](#), [DMA4_CSFli](#), [DMA4_CDEIi](#), and [DMA4_CDFli](#): Source and destination element and frame indexes (depending on addressing mode)

2. Start the transfer through the enable bit in the channel [DMA4_CCRi](#) register and DMA [DMA4_CCRi\[7\]](#) bit

The following example performs a DMA transfer on channel 10 of a 240*160 picture from RAM to RAM (0x80C00000 to 0x80F00000):

```
UWORD32 RegVal = 0;
DMA4_t *DMA4;
DMA4 = (DMA4_t *)malloc(sizeof(DMA4_t));

/* Init. parameters */
DMA4->DataType = 0x2; //DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0; //DMA4_CSDPi[8:7]
DMA4->WritePortAccessType = 0; //DMA4_CSDPi[15:14]
DMA4->SourceEndiansim = 0; //DMA4_CSDPi[21]
DMA4->DestinationEndianness = 0; //DMA4_CSDPi[19]
DMA4->WriteMode = 0; //DMA4_CSDPi[17:16]
DMA4->SourcePacked = 0; //DMA4_CSDPi[6]
DMA4->DestinationPacked = 0; //DMA4_CSDPi[13]
DMA4->NumberOfElementPerFrame = 240; //DMA4_CENi
DMA4->NumberOfFramePerTransferBlock = 160; //DMA4_CFNi
```

```

DMA4->SourceStartAddress = 0x80C00000; //DMA4_CSSAi
DMA4->DestinationStartAddress = 0x80F00000; //DMA4_CDSAi
DMA4->SourceElementIndex = 1; //DMA4_CSEIi
DMA4->SourceFrameIndex = 1; //DMA4_CSFii
DMA4->DestinationElementIndex = 1; //DMA4_CDEIi
DMA4->DestinationFrameIndex = 1; //DMA4_CDFii
DMA4->ReadPortAccessMode = 1; //DMA4_CCRi[13:12]
DMA4->WritePortAccessMode = 1; //DMA4_CCRi[15:14]
DMA4->ReadPriority = 0; //DMA4_CCRi[6]
DMA4->WritePriority = 0; //DMA4_CCRi[23]
DMA4->ReadRequestNumber = 0; //DMA4_CCRi[4:0]
DMA4->WriteRequestNumber = 0; //DMA4_CCRi[20:19]

/* 1) Configure the transfer
   parameters in the logical DMA registers
   */
/*-----*/

/*
   a) Set the data type CSDP[1:0], the Read/Write Port access type

   CCR[6]/CCR[26], the current LCH CCR[20:19]=00 and CCR[4:0]=00000*/

// Read CCR
RegVal = DMA4_CCR_CH10;

```

```

//
    Build reg
RegVal = ((RegVal & ~(0x3 << 12)) | (DMA4->ReadPortAccessMode << 12));
RegVal = ((RegVal & ~(0x3 << 14)) | (DMA4->WritePortAccessMode << 14));
RegVal = ((RegVal & ~(0x1 << 6)) | (DMA4->ReadPriority << 6));

RegVal = ((RegVal & ~(0x1 << 26)) | (DMA4->WritePriority << 26));

RegVal &= 0xFFCFFFE0 ;

// Write CCR
DMA4_CCR_CH10 = RegVal;

/* f)- Set the source element index CSEI[15:0]*/

DMA4_CSEI_CH10 = DMA4->SourceElementIndex;

/* g)-
    Set the source frame index CSFI[15:0]*/

DMA4_CSFI_CH10 = DMA4->SourceFrameIndex ;

/* h)- Set the destination element
    index CDEI[15:0]*/

DMA4_CDEI_CH10 = DMA4->DestinationElementIndex;

/* i)- Set the destination
    frame index CDFI[31:0]*/

DMA4_CDFI_CH10 = DMA4->DestinationFrameIndex;

/* 2) Start the DMA transfer by
    Setting the enable bit CCR[7]=1 */

/*-----*/

//write enable bit
DMA4_CCR_CH10 |= 1 << 7; /* start */

```

16.5.3 Hardware-Synchronized Transfer

To monitor a hardware synchronized DMA transfer, initialize the [DMA4_CDACi](#) register before the software enable.

To configure an LCh to synchronize by element, packet, frame, or block, the frame synchronization [DMA4_CCRi\[5\]](#) FS bit and the block synchronization [DMA4_CCRi\[18\]](#) BS bit must be programmed. For all the following synchronized transfers (element, packet, and frame or block-synchronized transfers), the user must first set the [DMA4_CCRi\[24\]](#) SEL_SRC_DST_SYNC bit to 1 when the source triggers on the DMA request and set it the [DMA4_CCRi\[24\]](#) SEL_SRC_DST_SYNC bit to 0 when the destination triggers on the DMA request.

NOTE: The user must take care when setting the [DMA4_CCRi\[23\]](#) PREFETCH bit it is in conjunction with [DMA4_CCRi\[24\]](#) SEL_SRC_DST_SYNC bit.

- To configure an LCh to transfer one element per DMA request:
 1. Set the number of DMA request associated with the current LCH in the [DMA4_CCRi\[20:19\]](#) SYNCHRO_CONTROL_UPPER and [DMA4_CCRi\[4:0\]](#) SYNCHRO bit field.
 2. Set the data type, also referenced as element size (ES), in the [DMA4_CSDPi\[1:0\]](#) DATA_TYPE bit field.

3. Set the Read Port access type (single or burst access) in the [DMA4_CSDPi\[8:7\]](#) SRC_BURST_EN bit field.
 4. Set the Write Port access type (single or burst access) in the [DMA4_CSDPi\[15:14\]](#) DST_BURST_EN bit field.
 5. Set the Read Port addressing mode in the [DMA4_CCRi\[13:12\]](#) SRC_AMODE bit field.
 6. Set the Write Port addressing mode in the [DMA4_CCRi\[15:14\]](#) DST_AMODE bit field.
 7. Set the Read start address in the [DMA4_CSSAi\[31:0\]](#) SRC_START_ADRS bit field.
 8. Set the Write start address in the [DMA4_CDSAi\[31:0\]](#) DST_START_ADRS bit field.
 9. Set both FS and BS to 0 in [DMA4_CCRi\[5\]](#) FS and [DMA4_CCRi\[18\]](#) BS.
 10. Set to 1 the channel enable bit [DMA4_CCRi\[7\]](#) EN.
- To configure an LCh to transfer one frame per DMA request:
 1. Set the number of DMA request associated to the current LCH in the [DMA4_CCRi\[20:19\]](#) SYNCHRO_CONTROL_UPPER and [DMA4_CCRi\[4:0\]](#) SYNCHRO bit field.
 2. Set the data type, also referenced as element size (ES), in the [DMA4_CSDPi\[1:0\]](#) DATA_TYPE bit field.
 3. Set the number of element per frame in the [DMA4_CENi\[23:0\]](#) CHANNEL_ELMNT_NBR bit field.
 4. Set the Read Port access type (single or burst access) in the [DMA4_CSDPi\[8:7\]](#) SRC_BURST_EN bit field.
 5. Set the Write Port access type (single or burst access) in the [DMA4_CSDPi\[15:14\]](#) DST_BURST_EN bit field.
 6. Set the Read Port addressing mode in the [DMA4_CCRi\[13:12\]](#) SRC_AMODE bit field.
 7. Set the Write Port addressing mode in the [DMA4_CCRi\[15:14\]](#) DST_AMODE bit field.
 8. Set the Read start address in the [DMA4_CSSAi\[31:0\]](#) SRC_START_ADRS bit field.
 9. Set the Write start address in the [DMA4_CDSAi\[31:0\]](#) DST_START_ADRS bit field.
 10. Set FS to 1 and BS to 0, respectively, in [DMA4_CCRi\[5\]](#) FS and [DMA4_CCRi\[18\]](#) BS.
 11. Set to 1 the channel enable bit [DMA4_CCRi\[7\]](#) EN.
 - To configure an LCh to transfer one block per DMA request:
 1. Set the number of DMA request associated to the current LCH in the [DMA4_CCRi\[20:19\]](#) SYNCHRO_CONTROL_UPPER and [DMA4_CCRi\[4:0\]](#) SYNCHRO bit field.
 2. Set the data type, also referenced as element size (ES), in the [DMA4_CSDPi\[1:0\]](#) DATA_TYPE bit field.
 3. Set the number of element per frame in the [DMA4_CENi\[23:0\]](#) CHANNEL_ELMNT_NBR bit field.
 4. Set in the [DMA4_CFNi\[15:0\]](#) CHANNEL_FRAME_NBR bit field the number of frame (transfers), to take place before the LCH gets disabled.
 5. Set the Read Port access type (single or burst access) in the [DMA4_CSDPi\[8:7\]](#) SRC_BURST_EN bit field.
 6. Set the Write Port access type (single or burst access) in the [DMA4_CSDPi\[15:14\]](#) DST_BURST_EN bit field.
 7. Set the Read Port addressing mode in the [DMA4_CCRi\[13:12\]](#) SRC_AMODE bit field.
 8. Set the Write Port addressing mode in the [DMA4_CCRi\[15:14\]](#) DST_AMODE bit field.
 9. Set the Read start address in the [DMA4_CSSAi\[31:0\]](#) SRC_START_ADRS bit field.
 10. Set the Write start address in the [DMA4_CDSAi\[31:0\]](#) DST_START_ADRS bit field.
 11. Set FS to 0 and BS to 1, respectively, in [DMA4_CCRi\[5\]](#) FS and [DMA4_CCRi\[18\]](#) BS.
 12. Set to 1 the channel enable bit [DMA4_CCRi\[7\]](#) EN.
 - To configure an LCh to transfer one packet per DMA request:
 1. Set the number of DMA request associated to the current LCH in the [DMA4_CCRi\[20:19\]](#) SYNCHRO_CONTROL_UPPER and [DMA4_CCRi\[4:0\]](#) SYNCHRO bit field.
 2. Set the data type, also referenced as element size (ES), in the [DMA4_CSDPi\[1:0\]](#) DATA_TYPE bit field.

3. Set the number of elements per packet to transfer: If the packet requestor is in the source, set [DMA4_CCRi](#) [24] SEL_SRC_DST_SYNC to 1 and set the packet element number in the [DMA4_CSFli](#) register and set the addressing mode of source to constant addressing in [DMA4_CCRi](#)[13:12] SRC_AMODE bit field; else, if the packet requestor is in the destination, set the [DMA4_CCRi](#)[24] SEL_SRC_DST_SYNC to 0 and set the packet element number in the [DMA4_CDFli](#) register and set the addressing mode of destination to constant addressing in [DMA4_CCRi](#)[15:14] DST_AMODE bit field.
4. Set the number of elements per frame in the [DMA4_CENi](#)[23:0] CHANNEL_ELMNT_NBR bit field.
5. Set in the [DMA4_CFNi](#)[15:0] CHANNEL_FRAME_NBR bit field the number of frames (transfers), to take place before the LCH gets disabled.
6. Set the element number in the packet in the [DMA4_CSFli](#)[15:0] PKT_ELNT_NBR, if constant addressing or post-incremented addressing modes are used in the source side. However, the number of element in the packet is set in the [DMA4_CDFli](#)[15:0] PKT_ELNT_NBR if constant addressing mode is used in the destination side.
7. Set the Read Port access type (single or burst access) in the [DMA4_CSDPi](#)[8:7] SRC_BURST_EN bit field.
8. Set the Write Port access type (single or burst access) in the [DMA4_CSDPi](#)[15:14] DST_BURST_EN bit field.
9. Set the Read Port addressing mode in the [DMA4_CCRi](#)[13:12] SRC_AMODE bit field.
10. Set the Write Port addressing mode in the [DMA4_CCRi](#)[15:14] DST_AMODE bit field.
11. Set the Read start address in the [DMA4_CSSAi](#)[31:0] SRC_START_ADRS bit field.
12. Set the Write start address in the [DMA4_CDSAi](#)[31:0] DST_START_ADRS bit field.
13. Set FS to 1 and BS to 1, respectively, in [DMA4_CCRi](#)[5] FS and [DMA4_CCRi](#)[18] BS.
14. Set to 1 the channel enable bit [DMA4_CCRi](#)[7] EN.

NOTE: It is possible to stop a transfer by disabling the channel by resetting the [DMA4_CCRi](#)[7] ENABLE bit.

16.5.4 Synchronized Transfer Monitoring Using CDAC

The [DMA4_CDACi](#) register is writable and non-initialized (value undefined). It can be initialized to monitor a transfer by applying the following programming model:

1. Write 0 in the [DMA4_CDACi](#) register.
2. Enable the channel.
3. If a time-out occurs, read [DMA4_CDACi](#) register.
4. If [DMA4_CDACi](#) != 0 (it is the value configured in [DMA4_CDACi](#)):

This indicates that the corresponding transfer has started. The user can then rely on [DMA4_CCENi](#) and [DMA4_CCFNi](#) element and frame counters.

Otherwise, if [DMA4_CDACi](#) = 0 (it is the value configured in the [DMA4_CDACi](#)):

This indicates that the corresponding transfer did not start.

16.5.5 Concurrent Software and Hardware Synchronization

This section describes thread allocation only; it does not describe the entire transfer. Because synchronized transfers are latency critical, you must allocate a thread at least on the synchronized target side.

Even for multiple concurrent channels, thread reservation ensures that when a hardware DMA request arrives, the read/write scheduler finds available thread(s) to initiate a channel schedule and issue a read/write transaction.

Consider six concurrent channels:

- Channels 0, 1, 2, and 3 are dedicated to memory-memory transfer; they are software triggered and not synchronized.

- Channel 4 is dedicated to memory-peripheral transfer, hardware triggered, and synchronized on the write side.
- Channel 5 is dedicated to peripheral-memory transfer, hardware triggered, and synchronized on the read side.

To perform thread reservation:

1. Allow thread reservation for priority channel 4 and channel 5:
Reserve one thread (Read ThreadID 0) on the read port and one thread (Write ThreadID 0) on the write port: set the `DMA4_GCR[13:12]` `HI_THREAD_RESERVED` bit field to 0x1.
2. Specify channel priority:
Channel 4 is a write high priority channel: set `DMA4_CCRi[26]` `WRITE_PRIORITY` = 1.
Channel 5 is a read high priority channel: set `DMA4_CCRi[6]` `READ_PRIORITY` = 1.

16.5.6 Chained Transfer

A chained DMA transfer can be programmed as follows:

1. Configure the transfer parameters for each logical DMA channel in the chain as in step 1 for either the synchronized or non-synchronized transfers describe in [Section 16.5.5, Concurrent Software and Hardware Synchronization](#).
2. For each channel in the chain, configure the `DMA4_CLNK_CTRLi` register as follows:
 - Next logical DMA channel number (for a looping chained transfer link last channel to first channel number), in the `DMA4_CLNK_CTRLi[4:0]` `NEXTLCH_ID` bit field.
 - Include the logical channel to the chain and enable link by setting the `DMA4_CLNK_CTRLi[15]` `ENABLE_LNK` bit.
 - For a non-looping chain, the last logical channel in the chain must have the `DMA4_CLNK_CTRLi[15]` `ENABLE_LNK` bit set to 0 to indicate the end of the chain.
3. Enable the transfer through the enable bit in the first logical channel `DMA4_CCRi[7]` `ENABLE` bit. All other channels in the chain must be disabled. Each channel is enabled automatically in turn when the previous logical channel transfer completes. A non-synchronized transfer starts immediately; a hardware-synchronized transfer starts when the DMA request line corresponding to the first DMA channel in the chain is asserted.

To stop a looping chained transfer, disable the `DMA4_CLNK_CTRLi[15]` `ENABLE_LNK` bit (by setting it to 0x0), of the final channel transfer.

In the RAM-to-RAM copy example, to copy in loop, it is possible to link channel 10 on itself. The following line can be added in the channel configuration:

```
/* g) Set link for loop */
DMA4_CLNK_CTRL_CH10 =
    0x0000800A;
```

16.5.7 90-Degree Clockwise Image Rotation

The 90-degree clockwise image rotation example described in [Section 16.4.5, Addressing Modes](#), can be programmed as follows:

1. Configure the transfer parameters in the logical DMA channel registers:
 - `DMA4_CSDPi`:
 - Transfer ES = 32-bit (32 bpp), `DMA4_CSDPi[1:0]` `DATA_TYPE` bit field
 - Read and write port access types = maximum burst size supported by memory device, `DMA4_CSDPi[8:7]` `SRC_BURST_EN` and `DMA4_CSDPi[15:14]` `DST_BURST_EN` bit fields
 - Source and destination endianness, `DMA4_CSDPi[21]` `SRC_ENDIAN` and `DMA4_CSDPi[19]` `DST_ENDIAN` bits
 - Write mode = posted with last element nonposted, `DMA4_CSDPi[17:16]` `WRITE_MODE` bit field
 - Source and destination packed = Yes (although destination writes do not benefit because E11),

DMA4_CSDPi[6] SRC_PACKED and **DMA4_CSDPi[13] DST_PACKED** bits

- **DMA4_CENi**: EN = 240
- **DMA4_CFNi**: FN per transfer block = 160
- **DMA4_CSSAi**: Source start address = 0x100000
- **DMA4_CDSAi**: destination start address = 0x20013E
- **DMA4_CCRi**:
 - Read and write port addressing modes = double-index addressing mode for both or post-increment addressing on source and double-index addressing on destination, **DMA4_CCRi[13:12] SRC_AMODE** and **DMA4_CCRi[15:14] DST_AMODE** bit fields
 - Low or high priority, **DMA4_CCRi[6] READ_PRIORITY** bit
 - DMA request number = 0 (for software-triggered transfer), **DMA4_CCRi[4:0] SYNCHRO_CONTROL** and **DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER** bit fields
- **DMA4_CSEIi**: Source EI = 1
- **DMA4_CSFII**: Source frame index = 1
- **DMA4_CDEIi**: destination EI = 637
- **DMA4_CDFIi**: destination frame index = 152967

2. Start the transfer through the enable bit in the channel **DMA4_CCRi** register.

The following parameters are used to perform this rotation from 0x80C00000 RAM address to 0x80F00000, with the same code used in [Section 16.5.2, Software-Triggered \(Nonsynchronized\) Transfer](#):

```

/* Init. parameters */
DMA4->DataType = 0x2; //
    DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0x3; // DMA4_CSDPi[8:7]

DMA4->WritePortAccessType = 0x3; // DMA4_CSDPi[15:14]

DMA4->SourceEndiansim = 0; // DMA4_CSDPi[21]

DMA4->DestinationEndianism = 0; // DMA4_CSDPi[19]

DMA4->WriteMode = 0x2; // DMA4_CSDPi[17:16]
DMA4->SourcePacked
    = 0x1; // DMA4_CSDPi[6]
DMA4->DestinationPacked = 0x1; //
    DMA4_CSDPi[13]
DMA4->NumberOfElementPerFrame = 240; // DMA4_CENi

DMA4->NumberOfFramePerTransferBlock = 160; // DMA4_CFNi

DMA4->SourceStartAddress = 0x80C00000; // DMA4_CSSAi

DMA4->DestinationStartAddress = 0x80F00000; // DMA4_CDSAi

DMA4->SourceElementIndex = 1; // DMA4_CSEIi

DMA4->SourceFrameIndex = 1; // DMA4_CSFII

DMA4->DestinationElementIndex = 637; // DMA4_CDEIi

DMA4->DestinationFrameIndex = -152967; // DMA4_CDFIi

DMA4->ReadPortAccessMode = 0x3; // DMA4_CCRi[13:12]

DMA4->WritePortAccessMode = 0x3; // DMA4_CCRi[15:14]

DMA4->ReadPriority = 0; // DMA4_CCRi[6]
DMA4->WritePriority =
    0; // DMA4_CCRi[23]
DMA4->ReadRequestNumber = 0; // DMA4_CCRi[4:0]

```

```
DMA4->WriteRequestNumber = 0; // DMA4_CCRi[20:19]
```

16.5.8 Graphic Operations

- Transparent copy:
 1. Set the [DMA4_CCRi\[17\]](#) TRANSPARENT_COPY_ENABLE bit to 1
 2. Set the [DMA4_CCRi\[16\]](#) CONST_FILL_ENABLE bit to 0
 3. Set the value of the key color in the [DMA4_COLORi\[15:0\]](#) COLOR_KEY bit field

To perform this graphic operation, the following lines can be added to the example of [Section 16.5.2, Software-Triggered \(Nonsynchronized\) Transfer](#).

```
DMA4_CCR_CH10 &= ~(0x1 << 16);
DMA4_CCR_CH10 |= 0x1 << 17;
```

```
DMA4_COLOR_CH10 = 0x00000003;
```

- Solid Color fill:
 1. Set the [DMA4_CCRi\[16\]](#) CONST_FILL_ENABLE bit to 1
 2. Set the [DMA4_CCRi\[17\]](#) TRANSPARENT_COPY_ENABLE bit to 0
 3. Set the value of key the color in the [DMA4_COLORi\[15:0\]](#) SOLID_COLOR bit field

To perform this graphic operation, the following lines can be added to the example of [Section 16.5.2, Software-Triggered \(Nonsynchronized\) Transfer](#).

```
DMA4_CCR_CH10 &= ~(0x1 << 17);
DMA4_CCR_CH10 |= 0x1 << 16;
```

```
DMA4_COLOR_CH10 = 0x00000003;
```

16.5.9 Linked-List Programming Guidelines

- With the exception of the [DMA4_CCRi\[7\]](#) ENABLE bit and the [DMA4_CDPi\[7\]](#) PAUSE_LINK_LIST bit during a linked-list transfer (descriptor load phase or data load phase), avoid programming any register through the configuration port.
- Before enabling any linked-list transfer, ensure that all global registers and all registers in the descriptor are initialized. Some static channel registers (registers that are not updated by the descriptor to be loaded) must also be initialized correctly:
 - For type 2, the following registers must be initialized with consistent values:
 - All global registers
 - [DMA4_CCRi](#)
 - [DMA4_CSDPi](#)
 - [DMA4_CLNK_CTRLi](#)
 - For type 3, the following registers must be initialized with consistent values:
 - All global registers
 - [DMA4_CCRi](#)
 - [DMA4_CSDPi](#)
 - [DMA4_CLNK_CTRLi](#)
 - [DMA4_CICRi](#)
 - [DMA4_CFNi](#)
- In case of a linked list with descriptor types 2 and 3, the content of the [DMA4_CCRi](#) register must not change during super-block life.
- The PAUSE_LINK_LIST bit must not be set in the initialization phase.

16.6 SDMA Register Manual

16.6.1 SDMA Instance Summary

Table 16-22. SDMA Instance Summary

Module Name	Base Address	Size
SDMA	0x4A05 6000	4KB

16.6.2 SDMA Registers

16.6.2.1 SDMA Register Summary

Index *i* represents the logical channel number (where $i = 0$ to 31). The offset address for some registers is calculated from the channel *c* number. For example, the DMA4_CCR10 (channel 10) register has an offset address of $10 \times 0x60 = 0x3C0$, and thus a physical address of $0x4A05\ 6080 + 0x3C0 = 0x4A05\ 6440$.

Index *j* represents the interrupt line number (where $j = 0$ to 3). The offset address for some registers is calculated from the channel *c* number. For example, the DMA4_IRQSTATUS_L3 (line 3) register has an offset address of $3 \times 0x4 = 0xC$, and thus a physical address of $0x4A05\ 6008 + 0xC = 0x4A05\ 6014$.

16.6.2.2 SDMA Register Description

NOTE: Some registers have no reset value (marked with -) because of hardware implementation in memory. Software must ensure the correct programming of these registers, if needed.

Shadow registers are used to read run-time registers such as CCEN, CCFN, CDAC, and CSAC. Typically, when accessed in 8-bit or 16-bit access for two consecutive accesses, the value of the previous registers can change. A shadow register holds the entire value to let the next access recover the remaining 24 or 16 bits.

For non-32-bit transactions, start reading or writing from the LSByte first to enable the register update. There is no issue for 32-bit read-write transactions.

Address Offset	0x0000 0078	Instance	SDMA
Physical Address	0x4A05 6078		
Description	DMA4_GCR		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED							CHANNEL_ID_GATE	ARBITRATION_RATE							HI_LO_FIFO_BUDGET	HI_THREAD_RESERVED	RESERVED				MAX_CHANNEL_FIFO_DEPTH										

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x00
24	CHANNEL_ID_GATE	Gates the Channel ID bus monitoring on both Read and Write ports 0x0: Gates the Channel ID qualifiers on both Read and Write Ports 0x1: Does not gate the Channel ID qualifiers on both Read and Write Ports	RW	0x0
23:16	ARBITRATION_RATE	Arbitration switching rate between prioritized and regular channel queues	RW	0x01
15:14	HI_LO_FIFO_BUDGET	Allow to have a separate Global FIFO budget for high and low priority channels. For Hi priority Channel: (Per_channel_Maximum FIFO depth + 1) x Number of active High priority Channel <= High Budget FIFO For Low priority channel: (Per_channel_Maximum FIFO depth + 1) x Number of active Low priority Channel <= Low Budget FIFO 0x0: no fixed budget for neither higher nor lower priority channel 0x1: 75% of FIFO for low priority and 25% for high priority channels 0x2: 25% of FIFO for low priority and 75% for high priority channels 0x3: 50% of FIFO for low priority and 50% for high priority channels	RW	0x0
13:12	HI_THREAD_RESERVED	Allow thread reservation for high priority channel on both read and write ports. 0x0: No ThreadID is reserved on the Read Port for high priority channels. No ThreadID is reserved on the Write Port for high priority channels. 0x1: Read Port ThreadID 0 is reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels. 0x2: Read port ThreadID 0 and ThreadID 1 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels. 0x3: Read PortThreadID 0, ThreadID 1 and ThreadID 2 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels.	RW	0x0
11:8	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x0
7:0	MAX_CHANNEL_FIFO_DEPTH	Maximum FIFO depth allocated to one logical channel. Maximum FIFO depth can not be 0x0. It should be at least 0x1 or greater. Note that If channel limit is less than destination burst size enough data will not be accumulated in the data FIFO and it will never be sent out on the WR port. The burst size should be less than the FIFO limit specified in this bit field.	RW	0x10

RESERVED	RESERVED	RESERVED	RESERVED	RESERVED	WRITE_PRIORITY	BUFFERING_DISABLE	SEL_SRC_DST_SYNC	PREFETCH	SUPERVISOR	RESERVED	SYNCHRO_CONTROL_UPPER	BS	TRANSPARENT_COPY_ENABLE	CONST_FILL_ENABLE	DST_AMODE	SRC_AMODE	RESERVED	WR_ACTIVE	RD_ACTIVE	SUSPEND_SENSITIVE	ENABLE	READ_PRIORITY	FS	SYNCHRO_CONTROL	SYNCHRO_CONTROL	SYNCHRO_CONTROL	SYNCHRO_CONTROL	SYNCHRO_CONTROL	SYNCHRO_CONTROL	SYNCHRO_CONTROL	SYNCHRO_CONTROL

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x0
29:27	RESERVED	Reserved for non-GP devices	RW	0x0
26	WRITE_PRIORITY	Channel priority on the Write side 0x0: Channel has low priority on the write side during the arbitration process. 0x1: Channel has high priority on write sided during the arbitration process.	RW	0
25	BUFFERING_DISABLE	This bit allows to disable the default buffering functionality when transfer is source synchronized. 0x0: Buffering is enabled across element/packet when source is synchronized to element, packet, frame or blocks. 0x1: Buffering is disabled across element/packet when source is synchronized to element, packet, frame or blocks.	RW	-

Bits	Field Name	Description	Type	Reset
24	SEL_SRC_DST_SYNC	Specifies that element, packet, frame or block transfer (depending on CCR.bs and CCR.fs) is triggered by the source or the destination on the DMA request 0x0: Transfer is triggered by the destination. If synch on packet the packet element number is specified in the CDFI register. 0x1: Transfer is triggered by the source. If synchronized on packet the packet element number is specified in the CSFI register.	RW	-
23	PREFETCH	Enables the prefetch mode 0x0: Prefetch mode is disabled. When Sel_Src_Dst_Sync=1 transfers are buffered and pipelined between DMA requests. 0x1: Prefetch mode is enabled. Prefetch mode is active only when destination is synchronized. It is software user responsibility not to have at the same time Prefetch=1 when Sel_Src_Dst_Sync=1. This mode is not supported.	RW	0
22	SUPERVISOR	Enables the supervisor mode 0x0: Supervisor mode is disabled. 0x1: Supervisor mode is enabled.	RW	0
21	RESERVED	Reserved for non-GP devices	RW	0
20:19	SYNCHRO_CONTROL_UPPER	Channel Synchronization control upper (used in conjunction with the 5 bits of synchro channel DMA4_CCRi[4:0]) Used in conjunction, as 2 MSB, with the 5 bits of the synchro channel bit field.	RW	0b00
18	BS	Block synchronization This bit used in conjunction with the fs to see how the DMA request is serviced in a synchronized transfer.	RW	-
17	TRANSPARENT_COPY_ENABLE	Transparent copy enable 0x0: Transparent copy mode is disabled. 0x1: Transparent copy mode is enabled.	RW	-
16	CONST_FILL_ENABLE	Constant fill enable 0x0: Constant fill mode is disabled. 0x1: Constant fill mode is enabled.	RW	0
15:14	DST_AMODE	Selects the addressing mode on the Write Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode	RW	0bxx
13:12	SRC_AMODE	Selects the addressing mode on the Read Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode	RW	0bxx
11	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0
10	WR_ACTIVE	Indicates if the channel write context is active or not Read 0x0: Channel is not active on the write port. Read 0x1: Channel is currently active on the write port.	R	0
9	RD_ACTIVE	Indicates if the channel read context is active or not Read 0x0: Channel is not active on the read port. Read 0x1: Channel is currently active on the read port.	R	0

Bits	Field Name	Description	Type	Reset
8	SUSPEND_SENSITIVE	Logical channel suspend enable bit 0x0: The channel ignores the MSuspend even if EMUFree is set to 0. 0x1: If EMUFree is set to 0 and MSuspend comes in then all current OCP services (single transaction or burst transaction as specified in the corresponding CSDP register) have to be completed before stopping processing any more transactions.	RW	0
7	ENABLE	Logical channel enable. It is SW responsibility to clear the CSR register and the IRQSTATUS bit for the different interrupt lines before enabling the channel. 0x0: The logical channel is disabled. 0x1: The logical channel is enabled.	RW	0
6	READ_PRIORITY	Channel priority on the read side 0x0: Channel has low priority on the read side during the arbitration process. 0x1: Channel has high priority on read sided during the arbitration process.	RW	0
5	FS	Frame synchronization This bit used in conjunction with the BS to see how the DMA request is serviced in a synchronized transfer FS = 0 and BS = 0: An element is transferred once a DMA request is made. FS = 0 and BS = 1: An entire block is transferred once a DMA request is made. FS = 1 and BS = 0: An entire frame is transferred once a DMA request is made. FS = 1 and BS = 1: A packet is transferred once a DMA request is made. All these different transfers can be interleaved on the port with other DMA requests.	RW	-
4:0	SYNCHRO_CONTROL	Channel synchronization control This bit field used in conjunction with the second_level_synchro_control_upper (as 2 MSB) 0000000 : Is reserved for non synchronized LCH transfer xxxxxxx (from 1 to 127)There are 127 possible DMA request to assign to any LCH. Note: The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, DMA4_CCR[4:0] SYNCHRO_CONTROL must be set to 0x2 (DMA request number + 1).	RW	0b00000

Interrupt Controllers

This chapter describes the interrupt controllers (INTCs) in the device.

Topic	Page
17.1 Interrupt Controllers Overview	3663
17.2 Interrupt Controllers Environment	3665
17.3 Interrupt Controller Integration	3666
17.4 Interrupt Controllers Functional Description	3672
17.5 Interrupt Controllers Register Manual.....	3673

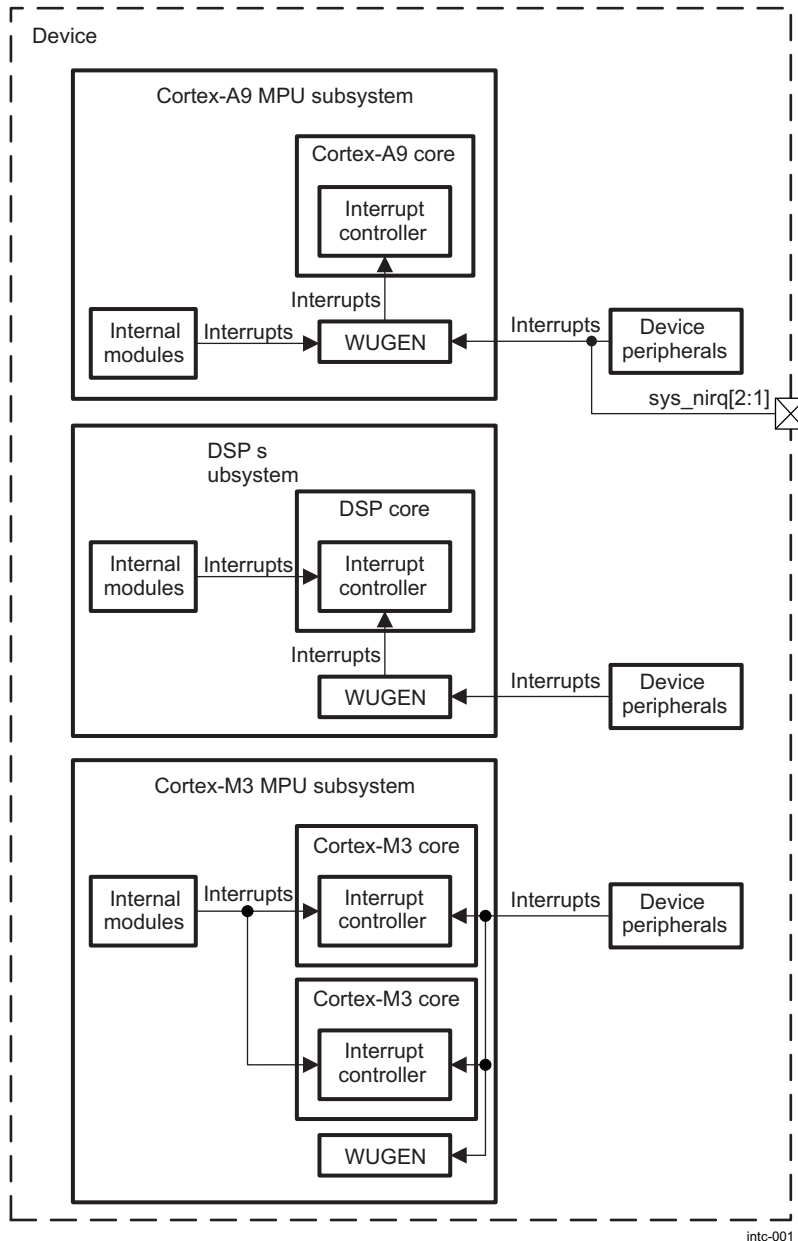

17.1 Interrupt Controllers Overview

The device provides three interrupt controller (INTC) modules, which handle interrupts at the device level:

- Cortex™-A9 microprocessor unit (MPU) subsystem interrupt controller (Cortex-A9 MPU INTC): This INTC module is a single functional unit that is integrated in the Cortex-A9 multiprocessor core alongside Cortex-A9 processors. It provides:
 - 128 hardware interrupt inputs
 - Generation of interrupts by software
 - Prioritization of interrupts
 - Masking of any interrupts
 - Distribution of the interrupts to the target Cortex-A9 processor(s)
 - Tracking the status of interrupts
 - Wake-up generator (WUGEN) module on external and local interrupts
- DSP subsystem interrupt controller (INTC): This module is a specific combination of WUGEN and the C64x+™ DSP INTC. It is used in the device but is not described in detail in this chapter. For detailed information about this module, see [Chapter 5, DSP Subsystem](#).
- Cortex™-M3 MPU subsystem INTC (Cortex-M3 MPU INTC): This module is also called Nested Vectored Interrupt Controller (NVIC) and is integrated within each Cortex-M3 so the different interrupt lines are directly connected to each core. The interrupt mapping is the same for the two cores to facilitate parallel processing. The NVIC supports:
 - 64 external interrupts (in addition to 16 Cortex-M3 internal interrupts), which are dynamically prioritized with 16 levels of priority defined for each core
 - Low-latency exception and interrupt handling
 - Prioritization and handling of exceptions
 - Control of the local power management
 - Debug accesses to the processor core
 - WUGEN module on external interrupts, coming from device peripherals

Figure 17-1 shows the internal interrupt scheme of the device.

Figure 17-1. Interrupt Controllers Overview

NOTE: For more information about the WUGEN module in the Cortex-A9 MPU subsystem (including integration, functional and register description), see [Chapter 4, Cortex-A9 MPU Subsystem](#). For more information about the WUGEN module in the Cortex-M3 MPU subsystem (including integration, functional and register description), see [Chapter 7, Cortex-M3 MPU Subsystem](#).

17.2 Interrupt Controllers Environment

This section describes the INTC application fields from the environment point of view (external connections).

Figure 17-2 shows the relationship between the module and external interrupts.

Figure 17-2. Interrupts From External Devices

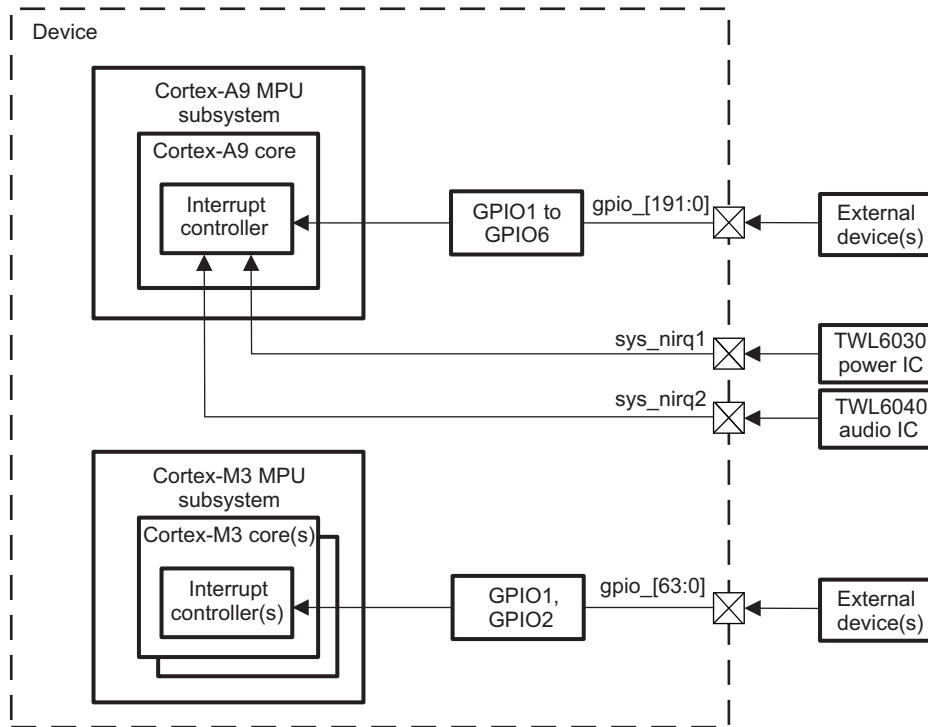

Table 17-1 describes the I/O signals that can be used by external devices to generate interrupts to the Cortex-A9 MPU INTC or Cortex-M3 MPU INTC.

Table 17-1. Interrupt Controllers I/O Signals

Signal Name	I/O ⁽¹⁾	Reset Value	Description	Cortex-A9 MPU INTC	Cortex-M3 MPU INTC
sys_nirq1	I	1	The TWL6030 power IC can use this pin to generate a system wake-up event to Cortex-A9 MPU INTC.	x	-
sys_nirq2	I	1	The TWL6040 audio IC can use this pin to generate a system wake-up event to Cortex-A9 MPU INTC.	x	-
gpio_[31:0]	I/O	-	External devices can use GPIO modules to generate interrupts to the Cortex-A9 MPU or Cortex-M3 MPU. There are six dedicated interrupt lines (for GPIO1 to GPIO6) to the Cortex-A9 MPU INTC and two dedicated interrupt lines (for GPIO1 and GPIO2) to the Cortex-M3 MPU INTC. Each GPIO module can generate a single interrupt whenever there is at least one event in any one of the configured 32 GPIO inputs. For more information about GPIO interrupt generation, see Chapter 25, General-Purpose Interface .	x	x
gpio_[63:32]	I/O	-		x	x
gpio_[95:64]	I/O	-		x	-
gpio_[127:96]	I/O	-		x	-
gpio_[159:128]	I/O	-		x	-
gpio_[191:160]	I/O	-		x	-

⁽¹⁾ I = Input, O = Output

17.3 Interrupt Controller Integration

The Cortex-A9 MPU INTC is integrated inside the Cortex-A9 MPU core. For more information about Cortex-A9 MPU INTC integration, see [Chapter 4, Cortex-A9 MPU Subsystem Integration](#).

The Cortex-M3 MPU INTC is integrated inside each Cortex-M3 MPU core. For more information about Cortex-M3 MPU INTC integration, see [Chapter 7, Dual Cortex-M3 MPU Subsystem Integration](#).

17.3.1 Interrupt Mapping

NOTE: All device peripherals interrupts (external to the Cortex-A9 MPU, DSP, and Cortex-M3 MPU subsystems) are active-high, level-sensitive.

CAUTION

A single interrupt source can be physically mapped to multiple INTCs (Cortex-A9 MPU, DSP, and Cortex-M3 MPU subsystems). With multiple-mapped interrupts, it is strongly recommended to unmask each interrupt source in only one INTC at a time.

17.3.2 Interrupt Requests to Cortex-A9 MPU INTC

[Table 17-2](#) lists the Cortex-A9 MPU INTC interrupt mapping.

Table 17-2. Cortex-A9 MPU INTC Interrupt Mapping

Interrupt Line (Destination)	Interrupt Line (Source)	Module Name	Description

- (3) Shared with Cortex-A9 MPU INTC
- (4) Shared with DSP and Cortex-A9 MPU INTCs

NOTE: MM_IRQ_0 triggers exception 16 inside the Cortex-M3 core(s).

NOTE: All Cortex-M3 MPU subsystem internal interrupts are edge interrupts, except the one generated from the MMU (XLATE_MMU_FAULT), which is level interrupt.

17.4 Interrupt Controllers Functional Description

17.4.1 Cortex-A9 MPU INTC Functional Description

Cortex-A9 MPU INTC is configured to have the following interrupt sources:

- Sixteen interprocessor interrupts (IPI): ID[15:0]
- Two private timer/watchdog interrupts: ID[30:29]
- Two legacy nFIQ nIRQ: one per CPU, bypasses the interrupt distributor logic and drives interrupt requests directly into the CPU, if used in legacy mode (otherwise, treated like other interrupts lines with ID28 and ID31, respectively)
- 128 hardware interrupts: ID[159:32] (rising-edge or high-level sensitive). The interrupt mapping of these interrupts is provided in [Table 17-2, Interrupt Requests to Cortex-A9 MPU INTC](#).

CAUTION

Although the hardware interrupts can be configured to be rising-edge or high-level sensitive in the INTC, the device supports only active-high, level-sensitive configuration.

For more information about the functionality of the Cortex-A9 MPU INTC, see the *ARM Cortex-A9 MP Core Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

17.4.2 Cortex-M3 MPU INTC Functional Description

The Cortex-M3 MPU INTC has the following configuration in the device:

- 64 hardware interrupts/16 levels of priority for each Cortex-M3 core. The interrupt mapping of these interrupts is provided in [Table 17-3, Interrupt Requests to Cortex-M3 MPU INTC](#).
- The calibration register, which is used to reload the SYSTICK timer to generate a fixed interval, is not supported in the Cortex-M3 core within the Cortex-M3 MPU subsystem. The TENMS field is not available due to the different frequencies during voltage scaling.
- The SYSRESETREQ reset feature is not supported at the Cortex-M3 processor level. Writing to this bit has no effect.

For more information about the functionality of the Cortex-M3 MPU INTC, see *ARM Cortex-M3 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

17.5 Interrupt Controllers Register Manual

17.5.1 Interrupt Controllers Instance Summary

For information about the Cortex-A9 MPU INTC and Cortex-M3 MPU INTC instances, see [Chapter 4](#), *Cortex-A9 MPU Subsystem* and [Chapter 7](#), *Dual Cortex-M3 Subsystem*.

17.5.2 Cortex-A9 MPU INTC Registers

For information about the Cortex-A9 MPU INTC registers and their description, see the *ARM Cortex-A9 MP Core Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

17.5.3 Cortex-M3 MPU INTC Registers

For information about the Cortex-M3 MPU INTC registers and their description, see the *ARM Cortex-M3 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

Control Module

This chapter describes the system control module for the device.

Topic	Page
18.1 Control Module Overview	3675
18.2 Control Module Environment.....	3677
18.3 Control Module Integration	3677
18.4 Control Module Functional Description	3682
18.5 Control Module Programming Guide	3903
18.6 Control Module Register Manual.....	3912

18.1 Control Module Overview

The control module allows software control of the various static modes supported by the device. It is composed of two control submodules: general control module and device (padconfiguration) control module.

The general control module has the following features:

- General status and control
- Hardware observability input/output (I/O) multiplexing
- Standard eFuse logic

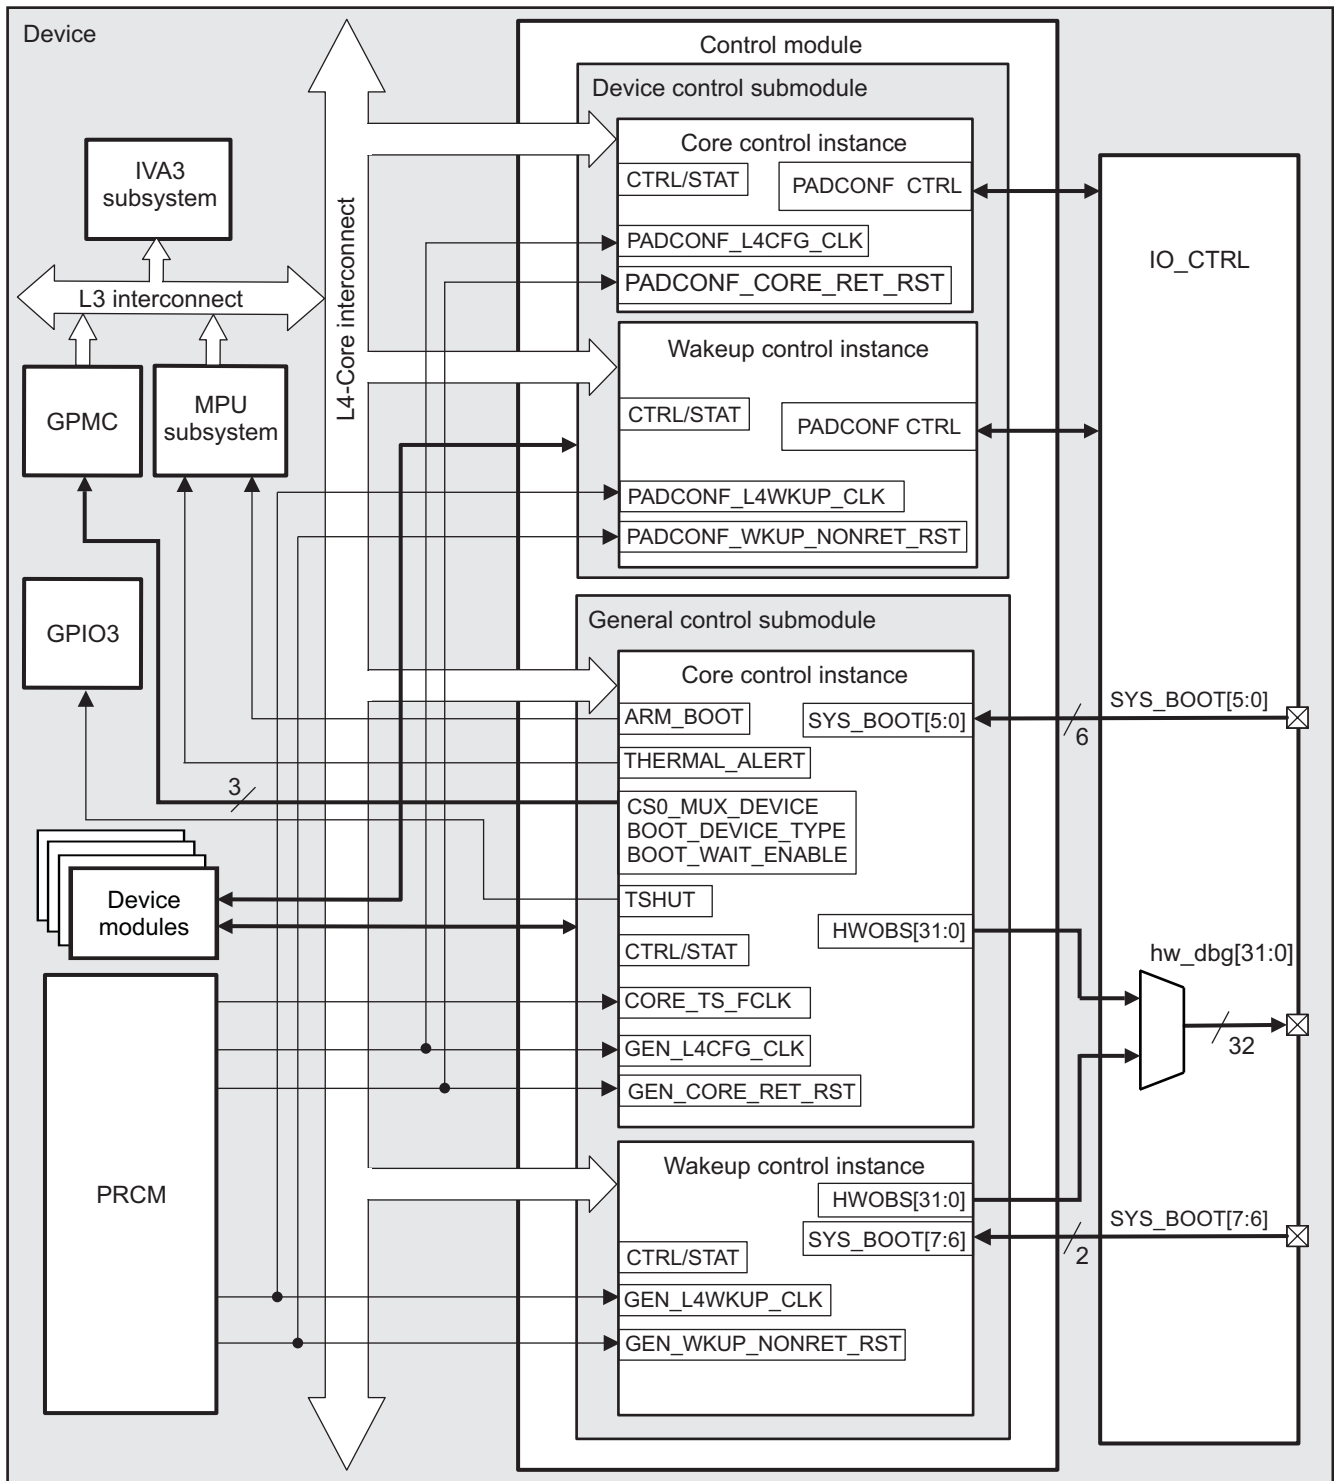

The device control module provides the following features:

- Pad functional I/O multiplexing
- Pad pullup/down configuration
- Pad groups associated signal integrity controls
- Complex I/O configuration
- Analog function control
- Device-specific eFuse registers

Both control submodules are split into two instances: the control core instance within the CORE power domain, and the control wake-up instance within the WKUP power domain. For more information about the four different control module instances, see [Section 18.3, Control Module Integration](#).

[Figure 18-1](#) is an overview of the control module.

Figure 18-1. Control Module Overview

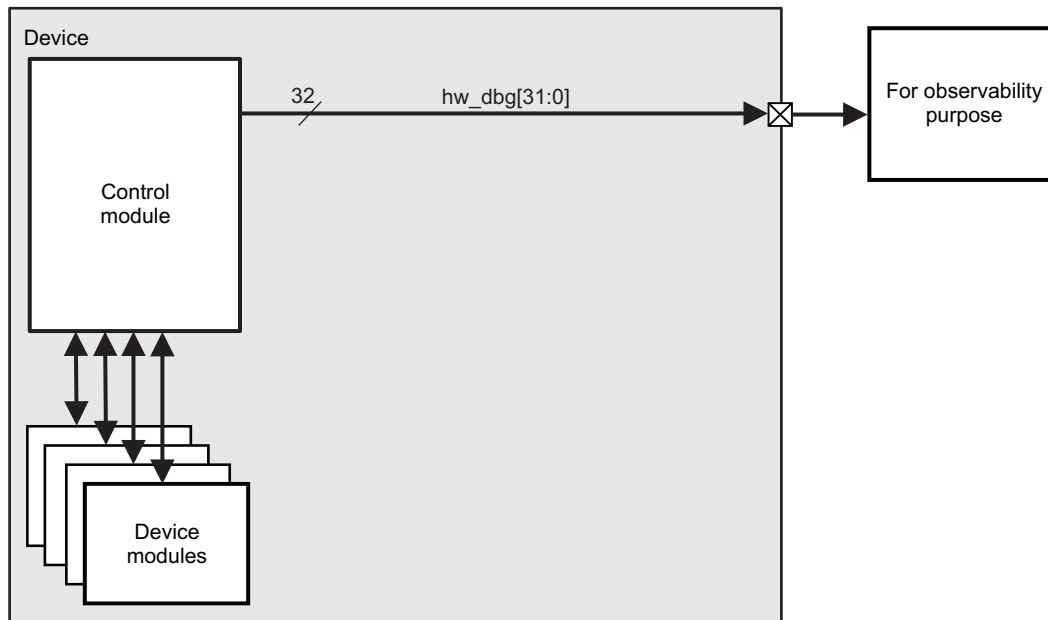

sysctrl-001

18.2 Control Module Environment

The control module controls the multiplexing of device internal module signals routed to the external pins (hw_dbg[31:0]) for hardware debug purposes. For more information, see [Section 18.4.11, Hardware Observability](#), and [Section 18.4.8, PAD Functional Multiplexing and Configuration](#). Using the correct pad configuration, the control module maps these pins at the device boundary to observe the internal signals from the power, reset, and clock management (PRCM) module, direct memory access (DMA) requests, and interrupts. [Figure 18-2](#) is an overview of the control module environment.

Figure 18-2. Control Module Environment

sysctrl-002

18.2.1 Control Module Signals

[Table 18-1](#) lists the control module hardware observability outputs configured to observe the debug signals of the device module. It describes the module signals and specifies their links to functions.

Table 18-1. Control Module I/O Description

Signal	I/O ⁽¹⁾	Description	Reset Value ⁽²⁾
hw_dbg[31:0]	O	Internal hardware observability signals 0 to 31	Hi-Z

⁽¹⁾ I = Input; O = Output

⁽²⁾ Hi-Z = High impedance

18.3 Control Module Integration

The control module of the device is on the L4-Core interconnect. It consists of four module instances:

- General core control module (SYSCTRL_GENERAL_CORE)
- General wakeup control module (SYSCTRL_GENERAL_WKUP)
- Device core control module (SYSCTRL_PADCONF_CORE)
- Device wakeup control module (SYSCTRL_PADCONF_WKUP)

For more information about the different control module instances, see [Table 18-4](#).

Each of these four module instances has an associated register set and shares one functional clock and one reset signal with the PRCM module. The exception is general core control module (SYSCTRL_GENERAL_CORE) which also receives a secondary functional clock, CORE_TS_FCLK. [Table 18-2](#) describes the signals.

Table 18-2. Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SYSCTRL_GENERAL_WKUP	GEN_L4WKUP_CLK	WKUP_L4_ICLK2	PRCM	L4_WKUP interface/functional clock propagated to the general wakeup control module
SYSCTRL_GENERAL_CORE	GEN_L4CFG_CLK	CFG_L4_ICLK	PRCM	L4_CFG interface/functional clock propagated to the general core control module
	CORE_TS_FCLK	CORE_TS_FCLK	PRCM	Functional clock for the band gap state-machine instantiated in the general core control module
SYSCTRL_PADCONF_WKUP	PADCONF_L4WKUP_CLK	WKUP_L4_ICLK2	PRCM	L4_WKUP interface/functional clock propagated to the device wakeup control module
SYSCTRL_PADCONF_CORE	PADCONF_L4CFG_CLK	CFG_L4_ICLK	PRCM	L4_CFG interface/functional clock propagated to the device core control module
Resets				
SYSCTRL_GENERAL_WKUP	GEN_WKUP_NONRET_RST	WKUP_PWRON_RST	PRCM	Internal power-on reset (POR) affecting the general wakeup control module
SYSCTRL_GENERAL_CORE	GEN_CORE_RET_RST	CORE_PWRON_RET_RST	PRCM	Internal POR affecting the general core control module
SYSCTRL_PADCONF_WKUP	PADCONF_WKUP_NONRET_RST	WKUP_PWRON_RST	PRCM	Internal POR affecting the device wakeup control module
SYSCTRL_PADCONF_CORE	PADCONF_CORE_RET_RST	CORE_PWRON_RET_RST	PRCM	Internal POR affecting the device core control module

Table 18-3. Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
SYSCTRL_GENERAL_CORE	THERMAL_ALERT	MA_IRQ_126	CORTEX-A9 INTC	Interrupt generated by general core control module to CORTEX™-A9

NOTE: For a description of the interrupt sources, see [Section 17.3.2, Interrupt Requests to the Cortex-A9 MPU Interrupt Controller](#).

The control module is reset by the internal POR, which is active low. The PRCM module provides a retention POR signal (CORE_PWRON_RET_RST) duplicated to both of the core control module instances, and a nonretention POR signal (WKUP_PWRON_RST) duplicated to each of the two wake-up control module instances in the control module. For more information, see [Reset Domains](#), in [Chapter 3, Power, Reset, and Clock Management](#). The control module does not respond to a warm reset or to an L4-Core reset.

The main sequential logic within the system control module is accessible in a register file through the L4-Core interconnect. The PRCM module provides the CFG_L4_ICLK functional clock signal (L4_CFG clock domain) separately to each of the two core control submodules. In addition, an instantiated inside the general core control, the band gap state-machine receives its functional clock (CORE_TS_FCLK) from the PRCM module. For more information about this signal, see [CM2 Clock Generator](#) in [Chapter 3, Power, Reset, and Clock Management](#).

The PRCM module also supplies the WKUP_L4_ICLK2 functional clock signal (L4_WKUP clock domain) to each of the two wake-up control module instances. For more information about this signal, see , *PRM Clock Source* in [Chapter 3, Power, Reset, and Clock Management](#).

The PRCM module latches the sys_boot[7:0] pad signals at POR and exports them as vector to the SYSBOOT[7:0] input of the general core control module. It is scanned in the [CONTROL_STATUS\[7:0\]](#) SYS_BOOT bit field. For more information, see [Section 27.2.4.2, Booting Device Order Selection](#), and [Section 27.2.4.1, Clock Source Selection](#).

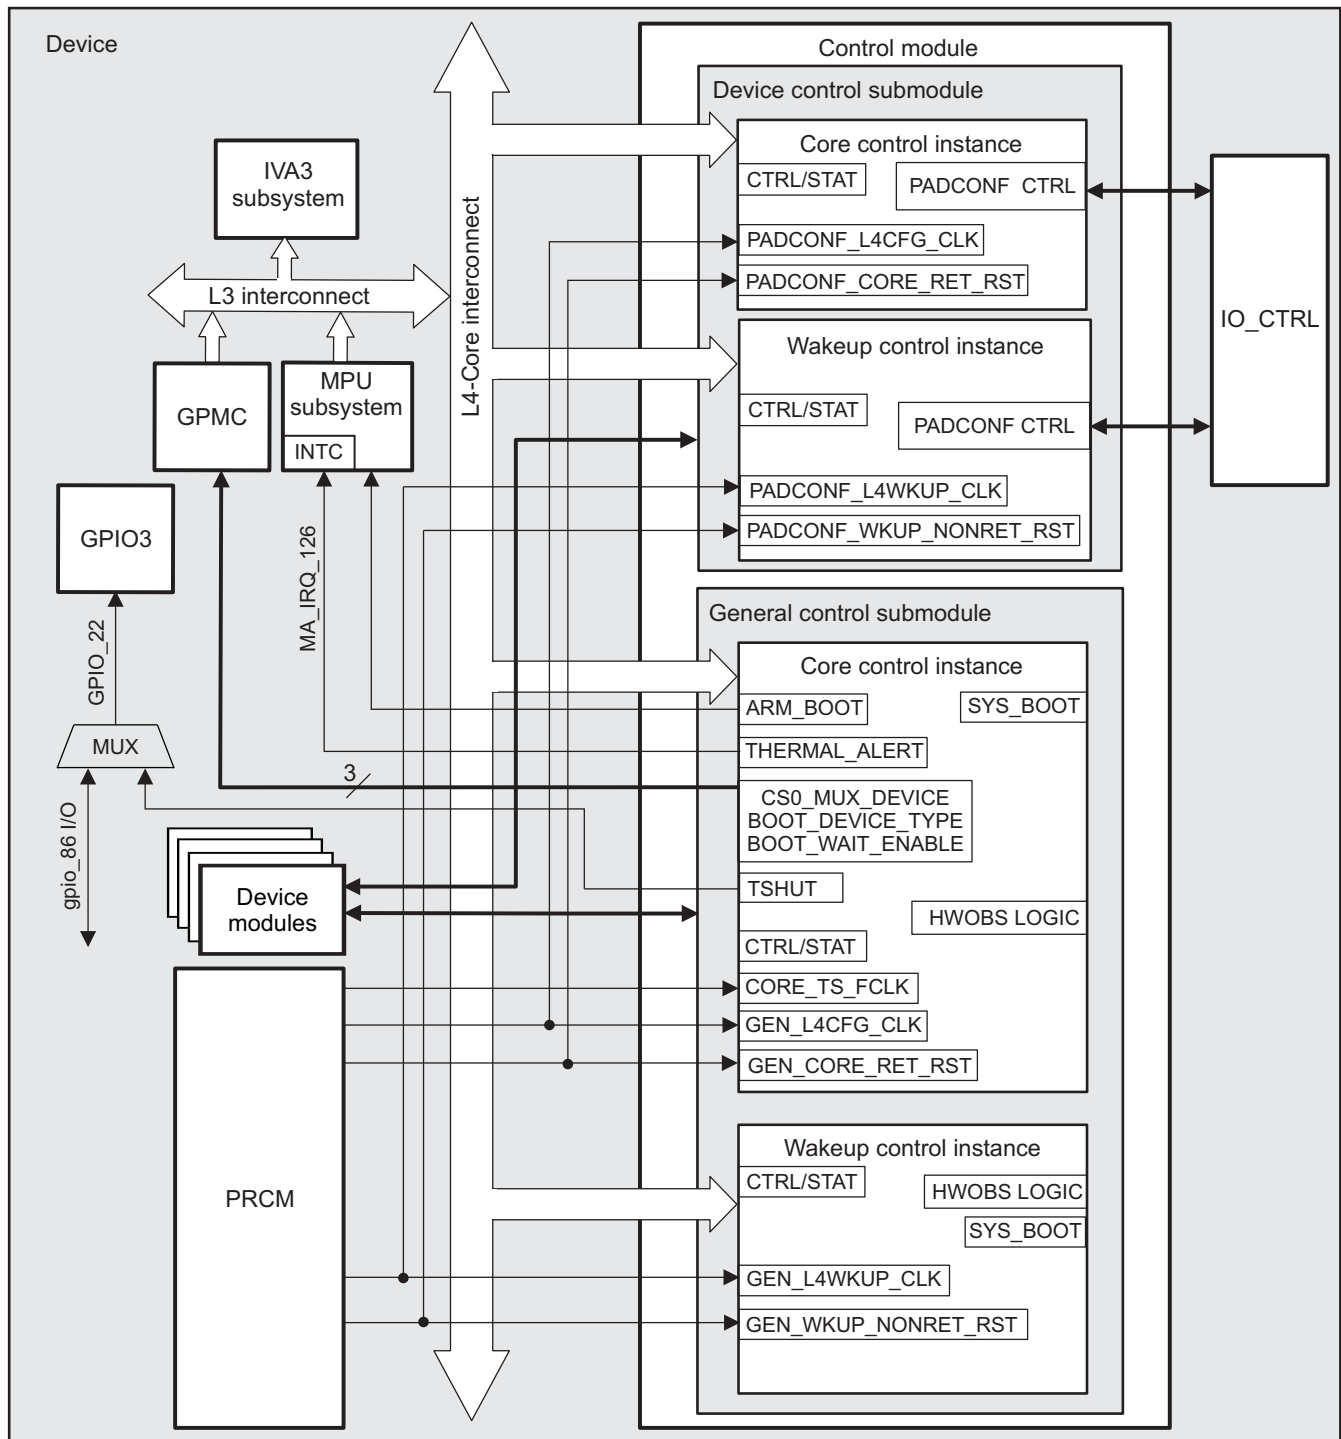

The thermal management subsystem inside the general core control module delivers one interrupt request (THERMAL_ALERT) to line MA_IRQ_126 of the MPU subsystem interrupt controller (INTC) (Cortex-A9 INTC), and delivers a thermal protection output signal (TSHUT) to the GPIO3 instance. For more information about the functional outputs of the thermal management control module, see [Section 18.4.10](#).

The signal integration of the control module features:

- No IDLE hardware handshake
- No STANDBY hardware handshake
- No SAVE and RESTORE hardware handshake
- No wake-up request generation
- No DMA request generation
- One interrupt request (IRQ) – THERMAL_ALERT to the MPU subsystem
- A thermal shutdown protection signal (TSHUT) delivered to a GPIO3 input.
- Three functional clocks: two clocks in the CFG and one in the WKUP clock domains
- One retention and one nonretention internal power-on-based resets

[Figure 18-3](#) shows the integration of the module in the device.

Figure 18-3. Control Module Integration

sysctrl-003

Table 18-4 lists the integration attributes.

Table 18-4. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
SYSCTRL_GENERAL_WKUP	PD_WKUP	L4_WKUP

Table 18-4. Integration Attributes (continued)

SYSCTRL_GENERAL_CORE	PD_CORE	L4_CFG
SYSCTRL_PADCONF_WKUP	PD_WKUP	L4_WKUP
SYSCTRL_PADCONF_CORE	PD_CORE	L4_CFG

Software sets the configuration registers to the desired values depending on the configuration of the requested device. Static device configuration registers can be set by software any time and are effective immediately.

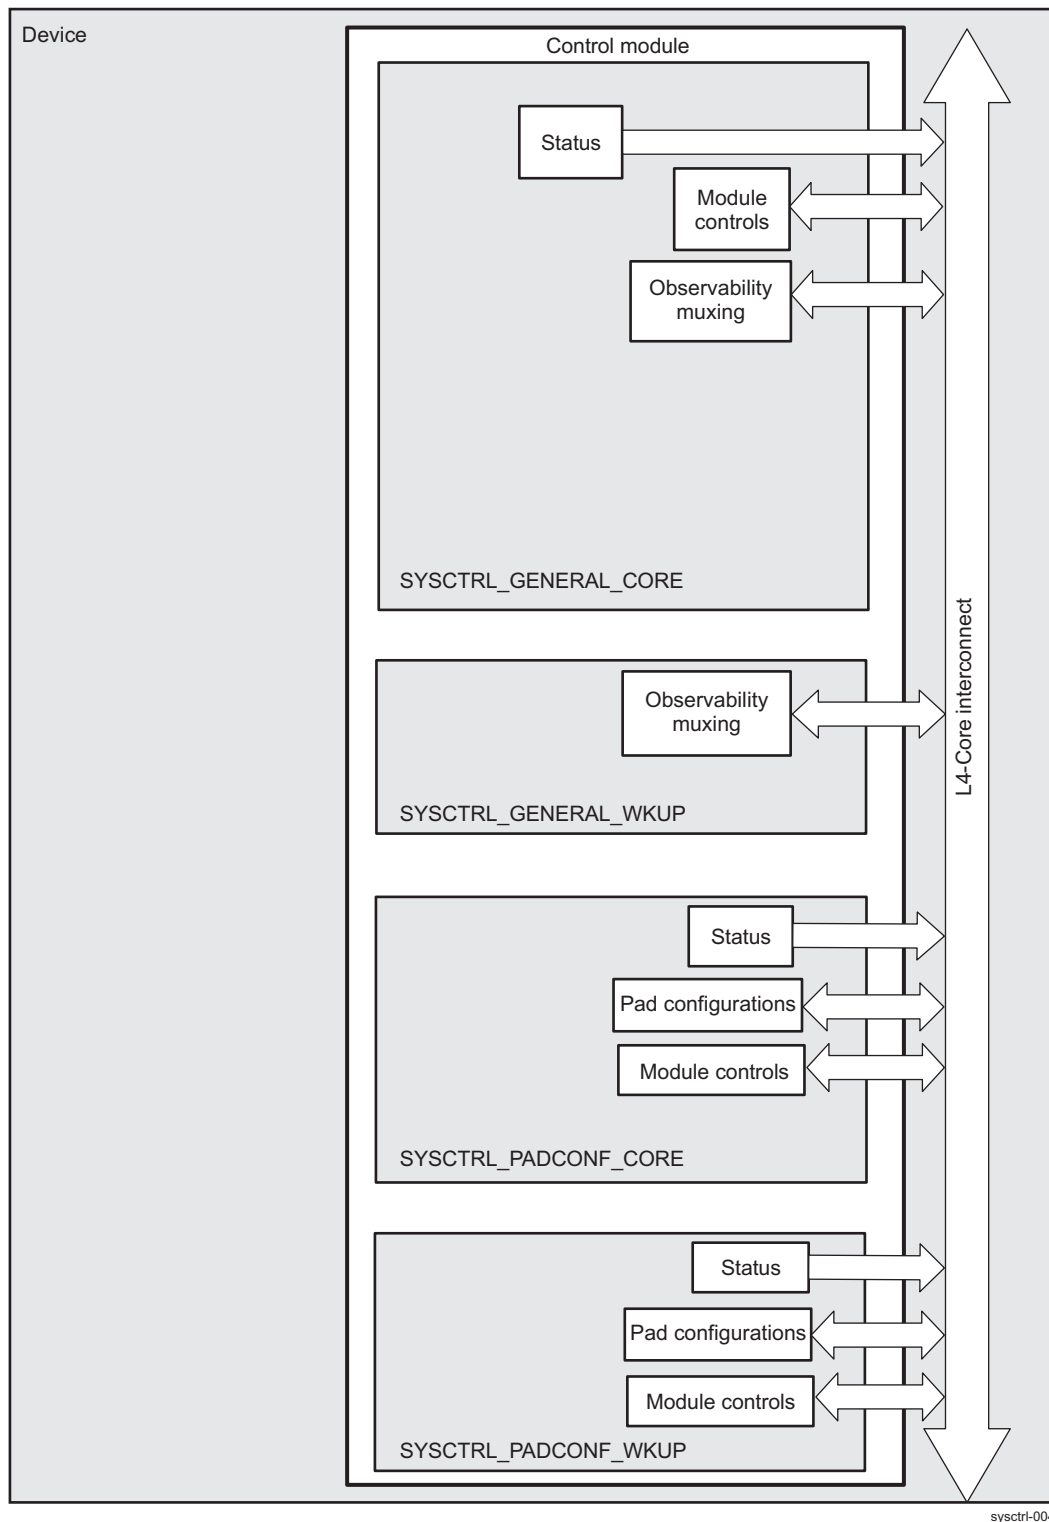

18.4 Control Module Functional Description

18.4.1 Control Module Block Diagram

The control module controls the settings of various device modules through the register configuration and internal signals. It also controls the pad configuration, pin functional multiplexing, and the routing of internal signals (such as PRCM signals or DMA requests) to output pins configured for hardware observability.

[Figure 18-4](#) is the control module block diagram.

Figure 18-4. Control Module Block Diagram

The control submodules primarily implement a bank of registers accessible (read/write) by software and some read-only registers that provide status information.

The read/write registers in the general control module can be divided into the following classes:

- Hardware observability registers (32-bit read/write registers)

- Status and configuration registers
- Boot registers
- eFuse ROM registers
- Miscellaneous functional registers

The read/write registers in the device(padconfiguration) control module can be divided into the following classes:

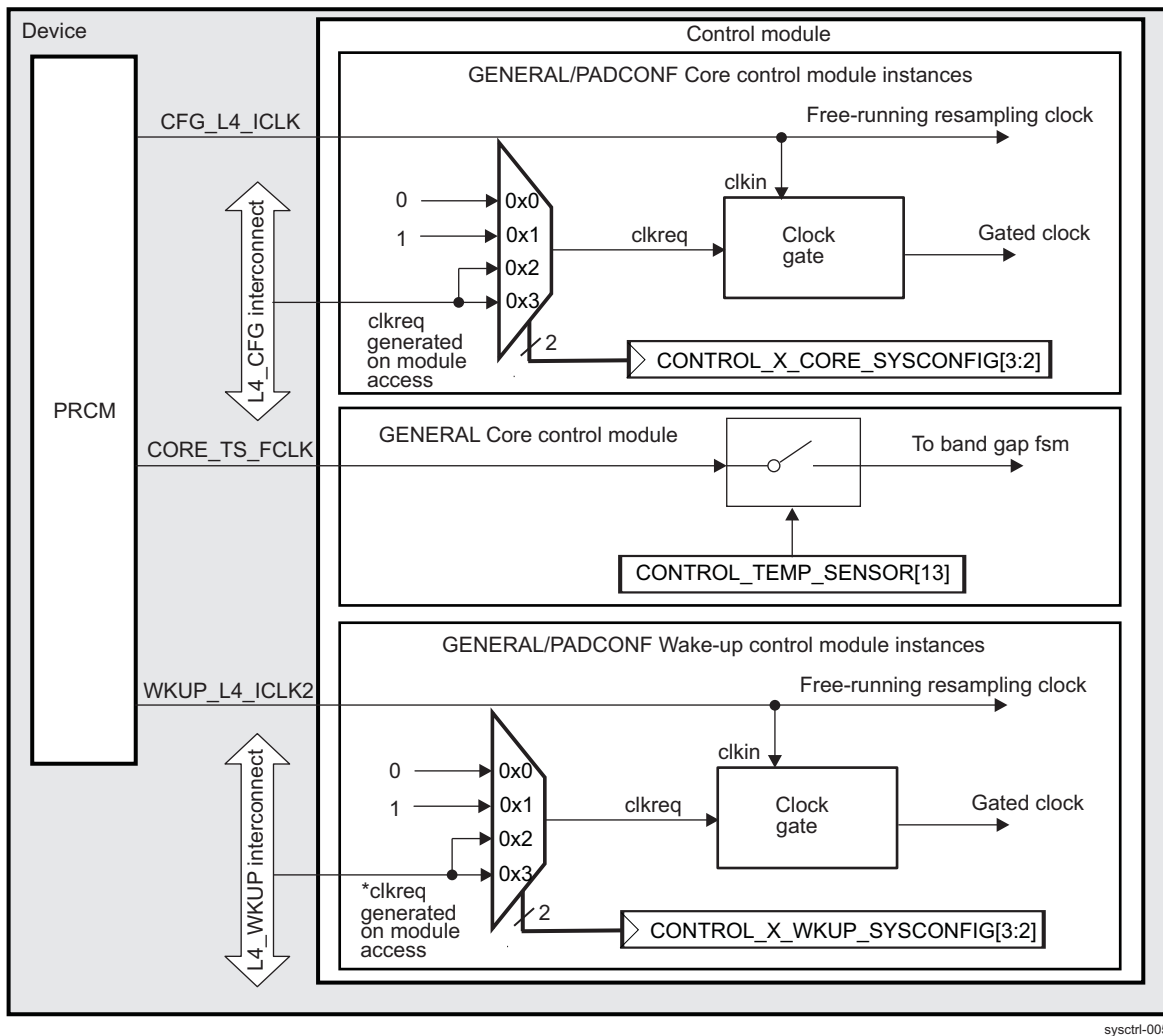

- Pad configuration registers (32-bit registers, one register for two pads)
- Pad groups (not individual per pad) associated registers for signal integrity parameters control (32-bit read/write registers)
- I/O cells associated specific control registers
- Device-specific status and configuration registers
- Miscellaneous functional registers

18.4.2 Control Module Clock Configuration

[Figure 18-5](#) shows the distribution schema of the control module internal clock . Each CFG_L4_ICLK and WKUP_L4_ICLK2 source clock is internally distributed into two clock paths: the first path directly mirrors the source clock and is an always-running clock. It is used to synchronize and resample some of the module inputs. The other clock path can be internally gated within the module.

The CORE_TS_FCLK clock, which drives the general core control band gap state-machine, can also be locally gated through a dedicated bit in the [CONTROL_TEMP_SENSOR](#) register. For more information about the temperature module off mode, see [Section 18.4.10, Band Gap Voltage and Temperature Sensor](#).

Figure 18-5. Control Module Internal Clock Paths

sysctrl-005

The clock-gating strategy for L4 clocks is selected through the CONTROL_SYSCONFIG[3:2] IP_SYSCONFIG_IDLEMODE bit field available in each of the four control module instances. Table 18-5 describes the different possibilities for clock management. There are no PRCM software controls for the CFG_L4_ICLK and WKUP_L4_ICLK2 clocks in the control module. There are, however, clock activity status bits in the PRCM module.

The CORE_TS_FCLK has the following software controls: enable, status, and divider ratio, in the PRCM module. See , Clock Domain Modes, and , CD_WKUP Clock Domain , in Chapter 3, Power, Reset, and Clock Management.

Table 18-5. Internal Clock Gating Options

Feature	CONTROL_SYSCONFIG[3:2] IP_SYSCONFIG_IDLEMODE Value	Description
Local clock control	0b00	Clock is manually gated.
Local clock control	0b01	Clock is manually enabled.
Local clock autogating	0b10, 0b11	Clock is automatically gated when there is no access to the control module through the L4-interconnect.

18.4.3 Control Module Software Reset

The control module is not sensitive to software reset.

18.4.4 Control Module Power Management

18.4.4.1 Retention

The general core module and device core control module instances are fully built with retention flip-flops (RFFs) and are powered in the CORE power domain; thus, they can be in active or retention mode. The core instances lose their content when the CORE power domain is in off mode. In contrast to the core control instances, the control wake-up instances are always powered and active. For more information about the device low-power states, see, *Device Low-Power States*, in [Chapter 3, Power, Reset, and Clock Management](#).

18.4.4.2 Power Management Protocols

The control module, which is slave on the L4 interconnect, does not support standby or idle mode protocols.

18.4.4.3 Save-and-Restore Mechanism

The control core module instances lose their contents when the CORE power domain is in off mode. To prevent this, before going to off mode, the core register context is copied by software into a dedicated SAR_RAM in the WKUP voltage domain. The save-and-restore (SAR) mechanism, controlled by the PRCM module, allows restoring registers to the value present before going to off mode. Thus, core domain registers have a correct configuration/state immediately after the core power is on again without requesting a software operation to reconfigure them.

Because the SAR mechanism is managed by software-accessible registers, no hardware-specific requirements exist. For more information about SAR, see, *Device Off State Management*, in [Chapter 3, Power, Reset, and Clock Management](#).

18.4.5 Hardware Requests

The control module does not generate DMA or wake-up requests. The general core control module generates one IRQ (THERMAL_ALERT) to the Cortex-A9 INTC (MA_IRQ_126 line). For more information, see [Section 17.3.2, Interrupt Requests to the Cortex-A9 MPU Interrupt Controller](#).

18.4.6 Control Module Initialization

The control module responds only to the internal POR and device type. At power-on, reset values for the registers define the *safe state* for the device. In the initialization mode, only modules to be used at boot time are associated with the pads. Other module inputs are internally tied and outputs pads are turned off. After POR, software must set the pad functional multiplexing and configuration registers to the desired values according to the requested device configuration. For more information, see [Chapter 27, Initialization](#).

General-purpose (GP) devices include features that are inaccessible or unavailable. These inaccessible registers define the default or fixed device configuration or behavior.

The `CONTROL_STATUS[7:0]` SYS_BOOT boot field reflects the state of the sys_boot pins captured at POR in the PRCM module.

18.4.7 General Control Module Instances

18.4.7.1 General Core Control Module Instance

The SYSCTRL_GENERAL_CORE instance contains most of the control logic that provides the hardware observability features for different digital phase-locked loop (DPLL) clockout and DPLL-specific signals, DMA requests, IRQs, and other internal hardware signals. The general core control provides the system boot decoding logic and has control over the standard eFuse settings. The system configuration registers, specific function controls, and some peripheral control and status registers are also mapped there.

The register sets available within the SYSCTRL_GENERAL_CORE are:

- Observability control registers:
 - [CONTROL_HWOBS_CONTROL](#)
 - [CONTROL_DEBOBS_FINAL_MUX_SEL](#)
 - [CONTROL_CONF_SDMA_REQ_SELx](#)
 - [CONTROL_CONF_CLK_SELx](#) (where x = 0 to 2)
 - [CONTROL_CONF_DPLL_X_SEL](#) (where X = FREQLOCK, TINITZ, PHASELOCK, TENABLE, TENABLEDIV, BYPASSACK, IDLE)
- Part of the debug view channel selection registers: [CONTROL_CORE_CONF_DEBUG_SEL_TST_X](#)
- MMU address translation-related registers: [CONTROL_CORTEX_M3_MMUADDRTRANSLTR](#) and [CONTROL_CORTEX_M3_MMUADDRLOGICTR](#)
- Standard fuse registers: [CONTROL_STD_FUSE_X](#)
- Clock gating configuration register: [CONTROL_GEN_CORE_SYSCONFIG](#)
- Control status register: [CONTROL_STATUS](#)
- Peripheral control registers:
 - [CONTROL_TEMP_SENSOR](#)
 - [CONTROL_BANDGAP_CTRL](#)
 - [CONTROL_BANDGAP_COUNTER](#)
 - [CONTROL_BANDGAP_THRESHOLD](#)
 - [CONTROL_TSHUT_THRESHOLD](#)
 - [CONTROL_BANDGAP_STATUS](#)
 - [CONTROL_DSS_CONTROL](#)
 - [CONTROL_USBOTGHS_CONTROL](#)
 - [CONTROL_LDOSRAM_MPU_VOLTAGE_CTRL](#)
 - Etc.

18.4.7.2 General Wakeup Control Module Instance

The registers associated with this module are:

- Clock gating configuration register: [CONTROL_GEN_WKUP_SYSCONFIG](#)
- Register with spare bits: [CONTROL_OCPREG_SPARE](#)
- Part of the debug view channel selection registers: [CONTROL_WKUP_CONF_DEBUG_SEL_TST_X](#)

18.4.7.3 Device Core Control Module Instance

The SYSCTRL_PADCONF_CORE instance provides the device-specific pad control features, such as pullup/down I/O configuration and pad functional multiplexing. Wake-up control/status features are also subjects of the device core control.

The registers associated with this module are:

- Clock gating configuration register: [CONTROL_PADCONF_CORE_SYSCONFIG](#)
- Different peripheral pad mode configuration and wake-up status/configuration registers:

- CONTROL_CORE_PAD0_X_PAD1_Y
- CONTROL_PADCONF_WAKEUPEVENTx
- [CONTROL_PADCONF_GLOBAL](#)
- CONTROL_SMARTxIO
- And so on.
- Peripheral pad voltage-level control register: CONTROL_PADCONF_MODE
- Miscellaneous controls for different device interface modules: CONTROL_X registers, such as the [CONTROL_MMC1](#) register (including the CONTROL_EFUSE registers)

18.4.7.4 Device Wake-Up Control Module Instance

Configuration registers for all pads linked to the wake-up voltage domain are in the WKUP device control module. The registers instantiated are:

- Clock gating configuration register: [CONTROL_PADCONF_WKUP_SYSCONFIG](#)
- CONTROL_WKUP_PAD0_X_PAD1_Y registers for configuring FREF clock oscillator pads, reset signals, and power mode pad configurations

NOTE: SYSCTRL_PADCONF_X alias notifies a device control module instance.

[Table 18-122](#) shows the memory size and base addresses assigned to the different control module instances

18.4.8 Pad Functional Multiplexing and Configuration

After POR, software must set the pad functional multiplexing and configuration registers to the desired values according to the requested device configuration. The configuration is controlled by pads or a group of pads. Each configurable pin has its own configuration register for pullup/down control and for assignment to a given module.

Two sets of 32-bit registers provide the pad functional multiplexing and configuration feature of the control module. The first set of registers (CONTROL_CORE_PAD0_X_PAD1_Y) configures the pads in the CORE power domain. The second set of registers (CONTROL_WKUP_PAD0_X_PAD1_Y) configures the pads in the WKUP power domain.

The pad configuration as defined in this module is used in the IO_CTRL logic along with the gating and protection features. The gating feature is implemented for the output pads. The protection feature is implemented for input lines. These features implement additional control and multiplexing capabilities hard-wired in the IO_CTRL logic and driven by the state and/or logic of the internal device.

The gating feature allows forcing an output pad to a fixed value (Z, pullup, pulldown, 1, 0) or to a given internal signal. Each gating command is defined with a logic equation and the output state or value to be set on the pad when the logic equation is "True."

The protection feature provides control on each input line of the control module when no pad is assigned to this input (protected value). When POR is released, the value on the pad is driven by the default configuration of the control module. This configuration is usually aligned with the default value selected on the I/O cell. The protected value can be logical level (0 or 1) or a signal from a pad; it is selected when none of the pad_x.MuxMod selects a device input.

Each 32-bit pad configuration register controls two pads: the first pad is controlled by the 16 least-significant bits (LSBs), and the second pad is controlled by the 16 most-significant bits (MSBs); thus, one pad configuration register provides control for two different pins. After POR, software sets the pad functional multiplexing and configuration registers to the requested device pad configurations. Data written in these registers directly commands the multiplexing of the pad configuration logic. [Figure 18-6](#) shows the 16-bit-wide pad configuration register field associated with each pin.

Figure 18-6. Pad Configuration Register Functionality

sysctrl-007

NOTE: These registers can be accessed using 8-, 16-, and 32-bit operations.

The functional bits of a pad configuration register field are divided into the following five fields:

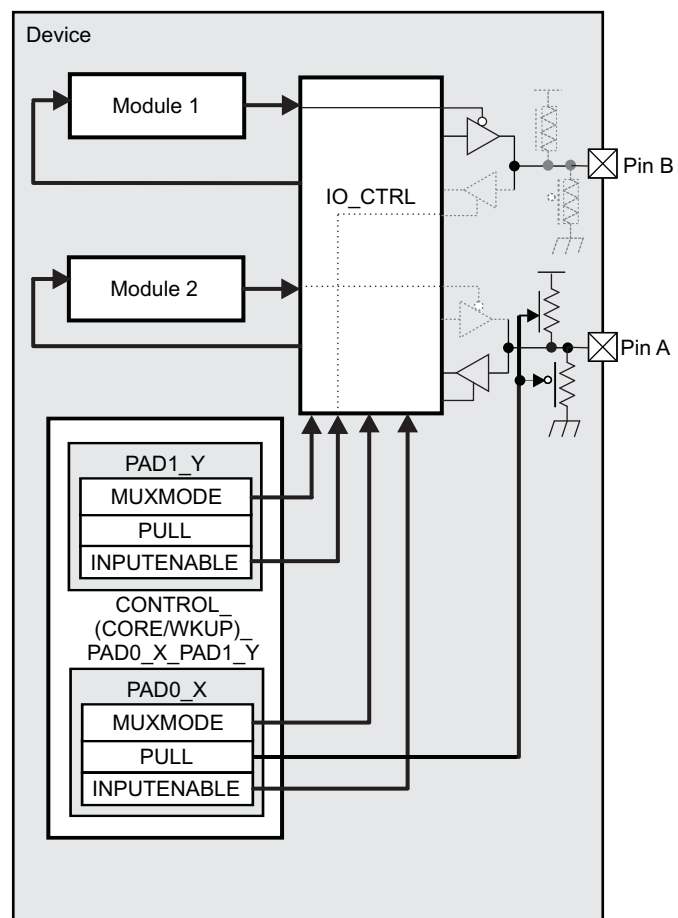

- MUXMODE (3 bits) defines the multiplexing mode applied to the pin. A mode corresponds to the selection of the function mapped on the pin with seven (0 to 6) possible functional modes for each pin.
- PULL (2 bits) for combinational pullup/down configuration:
 - PULLTYPESELECT: Pullup/down type selection for the pin
 - PULLUDENABLE: Enables pullup/down feature for the pin
- INPUTENABLE (1 bit) drives an input enable signal to the I/O CTRL.
 - INPUTENABLE = 0: Input disable. Pin is configured only in output mode.
 - INPUTENABLE = 1: Input enable. Pin is configured in bidirectional mode.
- Off mode values (1 bit) override the pin state when the OFFMODEENABLE bit in CONTROL_CORE_PAD0_X_PAD1_Y is set and off mode is active. This feature allows having separate configurations (5 bits) for the pins when in off mode:
 - OFFMODEENABLE: Off mode pin state override control. Set to 1 to enable the feature and set to 0 to disable it.
 - OFFMODEOUTENABLE: Off mode output enable value. Set to 0 to enable the feature and set to 1 to disable it.
 - OFFMODEOUTVALUE: Off mode output value.
 - OFFMODEPULLUDENABLE: Off mode pullup/down feature enable
 - OFFMODEPULLTYPESELECT: Off mode pullup/down type selection
- Wake-up bits (2 bits):
 - WAKEUPENABLE: Enable wake-up detection on input. It is also the off mode input enable value.
 - WAKEUPEVENT: Wake-up event status for the pin

CAUTION

The OFFOUTENABLE and OFFOUTVALUE bits are functional only if the pad configuration supports output mode on at least one MUXMODE. For a pad that supports only the input feature, the OFFOUTENABLE and OFFOUTVALUE bits cannot be configured (they are don't care and read always returns 0).

NOTE: Because off-mode affects pads only in the CORE power domain, OFFMODE-related bits are not present in the pad configuration registers of the WKUP power domain .

Figure 18-7 shows the pad configuration functionality when off mode is inactive. For more information about off mode, see [Section 18.4.8.4, Off Mode PAD Control Overview](#).

Figure 18-7. Pad Configuration Diagram

sysctrl-008

The I/O pads are controlled by software by:

- Writing to the CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y registers in the device control module for I/O and pullup/down configuration
- Writing to the GPIOi.GPIO_OE registers in the GPIO module for I/O configuration

For more information about how to configure the I/O pads, see [Section 18.5.1.2.5, Pad Configuration Programming Points](#).

For more information about the GPIO module, see [Section 25.4.8, General-Purpose Interface Data Input/Output Capabilities](#).

NOTE: For the proper functioning of the following modules, the INPUTENABLE bit in the corresponding pad configuration register must be set to 1 for pads configured to drive output clocks:

- GPMC
- I2Ci
- MMCi
- HSUSB HOST
- McPDM

NOTE: For a correct configuration of each pin direction (input, output, bidirectional), the CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y and GPIOi.GPIO_OE registers must be written.

NOTE: Software INPUTENABLE controls are not available for the Ipddr21_x, Ipddr22_x, usbb1_hsic_x, and usbb2_hsic_x pads. Once their buffers are enabled they are always bidirectional. For more information, see [Section 18.4.12.9.2, High-Speed I/O Buffers With Impedance, Slew Rate, and Weak Driver Settings](#).

[Table 18-6](#) lists the bit directions of the CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y registers.

Table 18-6. Bit Meanings for CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y Registers

Pad Configuration Bit	Bit Meaning	
	0	1
PULLUDENABLE	Not activated	Activated
PULLTYPESELECT	Pulldown	Pullup
INPUTENABLE	Input enable signal is inactive.	Input enable signal is active.
OFFMODEENABLE	Off mode values are invalid.	Off mode values are valid.
OFFMODEOUTENABLE	Output	Input
OFFMODEOUTVALUE	Low	High
OFFMODEPULLUDENABLE	Not activated	Activated
OFFMODEPULLTYPESELECT	Pulldown	Pullup
WAKEUPENABLE	Disable I/O wake-up function.	Enable I/O wake-up function.
WAKEUPEVENT	Wake-up event is not detected.	Wake-up event is detected.
MUXMODE bits	See Table 18-7, Mode Selection .	See Table 18-7, Mode Selection .

18.4.8.1 Mode Selection

[Table 18-7](#) lists the multiplexing modes and settings.

Table 18-7. Mode Selection

MUXMODE	Selected Mode
0b000	Primary mode = Mode 0
0b001	Mode 1
0b010	Mode 2
0b011	Mode 3
0b100	Mode 4
0b101	Mode 5
0b110	Mode 6
0b111	Safe mode = Mode 7

The MUXMODE field in the CONTROL_CORE_PAD0_X_PAD1_Y and CONTROL_WKUP_PAD0_X_PAD1_Y registers defines the multiplexing mode applied to the pad. Modes are referred to by their decimal (from 0 to 7) or binary (from 0b000 to 0b111) representation. Functional modes are defined from 0b000 to 0b110; mode 0b111 is referred to as the safe mode.

For most pads, the reset value for the MUXMODE field in the CONTROL_CORE_PAD0_X_PAD1_Y and CONTROL_WKUP_PAD0_X_PAD1_Y registers is 0b111. The exceptions are pads to be used at boot time to transfer data from selected peripherals to the external flash memory.

Mode 0 is the primary mode. When mode 0 is set, the function mapped to the pin corresponds to the name of the pin.

Modes 1–6 are possible modes for alternate functions. On each pin, some modes are used effectively for alternate functions, while other modes are unused and correspond to no functional configuration.

Safe mode (Mode 7) avoids any risk of electrical contention by configuring the pin as an input with no functional interface mapped to it. Safe mode is used mainly as the default mode for all pins containing no mandatory interface at the release of POR.

NOTE: When a pad is set into a mux mode that is not defined by pin multiplexing, the pad is actually set undriven (Hi-Z) with potential pullup/down.

For more information about the configurable mode on each pin, see [Table 18-10](#) and [Table 18-9](#).

NOTE: Pad names are signal names available in mode 0.

18.4.8.2 Pull Selection

There is no automatic gating control to ensure that internal weak pulldown/pullup resistors on a pad are disconnected whenever pad is configured as output. If a pad is always configured in output mode, it is recommended for user software to disable any internal pull resistor tied to it, to avoid unnecessary consumption.

Table 18-8. Pull Selection

PULL		Pin Behavior
PULLTYPESELECT	PULLUDENABLE	
0b0	0b0	Pulldown selected but not activated
0b0	0b1	Pulldown selected and activated
0b1	0b0	Pullup selected but not activated
0b1	0b1	Pullup selected and activated

For more information about the pull available on each pin, see [Table 18-10](#) and [Table 18-9](#).

NOTE: Software controls for internal active mode pullups and pulldowns on the lpddr21_x and lpddr22_x pads are available in the [CONTROL_LPDDR2IO1_0](#) through [CONTROL_LPDDR2IO1_2](#) and [CONTROL_LPDDR2IO2_0](#) through [CONTROL_LPDDR2IO2_2](#) registers, respectively.

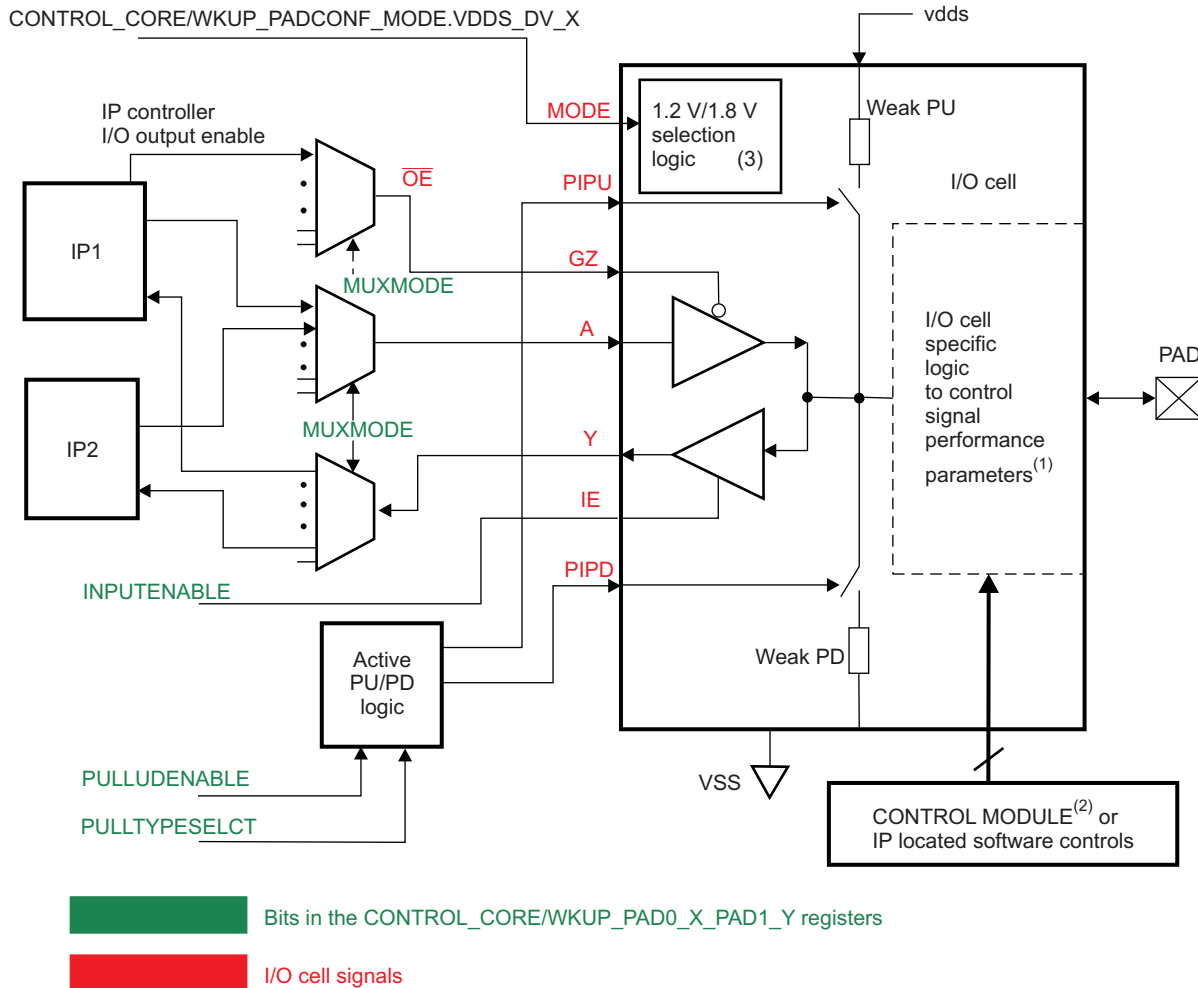

Software controls for internal active mode pullups and pulldowns on the usbb1_hsic_x and usbb2_hsic_x pads are available in the [CONTROL_USBB_HSIC](#) register.

For more information, see [Section 18.4.12.9.2, High-Speed I/O Buffers With Impedance, Slew Rate, and Weak Driver Settings](#).

18.4.8.2.1 Generic Pad Configuration Bit Fields vs I/O Cell Mapping

[Figure 18-8](#) provides a generic view of the relations between the pad configuration controls and I/O cell functions for a pad configured in active mode.

Figure 18-8. Active Mode Pad Configuration Bit Fields vs I/O Cell Mapping

sysctrl-028

- (1) [Section 18.4.12.9, Signal Integrity Parameter Control Registers With Pad Group Assignment](#), summarizes the I/O cell signal performance settings. For more information about the controlled I/O cell electrical parameters and interdependency considerations, see the device data manual.
- (2) For information about the mapping of software controls in the control module versus different device pads, see [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#). For more information about interface-specific signal parameter settings, see the device data manual.
- (3) The CONTROL_CORE/WKUP_PADCONF_MODE.VDDS_DV_x bit is available for each I/O that is part of the dual-voltage domain group x. For more information about 1.2-V/1.8-V dual-voltage domain I/Os, see the device data manual. For more information about peripheral dual-voltage software controls versus pad group mapping, see [Section 18.4.12.10, Dual-Voltage-Supplied Peripheral Controls](#).

NOTE: Dynamic switching between 1.2-V and 1.8-V voltage modes on dual-voltage peripheral I/Os is not allowed.

18.4.8.3 Pad Multiplexing Register Fields

Table 18-10 and Table 18-9 provide for each pad configuration register field the address offset and associated signal name for each multiplexing mode (as set by the MUXMODE bit field). Mode 0 is always defined. Modes with no signal name are undefined for the given pad. For more information about default padconfiguration settings (POR values) for pads in the CORE power domain, see [Section 18.6.7, SYSCTRL_PADCONF_CORE Register Description](#); for pads in the WKUP power domain, see [Section 18.6.9, SYSCTRL_PADCONF_WKUP Register Description](#).

NOTE:

- [Table 18-9](#) lists the pad configuration registers instantiated in the WKUP power domain that drive the pads in the WKUP power domain. [Table 18-10](#) lists the pad configuration registers instantiated in the CORE power domain that drive the pads in the CORE power domain.
 - In [Table 18-10](#) and [Table 18-9](#), an empty cell indicates that the mode or pull is not available for this pin.
-

⁽¹⁾ For the pad configuration registers in which the multiplexing set has only one signal (available in muxmode 0), the MUXMODE bit field is NOT implemented, and is described as RESERVED. Software must keep this bit field at its default (power-on reset) value.

⁽²⁾ This pad is built on an I/O cell of the extended-drain type, which can be configured to operate within the 1.8-V (standard) or 3.0-V (high) I/O power supply voltage range. A PBIAS cell, which acts as a level shifter, is connected to the extended-drain I/O cell of this pad to appropriately bias its voltage according to the externally applied I/O power supply voltage. To ensure I/O safe operation at 1.8 V or 3.0 V and desired signal performance, the extended-drain I/O cell and its corresponding PBIAS cell must be appropriately configured by software prior to signal selection on the pad, regardless of the signal multiplexing mode. For more details on extended-drain I/O cell and PBIAS cell descriptions and settings, see [Section 18.4.9, Extended-Drain I/O and PBIAS Cell](#), and [Section 18.5.1.2.2, Extended-Drain I/Os and PBIAS Cells Programming Guide](#).

⁽²⁾ This pad is built on an I/O cell of the extended-drain type, which can be configured to operate within the 1.8-V (standard) or 3.0-V (high) I/O power supply voltage range. A PBIAS cell, which acts as a level shifter, is connected to the extended-drain I/O cell of this pad to appropriately bias its voltage according to the externally applied I/O power supply voltage. To ensure I/O safe operation at 1.8 V or 3.0 V and desired signal performance, the extended-drain I/O cell and its corresponding PBIAS cell must be appropriately configured by software prior to signal selection on the pad, regardless of the signal multiplexing mode. For more details on extended-drain I/O cell and PBIAS cell descriptions and settings, see [Section 18.4.9, Extended-Drain I/O and PBIAS Cell](#), and [Section 18.5.1.2.2, Extended-Drain I/Os and PBIAS Cells Programming Guide](#).

18.4.8.4 Off Mode Pad Control Overview

When off mode is selected, which is true when `PRM_DEVICE_OFF_CTRL[0] DEVICE_OFF_ENABLE` from the PRCM module = 0b1 or `CONTROL_PADCONF_GLOBAL[31] FORCE_OFFMODE_ENABLE = 0b1` (force bit to test the value of off mode), the off mode values field `CONTROL_CORE_PAD0_X_PAD1_Y[27,11] OFFMODEOUTVALUE` overrides the pad state when the `CONTROL_CORE_PAD0_X_PAD1_Y[25,9] OFFMODEENABLE` bit is set.

The `CONTROL_CORE_PAD0_X_PAD1_Y[26,10] OFFMODEOUTENABLE` bit is active low.

Figure 18-9 shows the off mode pad control.

Figure 18-9. Off Mode Pad Control Overview

If off mode is active and the `OFFMODEENABLE` bit field is set to 0 (disable the off mode override feature), the pad keeps the AND value of the configuration (input/output, pullup/down) it had before going into off mode:

- For an input, the pad is isolated and the pull remains active.
- For an output, the value is latched before going into off mode, to drive the same value in off mode.

NOTE: Software controls for internal off-mode pullups and pulldowns on the `usbb1_hsic_x` and `usbb2_hsic_x` pads are available in the `CONTROL_USB_B_HSIC` register.

No internal off-mode pullups and pulldowns are available for the `lpddr21_x` and `lpddr22_x` pads of the device.

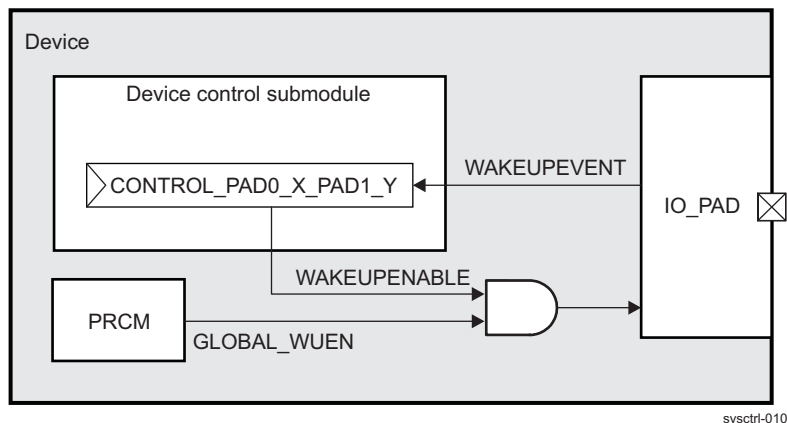

For more information, see [Section 18.4.12.9.2, High-Speed I/O Buffers With Impedance, Slew Rate, and Weak Driver Settings.](#)

18.4.8.4.1 Wake-Up Event Detection

In off mode, wake-up event detection can also be enabled on an input pad. The pad wake-up event is latched in the `CONTROL_CORE_PAD0_X_PAD1_Y[31,15]` and `CONTROL_WKUP_PAD0_X_PAD1_Y[31,15] WAKEUPEVENT` bits.

The off mode I/O pads wake-up scheme is enabled by setting the PRM_IO_PMCTRL[16] GLOBAL_WUEN bit from the PRCM module. The wake-up scheme status is transmitted by the WKUP_ENABLE signal. The wake-up event detection capability of each I/O pad of the device is individually enabled or disabled by writing the CONTROL_CORE_PAD0_X_PAD1_Y[30,14] and CONTROL_WKUP_PAD0_X_PAD1_Y[30,14] WAKEUPENABLE bits.

Figure 18-10. Wake-Up Event Detection Overview

NOTE: When wake-up detection is enabled for a pad, the pad must be configured as input to avoid contention between the device output buffer and an external driver. If this pin is already configured as an input in active mode, hardware automatically retains the same input state; no software action is required.

If this pin is configured as an output in active mode, the off override function must be enabled to set the pin as an input during off mode: in the CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y register, set the OFFMODEENABLE bit to 0x1 to enable the off override function and set the OFFMODEOUTENABLE bit to 0x1 to switch this pin to input mode.

NOTE: Regardless of whether the INPUTENABLE bit is set high or low during active mode, to enable wake-up detection for a pad, user software must set the WAKEUPENABLE bit to 0x1. It is recommended to apply pullup/down resistors at the pad to avoid spurious wake-up detection. User software can optionally enable the pad off-mode internal pullup/down resistors through the appropriate setting of the OFFMODEPULLUDENABLE and OFFMODEPULLTYPESELECT bits in the corresponding pad configuration register.

The CONTROL_PADCONF_WAKEUPEVENT_0 through CONTROL_PADCONF_WAKEUPEVENT_6 registers are dedicated 32-bit registers for a separate capture of the WAKEUPEVENT from different pads. Duplication of the CONTROL_CORE_PAD0_X_PAD1_Y[31,15] and CONTROL_WKUP_PAD0_X_PAD1_Y[31,15] wake-up event bits inside these seven additional registers helps reduce the software latency in identifying which pad has triggered a wake-up event.

18.4.8.4.2 I/O Power Optimization

To optimize I/O power, it is important to avoid unconnected or incorrectly pulled pins. According to the type of pins, the way to reduce power consumption can differ. [Table 18-11](#) shows the three available pin (or ball) types.

Table 18-11. Pin Types

The configuration differs according to the I/O cell types. The following advice can be useful to avoid extra current leakage:

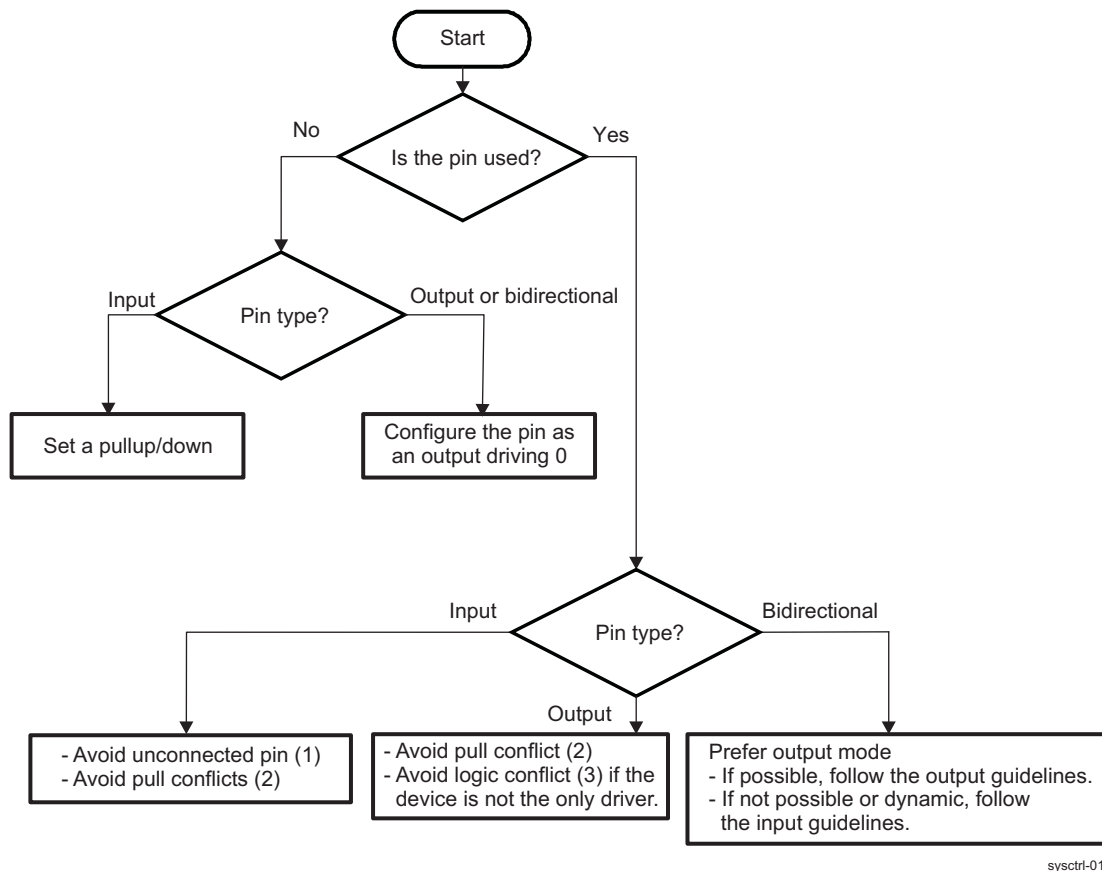

- For input pins, use a pullup/down when possible.
- For output pins, check existing pulls to avoid conflicts.
- For bidirectional pins, reconfigure the pin as an output driving 0 when possible.

NOTE: If the pad is always configured in output mode, it is recommended for software to disable the internal pull by programming the I/O pad configuration register of the corresponding control module.

NOTE: If a device pad is left unconnected, but power is supplied to the I/O, or the pad is used only as an output during the lifetime of the application, it is recommended to keep its corresponding pad configuration bit `CONTROL_CORE /WKUP_PAD0_X_PAD1_Y.INPUTENABLE` set to 0b0. This keeps the input buffer disabled and reduces static current consumption.

Some I/O configurations involve modifications during the software setup of I/Os and sometimes require several hardware updates.

[Figure 18-11](#) shows how to optimize the power consumption of pads.

Figure 18-11. I/O Power Optimization Flow Chart

The following notes explain more about the pin configuration.

- To avoid unconnected pins, the configuration depends on its use:
 - If the pin is not driven externally, a pullup/down is required.
 - Otherwise, a pullup/down is not necessary.
- Pull conflicts occur when different pulls are on the same line. To configure the pin correctly, avoid having external and internal pulls together.
- Logic conflicts consist in different electrical levels at the same time on the same line. This can occur when several devices are connected to the same line. The two possible cases are:
 - If no external device drives the line, configure the pin to drive 0.
 - If another device drives the line, the same value must be driven or the pin must be disconnected (high-impedance state [Hi-Z]).

NOTE: It is advised to use Hi-Z logical state on the device or on the external component when the line is driven by both components.

For unconnected device pads, `safe_mode` pad configuration is recommended if available. [Table 18-12](#) summarizes recommendations for the configuration of unconnected pads (in terms of mux mode, input, and output buffer states) for all cases, including those where `safe_mode` configuration is not available.

Table 18-12. Recommended Configuration For Unconnected Device Pads

Pad MuxMode Set Features			Power-on reset default configuration		Recommended Unconnected Device Pad Configuration				
Safe Mode Available?	GPIO Function Available?	More Than One (Non-GPIO) Function Available?	Multiplexed Signal Direction at Pad	Pad State ⁽¹⁾	Multiplexed Signal Direction at Pad	Pad State	Input Buffer Disabled?	Output Buffer Disabled?	MUX Function Selected
Yes	N/A	N/A	Input	PU	Safe Mode	PU	Yes ⁽²⁾	N/A	SAFE MODE ⁽³⁾
Yes	N/A	N/A	Input	PD	Safe Mode	PD	Yes	N/A	SAFE MODE
Yes	N/A	N/A	Output	1	Safe Mode	PD	Yes	N/A	SAFE MODE
Yes	N/A	N/A	Output	0	Safe Mode	PD	Yes	N/A	SAFE MODE
Yes	N/A	N/A	-	Hi-Z	Safe Mode	PD	Yes	N/A	SAFE MODE
No	Yes	N/A	Input	PU	Input	PU	Yes	Yes ⁽⁴⁾	GPIO_XX ⁽⁵⁾
No	Yes	N/A	Input	PD	Input	PD	Yes	Yes	GPIO_XX
No	Yes	N/A	Output	1	Input	PD	Yes	Yes	GPIO_XX
No	Yes	N/A	Output	0	Input	PD	Yes	Yes	GPIO_XX
No	Yes	N/A	-	Hi-Z	Input	PD	Yes	Yes	GPIO_XX
No	No	Yes	Input	PU	Input	PU	Yes	N/A ⁽⁴⁾	N/A (default)
No	No	Yes	Input	PD	Input	PD	Yes	N/A	N/A (default)
No	No	Yes	Output	1	Output	1	Yes	N/A	N/A (default) ⁽⁶⁾
No	No	Yes	Output	0	Output	0	Yes	N/A	N/A (default) ⁽⁶⁾
No	No	Yes	-	Hi-Z	Input	PD	Yes	N/A	N/A (default)
No	No	No	Input	PU	Input	PU	Yes	N/A ⁽⁴⁾	N/A (default)
No	No	No	Input	PD	Input	PD	Yes	N/A	N/A (default)
No	No	No	Output	1	Output	1	Yes	N/A	N/A (default)
No	No	No	Output	0	Output	0	Yes	N/A	N/A (default)
No	No	No	-	Hi-Z	Input	PD	Yes	N/A	N/A (default)

⁽¹⁾ PU = Pullup; PD = Pulldown; Hi-Z = High impedance

⁽²⁾ If a certain device pad is left unconnected, its associated padconfiguration register INPUTENABLE bit must be explicitly disabled in software (set to 0b0), regardless of pad MUXMODE bit field value.

⁽³⁾ If a certain pad has a defined safe_mode and is left unconnected in an application, it is recommended to keep its padconfiguration MuxMode value at 0x7 (that is, safe_mode).

⁽⁴⁾ There is no software control over the pad associated output buffer in the Control Module. In case of a GPIO function selection, the output buffer is hardware enabled once the user enables corresponding pin output direction in the GPIOx.GPIO_OE control register.

⁽⁵⁾ If a certain pad does not have a safe_mode but has an associated GPIO function, it is recommended to set its padconfiguration register MuxMode to select the GPIO mode.

⁽⁶⁾ If one of the other mux modes available is bidirectional or input-only, then the nondefault mux mode could be used and configured with input disabled.

18.4.9 Extended-Drain I/O and PBIAS Cell

The device primarily supports 1.8-V I/O voltage on its interfaces, with the exception of the MMC/SD/SDIO1 interface, which supports 1.8-V and 3.0-V voltages. The need for embedded extended-drain I/Os on the MMC/SD/SDIO1 interface imposes the use of embedded PBIAS cell MMC1_PBIAS to provide a 1.8-V or 3.0-V reference.

A second PBIAS cell (PBIAS1) is integrated in the device. One of its associated extended-drain I/O cells operates the signals of the gpio_wk0 through gpio_wk2 I/Os.

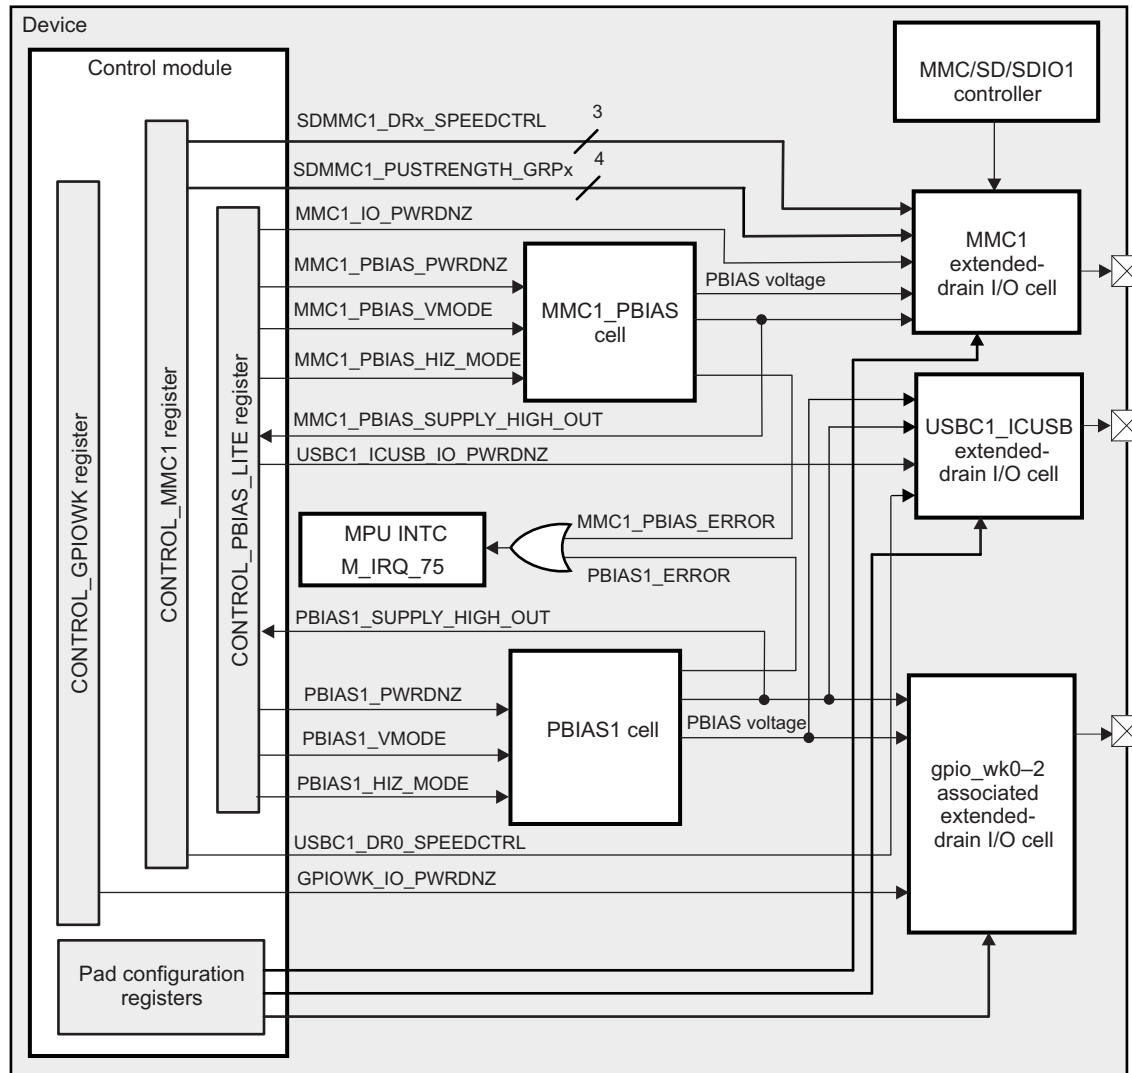

A separate extended-drain I/O cell (USBC1_ICUSB extended-drain I/O cell) is shared between usbc1_icusb_dp and usbc1_icusb_dm (MUXMODE = 0x0), and between the gpio_98 and gpio_99 (MUXMODE = 0x3) pads. The USBC1_ICUSB I/O cell and extended-drain I/O cells gpio_wk0 through gpio_wk2 are biased by the same PBIAS1 output voltage.

NOTE: With the appropriate PBIAS cell configuration, the different I/Os muxed on the sdmmc1, usbc1_icusb, and gpio_wk0 through gpio_wk2 pads can operate at 1.8-V or 3.0-V power supply.

The MMC1_PBIAS cell and its associated MMC1 extended-drain I/O is software-controlled by bits in the [CONTROL_PBIASLITE](#) and [CONTROL_MMC1](#) registers of the device core control module. PBIAS1 and associated GPIO_WKx and USBC1_ICUSB_x I/Os are software-controlled by bits in the [CONTROL_PBIASLITE](#), [CONTROL_MMC1](#), and [CONTROL_GPIOWK](#) registers.

[Figure 18-12](#) shows the functional block diagram with the connections between the PBIAS cells and the extended-drain I/O cells.

Figure 18-12. Functional Block Diagram

sysctrl-015

Table 18-13. PBIAS Cell and Extended-Drain I/O Pin CONTROL_PBIAS_LITE Bit Control

Control Signals for Different PBIAS and Extended-Drain I/O Cells	Description
MMC1_PBIAS_PWRDNZ	Protects the MMC1_PBIAS cell when the SDMMC1_VDDS supply voltage is not stable. Software must keep this signal to 0b0 whenever this voltage ramps up/down or changes. When this bit is set to 0, the PBIAS output voltage is equal to SDMMC1_VDDS voltage and the PBIAS supply detector is disabled.
MMC1_PBIAS_VMODE	Sets the SDMMC1_VDDS voltage level (MMC1_PBIAS side) according to which MMC1_PBIAS cell generates appropriate biasing levels for the MMC1 extended-drain I/O. The default state of this bit is HIGH, indicating that the voltage level SDMMC1_VDDS is 3.0 V.
MMC1_PBIAS_HIZ_MODE	When MMC1_PBIAS_HIZ_MODE is set to 1, the PBIAS output is in high impedance. MMC1_PBIAS_ERROR is automatically set to 1 when MMC1_PBIAS_HIZ_MODE = 1. When MMC1_PBIAS_HIZ_MODE = 0, MMC1_PBIAS cell is in normal operation mode.
MMC1_PBIAS_SUPPLY_HIGH_OUT	Output from the internal MMC1_PBIAS voltage supply detector, which indicates whether the SDMMC1_VDDS supply is 3.0 V or 1.8 V
MMC1_PBIAS_ERROR	Indicates whether the software-programmed MMC1_PBIAS_VMODE level matches the MMC1_PBIAS_SUPPLY_HI_OUT output signal during normal operation
MMC1_IO_PWRDNZ	Protects the MMC1 I/O extended-drain cell when the SDMMC1_VDDS voltage is not stable. Software must keep this signal to 0b0 whenever the SDMMC1_VDDS supply voltage ramps up/down or changes. When this bit is at 0, the pad is floating.
SDMMC1_DRx_SPEEDCTRL, x = (0...2)	Speed control signals for three different SDMMC1 pad groups identified within the MMC1 I/O cell
SDMMC1_PUSTRENGTH_GRPx, x = (0...3)	Pullup strength controls for four different SDMMC1 pad groups identified within the MMC1 I/O cell
PBIAS1_PWRDNZ	Protects the PBIAS1 cell when the SIM_VDDS supply voltage is not stable. Software must keep the PWRDNZ signal to 0b0 whenever this supply voltage ramps up/down or changes. When this bit is at 0, the PBIAS1 output voltage is equal to SIM_VDDS voltage and the PBIAS supply detector is disabled.
PBIAS1_VMODE	Sets the SIM_VDDS voltage level (PBIAS1 side) according to which PBIAS1 cell generates appropriate biasing levels for the GPIOWK0GPIOWK2 and USBC1_ICUSB associated extended-drain I/Os. The default state of this bit is HIGH, indicating that the voltage level SIM_VDDS is 3.0 V.
PBIAS1_HIZ_MODE	When PBIAS1_HIZ_MODE is set to 1, the PBIAS1 output is in HIGH impedance. PBIAS1_ERROR is automatically set to 1 when PBIAS1_HIZ_MODE = 1. When PBIAS1_HIZ_MODE = 0, PBIAS1 is in normal operation mode.
PBIAS1_SUPPLY_HIGH_OUT	Output from the internal PBIAS1 voltage supply detector, which indicates whether the SIM_VDDS supply is 3.0 V or 1.8 V
PBIAS1_ERROR	Indicates whether the software-programmed PBIAS1_VMODE level matches the PBIAS1_SUPPLY_HI_OUT output signal during normal operation
GPIOWK_IO_PWRDNZ	Protects the GPIOWK0GPIOWK2 associated extended-drain I/O cell when the SIM_VDDS voltage is not stable Software must keep this signal to 0b0 whenever the SIM_VDDS supply voltage ramps up/down or changes. When this bit is set to 0, the pad is floating.
PAD_GPIO_WK1_LOW	This signal must be set to 0b0 to disable the strong pulldown available after reset on the gpio_wk1 pad. This is to ensure normal use of the gpio_wk1 pad.
0.22 PAD_GPIO_WK2_LOW	This signal must be set to 0b0 to disable the strong pulldown available after reset on the gpio_wk2 pad. This is to ensure normal use of the gpio_wk2 pad.
0.23 USBC1_ICUSB_IO_PWRDNZ	Protects the USBC1_ICUSB extended-drain I/O cell when the SIM_VDDS voltage is not stable. Software must keep this signal to 0b0 whenever the SIM_VDDS supply voltage ramps up/down or changes. When this bit is at 0, the pad is floating.
0.24 USBC1_DR0_SPEEDCTRL	Speed controls for the ICUSB pads associated with the USBC1_ICUSB associated I/O cell

NOTE: When HIZ_MODE = 1, the PBIAS output (the pbias_mmc1 pin) must be tied to a defined external potential to avoid stress on transistors.

Table 18-14 lists the power supplies for PBIAS and the extended-drain I/O cells.

Table 18-14. Power Supplies

Name	Description
VDD2	Core voltage supply
SDMMC1_VDDS	MMC1 I/O cell supply voltage nominal 1.8 V/3.0 V
SIM_VDDS	USBC1_ICUSB and GPIOWK I/O cell supply voltage nominal 1.8 V/3.0 V
VDDS	1.8-V supply for the input buffer

18.4.9.1 PBIAS Cell

The MMC1_PBIAS cell provides a bias for the MMC/SD/SDIO1 extended-drain I/O cell used with high voltage for the MMC/SD/SDIO1 interface. This PBIAS cell provides a voltage reference (PBIAS voltage) for biasing extended-drain in the MMC/SD/SDIO1 cell. In addition to generating the bias voltage, the cell can detect the supply voltage (SDMMC1_VDDS) value (1.8 V or 3.0 V) and update, with its status, the [CONTROL_PBIASLITE](#)[24] MMC1_PBIASLITE_SUPPLY_HI_OUT bit. However, this is possible when the voltage reaches its steady state (the internal PBIAS voltage detector is enabled only when the MMC1_PBIAS_PWRDNZ signal is set to 0b1).

The PBIAS1 cell provides a reference voltage for biasing the gpio0k0gpio2k2 associated extended-drain I/O cell and the USBC1_ICUSB extended-drain I/O cell. In addition to generating the bias voltage, the cell can detect the supply voltage (SIM_VDDS) value (1.8 V or 3.0 V) and update, with its status, the [CONTROL_PBIASLITE](#)[30] PBIASLITE1_SUPPLY_HI_OUT bit. However, this is possible when voltage reaches its steady state (the internal PBIAS voltage detector is enabled only when the PBIAS1_PWRDNZ signal is set to 0b1).

CAUTION

A PBIAS cell lets the peripheral associated with its corresponding extended-drain I/O cells support 1.8-V and 3.0-V voltages. A PBIAS cell is not part of a peripheral, but part of the device I/Os to which this peripheral is internally connected. These device I/Os are not exclusive to one peripheral; through I/O multiplexing they can be connected to other internal signals. It is necessary to configure the PBIAS to enable the I/Os, regardless of how I/O multiplexing is configured for these device I/Os. In other words, independently of which signal is internally connected to a device I/O powered by SDMMC1_VDDS or SIM_VDDS, the corresponding PBIAS must be configured.

18.4.9.2 Extended-Drain I/O

The following MMC/SD/SDIO1 interface signals (selected when MuxMode = 0) use the device I/Os associated with the MMC1 extended-drain I/O cell:

- sdmmc1_clk
- sdmmc1_cmd
- sdmmc1_dati (where i = 0 to 7)

The MMC1 I/O cell is powered externally through the vdds_sdmmc1 pad.

NOTE: The MMC1 I/O cell-associated device I/Os are also shared with other signals. gpio100gpio109, etc. are available when MuxMode is different than 0x0. If signals other than sdmmc1_x are selected, the MMC1 I/O cell must also be configured.

NOTE: For multiplexed gpio signals on the MMC1 I/O cell (gpio_100 through gpio_109), to function appropriately in standard 1.8-V mode, the [CONTROL_PBIASLITE\[21\]](#) MMC1_PBIASLITE_VMODE through [CONTROL_PBIASLITE\[26\]](#) MMC1_PWRDNZ bits must be set to 0b0. When these bits are set, and the externally-applied I/O cell power supply voltage (1.8 V) is stabilized, gpio signals can be enabled on the pads by setting the [CONTROL_PBIASLITE\[22\]](#) MMC1_PBIASLITE_PWRDNZ bit to 0b1 (power-up MMC1_PBIAS cell) and the [CONTROL_PBIASLITE\[26\]](#) MMC1_PWRDNZ bit to 0b1 (power-up MMC1 extended-drain I/O cell).

For more information about signal multiplexing, see [Table 18-10](#).

For general-purpose (GP) device I/Os, which are part of the associated extended-drain cell of the GPIOWK pad, Muxmode = 3, Muxmode = 4 (gpio_wk0 pad only), and Muxmode = 6 are functional.

With Muxmode set to 0x3, the following signals are present:

- gpio_wk0
- gpio_wk1
- gpio_wk2

With Muxmode set to 0x6, the output signals (hw_dbg1, hw_dbg2, and hw_dbg3) are present at the gpio_wk0, gpio_wk1, and gpio_wk2 pads, respectively.

This PBIAS1 associated extended-drain I/O cell is externally powered through the vdds_sim pad.

NOTE: The GPIOWK-associated I/O cell must be properly configured when the gpio_wk0 through gpio_wk2 pads are used. For more information about signal multiplexing, see [Table 18-10](#).

NOTE: For the gpio_wk0 through gpio_wk2 signals to function appropriately in standard 1.8-V mode, the [CONTROL_PBIASLITE\[27\]](#) PBIASLITE1_VMODE through [CONTROL_PBIASLITE\[31\]](#) PBIASLITE1_HIZ_MODE bits and the [CONTROL_GPIOWK\[28\]](#) GPIOWK_IO_PWRDNZ bit must be set to 0b0. When these bits are set, and the externally-applied I/O cell power supply voltage (1.8 V) is stabilized, gpio signals can be enabled on the pads by setting the [CONTROL_PBIASLITE\[28\]](#) PBIASLITE1_PWRDNZ bit to 0b1 (power-up PBIAS1 cell) and the [CONTROL_GPIOWK\[28\]](#) GPIOWK_IO_PWRDNZ bit to 0b1 (power-up extended-drain I/O cell).

The following USBC1_ICUSB interface signals (selected through MuxMode = 0) use the device I/Os associated with the USBC1_ICUSB extended-drain I/O cell:

- usbc1_icusb_dp
- usbc1_icusb_dm

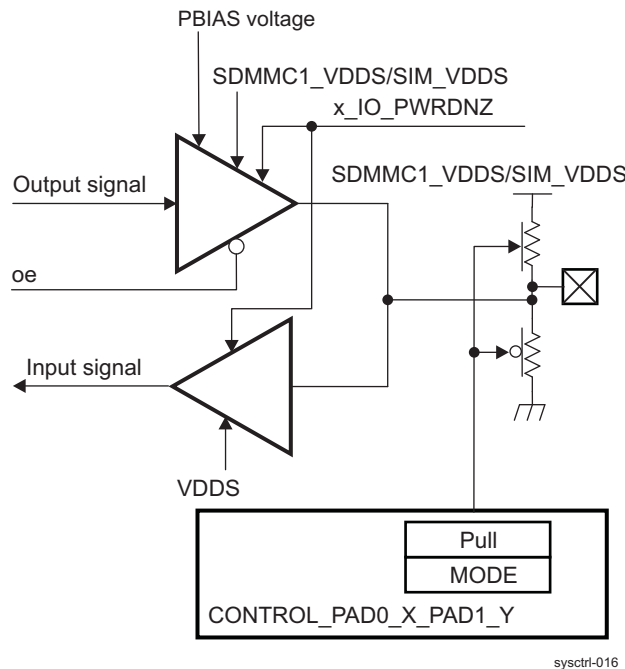

The USBC1_ICUSB I/O cell uses the same external power supply voltage as the GPIOWK cell (vdds_sim pad).

NOTE: The USBC1_ICUSB I/O cell associated device I/Os are also shared with the gpio_98 and gpio_99 signals when MuxMode = 0x3. The USBC1IC_ICUSB cell must be configured to allow for gpio_98 and gpio_99 operation. For more information about signal multiplexing, see [Table 18-10](#).

NOTE: For the gpio_98 through gpio_99 signals to function appropriately in standard 1.8-V mode, the [CONTROL_PBIASLITE\[27\]](#) PBIASLITE1_VMODE through [CONTROL_PBIASLITE\[31\]](#) PBIASLITE1_HIZ_MODE bits and the [CONTROL_PBIASLITE \[20\]](#) USBC1_ICUSB_PWRDNZ bit must be set to 0b0. When these bits are set, and the externally-applied I/O cell power supply voltage (1.8 V) is stabilized, gpio signals can be enabled on the pads by setting the [CONTROL_PBIASLITE\[28\]](#) PBIASLITE1_PWRDNZ bit to 0b1 (power-up PBIAS1 cell) and the [CONTROL_PBIASLITE\[20\]](#) USBC1_ICUSB_PWRDNZ bit to 0b1 (power-up extended-drain I/O cell).

Figure 18-13 shows the extended-drain I/O cells.

Figure 18-13. Extended-Drain I/O

The extended-drain I/O cells have the following I/O signals:

- The output signal, input signal, and oe, which comes from the selected I/O module with the correctly configured MUXMODE field within the corresponding CONTROL_CORE_PAD0_X_PAD1_Y or CONTROL_WKUP_PAD0_X_PAD1_Y register

NOTE: Extended-drain I/Os are muxed I/Os with mode and pullup/down configurations programmable in the control module.

- The PBIAS voltage is a voltage reference for biasing the extended-drain in the MMC1, USBC1_ICSUB, and GPIOWK I/O cells.
- The PWRDNZ signals are used to protect the I/O cells when the SDMMC1_VDDS/SIM_VDDS voltage is not stable.

CAUTION

Software must keep the PWRDNZ-related signals to 0b0 whenever the SDMMC1_VDDS or SIM_VDDS signal ramps up/down or changes. When it is set to 0, the pad is floating (the pad may not reflect the state of the output signal, and the input signal may not reflect the state of the pad).

- [CONTROL_PBIASLITE\[24\]](#) MMC1_PBIASLITE_SUPPLY_HI_OUT is a status bit on the

SDMMC1_VDDS value and is used to inform the MMC1 I/O cell about the value of the SDMMC1_VDDS signal.

- **CONTROL_PBIASLITE**[30] PBIASLITE1_SUPPLY_HI_OUT is a status bit on the SIM_VDDS value and is used to inform the gpiowk0 through gpiowk2 associated I/O cell and USBC1_ICUSB I/O cell about the value of the SIM_VDDS signal.

For more information about the software configurations of the extended drain I/Os and PBIAS cells, see [Section 18.5.1.2.2, Extended-Drain I/Os and PBIAS Cells Programming Guide](#).

NOTE: The device can be supplied by an external power IC. TI provides such a global solution to its customers with the TWL60xx power IC.

If the device is associated with the TWL60xx power IC, before using an extended-drain I/O interface, software must program the TWL60xx to enable VMMC1 (for the MMC/SD/SDIO1 or muxed I/O modules) or VSIM (for the GPIOWK0, GPIOWK2, USBC1_ICUSB, or muxed I/Os) and the LDO to provide 1.8-V/3.0-V voltage. This is done by software through the inter-integrated circuit (I²C™) interface that links the device and the TWL60xx IC.

CAUTION

The power supply voltage generated from the companion power IC and applied on the vdds_sdmmc1 or vdds_sim device pins must be programmed according to the recommendations for the currently selected I/O module power supply range.

If the application does not want the I/O interface to run at 3.0 V, software users must then assert the VMODE signal to low for 1.8-V activity: in this case, the PBIAS is connected to ground.

[Table 18-15](#) lists the control signal with the corresponding control bits from the [CONTROL_PBIASLITE](#), [CONTROL_MMC1](#), and [CONTROL_GPIOWK](#) registers to configure the PBIAS and the extended-drain I/O cells. These signals can be controlled by software.

Table 18-15. PBIAS/Extended-Drain I/O Cells Control Signals

Control Signals for Different PBIAS and Extended-Drain I/O Cells	Bits Used for PBIAS Cell and I/O Cell Configurations for Different I/O Modules	Reset Value
MMC1_PBIAS_PWRDNZ	CONTROL_PBIASLITE [22] MMC1_PBIASLITE_PWRDNZ	0
MMC1_PBIAS_VMODE	CONTROL_PBIASLITE [21] MMC1_PBIASLITE_VMODE	1
MMC1_PBIAS_HIZ_MODE	CONTROL_PBIASLITE [25] MMC1_PBIASLITE_HIZ_MODE	0
MMC1_PBIAS_SUPPLY_HIGH_OUT	CONTROL_PBIASLITE [24] MMC1_PBIASLITE_SUPPLY_HI_OUT	0
MMC1_PBIAS_ERROR	CONTROL_PBIASLITE [23] MMC1_PBIASLITE_VMODE_ERROR	0
MMC1_IO_PWRDNZ	CONTROL_PBIASLITE [26] MMC1_PWRDNZ	0
SDMMC1_DRx_SPEEDCTRL, x = (0...2)	CONTROL_MMC1 [27] SDMMC1_DR0_SPEEDCTRL	0
	CONTROL_MMC1 [26] SDMMC1_DR1_SPEEDCTRL	0
	CONTROL_MMC1 [25] SDMMC1_DR2_SPEEDCTRL	0
SDMMC1_PUSTRENGTH_GRPx, x = (0...3)	CONTROL_MMC1 [31] SDMMC1_PUSTRENGTH_GRP0	1
	CONTROL_MMC1 [30] SDMMC1_PUSTRENGTH_GRP1	0
	CONTROL_MMC1 [29] SDMMC1_PUSTRENGTH_GRP2	1
	CONTROL_MMC1 [28] SDMMC1_PUSTRENGTH_GRP3	1
PBIAS1_PWRDNZ	CONTROL_PBIASLITE [28] PBIASLITE1_PWRDNZ	0
PBIAS1_VMODE	CONTROL_PBIASLITE [27] PBIASLITE1_VMODE	1
PBIAS1_HIZ_MODE	CONTROL_PBIASLITE [31] PBIASLITE1_HIZ_MODE	0

Table 18-15. PBIAS/Extended-Drain I/O Cells Control Signals (continued)

Control Signals for Different PBIAS and Extended-Drain I/O Cells	Bits Used for PBIAS Cell and I/O Cell Configurations for Different I/O Modules	Reset Value
PBIAS1_SUPPLY_HIGH_OUT	CONTROL_PBIASLITE [30] PBIASLITE1_SUPPLY_HI_OUT	0
PBIAS1_ERROR	CONTROL_PBIASLITE [29] PBIASLITE1_VMODE_ERROR	0
GPIOWK_IO_PWRDNZ	CONTROL_GPIOWK [28] GPIOWK_IO_PWRDNZ	0
PAD_GPIO_WK1_LOW	CONTROL_GPIOWK [31] PAD_GPIO_WK1_LOW	1
PAD_GPIO_WK2_LOW	CONTROL_GPIOWK [29] PAD_GPIO_WK2_LOW	1
USBC1_ICUSB_IO_PWRDNZ	CONTROL_PBIASLITE [20] USBC1_ICUSB_PWRDNZ	0
USBC1_DR0_SPEEDCTRL	CONTROL_MMC1 [24] USBC1_DR0_SPEEDCTRL	0

The two PBIAS cells support two ranges of I/O SDMMC1_VDDS/SIM_VDDS: 1.8 V, typical for low-voltage applications, and 3.0 V, typical for high-voltage applications. For each supply voltage range, the cell generates suitable bias voltage (PBIAS) for extended-drain PMOS devices.

CAUTION

The PBIAS cell must be programmed according to peripheral power supply voltage. See [Table 18-16](#).

Table 18-16. Voltage Configuration⁽¹⁾

PBIASLITEVMODE Configuration	SDMMC1_VDDS/SIM_VDDS Voltage	Type of Operation
1.8 V	1.8 V	Normal 1.8-V operation
1.8 V	3.0 V	Damaging configuration ⁽²⁾
3.0 V	1.8 V	Degraded functionality ⁽²⁾
3.0 V	3.0 V	Normal 3.0-V operation

⁽¹⁾ For damaging configuration, hardware system protection is provided to prevent deterioration of the associated extended-drain I/Os.

⁽²⁾ These modes must not be used.

The PBIAS output voltage is the same as SDMMC1_VDDS/SIM_VDDS voltage when the corresponding PWRDNZ bit is low. Once the SDMMC1_VDDS / SIM_VDDS supply is stable, software can release the PWRNDZ (setting it high). This starts the PBIAS cell work to generate the PBIAS voltage. During the completion process the corresponding I/Os cannot be used to transmit data. If VMODE is set correctly (compared with supply detector output and found to be the same), then PBIAS output voltage is generated based on the value of VMODE.

NOTE: In the case of a damaging configuration, hardware system protection prevents deterioration of the associated extended-drain I/Os.

CAUTION

The following requirements are critical for an extended-drain I/O cell:

- The VMODE bit must be defined before the PWRNDZ bit is made high (cell is brought out of power-down mode).
- The default state of VMODE bit is high (indicates 3.0-V operation).
- The PWRNDZ bit must be kept low whenever the SDMMC1_VDDS/SIM_VDDS supply ramps up/down or changes. This can be damaging.
- Supply detector is disabled when PWRDNZ = 0, and in this case, supply detector output (SUPPLY_HI_OUT) is initialized to 0.

18.4.9.3 PBIAS Error Generation

If VMODE and supply detector outputs are unequal, it takes 4 μ s for the comparator to process the inputs and generate the VMODE_ERROR flag.

Table 18-17 summarizes the generation of the PBIAS error signals (MMC1_PBIAS_ERROR of the MMC1_PBIAS cell, and PBIAS1_ERROR of the PBIAS1 cell), which depend on the various CONTROL_PBIASLITE bit combinations. The shaded row in the table indicates a condition that could cause a reliability issue if not detected. To prevent this reliability issue, the PBIAS voltage is tied to SDMMC1_VDDS/SIM_VDDS when the PBIAS error signal is high. This disables the I/Os.

CAUTION

Although asserting VMODE_ERROR to 1 ensures that PBIAS voltage is equal to SDMMC1_VDDS/SIM_VDDS, this does not completely protect the I/O cells. It is recommended that all the I/Os are powered down, setting the PWRDNZ mode bits of the corresponding I/O cells to 0b0 by software as soon as VMODE_ERROR = 0b1.

Table 18-17. PBIAS Error Signal Truth Table

VMODE	PWRDNZ	HIZ_MODE	SUPPLY_HI_OUT	VMODE_ERROR
0	0	X	0	0
0	1	0	0	0
0	1	0	1	1
X	1	1	X	1
1	0	X	0	0
1	1	0	0	1
1	1	0	1	0

NOTE: VMODE_ERROR = 0b1: VMODE level is not the same as SUPPLY_HI_OUT, or Hi-Z mode is selected.

VMODE_ERROR = 0b0: VMODE level is the same as SUPPLY_HI_OUT, or VMODE is not considered (PWRDNZ = 0b0).

The MMC1_PBIAS_ERROR and PBIAS1_ERROR signals are ORed and the outputs are mapped to the microprocessor unit (MPU) subsystem INTC. The interrupt line MA_IRQ_75 is activated upon error occurrence. For more information about the Cortex™-A9 MPU INTC registers and their description, see the *ARM Cortex-A9 MPCore Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

The [CONTROL_PBIASLITE\[29\]](#) PBIASLITE1_VMODE_ERROR and [CONTROL_PBIASLITE\[23\]](#) MMC1_PBIASLITE_VMODE_ERROR bits also indicate whether this kind of error occurs.

18.4.9.4 Critical Timing Requirements

It is critical that the PBIAS and I/O cell-related PWRDNZ bits are deasserted (made 1 from 0) only after SDMMC1_VDDS/SIM_VDDS power supply voltage is stable in the device. The cells support only the case where the 1.8-V input buffer supply voltage VDDS ramps up before VDD2 (core voltage). This power-up sequence is automatically provided upon POR by hardware in the device. Take care to ensure that the externally provided SDMMC1_VDDS/SIM_VDDS voltage (1.8 V/ 3 V) is powered up only after VDD2 and VDDS reach their steady state.

[Figure 18-14](#) shows the only possible power-up sequence, as well as the expected behavior of PWRNDZ mode-related bits with regard to supplying voltage ramp up.

Figure 18-14. VDDS Ramps Up Before VDD2

18.4.10 Band Gap Voltage and Temperature Sensor

The device supplies a voltage reference and a temperature sensor feature that are gathered in the band gap voltage and temperature sensor (VBGAPTS) module. The band gap provides current and voltage reference for its internal circuits and other analog IP blocks. The analog-to-digital converter (ADC) produces an output value that is proportional to the silicon temperature.

The main features of the VBGAPTS module are:

- A constant voltage reference output of 0.5 V
- Five constant current reference outputs of 1 μ A
- Analog supply is a nominal 1.8 V.
- Small ADC with 10-bit digital output
- Off mode compatible

A small finite state-machine (FSM) (band gap FSM) is instantiated inside the general core control module to help the VBGAPTS cell accomplish different measurement modes (see [Section 18.4.10.2, Temperature Sensor](#)). In addition, two programmable comparator blocks inside the general core control module post-process the converted data and provide the following outputs:

- Thermal alert programmable comparator output
- Thermal shutdown programmable comparator output

[Figure 18-15](#) shows the functional block diagram of the band gap and the temperature sensor module.

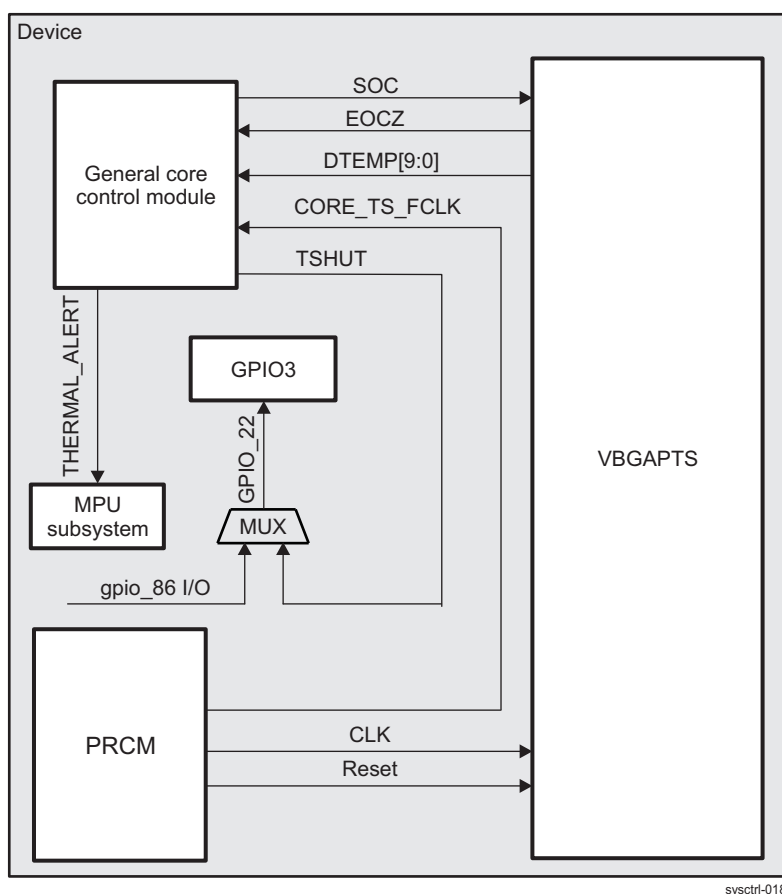

Figure 18-15. Functional Block Diagram

Table 18-18 describes the I/O signals, some of which (SOC, EOCZ, DTEMP[9:0]) build the interface between the VBGAPTS module and the bandgap state-machine of the general core control module.

Table 18-18. Band Gap Voltage and Temperature Sensor Signal Description

Pin	I/O ⁽¹⁾	Description
SOC	I	Start of Conversion signal. A transition to high starts a new ADC conversion cycle.
EOCZ	O	End of Conversion signal. When low, the signal indicates that the value of DTEMP[9:0] is valid.
DTEMP[9:0]	O	Temperature data from the temperature sensor. This value is valid when EOCZ is low.
CLRZ	I	When low, the temperature sensor is in reset mode. This signal must be low when OFFMODE is high.
CLK	I	Functional clock in the range (1–2 MHz) from the WKUP power domain used by the temperature sensor during temperature conversion

⁽¹⁾ I = Input, O = Output

All the configuration signals of the VBGAPTS temperature conversion logic are available through the [CONTROL_TEMP_SENSOR](#) register.

The bandgap state-machine of the general core control module is driven by a dedicated clock (CORE_TS_FCLK) that shares a common PRCM clock source with the VBGAPTS CLK. For more information about the thermal management clocks, see [Chapter 3, Power, Reset, and Clock Management](#).

NOTE: The VBGAPTS functional clock delivered on CLK input is used only for the temperature sensor. When ADC is not converting, this clock can be switched off (CLK = 0). In this case, DTEMP[9:0] retains the temperature code obtained at the previous conversion.

NOTE: User software must ensure that the `CONTROL_BANDGAP_STATUS[3]` `CLEAN_STOP` bit read-only flag is high before switching off the `VBGAPTS` cell (`CLK`) and the bandgap state (`CORE_TS_FCLK`) clocks by programming the `CONTROL_TEMP_SENSOR[13]` `BGAP_TEMPSONOFF` bit to 1. Status `CLEAN_STOP = 1` indicates that the band gap state-machine is in `IDLE` state, and clocks can be safely switched off.

Table 18-19 describes the functional outputs of the two post-processing comparator blocks integrated in the general core control module.

Table 18-19. General Core Control Thermal Logic Outputs Description

Functional Output	Description
THERMAL_ALERT	General core control module thermal alert output, mapped as an interrupt in the MPU subsystem. It is used by software to implement a thermal management policy of the device.
TSHUT	General core control module thermal shutdown comparator output, mapped on a GPIO input. This overheat protection signal is high during normal operation and goes low during a thermal shutdown event.

The configuration bits of the thermal post-processing logic are in several registers of the general core control module. For more information, see [Section 18.4.10.2.3, Thermal Data Post-Processing](#).

18.4.10.1 Band Gap Voltage Reference

The band gap voltage reference feature provides several constant voltage and current references for its internal circuits and for other analog modules.

The voltage reference signal is a 0.5-V output. This output is used internally by the module and is exported for external modules or tests.

The current reference signals consist of five lines, each of which generates a 1- μ A current with a 1.8-V voltage. These lines can be used to bias other modules.

18.4.10.2 Temperature Sensor

The temperature sensor feature is used to convert the temperature of the device into a decimal value coded on 10 bits. An internal ADC, which is part of the device embedded bandgap cell, is used for conversion.

For more information about the thermal sensor operating parameters (temperature range, accuracy, etc.), see the *Temperature Sensor* section in the device data manual.

For more information about the device operating junction temperature ranges under different conditions, see the *Recommended Operating Conditions* section in the device data manual.

NOTE: The temperature measured at the temperature sensor location is lower than the temperature of the hottest spot on the device die. This difference, defined also as the temperature offset between the on-die hottest spot temperature and the temperature registered by the on-die thermal sensor, depends on a number of factors, such as the current system power dissipation, device cooling conditions, etc.

CAUTION

User software must always take care to program thermal thresholds (thermal alert or TSHUT event points) at levels that do not exceed the device hottest spot maximal-allowed temperature minus the device temperature sensor offset estimated at current conditions.

The thermal alert interrupt events are described in [Section 18.4.10.2.4, Thermal Alert Functionality Comparators](#).

The TSHUT signal is connected internally to a GPIO controller pin. For more information, see [Chapter 25, General-Purpose Interface](#).

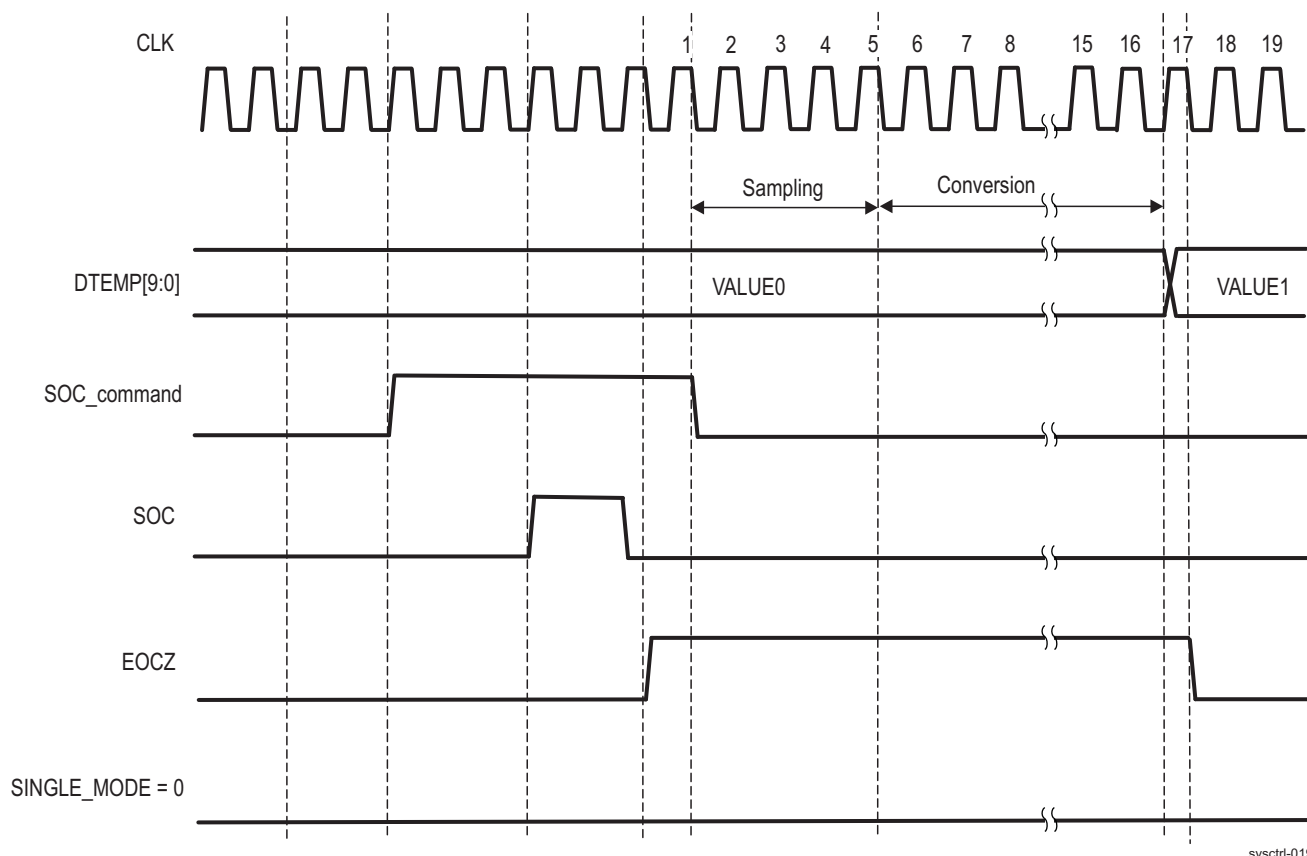

The bandgap state-machine offers two operating modes for the temperature sensor: single conversion mode and repeated single conversion mode.

18.4.10.2.1 Single Conversion Mode

When the ADC is idle ([CONTROL_TEMP_SENSOR\[10\] BGAP_TEMP_SENSOR_EOCZ = 0](#)) and the [CONTROL_BANDGAP_CTRL\[31\] SINGLE_MODE](#) bit is set to 0, it is possible to ask for a single temperature conversion. To initiate a new conversion, the start of conversion bit ([CONTROL_TEMP_SENSOR\[11\] BGAP_TEMP_SENSOR_SOC](#)) must be asserted and maintained high until the end of conversion flag ([CONTROL_TEMP_SENSOR\[10\] BGAP_TEMP_SENSOR_EOCZ](#)) goes high, after which the SOC signal must be made low by setting the [CONTROL_TEMP_SENSOR\[11\] BGAP_TEMP_SENSOR_SOC](#) bit to 0. Conversion completion is indicated by a negative edge of EOCZ (the [CONTROL_TEMP_SENSOR\[10\] BGAP_TEMP_SENSOR_EOCZ](#) bit).

[Figure 18-16](#) shows the timing sequence of a single temperature conversion. As can be seen in the figure, a single temperature conversion is performed by ADC for 17 band gap clock cycles.

Figure 18-16. Single Conversion Mode

sysctrl-019

18.4.10.2.2 Repeated Single Conversion Mode

A continuous temperature measurement on the device is performed as a sequence of single ADC conversions automatically initiated at regular intervals. A 24-bit counter inside the general core control module adds flexibility to program the delay between two consecutive SOC pulses generated from the band gap state-machine.

Two scenarios for ADC to work in a repeated single conversion mode are:

- Fixed-delay repeated single conversions
- Programmable-delay repeated single conversions

18.4.10.2.2.1 Fixed-Delay Repeated Single Conversions

The fixed-delay repeated single conversions scenario follows the sequence:

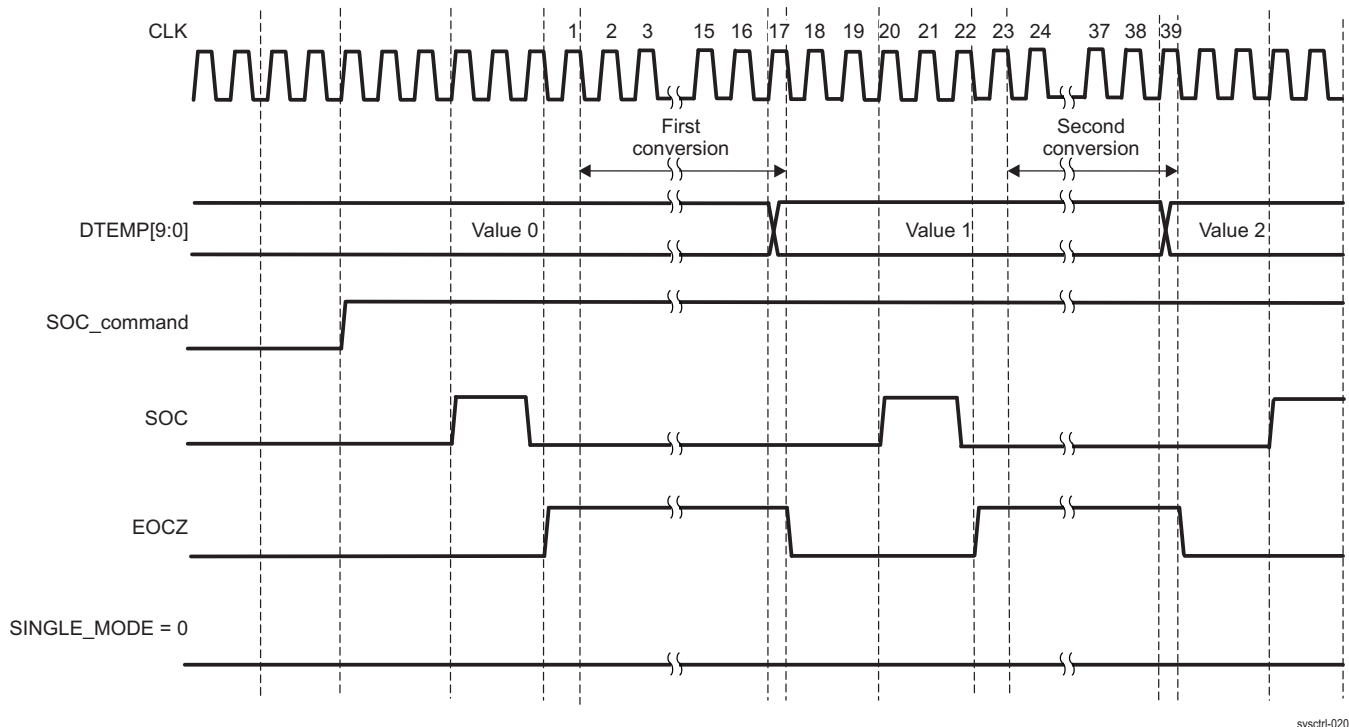

When the ADC is idle (`CONTROL_TEMP_SENSOR[10] BGAP_TEMP_SENSOR_EOCZ = 0`), and `CONTROL_BANDGAP_CTRL[31] SINGLE_MODE = 0`, the bandgap state-machine can be forced to generate a series of SOC pulses if the `CONTROL_TEMP_SENSOR[11] BGAP_TEMP_SENSOR_SOC` bit is asserted high and continuously maintained in this state during the required temperature monitoring period. The user software must deassert the `CONTROL_TEMP_SENSOR[11] BGAP_TEMP_SENSOR_SOC` bit to 0 when the `CONTROL_TEMP_SENSOR[10] BGAP_TEMP_SENSOR_EOCZ` status bit is set high for the last temperature measurement.

As described in Section 18.4.10.2.1, *Single Conversion Mode*, valid data on the DTEMP[9:0] bus upon single conversion completion is indicated by a negative edge of the EOCZ signal. For the software, `CONTROL_TEMP_SENSOR[10] BGAP_TEMP_SENSOR_EOCZ = 0` signals that the temperature data `CONTROL_TEMP_SENSOR[7:0] BGAP_TEMP_SENSOR_DTEMP` bit field is updated.

Figure 18-17 shows the timing sequence for fixed-delay repeated single mode.

In this case, there is no flexibility to control delay between two consecutive SOC pulses, because with `CONTROL_BANDGAP_CTRL[31] SINGLE_MODE = 0` band gap counter logic is disabled. The delay is fixed to 22 bandgap functional clock cycles.

Figure 18-17. Fixed-Delay Repeated Single Conversions

sysctrl-020

18.4.10.2.2.2 Programmable-Delay Repeated Single Conversions

In the programmable-delay repeated single conversions mode the bandgap state-machine uses a 24-bit incremental counter (part of the thermal post-processing logic of the general core control module) to generate a series of SOC pulses with a programmable delay between them.

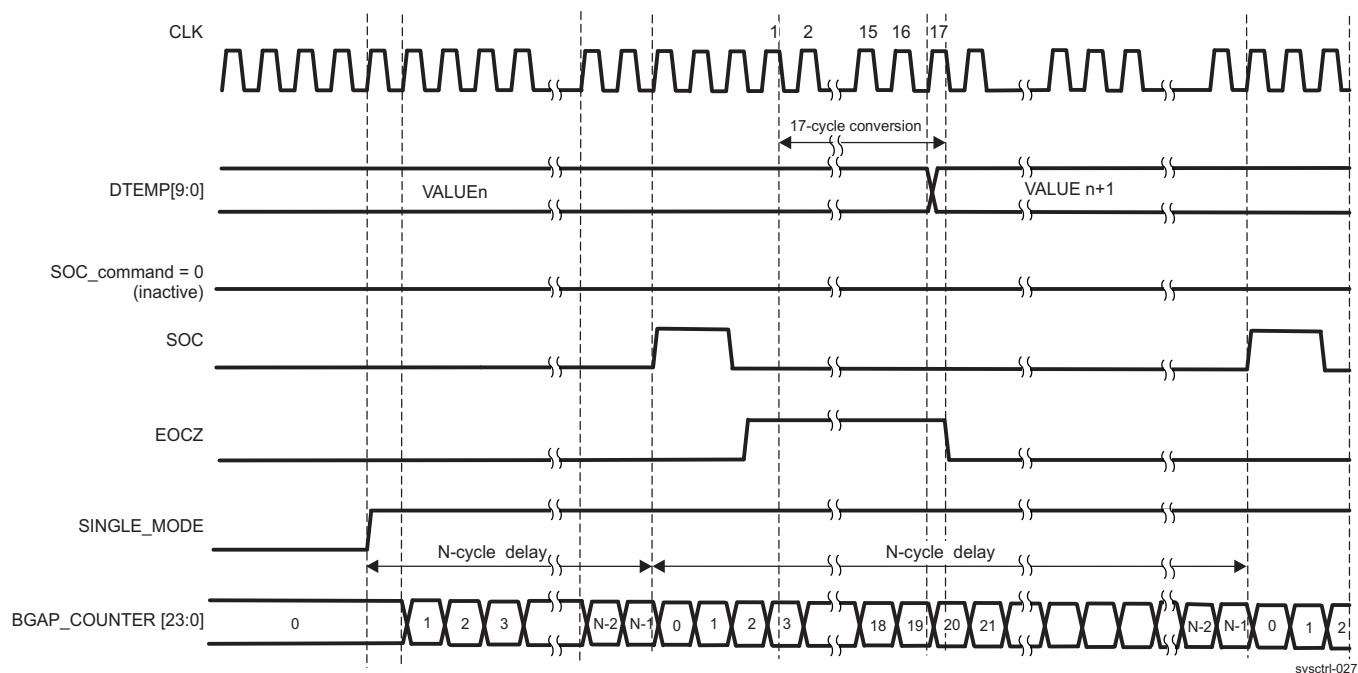

The programmable-delay repeated single conversions scenario follows this sequence:

Before enabling this mode, the user must write the desired delay value as the number of bandgap CLK cycles in the CONTROL_BGAP_COUNTER[23:0] COUNTER bit field. When the ADC is idle (CONTROL_TEMP_SENSOR[10] BGAP_TEMP_SENSOR_EOCZ = 0) and CONTROL_TEMP_SENSOR[11] BGAP_TEMP_SENSOR_SOC = 0, the user must assert CONTROL_BANDGAP_CTRL[31] SINGLE_MODE = 1 to enable programmable-delay repeated single conversions.

NOTE: The programmable-delay repeated single conversions require that software keeps CONTROL_TEMP_SENSOR[11] BGAP_TEMP_SENSOR_SOC = 0 during the measurement sequence.

Figure 18-18 shows the timing sequence for a programmable-delay repeated single mode.

Figure 18-18. Programmable-Delay Repeated Single Conversions

As Figure 18-18 shows, the initial SOC pulse of a sequence is generated N-cycles after assertion of the SINGLE_MODE bit, when BGAP_COUNTER reaches N-1. The N-cycle period is repeated for consecutive SOC insertions until the sequence is stopped in software by deasserting the CONTROL_BANDGAP_CTRL[31] SINGLE_MODE bit to 0.

The signal synchronization described in Section 18.4.10.2.1, *Single Conversion Mode*, applies to each single conversion in a measurement series. The general core control module sends the SOC pulses at regular programmable intervals defined through the value of the BGAP_COUNTER bit field and registers the temperature when EOCZ is asserted low. Software must populate the correct value based on the band gap frequency and monitoring frequency, knowing that the band gap, regardless of the clock frequency, delivers its temperature after 17 clock cycles.

Table 18-20 provides examples for programming SOC pulse generation periods based on minimal (1 MHz) and maximal (2 MHz) band gap clock frequency.

Table 18-20. Bandgap Counter Programming Examples

Bandgap Clock	Monitoring Period				
	10 ms	20 ms	50 ms	100 ms	500 ms
1 MHz – 1000 ns	10,000 cycles	20,000 cycles	50,000 cycles	100,000 cycles	200,000 cycles

Table 18-20. Bandgap Counter Programming Examples (continued)

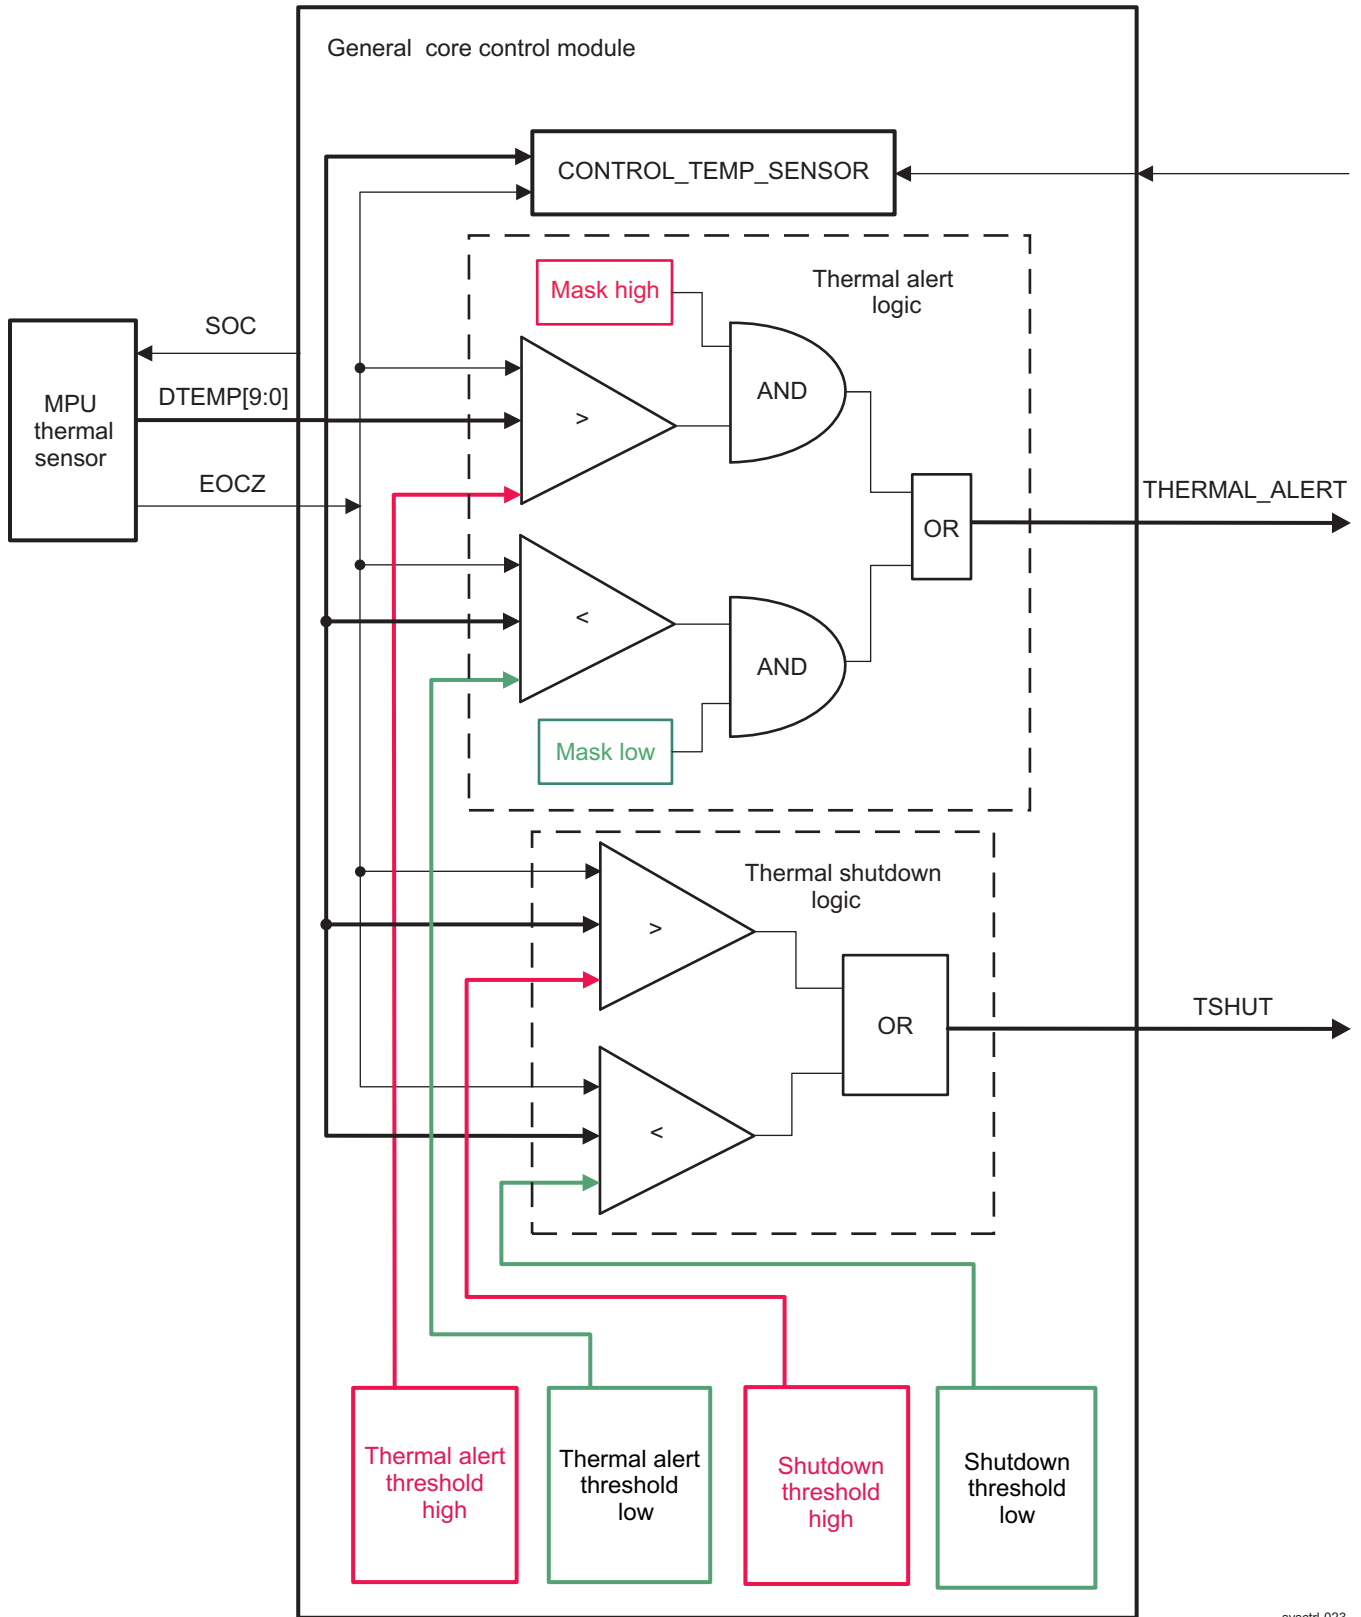

Bandgap Clock	Monitoring Period				
	10 ms	20 ms	50 ms	100 ms	500 ms
2 MHz – 500 ns	20,000 cycles	40,000 cycles	100,000 cycles	200,000 cycles	1,000,000 cycles

18.4.10.2.3 Thermal Data Post-Processing Logic

A thermal data post-processing logic with dedicated registers is implemented in the general core control module. The registered ADC value is passed in parallel to the inputs of four comparators (two sets of two comparators). In each set, the temperature data is compared to high- and low-temperature thresholds defined in software, to handle the hysteresis effect when temperature decreases. The two comparator sets provide different thermal management functions.

[Figure 18-19](#) shows the thermal management schema in the device.

Figure 18-19. Thermal Management Schema

sysctrl-023

NOTE: The software settings of the comparator blocks must be applied before starting a single or repeated-single measurement sequence.

18.4.10.2.4 Thermal Alert Functionality Comparators

The first set of comparators provides a thermal alert function output. The high- and low-temperature thresholds for this function are configurable through the 10-bit [CONTROL_BANDGAP_THRESHOLD\[25:16\]](#) T_HOT and [CONTROL_BANDGAP_THRESHOLD\[9:0\]](#) T_COLD bit fields, respectively. Thermal alert logic in the general core control module provides the capability to mask (active low) comparator outputs for hot and cold events through the [CONTROL_BANDGAP_CTRL\[1\]](#) MASK_HOT and [CONTROL_BANDGAP_CTRL\[0\]](#) MASK_COLD bits. [Figure 18-20](#) shows the functional logic of these 2 bits to mask comparator outputs for hot and cold thermal alert events. The masked HOT and COLD point monitoring signals are then ORed in the THERMAL_ALERT signal, which delivers an interrupt to the MPU subsystem on the MA_IRQ_126 input (see [Section 18.3, Control Module Integration](#)). It can be used by software to implement a thermal management policy of the device. For more information about this interrupt, see [Section 17.3.2, Interrupt Requests to the Cortex-A9 MPU Interrupt Controller](#).

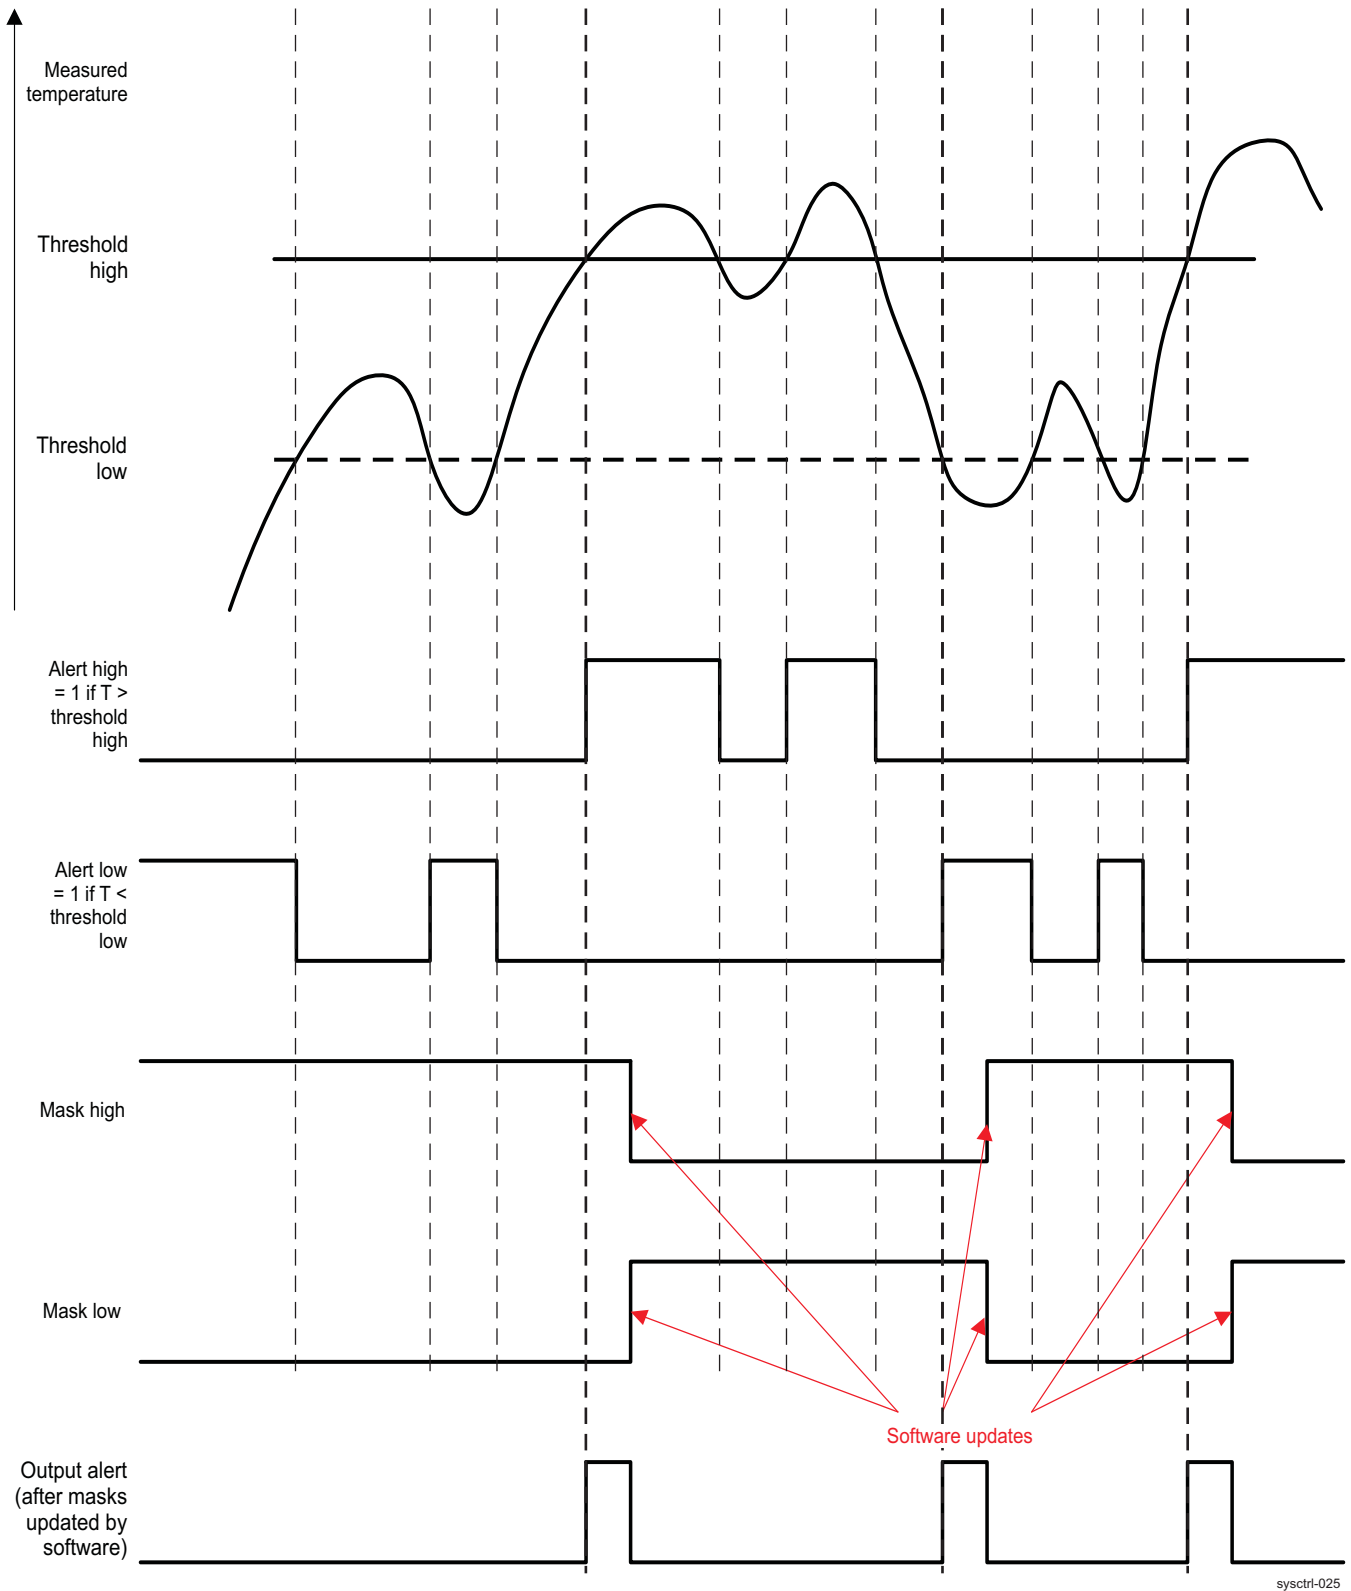

The nonmasked outputs of the thermal alert logic comparators are individually registered in the [CONTROL_BANDGAP_STATUS\[1\]](#) HOT_FLAG and [CONTROL_BANDGAP_STATUS\[0\]](#) COLD_FLAG read-only (RO) bits. The masked ORed event (that is, the THERMAL_ALERT signal) is mapped to the [CONTROL_BANDGAP_STATUS\[2\]](#) BGAP_ALERT RO bit. [Figure 18-20](#) shows the behavior of the thermal alert logic.

NOTE: The thermal processing logic of the general core control module generates an interrupt event to the MPU subsystem whenever the registered temperature of on-die thermal sensor crosses a software-configurable threshold.

CAUTION

Users must take care to program the value of the [CONTROL_BANDGAP_THRESHOLD\[25:16\]](#) T_HOT bit field such that its corresponding temperature value does not exceed the maximal-allowed on-die temperature minus the temperature sensor offset estimated for the current conditions. For more information about the sensed temperature value constraints, see [Section 18.4.10.2, Temperature Sensor](#).

Figure 18-20. Thermal Alert Generation Signals

18.4.10.2.5 Thermal Shutdown Functionality Comparators

The second set of two comparators in the general core control module is responsible for the thermal shutdown protection of the device. Two 10-bit fields ([CONTROL_TSHUT_THRESHOLD\[25:16\]](#) TSHUT_HOT and [CONTROL_TSHUT_THRESHOLD\[9:0\]](#) TSHUT_COLD) define the high- and low-threshold code values, respectively. The default value of the TSHUT_HOT bit field corresponds to the maximum allowed on the device die temperature. When the maximal temperature (TSHUT_HOT) is reached, TSHUT output is activated. The TSHUT output of the general core control module is tied internally to a GPIO3 module input pin (see [Section 18.3, Control Module Integration](#)). Its main purpose is to indicate that the maximum junction temperature of the die is reached, which is true when the temperature measured by the on-die sensor (at sensor location), satisfies the condition:

$$T_{\text{sensor_location_max_tshut}} \text{ } ^\circ\text{C} = T_{\text{max_allowed_hottest_spot}} \text{ } ^\circ\text{C} - \Delta T_{\text{estimated_temp_offset}} \text{ } ^\circ\text{C}$$

To prevent device malfunction or permanent damage to the device, software must take immediate action to reduce power dissipation by warm-resetting the device or freezing most internal activities.

CAUTION

User software must always provide that the temperature corresponding to the programmed value of the [CONTROL_TSHUT_THRESHOLD\[25:16\]](#) TSHUT_HOT bit field does not exceed the described $T_{\text{sensor_location_max_tshut}}$ limit value. For more information about the sensed temperature value constraints, see [Section 18.4.10.2, Temperature Sensor](#).

For more information about thermal-related GPIO interrupts, see [Chapter 25, General-Purpose Interface](#).

To deactivate TSHUT output, the temperature ADC-encoded value must go below the value of TSHUT_COLD threshold.

CAUTION

In case of a thermal shutdown event ($T_{\text{shut_hot}}$ $^\circ\text{C}$ value exceeded), users must take care to software-trigger a warm reset on the device upon a GPIO-generated TSHUT interrupt event. The device has no hardware mechanism to automatically generate a thermal-shutdown warm reset.

[Figure 18-21](#) shows the behavior of the TSHUT logic.

18.4.11 Hardware Observability

18.4.11.1 Device Internal Signals Observability Overview

The general control module provides observability features covering different module internal signals related to:

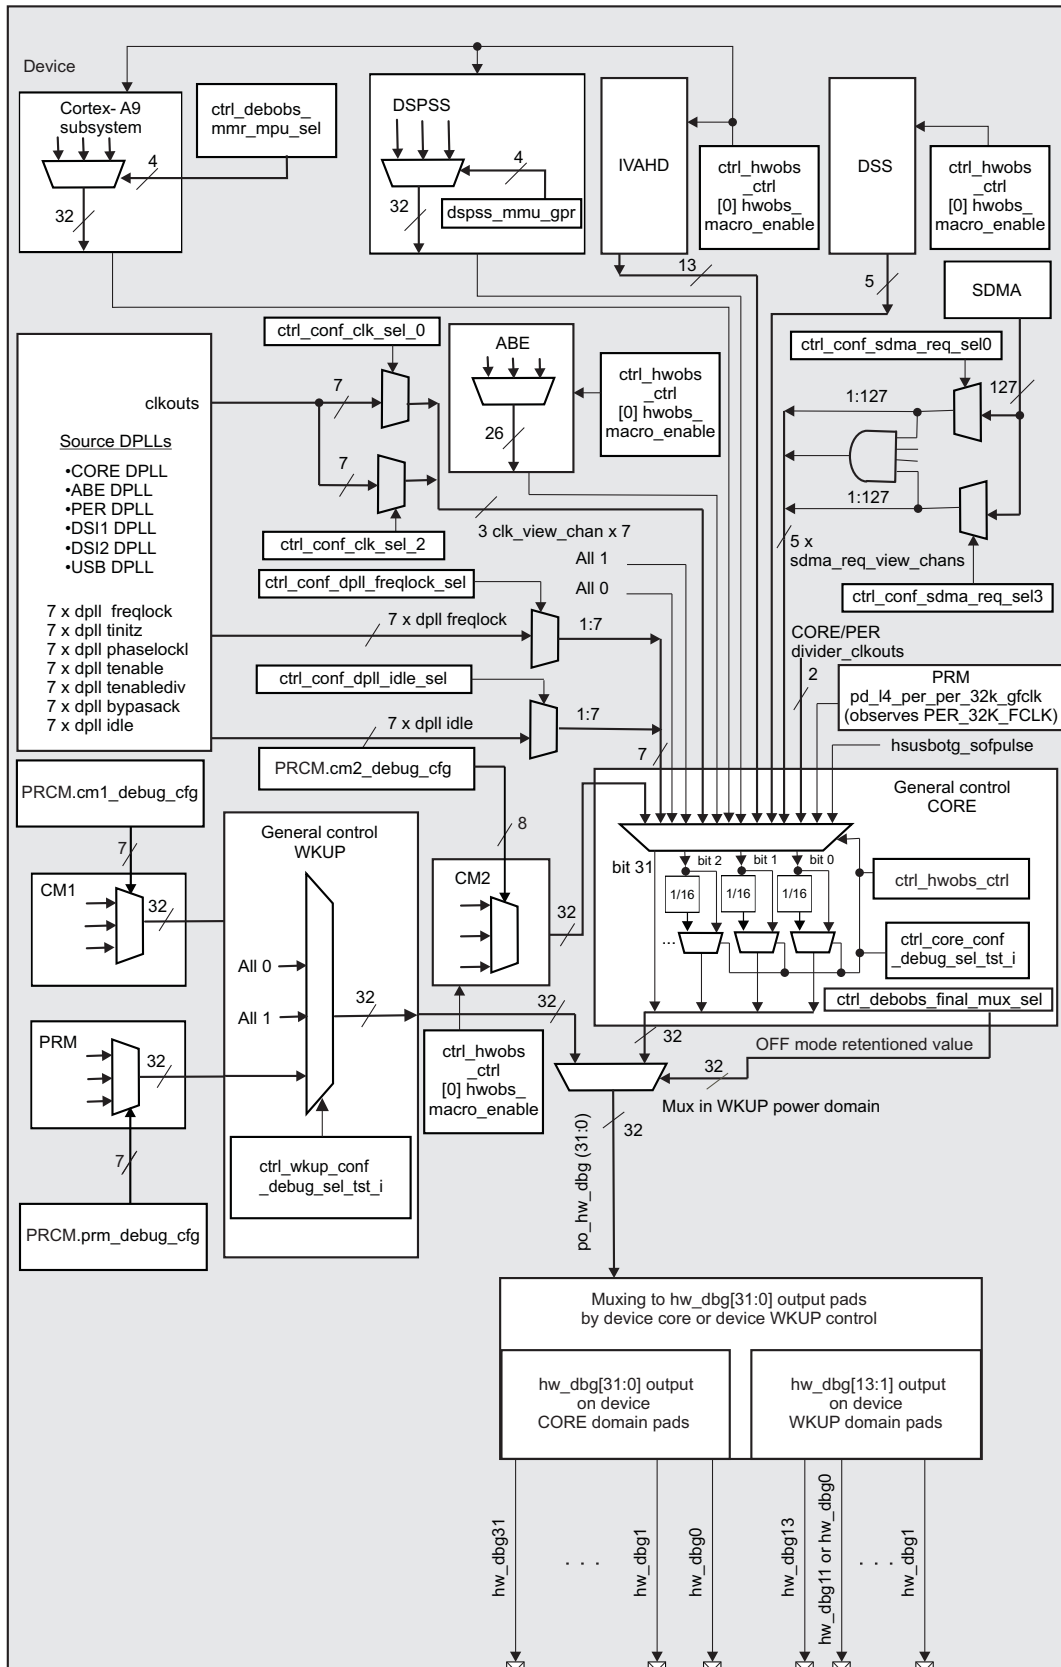

- Power and reset management protocol inside different power domains
- Power domain states/transition indication
- Interrupt requests by different modules
- DMA requests by different modules
- Clocks and clock management

The associated signal multiplexing function is controlled through the hardware observability I/O multiplexing registers (32-bit read/write registers). The selected observable signals are multiplexed between the general control module CORE and/or WKUP power domain and are output on the `po_hw_dbg[31:0]` observability bus at the boundaries of the general wake-up control module. The `po_hw_dbg[31:0]` observability outputs are then exported to the device control module logic to be further multiplexed as their corresponding `hw_dbg[31:0]` signals on the different pads of the WKUP or CORE power domain of the device control module (see [Section 18.4.11.4, Observability Signals Multiplexing at Device Control Module Level](#)).

NOTE: Each signal `po_hw_dbg_i` (where $i = 0$ to 31) of the general control wakeup `po_hw_dbg[31:0]` bus is propagated by device control module-level logic as its corresponding `hw_dbg_i` output signal at the device boundary (where $i = 0$ to 31) for the device CORE power domain pads and where $i = 0$ to 13 for the device WKUP power domain pads (with the constraint that `hw_dbg0` and `hw_dbg11` are multiplexed on the same WKUP power domain pad) described in [Section 18.4.11.4, Observability Signals Multiplexing at Device Control Module Level](#).

[Figure 18-22](#) is an overview of observability multiplexing, which minimizes the number of signals exchanged at the device boundary.

Figure 18-22. Overview of the Hardware Observability Functionality

sysctrl-006

18.4.11.2 Observability Gating Capabilities

The programmer has the option to gate all 32 signals of the observability bus simultaneously at the observability paths of the CORE and WKUP power domains, keeping them tied to 1 ([CONTROL_HWOBS_CONTROL\[1\]](#) HWOBS_ALL_ONE_MODE = 0b1) or keeping them tied to 0 ([CONTROL_HWOBS_CONTROL\[2\]](#) HWOBS_ALL_ZERO_MODE = 0b1). This can be useful to check the path from hardware observability to external pads. These two bits must be set to 0 to enable the observability feature for all observability pads.

Additionally, the [CONTROL_HWOBS_CONTROL\[0\]](#) HWOBS_MACRO_ENABLE bit provides the gating feature only to observability signals muxed in the CORE power domain that come from the following modules (identified in the so-called MACRO group):

- CORTEX-A9 MPU subsystem
- DSP subsystem
- IVA-HD
- Display subsystem
- CM2
- ABE

When [CONTROL_HWOBS_CONTROL\[0\]](#) HWOBS_MACRO_ENABLE = 0b0, the observability outputs associated with the MACRO group are gated and forced to 0b0.

NOTE: Do not set the observability gating bits [CONTROL_HWOBS_CONTROL\[1\]](#) HWOBS_ALL_ONE_MODE and [CONTROL_HWOBS_CONTROL\[2\]](#) HWOBS_ALL_ZERO_MODE simultaneously to 1 to avoid undefined states of the observability bus.

The clock frequency of the hw_dbg0, hw_dbg1, and hw_dbg2 signals can be optionally divided by 1, 2, 4, 8, or 16 through programming dedicated bit fields in [CONTROL_HWOBS_CONTROL](#).

Assignment of dividers to the hw_dbg0, hw_dbg1, and hw_dbg2 signals applies only in the CORE power domain, as follows:

- [7:3] HWOBS_CLKDIV_SEL for hw_dbg0
- [13:9] HWOBS_CLKDIV_SEL_1 for hw_dbg1
- [18:14] HWOBS_CLKDIV_SEL_2 for hw_dbg2

NOTE: Only the CORE power domain signals hw_dbg0, hw_dbg1, and hw_dbg2 pass through the [CONTROL_HWOBS_CONTROL](#) programmable dividers. These dividers are not available to the corresponding po_hw_dbg(0), po_hw_dbg(1), and po_hw_dbg(2) lines in the WKUP power domain.

NOTE: To enable observability over the po_hw_dbg(0), po_hw_dbg(1), and po_hw_dbg(2) bus lines, the HWOBS_CLKDIV_SEL, HWOBS_CLKDIV_SEL_1, and HWOBS_CLKDIV_SEL_2 bit fields in the [CONTROL_HWOBS_CONTROL](#) register must be set different than 0. The default value (0) is not sufficient to see the observability value at the hw_dbg0, hw_dbg1, and hw_dbg2 pins.

NOTE: The hw_dbg0, hw_dbg1, and hw_dbg2 frequency division and ability to gate the MACRO group observability signals (hw_dbg i, configurable in the [CONTROL_HWOBS_CONTROL](#) register) are limited to the hardware observability signals hw_dbg i (where i = 0 to 31) multiplexed and propagated in the CORE power domain ([CONTROL_DEBOBS_FINAL_MUX_SEL\[i\] SELECT = 0b1](#)).

These options do not apply to the hardware observability signals, hw_dbg i (where i = 0 to 31), which are muxed in the WKUP power domain ([CONTROL_DEBOBS_FINAL_MUX_SEL\[i\] SELECT = 0x0](#)).

18.4.11.3 Observability Signals Multiplexing at General Core/Wake-Up Control Level

Most of the observability multiplexers (MACRO group modules/DPLLs/sDMA associated) are configurable in the General Core Control Module, which is part of the switchable CORE power domain. Signal multiplexers are also instantiated in the general wakeup control module (CM1/PRM dedicated), which is part of the WKUP power domain. The [CONTROL_DEBOBS_FINAL_MUX_SEL\[31:0\] SELECT](#) bit field, instantiated in the CORE power domain, selects a signal to be observed between the outputs at the CORE and WKUP multiplexing levels. A bit from this register set to 1 selects to route a signal from the CORE power domain to a certain po_hw_dbg_n (where n = 0...31) line, and when the bit is set to 0, selects to route a signal from the WKUP power domain to the same line. The output of this top-level multiplexing is further passed to the padconfiguration muxing I/O level within device control module boundaries.

NOTE: Although the [CONTROL_DEBOBS_FINAL_MUX_SEL](#) observability control register is in the CORE power domain, its value is retentioned before the device goes into off mode. Thus, the preserved value is used to control the final observability muxer in the WKUP power domain, even when the PD_CORE supply in the device is switched off. Because the hw_dbg i signals, which are propagated in the CORE power domain, are not available in off mode, the value of [CONTROL_DEBOBS_FINAL_MUX_SEL\[i\] SELECT = 0b1](#) (where i = 0 to 31) in this case means that the hw_dbg i signal is not available at output.

The module and view-channel selection/reduction layer in the CORE domain is configured through the 4-bit field MODE in the 32 x 32-bit registers [CONTROL_CORE_CONF_DEBUG_SEL_TST_0](#) through [CONTROL_CORE_CONF_DEBUG_SEL_TST_31](#). The following modules can be selected as source of observability signals: Cortex-A9 MPU subsystem, DSP subsystem, IVA-HD, display subsystem, CM2, and ABE (MACRO signal sources).

Some of the [CONTROL_CORE_CONF_DEBUG_SEL_TST](#) registers are responsible for selection of sDMA view channels, different DPLL clock view channels, and other signal view channels.

- 3 x DPLL clockout signal view channels
- 7 x DPLL (other than clkout signal) view channels
- 5 x sDMA signal view channels
- 3 x additional clockout view channels monitoring the hwobs_coredivider_clkout3, hwobs_perdivider_clkout4, and hwobs_pd_l4_per_per32k_gfclk signals.

Table 18-22 summarizes the internal signals multiplexing schema for each of the 32 [CONTROL_CORE_CONF_DEBUG_SEL_TST](#) registers.

Table 18-22. CORE Power Domain Observability Signals Multiplexing

A third 1:N selection layer is applied over several signals to route them one-at-a-time to a certain view channel output:

- The [CONTROL_CONF_CLK_SEL0\[2:0\]](#) MULT through [CONTROL_CONF_CLK_SEL2\[2:0\]](#) MULT bit fields control the multiplexing of DPLL CLKOUT signals over three parallel DPLL clockout view channels. The signal source of a certain view channel can be selected to be one of six DPLLs in the device:
 - CORE DPLL
 - ABE DPLL
 - PER DPLL
 - DSI1 DPLL
 - DSI2 DPLL
 - USB DPLL
- The register bit fields associated with the seven different DPLL signal view channels are summarized in [Table 18-23](#). Again, the 3-bit MULT bit field in each of the seven registers makes it possible to choose the source of the DPLL signal to be one of the following device DPLLs:
 - CORE DPLL
 - ABE DPLL
 - PER DPLL
 - DSI1 DPLL
 - DSI2 DPLL
 - USB DPLL
- There are four independent sDMA request view channels, each of which has a dedicated register ([CONTROL_CONF_SDMA_REQ_SEL0](#) through [CONTROL_CONF_SDMA_REQ_SEL3](#)) with a 7-bit MULT bit field to select one from 127 possible sDMA request signals for observation purposes. For more information, see [Chapter 16, sDMA Controller](#). The fifth channel, `sdma_req_view_all`, is acquired by applying logical AND reduction over the four currently selected sDMA view channel output signals.

- The General Core observability logic input (hwobs_pd_l4_per_per32k_gfclk) is tied to the PRM output observability signal (pd_l4_per_per_32k_gfclk). The pd_l4_per_per_32k_gfclk signal corresponds to the hardware gated in the L4_PER clock domain clock (PER_32K_FCLK), which is directly sourced by the SCRM clock (32K_FCLK). For more information, see [Section 3.6.3.1, PRM Clock Source](#), in [Chapter 3, Power, Reset, and Clock Management](#). The PER_32K_FCLK and 32K_FCLK clocks are also multiplexed for observability in the WKUP domain when the PRCM.PRM_DEBUG_CFG[6:0] bit field is set to 0x6C. The observable signals are devfsm_I0.clk and gat_per_32k_gfclk_I0.clkGated, respectively. For more information, see [Table 18-49, PRM Observable Signals](#).
- The General Core observability logic input, hwobs_coredivider_clkout3, is tied to the Core DPLL observability output, CLK_FUNC_1_0_3, which is a direct (nongated, nondivided) version of the CORE DPLL clock output, CLKOUTX2_M3. For more information, see [Section 3.6.3.5, DPLL_CORE Description](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- The General Core observability logic input, hwobs_perdivider_clkout4, is tied to the Core DPLL observability output, CLK_FUNC_1_0_4, which is a direct (nongated, nondivided) version of the PER DPLL clock output, CLKOUTX2_M4. For more information, see [Section 3.6.3.4, DPLL_PER Description](#), in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 18-23](#) lists the DPLL signal observability controls.

Table 18-23. DPLL Signal Observability Controls

Feature	Type	Register/Bit Field/Observability Control	Description
Different domain DPLL freqlock observability	Control	CONTROL_CONF_DPLL_FREQLOCK_SEL [2:0] MULT	Selects DPLL freqlock view channel (1:8)
Different domain DPLL phaselock observability	Control	CONTROL_CONF_DPLL_PHASELOCK_SEL [2:0] MULT	Selects DPLL phaselock view channel (1:8)
Different domain DPLL tinitz observability	Control	CONTROL_CONF_DPLL_TINITZ_SEL [2:0] MULT	Selects to observe DPLL tinitzview channel (1:8)
Different domain DPLL tenable observability	Control	CONTROL_CONF_DPLL_TENABLE_SEL [2:0] MULT	Selects to observe DPLL tenableview channel (1:8)
Different domain DPLL tenablediv observability	Control	CONTROL_CONF_DPLL_TENABLEDIV_SEL [2:0] MULT	Selects to observe DPLL tenabledivview channel (1:8)
Different domain DPLL bypassack observability	Control	CONTROL_CONF_DPLL_BYPASSACK_SEL [2:0] MULT	Selects to observe DPLL bypassackview channel (1:8)
Different domain DPLL idle observability	Control	CONTROL_CONF_DPLL_IDLE_SEL [2:0] MULT	Selects to observe DPLL idleview channel (1:8)

NOTE: Features configured in the following registers are limited to hardware observability signals, hw_dbg i (where i = 0 to 31), multiplexed and propagated in the CORE power domain ([CONTROL_DEBOBS_FINAL_MUX_SEL\[i\] SELECT = 0b1](#)):

- [CONTROL_CORE_CONF_DEBUG_SEL_TST_0](#) through [CONTROL_CORE_CONF_DEBUG_SEL_TST_31](#)
- [CONTROL_CONF_CLK_SEL0\[2:0\] MULT](#) through [CONTROL_CONF_CLK_SEL2\[2:0\] MULT](#)
- [CONTROL_CONF_SDMA_REQ_SEL0](#) through [CONTROL_CONF_SDMA_REQ_SEL3](#)
- [CONTROL_CONF_DPLL_FREQLOCK_SEL](#)
- [CONTROL_CONF_DPLL_TINITZ_SEL](#)
- [CONTROL_CONF_DPLL_PHASELOCK_SEL](#)
- [CONTROL_CONF_DPLL_TENABLE_SEL](#)
- [CONTROL_CONF_DPLL_TENABLEDIV_SEL](#)
- [CONTROL_CONF_DPLL_BYPASSACK_SEL](#)
- [CONTROL_CONF_DPLL_IDLE_SEL](#)

These options are not applicable to hardware observability signals, hw_dbg i (where i = 0 to 31), which at the general control module level are muxed in the WKUP power domain ([CONTROL_DEBOBS_FINAL_MUX_SEL\[i\] SELECT = 0b0](#)).

The [CONTROL_WKUP_CONF_DEBUG_SEL_TST_i\[0\] MODE](#) bit (where i = 0...31) provides the option to choose between observation of power and reset manager signals in the device or observation of signals related to CM1. If [CONTROL_WKUP_CONF_DEBUG_SEL_TST_i\[0\] = 0b1](#), the hwobs_int_prm_i signal is selected. Otherwise, the hwobs_int_cm1_i signal is output.

NOTE: The CM1 and PRM observable signals are multiplexed in the WKUP power domain.

18.4.11.4 Observability Signals Multiplexing at Device Control Module Level

The pads used for the hardware debug must be properly configured by selecting the hardware debug function (hw_dbgn) of the pad.

18.4.11.4.1 Observability Signals Muxed on Pads in Core Power Domain

To map the hw_dbg0 through hw_dbg19 signals to their associated external device pads in the CORE power domain, set the related MUXMODE bit fields within the [CONTROL_CORE_PAD0_SYS_BOOT5_PAD1_DPM_EMU0](#) through [CONTROL_CORE_PAD0_DPM_EMU19_PAD1_CSI22_DX2](#) padconfiguration registers to 0b110 (Mode 6). To make the remaining signals (hw_dbg20 through the hw_dbg31) available at their corresponding device pads in the CORE power domain, set the MUXMODE bit fields within the [CONTROL_CORE_PAD0_CAM_GLOBALRESET_PAD1_USBB1_ULPITLL_CLK](#) through [CONTROL_CORE_PAD0_USBB1_ULPITLL_DAT7_PAD1_USBB1_HSIC_DATA](#) padconfiguration registers to 0b110 (Mode 6).

For more information, see [Table 18-10](#), *Device Core Control Module Pad Configuration Register Fields*.

For more information about hardware observability configuration, see [Table 18-121](#), *ACTIVE PADS Configuration Points*.

NOTE: The hw_dbg i signals (where i = 0 to 31), which are multiplexed and propagated in the CORE power domain, are not visible when the device is set in off mode (PD_CORE supply switched off).

18.4.11.4.2 Observability Signals Muxed on Pads in WKUP Power Domain

To have hw_dbg1 through hw_dbg13 signals multiplexed on the WKUP power domain pads, set MuxMode = 0x6 in the following SYSCTRL_PADCONF_WKUP registers:

- [CONTROL_WKUP_PAD0_GPIO_WK0_PAD1_GPIO_WK1](#) through [CONTROL_WKUP_PAD0_GPIO_WK2_PAD1_GPIO_WK3](#)[31:16] to have the hw_dbg1–hw_dbg4 signals output on the gpio_wk0–gpio_wk3 device pads, respectively
- [CONTROL_WKUP_PAD0_GPIO_WK4_PAD1_SR_SCL](#)[15:0] to have the hw_dbg5 signal output on the gpio_wk4 device pad
- [CONTROL_WKUP_PAD0_FREF_CLK0_OUT_PAD1_FREF_CLK3_REQ](#) through [CONTROL_WKUP_PAD0_FREF_CLK3_OUT_PAD1_FREF_CLK4_REQ](#) to have the hw_dbg6–hw_dbg9 signal output on the fref_clk0_out, fref_clk3_req, fref_clk3_out, and fref_clk4_req device pads, respectively
- [CONTROL_WKUP_PAD0_FREF_CLK4_OUT_PAD1_SYS_32K](#)[15:0] to have the hw_dbg10 signal output on the fref_clk4_out device pad
- [CONTROL_WKUP_PAD0_SYS_PWR_REQ_PAD1_SYS_PWRON_RESET_OUT](#)[31:16] to have the hw_dbg11 signal output on the sys_pwrn_reset_out device pad
- [CONTROL_WKUP_PAD0_SYS_BOOT6_PAD1_SYS_BOOT7](#) to have the hw_dbg12 and hw_dbg13 signals output on the sys_boot6 and sys_boot7 device pads, respectively

The hw_dbg0 signal is available on the sys_pwrn_reset_out pad in WKUP domain, through setting MuxMode=0x5 in the [CONTROL_WKUP_PAD0_SYS_PWR_REQ_PAD1_SYS_PWRON_RESET_OUT](#)[31:16] register. Because hw_dbg11 (MuxMode=0x6) and hw_dbg0 (MuxMode=0x5) are muxed on the same pad - sys_pwrn_reset_out, user should make choice between the two observable signals in WKUP domain

See [Table 18-9](#), *Device Wakeup Control Module Pad Configuration Register Fields* for more information.

See [Table 18-121](#), *ACTIVE PADS Configuration Points*, for more details on hardware observability configuration.

NOTE: If multiplexed on corresponding device pads in the WKUP power domain, the hw_dbg i signals (where i = 0 to 31), which are multiplexed and propagated in the WKUP power domain, can be observed even if the device goes into off mode.

18.4.11.5 Observability Signals Sourced at Module Level

Observable signals coming from within different device subsystems are mapped to general core control and general wakeup control observability inputs. Additional multiplexing is also implemented inside some of the observable modules (see [Figure 18-22, Overview of the Hardware Observability Functionality](#)).

18.4.11.5.1 Dual Cortex-A9 Subsystem Observable Signals

[Table 18-24](#) through [Table 18-32](#) list the Cortex-A9 MPU subsystem observable signals available in 12 functional multiplexing modes. The mode is selected at the general core control module level by programming the [CONTROL_DEBOBS_MMR_MPU\[3:0\] SELECT](#) bit field. The SELECT values in range (0xC–0xF) are reserved for future use.

Table 18-24. Observability Signals Multiplexing at Cortex-A9 MPU Subsystem Level – Mode 0

CONTROL_DEBOBS_MMR_MPU[3:0] SELECT = 0b0000			
SYSCTRL_GENERAL_CORE Observability Inputs Tied to Signals Inside Cortex-A9 MPU Subsystem	Cortex-A9 MPU Subsystem Observable Signals Mapped to SYSCTRL_GENERAL_CORE Observability Inputs	Signal Description	Logical Value Meaning

The POPPROFILING_EVENT2PRM bus signals, observable in modes 0, 1, 2, and 3, monitor the power states of the CPU. There are 6 status bits per Cortex-A9 CPU0 and CPU1, respectively. [Table 18-28](#) describes the encoding of the status bits.

POPPROFILING_EVENT2PRM[5:0] are the status bits for CPU0, and POPPROFILING_EVENT2PRM[11:6] are the status bits for CPU1.

18.4.11.5.3 Display Subsystem Observable Signals

The display subsystem observable signals described in [Table 18-38](#) are directly mapped to the display subsystem observability inputs of the SYSCTRL_GENERAL_CORE module, and no additional multiplexing is performed inside the display subsystem wrapper.

Table 18-38. Observability Signals at Display Subsystem Level

SYSCTRL_GENERAL_CORE Observability Inputs Tied to Signals Inside Display Subsystem	Display Subsystem Observable Signals Mapped to SYSCTRL_GENERAL_CORE Observability Inputs	Signal Description	Logical Value Meaning
hwobs_dssvenctvdetgp	DSS_VENC_TVDETGP	Display subsystem VENC tvdetgp	Active high pulse to detect the TV connection
hwobs_dssdacpwrndaczcvs_y	DSS_DAC_PWR_DNDACZCVBS/Y	Display subsystem DAC pwrnd daczcvs_y – Power down for DAC Y	0: DAC Y put in power-down mode 1: DAC Y put in ACTIVE state
hwobs_dssdacpwrndaczcroma	DSS_DAC_PWR_DNDACZCHROMA	Display subsystem DAC pwrnd daczcroma – Power down for DAC CHROMA	0: DAC CHROMA put in power-down mode 1: DAC CHROMA put in ACTIVE state
hwobs_dssdacpwrndaccvbs	DSS_DAC_PWR_DNDACCVBS	Display subsystem DAC pwrnd daczcvs – Power down for DAC CVBS	0: DAC CVBS put in power-down mode 1: DAC CVBS put in ACTIVE state

Table 18-38. Observability Signals at Display Subsystem Level (continued)

hwobs_dssdacpwrdbgz	DSS_DAC_PWR_DNBGZ	Display subsystem DAC pwrdbgz – Band gap power down for DAC	0: DAC Bandgap put in power-down mode 1: DAC Bandgap put in ACTIVE state

NOTE: The (VDAC) function is not supported.

18.4.11.5.4 DSP Subsystem Observable Signals

Table 18-39 through Table 18-45 show Cortex-A9 MPU subsystem observable signals available in eight multiplexing modes. The mode is selected at the general control module level through writing in the bit field DSPSS_MMU_GPR[3:0] HWDEBUG_MUX.

The DSPSS.DSPSS_MMU_GPR register provides mux control for hardware observability signals exported at the DSPSS boundary to the general control module. Interrupts, DMA requests, and other events can be seen on the PO_HW_DBG_OUT bus. The DSPSS.DSPSS_MMU_GPR register provides mux controls for selecting the appropriate 32-bit value to be output on the PO_HW_DBG_OUT signal bus. The mux values and associated signals that can be observed on the PO_HW_DBG_OUT bus are described in Chapter 20, *Memory Management Units*. Setting the DSPSS.DSPSS_MMU_GPR[15] FORCE_IDLE_REQ bit initiates IDLE request/acknowledgment protocol with various blocks; the acknowledge information can be observed when HWDEBUG_MUX = 4'b1110.

All interrupts into DSPSS can be observed by setting the DSPSS.DSPSS_MMU_GPR[3:0] HWDEBUG_MUX bit field to 0x6, 0x7, 0x8, and 0x9. All interrupts to the INTC, which includes external and internal interrupts, can be seen by setting the HWDEBUG_MUX values to 0x2, 0x3, 0x4, and 0x5. DMA requests can be seen when the HWDEBUG_MUX values are set to 0xA and 0xB.

DPLL_IVA and the associated HSDIVIDER values can be seen by values of 0x0, the default reset value. DSPSS raw CD0 clock is sent out without any division. Other clocks are divided by 32.

The DSPSS.DSPSS_MMU_GPR[15] FORCE_IDLE_REQ bit must be used only for observability purposes, not in functional mode. When set, the FORCE_IDLE_REQ bit causes IDLE requests to be sent to various components inside the DSPSS, and idle acknowledgment is displayed when the value of the HWDEBUG_MUX[3:0] bit field is 4'b1110; the signals listed can then be checked to determine which component is not idle.

NOTE: Once this feature is used, FORCE_IDLE_REQ must be set to 0 before continuing the observability process.

Table 18-39. Observability Signals Multiplexing at DSP Subsystem Level – Mode 0

DSPSS_MMU_GPR[3:0] HWDEBUG_MUX = 0x0

18.4.11.5.5 ABE Subsystem Observable Signals

The audio backend (ABE) observable signals described in [Table 18-46](#) are directly mapped to the ABE dedicated observability inputs, hwobs_int_abe[31:0] of the SYSCTRL_GENERAL_CORE module, and no additional multiplexing is performed inside the ABE.

Table 18-46. Observability Signals at ABE Subsystem Level

SYSCTRL_GENERAL_CORE Observability Inputs Tied to Signals Inside ABE subsystem	ABE Level Observability Signals	Signal Description	Logical Value Meaning
hwobs_int_abe[31:26]	–	–	–
hwobs_int_abe[25:24]	OPP_DIV	OPP DIVIDER bits [1:0]	–
hwobs_int_abe[23]	AESS_to_MPU_IRQ	IRQ sent from AESS to MCU. See Chapter 12, ABE .	–

Table 18-46. Observability Signals at ABE Subsystem Level (continued)

SYSCTRL_GENERAL_CORE Observability Inputs Tied to Signals Inside ABE subsystem	ABE Level Observability Signals	Signal Description	Logical Value Meaning
hwobs_int_abe[22]	AESS_to_DSPSS_IRQ	IRQ sent from AESS to DSP. See Section 5.3.7, Interrupt Requests , and Chapter 12, ABE .	–
hwobs_int_abe[21]	Reserved	–	–
hwobs_int_abe[20]	GPT_WDT_PWM_INP	PWM received from the GPTIMER or watchdog (OR)	–
hwobs_int_abe[19]	AESS_DMAREQ_ALL	(Logical OR with all DMA requests out)	High while outgoing DMA requests from audio engine have not been acknowledged by the host
hwobs_int_abe[18]	AESS_DMAREQ_PER	(Logical OR with all DMA requests coming from the peripheral)	High when incoming DMA requests from audio engine are still to be served
hwobs_int_abe[17]	AESS_IDLEPO	PO_IDLE AESS output	High when the audio engine executes a wait until an activation of the PI_WAKEUP pin is done
hwobs_int_abe[16:0]	RESERVED	–	–

18.4.11.5.6 USBOTGHS Subsystem Observable Signals

One of the General Wakeup Control observability inputs can be mapped to the USBOTGHS start-of-frame signal (hsusbogt_sofpulse) by setting [CONTROL_CORE_CONF_DEBUG_SEL_TST_11\[3:0\] MODE = 0x1](#).

18.4.11.5.7 CM2 Subsystem Observable Signals

The SYSCTRL_GENERAL_CORE observability inputs hwobs_int_cm2(i), (where i = 0...31) are mapped to the signals debugcm2(i), (where i = 0...31) coming out of the PRCM submodule, clock manager 2 (CM2).

Local multiplexing controls at the CM2 level are in the CM2_DEBUG_CFG register. The CM2 observability output signals are driven on the debugcm2(0) through debugcm2(7) lines. A certain mux set is selected by programming the CM2_DEBUG_CFG[7:0] SEL0 bit field. The remaining debugcm2(8) through debugcm2(31) lines are reserved for future use. For more information about the CM2 observability source select field, see [Section 3.11.30.1, INTRCONN_SOCKET_CM2 Register Summary](#), in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 18-47](#) provides different details about the signals inside the CM 2 that can be monitored on device hw_dbg pins.

18.4.11.5.8 CM1 Subsystem Observable Signals

The General Wakeup Control observability inputs hwobs_int_cm1(i) , (where i = 0...31) are mapped to the signals debugcm1(i), (where i = 0...31) coming out of the PRCM submodule clock manager 1 (CM1).

Local multiplexing controls at the CM1 level are in the CM1_DEBUG_CFG register. The CM1 observability output signals are driven on the debugcm1(0) through debugcm1(7) lines. A certain mux set is selected by programming the CM1_DEBUG_CFG[6:0] SEL0 bit field. The remaining debugcm1(8) through debugcm1(31) lines are reserved for future use. For more information about the CM1 observability source select field, see [Section 3.11.22.1, INTRCONN_SOCKET_CM1 Register Summary in Chapter 3, Power, Reset, and Clock Management](#).

[Table 18-48](#) provides different details about the signals inside CM1 that can be monitored on device hw_dbg pins.

18.4.11.5.9 PRM Subsystem Observable Signals

The General Wakeup Control observability inputs hwobs_int_prm(i), (where i = 0...31) are mapped to the signals debugprm(i), (where i = 0...31) coming out from the power reset manager (PRM) submodule.

Local multiplexing controls at the PRM level are in the PRM_DEBUG_CFG register. The PRM observability output signals are driven on the debugprm(0) through debugprm(7) lines. A certain mux set is selected by programming the PRM_DEBUG_CFG[6:0] SEL0 bit field. The remaining debugprm(8) through debugprm(31) lines are reserved for future use. For more information about the PRM observability source select field, see [Section 3.11.2.1, INTRCONN_SOCKET_PRM Register Summary](#) in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 18-49](#) provides different details about the signals inside the PRM that can be monitored on device hw_dbg pins.

18.4.11.5.10 PRCM FSM State Observable Signals Description

Some of the observable signals encode the different PRCM finite state-machine (FSM) states. Each state corresponds to a combination of FSM output signal values. The states of the different FSMs associated with the SAR RAM, DPLLs, EMIF, I/O controller, power manager, global reset manager warm reset generator, and clock managers, along with their corresponding output signal values (except for DPLL Ctrl outputs) are described in [Table 18-50](#) through [Table 18-56](#).

Table 18-50. SAR FSM State Description

18.4.12 Functional Register Description

18.4.12.1 DSP Boot Register

Table 18-64 describes the DSP boot address register.

Table 18-64. DSP Boot Address Register

Physical Address	Register Name	Description	Access
0x4A00 2304	CONTROL_DSP_BOOTADDR	DSP boot loader address register	R/W

The [CONTROL_DSP_BOOTADDR](#) register defines the physical address for the DSP boot loader and drives the DSP_BOOTADDR[31:10] signals out from the control block to the DSP subsystem.

18.4.12.1.1 PBIASLITE Control Register

Table 18-65 describes the [CONTROL_PBIASLITE](#) register, which controls some settings of PBIASLITE cells for the MMC I/O interface.

Table 18-65. PBIAS Control Register

Physical Address	Register Name	Description	Access
0x4A10 0600	CONTROL_PBIASLITE	Control settings for PBIAS cell	RW

18.4.12.2 Temperature Sensor Control Registers

Table 18-66 describes the [CONTROL_TEMP_SENSOR](#) registers of the general core control module, which control the temperature sensor, band gap state-machine, and thermal post-processing logic.

Table 18-66. Temperature Sensor Register

Physical Address	Register Name	Description	Access
0x4A00 232C	CONTROL_TEMP_SENSOR	Temperature sensor control register	R/W
0x4A00 2378	CONTROL_BANDGAP_CTRL	Mode selection and mask hot/cold event register	R/W
0x4A00 237C	CONTROL_BANDGAP_COUNTER	Band gap delay counter register	R/W
0x4A00 2380	CONTROL_BANDGAP_THRESHOLD	Band gap thermal alert threshold register	R/W
0x4A00 2384	CONTROL_TSHUT_THRESHOLD	Tshut threshold register	R/W
0x4A00 2388	CONTROL_BANDGAP_STATUS	Thermal alert and band gap idle events status register	RO

18.4.12.2.1 CSI Receiver Control Register

To enable the physical layer of the camera receiver, the programmer manipulates the bits within the [CONTROL_CAMERA_RX](#) register.

Table 18-67. CSI Receiver Control Register

Physical Address	Register Name	Description	Access
0x4A10 0608	CONTROL_CAMERA_RX	Module dedicated configurations	RW

18.4.12.3 Protection Status Registers

[Table 18-68](#) lists the status registers.

Table 18-68. Protection Status Registers

Physical Address	Register Name	Description	Access
0x4A00 22D0	CONTROL_SEC_ERR_STATUS_FUNC	Protection firewall error status register	Public (R)
0x4A00 22D4	CONTROL_SEC_ERR_STATUS_DEBUG	Protection firewall error status register debug	Public (RW Write 1 to Clear)

These registers do not depend on the device type.

The [CONTROL_SEC_ERR_STATUS_FUNC](#) can be read in public mode, but cannot be written.

The [CONTROL_SEC_ERR_STATUS_DEBUG](#) register is both read and write accessible in GP devices.

These bits are cleared when the L3 and L4 firewall embedded-error log registers are cleared. All bits in these registers reflect internal events in the device related to the device protection.

On a specific event (signal rising edge), the corresponding bit is set. On a rising edge, the input signal must stay high for at least two interface clock periods to be recognized. Software must clear each bit after reviewing the events.

When a protection violation occurs, the following bits are set:

- In application mode
 - [CONTROL_SEC_ERR_STATUS_FUNC](#)[01] = L3RAM protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC](#)[02] = GPMC protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC](#)[03] = EMIF protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC](#)[04] = IVA-HD protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC](#)[05] = Dual Cortex™-M3 protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC](#)[06] = SL2 protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC](#)[13] = SGX protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC](#)[14] = DSS protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC](#)[15] = ISS protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC](#)[16] = L4_PER protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC](#)[17] = L4_CFG protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC](#)[18] = DEBUGSS protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC](#)[19] = L4 AudioBE protection violation
- In debug mode:
 - [CONTROL_SEC_ERR_STATUS_DEBUG](#)[01] = L3RAM protection violation
 - [CONTROL_SEC_ERR_STATUS_DEBUG](#)[02] = GPMC protection violation
 - [CONTROL_SEC_ERR_STATUS_DEBUG](#)[03] = EMIF protection violation
 - [CONTROL_SEC_ERR_STATUS_DEBUG](#)[04] = IVA-HD protection violation
 - [CONTROL_SEC_ERR_STATUS_DEBUG](#)[05] = Dual Cortex-M3 protection violation
 - [CONTROL_SEC_ERR_STATUS_DEBUG](#)[06] = SL2 protection violation
 - [CONTROL_SEC_ERR_STATUS_DEBUG](#)[13] = SGX protection violation

- [CONTROL_SEC_ERR_STATUS_DEBUG\[14\]](#) = DSS protection violation
- [CONTROL_SEC_ERR_STATUS_DEBUG\[15\]](#) = ISS protection violation
- [CONTROL_SEC_ERR_STATUS_DEBUG\[16\]](#) = L4_PER protection violation
- [CONTROL_SEC_ERR_STATUS_DEBUG\[17\]](#) = L4_CFG protection violation
- [CONTROL_SEC_ERR_STATUS_DEBUG\[18\]](#) = DEBUGSS protection violation
- [CONTROL_SEC_ERR_STATUS_DEBUG\[19\]](#) = L4 AudioBE protection violation

For more information about L4 firewall protection-violation report mechanisms, see [Section 13.3.3.4.5, Firewall Error Logging in the Control Module](#), in [Chapter 13, Interconnect](#). For more information about L3 firewall protection-violation report mechanisms, see [Section 13.2.4.2.1, L3 Interconnect Error Analysis](#), in [Chapter 13, Interconnect](#).

18.4.12.4 Protection SDRAM Configuration Registers

[Table 18-69, Protection SDRAM Configuration Registers for EMIF1 and EMIF2](#), lists the protection SDRAM configuration registers for EMIF1 and EMIF2 that are part of the general wakeup control module. Upon POR, their values are exported as reset values of the EMIF1 and EMIF2 registers (EMIF_SDRAM_CONFIG and EMIF_SDRAM_CONFIG_2, respectively).

Table 18-69. Protection SDRAM Configuration Registers for EMIF1 and EMIF2

Physical Address	Register Name	Description	Access
0x4A30C11 0	CONTROL_WKUP_PROT_EMIF1_SDRAM_CONFIG_REG	Protection SDRAM configuration register 1, defining bit field reset values of the EMIF1.EMIF_SDRAM_CONFIG register	RW
0x4A30C11 4	CONTROL_WKUP_PROT_EMIF1_SDRAM_CONFIG2_REG	Protection SDRAM configuration register 2, defining bit field reset values of the EMIF1.EMIF_SDRAM_CONFIG_2 register	RW
0x4A30C11 8	CONTROL_WKUP_PROT_EMIF2_SDRAM_CONFIG_REG	Protection SDRAM configuration register 1, defining bit field reset values of the EMIF2.EMIF_SDRAM_CONFIG register	RW
0x4A30C11 C	CONTROL_WKUP_PROT_EMIF2_SDRAM_CONFIG2_REG	Protection SDRAM configuration register 2, defining bit field reset values of the EMIF2.EMIF_SDRAM_CONFIG_2 register	RW

18.4.12.5 Register Controls for the LPDDR2IO1 and LPDDR2IO2 I/O Buffer Modes

There are global controls related to LPDDR2IO1 and LPDDR2IO2 (EMIF1 and EMIF2 associated) CA I/O receivers (loopback mode only) and DQ I/O receivers. These controls reside in the SYSCTRL_GENERAL_CORE.CONTROL_GEN_CORE_OCPREG_SPARE register.

[Figure 18-23](#) in [Section 18.4.12.6, Reference Voltage for OMAP LPDDR2IO1 and LPDDR2IO2 I/O Buffers and LPDDR2 Memory](#), shows how these controls are related to mode selection and powerdown controls for LPDDR2IO receivers.

Their functionality is as follows:

- Setting the OCPREG_SPARE[3] bit to 0b1 simultaneously disables (powers-down) all receivers associated with DQ groups of the LPDDR22 I/Os.
- Setting the OCPREG_SPARE[1] bit to 0b1, simultaneously disables (power-downs) all receivers associated with DQ groups of the LPDDR21 I/Os.
- Only the four DQ I/O groups receivers are impacted by the OCPREG_SPARE[1] and OCPREG_SPARE[3] bits as follows:
 - lpddr2x_dm0, lpddr2x_dqs0, lpddr2x_ndqs0, lpddr2x_dq [7:0]
 - lpddr2x_dm1,dqs1,ndqs1,dq [15:8]
 - lpddr2x_dm2,dqs2,ndqs2,dq [23:16]
 - lpddr2x_dm3,dqs3,ndqs3,dq [31:24]
- Programming the OCPREG_SPARE[2] and OCPREG_SPARE[0] bits to 0b1 configures all the

LPDDR2 DQ and CA (CA receivers enabled in a loopback mode only) I/O groups receivers to use low-voltage CMOS (LVCMOS) buffer logic, for the LPDDR22 and LPDDR21 I/Os, respectively.

- There is one CA I/O group (lpddr2x_ca[0:9], lpddr2x_ncs0/1, lpddr2x_cke0/1, lpddr2x_ck, lpddr2x_nck) for the LPDDR21 and LPDDR22 command I/O lines. Programming the OCPREG_SPARE[2] and OCPREG_SPARE[0] bits to 0b0 configures all the LPDDR2 DQ and CA (loopback mode only) I/O groups receivers to use a true differential comparator logic (so called Vref-based receivers). For more details on the configuration of a Vref-based receiver, see [Section 18.4.12.6 Reference Voltage for OMAP LPDDR2IO1 and LPDDR2IO2 I/O Buffers and LPDDR2 Memory](#).

[Table 18-70](#) lists the register used to control the described EMIF1 and EMIF2 features.

Table 18-70. LPDDR2IO Buffer Control Register

Physical Address	Register Name	Description	Access
0x4A0023FC	CONTROL_GEN_CORE_OCPREG_SPARE	The lower 4 bits of this register are assigned to control the power-down mode for LPDDR2 DQ lines and select either a LVCMOS buffer or Vref-based receiver configuration for the LPDDR2 DQ/CA receivers.	RW

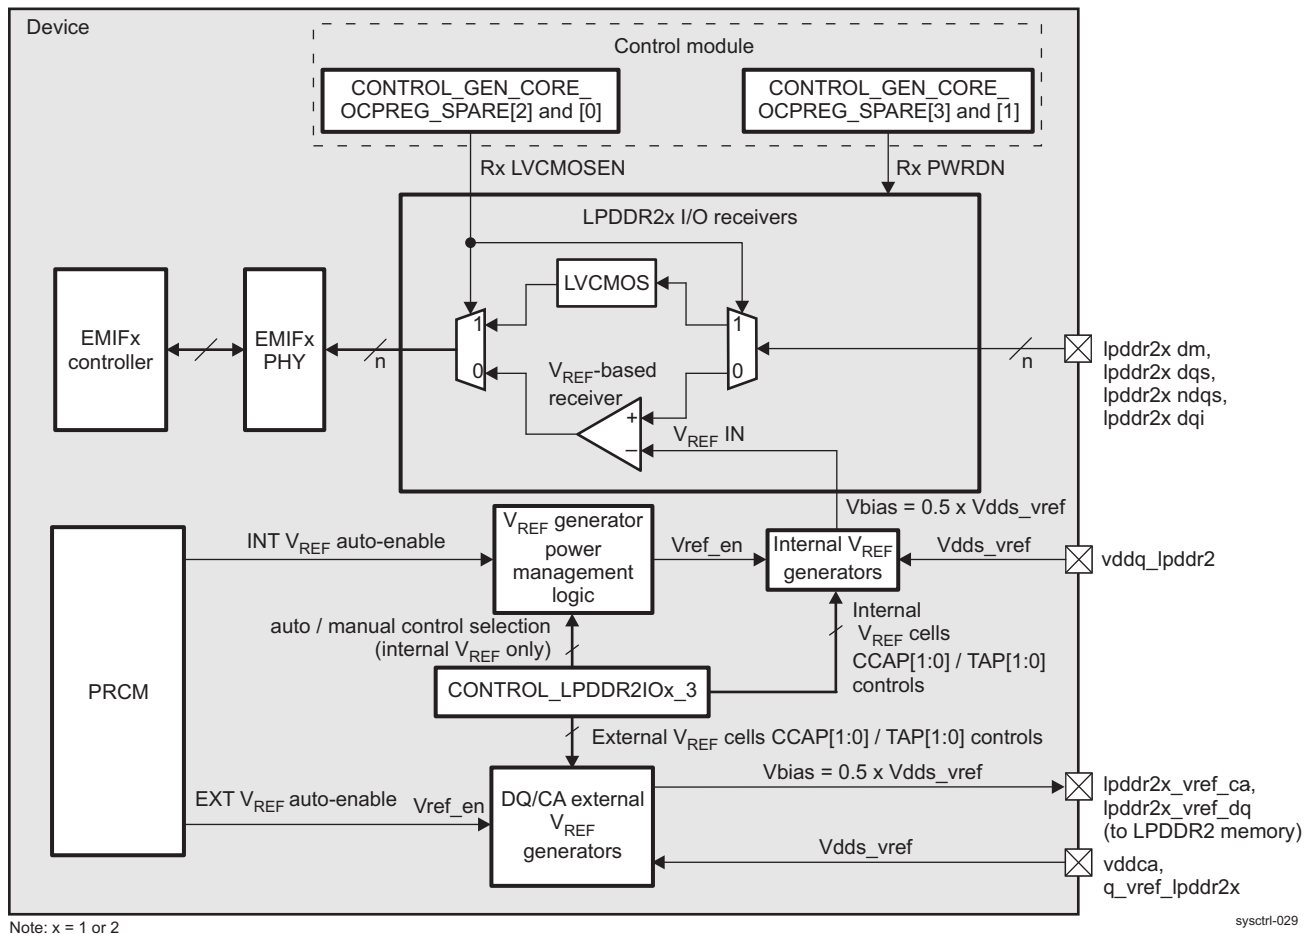

18.4.12.6 Reference Voltage for OMAP LPDDR2IO1 and LPDDR2IO2 I/O Buffers and LPDDR2 Memory

When device LPDDR2IO1 or LPDDR2IO2 I/O buffers are used in differential comparator mode (so called Vref based receivers), a reference voltage must be provided to the buffers. Several Vref-generation cells are integrated in the device to supply this internal reference voltage. [Figure 18-23](#) provides the details about different controls related to the external and internal Vref generation cells for the differential comparator receivers.

When the Vref generator is turned on, it supplies voltage reference to the Vref-based receivers associated with the LPDDR2IO DQ and CA interface lines. In Vref-based receiver mode, the LPDDR2 I/O cell receiver is a true differential comparator with positive terminal connected to the device pad on which signal from LPDDR2 memory is received, and negative terminal tied to the VREF voltage generated on the Vbias output of the receiver corresponding Vref cell (see [Figure 18-23](#)).

The Vbias equals $0.5 \times V_{\text{dds_vref}}$, where $V_{\text{dds_vref}}$ is power supply voltage of the Vref cell. The Vref-based receiver allows the improvement of speed performance at $V_{\text{DDS}} = 1.2\text{-V}$ I/O voltage supply. A reference voltage is also provided to externally attached LPDDR2 memory through the device lpddr2x_vref_ca and lpddr2x_vref_dq output pads. The same type of Vref-generation cells are used for these external reference voltages.

Figure 18-23. LPDDR2 Vref Cell and Receiver Type Controls

The voltage drive selection bit fields of these internal / external voltage reference cells are in the [CONTROL_LPDDR2IO1_3](#) and [CONTROL_LPDDR2IO2_3](#) registers. Individual VREF_TAP[1:0] control bits set the output drive capability for each reference voltage.

[Table 18-71](#) lists the possible options for internal reference voltage drive selection.

Table 18-71. LPDDR2 Internal Reference Configuration

VREF_TAP1	VREF_TAP0	Description
0	0	Pad/bias2 Connected to reference Vdds_vref / 2, for 2- μ A current load
0	1	Pad/bias2 Connected to reference Vdds_vref / 2, for 4- μ A current load
1	0	Pad/bias2 Connected to reference Vdds_vref / 2, for 6- μ A current load
1	1	Pad/bias2 Connected to reference Vdds_vref / 2, for 8- μ A current load

According to the noise environment, the user can choose to filter the reference voltage which is supplied.

Two coupling capacitors, internal to a Vref-generation cell, are available and are configurable as specified in [Table 18-72](#).

Table 18-72. LPDDR2 Vref Cell Decoupling Cap Selection

VREF_CCAP0	VREF_CCAP1	Capacitor
0	0	Capacitor between internal reference node (Vbias) and Vss (ground)
0	1	Capacitor between internal reference node (Vbias) and Vdds_vref as well as internal reference node (Vbias) and Vss
1	0	No capacitor connected
1	1	Capacitor between internal reference node (Vbias) and Vdds_vref

Individual VREF_CCAP0 and VREF_CCAP1 control bits in the [CONTROL_LPDDR2IO1_3](#) and [CONTROL_LPDDR2IO2_3](#) registers set the coupling capacitor connection on VREF nodes.

For leakage improvement the Vref-generation cells can be enabled and disabled.

The Vref-generation cells used for the device internal Vref voltage are controlled by software. Setting bit `CONTROL_LPDDR2IOx_3[0] LPDDR2x_INT_VREF_AUTO_EN_DQ = 0b1` or `CONTROL_LPDDR2IOx_3[1] LPDDR2x_INT_VREF_AUTO_EN_CA = 0b1` (where $x = 1, 2$) enables the device PRCM automatic shut off or switch-on of the internal Vref cell generators associated with the LPDDR2x interface, DQ and CA lines, respectively.

If user software sets the manual control bit `CONTROL_LPDDR2IOx_3[2] LPDDR2x_INT_VREF_EN_DQ=0b1` or `CONTROL_LPDDR2IOx_3[2] LPDDR2x_INT_VREF_EN_CA =0b1`, internal Vref cell generators are enabled, regardless of the state of the `LPDDR2x_INT_VREF_AUTO_EN_DQ / LPDDR2x_INT_VREF_AUTO_EN_CA` bits. Thus, PRCM automatic control over the internal Vref cell generators can always be overridden in the context of enabling the Vref generator.

In contrast to the internal Vref source generator cells, which enable/disable-control can be selected in software between PRCM and manual software control, the Vref-generation cells used for the external Vref output generation are controlled only by the PRCM.

[Table 18-73](#) provides different combinations of Vref cell control types and the state of the Vref cell.

Table 18-73. LPDDR2 Vref Cells State Description

LPDDR2x_INT_VREF_EN_DQ /CA (Manual Control Bits)	LPDDR2x_INT_VREF_AUTO_EN_DQ/CA (AUTO Control Bits)	Type of Control	Vref Cell State
1	x	Manual	Enabled
0	1	AUTO	Automatically enabled/disabled
0	0	–	Disable

There are four internal VREF cells ($k = 0$ to 3) associated with DQ line receivers and a single internal VREF cell associated with CA line receivers (loopback mode only) for each of the device LPDDR21 and LPDDR22 set of I/Os. The group assignment of a VREF cell Vbias output to different I/Os associated Vref-based receivers is covered in [Table 18-74](#).

Table 18-74. Internal VREF Generators CCAP and TAP Controls versus LPDDR2IO Receiver Pads

Control Module Register	LPDDR21 Pads	Internal Vref cell TAP / CCAP controls associated to device LPDDR21 pad corresponding Vref-based receivers
CONTROL_LPDDR2IO1_3	lpddr21_dm0, lpddr21_dqs0, lpddr21_ndqs0, lpddr21_dq[7:0]	LPDDR21_VREF_DQ_INT0_TAP/CCAP
	lpddr21_dm1, lpddr21_dqs1, lpddr21_ndqs1, lpddr21_dq[15:8]	LPDDR21_VREF_DQ_INT1_TAP/CCAP
	lpddr21_dm2, lpddr21_dqs2, lpddr21_ndqs2, lpddr21_dq[23:16]	LPDDR21_VREF_DQ_INT2_TAP/CCAP
	lpddr21_dm3, lpddr21_dqs3, lpddr21_ndqs3, lpddr21_dq[31:24]	LPDDR21_VREF_DQ_INT3_TAP/CCAP
	lpddr21_ca[9:0], lpddr21_ncs0, lpddr21_ncs1, lpddr21_cke0, lpddr21_cke1, lpddr21_ck, lpddr21_nck	LPDDR21_VREF_CA_INT_TAP/CCAP
Control Module Register	LPDDR22 Pads	Internal Vref cell TAP / CCAP controls associated to device LPDDR21 pad corresponding Vref-based receivers
CONTROL_LPDDR2IO2_3	lpddr22_dm0, lpddr22_dqs0, lpddr22_ndqs0, lpddr22_dq[7:0]	LPDDR22_VREF_DQ_INT0_TAP/CCAP
	lpddr22_dm1, lpddr22_dqs1, lpddr22_ndqs1, lpddr22_dq[15:8]	LPDDR22_VREF_DQ_INT1_TAP/CCAP
	lpddr22_dm2, lpddr22_dqs2, lpddr22_ndqs2, lpddr22_dq[23:16]	LPDDR22_VREF_DQ_INT2_TAP/CCAP
	lpddr22_dm3, lpddr22_dqs3, lpddr22_ndqs3, lpddr22_dq[31:24]	LPDDR22_VREF_DQ_INT3_TAP/CCAP
	lpddr22_ca[9:0], lpddr22_ncs0, lpddr22_ncs1, lpddr22_cke0, lpddr22_cke1, lpddr22_ck, lpddr22_nck	LPDDR22_VREF_CA_INT_TAP/CCAP

Different LPDDR2x_VREF_DQ / CA_INTk_TAP[1:0], LPDDR2x_VREF_DQ / CA_INTk_CCAP[1:0] bitfields from the [CONTROL_LPDDR2IO1_3](#) (for LPDDR2IO1 Vref cells) and [CONTROL_LPDDR2IO2_3](#) (for LPDDR2IO2 Vref cells) registers, apply to k=4 different DQ groups and a single group of CA I/Os per LPDDR2 I/O set, as specified in [Table 18-74](#).

The LPDDR2x_VREF_DQ[1:0] or CA_TAP[1:0] bit fields, and LPDDR2x_VREF_DQ[1:0] or CA_CCAP[1:0] bit fields are used to set the output drive capability and coupling capacitors at the Vbias node of the DQ/CA external Vref generation cells.

In contrast to VREF_TAP and VREF_CCAP (which are individual per LPDDR2x I/O group), the LPDDR2x_INT_VREF_EN_DQ, LPDDR2x_INT_VREF_EN_CA, LPDDR2x_INT_VREF_AUTO_EN_DQ, and LPDDR2x_INT_VREF_AUTO_EN_CA bit fields act as common controls to all internal Vref generator cells.

NOTE: The CA and DQ Vref-generation cells used as external Vref output generators are controlled only by the PRCM.

18.4.12.7 EMIF DLL Master/Slave Specific Registers

18.4.12.7.1 EMIF DLL Slaves Individual Offset Compensation

Delays used to time the DQS signals of the LPDDR2 interface vary for the different DDR PHY DLL slaves associated with an EMIF controller instance. An individual offset compensation is provided for each of the four DLL slaves to achieve symmetrical timings.

Two 32-bit registers ([CONTROL_EMIF1_OFFSET](#) and [CONTROL_EMIF2_OFFSET](#)) in the general core control module are dedicated to hold four signed-offset programmable values for the EMIF1 and EMIF2 PHY DLL slaves, respectively. The following programming points apply to these registers:

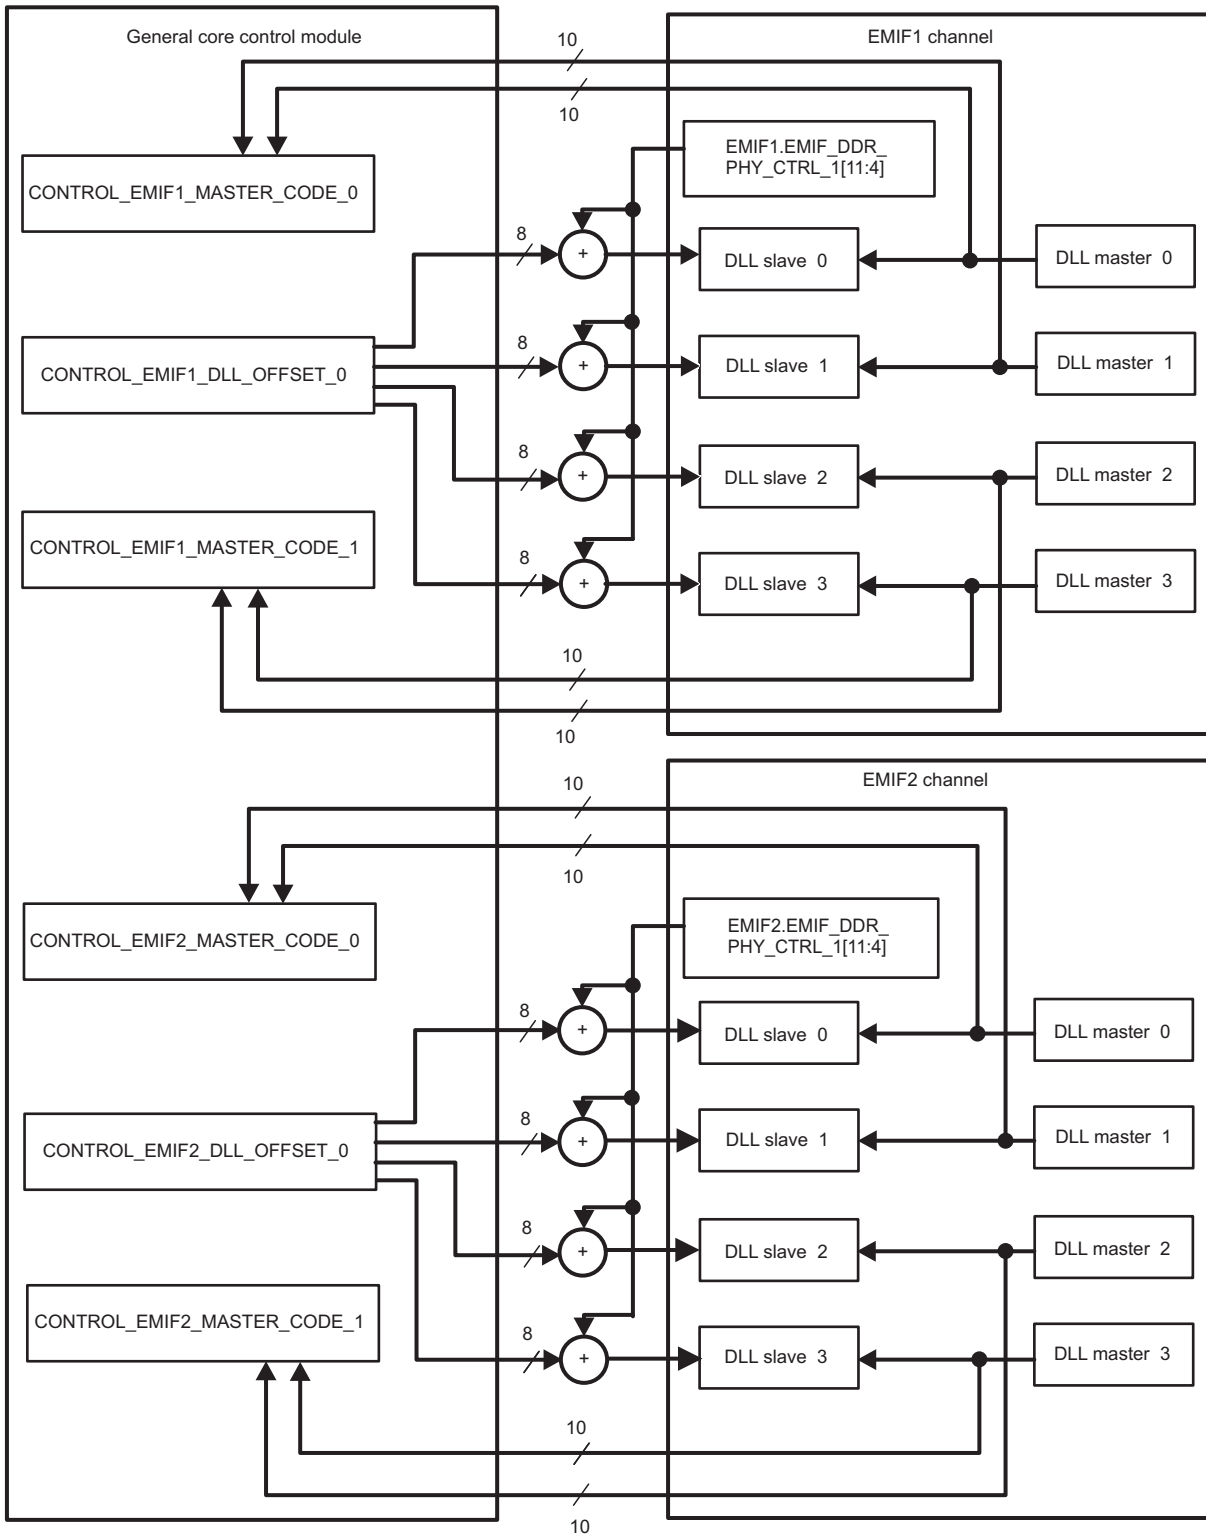

- Offset is stored as 2s complement 8-bit value, ranging from -128 to +127.

- Reset value is 0 (that is, by default, no offset is applied).
- The programmed values are saved and restored during an off mode transition.

The slave delay ratio value also has a single software control for all DLLs associated with an EMIF instance (the EMIF1.EMIF_DDR_PHY_CTRL_1[11:4] REG_DLL_SLAVE_DLY_CTRL bit field in the EMIF1 address space and EMIF2.EMIF_DDR_PHY_CTRL_1[11:4] REG_DLL_SLAVE_DLY_CTRL bit field in the EMIF2 address space). For more information, see [Chapter 15, Memory Subsystem](#).

The control sent to each DLL slave is the EMIF1/EMIF2 control (REG_DLL_SLAVE_DLY_CTRL) and the local signed offset, which is stored in the DLL slave corresponding bit field in the [CONTROL_EMIF1_OFFSET](#)/[CONTROL_EMIF2_OFFSET](#) registers. [DLL Slave Delay Control Schema](#) shows the DLL slave delay control schema.

Figure 18-24. DLL Slave Delay Control Schema

sysctrl-022

Because the adders work in saturation mode, there is no wrap-around on either end of the spectrum:

- Any value higher than 0xFF saturates to 0xFF.
- Any value lower than 0x00 saturates to 0x00.

Table 18-75 describes the control registers in general core control module dedicated to store delay offsets individually for the four DDR PHY DLL slaves.

Table 18-75. EMIF DLL Slave Offset Compensation Registers

Physical Address	Register Name	Description	Access
0x4A00 2360	CONTROL_EMIF1_OFFSET	EMIF1 slaves individual DLL offset controls	R/W
0x4A00 2364	CONTROL_EMIF2_OFFSET	EMIF2 slaves individual DLL offset controls	R/W

18.4.12.7.2 EMIF DLL Master Code Monitoring Registers

As can be seen in Figure 18-24, two read-only (RO) registers are provided in the general core control module to monitor DLL master codes for each of the EMIF1 and EMIF2 instances.

The 40 EMIF1 DLL master code monitoring signals are distributed as 20 read-only bits in the [CONTROL_EMIF1_MASTER_CODE_0](#) register and 20 read-only bits in the [CONTROL_EMIF1_MASTER_CODE_1](#) register, respectively.

Similarly, the 40 EMIF2 DLL master code monitoring signals are distributed as 20 read-only bits in the [CONTROL_EMIF2_MASTER_CODE_0](#) register and 20 read-only bits in the [CONTROL_EMIF2_MASTER_CODE_1](#) register, respectively.

Table 18-76 lists the control registers in general core control module dedicated to monitor the master code for the four DDR PHY DLLs.

Table 18-76. EMIF DLL Master Code-Monitoring Registers

Physical Address	Register Name	Description	Access
0x4A00 2368	CONTROL_EMIF1_MASTER_CODE_0	EMIF1 Master 0, 1 code	RO
0x4A00 236C	CONTROL_EMIF1_MASTER_CODE_1	EMIF1 Master 2, 3 code	RO
0x4A00 2370	CONTROL_EMIF2_MASTER_CODE_0	EMIF2 Master 0, 1 code	RO
0x4A00 2374	CONTROL_EMIF2_MASTER_CODE_1	EMIF2 Master 2, 3 code	RO

18.4.12.8 Force MPU Write Nonposted Transactions Control Register

At the top level, software can force all writes from the MPU subsystem to the L3 interconnect to be nonposted, regardless of the attributes of the transactions coming from the Cortex-A9 CPU. When active-high bit FORCEWRNP = 1, only nonposted write commands are sent to the L3 interconnect. This bit must remain stable for the entire transfer and must not change in between the transfer.

Table 18-77 describes the general core control module register with FORCEWRNP control.

Table 18-77. Force MPU Write Nonposted Transactions Control Register

Physical Address	Register Name	Description	Access
0x4A00 03C0	CONTROL_FORCEWRNP	Forces only nonposted write commands from the MPU subsystem to the L3 interconnect	R/W

18.4.12.9 Signal Integrity Parameter Control Registers With Pad Group Assignment

18.4.12.9.1 Signal Integrity Parameter Controls Overview

Most of the I/O cells associated with the device pads can be configured to deliver their carried signals to the targeted sink with maximum signal integrity. Configuration of these I/Os is done by pad group assignment and not individually per pad.

The different I/O-specific requirements determine the use of different types of I/O cells for the device I/Os. Software controls associated with the signal integrity parameters are implemented at the SYSCTRL_PADCONF_CORE and SYSCTRL_PADCONF_WKUP level.

The following types of I/O cells associated with pad groups can be identified:

- LPDDR2 high-speed I/O cells with impedance(I), slew rate(SR), and weak driver (WD) settings
- High-speed I/O cells with far-end load (LB) settings
- Low -speed I/O cells with combined slew rate (SC) and load versus transmission line (TL) length (LB) settings
- Two types of I/O cells with mode (MB) controls and load compensation (LB) settings
- I/O cells with control (DS0) of the impedance mode
- SDMMC2 or GPMC I/O cells with LB0 control adjustable according to interface requirement/voltage mode
- I/O cells with pullup strength (PUSTRENGTH) and speed controls
- I2Cx I/O cells with pullup resistance vers capacitance load settings
- JTAG I/O cells with bus-holder enable control

NOTE: I/Os are non-failsafe, which means that voltage must never be applied at a pad before the internal I/O supply voltage VDDS is powered.

The pad group-assigned signal integrity controls are provided through the registers described in [Table 18-78](#).

Table 18-78. Signal Integrity Parameter Control Registers

18.4.12.9.2 High-Speed I/O Buffers With Impedance, Slew Rate, and Weak Driver Settings

The LPDDR2IO (EMIF) buffers are based on high-speed unterminated logic and require excellent driver impedance control to achieve optimal timing–EMI trade-offs. A specific type of device I/O cell with programmable features is used to meet this requirement. These I/O cells also support the high-speed interchip (HSIC) interface.

Two types of software-configurable I/O cells are integrated to support high-speed unterminated logic:

- Single-ended I/O cells
- Two-pad differential I/O cells

Two-pad differential I/O cells are provided with a differential receiver and complementary transmitter. They are used to support the LPDDR2 clock pads (lpddr21_ck, lpddr21_nck, lpddr22_ck, lpddr22_nck) and LPDDR2 strobe pads (lpddr21_dqsi, lpddr21_ndqsi, lpddr22_dqsi, and lpddr22_ndqsi, where i = 0 to 3).

A LPDDR2 bidirectional-I/O cell receiver (Rx) can be configured to operate as a LVCMOS buffer and as a true differential comparator with a reference voltage (Vref input [a so called Vref-based receiver]). For more information on LPDDR2 I/O receiver-buffer type selection and power management controls, see [Section 18.4.12.5, Register Controls for the LPDDR2IO1/LPDDR2IO2 I/O Buffer Modes](#).

In addition, several Vref-generation cells are integrated in the device to supply reference voltage (Vref) to receiver buffers (when configured to operate as Vref-based receivers), and to provide Vref to externally-attached LPDDR2 memory. For more details on the functionality and controls of device Vref generation cells, see [Section 18.4.12.6, Reference Voltage for OMAP LPDDR2IO1 and LPDDR2IO2 I/O Buffers and LPDDR2 Memory](#).

The LPDDR2x I/O cells are integrated with the following controls in the SYSCTRL_PADCONF_CORE module:

- Driver output impedance (I) controls
- SR controls
- WD controls to support LPDDR2/HSIC interface and avoid floating pad
- Process-only impedance compensation using 5-bit binary coded schema separately for pullup p<1:5> and pulldown n<1:5> impedance

Programmable bits for impedance and SR control are provided when the I/Os are set to operate in driver mode (outputs).

The bits I[2:0] are used to program the desired impedance value of the driver.

The drive strengths corresponding to the I[2:0] value are aliased as Drv i (where i = 5 to 12) in the CONTROL_LPDDR2IO1_x and CONTROL_LPDDR2IO2_x, (where x = 0 to 2) register tables in [Section 18.6.7, SYSCTRL_PADCONF_CORE Register Description](#).

CAUTION

To ensure the best performance of the LPDDR2 I/Os, it is strongly recommended for user software to always set the impedance controlling bits (I) in the CONTROL_LPDDR2IO1_x and CONTROL_LPDDR2IO2_x registers (where x = 0 to 2) to 0x7, which corresponds to Drv12 mode.

For more information about LPDDR2 I/O-specific driver output impedance (respectively, corresponding drive strength) parameter, see the *Electrical Characteristics/DC Electrical Characteristics/LPDDR2 DC Electrical Characteristics* section in the device data manual.

User software can program the slew rate (turn-on time) of the output signal using the control bits SR[1:0] in the CONTROL_LPDDR2IO1_x and CONTROL_LPDDR2IO2_x (where x = 0 to 2) registers.

For more information about the LPDDR2 I/O slew rate parameter control, SR[1:0], see the *Electrical Characteristics/DC Electrical Characteristics/LPDDR2 DC Electrical Characteristics* section in the device data manual.

Weak pullup/down or a keeper on pad is enabled through the wd0 and wd1 bits. The weak pullup/down option is used to define the pad state (high or low) when no signal is driving the pad. The weak keeper option is used to maintain the previous output value when nothing is driving the pad. [Table 18-79](#) describes the WD controls.

NOTE: The WD[1:0] bit field controls play the role of the PULLTYPESELECT and PULLUDENABLE bits within the standard pad configuration registers, and provides the keeper function to the I/Os with the state WD = 0b11. For LPDDR2 I/Os, the WD controls do not apply during off mode.

CAUTION

To ensure the best performance of the LPDDR2 I/Os, it is strongly recommended for user software to always set the slew rate (SR) control bit field in the CONTROL_LPDDR2IO1_x and CONTROL_LPDDR2IO2_x registers (where x = 0 to 2) to 0b01.

It is also recommended to set the weak driver (WD) in the CONTROL_LPDDR2IO1_x and CONTROL_LPDDR2IO2_x registers to 0b10 (weak pull-down).

Similar to the lpddr1_x and lpddr2_x pads, the usbb1_hsic_data/strobe and usbb2_hsic_data/strobe pads also have weak driver software controls for active-mode internal weak pullups and pulldowns. They are in the [CONTROL_USBB_HSIC](#) register.

In contrast to the LPDDR2 I/Os, the usbb1_hsic and usbb2_hsic pads are also provided with bits in the same register to select weak pullup/down and keeper function during off mode. For a given usbbx_hsic_data/strobe pad (where x = 1, 2) the associated bit to allow an off mode-specific pullup/pulldown/keeper setting is OFFMODE_WD_ENABLE. The off mode option is defined through the OFFMODE_WD[1:0] bit field in the [CONTROL_USBB_HSIC](#) register..

Table 18-79. Weak Driver PUPD/Latch Mode

WD1	WD0	Operation
0	0	Pull logic disabled
0	1	Weak pullup enabled
1	0	Weak pulldown enabled
1	1	Weak keeper enabled

The following sequence is required to program the off-mode pullup/pulldown /latch (keeper) feature of the usbb1_hsic_data/usbb2_hsic_data and usbb1_hsic_strobe/usbb2_hsic_strobe pads:

1. Program the desired values for USBB1_HSIC_DATA_OFFMODE_WD/USBB2_HSIC_DATA_OFFMODE_WD and USBB1_HSIC_STROBE_OFFMODE_WD/USBB2_HSIC_STROBE_OFFMODE_WD in the [CONTROL_USBB_HSIC](#) register.
2. For an off-mode pullup/pulldown configuration different than the active-mode pullup/pulldown configuration, set the USBB1_HSIC_DATA_OFFMODE_WD_ENABLE/USBB2_HSIC_DATA_OFFMODE_WD_ENABLE and USBB1_HSIC_STROBE_OFFMODE_WD_ENABLE/USBB2_HSIC_STROBE_OFFMODE_WD_ENABLE bits to 1.

If USBB1_HSIC_DATA_OFFMODE_WD_ENABLE/USBB2_HSIC_DATA_OFFMODE_WD_ENABLE is set to 0, the applied value of the pullup/pulldown after the device goes to off mode will be same as the value of the active pullup/pulldown (that is, in this case, the value of the OFFMODE PU/PD bit field is disregarded).

If, for example, USBB1_HSIC_DATA_OFFMODE_WD_ENABLE/USBB2_HSIC_DATA_OFFMODE_WD_ENABLE is programmed with the same setting as USBB1_HSIC_DATA_WD_ENABLE/USBB2_HSIC_DATA_WD_ENABLE, then the value of USBB1_HSIC_DATA_OFFMODE_WD_ENABLE/USBB2_HSIC_DATA_OFFMODE_WD_ENABLE does not matter.

Therefore,

USBB1_HSIC_DATA_OFFMODE_WD_ENABLE/USBB2_HSIC_DATA_OFFMODE_WD_ENABLE and USBB1_HSIC_STROBE_OFFMODE_WD_ENABLE/USBB2_HSIC_STROBE_OFFMODE_WD_ENABLE apply only to off-mode pullup/pulldown selection.

The eFuse impedance compensation settings are exported upon POR to 10 bits in the [CONTROL_EFUSE_2](#) register of the device control module as follows:

[CONTROL_EFUSE_2](#)[23] LPDDR2_PTV_N1 through [CONTROL_EFUSE_2](#)[19] LPDDR2_PTV_N5 (pulldown impedance trimming)

[CONTROL_EFUSE_2](#)[18] LPDDR2_PTV_P1 through [CONTROL_EFUSE_2](#)[14] LPDDR2_PTV_P5 (pullup impedance trimming)

CAUTION

Do not override the eFuse impedance compensation settings in the [CONTROL_EFUSE_2](#) register.

NOTE: There is no software control (INPUTENABLE) for the input buffer of the high-speed unterminated logic I/Os associated with the lpddr21_x, lpddr22_x, usbb1_hsic_data/strobe, and usbb2_hsic_data/strobe pads. If the CMOS buffer is enabled, it is always bidirectional (that is, the input buffer is always enabled).

18.4.12.9.3 Low-Speed I/Os Combined Slew Rate Versus TL Length and Load Settings

The low-speed I/O cells slew modes are selectable through the slew mode control SC[1:0] bit field. These settings act like coarse settings for the signal performance behavior of the low-speed I/Os. The slew rate settings determine three target maximal frequencies of I/O operation at maximum load (see [Table 18-80](#))

The low-speed I/O cells far-end capacitance load can be selected according to the transmission line (TL) length settings by modifying load bits LB[1] and LB[0] appropriately. The four possible load bit settings described in [Table 18-81](#) are fully applicable and have maximum effect only when slew control mode 0 is selected. These settings fine-tune the signal performance.

The pads featuring low-speed I/O cells require different SC[1:0] and LB[1:0] bit field settings to achieve optimal electrical performance for the multiplexed interface. This behavior may depend on various factors:

- [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#), describes the different interfaces that have SC[1:0] and LB[1:0] controls and their pad corresponding software control registers.
- The *Electrical Characteristics/DC Electrical Characteristics* section of the device data manual provides more information about the specific SC[1:0] and LB[1:0] bit field settings applicable to these interfaces multiplexed to low-speed I/O pads.
- The *Timing Parameters* section of the device data manual provides the exact system conditions (far end load, trace length, etc.) at which pad-multiplexed interface I/O timing parameters reach their boundary values.

Table 18-80. Slew Control Mode (Coarse) Settings

SC[1] bit	SC[0] bit	Slew Rate Control Mode	Maximum Frequency Achieved at Maximum Load
0	0	0	20 MHz
0	1	1	60 MHz
1	0	2	40 MHz

Table 18-81. Load Bit (Fine) Settings

LB[1] (CLoad Capacitance Control)	LB[0] (TL-Length Control)	Effective TL Length (cm)	CLoad Capacitance (pF) (per TL)
0	0	2–20	1–10
0	1	20–40 (dual TL)	1–10
1	0	2–20	10–20
1	1	20–40 (dual TL)	10–20

NOTE: The load bit modes in [Table 18-81](#) are fully applicable and have maximum effect only in the case of slew control mode 0 (SC[1:0] = 00). For slew control modes 1 and 2, LB[1:0] = 0b11 is recommended.

18.4.12.9.4 I/Os With Combined Mode and Load Settings

There are two subtypes (conditionally described as type 1 and type 2 throughout this chapter) of device I/Os, with combined mode and load settings, that differ primarily in typical output impedance and mode-specific performance. Type 1 I/Os feature a lower typical output impedance than type 2.

Both I/Os have an output buffer with an internal pad voltage SR control mechanism. Each of the type 1 and type 2 corresponding I/O cells is controlled from two mode bits (MB0 and MB1) and a dedicated bit (LB0) for load compensation. LB0 programs the $C_{\text{far end load}}$ for the I/O cell associated pads. [Table 18-82](#) describes the mode bit settings for each mode and lists the load bit settings.

Table 18-82. Software Controls for I/Os With Combined Mode and Load Settings

Mode	MB1	MB0	LB0
Mode 1 – SDMMC/SPI	0	1	0
Mode 2 - DMIC/GPIO	1	0	0: ($C_{far\ end\ load}^{(1)} < 15pf$) 1: ($C_{far\ end\ load} \geq 15pf$)
Mode 3 – HSI	1	1	0: ($C_{far\ end\ load} < 5pf$) 1: ($C_{far\ end\ load} \geq 5pf$)
Mode 4 - ULPI	1	1	0: ($C_{far\ end\ load} < 4pf$) 1: ($C_{far\ end\ load} \geq 4pf$)

⁽¹⁾ The $C_{far\ end\ load}$ is the external capacitance load applied at the far end of the pad signal transmission line.

The *Electrical Characteristics / DC Electrical Characteristics* section of the device data manual provides more information on the specific MB[1:0] and LB[1:0] bit field settings applicable to different interfaces multiplexed to I/O pads with combined mode and load settings. The *Timing Parameters* section of the device data manual provides the exact system conditions (far end load, trace length, etc.) at which pad-multiplexed interface I/O timing parameters reach their boundary values.

The pads featuring type 1 and type 2 I/O cells with combined mode and load settings require different MB[1:0] and LB0 bit field settings to achieve optimal electrical performance for the multiplexed interface. This behavior may depend on various factors:

- [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#), describes the different interfaces that have type 1 and type 2 MB and LB0 controls and the type 1 and type 2 I/O cell pad corresponding software control registers.
- The *Electrical Characteristics/DC Electrical Characteristics* section the device data manual provides more information about the specific MB[1:0] and LB0 bit field settings applicable to these interfaces multiplexed to type 1 and type 2 I/O pads with combined mode and load controls.

A process-only compensation using a 4-bit binary-coded schema is used separately for pullup/down output parameter variations.

For type 1 I/Os, only mode 2 does not use such compensation.

For type 2 I/Os, only mode 1 and mode 2 use eFuse process-only compensation to reduce the spread in timing parameters.

The I/Os with combined mode and load controls share the same compensation settings with the I/Os with driver output impedance (DS) settings and with the SDMMC2 or GPMC I/O buffers. They are exported from eFuse upon POR to the following bits in the [CONTROL_EFUSE_2](#) register:

[CONTROL_EFUSE_2\[31\]](#) EFUSE_SMART2TEST_P0 through [CONTROL_EFUSE_2\[28\]](#) EFUSE_SMART2TEST_P3 (pullup output parameters trimming)
[CONTROL_EFUSE_2\[27\]](#) EFUSE_SMART2TEST_N0 through [CONTROL_EFUSE_2\[24\]](#) EFUSE_SMART2TEST_N3 (pulldown output parameters trimming)

CAUTION

Do not override the SMART2TEST_P/SMART2TEST_N eFuse compensation settings in the [CONTROL_EFUSE_2](#) register.

18.4.12.9.5 I/O Cells With Configurable Impedance Mode

The impedance mode at which this type of I/O cell operates is selected by setting a single bit drive strength control, DS0, as follows:

- DS0 = 1 selects mode 1, corresponding to 25-Ω impedance mode
- DS0 = 0 selects mode 2, corresponding to 50-Ω impedance mode

The pads featuring I/O cell with configurable impedance mode require different DS0 bit settings to achieve optimal electrical performance for the multiplexed interface. This behavior may depend on various factors:

- [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#), describes the different

interfaces that have DS0 impedance mode control and the pad corresponding software control registers.

- The *Electrical Characteristics/DC Electrical Characteristics* section of the device data manual provides more information about the specific DS0 bit settings applicable to these interfaces multiplexed to I/O pads with configurable impedance mode.

A process-only compensation using 4-bit binary coded schema is used separately for pullup/down output parameter variations. Only MODE1 and MODE2 use eFuse process-only compensation to reduce spread in timing parameters. The I/Os with DS0 impedance mode control share the same compensation settings with the I/Os with combined mode and load controls (both type 1 and type 2) and with the SDMMC2 or GPMC I/O buffers. They are exported from eFuse upon POR to the following bits in the [CONTROL_EFUSE_2](#) register:

[CONTROL_EFUSE_2](#)[31] EFUSE_SMART2TEST_P0 through [CONTROL_EFUSE_2](#)[28] EFUSE_SMART2TEST_P3 (pullup output parameters trimming)

[CONTROL_EFUSE_2](#)[27] EFUSE_SMART2TEST_N0 through [CONTROL_EFUSE_2](#)[24] EFUSE_SMART2TEST_N3 (pulldown output parameters trimming)

18.4.12.9.6 SDMMC2 or GPMC I/O Cells With Load Setting Adjustable According to Interface Requirement Voltage Mode

To configure this type of I/O cell for different interfaces multiplexed on it, the user must manipulate in software a single bit, LB0, depending on type of multiplexed interface (GPMC and SDMMC2) of the pad and the selected I/O voltage supply mode. Like LPDDR2IO, this I/O cell is provided with selectable LVCMOS and Vref-based receiver option. A vref pad is provided to supply reference voltage to the receiver in the 1.2-V mode. To save power at lower frequency operation, the LVCMOS receiver can be selected, and 2 bits, for each of the two SDMMC2 or GPMC pad groups, are used to enable/disable the LVCMOS receiver (CMOSEN_C2C_FRM_CTRL) manually in the [CONTROL_C2CIO_PADCONF_0](#) register.

The pads featuring SDMMC2 or GPMC I/O cells with load setting adjustable according to interface requirement/voltage mode require different LB0 bit settings to achieve optimal electrical performance for the multiplexed interface. This behavior may depend on various factors:

- [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#), describes the different interfaces that have the interface type versus voltage mode control (LB0) and the pad corresponding software control registers.
- The *Electrical Characteristics/DC Electrical Characteristics* section of the device data manual provides more information about the specific LB0 bit settings applicable to these interfaces multiplexed to I/O pads with configurable impedance mode.

NOTE: No bits are assigned to control the output drive capability of the internal SDMMC2 or GPMC Vref generator (at the c2c_vref pad). It is fixed to a 2- μ A current load.

If 1.2-V voltage mode is selected, the user can choose to have the LVCMOS receiver or Vref-based receiver on the SDMMC2 or GPMC I/O cell pads. For the description of the dual-voltage mode settings of the SDMMC2 or GPMC I/O cell pads, see [Section 18.4.12.10, Dual Voltage-Supplied Peripheral Controls](#).

In Vref-based receiver mode, the SDMMC2 or GPMC I/O cell receiver is a true differential comparator with pad connected to the positive terminal and VREF tied to the negative terminal. The Vref-based receiver allows the improvement of speed performance at VDD5 = 1.2-V I/O voltage supply.

NOTE: The Vref-based receiver is not supported in 1.8-V mode. In this mode, the LVCMOS receiver is the only option.

NOTE: While at VDD5 = 1.2 V, the LVCMOS receiver is supported for all SDMMC2 or GPMC I/O cell pads. The Vref-based receiver is supported on only some of these pads.

The [CONTROL_C2CIO_PADCONF_0\[12\]](#) CMOSEN_C2C_0_FRM_CTRL and [CONTROL_C2CIO_PADCONF_0\[11\]](#) CMOSEN_C2C_1_FRM_CTRL bits, each related to a separate group of pads, are dedicated to select Vref-based receiver mode or LVCMOS receiver mode when VDD5 = 1.2 V is selected in the [CONTROL_CORE_PADCONF_MODE](#) register.

CMOSEN_C2C_0_FRM_CTRL = 1 enables the 1.2-V mode LVCMOS receiver, and CMOSEN_C2C_0_FRM_CTRL = 0 enables the 1.2-V Vref-based receiver for the following pads:

- gpmc_ad8–gpmc_ad15
- gpmc_ncs4
- gpmc_ncs5

CMOSEN_C2C_1_FRM_CTRL = 1 enables the 1.2-V mode LVCMOS receiver and CMOSEN_C2C_1_FRM_CTRL = 0 enables the 1.2-V Vref-based receiver for the following pads:

- gpmc_a16–gpmc_a23

NOTE: The Vref-based receiver in 1.2-V mode is not supported for the following SDMMC2 or GPMC I/O cell pads:

- gpmc_ad0–gpmc_ad7
 - gpmc_a24
 - gpmc_a25
 - gpmc_ncs0–gpmc_ncs3
 - gpmc_clk
 - gpmc_nadv_ale
 - gpmc_noe
 - gpmc_nwe
 - gpmc_nbe0_cle
 - gpmc_nbe1
 - gpmc_wait1
 - gpmc_wait2
 - gpmc_ncs6
 - gpmc_ncs7
-

When the internal Vref generator is turned on, it supplies voltage reference to the Vref-based receivers supported for some SDMMC2 or GPMC I/O cell pads and can also be used to drive external modules with 1.2-V reference. In this case, the c2c_vref device pad outputs voltage of the internal SDMMC2 or GPMC Vref cell.

Setting bit [CONTROL_C2CIO_PADCONF_0\[7\]](#) C2C_INT_VREF_AUTO_EN = 0b1 enables the automatic shut off or switch-on of the internal Vref cell generator.

If user software sets the manual control bit [CONTROL_C2CIO_PADCONF_0\[8\]](#) C2C_INT_VREF_EN = 0b1, the internal Vref cell generator is enabled, regardless of the state of the [CONTROL_C2CIO_PADCONF_0\[7\]](#) C2C_INT_VREF_AUTO_EN bit. Thus, automatic control over the SDMMC2 or GPMC Vref cell generator can always be overridden in the context of enabling the Vref generator.

If the Vref cell generator is enabled, the c2c_vref pad acts as output and can be used to supply reference voltage to external devices.

NOTE: At VDD5 = 1.8-V voltage mode, the internal reference generator is shut off and the internal Vref cell reference node is connected to 0.

For the description of the dual-voltage mode settings of the SDMMC2 or GPMC I/O cell pads, see [Section 18.4.12.10, Dual Voltage-Supplied Peripheral Controls](#).

CAUTION

While using the Vref cell in internal reference mode, nothing else must drive the pad externally, although the pad can be connected to supply the Vref signal to other devices.

When the internal Vref cell generator is disabled and bypassed, which is provided when bits [CONTROL_C2CIO_PADCONF_0\[8\]](#) C2C_INT_VREF_EN = 0b0 and [CONTROL_C2CIO_PADCONF_0\[7\]](#) C2C_INT_VREF_AUTO_EN = 0b0, the c2c_vref pad acts as input that can supply voltage reference to the Vref-based receivers from external sources.

[Table 18-83](#) provides different combinations of Vref cell control types, the state of the Vref cell, and the associated voltage reference pad direction.

Table 18-83. SDMMC2 or GPMC Vref Cell State Description

C2C_INT_VREF_EN (Manual Control Bits)	C2C_INT_VREF_AUTO_EN (AUTO Control Bits)	Type of Control	Vref Cell State	Voltage Reference Pad Direction
1	x	Manual	Enabled	O
0	1	AUTO	Automatically enabled/disabled	O
0	0	–	Disabled and bypassed	I

CAUTION

The c2c_vref pad must be externally driven only in 1.2-V voltage mode.

According to the noise environment, the user can select to filter the reference voltage, which is supplied at the internal VREF node (receiver comparators Vref input) by the Vref cell generator or by an external source. Two coupling capacitors, internal to the SDMMC2 or GPMC Vref cell, are available at the internal VREF node, which is configurable as specified in [Table 18-84](#).

Table 18-84. SDMMC2 or GPMC Vref Cell Decoupling Cap Selection

VREF_CCAP0	VREF_CCAP1	Capacitor
0	0	No capacitor connected
0	1	Capacitor between internal reference node and VDD5
1	0	Capacitor between internal reference node and VSS
1	1	Capacitor between internal reference node and VDD5 as well as internal reference node and VSS

A process-only compensation using a 4-bit binary-coded schema is used separately for pullup/down output parameter variations. The SDMMC2 or GPMC I/O buffers share the same compensation settings with the I/Os with combined mode and load controls (both with 25- and 50-Ω output) and I/Os with driver output impedance (DS) settings. They are exported from eFuse upon POR to the following bits in the [CONTROL_EFUSE_2](#) register:

[CONTROL_EFUSE_2\[31\]](#) EFUSE_SMART2TEST_P0 through [CONTROL_EFUSE_2\[28\]](#) EFUSE_SMART2TEST_P3 (pullup output parameters trimming)

[CONTROL_EFUSE_2\[27\]](#) EFUSE_SMART2TEST_N0 through [CONTROL_EFUSE_2\[24\]](#) EFUSE_SMART2TEST_N3 (pulldown output parameters trimming)

18.4.12.9.7 SDMMC1 Pullup Strength Control

The SDMMC1_PUSTRENGTH_GRP_i (where $i = 1$ to 3) control bits are added in the [CONTROL_MMC1](#) register to program the pullup strength for the MMC/SD/SDIO1 I/Os group.

- [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#), describes the different interfaces that have the pullup strength control and the pad corresponding software control registers.
- The *Electrical Characteristics/DC Electrical Characteristics* section of the device data manual provides more information about the specific pullup strength settings applicable to these interfaces multiplexed to I/O pads with configurable pullup strength.

18.4.12.9.8 I2Cx I/Os Group Pullupresx Controls and Load Range Settings

The I2Cx buffer contains internal pullup resistors for F/S and HS modes. LB[1:0] bits are used to select an appropriate pullup resistor for a given load range.

The active high GLFENB[0] bit is implemented for I²C receivers to enable glitch-free operation.

NOTE: The pullup versus load settings applicable to I2Cx FS mode also apply to I2Cx standard speed mode.

The type of the pullup resistor (external or internal) for a certain I2Cx I/O group (where $x = 1$ to 4) is selected through the I2Cx_SCL_PULLUPRESX and I2Cx_SDA_PULLUPRESX bits which reside in the [CONTROL_I2C_0](#) register. The SR_SCL_PULLUPRESX and SR_SDA_PULLUPRESX bits reside in the [CONTROL_I2C_2](#) register, which is part of the wakeup voltage domain.

Internal pullups are activated when I2Cx_SCL_PULLUPRESX / I2Cx_SDA_PULLUPRESX = 0b0 or SR_SCL_PULLUPRESX/SR_SDA_PULLUPRESX = 0b0.

I²C functionality is not ensured if the weak internal pullup or pulldown is activated on any of the I/Os connected to the bus.

NOTE: The user must set PULLUDENABLE = 0b0 in the I2Cx padconf registers (disable internal weak pullup resistors on i2cx pads) to ensure the full I/O cell performance capabilities of the I²C.

The I²C pads require different LB[1:0] and GLFENB[0] bit field settings to achieve optimal electrical performance for the multiplexed (in MuxMode = 0x0) I²C signals. This behavior may depend on various factors:

- [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#), describes the I²C pads and their corresponding software control registers.
- The *Electrical Characteristics/DC Electrical Characteristics/I²C DC Electrical Characteristics* section of the device data manual provides more information about the specific LB[1:0] and GLFENB[0] bit settings applicable to I²C I/O pads.

18.4.12.9.9 Device Interfaces Signal Group Controls Mapping

[Table 18-85](#) through [Table 18-112](#) describe the mapping of the signal integrity control bit fields in the different signal integrity control registers described in [Table 18-78](#).

NOTE: The same I/O cell and I/O cell controls assigned to a pad signal available when Muxmode = 0 are shared between signals available on the same pad when Muxmode is selected different than 0. For more information, see [Section 18.4.8.3, Pad Multiplexing Register Fields](#).

18.4.12.10 Dual Voltage-Supplied Peripheral Controls

Some of the peripheral I/Os have the option to be supplied with a 1.2-V or 1.8-V power supply (VDD_S through device external pads). The power supply level to the dual-voltage I/Os of different peripherals is configurable through bit fields in the [CONTROL_CORE_PADCONF_MODE](#) register in the CORE domain (EMIF, GPMC, CAMERA, and SDMMC2 I/Os) and the [CONTROL_WKUP_PADCONF_MODE](#) register in the WKUP domain (EMIF and FREF generator). One control bit in these registers is dedicated to set dual-voltage per group of pads.

NOTE: Dynamic switching between 1.2-V and 1.8-V voltage modes on dual-voltage peripheral I/Os is not allowed.

[Table 18-113](#) describes dual-voltage controls versus the mapping of different pads.

Table 18-113. Dual-Voltage Peripheral Control Bits vs Pad Mapping

Dual-Voltage VDDS = 1.2-V/1.8-V Control Bits	Pads With Dual-Voltage Settings

18.5 Control Module Programming Guide

18.5.1 Control Module Low-Level Programming Models

This section describes the low-level programming sequences for the configuration and use of the control module.

18.5.1.1 Global Initialization

18.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the control module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the environment and integration of the control module. For more information, see [Section 18.2, Control Module Environment](#), and [Section 18.3, Control Module Integration](#).

Table 18-114. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The three clocks coming from the PRCM module (CFG_L4_ICLK , WKUP_L4_ICLK2 , and CORE_TS_FCLK) are not software-controlled by PRCM. For more information about the three clocks, see Section 3.6.3.2.4, CM2 Clock Generator , and Section 3.6.3.1, PRM Clock Source , in Chapter 3, Power, Reset, and Clock Management .
L4 interconnect	For information about the L4-CFG interconnect configuration, see Section 13.3, L4 Interconnects , in Chapter 13, Interconnects .

18.5.1.1.2 Control Module Global Initialization

18.5.1.1.2.1 Software Reset

The control module is not sensitive to a software reset.

18.5.1.1.2.2 Clock Gating Configuration

As described in [Section 18.4.2, Control Module Clock Configuration](#), the programmer can choose a clock-gating strategy individually for each of the four control module instances. [Table 18-115](#) explains the necessary steps.

Table 18-115. Configure Clock Gating for Different Control Module Instances

Step	Register/Bit Field/Programming Model	Value
Set clock gating for SYSCTRL_PADCONF_CORE.	CONTROL_PADCONF_CORE_SYSCONFIG [3:2]	0x-
Set clock gating for SYSCTRL_PADCONF_WKUP.	CONTROL_PADCONF_WKUP_SYSCONFIG [3:2]	0x-
Set clock gating for SYSCTRL_GENERAL_CORE.	CONTROL_GEN_CORE_SYSCONFIG [3:2] CONTROL_TEMP_SENSOR [13]	0x-
Set clock gating for SYSCTRL_GENERAL_WKUP.	CONTROL_GEN_WKUP_SYSCONFIG [3:2]	0x-

18.5.1.2 Operational Modes Configuration

18.5.1.2.1 Video Driver Configuration

This section provides information about all modules and features in the high-tier device.

For more information about the VDAC, see [Section 10.6, Video Encoder](#).

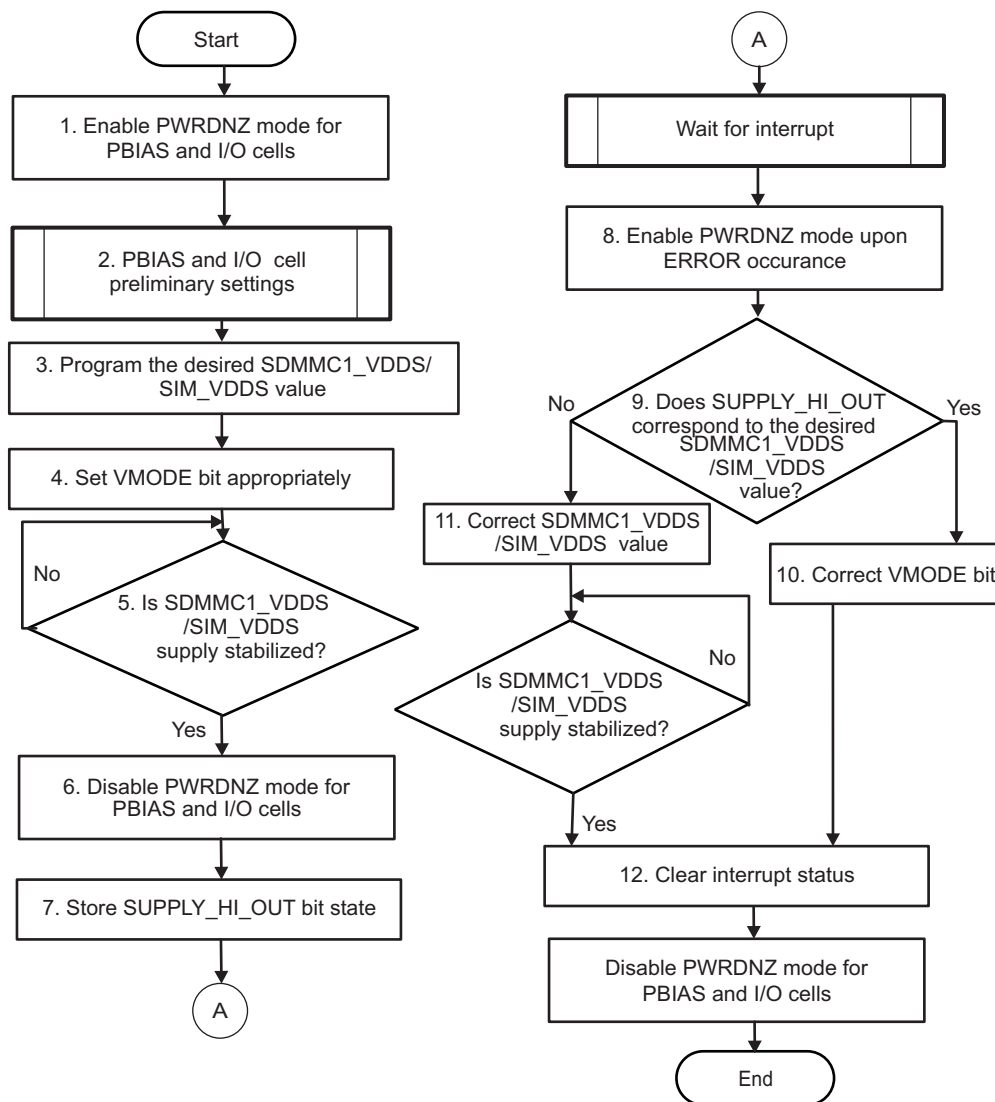

Table 18-116. Control Module AVDAC Configuration

Step	Register/Bit Field/Programming Model	Value
Video buffer is bypassed or not bypassed.	CONTROL_AVDAC[30] AVDAC_TVOUTBYPASS	0b-
Enable or disable ac coupling for TV output.	CONTROL_AVDAC[31] AVDAC_ACEN	0b-

NOTE: The (VDAC) function is not supported.

18.5.1.2.2 Extended-Drain I/Os and PBIAS Cells Programming Guide

This section describes the programming flow from 3.0 V to 1.8 V, and vice versa, when operating with the extended-drain I/Os and PBIAS cells.

Figure 18-25. Configuring PBIAS Cell to Operate in Different Modes, Interrupt Method

sysctrl-021

Table 18-117. Register Settings for Configuring the MMC1_PBIAS and MMC1 I/O Cells

Procedure Name	Description	Register Settings
1. Enable PWRDNZ mode for MMC1_PBIAS cell and MMC/SD/SDIO1 I/O cell.	Software must keep MMC1_PBIAS cell and MMC1_IO cell PWRDNZ signals low whenever SDMMC1_VDDS ramps up/down or changes. This is for cell protection purposes.	1. Set CONTROL_PBIASLITE [22] MMC1_PBIASLITE_PWRDNZ = 0b0. 2. Set CONTROL_PBIASLITE [26] MMC1_PWRDNZ = 0b0.
2. Preliminary MMC1_PBIAS and MMC1 IO cell settings	Enable MMC1_PBIAS cell output and MMC1_PBIAS error associated interrupt. Select desired I/Os within the MMC1 I/O cell and set the corresponding pad configuration fields appropriately. Set the group speed and pullup strength controls for the MMC/SD/SDIO1 pads.	1. Set CONTROL_PBIASLITE [25]MMC1_PBIASLITE_HIZ_MODE = 0b0. 2. For information about setting the MA_IRQ_75 line associated interrupt request PBIAS_IRQ, see Chapter 17, Interrupt Controller . 3. For I/O multiplexing and pad configuration settings, see Section 18.5.1.2.5, Pad Configuration Programming Points . 4. Set the speed control bits for the MMC1 I/O cell pads: <ul style="list-style-type: none"> • CONTROL_MMC1[27] SDMMC1_DR0_SPEEDCTRL = 0b- • CONTROL_MMC1[26] SDMMC1_DR1_SPEEDCTRL = 0b- • CONTROL_MMC1[28] SDMMC1_DR2_SPEEDCTRL = 0b- 5. Set the pullup strength control bits for the MMC1 I/O cell pad groups: <ul style="list-style-type: none"> • CONTROL_MMC1[31] SDMMC1_PUSTRENGTH_GRP0=0b- • CONTROL_MMC1[30] SDMMC1_PUSTRENGTH_GRP1=0b- • CONTROL_MMC1[29] SDMMC1_PUSTRENGTH_GRP2=0b- • CONTROL_MMC1[28] SDMMC1_PUSTRENGTH_GRP3=0b-
3. Program the desired SDMMC1_VDDS voltage for MMC/SD/SDIO1 I/Os.	Program external power supply IC to generate appropriate SDMMC1_VDDS voltage:(3.0 V/ 1.8 V).	For more information about I ² C interface operation, see Section 23.1, Multimaster High-Speed I²C .
4. Set VMODE bit appropriately.	PBIAS voltage generation is based on the value of VMODE, set according to externally applied SDMMC1_VDDS voltage.	Set CONTROL_PBIASLITE [21] MMC1_PBIASLITE_VMODE = 0b- ⁽¹⁾ .
5. Check whether the SDMMC1_VDDS supply is stabilized.	Check the state of the externally generated SDMMC1_VDDS voltage, which is provided through communication between the device and external power supply device over the I ² C interface.	For more information about I ² C interface settings, see Section 23.1, Multimaster High-Speed I²C .
6. Disable PWRDNZ mode for MMC1_PBIAS and associated extended-drain MMC1 I/O cell.	This starts the MMC1_PBIAS cell work to generate the PBIAS voltage.	1. Set CONTROL_PBIASLITE [22] MMC1_PBIASLITE_PWRDNZ = 0b1. 2. Set CONTROL_PBIASLITE [26] MMC1_PWRDNZ = 0b1.
7. Store the state of the SUPPLY_HI_OUT bit.	Done as a preliminary step for error handling analysis. (Whenever PWRDNZ = 0b0 , SUPPLY_HI_OUT is unconditionally set to 0b0.)	Store CONTROL_PBIASLITE [24] MMC1_PBIASLITE_SUPPLY_HI_OUT bit in memory.
8.Enable PWRDNZ mode upon error occurrence.	It is recommended that all the I/Os are powered down (PWRDNZ = 0) as soon as VMODE_ERROR is high.	1. Set CONTROL_PBIASLITE [26] MMC1_PWRDNZ = 0b0 . 2. Set CONTROL_PBIASLITE [22]MMC1_PBIASLITE_PWRDNZ = 0b0.
9. Does SUPPLY_HI_OUT correspond to the desired SDMMC1_VDDS?	Test whether the error comes from incorrectly set value of SDMMC1_VDDS or incorrectly set VMODE bit.	Check the SUPPLY_HI_OUT bit stored in memory.
10. Correct VMODE bit.	If the level of SUPPLY_HI_OUT corresponds to the desired value of SDMMC1_VDDS, the correct the value of the VMODE bit	Modify the value of the CONTROL_PBIASLITE [21] MMC1_PBIASLITE_VMODE bit.
11. Correct SDMMC1_VDDS value.	If SUPPLY_HI_OUT is different from expected, correct and set SDMMC1_VDDS value over I ² C again.	For more information about I ² C interface settings, see Section 23.1, Multimaster High-Speed I²C ,
12. Clear Interrupt status.	Clear the IRQ_MA_75 interrupt status flag.	For more information about setting the MA_IRQ_75 line associated interrupt request PBIAS_IRQ, see Chapter 17, Interrupt Controller .

⁽¹⁾ Must be set high when external SDMMC1_VDDS source is programmed to be 3.0 V, or low when the external SDMMC1_VDDS source is programmed to be 1.8 V. The reset default value corresponds to 3.0 V.

Table 18-118. Register Settings for Configuring the PBIAS1 Cell, USBC1_ICUSB and gpio_wk0gpio_wk2 Associated I/O Cells

Procedure Name	Description	Register Settings
1. Enable PWRDNZ mode for PBIAS1 cell ,USBC1_ICUSB I/O cel,l and gpiowk0–gpiowk2 associated I/O cell.	Software must keep the PBIAS1 cell and the USBC1_ICUSB and gpiowk0 - gpiowk2 I/O cells associated with the PWRDNZ signals low whenever SIM_VDDS ramps up/down or changes. This is for cell protection purposes.	1. Set CONTROL_PBIASLITE [28] PBIASLITE1_PWRDNZ = 0b0. 2. Set CONTROL_PBIASLITE [20] USBC1_ICUSB_PWRDNZ = 0b0. 3. Set CONTROL_GPIOWK [28] GPIOWK_IO_PWRDNZ = 0b0.
2. PBIAS1 cell, USBC1_ICUSB, and gpio_wk0-gpio_wk2 I/O cell settings	Enable PBIAS1 cell output and USBC1_ICUSB, gpio_wk0-gpio_wk2 error associated interrupt. Select desired I/Os within the USBC1_ICUSB and GPIOWK I/O cells and set appropriately their corresponding pad configuration fields Set the speed and pulldown controls for the pads (if applicable).	1. Set CONTROL_PBIASLITE [31] PBIASLITE1_HIZ_MODE = 0b0. 2. For more information about setting MA_IRQ_75 line associated interrupt request PBIAS_IRQ, see Chapter 17, Interrupt Controller . 3. For the I/O multiplexing and pad configuration settings, see Section 18.5.1.2.5, Pad Configuration Programming Points . 4. Set the speed control bits for USBC1_ICUSB I/O cell pads CONTROL_MMC1 [24] USBC1_DR0_SPEEDCTRL = 0b- (No speed ctrl available for GPIOWK associated I/O cell). 5. Disable strong pulldowns on the gpio_wk1 and gpio_wk2 pads available by default after reset: <ul style="list-style-type: none"> CONTROL_GPIOWK[31] PAD_GPIO_WK1_LOW = 0b0 CONTROL_GPIOWK[29] PAD_GPIO_WK2_LOW = 0b0
3. Program the desired voltage for SIM_VDDS for the USBC1_ICUSB/gpiowk0–gpiowk2 or (hw_dbg1–hw_dbg3 in WKUP domain) I/Os.	Program external power supply IC to generate appropriate SIM_VDDS voltage:(3.0 V/1.8 V)	For more information about I ² C interface operation, see Section 23.1, Multimaster High-Speed I²C .
4. Set VMODE bit appropriately.	PBIAS voltage generation is based on the value of VMODE, set according to externally applied SIM_VDDS voltage.	Set CONTROL_PBIASLITE [27] PBIASLITE1_VMODE = 0b-. ⁽¹⁾
5. Check whether SIM_VDDS supply is stabilized.	Check the state of the externally generated SIM_VDDS voltage.This is provided through communication between the device and the companion power supply device over the I ² C interface.	For more information about I ² C interface setting, see Section 23.1, Multimaster High-Speed I²C .
6. Disable PWRDNZ mode for PBIAS1 cell and its associated extended-drain USBC1_ICUSB and gpiowk0–gpiowk2 I/O cells.	This starts the PBIAS1 cell work to generate the PBIAS voltage.	1. Set CONTROL_PBIASLITE [28] PBIASLITE1_PWRDNZ = 0b1. 2. Set CONTROL_PBIASLITE [20] USBC1_ICUSB_PWRDNZ = 0b1. 3. Set CONTROL_GPIOWK [28] GPIOWK_IO_PWRDNZ = 0b1.
7. Store the state of the SUPPLY_HI_OUT bit.	Done as a preliminary step for error handling analysis. (Whenever PWRDNZ = 0b0 , SUPPLY_HI_OUT is unconditionally set to 0b0.)	Store the CONTROL_PBIASLITE [30] PBIASLITE1_SUPPLY_HI_OUT bit in memory.
8.Enable PWRDNZ mode upon error occurrence.	It is recommended that all the I/Os are powered down (PWRDNZ = 0) as soon as VMODE_ERROR is high.	1. Set CONTROL_PBIASLITE [28] PBIASLITE1_PWRDNZ = 0b0. 2. Set CONTROL_PBIASLITE [20] USBC1_ICUSB_PWRDNZ = 0b0. 3. Set CONTROL_GPIOWK [28] GPIOWK_IO_PWRDNZ = 0b0.
9. Does SUPPLY_HI_OUT correspond to the desired SIM_VDDS level?	Test whether the error comes from incorrectly set value of SIM_VDDS or incorrectly set VMODE bit.	Check the stored in memory SUPPLY_HI_OUT bit.
10. Correct VMODE bit.	If the level of SUPPLY_HI_OUT corresponds to the desired value for SIM_VDDS, the correct value of the VMODE bit.	Modify value of CONTROL_PBIASLITE [27] PBIASLITE1_VMODE.
11. Correct SIM_VDDS value.	If SUPPLY_HI_OUT is different than expected, correct and set SIM_VDDS value over I ² C again.	For more information about I ² C interface setting, see Section 23.1, Multimaster High-Speed I²C .
12. Clear Interrupt status.	Clear the IRQ_MA_75 interrupt status flag.	For more information about setting MA_IRQ_75 line associated interrupt request PBIAS_IRQ, see Chapter 17, Interrupt Controller .

⁽¹⁾ Must be set high when the external SIM_VDDS source is programmed to be 3.0 V, or low when the external SIM_VDDS source is programmed to be 1.8 V. The reset default value corresponds to 3.0 V.

18.5.1.2.3 Hardware Observability Settings

This section describes the procedures to control the hardware observability features of the device. To configure these features, the programmer must perform the steps listed in [Table 18-119](#).

Table 18-119. Configure Hardware Observability Features

Step	Register/Bit Field/Programming Model	Value
1. Select the hwobs(0)/hwobs(1)/hwobs(2) signal frequency divider value (applies only to po_hw_dbg0, po_hw_dbg1, and po_hw_dbg2 bus signals propagated in the CORE power domain).	CONTROL_HWOBS_CONTROL [7:3] HWOBS_CLKDIV_SEL CONTROL_HWOBS_CONTROL [13:9] HWOBS_CLKDIV_SEL_1 CONTROL_HWOBS_CONTROL [18:14] HWOBS_CLKDIV_SEL_2	0x- ⁽¹⁾
2. Enable/disable gating of hwobs and alternatively set all hwobs ports to 0 or 1.	.CONTROL_HWOBS_CONTROL [2] HWOBS_ALL_ZERO_MODE CONTROL_HWOBS_CONTROL [1] HWOBS_ALL_ONE_MODE	0x- ⁽²⁾
3. Enable/disable hwobs port gating only for signals coming from IPs identified in the MACRO group (applies only to po_hw_dbg bus signals propagated in the CORE power domain).	CONTROL_HWOBS_CONTROL [0] HWOBS_MACRO_ENABLE	0x- ⁽³⁾
4. Associate a certain hwobs channel to the CORE or WKUP power domain.	Configure each bit from the CONTROL_DEBOBS_FINAL_MUX_SEL [31:0] SELECT bit field appropriately for its corresponding hw_dbg channel.	0x-
5. Choose the source of a signal or signal view channel in the CORE power domain.	Configure each CONTROL_CORE_CONF_DEBUG_SEL_TST_0 [3:0] MODE through CONTROL_CORE_CONF_DEBUG_SEL_TST_31 [3:0] MODE bit field appropriately for its corresponding hw_dbg channel.	0x-
6. Choose the source of a signal within the WKUP power domain.	Configure each CONTROL_WKUP_CONF_DEBUG_SEL_TST_i [0] MODE bit, (where i = 0 to 31) appropriately for its corresponding hw_dbg channel i (where i = 0 to 31).	0x-
7. Choose to associate a certain DPLL signal to a given DPLL signal view channel (applies only to po_hw_dbg bus signals propagated in the CORE power domain).	CONTROL_CONF_DPLL_FREQLOCK_SEL [2:0] MULT .CONTROL_CONF_DPLL_TINITZ_SEL [2:0] MULT CONTROL_CONF_DPLL_PHASELOCK_SEL [2:0] MULT CONTROL_CONF_DPLL_TENABLE_SEL [2:0] MULT CONTROL_CONF_DPLL_TENABLEDIV_SEL [2:0] MULT CONTROL_CONF_DPLL_BYPASSACK_SEL [2:0] MULT CONTROL_CONF_DPLL_IDLE_SEL [2:0] MULT	0x-
8. Choose to associate a certain clockout signal to a given clockview channel (applies only to po_hw_dbg bus signals propagated in the CORE power domain).	CONTROL_CONF_CLK_SEL0 [2:0] MULT through CONTROL_CONF_CLK_SEL2 [2:0] MULT	0x-
9. Choose to associate an sDMA signal to a given sDMA view channel (applies only to po_hw_dbg bus signals propagated in the CORE power domain).	CONTROL_CONF_SDMA_REQ_SEL0 [6:0] MULT through CONTROL_CONF_SDMA_REQ_SEL3 [6:0] MULT	0x-
10. Set the appropriate pad configuration bit fields to associate the hw_dbggn pad function to output pins and configure additional output pad features.	For more information, see Section 18.4.11, Hardware Observability , and Section 18.4.8, Pad Functional Multiplexing and Configuration .	For more information, see Section 18.4.8, PAD Functional Multiplexing and Configuration .

⁽¹⁾ To configure the hwobs(0) channel to operate normally, the value of the HWOBS_CLKDIV_SEL, HWOBS_CLKDIV_SEL_1, or HWOBS_CLKDIV_SEL_2 bit must be set different than 0.

⁽²⁾ Set both bits to 0 to enable hardware observability. Set only one bit to 1 to gate hwobs ports according to the output state required.

⁽³⁾ The modules that belong to this group are: Cortex-A9 MPU subsystem, DSP subsystem, IVA-HD, display subsystem, CM2, and ABE.

For more information about the different functions and registers associated with the hardware observability features, see [Section 18.4.11, Hardware Observability](#).

18.5.1.2.4 Off Mode Preliminary Settings

This section describes configurations of pads to work in off mode. The following actions must be performed once, and remain valid for all device off <-> on transitions.

Table 18-120. Setting Pad Off Mode Through Padconfiguration Registers

Step	Register/Bit Field/Programming Model	Value
Set OFFMODEPULLTYPESELECT bit.	CONTROL_CORE_PAD0_X_PAD1_Y[29,13] – Select pullup/down type when pad in off mode.	0b-
Set OFFMODEPULLUDENABLE bit.	CONTROL_CORE_PAD0_X_PAD1_Y[28,12] – Enable/disable pullup/down feature when pad in off mode.	0b-
Set OFFMODEOUTVALUE bit.	CONTROL_CORE_PAD0_X_PAD1_Y[27,11] – Set off mode pad override value.	0b-
Set OFFMODEENABLE bit (enable/disable pad overriding capability in off mode).	CONTROL_CORE_PAD0_X_PAD1_Y[25,9] – Set pad to keep its previous state (it had before going to off mode) or force pad output to a certain override value (OFFMODEOUTVALUE) when pad in off mode.	0b-
Set OFFMODEOUTENABLE bit.	CONTROL_CORE_PAD0_X_PAD1_Y[26,10] – Enable/disable output in off mode.	0b-
Program a valid device ACTIVE pad configuration.	For more information about ACTIVE pad configuration, see Table 18-121 .	
Set clock gating strategy.	. CONTROL_PADCONF_CORE_SYSCONFIG[3:2] IP_SYSCONFIG CONTROL_PADCONF_WKUP_SYSCONFIG[3:2] IP_SYSCONFIG	0x2,0x3
Enable/disable the wake-up detection capability ⁽¹⁾ .	CONTROL_CORE_PAD0_X_PAD1_Y[30,14]	0b-

⁽¹⁾ When the wake-up detection is enabled for a pad, this pad is configured as input. Therefore, be sure to write 0b1 in the OFFOUTENABLE bit to disable the output capability.

18.5.1.2.5 Pad Configuration Programming Points

This section describes through an example the configurations of pads necessary for working in active mode.

To configure the pad, ensure that the following steps are done:

1. Identify signals required on the interface based on the target application.

Example: To configure the UART2 interface on balls, the required signals are `uart2_tx`, `uart2_rts`, `uart2_cts`, and `uart2_rx`.

2. Choose the pads used for those signals. Some signals may be available on several pads and/or may be multiplexed with other signals needed for another application. See [Section 18.4.8.3, Pad Multiplexing Register Fields](#).

Example: Unlike the UART2 interface signals, `uart2_rx` and `uart2_tx`, each of which is available on two pads, the `uart2_cts` and `uart2_rts` signals are available only on one pad each (MUXMODE = 0b000). The `uart2_cts` signal, however, is multiplexed with the MMC I/O signal `sdmmc3_clk`, and the `uart2_rts` signal is multiplexed with the MMC I/O signal `sdmmc3_cmd` on the same pad. Assume that the MMC I/O 3 interface is also required in the system. Therefore, for the MMC I/O interface signals, pads must be used where those signals are not multiplexed with a UART2 signal, if possible. In this case, the solution is to use `sdmmc3_clk` and `sdmmc3_cmd` on another two pads of the device (`usbb2_ulpitll_dat7` and `usbb2_ulpitll_dat6`) configuring (MUXMODE = 0b010).

3. Identify the signal integrity parameter settings (drive strength, impedance, slew rate, pullup/pulldown strength, etc.) necessary for the pads associated I/O cells, listed in [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#).

For the register settings of the signal integrity parameters for the `uart2_rx`, `uart2_tx`, `uart2_cts`, and `uart2_rts` pads (this is the variant when the desired `uart2` signals appear in MuxMode = 0x0), see [Table 18-101](#).

For the `uart2_cts`, `uart2_rts`, and `uart2_rx` pads, the following bit fields (Mode and Load bit group settings) must be set:

- [CONTROL_SMART3IO_PADCONF_1\[27:26\]](#) UART2_DR0_MB
- [CONTROL_SMART3IO_PADCONF_2\[13\]](#) UART2_DR0_LB

For the `uart2_tx` pad, the following bit fields (Mode and Load bit group settings) must be set:

- [CONTROL_SMART3IO_PADCONF_1\[25:24\]](#) UART2_DR1_MB
- [CONTROL_SMART3IO_PADCONF_2\[12\]](#) UART2_DR1_LB

For recommendations about the signal integrity parameter settings of the mentioned pad group, see the device data manual.

NOTE: To identify the signal-associated I/O cell signal parameter settings in [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#), the user must search for the device pad name on which the desired signal is muxed, because the I/O cell settings are designated and listed on a per pad basis. This means that a signal name does not appear (unless MuxMode = 0x0) in [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#), but only the pad on which the signal is muxed.

Pads that do not have software I/O cell signal integrity parameter controls are not listed in [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#).

Assume the user application configures the `sdmmc3_clk` and `sdmmc3_cmd` signals on the `usbb2_ulpitll_dat7` and `usbb2_ulpitll_dat6` pads (MuxMode = 0x2). The I/O cell setting (single-bit group control – SPI3_DR0_DS of driver output impedance) listed in [Table 18-89](#) also applies to the `sdmmc3_clk` and `sdmmc3_cmd` signals, which appear on the same pads, when MuxMode = 0x2.

In this case, the [CONTROL_SMART2IO_PADCONF_2\[21\]](#) SPI3_DR0_DS bit must be set to configure the I/O cell performance of `sdmmc3_clk` and `sdmmc3_clk`.

For recommendations about the mentioned pad group signal integrity parameter settings, see the device data manual.

4. Identify and program the peripheral dual-voltage settings, if they apply to the chosen pads:

[Table 18-113](#) lists the corresponding control bits of the pads in the [CONTROL_CORE_PADCONF_MODE](#) and [CONTROL_WKUP_PADCONF_MODE](#) registers. The identification of the I/O dual voltage domains/control bits for a signal must be made on a per-pad basis.

All pads (`uart2_cts`, `uart2_rts`, `uart2_rx`, and `uart2_tx`) fall within the same dual-voltage domain (VDDS_DV_BANK1) and the I/O supply voltage (1.2 V/1.8 V) is configured by setting the [CONTROL_CORE_PADCONF_MODE\[30\]](#) VDDS_DV_BANK1 bit.

As previously explained, the `sdmmc3_clk` and `sdmmc3_cmd` signals are muxed on the `usbb2_ulpitll_dat7` and `usbb2_ulpitll_dat6` pads. The dual-voltage control bit corresponding to these two pads is [CONTROL_CORE_PADCONF_MODE\[26\]](#) VDDS_DV_BANK6 (see [Table 18-113](#)).

For more information about pad performance dependencies from I/O dual-voltage supply settings, see the device data manual.

5. Identify the pad configuration registers associated with the pads to be used in the application. See [Section 18.4.8.3, Pad Multiplexing Register Fields](#).

Example: Under the previous hypothesis, the pad configuration registers to program are:

- `uart2_rts`: [CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS\[31:16\]](#)
- `uart2_cts`: [CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS\[15:0\]](#)
- `uart2_tx`: [CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX\[31:16\]](#)
- `uart2_rx`: [CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX\[15:0\]](#)
- `sdmmc3_clk` (MuxMode = 0x2): [CONTROL_CORE_PAD0_USBB2_ULPITLL_DAT6_PAD1_USBB2_ULPITLL_DAT7\[31:16\]](#)
- `sdmmc3_cmd` (MuxMode = 0x2): [CONTROL_CORE_PAD0_USBB2_ULPITLL_DAT6_PAD1_USBB2_ULPITLL_DAT7\[15:0\]](#)

Table 18-121. ACTIVE PADS Configuration Points

Step	Register/Bit Field/Programming Model	Value
1. Identify the interface signals and map them to the appropriate pads according to the application requirements and the device-specific pad I/O muxing capabilities. See Section 18.4.8.3, Pad Multiplexing Register Fields .	Define the list of I/O signal names: uart2_cts, uart2_rts, uart2_rx, uart2_tx, sdmmc3_clk, and sdmmc3_cmd Define the list of corresponding pads: uart2_cts, uart2_rts, uart2_rx, uart2_tx, usbb2_ulpitll_dat7, and usbb2_ulpitll_dat6	–
2. Identify the corresponding I/O cell signal integrity parameter controls for the pad (on a per-pad basis). See Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping .	(uart2_cts, uart2_rts, uart2_rx pads) CONTROL_SMART3IO_PADCONF_1 [27:26] UART2_DR0_MB CONTROL_SMART3IO_PADCONF_2 [13] UART2_DR0_LB (uart2_tx pad) CONTROL_SMART3IO_PADCONF_1 [25:24] UART2_DR1_MB CONTROL_SMART3IO_PADCONF_2 [12] UART2_DR1_LB (usbb2_ulpitll_dat7, usbb2_ulpitll_dat6) CONTROL_SMART2IO_PADCONF_2 [21] SPI3_DR0_DS	For more information about the recommended I/O settings, see the device data manual
3. Determine whether the pad is associated with a peripheral dual-voltage domain (see the device data manual). Identify its corresponding 1.2-V/1.8-V dual-voltage control bit in the CONTROL_CORE_PADCONF_MO CONTROL_WKUP_PADCONF_MO CONTROL_WKUP_PADCONF_MO register. See Table 18-113 .	(uart2_cts, uart2_rts, uart2_rx, uart2_tx) CONTROL_CORE_PADCONF_MODE [30] VDDS_DV_BANK1 (usbb2_ulpitll_dat7, usbb2_ulpitll_dat6) CONTROL_CORE_PADCONF_MODE [26] VDDS_DV_BANK6	For more information about the I/O performance dependency on dual-voltage settings, see the device data manual.
4. Configure MUXMODE field in pad configuration registers associated with the pads used.	CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS [18:16] UART2_RTS_MUXMODE CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS [2:0] UART2_CTS_MUXMODE CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX [18:16] UART2_TX_MUXMODE CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX [2:0] UART2_RX_MUXMODE CONTROL_CORE_PAD0_USBB2_ULPITLL_DAT6_PAD1_USBB2_ULPITLL_DAT7 [18:16] USBB2_ULPITLL_DAT7_MUXMODE CONTROL_CORE_PAD0_USBB2_ULPITLL_DAT6_PAD1_USBB2_ULPITLL_DAT7 [2:0] USBB2_ULPITLL_DAT6_MUXMODE	0b000 0b000 0b000 0b010 0b010
5. Select the type of the internal pullup/down resistor ⁽¹⁾ .	CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX [4] UART2_RX_PULLTYPESELECT CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS [2:0] UART2_CTS_PULLTYPESELECT	0b1 (pullup selected) 0b1 (pullup selected)
6. Enable/disable pullup/down feature of the pad ⁽²⁾ .	CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX [3] UART2_RX_PULLUDENABLE CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS [3] UART2_CTS_PULLUDENABLE	0b1 (pull feature enabled) 0b1 (pull feature enabled)
7. Set the direction of the pin signal. ⁽²⁾	CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX [8] UART2_RX_INPUTENABLE CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS [8] UART2_CTS_INPUTENABLE CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX [24] UART2_TX_INPUTENABLE CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS [24] UART2_RTS_INPUTENABLE CONTROL_CORE_PAD0_USBB2_ULPITLL_DAT6_PAD1_USBB2_ULPITLL_DAT7 [24] USBB2_ULPITLL_DAT7_INPUTENABLE (sdmmc3_clk) CONTROL_CORE_PAD0_USBB2_ULPITLL_DAT6_PAD1_USBB2_ULPITLL_DAT7 [8] USBB2_ULPITLL_DAT6_INPUTENABLE (sdmmc3_cmd)	0b1 (input pin) 0b1 (input pin) 0b0 (output pin) 0b0 (output pin) 0b1 (input pin) 0b1 (input pin)

⁽¹⁾ It is recommended to use internal pullup/down resistor if pad is used as input and external pullup/down is not used.⁽²⁾ If the pad is configured in output mode, it is recommended for software to disable the internal pullup/pulldown associated with it.

NOTE: The order for setting the previous pad configuration bits is not important.

NOTE: If a device pad is left unconnected, but power is supplied to the I/O, or the pad is used only as an output during the lifetime of the application, it is recommended to keep its corresponding pad configuration bit CONTROL_CORE /WKUP_PAD0_X_PAD1_Y.INPUTENABLE set to 0b0. This keeps the input buffer disabled and reduces static current consumption.

NOTE: I/Os are non-failsafe, which means that voltage must never be applied at a pad before the internal I/O supply voltage VDDS is powered.

18.6 Control Module Register Manual

18.6.1 Control Module Instance Summary

Table 18-122 lists the base address and address space for the control module instances.

Table 18-122. Control Module Instance Summary

Module instance	Base Address	Size	Description
SYSCTRL_GENERAL_C ORE	0x4A00 2000	4KB	Module
SYSCTRL_GENERAL_W KUP	0x4A30 C000	4KB	Module
SYSCTRL_PADCONF_C ORE	0x4A10 0000	4KB	Module
SYSCTRL_PADCONF_W KUP	0x4A31 E000	4KB	Module

NOTE: All module registers are 8-, 16-, or 32-bit accessible through the L4 interconnect (little-endian encoding).

18.6.2 SYSCTRL_GENERAL_CORE Register Summary

Table 18-123. SYSCTRL_GENERAL_CORE Register Mapping Summary

Bits	Field Name	Description	Type	Reset
31:29	EMIF1_SDRAM_TYPE	SDRAM type selection: Set to 0x4 for LPDDR2-S4. Set to 0x5 for LPDDR2-S2. All other values are reserved.	RW	0x4
28:27	EMIF1_SDRAM_IBANK_POS	Internal bank position: Set to 0x0 to assign internal bank address bits from the L3 address as shown in Table 15-101 , <i>64-Byte Linear Read Starting at Address 0x0</i> , and Table 15-102 , <i>64-Byte Linear Read Starting at Address 0x8 (LPDDR2-S2)</i> , in Chapter 15, Memory Subsystem . Set to 0x1, 0x2, or 0x3 to assign internal bank address bits from the L3 address as shown in Table 15-103 , <i>64-Byte Linear Read Starting at Address 0x8 (LPDDR2-S4)</i> , Table 15-104 , <i>64-Byte Linear Read Starting at Address 0x10</i> , and Table 15-105 , <i>64-Byte Linear Read Starting at Address 0x18</i> , in Chapter 15, Memory Subsystem .	RW	0x0
26:24	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
23	EMIF1_SDRAM_DDR2_DDQS	DDR2 differential DQS enable: Set to 0 for single ended DQS. Set to 1 for differential DQS. This bit is only for DDR2 mode; because the device supports LPDDR2, this bit is don't care.	RW	0x1
22:21	RESERVED		R	0x0
20	EMIF1_SDRAM_DDR_DISABLE_DLL	Disable DLL select: Set to 0x0 to enable DLL inside SDRAM. Set to 0x1 to disable DLL inside SDRAM.	RW	0x0
19:16	RESERVED		R	0x0
15:14	EMIF1_SDRAM_NARROW_MODE	SDRAM data bus width: Set to 0x0 for 64-bit width. Set to 0x1 for 32-bit width. Set to 0x2 for 16-bit width. All other values are reserved.	RW	0x0
13:10	EMIF1_SDRAM_CL	CAS latency (RL latency). The value of this field defines the CAS latency to be used when accessing connected SDRAM devices: Supported for LPDDR2-SDRAM: 0x3: CAS latency of 3 cycles 0x4: CAS latency of 4 cycles 0x5: CAS latency of 5 cycles 0x6: CAS latency of 6 cycles 0x7: CAS latency of 7 cycles 0x8: CAS latency of 8 cycles All other values are reserved.	RW	0x3
9:7	EMIF1_SDRAM_ROW_SIZE	Row size. Defines the number of row address bits of connected SDRAM devices: Set to 0x0 for 9 row bits. Set to 0x1 for 10 row bits. Set to 0x2 for 11 row bits. Set to 0x3 for 12 row bits. Set to 0x4 for 13 row bits. Set to 0x5 for 14 row bits. Set to 0x6 for 15 row bits. Set to 0x7 for 16 row bits. This field is used only when the <code>ibank_pos</code> field in the SDRAM Config register is set to 0x1, 0x2, or 0x3.	RW	0x4
6:4	EMIF1_SDRAM_IBANK	Internal bank setup. Defines number of banks inside connected SDRAM devices: Set to 0x0 for 1 bank. Set to 0x1 for 2 banks. Set to 0x2 for 4 banks. Set to 0x3 for 8 banks. All other values are reserved.	RW	0x3
3	EMIF1_SDRAM_EBANK	External CS setup. Defines whether SDRAM accesses will use 1 or 2 CS lines. Set to 0 to use <code>pad_cs_o_n[0]</code> only: Set to 0x0 to use only <code>pad_cs_o_n[0]</code> . Set to 0x1 to use <code>pad_cs_o_n[1:0]</code> . This bit is automatically set to 0 if either the <code>cs0nvmem</code> or <code>cs1nvmem</code> field in the LPDDR2-NVM is set to 1.	RW	0x0

Bits	Field Name	Description	Type	Reset
2:0	EMIF1_SDRAM_PAGESIZE	Page size. Defines the internal page size of the connected SDRAM devices: <hr/> Set to 0x0 for 256-word page (8 column bits). <hr/> Set to 0x1 for 512-word page (9 column bits). <hr/> Set to 0x2 for 1024-word page (10 column bits). <hr/> Set to 0x3 for 2048-word page (11 column bits). <hr/> All other values are reserved.	RW	0x0

Bits	Field Name	Description	Type	Reset
31	ABE_MCBSP2_CLKX_WAKEUPEVENT	Pad_x wake-up event status latched in the IO Read 0x0: No wake-up event occurred Read 0x1: A wake-up event occurred	R	0
30	ABE_MCBSP2_CLKX_WAKEUPENABLE	Input pad wake-up enable (and OFF mode input enable value) 0x0: wake-up detection is disabled 0x1: wake-up detection is enabled	RW	0

Bits	Field Name	Description	Type	Reset
29	ABE_MCBSP2_CLKX_OFFMODEPULLTYPESELECT	OffMode mode pullup/down selection for pad abe_mcbbsp2_clkx 0x0: Offmode pulldown selected 0x1: Offmode pullup selected	RW	0
28	ABE_MCBSP2_CLKX_OFFMODEPULLUDENABLE	OffMode mode pullup/down enable for pad abe_mcbbsp2_clkx 0x0: Offmode pullup/down disabled 0x1: Offmode pullup/down enabled	RW	0
27	ABE_MCBSP2_CLKX_OFFMODEOUTVALUE	OffMode mode output value for pad abe_mcbbsp2_clkx 0x0: Set value at 0 0x1: Set value at 1	RW	0
26	ABE_MCBSP2_CLKX_OFFMODEOUTENABLE	OffMode mode output enable value for pad abe_mcbbsp2_clkx. This is an active low signal 0x0: Output enable 0x1: Output disable	RW	0
25	ABE_MCBSP2_CLKX_OFFMODEENABLE	OffMode mode override control for pad abe_mcbbsp2_clkx 0x0: I/O state keeps its previous state when OFF mode is active 0x1: I/O state is forced to OFF mode value when OFF mode is active	RW	0
24	ABE_MCBSP2_CLKX_INPUTENABLE	Input enable value for pad abe_mcbbsp2_clkx 0x0: Input buffer of I/O cell is disabled 0x1: Input buffer of I/O cell is enabled	RW	1
23:21	RESERVED		R	0x0
20	ABE_MCBSP2_CLKX_PULLTYPESELECT	pullup/down selection for pad abe_mcbbsp2_clkx 0x0: pulldown selected 0x1: pullup selected	RW	0
19	ABE_MCBSP2_CLKX_PULLUDENABLE	pullup/down enable for pad abe_mcbbsp2_clkx 0x0: pullup/down disabled 0x1: pullup/down enabled	RW	1
18:16	ABE_MCBSP2_CLKX_MUXMODE	Functional multiplexing selection for pad abe_mcbbsp2_clkx 0x0: Select abe_mcbbsp2_clkx 0x1: Select mcspi2_clk 0x2: Select abe_mcaspi_ahclkx 0x3: Select gpio_110 0x4: Select usbb2_mm_rxdm 0x7: Select safe_mode	RW	0x7
15	SDMMC1_DAT7_WAKEUPEVENT	Pad_x wake-up event status latched in the IO Read 0x0: No wake-up event occurred Read 0x1: A wake-up event occurred	R	0
14	SDMMC1_DAT7_WAKEUPENABLE	Input pad wake-up enable (and OFF mode input enable value) 0x0: wake-up detection is disabled 0x1: wake-up detection is enabled	RW	0
13	SDMMC1_DAT7_OFFMODEPULLTYPESELECT	OffMode mode pullup/down selection for pad sdmmc1_dat7 0x0: Offmode pulldown selected 0x1: Offmode pullup selected	RW	0
12	SDMMC1_DAT7_OFFMODEPULLUDENABLE	OffMode mode pullup/down enable for pad sdmmc1_dat7 0x0: Offmode pullup/down disabled 0x1: Offmode pullup/down enabled	RW	0

Bits	Field Name	Description	Type	Reset
11	SDMMC1_DAT7_ OFFMODEOUTVALUE	OffMode mode output value for pad sdmmc1_dat7 0x0: Set value at 0 0x1: Set value at 1	RW	0
10	SDMMC1_DAT7_ OFFMODEOUTENABLE	OffMode mode output enable value for pad sdmmc1_dat7. This is an active low signal 0x0: Output enable 0x1: Output disable	RW	0
9	SDMMC1_DAT7_ OFFMODEENABLE	OffMode mode override control for pad sdmmc1_dat7 0x0: I/O state keeps its previous state when OFF mode is active 0x1: I/O state is forced to OFF mode value when OFF mode is active	RW	0
8	SDMMC1_DAT7_ INPUTENABLE	Input enable value for pad sdmmc1_dat7 0x0: Input buffer of I/O cell is disabled 0x1: Input buffer of I/O cell is enabled	RW	1
7:5	RESERVED		R	0x0
4	SDMMC1_DAT7_ PULLTYPESELECT	pullup/down selection for pad sdmmc1_dat7 0x0: pulldown selected 0x1: pullup selected	RW	0
3	SDMMC1_DAT7_ PULLUDENABLE	pullup/down enable for pad sdmmc1_dat7 0x0: pullup/down disabled 0x1: pullup/down enabled	RW	1
2:0	SDMMC1_DAT7_ MUXMODE	Functional multiplexing selection for pad sdmmc1_dat7 ⁽¹⁾ 0x0: Select sdmmc1_dat7 0x3: Select gpio_109 0x7: Select safe_mode	RW	0x7

⁽¹⁾ To ensure I/O safe operation at 1.8 V or 3.0 V and desired signal performance, the corresponding extended-drain I/O cell and PBIAS cell must be appropriately configured by software prior to signal selection on the pad, regardless of the signal multiplexing mode. For more details on extended-drain I/O cells and PBIAS cell descriptions and settings, see [Section 18.4.9, Extended-Drain I/O and PBIAS Cell](#), and [Section 18.5.1.2.2, Extended-Drain I/Os and PBIAS Cells Programming Guide](#).
