**Equalization Optimization**

Employing equalization techniques is an effective way of compensating for channel loss in JESD204B high-speed serial interfaces for data converters. This reference design discusses the ADC16DX370, a dual 16-bit, 370 MSPS analog-to-digital converter (ADC) that utilizes de-emphasis equalization to prepare the 7.4 Gbps serial data for transmission. Configuration allows a user to optimize the de-emphasis setting (DEM) and output voltage swing setting (VOD) of the output driver to inversely match the characteristics of the channel. Experiments demonstrate the reception of a clean data eye over 20" of FR-4 material at the full data rate.

- Achieve a high performance JESD204B serial link using low-cost PCB materials
- Understand the limitations of lossy channels and equalization techniques to overcome the limitations
- Use a formula-based approach to optimizing the equalization features of the ADC16DX370
- This reference design is tested and includes an EVM, configuration software and user’s guide

**An IMPORTANT NOTICE** at the end of this TI reference design addresses authorized use, intellectual property matters and other important disclaimers and information.
1 Introduction

The advancements of digital serializer and de-serializer (SERDES) technologies, the availability of gigabit SERDES transceivers in affordable FPGAs, and the progression of the JESD204 standard have made it possible for data converter designs to adopt serialized interfaces, and the proliferation of these interfaces is now a reality. SERDES speeds of up to 12.5 Gbps are accommodated today by the standard on printed-circuit-board (PCB) channels up to 8 inches long but the challenges of transmitting a digital signal across a lossy channel remain. Applications are constantly expanding the boundaries to faster speeds and longer channels. Data transfer rates at 3.125 Gbps and below with channel lengths shorter than 4" can be successful using cheap PCB materials, like FR-4, but pushing beyond these requirements often requires the use of low-loss dielectrics which significantly increase the cost of the design. Providing low-cost solutions to channel limitations is essential to the success of these data link designs.

Employing equalization techniques is an effective way of compensating for channel loss. This document discusses the ADC16DX370, a dual 16-bit, 370 MSPS analog-to-digital converter (ADC) that utilizes de-emphasis equalization to prepare the 7.4 Gbps serial data for transmission (Texas Instruments, 2014). Configuration allows a user to optimize the equalization and gain of the output driver to inversely match the characteristics of the channel. Experiments demonstrate the reception of a clean data eye over 20" of FR-4 material at the full data rate.

2 Correcting Channel Loss

There are a number of non-ideal qualities of a differential PCB transmission line that make it more difficult to recover the logical state of the signal at the receiver. These non-idealities can generally be grouped into channel irregularities and losses.

Channel irregularities, such as dielectric and traces variation, are minute errors in the fabrication of the channel which lead to impedance discontinuities and small signal reflections across the entire length of the channel and are common in PCB manufacturing. Channel irregularities may also include impedance discontinuities caused by stubs and vias.

Channel losses include radiative loss, coupling loss, conductor loss and dielectric loss and are generally related to the PCB materials used (conductor, dielectric) and how well the electro-magnetic wave is controlled (radiative, coupling). Assuming a design that extensively uses reference planes to minimize coupling and radiation, the losses are dominated by conductor losses (skin effect) and dielectric losses.

At frequencies above approximately 1 GHz, the dielectric loss dominates, a result of permanent electric dipoles in the dielectric re-aligning themselves to the transient electric field as the signal passes by which appears as a small AC leakage current through the substrate. (Bogatin, 2004) This dielectric loss increases with frequency and is described by the dissipation factor of the material, also called the loss tangent. The dissipation factors of a few dielectric materials are shown in Table 1, demonstrating that the improvement in the dissipation factor of premium over low cost dielectrics is nearly an order of magnitude.

The JESD204B standard (JEDEC, 2012) suggests loosely that 8” channels are supported but more rigorously specifies a compliant channel in terms of its insertion loss across frequency, shown in the loss mask of Figure 1. Example loss profiles are added to indicate a compliant and a non-compliant channel. The example 8” FR-4 channel conducting a 6.375 Gbps signal is marginally within the boundary of the standard whereas the longer 20” channel is not.

The quality of the signal at the output of the channel is effectively observed on an eye diagram where the eye opening indicates the horizontal (time) and vertical (voltage) window with which a clock and data recovery (CDR) receiver can recover the signal. In the presence of significant channel loss, the amplitude shrinks, the edge rates become slower and inter-symbol interference becomes so bad that the eye closes and the signal cannot be recovered as shown in the progression of Figure 2 (a)–(c).

The purpose of linear equalization is to apply a high-pass frequency shaping response at either the transmitter or receiver to counteract the frequency-dependent dielectric loss and conductor loss through the channel which typically has a low-pass profile. Linear equalization is not effective at correcting the loss due to channel irregularities because these losses result in discontinuities in the phase response (and group delay) of the channel. The high-pass equalization response can be created by either amplifying higher frequencies (pre-emphasis) or attenuating lower frequencies (de-emphasis). To obtain the desired equalization, the slope of the high-pass response must be adjusted to inversely match the loss profile, and the broadband gain must be adjusted to ensure that the vertical eye opening meets the requirements of the eye mask standard or capabilities of the receiving device.

3 De-Emphasis (DEM) and Voltage Swing (VOD) Control

The ADC16DX370 uses a linear, continuous-time equalization technique in the output drivers that performs de-emphasis of the signal. The de-emphasis function is configured to different high-pass slopes by changing the DEM setting. The voltage swing configuration varies the broadband gain of the output drivers and is adjusted using the VOD setting.
The effects of de-emphasis in the frequency domain can also be intuitively understood in the time domain. Figure 3 shows a waveform at the driver output with and without de-emphasis, demonstrating how the initial edge transient (influenced most by higher frequencies) remains unaffected but the waveform settles to a lower value as a result of attenuation at the lower frequencies. The amount of de-emphasis is given by comparing the settled waveforms with and without de-emphasis and calculating the amount of attenuation, expressed units of decibels, [dB]. In the case of Figure 3, the de-emphasis is 6 dB. At the output of the channel, the overshoot seen in the signal with optimal de-emphasis will be attenuated by the channel loss, resulting in a near-perfect eye with the swing reduced by the de-emphasis value, in this case by 6 dB. (1)

When the DEM setting is optimized, the horizontal opening of the eye is greatly recovered but the voltage swing may be unacceptably attenuated. To recover the vertical opening of the eye, the VOD setting can be adjusted, which controls the driver’s output voltage swing and is equivalent to modifying the broadband gain. (2)

Figure 3. Eye Diagram of 5-Gbps Signal with (Blue) and Without (Orange) De-Emphasis

4 Optimization Design Procedure

Use the following design procedure to optimize the DEM and VOD settings:

1. Characterize the Channel
   Use test hardware to characterize the channel with a network analyzer or simulate a channel model with an EM simulator to obtain the loss profile of the channel, similar to what is shown in Figure 5. The loss profile is the SDD21 (differential S-parameter), in units of [dB], on a plot versus frequency on a linear scale.

2. Fit the Loss Profile to Empirical De-Emphasis Data and Configure DEM Setting
   • Create a linear curve fit to the loss profile between the frequencies 0.2 × BR and 0.6 × BR where BR is the baud rate of the data. Note the slope of the line in units of [dB/GHz], referred to here as the loss gradient of the channel. (3)
   • Calculate the DEM parameter value using Equation 1, based on empirical characterization of the de-emphasis circuit. LG is the loss gradient calculated in the previous step.
   \[ \text{DEM} = 2.1 \times \text{LG} + 1.23 \] (1)
   • Round the DEM value to the nearest integer. Configure the DEM setting to this integer value.

(1) This is in contrast with pre-emphasis which amplifies signals at high frequencies, creates an amplification of the edge transient and therefore does not experience an over-all reduction in voltage swing at the channel output. This is equivalent to applying de-emphasis and increasing the voltage swing (broadband gain) at the same time.

(2) Modifying the output swing is a tradeoff between bit error rate and power. Increasing the swing improves the eye opening (equivalently the SNR) at the cost of increased power.

(3) The loss gradient term here is not to be confused with the loss tangent (also called dissipation factor), a unit-less quantity.
3. Adjust the Output Swing
   • Consult Table 2 to determine the VOD setting. From the column of the chosen DEM setting, select the desired differential voltage swing [mVpp-diff] at the output of the channel under perfect de-emphasis equalization. Configure the VOD setting appropriately.

Table 2. Channel output swing [mVpp-diff] in the case of perfect equalization for All VOD and DEM Settings

5 Measured Results

Differential 100-Ω microstrip traces of 5-mil width and lengths of 5”, 10”, 15”, and 20” were built over FR-4 dielectric as shown in Figure 4. The traces were characterized with a network analyzer and their loss profiles were plotted versus frequency on a linear scale as shown in Figure 5. The optimization procedure was followed and the optimal DEM and VOD settings were derived as shown in Table 3. The differential voltage swing at the output of the channel, as required by the JESD204B standard and LV-OIF-11G-SR electrical variant, must be between 110 and 1050 mVpp-diff (JEDEC, 2012) as shown in Figure 6(b), so an intermediate target swing value of 450 mVpp-diff was chosen when selecting the VOD setting.

The eye diagram is measured using a 7.4 Gbps K28.5 symbol pattern as the channel input (generated by the ADC16DX370) and an Agilent Infinium DCA-J oscilloscope to view the eye. The resulting waveforms at the output of the channel with and without optimization are shown in Figure 7 through Figure 10. At the 10” channel length, the eye opening with no equalization may marginally meet the eye mask while also meeting the required 1e−15 bit error rate (BER) requirement of the link, but a more involved BER test with a pseudo random bit sequence (PRBS) is recommended to verify the BER performance. Longer lengths would certainly yield too many symbol errors. Transmitting over the 20” channel length without equalization results in a completely closed eye.
Applying the derived DEM and VOD settings recovers an eye with significant margin in all cases. The DEM setting applies the equalization and the VOD setting recovers the broadband signal swing loss so that the resulting swing is approximately 450 mVpp-diff. (1)

Figure 7. Signal Output from 5” Channel (a) Without Optimization and (b) With DEM = 3, VOD = 0

Figure 8. Signal Output from 10” Channel (a) Without Optimization and (b) With DEM = 4, VOD = 2

(1) Figure 7 through Figure 10 have a y-axis major division of 100 mV and x-axis major division of 22.4 ps.
The large amount of margin seen in Figure 10(b) for the 20” length raises the question: How long of a FR-4 microstrip channel can be accommodated by the maximum optimization settings (DEM = 7, VOD = 7) while still meeting the JESD204B receive mask eye requirement? Figure 11 offers an interesting data point. A 5-Gbps K28.5 data pattern input into a 40” microstrip channel clearly violates the 110 mVpp-diff vertical requirement of the eye for JESD204B, but this does not discount a successful application under these limitations. From the diagram, one can see the spreading of deterministic jitter at the zero crossing due to incomplete equalization for the longer channel and yet the horizontal eye requirement still has plenty of margin. A simple high-speed gain buffer that adds only a modest amount of jitter can be enough to bring the eye back into compliance. Alternatively, the receiving device may have performance capabilities beyond the JESD204B specification to recover a signal with small amplitude but very low jitter.
6 Conclusion

Data converters that utilize the JESD204B interface are quickly becoming common in the industry and applications are increasingly pushing the speed and length limits of the interface, necessitating solutions that correct the non-idealities of the channel. Equalization is an effective solution for increasing the bit-rate and channel length for very high speed data transmission applications. The ADC16DX370 is one such JESD204B-compliant device that offers data transfer on one lane per channel up to 7.4 Gbps. Measurements demonstrate the clean transfer of data over a 20” microstrip channel above FR-4 dielectric by optimizing the de-emphasis and voltage swing features.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as “components”) are sold subject to TI’s terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI’s terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers’ products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers’ products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI’s goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or “enhanced plastic” are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have not been so designated is solely at the Buyer’s risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
