The first data of the burst is driven on the A/D bus at [GPMC_CONFIG6_i\[19:16\]](#) WRDATAONADMUXBUS.

When WRACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the [GPMC_CONFIG5_i\[27:24\]](#) PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For details, see [Section 15.4.4.9.2.3, Address/Data-Multiplexing Interface](#).

- Chip-select signal nCS:
 - nCS assertion time is controlled by the [GPMC_CONFIG2_i\[3:0\]](#) CSONTIME field (i = 0 to 7) and ensures address setup time to nCS assertion.
 - nCS deassertion time controlled by the [GPMC_CONFIG2_i\[20:16\]](#) CSWROFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the [GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME field.
 - nADV deassertion time is controlled by the [GPMC_CONFIG3_i\[20:16\]](#) ADVWROFFTIME field.
- Write enable signal nWE:
 - nWE assertion indicates a read cycle.
 - nWE assertion time is controlled by the [GPMC_CONFIG4_i\[19:16\]](#) WEONTIME field.

- nWE deassertion time is controlled by the [GPMC_CONFIG4_i\[28:24\]](#) WEOFFTIME field.

NOTE: The nWE falling edge must not be used to control the time when the burst first data is driven in the address/data bus because some new devices require the nWE signal at low during the address phase.

- Direction signal DIR is OUT during the entire access.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, and DIR signals are controlled as detailed above.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
 - nADV first assertion time is controlled by the [GPMC_CONFIG3_i\[6:4\]](#) ADVAADMUXONTIME field.
 - nADV first deassertion time is controlled by the [GPMC_CONFIG3_i\[26:24\]](#) ADVAADMUXRDOFFTIME field.
 - nADV second assertion time is controlled by the [GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME field.
 - nADV second deassertion time is controlled by the [GPMC_CONFIG3_i\[12:8\]](#) ADVRDOFFTIME field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
 - nOE first assertion time is controlled by the [GPMC_CONFIG4_i\[6:4\]](#) OEAADMUXONTIME field.
 - nOE first deassertion time is controlled by the [GPMC_CONFIG4_i\[15:13\]](#) OEAADMUXOFFTIME field.
 - nOE second assertion time is controlled by the [GPMC_CONFIG4_i\[3:0\]](#) OEONTIME field.
 - nOE second deassertion time is controlled by the [GPMC_CONFIG4_i\[12:8\]](#) OEOFFTIME field.

First write data is driven by the GPMC at [GPMC_CONFIG6_i\[19:16\]](#) WRDATAONADMUXBUS, when in address/data mux configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during [GPMC_CONFIG5_i\[27:24\]](#) PAGEBURSTACCESSTIME GPMC_FCLK cycles. The last data of the synchronous burst write is driven until [GPMC_CONFIG5_i\[12:8\]](#) WRCYCLETIME completes.

- WRACCESSTIME is defined in the [GPMC_CONFIG6_i\[28:24\]](#) register.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time [GPMC_CONFIG5_i\[12:8\]](#) WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from nCS deassertion. In [Figure 15-71](#), the WRCYCLETIME programmed value equals WRCYCLETIME0 + WRCYCLETIME1. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See [Section 15.4.4.10.10, Bus Keeping Support](#).

15.4.4.11.3 Asynchronous and Synchronous Accesses in Nonmultiplexed Mode

Page mode is only available in non-muxed mode. The non-muxed mode is described in this section even though its use is very limited (address space limited to 2 KBytes).

- Asynchronous single read operation on a nonmultiplexed device
- Asynchronous single write operation on a nonmultiplexed device
- Asynchronous multiple (page mode) read operation on a nonmultiplexed device
- Synchronous operations on a nonmultiplexed device

15.4.4.11.3.1 Asynchronous Single Read Operation on a Nonmultiplexed Device

[Figure 15-73](#) shows an asynchronous single read operation on a nonmultiplexed device.

Figure 15-73. Asynchronous Single Read on an Address/Data-Nonmultiplexed Device

gpmc-010

The 10-bit address is driven onto the address bus A[10:1] and the 16-bit data is driven onto the data bus D[15:0].

Read data is latched at [GPMC_CONFIG1_5\[20:16\]](#) RDACCESSTIME completion time. The end of the access is defined by the [GPMC_CONFIG1_5\[4:0\]](#) RDCYCLETIME parameter.

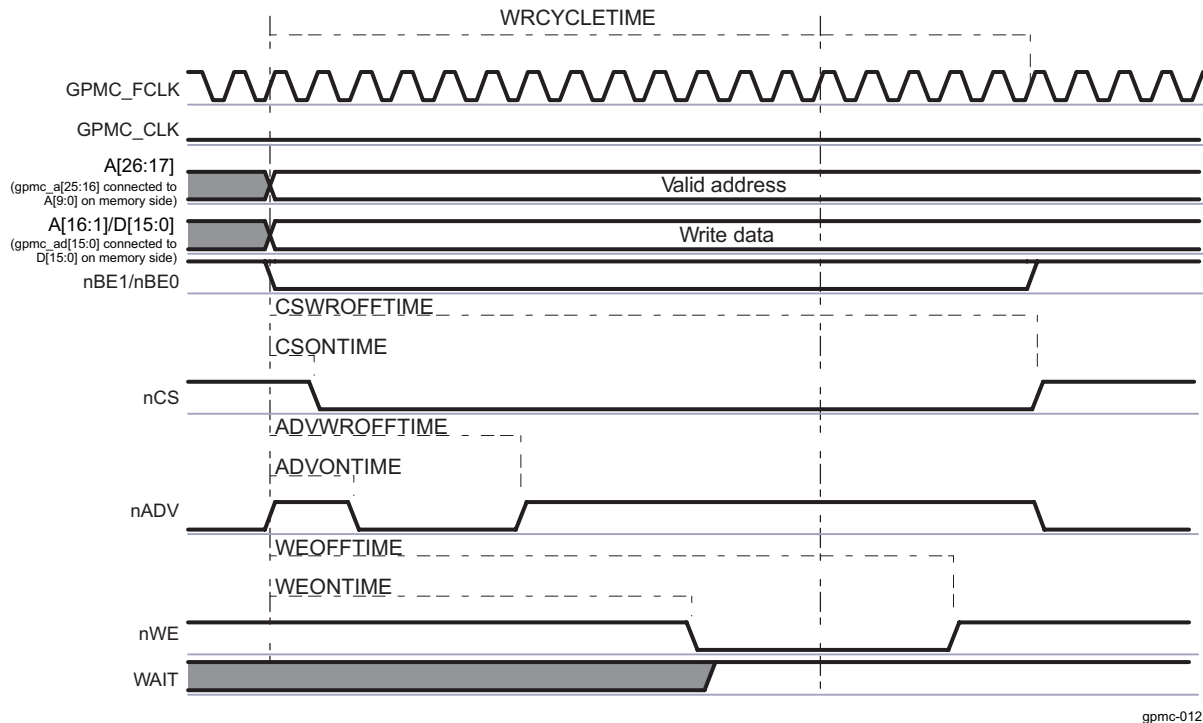

Set [GPMC_CONFIG\[1\]](#) LIMITEDADDRESS to 0x1 (A26-A11 are not modified during an external memory access).

nCS, nADV, nOE and DIR signals are controlled in the same way as address/data multiplexed accesses, see [Table 15-248](#).

15.4.4.11.3.2 Asynchronous Single Write Operation on a Nonmultiplexed Device

[Figure 15-74](#) shows an asynchronous single write operation on a nonmultiplexed device.

Figure 15-74. Asynchronous Single Write on an Address/Data-Nonmultiplexed Device

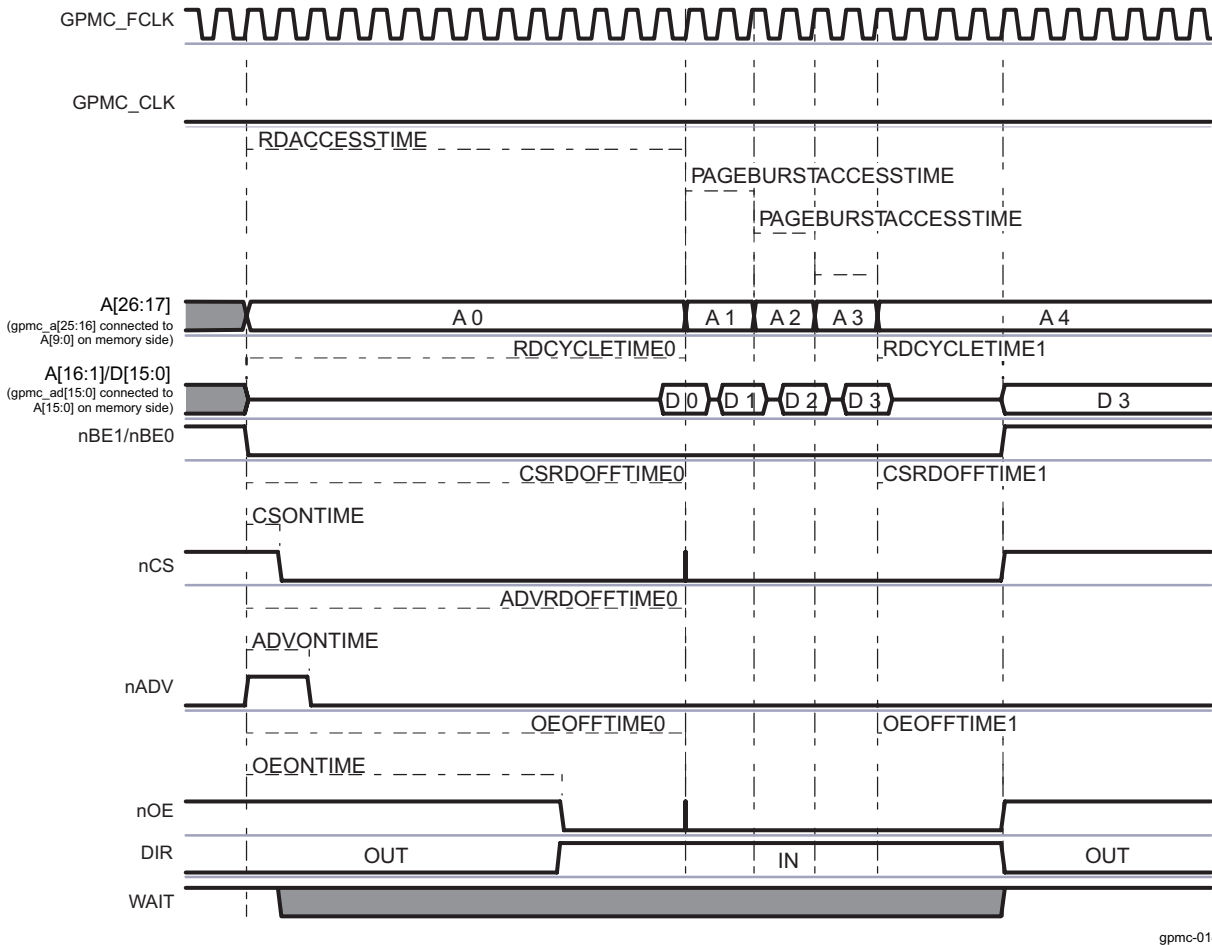

The 10-bit address is driven onto the address bus A[10:1] and the 16-bit data is driven onto the data bus D[15:0].

Set [GPMC_CONFIG\[1\] LIMITEDADDRESS](#) to 0x1 (A26-A11 are not modified during an external memory access).

nCS, nADV, nWE and DIR signals are controlled in the same way as address/data multiplexed accesses, see [Table 15-248](#).

15.4.4.11.3.3 Asynchronous Multiple (Page Mode) Read Operation on a Nonmultiplexed Device

[Figure 15-75](#) shows an asynchronous multiple read operation on a Nonmultiplexed Device, in which two word32 host read accesses to the GPMC are split into one multiple (page mode of 4 word16) read access to the attached device.

Figure 15-75. Asynchronous Multiple (Page Mode) Read

NOTE: The WAIT signal is active low.

nCS, nADV, nOE and DIR signals are controlled in the same way as address/data multiplexed accesses, see [Table 15-248](#).

When RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at [GPMC_CONFIG5_i\[20:16\]](#) RDACCESSTIME completion time ($i = 0$ to 7). The end of the access is defined by the [GPMC_CONFIG5_i\[4:0\]](#) RDCYCLETIME parameter.

Set [GPMC_CONFIG\[1\]](#) LIMITEDADDRESS to 0x1 (A26-A11 are not modified during an external memory access).

During consecutive accesses, the GPMC increments the address after each data read completes.

Delay between successive read data in the page is controlled by the [GPMC_CONFIG5_i\[27:24\]](#) PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Note that page crossing is only possible with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time starting from the nCS deassertion.

- The read cycle time is defined in the [GPMC_CONFIG5_i\[4:0\]](#) RDCYCLETIME field.
- In [Figure 15-75](#), the RDCYCLETIME programmed value equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

15.4.4.11.3.4 Synchronous Operations on a Nonmultiplexed Device

All information for this section is equivalent to similar operations for address/data- or AAD-multiplexed accesses. The only difference resides in the address phase. See [Section 15.4.5.3, GPMC Configuration in NOR Mode](#).

15.4.4.11.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The [GPMC_CONFIG1_i\[30\]](#) READMULTIPLE and [GPMC_CONFIG1_i\[28\]](#) WRITEMULTIPLE bits ($i = 0$ to 7) are associated with the READTYPE and WRITETYPE parameters.

NOTE:

- Asynchronous write page mode is not supported.
 - 8-bit wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
 - Not applicable to NAND device interfacing.
-

15.4.4.11.5 System Burst Versus External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte enable controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two words, four words, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length burst. The maximum length that can be issued is defined per CS by the [GPMC_CONFIG1_i\[24:23\]](#) ATTACHEDDEVICEPAGELENGTH field ($i = 0$ to 7). When the ATTACHEDDEVICEPAGELENGTH value is less than the system burst request length (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the ATTACHEDDEVICEPAGELENGTH field value must correspond to the maximum-length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the [GPMC_CONFIG1_i\[31\]](#) WRAPBURST bit ($i = 0$ to 7) must be set to 1. Similarly DEVICESPAGELENGTH is set to 4 and 8 for memories supporting respectively 4 and 8 Word16-length-wrapping burst.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the ATTACHEDDEVICEPAGELENGTH value.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed burst length mode and a continuous burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the [GPMC_CONFIG1_i\[24:23\]](#) ATTACHEDDEVICEPAGELENGTH field is set accordingly to 4 or 8 words.

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-words boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the ATTACHEDDEVICEPAGELENGTH value. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait states between data accesses. If the memory does not behave this way (nonzero wait state burstable memory), wait-pin monitoring must be enabled to dynamically control data-access completion within the burst.

NOTE: When the system burst request length is less than the ATTACHEDDEVICEPAGELENGTH value, the GPMC proceeds with the required accesses.

15.4.4.12 pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The [GPMC_CONFIG1_i\[11:10\]](#) DEVICETYPE field ($i = 0$ to 7) must be set to 0b00.

The pSRAM devices uses the NOR protocol. It support the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR Flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can either automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or pSRAM devices automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum nCS high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

15.4.4.13 NAND Access Description

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to *chip enable don't care* NAND devices since the chip-select allocated to the NAND device has to be deasserted if accesses to other chip-selects are requested.

15.4.4.13.1 NAND Memory Device in Byte or 16-bit Word Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data-stream-oriented (byte or 16-bit word).

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as Address Latch Enable (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as Command Latch Enable (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

15.4.4.13.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The [GPMC_CONFIG7_i](#) register (where $i = 0$ to 7) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16 Mbytes, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND Flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

CAUTION

To allow correct command, address, and data-access controls, the [GPMC_CONFIG1_i](#) register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters shown in [Table 15-226](#). Failure to comply with these settings corrupts the NAND interface protocol.

Table 15-226. Chip-Select Configuration for NAND Interfacing

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i[31] ⁽¹⁾	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i[30]	0	Single access
READTYPE	GPMC_CONFIG1_i[29]	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i[28]	0	Single access
WRITETYPE	GPMC_CONFIG1_i[27]	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i[26:25]	0b00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i[24:23]	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i[22]	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i[21]	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i[19:18]	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT	GPMC_CONFIG1_i[17:16]		Select which wait is monitored by edge detectors
DEVICESIZE	GPMC_CONFIG1_i[13:12]	0b00 or 0b01	8- or 16-bit interface
DEVICETYPE	GPMC_CONFIG1_i[11:10]	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1_i[9:8]	0b00	Nonmultiplexed mode

⁽¹⁾ $i = 0$ to 7

Table 15-226. Chip-Select Configuration for NAND Interfacing (continued)

Bit Field	Register	Value	Comments
TIMEPARAGRANULARITY	GPMC_CONFIG1_i [4]	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	GPMC_CONFIG1_i [1:0]	Don't care	Asynchronous mode

The [GPMC_CONFIG1_i](#) to [GPMC_CONFIG4_i](#) register (where i = 0 to 7) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

15.4.4.13.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The MPU software driver is responsible for issuing the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the [GPMC_NAND_COMMAND_i](#) and [GPMC_NAND_ADDRESS_i](#) register locations (i = 0 to 7) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the [GPMC_NAND_COMMAND_i](#) register location and to the [GPMC_NAND_ADDRESS_i](#) register location must be posted for faster operations (i = 0 to 7). The [GPMC_CONFIG\[0\]](#) NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An [GPMC_STATUS\[0\]](#) EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

[GPMC_NAND_COMMAND_i](#) and [GPMC_NAND_ADDRESS_i](#) (i = 0 to 7) are 32-bit word locations, which means any 32-bit word or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32-bit word or 16-bit word access to these registers, but it must account for the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to [GPMC_NAND_COMMAND_i](#) and [GPMC_NAND_ADDRESS_i](#) can be used, and any of the four byte locations of the registers are valid.

The same applies to a [GPMC_NAND_COMMAND_i](#) and a [GPMC_NAND_ADDRESS_i](#) (i = 0 to 7) 32-bit word write access to a 16-bit wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid.

15.4.4.13.1.3 Command Latch Cycle

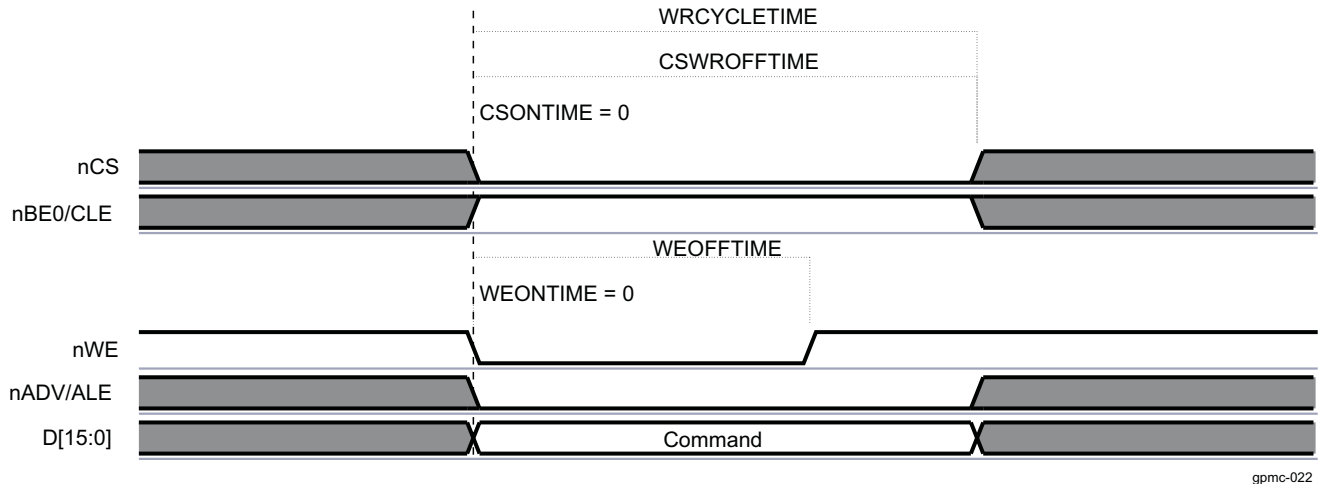

Writing data at the [GPMC_NAND_COMMAND_i](#) location (i = 0 to 7) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.

- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE and nRE (nOE) are maintained inactive.

Figure 15-76 shows the NAND command latch cycle.

Figure 15-76. NAND Command Latch Cycle

NOTE: CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

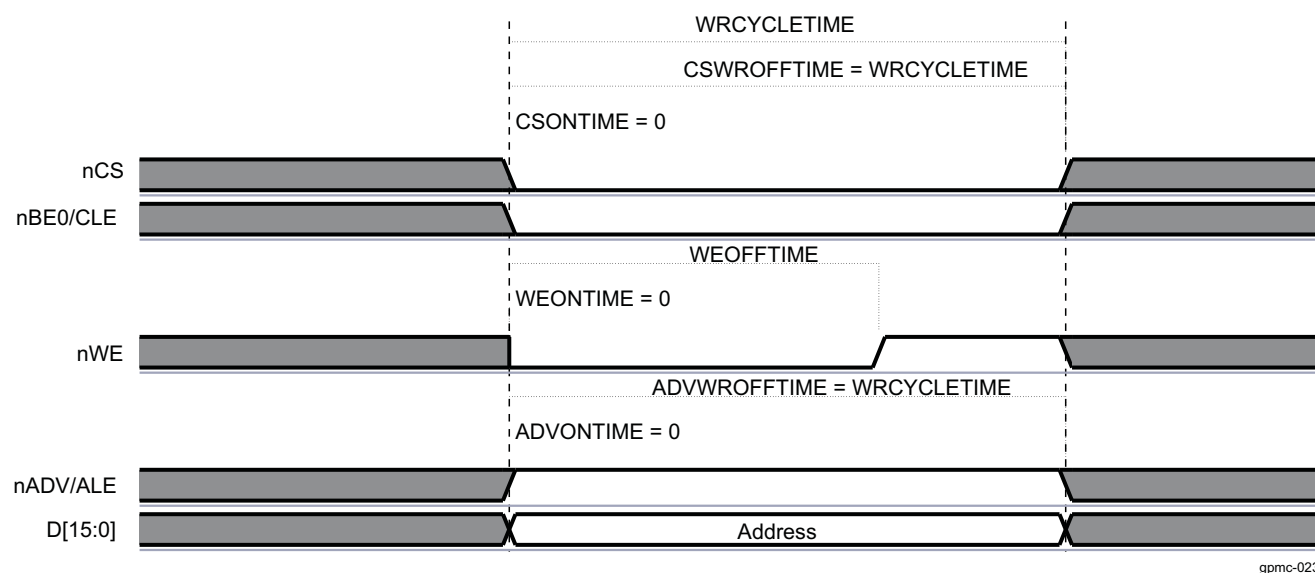

NAND Flash memories do not use byte enable signals at all.

15.4.4.13.1.4 Address Latch Cycle

Writing data at the [GPMC_NAND_ADDRESS_i](#) location ($i = 0$ to 7) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 15-77 shows the NAND address latch cycle.

Figure 15-77. NAND Address Latch Cycle

NOTE: ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

15.4.4.13.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the [GPMC_NAND_DATA_i](#) location ($i = 0$ to 7) mapped in the chip-select-associated control register region. [GPMC_NAND_DATA_i](#) is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Reading data from the [GPMC_NAND_DATA_i](#) location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, the RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device IC timing parameters.

ALE, CLE, and nWE are maintained inactive.

[Figure 15-78](#) shows the NAND data read cycle.

Figure 15-78. NAND Data Read Cycle

Writing data to the [GPMC_NAND_DATA_i](#) location or to any location in the associated chip-select memory region activates an asynchronous write access.

- nCS is controlled by the CSOnTIME and CSWROffTIME timing parameters.
- nWE is controlled by the WEOnTIME and WEOffTIME timing parameters.
- ALE, CLE, and nRE (nOE) are maintained inactive.

[Figure 15-79](#) shows the NAND data write cycle.

Figure 15-79. NAND Data Write Cycle

15.4.4.13.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by nCS-to-data-valid timing and has faster nRE-to-data-valid timing. Successive accesses with nCS deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that nCS always stays low between two accesses to the same chip-select. Moreover, an nCS deassertion time between the same chip-select NAND accesses is likely to be required as follows: the nCS deassertion requires programming CYCLETIME and RDACCEStIME according to the nCS-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSRDOFFTIME, CSWROFFTIME, ADVRDOFFTIME, ADVWROFFTIME, OEOFFTIME, and WEOFFTIME on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses. For more information about optimal prefetch engine access, see [Section 15.4.4.13.4, Prefetch and Write-Posting Engine](#).

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, CYCLE2CYCLESAMEECSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high to data bus in tristate mode. This requires a bus turnaround setting (BUSTURNAROUND = 1), so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND Flash are not affected by the programmed bus turnaround delay.

15.4.4.13.1.7 Read and Write Access Size Adaptation

15.4.4.13.1.7.1 8-bit wide NAND Device

Host 16-bit word and 32-bit word read and write access requests to a chip-select associated with an 8-bit wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the chip-select is associated with an 8-bit wide NAND device.

15.4.4.13.1.7.2 16-bit wide NAND Device

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit wide NAND device should be avoided, especially when ECC calculation is enabled. 8-bit or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

15.4.4.13.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the WAIT GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 micro second) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

NOTE: If a read access to a NAND flash is done using the wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the [GPMC_CONFIG1_i\[21\]](#) WAITWRITEMONITORING and [GPMC_CONFIG1_i\[22\]](#) WAITREADMONITORING bits to 0, where $i = 0$ to 7), and use one of the following methods instead:

- Use software to poll the WAITnSTATUS bit ($n = 0$ to 3) of the [GPMC_STATUS](#) register.
- Configure an interrupt that is generated on the WAIT signal change (through the [GPMC_IRQENABLE](#) register bits[11:8]).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed WAIT bit in the [GPMC_STATUS](#) register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

15.4.4.13.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the [GPMC_STATUS](#) WAITxSTATUS bit ($x = 0$ or 1). The software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

15.4.4.13.2.2 Ready Pin Monitored by Hardware Interrupt

Each gpmc_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the [GPMC_CONFIG](#) WAITxPINPOLARITY bits ($x = 0$ or 1) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit ($x = 0$ or 3) of the [GPMC_IRQSTATUS](#) register according to the gpmc_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the [GPMC_IRQENABLE](#) register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the [GPMC_IRQSTATUS](#) register is set.

The WAITMONITORINGTIME field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the [GPMC_IRQSTATUS](#) register according to the gpmc_wait pin used for the NAND device ready signal monitoring.

15.4.4.13.3 ECC Calculator

The General Purpose Memory Controller includes an Error Code Correction (ECC) calculator circuitry that enables on the fly ECC calculation during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the [GPMC_ECC_CONFIG\[16\]](#) ECCALGORITHM bit:

1. Hamming code for 1-bit error code correction on 8- or 16-bit NAND Flash organized with page size greater than 512 bytes
2. BCH (Bose-Chaudhuri-Hocquenghem) code for 4- to 16-bit error correction

The GPMC does not directly handle the error code correction itself. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (row and column) bit parity accumulation. This parity accumulation is either accomplished on the programmed number of bytes or 16-bit words read from the memory device, or written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the [GPMC_ECC_CONFIG\[3:1\]](#) ECCCS bit field. Even if two CS use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

15.4.4.13.3.1 Hamming Code

All references to Error Code Correction (ECC) in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a two-dimensional (row and column) bit parity accumulation known as Hamming Code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and it is the software NAND driver responsibility to read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time and parallel computations on different chip-selects are not possible. Since it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. It is the software responsibility to make sure only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is completed.

15.4.4.13.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers ([GPMC_ECCj_RESULT](#), j = 1 to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially; one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The [GPMC_ECCj_RESULT](#) register value is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

The [GPMC_ECC_CONTROL\[3:0\]](#) ECCPOINTER field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The [GPMC_ECCj_RESULT](#) register value (j = 1 to 9) can be considered valid when ECCPOINTER equals j + 1. When [GPMC_ECCj_RESULT](#) (where j = 9) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The [GPMC_ECC_CONTROL\[8\]](#) ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each [GPMC_ECCj_RESULT](#) register, j = 1 to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSISE bits (j = 1 to 9) in the [GPMC_ECC_SIZE_CONFIG](#) register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in [GPMC_ECCj_RESULT](#)).

The ECCSIZE0 and ECCSIZE1 fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2 Kbyte data page 8-bit wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine [GPMC_ECCj_RESULT](#) registers (j= 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1:8]RESULTSISE bits are set to 0, and the ECC9RESULTSISE bit is set to 1.

15.4.4.13.3.1.2 ECC Enabling

The [GPMC_ECC_CONFIG](#)[3:1] ECCCS field selects the allocated chip-select. The [GPMC_ECC_CONFIG](#)[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The ECCPOINTER, ECCCLEAR, ECCSIZE, ECCjRESULTSISE (where j = 1 to 9), ECC16B, and ECCCS fields must not be changed or cleared while an ECC computation is in progress.

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

[Table 15-227](#) describes the ECC enable settings.

Table 15-227. ECC Enable Settings

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0-3	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0/1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0-7	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CONTROL	0-7	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	0x00-0xFF	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	0x00-0xFF	Defines ECCSIZE0
ECCjRESULTSISE (j from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

15.4.4.13.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word 16 streams. The parity accumulation is split into row and column accumulations, as shown in [Figure 15-80](#) and [Figure 15-81](#). The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream

P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream

P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream

P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

Figure 15-80. Hamming Code Accumulation Algorithm (1/2)

gpmc-026

For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

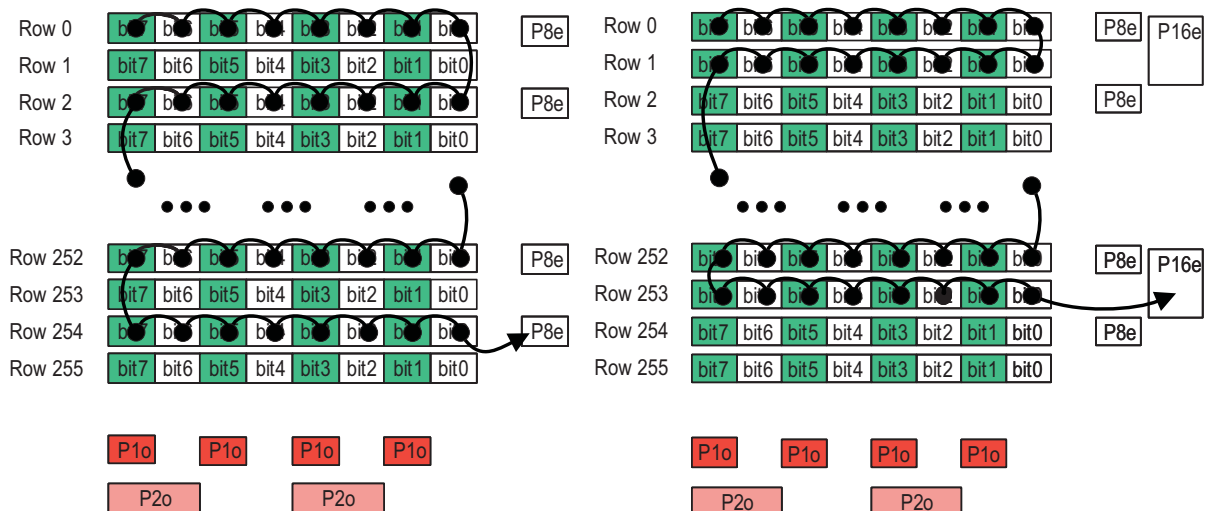

P8e = row0 XOR row2 XOR row4 XOR ... XOR row254

P8o = row1 XOR row3 XOR row5 XOR ... XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253

P16o = row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255

Figure 15-81. Hamming Code Accumulation Algorithm (2/2)

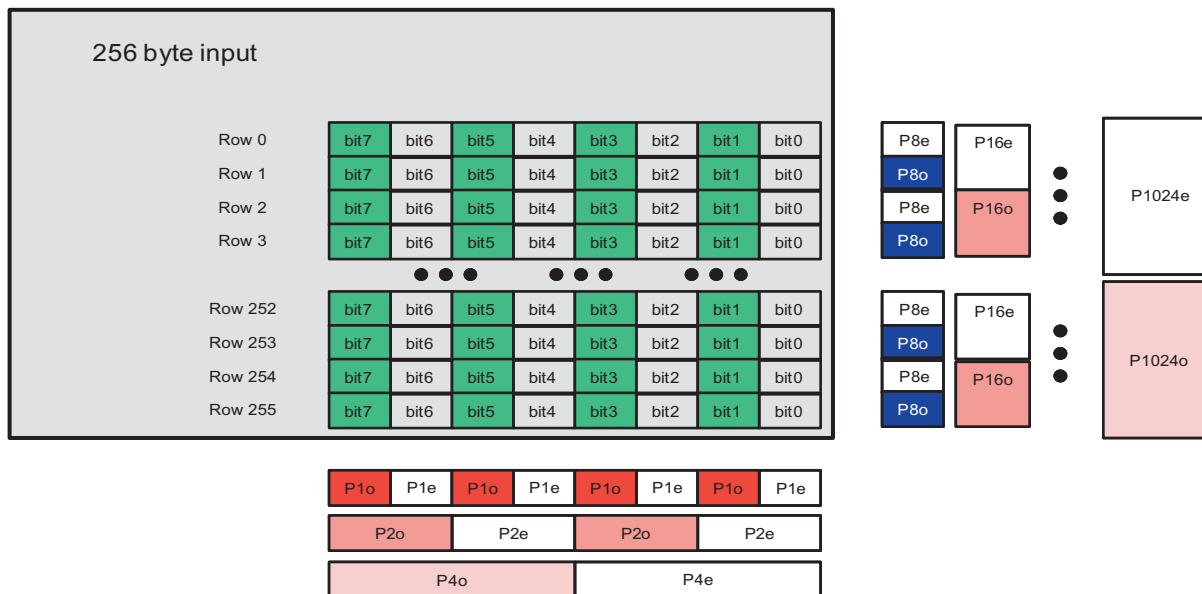

gpmc-027

Unused parity bits in the result registers are set to 0.

Figure 15-82 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

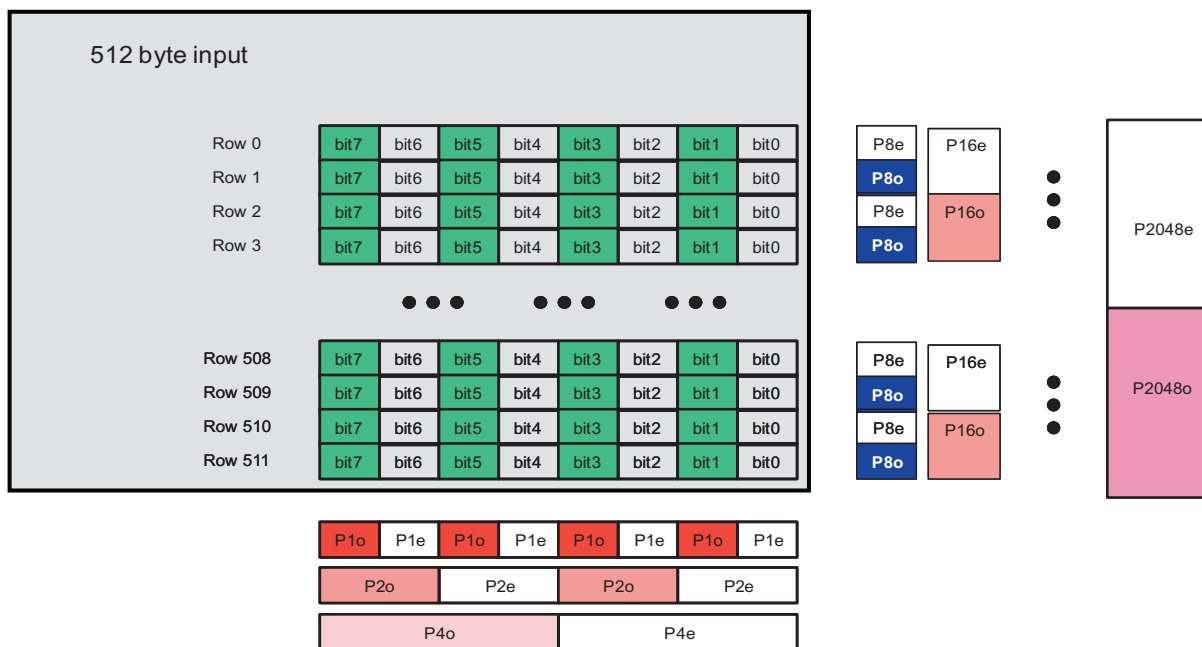

Figure 15-82. ECC Computation for a 256-Byte Data Stream (Read or Write)

gpmc-028

Figure 15-83 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o-P1024o - P2048o for odd parities, and P8e-P16e-P32e-P1024e- P2048e for even parities).

Figure 15-83. ECC Computation for a 512-Byte Data Stream (Read or Write)

gpmc-029

For a 2 Kbytes page, four 512 bytes ECC calculations plus one for the spare area are required. Results are stored in the [GPMC_ECCj_RESULT](#) registers (j = 1 to 9).

15.4.4.13.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, one bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). The software must correct the corresponding bit.
- If only one bit in the parity result is 1, it is an ECC error and the read data is correct.

15.4.4.13.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit based ECC computation is used for 8-bit wide NAND device interfacing.

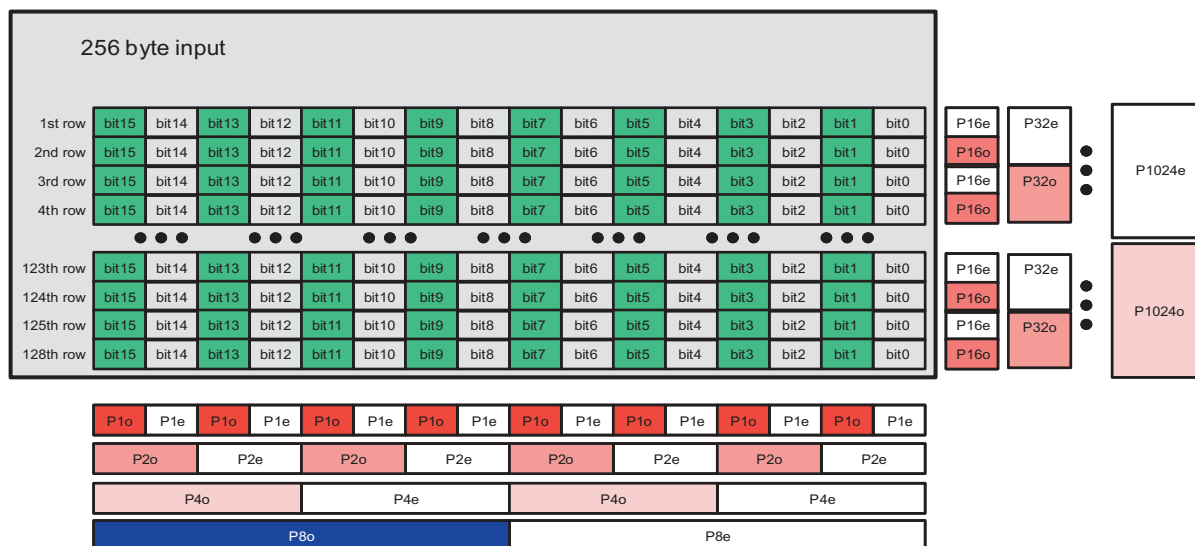

The 8-bit based ECC computation can be used for 16-bit wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit wide NAND devices. In this case, the 16-bit wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the least significant bit (LSB) of the 16-bit wide data is ordered first in the byte stream used for 8-bit based ECC computation.

15.4.4.13.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on a 16-bit word is used for 16-bit wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit wide NAND device, and the [GPMC_ECC_CONFIG\[7\]](#) ECC16B bit must be set to 0 when interfacing an 8-bit wide NAND device.

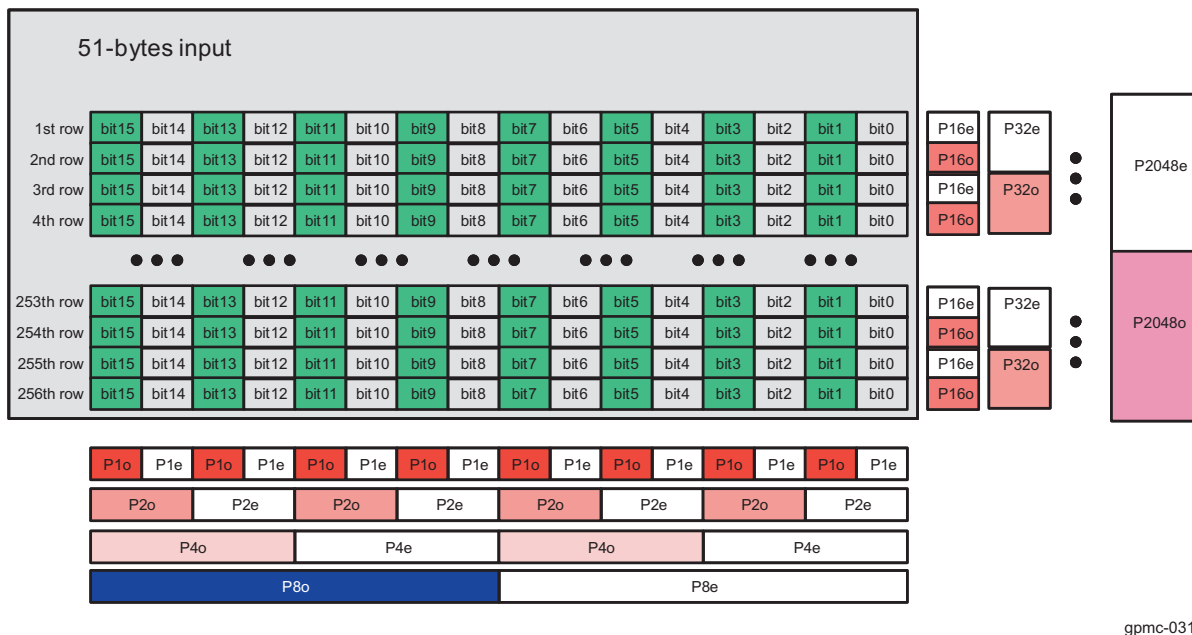

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit based ECC while there are computed on columns for a 16-bit based ECC. [Figure 15-84](#) and [Figure 15-85](#) show a 128 Word 16 ECC computation scheme and a 256 16-bit word ECC computation scheme.

Figure 15-84. 128 Word16 ECC Computation

gpmc-030

Figure 15-85. 256 Word16 ECC Computation

15.4.4.13.3.2 BCH Code (Bose-Chaudhuri-Hocquenghem)

All references to Error Code Correction (ECC) in this subsection refer to the 4- to 16-bit error correction BCH code.

15.4.4.13.3.2.1 Requirements

1. Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, then some spare bytes, including the BCH ECC (and other information). The NAND IC can cache a full page, including spares, for read and write accesses.
Typical page write sequence:
 - Sequential write to NAND cache of main data + spare data, for a page. ECC is calculated on the fly. Calculated ECC may be inserted on the fly in the spares, or replaced by dummy accesses.
 - When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
 - NAND writes its cache line (page) to the array.Typical page read sequence:
 - Sequential read of a page. ECC is calculated on the fly.
 - ECC module buffers status determines the presence of errors.
2. Accesses to several memories may be interleaved by the GPMC, but only one of those memories can be a NAND using the BCH engine at a time; in other words, only one BCH calculation (for example, for a single page) can be on-going at any time. Note also that the sequential nature of NAND accesses guarantees that the data is always written / read out in the same order. BCH-relevant accesses are selected by the GPMCs chip-select.
3. Each page may hold up to 4 Kbytes of data, spare bytes not included. This means up to 8 x 512-byte BCH messages. Since all the data is written / read out first, followed by the BCH ECC, this means that the BCH engine must be able to hold 8 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.
The BCH module has the capacity to store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.
4. NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least 4

cycles of the GPMCs internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least 4 clock cycles after optimization when using the BCH calculator.

5. The spare area is assumed to be large enough to hold the BCH ECC, that is, to have at least a message of 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (maximum codeword is 1023-byte long, ECC included, which leaves a lot of space to cover some spares bytes).

15.4.4.13.3.2.2 Memory-Mapping of the BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message $M(x)$. In our standard case, 512 bytes of data (that is, 2^{12} bits = 4096 bits) are seen as a polynomial of degree $2^{12} - 1 = 4095$, with parameters ranging from M0 to M4095. For 512 bytes of data, 52 bits are required for 4-bit error correction, and 104 bits are required for 8-bit error correction and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial $R(x)$ of degree 103 (or 51, depending on the selected mode). The complete codeword $C(x)$ is the concatenation of $M(x)$ and $R(x)$ as shown in [Table 15-228](#).

Table 15-228. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)

Bit number	Message $M(x)$			ECC $R(x)$		
	M4095	...	M0	R103	...	R0

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message $M(x)$ of degree $((512 + 3) * 8) - 1 = 4119$, for a total of $3+13 = 16$ spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in [GPMC_BCH_RESULT0_i](#), [GPMC_BCH_RESULT1_i](#), [GPMC_BCH_RESULT2_i](#), and [GPMC_BCH_RESULT3_i](#) (where $i = 0$ to 7).

15.4.4.13.3.2.2.1 Memory-Mapping of the Data Message

The data message mapping shall follow the following rules:

- Bit endianness within a byte is little-endian, that is, the bytes LS bit is also the lowest-degree polynomial parameter: a byte $b7-b0$ (with $b0$ the LS bit) represents a segment of polynomial $b7 * x^{(7+i)} + b6 * x^{(6+i)} + \dots + b0 * x^i$
- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the NANDs 16-bit words is big endian. This means that the same message mapped in 8- and 16-bit memories has the same content at the same byte address.

NOTE: The BCH module has no visibility over actual addresses. The most important point is the sequence of data word the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, and this produces the mapping patterns described below.

The following tables represent the mapping of the same 512-byte vector (typically a BCH message) in the NANDs memory space. Note that the byte 'address' is only an offset modulo 512 (0x200), since the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are respectively the bits M0 and $M(2^{12}-1)$ of the codeword mapping given above. In both cases the data vectors are aligned, that is, their boundaries coincide with the RAMs data word boundaries.

Table 15-229. Aligned Message Byte Mapping in 8-bit NAND

Byte offset	8-bit word
0x000	(msb) Byte 511 (0x1FF)
0x001	Byte 510 (0x1FE)
...	...
0x1FF	Byte 0 (0x0) (lsb)

Table 15-230. Aligned Message Byte Mapping in 16-bit NAND

Byte offset	16-bit words MSB	16-bit words LSB
0x000	Byte 510 (0x1FE)	(msb) Byte 511 (0x1FF)
0x002	Byte 508 (0x1FC)	Byte 509 (0x1FD)
...
0x1FE	Byte 0 (0x0)	(lsb) Byte 1 (0x1)

The following tables show the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on another sectors ECC).

Table 15-231. Aligned Nibble Mapping of Message in 8-bit NAND

Byte offset	8-bit word	
	4-bit most significant Nibble	4-bit less significant Nibble
1	(msb) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...
S/2 - 2	Nibble 3	Nibble 2
S/2 - 1	Nibble 1	Nibble 0 (lsb)

Table 15-232. Misaligned Nibble Mapping of Message in 8-bit NAND

...
$(S+3)/2 - 4$	Nibble 2	Nibble 1	Nibble 4	Nibble 3
$(S+3)/2 - 2$			Nibble 0 (lsb)	

Note that many other cases exist than the ones represented above, for example, where the message does not start on a word boundary.

15.4.4.13.3.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. It is up to the software to fetch those 13 bytes (or 6 bytes) from the modules interface, then store them to the NANDs spare area (page write) or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is a softwarecontrolled operation.

However, it is advised to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error as been detected. The creation of this codeword should be made as straightforward as possible.

There are cases where the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on-the-fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on-the-fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

15.4.4.13.3.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections, as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described below. To get a better understanding and see the real-life read and write sequences implemented with each mode, see [Section 15.4.4.13.3.2.3, Supported NAND Page Mappings and ECC Schemes](#).

For each mode:

- a sequence describes the mode in pseudo-language, with for each section the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0 and size1.
- a checksum condition is given. If the checksum condition is not respected for a given mode, the modules behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Note that wrapping modes 8, 9, 10, and 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for $t = 4$ ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

15.4.4.13.3.2.2.4 Manual Mode (0x0)

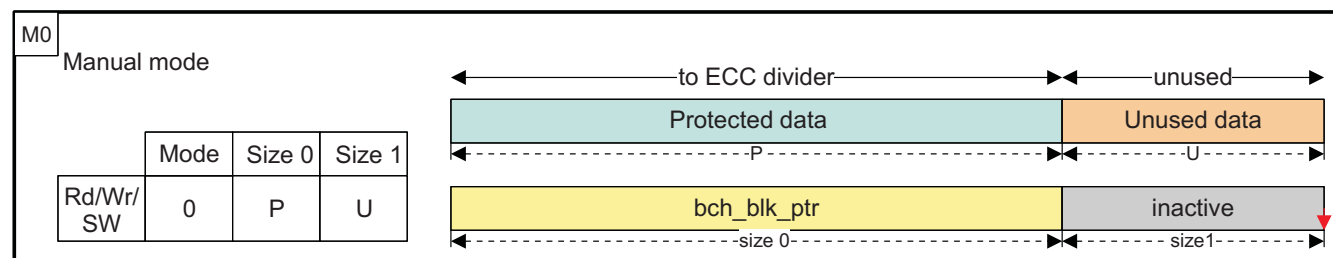

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port must be made, containing the appropriate data. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles need to be skipped, a number of unused nibbles must be programmed in `GPMC_ECC_SIZE_CONFIG[29:22] ECCSIZE1`. (In the same example: 5 nibbles to process + 3 to discard = 8 nibbles = exactly 2 x 16-bit accesses. Software must set:

- `GPMC_ECC_SIZE_CONFIG[19:12] ECCSIZE0 = 0x5`
- `GPMC_ECC_SIZE_CONFIG[29:22] ECCSIZE1 = 0x3`

NOTE: In the following figures size and size0 are the same parameter.

Figure 15-86. Manual Mode Sequence and Mapping

gpmc-032

Section processing sequence:

- One time with buffer
 - size0 nibbles of data, processing ON
 - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

In the following sections, S is the number of sectors in the page.

15.4.4.13.3.2.2.5 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S x (size0 + size1)

15.4.4.13.3.2.2.6 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
 - 1 nibble pad spare, processing OFF

- size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = $S \times (\text{size0} + 1 + \text{size1})$

15.4.4.13.3.2.2.7 Mode 0x2

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = $S \times (\text{size0} + \text{size1})$

15.4.4.13.3.2.2.8 Mode 0x3

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = $\text{size0} + (S \times \text{size1})$

15.4.4.13.3.2.2.9 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = $\text{size0} + (S \times \text{size1})$

15.4.4.13.3.2.2.10 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = $\text{size0} + (S \times (1 + \text{size1}))$

15.4.4.13.3.2.2.11 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
 - One time (no buffer used)
 - size0 nibbles spare, processing OFF
 - Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON
- Checksum: Spare area size (nibbles) = size0 + (S × size1)

15.4.4.13.3.2.2.12 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time (no buffer used)
 - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S × (1+size1))

15.4.4.13.3.2.2.13 Mode 0x5

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S × (size0 + size1)

15.4.4.13.3.2.2.14 Mode 0xB (11)

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S × (size0 + 1 + size1)

15.4.4.13.3.2.2.15 Mode 0x6

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1

- size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
- size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = $S \times (\text{size0} + \text{size1})$

15.4.4.13.3.2.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply throughout the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in [Section 15.4.4.13.3.2.2.1, Memory-Mapping of the Data Message](#).

Each one of the following sections shows a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In [Figure 15-87](#) to [Figure 15-89](#), tables on the left summarize the mode, size0, size1 parameters to program for respectively write and read processing of a page, with the given mapping, where :

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC itself (in nibbles)
- S is the number of Sectors per page (2 in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. Note that the processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1kByte + spares, that is, $S = 2$ sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can only happen in the codeword that was actually written to the NAND, and not in the mathematical codeword of $n = 2^{13} - 1 = 8191$ bits. That codeword (higher-order bits) is all-zero and implicit during computations.

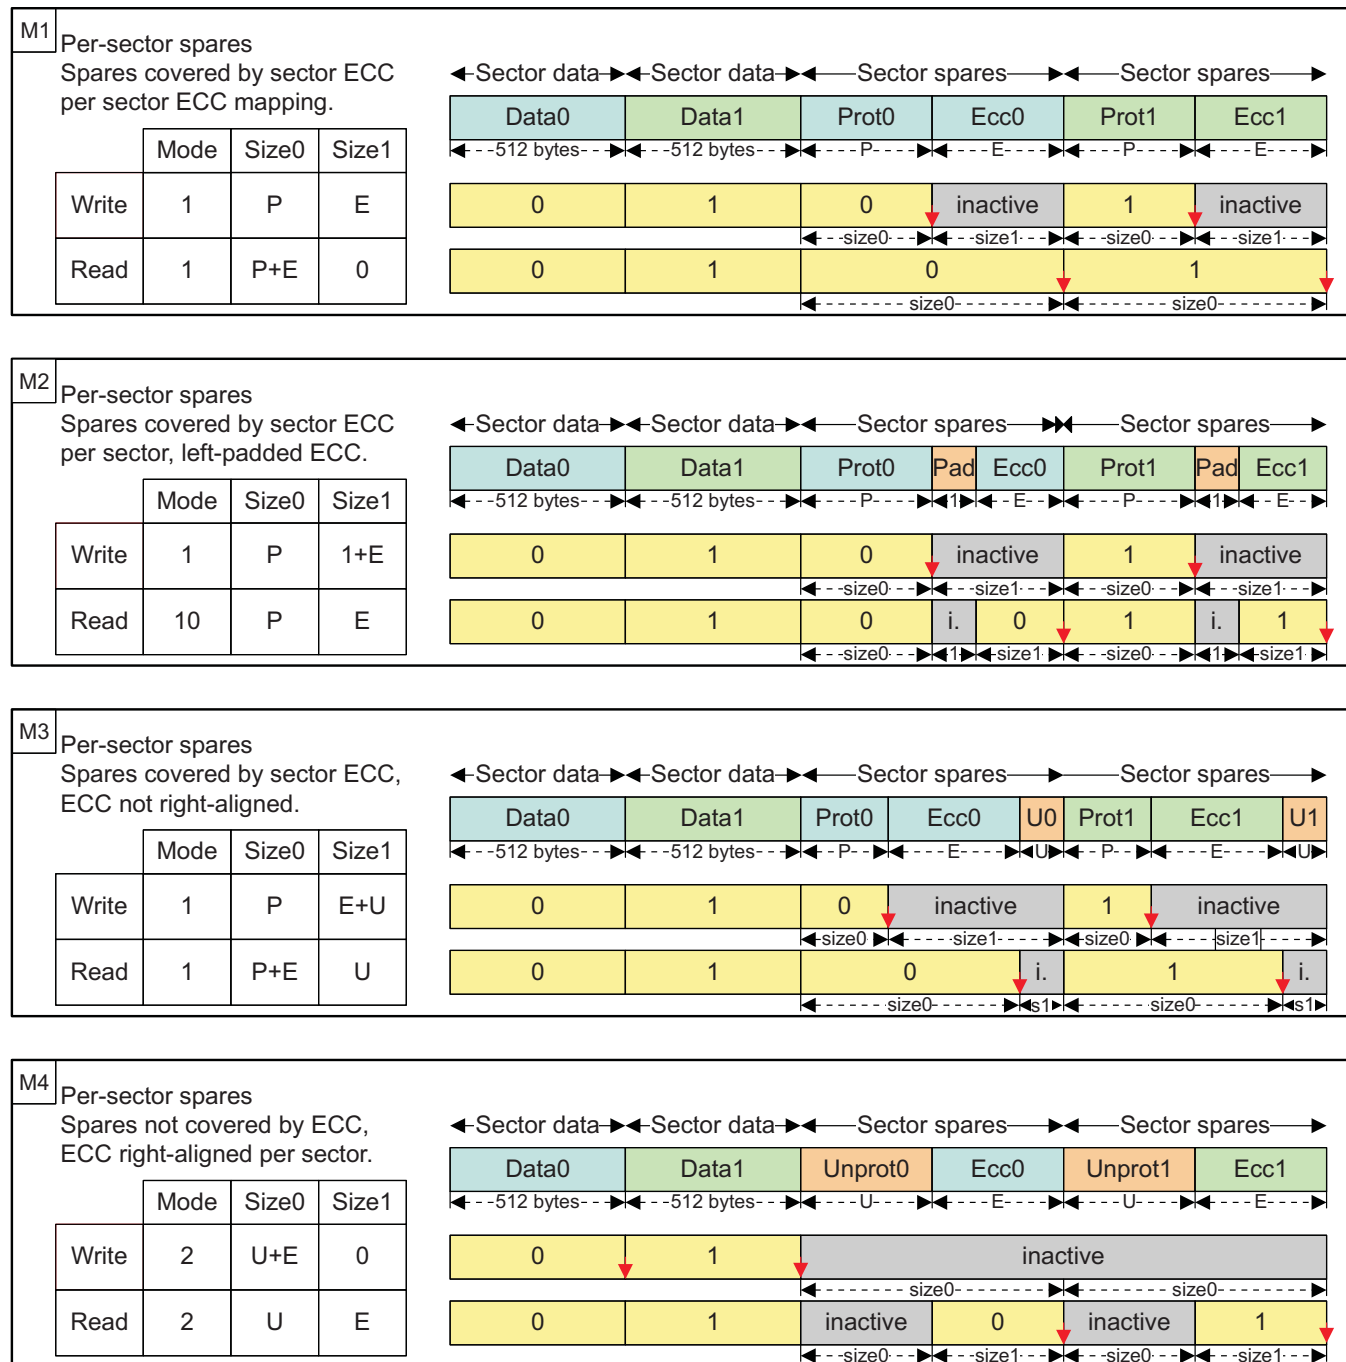

The actual BCH codeword size depends on the mode, on the programmed sizes and on the sector number (all sizes in nibbles):

- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
 - all sectors: $(512) + P + E$
- Spares pooled and protected by sector 0 (below: see M5-M6):
 - sector 0 codeword: $(512) + P + E$
 - other sectors: $(512) + E$
- Unprotected spares (below: see M4-M7-M8-M11-M12):
 - all codewords $(512) + E$

15.4.4.13.3.2.3.1 Per-Sector Spare Mappings

In these schemes, each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of :

- ECC, which must be located after the data it protects
- other data, which may or may not be protected by the sectors ECC

Figure 15-87. NAND Page Mapping and ECC: Per-Sector Schemes

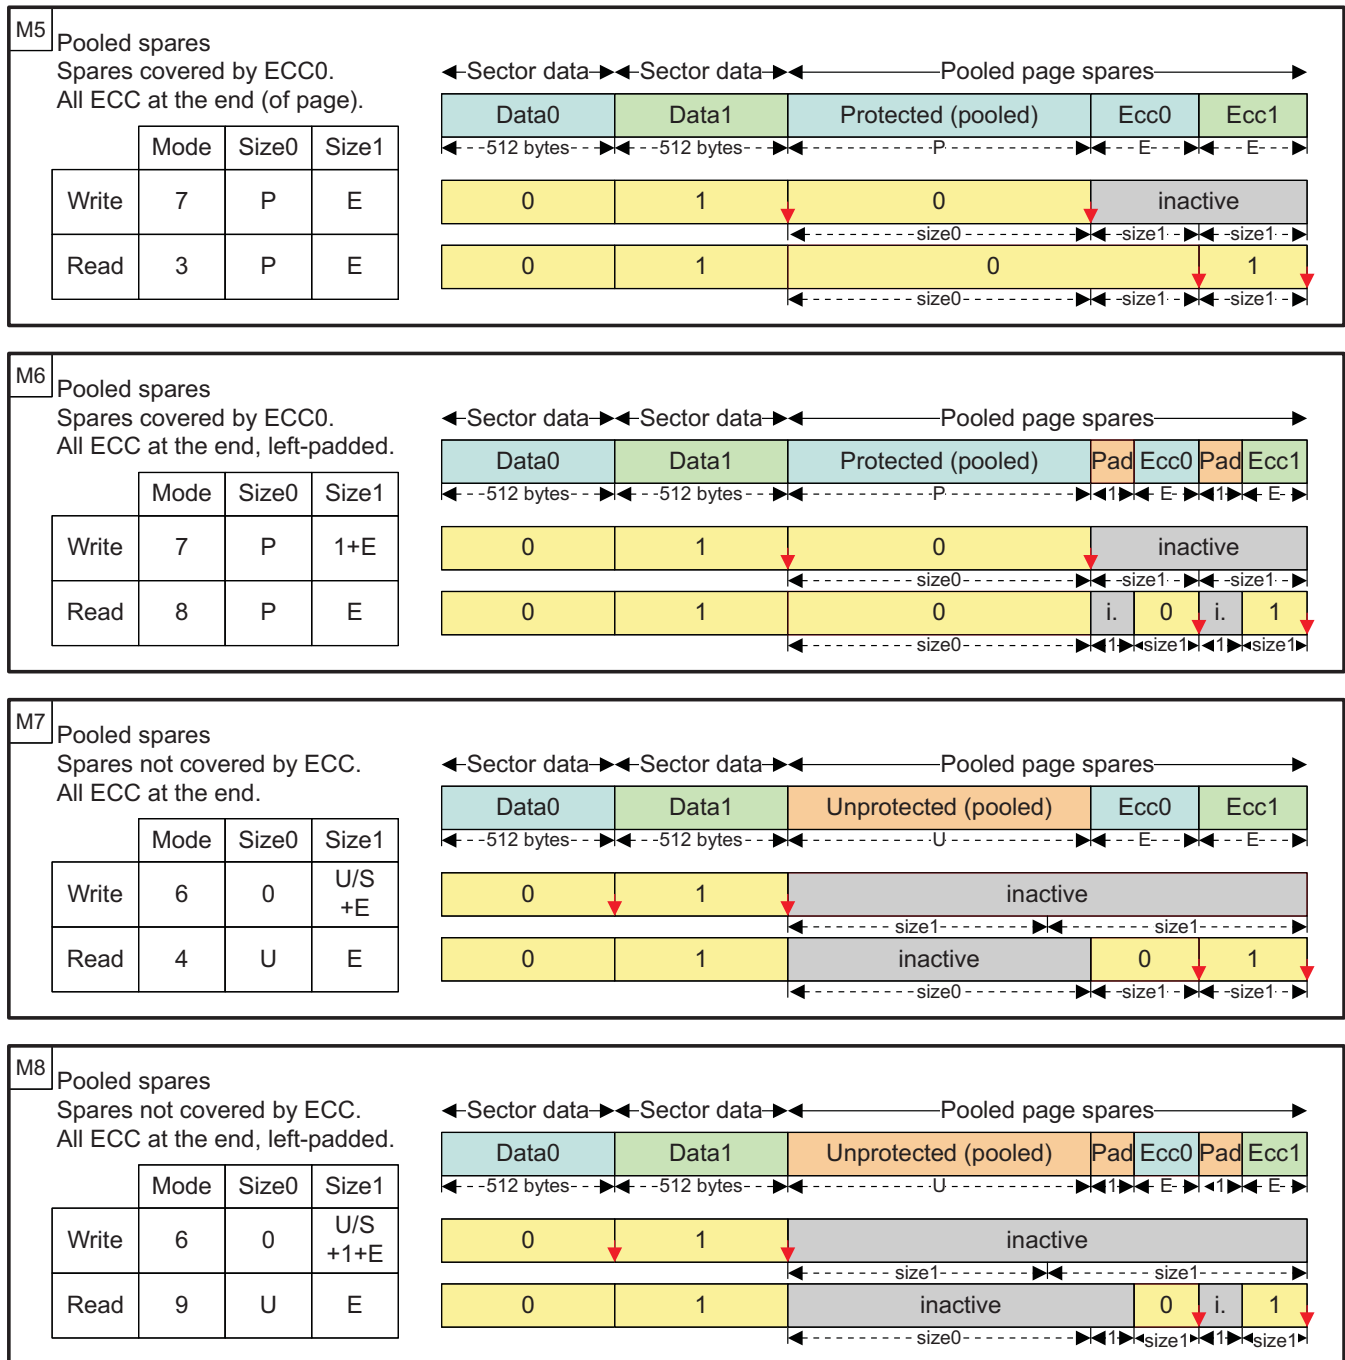

gpmc-033

15.4.4.13.3.2.3.2 Pooled Spare Mapping

In the schemes below, the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.
- The non-ECC spare data may or may not be covered by the ECC of sector 0

Figure 15-88. NAND Page Mapping and ECC: Pooled Spare Schemes

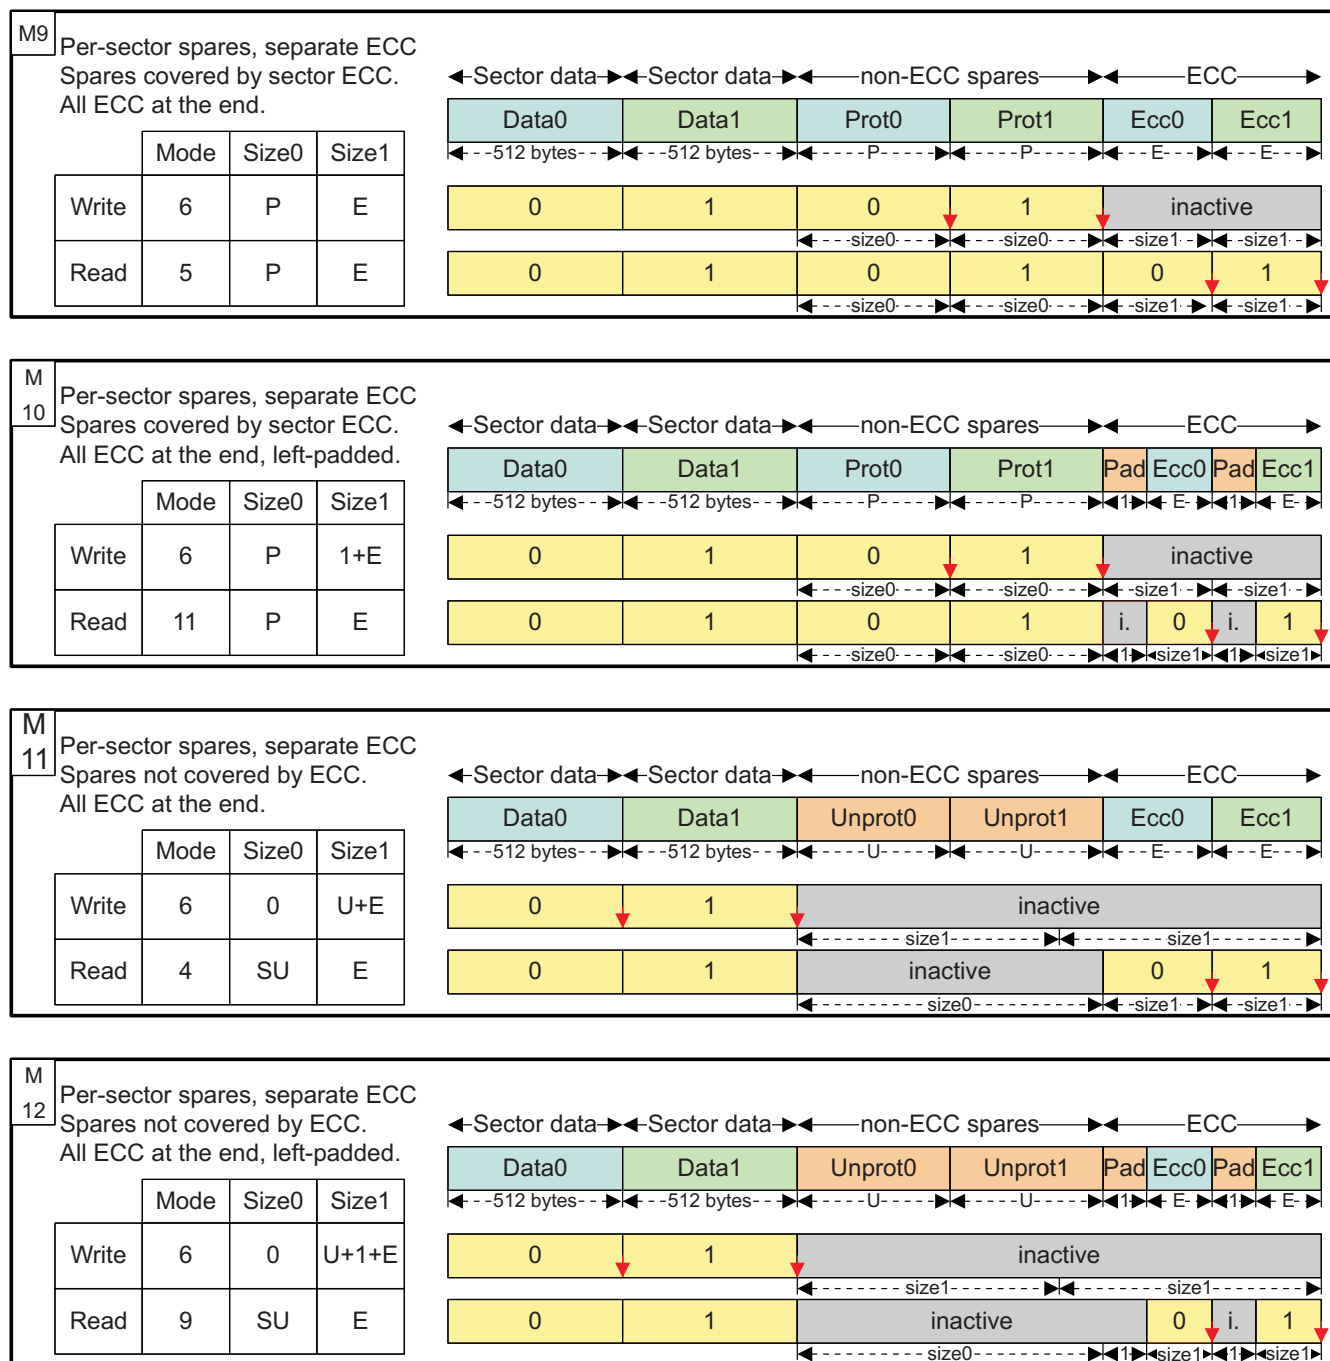

gpmc-034

15.4.4.13.3.2.3.3 Per-Sector Spare Mapping, with ECC Separated at the End of the Page

In these schemes, each 512-byte sector of the main area is associated with 2 sections of the spare area.

- ECC section, all aligned at the end of the page
- other data section, aligned before the ECCs, each of which may or may not be protected by its sectors ECC

Figure 15-89. NAND Page Mapping and ECC: Per-Sector Schemes, with Separate ECC

gpmc_035

15.4.4.13.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the MPU system frequency; such NAND read or write accesses issued by the processor will impact the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the L3 interface; as a default the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64 bytes (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled either by the MPU through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or the sDMA through DMA request synchronization, with a programmable request byte size in both prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. In consequence, it is limited to NAND data-stream access. The engine relies on the MPU NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, the engine data reads and writes sequencing is solely based on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the [GPMC_PREFETCH_CONFIG1\[23\] PFPWENROUNDROBIN](#) bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the [GPMC_PREFETCH_CONFIG1\[19:16\] PFPWWEIGHTEDPRIO](#) field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

NOTE: The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

15.4.4.13.4.1 General Facts About the Engine Configuration

The engine can be configured only if the [GPMC_PREFETCH_CONTROL\[0\] STARTENGINE](#) bit is deasserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the [GPMC_PREFETCH_CONFIG1\[26:24\] ENGINECSSELECTOR](#) field.

In both prefetch and write-posting modes, the engine respectively uses byte or 16-bit word access requests for an 8- or 16-bit-wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT fields must be programmed accordingly as a number of bytes.

When the [GPMC_PREFETCH_CONFIG1\[7\]](#) ENABLEENGINE bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the [GPMC_NAND_COMMAND_i](#), [GPMC_NAND_ADDRESS_i](#), and [GPMC_NAND_DATA_i](#) registers (where i = 0 to 7).

The FIFO entry on the L3 interconnect port can be accessed with byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32 bits wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The [GPMC_PREFETCH_STATUS\[30:24\]](#) FIFOPINTER field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots which can be written in write-posting mode. The [GPMC_PREFETCH_STATUS\[13:0\]](#) COUNTVALUE field monitors the number of remaining bytes to be read or written by the engine according to the TRANSFERCOUNT value. The FIFOPINTER and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPINTER equals 0, that is, the FIFO is empty, a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPINTER equals 0, that is, the FIFO is full, a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

15.4.4.13.4.2 Prefetch Mode

The prefetch mode is selected when the [GPMC_PREFETCH_CONFIG1\[0\]](#) ACCESSMODE bit is cleared.

The MPU NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the [GPMC_PREFETCH_CONTROL\[0\]](#) STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (that is, reset, configured, and enabled) before the prefetch engine is started, so that the ECC is correctly computed on all data read by the prefetch engine.

When the [GPMC_PREFETCH_CONFIG1\[3\]](#) SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it only sets the STARTENGINE bit when the NAND device is in a ready state, meaning data is valid for prefetching.

When the SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active to inactive wait signal transition is detected. The transition detector must be cleared before any transition detection; see [Section 15.4.4.13.2.2, Ready Pin Monitored by Hardware Interrupt](#). The [GPMC_PREFETCH_CONFIG1\[5:4\]](#) WAITPINSELECTOR field selects which gpmc_wait pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit field before NAND address phase completion when in synchronized mode. The prefetch engine will start when an active to inactive wait signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by [GPMC_PREFETCH_CONFIG2\[13:0\]](#) TRANSFERCOUNT field.

Table 15-237. Prefetch Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Prefetch engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active.

Table 15-237. Prefetch Mode Configuration (continued)

Bit Field	Register	Value	Comments
ACCESSMODE	GPMC_PREFETCH_CONFIG1 [0]	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1 [14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2 [13:0]		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1 [3]	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1 [17:16]	0 to 1	Selects wait pin edge detector (if GPMC_PREFETCH_CONFIG1 [3] SYNCHROMODE = 0x1)
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1 [27]	0/1	See Section 15.4.4.13.4.6, Optimizing NAND Access Using the Prefetch and Write-Posting Engine .
CYCLOOPTIMIZATION	GPMC_PREFETCH_CONFIG1 [30:28]		Number of clock cycle removed to timing parameters
ENABLEENGINE	GPMC_PREFETCH_CONFIG1 [7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL [0]	1	Starts the prefetch engine

15.4.4.13.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by the MPU or by an sDMA channel.

In MPU draining mode, the FIFO status can be monitored through the [GPMC_PREFETCH_STATUS](#)[30:24] FIFOPINTER field or through the [GPMC_PREFETCH_STATUS](#)[16] FIFOTHRESHOLDSTATUS bit. The FIFOPINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the [GPMC_IRQENABLE](#)[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the [GPMC_IRQSTATUS](#)[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must read all the available bytes, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the [GPMC_PREFETCH_STATUS](#)[13:0] COUNTVALUE field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the [GPMC_IRQENABLE](#)[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the [GPMC_IRQSTATUS](#)[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is only valid when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the [GPMC_PREFETCH_CONFIG1](#)[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel owning this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

15.4.4.13.4.4 Write-Posting Mode

The write-posting mode is selected when the [GPMC_PREFETCH_CONFIG1](#)[0] ACCESSMODE bit is set.

The MPU NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the [GPMC_PREFETCH_CONFIG1](#)[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are properly calculated on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the [GPMC_PREFETCH_CONFIG1](#)[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed [GPMC_PREFETCH_CONFIG2](#)[13:0] TRANSFERCOUNT accesses have been completed.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must only be issued when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

Table 15-238. Write-Posting Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONFIG1 [0]	0	Write-posting engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1 [26:24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active

Table 15-238. Write-Posting Mode Configuration (continued)

Bit Field	Register	Value	Comments
ACCESSMODE	GPMC_PREFETCH_CONFIG1 [0]	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1 [14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2 [13:0]		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1 [3]	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1 [27]	0/1	See Section 15.4.4.13.4.6, Optimizing NAND Access Using the Prefetch and Write-Posting Engine .
CYCLOOPTIMIZATION	GPMC_PREFETCH_CONFIG1 [30:28]		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1 [7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL [0]	1	Starts the prefetch engine

15.4.4.13.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by the MPU or by an sDMA channel.

In MPU filling mode, the FIFO status can be monitored through the [FIFOPOINTER](#) or through the [GPMC_PREFETCH_STATUS](#)[16] [FIFOTHRESHOLDSTATUS](#) bit. [FIFOPOINTER](#) indicates the current number of available free byte places in the FIFO, and the [FIFOTHRESHOLDSTATUS](#) bit, when set, indicates that at least [FIFOTHRESHOLD](#) free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the [GPMC_IRQENABLE](#)[0] [FIFOEVENTENABLE](#) bit is set. When the interrupt is fired, the [GPMC_IRQSTATUS](#)[0] [FIFOEVENTSTATUS](#) bit is set. To clear the interrupt, the MPU must write enough bytes to fill the FIFO, or enough bytes to get below the programmed threshold, and the [FIFOEVENTSTATUS](#) bit must be cleared to get further interrupt events. The [FIFOEVENTSTATUS](#) bit must always be cleared prior to asserting the [FIFOEVENTENABLE](#) bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the [STARTENGINE](#) bit.

The posting completion can be monitored through the [GPMC_PREFETCH_STATUS](#)[13:0] [COUNTVALUE](#) field. [COUNTVALUE](#) indicates the current number of remaining data to be written based on the [TRANSFERCOUNT](#) value. An interrupt is issued by the GPMC when the write-posting process completes (that is, [COUNTVALUE](#) equal to 0) if the [GPMC_IRQENABLE](#)[1] [TERMINALCOUNTEVENTENABLE](#) bit is set. When the interrupt is fired, the [GPMC_IRQSTATUS](#)[1] [TERMINALCOUNTSTATUS](#) bit is set. To clear the interrupt, the MPU must clear the [TERMINALCOUNTSTATUS](#) bit. The [TERMINALCOUNTSTATUS](#) bit must always be cleared prior to asserting the [TERMINALCOUNTEVENTENABLE](#) bit to clear any out-of-date logged interrupt event.

NOTE: The [COUNTVALUE](#) value is only valid if the write-posting engine is active and started, and an interrupt is only issued when [COUNTVALUE](#) reaches 0, that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the [DMA Mode](#) bit field in the [GPMC_PREFETCH_CONFIG1](#)[2] [DMAMODE](#) bit must be set so that the GPMC issues a DMA hardware request when at least [FIFOTHRESHOLD](#) bytes-free places are available in the FIFO. The DMA channel owning this DMA request must be programmed so that a number of bytes equal to the value programmed in the [FIFOTHRESHOLD](#) bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request has been completed.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, the DMA or the MPU fill the FIFO with no consideration to the associated byte enables. Any byte stored in the FIFO is written into the memory device.

15.4.4.13.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates the CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMEECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and MPU accesses to a NAND memory device (through the defined chip-select memory region or through the [GPMC_NAND_DATA_i](#) location, i = 0 to 7) are never optimized.

The [GPMC_PREFETCH_CONFIG1](#)[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the [GPMC_PREFETCH_CONFIG1](#)[30:28] CYCLEOPTIMIZATION field defines the number of GPMC_FCLK cycles to be suppressed from the RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSOFFTIME, ADVOFFTIME, OEOFFTIME, and WEOFFTIME timing parameters.

[Figure 15-90](#) highlights that, in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMEECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the [GPMC_PREFETCH_CONFIG1](#)[30:28] CYCLEOPTIMIZATION field.

Figure 15-90. NAND Read Cycle Optimization Timing Description

gpmc-036

15.4.4.13.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected to.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the [GPMC_PREFETCH_CONFIG1\[23\] PFPWENROUNDROBIN](#) bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the [GPMC_PREFETCH_CONFIG1\[19:16\] PFPWWEIGHTEDPRIO](#) bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 0x2. Considering the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

15.4.5 GPMC Basic Programming Model

15.4.5.1 GPMC High-Level Programming Model Overview

The goal of the basic high-level programming model is to introduce a top down approach to users that need to configure the GPMC module.

[Figure 15-91](#), [Table 15-239](#), [Table 15-240](#) and [Table 15-241](#) show a programming model top level diagram for the GPMC, and the description of each step. Each block of the diagram is detailed in one of the following subsections through a set of registers to configure.

Figure 15-91. Programming Model Top Level Diagram

gpmc-uc-001

Table 15-239. GPMC Initialization

Step	Description
Enable GPMC clocks	Module interface and functional clocks must be enabled. See Chapter 3, Power, Reset, and Clock Management .
Enable GPMC pads	Module-specific pad muxing and configuration must be set in the control module. See Chapter 18, Control Module .
Reset GPMC	See Table 15-242

Table 15-240. GPMC Configuration in NOR Mode

Step	Description
NOR Memory Type	See Table 15-243
NOR Chip-Select Configuration	See Table 15-244
NOR Timings Configuration	See Table 15-245
Wait Pin Configuration	See Table 15-253
Enable Chip-Select	See Table 15-254

Table 15-241. GPMC Configuration in NAND Mode

Step	Description
NAND Memory Type	See Table 15-248
NAND Chip-Select Configuration	See Table 15-249
Write Operations (Asynchronous)	See Table 15-250
Read Operations (Asynchronous)	See Table 15-250
ECC Engine	See Table 15-251
Prefetch and Write-Posting Engine	See Table 15-252
Wait Pin Configuration	See Table 15-253
Enable Chip-Select	See Table 15-254

15.4.5.2 GPMC Initialization

[Table 15-270](#) describes the settings required to prepare the GPMC, that is enabling its clock, its pads, and proceeding to a GPMC reset.

Table 15-242. Reset GPMC

Sub-process Name	Register / Bit Field	Value
Start a software reset	GPMC_SYSCONFIG [1] SOFTRESET	0x1
Wait until	GPMC_SYSSTATUS [0] RESETDONE =	0x1

15.4.5.3 GPMC Configuration in NOR Mode

This section gives a generic configuration for parameters related to the NOR memory connected to the GPMC.

Table 15-243. NOR Memory Type

Sub-process Name	Register / Bit Field	Value
Set the NOR protocol	GPMC_CONFIG1 _ <i>i</i> [11:10] DEVICETYPE	0x0
Set a device size	GPMC_CONFIG1 _ <i>i</i> [13:12] DEVICESIZE	x
Select an address and data multiplexing protocol	GPMC_CONFIG1 _ <i>i</i> [9] MUXADDDATA	x
Set the attached device page length	GPMC_CONFIG1 _ <i>i</i> [24:23] ATTACHEDDEVICEPAGELENGTH	x
Set the wrapping burst capabilities	GPMC_CONFIG1 _ <i>i</i> [31] WRAPBURST	x

Table 15-243. NOR Memory Type (continued)

Sub-process Name	Register / Bit Field	Value
Select a timing signals latencies factor	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Select an output clock frequency ⁽¹⁾	GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER	x
Choose an output clock activation time ⁽¹⁾	GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME	x
Set a single or multiple access for read operations ⁽¹⁾	GPMC_CONFIG1_i[30] READMULTIPLE	x
Set a synchronous or asynchronous mode for read operations	GPMC_CONFIG1_i[29] READTYPE	x
Set a single or multiple access for write operations	GPMC_CONFIG1_i[28] WRITEMULTIPLE	x
Set a synchronous or asynchronous mode for write operations	GPMC_CONFIG1_i[27] WRITETYPE	x

⁽¹⁾ Only applies to synchronous configurations (or non-multiplexed async for the multiple access one).

Table 15-244. NOR Chip-Select Configuration

Sub-process Name	Register / Bit Field	Value
Select the chip-select base address	GPMC_CONFIG7_i[5:0] BASEADDRESS	x
Select the chip-select mask address	GPMC_CONFIG7_i[11:8] MASKADDRESS	x

Table 15-245. NOR Timings Configuration

Sub-process Name	Register / Bit Field	Value
Configure adequate timing parameters in various memory modes	See Section 15.4.5.6 , <i>GPMC Timing Parameters</i>	

Table 15-246. Wait Pin Configuration

Sub-process Name	Register / Bit Field	Value
Enable or disable wait pin monitoring for read operations	GPMC_CONFIG1_i[22] WAITREADMONITORING	x
Enable or disable wait pin monitoring for write operations	GPMC_CONFIG1_i[21] WAITWRITEMONITORING	x
Select a wait pin monitoring time	GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME	x
Choose the input wait pin for the chip-select	GPMC_CONFIG1_i[17:16] WAITPINSELECT	x

Table 15-247. Enable Chip-Select

Sub-process Name	Register / Bit Field	Value
When all parameters are configured, enable the chip-select	GPMC_CONFIG7_i[6] CSVALID	x

15.4.5.4 GPMC Configuration in NAND Mode

This section gives a generic configuration for parameters related to the NAND memory connected to the GPMC.

Table 15-248. NAND Memory Type

Sub-process Name	Register / Bit Field	Value
Set the NAND protocol	GPMC_CONFIG1_i[11:10] DEVICETYPE	0x2
Set a device size	GPMC_CONFIG1_i[13:12] DEVICESIZE	x
Set the address and data multiplexing protocol to non-multiplexed attached device	GPMC_CONFIG1_i[9] MUXADDDATA	0x0
Select a timing signals latencies factor	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Set a synchronous or asynchronous mode and a single or multiple access for read and write operations	See Section 15.4.5.5 , <i>Set Memory Access</i>	x

Table 15-249. NAND Chip-Select Configuration

Sub-process Name	Register / Bit Field	Value
Select the chip-select base address	GPMC_CONFIG7_i[5:0] BASEADDRESS	x
Select the chip-select minimum granularity (16M bytes)	GPMC_CONFIG7_i[11:8] MASKADDRESS	x

Table 15-250. Asynchronous Read and Write Operations

Sub-process Name	Register / Bit Field	Value
Configure adequate timing parameters in asynchronous modes	See Section 15.4.5.6 , <i>GPMC Timing Parameters</i>	

Table 15-251. ECC Engine

Sub-process Name	Register / Bit Field	Value
Select the ECC result register where the first ECC computation is stored (Only applies to Hamming)	GPMC_ECC_CONTROL[3:0] ECCPOINTER	x ⁽¹⁾
Clear all ECC result registers	GPMC_ECC_CONTROL[8] ECCCLEAR	Write '1' to clear.
Define ECCSIZE0 and ECCSIZE1	GPMC_ECC_SIZE_CONFIG[19:12] ECCSIZE0 and [29:22] ECCSIZE1	x ⁽²⁾
Select the size of each of the 9 result registers (size specified by ECCSIZE0 or ECCSIZE1)	GPMC_ECC_SIZE_CONFIG[j-1] ECCjRESULTSIZ	x
Select the chip-select where ECC is computed	GPMC_ECC_CONFIG[3:1] ECCCS	x
Select the Hamming code or BCH code ECC algorithm in use	GPMC_ECC_CONFIG[16] ECCALGORITHM	x
Select word size for ECC calculation	GPMC_ECC_CONFIG[7] ECC16B	x
If the BCH code is used, Set an error correction capability and Select a number of sectors to process	GPMC_ECC_CONFIG[13:12] ECCBCHTSEL and GPMC_ECC_CONFIG[6:4] ECCTOPSECTOR	x
Enable the ECC computation	GPMC_ECC_CONFIG[0] ECCENABLE	0x1

⁽¹⁾ This parameter depends on the numbers of sectors in a page.

⁽²⁾ Depends on the size of each sector in the NAND page.

Table 15-252. Prefetch and Write-Posting Engine

Sub-process Name	Register / Bit Field	Value
Disable the engine before configuration	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x0
Select the chip-select associated with a NAND device where the prefetch engine is active	GPMC_PREFETCH_CONFIG1[26:24] ENGINECSSELECTOR	x
Select access direction through prefetch engine, read or write.	GPMC_PREFETCH_CONFIG1[0] ACCESSMODE	x
Select the threshold used to issue a DMA request	GPMC_PREFETCH_CONFIG1[14:8] FIFOTHRESHOLD	x
Select either DMA synchronized mode or software manual mode.	GPMC_PREFETCH_CONFIG1[2] DMAMODE	x
Select if the engine immediately starts accessing the memory upon STARTENGINE assertion or if hardware synchronization based on a WAIT signal is used.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which wait pin edge detector should start the engine in synchronized mode	GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR	x
Enter a number of clock cycles removed to timing parameters (For all back-to-back accesses to the NAND flash but not the first one)	GPMC_PREFETCH_CONFIG1[30:28] CYCLOPTIMIZATION	x
Enable the prefetch postwrite engine	GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE	0x1
Select the number of bytes to be read or written by the engine to the selected chip-select	GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT	x
Start the prefetch engine	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x1

Table 15-253. Wait Pin Configuration

Sub-process Name	Register / Bit Field	Value
Selects when the engine starts the access to CS	GPMC_PREFETCH_CONFIG1 [3] SYNCHROMODE	x
Select which wait pin edge detector should start the engine in synchronized mode	GPMC_PREFETCH_CONFIG1 [5:4] WAITPINSELECTOR	x

Table 15-254. Enable Chip-Select

Sub-process Name	Register / Bit Field	Value
When all parameters are configured, enable the chip-select	GPMC_CONFIG7 _[6] CSVALID	x

15.4.5.5 Set Memory Access

This section details the bit field to configure to set the GPMC in various memory modes.

Table 15-255. Mode Parameters Check List Table

Register	Bit	Bit field name	Asynchronous				Synchronous			
			Single Read Access	Single Write Access	Multiple Read (Page) Access	Multiple Write (Page) Access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access
GPMC_CONFIG1_i	30	READMULTIPLE	0x0	-	0x1 ⁽¹⁾	N/S	0x0	-	0x1	-
GPMC_CONFIG1_i	29	READTYPE	0x0	-	0x0 ⁽¹⁾	N/S	0x1	-	0x1	-
GPMC_CONFIG1_i	28	WRITEMULTIPLE	-	0x0	- ⁽¹⁾	N/S	-	0x0	-	0x1
GPMC_CONFIG1_i	27	WRITETYPE	-	0x0	- ⁽¹⁾	N/S	-	0x1	-	0x1

⁽¹⁾ Multiple read is not supported in address/data- and AAD-multiplexed modes. Multiple read is supported in Nonmultiplexed mode.

Table 15-256. Access Type Parameters Check List Table

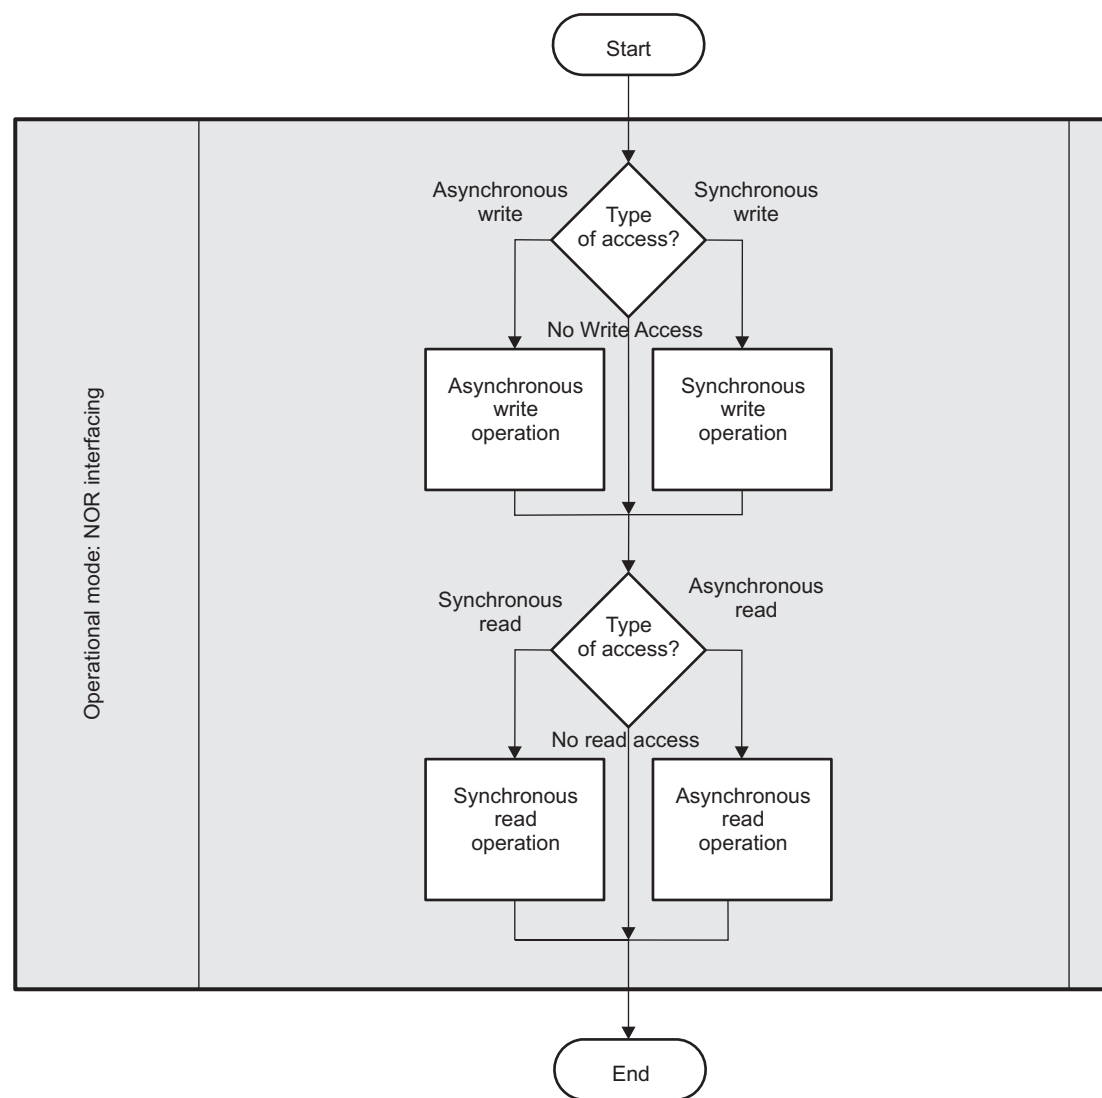

Register	Bit	Bit field name	Access Type		
			Non-mux	Address /Data Mux	AAD-mux
GPMC_CONFIG1_i	9:8	MUXADDDATA	0x0	0x2	0x1
GPMC_CONFIG	1	LIMITEDADDRESS ⁽¹⁾	0x1	0x0	0x0

⁽¹⁾ This parameter applies to all chip-selects. There is no per-CS configuration for this parameter.

15.4.5.6 GPMC Timing Parameters

Figure 15-92 shows a programming model diagram for the NOR interfacing timing parameters.

Figure 15-92. NOR Interfacing Timing Parameters Diagram

gpmc-uc-002

Table 15-257 lists bit fields to configure adequate timing parameter in various memory modes.

Table 15-257. Timing Parameters

Register	Bit	Bit field name	Asynchronous			Synchronous				Access Type		
			Single Read Access	Single Write Access	Multiple Read (Page) access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access	Non-multiplexed	Address/Data-multiplexed	AAD-multiplexed
GPMC_CONFIG1_i	9	MUXADDDATA	y	y	y	y	y	y	y	y	y	y

15.4.5.6.1 GPMC Timing Parameters Formulas

This section intends to help the user to calculate the GPMC timing bit fields values. Formulas are not listed exhaustively.

The section details:

- NAND Flash Interface Timing Parameters Formulas
- Synchronous NOR Flash Timing Parameters Formulas
- Asynchronous NOR Flash Timing Parameters Formulas

15.4.5.6.1.1 NAND Flash Interface Timing Parameters Formulas

This section lists formulas to use in order to calculate NAND timing parameters. This is the case when [GPMC_CONFIG1_i\[11:10\] DEVICETYPE = 0x2](#). [Table 15-258](#) details NAND timing parameters.

Table 15-258. NAND Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - gpmc_nwe valid time
B	ns	Delay time - gpmc_ncs valid to gpmc_nwe valid
C	ns	Delay time - gpmc_nbe0_cle/gpmc_nadv_ale high to gpmc_nwe valid
D	ns	Delay time - gpmc_ad[15:0] valid to gpmc_nwe valid
E	ns	Delay time - gpmc_nwe invalid to gpmc_ad[15:0] invalid
F	ns	Delay time - gpmc_nwe invalid to gpmc_nbe0_cle/gpmc_nadv_ale invalid
G	ns	Delay time - gpmc_nwe invalid to gpmc_ncs invalid
H	ns	Cycle time - Write cycle time
I	ns	Delay time - gpmc_ncs valid to gpmc_noe valid
J	ns	Setup time - gpmc_ad[15:0] valid to gpmc_noe invalid
K	ns	Pulse duration - gpmc_noe valid time
L	ns	Cycle time - Read cycle time
M	ns	Delay time - gpmc_noe invalid to gpmc_ncs invalid

The configuration parameters are calculated through the following formulas.

$$A = (WEOffTime - WEOnTime) * (TimeParaGranularity + 1) * GPMC_FCLK \text{ period}$$

$$B = ((WEOnTime - CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEEExtraDelay - CSEExtraDelay)) * GPMC_FCLK \text{ period}$$

$$C = ((WEOnTime - ADVOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEEExtraDelay - ADVExtraDelay)) * GPMC_FCLK \text{ period}$$

$$D = (WEOnTime * (TimeParaGranularity + 1) + 0.5 * WEEExtraDelay) * GPMC_FCLK \text{ period}$$

$$E = (WrCycleTime - WEOffTime * (TimeParaGranularity + 1) - 0.5 * WEEExtraDelay) * GPMC_FCLK \text{ period}$$

$$F = (ADVWrOffTime - WEOffTime * (TimeParaGranularity + 1) + 0.5 * (ADVExtraDelay - WEEExtraDelay)) * GPMC_FCLK \text{ period}$$

$$G = (CSWrOffTime - WEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSEExtraDelay - WEEExtraDelay)) * GPMC_FCLK \text{ period}$$

$$H = WrCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK \text{ period}$$

$$I = ((OEOnTime - CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (OEEExtraDelay - CSEExtraDelay)) * GPMC_FCLK \text{ period}$$

$$J = ((AccessTime - OEOffTime) * (TimeParaGranularity + 1) - 0.5 * OEEExtraDelay) * GPMC_FCLK \text{ period}$$

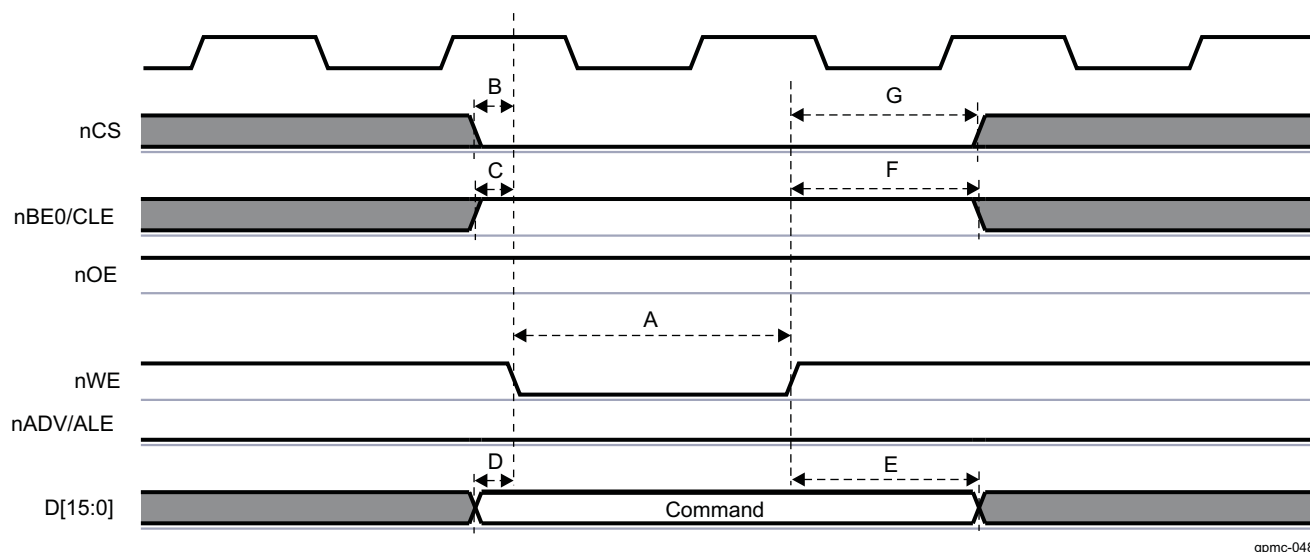

$$K = (OEOffTime - OEOnTime) * (1 + TimeParaGranularity) * GPMC_FCLK \text{ period}$$

$$L = RdCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK \text{ period}$$

$$M = (CSRdOffTime - OEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSEExtraDelay - OEEExtraDelay) * GPMC_FCLK \text{ period}$$

Figure 15-93 shows a command latch cycle timing simplified example where formulas are associated with signal waves.

Figure 15-93. NAND Command Latch Cycle Timing Simplified Example

15.4.5.6.1.2 Synchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to use in order to calculate synchronous NOR timing parameters. This is the case when `GPMC_CONFIG1_[11:10] DEVICETYPE = 0x0` and when `READTYPE` or `WRITETYPE` are set to synchronous mode.

Table 15-259. Synchronous NOR Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - gpmc_ncs low
B	ns	Delay time - address bus valid to gpmc_clk first edge Delay time - gpmc_nbe0_cle/gpmc_nbe1 valid to gpmc_clk first edge
C	ns	Pulse duration - gpmc_nbe0_cle/gpmc_nbe1 low
D	ns	Delay time - gpmc_clk rising edge to gpmc_nbe0_cle/gpmc_nbe1 invalid Delay time - gpmc_clk rising edge to gpmc_nadv_ale invalid
E	ns	Delay time - gpmc_clk rising edge to gpmc_ncs invalid Delay time - gpmc_clk rising edge to gpmc_noe invalid
F	ns	Delay time - gpmc_clk rising edge to gpmc_ncs transition
G	ns	Delay time - gpmc_clk rising edge to gpmc_nadv_ale transition
H	ns	Delay time - gpmc_clk rising edge to gpmc_noe transition
I	ns	Delay time - gpmc_clk rising edge to gpmc_nwe transition
J	ns	Delay time - gpmc_clk rising edge to gpmc_ad data bus transition Delay time - gpmc_clk rising edge to gpmc_nbe0_cle/gpmc_nbe1 transition
K	ns	Pulse duration - gpmc_nadv_ale low
L	ns	Delay time - gpmc_wait invalid to first data latching gpmc_clk edge

The configuration parameters are calculated through the following formulas.

1. For single read accesses:
 $A = (\text{CSRDOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$
 $C = \text{RDCYCLETIME} * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$
 $D = (\text{RDCYCLETIME} - \text{ACCESSTIME}) * \text{GPMC_FCLK period}$
 $E = (\text{CSRDOFFTIME} - \text{ACCESSTIME}) * \text{GPMC_FCLK period}$
2. For burst read accesses (where n is the page burst access number):
 $A = (\text{CSRDOFFTIME} - \text{CSONTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$
 $C = (\text{RDCYCLETIME} + (n - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$
 $D = (\text{RDCYCLETIME} - (\text{ACCESSTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME})) * \text{GPMC_FCLK period}$
 $E = (\text{CSRDOFFTIME} - (\text{ACCESSTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME})) * \text{GPMC_FCLK period}$
3. For burst write accesses (where n is the page burst access number):
 $A = (\text{CSWROFFTIME} - \text{CSONTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$
 $C = (\text{WRCYCLETIME} + (n - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$
 $D = (\text{WRCYCLETIME} - (\text{ACCESSTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME})) * \text{GPMC_FCLK period}$
 $E = (\text{CSWROFFTIME} - (\text{ACCESSTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME})) * \text{GPMC_FCLK period}$
4. For all accesses:
 For nCS falling edge (CS activated):
 - Case where [GPMC_CONFIG1_i\[1:0\]](#) GPMCFCLKDIVIDER = 0x0:
 $F = 0.5 * \text{CSEXTRADELAY} * \text{GPMC_FCLK period}$
 - Case where GPMCFCLKDIVIDER = 0x1:
 $F = 0.5 * \text{CSEXTRADELAY} * \text{GPMC_FCLK period}$, when (CLKACTIVATIONTIME and CSONTIME are odd) or (CLKACTIVATIONTIME and CSONTIME are even)
 $F = (1 + 0.5 * \text{CSEXTRADELAY}) * \text{GPMC_FCLK period}$ otherwise.
 - Case where GPMCFCLKDIVIDER = 0x2:
 $F = 0.5 * \text{CSEXTRADELAY} * \text{GPMC_FCLK period}$, when (CSONTIME - CLKACTIVATIONTIME) is a multiple of 3
 $F = (1 + 0.5 * \text{CSEXTRADELAY}) * \text{GPMC_FCLK period}$, when (CSONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3
 $F = (2 + 0.5 * \text{CSEXTRADELAY}) * \text{GPMC_FCLK period}$, when (CSONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3
 For nCS rising edge (CS deactivated) in reading mode:
 - Case where [GPMC_CONFIG1_i\[1:0\]](#) GPMCFCLKDIVIDER = 0x0:
 $F = 0.5 * \text{CSEXTRADELAY} * \text{GPMC_FCLK period}$
 - Case where GPMCFCLKDIVIDER = 0x1:
 $F = 0.5 * \text{CSEXTRADELAY} * \text{GPMC_FCLK period}$, when (CLKACTIVATIONTIME and CSRDOFFTIME are odd) or (CLKACTIVATIONTIME and CSRDOFFTIME are even)
 $F = (1 + 0.5 * \text{CSEXTRADELAY}) * \text{GPMC_FCLK period}$ otherwise.
 - Case where GPMCFCLKDIVIDER = 0x2:
 $F = 0.5 * \text{CSEXTRADELAY} * \text{GPMC_FCLK period}$, when (CSRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3
 $F = (1 + 0.5 * \text{CSEXTRADELAY}) * \text{GPMC_FCLK period}$, when (CSRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3
 $F = (2 + 0.5 * \text{CSEXTRADELAY}) * \text{GPMC_FCLK period}$, when (CSRDOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3
 For nCS rising edge (CS deactivated) in writing mode:

15.4.5.6.1.3 Asynchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to use in order to calculate asynchronous NOR timing parameters. This is the case when `GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x0` and when `READTYPE` or `WRITETYPE` are set to asynchronous mode.

Table 15-260. Asynchronous NOR Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - gpmc_ncs low
B	ns	Delay time - gpmc_ncs valid to gpmc_nadv_ale invalid
C	ns	Delay time - gpmc_ncs valid to gpmc_noe invalid (single read)
D	ns	Pulse duration - address bus valid - 2nd, 3rd and 4th accesses
E	ns	Delay time - gpmc_ncs valid to gpmc_nwe valid
F	ns	Delay time - gpmc_ncs valid to gpmc_nwe invalid
G	ns	Address invalid duration between 2 successive R/W accesses
H	ns	Setup time - read data valid before gpmc_noe high
I	ns	Delay time - gpmc_ncs valid to gpmc_noe invalid (burst read)
J	ns	Delay time - address bus valid to gpmc_ncs valid
		Delay time - data bus valid to gpmc_ncs valid
		Delay time - gpmc_nbe0_cle/gpmc_nbe1 valid to gpmc_ncs valid
K	ns	Delay time - gpmc_ncs valid to gpmc_nadv_ale valid

Table 15-260. Asynchronous NOR Formulas Description Table (continued)

Configuration Parameter	Unit	Description
L	ns	Delay time - gpmc_ncs valid to gpmc_noe valid
M	ns	Delay time - gpmc_ncs valid to first data latching edge
N	ns	Pulse duration - gpmc_nbe0_cle/gpmc_nbe1 valid time
O	ns	Delay time - gpmc_ncs valid to gpmc_nadv_ale valid

The configuration parameters are calculated through the following formulas. Note that these formulas are not exhaustive.

- gpmc_ncs low pulse:
For single read: $A = (\text{CSRDOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$
For burst read: $A = (\text{CSRDOFFTIME} - \text{CSONTIME} + (N - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$, where N = page burst access number
For single write: $A = (\text{CSWROFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$
For burst write: $A = (\text{CSWROFFTIME} - \text{CSONTIME} + (N - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$, where N = page burst access number
- gpmc_ncs valid to gpmc_nadv_ale invalid delay:
For reading: $B = ((\text{ADVRDOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
For writing: $B = ((\text{ADVWROFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $C = ((\text{OE OFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{OEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $D = \text{PAGEBURSTACCESSTIME} * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$
- $E = ((\text{WEONTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{WEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $F = ((\text{WEOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{WEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $G = \text{CYCLE2CYCLEDELAY} * \text{GPMC_FCLK period}$
- $H = ((\text{OE OFFTIME} - \text{ACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * \text{OEEXTRADELAY}) * \text{GPMC_FCLK period}$
- $I = ((\text{OE OFFTIME} + (N - 1) * \text{PAGEBURSTACCESSTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{OEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$, where N = page burst access number
- $J = (\text{CSONTIME} * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * \text{CSEXTRADELAY}) * \text{GPMC_FCLK period}$
- $K = ((\text{ADVONTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $L = ((\text{OEONTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{OEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $M = ((\text{ACCESSTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) - 0.5 * \text{CSEXTRADELAY}) * \text{GPMC_FCLK period}$
- gpmc_nbe0_cle/gpmc_nbe1 pulse:
For single read: $N = \text{RDCYCLETIME} * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$
For burst read: $N = (\text{RDCYCLETIME} + (N - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$, where N = page burst access number
For burst write: $N = (\text{WRCYCLETIME} + (N - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$, where N = page burst access number
- $O = ((\text{WRCYCLETIME} + (N - 1) * \text{PAGEBURSTACCESSTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$

Figure 15-95 shows an asynchronous NOR single write simplified example where formulas are associated with signal waves.

Figure 15-95. Asynchronous NOR Single Write Simplified Example

NOTE: Write multiple access is not supported in asynchronous mode. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

15.4.6 GPMC Use Cases And Tips

15.4.6.1 How to Set GPMC Timing Parameters for Typical Accesses

15.4.6.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8-bit or 16-bit-width memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples show how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104 MHz clock frequency
- Read access time: 80 ns

15.4.6.1.2 Typical GPMC Setup

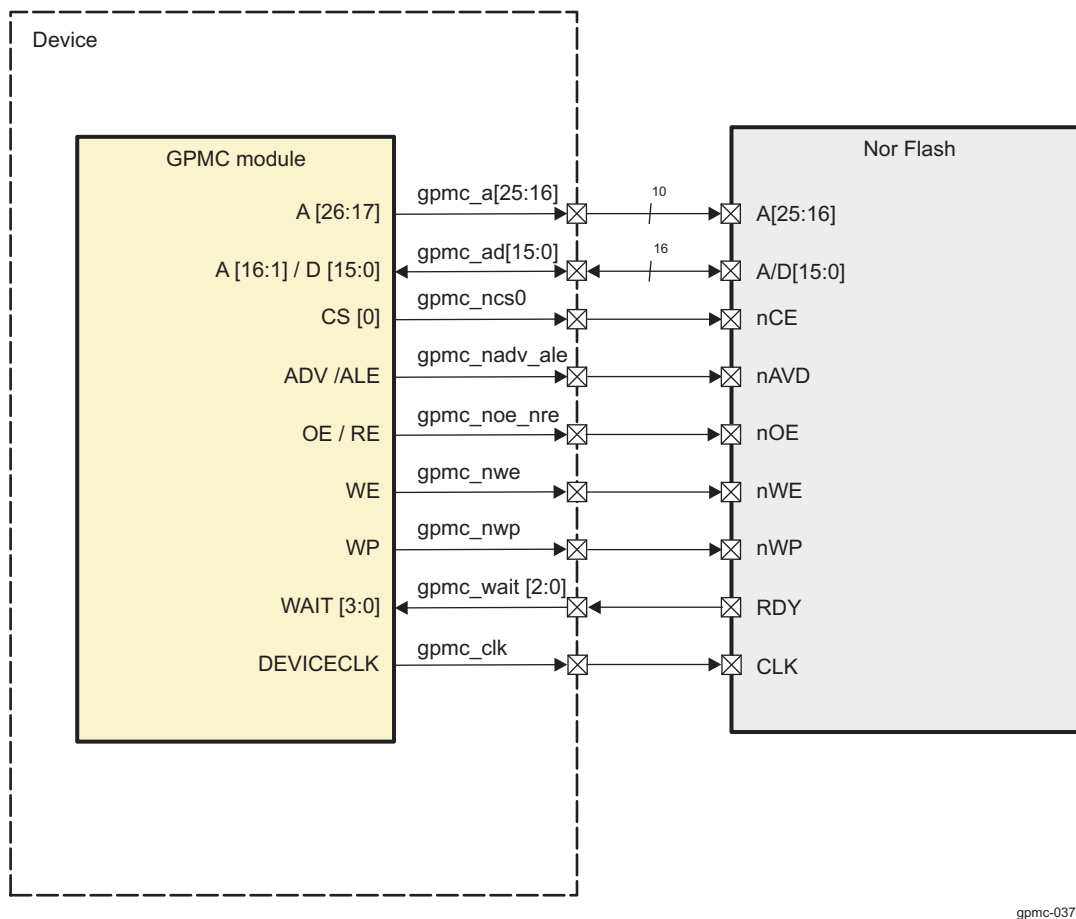

[Table 15-261](#) lists some of the I/Os of the GPMC module.

Table 15-261. GPMC Signals

Signal Name	I/O	Description
GPMC_FCLK	Internal	Functional and interface clock. Acts as the time reference.
gpmc_clk	O	External clock provided to the external device for synchronous operations
gpmc_a[25:16]	O	Address
gpmc_ad[15: 0]	I/O	Data-multiplexed with addresses A[16:1] on memory side
gpmc_ncsx	O	Chip-select (where x = 0, or 1)
gpmc_nadv_ale	O	Address valid enable
gpmc_noe_nre	O	Output enable (read access only)
gpmc_nwe	O	Write enable (write access only)
gpmc_wait[2:0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

Figure 15-96 shows the typical connection between the GPMC module and an attached NOR Flash memory.

Figure 15-96. GPMC Connection to an External NOR Flash Memory

gpmc-037

The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

15.4.6.1.2.1 GPMC Configuration for Synchronous Burst Read Access

The clock runs at 104 MHz ($f = 104 \text{ MHz}$; $T = 9,615 \text{ ns}$).

Table 15-262 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 15-263 shows how to calculate timings for the GPMC using the memory parameters.

Figure 15-97 shows the synchronous burst read access.

Table 15-262. Useful Timing Parameters on the Memory Side

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	nCS setup time to clock	0
tACS	Address setup time to clock	3
tlACC	Synchronous access time	80

Table 15-262. Useful Timing Parameters on the Memory Side (continued)

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tBACC	Burst access time valid clock to output delay	5,2
tCEZ	Chip-select to High-Z	7
tOEZ	Output enable to High-Z	7
tAVC	nADV setup time	6
tAVD	nAVD pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read Access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle ($T = 9,615$ ns). The read access time between 2 bursts of data is $tBACC = 5,2$ ns. Therefore, data setup time is a clock period - $tBACC = 4,415$ ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read Access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

Table 15-263. Calculating GPMC Timing Parameters

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
GPMC FCLK Divider	-	-	-	GPMCFCLKDIVIDER = 0x0
ClkActivationTime	$\min(tCES, tACS)$	3	1	CLKACTIVATIONTIME = 0x1
RdAccessTime	$\text{roundmax}(\text{ClkActivationTime} + tIACC + \text{DataSetupTime})$	94,03: (9,615 + 80 + 4,415)	10 : $\text{roundmax}(94,03 / 9,615)$	ACCESSTIME = 0x0A
PageBurstAccessTime	$\text{roundmax}(tBACC)$	$\text{roundmax}(5,2)$	1	PAGEBURSTACCESSTIME = 0x1
RdCycleTime	$\text{AccessTime} + \max(tCEZ, tOEZ)$	101, 03: (94, 03 + 7)	11	RDCYCLETIME = 0x0B
CsOnTime	tCES	0	0	CSONTIME = 0x0
CsReadOffTime	RdCycleTime	-	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAVC ⁽¹⁾	0	0	ADVONTIME = 0x0
AdvRdOffTime	tAVD + tAVC ⁽²⁾	12	2	ADVRDOFFTIME = 0x02
OeOnTime ⁽³⁾	$(\text{ClkActivationTime} + tACH) < \text{OeOnTime}(\text{ClkActivationTime} + tIACC)$	-	3 for instance.	OEONTIME = 0x3
OeOffTime	RdCycleTime	-	11	OEOFFTIME = 0x0B

⁽¹⁾ The external clock provided to the NOR flash is not yet available.

⁽²⁾ $\text{AdvRdOffTime} - \text{AdvOnTime} = \text{tAVD}$; thus, $\text{AdvRdOffTime} = \text{tAVD} + \text{AdvOnTime} = \text{tAVD} + \text{tAVC}$.

⁽³⁾ OeOnTime must guarantee that addresses are available. It must not exceed the availability of the first burst of data.

Figure 15-97. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)**15.4.6.1.2.2 GPMC Configuration for Asynchronous Read Access**

The clock runs at 104 MHz ($f = 104 \text{ MHz}$; $T = 9,615 \text{ ns}$).

[Table 15-264](#) shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

[Table 15-265](#) shows how to calculate timings for the GPMC using the memory parameters.

[Figure 15-98](#) shows the asynchronous read access.

Table 15-264. AC Characteristics for Asynchronous Read Access

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from nCS low	80
tAAVDS	Address setup time to rising edge of nADV	3
tAVDP	nADV low time	6
tCAS	nCS setup time to nADV	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Z	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

$$\text{RdCycleTime} = \text{RdAccessTime} + \text{AccessCompletion} = \text{RdAccessTime} + 1 \text{ clock cycle} + \text{tOEZ}$$

- First, on the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in [Table 15-264](#): the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus.

The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.

- To read the data correctly, the GPMC must be configured to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
- There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS

deassertion while reading the data). This data hold time is 1 clock cycle (that is, AccessTime + 1).

- To complete the access, nOE/nCS signals are driven to High-Z. AccessTime + 1 + tOEZ is the read cycle time.
- Addresses can now be relatched and a new read cycle begun.

Table 15-265. GPMC Timing Parameters for Asynchronous Read Access

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime		n/a (asynchronous mode)		
AccessTime	round max (tCE)	80	10	ACCESSTIME = 0x0A
PageBurstAccess Time	n/a (single access)			
RdCycleTime	AccessTime + 1cycle + tOEZ	96, 615	12	RDCYCLETIME = 0x0C
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsReadOffTime	AccessTime + 1 cycle	89, 615	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAAVDS	3	1	ADVONTIME = 0x1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 0x01
OeOnTime	OeOnTime >= AdvRdOffTime (multiplexed mode)	-	3 for instance	OEONTIME = 0x3
OeOffTime	AccessTime + 1cycle	89, 615	11	OEOFFTIME = 0x0B

Figure 15-98. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)

gpmc-039

15.4.6.1.2.3 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9, 615 ns).

Table 15-267 shows how to calculate timings for the GPMC using the memory parameters.

Table 15-266 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 15-99 shows the synchronous burst write access.

Table 15-266. AC Characteristics for Asynchronous Single Write (Memory Side)

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60
tAVDP	nADV low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	nCS setup time to nWE	3
tCAS	nCS setup time to nADV	0
tAVSC	nADV setup time	3

For asynchronous single write access, write cycle time is $WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1$. For the AccessCompletion, the GPMC requires 1 cycle of data hold time (nCS deassertion).

Table 15-267. GPMC Timing parameters for Asynchronous Single Write

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Registers Configuration
ClkActivationTime		n/a (asynchronous mode)		
AccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime		n/a (single access)		
WrCycleTime	WeOffTime + AccessCompletion	57, 615	6	WRCYCLETIME = 0x06
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsWrOffTime	WeOffTime + 1	57, 615	6	CSWROFFTIME = 0x06
AdvOnTime	tAVSC	3	1	ADVONTIME = 0x1
AdvWrOffTime	tAVSC + tAVDP	9	1	ADVWROFFTIME = 0x01
WeOnTime	tCS	3	1	WEONTIME = 0x1
WeOffTime	tCS + tWP + tWPH	48	5	WEOFFTIME = 0x05

gpmc-040

15.4.6.2 How to choose a suitable memory to use with the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

15.4.6.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or device, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit width asynchronous or synchronous memory or device (8-bit: non burst device only)
- 16-bit address and data multiplexed NOR flash devices (pSRAM, OneNAND™, ...)
- 8- and 16-bit NAND flash device

NOTE: Non-multiplexed NOR flash devices are supported by the GPMC but their usage is highly limited. As only ten address pins are available on the GPMC interface, the maximum device size supported is 2KB.

15.4.6.2.1.1 Memory Pin Multiplexing

This section highlights the interfacing differences of the GPMC supported memories.

Table 15-268. Supported memories interfaces

Function	16-bit Address/Data muxed pSRAM or NOR Flash ⁽¹⁾	OneNAND	16-bit NAND	8-bit NAND

15.4.6.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device, that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Thanks to its high density NAND is best suited to devices requiring high capacity data storage, such as pictures, music, or data files. NAND non-volatility, makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 15-269 summarizes the NAND interface signals level applied to external device or memories.

Table 15-269. NAND Interface Bus Operations Summary

Bus operation	CLE	ALE	nCE	nWE ⁽¹⁾	nRE ⁽¹⁾	nWP
Read (cmd input)	H	L	L	RE	H	x
Read (add input)	L	H	L	RE	H	x
Write (cmd input)	H	L	L	RE	H	H
Write (add input)	L	H	L	RE	H	H
Data input	L	L	L	RE	H	H
Data output	L	L	L	H	FE	x
Busy (during read)	x	x	H ⁽²⁾	H ⁽²⁾	H ⁽²⁾	x
Busy (during program)	x	x	x	x	x	H
Busy (during erase)	x	x	x	x	x	H
Write protect	x	x	x	x	x	L
Stand-by	x	x	H	x	x	H/L ⁽³⁾

⁽¹⁾ RE stands for rising edge, FE stands for falling edge

⁽²⁾ Can be either nCE high, or WE and nRE high.

⁽³⁾ nWP should be biased to CMOS high or CMOS low for standby

15.4.6.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND which is a sequential access device, NOR is directly addressable, that is, is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities it has slow write and erase functions compared to NAND architecture.

Table 15-270 summarizes the NOR interface signals level applied to external device or memories.

Table 15-270. NOR Interface Bus Operations Summary

Bus operation	CLK	nADV	nCS	nOE	nWE	WAIT	DQ[15:0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

15.4.6.2.1.4 Other Technologies

Other supported device type interact with the GPMC through the NOR interface protocol.

OneNAND™ is a high density and low-power memory device. OneNAND™ is based on single- or multi-level-cell NAND core with SRAM and logic, and interfaces as a synchronous NOR Flash, plus has synchronous write capability. It reads faster than conventional NAND and write faster than conventional NOR flash. Hence, it is appropriate for both mass storage and code storage.

pSRAM stands for pseudo-static random access memory. pSRAM is a low-power memory device for mobile applications. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR Flash, plus has synchronous write capability.

15.4.6.2.1.5 Supported Protocols

The GPMC supports the following interface protocols when communicating with external memory or external devices:

- Asynchronous read/write access
- Asynchronous read page access (4-8-16 Word16)
- Synchronous read/write access
- Synchronous read burst access without wrap capability (4-8-16 Word16)
- Synchronous read burst access with wrap capability (4-8-16 Word16)

15.4.6.2.2 GPMC Features and Settings

This section lists GPMC features and settings:

- Supported device type: up to four NAND or NOR protocol external memories or devices
- Operating Voltage: 1.8V;
- Maximum GPMC addressing capability: 1 GByte divided into eight chip-selects
- Maximum supported memory size: 256 MBytes (must be a power-of-2)
- Minimum supported memory size: 16 MBytes (must be a power-of-2). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8- and 16-bit wide
- Burst and page access: burst of 4-8-16 Word16
- Supports bus keeping
- Supports bus turn around

15.4.7 GPMC Register Manual

This section provides information about the GPMC instance in this product. [Table 15-272](#) provides a summary of the GPMC registers. The remaining parts of this section describe the registers within the module instance.

15.4.7.1 GPMC Register Summary

15.4.7.2 GPMC Register Descriptions

NOTE: All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except to [GPMC_NAND_DATA_i](#) register, are little endian. If the [GPMC_NAND_DATA_i](#) register location is accessed, the endianness is access-dependent.

In the whole section i corresponds to the chip-select number, i = 0 to 7.

15.5 Error Location Module

15.5.1 Error Location Module Overview

Non-managed NAND flash memories can be dense and nonvolatile in their own nature, but error-prone. When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as *bare NANDs*, the correction process is delegated to the memory controller.

The general-purpose memory controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-Chaudhuri-Hocquenghem (BCH) algorithm. The error-location module (ELM) extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM relies on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as *uncorrectable* in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

When the error-location process completes, an interrupt is triggered to inform the central processing unit (CPU) that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

15.5.1.1 ELM Features

The ELM has the following features:

- 4, 8, and 16 bits per 512-byte block error-location based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
 - When the full page has been processed in page mode
 - For each syndrome polynomial in continuous mode

15.5.2 ELM Integration

The ELM extracts error addresses from generated syndrome polynomials.

The ELM is used with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND flash page and stored in GPMC registers are passed to the ELM. The microprocessor unit (MPU) can then correct the data block by flipping the bits to which the ELM error-location outputs point.

Figure 15-100 shows the integration of the ELM subsystem in the device.

Figure 15-100. ELM Integration

Table 15-345. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect

Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
ELM	ELM_RST	L4_PER_RST	PRCM	Power domain hardware reset For information about PRCM reset sources and distribution, see Section 3.5.4, Reset Domains in Chapter 3, Power, Reset, and Clock Management .

Table 15-347. Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
ELM	ELM_IRQ	MA_IRQ_4	Cortex-A9	BCH error-location module interrupt For information about Cortex-A9 interrupt control, see Section 17.3.2, Interrupt Requests to Cortex-A9 MPU INTC .
		D_IRQ_26	DSP	BCH error-location module interrupt For information about DSP interrupt control, see Interrupts Requests .

15.5.3 ELM Functional Description

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

15.5.3.1 ELM Software Reset

To perform a software reset, write a 1 to the [ELM_SYSCONFIG\[1\] SOFTRESET](#) bit. The [ELM_SYSSTATUS\[0\] RESETDONE](#) bit indicates that the software reset is complete when its value is 1. When the software reset completes, the [ELM_SYSCONFIG\[1\] SOFTRESET](#) bit is automatically reset.

15.5.3.2 ELM Power Management

[Table 15-348](#) describes the power-management features available to the ELM module.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see the [Section 3.6.8, CD_L4_PER Clock Domain](#) in [Chapter 3, Power, Reset, and Clock Management](#).
- For a general description of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.6 Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#)

Table 15-348. Local Power Management Features

Feature	Registers	Description
Clock autogating	ELM_SYSCONFIG [0] AUTOGATING bit	This bit allows a local power optimization inside the module by gating the ELM_FCLK clock upon the interface activity.
Slave idle modes	ELM_SYSCONFIG [4:3] SIDLEMODE bit field	Force-idle, No-idle, and Smart-idle modes are available.
Clock activity	ELM_SYSCONFIG [8] CLOCKACTIVITY bit	The clock can be switched-off or maintained during the wake-up period.
Master Standby modes	N/A	
Global Wake-up Enable	N/A	
Wake-up Sources Enable	N/A	

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the ELM CLOCKACTIVITY and ELM clock PRCM control bits. For a description of the ClockActivity feature, see [Chapter 3, Power, Reset, and Clock Management](#).

15.5.3.3 ELM Interrupt Requests

[Table 15-349](#) lists the event flags, and their masks, that can cause module interrupts.

Table 15-349. Events

Event Flag	Event Mask	Map to	Description
ELM_IRQSTATUS [8] PAGE_VALID	ELM_IRQENABLE [8] PAGE_MASK	ELM_IRQ	Page interrupt
ELM_IRQSTATUS [7] LOC_VALID_7	ELM_IRQENABLE [7] LOCATION_MASK_7	ELM_IRQ	Error-location interrupt for syndrome polynomial 7
ELM_IRQSTATUS [6] LOC_VALID_6	ELM_IRQENABLE [6] LOCATION_MASK_6	ELM_IRQ	Error-location interrupt for syndrome polynomial 6
ELM_IRQSTATUS [5] LOC_VALID_5	ELM_IRQENABLE [5] LOCATION_MASK_5	ELM_IRQ	Error-location interrupt for syndrome polynomial 5
ELM_IRQSTATUS [4] LOC_VALID_4	ELM_IRQENABLE [4] LOCATION_MASK_4	ELM_IRQ	Error-location interrupt for syndrome polynomial 4
ELM_IRQSTATUS [3] LOC_VALID_3	ELM_IRQENABLE [3] LOCATION_MASK_3	ELM_IRQ	Error-location interrupt for syndrome polynomial 3
ELM_IRQSTATUS [2] LOC_VALID_2	ELM_IRQENABLE [2] LOCATION_MASK_2	ELM_IRQ	Error-location interrupt for syndrome polynomial 2
ELM_IRQSTATUS [1] LOC_VALID_1	ELM_IRQENABLE [1] LOCATION_MASK_1	ELM_IRQ	Error-location interrupt for syndrome polynomial 1
ELM_IRQSTATUS [0] LOC_VALID_0	ELM_IRQENABLE [0] LOCATION_MASK_0	ELM_IRQ	Error-location interrupt for syndrome polynomial 0

15.5.3.4 Processing Initialization

[ELM_LOCATION_CONFIG](#) global setting parameters must be set before using the error-location engine. The [ELM_LOCATION_CONFIG](#)[1:0] ECC_BCH_LEVEL bit defines the error-correction level used (4-, 8-, or 16-bit error-correction). The [ELM_LOCATION_CONFIG](#)[26:16] ECC_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

The CPU can choose to use the ELM in continuous mode or page mode. If all [ELM_PAGE_CTRL](#)[i] SECTOR_i bits are reset (i is the syndrome polynomial number, i = 0 to 7), continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently – results for a syndrome

can be retrieved and acknowledged at any time, whatever the status of the other seven processing contexts.

- Page mode: Syndrome polynomials are grouped into atomic entities – only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all [ELM_IRQENABLE\[i\]](#) [LOCATION_MASK_i](#) bits ($i = 0$ to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the [ELM_IRQENABLE\[8\]](#) [PAGE_MASK](#) bit must be set to 1 when in page mode.

The CPU initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers:

[ELM_SYNDROME_FRAGMENT_0_i](#) to [ELM_SYNDROME_FRAGMENT_6_i](#). The first six registers can be written in any order, but [ELM_SYNDROME_FRAGMENT_6_i](#) must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the [ELM_SYNDROME_FRAGMENT_6_i\[16\]](#) [SYNDROME_VALID](#) bit).

As soon as one validity bit is asserted ([ELM_SYNDROME_FRAGMENT_6_i\[16\]](#) [SYNDROME_VALID](#) = 0×1 , with $i = 0$ to 7), error-location processing can start for the corresponding syndrome polynomial. The associated [ELM_LOCATION_STATUS_i](#) and [ELM_ERROR_LOCATION_0_i](#) to [ELM_ERROR_LOCATION_15_i](#) registers are not reset ($i = 0$ to 7). The software must not consider them until the corresponding [ELM_IRQSTATUS\[i\]](#) [LOC_VALID_i](#) bit is set.

15.5.3.5 Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the [ELM_LOCATION_STATUS_i\[8\]](#) [ECC_CORRECTABLE](#) bit is set to 1 and the [ELM_LOCATION_STATUS_i\[4:0\]](#) [ECC_NB_ERRORS](#) bit field is set to 0×0 .
- Too many errors are detected; that is, when the [ELM_LOCATION_STATUS_i\[8\]](#) [ECC_CORRECTABLE](#) bit is set to 0 while the [ELM_LOCATION_STATUS_i\[4:0\]](#) [ECC_NB_ERRORS](#) bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if [ECC_CORRECTABLE](#) is 0 .

If the engine completes early, the associated error-location registers [ELM_ERROR_LOCATION_0_i](#) to [ELM_ERROR_LOCATION_15_i](#) are not updated ($i = 0$ to 7).

In all other cases, the engine goes through the entire error-location process. Each time an error-location is found, it is logged in the associated [ECC_ERROR_LOCATION](#) bit field. The first error detected is logged in the [ELM_ERROR_LOCATION_0_i\[12:0\]](#) [ECC_ERROR_LOCATION](#) bit field; the second in the [ELM_ERROR_LOCATION_1_i\[12:0\]](#) [ECC_ERROR_LOCATION](#) bit field, and so on.

Table 15-350. ELM_LOCATION_STATUS_i Value Decoding Table

ECC_CORRECTABLE Value	ECC_NB_ERRORS Value	Status	Number of Errors Detected	Action Required
1	0	OK	0	None
1	$\neq 0$	OK	ECC_NB_ERRORS	Correct the data buffer read based on the ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i results.
0	Any	Failed	Unknown	Software-dependant

15.5.3.6 Processing Completion

When the processing for a given syndrome polynomial completes, its [ELM_SYNDROME_FRAGMENT_6_i\[16\]](#) [SYNDROME_VALID](#) bit is reset. It must not be set again until the exit status registers, [ELM_LOCATION_STATUS_i](#) ($i = 0$ to 7), for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding [ELM_IRQSTATUS\[i\]](#) LOC_VALID_i bit is set (i = 0 to 7). The processing-exit status is available from the associated [ELM_LOCATION_STATUS_i](#) register, and error locations are stored in order in the ECC_ERROR_LOCATION fields. The software must only read valid error-location registers based on the number of errors detected and located.

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the [ELM_SYNDROME_FRAGMENT_6_i\[16\]](#) SYNDROME_VALID validity bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in [ELM_PAGE_CTRL](#) are reset), an interrupt is triggered whenever a [ELM_IRQSTATUS\[i\]](#) LOC_VALID_i bit is asserted. The CPU must read the [ELM_IRQSTATUS](#) register to determine which polynomial is processed and retrieve the exit status and error locations ([ELM_LOCATION_STATUS_i](#) and [ELM_ERROR_LOCATION_0_i](#) to [ELM_ERROR_LOCATION_15_i](#)). When done, the CPU must clear the corresponding [ELM_IRQSTATUS\[i\]](#) LOC_VALID_i bit by writing it to 1. Other status bits must be written to 0 so that other interrupts are not unintentionally cleared. When using this mode, the [ELM_IRQSTATUS\[8\]](#) PAGE_VALID interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the [ELM_IRQENABLE\[i\]](#) LOCATION_MASK_i bits are cleared. A page is defined using the [ELM_PAGE_CTRL](#) register. Each SECTOR_i bit set means the corresponding polynomial i is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the [ELM_IRQSTATUS\[i\]](#) LOC_VALID_i bit fields. The module triggers an [ELM_IRQSTATUS\[8\]](#) PAGE_VALID interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the [ELM_IRQSTATUS](#) register must be cleared by using a single atomic-write access.

NOTE: Do not modify page setting parameters in the [ELM_PAGE_CTRL](#) register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the [ELM_PAGE_CTRL\[i\]](#) SECTOR_i bit fields (i = 0 to 7) are processed as usual, but are essentially ignored. The CPU must manually poll the [ELM_IRQSTATUS](#) bits to check for their status.

15.5.4 ELM Basic Programming Model

15.5.4.1 ELM Low Level Programming Model

15.5.4.1.1 Processing Initialization

Table 15-351. ELM Processing Initialization

Step	Register/ Bit Field / Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management.	ELM_SYSCONFIG[4:3] SIDLEMODE	Set value
Defines the error-correction level used	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	Set value
Defines the maximum buffer length	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	Set value
Sets the ELM in continuous mode or page mode	ELM_PAGE_CTRL	Set value
If continuous mode is used	All ELM_PAGE_CTRL[i] SECTOR_i (i = 0 to 7)	0x0
Enables interrupt for syndrome polynomial i	ELM_IRQENABLE[i] LOCATION_MASK_i	0x1
else (page mode is used)	One syndrome polynomial i is set ELM_PAGE_CTRL[i] SECTOR_i (i = 0 to 7)	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	All ELM_IRQENABLE[i] LOCATION_MASK_i = 0x0 and ELM_IRQENABLE[8] PAGE_MASK = 0x1	Set value
endif		Set value

Table 15-351. ELM Processing Initialization (continued)

Step	Register/ Bit Field / Programming Model	Value
Set the input syndrome polynomial i.	ELM_SYNDROME_FRAGMENT_0_i	Set value
	ELM_SYNDROME_FRAGMENT_1_i	Set value
	ELM_SYNDROME_FRAGMENT_5_i	Set value
	ELM_SYNDROME_FRAGMENT_6_i	Set value
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i [16] SYNDROME_VALID	0x1

15.5.4.1.2 Read Results

The engine goes through the entire error-location process and results can be read. [Table 15-352](#) and [Table 15-353](#) describe the processing completion for continuous and page modes, respectively.

Table 15-352. ELM Processing Completion for Continuous Mode

Step	Register/ Bit Field / Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Read for which i the error-location process is complete.	ELM_IRQSTATUS [i] LOC_VALID_i	0x1
if the process fails (too many errors)	ELM_LOCATION_STATUS_i [8] ECC_CORRECTABLE	0x0
It is software dependant.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i [8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i [4:0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers. It is the software responsibility to correct errors in the data buffer.	ELM_ERROR_LOCATION_0_i [12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i [12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i [12:0] ECC_ERROR_LOCATION	
endif		
Clear the corresponding i interrupt.	ELM_IRQSTATUS [i] LOC_VALID_i	0x1

A new syndrome polynomial can be processed after the end of processing ([ELM_SYNDROME_FRAGMENT_6_i](#)[16] SYNDROME_VALID = 0x0) and after the exit status register check ([ELM_LOCATION_STATUS_i](#)).

Table 15-353. ELM Processing Completion for Page Mode

Step	Register/ Bit Field / Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS [8] PAGE_VALID	0x1
Repeat the following actions the necessary number of times. That is, once for each valid defined block in the page.		
Read the process exit status.	ELM_LOCATION_STATUS_i [8] ECC_CORRECTABLE	
if the process fails (too many errors)	ELM_LOCATION_STATUS_i [8] ECC_CORRECTABLE	0x0
It is software dependant.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i [8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i [4:0] ECC_NB_ERRORS	

Table 15-353. ELM Processing Completion for Page Mode (continued)

Step	Register/ Bit Field / Programming Model	Value
Read the error-location bit addresses for syndrome polynomial <i>i</i> of the ECC_NB_ERRORS first registers.	ELM_ERROR_LOCATION_0_i [12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i [12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i [12:0] ECC_ERROR_LOCATION	
endif		
End Repeat		
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed ([ELM_IRQSTATUS](#)[*i*] LOC_VALID_*i* = 0x1 for all syndrome polynomials *i* used in the page).

15.5.4.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM module is programmed for an 8-bit error-correction capability in continuous mode. After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a non-zero polynomial syndrome is reported from the GPMC (Polynomial syndrome 0 is used in the ELM):

- P = 0x0A16ABE115E44F767BFB0D0980

Table 15-354. Use Case: Continuous Mode

Step	Register/ Bit Field / Programming Model	Value
Resets the module	ELM_SYSCONFIG [1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS [0] RESETDONE	0x1
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG [4:3] SIDLEMODE	0x2
Defines the error-correction level used: 8 bits	ELM_LOCATION_CONFIG [1:0] ECC_BCH_LEVEL	0x1
Defines the maximum buffer length: 528 bytes (2x528 = 1056)	ELM_LOCATION_CONFIG [26:16] ECC_SIZE	0x420
Sets the ELM in continuous mode	ELM_PAGE_CTRL	0
Enables interrupt for syndrome polynomial 0	ELM_IRQENABLE [0] LOCATION_MASK_0	0x1
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (i=0)	0xFB0D0980
	ELM_SYNDROME_FRAGMENT_1_i (i=0)	0xE44F767B
	ELM_SYNDROME_FRAGMENT_2_i (i=0)	0x16ABE115
	ELM_SYNDROME_FRAGMENT_3_i (i=0)	0x0000000A
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i [16]	0x1
	SYNDROME_VALID (i=0)	
Wait until process is complete for syndrome polynomial 0: IRQ_ELM is generated or poll the status register.		
Read that error-location process is complete for syndrome polynomial 0.	ELM_IRQSTATUS [0] LOC_VALID_0	0x1
Read the process exit status: All errors were successfully located.	ELM_LOCATION_STATUS_i [8] ECC_CORRECTABLE (i=0)	0x1
Read the number of errors: Four errors detected.	ELM_LOCATION_STATUS_i [4:0] ECC_NB_ERRORS (i=0)	0x4

Table 15-354. Use Case: Continuous Mode (continued)

Step	Register/ Bit Field / Programming Model	Value
Read the error-location bit addresses for syndrome polynomial 0 of the 4 first registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452.	ELM_ERROR_LOCATION_0_i (i=0)	0x1AF
	ELM_ERROR_LOCATION_1_i (i=0)	0x426
	ELM_ERROR_LOCATION_2_i (i=0)	0x775
	ELM_ERROR_LOCATION_3_i (i=0)	0xD7C
Clear the corresponding interrupt for polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in [Table 15-355](#) are given in decimal format.

Table 15-355. 16-bit NAND Sector Buffer Address Map

NAND Memory Address	Message bit addresses in the memory word															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	4215	4214	4213	4212	4211	4210	4209	4208	4223	4222	4221	4220	4219	4218	4217	4216
1	4175	4174	4173	4172	4171	4170	4169	4168	4183	4182	4181	4180	4179	4178	4177	4176
...																
47	3463	3462	3461	3460	3459	3458	3457	3456	3471	3470	3469	3468	3467	3466	3465	3464
48	3447	3446	3445	3444	3443	3442	3441	3440	3455	3454	3453	3452	3451	3450	3449	3448
49	3431	3430	3429	3428	3427	3426	3425	3424	3439	3438	3437	3436	3435	3434	3433	3432
50	3415	3414	3413	3412	3411	3410	3409	3408	3423	3422	3421	3420	3419	3418	3417	3416
...																
255	135	134	133	132	131	130	129	128	143	142	141	140	139	138	137	136
256	119	118	117	116	115	114	113	112	127	126	125	124	123	122	121	120
257	103	102	101	100	99	98	97	96	111	110	109	108	107	106	105	104
258	87	86	85	84	83	82	81	80	95	94	93	92	91	90	89	88
259	71	70	69	68	67	66	65	64	79	78	77	76	75	74	73	72
260	55	54	53	52	51	50	49	48	63	62	61	60	59	58	57	56
261	39	38	37	36	35	34	33	32	47	46	45	44	43	42	41	40
262	23	22	21	20	19	18	17	16	31	30	29	28	27	26	25	24
263	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and to flip this bit. The same process must be repeated for all detected errors.

15.5.4.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for an 16-bit error-correction capability in page mode. After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (Polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF
- P1 = 0xBAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EB
- P2 = 0x69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189
- P3 = 0x0

Table 15-356. Use Case: Page Mode

Table 15-361. ELM_SYSCONFIG

Address Offset	0x0000 0010	Instance	ELM
Physical Address	0x4807 8010		
Description	This register allows controlling various parameters of the OCP interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							CLOCKACTIVITYOCP	RESERVED			SIDLEMODE		RESERVED	SOFTRESET	AUTOGATING

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	R	0x000000
8	CLOCKACTIVITYOCP	OCP Clock activity when module is in IDLE mode (during wake up mode period) 0x0: OCP Clock can be switch-off 0x1: OCP Clock is maintained during wake up period	RW	0
7:5	RESERVED	Reserved	R	0x0
4:3	SIDLEMODE	Slave interface power management (IDLE req/ack control) 0x0: FORCE Idle. IDLE request is acknowledged unconditionally and immediately (Default <i>Dumb</i> mode for safety) 0x1: NO idle. IDLE request is never acknowledged. 0x2: SMART Idle. The acknowledgment to an IDLE request is given based on the internal activity. 0x3: Reserved - do not use	RW	0x2
2	RESERVED	Reserved	R	0
1	SOFTRESET	Module software reset This bit is automatically reset by hardware (During reads, it always returns 0.) It has same effect as the OCP hardware reset. 0x0: Normal mode 0x1: Start soft reset sequence.	RW	0
0	AUTOGATING	Internal OCP clock gating strategy (no module visible impact other than saving power) 0x0: OCP clock is free-running 0x1: Automatic internal OCP clock gating strategy is applied based on the OCP interface activity.	RW	1

15.6 On-Chip Memory (OCM) Subsystem

15.6.1 OCM Subsystem Overview

There are three on-chip memories in the device.

- A 4K-byte SAR read-only memory (ROM)
- A 8K-byte SAR random-access memory (RAM)
- A 56K-byte L3 static random-access memory (L3 OCM_RAM)

There are other on-chip memories located inside other subsystems (Cortex-A9 MPU, DSP IVA-HD, ABE, Cortex-M3 MPU) that are not described in the following sections. Refer to each subsystem chapter for more details.

15.6.2 OCM Subsystem Integration

[Figure 15-101](#) shows the integration of the OCM subsystem to the device.

Figure 15-101. OCM Subsystem Integration to the Device

15.6.3 OCM Subsystem Functional Description

15.6.3.1 SAR ROM

This on-chip ROM contains 4K bytes of memory and a linked list of descriptors used by the system DMA (sDMA) during the restore context operation (when device transitions from OFF to ON modes).

The device-embedded SAR ROM has the following characteristics:

- 4K-bytes ROM
- 32-bit access per cycle
- Support for single and burst access transactions

The memory space of the embedded ROM starts at 0x4A05 E000 and ends at 0x4A05 FFFF (8K bytes are reserved, but only 4K bytes are used).

15.6.3.2 SAR RAM

The on-chip SAR RAM contains 8K bytes and is mapped as 4 blocks with irregular region sizes. This memory content is preserved when the device goes into OFF mode (as long as the wake-up voltage domain remains supplied). It is used as context-saving memory to be written by the software, so that the sDMA restores its saved content when the device transitions from OFF to ON mode. Locations not used by the sDMA can be used as a scratch-pad memory by the software. It is mapped on the wake-up voltage domain.

The device-embedded SAR RAM has the following characteristics:

- Support for single-access transactions
 - Operates at full L4-PER interconnect clock frequency
 - 32-bit access per cycle

The SAR RAM space is at the following location:

- SAR space 1 (4KB): Starts at 0x4A32 6000 and ends at 0x4A32 6FFF

- SAR space 2 (1KB): Starts at 0x4A32 7000 and ends at 0x4A32 73FF
- SAR space 3 (2KB): Starts at 0x4A32 8000 and ends at 0x4A32 87FF
- SAR space 4 (1KB): Starts at 0x4A32 9000 and ends at 0x4A32 93FF

15.6.3.3 L3 OCM_RAM

The on-chip L3 OCM_RAM contains 56K bytes of RAM, partitioning is defined by the L3 firewall logic.

The device-embedded L3 OCM_RAM has the following characteristics:

- Support for single and burst access transactions:
 - Operates at full L3 interconnect clock frequency
 - Fully pipelined, one 32-bit access per cycle
- Restricted access support based on:
 - A region-based partitioning (refer to L3 firewall description)
 - The module owner of the access, with respect to its read and write permissions to that region
 - The transaction attributes of the access, with respect to the region permission properties. See [Section 13.2, L3 Interconnect](#) for details.

The memory space of the embedded RAM starts at 0x4030 0000 and ends at 0x4030 DFFF.

This chapter describes the system direct memory access (sDMA) module.

Topic	Page
16.1 sDMA Module Overview	3316
16.2 sDMA Controller Environment	3318
16.3 sDMA Module Integration	3320
16.4 sDMA Functional Description	3325
16.5 sDMA Basic Programming Model	3358
16.6 sDMA Register Manual	3367

16.1 sDMA Module Overview

The system direct memory access (sDMA), also called DMA4, performs high-performance data transfers between memories and peripheral devices without microprocessor unit (MPU) or digital signal processor (DSP) support during transfer. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

The DMA controller includes the following main features:

- Data transfer support in either direction between:
 - Memory and memory
 - Memory and peripheral device
- 32 logical DMA channels supporting:
 - Multiple concurrent transfers
 - Independent transfer profile for each channel
 - 8-bit, 16-bit, or 32-bit data element transfer size
 - Software-triggered or hardware-synchronized transfers
 - Flexible source and destination address generation
 - Burst read and write
 - Chained multiple-channel transfers
 - Endianism conversion
 - Draining
 - Linked-list support for descriptor types 1, 2, and 3
- First-come, first-serve DMA scheduling with fixed priority
- Up to 127 DMA requests
- Constant fill
- Transparent copy
- Four programmable interrupt request output lines
- FIFO depth: 256 × 64-bit
- Data buffering
- FIFO budget allocation
- Power-management support
- Auto-idle power-saving support
- Implementation of retention flip-flops (RFFs) to support dynamic power switching (DPS) between system power modes without MPU involvement. For more information about DPS, see [Section 3.1.2.3, Dynamic Power Switching \(DPS\)](#).

Figure 16-1 shows an overview of the sDMA module.

Figure 16-1. sDMA Overview

The sDMA module has three ports: one read, one write, and one configuration port and provides multiple logical channel support. A dynamically allocated FIFO queue memory pool provides buffering between the read and write ports, which are multithreaded (two threads for the write port and four threads for the read port); this means that each transaction is flagged by a thread ID (0, 1, 2, or 3) in the request direction and in the response direction. This allows the read port to have four outstanding requests at a time. The write port has two threads budget available.

The MPU (or DSP) configures the sDMA through the L4-CFG interconnect.

16.2 sDMA Controller Environment

The sDMA controller supports external DMA requests through the sys_ndmareq[3:0] pins (see [Table 16-1](#)). A logical channel can be configured to respond to an external synchronization request.

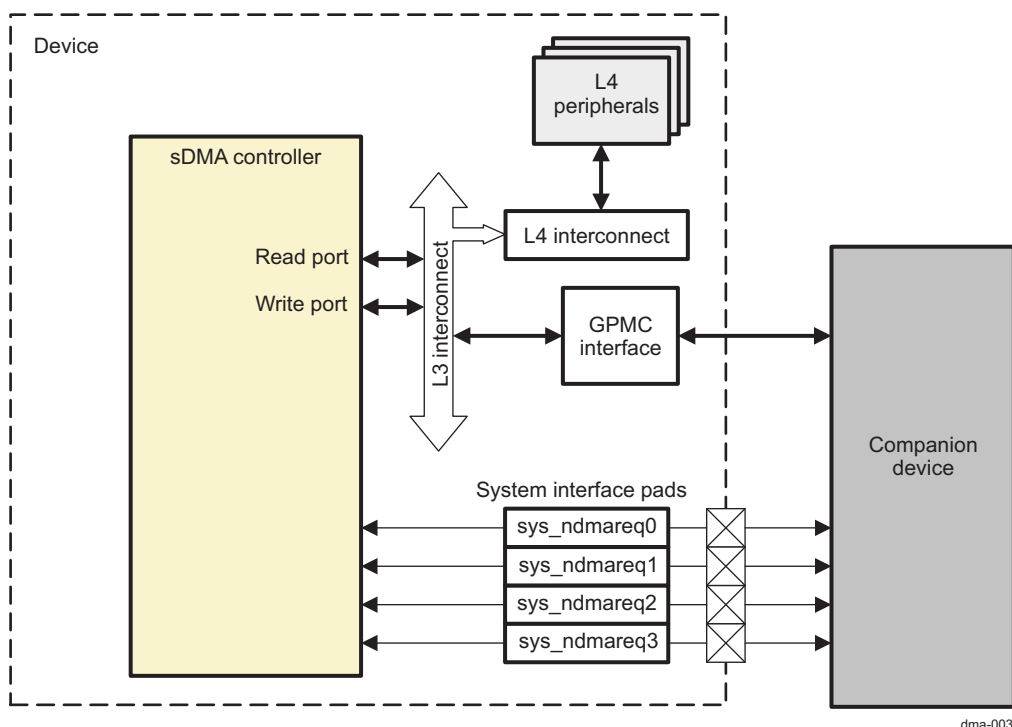

Table 16-1. External sDMA Request Signals

Signal Name	I/O ⁽¹⁾	Description	Reset Value
sys_ndmareq0	I	External DMA request 0 (system expansion)	Z
sys_ndmareq1	I	External DMA request 1 (system expansion)	Z
sys_ndmareq2	I	External DMA request 2 (system expansion)	Z
sys_ndmareq3	I	External DMA request 3 (system expansion)	Z

⁽¹⁾ I = Input; O = Output; I/O = Bidirectional

[Figure 16-2](#) shows an example of how to use the external hardware DMA request pins in the sDMA environment.

Figure 16-2. Example of External DMA Requests Use

An external device can use the external DMA request pins to start a logical channel transfer over the general-purpose memory controller (GPMC) interface. The transfer can be a memory-to-memory transfer in which the source memory is in the external device.

By default, the external DMA request signals are not available on external pins after a cold reset. For more information about multiplexing out the four signal lines to pins, see [Chapter 18, Control Module](#).

All 127 DMA request lines are transition-sensitive.

For a transition-sensitive DMA request (see [Figure 16-3](#)), the line must be maintained low (asserted) until the first DMA access is complete, after which the line must be maintained high (deasserted) for greater than one clock cycle (DMA_L3_ICLK):

- When the deassertion time is less than one clock cycle, the sDMA might not detect the deassertion.
- When the channel is enabled one cycle after a DMA request is disabled, the channel detects the DMA request and starts the corresponding transfer.
- When the channel is enabled two cycles after the DMA request is disabled, the channel does not

detect the DMA request.

Figure 16-3. Transition-Sensitive DMA Request Scheme

16.3 sDMA Module Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 16-4 shows the sDMA controller integration.

Figure 16-4. sDMA Controller Integration

NOTE: For more information about the wake-up generator (WUGEN), the STANDBY/IDLE hardware handshake, and the wake-up request, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 16-2 through Table 16-4 summarize the integration of the module in the device.

Table 16-2. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
sDMA	PD_CORE	L3 and L4-CFG

Table 16-3. Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
sDMA	SDMA_FCLK	DMA_L3_ICLK	PRCM	It is both a functional clock for all internal logic and for the two master read and write ports. For information about PRCM clock gating and management, see Chapter 3, Power, Reset, and Clock Management .
sDMA	SDMA_ICLK	DMA_L4_ICLK	PRCM	Interface clock. It supports the configuration port. For information about PRCM clock gating and management, see Chapter 3, Power, Reset, and Clock Management .
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
sDMA	SDMA_RST	SDMA_RET_RST	PRCM	Hardware reset. It initializes all internal logic of the sDMA module, all global registers and some of the per-channel registers, implemented in flip-flops. However, all remaining per-channel registers are memory-based, and, therefore, are not reset (have undefined values). Thus, when programming a channel for the first time, all bits that have undefined reset values must be configured before enabling the channel. For information about PRCM reset sources and distribution, see Chapter 3, Power, Reset, and Clock Management .

Table 16-4. Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
sDMA	SDMA_IRQ_0	MA_IRQ_12	Cortex-A9 MPU INTC	sDMA interrupt request 0. For information about the Cortex-A9 MPU INTC, see Section 17.3.2 .
	SDMA_IRQ_1	MA_IRQ_13	Cortex-A9 MPU INTC	sDMA interrupt request 1
	SDMA_IRQ_2	MA_IRQ_14	Cortex-A9 MPU INTC	sDMA interrupt request 2
	SDMA_IRQ_3	MA_IRQ_15	Cortex-A9 MPU INTC	sDMA interrupt request 3
sDMA	SDMA_IRQ_0	MM_IRQ_18	Cortex-M3 MPU INTC	sDMA interrupt request 0. For information about the Cortex-M3 MPU INTC, see Section 17.3.3 .
	SDMA_IRQ_1	MM_IRQ_19	Cortex-M3 MPU INTC	sDMA interrupt request 1
	SDMA_IRQ_2	MM_IRQ_20	Cortex-M3 MPU INTC	sDMA interrupt request 2
	SDMA_IRQ_3	MM_IRQ_21	Cortex-M3 MPU INTC	sDMA interrupt request 3
sDMA	SDMA_IRQ_0	D_IRQ_89	DSP INTC	sDMA interrupt request 0. For information about the DSP INTC, see .
	SDMA_IRQ_1	D_IRQ_90	DSP INTC	sDMA interrupt request 1

NOTE: For a description of the interrupt source, see [Section 16.4.2, sDMA Controller Interrupt Requests](#).

16.3.1 DMA Requests to the sDMA Controller

[Table 16-5](#) lists the sDMA controller request mapping.

Table 16-5. sDMA Controller Request Mapping

DMA Request Line	Source	Description
S_DMA_0	Reserved	Reserved
S_DMA_1	sys_dma_req0	External DMA request 0 (system expansion)
S_DMA_2	sys_dma_req1	External DMA request 1 (system expansion)

16.4 sDMA Functional Description

The sDMA module provides high-performance data transfers between memories and peripheral devices with low processor use. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

Figure 16-5 shows the sDMA controller top-level block diagram.

Figure 16-5. sDMA Controller Top-Level Block Diagram

dma-005

16.4.1 sDMA Controller Power Management

Table 16-6 describes power-management features available for the sDMA controller.

NOTE:

- For information about source clock gating and sleep/wake-up transitions, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- For a description of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 16-6. Local Power Management Features

Feature	Registers	Description
Clock auto gating	DMA4_OCP_SYSCONFIG [0] AUTOIDLE bit	This bit allows local power optimization inside the module by gating the SDMA_ICLK clock upon the interface activity.
Slave idle modes	DMA4_OCP_SYSCONFIG [4:3] SIDLEMODE bit field	Force-idle, no-idle and smart-idle modes are available.
Clock activity	DMA4_OCP_SYSCONFIG [9:8] CLOCKACTIVITY bit field	For configuration details, see Table 16-7 .
Master standby modes	DMA4_OCP_SYSCONFIG [13:12] MIDLEMODE bit field	Force-standby, no-standby and smart-standby modes are available.
Global Wake-up Enable	N/A	Feature not available
Wake-up Sources Enable	N/A	Feature not available

Table 16-7. Clock Activity Settings

SDMA_CLOCKACTIVITY Values	Clock State When Module is in IDLE State	
	SDMA_ICLK	SDMA_FCLK
00	Off	Off
10	Off	On
01	On	Off
11	On	On

CAUTION

Because the PRCM module cannot read CLOCKACTIVITY settings through hardware, software must ensure consistent programming between the SDMA_CLOCKACTIVITY and sDMA clock PRCM control bits. For a description of the ClockActivity feature, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

16.4.2 sDMA Controller Interrupt Requests

DMA4 has four interrupt lines (L_j, where j = 0, 1, 2, 3). Each logical channel can request an interrupt over any line. The attachment of a channel interrupt event to one of these four external lines is programmable. Software determines whether it attaches a channel interrupt to a single IRQ line or to multiple IRQ lines.

There are two different registers per interrupt line:

- The [DMA4_IRQSTATUS_Lj](#) CH_31_0_Lj field shows the status of the different sources of interrupt. If the [DMA4_IRQENABLE_Lj](#) bit is 1, channel *i* is the source of interrupt in line *j*. In contrast to the [DMA4_CSRI](#) registers, the [DMA4_IRQSTATUS_Lj](#) registers are updated regardless of the corresponding bits in the [DMA4_IRQENABLE_Lj](#) registers.
- The [DMA4_IRQENABLE_Lj](#) CH_31_0_Lj_EN field masks/unmasks the channel interrupt. If the [DMA4_IRQENABLE_Lj](#) bit is set to 0, channel interrupt *i* of the line *j* is masked.

Each logical channel can generate a number of different interrupt events when enabled (that is, set to 1) in the [DMA4_CICRI](#) register. Each status bit is updated in the [DMA4_CSRI](#) register only when the corresponding enable bit is enabled in the [DMA4_CICRI](#) register.

To determine an interrupt source when an interrupt rises on an interrupt line L_j:

- Identify the channel (LCH_i) generating the interrupt.
Read the [DMA4_IRQSTATUS_Lj](#).LCH_i (LCH₀ to LCH₃₁). If LCH_i = 1, channel *i* is the originator of the interrupt.
- Identify the interrupt event.
Read the LCH_i [DMA4_CSRI](#). For example, if the drop event (the [DMA4_CSRI](#)[1] DROP bit) is 1, there

will be a request collision.

The interrupt event status bit in the [DMA4_CSRi](#) register is immediately reset after it is written to 1.

The interrupt status bit in the [DMA4_IRQSTATUS_Lj](#) register is cleared after it is written to 1.

16.4.2.1 Interrupt Generation

The sDMA module has four interrupt request output lines, SDMA_IRQ_0 to SDMA_IRQ_3. One or more logical channels can be programmed to generate an interrupt request on any of these lines when any one of the maskable DMA events listed in [Table 16-8](#) occurs.

Table 16-8. Logical DMA Channel Events

Event	Description
End of packet	A packet transfer completed.
End of block	A block transfer completed.
End of frame	A frame transfer completed.
End of super block	A super block transfer completed.
Half of frame	Half of the current frame transferred.
Start of last frame	The first element of the last frame transferred.
Transaction error	A transaction error is returned by the interconnect in either the read or write port.
Address error	An attempt was made to perform a DMA access to an address not aligned on an ES boundary. Condition to occur: if DMA4_CEN[23:0] CHANNEL_ELMNT_NBR = 0x000000 or DMA4_CFN[15:0] CHANNEL_FRAME_NBR = 0x0000 or DMA4_CSDP[1:0] DATA_TYPE = 0x3.
Supervisor transaction error	An error occurred, for example, when an unauthorized initiator (that is not a supervisor) tries to use a supervisor transfer.
Drain end	Drain is completed (DMA4_CCRi [10] WR_ACTIVE becomes 0).
Drop error	A drop event interrupt is generated when a DMA request is being serviced while a second one is asserted and a third one arrives before the second DMA request is serviced.

The logical DMA channels that generate an interrupt on a particular IRQ output are specified through the [DMA4_IRQENABLE_Lj](#) register (where *j* is the IRQ number: 0, 1, 2, or 3). The events that generate an interrupt for a particular channel can be configured through the channel [DMA4_CICRi](#) register.

When an interrupt is detected, the logical DMA channel generating the event can first be identified by reading the [DMA4_IRQSTATUS_Lj](#) register. The event causing the interrupt then can be identified by reading the interrupt status via the relevant DMA channel [DMA4_CSRi](#) register.

16.4.3 Logical Channel Transfer Overview

As [Figure 16-5](#) shows, the sDMA module has one read port and one write port operating independently of each other. Buffering is provided between the read and write ports through a FIFO queue memory pool that is shared dynamically between the active logical channels.

- Logical channel synchronization
A logical channel is described as hardware-synchronized when the DMA transfers are triggered by DMA requests from a hardware device. Alternatively, a logical channel is described as nonsynchronized when the DMA transfer is triggered by software.
- Logical channel activation
A logical channel becomes active as follows:
 - For hardware-synchronized transfers, when the logical channel is enabled and the hardware DMA request line is asserted
 - For software-triggered (nonsynchronized) transfers, as soon as software enables the logical channel
- Logical channel transfer composition
A DMA transfer is divided automatically into a number of transactions. Depending on the logical channel context configured, the transfer size, the start address alignment, the addressing mode, and

the configured maximum burst size, each transaction can be either a single access or a burst of accesses.

- Logical channel scheduling

When several logical channels are active at the same time, schedulers manage the read and write ports. The scheduling of logical channel transfers is similar for both read and write ports. When a logical channel becomes active, it is added to the tail of a scheduling queue. If more than one logical channel becomes active at the same time, the one with the lower number is queued first. This mechanism provides a first-come, first-serve scheduling scheme between the concurrently active logical channels.

In addition, each read and write port has a high-priority queue and a low-priority queue. The priority bits (WRITE_PRIORITY and READ_PRIORITY) in the logical channel DMA4_CCRi register determine if a logical channel is queued as high or low priority. A software-configurable 8-bit priority counter gives weighting to the priority write queue. For every N (1 to 255) schedules from the priority write queue, one is scheduled from the regular write queue. A channel that is scheduled goes to the end of the queue after it completes its turn on the port. The relative weighting of the scheduling of the high-priority queue to the low priority queue is programmable from 1:1 to 1:256 through the DMA global channel register using the DMA4_GCR[23:16] ARBITRATION_RATE bit field.

NOTE: The DMA4_GCR[23:16] ARBITRATION_RATE field does not depend on the DMA4_GCR[13:12] HI_THREAD_RESERVED field. The ARBITRATION_RATE field depends on the DMA4_CCRi[26] WRITE_PRIORITY bit and the DMA4_CCRi[6] READ_PRIORITY bit.

- Read/write port access scheduling policy

When either the read or write port becomes available, the port access scheduler selects the next logical channel for which to perform a DMA transaction from either the high- or low-priority queue.

When the current DMA transaction (single or burst access) is complete and the full DMA transfer is not finished, the logical channel returns to the tail of the queue. Because the port access scheduling is on a per-transaction basis, a logical channel can be queued repeatedly this way several times during its block transfer.

The sDMA module can have up to four outstanding read transactions and two outstanding write transactions in the system interconnect; four read and two write thread IDs exist. For an arbitration cycle to occur, these two conditions must be met:

- At least one channel is requesting.
- At least one free thread ID is available.

On an arbitration cycle, the scheduler grants the highest priority channel that has an active request, allocates the thread ID, and tags this thread as busy. At a given time, a channel cannot be allocated for more than one thread ID.

NOTE: If more than one channel is active, each channel is given a thread ID for the current service only, not for the whole channel transfer.

When only one channel is enabled, only one thread is allocated for the channel. In such a situation the channel can have maximum of four outstanding commands (without getting the responses) without rescheduling the channel at the end of each transaction. Each command can be either single access (8-bit, 16-bit or 32-bit) or burst access (2 x M, 4 x M, 8 x M or 16 x M, where M can be 8-bit, 16-bit or 32-bit).

When nonburst alignment is at the beginning of the transfer, the channel is rescheduled for each smaller access until burst-aligned. When the end of the transfer is not burst-aligned, the channel is rescheduled for each of the remaining smaller accesses.

For a logical channel transfer completion, when the last access is written to the destination, the logical channel becomes inactive. If enabled, an interrupt request is generated (see [Section 16.4.2.1, Interrupt Generation](#)).

16.4.4 FIFO Queue Memory Pool

A FIFO queue memory pool provides buffering between the read and write ports. The hardware allocates the space dynamically to a number of FIFO queues, and each queue is associated with an active logical channel.

To avoid a memory pool overflow, if there are fewer entries in the FIFO queue memory pool than are required for the maximum configured source burst size of the next logical channel to be scheduled, the logical channel is returned to the tail of the queue, and the port access scheduler continues to search the queue until it finds a logical channel that can be scheduled.

The maximum FIFO depth that can be allocated to each individual logical channel can be limited globally through the [DMA4_GCR\[7:0\] MAX_CHANNEL_FIFO_DEPTH](#) bit field. This value should be configured to allow a fair allocation of the memory pool between the active channels.

A logical channel is scheduled if it has not yet reached its allocation limit, even if the access to be performed will exceed this limit. This means that the effective number of entries used by a particular logical channel is limited to the configured maximum entries per channel + channel maximum configured burst size (in words) 1.

16.4.5 Addressing Modes

A DMA transfer block consists of a number of frames (FN). Each frame consists of a number of elements (EN), and each element can have a size of 8, 16, or 32 bits (ES), as follows:

$$\text{transfer block size} = \text{FN} \times \text{EN} \times \text{ES}$$

The FN, EN, and ES are common for both the source and destination. However, the way in which the data is represented (addressing profile/mode) is independently programmable for the source and destination devices, using one of these four addressing modes:

- Constant: The address remains the same for consecutive element accesses.
- Post-increment: The address increases by the ES, even across consecutive frames.
- Single-index: The address increases by the ES plus the element index (EI) value minus 1 (even across consecutive frames).
- Double-index: The address increases by the ES plus the EI value minus 1 within a frame. When a full frame is transferred, the address increases by the ES plus the frame index (FI) value minus 1.

The ES, EI, and FI values are expressed in bytes. The EI and FI values can be positive or negative.

When calculating the EI and FI values, it is critical to note that, after an element is accessed, the logical channel address pointer equals the address of the last byte (highest address) of the accessed element. The correct value for the EI or FI should be such that, when added to the logical channel address pointer, results in the address of the first byte (lowest address) of the next element to be accessed.

The EI and FI values must be configured so that the address of each element in the transfer is aligned on an ES boundary.

Consequently, the single-index addressing mode with EI = 1 or double-index addressing mode with EI = 1 and FI = 1 is equivalent to post-increment addressing.

NOTE: The source and destination start addresses must also be aligned on an ES boundary.

When the address of an element to be accessed is not aligned on an ES boundary, the transfer is stopped and a misaligned address error interrupt occurs, if enabled (see [Section 16.4.2.1, Interrupt Generation](#)).

The [DMA4_CFNi](#) register configures the FN in a block.

The [DMA4_CENi](#) register configures the EN.

The [DMA4_CSDPi](#) register configures the ES.

The [DMA4_CSSAi](#) and [DMA4_CDSAi](#) registers configure the source and destination start addresses.

The [DMA4_CCRi](#) register configures the source and destination addressing modes.

The [DMA4_CSEIi](#), [DMA4_CSFIi](#), [DMA4_CDEIi](#), and [DMA4_CDFIi](#) registers configure the source EI, source FI, destination EI, and destination FI, respectively.

The addressing profiles are expressed as equations as follows:

Equation 1. Constant addressing:

$$A(n + 1) = A(n)$$

NOTE: Constant addressing mode with DMA4 to/from DDR memory is not supported on the OMAP4430 device.

To fill DDR memory with a single value, the constant fill feature of DMA4 must be used instead of a constant addressing mode transfer.

Equation 2. Post-increment addressing:

$$A(n + 1) = A(n) + ES$$

Equation 3. Single-indexed addressing:

$$A(n + 1) = A(n) + ES + (EI - 1)$$

Equation 4. Double-indexed addressing:

When not at the end of a frame or transfer (that is, when the element counter $\neq 0$):

$$A(n + 1) = A(n) + ES + (EI - 1)$$

When at the end of a frame but not at the end of the transfer (that is, when the element counter = 0 and the frame counter $\neq 0$):

$$A(n + 1) = A(n) + ES + (FI - 1)$$

Calculate the element and frame index as follows:

Equation 5. Element index

$$EI = [(Stride\ EI - 1) * ES] + 1$$

Equation 6. Frame index

$$FI = [(Stride\ FI - 1) * ES] + 1$$

where:

$A(n)$: Byte address of the element n within the transfer.

ES is in bytes, ES{1, 2, 4}.

EI is in bytes, specified in a configuration register, 32768 EI 32767.

Stride EI: The difference in the number of elements between the start of the current element n to the start of next element, $n+1$.

Element counter: A counter that is (re)initiated with the number of elements per frame or per transfer. Decreased by 1 for each element transferred. The initial value is configured in the register DMA channel element number, [DMA4_CENi](#).

FI is in bytes, specified in a configuration register, 2147483648 FI 2147483647.

Stride FI: The difference in the number of elements between the start of the last element of the current frame and the beginning of the first element of the next frame.

Frame counter: A counter that is (re)initiated with the FN per transfer. Decreased by 1 for each frame transferred. The initial value is configured in the register DMA channel frame number, [DMA4_CFNi](#).

[Figure 16-6](#) shows how a stride EI and FI are defined. When handling complex configurations, using strides can make it easier to calculate EI and FI because you can calculate in elements instead of bytes. (This approach is used in the 90-degree clockwise image rotation example shown in [Figure 16-10](#).) The double-index addressing example shown in [Figure 16-6](#) uses ES = 4, EN = 2, EI = 5, FI = 5, and FN = 2.

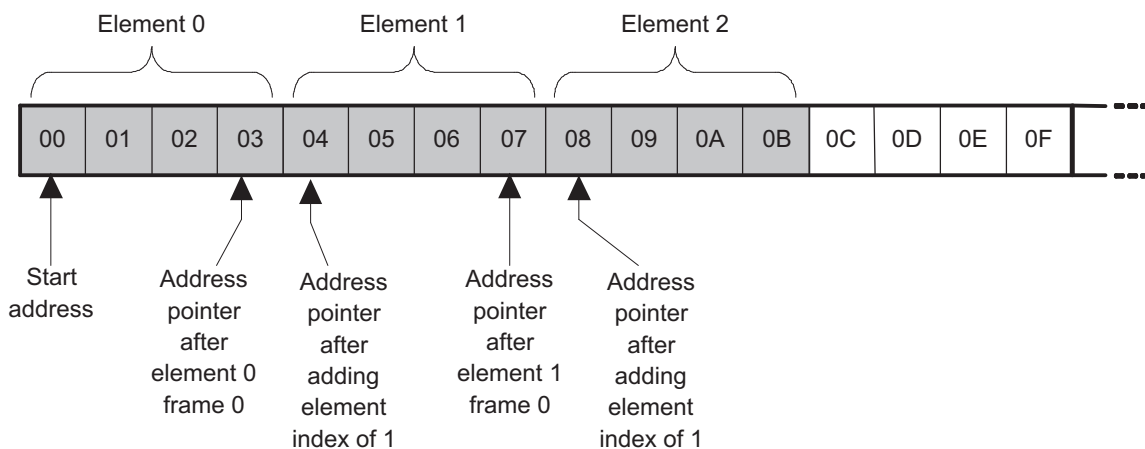

[Figure 16-6](#) through [Figure 16-9](#) show examples of addressing mode configurations. [Table 16-9](#) lists parameter values for the examples.

Figure 16-6. Example Showing Double-Index Addressing, Elements, Frames, and Strides

dma-011

Figure 16-7. Addressing Mode Example (a)

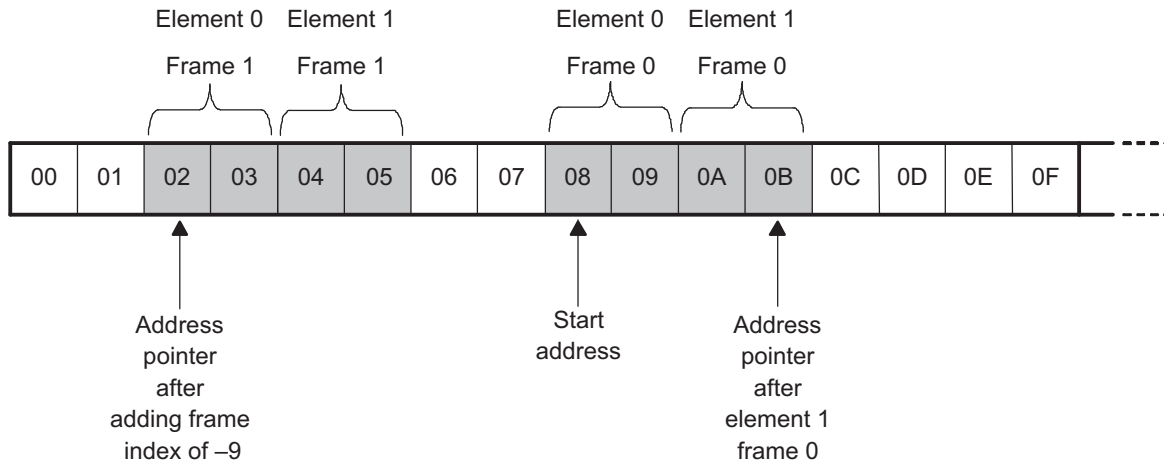

dma-010

Figure 16-8. Addressing Mode Example (b)

dma-009

Figure 16-9. Addressing Mode Example (c)

dma-008

Table 16-9. Parameter Values for Addressing Mode Examples (a), (b), and (c)

Parameter	Example (a)	Example (b)	Example (c)
Addressing mode	Single index (or post-increment)	Double index	Double index
Start address	0	0	8
ES	4 (32-bit)	4 (32-bit)	2 (16-bit)
EN	3	2	2
EI	1	5	1
FN	1	2	2
Frame index	N/A	5	-9

Double indexing can occur either on source (read) or destination (write). Equations for rotation of xx degrees on destination are obtained by taking equations for rotation of $(360 - xx)$ degrees on source, and swapping the width (x) and height (y) of the image in them. The opposite is also true. [Table 16-10](#) lists the equations for 90-, 180-, and 270-degree rotations.

Table 16-10. Equations for Rotation

		90 Rotation	180 Rotation	270 Rotation
Double indexing on destination (write)	Base address	$ES \cdot (y-1)$	$ES \cdot (x \cdot y-1)$	$ES \cdot y \cdot (x-1)$
	EI	$ES \cdot (y-1) + 1$	$1-2 \cdot ES$	$1-ES \cdot (y+1)$
	FI	$1 \cdot ES \cdot [(x-1) \cdot y + 2]$	$1-2 \cdot ES$	$1+ES \cdot (x-1) \cdot y$
Double indexing on source (read)	Base address	$ES \cdot x \cdot (y-1)$	$ES \cdot (x \cdot y-1)$	$ES \cdot (x-1)$
	EI	$1-ES \cdot (x+1)$	$1-2 \cdot ES$	$ES \cdot (x-1) + 1$
	FI	$1+ES \cdot (y-1) \cdot x$	$1-2 \cdot ES$	$1 \cdot ES \cdot [(y-1) \cdot x + 2]$

[Table 16-11](#) and [Figure 16-10](#) show the configuration required to perform a 90-degree clockwise rotation of a 240 x 160 pixel, 32-bit image. The EI, frame size, and FI values are configured so that the image is rotated line by line starting at the left end of the top line.

NOTE: The FI value for the destination is negative so that the first pixel of each subsequent line of the source image is written to the correct location at the destination.

Equation 5 and Equation 6 calculate the destination, FI and EI. The example assumes that the image lines are stored at consecutive addresses in memory, meaning that both EI and FI on the source side are 1.

Rotations:

[Section 16.5.7, 90-Degree Clockwise Image Rotation](#), describes how to program an example of a 90-degree clockwise image rotation.

Observe that:

- One pixel = one element
- One line = one DMA frame
- Pixel size = element size = ES

Table 16-11. Example Parameter Values for a 90-Degree Clockwise Image Rotation

Parameter	Source Value	Destination Value
Bits per pixel	32	32
ES	4	4
Image width	SW	SH
Image height	SH	SW
Stride elements (stride EI)	1 element	SH
Stride frames (stride FI)	1 element	$-[(SW-1)*SH + 1] = 38,241$ elements
Start address	0x100000	$0x200000 + (SH - 1) \times ES = 0x20027C$
EN	SW	SW
EI	$[(Stride EI - 1) * ES] + 1 = 1$	$[(Stride EI - 1) * ES] + 1 = 637$
FN	SH	SH
FI	$[(Stride FI - 1) * ES] + 1 = 1$	$[(Stride FI - 1) * ES] + 1 = 152,967$

Figure 16-10. Example of a 90-Degree Clockwise Image Rotation

16.4.6 Packed Accesses

To pack data means to group data to match the bus size, thus optimizing a transfer. When the logical channel ES is less than the DMA module read/write port size, and the addressing profile supports it (post-increment mode or single- or double-index mode with $EI = 1$), the number of elements to transfer in each read/write port access can be maximized by specifying that the source or destination is packed through the channel [DMA4_CSDPi](#) register. Thus:

- For a read/write port size of 32 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (four elements per access) and 16 bits (two elements per access).

- For a read/write port size of 64 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (eight elements per access), 16 bits (four elements per access), and 32 bits (two elements per access).

Depending on the start address and transfer length, the first or last packed access can be only partially filled. This is indicated to the source or destination using the byte-enable signals.

16.4.7 Burst Transactions

Transfer performance can be improved so that the source or destination and addressing profile supports it. This can be achieved by configuring the logical channel to perform burst transactions consisting of multiple instead of single accesses. The channel can be programmed to use burst sizes equal to 16, 32, or 64 bytes through the [DMA4_CSDPi](#) register, with the read burst size programmable independently of the write burst size. Typically, the optimal burst size is 64 bytes (16 accesses for a 32-bit read/write port size or 8 accesses for a 64-bit read/write port size).

To obtain the maximum benefit from burst transactions, the source and destination start addresses must be aligned with the burst size. If this is not the case, the start of the transfer can consist of a number of smaller (single or burst) transactions until the first burst size boundary is reached.

Similarly, if the end of the transfer is not aligned on a burst size boundary, the final part of the transfer can consist of a number of smaller transactions.

NOTE: If post-incrementing is used, data must be packed to DMA data-port width, to use burst.

16.4.8 Endianism Conversion

The source and destination are each specified as little-endian or big-endian through the [DMA4_CSDPi](#) register for the particular logical channel. If the endianism of the source and destination differ, and if the logical channel ES is less than the sDMA module read/write port size, an endianism conversion is applied to the data before it is written to the destination.

When transferring data between a source and a destination with different endianism, it is important to specify an ES that equals the type of data being transferred to preserve the correct data image at the destination.

In the system, endianism conversion can be performed in more than one place. It is possible to instruct the source and/or destination to lock the endianism (that is, to not perform a conversion) through the logical DMA channel [DMA4_CSDPi](#) register.

NOTE: Because the device is little-endian by construction, the sDMA endianism registers must never be set to big-endian.

If sDMA is used to execute endian conversion by setting the source and destination to different endianism values, it is important to consider that the L3 interconnect also executes endian conversion if the sDMA and the source or destination have a different data bus width.

16.4.9 Transfer Synchronization

A logical channel can be programmed for either software-triggered or hardware synchronized transfers.

16.4.9.1 Software Synchronization

A transfer is software-triggered when the logical channel is set up and started by software. To specify a software-triggered transfer, set the channel DMA [DMA4_CCRi\[4:0\]](#) and [DMA4_CCRi\[20:19\]](#) bit fields to 0. The transfer starts as soon as the DMA [DMA4_CCRi\[7\]](#) bit is set (when it enters the scheduling process).

16.4.9.2 Hardware Synchronization

A transfer is hardware-synchronized if the logical channel activation is driven by hardware requests from the source or destination target. A hardware-synchronized transfer is specified by configuring the DMA request line number in the channel [DMA4_CCRi](#) register to a value that corresponds to the DMA request line from the source or destination that generates the DMA requests. The DMA request numbers to be configured are specified in the DMA request mapping (see [Table 16-8](#)).

Specify the DMA request number in the [DMA4_CCRi](#)[4:0] SYNCHRO_CONTROL and [DMA4_CCRi](#)[20:19] SYNCHRO_CONTROL_UPPER bit fields. After the [DMA4_CCRi](#)[7] ENABLE bit is set, the logical channel becomes enabled but not activated (it does not enter the scheduling process), which means that channel registers are not updated until the first DMA request is received.

NOTE: The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, the [DMA4_CCRi](#)[4:0] SYNCHRO_CONTROL bit field must be set to 0x2 (DMA request number + 1).

NOTE: DMA Request Line

A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared among several chained logical channels.

For hardware synchronization, the amount of data to be transferred for each assertion of the DMA request line is configured through the frame synchronization (FS) and block synchronization (BS) bits in the logical channel [DMA4_CCRi](#) register and the [DMA4_CCRi](#)[5] FS and [DMA4_CCRi](#)[18] BS bits, respectively.

The amount of data can be any of the following:

- A single element transfer: A complete element defined by data type. For example, 8/16/32 bits are transferred in response to a DMA request.
- A full frame: A complete frame of several elements is transferred in response to a DMA request.
- A full block (a full channel transfer): A complete block of several frames is transferred in response to a DMA request.
- A full packet (a full channel transfer): A complete packet of several elements is transferred in response to a DMA request.

Packets allow the size of each part of the full DMA transfer to be configured independently of the organization of the data to be transferred (typically a number of elements). This can be useful when the source or destination has a buffer (such as a FIFO queue) with a size unrelated to the frame size of the transfer. The packet size then can be set to the size of the buffer.

Packet transfer must be used only where the source or destination is addressed in constant addressing mode, because FI registers are reused to specify the packet size.

To support the burst mode, the logical channel must also be configured in target-port packed access mode.

The packet size is configured based on the [DMA4_CCRi](#)[24] SEL_SRC_DST_SYNC bit through either the channel [DMA4_CDFIi](#) register (source synchronized) or the [DMA4_CSFII](#) register (destination synchronized).

When the logical channel transfer block is not an exact multiple of the packet size, the final packet consists of the remaining elements in the transfer, using burst or single accesses to complete the block transfer.

The maximum transfer size, regardless of the packet size, is always as follows:

$$\text{Block_size} = \text{Number_of_Frame_in_Block} * \text{Number_of_Element_in_Frame} * \text{Element_Size}$$

- Synchronized at the source

The DMA module optimizes the transfer with respect to the number and size of burst transactions for the given source and destination addressing profiles and configured maximum burst sizes. When writing to the destination is slower than reading from the source, data is buffered in the channel FIFO queue. If the transfer is packet-synchronized at the source, the end-of-packet interrupt is disabled (see

Section 16.4.13, Reprogramming an Active Channel).

For a source synchronized transfer, buffering can be enabled or disabled by setting the [DMA4_CCRi\[25\] BUFFERING_DISABLE](#) bit. For a packet source synchronization with buffering disabled and the packed/burst across the packet boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the packet transfer size. However, for a packet source synchronized transfer with buffering enabled and with the packed/burst across the packet boundary, the DMA module waits for the next DMA request(s) to read enough data to issue an atomic packed/burst write transaction (assuming that the address is packed/burst aligned).

NOTE: Buffering is not performed between frames, even if it is enabled. If the packed/burst is across the frame boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the frame transfer size.

- Synchronized at the destination

The performance of a hardware-synchronized transfer can be improved by using the prefetch mode, enabled through the channel [DMA4_CCRi\[23\] PREFETCH](#) bit. Data is prefetched on the read port side before the DMA request received and buffered in the FIFO queue. Up to a full transfer block can be prefetched, although this can be limited by the specified maximum channel FIFO queue depth (see [Section 16.4.4, FIFO Queue Memory Pool](#)).

Buffering disable is not allowed for a destination-synchronized transfer.

NOTE: Behavior is undefined when prefetch is enabled and a transfer is synchronized to the source.

Regardless of whether buffering is enabled, the last transaction in the frame or in the block is write nonposted (WNP) even if the write mode is specified as write last nonposted (WLNP; the [DMA4_CSDPi\[17:16\] WRITE_MODE](#) bit field = 0x2). However, in a packet synchronization mode, the last transaction of each packet in the transfer is WNP only if the buffering disable is on (even if the write mode is specified as WLNP).

Regardless of whether buffering is enabled, the packet interrupt is not generated in the packet source synchronized mode.

CAUTION

The [DMA4_CCRi\[25\] BUFFERING_DISABLE](#) bit must be filled with an allowed value, as specified in [Table 16-12](#).

Table 16-12. Buffering Disable

	BUFFERING_DISABLE (0: Buffering enable, 1: Buffering disable)	
Destination synchronized	0	Allowed
	1	Not allowed
Source synchronized	0	Allowed
	1	Allowed

- Synchronized transfer monitoring using CDAC ([DMA4_CDACi](#)):
Context is restored only when the channel becomes active on a DMA request (not at software enable). The channel is software-enabled first, and then a DMA request is asserted followed by the first context restore.

The CDAC register is writable; thus, the CDAC can be initialized to monitor the transfer and determine whether the transfer is started (for more information, see [Section 16.5.4, Synchronized Transfer Monitoring Using CDAC](#)).

NOTE: For 16-bit transactions, start reading from or writing to the LSByte first to enable the register update. This is not an issue for 32-bit read-write transactions.

16.4.10 Thread Budget Allocation

When several concurrent channels are latency critical and hardware synchronized, a specific latency cannot be ensured until the target is served. This situation occurs when the number of concurrent channels is greater than the number of available threads.

NOTE: Four threads are available on the read port, and two threads are available on the write port.

For a hardware-synchronized transfer (memory to peripheral), a minimum bandwidth for a latency-critical transfer must be ensured to avoid collisions between two hardware requests.

Because it is latency critical, the software user is responsible for the following:

- Programming the synchronized channel as a high-priority channel
- Reserving one or several threads for high-priority channels

The proposed implementation is as follows (see [Section 16.5.5, Concurrent Software and Hardware Synchronization](#)):

Prevent the regular channel queue from exceeding more than a programmable (3, 2, or 1) number of threads on the read port and no more than one thread on the write port. This number can be set in the global register [DMA4_GCR\[13:12\]](#).

The thread reservation is programmable for maximum use of thread resources for concurrent, low-priority channel transfer. Programmability can also allow a partial throughput control by limiting in software the number of concurrent outstanding requests that break the pipelining.

Depending on the [DMA4_GCR \[13:12\]](#) value, the following threadID on the read/write ports are allocated for a high-priority channel:

Read port priority thread reservation:

- [DMA4_GCR\[13:12\] = 0x0](#) => No ThreadID is reserved for high-priority channels.
- [DMA4_GCR\[13:12\] = 0x1](#) => Read ThreadID 0 is reserved for high-priority channels.
- [DMA4_GCR\[13:12\] = 0x2](#) => Read ThreadID 0 and Read ThreadID 1 are reserved for high-priority channels.
- [DMA4_GCR\[13:12\] = 0x3](#) => Read ThreadID 0, Read ThreadID 1, and Read ThreadID 2 are reserved for high-priority channels.

Write port priority thread reservation:

- [DMA4_GCR\[13:12\] = 0x0](#) => No ThreadID is reserved for high-priority channels
- [DMA4_GCR\[13:12\] = 0x1](#) => Write ThreadID 0 is reserved for high-priority channels.
- [DMA4_GCR\[13:12\] = 0x2](#) => Write ThreadID 0 is reserved for high-priority channels.
- [DMA4_GCR\[13:12\] = 0x3](#) => Write ThreadID 0 is reserved for high-priority channels.

Regardless of whether the enabled channels are high priority, only the setting of the [DMA4_GCR\[13:12\]](#) value forces the thread reservation to these values. Set the appropriate value to avoid losing threads using only regular channels.

To have an independent read and write priority context, a per-channel bit ([DMA4_CCRI\[26\]](#)) is added for write priority, and the previous priority bit becomes read priority bit ([DMA4_CCRI\[6\]](#)).

NOTE: The device has one priority bit per logical channel, not one priority bit per port.

16.4.11 FIFO Budget Allocation

To avoid fully occupying the FIFO with a high-priority transfer while low-priority channels wait in the arbitration queue, two separate FIFO budgets are specified: one for high-priority channels and one for low-priority channels. This is defined in the [DMA4_GCR](#) register, allowing the user to share the FIFO budget between the low- and high-priority channels. The amount of the FIFO allocated by the low- and high-priority channels is fixed by the value set in the [DMA4_GCR\[15:14\]](#) HI_LO_FIFO_BUDGET field. The maximum channel FIFO depth is limited by the HI_LO_FIFO_BUDGET field as follows:

If the channel is low priority:

- When HI_LO_FIFO_BUDGET = 0x1, then low priority cannot exceed 75 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x2, then low priority cannot exceed 25 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x3, then low priority cannot exceed 50 percent of the total FIFO.

If channel is high priority

- When HI_LO_FIFO_BUDGET = 0x1, then high priority cannot exceed 25 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x2, then high priority cannot exceed 75 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x3, then high priority cannot exceed 50 percent of the total FIFO.

The user is responsible for performing the following equation:

- For a high-priority channel: $(\text{Per_Channel_Maximum FIFO Depth} + 1) \times \text{Number of High Channel} \leq \text{High Budget FIFO}$
- For a low-priority channel: $(\text{Per_Channel_Maximum FIFO Depth} + 1) \times \text{Number of Low Channel} \leq \text{Low Budget FIFO}$

NOTE: Ensure that *Number of High Channel* means *Number of Active High-Priority Channel* and that *Number of Low Channel* means *Number of Active Low-Priority Channel*.

16.4.12 Chained Logical Channel Transfers

Chaining multiple logical channels permits transfers consisting of multiple parts to be executed without repeated software intervention. This results in better performance than the alternative of software setting up and starting each transfer separately. Each part of a chained transfer can have the data addressed in a different manner that permits the programming of a variety of complex transfers. For example:

- Interlaced video data with one logical channel configured to transfer the even lines and another logical channel configured to transfer the odd lines
- Protocol headers with a separate DMA4 channel configured to transfer each field in the header

Channels can be chained through each channel [DMA4_CLNK_CTRLi](#) register. When the transfer for the first channel completes, the next channel in the chain is enabled. The number of channels in the chain that are configured for hardware-synchronized transfers is flexible (although typically it might be all, none, or just the first one). The DMA request line number should be set to 0 to specify that any or all of the channels in a chain are software-triggered or nonsynchronized.

The last channel in a chain can be chained to the first channel to create a continuously looping chain. The continuously looping transfer can be stopped on the fly at a specific channel by disabling the [DMA4_CLNK_CTRLi\[15\]](#) ENABLE_LNK bit. The looping transfer stops after the specified channel transfer is complete.

NOTE: DMA Request Line

A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared between several chained logical channels.

For more information on the programming model, see [Section 16.5](#), *sDMA Basic Programming Model*.

16.4.13 Reprogramming an Active Channel

A currently active logical DMA channel can be disabled through the [DMA4_CCRi\[7\]](#) ENABLE bit. When an ongoing transaction is complete and the read-active and write-active bits in the [DMA4_CCRi](#) register ([DMA4_CCRi\[9\]](#) RD_ACTIVE and [DMA4_CCRi\[10\]](#) WR_ACTIVE) are reset, the channel can be reprogrammed for a new transfer.

16.4.14 Packet Synchronization

A packet transfer notion is related to the behavior of some peripherals, which have certain buffering capability and requires to transfer the buffer content once an element number threshold is reached (a hardware DMA request is generated). To associate a frame synchronization to each DMA request is possible, but this limits the maximum transfer size. Indeed the maximum transfer size is proportional to the FIFO depth of the peripheral:

$$\text{maximum_transfer_size} = \text{peripheral_FIFO_depth} \times \text{number_of_frame_in_block}$$

The packet synchronization allows to dissociate the transfer size from the FIFO depth of the peripheral. Only Constant addressing mode is allowed on a read port or a write port if source target or destination target is packet synchronized respectively.

Example:

Consider a camera interface with a FIFO_depth of 128 words and a FIFO_element_number_threshold of 128, and a picture to transfer with a size 320 lines by 240 columns. If frame synchronization is associated with each DMA request then the maximum transfer size that can be performed is 128×2^{16} words. In this case, a frame is 128-word long, which does not fit the size of a line, and it is not possible to generate an interrupt at the end of line. However, by introducing the packet transfer notion, which is related to the peripheral FIFO behavior/structure, the maximum transfer size ($\text{maximum_transfer_size} = 2^{24} \times 2^{16}$ words) is independent of both peripheral_FIFO_depth and FIFO_element_number_threshold. This allows a long-enough transfer within one channel context and rotation operation on a large image format.

The main features of DMA Packet transfer are as follows:

- DMA Packet_Data_Size for each DMA Request: the Peripheral_element_number_threshold (the number of elements in a packet) shares the [DMA4_CSFi](#) and [DMA4_CDFi](#) configuration registers. If the peripheral is the source target, the addressing mode is constant, and the [DMA4_CSFi\[15:0\]](#) bit field is used to specify the packet data size in the [DMA4_CSFi](#) register. The user must set the [DMA4_CCRi\[24\]](#) SEL_SRC_DST_SYNC bit to 1. If the peripheral is the destination target, the addressing mode is constant, the [DMA4_CDFi\[15:0\]](#), is used to specify the packet data size (PKT_ELNT_NBR), and the bit field [31:16] is unused. To specify the packet data size in the [DMA4_CDFi](#) register, the user must set the [DMA4_CCRi\[24\]](#) SEL_SRC_DST_SYNC bit to 0.

NOTE: The packet size can be a submultiple or non-submultiple of a frame size. If DMA Packet_Data_Size is aligned on the DMA channel block data size boundary, then DMA transfers the last data in the channel block boundary, and stops at the block boundary for the last packet DMA Request. If the Packet_Data_size is not aligned on the block boundary, the remaining data smaller than a packet size are transferred using burst or single accesses to complete the block.

- DMA Packet_Data_Transfer does not affect DMA channel capabilities in term of packing and bursting. The Packet synchronization mode is active when [DMA4_CCRi\[5\]](#) FS = [DMA4_CCRi\[18\]](#) BS = 1. Then
 - if [DMA4_CCRi\[24\]](#) SEL_SRC_DST_SYNC=0, the [DMA4_CDFi\[15:0\]](#) bit field gives the number of elements in the packet and the [DMA4_CDFi\[31:16\]](#) bit field is unused for the packet size.
 - if [DMA4_CCRi\[24\]](#) SEL_SRC_DST_SYNC=1, the [DMA4_CSFi\[15:0\]](#) bit field gives the number of element in the packet and the [DMA4_CSFi\[31:16\]](#) bit field is unused for the packet size.

NOTE: The maximum transfer size, regardless of the packet size, is always:
 $\text{Block_size} = \text{Number_of_Frame_in_Block} \times \text{Number_of_Element_in_Frame} \times \text{Element_Size}$.

If DMA channel packet/burst access is across the packet boundary, the DMA hardware automatically splits this packing/burst access into multiple smaller accesses that are aligned on the packet boundary. Otherwise, the DMA transfers data as a usual packing/burst access.

16.4.15 Graphics Acceleration Support

The sDMA supports two graphic acceleration features:

- Transparent copy
- Constant fill

Only one of these features can be enabled at a time through the [DMA4_CCRi](#) register for the particular logical DMA channel.

The transparent copy feature enables specification of a particular color through the [DMA4_COLORi](#) register, so that when it is recognized in the data from the source, it is not copied to the corresponding location in the destination, but instead leaves the data in the corresponding location in the destination as it is.

Figure 16-11 shows the 2-D graphic transparent color block diagram.

The constant fill feature provides the ability to specify a particular color through the [DMA4_COLORi](#) register for every specified location in the destination. In this case, the transfer consists only of writing to the destination without reading from a source.

Both features support 8 bpp (bits per pixel), 16 bpp, and 24 bpp, depending on what is specified as the DMA transfer ES via the [DMA4_CSDPi](#) register. An ES of 32 bits corresponds to 24 bpp. During a 32-bit (24 bpp) transfer, the 8 most-significant bits (MSB) ([31:24]) are 0. Both features are compatible with packed and burst transactions.

16.4.16 Supervisor Modes

A logical DMA channel can be configured to operate in supervisor mode through the [DMA4_CCRi](#)[22] SUPERVISOR bit. This must be done using supervisor access. Once a channel is configured in supervisor mode, the channel configuration is protected from nonsupervisor accesses. All DMA transactions on a supervisor channel are supervisor transactions.

16.4.17 Posted and Nonposted Writes

A logical channel can be configured in its [DMA4_CSDPi](#)[17:16] bits to use one of three write access handshake modes for the destination:

- Nonposted write: Each write must complete before transfer can continue or complete.
- Posted write: Transfer continues without waiting for each write to complete (might improve performance with slow devices).
- Posted with final write nonposted: Transfer continues without waiting for each write to complete, but final write is completed before transfer can complete.

16.4.18 Disabling a Channel During Transfer

When a channel is disabled during a transfer, the channel undergoes an abort, unless it is hardware source synchronized with buffering enabled ([DMA4_CCRI\[25\] BUFFERING_DISABLE = 0](#)). If this is the case, the FIFO is drained to prevent the loss of data. See [Section 16.4.19, FIFO Draining Mechanism](#), for details about this feature.

16.4.19 FIFO Draining Mechanism

When a source synchronized channel is disabled during a transfer, then the current hardware request (element/packet/frame/block) service is completed and the channel [DMA4_CCRI\[9\] RD_ACTIVE](#) bit is set to 0, which means the channel is not active on the read port. The remaining data in the corresponding disabled channel FIFO is drained onto the write port and transferred to the programmed destination as in normal transfer.

At the end of the draining the [DMA4_CCRI\[10\] WR_ACTIVE](#) bit is set to 0 (channel is no longer active on the write port) and if the [DMA4_CICRI\[12\] DRAIN_END_IE](#) is set to 1, the [DMA4_CSRI\[12\] DRAIN_END](#) status bit is updated and an interrupt is generated.

Once a channel is disabled during a transfer, it must wait for [DMA4_CCRI\[9\] RD_ACTIVE](#) and [DMA4_CCRI\[10\] WR_ACTIVE](#) to become 0 before being reenabled for a new transfer. The FIFO drain for a channel occurs only in the following cases:

- If the channel is a source synchronized channel and [DMA4_CCRI\[25\] BUFFERING_DISABLE = 0](#) and
- If the channel is not a solid fill channel and
- If the channel is not a transparent and copy channel and
- If the channel is a hardware, synchronized channel

NOTE: For a self-linked or chain-linked channel, the user must disable the [DMA4_CLNK_CTRL\[15\] ENABLE_LINK](#) bit before disabling the channel.

In all other cases, the channel undergoes an abort.

16.4.20 Linked List

16.4.20.1 Overview

The sDMA supports the logical transfer descriptor loader feature. A transfer descriptor represents a set of values that maps to a set of logical channel configuration registers.

A logical channel transfer descriptor can be loaded by DMA from memories, and then successive transfer descriptors can be autonomously loaded based on a linked-list scheme. This enables DMA4 scatter gather transfers with minimum MPU support by removing successive channel configuration processing and associated interrupt handling overheads. It also optimizes DMA4 channel resources by enabling efficient transfer serialization on a single logical channel versus concurrent (multiple) logical channel use.

Different types of transfer descriptors are supported (full or partial logical channel configuration registers are set). This optimizes the memory size required for storing a long linked list, because parameter changes are limited to only a few logical channel configuration registers.

16.4.20.2 Link-List Transfer Profile

A linked-list transfer can be seen as a super-block transfer (where the block is composed of FN frames and each frame includes EN elements). The block size (FN x EN x ES) can be changed in the linked list by loading an updated transfer descriptor.

The end of the super block is signaled in the last descriptor associated with the last block. Generally, for a given link-list transfer, the logical channel is set at the beginning of the transfer and the logical channel configurations for the subsequent blocks are slightly changed. Thus, the descriptor can be limited to an update of only few parameters, such as FN or EN. This assumes that the content of unmodified registers is preserved when a new descriptor is loaded.

A transfer descriptor is composed of a set of channel configuration register values with the addition of the next-descriptor pointer register ([DMA4_CNDPi](#)) and a channel-descriptor parameter register ([DMA4_CDPi](#)). The next-descriptor pointer is the 32-bit address pointer from where the next transfer descriptor is to be loaded. The next-descriptor pointer is mapped depending on the descriptor type (1, 2, or 3).

16.4.20.3 Descriptors

A transfer descriptor is a set of values that maps to a set of logical channel configuration registers. The descriptor contains the parameters associated with a transfer profile (transfer size, source or destination addresses, etc). Four different types of transfer descriptors are supported to optimize the memory size required to store a long linked list and to minimize MPU use to create and maintain the descriptor list.

A transfer descriptor is a list of 32-bit values. A descriptor must be 32-bit aligned in memory. Only the 30 least-significant bits (LSBs) of the next-descriptor address pointer are updated from the descriptor, and the DMA4 forces the 2 LSBs to 0 on generation of the pointer address. The descriptor size is variable depends on the descriptor type and the `Nxt_Dv` and `Nxt_Sv` bit fields.

Transfer descriptor bit mapping is the same as DMA4 logical-channel configuration register bit mapping, with the following exceptions:

- `Src_Element_index` and `Dst_Element_index` are concatenated in the same 32-bit location.
- [DMA4_CICRi](#) (interrupt event mask)
- CFN (frame number)
- Bit fields
 - P: Corresponds to the `PAUSE_LINK_LIST` bit:
 - When set to 1 in the descriptor, the channel is suspended when the descriptor load completes.
 - The user must not set the `PAUSE_LINK_LIST` bit through the configuration port. Otherwise, behavior is undefined.
 - When set to 0 (through the configuration port) after pause, the linked-list channel resumes its transfer (either descriptor load or data load).
 - B: Corresponds to the end-of-block enable bit (`BLOCK_IE`) of the [DMA4_CICRi](#) register; valid only for type 3. This value is don't care for descriptor types 1 and 2, where [DMA4_CICRi](#) is fully specified.
 - `Nxt_Dv`, `Nxt_Sv`: Mapped in the [DMA4_CDPi](#) register. They indicate one of the following possibilities:
 - Next descriptor contains an updated destination or source address.
 - Next descriptor does not update the source or destination address, but increments the last source or destination address (from the end of the last transfer).
 - The next source address and/or destination address are the last valid ones in the configuration memory. This means that the corresponding location in the configuration memory is not updated (assuming that they were initialized at least once in the past). This is also called wrapping addressing.
 - `Next_Descriptor_Type`: Specifies the next descriptor type that corresponds to the `NEXT_DESCRIPTOR_TYPE` bit field in the [DMA4_CDPi](#) register

16.4.20.3.1 Type 1

A type 1 descriptor includes the overall channel configuration register value to be loaded (global registers are not part of the type 1 descriptor). This descriptor is used primarily when major changes are required:

- Channel read or write access profiles must be modified, for example, bursting and packing (included in the [DMA4_CSDPi](#) register)
- Attach a new DMA request to the same channel or change the priority or change the access privilege (included in the [DMA4_CCRi](#) register)
- Enable solid or transparent color fill (included in the [DMA4_CCRi](#) and [DMA4_COLORi](#) registers)
- Enable a channel link (included in the [DMA4_CLNK_CTRLi](#) register)

[Table 16-13](#) shows a type 1 descriptor.

Table 16-13. Type 1

16.4.20.3.2 Type 2

A type 2 descriptor includes the overall logical channel transfer address register and transfer format register to be loaded. This descriptor enables 2D addressing linked-list transfer (for example, a multimedia application where 2D objects are moved in a link). [Table 16-14](#) shows a type 2 descriptor with source and destination address updates. [Table 16-15](#) shows a type 2 descriptor with one source or destination address update.

Table 16-14. Type 2 With Source and Destination Address Updates

16.4.20.3.3 Type 3

A type 3 descriptor is limited to a few logical channel transfer address registers and transfer format registers to be loaded. This descriptor enables simple 1D addressing link transfer (for example, scatter-gather or ping-pong memory movement using a linked list). [Table 16-16](#) shows a type 3 descriptor with source and destination address updates. [Table 16-17](#) shows a type 3 descriptor with one source or address destination update.

16.4.20.4 Linked-List Control and Monitoring

16.4.20.4.1 Transfer Mode Setting

Four descriptor types are available in DMA4_CDPI[9:8] TRANSFER_MODE to distinguish the different transfer modes:

- [DMA4_CDPi\[9:8\]](#) TRANSFER_MODE = 00: The current channel is using normal mode.
- [DMA4_CDPi\[9:8\]](#) TRANSFER_MODE = 01: The current channel is using link-list channel mode for a type 1, 2, or 3 descriptor.

The reset value is normal mode (DMA4 CDPI[9:8] TRANSFER MODE = 0).

16.4.20.4.2 Starting a Linked List

Like a nonlinked-list transfer, a link transfer starts under host control by enabling the associated logical channel (set the [DMA4_CCRi\[7\]](#) ENABLE bit to 1). The [DMA4_CDPi\[10\]](#) FAST bit sets the start mode of the link-list transfer:

In nonfast-start mode, the logical channel configuration is fully initialized so that the transfer can start without descriptor loading.

In fast-start mode, the descriptor pointer and other inputs are given. The channel starts by loading the descriptor and then starts the data transfer phase.

16.4.20.4.3 Monitoring a Linked-List Progression

In addition to the [DMA4_CCENi](#) (remaining elements) and [DMA4_CCFNi](#) (remaining frames) registers that are used to monitor the transfer progress, a per-channel register, [DMA4_CCDNi](#) (channel current active descriptor number), monitors which descriptor in the list is active. The user must initialize the [DMA4_CCDNi](#) register to 0 during the initial configuration. When the [DMA4_CCDNi](#) register is updated, the [DMA4_CCFNi](#) and the [DMA4_CCENi](#) registers are updated. The user must also initialize the [DMA4_CCFNi](#) and [DMA4_CCENi](#) registers to 0xFFFF and to 0xFFFFFFFF, respectively, to track the effective transfer start of synchronized transfer.

16.4.20.4.4 Interrupt During Linked-List Execution

Any logical channel source of interrupt can be triggered during a linked-list execution, if the interrupt source is enabled during the initial configuration in CICR. The [DMA4_CICRi](#) register can also be updated during the linked-list execution if descriptor types 1 and 2 are used.

The use of an interrupt event in a link execution can be difficult, because the link can progress in parallel with interrupt service routine (ISR) execution. This makes it difficult to synchronize them unless system assumptions are used. The most appropriate synchronization model is to get an interrupt-only on linked-list completion, when the last transfer block is complete. This prevents the interrupt from occurring during the link execution. An end-of-super-block interrupt event available in the [DMA4_CICRi](#) and [DMA4_CSRi](#) registers can be enabled at initial configuration or when using descriptor types 1 and 2. To prevent the use of descriptor type 1 or 2 to update BLOCK_IE (full [DMA4_CICRi](#) update), a dedicated BLOCK_IE bit field is also available in a type 3 descriptor.

16.4.20.4.5 Pause a Linked List

When the channel is suspended, it remains enabled.

The pause behaves differently, depending on the transfer mode:

- Normal transfer mode: If the user sets the [DMA4_CDPi\[7\] PAUSE_LINK_LIST](#) bit to 1, the channel completes the current read and write transactions and then suspends the channel. The channel can be resumed by setting the channel [DMA4_CDPi\[7\] PAUSE_LINK_LIST](#) bit to 0.
- Linked-list type 1, 2, or 3 mode: The user must not set the [DMA4_CDPi\[7\] PAUSE_LINK_LIST](#) bit through the configuration port; otherwise, transfer behavior is undefined.

A [PAUSE_LINK_LIST](#) bit (P) is set to 1 in the descriptor.

- The channel is suspended after the descriptor load, translation, and configuration memory update are complete.
- The linked list can be resumed by resetting the [DMA4_CDPi\[7\] PAUSE_LINK_LIST](#) bit (through the configuration port).

16.4.20.4.6 Stop a Linked List (Abort or Drain)

The channel can be stopped for a drain or an abort. These cases are exclusive.

16.4.20.4.6.1 Drain

- Drain conditions:

A channel is a drain candidate if it is a hardware-source-synchronized transfer with [DMA4_CCRi\[25\] BUFFERING_DISABLE](#) = 0 and should not be doing any of the graphics operation (transparent copy or solid-color fill).

- Drain trigger:

A drain candidate channel is drained if it is disabled ([DMA4_CCRi\[7\] ENABLE](#) = 0) or if it receives a transaction error on the read port.

- Drain behavior with a type 1, 2, or 3 descriptor. Drain trigger can occur in two situations:
 - During descriptor loading: Any ongoing current transaction is complete and the channel is aborted.
 - During data loading: The read is completed at the boundary of the request (element/frame/packet/block boundary), the FIFO is drained to the destination, and then a [DRAIN_END](#) interrupt can be asserted.

16.4.20.4.6.2 Abort

- Abort condition:

A channel is an abort candidate if it is software-synchronized, hardware-destination-synchronized, solid color-fill, transparent-color fill, or hardware-source-synchronized with [DMA4_CCRi\[25\] BUFFERING_DISABLE](#) = 1.

- Abort trigger:

A channel is an abort candidate if it is disabled ([DMA4_CCRi\[7\] ENABLE](#) = 0), if it receives a transaction error on the read or write port, or if there is a [MISALIGNMENT_ERROR](#).

- Abort behavior with a type 1, 2, or 3 descriptor:

If an abort trigger occurs, the channel aborts immediately after completion of current read/write transactions and then the FIFO is cleaned up.

In type 1, 2, or 3, if an abort trigger or drain trigger occurs during the descriptor load phase, the channel aborts.

16.4.20.4.7 Status Bit Behavior

This section describes the behavior of the [DMA4_CSRI\[6\] SYNC](#), [DMA4_CCRi\[9\] RD_ACTIVE](#) and [DMA4_CCRi\[10\] WR_ACTIVE](#) status bits:

- For a hardware-synchronized channel in linked-list mode, the [DMA4_CSRI\[6\] SYNC](#) bit becomes active ([DMA4_CSRI\[6\] SYNC](#) = 1) when the first data load transaction is scheduled and remains active

until the last data load transaction in the block (not super block) is descheduled ([DMA4_CSRI\[6\]](#) SYNC = 0). The SYNC bit is not active during the descriptor load phase.

- The [DMA4_CCRi\[9\]](#) RD_ACTIVE bit is active during the data load phase and the descriptor load phase. It becomes active when the first read transaction is scheduled. It becomes inactive:
 - When (during the descriptor load phase) the last descriptor write request is descheduled
 - When (during the data load phase) the last read transaction in the block (not super block) is descheduled for software-synchronized transfer or destination-synchronized transfer with prefetch enabled
 - When (during the data load phase) the last read transaction in the request (element/frame/packet/block sync) is descheduled for hardware-source-synchronized transfer or hardware-destination-synchronized transfer without prefetch
- The [DMA4_CCRi\[10\]](#) WR_ACTIVE bit is active only during the data load phase. It becomes active when the first write transaction is scheduled and becomes inactive:
 - Until the last write transaction in the block (not super block) is descheduled and the FIFO is cleaned up for software-synchronized transfer
 - Until the last write transaction in the request (element/frame/packet/block sync) is descheduled and the FIFO is cleaned up for hardware-source-synchronized transfer (with [DMA4_CCRi\[25\]](#) BUFFERING_DISABLE = 0) or hardware-destination-synchronized transfer.

16.4.20.4.8 Linked-List Channel Linking

Channel linking for inter and intra super blocks is supported for type 1, 2, and 3 descriptors.

Assume that CHx and CHz are linked-list channels using generic descriptors. If CHx is composed of N descriptors and CHz is composed of M descriptors, then in nonfast mode,

CHx: CHx[Data1] -> CHx[DES1] -> . -> CHx[DESN] -> CHx[DataN + 1]

CHz: CHz[Data1] -> CHz[DES1] -> . -> CHz[DESM] -> CHz[DataM + 1]

It is possible to link CHx to CHz or CHx to itself after the completion of the CHx transfer (end of super block). To do this, the user must set the [DMA4_CLNK_CTRLi\[15\]](#) ENABLE_LNK bit to 1 and the [DMA4_CLNK_CTRLi\[4:0\]](#) NEXTLCH_ID bit to z (or to x for self linking) through the last descriptor using a type 1 descriptor. The sequence is:

CHx: CHx[Data1] -> CHx[DES1] -> . -> CHx[DESN] -> CHx[DataN+1] -> CHz: CHz[Data1] -> CHz[DES1] -> . -> CHz[DESM] -> CHz[DataM+1]

It is also possible to link CHx to CHz during the CHx transfer and before the end of super block. The user must set the [DMA4_CLNK_CTRLi\[15\]](#) ENABLE_LNK bit to 1 and the [DMA4_CLNK_CTRLi\[4:0\]](#) NEXTLCH_ID bit to z through descriptor p (CHx[DESp]) using a type 1 descriptor. The sequence is:

CHx: CHx[Data1] -> CHx[DES1] ->...-> CHx[DESp] -> CHx[Data(p + 1)] -> CHz[Data1] -> CHz[DES1] -> .

The user must continue the linking until channels CHx and CHz complete their super-block transfers; otherwise, the channels remain enabled.

NOTE: In channel linking, the head of a chain can be in fast mode or nonfast mode. All channels that are not in the head of the chain can be in nonfast mode only. In self-linking, the channel cannot be in fast mode.

NOTE: If channel CHx links to CHz in the middle of the superblock transfer (remember link bit can be set through Type-1 descriptor load), CHx will get disabled after the corresponding data load and enables the channel CHz.

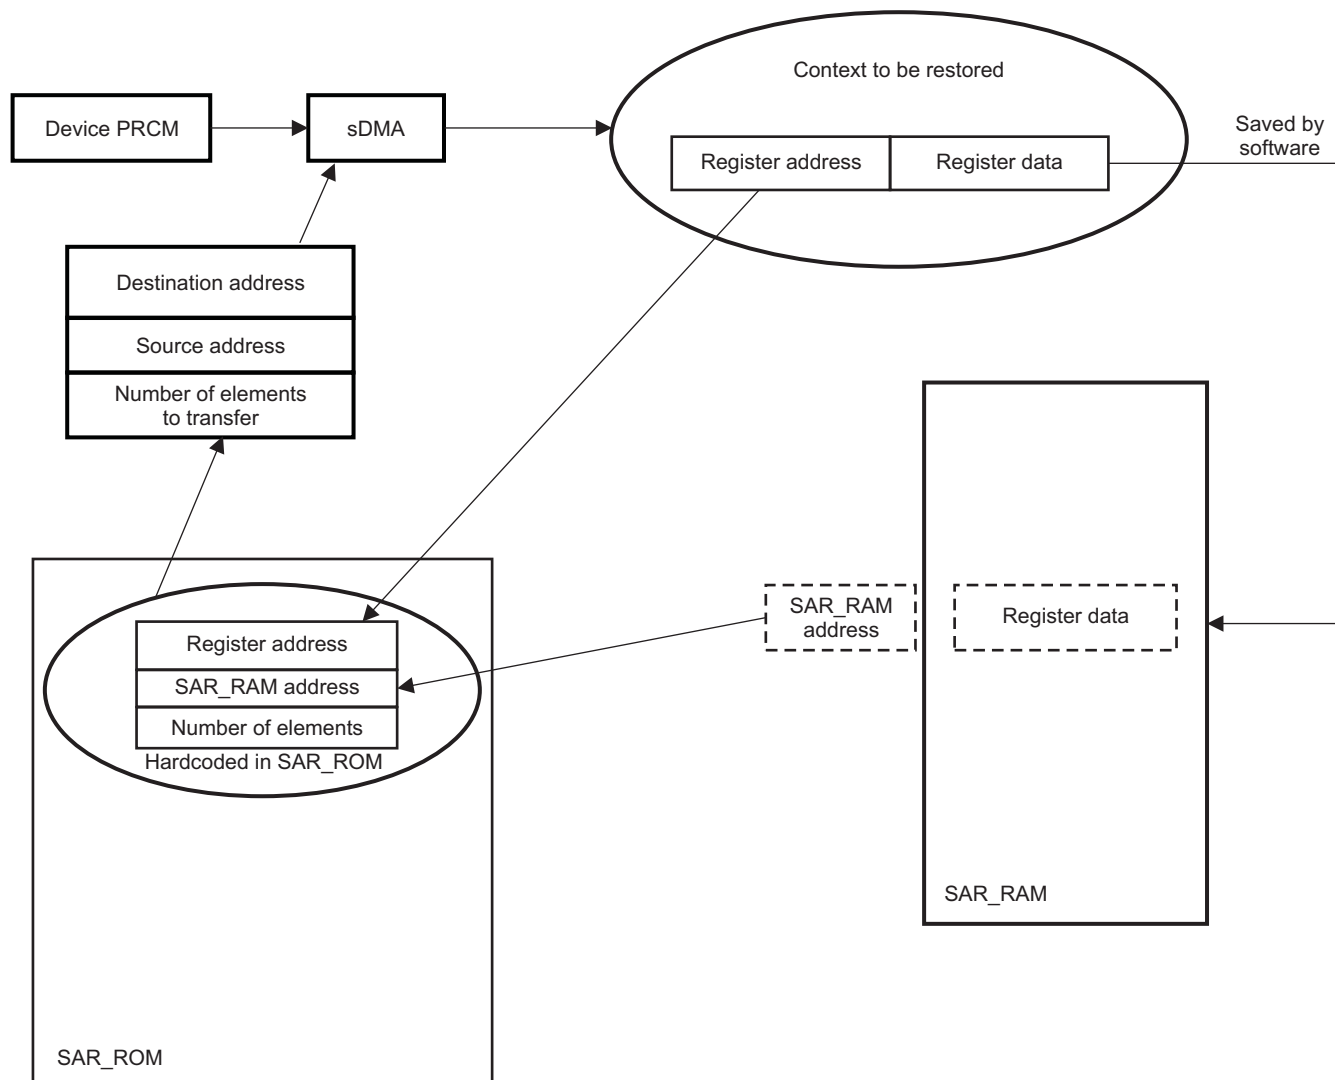

16.4.21 Auto-Restore Feature

The auto-restore feature is introduced mainly to accelerate the restore process, which otherwise is complex as well as time and resource consuming. In many system applications, it is required that the modem wake up and use only a few modules to wake up, without the main MPU (Cortex-A9 MPU) intervention. The MPU still might be in OFF mode; however, some modules might need to come out of OFF mode. The sDMA can be used to restore the register contents of these modules. The auto-restore feature consists in saving the registers data into a memory (SAR RAM sitting in the WKUP domain) that remains powered even during OFF-mode then it consists in retrieving automatically data when returning from OFF-mode.

The restore feature is enabled by default and cannot be disabled.

Figure 16-12 shows an overview of the save and restore mechanism using SAR RAM and SAR ROM.

Figure 16-12. Save and Restore Mechanism Overview Using SAR RAM and SAR ROM

dma-014

16.4.21.1 Save Process

The save process is done entirely by software; the sDMA module normally is not involved. The software must save the data to be restored in a dedicated location in SAR RAM. To reduce the save sequence execution time, the sDMA can be used with linked-list descriptors. These save descriptors are symmetrical with regards to descriptors that lay in the SAR ROM.

The register content to be saved can be the register value before going into OFF-mode or a value that is required on wake up. This means that the restored register value can be different from the last value of the register before going into OFF-mode.

The following registers are impacted:

- CM1 and CM2 configuration
Bits 0 of the CM_SHADOW_FREQ_CONFIG1 register and the CM_SHADOW_FREQ_CONFIG2 register are self-clearing and must be set at restore time. Thus, these data must always be overwritten in the SAR RAM.
- Because USBHOSTHS and USBTLL restore needs a particular sequencing, the software must overwrite data read from the following registers implied in phase2a and phase 2b:
 - **CM_L3INIT_HSUSBHOST_CLKCTRL_RESTORE**
 - **CM_L3INIT_HSUSBTLL_CLKCTRL_RESTORE**
 - **CM_SDMA_STATICDEP_RESTORE**

The USBHOSTHS and USBTLL modules must be put in a particular mode when saving (and restoring) their context. In the case of context saving, the software must follow the following sequence:

- Configure the L3INIT clock domain to SW_WKUP to ensure module transitions.
- Disable both modules.
- Assert the SAR_MODE pins.
- Enable back both modules. Optional clocks must be kept gated.
- Save both modules context.
- Disable both modules.
- Deassert SAR_MODE pins.
- At this point, the software might enable back both modules and get out L3INIT clock domain from the SW_WKUP state.

16.4.21.2 Restore Process

As explained earlier, every time modem wakes up, the MPU must not necessarily wake up. This needs an automated way of restore. E.g. when mobile is in roaming, and not in active use, it needs to change base stations. For this task, the MPU need not wake up, only a few peripherals/subsystems need to be in ON mode. Before executing any task, we need to restore their register contents.

16.4.21.2.1 PRCM and sDMA interaction During Restore Phase

Restore is performed during three phases. At the end of each phase, the sDMA stops and waits for the PRCM to perform the next phase transfer. For more information, see the *Device Off Mode Wake-Up Sequences* section in [Chapter 3, Power, Reset and Clock Management](#).

16.4.21.2.2 sDMA Descriptors Description

The restore phase is automatically done by the sDMA. The sDMA gets the register address (**Destination address**), the **number of elements** to transfer and the address of the data to transfer (**Source address**) from SAR ROM. As mentioned previously the register data is stored in the SAR RAM.

SAR ROM content:

The SAR ROM contains two types of descriptors that the DMA-4 should use:

- Type-1 descriptors
- Type-3 descriptors with both source and destination address update

Type-1 descriptor (48 bytes) is to be used at the beginning of each phase. Indeed, in addition of source and destination address and number of elements, it contains the required data that initializes the sDMA. [Table 16-13](#) shows the Type-1 descriptor structure.

Type-3 descriptors (16 bytes) are to be used for subsequent sDMA transfers and contain mainly source and destination address and number of elements. [Table 16-16](#) shows the Type-3 descriptor structure.

Figure 16-13 shows an example of SAR ROM code (Type-3 Descriptor):

Figure 16-13. Type-3 SAR ROM Code Example

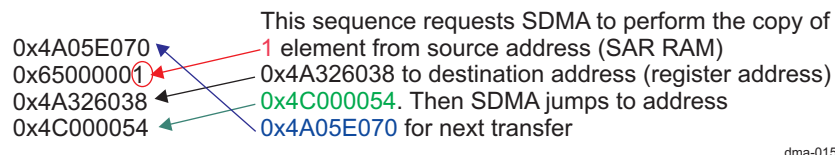

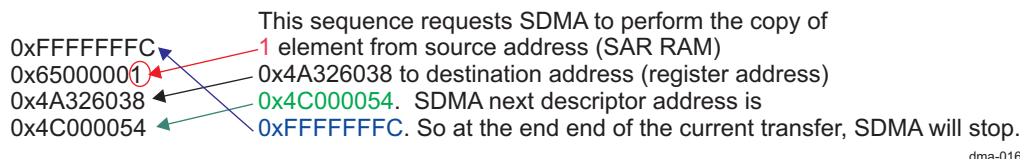

Figure 16-14 shows an example of Last DMA transfer (Type-3 Descriptor):

To indicate to the DMA that this is the last transfer, then the next descriptor address must be set to 0xFFFFFFF0 as in the example below :

Figure 16-14. Type-3 SAR ROM Last transfer Example

16.4.21.3 SAR RAM

The SAR RAM contains the **data** which needs to be maintained during OFF-mode. The SAR RAM is split into 3 banks:

Table 16-18. SAR RAM Allocation

Access Mode	Bank	Address Range
public	1 (SAR_RAM_1)	0x4A32_6000 0x4A32_6FFF (4kB)
public, for IO Pad	2 (SAR_RAM_2)	0x4A32_7000 0x4A32_73FF (1kB)
public	3 (SAR_RAM_3)	0x4A32_8000 0x4A32_87FF (2kB)

16.4.21.4 SAR ROM

The SAR ROM contains the list of registers that need to be saved before OFF-mode and so restored after OFF-mode and contains also the location where the register data is stored in SAR RAM. The SAR ROM start address is 0x4A05_E000.

When exiting OFF-mode, PRCM automatically redirects sDMA to address:

- 0x4A05_E000 for phase 1 (in SAR ROM)
- 0x4A05_E030 for phase 2a (in SAR ROM)
- 0x4A05_E060 for phase 2b (in SAR ROM)

The SAR ROM is build so that sDMA will perform all the transfers for each phase. At the end of each phase, sDMA will stop. PRCM will then request to perform the next phase transfer depending on wake-up source.

Remarks:

- Phase 1 is always to happen, the RESTORE mechanism is enabled by default and can not be disabled.
- Phase 2 (2a and 2b) is to happen depending on the wake-up source from OFF-mode. Phase 2 will not be performed if C2C is the wake-up source, but it will be performed for all the other wake-up sources. So it is mandatory to correctly fill the SAR RAM locations used for USB restore, even USB is not used because the restore sequence will happen.
- USB host RESTORE is to be performed before USB TLL RESTORE

NOTE: Some consecutive address registers cannot be saved/restored with burst. This is the case for:

- CLK1_DSS_BW_REGULATOR.L3_BW_R_BANDWIDTH and CLK1_DSS_BW_REGULATOR.L3_BW_R_WATERMARK registers
- CLK2_XXX_BW_REGULATOR.L3_BW_R_BANDWIDTH and CLK2_XXX_BW_REGULATOR.L3_BW_R_WATERMARK registers, where XXX stands for ISS, IVAHD and SGX.

To avoid sDMA transfer failure, the transfer of the above register is performed using a single sDMA transfer.

16.4.21.5 SAR RAM Memory Allocation Reserved for Save and Restore

The memory size of the SAR RAM reserved for the Save and Restore mechanism is:

- 57% (2344 bytes) reserved for the SAR mechanism from SAR_RAM_1. The whole SAR_RAM_1 size is 4KB.
- 40% (408 bytes) reserved for the SAR mechanism from SAR_RAM_2. The whole SAR_RAM_2 size is 1KB.
- 51% (1052 bytes) reserved for the SAR mechanism from SAR_RAM_3. The whole SAR_RAM_3 size is 2KB.

The free part of the SAR RAM can be used by the user software to store any data that needs to be in always-on memory.

16.4.21.6 Register Mapping in SAR RAM

Table 16-19 shows the SAR_RAM_1 memory mapping.

Table 16-19. SAR_RAM_1 Memory Mapping

Order	Register Name	Register Start Addr	Register End Addr	Size	SAR_RAM_1 Addr
1	EMIF1.EMIF_SDRAM_CONFIG	0x4C000008		4	0x4A326000
2	EMIF1.EMIF_LPDDR2_NVM_CONFIG	0x4C00000C		4	0x4A326004
3	EMIF1.EMIF_SDRAM_REF_CTRL	0x4C000010		4	0x4A326008

16.5 sDMA Basic Programming Model

16.5.1 Setup Configuration

After a hardware reset, program all fields in the logical channel registers to default values for any channels used, because most fields are undefined following reset.

Before programming any DMA transfers, the priority arbitration rate and the maximum FIFO depth must be configured through the [DMA4_GCR](#) register, and any required interrupts must be enabled through the [DMA4_IRQENABLE_Lj](#) registers and the logical channel [DMA4_CICRi](#) registers.

Software clears the [DMA4_CSRi](#) register and the IRQSTATUS bit for the different interrupt lines before enabling the channel.

16.5.2 Software-Triggered (Nonsynchronized) Transfer

To program a software-triggered DMA transfer:

1. Configure the transfer parameters in the logical DMA channel registers:

- [DMA4_CSDPi](#):
 - Transfer ES (8 bits, 16 bits, or 32 bits) in DMA register bits [DMA4_CSDPi\[1:0\]](#)
 - Read and write port access types (single/burst), DMA register bits [DMA4_CSDPi\[8:7\]](#) and [DMA4_CSDPi\[15:14\]](#)
 - Source and destination endianness, DMA register bits [DMA4_CSDPi\[21\]](#) and [DMA4_CSDPi\[19\]](#)
 - Write mode (posted or nonposted) and DMA register bits [DMA4_CSDPi\[17:16\]](#)
 - Source or destination packed or nonpacked (if the ES is less than the read/write port size), DMA register bits [DMA4_CSDPi\[6\]](#) and [DMA4_CSDPi\[13\]](#)
- [DMA4_CENi](#): EN
- [DMA4_CFNi](#): FN per transfer block
- [DMA4_CSSAi](#) and [DMA4_CDSAi](#): Source and destination start address (aligned with transfer ES)
- [DMA4_CCRi](#):
 - Read and write port addressing modes, DMA register bits [DMA4_CCRi\[13:12\]](#) and [DMA4_CCRi\[15:14\]](#)
 - Priority bit for both read and write ports, DMA register bits [DMA4_CCRi\[6\]](#) and [DMA4_CCRi\[26\]](#)
 - DMA request number (set to 0 for a software-triggered transfer) and DMA register bits [DMA4_CCRi\[4:0\]](#) = 0 and [DMA4_CCRi\[20:19\]](#) = 0
- [DMA4_CSEIi](#), [DMA4_CSFli](#), [DMA4_CDEIi](#), and [DMA4_CDFli](#): Source and destination element and frame indexes (depending on addressing mode)

2. Start the transfer through the enable bit in the channel [DMA4_CCRi](#) register and DMA register bit [DMA4_CCRi\[7\]](#)

The example below perform a DMA transfer on channel 10 of a 240*160 picture from RAM to RAM (0x80C00000 to 0x80F00000) :

```
UWORD32 RegVal = 0;
DMA4_t *DMA4;
DMA4 = (DMA4_t *)malloc(sizeof(DMA4_t));

/* Init. parameters */
DMA4->DataType = 0x2; // DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0; // DMA4_CSDPi[8:7]
DMA4->WritePortAccessType = 0; // DMA4_CSDPi[15:14]
DMA4->SourceEndiansim = 0; // DMA4_CSDPi[21]
DMA4->DestinationEndianness = 0; // DMA4_CSDPi[19]
DMA4->WriteMode = 0; // DMA4_CSDPi[17:16]
DMA4->SourcePacked = 0; // DMA4_CSDPi[6]
DMA4->DestinationPacked = 0; // DMA4_CSDPi[13]
DMA4->NumberOfElementPerFrame = 240; // DMA4_CENi
DMA4->NumberOfFramePerTransferBlock = 160; // DMA4_CFNi
DMA4->SourceStartAddress = 0x80C00000; // DMA4_CSSAi
DMA4->DestinationStartAddress = 0x80F00000; // DMA4_CDSAi
DMA4->SourceElementIndex = 1; // DMA4_CSEIi
DMA4->SourceFrameIndex = 1; // DMA4_CSFli
DMA4->DestinationElementIndex = 1; // DMA4_CDEIi
DMA4->DestinationFrameIndex = 1; // DMA4_CDFli
DMA4->ReadPortAccessMode = 1; // DMA4_CCRi[13:12]
DMA4->WritePortAccessMode = 1; // DMA4_CCRi[15:14]
```

```

DMA4->ReadPriority = 0; // DMA4_CCRi[6]
DMA4->WritePriority = 0; // DMA4_CCRi[23]
DMA4->ReadRequestNumber = 0; // DMA4_CCRi[4:0]
DMA4->WriteRequestNumber = 0; // DMA4_CCRi[20:19]

/* 1) Configure the transfer parametres in the logical DMA registers */
/*-----*/

/* a) Set the data type CSDP[1:0], the Read/Write Port access type CSDP[8:7]/[15:14], the
Source/dest endiansim CSDP[21]/CSDP[19], write mode CSDP[17:16], source/dest packed or non-
packed CSDP[6]/CSDP[13]*/

// Read CSDP
RegVal = DMA4_CSDP_CH10;

// Build reg
RegVal = ((RegVal & ~0x3) | DMA4-DataType );

RegVal = ((RegVal & ~(0x3 << 14)) | (DMA4->WritePortAccessType << 14));
RegVal = ((RegVal & ~(0x1 << 21)) | (DMA4->SourceEndiansim << 21));
RegVal = ((RegVal & ~(0x1 << 19)) | (DMA4->DestinationEndianism << 19));
RegVal = ((RegVal & ~(0x3 << 16)) | (DMA4->WriteMode << 16));
RegVal = ((RegVal & ~(0x1 << 6)) | (DMA4->SourcePacked << 6));
RegVal = ((RegVal & ~(0x1 << 13)) | (DMA4->DestinationPacked << 13));

// Write CSDP
DMA4_CSDP_CH10 = RegVal;

/* b) Set the number of element per frame CEN[23:0]*/

DMA4_CEN_CH10 = DMA4->NumberOfElementPerFrame;

/* c) Set the number of frame per block CFN[15:0]*/

DMA4_CFN_CH10 = DMA4->NumberOfFramePerTransferBlock;

/* d) Set the Source/dest start address index CSSA[31:0]/CDSA[31:0]*/

DMA4_CSSA_CH10 = DMA4->SourceStartAddress; // address start
DMA4_CDSA_CH10 = DMA4->DestinationStartAddress; // address dest

/* e) Set tlhe Read Port adresssing mode CCR[13:12], the Write Port adresssing mode CCR[15:14],
read/write priority CCR[6]/CCR[26], the current LCH CCR[20:19]=00 and CCR[4:0]=00000*/

// Read CCR
RegVal = DMA4_CCR_CH10;

// Build reg
RegVal = ((RegVal & ~(0x3 << 12)) | (DMA4->ReadPortAccessMode << 12));
RegVal = ((RegVal & ~(0x3 << 14)) | (DMA4->WritePortAccessMode << 14));
RegVal = ((RegVal & ~(0x1 << 6)) | (DMA4->ReadPriority << 6));
RegVal = ((RegVal & ~(0x1 << 26)) | (DMA4->WritePriority << 26));
RegVal &= 0xFFCFFFE0 ;

// Write CCR
DMA4_CCR_CH10 = RegVal;

/* f)- Set the source element index CSEI[15:0]*/

DMA4_CSEI_CH10 = DMA4->SourceElementIndex;

/* g)- Set the source frame index CSFI[15:0]*/

DMA4_CSFI_CH10 = DMA4->SourceFrameIndex ;

```

```

/* h)- Set the destination element index CDEI[15:0]*/

DMA4_CDEI_CH10 = DMA4->DestinationElementIndex;

/* i)- Set the destination frame index CDFI[31:0]*/

DMA4_CDFI_CH10 = DMA4->DestinationFrameIndex;

/* 2) Start the DMA transfer by Setting the enable bit CCR[7]=1 */
/*-----*/

//write enable bit
DMA4_CCR_CH10 |= 1 << 7; /* start */

```

16.5.3 Hardware-Synchronized Transfer

To monitor a hardware synchronized DMA transfer, initialize the [DMA4_CDACi](#) register before the software enable.

To configure an LCh to synchronize by element, packet, frame, or block, the frame synchronization [DMA4_CCRi\[5\]](#) FS bit and the block synchronization [DMA4_CCRi\[18\]](#) BS bit register must be programmed. For all the following synchronized transfers (element, packet, frame or block synchronized transfers) User must set first : [DMA4_CCRi\[24\]](#) SEL_SRC_DST_SYNC to 1 when the source triggers on the DMA request and [DMA4_CCRi\[24\]](#) SEL_SRC_DST_SYNC to 0 when the Destination triggers on the DMA request. Note: User must take care when setting the [DMA4_CCRi\[23\]](#) PREFETCH bit it is in conjunction with [DMA4_CCRi\[24\]](#) SEL_SRC_DST_SYNC bit.

- To configure an LCh to transfer one element per DMA request:
 1. Set the number of DMA request associated to the current LCH in the [DMA4_CCRi\[20:19\]](#) SYNCHRO_CONTROL_UPPER and [DMA4_CCRi\[4:0\]](#) SYNCHRO bit field.
 2. Set the data type, also referenced as element size (ES), in the [DMA4_CSDPi\[1:0\]](#) DATA_TYPE bit field.
 3. Set the Read Port access type (single or burst access) in the [DMA4_CSDPi\[8:7\]](#) SRC_BURST_EN bit field.
 4. Set the Write Port access type (single or burst access) in the [DMA4_CSDPi\[15:14\]](#) DST_BURST_EN bit field.
 5. Set the Read Port addressing mode in the [DMA4_CCRi\[13:12\]](#) SRC_AMODE bit field.
 6. Set the Write Port addressing mode in the [DMA4_CCRi\[15:14\]](#) DST_AMODE bit field.
 7. Set the Read start address in the [DMA4_CSSAi\[31:0\]](#) SRC_START_ADRS bit field.
 8. Set the Write start address in the [DMA4_CDSAi\[31:0\]](#) DST_START_ADRS bit field.
 9. Set both FS and BS to 0 in [DMA4_CCRi\[5\]](#) FS and [DMA4_CCRi\[18\]](#) BS.
 10. Set to 1 the channel enable bit [DMA4_CCRi\[7\]](#) EN.
- To configure an LCh to transfer one frame per DMA request:
 1. Set the number of DMA request associated to the current LCH in the [DMA4_CCRi\[20:19\]](#) SYNCHRO_CONTROL_UPPER and [DMA4_CCRi\[4:0\]](#) SYNCHRO bit field.
 2. Set the data type, also referenced as element size (ES), in the [DMA4_CSDPi\[1:0\]](#) DATA_TYPE bit field.
 3. Set the number of element per frame in the [DMA4_CENi\[23:0\]](#) CHANNEL_ELMNT_NBR bit field.
 4. Set the Read Port access type (single or burst access) in the [DMA4_CSDPi\[8:7\]](#) SRC_BURST_EN bit field.
 5. Set the Write Port access type (single or burst access) in the [DMA4_CSDPi\[15:14\]](#) DST_BURST_EN bit field.
 6. Set the Read Port addressing mode in the [DMA4_CCRi\[13:12\]](#) SRC_AMODE bit field.
 7. Set the Write Port addressing mode in the [DMA4_CCRi\[15:14\]](#) DST_AMODE bit field.
 8. Set the Read start address in the [DMA4_CSSAi\[31:0\]](#) SRC_START_ADRS bit field.
 9. Set the Write start address in the [DMA4_CDSAi\[31:0\]](#) DST_START_ADRS bit field.

10. Set FS to 1 and BS to 0, respectively, in [DMA4_CCRi\[5\]](#) FS and [DMA4_CCRi\[18\]](#) BS.
11. Set to 1 the channel enable bit [DMA4_CCRi\[7\]](#) EN.
- To configure an LCh to transfer one block per DMA request:
 1. Set the number of DMA request associated to the current LCH in the [DMA4_CCRi\[20:19\]](#) SYNCHRO_CONTROL_UPPER and [DMA4_CCRi\[4:0\]](#) SYNCHRO bit field.
 2. Set the data type, also referenced as element size (ES), in the [DMA4_CSDPi\[1:0\]](#) DATA_TYPE bit field.
 3. Set the number of element per frame in the [DMA4_CENi\[23:0\]](#) CHANNEL_ELMNT_NBR bit field.
 4. Set in the [DMA4_CFNi\[15:0\]](#) CHANNEL_FRAME_NBR bit field the number of frame (transfers), to take place before the LCH gets disabled.
 5. Set the Read Port access type (single or burst access) in the [DMA4_CSDPi\[8:7\]](#) SRC_BURST_EN bit field.
 6. Set the Write Port access type (single or burst access) in the [DMA4_CSDPi\[15:14\]](#) DST_BURST_EN bit field.
 7. Set the Read Port addressing mode in the [DMA4_CCRi\[13:12\]](#) SRC_AMODE bit field.
 8. Set the Write Port addressing mode in the [DMA4_CCRi\[15:14\]](#) DST_AMODE bit field.
 9. Set the Read start address in the [DMA4_CSSAi\[31:0\]](#) SRC_START_ADRS bit field.
 10. Set the Write start address in the [DMA4_CDSAi\[31:0\]](#) DST_START_ADRS bit field.
 11. Set FS to 0 and BS to 1, respectively, in [DMA4_CCRi\[5\]](#) FS and [DMA4_CCRi\[18\]](#) BS.
 12. Set to 1 the channel enable bit [DMA4_CCRi\[7\]](#) EN.
- To configure an LCh to transfer one packet per DMA request:
 1. Set the number of DMA request associated to the current LCH in the [DMA4_CCRi\[20:19\]](#) SYNCHRO_CONTROL_UPPER and [DMA4_CCRi\[4:0\]](#) SYNCHRO bit field.
 2. Set the data type, also referenced as element size (ES), in the [DMA4_CSDPi\[1:0\]](#) DATA_TYPE bit field.
 3. Set the number of elements per packet to transfer: If the packet requestor is in the source, set [DMA4_CCRi\[24\]](#) SEL_SRC_DST_SYNC to 1 and set the packet element number in the [DMA4_CSFli](#) register and set the addressing mode of source to constant addressing in [DMA4_CCRi\[13:12\]](#) SRC_AMODE bit field; else, if the packet requestor is in the destination, set the [DMA4_CCRi\[24\]](#) SEL_SRC_DST_SYNC to 0 and set the packet element number in the [DMA4_CDFli](#) register and set the addressing mode of destination to constant addressing in [DMA4_CCRi\[15:14\]](#) DST_AMODE bit field.
 4. Set the number of elements per frame in the [DMA4_CENi\[23:0\]](#) CHANNEL_ELMNT_NBR bit field.
 5. Set in the [DMA4_CFNi\[15:0\]](#) CHANNEL_FRAME_NBR bit field the number of frames (transfers), to take place before the LCH gets disabled.
 6. Set the element number in the packet in the [DMA4_CSFli\[15:0\]](#) PKT_ELNT_NBR, if constant addressing or post-incremented addressing modes are used in the source side. However, the number of element in the packet is set in the [DMA4_CDFli\[15:0\]](#) PKT_ELNT_NBR if constant addressing mode is used in the destination side.
 7. Set the Read Port access type (single or burst access) in the [DMA4_CSDPi\[8:7\]](#) SRC_BURST_EN bit field.
 8. Set the Write Port access type (single or burst access) in the [DMA4_CSDPi\[15:14\]](#) DST_BURST_EN bit field.
 9. Set the Read Port addressing mode in the [DMA4_CCRi\[13:12\]](#) SRC_AMODE bit field.
 10. Set the Write Port addressing mode in the [DMA4_CCRi\[15:14\]](#) DST_AMODE bit field.
 11. Set the Read start address in the [DMA4_CSSAi\[31:0\]](#) SRC_START_ADRS bit field.
 12. Set the Write start address in the [DMA4_CDSAi\[31:0\]](#) DST_START_ADRS bit field.
 13. Set FS to 1 and BS to 1, respectively, in [DMA4_CCRi\[5\]](#) FS and [DMA4_CCRi\[18\]](#) BS.
 14. Set to 1 the channel enable bit [DMA4_CCRi\[7\]](#) EN.

NOTE: It is possible to stop a transfer by disabling the channel by resetting the [DMA4_CCRi\[7\] ENABLE](#) bit.

16.5.4 Synchronized Transfer Monitoring Using CDAC

The [DMA4_CDACi](#) register is writable and non-initialized (value undefined). It can be initialized to monitor a transfer by applying the following programming model:

1. Write 0 in the [DMA4_CDACi](#) register.
2. Enable the channel.
3. If a time-out occurs, read [DMA4_CDACi](#) register.
4. If [DMA4_CDACi](#) != 0 (it is the value configured in [DMA4_CDACi](#)):

This indicates that the corresponding transfer has started. User can then rely on [DMA4_CCENi](#) and [DMA4_CCFNi](#) element and frame counters.

Else, if [DMA4_CDACi](#) = 0 (it is the value configured in the [DMA4_CDACi](#)):

This indicates that the corresponding transfer did not start.

16.5.5 Concurrent Software and Hardware Synchronization

This section describes thread allocation only; it does not describe the entire transfer. Because synchronized transfers are latency critical, you must allocate a thread at least on the synchronized target side.

Even for multiple concurrent channels, thread reservation ensures that when a hardware DMA request arrives, the read/write scheduler finds available thread(s) to initiate a channel schedule and issue a read/write transaction.

Consider six concurrent channels:

- Channels 0, 1, 2, and 3 are dedicated to memory-memory transfer; they are software triggered and not synchronized.
- Channel 4 is dedicated to memory-peripheral transfer, hardware triggered, and synchronized on the write side.
- Channel 5 is dedicated to peripheral-memory transfer, hardware triggered, and synchronized on the read side.

To perform thread reservation:

1. Allow thread reservation for priority channel 4 and channel 5:
Reserve one thread (Read ThreadID 0) on the read port and one thread (Write ThreadID 0) on the write port: set the [DMA4_GCR\[13:12\] HI_THREAD_RESERVED](#) bit field to 0x1.
2. Specify channel priority:
Channel 4 is a write high priority channel: set [DMA4_CCRi\[26\] WRITE_PRIORITY](#) = 1.
Channel 5 is a read high priority channel: set [DMA4_CCRi\[6\] READ_PRIORITY](#) = 1.

16.5.6 Chained Transfer

A chained DMA transfer can be programmed as follows:

1. Configure the transfer parameters for each logical DMA channel in the chain as in step 1 for either the synchronized or non-synchronized transfers describe in [Section 16.5.5, Concurrent Software and Hardware Synchronization](#).
2. For each channel in the chain, configure the [DMA4_CLNK_CTRLi](#) register as follows:
 - Next logical DMA channel number (for a looping chained transfer link last channel to first channel number), in the [DMA4_CLNK_CTRLi\[4:0\] NEXTLCH_ID](#) bit field.
 - Include the logical channel to the chain and enable link by setting the [DMA4_CLNK_CTRLi\[15\] ENABLE_LNK](#) bit.
 - For a non-looping chain, the last logical channel in the chain must have the

[DMA4_CLNK_CTRLi](#)[15] ENABLE_LNK bit set to 0 to indicate the end of the chain.

3. Enable the transfer through the enable bit in the first logical channel [DMA4_CCRi](#)[7] ENABLE bit. All other channels in the chain must be disabled. Each channel is enabled automatically in turn when the previous logical channel transfer completes. A non-synchronized transfer starts immediately; a hardware-synchronized transfer starts when the DMA request line corresponding to the first DMA channel in the chain is asserted.

To stop a looping chained transfer, disable the [DMA4_CLNK_CTRLi](#)[15] ENABLE_LNK bit (by setting it to 0x0), of the final channel transfer.

In the RAM-to-RAM copy example, to copy in loop, it is possible to link channel 10 on itself. The following line can be added in the channel configuration:

```
/* g) Set link for loop */
DMA4_CLNK_CTRL_CH10 = 0x0000800A;
```

16.5.7 90-Degree Clockwise Image Rotation

The 90-degree clockwise image rotation example described in [Section 16.4.5, Addressing Modes](#), can be programmed as follows:

1. Configure the transfer parameters in the logical DMA channel registers:

- [DMA4_CSDPi](#):
 - Transfer ES = 32-bit (32 bpp), [DMA4_CSDPi](#)[1:0] DATA_TYPE bit field
 - Read and write port access types = maximum burst size supported by memory device, [DMA4_CSDPi](#)[8:7] SRC_BURST_EN and [DMA4_CSDPi](#)[15:14] DST_BURST_EN bit fields
 - Source and destination endianness, [DMA4_CSDPi](#)[21] SRC_ENDIAN and [DMA4_CSDPi](#)[19] DST_ENDIAN bits
 - Write mode = posted with last element nonposted, [DMA4_CSDPi](#)[17:16] WRITE_MODE bit field
 - Source and destination packed = Yes (although destination writes do not benefit because EI1), [DMA4_CSDPi](#)[6] SRC_PACKED and [DMA4_CSDPi](#)[13] DST_PACKED bits
- [DMA4_CENi](#): EN = 240
- [DMA4_CFNi](#): FN per transfer block = 160
- [DMA4_CSSAi](#): Source start address = 0x100000
- [DMA4_CDSAi](#): destination start address = 0x20013E
- [DMA4_CCRi](#):
 - Read and write port addressing modes = double-index addressing mode for both or post-increment addressing on source and double-index addressing on destination, [DMA4_CCRi](#)[13:12] SRC_AMODE and [DMA4_CCRi](#)[15:14] DST_AMODE bit fields
 - Low or high priority, [DMA4_CCRi](#)[6] READ_PRIORITY bit
 - DMA request number = 0 (for software-triggered transfer), [DMA4_CCRi](#)[4:0] SYNCHRO_CONTROL and [DMA4_CCRi](#)[20:19] SYNCHRO_CONTROL_UPPER bit fields
- [DMA4_CSEIi](#): Source EI = 1
- [DMA4_CSFIi](#): Source frame index = 1
- [DMA4_CDEIi](#): destination EI = 637
- [DMA4_CDFIi](#): destination frame index = 152967

2. Start the transfer through the enable bit in the channel [DMA4_CCRi](#) register.

The following parameters are used to perform this rotation from 0x80C00000 RAM address to 0x80F00000, with the same code used in [Section 16.5.2, Software-Triggered \(Nonsynchronized\) Transfer](#).

```
/* Init. parameters */
DMA4->DataType = 0x2; // DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0x3; // DMA4_CSDPi[8:7]
DMA4->WritePortAccessType = 0x3; // DMA4_CSDPi[15:14]
DMA4->SourceEndiansim = 0; // DMA4_CSDPi[21]
DMA4->DestinationEndianness = 0; // DMA4_CSDPi[19]
```

```

DMA4->WriteMode = 0x2; // DMA4_CSDPi[17:16]
DMA4->SourcePacked = 0x1; // DMA4_CSDPi[6]
DMA4->DestinationPacked = 0x1; // DMA4_CSDPi[13]
DMA4->NumberOfElementPerFrame = 240; // DMA4_CENi
DMA4->NumberOfFramePerTransferBlock = 160; // DMA4_CFNi
DMA4->SourceStartAddress = 0x80C00000; // DMA4_CSSAi
DMA4->DestinationStartAddress = 0x80F00000; // DMA4_CDSAi
DMA4->SourceElementIndex = 1; // DMA4_CSEIi
DMA4->SourceFrameIndex = 1; // DMA4_CSFii
DMA4->DestinationElementIndex = 637; // DMA4_CDEIi
DMA4->DestinationFrameIndex = -152967; // DMA4_CDFii
DMA4->ReadPortAccessMode = 0x3; // DMA4_CCRi[13:12]
DMA4->WritePortAccessMode = 0x3; // DMA4_CCRi[15:14]
DMA4->ReadPriority = 0; // DMA4_CCRi[6]
DMA4->WritePriority = 0; // DMA4_CCRi[23]
DMA4->ReadRequestNumber = 0; // DMA4_CCRi[4:0]
DMA4->WriteRequestNumber = 0; // DMA4_CCRi[20:19]

```

16.5.8 Graphic Operations

- Transparent copy:
 1. Set the [DMA4_CCRi\[17\]](#) TRANSPARENT_COPY_ENABLE bit to 1
 2. Set the [DMA4_CCRi\[16\]](#) CONST_FILL_ENABLE bit to 0
 3. Set the value of the key color in the [DMA4_COLORi\[15:0\]](#) COLOR_KEY bit field

To perform this graphic operation, the following lines can be added to the example of [Section 16.5.2, Software-Triggered \(Nonsynchronized\) Transfer](#).

```

DMA4_CCR_CH10 &= ~(0x1 << 16);
DMA4_CCR_CH10 |= 0x1 << 17;
DMA4_COLOR_CH10 = 0x00000003;

```

- Solid Color fill:
 1. Set the [DMA4_CCRi\[16\]](#) CONST_FILL_ENABLE bit to 1
 2. Set the [DMA4_CCRi\[17\]](#) TRANSPARENT_COPY_ENABLE bit to 0
 3. Set the value of key the color in the [DMA4_COLORi\[15:0\]](#) SOLID_COLOR bit field

To perform this graphic operation, the following lines can be added to the example of [Section 16.5.2, Software-Triggered \(Nonsynchronized\) Transfer](#).

```

DMA4_CCR_CH10 &= ~(0x1 << 17);
DMA4_CCR_CH10 |= 0x1 << 16;
DMA4_COLOR_CH10 = 0x00000003;

```

16.5.9 Linked-List Programming Guidelines

- With the exception of the [DMA4_CCRi\[7\]](#) ENABLE bit and the [DMA4_CDPi\[7\]](#) PAUSE_LINK_LIST bit during a linked-list transfer (descriptor load phase or data load phase), avoid programming any register through the configuration port.
- Before enabling any linked-list transfer, ensure that all global registers and all registers in the descriptor are initialized. Some static channel registers (registers that are not updated by the descriptor to be loaded) must also be initialized correctly:
 - For type 2, the following registers must be initialized with consistent values:
 - All global registers
 - [DMA4_CCRi](#)
 - [DMA4_CSDPi](#)
 - [DMA4_CLNK_CTRLi](#)
 - For type 3, the following registers must be initialized with consistent values:
 - All global registers
 - [DMA4_CCRi](#)
 - [DMA4_CSDPi](#)

- [DMA4_CLNK_CTRLi](#)
- [DMA4_CICRi](#)
- [DMA4_CFNi](#)
- In case of a linked list with descriptor types 2 and 3, the content of the [DMA4_CCRi](#) register must not change during super-block life.
- The PAUSE_LINK_LIST bit must not be set in the initialization phase.

16.6 sDMA Register Manual

16.6.1 sDMA Instance Summary

Table 16-22. sDMA Instance Summary

Module Name	Base Address	Size
sDMA	0x4A05 6000	4KB

16.6.2 sDMA Registers

16.6.2.1 sDMA Register Summary

Index *i* represents the logical channel number (where *i* = 0 to 31). The offset address for some registers is calculated from channel *c* number. For example, register DMA4_CCR10 (channel 10) has an offset address of $10 \times 0x60 = 0x3C0$, and so a physical address of $0x4A05\ 6080 + 0x3C0 = 0x4A05\ 6440$.

Index *j* represents the interrupt line number (where *j* = 0 to 3). The offset address for some registers is calculated from channel *c* number. For example, register DMA4_IRQSTATUS_L3 (line 3) has an offset address of $3 \times 0x4 = 0xC$, and so a physical address of $0x4A05\ 6008 + 0xC = 0x4A05\ 6014$.

⁽³⁾ i = 0 to 31**16.6.2.2 sDMA Register Description**

NOTE: Some registers have no reset value (marked with -) because of hardware implementation in memory. Software must ensure the correct programming of these registers, if needed.

Shadow registers are used to read run-time registers such as CCEN, CCFN, CDAC, and CSAC. Typically, when accessed in 8-bit or 16-bit access for two consecutive accesses, the value of the previous registers can change. A shadow register holds the entire value to let the next access recover the remaining 24 bits or 16 bits.

For non-32-bit transactions, start reading or writing from the LSByte first to enable the register update. There is no issue for 32-bit read-write transactions.

RESERVED								ARBITRATION_RATE								HI_LO_FIFO_BUDGET		HI_THREAD_RESERVED		RESERVED				MAX_CHANNEL_FIFO_DEPTH							
CHANNEL_ID_GATE																															

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x00
24	CHANNEL_ID_GATE	Gates the Channel ID bus monitoring on both Read and Write ports 0x0: Gates the Channel ID qualifiers on both Read and Write Ports 0x1: Does not gate the Channel ID qualifiers on both Read and Write Ports	RW	0x0
23:16	ARBITRATION_RATE	Arbitration switching rate between prioritized and regular channel queues	RW	0x01
15:14	HI_LO_FIFO_BUDGET	Allow to have a separate Global FIFO budget for high and low priority channels. For Hi priority Channel: (Per_channel_Maximum FIFO depth + 1) x Number of active High priority Channel =< High Budget FIFO For Low priority channel: (Per_channel_Maximum FIFO depth + 1) x Number of active Low priority Channel =< Low Budget FIFO 0x0: no fixed budget for neither higher nor lower priority channel 0x1: 75% of FIFO for low priority and 25% for high priority channels 0x2: 25% of FIFO for low priority and 75% for high priority channels 0x3: 50% of FIFO for low priority and 50% for high priority channels	RW	0x0
13:12	HI_THREAD_RESERVED	Allow thread reservation for high priority channel on both read and write ports. 0x0: No ThreadID is reserved on the Read Port for high priority channels. No ThreadID is reserved on the Write Port for high priority channels. 0x1: Read Port ThreadID 0 is reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels. 0x2: Read port ThreadID 0 and ThreadID 1 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels. 0x3: Read PortThreadID 0, ThreadID 1 and ThreadID 2 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels.	RW	0x0
11:8	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x0

Bits	Field Name	Description	Type	Reset
7:0	MAX_CHANNEL_FIFO_DEPTH	Maximum FIFO depth allocated to one logical channel. Maximum FIFO depth can not be 0x0. It should be at least 0x1 or greater. Note that If channel limit is less than destination burst size enough data will not be accumulated in the data FIFO and it will never be sent out on the WR port. The burst size should be less than the FIFO limit specified in this bit field.	RW	0x10

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x0
29:27	RESERVED	Reserved	RW	0x0
26	WRITE_PRIORITY	Channel priority on the Write side 0x0: Channel has low priority on the Write side during the arbitration process 0x1: Channel has high priority on Write sided during the arbitration process	RW	0

Bits	Field Name	Description	Type	Reset
25	BUFFERING_DISABLE	This bit allows to disable the default buffering functionality when transfer is source synchronized. 0x0: buffering is enable across element/packet when source is synchronized to element, packet, frame or bolcks 0x1: buffering is disabled across element/packet when source is synchronized to element, packet, frame or bolcks	RW	-
24	SEL_SRC_DST_SYNC	Specifyes that element, packet, frame or block transfer (depending on CCR.bs and CCR.fs) is triggered by the source or the destination on the DMA request 0x0: Transfer is triggered by the destination. If synch on packet the packet element number is specified in the CDFI register 0x1: Transfer is triggered by the source. If synchronized on packet the packet element number is specified in the CSFI register	RW	-
23	PREFETCH	Enables the prefetch mode 0x0: Prefetch mode is disabled. When Sel_Src_Dst_Sync=1 transfers are buffred and pipelined between DMA requests 0x1: Prefetch mode is enabled. Prefetch mode is active only when destination is synchronised. It is SW user responsibility not to have at the same time Prefetch=1 when Sel_Src_Dst_Sync=1. This mode is not supported	RW	0
22	SUPERVISOR	Enables the supervisor mode 0x0: Supervisor mode is disabled 0x1: Supervisor mode is enabled	RW	0
21	RESERVED	Reserved	RW	0
20:19	SYNCHRO_CONTROL_UPPER	Channel Synchronization control upper (used in conjunction with the 5 bits of synchro channel DMA4_CCRi[4:0]) Used in conjunction, as two msb, with the five bits of the synchro channel bit field.	RW	0b00
18	BS	Block synchronization This bit used in conjunction with the fs to see how the DMA request is serviced in a synchronized transfer	RW	-
17	TRANSPARENT_COPY_ENABLE	Transparent copy enable 0x0: Transparent copy mode is disabled 0x1: Transparent copy mode is enabled	RW	-
16	CONST_FILL_ENABLE	Constant fill enable 0x0: Constant fill mode is disabled 0x1: Constant fill mode is enabled	RW	0
15:14	DST_AMODE	Selects the addressing mode on the Write Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode	RW	0bxx
13:12	SRC_AMODE	Selects the addressing mode on the Read Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode	RW	0bxx
11	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0

Bits	Field Name	Description	Type	Reset
10	WR_ACTIVE	Indicates if the channel write context is active or not Read 0x0: Channel is not active on the write port Read 0x1: Channel is currently active on the write port	R	0
9	RD_ACTIVE	Indicates if the channel read context is active or not Read 0x0: Channel is not active on the read port Read 0x1: Channel is currently active on the read port	R	0
8	SUSPEND_SENSITIVE	Logical channel suspend enable bit 0x0: The channel ignores the MSuspend even if EMUFree is set to 0. 0x1: If EMUFree is set to 0 and MSuspend comes in then all current OCP services (single transaction or burst transaction as specified in the corresponding CSDP register) have to be completed before stopping processing any more transactions	RW	0
7	ENABLE	Logical channel enable. It is SW responsibility to clear the CSR register and the IRQSTATUS bit for the different interrupt lines before enabling the channel. 0x0: The logical channel is disabled 0x1: The logical channel is enabled	RW	0
6	READ_PRIORITY	Channel priority on the read side 0x0: Channel has low priority on the Read side during the arbitration process 0x1: Channel has high priority on read sided during the arbitration process	RW	0
5	FS	Frame synchronization This bit used in conjunction with the BS to see how the DMA request is serviced in a synchronized transfer FS=0 and BS=0: An element is transferred once a DMA request is made. FS=0 and BS=1: An entire block is transferred once a DMA request is made. FS=1 and BS=0: An entire frame is transferred once a DMA request is made. FS=1 and BS=1: A packet is transferred once a DMA request is made. All these different transfers can be interleaved on the port with other DMA requests.	RW	-
4:0	SYNCHRO_CONTROL	Channel synchronization control This bit field used in conjunction with the second_level_synchro_control_upper (as two msb) 0000000 : Is reserved for non synchronized LCH transfer xxxxxxx (from 1 to 127) There are 127 possible DMA request to assign to any LCH. Note: The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, DMA4_CCR[4:0] SYNCHRO_CONTROL must be set to 0x2 (DMA request number + 1).	RW	0b00000

RESERVED																ENABLE_LNK	RESERVED								NEXTLCH_ID							

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x0000
15	ENABLE_LNK	Enables or disable the channel linking. 0x0: Channel linking mode is disabled When set on the fly to 0 the current channel will complete the transfer and stops the chain linking 0x1: Channel linking mode is enabled. The logical channel defined in the NextLCH_ID is enabled at the end of the current transfer	RW	0
14:5	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x000

Bits	Field Name	Description	Type	Reset
4:0	NEXTLCH_ID	Defines the NextLCh_ID, which is used to build logical channel chaining queue.	RW	0bxxxxx

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x00000
14	SUPER_BLOCK_IE	Enables the end of super block interrupt	RW	-
13	RESERVED	Reserved	RW	1
12	DRAIN_IE	Enables the end of draining interrupt	RW	0
11	MISALIGNED_ERR_IE	Enables the address misaligned error event interrupt 0x0: Disables the misaligned address error event interrupt 0x1: Enables the misaligned address error event interrupt	RW	-
10	SUPERVISOR_ERR_IE	Enables the supervisor transaction error event interrupt 0x0: Disables the supervisor transaction error event interrupt 0x1: Enables the supervisor transaction error event interrupt	RW	1
9	RESERVED	Reserved	RW	1
8	TRANS_ERR_IE	Enables the transaction error event interrupt 0x0: Disables the transaction error event interrupt 0x1: Enables the transaction error event interrupt	RW	-

Bits	Field Name	Description	Type	Reset
7	PKT_IE	Enables the end of Packet interrupt 0x0: Disables the end of Packet transfer interrupt 0x1: Enables the end of Packet transfer interrupt	RW	-
6	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0
5	BLOCK_IE	Enables the end of block interrupt 0x0: Disables the end of block interrupt 0x1: Disables the end of block interrupt	RW	-
4	LAST_IE	Last frame interrupt enable (start of last frame) 0x0: Disables the last frame interrupt 0x1: Enables the last frame interrupt	RW	-
3	FRAME_IE	Frame interrupt enable (end of frame) 0x0: Disables the end of frame interrupt 0x1: Enables the end of frame interrupt	RW	-
2	HALF_IE	Enables or disables the half frame interrupt. 0x0: Disables the half frame interrupt 0x1: Enables the half frame interrupt	RW	-
1	DROP_IE	Synchronization event drop interrupt enable (request collision) 0x0: Disables the event drop interrupt 0x1: Enables the event drop interrupt	RW	0
0	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0

Interrupt Controllers

This chapter describes the interrupt controllers (INTCs) in the device.

Topic	Page
17.1 Interrupt Controllers Overview	3398
17.2 Interrupt Controllers Environment	3400
17.3 Interrupt Controllers Integration	3401
17.4 Interrupt Controllers Functional Description	3407
17.5 Interrupt Controllers Register Manual	3408

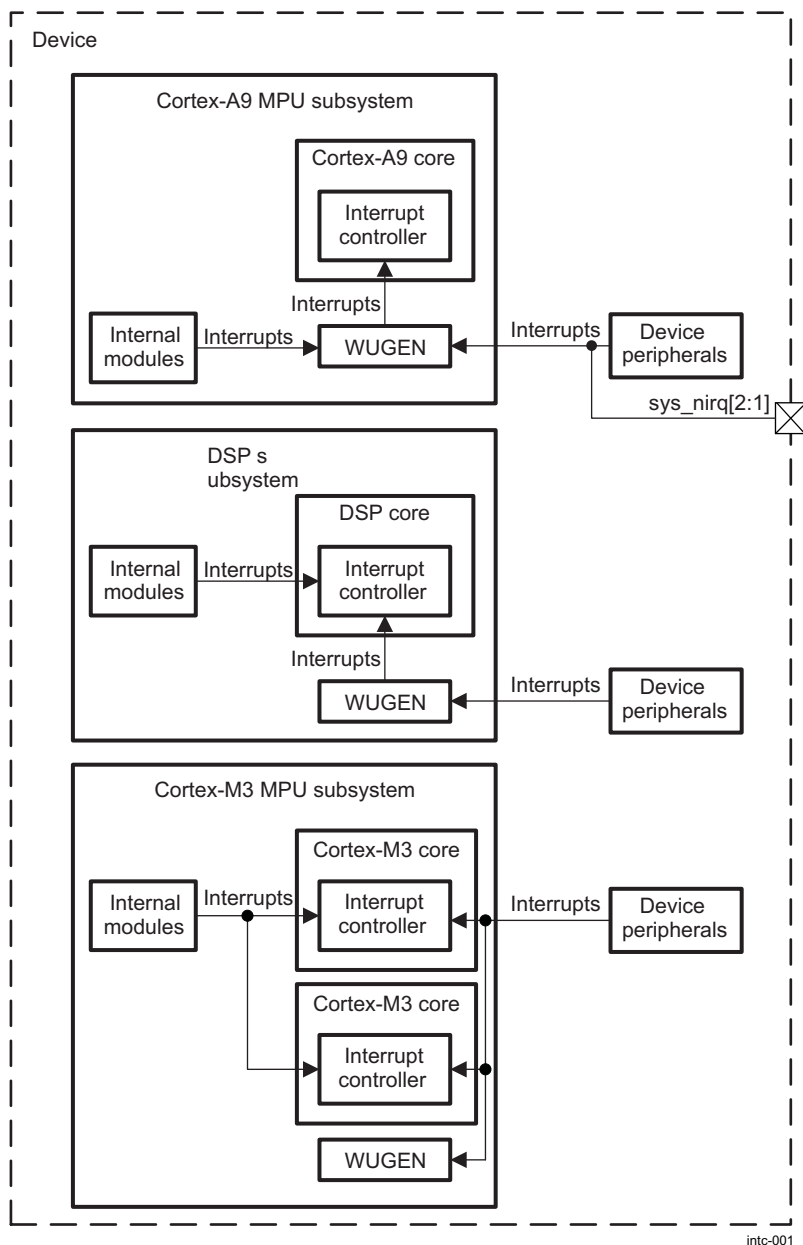

17.1 Interrupt Controllers Overview

The device provides three interrupt controller (INTC) modules, which handle interrupts at the device level:

- Cortex™-A9 MPU subsystem (MPUSS) interrupt controller (Cortex-A9 MPU INTC): This INTC module is a single functional unit that is integrated in the Cortex-A9 multiprocessor core alongside Cortex-A9 processors. It provides:
 - 128 hardware interrupt inputs
 - Generation of interrupts by software
 - Prioritization of interrupts
 - Masking of any interrupts
 - Distribution of the interrupts to the target Cortex-A9 processor(s)
 - Tracking the status of interrupts
 - Wake-up generator (WUGEN) module on external and local interrupts
- DSP subsystem (DSPSS) interrupt controller: This module is a specific combination of wake-up generator (WUGEN) and the C64x+ DSP INTC. It is used in the device but not described in detail in this chapter. For detailed information about this module, see [Chapter 5, DSP Subsystem](#).
- Cortex-M3 MPUSS interrupt controller (Cortex-M3 MPU INTC): This module is also called Nested Vectored Interrupt Controller (NVIC) and is integrated within each Cortex-M3 so the different interrupt lines are directly connected to each core. The interrupt mapping is the same for the two cores to facilitate parallel processing. The NVIC supports:
 - 64 external interrupts (in addition to 16 Cortex-M3 internal interrupts), which are dynamically prioritized with 16 levels of priority defined for each core
 - Low-latency exception and interrupt handling
 - Prioritization and handling of exceptions
 - Control of the local power management
 - Debug accesses to the processor core
 - Wake-up generator (WUGEN) module on external interrupts, coming from device peripherals

Figure 17-1 shows the internal interrupt scheme of the device.

Figure 17-1. Interrupt Controllers Overview

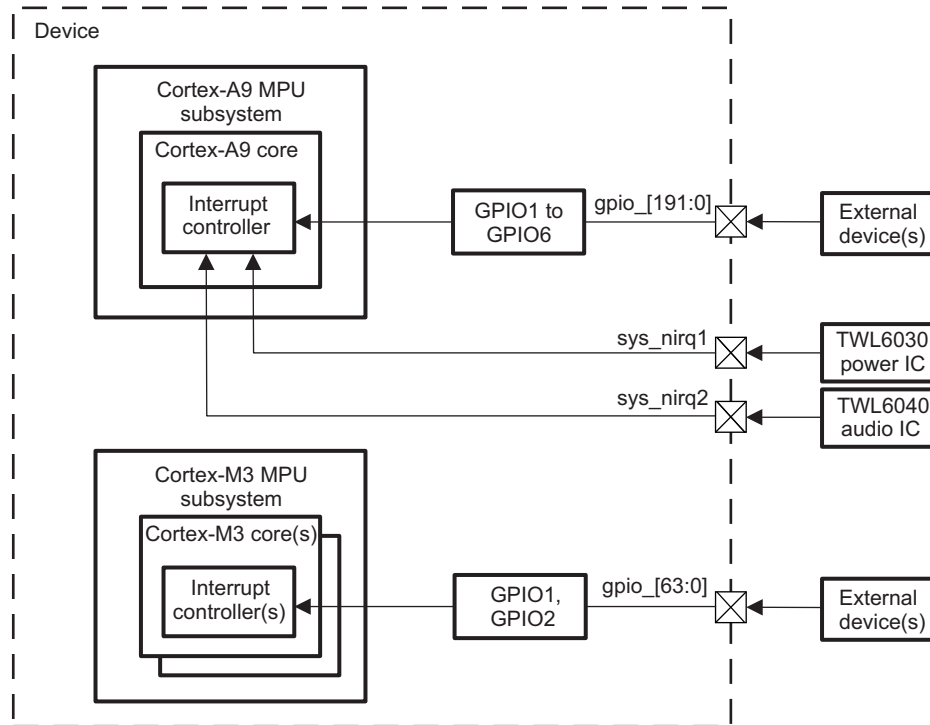

NOTE: For more information about the WUGEN module in the Cortex-A9 MPUSS (including integration, functional and register description), see [Chapter 4, Cortex-A9 MPU Subsystem](#). For more information about the WUGEN module in the Cortex-M3 MPUSS (including integration, functional and register description), see [Chapter 7, Cortex-M3 MPU Subsystem](#).

17.2 Interrupt Controllers Environment

This section describes the INTC application fields from the environment point of view (external connections).

Figure 17-2 shows the relationship between the module and external interrupts.

Figure 17-2. Interrupts From External Devices

intc-002

Table 17-1 describes the I/O signals that can be used by external devices to generate interrupts to the Cortex-A9 MPU INTC or Cortex-M3 MPU INTC.

Table 17-1. Interrupt Controllers I/O Signals

Signal Name	I/O ⁽¹⁾	Reset Value	Description	Cortex-A9 MPU INTC	Cortex-M3 MPU INTC
sys_nirq1	I	1	TWL6030 power IC can use this pin to generate a system wake-up event to Cortex-A9 MPU INTC.	x	-
sys_nirq2	I	1	TWL6040 audio IC can use this pin to generate a system wake-up event to Cortex-A9 MPU INTC.	x	-
gpio_[31:0]	I/O	-	External devices can use GPIO modules to generate interrupts to the Cortex-A9 MPU or Cortex-M3 MPU. There are six dedicated interrupt lines (for GPIO1 to GPIO6) to the Cortex-A9 MPU INTC and two dedicated interrupt lines (for GPIO1 and GPIO2) to the Cortex-M3 MPU INTC. Each GPIO module can generate a single interrupt whenever there is at least one event in any one of the configured 32 GPIO inputs. For more information about GPIO interrupt generation, see Chapter 25, General-Purpose Interface .	x	x
gpio_[63:32]	I/O	-		x	x
gpio_[95:64]	I/O	-		x	-
gpio_[127:96]	I/O	-		x	-
gpio_[159:128]	I/O	-		x	-
gpio_[191:160]	I/O	-		x	-

⁽¹⁾ I = Input, O = Output

17.3 Interrupt Controllers Integration

The Cortex-A9 MPU INTC is integrated inside the Cortex-A9 MPU core. For more information about Cortex-A9 MPU INTC integration, see [Chapter 4, Cortex-A9 MPU Subsystem Integration](#).

The Cortex-M3 MPU INTC is integrated inside each Cortex-M3 MPU core. For more information about Cortex-M3 MPU INTC integration, see [Chapter 7, Dual Cortex-M3 MPU Subsystem Integration](#).

17.3.1 Interrupts Mapping

NOTE: All device peripherals interrupts (external to the Cortex-A9 MPU, DSP, and Cortex-M3 MPU subsystems) are active-high, level sensitive.

CAUTION

A single interrupt source can be physically mapped to multiple INTCs (Cortex-A9 MPU, DSP, and Cortex-M3 MPU subsystems). With multiple-mapped interrupts, it is strongly recommended to unmask each interrupt source in only one INTC at a time.

17.3.2 Interrupt Requests to Cortex-A9 MPU INTC

[Table 17-2](#) shows the Cortex-A9 MPU INTC interrupt mapping.

Table 17-2. Cortex-A9 MPU INTC Interrupt Mapping

- (1) Internally generated within the Cortex-M3 MPU subsystem
- (2) Shared with DSP INTC
- (3) Shared with Cortex-A9 MPU INTC
- (4) Shared with DSP and Cortex-A9 MPU INTCs

NOTE: MM_IRQ_0 triggers exception #16 inside the Cortex-M3 core(s).

NOTE: All Cortex-M3 MPUSS internal interrupts are edge interrupts, except the one generated from the MMU (XLATE_MMU_FAULT), which is level interrupt.

17.4 Interrupt Controllers Functional Description

17.4.1 Cortex-A9 MPU INTC Functional Description

Cortex-A9 MPU INTC is configured to have the following interrupt sources:

- 16 Interprocessor interrupts (IPI): ID[15:0]
- 2 private Timer/Watchdog interrupts: ID[30:29]
- 2 legacy nFIQ & nIRQ: one per CPU, bypasses the interrupt distributor logic and directly drives interrupt requests into CPU if used in legacy mode (else treated like other interrupts lines with ID28 and ID31 respectively)
- 128 hardware interrupts: ID[159:32] (rising-edge or high-level sensitive). The interrupt mapping of these interrupts is presented in [Table 17-2, Interrupt Requests to Cortex-A9 MPU INTC](#).

CAUTION

Although the hardware interrupts can be configured to be rising-edge or high-level sensitive in the INTC, the device supports only active-high, level-sensitive configuration.

For more information about the functionality of the Cortex-A9 MPU INTC, see *ARM Cortex-A9 MP Core Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

17.4.2 Cortex-M3 MPU INTC Functional Description

The Cortex-M3 MPU INTC has the following configuration in the device:

- 64 hardware interrupts/16 levels of priority for each Cortex-M3 core. The interrupt mapping of these interrupts is presented in [Table 17-3, Interrupt Requests to Cortex-M3 MPU INTC](#).
- The calibration register, which is used to reload the SYSTICK timer to generate a fixed interval, is not supported in the Cortex-M3 core within the Cortex-M3 MPUSS. The TENMS field is not available due to the different frequencies during voltage scaling.
- The SYSRESETREQ reset feature is not supported at the Cortex-M3 processor level. Writing to this bit has no effect.

For more information about the functionality of the Cortex-M3 MPU INTC, see *ARM Cortex-M3 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

17.5 Interrupt Controllers Register Manual

17.5.1 Interrupt Controllers Instance Summary

For information about the Cortex-A9 MPU INTC and Cortex-M3 MPU INTC instances, see [Chapter 4](#), *Cortex-A9 MPU Subsystem* and [Chapter 7](#), *Dual Cortex-M3 Subsystem*.

17.5.2 Cortex-A9 MPU INTC Registers

For information about the Cortex-A9 MPU INTC registers and their description, see *ARM Cortex-A9 MP Core Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

17.5.3 Cortex-M3 MPU INTC Registers

For information about the Cortex-M3 MPU INTC registers and their description, see *ARM Cortex-M3 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

Control Module

This chapter describes the system control module for the device.

Topic	Page
18.1 Control Module Overview	3410
18.2 Control Module Environment	3412
18.3 Control Module Integration	3413
18.4 Control Module Functional Description	3417
18.5 Control Module Programming Guide	3630
18.6 Control Module Register Manual	3639

18.1 Control Module Overview

The control module allows software control of the various static modes supported by the device. It is composed of two control submodules: general control module and device (padconfiguration) control module.

The general control module has the following features:

- General status and control
- Hardware observability input/output (I/O) multiplexing
- Standard eFuse logic

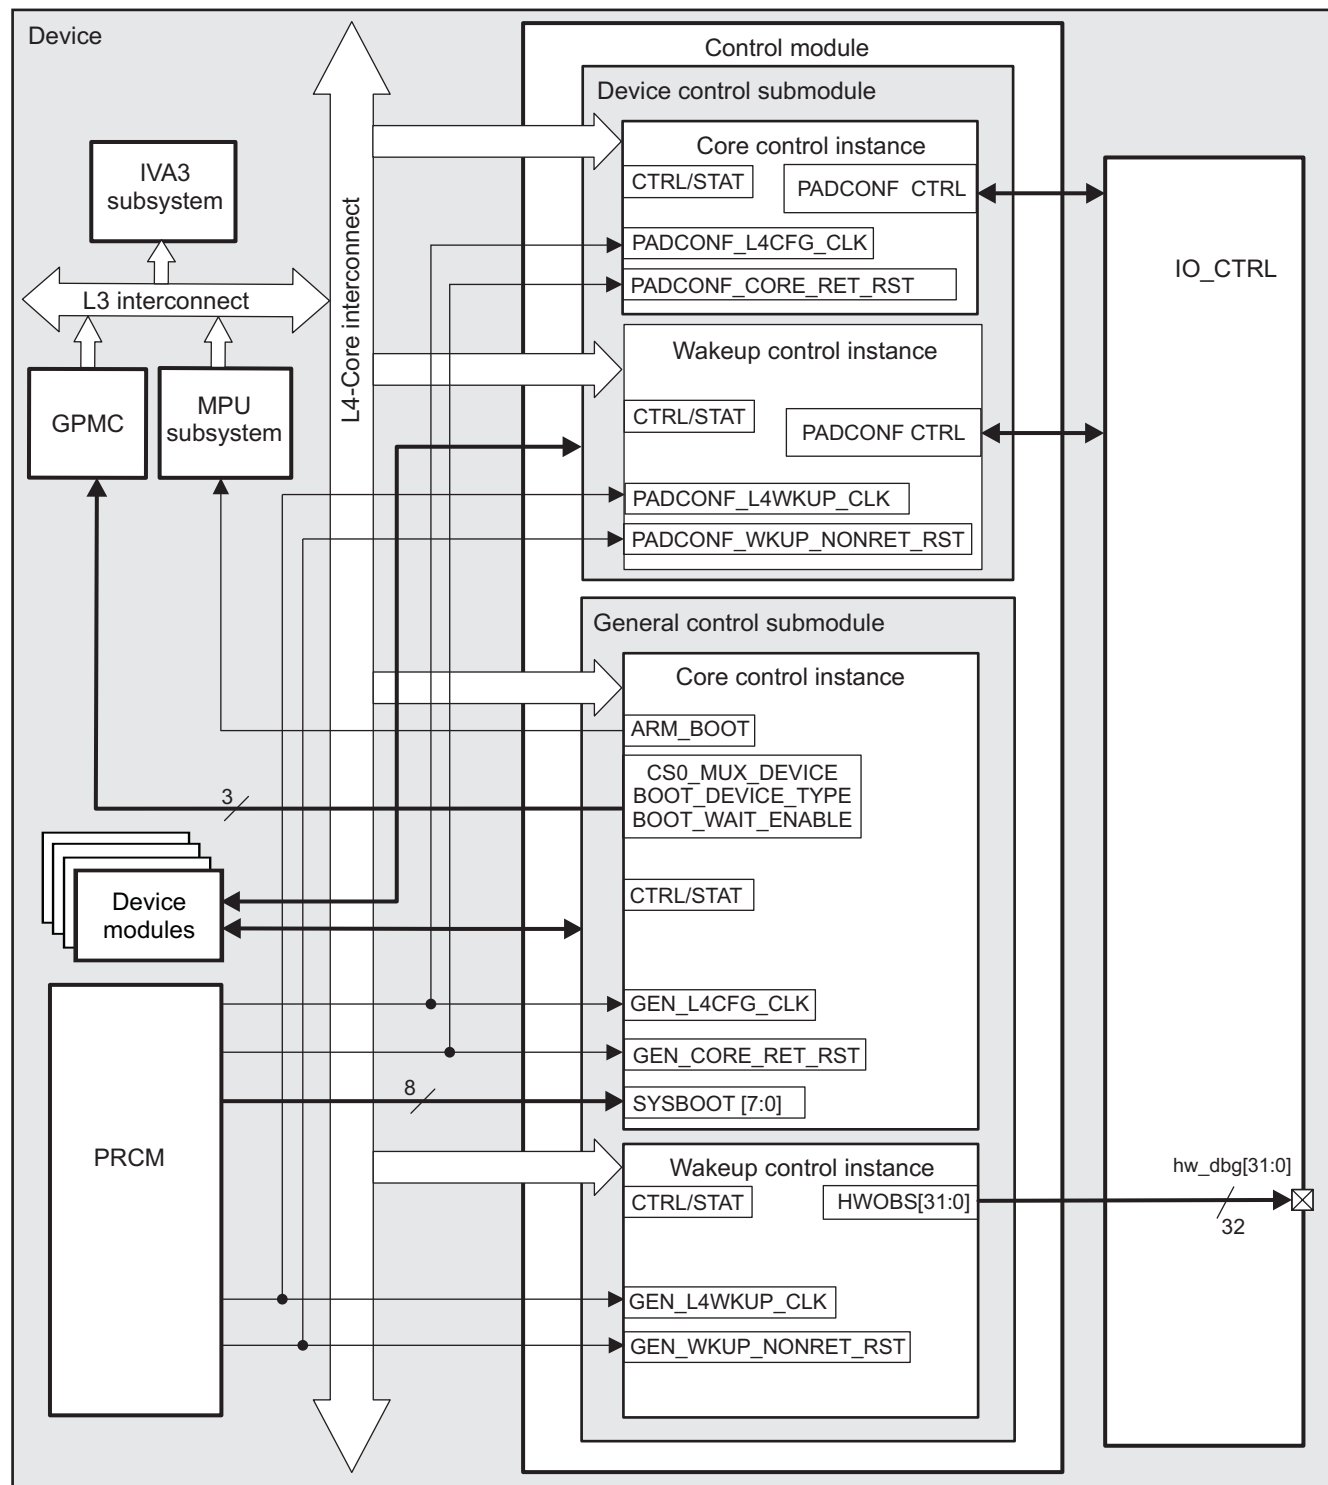

The device control module provides the following features:

- Pad functional I/O multiplexing
- Pad pullup/down configuration
- Pad groups associated signal integrity controls
- Complex I/O configuration
- Analog function control
- Device-specific eFuse registers

Both control submodules are split into two instances: the control core instance within the CORE power domain, and the control wake-up instance within the WKUP power domain. For more information about the four different control module instances, see [Section 18.3, Control Module Integration](#).

[Figure 18-1](#) shows the overview of the control module.

Figure 18-1. Control Module Overview

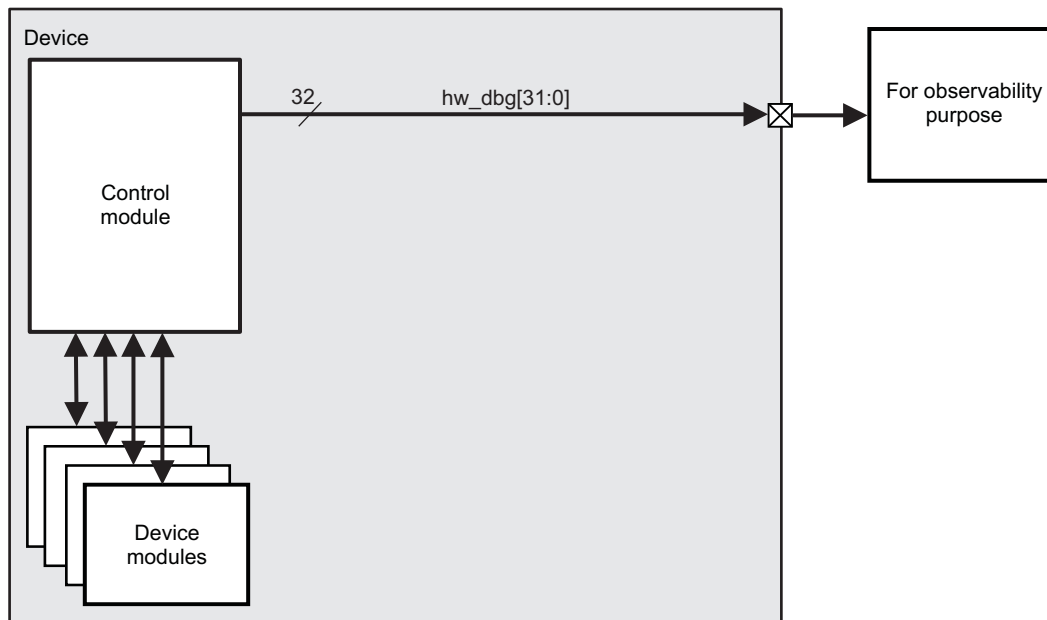

sysctrl-001

18.2 Control Module Environment

The control module controls the multiplexing of device internal module signals routed to the external pins (hw_dbg[31:0]) for hardware debug purposes. For more information, see [Section 18.4.11, Hardware Observability](#), and [Section 18.4.8, PAD Functional Multiplexing and Configuration](#). Using the correct pad configuration, the control module maps these pins at the device boundary to observe the internal signals from the power, reset, and clock management (PRCM) module signals, direct memory access (DMA) requests, and interrupts. [Figure 18-2](#) shows an overview of the control module environment.

Figure 18-2. Control Module Environment

sysctrl-002

18.2.1 Control Module Signals

[Table 18-1](#) lists the control module hardware observability outputs configured to observe device module debug signals. It describes the module signals and specifies their links to functions.

Table 18-1. Control Module I/O Description

Signal	I/O ⁽¹⁾	Description	Reset Value ⁽²⁾
hw_dbg[31:0]	O	Internal hardware observability signals 0 to 31	Hi-Z

⁽¹⁾ I = Input; O = Output

⁽²⁾ Hi-Z = High impedance

18.3 Control Module Integration

The control module of the device is on the L4-Core interconnect. It consists of four module instances:

- General core control module (SYSCTRL_GENERAL_CORE)
- General wakeup control module (SYSCTRL_GENERAL_WKUP)
- Device core control module (SYSCTRL_PADCONF_CORE)
- Device wakeup control module (SYSCTRL_PADCONF_WKUP)

For more information about the different control module instances, see [Table 18-3](#).

Each of these four module instances has an associated register set and shares one functional clock and one reset signal with the PRCM module. These signals are described in [Table 18-2](#).

Table 18-2. Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SYSCTRL_GENERAL_WKUP	GEN_L4WKUP_CLK	WKUP_L4_ICLK2	PRCM	L4_WKUP interface/functional clock propagated to the general wakeup control module
SYSCTRL_GENERAL_CORE	GEN_L4CFG_CLK	CFG_L4_ICLK	PRCM	L4_CFG interface/functional clock propagated to the general core control module
SYSCTRL_PADCONF_WKUP	PADCONF_L4WKUP_CLK	WKUP_L4_ICLK2	PRCM	L4_WKUP interface/functional clock propagated to the device wakeup control module
SYSCTRL_PADCONF_CORE	PADCONF_L4CFG_CLK	CFG_L4_ICLK	PRCM	L4_CFG interface/functional clock propagated to the device core control module
Resets				
SYSCTRL_GENERAL_WKUP	GEN_WKUP_NONRET_RST	WKUP_PWRON_RST	PRCM	Internal power-on reset affecting general wakeup control module
SYSCTRL_GENERAL_CORE	GEN_CORE_RET_RST	CORE_PWRON_RET_RST	PRCM	Internal power-on reset affecting the general core control module
SYSCTRL_PADCONF_WKUP	PADCONF_WKUP_NONRET_RST	WKUP_PWRON_RST	PRCM	Internal power-on reset affecting the device wakeup control module
SYSCTRL_PADCONF_CORE	PADCONF_CORE_RET_RST	CORE_PWRON_RET_RST	PRCM	Internal power-on reset affecting the device core control module

The control module is reset by the internal power-on reset (POR), which is active low. The PRCM provides a retention POR signal (CORE_PWRON_RET_RST) duplicated to each of the two core control module instances, and a nonretention POR signal (WKUP_PWRON_RST) duplicated to each of the two wake-up control module instances in the control module. For more information, see [Section 3.5.4](#), *Reset Domains*, in [Chapter 3](#), *Power, Reset, and Clock Management*. The control module does not respond to a warm reset or to an L4-Core reset.

The main sequential logic within the system control module is accessible in a register file through the L4-Core interconnect. The PRCM module provides the CFG_L4_ICLK functional clock signal (L4_CFG clock domain) separately to both of the core control submodules. See [Section 3.6.3.2.4](#), *CM2 Clock Generator* in [Chapter 3](#), *Power, Reset, and Clock Management*, for more information about this signal.

The PRCM module also supplies the WKUP_L4_ICLK2 functional clock signal (L4_WKUP -clock domain) to both of wake-up control module instances. See [Section 3.6.3.1](#), *PRM Clock Source*, in [Chapter 3](#), *Power, Reset, and Clock Management*, for more information about this signal.

The PRCM module latches the sys_boot [7:0] pad signals at power-on reset and exports them as vector to the SYSBOOT[7:0] input of the General Core Control module. It is scanned in the CONTROL_STATUS[7:0] SYS_BOOT bit field. For more information, see [Section 27.2.4.2](#), *Booting Device Order Selection*, and [Section 27.2.4.1](#), *Clock Source Selection*.

The signal integration of the control module features:

- No IDLE hardware handshake

- No STANDBY hardware handshake
- No SAVE and RESTORE hardware handshake
- No Wake-up request generation
- No DMA request generation
- No interrupt request (IRQ) generation
- Two functional clocks, one within the CFG and the other within WKUP clock domains
- One retention and one nonretention internal power-on based resets

[Figure 18-3](#) summarizes the integration of the module in the device.

Figure 18-3. Control Module Integration

sysctrl-003

Table 18-3 lists the integration attributes.

Table 18-3. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
SYSCTRL_GENERAL_WKUP	PD_WKUP	L4_WKUP
SYSCTRL_GENERAL_CORE	PD_CORE	L4_CFG
SYSCTRL_PADCONF_WKUP	PD_WKUP	L4_WKUP
SYSCTRL_PADCONF_CORE	PD_CORE	L4_CFG

Software sets the configuration registers to the desired values depending on the configuration of the requested device. Static device configuration registers can be set by software at any time and are effective immediately.

18.4 Control Module Functional Description

18.4.1 Control Module Block Diagram

The control module controls the settings of various device modules through register configuration and internal signals. It also controls the pad configuration, pin functional multiplexing, and the routing of internal signals (such as PRCM signals or DMA requests) to output pins configured for hardware observability.

[Figure 18-4](#) is the control module block diagram.

Figure 18-4. Control Module Block Diagram

Each control submodule primarily implements a bank of registers accessible (read/write) by the software along with some read-only registers carrying status information.

Read/write registers available in the general control module can be divided into the following classes:

- Hardware observability registers (32-bit read/write register)

- Status and configuration registers
- Boot registers
- eFuse ROM registers
- Miscellaneous functional registers

Read/write registers available in the device(padconfiguration) control module can be divided into the following classes:

- Pad configuration registers (32-bit registers, one register for two pads)
- Pad groups (not individual per pad) associated registers for signal integrity parameters control (32-bit read/write registers)
- I/O cells associated specific control registers
- Device-specific status and configuration registers
- Miscellaneous functional registers

18.4.2 Control Module Clock Configuration

Figure 18-5 shows the control module internal clock distribution schema. Each CFG_L4_ICLK and WKUP_L4_ICLK2 source clock is internally distributed into two clock paths: the first one directly mirrors the source clock and is an always-running clock. It is used to synchronize and resample some of the module inputs. The other clock path can be internally gated within the module.

Figure 18-5. Control Module Internal Clock Paths

The clock-gating strategy is selected through the CONTROL_SYSCONFIG[3:2] IP_SYSCONFIG_IDLEMODE bit field available in each of the four control module instances. The different possibilities for clock management are described in Table 18-4. There are no PRCM software controls for the control module clocks. There are, however, clock activity status bits in the PRCM module. See Section 3.6.15.2, *Clock Domain Modes*, and Section 3.6.4, *CD_WKUP Clock Domain*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 18-4. Internal Clock Gating Options

Feature	CONTROL_SYSCONFIG[3:2] IP_SYSCONFIG_IDLEMODE value	Description
Local clock control	0b00	Clock is manually gated.
Local clock control	0b01	Clock is manually enabled.
Local clock autogating	0b10, 0b11	Clock is automatically gated when there is no access to the control module through L4-interconnect.

18.4.3 Control Module Software Reset

The control module is not sensitive to software reset.

18.4.4 Control Module Power Management

18.4.4.1 Retention

The general- and device core control module instances are fully built with retention flip-flop (RFF) and are powered in the CORE domain, so they can be in active or retention mode. The core instances lose their content when the CORE power domain is in off mode. In contrast to the core control instances, the control wake-up instances are always powered and active. [Section 3.9, Device Low-Power States](#), in [Chapter 3, Power, Reset, and Clock Management](#), provides more information about the device low-power states.

18.4.4.2 Power Management Protocols

The control module, which is slave on the L4 interconnect, does not support standby or idle mode protocols.

18.4.4.3 Save-and-Restore Mechanism

The control core module instances lose their contents when the CORE power domain is in off mode. To prevent this, before going to off mode, the core register context is copied by software into a dedicated SAR_RAM sitting in the WKUP voltage domain. The save-and-restore (SAR) mechanism, controlled by the PRCM module, allows them to restore registers to the value present before going to off mode. Thus, core domain registers will have a correct configuration/state immediately after core power is on again without requesting a software operation to reconfigure them.

Because the SAR mechanism is managed by software-accessible registers, no hardware-specific requirements exist. For more information about SAR, see [Section 3.9.3, Device Off State Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

18.4.5 Hardware Requests

The control module does not generate interrupt, DMA, or wake-up requests.

18.4.6 Control Module Initialization

The control module responds only to the internal POR and device type. At power on, reset values for the registers define the *safe state* for the device. In the initialization mode, only modules to be used at boot time are associated with the pads. Other module inputs are internally tied and output pads are turned off. After POR, software sets the pad functional multiplexing and configuration registers to the desired values according to the requested device configuration. For more information, see [Chapter 27, Initialization](#).

General-purpose (GP) devices include features that are inaccessible or unavailable. These inaccessible registers define the default or fixed device configuration or behavior.

The [CONTROL_STATUS\[7:0\]](#) SYS_BOOT bit field reflects the state of the sys_boot pins captured at POR in the PRCM module.

18.4.7 Control Module Instances

18.4.7.1 General Core Control Module Instance

The SYSCTRL_GENERAL_CORE instance contains most of the control logic providing hardware observability features for different DPLL clockout and DPLL-specific signals, DMA requests, IRQs, and other internal hardware signals. The general core control provides the system boot decoding logic and has control over the standard eFuse settings. The system configuration registers, specific function controls, some peripheral control and status registers are also mapped there.

The register sets available within the SYSCTRL_GENERAL_CORE are:

- Observability control registers:
 - [CONTROL_HWOBS_CONTROL](#)
 - [CONTROL_DEBOBS_FINAL_MUX_SEL](#)
 - [CONTROL_CONF_SDMA_REQ_SELx](#)
 - [CONTROL_CONF_CLK_SELx](#) (where x = 0 to 2)
 - [CONTROL_CONF_DPLL_X_SEL](#) (where X is FREQLOCK, TINITZ, PHASELOCK, TENABLE, TENABLEDIV, BYPASSACK, IDLE)
- Part of the debug view channel selection registers: [CONTROL_CORE_CONF_DEBUG_SEL_TST_X](#)
- MMU address translation related registers: [CONTROL_CORTEX_M3_MMUADDRTRANSLTR](#) and [CONTROL_CORTEX_M3_MMUADDRLOGICTR](#)
- Standard fuse registers: [CONTROL_STD_FUSE_X](#)
- Clock gating configuration register: [CONTROL_GEN_CORE_SYSCONFIG](#)
- Control status register: [CONTROL_STATUS](#)
- Peripheral controls:
 - [CONTROL_TEMP_SENSOR](#)
 - [CONTROL_DSS_CONTROL](#)
 - [CONTROL_USBOTGHS_CONTROL](#)
 - [CONTROL_LDOSRAM_MPU_VOLTAGE_CTRL](#)
 - Etc.

18.4.7.2 General Wakeup Control Module Instance

The registers associated with this module are:

- Clock gating configuration register: [CONTROL_GEN_WKUP_SYSCONFIG](#)
- Register with spare bits: [CONTROL_OCPREG_SPARE](#)
- Part of the debug view channel selection registers: [CONTROL_WKUP_CONF_DEBUG_SEL_TST_X](#)

18.4.7.3 Device Core Control Module Instance

The SYSCTRL_PADCONF_CORE instance provides the device-specific pad control features such as pullup/down I/O configuration and pad functional multiplexing. Wake-up control/status features are also subject of the device core control.

The registers associated with this module are:

- Clock gating configuration register:
- Different peripheral pad mode configuration and wake-up status/configuration registers:
 - [CONTROL_PADCONF_CORE_SYSCONFIG](#)
 - [CONTROL_CORE_PAD0_X_PAD1_Y](#)
 - [CONTROL_PADCONF_WAKEUPEVENTx](#)
 - [CONTROL_PADCONF_GLOBAL](#)
 - [CONTROL_SMARTxIO](#)

- [CONTROL_C2CIO_PADCONF_0](#)
- Etc.
- Peripheral pad voltage-level control registers: [CONTROL_PADCONF_MODE](#)
- Miscellaneous controls for different device interface modules: [CONTROL_X](#) registers (including [CONTROL_EFUSE](#) registers)

18.4.7.4 Device Wakeup Control Module Instance

Configuration registers for all pads linked to the wake-up voltage domain are in the wake-up device control module. The registers instantiated here are:

- Clock gating configuration register: [CONTROL_PADCONF_WKUP_SYSCONFIG](#)
- [CONTROL_WKUP_PAD0_X_PAD1_Y](#) registers for configuring FREF clock oscillator pads, reset signals, and power mode pad configurations

NOTE: [SYSCTRL_PADCONF_X](#) alias notifies a device control module Instance.

[Table 18-104](#) shows the memory size and base addresses assigned to the different control module instances

18.4.8 Pad Functional Multiplexing and Configuration

After POR, software must set the pad functional multiplexing and configuration registers to the desired values according to the requested device configuration. The configuration is controlled by pads or by a group of pads. Each configurable pin has its own configuration register for pullup/down control and for the assignment to a given module.

Two sets of 32-bit registers provide the pad functional multiplexing and configuration feature of the control module. The first set of registers ([CONTROL_CORE_PAD0_X_PAD1_Y](#)) configures the pads in the CORE power domain. The second set of registers ([CONTROL_WKUP_PAD0_X_PAD1_Y](#)) configures pads in the WKUP power domain.

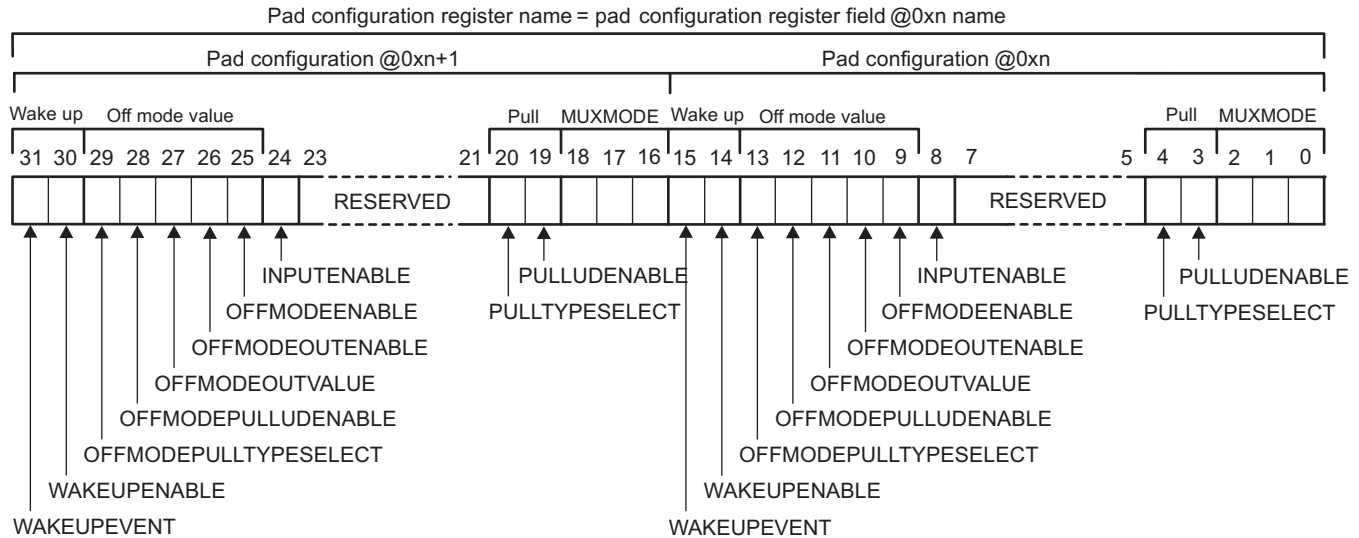

The pad configuration as defined in this module is used in the [IO_CTRL](#) logic along with the gating and protection features. The gating feature is implemented for the output pads. The protection feature is implemented for input lines. These features implement additional control and multiplexing capabilities hard-wired in the [IO_CTRL](#) logic and driven by the internal device state and/or logic.

The gating feature allows forcing of an output pad to a fixed value (Z, pullup, pulldown, 1, 0) or to a given internal signal. Each gating command is defined with a logic equation and the output state/value to be set on the pad when the logic equation is "True."

The protection feature provides control on each input line of the module when no pad is assigned to this input (protected value). When POR is released, the value on the pad is driven by the default configuration of the control module. This configuration is usually aligned with the default value selected on the I/O cell. The protected value can be logical level (0 or 1) or a signal from a pad; it is selected when none of the [pad_x.MuxMod](#) selects a device input.

Each 32-bit pad configuration register controls two pads: the first pad is controlled by the 16-least significant bits (LSBs), and the second pad is controlled by the 16 most-significant bits (MSBs); hence, one pad configuration register provides control for two different pins. After POR, software sets the pad functional multiplexing and configuration registers to the requested device pad configurations. Data written in these registers directly commands the multiplexing of the pad configuration logic. [Figure 18-6](#) describes the 16-bit-wide pad configuration register field associated with each pin.

Figure 18-6. Pad Configuration Register Functionality

sysctrl-007

NOTE: These registers can be accessed using 8-, 16-, and 32-bit operations.

The functional bits of a pad configuration register field are divided into the following five fields:

- MUXMODE (3 bits) defines the multiplexing mode applied to the pin. A mode corresponds to the selection of the functionality mapped on the pin with seven (0 to 6) possible functional modes for each pin.
- PULL (2 bits) for combinational pullup/down configuration:
 - PULLTYPESELECT: Pullup/down type selection for the pin
 - PULLUDENABLE: Enables pullup/down feature for the pin
- INPUTENABLE (1 bit) drives an input enable signal to the I/O CTRL
 - INPUTENABLE = 0: Input disable. Pin is configured only in output mode.
 - INPUTENABLE = 1: Input enable. Pin is configured in bidirectional mode.
- Off mode values (1 bit) override the pin state when the OFFMODEENABLE bit in CONTROL_CORE_PAD0_X_PAD1_Y register is set and off mode is active. This feature allows having separate configurations (5 bits) for the pins when in off mode:
 - OFFMODEENABLE: Off mode pin state override control. Set to 1 to enable the feature and to 0 to disable it
 - OFFMODEOUTENABLE: Off mode output enable value. Set to 0 to enable the feature and to 1 to disable it
 - OFFMODEOUTVALUE: Off mode output value
 - OFFMODEPULLUDENABLE: Off mode pullup/down feature enable
 - OFFMODEPULLTYPESELECT: Off mode pullup/down type selection
- Wake-up bits (2 bits):
 - WAKEUPENABLE: Enable wake-up detection on input. It is also the off mode input enable value.
 - WAKEUPEVENT: Wake-up event status for the pin

CAUTION

The OFFOUTENABLE and OFFOUTVALUE bits are functional only if the pad configuration supports output mode on at least one MUXMODE. For a pad that supports only the input feature, the OFFOUTENABLE and OFFOUTVALUE bits cannot be configured (they are don't care and read always returns 0).

NOTE: Because off mode affects only the pads in the CORE domain, OFFMODE-related bits are not present in the padconfiguration registers of the WKUP power domain .

Figure 18-7 shows the pad configuration function when off mode is inactive. For more information about off mode, see [Section 18.4.8.4, Off Mode](#).

Figure 18-7. Pad Configuration Diagram

The I/O pads are software-controlled by:

- Writing to the CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y registers in the device control module for I/O and pullup/down configuration.
- Writing to the GPIOi.GPIO_OE registers in the GPIO module for I/O configuration.

For more information about how to configure the I/O pads, see [Section 18.5.1.2.5, Pad Configuration Programming Points](#).

For more information about the GPI/O module, see [Section 25.4.8, General-Purpose Interface Data Input/Output Capabilities](#).

NOTE: For the proper functioning of the following modules, the INPUTENABLE bit in the corresponding pad configuration register must be set to 1 for pads configured to drive output clocks:

- GPMC
- I2Ci
- MMCi
- HSUSB HOST
- McPDM

NOTE: For a correct configuration of each pin direction (input, output, bidirectional), the CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y and the GPIOi.GPIO_OE registers must be written.

NOTE: Software INPUTENABLE controls are not available for the lpddr21_x, lpddr22_x, usbb1_hsic_x, and usbb2_hsic_x pads. Once their buffers are enabled they are always bidirectional. For more information, see [Section 18.4.12.9.2, High-Speed I/O Buffers With Impedance, Slew Rate, and Weak Driver Settings](#).

[Table 18-5](#) lists the bit directions of the CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y registers.

Table 18-5. Bit Meanings for CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y Registers

Pad Configuration Bit	Bit Meaning	
	0	1
PULLUDENABLE	Not activated	Activated
PULLTYPESELECT	Pulldown	Pullup
INPUTENABLE	Input enable signal is inactive.	Input enable signal is active.
OFFMODEENABLE	Off mode values are invalid.	Off mode values are valid.
OFFMODEOUTENABLE	Output	Input
OFFMODEOUTVALUE	Low	High
OFFMODEPULLUDENABLE	Not activated	Activated
OFFMODEPULLTYPESELECT	Pulldown	Pullup
WAKEUPENABLE	Disable I/O wake-up function.	Enable I/O wake-up function.
WAKEUPEVENT	Wake-up event is not detected.	Wake-up event is detected.
MUXMODE bits	See Table 18-6 .	See Table 18-6 .

18.4.8.1 Mode Selection

[Table 18-6](#) lists the multiplexing modes and settings.

Table 18-6. Mode Selection

MUXMODE	Selected Mode
0b000	Primary mode = Mode 0
0b001	Mode 1
0b010	Mode 2
0b011	Mode 3
0b100	Mode 4
0b101	Mode 5
0b110	Mode 6
0b111	Safe mode = Mode 7

The MUXMODE field in the CONTROL_CORE_PAD0_X_PAD1_Y and CONTROL_WKUP_PAD0_X_PAD1_Y registers defines the multiplexing mode applied to the pad. Modes are referred to by their decimal (from 0 to 7) or binary (from 0b000 to 0b111) representation. Functional modes are defined from 0b000 to 0b110; mode 0b111 is referred to as the safe mode.

For most pads, the reset value for the MUXMODE field in the CONTROL_CORE_PAD0_X_PAD1_Y and CONTROL_WKUP_PAD0_X_PAD1_Y registers is 0b111. The exceptions are pads to be used at boot time to transfer data from selected peripherals to the external flash memory.

Mode 0 is the primary mode. When mode 0 is set, the function mapped to the pin corresponds to the name of the pin.

Mode 1 to mode 6 are possible modes for alternate functions. On each pin, some modes are used effectively for alternate functions, while other modes are unused and correspond to no functional configuration.

The safe mode (mode 7) avoids any risk of electrical contention by configuring the pin as an input with no functional interface mapped to it. The safe mode is used mainly as the default mode for all pins containing no mandatory interface at the release of POR.

NOTE: When a pad is set into a mux mode that is not defined by pin multiplexing, this pad is set undriven (Hi-Z) with potential pullup/down.

For more information about the configurable mode on each pin, see [Table 18-9](#) and [Table 18-8](#).

NOTE: Pad names are signal names available in mode 0.

18.4.8.2 Pull Selection

There is no automatic gating control to ensure that internal weak pulldown/pullup resistors on a pad are disconnected whenever the pad is configured as output. If a pad is always configured in output mode, it is recommended for user software to disable any internal pull resistor tied to it, to avoid unnecessary consumption.

Table 18-7. Pull Selection

PULL		Pin Behavior
PULLTYPESELECT	PULLUDENABLE	
0b0	0b0	Pulldown selected but not activated
0b0	0b1	Pulldown selected and activated
0b1	0b0	Pullup selected but not activated
0b1	0b1	Pullup selected and activated

For more information about the pull available on each pin, see [Table 18-8](#) and [Table 18-9](#).

NOTE: Software controls for internal active mode pullups and pulldowns on the lpddr21_x and lpddr22_x pads are available in the [CONTROL_LPDDR2IO1_0](#) through [CONTROL_LPDDR2IO1_2](#) and [CONTROL_LPDDR2IO2_0](#) through [CONTROL_LPDDR2IO2_2](#) registers, respectively.

Software controls for internal active mode pullups and pulldowns on the usbb1_hsic_x and usbb2_hsic_x pads are available in the [CONTROL_USBB_HSIC](#) register.

For more information, see [Section 18.4.12.9.2, High-Speed I/O Buffers With Impedance, Slew Rate, and Weak Driver Settings](#).

18.4.8.2.1 Generic Pad Configuration Bit Fields vs I/O Cell Mapping

Figure 18-8 provides a generic view of the relations between the pad configuration controls and I/O cell functions for a pad configured in active mode.

Figure 18-8. Active Mode Pad Configuration Bit Fields vs I/O Cell Mapping

sysctrl-022

- (1) [Section 18.4.12.9, Signal Integrity Parameter Control Registers With Pad Group Assignment](#), summarizes the I/O cell signal performance settings. For more information about the controlled I/O cell electrical parameters and interdependency considerations, see the device data manual.
- (2) For information about the mapping of software controls in the control module versus different device pads, see [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#). For more information about interface-specific signal parameter settings, see the device data manual.
- (3) The `CONTROL_CORE/WKUP_PADCONF_MODE.VDDS_DV_x` bit is available for each I/O that is part of the dual-voltage domain group x. For more information about 1.2-V/1.8-V dual-voltage domain I/Os, see the device data manual. For more information about peripheral dual-voltage software controls versus pad group mapping, see [Section 18.4.12.10, Dual-Voltage-Supplied Peripheral Controls](#).

NOTE: Dynamic switching between 1.2-V and 1.8-V voltage modes on dual-voltage peripheral I/Os is not allowed.

18.4.8.3 Pad Multiplexing Register Fields

Table 18-8 and Table 18-9 provide for each pad configuration register field the address offset and associated signal name for each multiplexing mode (as set by the MUXMODE bit field). Mode 0 is always defined. Modes with no signal name are undefined for the given pad. For more information about default padconfiguration settings (POR values) for pads in the CORE power domain, see [Section 18.6.7](#), *SYSCTRL_PADCONF_CORE Register Description*; for pads in the WKUP power domain, see [Section 18.6.9](#), *SYSCTRL_PADCONF_WKUP Register Description*.

NOTE:

- [Table 18-8](#) lists the pad configuration registers instantiated in the WKUP power domain that drive the pads in the WKUP power domain. [Table 18-9](#) lists the pad configuration registers instantiated in the CORE power domain that drive the pads in the CORE power domain.
 - In [Table 18-8](#) and [Table 18-9](#), an empty cell indicates that the mode or pull is not available for this pin.

⁽¹⁾ For the pad configuration registers which multiplexing has only one signal set (available in muxmode 0), the MUXMODE bitfield is not implemented, and is described as RESERVED. Software must keep this bit field at its default (Power-on Reset) value.

⁽²⁾ This pad is built on an I/O cell of the extended-drain type, which can be configured to operate within the 1.8-V (standard) or 3.0-V (high) I/O power supply voltage range. A PBIAS cell, which acts as a level shifter, is connected to the extended-drain I/O cell of this pad to appropriately bias its voltage according to the externally applied I/O power supply voltage. To ensure I/O safe operation at 1.8 V or 3.0 V and desired signal performance, the extended-drain I/O cell and its corresponding PBIAS cell must be appropriately configured by software prior to signal selection on the pad, regardless of the signal multiplexing mode. For more details on extended-drain I/O cell and PBIAS cell descriptions and settings, see [Section 18.4.9, Extended-Drain I/O and PBIAS Cell](#), and [Section 18.5.1.2.2, Extended-Drain I/Os and PBIAS Cells Programming Guide](#).

⁽²⁾ This pad is built on an I/O cell of the extended-drain type, which can be configured to operate within the 1.8-V (standard) or 3.0-V (high) I/O power supply voltage range. A PBIAS cell, which acts as a level shifter, is connected to the extended-drain I/O cell of this pad to appropriately bias its voltage according to the externally applied I/O power supply voltage. To ensure I/O safe operation at 1.8 V or 3.0 V and desired signal performance, the extended-drain I/O cell and its corresponding PBIAS cell must be appropriately configured by software prior to signal selection on the pad, regardless of the signal multiplexing mode. For more details on extended-drain I/O cell and PBIAS cell descriptions and settings, see [Section 18.4.9, Extended-Drain I/O and PBIAS Cell](#), and [Section 18.5.1.2.2, Extended-Drain I/Os and PBIAS Cells Programming Guide](#).

18.4.8.4 Off Mode Pad Control Overview

When off mode is selected, which is true when `PRM_DEVICE_OFF_CTRL[0] DEVICE_OFF_ENABLE = 0b1` from the PRCM module or `CONTROL_PADCONF_GLOBAL[31] FORCE_OFFMODE_ENABLE = 0b1` (force bit to test the value of off mode), the off mode values field `CONTROL_CORE_PAD0_X_PAD1_Y[27,11] OFFMODEOUTVALUE` overrides the pad state when the `CONTROL_CORE_PAD0_X_PAD1_Y[25,9] OFFMODEENABLE` bit is set.

The `CONTROL_CORE_PAD0_X_PAD1_Y[26,10] OFFMODEOUTENABLE` bit is active low.

Figure 18-9 shows the off mode pad control.

Figure 18-9. Off Mode Pad Control Overview

If off mode is active and the `OFFMODEENABLE` bit is set to 0 (disable OFF mode override feature), the pad keeps the AND value of the configuration (input/output, PU/PD) it had before going into off mode:

- For an input, the pad is isolated and the pull remains active.
- For an output, the value is latched before going into off mode, to drive the same value in off mode.

NOTE: Software controls for internal off-mode pullups and pulldowns on the `usbb1_hsic_x` and `usbb2_hsic_x` pads are available in the `CONTROL_USBB_HSIC` register.

No internal off-mode pullups and pulldowns are available for the `lpddr21_x` and `lpddr22_x` pads of the device.

For more information, see [Section 18.4.12.9.2, High-Speed I/O Buffers With Impedance, Slew Rate, and Weak Driver Settings](#).

18.4.8.4.1 Wake-Up Event Detection

In off mode, wake-up event detection can also be enabled on an input pad. The pad wake-up event is latched in the `CONTROL_CORE_PAD0_X_PAD1_Y[31,15]` and `CONTROL_WKUP_PAD0_X_PAD1_Y[31,15] WAKEUPEVENT` bits.

The off mode I/O pads wake-up scheme is enabled by setting the PRM_IO_PMCTRL[16] GLOBAL_WUEN bit from PRCM module. The wake-up scheme status is transmitted by the WKUP_ENABLE signal. The wake-up event detection capability of each I/O pad of the device is individually enabled or disabled by writing the CONTROL_CORE_PAD0_X_PAD1_Y[30,14] and CONTROL_WKUP_PAD0_X_PAD1_Y[30,14] WAKEUPENABLE bits.

Figure 18-10. Wake-Up Event Detection Overview

NOTE: When wake-up detection is enabled for a pad, the pad must be configured as input to avoid contention between the device output buffer and an external driver. If this pin is already configured as an input in active mode, hardware automatically retains the same input state; no software action is required.

If this pin is configured as an output in active mode, the off override function must be enabled to set the pin as an input during off mode: in the CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y register, set the OFFMODEENABLE bit to 0x1 to enable the off override function, and set the OFFMODEOUTENABLE bit to 0x1 to switch this pin to input mode.

NOTE: Regardless of whether the INPUTENABLE bit is set high or low during active mode, to enable wake-up detection for a pad, user software must set the WAKEUPENABLE bit to 0x1. It is recommended to apply pullup/down resistors at the pad to avoid spurious wake-up detection. User software can optionally enable the pad off-mode internal pullup/down resistors through the appropriate setting of the OFFMODEPULLUDENABLE and OFFMODEPULLTYPESELECT bits in the corresponding pad configuration register.

The registers [CONTROL_PADCONF_WAKEUPEVENT_0](#) through [CONTROL_PADCONF_WAKEUPEVENT_6](#) are dedicated 32-bit registers for a separate capture of the WAKEUPEVENT from different pads. Duplication of the CONTROL_CORE_PAD0_X_PAD1_Y[31,15] and CONTROL_WKUP_PAD0_X_PAD1_Y[31,15] wake-up event bits inside these seven additional registers helps reduce the software latency in identifying which pad has triggered a wake-up event.

18.4.8.4.2 I/O Power Optimization

To optimize I/O power, it is important to avoid unconnected or incorrectly pulled pins. According to the type of pins, the way to reduce power consumption can differ. [Table 18-10](#) shows the three available pin (or ball) types.

Table 18-10. Pin Types

Input	Output	Bidirectional
 <p>sysctrl-011</p>	 <p>sysctrl-012</p>	 <p>sysctrl-013</p>

The configuration differs according to the I/O cell types. The following advices can be useful to avoid extra current leakage:

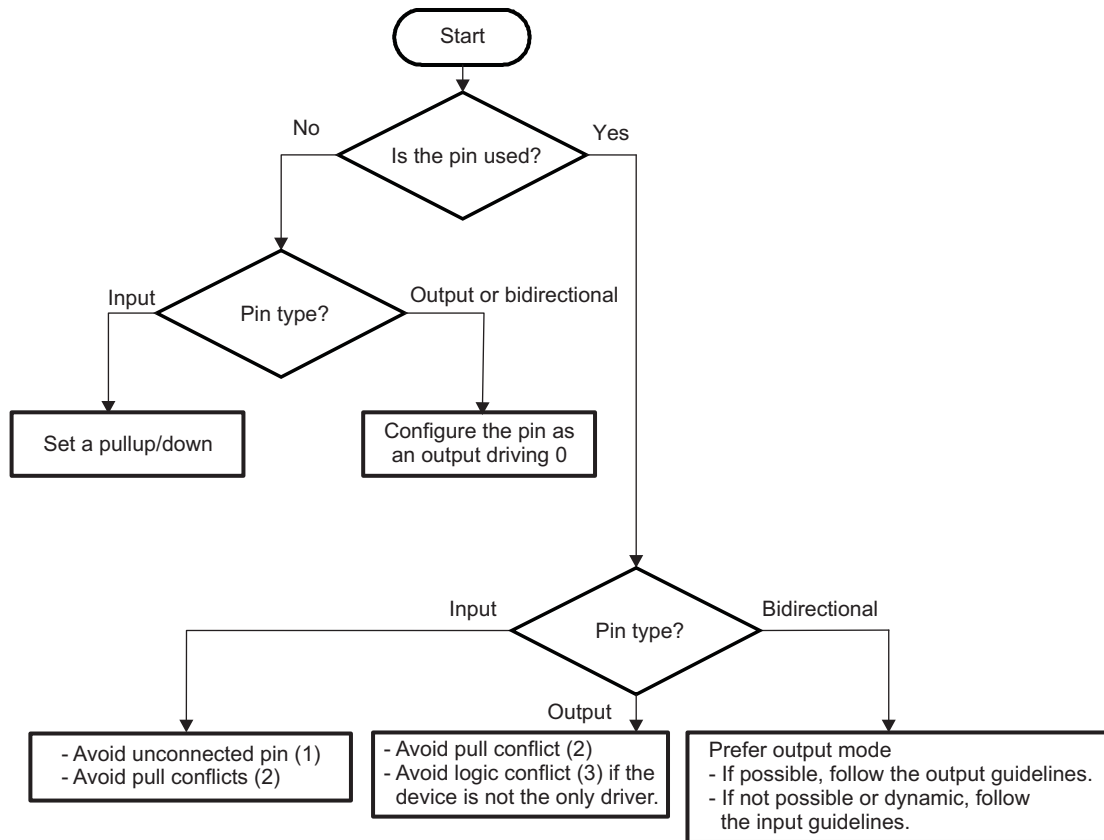

- For input pins, use a pullup/down when possible.
- For output pins, check existing pulls to avoid conflicts.
- For bidirectional pins, reconfigure the pin as an output driving 0 when possible.

NOTE: If the pad is always configured in output mode, it is recommended for software to disable the internal pull by programming the I/O pad configuration register of the corresponding control module.

NOTE: If a device pad is left unconnected, but power is supplied to the I/O, or the pad is used only as an output during the lifetime of the application, it is recommended to keep its corresponding padconfiguration bit `CONTROL_CORE/WKUP_PAD0_X_PAD1_Y.INPUTENABLE` set to 0b0. This keeps the input buffer disabled and reduces static current consumption.

Some I/O configurations involve modifications during the software setup of I/Os and sometimes require several hardware updates.

[Figure 18-11](#) shows how to optimize the power consumption of pads.

Figure 18-11. I/O Power Optimization Flow Chart

sysctrl-014

The following notes give additional explanation about the pin configuration.

- To avoid unconnected pins, the configuration depends on its use:
 - If the pin is not driven externally, a pullup/down is required.
 - Otherwise, a pullup/down is not necessary.
- Pull conflicts occur when different pulls are on the same line. To correctly configure the pin, avoid external and internal pull together.
- Logic conflicts consist in different electrical levels at the same time on one line. This can occur when several devices are connected to the same line. The two possible cases are:
 - If no external device drives the line, configure the pin to drive a 0.
 - If another device drives the line, either the same value must be driven or the pin must be disconnected (high-impedance state [Hi-Z]).

NOTE: It is advised to use Hi-Z logical state on the device or the external component when the line is driven by both components.

For unconnected device pads, `safe_mode` pad configuration is recommended if available. [Table 18-11](#) summarizes recommendations for the configuration of unconnected pads (in terms of mux mode, input, and output buffer states) for all cases, including those where `safe_mode` configuration is not available.

Table 18-11. Recommended Configuration For Unconnected Device Pads

Pad MuxMode Set Features			Power-on reset default configuration		Recommended Unconnected Device Pad Configuration				
Safe Mode Available?	GPIO Function Available?	More Than One (Non-GPIO) Function Available?	Multiplexed Signal Direction at Pad	Pad State ⁽¹⁾	Multiplexed Signal Direction at Pad	Pad State	Input Buffer Disabled?	Output Buffer Disabled?	MUX Function Selected
Yes	N/A	N/A	Input	PU	Safe Mode	PU	Yes ⁽²⁾	N/A	SAFE MODE ⁽³⁾
Yes	N/A	N/A	Input	PD	Safe Mode	PD	Yes	N/A	SAFE MODE
Yes	N/A	N/A	Output	1	Safe Mode	PD	Yes	N/A	SAFE MODE
Yes	N/A	N/A	Output	0	Safe Mode	PD	Yes	N/A	SAFE MODE
Yes	N/A	N/A	-	Hi-Z	Safe Mode	PD	Yes	N/A	SAFE MODE
No	Yes	N/A	Input	PU	Input	PU	Yes	Yes ⁽⁴⁾	GPIO_XX ⁽⁵⁾
No	Yes	N/A	Input	PD	Input	PD	Yes	Yes	GPIO_XX
No	Yes	N/A	Output	1	Input	PD	Yes	Yes	GPIO_XX
No	Yes	N/A	Output	0	Input	PD	Yes	Yes	GPIO_XX
No	Yes	N/A	-	Hi-Z	Input	PD	Yes	Yes	GPIO_XX
No	No	Yes	Input	PU	Input	PU	Yes	N/A ⁽⁴⁾	N/A (default)
No	No	Yes	Input	PD	Input	PD	Yes	N/A	N/A (default)
No	No	Yes	Output	1	Output	1	Yes	N/A	N/A (default) ⁽⁶⁾
No	No	Yes	Output	0	Output	0	Yes	N/A	N/A (default) ⁽⁶⁾
No	No	Yes	-	Hi-Z	Input	PD	Yes	N/A	N/A (default)
No	No	No	Input	PU	Input	PU	Yes	N/A ⁽⁴⁾	N/A (default)
No	No	No	Input	PD	Input	PD	Yes	N/A	N/A (default)
No	No	No	Output	1	Output	1	Yes	N/A	N/A (default)
No	No	No	Output	0	Output	0	Yes	N/A	N/A (default)
No	No	No	-	Hi-Z	Input	PD	Yes	N/A	N/A (default)

⁽¹⁾ PU = Pullup; PD = Pulldown; Hi-Z = High impedance

⁽²⁾ If a certain device pad is left unconnected, its associated padconfiguration register INPUTENABLE bit must be explicitly disabled in software (set to 0b0), regardless of pad MUXMODE bit field value.

⁽³⁾ If a certain pad has a defined safe_mode and is left unconnected in an application, it is recommended to keep its padconfiguration MuxMode value at 0x7 (that is, safe_mode).

⁽⁴⁾ There is no software control over the pad associated output buffer in the Control Module. In case of a GPIO function selection, the output buffer is hardware enabled once the user enables corresponding pin output direction in the GPIOx.GPIO_OE control register.

⁽⁵⁾ If a certain pad does not have a safe_mode but has an associated GPIO function, it is recommended to set its padconfiguration register MuxMode to select the GPIO mode.

⁽⁶⁾ If one of the other mux modes available is bidirectional or input-only, then the nondefault mux mode could be used and configured with input disabled.

18.4.9 Extended-Drain I/O and PBIAS Cell

The device mainly supports 1.8-V I/O voltage on its interfaces, with the exception of MMC/SD/SDIO1 interface, which supports both 1.8-V and 3.0-V voltages. The need for embedded extended-drain I/Os on MMC/SD/SDIO1 interface imposes the use of embedded PBIAS cell MMC1_PBIAS to provide a 1.8-V or 3.0-V reference.

A second PBIAS cell (PBIAS1) is integrated in the device. One of its associated extended-drain I/O cells operates signals of the gpio_wk0 through gpio_wk2 I/Os.

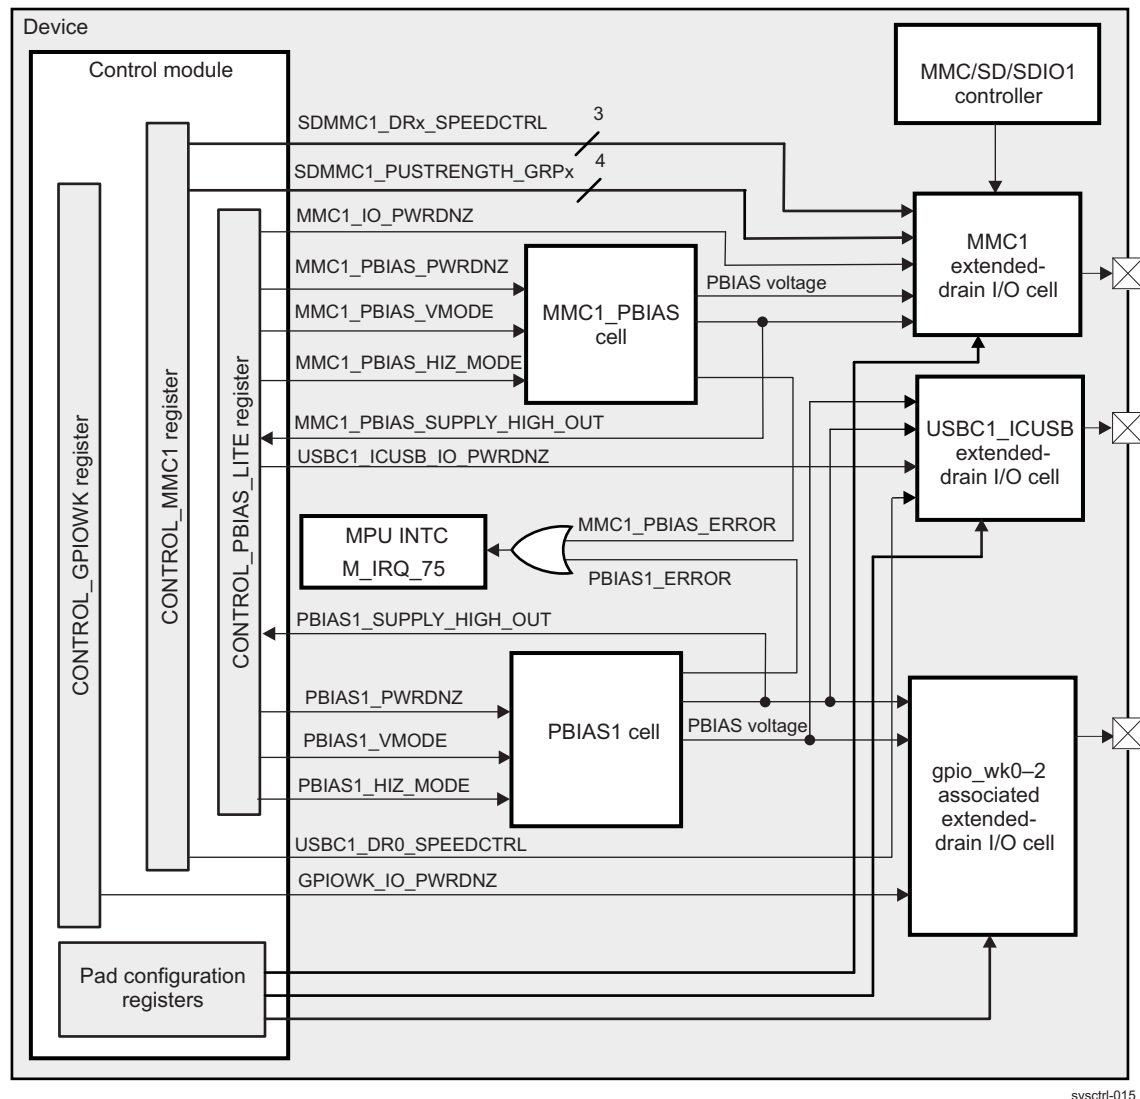

A separate extended-drain I/O cell (USBC1_ICUSB extended-drain I/O cell) is shared between usbc1_icusb_dp, usbc1_icusb_dm (MUXMODE = 0x0), and gpio_98 and gpio_99 (MUXMODE = 0x3) pads. The USBC1_ICUSB I/O cell and extended-drain I/O cells gpio_wk0 through gpio_wk2 are biased by the same PBIAS1 output voltage.

NOTE: With the appropriate PBIAS cell configuration, the different I/Os muxed on the sdmmc1, usbc1_icusb, and gpio_wk0 through gpio_wk2 pads can operate at 1.8-V or 3.0-V-power supply.

The MMC1_PBIAS cell and its associated MMC1 extended-drain I/O is software-controlled by bits in the [CONTROL_PBIASLITE](#) and [CONTROL_MMC1](#) registers of the device core control module. For descriptions of these registers, see [Table 18-566](#) and [CONTROL_MMC1](#) in [Section 18.6.6](#), [SYSCTRL_PADCONF_CORE Register](#). PBIAS1 and associated GPIO_WKx and USBC1_ICUSB_x I/Os are software-controlled by bits in the [CONTROL_PBIASLITE](#), [CONTROL_MMC1](#), and [CONTROL_GPIOWK](#) registers. For descriptions of these registers, see [Table 18-566](#), [CONTROL_MMC1](#) in [Section 18.6.6](#), [SYSCTRL_PADCONF_CORE Register Summary](#), and [CONTROL_GPIOWK](#) in [Section 18.6.9](#), [SYSCTRL_PADCONF_WKUP Register Description](#).

[Figure 18-12](#) shows the functional block diagram with the connections between the PBIAS cells and the extended-drain I/O cells.

Figure 18-12. Functional Block Diagram

sysctrl-015

Table 18-12. PBIAS Cell and Extended-Drain I/O Pin CONTROL_PBIAS_LITE Bit Control

Control Signals for Different PBIAS and Extended-Drain I/O Cells	Description
MMC1_PBIAS_PWRDNZ	Protects the MMC1_PBIAS cell when the SDMMC1_VDDS supply voltage is not stable. Software must keep this signal to 0b0 whenever this voltage ramps up/down or changes. When this bit is at 0, the PBIAS output voltage is equal to SDMMC1_VDDS voltage and the PBIAS supply detector is disabled.
MMC1_PBIAS_VMODE	Sets the SDMMC1_VDDS voltage level (MMC1_PBIAS side) according to which MMC1_PBIAS cell generates appropriate biasing levels for the MMC1 extended-drain I/O. The default state of this bit is high, indicating that the voltage level SDMMC1_VDDS is 3.0 V.
MMC1_PBIAS_HIZ_MODE	When MMC1_PBIAS_HIZ_MODE is set to 1 the PBIAS output is in high impedance. MMC1_PBIAS_ERROR is automatically set to 1, when MMC1_PBIAS_HIZ_MODE = 1. When MMC1_PBIAS_HIZ_MODE = 0, MMC1_PBIAS cell is in normal operation mode.
MMC1_PBIAS_SUPPLY_HIGH_OUT	Output from the internal MMC1_PBIAS voltage supply detector, which describes whether the SDMMC1_VDDS supply is 3.0 V or 1.8 V.

Table 18-12. PBIAS Cell and Extended-Drain I/O Pin CONTROL_PBIAS_LITE Bit Control (continued)

Control Signals for Different PBIAS and Extended-Drain I/O Cells	Description
MMC1_PBIAS_ERROR	Indicates whether the software-programmed MMC1_PBIAS_VMODE level matches the MMC1_PBIAS_SUPPLY_HI_OUT output signal during normal operation.
MMC1_IO_PWRDNZ	Protects the MMC1 I/O extended-drain cell when the SDMMC1_VDDS voltage is not stable. Software must keep this signal to 0b0 whenever the SDMMC1_VDDS supply voltage ramps up/down or changes. When this bit is at 0, the pad is floating.
SDMMC1_DRx_SPEEDCTRL, x = (0..2)	Speed control signals for three different SDMMC1 pad groups identified within the MMC1 I/O cell
SDMMC1_PUSTRNGTH_GRPx, x = (0..3)	Pullup strength controls for four different SDMMC1 pad groups identified within the MMC1 I/O cell
PBIAS1_PWRDNZ	Protects the PBIAS1 cell when the SIM_VDDS supply voltage is not stable. Software must keep PWRDNZ signal to 0b0 whenever this supply voltage is ramps up/down or changes. When this bit is at 0, the PBIAS1 output voltage is equal to SIM_VDDS voltage and the PBIAS supply detector is disabled.
PBIAS1_VMODE	Sets the SIM_VDDS voltage level (PBIAS1 side) according to which PBIAS1 cell generates appropriate biasing levels for the GPIOWK0GPIOWK2 and USBC1_ICUSB associated extended-drain I/Os. The default state of this bit is high, indicating that the voltage level SIM_VDDS is 3.0 V.
PBIAS1_HIZ_MODE	When PBIAS1_HIZ_MODE is set to 1 the PBIAS1 output is in HIGH impedance. PBIAS1_ERROR is automatically set to 1, when PBIAS1_HIZ_MODE = 1. When PBIAS1_HIZ_MODE = 0, PBIAS1 is in normal operation mode.
PBIAS1_SUPPLY_HIGH_OUT	Output from the internal PBIAS1 voltage supply detector, which describes whether the SIM_VDDS supply is 3.0 V or 1.8 V.
PBIAS1_ERROR	Indicates whether the software-programmed PBIAS1_VMODE level matches the PBIAS1_SUPPLY_HI_OUT output signal during normal operation.
GPIOWK_IO_PWRDNZ	Protects the GPIOWK0GPIOWK2 associated extended-drain I/O cell when the SIM_VDDS voltage is not stable. Software must keep this signal to 0b0 whenever the SIM_VDDS supply voltage ramps up/down or changes. When this bit is at 0, the pad is floating.
PAD_GPIO_WK1_LOW	This signal should be set to 0b0 to disable the strong pulldown available after reset on the gpio_wk1 pad. This is to ensure normal use of the gpio_wk1 pad.
0.22 PAD_GPIO_WK2_LOW	This signal should be set to 0b0 to disable the strong pulldown available after reset on the gpio_wk2 pad. This is to ensure normal use of the gpio_wk2 pad.
0.23 USBC1_ICUSB_IO_PWRDNZ	Protects the USBC1_ICUSB extended-drain I/O cell when the SIM_VDDS voltage is not stable. Software must keep this signal to 0b0 whenever the SIM_VDDS supply voltage ramps up/down or changes. When this bit is at 0, the pad is floating.
0.24 USBC1_DR0_SPEEDCTRL	Speed controls for the ICUSB pads associated with the USBC1_ICUSB associated I/O cell

NOTE: When HIZ_MODE = 1, the PBIAS output (the pbias_mmc1 pin) must be tied to a defined external potential to avoid stress on transistors.

Table 18-13 lists the power supplies for PBIAS and the extended-drain I/O cells.

Table 18-13. Power Supplies

Name	Description
VDD2	Core voltage supply
SDMMC1_VDDS	MMC1 I/O cell supply voltage nominal 1.8 V/3.0 V
SIM_VDDS	USBC1_ICUSB and GPIOWK I/O cell supply voltage nominal 1.8 V/3.0 V
VDDS	1.8-V supply for the input buffer

18.4.9.1 PBIAS Cell

The MMC1_PBIAS cell provides a bias for the MMC/SD/SDIO1 extended-drain I/O cell used with high voltage for the MMC/SD/SDIO1 interface. This PBIAS cell provides a voltage reference (PBIAS voltage) for biasing extended-drain in the MMC/SD/SDIO1 cell. In addition to generating the bias voltage, the cell can detect the supply voltage (SDMMC1_VDDS) value (1.8 V or 3.0 V) and update, with its status, the [CONTROL_PBIASLITE](#)[24] MMC1_PBIASLITE_SUPPLY_HI_OUT bit. However, this is possible when voltage reaches its steady state (the internal PBIAS voltage detector is enabled only when the MMC1_PBIAS_PWRDNZ signal is set to 0b1).

The PBIAS1 cell provides a reference voltage for biasing the gpiowk0gpiowk2 associated extended-drain I/O cell and the USBC1_ICUSB extended-drain I/O cell. In addition to generating the bias voltage, the cell can detect the supply voltage (SIM_VDDS) value (1.8 V or 3.0 V) and update, with its status, the [CONTROL_PBIASLITE](#)[30] PBIASLITE1_SUPPLY_HI_OUT bit. However, this is possible when voltage reaches its steady state (the internal PBIAS voltage detector is enabled only when the PBIAS1_PWRDNZ signal is set to 0b1).

CAUTION

A PBIAS cell lets the peripheral associated with its corresponding extended-drain I/O cells support 1.8-V and 3.0-V voltages. A PBIAS cell is not a part of a peripheral, but a part of the device I/Os to which this peripheral is internally connected. These device I/Os are not exclusive to one peripheral; through I/O multiplexing they can be connected to other internal signals. It is necessary to configure the PBIAS to enable the I/Os, regardless of how I/O multiplexing is configured for these device I/Os. In other words, independently of which signal is internally connected to a device I/O powered by SDMMC1_VDDS or SIM_VDDS, the corresponding PBIAS must be configured.

18.4.9.2 Extended-Drain I/O

The following MMC/SD/SDIO1 interface signals (selected when MuxMode = 0) use the device I/Os associated with the MMC1 extended-drain I/O cell:

- sdmmc1_clk
- sdmmc1_cmd
- sdmmc1_dati (where i = 0 to 7)

The MMC1 I/O cell is powered externally through the vdds_sdmmc1 pad.

NOTE: The MMC1 I/O cell associated device I/Os are also shared with other signals. gpio100gpio109, etc. are available when MuxMode is different than 0x0. If signals other than sdmmc1_x are selected, the MMC1 I/O cell must also be configured.

NOTE: For multiplexed gpio signals on the MMC1 I/O cell (gpio_100 through gpio_109), to function appropriately in standard 1.8-V mode, the [CONTROL_PBIASLITE](#)[21] MMC1_PBIASLITE_VMODE through [CONTROL_PBIASLITE](#)[26] MMC1_PWRDNZ bits must be set to 0b0. When these bits are set, and the externally-applied I/O cell power supply voltage (1.8 V) is stabilized, gpio signals can be enabled on the pads by setting the [CONTROL_PBIASLITE](#)[22] MMC1_PBIASLITE_PWRDNZ bit to 0b1 (power-up MMC1_PBIAS cell) and the [CONTROL_PBIASLITE](#)[26] MMC1_PWRDNZ bit to 0b1 (power-up MMC1 extended-drain I/O cell).

For more information about signal multiplexing, see [Table 18-9](#).

For GP device I/Os, which are part of the GPIOWK pads associated extended-drain cell, Muxmode = 3 and Muxmode = 6 are functional.

With Muxmode set to 0x3, the following signals are present:

- gpio_wk0
- gpio_wk1
- gpio_wk2

With Muxmode set to 0x6, the output signals hw_dbg1, hw_dbg2, and hw_dbg3 are present at the gpio_wk0, gpio_wk1, and gpio_wk2 pads, respectively.

This PBIAS1 associated extended-drain I/O cell is externally powered through the vdds_sim pad.

NOTE: The GPIOWK-associated I/O cell must be properly configured when the gpiowk0gpiowk2 pads are used. For more information about signal multiplexing, see [Table 18-9](#).

NOTE: For the gpio_wk0 through gpio_wk2 signals to function appropriately in standard 1.8-V mode, the [CONTROL_PBIASLITE\[27\]](#) PBIASLITE1_VMODE through [CONTROL_PBIASLITE\[31\]](#) PBIASLITE1_HIZ_MODE bits and the [CONTROL_GPIOWK\[28\]](#) GPIOWK_IO_PWRDNZ bit must be set to 0b0. When these bits are set, and the externally-applied I/O cell power supply voltage (1.8 V) is stabilized, gpio signals can be enabled on the pads by setting the [CONTROL_PBIASLITE\[28\]](#) PBIASLITE1_PWRDNZ bit to 0b1 (power-up PBIAS1 cell) and the [CONTROL_GPIOWK\[28\]](#) GPIOWK_IO_PWRDNZ bit to 0b1 (power-up extended-drain I/O cell).

The following USBC1_ICUSB interface signals (selected through MuxMode = 0) use the device I/Os associated with the USBC1_ICUSB extended-drain I/O cell:

- usbc1_icusb_dp
- usbc1_icusb_dm

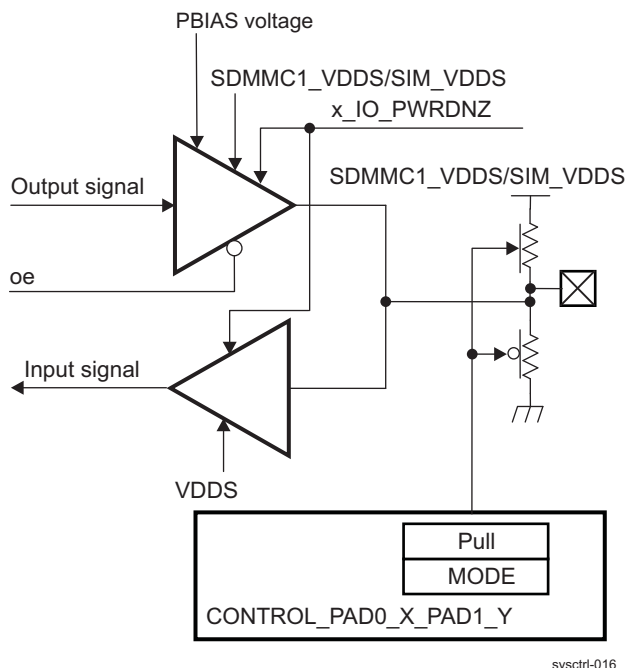

The USBC1_ICUSB I/O cell uses the same external power supply voltage as the GPIOWK cell (vdds_sim pad).

NOTE: The USBC1_ICUSB I/O cell associated device I/Os are also shared with the gpio_98 and gpio_99 signals, when MuxMode = 0x3. USBC1_ICUSB cell must be configured to allow for gpio_98 and gpio_99 operation. For more information about signal multiplexing, see [Table 18-9](#).

NOTE: For the gpio_98 through gpio_99 signals to function appropriately in standard 1.8-V mode, the [CONTROL_PBIASLITE\[27\]](#) PBIASLITE1_VMODE through [CONTROL_PBIASLITE\[31\]](#) PBIASLITE1_HIZ_MODE bits and the [CONTROL_PBIASLITE \[20\]](#) USBC1_ICUSB_PWRDNZ bit must be set to 0b0. When these bits are set, and the externally-applied I/O cell power supply voltage (1.8 V) is stabilized, gpio signals can be enabled on the pads by setting the [CONTROL_PBIASLITE\[28\]](#) PBIASLITE1_PWRDNZ bit to 0b1 (power-up PBIAS1 cell) and the [CONTROL_PBIASLITE\[20\]](#) USBC1_ICUSB_PWRDNZ bit to 0b1 (power-up extended-drain I/O cell).

[Figure 18-13](#) describes the extended-drain I/O cells.

Figure 18-13. Extended-Drain I/O

The extended-drain I/O cells have the following I/O signals:

- Output signal, input signal, and oe, which comes from the selected I/O module with the correctly configured MUXMODE field within the corresponding CONTROL_CORE_PAD0_X_PAD1_Y or CONTROL_WKUP_PAD0_X_PAD1_Y register.

NOTE: Extended-drain I/Os are muxed I/Os with mode and pullup/down configurations programmable in the control module.

- The PBIAS voltage is a voltage reference for biasing the extended-drain in the MMC1, USBC1_ICSUB, and GPIOWK I/O cells.
- The PWRDNZ signals are used to protect the I/O cells when the SDMMC1_VDDS/SIM_VDDS voltage is not stable.

CAUTION

Software must keep the PWRDNZ-related signals to 0b0 whenever the SDMMC1_VDDS or SIM_VDDS signal ramps up/down or changes. When it is 0, the pad is floating (the pad may not reflect the state of the output signal, and the input signal may not reflect the state of the pad).

- The [CONTROL_PBIASLITE](#)[24] MMC1_PBIASLITE_SUPPLY_HI_OUT bit is a status bit on the SDMMC1_VDDS value and is used to inform the MMC1 I/O cell about the value of the SDMMC1_VDDS signal.
- The [CONTROL_PBIASLITE](#)[30] PBIASLITE1_SUPPLY_HI_OUT bit is a status bit on the SIM_VDDS value and is used to inform the gpiowk0gpiowk2 associated I/O cell and USBC1_ICUSB I/O cell about the value of the SIM_VDDS signal.

For more information about the software configurations of the extended-drain I/Os and PBIAS cells, see [Section 18.5.1.2.2, Extended-Drain I/Os and PBIAS Cells Programming Guide](#).

NOTE: The device can be supplied by an external power IC. TI provides such a global solution to its customers with the TWL60xx power IC.

If the device is associated with the TWL60xx power IC, before using an extended-drain I/O interface, software must program the TWL60xx to enable the VMMC1 (for the MMC/SD/SDIO1 or muxed I/O modules) or VSIM (for the GPIOWK0, GPIOWK2, USBC1_ICUSB, or muxed I/Os) and the LDO to provide a 1.8-V/3.0-V voltage. This is done by software through the inter-integrated circuit (I²C) interface that links the device and the TWL60xx IC.

CAUTION

The power supply voltage generated from the companion power IC and applied on the vdds_sdmmc1 or vdds_sim device pins must be programmed according to the recommendations for the currently selected I/O module power supply range.

If the application does not want the I/O interface to run at 3.0 V, software users must then assert the VMODE signal to low for 1.8-V activity: in this case, the PBIAS is connected to ground.

Table 18-14 lists the control signal with the corresponding control bits from the [CONTROL_PBIASLITE](#), [CONTROL_MMC1](#), and [CONTROL_GPIOWK](#) registers to configure the PBIAS and the extended-drain I/O cells. These signals can be software-controlled.

Table 18-14. PBIAS/Extended-Drain I/O Cells Control Signals

Control Signals for Different PBIAS and Extended-Drain I/O Cells	Bits Used for PBIAS Cell and I/O Cell Configurations for Different I/O Modules	Reset Value
MMC1_PBIAS_PWRDNZ	CONTROL_PBIASLITE [22] MMC1_PBIASLITE_PWRDNZ	0
MMC1_PBIAS_VMODE	CONTROL_PBIASLITE [21] MMC1_PBIASLITE_VMODE	1
MMC1_PBIAS_HIZ_MODE	CONTROL_PBIASLITE [25] MMC1_PBIASLITE_HIZ_MODE	0
MMC1_PBIAS_SUPPLY_HIGH_OUT	CONTROL_PBIASLITE [24] MMC1_PBIASLITE_SUPPLY_HI_OUT	0
MMC1_PBIAS_ERROR	CONTROL_PBIASLITE [23] MMC1_PBIASLITE_VMODE_ERROR	0
MMC1_IO_PWRDNZ	CONTROL_PBIASLITE [26] MMC1_PWRDNZ	0
SDMMC1_DRx_SPEEDCTRL, x = (0...2)	CONTROL_MMC1 [27] SDMMC1_DR0_SPEEDCTRL	0
	CONTROL_MMC1 [26] SDMMC1_DR1_SPEEDCTRL	0
	CONTROL_MMC1 [25] SDMMC1_DR2_SPEEDCTRL	0
SDMMC1_PUSTRENGTH_GRPx, x = (0...3)	CONTROL_MMC1 [31] SDMMC1_PUSTRENGTH_GRP0	1
	CONTROL_MMC1 [30] SDMMC1_PUSTRENGTH_GRP1	0
	CONTROL_MMC1 [29] SDMMC1_PUSTRENGTH_GRP2	1
	CONTROL_MMC1 [28] SDMMC1_PUSTRENGTH_GRP3	1
PBIAS1_PWRDNZ	CONTROL_PBIASLITE [28] PBIASLITE1_PWRDNZ	0
PBIAS1_VMODE	CONTROL_PBIASLITE [27] PBIASLITE1_VMODE	1
PBIAS1_HIZ_MODE	CONTROL_PBIASLITE [31] PBIASLITE1_HIZ_MODE	0
PBIAS1_SUPPLY_HIGH_OUT	CONTROL_PBIASLITE [30] PBIASLITE1_SUPPLY_HI_OUT	0
PBIAS1_ERROR	CONTROL_PBIASLITE [29] PBIASLITE1_VMODE_ERROR	0
GPIOWK_IO_PWRDNZ	CONTROL_GPIOWK [28] GPIOWK_IO_PWRDNZ	0
PAD_GPIO_WK1_LOW	CONTROL_GPIOWK [31] PAD_GPIO_WK1_LOW	1
PAD_GPIO_WK2_LOW	CONTROL_GPIOWK [29] PAD_GPIO_WK2_LOW	1
USBC1_ICUSB_IO_PWRDNZ	CONTROL_PBIASLITE [20] USBC1_ICUSB_PWRDNZ	0
USBC1_DR0_SPEEDCTRL	CONTROL_MMC1 [24] USBC1_DR0_SPEEDCTRL	0

The two PBIAS cells support two ranges of I/O: SDMMC1_VDDS/SIM_VDDS: 1.8 V, typical for low-voltage applications, and 3.0 V, typical for high-voltage applications. For each supply voltage range, the cell generates suitable bias voltage (PBIAS) for extended-drain PMOS devices.

CAUTION

The PBIAS cell must be programmed according to peripheral power supply voltage. See [Table 18-15](#).

Table 18-15. Voltage Configuration⁽¹⁾

PBIASLITEVMODE Configuration	SDMMC1_VDDS/SIM_VDDS Voltage	Type of Operation
1.8 V	1.8 V	Normal 1.8-V operation
1.8 V	3.0 V	Damaging configuration ⁽²⁾
3.0 V	1.8 V	Degraded functionality ⁽²⁾
3.0 V	3.0 V	Normal 3.0-V operation

⁽¹⁾ For damaging configuration, hardware system protection is provided to prevent deterioration of the associated extended-drain I/Os.

⁽²⁾ These modes must not be used.

The PBIAS output voltage is the same as SDMMC1_VDDS/SIM_VDDS voltage when the corresponding PWRDNZ bit is low. Once the SDMMC1_VDDS / SIM_VDDS supply is stable, software can release the PWRNDZ (setting it high). This starts up the PBIAS cell work to generate the PBIAS voltage. During the completion process the corresponding I/Os cannot be used for transmitting data. If VMODE is set correctly (compared with supply detector output and found to be the same), then PBIAS output voltage is generated based on the value of VMODE.

NOTE: In the case of a damaging configuration, hardware system protection prevents deterioration of the associated extended-drain I/Os.

CAUTION

The following requirements are critical for an extended-drain I/O cell:

- The VMODE bit must be defined before the PWRNDZ bit is made high (cell is brought out of power-down mode).
- The default state of the VMODE bit is high (indicates 3.0-V operation).
- The PWRNDZ bit must be kept low whenever the SDMMC1_VDDS/SIM_VDDS supply ramps up/down or changes. This can be damaging.
- Supply detector is disabled when PWRDNZ = 0 and in this case, supply detector output (SUPPLY_HI_OUT) is initialized to 0.

18.4.9.3 PBIAS Error Generation

If VMODE and supply detector outputs are unequal. It takes 4 μ s for the comparator to process the inputs and generate VMODE_ERROR flag.

[Table 18-16](#) summarizes the generation of the PBIAS error signals, MMC1_PBIAS_ERROR of the MMC1_PBIAS cell and PBIAS1_ERROR of the PBIAS1 cell. They depend on the various [CONTROL_PBIASLITE](#) bit combinations. The shaded row is a potential condition that could cause a reliability issue if not detected. To prevent this reliability issue, the PBIAS voltage is tied to SDMMC1_VDDS/SIM_VDDS when the PBIAS error signal is high. This disables the I/Os.

CAUTION

Although asserting VMODE_ERROR to 1 provides that PBIAS voltage is equal to SDMMC1_VDDS/SIM_VDDS, this does not completely protect the I/O cells. It is also recommended that all the I/Os are powered down, setting the PWRDNZ mode bits of the corresponding I/O cells to 0b0 by software as soon as VMODE_ERROR = 0b1.

Table 18-16. PBIAS Error Signal Truth Table

VMODE	PWRDNZ	HIZ_MODE	SUPPLY_HI_OUT	VMODE_ERROR
0	0	X	0	0
0	1	0	0	0
0	1	0	1	1
X	1	1	X	1
1	0	X	0	0
1	1	0	0	1
1	1	0	1	0

NOTE: VMODE_ERROR = 0b1: VMODE level is not the same as SUPPLY_HI_OUT or Hi-Z mode is selected.

VMODE_ERROR = 0b0: VMODE level is the same as SUPPLY_HI_OUT or VMODE is not considered (PWRDNZ = 0b0).

The MMC1_PBIAS_ERROR and PBIAS1_ERROR signals are ORed and the outputs are mapped to the microprocessor unit (MPU) subsystem interrupt controller (INTC). The interrupt line MA_IRQ_75 is activated upon error occurrence. For more information about the Cortex™-A9 MPU INTC registers and their description, see the *ARM Cortex-A9 MPCore Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

The [CONTROL_PBIASLITE](#)[29] PBIASLITE1_VMODE_ERROR bit and [CONTROL_PBIASLITE](#)[23] MMC1_PBIASLITE_VMODE_ERROR bits also indicate whether this kind of error occurs.

18.4.9.4 Critical Timing Requirements

It is crucial that the PBIAS and I/O cell-related PWRDNZ bits are deasserted (made 1 from 0) only after the SDMMC1_VDDS/SIM_VDDS power supply voltage is stable in the device. The cells support only the case when 1.8-V input buffer supply voltage VDDS ramps up before VDD2 (core voltage). This power-up sequence is automatically provided upon power-on reset by hardware in the device. Take care to ensure that the externally provided SDMMC1_VDDS/SIM_VDDS voltage (1.8 V/ 3 V) is powered up, only after VDD2 and VDDS reach their steady state.

[Figure 18-14](#) shows the only possible power-up sequence and the expected behavior of the PWRNDZ mode-related bits with regard to supplying voltage ramp up.

Figure 18-14. VDDS Ramps Up Before VDD2

18.4.10 Band Gap Voltage and Temperature Sensor

The device supplies a voltage reference and a temperature sensor feature that are gathered in the band gap voltage and temperature sensor (VBGAPTS) module. The band gap provides current and voltage reference for its internal circuits and other analog IP blocks. The analog-to-digital converter (ADC) produces an output value that is proportional to the silicon temperature.

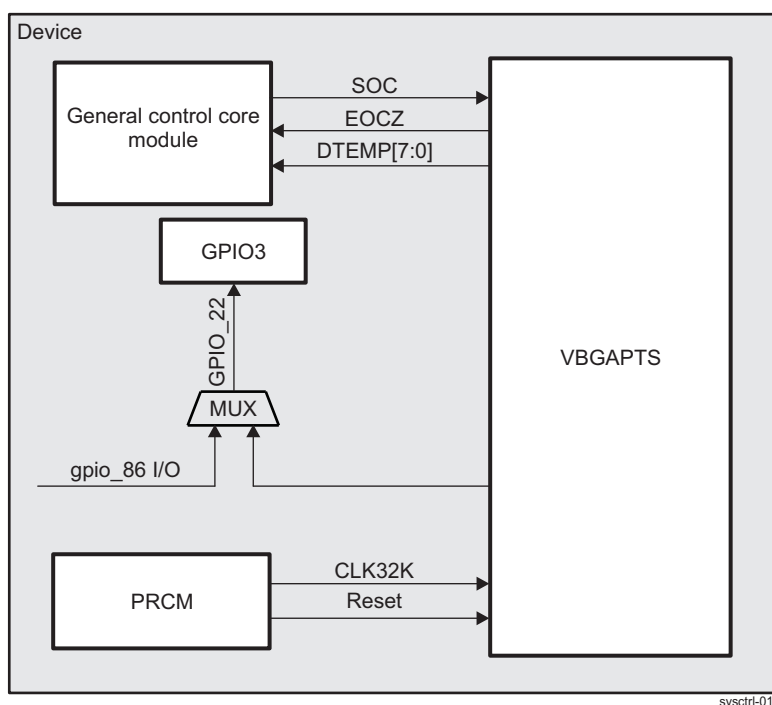

The main features of the BGAPTS module are:

- A constant voltage reference output: 0.5 V
- Five constant current reference outputs of 1 μ A
- Analog supply is a nominal 1.8 V.
- Small ADC with 8-bit digital output
- Off mode compatible
- Thermal shutdown comparator output

The band gap and the temperature sensor are software-controlled by bits in the [CONTROL_TEMP_SENSOR](#) register within the SYSCTRL_GENERAL_CORE module instance. For the description of this register, see [Table 18-178](#).

[Figure 18-15](#) is the functional block diagram of the band gap and the temperature sensor module.

Figure 18-15. Functional Block Diagram

[Table 18-17](#) describes the input and output signals for the BGAPTS module.

Table 18-17. Band Gap Voltage and Temperature Sensor Signal Description

Pin	I/O ⁽¹⁾	Description
SOC	I	Start of Conversion signal. A transition to high starts a new ADC conversion cycle.
EOCZ	O	End of Conversion signal. When low, the signal indicates that the value of DTEMP[7:0] is valid.
DTEMP[7:0]	O	Temperature data from the temperature sensor. This value is valid when EOCZ is low.

⁽¹⁾ I=Input, O=Output

Table 18-17. Band Gap Voltage and Temperature Sensor Signal Description (continued)

Pin	I/O ⁽¹⁾	Description
CONTCONV	I	Configures the temperature sensor in continuous conversion mode. 0: ADC single conversion mode 1: ADC continuous conversion mode
TSHUT	O	Thermal shutdown comparator output. The signal is high during normal operation and goes low during a thermal shutdown event.
CLRZ	I	When low the temperature sensor is in reset mode. This signal must be low when OFFMODE is high.
CLK32K	I	32-kHz functional clock from the CORE power domain used by the temperature sensor during temperature conversion

All the configuration signals are available through the [CONTROL_TEMP_SENSOR](#) register.

NOTE: VBGAPTS CLK32K is used only for the temperature sensor. When ADC is not converting, this clock can be switched off (CLK32K = 0). In this case, DTEMP[7:0] retains the temperature code obtained at the previous conversion.

18.4.10.1 Band Gap Voltage Reference

The band gap voltage reference feature provides several constant voltage and current references for its internal circuits, but also for other analog modules.

The voltage reference signal is a 0.5-V output. This output is used internally by the module and is exported for external modules or for tests.

The current reference signals consist in five lines, each of which generates a 1-μA current with a 1.8-V voltage. These lines can be used to bias other modules.

18.4.10.2 Temperature Sensor

The temperature sensor feature is used to convert the temperature of the device into a decimal value coded on 8 bits. An internal ADC is used for conversion. This signal is connected internally to a GPIO pin. For more information, see [Chapter 25, General-Purpose Interface](#).

The temperature sensor offers two operating modes: a single conversion mode and a continuous conversion mode.

For more information on thermal sensor characteristics, see the *Junction Temperature Sensor* section in the device data manual.

18.4.10.2.1 Single Conversion Mode (CONTCONV = 0)

When the ADC is idle ([CONTROL_TEMP_SENSOR](#)[8] BGAP_TEMP_SENSOR_EOCZ = 0) and the [CONTROL_TEMP_SENSOR](#)[10] BGAP_TEMP_SENSOR_CONTCONV bit is set to 0, it is possible to ask for a single temperature conversion. To initiate a new conversion, the start of conversion (SOC) signal must be asserted and maintained high until the end of conversion (EOCZ) signal goes high, after which the SOC must be made low by setting the [CONTROL_TEMP_SENSOR](#)[9] BGAP_TEMP_SENSOR_SOC bit to 0. Conversion completion is indicated by a negative edge on EOCZ (the [CONTROL_TEMP_SENSOR](#)[8] BGAP_TEMP_SENSOR_EOCZ bit).

[Figure 18-16](#) shows the timing sequence for a single temperature conversion.

Figure 18-16. Single Conversion Mode (CONTCONV = 0)

18.4.10.2.2 Continuous Conversion Mode (CONTCONV = 1)

When the ADC is idle ([CONTROL_TEMP_SENSOR](#)[8] BGAP_TEMP_SENSOR_EOCZ = 0) and the [CONTROL_TEMP_SENSOR](#)[10] BGAP_TEMP_SENSOR_CONTCONV bit is set to 1, it is possible to ask for a continuous temperature conversion. To initiate a new conversion, the SOC signal must be asserted and maintained high until the EOCZ signal goes high, after which the SOC must be made low by setting the [CONTROL_TEMP_SENSOR](#)[9] BGAP_TEMP_SENSOR_SOC bit to 0. The ADC starts converting continuously, and when a conversion is complete, data is written to the [CONTROL_TEMP_SENSOR](#)[7:0] BGAP_TEMP_SENSOR_DTEMP bit field and EOCZ goes low after four clock cycles.

[Section 18.4.11.1](#) shows the timing sequence for a continuous temperature conversion.

Figure 18-17. Continuous Conversion Mode (CONTCONV = 1)

18.4.10.2.3 ADC Codes Versus Temperature

[Table 18-18](#) gives the temperature range corresponding to each value of the [CONTROL_TEMP_SENSOR](#)[7:0] BGAP_TEMP_SENSOR_DTEMP bit field.

Table 18-18. ADC Code Versus Temperature

ADC Code	Temperature °C		ADC Code	Temperature °C		ADC Code	Temperature °C		ADC Code	Temperature °C	
	From	To		From	To		From	To		From	To
0	-40	-40	32	-5	-3.5	64	50	52	96	105	107
1	-40	-40	33	-3.5	-1.5	65	52	53.5	97	107	109

NOTE: ADC code values in the subrange 128–255 are reserved for future use.

18.4.11 Hardware Observability

18.4.11.1 Device Internal Signals Observability Overview

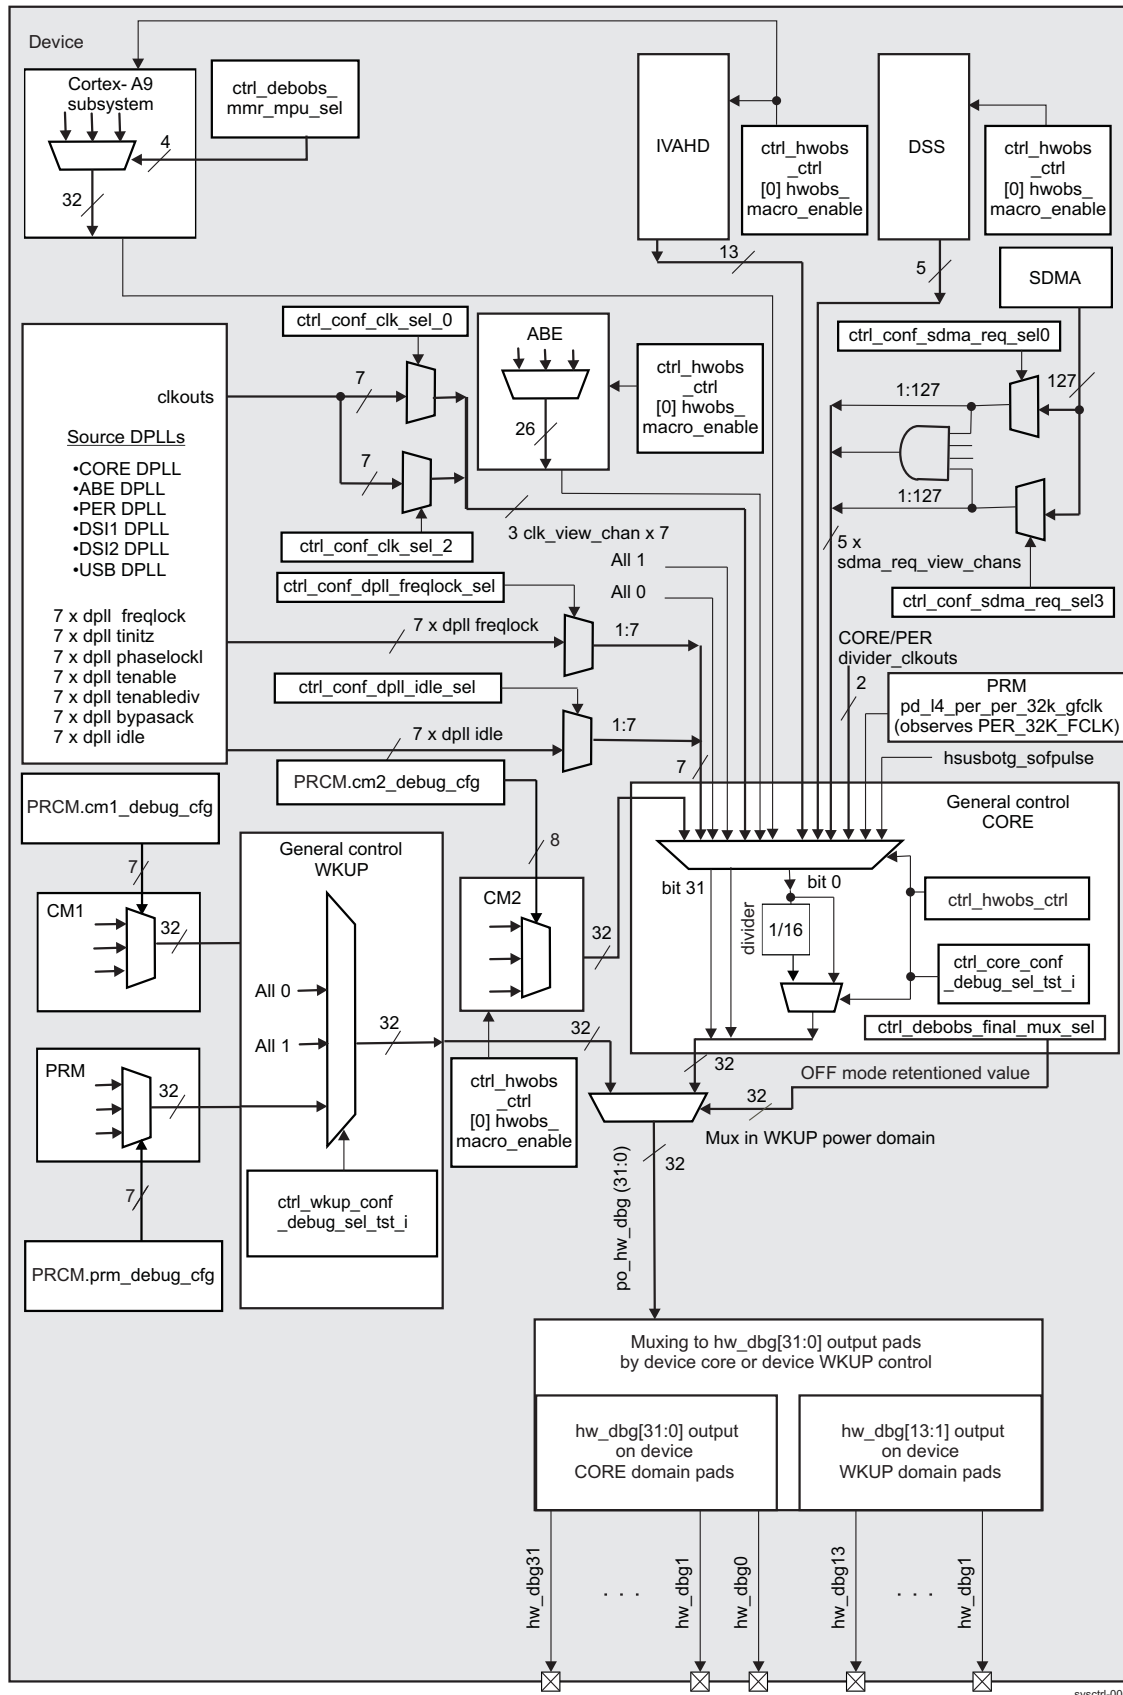

The general control module provides observability features covering different module internal signals related to:

- Power and reset management protocol inside different power domains
- Power domain states/transition indication
- IRQs by different modules
- DMA requests by different modules
- Clocks and clock management

The associated signal multiplexing function is controlled through the hardware observability I/O multiplexing registers (32-bit read/write registers). The selected observable signals are multiplexed between the general control module CORE and/or WKUP power domain and are output on the po_hw_dbg[31:0] observability bus at the boundaries of the general wake-up control module. The po_hw_dbg[31:0] observability outputs are then exported to the device control module logic to be further multiplexed as their corresponding hw_dbg[31:0] signals on the different pads of the WKUP or CORE power domain of the device control module (see [Section 18.4.11.4, Observability Signals Multiplexing at Device Control Module Level](#)).

NOTE: Each signal `po_hw_dbg_i` (where `i = 0` to `31`) of the general control wakeup `po_hw_dbg[31:0]` bus is propagated by device control module-level logic as its corresponding `hw_dbg_i` (where `i = 0` to `31`) signal on the CORE or WKUP power domain pads described in [Section 18.4.11.4, Observability Signals Multiplexing at Device Control Module Level](#).

[Figure 18-18](#) shows an overview of observability multiplexing, which minimizes the number of signals exchanged at the device boundary.

Figure 18-18. Overview of the Hardware Observability Functionality

sysctrl-006

18.4.11.2 Observability Gating Capabilities

The programmer can gate all 32 signals of the observability bus at the observability paths of the CORE and WKUP power domains simultaneously, keeping them either tied to 1, programming [CONTROL_HWOBS_CONTROL](#)[1] HWOBS_ALL_ONE_MODE = 0b1, or keeping them tied to 0, programming [CONTROL_HWOBS_CONTROL](#)[2] HWOBS_ALL_ZERO_MODE = 0b1. This can be useful to check the path from hardware observability to external pads. These two bits must be set to 0 to enable the observability feature for all observability pads.

Additionally, the [CONTROL_HWOBS_CONTROL](#)[0] HWOBS_MACRO_ENABLE bit provides the gating feature only to observability signals muxed in the CORE power domain that come from the following modules (identified in the so-called MACRO group):

- CORTEX-A9 MPU subsystem
-
- IVA-HD
- Display subsystem
- CM2
- ABE

When [CONTROL_HWOBS_CONTROL](#)[0] HWOBS_MACRO_ENABLE = 0b0, the observability outputs associated with the MACRO group are gated and forced to 0b0.

NOTE: Do not set the observability gating bits ([CONTROL_HWOBS_CONTROL](#)[1] HWOBS_ALL_ONE_MODE and [CONTROL_HWOBS_CONTROL](#)[2] HWOBS_ALL_ZERO_MODE) simultaneously to 1 to avoid undefined states of the observability bus.

The clock frequency of the hw_dbg0 signal can be optionally divided by 1, 2, 4, 8, or 16 by programming the [CONTROL_HWOBS_CONTROL](#)[7:3] HWOBS_CLKDIV_SEL bit field.

NOTE: Only CORE power domain signal hw_dbg0 passes through the [CONTROL_HWOBS_CONTROL](#) programmable divider. This divider is not available to the po_hw_dbg(0) line in the WKUP power domain.

NOTE: To enable observability over the po_hw_dbg(0) bus line, the [CONTROL_HWOBS_CONTROL](#)[7:3] HWOBS_CLKDIV_SEL bit field must be set different than 0. The default value (0) is not enough to see the observability value at the hw_dbg0 pin.

NOTE: The hw_dbg0 frequency division and capability to gate the MACRO group observability signals (hw_dbg i, configurable in the [CONTROL_HWOBS_CONTROL](#) register) are limited to the hardware observability signals hw_dbg i (where i = 0 to 31) multiplexed and propagated in the CORE power domain ([CONTROL_DEBOBS_FINAL_MUX_SEL](#)[i] SELECT = 0b1).

These options do not apply to the hardware observability signals, hw_dbg i (where i = 0 to 31), which are muxed in the WKUP power domain ([CONTROL_DEBOBS_FINAL_MUX_SEL](#)[i] SELECT = 0x0).

18.4.11.3 Observability Signals Multiplexing at General Core/Wake-Up Control Level

Most of the observability multiplexers (MACRO group-modules/DPLLs/sDMA associated) are configurable in the general core control module, which is part of the switchable CORE power domain. There are also signal multiplexers instantiated inside the general wake-up control module (CM1/PRM dedicated), which is part of the WKUP power domain. The 32-bit [CONTROL_DEBOBS_FINAL_MUX_SEL\[31:0\]](#) SELECT bit field, instantiated inside the CORE power domain, selects a signal to be observed between the outputs at CORE and the WKUP multiplexing level. A bit from this register set to 1 selects to route a signal from the CORE power domain to a certain `po_hw_dbg` ($n = 0 \dots 31$) line, and when set to 0 selects to route a signal from the WKUP power domain to the same line. The output of this top-level multiplexing is further passed to padconfiguration muxing I/O level inside boundaries of the device control module.

NOTE: Although the [CONTROL_DEBOBS_FINAL_MUX_SEL](#) observability control register is in the CORE power domain, its value is retentioned before the device goes into off mode. Thus, the preserved value is used to control the final observability muxer in the WKUP power domain, even when the PD_CORE supply in the device is switched off. Because the `hw_dbg i` signals, which are propagated in the CORE power domain, are not available in off mode, the value of [CONTROL_DEBOBS_FINAL_MUX_SEL\[i\]](#) SELECT = 0b1 (where $i = 0$ to 31) in this case means that the `hw_dbg i` signal is not available at output.

The module and view-channel selection/reduction layer in the CORE domain is configured through the 4-bit MODE bit field in the 32 x 32-bit registers [CONTROL_CORE_CONF_DEBUG_SEL_TST_0](#) through [CONTROL_CORE_CONF_DEBUG_SEL_TST_31](#). The following modules can be selected as source of observability signals (MACRO signal sources):

- Cortex-A9 MPU subsystem
-
- IVA-HD
- Display subsystem
- CM2
- ABE

Part of the [CONTROL_CORE_CONF_DEBUG_SEL_TST](#) registers are responsible for selecting the sDMA view channels, different DPLL-clock view channels, and other signal view channels.

- 3 x DPLL clockout signal view channels
- 7 x DPLL (other than clkout signal) view channels
- 5 x sDMA signal view channels
- 3 x additional clockout view channels monitoring signals `hwobs_coredivider_clkout3`, `hwobs_perdivider_clkout4` and `per32k_gfclk`.

[Table 18-19](#) summarizes the internal signals multiplexing schema for each of the 32 [CONTROL_CORE_CONF_DEBUG_SEL_TST](#) registers.

A third 1:N selection layer is applied over several signals to route one at a time to a certain view channel output:

- The [CONTROL_CONF_CLK_SEL0\[2:0\]](#) MULT through [CONTROL_CONF_CLK_SEL2\[2:0\]](#) MULT bit fields control multiplexing of DPLL CLKOUT signals over three parallel DPLL clockout view channels. The signal source of a certain view channel can be selected to be one of six DPLLs in the device: CORE DPLL, ABE DPLL, PER DPLL, DSI1 DPLL, DSI2 DPLL, and USB DPLL.
- The register bit fields associated with the seven different DPLL signal view channels are summarized in [Table 18-20](#). Again, the 3-bit MULT bit field in each of the seven different registers makes it possible to choose the source of the DPLL signal to be one of the following device DPLLs: CORE DPLL, ABE DPLL, PER DPLL, DSI1 DPLL, DSI2 DPLL, and USB DPLL.
- There are four independent sDMA request view channels, each of which has a dedicated register ([CONTROL_CONF_SDMA_REQ_SEL0](#) through [CONTROL_CONF_SDMA_REQ_SEL3](#)) with a 7-bit MULT bit field to select 1 from a possible 127 sDMA request signals for observation purposes. For more information, see [Chapter 16](#), *sDMA Controller*. The fifth channel, sdma_req_view_all, is acquired by applying logical AND reduction over the four currently selected sDMA view channel output signals.
- The general core observability logic input, hwobs_pd_l4_per_per32k_gfclk, is tied to the PRM output observability signal, pd_l4_per_per_32k_gfclk.

The pd_l4_per_per_32k_gfclk signal corresponds to the hardware gated in the L4_PER clock domain clock, PER_32K_FCLK, which is directly sourced by the SCRM 32K_FCLK clock.

For more information, see [Section 3.6.3.1](#), *PRM Clock Source*, in [Chapter 3](#), *Power, Reset, and Clock Management*. The PER_32K_FCLK and 32K_FCLK clocks are also multiplexed for observability in the WKUP power domain when the PRCM.PRM_DEBUG_CFG[6:0] bit field is set to 0x6c. These are the observable signals devfsm_l0.clk and gat_per_32k_gfclk_l0.clkGated, respectively. For more information, see [Table 18-35](#).

- The general core observability logic input, hwobs_pd_l4_per_per32k_gfclk, is tied to the PRM output observability signal, pd_l4_per_per_32k_gfclk. The pd_l4_per_per_32k_gfclk signal corresponds to the hardware gated in the PER_32K_FCLK clock in the L4_PER clock domain. The PER_32K_FCLK clock is directly sourced by SCRM (32K_FCLK clock). For more information, see [Section 3.6.3.1, PRM Clock Source](#), in [Chapter 3, Power, Reset, and Clock Management](#). The PER_32K_FCLK and 32K_FCLK clock are also multiplexed for observability in the WKUP domain when the PRCM.PRM_DEBUG_CFG[6:0] bit field is set to 0x6c. These are the observable signals devfsm_l0.clk and gat_per_32k_gfclk_l0.clkGated, respectively. For more information, see [Table 18-35](#).
- The general core observability logic input, hwobs_coredivider_clkout3, is tied to the Core DPLL observability output, CLK_FUNC_1_0_3, which is a direct (nongated, nondivided) version of the CORE DPLL clock output, CLKOUTX2_M3. For more information, see [DPLL_CORE Description](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- The general core observability logic input, hwobs_perdivider_clkout4, is tied to the Core DPLL observability output, CLK_FUNC_1_0_4, which is a direct (nongated, nondivided) version of the PER DPLL clock output, CLKOUTX2_M4. For more information, see [Section 3.6.3.4, DPLL_PER Description](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 18-20. DPLL Signal Observability Controls

Feature	Type	Register/Bit Field/Observability Control	Description
Different domain dpll freqlock observability	Control	CONTROL_CONF_DPLL_FREQLOCK_SEL [2:0] MULT	Select DPLL freqlockview channel(1:8)
Different domain dpll phaselock observability	Control	CONTROL_CONF_DPLL_PHASELOCK_SEL [2:0] MULT	Select DPLL phaselockview channel(1:8)
Different domain dpll tinitz observability	Control	CONTROL_CONF_DPLL_TINITZ_SEL [2:0] MULT	Selects to observe DPLL tinitzview channel (1:8)
Different domain dpll tenable observability	Control	CONTROL_CONF_DPLL_TENABLE_SEL [2:0] MULT	Selects to observe DPLL tenableview channel (1:8)
Different domain dpll tenablediv observability	Control	CONTROL_CONF_DPLL_TENABLEDIV_SEL [2:0] MULT	Selects to observe DPLL tenabledivview channel (1:8)
Different domain dpll bypassack observability	Control	CONTROL_CONF_DPLL_BYPASSACK_SEL [2:0] MULT	Selects to observe DPLL bypassackview channel (1:8)
Different domain dpll idle observability	Control	CONTROL_CONF_DPLL_IDLE_SEL [2:0] MULT	Selects to observe DPLL idleview channel (1:8)

NOTE: Features configured in the following registers are limited to the hardware observability signals, hw_dbg i (where i = 0 to 31), multiplexed and propagated in the CORE power domain ([CONTROL_DEBOBS_FINAL_MUX_SEL\[i\]](#) SELECT = 0b1).

- [CONTROL_CORE_CONF_DEBUG_SEL_TST_0](#) through [CONTROL_CORE_CONF_DEBUG_SEL_TST_31](#)
- [CONTROL_CONF_CLK_SEL0\[2:0\] MULT](#) through [CONTROL_CONF_CLK_SEL2\[2:0\] MULT](#)
- [CONTROL_CONF_SDMA_REQ_SEL0](#) through [CONTROL_CONF_SDMA_REQ_SEL3](#)
- [CONTROL_CONF_DPLL_FREQLOCK_SEL](#)
- [CONTROL_CONF_DPLL_TINITZ_SEL](#)
- [CONTROL_CONF_DPLL_PHASELOCK_SEL](#)
- [CONTROL_CONF_DPLL_TENABLE_SEL](#)
- [CONTROL_CONF_DPLL_TENABLEDIV_SEL](#)
- [CONTROL_CONF_DPLL_BYPASSACK_SEL](#)
- [CONTROL_CONF_DPLL_IDLE_SEL](#)

These options do not apply to the hardware observability signals, hw_dbg i (where i = 0 to 31), which at the general control module level are muxed in the WKUP power domain ([CONTROL_DEBOBS_FINAL_MUX_SEL\[i\]](#) SELECT = 0b0).

The [CONTROL_WKUP_CONF_DEBUG_SEL_TST_i\[0\]](#) MODE bit (where i = 0...31) provides the option to choose between the observation of device power and reset manager signals or observation of clock manager 1-related signals. If [CONTROL_WKUP_CONF_DEBUG_SEL_TST_i\[0\]](#) = 0b1, the hwobs_int_prm_i signal is selected. Otherwise, the hwobs_int_cm1_i signal is output.

NOTE: The CM1 and PRM observable signals are multiplexed in the WKUP power domain.

18.4.11.4 Observability Signals Multiplexing at Device Control Module Level

The pads used for the hardware debug must be properly configured by selecting the hardware debug function (hw_dbgn) of the pad.

18.4.11.4.1 Observability Signals Muxed on Pads in CORE Power Domain

To map the hw_dbg0 through hw_dbg19 signals to their associated external device pads in the CORE power domain, set the related MUXMODE fields within [CONTROL_CORE_PAD0_SYS_BOOT5_PAD1_DPM_EMU0](#) through [CONTROL_CORE_PAD0_DPM_EMU19](#) padconfiguration registers to 0b110 (Mode 6).

To make the remaining signals, hw_dbg20 through hw_dbg31, available at their corresponding device pads in the CORE power domain, set the MUXMODE fields within the [CONTROL_CORE_PAD0_CAM_GLOBALRESET_PAD1_USBB1_ULPITLL_CLK](#) through [CONTROL_CORE_PAD0_USBB1_ULPITLL_DAT7_PAD1_USBB1_HSIC_DATA](#) padconfiguration registers to 0b110 (mode 6).

For more information, see [Table 18-9](#).

For more information about hardware observability configuration, see [Table 18-103](#).

NOTE: The hw_dbg i signals (where i = 0 to 31), which are multiplexed and propagated in the CORE power domain, are not visible when the device is set into off mode (PD_CORE supply switched off).

18.4.11.4.2 Observability Signals Muxed on Pads in WKUP Power Domain

To have the hw_dbg1 through hw_dbg13 signals multiplexed on the WKUP power domain pads, set MuxMode = 0x6 in the following SYSCTRL_PADCONF_WKUP registers:

- [CONTROL_WKUP_PAD0_GPIO_WK0_PAD1_GPIO_WK1](#) through [CONTROL_WKUP_PAD0_GPIO_WK2_PAD1_GPIO_WK3](#)[31:16] to have the hw_dbg1–hw_dbg4 signals output on the gpio_wk0–gpio_wk3 device pads, respectively.
- [CONTROL_WKUP_PAD0_GPIO_WK4_PAD1_SR_SCL](#)[15:0] to have the hw_dbg5 signal output on the gpio_wk4 device pad
- [CONTROL_WKUP_PAD0_FREF_CLK0_OUT_PAD1_FREF_CLK3_REQ](#) through [CONTROL_WKUP_PAD0_FREF_CLK3_OUT_PAD1_FREF_CLK4_REQ](#) to have the hw_dbg6–hw_dbg9 signal output on the fref_clk0_out, fref_clk3_req, fref_clk3_out, and fref_clk4_req device pads, respectively.
- [CONTROL_WKUP_PAD0_FREF_CLK4_OUT_PAD1_SYS_32K](#)[15:0] to have the hw_dbg10 signal output on the fref_clk4_out device pad
- [CONTROL_WKUP_PAD0_SYS_PWR_REQ_PAD1_SYS_PWRON_RESET_OUT](#)[31:16] to have the hw_dbg11 signal output on the sys_pwrn_reset_out device pad
- [CONTROL_WKUP_PAD0_SYS_BOOT6_PAD1_SYS_BOOT7](#) to have the hw_dbg12 and hw_dbg13 signals output on the sys_boot6 and sys_boot7 device pads, respectively.

For more information, see [Table 18-8](#).

For more information about hardware observability configuration, see [Table 18-103](#).

NOTE: If multiplexed on corresponding device pads in the WKUP power domain, the hw_dbg i signals (where i = 0 to 31), which are multiplexed and propagated in the WKUP power domain, can be observed even if the device goes into off mode.

18.4.11.5 Observability Signals Sourced at Module Level

Observable signals coming from within different device subsystems are mapped to general core control and general wakeup control observability inputs. Additional multiplexing is also implemented inside some of the observable modules (See [Figure 18-18](#)).

18.4.11.5.1 Dual Cortex-A9 Subsystem Observable Signals

Table 18-21 through Table 18-29 show the Cortex-A9 MPU subsystem observable signals available in 8 functional multiplexing modes. The mode is selected at the general core control module level by programming the [CONTROL_DEBOBS_MMR_MPU\[3:0\]](#) SELECT bit field. The SELECT values in range (0x8–0xF) are reserved for future use.

The POPPROFILING_EVENT2PRM bus signals, observable in modes 0, 1, 2, and 3, monitor the power states of the CPU. There are 6 status bits per Cortex-A9 CPU0 and CPU1, respectively. The encoding of the status bits is described in [Table 18-25](#).

POPPROFILING_EVENT2PRM[5:0] are the status bits for CPU0, and POPPROFILING_EVENT2PRM [11:6] are the status bits for CPU1.

18.4.11.5.4 DSP Subsystem Observable Signals

This information is not available in the public domain

18.4.11.5.5 ABE Subsystem Observable Signals

The audio back-end observable signals described in [Table 18-32](#) are directly mapped to the ABE dedicated observability inputs(hwobs_int_abe[31:0] of the SYSCTRL_GENERAL_CORE module) and no additional multiplexing is performed inside the ABE subsystem.

Table 18-32. Observability Signals at ABE Subsystem Level

ABE Subsystem	ABE Level Observability Signals	Signal Description	Logical Value Meaning
hwobs_int_abe[31:26]	–	–	–
hwobs_int_abe[25:24]	OPP_DIV	OPP DIVIDER bit[1:0]	–
hwobs_int_abe[23]	AESS_to_MPU_IRQ	IRQ sent from AESS to MCU. See Chapter 12, ABE .	–
hwobs_int_abe[22]	AESS_to_DSPSS_IRQ	IRQ sent from AESS to DSP. See , Interrupt Requests , and Chapter 12, ABE .	–
hwobs_int_abe[21]	Reserved	–	–
hwobs_int_abe[20]	GPT_WDT_PWM_INP	PWM received from the GPTIMER or watchdog (OR)	–
hwobs_int_abe[19]	AESS_DMAREQ_ALL	(Logical OR with all DMA req out)	High while outgoing DMA requests from audio engine have not been acknowledged by the host.
hwobs_int_abe[18]	AESS_DMAREQ_PER	(Logical OR with all DMA req coming from the peripheral)	High when incoming DMA requests from audio engine are still to be served.
hwobs_int_abe[17]	AESS_IDLEPO	The PO_IDLE AESS output	High when the audio engine executes a wait until an activation of the PI_WAKEUP pin has been done.
hwobs_int_abe[16:0]	RESERVED	-	-

18.4.11.5.6 USBOTGHS Subsystem Observable Signals

One of the general wakeup control observability inputs can be mapped to the USBOTGHS "start of frame signal" (hsusbotg_sofpulse by setting [CONTROL_CORE_CONF_DEBUG_SEL_TST_11\[3:0\]](#) MODE = 0x1).

18.4.11.5.7 CM2 Subsystem Observable Signals

The SYSCTRL_GENERAL_CORE observability inputs hwobs_int_cm2(i) (where i = 0...31) are mapped to the signals debugcm2(i) (where i = 0...31) coming out of the PRCM submodule, Clock Manager 2 (CM2).

Local multiplexing controls at the CM2 level reside in the CM2_DEBUG_CFG register. The CM2 observability output signals are driven on the debugcm2(0) through debugcm2(7) lines. A certain mux set is selected by programming the CM2_DEBUG_CFG[7:0] SEL0 bit field. The remaining debugcm2(8) through debugcm2(31) lines are reserved for future use. For more information about the CM2 observability source select field, see [Section 3.11.30.1, INTRCONN_SOCKET_CM2 Register Summary](#), in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 18-33](#) provides different details about the signals inside CM2 that can be monitored on device hw_dbg pins.

Table 18-33. CM2 Observable Signals

Byte	0x00	Type	AutoPRCM signal identifier	B#	Info +	Info +	Info +	Comments
Bit	0	Internal	ifsm_ccptx_ccpt_stby_I0.MStandby				Input

18.4.11.5.8 CM1 Subsystem Observable Signals

The general wakeup control observability inputs hwobs_int_cm1(i) (where i = 0...31) are mapped to the signals debugcm1(i) (where i = 0...31) coming out of the PRCM submodule, clock manager 1 (CM1).

Local multiplexing controls at the CM1 level reside in the CM1_DEBUG_CFG register. The CM1 observability output signals are driven on the debugcm1(0) through debugcm1(7) lines. A certain mux set is selected by programming the CM1_DEBUG_CFG[6:0] SEL0 bit field. The remaining debugcm1(8) through debugcm1(31) lines are reserved for future use. For more information about the CM1 observability source select field, see [Section 3.11.22.1, INTRCONN_SOCKET_CM1 Register Summary](#) in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 18-34](#) provides different details about the signals inside CM1 that can be monitored on device hw_dbg pins.

Table 18-34. CM1 Observable Signals

Byte	0x00	Type	AutoPRCM signal identifier	B#	Info +	Info +	Info +	Comments
Bit	0	Internal	ifsm_aess_standby_prot_I0.MStandby				Input

18.4.11.5.9 PRM Subsystem Observable Signals

The general wakeup control observability inputs hwobs_int_prm(i) (where i = 0...31) are mapped to the signals debugprm(i) (where i = 0...31) coming from the power reset manager (PRM) submodule.

Local multiplexing controls at the PRM level reside in the PRM_DEBUG_CFG register. The PRM observability output signals are driven on the debugprm(0) through debugprm(7) lines. A certain mux set is selected by programming the PRM_DEBUG_CFG[6:0] SEL0 bit field. The remaining debugprm(8) through debugprm(31) lines are reserved for future use. For more information about the PRM observability source select field, see [Section 3.11.2.1, INTRCONN_SOCKET_PRM Register Summary](#) in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 18-35](#) provides different details about the signals inside the PRM that can be monitored on device hw_dbg pins.

18.4.11.5.10 PRCM FSM State Observable Signals Description

Some of the observable signals encode the different PRCM finite state-machine (FSM) states. Each state corresponds to a combination of FSM output signal values. The states of the different FSMs associated with SAR RAM, DPLLs, EMIF, I/O controller, power manager, global reset manager warm reset generator, and clock managers, along with their corresponding output signal values (except for DPLLCtrl outputs) are described in [Table 18-36](#) through [Table 18-42](#).

18.4.12 Functional Register Description

18.4.12.1 DSP Boot Register

This information is not available in the public domain.

18.4.12.2 PBIASLITE Control Register

Table 18-50 describes the [CONTROL_PBIASLITE](#) register, which controls some settings of PBIAS LITE cells for the MMC I/O interface.

Table 18-50. PBIAS Control Register

Physical Address	Register Name	Description	Access
0x4A10 0600	CONTROL_PBIASLITE	Control settings for PBIAS cell	R/W

For more information about the PBIAS cells, see [Section 18.4.9, Extended-Drain I/O and PBIAS Cell](#).

18.4.12.3 Temperature Sensor Control Register

Table 18-51 describes the [CONTROL_TEMP_SENSOR](#) register, which controls the temperature sensor.

Table 18-51. Temperature Sensor Register

Physical Address	Register Name	Description	Access
0x4A00 232C	CONTROL_TEMP_SENSOR	Temperature sensor control register	R/W

18.4.12.4 CSI Receiver Control Register

To enable the physical layer of the camera receiver, the programmer manipulates the bits within the [CONTROL_CAMERA_RX](#) register.

Table 18-52. CSI Receiver control Register

Physical Address	Register Name	Description	Access
0x4A10 0608	CONTROL_CAMERA_RX	Module dedicated configurations	R/W

18.4.12.5 Protection Status Registers

Table 18-53 lists the status registers.

Table 18-53. Protection Status Registers

Physical Address	Register Name	Description	Access
0x4A00 22D0	CONTROL_SEC_ERR_STATUS_FUNC	Protection firewall error status register	Public (R)
0x4A00 22D4	CONTROL_SEC_ERR_STATUS_DEBUG	Protection firewall error status register debug	Public (RW Write 1 to Clear)

These registers do not depend on the device type.

The [CONTROL_SEC_ERR_STATUS_FUNC](#) can be read in public mode, but cannot be written.

The [CONTROL_SEC_ERR_STATUS_DEBUG](#) register is both read and write accessible in GP devices.

These bits are cleared when the L3 and L4 firewall embedded error log registers are cleared. All bits in these registers reflect device internal events related to the device protection.

On a specific event (signal rising edge), the corresponding bit is set. On a rising edge, the input signal must stay high for at least two interface clocks periods to be recognized. Software must clear each bit after reviewing the events.

When a protection violation occurs, the following bits are set:

- In application mode
 - [CONTROL_SEC_ERR_STATUS_FUNC](#)[01] = L3RAM protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC](#)[02] = GPMC protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC](#)[03] = EMIF protection violation

- [CONTROL_SEC_ERR_STATUS_FUNC\[04\]](#) = IVA-HD protection violation
- [CONTROL_SEC_ERR_STATUS_FUNC\[05\]](#) = Dual Cortex™-M3 protection violation
- [CONTROL_SEC_ERR_STATUS_FUNC\[06\]](#) = SL2 protection violation
- [CONTROL_SEC_ERR_STATUS_FUNC\[12\]](#) = C2C protection violation
- [CONTROL_SEC_ERR_STATUS_FUNC\[13\]](#) = SGX protection violation
- [CONTROL_SEC_ERR_STATUS_FUNC\[14\]](#) = Display subsystem protection violation
- [CONTROL_SEC_ERR_STATUS_FUNC\[15\]](#) = ISS protection violation
- [CONTROL_SEC_ERR_STATUS_FUNC\[16\]](#) = L4_PER protection violation
- [CONTROL_SEC_ERR_STATUS_FUNC\[17\]](#) = L4_CFG protection violation
- [CONTROL_SEC_ERR_STATUS_FUNC\[18\]](#) = DEBUGSS protection violation
- [CONTROL_SEC_ERR_STATUS_FUNC\[19\]](#) = L4 AudioBE protection violation
- [CONTROL_SEC_ERR_STATUS_FUNC\[20\]](#) = C2C INIT protection violation
- In debug mode
 - [CONTROL_SEC_ERR_STATUS_DEBUG\[01\]](#) = L3RAM protection violation
 - [CONTROL_SEC_ERR_STATUS_DEBUG\[02\]](#) = GPMC protection violation
 - [CONTROL_SEC_ERR_STATUS_DEBUG\[03\]](#) = EMIF protection violation
 - [CONTROL_SEC_ERR_STATUS_DEBUG\[04\]](#) = IVA-HD protection violation
 - [CONTROL_SEC_ERR_STATUS_DEBUG\[05\]](#) = Dual Cortex-M3 protection violation
 - [CONTROL_SEC_ERR_STATUS_DEBUG\[06\]](#) = SL2 protection violation
 - [CONTROL_SEC_ERR_STATUS_DEBUG\[12\]](#) = C2C protection violation
 - [CONTROL_SEC_ERR_STATUS_DEBUG\[13\]](#) = SGX protection violation
 - [CONTROL_SEC_ERR_STATUS_DEBUG\[14\]](#) = Display subsystem protection violation
 - [CONTROL_SEC_ERR_STATUS_DEBUG\[15\]](#) = ISS protection violation
 - [CONTROL_SEC_ERR_STATUS_DEBUG\[16\]](#) = L4_PER protection violation
 - [CONTROL_SEC_ERR_STATUS_DEBUG\[17\]](#) = L4_CFG protection violation
 - [CONTROL_SEC_ERR_STATUS_DEBUG\[18\]](#) = DEBUGSS protection violation
 - [CONTROL_SEC_ERR_STATUS_DEBUG\[19\]](#) = L4 AudioBE protection violation
 - [CONTROL_SEC_ERR_STATUS_DEBUG\[20\]](#) = C2C INIT protection violation

For more information about L4 firewall protection violation report mechanisms, see [Section 13.3.3.4.5, Firewall Error Logging in the Control Module](#). For more information about L3 firewall protection violation report mechanisms, see [Section 13.2.3.8, L3 Interconnect Error Analysis](#).

18.4.12.6 Protection SDRAM Configuration Registers

[Table 18-54](#) lists the protection SDRAM configuration registers for EMIF1 and EMIF2 that are part of the general wakeup control module. Upon POR, their values are exported as reset values of the EMIF1 and EMIF2 registers (EMIF_SDRAM_CONFIG and EMIF_SDRAM_CONFIG_2, respectively).

Table 18-54. Protection SDRAM Configuration Registers for EMIF1 and EMIF2

Physical Address	Register Name	Description	Access
0x4A30C110	CONTROL_WKUP_PROT_EMIF1_SDRAM_CONFIG_REG	Protection SDRAM configuration register 1, defining bit field reset values of the EMIF1.EMIF_SDRAM_CONFIG register	RW
0x4A30C114	CONTROL_WKUP_PROT_EMIF1_SDRAM_CONFIG2_REG	Protection SDRAM configuration register 2, defining bit field reset values of the EMIF1.EMIF_SDRAM_CONFIG_2 register	RW
0x4A30C118	CONTROL_WKUP_PROT_EMIF2_SDRAM_CONFIG_REG	Protection SDRAM configuration register 1, defining bit field reset values of the EMIF2.EMIF_SDRAM_CONFIG register	RW

Table 18-54. Protection SDRAM Configuration Registers for EMIF1 and EMIF2 (continued)

Physical Address	Register Name	Description	Access
0x4A30C11C	CONTROL_WKUP_PROT_EMIF2_SDRAM_CONFIG2_REG	Protection SDRAM configuration register 2, defining bit field reset values of the EMIF2.EMIF_SDRAM_CONFIG_2 register	RW

18.4.12.7 Register Controls for the LPDDR2IO1 and LPDDR2IO2 I/O Buffer Modes

There are global controls related to LPDDR2IO1 and LPDDR2IO2 (EMIF1 and EMIF2 associated) CA I/O receivers (loopback mode only) and DQ I/O receivers. These controls reside in the SYSCTRL_GENERAL_CORE.[CONTROL_GEN_CORE_OCPREG_SPARE](#) register.

[Figure 18-19](#) in [Section 18.4.12.8, Reference Voltage for OMAP LPDDR2IO1 and LPDDR2IO2 I/O Buffers and LPDDR2 Memory](#), shows how these controls are related to mode selection and powerdown controls for LPDDR2IO receivers.

Their functionality is as follows:

- Setting the OCPREG_SPARE[3] bit to 0b1 simultaneously disables (powers-down) all receivers associated with DQ groups of the LPDDR22 I/Os.
- Setting the OCPREG_SPARE[1] bit to 0b1, simultaneously disables (power-downs) all receivers associated with DQ groups of the LPDDR21 I/Os.
- Only the four DQ I/O groups receivers are impacted by the OCPREG_SPARE[1] and OCPREG_SPARE[3] bits as follows:
 - lpddr2x_dm0, lpddr2x_dqs0, lpddr2x_ndqs0, lpddr2x_dq [7:0]
 - lpddr2x_dm1, lpddr2x_dqs1, lpddr2x_ndqs1, lpddr2x_dq [15:8]
 - lpddr2x_dm2, lpddr2x_dqs2, lpddr2x_ndqs2, lpddr2x_dq [23:16]
 - lpddr2x_dm3, lpddr2x_dqs3, lpddr2x_ndqs3, lpddr2x_dq [31:24]
- Programming the OCPREG_SPARE[2] and OCPREG_SPARE[0] bits to 0b1 configures all the LPDDR2 DQ and CA (CA receivers enabled in a loopback mode only) I/O groups receivers to use low-voltage CMOS (LVCMOS) buffer logic, for the LPDDR22 and LPDDR21 I/Os, respectively.
- There is a single CA I/O group (lpddr2x_ca[0:9], lpddr2x_ncs0/1, lpddr2x_cke0/1, lpddr2x_ck, lpddr2x_nck) for the LPDDR21 and LPDDR22 command I/O lines. Programming the OCPREG_SPARE[2] and OCPREG_SPARE[0] bits to 0b0 configures all the LPDDR2 DQ and CA (loopback mode only) I/O groups receivers to use a true differential comparator logic (so called Vref-based receivers). For more details on the configuration of a Vref-based receiver, see [Section 18.4.12.8 Reference Voltage for OMAP LPDDR2IO1 and LPDDR2IO2 I/O Buffers and LPDDR2 Memory](#).

[Table 18-55](#) lists the register used to control the described EMIF1 and EMIF2 features.

Table 18-55. LPDDR2IO Buffer Control Register

Physical Address	Register Name	Description	Access
0x4A0023FC	CONTROL_GEN_CORE_OCPREG_SPARE	The lower 4 bits of this register are assigned to control the power-down mode for LPDDR2 DQ lines and select LVCMOS buffer or Vref-based receiver configuration for the LPDDR2 DQ/CA receivers.	RW

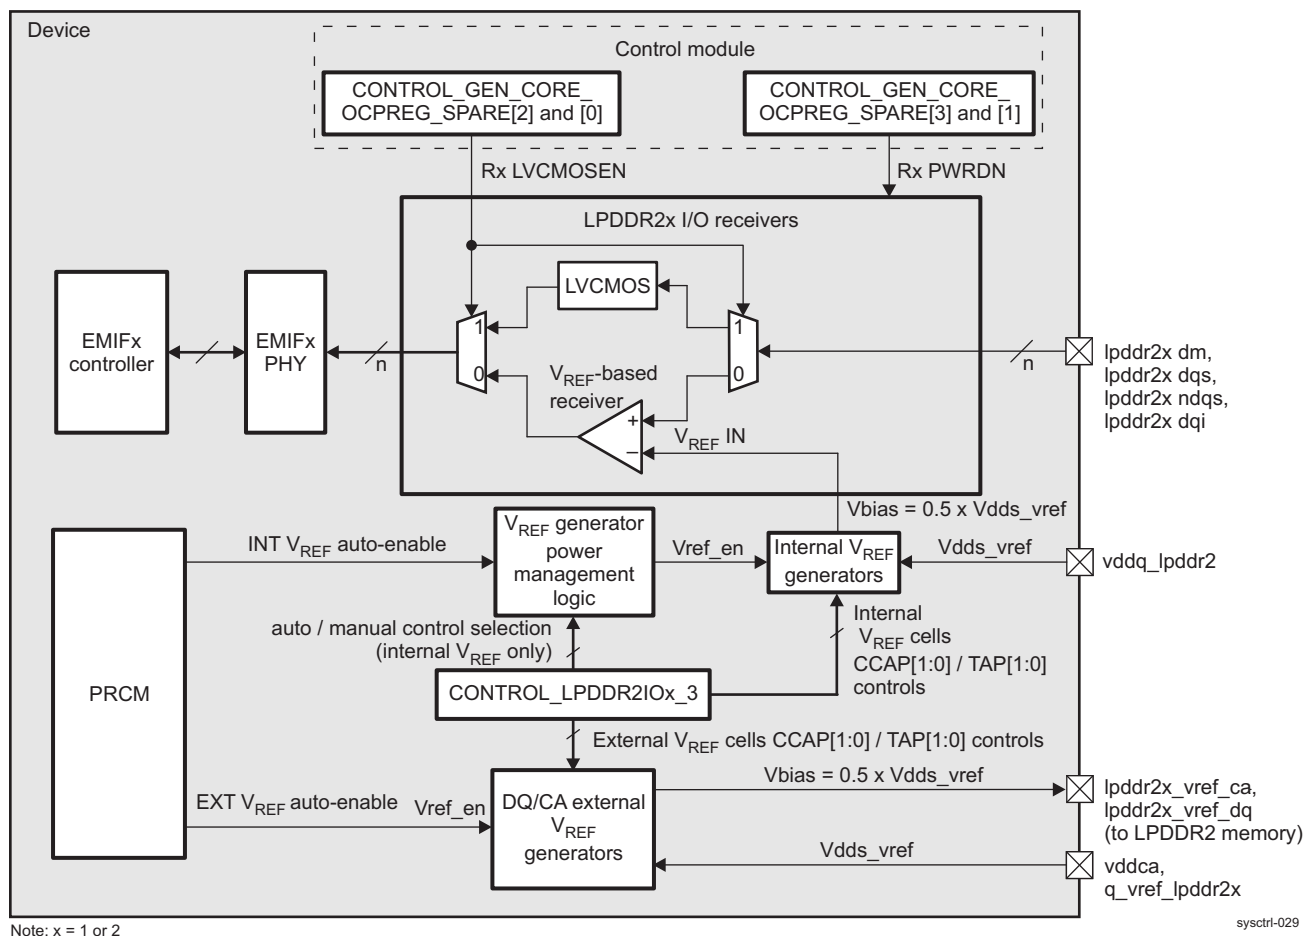

18.4.12.8 Reference Voltage for OMAP LPDDR2IO1 and LPDDR2IO2 I/O Buffers and LPDDR2 Memory

When device LPDDR2IO1 and LPDDR2IO2 I/O buffers are used in differential comparator mode (so called Vref based receivers), a reference voltage needs to be provided to the buffers. Several Vref-generation cells are integrated in the device to supply this internal reference voltage. [Figure 18-19](#) provides the details about different controls related to the external and internal Vref generation cells for the differential comparator receivers.

When the Vref generator is turned on, it supplies voltage reference to the Vref-based receivers associated with the LPDDR2IO DQ and CA interface lines. In Vref-based receiver mode, the LPDDR2 I/O cell receiver is a true differential comparator with positive terminal connected to the device pad on which signal from LPDDR2 memory is received, and negative terminal tied to the VREF voltage generated on the Vbias output of the receiver corresponding Vref cell (see [Figure 18-19](#)).

The Vbias equals $0.5 \times V_{\text{dds_vref}}$, where $V_{\text{dds_vref}}$ is power supply voltage of the Vref cell. The Vref-based receiver allows the improvement of speed performance at $V_{\text{DDS}} = 1.2\text{-V}$ I/O voltage supply. A reference voltage is also provided to externally attached LPDDR2 memory through the device `lpddr2x_vref_ca` and `lpddr2x_vref_dq` output pads. The same type of Vref-generation cells are used for these external reference voltages.

Figure 18-19. LPDDR2 Vref Cell and Receiver Type Controls

The voltage drive selection bit fields of these internal / external voltage reference cells are in the [CONTROL_LPDDR2IO1_3](#) and [CONTROL_LPDDR2IO2_3](#) registers. Individual `VREF_TAP[1:0]` control bits set the output drive capability for each reference voltage.

[Table 18-56](#) lists the possible options for internal reference voltage drive selection.

Table 18-56. LPDDR2 Internal Reference Configuration

VREF_TAP1	VREF_TAP0	Description
0	0	Pad/bias2 Connected to reference $V_{\text{dds_vref}} / 2$, for 2- μA current load
0	1	Pad/bias2 Connected to reference $V_{\text{dds_vref}} / 2$, for 4- μA current load
1	0	Pad/bias2 Connected to reference $V_{\text{dds_vref}} / 2$, for 6- μA current load

Table 18-56. LPDDR2 Internal Reference Configuration (continued)

VREF_TAP1	VREF_TAP0	Description
1	1	Pad/bias2 Connected to reference Vdds_vref / 2, for 8-μA current load

According to the noise environment, the user can choose to filter the reference voltage which is supplied. Two coupling capacitors, internal to a Vref-generation cell, are available and are configurable as specified in [Table 18-57](#).

Table 18-57. LPDDR2 Vref Cell Decoupling Cap Selection

VREF_CCAP0	VREF_CCAP1	Capacitor
0	0	Capacitor between internal reference node (Vbias) and Vss (ground)
0	1	Capacitor between internal reference node (Vbias) and Vdds_vref as well as internal reference node (Vbias) and Vss
1	0	No capacitor connected
1	1	Capacitor between internal reference node (Vbias) and Vdds_vref

Individual VREF_CCAP0 and VREF_CCAP1 control bits in the [CONTROL_LPDDR2IO1_3](#) and [CONTROL_LPDDR2IO2_3](#) registers set the coupling capacitor connection on VREF nodes.

For leakage improvement the Vref-generation cells can be enabled and disabled.

The Vref-generation cells used for the device internal Vref voltage are controlled by software. Setting bit [CONTROL_LPDDR2IOx_3\[0\]](#) LPDDR2x_INT_VREF_AUTO_EN_DQ = 0b1 or [CONTROL_LPDDR2IOx_3\[1\]](#) LPDDR2x_INT_VREF_AUTO_EN_CA = 0b1 (where x = 1, 2) enables the device PRCM automatic shut off or switch-on of the internal Vref cell generators associated with the LPDDR2x interface, DQ and CA lines, respectively.

If user software sets the manual control bit [CONTROL_LPDDR2IOx_3\[2\]](#) LPDDR2x_INT_VREF_EN_DQ=0b1 or [CONTROL_LPDDR2IOx_3\[2\]](#) LPDDR2x_INT_VREF_EN_CA =0b1, internal Vref cell generators are enabled, regardless of the state of the LPDDR2x_INT_VREF_AUTO_EN_DQ / LPDDR2x_INT_VREF_AUTO_EN_CA bits. Thus, PRCM automatic control over the internal Vref cell generators can always be overridden in the context of enabling the Vref generator.

In contrast to the internal Vref source generator cells, which enable/disable-control can be selected in software between PRCM and manual software control, the Vref-generation cells used for the external Vref output generation are controlled only by the PRCM.

[Table 18-58](#) provides different combinations of Vref cell control types and the state of the Vref cell.

Table 18-58. LPDDR2 Vref Cells State Description

LPDDR2x_INT_VREF_EN_DQ /CA (Manual Control Bits)	LPDDR2x_INT_VREF_AUTO_EN_DQ/CA (AUTO Control Bits)	Type of Control	Vref Cell State
1	x	Manual	Enabled
0	1	AUTO	Automatically enabled/disabled
0	0	–	Disable

There are 4 internal VREF cells (k = 0 to 3) associated with DQ line receivers and a single internal VREF cell associated with CA line receivers (loopback mode only) for each of the device LPDDR21 and LPDDR22 set of I/Os. The group assignment of a VREF cell Vbias output to different I/Os associated Vref-based receivers is covered in [Table 18-59](#)

Table 18-59. Internal VREF Generators CCAP and TAP Controls versus LPDDR2IO Receiver Pads

Control Module Register	LPDDR21 Pads	Internal Vref cell TAP / CCAP controls associated to device LPDDR21 pad corresponding Vref-based receivers

Control Module Register	LPDDR22 Pads	Internal Vref cell TAP / CCAP controls associated to device LPDDR21 pad corresponding Vref-based receivers
CONTROL_LPDDR2IO2_3	lpddr22_dm0, lpddr22_dqs0, lpddr22_ndqs0, lpddr22_dq[7:0]	LPDDR22_VREF_DQ_INT0_TAP/CCAP
	lpddr22_dm1, lpddr22_dqs1, lpddr22_ndqs1, lpddr22_dq[15:8]	LPDDR22_VREF_DQ_INT1_TAP/CCAP
	lpddr22_dm2, lpddr22_dqs2, lpddr22_ndqs2, lpddr22_dq[23:16]	LPDDR22_VREF_DQ_INT2_TAP/CCAP
	lpddr22_dm3, lpddr22_dqs3, lpddr22_ndqs3, lpddr22_dq[31:24]	LPDDR22_VREF_DQ_INT3_TAP/CCAP
	lpddr22_ca[9:0], lpddr22_ncs0, lpddr22_ncs1, lpddr22_cke0, lpddr22_cke1, lpddr22_ck, lpddr22_nck	LPDDR22_VREF_CA_INT_TAP/CCAP

Different LPDDR2x_VREF_DQ / CA_INTk_TAP[1:0], LPDDR2x_VREF_DQ / CA_INTk_CCAP[1:0] bit fields from the [CONTROL_LPDDR2IO1_3](#) (for LPDDR2IO1 Vref cells) and [CONTROL_LPDDR2IO2_3](#) (for LPDDR2IO2 Vref cells) registers, apply to k = 4 different DQ groups and a single group of CA I/Os per LPDDR2 I/O set, as specified in [Table 18-59](#).

The LPDDR2x_VREF_DQ[1:0] or CA_TAP[1:0] bit fields, and LPDDR2x_VREF_DQ[1:0] or CA_CCAP[1:0] bit fields are used to set the output drive capability and coupling capacitors at the Vbias node of the DQ/CA external Vref generation cells.

In contrast to VREF_TAP and VREF_CCAP (which are individual per LPDDR2x I/O group), the LPDDR2x_INT_VREF_EN_DQ, LPDDR2x_INT_VREF_EN_CA, LPDDR2x_INT_VREF_AUTO_EN_DQ, and LPDDR2x_INT_VREF_AUTO_EN_CA bit fields act as common controls to all internal Vref generator cells.

NOTE: The CA and DQ Vref-generation cells used as external Vref output generators are controlled only by the PRCM.

18.4.12.9 Signal Integrity Parameter Control Registers With Pad Group Assignment

18.4.12.9.1 Signal Integrity Parameter Controls Overview

Most of the I/O cells associated with the device pads are configurable to deliver their carried signals to the targeted sink with maximum signal integrity. These I/Os are configured by pad group assignment and not individually per pad.

The different I/O-specific requirements determine the use of different types of I/O cells for the device I/Os. Software controls associated with the signal integrity parameters are implemented at the SYSCTRL_PADCONF_CORE and SYSCTRL_PADCONF_WKUP levels.

The following types of I/O cells associated with pad groups can be identified:

- LPDDR2 high-speed I/O cells with impedance (I), slew rate (SR), and weak driver (WD) settings
- High-speed I/O cells with far-end load (LB) settings
- Low -speed I/O cells with combined slew rate (SC) and load versus transmission line (TL) length -(LB) settings
- Two types of I/O cells with mode (MB) controls and load compensation (LB) settings with a difference in typical output impedance
- I/O cells with control (DS0) of the impedance mode
- C2C I/O cells with LB0 control adjustable according to interface requirement/voltage mode
- I/O cells with pullup strength (PUSTRENGTH) and speed controls
- I2Cx I/O cells with pullup resistance vs capacitance load settings
- JTAG™ I/O cells with bus-holder enable control

NOTE: I/Os are non-failsafe, which means that voltage must never be applied at a pad before the internal I/O supply voltage VDDS is powered.

The pad group-assigned signal integrity controls are provided through the registers described in [Table 18-60](#).

18.4.12.9.2 High-Speed I/O Buffers With Impedance, Slew Rate, and Weak Driver Settings

The LPDDR2IO (EMIF) buffers are based on high-speed unterminated logic and require excellent driver impedance control to achieve optimal timing—EMI trade-offs. A specific type of device I/O cell with programmable features is used to meet this requirement. These I/O cells also support high-speed interchip (HSIC) interface.

Two types of software configurable I/O cells are integrated to support high-speed unterminated logic:

- Single-ended I/O cells
- Two-pad differential I/O cells

Two-pad differential I/O cells are provided with a differential receiver and a complementary transmitter. They are used to support the LPDDR2 clock pads (lpddr21_ck, lpddr21_nck, lpddr22_ck, lpddr22_nck) and LPDDR2 strobe pads (lpddr21_dqsi, lpddr21_ndqsi, lpddr22_dqsi, lpddr22_ndqsi, where i = 0 to 3).

A LPDDR2 bidirectional-I/O cell receiver (Rx) can be configured to operate as a LVCMOS buffer and as a true differential comparator with a reference voltage (Vref input [a so called Vref-based receiver]). For more information on LPDDR2 I/O receiver-buffer type selection and power management controls, see [Section 18.4.12.7](#), *Register Controls for the LPDDR2IO1 and LPDDR2IO2 I/O Buffer Modes*.

In addition, several Vref-generation cells are integrated in the device to supply reference voltage (Vref) to receiver buffers (when configured to operate as Vref-based receivers), and to provide Vref to externally-attached LPDDR2 memory. For more details on the functionality and controls of device Vref generation cells, see [Section 18.4.12.8](#), *Reference Voltage for OMAP LPDDR2IO1 and LPDDR2IO2 I/O Buffers and LPDDR2 Memory*.

These LPDDR2x cells are integrated with the following controls located in the SYSCTRL_PADCONF_CORE module:

- Driver output impedance (I) controls
- SR controls
- WD controls to support LPDDR2/HSIC interface and avoid floating pad

- Process-only impedance compensation using 5-bit binary coded schema separately for pullup p<1:5> and pulldown n<1:5> impedance

Programmable bits for impedance and SR control are provided when the I/Os are set to operate in driver mode (outputs).

The bits I[2:0] are used to program desired impedance value of the driver .

The drive strengths corresponding to the I[2:0] value are aliased as Drv i (where i = 5 to 12) in the CONTROL_LPDDR2IO1_x and CONTROL_LPDDR2IO2_x, (where x = 0 to 2) register tables in [Section 18.6.7, SYSCTRL_PADCONF_CORE Register Description](#).

CAUTION

To ensure the best performance of the LPDDR2 I/Os, it is strongly recommended for user software to always set the impedance controlling bits (I) in the CONTROL_LPDDR2IO1_x and CONTROL_LPDDR2IO2_x registers (where x = 0 to 2) to 0x7, which corresponds to Drv12 mode.

For more information about LPDDR2 I/O-specific driver output impedance (respectively corresponding drive strength) parameter, see the *Electrical Characteristics/DC Electrical Characteristics/LPDDR2 DC Electrical Characteristics* section in the device data manual.

User software can program the slew rate (turn-on time) of the output signal using the control bits SR[1:0] in the CONTROL_LPDDR2IO1_x and CONTROL_LPDDR2IO2_x (where x = 0 to 2) registers.

For more information about the LPDDR2 I/O slew rate parameter control, SR[1:0], see the *Electrical Characteristics/DC Electrical Characteristics/LPDDR2 DC Electrical Characteristics* section in the device data manual.

Weak pullup, pulldown, or a keeper on pad is enabled through bits wd0 and wd1. Weak pullup, pulldown option is used to define the pad state (high or low) when no signal is driving the pad. The weak keeper option is used to maintain the previous output value, when nothing is driving the pad. [Table 18-61](#) describes the WD controls.

NOTE: The WD[1:0] bit field controls play the role of the PULLTYPESELECT and PULLUDENABLE bits within the standard pad configuration registers, additionally providing the keeper function to the I/Os with the state WD = 0b11. For LPDDR2 I/Os, the WD controls do not apply during off mode.

Similar to the lpddr1_x and lpddr2_x pads, the usbb1_hsic_data/strobe and usbb2_hsic_data/strobe pads also have weak driver software controls for active-mode internal weak pullups and pulldowns. They are in the [CONTROL_USBB_HSIC](#) register.

In contrast to the LPDDR2 I/Os, the usbb1_hsic and usbb2_hsic pads are additionally provided with bits in the same register to select weak pullup/down and keeper function during off mode. For a given usbbx_hsic_data/strobe pad (where x = 1, 2) the associated bit to allow an off-mode-specific pullup/pulldown/keeper setting is OFFMODE_WD_ENABLE. The off mode option is defined through the OFFMODE_WD[1:0] bit field in the [CONTROL_USBB_HSIC](#) register.

Table 18-61. Weak Driver PUPD/Latch Mode

WD1	WD0	Operation
0	0	Pull logic disabled
0	1	Weak pullup enabled
1	0	Weak pulldown enabled
1	1	Weak keeper enabled

The following sequence is required to program the off-mode pullup/pulldown/latch (keeper) feature of the usbb1_hsic_data/usbb2_hsic_data and usbb1_hsic_strobe/usbb2_hsic_strobe pads:

1. Program the desired values for USBB1_HSIC_DATA_OFFMODE_WD/USBB2_HSIC_DATA_OFFMODE_WD and USBB1_HSIC_STROBE_OFFMODE_WD/USBB2_HSIC_STROBE_OFFMODE_WD in the [CONTROL_USBB_HSIC](#) register.
2. For an off-mode pullup/pulldown configuration different than the active mode pullup/pulldown configuration, set the USBB1_HSIC_DATA_OFFMODE_WD_ENABLE/USBB2_HSIC_DATA_OFFMODE_WD_ENABLE and USBB1_HSIC_STROBE_OFFMODE_WD_ENABLE/USBB2_HSIC_STROBE_OFFMODE_WD_ENABLE bits to 1.

If USBB1_HSIC_DATA_OFFMODE_WD_ENABLE/USBB2_HSIC_DATA_OFFMODE_WD_ENABLE is set to 0, the applied value of the pullup/pulldown after the device goes to off mode will be same as the value of the active pullup/pulldown (that is, in this case, the value of the OFFMODE PU/PD bit field is disregarded).

If, for example, USBB1_HSIC_DATA_OFFMODE_WD/USBB2_HSIC_DATA_OFFMODE_WD is programmed with the same setting as USBB1_HSIC_DATA_WD/USBB2_HSIC_DATA_WD, then the value of USBB1_HSIC_DATA_OFFMODE_WD_ENABLE/USBB2_HSIC_DATA_OFFMODE_WD_ENABLE does not matter.

Therefore,

USBB1_HSIC_DATA_OFFMODE_WD_ENABLE/USBB2_HSIC_DATA_OFFMODE_WD_ENABLE and USBB1_HSIC_STROBE_OFFMODE_WD_ENABLE/USBB2_HSIC_STROBE_OFFMODE_WD_ENABLE apply only to off-mode pullup/pulldown selection.

The eFuse impedance compensation settings are exported upon POR to 10 bits in the [CONTROL_EFUSE_2](#) register of the device control module as follows:

- [CONTROL_EFUSE_2\[23\]](#) LPDDR2_PTV_N1 through [CONTROL_EFUSE_2\[19\]](#) LPDDR2_PTV_N5 (pulldown impedance trimming)
- [CONTROL_EFUSE_2\[18\]](#) LPDDR2_PTV_P1 through [CONTROL_EFUSE_2\[14\]](#) LPDDR2_PTV_P5 (pullup impedance trimming)

CAUTION

Do not override the eFuse impedance compensation settings in the [CONTROL_EFUSE_2](#) register.

NOTE: There is no software control (INPUTENABLE) for the input buffer of the high-speed unterminated logic I/Os associated with the lpddr21_x, lpddr22_x, usbb1_hsic_data/strobe, and usbb2_hsic_data/strobe pads. If the CMOS buffer is enabled, it is always bidirectional (that is, the input buffer is always enabled).

18.4.12.9.3 Low-Speed I/Os Combined Slew Rate Versus TL Length and Load Settings

The low-speed I/O cells slew modes are selectable through the slew mode control SC[1:0] bit field. These settings act like coarse settings for the signal performance behavior of the low-speed I/Os. The slew rate settings determine three target maximal frequencies of I/O operation at maximum load (see [Table 18-62](#))

The low-speed I/O cells far-end capacitance load can be selected according to the transmission line (TL) length settings by modifying the load bits LB[1] and LB[0] appropriately. The four possible load bit settings described in [Table 18-63](#) are fully applicable and have maximum effect only when slew control mode 0 is selected. These settings fine tune the signal performance.

The pads featuring low-speed I/O cells require different SC[1:0] and LB[1:0] bit field settings to achieve optimal electrical performance for the multiplexed interface. This behavior may depend on various factors:

- [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#), describes the different interfaces that have SC[1:0] and LB[1:0] controls and their pad corresponding software control registers.

- The *Electrical Characteristics/DC Electrical Characteristics* section of the device data manual provides more information about the specific SC[1:0] and LB[1:0] bit field settings applicable to these interfaces multiplexed to low-speed I/O pads.
- The *Timing Parameters* section of the device data manual provides the exact system conditions (far end load, trace length, etc.) at which pad-multiplexed interface I/O timing parameters reach their boundary values.

Table 18-62. Slew Control Mode (Coarse) Settings

SC[1] bit	SC[0] bit	Slew Rate Control Mode	Maximum Frequency Achieved at Maximum Load
0	0	0	20 MHz
0	1	1	60 MHz
1	0	2	40 MHz

Table 18-63. Load Bit (Fine) Settings

LB[1] (CLoad Capacitance Control)	LB[0] (TL-Length Control)	Effective TL Length (cm)	CLoad Capacitance (pF) (per TL)
0	0	2–20	1–10
0	1	20–40 (dual TL)	1–10
1	0	2–20	10–20
1	1	20–40 (dual TL)	10–20

NOTE: The load bit modes in [Table 18-63](#) are fully applicable and have maximum effect only in the case of slew control mode 0 (SC[1:0] = 00). For slew control modes 1 and 2, LB[1:0] = 0b11 is recommended.

18.4.12.9.4 I/Os With Combined Mode and Load Settings

There are two subtypes (conditionally described as type 1 and type 2 throughout this chapter) of device I/Os, with combined mode and load settings, that differ primarily in typical output impedance and mode-specific performance. Type 1 I/Os feature a lower typical output impedance than type 2.

Both I/Os have an output buffer with an internal pad voltage SR control mechanism. Each of the type 1 and type 2 corresponding I/O cells is controlled from 2 mode bits (MB0 and MB1) and a dedicated bit (LB0) for load compensation. LB0 programs the $C_{\text{far end load}}$ for the I/O cell associated pads. [Table 18-64](#) describes the mode bit settings for each mode and lists the load bit settings.

Table 18-64. Software Controls for I/Os With Combined Mode and Load Settings

Mode	MB1	MB0	LB0
Mode 1 – SDMMC/SPI	0	1	0
Mode 2 - DMIC/GPIO	1	0	0: ($C_{\text{far end load}}^{(1)} < 15\text{pf}$) 1: ($C_{\text{far end load}} \geq 15\text{pf}$)
Mode 3 – HSI	1	1	0: ($C_{\text{far end load}} < 5\text{pf}$) 1: ($C_{\text{far end load}} \geq 5\text{pf}$)
Mode 4 - ULPI	1	1	0: ($C_{\text{far end load}} < 4\text{pf}$) 1: ($C_{\text{far end load}} \geq 4\text{pf}$)

⁽¹⁾ The $C_{\text{far end load}}$ is the external capacitance load applied at the far end of the pad signal transmission line.

The *Electrical Characteristics / DC Electrical Characteristics* section of the device data manual provides more information on the specific MB[1:0] and LB[1:0] bit field settings applicable to different interfaces multiplexed to I/O pads with combined mode and load settings. The *Timing Parameters* section of the device data manual provides the exact system conditions (far end load, trace length, etc.) at which pad-multiplexed interface I/O timing parameters reach their boundary values.

The pads featuring type 1 and type 2 I/O cells with combined mode and load settings require different MB[1:0] and LB0 bit field settings to achieve optimal electrical performance for the multiplexed interface. This behavior may depend on various factors:

- [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#), describes the different interfaces that have type 1 and type 2 MB and LB0 controls and the type 1 and type 2 I/O cell pad corresponding software control registers.
- The *Electrical Characteristics/DC Electrical Characteristics* section of the device data manual provides more information about the specific MB[1:0] and LB0 bit field settings applicable to these interfaces multiplexed to type 1 and type 2 I/O pads with combined mode and load controls.

A process-only compensation using 4-bit binary coded schema is used separately for pullup/down output parameter variations.

For type 1 I/Os, only mode 2 does not use such compensation.

For type 2 I/Os, only mode 1 and mode 2 use eFuse process-only compensation to reduce the spread in timing parameters.

The I/Os with combined mode and load controls share the same compensation settings with the I/Os with driver output impedance (DS) settings as well as with the C2CI/O buffers. They are exported from eFuse upon POR to the following bits in the [CONTROL_EFUSE_2](#) register:

- [CONTROL_EFUSE_2\[31\]](#) EFUSE_SMART2TEST_P0 through [CONTROL_EFUSE_2\[28\]](#) EFUSE_SMART2TEST_P3 (pullup output parameters trimming)
- [CONTROL_EFUSE_2\[27\]](#) EFUSE_SMART2TEST_N0 through [CONTROL_EFUSE_2\[24\]](#) EFUSE_SMART2TEST_N3 (pulldown output parameters trimming)

CAUTION

Do not override the SMART2TEST_P/SMART2TEST_N eFuse compensation settings in the [CONTROL_EFUSE_2](#) register.

18.4.12.9.5 I/O Cells With Configurable Impedance Mode

The impedance mode at which this type of I/O cell operates is selected by setting a single bit drive strength control, DS0, as follows:

- DS0 = 1 selects mode 1, corresponding to 25-Ω impedance mode
- DS0 = 0 selects mode 2, corresponding to 50-Ω impedance mode

The pads featuring I/O cell with configurable impedance mode require different DS0 bit settings to achieve optimal electrical performance for the multiplexed interface. This behavior may depend on various factors:

- [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#), describes the different interfaces that have DS0 impedance mode control and the pad corresponding software control registers.
- The *Electrical Characteristics/DC Electrical Characteristics* section of the device data manual provides more information about the specific DS0 bit settings applicable to these interfaces multiplexed to I/O pads with configurable impedance mode.

A process-only compensation using 4-bit binary coded schema is used separately for pullup/down output parameter variations. Only mode 1 and mode 2 use eFuse process-only compensation to reduce spread in timing parameters. The I/Os with DS0 impedance mode control share the same compensation settings with the I/Os with combined mode and load controls (both type 1 and type 2) as well as with the C2CI/O buffers. They are exported from eFuse upon POR to the following bits in the [CONTROL_EFUSE_2](#) register:

- [CONTROL_EFUSE_2\[31\]](#) EFUSE_SMART2TEST_P0 through [CONTROL_EFUSE_2\[28\]](#) EFUSE_SMART2TEST_P3 (pullup output parameters trimming)
- [CONTROL_EFUSE_2\[27\]](#) EFUSE_SMART2TEST_N0 through [CONTROL_EFUSE_2\[24\]](#) EFUSE_SMART2TEST_N3 (pulldown output parameters trimming)

18.4.12.9.6 C2C I/O Cells With Load Setting Adjustable According to Interface Requirement /Voltage Mode

To configure this type of I/O cell for different interfaces multiplexed on it, the user must manipulate in software a single bit, LB0, depending on type of multiplexed interface (C2C, GPMC, or SDMMC2) of the pad and the selected I/O voltage supply mode. Like LPDDR2IO, this I/O cell is provided with selectable LVCMOS and Vref-based receiver option. A Vref pad is provided to supply reference voltage to the receiver in the 1.2-V mode. To save power at lower frequency operation, LVCMOS receiver can be selected, and 2 bits, for each of the two C2C pad groups, are used to enable/disable the LVCMOS receiver, CMOSEN_C2C_FRM_CTRL, manually in the [CONTROL_C2CIO_PADCONF_0](#) register.

The pads featuring C2C I/O cells with load setting adjustable according to interface requirement/voltage mode require different LB0 bit settings to achieve optimal electrical performance for the multiplexed interface. This behavior may depend on various factors:

- [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#), describes the different interfaces that have the interface type versus voltage mode control (LB0) and the pad corresponding software control registers.
- The *Electrical Characteristics/DC Electrical Characteristics* section of the device data manual provides more information about the specific LB0 bit settings applicable to these interfaces multiplexed to I/O pads with configurable impedance mode.

NOTE: No bits are assigned to control the output drive capability of the internal C2C Vref generator (at the c2c_vref pad). It is fixed to a 2-μA current load.

If 1.2-V voltage mode is selected, the user can choose to have the LVCMOS receiver or Vref-based receiver on the C2C I/O cell pads. For the description of the dual-voltage mode settings of the C2C I/O cell pads, see [Section 18.4.12.10, Dual Voltage-Supplied Peripheral Controls](#).

In Vref-based receiver mode, the C2C I/O cell receiver is a true differential comparator with pad connected to the positive terminal and Vref tied to the negative terminal. The Vref-based receiver allows the improvement of speed performance at VDD5 = 1.2-V I/O voltage supply.

NOTE: The Vref-based receiver is not supported in 1.8-V mode. In this mode, the LVCMOS receiver is the only option.

NOTE: While at VDD5 = 1.2 V, the LVCMOS receiver is supported for all C2C I/O cell pads. The Vref-based receiver is supported on only some of these pads.

Two bits, [CONTROL_C2CIO_PADCONF_0\[12\]](#) CMOSEN_C2C_0_FRM_CTRL and [CONTROL_C2CIO_PADCONF_0\[11\]](#) CMOSEN_C2C_1_FRM_CTRL, each related to a separate group of pads, are dedicated to select Vref-based receiver mode or LVCMOS receiver mode when VDD5 = 1.2 V is selected in the [CONTROL_CORE_PADCONF_MODE](#) register.

CMOSEN_C2C_0_FRM_CTRL = 1 enables the 1.2-V mode LVCMOS receiver, and
CMOSEN_C2C_0_FRM_CTRL = 0 enables the 1.2-V Vref-based receiver for the following pads:

- gpmc_ad8–gpmc_ad15
- gpmc_ncs4
- gpmc_ncs5

CMOSEN_C2C_1_FRM_CTRL = 1 enables the 1.2-V mode LVCMOS receiver and
CMOSEN_C2C_1_FRM_CTRL = 0 enables the 1.2-V Vref-based receiver for the following pads:

- gpmc_a16–gpmc_a23

NOTE: The Vref-based receiver in 1.2-V mode is not supported for the following C2C I/O cell pads:

- gpmc_ad0–gpmc_ad7
- gpmc_a24
- gpmc_a25
- gpmc_ncs0–gpmc_ncs3
- gpmc_clk
- gpmc_nadv_ale
- gpmc_noe
- gpmc_nwe
- gpmc_nbe0_cle
- gpmc_nbe1
- gpmc_wait1
- gpmc_wait2
- gpmc_ncs6
- gpmc_ncs7

When the internal Vref generator is turned on, it supplies voltage reference to the Vref-based receivers supported for some C2C I/O cell pads and can also be used to drive external modules with 1.2-V reference. In this case, the c2c_vref device pad outputs voltage of the internal C2C Vref cell.

Setting bit [CONTROL_C2CIO_PADCONF_0\[7\] C2C_INT_VREF_AUTO_EN](#) = 0b1 enables the automatic shut-off or switch-on of the internal Vref cell generator.

If user software sets the manual control bit [CONTROL_C2CIO_PADCONF_0\[8\] C2C_INT_VREF_EN](#) = 0b1, the internal Vref cell generator is enabled, regardless of the state of the [CONTROL_C2CIO_PADCONF_0\[7\] C2C_INT_VREF_AUTO_EN](#) bit. Thus, automatic control over the C2C Vref cell generator can always be overridden in the context of enabling the Vref generator.

If the Vref cell generator is enabled, the c2c_vref pad acts as output and can be used to supply reference voltage to external devices.

NOTE: At VDD5 = 1.8-V voltage mode, the internal reference generator is shut off and the internal Vref cell reference node is connected to 0.

For the description of the dual-voltage mode settings of the C2C I/O cell pads, see [Section 18.4.12.10, Dual Voltage-Supplied Peripheral Controls](#).

CAUTION

While using the Vref cell in internal reference mode, nothing else must drive the pad externally, although the pad can be connected to supply the Vref signal to other devices.

When the internal Vref cell generator is disabled and bypassed, which is provided when [CONTROL_C2CIO_PADCONF_0\[8\] C2C_INT_VREF_EN](#) = 0b0 and [CONTROL_C2CIO_PADCONF_0\[7\] C2C_INT_VREF_AUTO_EN](#) = 0b0, the c2c_vref pad acts as input that can supply voltage reference to the Vref-based receivers from external sources.

[Table 18-65](#) lists different combinations of Vref cell control types, the state of the Vref cell, and the associated voltage reference pad direction.

Table 18-65. C2C Vref Cell State Description

C2C_INT_VREF_EN (Manual Control Bits)	C2C_INT_VREF_AUTO_EN (AUTO Control Bits)	Type of Control	Vref Cell State	Voltage Reference Pad Direction
1	x	Manual	Enabled	O
0	1	AUTO	Automatically enabled/disabled	O

Table 18-65. C2C Vref Cell State Description (continued)

C2C_INT_VREF_EN (Manual Control Bits)	C2C_INT_VREF_AUTO_EN (AUTO Control Bits)	Type of Control	Vref Cell State	Voltage Reference Pad Direction
0	0	–	Disabled and bypassed	I

CAUTION

The c2c_vref pad must be externally driven only in 1.2-V voltage mode.

According to the noise environment, the user can select to filter the reference voltage, which is supplied at the internal VREF node (receiver comparators Vref input) by the Vref cell generator or by an external source. Two coupling capacitors, internal to the C2C Vref cell, are available at the internal VREF node, which is configurable, as specified in [Table 18-66](#).

Table 18-66. C2C Vref Cell Decoupling Cap Selection

VREF_CCAP0	VREF_CCAP1	Capacitor
0	0	No capacitor connected
0	1	Capacitor between internal reference node and VDD5
1	0	Capacitor between internal reference node and VSS
1	1	Capacitor between internal reference node and VDD5 and between internal reference node and VSS

A process-only compensation using 4-bit binary coded schema is used separately for pullup/down output parameter variations. The C2C I/O buffers share the same compensation settings with the I/Os with combined mode and load controls (both with 25- and 50-Ω output) and I/Os with driver output impedance (DS) settings. They are exported from eFuse upon POR to the following bits in the [CONTROL_EFUSE_2](#) register:

- [CONTROL_EFUSE_2\[31\]](#) EFUSE_SMART2TEST_P0 through [CONTROL_EFUSE_2\[28\]](#) EFUSE_SMART2TEST_P3 (pullup output parameters trimming)
- [CONTROL_EFUSE_2\[27\]](#) EFUSE_SMART2TEST_N0 through [CONTROL_EFUSE_2\[24\]](#) EFUSE_SMART2TEST_N3 (pulldown output parameters trimming)

18.4.12.9.7 SDMMC1 Pullup Strength Control

The SDMMC1_PUSTRENGTH_GRPi (where i = 1 to 3) control bits are added in the [CONTROL_MMC1](#) register to program the pullup strength for the MMC/SD/SDIO1 I/Os group.

- [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#), describes the different interfaces that have the pullup strength control and the pad corresponding software control registers.
- The *Electrical Characteristics/DC Electrical Characteristics* section of the device data manual provides more information about the specific pullup strength settings applicable to these interfaces multiplexed to I/O pads with configurable pullup strength.

18.4.12.9.8 I2Cx I/Os Group Pullupresx Controls and Load Range Settings

The I2Cx buffer contains internal pullup resistors for both F/S and HS modes. LB[1:0] bits are used to select an appropriate pullup resistor for a given load range.

The active high GLFENB[0] bit is implemented for I²C receivers to enable glitch-free operation.

NOTE: The pullup versus load settings applicable to I2Cx FS mode also apply to I2Cx standard speed mode.

The type of pullup resistor (external or internal) for a certain I2Cx I/O group (where x = 1 to 4) is selected through the I2Cx_SCL_PULLUPRESX and I2Cx_SDA_PULLUPRESX bits which reside in the [CONTROL_I2C_0](#) register. The SR_SCL_PULLUPRESX and SR_SDA_PULLUPRESX bits reside in the [CONTROL_I2C_2](#) register, which is part of the wakeup voltage domain.

Internal pullups are activated when I2Cx_SCL_PULLUPRESX/I2Cx_SDA_PULLUPRESX = 0b0 or SR_SCL_PULLUPRESX/SR_SDA_PULLUPRESX = 0b0.

I²C functionality is not ensured if the weak internal pullup or pulldown is activated on any of the I/Os connected to the bus.

NOTE: The user must set PULLUDENABLE = 0b0 in the I2Cx padconf registers (disable internal weak pullup resistors on i2cx pads) to ensure the full I/O cell performance capabilities of the I²C.

The I²C pads require different LB[1:0] and GLFENB[0] bit field settings to achieve optimal electrical performance for the multiplexed (in MuxMode = 0x0) I²C signals. This behavior may depend on various factors:

- [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#), describes the I²C pads and their corresponding software control registers.
- The *Electrical Characteristics/DC Electrical Characteristics/I²C DC Electrical Characteristics* section of the device data manual provides more information about the specific LB[1:0] and GLFENB[0] bit settings applicable to I²C I/O pads.

18.4.12.9.9 Device Interfaces Signal Group Controls Mapping

[Table 18-67](#) through [Table 18-94](#) describe the mapping of the different signal integrity control bit fields in the different signal integrity control registers described in [Table 18-60](#).

NOTE: The same I/O cell and I/O cell controls assigned to pad signal available when Muxmode = 0 are shared between signals available on the same pad when Muxmode is selected different than 0. For more information, see [Section 18.4.8.3, Pad Multiplexing Register Fields](#).

GPIO Interface I/O Controls		
Bit Fields for Pad Group Controls	Signals (Muxmode = 3) in Group	Type of I/O Group-Associated Control Bit Fields
CONTROL_SMART1NOPMIO_PADCONF_0 [13:12] GPIOWK4_DR0_SC CONTROL_SMART1NOPMIO_PADCONF_1 [13:12] GPIOWK4_DR0_LB	gpio_wk4	Low-speed I/Os LB[1: 0] + SC[1:0] controls (See Section 18.4.12.9.3 for more information.)
CONTROL_SMART1IO_PADCONF_0 [13:12] GPIO_63_64_DR0_SC CONTROL_SMART1IO_PADCONF_1 [13:12] GPIO_63_64_DR0_LB	gpio_63 - gpio_64	Low-speed I/Os LB[1: 0]+SC[1:0] controls (See Section 18.4.12.9.3 for more information.)

Table 18-76. SDMMC1 Signal Group Parameter Controls to Different Interface I/O Pads Mapping

SDMMC1 Interface I/O Controls		
Bit Fields for Pad Group Controls	Pads (Muxmode = 0) in Group	Type of I/O Group-Associated Control Bit Fields
CONTROL_MMC1 [31] SDMMC1_PUSTRENGTH_GRP0	sdmmc1_clk	Pad pullup strength control (See Section 18.4.12.9.7 , Section 18.4.9.2 , and Section 18.5.1.2.2 for more details.)
CONTROL_MMC1 [27] SDMMC1_DR0_SPEEDCTRL		Pad speed control. (See Section 18.4.9.2 and Section 18.5.1.2.2 for more details.)

Table 18-76. SDMMC1 Signal Group Parameter Controls to Different Interface I/O Pads Mapping (continued)

SDMMC1 Interface I/O Controls		
Bit Fields for Pad Group Controls	Pads (Muxmode = 0) in Group	Type of I/O Group-Associated Control Bit Fields
CONTROL_MMC1 [30] SDMMC1_PUSTRENGTH_GRP1	sdmmc1_cmd	Pad pullup strength control (See Section 18.4.12.9.7 , Section 18.4.9.2 , and Section 18.5.1.2.2 for more details.)
CONTROL_MMC1 [27] SDMMC1_DR0_SPEEDCTRL		Pad speed control (See Section 18.4.9.2 and Section 18.5.1.2.2 for more details.)
CONTROL_MMC1 [29] SDMMC1_PUSTRENGTH_GRP2;	sdmmc1_dat0; sdmmc1_dat1	Pad pullup strength control (See Section 18.4.12.9.7 , Section 18.4.9.2 , and Section 18.5.1.2.2 for more details.)
CONTROL_MMC1 [27] SDMMC1_DR0_SPEEDCTRL		Pad speed control (See Section 18.4.9.2 and Section 18.5.1.2.2 for more details.)
CONTROL_MMC1 [29] SDMMC1_PUSTRENGTH_GRP2;	sdmmc1_dat2; sdmmc1_dat3	Pad pullup strength control (See Section 18.4.12.9.7 , Section 18.4.9.2 , and Section 18.5.1.2.2 for more details.)
CONTROL_MMC1 [25] SDMMC1_DR2_SPEEDCTRL		Pad speed control (See Section 18.4.9.2 and Section 18.5.1.2.2 for more details.)
CONTROL_MMC1 [28] SDMMC1_PUSTRENGTH_GRP3;	sdmmc1_dat4 - sdmmc1_dat7	Pad pullup strength control (See Section 18.4.12.9.7 , Section 18.4.9.2 , and Section 18.5.1.2.2 for more details.)
CONTROL_MMC1 [26] SDMMC1_DR1_SPEEDCTRL		Pad speed control (See Section 18.4.9.2 and Section 18.5.1.2.2 for more details.)

Table 18-77. SDMMC5 Signal Group Parameter Controls to Different Interface I/O Pads Mapping

SDMMC5 Interface I/O Controls		
Bit Fields for Pad Group Controls	Pads (Muxmode = 0) in Group	Type of I/O Group-Associated Control Bit Fields
CONTROL_SMART3IO_PADCONF_1 [31:30] SPI2_DR1_MB CONTROL_SMART3IO_PADCONF_2 [15] SPI2_DR1_LB	sdmmc5_clk; sdmmc5_cmd; sdmmc5_dat0	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4 , <i>I/Os With Combined Mode and Load Settings</i>)
CONTROL_SMART3IO_PADCONF_1 [29:28] SPI2_DR2_MB CONTROL_SMART3IO_PADCONF_2 [14] SPI2_DR2_LB	sdmmc5_dat1	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4 , <i>I/Os With Combined Mode and Load Settings</i>)
CONTROL_SMART3IO_PADCONF_0 [25:24] GPIO_DR5_MB CONTROL_SMART3IO_PADCONF_2 [28] GPIO_DR5_LB	sdmmc5_dat2	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4 , <i>I/Os With Combined Mode and Load Settings</i>)
CONTROL_SMART3IO_PADCONF_0 [23:22] GPIO_DR6_MB; CONTROL_SMART3IO_PADCONF_2 [27] GPIO_DR6_LB	sdmmc5_dat3	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4 , <i>I/Os With Combined Mode and Load Settings</i>)

Table 18-78. ABE McBSP1 Signal Group Parameter Controls to Different Interface I/O Pads Mapping

McBSP1Interface I/O Controls		
Bit Fields for Pad Group Controls	Pads (Muxmode = 0) in Group	Type of I/O Group-Associated Control Bit Fields
CONTROL_SMART3IO_PADCONF_3 [31:30] SLIMBUS1_DR0_MB CONTROL_SMART3IO_PADCONF_3 [19] SLIMBUS1_DR0_LB	abe_mcbbsp1_clkx	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4, I/Os With Combined Mode and Load Settings)
CONTROL_SMART3IO_PADCONF_3 [29:28] SLIMBUS1_DR1_MB CONTROL_SMART3IO_PADCONF_3 [15] SLIMBUS1_DR1_LB	abe_mcbbsp1_dr

Table 18-79. ABE McBSP2 Signal Group Parameter Controls to Different Interface I/O Pads Mapping

McBSP2 Interface I/O Controls		
Bit Fields for Pad Group Controls	Pads (Muxmode = 0) in Group	Type of I/O Group-Associated Control Bit Fields
CONTROL_SMART3IO_PADCONF_0 [15:14] MCBSP2_DR0_MB CONTROL_SMART3IO_PADCONF_2 [23] MCBSP2_DR0_LB	abe_mcbbsp2_clkx; abe_mcbbsp2_dr; abe_mcbbsp2_dx	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4, I/Os With Combined Mode and Load Settings)
CONTROL_SMART3IO_PADCONF_0 [1:0] SPI2_DR0_MB CONTROL_SMART3IO_PADCONF_2 [16] SPI2_DR0_LB	abe_mcbbsp2_fsx	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4, I/Os With Combined Mode and Load Settings)

Table 18-80. ABE McPDM Signal Group Parameter Controls to Different Interface I/O Pads Mapping

McPDM Interface I/O Controls		
Bit Fields for Pad Group Controls	Pads (Muxmode = 0) in Group	Type of I/O Group-Associated Control Bit Fields
CONTROL_SMART3IO_PADCONF_1 [7:6] PDM_DR0_MB CONTROL_SMART3IO_PADCONF_2 [7] PDM_DR0_LB	abe_pdm_ul_data; abe_pdm_dl_data; abe_pdm_frame; abe_pdm_lb_clk	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4, I/Os With Combined Mode and Load Settings)

Table 18-81. ABE DMIC Signal Group Parameter Controls to Different Interface I/O Pads Mapping

DMIC Interface I/O Controls		
Bit Fields for Pad Group Controls	Pads (Muxmode = 0) in Group	Type of I/O Group-Associated Control Bit Fields
CONTROL_SMART3IO_PADCONF_0 [31:30] DMIC_DR0_MB CONTROL_SMART3IO_PADCONF_2 [31] DMIC_DR0_LB	abe_dmic_clk1; abe_dmic_din1	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4, I/Os With Combined Mode and Load Settings)
CONTROL_SMART3IO_PADCONF_3 [27:26] SLIMBUS2_DR0_MB CONTROL_SMART3IO_PADCONF_3 [14] SLIMBUS2_DR0_LB	abe_dmic_din2	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4, I/Os With Combined Mode and Load Settings)
CONTROL_SMART3IO_PADCONF_3 [23:22] SLIMBUS2_DR2_MB CONTROL_SMART3IO_PADCONF_3 [17] SLIMBUS2_DR2_LB	abe_dmic_din3	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4, I/Os With Combined Mode and Load Settings)

Table 18-82. ABE Shared Signal Group Parameter Controls to Different Interface I/O Pads Mapping

ABE Modules Shared I/O Controls		
Bit Fields for Pad Group Controls	Pads (Muxmode = 0) in Group	Type of I/O Group-Associated Control Bit Fields
CONTROL_SMART1IO_PADCONF_0 [31:30] ABE_DR0_SC CONTROL_SMART1IO_PADCONF_1 [31:30] ABE_DR0_LB	abe_clks	Low-speed I/Os LB[1: 0] + SC[1:0] controls (See Section 18.4.12.9.3 for more information.)

Table 18-83. UART2 Signal Group Parameter Controls to Different Interface I/O Pads Mapping

UART2 Interface I/O Controls		
Bit Fields for Pad Group Controls	Pads (Muxmode = 0) in Group	Type of I/O Group-Associated Control Bit Fields
CONTROL_SMART3IO_PADCONF_1 [27:26] UART2_DR0_MB CONTROL_SMART3IO_PADCONF_2 [13] UART2_DR0_LB	uart2_cts; uart2_rts; uart2_rx	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4, I/Os With Combined Mode and Load Settings)
CONTROL_SMART3IO_PADCONF_1 [25:24] UART2_DR1_MB CONTROL_SMART3IO_PADCONF_2 [12] UART2_DR1_LB	uart2_tx	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4, I/Os With Combined Mode and Load Settings)

Table 18-84. UART3 Signal Group Parameter Controls to Different Interface I/O Pads Mapping

UART3 Interface I/O Controls		
Bit Fields for Pad Group Controls	Pads (Muxmode = 0) in Group	Type of I/O Group-Associated Control Bit Fields
CONTROL_SMART1IO_PADCONF_0 [7:6] UART3_DR0_SC CONTROL_SMART1IO_PADCONF_1 [7:6] UART3_DR0_LB	uart3_cts_rctx;	Low-speed I/Os LB[1: 0] + SC[1:0] controls (See Section 18.4.12.9.3 for more information.)
CONTROL_SMART1IO_PADCONF_0 [5:4] UART3_DR1_SC CONTROL_SMART1IO_PADCONF_1 [5:4] UART3_DR1_LB	uart3_rts_sd; uart3_rx_irrx; uart3_tx_irtx	Low-speed I/Os LB[1: 0] + SC[1:0] controls (See Section 18.4.12.9.3 for more information.)

Table 18-85. UART4 Signal Group Parameter Controls to Different Interface I/O Pads Mapping

UART4 Interface I/O Controls		
Bit Fields for Pad Group Controls	Pads (Muxmode = 0) in Group	Type of I/O Group-Associated Control Bit Fields
CONTROL_SMART3IO_PADCONF_1 [23:22] UART4_DR0_MB CONTROL_SMART3IO_PADCONF_2 [11] UART4_DR0_LB	uart4_rx; uart4_tx;	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4, I/Os With Combined Mode and Load Settings)

Table 18-86. McSPI1 Signal Group Parameter Controls to Different Interface I/O Pads Mapping

McSPI1 Interface I/O Controls		
Bit Fields for Pad Group Controls	Pads (Muxmode = 0) in Group	Type of the I/O Group-Associated Control Bit Fields
CONTROL_SMART1IO_PADCONF_0 [11:10] MCSPI1_DR0_SC CONTROL_SMART1IO_PADCONF_1 [11:10] MCSPI1_DR0_LB	mcspi1_clk; mcspi1_somi; mcspi1_simo; mcspi1_cs0	Low-speed I/Os LB[1: 0] + SC[1:0] controls (See Section 18.4.12.9.3 for more information.)
CONTROL_SMART1IO_PADCONF_0 [9:8] UART1_DR0_SC CONTROL_SMART1IO_PADCONF_1 [9:8] UART1_DR0_LB	mcspi1_cs1	Low-speed I/Os LB[1: 0] + SC[1:0] controls (See Section 18.4.12.9.3 for more information.)

Table 18-86. McSPI1 Signal Group Parameter Controls to Different Interface I/O Pads Mapping (continued)

McSPI1 Interface I/O Controls		
Bit Fields for Pad Group Controls	Pads (Muxmode = 0) in Group	Type of the I/O Group-Associated Control Bit Fields
CONTROL_SMART3IO_PADCONF_3 [25:24] SLIMBUS2_DR1_MB CONTROL_SMART3IO_PADCONF_3 [18] SLIMBUS2_DR1_LB	mcspi1_cs2	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4, I/Os With Combined Mode and Load Settings)
CONTROL_SMART3IO_PADCONF_3 [21:20] SLIMBUS2_DR3_MB CONTROL_SMART3IO_PADCONF_3 [16] SLIMBUS2_DR3_LB	mcspi1_cs3	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4, I/Os With Combined Mode and Load Settings)

Table 18-87. McSPI4 Signal Group Parameter Controls to Different Interface I/O Pads Mapping

McSPI4 Interface I/O Controls		
Bit Fields for Pad Group Controls	Pads (Muxmode = 0) in Group	Type of I/O Group-Associated Control Bit Fields
CONTROL_SMART3IO_PADCONF_0 [13:12] MCSPI4_DR0_MB CONTROL_SMART3IO_PADCONF_2 [22] MCSPI4_DR0_LB	mcspi4_clk; mcspi4_simo; mcspi4_somi;	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4, I/Os With Combined Mode and Load Settings)
CONTROL_SMART3IO_PADCONF_0 [11:10] MCSPI4_DR1_MB CONTROL_SMART3IO_PADCONF_2 [21] MCSPI4_DR1_LB	mcspi4_cs0	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4, I/Os With Combined Mode and Load Settings)

Table 18-88. I2C1 Signal Group Parameter Controls to Different Interface I/O Pads Mapping

I2C1 Interface I/O Controls		
Bit Fields for Pad Group Controls	Pads (Muxmode = 0) in Group	Type of I/O Group-Associated Control Bit Fields
CONTROL_I2C_0 [3] I2C1_SCL_GLFENB	i2c1_scl	Enable glitch-free operation for I ² C receiver (See Section 18.4.12.9.8 for more information.)
CONTROL_I2C_0 [2:1] I2C1_SCL_LOAD_BITS		LB[1:0] – load bit controls to select internal pullup resistor value (See for more information.)
CONTROL_I2C_0 [0] I2C1_SCL_PULLUPRESX		Bit to enable internal pullup resistor option (See Section 18.4.12.9.8 for more information.)
CONTROL_I2C_0 [19] I2C1_SDA_GLFENB	i2c1_sda	Enable glitch-free operation for I ² C receiver (See Section 18.4.12.9.8 for more information.)
CONTROL_I2C_0 [18:17] I2C1_SDA_LOAD_BITS		LB[1:0] – load bit controls to select internal pullup resistor value (See Section 18.4.12.9.8 for more information.)
CONTROL_I2C_0 [16] I2C1_SDA_PULLUPRESX		Bit to enable internal pullup resistor option (See Section 18.4.12.9.8 for more information.)

Table 18-89. I2C2 Signal Group Parameter Controls to Different Interface I/O Pads Mapping

I2C2 Interface I/O Controls		
Bit Fields for Pad Group Controls	Pads (Muxmode = 0) in Group	Type of I/O Group-Associated Control Bit Fields
CONTROL_I2C_0[7] I2C2_SCL_GLFENB	i2c2_scl	Enable glitch-free operation for I ² C receiver (See Section 18.4.12.9.8 for more information.)
CONTROL_I2C_0[6:5] I2C2_SCL_LOAD_BITS		LB[1:0] – load bit controls to select internal pullup resistor value (See for more information.)
CONTROL_I2C_0[4] I2C2_SCL_PULLUPRESX		Bit to enable internal pullup resistor option (See Section 18.4.12.9.8 for more information.)
CONTROL_I2C_0[23] I2C2_SDA_GLFENB	i2c2_sda	Enable glitch-free operation for I ² C receiver (See Section 18.4.12.9.8 for more information.)
CONTROL_I2C_0[22:21] I2C2_SDA_LOAD_BITS		LB[1:0] – load bit controls to select internal pullup resistor value (See for more information.)
CONTROL_I2C_0[20] I2C2_SDA_PULLUPRESX		Bit to enable internal pullup resistor option (See Section 18.4.12.9.8 for more information.)

Table 18-90. I2C3 Signal Group Parameter Controls to Different Interface I/O Pads Mapping

I2C3 Interface I/O Controls		
Bit Fields for Pad Group Controls	Pads (Muxmode = 0) in Group	Type of I/O Group-Associated Control Bit Fields
CONTROL_I2C_0[11] I2C3_SCL_GLFENB	i2c3_scl	Enable glitch-free operation for I ² C receiver (See Section 18.4.12.9.8 for more information.)
CONTROL_I2C_0[10:9] I2C3_SCL_LOAD_BITS		LB[1:0] – load bit controls to select internal pullup resistor value (See for more information.)
CONTROL_I2C_0[8] I2C3_SCL_PULLUPRESX		Bit to enable internal pullup resistor option (See Section 18.4.12.9.8 for more information.)
CONTROL_I2C_0[27] I2C3_SDA_GLFENB	i2c3_sda	Enable glitch-free operation for I ² C receiver (See Section 18.4.12.9.8 for more information.)
CONTROL_I2C_0[26:25] I2C3_SDA_LOAD_BITS		LB[1:0] - load bit controls to select internal pullup resistor value (See for more information.)
CONTROL_I2C_0[24] I2C3_SDA_PULLUPRESX		Bit to enable internal pullup resistor option (See Section 18.4.12.9.8 for more information.)

Table 18-91. I2C4 Signal Group Parameter Controls to Different Interface I/O Pads Mapping

I2C4 Interface I/O Controls		
Bit Fields for Pad Group Controls	Pads (Muxmode = 0) in Group	Type of I/O Group-Associated Control Bit Fields
CONTROL_I2C_0[15] I2C4_SCL_GLFENB	i2c4_scl	Enable glitch-free operation for I ² C receiver (See Section 18.4.12.9.8 for more information.)
CONTROL_I2C_0[14:13] I2C4_SCL_LOAD_BITS		LB[1:0] – load bit controls to select internal pullup resistor value (See for more information.)
CONTROL_I2C_0[12] I2C4_SCL_PULLUPRESX		Bit to enable internal pullup resistor option (See Section 18.4.12.9.8 for more information.)
CONTROL_I2C_0[31] I2C4_SDA_GLFENB	i2c4_sda	Enable glitch-free operation for I ² C receiver (See Section 18.4.12.9.8 for more information.)
CONTROL_I2C_0[30:29] I2C4_SDA_LOAD_BITS		LB[1:0] – load bit controls to select internal pullup resistor value (See for more information.)
CONTROL_I2C_0[28] I2C4_SDA_PULLUPRESX		Bit to enable internal pullup resistor option (See Section 18.4.12.9.8 for more information.)

Table 18-92. SR Signal Group Parameter Controls to Different Interface I/O Pads Mapping

SR Interface I/O Controls		
Bit Fields for Pad Group Controls	Pads (Muxmode = 0) in Group	Type of I/O Group-Associated Control Bit Fields
CONTROL_I2C_2[31] SR_SCL_GLFENB	sr_scl	Enable glitch-free operation for SmartReflex I ² C receiver (See Section 18.4.12.9.8 for more information.)
CONTROL_I2C_2[30:29] SR_SCL_LOAD_BITS		LB[1:0] – load bit controls to select internal pullup resistor value (See for more information.)
CONTROL_I2C_2[28] SR_SCL_PULLUPRESX		Bit to enable internal pullup resistor option (See Section 18.4.12.9.8 for more information.)
CONTROL_I2C_2[27] SR_SDA_GLFENB	sr_sda	Enable glitch-free operation for SmartReflex I ² C receiver (See Section 18.4.12.9.8 for more information.)
CONTROL_I2C_2[26:25] SR_SDA_LOAD_BITS		LB[1:0] – load bit controls to select internal pullup resistor value (See for more information.)
CONTROL_I2C_2[24] SR_SDA_PULLUPRESX		Bit to enable internal pullup resistor option. (See Section 18.4.12.9.8 for more information.)

Table 18-93. System Signals Group Parameter Controls to Different Interface I/O Pads Mapping

System Interface I/O Controls		
Bit Fields for Pad Group Controls	Pads (Muxmode = 0) in Group	Type of I/O Group-Associated Control Bit Fields
CONTROL_SMART1NOPMIO_PADCONF_0 [31:30] FREF_DR0_SC CONTROL_SMART1NOPMIO_PADCONF_1 [31:30] FREF_DR0_LB	fref_clk_ioreq	Low speed I/Os LB[1: 0] + SC[1:0] controls (See Section 18.4.12.9.3 for more information.)
CONTROL_SMART3NOPMIO_PADCONF_0 [31:30] FREF_DR1_MB CONTROL_SMART3NOPMIO_PADCONF_1 [31] FREF_DR1_LB0	fref_clk0_out	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4, I/Os With Combined Mode and Load Settings)
CONTROL_SMART3IO_PADCONF_1 [5:4] FREF_DR2_MB CONTROL_SMART3IO_PADCONF_2 [6] FREF_DR2_LB	fref_clk1_out	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4, I/Os With Combined Mode and Load Settings)
CONTROL_SMART3IO_PADCONF_1 [3:2] FREF_DR3_MB CONTROL_SMART3IO_PADCONF_2 [9] FREF_DR3_LB	fref_clk2_out	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4, I/Os With Combined Mode and Load Settings)
CONTROL_SMART3NOPMIO_PADCONF_0 [23:22] FREF_DR4_MB CONTROL_SMART3NOPMIO_PADCONF_1 [27] FREF_DR4_LB0	fref_clk3_req	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4, I/Os With Combined Mode and Load Settings)
CONTROL_SMART3NOPMIO_PADCONF_0 [29:28] FREF_DR5_MB CONTROL_SMART3NOPMIO_PADCONF_1 [30] FREF_DR5_LB0	fref_clk3_out	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4, I/Os With Combined Mode and Load Settings)
CONTROL_SMART3NOPMIO_PADCONF_0 [27:26] FREF_DR6_MB CONTROL_SMART3NOPMIO_PADCONF_1 [29] FREF_DR6_LB0	fref_clk4_req	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4, I/Os With Combined Mode and Load Settings)
CONTROL_SMART3NOPMIO_PADCONF_0 [25:24] FREF_DR7_MB CONTROL_SMART3NOPMIO_PADCONF_1 [28] FREF_DR7_LB0	fref_clk4_out	Type 2 I/Os with MB[1:0] + LB[0] settings (for more information, see Section 18.4.12.9.4, I/Os With Combined Mode and Load Settings)
CONTROL_SMART1NOPMIO_PADCONF_0 [19:18] GPIO_DR7_SC CONTROL_SMART1NOPMIO_PADCONF_1 [19:18] GPIO_DR7_LB	sys_pwron_reset_out	Low-speed I/Os LB[1: 0] + SC[1:0] controls (See Section 18.4.12.9.3 for more information.)
CONTROL_SMART1IO_PADCONF_0 [23:22] GPIO_DR8_SC CONTROL_SMART1IO_PADCONF_1 [23:22] GPIO_DR8_LB	sys_nirq2	Low-speed I/Os LB[1: 0] + SC[1:0] controls (See Section 18.4.12.9.3 for more information.)
CONTROL_SMART1IO_PADCONF_0 [21:20] GPIO_DR9_SC CONTROL_SMART1IO_PADCONF_1 [21:20] GPIO_DR9_LB	sys_boot0 -sys_boot5	Low-speed I/Os LB[1: 0] + SC[1:0] controls (See Section 18.4.12.9.3 for more information.)

Table 18-93. System Signals Group Parameter Controls to Different Interface I/O Pads Mapping (continued)

System Interface I/O Controls		
Bit Fields for Pad Group Controls	Pads (Muxmode = 0) in Group	Type of I/O Group-Associated Control Bit Fields
CONTROL_SMART1NOPMIO_PADCONF_0 [15:14] DPM_DR0_SC CONTROL_SMART1NOPMIO_PADCONF_1 [15:14] DPM_DR0_LB	sys_boot6; sys_boot7	Low-speed I/Os LB[1: 0] + SC[1:0] controls (See Section 18.4.12.9.3 for more information.)

Table 18-94. DPM Signals Group Parameter Controls to Different Interface I/O Pads Mapping

System Interface I/O Controls		
Bit Fields for Pad Group Controls	Pads (Muxmode = 0) in Group	Type of I/O Group-Associated Control Bit Fields
CONTROL_SMART2IO_PADCONF_2 [31] DPM_DR1_DS	dpm_emu0; dpm_emu1	I/O cell with single-bit drive strength (DS) control for driver output impedance (See Section 18.4.12.9.5 for more information.)
CONTROL_SMART2IO_PADCONF_2 [15] USB_A0_DR0_DS	dpm_emu2	I/O cell with single-bit drive strength (DS) control for driver output impedance (See Section 18.4.12.9.5 for more information.)
CONTROL_SMART2IO_PADCONF_2 [14] USB_A0_DR1_DS	dpm_emu3 - dpm_emu5	I/O cell with single-bit drive strength (DS) control for driver output impedance (See Section 18.4.12.9.5 for more information.)
CONTROL_SMART2IO_PADCONF_2 [19] UART3_DR2_DS	dpm_emu6	I/O cell with single-bit drive strength (DS) control for driver output impedance (See Section 18.4.12.9.5 for more information.)
CONTROL_SMART2IO_PADCONF_2 [18] UART3_DR3_DS	dpm_emu7	I/O cell with single-bit drive strength (DS) control for driver output impedance (See Section 18.4.12.9.5 for more information.)
CONTROL_SMART2IO_PADCONF_2 [17] UART3_DR4_DS	dpm_emu8	I/O cell with single-bit drive strength (DS) control for driver output impedance (See Section 18.4.12.9.5 for more information.)
CONTROL_SMART2IO_PADCONF_2 [16] UART3_DR5_DS	dpm_emu9	I/O cell with single-bit drive strength (DS) control for driver output impedance (See Section 18.4.12.9.5 for more information.)
CONTROL_SMART2IO_PADCONF_2 [13] USB_A_DR2_DS	dpm_emu10 - dpm_emu13	I/O cell with single-bit drive strength (DS) control for driver output impedance (See Section 18.4.12.9.5 for more information.)
CONTROL_SMART2IO_PADCONF_2 [28] GPIO_DR10_DS	dpm_emu14 ; dpm_emu15	I/O cell with single-bit drive strength (DS) control for driver output impedance (See Section 18.4.12.9.5 for more information.)
CONTROL_SMART2IO_PADCONF_2 [30] DPM_DR2_DS	dpm_emu16; dpm_emu17	I/O cell with single-bit drive strength (DS) control for driver output impedance (See Section 18.4.12.9.5 for more information.)
CONTROL_SMART2IO_PADCONF_2 [29] DPM_DR3_DS	dpm_emu18; dpm_emu19	I/O cell with single-bit drive strength (DS) control for driver output impedance (See Section 18.4.12.9.5 for more information.)

18.4.12.10 Dual Voltage-Supplied Peripheral Controls

Some of the peripheral I/Os have the option to be supplied with a 1.2-V or 1.8-V power supply (VDDS through device external pads). The power supply level to the dual-voltage I/Os of different peripherals is configurable through bit fields in the [CONTROL_CORE_PADCONF_MODE](#) register in the CORE power domain (EMIF, GPMC, C2C, CAMERA, SDMMC2 I/Os) and the [CONTROL_WKUP_PADCONF_MODE](#) register in the WKUP power domain (EMIF and FREF generator). One control bit in these registers is dedicated to set dual voltage per group of pads.

NOTE: Dynamic switching between 1.2-V and 1.8-V voltage modes on dual-voltage peripheral I/Os is not allowed.

[Table 18-95](#) describes dual-voltage controls versus the mapping of different pads.

Table 18-95. Dual-Voltage Peripheral Control Bits vs Pad Mapping

18.5 Control Module Programming Guide

18.5.1 Control Module Low-Level Programming Models

This section covers the low-level programming sequences for configuration and use of the control module.

18.5.1.1 Global Initialization

18.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the control module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the environment and integration of the control module. For more information, see [Section 18.2](#), *Control Module Environment*, and [Section 18.3](#), *Control Module Integration*.

Table 18-96. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The two clocks, CFG_L4_ICLK and WKUP_L4_ICLK2, coming from the PRCM module are not software-controlled by the module. For more information about the two clocks, see Section 3.6.3.2.4 , <i>CM2 Clock Generator</i> , and Section 3.6.3.1 , <i>PRM Clock Source</i> , in Chapter 3 , <i>Power, Reset, and Clock Management</i> .
L4 interconnect	For information about the L4_CFG interconnect configuration, see Section 13.3 , <i>L4 Interconnects</i> , in Chapter 13 , <i>Interconnects</i> .

18.5.1.1.2 Control Module Global Initialization

18.5.1.1.2.1 Software Reset

The control module is not sensitive to a software reset.

18.5.1.1.2.2 Clock Gating Configuraton

As described in [Section 18.4.2](#), *Control Module Clock Configuration*, the programmer can choose clock-gating strategy individually for each of the four control module instances. [Table 18-97](#) explains the necessary steps.

Table 18-97. Configure Clock Gating for Different Control Module Instances

Step	Register/Bit Field/Programming Model	Value
1. Set clock gating for SYSCTRL_PADCONF_CORE.	CONTROL_PADCONF_CORE_SYSCONFIG[3:2]	0x-
2. Set clock gating for SYSCTRL_PADCONF_WKUP.	CONTROL_PADCONF_WKUP_SYSCONFIG[3:2]	0x-
3. Set clock gating for SYSCTRL_GENERAL_CORE.	CONTROL_GEN_CORE_SYSCONFIG[3:2]	0x-
4. Set clock gating for SYSCTRL_GENERAL_WKUP.	CONTROL_GEN_WKUP_SYSCONFIG[3:2]	0x-

18.5.1.2 Operational Modes Configuration

18.5.1.2.1 Video Driver Configuration

This section gives information about all modules and features in the high-tier device.

For more information about video digital-to-analog (DAC), see [Section 10.6](#), *Video Encoder*. [Table 18-98](#) lists the steps to configure the control module AVDAC.

Table 18-98. Control Module AVDAC Configuration

Step	Register/Bit Field/Programming Model	Value
1. Video buffer is bypassed/not bypassed.	CONTROL_AVDAC[30] AVDAC_TVOUTBYPASS	0b-
2. Enable/disable ac coupling for TV output.	CONTROL_AVDAC[31] AVDAC_ACEN	0b-

18.5.1.2.2 Extended-Drain I/Os and PBIAS Cells Programming Guide

This section describes the programming flow to go from 3.0 V to 1.8 V, and vice versa, when operating with the extended-drain I/Os and PBIAS cells. [Figure 18-20](#) shows the configuration of the PBIAS cell to operate in different modes (interrupt method).

[Table 18-99](#) provides the register settings for configuring the MMC1_PBIAS and MMC1 I/O cells, and [Table 18-100](#) provides the register settings for configuring the PBIAS1 cell, USBC1_ICUSB cell, and gpio_wk0gpio_wk2 associated I/O cells.

Figure 18-20. Configuring PBIAS Cell to Operate in Different Modes, Interrupt Method

sysctrl-021

Table 18-99. Register Settings for Configuring the MMC1_PBIAS and MMC1 I/O Cells

Procedure Name	Description	Register Settings
1. Enable PWRDNZ mode for MMC1_PBIAS cell , and MMC/SD/SDIO1 I/O cell.	Software must keep MMC1_PBIAS cell and MMC1_IO cell PWRDNZ signals low whenever SDMMC1_VDDS ramps up/down or changes. This is for cell protection purposes.	1. Set CONTROL_PBIASLITE [22] MMC1_PBIASLITE_PWRDNZ = 0b0. 2. Set CONTROL_PBIASLITE [26] MMC1_PWRDNZ = 0b0.
2. Preliminary MMC1_PBIAS and MMC1 I/O cell settings	Enable MMC1_PBIAS cell output and MMC1_PBIAS error associated interrupt. Select desired I/Os within the MMC1 I/O cell and set their corresponding pad configuration fields appropriately. Set the group speed and pullup strength controls for the MMC/SD/SDIO1 pads.	1. Set CONTROL_PBIASLITE [25] MMC1_PBIASLITE_HIZ_MODE = 0b0. 2. See Chapter 17, Interrupt Controller , for more information about setting MA_IRQ_75 line associated interrupt request PBIAS_IRQ. 3. For I/O multiplexing and pad configuration settings, see Section 18.5.1.2.5, Pad Configuration Programming Points . 4. Set the speed control bits for the MMC1 I/O cell pads: <ul style="list-style-type: none"> • CONTROL_MMC1[27] SDMMC1_DR0_SPEEDCTRL = 0b- • CONTROL_MMC1[26] SDMMC1_DR1_SPEEDCTRL = 0b- • CONTROL_MMC1[28] SDMMC1_DR2_SPEEDCTRL = 0b- 5. Set the pullup strength control bits for the MMC1 I/O cell pad groups: <ul style="list-style-type: none"> • CONTROL_MMC1[31] SDMMC1_PUSTRENGTH_GRP0=0b- • CONTROL_MMC1[30] SDMMC1_PUSTRENGTH_GRP1=0b- • CONTROL_MMC1[29] SDMMC1_PUSTRENGTH_GRP2=0b- • CONTROL_MMC1[28] SDMMC1_PUSTRENGTH_GRP3=0b-
3. Program the desired SDMMC1_VDDS voltage for MMC/SD/SDIO1 I/Os.	Program external power supply IC to generate appropriate SDMMC1_VDDS voltage: 3.0 V/1.8 V).	For more information about I ² C interface operation, see Section 23.1, Multimaster High-Speed I²C .
4. Set VMODE bit appropriately.	PBIAS voltage generation is based on the value of VMODE, set according to externally applied SDMMC1_VDDS voltage.	Set CONTROL_PBIASLITE [21] MMC1_PBIASLITE_VMODE = 0b- ⁽¹⁾
5. Check if SDMMC1_VDDS supply is stabilized?	Check the state of the externally generated SDMMC1_VDDS voltage, which is provided through communication between the device and external power supply device over the I ² C interface.	For more information about I ² C interface settings, see Section 23.1, Multimaster High-Speed I²C .
6. Disable PWRDNZ (power down) mode for MMC1_PBIAS and associated extended-drain MMC1 I/O cell.	This starts up the MMC1_PBIAS cell work to generate the PBIAS voltage.	1. Set CONTROL_PBIASLITE [22] MMC1_PBIASLITE_PWRDNZ = 0b1. 2. Set CONTROL_PBIASLITE [26] MMC1_PWRDNZ = 0b1.
7. Store SUPPLY_HI_OUT bit state.	Done as a preliminary step for error-handling analysis. (Whenever PWRDNZ = 0b0, SUPPLY_HI_OUT is unconditionally set to 0b0.)	Store CONTROL_PBIASLITE [24] MMC1_PBIASLITE_SUPPLY_HI_OUT bit in memory.
8. Enable PWRDNZ mode upon error occurrence.	It is recommended that all the I/Os are powered down (PWRDNZ = 0) as soon as VMODE_ERROR is high.	1. Set CONTROL_PBIASLITE [26] MMC1_PWRDNZ = 0b0 . 2. Set CONTROL_PBIASLITE [22]MMC1_PBIASLITE_PWRDNZ = 0b0.
9. Does SUPPLY_HI_OUT correspond to the desired SDMMC1_VDDS?	Test if error comes from incorrectly set SDMMC1_VDDS value or incorrectly set VMODE bit.	Check the SUPPLY_HI_OUT bit stored in memory.
10. Correct VMODE bit	If SUPPLY_HI_OUT level corresponds to desired SDMMC1_VDDS value, then correct the value of the VMODE bit.	Modify the value of the CONTROL_PBIASLITE [21] MMC1_PBIASLITE_VMODE bit.
11. Correct SDMMC1_VDDS value.	If SUPPLY_HI_OUT is different from expected, correct and set SDMMC1_VDDS value over I ² C again.	For more information about I ² C interface settings, see Section 23.1, Multimaster High-Speed I²C .
12. Clear Interrupt status.	Clear the IRQ_MA_75 interrupt status flag.	For more information about setting the MA_IRQ_75 line associated interrupt request PBIAS_IRQ, see Chapter 17, Interrupt Controller .

⁽¹⁾ Must be set high when external MMC1_VDDS source programmed to be 3.0 V, or low when external MMC1_VDDS source programmed to be 1.8 V. Reset default value corresponds to 3.0 V.

Table 18-100. Register Settings for Configuring the PBIAS1 Cell, USBC1_ICUSB, and gpio_wk0gpio_wk2 Associated I/O Cells

Procedure Name	Description	Register Settings
1. Enable PWRDNZ mode for the PBIAS1 cell USBC1_ICUSB I/O cell, and gpio_wk0–gpio_wk2 associated I/O cells.	Software must keep PBIAS1 cell and the associated USBC1_ICUSB and gpio_wk0gpio_wk2 I/O cells PWRDNZ signals low whenever SIM_VDDS is ramps up/down or changes. This is for cell protection purposes.	1. Set CONTROL_PBIASLITE [28] PBIASLITE1_PWRDNZ = 0b0. 2. Set CONTROL_PBIASLITE [20] USBC1_ICUSB_PWRDNZ = 0b0. 3. Set CONTROL_GPIOWK [28] GPIOWK_IO_PWRDNZ = 0b0.
2. Preliminary PBIAS1 cell, USBC1_ICUSB, and gpio_wk0–gpio_wk2 cell settings	Enable PBIAS1 cell output and USBC1_ICUSB and gpio_wk0–gpio_wk2 error associated interrupt. Select desired I/Os within the USBC1_ICUSB and GPIOWK I/O cells and set their corresponding pad configuration fields appropriately. Set the speed and pulldown controls for the pads (if applicable).	1. Set CONTROL_PBIASLITE [31] PBIASLITE1_HIZ_MODE = 0b0. 2. See Chapter 17, Interrupt Controller , for more information about setting MA_IRQ_75 line associated interrupt request PBIAS_IRQ. 3. For I/O multiplexing and pad configuration settings, see Section 18.5.1.2.5, Pad Configuration Programming Points . 4. Set the speed control bits for USBC1_ICUSB I/O cell pads CONTROL_MMC1 [24] USBC1_DR0_SPEEDCTRL = 0b- (No speedctrl available for GPIOWK associated I/O cell). 5. Disable strong pulldowns on the gpio_wk1 and gpio_wk2 pads available by default after reset: <ul style="list-style-type: none"> CONTROL_GPIOWK[31] PAD_GPIO_WK1_LOW = 0b0 CONTROL_GPIOWK[29] PAD_GPIO_WK2_LOW = 0b0
3. Program the desired SIM_VDDS voltage for the USBC1_ICUSB/gpio_wk0–gpio_wk2 or(hw_dbg1–hw_dbg3 in WKUP domain) I/Os.	Program external power supply IC to generate appropriate SIM_VDDS voltage: 3.0 V/1.8 V	For more information about I ² C interface operation, see Section 23.1, Multimaster High-Speed I²C
4. Set VMODE bit appropriately.	PBIAS voltage generation is based on the value of VMODE, set according to externally applied SIM_VDDS voltage.	Set CONTROL_PBIASLITE [27] PBIASLITE1_VMODE = 0b-. ⁽¹⁾
5. Check if SIM_VDDS supply is stabilized?	Check the state of the externally generated SIM_VDDS voltage. This is provided through communication between device and companion power supply device over the I ² C interface.	For more information about I ² C interface settings, see Section 23.1, Multimaster High-Speed I²C ,
6. Disable PWRDNZ mode for PBIAS1 cell and its associated extended-drain USBC1_ICUSB and gpio_wk0–gpio_wk2 I/O cells.	This starts up the the PBIAS1 cell work to generate the PBIAS voltage.	1. Set CONTROL_PBIASLITE [28] PBIASLITE1_PWRDNZ = 0b1. 2. Set CONTROL_PBIASLITE [20] USBC1_ICUSB_PWRDNZ = 0b1. 3. Set CONTROL_GPIOWK [28] GPIOWK_IO_PWRDNZ = 0b1.
7. Store SUPPLY_HI_OUT bit state.	Done as a preliminary step for error-handling analysis. (Whenever PWRDNZ = 0b0, SUPPLY_HI_OUT is unconditionally set to 0b0.)	Store the CONTROL_PBIASLITE [30] PBIASLITE1_SUPPLY_HI_OUT bit in memory.
8. Enable PWRDNZ mode upon error occurrence.	It is recommended that all the I/Os are powered down (PWRDNZ = 0) as soon as VMODE_ERROR is high.	1. Set CONTROL_PBIASLITE [28] PBIASLITE1_PWRDNZ = 0b0. 2. Set CONTROL_PBIASLITE [20] USBC1_ICUSB_PWRDNZ = 0b0. 3. Set CONTROL_GPIOWK [28] GPIOWK_IO_PWRDNZ = 0b0.
9. Does SUPPLY_HI_OUT correspond to the desired SIM_VDDS level?	Test if error comes from incorrectly set SIM_VDDS value or incorrectly set VMODE bit.	Check the SUPPLY_HI_OUT bit stored in memory.
10. Correct VMODE bit.	If SUPPLY_HI_OUT level corresponds to desired SIM_VDDS value, then correct the value of the VMODE bit.	Modify the value of the CONTROL_PBIASLITE [27] PBIASLITE1_VMODE bit.
11. Correct SIM_VDDS value.	If SUPPLY_HI_OUT is different than expected, correct and set SIM_VDDS value over I ² C again.	For more information about I ² C interface settings, see Section 23.1, Multimaster High-Speed I²C .
12. Clear interrupt status.	Clear the IRQ_MA_75 interrupt status flag.	For more information about setting the MA_IRQ_75 line associated interrupt request PBIAS_IRQ, see Chapter 17, Interrupt Controller .

⁽¹⁾ Must be set high when external SIM_VDDS source programmed to be 3.0 V, or low when external SIM_VDDS source programmed to be 1.8 V. Reset default value corresponds to 3.0 V. Reset default value corresponds to 3.0 V.

18.5.1.2.3 Hardware Observability Settings

This section describes the procedures to control hardware observability features of the device. To configure hardware observability feature, the programmer must perform the steps listed in [Table 18-101](#).

Table 18-101. Configure Hardware Observability Features

Step	Register/Bit Field/Programming Model	Value
1. Select hwobs(0) signal frequency divider value (applies only to po_hw_dbg0 bus signal propagated in the CORE power domain).	CONTROL_HWOBS_CONTROL [7:3] HWOBS_CLKDIV_SEL	0x- ⁽¹⁾
2. Enable/disable hwobs gating and alternatively set all hwobs ports to 0 or 1.	1. CONTROL_HWOBS_CONTROL [2] HWOBS_ALL_ZERO_MODE 2. CONTROL_HWOBS_CONTROL [1] HWOBS_ALL_ONE_MODE	0x- ⁽²⁾
3. Enable/disable hwobs port gating only for signals coming from IPs identified in the MACRO group (applies only to po_hw_dbg bus signals propagated in the CORE power domain).	CONTROL_HWOBS_CONTROL [0] HWOBS_MACRO_ENABLE	0x- ⁽³⁾
4. Associate a certain hwobs channel to the CORE or WKUP power domain.	Configure each bit from the CONTROL_DEBOBS_FINAL_MUX_SEL [31:0] SELECT bit field appropriately for its corresponding hw_dbg channel.	0x-
5. Choose the source of a signal or signal view channel in the CORE power domain.	Configure each of the bit fields CONTROL_CORE_CONF_DEBUG_SEL_TST_0 [3:0] MODE through CONTROL_CORE_CONF_DEBUG_SEL_TST_31 [3:0] MODE appropriately for its corresponding hw_dbg channel.	0x-
6. Choose the source of a signal within the WKUP power domain.	Configure each bit CONTROL_WKUP_CONF_DEBUG_SEL_TST_i [0] MODE, (where i =0 to 31) appropriately for its corresponding hw_dbg channel i (where i = 0 to 31).	0x-
7. Choose to associate a certain DPLL signal to a given DPLL signal view channel (applies only to po_hw_dbg bus signals propagated in the CORE power domain).	1. CONTROL_CONF_DPLL_FREQLOCK_SEL [2:0] MULT 2. CONTROL_CONF_DPLL_TINITZ_SEL [2:0] MULT 3. CONTROL_CONF_DPLL_PHASELOCK_SEL [2:0] MULT 4. CONTROL_CONF_DPLL_TENABLE_SEL [2:0] MULT 5. CONTROL_CONF_DPLL_TENABLEDIV_SEL [2:0] MULT 6. CONTROL_CONF_DPLL_BYPASSACK_SEL [2:0] MULT 7. CONTROL_CONF_DPLL_IDLE_SEL [2:0] MULT	0x-
9. Choose to associate a certain clockout signal to a given clockview channel (applies only to po_hw_dbg bus signals propagated in the CORE power domain).	CONTROL_CONF_CLK_SEL0 [2:0] MULT through CONTROL_CONF_CLK_SEL2 [2:0] MULT	0x-
10. Choose to associate an sDMA signal to a given sDMA view channel (applies only to po_hw_dbg bus signals propagated in the CORE power domain).	CONTROL_CONF_SDMA_REQ_SEL0 [6:0] MULT through CONTROL_CONF_SDMA_REQ_SEL3 [6:0] MULT	0x-
11. Set the appropriate pad configuration bit fields to associate hw_dbg0 pad function to output pins and configure additional output pad features.	For more information, see Section 18.4.11, Hardware Observability , and Section 18.4.8, Pad Functional Multiplexing and Configuration .	See Section 18.4.8, PAD Functional Multiplexing and Configuration , for more information

⁽¹⁾ To configure the hwobs(0) channel to operate normally, the value of the HWOBS_CLKDIV_SEL bit must be set different from 0.

⁽²⁾ Set both bits to 0 to enable hardware observability. Set only one of them to 1 to gate hwobs ports according to output state required.

⁽³⁾ The modules which belong to this group are: Cortex-A9 MPU subsystem, IVA-HD, display subsystem, CM2, and ABE.

For more information about different functionalities and registers associated with the hardware observability features, see [Section 18.4.11, Hardware Observability](#).

18.5.1.2.4 Off Mode Preliminary Settings

This section describes configurations of pads to work in off mode. [Table 18-102](#) lists the actions that must be performed once, and remain valid for all device OFF <-> ON transitions.

Table 18-102. Setting Pads Off Mode Through Padconfiguration Registers

Step	Register/Bit Field/Programming Model	Value
1. Set the OFFMODEPULLTYPESELECT bit.	CONTROL_CORE_PAD0_X_PAD1_Y[29,13]: Select pullup/down type when pad in off mode.	0b-
2. Set the OFFMODEPULLUDENABLE bit.	CONTROL_CORE_PAD0_X_PAD1_Y[28,12]: Enable/disable pullup/down feature when pad in off mode.	0b-
3. Set the OFFMODEOUTVALUE bit.	CONTROL_CORE_PAD0_X_PAD1_Y[27,11]: Set off mode pad override value.	0b-
4. Set the OFFMODEENABLE bit (enable/disable pad overriding capability in off mode).	CONTROL_CORE_PAD0_X_PAD1_Y[25,9]: Set pad to keep its previous state (it had before going to off mode) or force pad output to a certain override value (OFFMODEOUTVALUE) when pad in off mode.	0b-
5. Set the OFFMODEOUTENABLE bit.	CONTROL_CORE_PAD0_X_PAD1_Y[26,10]: Enable/disable output in off mode.	0b-
6. Program a valid device ACTIVE pads configuration.	See Table 18-103 for more information about ACTIVE pads configuration.	
7. Set the clock-gating strategy.	1. CONTROL_PADCONF_CORE_SYSCONFIG [3:2] IP_SYSCONFIG 2. CONTROL_PADCONF_WKUP_SYSCONFIG [3:2] IP_SYSCONFIG	0x2 ,0x3
8. Enable/disable the wake-up detection capability. ⁽¹⁾	CONTROL_CORE_PAD0_X_PAD1_Y[30,14]	0b-

⁽¹⁾ When the wake-up detection is enabled for a pad, this pad is configured as input. Therefore, do not forget to write 0b1 in the OFFOUTENABLE bit to disable the output capability.

18.5.1.2.5 Pad Configuration Programming Points

This section describes through an example the configurations of pads necessary for working in active mode.

To configure the pad, ensure that the following steps are done:

1. Identify signals required on the interface based on the target application.

Example: To configure the UART2 interface on balls, the required signals are uart2_tx, uart2_rts, uart2_cts, and uart2_rx.

2. Choose the pads used for those signals. Some signals may be available on several pads and/or may be multiplexed with other signals needed for another application. See [Section 18.4.8.3, Pad Multiplexing Register Fields](#).

Example: Unlike the UART2 interface signals, uart2_rx and uart2_tx, each of which is available on two pads, the uart2_cts and uart2_rts signals are available on only one pad each (MUXMODE = 0b000). However, uart2_cts is multiplexed with the MMC I/O signal sdmmc3_clk and uart2_rts is multiplexed with the MMC I/O signal sdmmc3_cmd on the same pad. Assume that the MMC I/O 3 interface is also required in the system. Therefore, for the MMC I/O interface signals, pads must be used where those signals are not multiplexed with a UART2 signal if possible. In this case the solution is to use sdmmc3_clk and sdmmc3_cmd on another two pads of the device (usbb2_ulpitll_dat7 and usbb2_ulpitll_dat6) configuring MUXMODE = 0b010.

3. Identify the signal integrity parameter settings (drive strength, impedance, slew rate, pullup/down strength, etc.) necessary for the I/O cells associated with the pad (see [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#)).

For the register settings of the signal integrity parameters for the uart2_rx, uart2_tx, uart2_cts, and urat2_rts pads (this is the variant when the desired uart2 signals appear in MuxMode = 0x0), see [Table 18-83](#).

For the uart2_cts, uart2_rts, and uart2_rx pads, the following bit fields (Mode and Load bit group settings) must be set:

- [CONTROL_SMART3IO_PADCONF_1](#)[27:26] UART2_DR0_MB
- [CONTROL_SMART3IO_PADCONF_2](#) [13] UART2_DR0_LB

For the uart2_tx pad, the following bit fields (Mode and Load bit group settings) must be set:

- [CONTROL_SMART3IO_PADCONF_1](#) [25:24] UART2_DR1_MB

- [CONTROL_SMART3IO_PADCONF_2](#) [12] UART2_DR1_LB

For recommendations about the signal integrity parameter settings of the mentioned pad group, see the device data manual.

NOTE: To identify the signal-associated I/O cell signal parameter settings in [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#), the user must search for the device pad name on which the desired signal is muxed, because the I/O cell settings are designated and listed on a per-pad basis. This means that a signal name does not appear (unless MuxMode = 0x0) in [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#), but only the pad on which the signal is muxed.

Pads that do not have software I/O cell signal integrity parameter controls are not listed in [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#).

Assume the user application configures the sdmmc3_clk and sdmmc3_cmd signals on the usbb2_ulpitll_dat7 and usbb2_ulpitll_dat6 pads (MuxMode = 0x2). The I/O cell setting (single-bit group control – SPI3_DR0_DS of driver output impedance) listed in [Table 18-71](#) also applies to the sdmmc3_clk and sdmmc3_cmd signals, which appear on the same pads, when MuxMode = 0x2.

In this case, the [CONTROL_SMART2IO_PADCONF_2](#)[21] SPI3_DR0_DS bit must be set to configure the I/O cell performance of sdmmc3_clk and sdmmc3_cmd.

For recommendations about the signal integrity parameter settings of the mentioned pad group, see the device data manual.

4. Identify and program the peripheral dual-voltage settings, if they apply to the chosen pads.

[Table 18-95](#) lists the corresponding control bits of the pads in the [CONTROL_CORE_PADCONF_MODE](#) and [CONTROL_WKUP_PADCONF_MODE](#) registers. The identification of the I/O dual-voltage domains/control bits for a signal must be made on a per-pad basis.

All pads (uart2_cts, uart2_rts, uart2_rx, and uart2_tx) fall within the same dual-voltage domain (VDDS_DV_BANK1), and the I/O supply voltage (1.2 V/1.8 V) is configured by setting the [CONTROL_CORE_PADCONF_MODE](#)[30] VDDS_DV_BANK1 bit.

As previously explained, the sdmmc3_clk and sdmmc3_cmd signals are muxed on the usbb2_ulpitll_dat7 and usbb2_ulpitll_dat6 pads. The dual-voltage control bit corresponding to these two pads is [CONTROL_CORE_PADCONF_MODE](#)[26] VDDS_DV_BANK6 (see [Table 18-95](#)).

For more information about pad performance dependencies from I/O dual-voltage supply settings, see the device data manual.

5. Identify the pad configuration registers associated with the pads to be used in the application. See [Section 18.4.8.3, Pad Multiplexing Register Fields](#).

Example: Under the previous hypothesis, the pad configuration registers to program are:

- uart2_rts: [CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS](#)[31:16]
- uart2_cts: [CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS](#)[15:0]
- uart2_tx: [CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX](#)[31:16]
- uart2_rx: [CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX](#)[15:0]
- sdmmc3_clk (MuxMode = 0x2): [CONTROL_CORE_PAD0_USBB2_ULPITLL_DAT6_PAD1_USBB2_ULPITLL_DAT7](#)[31:16]
- sdmmc3_cmd (MuxMode = 0x2): [CONTROL_CORE_PAD0_USBB2_ULPITLL_DAT6_PAD1_USBB2_ULPITLL_DAT7](#)[15:0]

Table 18-103. ACTIVE PADS Configuration Points

Step	Register/Bit Field/Programming Model	Value
1. Identify the interface signals and map them to the appropriate pads according to the application requirements and the device-specific pad I/O muxing capabilities. See Section 18.4.8.3, Pad Multiplexing Register Fields .	Define the list of I/O signal names: uart2_cts, uart2_rts, uart2_rx, uart2_tx, sdmmc3_clk, and sdmmc3_cmd	–

Table 18-103. ACTIVE PADS Configuration Points (continued)

Step	Register/Bit Field/Programming Model	Value
	Define the list of corresponding pads: uart2_cts, uart2_rts, uart2_rx, uart2_tx, usbb2_ulpitll_dat7, and usbb2_ulpitll_dat6	
2. Identify the corresponding I/O cell signal integrity parameter controls for the pad (on a per-pad basis). See Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping .	(uart2_cts, uart2_rts, uart2_rx pads) CONTROL_SMART3IO_PADCONF_1 [27:26] UART2_DR0_MB CONTROL_SMART3IO_PADCONF_2 [13] UART2_DR0_LB uart2_tx pad) CONTROL_SMART3IO_PADCONF_1 [25:24] UART2_DR1_MB CONTROL_SMART3IO_PADCONF_2 [12] UART2_DR1_LB (usbb2_ulpitll_dat7, usbb2_ulpitll_dat6) CONTROL_SMART2IO_PADCONF_2 [21] SPI3_DR0_DS	For more information about the recommended I/O settings, see the device data manual.
3. Determine whether the pad is associated with a peripheral dual-voltage domain (see the device data manual). Identify its corresponding 1.2-V/1.8-V dual-voltage control bit in the CONTROL_CORE_PADCONF_MODE or CONTROL_WKUP_PADCONF_MODE register. See Table 18-95 .	(uart2_cts, uart2_rts, uart2_rx, uart2_tx) CONTROL_CORE_PADCONF_MODE [30] VDDSDV_BANK1 (usbb2_ulpitll_dat7, usbb2_ulpitll_dat6) CONTROL_CORE_PADCONF_MODE [26] VDDSDV_BANK6	For more information about the I/O performance dependency on dual-voltage settings, see the device data manual.
4.. Configure MUXMODE field in pad configuration registers associated with the pads used.	CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS [18:16] UART2_RTS_MUXMODE CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS [2:0] UART2_CTS_MUXMODE CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX [18:16] UART2_TX_MUXMODE CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX [2:0] UART2_RX_MUXMODE CONTROL_CORE_PAD0_USBB2_ULPITLL_DAT6_PAD1_USBB2_ULPITLL_DAT7 [18:16] USBB2_ULPITLL_DAT7_MUXMODE CONTROL_CORE_PAD0_USBB2_ULPITLL_DAT6_PAD1_USBB2_ULPITLL_DAT7 [2:0] USBB2_ULPITLL_DAT6_MUXMODE	0b000 0b000 0b000 0b000 0b010 0b010
5.. Select the type of the internal pullup/down resistor ⁽¹⁾ .	CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX [4] UART2_RX_PULLTYPESELECT CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS [2:0] UART2_CTS_PULLTYPESELECT	0b1 (pullup selected) 0b1 (pullup selected)
6.. Enable/disable pullup/down feature of the pad ⁽²⁾ .	CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX [3] UART2_RX_PULLUDENABLE CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS [3] UART2_CTS_PULLUDENABLE	0b1 (pull feature enabled) 0b1 (pull feature enabled)

⁽¹⁾ It is recommended to use internal pullup/down resistor if pad is used as input and external pullup/down is not used.

⁽²⁾ If the pad is configured in output mode, it is recommended for software to disable the internal pullup/pulldown associated with it.

Table 18-103. ACTIVE PADS Configuration Points (continued)

Step	Register/Bit Field/Programming Model	Value
7. Set the direction of the pin signal. ⁽²⁾	CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX [8] UART2_RX_INPUTENABLE	0b1 (input pin)
	CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS [8] UART2_CTS_INPUTENABLE	0b1 (input pin)
	CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX [24] UART2_TX_INPUTENABLE	0b0 (output pin)
	CONTROL_CORE_PAD0_UART2_CTS_PAD1_UART2_RTS [24] UART2_RTS_INPUTENABLE	0b0 (output pin)
	CONTROL_CORE_PAD0_USBB2_ULPITLL_DAT6_ PAD1_USBB2_ULPITLL_DAT7[24] USBB2_ULPITLL_DAT7_INPUTENABLE (sdmmc3_clk)	0b1 (input pin)
	CONTROL_CORE_PAD0_USBB2_ULPITLL_DAT6_PAD1 _USBB2_ULPITLL_DAT7[8] USBB2_ULPITLL_DAT6_INPUTENABLE (sdmmc3_cmd)	0b1 (input pin)

NOTE: The order for setting the previous pad configuration bits is not important.

NOTE: If a device pad is left unconnected, but power is supplied to the I/O, or the pad is used only as an output during the lifetime of the application, it is recommended to keep its corresponding padconfiguration bit [CONTROL_CORE/WKUP_PAD0_X_PAD1_Y.INPUTENABLE](#) set to 0b0. This keeps the input buffer disabled and reduces static current consumption.

NOTE: I/Os are non-failsafe, which means that voltage must never be applied at a pad before the internal I/O supply voltage VDD5 is powered.

18.6 Control Module Register Manual

18.6.1 Control Module Instance Summary

Table 18-104 lists the base address and address space for the control module instances.

Table 18-104. Control Module Instance Summary

Module instance	Base Address	Size	Description
SYSCTRL_GENERAL_C ORE	0x4A00 2000	4KB	Module
SYSCTRL_GENERAL_W KUP	0x4A30 C000	4KB	Module
SYSCTRL_PADCONF_C ORE	0x4A10 0000	4KB	Module
SYSCTRL_PADCONF_W KUP	0x4A31 E000	4KB	Module

NOTE: All module registers are 8-, 16-, or 32-bit accessible through the L4 interconnect (little-endian encoding).

Bits	Field Name	Description	Type	Reset
31:29	EMIF1_SDRAM_TYPE	SDRAM type selection: Set to 0x4 for LPDDR2-S4. Set to 0x5 for LPDDR2-S2. All other values are reserved.	RW	0x4
28:27	EMIF1_SDRAM_IBANK_POS	Internal bank position: Set to 0x0 to assign internal bank address bits from the L3 address as shown in , <i>64-Byte Linear Read Starting at Address 0x0</i> , and , <i>64-Byte Linear Read Starting at Address 0x8 (LPDDR2-S2)</i> , in Chapter 15, Memory Subsystem . Set to 0x1, 0x2, or 0x3 to assign internal bank address bits from the L3 address as shown in , <i>64-Byte Linear Read Starting at Address 0x8 (LPDDR2-S4)</i> , , <i>64-Byte Linear Read Starting at Address 0x10</i> , and , <i>64-Byte Linear Read Starting at Address 0x18</i> , in Chapter 15, Memory Subsystem .	RW	0x0
26:24	RESERVED		R	0x0
23	EMIF1_SDRAM_DDR2_DDQS	DDR2 differential DQS enable: Set to 0 for single ended DQS. Set to 1 for differential DQS. This bit is only for DDR2 mode; because the device supports LPDDR2, this bit is don't care.	RW	0x1
22:21	RESERVED		R	0x0
20	EMIF1_SDRAM_DDR_DISABLE_DLL	Disable DLL select: Set to 0x0 to enable DLL inside SDRAM. Set to 0x1 to disable DLL inside SDRAM.	RW	0x0
19:16	RESERVED		R	0x0
15:14	EMIF1_SDRAM_NARROW_MODE	SDRAM data bus width: Set to 0x0 for 64-bit width. Set to 0x1 for 32-bit width. Set to 0x2 for 16-bit width. All other values are reserved.	RW	0x0

Bits	Field Name	Description	Type	Reset
13:10	EMIF1_SDRAM_CL	CAS latency (RL latency). The value of this field defines the CAS latency to be used when accessing connected SDRAM devices: Supported for LPDDR2-SDRAM: 0x3: CAS latency of 3 cycles 0x4: CAS latency of 4 cycles 0x5: CAS latency of 5 cycles 0x6: CAS latency of 6 cycles 0x7: CAS latency of 7 cycles 0x8: CAS latency of 8 cycles All other values are reserved.	RW	0x3
9:7	EMIF1_SDRAM_ROWSIZE	Row size. Defines the number of row address bits of connected SDRAM devices: Set to 0x0 for 9 row bits. Set to 0x1 for 10 row bits. Set to 0x2 for 11 row bits. Set to 0x3 for 12 row bits. Set to 0x4 for 13 row bits. Set to 0x5 for 14 row bits. Set to 0x6 for 15 row bits. Set to 0x7 for 16 row bits. This field is used only when the ibank_pos field in the SDRAM Config register is set to 0x1, 0x2, or 0x3.	RW	0x4
6:4	EMIF1_SDRAM_IBANK	Internal bank setup. Defines number of banks inside connected SDRAM devices: Set to 0x0 for 1 bank. Set to 0x1 for 2 banks. Set to 0x2 for 4 banks. Set to 0x3 for 8 banks. All other values are reserved.	RW	0x3
3	EMIF1_SDRAM_EBANK	External CS setup. Defines whether SDRAM accesses will use 1 or 2 CS lines. Set to 0 to use pad_cs_o_n[0] only: Set to 0x0 to use only pad_cs_o_n[0]. Set to 0x1 to use pad_cs_o_n[1:0]. This bit is automatically set to 0 if either the cs0nvmen or cs1nvmen field in the LPDDR2-NVM is set to 1.	RW	0x0
2:0	EMIF1_SDRAM_PAGESIZE	Page size. Defines the internal page size of the connected SDRAM devices: Set to 0x0 for 256-word page (8 column bits). Set to 0x1 for 512-word page (9 column bits). Set to 0x2 for 1024-word page (10 column bits). Set to 0x3 for 2048-word page (11 column bits). All other values are reserved.	RW	0x0

Mailbox

This chapter describes the Mailbox module in the device.

Topic	Page
19.1 Mailbox Overview	4096
19.2 Mailbox Integration	4098
19.3 Mailbox Functional Description	4102
19.4 Mailbox Programming Guide	4108
19.5 Mailbox Register Manual	4111

19.1 Mailbox Overview

Communication between the on-chip processors of the device uses a queued mailbox-interrupt mechanism.

The queued mailbox-interrupt mechanism allows the software to establish a communication channel between two processors through a set of registers and associated interrupt signals by sending and receiving messages (mailboxes).

Figure 19-1 shows an overview of the mailbox module.

Figure 19-1. Mailbox Overview

There are two mailbox module instances in the device:

- **System mailbox** - used for Cortex-A9 microprocessor unit (Cortex-A9 MPU), digital signal processor (DSP) and Cortex-M3 microprocessor unit (Cortex-M3 MPU) communications.
- **IVA-HD mailbox** - used for communication between one internal to the IVA-HD subsystem user (imaging controller 1 - iCONT1, or imaging controller 2 - iCONT2) and three external to the IVA-HD subsystem users (Cortex-A9 MPU, DSP and Cortex-M3 MPU). This communication is insured through three pairs of mailboxes.

The mailbox module includes the following features:

- Three users for the system mailbox instance (Cortex-A9 MPU, DSP and Cortex-M3 MPU)/four users for the IVA-HD mailbox instance (iCONT1/iCONT2, Cortex-A9 MPU, DSP and Cortex-M3 MPU)
- Eight mailbox message queues for the system mailbox instance/six mailbox message queues for the

IVA-HD mailbox instance

- Flexible assignment of receiver and sender for each mailbox through interrupt configuration
- Three interrupts (one per user) for the system mailbox instance/four interrupts (one per user) for the IVA-HD mailbox instance
- 32-bit message width
- Four-message FIFO depth for each message queue
- Message reception and queue-not-full notification using interrupts
- Support of 16-/32-bit addressing scheme
- Power management support

19.2 Mailbox Integration

This section describes the mailbox integration in the device, including information about clocks, resets, and hardware requests.

19.2.1 System Mailbox Integration

Figure 19-2 shows the system mailbox integration.

Figure 19-2. System Mailbox Integration

NOTE: For more information about the IDLE hardware handshake, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 19-1 through Table 19-3 summarize the system mailbox integration in the device.

Table 19-1. Integration Attributes

Module Instance	Attributes

NOTE: For information about interrupt source description, see [Section 19.3.4, Interrupt Requests](#).

19.3 Mailbox Functional Description

NOTE: In the mailbox functional description, u is the user number and m is the mailbox number as follows:

- for the system mailbox module instance, $u=0$ to 2 and $m=0$ to 7
- for the IVA-HD mailbox module instance, $u=0$ to 3 and $m=0$ to 5

The mailbox module provides a means of communication through message queues among the users (depending on the mailbox module instance). The individual mailbox modules (8 for the system mailbox instance, 6 for the IVA-HD mailbox instance), or FIFOs, can associate (or de-associate) with any of the processors using the [MAILBOX_IRQENABLE_SET_u](#) (or [MAILBOX_IRQENABLE_CLR_u](#)) register.

CAUTION

For the IVA-HD mailbox instance, communication is possible only if one of the users is iCONT1 or iCONT2.

The mailbox module includes the following user subsystems:

- User 0: Cortex-A9 MPU subsystem ($u = 0$)
- User 1: DSP subsystem ($u = 1$)
- User 2: Cortex-M3 MPU subsystem ($u = 2$)
- User 3:
 - IVA-HD subsystem ($u = 3$) - only available to the IVA-HD mailbox instance
 - Mailbox subsystem - only available to SSCM module of C2C interface

Each user has a dedicated interrupt signal from the corresponding mailbox module instance and dedicated interrupt enabling and status registers.

Each [MAILBOX_IRQSTATUS_RAW_u](#)/[MAILBOX_IRQSTATUS_CLR_u](#) interrupt status register corresponds to a particular user.

For the system mailbox instance, a user can query its interrupt status register through the L4_CFG interconnect.

For the IVA-HD mailbox instance, a user can query its interrupt status register as follows:

- Cortex-A9 MPU and Cortex-M3 MPU - through the L3 interconnect
- iCONT1/iCONT2 and DSP - private access (directly through the IVA-HD local interconnect)

19.3.1 Mailbox Block Diagram

Figure 19-4 shows the mailbox block diagram.

Figure 19-4. Mailbox Block Diagram

NOTE: The interrupt requests and the interconnect depend on the mailbox module instance. For more information, see [Section 19.2, Mailbox Integration](#).

19.3.2 Mailbox Software Reset

The mailbox module supports a software reset through the [MAILBOX_SYSCONFIG\[0\]](#) SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Reading the [MAILBOX_SYSCONFIG\[0\]](#) SOFTRESET bit gives the status of the software reset:

- Read 1: the software reset is on-going.
- Read 0: the software reset is complete.

The software must ensure that the software reset completes before doing mailbox operations.

19.3.3 Mailbox Power Management

[Table 19-7](#) describes power-management features available for the mailbox module.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1.4, Clock-Domain Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 19-7. Local Power Management Features

Feature	Registers	Description
Clock autogating	NA	Feature not available
Slave idle modes	MAILBOX_SYSCONFIG [3:2] SIDLEMODE bit field	Force-idle, no-idle and smart-idle modes are available
Clock activity	NA	Feature not available
Master standby modes	NA	Feature not available
Global wake-up enable	NA	Feature not available
Wake-up sources enable	NA	Feature not available

The mailbox module can be configured using the [MAILBOX_SYSCONFIG](#)[3:2] SIDLEMODE bit field to one of the following acknowledgment modes:

- Force-idle mode (SIDLEMODE = 0x0): The mailbox module immediately enters the idle state on receiving a low-power-mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state.
- No-idle mode (SIDLEMODE = 0x1): The mailbox module never enters the idle state.
- Smart-idle mode (SIDLEMODE = 0x2): After receiving a low-power-mode request from the PRCM module, the mailbox module enters the idle state only after all asserted output interrupts are acknowledged.

19.3.4 Mailbox Interrupt Requests

An interrupt request allows the user of the mailbox to be notified when a message is received or when the message queue is not full. There is one interrupt per user.

NOTE: For more information about interrupt requests, see [Section 19.2, Mailbox Integration](#).

[Table 19-8](#) lists the event flags, and their mask, that can cause module interrupts.

Table 19-8. Interrupt Events

Non-Maskable Event Flag ⁽¹⁾	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
MAILBOX_IRQSTATUS_RAW_u [0+m*2] NEWMSGSTATUSUUM Bm	MAILBOX_IRQSTATUS_CLR_u [0+m*2] NEWMSGSTATUSUUM Bm	MAILBOX_IRQENABLE_CLR_u [0+m*2] NEWMSGSTATUSUUM Bm	MAILBOX_IRQENABLE_SET_u [0+m*2] NEWMSGSTATUSUUM Bm	Mailbox <i>m</i> receives a new message.
MAILBOX_IRQSTATUS_RAW_u [1+m*2] NOTFULLSTATUSUUM Bm	MAILBOX_IRQSTATUS_CLR_u [1+m*2] NOTFULLSTATUSUUM Bm	MAILBOX_IRQENABLE_CLR_u [1+m*2] NOTFULLSTATUSUUM Bm	MAILBOX_IRQENABLE_SET_u [1+m*2] NOTFULLSTATUSUUM Bm	Mailbox <i>m</i> message queue is not full.

⁽¹⁾ MAILBOX.MAILBOX_IRQSTATUS_RAW_u register is mostly used for debug purposes.

CAUTION

Once an event generating the interrupt request has been processed by the software, it must be cleared by writing a logical 1 in the corresponding bit of the [MAILBOX_IRQSTATUS_CLR_u](#) register.

Writing a logical 1 in a bit of the [MAILBOX_IRQSTATUS_CLR_u](#) register will also clear to 0 the corresponding bit in the appropriate [MAILBOX_IRQSTATUS_RAW_u](#) register.

An event can generate an interrupt request when a logical 1 is written to the corresponding unmask bit in the [MAILBOX_IRQENABLE_SET_u](#) register. Events are reported in the appropriate [MAILBOX_IRQSTATUS_CLR_u](#) and [MAILBOX_IRQSTATUS_RAW_u](#) registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the [MAILBOX_IRQENABLE_CLR_u](#) register. Events are only reported in the appropriate [MAILBOX_IRQSTATUS_RAW_u](#) register.

In case of the [MAILBOX_IRQSTATUS_RAW_u](#) register, the event is reported in the corresponding bit even if the interrupt request generation is disabled for this event.

19.3.5 Mailbox Assignment

19.3.5.1 Description

To assign a receiver to a mailbox, set the new message interrupt enable bit corresponding to the desired mailbox in the [MAILBOX_IRQENABLE_SET_u](#) register. The receiver reads the [MAILBOX_MESSAGE_m](#) register to retrieve a message from the mailbox.

An alternate method for the receiver that does not use the interrupts is to poll the [MAILBOX_FIFOSTATUS_m](#) and/or [MAILBOX_MSGSTATUS_m](#) registers to know when to send or retrieve a message to or from the mailbox. This method does not require assigning a receiver to a mailbox. Because this method does not include the explicit assignment of the mailbox, the software must avoid having multiple receivers use the same mailbox, which can result in incoherency.

To assign a sender to a mailbox, set the queue-not-full interrupt enable bit of the desired mailbox in the [MAILBOX_IRQENABLE_SET_u](#) register, where *u* is the number of the sending user. However, direct allocation of a mailbox to a sender is not recommended because it can cause the sending processor to be constantly interrupted.

It is recommended that register polling be used to:

- Check the status of either the [MAILBOX_FIFOSTATUS_m](#) or [MAILBOX_MSGSTATUS_m](#) registers
- Write the message to the corresponding [MAILBOX_MESSAGE_m](#) register, if space is available.

The sender might use the queue-not-full interrupt when the initial mailbox status check indicates the mailbox is full. In this case, the sender can enable the queue-not-full interrupt for its mailbox in the appropriate [MAILBOX_IRQENABLE_SET_u](#) register. This allows the sender to be notified by interrupt only when a FIFO queue has at least one available entry.

Reading the [MAILBOX_IRQSTATUS_CLR_u](#) register determines the status of the new message and the queue-not-full interrupts for a particular user. Writing 1 to the corresponding bit in the [MAILBOX_IRQSTATUS_CLR_u](#) register acknowledges, and subsequently clears, an interrupt.

CAUTION

Assigning multiple senders or multiple receivers to the same mailbox is not recommended.

19.3.6 Sending and Receiving Messages

19.3.6.1 Description

When a 32-bit message is written to the [MAILBOX_MESSAGE_m](#) register, the message is appended into the FIFO queue. This queue holds four messages. If the queue is full, the message is discarded.

Queue overflow can be avoided by first reading the [MAILBOX_FIFOSTATUS_m](#) register to check that the mailbox message queue is not full before writing a new message to it.

Reading the [MAILBOX_MESSAGE_m](#) register returns the message at the beginning of the FIFO queue and removes it from the queue. If the FIFO queue is empty when the [MAILBOX_MESSAGE_m](#) register is read, the value 0 is returned.

The new message interrupt is asserted when at least one message is in the mailbox message FIFO queue. To determine the number of messages in the mailbox message FIFO queue, read the [MAILBOX_MSGSTATUS_m](#) register.

19.3.7 16-Bit Register Access

19.3.7.1 Description

So that 16-bit processors can access the mailbox module, the module allows 16-bit register read and write access, with restrictions for the [MAILBOX_MESSAGE_m](#) registers. The 16-bit half-words are organized in little endian fashion; that is, the least-significant 16 bits are at the low address and the most-significant 16 bits are at the high address (low address + 0x02).

All mailbox module registers can be read or written to directly using individual 16-bit accesses with no restriction on interleaving, except the [MAILBOX_MESSAGE_m](#) registers, which must always be accessed by either single 32-bit accesses or two consecutive 16-bit accesses.

CAUTION

When using 16-bit accesses, it is critical to ensure that the mailbox used has only one assigned receiver and only one assigned sender.

When using 16-bit accesses to the [MAILBOX_MESSAGE_m](#) registers, the order of access must be the least-significant half-word first (low address) and the most-significant half-word last (high address). This requirement is because of the update operation by the message FIFO of the [MAILBOX_MSGSTATUS_m](#) registers. The update of the FIFO queue contents and the associated status registers and possible interrupt generation occurs only when the most-significant 16 bits of a [MAILBOX_MESSAGE_m](#) are accessed.

19.3.8 Example of Communication

Figure 19-5 shows an example of communication between Cortex-A9 MPU and DSP subsystems.

Figure 19-5. Example of Communication

19.4 Mailbox Programming Guide

19.4.1 Mailbox Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the mailbox module.

19.4.1.1 Global Initialization

19.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the mailbox module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the mailbox.

See [Section 19.2, Mailbox Integration](#), for further information.

Table 19-9. Global Initialization of Surrounding Modules for System Mailbox

Surrounding Modules	Comments
PRCM	Mailbox functional/interface clock must be enabled. For more information, see Section 3.6.15 , <i>CD_L4_CFG Clock Domain</i> , in Chapter 3, Power, Reset, and Clock Management .
Interrupt Controllers	Cortex-A9 MPU, or Cortex-M3 MPU, or DSP interrupt controller must be configured to enable the interrupt request generation to the Cortex-A9 MPU, or Cortex-M3 MPU, or DSP subsystem. For information about enabling interrupts in Cortex-A9 MPU INTC, see the <i>ARM Cortex™-A9 MPCore Technical Reference Manual</i> (available at infocenter.arm.com/help/index.jsp). For information about enabling interrupts in Cortex-M3 MPU INTC, see the <i>ARM Cortex™-M3 Technical Reference Manual</i> (available at infocenter.arm.com/help/index.jsp). For information about enabling interrupts in DSP INTC, see Chapter 5, DSP Subsystem .
Interconnect	For information about L4-CFG interconnect configuration, see Section 13.3, L4 Interconnects , in Chapter 13, Interconnect .

Table 19-10. Global Initialization of Surrounding Modules for IVA-HD Mailbox

Surrounding Modules	Comments
PRCM	Mailbox functional/interface clock must be enabled. For more information, see Chapter 3, Power, Reset, and Clock Management .
Interrupt Controllers	Cortex-A9 MPU, or Cortex-M3 MPU, or DSP, or iCONT1/iCONT2 interrupt controller must be configured to enable the interrupt request generation to the Cortex-A9 MPU, or Cortex-M3 MPU, or DSP, or IVA-HD subsystem. For information about enabling interrupts in Cortex-A9 MPU INTC, or Cortex-M3 MPU INTC, or DSP INTC, see Table 19-9, Global Initialization of Surrounding Modules for System Mailbox . For information about enabling interrupts in iCONT1/iCONT2, see <i>iCONT</i> in Chapter 6, IVA-HD Subsystem .
Interconnect	For information about L3 interconnect configuration, see Section 13.2, L3 Interconnects , in Chapter 13, Interconnect .

19.4.1.1.2 Mailbox Global Initialization

19.4.1.1.2.1 Main Sequence - Mailbox Global Initialization

This procedure initializes the mailbox module after a power-on or software reset.

Table 19-11. Mailbox Global Initialization

Step	Register/ Bit Field / Programming Model	Value
Perform a software reset	MAILBOX_SYSCONFIG [0] SOFTRESET	0x1
Wait until reset is complete	MAILBOX_SYSCONFIG [0] SOFTRESET	= 0x0
Set idle mode configuration	MAILBOX_SYSCONFIG [3:2] SIDLEMODE	0x-

19.4.1.2 Mailbox Operational Modes Configuration

19.4.1.2.1 Mailbox Processing modes

19.4.1.2.1.1 Main Sequence - Sending a Message (Polling Method)

Table 19-12. Sending a Message (Polling Method)

Step	Register/ Bit Field / Programming Model	Value
IF : Is FIFO full ?	MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB	= 0x1
Wait until at least one message slot is available	MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB	= 0x0
ELSE		
Write message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ENDIF		

19.4.1.2.1.2 Main Sequence - Sending a Message (Interrupt Method)

Table 19-13. Sending a Message (Interrupt Method)

Step	Register/ Bit Field / Programming Model	Value
IF : Is FIFO full ?	MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB	= 0x1
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[1+ m*2]	0x1
User (processor) can perform another task until interrupt occurs See Section 19.4.1.3.1 for interrupt handling in sending mode		
ELSE		
Write message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ENDIF		

19.4.1.2.1.3 Main Sequence - Receiving a Message (Polling Method)

Table 19-14. Receiving a Message (Polling Method)

Step	Register/ Bit Field / Programming Model	Value
IF : Number of messages is not equal to 0	MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB	!= 0x0
Read message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ENDIF		

19.4.1.2.1.4 Main Sequence - Receiving a Message (Interrupt Method)

Table 19-15. Receiving a Message (Interrupt Method)

Step	Register/ Bit Field / Programming Model	Value
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[0 + m*2]	0x1
User (processor) can perform another task until interrupt occurs See Section 19.4.1.3.2 for interrupt handling in receiving mode		

19.4.1.3 Mailbox Events Servicing

19.4.1.3.1 Events Servicing in Sending Mode

Table 19-16 describes the events servicing in sending mode.

Table 19-16. Events Servicing in Sending Mode

Step	Register/ Bit Field / Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	0x1
Write message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	0x1

19.4.1.3.2 Events Servicing in Receiving Mode

Table 19-17 describes the events servicing in receiving mode.

Table 19-17. Events Servicing in Receiving Mode

Step	Register/ Bit Field / Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	0x1
IF : Number of messages is not equal to 0 ?	MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB	!= 0x0
Read message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ELSE		
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	0x1
ENDIF

NOTE: For each interrupt status and enable register ([MAILBOX_IRQSTATUS_RAW_u](#), [MAILBOX_IRQSTATUS_CLR_u](#), [MAILBOX_IRQENABLE_SET_u](#) and [MAILBOX_IRQENABLE_CLR_u](#)), bits [15:12] have the given meaning only for the System Mailbox instance. For the IVA-HD Mailbox instance, these bits are considered as Reserved.

Memory Management Units

This chapter describes the memory management units (MMUs).

Topic	Page
20.1 MMU Overview	4126
20.2 MMU Integration	4127
20.3 MMU Functional Description	4130
20.4 MMU Low-level Programming Models	4143
20.5 MMU Register Manual	4147

20.1 MMU Overview

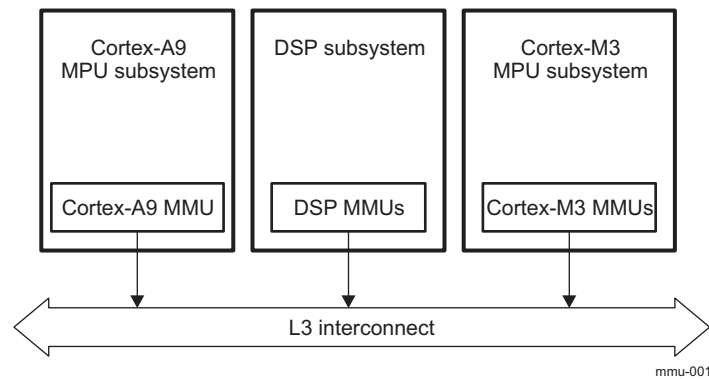

A memory management unit (MMU) is a hardware component responsible for handling accesses to memory requested by a processing unit. MMU functions include translation of virtual addresses to physical addresses (that is, virtual memory management) and cache control.

The device contains the following MMUs:

- In DSP - L1 Shared cache MMU and attribute MMU.
- In Dual Cortex-M3 MPU Subsystem - L1 Shared cache MMU and L2 MMU
- Cortex-A9 MMU

Figure 20-1 shows the MMU instances in the device.

Figure 20-1. Device MMU Instances

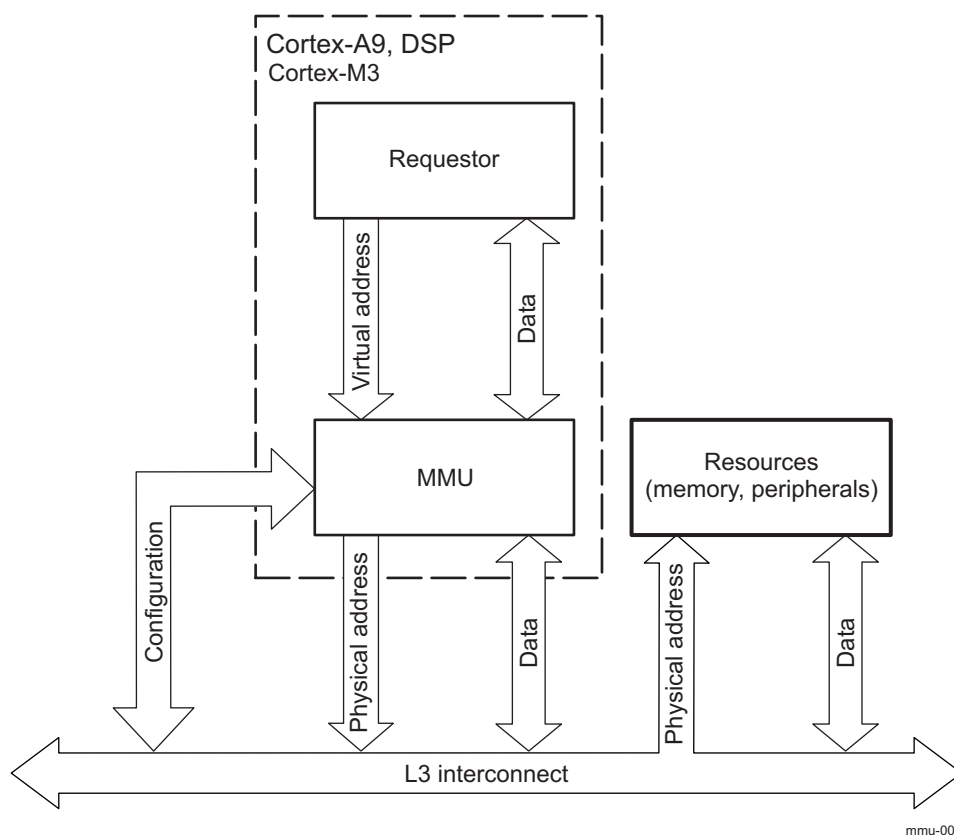

20.2 MMU Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

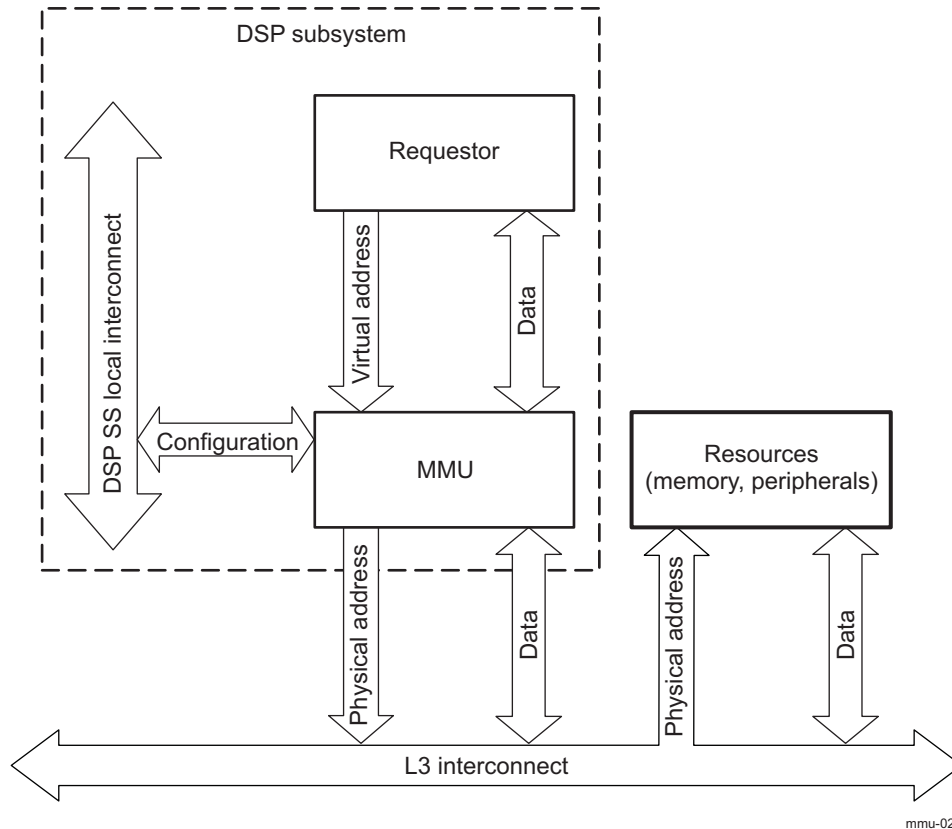

The MMU communicates accesses from the requestor (DSP, Cortex-M3 microprocessor unit (MPU), or Cortex-A9 MPU) to the L3 main interconnect, performing virtual to physical address translation. Although all MMUs are programmed (configured) through the L3 interconnect, the DSP MMU can be programmed both through the L3 interconnect or through the DSP local interconnect. DSP MMU and Cortex-M3 MMU error conditions are signaled as interrupts to the system main processor Cortex-A9 MPU.

Figure 20-2 shows typical MMU integration.

Figure 20-2. MMU Integration

NOTE: All MMUs are programmed through the L3 interconnect.

Figure 20-3. DSP MMU Integration

NOTE: The DSP MMU can be programmed from both the DSP local interconnect and from the L3 interconnect.

Table 20-1 through Table 20-3 summarize the MMU integration in the various modules of the device.

Table 20-1. Integration Attributes

Module Instance	Power Domain
CORTEXM3_L2MMU and CORTEXM3_SCACHE_MMU	PD_CORE
CORTEXA9_MMU	PD_MPU

Table 20-2. Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
CORTEXA9_MMU	ARM_FCLK	MPU_DPLL_CLK	MPU DPLL	Internal clock in the Cortex-A9 MPU subsystem; supplies the MMU in Cortex-A9.
CORTEXM3_L2MMU and CORTEXM3_SCACHE_MMU	MPU_M3_CLK	MPU_M3_CLK	PRCM	External clock from the power, reset, and clock management (PRCM) module; supplies the shared cache MMU and L2 MMU in Cortex-M3.
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
CORTEXM3_L2MMU	CORTEXM3_PWRON_RST	CORTEXM3_PWRON_RST	PRCM	Power-on reset signal for the Cortex-M3 MPU subsystem
	CORTEXM3_RST3	CORTEXM3_RST3	PRCM	Reset signal to the L2 MMU

Table 20-2. Clocks and Resets (continued)

CORTEXM3_SCACHE_MMU	CORTEXM3_RST3	CORTEXM3_RST3	PRCM	Reset signal for the shared cache MMU
	CORTEXM3_RET_RST	CORTEXM3_RET_RST	PRCM	Retention reset signal for the Cortex-M3 MPU subsystem
CORTEXA9_MMU	MPU_PWRON_RST	MPU_PWRON_RST	PRCM	Power-on reset signal to the MMU and the rest of the Cortex-A9 MPU subsystem
	MPU_RST	MPU_RST	PRCM	Reset signal to the MMU and the rest of the Cortex-A9 MPU subsystem

Table 20-3. Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
CORTEXM3_L2MMU	CORTEXM3_MMU_IRQ	MA_IRQ_100	MPU_INT_C	Cortex-M3 MPU L2MMU interrupt to the main MPU subsystem
	XLATE_MMU_FAULT	MM_IRQ_0	CortexM3_INTC	Internal interrupt from the L2MMU to the Cortex-M3 interrupt controller (INTC)
CORTEXM3_SCACHE_MMU	SHARED_CACHE_MMU_C PU_INT	MM_IRQ_1	CortexM3_INTC	Internal interrupt from the shared cache MMU to the CortexM3 INTC

NOTE:

- For a description of the interrupt source, see [Section 20.3.5, Interrupt Requests](#).

There are 5 MMU modules in the device:

- Shared cache MMU – there are two Share cache MMUs, one in the Cortex-M3 MPU and other in DSP subsystem. Refer to the corresponding chapters for more information.
- L2 MMUs – there are two L2 MMUs, one in the Cortex-M3 MPU and other in DSP subsystem. The L2 MMUs are directly operating with the L3 interconnect (shared device memory space). These L2 MMUs are described in this chapter.
- Cortex-A9 MMU – this MMU is located in the ARM Cortex-A9 processor. For information about this MMU, see the *ARM® Cortex™-A9 MPCore Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

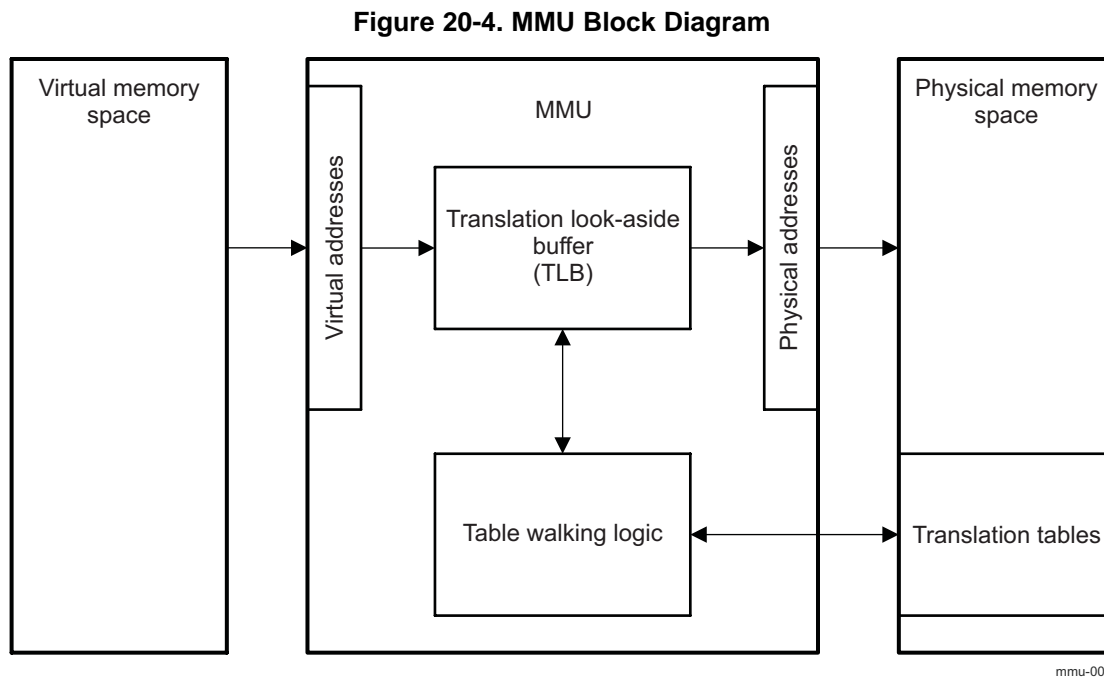

NOTE: There is PAT module in the Dynamic Memory Manager, which has similar to the MMU functionality. Refer to the DMM chapter, for more information.

20.3 MMU Functional Description

20.3.1 MMU Block Diagram

The MMU manages the virtual to physical address translation for external addresses, as well as endianness conversion. The MMU can be programmed through the L3 interconnect. MMU programming is expected to be accomplished by the Cortex-A9 MPU, except for the DSP MMU, of which the configuration can be accomplished through the DSP local interconnect.

Figure 20-4 is the MMU block diagram.

Each table entry describes the translation of one contiguous memory region. For a description of the structure of these tables, see [Section 20.3.1.2, Translation Tables](#).

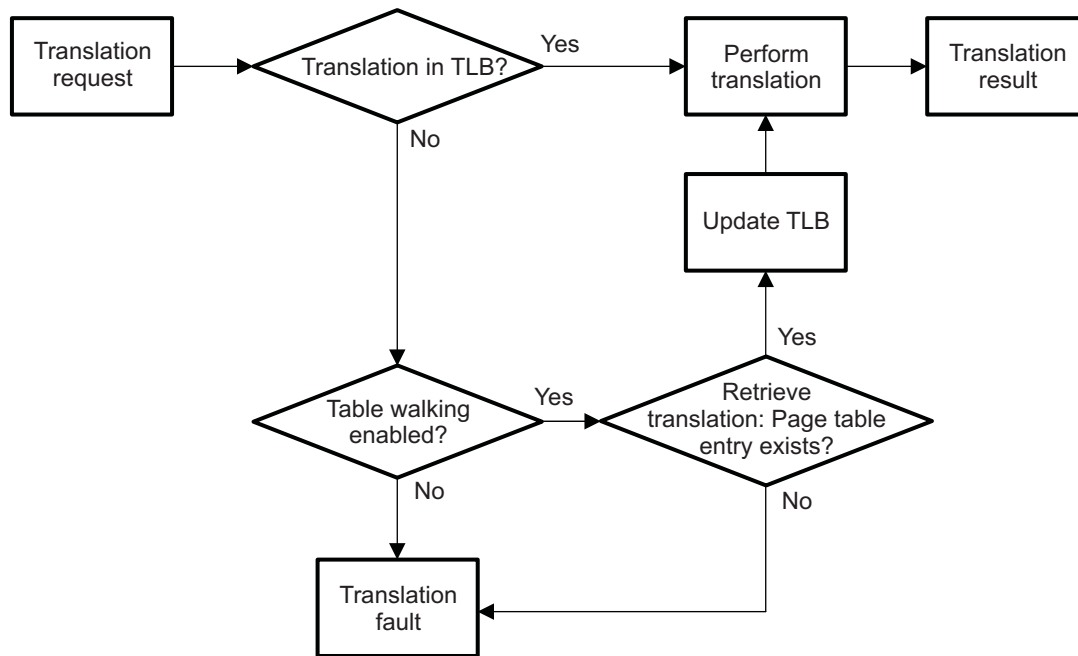

Two major functional units exist in the MMU to provide address translation automatically based on the table entries:

- The table walker automatically retrieves the correct translation table entry for a requested translation. If two-level translation is used (for the translation of small memory pages), the table walker also automatically reads the required second-level translation table entry. The two-level translation is described later in the chapter.
- The translation look-aside buffer (TLB) stores recently used translation entries, acting like a cache of the translation table.

20.3.1.1 MMU Address Translation Process

Whenever an address translation is requested (that is, for every access with the MMU enabled), the MMU first checks whether the translation is contained in the TLB, which acts like a cache storing recent translations. The TLB can also be programmed manually to ensure that time-critical data can be translated without delay.

If the requested translation is not in the TLB, the table-walking logic retrieves this translation from the translation table(s), and then updates the TLB. The address translation is then performed. [Figure 20-5](#) summarizes the process.

Figure 20-5. Translation Process

mmu-007

20.3.1.2 Translation Tables

The translation of virtual to physical addresses is based on entries in translation tables that define the following properties:

- Address translation, that is, the correspondence between virtual and physical addresses
- Size of the memory region the entry translates
- Endianness, data access size, and the mixed property of this memory region

The virtual addresses index the translation tables. Each virtual address corresponds to exactly one entry in the translation table.

20.3.1.2.1 Translation Table Hierarchy

When developing a table-based address translation scheme, one of the most important design parameters is the memory page size described by each translation table entry. MMU instances support 4KB and 64KB pages, a 1MB section, and a 16MB supersection. Using bigger page sizes means a smaller translation table.

Using a smaller page size greatly increases the efficiency of dynamic memory allocation and defragmentation. That is why many operating systems (OSs) can operate on memory blocks as small as 4KB; however, the smaller size implies a more complex table structure.

A quick calculation shows that using 4KB memory pages with one translation table would require one million entries to span the entire 4GB address range. The table itself would be 32MB, a size that is not feasible.

However, using bigger pages greatly reduces the functionality of the OS memory management. Implementing a two-level hierarchy reconciles these two requirements. Within this hierarchy, one first-level translation table describes the translation properties based on 1MB memory regions.

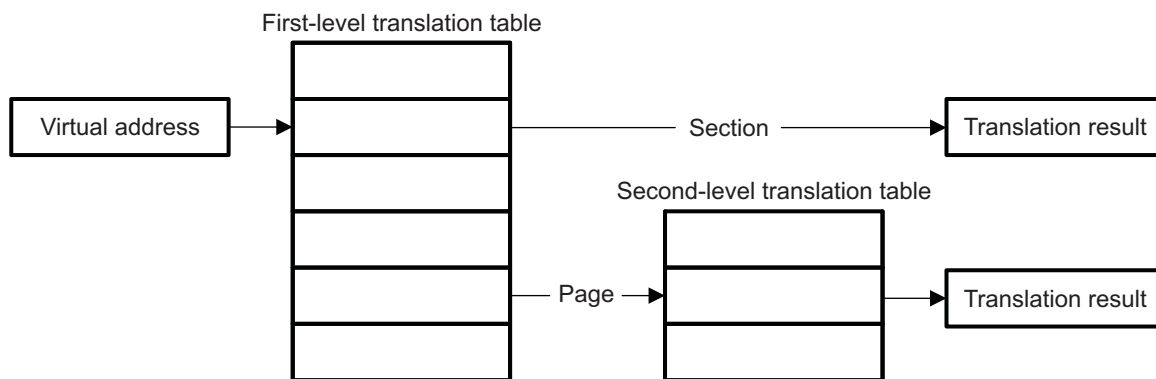

Each of the entries in this first-level translation table can specify the following:

- The translation properties for a big memory section. This memory section can be either 1MB (section) or 16MB (supersection). In this case, all translation parameters are specified in the first-level translation table entry.

- A pointer to a second-level translation table that specifies individual translation properties based on smaller pages within the 1MB page of memory. These pages can be either 64KB (large page) or 4KB (small page). In this case, the actual translation parameters are specified in the second-level translation table entry. The first-level translation table entry specifies only the base address of the second-level translation table.

This hierarchical approach means that additional translation information for smaller pages must be provided only when the pages are actually used. [Figure 20-6](#) shows the hierarchy.

Figure 20-6. Translation Hierarchy

mmu-008

The structure of the first and second-level translation tables and their entries are described in more detail in [Section 20.3.1.2.2, First-Level Translation Table](#), and [Section 20.3.1.2.3, Two-Level Translation](#).

20.3.1.2.2 First-Level Translation Table

The first-level translation table describes the translation properties for 1MB sections. To describe a 4GB address range requires 4096 32-bit entries (so-called first-level descriptors).

The first-level translation table start address must be aligned on a multiple of the table size with a 128-byte minimum. Consequently, an alignment of at least 16K bytes is required for a complete 4096-entry table; that is, at least the last fourteen address bits must be zero.

The start address of the first-level translation table is specified by the so-called translation table base. The table is indexed by the upper 12-bits of the virtual address. [Figure 20-7](#) shows this mechanism.

Figure 20-7. First-level Descriptor Address Calculation

mmu-009

To summarize, the translation table base and the translation table index together define the first-level descriptor address. [Figure 20-8](#) outlines the precise mechanism used to calculate this address.

Figure 20-8. Detailed First-Level Descriptor Address Calculation

mmu-010

As an example of this mechanism, consider a translation table base address of 0x8000:0000 and a virtual address of 0x1234:5678. In this case, the first-level descriptor address is $0x8000:0000 + (0x123 \ll 2) = 0x8000:048C$.

20.3.1.2.2.1 First-Level Descriptor Format

Each first-level descriptor provides either the complete address translation for 1MB or 16MB sections or provides a pointer to a second-level translation table for 4KB or 64KB pages. [Table 20-4](#) shows the first-level descriptor format.

Table 20-4. First-Level Descriptor Format

First-Level Descriptor Format											
31:24	23:20	19	18	17	16	15	14:12	11:10	9:2	1	0
X										0	0
Second-Level Translation Table Base Address										X	0
Section Base Address		X	0	M	X	E ⁽¹⁾	X	ES	X	1	0
Supersection Base Address		X	1	M	X	E	X	ES	X	1	0
X										1	1
											Fault
											Page
											Section
											Supersection
											Fault

⁽¹⁾ See for endianness limitations.

M = Mixed region: 0 = Page-based endianness, 1 = Access-based endianness

E = Endianness: 0 = Little endian, 1 = Big endian (endianness is locked on little endian)

ES = Element Size: 00 = 8-bit, 01 = 16-bit, 10 = 32-bit, 11 = No endianness conversion

X = Don't care

20.3.1.2.2.2 First-Level Page Descriptor Format

If a translation granularity smaller than 1MB is required, a two-level translation process is used. In this case, the first-level block descriptor specifies only the start address of a second-level translation table. The second-level translation table entries specify the actual translation properties.

20.3.1.2.2.3 First-Level Section Descriptor Format

Each section descriptor in the first-level translation table specifies the complete translation properties for a 1MB section or a 16MB supersection.

NOTE: Supersection descriptors must be repeated 16 times, because each descriptor in the first-level translation table describes 1MB of memory. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

In addition to the address translation itself, three parameters are specified in the section descriptors:

- Endianness

The *endianness* parameter specifies whether the memory section uses a big- or little-endian data format. This parameter is locked to little endian. See for more information.

- Element size

The *element size* parameter can optionally specify the data access size (8, 16, or 32 bits) for all data items in the defined section.

- Mixed region

The *mixed region* parameter specifies whether the information about the data access size is detected from the access itself (access-based detection) or if the specified element size parameter is used (page-based detection). For example, the specified element size parameter can be used when several smaller sized accesses are packed into a bigger sized access, such as two 16-bit accesses packed into one 32-bit access. In this case, with no specified data access size, 32 bits would be the access size detected, leading to an incorrect result. To avoid this problem, specify the data access size for the memory section.

20.3.1.2.2.4 Section Translation Summary

Sections and supersections can be translated based solely on the information in the first-level translation table. [Figure 20-9](#) summarizes the address translation process for a section.

Figure 20-9. Section Translation Summary

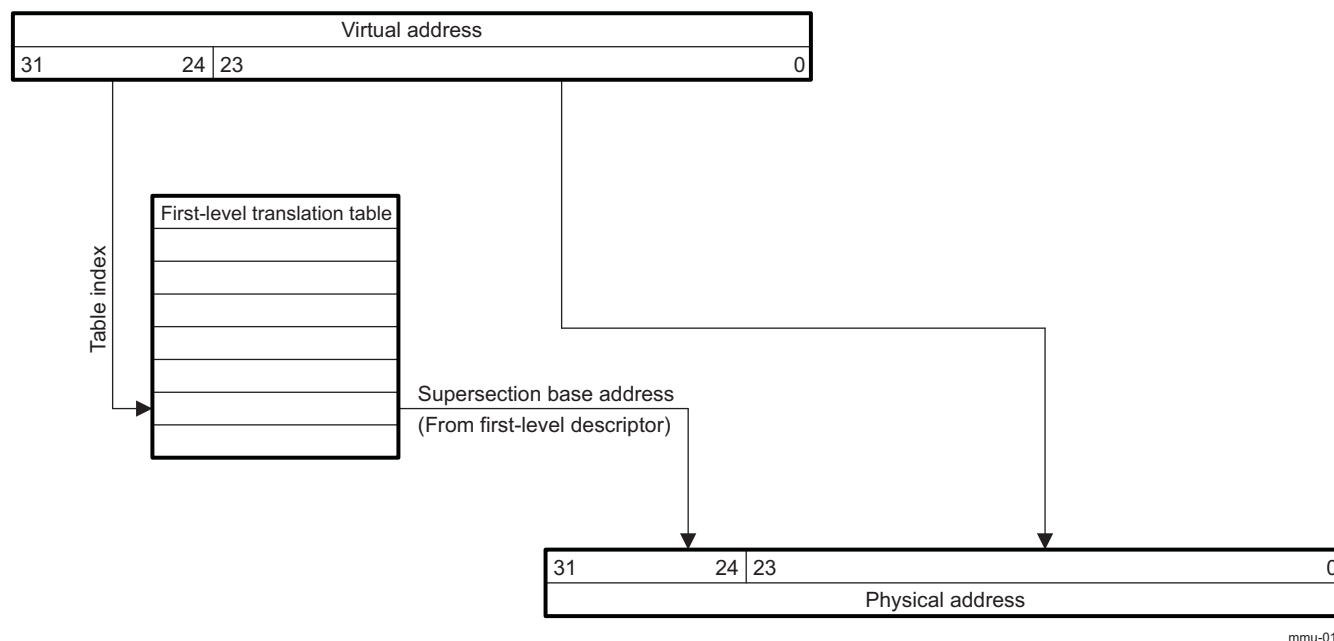

mmu-011

20.3.1.2.2.5 Supersection Translation Summary

The translation of a supersection is similar to the translation of a section. The difference is that for a supersection only bits 31 to 24 index into the first-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a supersection.

Figure 20-10 shows the translation mechanism for a supersection.

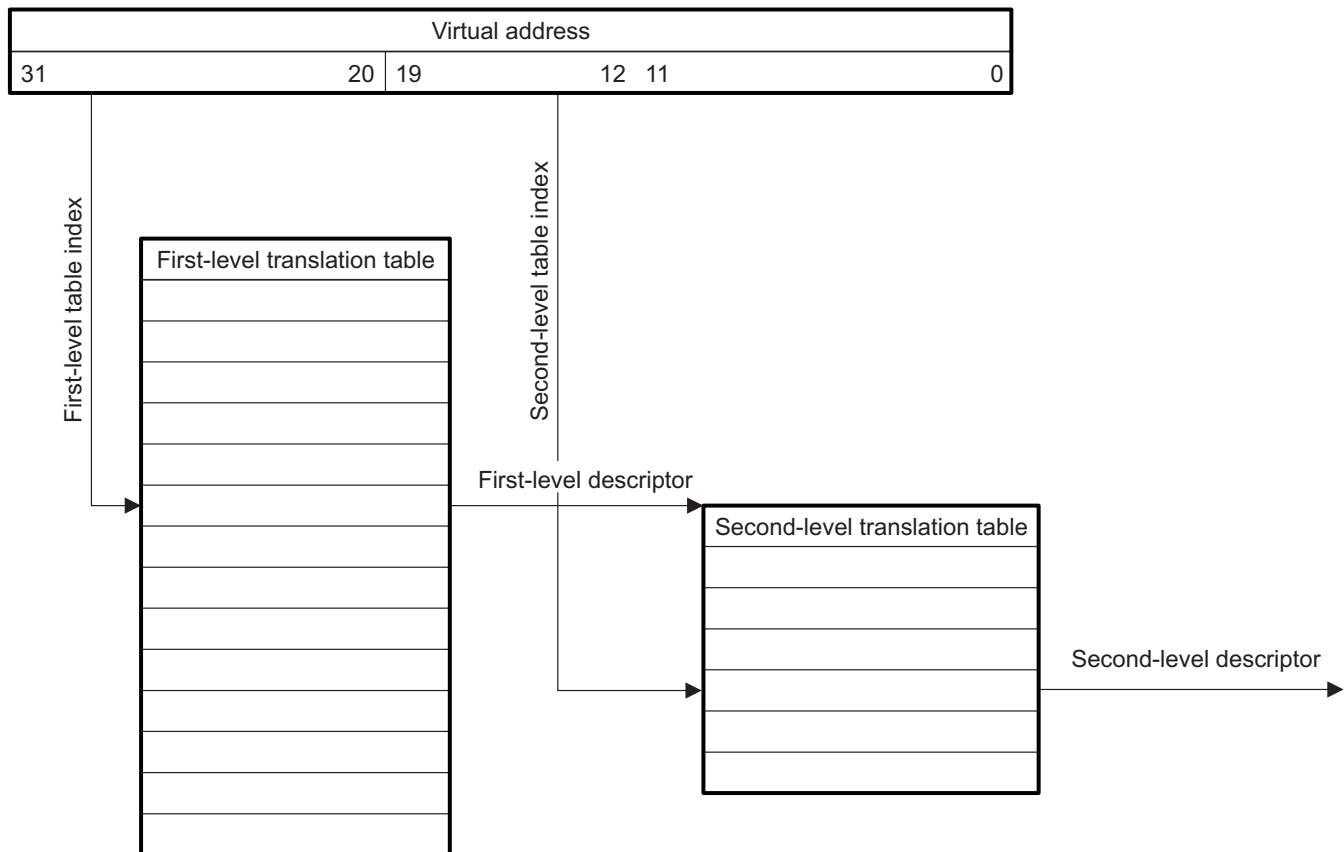

Figure 20-10. Supersection Translation Summary

mmu-012

20.3.1.2.3 Two-Level Translation

Two-level translation is used when fine-grain granularity is required, that is, when memory sections smaller than 1MB are needed. In this case, the first-level descriptor provides a pointer to the base address of a second-level translation table. This second-level table is indexed by bits 19 to 12 of the virtual address. Figure 20-11 shows this indexing mechanism.

Figure 20-11. Two-Level Translation

mmu-013

Each second-level translation table describes the translation of 1MB of address space in pages of 64KB (large page) or 4KB (small page). It consists of 256 second-level descriptors describing 4KB each.

NOTE: In the case of a large page, the same descriptor must be repeated 16 times. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

20.3.1.2.3.1 Second-Level Descriptor Format

Similar to first-level section descriptors, second-level descriptors provide all of the necessary information for the translation of a large or small page. [Table 20-5](#) shows the format of second-level descriptors. The translation parameters (endianness, element size, and mixed region) have the same meaning as those for sections.

Table 20-5. Second-Level Descriptor Format

Second-Level Descriptor Format										
31:16	15:12	11	10	9	8:6	5:4	3:2	1	0	
X									0	0
Large Page Base Address									0	1
Small Page Base Address									1	X
		M	X	E ⁽¹⁾	X	ES	X			
		M	X	E	X	ES	X			

⁽¹⁾ See for endianness limitations.

M = Mixed region: 0 = Page-based endianness, 1 = Access-based endianness

E = Endianness: 0 = Little-endian, 1 = Big-endian (endianness is locked on little endian)

ES = Element Size: 00 = 8-bit, 01 = 16-bit, 10 = 32-bit, 11 = No endianness conversion

X = Don't care

20.3.1.2.3.2 Small Page Translation Summary

Figure 20-12 summarizes the translation process for small pages.

Figure 20-12. Small Page Translation Summary

mmu-014

20.3.1.2.3.3 Large Page Translation Summary

The translation of a large page is similar to the translation of a small page. The difference is that, for a large page, only bits 19 to 16 index into the second-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a large page. This is shown in Figure 20-13.

Figure 20-13. Large Page Translation Summary

mmu-015

20.3.1.3 Translation Lookaside Buffer

Translating virtual addresses to physical addresses is required for each memory access in systems using an MMU. To accelerate this translation process, a cache, or TLB, holds the result of recent translations.

For every translation, the MMU internal logic first checks whether the requested translation is already cached in the TLB. If the translation is cached, this translation is used; otherwise the translation is retrieved from the translation tables and the TLB is updated. If the TLB is full, one of its entries must be replaced. This entry is selected on a random basis.

The first n TLB entries, where $n < \text{Total Number } N \text{ of TLB Entries}$, can be protected (locked) against being overwritten by setting the TLB base pointer to n . When this mechanism is used, only unprotected entries can be overwritten. The victim pointer indicates the next TLB entry to be written. [Figure 20-14](#) shows an example of the TLB with N TLB entries (ranging from 0 to $N-1$). The base pointer contains the value "3" protecting Entry 0, Entry 1, and Entry 2 and the victim pointer points to the next TLB entry to be updated.

NOTE: The last TLB entry (Entry $N-1$) always remains unprotected.

Figure 20-14. TLB Entry Lock Mechanism

mmu-016

The table walking logic automatically writes the TLB entries. The entries can also be manually written, which is done typically to ensure that the translation of time-critical data accesses is already present in the TLB so that they execute as fast as possible. The entries must be locked to prevent them from being overwritten.

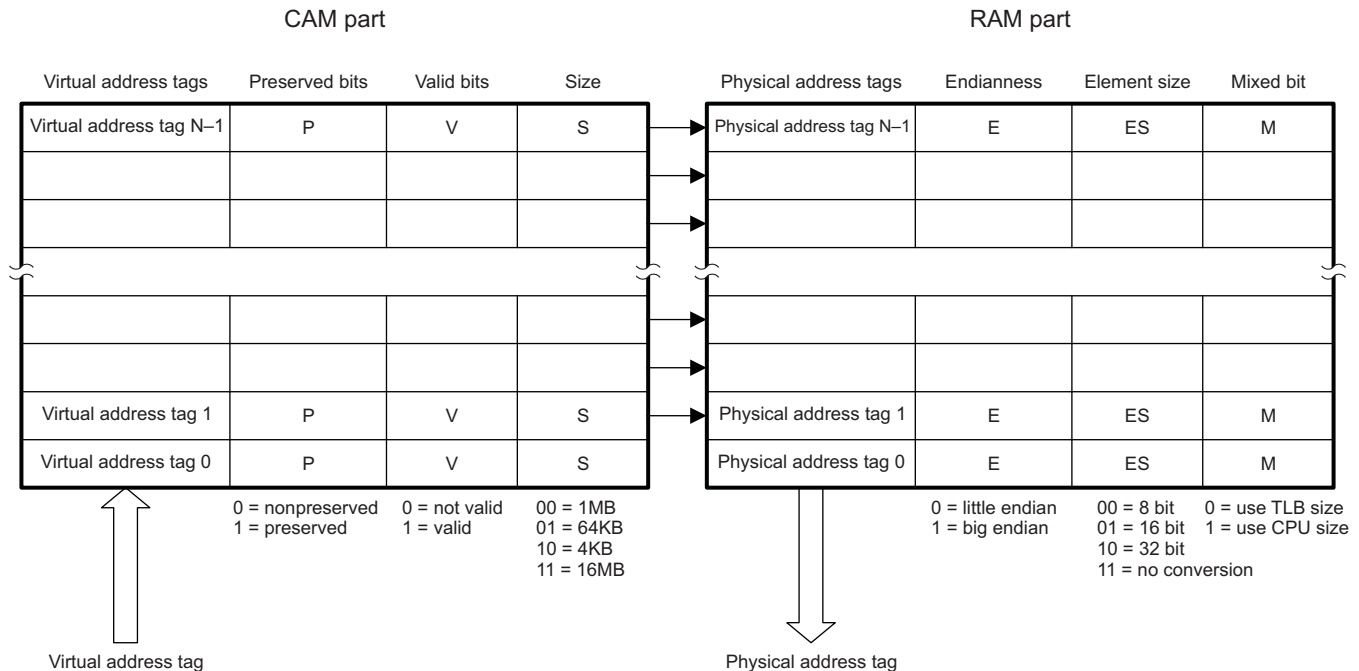

20.3.1.3.1 TLB Entry Format

TLB entries consist of two parts:

- The CAM part contains the virtual address tag used to determine if a virtual address translation is in the TLB. The TLB acts like a fully associative cache addressed by the virtual address tag. The CAM part also contains the section/page size, as well as the preserved and the valid parameters. See the [MMU_CAM](#) register table for more details.
- The RAM part contains the address translation that belongs to the virtual address tag as well as the endianness, element size, and mixed parameters described in [Section 20.3.1.2.2, First-Level Translation Table](#). See the [MMU_RAM](#) register table for more details.

The valid parameter specifies whether an entry is valid or not. The preserved parameter determines the behavior of an entry in the event of a TLB flush. If an entry is set as preserved, it is not deleted when a TLB is flushed, that is, when [MMU_GFLUSH\[0\] GLOBALFLUSH](#) is set to 1. Preserved entries must be deleted manually. [Section 20.3.1.2.2](#) describes the procedure to delete TLB entries.

[Figure 20-16](#) shows the TLB entry structure.

Figure 20-15. TLB Entry Structure

mmu-017

20.3.2 MMU Clock Configuration

There are two clock domains: The functional clock domain for the MMU, which is synchronous to the clock for the interconnect slave and master access ports; and the clock domain for the interconnect slave configuration port. As these clocks are matched, there is a single input clock with enables for each of the clock domains. If a clock domain should run at the same frequency as the input clock, that enable can be tied high.

Two clock enable signals exist, one to enable the interconnect data master and slave ports, and the other to enable the clock on the configuration L3 interconnect port. The clock signals are configured through the [MMU_SYSCONFIG](#) register. This is a system configuration register that controls the various parameters of the L3 interface.

20.3.3 MMU Software Reset

This section describes the software reset feature of the module. The MMU instances are reset together with their respective reset domains. See [Table 20-2](#) for information about the reset domains of the different MMU instances.

To perform a software reset, write 1 in the [MMU_SYSCONFIG](#)[1] SOFTRESET bit. The [MMU_SYSSTATUS](#)[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the [MMU_SYSCONFIG](#)[1] SOFTRESET bit is automatically reset. The software must ensure that the software reset completes before doing MMU operations. When an MMU instance is released from reset, its TLB is empty and the MMU is disabled.

20.3.4 MMU Power Management

As part of the device system-wide power management scheme, each MMU instance supports a communication protocol with the PRCM module that allows the PRCM module to request an MMU instance to enter a low-power state. When the MMU instance acknowledges a low-power mode request from the PRCM module, the clock to the instance is gated off at the PRCM clock generator. Because the clock is disabled at the source, the low-power mode offers lower power consumption than the internal clock gating method in the local power management.

[Table 20-6](#) describes the power-management features available for the MMU modules.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 20-6. MMU Local Power Management Features

Feature	Register
Idle modes	MMU_SYSCONFIG [4:3] IDLEMODE
Clock activity	MMU_SYSCONFIG [9:8] CLOCKACTIVITY
Clock autogating	MMU_SYSCONFIG [0] AUTOIDLE

NOTE: The [MMU_SYSCONFIG](#)[9:8] CLOCKACTIVITY bits are read only.

20.3.5 MMU Interrupt Requests

[Table 20-7](#) lists the event flags and their masks that can cause module interrupts.

Table 20-7. Events

Event Flag	Event Mask	Synchrono us	Sensitivit y	Map to	Description
MMU_IRQSTATUS [4] MULTIHITFAULT	MMU_IRQENABLE [4] MULTIHITFAULT	Yes	Level	M3_IRQ_0	Error in the L2 MMU due to multiple matches in the TLB
MMU_IRQSTATUS [3] TABLEWALKFAULT	MMU_IRQENABLE [3] TABLEWALKFAULT	Yes	Level	M3_IRQ_0	Error in the L2 MMU due to error response received during a Table Walk
MMU_IRQSTATUS [2] EMUMISS	MMU_IRQENABLE [2] EMUMISS				For more information about emulation and debug features, see Chapter 28, On-Chip Debug Support .
MMU_IRQSTATUS [1] TRANSLATIONFAULT	MMU_IRQENABLE [1] TRANSLATIONFAULT	Yes	Level	M3_IRQ_0	Error in the L2 MMU due to invalid descriptor in the translation tables (translation fault)
MMU_IRQSTATUS [0] TLBMISS	MMU_IRQENABLE [0] TLBMISS	Yes	Level	M3_IRQ_0	Error in L2 MMU due to unrecoverable TLB miss (hardware TWL disabled)

20.3.6 MMU Error Handling

[Table 20-8](#) summarizes the intended operation for real and potential error conditions.

Table 20-8. Error Handling

Item	Condition	Action
1	Table-walk read has an error response.	Treat generally the same as a translation fault, but set the TableWalkFault interrupt status bit to aid in diagnosis
2	MMU is disabled during table-walk.	Not permitted; can result in loss of the current transaction but must not deadlock the MMU. Avoid this condition by first disabling the table-walk logic and then polling the TWLRunning bit to ensure that no table walk is pending
3	MMU is disabled during an address translation.	Not permitted; can result in access to an unintended location, but must not deadlock MMU. This condition should be avoided by ensuring that no accesses are pending.

Table 20-8. Error Handling (continued)

Item	Condition	Action
4	TLB is accessed during an address translation or a table walk.	Reading permitted; write should be done with care to ensure that the TLB is self-consistent at all times that a translation can occur.
5	TLB is flushed during address translation or a table walk.	Permitted; the flush is processed first, followed by the TWL update.
6	MMU is disabled while an interrupt is pending.	Not permitted; all pending interrupts should be processed before disabling the MMU.

L3 Interconnect configuration port: Accesses to undecoded register addresses must not give an error response.

To protect against changes to the address translation between a READEX and the corresponding write or during a burst the following configuration operations are protected against writes during these processes:

- TLB update
- Global flush
- Flush entry
- MMU disable

The protection is implemented by stalling the configuration interconnect transaction until the write can proceed safely.

20.4 MMU Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

20.4.1 Global Initialization

20.4.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the MMU module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MMU. For more information, see [Section 20.2, MMU Module Integration](#).

Table 20-9. Global Initialization of Surrounding Modules

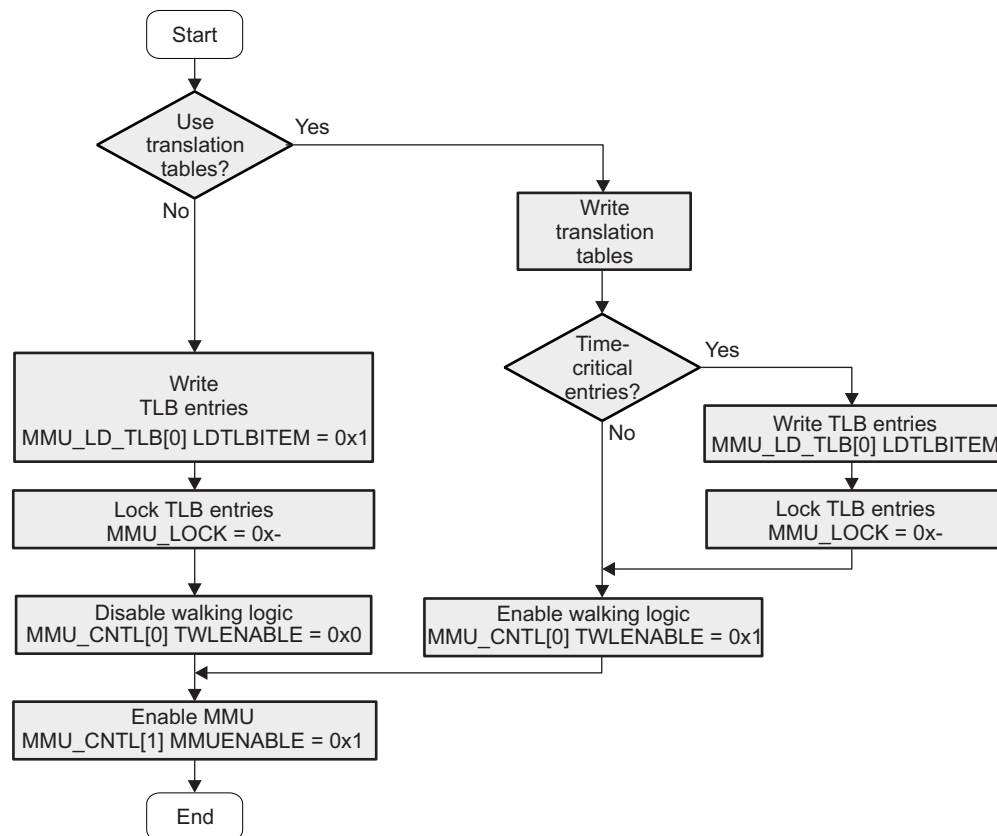

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. For more information, see Chapter 3, Power, Reset, and Clock Management .
(optional) MPU INTC or DSP INTC or Cortex-M3 INTC	MPU, DSP, and Cortex-M3 interrupt controller configuration must be done to enable the interrupts from module.
Interconnect	For more information about the L3 interconnect configuration, see Section 13.2, L3 Interconnect .

NOTE: If the interrupt-based communication mode is used, the MPU, DSP, and Cortex-M3 interrupt controllers configurations are required.

20.4.1.2 MMU Global Initialization

20.4.1.2.1 Main Sequence—MMU Global Initialization

[Figure 20-16](#) shows the procedure to initialize the MMU after a power-on or software reset.

Figure 20-16. MMU Global Initialization

mmu-018

Table 20-10. Register Call Summary for Main Sequence—MMU Global Initialization

Register Name	Register Name	Register Name
MMU_LD_TLB	MMU_LOCK	MMU_CNTL

20.4.1.2.2 Subsequence—Configure a TLB entry

Table 20-11. Configure a TLB Entry

Step	Register / Bit Field / Programming Model	Value
Load the Virtual Address Tag	MMU_CAM [31:12] VATAG	0x-
Protect the TLB entry against flush	MMU_CAM [3] P	0x1
Validate the TLB entry	MMU_CAM [2] V	0x1
Define the page size	MMU_CAM [1:0] PAGESIZE	0x-

20.4.1.3 Operational Modes Configuration

20.4.1.3.1 Main Sequence—Writing TLB Entries Staticly

Writing TLB entries statically avoids the need to write translation tables in memory and is commonly used for relatively small address spaces. This method ensures that the translation of time-critical data accesses execute as fast as possible with entries already present in the TLB. These entries must be locked to prevent them from being overwritten.

Table 20-12. MMU Writing TLB Entries Statically

Step	Register/ Bit Field / Programming Model	Value
Execute software reset	MMU_SYSCONFIG[1] SOFTRESET	0x1
Wait for reset to complete	MMU_SYSSTATUS[0] RESETDONE	=0x1
Enable power saving via automatic interface clock gating	MMU_SYSCONFIG[0] AUTOIDLE	0x1
Configure TLB entries	See Table 20-11	
Load the physical Address of the page	MMU_RAM[31:12] PHYSICALADDRESS	0x-
Define the endianness of the page (little endian or big endian)	MMU_RAM[9] ENDIANNESS	0x-
Select the element size	MMU_RAM[8:7] ELEMENTSIZE	0x-
Define mixed page attribute	MMU_RAM[6] MIXED	0x-
Specify the TLB entry you want to write	MMU_LOCK[8:4] CURRENTVICTIM	0x-
Load the specified entry in the TLB	MMU_LD_TLB[0] LDTLBITEM	0x1
Enable multihit fault and TLB miss	MMU_IRQENABLE[4] MULTIHITFAULT	0x1
	MMU_IRQENABLE[0] TLBMISS	0x1
Enable memory translations	MMU_CNTL[1] MMUENABLE	0x1

20.4.1.3.2 Main Sequence—Protecting TLB Entries

The first n TLB entries (with $n <$ total number of TLB entries) can be protected from being overwritten with new translations. This is useful to ensure that certain commonly used or time-critical translations are always in the TLB and do not require retrieval using the table walking process.

Table 20-13. Protecting TLB Entries

Step	Register/Bit Field/Programming Model	Value
Locks the TLB entries	MMU_LOCK[14:10] BASEVALUE	0x-

20.4.1.3.3 Main Sequence—Deleting TLB Entries

Two mechanisms exist to delete TLB entries. All unpreserved TLB entries, that is, TLB entries written with the preserved bit set to zero, can be deleted by invoking a TLB flush. The preserved bit should only be used on protected TLB entries, as it does not prevent replacement by the table walking logic.

Table 20-14. Deleting TLB Entries

Step	Register / Bit Field / Programming Model	Value
Flush all nonprotected TLB entries	MMU_GFLUSH[0] GLOBALFLUSH	0x1
Flush all TLB entries specified by the CAM register	MMU_FLUSH_ENTRY[0] FLUSHENTRY	0x1

20.4.1.3.4 Main Sequence—Read TLB Entries

TLB entries can be read by the programmer to determine the TLB content at runtime.

Table 20-15. Read TLB Entries

Step	Register / Bit Field / Programming Model	Value
Set the current victim pointer	MMU_LOCK[8:4] CURRENTVICTIM	0x-
Read RAM parts of the TLB entry	MMU_READ_RAM	
Read CAM parts of the TLB entry	MMU_READ_CAM

Spinlock

This chapter describes the Spinlock module of the device.

Topic	Page
21.1 Spinlock Overview	4164
21.2 Spinlock Integration	4165
21.3 Spinlock Functional Description	4166
21.4 Spinlock Programming Guide	4169
21.5 Spinlock Register Manual	4172

21.1 Spinlock Overview

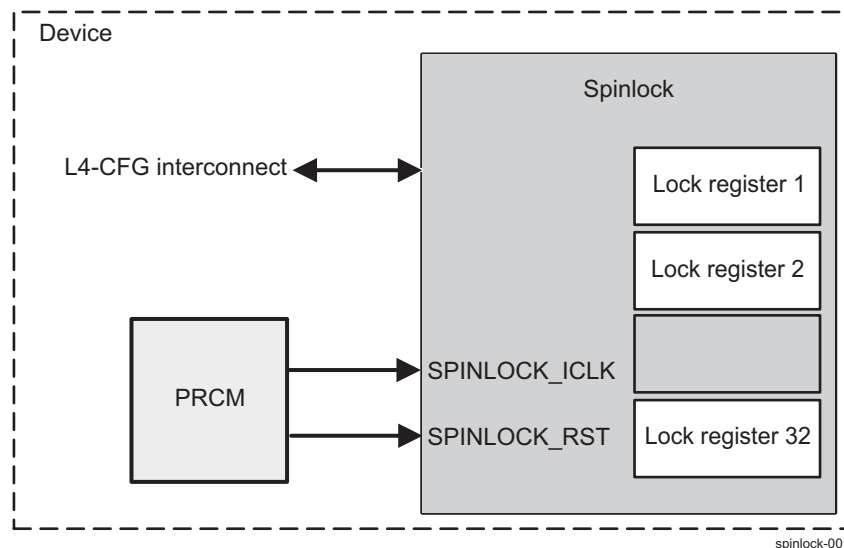

The Spinlock module provides hardware assistance for synchronizing the processes running on multiple processors in the device:

- Cortex-A9 microprocessor unit (MPU) subsystem
- Digital signal processor (DSP) subsystem
- Cortex-M3 MPU subsystem

The Spinlock module implements 32 spinlocks (or hardware semaphores), which provide an efficient way to perform a lock operation of a device resource using a single read-access, avoiding the need of a read-modify-write bus transfer that the programmable cores are not capable of.

Figure 21-1 shows the Spinlock module.

Figure 21-1. Spinlock Module

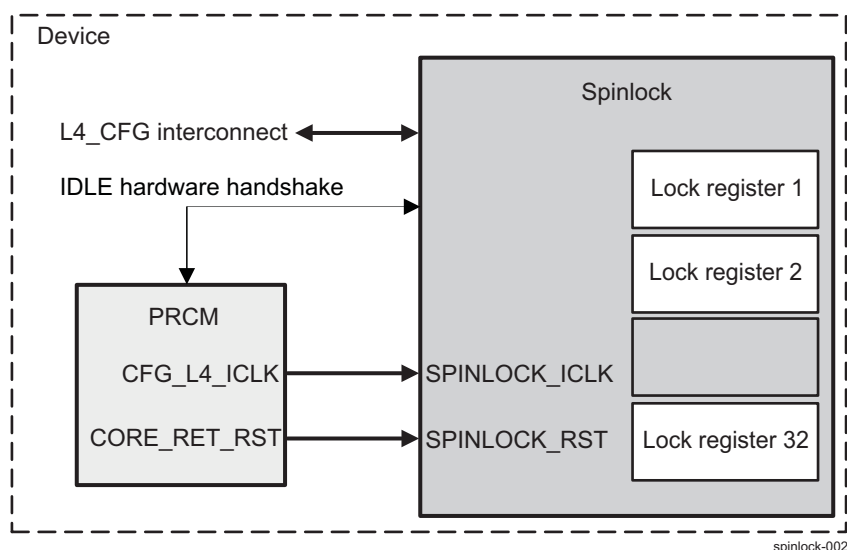

21.2 Spinlock Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 21-2 shows the Spinlock integration.

Figure 21-2. Spinlock Integration

NOTE: For more information about the IDLE hardware handshake and the wake-up request, see [Section 3.1.1.1.2, Module Level Clock Management](#), [Chapter 3, Power, Reset, and Clock Management](#).

[Table 21-1](#) and [Table 21-2](#) summarize the integration of the module in the device.

Table 21-1. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
SPINLOCK	PD_CORE	L4_CFG

Table 21-2. Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SPINLOCK	SPINLOCK_ICLK	CFG_L4_ICLK	PRCM	Spinlock interface clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SPINLOCK	SPINLOCK_RST	CORE_RET_RST	PRCM	Spinlock hardware reset. This reset is asynchronously applied to the Spinlock internal registers.

The Spinlock module does not support any interrupt and DMA requests.

21.3 Spinlock Functional Description

21.3.1 Spinlock Software Reset

The Spinlock module can be reset by software through the [SPINLOCK_SYSCONFIG\[1\]](#) SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. The [SPINLOCK_SYSTATUS\[0\]](#) RESETDONE bit can be polled to check the reset status (reading 1 indicates that reset sequence is done; reading 0 indicates that reset sequence is in progress). The software must ensure that the software reset completes before doing Spinlock operations.

21.3.2 Spinlock Power Management

[Table 21-3](#) describes power-management features available to the Spinlock module.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1.4, Clock Domain Level Clock Management, Chapter 3, Power, Reset, and Clock Management](#).
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.1.1.1.2, Module Level Clock Management, Chapter 3, Power, Reset, and Clock Management](#).

Table 21-3. Local Power Management Features

Feature	Registers	Description
Clock auto gating	SPINLOCK_SYSCONFIG[0] AUTOGATING bit	This bit indicates that the module uses an automatic internal interface clock gating strategy, based on interface activity.
Slave idle modes	SPINLOCK_SYSCONFIG[4:3] SIDLEMODE bit field	This bit field indicates that the module uses smart-idle mode.
Clock activity	SPINLOCK_SYSCONFIG[8] CLOCKACTIVITY bit	This bit indicates that the interface clock is not required by the module during idle mode and may be switched off.
Global wake-up enable	SPINLOCK_SYSCONFIG[2] ENAWAKEUP bit	This bit indicates that the wake-up generation feature (at module level) is disabled.

NOTE: All the local power management features are non-configurable (that is, their respective bits or bit fields are read-only).

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the CLOCKACTIVITY bit and Spinlock clock PRCM control bits.

The Spinlock module is normally idle, except when processing a request from its slave interface port. The smart-idle mode acknowledges idle requests from the PRCM only when the module is prepared to go idle. The Spinlock module is always ready to go idle if it does not have any request that it is processing.

The Spinlock module uses retention flops to retain state including the Taken state of each lock register. This means that the module can be placed in retention at any time when it is not processing a request and it is known that the system will not need to access the module.

Software must ensure to only power off the Spinlock module when no locks would be lost. In general, the steps to powering down the Spinlock module are:

- Check that all masters which might use the Spinlock module are either:
 - Already powered off, or
 - Notified that Spinlock is not available and the notification is acknowledged.

- If desired, check that no locks are currently held in the Spinlock module. The status of each bank of 32 locks can be read from the [SPINLOCK_SYSTATUS](#) register. If any locks are held, they are orphaned because they are not held by any master that is still active. Alternatively, you may decide to wait a timeout period to allow any active master to clean up its locks before powering down.
- The Spinlock module can now be powered off by writing the appropriate status to the PRCM.

In the case of powering off the whole system, these steps are unnecessary.

21.3.3 About Spinlocks

Spinlocks are present to solve the need for synchronization and mutual exclusion between heterogeneous processors and those not operating under a single, shared operating system. There is no alternative mechanism to accomplish these operations between processors in separate subsystems.

Spinlocks are not the best way to synchronize between tasks or threads on one CPU. Instead, spinlocks are for use in synchronization between different subsystems in the device that don't have any other means of hardware-based synchronization.

Spinlocks do not solve all system synchronization issues. They have limited applicability and should be used with care to implement higher level synchronization protocols.

A spinlock is appropriate for mutual exclusion for access to a shared data structure. It should be used only when:

1. The time to hold the lock is predictable and small (for example, a maximum hold time of less than 200 CPU cycles may be acceptable).
2. The locking task cannot be preempted, suspended, or interrupted while holding the lock (this would make the hold time large and unpredictable).
3. The lock is lightly contended, that is the chance of any other process (or processor) trying to acquire the lock while it is held is small.

If these conditions are met, then the locking code can retry a failed attempt to acquire the lock until success.

If the conditions are not met, then a spinlock is not a good candidate. One alternative is to use a spinlock for critical section control (engineered to meet the conditions) to implement a higher level semaphore that can support preemption, notification, timeout or other higher level properties.

21.3.4 Spinlock Functional Operation

The Spinlock module supports 32 spinlocks. It accepts only a single command at a time and processes the command fully before accepting the next command. A lock is requested by reading the [SPINLOCK_LOCK_REG_i\[0\]](#) TAKEN bit. There are two states: Taken ([SPINLOCK_LOCK_REG_i\[0\]](#) TAKEN = 1) or Not Taken ([SPINLOCK_LOCK_REG_i\[0\]](#) TAKEN = 0).

When the status of lock *i* (where *i* = 0 to 31) is Not Taken (free), a read from the [SPINLOCK_LOCK_REG_i](#) register returns 0 and sets the lock to Taken (locked). When the status of lock *i* is Taken, a read returns 1 and does not change the state of the lock.

A write to the [SPINLOCK_LOCK_REG_i](#) register does not change the state of lock, unless when writing 0 when the lock is in Taken state. By doing this, the requester frees the lock.

CAUTION

Only 32-bit reads and writes are supported.

Figure 21-3 shows the [SPINLOCK_LOCK_REG_i](#) register state diagram.

Figure 21-3. Lock Register State Diagram**NOTE:**

- There is no support to ensure that a lock register is locked and unlocked by the same process. This must be ensured in software.
- There is no support to check that the same initiator that acquired the lock is the one that is freeing the lock.

21.4 Spinlock Programming Guide

21.4.1 Spinlock Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

21.4.1.1 Surrounding Modules Global Initialization

This procedure initializes the surrounding modules when the Spinlock module is used for the first time after a device reset.

Table 21-4. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Spinlock interface clock must be enabled. For more information, see Section 3.6.15 , CD_L4_CFG Clock Domain , Chapter 3, Power, Reset, and Clock Management .
Interconnect	For more information about the L4-CFG interconnect configuration, see Section 13.3, L4 Interconnects .

21.4.1.2 Basic Spinlock Operations

The main spinlock operations are:

- Clear all the Taken spinlocks (only after a system bug recovery)
- Take a spinlock
- Release spinlock

21.4.1.2.1 Spinlocks Clearing After a System Bug Recovery

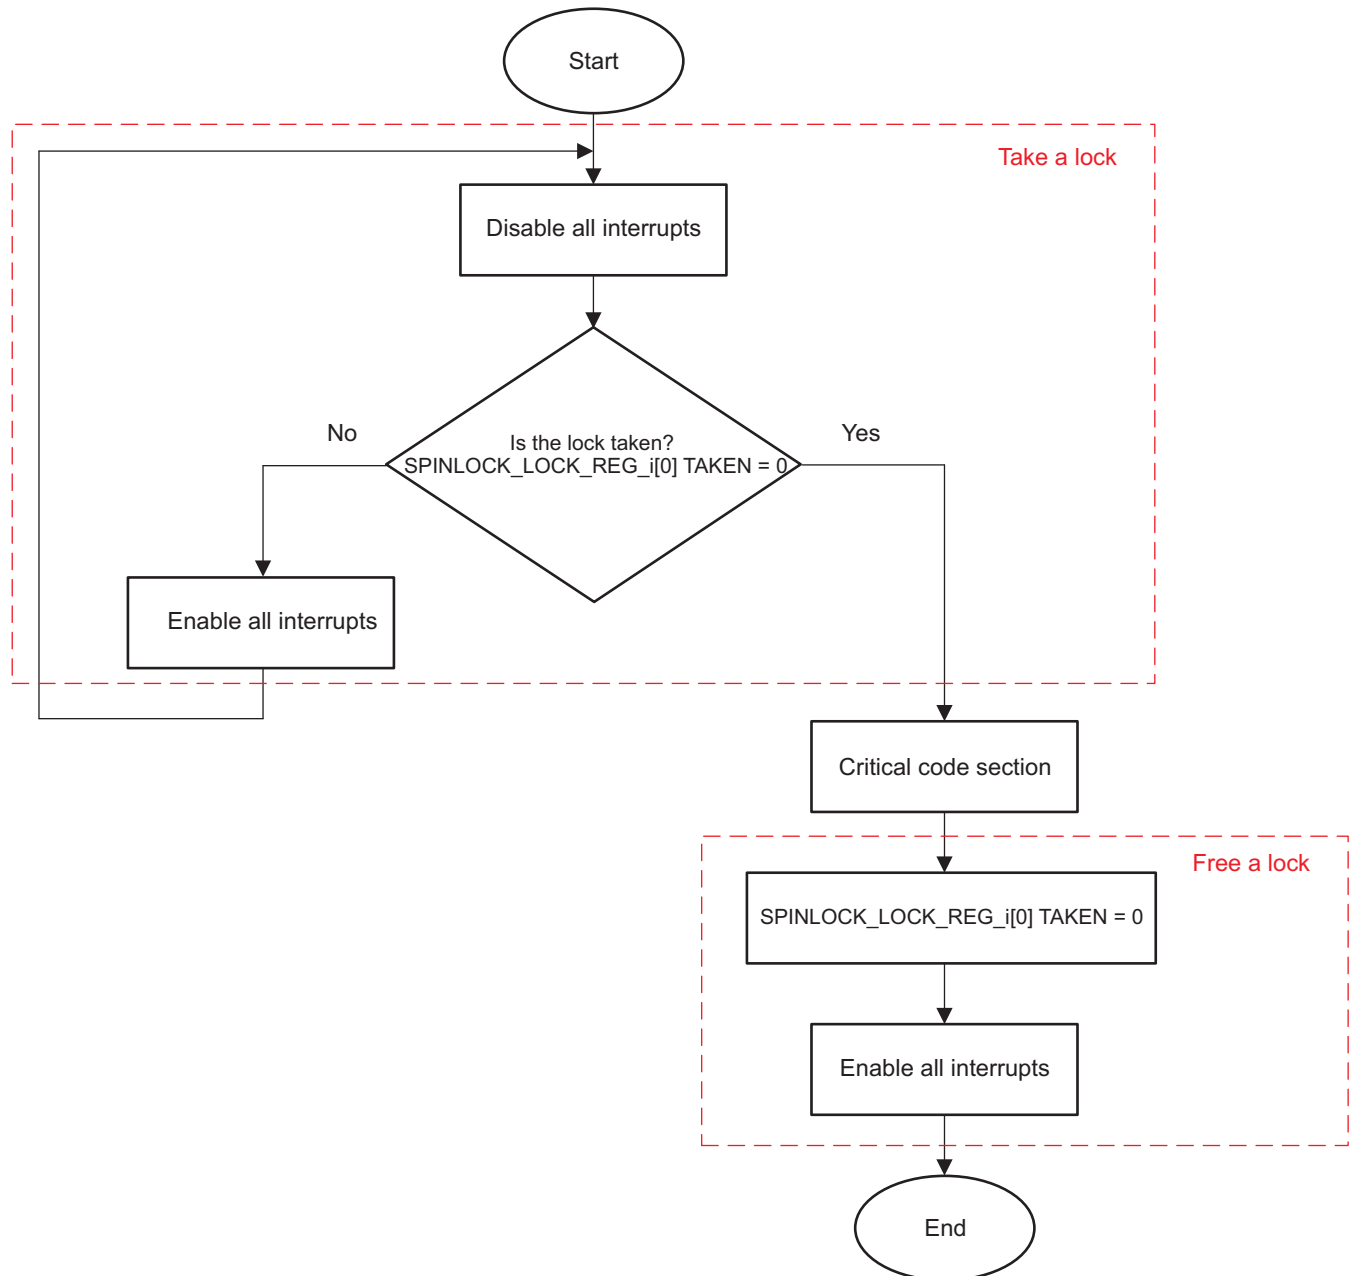

Module initialization (after reset) is not needed, except after system bug recovery. The following table presents the Spinlock initialization after a system bug recovery. Software should store 0 into each of the [SPINLOCK_LOCK_REG_i](#) registers at system startup to insure that all locks are initialized to Not Taken.

Table 21-5. Spinlock System Bug Recovery

Step	Register	Value
IF: SPINLOCK_SYSTATUS[0] IU0 = = 1?	SPINLOCK_SYSTATUS[0] IU0	
Free the 32 locks	SPINLOCK_LOCK_REG_i[0] TAKEN (i=0 to 31)	0x0
END		

21.4.1.2.2 Take and Release Spinlock

This procedure configures the take and release (free) operations for the Spinlock module. A spinlock should only be held with interrupts disabled. So, before attempting to obtain the spinlock, software should disable interrupts. Then it should read the [SPINLOCK_LOCK_REG_i\[0\]](#) TAKEN bit to attempt to obtain the lock. If it succeeds, it should proceed directly through the critical section then unlock and re-enable interrupts. If the acquisition attempt fails, the acquisition should be reattempted. To prevent unknown interrupt disabled time, interrupts should be re-enabled and then disabled before reattempting to acquire the lock. [Figure 21-4](#) shows the described above procedure.

Timers

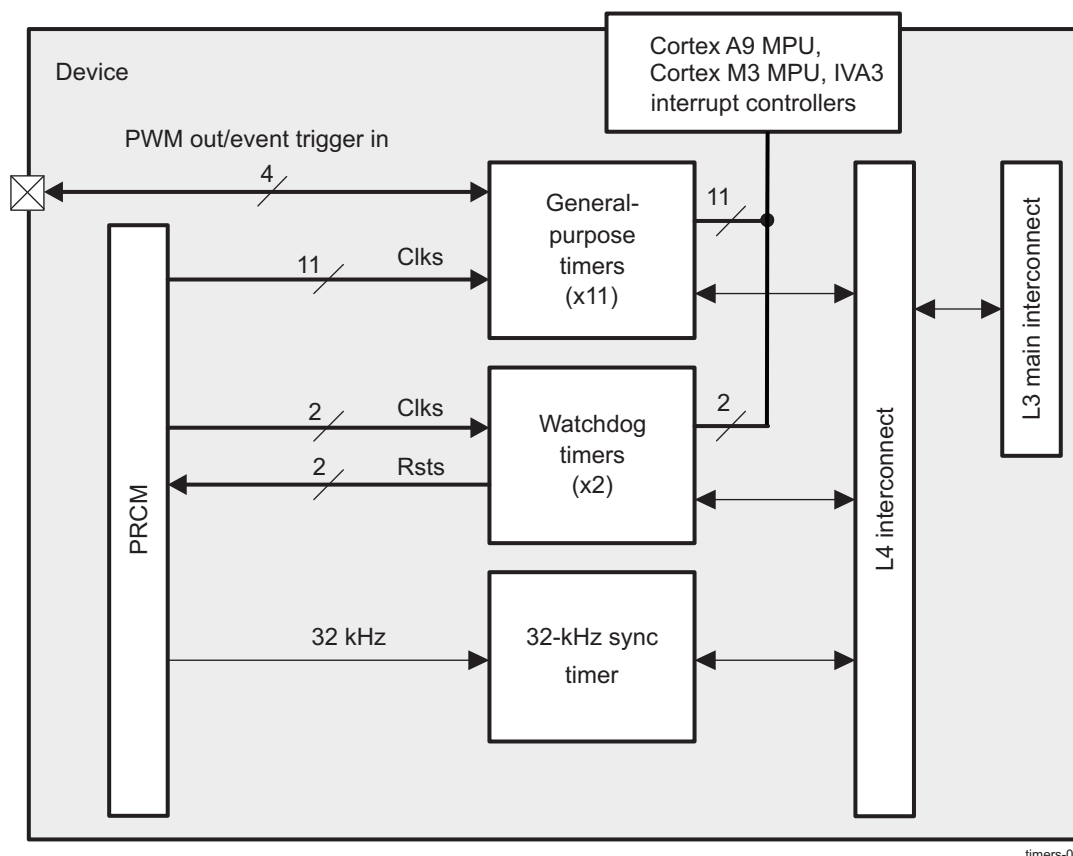

This chapter describes the timer modules for the device.

Topic	Page
22.1 Timers Overview	4177
22.2 General-Purpose Timers	4178
22.3 Watchdog Timers	4233
22.4 32-kHz Synchronized Timer	4261

22.1 Timers Overview

The device includes several types of timers used by the system software, including 11 general-purpose (GP) timers, two watchdog timers, and a 32-kHz synchronized timer (sync timer). Figure 22-1 is a high-level block diagram of the device timers.

Figure 22-1. Timers

The two watchdog timers are clocked with 32-kHz clocks. The 32-kHz sync timer, which is reset only at power up, provides the operating system (OS) with a stable timing source that stores the relative time since the last power cycle of the product. Finally, 11 GP timers, which are useful simply as basic timers, are included to generate time-stamp-based interrupts to the system software or to use as a source of pulse-width modulation (PWM) signals.

22.2 General-Purpose Timers

22.2.1 General-Purpose Timers Overview

The device has 11 general-purpose (GP) timers: GPTIMER1 through GPTIMER11.

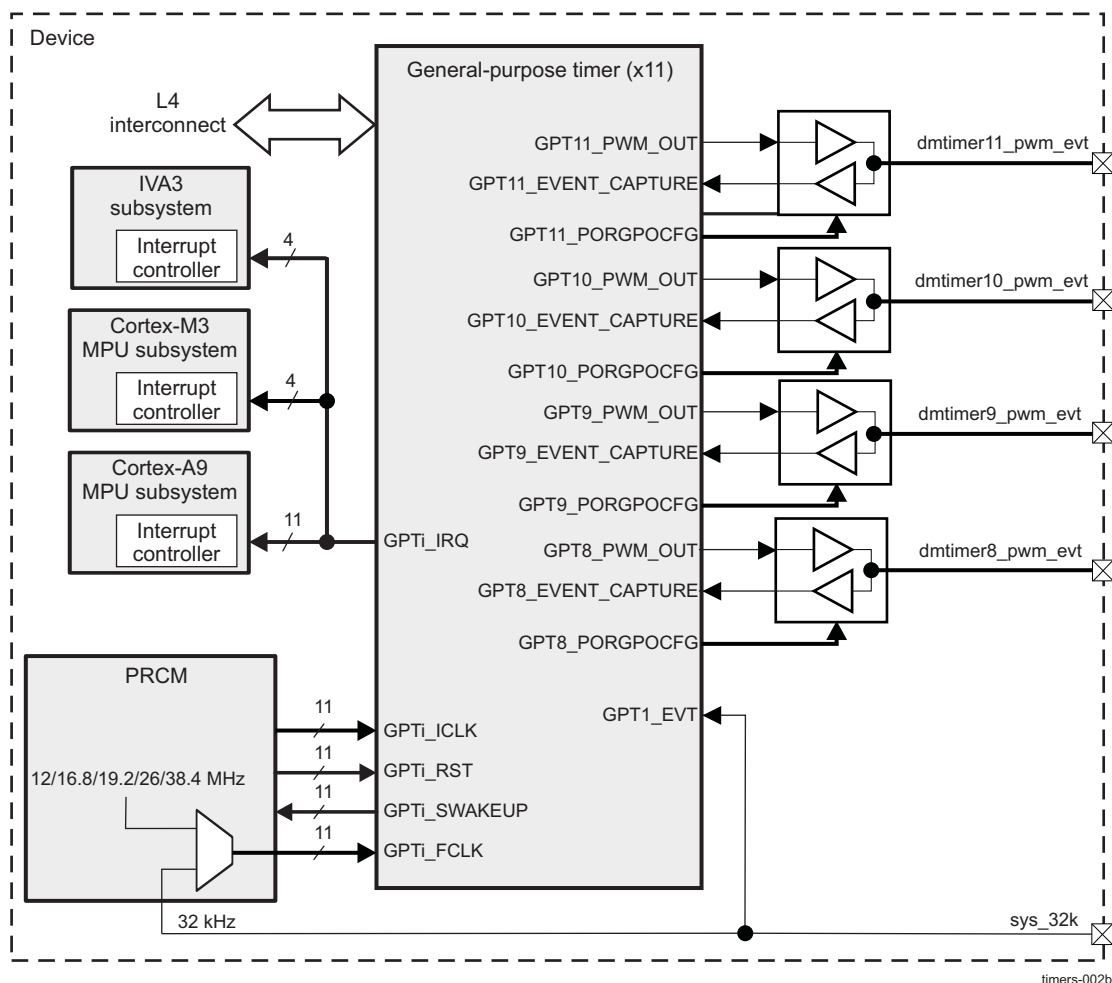

Each timer can be clocked from either the system clock (12, 16.8, 19.2, 26, or 38.4 MHz) or the 32-kHz clock. The selection of clock source is made at the power, reset, and clock management (PRCM) module level. For more information, see [Section 3.6.3.1, PRM Clock Source](#) in [Chapter 3, Power, Reset, and Clock Management](#).

GPTIMER1 has its GPT1_EVENT_CAPTURE pin tied to the 32-kHz clock and can be used to gauge the system clock input; it detects its frequency among 12, 16.8, 19.2, 26, or 38.4 MHz.

Each timer can provide an interrupt to the microprocessor unit (MPU) subsystem. In addition, GPTIMER5 through GPTIMER8 also have interrupts connected to the IVA3 subsystem.

GPTIMER1, GPTIMER2, and GPTIMER10 include specific functions to generate accurate tick interrupts to the operating system. GPTIMER8 through GPTIMER11 are connected to external pins by their PWM output or their event capture input pin (for external timer triggering). [Figure 22-2](#) is an overview of the GP timers.

Figure 22-2. GP Timers Overview

22.2.1.1 GP Timer Features

The following are the main features of the GP timer controllers:

- L4 slave interface support:

- 32-bit data bus width
- 32-/16-bit access supported
- 8-bit access not supported
- 10-bit address bus width
- Burst mode not supported
- Software-selectable nonposted or posted write/read internal resynchronization modes
- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Compare and capture modes
- Autoreload mode
- Start/stop mode
- Programmable divider clock source (2^n where $n = [0:8]$)
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- Dedicated GP output signal for using the GPTi_GPOCFG signal
- On-the-fly read/write register (while counting)
- 1-ms tick with 32,768-Hz functional clock generated (only GPTIMER1, GPTIMER2, and GPTIMER10)

22.2.2 GP Timer Environment

22.2.2.1 GP Timer External System Interface

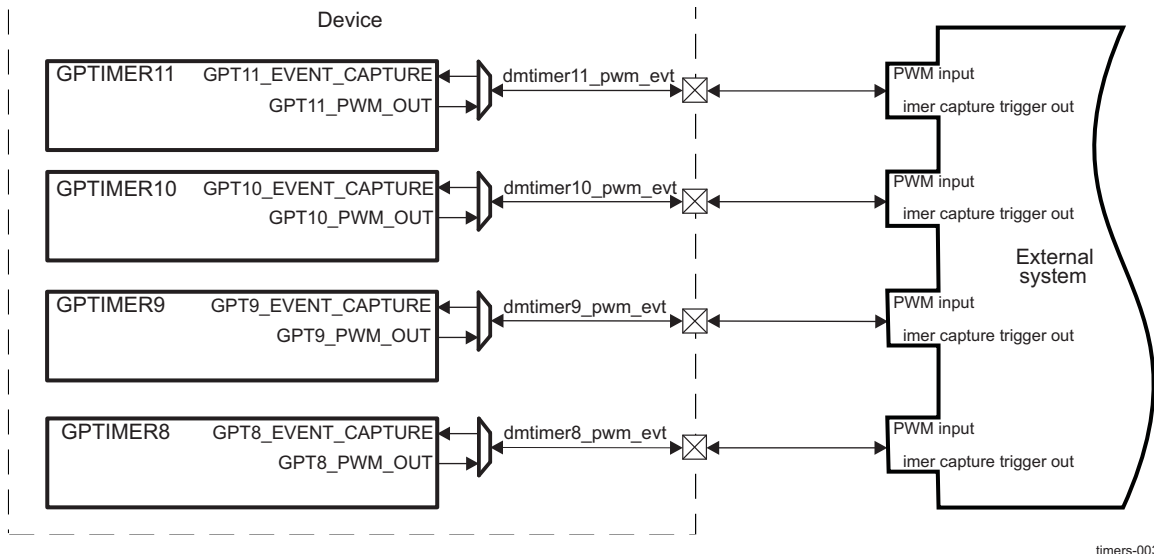

Four of the 11 GP timers can send or receive stimulus to/from the external (off-chip) system. In the device; however, only GPTIMER8 through GPTIMER11 are configured to output a pulse-width modulation (PWM) pulse or receive an external event signal used as a trigger to capture the current timer count. GPTIMER1 is also configured to receive an event trigger input (GPT1_EVENT_CAPTURE) tied to the internal 32-kHz clock. This event signal gauges the system clock input; detecting its frequency among 12, 16.8, 19.2, 26, or 38.4 MHz.

Figure 22-3 shows the external system interface for the GP timers, and Table 22-1 describes the GP timer inputs and outputs.

NOTE: Software control must ensure that MUX mode is configured to select the dmtimerx_pwm_evt (where x = 8 to 11) signal on only one pad. Other pads on which the same signal is multiplexed must be configured in safe mode or non-dmtimer mode to avoid two different pads driving the same signal.

For more information about the configuration of the dmtimer8_pwm_evt through dmtimer11_pwm_evt I/O pads, see Section 18.4.8, *PAD Functional Multiplexing and Configuration*.

Figure 22-3. GP Timers External System Interface

timers-003

Table 22-1. Input/Output Description

Pin Name	Type ⁽¹⁾	Reset Value	Signal Name	Description
dmtimer8_pwm_evt	I/O	0	GPT8_EVENT_CAPTURE GPT8_PWM_OUT	GPTIMER8 trigger input/ PWM output
dmtimer9_pwm_evt	I/O	0	GPT9_EVENT_CAPTURE GPT9_PWM_OUT	GPTIMER9 trigger input/ PWM output
dmtimer10_pwm_evt	I/O	0	GPT10_EVENT_CAPTURE GPT10_PWM_OUT	GPTIMER10 trigger input/ PWM output
dmtimer11_pwm_evt	I/O	0	GPT11_EVENT_CAPTURE GPT11_PWM_OUT	GPTIMER11 trigger input/ PWM output

⁽¹⁾ When configured for that function; I = input, O = output

NOTE: The event trigger input (GPTi_EVENT_CAPTURE) for GPTIMER2 through GPTIMER7 is internally tied low, and the PWM output (GPTi_PWM_OUT) is not connected.

NOTE: For GPTIMER8 through GPTIMER11, the GPTi_PORGPOCFG signal selects to connect the GPT pwm output or the GPT capture input to the dmtimerx_pwm_evt (where x = 8 to 11) pad at the top level. When the TCLR[14] GPO_CFG bit = 0b1, the dmtimerx_pwm_evt functions as a capture input. When the TCLR[14] GPO_CFG bit = 0b0, the dmtimerx_pwm_evt functions as a pwm output (GPO_CFG = 0b0).

22.2.3 GP Timer Integration

Figure 22-4 shows the integration of the GP timer in the device.

Figure 22-4. GP Timer Integration

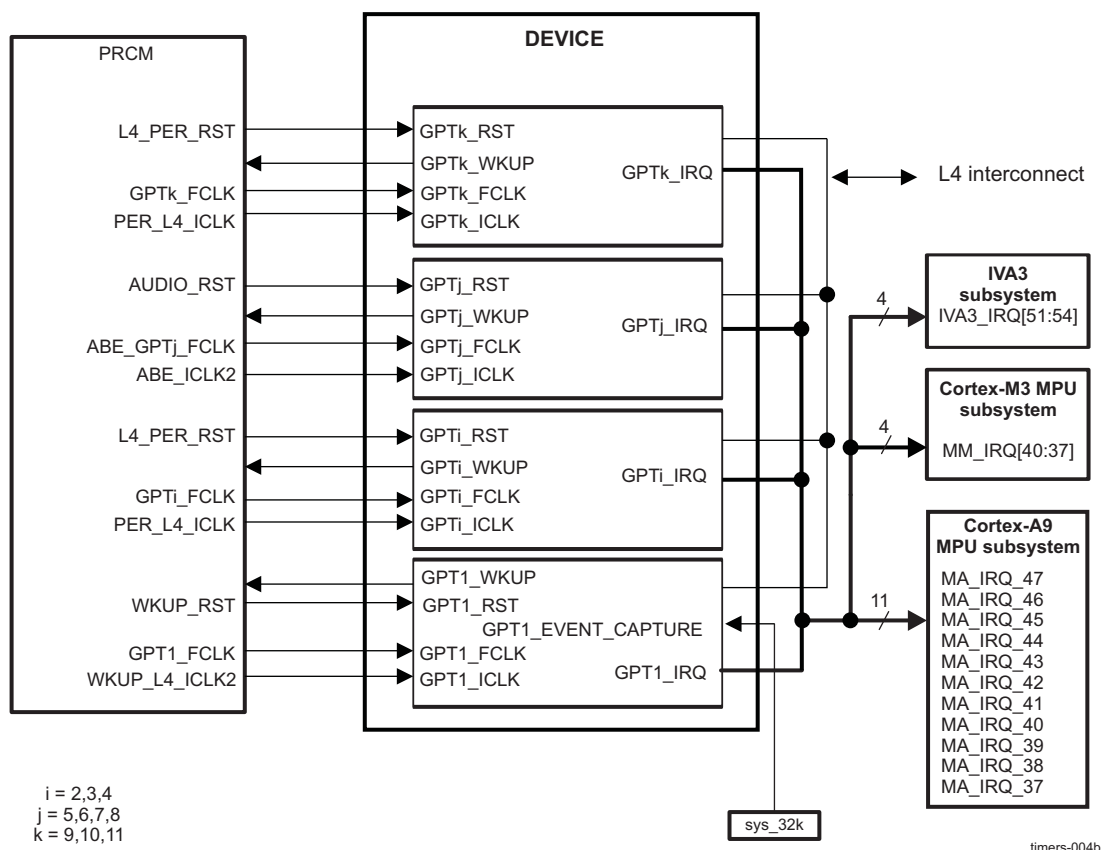

Table 22-2 through Table 22-4 summarize the integration of the module in the device.

Table 22-2. Integration Attributes

No DMA Requests				

NOTE: For the description of the interrupt source description, see [Section 22.2.4.5, GP Timer Interrupts](#).

22.2.4 GP Timer Functional Description

Each GP timer contains a free-running upward counter with autoreload capability on overflow. The timer counter can be read and written on-the-fly (while counting). Each GP timer includes compare logic to allow an interrupt event on a programmable counter matching value. A dedicated output signal can be pulsed or toggled on either an overflow or a match event. This offers time-stamp trigger signaling or PWM signal sources. A dedicated input signal can be used to trigger an automatic timer counter capture or an interrupt event on a programmable input signal transition. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged into one module interrupt line and one wake-up line.

Each internal interrupt source can be independently enabled/disabled with a dedicated bit of the [GPT_TIER](#) register for the interrupt features, and a dedicated bit of the [GPT_TWER](#) register for the wake-up of GPTIMER1, GPTIMER2, and GPTIMER10. In addition, these timers have a mechanism implemented to generate an accurate tick interrupt.

For the other GP Timers, each internal interrupt source can be independently enabled/disabled through the [GPT_IRQENABLE_SET](#) and [GPT_IRQENABLE_CLR](#) register bit fields.

For each GP timer implemented in the device, there are two possible clock sources:

- 32-kHz clock
- System clock

Selection of the input clock source is done in the registers in the PRCM configuration (see [Section 22.2.1, GP Timer Overview](#)).

Each GP timer supports three functional modes:

- Timer mode
- Capture mode
- Compare mode

The capture and compare modes are disabled by default after core reset.

22.2.4.1 GP Timer Block Diagram

[Figure 22-5](#) is a block diagram of the common GP timers, and [Figure 22-6](#) is a block diagram of the GP timers with 1-ms tick generation module.

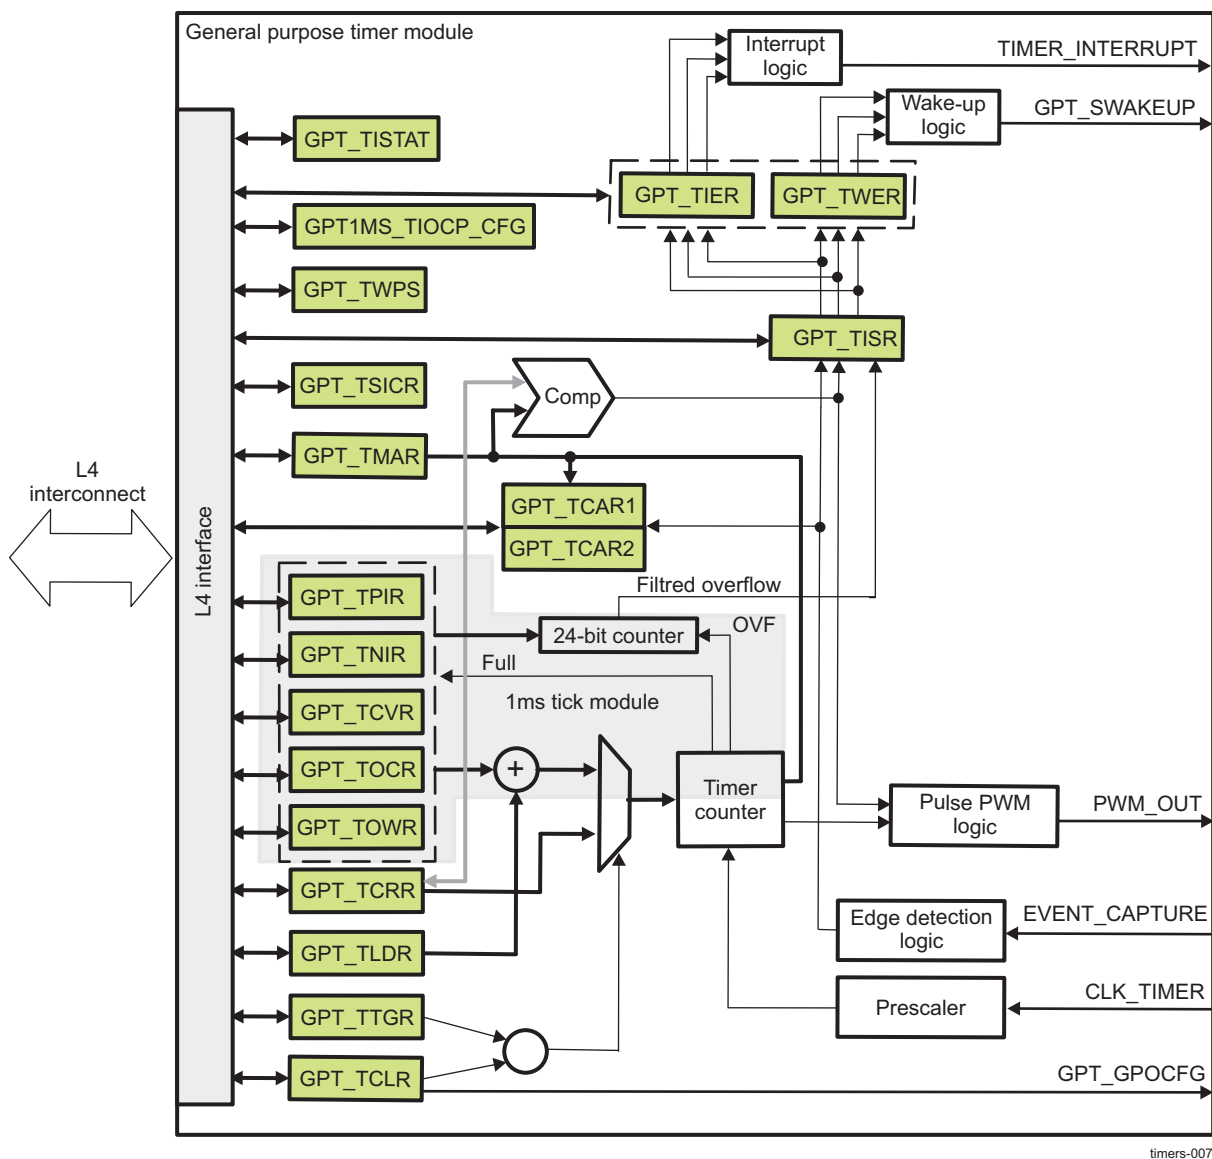

Figure 22-5. Block Diagram of GPTIMER3 Through GPTIMER9, and GPTIMER11

Figure 22-6. Block Diagram of GPTIMER1, GPTIMER2, and GPTIMER10

22.2.4.2 GPTIMER1, GPTIMER2, and GPTIMER10 Power Management

The GP timer modules have an internal bit, [GPT1MS_TIOCP_CFG\[0\]](#) AUTOIDLE, that is used to apply an internal interface clock gating strategy.

At the PRCM module level, when all conditions to shut off the PRCM module functional or interface output clocks are met (see [Section 3.1.1.1.4, Clock Domain-Level Clock Management](#)), the PRCM module automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the [GPT1MS_TIOCP_CFG\[4:3\]](#) IDLEMODE bit field.

[Table 22-7](#) lists the IDLEMODE settings and the related acknowledgment modes.

Table 22-5. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The GP timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
10	Smart-idle	The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach to efficient system power management.
11	Reserved	

When configured in smart-idle mode, the GP timer also offers an additional granularity on GPTi_FCLK and GPTi_ICLK gating. The [GPT1MS_TIOCP_CFG\[9:8\]](#) CLOCKACTIVITY bit field is used to determine which clock is shut down (GPTi_FCLK, GPTi_ICLK, neither, or both clocks).

The CLOCKACTIVITY setting is used internally to the GP timer to determine the part of the module on which the conditions to acknowledge the PRCM IDLE request are tested. For example, if GPTi_FCLK is not to be shut down on a PRCM IDLE request, the GP timer considers only GPTi_ICLK and associated pending activities before acknowledging the request.

Some GP timer features are associated with GPTi_ICLK and others are associated with GPTi_FCLK. Using the CLOCKACTIVITY setting along with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if the GP timer acknowledges an IDLE request.

[Table 22-6](#) lists the CLOCKACTIVITY settings and associated features.

Table 22-6. CLOCKACTIVITY Settings

CLOCKACTIVITY Value	GPTi_ICLK Effects	GPTi_FCLK Effects	Description	Associated Features
00	OFF	OFF	GPTi_ICLK and GPTi_FCLK are considered for generating the acknowledge. This setting also means GPTi_FCLK and GPTi_ICLK are likely to be shut down on PRCM IDLE request.	The idle acknowledge signal is asserted when there are no pending activities on the functional clock domain (improved latency in assertion of idle acknowledge). The wake-up capability of the GP timer is disabled.
01	ON	OFF	GPTi_ICLK is not shut down on PRCM IDLE request; only GPTi_FCLK is affected.	

Table 22-6. CLOCKACTIVITY Settings (continued)

CLOCKACTIVITY Value	GPTi_ICLK Effects	GPTi_FCLK Effects	Description	Associated Features
10	OFF	ON	GPTi_FCLK is not shut down on PRCM IDLE request; only GPTi_ICLK is affected.	The idle acknowledge signal is asserted when there are no pending activities on the interface clock domain, without evaluating the pending activities on the functional clock domain (the GP timer enters into sleep mode, and if a pending interrupt event is completed during idle mode, the wake-up signal is asserted). The wake-up signal is enabled.
11	ON	ON	None of the clocks are shut down. Therefore, the GP timer can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clocks.	

CAUTION

The PRCM module does not have any hardware means to read the CLOCKACTIVITY settings. The software must ensure consistent programming between the GP timer CLOCKACTIVITY and the PRCM module functional clock and interface clock control bits. If the GP timer is disabled in the CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the GP timer clocks. This can lead to unpredictable behavior.

22.2.4.2.1 Wake-Up Capability

If the [GPT1MS_TIOCP_CFG\[4:3\]](#) IDLEMODE bit field sets the smart-idle mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request. This wake-up request is sent only if the [GPT1MS_TIOCP_CFG\[2\]](#) ENAWAKEUP bit enables the timer wake-up capability.

[Figure 22-7](#) shows the wake-up request generation. For more information on the GP timer clock control, see [Section 3.6, Clock Management Functional Description](#) in [Chapter 3, Power, Reset and Clock Management](#).

Figure 22-7. Wake-Up Request Generation

timers-005

For GPTIMER1, GPTIMER2, and GPTIMER10, the timer wake-up enable-register (**GPT_TWER**) allows masking the expected source of the wake-up event that generates a wake-up request. The **GPT_TWER** register is synchronously programmed with the interface clock before the PRCM module sends an idle mode request. The expected source of the wake-up event is an overflow (**GPT_TCRR**), a timer match (the compare result of **GPT_TCRR** and **GPT_TMAR** matches the counter value), and a timer capture (detection of an external pulse transition of the correct polarity on the **GPT_EVENT_CAPTURE**).

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (**GPT_TISR**). The pending wake-up event is reset when the set status bit is overwritten with 1.

NOTE: The status bit must be reset to re-enter idle mode.

22.2.4.3 Power Management of Other GP Timers

At the PRCM module level, when all conditions to shut off the PRCM module functional or interface output clocks are met (see [Section 3.1.1.1.4, Clock Domain Level Clock Management](#)), the PRCM module automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the **GPT_TIOCP_CFG**[3:2] IDLEMODE bit field.

[Table 22-7](#) lists the IDLEMODE settings and the related acknowledgment modes.

Table 22-7. IDLEMODE Settings

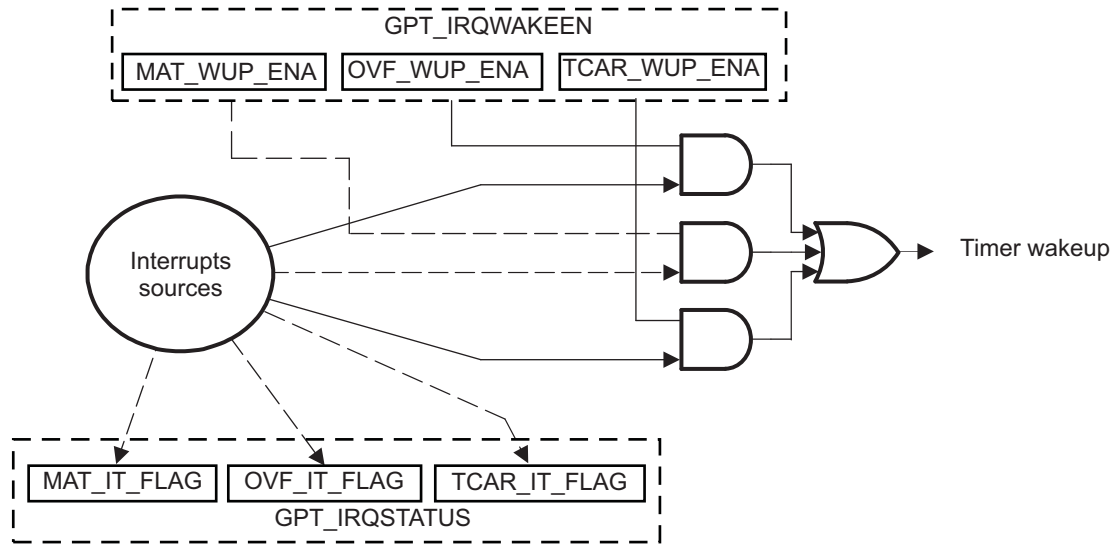

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The GP timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, however, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
10	Smart-idle	The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach to efficient system power management.
11	Reserved	

22.2.4.3.1 Wake-Up Capability

If the **GPT_TIOCP_CFG**[3:2] IDLEMODE bit field sets the smart-idle mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request. This wake-up request is sent only if the **GPT_IRQWAKEEN**[2:0] bit field enables the timer wake-up capability.

[Figure 22-8](#) shows the wake-up request generation. For more information on the GP timer clock control, see [Section 3.6, Clock Management Functional Description](#) in [Chapter 3, Power, Reset and Clock Management](#).

Figure 22-8. Wake-Up Request Generation

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register ([GPT_IRQSTATUS](#)). The pending wake-up event is reset when the set status bit is overwritten with 1.

NOTE: The status bit must be reset to re-enter idle mode.

22.2.4.4 Software Reset

Two bit fields can generate a software reset of the GP timer:

- [GPT1MS_TIOCP_CFG\[1\]](#) SOFTRESET for GPTIMER1, GPTIMER2, and GPTIMER10, and [GPT_TIOCP_CFG\[0\]](#) SOFTRESET for other timers
- [GPT_TSICR\[1\]](#) SFT for all timers

For both bits, all read accesses return 0.

The [GPT1MS_TIOCP_CFG\[1\]](#) SOFTRESET/[GPT_TIOCP_CFG\[0\]](#) SOFTRESET bit allows resetting the functional and interface domains. The [GPT_TSICR\[1\]](#) SFT bit allows resetting the functional part of the GP timer.

Before accessing or using the GP timer, the local host must ensure that both internal resets are released by reading the [GPT_TISTAT\[0\]](#) RESETDONE (for GPTIMER1, GPTIMER2, and GPTIMER10), or the [GPT_TIOCP_CFG\[0\]](#) SOFTRESET bit (for other timers). This bit monitors the internal reset status.

22.2.4.5 GP Timer Interrupts

The timer can issue an overflow interrupt, a timer match interrupt, and a timer capture interrupt. Each internal interrupt source can be independently enabled/disabled in the interrupt-enable register ([GPT_TIER](#) for GPTIMER1, GPTIMER2, and GPTIMER10), or, for other timers, enable in the interrupt-enable register ([GPT_IRQENABLE_SET](#)) and disable in the interrupt disable register ([GPT_IRQENABLE_CLR](#)). When the interrupt event is issued, the associated interrupt status bit is set in the timer status register ([GPT_TISR](#) for GPTIMER1, GPTIMER2, and GPTIMER10, and [GPT_IRQSTATUS](#) for other timers).

22.2.4.6 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the timer control register (**GPT_TCLR**[0] ST bit). The timer counter register (**GPT_TCRR**) can be loaded when stopped or on-the-fly (while counting). **GPT_TCRR** can be loaded directly by a **GPT_TCRR** write access with a new timer value. The **GPT_TCRR** register can also be loaded with the value held in the timer-load register **GPT_TLDR** by a trigger register (**GPT_TTGR**) write access. Loading of **GPT_TCRR** is done regardless of the **GPT_TTGR** written value. The timer counter register **GPT_TCRR** value can be read when stopped, or captured on-the-fly by a **GPT_TCRR** read access. The timer is stopped and the counter value is set to 0 when the module reset is asserted. The timer is maintained at stop after the reset is released.

In one-shot mode (the **GPT_TCLR**[1] AR bit set to 0), the counter is stopped after counting overflow occurs (the counter value remains at 0).

When the autoreload mode is enabled (the **GPT_TCLR**[1] AR bit set to 1), the **GPT_TCRR** register is reloaded with the timer-load register (**GPT_TLDR**) value after a counting overflow occurs.

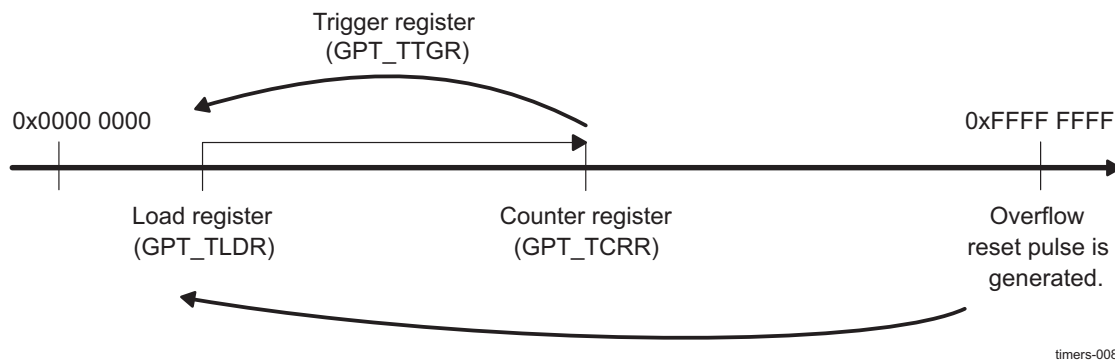

CAUTION

Do not put the overflow value (0xFFFF FFFF) in the **GPT_TLDR** register because it can lead to undesirable results.

An interrupt can be issued on overflow if the overflow interrupt-enable bit is set in the timer interrupt-enable register (**GPT_TIER**[1] OVF_IT_ENA bit set to 1 for GPTIMER1, GPTIMER2, and GPTIMER10, or **GPT_IRQENABLE_SET**[1] OVF_IT_FLAG bit set to 1 for other timers). A dedicated output pin (timer PWM) can be programmed in **GPT_TCLR**[12] through **GPT_TCLR**[11:10] (PT and TRG bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs. The **GPT_TCLR**[12] PT bit selects pulse/toggle modulation (**GPT_TCLR**[11:10] TRG bit field selects trigger mode).

Figure 22-9 shows the **GPT_TCRR** timing value.

Figure 22-9. GPT_TCRR Timing Value

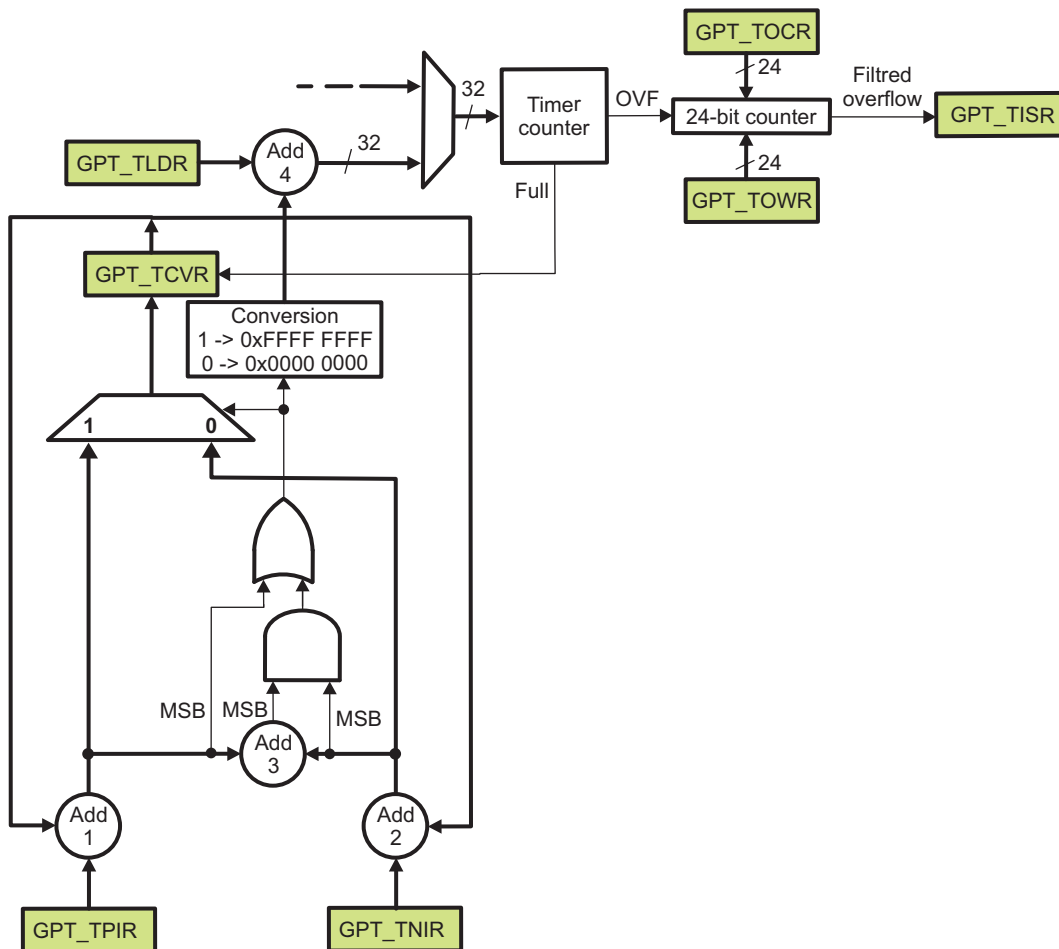

22.2.4.6.1 1-ms Tick Generation (Only GPTIMER1, GPTIMER2, and GPTIMER10)

The interrupt period is not exactly 1 ms because the timer input clock is 32,768 Hz. If the clock counts up to 32, it obtains a 0.977-ms period; if it counts up to 33, it obtains a 1.007-ms period. For large granularity, the error is cumulative and can generate important deviations from the standard value.

To minimize the error between a true 1-ms tick and the tick generated by the 32,768 Hz timer, the sequencing of periods less than 1 ms and periods greater than 1 ms must be shuffled. An additional 1-ms block is used to correct this error. See Figure 22-10.

In this implementation, the increment sequencing is automatically managed by the timer to minimize the error. The user must define only the value of the timer positive increment register (**GPT_TPIR**[31:0] POSITIVE_INC_VALUE bit field) and the timer negative increment register (**GPT_TNIR**[31:0] NEGATIVE_INC_VALUE bit field). An automatic adaptation mechanism is used to simplify the programming model.

Figure 22-10. Block Diagram of the 1-ms Tick Module

timers-009

The [GPT_TPIR](#), [GPT_TNIR](#), and [GPT_TCCR](#) registers and adders Add1, Add2, and Add3 are used to define whether the next value loaded in the timer counter register ([GPT_TCRR\[31:0\]](#) [TIMER_COUNTER](#) bit field) is the value of the [GPT_TLDR\[31:0\]](#) [LOAD_VALUE](#) bit field (period less than 1 ms) or the value of [GPT_TLDR\[31:0\]](#) [LOAD_VALUE](#) –1 (period greater than 1 ms).

[Table 22-8](#) lists the value loaded in the [GPT_TCRR](#) register according to the sign of the result of Add1, Add2, and Add3.

MSB = 0: Positive value, MSB = 1: Negative value

Table 22-8. Value Loaded in [GPT_TCRR](#) to Generate 1-ms Tick

Add1 MSB	Add2 MSB	Add3 MSB	Value of GPT_TCRR Register
0	0	0	GPT_TLDR[31:0] LOAD_VALUE bit field
0	0	1	GPT_TLDR[31:0] LOAD_VALUE bit field
0	1	0	GPT_TLDR[31:0] LOAD_VALUE bit field
0	1	1	GPT_TLDR[31:0] LOAD_VALUE –1
1	0	0	N/A
1	0	1	N/A
1	1	0	GPT_TLDR[31:0] LOAD_VALUE –1
1	1	1	GPT_TLDR[31:0] LOAD_VALUE –1

The values of the [GPT_TPIR](#) and [GPT_TNIR](#) registers are calculated using the following formula:

- Positive increment value = $(\text{INTEGER}[F_{\text{clk}} * T_{\text{tick}}] + 1) * 1\text{e}6 - (F_{\text{clk}} * T_{\text{tick}} * 1\text{e}6)$
- Negative increment value = $(\text{INTEGER}[F_{\text{clk}} * T_{\text{tick}}] * 1\text{e}6) - (F_{\text{clk}} * T_{\text{tick}} * 1\text{e}6)$

NOTE: Fclk clock frequency (kHz)

Ttick tick period (ms)

The timer overflow counter register ([GPT_TOCR](#)) and the timer overflow wrapping register [GPT_TOWR](#) are used to filter interrupts. When the timer overflows, it increments the 24-bit [GPT_TOCR](#) register. When the 24-bit [GPT_TOCR](#) register values match the value in the 24-bit [GPT_TOWR](#) register and the timer overflow is asserted, the [GPT_TOCR](#) register is reset and an interrupt is generated to the [GPT_TISR](#) register.

With the conversion block in reset state (the positive increment register, negative increment register, and counter value register are zeroed), the programming model and the behavior of GPTIMER1, GPTIMER2, and GPTIMER10 remain unchanged.

For 1-ms tick with a 32,768-Hz clock:

- [GPT_TPIR](#)[31:0] POSITIVE_INC_VALUE = 232000
- [GPT_TNIR](#)[31:0] NEGATIVE_INC_VALUE = -768000
- [GPT_TLDR](#)[31:0] LOAD_VALUE = 0xFFFF FFE0

NOTE: Any value of the tick period can be generated with the appropriate value of the [GPT_TPIR](#), [GPT_TNIR](#), and [GPT_TLDR](#) registers.

By default, the [GPT_TPIR](#), [GPT_TNIR](#), [GPT_TCVR](#), [GPT_TOCR](#), and [GPT_TOWR](#) registers and the associated logic are in reset mode (all 0s) and have no action on the programming model.

22.2.4.7 Capture Mode Functionality

When a transition is detected on the module input pin (EVENT_CAPTURE), the timer value in the [GPT_TCRR](#) register can be captured and saved in the [GPT_TCAR1](#) or [TCAR2](#) register function of the mode selected in the [GPT_TCLR](#)[13] CAPT_MODE bit. The edge detection circuitry monitors transitions on the input pin (EVENT_CAPTURE).

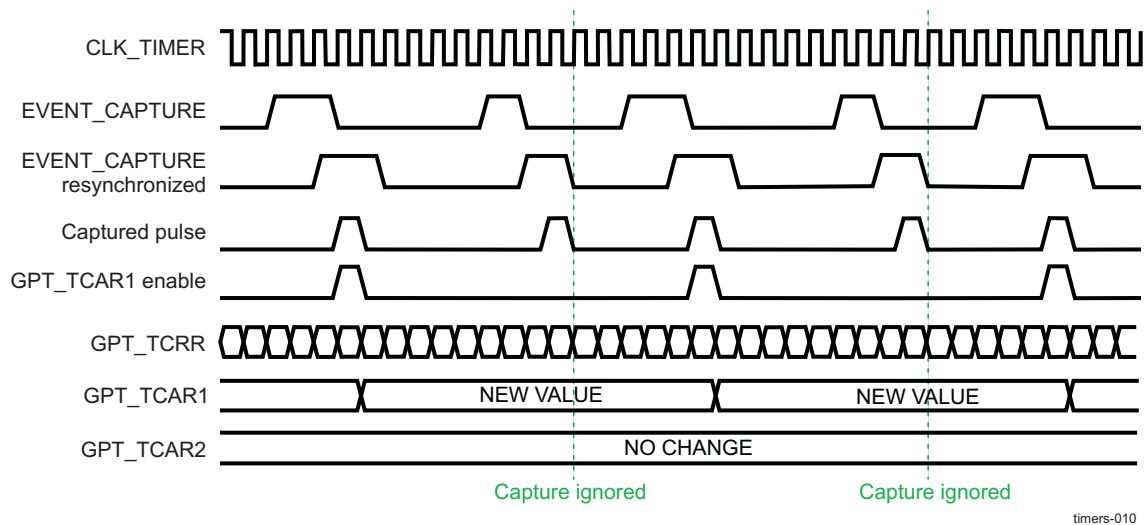

The rising edge, falling edge, or both, can be selected in the [GPT_TCLR](#)[9:8] TCM bit field to trigger the timer counter capture. The module sets the [GPT_TISR](#)[2] [TCAR_IT_FLAG](#) bit for GPTIMER1, GPTIMER2, or GPTIMER10, and the [GPT_IRQSTATUS](#)[2] [TCAR_IT_FLAG](#) bit for other timers, when an active edge is detected, and at the same time, the counter value [GPT_TCRR](#) is stored in timer capture register [GPT_TCAR1](#) or [GPT_TCAR2](#), as follows:

- If the [GPT_TCLR](#)[13] CAPT_MODE bit is 0, on the first enabled capture event, the value of the counter register is saved in the [GPT_TCAR1](#) register, and all the next events are ignored (no update on the [GPT_TCAR1](#) register and no interrupt triggering) until the detection logic is reset or the [GPT_TISR](#)[2] [TCAR_IT_FLAG](#) bit (or [GPT_IRQSTATUS](#)[2] [TCAR_IT_FLAG](#), depending on the timer) is cleared by writing 1 to it.
- If the [GPT_TCLR](#)[13] CAPT_MODE bit is 1, on the first enabled capture event, the value of the counter register is saved in the [GPT_TCAR1](#) register, and on the second enabled capture event, the value of the counter register is saved in the [GPT_TCAR2](#) register. If a capture interrupt is enabled, the interrupt triggers on the second event capture. All other events are ignored (no update on [GPT_TCAR1](#)/[GPT_TCAR2](#) and no interrupt triggering) until the detection logic is reset or [GPT_TISR](#)[2] [TCAR_IT_FLAG](#) bit (or [GPT_IRQSTATUS](#)[2] [TCAR_IT_FLAG](#), depending on the timer) is cleared by writing 1 to it. This mechanism is useful for period calculation of a clock, if that clock is connected to the EVENT_CAPTURE input pin.

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served. The `GPT_TISR[2]` `TCAR_IT_FLAG` bit or the `GPT_IRQSTATUS[2]` `TCAR_IT_FLAG` (previously 1) is cleared by writing 1 to it or when the edge detection mode bits (the `GPT_TCLR[9:8]` `TCM` bit field) are changed from no-capture mode detection to any other mode. The timer functional clock (input to prescaler) is used to sample the input pin (`EVENT_CAPTURE`). A negative or positive pulse input can be detected when the pulse time is greater than the functional clock period. An interrupt is issued on edge detection if the capture interrupt-enable bit is set in the `GPT_TIER[2]` `TCAR_IT_ENA` bit (for `GPTIMER1`, `GPTIMER2`, or `GPTIMER10`), or in the `GPT_IRQENABLE_SET[2]` `TCAR_EN_FLAG` bit (for other timers). See the examples in [Figure 22-11](#) and [Figure 22-12](#).

In [Figure 22-11](#), the `GPT_TCLR[9:8]` `TCM` bit field value is 0b01, and `GPT_TCLR[13]` `CAPT_MODE` bit is 0. Only the rising edge of `EVENT_CAPTURE` triggers a capture in the `GPT_TCAR1` and `GPT_TCAR2` registers, and only the `GPT_TCAR1` register updates.

Figure 22-11. Capture Wave Example for `GPT_TCLR[13]` `CAPT_MODE` = 0

In [Figure 22-12](#), the value of the `GPT_TCLR[9:8]` `TCM` bit field is 0b01, and the `GPT_TCLR[13]` `CAPT_MODE` bit is 1. Only the rising edge of `EVENT_CAPTURE` triggers a capture in the `GPT_TCAR1` register on the first enabled event, and the `GPT_TCAR2` register updates on the second enabled event.

Figure 22-12. Capture Wave Example for `GPT_TCLR[13]` `CAPT_MODE` = 1

22.2.4.8 Compare Mode Functionality

When compare enable-register [GPT_TCLR](#)[6] CE bit is set to 1, the timer value ([GPT_TCR](#)[31:0] TIMER_COUNTER bit field) is continuously compared to the value held in the timer match register ([GPT_TMAR](#)). The [GPT_TMAR](#)[31:0] COMPARE_VALUE bit field value can be loaded at any time (timer counting or stopped). When the [GPT_TCR](#) and the [GPT_TMAR](#) values match, an interrupt is issued, if the [GPT_TIER](#)[0] MAT_IT_ENA (for GPTIMER1, GPTIMER2, and GPTIMER10), or [GPT_IRQSTATUS_SET](#)[0] MAT_EN_FLAG bit (for other timers) is set.

The right programming way is to write a compare value to the [GPT_TMAR](#) register before setting the [GPT_TCLR](#)[6] CE bit to prevent any unwanted interrupts due to a reset value matching effect.

The dedicated output pin (timer PWM) can be programmed in the [GPT_TCLR](#)[12] PT bit through the [GPT_TCLR](#)[11:10] TRG bit field to generate one positive pulse (timer clock duration) or to invert the current value (toggle mode) when an overflow or a match occurs.

22.2.4.9 Prescaler Functionality

A prescaler can be used to divide the timer counter input clock frequency. The prescaler is enabled when the [GPT_TCLR](#)[5] PRE bit is set. The [GPT_TCLR](#)[4:2] PTV bit field sets the second prescaler ratio. The prescaler counter is reset when the timer counter is stopped or reloaded on-the-fly.

[Table 22-9](#) lists the prescaler/timer reload values versus contexts.

Table 22-9. Prescaler/Timer Reload Values Versus Contexts

Context	Prescaler	Timer Counter
Overflow (when autoreload is on)	Reset	GPT_TLDR [31:0]
GPT_TCR write	Reset	GPT_TCR [31:0]
GPT_TTGR write	Reset	GPT_TLDR [31:0]
Stop	Reset	Frozen

22.2.4.10 Pulse-Width Modulation

The timer can be configured to provide a programmable PWM output. The timer PWM output pin can be configured to toggle on an event. The [GPT_TCLR](#)[11:10] TRG bit field determines on which register value the PWM pin toggles. Either overflow alone or both overflow and match can be selected to toggle the timer PWM pin when a compare condition occurs.

CAUTION

In toggle mode, when [GPT_TCLR](#)[11:10] TRG = 0x2 (overflow and match), the first event that toggles the PWM line is an overflow event. If a match event occurs first; it does not toggle the PWM line (see [Figure 22-14](#)).

The [GPT_TCLR](#)[7] SCPWM bit can be programmed to set or clear the timer PWM output signal only while the counter is stopped or the trigger is off. This allows setting the output pin to a known state before modulation starts. Modulation synchronously stops when the [GPT_TCLR](#)[11:10] TRG bit field is cleared and overflow occurs. This allows fixing a deterministic state of the output pin when modulation stops.

In [Figure 22-13](#), the internal overflow pulse is set each time (0xFFFF FFFF - [GPT_TLDR](#)[31:0] LOAD_VALUE + 1) the value is reached, and the internal match pulse is set when the counter reaches the [GPT_TMAR](#) register value. Depending on the value of the [GPT_TCLR](#)[12] PT bit and [GPT_TCLR](#)[11:10] TRG bit field, the timer provides pulse or PWM event on the output pin (timer PWM).

The [GPT_TLDR](#) and [GPT_TMAR](#) registers must keep values below the overflow value (0xFFFF FFFF) by at least two units. In case the PWM trigger events are both overflow and match, the difference between the values kept in the [GPT_TMAR](#) register and the value in the [GPT_TLDR](#) register must be at least two units. When match event is used, the compare mode [GPT_TCLR](#)[6] CE bit must be set.

In Figure 22-13, the `GPT_TCLR[7]` SCPWM bit is set to 0. In Figure 22-14, the `GPT_TCLR[7]` SCPWM bit is set to 1. To obtain the desired wave form, start the counter at 0xFFFF FFFE value (to ensure an overflow first) or adjust the line polarity (`GPT_TCLR[7]` SCPWM bit).

Figure 22-13. Timing Diagram of PWM With `GPT_TCLR[7]` SCPWM Bit = 0

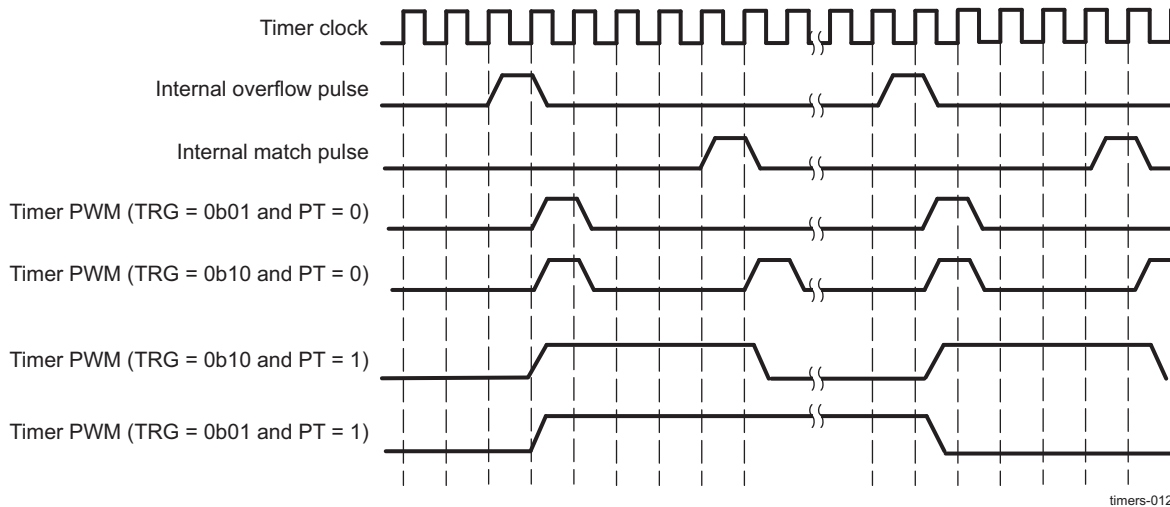

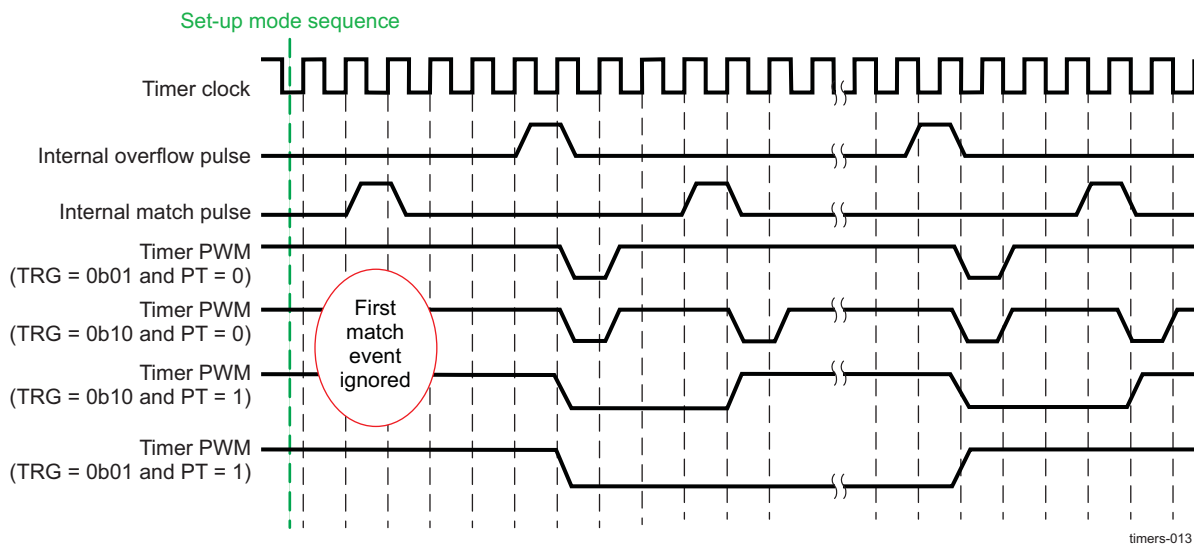

Figure 22-14. Timing Diagram of PWM With `GPT_TCLR[7]` SCPWM Bit = 1

22.2.4.11 Timer Counting Rate

The timer rate is defined by the following values:

- Value of the prescaler fields (the `GPT_TCLR[5]` PRE bit and the `GPT_TCLR[4:2]` PTV bit field)
- Value loaded into the timer-load register (`GPT_TLDR`)
