TI Designs – Precision

TI Designs – Precision are analog solutions created by TI’s analog experts. Verified Designs offer the theory, component selection, simulation, complete PCB schematic & layout, bill of materials, and measured performance of useful circuits. Circuit modifications that help to meet alternate design goals are also discussed.

Circuit Description

This split-supply, high-performance guitar tone circuit provides control of the bass, mid, and treble frequencies of an electric guitar signal, while also providing gain with minimal distortion and noise. Buffered inputs and outputs preserve the behavior of the system independent of the source and load impedances, and a radio frequency (RF) filter on the circuit front end attenuates noise from outside the audio band.

1 Design Summary

The design requirements are as follows:

- Supply voltage: ± 15 V
- Input voltage: 1 V_RMS
- Source impedance: 6 kΩ
- Input stage signal gain: 6 dB – 28 dB
- Total harmonic distortion + noise (THD+N) level at 1 kHz: -100 dB (0.001%)
- Treble adjustment range: 10 dB
- Mid adjustment range: 6 dB
- Bass adjustment range: 15 dB

The design goals and performance are summarized in Table 1. Figure 1 depicts the measured transfer function of the design.

2 Theory of Operation

A more complete schematic for this design is shown in Figure 2. The three primary functional blocks of the circuit are the input filter and gain stage, tone stack, and output buffer.

Figure 2: Complete Circuit Schematic
2.1 Input Filter

A passive filter at the input of the circuit serves two purposes: provide significant attenuation at frequencies outside the audio band, and remove any dc voltage from the input signal. The filter is made up of $R_{SRC}$, the guitar pickup output impedance, capacitors $C_7$ and $C_4$, and resistor $R_4$, as shown in Figure 3.

![Input Filter Schematic](image)

**Figure 3: Input Filter Schematic**

### 2.1.1 Low Pass Filter

$R_{SRC}$ and $C_7$ create a first-order low pass filter. The -3 dB cutoff frequency of the filter is calculated using Equation 1.

$$f_{C,\text{LPF}} = \frac{1}{2\pi \ast R_{SRC} \ast C_7}$$  \hspace{1cm} (1)

400 kHz is selected as the -3 dB cutoff frequency for the filter. This will effectively attenuate RF noise while preserving the gain and phase behavior at 20 kHz. Since $R_{SRC}$ is specified at 6 kΩ, simply rearrange terms and solve for $C_7$ in order to achieve the desired cutoff frequency, as shown in Equation 2.

$$C_7 = \frac{1}{2\pi \ast R_{SRC} \ast f_{C,\text{LPF}}} = \frac{1}{2\pi \ast 6\,\text{kΩ} \ast 400\,\text{kHz}} = 66.3\,\text{pF}$$  \hspace{1cm} (2)

The required value for $C_7$ is calculated to be 66.3 pF. The nearest standard capacitor value of 68 pF is selected as the actual value. The actual cutoff frequency of the filter is calculated using Equation 3.

$$f_{C,\text{LPF}} = \frac{1}{2\pi \ast R_{SRC} \ast C_7} = \frac{1}{2\pi \ast 6\,\text{kΩ} \ast 68\,\text{pF}} = 390\,\text{kHz}$$  \hspace{1cm} (3)
2.1.2 High Pass Filter

$C_4$ and $R_4$ create a first-order high pass filter. The -3 dB cutoff frequency of the filter is calculated using Equation 4.

$$f_{C_{HPF}} = \frac{1}{2\pi \cdot R_4 \cdot C_4}$$  \hspace{1cm} (4)

A value of 10 $\mu$F is selected for $C_4$, as it is a common value already used in the circuit for power supply decoupling. $R_4$ must be significantly higher resistance than $R_{SRC}$ in order to prevent unwanted attenuation from the voltage divider formed by these two resistances. Therefore, an initial value of 499 k$\Omega$ is selected for $R_4$ and the high pass filter cutoff frequency is calculated using Equation 5.

$$f_{C_{HPF}} = \frac{1}{2\pi \cdot R_4 \cdot C_4} = \frac{1}{2\pi \cdot 499k\Omega \cdot 10\mu F} = 0.03\ Hz$$  \hspace{1cm} (5)

The -3 dB cutoff frequency of the filter is calculated to be 0.03 Hz. This will effectively ac couple the input signal while preserving the gain and phase behavior at 20 Hz.

2.1.3 Input Filter Transfer Function

The complete transfer function of the input filter is shown in Figure 4.

![Figure 4: Transfer Function - Input Filter](image-url)
2.2 Input Gain Stage

The input signal in this design is specified at 1 V_{RMS}, or 1.414 V_{PK}. Since the OPA1642 used in this design can swing its output voltage within 200 mV from each rail and ±15 V power supply rails are provided, an input gain stage is used to amplify the input signal as needed. The gain stage is made up of amplifier U_{1A}, potentiometer P_1, and resistors R_1 and R_2, as shown in Figure 5.

![Input Gain Stage Schematic](image)

Figure 5: Input Gain Stage Schematic

This straightforward non-inverting gain stage has a transfer function as defined as in Equation 6, where \( R_{P1} \) is the equivalent series resistance of potentiometer P_1.

\[
V_{\text{GAIN}} = \left( 1 + \frac{R_2 + R_{P1}}{R_1} \right) * V_{\text{FILTER}} \tag{6}
\]

At 0% rotation of potentiometer P_1, its equivalent series resistance is 0 Ω. Therefore the transfer function of the gain stage simplifies to Equation 7.

\[
V_{\text{GAIN}} = \left( 1 + \frac{R_2}{R_1} \right) * V_{\text{FILTER}} \tag{7}
\]

The minimum gain of the circuit is specified at 6 dB, or 2 V/V. To achieve this, the resistances of R_1 and R_2 must be equal. A value of 1 kΩ is selected for R_1 and R_2 in order to ensure low thermal noise. The maximum gain of the circuit is specified at 28 dB, or approximately 25 V/V. This gain occurs at 100% rotation of potentiometer P_1. The required value of \( R_{P1} \) is calculated by rearranging the terms of Equation 6 and solving for \( R_{P1} \), as shown in Equation 8.

\[
R_{P1} = R_1 * \frac{V_{\text{GAIN}}}{V_{\text{FILTER}}} - 1 - R_2 = 1kΩ * (25 - 1) - 1kΩ = 23kΩ \tag{8}
\]

The required value for \( R_{P1} \) is calculated to be 23 kΩ. The nearest standard value of 25 kΩ is selected as the actual value.
2.3 Tone Stack

The tone stack is a passive filter network which allows a guitarist to control the frequency response of the amplifier [1]. Many different tone stack implementations exist, but this design uses what is known as the FMV tone stack. Introduced by Fender in 1957 in the 5F6 Bassman, it was later copied by Marshall, Vox, and many other guitar amplifier manufacturers [2]. Because of its ubiquity, the circuit is very well understood with extensive analysis and documentation widely available.

The tone stack is made up of capacitors $C_1$, $C_3$, $C_8$, and $C_9$, jumper JMP1, resistor $R_3$, and potentiometers $P_2$, $P_3$, and $P_4$, as shown in Figure 6.

![Tone Stack Schematic](image)

**Figure 6: Tone Stack Schematic**

Since the tone stack contains multiple filters with many possible states and interactive impedances, it is not trivial to analyze. Rather than perform a complete analysis here, the approach of this document will be to summarize the effect of each potentiometer on the circuit behavior, provide equations which allow the user to customize component values, and then refer to material where the full analysis is available.

2.3.1 Potentiometer Effects

The treble potentiometer $P_2$ acts as a balance control between the output of a high-pass filter formed by $C_3$ (in parallel with $C_1$ if JMP1 is closed) and the series combination of all three potentiometers, and the output of the complex filter created by $R_3$, $C_8$, $C_9$, $P_3$, and $P_4$.

The bass potentiometer $P_3$ sets the lower -3 dB cutoff frequency of a band-pass filter formed by $R_3$, $C_8$, $P_3$, and $P_4$. It also affects the -3 dB cutoff frequency of the treble control circuit.

The mid potentiometer $P_4$ controls the attenuation of the band-pass filter formed by $R_3$, $C_9$, and $P_4$. It also acts as a variable attenuator for the tone stack output [3].
2.3.2 Tone Stack Component Values

Calculating the values of $R_3$ and $P_4$ first allows the circuit designer to set the attenuation of all frequencies when the bass and treble controls are at 0% and the mid control is at 100%. An initial value of 25 kΩ is selected for $P_4$ as it is already used for the gain potentiometer $P_1$. The value of $R_3$ can then be calculated using Equation 9, where $R_{P4}$ is the maximum resistance of $P_4$ and $A$ is a positive number representing the desired amount of attenuation in dB. This design targets the frequency response of the Marshall JMP50 amplifier, where a value of 7.3 is used for $A$.

$$R_3 = R_{P4} \times \left(10^{\frac{A}{20}} - 1\right) = 25 \text{kΩ} \times \left(10^{\frac{7.3}{20}} - 1\right) = 33 \text{kΩ}$$  \hspace{1cm} (9)

The required value for $R_3$ is calculated to be 33 kΩ, which is a standard value.

Once the values of $R_3$ and $P_4$ are set, the value of $C_9$ can be determined. This capacitor defines the upper cutoff frequency off the bass passband, which is a function of $C_9$ and $R_3$. $C_9$ is calculated as shown in Equation 10, where $f_1$ is the upper cutoff frequency of the bass passband. The Marshall JMP50 uses a cutoff frequency of 219 Hz.

$$C_9 = \frac{1}{2\pi \times f_1 \times R_3} = \frac{1}{2\pi \times 219 \text{Hz} \times 33 \text{kΩ}} = 22 \text{nF}$$  \hspace{1cm} (10)

The required value for $C_9$ is calculated to be 22 nF, which is a standard value.

Next, the value of $C_8$ can be determined in order to complete the bass passband design. $C_8$ controls the amount of bass attenuation when the bass potentiometer is at 0% (in a short-circuit condition), so the resistance of $P_3$ is not included in the calculation. A value of 1 MΩ is selected for $P_3$, consistent with the values used in the Marshall JMP50. This ensures that the lower end of the bass passband is well below the lowest frequencies output by a guitar. $C_8$ is calculated as shown in Equation 11, where $f_2$ is the lower cutoff frequency of the bass passband. The Marshall JMP50 uses a cutoff frequency of 62 Hz.

$$C_8 = \frac{1}{2\pi \times f_2 \times (R_3 + R_{P4})} = \frac{1}{2\pi \times 62 \text{Hz} \times (33 \text{kΩ} + 25 \text{kΩ})} = 22 \text{nF} = 22 \text{nF}$$  \hspace{1cm} (11)

The required value for $C_8$ is also calculated to be 22 nF.

Finally, the values of $C_3$ and $P_2$ can be selected, which set the cutoff frequency of the treble high pass filter. A value of 250 kΩ is selected for $P_2$, and $C_3$ is calculated as shown in Equation 12, where $f_3$ is the cutoff frequency of the treble high pass filter and $R_{P2}$ is the maximum resistance of $P_2$. The Marshall JMP50 uses a cutoff frequency of 1.4 kHz.

$$C_3 = \frac{1}{2\pi \times f_3 \times R_{P2}} = \frac{1}{2\pi \times 1.4 \text{kHz} \times 250 \text{kΩ}} = 455 \text{pF}$$  \hspace{1cm} (12)

The required value for $C_3$ is calculated to be 455 pF. The nearest standard value of 470 pF is selected as the actual value.

Closing switch JMP1 connects $C_1$ in parallel with $C_3$, adding the two capacitances to the cutoff frequency calculation. If $C_1$ also has a value of 470 pF, the cutoff frequency will be reduced by a factor of two to approximately 700 Hz [4].
The calculated component values and associated tone stack characteristics are summarized in Table 2.

### 2.3.3 Further Reading

If the reader wishes to expand their understanding of the FMV tone stack, a more thorough analysis is available in *Circuit Analysis of a Legendary Tube Amplifier: The Fender Bassman 5F6-A* by Richard Kuehnel. Another useful resource is *Designing Tube Preamps for Guitar and Bass* by Merlin Blencowe, which discusses the FMV tone stack as well as several other topologies along with their advantages and disadvantages.
3 Component Selection

3.1 Amplifier

This tone stack circuit must provide gain and accurate control over the frequency response of the input audio signal while introducing as little distortion or noise as possible. Therefore, the amplifier selected must have very low distortion and noise performance in the audio frequency range, even when high source impedances are present [5]. A wide supply voltage range is also required, as most professional audio circuits use large split supplies in order to avoid output clipping. Low quiescent current and relatively low cost are also desirable qualities which help to maintain an efficient design.

The OPA1642 is an excellent choice for this high-performance audio application, with total harmonic distortion + noise (THD+N) of only -126 dB (0.00005%) and input voltage noise density of 5.1 nV/√Hz. The amplifier can utilize power supply voltages up to ±18 V while consuming only 1.8 mA of quiescent current per channel, and its reasonable price point ensures that the total solution cost remains competitive.

3.2 Passive Component Selection

3.2.1 Resistor Selection

The type of resistors used in an ultra-low distortion audio circuit can have a significant impact on the circuit’s overall performance. Real resistors have a certain amount of nonlinearity, which results in unwanted contributions to distortion and noise [6]. The most common sources of resistor nonlinearity are temperature coefficient of resistance (TCR), which describes how the resistance changes as a function of temperature, and voltage coefficient of resistance (VCR), which describes how the resistance changes as a function of applied voltage. Both VCR and TCR are related to the resistor’s self-heating – as the voltage across the resistor increases, the current through the resistor increases and its temperature rises.

Two of the most common types of surface mount resistors are thick film and thin film. Thin film resistors typically perform better than thick film resistors, but thin film resistors also typically cost several times as much. When high-level audio signals are involved, the lower VCR and TCR of thin film resistors can become critical to achieving ultra-low distortion performance.

This design involves audio signals with maximum amplitude of 15 VPK, or 10.6 VRMS. Despite the significant voltage, current through the signal path resistors remains low and meaningful self-heating does not occur. Therefore, all signal path resistors on the board are thick film, ±1% tolerance, 0.1 watt devices in a 0603 package.

3.2.2 Capacitor Selection

Like resistors, capacitors also have a voltage coefficient (VCC), which describes how the capacitance changes as a function of applied voltage. This change in capacitance results in unwanted distortion [7], so any capacitors in the audio signal path which can be subjected to significant voltages should have low VCC.

The critical signal path capacitors in this design are C7 in the input filter and C1, C3, C8, and C9 in the tone stack. For these components NP0-type capacitors are used. All other capacitors for ac coupling and power supply bypass are of type X7R.

3.2.3 Potentiometer Selection

Other than the maximum resistance and taper characteristics, the potentiometers selected for this design are not critical. Single-turn rotary potentiometers with ±20% tolerance and right-angle PCB mount termination were selected for this application.
4 Simulation

The TINA-TI™ schematic shown in Figure 7 includes the circuit values obtained in the design process. The source impedance of \( V_{\text{IN}} \), the input signal, is included as a discrete resistance \( R_{\text{SRC}} \). A load resistance of 100 kΩ is added to simulate the input resistance of the audio analyzer which is used for real-world measurements.

![Figure 7: TINA-TI™ Schematic](image-url)
4.1 Gain Characteristic

The result of the simulated gain characteristic as a function of gain potentiometer P₁ rotation is shown in Figure 8.

![Figure 8: Simulated Gain Characteristic](image-url)
4.2 Frequency Response

4.2.1 Input Filter and Gain Stage

The result of the simulated ac analysis of the input filter and gain stage when gain = 6 dB is shown in Figure 9.

![Graph of Frequency Response](image)

**Figure 9: Simulated AC Analysis – Input Filter and Gain Stage**

The gain of the simulation throughout the audio band was measured to be 6 dB. The -3 dB bandwidth was 358 kHz. The phase of the simulation was 0.1° at 20 Hz and -3.3° at 20 kHz.
4.2.2 Tone Stack

4.2.2.1 Treble Control

The result of the simulated ac analysis of the complete circuit as the treble potentiometer \( P_2 \) is rotated, when gain = 6 dB, the mid and bass potentiometers are set to 50%, and mid boost is off, is shown in Figure 10.

![Simulated AC Analysis – Treble Control](image)

Figure 10: Simulated AC Analysis – Treble Control

In this condition, the treble gain varies from -4.3 dB at 0% potentiometer rotation to +6.0 dB at 100% potentiometer rotation. This gives an adjustment range of 10.3 dB, which meets the design requirement of 10 dB.
4.2.2.2 Mid Control

The result of the simulated ac analysis of the complete circuit as the mid potentiometer $P_4$ is rotated, when gain = 6 dB, the treble and bass potentiometers are set to 50%, and mid boost is off, is shown in Figure 11.

In this condition, the mid gain varies from -9.1 dB at 0% potentiometer rotation to +0.4 dB at 100% potentiometer rotation. This gives an adjustment range of 9.5 dB, which meets the design requirement of 6 dB.
4.2.2.3 Mid Boost

The result of the simulated ac analysis of the complete circuit as the mid boost jumper is connected and disconnected, when gain = 6dB and all potentiometers are set to 50%, is shown in Figure 12.

![Simulated AC Analysis - Mid Boost](image)

Figure 12: Simulated AC Analysis – Mid Boost

Activating the mid boost lowered the mid cut frequency from 617 Hz to 479 Hz and boosted the gain at the cut frequency from -2.4 dB to -0.8 dB.
4.2.2.4  Bass Control

The result of the simulated ac analysis of the complete circuit as the bass potentiometer $P_3$ is rotated, when gain $= 6$ dB, the treble and mid potentiometers are set to 50%, and mid boost is off, is shown in Figure 13.

![Simulated AC Analysis - Bass Control](image)

**Figure 13: Simulated AC Analysis – Bass Control**

In this condition, the bass gain varies from -13.2 dB at 0% potentiometer rotation to +5.5 dB at 100% potentiometer rotation. This gives an adjustment range of 18.7 dB, which meets the design requirement of 15 dB.
4.3 **THD+N Performance**

Unfortunately, TI's op amp macromodels do not currently support proper THD+N analysis. However, the THD+N ratio of a circuit (when noise is dominant) can be predicted from the total noise analysis by using Equation 13, where $V_N$ is the total voltage noise in $V_{\text{RMS}}$ over a specified bandwidth and $V_F$ is the fundamental signal amplitude in $V_{\text{RMS}}$.

\[
\text{THD+N}(\%) = \frac{V_N^2}{V_F^2} \times 100
\]

(Equation 13)

The result of the simulated total noise analysis at gain = 6 dB, all tone potentiometers set to 100%, and mid boost on is shown in Figure 14. The audio analyzer which is used for real-world measurements will be set to a measurement bandwidth of 90 kHz, so this simulated noise analysis is performed to 90 kHz.

![Figure 14: Simulated Total Noise Analysis](image)

The total noise at 90 kHz was found to be 7.4 $\mu V_{\text{RMS}}$. Given our input signal amplitude of 1 $V_{\text{RMS}}$, the predicted THD+N ratio is calculated using Equation 14.

\[
\text{THD+N}(\%) = \frac{V_N^2}{V_F^2} \times 100 = \frac{(7.4 \, \mu V_{\text{RMS}})^2}{(1 \, V_{\text{RMS}})^2} \times 100 = 0.00074\% = -102.6 \text{ dB}
\]

(Equation 14)

The simulated THD+N ratio was found to be -102.6 dB (0.00074%), which meets the design requirement of -100 dB. However, this does not account for the possibility of harmonic distortion due to output clipping which can occur at higher gain settings.
4.4 Resistor Nonlinearity

As mentioned in Section 3.2.1, resistor nonlinearity due to $\text{TC}_R$ and $\text{VC}_R$ can have a negative effect on distortion performance. In order to determine if thin film resistors are required, the current through feedback resistors $R_1$ and $R_2$ is simulated during the worst-case condition when $V_{IN} = 20 \, \text{Hz}$ and gain = 6 dB. The result of the transient analysis is shown in Figure 15.

![Figure 15: Simulated Transient Analysis – Feedback Resistor Current](image)

In this condition, the maximum current through the feedback network is approximately 1.4 mA. We calculate the maximum power dissipation through the feedback network using Equation 15.

$$P_{\text{DIS}}(W) = I^2 \cdot R = 1.4 \, \text{mA}^2 \cdot 1\,\text{k\Omega} = 2 \, \text{mW}$$

(15)

The maximum power dissipation of approximately 2 mW is well below the resistors’ power handling of 100 mW, so $\text{TC}_R$ and $\text{VC}_R$ will not be an issue and thin film resistors are not required to achieve low-distortion performance.

4.5 Simulated Results Summary

5 PCB Design

The PCB schematic and bill of materials can be found in the Appendix.

5.1 PCB Layout

The PCB used in this design is a 3.4” by 3.4” square. This generous size allows for efficient routing of critical components and the use of larger RCA, ¼”, and banana jacks, as well as the four required potentiometers. The high-level approach to this layout was to place nearly all components on the top layer, with the op amp in the center of the board, input connections on the left, output connections on the right, and gain and tone control potentiometers on the bottom. The power supply bulk capacitors were placed on the bottom layer close to the banana jacks. The two low-frequency tone control capacitors were also placed on the bottom layer close to their associated potentiometers.

Standard precision analog PCB layout practices were used in order to achieve the best possible performance. All passive components in the analog signal path are placed and routed very tightly in order to minimize parasitics, and all decoupling capacitors are located very close to their associated power pins. Solid copper planes on both layers provide an excellent low-impedance path for return currents to ground, and stitching vias are used where necessary.

Connections to the split power supply are made at J₅, J₆, and J₇. Connections to the audio inputs and outputs are made at J₁, J₂, J₃, and J₄. RCA connectors J₁ and J₂ are used to easily connect to the test equipment when measuring system performance, while ¼” connectors J₃ and J₄ are used to connect standard guitar cables.

The PCB layout for both layers is shown in Figure 16.
6 Verification & Measured Performance

6.1 Bench Test Hardware Setup

The tone stack circuit defined by this reference design is intended for use within a complete guitar amplifier system. However, the circuit is also a standalone functional block whose real-world performance can be characterized. The convenient input, output and power connectors on the PCB allow the circuit to be easily tested on a bench using standard lab equipment. The test setup used consists of the components listed below. Figure 17 shows the bench test setup (computer not shown).

1. High performance audio analyzer: Provides the audio input and measures the audio output of the system.
2. Bode analyzer: Measures the gain and phase response of the system over frequency.
3. Personal computer (PC): Communicates with and controls the audio analyzer and Bode analyzer through a digital interface. Software provided by the hardware manufacturers allows the user to specify signal characteristics and perform measurements.
4. Triple output power supply: Provides ±15 V power supply rails to the system.

Figure 17: Bench Test Hardware Setup
6.2 Gain Characteristic

The result of the measured gain characteristic as a function of gain potentiometer $P_1$ rotation is shown in Figure 18. Gain was measured at 0%, 25%, 50%, 75%, and 100% rotation.

![Figure 18: Measured Gain Characteristic](image-url)
6.3 Frequency Response

6.3.1 Input Filter and Gain Stage

The result of the measured ac analysis of the input filter and gain stage when gain = 6 dB is shown in Figure 19.

![Graph showing frequency response](image)

**Figure 19: Measured AC Analysis – Input Filter and Gain Stage**

The gain of the measurement throughout the audio band was measured to be 6 dB. The measured -3 dB bandwidth was 353 kHz, which correlates very well to the simulated -3 dB bandwidth of 358 kHz. The phase of the circuit was measured to be 0.2° at 20 Hz and -3.3° at 20 kHz, which is nearly the exact result found in simulation.
6.3.2 Tone Stack

6.3.2.1 Treble Control

The result of the measured ac gain analysis of the complete circuit as the treble potentiometer $P_2$ is rotated, when gain = 6 dB, the mid and bass potentiometers are set to 50%, and mid boost is on, is shown in Figure 20.

![Figure 20: Measured AC Gain Analysis – Treble Control](image)

In this condition, the treble gain varies from -5.0 dB at 0% potentiometer rotation to +5.6 dB at 100% potentiometer rotation. This gives an adjustment range of 10.6 dB, which meets the design requirement of 10 dB.

The result of the measured ac phase analysis under the same conditions is shown in section A.3.
6.3.2.2 Mid Control

The result of the measured ac gain analysis of the complete circuit as the mid potentiometer $P_4$ is rotated, when gain = 6 dB, the treble and bass potentiometers are set to 50%, and mid boost is on, is shown in Figure 21.

![Diagram showing gain vs frequency at different mid potentiometer settings.

Range = 8.9 dB

Figure 21: Measured AC Gain Analysis – Mid Control

In this condition, the mid gain varies from -8.9 dB at 0% potentiometer rotation to 0 dB at 100% potentiometer rotation. This gives an adjustment range of 8.9 dB, which meets the design requirement of 6 dB.

The result of the measured ac phase analysis under the same conditions is shown in section A.3.
6.3.2.3 Mid Boost

The result of the measured ac gain analysis of the complete circuit as the mid boost jumper is connected and disconnected, when gain = 6dB and all potentiometers are set to 50%, is shown in Figure 22.

![Graph showing Mid Boost analysis](image)

**Figure 22: Measured AC Gain Analysis – Mid Boost**

Activating the mid boost lowered the mid cut frequency from 679 Hz to 511 Hz and boosted the gain at the cut frequency from -2.7 dB to -1.0 dB.

The result of the measured ac phase analysis under the same conditions is shown in section A.3.
6.3.2.4 Bass Control

The result of the measured ac gain analysis of the complete circuit as the bass potentiometer $P_3$ is rotated, when gain = 6 dB, the treble and mid potentiometers are set to 50%, and mid boost is on, is shown in Figure 23.

![Graph](image)

Range = 19.2 dB

**Figure 23: Measured AC Gain Analysis – Bass Control**

In this condition, the bass gain varies from -13.9 dB at 0% potentiometer rotation to +5.3 dB at 100% potentiometer rotation. This gives an adjustment range of 19.2 dB, which meets the design requirement of 15 dB.

The result of the measured ac phase analysis under the same conditions is shown in section A.3.
6.4 THD+N Performance

The result of the THD+N measurement over frequency with gain = 6 dB, all potentiometers set to 100%, and mid boost off is shown in Figure 24. The audio analyzer is set to a measurement bandwidth of 90 kHz and no additional filtering or weighting is applied.

![Figure 24: Measured THD+N Level vs. Frequency](image)

This THD+N level at 1 kHz is measured to be -105.4 dB (0.00054%), which meets the design requirement of -100 dB. The THD+N levels at 20 Hz and 20 kHz are measured to be -100.1 dB (0.00099%) and -102.8 dB (0.00072%), respectively.
The Fast Fourier transform (FFT) measurement with $V_{IN}$ at 1 kHz, gain = 6 dB, all potentiometers set to 100%, and mid boost off is shown in Figure 25. The FFT measurement is set to 192k points and 4x averaging.

![Figure 25: Measured Fast Fourier Transform (FFT)](image)

The y-axis is referenced to the fundamental frequency output level of 1.58 $V_{RMS}$. The second harmonic is measured at 123 dB below the fundamental, while the third harmonic is measured at 127 dB below the fundamental.

### 6.5 Measured Results Summary

Table 4 summarizes the measured performance of the design.

7 Audio Recordings

While frequency response curves and FFTs can be useful in measuring the performance of a circuit, in audio applications many times “hearing is believing.” The following audio recordings capture the tonal differences between circuit settings as the author plays an E major chord on a Gibson SG through its neck pickup.

2. Bass 100% vs. bass 0% (mid and treble 50%): Download
3. Mid 100% vs. mid 0% (bass and treble 50%): Download
4. Treble 100% vs. treble 0% (bass and mid 50%): Download
5. Mid boost off vs. mid boost on (all controls 50%): Download

8 Modifications

The components selected for this design were based on the design goals outlined at the beginning of the design process.

This design specifies an input impedance of 6 kΩ. While this is a reasonable specification for passive electric guitar pickups, the actual value will vary across electric guitar and pickup manufacturers. It may be necessary to adjust the values of R₄, C₄ and C₇ in the input filter to achieve the desired cutoff frequencies.

If modifications to the frequency response of the tone stack are desired, the component values of the FMV tone stack may easily be modified using the equations given in section 2.3.2. Duncan's Tone Stack Calculator is a free software tool which may also be used to model the response of different tone stack topologies, component values and potentiometer settings [8].

A JFET-input amplifier was selected for this application because of the high impedances present in the circuit. The extremely low input bias current (Iᵦ) and input current noise (Iᵦᵣ) of FET-input devices prevent large offset and noise voltages from developing and degrading audio performance.

Among the FET-input audio amplifiers offered by Texas Instruments, the OPA1642 was selected for this application because of its extremely stable input common-mode capacitance which preserves excellent distortion performance even with high source impedances. The OPA1652 is another FET-input audio amplifier with excellent THD+N performance, low noise, and low cost; however its in-circuit distortion performance may be reduced compared to the OPA1642. Table 5 summarizes the key specs between these two devices.

</tr>
</tbody>
</table>

It is often desirable for a gain or volume control to have a response which is linear-in-dB with respect to the rotation of the controlling potentiometer. This results in a very natural change in perceived volume as the user rotates the volume knob.

Because the gain control in this circuit is a potentiometer with a linear taper, the characteristic is not linear-in-dB. If linear-in-dB behavior is desired a potentiometer with an audio taper may be used, or the gain control circuit can be modified to include a Baxandall active volume control as described in TIPD136 [9].
About the Author

Ian Williams (ian@ti.com) is an applications engineer in the Precision Analog – Linear team at Texas Instruments where he supports industrial products and applications. Ian graduated from the University of Texas, Dallas, where he earned a Bachelor of Science in Electrical Engineering with a concentration in Microelectronics.

IMPORTANT NOTICE FOR TI REFERENCE DESIGNS

Texas Instruments Incorporated ("TI") reference designs are solely intended to assist designers ("Buyers") who are developing systems that incorporate TI semiconductor products (also referred to herein as "components"). Buyer understands and agrees that Buyer remains responsible for using its independent analysis, evaluation and judgment in designing Buyer's systems and products.

TI reference designs have been created using standard laboratory conditions and engineering practices. TI has not conducted any testing other than that specifically described in the published documentation for a particular reference design. TI may make corrections, enhancements, improvements and other changes to its reference designs.

Buyers are authorized to use TI reference designs with the TI component(s) identified in each particular reference design and to modify the reference design in the development of their end products. HOWEVER, NO OTHER LICENSE, EXPRESS OR IMPLIED, BY ESTOPPEL OR OTHERWISE TO ANY OTHER TI INTELLECTUAL PROPERTY RIGHT, AND NO LICENSE TO ANY THIRD PARTY TECHNOLOGY OR INTELLECTUAL PROPERTY RIGHT, IS GRANTED HEREIN, including but not limited to any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used.

Information published by TI regarding third-party products or services does not constitute a license to use such products or services, or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

TI REFERENCE DESIGNS ARE PROVIDED "AS IS". TI MAKES NO WARRANTIES OR REPRESENTATIONS WITH REGARD TO THE REFERENCE DESIGNS OR USE OF THE REFERENCE DESIGNS, EXPRESS, IMPLIED OR STATUTORY, INCLUDING ACCURACY OR COMPLETENESS. TI DISCLAIMS ANY WARRANTY OF TITLE AND ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, QUIET ENJOYMENT, QUIET POSSESSION, AND NON-INFRINGEMENT OF ANY THIRD PARTY INTELLECTUAL PROPERTY RIGHTS WITH REGARD TO TI REFERENCE DESIGNS OR USE THEREOF. TI SHALL NOT BE LIABLE FOR AND SHALL NOT DEFEND OR INDEMNIFY BUYERS AGAINST ANY THIRD PARTY INFRINGEMENT CLAIM THAT RELATES TO OR IS BASED ON A COMBINATION OF COMPONENTS PROVIDED IN A TI REFERENCE DESIGN. IN NO EVENT SHALL TI BE LIABLE FOR ANY ACTUAL, SPECIAL, INCIDENTAL, CONSEQUENTIAL OR INDIRECT DAMAGES, HOWEVER CAUSED, ON ANY THEORY OF LIABILITY AND WHETHER OR NOT TI HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES, ARISING IN ANY WAY OUT OF TI REFERENCE DESIGNS OR BUYER'S USE OF TI REFERENCE DESIGNS.

TI reserves the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products are sold subject to TI’s terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI’s terms and conditions of sale of semiconductor products. Testing and other quality control techniques for TI components are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers’ products and applications, Buyers should provide adequate design and operating safeguards.

Reproduction of significant portions of TI information in TI data books, data sheets or reference designs is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards that anticipate dangerous failures, monitor failures and their consequences, lessen the likelihood of dangerous failures and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in Buyer's safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI’s goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed an agreement specifically governing such use.

Only those TI components that TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components that have not been so designated is solely at Buyer's risk, and Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
