Industrial automation components

There are four major components in industrial automation including PLC controllers, HMI panels, industrial drives and sensors.

The PLC controller is the brain of an industrial automation system; it provides relay control, motion control, industrial input and output process control, distributed system, and networking control. PLCs often need to work in harsh environmental conditions, withstanding heat, cold, moisture, vibration and other extreme conditions while providing precise, deterministic and real-time controls to the other parts of the industrial automation system through reliable communication links.

The HMI is the graphical user interface for industrial control. It provides a command input and feedback output interface for controlling the industrial machinery. An HMI is connected through common communication links to other parts of industrial systems.

Industrial drives are motor controllers used for controlling optimal motor operation. They are used in a very diverse range of industrial applications and come with a wide range of voltage and power levels. Industrial drives include but are not limited to AC and DC drives as well as servo drives that use a motor feedback system to control and adjust the behavior and performance of servo mechanisms.

Sensors are the hands and legs of the industrial automation system that monitor the industrial operation conditions, inspections, measurements, and more, in real time. They are an integral part of industrial automation systems and provide trigger point and feedback for system control.

Communication is the backbone of all the industrial components for efficient automation production systems. On the following page is an example picture how all the components work together through communication links.

Legacy industrial communication protocols

Historically, industrial communications have been developed on serial-based interfaces that were originally created by different companies and later became standards. The result is
many different standards in the market. Because big companies are behind these standards, there is a need for industrial automation equipment companies to implement many of these protocols within an industrial system. Due to long life cycle of industrial systems, many serial-based protocols, including PROFIBUS®, CAN bus, Modbus® and CC-Link® with master slave configurations, are still very popular today.

PROFIBUS is the world’s most successful fieldbus technology and is widely deployed in industrial automation systems including factory and process automation. PROFIBUS provides digital communication for process data and auxiliary data with speeds up to 12 Mbps and supports up to 126 addresses.

Control Area Network (CAN) bus, a high-integrity serial bus system, was originally created as an automotive vehicle bus and later came to be used as one of the fieldbuses for industrial automation. It provides a physical and data link layer for serial communication with speeds up to 1 Mbps. CANopen® and DeviceNet are higher level protocols standardized on top of CAN bus to allow interoperability with devices on the same industrial network. CANopen supports 127 nodes on the network while DeviceNet supports 64 nodes on the same network.

Modbus is a simple, robust and openly published, royalty free serial bus that connects up to 247 nodes in the link. Modbus is easy to implement and run on RS-232 or RS-485 physical links with speeds up to 115K baud.

CC-Link was originally developed by Mitsubishi and is a popular open-architecture, industrial network protocol in Japan and Asia. CC-Link is based on RS-485 and can connect with up to 64 nodes on the same network with speeds up to 10 Mbps.

Ethernet is becoming ubiquitous and cost effective, with common physical links and increased speed. As such, many industrial communication protocols are moving to Ethernet-based solutions. Ethernet communications with TCP/IP typically are non-deterministic, and reaction time is often around 100 ms. Industrial
Ethernet protocols use a modified Media Access Control (MAC) layer to achieve very low latency and deterministic responses. Ethernet also enables a flexible network topology and a flexible number of nodes in the system. Let’s look at some of the popular Industrial Ethernet protocols in detail.

**EtherCAT** was originally developed by Beckhoff to enable on-the-fly packet processing and deliver real-time Ethernet to automation applications and that can provide scalable connectivity for entire automation systems, from large PLCs all the way down to the I/O and sensor level.

EtherCAT, a protocol optimized for process data, uses standard IEEE 802.3 Ethernet Frames. Each slave node processes its datagram and inserts the new data into the frame while each frame is passing through. The process is handled in hardware so each node introduces minimum processing latency, enabling the fastest possible response time. EtherCAT is the MAC layer protocol and is transparent to any higher level Ethernet protocols such as TCP/IP, UDP, Web server, etc. EtherCAT can connect up to 65,535 nodes in a system, and EtherCAT master can be a standard Ethernet controller, thus simplifying the network configuration. Due to the low latency of each slave node, EtherCAT delivers flexible, low-cost and network-compatible industrial Ethernet solutions.

**EtherNet/IP** is an industrial Ethernet protocol originally developed by Rockwell. Unlike EtherCAT, which is a MAC-layer protocol, EtherNet/IP is an application-layer protocol on top of TCP/IP. EtherNet/IP uses standard Ethernet physical, data link, network and transport layers, while using Common Industrial Protocol (CIP) over TCP/IP. CIP provides a common set of messages and services for industrial automation control systems, and it can be used in multiple physical media. For example, CIP over CAN bus is called DeviceNet, CIP over dedicated network is called ControlNet and CIP over Ethernet is called EtherNet/IP. EtherNet/IP establishes communication from one application node to another through CIP connections over a TCP connection, and multiple CIP connections can be established over one TCP connection.

EtherNet/IP uses the standard Ethernet and switches, thus it can have an unlimited number of nodes in a system. This enables one network across many different end points in a factory floor. EtherNet/IP offers complete producer-consumer service and enables very efficient slave peer-to-peer communications. EtherNet/IP is compatible with many standard Internet and Ethernet protocols but has limited real-time and deterministic capabilities.

**PROFINET** is widely used industrial Ethernet by major industrial equipment manufacturers such as Siemens and GE. It has three different classes. PROFINET Class A provides access to a PROFIBUS network through proxy, bridging Ethernet and PROFIBUS with a remote procedure calling on TCP/IP. Its cycle time is around 100ms, and it is mostly used for parameter data and cyclic I/O. The typical application includes infrastructure and building automation. PROFINET Class B, also referred as PROFINET Real-Time (PROFINET RT), introduces a software-based real-time approach and has reduced the cycle time to around 10ms. Class B is typically
used in factory automation and process automation. PROFINET Class C (PROFINET IRT), is Isochronous and Real-Time, requiring special hardware to reduce the cycle time to less than 1ms to deliver the sufficient performance on the real-time industrial Ethernet for motion control operations.

PROFINET RT can be used in PLC-type applications, while PROFINET IRT is a good fit for motion applications. Branch and Star are the common topology used for PROFINET. Careful topology planning is required for PROFINET networks to achieve the required performance of the system.

**POWERLINK** was originally developed by B&R. Ethernet POWERLINK is implemented on top of IEEE 802.3 and, therefore, allows a free selection of network topology, cross connect and hot plug. It uses a polling and time slicing mechanism for real-time data exchange. A POWERLINK master or “Managed Node” controls the time synchronization through packet jitter in the range of 10s of nanoseconds. Such a system is suitable for all kinds of automation systems ranging from PLC-to-PLC communication and visualization down to motion and I/O control. Barriers to implement POWERLINK are quite low due to the availability of open-source stack software. In addition, CANopen is part of the standard which allows for easy system upgrades from previous fieldbus protocols.

**Sercos III** is the third generation of Serial Real-time Communication System (Sercos). It combines on-the-fly packet processing for delivering real-time Ethernet and standard TCP/IP communication to deliver low latency industrial Ethernet.

Much like EtherCAT, a Sercos III slave processes the packet by extracting and inserting data to the Ethernet frame on-the-fly to achieve low latency. Sercos III separates input and output data into two frames. With cycle times from 31.25 microseconds, it is as fast as EtherCAT and PROFINET IRT. Sercos III supports ring or line topology. One key advantage to using ring topology is communication redundancy: Even if the ring breaks due to failure of one slave, all remaining slaves still get the Sercos III frames with input/output data. Sercos III can have 511 slave nodes in one network and is most used in servo drive controls.

**CC-Link IE** is the industrial Ethernet technology of CC-Link, which was originally developed by Mitsubishi. CC-Link IE has two versions: CC-Link IE Control and CC-Link IE Field. CC-Link IE control is intended for controller-to-controller communications and can have 120 nodes per network. CC-Link IE field is intended for I/O communications and motion control, and it can have 254 nodes per network. CC-Link IE leverages the Ethernet data link layer, and its control frames are directly embedded in the Ethernet frame. Only ring topology is supported in CC-Link without switches. This can provide network redundancy, but a limited number of nodes can be supported in a network, and the cycle time is dependent on the number of the nodes in the network.
Modbus/TCP, an extension of Modbus, was originally developed by Schneider Electric and uses Modbus messaging over TCP/IP on top of Ethernet. Modbus/TCP is simple to implement on the standard Ethernet network, but it does not guarantee real-time and deterministic communications.

To enable industrial equipment manufacturers with an economic and flexible means to implement a variety of industrial communication protocols, Texas Instruments has integrated a low-latency, low-power and programmable Industrial Communication SubSystem (ICSS) into many of its system on chips. The ICSS provides a more cost-effective, flexible and future-proof solution for industrial communications as compared to FPGAs, ASICs and other alternative solutions. By integrating the ICSS into a single chip, TI’s flexible hardware platform empowers manufacturers to implement more cost-effective, deterministic, efficient and software-programmable industrial automation systems.

Future trend

We are at the dawn of the third industrial revolution in which industrial automation will again drive the economy. The success of industrial automation depends on a reliable and efficient communication network that connects all the components of the factory to work together effectively. The popularity and ubiquity of Ethernet will continue to motivate the legacy factory to upgrade to industrial Ethernet. Many different industrial Ethernet protocols have been implemented in the field, each with its own pros and cons. Future industrial Ethernet protocols will continue to evolve and converge to deliver hard real-time, deterministic communication links with better reliability and integrated safety. Ethernet also requires a common, programmable hardware platform, such as Texas Instruments’ Sitara™ AM335x ARM® processor with integrated ICSS to enable a low-cost, flexible system capable of supporting multiple protocols and forward-looking implementation for new protocols to power the industrial communication engine of the industrial automation.

For more information on the Sitara AM335x product line, please visit www.ti.com/lsds/ti/arm/sitara_arm_cortex_a_processor/products.page. Also, to preview the new AM4x and AM5x Sitara processors families, which will offer even more performance for your industrial needs, please visit www.ti.com/am4x-sps and www.ti.com/am5x-sps.

Important Notice: The products and services of Texas Instruments incorporated and its subsidiaries described herein are sold subject to TI’s standard terms and conditions of sale. Customers are advised to obtain the most current and complete information about TI products and services before placing orders. TI assumes no liability for applications assistance, customer’s applications or product designs, software performance, or infringement of patents. The publication of information regarding any other company’s products or services does not constitute TI’s approval, warranty or endorsement thereof.

Sitara is a trademark of Texas Instruments Incorporated. All other trademarks are the property of their respective owners.
Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as “components”) are sold subject to TI’s terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI’s terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers’ products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers’ products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI’s goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or “enhanced plastic” are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have not been so designated is solely at the Buyer’s risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
