PRELIMINARY

Mailbox

This chapter describes the Mailbox module in the device.

| Topic | Page |
|--|-------------|
| 20.1 Mailbox Overview | 4170 |
| 20.2 Mailbox Integration | 4172 |
| 20.3 Mailbox Functional Description | 4176 |
| 20.4 Mailbox Programming Guide | 4182 |
| 20.5 Mailbox Register Manual | 4185 |

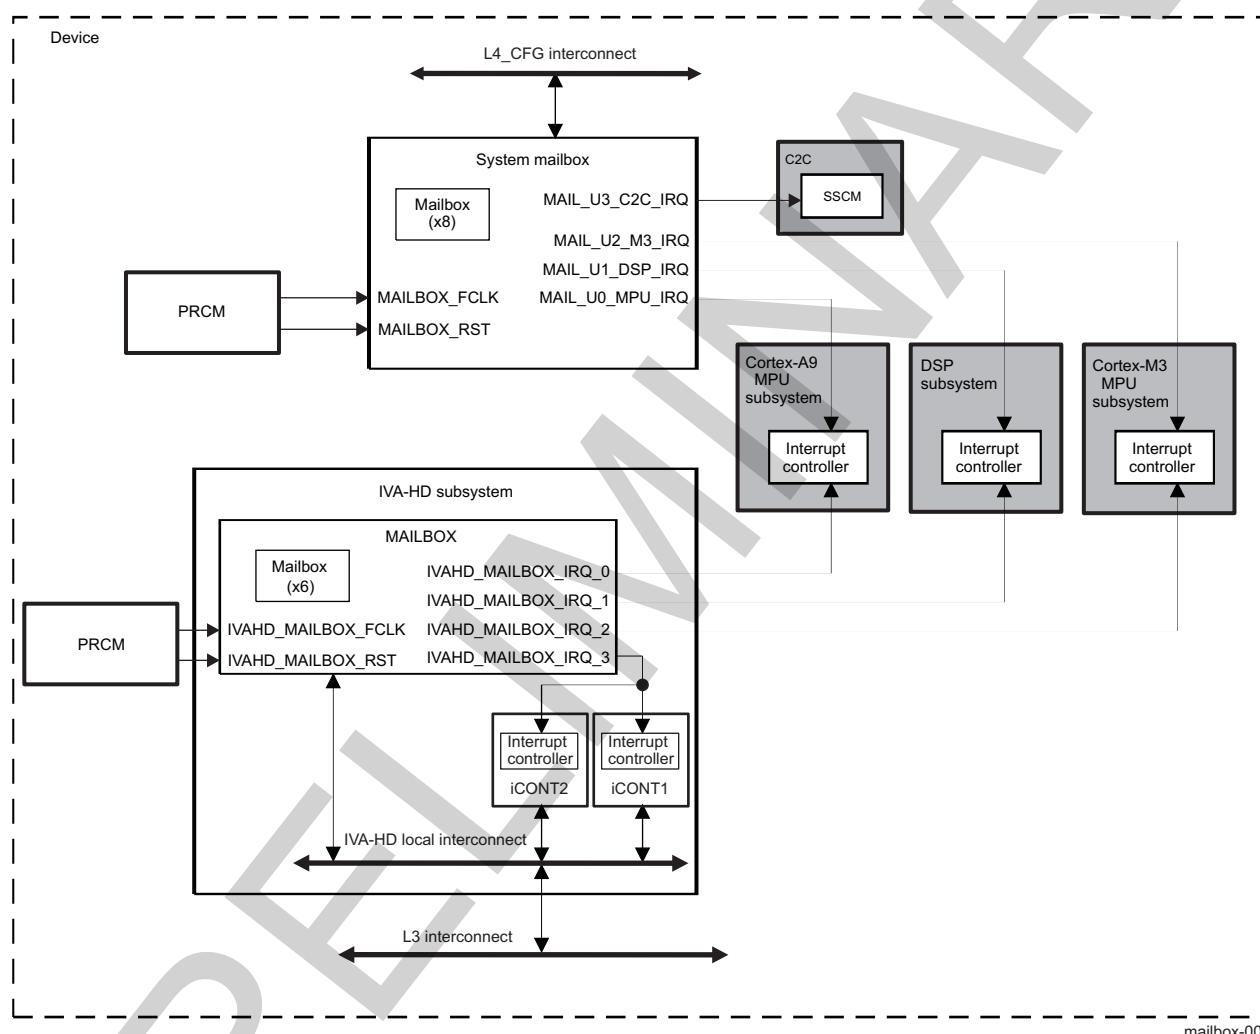

20.1 Mailbox Overview

Communication between the on-chip processors of the device uses a queued mailbox-interrupt mechanism.

The queued mailbox-interrupt mechanism allows the software to establish a communication channel between two processors through a set of registers and associated interrupt signals by sending and receiving messages (mailboxes).

Figure 20-1 shows an overview of the mailbox module.

Figure 20-1. Mailbox Overview

There are two mailbox module instances in the device:

- System mailbox - used for Cortex-A9 microprocessor unit (Cortex-A9 MPU), digital signal processor (DSP) and Cortex-M3 microprocessor unit (Cortex-M3 MPU) communications.
- IVA-HD mailbox - used for communication between one internal to the IVA-HD subsystem user (imaging controller 1 - iCONT1, or imaging controller 2 - iCONT2) and three external to the IVA-HD subsystem users (Cortex-A9 MPU, DSP and Cortex-M3 MPU). This communication is insured through three pairs of mailboxes.

The mailbox module includes the following features:

- Three users for the system mailbox instance (Cortex-A9 MPU, DSP and Cortex-M3 MPU)/four users for the IVA-HD mailbox instance (iCONT1/iCONT2, Cortex-A9 MPU, DSP and Cortex-M3 MPU)

- Eight mailbox message queues for the system mailbox instance/six mailbox message queues for the IVA-HD mailbox instance
- Flexible assignment of receiver and sender for each mailbox through interrupt configuration
- Three interrupts (one per user) for the system mailbox instance/four interrupts (one per user) for the IVA-HD mailbox instance
- 32-bit message width
- Four-message FIFO depth for each message queue
- Message reception and queue-not-full notification using interrupts
- Support of 16-/32-bit addressing scheme
- Power management support

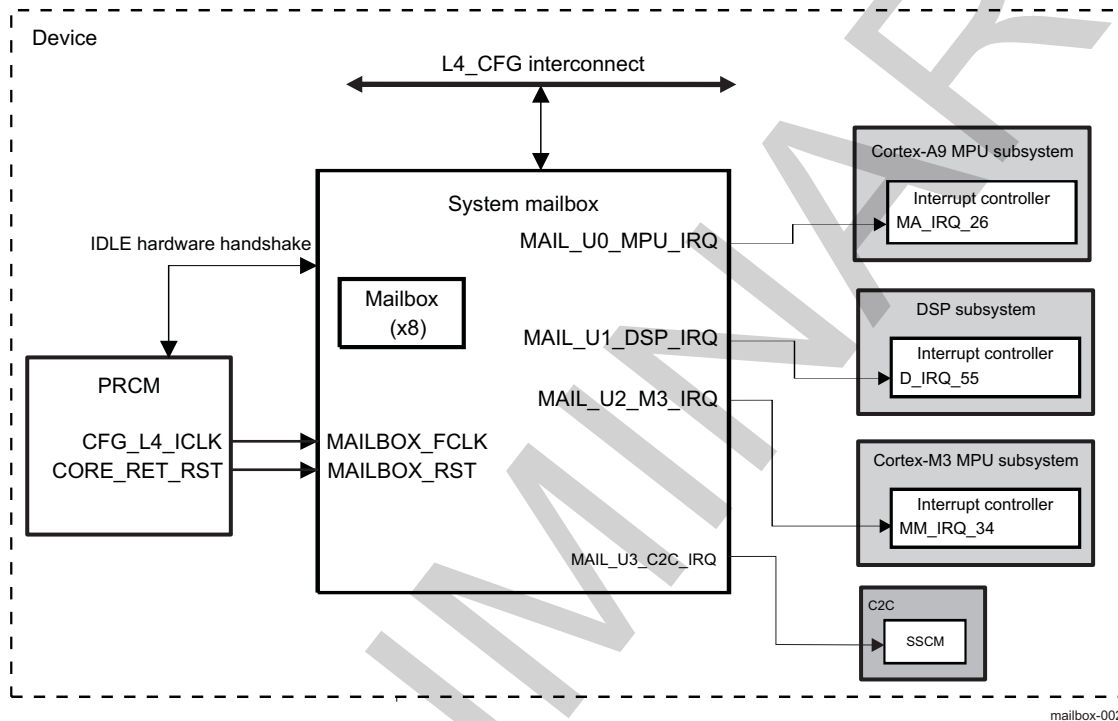

20.2 Mailbox Integration

This section describes the mailbox integration in the device, including information about clocks, resets, and hardware requests.

20.2.1 System Mailbox Integration

Figure 20-2 shows the system mailbox integration.

Figure 20-2. System Mailbox Integration

NOTE: For more information about the IDLE hardware handshake, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 20-1 through Table 20-3 summarize the system mailbox integration in the device.

Table 20-1. Integration Attributes

| Module Instance | Attributes | | |
|-----------------|--------------|--------------------|--------------|
| | Power Domain | Wake-Up Capability | Interconnect |
| SYSTEM_MAILBOX | PD_CORE | NA | L4_CFG |

Table 20-2. Clocks and Resets

| Clocks | | | | |
|-----------------|-------------------------|--------------------|--------|---|
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| SYSTEM_MAILBOX | MAILBOX_FCLK | CFG_L4_ICLK | PRCM | System mailbox functional/interface clock. For information about PRCM clock gating and management, see Section 3.6.14, CD_L4_CFG Clock Management , in Chapter 3, Power, Reset, and Clock Management . |
| Resets | | | | |
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| SYSTEM_MAILBOX | MAILBOX_RST | CORE_RET_RST | PRCM | System mailbox hardware reset. For information about PRCM reset sources and distribution, see Section 3.5.4, Reset Domains , in Chapter 3, Power, Reset, and Clock Management . |

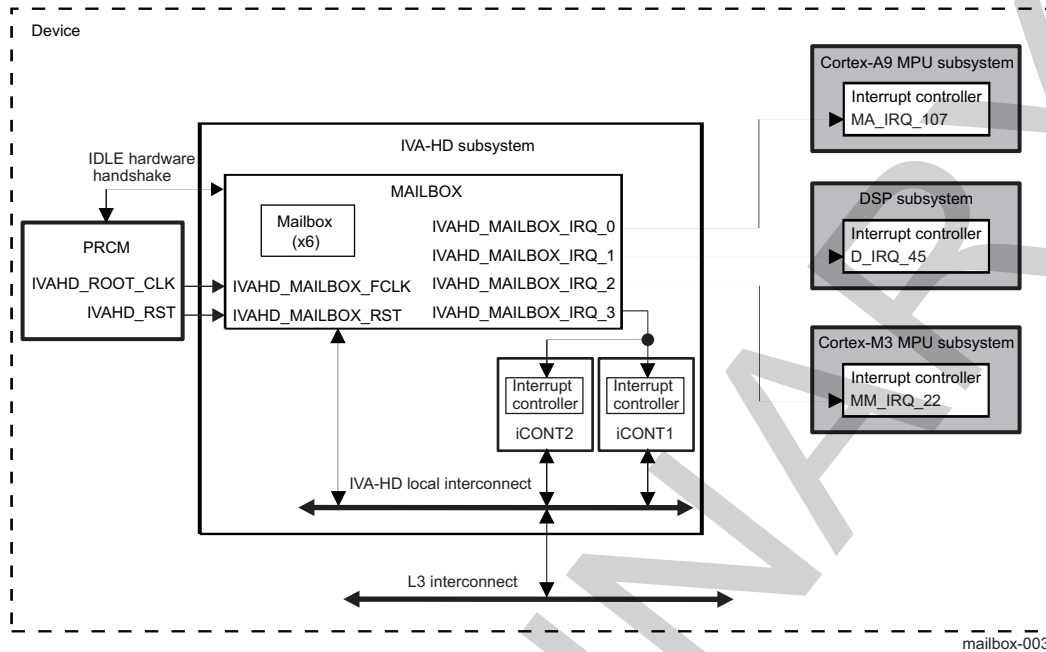

Table 20-3. Hardware Requests

| Interrupt Requests | | | | |
|--------------------|--------------------|-------------------------|-------------|--|
| Module Instance | Source Signal Name | Destination Signal Name | Destination | Description |
| SYSTEM_MAILBOX | MAIL_U0_MPU_IRQ | MA_IRQ_26 | Cortex-A9 | System mailbox user 0 interrupt request. For information about Cortex-A9 MPU interrupt mapping, see Section 18.3.2, Interrupt Requests to the Cortex-A9 MPU Interrupt Controller , in Chapter 18, Interrupt Controllers . |
| | MAIL_U1_DSP_IRQ | D_IRQ_55 | DSP | System mailbox user 1 interrupt request. For information about DSP interrupt mapping, see Section 18.3.3, Interrupt Requests to the Cortex-M3 MPU Interrupt Controller , in Chapter 18, Interrupt Controllers . |
| | MAIL_U2_M3_IRQ | MM_IRQ_34 | Cortex-M3 | System mailbox user 2 interrupt request. For information about Cortex-M3 MPU interrupt mapping, see Section 18.3.3, Interrupt Requests to the Cortex-M3 MPU Interrupt Controller , in Chapter 18, Interrupt Controllers . |
| | MAIL_U3_C2C_IRQ | C2C_SSCM_GPI_1 | C2C INTC | Interrupt to the SSCM of C2C |
| No DMA Requests | | | | |

NOTE: For information about interrupt source description, see [Section 20.3.4, Interrupt Requests](#).

20.2.2 IVA-HD Mailbox Integration

Figure 20-3 shows the IVA-HD mailbox integration.

Figure 20-3. IVA-HD Mailbox Integration

NOTE: For more information about the IDLE hardware handshake, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

NOTE: The two imaging controllers - iCONT1 and iCONT2, are mapped on a shared interrupt line. The choice between them is done by masking mailbox interrupt on iCONT1 or iCONT2. For more information, see [IVA-HD Imaging Controller](#) in [Chapter 6, IVA-HD Subsystem](#).

[Table 20-4](#) through [Table 20-6](#) summarize the IVA-HD mailbox integration in the device.

Table 20-4. Integration Attributes

| Module Instance | Attributes | | |
|-----------------|--------------|--------------------|---------------------------|
| | Power Domain | Wake-Up Capability | Interconnect |
| IVAHD_MAILBOX | PD_IVAHD | NA | IVA-HD local interconnect |

Table 20-5. Clocks and Resets

| IVAHD_MAILBOX | IVAHD_MAILBOX_IRQ_0 | MA_IRQ_107 | Cortex-A9 | IVA-HD mailbox user 0 interrupt request |
| | IVAHD_MAILBOX_IRQ_1 | D_IRQ_45 | DSP | IVA-HD mailbox user 1 interrupt request |
| | IVAHD_MAILBOX_IRQ_2 | MM_IRQ_22 | Cortex-M3 | IVA-HD mailbox user 2 interrupt request |
| | IVAHD_MAILBOX_IRQ_3 | IRQ#11 | iCONT1/iCONT2 | IVA-HD mailbox user 3 interrupt request. For information about iCONT1/iCONT2 interrupt mapping, see , iCONT. |
| No DMA Requests | | | | |

NOTE: For information about interrupt source description, see [Section 20.3.4, Interrupt Requests](#).

20.3 Mailbox Functional Description

NOTE: In the mailbox functional description, u is the user number and m is the mailbox number as follows:

- for the system mailbox module instance, $u=0$ to 2 and $m=0$ to 7
- for the IVA-HD mailbox module instance, $u=0$ to 3 and $m=0$ to 5

The mailbox module provides a means of communication through message queues among the users (depending on the mailbox module instance). The individual mailbox modules (8 for the system mailbox instance, 6 for the IVA-HD mailbox instance), or FIFOs, can associate (or de-associate) with any of the processors using the [MAILBOX_IRQENABLE_SET_u](#) (or [MAILBOX_IRQENABLE_CLR_u](#)) register.

CAUTION

For the IVA-HD mailbox instance, communication is possible only if one of the users is iCONT1 or iCONT2.

The mailbox module includes the following user subsystems:

- User 0: Cortex-A9 MPU subsystem ($u = 0$)
- User 1: DSP subsystem ($u = 1$)
- User 2: Cortex-M3 MPU subsystem ($u = 2$)
- User 3:
 - IVA-HD subsystem ($u = 3$) - only available to the IVA-HD mailbox instance
 - Mailbox subsystem - only available to SSCM module of C2C interface

Each user has a dedicated interrupt signal from the corresponding mailbox module instance and dedicated interrupt enabling and status registers.

Each [MAILBOX_IRQSTATUS_RAW_u](#)/[MAILBOX_IRQSTATUS_CLR_u](#) interrupt status register corresponds to a particular user.

For the system mailbox instance, a user can query its interrupt status register through the L4_CFG interconnect.

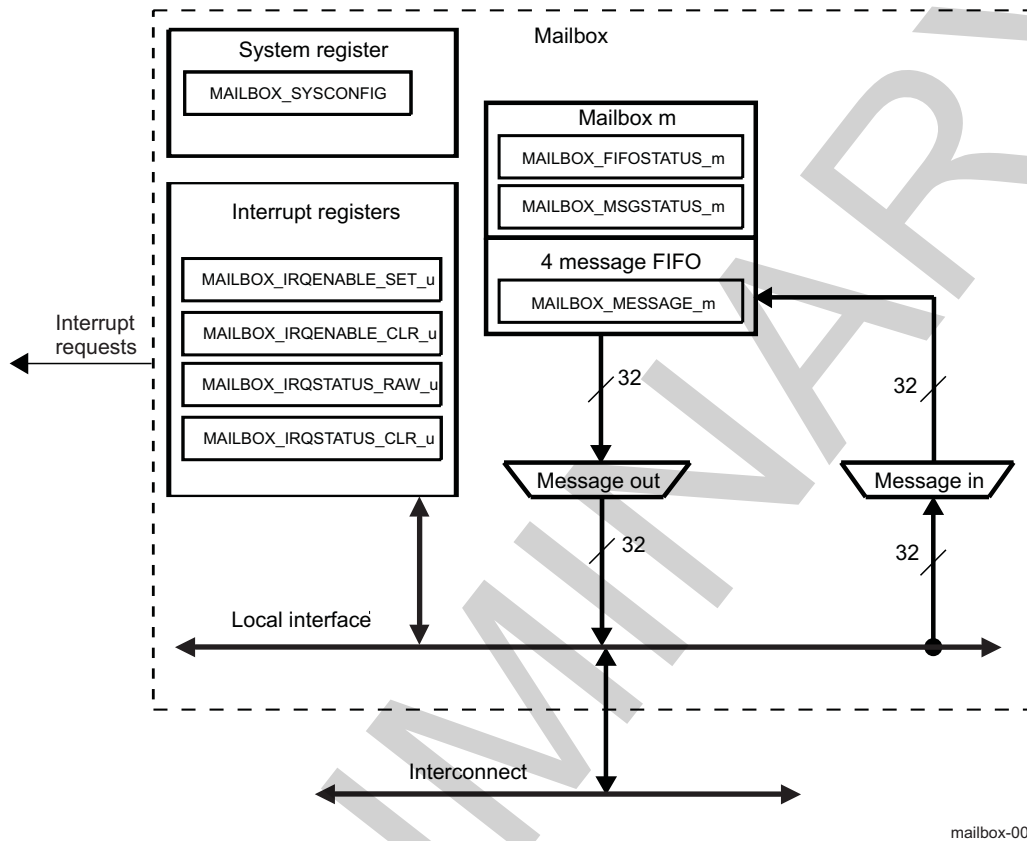

For the IVA-HD mailbox instance, a user can query its interrupt status register as follows:

- Cortex-A9 MPU and Cortex-M3 MPU - through the L3 interconnect
- iCONT1/iCONT2 and DSP - private access (directly through the IVA-HD local interconnect)

20.3.1 Mailbox Block Diagram

Figure 20-4 shows the mailbox block diagram.

Figure 20-4. Mailbox Block Diagram

NOTE: The interrupt requests and the interconnect depend on the mailbox module instance. For more information, see [Section 20.2, Mailbox Integration](#).

20.3.2 Mailbox Software Reset

The mailbox module supports a software reset through the [MAILBOX_SYSCONFIG\[0\]](#) SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Reading the [MAILBOX_SYSCONFIG\[0\]](#) SOFTRESET bit gives the status of the software reset:

- Read 1: the software reset is on-going.
- Read 0: the software reset is complete.

The software must ensure that the software reset completes before doing mailbox operations.

20.3.3 Mailbox Power Management

[Table 20-7](#) describes power-management features available for the mailbox module.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1.4, Clock-Domain Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 20-7. Local Power Management Features

| Feature | Registers | Description |
|------------------------|---|--|
| Clock autogating | NA | Feature not available |
| Slave idle modes | MAILBOX_SYSCONFIG [3:2] SIDLEMODE bit field | Force-idle, no-idle and smart-idle modes are available |
| Clock activity | NA | Feature not available |
| Master standby modes | NA | Feature not available |
| Global wake-up enable | NA | Feature not available |
| Wake-up sources enable | NA | Feature not available |

The mailbox module can be configured using the [MAILBOX_SYSCONFIG](#)[3:2] SIDLEMODE bit field to one of the following acknowledgment modes:

- Force-idle mode (SIDLEMODE = 0x0): The mailbox module immediately enters the idle state on receiving a low-power-mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state.
- No-idle mode (SIDLEMODE = 0x1): The mailbox module never enters the idle state.
- Smart-idle mode (SIDLEMODE = 0x2): After receiving a low-power-mode request from the PRCM module, the mailbox module enters the idle state only after all asserted output interrupts are acknowledged.

20.3.4 Mailbox Interrupt Requests

An interrupt request allows the user of the mailbox to be notified when a message is received or when the message queue is not full. There is one interrupt per user.

NOTE: For more information about interrupt requests, see [Section 20.2, Mailbox Integration](#).

[Table 20-8](#) lists the event flags, and their mask, that can cause module interrupts.

Table 20-8. Interrupt Events

| Non-Maskable Event Flag ⁽¹⁾ | Maskable Event Flag | Event Mask Bit | Event Unmask Bit | Description |
|---|---|---|---|---|
| MAILBOX_IRQSTATUS_RAW_u [0+m*2] NEWMSGSTATUSUUM Bm | MAILBOX_IRQSTATUS_CLR_u [0+m*2] NEWMSGSTATUSUUM Bm | MAILBOX_IRQENABLE_CLR_u [0+m*2] NEWMSGSTATUSUUM Bm | MAILBOX_IRQENABLE_SET_u [0+m*2] NEWMSGSTATUSUUM Bm | Mailbox <i>m</i> receives a new message. |
| MAILBOX_IRQSTATUS_RAW_u [1+m*2] NOTFULLSTATUSUUM Bm | MAILBOX_IRQSTATUS_CLR_u [1+m*2] NOTFULLSTATUSUUM Bm | MAILBOX_IRQENABLE_CLR_u [1+m*2] NOTFULLSTATUSUUM Bm | MAILBOX_IRQENABLE_SET_u [1+m*2] NOTFULLSTATUSUUM Bm | Mailbox <i>m</i> message queue is not full. |

⁽¹⁾ MAILBOX.MAILBOX_IRQSTATUS_RAW_u register is mostly used for debug purposes.

CAUTION

Once an event generating the interrupt request has been processed by the software, it must be cleared by writing a logical 1 in the corresponding bit of the [MAILBOX_IRQSTATUS_CLR_u](#) register.

Writing a logical 1 in a bit of the [MAILBOX_IRQSTATUS_CLR_u](#) register will also clear to 0 the corresponding bit in the appropriate [MAILBOX_IRQSTATUS_RAW_u](#) register.

An event can generate an interrupt request when a logical 1 is written to the corresponding unmask bit in the [MAILBOX_IRQENABLE_SET_u](#) register. Events are reported in the appropriate [MAILBOX_IRQSTATUS_CLR_u](#) and [MAILBOX_IRQSTATUS_RAW_u](#) registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the [MAILBOX_IRQENABLE_CLR_u](#) register. Events are only reported in the appropriate [MAILBOX_IRQSTATUS_RAW_u](#) register.

In case of the [MAILBOX_IRQSTATUS_RAW_u](#) register, the event is reported in the corresponding bit even if the interrupt request generation is disabled for this event.

20.3.5 Mailbox Assignment

20.3.5.1 Description

To assign a receiver to a mailbox, set the new message interrupt enable bit corresponding to the desired mailbox in the [MAILBOX_IRQENABLE_SET_u](#) register. The receiver reads the [MAILBOX_MESSAGE_m](#) register to retrieve a message from the mailbox.

An alternate method for the receiver that does not use the interrupts is to poll the [MAILBOX_FIFOSTATUS_m](#) and/or [MAILBOX_MSGSTATUS_m](#) registers to know when to send or retrieve a message to or from the mailbox. This method does not require assigning a receiver to a mailbox. Because this method does not include the explicit assignment of the mailbox, the software must avoid having multiple receivers use the same mailbox, which can result in incoherency.

To assign a sender to a mailbox, set the queue-not-full interrupt enable bit of the desired mailbox in the [MAILBOX_IRQENABLE_SET_u](#) register, where *u* is the number of the sending user. However, direct allocation of a mailbox to a sender is not recommended because it can cause the sending processor to be constantly interrupted.

It is recommended that register polling be used to:

- Check the status of either the [MAILBOX_FIFOSTATUS_m](#) or [MAILBOX_MSGSTATUS_m](#) registers
- Write the message to the corresponding [MAILBOX_MESSAGE_m](#) register, if space is available.

The sender might use the queue-not-full interrupt when the initial mailbox status check indicates the mailbox is full. In this case, the sender can enable the queue-not-full interrupt for its mailbox in the appropriate [MAILBOX_IRQENABLE_SET_u](#) register. This allows the sender to be notified by interrupt only when a FIFO queue has at least one available entry.

Reading the [MAILBOX_IRQSTATUS_CLR_u](#) register determines the status of the new message and the queue-not-full interrupts for a particular user. Writing 1 to the corresponding bit in the [MAILBOX_IRQSTATUS_CLR_u](#) register acknowledges, and subsequently clears, an interrupt.

CAUTION

Assigning multiple senders or multiple receivers to the same mailbox is not recommended.

20.3.6 Sending and Receiving Messages

20.3.6.1 Description

When a 32-bit message is written to the [MAILBOX_MESSAGE_m](#) register, the message is appended into the FIFO queue. This queue holds four messages. If the queue is full, the message is discarded.

Queue overflow can be avoided by first reading the [MAILBOX_FIFOSTATUS_m](#) register to check that the mailbox message queue is not full before writing a new message to it.

Reading the [MAILBOX_MESSAGE_m](#) register returns the message at the beginning of the FIFO queue and removes it from the queue. If the FIFO queue is empty when the [MAILBOX_MESSAGE_m](#) register is read, the value 0 is returned.

The new message interrupt is asserted when at least one message is in the mailbox message FIFO queue. To determine the number of messages in the mailbox message FIFO queue, read the [MAILBOX_MSGSTATUS_m](#) register.

20.3.7 16-Bit Register Access

20.3.7.1 Description

So that 16-bit processors can access the mailbox module, the module allows 16-bit register read and write access, with restrictions for the [MAILBOX_MESSAGE_m](#) registers. The 16-bit half-words are organized in little endian fashion; that is, the least-significant 16 bits are at the low address and the most-significant 16 bits are at the high address (low address + 0x02).

All mailbox module registers can be read or written to directly using individual 16-bit accesses with no restriction on interleaving, except the [MAILBOX_MESSAGE_m](#) registers, which must always be accessed by either single 32-bit accesses or two consecutive 16-bit accesses.

CAUTION

When using 16-bit accesses, it is critical to ensure that the mailbox used has only one assigned receiver and only one assigned sender.

When using 16-bit accesses to the [MAILBOX_MESSAGE_m](#) registers, the order of access must be the least-significant half-word first (low address) and the most-significant half-word last (high address). This requirement is because of the update operation by the message FIFO of the [MAILBOX_MSGSTATUS_m](#) registers. The update of the FIFO queue contents and the associated status registers and possible interrupt generation occurs only when the most-significant 16 bits of a [MAILBOX_MESSAGE_m](#) are accessed.

Figure 20-5 shows an example of communication between Cortex-A9 MPU and DSP subsystems.

Figure 20-5. Example of Communication

20.4 Mailbox Programming Guide

20.4.1 Mailbox Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the mailbox module.

20.4.1.1 Global Initialization

20.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the mailbox module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the mailbox.

See [Section 20.2, Mailbox Integration](#), for further information.

Table 20-9. Global Initialization of Surrounding Modules for System Mailbox

| Surrounding Modules | Comments |
|-----------------------|--|
| PRCM | Mailbox functional/interface clock must be enabled. For more information, see Section 3.6.14, CD_L4_CFG Clock Domain , in Chapter 3, Power, Reset, and Clock Management . |
| Interrupt Controllers | Cortex-A9 MPU, or Cortex-M3 MPU, or DSP interrupt controller must be configured to enable the interrupt request generation to the Cortex-A9 MPU, or Cortex-M3 MPU, or DSP subsystem. For information about enabling interrupts in Cortex-A9 MPU INTC, see the <i>ARM Cortex™-A9 MPCore Technical Reference Manual</i> . For information about enabling interrupts in Cortex-M3 MPU INTC, see the <i>ARM Cortex™-M3 Technical Reference Manual</i> . For information about enabling interrupts in DSP INTC, see Chapter 5, DSP Subsystem . |
| Interconnect | For information about L4-CFG interconnect configuration, see Section 14.3, L4 Interconnects , in Chapter 14, Interconnect . |

Table 20-10. Global Initialization of Surrounding Modules for IVA-HD Mailbox

| Surrounding Modules | Comments |
|-----------------------|--|
| PRCM | Mailbox functional/interface clock must be enabled. For more information, see Chapter 3, Power, Reset, and Clock Management . |
| Interrupt Controllers | Cortex-A9 MPU, or Cortex-M3 MPU, or DSP, or iCONT1/iCONT2 interrupt controller must be configured to enable the interrupt request generation to the Cortex-A9 MPU, or Cortex-M3 MPU, or DSP, or IVA-HD subsystem. For information about enabling interrupts in Cortex-A9 MPU INTC, or Cortex-M3 MPU INTC, or DSP INTC, see Table 20-9, Global Initialization of Surrounding Modules for System Mailbox . For information about enabling interrupts in iCONT1/iCONT2, see <i>iCONT</i> in Chapter 6, IVA-HD Subsystem . |
| Interconnect | For information about L3 interconnect configuration, see Section 14.2, L3 Interconnects , in Chapter 14, Interconnect . |

20.4.1.1.2 Mailbox Global Initialization

20.4.1.1.2.1 Main Sequence - Mailbox Global Initialization

This procedure initializes the mailbox module after a power-on or software reset.

Table 20-11. Mailbox Global Initialization

| Step | Register/ Bit Field / Programming Model | Value |
|------------------------------|--|-------|
| Perform a software reset | MAILBOX_SYSCONFIG[0] SOFTRESET | 0x1 |
| Wait until reset is complete | MAILBOX_SYSCONFIG[0] SOFTRESET | = 0x0 |
| Set idle mode configuration | MAILBOX_SYSCONFIG[3:2] SIDLEMODE | 0x- |

20.4.1.2 Mailbox Operational Modes Configuration

20.4.1.2.1 Mailbox Processing modes

20.4.1.2.1.1 Main Sequence - Sending a Message (Polling Method)

Table 20-12. Sending a Message (Polling Method)

| Step | Register/ Bit Field / Programming Model | Value |
|---|--|--------|
| IF : Is FIFO full ? | MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB | = 0x1 |
| Wait until at least one message slot is available | MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB | = 0x0 |
| ELSE | | |
| Write message | MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM | 0x---- |
| ENDIF | | |

20.4.1.2.1.2 Main Sequence - Sending a Message (Interrupt Method)

Table 20-13. Sending a Message (Interrupt Method)

| Step | Register/ Bit Field / Programming Model | Value |
|---|--|--------|
| IF : Is FIFO full ? | MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB | = 0x1 |
| Enable interrupt event | MAILBOX_IRQENABLE_SET_u[1+ m*2] | 0x1 |
| User (processor) can perform another task until interrupt occurs See Section 20.4.1.3.1 for interrupt handling in sending mode | | |
| ELSE | | |
| Write message | MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM | 0x---- |
| ENDIF | | |

20.4.1.2.1.3 Main Sequence - Receiving a Message (Polling Method)

Table 20-14. Receiving a Message (Polling Method)

| Step | Register/ Bit Field / Programming Model | Value |
|---|--|--------|
| IF : Number of messages is not equal to 0 | MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB | != 0x0 |
| Read message | MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM | 0x---- |
| ENDIF | | |

20.4.1.2.1.4 Main Sequence - Receiving a Message (Interrupt Method)

Table 20-15. Receiving a Message (Interrupt Method)

| Step | Register/ Bit Field / Programming Model | Value |
|---|--|-------|
| Enable interrupt event | MAILBOX_IRQENABLE_SET_u[0 + m*2] | 0x1 |
| User (processor) can perform another task until interrupt occurs See Section 20.4.1.3.2 for interrupt handling in receiving mode | | |

20.4.1.3 Mailbox Events Servicing

20.4.1.3.1 Events Servicing in Sending Mode

Table 20-16 describes the events servicing in sending mode.

Table 20-16. Events Servicing in Sending Mode

| Step | Register/ Bit Field / Programming Model | Value |
|----------------------------------|---|--------|
| Read interrupt status bit | MAILBOX_IRQSTATUS_CLR_u [1 + m*2] | 0x1 |
| Write message | MAILBOX_MESSAGE_m [31:0] MESSAGEVALUEMBM | 0x---- |
| Write 1 to acknowledge interrupt | MAILBOX_IRQSTATUS_CLR_u [1 + m*2] | 0x1 |

20.4.1.3.2 Events Servicing in Receiving Mode

Table 20-17 describes the events servicing in receiving mode.

Table 20-17. Events Servicing in Receiving Mode

| Step | Register/ Bit Field / Programming Model | Value |
|--|---|--------|
| Read interrupt status bit | MAILBOX_IRQSTATUS_CLR_u [0 + m*2] | 0x1 |

NOTE: For each interrupt status and enable register ([MAILBOX_IRQSTATUS_RAW_u](#), [MAILBOX_IRQSTATUS_CLR_u](#), [MAILBOX_IRQENABLE_SET_u](#) and [MAILBOX_IRQENABLE_CLR_u](#)), bits [15:12] have the given meaning only for the System Mailbox instance. For the IVA-HD Mailbox instance, these bits are considered as Reserved.

PRELIMINARY

Memory Management Units

This chapter describes the memory management units (MMUs).

| Topic | Page |
|---|------|
| 21.1 MMU Overview | 4202 |
| 21.2 MMU Integration | 4203 |
| 21.3 MMU Functional Description | 4206 |
| 21.4 MMU Low-level Programming Models | 4219 |
| 21.5 MMU Register Manual | 4223 |

21.1 MMU Overview

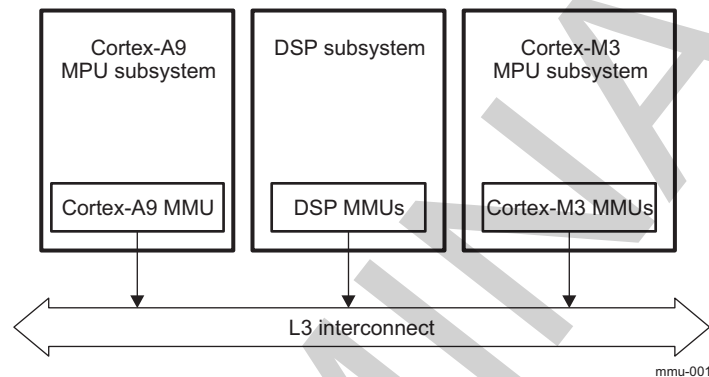

A memory management unit (MMU) is a hardware component responsible for handling accesses to memory requested by a processing unit. MMU functions include translation of virtual addresses to physical addresses (that is, virtual memory management) and cache control.

The device contains the following MMUs:

- In DSP - L1 Shared cache MMU and attribute MMU.
- In Dual Cortex-M3 MPU Subsystem - L1 Shared cache MMU and L2 MMU
- Cortex-A9 MMU

Figure 21-1 shows the MMU instances in the device.

Figure 21-1. Device MMU Instances

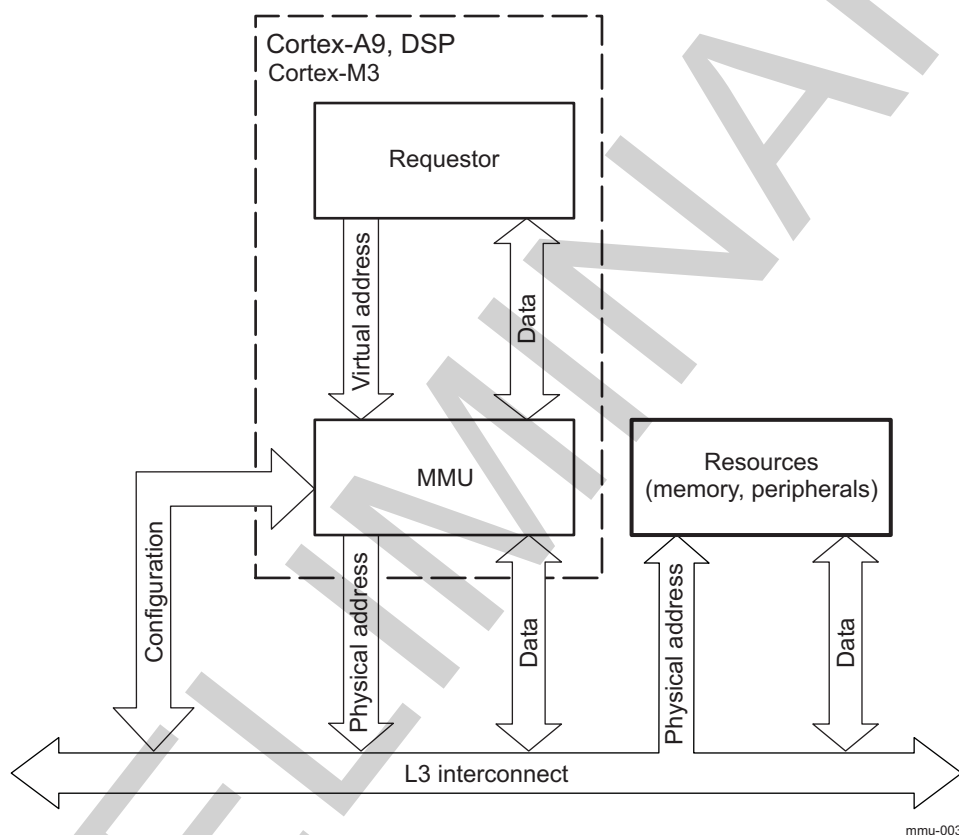

21.2 MMU Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

The MMU communicates accesses from the requestor (DSP, Cortex-M3 microprocessor unit (MPU), or Cortex-A9 MPU) to the L3 main interconnect, performing virtual to physical address translation. Although all MMUs are programmed (configured) through the L3 interconnect, the DSP MMU can be programmed both through the L3 interconnect or through the DSP local interconnect. DSP MMU and Cortex-M3 MMU error conditions are signaled as interrupts to the system main processor Cortex-A9 MPU.

Figure 21-2 shows typical MMU integration.

Figure 21-2. MMU Integration

NOTE: All MMUs are programmed through the L3 interconnect.

Figure 21-3. DSP MMU Integration

NOTE: The DSP MMU can be programmed from both the DSP local interconnect and from the L3 interconnect.

Table 21-1 through Table 21-3 summarize the MMU integration in the various modules of the device.

Table 21-1. Integration Attributes

| Module Instance | Power Domain |
|--|--------------|
| CORTEXM3_L2MMU and CORTEXM3_SCACHE_MMU | PD_CORE |
| CORTEXA9_MMU | PD_MPU |

Table 21-2. Clocks and Resets

| Clocks | | | | |
|--|-------------------------|--------------------|----------|--|
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| CORTEXA9_MMU | ARM_FCLK | MPU_DPLL_CLK | MPU DPLL | Internal clock in the Cortex-A9 MPU subsystem; supplies the MMU in Cortex-A9. |
| CORTEXM3_L2MMU and CORTEXM3_SCACHE_MMU | MPU_M3_CLK | MPU_M3_CLK | PRCM | External clock from the power, reset, and clock management (PRCM) module; supplies the shared cache MMU and L2 MMU in Cortex-M3. |
| Resets | | | | |
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| CORTEXM3_L2MMU | CORTEXM3_PWRON_RST | CORTEXM3_PWRON_RST | PRCM | Power-on reset signal for the Cortex-M3 MPU subsystem |
| | CORTEXM3_RST3 | CORTEXM3_RST3 | PRCM | Reset signal to the L2 MMU |

Table 21-2. Clocks and Resets (continued)

| | | | | |
|---------------------|------------------|------------------|------|--|
| CORTEXM3_SCACHE_MMU | CORTEXM3_RST3 | CORTEXM3_RST3 | PRCM | Reset signal for the shared cache MMU |
| | CORTEXM3_RET_RST | CORTEXM3_RET_RST | PRCM | Retention reset signal for the Cortex-M3 MPU subsystem |
| CORTEXA9_MMU | MPU_PWRON_RST | MPU_PWRON_RST | PRCM | Power-on reset signal to the MMU and the rest of the Cortex-A9 MPU subsystem |
| | MPU_RST | MPU_RST | PRCM | Reset signal to the MMU and the rest of the Cortex-A9 MPU subsystem |

Table 21-3. Hardware Requests

| Interrupt Requests | | | | |
|---------------------|------------------------------|-------------------------|----------------|--|
| Module Instance | Source Signal Name | Destination Signal Name | Destination | Description |
| CORTEXM3_L2MMU | CORTEXM3_MMU_IRQ | MA_IRQ_100 | MPU_INT_C | Cortex-M3 MPU L2MMU interrupt to the main MPU subsystem |
| | XLATE_MMU_FAULT | MM_IRQ_0 | CortexM3_INT_C | Internal interrupt from the L2MMU to the Cortex-M3 interrupt controller (INTC) |
| CORTEXM3_SCACHE_MMU | SHARED_CACHE_MMU_C PU_INT | MM_IRQ_1 | CortexM3_INT_C | Internal interrupt from the shared cache MMU to the CortexM3 INTC |

NOTE:

- For a description of the interrupt source, see [Section 21.3.5, Interrupt Requests](#).

There are 5 MMU modules in the device:

- Shared cache MMU – there are two Share cache MMUs, one in the Cortex-M3 MPU and other in DSP subsystem. Refer to the corresponding chapters for more information.
- L2 MMUs – there are two L2 MMUs, one in the Cortex-M3 MPU and other in DSP subsystem. The L2 MMUs are directly operating with the L3 interconnect (shared device memory space). These L2 MMUs are described in this chapter.
- Cortex-A9 MMU – this MMU is located in the ARM Cortex-A9 processor. For information about this MMU, see the ARM® Cortex™-A9 MPCore Technical Reference Manual.

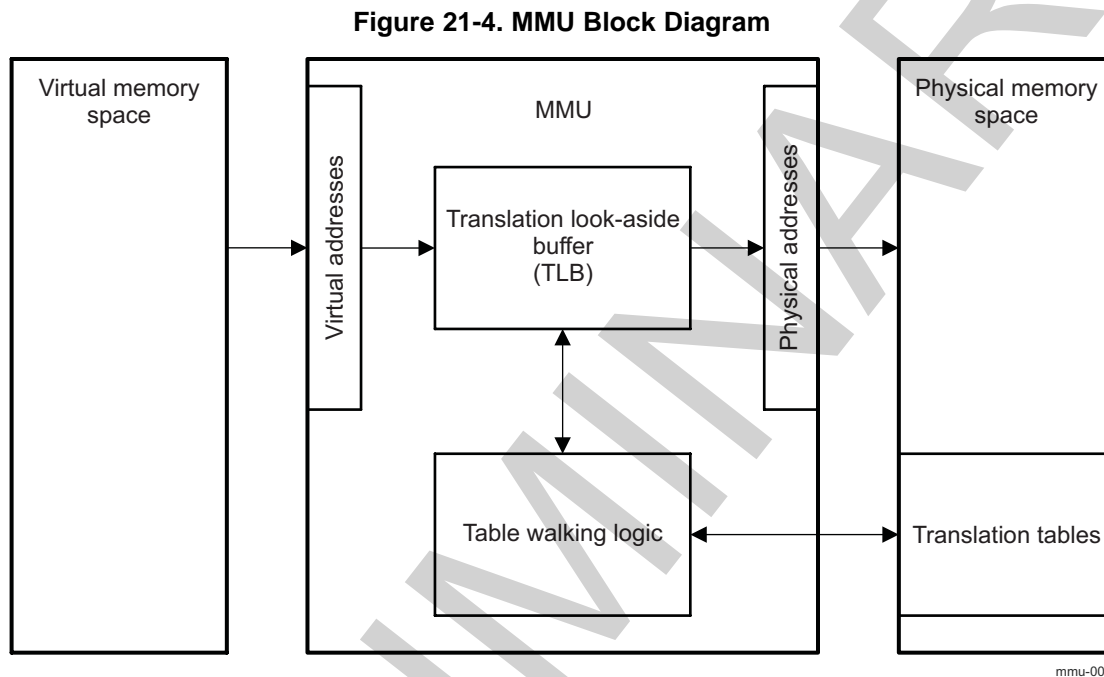

NOTE: There is PAT module in the Dynamic Memory Manager, which has similar to the MMU functionality. Refer to the DMM chapter, for more information.

21.3 MMU Functional Description

21.3.1 MMU Block Diagram

The MMU manages the virtual to physical address translation for external addresses, as well as endianness conversion. The MMU can be programmed through the L3 interconnect. MMU programming is expected to be accomplished by the Cortex-A9 MPU, except for the DSP MMU, of which the configuration can be accomplished through the DSP local interconnect.

Figure 21-4 is the MMU block diagram.

Each table entry describes the translation of one contiguous memory region. For a description of the structure of these tables, see [Section 21.3.1.2, Translation Tables](#).

Two major functional units exist in the MMU to provide address translation automatically based on the table entries:

- The table walker automatically retrieves the correct translation table entry for a requested translation. If two-level translation is used (for the translation of small memory pages), the table walker also automatically reads the required second-level translation table entry. The two-level translation is described later in the chapter.
- The translation look-aside buffer (TLB) stores recently used translation entries, acting like a cache of the translation table.

21.3.1.1 MMU Address Translation Process

Whenever an address translation is requested (that is, for every access with the MMU enabled), the MMU first checks whether the translation is contained in the TLB, which acts like a cache storing recent translations. The TLB can also be programmed manually to ensure that time-critical data can be translated without delay.

If the requested translation is not in the TLB, the table-walking logic retrieves this translation from the translation table(s), and then updates the TLB. The address translation is then performed. [Figure 21-5](#) summarizes the process.

Figure 21-5. Translation Process

mmu-007

21.3.1.2 Translation Tables

The translation of virtual to physical addresses is based on entries in translation tables that define the following properties:

- Address translation, that is, the correspondence between virtual and physical addresses
- Size of the memory region the entry translates
- Endianness, data access size, and the mixed property of this memory region

The virtual addresses index the translation tables. Each virtual address corresponds to exactly one entry in the translation table.

21.3.1.2.1 Translation Table Hierarchy

When developing a table-based address translation scheme, one of the most important design parameters is the memory page size described by each translation table entry. MMU instances support 4KB and 64KB pages, a 1MB section, and a 16MB supersection. Using bigger page sizes means a smaller translation table.

Using a smaller page size greatly increases the efficiency of dynamic memory allocation and defragmentation. That is why many operating systems (OSs) can operate on memory blocks as small as 4KB; however, the smaller size implies a more complex table structure.

A quick calculation shows that using 4KB memory pages with one translation table would require one million entries to span the entire 4GB address range. The table itself would be 32MB, a size that is not feasible.

However, using bigger pages greatly reduces the functionality of the OS memory management. Implementing a two-level hierarchy reconciles these two requirements. Within this hierarchy, one first-level translation table describes the translation properties based on 1MB memory regions.

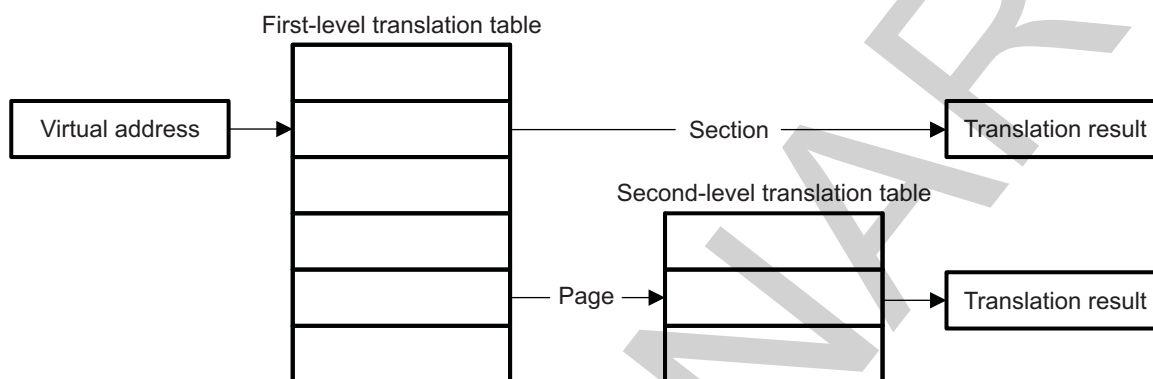

Each of the entries in this first-level translation table can specify the following:

- The translation properties for a big memory section. This memory section can be either 1MB (section) or 16MB (supersection). In this case, all translation parameters are specified in the first-level translation table entry.

- A pointer to a second-level translation table that specifies individual translation properties based on smaller pages within the 1MB page of memory. These pages can be either 64KB (large page) or 4KB (small page). In this case, the actual translation parameters are specified in the second-level translation table entry. The first-level translation table entry specifies only the base address of the second-level translation table.

This hierarchical approach means that additional translation information for smaller pages must be provided only when the pages are actually used. [Figure 21-6](#) shows the hierarchy.

Figure 21-6. Translation Hierarchy

mmu-008

The structure of the first and second-level translation tables and their entries are described in more detail in [Section 21.3.1.2.2, First-Level Translation Table](#), and [Section 21.3.1.2.3, Two-Level Translation](#).

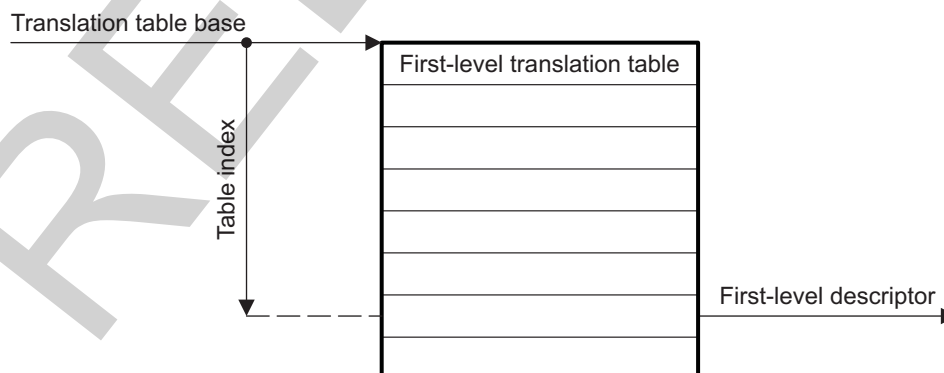

21.3.1.2.2 First-Level Translation Table

The first-level translation table describes the translation properties for 1MB sections. To describe a 4GB address range requires 4096 32-bit entries (so-called first-level descriptors).

The first-level translation table start address must be aligned on a multiple of the table size with a 128-byte minimum. Consequently, an alignment of at least 16K bytes is required for a complete 4096-entry table; that is, at least the last fourteen address bits must be zero.

The start address of the first-level translation table is specified by the so-called translation table base. The table is indexed by the upper 12-bits of the virtual address. [Figure 21-7](#) shows this mechanism.

Figure 21-7. First-level Descriptor Address Calculation

mmu-009

To summarize, the translation table base and the translation table index together define the first-level descriptor address. [Figure 21-8](#) outlines the precise mechanism used to calculate this address.

Figure 21-8. Detailed First-Level Descriptor Address Calculation

mmu-010

As an example of this mechanism, consider a translation table base address of 0x8000:0000 and a virtual address of 0x1234:5678. In this case, the first-level descriptor address is 0x8000:0000 + (0x123 2) = 0x8000:048C.

21.3.1.2.2.1 First-Level Descriptor Format

Each first-level descriptor provides either the complete address translation for 1MB or 16MB sections or provides a pointer to a second-level translation table for 4KB or 64KB pages. Table 21-4 shows the first-level descriptor format.

Table 21-4. First-Level Descriptor Format

| First-Level Descriptor Format | | | | | | | | | | | | | |
|---|-------|----|----|----|----|------------------|-------|-------|-----|---|---|---------|--------------|
| 31:24 | 23:20 | 19 | 18 | 17 | 16 | 15 | 14:12 | 11:10 | 9:2 | 1 | 0 | | |
| X | | | | | | | | | | 0 | 0 | Fault | |
| Second-Level Translation Table Base Address | | | | | | | | | X | 0 | 1 | Page | |
| Section Base Address | | X | 0 | M | X | E ⁽¹⁾ | X | ES | X | 1 | 0 | Section | |
| Supersection Base Address | | X | | 1 | M | X | E | X | ES | X | 1 | 0 | Supersection |
| X | | | | | | | | | | 1 | 1 | Fault | |

⁽¹⁾ See for endianness limitations.

M = Mixed region: 0 = Page-based endianness, 1 = Access-based endianness

E = Endianness: 0 = Little endian, 1 = Big endian (endianness is locked on little endian)

ES = Element Size: 00 = 8-bit, 01 = 16-bit, 10 = 32-bit, 11 = No endianness conversion

X = Don't care

21.3.1.2.2.2 First-Level Page Descriptor Format

If a translation granularity smaller than 1MB is required, a two-level translation process is used. In this case, the first-level block descriptor specifies only the start address of a second-level translation table. The second-level translation table entries specify the actual translation properties.

21.3.1.2.2.3 First-Level Section Descriptor Format

Each section descriptor in the first-level translation table specifies the complete translation properties for a 1MB section or a 16MB supersection.

NOTE: Supersection descriptors must be repeated 16 times, because each descriptor in the first-level translation table describes 1MB of memory. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

In addition to the address translation itself, three parameters are specified in the section descriptors:

- Endianness

The *endianness* parameter specifies whether the memory section uses a big- or little-endian data format. This parameter is locked to little endian. See for more information.

- Element size

The *element size* parameter can optionally specify the data access size (8, 16, or 32 bits) for all data items in the defined section.

- Mixed region

The *mixed region* parameter specifies whether the information about the data access size is detected from the access itself (access-based detection) or if the specified element size parameter is used (page-based detection). For example, the specified element size parameter can be used when several smaller sized accesses are packed into a bigger sized access, such as two 16-bit accesses packed into one 32-bit access. In this case, with no specified data access size, 32 bits would be the access size detected, leading to an incorrect result. To avoid this problem, specify the data access size for the memory section.

21.3.1.2.2.4 Section Translation Summary

Sections and supersections can be translated based solely on the information in the first-level translation table. [Figure 21-9](#) summarizes the address translation process for a section.

Figure 21-9. Section Translation Summary

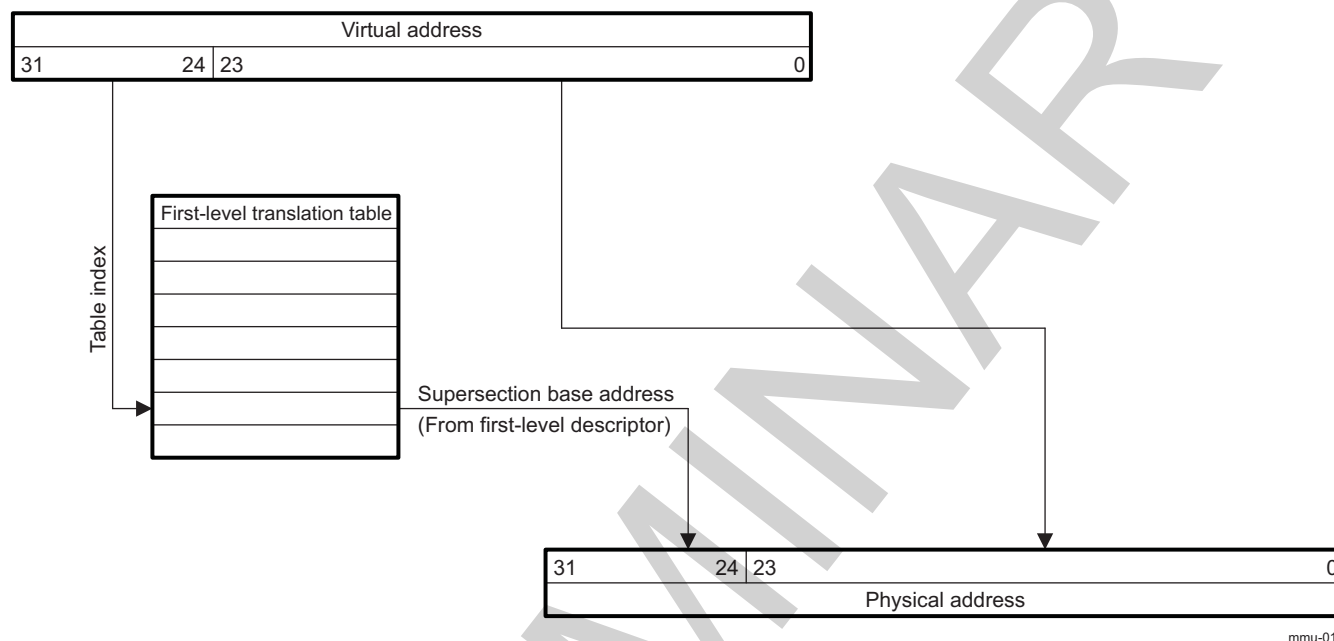

mmu-011

21.3.1.2.2.5 Supersection Translation Summary

The translation of a supersection is similar to the translation of a section. The difference is that for a supersection only bits 31 to 24 index into the first-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a supersection.

Figure 21-10 shows the translation mechanism for a supersection.

Figure 21-10. Supersection Translation Summary

mmu-012

21.3.1.2.3 Two-Level Translation

Two-level translation is used when fine-grain granularity is required, that is, when memory sections smaller than 1MB are needed. In this case, the first-level descriptor provides a pointer to the base address of a second-level translation table. This second-level table is indexed by bits 19 to 12 of the virtual address. Figure 21-11 shows this indexing mechanism.

Figure 21-11. Two-Level Translation

mmu-013

Each second-level translation table describes the translation of 1MB of address space in pages of 64KB (large page) or 4KB (small page). It consists of 256 second-level descriptors describing 4KB each.

NOTE: In the case of a large page, the same descriptor must be repeated 16 times. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

21.3.1.2.3.1 Second-Level Descriptor Format

Similar to first-level section descriptors, second-level descriptors provide all of the necessary information for the translation of a large or small page. Table 21-5 shows the format of second-level descriptors. The translation parameters (endianness, element size, and mixed region) have the same meaning as those for sections.

Table 21-5. Second-Level Descriptor Format

| Second-Level Descriptor Format | | | | | | | | | | |
|--------------------------------|-------|----|----|------------------|-----|-----|-----|---|---|------------|
| 31:16 | 15:12 | 11 | 10 | 9 | 8:6 | 5:4 | 3:2 | 1 | 0 | |
| X | | | | | | | | 0 | 0 | Fault |
| Large Page Base Address | X | M | X | E ⁽¹⁾ | X | ES | X | 0 | 1 | Large Page |
| Small Page Base Address | | M | X | E | X | ES | X | 1 | X | Small Page |

⁽¹⁾ See for endianness limitations.

M = Mixed region: 0 = Page-based endianness, 1 = Access-based endianness

E = Endianness: 0 = Little-endian, 1 = Big-endian (endianness is locked on little endian)

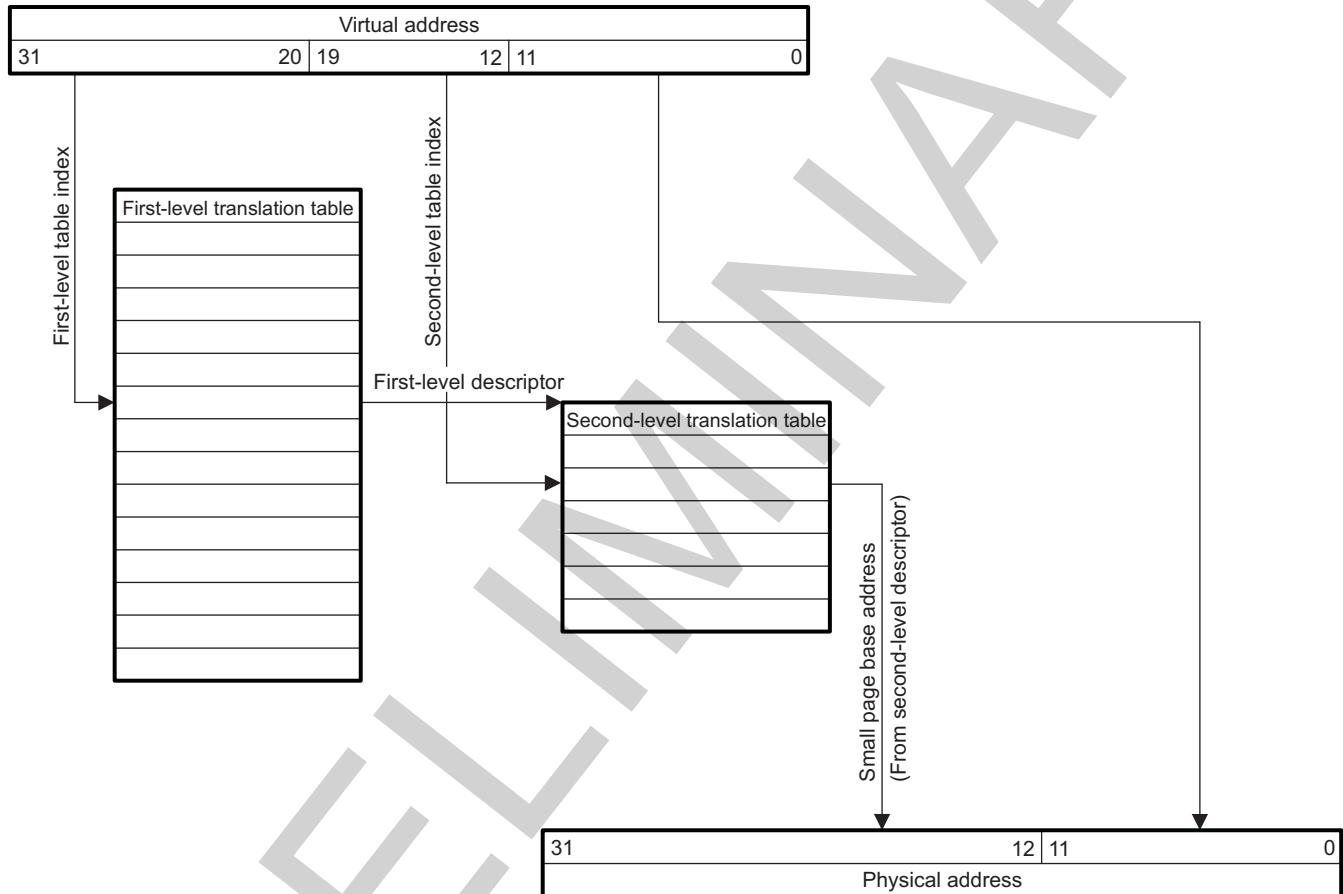

ES = Element Size: 00 = 8-bit, 01 = 16-bit, 10 = 32-bit, 11 = No endianness conversion

X = Don't care

21.3.1.2.3.2 Small Page Translation Summary

Figure 21-12 summarizes the translation process for small pages.

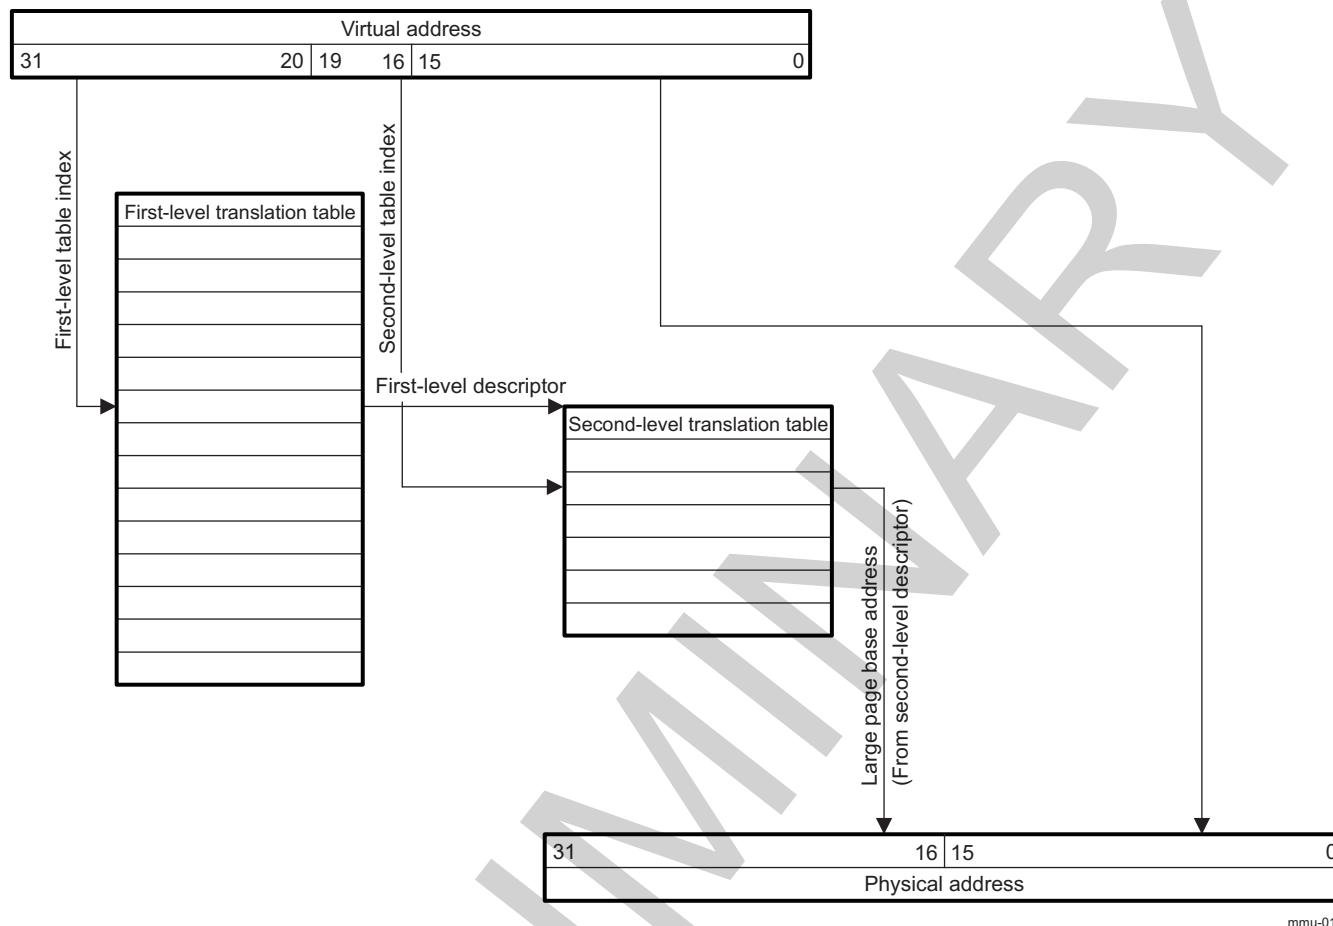

Figure 21-12. Small Page Translation Summary

mmu-014

21.3.1.2.3.3 Large Page Translation Summary

The translation of a large page is similar to the translation of a small page. The difference is that, for a large page, only bits 19 to 16 index into the second-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a large page. This is shown in Figure 21-13.

Figure 21-13. Large Page Translation Summary

mmu-015

21.3.1.3 Translation Lookaside Buffer

Translating virtual addresses to physical addresses is required for each memory access in systems using an MMU. To accelerate this translation process, a cache, or TLB, holds the result of recent translations.

For every translation, the MMU internal logic first checks whether the requested translation is already cached in the TLB. If the translation is cached, this translation is used; otherwise the translation is retrieved from the translation tables and the TLB is updated. If the TLB is full, one of its entries must be replaced. This entry is selected on a random basis.

The first n TLB entries, where n Total Number N of TLB Entries, can be protected (locked) against being overwritten by setting the TLB base pointer to n . When this mechanism is used, only unprotected entries can be overwritten. The victim pointer indicates the next TLB entry to be written. [Figure 21-14](#) shows an example of the TLB with N TLB entries (ranging from 0 to $N-1$). The base pointer contains the value "3" protecting Entry 0, Entry 1, and Entry 2 and the victim pointer points to the next TLB entry to be updated.

NOTE: The last TLB entry (Entry $N-1$) always remains unprotected.

Figure 21-14. TLB Entry Lock Mechanism

The table walking logic automatically writes the TLB entries. The entries can also be manually written, which is done typically to ensure that the translation of time-critical data accesses is already present in the TLB so that they execute as fast as possible. The entries must be locked to prevent them from being overwritten.

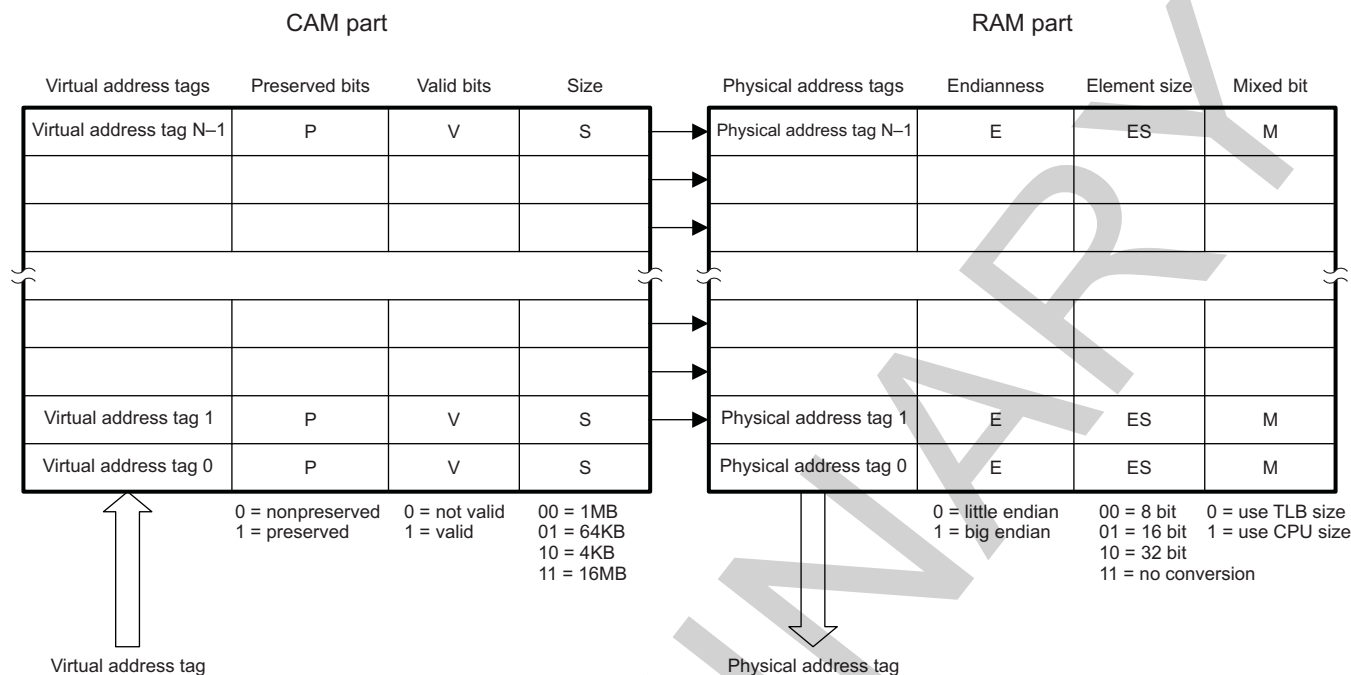

21.3.1.3.1 TLB Entry Format

TLB entries consist of two parts:

- The CAM part contains the virtual address tag used to determine if a virtual address translation is in the TLB. The TLB acts like a fully associative cache addressed by the virtual address tag. The CAM part also contains the section/page size, as well as the preserved and the valid parameters. See the [MMU_CAM](#) register table for more details.
- The RAM part contains the address translation that belongs to the virtual address tag as well as the endianness, element size, and mixed parameters described in [Section 21.3.1.2.2, First-Level Translation Table](#). See the [MMU_RAM](#) register table for more details.

The valid parameter specifies whether an entry is valid or not. The preserved parameter determines the behavior of an entry in the event of a TLB flush. If an entry is set as preserved, it is not deleted when a TLB is flushed, that is, when [MMU_GFLUSH\[0\] GLOBALFLUSH](#) is set to 1. Preserved entries must be deleted manually. [Section 21.3.1.2.2](#) describes the procedure to delete TLB entries.

[Figure 21-16](#) shows the TLB entry structure.

Figure 21-15. TLB Entry Structure

mmu-017

21.3.2 MMU Clock Configuration

There are two clock domains: The functional clock domain for the MMU, which is synchronous to the clock for the interconnect slave and master access ports; and the clock domain for the interconnect slave configuration port. As these clocks are matched, there is a single input clock with enables for each of the clock domains. If a clock domain should run at the same frequency as the input clock, that enable can be tied high.

Two clock enable signals exist, one to enable the interconnect data master and slave ports, and the other to enable the clock on the configuration L3 interconnect port. The clock signals are configured through the [MMU_SYSCONFIG](#) register. This is a system configuration register that controls the various parameters of the L3 interface.

21.3.3 MMU Software Reset

This section describes the software reset feature of the module. The MMU instances are reset together with their respective reset domains. See [Table 21-2](#) for information about the reset domains of the different MMU instances.

To perform a software reset, write 1 in the [MMU_SYSCONFIG](#)[1] SOFTRESET bit. The [MMU_SYSSTATUS](#)[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the [MMU_SYSCONFIG](#)[1] SOFTRESET bit is automatically reset. The software must ensure that the software reset completes before doing MMU operations. When an MMU instance is released from reset, its TLB is empty and the MMU is disabled.

21.3.4 MMU Power Management

As part of the device system-wide power management scheme, each MMU instance supports a communication protocol with the PRCM module that allows the PRCM module to request an MMU instance to enter a low-power state. When the MMU instance acknowledges a low-power mode request from the PRCM module, the clock to the instance is gated off at the PRCM clock generator. Because the clock is disabled at the source, the low-power mode offers lower power consumption than the internal clock gating method in the local power management.

[Table 21-6](#) describes the power-management features available for the MMU modules.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 21-6. MMU Local Power Management Features

| Feature | Register |
|------------------|---|
| Idle modes | MMU_SYSCONFIG [4:3] IDLEMODE |
| Clock activity | MMU_SYSCONFIG [9:8] CLOCKACTIVITY |
| Clock autogating | MMU_SYSCONFIG [0] AUTOIDLE |

NOTE: The [MMU_SYSCONFIG](#)[9:8] CLOCKACTIVITY bits are read only.

21.3.5 MMU Interrupt Requests

[Table 21-7](#) lists the event flags and their masks that can cause module interrupts.

Table 21-7. Events

| Event Flag | Event Mask | Synchrono us | Sensitivit y | Map to | Description |
|---|---|-----------------|-----------------|----------|--|
| MMU_IRQSTATUS [4] MULTIHITFAULT | MMU_IRQENABLE [4] MULTIHITFAULT | Yes | Level | M3_IRQ_0 | Error in the L2 MMU due to multiple matches in the TLB |
| MMU_IRQSTATUS [3] TABLEWALKFAULT | MMU_IRQENABLE [3] TABLEWALKFAULT | Yes | Level | M3_IRQ_0 | Error in the L2 MMU due to error response received during a Table Walk |
| MMU_IRQSTATUS [2] EMUMISS | MMU_IRQENABLE [2] EMUMISS | | | | For more information about emulation and debug features, see Chapter 29, On-Chip Debug Support . |
| MMU_IRQSTATUS [1] TRANSLATIONFAULT | MMU_IRQENABLE [1] TRANSLATIONFAULT | Yes | Level | M3_IRQ_0 | Error in the L2 MMU due to invalid descriptor in the translation tables (translation fault) |
| MMU_IRQSTATUS [0] TLBMISS | MMU_IRQENABLE [0] TLBMISS | Yes | Level | M3_IRQ_0 | Error in L2 MMU due to unrecoverable TLB miss (hardware TWL disabled) |

21.3.6 MMU Error Handling

[Table 21-8](#) summarizes the intended operation for real and potential error conditions.

Table 21-8. Error Handling

| Item | Condition | Action |
|------|--|---|
| 1 | Table-walk read has an error response. | Treat generally the same as a translation fault, but set the TableWalkFault interrupt status bit to aid in diagnosis |
| 2 | MMU is disabled during table-walk. | Not permitted; can result in loss of the current transaction but must not deadlock the MMU. Avoid this condition by first disabling the table-walk logic and then polling the TWLRunning bit to ensure that no table walk is pending |
| 3 | MMU is disabled during an address translation. | Not permitted; can result in access to an unintended location, but must not deadlock MMU. This condition should be avoided by ensuring that no accesses are pending. |

Table 21-8. Error Handling (continued)

| Item | Condition | Action |
|------|--|--|
| 4 | TLB is accessed during an address translation or a table walk. | Reading permitted; write should be done with care to ensure that the TLB is self-consistent at all times that a translation can occur. |
| 5 | TLB is flushed during address translation or a table walk. | Permitted; the flush is processed first, followed by the TWL update. |
| 6 | MMU is disabled while an interrupt is pending. | Not permitted; all pending interrupts should be processed before disabling the MMU. |

L3 Interconnect configuration port: Accesses to undecoded register addresses must not give an error response.

To protect against changes to the address translation between a READEX and the corresponding write or during a burst the following configuration operations are protected against writes during these processes:

- TLB update
- Global flush
- Flush entry
- MMU disable

The protection is implemented by stalling the configuration interconnect transaction until the write can proceed safely.

21.4 MMU Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

21.4.1 Global Initialization

21.4.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the MMU module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MMU. For more information, see [Section 21.2, MMU Module Integration](#).

Table 21-9. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|---|---|
| PRCM | Module interface and functional clocks must be enabled. For more information, see Chapter 3, Power, Reset, and Clock Management . |
| (optional) MPU INTC or DSP INTC or Cortex-M3 INTC | MPU, DSP, and Cortex-M3 interrupt controller configuration must be done to enable the interrupts from module. |
| Interconnect | For more information about the L3 interconnect configuration, see Section 14.2, L3 Interconnect . |

NOTE: If the interrupt-based communication mode is used, the MPU, DSP, and Cortex-M3 interrupt controllers configurations are required.

21.4.1.2 MMU Global Initialization

21.4.1.2.1 Main Sequence—MMU Global Initialization

[Figure 21-16](#) shows the procedure to initialize the MMU after a power-on or software reset.

Figure 21-16. MMU Global Initialization

mmu-018

Table 21-10. Register Call Summary for Main Sequence—MMU Global Initialization

| Register Name | Register Name | Register Name |
|---------------|---------------|---------------|
| MMU_LD_TLB | MMU_LOCK | MMU_CNTL |

21.4.1.2.2 Subsequence—Configure a TLB entry

Table 21-11. Configure a TLB Entry

| Step | Register / Bit Field / Programming Model | Value |
|-------------------------------------|--|-------|
| Load the Virtual Address Tag | MMU_CAM[31:12] VATAG | 0x- |
| Protect the TLB entry against flush | MMU_CAM[3] P | 0x1 |
| Validate the TLB entry | MMU_CAM[2] V | 0x1 |
| Define the page size | MMU_CAM[1:0] PAGESIZE | 0x- |

21.4.1.3 Operational Modes Configuration

21.4.1.3.1 Main Sequence—Writing TLB Entries Statically

Writing TLB entries statically avoids the need to write translation tables in memory and is commonly used for relatively small address spaces. This method ensures that the translation of time-critical data accesses execute as fast as possible with entries already present in the TLB. These entries must be locked to prevent them from being overwritten.

Table 21-12. MMU Writing TLB Entries Statically

| Step | Register/ Bit Field / Programming Model | Value |
|---|--|-------|
| Execute software reset | MMU_SYSCONFIG[1] SOFTRESET | 0x1 |
| Wait for reset to complete | MMU_SYSSTATUS[0] RESETDONE | =0x1 |
| Enable power saving via automatic interface clock gating | MMU_SYSCONFIG[0] AUTOIDLE | 0x1 |
| Configure TLB entries | See Table 21-11 | |
| Load the physical Address of the page | MMU_RAM[31:12] PHYSICALADDRESS | 0x- |
| Define the endianness of the page (little endian or big endian) | MMU_RAM[9] ENDIANNESS | 0x- |
| Select the element size | MMU_RAM[8:7] ELEMENTSIZE | 0x- |
| Define mixed page attribute | MMU_RAM[6] MIXED | 0x- |
| Specify the TLB entry you want to write | MMU_LOCK[8:4] CURRENTVICTIM | 0x- |
| Load the specified entry in the TLB | MMU_LD_TLB[0] LDTLBITEM | 0x1 |
| Enable multihit fault and TLB miss | MMU_IRQENABLE[4] MULTIHITFAULT | 0x1 |
| | MMU_IRQENABLE[0] TLBMISS | 0x1 |
| Enable memory translations | MMU_CNTL[1] MMUENABLE | 0x1 |

21.4.1.3.2 Main Sequence—Protecting TLB Entries

The first n TLB entries (with n total number of TLB entries) can be protected from being overwritten with new translations. This is useful to ensure that certain commonly used or time-critical translations are always in the TLB and do not require retrieval using the table walking process.

Table 21-13. Protecting TLB Entries

| Step | Register/Bit Field/Programming Model | Value |
|-----------------------|---|-------|
| Locks the TLB entries | MMU_LOCK[14:10] BASEVALUE | 0x- |

21.4.1.3.3 Main Sequence—Deleting TLB Entries

Two mechanisms exist to delete TLB entries. All unpreserved TLB entries, that is, TLB entries written with the preserved bit set to zero, can be deleted by invoking a TLB flush. The preserved bit should only be used on protected TLB entries, as it does not prevent replacement by the table walking logic.

Table 21-14. Deleting TLB Entries

| Step | Register / Bit Field / Programming Model | Value |
|---|---|-------|
| Flush all nonprotected TLB entries | MMU_GFLUSH[0] GLOBALFLUSH | 0x1 |
| Flush all TLB entries specified by the CAM register | MMU_FLUSH_ENTRY[0] FLUSHENTRY | 0x1 |

21.4.1.3.4 Main Sequence—Read TLB Entries

TLB entries can be read by the programmer to determine the TLB content at runtime.

Table 21-15. Read TLB Entries

| Step | Register / Bit Field / Programming Model | Value |
|---------------------------------|---|-------|
| Set the current victim pointer | MMU_LOCK[8:4] CURRENTVICTIM | 0x- |
| Read RAM parts of the TLB entry | MMU_READ_RAM | |
| Read CAM parts of the TLB entry | MMU_READ_CAM | |

Spinlock

This chapter describes the Spinlock module of the device.

| Topic | Page |
|--|------|
| 22.1 Spinlock Overview | 4240 |
| 22.2 Spinlock Integration | 4241 |
| 22.3 Spinlock Functional Description | 4242 |
| 22.4 Spinlock Programming Guide | 4245 |
| 22.5 Spinlock Register Manual | 4248 |

22.1 Spinlock Overview

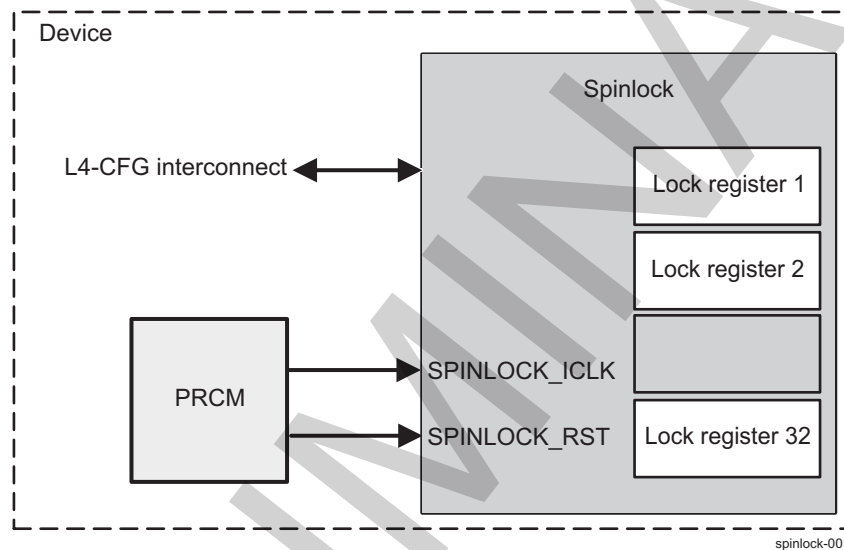

The Spinlock module provides hardware assistance for synchronizing the processes running on multiple processors in the device:

- Cortex-A9 microprocessor unit (MPU) subsystem
- Digital signal processor (DSP) subsystem
- Cortex-M3 MPU subsystem

The Spinlock module implements 32 spinlocks (or hardware semaphores), which provide an efficient way to perform a lock operation of a device resource using a single read-access, avoiding the need of a read-modify-write bus transfer that the programmable cores are not capable of.

Figure 22-1 shows the Spinlock module.

Figure 22-1. Spinlock Module

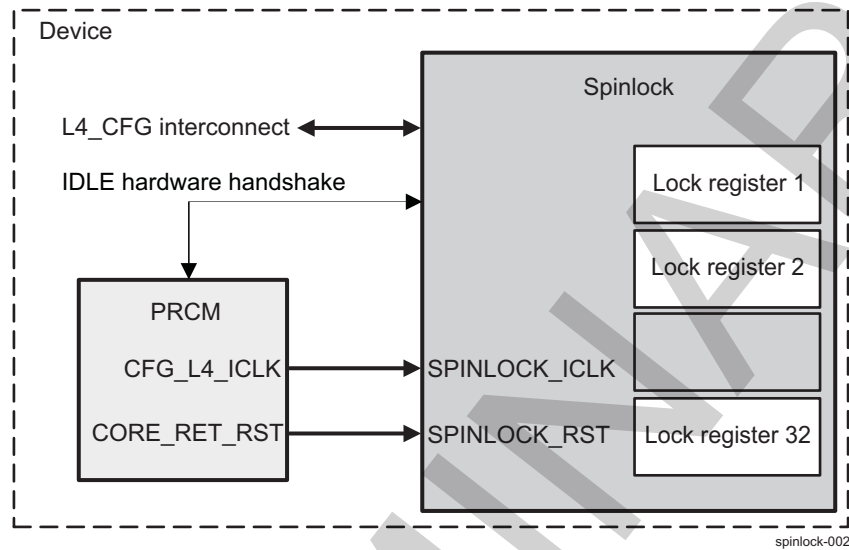

22.2 Spinlock Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 22-2 shows the Spinlock integration.

Figure 22-2. Spinlock Integration

NOTE: For more information about the IDLE hardware handshake and the wake-up request, see [Section 3.1.1.1.2, Module Level Clock Management](#), [Chapter 3, Power, Reset, and Clock Management](#).

Table 22-1 and Table 22-2 summarize the integration of the module in the device.

Table 22-1. Integration Attributes

| Module Instance | Attributes | |
|-----------------|--------------|--------------|
| | Power Domain | Interconnect |
| SPINLOCK | PD_CORE | L4_CFG |

Table 22-2. Clocks and Resets

| Clocks | | | | |
|-----------------|-------------------------|--------------------|--------|---|
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| SPINLOCK | SPINLOCK_ICLK | CFG_L4_ICLK | PRCM | Spinlock interface clock. This clock is used for all interface and functional operations. |
| Resets | | | | |
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| SPINLOCK | SPINLOCK_RST | CORE_RET_RST | PRCM | Spinlock hardware reset. This reset is asynchronously applied to the Spinlock internal registers. |

The Spinlock module does not support any interrupt and DMA requests.

22.3 Spinlock Functional Description

22.3.1 Spinlock Software Reset

The Spinlock module can be reset by software through the [SPINLOCK_SYSCONFIG\[1\]](#) SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. The [SPINLOCK_SYSTATUS\[0\]](#) RESETDONE bit can be polled to check the reset status (reading 1 indicates that reset sequence is done; reading 0 indicates that reset sequence is in progress). The software must ensure that the software reset completes before doing Spinlock operations.

22.3.2 Spinlock Power Management

[Table 22-3](#) describes power-management features available to the Spinlock module.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1.4, Clock Domain Level Clock Management, Chapter 3, Power, Reset, and Clock Management](#).
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.1.1.1.2, Module Level Clock Management, Chapter 3, Power, Reset, and Clock Management](#).

Table 22-3. Local Power Management Features

| Feature | Registers | Description |
|-----------------------|--|---|
| Clock auto gating | SPINLOCK_SYSCONFIG[0] AUTOGATING bit | This bit indicates that the module uses an automatic internal interface clock gating strategy, based on interface activity. |
| Slave idle modes | SPINLOCK_SYSCONFIG[4:3] SIDLEMODE bit field | This bit field indicates that the module uses smart-idle mode. |
| Clock activity | SPINLOCK_SYSCONFIG[8] CLOCKACTIVITY bit | This bit indicates that the interface clock is not required by the module during idle mode and may be switched off. |
| Global wake-up enable | SPINLOCK_SYSCONFIG[2] ENAWAKEUP bit | This bit indicates that the wake-up generation feature (at module level) is disabled. |

NOTE: All the local power management features are non-configurable (that is, their respective bits or bit fields are read-only).

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the CLOCKACTIVITY bit and Spinlock clock PRCM control bits.

The Spinlock module is normally idle, except when processing a request from its slave interface port. The smart-idle mode acknowledges idle requests from the PRCM only when the module is prepared to go idle. The Spinlock module is always ready to go idle if it does not have any request that it is processing.

The Spinlock module uses retention flops to retain state including the Taken state of each lock register. This means that the module can be placed in retention at any time when it is not processing a request and it is known that the system will not need to access the module.

Software must ensure to only power off the Spinlock module when no locks would be lost. In general, the steps to powering down the Spinlock module are:

- Check that all masters which might use the Spinlock module are either:
 - Already powered off, or
 - Notified that Spinlock is not available and the notification is acknowledged.

- If desired, check that no locks are currently held in the Spinlock module. The status of each bank of 32 locks can be read from the [SPINLOCK_SYSTATUS](#) register. If any locks are held, they are orphaned because they are not held by any master that is still active. Alternatively, you may decide to wait a timeout period to allow any active master to clean up its locks before powering down.
- The Spinlock module can now be powered off by writing the appropriate status to the PRCM.

In the case of powering off the whole system, these steps are unnecessary.

22.3.3 About Spinlocks

Spinlocks are present to solve the need for synchronization and mutual exclusion between heterogeneous processors and those not operating under a single, shared operating system. There is no alternative mechanism to accomplish these operations between processors in separate subsystems.

Spinlocks are not the best way to synchronize between tasks or threads on one CPU. Instead, spinlocks are for use in synchronization between different subsystems in the device that don't have any other means of hardware-based synchronization.

Spinlocks do not solve all system synchronization issues. They have limited applicability and should be used with care to implement higher level synchronization protocols.

A spinlock is appropriate for mutual exclusion for access to a shared data structure. It should be used only when:

1. The time to hold the lock is predictable and small (for example, a maximum hold time of less than 200 CPU cycles may be acceptable).
2. The locking task cannot be preempted, suspended, or interrupted while holding the lock (this would make the hold time large and unpredictable).
3. The lock is lightly contended, that is the chance of any other process (or processor) trying to acquire the lock while it is held is small.

If these conditions are met, then the locking code can retry a failed attempt to acquire the lock until success.

If the conditions are not met, then a spinlock is not a good candidate. One alternative is to use a spinlock for critical section control (engineered to meet the conditions) to implement a higher level semaphore that can support preemption, notification, timeout or other higher level properties.

22.3.4 Spinlock Functional Operation

The Spinlock module supports 32 spinlocks. It accepts only a single command at a time and processes the command fully before accepting the next command. A lock is requested by reading the [SPINLOCK_LOCK_REG_i\[0\]](#) TAKEN bit. There are two states: Taken ([SPINLOCK_LOCK_REG_i\[0\]](#) TAKEN = 1) or Not Taken ([SPINLOCK_LOCK_REG_i\[0\]](#) TAKEN = 0).

When the status of lock *i* (where *i* = 0 to 31) is Not Taken (free), a read from the [SPINLOCK_LOCK_REG_i](#) register returns 0 and sets the lock to Taken (locked). When the status of lock *i* is Taken, a read returns 1 and does not change the state of the lock.

A write to the [SPINLOCK_LOCK_REG_i](#) register does not change the state of lock, unless when writing 0 when the lock is in Taken state. By doing this, the requester frees the lock.

CAUTION

Only 32-bit reads and writes are supported.

Figure 22-3 shows the [SPINLOCK_LOCK_REG_i](#) register state diagram.

Figure 22-3. Lock Register State Diagram**NOTE:**

- There is no support to ensure that a lock register is locked and unlocked by the same process. This must be ensured in software.
- There is no support to check that the same initiator that acquired the lock is the one that is freeing the lock.

22.4 Spinlock Programming Guide

22.4.1 Spinlock Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

22.4.1.1 Surrounding Modules Global Initialization

This procedure initializes the surrounding modules when the Spinlock module is used for the first time after a device reset.

Table 22-4. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|---------------------|---|
| PRCM | Spinlock interface clock must be enabled. For more information, see Section 3.6.14 , CD_L4_CFG Clock Domain , Chapter 3, Power, Reset, and Clock Management . |
| Interconnect | For more information about the L4-CFG interconnect configuration, see Section 14.3, L4 Interconnects . |

22.4.1.2 Basic Spinlock Operations

The main spinlock operations are:

- Clear all the Taken spinlocks (only after a system bug recovery)
- Take a spinlock
- Release spinlock

22.4.1.2.1 Spinlocks Clearing After a System Bug Recovery

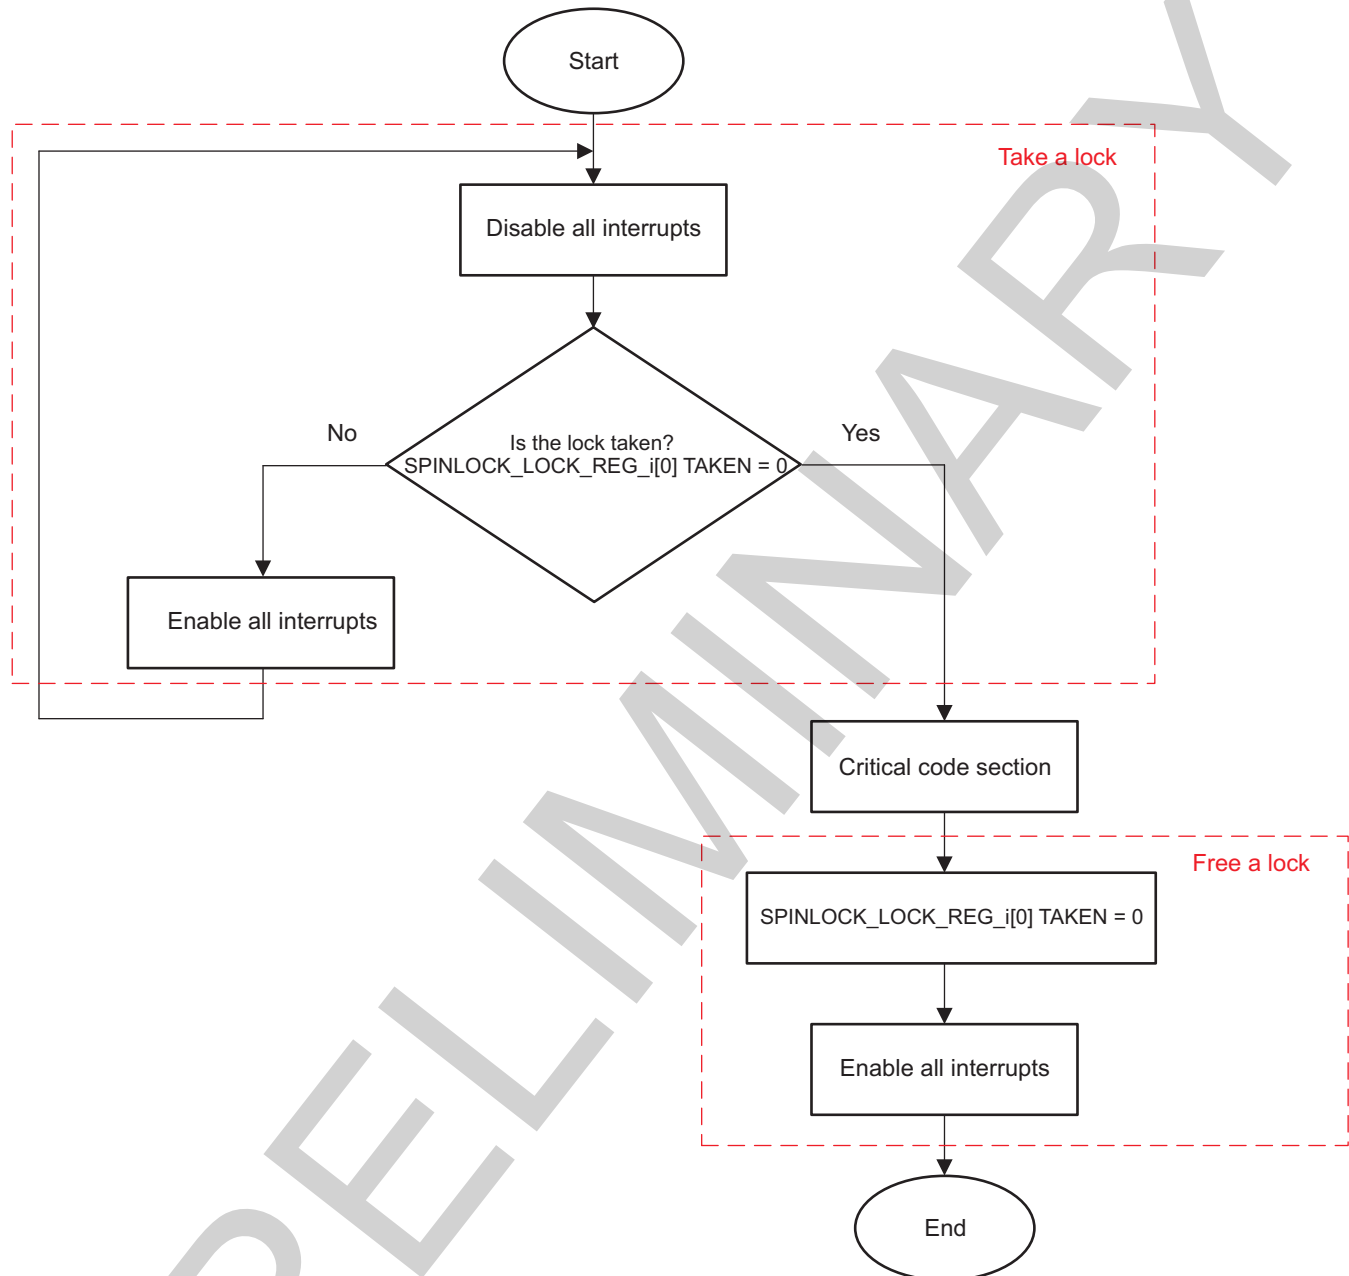

Module initialization (after reset) is not needed, except after system bug recovery. The following table presents the Spinlock initialization after a system bug recovery. Software should store 0 into each of the [SPINLOCK_LOCK_REG_i](#) registers at system startup to insure that all locks are initialized to Not Taken.

Table 22-5. Spinlock System Bug Recovery

| Step | Register | Value |
|---|---|-------|
| IF: SPINLOCK_SYSTATUS [0] IU0 == 1? | SPINLOCK_SYSTATUS [0] IU0 | |
| Free the 32 locks | SPINLOCK_LOCK_REG_i [0] TAKEN (i=0 to 31) | 0x0 |
| END | | |

22.4.1.2.2 Take and Release Spinlock

This procedure configures the take and release (free) operations for the Spinlock module. A spinlock should only be held with interrupts disabled. So, before attempting to obtain the spinlock, software should disable interrupts. Then it should read the [SPINLOCK_LOCK_REG_i](#)[0] TAKEN bit to attempt to obtain the lock. If it succeeds, it should proceed directly through the critical section then unlock and re-enable interrupts. If the acquisition attempt fails, the acquisition should be reattempted. To prevent unknown interrupt disabled time, interrupts should be re-enabled and then disabled before reattempting to acquire the lock. [Figure 22-4](#) shows the described above procedure.

PRELIMINARY

Timers

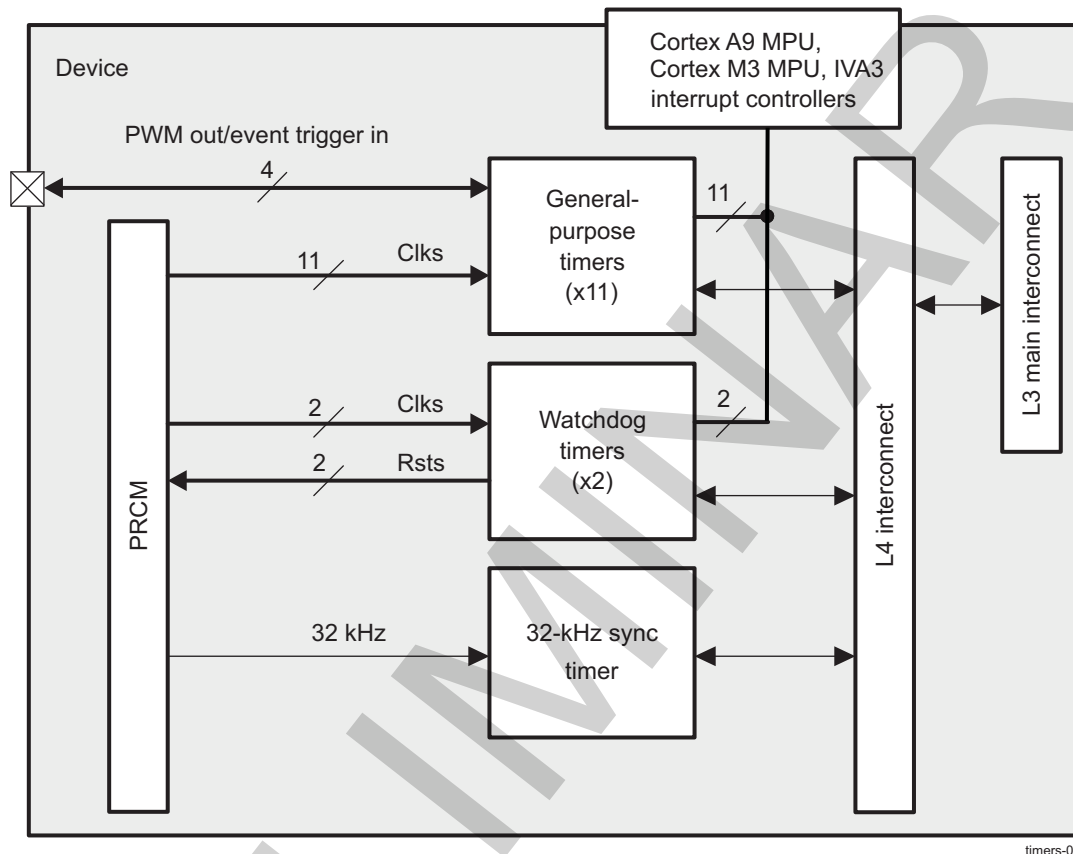

This chapter describes the timer modules for the device.

| Topic | Page |
|---|-------------|
| 23.1 Timers Overview | 4254 |
| 23.2 General-Purpose Timers | 4255 |
| 23.3 Watchdog Timers | 4311 |
| 23.4 32-kHz Synchronized Timer | 4339 |

23.1 Timers Overview

The device includes several types of timers used by the system software, including 11 general-purpose (GP) timers, two watchdog timers, and a 32-kHz synchronized timer (sync timer). Figure 23-1 is a high-level block diagram of the device timers.

Figure 23-1. Timers

The two watchdog timers are clocked with 32-kHz clocks. The 32-kHz sync timer, which is reset only at power up, provides the operating system (OS) with a stable timing source that stores the relative time since the last power cycle of the product. Finally, 11 GP timers, which are useful simply as basic timers, are included to generate time-stamp-based interrupts to the system software or to use as a source of pulse-width modulation (PWM) signals.

23.2 General-Purpose Timers

23.2.1 General-Purpose Timers Overview

The device has 11 general-purpose (GP) timers: GPTIMER1 through GPTIMER11.

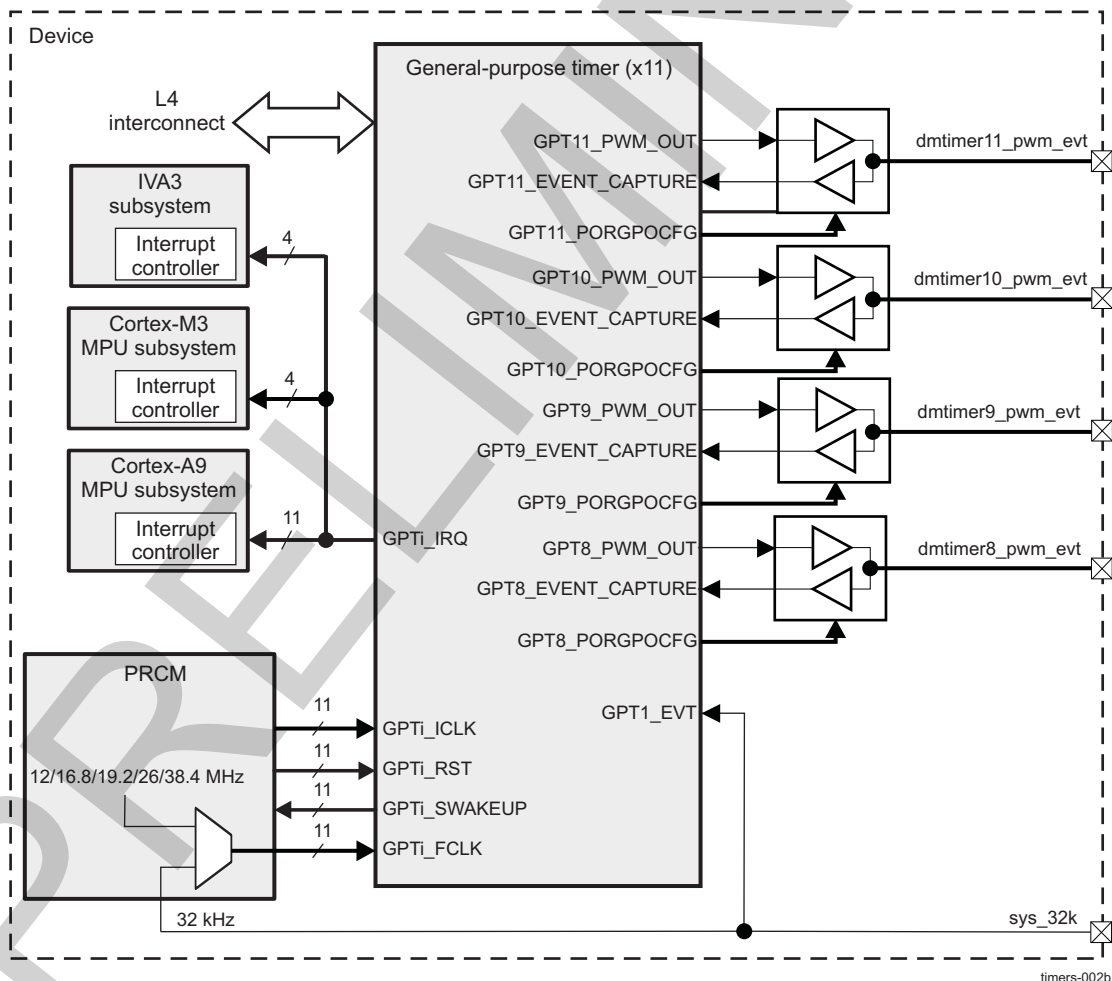

Each timer can be clocked from either the system clock (12, 16.8, 19.2, 26, or 38.4 MHz) or the 32-kHz clock. The selection of clock source is made at the power, reset, and clock management (PRCM) module level. For more information, see [Section 3.6.3.1, PRM Clock Source](#) in [Chapter 3, Power, Reset, and Clock Management](#).

GPTIMER1 has its GPT1_EVENT_CAPTURE pin tied to the 32-kHz clock and can be used to gauge the system clock input; it detects its frequency among 12, 16.8, 19.2, 26, or 38.4 MHz.

Each timer can provide an interrupt to the microprocessor unit (MPU) subsystem. In addition, GPTIMER5 through GPTIMER8 also have interrupts connected to the IVA3 subsystem.

GPTIMER1, GPTIMER2, and GPTIMER10 include specific functions to generate accurate tick interrupts to the operating system. GPTIMER8 through GPTIMER11 are connected to external pins by their PWM output or their event capture input pin (for external timer triggering). [Figure 23-2](#) is an overview of the GP timers.

Figure 23-2. GP Timers Overview

23.2.1.1 GP Timer Features

The following are the main features of the GP timer controllers:

- L4 slave interface support:

- 32-bit data bus width
- 32-/16-bit access supported
- 8-bit access not supported
- 10-bit address bus width
- Burst mode not supported
- Software-selectable nonposted or posted write/read internal resynchronization modes
- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Compare and capture modes
- Autoreload mode
- Start/stop mode
- Programmable divider clock source (2^n where $n = [0:8]$)
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- Dedicated GP output signal for using the GPTi_GPOCFG signal
- On-the-fly read/write register (while counting)
- 1-ms tick with 32,768-Hz functional clock generated (only GPTIMER1, GPTIMER2, and GPTIMER10)

23.2.2 GP Timer Environment

23.2.2.1 GP Timer External System Interface

Four of the 11 GP timers can send or receive stimulus to/from the external (off-chip) system. In the device; however, only GPTIMER8 through GPTIMER11 are configured to output a pulse-width modulation (PWM) pulse or receive an external event signal used as a trigger to capture the current timer count. GPTIMER1 is also configured to receive an event trigger input (GPT1_EVENT_CAPTURE) tied to the internal 32-kHz clock. This event signal gauges the system clock input; detecting its frequency among 12, 16.8, 19.2, 26, or 38.4 MHz.

Figure 23-3 shows the external system interface for the GP timers, and Table 23-1 describes the GP timer inputs and outputs.

NOTE: Software control must ensure that MUX mode is configured to select the dmtimerx_pwm_evt (where x = 8 to 11) signal on only one pad. Other pads on which the same signal is multiplexed must be configured in safe mode or non-dmtimer mode to avoid two different pads driving the same signal.

For more information about the configuration of the dmtimer8_pwm_evt through dmtimer11_pwm_evt I/O pads, see Section 19.4.8, *PAD Functional Multiplexing and Configuration*.

Figure 23-3. GP Timers External System Interface

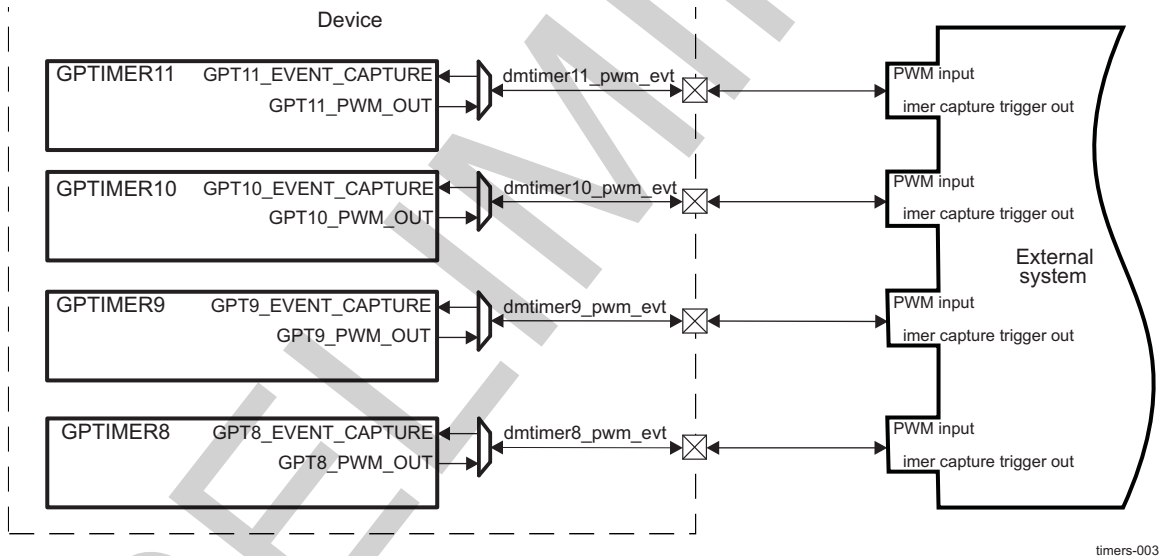

Table 23-1. Input/Output Description

| Pin Name | Type ⁽¹⁾ | Reset Value | Signal Name | Description |
|-------------------|---------------------|-------------|--------------------------------------|--|
| dmtimer8_pwm_evt | I/O | 0 | GPT8_EVENT_CAPTURE GPT8_PWM_OUT | GPTIMER8 trigger input/ PWM output |
| dmtimer9_pwm_evt | I/O | 0 | GPT9_EVENT_CAPTURE GPT9_PWM_OUT | GPTIMER9 trigger input/ PWM output |
| dmtimer10_pwm_evt | I/O | 0 | GPT10_EVENT_CAPTURE GPT10_PWM_OUT | GPTIMER10 trigger input/ PWM output |
| dmtimer11_pwm_evt | I/O | 0 | GPT11_EVENT_CAPTURE GPT11_PWM_OUT | GPTIMER11 trigger input/ PWM output |

⁽¹⁾ When configured for that function; I = input, O = output

NOTE: The event trigger input (GPTi_EVENT_CAPTURE) for GPTIMER2 through GPTIMER7 is internally tied low, and the PWM output (GPTi_PWM_OUT) is not connected.

NOTE: For GPTIMER8 through GPTIMER11, the GPTi_PORGPOCFG signal selects to connect the GPT pwm output or the GPT capture input to the dmtimerx_pwm_evt (where x = 8 to 11) pad at the top level. When the TCLR[14] GPO_CFG bit = 0b1, the dmtimerx_pwm_evt functions as a capture input. When the TCLR[14] GPO_CFG bit = 0b0, the dmtimerx_pwm_evt functions as a pwm output (GPO_CFG = 0b0).

23.2.3 GP Timer Integration

Figure 23-4 shows the integration of the GP timer in the device.

Figure 23-4. GP Timer Integration

Table 23-2 through Table 23-4 summarize the integration of the module in the device.

Table 23-2. Integration Attributes

| Module Instance | Attributes | | |

NOTE: For the description of the interrupt source description, see [Section 23.2.4.5, GP Timer Interrupts](#).

23.2.4 GP Timer Functional Description

Each GP timer contains a free-running upward counter with autoreload capability on overflow. The timer counter can be read and written on-the-fly (while counting). Each GP timer includes compare logic to allow an interrupt event on a programmable counter matching value. A dedicated output signal can be pulsed or toggled on either an overflow or a match event. This offers time-stamp trigger signaling or PWM signal sources. A dedicated input signal can be used to trigger an automatic timer counter capture or an interrupt event on a programmable input signal transition. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged into one module interrupt line and one wake-up line.

Each internal interrupt source can be independently enabled/disabled with a dedicated bit of the [GPT_TIER](#) register for the interrupt features, and a dedicated bit of the [GPT_TWER](#) register for the wake-up of GPTIMER1, GPTIMER2, and GPTIMER10. In addition, these timers have a mechanism implemented to generate an accurate tick interrupt.

For the other GP Timers, each internal interrupt source can be independently enabled/disabled through the [GPT_IRQENABLE_SET](#) and [GPT_IRQENABLE_CLR](#) register bit fields.

For each GP timer implemented in the device, there are two possible clock sources:

- 32-kHz clock
- System clock

Selection of the input clock source is done in the registers in the PRCM configuration (see [Section 23.2.1, GP Timer Overview](#)).

Each GP timer supports three functional modes:

- Timer mode
- Capture mode
- Compare mode

The capture and compare modes are disabled by default after core reset.

23.2.4.1 GP Timer Block Diagram

[Figure 23-5](#) is a block diagram of the common GP timers, and [Figure 23-6](#) is a block diagram of the GP timers with 1-ms tick generation module.

Figure 23-5. Block Diagram of GPTIMER3 Through GPTIMER9, and GPTIMER11

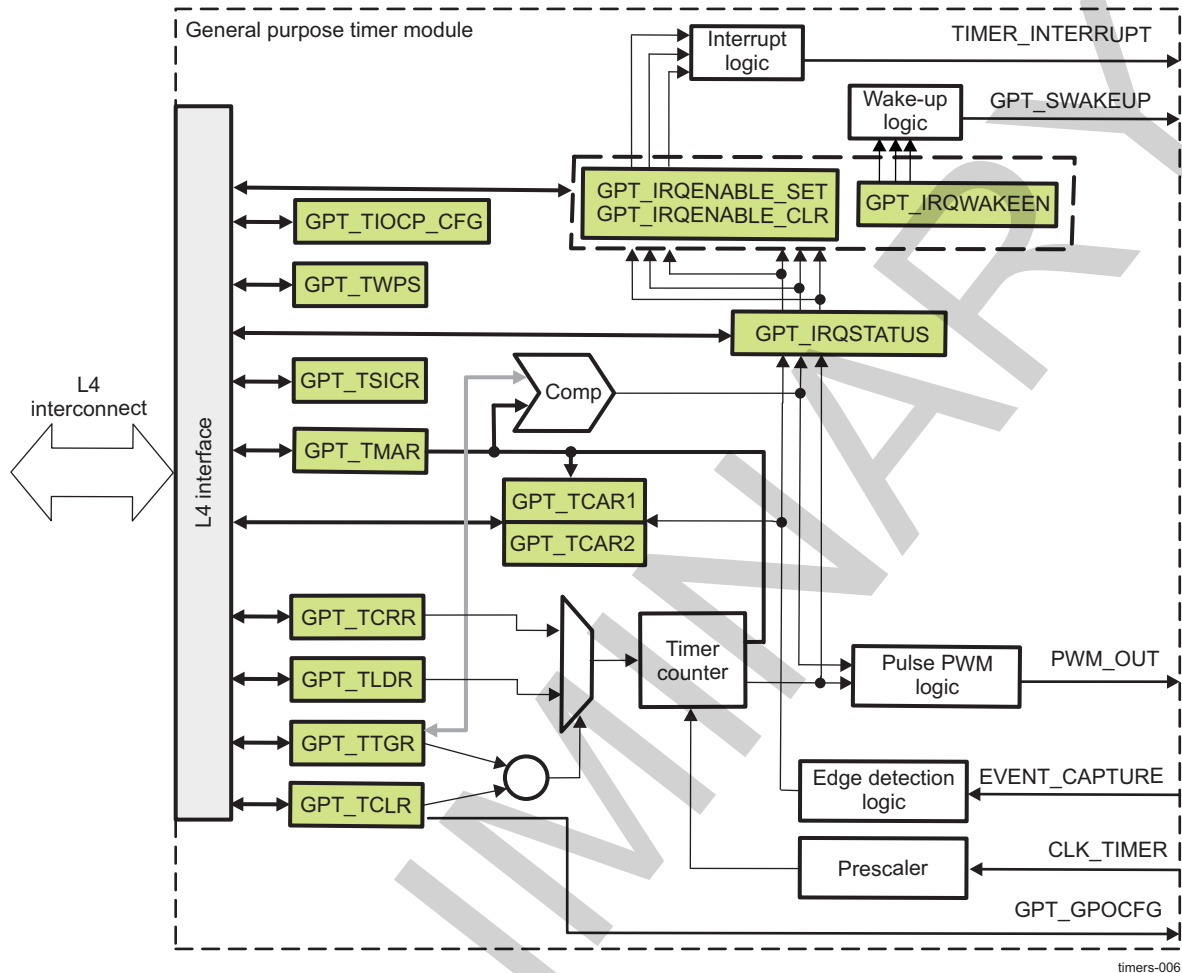

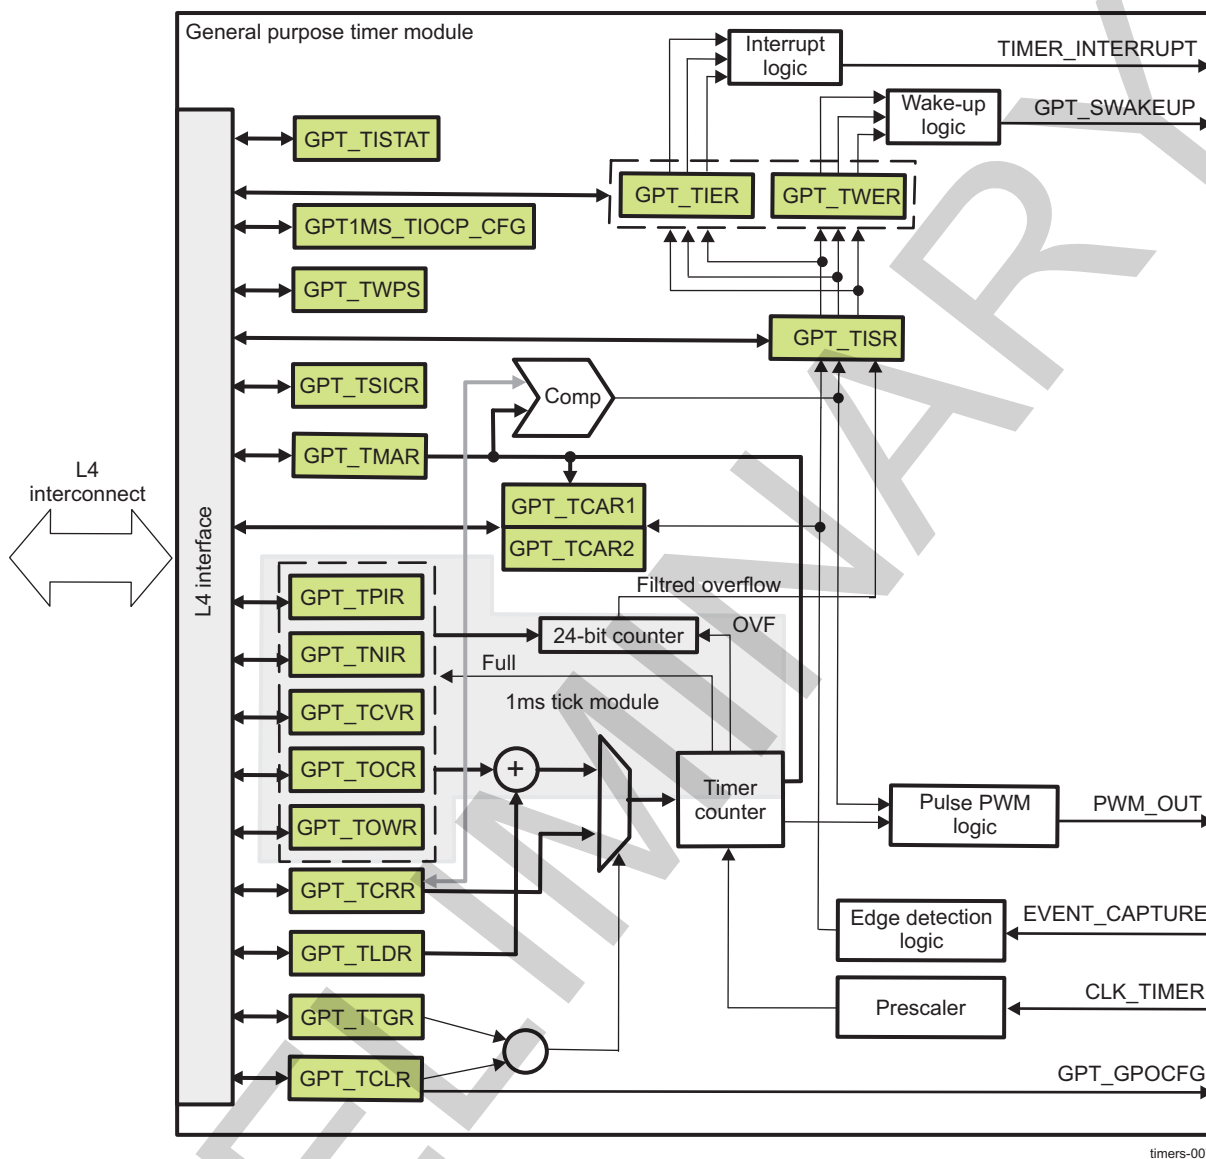

Figure 23-6. Block Diagram of GPTIMER1, GPTIMER2, and GPTIMER10

23.2.4.2 GPTIMER1, GPTIMER2, and GPTIMER10 Power Management

The GP timer modules have an internal bit, [GPT1MS_TIOCP_CFG\[0\]](#) AUTOIDLE, that is used to apply an internal interface clock gating strategy.

At the PRCM module level, when all conditions to shut off the PRCM module functional or interface output clocks are met (see [Section 3.1.1.1.4, Clock Domain-Level Clock Management](#)), the PRCM module automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the [GPT1MS_TIOCP_CFG\[4:3\]](#) IDLEMODE bit field.

[Table 23-7](#) lists the IDLEMODE settings and the related acknowledgment modes.

Table 23-5. IDLEMODE Settings

| IDLEMODE Value | Selected Mode | Description |
|----------------|---------------|--|
| 00 | Force-idle | The GP timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off. |
| 01 | No-idle | The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state. |
| 10 | Smart-idle | The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach to efficient system power management. |
| 11 | Reserved | |

When configured in smart-idle mode, the GP timer also offers an additional granularity on GPTi_FCLK and GPTi_ICLK gating. The [GPT1MS_TIOCP_CFG\[9:8\]](#) CLOCKACTIVITY bit field is used to determine which clock is shut down (GPTi_FCLK, GPTi_ICLK, neither, or both clocks).

The CLOCKACTIVITY setting is used internally to the GP timer to determine the part of the module on which the conditions to acknowledge the PRCM IDLE request are tested. For example, if GPTi_FCLK is not to be shut down on a PRCM IDLE request, the GP timer considers only GPTi_ICLK and associated pending activities before acknowledging the request.

Some GP timer features are associated with GPTi_ICLK and others are associated with GPTi_FCLK. Using the CLOCKACTIVITY setting along with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if the GP timer acknowledges an IDLE request.

[Table 23-6](#) lists the CLOCKACTIVITY settings and associated features.

Table 23-6. CLOCKACTIVITY Settings

| CLOCKACTIVITY Value | GPTi_ICLK Effects | GPTi_FCLK Effects | Description | Associated Features |
|---------------------|-------------------|-------------------|---|--|
| 00 | OFF | OFF | GPTi_ICLK and GPTi_FCLK are considered for generating the acknowledge. This setting also means GPTi_FCLK and GPTi_ICLK are likely to be shut down on PRCM IDLE request. | The idle acknowledge signal is asserted when there are no pending activities on the functional clock domain (improved latency in assertion of idle acknowledge). The wake-up capability of the GP timer is disabled. |
| 01 | ON | OFF | GPTi_ICLK is not shut down on PRCM IDLE request; only GPTi_FCLK is affected. | |

Table 23-6. CLOCKACTIVITY Settings (continued)

| CLOCKACTIVITY Value | GPTi_ICLK Effects | GPTi_FCLK Effects | Description | Associated Features |
|---------------------|-------------------|-------------------|--|--|
| 10 | OFF | ON | GPTi_FCLK is not shut down on PRCM IDLE request; only GPTi_ICLK is affected. | The idle acknowledge signal is asserted when there are no pending activities on the interface clock domain, without evaluating the pending activities on the functional clock domain (the GP timer enters into sleep mode, and if a pending interrupt event is completed during idle mode, the wake-up signal is asserted). The wake-up signal is enabled. |
| 11 | ON | ON | None of the clocks are shut down. Therefore, the GP timer can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clocks. | |

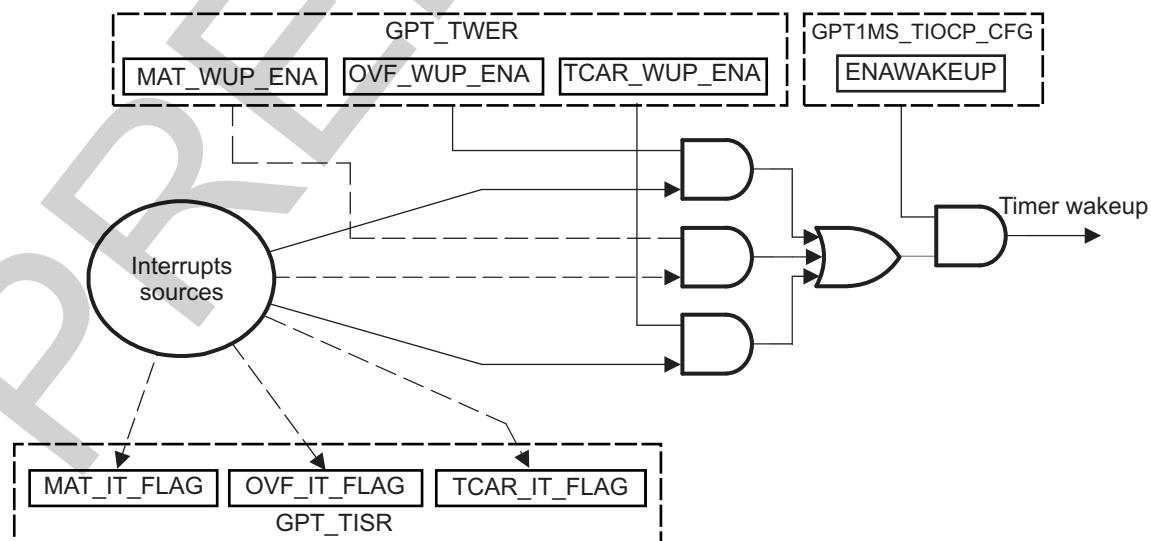

CAUTION

The PRCM module does not have any hardware means to read the CLOCKACTIVITY settings. The software must ensure consistent programming between the GP timer CLOCKACTIVITY and the PRCM module functional clock and interface clock control bits. If the GP timer is disabled in the CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the GP timer clocks. This can lead to unpredictable behavior.

23.2.4.2.1 Wake-Up Capability

If the [GPT1MS_TIOCP_CFG\[4:3\]](#) IDLEMODE bit field sets the smart-idle mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request. This wake-up request is sent only if the [GPT1MS_TIOCP_CFG\[2\]](#) ENAWAKEUP bit enables the timer wake-up capability.

[Figure 23-7](#) shows the wake-up request generation. For more information on the GP timer clock control, see [Section 3.6, Clock Management Functional Description](#) in [Chapter 3, Power, Reset and Clock Management](#).

Figure 23-7. Wake-Up Request Generation

timers-005

For GPTIMER1, GPTIMER2, and GPTIMER10, the timer wake-up enable-register (**GPT_TWER**) allows masking the expected source of the wake-up event that generates a wake-up request. The **GPT_TWER** register is synchronously programmed with the interface clock before the PRCM module sends an idle mode request. The expected source of the wake-up event is an overflow (**GPT_TCRR**), a timer match (the compare result of **GPT_TCRR** and **GPT_TMAR** matches the counter value), and a timer capture (detection of an external pulse transition of the correct polarity on the **GPT_EVENT_CAPTURE**).

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (**GPT_TISR**). The pending wake-up event is reset when the set status bit is overwritten with 1.

NOTE: The status bit must be reset to re-enter idle mode.

23.2.4.3 Power Management of Other GP Timers

At the PRCM module level, when all conditions to shut off the PRCM module functional or interface output clocks are met (see [Section 3.1.1.1.4, Clock Domain Level Clock Management](#)), the PRCM module automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the **GPT_TIOCP_CFG**[3:2] IDLEMODE bit field.

[Table 23-7](#) lists the IDLEMODE settings and the related acknowledgment modes.

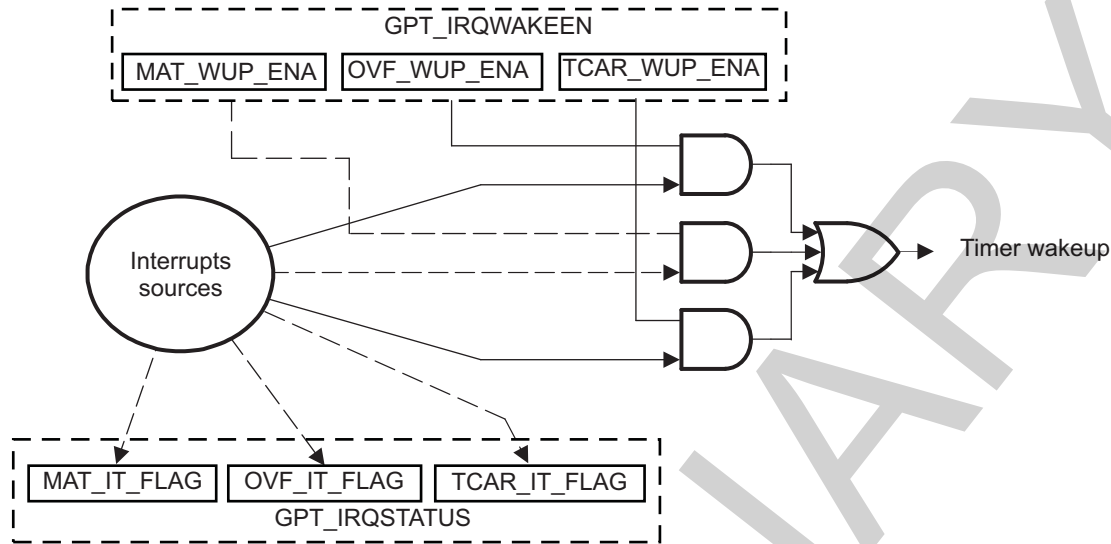

Table 23-7. IDLEMODE Settings

| IDLEMODE Value | Selected Mode | Description |
|----------------|---------------|---|
| 00 | Force-idle | The GP timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off. |
| 01 | No-idle | The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, however, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state. |
| 10 | Smart-idle | The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach to efficient system power management. |
| 11 | Reserved | |

23.2.4.3.1 Wake-Up Capability

If the **GPT_TIOCP_CFG**[3:2] IDLEMODE bit field sets the smart-idle mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request. This wake-up request is sent only if the **GPT_IRQWAKEEN**[2:0] bit field enables the timer wake-up capability.

[Figure 23-8](#) shows the wake-up request generation. For more information on the GP timer clock control, see [Section 3.6, Clock Management Functional Description](#) in [Chapter 3, Power, Reset and Clock Management](#).

Figure 23-8. Wake-Up Request Generation

timers-014

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register ([GPT_IRQSTATUS](#)). The pending wake-up event is reset when the set status bit is overwritten with 1.

NOTE: The status bit must be reset to re-enter idle mode.

23.2.4.4 Software Reset

Two bit fields can generate a software reset of the GP timer:

- [GPT1MS_TIOCP_CFG\[1\]](#) SOFTRESET for GPTIMER1, GPTIMER2, and GPTIMER10, and [GPT_TIOCP_CFG\[0\]](#) SOFTRESET for other timers
- [GPT_TSICR\[1\]](#) SFT for all timers

For both bits, all read accesses return 0.

The [GPT1MS_TIOCP_CFG\[1\]](#) SOFTRESET/[GPT_TIOCP_CFG\[0\]](#) SOFTRESET bit allows resetting the functional and interface domains. The [GPT_TSICR\[1\]](#) SFT bit allows resetting the functional part of the GP timer.

Before accessing or using the GP timer, the local host must ensure that both internal resets are released by reading the [GPT_TISTAT\[0\]](#) RESETDONE (for GPTIMER1, GPTIMER2, and GPTIMER10), or the [GPT_TIOCP_CFG\[0\]](#) SOFTRESET bit (for other timers). This bit monitors the internal reset status.

23.2.4.5 GP Timer Interrupts

The timer can issue an overflow interrupt, a timer match interrupt, and a timer capture interrupt. Each internal interrupt source can be independently enabled/disabled in the interrupt-enable register ([GPT_TIER](#) for GPTIMER1, GPTIMER2, and GPTIMER10), or, for other timers, enable in the interrupt-enable register ([GPT_IRQENABLE_SET](#)) and disable in the interrupt disable register ([GPT_IRQENABLE_CLR](#)). When the interrupt event is issued, the associated interrupt status bit is set in the timer status register ([GPT_TISR](#) for GPTIMER1, GPTIMER2, and GPTIMER10, and [GPT_IRQSTATUS](#) for other timers).

23.2.4.6 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the timer control register ([GPT_TCLR\[0\]](#) ST bit). The timer counter register ([GPT_TCR](#)) can be loaded when stopped or on-the-fly (while counting). [GPT_TCR](#) can be loaded directly by a [GPT_TCR](#) write access with a new

timer value. The `GPT_TCR` register can also be loaded with the value held in the timer-load register `GPT_TLDR` by a trigger register (`GPT_TTGR`) write access. Loading of `GPT_TCR` is done regardless of the `GPT_TTGR` written value. The timer counter register `GPT_TCR` value can be read when stopped, or captured on-the-fly by a `GPT_TCR` read access. The timer is stopped and the counter value is set to 0 when the module reset is asserted. The timer is maintained at stop after the reset is released.

In one-shot mode (the `GPT_TCLR[1]` AR bit set to 0), the counter is stopped after counting overflow occurs (the counter value remains at 0).

When the autoreload mode is enabled (the `GPT_TCLR[1]` AR bit set to 1), the `GPT_TCR` register is reloaded with the timer-load register (`GPT_TLDR`) value after a counting overflow occurs.

CAUTION

Do not put the overflow value (0xFFFF FFFF) in the `GPT_TLDR` register because it can lead to undesirable results.

An interrupt can be issued on overflow if the overflow interrupt-enable bit is set in the timer interrupt-enable register (`GPT_TIER[1]` OVF_IT_ENA bit set to 1 for GPTIMER1, GPTIMER2, and GPTIMER10, or `GPT_IRQENABLE_SET[1]` OVF_IT_FLAG bit set to 1 for other timers). A dedicated output pin (timer PWM) can be programmed in `GPT_TCLR[12]` through `GPT_TCLR[11:10]` (PT and TRG bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs. The `GPT_TCLR[12]` PT bit selects pulse/toggle modulation (`GPT_TCLR[11:10]` TRG bit field selects trigger mode).

Figure 23-9 shows the `GPT_TCR` timing value.

Figure 23-9. GPT_TCR Timing Value

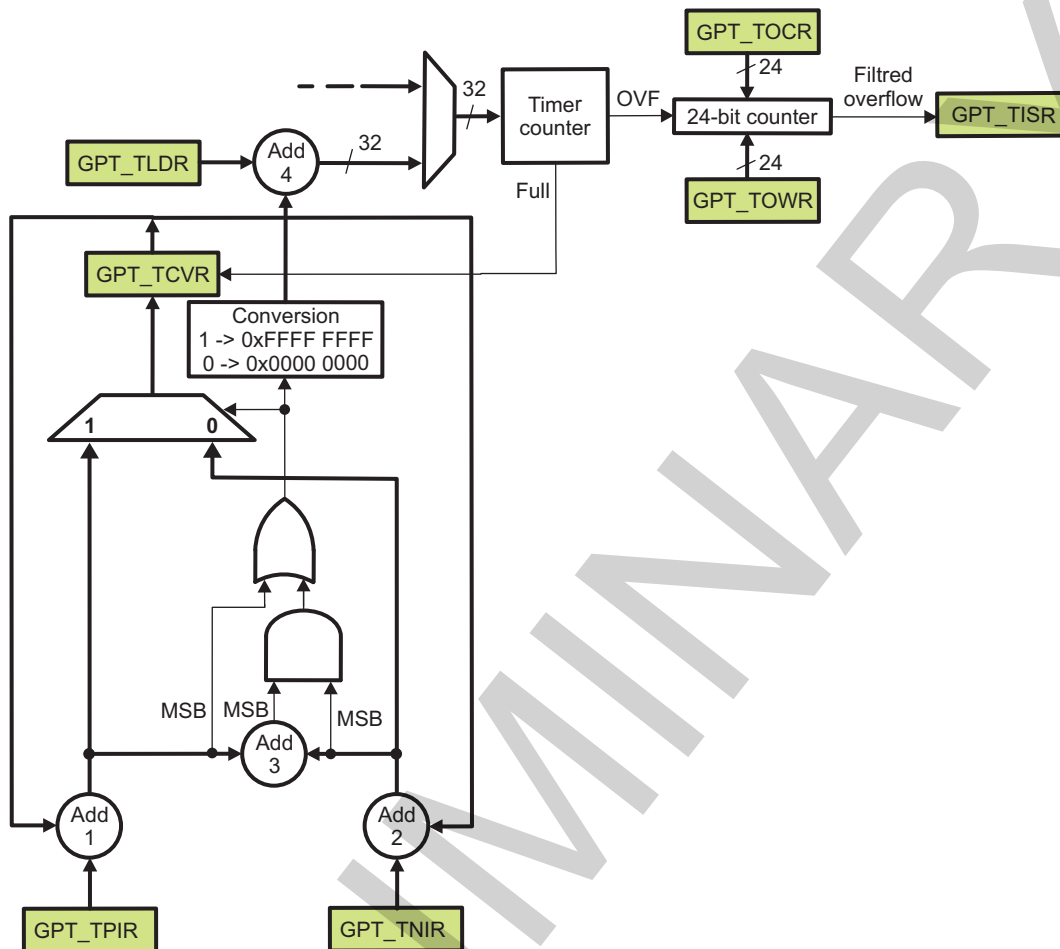

23.2.4.6.1 1-ms Tick Generation (Only GPTIMER1, GPTIMER2, and GPTIMER10)

The interrupt period is not exactly 1 ms because the timer input clock is 32,768 Hz. If the clock counts up to 32, it obtains a 0.977-ms period; if it counts up to 33, it obtains a 1.007-ms period. For large granularity, the error is cumulative and can generate important deviations from the standard value.

To minimize the error between a true 1-ms tick and the tick generated by the 32,768 Hz timer, the sequencing of periods less than 1 ms and periods greater than 1 ms must be shuffled. An additional 1-ms block is used to correct this error. See Figure 23-10.

In this implementation, the increment sequencing is automatically managed by the timer to minimize the error. The user must define only the value of the timer positive increment register (`GPT_TPIR[31:0]` POSITIVE_INC_VALUE bit field) and the timer negative increment register (`GPT_TNIR[31:0]` NEGATIVE_INC_VALUE bit field). An automatic adaptation mechanism is used to simplify the programming model.

Figure 23-10. Block Diagram of the 1-ms Tick Module

timers-009

The **GPT_TPIR**, **GPT_TNIR**, and **GPT_TCVR** registers and adders Add1, Add2, and Add3 are used to define whether the next value loaded in the timer counter register (**GPT_TCCR**[31:0] **TIMER_COUNTER** bit field) is the value of the **GPT_TLDR**[31:0] **LOAD_VALUE** bit field (period less than 1 ms) or the value of **GPT_TLDR**[31:0] **LOAD_VALUE** – 1 (period greater than 1 ms).

Table 23-8 lists the value loaded in the **GPT_TCCR** register according to the sign of the result of Add1, Add2, and Add3.

MSB = 0: Positive value, MSB = 1: Negative value

Table 23-8. Value Loaded in GPT_TCCR to Generate 1-ms Tick

| Add1 MSB | Add2 MSB | Add3 MSB | Value of GPT_TCCR Register |
|----------|----------|----------|--|
| 0 | 0 | 0 | GPT_TLDR [31:0] LOAD_VALUE bit field |
| 0 | 0 | 1 | GPT_TLDR [31:0] LOAD_VALUE bit field |
| 0 | 1 | 0 | GPT_TLDR [31:0] LOAD_VALUE bit field |
| 0 | 1 | 1 | GPT_TLDR [31:0] LOAD_VALUE – 1 |
| 1 | 0 | 0 | N/A |
| 1 | 0 | 1 | N/A |
| 1 | 1 | 0 | GPT_TLDR [31:0] LOAD_VALUE – 1 |
| 1 | 1 | 1 | GPT_TLDR [31:0] LOAD_VALUE – 1 |

The values of the [GPT_TPIR](#) and [GPT_TNIR](#) registers are calculated using the following formula:

- Positive increment value = $(\text{INTEGER}[F_{\text{clk}} * T_{\text{tick}}] + 1) * 1\text{e6} - (F_{\text{clk}} * T_{\text{tick}} * 1\text{e6})$
- Negative increment value = $(\text{INTEGER}[F_{\text{clk}} * T_{\text{tick}}] * 1\text{e6}) - (F_{\text{clk}} * T_{\text{tick}} * 1\text{e6})$

NOTE: Fclk clock frequency (kHz)

Ttick tick period (ms)

The timer overflow counter register ([GPT_TOCR](#)) and the timer overflow wrapping register [GPT_TOWR](#) are used to filter interrupts. When the timer overflows, it increments the 24-bit [GPT_TOCR](#) register. When the 24-bit [GPT_TOCR](#) register values match the value in the 24-bit [GPT_TOWR](#) register and the timer overflow is asserted, the [GPT_TOCR](#) register is reset and an interrupt is generated to the [GPT_TISR](#) register.

With the conversion block in reset state (the positive increment register, negative increment register, and counter value register are zeroed), the programming model and the behavior of GPTIMER1, GPTIMER2, and GPTIMER10 remain unchanged.

For 1-ms tick with a 32,768-Hz clock:

- [GPT_TPIR](#)[31:0] POSITIVE_INC_VALUE = 232000
- [GPT_TNIR](#)[31:0] NEGATIVE_INC_VALUE = -768000
- [GPT_TLDR](#)[31:0] LOAD_VALUE = 0xFFFF FFE0

NOTE: Any value of the tick period can be generated with the appropriate value of the [GPT_TPIR](#), [GPT_TNIR](#), and [GPT_TLDR](#) registers.

By default, the [GPT_TPIR](#), [GPT_TNIR](#), [GPT_TCVR](#), [GPT_TOCR](#), and [GPT_TOWR](#) registers and the associated logic are in reset mode (all 0s) and have no action on the programming model.

23.2.4.7 Capture Mode Functionality

When a transition is detected on the module input pin (EVENT_CAPTURE), the timer value in the [GPT_TCRR](#) register can be captured and saved in the [GPT_TCAR1](#) or TCAR2 register function of the mode selected in the [GPT_TCLR](#)[13] CAPT_MODE bit. The edge detection circuitry monitors transitions on the input pin (EVENT_CAPTURE).

The rising edge, falling edge, or both, can be selected in the [GPT_TCLR](#)[9:8] TCM bit field to trigger the timer counter capture. The module sets the [GPT_TISR](#)[2] TCAR_IT_FLAG bit for GPTIMER1, GPTIMER2, or GPTIMER10, and the [GPT_IRQSTATUS](#)[2] TCAR_IT_FLAG bit for other timers, when an active edge is detected, and at the same time, the counter value [GPT_TCRR](#) is stored in timer capture register [GPT_TCAR1](#) or [GPT_TCAR2](#), as follows:

- If the [GPT_TCLR](#)[13] CAPT_MODE bit is 0, on the first enabled capture event, the value of the counter register is saved in the [GPT_TCAR1](#) register, and all the next events are ignored (no update on the [GPT_TCAR1](#) register and no interrupt triggering) until the detection logic is reset or the [GPT_TISR](#)[2] TCAR_IT_FLAG bit (or [GPT_IRQSTATUS](#)[2] TCAR_IT_FLAG, depending on the timer) is cleared by writing 1 to it.
- If the [GPT_TCLR](#)[13] CAPT_MODE bit is 1, on the first enabled capture event, the value of the counter register is saved in the [GPT_TCAR1](#) register, and on the second enabled capture event, the value of the counter register is saved in the [GPT_TCAR2](#) register. If a capture interrupt is enabled, the interrupt triggers on the second event capture. All other events are ignored (no update on [GPT_TCAR1](#)/[GPT_TCAR2](#) and no interrupt triggering) until the detection logic is reset or [GPT_TISR](#)[2] TCAR_IT_FLAG bit (or [GPT_IRQSTATUS](#)[2] TCAR_IT_FLAG, depending on the timer) is cleared by writing 1 to it. This mechanism is useful for period calculation of a clock, if that clock is connected to the EVENT_CAPTURE input pin.

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served. The [GPT_TISR](#)[2] TCAR_IT_FLAG bit or the [GPT_IRQSTATUS](#)[2] TCAR_IT_FLAG (previously 1) is cleared by writing 1 to it or when the edge detection mode bits (the [GPT_TCLR](#)[9:8] TCM bit field) are

changed from no-capture mode detection to any other mode. The timer functional clock (input to prescaler) is used to sample the input pin (EVENT_CAPTURE). A negative or positive pulse input can be detected when the pulse time is greater than the functional clock period. An interrupt is issued on edge detection if the capture interrupt-enable bit is set in the [GPT_TIER\[2\]](#) TCAR_IT_ENA bit (for GPTIMER1, GPTIMER2, or GPTIMER10), or in the [GPT_IRQENABLE_SET\[2\]](#) TCAR_EN_FLAG bit (for other timers). See the examples in [Figure 23-11](#) and [Figure 23-12](#).

In [Figure 23-11](#), the [GPT_TCLR\[9:8\]](#) TCM bit field value is 0b01, and [GPT_TCLR\[13\]](#) CAPT_MODE bit is 0. Only the rising edge of EVENT_CAPTURE triggers a capture in the [GPT_TCARR1](#) and [GPT_TCARR2](#) registers, and only the [GPT_TCARR1](#) register updates.

Figure 23-11. Capture Wave Example for GPT_TCLR[13] CAPT_MODE = 0

In [Figure 23-12](#), the value of the [GPT_TCLR\[9:8\]](#) TCM bit field is 0b01, and the [GPT_TCLR\[13\]](#) CAPT_MODE bit is 1. Only the rising edge of EVENT_CAPTURE triggers a capture in the [GPT_TCARR1](#) register on the first enabled event, and the [GPT_TCARR2](#) register updates on the second enabled event.

Figure 23-12. Capture Wave Example for GPT_TCLR[13] CAPT_MODE = 1

23.2.4.8 Compare Mode Functionality

When compare enable-register [GPT_TCLR\[6\]](#) CE bit is set to 1, the timer value ([GPT_TCRR\[31:0\]](#))

TIMER_COUNTER bit field) is continuously compared to the value held in the timer match register (**GPT_TMAR**). The **GPT_TMAR**[31:0] COMPARE_VALUE bit field value can be loaded at any time (timer counting or stopped). When the **GPT_TCRR** and the **GPT_TMAR** values match, an interrupt is issued, if the **GPT_TIER**[0] MAT_IT_ENA (for GPTIMER1, GPTIMER2, and GPTIMER10), or **GPT_IRQSTATUS_SET**[0] MAT_EN_FLAG bit (for other timers) is set.

The right programming way is to write a compare value to the **GPT_TMAR** register before setting the **GPT_TCLR**[6] CE bit to prevent any unwanted interrupts due to a reset value matching effect.

The dedicated output pin (timer PWM) can be programmed in the **GPT_TCLR**[12] PT bit through the **GPT_TCLR**[11:10] TRG bit field to generate one positive pulse (timer clock duration) or to invert the current value (toggle mode) when an overflow or a match occurs.

23.2.4.9 Prescaler Functionality

A prescaler can be used to divide the timer counter input clock frequency. The prescaler is enabled when the **GPT_TCLR**[5] PRE bit is set. The **GPT_TCLR**[4:2] PTV bit field sets the second prescaler ratio. The prescaler counter is reset when the timer counter is stopped or reloaded on-the-fly.

Table 23-9 lists the prescaler/timer reload values versus contexts.

Table 23-9. Prescaler/Timer Reload Values Versus Contexts

| Context | Prescaler | Timer Counter |
|----------------------------------|-----------|------------------------|
| Overflow (when autoreload is on) | Reset | GPT_TLDR [31:0] |
| GPT_TCRR write | Reset | GPT_TCRR [31:0] |
| GPT_TTGR write | Reset | GPT_TLDR [31:0] |
| Stop | Reset | Frozen |

23.2.4.10 Pulse-Width Modulation

The timer can be configured to provide a programmable PWM output. The timer PWM output pin can be configured to toggle on an event. The **GPT_TCLR**[11:10] TRG bit field determines on which register value the PWM pin toggles. Either overflow alone or both overflow and match can be selected to toggle the timer PWM pin when a compare condition occurs.

CAUTION

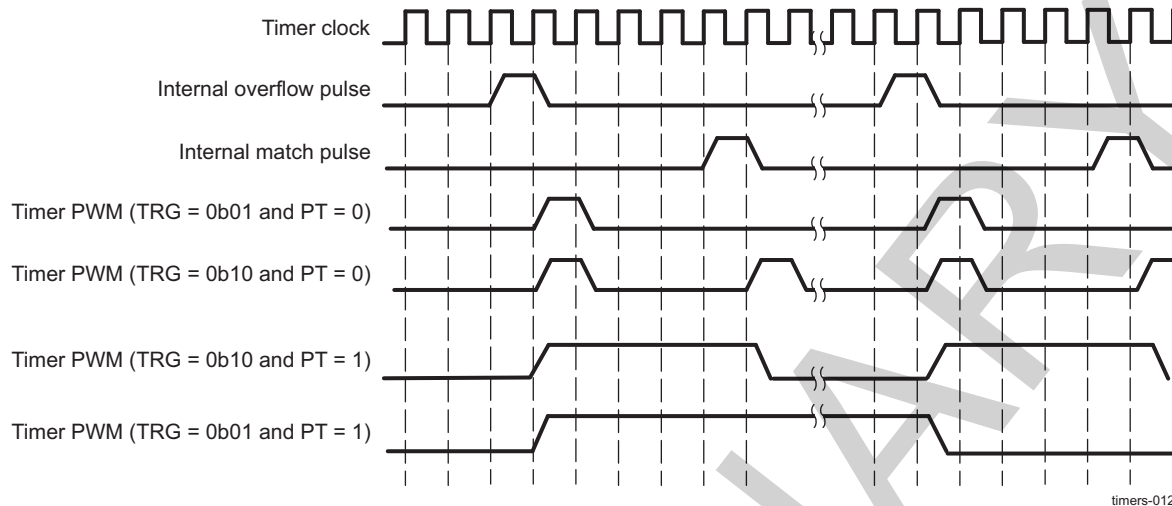

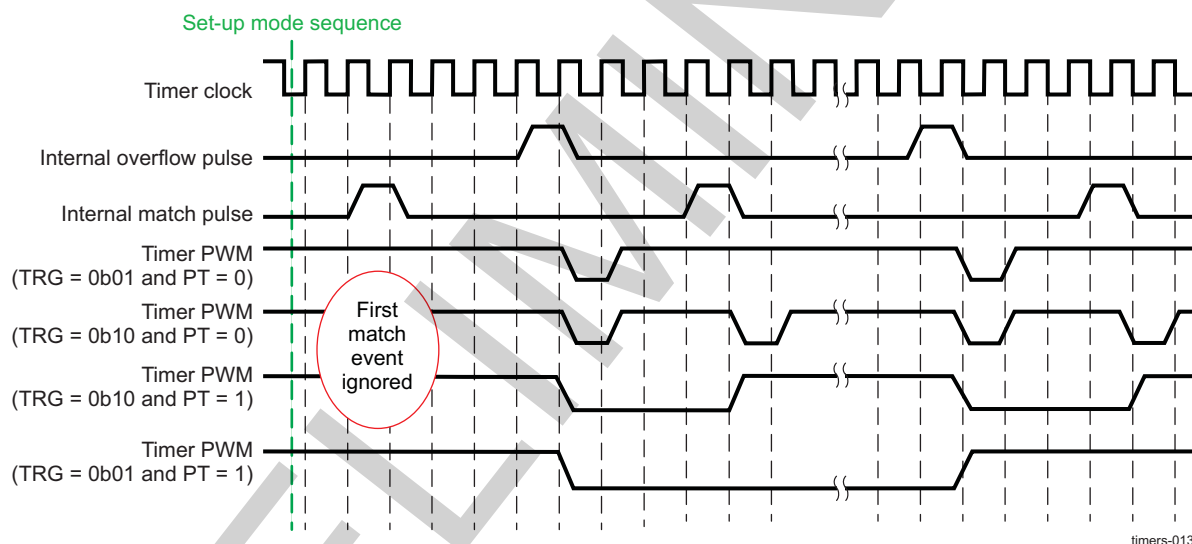

In toggle mode, when **GPT_TCLR**[11:10] TRG = 0x2 (overflow and match), the first event that toggles the PWM line is an overflow event. If a match event occurs first; it does not toggle the PWM line (see Figure 23-14).

The **GPT_TCLR**[7] SCPWM bit can be programmed to set or clear the timer PWM output signal only while the counter is stopped or the trigger is off. This allows setting the output pin to a known state before modulation starts. Modulation synchronously stops when the **GPT_TCLR**[11:10] TRG bit field is cleared and overflow occurs. This allows fixing a deterministic state of the output pin when modulation stops.

In Figure 23-13, the internal overflow pulse is set each time (0xFFFF FFFF - **GPT_TLDR**[31:0] LOAD_VALUE + 1) the value is reached, and the internal match pulse is set when the counter reaches the **GPT_TMAR** register value. Depending on the value of the **GPT_TCLR**[12] PT bit and **GPT_TCLR**[11:10] TRG bit field, the timer provides pulse or PWM event on the output pin (timer PWM).

The **GPT_TLDR** and **GPT_TMAR** registers must keep values below the overflow value (0xFFFF FFFF) by at least two units. In case the PWM trigger events are both overflow and match, the difference between the values kept in the **GPT_TMAR** register and the value in the **GPT_TLDR** register must be at least two units. When match event is used, the compare mode **GPT_TCLR**[6] CE bit must be set.

In Figure 23-13, the **GPT_TCLR**[7] SCPWM bit is set to 0. In Figure 23-14, the **GPT_TCLR**[7] SCPWM bit is set to 1. To obtain the desired wave form, start the counter at 0xFFFF FFFE value (to ensure an overflow first) or adjust the line polarity (**GPT_TCLR**[7] SCPWM bit).

Figure 23-13. Timing Diagram of PWM With GPT_TCLR[7] SCPWM Bit = 0**Figure 23-14. Timing Diagram of PWM With GPT_TCLR[7] SCPWM Bit = 1****23.2.4.11 Timer Counting Rate**

The timer rate is defined by the following values:

- Value of the prescaler fields (the [GPT_TCLR\[5\]](#) PRE bit and the [GPT_TCLR\[4:2\]](#) PTV bit field)
- Value loaded into the timer-load register ([GPT_TLDR](#))

[Table 23-10](#) lists the prescaler clock ratio values.

Table 23-10. Prescaler Clock Ratio Values

| GPT_TCLR[5] PRE | GPT_TCLR[4:2] PTV | Divisor (PS) |
|---------------------------------|-----------------------------------|--------------|
| 0 | X | 1 |
| 1 | 0 | 2 |
| 1 | 1 | 4 |
| 1 | 2 | 8 |
| 1 | 3 | 16 |
| 1 | 4 | 32 |

Table 23-10. Prescaler Clock Ratio Values (continued)

| GPT_TCLR[5] PRE | GPT_TCLR[4:2] PTV | Divisor (PS) |
|------------------------|--------------------------|---------------------|
| 1 | 5 | 64 |
| 1 | 6 | 128 |
| 1 | 7 | 256 |

Thus, the timer overflow rate is expressed as:

$$\text{OVF_Rate} = (0xFFFF FFFF - \text{GPT_TLDR} + 1) * (\text{timer-functional clock period}) * \text{PS}$$

With (timer-functional clock period) = 1/(timer-functional clock frequency) and PS = $2^{(\text{PTV} + 1)}$ if prescaler is enabled, or PS = 1 if prescaler is disabled.

CAUTION

Internal resynchronization causes any write to the **GPT_TCLR[1]** ST bit to have some latency before the register is updated:

2.5 * functional clock cycles write_GPT_TCLR_latency 3.5 * functional clock cycles

Remember to consider this latency whenever the timer must be started or stopped by a software change to the **GPT_TCLR[1]** ST bit.

CAUTION

- In the non-PWM mode, **GPT_TLDR** must be maintained at less than or equal to 0xFFFF FFFE.
- In the PWM mode, **GPT_TLDR** must be maintained at less than or equal to 0xFFFF FFED.

For example, with a timer clock input of 32 kHz and the **GPT_TCLR[5]** PRE bit set to 0, the timer output period is as listed in [Table 23-11](#).

Table 23-11. Value and Corresponding Interrupt Period

| GPT_TLDR[31:0] LOAD_VALUE | Interrupt Period |
|----------------------------------|-------------------------|
| 0x0000 0000 | 39 h |
| 0xFFFF 0000 | 2.1 s |
| 0xFFFF FFF0 | 524 μ s |
| 0xFFFF FFFE | 65.5 μ s |

23.2.4.12 Timer Under Emulation

During emulation mode, the timer continues to run according to the value of the **GPT1MS_TIOCP_CFG[5]/GPT_TIOCP_CFG[1]** EMUFREE bit.

If the **GPT1MS_TIOCP_CFG[5]/GPT_TIOCP_CFG[1]** EMUFREE bit is set to 1, timer execution is not stopped in emulation mode and the interrupt is still generated when overflow or match is reached.

If the **GPT1MS_TIOCP_CFG[5]/GPT_TIOCP_CFG[1]** EMUFREE bit is set to 0, the prescaler and timer are frozen and both resume on exit from emulation mode. The asynchronous external input pin (dmtimer_i_pwm_evt, with i=[8:11]) is internally synchronized on two timer-clock rising edges.

23.2.4.13 Accessing GP Timer Registers

All accesses are nonposted until software reconfiguration. All registers are 32 bits wide, accessible through the L4 interface with 16-bit or 32-bit access (read/write).

Any 16-bit write access must be least-significant bit (LSB) first, and the second write access must be most-significant bit (MSB) first. Write operations to the following GP timer registers can skip the MSB access if it is not necessary to update the 16 MSBs of the register:

- [GPT_TIDR](#)
- [GPT_TIOCP_CFG](#)
- [GPT1MS_TIOCP_CFG](#)
- [GPT_IRQSTATUS_RAW](#)
- [GPT_IRQSTATUS](#)
- [GPT_IRQENABLE_SET](#)
- [GPT_IRQENABLE_CLR](#)
- [GPT_IRQWAKEEN](#)
- [GPT_TISR](#)
- [GPT_TIER](#)
- [GPT_TWER](#)
- [GPT_TSICR](#)

Write operations to the following functional registers must be complete (the MSB must be written even if the MSB data is not used):

- [GPT_TCLR](#)
- [GPT_TCRR](#)
- [GPT_TLDR](#)
- [GPT_TTGR](#)
- [GPT_TMAR](#)
- [GPT_TPIR](#)
- [GPT_TNIR](#)
- [GPT_TCVR](#)
- [GPT_TOCR](#)
- [GPT_TOWR](#)

The following L4 synchronous registers are not affected by the posted/nonposted mode selection; the write/read operation is effective and acknowledged (command accepted) after one L4 clock cycle from command assertion:

- [GPT_TIDR](#)
- [GPT_TIOCP_CFG](#)
- [GPT1MS_TIOCP_CFG](#)
- [GPT_TISTAT](#)
- [GPT_IRQSTATUS](#)
- [GPT_IRQSTATUS_RAW](#)
- [GPT_IRQENABLE_SET](#)
- [GPT_IRQENABLE_CLR](#)
- [GPT_IRQWAKEEN](#)
- [GPT_TWPS](#)
- [GPT_TSICR](#)

23.2.4.13.1 Writing to Timer Registers

The host uses the L4 interface to write to the following registers synchronously with the timer interface clock:

- [GPT_TLDR](#)
- [GPT_TCRR](#)
- [GPT_TCLR](#)
- [GPT_TIOCP_CFG](#)
- [GPT1MS_TIOCP_CFG](#)
- [GPT_IRQSTATUS](#)
- [GPT_IRQENABLE_SET](#)
- [GPT_IRQENABLE_CLR](#)
- [GPT_IRQWAKEEN](#)
- [GPT_TTGR](#)
- [GPT_TSICR](#)
- [GPT_TMAR](#)

GPTIMER1, GPTIMER2, and GPTIMER10 also have the following registers:

- [GPT_TPIR](#)
- [GPT_TNIR](#)
- [GPT_TCVR](#)
- [GPT_TOCR](#)
- [GPT_TOWR](#)
- [GPT_TIER](#)
- [GPT_TISR](#)
- [GPT_TWER](#)

In 16-bit access mode, the 16 LSBs must be written before writing to the 16 MSBs.

23.2.4.13.1.1 Write Posting Synchronization Mode

This mode is used if the [GPT_TSICR](#)[2] POSTED bit is set to 1.

This mode uses a posted write scheme to update any internal register ([GPT_TCLR](#), [GPT_TCRR](#), [GPT_TLDR](#), [GPT_TTGR](#), [GPT_TMAR](#), and [GPT_TPIR](#), [GPT_TNIR](#), [GPT_TCVR](#), [GPT_TOCR](#), and [GPT_TOWR](#) for GPTIMER1, GPTIMER2, and GPTIMER10). Therefore, the write transaction is immediately acknowledged on the L4 interface, although the effective write operation occurs later due to a resynchronization in the timer clock domain. The advantage is that neither the interconnect nor the device that requested the write transaction are stalled.

For each register, a status bit is provided in the timer write-posted status register [GPT_TWPS](#). In this mode, it is mandatory that the software checks this status bit prior to any write access. In case a write is attempted to a register with a previous access pending, the previous access is discarded without notice.

The timer module updates the timer counter register value synchronously with the L4 clock. Consequently, any read access to the timer counter register [GPT_TCRR](#) does not add any resynchronization latency; the current value is always available.

NOTE: Since the overflow IRQ is generated, when the TCRR value reaches 0xFFFF FFFF, and not when it changes its value to the value after overflow, one must wait a delay of (1 * PS * timer-functional clock period) before any read access to the timer counter register [GPT_TCRR](#) to ensure a correct reading of its content.

If a write access is pending for a register, reading from this register does not yield a correct result. Software synchronization must be used to avoid incorrect results.

The drawback of this automatic update mechanism is that it assumes a given relationship between the timer interface frequency and the timer clock frequency.

Functional frequency range: $\text{freq}(\text{timer clock}) < \text{freq}(\text{L4 interface clock})/4$.

23.2.4.13.1.2 Write Nonposting Synchronization Mode

This mode is used if the [GPT_TSICR\[2\]](#) POSTED bit is set to 0. It uses a nonposted write scheme to update any internal register. Therefore, the write transaction is not acknowledged on the L4 interface until the effective write operation occurs after the resynchronization in the timer functional clock domain. The drawback is that both the interconnect and the device that requested the write transaction are stalled during this period.

The same full resynchronization scheme is used for a read transaction, and the same stall period applies. A register read following a write to the same register is always coherent.

This mode is functional regardless of the ratio between the L4 interface frequency and the timer clock frequency.

23.2.4.13.2 Reading From Timer Counter Registers

In 16-bit access mode, reading the 16 LSBs from the timer counter registers ([GPT_TCRR](#), [GPT_TCAR1](#), and [GPT_TCAR2](#)) captures the current timer counter value. This must be followed by reading the 16 MSBs.

IVA3 subsystem 16-bit accesses can be interleaved with MPU subsystem 32-bit accesses.

NOTE: LSB/MSB accesses cannot be interleaved (that is, the sequence LSB register 1, LSB register 2, MSB register 1, MSB register 2 is not supported).

23.2.5 GP Timer Low-Level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

23.2.5.1 Global Initialization

23.2.5.1.1 Global Initialization of Surrounding Modules

This section identifies the requirements for initializing the surrounding modules when the GP timer module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the GP timer. For more information, see [Section 23.2.3 GP Timers Integration](#) and [Section 23.2.2, GP Timers Environment](#).

Table 23-12. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|---------------------|--|
| PRCM | The module interface and functional clocks must be enabled. For more information about the module configuration, see Section 3.1.1.1.2, Module Level Clock Management , in Chapter 3, Power, Reset, and Clock Management . |
| Control Module | The module specific pad muxing must be set in the control module. For more information about the module configuration, see Section 19.4.8 PAD Functional Multiplexing and Configuration , in Chapter 19, Control Module . |
| MPU INTC | The MPU INTC configuration must be done to enable the interrupts from the GP timer module. See Section 4.4.3, Interrupt Controller Registers , in Section 4.4.3, Cortex-A9 MPU Subsystem . |
| DSP INTC | The DSP INTC configuration must be done to enable the interrupts from GP timer module. See , INTC , in Chapter 5, DSP Subsystem . |

23.2.5.1.2 GP Timer Module Global Initialization

23.2.5.1.2.1 Main Sequence – GP Timer Module Global Initialization

This section identifies the main steps for initializing the GP timer module when the module is to be used for the first time.

Table 23-13. GP Timer Module Global Initialization

| Step | Register/Bit Field/Programming Model | Value |
|----------------------------------|---|-------|
| Execute software reset. | GPT_TIOCP_CFG[0] SOFTRESET⁽¹⁾ or GPT1MS_TIOCP_CFG[0] SOFTRESET⁽²⁾ | 0x1 |
| Wait until reset release? | GPT_TIOCP_CFG[0] SOFTRESET⁽¹⁾ or GPT1MS_TIOCP_CFG[0] SOFTRESET⁽²⁾ | 0x0 |
| Configure Idle mode. | GPT_TIOCP_CFG[3:2] IDLEMODE⁽¹⁾ or GPT1MS_TIOCP_CFG[4:3] IDLEMODE⁽²⁾ | xx |
| Configure clock activity. | GPT1MS_TIOCP_CFG[9:8] CLOCKACTIVITY⁽²⁾ | xx |
| Configure wake-up feature. | GPT1MS_TIOCP_CFG[2] ENAWAKEUP⁽²⁾ | x |
| Enable wake-up interrupt events. | GPT_IRQWAKEEN[2:0]⁽¹⁾ or GPT_TWER[2:0]⁽²⁾ | x |
| Select posted mode. | GPT_TSICR[2] POSTED | x |

⁽¹⁾ Applies only to GPTIMER3 through GPTIMER9, and GPTIMER11

⁽²⁾ Applies only to GPTIMER1, GPTIMER2, and GPTIMER10

23.2.5.2 Operational Mode Configuration

23.2.5.2.1 GP Timer Mode

23.2.5.2.1.1 Main Sequence – GP Timer Mode Configuration

Table 23-14. GP Timer Mode Configuration

| Step | Register/Bit Field/Programming Model | Value |
|----------------------------|--|-------|
| Select autoreload mode | GPT_TCLR[1] AR | x |
| Set prescale timer value. | GPT_TCLR[4:2] PTV | xxx |
| Enable prescaler. | GPT_TCLR[5] PRE | 0x1 |
| Enable overflow interrupt. | GPT_TIER[1] OVF_IT_ENA⁽¹⁾ or GPT_IRQENABLE_SET[1] OVF_EN_FLAG⁽²⁾ | 0x1 |
| Load timer counter value. | GPT_TCRR | xxx |
| Load timer load value. | GPT_TLDR | xxx |
| Start the timer. | GPT_TCLR[0] ST | 0x1 |

⁽¹⁾ Applies only to GPTIMER1, GPTIMER2, and GPTIMER10.

⁽²⁾ Applies only to GPTIMER3 through GPTIMER 9, and GPTIMER11.

23.2.5.2.2 GP Timer Compare Mode

23.2.5.2.2.1 Main Sequence – GP Timer Compare Mode Configuration

Table 23-15. GP Timer Compare Mode Configuration

| Step | Register/Bit Field/Programming Model | Value |
|---------------------------|--------------------------------------|-------|
| Select autoreload mode. | GPT_TCLR[1] AR | x |
| Set prescale timer value. | GPT_TCLR[4:2] PTV | xxx |
| Enable prescaler. | GPT_TCLR[5] PRE | 0x1 |

Table 23-15. GP Timer Compare Mode Configuration (continued)

| Step | Register/Bit Field/Programming Model | Value |
|---------------------------|--|-------|
| Enable match interrupt. | GPT_TIER[0] MAT_IT_ENA⁽¹⁾ or GPT_IRQENABLE_SET[0] MAT_EN_FLAG⁽²⁾ | 0x1 |
| Load timer counter value. | GPT_TCR | xxx |
| Load timer compare value. | GPT_TMAR | xxx |
| Enable Compare mode. | GPT_TCLR[6] CE | 0x1 |
| Start the timer. | GPT_TCLR[0] ST | 0x1 |

⁽¹⁾ Applies only to GPTIMER1, GPTIMER2, and GPTIMER10.

⁽²⁾ Applies only to GPTIMER3 through GPTIMER9, and GPTIMER11.

23.2.5.2.3 GP Timer Capture Mode

23.2.5.2.3.1 Main Sequence – GP Timer Capture Mode Configuration

Table 23-16. GP Timer Capture Mode Configuration

| Step | Register/Bit Field/Programming Model | Value |
|---------------------------|--|-------|
| Initialize capture mode. | See Section 23.2.5.2.3.2 . | |
| Enable capture interrupt. | GPT_TIER[2] TCAR_IT_ENA⁽¹⁾ or GPT_IRQENABLE_SET[2] TCAR_EN_FLAG⁽²⁾ | 0x1 |
| Start the timer. | GPT_TCLR[0] ST | 0x1 |
| Detect event. | See Section 23.2.5.2.3.3 . | |

⁽¹⁾ Applies only to GPTIMER1, GPTIMER2, and GPTIMER10.

⁽²⁾ Applies only to GPTIMER3 through GPTIMER9, and GPTIMER11.

23.2.5.2.3.2 Subsequence – Initialize Capture Mode

Table 23-17. Initialize Capture Mode

| Step | Register/Bit Field/Programming Model | Value |
|--|--|-------|
| Select autoreload mode. | GPT_TCLR[1] AR | x |
| Set prescale timer value. | GPT_TCLR[4:2] PTV | xxx |
| Enable prescaler. | GPT_TCLR[5] PRE | 0x1 |
| Select GPTx (where x = 8 to 11). Capture input at device pin dmtimerx_pwm_evt. | GPT_TCLR[14] GPO_CFG⁽¹⁾ | 0x1 |
| Select single or second event capture. | GPT_TCLR[13] CAPT_MODE | x |
| Select transition capture mode. | GPT_TCLR[9:8] TCM | xx |

⁽¹⁾ Applies only to GPTIMER8 through GPTIMER11

23.2.5.2.3.3 Subsequence – Detect Event

Table 23-18. Detect Event

| Step | Register/Bit Field/Programming Model | Value |
|----------------------------|---|-------|
| Wait until event detected? | GPT_TISR[2] TCAR_IT_FLAG⁽¹⁾ or GPT_IRQSTATUS[2] TCAR_IT_FLAG⁽²⁾ | = 0x1 |
| Read Timer capture value. | GPT_TCAR1 and/or GPT_TCAR2 | |

⁽¹⁾ Applies only to GPTIMER1, GPTIMER2, and GPTIMER10.

⁽²⁾ Applies only to GPTIMER3 through GPTIMER9, and GPTIMER11.

Table 23-18. Detect Event (continued)

| Step | Register/Bit Field/Programming Model | Value |
|----------------------------------|--|-------|
| Clear capture interrupt request. | GPT_TISR [2] TCAR_IT_FLAG ⁽¹⁾ or GPT_IRQSTATUS [2] TCAR_IT_FLAG ⁽²⁾ | 0x1 |

23.2.5.2.4 GP Timer PWM Mode

23.2.5.2.4.1 Main Sequence – GP Timer PWM Mode Configuration

Table 23-19. GP Timer PWM Mode Configuration

| Step | Register/Bit Field/Programming Model | Value |
|--|--|-------|
| Select autoreload mode. | GPT_TCLR [1] AR | x |
| Set prescale timer value. | GPT_TCLR [4:2] PTV | xxx |
| Enable prescaler. | GPT_TCLR [5] PRE | 0x1 |
| Select trigger output mode. | GPT_TCLR [11:10] TRG | xx |
| Select pulse or toggle modulation PWM mode. | GPT_TCLR [12] PT | x |
| Select GPTx (where x = 8 to 11) pwm output at device pin dmtimerx_pwm_evt. | GPT_TCLR [14] GPO_CFG ⁽¹⁾ | 0x0 |
| Configure PWM output pin default value. | GPT_TCLR [7] SCPWM | x |
| Load timer load value. | GPT_TLDR | xxx |
| Load timer compare value. | GPT_TMAR | xxx |
| Enable compare. | GPT_TCLR [6] CE | 0x1 |
| Start the timer. | GPT_TCLR [0] ST | 0x1 |

⁽¹⁾ Applies only to GPTIMER8 through GPTIMER11

23.2.6 GP Timer Register Manual

23.2.6.1 GP Timer Instance Summary

Table 23-20 lists the base address and block size for the GP timer module instances.

Table 23-20. GP Timer Instance Summary

| Module Name | Base Address L4 Interconnect | Base Address L3 Interconnect | Base Address Cortex-A9 Private Access | Base Address DSP Private Access | Size |
|-------------|---------------------------------|---------------------------------|---|---------------------------------------|------|
| GPTIMER2 | 0x4803 2000 | - | - | - | 4 KB |
| GPTIMER3 | 0x4803 4000 | - | - | - | 4 KB |
| GPTIMER4 | 0x4803 6000 | - | - | - | 4 KB |

| GPTIMER7 | - | 0x4903 C000 | 0x4013 C000 | 0x01D3 C000 | 4 KB |
| GPTIMER8 | - | 0x4903 E000 | 0x4013 E000 | 0x01D3 E000 | 4 KB |
| GPTIMER1 | 0x4A31 8000 | - | - | - | 4 KB |

NOTE: Private Access is an access which is not using the L3/L4 interconnects.

23.2.6.2 GP Timer Registers

23.2.6.2.1 GP Timer Register Summary

CAUTION

The GP timer registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 23-21 through Table 23-27 provide the register summary and associated offset addresses for the 11 GP timer internal registers.

Table 23-21. GPTIMER1, GPTIMER2, and GPTIMER10 Register Mapping Summary

| Register Name | Type | Register Width (Bits) | Address Offset | GPTIMER1 Physical Address L4 Interconnect | GPTIMER2 Physical Address L4 Interconnect | GPTIMER10 Physical Address L4 Interconnect |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|------------|
| 31:4 | RESERVED | Reserved | R | 0x00000000 |
| 3:2 | IDLEMODE | Power management, req/ack control 0x0: Force-idle mode: local target idle state follows (acknowledges) the system idle requests unconditionally, that is, regardless of the IP module internal requirements. Back-up mode, for debug only. 0x1: No-idle mode: local target never enters idle state. Back-up mode, for debug only. 0x2: Smart-idle mode: local target idle state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module should not generate (IRQ- or DMA-request-related) wake-up events. 0x3: Smart-idle wake-up-capable mode: local target idle state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module may generate (IRQ- or DMA-request-related) wake-up events when in idle state. Mode is only relevant if the appropriate IP module <i>wake-up</i> output(s) is (are) implemented. | RW | 0x0 |
| 1 | EMUFREE | Emulation mode 0x0: The timer is frozen in emulation mode (PINSUSPENDN signal active). 0x1: The timer runs free, regardless of PINSUSPENDN value. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-------|
| 0 | SOFTRESET | Software reset 0x0: Read 0: reset done, no pending action Write 0: No action 0x1: Read 1: initiate software reset Write 1: Reset ongoing | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|---------|
| 31:15 | RESERVED | Reserved | R | 0x00000 |
| 14 | GPO_CFG | General-purpose output - this register directly drives the GPTi_PORGPOCFG output pin. For specific use of the GPO_CFG bit, see Section 23.2.2.1 , <i>GP Timer External System Interface</i> . 0x0: GPTi_PORGPOCFG drives 0. 0x1: GPTi_PORGPOCFG drives 1. | RW | 0 |
| 13 | CAPT_MODE | Capture mode select bit (first/second) 0x0: Single capture: Capture the first enabled capture event in TCAR1. 0x1: Capture on second event: Capture the second enabled capture event in TCAR2. | RW | 0 |
| 12 | PT | Pulse or toggle mode on GPTi_PWM_out output pin 0x0: Pulse modulation 0x1: Toggle modulation | RW | 0 |
| 11:10 | TRG | Trigger output mode on GPTi_PWM_out output pin 0x0: No trigger 0x1: Trigger on overflow. 0x2: Trigger on overflow and match. 0x3: Reserved | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-------|
| 9:8 | TCM | Transition capture mode on GPTi_EVENT_CAPTURE input pin (When the TCM field passed from (00) to any other combination, the TCAR_IT_FLAG and the edge detection logic are cleared.) 0x0: No capture 0x1: Capture on rising edges of GPTi_EVENT_CAPTURE pin 0x2: Capture on falling edges of GPTi_EVENT_CAPTURE pin 0x3: Capture on both edges of GPTi_EVENT_CAPTURE pin | RW | 0x0 |
| 7 | SCPWM | Pulse width modulation output pin default setting This bit must be set or clear while the timer is stopped or the trigger is off. 0x0: Clear the GPTi_PWM_out output pin and select positive pulse for pulse mode. 0x1: Set the GPTi_PWM_out output pin and select negative pulse for pulse mode. | RW | 0 |
| 6 | CE | Compare enable 0x0: Compare mode is disable. 0x1: Compare mode is enable. | RW | 0 |
| 5 | PRE | Prescaler enable 0x0: The TIMER clock input pin clocks the counter. 0x1: The divided input pin clocks the counter. | RW | 0 |
| 4:2 | PTV | Prescale clock timer value The timer counter is prescaled with the value $2^{(PTV+1)}$. Example: PTV = 3, counter increases value (if started) after 16 functional clock periods. | RW | 0x0 |
| 1 | AR | Autoreload mode 0x0: One shot timer 0x1: Autoreload timer | RW | 0 |
| 0 | ST | Start/stop timer control 0x0: Stop timer: Only the counter is frozen. If one-shot mode selected (AR = 0), this bit is automatically reset by internal logic when the counter is overflowed. 0x1: Start timer | RW | 0 |

PRELIMINARY

23.3 Watchdog Timers

23.3.1 Watchdog Timers Overview

The device includes two instances of the 32-bit watchdog timer: WDT2 and WDT3. Figure 23-15 shows how each timer is connected in the device.

NOTE: WDTi (where i is the watchdog timer instance: i = 2 or 3) stands for the following:

- WDT2: Watchdog timer 2, also called MPU watchdog timer
- WDT3: Watchdog timer 3, also called IVA3 watchdog timer

Each watchdog timer is an upward counter capable of generating a pulse on the reset pin and an interrupt to the device system modules following an overflow condition. The MPU watchdog timer serves resets to the PRCM module (its interrupt outputs are unused), and the IVA3 watchdog timer serves watchdog interrupts to the MPU (its reset outputs are unused).

The watchdog timers can be accessed, loaded, and cleared by registers through the L4 interface. The MPU and IVA3 watchdog timers have the 32-kHz clock for their timer clock input.

The MPU watchdog timer directly generates a warm reset condition on overflow. The IVA3 watchdog timer generates an MPU interrupt condition on overflow, which can be used by the application software through the PRCM module to indirectly trigger a reset condition (that is, to the IVA3 subsystem).

The MPU watchdog timer connects to a single target agent port on the L4 interconnect.

Figure 23-15. Watchdog Timers Block Diagram

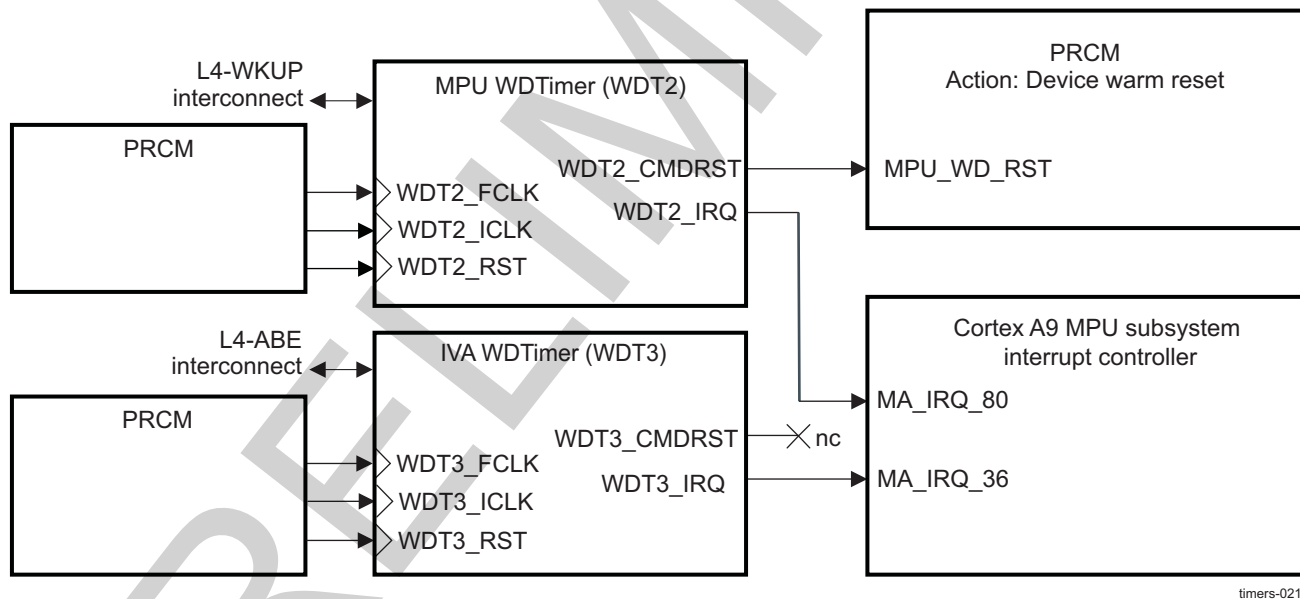

Table 23-80 lists the default state of the watchdog timers in the device.

Table 23-80. Watchdog Timers Default State

| Timer | Default State | | |
|-----------|---------------|-------------|--|
| MPU WDT2 | Enabled | Not running | |
| IVA3 WDT3 | Enabled | Not running | |

NOTE: The default state of the watchdog timers described in [Table 23-80](#) is considered to be their state immediately after ROM code execution. For more information, see [Chapter 28, Initialization](#).

23.3.1.1 Watchdog Timers Features

The main features of the watchdog timer controllers are:

- L4 slave interface support:
 - 32-bit data bus width
 - 32-/16-bit access supported
 - 8-bit access not supported
 - 11-bit address bus width
 - Burst mode not supported
 - Only posted write/read internal resynchronization mode supported
- Free-running 32-bit upward counter
- Programmable divider clock source (2^n where $n = [0:7]$)
- On-the-fly read/write register (while counting)
- Subset programming model of the GP timer
- The watchdog timers are reset either on power-on or after a warm reset before they start counting.
- Reset or interrupt actions when a timer overflow condition occurs
- The watchdog timer generates a reset or an interrupt in its hardware integration (WDT2 or WDT3).

23.3.2 Watchdog Timer Environment

The watchdog timers are accessible through the L4 interface.

23.3.3 Watchdog Timer Integration

Figure 23-16 shows the integration of the watchdog timers in the device.

Figure 23-16. Watchdog Timers Integration

Table 23-81 through Table 23-83 summarize the integration of the module in the device.

Table 23-81. Integration Attributes

| Module Instance | Attributes | | |
|-----------------|--------------|--------------------|--------------|
| | Power Domain | Wake-Up Capability | Interconnect |
| WDT2 | PD_WKUP | Yes | L4_WKUP |
| WDT3 | PD_AUDIO | Yes | L4_ABE |

Table 23-82. Clocks and Resets

| Clocks | | | | |
|-----------------|-------------------------|--------------------|--------|-----------------------|
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| WDT2 | WDT2_FCLK | WKUP_32K_FCLK | PRCM | WDT2 functional clock |
| WDT2 | WDT2_ICLK | WKUP_L4_ICLK2 | PRCM | WDT2 interface clock |
| WDT3 | WDT3_FCLK | ABE_ALWON_32K_CLK | PRCM | WDT3 functional clock |
| WDT3 | WDT3_ICLK | ABE_ICLK2 | PRCM | WDT3 interface clock |
| Resets | | | | |
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| WDT2 | WDT2_RST | WKUP_RST | PRM | Reset to WDT2 |
| WDT2 | MPU_WDT_RST | WDT2_CMDRST | WDT2 | Reset to PRCM |
| WDT3 | WDT3_RST | AUDIO_RST | PRM | Reset to WDT3 |

NOTE: WDT2 is reset on power on or after a warm reset before it starts counting.

WDT3 is reset on power on or after a warm reset, and then it does not start counting.

Table 23-83. Hardware Requests

| Interrupt Requests | | | | |
|--------------------|--------------------|-------------------------|---------------|---------------------------------|
| Module Instance | Source Signal Name | Destination Signal Name | Destination | Description |
| WDT2 | WDT2_IRQ | MA_IRQ_80 | Cortex-A9 MPU | WDT2 interrupt to Cortex-A9 MPU |
| WDT3 | WDT3_IRQ | MA_IRQ_36 | Cortex-A9 MPU | IVA3 watchdog overflow |
| No DMA Requests | | | | |

NOTE:

- See [Section 23.3.4.2, Interrupts](#), for interrupt source description.

23.3.4 Watchdog Timers Functional Description

23.3.4.1 Power Management

There are two clock domains in the watchdog timers:

- Functional clock domain: WDTi_FCLK is the watchdog timer functional clock. It is used to clock the watchdog timer internal logic.
- Interface clock domain: WDTi_ICLK is the watchdog timer interface clock. It is used to synchronize the watchdog timer L4 port to the L4 interconnect. All accesses from the interconnect are synchronous to WDTi_ICLK.

Table 23-82 lists the source clocks for each watchdog timer in the device. For more information about clock control and domains, see Section 3.1.1.1, *Clock Management* in Chapter 3, *Power, Reset, and Clock Management*.

From a global system power-management perspective, when one or both of the watchdog timer clocks is no longer required, the watchdog timers can be deactivated at the PRCM module level in the corresponding registers.

At the PRCM module level, when the conditions to shut off the PRCM module functional or interface output clocks are met (for more information, see the , *Clock Domain Level Clock Management*), the PRCM module automatically launches a hardware handshake protocol to ensure the watchdog timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the watchdog timer.

Although this handshake is a hardware function and out of software control, the way the watchdog timer acknowledges the PRCM IDLE request is configurable through the WDT_WDSC[4:3] IDLEMODE bit field. Table 23-84 lists the settings and related acknowledgment modes of the IDLEMODE bit field.

Table 23-84. IDLEMODE Settings

| IDLEMODE Value | Selected Mode | Description |
|----------------|--------------------------------|--|
| 00 | Force-idle | The watchdog timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent loss of data when the clock is switched off. |
| 01 | No-idle | The watchdog timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, however, because it does not allow the PRCM module output clock to be shut off and thus the power domain to be set to a lower power state. |
| 10 | Smart-idle | The watchdog timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach for efficient system power management. |
| 11 | Smart-idle wakeup-capable mode | The watchdog timer acknowledges the IDLE request, basing its decision on its internal activity. The timer generates (IRQ-request-related) wake-up events when in IDLE state if the WDT_WIRQWAKEEN[1:0] bits are set to 1. |

23.3.4.1.1 Wake-Up Capability

If the WDT_WDSC[4:3] IDLEMODE bit field sets smart-idle wakeup-capable mode ($= 0 \times 3$), the timer evaluates its internal capability to have the interface clock switched off. When there is no more internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters into sleep mode, ready to issue a wake-up request. This wake-up request is sent only if the WDT_WIRQWAKEEN[0] OVF_WK_ENA and/or the WDT_WIRQWAKEEN[1] DLY_WK_ENA bits enable the overflow and/or the delay wake-up capability.

23.3.4.2 Interrupts

Table 23-85 list the event flags, and their masks, that cause module interrupts.

Table 23-85. Watchdog Timer Events

| Event Flag | Event Mask | Mapping | Comments |
|---------------------------|---|----------|------------------------------|
| WDT_WIRQSTAT[0] EVENT_OVF | WDT_WIRQENSET/WDT_WIRQENCLR[0] OVF_IT_ENA | WDTi_IRQ | Watchdog timer overflow |
| WDT_WIRQSTAT[1] EVENT_DLY | WDT_WIRQENSET/WDT_WIRQENCLR[1] DLY_IT_ENA | WDTi_IRQ | Watchdog delay value reached |

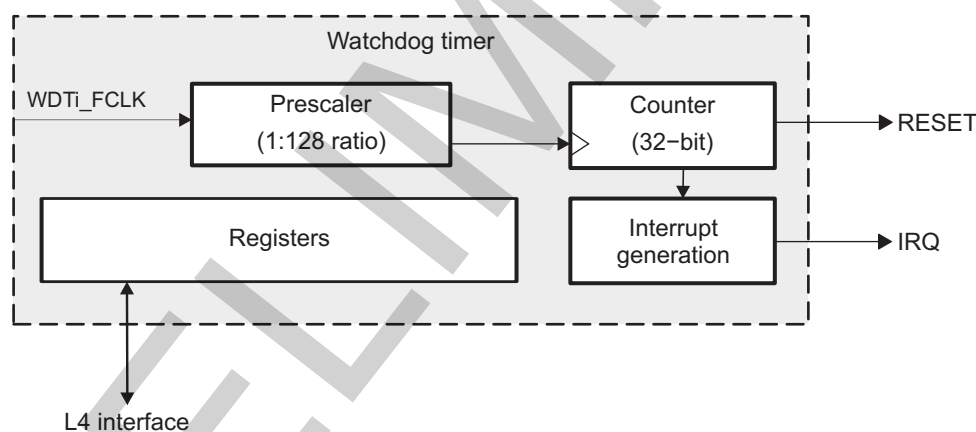

23.3.4.3 General Watchdog Timer Operation

The watchdog timers are based on an upward 32-bit counter coupled with a prescaler. The counter overflow is signaled through two independent signals: a simple reset signal and an interrupt signal, both active low. The use of these signals depends on whether they are connected or not. For this information, see [Figure 23-15](#). The interrupt generation mechanism is controlled through the [WDT_WIRQENSET/WDT_WIRQENCLR](#) and [WDT_WIRQSTAT](#) registers.

The prescaler ratio can be set from 1 to 128 by accessing the [WDT_WCLR\[4:2\]](#) PTV bit field and the [WDT_WCLR\[5\]](#) PRE bit of the watchdog control register ([WDT_WCLR](#)).

The current timer value can be accessed on-the-fly by reading the watchdog timer counter register ([WDT_WCRR](#)), modified by accessing the watchdog timer load register ([WDT_WLDR](#)) (no on-the-fly update), or reloaded by following a specific reload sequence on the watchdog timer trigger register ([WDT_WTGR](#)). A start/stop sequence applied to the watchdog timer start/stop register ([WDT_WSPR](#)) can start and stop the watchdog timers.

[Figure 23-17](#) is a functional block diagram of the watchdog timer.

Figure 23-17. 32-Bit Watchdog Timer Functional Block Diagram

timers-016

23.3.4.4 Reset Context

The watchdog timers are enabled after reset. [Table 23-86](#) lists the default reset values of the two watchdog timer load registers (the [WDT_WLDR](#)) and prescaler ratios (the [WDT_WCLR\[4:2\]](#) PTV bit field). To get these values, software must read the corresponding [WDT_WCLR\[4:2\]](#) PTV bit field and the 32-bit register to retrieve the static configuration of the module.

Table 23-86. Count and Prescaler Default Reset Values

| Timer | WDT_WLDR Reset Value | PTV Reset Value |
|-----------------|----------------------|-----------------|
| MPU WDT (WDT2) | 0xFFFB 0000 | 0 |
| IVA3 WDT (WDT3) | 0xFFFB 0000 | 0 |

23.3.4.5 Overflow/Reset Generation

When the watchdog timer counter register ([WDT_WCRR](#)) overflows, an active-low reset pulse is generated to the PRCM module. This pulse is one prescaled timer clock cycle wide and occurs at the same time as the timer counter overflow.

After reset generation, the counter is automatically reloaded with the value stored in the watchdog load register ([WDT_WLDR](#)) and the prescaler is reset (the prescaler ratio remains unchanged). When the reset pulse output is generated, the timer counter begins incrementing again.

Figure 23-18 shows a general functional view of the watchdog timers.

23.3.4.6 Prescaler Value/Timer Reset Frequency

Each watchdog timer is composed of a prescaler stage and a timer counter.

The timer rate is defined by the following values:

- Value of the prescaler fields (the [WDT_WCLR\[5\]](#) PRE bit and the [WDT_WCLR\[4:2\]](#) PTV bit field)
- Value loaded into the timer load register ([WDT_WLDR](#))

The prescaler stage is clocked with the timer clock and acts as a clock divider for the timer counter stage. The ratio is managed by accessing the ratio definition field (the [WDT_WCLR\[4:2\]](#) PTV bit field) and is enabled with the [WDT_WCLR\[5\]](#) PRE bit.

Table 23-87 lists the prescaler clock ratio values.

Table 23-87. Prescaler Clock Ratio Values

| WDT_WCLR[5] PRE | WDT_WCLR[4:2] PTV | Clock Divider (PS) |
|---------------------------------|-----------------------------------|--------------------|
| 0 | X | 1 |
| 1 | 0 | 1 |
| 1 | 1 | 2 |
| 1 | 2 | 4 |
| 1 | 3 | 8 |
| 1 | 4 | 16 |
| 1 | 5 | 32 |
| 1 | 6 | 64 |
| 1 | 7 | 128 |

Thus the watchdog timer overflow rate is expressed as:

$$\text{OVF_Rate} = (0\text{x}\text{FFFF FFFF} - \text{WDT_WLDR} + 1) \times (\text{wd-functional clock period}) \times \text{PS}$$

where wd-functional clock period = $1/(\text{wd-functional clock frequency})$ and $\text{PS} = 2^{(\text{PTV})}$

CAUTION

Internal resynchronization causes some latency in any software write to **WDT_WSPR** before **WDT_WSPR** is updated with the programmed value:

$$1.5 \times \text{functional clock cycles} \leq \text{write_WDT_WSPR_latency} \leq 2.5 \times \text{functional clock cycles}$$

Remember to consider this latency whenever the watchdog timer must be started or stopped.

For example, for a timer clock input of 32 kHz with a prescaler ratio value of 0x1 (clock divided by 2) and **WDT_WCLR**[5] PRE = 1 (clock divider enabled), the reset period is as listed in [Table 23-88](#).

Table 23-88. Reset Period Examples

| WDT_WLDR Value | Reset Period |
|-----------------------|---------------------|
| 0x0000 0000 | 74 h 56 min |
| 0xFFFF 0000 | 4 s |
| 0xFFFF FFF0 | 1 ms |
| 0xFFFF FFFF | 62.5 us |

CAUTION

- Ensure that the reloaded value allows the correct operation of the application. When a watchdog timer is enabled, software must periodically trigger a reload before the counter overflows. Hence, the value of the **WDT_WLDR**[31:0] bit field must be chosen according to the ongoing activity preceding the watchdog reload.
- Due to design reasons, **WDT_WLDR**[31:0] = 0xFFFF FFFF is a special case, although such a value of **WDT_WLDR** is meaningless. When **WDT_WLDR** is programmed with the overflow value, a triggering event generates a reset/interrupt one functional clock cycle later, even if the watchdog timer is stopped.

[Table 23-89](#) lists the default reset periods for the watchdog timers.

Table 23-89. Default Watchdog Timer Reset Periods

| Watchdog Timers | Clock Source | Default Reset Period |
|------------------------|---------------------|-----------------------------|
| MPU/IVA3 WDTs | 32 kHz | 10 s |

23.3.4.7 Triggering a Timer Reload

To reload the timer counter and reset the prescaler before reaching overflow, a reload command is executed by accessing the watchdog timer trigger register (**WDT_WTGR**) using a specific reload sequence.

The specific reload sequence is performed whenever the written value on the **WDT_WTGR** register differs from its previous value. In this case, reload is executed in the same way as an overflow autoreload, but without the generation of a reset pulse.

The timer counter is loaded with the value of the watchdog timer load register (the [WDT_WLDR](#)[31:0] [TIMER_LOAD](#) bit field), and the prescaler is reset.

23.3.4.8 Start/Stop Sequence for Watchdog Timers (Using the WDT_WSPR Register)

To start and stop a watchdog timer, access must be made through the start/stop register ([WDT_WSPR](#)) using a specific sequence.

To disable the timer, follow this sequence:

1. Write 0xFFFF AAAA in [WDT_WSPR](#).
2. Write 0xFFFF 5555 in [WDT_WSPR](#).

To enable the timer, follow this sequence:

1. Write 0xFFFF BBBB in [WDT_WSPR](#).
2. Write 0xFFFF 4444 in [WDT_WSPR](#).

All other write sequences on the [WDT_WSPR](#) register have no effect on the start/stop feature of the module.

23.3.4.9 Modifying Timer Count/Load Values and Prescaler Setting

To modify the timer counter value (the [WDT_WCRR](#) register), prescaler ratio (the [WDT_WCLR](#)[4:2] [PTV](#) bit field), delay configuration value (the [WDT_WDLY](#)[31:0] [DLY_VALUE](#) bit field), or the load value (the [WDT_WLDR](#)[31:0] [TIMER_LOAD](#) bit field), the watchdog timer must be disabled by using the start/stop sequence (the [WDT_WSPR](#) register).

After a write access, the load register value and prescaler ratio registers are updated immediately, but new values are considered only after the next consecutive counter overflow or after a new trigger command (the [WDT_WTGR](#) register).

23.3.4.10 Watchdog Counter Register Access Restriction (WDT_WCRR Register)

A 32-bit shadow register is implemented to read a coherent value of the [WDT_WCRR](#) register because the [WDT_WCRR](#) register is directly related to the timer counter value and is updated on the timer clock ([WDT_FCLK](#)). The shadow register is updated by a 16-bit LSB read command.

NOTE: Although the L4 clock ([WDT_ICLK](#)) is completely asynchronous with the timer clock ([WDT_FCLK](#)), some synchronization is performed to ensure that the value of the [WDT_WCRR](#) register is not read while it is being incremented.

When 32-bit read access is performed, the shadow register is not updated. Read access is performed directly from the accessed register.

To ensure that a coherent value is read inside [WDT_WCRR](#), the first read access is to the lower 16 bits (offset = 0x08), followed by read access to the upper 16 bits (offset = 0x0A).

23.3.4.11 Watchdog Timer Interrupt Generation

When an interrupt source occurs, the interrupt status bit (the [WDT_WIRQSTAT](#)[0] [EVENT_OVF](#) or [WDT_WIRQSTAT](#)[1] [EVENT_DLY](#) bit) is set to 1. The output interrupt line ([WDTi_IRQ](#)) is asserted (active low) when status (the [EVENT_xxx](#) bit) and enable (the [xxx_IT_ENA](#) bit) flags are set to 1; the order is not relevant. Writing 1 to the enable bit (the status is already set at 1) also triggers the interrupt in the normal order (enable first, status next). The pending interrupt event is cleared when the set status bit is overwritten by a value of 1 by a write command in the [WDT_WIRQSTAT](#) register. Reading the [WDT_WIRQSTAT](#) register and writing the value back allows a fast interrupt acknowledge process.

The watchdog timer issues an overflow interrupt if this interrupt is enabled in the watchdog interrupt enable register ([WDT_WIRQENSET](#)[0] [OVF_IT_ENA](#) = 1). When the overflow occurs, the interrupt status bit (the [WDT_WIRQSTAT](#)[0] [EVENT_OVF](#) bit) is set to 1. The output interrupt line ([WDT_IRQ](#)) is asserted (active low) when status ([EVENT_OVF](#)) and enable ([OVF_IT_ENA](#)) flags are set to 1; the order is not relevant. This interrupt can be disabled by setting the [WDT_WIRQENCLR](#)[0] [OVF_IT_ENA](#) bit to 1.

The watchdog can issue the delay interrupt if this interrupt is enabled in the interrupt enable register ([WDT_WIRQENSET](#)[1] DLY_IT_ENA = 1). When the counter is running and the counter value matches the value stored in the delay configuration register ([WDT_WDLY](#)), the corresponding interrupt status bit is set in the watchdog status register ([WDT_WIRQSTAT](#)) and the output interrupt line is asserted (active low) when the flag (EVENT_DLY) and enable (DLY_IT_ENA) bits are 1 in the [WDT_WIRQSTAT](#) and [WDT_WIRQENSET](#) registers, respectively; the order (normally enable, then flag), is not relevant. This interrupt can be disabled by setting the [WDT_WIRQENCLR](#)[1] DLY_IT_ENA bit to 1.

NOTE: Writing 0 to the [WDT_WIRQSTAT](#)[0] EVENT_OVF bit or the [WDT_WIRQSTAT](#)[1] EVENT_DLY bit has no effect.

The two clock domains are resynchronized because the interrupt event is generated on the functional clock domain (WDTi_FCLK) during the updating of the interrupt status register ([WDT_WIRQSTAT](#)).

The [WDT_WDLY](#) register is used to specify the value of the delay configuration register. The delay time to interrupt is the difference between the reload value stored in the counter load register ([WDT_WLDR](#)) and the programmed value in this register ([WDT_WDLY](#)).

Use the following formula to estimate the delay time:

Delay time period = ([WDT_WDLY](#) – [WDT_WLDR](#) + 1) × Timer clock period × Clock divider

Where:

- Timer clock period = 1/(Timer clock frequency)
- Clock divider = 2PTV

If the counter value ([WDT_WCRR](#)) reaches the programmed value ([WDT_WDLY](#)), the status bit (EVENT_DLY) gets set in the interrupt status register ([WDT_WIRQSTAT](#)), and an interrupt occurs if the corresponding enable bit is set in the interrupt enable register ([WDT_WIRQENSET](#)).

CAUTION

If the reload event occurs (after a triggering sequence or after a reset sequence) before reaching the programmed value ([WDT_WDLY](#)[31:0] WDLY_VALUE), no interrupt is generated.

Also, no interrupt is generated if the value programmed in the delay configuration register ([WDT_WDLY](#)) is less than the value stored in the counter load register ([WDT_WLDR](#)).

23.3.4.12 Watchdog Timers Under Emulation

During emulation mode, the watchdog timer can/cannot continue running, according to the value of the [WDT_WDSC](#)[5] EMUFREE bit of the system configuration register ([WDT_WDSC](#)).

- When EMUFREE is 1, watchdog timer execution is not stopped and a reset pulse is still generated when overflow is reached.
- When EMUFREE is 0, the counters (prescaler/timer) are frozen and incrementation restarts after exiting from emulation mode.

23.3.4.13 Accessing Watchdog Timer Registers

Posted/nonposted selection applies only to functional registers that require synchronization on/from the timer functional clock domain (WDTi_FCLK). For write/read operation, the following registers are affected:

- [WDT_WCLR](#)
- [WDT_WCRR](#)
- [WDT_WLDR](#)
- [WDT_WTGR](#)
- [WDT_WDLY](#)

- [WDT_WSPR](#)

NOTE: To ensure completion of successive writes in a WDT2 or WDT3 functional clock domain register, user software must poll the appropriate WDT_WWPS status bit.

NOTE: To ensure coherent reading when a read transaction immediately follows a write access to a WDT2 or WDT3 functional clock domain register, user software must check the appropriate WDT_WWPS status bit.

The timer interface clock domain synchronous registers are not affected by the posted mode mechanism; the write/read operation is effective and acknowledged (command accepted) after one WDT_ICLK cycle from the command assertion. The timer interface clock domain synchronous registers are:

- [WDT_WIDR](#)
- [WDT_WDSC](#)
- [WDT_WDST](#)
- [WDT_WIRQSTATRAW](#)
- [WDT_WIRQSTAT](#)
- [WDT_WIRQENSET](#)
- [WDT_WIRQENCLR](#)
- [WDT_WIRQWAKEEN](#)
- [WDT_WWPS](#)

NOTE: Accesses to WDT2 and WDT3 functional clock domain synchronous registers are posted.

23.3.5 Watchdog Timer Low-Level Programming Model

This section covers the low-level hardware programming sequences for configuration and use of the module.

23.3.5.1 Global Initialization

23.3.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the watchdog timer is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the watchdog timer (see [Table 23-90](#)). For more information, see [Section 23.3.2](#), *Watchdog Timer Environment*, and [Section 23.3.3](#), *Watchdog Timer Integration*.

Table 23-90. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|---------------------|---|
| PRCM | The module interface and functional clocks must be enabled. for more information about the module configuration. For more information about the module configuration, see Section 3.1.1.1.2 , <i>Module Level Clock Management</i> , in Chapter 3 , <i>Power, Reset, and Clock Management</i> . |
| Control module | Module-specific pad muxing must be set in the control module. For more information about the module configuration, see Section 19.4.8 , <i>PAD Functional Multiplexing and Configuration</i> in Chapter 19 , <i>Control Module</i> . |
| MPU INTC | The MPU INTC configuration must be performed to enable the interrupts from the watchdog timer. See Section 4.4.3 , <i>Interrupt Controller Registers</i> in Chapter 4 , <i>Cortex-A9 MPU Subsystem</i> . |

PRELIMINARY

23.3.5.1.2 Watchdog Timer Module Global Initialization

23.3.5.1.2.1 Main Sequence – Watchdog Timer Module Global Initialization

Table 23-91 lists the steps for initializing the watchdog timer module when the module is to be used for the first time.

Table 23-91. Watchdog Timer Module Global Initialization

| Step | Register/Bit Field/Programming Model | Value |
|----------------------------|--------------------------------------|-------|
| Execute software reset. | WDT_WDSC[1] SOFTRESET | 0x1 |
| Wait until reset release? | WDT_WDSC[1] SOFTRESET | 0x0 |
| Configure idle mode. | WDT_WDSC[4:3] IDLEMODE | xx |
| Enable delay wakeup. | WDT_WIRQWAKEEN[1] DLY_WK_ENA | 0x1 |
| Enable overflow wakeup. | WDT_WIRQWAKEEN[0] OVF_WK_ENA | 0x1 |
| Enable delay interrupt. | WDT_WIRQENSET[1] ENABLE_DLY | 0x1 |
| Enable overflow interrupt. | WDT_WIRQENSET[0] ENABLE_OVF | 0x1 |

23.3.5.2 Operational Mode Configuration

23.3.5.2.1 Watchdog Timer Basic Configuration

23.3.5.2.1.1 Main Sequence – Watchdog Timer Basic Configuration

Table 23-92 lists the steps for the basic configuration of the watchdog timer.

Table 23-92. Watchdog Timer Basic Configuration

| Step | Register/Bit Field/Programming Model | Value |
|---------------------------------|--------------------------------------|-------|
| Disable the watchdog timer. | See Section 23.3.5.2.1.2. | |
| Set prescaler value. | WDT_WCLR[4:2] PTV | xxx |
| Enable prescaler. | WDT_WCLR[5] PRE | 0x1 |
| Load delay configuration value. | WDT_WDLY | xxx |
| Load timer counter value. | WDT_WCRR | xxx |
| Enable the watchdog timer. | See Section 23.3.5.2.1.3. | |

23.3.5.2.1.2 Subsequence – Disable the Watchdog Timer

Table 23-93 lists the steps to disable the watchdog timer.

Table 23-93. Disable the Watchdog Timer

| Step | Register/Bit Field/Programming Model | Value |
|-------------------------------|--------------------------------------|-------------|
| Write disable sequence Data1. | WDT_WSPR | 0xFFFF AAAA |
| Write disable sequence Data2. | WDT_WSPR | 0xFFFF 5555 |

23.3.5.2.1.3 Subsequence – Enable the Watchdog Timer

Table 23-94 lists the steps to enable the watchdog timer.

Table 23-94. Enable the Watchdog Timer

| Step | Register/Bit Field/Programming Model | Value |
|------------------------------|--------------------------------------|-------------|
| Write enable sequence Data1. | WDT_WSPR | 0xFFFF BBBB |
| Write enable sequence Data2. | WDT_WSPR | 0xFFFF 4444 |

23.3.6 Watchdog Timer Register Manual

23.3.6.1 Watchdog Timer Instance Summary

Table 23-95 lists the base address and address space for the watchdog timer module instances.

Table 23-95. Watchdog Timer Instance Summary

| Module Name | Base Address L4 Interconnect | Base Address L3 Interconnect | Base Address Cortex-A9 Private Access | Base Address DSP Private Access | Size |
|-------------|---------------------------------|---------------------------------|---|---------------------------------------|------|
| WDTIMER2 | 0x4A31 4000 | - | - | - | 4KB |
| WDTIMER3 | - | 0x4903 0000 | 0x4013 0000 | 0x01D3 0000 | 4KB |

NOTE: Private access is an access which is not using the L3/L4 interconnects.

23.3.6.2 Watchdog Timer Registers

23.3.6.2.1 Watchdog Timer Register Summary

CAUTION

The watchdog timers registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt register content.

Table 23-96 lists the WDTIMER2 registers.

Table 23-96. WDTIMER2 Register Mapping Summary

| Register Name | Type | Register Width (Bits) | Address Offset | Physical Address L4 Interconnect |
|-----------------|------|--------------------------|----------------|-------------------------------------|

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-----------|
| 31:6 | RESERVED | Write os for future compatibility. Reads return 0. | R | 0x0000000 |
| 5 | EMUFREE | Emulation mode | RW | 0 |
| | | 0x0: Timer counter frozen in emulation | | |
| | | 0x1: Timer counter free-running in emulation | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 4:3 | IDLEMODE | Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state. 0x0: Force-idle mode: local target IDLE state follows (acknowledges) the system idle requests unconditionally, that is, regardless of the IP module internal requirements. Backup mode, for debug only. 0x1: No-idle mode: local target never enters IDLE state. Backup mode, for debug only. 0x2: Smart-idle mode: local target IDLE state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module should not generate (IRQ- or DMA-request-related) wake-up events. 0x3: Smart-idle wake-up-capable mode: local target IDLE state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module may generate (IRQ- or DMA-request-related) wake-up events when in IDLE state. Mode is relevant only if the appropriate IP module <i>swake-up</i> output(s) is (are) implemented. | RW | 0x2 |
| 2 | RESERVED | Write 0s for future compatibility. Reads return 0. | R | 0 |
| 1 | SOFTRESET | Software reset. (Optional) Read 0x0: Reset done, no pending action Write 0x0: No action Write 0x1: Initiate software reset. Read 0x1: Reset (software or other) ongoing | RW | 0 |
| 0 | RESERVED | Write 0s for future compatibility. Reads return 0. | R | 0 |

23.4 32-kHz Synchronized Timer

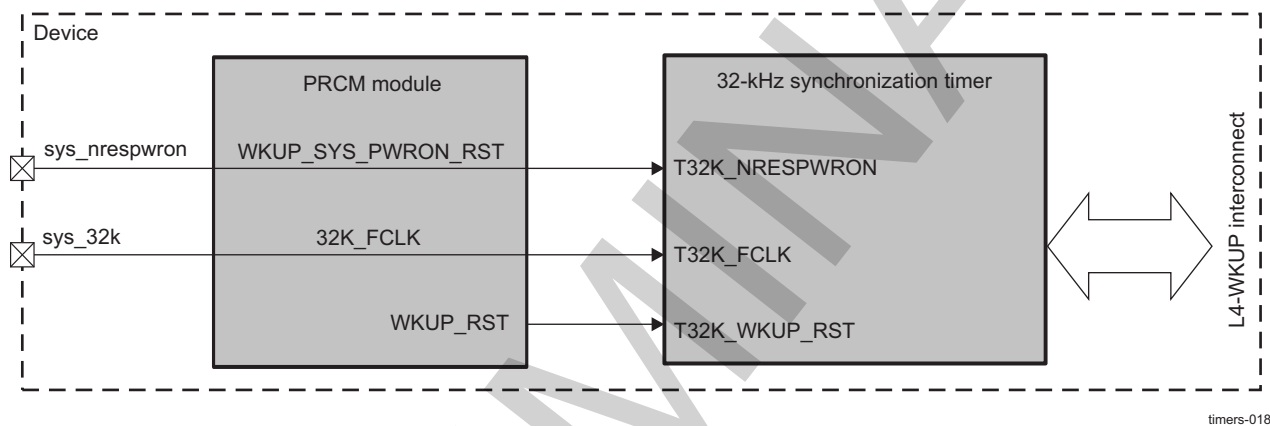

23.4.1 32-kHz Synchronized Timer Overview

The 32-kHz synchronized timer is a 32-bit counter clocked by the falling edge of the 32-kHz system clock. It is reset while the external asynchronous power-up reset (sys_nrespwron) primary input/output (I/O) is active (main device reset). When sys_nrespwron is released (on the rising edge of sys_nrespwron), after three 32-kHz clock periods, the counter starts counting up from the reset value of the counter register on the falling edge of the 32-kHz system clock. After reaching its highest value, the counter wraps back to 0 and starts counting again.

Figure 23-19 is the block diagram of the 32-kHz synchronized timer.

NOTE: sys_nrespwron is an active-low I/O.

Figure 23-19. 32-kHz Synchronized Timer Block Diagram

23.4.1.1 32-kHz Synchronized Timer Features

The main features of the 32-kHz synchronized timer controller are:

- L4 slave interface support:
 - 32-bit data bus width
 - 32-/16-bit access supported
 - 8-bit access not supported
 - 5-bit address bus width
 - Burst mode not supported
- Only read operations are supported on the module registers; no write operation is supported (no error/no action on write).
- Free-running 32-bit upward counter
- Start and keep counting after power-on reset
- Automatic roll over to 0; highest value reached: 0xFFFF FFFF
- On-the-fly read (while counting)

23.4.2 32-kHz Synchronized Timer Environment

The synchronized timer is accessible only through the L4 interface.

23.4.3 32-kHz Synchronized Timer Integration

Table 23-134 through Table 23-136 summarize the integration of the module in the device.

Table 23-134. Integration Attributes

| Module Instance | Attributes | | |
|-----------------|--------------|--------------------|--------------|
| | Power Domain | Wake-Up Capability | Interconnect |

Table 23-136. Hardware Requests

| |
|-----------------------|
| No Interrupt Requests |
| No DMA Requests |

23.4.4 32-kHz Synchronized Timer Functional Description

The synchronized timer is a counter that starts on the rising edge of an external asynchronous signal (sys_nrespwron). When sys_nrespwron is released (on the rising edge of sys_nrespwron), the counter starts counting up from the reset value of the counter register on the falling edge of the 32-kHz system clock after three inverted 32-kHz clock periods. After reaching its highest value, the counter wraps back to 0 and starts counting again with no additional delay. When sys_nrespwron is released (on the rising edge of sys_nrespwron), after three inverted 32-kHz clock periods, the counter starts counting up from the reset value of the counter register on the falling edge of the 32-kHz system clock.

Figure 23-20 shows the reset synchronization timing diagram. After reaching its highest value, the counter wraps back to 0 and starts counting again without any extra delay.

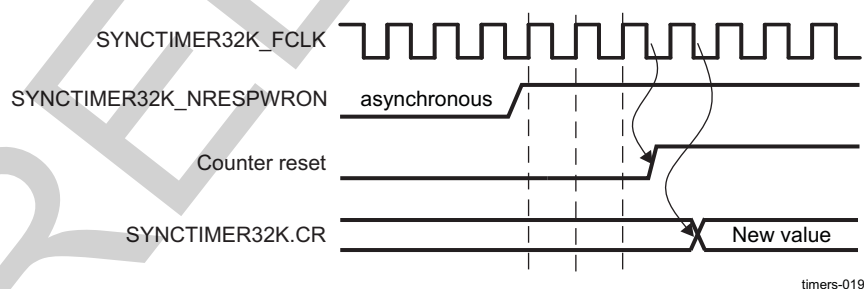

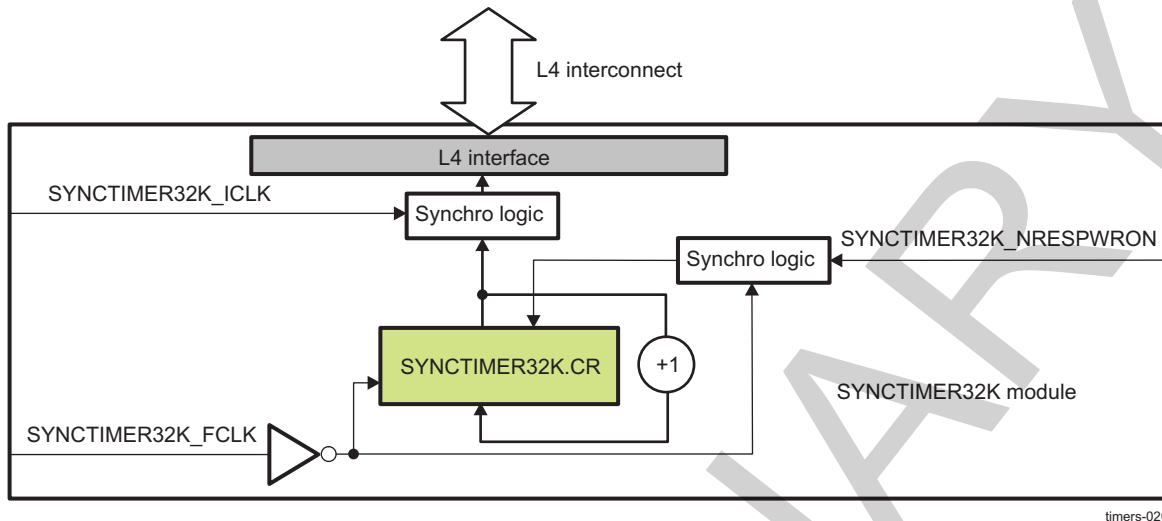

Figure 23-20. Reset Resynchronization Timing Diagram

Figure 23-21 is the block diagram of the synchronized timer.

NOTE: sys_nrespwron is an active-low input.

Figure 23-21. SYNCTIMER32K Block Diagram

The sync logic ensures the read transaction correctness by synchronizing the counter register read access on 32KSYNCNT_ICLK because the 32KSYNCNT_ICLK clock signal is completely asynchronous with S32KSYNCNT_FCLK. The sys_nrespwron input resets the counter register (32KSYNCNT_CR). The inverted 32KSYNCNT_FCLK clocks the sys_nrespwron reset signal.

23.4.4.1 Reading the 32-kHz Synchronized Timer

The counter register (32KSYNCNT_CR) is 32 bits wide. For correct count capture, it must be accessed as 16-bit LSB access first and 16-bit MSB access next. Internal synchronization logic allows reading of the counter value with 32KSYNCNT_ICLK while the counter is running. The time latency to read the synchronized counter register is one 32KSYNCNT_ICLK clock period.

23.4.5 32KTimer Register Manual

Table 23-137 lists the base address and block size for the 32-kHz synchronized timer. It is memory mapped to the L4 peripheral bus memory space.

Table 23-137. 32KTimer Instance Summary

| Module Name | Base Address L4 Interconnect | Size |
|-------------|---------------------------------|------|
| 32KTimer | 0x4A30 4000 | 4KB |

23.4.5.1 32KTimer Register Mapping Summary

CAUTION

The 32-kHz synchronized timer registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 23-138 lists the 32-kHz synchronized timer registers. through describe the register bits.

| 24.12 High-Speed USB OTG Controller | 5209 |

24.1 Multimaster High-Speed I²C Controller

24.1.1 HS I²C Overview

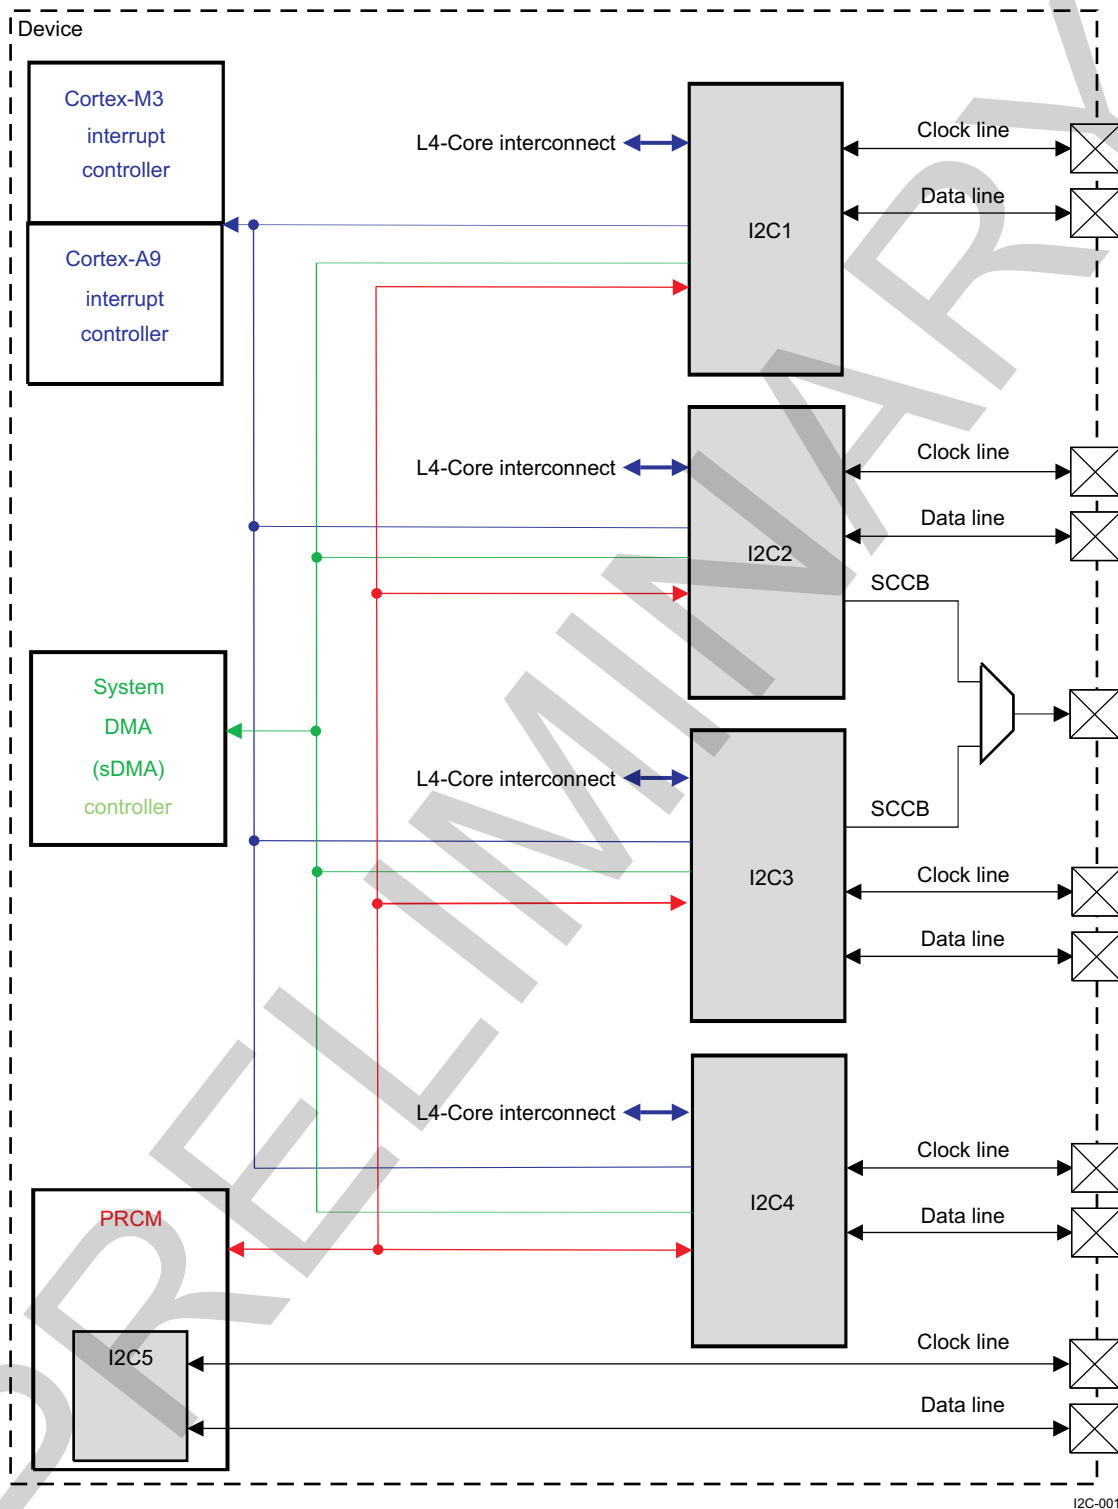

The device contains four multimaster high-speed (HS) inter-integrated circuit (I²C™) controllers (I2Ci modules, where i = 1, 2, 3, 4), each of which provides an interface between a local host (LH), such as a digital signal processor (DSP), and any I²C-bus-compatible device that connects through the I²C serial bus. External components attached to the I²C bus can serially transmit and receive up to 8 bits of data to and from the LH device through the 2-wire I²C interface.

Each multimaster HS I²C controller can be configured to act like a slave or master I²C-compatible device. Moreover, each multimaster HS I²C controller can be configured in serial camera control bus (SCCB) mode (the SCCB is a serial bus developed by Omnivision Technologies, Inc.) to act as a master on a 2-wire SCCB bus. Only multimaster HS I²C controllers I2C2 and I2C3 can be configured in SCCB mode to act as a master device on a 3-wire SCCB bus.

The device contains a fifth master transmitter HS I²C interface (I2C5) in the power, reset, and clock management (PRCM) module to perform dynamic voltage control and power sequencing with an external power integrated circuit (IC).

[Figure 24-1](#) shows the HS I²C controllers.

Figure 24-1. HS I²C Controllers

The four multimaster HS I²C controllers have the following features:

- Compliant with Philips I²C specification version 2.1
- Supports standard mode (up to 100 Kbps) and fast mode (up to 400 Kbps)
- Supports HS mode for transfer up to 3.4 Mbps

- Support for 3-wire/2-wire SCCB master mode for I2C2 and I2C3 modules, 2-wire SCCB master mode for I2C1 and I2C4 modules, up to 100 Kbps
- 7-bit and 10-bit device addressing modes
- General call
- Start/restart/stop
- Multimaster transmitter/slave receiver mode
- Multimaster receiver/slave transmitter mode
- Combined master transmit/receive and receive/transmit mode
- Built-in configurable FIFOs (8, 16, 32, 64 bytes) for buffered read or write
- Module enable/disable capability
- Programmable multislave channel (responds to four separate addresses)
- Programmable clock generation
- 8-bit-wide data access
- Open-core protocol (OCP) interface with LH application (OCP-IP 2.0 compliant)
- Designed for low power consumption
- Implement Auto Idle mechanism
- Implement Idle Request/Idle Acknowledge handshake mechanism
- Support for asynchronous wake-up mechanism
- Two direct memory access (DMA) channels
- Wide interrupt capability
- Supports OmniVision SCCB protocol
- Compliant with Highlander 0.8

The master transmitter HS I²C controller I2C5 has the following features:

- Support of HS and fast modes
- 7-bit addressing mode only
- Master transmitter mode only
- Start/restart/stop

NOTE: Before using HS I²C mode, determine that the target device supports this mode.

24.1.2 HS I²C Environment

This section describes the HS I²C application fields from an environment point of view (external connections). It describes HS I²C connectivity options, lists all possible interfaces, and describes the protocol and data format used in each case.

24.1.2.1 HS I²C in I²C Mode

Figure 24-2 shows the multimaster HS I²C controllers and their related connections with I²C-compliant devices in I²C mode.

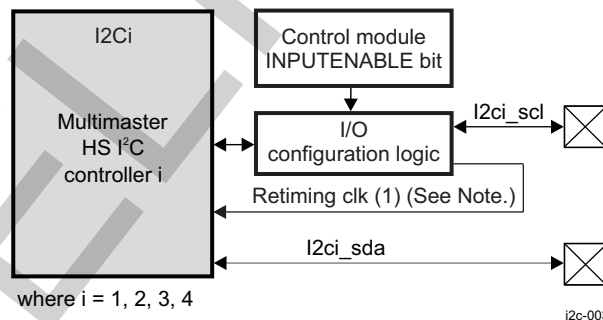

Figure 24-2. HS I²C and Typical Connections to I²C Devices

24.1.2.1.1 HS I²C Pins for Typical Connections in I²C Mode

Figure 24-3 shows the multimaster HS I²C controller pins used for typical connections with I²C devices.

Figure 24-3. HS I²C Interface Signals in I²C Mode

NOTE: In master mode, the clock signal (IP clk configured as output) is also used as retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).

24.1.2.1.2 HS I²C Interface Typical Connections

Table 24-1 lists the pins associated with the I²C interface.

Table 24-1. HS I²C Input/Output

| Signal | I/O ⁽¹⁾ | Description | Reset Value |
|----------|--------------------|---|-------------|
| i2ci_scl | I/O | I ² C serial clock line ⁽²⁾ . Open-drain output buffer. Requires external pullup resistor (Rp). | 1 |

⁽¹⁾ I = Input; O = Output

⁽²⁾ This output signal is also used as retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).

Table 24-1. HS I²C Input/Output (continued)

| Signal | I/O ⁽¹⁾ | Description | Reset Value |
|----------|--------------------|--|-------------|
| i2ci_sda | I/O | I ² C serial data line. Open-drain output buffer. Requires external Rp. | 1 |

24.1.2.1.3 HS I²C Typical Connection Protocol and Data Format

24.1.2.1.3.1 HS I²C Serial Data Format

The I²C controller operates in 8-bit word data format (byte write access supported for the last access). Each byte transmitted or received on the serial data line is 8 bits long. The number of bytes that can be transmitted or received is not restricted. The data is transferred with the most-significant bit (MSB) first. In receiver mode, each byte is followed by an acknowledge bit from the I²C. Figure 24-4 shows a typical I²C communication format.

Figure 24-4. HS I²C Data Transfer

24.1.2.1.3.2 HS I²C Data Validity

The data on the serial data line (SDA) must be stable during the high period of the serial clock line. The high and low states of the data line can change only when the clock signal on the serial clock line (SCL) is low.

Figure 24-5 is an example of data validity requirements.

Figure 24-5. HS I²C Bit Transfer on the I²C Bus

24.1.2.1.3.3 HS I²C Start and Stop Conditions

The I²C module generates start (S) and stop (P) conditions when it is configured as a master.

- An S condition is a high-to-low transition on the serial data line while serial clock line is high.
- A P condition is a low-to-high transition on the serial data line while serial clock line is high.

The bus is considered busy after the S condition (the I2Ci.I2C_STAT[12] BB bit is 1 to indicate that the bus is busy) and free after the P condition (the I2Ci.I2C_STAT[12] BB bit is 0 to indicate that the bus is free).

Figure 24-6 shows the waveforms that occur during an S and a P condition.

Figure 24-6. HS I²C S and P Condition Events

24.1.2.1.3.4 HS I²C Addressing

The I²C module supports two data formats in fast/standard (F/S) and HS modes:

- 7-bit/10-bit addressing format
- 7-bit/10-bit addressing format with repeated start (Sr) condition

24.1.2.1.3.4.1 Data Transfer Formats in F/S Mode

Figure 24-7 shows the I²C data transfer formats in F/S mode.

Figure 24-7. HS I²C Data Transfer Formats in F/S Mode

(a) 7-bit addressing format

(b) 10-bit addressing format

(c) Addressing format with repeated start condition

i2c-007

The first word after an S condition consists of 8 bits. In acknowledge mode, an extra dedicated acknowledgment bit is inserted after each byte.

In addressing formats with 7-bit addresses, the first byte is composed of 7 MSB slave address bits and 1 least-significant bit (LSB) R/W_ bit.

The LSB R/W_ bit of the address byte indicates the transmission direction of the data bytes that follow it. If R/W_ is 0, the master writes data to the selected slave; if it is 1, the master reads data from the slave.

In addressing formats with 10-bit addresses, the structure of the first byte is 11110XXY, where XX is the 2 MSBs of the 10-bit addresses, and Y is the R/W_ bit. If the R/W_ bit is 0, the next byte contains the last 8 bits of the slave address. If the R/W_ bit is 1, the next byte contains data transmitted from the slave to the master.

24.1.2.1.3.4.2 Data Transfer Format in HS Mode

Figure 24-8 shows the I²C data transfer format in HS mode.

Figure 24-8. HS I²C Data Transfer in HS Mode

S = Start; Sr = repeated start; P = Stop; F/S = Fast/standard mode; HS = High-speed mode

i2c-008

Each multimaster HS I²C controller can also operate in HS mode. In this case, after the S condition, the module, which is in F/S mode, writes the master code address (000001XXX, where XXX is the variable portion of the master code) on the bus. No device connected on the same bus acknowledges this address. The module switches the clock to the HS clock and after an Sr condition, and sends the slave address and the data, as shown in Figure 24-8.

24.1.2.1.3.5 HS I²C Master Transmitter

In master transmitter mode, data assembled in one of the previously described data formats is shifted out on the serial data line SDA in sync with the self-generated clock pulses on the serial clock line SCL. The clock pulses are inhibited and SCL is held low when the intervention of the processor is required (XUDF) after a byte is transmitted.

24.1.2.1.3.6 HS I²C Master Receiver

Master receiver mode can be entered only from master transmitter mode. With any of the address formats (a), (b), or (c) (see Figure 24-7), if R/W_ is high, the module enters master receiver mode after the slave address byte and bit R/W_ are transmitted. Serial data bits received on bus line SDA are shifted in synchronization with the self-generated clock pulses on SCL.

24.1.2.1.3.7 HS I²C Slave Transmitter

Slave transmitter mode can be entered only from slave receiver mode. With any of the address formats (a), (b), or (c) (see Figure 24-7), the slave transmitter is entered if the slave address byte is the same as its own address and bit R/W_ is transmitted, if R/W_ is high. The slave transmitter shifts the serial data out on the data line SDA in sync with the clock pulses that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (XUDF).

24.1.2.1.3.8 HS I²C Slave Receiver

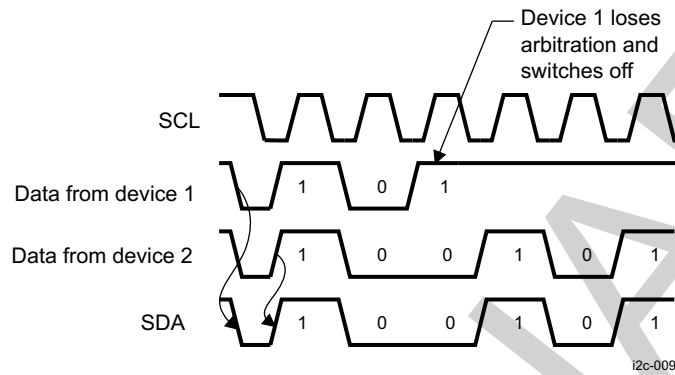

In this mode, serial data bits received on the bus line SDA are shifted-in in sync with the clock pulses on SCL that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (ROVR) after a byte is received.

24.1.2.1.3.9 HS I²C Bus Arbitration

If two or more master transmitters start a transmission on the same bus almost simultaneously, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial bus by the competing transmitters. When a transmitter senses that a high signal it has presented on the bus has

been overruled by a low signal, it switches to the slave receiver mode, sets the arbitration lost (AL) flag, and generates the arbitration lost interrupt. Figure 24-9 shows the arbitration procedure between two devices. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

Figure 24-9. HS I²C Arbitration Between Master Transmitters

24.1.2.1.3.10 HS I²C Clock Generation and Synchronization

Under normal conditions, only one master device generates the clock signal, SCL. During the arbitration procedure, however, there are two or more master devices and the clock must be synchronized so that the data output can be compared. The wired-AND property of the clock line means that a device that first generates a low period of the clock line overrules the other devices. At this high/low transition, the clock generators of the other devices are forced to start generating their own low period. The clock line is then held low by the device with the longest low period, while the other devices that finish their low periods must wait for the clock line to be released before starting their high periods. A synchronized signal on the clock line is thus obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period. If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the WAIT-state. In this way a slave can slow down a fast master and the slow device can create enough time to store a received byte or prepare a byte to be transmitted (Clock Stretching).

NOTE: In case the SCL or SDA lines are stuck low, the Bus Clear operation is supported.

If the clock line (SCL) is stuck low, the preferred procedure is to reset the bus using the hardware reset signal if your I²C devices have hardware reset inputs. If the I²C devices do not have hardware reset inputs, cycle power to the devices to activate the mandatory internal power-on reset (POR) circuit.

If the data line (SDA) is stuck low, the master should send nine clock pulses. The device that held the bus low should release it sometime within those nine clocks. If not, then use the hardware reset or cycle power to clear the bus.

Figure 24-10 shows clock synchronization.

Figure 24-10. HS I²C Clock Generators Synchronization**24.1.2.1.3.11 HS I²C External Clock Configuration**

Each multimaster HS I²C controller is clocked with an independent functional clock (I2Ci_FCLK) and an interface clock (I2Ci_ICLK) for interfacing with the L4_PER interconnect. These clocks are provided by the APE PRCM module for I2Ci (where i = 1, 2, 3, 4).

The SYS_CLK clock provided by the clock generator of the PRCM module is connected to the functional and interface clocks of the HS I²C controller I2C5. For detailed information about the module clocking, see [Chapter 3, Power, Reset, and Clock Management](#).

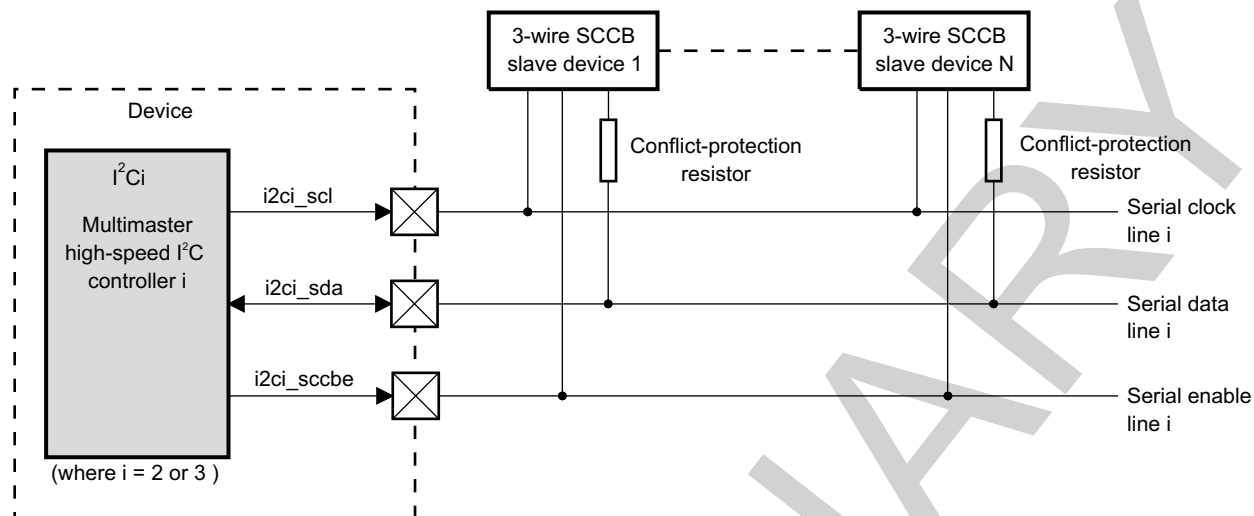

The functional clock is processed by a prescaler block to produce the internal sampling clock. This clock is generated by the I²C prescaler block. The prescaler block consists of the I2Ci.I2C_PSC[7:0] PSC bit field (where i = 1, 2, 3, 4) that is used to divide down the functional clock to obtain an internal sampling clock with a frequency value of I2Ci_FCLK/(I2Ci.I2C_PSC[7:0] PSC bit field value + 1, where i = 1, 2, 3, 4).

NOTE: The I2Ci.I2C_PSC[7:0] PSC bit field (where i = 5) of I2C5 is not accessible by software.

24.1.2.2 HS I²C in SCCB Mode

The multimaster HS I²C controllers support the 2-wire SCCB protocol in master mode as listed in [Figure 24-11](#). Only I2C2 and I2C3 support the 3-wire SCCB protocol in master mode.

Figure 24-11. HS I²C and Typical Connections to SCCB Devices

(a) Typical connection with 3-wire SCCB devices

(b) Typical connection with 2-wire SCCB devices

I2C-011

NOTE: Only one 2-wire SCCB slave device can be connected to the 2-wire SCCB bus.

24.1.2.2.1 HS I²C Pins for Typical Connections in SCCB Mode

Figure 24-12 shows the multimaster HS I²C controller pins used for typical connections with 3-wire or 2-wire SCCB devices.

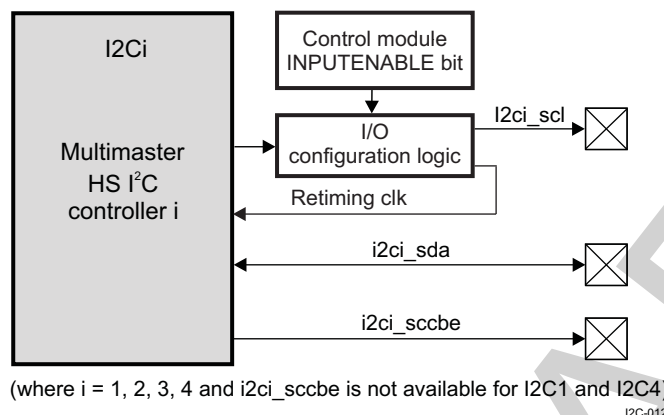

Figure 24-12. HS I²C Interface Signals in SCCB Mode**24.1.2.2.2 HS I²C SCCB Interface Typical Connections**

Table 24-2 lists the pins associated with the SCCB interface.

Table 24-2. HS I²C Input/Output

| Signal | I/O ⁽¹⁾ | Description | Reset Value ⁽²⁾ | I2Ci.I2C_CON[15] I2C_EN bit = 0 |
|--------------------------|--------------------|--|----------------------------|------------------------------------|
| i2ci_scl | O | SCCB serial clock line ⁽³⁾ . Standard CMOS output buffer. | Hi-Z | High |
| i2ci_sda | I/O(OD) | SCCB serial data line. Standard CMOS 3-state output buffer. Requires external conflict-protection resistor for each slave device connected to the bus. | Hi-Z | Hi-Z |
| i2ci_sccb ⁽⁴⁾ | O | SCCB enable line. Standard CMOS output buffer. | High | High |

⁽¹⁾ I = Input; O = Output; OD = Open Drain

⁽²⁾ Hi-Z = High Impedance

⁽³⁾ This output signal is also used as retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).

⁽⁴⁾ This signal is used for the 3-wire SCCB protocol only.

NOTE: Because they share the same ball, the i2c2_sccb and i2c3_sccb signals are not available at the same time. For detailed information about pin configuration, see [Chapter 19, Control Module](#).

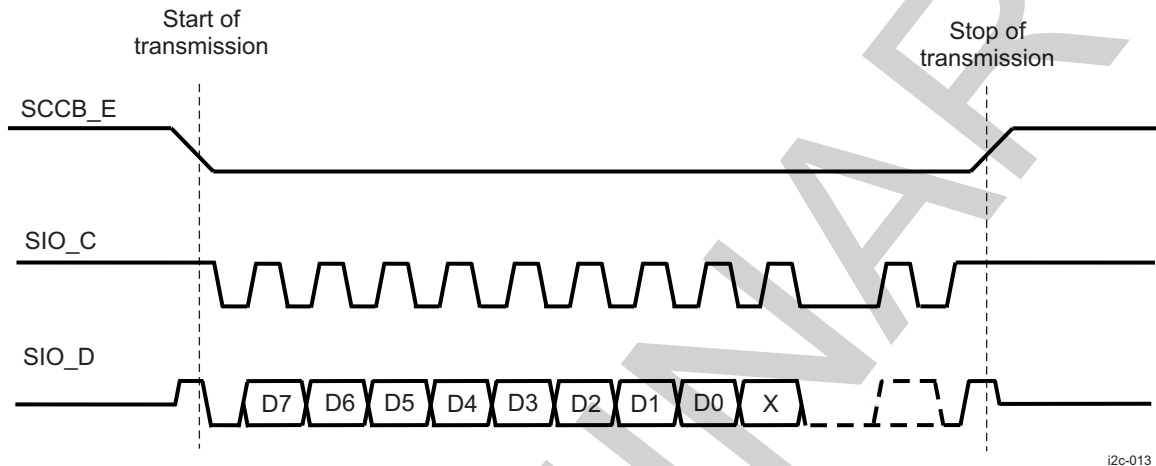

I2C1 and I2C4 do not provide any i2c1_sccb signal at the chip boundary of the device; thus, these modules do not support the 3-wire SCCB protocol.

24.1.2.2.3 HS I²C SCCB Typical Connection Protocol and Data Format

24.1.2.2.3.1 HS I²C SCCB Data Format

If the module is configured in SCCB mode of operation, the data format of transmissions appears as shown in Figure 24-13. For SCCB protocol compatibility I²C provides one more signal, SCCB_E, which acts like a transaction enable signal.

Figure 24-13. HS I²C 3-wire SCCB Transmission Timing Diagram

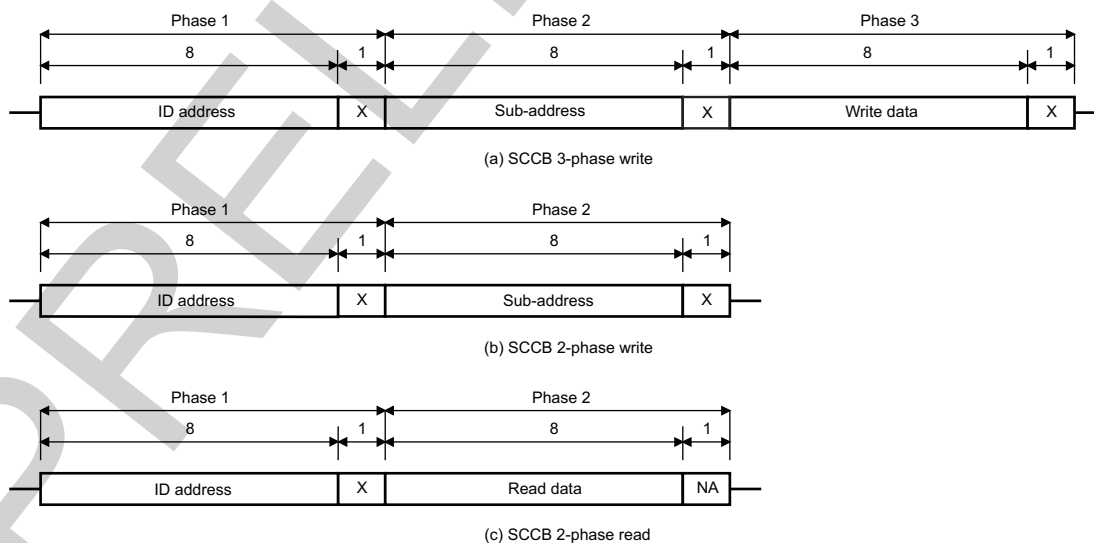

NOTE: When operating in 2-wire SCCB mode, the i2ci_sccb_e signal is not used by the 2-wire SCCB-compliant slave device attached to the 2-wire SCCB bus.

24.1.2.2.3.2 HS I²C SCCB Transmission Data Formats

Figure 24-14 describes the data format of the three kinds of transmission.

Figure 24-14. HS I²C SCCB Transmission Data Formats

R/W: 0 = Write, 1 = Read

X: don't care

NA: ninth bit of a read phase. This bit must be set to 1 by the master device.

I2C-014

The basic element of a data transmission is a phase. A phase contains 9 bits, which consist of an 8-bit sequential data transmission followed by a ninth bit. The ninth bit is a don't-care bit (X) or an NA bit, depending on whether the data transmission is a write or a read. The maximum number of phases that can be included in a transmission is three. The MSB is always asserted first for each phase.

A data transmission is one of three types:

- 3-phase write transmission:

The 3-phase write transmission cycle (see (a) of [Figure 24-14](#)) is a full write operation in which the master can write 1 byte of data to a specific slave(s). The 7-bit slave address in the ID value identifies the specific slave that the master intends to access. The subaddress identifies the register location of the specified slave. The write data contains 8-bit data that the master intends to write over the content of this specific address. The ninth bit of each of the three phases is a don't-care bit (X bit).

- 2-phase write transmission:

The 2-phase write transmission cycle is followed by a 2-phase read transmission cycle (see the following bullet). The purpose of issuing a 2-phase write transmission cycle (see (b) of [Figure 24-14](#)) is to identify the subaddress of some specific slave from which the master intends to read data for the following 2-phase read transmission cycle. The ninth bit of each phase is a don't-care bit (X bit).

- 2-phase read transmission:

Either a 3-phase or a 2-phase write transmission cycle must be asserted ahead of a 2-phase read transmission cycle. The 2-phase read transmission cycle (see (c) of [Figure 24-14](#)) cannot identify the subaddress. The 2-phase write transmission cycle contains read data of 8 bits and a ninth don't-care bit or NA bit. The master must drive the NA bit at logical 1.

In each transmission type, phase 1 (the 7-bit slave address of the ID value) is asserted by the master to identify the selected slave to which the data is read or written. Each slave has a unique 7-bit slave address. The 7-bit slave address of the ID value comprises 7 bits, from bit 7 to bit 1, that can identify up to 128 slaves. The eighth bit, bit 0, is the read/write selector bit that specifies the transmission direction of the current cycle. A logical 0 represents a write cycle and a logical 1 represents a read cycle. The ninth bit of phase 1 is a don't-care bit (X bit).

Phase 2 (subaddress/read data) is asserted by the master (subaddress) or the slave(s) (read data). A phase 2 transmission asserted by the master identifies the subaddress of the slave(s) the master intends to access. A phase 2 transmission asserted by the slave(s) indicates the read data that the master will receive. The slave(s) recognize the subaddress of this read data according to the previous 3-phase or 2-phase write transmission cycle. The ninth bit is defined as a don't-care bit (X bit) when the master asserts phase 2. The ninth bit is defined as an NA bit when the slave(s) asserts the phase 2 transmission. The master is responsible for a logical 1 during the period of the NA bit.

Phase 3 (write data) is asserted only by the master. This phase contains the data the master intends to write to the slave(s). Because the master asserts the transmission, the ninth bit of the phase 3 transmission is defined as a don't-care bit (X bit).

NOTE: A multimaster HS I²C controller configured in SCCB mode can perform two operations:

- Write a single byte to an SCCB slave device by using the 3-phase write transmission cycle
 - Read a single byte from an SCCB slave device by using the 2-phase write transmission cycle followed by the 2-phase read transmission cycle
-

24.1.2.2.3.3 HS I²C Data Validity

The data validity is the same as described in [Section 24.1.2.1.3.2, HS I²C Data Validity](#).

24.1.2.2.3.4 HS I²C S and P Conditions

The S and P conditions are the same as described in [Section 24.1.2.1.3.3, HS I²C Start and Stop Conditions](#).

24.1.2.3 HS I²C for Communication With Power Chip(s)

Figure 24-15 shows a typical connection between the master transmitter HS I²C controller I2C5 of the device and external power chip(s).

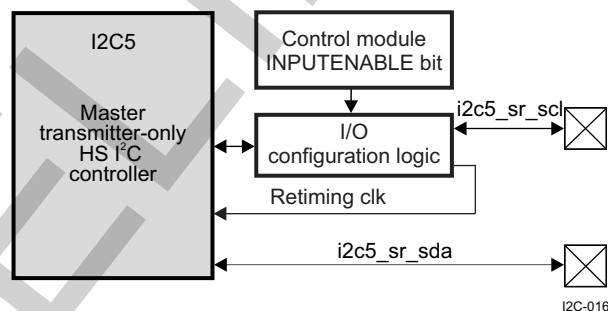

Figure 24-15. HS I²C and Typical Connection Between the HS I²C and Power Chip(s)

24.1.2.3.1 HS I²C I2C5 Pins for Typical Connections

Figure 24-16 shows the HS I²C controller I2C5 pins used for typical connections with power chips.

Figure 24-16. HS I²C I2C5 Interface Signals

24.1.2.3.2 HS I²C I2C5 Interface Typical Connections

The master transmitter HS I²C controller I2C5 interfaces between the device and external power chip(s) for voltage control. This module is always configured as an I²C master transmitter; it does not support the SCCB protocol.

Table 24-3 lists the pins associated with the I²C interface of the HS I²C controller I2C5 of the device.

Table 24-3. HS I²C Input/Output Description

| Signal | I/O ⁽¹⁾ | Description | Reset Value |
|-------------|--------------------|---|-------------|
| i2c5_sr_scl | I/O(OD) | I ² C serial clock line ⁽²⁾ . Open-drain output buffer. Requires external Rp. | 1 |

⁽¹⁾ I = Input; O = Output; OD = Open Drain

⁽²⁾ This signal is also used as retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).

Table 24-3. HS I²C Input/Output Description (continued)

| Signal | I/O ⁽¹⁾ | Description | Reset Value |
|-------------|--------------------|--|-------------|
| i2c5_sr_sda | I/O(OD) | I ² C serial data line. Open-drain output buffer. Requires external Rp. | 1 |

24.1.2.3.3 HS I²C Typical Connections Protocol and Data Format for I2C5

24.1.2.3.3.1 HS I²C Serial Data Format for I2C5

The serial data format is the same as described in [Section 24.1.2.1.3.1](#), *HS I²C Serial Data Format*.

24.1.2.3.3.2 HS I²C Data Validity for I2C5

The data validity is the same as described in [Section 24.1.2.1.3.2](#), *HS I²C Data Validity*.

24.1.2.3.3.3 HS I²C S and P Conditions for I2C5

The S and P conditions are the same as described in [Section 24.1.2.1.3.3](#), *HS I²C Start and Stop Conditions*.

24.1.2.3.3.4 HS I²C Addressing for I2C5

The master transmitter HS I²C controller I2C5 supports only the 7-bit addressing mode. For each frame, the master writes the 8-bit value (DATA) in the register specified by the 8-bit register address (RA) of the slave addressed by the slave address (SA).

24.1.2.3.3.4.1 HS I²C Data Transfer Format in F/S Mode

Figure 24-17 shows the I²C data transfer format in F/S mode for I2C5.

Figure 24-17. HS I²C Data Transfer Format in F/S Mode for I2C5

- For a description of DMA source, see [Table 24-13](#).

24.1.4 HS I²C Functional Description

24.1.4.1 HS I²C Block Diagram

Figure 24-21 is the multimaster I²C HS controller block diagram.

Figure 24-21. HS I²C Block Diagram

The five multimaster HS I²C controllers can be configured in F/S I²C mode, HS I²C mode, or SCCB mode. The operation mode is selected by configuring the I2Ci.I2C_CON[13:12] OPMODE bit field. Table 24-7 lists the available operation modes.

NOTE: The fifth master transmitter HS I²C interface (I2C5) in the PRCM module can also be configured in HS mode.

Table 24-7. HS I²C Operation Mode Selection

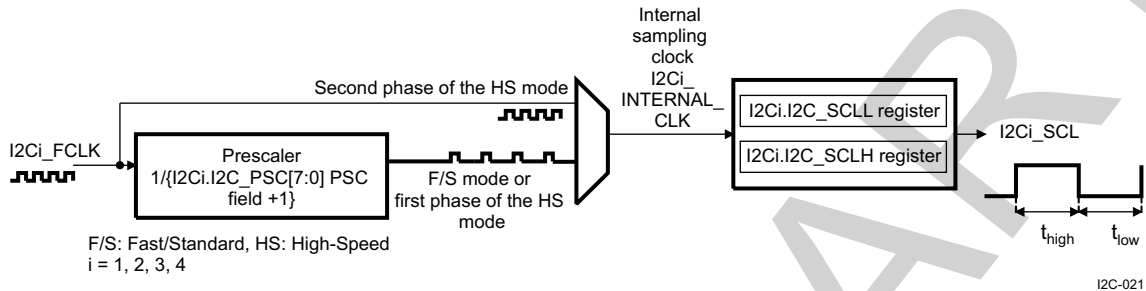

| Operation Mode | Value of I2Ci.I2C_CON[13:12] OPMODE Bit Field |
|----------------------|---|
| F/S I ² C | 0x0 |
| HS I ² C | 0x1 |
| SCCB | 0x2 |
| Reserved (not used) | 0x3 |

24.1.4.2 HS I²C Clocks

24.1.4.2.1 HS I²C Clocking

Figure 24-22 shows the I²C clock generation of the HS I²C controllers.

Figure 24-22. HS I²C Clock Generation

Each multimaster HS I²C controller uses the I2Ci_FCLK functional clock in the PRCM module. The internal sampling clock I2Ci_INTERNAL_CLK is generated by dividing the functional clock by the I2Ci.I2C_PSC[7:0] PSC bit field value + 1 in F/S mode, in SCCB mode, or in the first phase of HS mode; or by directly using the functional clock in the second phase of HS mode (prescaler is bypassed).

The low time of the I2Ci_SCL signal is determined by the I2Ci.I2C_SCLL[7:0] SCLL bit field in F/S mode, in SCCB mode, or in the first phase of HS mode; or by the I2Ci.I2C_SCLL[15:8] HSSCLL bit field in the second phase of HS mode.

The high time of the I2Ci_SCL signal is determined by the I2Ci.I2C_SCLH[7:0] SCLH bit field in F/S mode, in SCCB mode, or in the first phase of HS mode; or by the I2Ci.I2C_SCLH[15:8] HSSCLH bit field in the second phase of HS mode.

The low time of the I2C5 signal is determined by the PRM_VC_CFG_I2C_CLK[15:8] SCLL bit field in F/S mode or in the first phase of HS mode, or by the PRM_VC_CFG_I2C_CLK[31:24] HSSCLL bit field in the second phase of HS mode.

The high time of the I2C5 signal is determined by the PRM_VC_CFG_I2C_CLK[7:0] SCLH bit field in F/S mode or in the first phase of HS mode, or by the PRM_VC_CFG_I2C_CLK[23:16] HSSCLH bit field in the second phase of HS mode.

Table 24-8 lists the T_{LOW} and T_{HIGH} values in master mode only (in slave mode, the I²C controller does not generate the I²C clock).

Table 24-8. HS I²C T_{LOW} and T_{HIGH} Values of the I²C Clock

| Mode | I ² C Clock | t_{LOW} | t_{HIGH} | |
|--------------------------------|---|--|---|---|
| | | | DFILTEREN bit = 0 | DFILTEREN bit = 1 |
| F/S, SCCB, or HS first phase | $I2Ci_INTERNAL_CLK = I2Ci_FCLK / (I2Ci.I2C_PSC[7:0] \text{ PSC bit field} + 1)$ | $(I2Ci.I2C_SCLL[7:0] \text{ SCLL bit field value} + 7) \times I2Ci_INTERNAL_CLK \text{ period}$ | $(I2Ci.I2C_SCLH[7:0] \text{ SCLH bit field value} + 5 + PROP_DELAY0) \times I2Ci_INTERNAL_CLK \text{ period}$ | $(I2Ci.I2C_SCLH[7:0] \text{ SCLH bit field value} + 5 + PROP_DELAY1) \times I2Ci_INTERNAL_CLK \text{ period}$ |
| HS second phase | I2Ci_FCLK | $(I2Ci.I2C_SCLL[15:8] \text{ HSSCLL bit field value} + 7) \times I2Ci_FCLK \text{ period}$ | $(I2Ci.I2C_SCLH[15:8] \text{ HSSCLH bit field value} + 5 + PROP_DELAY0) \times I2Ci_FCLK \text{ period}$ | $(I2Ci.I2C_SCLH[15:8] \text{ HSSCLH bit field value} + 5 + PROP_DELAY1) \times I2Ci_FCLK \text{ period}$ |
| F/S or HS first phase for I2C5 | I2C5_FCLK | $(PRM_VC_CFG_I2C_CLK[15:8] \text{ SCLL} + 1) \times I2C5_FCLK \text{ period}$ | $(PRM_VC_CFG_I2C_CLK[7:0] \text{ SCLH} + 5 + PROP_DELAY0) \times I2C5_FCLK \text{ period}$ | $(PRM_VC_CFG_I2C_CLK[7:0] \text{ SCLH} + 5 + PROP_DELAY1) \times I2C5_FCLK \text{ period}$ |

Table 24-8. HS I²C T_{LOW} and T_{HIGH} Values of the I²C Clock (continued)

| Mode | I ² C Clock | t _{LOW} | t _{HIGH} | |
|--------------------------|------------------------|---|---|---|
| | | | DFILTEREN bit = 0 | DFILTEREN bit = 1 |
| HS second phase for I2C5 | I2C5_FCLK | (PRM_VC_CFG_I2C_CLK[31:24] HSSCLL + 1) x I2C5_FCLK period | (PRM_VC_CFG_I2C_CLK[23:16] HSSCLH + 5 + PROP_DELAY0) x I2C5_FCLK period | (PRM_VC_CFG_I2C_CLK[23:16] HSSCLH + 5 + PROP_DELAY1) x I2C5_FCLK period |

NOTE: For HS mode, the I2Ci.I2C_SCLL[15:8] HSSCLL and I2Ci.I2C_SCLL[7:0] SCLL bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

For HS mode, the I2Ci.I2C_SCLH[15:8] HSSCLH and I2Ci.I2C_SCLH[7:0] SCLH bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

NOTE: The equations in Table 24-8 give the SCL timing values for SCLL/SCLH/HSSCLL/HSSCLH at HS I²C controller outputs. Actual T_{LOW} and T_{HIGH} periods may vary depending on the board (the load capacitance on the SCL signal). If necessary, any adjustments to the SCLL/SCLH/HSSCLL/HSSCLH values must be determined by measurements of actual SCL signal on the board

CAUTION

During active mode (the I2Ci.I2C_CON[15] I2C_EN bit is set to 1), make no changes to the I2Ci.I2C_SCLL and I2Ci.I2C_SCLH registers. Changes can result in unpredictable behavior.

NOTE: Each multimaster HS I²C controller can be used with an internal secondary pullup. This pullup is mandatory when the I²C controller is configured in HS mode for a bit rate of 3.4 Mbps, and the bus line capacitance exceeds 45 pF. Pullups can be programmed through:

- CONTROL_I2C_0[0] I2C1_SCL_PULLUPRESX bit or CONTROL_I2C_0[16] I2C1_SDA_PULLUPRESX bit for I2C1
- CONTROL_I2C_0[4] I2C2_SCL_PULLUPRESX bit or CONTROL_I2C_0[20] I2C2_SDA_PULLUPRESX bit for I2C2
- CONTROL_I2C_0[8] I2C3_SCL_PULLUPRESX bit or CONTROL_I2C_0[24] I2C3_SDA_PULLUPRESX bit for I2C3
- CONTROL_I2C_0[12] I2C4_SCL_PULLUPRESX bit or CONTROL_I2C_0[28] I2C4_SDA_PULLUPRESX bit for I2C4

The maximum bit rate specified by the SCCB specifications is 100 Kbps.

For more information see Section 19.4.12.8.8, I2Cx I/Os Group Pullupresx Controls and Load Range Settings.

Table 24-9 lists the register values for obtaining the maximum I²C bit rates and the maximum period of the filtered spikes in F/S mode and HS mode.

Table 24-9. HS I²C Register Values for Maximum I²C Bit Rates in I²C F/S, I²C HS, and SCCB Modes⁽¹⁾

| | I ² C Mode for I2Ci, where i = 1, 2, 3, 4 | | | Description | SCCB Mode for I2Ci, where i = 2, 3 | | I ² C Mode for I2C5 Fast and High-Speed Mode | | |
|---|---|--------------|--------------------|--|---------------------------------------|-------------------------------|---|-----|---|
| | Standard Mode | Fast Mode | High-Speed Mode | | | | | | |
| I2Ci_FCLK frequency (MHz) | 96 | | | | 96 | | 38.4 | | SYS_CLK clock frequency |
| I2Ci.I2C_PSC[7:0] PSC bit field value | 23 | 9 | 1 | Prescaler value for F/S and HS modes | 4 | Prescaler value for SCCB mode | Not accessible by software | | |
| I2Ci_INTERNAL_CLK frequency (MHz) | 4 | 9.6 | 96 | 19.2 | | | | | |
| I2Ci.I2C_SCLL[7:0] SCLL bit field value | 13 | 7 | 113 | Value for F/S mode and first phase of HS mode | 89 | Value for SCCB mode | PRM_VC_CFG_I2C_CLK[15:8] SCLL (see Chapter 3, Power, Reset, and Clock Management) | 43 | Value for F/S mode and first phase of HS mode |
| I2Ci.I2C_SCLH[7:0] SCLH bit field value | 15 | 5 | 115 | Value for F/S mode and first phase of HS mode | 91 | Value for SCCB mode | PRM_VC_CFG_I2C_CLK[7:0] SCLH (see Chapter 3, Power, Reset, and Clock Management) | 41 | Value for F/S mode and first phase of HS mode |
| Maximum bit rate (Mbps) | 0.1 | 0.4 | 0.4 | F/S mode and first phase in HS mode maximum bit rate | 0.1 | SCCB mode maximum bit rate | Maximum bit rate (Mbps) | 0.4 | F/S mode and first phase in HS mode maximum bit rate |
| Maximum filter period (ns) | 250 | 104 | 10 | | 50 | | Maximum filter period (ns) | 50 | |
| I2Ci.I2C_SCLL[15:8] HSSCLL bit field value | 12 | | | Values for second phase of HS mode | | | PRM_VC_CFG_I2C_CLK[31:24] HSSCLL (see Chapter 3, Power, Reset, and Clock Management) | 14 | Values for second phase of HS mode |
| I2Ci.I2C_SCLH[15:8] HSSCLH bit field value | 5 | | | Values for second phase of HS mode | | | PRM_VC_CFG_I2C_CLK[23:16] HSSCLH (see Chapter 3, Power, Reset, and Clock Management) | 0 | Values for second phase of HS mode |
| HS mode maximum bit rate (Mbps) | 3.31 | | | HS mode maximum bit rate | | | HS mode maximum bit rate (Mbps) | 3.2 | HS mode maximum bit rate according to the corresponding SYS_CLK clock frequency |
| Maximum filter period (ns) | 10 | | | | | | | 10 | |

⁽¹⁾ Programmable fields are in bold.

NOTE: This table presents informative values only for the configuration parameters and the I²C bus performance obtained according to these values. The delays added by the analog pads are not considered in these figures.

NOTE: For I2Ci (where i = 1, 2, 3, 4)

$I2Ci_INTERNAL_CLK \text{ freq} = I2Ci_FCLK / (PSC + 1)$

$FS \text{ filter period} = 1 / I2Ci_INTERNAL_CLK$

$HS \text{ filter period} = 1 / I2Ci_FCLK \text{ freq}$

- If the DFILTEREN bit = 0:

$HS \text{ bit rate} = I2Ci_FCLK \text{ freq} / (HSSCLL + 7 + HSSCLH + 5 + PROP_DELAY0)$

$FS \text{ bit rate} = I2Ci_INTERNAL_CLK / (SCLL + 7 + SCLH + 5 + PROP_DELAY0)$

- If the DFILTEREN bit = 1:

$HS \text{ bit rate} = I2Ci_FCLK \text{ freq} / (HSSCLL + 7 + HSSCLH + 5 + PROP_DELAY1)$

$FS \text{ bit rate} = I2Ci_INTERNAL_CLK / (SCLL + 7 + SCLH + 5 + PROP_DELAY1)$

For I2C5 (SR):

$I2C5_FCLK \text{ freq} = SYS_CLK \text{ freq}$

$HS/FS \text{ filter period} = 1 / I2C5_FCLK \text{ freq}$

- If the DFILTEREN bit = 0:

$HS \text{ bit rate} = I2C5_FCLK \text{ freq} / (HSSCLL + 1 + HSSCLH + 5 + PROP_DELAY0)$

$FS \text{ bit rate} = I2C5_FCLK \text{ freq} / (SCLL + 1 + SCLH + 5 + PROP_DELAY0)$

- If the DFILTEREN bit = 1:

$HS \text{ bit rate} = I2C5_FCLK \text{ freq} / (HSSCLL + 1 + HSSCLH + 5 + PROP_DELAY1)$

$FS \text{ bit rate} = I2C5_FCLK \text{ freq} / (SCLL + 1 + SCLH + 5 + PROP_DELAY1)$

DFILTEREN refers to the VC_CFG_I2C_MODE[6] DFILTEREN bit. PROP_DELAYx (where x = 0 or 1) represents frequency-normalized I/O low-to-high propagation delay.

PROP_DELAY0 = 0 or 3 (values for bit rate maximum/minimum range)

PROP_DELAY1 = 1 or 4 (values for bit rate maximum/minimum range)

24.1.4.2.2 HS I²C Automatic Blocking of the I²C Clock Feature (I²C Mode Only)

This feature offers the possibility for the LH to command the blocking of the I²C clock after the slave addressing phase, when the I²C controller is addressed by an external master device using a certain Own Address.

The release of the I²C clock can be performed independently for each Own Address (I2Ci.I2C_OA , where i = 1, 2, 3, 4 and I2Ci.I2C_OAx registers, where x = 1, 2, 3) by deasserting the corresponding bit in the I2Ci.I2C_SBLOCK register.

24.1.4.3 HS I²C Software Reset

Each multimaster HS I²C controller supports the software reset by accessing the I2Ci.I2C_SYSC[1] SRST bit (1: reset; 0: normal mode).

The software reset status can be checked by accessing the I2Ci.I2C_SYSS[0] RDONE bit (1: reset is done; 0: reset is ongoing).

To perform a software reset:

1. Ensure that the module is disabled (clear the I2Ci.I2C_CON[15] I2C_EN bit to 0).
2. Set the I2Ci.I2C_SYSC[1] SRST bit to 1.
3. Enable the module by setting I2Ci.I2C_CON[15] I2C_EN bit to 1.
4. Check the I2Ci.I2C_SYSS[0] RDONE bit until it is set to 1 to indicate the software reset is complete.

NOTE: The I2Ci.I2C_CON[15] I2C_EN bit can hold the functional clock domain of the multimaster HS I²C controller in reset after the device reset has been released. When the system bus reset is removed, this bit remains cleared. The functional part of the I²C controller is held in reset state while this bit is 0, and all configuration registers can be accessed.

The I2Ci.I2C_CON[15] I2C_EN bit must be set to 1 to enable the functional part of the I²C controller.

The I2Ci.I2C_SYSS[0] RDONE bit is asserted only after the module is enabled by setting the I2Ci.I2C_CON[15] I2C_EN bit to 1.

24.1.4.4 HS I²C Power Management

Table 24-10 describes power-management features available for the multimaster HS I²C controllers.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 24-10. HS I²C Local Power-Management Features

| Feature | Registers | Description |
|-----------------------|----------------------------------|--|
| Clock auto gating | I2Ci.I2C_SYSC[0] AUTOIDLE | This bit allows a local power optimization inside the module |
| Slave idle modes | I2Ci.I2C_SYSC[4:3] IDLEMODE | Force-idle, no-idle, smart-idle, and smart-idle wake-up-capable modes are available. |
| Clock activity | I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY | For configuration details, see Table 24-11 . |
| Global wake-up enable | I2Ci.I2C_SYSC[2] ENAWAKEUP | This bit enables the wake-up feature at module level. |

NOTE: The voltage controllers, in which the HS I²C controller I2C5 are implemented, have no idle request/acknowledge mechanism. The idle modes for the voltage controllers are directly managed by the PRCM module.

Table 24-11. HS I²C Clock Activity Settings

| I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY | Clock State When Module is in IDLE State | | Features Available/Unavailable When Module is in IDLE State |
|-------------------------------------|--|----------|---|
| | I2Ci_ICLK | I2C_FCLK | |
| 00 | OFF | OFF | Both clocks are disabled |
| 10 | OFF | ON | Interface clock is disabled; functional clock is enabled |
| 01 | ON | OFF | Functional clock is disabled; interface clock is enabled |
| 11 | ON | ON | Both clocks are enabled |

CAUTION

The PRCM module has no hardware means of reading the settings of CLOCKACTIVITY. Thus, software must ensure consistent programming between the I2C CLOCKACTIVITY and I2C clock PRCM control bits. For a description of the ClockActivity feature, see [Section 3.1.1.1.2, Module Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

24.1.4.5 HS I²C Interrupt Requests

[Table 24-12](#) lists the event flags, and their mask, that can cause module interrupts.

Table 24-12. HS I²C Events

| Event Flag | Event Mask | Event Unmask | Map to | Description |
|----------------------------|-----------------------------------|------------------------------------|----------|---|
| I2Ci.I2C_IRQSTATUS[0] AL | I2Ci.I2C_IRQENABLE_SET[0] AL_IE | I2Ci.I2C_IRQENABLE_C LR[0] AL_IE | I2Ci_IRQ | Arbitration lost IRQ enabled status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to the MPU subsystem. During reads, it always returns 0. |
| I2Ci.I2C_IRQSTATUS[1] NACK | I2Ci.I2C_IRQENABLE_SET[1] NACK_IE | I2Ci.I2C_IRQENABLE_C LR[1] NACK_IE | I2Ci_IRQ | No acknowledgment IRQ enabled status. Bit is set when No Acknowledge has been received, an interrupt is signaled to MPU subsystem. Write 1 to clear this bit. |
| I2Ci.I2C_IRQSTATUS[2] ARDY | I2Ci.I2C_IRQENABLE_SET[2] ARDY_IE | I2Ci.I2C_IRQENABLE_C LR[2] ARDY_IE | I2Ci_IRQ | Register access ready IRQ enabled status. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to MPU subsystem. Write 1 to clear. |
| I2Ci.I2C_IRQSTATUS[3] RRDY | I2Ci.I2C_IRQENABLE_SET[3] RRDY_IE | I2Ci.I2C_IRQENABLE_C LR[3] RRDY_IE | I2Ci_IRQ | Receive data ready IRQ enabled status. Set to 1 by core when receiver mode, a new data is able to be read. When set to 1 by core, an interrupt is signaled to MPU subsystem. Write 1 to clear. |

Table 24-12. HS I²C Events (continued)

| Event Flag | Event Mask | Event Unmask | Map to | Description |
|--------------------------------|---|---|----------|---|
| I2Ci.I2C_IRQSTATUS[4] XRDY | I2Ci.I2C_IRQENABLE_SET[4] XRDY_IE | I2Ci.I2C_IRQENABLE_C LR[4] XRDY_IE | I2Ci_IRQ | Transmit data ready IRQ enabled status. Set to 1 by core when transmitter and when new data is requested. When set to 1 by core, an interrupt is signaled to MPU subsystem. Write 1 to clear. |
| I2Ci.I2C_IRQSTATUS[5] GC | I2Ci.I2C_IRQENABLE_SET[5] GC_IE | I2Ci.I2C_IRQENABLE_C LR[5] GC_IE | I2Ci_IRQ | General call IRQ enabled status. Set to 1 by core when General call address detected and interrupt signaled to MPU subsystem. Write 1 to clear. |
| I2Ci.I2C_IRQSTATUS[6] STC | I2Ci.I2C_IRQENABLE_SET[6] STC_IE | I2Ci.I2C_IRQENABLE_C LR[6] STC_IE | I2Ci_IRQ | Start Condition IRQ enabled status. |
| I2Ci.I2C_IRQSTATUS[7] AERR | I2Ci.I2C_IRQENABLE_SET[7] AERR_IE | I2Ci.I2C_IRQENABLE_C LR[7] AERR_IE | I2Ci_IRQ | Access Error IRQ enabled status. |
| I2Ci.I2C_IRQSTATUS[8] BF | I2Ci.I2C_IRQENABLE_SET[8] BF_IE | I2Ci.I2C_IRQENABLE_C LR[8] BF_IE | I2Ci_IRQ | Access Error IRQ enabled status. |
| I2Ci.I2C_IRQSTATUS[9] AAS | I2Ci.I2C_IRQENABLE_SET[9] AAS_IE | I2Ci.I2C_IRQENABLE_C LR[9] AAS_IE | I2Ci_IRQ | Address recognized as slave IRQ enabled status. |
| I2Ci.I2C_IRQSTATUS[10] XUDF | I2Ci.I2C_IRQENABLE_SET[1 0] XUDF_IE | I2Ci.I2C_IRQENABLE_C LR[10] XUDF_IE | I2Ci_IRQ | Transmit underflow enabled status. Writing into this bit has no effect. |
| I2Ci.I2C_IRQSTATUS[11] ROVR | I2Ci.I2C_IRQENABLE_SET[1 1] ROVR_IE | I2Ci.I2C_IRQENABLE_C LR[11] ROVR_IE | I2Ci_IRQ | Receive overrun enabled status. Writing into this bit has no effect. |
| I2Ci.I2C_IRQSTATUS[12] BB | I2Ci.I2C_IRQENABLE_SET[1 2] BB_IE | I2Ci.I2C_IRQENABLE_C LR[12] BB_IE | I2Ci_IRQ | Bus busy enabled status. Writing into this bit has no effect. |
| I2Ci.I2C_IRQSTATUS[13] RDR | I2Ci.I2C_IRQENABLE_SET[1 3] RDR_IE | I2Ci.I2C_IRQENABLE_C LR[13] RDR_IE | I2Ci_IRQ | Receive draining IRQ enabled status. |
| I2Ci.I2C_IRQSTATUS[14] XDR | I2Ci.I2C_IRQENABLE_SET[1 4] XDR_IE | I2Ci.I2C_IRQENABLE_C LR[14] XDR_IE | I2Ci_IRQ | Transmit draining IRQ enabled status. |

24.1.4.6 HS I²C DMA Requests

Each multimaster HS I²C controller can generate two DMA requests to the system DMA (sDMA) controller. [Table 24-13](#) lists the DMA requests with mapping on the sDMA controller. For information about DMA generation, see [Section 24.1.4.8.3, HS I²C FIFO DMA Mode \(I²C Mode Only\)](#).

Table 24-13. HS I²C DMA Requests

| Name | Source | Destination | Description |
|-------------|--------|-------------|--|
| I2C1_DMA_TX | I2C1 | S_DMA_26 | I2C1 DMA write request to inform the sDMA to write new data in the I2C1.I2C_DATA[7:0] register |
| I2C1_DMA_RX | I2C1 | S_DMA_27 | I2C1 DMA read request to inform the sDMA to read the data in the I2C1.I2C_DATA[7:0] register |
| I2C2_DMA_TX | I2C2 | S_DMA_28 | I2C2 DMA write request to inform the sDMA to write new data in the I2C2.I2C_DATA[7:0] register |
| I2C2_DMA_RX | I2C2 | S_DMA_29 | I2C2 DMA read request to inform the sDMA to read the data in the I2C2.I2C_DATA[7:0] register |
| I2C3_DMA_TX | I2C3 | S_DMA_24 | I2C3 DMA write request to inform the sDMA to write new data in the I2C3.I2C_DATA[7:0] register |

Table 24-13. HS I²C DMA Requests (continued)

| Name | Source | Destination | Description |
|-------------|--------|-------------|--|
| I2C3_DMA_RX | I2C3 | S_DMA_25 | I2C3 DMA read request to inform the sDMA to read the data in the I2C3.I2C_DATA[7:0] register |
| I2C4_DMA_TX | I2C4 | S_DMA_123 | I2C4 DMA write request to inform the sDMA to write new data in the I2C4.I2C_DATA[7:0] register |
| I2C4_DMA_RX | I2C4 | S_DMA_124 | I2C4 DMA read request to inform the sDMA to read the data in the I2C4.I2C_DATA[7:0] register |

NOTE: The HS I²C controller I2C5 does not generate any DMA requests.

24.1.4.7 HS I²C Programmable Multislave Channel Feature (I²C Mode Only)

This feature allows each multimaster HS I²C controller to be addressed using four separate Own Addresses configured in the I2Ci.I2C_OA and I2Ci.I2C_OAx registers (where x = 1, 2, 3). An additional register (I2Ci.I2C_ACTOA) is used to indicate to the LH which address is used by the external master to communicate with the I²C controller.

Each Own Address can be independently configured in 7-bit or 10-bit mode by setting the corresponding bit (I2Ci.I2C_CON[7] XOA, I2Ci.I2C_CON[6] XOA1, I2Ci.I2C_CON[5] XOA2, or I2Ci.I2C_CON[4] XOA3).

24.1.4.8 HS I²C FIFO Management

Each multimaster HS I²C controller implements two internal 8-bit FIFOs, the RX and TX FIFOs.

The depth of the RX and TX FIFOs is fixed at 16 bytes and can be checked by reading the I2Ci.I2C_BUFSTAT[15:14] FIFODEPTH bit field (0x0: 8 bytes, 0x1: 16 bytes, 0x2: 32 bytes, and 0x3: 64 bytes).

NOTE: FIFO depth is configured at design time and cannot be modified by software. FIFO thresholds must not exceed configured FIFO depth.

24.1.4.8.1 HS I²C FIFO Interrupt Mode

In first in first out (FIFO) interrupt mode (relevant interrupts enabled by the I2Ci.I2C_IE register), an interrupt signal informs the processor of the receiver and transmitter status. These interrupts are raised when the RX/TX FIFO thresholds (defined by the I2Ci.I2C_BUF[13:8] RTRSH bit field value + 1 for the RX FIFO or the I2Ci.I2C_BUF[5:0] TXTRSH bit field value + 1 for the TX FIFO) are reached; the interrupt signals instruct the LH to transfer data to the destination (from the I²C controller in receive mode and/or from any source to the I²C controller FIFO in transmit mode).

Figure 24-23 and Figure 24-24 show receive and transmit operations, respectively, from a FIFO management point of view.

Figure 24-23. HS I²C Receive FIFO Interrupt Request Generation

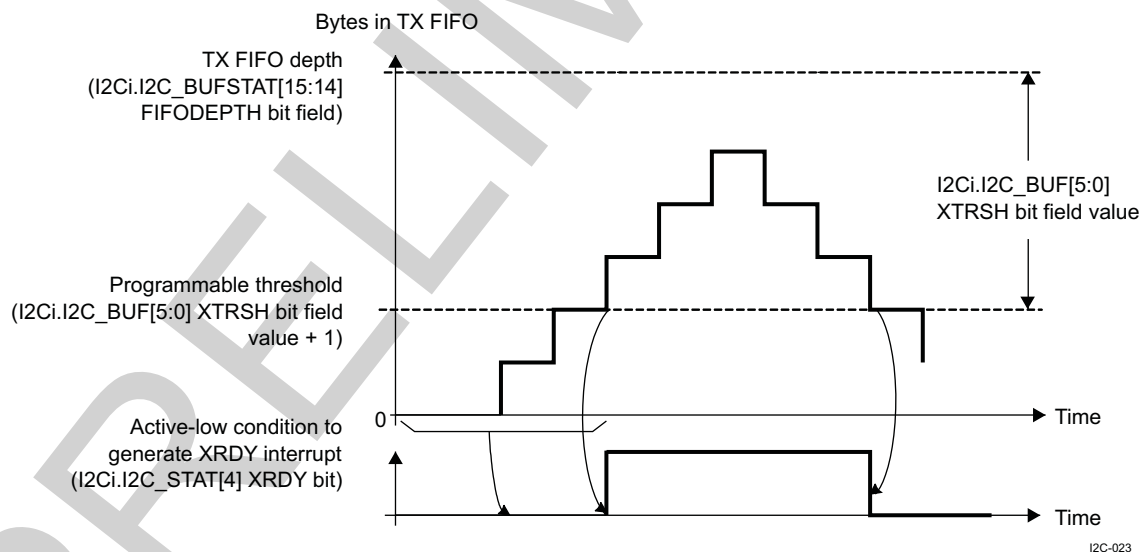

I2C-022

In Figure 24-23, the RRDY interrupt condition shows that the condition for generating an RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the LH by writing 1 in the I2Ci.I2C_STAT[3] RRDY bit. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In receive mode, an RRDY interrupt is generated as soon as the FIFO reaches its receive threshold (I2Ci.I2C_BUF[13:8] RTRSH bit field value + 1). The interrupt can be deasserted only when the LH has handled enough bytes to make the number of bytes in the RX FIFO lower than the programmed threshold. For each interrupt, the LH can be configured to read a number of bytes equal to the value of the RX FIFO threshold.

Figure 24-24. HS I²C Transmit FIFO Interrupt Request Generation

I2C-023

In Figure 24-24, the XRDY interrupt condition shows that the condition for generating an XRDY interrupt is achieved. The interrupt request is generated when TX FIFO is empty or when the TX FIFO threshold is not reached, and the LH can clear the XRDY status bit by setting the I2Ci.I2C_STAT[4] XRDY bit to 1 after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In interrupt mode, the module offers two options for the LH application to handle the interrupts:

- When detecting an interrupt request (XRDY or RRDY type), the LH can write/read 1 data byte to/from the TX/RX FIFO and then clear the interrupt. The module reasserts the interrupt until the interrupt condition is not met.

- When detecting an interrupt request (XRDY or RRDY type), the LH can be programmed to write/read the amount of data bytes specified by the corresponding FIFO threshold (I2C_BUF[5:0] TXTRSH + 1 or I2C_BUF[5:0] RXTRSH + 1). In this case, the interrupt condition is cleared and the next interrupt is asserted again when the XRDY or RRDY condition is met again.

If the second-interrupt-serving approach is used, an additional mechanism (draining feature) is implemented for cases where the transfer length is not a multiple of the FIFO threshold value (see [Section 24.1.4.8.4, Draining Feature \[I²C Mode Only\]](#)).

NOTE: In slave transmit mode (the I2Ci.I2C_CON[10] MST bit is cleared and the I2Ci.I2C_CON[9] TRX bit is set to 1), the draining feature must not be used, because the transfer length is not known at configuration time, and the external master can end the transfer at any point by not acknowledging 1 data byte. If the draining feature is used in slave transmit mode, data can remain in the TX FIFO without being transmitted over the I²C bus. In this case, the TX FIFO must be cleared by setting the I2Ci.I2C_BUF[6] TXFIFO_CLR bit.

NOTE: In SCCB mode, the RX and TX threshold values must be set to 1 by setting the I2Ci.I2C_BUF[13:8]RTRSH and I2Ci.I2C_BUF[5:0] TXTRSH fields to 0x0.

24.1.4.8.2 HS I²C FIFO Polling Mode

In FIFO polling mode (the I2Ci.I2C_IE[4] XRDY_IE and I2Ci.I2C_IE[3] RRDY_IE bits are disabled, and the I2Ci.I2C_BUF[15] RDMA_EN and I2Ci.I2C_BUF[7] XDMA_EN bits are disabled), the status of the module (receiver or transmitter) can be checked by polling the I2Ci.I2C_STAT[4] XRDY and the I2Ci.I2C_STAT[3] RRDY bits (the I2Ci.I2C_STAT[13] RDR and I2Ci.I2C_STAT[14] XDR bits can also be polled if the draining feature is enabled). The I2Ci.I2C_STAT[4] XRDY and I2Ci.I2C_STAT[3] RRDY bits accurately reflect the interrupt conditions described in the discussion of FIFO interrupt mode.

24.1.4.8.3 HS I²C FIFO DMA Mode (I²C Mode Only)

In receive mode, a DMA request is generated by the I2Ci_DMA_RX signal as soon as the RX FIFO exceeds its threshold level (the I2Ci.I2C_BUF[13:8] RTRSH bit field value + 1). This request is deasserted when the number of bytes defined by the threshold level is read by the DMA controller.

[Figure 24-25](#) shows the DMA request generation in receive mode.

Figure 24-25. HS I²C Receive FIFO DMA Request Generation

I2C-024

In transmit mode, a DMA request is automatically asserted by the I2Ci_DMA_TX signal when the TX FIFO is empty. This request is deasserted when the number of bytes (the 2Ci.I2C_BUF[5:0] TXTRSH bit field value + 1) is written in the FIFO by the DMA controller. If an insufficient number of bytes is written, the sDMA request remains active. Figure 24-26 and Figure 24-27 show the DMA TX transfers with different values for the I2Ci.I2C_BUF[5:0] TXTRSH bit field.

Figure 24-26. HS I²C Transmit FIFO Request Generation (High Threshold)

Figure 24-27. HS I²C Transmit FIFO Request Generation (Low Threshold)

NOTE: In SCCB mode, the RX and TX threshold values must be set to 1 by setting the I2Ci.I2C_BUF[13:8] RTRSH and I2Ci.I2C_BUF[5:0] XTRSH bit fields to 0x0.

The I²C module allows the user to clear the RX or TX FIFO by setting the I2Ci.I2C_BUF[14] RXFIFO_CLR and I2Ci.I2C_BUF[6] TXFIFO_CLR registers, respectively, which act like software reset for the FIFOs. In DMA mode, these bits also reset the DMA state-machines. The FIFO clearing feature can be used when the following conditions are met:

- The module is configured as a transmitter.
- The external receiver responds with a NACK in the middle of the transfer.
- Data in the TX FIFO is waiting to be transferred.

24.1.4.8.4 HS I²C Draining Feature (I²C Mode Only)

The draining feature is implemented to handle the end of a transfer whose length is not a multiple of the FIFO threshold values (the I2Ci.I2C_BUF[13:8] RTRSH bit field value + 1 for the RX threshold and I2Ci.I2C_BUF[5:0] TXTRSH field value + 1 for the TX threshold). It can also transfer the remaining number of bytes (because the threshold is not reached).

This feature prevents the LH or the DMA controller from trying more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having fewer bytes in the FIFO than the configured DMA transfer length). Otherwise, an AERR interrupt is generated by the I2Ci.I2C_STAT[7] AERR bit.

The draining mechanism generates an interrupt using the I2Ci.I2C_STAT[13] RDR or I2Ci.I2C_STAT[14] XDR bit at the end of the transfer, informing the LH that it must check the amount of data left to be transferred (the I2Ci.I2C_BUFSTAT[13:8] RXSTAT or I2Ci.I2C_BUFSTAT[5:0] TXSTAT bit fields) and enable the draining feature of the DMA controller by reconfiguring the DMA transfer length according to this value (when the DMA mode is enabled) or perform only the required number of data accesses (when the DMA mode is disabled).

In receive mode (master or slave), if the RX FIFO threshold (the I2Ci.I2C_BUF[13:8] RTRSH bit field value + 1) is not reached, but the transfer ends on the I²C bus and data remains in the RX FIFO (less than the threshold), the receive draining interrupt (the I2Ci.I2C_STAT[13] RDR bit) is asserted to inform the LH that it can read the amount of data in the RX FIFO (the I2Ci.I2C_BUFSTAT[13:8] RXSTAT bit field). The LH performs a number of data read accesses equal to the I2Ci.I2C_BUFSTAT[13:8] RXSTAT bit field (interrupt or polling mode), or reconfigures the sDMA controller with the required value to drain the FIFO.

In master transmit mode, if the TX FIFO threshold (I2Ci.I2C_BUF[5:0] TXTRSH bit field value + 1) is not reached, but the amount of data remaining to be written in the TX FIFO is less than the threshold, the transmit draining interrupt (the I2Ci.I2C_STAT[14] XDR bit) is asserted to inform the LH that it can read the amount of data remaining to be written in the TX FIFO (the I2Ci.I2C_BUFSTAT[5:0] TXSTAT bit field). The LH must write the required number of data bytes specified by the I2Ci.I2C_BUFSTAT[5:0] TXSTAT bit field value or reconfigure the sDMA controller with the value required to transfer the last bytes to the FIFO.

In master mode, the LH can alternately not check the values of the I2Ci.I2C_BUFSTAT[5:0] TXSTAT and I2Ci.I2C_BUFSTAT[13:8] RXSTAT bit fields, the LH can obtain this information internally (by computing the I2Ci.I2C_CNT[15:0] DATACOUNT bit field value modulo I2Ci.I2C_BUF[13:8] RTRSH or I2Ci.I2C_BUF[5:0] TXTRSH).

By default, the draining feature is disabled; it can be enabled using the I2Ci.I2C_IE[14] XDR_IE or I2Ci.I2C_IE[13] RDR_IE bits (default disabled) only for transfers with lengths not equal to the threshold values (I2Ci.I2C_BUF[5:0] TXTRSH bit field value + 1 for the TX threshold or I2Ci.I2C_BUF[13:8] RTRSH bit field value + 1 for the RX threshold).

24.1.4.9 HS I²C Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less in case of F/S operation modes and SCCB modes, and any noise that is 10 ns or less in case of HS mode operation. The noise filter is always one period of the I2Ci_INTERNAL_CLK clock. This way, for HS mode operation (prescaler bypassed), the filter suppresses spikes of less than 10.4 ns.

For SCCB modes (for example, I2Ci.I2C_PSC[7:0] PSC bit field = 4), the maximum width of suppressed spikes is 52 ns.

To ensure correct filtering, the prescaler must be programmed accordingly by the I2Ci.I2C_PSC[7:0] PSC bit field.

24.1.4.10 HS I²C Write and Read Operations in SCCB Mode

In SCCB mode, the multimaster HS I²C controller can write or read a single byte to or from the external SCCB device.

To write a single byte to the external SCCB device, the multimaster HS I²C controller must be configured in multimaster transmitter mode by setting the I2Ci.I2C_CON[10] MST and I2Ci.I2C_CON[9] TRX bits to 1. The external device slave address (7-bit address of the ID value) is set in the I2Ci.I2C_SA register; the register address (8-bit subaddress in the external SCCB device) is set in the I2Ci.I2C_OA0 register. The 8-bit data to be transmitted is written by the LH in the I2Ci.I2C_DATA register.

To read a single byte from the external SCCB device, the multimaster HS I²C controller must be configured in multimaster receiver mode by setting the I2Ci.I2C_CON[10] MST bit to 1 and by clearing the I2Ci.I2C_CON[9] TRX bit to 0. The external device slave address (7-bit address of the ID value) is set in the I2Ci.I2C_SA register; the register address (8-bit subaddress in the external SCCB device) is set in the I2Ci.I2C_OA0 register. The 8-bit data received from the external SCCB device is read by the LH from the I2Ci.I2C_DATA register.

NOTE: In SCCB mode, the RX and TX thresholds must be set to 1 by configuring the I2Ci.I2C_BUF[13:8] RTRSH and I2Ci.I2C_BUF[5:0] XTRSH fields to 0x0.

24.1.4.11 HS I²C System Test Mode

A system test mode is available for multimaster HS I²C controller module testing. This mode is enabled by setting the I2Ci.I2C_SYSTEST[15] ST_EN bit to 1. When this bit is cleared to 0, the I²C controller is configured in normal operation mode.

In system test mode, the I2Ci_SYSTEST[13:12] TMODE bit field selects the type of test. Table 24-14 lists the tests available for the multimaster HS I²C controllers.

Table 24-14. HS I²C List of Tests

| I2Ci.I2C_SYSTEST[13:12] TMODE | Test | Description |
|-------------------------------|--|--|
| 00 | Functional mode | Normal operation mode |
| 01 | Reserved (not used) | |
| 10 | Test of i2ci_scl serial clock line | The i2ci_scl line is driven with a permanent clock as if mastered with the parameters set in the I2Ci.I2C_PSC, I2Ci.I2C_SCLL, and I2Ci.I2C_SCLH registers. |
| 11 | Loop-back mode + i2ci_scl/ i2ci_sda input/output | In master transmit mode only, data transmitted out of the I2Ci.I2C_DATA register (write action) is received in the same I2Ci.I2C_DATA register through an internal path through the FIFO buffers. The DMA and interrupt requests are normally generated if they are enabled. Moreover, the i2ci_scl, i2ci_sda, and i2ci_sccbe lines are controlled with the I2Ci.I2C_SYSTEST[4:0] bits.. |

NOTE: When the I2Ci.I2C_SYSTEST[13:12] TMODE bit field is set to 11, the I²C controller must be configured in I²C F/S (the I2Ci.I2C_CON[13:12] OPMODE set to 00) or I²C HS mode (the I2Ci.I2C_CON[13:12] OPMODE set to 01). The loop-back mode is not available in SCCB mode (the I2Ci.I2C_CON[13:12] OPMODE = b10).

NOTE: In normal operation mode (I2Ci.I2C_SYSTEST[15] ST_EN clear to 0), the I2Ci.I2C_SYSTEST[4:0] bits that control the i2ci_scl, i2ci_sda, and i2ci_sccbe lines in system test mode are read-only bits.

In system test mode (I2Ci.I2C_SYSTEST[15] ST_EN set to 1), the I2Ci.I2C_STAT[5:0] status bits can be set to 1 when the I2Ci.I2C_SYSTEST[11] SSB bit is set to 1. Clearing the I2Ci.I2C_SYSTEST[11] SSB bit to 0 does not clear the I2Ci.I2C_STAT[5:0] bits to 0. The I2Ci.I2C_STAT[5:0] bit field can be cleared to 0 only by writing 1 in the corresponding bits.

24.1.5 HS I²C Programming Guide

24.1.5.1 HS I²C Low-Level Programming Models

24.1.5.1.1 HS I²C Programming Model in I²C Mode

This section describes the programming model of the multimaster HS I²C controllers configured in I²C mode.

24.1.5.1.1.1 Main Program

24.1.5.1.1.1.1 Configure the Module Before Enabling the I²C Controller

Before enabling the I²C controller, perform the following:

1. Enable the functional and interface clocks.
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock by programming the corresponding value in the I2Ci.I2C_PSC[7:0] PSC field. This value depends on the frequency of the functional clock (I2Ci_FCLK).
3. Program the I2Ci.I2C_SCLL[7:0] SCLL and I2Ci.I2C_SCLH[7:0] SCLH bit fields to obtain a bit rate of 100 Kbps, 400 Kbps or 1Mbps. These values depend on the internal sampling clock frequency (see [Table 24-8](#)).
4. (Optional) Program the I2Ci.I2C_SCLL[15:8] HSSCLL and I2Ci.I2C_SCLH[15:8] HSSCLH bit fields to obtain a bit rate of 400 Kbps or 3.4 Mbps (for the second phase of HS mode). These values depend on the internal sampling clock frequency (see [Table 24-8](#)).
5. (Optional) If a bit rate of 3.4 Mbps is used and the bus line capacitance exceeds 45 pF, see [Section 19.4.8, PAD Functional Multiplexing and Configuration](#).
6. Configure the Own Address of the I2C controller by storing it in the I2Ci.I2C_OA register. Up to four Own Addresses can be programmed in the I2Ci.I2C_OAx registers (where x = 0, 1, 2, 3) for each I²C controller.

NOTE: For a 10-bit address, set the corresponding expand Own Address bit in the I2Ci.I2C_CON register.

7. Set the TX threshold (in transmitter mode) and the RX threshold (in receiver mode) by setting the I2Ci.I2C_BUF[5:0] TXTRSH bit field to (TX threshold to 1) and the I2Ci.I2C_BUF[13:8] RTRSH bit field to (RX threshold to 1), where the TX and RX thresholds are greater than or equal to 1.
8. Take the I²C controller out of reset by setting the I2Ci.I2C_CON[15] I2C_EN bit to 1.

24.1.5.1.1.1.2 Initialize the I²C Controller

To initialize the I²C controller, perform the following steps:

1. Configure the I2Ci.I2C_CON register:
 - For master or slave mode, set the I2Ci.I2C_CON[10] MST bit (0: slave; 1: master).
 - For transmitter or receiver mode, set the I2Ci.I2C_CON[9] TRX bit (0: receiver; 1: transmitter).
2. If using an interrupt to transmit and receive data, set the corresponding bit in the I2Ci.I2C_IE register to 1 (the I2Ci.I2C_IE[4] XRDY_IE bit for the transmit interrupt, the I2Ci.I2C_IE[3] RRDY bit for the receive interrupt).
3. If using DMA to receive and transmit data, set the corresponding bit in the I2Ci.I2C_BUF register to 1 (the I2Ci.I2C_BUF[15] RDMA_EN bit for the receive DMA channel, the I2Ci.I2C_BUF[7] XDMA_EN bit for the transmit DMA channel).

24.1.5.1.1.1.3 Configure Slave Address and the Data Control Register

In master mode, configure the slave address register by programming the I2Ci.I2C_SA[9:0] SA bit field and the number of data bytes (I²C data payload) associated with the transfer by programming the I2Ci.I2C_CNT[15:0] DCOUNT bit field.

NOTE: For a 10-bit address, set the I2Ci.I2C_CON[8] XSA bit to 1.

24.1.5.1.1.1.4 Initiate a Transfer

Poll the I2Ci.I2C_STAT[12] BB bit. If it is cleared to 0 (bus not busy), configure the I2Ci.I2C_CON[0] STT and I2Ci.I2C_CON[1] STP bits. To initiate a transfer, the I2Ci.I2C_CON[0] STT bit must be set to 1, and it is not mandatory to set the I2Ci.I2C_CON[1] STP bit to 1.

24.1.5.1.1.1.5 Receive Data

Poll the I2Ci.I2C_STAT[3] RRDY bit, or use the RRDY interrupt (the I2Ci.I2C_IE[3] RRDY_IE bit must be set to 1) or the DMA RX channel (the I2Ci.I2C_BUF[15] RDMA_EN bit must be set to 1) to read the receive data in the I2Ci.I2C_DATA register.

If the transfer length does not equal the RX FIFO threshold (I2Ci.I2C_BUF[13:8] RTRSH field + 1), use the draining feature (enable the RDR interrupt by setting the I2Ci.I2C_IE[13] RDR_IE bit to 1).

NOTE: In receive mode only, the I2Ci.I2C_STAT[11] ROVR (receive overrun) bit indicates whether the receiver has experienced overrun. An overrun condition occurs when the shift register and the RX FIFO are full. An overrun condition does not result in data loss; the I²C controller simply holds i2ci_scl to low to prevent other bytes from being received.

The I2Ci.I2C_STAT[7] AERR bit is set to 1 when a read access is performed in the I2Ci.I2C_DATA register while the RX FIFO is empty. The corresponding interrupt can be enabled by setting the I2Ci.I2C_IE[7] AERR_IE bit to 1.

24.1.5.1.1.1.6 Transmit Data

Poll the I2Ci.I2C_STAT[4] XRDY bit, or use the XRDY interrupt (the I2Ci.I2C_IE[4] XRDY_IE bit must be set to 1) or the DMA TX channel (the I2Ci.I2C_BUF[7] XDMA_EN bit must be set to 1) to write data to the I2Ci.I2C_DATA register.

If the transfer length does not equal the TX FIFO threshold (I2Ci.I2C_BUF[5:0] TXTRSH field + 1), use the draining feature (enable the XDR interrupt by setting the I2Ci.I2C_IE[14] XDR_IE bit to 1).

NOTE: In transmit mode only, the I2Ci.I2C_STAT[10] XUDF bit indicates whether the transmitter has experienced underflow.

In master transmit mode, underflow occurs when the shift register and the TX FIFO are empty and there are still some bytes to transmit (the value of the I2Ci.I2C_CNT[15:0] DCOUNT bit field is not 0).

In slave transmit mode, underflow occurs when the shift register and the TX FIFO are empty and the external I²C master device still requests data bytes to be read.

The I2Ci.I2C_STAT[7] AERR bit is set to 1 when a write access is performed in the I2Ci.I2C_DATA register while the TX FIFO is full. The corresponding interrupt can be enabled by setting the I2Ci.I2C_IE[7] AERR_IE bit to 1.

24.1.5.1.1.2 Interrupt Subroutine Sequence

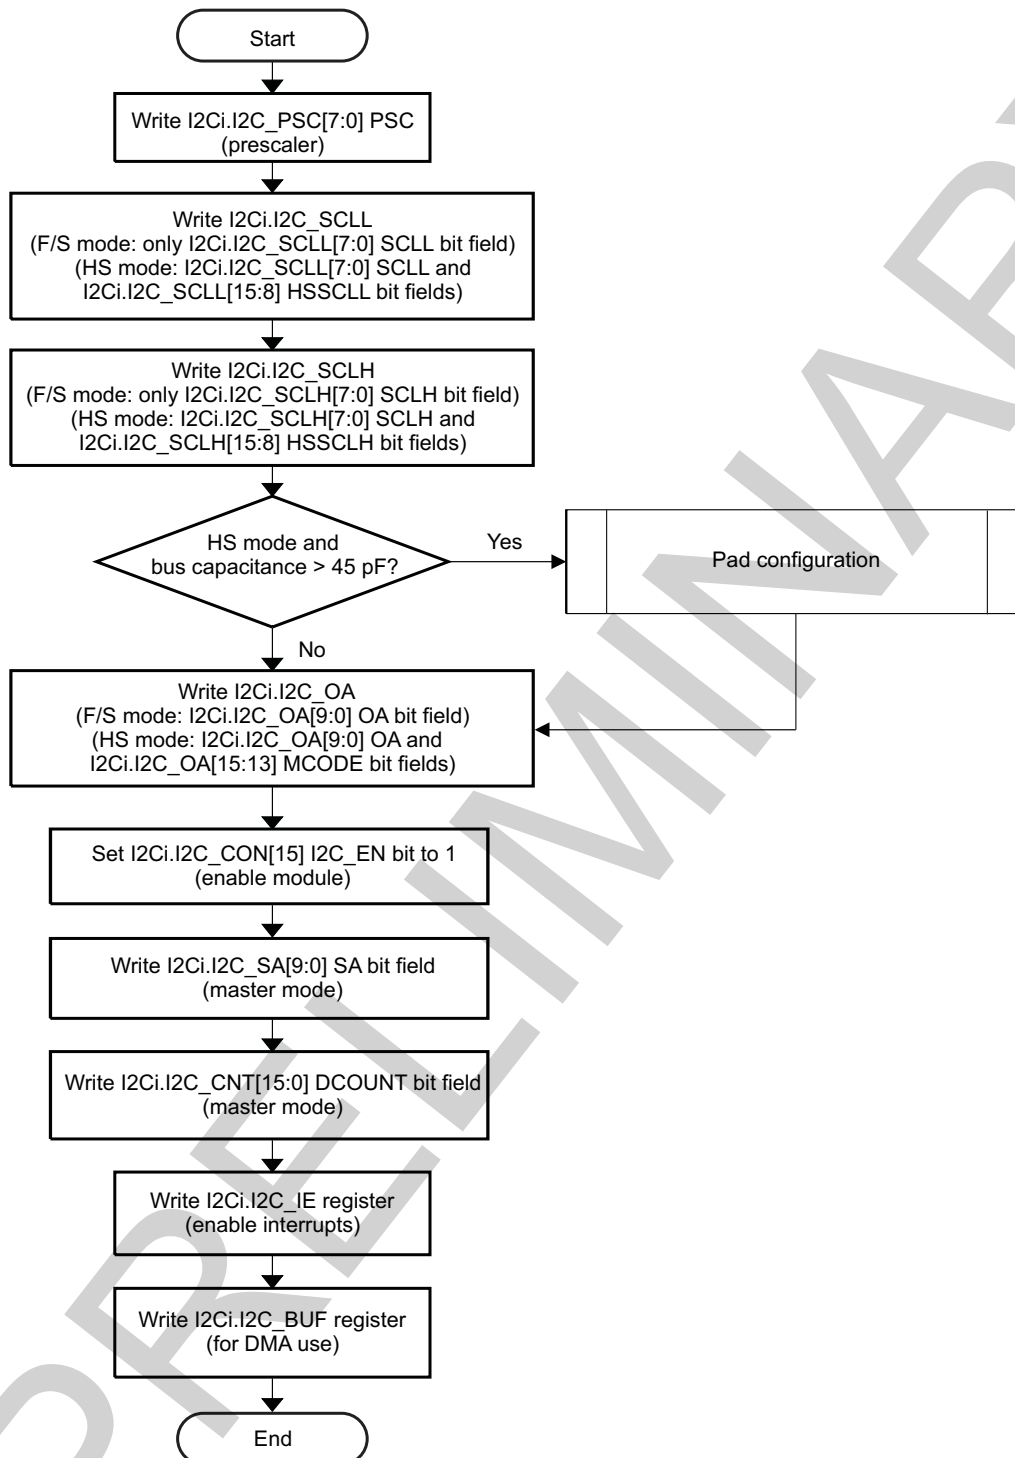

1. Test for arbitration lost (the I2Ci.I2C_STAT[0] AL bit) and resolve accordingly.
2. Test for no acknowledgment (the I2Ci.I2C_STAT[1] NACK bit) and resolve accordingly.
3. Test for register access ready (the I2Ci.I2C_STAT[2] ARDY bit) and resolve accordingly.

4. Test for receive data ready (the I2Ci.I2C_STAT[3] RRDY bit) and resolve accordingly.
5. Test for transmit data ready (the I2Ci.I2C_STAT[4] XRDY bit) and resolve accordingly.
6. Test for general call (the I2Ci.I2C_STAT[5] GC bit) and resolve accordingly.
7. Test for start (S) condition (the I2Ci.I2C_STAT[6] STC bit) and resolve accordingly. For this test, the functional clock must be inactive.
8. Test for access error (the I2Ci.I2C_STAT[7] AERR bit) and resolve accordingly.
9. Test for bus free (the I2Ci.I2C_STAT[8] BF bit) and resolve accordingly.

24.1.5.1.1.3 Programming Flow Diagrams

Figure 24-28 through Figure 24-36 are procedure flow charts for programming the F/S and HS I²C modes.

⁽¹⁾ i = 1 to 4

Figure 24-34. HS I²C Master Receiver Mode, DMA Method in F/S and HS Modes

I2C-033

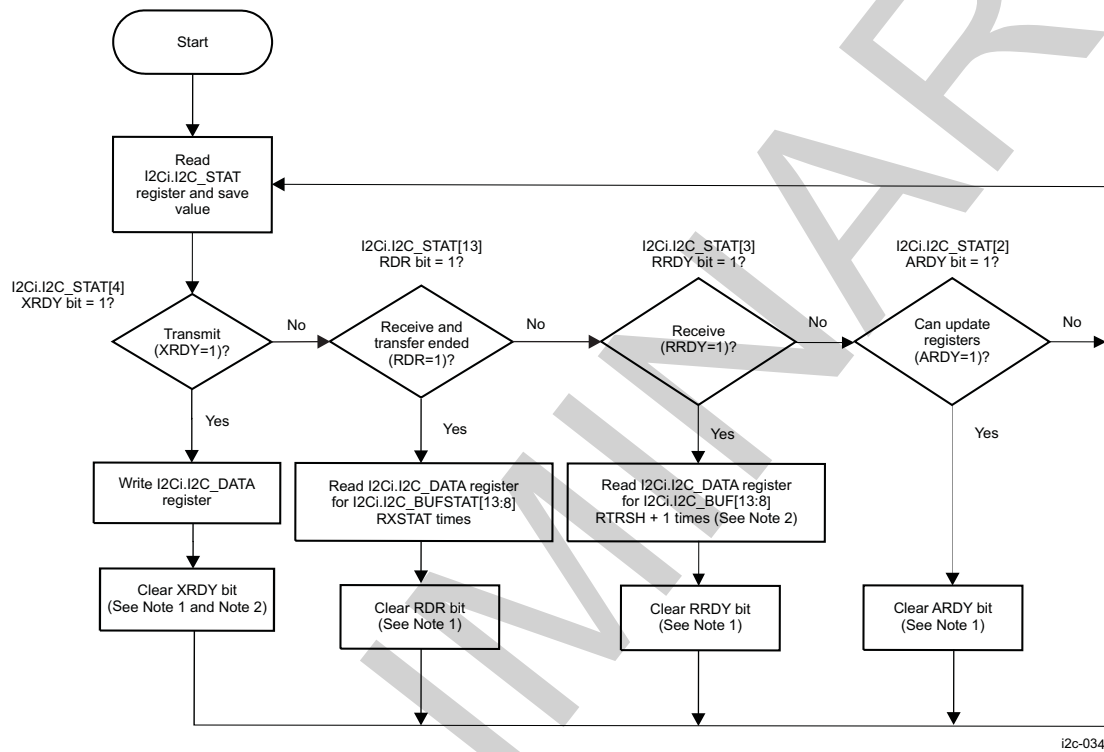

- (1) In HS mode, the Sr condition and clock frequency switching are automatically generated by the multimaster HS I²C controller.
- (2) The NACK, AL, ARDY, and RDR bits are cleared by writing 1 to each corresponding bit in the I2Ci.I2C_STAT register.
- (3) Reprogram registers means: I2Ci.I2C_CON[11] STB and/or I2Ci.I2C_CON[10] MST bit and/or I2Ci.I2C_SA[9:0] SA register and/or I2Ci.I2C_CNT[15:0] DCOUNT register and/or I2Ci.I2C_CON[0] STT bit and/or I2Ci.I2C_CON[1] STP bit.

24.1.5.1.2 HS I²C (I2C5) Programming Model for Communication With Power Chips

This section describes the programming model of the master transmitter HS I²C controller (I2C5) for communication with one or more power chips. The HS I²C controller (I2C5) allows the two voltage Finite State Machines (FSMs) in the PRCM module of the device to be interfaced to external power chips through the I²C bus for dynamic voltage control of two power supplies and power sequencing. The primary programming tasks are to set up the configuration registers according to the external power supply chip(s) being used.

24.1.5.1.2.1 Configure the Voltage Controller Registers

To use the voltage control function, the LH must configure the following registers in the voltage controller of the APE and 3G modem SS PRCM modules:

- The voltage configuration register address for each VDD channel in the PRCM.PRM_VC_VAL_SMPS_RA_VOL register
- The ON/ON-low-power-Retention/OFF command configuration register address for each VDD channel in the PRCM.PRM_VC_VAL_SMPS_RA_CMD register
- The set of ON/ON-low-power/Retention/OFF voltage/mode values in the APE PRCM.PRM_VC_VAL_CMD_VDD_CORE_L, APE PRCM.PRM_VC_VAL_CMD_VDD_IVA_L, and APE PRCM.PRM_VC_VAL_CMD_VDD_MPU_L registers, and 3G modem SS PRCM.PRM_VC_VAL_CMD_VDD_WGM_L register.
- The VDD channels configuration selection in the PRCM.PRM_VC_CFG_CHANNEL register

For more information about the voltage controller register configuration, see [Chapter 3, Power, Reset, and Clock Management](#).

24.1.5.1.2.2 Configure the HS I²C Controller I2C5

At POR, the I2C5 is in HS mode (PRCM.PRM_VC_CFG_I2C_MODE[3] HSMODEEN bit). In HS mode, the LH must configure the master code value for the preamble I²C high-speed transmission by configuring the PRCM.PRM_VC_CFG_I2C_MODE[2:0] HSMCODE bit field. If the external power chips do not support the I²C HS mode, HS mode can be disabled and F/S mode enabled by clearing the PRCM.PRM_VC_CFG_I2C_MODE[3] HSMODEEN bit to 0.

By default, the Sr operation is enabled (PRCM.PRM_VC_CFG_I2C_MODE[4] SRMODEEN bit set to 1 at POR). In F/S mode, the Sr operation can be disabled by clearing the PRCM.PRM_VC_CFG_I2C_MODE[4] SRMODEEN bit to 0.

24.1.5.1.3 HS I²C Basic Programming Model in SCCB Mode

This section describes the programming model of the multimaster HS I²C controllers configured in SCCB mode.

24.1.5.1.3.1 Main Program

24.1.5.1.3.1.1 Configure the Module Before Enabling the I²C Controller

Before enabling the I²C controller, perform the following steps:

1. Enable the functional and interface clocks (see [Table 24-7](#)).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock (I2Ci_INTERNAL_CLK) by programming the corresponding value in the I2Ci.I2C_PSC[7:0] PSC field. This value depends on the frequency of the functional clock (I2Ci_FCLK). Because this frequency is 96MHz, the I2Ci.I2C_PSC[7:0] PSC field value is 0x7.
3. Program the I2Ci.I2C_SCLL[7:0] SCLL and I2Ci.I2C_SCLH[7:0] SCLH fields to obtain a bit rate of 100K bps (maximum authorized bit rate in SCCB mode). This value depends on the internal sampling clock frequency (see [Table 24-8](#)).
4. Configure the 7-bit slave address (ID value) by storing it in the I2Ci.I2C_SA register.
5. Configure the 8-bit register address (subaddress) by storing it in the I2Ci.I2C_OA0 register.
6. Configure the I2Ci.I2C_BUF[13:8]RTRSH field to 0x0 (RX threshold to 1) and the I2Ci.I2C_BUF[5:0]XTRSH field to 0x0 (TX threshold to 1).
7. Take the I²C controller out of reset by setting the I2Ci.I2C_CON[15] I2C_EN bit to 1.

24.1.5.1.3.1.2 Initialize the I²C Controller

To initialize the I²C controller, perform the following steps:

1. Configure the I2Ci.I2C_CON register:

- In SCCB mode, only the master mode is supported; set the I2Ci.I2C_CON[10] MST bit to 1.
 - For transmitter mode (write to the external SCCB device register) or receiver mode (read from the external SCCB device register), set the I2Ci.I2C_CON[9] TRX bit (0: receiver, 1: transmitter).
2. If using an interrupt to transmit/receive data, set to 1 the corresponding bit in the I2Ci.I2C_IE register (the I2Ci.I2C_IE[4] XRDY_IE bit for the transmit interrupt, the I2Ci.I2C_IE[3] RRDY bit for the receive interrupt).

24.1.5.1.3.1.3 Initiate a Transfer

Poll the I2Ci.I2C_STAT[12] BB bit. If it is cleared to 0 (bus not busy), set the I2Ci.I2C_CON[0] STT bit to 1. Because a transfer allows the LH to write or read only a single byte to or from the external SCCB device, the transmission automatically stops at the end of the transfer. When the transfer is complete, the I2Ci.I2C_STAT[2] ARDY bit is set to 1. In SCCB mode, the I2Ci.I2C_CON[1] STP bit is not used.

24.1.5.1.3.1.4 Receive Data

Poll the I2Ci.I2C_STAT[3] RRDY bit, or use the RRDY interrupt (the I2Ci.I2C_IE[3] RRDY_IE bit must be set to 1) to read the receive data in the I2Ci.I2C_DATA register.

NOTE: In SCCB mode, the I2Ci.I2C_BUF[13:8] RTRSH field (RX threshold) must be set to a value of 0x0 (RX threshold = 1).

24.1.5.1.3.1.5 Transmit Data

Poll the I2Ci.I2C_STAT[4] XRDY bit, or use the XRDY interrupt (the I2Ci.I2C_IE[4] XRDY_IE bit must be set to 1) to write the data to the I2Ci.I2C_DATA register.

NOTE: In SCCB mode, the I2Ci.I2C_BUF[5:0] TXTRSH field (TX threshold) must be set to a value of 0x0 (TX threshold = 1).

24.1.5.1.3.2 Interrupt Subroutine Sequence

1. Test for register access ready (I2Ci.I2C_STAT[2] ARDY status bit) and resolve accordingly.
2. Test for receive data ready (I2Ci.I2C_STAT[3] RRDY status bit) and resolve accordingly.
3. Test for transmit data ready (I2Ci.I2C_STAT[4] XRDY status bit) and resolve accordingly.

24.1.5.1.3.3 Programming Flow Diagrams

Figure 24-37 through Figure 24-41 are procedure flowcharts for programming the SCCB mode.

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 15 | RESERVED | Write 0s for future compatibility. Read returns 0. | RW | 0 |
| 14 | XDR | Transmit draining IRQ status. 0x0: Transmit draining inactive. 0x1: Transmit draining enabled. | RW | 0 |
| 13 | RDR | Receive draining IRQ status. 0x0: Receive draining inactive. 0x1: Receive draining enabled. | RW | 0 |
| 12 | BB | Bus busy status. Writing into this bit has no effect. Read 0x1: Bus is occupied. Read 0x0: Bus is free. | R | 0 |
| 11 | ROVR | Receive overrun status. Writing into this bit has no effect. Read 0x1: Receiver overrun. Read 0x0: Normal operation. | RW | 0 |
| 10 | XUDF | Transmit underflow status. Writing into this bit has no effect. Read 0x1: Transmit underflow. Read 0x0: Normal operation. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-------|
| 9 | AAS | Address recognized as slave IRQ status. 0x0: No action. 0x1: Address recognized. | RW | 0 |
| 8 | BF | Bus Free IRQ status. 0x0: No action. 0x1: Bus Free. | RW | 0 |
| 7 | AERR | Access Error IRQ status. 0x0: No action. 0x1: Access Error. | RW | 0 |
| 6 | STC | Start Condition IRQ status. 0x0: No action. 0x1: Start Condition detected. | RW | 0 |
| 5 | GC | General call IRQ status. Set to 1 by core when General call address detected and interrupt signaled to MPUSS. (1) 0x0: No general call detected. 0x1: General call address detected. | RW | 0 |
| 4 | XRDY | Transmit data ready IRQ status. Set to 1 by core when transmitter and when new data is requested. When set to 1 by core, an interrupt is signaled to MPUSS. (1) 0x0: Transmission ongoing. 0x1: Transmit data ready. | RW | 0 |
| 3 | RRDY | Receive data ready IRQ status. Set to 1 by core when receiver mode, a new data is able to be read. When set to 1 by core, an interrupt is signaled to MPUSS. (1) 0x0: No data available. 0x1: Receive data available. | RW | 0 |
| 2 | ARDY | Register access ready IRQ status. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to MPUSS. (1) 0x0: Module busy. 0x1: Access ready. | RW | 0 |
| 1 | NACK | No acknowledgement IRQ status. Bit is set when No Acknowledge has been received, an interrupt is signaled to MPUSS. (1) 0x0: Normal operation. 0x1: Not Acknowledge detected. | RW | 0 |
| 0 | AL | Arbitration lost IRQ status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to MPUSS. During reads, it always returns 0. 0x0: Normal operation. 0x1: Arbitration lost detected. | RW | 0 |

1. Writing 1 in the bit field only sets the respective field to 1, used mainly for debug.

24.2 HDQ/1-Wire

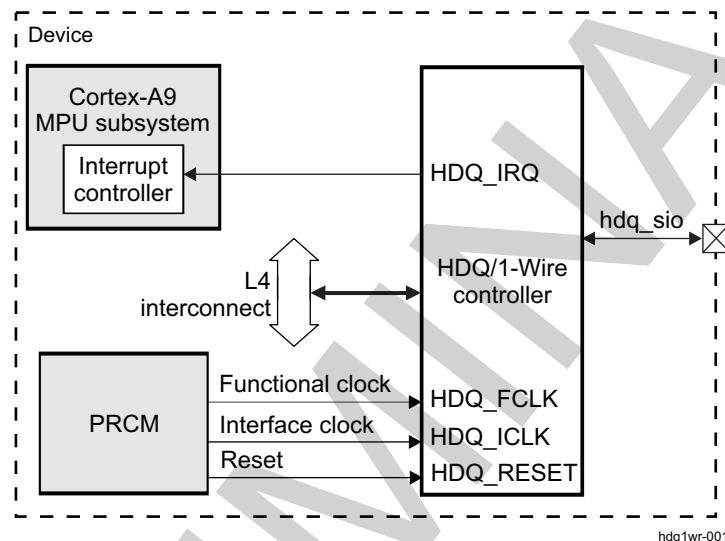

This section describes the HDQ™/ 1-Wire® interface for the device.

24.2.1 HDQ/1-Wire Overview

The HDQ/1-Wire module implements the hardware protocol of the master functions of the TI/Benchmark HDQ and the Dallas Semiconductor 1-Wire® protocols. These protocols use a single wire for communication between the master (HDQ/1-Wire controller) and the slaves (HDQ/1-Wire external compliant devices).

Figure 24-42 shows the HDQ/1-Wire.

Figure 24-42. HDQ/1-Wire Overview

The HDQ/1-Wire has a generic L4 interface and is intended to be used in an interrupt-driven fashion. The 1-pin interface is implemented as an open-drain output at the device level.

The main features supported by the HDQ/1-Wire are the following:

- Benchmark HDQ protocol
- Dallas Semiconductor 1-Wire protocol
- Power-down mode

The HDQ/1-Wire provides a communication rate of 5 Kbps over an address space of 128 bytes.

A typical application of the HDQ/1-Wire is the communication with battery monitor (gas gauge) integrated circuits.

24.2.2 HDQ/1-Wire Environment

24.2.2.1 HDQ/1-Wire Functional Modes

The HDQ/1-Wire has two main modes: HDQ and 1-Wire. Each of these modes includes idle, active, and power-down submodes. [Table 24-99](#) lists the HDQ/1-Wire functional modes, and [Figure 24-43](#) shows an overview of a typical application.

Table 24-99. Functional Modes

| Functions | Description |
|-----------|--------------------------------------|
| HDQ | Benchmark HDQ protocol |
| 1-Wire | Dallas Semiconductor 1-Wire protocol |

Figure 24-43. HDQ/1-Wire Typical Application System Overview

An external pullup is required, because the two protocols use a return-to-1 mechanism (that is, after any command by any of the connected devices, the line is pulled to a logical high level).

The HDQ/1-Wire operates according to a command structure that is programmed into transmit command registers (as described in [Section 24.2.5.1.2, HDQ/1-Wire Low-level Programming Model](#)).

The 1-Wire mode runs at slower speeds than the capabilities of the mode.

[Table 24-100](#) describes the external signal of the HDQ/1-Wire compliant module.

Table 24-100. I/O Description

| Signal | I/O ⁽¹⁾ | Description | Value at Reset |
|---------|--------------------|--|------------------------------|
| hdq_sio | I/O | Serial data input/output. Output is open drain type. | hi-Z (pulled to 1 by pullup) |

⁽¹⁾ I = Input; O = Output; I/O = Bidirectional; hi-Z = High impedance

24.2.2.2 HDQ and 1-Wire (SDQ) Protocols

24.2.2.2.1 HDQ Protocol Initialization (Default)

In HDQ mode, the firmware does not require the host to create an initialization pulse to the slave. However, the slave can be reset by using an initialization pulse (also referred to as a break pulse). The initialization pulse is generated by setting the [HDQ_CTRL_STATUS\[2\] INITIALIZATION](#) bit and then setting the [HDQ_CTRL_STATUS\[4\] GO](#) bit. The slave does not respond with a presence pulse as it does in the 1-Wire protocol.

The HDQ is a command-based protocol in which the host sends a command byte to the slave. The command directs the slave either to store the next eight bits of data received to a register specified by the command byte (write operation) or to output the eight bits of data from a register specified by the command byte (read operation). The master implementation is a simple byte engine. Sending of the ID, command/address, and data is controlled by firmware. The master engine provides only a single [HDQ.HDQ_TX_DATA](#) register.

The command and data bytes consist of a stream of eight bits with a maximum transmission rate of 5 Kbps. The least-significant bit (LSB) of a command or data byte is transmitted first. If a communication time-out occurs between the host and the slave (for example, if the host waits longer than the specified time for the slave to respond, or if this is the first access command), then the host must send an initialization pulse (BREAK) before sending the command again.

The slave detects a break when the HDQ pin is driven to a logic-low state for a specified break time $t_{(B)}$ or greater. The HDQ pin then returns to its normal ready-high logic state for a specified break-recovery time $t_{(BR)}$. The slave is then ready for a command from the host processor. Figure 24-44 shows this behavior.

An interrupt condition indicates a TX-complete, an RX-complete, or a time-out condition. Reading the interrupt status register clears all interrupt conditions. Only one interrupt signal is sent to the microcontroller, and only one overall mask bit can enable or disable the interrupt. The interrupt conditions cannot be individually masked.

Figure 24-44. HDQ Break-Pulse Timing Diagram

24.2.2.2.2 1-Wire (SDQ) Protocol Initialization

In 1-Wire (SDQ) protocol, the host first sends an initialization pulse (by pulling the line to a logic-low state) and then waits for the slave to respond with a presence pulse before enabling any communication sequence.

As for the initialization pulse, the presence pulse is a low-level pulse on the line initiated by the slave. The timing diagram in Figure 24-45 shows the 1-Wire (SDQ) reset sequence.

Figure 24-45. 1-Wire (SDQ) Reset Timing Diagram

The host drives the line to a logic-low state for a minimum of reset low time. Once the slave detects this pulse, it must drive the line to a logic-low state within the presence pulse high delay for a minimum period of presence pulse low time.

If the slave does not respond within this interval of time, a time-out event occurs and no transaction can be initiated. The host must initiate the reset sequence again before sending any command to the slave.

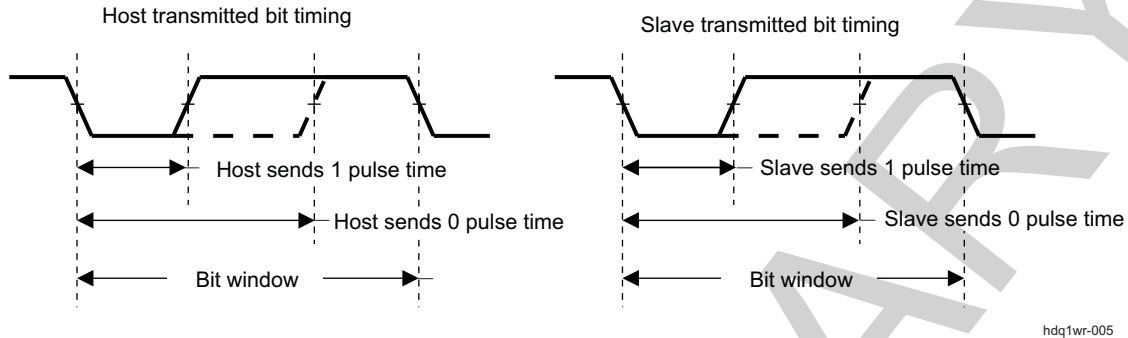

On the other hand, if the slave sends back its presence pulse within the specified time interval, the communication can be enabled after the reset high time.

24.2.2.2.3 Communication Sequence (HDQ and 1-Wire Protocols)

The description in this section applies to both protocols.

After a successful break pulse (HDQ mode) or initialization sequence (1-Wire protocol), the host and slave are ready for bit transmission. Each bit to transmit (either from the host to the slave or from the slave to the host) is preceded by a low-going edge on the line, as shown in [Figure 24-46](#).

Figure 24-46. HDQ/1-Wire Transmitted Bit Timing

The return-to-1 data-bit frame consists of three distinct sections. The first section starts the transmission when either the slave or the host takes the line to a logic-low state. The next section is the actual data transmission in which the data must be valid during a specified period of time after the negative edge that starts the communication. The final section stops the transmission by returning the HDQ/1-Wire line to a logic-high state. Communication with an HDQ/1-Wire slave always occurs with the LSB being transmitted first.

The command byte of the HDQ/1-Wire protocols consists of eight contiguous valid command bits. The command byte contains two fields: R/W command and address. The R/W bit of the command byte determines whether the command is a read or a write, and the address field containing bits AD6-AD0 indicates the address to be read or written. [Table 24-101](#) lists the command byte values.

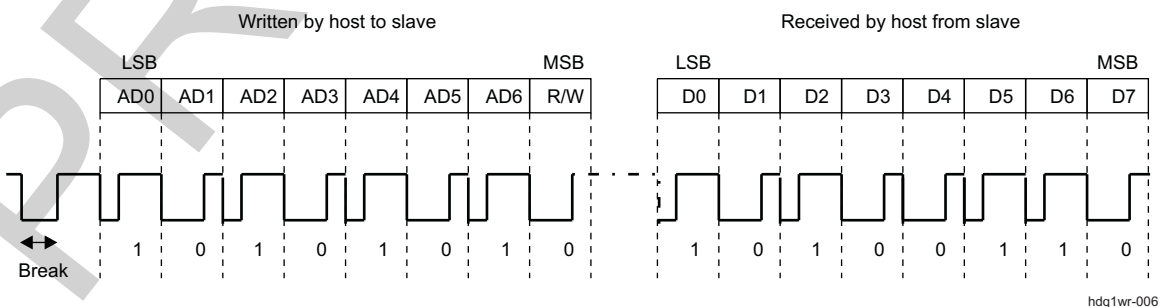

Table 24-101. HDQ/1-Wire Command Byte

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-----|-----|-----|-----|-----|-----|-----|-----|
| R/W | AD6 | AD5 | AD4 | AD3 | AD2 | AD1 | AD0 |

R/W Indicates whether the command byte is a read or a write. A 1 indicates a write command; the following eight bits must be written to the register specified by the address field of the command byte. A 0 indicates that the command is a read. On a read command, the slave outputs the requested register contents.

AD6-AD0 Represent the seven bits labeled AD6-AD0 containing the address portion of the register to be accessed. The communication sequence example in [Figure 24-47](#) shows a read command at address 0x55; the received data is 0x65.

Figure 24-47. HDQ/1-Wire Communication Sequence

24.2.3 HDQ/1-Wire Integration

Figure 24-48 shows HDQ/1-Wire integration in the device.

Figure 24-48. HDQ/1-Wire Integration

Table 24-102 through Table 24-104 summarize the integration of the module in the device.

NOTE: For the description of the interrupt source, see [Section 18.4.1, Cortex-A9 MPU INTC Functional Description](#), in [Chapter 18, Interrupt Controllers](#).

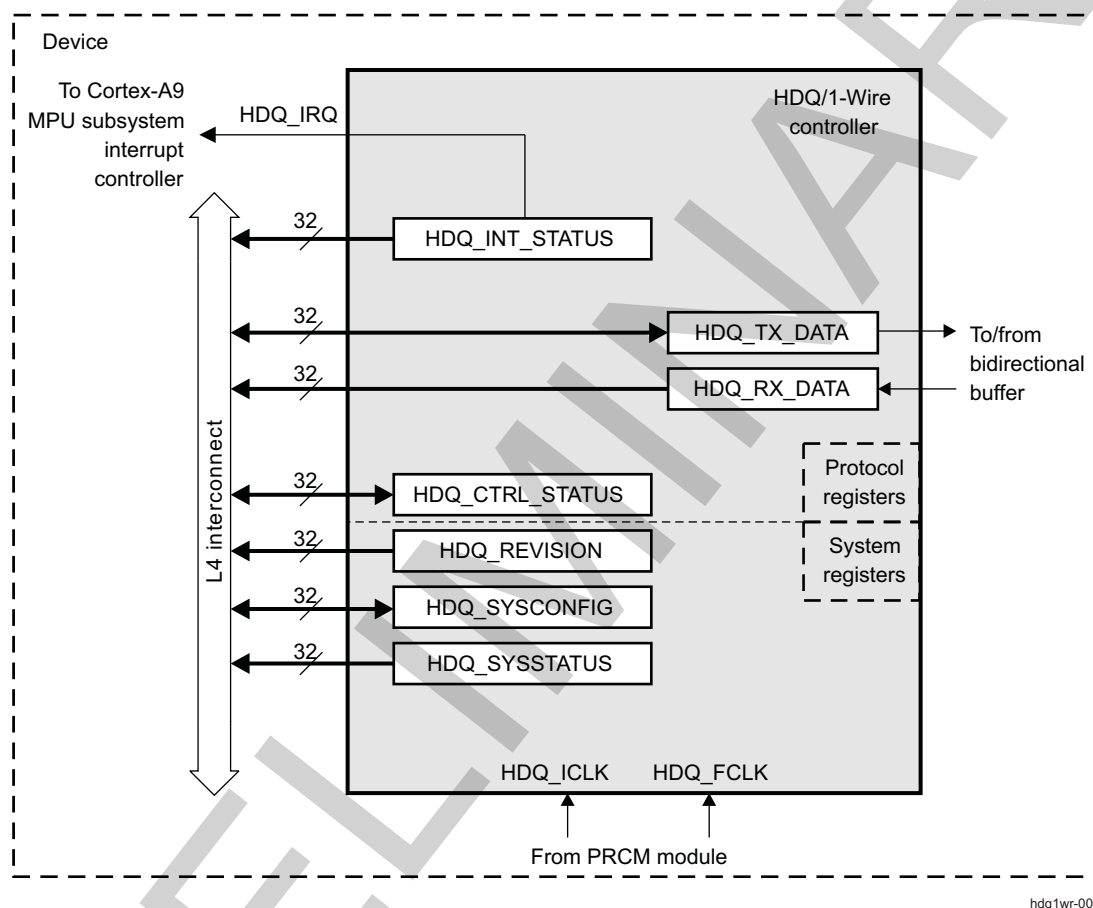

24.2.4 HDQ/1-Wire Functional Description

The HDQ/1-Wire works with HDQ and 1-Wire protocols. The protocols use a single wire to establish communication between the master and the slave. Both protocols use a return-to-1 mechanism; that is, after any command is driven, the line is pulled to a high level. This mechanism requires an external pullup.

24.2.4.1 HDQ/1-Wire Block Diagram

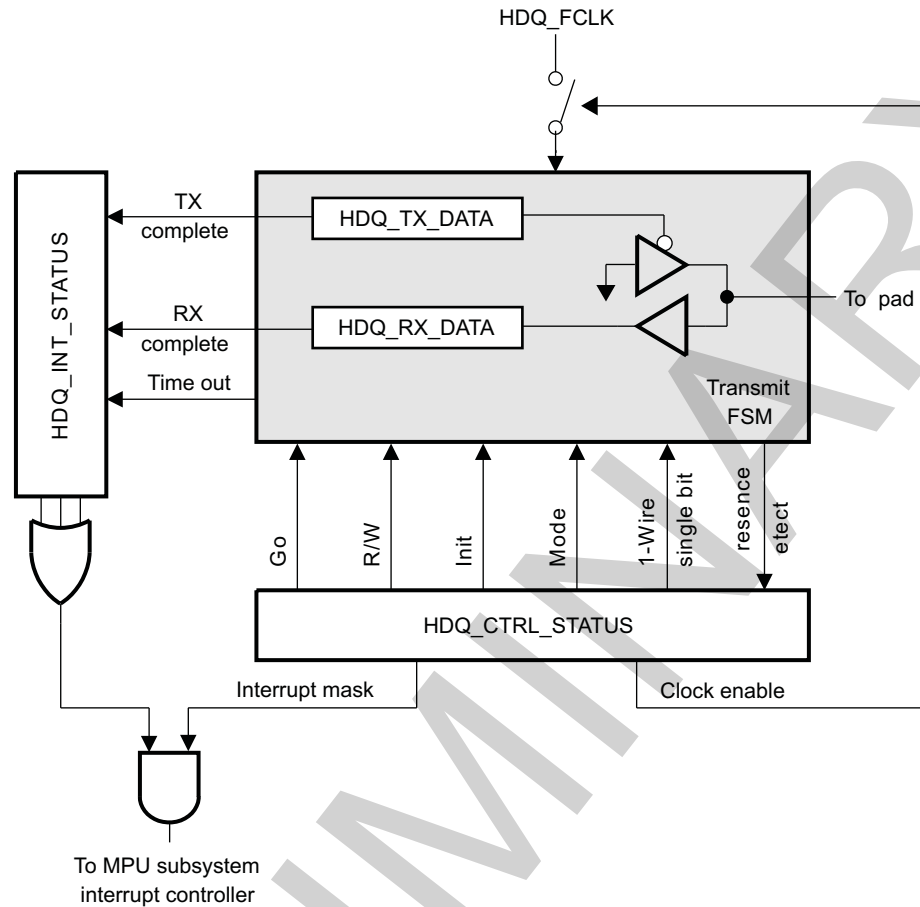

Figure 24-49 is the HDQ/1-Wire block diagram.

Figure 24-49. HDQ/1-Wire Block Diagram

The HDQ.HDQ_CTRL_STATUS[0] MODE bit allows selection between the HDQ and 1-Wire protocols. This bit is assumed static for design purposes. The configuration is in HDQ mode by default.

Figure 24-50 shows the protocol-dedicated register scheme.

Figure 24-50. Protocol Registers Description

hdq1wr-009

The receive and transmit operations of the HDQ/1-Wire module are performed with respect to the timing of the slower HDQ protocol. When the 1-Wire protocol is used, it runs at lower speed than its full capabilities, but is still able to meet the timing requirements and practical considerations.

24.2.4.2 HDQ/1-Wire Clocking Configuration

24.2.4.2.1 HDQ/1-Wire Clocks

The HDQ/1-Wire subsystem operates from two clocks: a functional clock (**HDQ_FCLK**) and an interface clock (**HDQ_ICLK**). When these clocks are set in the PRCM module, the following rule must be observed: $\text{HDQ_ICLK} \geq \text{HDQ_FCLK}$.

- The **HDQ_FCLK** functional clock is a fixed clock provided by the PRCM module. It is used to clock the internal module logic.

For more information about the clock, see [Section 3.6.8, CD_L4_PER Clock Domain](#), in [Chapter 3, Power, Reset, and Clock Management](#).

When the HDQ/1-Wire no longer requires the **HDQ_FCLK**, the software can disable it at the PRCM level. The clock is effectively cut, provided the other modules that receive it do not require it either.

For details about the PRCM register settings and clock configuration, see [Section 3.6.8, CD_L4_PER Clock Domain](#), in [Chapter 3, Power, Reset, and Clock Management](#).

- The **HDQ_ICLK** interface clock runs at L4 interconnect clock speed and is used to trigger access to the HDQ/1-Wire L4 interface.

When the HDQ/1-Wire no longer requires the **HDQ_ICLK** (no transfer is in progress), the software can disable it at the PRCM level. The clock is effectively cut, provided the other modules that receive it do

not require it either.

For more information, see [Section 3.6.8, CD_L4_PER Clock Domain](#).

24.2.4.3 HDQ/1-Wire Hardware and Software Reset

Global reset of the module is done at the power, reset, and clock management (PRCM) module level (for more information, see [Section 3.6.8, CD_L4_PER Clock Domain](#)) or by setting the HDQ.HDQ_SYSCONFIG[1] SOFTRESET bit to 1. Setting this bit enables an active software reset functionality equivalent to a hardware reset. The HDQ_FCLK functional clock must be enabled from the PRCM level and locally through the HDQ_CTRL_STATUS[5] CLOCKENABLE bit (set to 1) for the software reset to complete.

24.2.4.4 HDQ/1-Wire Power Management

[Table 24-105](#) describes power-management features available to the HDQ/1-Wire.

Table 24-105. Local Power-Management Features

| Feature | Registers | Description |
|------------------------|--|-----------------|
| Clock auto gating | HDQ_SYSCONFIG [0] AUTOIDLE bit | Auto-idle mode |
| Slave idle modes | N/A | N/A |
| Clock enable | HDQ.HDQ_CTRL_STATUS[5] CLOCKENABLE bit | Power-down mode |
| Master standby modes | N/A | N/A |
| Global wake-up enable | N/A | N/A |
| Wake-up sources enable | N/A | N/A |

24.2.4.4.1 Auto-Idle Mode

The HDQ/1-Wire provides an auto-idle function in its interconnect clock domain.

The interconnect clock auto-idle power-saving mode is enabled or disabled through the HDQ.HDQ_SYSCONFIG[0] AUTOIDLE bit. When this mode is enabled and there is no activity on the interconnect interface, the interconnect clock (HDQ_ICLK) is disabled inside the module, thereby reducing power consumption. When there is new activity on the interconnect interface, the interconnect clock is restarted with no latency penalty. This mode is disabled by default after a reset.

The auto-idle mode can be enabled in order to reduce power consumption.

24.2.4.4.2 Power-Down Mode

The HDQ/1-Wire also provides a power-saving function in its functional clock domain.

Setting the CLOCKENABLE bit in the control and status register (HDQ.HDQ_CTRL_STATUS[5] CLOCKENABLE bit) to 0 shuts off the functional clock (HDQ_FCLK) to the state-machine. The state-machine is reset when the functional clock is disabled; if any transaction is ongoing, it is aborted into the reset state.

Before shutting off the functional clock, the software must wait for transaction-complete interrupt. In write operation the software must check whether the interrupt was generated after address/command byte was sent or after data byte was sent. The functional clock must not be shut off after address/command byte is sent; otherwise, the data is not written to the slave.

The register values are not affected by disabling the functional clock.

CAUTION

There is no hardware mechanism to prevent cutting off the HDQ/1-Wire clocks while the module is performing a transfer. This would result in loss of data being transferred.

24.2.4.5 HDQ Interrupt Requests

The HDQ/1-Wire can generate one interrupt:

- HDQ_IRQ: This is an interrupt to the MPU subsystem INTC. It is mapped on MA_IRQ_58. [Table 24-106](#) lists the events that can generate this interrupt.

Table 24-106. Events

| Event Flag | Event Mask | Sync | Sensitivity | Map to | Description |
|---|--|------|-------------|---------|--|
| HDQ_INT_STATUS [2] TXCOMPLETE | HDQ_CTRL_STATUS [31] INTERRUPTMASK | Yes | Level | HDQ_IRQ | A write operation of one byte was completed. |
| HDQ_INT_STATUS [1] RXCOMPLETE | HDQ_CTRL_STATUS [31] INTERRUPTMASK | Yes | Level | HDQ_IRQ | A byte has been successfully read. |
| HDQ_INT_STATUS [0] TIMEOUT | HDQ_CTRL_STATUS [31] INTERRUPTMASK | Yes | Level | HDQ_IRQ | After a read command initiated by the host, the slave did not pull the line low within the specified time. |

24.2.4.6 HDQ Mode (Default)

24.2.4.6.1 HDQ Mode Features

The HDQ mode supports the following:

- Benchmarq HDQ protocol
- Power-down mode

24.2.4.6.2 Description

In the HDQ mode, there is no need for the host to create an initialization pulse to the slave. However, the host can reset the slave by using an initialization pulse (also known as a break pulse). Setting the [HDQ.HDQ_CTRL_STATUS](#)[2] INITIALIZATION bit and then setting the [HDQ_CTRL_STATUS](#)[4] GO bit creates this pulse by pulling the line down for a defined duration. When the slave receives the pulse, it is ready for communication but does not respond with a presence pulse.

In a typical write operation, two bytes are sent to the slave. The first byte corresponds to the command/address byte, and the second byte corresponds to the data to be written.

In a typical read operation, the host sends a command/address byte and the slave returns a byte of data.

The master is implemented to send and receive bytes. Sending the command/address and data is controlled by the firmware. The master provides only a single data TX register.

The HDQ protocol is a return-to-1 protocol. Consequently, after a byte is sent to the slave (either command/address + data for a write, or just command/address for a read), the host pulls the line up. The line is set to the high-impedance state in the device and an external pullup brings it to a logical high level.

In the case of a read operation, the slave also drives the line to a logic-low state before sending the requested data.

If the host initiates a read and does not receive data within a specified interval of time (that is, the slave does not drive the line low within this interval), the [HDQ.HDQ_INT_STATUS](#)[0] TIMEOUT bit is set, thereby indicating a read failure. The TIMEOUT bit remains set until the host reads the interrupt status register ([HDQ.HDQ_INT_STATUS](#)).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out on a transaction. The corresponding bit is set in the interrupt status register ([HDQ.HDQ_INT_STATUS](#)). This register is cleared as soon as it is read.

Only one interrupt signal is sent to the MPU, and only an overall mask can enable or disable the interrupts. These interrupts cannot be individually masked.

24.2.4.6.3 Single-Bit Mode

In HDQ mode, the single-bit mode (HDQ.HDQ_CTRL_STATUS[7] ONE_WIRE_SINGLE_BIT bit set to 1) has no effect because the HDQ protocol supports only byte transfers.

24.2.4.6.4 Interrupt Conditions

The HDQ/1-Wire provides the following interrupt status:

- Transmission complete:
A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in HDQ protocol. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).
- Read complete:
In HDQ mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).
- Presence detect/time-out:
In HDQ mode, the interrupt status indicates that after a read command initiated by the host, the slave did not pull the line low within the specified time. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).
In HDQ mode, a time-out condition is also used to indicate the successful completion of a break pulse. That is, if the master has sent the break pulse, it is indicated with a time-out instead of a TX-complete.

Only one interrupt is generated to the MPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all the interrupt status bits that were previously set.

24.2.4.7 1-Wire Mode

24.2.4.7.1 1-Wire Mode Features

The 1-Wire mode supports the following:

- Dallas Semiconductor 1-Wire protocol
- Power-down mode
- Single-bit mode

24.2.4.7.2 Description

The 1-Wire mode requires an initialization pulse to be sent to the slave(s) connected on the interface. If a slave is present, it responds with a presence pulse.

The initialization pulse is sent when the HDQ.HDQ_CTRL_STATUS[2] INITIALIZATION bit is set and the HDQ_CTRL_STATUS[4] GO bit is set afterwards.

When the slave receives the initialization pulse, it sends back its presence pulse by pulling down the line for a defined duration. The module detects this low-level pulse and sets the HDQ.HDQ_CTRL_STATUS[3] PRESENCEDETECT bit.

In a similar way, if a presence pulse is not received from the slave after an initialization pulse is sent, the PRESENCEDETECT bit remains cleared.

Whether or not a presence pulse is detected after an initialization pulse is sent, the HDQ.HDQ_INT_STATUS[0] TIMEOUT bit is set and an interrupt condition is generated.

In 1-Wire mode, the generated interrupt condition means the maximum time allowed for receiving the response has elapsed and the software must check the PRESENCEDETECT bit to determine whether or not there was a presence pulse.

The INITIALIZATION bit is cleared at the end of the initialization pulse at the same time as the TIMEOUT bit is set. The TIMEOUT bit is cleared when the interrupt status register (HDQ.HDQ_INT_STATUS) is read.

For read operations, 1-Wire is a bit-by-bit protocol, which means the slave must be clocked by the host for each bit of the byte to read.

The line is pulled up at the end of the command/address byte. On the first read, the host creates a low-going edge to initiate a bit read. The line is then pulled up (pulled to the high-impedance state by the host and set to a high logical level by the external pullup) and the slave either drives the line low to transmit a 0, or does not drive the line to transmit a 1. This sequence is repeated for each bit to read.

The first bit the host receives is the LSB, and the last bit is the most-significant bit (MSB) in the receive data register (HDQ.HDQ_RX_DATA).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out condition (that is, the time allowed for the slave to indicate its presence has elapsed). A read operation on the interrupt status register clears the interrupt conditions previously set. As in the HDQ mode, only one interrupt signal is sent to the MPU. Only an overall mask bit can enable or disable the interrupt (the interrupt conditions cannot be masked individually).

24.2.4.7.3 1-Wire Single-Bit Mode Operation

A single-bit mode can be entered by setting the appropriate bit in the control and status register (ONE_WIRE_SINGLE_BIT bit HDQ.HDQ_CTRL_STATUS[7]). In this mode, only one bit of data at a time is transferred between the master and the slave. After the bit is transferred, an interrupt is generated (that is, there is an RX-complete for a read operation and a TX-complete for a write operation). The ONE_WIRE_SINGLE_BIT bit is cleared by hardware after every single bit is received. Software must set this bit to re-enable reception in single-bit mode. Bit 0 of the RX register (HDQ.HDQ_RX_DATA) is updated each time a bit is received from the slave; bit 0 of the TX register (HDQ.HDQ_TX_DATA) contains the bit to be sent.

24.2.4.7.4 Interrupt Conditions

The HDQ/1-Wire provides the following interrupt status:

- Transmission complete:
A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in 1-Wire protocol. This interrupt condition is cleared by reading the interrupt status register (HDQ.[HDQ_INT_STATUS](#)).
- Read complete:
In 1-Wire mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register (HDQ.[HDQ_INT_STATUS](#)).
- Presence detect/time-out:
In 1-Wire mode, the interrupt status indicates that it is now valid to check the PRESENCEDETECT bit. This interrupt condition is cleared by reading the interrupt status register (HDQ.[HDQ_INT_STATUS](#)).

Only one interrupt is generated to the MPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all interrupt status bits that were previously set.

24.2.4.7.5 Status Flags

The presence-condition-detected status flag is contained in the HDQ.[HDQ_CTRL_STATUS](#)[3] PRESENCEDETECT bit. This is valid only in 1-Wire mode. The flag is updated when the HDQ.[HDQ_INT_STATUS](#)[0] TIMEOUT bit is set. Therefore, its correct value shows only after the interrupt is generated. The firmware must wait for the time-out condition; otherwise, the flag keeps its previous value and is undefined.

24.2.5 HDQ/1-Wire Programming Models

This section describes the low-level hardware programming sequences for configuration and usage of the module. The basic protocol functions, such as slave initialization (reset), read-byte, and write-byte operations, are described. For a description of the functions, see the HDQ/1-Wire protocol documentation.

24.2.5.1 Global Initialization

24.2.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the HDQ/1-Wire module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the HDQ/1-Wire. Refer to the HDQ/1-Wire Module Integration and Environment Sections for further information.

Table 24-107. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|---------------------|---|
| PRCM | Module interface and functional clocks must be enabled. The interface clock must not be slower than the functional clock ($HDQ_ICLK \geq HDQ_FCLK$). For more information about the module configuration, see Chapter 3, Power, Reset, and Clock Management . |
| Control Module | Module specific pad muxing and pullup must be set in the control module. For more information about the module configuration, see Chapter 19, Control Module . |
| MPU INTC | MPU INTC configuration must be done to enable the interrupts from HDQ/1-Wire module. See Section 18.4.1, Cortex-A9 MPU INTC Functional Description , in Chapter 18, Interrupt Controllers . |

Table 24-117. HDQ/1-Wire Instance Summary

| Module Name | Base Address | Size |
|-------------|--------------|------|
| HDQ/1-Wire | 0x480B 2000 | 4KB |

24.2.6.2 HDQ/1-Wire Registers

CAUTION

The following rules must be observed when accessing the module registers:

- A read from the [HDQ_INT_STATUS](#) register or the [HDQ_RX_DATA](#) register is not allowed unless the processor has been interrupted by the module.
- After the release of the GO bit in the [HDQ_CTRL_STATUS](#) register, no access to the [HDQ_TX_DATA](#) or [HDQ_CTRL_STATUS](#) register is allowed until the processor has been interrupted by the module.
- Polling of the [HDQ_INT_STATUS](#) register by software to determine whether an interrupt was generated is not allowed.

CAUTION

The HDQ/1-Wire registers are limited to 32-bit data accesses; 16-bit and 8-bit data accesses are not allowed and can corrupt register content.

24.3 UART/IrDA/CIR

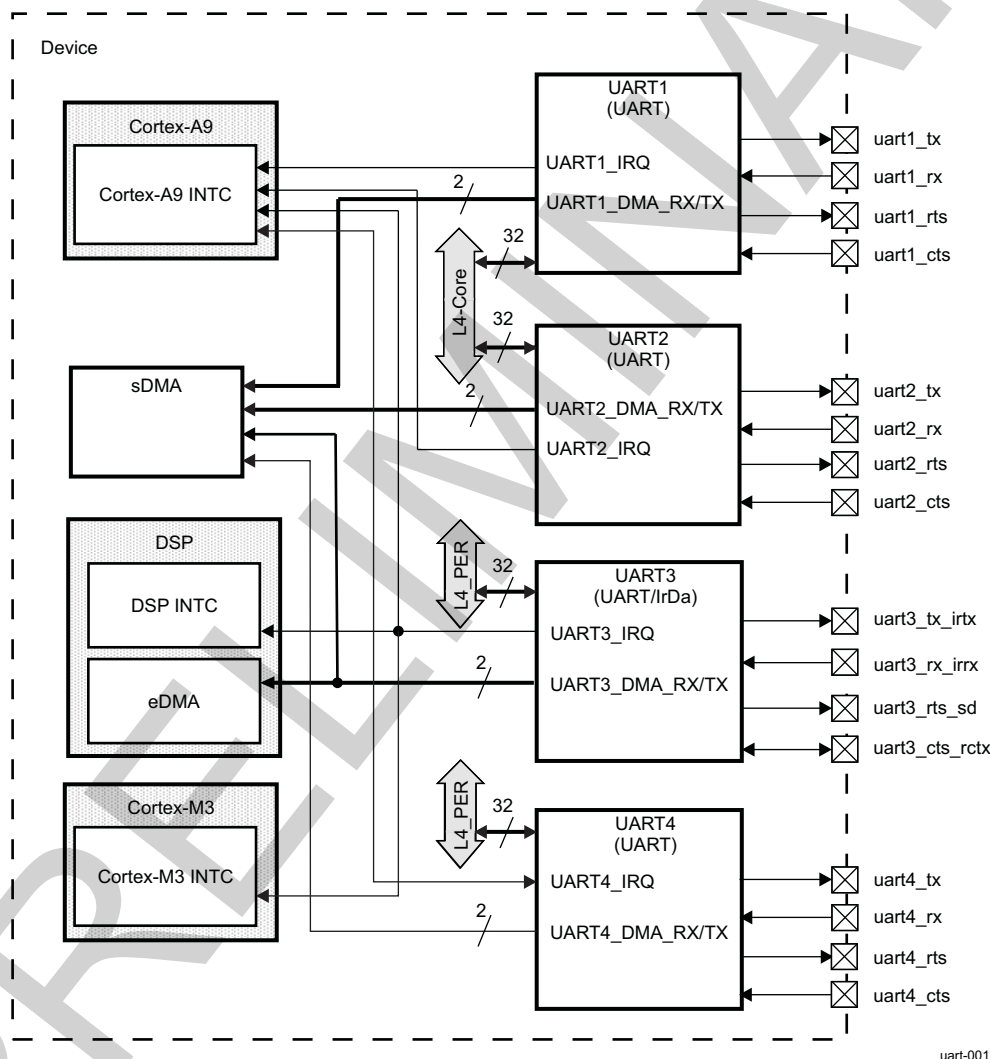

This chapter describes the function, operation, and configuration of the universal asynchronous receiver/transmitter (UART)/infrared data association (IrDA)/consumer infrared (CIR) module in the device.

24.3.1 UART/IrDA/CIR Overview

The device contains four UART devices controlled by the MPU (see Figure 24-51):

- Three UART-only modules (UART1, UART2, and UART4) are pinned out for use as UART devices only.
- UART3, which adds infrared communication support, is pinned out for use as a UART, IrDA, or CIR device, and can be programmed to any available operating mode.

Figure 24-51. UART Module

24.3.1.1 UART Features

The UARTs (UART1, UART2, UART3 when in UART mode, and UART4) include the following key features:

- 16C750 compatibility
- 64-byte FIFO buffer for receiver and 64-byte FIFO for transmitter
- Programmable interrupt trigger levels for FIFOs

- Baud generation based on programmable divisors N (N = 1...16,384) operating from a fixed functional clock of 48 MHz

Oversampling is programmed by software as 16 or 13; thus, the baud rate computation is one of two options:

- Baud rate = (functional clock/16)/N
- Baud rate = (functional clock/13)/N

This software programming mode enables higher baud rates with the same error amount without changing the clock source:

- Break character detection and generation
- Configurable data format:
 - Data bit: 5, 6, 7, or 8 bits
 - Parity bit: Even, odd, none
 - Stop-bit: 1, 1.5, 2 bit(s)
- Flow control: Hardware (RTS/CTS) or software (XON/XOFF)

The UART clocks are connected to produce a baud rate of up to 3.6 Mbps. [Table 24-133](#) lists the supported baud rates, the requested divisor, and the corresponding error versus the standard baud rate.

Table 24-133. UART Mode Baud Rates, Divisor Values, and Error Rates

| Baud Rate | Oversampling | Divisor | Error (%) |
|-----------|--------------|---------|-----------|
| 300 | 16 | 10,000 | 0 |
| 600 | 16 | 5000 | 0 |
| 1200 | 16 | 2500 | 0 |
| 2400 | 16 | 1250 | 0 |
| 4800 | 16 | 625 | 0 |
| 9600 | 16 | 312 | 0.16 |
| 14,400 | 16 | 208 | 0.16 |
| 19,200 | 16 | 156 | 0.16 |
| 28,800 | 16 | 704 | 0.16 |
| 38,400 | 16 | 78 | 0.16 |
| 57,600 | 16 | 52 | 0.16 |
| 115,200 | 16 | 26 | 0.16 |
| 230,400 | 16 | 13 | 0.16 |
| 460,800 | 13 | 8 | 0.16 |
| 921,600 | 13 | 4 | 0.16 |
| 1,843,200 | 13 | 2 | 0.16 |
| 3,000,000 | 16 | 1 | 0 |
| 3,686,400 | 13 | 1 | 0.16 |

24.3.1.2 IrDA Features

The IrDA (UART3 only) includes the following key features:

- Support of IrDA 1.4 slow infrared (SIR), medium infrared (MIR), and fast infrared (FIR) communications:
 - Frame formatting: Addition of variable beginning-of-frame (xBOF) characters and end-of-frame (EOF) characters
 - Uplink/downlink cyclic redundancy check (CRC) generation/detection
 - Asynchronous transparency (automatic insertion of break character)
 - Eight-entry status FIFO (with selectable trigger levels) to monitor frame length and frame errors
 - Framing error, CRC error, illegal symbol (FIR), and abort pattern (SIR, MIR) detection

Table 24-134 lists the supported baud rates, the requested divisor, and the corresponding error versus the standard baud rate.

Table 24-134. UART IrDA Mode Baud Rates, Divisor Values, and Error Rates

| Baud Rate | IR Mode | Encoding | Divisor | Error (%) |
|-----------|---------|----------------------|---------|-----------|
| 2400 | SIR | 3/16 | 1250 | 0 |
| 9600 | SIR | 3/16 | 312 | 0.16 |
| 19,200 | SIR | 3/16 | 156 | 0.16 |
| 38,400 | SIR | 3/16 | 78 | 0.16 |
| 57,600 | SIR | 3/16 | 52 | 0.16 |
| 115,200 | SIR | 3/16 | 26 | 0.16 |
| 576,000 | MIR | 1/4 | 2 | 0 |
| 1,152,000 | MIR | 1/4 | 1 | 0 |
| 4,000,000 | FIR | 4 PPM ⁽¹⁾ | 1 | 0 |

⁽¹⁾ PPM = pulse-position modulation

24.3.1.3 CIR Features

The CIR mode uses a variable pulse-width modulation (PWM) technique (based on multiples of a programmable t period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on a user-definable frame structure and packet content.

The CIR (UART3 only) includes the following key features to provide CIR support for remote-control applications:

- Transmit mode only (Receive mode is not supported.)
- Free data format (supports any remote-control private standards)
- Selectable bit rate
- Configurable carrier frequency
- 1/2, 5/12, 1/3, or 1/4 carrier duty cycle

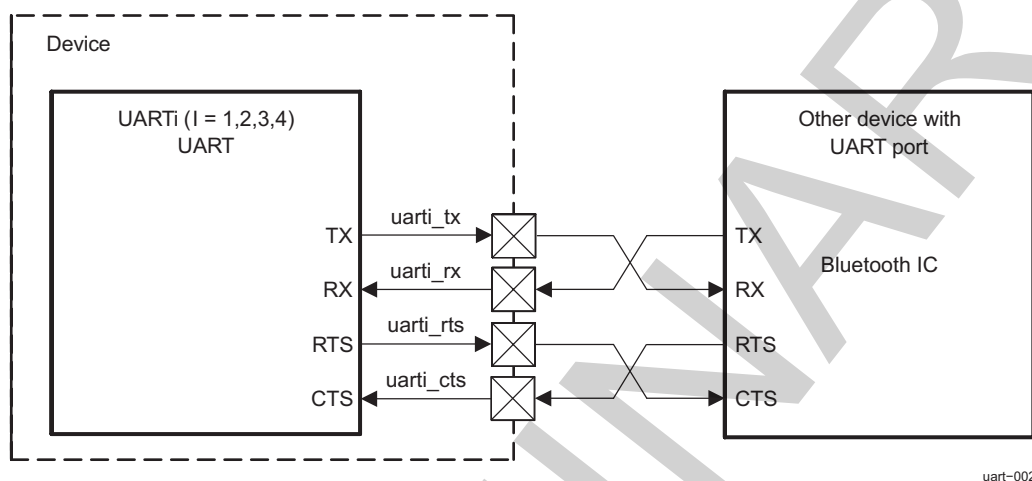

24.3.2 UART/IrDA/CIR Environment

This section describes the UART/IrDA/CIR connection with an external device.

24.3.2.1 System Using UART Communication With Hardware Handshake

Each UART instance can be easily connected to the UART port of an external IC (see [Figure 24-52](#)).

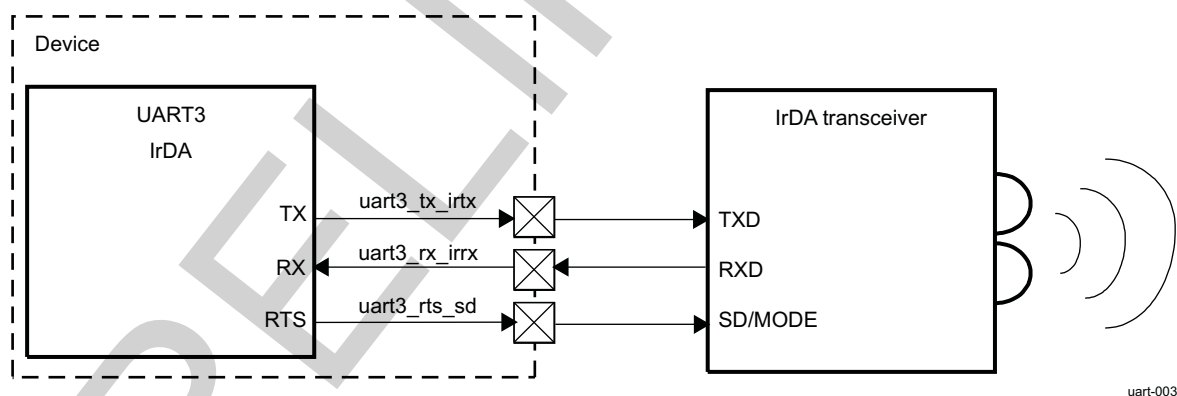

Figure 24-52. UART Mode Bus System Overview

24.3.2.2 System Using IrDA Communication Protocol

As [Figure 24-53](#) shows, UART3 can be connected to an external infrared transceiver in the IrDA modes (FIR, SIR, and MIR).

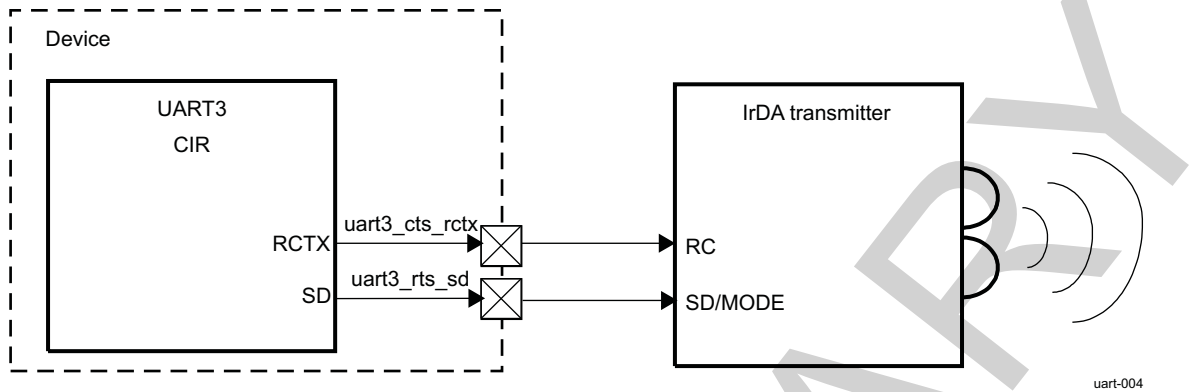

Figure 24-53. IrDA System Overview

24.3.2.3 System Using CIR Communication Protocol With Remote Control

UART3 can be connected to an external infrared transceiver in CIR mode (see [Figure 24-54](#)).

Figure 24-54. CIR System Overview

24.3.2.4 UART Interface

24.3.2.4.1 Description

Table 24-135 lists the UART interface input/output (I/O) signals.

Table 24-135. UART I/O Pins

| Signal | I/O ⁽¹⁾ | Description | Reset |
|---------------------------|--------------------|---|---------|
| UART Modem Signals | | | |
| uarti_rx | I | Serial data input | Unknown |
| uarti_tx | O | Serial data output | 1 |
| | | Because this pin is active high in IrDA mode and the output is muxed, this pin is set to low on reset (when the UARTi.UART_MDR1[2:0] bit field is set to 0x7) and takes the defined inactive level of that signal corresponding to when and how the UARTi.UART_MDR1 register is programmed; that is, the output is 1 (inactive for UART modem modes) and 0 (inactive for IrDA modes). | |
| uarti_cts | I | Clear to send | Unknown |
| | | Active-low modem status signal. Reading the UARTi.UART_MSR[4] NCTS_STS bit checks the condition of uarti_cts. Reading the UARTi.UART_MSR[0] CTS_STS bit checks a change of state of uarti_cts since the last read of the modem status register. The auto-nCTS mode uses uarti_cts to control the transmitter. | |
| uarti_rts | O | Request to send | 1 |
| | | When active (low), the module is ready to receive data. Setting the UARTi.UART_MCR[1] RTS bit activates uarti_rts, which becomes inactive as the result of a module reset, loopback mode, or clearing the UARTi.UART_MCR[1] RTS bit. In auto-RTS mode, uarti_rts becomes inactive as a result of the receiver threshold logic. | |

⁽¹⁾ I = Input; O = Output

24.3.2.4.2 UART Protocol and Data Format

The UART device operates in three modes:

- UART 16x (= 230.4 kbps)
- UART 16x with autobauding (= 1200 bps and = 115.2 kbps)
- UART 13x (= 460.8 kbps)

CAUTION

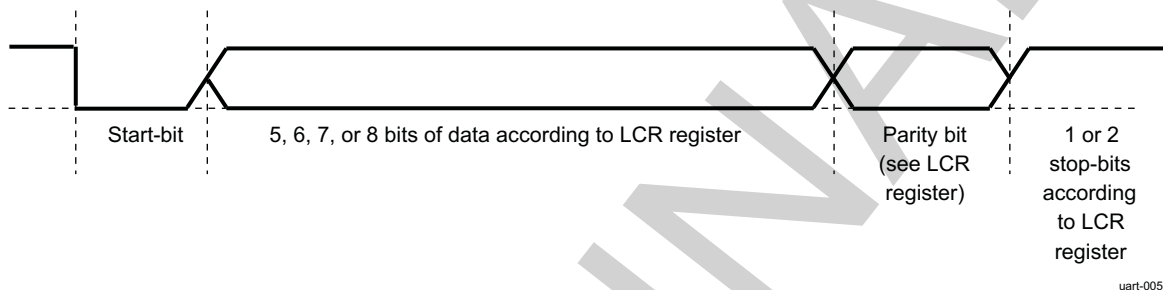

To be used as a UART, the operating mode must be programmed appropriately in the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to select UART, IrDA, or CIR mode.

The UART uses a wired interface for serial communication with a remote device.

The UART is functionally compatible with the TL16C750 UART and earlier designs such as the TL16C550.

Figure 24-55 shows the UART frame data format.

Figure 24-55. UART Frame Data Format

24.3.2.5 IrDA Functional Interfaces

24.3.2.5.1 UART3 Interface Description

Table 24-136 lists the UART3 interface I/O signals.

Table 24-136. UART3 I/O Signals

| Signal | I/O ⁽¹⁾ | Description | Reset |
|---------------------|--------------------|---|---------|
| IrDA Signals | | | |
| uart3_rx_irrx | I | Serial data input | Unknown |
| uart3_tx_irtx | O | Serial data output in IrDA modes (SIR, MIR, and FIR). In other modes, this pin is set to the reset value (inactive state). | 0 |
| uart3_rts_sd | O | SD mode is used to configure the transceivers. The SD pinout is an inverted value of the UART3.UART_ACREG[6] SD_MOD bit. | 1 |

⁽¹⁾ I = Input; O = Output

24.3.2.5.2 IrDA Protocol and Data Format

24.3.2.5.2.1 SIR Mode

In SIR mode, data is transferred between the MPU and peripheral devices at speeds of up to 115,200 baud. A SIR transmit frame begins with start flags (a single 0xC0, a multiple 0xC0, or a single 0xC0 preceded by a number of 0xFF flags), is followed by frame data and a CRC-16, and ends with a stop flag (0xC1).

The bit format for a single word uses 1 start-bit, 8 data bits, and 1 stop-bit, and is unaffected by the use and settings of the UART3.UART_LCR register.

The UART3.UART_BLR[6] XBOF_TYPE bit selects whether the 0xC0 or 0xFF start patterns are used when multiple start flags are required.

The SIR transmit state-machine attaches start flags, CRC-16, and stop flags, and checks the outgoing data to establish whether data transparency is required.

SIR transparency is carried out if the outgoing data between the start and stop flags contains 0xC0, 0xC1, or 0x7D. If one of these start flags is about to be transmitted, the SIR state-machine first sends an escape character (0x7D), then inverts the fifth bit of the real data to be sent and sends this data immediately after the 0x7D character.

The SIR receive state-machine recovers the receive clock, removes the start flags and any transparency from the incoming data, and determines the frame boundary with reception of the stop flag. The SIR state-machine also checks for errors such as a frame abort (0x7D character followed immediately by a 0xC1 stop flag without transparency), a CRC error, or a frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.UART_LSR) to find possible errors of the received frame.

NOTE: The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. See the description of the UART3.UART_ACREG[5] DIS_IR_RX bit. This applies to all three modes: SIR, MIR, and FIR.

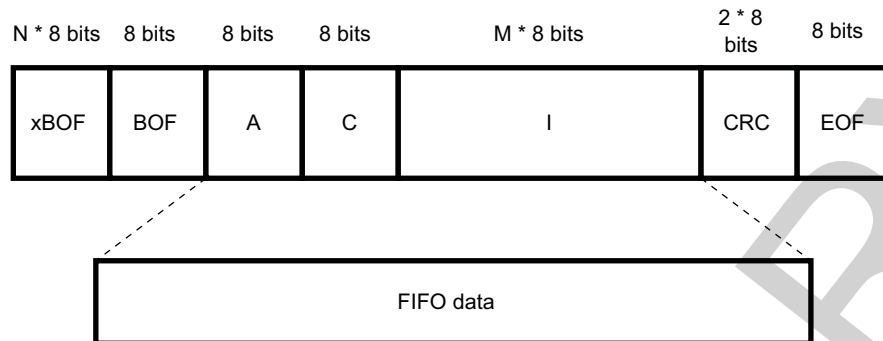

Infrared output in SIR mode can be 1.6-μs or 3/16 encoding, selected by the UART3.UART_ACREG[7] PULSE_TYPE bit. In 1.6-μs encoding, the infrared pulse width is 1.6 μs; and in 3/16th encoding, the infrared pulse width is 3/16th of a bit duration (1/ baud rate).

For back-to-back frames, the transmitting device must send at least two start flags at the start of each frame.

NOTE: Reception supports variable-length stop-bits.

24.3.2.5.2.1.1 Frame Format

Figure 24-56 shows the IrDA SIR frame format.

Figure 24-56. IrDA SIR Frame Format

The CRC is applied on the address (A), control (C), and information (I) bytes.

NOTE: The two words of CRC are written to the FIFO in reception.

24.3.2.5.2.1.2 Asynchronous Transparency

Before transmitting a byte, the UART IrDA controller examines each byte of the payload and the CRC field (between BOF and EOF). For each byte equal to 0xC0 (BOF), 0xC1 (EOF), or 0x7D (control escape), the controller performs certain tasks:

- In transmission:

- Inserts a control escape (CE) byte preceding the byte
- Complements bit 5 of the byte (that is, exclusive ORs the byte with 0x20)

The byte sent for the CRC computation is the initial byte written in the TX FIFO (before the XOR with 0x20).

- In reception:

For the A, C, I, CRC field:

- Compares the byte with the CE byte; if they are not equal, sends the byte to the CRC detector and stores it in the RX FIFO.
- If the byte is equal to the CE byte, discards the CE byte
- Complements bit 5 of the byte following the CE
- Sends the complemented byte to the CRC detector and stores it in the RX FIFO

24.3.2.5.2.1.3 Abort Sequence

The transmitter can prematurely close a frame (abort) by sending the sequence 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

When a 0x7D character that is followed immediately by a 0xC1 character is received without transparency, the receiver treats the frame as an aborted frame.

24.3.2.5.2.1.4 Pulse Shaping

The SIR mode supports the 3/16 and the 1.6-us pulse duration methods in receive and transmit. The UART3.UART_ACREG[7] PULSE_TYPE bit selects the pulse-width method in transmit mode.

24.3.2.5.2.1.5 Encoder

Serial data from the transmit state-machine are encoded to transmit data to the optoelectronics. While the TX FIFO output is high, the uart3_tx_irtx line is always low, and the counter used to form a pulse on uart3_tx_irtx is cleared continuously.

After the TX FIFO output resets to 0, `uart3_tx_irtx` rises on the falling edge of the seventh 16XCLK. On the falling edge of the tenth 16XCLK pulse, `uart3_tx_irtx` falls, creating a 3-clock-wide pulse. While the TX FIFO output stays low, a pulse is transmitted during the seventh to the tenth clock of each 16-clock bit cycle.

Figure 24-57 shows the IrDA SIR encoding mechanism.

Figure 24-57. IrDA SIR Encoding Mechanism

uart-007

24.3.2.5.2.1.6 Decoder

After reset, the RX FIFO input is high and the 4-bit counter is cleared. When a rising edge is detected on RX, the RX FIFO input falls on the next rising edge of 16XCLK with sufficient setup time. The RX FIFO input stays low for 16 cycles (16XCLK) and then returns to high as required by the IrDA specification. As long as no pulses (rising edges) are detected on the RX, the RX FIFO input remains high.

Figure 24-58 shows the IrDA SIR decoding mechanism.

Figure 24-58. IrDA SIR Decoding Mechanism

uart-008

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. The operation of the `uart3_rx_irrx` input can be disabled using the `UART3.UART_ACREG[5] DIS_IR_RX` bit. The `UART3.UART_MDR2[6] IRRXINVERT` bit can invert the signal from the transceiver (RXD) pin to the IR RX logic in the UART. This inversion is performed by default.

24.3.2.5.2.1.7 IR Address Checking

In all IR modes, when address checking is enabled by setting the `UART_EFR[1:0]` bit field (see [Table 24-137](#)), only frames intended for the device are written to the RX FIFO. This is to avoid receiving frames not meant for this device in a multipoint infrared environment. To program two frame addresses that the UART3 receives in IrDA mode, use the `UART3.UART_XON1_ADDR1[7:0]` and `UART3.UART_XON2_ADDR2[7:0]` bit fields.

Table 24-137. UART_EFR[1:0] IR Address Checking Options

| UART_EFR[1] | UART_EFR[0] | IR Address Checking |
|-------------|-------------|--|
| 0 | 0 | All address-checking operations disabled |
| 0 | 1 | Only address 1 checking enabled |
| 1 | 0 | Only address 2 checking enabled |
| 1 | 1 | All address-checking operations enabled |

24.3.2.5.2.2 SIR Free-Format Mode

To allow complete software flexibility when transmitting and receiving infrared data packets, the SIR free-format (FF) mode is a subfunction of the existing SIR mode. In FF mode, all frames going to and from the FIFO buffers are untouched with respect to appending and removing control characters and CRC values.

The FF mode corresponds to a UART mode with a pulse modulation of 3/16 of baud rate pulse width.

For example, a normal SIR packet has BOF control and CRC error-checking data appended (transmitting) or removed (receiving) from the data going to and from the FIFOs.

[Figure 24-59](#) shows SIR FF mode.

Figure 24-59. SIR FF Mode

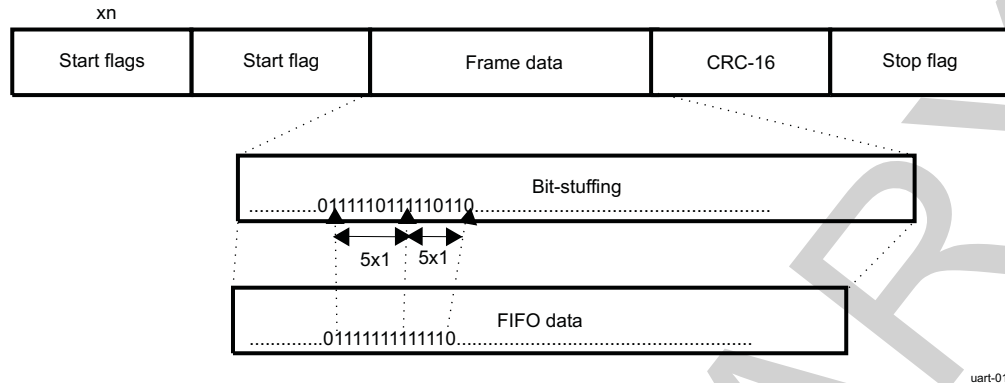

In SIR FF mode, the MPU software must construct (that is, encode and decode) the entire FIFO data packet.

24.3.2.5.2.3 MIR Mode

In MIR mode, data is transferred between the MPU and the peripheral devices at 0.576 or 1.152 Mbps speed. A MIR transmit frame starts with at least two start flags followed by a frame data and a CRC-16, and ends with a stop flag (see [Figure 24-60](#)).

Figure 24-60. MIR Transmit Frame Format

On transmit, the MIR state-machine attaches start flags, a CRC-16, and stop flags, as in SIR mode. All fields are transmitted LSB of each byte first.

In MIR mode:

- The state-machine looks for consecutive 1s in the frame data and automatically inserts 0 after five consecutive 1s (this is called bit-stuffing).
- 0x7E is used for start and stop flags (unambiguously, not data, because of bit-stuffing).
- An abort sequence requires a minimum of seven consecutive 1s (unambiguously, not data, because of bit-stuffing).
- Back-to-back frames are allowed with three or more stop flags between them. If two consecutive frames are not back to back, the gap between the last stop flag of the first frame and the start flag of the second frame must be separated by at least seven bit durations.

On receive, the MIR receive state-machine recovers the receive clock, removes the start flags, destuffs the incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors such as frame abort, CRC error, and frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.UART_LSR) to detect errors of the received frame.

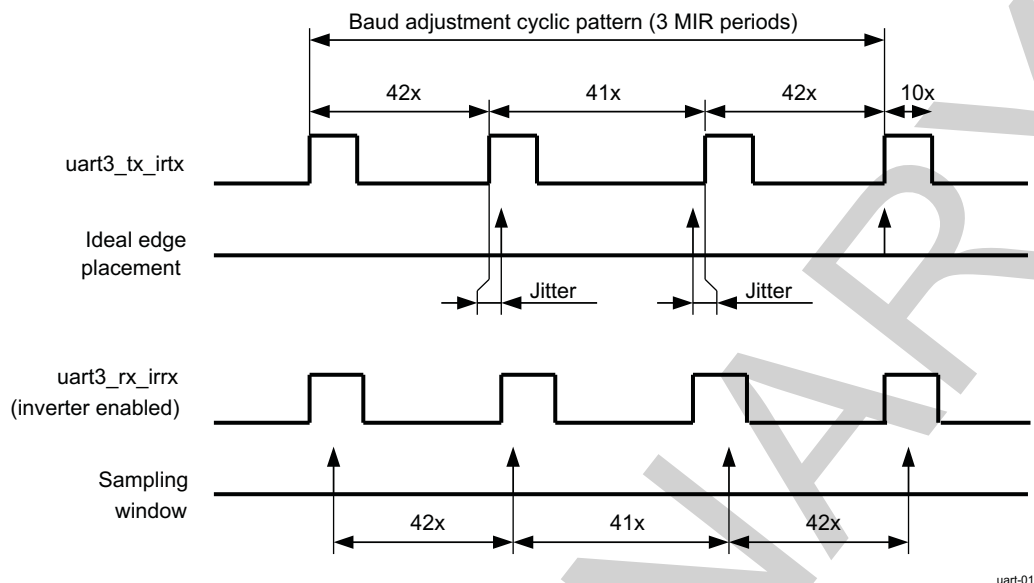

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

24.3.2.5.2.3.1 MIR Encoder/Decoder

To meet the MIR baud rate tolerance of 0.1 percent with a 48-MHz clock input, a 42-41-42 encoding/decoding adjustment is performed. The reference start point is the first start flag, and the 42-41-42 cyclic pattern is repeated until the stop flag is sent or detected.

The jitter created this way is within MIR tolerances. The pulse width is not exactly 1/4, but it is within the tolerances defined by IrDA specifications.

Figure 24-61 shows the MIR baud rate adjustment mechanism.

Figure 24-61. MIR Baud Rate Adjustment Mechanism**24.3.2.5.2.3.2 SIP Generation**

In the MIR and FIR operation modes, the transmitter must send a serial infrared interaction pulse (SIP) at least once every 500 ms. The SIP informs slow devices (operating in SIR mode) that the medium is occupied.

Figure 24-62 shows the SIP.

Figure 24-62. SIP**24.3.2.5.2.4 FIR Mode**

In FIR mode, data is transferred between the MPU and the peripheral devices at 4 Mbps. A FIR transmit frame starts with a preamble that is followed by a start flag, frame data, CRC-32, and ends with a stop flag.

Figure 24-63 shows the FIR transmit frame format.

Figure 24-63. FIR Transmit Frame Format

| | | | | |
|-------------------|------------|------------|--------|-----------|
| Preamble (16x) | Start flag | Frame data | CRC-32 | Stop flag |
|-------------------|------------|------------|--------|-----------|

On transmit, the FIR transmit state-machine attaches the preamble, start flag, CRC-32, and stop flag. An abort sequence requires at least two transmissions of 0000. Back-to-back frames are allowed, but each frame must be complete.

The state-machine also encodes the transmit data into 4-PPM format (see [Table 24-138](#)) and generates the SIP (see [Section 24.3.2.5.2.3.2, SIP Generation](#)).

Table 24-138. 4-PPM Format

| Data Bit Pair (Bin) | 4-PPM Data Symbol (Bin) |
|---------------------|-------------------------|
| 00 | 1000 |
| 01 | 0100 |
| 10 | 0010 |
| 11 | 0001 |

The four symbols described in [Table 24-138](#) are the legal, encoded data symbols. All other combinations are illegal for encoding data. Some of these illegal symbols are used in the definition of the preamble, start flag, and stop flag because they are unambiguously not data (see [Table 24-139](#)).

Table 24-139. FIR Preamble, Start Flag, and Stop Flag

| Frame Part | Transmitted Frame (Bin) |
|------------|---|
| Preamble | 1000 0000 1010 1000 (16 repeated transmissions) |
| Start flag | 0000 1100 0000 1100 0110 0000 0110 0000 |
| Stop flag | 0000 1100 0000 1100 0000 0110 0000 0110 |

All fields are transmitted the LSBs of each byte first (see [Table 24-140](#)).

Table 24-140. FIR Data Byte Transmission Order Example

| Data Byte (Hex) | Data Byte Pair (Bin) | 4-PPM Data Symbol (Bin) | Transmission Order |
|-----------------|----------------------|-------------------------|--------------------|
| 0x0B | 00 | 1000 | 4 |
| | 00 | 1000 | 3 |
| | 10 | 0010 | 2 |
| | 11 | 0001 | 1 |

On receive, the FIR receive state-machine recovers the receive clock, removes the preamble and the start flag, decodes the 4-PPM incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors such as illegal symbol, CRC error, and frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.UART_LSR) to detect errors of the received frame.

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

24.3.2.6 CIR Functional Interfaces

24.3.2.6.1 CIR Interface Description

[Table 24-141](#) lists the CIR interface I/O signals.

Table 24-141. CIR I/O Signals

| Signal | I/O ⁽¹⁾ | Description | Reset |
|--------------------|--------------------|--|---------|
| CIR Signals | | | |
| uart3_rx_irrx | I | Serial data input | Unknown |
| uart3_cts_rctx | O | Serial data output in CIR mode. In other modes, this pin is set to the reset value (inactive state). | 0 |

⁽¹⁾ I = Input; O = Output

Table 24-141. CIR I/O Signals (continued)

| Signal | I/O ⁽¹⁾ | Description | Reset |
|--------------|--------------------|---|-------|
| uart3_rts_sd | O | SD mode is used to configure the transceivers. The SD pinout is an inverted value of the UART3.UART_ACREG[6] SD_MOD bit. | 1 |

24.3.2.6.2 CIR Protocol and Data Format

In CIR mode, the infrared operation functions as a programmable (universal) remote control.

CIR mode uses a variable PWM technique (based on multiples of a programmable t period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on user-defined frame structure and packet content.

24.3.2.6.2.1 Carrier Modulation

Each modulated pulse that constitutes a digit is a train of on/off pulses (see [Figure 24-64](#)).

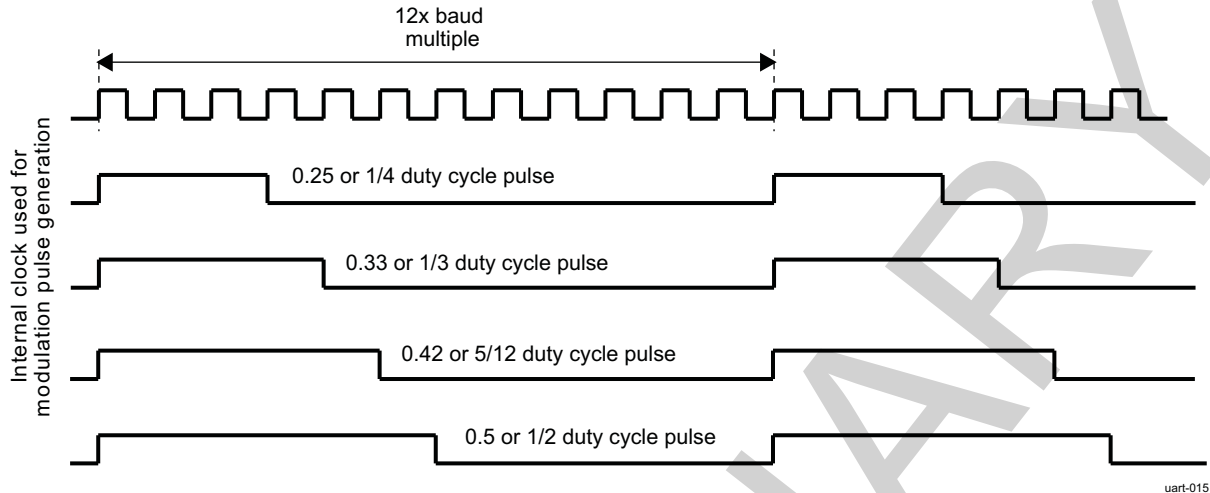

Figure 24-64. CIR Pulse Modulation

24.3.2.6.2.2 Pulse Duty Cycle

The programmer can choose one of four duty cycles for modulation pulses by setting the appropriate value in the UART3.UART_MDR2[5:4] CIR_PULSE_MODE bit field (1/4, 1/3, 5/12, or 1/2).

[Figure 24-65](#) shows the CIR modulation duty cycles.

Figure 24-65. CIR Modulation Duty Cycle

The transmission logic ensures that all pulses are transmitted completely (no cutoff during transmission). While transmitting continuous bytes back-to-back, no delay is inserted between 2 transmitted bytes. Thus, software must handle the delay between consecutively transmitted bytes if the receiving end requires it.

24.3.2.6.2.3 Consumer IR Encoding/Decoding

There are two methods of encoding for remote-control applications:

- Pulse duration encoding (time-extended bit forms): A variable pulse distance, or duration, in which the difference between logic 1 and logic 0 is the length of the pulse width
- Biphase encoding: The encoding of logic 0 and logic 1 is in the change of signal level from 1 to 0 or 0 to 1, respectively.

Japanese manufacturers favor pulse duration encoding; European manufacturers favor biphase encoding.

The CIR mode uses a completely flexible free-format encoding in which 1 is transmitted from the TX FIFO as a modulated pulse with duration t .

Similarly, 0 is transmitted as a blank duration T . The MPU constructs and deciphers the protocol of the data. For example, the RC-5 protocol using Manchester encoding can be emulated as using a 01 pair for 1 and a 10 pair for 0 (see [Figure 24-66](#)).

Figure 24-66. RC-5 Bit Encoding

Because CIR mode logic does not impose a fixed format for infrared packets of data, the MPU software can define the format using simple data structures that are then modulated into an industry standard, such as RC-5 or SIRC. To send a sequence of 0101 in RC-5, the MPU software must write an 8-bit binary character of 10011001 to the data FIFO of the UART.

For SIRC, the modulation length (multiples of t) is used to distinguish between 1 and 0. The subsequent SIRC digits show the difference in encoding between this and, for example, RC-5. The pulse width is extended for one digit.

Figure 24-67 shows SIRC bit encoding.

Figure 24-67. SIRC Bit Encoding

To construct comprehensive packets constituting remote-control commands, the MPU software must combine a number of 8-bit data characters in a sequence that follows one of the universally accepted formats.

Figure 24-68 shows a standard RC-5 frame as detected by UART3 in CIR mode (the SIRC format follows this). Each field in RC-5 can be considered as two t pulses (digital bits) from the TX FIFO.

Figure 24-68. RC-5 Standard Packet Format

Where:

- S1, S2: Start-bits (always 1)
- T: Toggle bit
- A4..A0: Address (or system) bits
- C5..C0: Command bits

The toggle bit T changes when a new command is transmitted to detect when the same key is pressed twice (effectively receiving the same data from the host consecutively). A brief delay in the transmission of the same command is detected by the use of the toggle bit because a code is sent while the MPU transmits characters to the UART for transmission. The address bits define the machine or device for which the infrared transmission is intended, and the command defines the operation.

To accommodate an extended RC-5 format, the S2 bit is replaced by an additional command bit (C6) that lets the command range increase to 7 bits. This format is known as the extended RC-5 format.

SIRC encoding uses the duration of modulation for mark and space; therefore, the duration of data bits in the standard frame length varies.

Figure 24-69 shows the packet format and bit encoding. As Figure 24-70 shows, 1 start-bit of 2.4 ms and control codes are followed by data that constitute the entire frame.

Figure 24-69. SIRC Packet Format

uart-019

NOTE: The encoding must take a standard duration, but the contents of the data can vary. This implies that the control software for sending and receiving data packets must exercise a scheme of interpacket delay, where successive packets can be sent only after a real-time delay expires.

Figure 24-70. SIRC Bit Transmission Example

uart-020

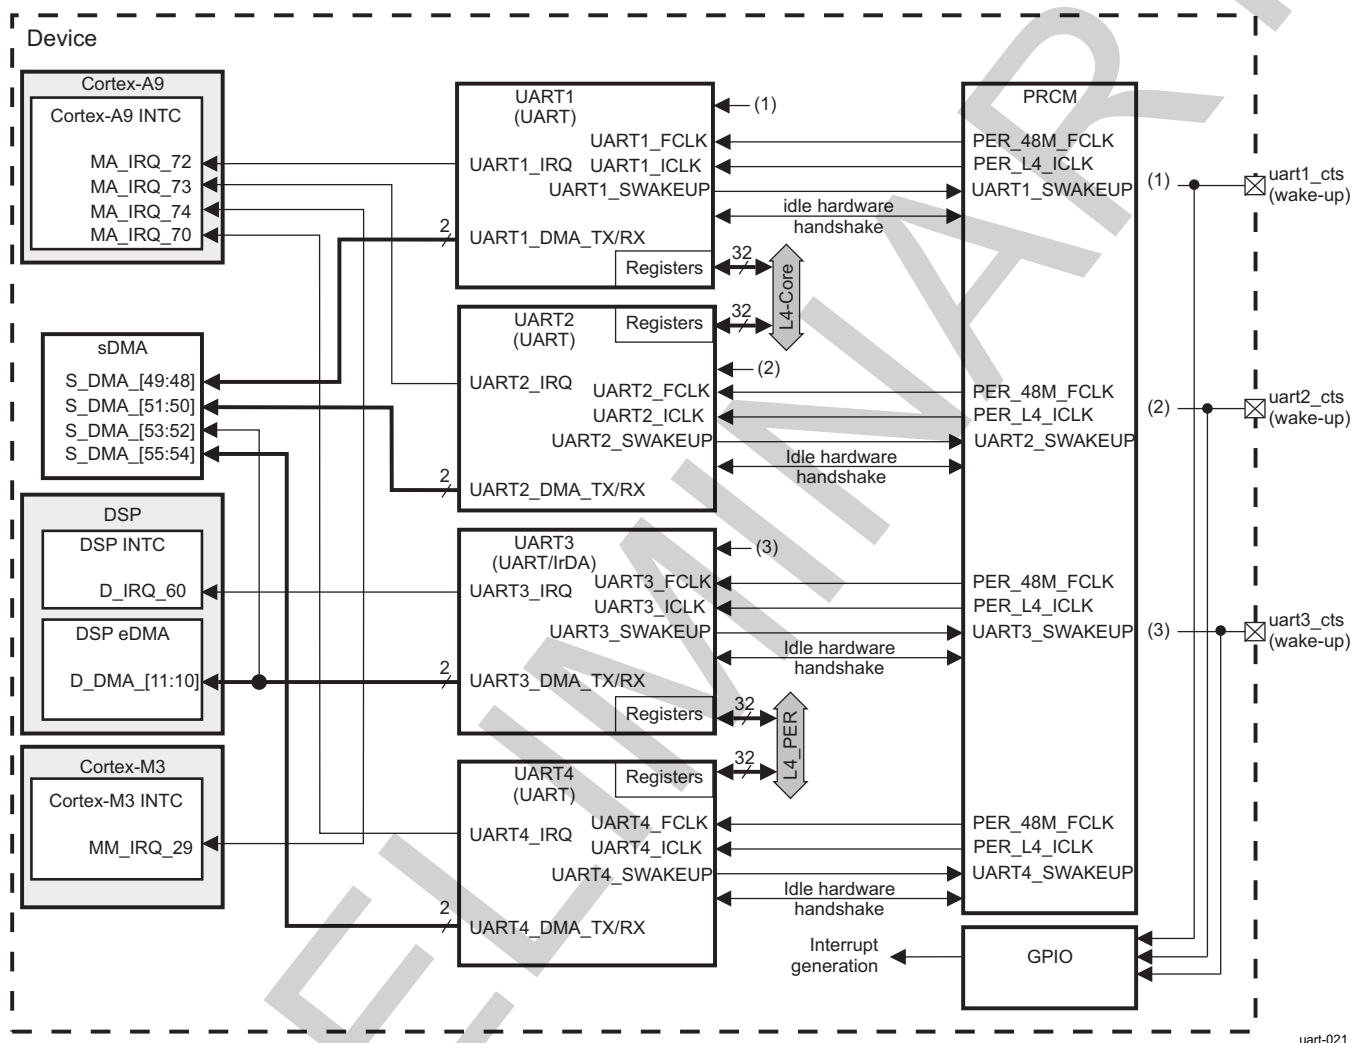

This document does not describe all encoding methods and techniques; the previous information discusses the considerations required to employ different encoding methods for different industry-standard protocols. See industry-standard documentation for specific methods of encoding and protocol use.

24.3.3 UART/IrDA/CIR Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 24-71 shows the device internal connections with related modules for UART functions.

Figure 24-71. UART/IrDA/CIR Integration

NOTE: For more information about the idle and standby hardware handshakes and the wake-up request, see *Clock Domain-Level Clock Management*, in [Chapter 3, Power, Reset, and Clock Management](#).

Table 24-142 through Table 24-144 summarize the integration of the module in the device.

Table 24-142. Integration Attributes

| Module Instance | Attributes | | |
|-----------------|--------------|--------------------|--------------|
| | Power Domain | Wake-Up Capability | Interconnect |
| UART1 | PD_L4_PER | Yes | L4_PER |
| UART2 | PD_L4_PER | Yes | L4_PER |
| UART3 | PD_L4_PER | Yes | L4_PER |
| UART4 | PD_L4_PER | Yes | L4_PER |

Table 24-143. Clocks and Resets

| Clocks | | | | |

24.3.4 UART/IrDA/CIR Functional Description

24.3.4.1 Block Diagram

The UART/IrDA/CIR module can be divided into three main blocks:

- FIFO management
- Mode selection
- Protocol formatting

FIFO management is common to all functions and enables the transmission and reception of data from the host processor point of view.

There are two modes:

- Function mode: Routes the data to the chosen function (UART, IrDA, or CIR) and enables the mechanism corresponding to the chosen function
- Register mode: Enables conditional access to registers

For more information about mode configuration, see [Section 24.3.4.7, Mode Selection](#).

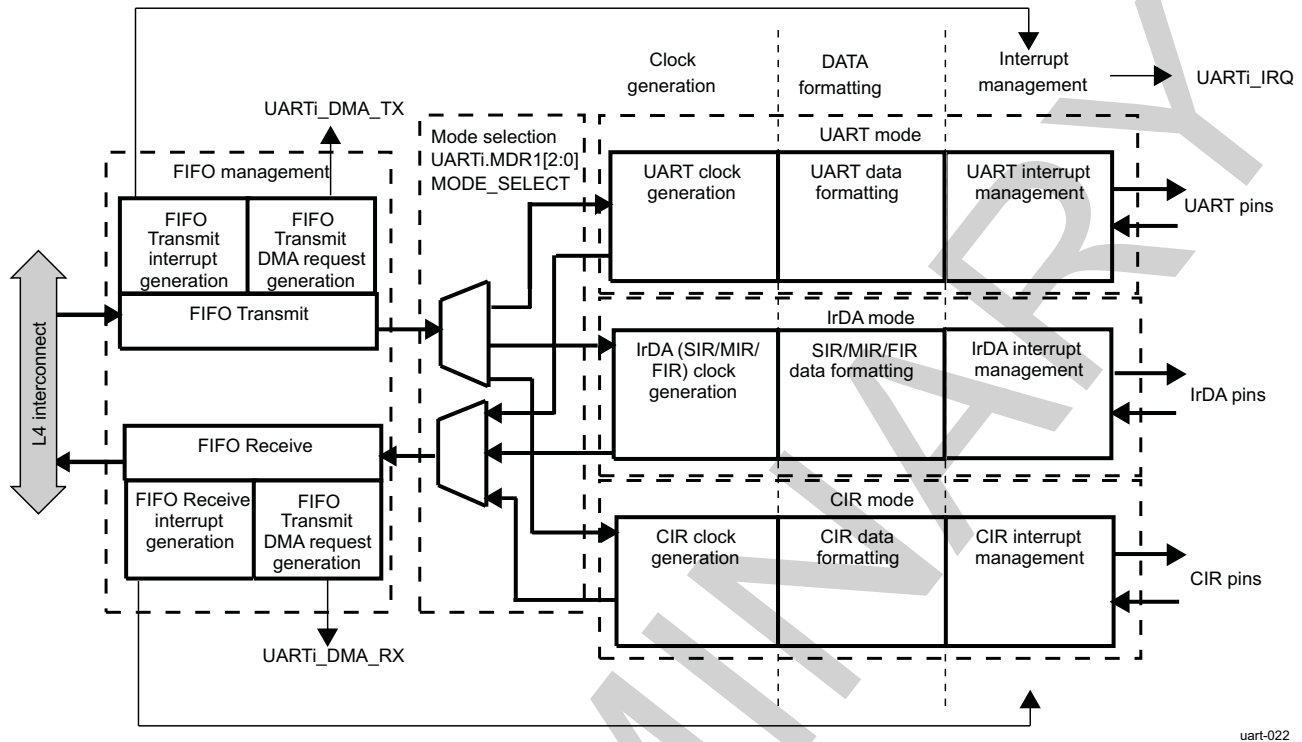

Protocol formatting has three subcategories:

- Clock generation: The 48-MHz input clock generates all necessary clocks.
- Data formatting: Each function uses its own state-machine that is responsible for the transition between FIFO data and frame data associated with it.
- Interrupt management: Different interrupt types are generated depending on the chosen function:
 - UART mode interrupts: Seven interrupts prioritized in six different levels
 - IrDA mode interrupts: Eight interrupts. The interrupt line is activated when any interrupt is generated (there is no priority).
 - CIR mode interrupts: A subset of existing IrDA mode interrupts is used.In each mode, when an interrupt is generated, the [UART_IIR](#) register indicates the interrupt type.

In parallel with these functional blocks, a power-saving strategy exists for each function.

[Figure 24-72](#) is the UART/IrDA/CIR block diagram.

Figure 24-72. UART/IrDA/CIR Functional Specification Block Diagram

uart-022

24.3.4.2 Clock Configuration

Each UART uses a 48-MHz functional clock for its logic and to generate external interface signals. Each UART uses an interface clock for register accesses. The PRCM module generates and controls all these clocks (for more information, see [Clock Domain Module Attributes](#), in [Chapter 3, Power, Reset, and Clock Management](#)).

The idle and wake-up processes use a handshake protocol between the PRCM and the UART (for a description of the protocol, see [Section 3.1.1.1.2, Module-Level Clock Managment](#), in [Chapter 3, Power, Reset, and Clock Management](#)). The `UARTi.UART_SYSC[4:3] IDLEMODE` bit field controls UART idle mode.

24.3.4.3 Software Reset

The `UARTi.UART_SYSC[1] SOFTRESET` bit controls the software reset; setting this bit to 1 triggers a software reset functionally equivalent to hardware reset.

24.3.4.4 Power Management

24.3.4.4.1 UART Mode Power Management

24.3.4.4.1.1 Module Power Saving

In UART modes, sleep mode is enabled by setting the `UARTi.UART_IER[4] SLEEP_MODE` bit to 1 (when the `UARTi.UART_EFR[4] ENHANCED_EN` bit is set to 1).

Sleep mode is entered when all the following conditions exist:

- The serial data input line, `uarti_rx`, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- The only pending interrupts are THR interrupts.

Sleep mode is a good way to lower UART power consumption, but this state can be achieved only when the UART is set to modem mode. Therefore, even if the UART has no key role functionally, it must be initialized in a functional mode to take advantage of sleep mode.

In sleep mode, the module clock and baud rate clock are stopped internally. Because most registers are clocked by these clocks, this greatly reduces power consumption. The module wakes up when a change is detected on the uarti_rx line, when data is written to the TX FIFO, and when there is a change in the state of the modem input pins.

An interrupt can be generated on a wake-up event by setting the UARTi.UART_SCR[4] RX_CTS_WU_EN bit to 1. To understand how to manage the interrupt, see [Section 24.3.4.5.1.2, Wake-Up Interrupt](#).

NOTE: There must be no writing to the divisor latches, UARTi.UART_DLL and UARTi.UART_DLH, to set the baud clock (BCLK) while in sleep mode. It is advisable to disable sleep mode using the UARTi.UART_IER[4] SLEEP_MODE bit before writing to the UARTi.UART_DLL register or the UARTi.UART_DLH register.

24.3.4.4.1.2 System Power Saving

Sleep and auto-idle modes are embedded power-saving features. Power-reduction techniques can be applied at the system level by shutting down certain internal clock and power domains of the device.

The UART supports an idle req/idle ack handshaking protocol used at the system level to shut down the UART clocks in a clean and controlled manner and to switch the UART from interrupt-generation mode to wake-up generation mode for unmasked events (see the UARTi.UART_SYSC[2] ENAWAKEUP bit and the UARTi.UART_WER register).

For more information, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

24.3.4.4.2 IrDA Mode Power Management (UART3 Only)

24.3.4.4.2.1 Module Power Saving

In IrDA modes, sleep mode is enabled by setting the UART3.MDR[3] IR_SLEEP bit to 1.

Sleep mode is entered when all the following conditions exist:

- The serial data input line, uart3.rx_irrx, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

The module wakes up when a change is detected on the uart3_rx_irrx line or when data is written to the TX FIFO.

24.3.4.4.2.2 System Power Saving

System power saving for the IrDA mode has the same function as for the UART mode (see [Section 24.3.4.4.1.2, System Power Saving](#)).

24.3.4.4.3 CIR Mode Power Management (UART3 Only)

24.3.4.4.3.1 Module Power Saving

Module power saving for the CIR mode has the same function as for the IrDA mode (see [Section 24.3.4.4.2.1, Module Power Saving](#)).

24.3.4.4.3.2 System Power Saving

System power saving for the CIR mode has the same function as for the UART mode (see [Section 24.3.4.4.1.2, System Power Saving](#)).

24.3.4.4.4 Local Power Management

[Table 24-145](#) describes power-management features available for the UART.

NOTE: For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 24-145. Local Power-Management Features

| Feature | Registers | Description |
|------------------------|--|--|
| Clock autogating | UART_SYSC [0] AUTOIDLE | This bit allows local power optimization in the module by gating the UARTi_ICLK clock on interface activity or gating the UARTi_FCLK clock on internal activity. |
| Slave idle modes | UART_SYSC [4:3] IDLEMODE | Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available |
| Clock activity | N/A | Feature not available |
| Master standby modes | N/A | Feature not available |
| Global wake-up enable | UART_SYSC [2] ENAWAKEUP | This bit enables the wake-up feature at module level. |
| Wake-Up sources enable | N/A | Feature not available |

24.3.4.5 Interrupt Requests

24.3.4.5.1 UART Mode Interrupt Management

24.3.4.5.1.1 UART Interrupts

UART mode includes seven possible interrupts prioritized to six levels.

When an interrupt is generated, the interrupt identification register (UARTi.[UART_IIR](#)) sets the UARTi.[UART_IIR](#)[0] IT_PENDING bit to 0 to indicate that an interrupt is pending, and indicates the type of interrupt through the UARTi.[UART_IIR](#)[5:1] bit field. [Table 24-146](#) summarizes the interrupt control functions.

Table 24-146. UART Mode Interrupts

| UART_IIR [5:0] | Priority Level | Interrupt Type | Interrupt Source | Interrupt Reset Method |
|--------------------------------|----------------|----------------------|---|---|
| 000001 | None | None | None | None |
| 000110 | 1 | Receiver line status | OE, FE, PE, or BI errors occur in characters in the RX FIFO. | FE, PE, BI: Read the UART_RHR register. OE: Read the UART_LSR register. |
| 001100 | 2 | RX time-out | Stale data in RX FIFO | Read the UART_RHR register. |
| 000100 | 2 | RHR interrupt | DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable) | Read the UART_RHR register until the interrupt condition disappears. |
| 000010 | 3 | THR interrupt | TFE (UART_THR empty) (FIFO disable) TX FIFO below trigger level (FIFO enable) | Write to the UART_THR until the interrupt condition disappears. |

Table 24-146. UART Mode Interrupts (continued)

| UART_IIR[5:0] | Priority Level | Interrupt Type | Interrupt Source | Interrupt Reset Method |
|---------------|----------------|--|---|--|
| 000000 | 4 | Modem status | See the UART_MSR register. | Read the UART_MSR register. |
| 010000 | 5 | XOFF interrupt/special character interrupt | Receive XOFF characters/special character | Receive XON character(s), if XOFF interrupt/read of the UART_IIR register, if special character interrupt. |
| 100000 | 6 | CTS, RTS | RTS pin or CTS pin change state from active (low) to inactive (high). | Read the UART_IIR register. |

For the receiver-line status interrupt, the RX_FIFO_STS bit (UARTi.[UART_LSR](#)[7]) generates the interrupt.

For the XOFF interrupt, if an XOFF flow character detection caused the interrupt, the interrupt is cleared by an XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the UARTi.[UART_IIR](#) register.

24.3.4.5.1.2 Wake-Up Interrupt

Wake-up interrupt is a special interrupt that works differently from other interrupts. This interrupt is enabled when the UARTi.[UART_SCR](#)[4] RX_CTS_WU_EN bit is set to 1. The UARTi.[UART_IIR](#) register is not modified when this occurs; the UART3.[UART_SSR](#)[1] RX_CTS_WU_STS bit must be checked to detect a wake-up event.

When a wake-up interrupt occurs, it can be cleared only by resetting the UARTi.[UART_SCR](#)[4] RX_CTS_WU_EN bit. This bit must be reenabled (set to 1) after the current wake-up interrupt event is processed to detect the next incoming wake-up event.

24.3.4.5.2 IrDA Mode Interrupt Management

24.3.4.5.2.1 IrDA Interrupts

The IrDA function generates interrupts. All interrupts can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UART3.[UART_IER](#)). The interrupt status of the device can be checked by reading the interrupt identification register (UART3.[UART_IIR](#)).

UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UART3.[UART_IER](#) and UART3.[UART_IIR](#) mappings, depending on the selected mode.

IrDA modes have eight possible interrupts (see [Table 24-147](#)). The interrupt line is activated when any interrupt is generated (there is no priority).

Table 24-147. IrDA Mode Interrupts

| UART_IIR Bit | Interrupt Type | Interrupt Source | Interrupt Reset Method |
|--------------|----------------------|---|--|
| 0 | RHR interrupt | DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable) | Read the UART_RHR register until the interrupt condition disappears. |
| 1 | THR interrupt | TFE (UART_THR empty) (FIFO disable) TX FIFO below trigger level (FIFO enable) | Write to the UART_THR until the interrupt condition disappears. |
| 2 | Last byte in RX FIFO | Last byte of frame in RX FIFO is available to be read at the RHR port. | Read the UART_RHR register. |
| 3 | RX overrun | Write to the UART_RHR register when the RX FIFO is full. | Read UART_RESUME register. |

Table 24-147. IrDA Mode Interrupts (continued)

| UART_IIR Bit | Interrupt Type | Interrupt Source | Interrupt Reset Method |
|--------------|--------------------------------|--|---|
| 4 | Status FIFO interrupt | Status FIFO triggers level reached. | Read STATUS FIFO. |
| 5 | TX status | <ol style="list-style-type: none"> 1. UART_THR empty before EOF sent. Last bit of transmission of the IrDA frame occurred, but with an underrun error. OR 2. Transmission of the last bit of the IrDA frame completed successfully. | <ol style="list-style-type: none"> 1. Read the UART_RESUME register. OR 2. Read the UART_IIR register. |
| 6 | Receiver line status interrupt | CRC, ABORT, or frame-length error is written into the STATUS FIFO. | Read the STATUS FIFO (read until empty - maximum of eight reads required). |
| 7 | Received EOF | Received end-of-frame | Read the UART_IIR register. |

24.3.4.5.2.2 Wake-Up Interrupts

The wake-up interrupt for IrDA mode has the same function as that for UART mode (see [Section 24.3.4.5.1.2, Wake-Up Interrupt](#)).

CAUTION

Wake-Up interface implementation in this mode is based on the UARTi_SIDLEACK low-to-high transition instead of the UARTi_SIDLEACK state.

This does not ensure wake-up event generation as expected when configured in smart-idle mode, and the system wakes up for a short period.

24.3.4.5.3 CIR Mode Interrupt Management

24.3.4.5.3.1 CIR Interrupts

The CIR function generates interrupts that can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UART3.[UART_IER](#)). The interrupt status of the device can be checked by reading the interrupt identification register (UART3.[UART_IIR](#)).

UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UART3.[UART_IER](#) and UART3.[UART_IIR](#) mappings, depending on the selected mode.

[Table 24-148](#) lists the interrupt modes to be maintained. In CIR mode, the sole purpose of the UART3.[UART_IIR](#)[5] bit is to indicate that the last bit of infrared data was passed to the uart3_cts_rctx pin.

Table 24-148. CIR Mode Interrupts

| UART_IIR Bit Number | Interrupt Type | Interrupt Source | Interrupt Reset Method |
|---------------------|------------------|---|--|
| 0 | N/A for CIR mode | N/A for CIR mode | N/A for CIR mode |
| 1 | THR interrupt | TFE (UART_THR empty) (FIFO disable) TX FIFO below trigger level (FIFO enable) | Write to the UART_THR register until the interrupt condition disappears. |
| 2 | N/A for CIR mode | N/A for CIR mode | N/A for CIR mode |
| 3 | N/A for CIR mode | N/A for CIR mode | N/A for CIR mode |
| 4 | N/A for CIR mode | N/A for CIR mode | N/A for CIR mode |

Table 24-148. CIR Mode Interrupts (continued)

| UART_IIR Bit Number | Interrupt Type | Interrupt Source | Interrupt Reset Method |
|----------------------------|-----------------------|---|---|
| 5 | TX status | Transmission of the last bit of the frame is complete successfully. | Read the UART_IIR register. |
| 6 | N/A for CIR mode | N/A for CIR mode | N/A for CIR mode |
| 7 | N/A for CIR mode | N/A for CIR mode | N/A for CIR mode |

24.3.4.5.3.2 Wake-Up Interrupts

The wake-up interrupt for CIR mode has the same function as that for UART mode (see [Section 24.3.4.5.1.2, Wake-Up Interrupt](#)).

24.3.4.6 FIFO Management

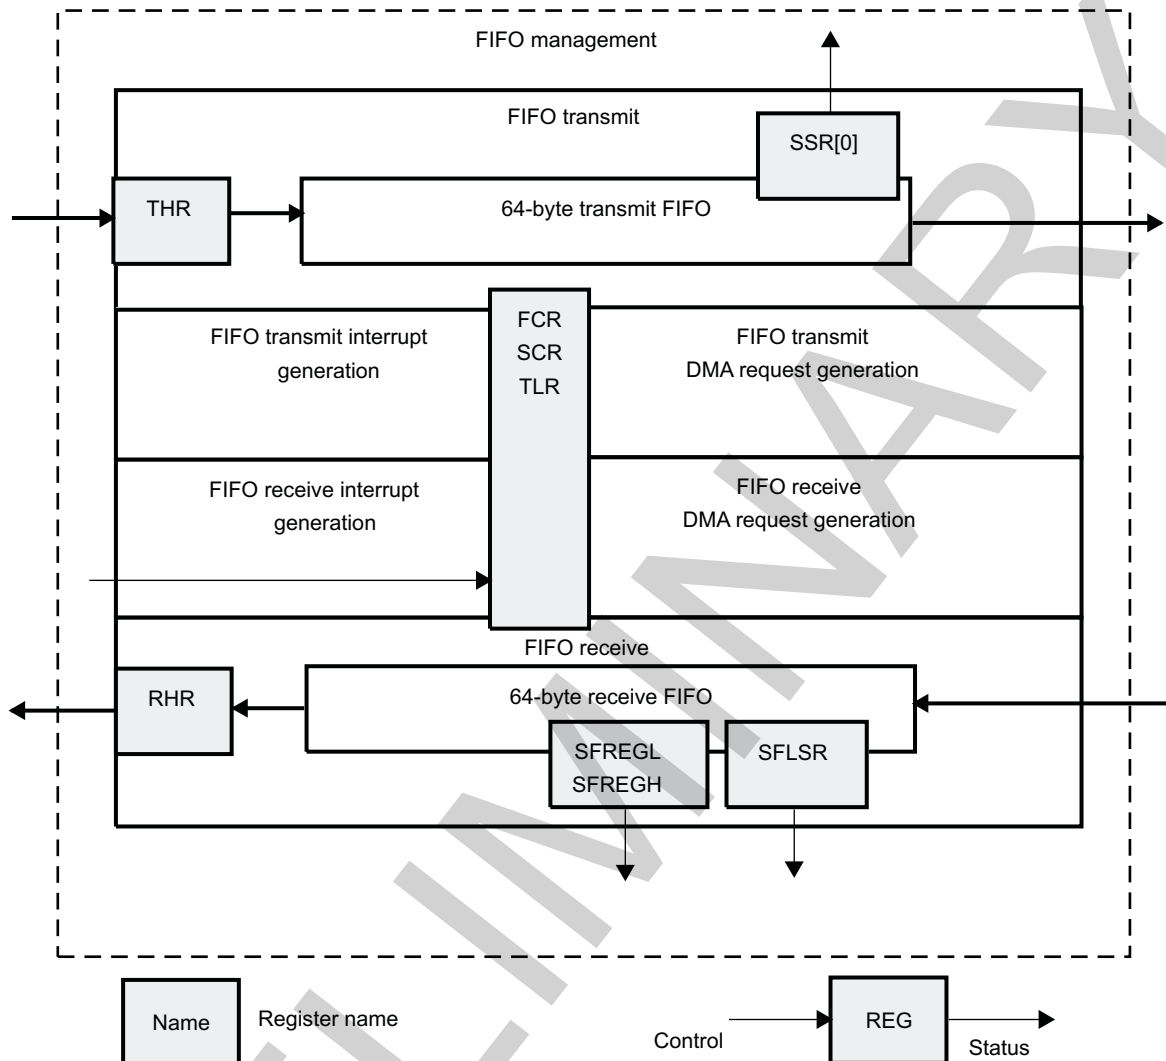

The FIFO is accessed by reading and writing the UARTi.[UART_RHR](#) and UARTi.[UART_THR](#) registers. Parameters are controlled using the FIFO control register (UARTi.[UART_FCR](#)) and supplementary control register (UARTi.[UART_SCR](#)). Reading the UARTi.[UART_SSR](#)[0] TX_FIFO_FULL bit at 1 means the FIFO is full.

The UARTi.[UART_TLR](#) register controls the FIFO trigger level, which enables DMA and interrupt generation. After reset, transmit (TX) and receive (RX) FIFOs are disabled; thus, the trigger level is the default value of 1 byte. [Figure 24-73](#) shows the FIFO management registers.

NOTE: Data in the UARTi.[UART_RHR](#) register is not overwritten when an overflow occurs.

NOTE: The UARTi.[UART_SFLSR](#), UARTi.[UART_SFREGL](#), and UARTi.[UART_SFREGH](#) status registers are used in IrDA mode only. For use, see [Section 24.3.4.8.2.3, IrDA Data Formatting](#).

Figure 24-73. FIFO Management Registers

uart-023

24.3.4.6.1 FIFO Trigger

24.3.4.6.1.1 Transmit FIFO Trigger

Table 24-149 lists the TX FIFO trigger level settings.

Table 24-149. TX FIFO Trigger Level Setting Summary

| UART_SCR[6] | UART_TLR[3:0] | TX FIFO Trigger Level |
|-------------|---------------|---|
| 0 | = 0x0 | Defined by the UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit field (8,16, 32, or 56 spaces) |
| 0 | != 0x0 | Defined by the UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit field (from 4 to 60 spaces with a granularity of 4 spaces) |
| 1 | Value | Defined by the concatenated value of TX_FIFO_TRIG_DMA and TX_FIFO_TRIG (from 1 to 63 spaces with a granularity of 1 space) Note: The combination of TX_FIFO_TRIG_DMA = 0x0 and TX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of one space required). All zeros result in unpredictable behavior. |

24.3.4.6.1.2 Receive FIFO Trigger

Table 24-150 lists the RX FIFO trigger level settings.

Table 24-150. RX FIFO Trigger Level Setting Summary

| UART_SCR[7] | UART_TLR[7:4] | RX FIFO Trigger Level |
|-------------|---------------|---|
| 0 | = 0x0 | Defined by the UARTi.UART_FCR[7:6] RX_FIFO_TRIG bit field (8,16, 56, or 60 characters) |
| 0 | != 0x0 | Defined by the UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA bit field (from 4 to 60 characters with a granularity of 4 characters) |
| 1 | Value | Defined by the concatenated value of RX_FIFO_TRIG_DMA and RX_FIFO_TRIG (from 1 to 63 characters with a granularity of 1 character) Note: The combination of RX_FIFO_TRIG_DMA = 0x0 and RX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of one character required). All zeros result in unpredictable behavior. |

The receive threshold is programmed using the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START and UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit fields:

- Trigger levels from 0 to 60 bytes are available with a granularity of 4 (trigger level = 4 x [4-bit register value]).
- To ensure correct device operation, ensure that RX_FIFO_TRIG_HALT RX_FIFO_TRIG when auto-RTS is enabled.

$$\text{Delay} = [4 + 16 \times (1 + \text{CHAR_LENGTH} + \text{Parity} + \text{Stop } 0.5)] \times \text{Baud_rate} + 4 \times \text{FCLK}$$

NOTE: The RTS signal is deasserted after the UART module receives the data over RX_FIFO_TRIG_HALT. Delay means how long the UART module takes to deassert the RTS signal after reaching RX_FIFO_TRIG_HALT.

- In FIFO interrupt mode with flow control, ensure that the trigger level to HALT transmission is greater than or equal to the RX FIFO trigger level (the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START bit field or the UARTi.UART_FCR[7:6] RX_FIFO_TRIG bit field); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist, because a DMA request is sent when a byte is received.

24.3.4.6.2 FIFO Interrupt Mode

In FIFO interrupt mode (the FIFO control register UARTi.UART_FCR[0] FIFO_EN bit is set to 1 and

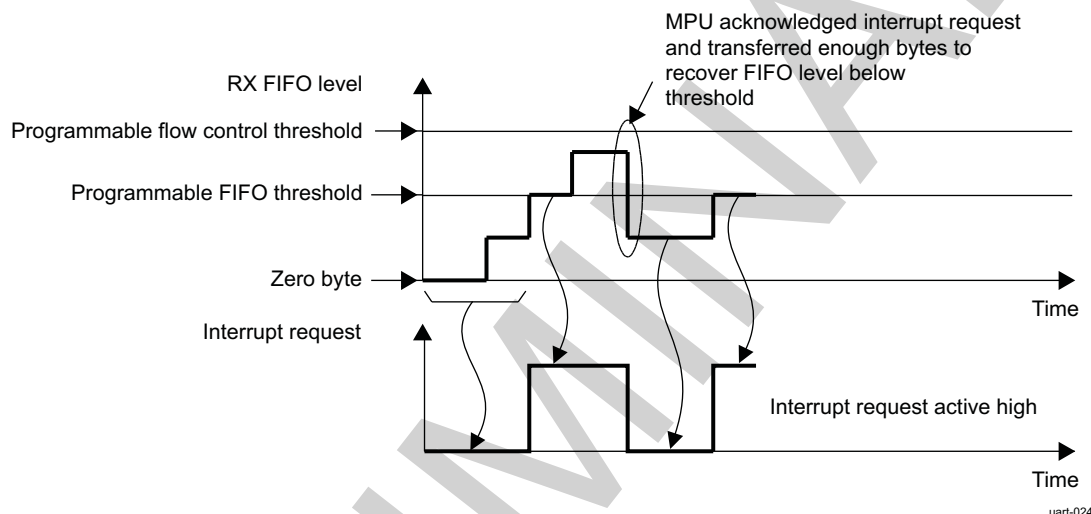

relevant interrupts are enabled by the UARTi.UART_IER register), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the RX/TX FIFO threshold (the UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA and UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit fields or the UARTi.UART_FCR[7:6] RX_FIFO_TRIG and UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit fields, respectively) is reached.

The interrupt signals instruct the MPU to transfer data to the destination (from the UART in receive mode and/or from any source to the UART FIFO in transmit mode).

When UART flow control is enabled with interrupt capabilities, the UART flow control FIFO threshold (the UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit field) must be greater than or equal to the RX FIFO threshold.

Figure 24-74 shows the generation of the RX FIFO interrupt request.

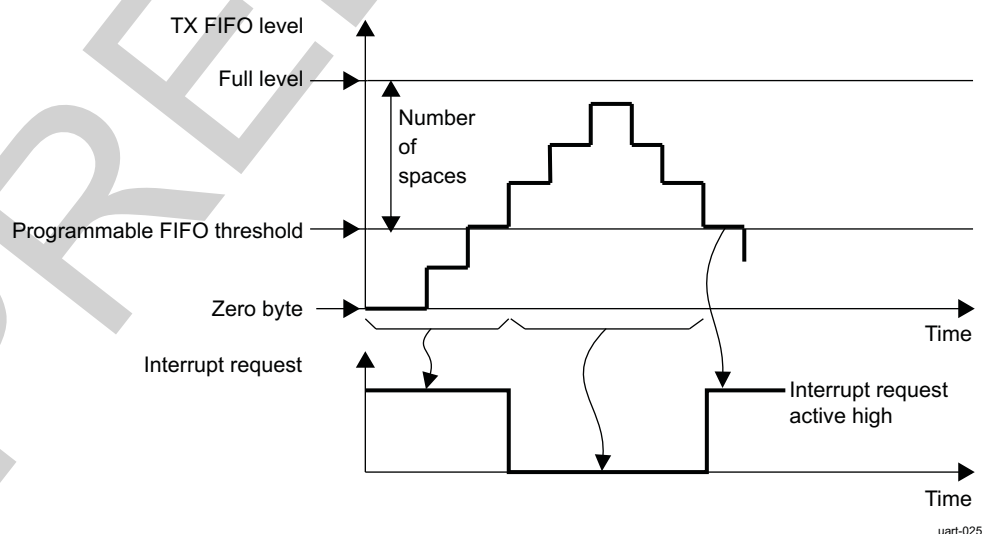

Figure 24-74. RX FIFO Interrupt Request Generation

In receive mode, no interrupt is generated until the RX FIFO reaches its threshold. Once low, the interrupt can be deasserted only when the MPU has handled enough bytes to put the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

Figure 24-75 shows the generation of the TX FIFO interrupt request.

Figure 24-75. TX FIFO Interrupt Request Generation

In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is deasserted when the TX FIFO crosses the threshold level. The interrupt line is deasserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

24.3.4.6.3 FIFO Polled Mode Operation

In FIFO polled mode (the UARTi.UART_FCR[0] FIFO_EN bit is set to 0 and the relevant interrupts are disabled by the UARTi.UART_IER register), the status of the receiver and transmitter can be checked by polling the line status register (UARTi.UART_LSR).

This mode is an alternative to the FIFO interrupt mode of operation in which the status of the receiver and transmitter is automatically determined by sending interrupts to the MPU.

24.3.4.6.4 FIFO DMA Mode Operation

Although DMA operation includes four modes (DMA modes 0 through 3), the information in [Table 24-144](#) assumes that mode 1 is used. (Mode 2 and mode 3 are legacy modes that use only one DMA request for each module.)

In mode 2, the remaining DMA request is used for RX. In mode 3, the remaining DMA request is used for TX.

DMA requests in mode 2 and mode 3 use the following signals:

- S_DMA_48
- S_DMA_50
- S_DMA_52/D_DMA_10
- S_DMA_54

The following signals are not used by the module in mode 2 and mode 3:

- S_DMA_49
- S_DMA_51
- S_DMA_53/D_DMA_11
- S_DMA_55

These signals can be selected as follows:

- When the UARTi.UART_SCR[0] DMA_MODE_CTL bit is set to 0, setting the UARTi.UART_FCR[3] DMA_MODE_CTL bit to 0 enables DMA mode 0. Setting the DMA_MODE_CTL bit to 1 enables DMA mode 1.
- When the DMA_MODE_CTL bit is set to 1, the UARTi.UART_FCR[2:1] DMA_MODE_2 bit field determines DMA mode 0 to mode 3 based on the supplementary control register (UART_SCR) description.

For example:

- If no DMA operation is desired, set the DMA_MODE_CTL bit to 1 and the DMA_MODE_2 bit field to 0x0. (The DMA_MODE bit is discarded.)
- If DMA mode 1 is desired, set the DMA_MODE_CTL bit to 0 and the DMA_MODE bit to 1, or set the DMA_MODE_CTL bit to 1 and the DMA_MODE_2 bit field to 01. (The DMA_MODE bit is discarded.)

If the FIFOs are disabled (the UARTi.UART_FCR[0] FIFO_EN bit is set to 0), the DMA occurs in single-character transfers.

When DMA mode 0 is programmed, the signals associated with DMA operation are not active.

Depending on UART_MDR3[2] SET_DMA_TX_THRESHOLD, the threshold can be programmed different ways:

- SET_TX_DMA_THRESHOLD = 1:

The threshold value will be the value of the UART_TX_DMA_THRESHOLD register. If SET_TX_DMA_THRESHOLD + TX trigger spaces 64, then the default method of threshold is used: threshold value = TX FIFO size.

- SET_TX_DMA_THRESHOLD = 0:

The threshold value = TX FIFO size TX trigger space. The TX DMA line is asserted if the TX FIFO level is lower than the threshold. It remains asserted until TX trigger spaces number of bytes are written into the FIFO. The DMA line is then deasserted and the FIFO level is compared with the threshold value.

24.3.4.6.4.1 DMA Transfers (DMA Mode 1, 2, or 3)

Figure 24-76 through Figure 24-79 show the supported DMA operations.

Figure 24-76. Receive FIFO DMA Request Generation (32 Characters)

uart-026

In receive mode, a DMA request is generated when the RX FIFO reaches its threshold level defined in the trigger level register (UARTi.UART_TLR). This request is deasserted when the number of bytes defined by the threshold level is read by the sDMA.

In transmit mode, a DMA request is automatically asserted when the TX FIFO is empty. This request is deasserted when the number of bytes defined by the number of spaces in the UARTi.UART_TLR register is written by the sDMA. If an insufficient number of characters is written, the DMA request stays active.

Figure 24-77. Transmit FIFO DMA Request Generation (56 Spaces)

uart-027

The DMA request is again asserted if the FIFO can receive the number of bytes defined by the UARTi.UART_TLR register.

The threshold can be programmed in a number of ways. Figure 24-77 shows a DMA transfer operating with a space setting of 56 that can arise from using the auto settings in the UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit field or the UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit field concatenated with the TX_FIFO_TRIG bit field.

The setting of 56 spaces in the UART/IrDA/CIR module must correlate with the settings of the sDMA so that the buffer does not overflow (program the DMA request size of the LH controller to equal the number of spaces in the UART/IrDA/CIR module).

Figure 24-78 shows an example with eight spaces to show the buffer level crossing the space threshold. The LH DMA controller settings must correspond to those of the UART/IrDA/CIR module.

Figure 24-78. Transmit FIFO DMA Request Generation (8 Spaces)

uart-028

The next example shows the setting of one space that uses the DMA for each transfer of one character to the transmit buffer (see Figure 24-79). The buffer is filled faster than the baud rate at which data is transmitted to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer.

On two occasions, the buffer holds the maximum amount of data words; shortly after this, the DMA is disabled to show the slower transmission of the data words to the TX pin. Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UARTi.UART_DLL and UARTi.UART_DLH registers.

The DMA settings must correspond to the system LH DMA controller settings to ensure correct operation of this logic.

Figure 24-79. Transmit FIFO DMA Request Generation (1 Space)

The final example shows the setting of eight spaces, but setting the TX DMA threshold directly by setting the `UART_MDR3[1]` `NONDEFAULT_FREQ` bit and the `UART_TX_DMA_THRESHOLD` register (see Figure 24-80). In the example, `UART_TX_DMA_THRESHOLD[5:0]` `TX_DMA_THRESHOLD` = 3 and the trigger level is 8. The buffer is filled at a faster rate than the baud rate transmits data to the TX pin. The buffer is filled with 8 bytes and the DMA operations stop transferring data to the transmit buffer. When the buffer is emptied to the threshold level by transmission, the DMA operation activates again to fill the buffer with 8 bytes.

Eventually, the buffer is emptied at the rate specified by the baud rate settings of the `UART_DLL` and `UART_DLH` registers.

If the selected threshold level plus the trigger level exceed the maximum buffer size, the original TX DMA threshold method is used to prevent TX overrun, regardless of the value of the `UART_MDR3[1]` `NONDEFAULT_FREQ` bit.

The DMA settings must correspond to the settings of the system local host DMA controller to ensure the correct operation of this logic.

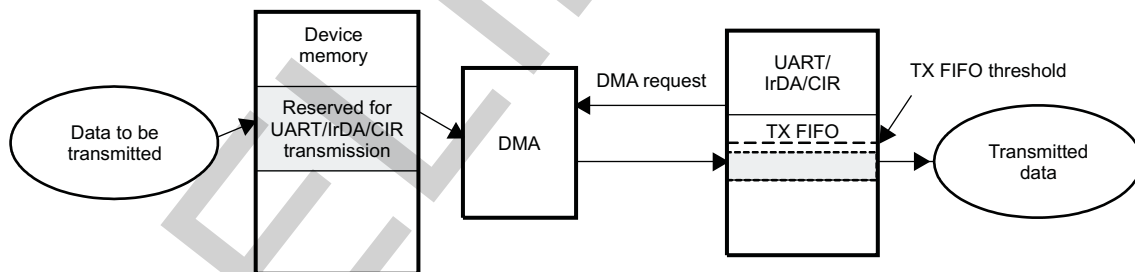

**Figure 24-80. Transmit FIFO DMA Request Generation Using Direct TX DMA Threshold Programming.
(Threshold = 3; Spaces = 8)**

24.3.4.6.4.2 DMA Transmission

Figure 24-81 shows DMA transmission.

Figure 24-81. DMA Transmission

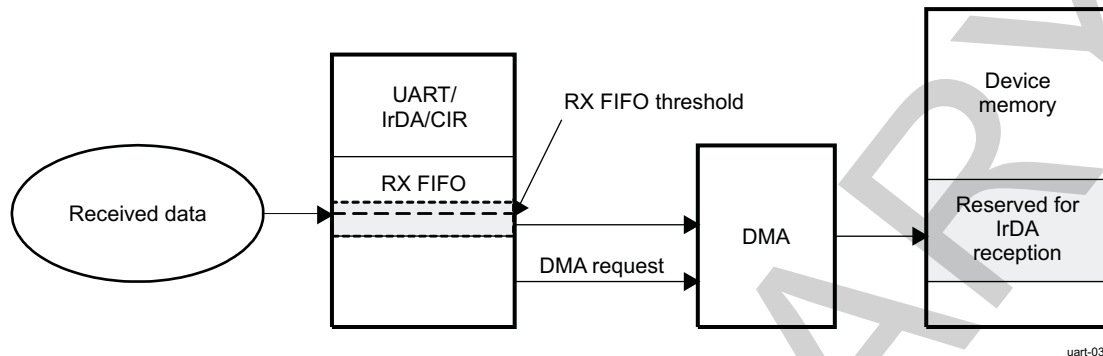

1. Data to be transmitted are put in the device memory reserved for UART/IrDA/CIR transmission by the DMA:
 - (a) Until the TX FIFO trigger level is not reached, a DMA request is generated
 - (b) An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).
2. Data in the TX FIFO are automatically transmitted.
3. The end of the transmission is signaled by the UARTi.UART_THR empty (TX FIFO empty).

NOTE: In IrDA mode, the transmission does not end immediately after the TX FIFO empties, at which point the last data byte, the CRC field, and the stop flag still must be transmitted; thus, the end of transmission occurs a few milliseconds after the UARTi.UART_THR register empties.

24.3.4.6.4.3 DMA Reception

Figure 24-82 shows DMA reception.

Figure 24-82. DMA Reception

1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA:
 - (a) At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
 - (b) An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

24.3.4.7 Mode Selection

24.3.4.7.1 Register Access Modes

24.3.4.7.1.1 Operational Mode and Configuration Modes

Register access depends on the register access mode, although register access modes are not correlated to functional mode selection. Three different modes are available:

- Operational mode
- Configuration mode A
- Configuration mode B

Operational mode is the selected mode when the function is active; serial data transfer can be performed in this mode.

Configuration mode A and configuration mode B are used during module initialization steps. These modes enable access to configuration registers, which are hidden in the operational mode. The modes are used when the module is inactive (no serial data transfer processed) and only for initialization or reconfiguration of the module.

The value of the UARTi.UART_LCR register determines the register access mode (see Table 24-151).

Table 24-151. UART/IrDA/CIR Register Access Mode Programming (Using UART_LCR)

| Mode | Condition |
|----------------------|---|
| Configuration mode A | UART_LCR[7] = 0x1 and UART_LCR[7:0] != 0xBF |
| Configuration mode B | UART_LCR[7] = 0x1 and UART_LCR[7:0] = 0xBF |
| Operational mode | UART_LCR[7] = 0x0 |

24.3.4.7.1.2 Register Access Submode

In each access register mode (operational mode or configuration mode A/B), some register accesses are conditional on the programming of a submode (MSR_SPR, TCR_TLR, and XOFF). These registers are identified in [Section 24.3.6, UART/IrDA/CIR Register Manual](#).

[Table 24-152](#) through [Table 24-154](#) summarize the register access submodes.

Table 24-152. Subconfiguration Mode A Summary

| Mode | Condition |
|---------|---|
| MSR_SPR | (UART_EFR [4] = 0x0 or UART_MCR [6] = 0x0) |
| TCR_TLR | UART_EFR [4] = 0x1 and UART_MCR [6] = 0x1 |

Table 24-153. Subconfiguration Mode B Summary

| Mode | Condition |
|---------|---|
| TCR_TLR | UART_EFR [4] = 0x1 and UART_MCR [6] = 0x1 |
| XOFF | (UART_EFR [4] = 0x0 or UART_MCR [6] = 0x0) |

Table 24-154. Suboperational Mode Summary

| Mode | Condition |
|---------|---|
| MSR_SPR | UART_EFR [4] = 0x0 or UART_MCR [6] = 0x0 |
| TCR_TLR | UART_EFR [4] = 0x1 and UART_MCR [6] = 0x1 |

24.3.4.7.1.3 Registers Available for the Register Access Modes

[Table 24-155](#) lists the names of the register bits in each access register mode. Gray shading indicates that the register does not depend on the register access mode (available in all modes).

Table 24-155. UART/IrDA/CIR Register Access Mode Overview

| Address Offset | Registers | | | | | |
|-------------------|---|--|--|---|--|---|
| | Configuration Mode A | | Configuration Mode B | | Operational Mode | |
| | Read | Write | Read | Write | Read | Write |
| 0x000 | UART_DLL | UART_DLL | UART_DLL | UART_DLL | UART_RHR | UART_THR |

24.3.4.7.2 UART/IrDA (SIR, MIR, FIR)/CIR Mode Selection

To select a mode, set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field (see Table 24-156).

Table 24-156. UART Mode Selection

| Value | Mode |
|-------|-----------------------|
| 0x0: | UART 16x mode |
| 0x1: | SIR mode (UART3 only) |
| 0x2: | UART 16x auto-baud |
| 0x3: | UART 13x mode |
| 0x4: | MIR mode (UART3 only) |
| 0x5: | FIR mode (UART3 only) |
| 0x6: | CIR mode (UART3 only) |

MODE_SELECT is effective when the module is in operational mode (see [Section 24.3.4.7.1, Register Access Modes](#)).

24.3.4.7.2.1 Registers Available for the UART Function

Only the registers listed in [Table 24-157](#) are used for the UART function.

Table 24-157. UART Mode Register Overview^{(1) (2)}

| Address Offset | Registers | | | | | |
|-------------------|----------------------|-------------------|----------------------|---------------------|-------------------|-------------------|

24.3.4.8 Protocol Formatting

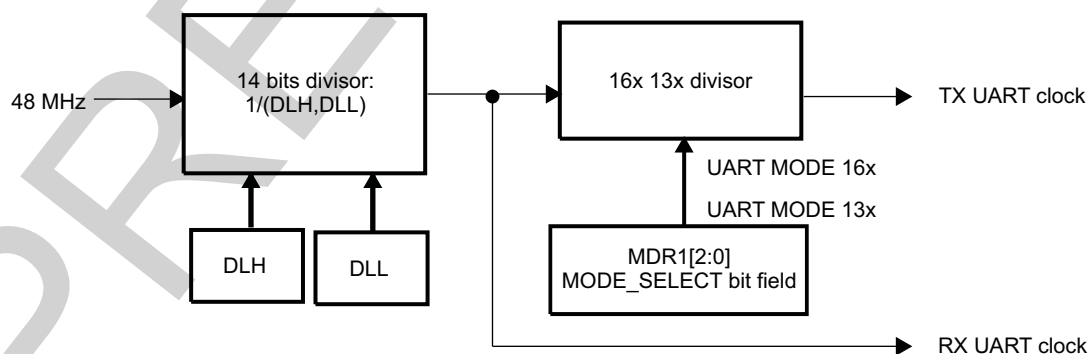

24.3.4.8.1 UART Mode

24.3.4.8.1.1 UART Clock Generation: Baud Rate Generation

The UART function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 24-83 shows the baud rate generator and associated controls.

Figure 24-83. Baud Rate Generation

uart-032

CAUTION

Before initializing or modifying clock parameter controls (UARTi.UART_DLH, UARTi.UART_DLL), MODE_SELECT = DISABLE (UARTi.UART_MDR1[2:0]) must be set to 0x7. Failure to observe this rule can result in unpredictable module behavior.

24.3.4.8.1.2 Choosing the Appropriate Divisor Value

Two divisor values are:

- UART 16x mode: Divisor value = Operating frequency/(16x baud rate)
- UART 13x mode: Divisor value = Operating frequency/(13x baud rate)

Table 24-160 describes the UART baud rate settings.

Table 24-160. UART Baud Rate Settings (48-MHz Clock)

24.3.4.8.1.3 UART Data Formatting

The UART can use hardware flow control to manage transmission and reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals.

The UART is enhanced with the autobauding function. In control mode, autobauding lets the speed, the number of bits per character, and the parity selected be set automatically.

24.3.4.8.1.3.1 Frame Formatting

When autobauding is not used, frame format attributes must be defined in the UARTi.UART_LCR register.

Character length is specified using the UARTi.UART_LCR[1:0] CHAR_LENGTH bit field.

The number of stop-bits is specified using the UARTi.UART_LCR[2] NB_STOP bit.

The parity bit is programmed using the UARTi.UART_LCR[5:3] PARITY_EN, PARITY_TYPE_1, and PARITY_TYPE_2 bit fields (see Table 24-161).

Table 24-161. UART Parity Bit Encoding

| PARITY_EN | PARITY_TYPE_1 | PARITY_TYPE_2 | Parity |
|-----------|---------------|---------------|-------------|
| 0 | N/A | N/A | No parity |
| 1 | 0 | 0 | Odd parity |
| 1 | 1 | 0 | Even parity |
| 1 | 0 | 1 | Forced 1 |
| 1 | 1 | 1 | Forced 0 |

24.3.4.8.1.3.2 Hardware Flow Control

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled and disabled independently by programming the UARTi.UART_EFR[7:6] AUTO_CTS_EN and AUTO_RTS_EN bit fields, respectively.

With auto-CTS, uarti_cts must be active before the module can transmit data.

Auto-RTS activates the uarti_rts output only when there is enough room in the RX FIFO to receive data. It deactivates the uarti_rts output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the UARTi.UART_TCR register determine the levels at which uarti_rts is activated and deactivated.

If auto-CTS and auto-RTS are enabled, data transmission does not occur unless the RX FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If auto-CTS and auto-RTS are not enabled, overrun errors occur if the transmit data rate exceeds the RX FIFO latency.

- Auto-RTS:

Auto-RTS data flow control originates in the receiver block. The RX FIFO trigger levels used in auto-RTS are stored in the UARTi.UART_TCR register. uarti_rts is active if the RX FIFO level is below the HALT trigger level in the UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit field. When the RX FIFO HALT trigger level is reached, uarti_rts is deasserted. The sending device (for example, another UART) can send an additional byte after the trigger level is reached because it may not recognize the deassertion of RTS until it begins sending the additional byte.

uarti_rts is automatically reasserted when the RX FIFO reaches the RESUME trigger level programmed by the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START bit field. This reassertion requests the sending device to resume transmission.

In this case, uarti_rts is an active-low signal.

- Auto-CTS:

The transmitter circuitry checks uarti_cts before sending the next data byte. When uarti_cts is active, the transmitter sends the next byte. To stop the transmitter from sending the next byte, uarti_cts must be deasserted before the middle of the last stop-bit currently sent.

The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled, the uarti_cts state changes do not have to trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO, and a receiver overrun error can result.

In this case, uarti_cts is an active-low signal.

24.3.4.8.1.3.3 Software Flow Control

Software flow control is enabled through the enhanced feature register (UARTi.UART_EFR) and the modem control register (UARTi.UART_MCR). Different combinations of software flow control can be enabled by setting different combinations of the UARTi.UART_EFR[3:0] bit field (see Table 24-162).

Two other enhanced features relate to software flow control:

- XON any function (UARTi.UART_MCR[5]): Operation resumes after receiving any character after the XOFF character is recognized. If special character detect is enabled and special character is received after XOFF1, it does not resume transmission. The special character is stored in the RX FIFO.

NOTE: The XON-any character is written into the RX FIFO even if it is a software flow character.

- Special character (UARTi.UART_EFR[5]): Incoming data is compared to XOFF2. When the special character is detected, the XOFF interrupt (UARTi.UART_IIR[4]) is set, but it does not halt transmission. The XOFF interrupt is cleared by a read of UARTi.UART_IIR. The special character is transferred to the RX FIFO. Special character does not work with XON2, XOFF2, or sequential XOFFs.

Table 24-162. UART_EFR[3:0] Software Flow Control Options

| Bit 3 | Bit 2 | Bit 1 | Bit 0 | TX, RX Software Flow Controls |
|-------|-------|-------|-------|---|
| 0 | 0 | X | X | No transmit flow control |
| 1 | 0 | X | X | Transmit XON1, XOFF1 |
| 0 | 1 | X | X | Transmit XON2, XOFF2 |
| 1 | 1 | X | X | Transmit XON1, XON2: XOFF1, XOFF2 ⁽¹⁾ |
| X | X | 0 | 0 | No receive flow control |
| X | X | 1 | 0 | Receiver compares XON1, XOFF1 |
| X | X | 0 | 1 | Receiver compares XON2, XOFF2 |
| X | X | 1 | 1 | Receiver compares XON1, XON2: XOFF1, XOFF2 ⁽¹⁾ |

⁽¹⁾ In these cases, the XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2. XON1 is defined in the UARTi.UART_XON1_ADDR1[7:0] XON_WORD1 bit field. XON2 is defined in the UARTi.UART_XON2_ADDR2[7:0] XON_WORD2 bit field. XOFF1 is defined in the UARTi.UART_XOFF1[7:0] XOFF_WORD1 bit field. XOFF2 is defined in the UARTi.UART_XOFF2[7:0] XOFF_WORD2 bit field.

24.3.4.8.1.3.3.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases, XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission stops after transmission of the current character completes. Detection of XOFF also sets the UARTi.UART_IIR[4] bit (if enabled by UARTi.UART_IER[5]) and causes the interrupt line to go low.

To resume transmission, an XON1/2 character must be received (in certain cases, XON1 and XON2 must be received sequentially). When the correct XON characters are received, the UARTi.UART_IIR[4] bit is cleared and the XOFF interrupt disappears.

NOTE: When a parity, framing, or break error occurs while receiving a software flow control character, this character is treated as normal data and is written to the RX FIFO.

When XON-any and special character detect are disabled and software flow control is enabled, no valid XON or XOFF characters are written to the RX FIFO. For example, when UARTi.UART_EFR[1:0] = 0x2, if XON1 and XOFF1 characters are received, they are not written to the RX FIFO.

When pairs of software flow characters are programmed to be received sequentially (UARTi.UART_EFR[1:0] = 0x3), the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

24.3.4.8.1.3.3.2 Transmit (TX)

Two XOFF1 characters are transmitted when the RX FIFO passes the trigger level programmed by UARTi.UART_TCR[3:0]. As soon as the RX FIFO reaches the trigger level programmed by UARTi.UART_TCR[7:4], two XON1 characters are sent, so the data transfer recovers.

NOTE: If software flow control is disabled after an XOFF character is sent, the module transmits XON characters automatically to enable normal transmission.

The transmission of XOFF(s)/XON(s) follows the same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is 5, 6, or 7 characters, the 5, 6, or 7 LSBs of XOFF1/2 and XON1/2 are transmitted. The 5, 6, or 7 bits of a character are seldom transmitted, but this function is included to maintain compatibility with earlier designs.

It is assumed that software flow control and hardware flow control are never enabled simultaneously.

24.3.4.8.1.3.4 Autobauding Modes

In autobauding mode, the UART can extract transfer characteristics (speed, length, and parity) from an "at" (AT) command (ASCII code). These characteristics are used to receive data after an AT and to send data.

The following AT commands are valid:

| | | |
|----|------|----|
| AT | DATA | CR |
| at | DATA | CR |
| A/ | | |
| a/ | | |

A line break during the acquisition of the sequence AT is not recognized, and an echo function is not implemented in hardware.

A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final CR (0x0D), are saved to the RX FIFO. The autobaud state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved in the RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The UARTi.UART_UASR register reflects the correct settings for the baud rate detected. Interrupt activity can continue in this fashion when a subsequent character is received. Therefore, it is recommended that the software enable the RHR interrupt when using the autobaud mode.

The following settings are detected in autobaud mode with a module clock of 48 MHz:

- Speed:
 - 115.2K baud
 - 57.6K baud
 - 38.4K baud
 - 28.8K baud
 - 19.2K baud
 - 14.4K baud
 - 9.6K baud
 - 4.8K baud
 - 2.4K baud
 - 1.2K baud
- Length: 7 or 8 bits
- Parity: Odd, even, or space

NOTE: The combination of 7-bit character plus space parity is not supported.

Autobauding mode is selected when the UARTi.UART_MDR1[2:0] MODE_SELECT bit field is set to 0x2. In UART autobauding mode, UARTi.UART_DLL, UARTi.UART_DLH, and UARTi.UART_LCR[5:0] bit field settings are not used; instead, UART_UASR is updated with the configuration detected by the autobauding logic.

UART_UASR Autobauding Status Register Use

This register is used to set up transmission according to the characteristics of the previous reception instead of the UARTi.UART_LCR, UARTi.UART_DLL, and UARTi.UART_DLH registers when the UART is in autobauding mode.

To reset the autobauding hardware (to start a new AT detection) or to set the UART in standard mode (no autobaud), the UARTi.UART_MDR1[2:0] MODE_SELECT bit field must be set to reset state (0x7) and then to the UART in autobauding mode (0x2) or to the UART in standard mode (0x0).

Use limitation:

- Only 7- and 8-bit characters (5- and 6-bit not supported)
- 7-bit character with space parity not supported
- Baud rate between 1200 and 115,200 bps (10 possibilities)

24.3.4.8.1.3.5 Error Detection

When the UARTi.UART_LSR register is read, the UARTi.UART_LSR[4:2] bit field reflects the error bits (BI: break condition, FE: framing error, PE: parity error) of the character at the top of the RX FIFO (the next character to be read). Therefore, reading the UARTi.UART_LSR register and then reading the UARTi.UART_RHR register identifies errors in a character.

Reading the UARTi.UART_RHR register updates the BI, FE, and PE bits (see Table 24-146 for the UART mode interrupts).

The UARTi.UART_LSR[7] RX_FIFO_STS bit is set when there is an error in the RX FIFO and is cleared only when no errors remain in the RX FIFO.

NOTE: Reading the UARTi.UART_LSR register does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading the UARTi.UART_RHR register.

Reading the UARTi.UART_LSR register clears the OE bit if it is set (see Table 24-146 for the UART mode interrupts).

24.3.4.8.1.3.6 Overrun During Receive

Overrun during receive occurs if the RX state-machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the MPU with the UARTi.UART_IIR[5:1] IT_TYPE bit field set to 0x3 (receiver line status error) and discards the remaining portion of the frame.

Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received, the MPU must:

- Reset the RX FIFO.
- Read the UARTi.UART_RESUME register, which clears the internal flag.

24.3.4.8.1.3.7 Time-Out and Break Conditions

24.3.4.8.1.3.7.1 Time-Out Counter

An RX idle condition is detected when the receiver line (uarti_rx) is high for a time that equals 4x the programmed word length + 12 bits. uarti_rx is sampled midway through each bit.

For sleep mode, the counter is reset when there is activity on uarti_rx.

For the time-out interrupt, the counter counts only when there is data in the RX FIFO, and the count is reset when there is activity on uarti_rx or when the UARTi.UART_RHR register is read.

24.3.4.8.1.3.7.2 Break Condition

When a break condition occurs, `uarti_tx` is pulled low. A break condition is activated by setting the UARTi.UART_LCR[6] BREAK_EN bit. The break condition is not aligned on word stream (a break condition can occur in the middle of a character). The only way to send a break condition on a full character is:

1. Reset the TX FIFO (if enabled).
2. Wait for the transmit shift register to empty (the UARTi.UART_LSR[6] TX_SR_E bit is set to 1).
3. Take a guard time according to stop-bit definition.
4. Set the BREAK_EN bit to 1.

The break condition is asserted while the BREAK_EN bit is set to 1.

The time-out counter and break condition apply only to UART modem operation and not to IrDA/CIR mode operation.

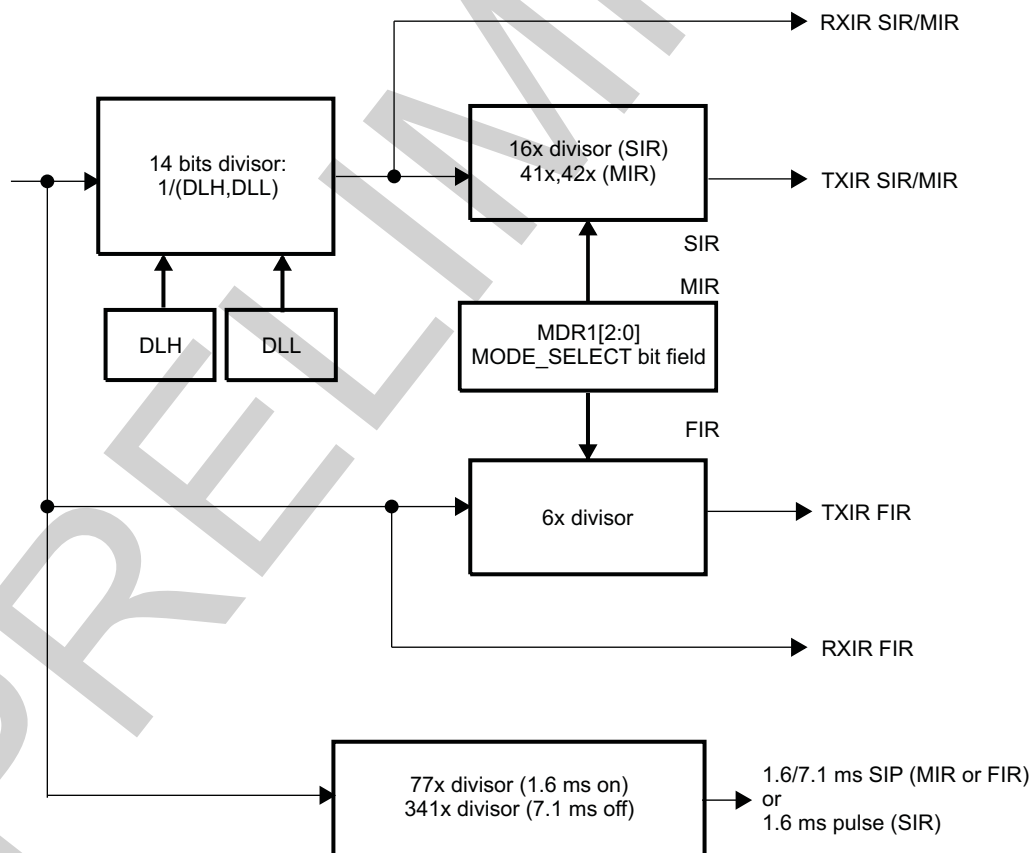

24.3.4.8.2 IrDA Mode (UART3 Only)

24.3.4.8.2.1 IrDA Clock Generation: Baud Generator

The IrDA function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 24-84 shows the baud rate generator and associated controls.

Figure 24-84. Baud Rate Generator

uart-033

CAUTION

Before initializing or modifying clock parameter controls (UARTi.UART_DLH, UARTi.UART_DLL), MODE_SELECT=DISABLE (UARTi.UART_MDR1[2:0]) must be set to 0x7). Failure to observe this rule can result in unpredictable module behavior.

24.3.4.8.2.2 Choosing the Appropriate Divisor Value

Three divisor values are:

- SIR mode: Divisor value = Operating frequency/(16x baud rate)
- MIR mode: Divisor value = Operating frequency/(41x/42x baud rate)
- FIR mode: Divisor value = None

Table 24-163 lists the IrDA baud rate settings.

Table 24-163. IrDA Baud Rate Settings

| Baud Rate | IR Mode | Baud Multiple | Encoding | DLH, DLL (Decimal) | Actual Baud Rate | Error (%) | Source Jitter (%) | Pulse Duration |
|------------|---------|---------------|----------|--------------------|----------------------------|-----------|-------------------|----------------|
| 2.4 kbps | SIR | 16x | 3/16 | 1250 | 2.4 kbps | 0 | 0 | 78.1 µs |
| 9.6 kbps | SIR | 16x | 3/16 | 312 | 9.6153 kbps | +0.16 | 0 | 19.5 µs |
| 19.2 kbps | SIR | 16x | 3/16 | 156 | 19.231 kbps | +0.16 | 0 | 9.75 µs |
| 38.4 kbps | SIR | 16x | 3/16 | 78 | 38.462 kbps | +0.16 | 0 | 4.87 µs |
| 57.6 kbps | SIR | 16x | 3/16 | 52 | 57.692 kbps | +0.16 | 0 | 3.25 µs |
| 115.2 kbps | SIR | 16x | 3/16 | 26 | 115.38 kbps | +0.16 | 0 | 1.62 µs |
| 0.576 Mbps | MIR | 41x/42x | 1/4 | 2 | 0.5756 Mbps ⁽¹⁾ | 0 | +1.63/–0.80 | 416 ns |
| 1.152 Mbps | MIR | 41x/42x | 1/4 | 1 | 1.1511 Mbps ⁽¹⁾ | 0 | +1.63/–0.80 | 208 ns |
| 4 Mbps | FIR | 6x | 4 PPM | – | 4 Mbps | 0 | 0 | 125 ns |

⁽¹⁾ Average value

NOTE: Baud rate error and source jitter table values do not include 48-MHz reference clock error and jitter.

24.3.4.8.2.3 IrDA Data Formatting

The methods described in this section apply to all IrDA modes (SIR, MIR, and FIR).

24.3.4.8.2.3.1 IR RX Polarity Control

The UART3.UART_MDR2[6] IRRXINVERT bit provides the flexibility to invert the uart3_rx_irrx pin in the UART to ensure that the protocol at the output of the transceiver has the same polarity at module level. By default, the uart3_rx_irrx pin is inverted because most transceivers invert the IR receive pin.

24.3.4.8.2.3.2 IrDA Reception Control

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

Operation of the uart3_rx_irrx input can be disabled by the UART3.UART_ACREG[5] DIS_IR_RX bit.

24.3.4.8.2.3.3 IR Address Checking

In all IR modes, when address checking is enabled, only frames intended for the device are written to the RX FIFO. This restriction avoids receiving frames not meant for this device in a multipoint infrared environment. It is possible to program two frame addresses that the UART IrDA receives, with the UART3.UART_XON1_ADDR1[7:0] XON_WORD1 and UART3.UART_XON2_ADDR2[7:0] XON_WORD2 bit fields.

Setting the UART_EFR[0] bit to 1 selects address1 checking. Setting the UART_EFR[1] bit to 1 selects address2 checking. Setting the UART_EFR[1:0] bit field to 0 disables all address checking operations. If both bits are set, the incoming frame is checked for private and public addresses.

If address checking is disabled, all received frames write to the RX FIFO.

24.3.4.8.2.3.4 Frame Closing

A transmission frame can be terminated in two ways:

- Frame-length method: Set the UART3.UART_MDR1[7] FRAME_END_MODE bit to 0. The MPU writes the value of the frame length to the UART3.UART_TXFLH and UART3.UART_TXFLL registers. The device automatically attaches end flags to the frame when the number of bytes transmitted equals the value of the frame length.
- Set-EOT bit method: Set the FRAME_END_MODE bit to 1. The MPU writes 1 to the UART3.UART_ACREG[0] EOT bit just before it writes the last byte to the TX FIFO. When the MPU writes the last byte to the TX FIFO, the device internally sets the tag bit for that character in the TX FIFO. As the TX state-machine reads data from the TX FIFO, it uses this tag-bit information to attach end flags and correctly terminate the frame.

24.3.4.8.2.3.5 Store and Controlled Transmission

In store and controlled transmission (SCT) mode, the MPU starts writing data to the TX FIFO. Then, after writing a part of a frame (for a bigger frame) or an entire frame (a small frame; that is, a supervisory frame), the MPU writes 1 to the UART3.UART_ACREG[2] SCTX_EN bit (deferred TX start) to start transmission.

SCT mode is enabled by setting the UART3.UART_MDR1[5] SCT bit to 1. This transmission method differs from normal mode, in which data transmission starts immediately after data is written to the TX FIFO. SCT mode is useful for sending short frames without TX underrun.

24.3.4.8.2.3.6 Error Detection

When the UART3.UART_LSR register is read, the UART3.UART_LSR[4:2] bit field reflects the error bits [FL, CRC, ABORT] of the frame at the top of the STATUS FIFO (the next frame status to be read).

The error is triggered by an interrupt (for IrDA mode interrupts, see Table 24-147). The STATUS FIFO must be read until empty (a maximum of eight reads is required).

24.3.4.8.2.3.7 Underrun During Transmission

Underrun during transmission occurs when the TX FIFO is empty before the end of the frame is transmitted. When underrun occurs, the device closes the frame with end flags but attaches an incorrect CRC value. The receiving device detects a CRC error and discards the frame; it can then ask for a retransmission.

Underrun also causes an internal flag to be set, which disables additional transmissions. Before the next frame can be transmitted, the MPU must:

- Reset the TX FIFO.
- Read the UART3.UART_RESUME register, which clears the internal flag.

This function can be disabled by the UART3.UART_ACREG[4] DIS_TX_UNDERRUN bit, compensated by the extension of the stop-bit in transmission if the TX FIFO is empty.

24.3.4.8.2.3.8 **Overrun During Receive**

Overrun during receive for the IrDA mode has the same function as that for the UART mode (see [Section 24.3.4.8.1.3.6, Overrun During Receive](#)).

24.3.4.8.2.3.9 **Status FIFO**

In IrDA modes, a status FIFO records the received frame status. When a complete frame is received, the length of the frame and the error bits associated with the frame are written to the status FIFO.

Reading the UART3.UART_SFREGH[3:0] MSB and UART3.UART_SFREGL[3:0] (LSB) bit fields obtains the frame length. The frame error status is read in the UART3.UART_SFLSR register. Reading the UART3.UART_SFLSR register increments the status FIFO read pointer. Because the status FIFO is eight entries deep, it can hold the status of eight frames.

The MPU uses the frame-length information to locate the frame boundary in the received frame data. The MPU can screen bad frames using the error status information and can later request the sender to resend only the bad frames.

This status FIFO can be used effectively in DMA mode because the MPU must be interrupted only when the programmed status FIFO trigger level is reached, not each time a frame is received.

24.3.4.8.2.4 **SIR Mode Data Formatting**

This section provides specific instructions for SIR mode programming.

24.3.4.8.2.4.1 **Abort Sequence**

The transmitter can prematurely close a frame (abort) by sending the sequence 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

A transmission frame can be aborted by setting the UART3.UART_ACREG[1] ABORT_EN bit to 1. When this bit is set to 1, 0x7D and 0xC1 are transmitted and the frame is not terminated with CRC or stop flags.

When a 0x7D character followed immediately by a 0xC1 character is received without transparency, the receiver treats a frame as an aborted frame.

CAUTION

When the TX FIFO is not empty and the UART3.UART_MDR1[5] SCT bit is set to 1, the UART IrDA starts a new transfer with data of a previous frame when the aborted frame is sent. Therefore, the TX FIFO must be reset before sending an aborted frame.

24.3.4.8.2.4.2 **Pulse Shaping**

SIR mode supports the 3/16 or the 1.6-μs pulse duration methods in receive and transmit. The UART3.UART_ACREG[7] PULSE_TYPE bit selects the pulse width method in the transmit mode.

24.3.4.8.2.4.3 **SIR Free Format Programming**

The SIR FF mode is selected by setting the module in the UART mode (UART3.UART_MDR1[2:0] MODE_SELECT = 0x0) and the UART3.UART_MDR2[3] UART_PULSE bit to 1 to allow pulse shaping.

Because the bit format stays the same, some UART mode configuration registers must be set at specific values:

- UART3.UART_LCR[1:0] CHAR_LENGTH bit field = 0x3 (8 data bits)
- UART3.UART_LCR[2] NB_STOP bit = 0x0 (1 stop-bit)
- UART3.UART_LCR[3] PARITY_EN bit = 0x0 (no parity)

The UART mode interrupts are used for the SIR FF mode, but many are not relevant (XOFF, RTS, CTS, modem status register, etc.).

24.3.4.8.2.5 MIR and FIR Mode Data Formatting

This section describes common instructions for FIR and MIR mode programming.

At the end of a frame reception, the MPU reads the line status register (UART3.UART_LSR) to detect errors in the received frame.

When the UART3.UART_MDR1[6] SIP_MODE bit is set to 1, the TX state-machine always sends one SIP at the end of a transmission frame. However, when the SIP_MODE bit is set to 0, SIP transmission depends on the UART3.UART_ACREG[3] SEND_SIP bit.

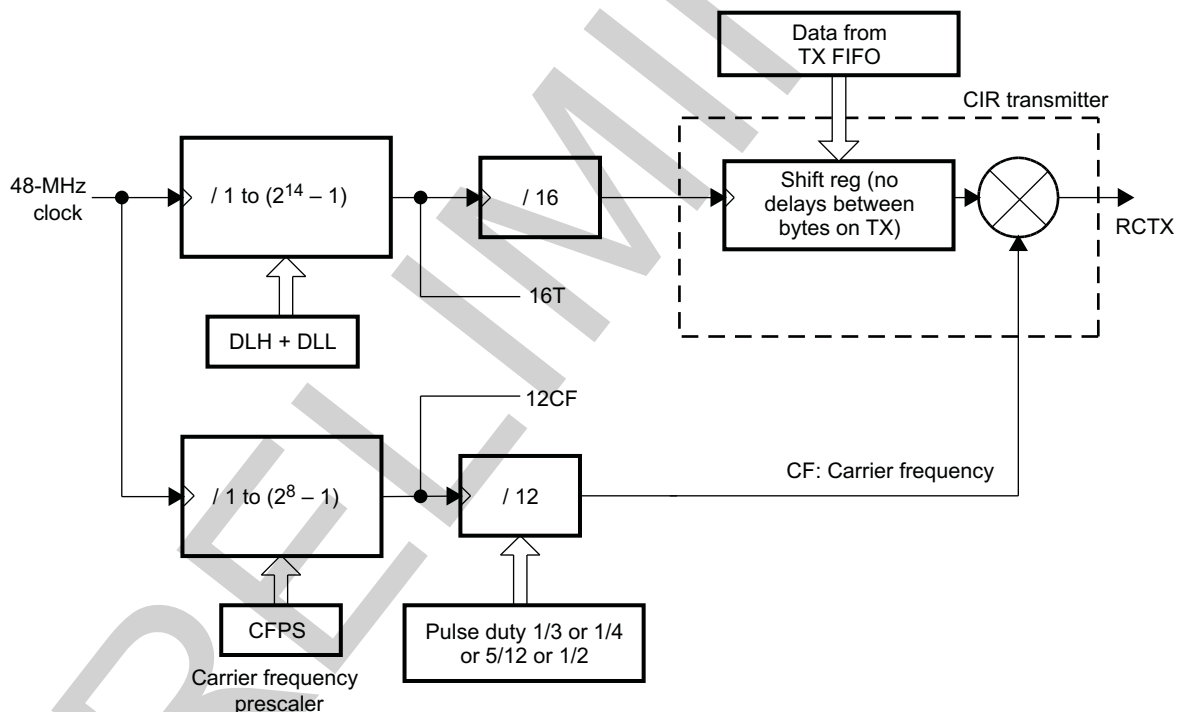

The MPU can set the SEND_SIP bit at least once every 500 ms. The advantage of this approach over the default approach is that the TX state-machine does not have to send the SIP at the end of each frame, thus reducing the overhead required.

24.3.4.8.3 CIR Mode (UART3 Only)

24.3.4.8.3.1 CIR Mode Clock Generation

Depending on the encoding method (variable pulse distance/biphase), the MPU must develop a data structure that combines 1 and 0 with a t period to encode the complete frame to transmit. This can then be transmitted to the infrared output with a modulation method, as shown in Figure 24-85.

Figure 24-85. CIR Mode Block Components

uart-034

Based on the requested modulation frequency, the UART3.UART_CFPS register must be set with the correct dividing value to provide an accurate pulse frequency:

$$\text{Dividing value} = (\text{FCLK}/12)/\text{MODfreq}$$

Where:

FCLK = System clock frequency (48 MHz)

12 = Real value of baud multiple

MODfreq = Effective frequency of the modulation (MHz)

Example: For a targeted modulation frequency of 36 kHz, the value of UART_CFPS must be set to 0x7 (decimal), which provides a modulation frequency of 36.04 kHz.

NOTE: The UART3.UART_CFPS register starts with a reset value of 105 (decimal), which translates to a frequency of 38.1 kHz.

The duty cycle of these pulses is user-defined by the pulse duty register bits in the UART3.UART_MDR2 register. [Table 24-164](#) shows the duty cycle.

Table 24-164. Duty Cycle

| UART_MDR2[5:4] | Duty Cycle (High-Level) |
|----------------|-------------------------|
| 00 | 1/4 |
| 01 | 1/3 |
| 10 | 5/12 |
| 11 | 1/2 |

24.3.4.8.3.2 CIR Data Formatting

The methods described in this section apply to all CIR modes.

24.3.4.8.3.2.1 IR RX Polarity Control

The IR RX polarity control for CIR mode has the same function as that for IrDA mode (see [Section 24.3.4.8.2.3.1, IR RX Polarity Control](#)).

24.3.4.8.3.2.2 CIR Transmission

In transmission, the MPU software must exercise an element of real-time control to transmit data packets, each of which must be emitted at a constant delay from the start-bits of each individual packet. Thus, when sending a series of packets, the packet-to-packet delay must respect a specific delay. Two methods can be used to control this delay:

- Filling the TX FIFO with a number of zero bits that are transmitted with a t period
- Using an external system timer to control the delay between each start-of-frame or between the end of a frame and the start of the next one. This can be performed by:
 - Controlling the start of the frame using the UART3.UART_MDR1[5] SCT bit and the UART3.UART_ACREG[2] SCTX_EN bit, depending on the timer status
 - Using the UART3.UART_IIR[5] TX_STATUS_IT interrupt bit to preload the next frame in the TX FIFO and to control the start of the timer (in case of control delay between the end of a frame and the start of the next frame)

24.3.5 UART/IrDA/CIR Basic Programming Model

24.3.5.1 UART Programming Model

24.3.5.1.1 Quick Start

This section describes the procedure for operating the UART with FIFO and DMA or interrupts. This three-part procedure ensures the quick start of the UART. It does not cover every UART feature.

The first programming model covers software reset of the UART. The second programming model describes FIFO and DMA configuration. The last programming model describes protocol, baud rate, and interrupt configuration.

NOTE: Each programming model can be used independently of the other two; for instance, reconfiguring the FIFOs and DMA settings only.

Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see [Section 24.3.4.7.1, Register Access Modes](#).

24.3.5.1.1.1 Software Reset

To clear the UART registers, perform the following steps:

1. Initiate a software reset:
Set the UARTi.UART_SYSC[1] SOFTRESET bit to 1.
2. Wait for the end of the reset operation:
Poll the UARTi.UART_SYSS[0] RESETDONE bit until it equals 1.

24.3.5.1.1.2 FIFOs and DMA Settings

To enable and configure the receive and transmit FIFOs and program the DMA mode, perform the following steps:

1. Switch to register configuration mode B to access the UARTi.UART_EFR register:
 - (a) Save the current UARTi.UART_LCR register value.
 - (b) Set the UARTi.UART_LCR register value to 0x00BF.
2. Enable register submode TCR_TLR to access the UARTi.UART_TLR register (part 1 of 2):
 - (a) Save the UARTi.UART_EFR[4] ENHANCED_EN value.
 - (b) Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 1.
3. Switch to register configuration mode A to access the UARTi.UART_MCR register:
Set the UARTi.UART_LCR register value to 0x0080.
4. Enable register submode TCR_TLR to access the UARTi.UART_TLR register (part 2 of 2):
 - (a) Save the UARTi.UART_MCR[6] TCR_TLR value.
 - (b) Set the UARTi.UART_MCR[6] TCR_TLR bit to 1.
5. Enable the FIFO; load the new FIFO triggers (part 1 of 3) and the new DMA mode (part 1 of 2):
Set the following bits to the desired values:
 - UARTi.UART_FCR[7:6] RX_FIFO_TRIG
 - UARTi.UART_FCR[5:4] TX_FIFO_TRIG
 - UARTi.UART_FCR[3] DMA_MODE
 - UARTi.UART_FCR[0] FIFO_ENABLE (0: Disable the FIFO; 1: Enable the FIFO)

NOTE: The UARTi.UART_FCR register is not readable.

6. Switch to register configuration mode B to access the UARTi.UART_EFR register:
Set the UARTi.UART_LCR register value to 0x00BF.
7. Load the new FIFO triggers (part 2 of 3):
Set the following bits to the desired values:
 - UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA
 - UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA
8. Load the new FIFO triggers (part 3 of 3) and the new DMA mode (part 2 of 2):
Set the following bits to the desired values:
 - UARTi.UART_SCR[7] RX_TRIG_GRANU1
 - UARTi.UART_SCR[6] TX_TRIG_GRANU1
 - UARTi.UART_SCR[2:1] DMA_MODE_2
 - UARTi.UART_SCR[0] DMA_MODE_CTL
9. Restore the UARTi.UART_EFR[4] ENHANCED_EN value saved in Step 2a.
10. Switch to register configuration mode A to access the UARTi.UART_MCR register:
Set the UARTi.UART_LCR register value to 0x0080.
11. Restore the UARTi.UART_MCR[6] TCR_TLR value saved in Step 4a.
12. Restore the UARTi.UART_LCR value saved in Step 1a.

Triggers are used to generate interrupt and DMA requests. See [Section 24.3.4.6.1.1, Transmit FIFO Trigger](#), to choose the following values:

- UArTi.UArT_FCR[5:4] TX_FIFO_TRIG
- UArTi.UArT_TLR[3:0] TX_FIFO_TRIG_DMA
- UArTi.UArT_SCR[6] TX_TRIG_GRANU1

Triggers are used to generate interrupt and DMA requests. See [Section 24.3.4.6.1.2, Receive FIFO Trigger](#), to choose the following values:

- UArTi.UArT_FCR[7:6] RX_FIFO_TRIG
- UArTi.UArT_TLR[7:4] RX_FIFO_TRIG_DMA
- UArTi.UArT_SCR[7] RX_TRIG_GRANU1

DMA mode enables DMA requests. See [Section 24.3.4.6.4, FIFO DMA Mode Operation](#), to choose the following values:

- UArTi.UArT_FCR[3] DMA_MODE
- UArTi.UArT_SCR[2:1] DMA_MODE_2
- UArTi.UArT_SCR[0] DMA_MODE_CTL

24.3.5.1.1.3 Protocol, Baud Rate, and Interrupt Settings

To program the protocol, baud rate, and interrupt settings, perform the following steps:

1. Disable UART to access the UArTi.UArT_DLL and UArTi.UArT_DLH registers:
Set the UArTi.UArT_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Switch to register configuration mode B to access the UArTi.UArT_EFR register:
Set the UArTi.UArT_LCR register value to 0x00BF.
3. Enable access to the UArTi.UArT_IER[7:4] bit field:
 - (a) Save the UArTi.UArT_EFR[4] ENHANCED_EN value.
 - (b) Set the UArTi.UArT_EFR[4] ENHANCED_EN bit to 1.
4. Switch to register operational mode to access the UArTi.UArT_IER register:
Set the UArTi.UArT_LCR register value to 0x0000.
5. Clear the UArTi.UArT_IER register (set the UArTi.UArT_IER[4] SLEEP_MODE bit to 0 to change the UArTi.UArT_DLL and UArTi.UArT_DLH registers). Set the UArTi.UArT_IER register value to 0x0000.
6. Switch to register configuration mode B to access the UArTi.UArT_DLL and UArTi.UArT_DLH registers:
Set the UArTi.UArT_LCR register value to 0x00BF.
7. Load the new divisor value:
Set the UArTi.UArT_DLL[7:0] CLOCK_LSB and UArTi.UArT_DLH[5:0] CLOCK_MSB bit fields to the desired values.
8. Switch to register operational mode to access the UArTi.UArT_IER register:
Set the UArTi.UArT_LCR register value to 0x0000.
9. Load the new interrupt configuration (0: Disable the interrupt; 1: Enable the interrupt):
Set the following bits to the desired values:
 - UArTi.UArT_IER[7] CTS_IT
 - UArTi.UArT_IER[6] RTS_IT
 - UArTi.UArT_IER[5] XOFF_IT
 - UArTi.UArT_IER[4] SLEEP_MODE
 - UArTi.UArT_IER[3] MODEM_STS_IT
 - UArTi.UArT_IER[2] LINE_STS_IT
 - UArTi.UArT_IER[1] THR_IT

- UARTi.UART_IER[0] RHR_IT
10. Switch to register configuration mode B to access the UARTi.UART_EFR register:
Set the UARTi.UART_LCR register value to 0x00BF.
 11. Restore the UARTi.UART_EFR[4] ENHANCED_EN value saved in Step 3a.
 12. Load the new protocol formatting (parity, stop-bit, character length) and switch to register operational mode:
Set the UARTi.UART_LCR[7] DIV_EN bit to 0.
Set the UARTi.UART_LCR[6] BREAK_EN bit to 0.
Set the following bits to the desired values:
 - UARTi.UART_LCR[5] PARITY_TYPE_2
 - UARTi.UART_LCR[4] PARITY_TYPE_1
 - UARTi.UART_LCR[3] PARITY_EN
 - UARTi.UART_LCR[2] NB_STOP
 - UARTi.UART_LCR[1:0] CHAR_LENGTH
 13. Load the new UART mode:
Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to the desired value.
- See [Section 24.3.4.8.1.2](#), *Choosing the Appropriate Divisor Value*, to choose the following values:
- UARTi.UART_DLL[7:0] CLOCK_LSB
 - UARTi.UART_DLH[5:0] CLOCK_MSB
 - UARTi.UART_MDR1[2:0] MODE_SELECT
- See [Section 24.3.4.8.1.3.1](#), *Frame Formatting*, to choose the following values:
- UARTi.UART_LCR[5] PARITY_TYPE_2
 - UARTi.UART_LCR[4] PARITY_TYPE_1
 - UARTi.UART_LCR[3] PARITY_EN
 - UARTi.UART_LCR[2] NB_STOP
 - UARTi.UART_LCR[1:0] CHAR_LENGTH

24.3.5.1.2 Hardware and Software Flow Control Configuration

This section describes the programming steps to enable and configure hardware and software flow control. Hardware and software flow control cannot be used at the same time.

NOTE: Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see [Section 24.3.4.7.1](#), *Register Access Modes*.

24.3.5.1.2.1 Hardware Flow Control Configuration

To enable and configure hardware flow control, perform the following steps:

1. Switch to register configuration mode A to access the UARTi.UART_MCR register:
 - (a) Save the current UARTi.UART_LCR register value.
 - (b) Set the UARTi.UART_LCR register value to 0x0080.
2. Enable register submode TCR_TLR to access the UARTi.UART_TCR register (part 1 of 2):
 - (a) Save the UARTi.UART_MCR[6] TCR_TLR value.
 - (b) Set the UARTi.UART_MCR[6] TCR_TLR bit to 1.
3. Switch to register configuration mode B to access the UARTi.UART_EFR register:

Set the UARTi.UART_LCR register value to 0x00BF.

4. Enable register submode TCR_TLR to access the UARTi.UART_TCR register (part 2 of 2):
 - (a) Save the UARTi.UART_EFR[4] ENHANCED_EN value.
 - (b) Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 1.

5. Load the new start and halt trigger values for hardware flow control:

Set the following bits to the desired values:

- UARTi.UART_TCR[7:4] AUTO_RTS_START
- UARTi.UART_TCR[3:0] AUTO_RTS_HALT

6. Enable or disable receive and transmit hardware flow control mode and restore the UARTi.UART_EFR[4] ENHANCED_EN value saved in Step 4a.

Set the following bits to the desired values:

- UARTi.UART_EFR[7] AUTO_CTS_EN (0: Disable; 1: Enable)
- UARTi.UART_EFR[6] AUTO_RTS_EN (0: Disable; 1: Enable)

Restore the UARTi.UART_EFR[4] ENHANCED_EN bit to the saved value.

7. Switch to register configuration mode A to access the UARTi.UART_MCR register:

Set the UARTi.UART_LCR register value to 0x0080.

8. Restore the UARTi.UART_MCR[6] TCR_TLR value saved in Step 2a.
9. Restore the UARTi.UART_LCR value saved in Step 1a.

See [Section 24.3.4.8.1.3.2, Hardware Flow Control](#), to choose the following values:

- UARTi.UART_EFR[7] AUTO_CTS_EN
- UARTi.UART_EFR[6] AUTO_RTS_EN
- UARTi.UART_TCR[7:4] AUTO_RTS_START
- UARTi.UART_TCR[3:0] AUTO_RTS_HALT

24.3.5.1.2.2 Software Flow Control Configuration

To enable and configure software flow control, perform the following steps:

1. Switch to register configuration mode B to access the UARTi.UART_EFR register.
 - (a) Save the current UARTi.UART_LCR register value.
 - (b) Set the UARTi.UART_LCR register value to 0x00BF.
2. Enable register submode XOFF to access the UARTi.UART_XOFF1 and UARTi.UART_XOFF2 registers:
 - (a) Save the UARTi.UART_EFR[4] ENHANCED_EN value.
 - (b) Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 0.
3. Load the new software flow control characters:

Set the following bits to the desired values:

 - UARTi.UART_XON1_ADDR1[7:0] XON_WORD1
 - UARTi.UART_XON2_ADDR2[7:0] XON_WORD2
 - UARTi.UART_XOFF1[7:0] XOFF_WORD1
 - UARTi.UART_XOFF2[7:0] XOFF_WORD2
4. Enable access to the UARTi.UART_MCR[7:5] bit field and enable register submode TCR_TLR to access the UARTi.UART_TCR register (part 1 of 2):

Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 1.
5. Switch to register configuration mode A to access the UARTi.UART_MCR register:

Set the UARTi.UART_LCR register value to 0x0080.
6. Enable register submode TCR_TLR to access the UARTi.UART_TCR register (part 2 of 2) and enable or disable XON any function:

- (a) Save the UARTi.UART_MCR[6] TCR_TLR value.
 - (b) Set the UARTi.UART_MCR[6] TCR_TLR bit to 1.
 - (c) Set the UARTi.UART_MCR[5] XON_EN bit to the desired value (0: Disable; 1: Enable).
 7. Switch to register configuration mode B to access the UARTi.UART_EFR register:
Set the UARTi.UART_LCR register value to 0x00BF.
 8. Load the new start and halt trigger values for software flow control:
Set the following bits to the desired values:
 - UARTi.UART_TCR[7:4] AUTO_RTS_START
 - UARTi.UART_TCR[3:0] AUTO_RTS_HALT
 9. Enable or disable special character function and load the new software flow control mode and restore the UARTi.UART_EFR[4] ENHANCED_EN value saved in Step 2a:
Set the following bits to the desired values:
 - UARTi.UART_EFR[5] SPEC_CHAR (0: Disable; 1: Enable)
 - UARTi.UART_EFR[3:0] SW_FLOW_CONTROLRestore the UARTi.UART_EFR[4] ENHANCED_EN bit to the saved value.
 10. Switch to register configuration mode A to access the UARTi.UART_MCR register:
Set the UARTi.UART_LCR register value to 0x0080.
 11. Restore the UARTi.UART_MCR[6] TCR_TLR bit value saved in Step 6a.
 12. Restore the UARTi.UART_LCR value saved in Step 1a.
- See [Section 24.3.4.8.1.3.3, Software Flow Control](#), to choose the following values:
- UARTi.UART_EFR[5] SPEC_CHAR
 - UARTi.UART_EFR[3:0] SW_FLOW_CONTROL
 - UARTi.UART_TCR[7:4] AUTO_RTS_START
 - UARTi.UART_TCR[3:0] AUTO_RTS_HALT
 - UARTi.UART_XON1_ADDR1[7:0] XON_WORD1
 - UARTi.UART_XON2_ADDR2[7:0] XON_WORD2
 - UARTi.UART_XOFF1[7:0] XOFF_WORD1
 - UARTi.UART_XOFF2[7:0] XOFF_WORD2

24.3.5.2 IrDA Programming Model (UART3 Only)

24.3.5.2.1 SIR Mode

24.3.5.2.1.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with parity forced to 1, baud rate = 112.5KB, FIFOs disabled, 2 stop-bits, and 8-bit word length:

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers:
Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_DLL and UART_DLH registers (the UART_LCR[7] DIV_EN bit = 1):
UART3.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UART3.UART_LCR register in IrDA mode.)
3. Load the new baud rate (115.2 kbps):
UART3.UART_DLL = 0x1A
UART3.UART_DLH = 0x00
4. Set SIR mode:
UART3.UART_MDR1[2:0] MODE_SELECT = 0x1
5. Disable access to the UART_DLL and UART_DLH registers and switch to register operational mode:
UART3.UART_LCR = 0x00.
6. Optional: Enable the RHR interrupt:
UART3.UART_IER[0] RHR_IT = 0x1

24.3.5.2.1.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 6-byte frame with no parity, baud rate = 112.5 kbps, FIFOs disabled, 3/16 encoding, 2 stop-bits, and 7-bit word length:

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers:
Set the UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_EFR register:
UART3.UART_LCR = 0xBF
3. Enable the enhanced features (the UART_EFR[4] ENHANCED_EN bit = 1):
Set the UART3.UART_EFR register value to 0x10.
4. Grant access to the UART_DLL and UART_DLH registers (the UART_LCR[7] DIV_EN bit = 1):
UART3.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UART3.UART_LCR register in IrDA mode.)
5. Load the new baud rate (115.2 kbps):
UART3.UART_DLL = 0x1A
UART3.UART_DLH = 0x00
6. Set SIR mode (the UART_MDR1[2:0] MODE_SELECT bit field = 0x1):
UART3.UART_MDR1 = 0x01
7. Disable access to the UART_DLL and UART_DLH registers and switch to register operational mode:
UART3.UART_LCR = 0x00.
8. Force DTR output to active:
UART3.UART_MCR[0] DTR = 1
9. Optional: Enable the THR interrupt:
UART3.UART_IER[1] THR_IT = 1
10. Set transmit frame length to 6 bytes:
UART3.UART_TXFL = 0x06
11. Set 7 starts of frame transmission:
UART3.UART_EBLR = 0x08
12. Optional: Set SIR pulse width to be 1.6 us:
UART3.UART_ACREG[7] PULSE_TYPE = 1
13. Load the UART_THR register with the data to be transmitted.

24.3.5.2.2 MIR Mode

24.3.5.2.2.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with no parity, baud rate = 1.152 Mbps, and FIFOs disabled.

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers:
Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_DLL and UART_DLH registers (UART_LCR[7] DIV_EN bit = 1):
UART3.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UART3.UART_LCR register in IrDA mode.)
3. Load the new baud rate (1.152 Mbps):
UART3.UART_DLL = 0x01
UART3.UART_DLH = 0x00
4. Set MIR mode:
UART3.UART_MDR1[2:0] MODE_SELECT = 0x4
5. Disable access to the UART_DLL and UART_DLH registers and switch to register operational mode:
UART3.UART_LCR = 0x00
6. Force DTR output to active (UART_MCR[0] DTR = 1):
Force RTS output to active (UART_MCR[1] RTS = 1).
UART3.UART_MCR = 0x3
7. Optional: Enable the RHR interrupt:
UART3.UART_IER[0] RHR_IT = 1

24.3.5.2.2.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 60-byte frame with no parity, baud rate = 1.152 Mbps, and FIFOs disabled:

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers:
Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_DLL and UART_DLH registers (UART_LCR[7] DIV_EN bit = 1):
UART3.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UART3.UART_LCR register in IrDA mode.)
3. Load the new baud rate (1.152 Mbps):
UART3.UART_DLL = 0x01
UART3.UART_DLH = 0x00
4. Set MIR mode:
UART3.UART_MDR1[2:0] MODE_SELECT = 0x4
5. Disable access to the UART_DLL and UART_DLH registers and switch to register operational mode:
UART3.UART_LCR = 0x00
6. Force DTR output to active:
UART3.UART_MCR[0] DTR = 1
7. Optional: Enable the THR interrupt:
UART3.UART_IER[1] THR_IT = 1
8. Set the frame length to 60 bytes:
UART3.UART_TXFL = 0x3C
9. Optional: Transmit eight additional starts of frame (MIR mode requires two starts):
UART3.UART_EBLR = 0x08
10. SIP is sent at the end of transmission:
UART3.UART_ACREG[3] = 1
11. Load the UART_THR register with the data to be transmitted.

24.3.5.2.3 FIR Mode

24.3.5.2.3.1 Receive

The following programming model explains how to program the module to receive the IrDA frame with no parity, baud rate = 4 Mbps, FIFOs enabled, 8-bit word length.

1. Disable the UART before accessing the UART3.UART_DLL and UART3.UART_DLH registers:
Set the UART3.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_DLL and UART_DLH registers (UART_LCR[7] DIV_EN bit = 1):
UART3.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UART3.UART_LCR register in IrDA mode.)
3. FIFO clear and enable:
UART3.UART_FCR = 0x7 (TX/RX FIFO trigger: UART_FCR[7:6] and UART_FCR[5:4])
UART3.UART_LCR[7] = 0
4. Set FIR mode:
UART3.UART_MDR1[2:0] MODE_SELECT = 0x5
5. Set frame length:
UART3.UART_RXFLL = 0xA (Data + CRC + STOP)
6. Disable access to the UART3.UART_DLL registers and UART3.UART_DLH and switch to register operational mode:
UART3.UART_LCR[7] DIV_EN = 0x0
7. Optional: Enable the RHR interrupt:
UART3.UART_IER[0] RHR_IT = 1

24.3.5.2.3.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 4-byte frame with no parity, baud rate = 4 Mbps, FIFOs enabled, and 8-bit word length.

1. Disable the UART before accessing the UART3.UART_DLL and UART3.UART_DLH registers:
Set the UART3.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to EFR_REG:
UART3.UART_LCR = 0xBF
3. Enable the enhanced features (EFR_REG[4] ENHANCED_EN = 0x1):
UART3.UART_EFR = 0x10
4. FIFO clear and enable:
UART3.UART_FCR = 0x7 (TX/RX FIFO trigger: UART_FCR[7:6] and UART_FCR[5:4]).
UART3.UART_LCR[7] = 0
5. Set FIR mode and enable auto-SIP mode:
UART3.UART_MDR1 = 0x45
6. Set frame length:
UART3.UART_TXFLL = 0x4
UART3.UART_TXFLH = 0x0
UART3.UART_RXFLL = 0xA (Data + CRC + STOP)
UART3.UART_RXFLH = 0x0
7. Force DTR output to active:
UART3.UART_MCR[0] DTR = 0x1
8. Optional: Enable the THR interrupt:
UART3.UART_IER[1] THR_IT = 0x1
9. Optional: Transmit eight additional starts of frame (MIR mode requires two starts):
UART3.UART_EBLR = 0x08
10. SIP is sent at the end of transmission:
UART3.UART_ACREG[3] = 1
11. Load the UART_THR register with the data to be transmitted.

24.3.6 UART/IrDA/CIR Register Manual

24.3.6.1 UART/IrDA/CIR Instance Summary

Table 24-165 shows the base address and address space for the UART/IrDA/CIR module instances.

Table 24-165. UART/IrDA/CIR Instance Summary

| Module Name | Base Address | Size |
|----------------------|--------------|------|
| UART1 ⁽¹⁾ | 0x4806 A000 | 1KB |
| UART2 ⁽¹⁾ | 0x4806 C000 | 1KB |
| UART3 ⁽²⁾ | 0x4802 0000 | 1KB |
| UART4 ⁽¹⁾ | 0x4806 E000 | 1KB |

⁽¹⁾ UART mode only

⁽²⁾ UART, IrDA, or CIR mode

24.3.6.2 UART/IrDA/CIR Registers

24.3.6.2.1 UART/IrDA/CIR Register Summary

Table 24-166. UART/IrDA/CIR Register Mapping Summary (UART1 and UART2)

| Register Name | Type | Register Width (Bits) | Address Offset | UART1 Base Address | UART2 Base Address |
|-----------------|------|-----------------------|----------------|--------------------|--------------------|
| UART_THR | W | 32 | 0x0000 0000 | 0x4806 A000 | 0x4806 C000 |

24.3.6.2.2 UART/IrDA/CIR Registers**Table 24-168. UART_THR**

| | | | |
|------------------|---|----------|-------------------------|
| Address Offset | 0x0000 0000 | Instance | UART1 |
| Physical Address | 0x4806 A000 0x4806 C000 0x4802 0000 0x4806 E000 | | UART2 UART3 UART4 |
| Description | The transmitter section consists of the transmit holding register (THR) and the transmit shift register. The THR is a 64-byte FIFO. The local host (LH) writes data to the THR. The data is placed in the transmit shift register where it is shifted out serially on the TX output. If the FIFO is disabled, location 0 of the FIFO stores the data. | | |

| | Instance | | | | | | | | | | | | | | | |
| | UART1 UART2 UART3 UART4 | | | | | | | | | | | | | | | |
| Description | The receiver section consists of the receiver holding register (RHR) and the receiver shift register. The RHR is a 64-byte FIFO. The receiver shift register receives serial data from RX input. The data is converted to parallel data and moved to the RHR. If the FIFO is disabled, location 0 of the FIFO stores the single data character. Note: If an overflow occurs, the data in the RHR is not overwritten. | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|----------------|--|------|----------|
| 31:8 | RESERVED | Read returns 0. | R | 0x000000 |
| 7 | THR_EMPTY | Read 0x0: Transmit holding register (TX FIFO) is not empty. Read 0x1: Transmit hold register (TX FIFO) is empty. The transmission is not necessarily complete. | R | 1 |
| 6 | STS_FIFO_FULL | Read 0x0: Status FIFO not full Read 0x1: Status FIFO full | R | 0 |
| 5 | RX_LAST_BYTE | Read 0x0: The RX FIFO (RHR) does not contain the last byte of the frame to be read. Read 0x1: The RX FIFO (RHR) contains the last byte of the frame to be read. This bit is set only when the last byte of a frame is available to be read. It determines the frame boundary. It is cleared on a single read of the LSR register. See the note below. | R | 0 |
| 4 | FRAME_TOO_LONG | Read 0x0: No frame-too-long error in frame Read 0x1: Frame-too-long error in the frame at the top of the STATUS FIFO, (next character to be read). This bit is set to 1 when a frame exceeding the maximum length (set by RXFLH and RXFLL registers) is received. When this error is detected, current frame reception is terminated. Reception is stopped until the next START flag is detected. | R | 0 |
| 3 | ABORT | Read 0x0: No abort pattern error in frame Read 0x1: Abort pattern is received. SIR and MIR: Abort pattern FIR: Illegal symbol | R | 0 |
| 2 | CRC | Read 0x0: No CRC error in frame Read 0x1: CRC error in the frame at the top of the STATUS FIFO (next character to be read) | R | 0 |
| 1 | STS_FIFO_E | Read 0x0: Status FIFO not empty Read 0x1: Status FIFO empty | R | 1 |
| 0 | RX_FIFO_E | Read 0x0: No data in the RX FIFO Read 0x1: At least one data character in the RX FIFO | R | 1 |

| Physical Address | 0x4806 A018 0x4806 C018 0x4802 0018 0x4806 E018 | Instance | UART1 UART2 UART3 UART4 | |
| Description | Transmission control register This register stores the RX FIFO threshold levels to start/stop transmission during hardware/software flow control. Notes: Trigger levels from 0 to 60 bytes are available with a granularity of 4. (Trigger level = 4 x [4-bit register value]) The programmer must ensure that UART_TCR[3:0] UART_TCR[7:4] when auto-RTS or software flow control is enabled to avoid a mis-operation of the device. In FIFO interrupt mode with flow control, the programmer must ensure that the trigger level to halt transmission is greater than or equal to the RX FIFO trigger level (UART_TLR[7:4] or UART_FCR[7:6]); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist because a DMA request is sent each time a byte is received. | | | |

| | | | |
|-------------------------|---|-----------------|----------------------------------|
| Address Offset | 0x0000 0020 | Instance | UART1 UART2 UART3 UART4 |
| Physical Address | 0x4806 A020 0x4806 C020 0x4802 0020 0x4806 E020 | | |
| Description | Mode definition register 1 The mode of operation can be programmed by writing to MDR1[2:0] and therefore the MDR1 must be programmed on startup after configuration of the configuration registers (UART_DLL , UART_DLH , and UART_LCR). The value of MDR1[2:0] must not be changed again during normal operation. Note: If the module is disabled by setting the MODE_SELECT field to 111, interrupt requests can still be generated unless disabled through the interrupt enable register (IER). In this case, UART mode interrupts are visible. Reading the interrupt identification register (IIR) shows UART mode interrupt flags. | | |

Table 24-208. UART_MDR2

| | | | |
|-------------------------|---|-----------------|-------------------------|
| Address Offset | 0x0000 0024 | Instance | UART1 |
| Physical Address | 0x4806 A024 0x4806 C024 0x4802 0024 0x4806 E024 | | UART2 UART3 UART4 |
| Description | Mode definition register 2 IR-IrDA and IR-CIR modes only. UART_MDR2[0] describes the status of the interrupt in UART_IIR[5] . The IRTX_UNDERRUN bit should be read after an UART_IIR[5] TX_STATUS_IT interrupt. The bits [2:1] of this register set the trigger level for the frame status FIFO (8 entries) and must be programmed before the mode is programmed in UART_MDR1[2:0] . Note: The UART_MDR2[6] gives the flexibility to invert the RX pin in the UART to ensure that the protocol at the input of the transceiver module has the same polarity at module level. By default, the RX pin is inverted because most transceivers invert the IR receive pin. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|--------------|----|------------|----|----------------|----|------------|---|---------------|---|---------------|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | SET_TXIR_ALT | | IRRXINVERT | | CIR_PULSE_MODE | | UART_PULSE | | STS_FIFO_TRIG | | IRTX_UNDERRUN | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|--------------|--|------|----------|
| 31:8 | RESERVED | Read returns 0. Write has no effect. | RW | 0x000000 |
| 7 | SET_TXIR_ALT | Provide alternate function for MDR1[4] (SET_TXIR). 0x0: Normal mode 0x1: Alternate mode for SET_TXIR | R | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|----------------|--|------|-------|
| 6 | IRRXINVERT | IR mode only (IrDA and CIR). Invert RX pin in the module before the voting or sampling system logic of the infrared block. This does not affect the RX path in UART modem modes. 0x0: Inversion is performed. 0x1: No inversion is performed. | RW | 0 |
| 5:4 | CIR_PULSE_MODE | CIR pulse modulation definition. Defines high level of the pulse width associated with a digit: 0x0: Pulse width of 3 from 12 cycles 0x1: Pulse width of 4 from 12 cycles 0x2: Pulse width of 5 from 12 cycles 0x3: Pulse width of 6 from 12 cycles | RW | 0x0 |
| 3 | UART_PULSE | UART mode only. Allows pulse shaping in UART mode. 0x0: Normal UART mode 0x1: UART mode with a pulse shaping | RW | 0 |
| 2:1 | STS_FIFO_TRIG | IR-IrDA mode only. Frame status FIFO threshold select: 0x0: 1 entry 0x1: 4 entries 0x2: 7 entries 0x3: 8 entries | RW | 0x0 |
| 0 | IRTX_UNDERRUN | IrDA transmission status interrupt. When the UART_IIR[5] interrupt occurs, the meaning of the interrupt is: Read 0x0: The last bit of the frame transmitted successfully without error. Read 0x1: An underrun occurred. The last bit of the frame was transmitted but with an underrun error. The bit is reset to 0 when the UART_RESUME register is read. | R | 0 |

Table 24-228. UART_UASR

| | | | |
|-------------------------|---|-----------------|----------------------------------|
| Address Offset | 0x0000 0038 | Instance | UART1 UART2 UART3 UART4 |
| Physical Address | 0x4806 A038 0x4806 C038 0x4802 0038 0x4806 E038 | | |
| Description | UART autobauding status register UART autobauding mode only. This status register returns the speed, the number of bits by characters, and the type of the parity in UART autobauding mode. In autobauding mode, the input frequency of the UART modem must be fixed to 48 MHz. Any other module clock frequency results in incorrect baud rate recognition. Note: When the UART is in autobauding mode, this register, instead of the LCR, DLL, and DLH registers, is used to set up transmission according to the characteristics of the previous reception. To reset the autobauding hardware (to start a new AT detection), set MDR1[2:0] to 111 (reset value), then set MDR1[2:1] to 010 (UART in autobaud mode). To set the UART to standard mode (no autobaud), set MDR1[2:1] to 000. | | |

| Physical Address | 0x4806 A03C 0x4806 C03C 0x4802 003C 0x4806 E03C | | |
| Description | Auxiliary control register. IR-IrDA and IR-CIR modes only. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------------|----|--------|----|-----------|----|-----------------|---|----------|---|---------|---|----------|---|--------|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | PULSE_TYPE | | SD_MOD | | DIS_IR_RX | | DIS_TX_UNDERRUN | | SEND_SIP | | SCTX_EN | | ABORT_EN | | EOT_EN | |

| Bits | Field Name | Description | Type | Reset |
|------|-----------------|---|------|-----------|
| 31:8 | RESERVED | Read returns 0. Write has no effect. | RW | 0x0000000 |
| 7 | PULSE_TYPE | SIR pulse width select 0x0: 3/16 of baud-rate pulse width 0x1: 1.6 μ s | RW | 0 |
| 6 | SD_MOD | Primary output used to configure transceivers. Connected to the SD/MODE input pin of IrDA transceivers. 0x0: SD pin is set to high. 0x1: SD pin is set to low. | RW | 0 |
| 5 | DIS_IR_RX | 0x0: Normal operation (RX input automatically disabled during transmit but enabled outside of transmit operation) 0x1: Disables RX input (permanent state - independent of transmit) | RW | 0 |
| 4 | DIS_TX_UNDERRUN | It is recommended to disable TX FIFO underrun capability by masking corresponding underrun interrupt. When disabling underrun by setting ACREG[4] = 1, garbage data is sent over TX line. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| | | 0x0: Long stop-bits cannot be transmitted; TX underrun is enabled. 0x1: Long stop-bits can be transmitted; TX underrun is disabled. | | |
| 3 | SEND_SIP | MIR/FIR modes only. Send serial infrared interaction pulse (SIP). If this bit is set during an MIR/FIR transmission, the SIP is sent at the end of it. This bit is cleared automatically at the end of the SIP transmission. 0x0: No action 0x1: Send SIP pulse. | RW | 0 |
| 2 | SCTX_EN | Store and controlled TX start. When MDR1[5] = 1 and the LH writes 1 to this bit, the TX state-machine starts frame transmission. This bit is self-clearing. | RW | 0 |
| 1 | ABORT_EN | Frame abort. The LH can intentionally abort transmission of a frame by writing 1 to this bit. Neither the end flag nor the CRC bits are appended to the frame. If TX FIFO is not empty and MDR1[5] = 1, UART IrDA starts a new transfer with data of the previous frame when the abort frame is sent. Therefore, TX FIFO must be reset before sending an abort frame. | RW | 0 |
| 0 | EOT_EN | EOT (end of transmission) bit. The LH writes 1 to this bit just before it writes the last byte to the TX FIFO in set-EOT bit frame closing method. This bit is cleared automatically when the LH writes to the THR (TX FIFO). | RW | 0 |

| Physical Address | 0x4806 A048 0x4806 C048 0x4802 0048 0x4806 E048 | Instance | UART1 UART2 UART3 UART4 |
| Description | BOF length register IR-IrDA and IR-CIR modes only. In IR-IrDA SIR operation, this register specifies the number of BOF + xBOFs to transmit. Value set into this register must account for the BOF character; therefore, to send only one BOF with no XBOF, this register must be set to 1. To send one BOF with N XBOF, this register must be set to N + 1. The value 0 sends 1 BOF plus 255 XBOF. In IR-IrDA MIR mode, this register specifies the number of additional start flags (MIR protocol mandates a minimum of 2 start flags). In IR-CIR mode, this register specifies the number of consecutive 0s to be received before generating the RX_STOP interrupt (UART_IIR[2]). All received 0s are stored in the RX FIFO. When the register is set to 0, this feature is deactivated and always in reception state, which can be disabled by setting the ACREG[5] to 1. Note: If the RX_STOP interrupt occurs before a byte boundary, the remaining bits of the last byte are filled with 0s and passed into the RX FIFO. | | |

| Description | Wake-up enable register The UART wake-up enable register is used to mask and unmask a UART event that would subsequently notify the system. An event is any activity in the logic that could cause an interrupt and/or an activity that would require the system to wake up. Even if the wakeup is disabled for certain events, if these events are also an interrupt to the UART, the UART registers the interrupt. | | |

| Description | <div>Carrier frequency prescaler</div> <div>Because the consumer IR works at modulation rates of 30 to 56.8 kHz, the 48-MHz clock must be prescaled before the clock can drive the IR logic. This register sets the divisor rate to give a range to accommodate the remote-control requirements in baud multiples of 12x. The value of the CFPS at reset is 0105 decimal, which equals 38.1 kHz output from starting conditions. The 48-MHz carrier is prescaled by the CFPS, which is then divided by the 12x baud multiple.</div> | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

24.4 Multichannel Serial Port Interface

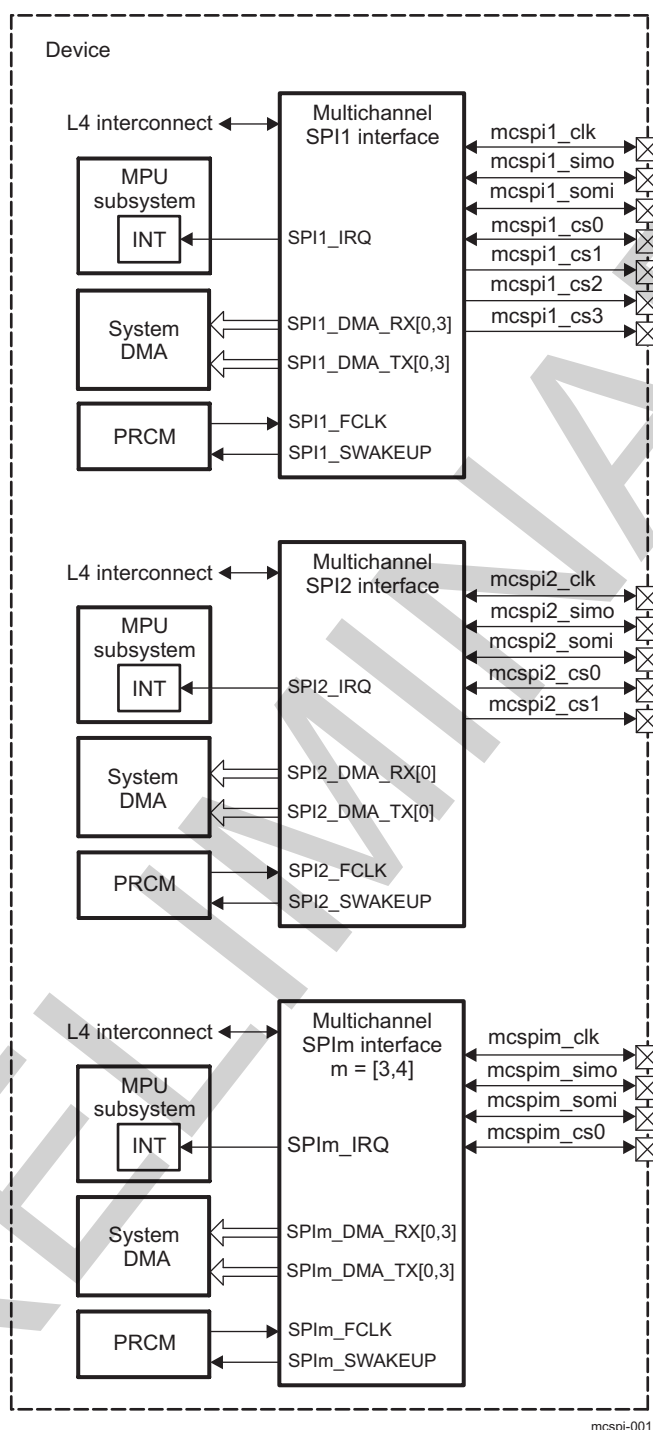

This section describes the four multichannel serial port interface (MCSPi) modules for the device.

24.4.1 MCSPi Overview

The MCSPi is a master/slave synchronous serial bus. The MCSPi has four separate modules (SPi1, SPi2, SPi3, and SPi4) in the device (see [Figure 24-86](#)). The MCSPi modules differ as follows: SPi1 supports up to four peripherals, SPi2 supports up to two peripherals, SPi3 and SPi4 support only one peripheral.

NOTE: In this chapter, $m = [1,4]$ represents the module instance and x represents the channel in signal and register naming. The MCSPi has four instances, with each module instance having different channel numbers:

- SPi1: 4 channels (if $m = 1$, $x = 4$)
 - SPi2: 2 channels (if $m = 2$, $x = 2$)
 - SPi3: 1 channel (if $m = 3$, $x = 1$)
 - SPi4: 1 channel (if $m = 4$, $x = 1$)
-

Figure 24-86. Multichannel Modules SPI1, SPI2, SPI3, and SPI4

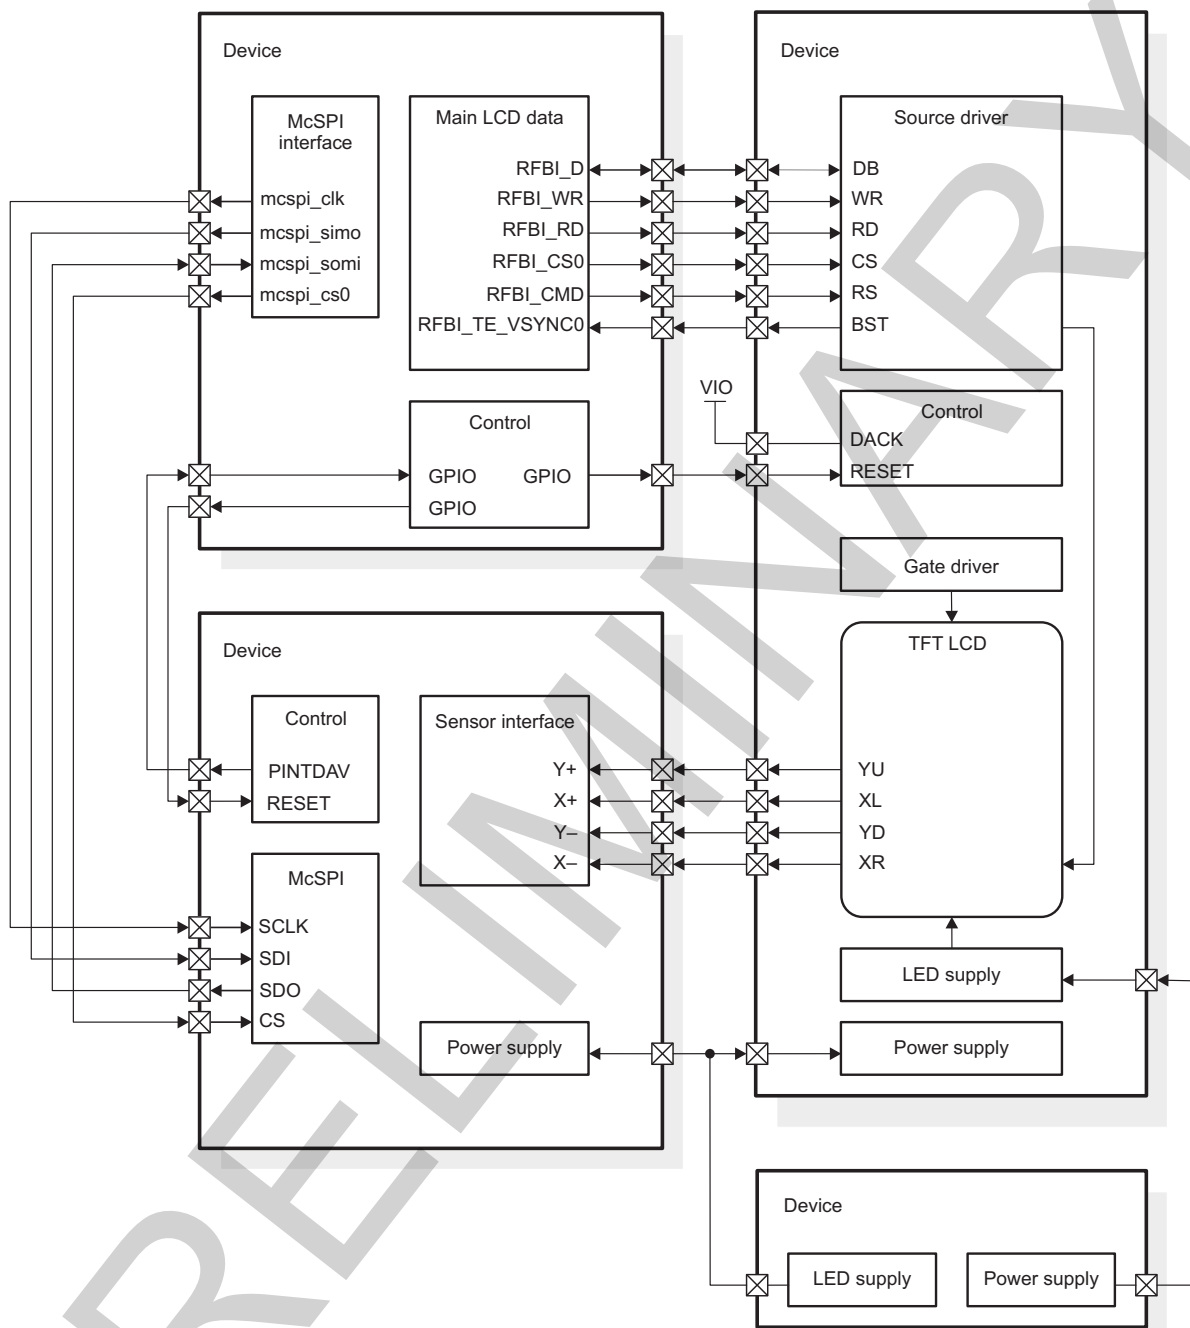

The MCSPI instances include the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of SPI word lengths, ranging from 4 to 32 bits
- Up to four master channels, or single channel in slave mode
- Master multichannel mode:
 - Full duplex/half duplex
 - Transmit-only/receive-only/transmit-and-receive modes

- Flexible I/O port controls per channel
- Two DMA requests (read/write) per channel
- Single interrupt line for multiple interrupt source events
- Power management through wake-up capabilities
- Enable the addition of a programmable start-bit for SPI transfer per channel (start-bit mode)
- Supports start-bit write command
- Supports start-bit pause and break sequence
- 64-byte built-in FIFO available for a single channel
- Force CS mode for continuous transfers

24.4.2 MCSPI Environment

Figure 24-87 shows a simplified overview of a typical application system using the MCSPI. This example is based on a TFS chip set, including a 2.2-inch color-active matrix thin-film transistor (TFT) liquid crystal display (LCD) with a light-emitting diode (LED) front light, a 4-wire resistive touch-screen panel, and LCD controllers. This chip set is associated with a touch-screen controller, powered by a power-management unit, and driven by the device. The MCSPI device interface is set to master mode; the touch-screen MCSPI controller interface operates in slave mode.

Figure 24-87. Typical Application Using the MCSPI

mcspi-034

24.4.2.1 MCSPI Interface

24.4.2.1.1 Basic MCSPI Pins for Master Mode

Figure 24-88 shows all of the MCSPI interface signals in master mode.

Figure 24-88. MCSPI Interface Signals in Master Mode

Table 24-262 describes the MCSPI I/O in master mode.

Table 24-262. MCSPI I/O Description (Master Mode)

| Signal Name | I/O | Description | Reset ⁽¹⁾ |
|-------------|-----|---|----------------------|
| mcspim_clk | O | SPIm module serial clock | Unknown |
| mcspim_simo | O | SPIm module serial data master out (slave input, master output) | Unknown |
| mcspim_somi | I | SPIm module serial data master input (slave output, master input) | — |
| mcspim_csx | O | SPIm module chip-select x output | Low |

⁽¹⁾ After reset, the SPI modules are in slave mode by default. This paragraph implies that the MCSPI module is configured in slave mode. (See the MCSPI_MODULCTRL[2] MS bit in the module control register [MCSPI_MODULCTRL]).

24.4.2.1.2 Basic MCSPI Pins for Slave Mode

Figure 24-89 shows all of the MCSPI interface signals in slave mode.

Figure 24-89. MCSPI Interface Signals in Slave Mode

Table 24-263 describes the MCSPI I/O in slave mode.

Table 24-263. MCSPI I/O Description (Slave Mode)

| Signal Name | I/O | Description | Reset ⁽¹⁾ |
|-------------|-----|--------------------------|----------------------|
| mcspim_clk | I | SPIm module serial clock | Unknown |

⁽¹⁾ After reset, the SPI modules are in slave mode by default. This paragraph implies that the MCSPI module is configured in slave mode. (See the MCSPI_MODULCTRL[2] MS bit in the module control register (MCSPI_MODULCTRL).)

Table 24-263. MCSPI I/O Description (Slave Mode) (continued)

| Signal Name | I/O | Description | Reset ⁽¹⁾ |
|-------------|-----|---|----------------------|
| mcsnim_simo | I | SPIm module serial data master out (slave input, master output) | Unknown |
| mcsnim_somi | O | SPIm module serial data master input (slave output, master input) | — |
| mcsnim_csx | I | SPIm module chip-select x output | Low |

24.4.2.1.3 Multichannel SPI Protocol and Data Format

The synchronous SPI protocol allows a master device to initiate serial data transfers to a slave device. A slave select line (mcsnim_csx) allows selection of an individual slave SPI device. Slave devices that are not selected do not interfere with SPI bus activities.

MCSPI offers the flexibility to modify the following parameters to adapt to the device features:

- Word length
MCSPI supports any SPI word ranging from 4 bits to 32 bits long (the SPIm.MCSPI_CHxCONF[11:7] WL bit field).
SPI word length can be changed between transmissions to allow the master device to communicate with peripheral slaves that have different requirements.
- SPI enable (mcsnim_csx, for channel x of instance m)
The polarity of the SPI enable signals is programmable (the SPIm.MCSPI_CHxCONF[6] EPOL bit). mcsnim_csx signals can be active high or low.
Assertion of the mcsnim_csx signals is programmable and can be done manually or automatically. The manual assertion mode is available in single master mode only. mcsnim_csx can be kept active between words with the SPIm.MCSPI_CHxCONF[20] FORCE bit.
Two consecutive words for two different slave devices can go along with active mcsnim_csx signals with different polarity.
- Programmable start-bit
In start-bit mode a start-bit is added before the SPI word length to indicate how the next SPI word must be handled. The start-bit is enabled by setting the SPIm.MCSPI_CHxCONF[23] SBE bit to 1. The SPIm.MCSPI_CHxCONF[24] SBPOL bit defines the polarity of the start-bit.
- Programmable SPI clock
 - Bit rate
In master mode, the baud rate of the SPI serial clock is programmable using the 48-MHz reference clock (from the PRCM module). Table 24-264 lists the spim_clk bit rates obtained for data transfer when programming the clock divider (the SPIm.MCSPI_CHxCONF[5:2] CLKD bit field).

Table 24-264. SPI Master Clock Rates

| Divider | Clock Rate |
|---------|------------|
| 1 | 48 MHz |
| 2 | 24 MHz |
| 4 | 12 MHz |
| 8 | 6 MHz |
| 16 | 3 MHz |
| 32 | 1.5 MHz |
| 64 | 750 kHz |
| 128 | 375 kHz |
| 256 | ~187 kHz |
| 512 | ~93.7 kHz |
| 1024 | ~46.8 kHz |

Table 24-264. SPI Master Clock Rates (continued)

| Divider | Clock Rate |
|---------|------------|
| 2048 | ~23.4 kHz |
| 4096 | ~11.7 kHz |

– Polarity and phase

The polarity (the SPI_{Im}.MCSPI_CHxCONF[1] POL bit) and the phase (the SPI_{Im}.MCSPI_CHxCONF[0] PHA bit) of the SPI serial clock (mcspim_clk) are configurable to offer four combinations. Software selects the right combination, depending on the device. See [Table 24-265](#) and [Figure 24-90](#).

Table 24-265. Phase and Polarity Combinations

| Polarity (POL) | Phase (PHA) | SPI Mode | Comments |
|----------------|-------------|----------|--|
| 0 | 0 | Mode 0 | mcspim_clk is active high and sampling occurs on the rising edge. |
| 0 | 1 | Mode 1 | mcspim_clk is active high and sampling occurs on the falling edge. |
| 1 | 0 | Mode 2 | mcspim_clk is active low and sampling occurs on the falling edge. |
| 1 | 1 | Mode 3 | mcspim_clk is active low and sampling occurs on the rising edge. |

Figure 24-90. Phase and Polarity Combinations

24.4.2.1.3.1 Transfer Format

In master and slave modes, the MCSPI drives the data lines when spim_csx is asserted.

Each word is transmitted starting with the MSB.

This section explains the two cases of data transmission determined by the clock phase (PHA) and the type of data transmission using a start-bit (SBE) called the start-bit mode:

- Transmission in mode 0 and mode 2 (PHA = 0)

When PHA = 0, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid one-half cycle of spim_clk after the assertion of spim_csx.

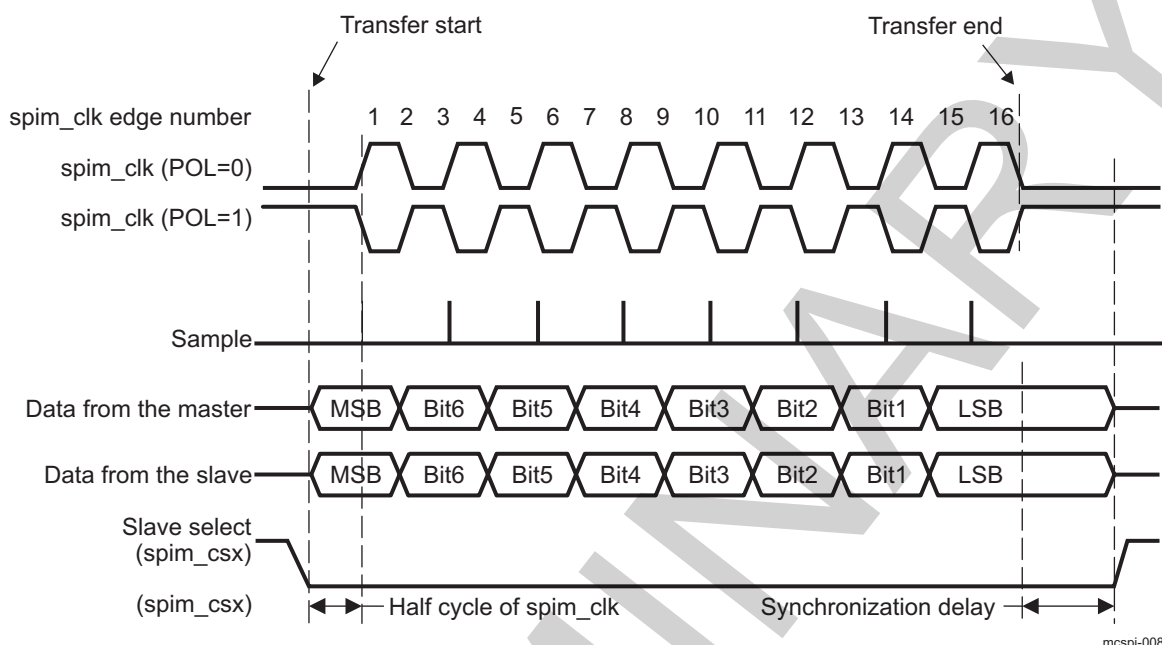

Therefore, the first edge of the mcspim_clk line is used by the master to sample the first data bit sent by the slave. On the same edge, the first data bit sent by the master is sampled by the slave.

On the next mcspim_clk edge, the received data bit is shifted into the receive shift register and a new data bit is transmitted on the serial data line.

This process continues for a number of pulses on the spim_clk line defined by the SPI word length

programmed in the master device, with data being latched on odd-numbered edges and shifted on even-numbered edges. See [Figure 24-91](#).

Figure 24-91. Full-Duplex Transfer Format With PHA = 0

- Transmission in mode 1 and mode 3 (PHA = 1)

When PHA = 1, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid on the following mcspim_clk edge (one-half cycle later). This is the sampling edge for the master and slave. A synchronization delay is added between the activation of mcspim_csx and the first mcspim_clk edge.

The received data bit is shifted into the shift register on the third mcspim_clk edge.

This process continues for a number of pulses on the mcspim_clk line defined by the SPI word length programmed in the master device, with data being latched on even-numbered edges and shifted on odd-numbered edges.

NOTE: The minimum synchronization delay is one cycle of mcspim_clk, if the frequency of mcspim_clk equals the frequency of SPIm_FCLK (MCSPIm functional clock) in master mode. The minimum synchronization delay is one-half cycle of mcspim_clk, if the frequency of mcspim_clk is lower than the frequency of SPIm_FCLK in the master and slave modes.

- Transmission with a start-bit (SBE = 1)

When the SPIm.MCSPI_CHxCONF[23] SBE bit is set to 1, a start-bit is added before the MSB to indicate whether the next SPI word must be handled as a command or as data.

[Figure 24-92](#) shows an example of a data transfer with an extra start-bit.

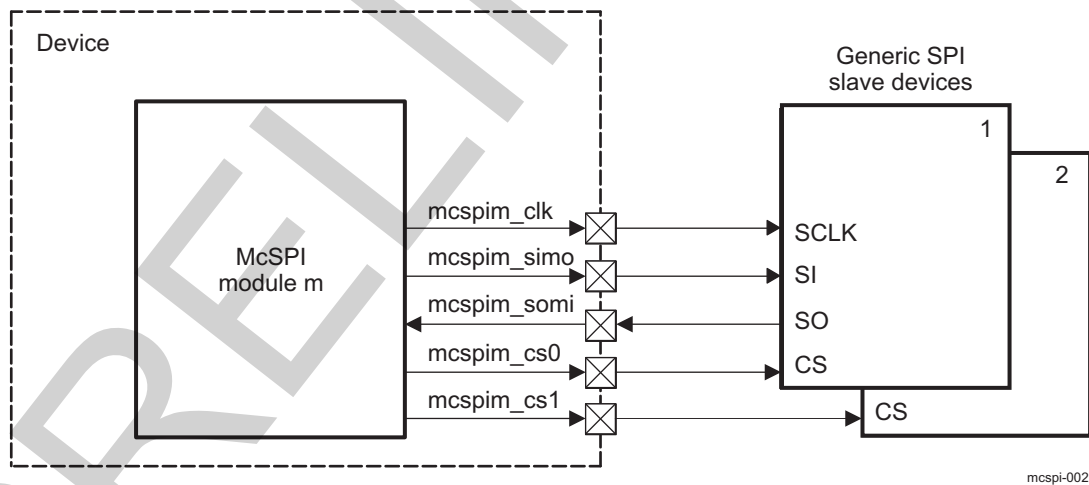

Figure 24-92. Extended SPI Transfer With a Start-Bit (SBE = 1)

24.4.2.2 SPI in Master Mode

Figure 24-93 shows a case in master mode (full-duplex) where the MCSPI module is connected with two slave devices.

Figure 24-93. MCSPI Master Mode (Full Duplex)

NOTE: In this case $m = [1,3]$.

Figure 24-94 shows the master single mode, which can also be configured in receive-only mode.

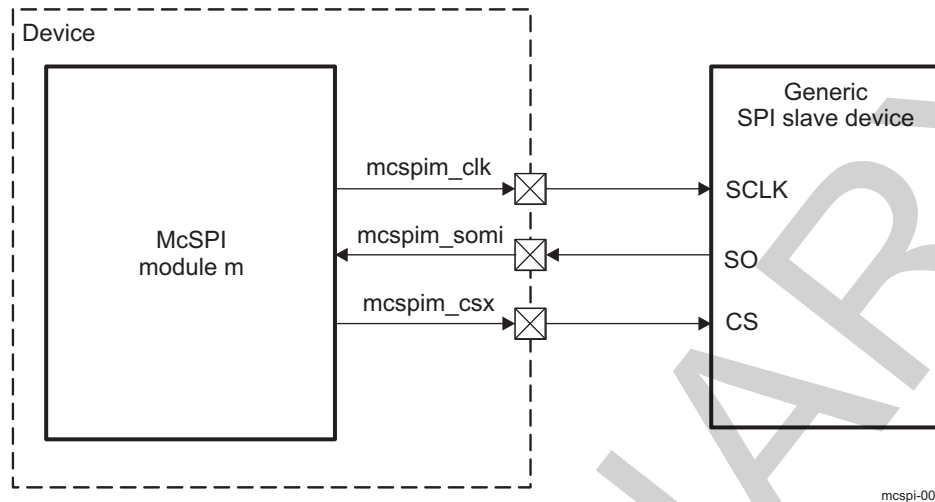

Figure 24-94. MCSPI Master Single Mode (Receive Only)**24.4.2.3 SPI in Slave Mode**

Figure 24-95 shows a case in slave mode (full-duplex).

NOTE: Only channel 0 can be configured as slave, but the chip-enable signal can be connected to any mcspim_csx pin and then rerouted internally to channel 0 (the SPI_m.MCSPI_CHxCONF[22:21] SPIENSLV bit field [where x = 0]). For more information, see Section 24.4.4.3, *Slave Mode*.

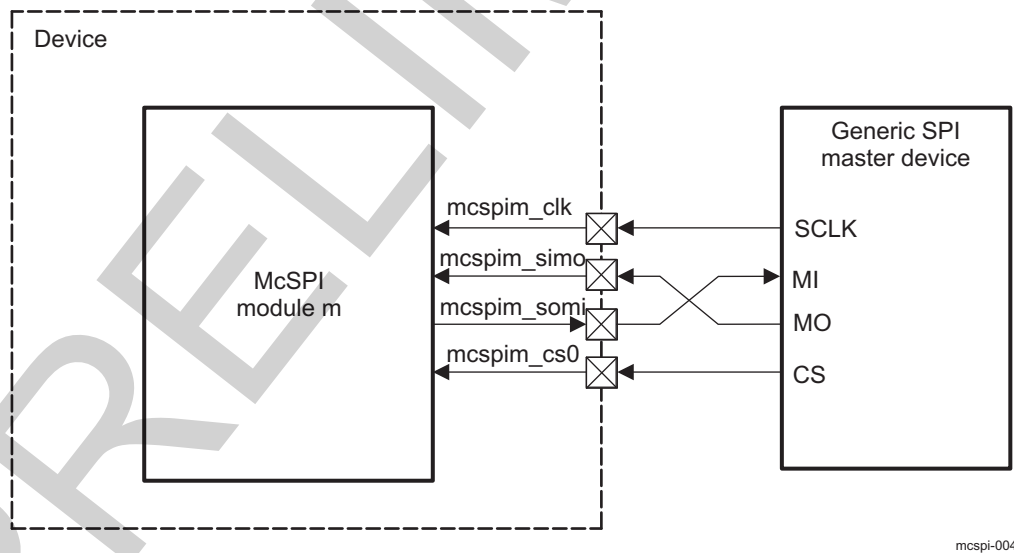

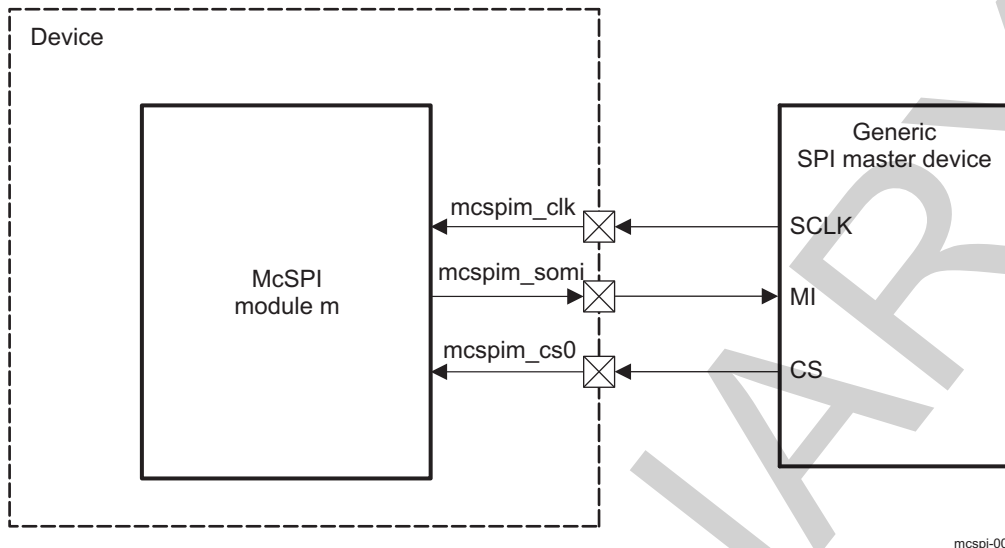

Figure 24-95. MCSPI Slave Mode (Full Duplex)

Figure 24-96 shows the slave single mode, which can also be configured in transmit-only mode.

Figure 24-96. MCSPI Slave Single Mode (Transmit Only)

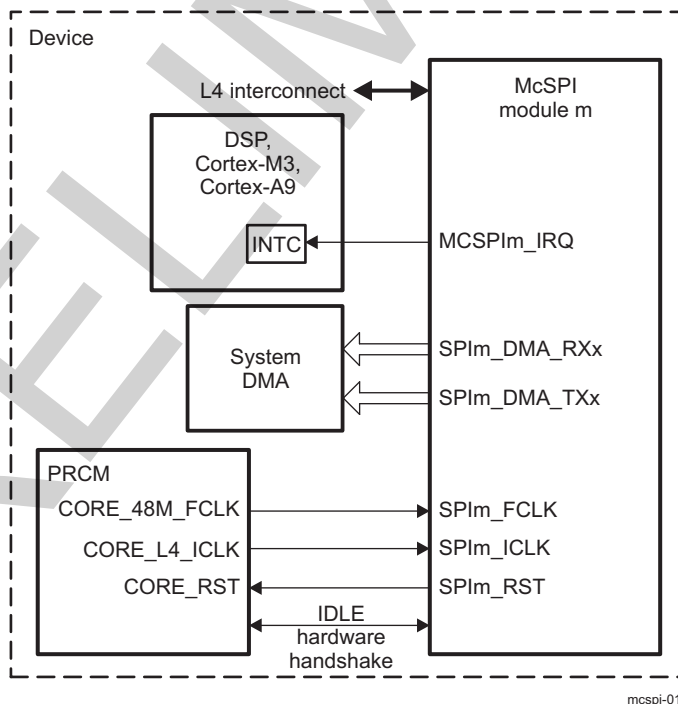

24.4.3 MCSPI Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 24-97 shows MCSPI integration.

Figure 24-97. MCSPI Integration

NOTE: For more information about the IDLE hardware handshake and the wake-up request, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

NOTE: For the names of the signals going from the MCSPI and to the DSP, Cortex-M3, and Cortex-A9 INTC, see [Table 24-268](#).

[Table 24-266](#) through [Table 24-268](#) summarize the integration of the module in the device.

Table 24-266. Integration Attributes

| Module Instance | Attributes | |
|-----------------|--------------|--------------|
| | Power Domain | Interconnect |
| MCSP1 | PD_L4_PER | L4_PER |
| MCSP2 | PD_L4_PER | L4_PER |
| MCSP3 | PD_L4_PER | L4_PER |
| MCSP4 | PD_L4_PER | L4_PER |

Table 24-267. Clocks and Resets

| Clocks | | | | |
|-----------------|-------------------------|--------------------|--------|----------------------------|
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| MCSP1 | SPI1_ICLK | PER_L4_ICLK | PRCM | Interface clock |
| | SPI1_FCLK | PER_48M_FCLK | PRCM | Functional clock |
| MCSP2 | SPI2_ICLK | PER_L4_ICLK | PRCM | Interface clock |
| | SPI2_FCLK | PER_48M_FCLK | PRCM | Functional clock |
| MCSP3 | SPI3_ICLK | PER_L4_ICLK | PRCM | Interface clock |
| | SPI3_FCLK | PER_48M_FCLK | PRCM | Functional clock |
| MCSP4 | SPI4_ICLK | PER_L4_ICLK | PRCM | Interface clock |
| | SPI4_FCLK | PER_48M_FCLK | PRCM | Functional clock |

| | SPI4_DMA_RX0 | S_DMA_70 | sDMA | Destination is system DMA. |

Table 24-269 lists the wake-up requests.

Table 24-269. Wake-Up Requests

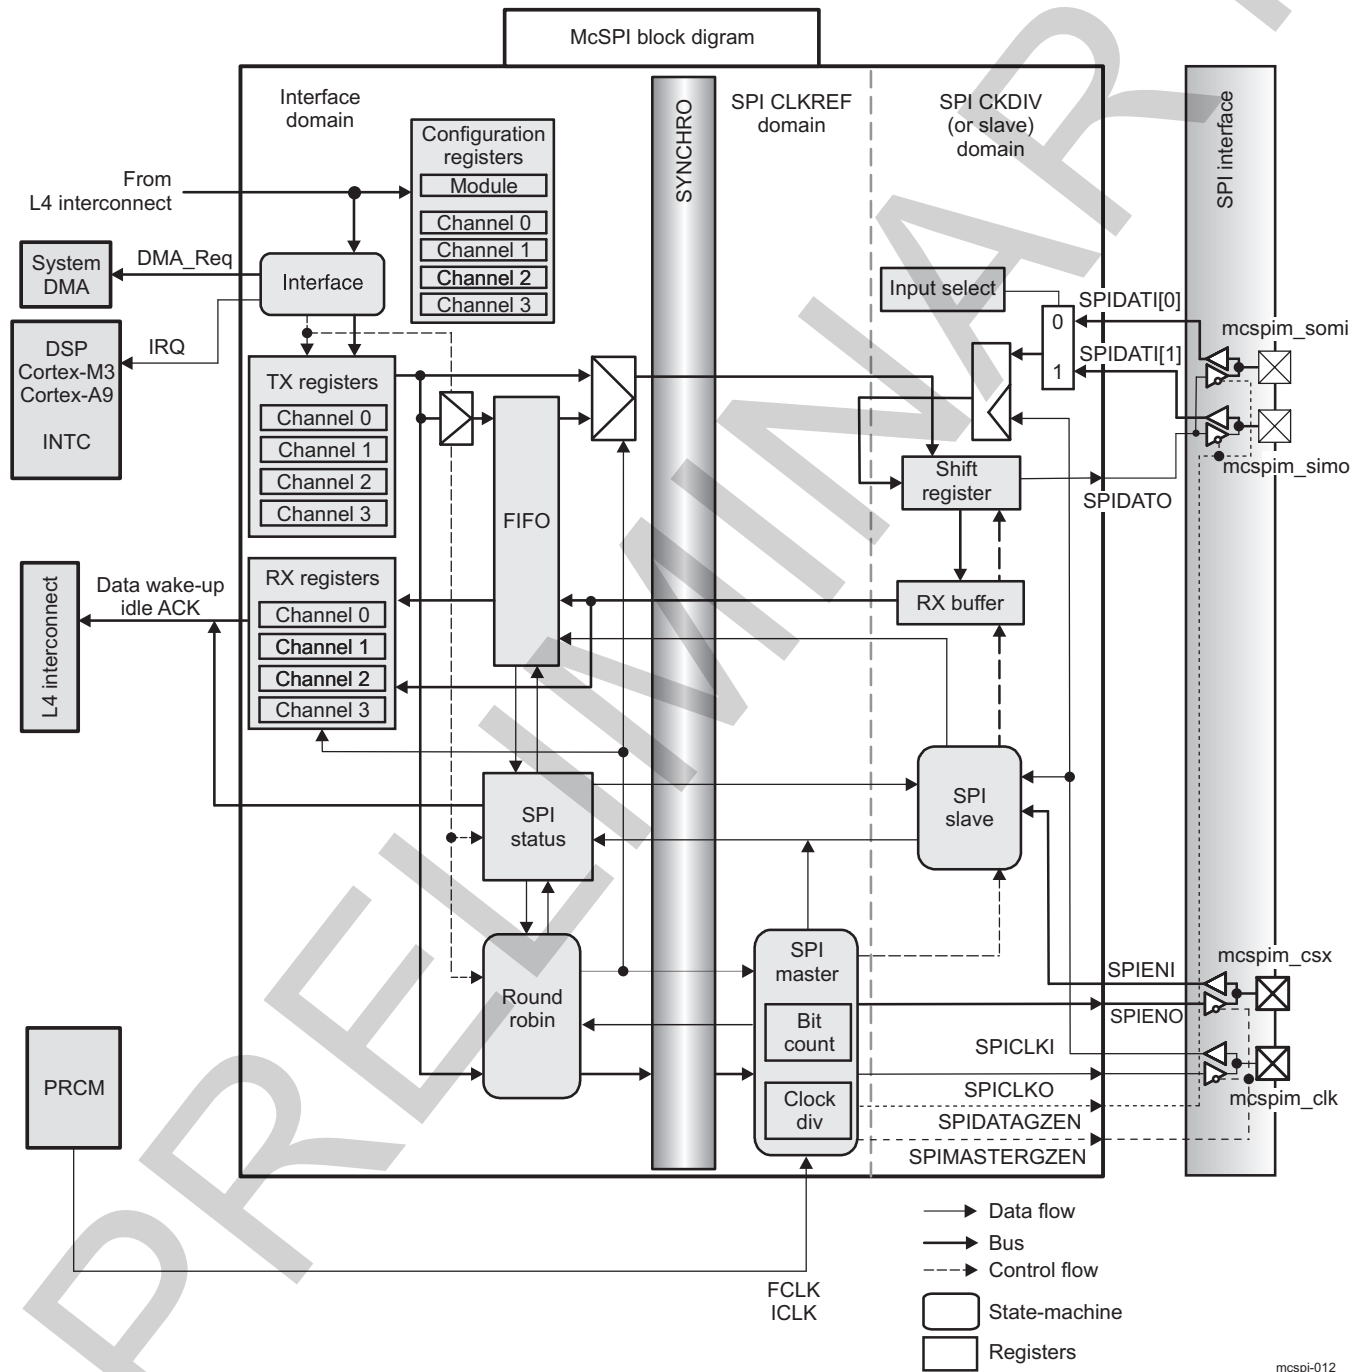

| Attributes | Wake Request | Name | Mapping | Comments |
|------------|--------------|----------|--------------|---------------------------------|
| SPI1 | 1 | spi1_cs0 | SPI1_SWAKEUP | Destination is the PRCM module. |
| SPI2 | 1 | spi2_cs0 | SPI2_SWAKEUP | Destination is the PRCM module. |
| SPI3 | 1 | spi3_cs0 | SPI3_SWAKEUP | Destination is the PRCM module. |
| SPI4 | 1 | spi4_cs0 | SPI4_SWAKEUP | Destination is the PRCM module. |

24.4.4 MCSPI Functional Description

24.4.4.1 MCSPI Block Diagram

Figure 24-98 shows the MCSPI module.

Figure 24-98. MCSPI Block Diagram

24.4.4.2 Master Mode

24.4.4.2.1 Master Mode Features

The MCSPI master mode supports multichannel communication with up to four independent SPI communication channel contexts. The MCSPI initiates a data transfer on the data lines (mcspim_simo and mcspim_somi) and generates clock (mcspim_clk) and control (mcspim_csx) signals.

Connected to multiple external devices, the MCSPI exchanges data with one SPI device at a time through two main modes (available in slave mode):

- Two-data-pins interface mode (transmit-and-receive mode for full-duplex transmission)
- Single-data-pin interface mode (recommended for half-duplex transmission)

Two DMA request events (read and write) allow synchronized accesses of the DMA controller with the activity of MCSPI.

Three interrupt events can be used for data transmission and reception in master mode (for more information about interrupts, see [Section 24.4.4.5.1, Interrupt Events in Master Mode](#)).

24.4.4.2.2 Master Transmit-and-Receive Mode (Full Duplex)

In full-duplex transmission, data is transmitted (shifted out serially on mcspim_simo) and received (shifted in serially on mcspim_somi) simultaneously on separate data lines.

The master transmit-and-receive mode is programmable per channel (the SPI1.MCSPI_CHxCONF[13:12] TRM bit field).

Channel access to the shift registers for transmission/reception is based on the MCSPI_TXx transmitter register state, the MCSPI_RXx receiver register state, and round-robin arbitration.

Channels that meet the following rules are included in the round-robin list of active channels scheduled for transmission and/or reception. The arbiter skips channels that do not meet the rules and searches in the rotation for the next enabled channel.

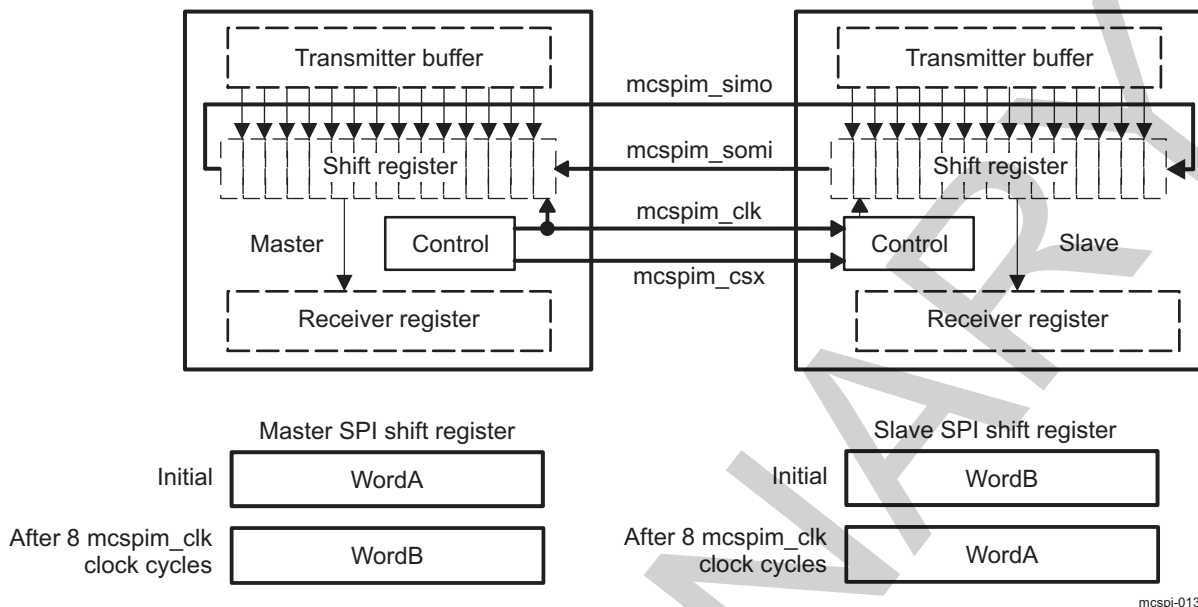

- Rule 1: Only enabled channels (the SPI1.MCSPI_CHxCTRL[0] EN bit) can be scheduled for transmission and/or reception.
- Rule 2: If its MCSPI_TXx transmitter register is not empty (the SPI1.MCSPI_CHxSTAT[1] TXS bit), an enabled channel can be scheduled when the shift register is assigned. If the MCSPI_TXx register is empty when the shift register is assigned, the TXx_UNDERFLOW event is activated, and the next enabled channel with new data to transmit is scheduled (see also transmit-only mode).
- Rule 3: An enabled channel can be scheduled if its receive register is not full (the SPI1.MCSPI_CHxSTAT[0] RXS bit) when the shift register is assigned (see also receive-only mode). Therefore, the MCSPI_RXx register cannot be overwritten. The SPI1.MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set to this mode.

When SPI word transfer completes (the SPI1.MCSPI_CHxSTAT[2] EOT bit is set), the updated MCSPI_TXx register of the next scheduled channel is loaded into the shift register. The serialization (transmit-and-receive) starts depending on the channel communication configuration. When serialization completes, the received data transfers to the channel receive register.

The serial clock (mcspim_clk) synchronizes shifting and sampling of the information on the two serial data lines (mcspim_simo and mcspim_somi). Each time a bit transfers out from the master, 1 bit transfers in from the slave.

[Figure 24-99](#) shows an example of a full-duplex system with a master device (MCSPI module *m*) on the left and a slave device on the right. After eight cycles of the serial clock mcspim_clk, WordA transfers from the master to the slave. At the same time, WordB transfers from the slave to the master.

Figure 24-99. SPI Full-Duplex Transmission (Example)

24.4.4.2.3 Master Transmit-Only Mode (Half Duplex)

The master transmit-only mode prevents the MPU from reading the **MCSPi_RXx** register (minimizing data movement) when only transmission is meaningful.

The master transmit-only mode is programmable per channel (the `SPIm.MCSPIm_CHxCONF[13:12]` TRM field). Transmission starts only after data is loaded into the `MCSPIm_TXx` register.

Rule 1 and Rule 2, defined in [Section 24.4.4.2.2](#), apply in this mode.

Rule 3, defined in [Section 24.4.4.2.2](#), does not apply.

In master transmit-only mode, the **MCSPi_RXx** register state FULL does not prevent transmission and the **MCSPi_RXx** register is always overwritten with the new SPI word. This event is not significant when only transmission is meaningful. Thus, the RX0_OVERFLOW bit in the SPIm.**MCSPi_IRQSTATUS** register is never set in this mode.

The hardware automatically disables the RX FULL interrupt and the DMA read requests.

The transfer status is given by the SPIm.MCSPI_CHxSTAT[2] EOT bit.

24.4.4.2.4 Master Receive-Only Mode (Half Duplex)

The master receive mode prevents the MPU from refilling the `MCSPi_TXx` register (minimizing data movement) when only reception is meaningful.

The master receive mode is programmable per channel (the SPIm.MCSPI_CHxCONF[13:12] TRM bit field).

The master receive-only mode enables channel scheduling only on the empty state of the [MCSPI_RXx](#) register.

Rule 1 and Rule 3, defined in [Section 24.4.4.2.2](#), apply in this mode.

Rule 2, defined in [Section 24.4.4.2.2](#), does not apply.

In the master receive-only mode, software must write dummy data to the [MCSPI_TXx](#) register. Only one dummy write is enough to receive any number of words from the slave. Software should ensure that the [MCSPI_TXx](#) register is always full (the TXx_EMPTY bits of SPIm.[MCSPI_IRQSTATUS](#)) when receiving. The content of the [MCSPI_TXx](#) register is always loaded into the shift register when the shift register is assigned. After writing the dummy data to the [MCSPI_TXx](#) register, the TXx_EMPTY and TXx_UNDERFLOW bits in the SPIm.[MCSPI_IRQSTATUS](#) register are never set in receive-only mode.

The SPIm.[MCSPI_CHxSTAT](#)[2] EOT bit gives the status of serialization. The RXx_FULL bits of the SPIm.[MCSPI_IRQSTATUS](#) register are set when received data is loaded from the shift register to the corresponding [MCSPI_RXx](#) register. The SPIm.[MCSPI_IRQSTATUS](#)[3] RX0_OVERFLOW bit is never set in this mode.

24.4.4.2.5 Single-Channel Master Mode

When the MCSPI is configured as a master device with a single enabled channel, the assertion of the mcsnim_csx signal can be controlled in two different ways:

- If the [MCSPI_MODULCTRL](#)[0] SINGLE bit is set to 0, mcsnim_csx assertion and deassertion after each SPI word is automatically controlled by the MCSPI (see subsections of [Section 24.4.4.2.1](#), *Master Mode Features*).
- If the [MCSPI_MODULCTRL](#)[0] SINGLE and [MCSPI_CHxCONF](#)[20] FORCE bits are set to 1, mcsnim_csx assertion and deassertion is controlled by software (see [Section 24.4.4.2.5.1](#), *Programming Tips When Switching to Another Channel*).

24.4.4.2.5.1 Programming Tips When Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for completion of the SPI word transfer (wait until the SPIm.[MCSPI_CHxSTAT](#)[2] EOT bit is set to 1) before disabling the current channel and enabling a different channel.
- Disable the current channel, and then enable the other channel.

24.4.4.2.5.2 Force mcsnim_csx Mode

Continuous transfers are allowed manually by keeping the mcsnim_csx signal active for successive SPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the mcsnim_csx line. This mode is supported by all channels and any master sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the mcsnim_csx active mode is supported when:

- A single channel is used (with the SPIm.[MCSPI_MODULCTRL](#)[0] SINGLE bit set to 1).
- Transfer parameters are loaded in the configuration register of the appropriate channel (SPIm.[MCSPI_CHxCONF](#)).

The state of the mcsnim_csx signal is programmable.

- Writing 1 to the SPIm.[MCSPI_CHxCONF](#)[20] FORCE bit drives the mcsnim_csx line high when the SPIm.[MCSPI_CHxCONF](#)[6] EPOL bit is set to 0. mcsnim_csx is driven low when the SPIm.[MCSPI_CHxCONF](#)[6] EPOL bit is set to 1.
- Writing 0 to the SPIm.[MCSPI_CHxCONF](#)[20] FORCE bit drives the mcsnim_csx line low when the SPIm.[MCSPI_CHxCONF](#)[6] EPOL bit is set to 0. mcsnim_csx is driven high when the SPIm.[MCSPI_CHxCONF](#)[6] EPOL bit is set to 1.
- A single channel is enabled (the SPIm.[MCSPI_CHxCTRL](#)[0] EN bit is set to 1). The first enabled channel activates the mcsnim_csx line.

When the channel is enabled, the mcsnim_csx signal activates with the programmed polarity. As in the multichannel master mode, the transfer start depends on the status of the [MCSPI_TXx](#) register (the SPIm.[MCSPI_CHxSTAT](#)[1] TXS bit), the status of the [MCSPI_RXx](#) register (the SPIm.[MCSPI_CHxSTAT](#)[1] RXS bit), and the defined mode (the SPIm.[MCSPI_CHxCONF](#)[13:12] TRM bit field) of the channel enabled.

The SPI_m.MCSPI_CHxSTAT[2] EOT bit gives the transfer status of each SPI word. The RXx_FULL bit in the SPI_m.MCSPI_IRQSTATUS register is set when received data is loaded from the shift register to the MCSPI_RXx register.

A change in the configuration parameters is propagated directly on the SPI interface. If the mcspim_csx signal is activated, ensure that the configuration is changed only between SPI words to avoid corrupting the current transfer.

NOTE: To avoid data corruption, mcspim_csx polarity and mcspim_clk phase and mcspim_clk polarity must not be modified when the mcspim_csx signal is activated.

A delay between SPI words that requires the connected SPI slave device to switch from one configuration to another (for instance, from transmit-only to receive-only) must be handled by software.

At the end of the last SPI word, the channel must be deactivated (the SPI_m.MCSPI_CHxCTRL[0] EN bit set to 0) and mcspim_csx can be forced to its INACTIVE state using the SPI_m.MCSPI_CHxCONF[20] FORCE bit.

Figure 24-100 and Figure 24-101 show successive transfers with mcspim_csx maintained active low with a different configuration for each SPI word in single-data-pin and dual-data-pin interface modes, respectively.

Figure 24-100. Continuous Transfers With mcspim_csx Maintained Active (Single-Data-Pin Interface Mode)

Figure 24-101. Continuous Transfers With mcspim_csx Maintained Active (Dual-Data-Pin Interface Mode)

NOTE: Turbo mode described in Section 24.4.4.2.5.3, *Turbo Mode*, maintains mcspim_csx in active mode when the following conditions are met:

- A single channel is explicitly used (the SPI_m.MCSPI_MODULCTRL[0] SINGLE bit is set to 1).
- Turbo mode is enabled in the configuration of the channel (the SPI_m.MCSPI_CHxCONF[19] TURBO bit is set to 1).

24.4.4.2.5.3 Turbo Mode

Turbo mode improves the throughput of the SPI interface when a single channel is enabled by allowing transfers until the shift register and the `MCSPI_RXx` register are full. Turbo mode is time saving when a transfer exceeds two words. This mode is programmable per channel (through the `SPI1.MCSPI_CHxCONF[9]` TURBO bit).

When several channels are enabled, the TURBO bit has no effect and the channel access to the shift registers remains as previously described.

In turbo mode, Rule 1 and Rule 2 apply, but Rule 3 does not (see [Section 24.4.4.2.2](#)). An enabled channel can be scheduled if its receive register is full (the `SPI1.MCSPI_CHxSTAT[0]` RXS bit) at the time of the shift-register assignment until the shift register is full.

The `MCSPI_RXx` register cannot be overwritten in turbo mode. Consequently, the `SPI1.MCSPI_IRQSTATUS[3]` RX0_OVERFLOW bit is never set in this mode.

24.4.4.2.6 Start-Bit Mode

In start-bit mode, an extended bit is added before the SPI word to indicate whether the next SPI word must be handled as a command or as data. This feature is available only in master mode. Start-bit mode cannot be used at the same time as turbo mode and/or force `mcsnim_csx` mode. In this case, only one channel can be used; round-robin arbitration is not possible.

This mode is programmable per channel by setting the `SPI1.MCSPI_CHxCONF[23]` SBE bit to 1. The polarity of the extended bit is programmable per channel. When the `SPI1.MCSPI_CHxCONF[24]` SBPOL bit is set to 0, the SPI word must be handled as a command. When the `SPI1.MCSPI_CHxCONF[24]` SBPOL bit is set to 1, the SPI word must be handled as data. Moreover, start-bit polarity can be changed dynamically during start-bit transfer without disabling the channel for reconfiguration; in this case, users must configure the `SPI1.MCSPI_CHxCONF[24]` SBPOL bit before writing the SPI word to be transmitted to the TX register.

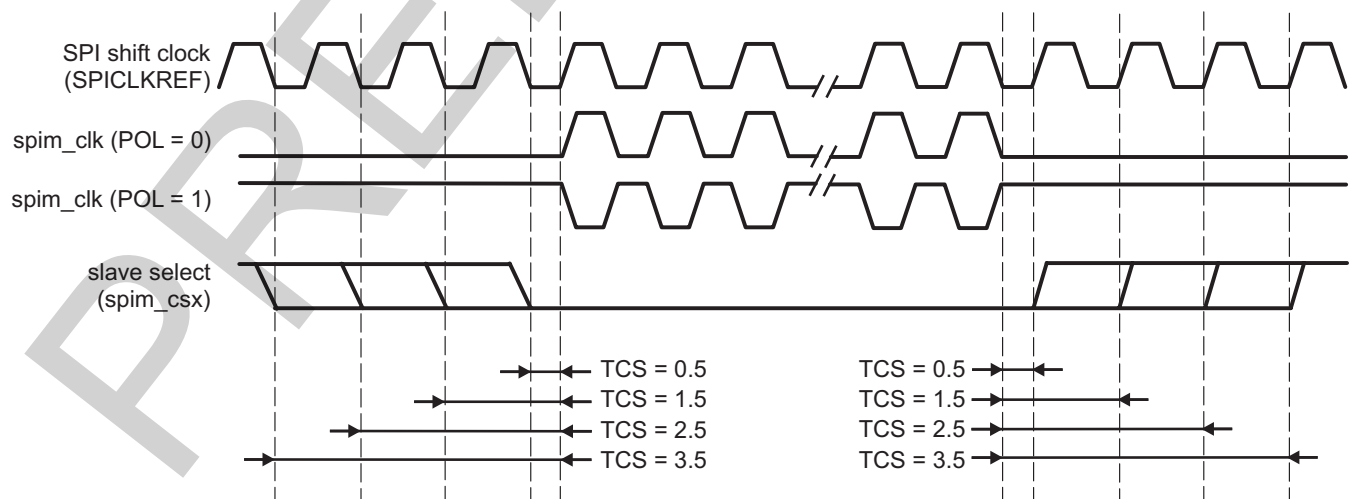

24.4.4.2.7 Chip-Select Timing Control

The chip-select (CS) timing control is available only in master mode with automatic CS generation (the `MCSPI_MODULCTRL[0]` SINGLE bit field set to 0) to add a programmable delay between CS assertion and first clock edge, or CS removal and last clock edge.

This mode is programmable per channel (the `SPI1.MCSPI_CHxCONF` TCS bit).

[Figure 24-102](#) shows the CS SPIEN timing control.

Figure 24-102. CS SPIEN Timing Controls

mcspl-016

NOTE: Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between CS assertion and the first clock edge with PHA = 1 or between CS removal and the last clock edge with PHA = 0.

24.4.4.2.8 Programmable SPI Clock (mcspim_clk)

In master mode, the baud rate of the SPI serial clock is programmable.

An internal reference clock, SPIm_FCLK, is used as input of a programmable divider (the SPIm.MCSPI_CHxCONF[5:2] CLKD bit field) to generate the bit rate of the serial output clock mcspim_clk. Table 24-270 summarizes the supported divisor values.

Table 24-270. SPI Master Clock Rates

| Divider | Clock Rate |
|---|------------|
| 1 | 48 MHz |
| 2 | 24 MHz |
| 4 | 12 MHz |
| 8 | 6 MHz |
| 16 | 3 MHz |
| 32 | 1.5 MHz |
| 64 | 750 kHz |
| 128 | 375 kHz |
| 256 | ~187 kHz |
| 512 | ~93.7 kHz |
| 1024 | ~46.8 kHz |
| 2048 | ~23.4 kHz |
| 4096 | ~11.7 kHz |
| 8192 and higher: Division not supported | |
| | – |

24.4.4.2.8.1 Clock Ratio Granularity

By default, the clock division ratio is defined by the SPIm.MCSPI_CHxCONF[5:2] CLKD bit field with power-of-2 granularity leading to a clock division in the range 1 to 4096; in this case, the duty cycle is always 50 percent. With the SPIm.MCSPI_CHxCONF[29] CLKG bit, clock division granularity can be changed to one clock cycle; in that case the SPIm.MCSPI_CHxCTRL[15:8] EXTCLK bit field is concatenated with the SPIm.MCSPI_CHxCONF[5:2] CLKD bit field to give a 12-bit-wide division ratio in the range 1 to 4096.

When granularity is one clock cycle (the CLKG bit set to 1), for the odd value of the clock ratio, the clock high level lasts one clock cycle more than the low level, depending on the SPIm.MCSPI_CHxCONF[1] POL and SPIm.MCSPI_CHxCONF[0] PHA bits (see Table 24-271).

Table 24-271. CLKSPIO High/Low Time Computation

| Clock Ratio Fratio | CLKSPIO High Time | CLKSPIO Low Time |
|---------------------|------------------------|------------------------|
| 1 | Thigh_ref | Tlow_ref |
| Even >= 2 | T_ref * (Fratio/2) | T_ref * (Fratio/2) |
| Odd >= (POL = PHA) | T_ref * (Fratio – 1)/2 | T_ref * (Fratio + 1)/2 |
| Odd >= (POL != PHA) | T_ref * (Fratio + 1)/2 | T_ref * (Fratio – 1)/2 |

NOTE: Fratio = spi1_clk frequency (Fout) division ratio
Thigh = spi1_clk high time period
Tlow = spi1_clk low time period
T_ref = SPI1_FCLK period
Thigh_ref = SPI1_FCLK high time period
Tlow_ref = SPI1_FCLK low time period

If the CLKG bit is set to 1; Fratio = EXTCLK concatenated with CLKD + 1.

For odd ratio values, the duty cycle is calculated as follows:

$$\text{Duty_cycle} = (1 - 1/\text{Fratio})/2$$

Table 24-272 shows examples of clock granularity with a clock source frequency of 48 MHz.

Table 24-272. Clock Granularity Examples

| EXTCLK | CLKD | CLKG | Fratio | PHA | POL | Thigh (ns) | Tlow (ns) | Tperiod (ns) | Duty Cycle | Fout (MHz) |
|--------|------|------|--------|-----|-----|------------|-----------|--------------|------------|------------|
| X | 0 | 0 | 1 | X | X | 10.4 | 10.4 | 20.8 | 50–50 | 48 |
| X | 1 | 0 | 2 | X | X | 20.8 | 20.8 | 41.6 | 50–50 | 24 |
| X | 2 | 0 | 4 | X | X | 41.6 | 41.6 | 83.2 | 50–50 | 12 |
| X | 3 | 0 | 8 | X | X | 83.2 | 83.2 | 166.4 | 50–50 | 6 |
| 0 | 0 | 1 | 1 | X | X | 10.4 | 10.4 | 20.8 | 50–50 | 48 |
| 0 | 1 | 1 | 2 | X | X | 20.8 | 20.8 | 41.6 | 50–50 | 24 |
| 0 | 2 | 1 | 3 | 1 | 0 | 41.6 | 20.8 | 62.4 | 66–33 | 16 |
| 0 | 2 | 1 | 3 | 1 | 1 | 20.8 | 41.6 | 62.4 | 33–66 | 16 |
| 0 | 3 | 1 | 4 | X | X | 41.6 | 41.6 | 83.2 | 50–50 | 12 |
| 5 | 0 | 1 | 81 | 1 | 0 | 852.8 | 832 | 1684.8 | 50.6–49.4 | 0.592 |
| 5 | 7 | 1 | 88 | X | X | 915.2 | 915.2 | 1830.4 | 50–50 | 0.545 |

24.4.4.3 Slave Mode

To select the MCSPI slave mode, set the SPI1.MCSPI_MODULCTRL[2] MS bit.

A MCSPI slave device can be connected to up to four external SPI master devices but handles transactions with one SPI master device at a time.

In slave mode, the MCSPI initiates data transfer on the data lines (mcspim_simo and mcspim_somi) when it is selected by an active control signal (mcspim_csx) and receives an SPI clock (mcspim_clk) from the external SPI master device. Only channel 0 can be configured as a slave. In slave mode, the MCSPI uses the edge of mcspim_csx to detect word length. For this reason, mcspim_csx must become inactive between each word.

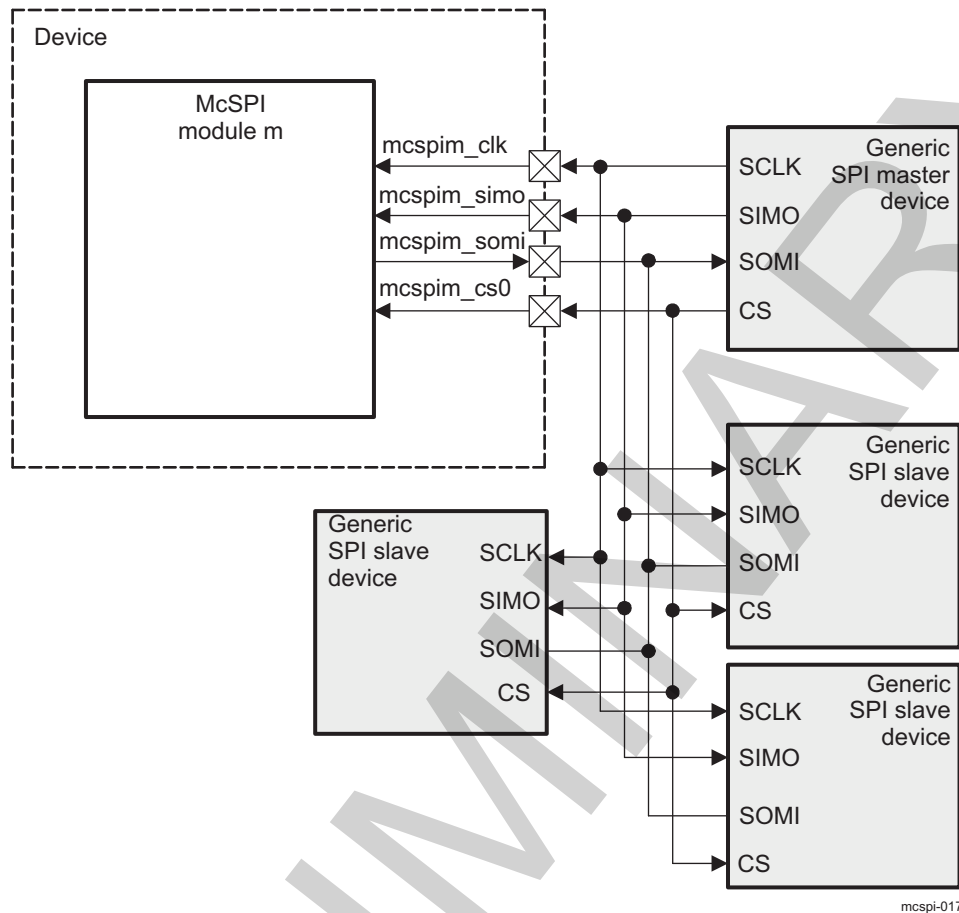

The MCSPI does not support mcspim_csx active between SPI words. It uses the edge to detect word length.

24.4.4.3.1 Dedicated Resources

Only channel 0 can be enabled in slave mode. In this section register names such as SPI1.MCSPI_CHxCTRL stand for SPI1.MCSPI_CH0CTRL, where x = 0 (channel 0 control register).

Figure 24-103 shows an example of four slaves wired on a single master device.

Figure 24-103. Example of MCSPI Slave With One Master and Multiple Slave Devices on Channel 0

The channel 0 in slave mode has the following resources:

- Its own channel enable, programmable with the SPI_m.[MCSPI_CHxCTRL](#)[0] EN bit (where x = 0). This channel must be enabled before transmission and reception.
- For this mode, the slave-select signal can be detected on any one of the mcspim_csx ports. This is programmable with the SPI_m.[MCSPI_CHxCONF](#)[22:21] SPIENSLV bit field (where x = 0).
- Its own transmitter register, SPI_m.[MCSPI_TXx](#) (where x = 0), on top of the common transmit shift register. If the [MCSPI_TXx](#) register is empty, the SPI_m.[MCSPI_CHxSTAT](#)[1] TXS bit (where x = 0) is set. If MCSPI is selected by an external master (the active signal on the mcspim_csx port assigned to channel 0), the [MCSPI_TXx](#) register content of channel 0 is always loaded into the shift register, whether its content is updated or not. The [MCSPI_TXx](#) register must be loaded before MCSPI is selected by a master.
- Its own receiver register, SPI_m.[MCSPI_RXx](#) (where x = 0), on top of the common receive shift register. If the [MCSPI_RXx](#) register is full, the SPI_m.[MCSPI_CHxSTAT](#)[0] RXS bit (where x = 0) is set.

NOTE: The [MCSPI_TXx](#) register and [MCSPI_RXx](#) registers of the other channels are not used. Reading from or writing to a channel register other than channel 0 has no effect.

- Its own communication configuration with the following parameters through the SPI_m.[MCSPI_CHxCONF](#) register (where x = 0):
 - Transmit and receive modes, programmable with the TRM field
 - Interface mode (two data pins or single data pin) and data pins assignment, both programmable with the IS and DPE bits. (The SPI_m modules are in slave mode after reset and must be properly configured for the modules to act in master mode.)

- SPI word length, programmable with the WL bit
- mcsnim_csx polarity, programmable with the EPOL bit
- mcsnim_clk polarity, programmable with the POL bit
- mcsnim_clk phase, programmable with the PHA bit

The mcsnim_clk frequency of a transfer is controlled by the external SPI master connected to the MCSPI slave device. The SPIm.MCSPI_CHxCONF[5:2] CLKD bit field (where x = 0) is not used in slave mode.

NOTE: The configuration of the channel can be loaded in the SPIm.MCSPI_CHxCONF register (where x = 0) only when the channel is disabled.

- Two DMA request events, read and write, synchronize read/write accesses of the DMA controller with the activity of MCSPI. DMA requests are asserted using the SPIm.MCSPI_CHxCONF[15] DMAR bit (where x = 0) for reading and the SPIm.MCSPI_CHxCONF[14] DMAW bit (where x = 0) for writing.
- Four interrupt events (see [Section 24.4.4.5.2, Interrupt Events in Slave Mode](#))

24.4.4.3.2 Slave Transmit-and-Receive Mode

The slave receive mode is programmable (set the SPIm.MCSPI_CHxCONF[13:12] TRM bit field [where x = 0] to 0x0).

In slave transmit-and-receive mode, the MCSPI_TXx register must be loaded before MCSPI is selected by an external SPI master device.

After a channel is enabled, transmission and reception proceed with interrupt and DMA request events.

The MCSPI_TXx register content is always loaded in the shift register whether it is updated or not. The event TXx_UNDERFLOW is activated accordingly and does not prevent transmission.

When an SPI word transfer completes (the SPIm.MCSPI_CHxSTAT0[2] EOT bit [where x = 0] set to 1), the received data is transferred to the channel receive register.

To use MCSPI as a slave transmit-only device, the RXx_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled due to the MCSPI_RXx register state (see [Section 24.4.4.5.2, Interrupt Events in Slave Mode](#)).

24.4.4.3.3 Slave Transmit-Only Mode

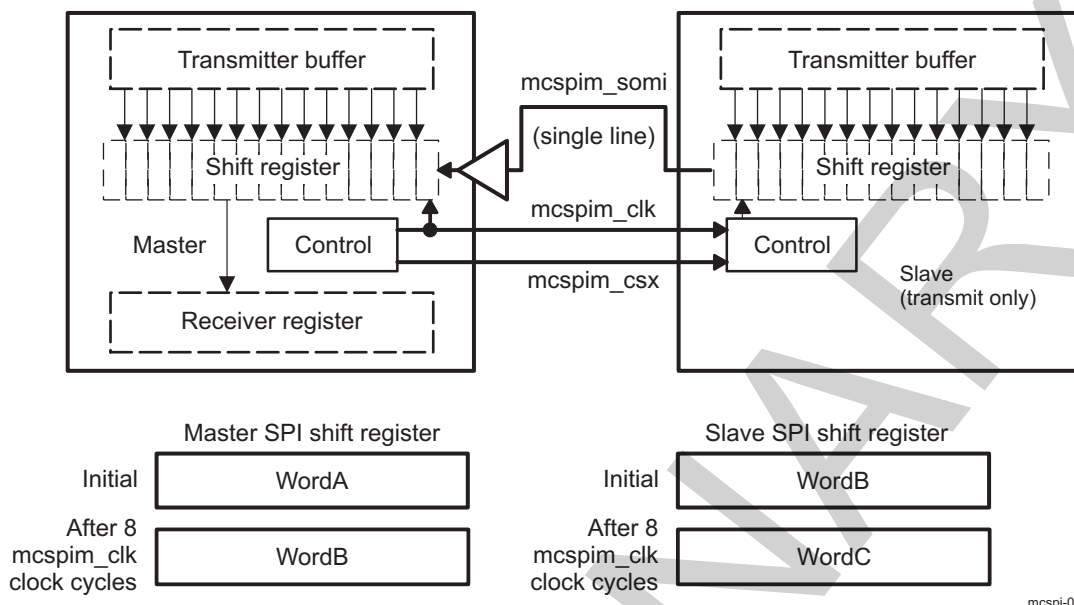

The slave transmit-only mode is programmable (set the SPIm.MCSPI_CHxCONF[13:12] TRM bit field [where x = 0] to 0x2) and avoids the requirement for the MPU to read the MCSPI_RXx register (minimizing data movement) only when transmission is meaningful.

To use the MCSPI as a slave transmit-only device, the RXx_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled due to the MCSPI_RXx register state.

When the SPI word transfer completes, the SPIm.MCSPI_CHxSTAT[2] EOT bit is set (where x = 0).

[Figure 24-104](#) shows a half-duplex system with a master device on the left and a transmit-only slave device on the right. Each time a bit transfers out from the slave device, 1 bit transfers in the master. After eight cycles of the serial clock mcsnim_clk, WordB transfers from the slave to the master.

Figure 24-104. SPI Half-Duplex Transmission (Transmit-Only Slave)

24.4.4.3.4 Slave Receive-Only Mode

The slave receive mode is programmable (set the SPI_m.MCSPI_CHxCONF[13:12] TRM bit field [where x = 0] to 0x1).

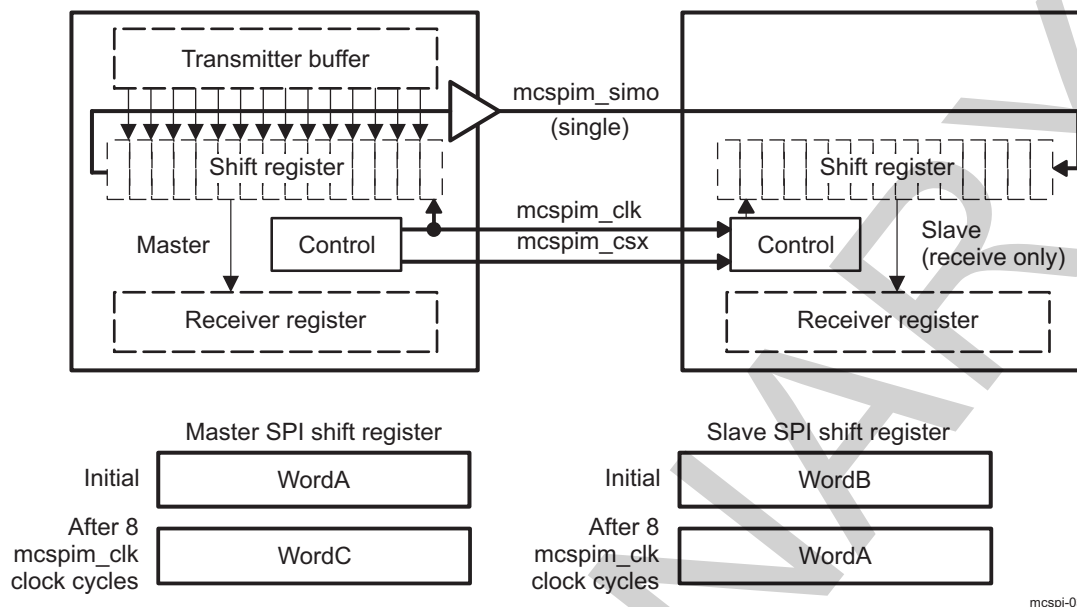

In receive-only mode, the MCSPI_Tx_x register must be loaded before the MCSPI is selected by an external SPI master device. The MCSPI_Tx_x register content is always loaded into the shift register whether it is updated or not. The TX_x_UNDERFLOW event is activated accordingly and does not prevent transmission.

When an SPI word transfer completes (the SPI_m.MCSPI_CHxSTAT0[2] EOT bit [where x = 0] is set to 1), the received data is transferred to the channel receive register.

To use the MCSPI as a slave receive-only device, the TX_x_EMPTY and TX_x_UNDERFLOW interrupts and the DMA write requests must be disabled due to the MCSPI_Tx_x register state.

For a full-duplex transmission, the serial clock (mcs pim_clk) synchronizes shifting and sampling of the information on the single serial data line. For full duplex, two data lines are required. If mcs pim_clk synchronizes on a single serial data line, the data line should be half-duplex.

Figure 24-105 shows an example of a half-duplex system with a master device on the left and a receive-only slave device on the right. Each time a bit transfers out from the master, 1 bit transfers in from the slave. After eight cycles of the serial clock mcs pim_clk, Word A transfers from the master to the slave.

Figure 24-105. SPI Half-Duplex Transmission (Receive-Only Slave)

24.4.4.4 FIFO Buffer Management

The MCSPI controller has a built-in 64-byte buffer to unload the DMA or interrupt handler and improve data throughput.

This buffer can be used by only one channel at a time and is selected by setting the `SPI.MCSPI_CHxCONF[28] FFER` or `SPI.MCSPI_CHxCONF[27] FFEW` bits to 1. If several channels are selected and several FIFO enable bit fields are set to 1, the controller forces the buffer not to be used; the driver must set only one FIFO enable bit field.

The buffer can be used in the following modes:

- Master or slave mode
- Transmit-only, receive-only, or transmit-and-receive mode
- Single channel or turbo mode, or normal round-robin mode. In round-robin mode the buffer is used by only one channel.

Every word length (`SPI.MCSPI_CHxCONF[11:7] WL`) is supported.

In transmit-and-receive mode, the buffer can be used in transmit (see [Figure 24-106](#)) or receive (see [Figure 24-107](#)) directions, or in both directions. If only one direction is chosen in transmit-and-receive mode, the full buffer is used for this direction. In both directions, the buffer is split into two 32-byte buffers, one for each direction (see [Figure 24-108](#)).

Figure 24-106. Buffer Used in Transmit Direction Only

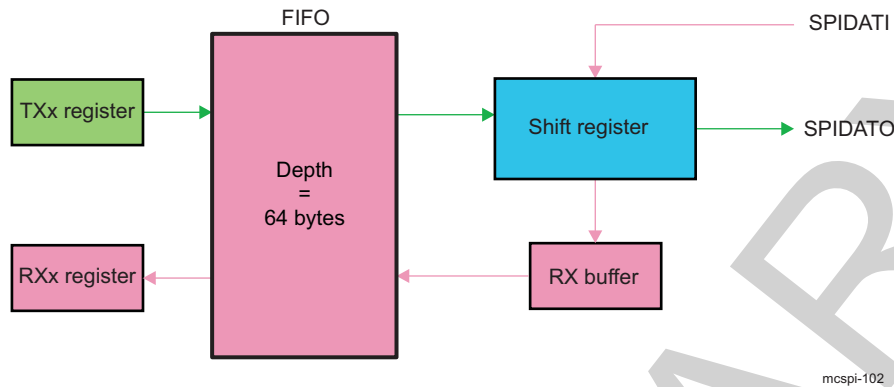

Figure 24-107. Buffer Used in Receive Direction Only

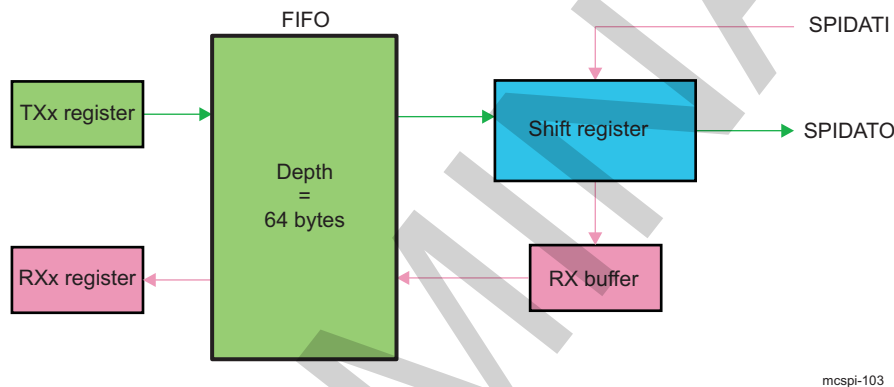

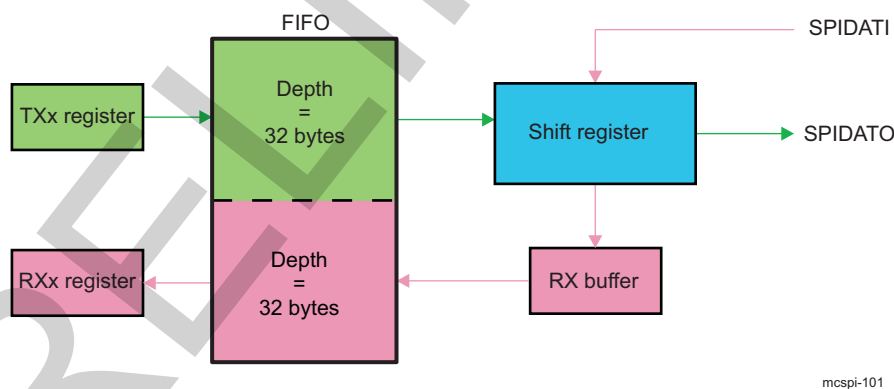

Figure 24-108. Buffer Used for Transmit and Receive Directions

Two levels (SPIm.MCSPI_XFERLEVEL[5:0] AEL and SPIm.MCSPI_XFERLEVEL[13:8] AFL) rule the buffer management. The granularity of these levels is 1 byte; it is not aligned with the SPI word length. The driver must set these values as a multiple of the SPI word length defined in WL. Table 24-273 shows the number of bytes written in the FIFO, depending on the word length.

Table 24-273. FIFO Writes, Word Length Relationship

| SPI Word Length WL | 3 ≤ WL ≤ 7 | 8 ≤ WL ≤ 15 | 16 ≤ WL ≤ 31 |
|-------------------------------------|------------|-------------|--------------|
| Number of bytes written in the FIFO | 1 byte | 2 bytes | 4 bytes |

The FIFO buffer pointers are reset when the corresponding channel is enabled or the FIFO configuration changes.

24.4.4.4.1 Buffer Almost Full

The [MCSPI_XFERLEVEL](#)[15:8] AFL bit field is needed when the buffer is used to receive an SPI word from a slave (the [MCSPI_CHxCONF](#)[28] FFER bit must be set to 1). It defines the almost-full buffer status. See [Figure 24-109](#).

When the FIFO pointer reaches this level, an interrupt or a DMA request is sent to the MPU to enable the system to read AFL + 1 bytes from the receive register.

NOTE: AFL + 1 must correspond to a multiple value of the [MCSPI_CHxCONF](#)[11:7] WL bit field.

When DMA is used, the request is deasserted after the first receive register read.

No new request will be asserted again as long as the system has not performed the right number of read accesses.

Figure 24-109. Buffer Almost Full Level (AFL)

NOTE: The [MCSPI_IRQSTATUS](#) register bits are not available in DMA mode. In DMA mode, the SPI_{IM}_DMA_RXx request is asserted on the same conditions as the [MCSPI_IRQSTATUS](#) Rx_x_FULL flag.

24.4.4.4.2 Buffer Almost Empty

The [MCSPI_XFERLEVEL](#)[7:0] AEL bit field is needed when the buffer is used to transmit an SPI word to a slave (the [MCSPI_CHxCONF](#)[27] FFEW bit must be set to 1). It defines the almost-empty buffer status. See [Figure 24-110](#).

When the FIFO pointer has not reached this level, an interrupt or a DMA request is sent to the MPU to enable the system to write AEL + 1 bytes to the transmit register.

NOTE: AEL + 1 must correspond to a multiple value of the [MCSPI_CHxCONF](#)[11:7] WL bit field.

When DMA is used, the request is deasserted after the first transmit register write.

No new request will be asserted again as long as the system has not performed the right number of write accesses.

Figure 24-110. Buffer Almost Empty Level (AEL)

NOTE: The [MCSPi_IRQSTATUS](#) register bits are not available in DMA mode. In DMA mode, the [SPIm_DMA_TXx](#) request is asserted on the same conditions as the [MCSPi_IRQSTATUS TXx_EMPTY](#) flag.

24.4.4.4.3 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user must previously configure in the [MCSPi_XFERLEVEL](#) register the AEL and AFL levels and especially the [MCSPi_XFERLEVEL\[31:16\]](#) WCNT bit field to define the number of SPI words to be transferred using the FIFO before enabling the channel.

This counter allows the controller to stop the transfer correctly after a defined number of SPI word transfers. If WCNT is set to 0x0000, the counter is not used and the user must stop the transfer manually by disabling the channel; in this case, the user does not know how many SPI transfers have been done. For received words, software must poll the [CHxSTAT\[5\]](#) RXFFE bit and read the [MCSPi_RXx](#) receive register to empty the FIFO buffer.

When the end-of-word count interrupt is generated (the [MCSPi_IRQSTATUS\[17\]](#) EOW bit is set), the user can disable the channel and poll the [MCSPi_CHxSTAT\[5\]](#) RXFFE bit to know it lasts SPI words in the FIFO buffer and read them.

No new request is asserted as long as the system has not performed the correct number of write accesses.

24.4.4.5 Interrupts

Each channel can issue interrupt events.

Each interrupt event has status bits in the [SPIm.MCSPi_IRQSTATUS](#) register ([RXx_FULL](#), [TXx_UNDERFLOW](#), [TXx_EMPTY](#), ...) (where x = 0, 3) that indicate whether service is required. Each status bit has an interrupt enable bit (a mask) in the [SPIm.MCSPi_IRQENABLE](#) register ([RXx_FULL_ENABLE](#), [TXx_UNDERFLOW_ENABLE](#), [TXx_EMPTY_ENABLE](#), ...).

When an interrupt occurs and a mask is later applied on it, the interrupt line is not asserted again, even if the interrupt source is not serviced.

The MCSPi supports interrupt-driven and polling operations.

24.4.4.5.1 Interrupt Events in Master Mode

In master mode, the interrupt events related to the [MCSPi_TXx](#) register state are [TXx_EMPTY](#) and [TXx_UNDERFLOW](#). The interrupt event related to the [MCSPi_RXx](#) register state is [RXx_FULL](#).

24.4.4.5.1.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its MCSPI_TXx register is empty (transient event). Enabling a channel automatically triggers this event, except in master receive-only mode (see [Section 24.4.4.2.4, Master Receive-Only Mode](#)). When the FIFO buffer is enabled (the MCSPI_CHxCONF[27] FFEW bit is set to 1), the MCSPI_IRQSTATUS TXx_EMPTY bit is set as soon as there is enough space in the buffer to write a number of bytes defined by the MCSPI_XFERLEVEL[5:0] AEL bit field.

The MCSPI_TXx register must be loaded with data to remove the source of the interrupt; the SPI.MCSPI_IRQSTATUS TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event will be asserted as soon as the MPU has not performed the number of writes into the MCSPI_TXx register defined by the MCSPI_XFERLEVEL[5:0] AEL bit field. The MPU must perform the right number of writes.

24.4.4.5.1.2 TXx_UNDERFLOW

The event TXx_UNDERFLOW is activated when the channel is enabled and if the MCSPI_TXx register or the FIFO is empty (not updated with new data) when an external master device starts a data transfer with the MCSPI (transmit and receive).

The TXx_UNDERFLOW is a harmless warning in master mode.

To avoid having a TXx_UNDERFLOW event at the beginning of a transmission, the event TXx_UNDERFLOW is not activated when no data has been loaded into the MCSPI_TXx register, because the channel has been enabled. To avoid having a TXx_UNDERFLOW event, the MCSPI_TXx register must seldom be loaded.

The SPI.MCSPI_IRQSTATUS TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if event enabled as the interrupt source).

24.4.4.5.1.3 RXx_FULL

The RXx_FULL event is activated when channel is enabled and MCSPI_RXx register becomes filled (transient event). When the FIFO buffer is enabled (the MCSPI_CHxCONF[28] FFER bit is set to 1), RXx_FULL is asserted as soon as the number of bytes holds in the FIFO to be read reaches the MCSPI_XFERLEVEL[13:8] AFL threshold.

The MCSPI_RXx register must be read to remove the source of the interrupt; the MCSPI_IRQSTATUS RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event will be asserted as soon as the MPU has not performed AFL + 1 reads into MCSPI_RXx. The MPU must perform the right number of reads.

24.4.4.5.1.4 End Of Word Count

The MCSPI_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the MCSPI_XFERLEVEL[31:16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the SPI transfer is halted on the channel using the FIFO buffer as soon as MCSPI_XFERLEVEL[31:16] WCNT is not reloaded and the channel is not re-enabled.

The MCSPI_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event enabled as interrupt source).

24.4.4.5.2 Interrupt Events in Slave Mode

In slave mode, the interrupt events related to the [MCSPI_TXx](#) register state are TXx_EMPTY and TXx_UNDERFLOW. The interrupt events related to the [MCSPI_RXx](#) register state are RXx_FULL and RX0_OVERFLOW (channels 1, 2, and 3 do not have a receiver overflow status bit). See the [MCSPI_IRQSTATUS](#) register.

24.4.4.5.2.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its [MCSPI_TXx](#) register is empty. Enabling the channel automatically raises this event. If the FIFO buffer is enabled (the [MCSPI_CHxCONF](#)[27] FFEW bit is set to 1), the TXx_EMPTY event will be asserted as soon as there is enough space in buffer to write a number of bytes defined by the [MCSPI_XFERLEVEL](#)[5:0] AEL bit field.

The [MCSPI_TXx](#) register must be loaded with data to remove the source of the interrupt; the SPIm.[MCSPI_IRQSTATUS](#) TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event will be asserted as soon as the MPU has not performed the number of write into the [MCSPI_TXx](#) register defined by [MCSPI_XFERLEVEL](#)[5:0] AEL bit field. The MPU must perform the right number of writes.

24.4.4.5.2.2 TXx_UNDERFLOW

The TXx_UNDERFLOW event is activated when a channel is enabled and if the [MCSPI_TXx](#) register is empty (not updated with new data) when an external master device starts a data transfer with the MCSPI (transmit and receive).

When FIFO is enabled, the data emitted while the underflow event is raised is not the last data written in the FIFO but the next data in the FIFO (an old transmitted value or a dummy data in the FIFO has been reset).

TXx_UNDERFLOW indicates an error (data loss) in slave mode.

To avoid having a TXx_UNDERFLOW event at the beginning of a transmission, the TXx_UNDERFLOW event is not activated when no data has been loaded into the [MCSPI_TXx](#) register because the channel is enabled.

The SPIm.[MCSPI_IRQSTATUS](#) TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

24.4.4.5.2.3 RXx_FULL

The RXx_FULL event is activated when a channel is enabled and the [MCSPI_RXx](#) register is being filled (transient event). When the FIFO buffer is enabled (the [MCSPI_CHxCONF](#)[28] FFER bit is set to 1), RXx_FULL is asserted as soon as the number of bytes holds in the buffer to read defined by the [MCSPI_XFERLEVEL](#)[13:8] AFL bit field.

The [MCSPI_RXx](#) register must be read to remove the source of the interrupt; the SPIm.[MCSPI_IRQSTATUS](#) RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event will be asserted as soon as the MPU has not performed AFL + 1 reads into [MCSPI_RXx](#). The MPU must perform the correct number of reads.

24.4.4.5.2.4 RX0_OVERFLOW

The RX0_OVERFLOW event is activated in slave mode in either transmit-and-receive or receive-only mode, when a channel is enabled and the [MCSPI_RXx](#) register or FIFO is full when a new SPI word is received. The [MCSPI_RXx](#) register is always overwritten with the new SPI word. If the FIFO is enabled data within the FIFO are overwritten, it must be considered as corrupted. The RX0_OVERFLOW event should not appear in slave mode using the FIFO.

The RX0_OVERFLOW event indicates an error (data loss) in slave mode.

The [MCSPI_IRQSTATUS](#)[3] `RX0_OVERFLOW` interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

24.4.4.5.2.5 End Of Word Count

The [MCSPI_IRQSTATUS](#)[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfer defined in the [MCSPI_XFERLEVEL](#)[31:16] `WCNT` bit field. If `WCNT` is set to `0x0000`, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the SPI transfer is halted on the channel using the FIFO buffer as soon as `WCNT` is not reloaded and the channel re-enabled.

The [MCSPI_IRQSTATUS](#)[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if event enable as interrupt source).

24.4.4.5.3 Interrupt-Driven Operation

An interrupt enable bit in the SPIm.[MCSPI_IRQENABLE](#) register can be set to enable each event to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the MPU must:

1. Read the SPIm.[MCSPI_IRQSTATUS](#) register to identify which event occurred.
2. Read the [MCSPI_RXx](#) register that corresponds to the event to remove the source of an `RXx_FULL` event or write into the [MCSPI_TXx](#) register that corresponds to the event to remove the source of a `TXx_EMPTY` event. No action is required to remove the source of the `WKS` (wake-up), `TXx_UNDERFLOW`, and `RX0_OVERFLOW` events.
3. Set the corresponding bit of the SPIm.[MCSPI_IRQSTATUS](#) register to 1 to clear an interrupt status and then release the interrupt line.

The interrupt status bit must always be reset after channel enabling and before events are enabled as interrupt sources.

24.4.4.5.4 Polling

When the interrupt capability of an event is disabled in the SPIm.[MCSPI_IRQENABLE](#) register, the interrupt line is not asserted, but the status bits in the SPIm.[MCSPI_IRQSTATUS](#) register can be polled by software to detect when the corresponding event occurs.

Once the expected event occurs:

- `RXx_FULL`: To remove the source of the event, the MPU must read the corresponding [MCSPI_RXx](#) register.
- `TXx_EMPTY`: To remove the source of the event, the MPU must write into the corresponding [MCSPI_TXx](#) register.
- `WKS` (wake-up), `TXx_UNDERFLOW`, and `RX0_OVERFLOW`: No action is required to remove the source of the event.

To clear an interrupt, set the corresponding status bit of the SPIm.[MCSPI_IRQSTATUS](#) register to 1. This does not affect the interrupt line state.

24.4.4.6 DMA Requests

The sDMA controller module manages DMA accesses. The sDMA controller advantage is to reduce the MPU charge for data transfers.

Each MCSPI channel, if enabled, can issue DMA requests. There are two DMA request lines per MCSPI channel (one for read and one for write).

The DMA read request line is asserted when the MCSPI channel is enabled and new data is available in the receive register of the MCSPI channel. A DMA read request can be individually masked with the SPI1.MCSPI_CHxCONF[15] DMAR bit. The DMA read request line is deasserted when reading of the MCSPI_RXx register of the MCSPI channel is complete.

The DMA write request line is asserted when the MCSPI channel is enabled and the MCSPI_TXx register of the MCSPI channel is empty. A DMA write request can be individually masked with the SPI1.MCSPI_CHxCONF[14] DMAW bit. The DMA write request line is deasserted when loading of the MCSPI_TXx register of the channel is complete.

24.4.4.7 Power Saving Management

Power consumption can be optimized by switching off internal clocks (interface and functional clock) when there is no activity. The MCSPI is compliant with the idle and wake-up system handshake protocol.

24.4.4.7.1 Normal Mode

In normal mode, internal SPI module clocks are automatically switched off (autogated) when there is no activity in slave or master mode.

Autogating of the module interface clock and functional clock occurs when the following conditions are met:

- The SPI1.MCSPI_SYSCONFIG[0] AUTOIDLE bit is set.
- In master mode, there is no data to transmit or receive in all channels.
- In slave mode, the MCSPI is not selected by the external master and there are no register accesses.

Autogating of the module interface clock and functional clock stops when the following conditions are met:

- In master mode, an internal access occurs.
- In slave mode, an internal access occurs or the MCSPI is selected by the external master.

24.4.4.7.2 Idle Mode

At the PRCM module level, when all conditions are met to shut off the CORE_48M_FCLK or CORE_L4_ICLK output clocks (for details, see [Chapter 3, Power, Reset, and Clock Management](#)), the PRCM module automatically launches a hardware handshake protocol to ensure that the MCSPI is ready to have its clocks switched off. Namely, the PRCM module asserts an idle request to the MCSPI.

Although this handshake is completely hardware-oriented and out of software control, the method in which the MCSPI module acknowledges the PRCM idle request is configurable through the MCSPI.SYSCONFIG[4:3] SIDLEMODE bit field.

The settings of the SIDLEMODE bit field and the related acknowledgment modes are:

- Force-idle mode (the SPI1.MCSPI_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0): The MCSPI module acknowledges unconditionally the idle request from the PRCM module, regardless of its internal operations. This mode must be used carefully in this case because it does not prevent the loss of data when the clock is switched off.
- No-idle mode (the SIDLEMODE bit is set to 0x1): The MCSPI never acknowledges an idle request from the PRCM module and is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient to save power because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
- Smart-idle mode (the SIDLEMODE bit is set to 0x2): The MCSPI acknowledges the idle request, basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for efficient system power management.

When configured in smart-idle mode, the MCSPI also offers an additional granularity on the CORE_48M_FCLK and CORE_L4_ICLK gating. The SPI1.SYSCONFIG[9:8] CLOCKACTIVITY bit field determines which clock shuts down (the CORE_48M_FCLK, CORE_L4_ICLK, neither clock, or both clocks).

The CLOCKACTIVITY setting is used internally to the MCSPI to determine on which part of the module the conditions to acknowledge the PRCM idle request are tested. For example, if CORE_48M_FCLK is not shut down on a PRCM idle request, the MCSPI considers only CORE_L4_ICLK and the associated pending activities before acknowledging the request.

Some MCSPI features are associated with CORE_L4_ICLK and others with CORE_48M_FCLK. Using the CLOCKACTIVITY bit field with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if the MCSPI acknowledges an idle request.

The CLOCKACTIVITY settings and the associated features are:

- CLOCKACTIVITY set to 00: ICLK off and FCLK off, ICLK and FCLK are considered for generating the acknowledge. This setting also means that FCLK and ICLK are likely to be shut down on a PRCM idle request.
- CLOCKACTIVITY set to 01: ICLK on and FCLK off, ICLK is not shut down on a PRCM idle request; only FCLK is concerned.
- CLOCKACTIVITY set to 10: ICLK off and FCLK on, FCLK is not shut down on a PRCM idle request; only ICLK is concerned.
- CLOCKACTIVITY set to 11: ICLK on and FCLK on, none of the clocks are shut down. This means the MCSPI can potentially acknowledge the idle request without checking the internal functions linked to its clocks.

CAUTION

The PRCM module does not have a hardware means of reading the CLOCKACTIVITY settings. Therefore, software must ensure consistent programming between CLOCKACTIVITY and the CORE_48M_FCLK and CORE_L4_ICLK control bits in the PRCM module. If the MCSPI is disabled in the CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its idle request, which is acknowledged regardless of the features associated with the MCSPI clocks. This can lead to unpredictable behavior.

24.4.4.7.2.1 Wake-Up Event in Smart-Idle Mode

The module wake-up feature is enabled when the SPIm.MCSPI_SYSCONFIG[2] ENAWAKEUP and SPIm.MCSPI_WAKEUPENABLE[0] WKEN bits are set. Wake-up capability is relevant only when the module is configured in slave mode.

The module generates an asynchronous wakeup request to the system power manager to switch back the interface clock and the functional clock. A wake-up is requested when channel 0 is enabled and an asynchronous selection occurs on the mcs pim.csx port associated with channel 0 (see the definition for the SPIm.MCSPI_CHxCONF[22:21] SPIENSLV bit field [where x = 0] in the register description table).

After the McSPI wake-up request, the system power manager must reactivate the interface clock:

- Before the beginning of the second SPI word serialization when the McSPI is in slave transmit-only mode or in slave transmit-and-receive mode
- Before the end of the second received SPI word in slave receive-only mode. To avoid data loss, the first received SPI word must be read from the SPIm.MCSPI_RXx register (where x = 0) before the completion of the second SPI word serialization.

Table 24-274 lists the supported cases in wake-up mode.

Table 24-274. Smart-Idle Mode and Wake-Up Capabilities

| Mode | Interface Clock | SPI Clock Ref | Functionality | Wake-Up Event |
|--------|--------------------|--------------------|---|------------------|
| Master | Must be maintained | Must be maintained | Full functionality, but the module does not generate a new interrupt or DMA request until the system exits wake-up mode | No wake-up event |

Table 24-274. Smart-Idle Mode and Wake-Up Capabilities (continued)

| Mode | Interface Clock | SPI Clock Ref | Functionality | Wake-Up Event |
|-------|---------------------|---------------------|--|---|
| Slave | Can be switched off | Can be switched off | An SPI word can be transmitted and/or received, but the module does not generate any new interrupts or DMA requests until the system exits wake-up mode. | The module asynchronously sends a wake-up request if an event on the mcsxim_csx port associated with channel 0 is detected. |

In wake-up mode, the interrupt and DMA request lines are no longer asserted.

Any access to the module in wake-up mode generates an error as long as the interface clock is alive.

24.4.4.7.2.2 Transitions From Smart-Idle Mode to Normal Mode

The MCSPI detects the end of the wake period through the idle and wake-up hardware handshake protocol.

The interrupt status register (the SPI.MCSPI_IRQSTATUS[16] WKS bit) is updated with the event causing the wakeup; the wake-up event at the origin of the transition to the normal mode is converted to its corresponding interrupt when enabled by the SPI.MCSPI_IRQENABLE[16] WKE bit or the DMA request.

Interrupts and wake-up events have independent enable and disable controls, accessible through the SPI.MCSPI_IRQENABLE and SPI.MCSPI_WAKEUPENABLE registers. Software must ensure the overall consistency.

The interrupt status register SPI.MCSPI_IRQSTATUS is updated with the event causing the wake-up; the wake-up event at the origin of the transition to normal mode is converted to its corresponding interrupt request or DMA request. The module is fully operational.

24.4.4.7.2.3 Force-Idle Mode

Force-idle mode is enabled and exited as follows:

- Force-idle mode is enabled when the SPI.MCSPI_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0.
 - In force-idle mode, the MCSPI responds unconditionally to the idle request by deasserting unconditionally the interrupt and DMA request lines, if asserted. In addition, the wake-up capability is totally inhibited even if the SPI.MCSPI_SYSCONFIG[2] ENAWAKEUP and SPI.MCSPI_WAKEUPENABLE[0] WKEN bits are set.
 - The transition from normal mode to idle mode does not affect the interrupt event bits of the SPI.MCSPI_IRQSTATUS register.
 - In force-idle mode, because the module must be disabled, the interrupt and DMA request lines are likely deasserted. The interface clock and SPI clock provided to the MCSPI can be switched off.
 - An idle request during an SPI data transfer can lead to an unexpected and unpredictable result. Software must avoid such a request.
- The module exits force-idle mode through the idle and wake-up hardware handshake protocol. The module is fully operational. The interrupt and DMA request lines are optionally asserted one clock cycle later.

24.4.5 MCSPI Programming Guide

24.4.5.1 MCSPI Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the MCSPI module.

24.4.5.1.1 Global Initialization

24.4.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the I²C module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the I²C. For further information, see the *I²C Module Integration* and *Environment* sections.

For more information, see [Section 24.4.3](#).

[Table 24-275](#) lists the information on the global initialization of the surrounding modules.

Table 24-275. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|---------------------|--|
| PRCM | MCSPI_FCLK functional clock must be enabled. See Section 3.1.1.1.2 , <i>Module Level Clock Management</i> , in Chapter 3 , <i>Power, Reset, and Clock Management</i> . |
| L4 Interconnect | For information about L4-PER interconnect configuration, see Section 14.3 , <i>L4 Interconnects</i> , in Chapter 14 , <i>Interconnect</i> . |
| sDMA | DMA configuration must be done to enable the module DMA channel requests. See Chapter 17 , <i>SDMA</i> . |
| MPU INTC | Cortex-A9 MPU, Cortex-M3 MPU, or DSP INTC must be configured to enable the interrupt request generation to the Cortex-A9 MPU or Cortex-M3 MPU, or in <i>INTC</i> , in Chapter 5 , <i>DSP Subsystem</i> . |

24.4.5.1.1.2 MCSPI Global Initialization

24.4.5.1.1.2.1 Main Sequence – MCSPI Global Initialization

This procedure initializes the MCSPI module after a POR or software reset.

Table 24-276. MCSPI Global Initialization

| Step | Register/Bit Field/Programming Model | Value |
|-------------------------------|--------------------------------------|-------|
| Perform a software reset. | SPIm.MCSPI_SYSCONFIG[1] SOFTRESET | 0x1 |
| Wait until reset is finished? | SPIm.MCSPI_SYSSTATUS[0] RESETDONE | =0x1 |

24.4.5.1.2 Operational Mode Configuration

24.4.5.1.2.1 MCSPI Operational Modes

The selection of the working mode is done with the SPIm.MCSPI_CHxCONF register. [Table 24-277](#) through [Table 24-279](#) list the possible operating modes and their configurations.

Table 24-277. MCSPI Receive Mode Initialization

| Step | Register/Bit Field/Programming Model | Value |
|---|--------------------------------------|-------|
| Set receive mode. | SPIm.MCSPI_CHxCONF[13:12] TRM | 0x1 |
| Set the word length. | SPIm.MCSPI_CHxCONF[11:7] WL | 0x8 |
| Clock initialization and channel enabling | SPIm.MCSPI_MODULCTRL[2] MS | 0x0 |
| | SPIm.MCSPI_CHxCTRL[0] EN | 0x1 |

Table 24-277. MCSPI Receive Mode Initialization (continued)

| Step | Register/Bit Field/Programming Model | Value |
|---|--------------------------------------|-------|
| Channels activated low during active state | SPIm.MCSPI_CHxCONF[6] EPOL | 0x1 |
| Clock held high during active state | SPIm.MCSPI_CHxCONF[1] POL | 0x0 |
| Data latched on odd-numbered edges of the SPI clock | SPIm.MCSPI_CHxCONF[0] PHA | 0x0 |
| Reset the status bits. | SPIm.MCSPI_IRQSTATUS | 0x0 |

Table 24-278. MCSPI Transmit Mode Initialization

| Step | Register/Bit Field/Programming Model | Value |
|---|--|------------|
| Set transmit mode. | SPIm.MCSPI_CHxCONF[13:12] TRM | 0x2 |
| Set the word length. | SPIm.MCSPI_CHxCONF[11:7] WL | 0x8 |
| Clock initialization and channel enabling | SPIm.MCSPI_MODULCTRL[2] MS SPIm.MCSPI_CHxCTRL[0] EN | 0x0 0x1 |
| Channels activated low during active state | SPIm.MCSPI_CHxCONF[6] EPOL | 0x1 |
| Clock held high during active state | SPIm.MCSPI_CHxCONF[1] POL | 0x0 |
| Data latched on odd-numbered edges of the SPI clock | SPIm.MCSPI_CHxCONF[0] PHA | 0x0 |
| Reset the status bits. | SPIm.MCSPI_IRQSTATUS | 0x0 |

Table 24-279. MCSPI Transmit-and-Receive Mode Initialization

| Step | Register/Bit Field/Programming Model | Value |
|---|--|------------|
| Set transmit and receive mode. | SPIm.MCSPI_CHxCONF[13:12] TRM | 0x0 |
| Set the word length. | SPIm.MCSPI_CHxCONF[11:7] WL | 0x8 |
| Clock initialization and channel enabling | SPIm.MCSPI_MODULCTRL[2] MS SPIm.MCSPI_CHxCTRL[0] EN | 0x0 0x1 |
| Channels activated low during active state | SPIm.MCSPI_CHxCONF[6] EPOL | 0x1 |
| Clock held high during active state | SPIm.MCSPI_CHxCONF[1] POL | 0x0 |
| Data latched on odd-numbered edges of the SPI clock | SPIm.MCSPI_CHxCONF[0] PHA | 0x0 |
| Reset the status bits. | SPIm.MCSPI_IRQSTATUS | 0x0 |

24.4.5.1.2.1.1 Common Transfer Procedures Without FIFO – Polling Method

24.4.5.1.2.1.1.1 Receive-Only Procedure – Polling Method

Table 24-280 lists the receive-only procedure using the polling method. The MCSPI is acting as slave.

Table 24-280. Receive-Only Procedure – Polling Method

| Step | Register/Bit Field/Programming Model | Value |
|---|--------------------------------------|-------|
| Configure the channel according to the mode | See Table 24-277. | |
| Start the channel. | SPIm.MCSPI_CHxCTRL[0] EN | 0x1 |
| Wait until receive register is full? | SPIm.MCSPI_RXx | =0x1 |
| Stop the channel. | SPIm.MCSPI_CHxCTRL[0] EN | 0x0 |

24.4.5.1.2.1.1.2 Receive-Only Procedure – Interrupt Method

Table 24-281 lists the receive-only procedure using the interrupt method. The MCSPI is acting as slave.

Table 24-281. Receive-Only Procedure – Interrupt Method

| Step | Register/Bit Field/Programming Model | Value |
|---|--|-------|
| Configure the channel according to the mode. | See Table 24-277 . | |
| Start the channel. | SPIm.MCSPI_CHxCTRL[0] EN | 0x1 |
| Enable the interrupt for the receiver register. | SPIm.MCSPI_IRQENABLE[2] RX_FULL_ENABLE | 0x1 |
| Read the status register. | SPIm.MCSPI_IRQSTATUS[2] RX_FULL | 0x0 |
| Disable the interrupt. | SPIm.MCSPI_IRQENABLE[2] RX_FULL_ENABLE | 0x0 |
| Stop the channel. | SPIm.MCSPI_CHxCTRL[0] EN | 0x0 |
| Read the receiver register. | SPIm.MCSPI_RXx | xxxx |

24.4.5.1.2.1.1.3 Transmit-Only Procedure – Polling Method

[Table 24-282](#) lists the transmit-only procedure using the polling method. The MCSPI is acting as master.

Table 24-282. Transmit-Only Procedure – Polling Method

| Step | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|-------|
| Configure the channel according to the mode. | See Table 24-278 | |
| Start the channel. | SPIm.MCSPI_CHxCTRL[0] EN | 0x1 |
| Wait until end of transfer? | SPIm.MCSPI_CHxSTAT[2:1] | =0x2 |
| Stop the channel. | SPIm.MCSPI_CHxCTRL[0] EN | 0x0 |

24.4.5.1.2.1.1.4 Transmit-and-Receive Procedure – Polling Method

[Table 24-282](#) lists the transmit-and-receive procedure using the polling method. The MCSPI is acting as master and slave.

Table 24-283. Transmit-and-Receive Procedure – Polling Method

| Step | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|-------|
| Configure the channel according to the mode. | See Table 24-279 . | |
| Start the channel. | SPIm.MCSPI_CHxCTRL[0] EN | 0x1 |
| Wait until transmit/receive word? | SPIm.MCSPI_CHxSTAT[2:0] | =0x3 |
| Stop the channel. | SPIm.MCSPI_CHxCTRL[0] EN | 0x0 |

24.4.5.1.3 Common Transfer Procedures With FIFO – Polling Method

When using FIFO the MCSPI module can start the transfer only after the first write request is released by writing the [MCSPI_TXx](#) register. The first write request can be managed by the IRQ routine or DMA handler. The end of transfer is more complex and depends on the transfer type. See [Table 24-282](#) through [Table 24-289](#).

24.4.5.1.3.1 Receive-Only Procedure With Word Count – Polling Method

Table 24-284. Receive-Only Procedure With Word Count – Polling Method

| Step | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|-------|
| Configure the channel according to the mode. | See Table 24-277 . | |
| Start the channel. | SPIm.MCSPI_CHxCTRL[0] EN | 0x1 |
| Wait until end of word count? | SPIm.MCSPI_IRQSTATUS[17] EOW | =0x1 |
| Stop the channel. | SPIm.MCSPI_CHxCTRL[0] EN | 0x0 |
| Read from the receiver register. | SPIm.MCSPI_RXx | xxxx |

24.4.5.1.3.2 Transmit-Only Procedure With and Without Word Count – Polling Method

Table 24-285. Transmit-Only Procedure Without Word Count – Polling Method

| Step | Register/Bit Field/Programming Model | Value |
|--|--|--------------|
| Configure the channel according to the mode. | See Table 24-278 . | |
| Start the channel. | SPIm.MCSPI_CHxCTRL[0] EN | 0x1 |
| Wait until end of word count? | SPIm.MCSPI_IRQSTATUS[17] EOW | =0x1 |
| Wait until end of transfer? | SPIm.MCSPI_CHxSTAT[2] EOT SPIm.MCSPI_CHxSTAT[3] TXFFE | =0x1 =0x1 |
| Stop the channel. | SPIm.MCSPI_CHxCTRL[0] EN | 0x0 |

24.4.5.1.3.3 Transmit-Only Procedure With and Without Word Count – Interrupt Method

Table 24-286. Transmit-Only Procedure With Word Count – Interrupt Method

| Step | Register/Bit Field/Programming Model | Value |
|--|--|--------------|
| Configure the channel according to the mode. | See Table 24-278 . | |
| Start the channel. | SPIm.MCSPI_CHxCTRL[0] EN | 0x1 |
| Enable the interrupt for the transmit register. | SPIm.MCSPI_IRQENABLE[4] TX_EMPTY_ENABLE | 0x1 |
| End of word count. | SPIm.MCSPI_IRQSTATUS[17] EOW | =0x1 |
| End of transfer | SPIm.MCSPI_CHxSTAT[2] EOT SPIm.MCSPI_CHxSTAT[3] TXFFE | =0x1 =0x1 |
| Clear the interrupt. | SPIm.MCSPI_IRQENABLE[17] EOW_ENABLE | =0x0 |
| Disable the interrupt for the transmit register. | SPIm.MCSPI_IRQENABLE[4] TX_EMPTY_ENABLE | 0x0 |
| Stop the channel. | SPIm.MCSPI_CHxCTRL[0] EN | 0x0 |

24.4.5.1.3.4 Transmit-and-Receive Procedure With Word Count – Polling Method

Table 24-287. Transmit-and-Receive Procedure With Word Count – Polling Method

| Step | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|-------|
| Configure the channel according to the mode. | See Table 24-279 . | |
| Start the channel. | SPIm.MCSPI_CHxCTRL[0] EN | 0x1 |
| Wait until end of word count? | SPIm.MCSPI_IRQSTATUS[17] EOW | =0x1 |
| Stop the channel. | SPIm.MCSPI_CHxCTRL[0] EN | 0x0 |
| Read from the receiver register. | SPIm.MCSPI_RXx | xxxx |

24.4.5.1.3.5 Transmit-and-Receive Procedure with Word Count – Interrupt Method

Table 24-288. Transmit-and-Receive Procedure With Word Count – Interrupt Method

| Step | Register/Bit Field/Programming Model | Value |
|---|--|-------|
| Configure the channel according to the mode. | See Table 24-279 . | |
| Start the channel. | SPIm.MCSPI_CHxCTRL[0] EN | 0x1 |
| Enable the interrupt for the receiver register. | SPIm.MCSPI_IRQENABLE[2] RX_FULL_ENABLE | 0x1 |
| Enable the interrupt for the transmit register. | SPIm.MCSPI_IRQENABLE[4] TX_EMPTY_ENABLE | 0x1 |
| End of word count? | SPIm.MCSPI_IRQSTATUS[17] EOW | =0x1 |
| Clear the interrupt. | SPIm.MCSPI_IRQENABLE[17] EOW_ENABLE | =0x0 |

Table 24-288. Transmit-and-Receive Procedure With Word Count – Interrupt Method (continued)

| Step | Register/Bit Field/Programming Model | Value |
|--|--|-------|
| Disable the interrupt for the receiver register. | SPIm.MCSPI_IRQENABLE[4] TX_EMPTY_ENABLE | 0x0 |
| Disable the interrupt for the transmit register. | SPIm.MCSPI_IRQENABLE[2] RX_FULL_ENABLE | 0x0 |
| Stop the channel. | SPIm.MCSPI_CHxCTRL[0] EN | 0x0 |
| Read from the receiver register. | SPIm.MCSPI_RXx | xxxx |

| Address Offset | 0x110 | | |
| Physical Address | See Table 24-291 | Instance | MCSPI1 MCSPI2 MCSPI3 MCSPI4 |
| Description | This register allows controlling various parameters of the OCP interface. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---------------|----|----------|----|-----------|----|-----------|---|-----------|---|----------|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | CLOCKACTIVITY | | RESERVED | | SIDLEMODE | | ENAWAKEUP | | SOFTRESET | | AUTOIDLE | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|---------------|--|------|----------|
| 31:10 | RESERVED | Reads returns 0 | RW | 0x000000 |
| 9:8 | CLOCKACTIVITY | Clocks activity during wake-up mode period 0x0: OCP and functional clocks may be switched off. 0x1: OCP clock is maintained. Functional clock may be switched off. 0x2: Functional clock is maintained. OCP clock may be switched off. 0x3: OCP and functional clocks are maintained. | RW | 0x0 |
| 7:5 | RESERVED | Reads returns 0 | RW | 0x0 |
| 4:3 | SIDLEMODE | Power management 0x0: If an idle request is detected, the McSPI acknowledges it unconditionally and goes in inactive mode. Interrupt, DMA requests and wake-up lines are unconditionally deasserted and the module wake-up capability is deactivated even if the MCSPI_SYSCONFIG[EnaWakeUp] bit is set. 0x1: If an idle request is detected, the request is ignored and the module does not switch to wake-up mode, and keeps on behaving normally. 0x2: If an idle request is detected, the module will switch to wake-up mode based on its internal activity, and the wake-up capability can be used if the bit MCSPI_SYSCONFIG[EnaWakeUp] is set. 0x3: Reserved - do not use. | RW | 0x2 |
| 2 | ENAWAKEUP | Wake-up feature control 0x0: Wake-up capability is disabled. 0x1: Wake-up capability is enabled. | RW | 1 |
| 1 | SOFTRESET | Software reset. During reads it always returns 0. 0x0: (write) Normal mode 0x1: (write) Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. | RW | 0 |
| 0 | AUTOIDLE | Internal OCP clock-gating strategy 0x0: OCP clock is free-running. 0x1: Automatic OCP clock gating strategy is applied, based on the OCP interface activity. | RW | 1 |

| 11 | SSB | Set status bit 0x0: No action. Writing 0 does not clear already set status bits. This bit must be cleared before trying to clear a status bit of the <MCSPI_IRQSTATUS> register. 0x1: Force to 1 all status bits of MCSPI_IRQSTATUS register. Writing 1 into this bit sets to 1 all status bits in the <MCSPI_IRQSTATUS> register. | RW | 0 |
| 10 | SPIENDIR | Set the direction of the SPIEN[3:0] lines and SPICLK line. 0x0: Output (as in master mode) 0x1: Input (as in slave mode) | RW | 0 |
| 9 | SPIDATDIR1 | Set the direction of the SPIDAT[1]. 0x0: Output 0x1: Input | RW | 0 |
| 8 | SPIDATDIR0 | Set the direction of the SPIDAT[0]. 0x0: Output 0x1: Input | RW | 0 |
| 7 | WAKD | SWAKEUP output (signal data value of internal signal to system). The signal is driven high or low according to the value written into this register bit. 0x0: The pin is driven low. 0x1: The pin is driven high. | RW | 0 |
| 6 | SPICLK | SPICLK line (signal data value) If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the CLKSPI line (high or low), and a write into this bit has no effect. If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the CLKSPI line is driven high or low according to the value written into this register. | RW | 0 |
| 5 | SPIDAT_1 | SPIDAT[1] line (signal data value) If MCSPI_SYST[SPIDATDIR1] = 0 (output mode direction), the SPIDAT[1] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIDATDIR1] = 1 (input mode direction), this bit returns the value on the SPIDAT[1] line (high or low), and a write into this bit has no effect. | RW | 0 |
| 4 | SPIDAT_0 | SPIDAT[0] line (signal data value) If MCSPI_SYST[SPIDATDIR0] = 0 (output mode direction), the SPIDAT[0] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIDATDIR0] = 1 (input mode direction), this bit returns the value on the SPIDAT[0] line (high or low), and a write into this bit has no effect. | RW | 0 |
| 3 | SPIEN_3 | SPIEN[3] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the SPIEN[3] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the SPIEN[3] line (high or low), and a write into this bit has no effect. | RW | 0 |
| 2 | SPIEN_2 | SPIEN[2] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the SPIEN[2] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the SPIEN[2] line (high or low), and a write into this bit has no effect. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 1 | SPIEN_1 | SPIEN[1] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the SPIEN[1] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the SPIEN[1] line (high or low), and a write into this bit has no effect. | RW | 0 |
| 0 | SPIEN_0 | SPIEN[0] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the SPIEN[0] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the SPIEN[0] line (high or low), and a write into this bit has no effect. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|----------|
| 31:9 | RESERVED | Reads returns 0. | RW | 0x000000 |
| 8 | FDA | FIFO DMA address 256-bit aligned This register is used when a FIFO is managed by the module and DMA connected to the controller provides only 256-bit aligned address. If this bit is set the enabled channel which uses the FIFO has its data managed through MCSPI_DAFTX and MCSPI_DAFRX registers instead of MCSPI_TX(i) and MCSPI_RX(i) registers. 0x0: FIFO data managed by MCSPI_TX(i) and MCSPI_RX(i) registers. 0x1: FIFO data managed by MCSPI_DAFTX and MCSPI_DAFRX registers. | RW | 0 |
| 7 | MOA | Multiple word OCP access: This register can only be used when a channel is enabled using a FIFO. It allows the system to perform multiple SPI word access for a single 32-bit OCP word access. This is possible for WL < 16. 0x0: Multiple word access disabled 0x1: Multiple word access enabled with FIFO | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|-------------|--|------|-------|
| 6:4 | INITDLY | Initial SPI delay for first transfer: This register is an option only available in SINGLE master mode. The controller waits for a delay to transmit the first SPI word after channel enabled and corresponding TX register filled. This delay is based on SPI output frequency clock. No clock output provided to the boundary and chip select is not active in 4-pin mode within this period. 0x0: No delay for first spi transfer. 0x1: The controller wait 4 SPI bus clock 0x2: The controller wait 8 SPI bus clock 0x3: The controller wait 16 SPI bus clock 0x4: The controller wait 32 SPI bus clock | RW | 0x0 |
| 3 | SYSTEM_TEST | Enables the system test mode 0x0: Functional mode 0x1: System test mode (SYSTEST) | RW | 0 |
| 2 | MS | Master/slave 0x0: Master - The module generates the SPICLK and SPIEN[3:0]. 0x1: Slave - The module receives the SPICLK and SPIEN[3:0]. | RW | 1 |
| 1 | PIN34 | Pin mode selection: This register is used to configure the SPI pin mode, in master or slave mode. If asserted the controller only use SIMO, SOMI, and SPICLK clock pin for SPI transfers. 0x0: SPIEN is used as a chip-select. 0x1: SPIEN is not used. In this mode all related options to chip-select have no meaning. | RW | 0 |
| 0 | SINGLE | Single channel/Multi Channel (master mode only) 0x0: More than one channel will be used in master mode. 0x1: Only one channel will be used in master mode. This bit must be set in Force SPIEN mode. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|-------|
| 31:30 | RESERVED | Read returns 0. | R | 0x0 |
| 29 | CLKG | Clock divider granularity This register defines the granularity of channel clock divider: power of 2 or one clock cycle granularity. When this bit is set the register MCSPI_CHCTRL[EXTCLK] must be configured to reach a maximum of 4096 clock divider ratio. Then the clock divider ratio is a concatenation of MCSPI_CHCONF[CLKD] and MCSPI_CHCTRL[EXTCLK] values 0x0: Clock granularity of power of 2 0x1: One clock cycle granularity | RW | 0 |
| 28 | FFER | FIFO enabled for receive: Only one channel can have this bit field set. 0x0: The buffer is not used to receive data. 0x1: The buffer is used to receive data. | RW | 0 |
| 27 | FFEW | FIFO enabled for transmit: Only one channel can have this bit field set. 0x0: The buffer is not used to transmit data. 0x1: The buffer is used to transmit data. | RW | 0 |
| 26:25 | TCS0 | Chip-select time control This 2-bit field defines the number of interface clock cycles between CS toggling and first or last edge of SPI clock. 0x0: 0.5 clock cycle 0x1: 1.5 clock cycles 0x2: 2.5 clock cycles 0x3: 3.5 clock cycles | RW | 0x0 |
| 24 | SBPOL | Start-bit polarity 0x0: Start-bit polarity is held to 0 during SPI transfer. 0x1: Start-bit polarity is held to 1 during SPI transfer. | RW | 0 |
| 23 | SBE | Start-bit enable for SPI transfer 0x0: Default SPI transfer length as specified by WL bit field 0x1: Start bit D/CX added before SPI transfer polarity is defined by MCSPI_CH0CONF[SBPOL] | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--|------|-------|
| 22:21 | SPIENSLV | Channel 0 only and slave mode only: SPI slave select signal detection. Reserved bits for other cases. 0x0: Detection enabled only on SPIEN[0] 0x1: Detection enabled only on SPIEN[1] 0x2: Detection enabled only on SPIEN[2] 0x3: Detection enabled only on SPIEN[3] | RW | 0x0 |
| 20 | FORCE | Manual SPIEN assertion to keep SPIEN active between SPI words (single channel master mode only). 0x0: Writing 0 into this bit drives low the SPIEN line when MCSPI_CHCONF(i)[EPOL]=0, and drives it high when MCSPI_CHCONF(i)[EPOL]=1. 0x1: Writing 1 into this bit drives high the SPIEN line when MCSPI_CHCONF(i)[EPOL]=0, and drives it low when MCSPI_CHCONF(i)[EPOL]=1. | RW | 0 |
| 19 | TURBO | Turbo mode 0x0: Turbo is deactivated (recommended for single SPI word transfer). 0x1: Turbo is activated to maximize the throughput for multiple SPI words transfer. | RW | 0 |
| 18 | IS | Input Select 0x0: Data line 0 (SPIDAT[0]) selected for reception 0x1: Data line 1 (SPIDAT[1]) selected for reception | RW | 1 |
| 17 | DPE1 | Transmission enable for data line 1 (SPIDATAGZEN[1]) 0x0: Data line 1 (SPIDAT[1]) selected for transmission 0x1: No transmission on Data Line1 (SPIDAT[1]) | RW | 1 |
| 16 | DPE0 | Transmission Enable for data line 0 (SPIDATAGZEN[0]) 0x0: Data Line0 (SPIDAT[0]) selected for transmission 0x1: No transmission on data line 0 (SPIDAT[0]) | RW | 0 |
| 15 | DMAR | DMA read request The DMA read request line is asserted when the channel is enabled and a new data is available in the receive register of the channel. The DMA read request line is deasserted on read completion of the receive register of the channel. 0x0: DMA read request disabled 0x1: DMA read request enabled | RW | 0 |
| 14 | DMAW | DMA write request. The DMA write request line is asserted when The channel is enabled and the transmitter register of the channel is empty. The DMA write request line is deasserted on load completion of the transmitter register of the channel. 0x0: DMA write request disabled 0x1: DMA write request enabled | RW | 0 |
| 13:12 | TRM | Transmit/receive modes 0x0: Transmit-and-receive mode 0x1: Receive-only mode 0x2: Transmit-only mode 0x3: Reserved | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-------|
| 5:2 | CLKD | <p>Frequency divider for SPICLK (only when the module is a Master SPI device). A programmable clock divider divides the SPI reference clock (CLKSPIREF) with a 4-bit value, and results in a new clock SPICLK available to shift-in and shift-out data. By default the clock divider ratio has a power of 2 granularity when MCSPI_CHCONF[CLKG] is cleared. Otherwise this register is the 4-LSB bit of a 12-bit register concatenated with clock divider extension MCSPI_CHCTRL[EXTCLK] register. The value description below defines the clock ratio when MCSPI_CHCONF[CLKG] is set to 0.</p> <p>0x0: 1 0x1: 2 0x2: 4 0x3: 8 0x4: 16 0x5: 32 0x6: 64 0x7: 128 0x8: 256 0x9: 512 0xA: 1024 0xB: 2048 0xC: 4096 0xD: 8192 0xE: 16384 0xF: 32768</p> | RW | 0x0 |

24.5 Multichannel Buffered Serial Port (McBSP)

This section introduces the multichannel buffered serial port (McBSP)

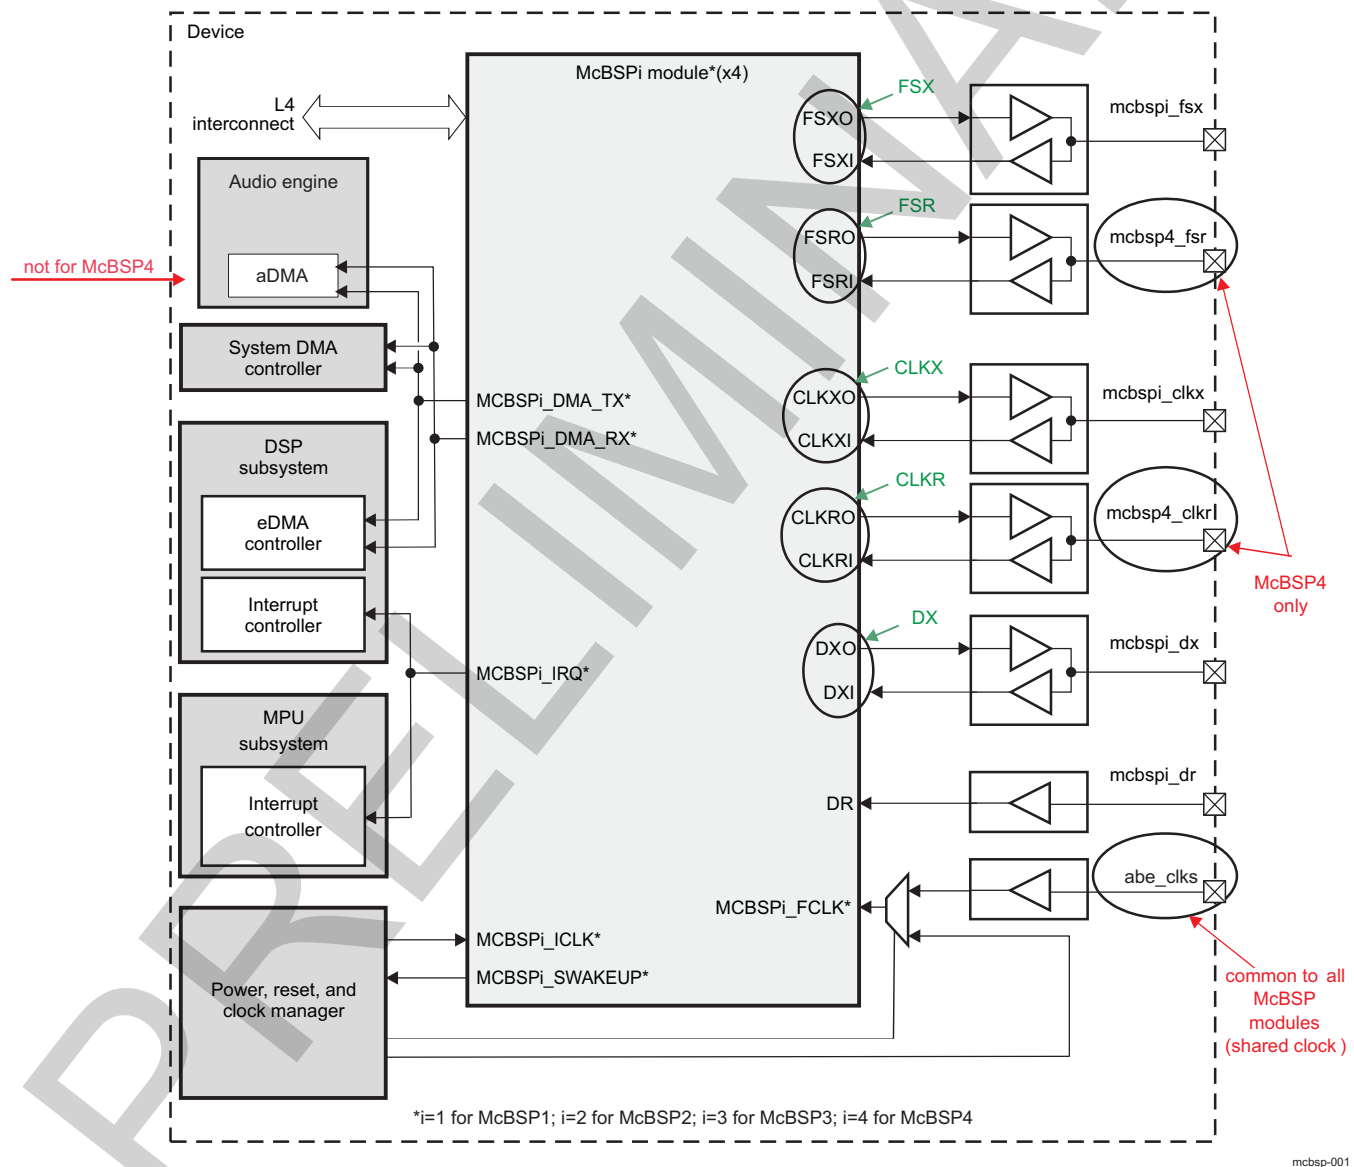

24.5.1 McBSP Overview

The McBSP provides a full-duplex direct serial interface between the device and other devices in a system such as other application devices (digital base band), audio and voice codec, etc. Because of its high level of versatility, it can accommodate a wide range of peripherals and clocked frame oriented protocols (for more information, see [Section 24.5.1.1, McBSP Features](#)).

The device provides four instances of the McBSP module.

[Figure 24-111](#) is an overview of the McBSP in the device.

Figure 24-111. McBSP Highlight

24.5.1.1 McBSP Features

The main features of the McBSP modules are:

- L4 interconnect slave interface supports:

- 32-bit data bus width
- 32-bit access supported
- 16-/8-bit access not supported
- 10-bit address bus width
- Burst mode not supported
- Write nonposted transaction mode supported
- 128 × 32-bit words (512 bytes) for each buffer for transmit/receive operations
- Transmit and receive direct memory access (DMA) requests triggered with programmable FIFO thresholds
- Serial interface description
 - 6-pin configuration (McBSP 4 only)
 - 4-pin configuration (McBSP1, 2, 3)
 - Full-duplex communication
 - Multichannel selection modes
 - Support to enable or block transfers in each channel
 - 128 channels for transmission and reception
 - Direct interface to industry-standard codecs, analog interface chips (AICs), and other serially connected A/D and D/A devices:
 - Inter-IC sound (I2S™) compliant devices
 - Pulse code modulation (PCM) devices
 - Time division multiplexed (TDM) bus devices

CAUTION

McBSP modules do not offer support for μ -law and A-law companding, two partitions mode dynamic reassignment, AC'97, and SPI protocol.

- A wide selection of data sizes: 8, 12, 16, 20, 24, and 32 bits
- Bit reordering (send/receive least-significant bit [LSB])
- Clock and frame-synchronization generation support:
 - Independent clocking and framing for reception and for transmission up to 48 MHz
 - Support for external generation of clock signals and frame-synchronization (frame-sync) signals
 - A programmable sample rate generator (SRG) for internal generation and control of clock signals and frame-sync signals
 - Programmable polarity for frame-sync pulses and clock signals

NOTE:

- McBSP modules do not support features such as retransmit or re-receive of an erroneous frame or word.
- McBSP modules support dual-phase frames to provide I2S fully compliant capabilities. This dual-phase mode, however, is limited to one channel (or word) for each phase instead of 128 channels maximum for single-phase mode.

24.5.2 McBSP Environment

This section describes the intended functions for the McBSP module from an environment point of view (that is, external connections). It presents the McBSP connectivity options, lists the possible interfaces, and details the protocol and data format used in each case.

24.5.2.1 McBSP Functions

The device provides four instances of the McBSP module called McBSP1, McBSP2, McBSP3, and McBSP4.

The recommended use (nonexhaustive) for each McBSP module in the device is:

- McBSP1: Digital baseband (DBB) data
- McBSP2: Audio data
- McBSP3: Bluetooth® voice data
- McBSP4: Midi data

[Table 24-326](#) describes the functions and the corresponding application fields.

Table 24-326. Functions Description

| Function | Application Field | Recommended McBSP Module | Description |
|------------------|--|--------------------------|---|
| Control and data | DBB data | McBSP1 | Serial interface to transfer data |
| Audio data | Audio data without audio buffer and sidetone feature | McBSP2 | Audio interface to transfer audio data with I2S |
| | Midi data | McBSP4 | |
| Voice data | Bluetooth voice data without sidetone feature | McBSP3 | Voice interface to transfer voice data with PCM |

24.5.2.2 McBSP Signals Descriptions

The four McBSP modules consist of a data-flow path and a control path connected to external devices by a serial interface with 6-pin configuration (McBSP 4 only) or 4-pin configuration (McBSP1, 2, 3).

For a McBSP module with 6-pin configuration, an internal loopback capability between transmitter and receiver clock signals, and both frame-sync signals, enables using the McBSP module with 4-pin configuration. The related internal multiplexers are controlled through the system control module on the device (see [Section 24.5.3, McBSP Integration](#)). [Table 24-327](#) describes the inputs/outputs (I/Os).

Table 24-327. I/O Description

| Pin Name | I/O | Description | Internal Signal Name | Reset Value | Control and Data | Audio Data | Voice Data |
|-----------------|---------------------|---|----------------------|-------------|------------------|------------|------------|
| abe_clks | I | External clock (shared by all McBSP modules) | CLKS | 0 | ✓ | ✓ | ✓ |
| abe_mcbspi_dr | I | Receive serial data | DR | Z | ✓ | ✓ | ✓ |
| abe_mcbspi_dx | (I)O ⁽¹⁾ | Transmit serial data | DX | Z | ✓ | ✓ | ✓ |
| abe_mcbspi_clkx | I/O ⁽²⁾ | Transmit clock ⁽³⁾ | CLKX | Z | ✓ | ✓ | ✓ |
| abe_mcbspi_fsx | I/O ⁽²⁾ | Transmit frame synchronization ⁽⁴⁾ | FSX | Z | ✓ | ✓ | ✓ |
| mcbbsp4_dr | I | Receive serial data | DR | Z | ✓ | ✓ | ✓ |
| mcbbsp4_dx | (I)O ⁽¹⁾ | Transmit serial data | DX | Z | ✓ | ✓ | ✓ |
| mcbbsp4_clkx | I/O ⁽²⁾ | Transmit clock ⁽³⁾ | CLKX | Z | ✓ | ✓ | ✓ |
| mcbbsp4_fsx | I/O ⁽²⁾ | Transmit frame synchronization ⁽⁴⁾ | FSX | Z | ✓ | ✓ | ✓ |
| mcbbsp4_clkr | I/O ⁽²⁾ | Receive clock ⁽⁵⁾ | CLKR | Z | ✓ | | |
| mcbbsp4_fsr | I/O ⁽²⁾ | Receive frame synchronization ⁽⁶⁾ | FSR | Z | ✓ | | |

⁽¹⁾ i = 1 to 3; I = Input; O = Output; I/O = Bidirectional

⁽²⁾ For details of the I/O selection, see [Section 24.5.2.3.1, McBSP Modes](#).

⁽³⁾ This signal is also used as CLKR when it is configured as output.

⁽⁴⁾ This signal is also used as FSR when it is configured as output.

⁽⁵⁾ This signal is also used as CLKX when it is configured as input.

⁽⁶⁾ This signal is also used as FSX when it is configured as input.

- The abe_clks pin can be used to inject an external clock. This clock is used to generate control signals depending on the module internal configuration (see [Section 24.5.4.9, McBSP SRG](#)). The CLKS signal of the McBSP modules is linked to an external signal through the abe_clks pin, but the CLKS signal can also be linked to an internal clock provided by the power, reset, and clock management (PRCM) module of the device. For more information, see [Section 24.5.3, McBSP Integration](#).
- Data are transmitted to external devices interfacing with McBSP modules through the mcbspi_dx pin. Data from those devices are received on the mcbspi_dr pin.

NOTE: The mcbspi_dx pin is an I/O signal to use the McBSP module in half-duplex mode.

- Control information is communicated by the following pins:
 - mcbspi_clkx (transmit clock)
 - mcbbsp4_clkr (receive clock)
 - mcbspi_fsx (transmit frame-sync)
 - mcbbsp4_fsr (receive frame-sync)

CAUTION

External pins mcbbsp4_clkr and mcbbsp4_fsr are connected to pads only for McBSP4; other McBSP modules do not have these connections. For these modules, CLKR and FSR signals sources are mcbspi_clkx and mcbspi_fsx pins, respectively. Consequently, there is a light restriction on other McBSP modules when used in full-duplex mode. Reception and transmission use the same clock signal and the same frame-sync signal.

24.5.2.3 McBSP Functions Description**24.5.2.3.1 McBSP Modes**

For all McBSP functions, McBSP modules can operate in master or slave mode. The difference between these modes is the definition of the source of McBSP clocks and McBSP frames synchronization:

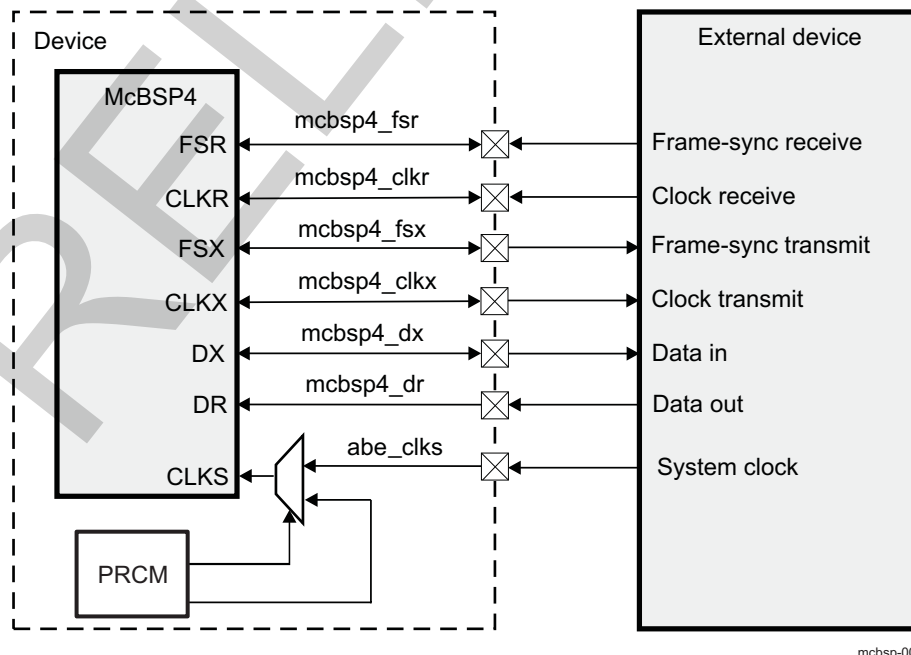

- Master mode: McBSP module provides them to the external device
- Slave mode: McBSP module receives them from the external device

The choice between the two modes depends on technical data of the external device and the type of interface (protocols and data formats). For one McBSP module, there are four possible functions:

- Transmit-and-receive master mode
- Transmit-and-receive slave mode
- Transmit master mode and receive slave mode
- Transmit slave mode and receive master mode

NOTE: If the McBSP has a serial interface with 4-pin configuration (McBSP1, 2, 3), only modes 1 and 2 are possible.

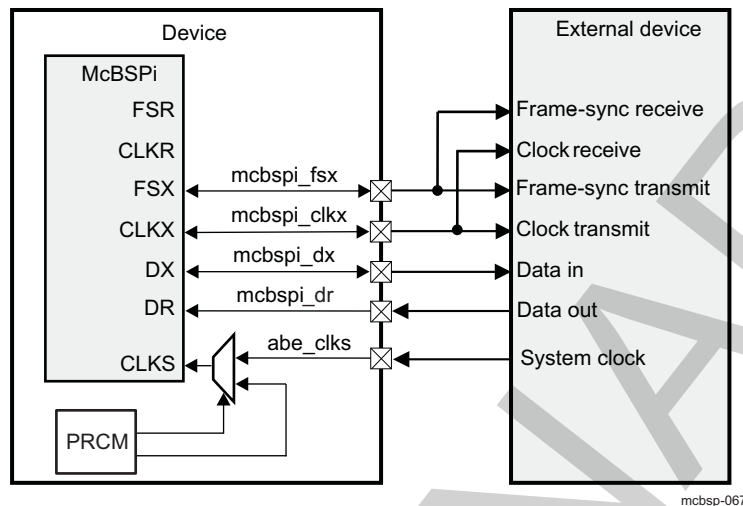

Figure 24-112 shows the connection between McBSP4 (6-pin configuration) and an external device in transmit master mode and receive slave mode.

Figure 24-112. Mode Overview of McBSP4

mcbbsp-003

Figure 24-113 shows the connection between the McBSPi module, where i = 1, 2, or 3 (4-pin configuration) and an external device in transmit and receive master mode.

Figure 24-113. Mode Overview of McBSPi

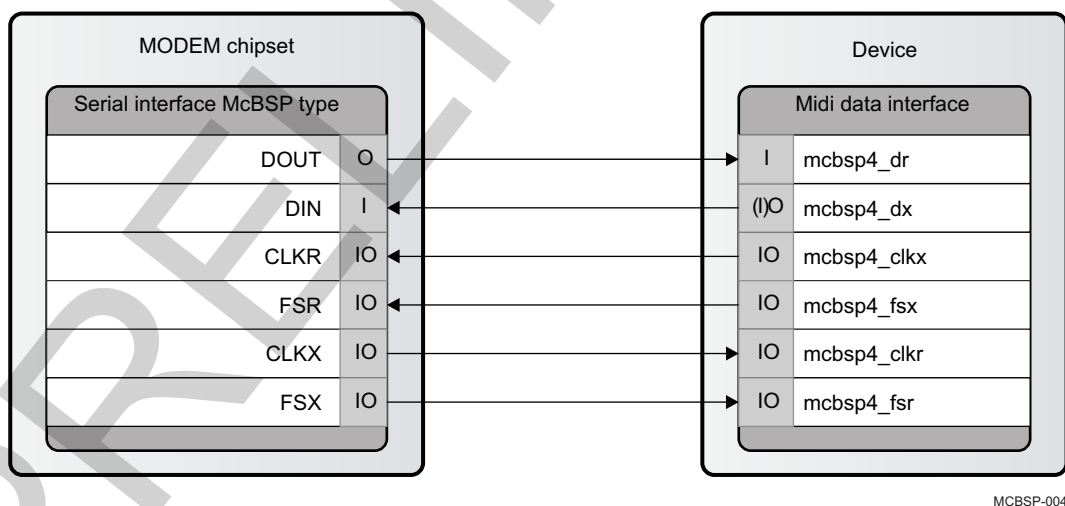

24.5.2.3.2 McBSP Functions

24.5.2.3.2.1 McBSP Function 1: Control and Data

In full-duplex mode (reception and transmission use independent clock signals and frame-sync signals), the McBSP module can be used to exchange control and data with an external chipset, allowing the device to be interfaced with a modem device. Figure 24-114 shows typical connections between device and modem chipset to show the Midi data application.

Figure 24-114. Midi Data Application

In Figure 24-114, McBSP4 is configured in transmit master mode and receive slave mode.

24.5.2.3.2.2 McBSP Function 2: Audio Data

The McBSP module is connected to audio devices through the I2S interface. The I2S link serial interface is a TDM slot-based serial interface that is used to transfer audio data. Those audio devices can be either AICs or other serially connected A/D and D/A devices.

Figure 24-115 shows typical connections between a device and a typical device of analog audio interface to show the audio data application. The typical device contains several audio analog inputs and outputs and digital microphone inputs.

Figure 24-115. Audio Data Application

In Figure 24-115, McBSP2 is configured in transmit-and-receive master mode.

24.5.2.3.3 McBSP Function 3: Voice Data

The McBSP module is connected to a voice device through the PCM interface. The PCM link serial interface is a TDM slot-based serial interface that is used to transfer voice data. The voice devices can be modem chipsets, Bluetooth chipsets, or other devices with voice data interface.

Figure 24-116 shows typical connections between a device and a Bluetooth chipset (TI BRF6300 or TI BRF6350) to show voice data application.

Figure 24-116. Voice Data Application

In Figure 24-116, McBSP3 is configured in transmit-and-receive master mode.

24.5.2.4 McBSP Protocols and Data Formats

The McBSP module can use one of the three protocols with associated data formats:

- Serial protocol to exchange serial data
- Audio protocol to exchange the audio samples
- Voice protocol to exchange the voice samples

The McBSP modules offer the flexibility to modify the following parameters to adapt to the device features as described in the following subsections.

24.5.2.4.1 Words, Frames, and Phases Definitions

24.5.2.4.1.1 Words or Channels

The data bits are transferred (transmission or reception) in a group called a serial word or channel. The number of bits in a word (length) is programmable through bit fields (McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 and McBSPi.MCBSPLP_RCR2_REG[7:5] RWDLEN2, McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 and McBSPi.MCBSPLP_XCR2_REG[7:5] XWDLEN2) and can be 8, 12, 16, 20, 24, or 32 bits (see [Section 24.5.4.8.3, Clocking and Framing Data](#)). The McBSP module uses clock signals to control the time for each bit transfer. Data are sampled/driven on the rising or falling edge of clock signals. This clock polarity is programmable through bit fields of the pin-control register (McBSPi.MCBSPLP_PCR_REG).

For more information, see [Section 24.5.4.8.4, Frame Phases \(Dual-Phase Frame I2S Support\)](#).

24.5.2.4.1.2 Frames

One or more words (maximum 128) are transferred in a group called a frame. The McBSP module can transmit and receive a maximum of 128 words per frame, programmable through bit fields of transmit-and-receive control registers (McBSPi.MCBSPLP_XCR1_REG/McBSPi.MCBSPLP_XCR2_REG and McBSPi.MCBSPLP_RCR1_REG/McBSPi.MCBSPLP_RCR2_REG). For more details, see [Section 24.5.4.8.3, Clocking and Framing Data](#).

All the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The McBSP module uses frame-sync signals to determine when each frame is received or transmitted. When a pulse occurs on a frame-sync signal, the McBSP module begins receiving or transmitting a frame of data. When the next pulse occurs, the McBSP module receives or transmits the next frame, and so on. The frame-sync pulse is active high or low. This pulse polarity is programmable through bit fields of the pin control register (McBSPi.MCBSPLP_PCR_REG).

Each frame transfer can be delayed by 0, 1, or 2 clock cycles, depending on the value of bits for transmit and receive control registers (McBSPi.MCBSPLP_XCR2_REG and McBSPi.MCBSPLP_RCR2_REG). For more information, see [Section 24.5.4.10.6.3, Preventing Unexpected Transmit Frame-sync Pulses](#) and [Section 24.5.4.10.3.3, Preventing Unexpected Receive Frame-sync Pulses](#).

24.5.2.4.1.3 Phases

The McBSP module allows configuring of each frame to contain one or two phases. The McBSP module supports dual-phase frames to provide I2S fully compliant capabilities. These two phases represent left and right channels of audio stereo signals.

The limitation on dual-phase frame is that the number of words per phase must be set to 1 for both first and second phases. The number of bits per word, however, can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers.

For example, software may define a frame composed of a first phase with one 12-bit word and a second phase with one 16-bit word. This configuration allows the software to compose frames for custom applications. For more details, see [Section 24.5.4.8.4, Frame Phases \(Dual-Phase Frame I2S Support\)](#).

[Figure 24-117](#) shows signal activity for two possible reception/transmission scenarios.

Figure 24-117. McBSP Reception/Transmission Signal Activity

mcbasp-007

24.5.2.4.2 Serial Protocol and Data Formats

24.5.2.4.2.1 Protocol

The serial protocol is used to send and receive control data without specific formats. This allows the McBSP module to accommodate all serial devices and their protocols.

24.5.2.4.2.2 Data Format

Figure 24-118 shows typical operation of the McBSP clock and frame-sync signals. Serial clocks CLKR and CLKX define the boundaries between bits for receive and transmit, respectively. Similarly, frame-sync signals FSR and FSX define the beginning of an element and/or frame transfer. The McBSP module allows the configuration of the following parameters for data and frame synchronization:

- Polarity of FSR, FSX, CLKX, and CLKR
- The number of words per frame
- The number of bits per word
- Whether subsequent frame synchronization restarts the serial data stream or is ignored
- The data delay from frame synchronization to first data bit which can be 0-, 1-, or 2-bit delays

The configuration is independent for receive and transmit parts. For more details and configuration examples, see [Section 24.5.4, McBSP Functional Description](#), and [Section 24.5.5, McBSP Basic Programming Model](#).

Figure 24-118. Serial Data Formats

mcbasp-009

24.5.2.4.3 Audio Protocol and Data Formats

24.5.2.4.3.1 Protocol

The I2S protocol is used to send and receive audio data from 8-kHz to 48-kHz sampling rate (frame-sync frequency), with 16 bits or 32 bits per words (supported frequencies are 8, 11.025, 12, 16, 22.05, 24, 32, 44.1, and 48 kHz).

The frame-sync signal defines the frame length in the I2S protocol. Each frame consists of a fixed number of words. In dual-phase frame, the frame-sync signal is low for the left phase time slot and is high for the right phase time slot. In addition, the frame-sync signal is synchronous to the falling edge of the clock signal.

24.5.2.4.3.2 Data Formats

The I2S protocol supports TDM, I2S, left-justified, and right-justified data formats.

Bits of each word (sample) are clocked using the clock signal. For each word, the most-significant bit (MSB) is first. LSBs are padded to 0 when the data length (8, 12, 16, 20, or 24 bits) is less than the sample word width (16 or 32 bits).

24.5.2.4.3.2.1 TDM Data Format

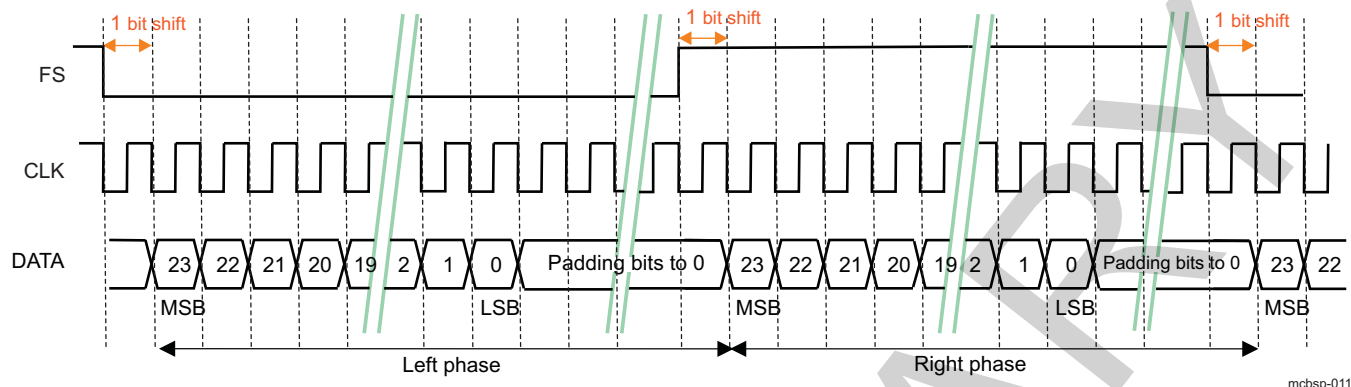

Figure 24-119 shows that each frame of TDM data format is composed of four words (or channels).

Figure 24-119. TDM Data Format; Word Width: 32 Bits; Data Length: 24 Bits

24.5.2.4.3.2.2 I2S Data Format

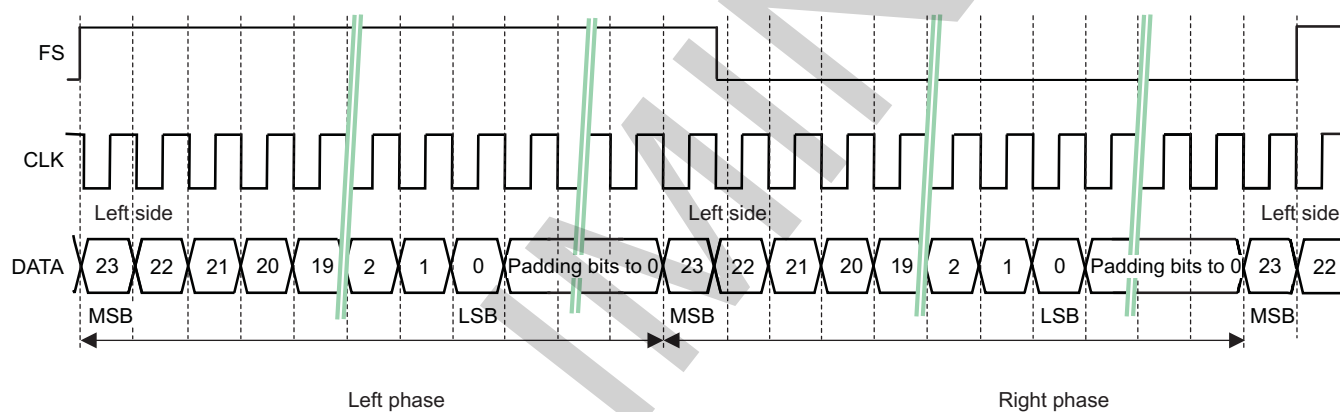

Figure 24-120 shows an example with 24-bit data (MSB first) and 8 padding bits at 0.

Figure 24-120. I2S Data Format; Word Width: 32 Bits; Data Length: 24 Bits

mcbasp-011

24.5.2.4.3.2.3 Left-Justified Data Format

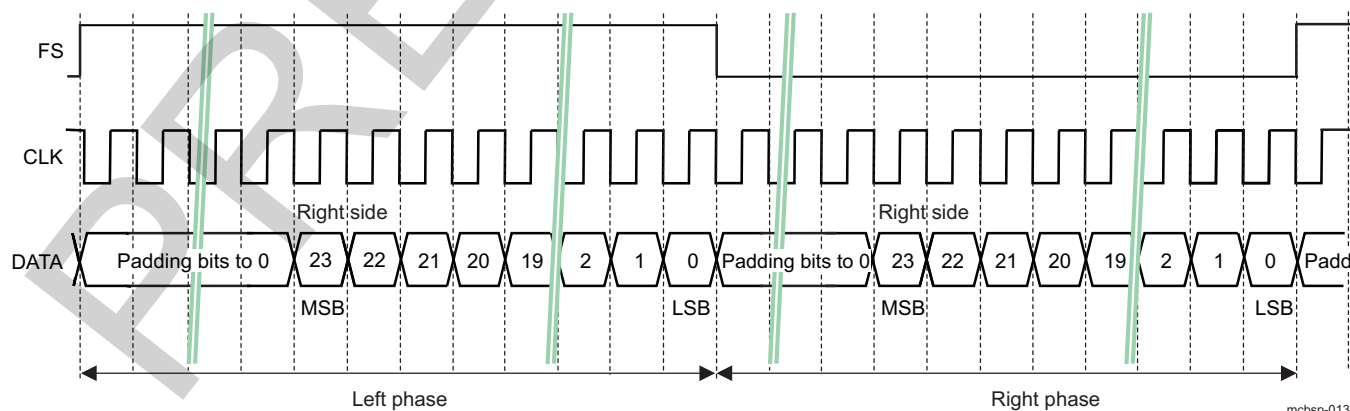

Figure 24-121 shows an example with 24-bit data (MSB first) and 8 padding bits at 0.

Figure 24-122. Right-Justified Data Format; Word Width: 32 Bits; Data Length: 24 Bits

mcbasp-013

24.5.2.4.4 Voice Protocol and Data Formats

24.5.2.4.4.1 Protocol

The PCM protocol is intended to transfer voice data at 8-kHz (default narrowband mode) or 16-kHz (wideband mode) sample rate (frame-sync frequency). PCM protocol can act as a slave or master, and is used by the Bluetooth interface and the modem generic interface. The frame synchronization defines the frame length in the PCM protocol. Bits are clocked using the PCM clock signal, with the MSB first.

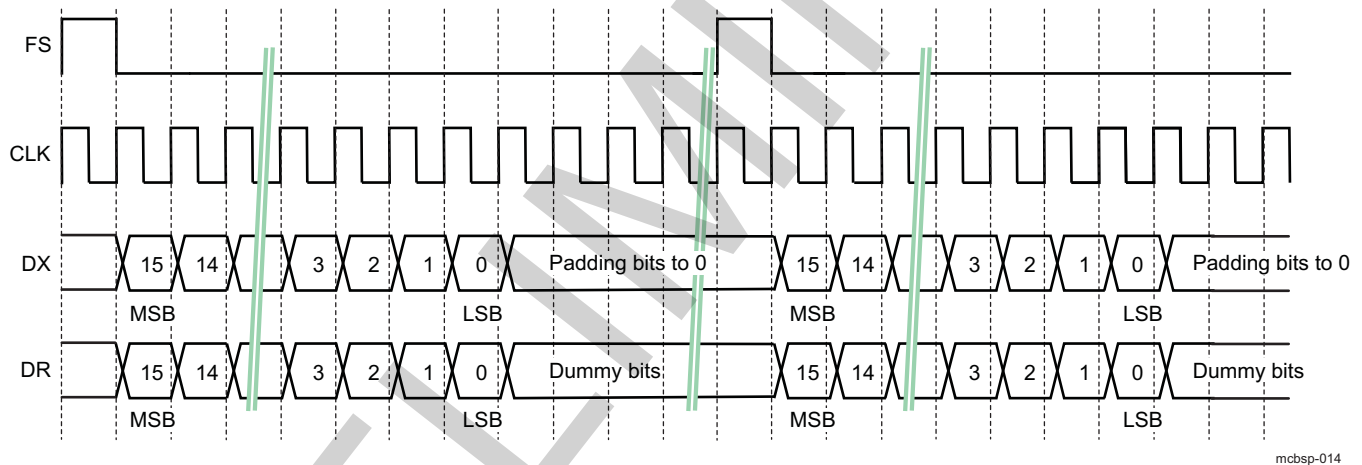

24.5.2.4.4.2 Data Formats

Two modes are available for the PCM protocol: mode 1 and mode 2. Both modes have two types of operations: mono or stereo channels. The difference between PCM mode 1 and PCM mode 2 is in the way in which they use the rising or the falling edge of the clock signal, and the frame-sync polarity.

- PCM mode 1: Input data is latched on the falling edge of the clock, and the transmitted data starts on the rising edge of the clock. The frame-sync pulse is active high.
- PCM mode 2: Input data is latched on the rising edge of the clock, and the transmitted data starts on the falling edge of the clock. The frame-sync pulse is active low.

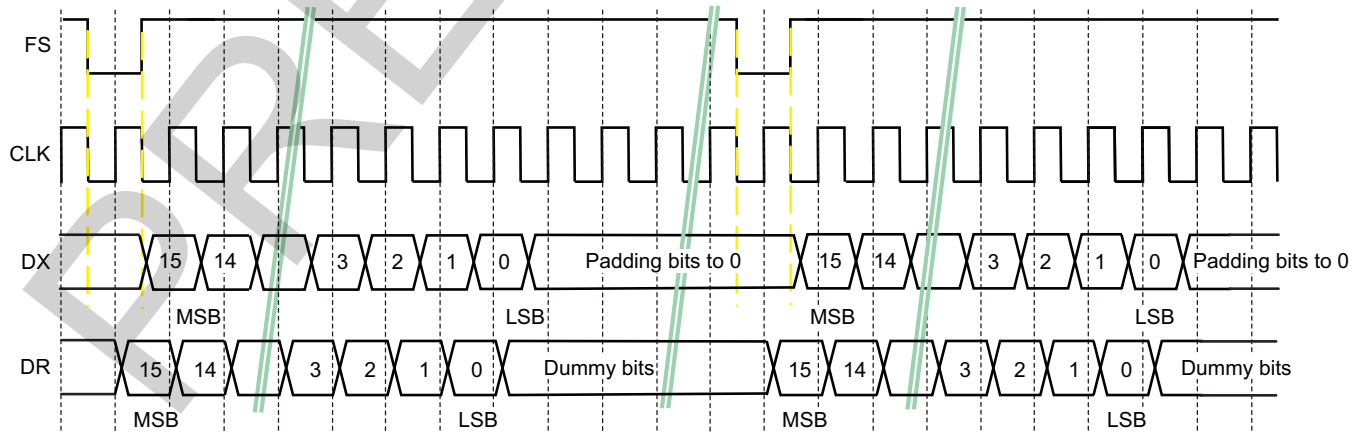

Figure 24-123 and Figure 24-124 show an example of PCM protocol, mode 1 and mode 2, respectively, for a frame composed of one word (32 bits wide) with 16 bits of data.

mcbasp-015

24.5.3 McBSP Integration

This section describes the integration of the McBSP module in the device, including information about clocks, resets, and hardware requests.

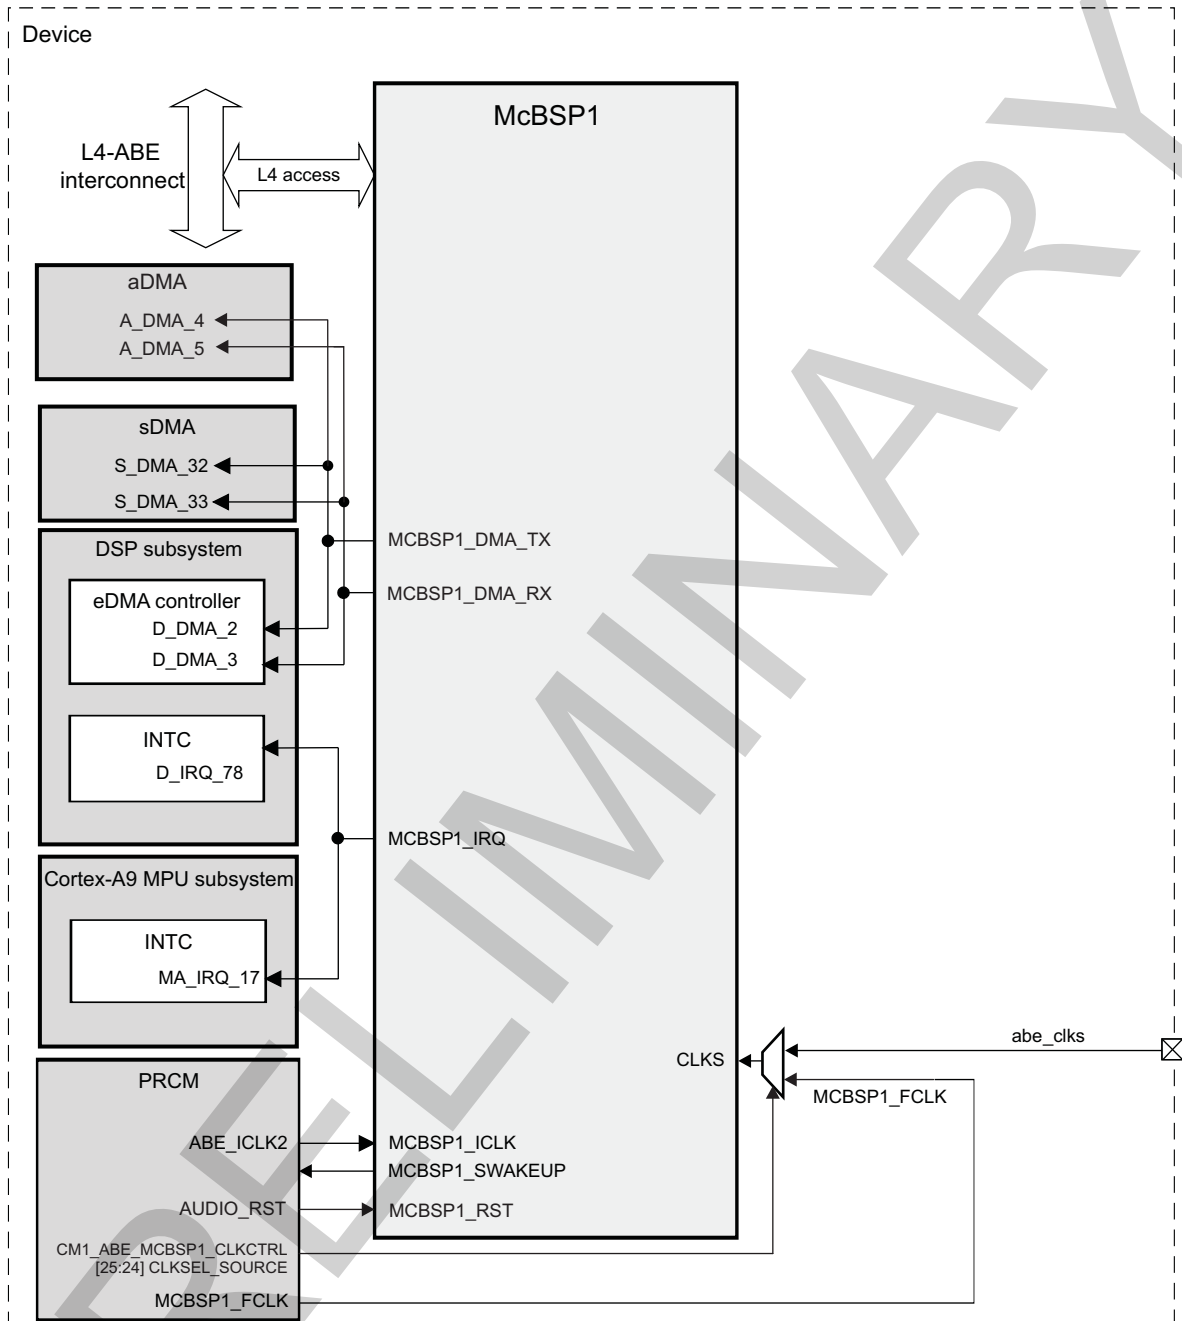

McBSP modules are divided into two families: McBSP modules that are gated in the AUDIO power domain (McBSP1, 2, and 3) and in the L4_PER power domain (McBSP4).

[Figure 24-125](#) through [Figure 24-128](#) show the integration of the McBSP modules in the device, including interrupt handlers, DMA requests, clock generators, and interconnections.

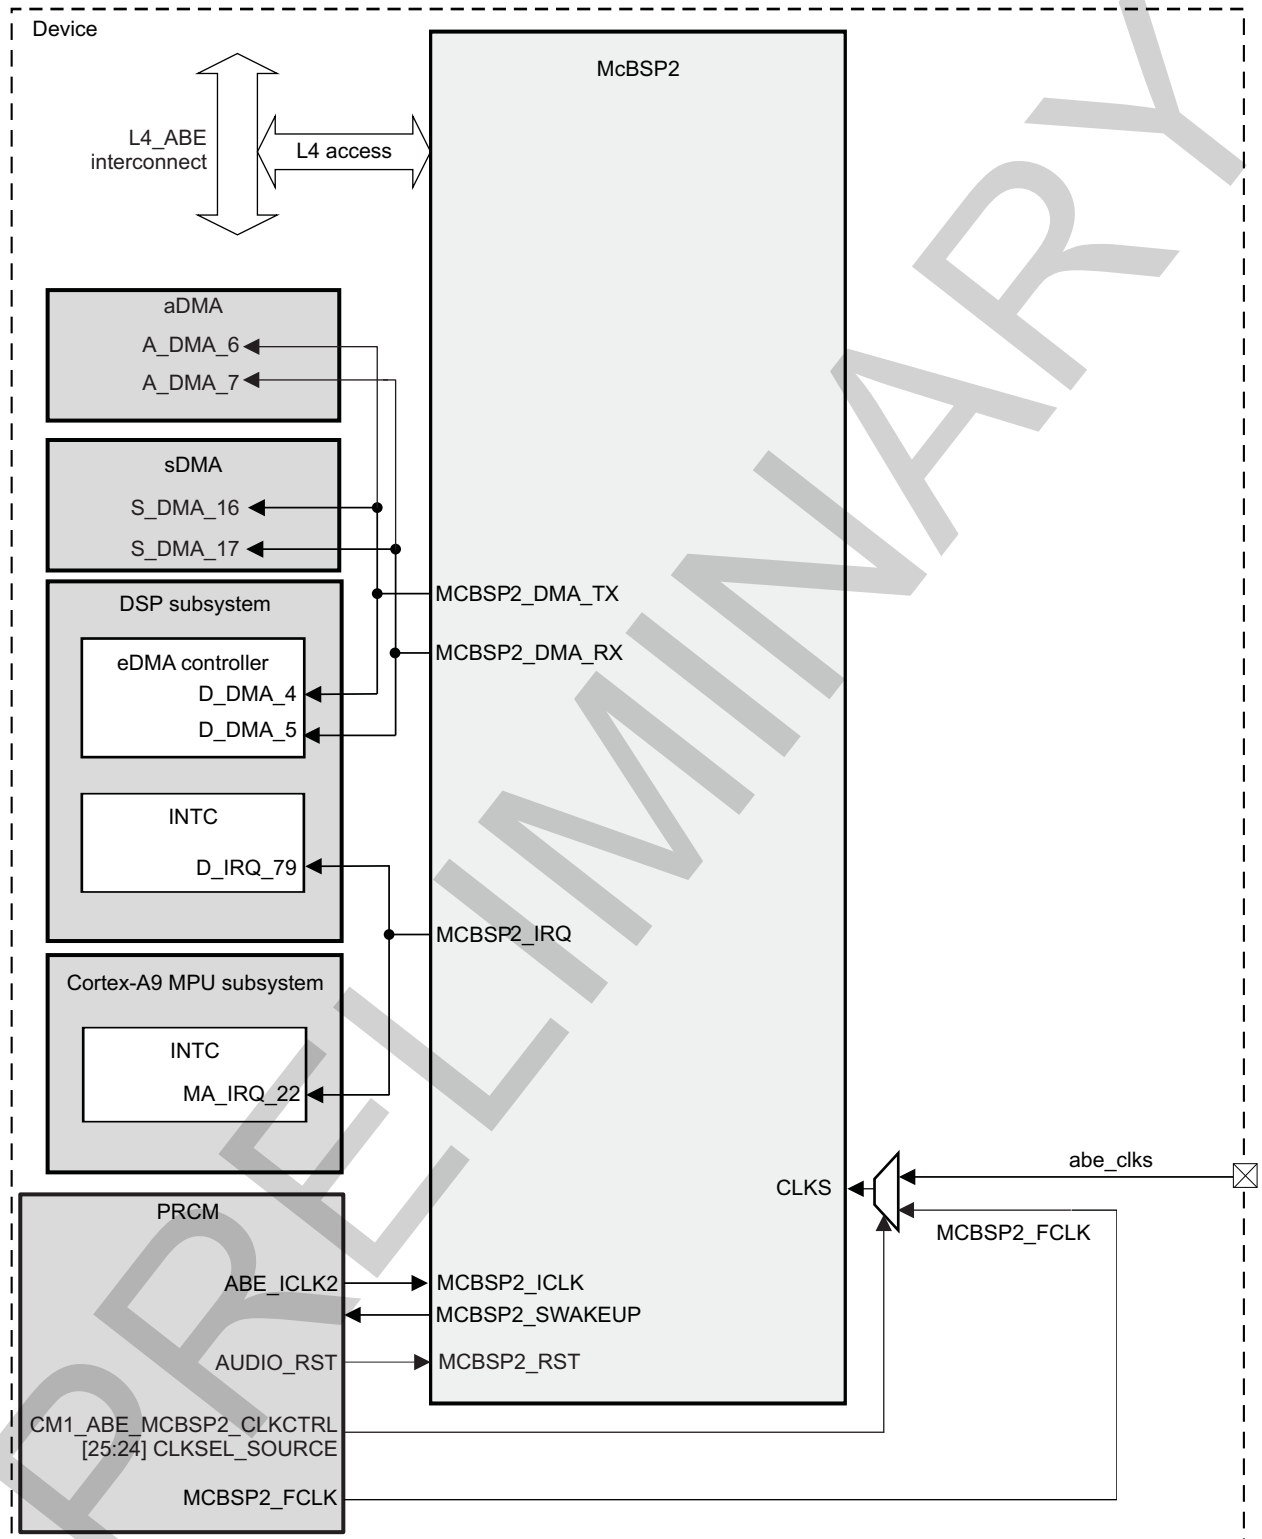

The features of the McBSP modules are:

- Wake-up request
- Two DMA requests
- One IRQ
- One functional clock
- One interface clock

Figure 24-125. McBSP1 Integration

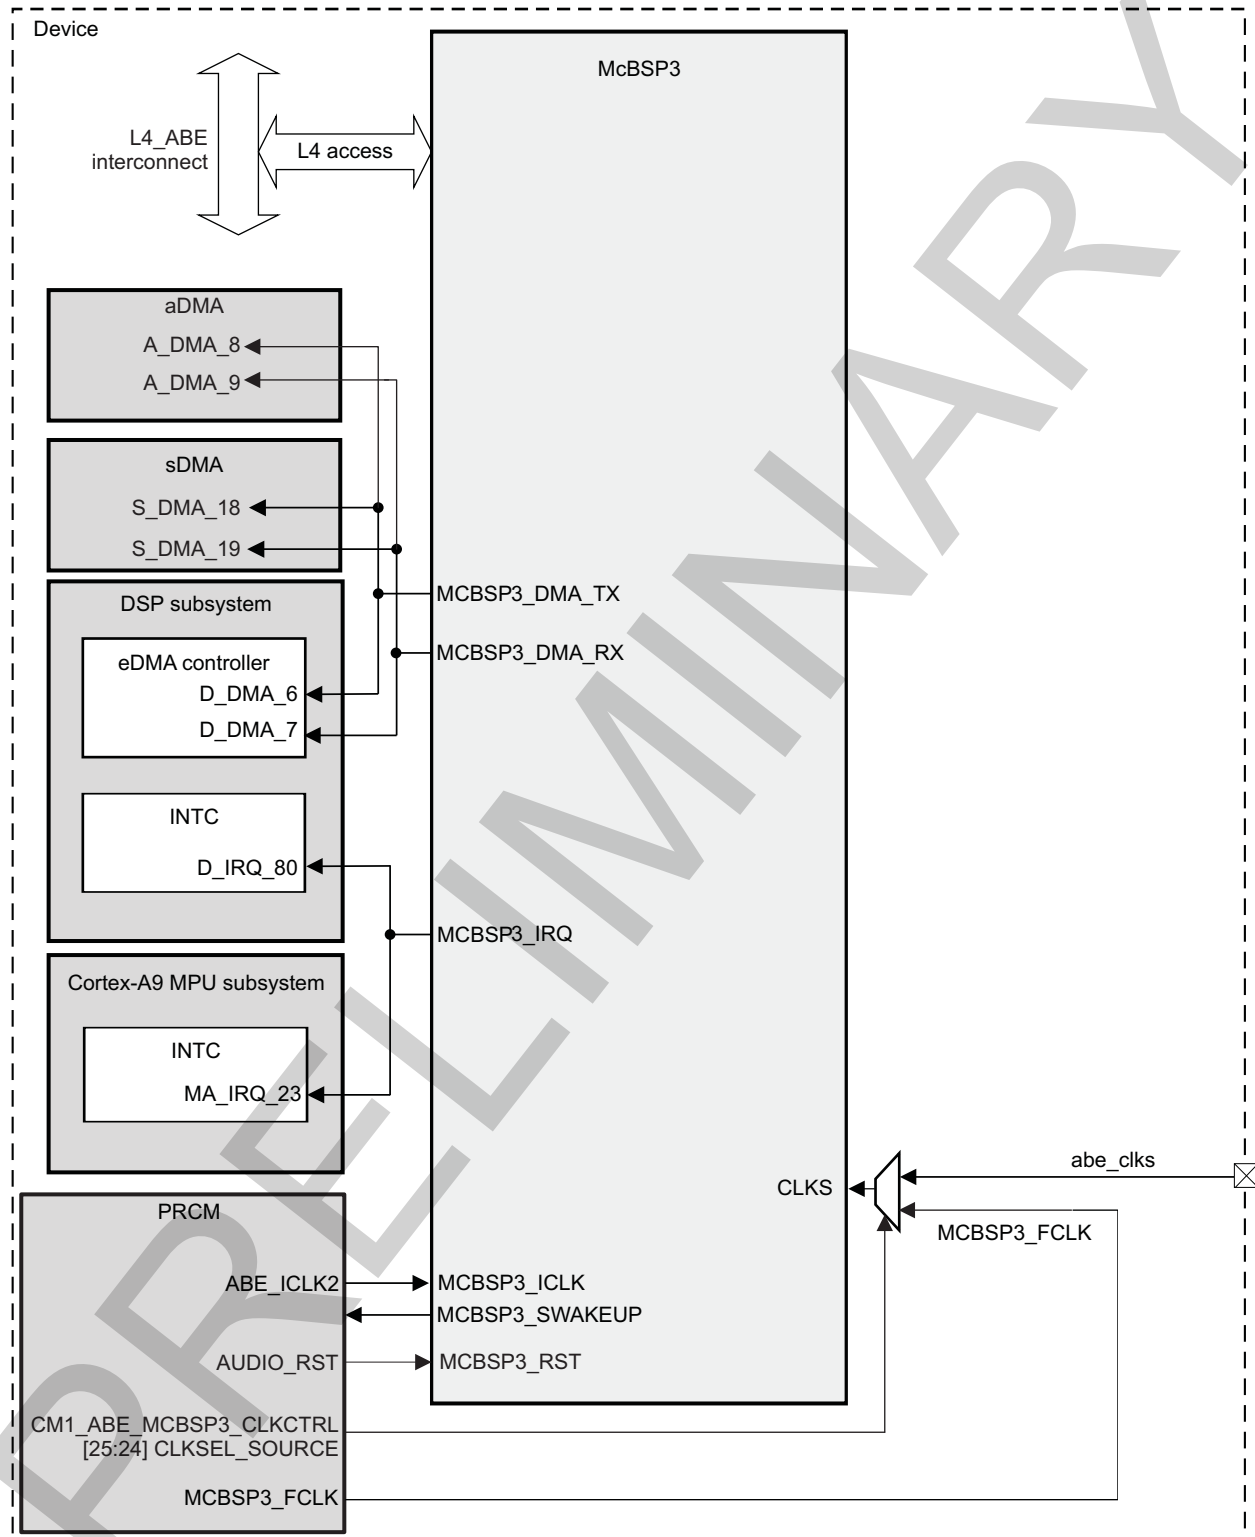

mcbasp-074

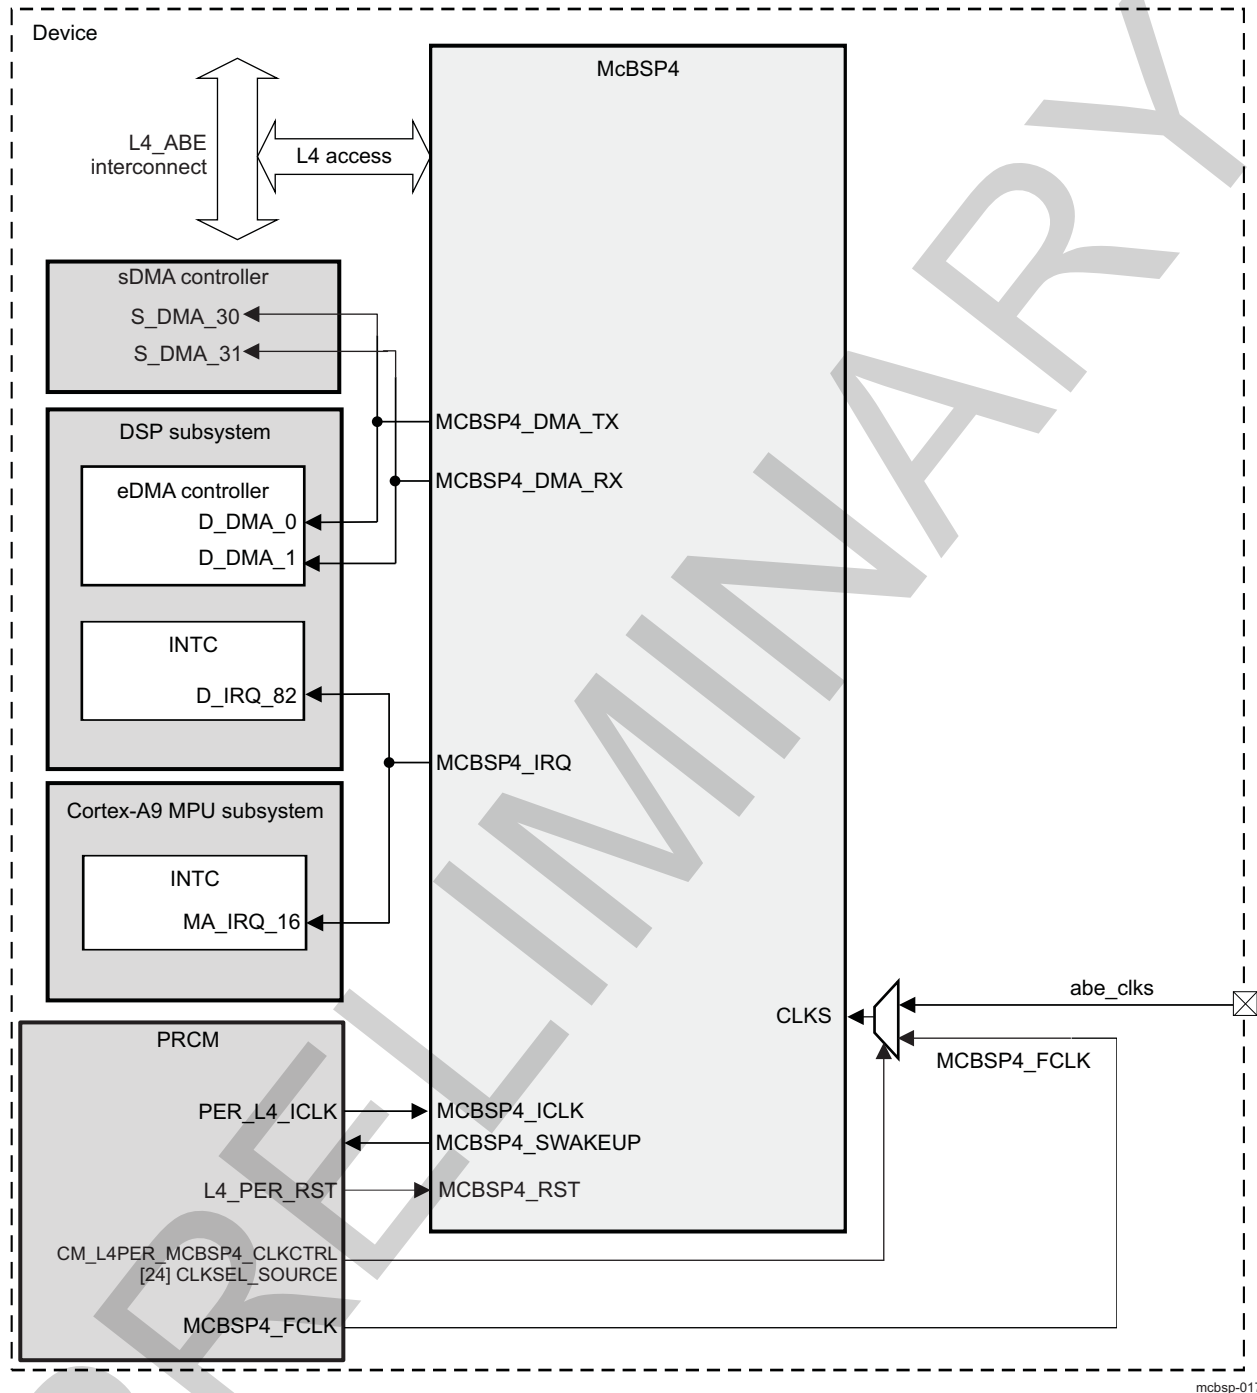

Figure 24-126. McBSP2 Integration

mcbasp-018

Figure 24-127. McBSP3 Integration

mcbasp-019

Figure 24-128. McBSP4 Integration

mcbasp-017

NOTE: The selection between the FSX and FSR signals is made in the CONTROL_MCBSP4[31] ALBCTRLRX_FSX bit in the control module register. The selection between the CLKR and CLKX signals is made in the CONTROL_MCBSP4[30] ALBCTRLRX_CLKX bit in the control module register.

Table 24-328 through Table 24-330 summarize the integration of the module in the device.

Table 24-328. Integration Attributes

| Module Instance | Attributes | | |
|-----------------|--------------|--------------------|--------------|
| | Power Domain | Wake-Up Capability | Interconnect |
| MCBSP1 | PD_AUDIO | Yes | L4_ABE |
| MCBSP2 | PD_AUDIO | Yes | L4_ABE |
| MCBSP3 | PD_AUDIO | Yes | L4_ABE |
| MCBSP4 | PD_L4_PER | Yes | L4_PER |

Table 24-329. Clocks and Resets

| Clocks | | | | |
|-----------------|-------------------------|--------------------|--------|---------------------------|
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| MCBSP1 | MCBSP1_ICLK | ABE_ICLK2 | PRCM | MCBSP1 interface clock |
| | MCBSP1_FCLK | MCBSP1_FCLK | PRCM | MCBSP1 functional clock |
| MCBSP2 | MCBSP2_ICLK | ABE_ICLK2 | PRCM | MCBSP2 interface clock |
| | MCBSP2_FCLK | MCBSP2_FCLK | PRCM | MCBSP2 functional clock |
| MCBSP3 | MCBSP3_ICLK | ABE_ICLK2 | PRCM | MCBSP3 interface clock |
| | MCBSP3_FCLK | MCBSP3_FCLK | PRCM | MCBSP3 functional clock |
| MCBSP4 | MCBSP4_ICLK | PER_L4_ICLK | PRCM | MCBSP4 interface clock |
| | MCBSP4_FCLK | MCBSP4_FCLK | PRCM | MCBSP4 functional clock |
| Resets | | | | |
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| MCBSP1 | MCBSP1_RST | AUDIO_RST | PRCM | AUDIO power domain reset |
| MCBSP2 | MCBSP2_RST | AUDIO_RST | PRCM | AUDIO power domain reset |
| MCBSP3 | MCBSP3_RST | AUDIO_RST | PRCM | AUDIO power domain reset |
| MCBSP4 | MCBSP4_RST | L4_PER_RST | PRCM | L4_PER power domain reset |

Table 24-330. Hardware Requests

| Interrupt Requests | | | | |
|--------------------|--------------------|-------------------------|--------------------|--|
| Module Instance | Source Signal Name | Destination Signal Name | Destination | Description |
| MCBSP1 | MCBSP1_IRQ | D_IRQ_78 | DSP INTC | McBSP 1: Common synchronous interrupt request line |
| | MCBSP1_IRQ | MA_IRQ_17 | Cortex-A9 MPU INTC | McBSP 1: Common synchronous interrupt request line |
| MCBSP2 | MCBSP2_IRQ | D_IRQ_79 | DSP INTC | McBSP 2: Common synchronous interrupt request line |
| | MCBSP2_IRQ | MA_IRQ_22 | Cortex-A9 MPU INTC | McBSP 2: Common synchronous interrupt request line |
| MCBSP3 | MCBSP3_IRQ | D_IRQ_80 | DSP INTC | McBSP 3: Common synchronous interrupt request line |
| | MCBSP3_IRQ | MA_IRQ_23 | Cortex-A9 MPU INTC | McBSP 3: Common synchronous interrupt request line |
| MCBSP4 | MCBSP4_IRQ | D_IRQ_82 | DSP INTC | McBSP 4: Common synchronous interrupt request line |
| | MCBSP4_IRQ | MA_IRQ_16 | Cortex-A9 MPU INTC | McBSP 4: Common synchronous interrupt request line |
| DMA Requests | | | | |
| Module Instance | Source Signal Name | Destination Signal Name | Destination | Description |
| MCBSP1 | MCBSP1_DMA_TX | A_DMA_4 | aDMA | MCBSP module 1: Transmit DMA request |
| | MCBSP1_DMA_RX | A_DMA_5 | aDMA | MCBSP module 1: Receive DMA request |

Table 24-330. Hardware Requests (continued)

| | | | | |
|--------|---------------|----------|------|--------------------------------------|
| | MCBSP1_DMA_TX | S_DMA_32 | sDMA | MCBSP module 1: Transmit DMA request |
| | MCBSP1_DMA_RX | S_DMA_33 | sDMA | MCBSP module 1: Receive DMA request |
| | MCBSP1_DMA_TX | D_DMA_2 | dDMA | MCBSP module 1: Transmit DMA request |
| | MCBSP1_DMA_RX | D_DMA_3 | dDMA | MCBSP module 1: Receive DMA request |
| MCBSP2 | MCBSP2_DMA_TX | A_DMA_6 | aDMA | MCBSP module 2: Transmit DMA request |
| | MCBSP2_DMA_RX | A_DMA_7 | aDMA | MCBSP module 2: Receive DMA request |
| | MCBSP2_DMA_TX | S_DMA_16 | sDMA | MCBSP module 2: Transmit DMA request |
| | MCBSP2_DMA_RX | S_DMA_17 | sDMA | MCBSP module 2: Receive DMA request |
| | MCBSP2_DMA_TX | D_DMA_4 | dDMA | MCBSP module 2: Transmit DMA request |
| | MCBSP2_DMA_RX | D_DMA_5 | dDMA | MCBSP module 2: Receive DMA request |
| MCBSP3 | MCBSP3_DMA_TX | A_DMA_8 | aDMA | MCBSP module 3: Transmit DMA request |
| | MCBSP3_DMA_RX | A_DMA_9 | aDMA | MCBSP module 3: Receive DMA request |
| | MCBSP3_DMA_TX | S_DMA_18 | sDMA | MCBSP module 3: Transmit DMA request |
| | MCBSP3_DMA_RX | S_DMA_19 | sDMA | MCBSP module 3: Receive DMA request |
| | MCBSP3_DMA_TX | D_DMA_6 | dDMA | MCBSP module 3: Transmit DMA request |
| | MCBSP3_DMA_RX | D_DMA_7 | dDMA | MCBSP module 3: Receive DMA request |
| MCBSP4 | MCBSP4_DMA_TX | S_DMA_30 | sDMA | MCBSP module 4: Transmit DMA request |
| | MCBSP4_DMA_RX | S_DMA_31 | sDMA | MCBSP module 4: Receive DMA request |
| | MCBSP4_DMA_TX | D_DMA_0 | aDMA | MCBSP module 4: Transmit DMA request |
| | MCBSP4_DMA_RX | D_DMA_1 | aDMA | MCBSP module 4: Receive DMA request |

NOTE:

- For more information about the interrupt source, see [Section 24.5.4.6, Interrupt Requests](#).
- For more information about the DMA source, see [Section 24.5.4.7, DMA Requests](#).

24.5.4 McBSP Functional Description

This section is a functional description of the McBSP module.

24.5.4.1 Block Diagram

Figure 24-129 shows the functional block diagram of the four instances of the McBSP modules.

Figure 24-129. McBSPi Block Diagram

mcbbsp-021

24.5.4.2 Signal Source Control

The sources of the CLKX, DX, DR, FSX, FSR, and CLKR signals are defined by the system control module. The control registers of the system control module are used to select these signal sources. For more information, see [Chapter 19, Control Module](#).

24.5.4.3 McBSP Clock Configuration

24.5.4.3.1 McBSP1 Clocks

McBSP1 is clocked by a functional clock (CLKS and CLKX) and an interface clock (MCBSP1_ICLK).

- The functional clock is used to generate control signals depending on the internal configuration of the module (see [Section 24.5.4, McBSP Functional Description](#)). For McBSP1, the functional clock comes from the CLKS and CLKX signals. The choice between these two clocks is defined by the MCBSP1.MCBSPLP_PCR_REG[7] SCLKME bit and the MCBSP1.MCBSPLP_SRGR2_REG[13] CLKSM bit.

The CLKS signal of McBSP1 is linked to an internal clock (MCBSP1_FCLK) provided by the PRCM module. The CLKS signal can also be linked to an external signal through the `abe_clks` pin of the device boundary.

NOTE: When McBSP1 no longer requires the functional clock, software can disable it at the PRCM level by configuring the MODULEMODE bit field to 0x0 (PRCM.CM1_ABE_MCBSP1_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At the PRCM level, when all the conditions to shut off the MCBSP1_FCLK clock are met, the PRCM module automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the McBSP module. For more information, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Only the CLKX signal is connected by `mcbbsp4_clkx` pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.

- The MCBSP1_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP1 L4 interface and McBSP1 configuration interface through the Cortex-A9 MPU/DSP shared bus. It can also be an input clock for the McBSP SRG (clock divider), depending on the module configuration (see [Section 24.5.4.9, McBSP SRG](#)). Its source is the ABE_ICLK2 signal.

NOTE: When McBSP1 no longer requires the interface clock, software can disable it at the PRCM level by configuring the MODULEMODE bit field (PRCM.CM1_ABE_MCBSP1_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At the PRCM level, when all the conditions to shut off the ABE_ICLK2 clock are met the PRCM module automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the McBSP module. For more information, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

24.5.4.3.2 McBSP2 Clocks

McBSP2 is clocked by a functional clock (CLKS or CLKX) and an interface clock (MCBSP2_ICLK).

- The functional clock is used to generate control signals depending on the internal configuration of the module (see [Section 24.5.4, McBSP Functional Description](#)). For McBSP2, the functional clock comes from the CLKS and CLKX signals. The choice between these two clocks is defined by the MCBSP2.MCBSPLP_PCR_REG[7] SCLKME bit and the MCBSP2.MCBSPLP_SRGR2_REG[13] CLKSM bit.

NOTE: When McBSP2 no longer requires the functional clock, software can disable it at the PRCM level by configuring the MODULEMODE bit field to 0x0 (PRCM.CM1_ABE_MCBSP2_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At the PRCM level, when all the conditions to shut off the MCBSP2_FCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the McBSP module. For more information, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Only the CLKX signal is connected by mcbasp2_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of the SRG.

- The MCBSP2_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP2 L4 interface and McBSP2 configuration interface through the Cortex-A9 MPU/DSP shared bus. It can also be an input clock for the McBSP SRG (clock divider), depending on the module configuration (see [Section 24.5.4.9, McBSP SRG](#)). Its source is the ABE_ICLK2 signal.

NOTE: When McBSP2 no longer requires the interface clock, software can disable it at the PRCM level by configuring the MODULEMODE bit field (PRCM.CM1_ABE_MCBSP2_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At the PRCM level, when all the conditions to shut off the ABE_ICLK2 clock are met the PRCM module automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the McBSP module. For more information, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

24.5.4.3.3 McBSP3 Clocks

McBSP3 is clocked by a functional clock (CLKS or CLKX) and an interface clock (MCBSP3_ICLK).

- The functional clock is used to generate control signals depending on the internal configuration of the module (see [Section 24.5.4, McBSP Functional Description](#)). For McBSP3, the functional clock comes from the CLKS and CLKX signals. The choice between these two clocks is defined by the MCBSP3.MCBSPLP_PCR_REG[7] SCLKME bit and the MCBSP3.MCBSPLP_SRGR2_REG[13] CLKSM bit.

NOTE: When McBSP3 no longer requires the functional clock, software can disable it at the PRCM level by configuring the MODULEMODE bit field to 0x0 (PRCM.CM1_ABE_MCBSP3_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At the PRCM level, when all the conditions to shut off the MCBSP3_FCLK clock are met the PRCM module automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the McBSP module. For more information, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Only, the CLKX signal is connected by mcbasp3_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.

- The MCBSP3_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP3 L4 interface and McBSP3 configuration interface via the Cortex-A9 MPU/DSP shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 24.5.4.9, McBSP SRG](#)). Its source is either the ABE_ICLK2 signal.

NOTE: When the McBSP2 module does not require the interface clock anymore, the software can disable it at the PRCM level by configuring the MODULEMODE bit field (PRCM.CM1_ABE_MCBSP3_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At PRCM level, when all the conditions to shut-off ABE_ICLK2 clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to McBSP module. For more information, see [Section 3.1.1.1.2, Module Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE_PER[1] register AUTO_MCBSP3 bit set to 1). In this case, McBSP3_ICLK follows the AUDIO_L4 clock domain behavior on the device. For more information, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

24.5.4.3.4 McBSP4 Clocks

McBSP4 is clocked by a functional clock (CLKS, CLKX, or CLKR) and an interface clock (MCBSP4_ICLK).

- The functional clock is used to generate control signals depending on the internal configuration of the module (see [Section 24.5.4, McBSP Functional Description](#)). For McBSP4, the functional clock comes from the CLKS, CLKX, or CLKR signal. The choice between these three clocks is defined by the MCBSP4.MCBSPLP_PCR_REG[7] SCLKME bit and the MCBSP4.MCBSPLP_SRGR2_REG[13] CLKSM bit.

NOTE: When McBSP4 no longer requires the PRCM functional clock, software can disable it at the PRCM level by setting the MODULEMODE bit (PRCM.CM_L4PER_MCBSP4_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At the PRCM level, when all the conditions to shut off the MCBSP4_FCLK clock are met the PRCM module automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to McBSP module. For more information, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

The CLKX and CLKR signals are connected either by mcbbsp4_clkx or mcbbsp4_clkr pads. These signals are used like functional clocks by the intermediary of the SRG.

- The McBSP4_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP4 L4 interface and McBSP4 configuration interface via the Cortex-A9 MPU/DSP shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 24.5.4.9, McBSP SRG](#)). Its source is the PER_L4_ICLK signal.

NOTE: When the McBSP4 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the MODULEMODE bit (PRCM.CM_L4PER_MCBSP4_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At PRCM level, when all the conditions to shut-off PER_L4_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the McBSP module. For more information, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

24.5.4.4 McBSP Software Reset

McBSP4 belongs to the L4_PER domain and its reset signal is L4_PER_RST from the PRCM module. The McBSP1, 2, and 3 modules belong to the AUDIO domain and their reset signal is AUDIO_RST from the PRCM module. [Table 24-331](#) lists the software reset signals to all McBSP modules.

Table 24-331. Software Reset Signals to All McBSP Modules

| Type | Bit Field | Register Source | Activation | Description |
|----------|-----------|---------------------------------|-------------|---|
| Software | SOFTRESET | MCBSPi.MCBSPLP_SYSCONFIG_REG[1] | Active high | McBSP global software reset |
| | RRST | MCBSPi.MCBSPLP_SPCR1_REG[0] | Active low | This resets and disables the receiver, including the RB. |
| | XRST | MCBSPi.MCBSPLP_SPCR2_REG[0] | | This resets and disables the transmitter, including the XB. |
| | GRST | MCBSPi.MCBSPLP_SPCR2_REG[6] | | SRG is reset. |
| | FRST | MCBSPi.MCBSPLP_SPCR2_REG[7] | | Frame-sync logic is reset. Frame-sync generated signal is not generated by the SRG. |

For a complete description of the McBSP initialization procedure, see [Section 24.5.5.1, McBSP Initialization Procedure](#).

24.5.4.5 McBSP Power Management

24.5.4.5.1 McBSP Operating States

Two operating states are defined for all the McBSP modules:

- **ACTIVE state:** The module is running synchronously on the interface and functional clocks. Interrupts and DMA requests can be generated according to the configuration (register, master or slave mode, etc) and the external signals.
- **IDLE state:** As part of the system power management, the PRCM module can request the McBSP modules to enter IDLE state. Depending on the configured acknowledgment mode (force-idle, no-idle and smart-idle modes), a McBSP module effectively enters IDLE state or not. As soon as a McBSP module enters IDLE state, its only activities are those unrelated to clock activity (for example, wake-up features) and its clocks are likely to be switched off at the PRCM level.

NOTE: IDLE request and IDLE acknowledge are only internal signals, with no means to observe or to control. The generation and control of the signals is purely hardware (managed automatically by the PRCM module and the McBSP depending on the SIDLEMODE settings).

24.5.4.5.2 McBSP Acknowledgment Modes

During initialization or configuration of the McBSP module, software must configure how the McBSP module will answer an IDLE solicitation from the PRCM module (that is, the way IDLE acknowledge is asserted following assertion of an idle request).

Each McBSP module can be configured through the MCBSPi.MCBSPLP_SYSCONFIG_REG[4:3] SIDLEMODE bit field as one of the following acknowledgment modes:

- **Force-idle mode (SIDLEMODE bit = 0x0):** An IDLE request is acknowledged unconditionally, regardless of the internal state of the module. The McBSP module immediately enters IDLE state (no activity), interface and PRCM functional clocks can be stopped, and no interrupts and DMA requests can be generated. In this mode, the McBSP module freezes all the internal activity when the PRCM clocks are switched off by the PRCM module, leading to a potential loss of data.

CAUTION

In force-idle mode, the wake-up feature is inhibited.

CAUTION

If the McBSP functional part, transmitter or receiver, is running within this period of time (the functional clock source is not the PRCM functional clock), the internal state of the McBSP module will not be idle (FSM states, processes, etc.), and when the McBSP module exits from the Force Idle state unexpected behavior may happen in both receiver and transmitter. To avoid this, both receive and transmit parts, must be disabled by software prior to idle request assertion (all functional clock external sources must be disabled).

- No-idle mode (SIDLEMODE bit = 0x1): An IDLE request is never acknowledged, meaning it prevents the PRCM module from switching off its related clocks and from putting in a lower power state than the power domain to which it belongs. The McBSP module never enters IDLE state (is active).
- Smart-idle mode (SIDLEMODE bit = 0x2): Acknowledgement to an IDLE request is given based on the internal activity of the McBSP module. The McBSP module is in a waiting state, interface and functional clocks can be stopped, no interrupts can be generated, and a wake-up signal can be generated according to the configuration (see [Section 24.5.4.5.4, Analysis of the Receiver Smart-Idle Behavior](#)) and external signals.

NOTE: The value MCBSPi.MCBSPLP_SYSCONFIG_REG[4:3] SIDLEMODE field = 0x3 must not be used.

When configured in smart-idle mode, the McBSP module also offers an additional granularity on MCBSPi_FCLK and MCBSPi_ICLK gating. The MCBSPi.MCBSPLP_SYSCONFIG_REG[9:8] CLOCKACTIVITY bit field is used to determine which clock will be shut down (MCBSPi_FCLK, MCBSPi_ICLK, none of them, or both of them).

CLOCKACTIVITY setting is used in the McBSP module to determine on which part of the module the conditions to acknowledge the PRCM IDLE request will be tested. As an example, if MCBSPi_FCLK is said not to be shut down upon a PRCM IDLE request, this means the McBSP module will consider only MCBSPi_ICLK and the associated pending activities before acknowledging the request.

NOTE: Some McBSP features are associated with MCBSPi_ICLK and others with MCBSPi_FCLK. Using CLOCKACTIVITY along with the smart-idle mode ensures that the features associated with the clock that remain active are always enabled, even if the McBSP has acknowledged an IDLE request. For more information, see [Section 24.5.4.5.4, Analysis of the Receiver Smart-Idle Behavior](#).

[Table 24-332](#) lists the value of the bit field and indicates whether the interface (MCBSPi_ICLK) and PRCM functional (MCBSPi_FCLK) clocks can be switched off or not when an IDLE request is received by the McBSP module.

Table 24-332. State of Clocks When the Module is in Idle State

| CLOCKACTIVITY Value | Interface Clock (MCBSPi_ICLK) | PRCM Functional Clock |
|---------------------|-------------------------------|-----------------------|
| 0b00 | Off | Off |
| 0b01 | Off | On |
| 0b10 | On | Off |
| 0b11 | On | On |

NOTE: Off means this clock can be switched off.

On means this clock must be maintained during the wake-up period.

CAUTION

The PRCM module does not have any hardware means to read CLOCKACTIVITY settings. Software must ensure a consistent programming between the McBSPi.MCBSPLP_SYSCONFIG_REG[9:8] CLOCKACTIVITY bit field and the PRCM McBSPi_FCLK and L4_ICLK control bits (see notes in [Section 24.5.4.3, McBSP Clock Configuration](#)). If the McBSP module is disabled while CLOCKACTIVITY is set to 0x3, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the McBSP clocks. This may lead to unpredictable behaviors.

24.5.4.5.3 Wake-Up Capability

When configured in smart-idle mode, the sources for wake-up generation are a subset of the interrupt sources. The wake-up sources are enabled by setting the McBSPi.MCBSPLP_SYSCONFIG_REG[2] ENAWAKEUP bit (wake-up feature control):

- Set to 0, wake-up capability is disabled.
- Set to 1, wake-up capability is enabled.

The McBSPi_SWAKEUP signal is the McBSP module asynchronous wake-up signal sent to the PRCM module when a wake-up generation is requested.

The wake-up configurations are defined by setting the corresponding bits in the McBSPi.MCBSPLP_WAKEUPEN_REG register.

24.5.4.5.3.1 Receive Wakeup

There are four receive possible wake-up configurations:

- McBSPi.MCBSPLP_WAKEUPEN_REG[3] RRDYEN bit: The McBSP module asserts the McBSPi_SWAKEUP request when the receive buffer reaches the high threshold value (RTHRESHOLD value + 1) of the McBSPi.MCBSPLP_THRSH1_REG register. If the McBSPi.MCBSPLP_IRQENABLE_REG[3] RRDYEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or DSP subsystems when exiting from idle mode (interrupt will be asserted once the McBSPi.MCBSPLP_IRQSTATUS_REG[3] RRDY bit changes from 0 to 1, indicating that received data is ready to be read).
- McBSPi.MCBSPLP_WAKEUPEN_REG[2] REOFEN bit: The McBSP module asserts the McBSPi_SWAKEUP request at the end of the frame. If the McBSPi.MCBSPLP_IRQENABLE_REG[2] REOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or DSP subsystems when exiting idle mode.
- McBSPi.MCBSPLP_WAKEUPEN_REG[1] RFSREN bit: The McBSP module sends a McBSPi_SWAKEUP request to the PRCM module when a receive frame-sync pulse is detected while the McBSP module is in idle mode. If the McBSPi.MCBSPLP_IRQENABLE_REG[1] RFSREN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or DSP subsystems when exiting idle mode.
- McBSPi.MCBSPLP_WAKEUPEN_REG[0] RSYNCERREN bit: The McBSP module asserts the McBSPi_SWAKEUP request when an unexpected receive frame-sync pulse is detected. If the McBSPi.MCBSPLP_IRQENABLE_REG[0] RSYNCERREN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or DSP subsystems when exiting from idle mode (interrupt is asserted once the McBSPi.MCBSPLP_IRQSTATUS_REG[0] RSYNCERR bit changes from 0 to 1, indicating that a receive error occurred).

24.5.4.5.3.2 Transmit Wakeup

For transmit, there are five possible wake-up configuration scenarios:

- McBSPi.MCBSPLP_WAKEUPEN_REG[14] XEMPTYEOFEN bit: The McBSP module asserts the McBSPi_SWAKEUP request when a complete frame was transmitted and the transmit buffer is empty. If the McBSPi.MCBSPLP_IRQENABLE_REG[14] XEMPTYEOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or DSP subsystems when exiting idle mode.
- McBSPi.MCBSPLP_WAKEUPEN_REG[10] XRDYEN bit: The McBSP module asserts the McBSPi_SWAKEUP request when the transmit buffer reaches the high threshold value (XTHRESHOLD value + 1) of the McBSPi.MCBSPLP_THRSH2_REG register. If the McBSPi.MCBSPLP_IRQENABLE_REG[10] XRDYEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or DSP subsystems when exiting from idle mode (interrupt is asserted once the McBSPi.MCBSPLP_IRQSTATUS_REG[10] XRDY bit changes from 0 to 1, indicating that transmit buffer data is ready to accept new data).
- McBSPi.MCBSPLP_WAKEUPEN_REG[9] XEOFEN bit: The McBSP module asserts the McBSPi_SWAKEUP request at the end of the frame. If the McBSPi.MCBSPLP_IRQENABLE_REG[9] XEOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or DSP subsystems when exiting idle mode.
- McBSPi.MCBSPLP_WAKEUPEN_REG[8] XFSXEN bit: The McBSP module sends a McBSPi_SWAKEUP request when a transmit frame-sync pulse is detected while the module is in idle mode. If the McBSPi.MCBSPLP_IRQENABLE_REG[8] XFSXEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or DSP subsystems when exiting idle mode.
- McBSPi.MCBSPLP_WAKEUPEN_REG[7] XSYNCERREN bit: The McBSP module asserts the McBSPi_SWAKEUP request when an unexpected transmits frame-sync pulse is detected. If the McBSPi.MCBSPLP_IRQENABLE_REG[7] XSYNCERREN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or DSP subsystems when exiting idle mode (interrupt is asserted once the McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR bit changes from 0 to 1, indicating that a transmit error occurred).

24.5.4.5.3.3 Notes

When the mcbbsp4_fsr/mcbbspi_fsx pin is configured as an output, FSR/FSX wake-up generation makes no sense (the module cannot be in smart-idle mode).

Detection of RSYNCERR/XSYNCERR during idle mode can be used only when the mcbbsp4_fsr/mcbbspi_fsx pin is configured as an input and the remote system knows to assert such an error to trigger the wakeup of the McBSP module.

The module does not implement interrupt request (IRQ) assertion when configured as GPIO (pins that can be used to accept input signals and/or send output signals but are not linked to specific uses); also a wake-up capability in this mode is not available.

24.5.4.5.4 Analysis of the Receiver Smart-Idle Behavior

Table 24-333 provides an analysis of the power mode behavior.

In this table, the CLKRM bit is in the McBSPi.MCBSPLP_PCR_REG register on position 8, the CLKXM bit is in the McBSPi.MCBSPLP_PCR_REG[9] register, and the CLOCKACTIVITY bit is in the McBSPi.MCBSPLP_SYSCONFIG_REG[9:8] register.

The value X indicates that the bit value is not significant.

Table 24-333. McBSP Smart-Idle Mode Configuration Behavior

| CLKRM Bit | CLKXM Bit | McBSP Mode | Source of Functional Clock | CLOCKACTIVITY Bit | Behavior |
|-----------|-----------|-----------------|----------------------------|-------------------|--|
| 0 | 0 | Slave | Outside | 0bXX | The module acknowledges the IDLE request as soon as there is no pending DMA, interrupt request, or transmit buffer threshold synchronization (only when wake-up event is set on transmit threshold reached), regardless of the CLOCKACTIVITY settings or receive and transmit activity. |
| 0 | 1 | Transmit master | MCBSPi_ICLK | 0b0X | The McBSP does not acknowledge the IDLE request unless: <ul style="list-style-type: none"> The transmit part is disabled (XDISABLE) or under software reset (XRST). Transmit and receive parts are disabled (XDISABLE/RDISABLE) or under software reset (XRST/RRST). The IDLE acknowledge is asserted as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when the wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames were completed in case of transmit and/or receive disable. |
| | | | CLKS | 0bX0 | |
| | | | MCBSPi_ICLK | 0b1X | The module acknowledges the IDLE request as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when the wake-up event is set on transmit/receive threshold reached). |
| | | | CLKS | 0bX1 | |
| | | | CLKR (outside) | 0bXX | The module acknowledges the idle request as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when the wake-up event is set on transmit/receive threshold reached), regardless of the CLOCKACTIVITY settings. |
| | | | | | |
| 1 | 0 | Receive master | MCBSPi_ICLK | 0b0X | The McBSP does not acknowledge the IDLE request unless the receive part is disabled (RDISABLE) or under software reset (RRST). The IDLE acknowledge is asserted as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when the wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames were completed in case of transmit and/or receive disable. |
| | | | CLKS | 0bX0 | |
| | | | MCBSPi_ICLK | 0b1X | The module acknowledges the IDLE request as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached). |
| | | | CLKS | 0bX1 | |
| | | | CLKX | 0bXX | When CLKX is used as source (the functional clock is provided from outside), the module acknowledges the IDLE request as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when the wake-up event is set on transmit/receive threshold reached), regardless of the CLOCKACTIVITY settings. |
| | | | | | |

Table 24-333. McBSP Smart-Idle Mode Configuration Behavior (continued)

| CLKRM Bit | CLKXM Bit | McBSP Mode | Source of Functional Clock | CLOCKACTIVITY Bit | Behavior |
|-----------|-----------|-----------------------------|----------------------------|-------------------|---|
| 1 | 1 | Transmit and receive master | MCBSPi_ICLK | 0b0X | The McBSP does not acknowledge the IDLE request unless transmit and receive parts are disabled (XDISABLE/RDISABLE) or under software reset (XRST/RRST). The IDLE acknowledge is asserted as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when the wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames were completed in case of transmit and/or receive disable. No wake-up event is available in this mode, because the entire McBSP and remote device activity is frozen. |
| | | | CLKS | 0bX0 | |
| | | | MCBSPi_ICLK | 0b1X | The module acknowledges the IDLE request as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when the wake-up event is set on transmit/receive threshold reached). |
| | | | CLKS | 0bX1 | |

NOTE: The RFSREN/XFSXEN mode is suitable for wake-up generation when both clocks (PRCM functional and interface) are switched off and the mcbasp4_fsr/mcbspi_fsx pin is configured as input. The frame-sync pulse is asynchronously detected during idle.

The RSYNCERREN/XSYNCERREN mode can be used to wake up the McBSP module only by a remote module implementing such a feature to trigger a wakeup. In this mode, the functional clock must be active.

24.5.4.6 McBSP Interrupt Requests

Each of the four McBSP modules can generate one common interrupt (MCBSPi_IRQ), shared between the Cortex-A9 MPU subsystem and DSP subsystem interrupt controllers (INTCs).

An event can generate an interrupt request when the corresponding mask bit in the MCBSPi.MCBSPLP_IRQENABLE_REG register is set to 1.

Once an interrupt request is generated, software must read the MCBSPi.MCBSPLP_IRQSTATUS_REG register to check which event has caused the interrupt request generation, and acknowledge each processed event by setting the corresponding bit in the MCBSPi.MCBSPLP_IRQSTATUS_REG register to 1.

24.5.4.7 McBSP DMA Requests

The DMA requests are shared between the DSP subsystem DMA (eDMA) controller, system DMA (sDMA) controller, and audio engine DMA (aDMA) controller. Each of the four McBSP modules can generate two DMA events:

- MCBSPi_DMA_TX: McBSPi module transmit DMA request
- MCBSPi_DMA_RX: McBSPi module receive DMA request

Table 24-330 summarizes the DMA events with the mapping on both DMA controllers.

The receive and transmit DMA requests can be individually disabled by setting the MCBSPi.MCBSPLP_RCCR_REG[3] RDMAEN and MCBSPi.MCBSPLP_XCCR_REG[3] XDMAEN bits to 0. When disabling the DMA, the DMA request line is deasserted even if a DMA transfer is pending and the DMA state-machine is not reset.

For more information, see [Section 24.5.4.11, McBSP DMA Configuration](#).

24.5.4.8 McBSP Data Transfer Process

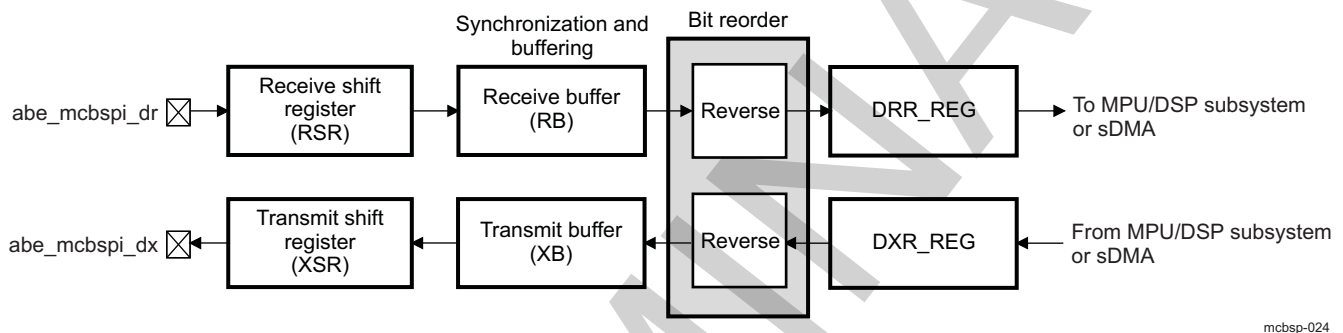

For McBSP modules, receive and transmit operations are triple-buffered (512 bytes buffers organized in 32-bit words are used).

All registers of McBSP data transfer paths are 32 bits wide. Figure 24-130 shows the McBSP data transfer paths.

CAUTION

The McBSP registers (DRR_REG and DXR_REG) are limited to 32-bit data accesses (L4 Interconnect); 16-and 8-bit accesses are not allowed and can corrupt register content.

Figure 24-130. McBSP Data Transfer Paths

mcbasp-024

24.5.4.8.1 Data Transfer Process for 8-/12-/16-/20-/24-/32-Bit-Long Words

NOTE: For each data word length, one data occupies one 32-bit buffer word.

Receive data arrives on the mcbspi_dr pin and is shifted into the receive shift register (RSR). When a full word (depending on the data length configuration) is received, the content of the shift register is copied into the receive buffer (RB) if it is not full. When the threshold of the RB is reached, the McBSP module asserts DMA or interrupt request and the content of the RB is then transferred (the sDMA or the eDMA controller reads the data receive register McBSPi.MCBSPLP_DRR_REG).

Transmit data is written by the MPU subsystem, DSP subsystem, or the DMA controller to the data transmit register (McBSPi.MCBSPLP_DXR_REG) using the McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit enable input (when a byte is not enabled, the byte value in the memory contains the previous written value). If there is no previous data in the transmit shift register (XSR), the value from the transmit buffer (XB) is copied to the XSR; otherwise, the content is copied to the XSR when the last bit of the previous data is shifted out on the mcbspi_dx pin.

24.5.4.8.2 Bit Reordering (Option to Transfer LSB First)

Generally, the McBSP module transmits or receives all data with the MSB first. However, some data protocols require the LSB to be transferred first.

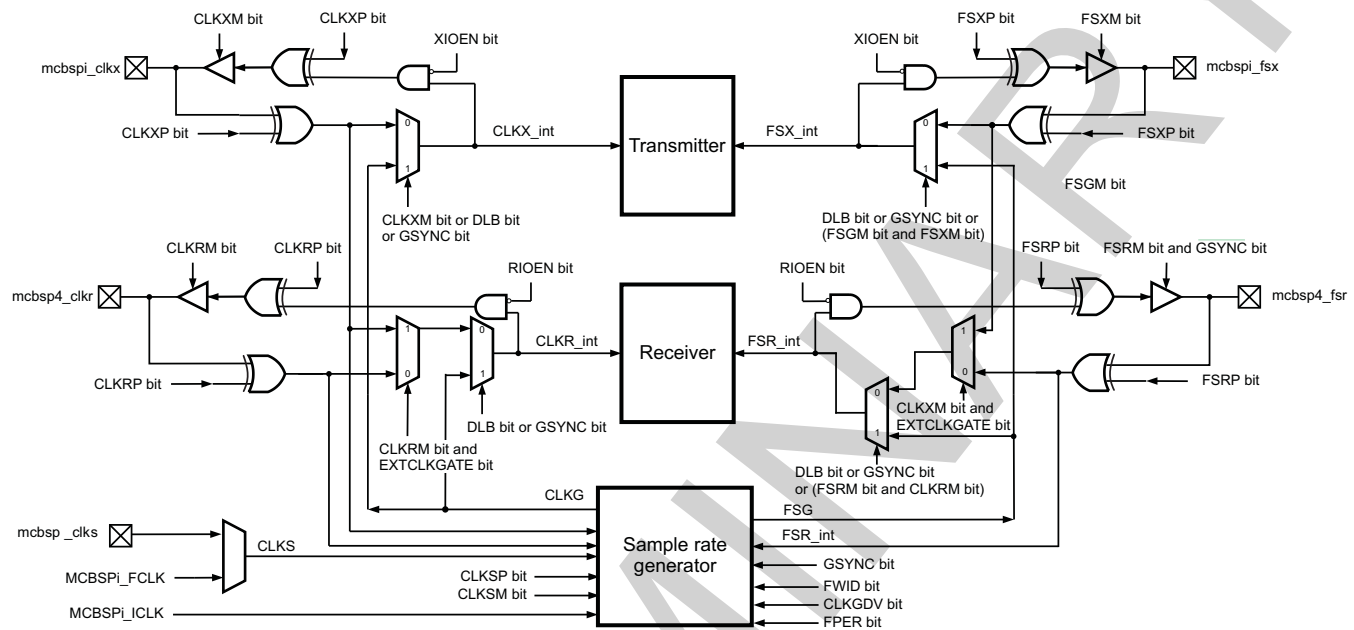

If the McBSPi.MCBSPLP_XCR2_REG[4:3] XREVERSE bit field is set to 0b01, the bit ordering of the data words is reversed (LSB first) before being sent to the serial port. If McBSPi.MCBSPLP_RCR2_REG[4:3] RREVERSE bit field is set to 0b01, the bit ordering of the data words is reversed during reception (LSB first).

This feature is available for all the data formats from 8- to 32-bit data length.

24.5.4.8.3 Clocking and Framing Data

This section explains basic concepts and terminology important for understanding how McBSP data transfers are timed and delimited.

Figure 24-131. Conceptual Block Diagram for Clock and Frame Generation When MCBSP1P_SPCR1_REG[15] ALB = 0

mcbbsp-025

NOTE: For McBSP1, McBSP2, and McBSP3, the mcbspi_clkr pin is connected to the mcbspi_clkx pin, and the mcbspi_fsr pin is connected to the mcbspi_fsx pin.

The CLKR_int clock signal can be derived from three sources:

- The sample rate generator (CLKG): When [MCBSPLP_XCCR_REG\[5\] DLB = 1](#) or [MCBSPLP_SRGR2_REG\[15\] GSYNC = 1](#)
- mcbbsp4_clkr pin (CLKR): When [MCBSPLP_PCR_REG\[9\] CLKXM = 0](#) and [MCBSPLP_XCCR_REG\[15\] EXTCLKGATE = 0](#) and ([MCBSPLP_XCCR_REG\[5\] DLB = 0](#) or [MCBSPLP_SRGR2_REG\[15\] GSYNC = 0](#))
- mcbspi_clkx pin (CLKX) driven by sample rate generator (CLKG): When [MCBSPLP_PCR_REG\[9\] CLKXM = 1](#) and [MCBSPLP_XCCR_REG\[15\] EXTCLKGATE = 1](#) and ([MCBSPLP_XCCR_REG\[5\] DLB = 0](#) or [MCBSPLP_SRGR2_REG\[15\] GSYNC = 0](#))

The CLKX_int clock signal can be derived from two sources:

- The sample rate generator (CLKG): When [MCBSPLP_PCR_REG\[9\] CLKXM = 1](#) or [MCBSPLP_XCCR_REG\[5\] DLB = 1](#) or [MCBSPLP_SRGR2_REG\[15\] GSYNC = 1](#)
- mcbspi_clkx pin (CLKX): When [MCBSPLP_PCR_REG\[9\] CLKXM = 0](#) or [MCBSPLP_XCCR_REG\[5\] DLB = 0](#) or [MCBSPLP_SRGR2_REG\[15\] GSYNC = 0](#)

The FSR_int frame-sync signal can be derived from three sources:

- The sample rate generator (FSG): When [MCBSPLP_XCCR_REG\[5\] DLB = 1](#) or [MCBSPLP_SRGR2_REG\[15\] GSYNC = 1](#) or ([MCBSPLP_PCR_REG\[10\] FSRM = 1](#) and [MCBSPLP_PCR_REG\[8\] CLKRM = 1](#))
- mcbbsp4_fsr pin (FSR): When [MCBSPLP_PCR_REG\[9\] CLKXM = 0](#) and [MCBSPLP_XCCR_REG\[15\] EXTCLKGATE = 0](#) and ([MCBSPLP_XCCR_REG\[5\] DLB = 0](#) or [MCBSPLP_SRGR2_REG\[15\] GSYNC = 0](#) or ([MCBSPLP_PCR_REG\[10\] FSRM = 0](#) and [MCBSPLP_PCR_REG\[8\] CLKRM = 0](#)))
- mcbspi_fsx pin (FSX) driven by sample rate generator (FSG): When [MCBSPLP_PCR_REG\[9\] CLKXM = 1](#) and [MCBSPLP_XCCR_REG\[15\] EXTCLKGATE = 1](#) and ([MCBSPLP_XCCR_REG\[5\] DLB = 0](#) or

MCBSPLP_SRGR2_REG[15] GSYNC = 0 or (MCBSPLP_PCR_REG[10] FSRM = 0 and MCBSP_PCR_REG[8] CLKRM = 0))

The FSX_int frame-sync signal can be derived from two sources:

- The sample rate generator (FSG): When MCBSP_XCCR_REG[5] DLB = 1 or MCBSP_SRGR2_REG[15] GSYNC = 1 or (MCBSPLP_SRGR2_REG[12] FSGM = 1 and MCBSP_PCR_REG[11] FSXM = 1)
- mcbspi_fsx pin (FSX): When MCBSP_XCCR_REG[5] DLB = 0 or MCBSP_SRGR2_REG[15] GSYNC = 0 or (MCBSPLP_SRGR2_REG[12] FSGM = 0 and MCBSP_PCR_REG[11] FSXM = 0)

24.5.4.8.3.1 Clocking

Data is shifted 1 bit at a time from the mcbspi_dr pin to the RSRs or from the XSRs to the mcbspi_dx pin. The time for each bit transfer is controlled by the rising or falling edge of a clock signal.

The receive clock signal (CLKR_int) controls bit transfers from the mcbspi_dr pin to the RSRs. The transmit clock signal (CLKX_int) controls bit transfers from the XSRs to the mcbspi_dx pin. The CLKR_int and CLKX_int signals can be derived from a pin at the boundary of the McBSP module (mcbbsp4_clkr and mcbspi_clkx, respectively) or derived from inside the McBSP module (see Figure 24-131). The clock source is selected by programming the McBSPi.MCBSPLP_PCR_REG[9] CLKXM and McBSPi.MCBSPLP_PCR_REG[8] CLKRM bits, respectively.

When the McBSPi.MCBSPLP_PCR_REG[9] CLKXM bit (transmitter clock mode) is set to:

- 0: CLKX_int is driven by an external clock and mcbspi_clkx is an input pin.
- 1: CLKX_int is driven by the internal SRG and mcbspi_clkx is an output pin.

For the McBSPi.MCBSPLP_PCR_REG[8] CLKRM bit (receiver clock mode), see Table 24-334.

Table 24-334. Receiver Clock Mode

| Value | Digital Loopback Mode | mcbbsp4_clkr Pin | Description |
|-------|------------------------------------|------------------|--|
| 0x0 | McBSPi.MCBSPLP_XCCR_REG[5] DLB = 0 | Input | CLKR_int is driven by an external clock. |
| | McBSPi.MCBSPLP_XCCR_REG[5] DLB = 1 | High -impedance | CLKR_int is driven by CLKX_int. The CLKX_int is derived based on the value of CLKXM. |
| 0x1 | McBSPi.MCBSPLP_XCCR_REG[5] DLB = 0 | Output | CLKR_int is driven by the internal SRG. |
| | McBSPi.MCBSPLP_XCCR_REG[5] DLB = 1 | Output | CLKR_int is driven by CLKX_int. The CLKX_int is derived based on the value of CLKXM. |

The polarities of CLKR and CLKX signals are configured in McBSPi.MCBSPLP_PCR_REG register.

The McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit defines the transmit clock polarity:

- When set to 0, transmit data is driven on the rising edge of the CLKX signal.
- When set to 1, transmit data is driven on the falling edge of the CLKX signal.

The McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit defines the receive clock polarity:

- When set to 0, receive data is sampled on the falling edge of the CLKX signal.
- When set to 1, transmit data sampled on the rising edge of the CLKX signal.

Figure 24-132 shows an example in which the clock signal controls the timing of each bit transfer on the pin.

Figure 24-132. Clock Signal Control of Bit Transfer Timing

NOTE: The McBSP module is constrained to operate at an internal functional frequency of up to L4 interface frequency divided by 2. When driving CLKX or CLKR at the pin, choose an appropriate input clock frequency. When using the internal SRG for CLKX/CLKR/CLKS, choose an appropriate input clock frequency (up to L4 interface frequency) and divide down value by programming the McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV bit field.

24.5.4.8.3.2 Serial Words

Bits traveling between a shift register (RSR or XSR) and a data pin (mcbspi_dr or mcbspi_dx) are transferred in a group called a serial word. Software defines how many bits are in a word by programming:

- For the receiver: The McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 and McBSPi.MCBSPLP_RCR2_REG[7:5] RWDLEN2 bit fields
- For the transmitter: The McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 and McBSPi.MCBSPLP_XCR2_REG[7:5] XWDLEN2 bit fields

The difference of use is explained in [Section 24.5.4.8.4.1, Number of Phases, Words, and Bits per Frame](#).

The various possibilities of word length are 8, 12, 16, 20, 24, and 32 bits (for field values, see [Section 24.5.6, McBSP Register Manual](#))

Bits coming from the mcbspi_dr pin are held in the RSR until it holds a full serial word, and then the word is passed to the RB and the McBSPi.MCBSPLP_DRR_REG register.

During transmission, the XSR accepts new data from the XB after a full serial word has been passed from the XSR to the mcbspi_dx pin.

In the example in [Figure 24-135](#), an 8-bit word size was defined (see the transfer of the 8-bit word B).

24.5.4.8.3.3 Frames and Frame Synchronization

One or more words (up to 128) are transferred in a group called a frame. Software defines how many words are in a frame by programming:

- For the receiver: The McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLLEN1 and McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLLEN2 bit fields
- For the transmitter: The McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLLEN1 and McBSPi.MCBSPLP_XCR2_REG[14:8] XFRLLEN2 bit fields

The difference between these registers is explained in [Section 24.5.4.8.4.1, Number of Phases, Words, and Bits per Frame](#). For the corresponding field values and number of words, see [Section 24.5.6, McBSP Register Manual](#).

All the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The McBSP module uses frame-sync signals (FSG) to determine when each frame is received/transmitted. When a pulse occurs on a frame-sync signal, the McBSP module begins receiving/transmitting a frame of data. When the next pulse occurs, the McBSP module receives/transmits the next frame, and so on.

Pulses on the receive frame-sync (FSR_int) signal initiate frame transfers on mcbspi_dr. Pulses on the transmit frame-sync (FSX_int) signal initiate frame transfers on mcbspi_dx. FSR_int or FSX_int signals can be derived from a pin at the boundary of the McBSP module (mcbbsp4_fsr and mcbbsp4_fsx, respectively) or derived from inside the McBSP module (see [Figure 24-130](#)). The frame-sync source is selected by programming the McBSPi.MCBSPLP_PCR_REG[11] FSXM and McBSPi.MCBSPLP_PCR_REG[10] FSRM bits, respectively.

When the McBSPi.MCBSPLP_PCR_REG[11] FSXM bit (transmitter frame-sync mode) is set to:

- 0: FSX_int is derived from an external source and mcbbsp4_fsx is an input pin.
- 1: FSX_int is determined by the McBSPi.MCBSPLP_SRGR2_REG[12] FSGM bit and mcbbsp4_fsx is an output pin.

For the McBSPi.MCBSPLP_PCR_REG[10] FSRM bit (receiver frame-sync mode), is set to:

- 0: FSR_int is generated by an external source and mcbbsp4_fsr is an input pin.
- 1: FSR_int is generated internally by the SRG. The mcbbsp4_fsr is an output pin except when McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit is set to 0x1.

In the example in [Figure 24-131](#), a one-word frame is transferred when a frame-sync pulse occurs. The polarities of FSR and FSX signals are programmable by bits in the McBSPi.MCBSPLP_PCR_REG register.

The McBSPi.MCBSPLP_PCR_REG[3] FSXP bit defines the transmit frame-sync polarity:

- When set to 0, frame-sync pulse FSX is active high.
- When set to 1, frame-sync pulse FSX is active low.

The McBSPi.MCBSPLP_PCR_REG[2] FSRP bit defines the receive frame-sync polarity:

- When set to 0, frame-sync pulse FSR is active high.
- When set to 1, frame-sync pulse FSR is active low.

In McBSP operation, the inactive-to-active transition of the frame-sync signal indicates the start of the next frame. For this reason, the frame-sync signal may be high for an arbitrary number of clock cycles. Only after the signal is recognized to have gone inactive, and then active again, does the next frame synchronization occur.

24.5.4.8.3.4 Detecting Frame-Sync Pulses, Even in Reset State

The McBSP module can generate receive and transmit interrupts to the Cortex-A9 MPU/DSP subsystems to indicate specific events in the McBSP module. To facilitate detection of frame synchronization, these interrupts can be sent in response to frame-sync pulses (see [Section 24.5.5, McBSP Basic Programming Model](#) for more information).

Unlike other serial port interrupt modes, this mode can operate while the associated portion of the serial port is in reset (such as activating receive interrupt when the receiver is in reset). In this case, the McBSPi.MCBSPLP_PCR_REG[0] FSRM/McBSPi.MCBSPLP_PCR_REG[1] FSXM bit and the McBSPi.MCBSPLP_PCR_REG[2] FSRP/McBSPi.MCBSPLP_PCR_REG[3] FSXP bit still selects the appropriate source and polarity of frame synchronization. Thus, even when the serial port is in reset state, these signals are synchronized to the interface clock (MCBSPi_ICLK) and then sent to the Cortex-A9 MPU/DSP subsystem in the form of receive interrupt and transmit interrupt at the point where they feed the receiver and transmitter of the serial port. Consequently, a new frame-sync pulse can be detected, and then the Cortex-A9 MPU/DSP subsystem can take the serial port out of reset safely.

24.5.4.8.3.5 Ignoring Frame-Sync Pulses

The McBSP module ignores transmit and/or receive frame-sync pulses if the frame transfer was started by a previous frame-sync pulse (unexpected frame-sync pulses). The McBSP module does not support features such as retransmit or re-receive of an erroneous frame or word. The receiver or transmitter ignores frame-sync pulses until the desired frame length or number of words is reached. For more information about unexpected frame-sync pulses, see [Section 24.5.4.10.3, Unexpected Receive Frame-Sync Pulse](#), or [Section 24.5.4.10.6, Unexpected Transmit Frame-Sync Pulse](#).

24.5.4.8.3.6 Frame Frequency

The frame frequency is determined by the period between frame-sync pulses and is defined as shown in the following equation:

Frame frequency = Clock frequency / (number of clock cycles between two rising edges [or falling edges] of two consecutive frame-sync pulses)

The frame frequency can be increased by decreasing the time between frame-sync pulses (limited only by the number of bits per frame). As the frame transmit frequency increases, the inactivity period between the data packets for adjacent transfers decreases to zero.

24.5.4.8.3.7 Maximum Frame Frequency

The minimum number of clock cycles between frame-sync pulses is equal to the number of bits transferred per frame. The maximum frame frequency is defined as shown in the following equation:

Maximum frame frequency = Clock frequency / number of bits per frame

Figure 24-133 shows the McBSP operating at maximum packet frequency. At maximum packet frequency, the data bits in consecutive packets are transmitted contiguously with no inactivity between bits.

Figure 24-133. McBSP Operating at Maximum Packet Frequency

mcbasp-027

If there is a 1-bit data delay as shown in Figure 24-133, the frame-sync pulse overlaps the last bit transmitted in the previous frame. Effectively, this permits a continuous stream of data, back-to-back transfers.

NOTE: When the McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY bit field is set to 0x0 (0-bit data delay), the first bit of data is transmitted asynchronously to the internal transmit clock signal (CLKX_int). For more information, see Table 24-384.

24.5.4.8.4 Frame Phases (Dual-Phase Frame I2S Support)

The McBSP module allows configuration of each frame to contain one or two phases. The support for dual-phase frames is required to provide I2S fully compliant capabilities (audio left and right channels—stereo audio stream).

CAUTION

The limitation on dual-phase frame support is that the number of words per phase must be set to 1 for both first and second phases. It is the only possible value for word per frame when using the dual-phase frame.

The number of bits per word can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers. For example, a user may define a frame as consisting of one phase containing one 16-bit word, followed by a second phase consisting of one 32-bit word. This configuration allows the user to compose frames for custom applications such as I2S protocol.

24.5.4.8.4.1 Number of Phases, Words, and Bits per Frame

Table 24-335 shows which bit fields in the receive control registers (McBSPi.MCBSPLP_RCR1_REG and McBSPi.MCBSPLP_RCR2_REG) and in the transmit control registers (McBSPi.MCBSPLP_XCR1_REG and McBSPi.MCBSPLP_XCR2_REG) determine the number of phases per frame, the number of words per frame, and the number of bits per word for each phase, for both receiver and transmitter. The maximum number of words per frame is limited to 2 when using dual-phase frames (one word for each phase), and to 128 for a single-phase frame. The number of bits per word can be 8, 12, 16, 20, 24, or 32 bits.

The following legend applies to Table 24-335:

- RPHASE = McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit
- XPHASE = McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit
- RFRLEN1 = McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1 bit field
- RFRLEN2 = McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLEN2 bit field
- XFRLEN1 = McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 bit field
- XFRLEN2 = McBSPi.MCBSPLP_XCR2_REG[14:8] XFRLEN2 bit field
- RWDLEN1 = McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 bit field
- RWDLEN2 = McBSPi.MCBSPLP_RCR2_REG[7:5] RWDLEN2 bit field

Table 24-335. Phases, Words and Bits per Frame Control Bit

| Operation | Number of Phases | Words per Frame Set With | Bits per Word Set With |
|--------------|------------------|---------------------------------|---|
| Reception | 1 (RPHASE = 0) | RFRLEN1 | RWDLEN1 |
| Reception | 2 (RPHASE = 1) | RFRLEN1 = 0x0 and RFRLEN2 = 0x0 | RWDLEN1 for phase 1 RWDLEN2 for phase 2 |
| Transmission | 1 (XPHASE = 0) | XFRLEN1 | XWDLEN1 |
| Transmission | 2 (XPHASE = 1) | XFRLEN1 = 0x0 and XFRLEN2 = 0x0 | XWDLEN1 for phase 1 XWDLEN2 for phase 2 |

24.5.4.8.4.2 Single-Phase Frame Example

Figure 24-134 shows an example of a single-phase data frame containing one 8-bit word. Because the transfer is configured for one data bit delay, the data on the mcbspi_dx and mcbspi_dr pins are available one clock cycle after FS(R/X) goes active. Table 24-336 lists the assumptions used in the example in Figure 24-134.

Table 24-336. Assumptions for the Single-Phase Frame Example

| Assumption | Value | Bit or Field Name |
|--------------------------------------|---------|---------------------------------------|
| Single-phase frame | 0 | McBSPi.MCBSPLP_RCR2_REG[15] RPHASE |
| | | McBSPi.MCBSPLP_XCR2_REG[15] XPHASE |
| One word per frame | 0x0 | McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1 |
| | | McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 |
| 8-bit word length | 0x0 | McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 |
| | | McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 |
| Word length in register2 | Ignored | McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLEN2 |
| | | McBSPi.MCBSPLP_XCR2_REG[14:8] XWDLEN2 |
| Receive data clocked on falling edge | 0 | McBSPi.MCBSPLP_PCR_REG[0] CLKRP |
| Transmit data clocked on rising edge | | McBSPi.MCBSPLP_PCR_REG[1] CLKXP |
| Active-high frame-sync signals | 0 | McBSPi.MCBSPLP_PCR_REG[2] FSRP |
| | | McBSPi.MCBSPLP_PCR_REG[3] FSXP |
| 1-bit data delay | 01b | McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY |
| | | McBSPi.MCBSPLP_XCR2_REG[1:0] XDARDLY |

Figure 24-134. Single-Phase Frame for a McBSP Data Transfer**24.5.4.8.4.3 Dual-Phase Frame Example**

Figure 24-135 shows an example of a frame. The first phase consists of one word of 16 bits, followed by a second phase of one word of 8 bits. The entire bitstream in the frame is contiguous. There are no gaps between words/phases. Table 24-337 lists the assumptions used in the example in Figure 24-135.

Table 24-337. Assumptions for the Dual-Phase Frame Example

| Assumption | Value | Bit or Field Name |
|--------------------------------------|-------|---------------------------------------|
| Single-phase frame | 1 | McBSPi.MCBSPLP_RCR2_REG[15] RPHASE |
| | | McBSPi.MCBSPLP_XCR2_REG[15] XPHASE |
| One word per frame | 0x0 | McBSPi.MCBSPLP_RCR1_REG[14:8] RFLEN1 |
| | | McBSPi.MCBSPLP_XCR1_REG[14:8] XFLEN1 |
| 16-bit word length | 0x0 | McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 |
| | | McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 |
| 8-bit word length | 0x2 | McBSPi.MCBSPLP_RCR2_REG[14:8] RFLEN2 |
| | | McBSPi.MCBSPLP_XCR2_REG[14:8] XWDLEN2 |
| Receive data clocked on falling edge | 0 | McBSPi.MCBSPLP_PCR_REG[0] CLKRP |
| Transmit data clocked on rising edge | | McBSPi.MCBSPLP_PCR_REG[1] CLKXP |
| Active-high frame-sync signals | 0 | McBSPi.MCBSPLP_PCR_REG[2] FSRP |
| | | McBSPi.MCBSPLP_PCR_REG[3] FSXP |
| 0-bit data delay | 00b | McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY |
| | | McBSPi.MCBSPLP_XCR2_REG[1:0] XDARDLY |

Figure 24-135. Dual-Phase Frame for a McBSP Data Transfer**24.5.4.8.5 McBSP Reception**

This section explains the fundamental process of reception in the McBSP module. For information about how to program the McBSP receiver, see Section 24.5.5, *McBSP Basic Programming Model*, Section 24.5.5.4, *Interrupt Configuration*, and Section 24.5.5.5, *Receiver Configuration*.

Figure 24-136 and Figure 24-137 show how reception occurs in the McBSP module. A description of the process follows the figures. Figure 24-136 shows the physical path for the data.

Figure 24-136. McBSP Reception Physical Data Path

mcbbsp-030

Figure 24-137 is a timing diagram showing signal activity for one possible reception scenario.

Figure 24-137. McBSP Reception Signal Activity

RRDY: Status of receiver ready bit (high is 1)

mcbbsp-031

The following process describes how data travels from the mcbspi_dr pin to the MPU/DSP subsystem or to the sDMA controller:

1. The McBSP module waits for a receive frame-sync pulse on FSR_int.
2. When the pulse arrives, the McBSP module inserts the appropriate data delay that is selected with the McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY bit field. In the preceding timing diagram a 1-bit data delay is selected.
3. The McBSP module accepts data bits on the mcbspi_dr pin and shifts them into the RSR. For information about choosing a word length, see [Section 24.5.5.6, Transmitter Configuration](#).
4. When a full word is received, the McBSP module copies the contents of the RSR to the RB, provided that RB is not full.
5. When the programmed receive threshold is reached (McBSPi.MCBSPLP_THRSH1_REG[6:0] RTHRESHOLD bit field), the McBSP module asserts the receiver ready bit (McBSPi.MCBSPLP_SPCR1_REG[1] RRDY). This indicates that receive data is ready to be read by the Cortex-A9 MPU/DSP subsystem or the sDMA controller by accessing the McBSPi.MCBSPLP_DRR_REG register.
The data copied from RB to McBSPi.MCBSPLP_DRR_REG is justified and bit-filled according to the McBSPi.MCBSPLP_SPCR1_REG[14:13] RJUST bit field.
6. The Cortex-A9 MPU/DSP subsystem or the sDMA controller reads the data from the data receive register. When the RB is empty, the McBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit is cleared.

24.5.4.8.6 McBSP Transmission

This section explains the fundamental process of transmission in the McBSP module. For information about how to program the McBSP transmitter, see [Section 24.5.5, McBSP Basic Programming Model](#) and [Section 24.5.5.6, Transmitter Configuration](#).

Figure 24-138 and Figure 24-139 show how transmission occurs in the McBSP module. A description of the process follows the figures. Figure 24-138 shows the physical path for the data.

Figure 24-138. McBSP Transmission Physical Data Path

Figure 24-139 is a timing diagram showing signal activity for one possible transmission scenario.

Figure 24-139. McBSP Transmission Signal Activity

1. The Cortex-A9 MPU/DSP subsystem or the sDMA controller writes data to the data transmit register (McBSPi.MCBSPLP_DXR_REG). When the XB is reached the transmitter ready bit (McBSPi.MCBSPLP_SPCR2_REG[1] XRDY) is cleared to indicate that the transmitter is not ready for new data. For information about choosing a word length, see [Table 24-380](#).
2. When new data arrives in the McBSPi.MCBSPLP_DXR_REG register, the McBSP module copies the content of the data transmit register to the XB. In addition, the transmit ready bit (McBSPi.MCBSPLP_SPCR2_REG[1] XRDY) is set as long as the buffer contains at least the transmit threshold number of free locations (the McBSPi.MCBSPLP_THRSH2_REG[6:0] XTHRESHOLD bit field). This indicates that the transmitter is ready to accept new data from the MPU/DSP subsystem or the sDMA controller.
3. The McBSP module waits for a transmit frame-sync pulse on FSX_int.
4. When the pulse arrives, the McBSP module inserts the appropriate data delay that is selected with the McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY bit field.
In the preceding timing diagram, a 1-bit data delay is selected.
5. The McBSP module shifts data bits from the XSR to the mcbspi_dx pin.

24.5.4.8.7 Enable/Disable the Transmit and Receive Processes

The McBSP module has the option to stop and resume the transmit/receive process while the module is in functional mode (out of transmit/receive reset).

When the transmit/receive disable bit (McBSPi.MCBSPLP_XCCR_REG[0] XDISABLE/McBSPi.MCBSPLP_RCCR_REG[0] RDISABLE) is set, the McBSP module stops the transmit/receive operation at the next frame boundary (frame corruption avoided).

During the receive disable state, the frames that are sent (when the FSR signal is asserted while receive disable) by the remote device are lost, and the receive buffer overflow status bit (McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT) is not set. Also, the frames received by the remote device while the McBSPi.MCBSPLP_XCCR_REG[0] XDISABLE bit is set (when the FSX signal is asserted while transmit disable) are meaningless undefined data frames, and transmit buffer underflow status bit (McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT) is not set. The presence of the frame synchronization while transmit/receive process is disabled can be checked by reading the transmit/receive frame-sync interrupt status: McBSPi.MCBSPLP_IRQSTATUS_REG[8] XFSX/McBSPi.MCBSPLP_IRQSTATUS_REG[1] RFSR bits.

As soon as the McBSPi.MCBSPLP_XCCR_REG[0] XDISABLE/McBSPi.MCBSPLP_RCCR_REG[0] RDISABLE bit is cleared, the transmit/receive process resumes at the next frame boundary.

NOTE: It is not recommended to use this mechanism together with the possibility to interrogate the transmit/receive buffer status register (McBSPi.MCBSPLP_XBUFFSTAT_REG[7:0] XBUFFSTAT/McBSPi.MCBSPLP_RBUFFSTAT_REG[7:0] RBUFFSTAT bit field indicating the occupied/available buffer locations), because this register is an interface clock (McBSPi_ICLK) synchronous register and does not reflect the exact number of occupied/free locations available in the functional clock domain.

24.5.4.8.8 MCBSP Data Transfer Mode

NOTE: For all examples in this section, the configured CLKX edge is the rising edge (McBSPi.MCBSPLP_PCR_REG[1] CLKXP = 0x0) and the configured CLKR edge is the falling edge (McBSPi.MCBSPLP_PCR_REG[0] CLKRP = 0x0). These are the reset values.

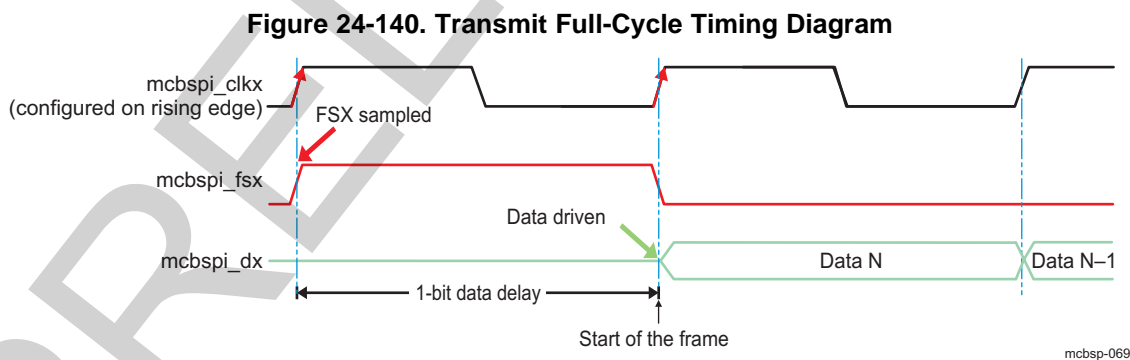

In the following timing diagrams, a 1-bit data delay is selected (McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY = 0x01 and McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY = 0x01), because data often follows a 1-cycle active frame-synchronization.

McBSP modules can support two edge selection modes for transmit and receive data transfer at the system level:

- The full-cycle mode, for which one clock period is used to transfer the data, generated on one edge and captured on the same edge (one clock period later)
- The half-cycle mode, for which one-half clock period is used to transfer the data, generated on one edge and captured on the opposite edge (one-half clock period later). New data are generated only every clock period, which ensures the required hold time.

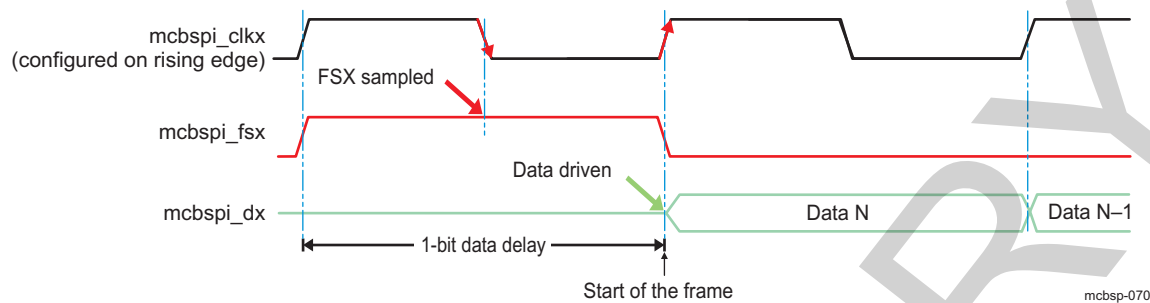

24.5.4.8.8.1 Transmit Full-Cycle Mode

When configured in full-cycle mode (McBSPi.MCBSPLP_XCCR_REG[11] XFULL_CYCLE = 0x1), the FSX signal is sampled on the configured CLKX edge and the data is driven on the same configured edge. See Figure 24-140.

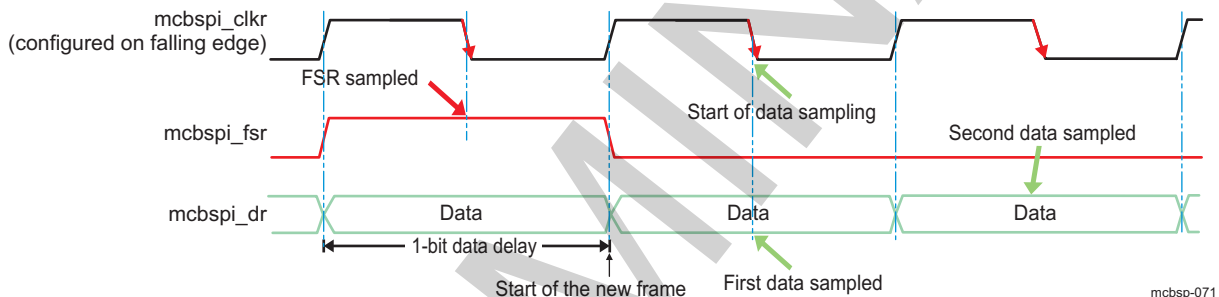

24.5.4.8.8.2 Transmit Half-Cycle Mode

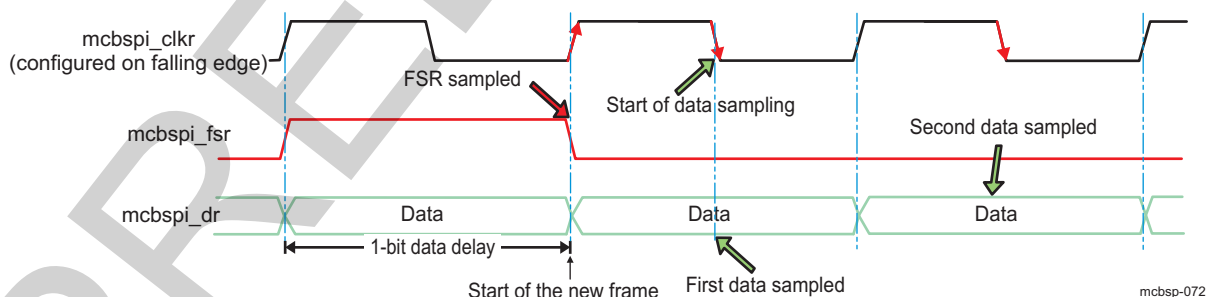

When configured in half-cycle mode (McBSPi.MCBSPLP_XCCR_REG[11] XFULL_CYCLE = 0x0, reset value), the FSX signal is sampled on the opposite configured CLKX edge and the data is driven on the next configured edge. See Figure 24-141.

Figure 24-141. Transmit Half-Cycle Timing Diagram**24.5.4.8.8.3 Receive Full-Cycle Mode**

When configured in full-cycle mode (McBSPi.MCBSPLP_RCCR_REG[11] RFULL_CYCLE = 0x1, reset value), the FSR signal is sampled on the configured CLKR edge and the data is driven on the same configured edge. See [Figure 24-142](#).

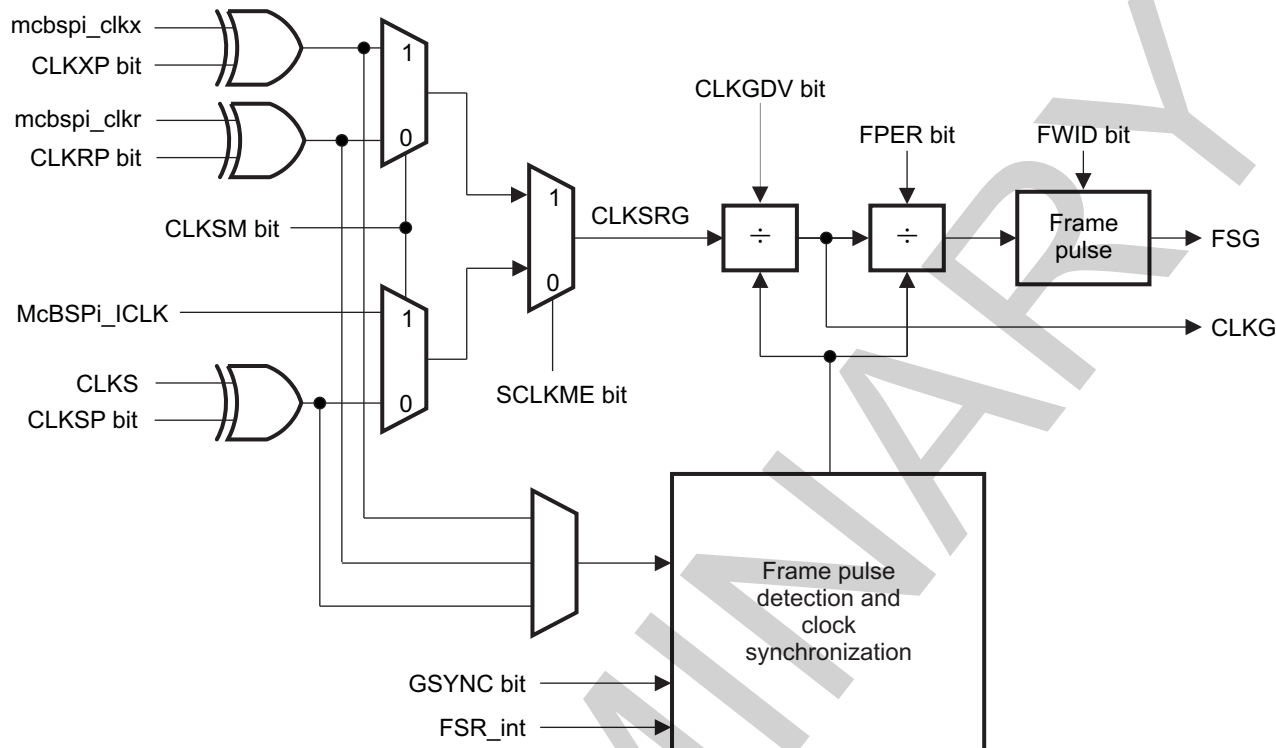

Figure 24-142. Receive Full-Cycle Timing Diagram**24.5.4.8.8.4 Receive Half-Cycle Mode**

When configured in half-cycle mode (McBSPi.MCBSPLP_RCCR_REG[11] RFULL_CYCLE = 0x0), the FSR signal is sampled on the opposite configured CLKR edge and the data is driven on the next configured edge. See [Figure 24-143](#).

Figure 24-143. Receive Half-Cycle Timing Diagram**24.5.4.9 McBSP SRG**

The McBSP module contains an internal SRG that can be used to generate an internal data clock (CLKG) and an internal frame-sync signal (FSG). CLKG can be used for bit shifting on the data receive pin (mcbspi_dr) and/or the data transmit pin (mcbspi_dx). FSG can be used to initiate frame transfers on the mcbspi_dr pin and/or mcbspi_dx pin. [Figure 24-144](#) is a conceptual block diagram of the SRG.

Figure 24-144. Conceptual Block Diagram of the SRG

mcbasp-034

The source clock for the SRG (labeled CLKS_{RG} in the diagram) can be supplied by the interface clock (McBSPi_ICLK) or the functional clock (CLKS input), or by an external pin (mcbspi_clkx or mcbasp4_clkr). The source is selected with the McBSPi.MCBSPLP_PCR_REG[7] SCLKME bit and the McBSPi.MCBSPLP_SRGR2_REG[13] CLKSM bit.

If a pin or CLKS signal is used, the polarity of the incoming signal can be inverted with the appropriate polarity bit (McBSPi.MCBSPLP_SRGR2_REG[14] CLKSP, McBSPi.MCBSPLP_PCR_REG[1] CLKXP, or McBSPi.MCBSPLP_PCR_REG[0] CLKRP).

The SRG has a 3-stage clock divider that gives CLKG and FSG programmability.

The three stages provide:

- Clock divide-down: The source clock (CLKS_{RG}) is divided according to the McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV bit field to produce the CLKG signal.
- Frame period divide-down: CLKG is divided according to the McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER bit field to control the period from the start of a frame-pulse to the start of the next pulse.
- Frame-sync pulse-width countdown: CLKG cycles are counted according to the McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID bit field to control the width of each frame-sync pulse.

NOTE: The McBSP module cannot operate at an internal functional frequency faster than L4 interface frequency divided by 2. Choose an input clock frequency and a McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV value such that CLKG is less than or equal to L4 interface frequency divided by 2.

In addition to the 3-stage clock divider, the SRG has a frame-sync pulse detection and clock synchronization module that allows synchronization of the clock divide-down with an incoming frame-sync pulse on the mcbasp4_fsr pin. This feature is enabled or disabled with the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit.

CLKG is used as source to generate the output clocks CLKX and CLKR when the McBSPi.MCBSPLP_PCR_REG[9] CLKXM/McBSPi.MCBSPLP_PCR_REG[8] CLKRM bit indicates that the clock is an output. The output CLKX/CLKR is generated according to the clock polarity setting (see [Figure 24-131](#)).

For information about preparing the SRG for operation, see [Section 24.5.5, McBSP Basic Programming Model](#).

24.5.4.9.1 Clock Generation in the SRG

The SRG can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both. Use of the SRG to drive clocking is controlled by the clock mode bits (McBSPi.MCBSPLP_PCR_REG[9] CLKXM and McBSPi.MCBSPLP_PCR_REG[8] CLKRM) and polarity mode bits (McBSPi.MCBSPLP_PCR_REG[1] CLKXP and McBSPi.MCBSPLP_PCR_REG[0] CLKRP).

When a clock mode bit is set to 1 (CLKRM = 1 for reception, CLKXM = 1 for transmission), the corresponding data clock (CLKR for reception, CLKX for transmission) is driven by the internal SRG output clock (CLKG) according to the polarity setting.

The effects of this setting on the McBSP module are partially affected by use of the digital loopback (DLB) mode, the analog loopback (ALB) mode, and by the synchronous receive/transmit setting, respectively, as described in [Table 24-338](#). ALB mode is selected with the McBSPi.MCBSPLP_SPCR1_REG[15] ALB bit. DLB mode is selected with the McBSPi.MCBSPLP_XCCR_REG[5] DLB bit. The synchronous setting is controlled by input signals. These signals are defined by the control registers of the control module (for more information, see [Chapter 19, Control Module](#)).

When using the SRG as a clock source, ensure that the SRG is enabled (the McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit is set to 1).

Table 24-338. Effects of DLB and ALB Bits on Clock Modes

| Mode Bit Settings | | Effect |
|-------------------|---|--|
| CLKRM=1 | DLB = 0 and ALB = 0 (Digital and analog loopback mode disabled) | mcbasp1_clkr is an output pin driven by the SRG output clock (CLKG). |
| | DLB = 0 and ALB = 1 (Digital loopback mode disabled and analog loopback mode enabled) | <p>mcbasp1_clkr is an output pin driven by the SRG output clock (CLKG).</p> <p>The receiver functional part internal clock is driven by the CLKX input signal provided by the mcbasp1_clkx pin. The source of CLKX depends on the CLKXM bit.</p> <p>The receive frame synchronization is driven by the FSX input signal provided by the mcbasp1_fsx pin.</p> <p>The receive data is driven by the DX input loopback pin (mcbasp1_dx).</p> |
| | DLB = 1 and ALB = 0 (Digital loopback mode enabled and analog loopback mode disabled) | <p>The SRG and the frame-sync generator must be enabled.</p> <p>The internal transmit and receive clocks are driven by the SRG (CLKG having the appropriate CLKXP polarity).</p> <p>The transmit and receive frame-sync signals are driven by the FSG (having the appropriate FSXP polarity).</p> <p>The transmit data is connected to the DR input data.</p> <p>In digital loopback mode, no serial link activity is seen by the remote device.</p> |
| | DLB = 1 and ALB = 1 (Reserved mode) | Undefined functionality. |

Table 24-338. Effects of DLB and ALB Bits on Clock Modes (continued)

| Mode Bit Settings | | Effect |
|-------------------|---|--|
| CLKXM=1 | DLB = 0 and ALB = 0 (Digital and analog loopback mode disabled) | mcbspi_clkx is an output pin driven by the SRG output clock (CLKG). |
| | DLB = 0 and ALB = 1 (Digital loopback mode disabled and analog loopback mode enabled) | mcbspi_clkx is an output pin driven by the SRG output clock (CLKG). |
| | DLB = 1 and ALB = 0 (Digital loopback mode enabled and analog loopback mode disabled) | <p>The SRG and the frame-sync generator must be enabled.</p> <p>The internal transmit and receive clocks are driven by the SRG (CLKG having the appropriate CLKXP polarity).</p> <p>The transmit and receive frame-sync signals are driven by the FSG (having the appropriate FSXP polarity).</p> <p>The transmit data is connected to the DR input data.</p> <p>In digital loopback mode, no serial link activity is seen by the remote device.</p> |
| | DLB = 1 and ALB = 1 (Reserved mode) | Undefined functionality |
| | CONTROL_MCBSPPLP[30] ALBCTRLRX_CLKX bit = 1 (synchronous setting and DLB = 0 and ALB = 0) | CLKX is an output pin driven by the SRG output clock (CLKG). CLKR is connected to the CLKX. |

24.5.4.9.2 Frame-Sync Generation in the SRG

The SRG can produce a frame-sync signal (FSG) for use by the receiver, the transmitter, or both.

For the receiver to use FSG for frame synchronization, make sure the McBSPi.MCBSPPLP_PCR_REG[10] FSRM bit is set to 1. (When FSRM is set to 0, receive frame synchronization is supplied through the mcbbsp4_fsr pin.)

For the transmitter to use FSG for frame synchronization, the following bits must be set:

- McBSPi.MCBSPPLP_PCR_REG[11] FSXM = 1: This indicates that transmit frame synchronization is supplied by the McBSP module rather than from the mcbspi_fsx pin.
- McBSPi.MCBSPPLP_SRGR2_REG[12] FSGM = 1: This indicates that when FSXM is set to 1, transmit frame synchronization is supplied by the SRG.

NOTE: When FSGM = 0 and FSXM = 1, the transmit frame-sync signal (FSX) is generated when XB is not empty. When FSGM = 0, the McBSPi.MCBSPPLP_SRGR2_REG[11:0] FPER and McBSPi.MCBSPPLP_SRGR1_REG[15:8] FWID bit fields are used to determine the frame-sync period and width (external FSX is gated by the buffer empty condition).

In either case, the SRG must be enabled (the McBSPi.MCBSPPLP_SPCR2_REG[6] GRST bit is set to 1) and the frame-sync logic in the SRG must be enabled (the McBSPi.MCBSPPLP_SPCR2_REG[7] FRST bit is set to 0).

24.5.4.9.2.1 Choosing the Width of the Frame-Sync Pulse

Each pulse on FSG has a programmable width. Program the McBSPi.MCBSPPLP_SRGR1_REG[15:8] FWID bit field, and the resulting pulse width is (FWID + 1) CLKG cycles, where CLKG is the output clock of the SRG. The range is from 1 to 256 clock periods.

24.5.4.9.2.2 Controlling the Period Between the Starting Edges of Frame-Sync Pulses

The user can control the amount of time from the starting edge of one FSG pulse to the starting edge of the next FSG pulse. This period is controlled in one of two ways, depending on the configuration of the SRG:

- If the SRG is using an external input clock and the cBSPi.MCBSPPLP_SRGR2_REG[15] GSYNC bit is set to 1, FSG pulses in response to an inactive-to-active transition on the mcbbsp4_fsr pin. Thus, an external device controls the frame-sync period.

- Otherwise, software programs the McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER bit field, and the resulting frame-sync period is (FPER + 1) CLKG cycles, where CLKG is the output clock of the SRG. The range is from 1 to 4096 clock periods.

24.5.4.9.2.3 Keeping FSG Synchronized to an External Clock

When an external signal is selected to drive the SRG, the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit and the mcbbsp4_fsr pin can be used to configure the timing of FSG pulses.

Setting the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit to 1 ensures that the McBSP module and an external device are dividing down the input clock with the same phase relationship.

If the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit is set to 1, an inactive-to-active transition on the mcbbsp4_fsr pin triggers a resynchronization of CLKG and generation of FSG.

24.5.4.9.3 Synchronizing SRG Outputs to an External Clock

The SRG can produce a clock signal (CLKG) and an FSG based on an input clock signal that is either:

- The interface clock signal (McBSPi_ICLK)
- The CLKS signal (PRCM functional clock or abe_clks)
- A signal at the mcbbsp4_clkr
- The mcbspi_clkx pin

When an external clock (abe_clks, mcbbsp4_clkr, or mcbspi_clkx) is selected to drive the SRG, the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit and the mcbbsp4_fsr pin can be used to control the timing of CLKG and the pulsing of FSG relative to the chosen input clock. Set the GSYNC bit to 1 so that the McBSP module and an external device divide-down the input clock with the same phase relationship.

If the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit is set to 1:

- An inactive-to-active transition on the mcbbsp4_fsr pin triggers a resynchronization of the CLKG signal and a pulsing of the FSG signal.
- The CLKG signal always begins with a high state after synchronization.
- The FSR signal is always detected at the same edge of the input clock signal that generates the CLKG signal, no matter how long the FSR pulse is.
- The McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER bit field is ignored because the frame-sync period on FSG is determined by the arrival of the next frame-sync pulse on the mcbbsp4_fsr pin.

If the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit is set to 0, the CLKG signal runs freely and is not resynchronized, and the frame-sync period on the FSG signal is determined by the McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER bit field.

24.5.4.9.3.1 Operating the Transmitter Synchronously With the Receiver

When the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit is set to 1, the transmitter can operate synchronously with the receiver, provided that the FSX signal is programmed to be driven by the FSG signal (McBSPi.MCBSPLP_SRGR2_REG[12] FSGM = 1 and McBSPi.MCBSPLP_PCR_REG[11] FSXM = 1). If the FSR input signal has appropriate timing so that it can be sampled by the falling edge of the CLKG signal, it can be used, instead, by setting the McBSPi.MCBSPLP_PCR_REG[11] FSXM bit to 0 and connecting the FSR signal to FSX externally.

The SRG clock drives the transmit and receive clocking (the McBSPi.MCBSPLP_PCR_REG[8] CLKRM and McBSPi.MCBSPLP_PCR_REG[9] CLKXM bits are set to 1). Therefore, the CLK(R/X) pin must not be driven by any other driving source.

24.5.4.9.3.2 Synchronization Examples

Figure 24-145 and Figure 24-146 show the clock and frame-sync operation with various polarities of CLKS (the chosen input clock) and FSR signals. These figures assume McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID = 0x0, for an FSG pulse that is one CLKG cycle wide. The McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER bit field is not programmed; the period from the start of a frame-sync pulse to the start of the next pulse is determined by the arrival of the next inactive-to-active transition on the mcbbsp4_fsr pin.

Both figures show what happens to the CLKG signal when the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit is set to 1 and if it is initially synchronized or not initially synchronized. Figure 24-146 has a slower CLKG frequency (it has a larger divide-down value in the McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV bit field).

Figure 24-145. CLKG Synchronization and FSG Generation (GSYNC = 1 and CLKGDV = 0x1)

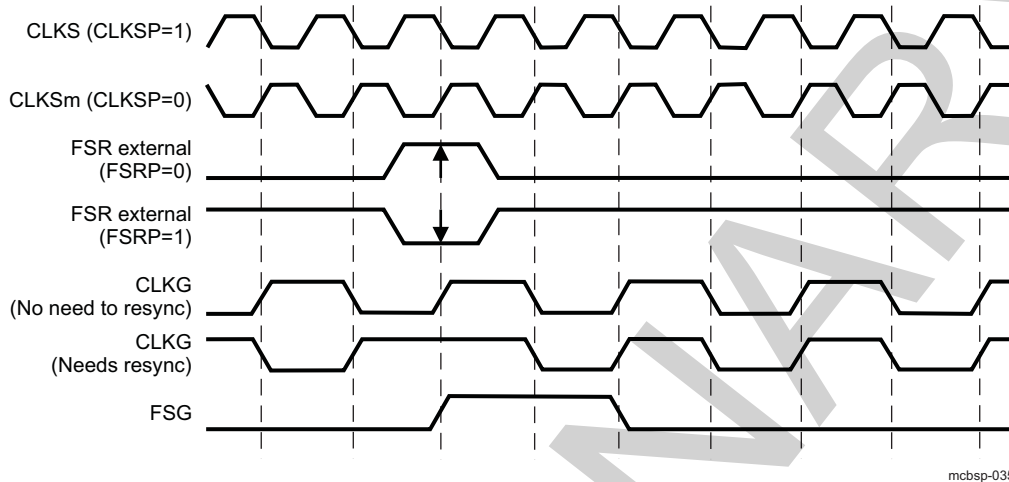

Figure 24-146. CLKG Synchronization and FSG Generation (GSYNC = 1 and CLKGDV = 0x3)

24.5.4.10 McBSP Exception/Error Conditions

24.5.4.10.1 Introduction

Several serial port events can constitute a system error. Any error condition can be a source of an interrupt:

- Receiver overrun (the McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT bit is set to 1, and the legacy mode McBSPi.MCBSPLP_SPCR1_REG[2] RFULL bit is set to 1)

This occurs when the RB is full and the RSR is full with another new word shifted in from *mcbspi_dr*. Therefore, the McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT bit (McBSPi.MCBSPLP_SPCR1_REG[2] RFULL) indicates an error condition wherein any new data that can arrive at this time on *mcbspi_dr* replaces the contents of the RSR, and the previous word is lost. The RSR continues to be overwritten as long as new data arrives on *mcbspi_dr* and the McBSPi.MCBSPLP_DRR_REG register is not read. For more information about overrun in the receiver, see Section 24.5.4.10.2, *Overrun in the Receiver*.

- Unexpected receive frame-sync pulse (the McBSPi.MCBSPLP_IRQSTATUS_REG[0] RSYNCERR bit is set to 1, and the legacy mode McBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR bit is set to 1)
This occurs during reception when an unexpected frame-sync pulse arrives. An unexpected frame-sync pulse is one that is supposed to begin the next frame transfer before all the bits of the current frame are received. Such a pulse is ignored by the receiver, but sets the McBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR bit. For more information about receive frame-sync errors, see [Section 24.5.4.10.3, Unexpected Receive Frame-Sync Pulse](#).
- Receiver underflow (the McBSPi.MCBSPLP_IRQSTATUS_REG[4] RUNDFLSTAT bit is set to 1)
This occurs when the sDMA controller or MPU/DSP subsystem reads data from an empty receive buffer. For more information about underflow in the receiver, see [Section 24.5.4.10.4, Underflow in the Receiver](#).
- Transmitter underflow (the McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT bit is set to 1, and the legacy mode McBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY bit is set to 0)
If a new frame-sync signal arrives when the XB is empty, the previous data in the XSR is re-sent. This procedure continues for every new frame-sync pulse that arrives until the McBSPi.MCBSPLP_DXR_REG register is loaded with new data (and the XB is no longer empty). For more information about underflow in the transmitter, see [Section 24.5.4.10.5, Underflow in the Transmitter](#).
- Unexpected transmit frame-sync pulse (the McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR bit is set to 1, and the legacy mode McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR bit is set to 1)
This occurs during transmission when an unexpected frame-sync pulse arrives. An unexpected frame-sync pulse is one that is supposed to begin the next frame transfer before all the bits of the current frame are transferred. Such a pulse is ignored by the transmitter, but sets the McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR bit. For more information, see [Section 24.5.4.10.6, Unexpected Transmit Frame-Sync Pulse](#).
- Transmitter overflow (the McBSPi.MCBSPLP_IRQSTATUS_REG[12] XOVLSTAT bit is set to 1)
This occurs when the sDMA controller or MPU/DSP subsystem writes data to a full XB. For more information about overflow in the transmitter, see [Section 24.5.4.10.7, Overflow in the Transmitter](#).

24.5.4.10.2 Overrun in the Receiver

When the McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVLSTAT bit is set to 1, and the McBSPi.MCBSPLP_SPCR1_REG[2] RFULL bit is set to 1 (legacy mode) indicates that the receiver has experienced overrun and is in an error condition. Receive overrun is set when all of the following conditions are met:

1. McBSPi.MCBSPLP_DRR_REG is not read even if the McBSPi.MCBSPLP_IRQSTATUS_REG[3] RRDY bit is set (legacy mode) and DMA or interrupt request has been asserted.
2. RB is full.
3. RSR is full.

As previously described, data arriving on mcbspi_dr is continuously shifted into the RSR. Once a complete word is shifted into the RSR, an RSR-to-RB copy can occur only if the RB is not full.

Either of the following events clears the legacy mode McBSPi.MCBSPLP_SPCR1_REG[2] RFULL bit and allows subsequent transfers to be read properly:

- The MPU/DSP subsystems or sDMA controller reads the McBSPi.MCBSPLP_DRR_REG register.
- The receiver is reset individually (the McBSPi.MCBSPLP_SPCR1_REG[0] RST bit is set to 0) or as part of a global reset.

Another frame-sync pulse is required to restart the receiver.

According to the McBSPi.MCBSPLP_IRQENABLE_REG register setting, this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in the McBSPi.MCBSPLP_IRQSTATUS_REG register clears the interrupt.

[Figure 24-147](#) shows the receive overrun condition.

24.5.4.10.3.3 Preventing Unexpected Receive Frame-Sync Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKR cycles, depending on the value of the McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY bit field. For each possible data delay, Figure 24-149 shows when a new frame-sync pulse on FSR can safely occur relative to the last bit of the current frame.

Figure 24-149. Proper Positioning of Receive Frame-Sync Pulses

24.5.4.10.4 Underflow in the Receiver

The McBSP module indicates a receiver underflow condition by setting the McBSPi.MCBSPLP_IRQSTATUS_REG[4] RUNDLSTAT bit. This error occurs when sDMA controller or MPU/DSP subsystem reads data from an empty RB; this happens only if the MPU/DSP subsystem or sDMA controller does not respect the DMA length, does not wait for DMA request, or does not check the buffer status before reading data. According to the McBSPi.MCBSPLP_IRQENABLE_REG register settings, this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.MCBSPLP_IRQSTATUS_REG register clears the interrupt.

24.5.4.10.5 Underflow in the Transmitter

The McBSP module indicates a transmitter empty (or underflow) condition by setting the McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDLSTAT bit. The legacy mode McBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY bit is also cleared. Either of the following events activates the XEMPTY bit (XEMPTY = 0):

- The McBSPi.MCBSPLP_DXR_REG register has not been loaded and the XB is empty, and all bits of the data word in the XSR have been shifted out on the mcbspi_dx pin.
- The transmitter is reset (by forcing McBSPi.MCBSPLP_SPCR2_REG[0] XRST to 0, or by a global reset) and is then restarted.

The XEMPTY bit is deactivated (XEMPTY = 1) when a new word in the McBSPi.MCBSPLP_DXR_REG register is transferred to the XB. If the McBSPi.MCBSPLP_PCR_REG[11] FSXM bit is set to 1 and the McBSPi.MCBSPLP_SRGR2_REG[12] FSGM bit is set to 0, the FSX signal is generated when the XB is not empty. When the McBSPi.MCBSPLP_SRGR2_REG[12] FSGM bit is set to 0, the McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER and McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID bit fields are used to determine the frame-sync period and width (external FSX is gated by the buffer empty condition). Otherwise, the transmitter waits for the next frame-sync pulse before sending the next frame on the mcbspi_dx pin.

When the transmitter is taken out of reset (the McBSPi.MCBSPLP_SPCR2_REG[0] XRST bit is set to 1), it is in a transmitter ready state (the McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit is set to 1) and transmitter empty (the McBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY bit is set to 0) state. If the

McBSPi.MCBSPLP_DXR_REG register is loaded by the MPU/DSP subsystem or the sDMA controller before internal the FSX goes active high, a valid XB-to-XSR transfer occurs. This allows for the first word of the first frame to be valid even before the transmit frame-sync pulse is generated or detected. Alternatively, if a transmit frame-sync pulse is detected before McBSPi.MCBSPLP_DXR_REG is loaded, zeros are output on the mcbspi_dx pin.

The McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT bit indicates a real underflow condition, in which the frame is corrupted due to lack of data availability during the transmit process. According to the settings of the McBSPi.MCBSPLP_IRQENABLE_REG register, this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.MCBSPLP_IRQSTATUS_REG register clears the interrupt.

24.5.4.10.6 Unexpected Transmit Frame-Sync Pulse

24.5.4.10.6.1 Possible Responses to Transmit Frame-Sync Pulses

If a frame-sync pulse starts the transfer of a new frame before the current frame is fully transmitted, this pulse is treated as an unexpected frame-sync pulse, and the transmitter sets the transmit frame-sync error bit McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR (and the legacy McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR bit).

According to the settings of the McBSPi.MCBSPLP_IRQENABLE_REG register, this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in the status register clears the interrupt.

Using the legacy mode, the McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR bit can be cleared only by a transmitter reset or by setting this bit to 0. For the McBSP module to notify the MPU/DSP subsystem of frame-sync errors, set a special transmit interrupt mode with the McBSPi.MCBSPLP_SPCR2_REG[5:4] XINTM bit field. When XINTM is set to 0b11, the McBSP module sends a transmit interrupt request to the MPU/DSP subsystem each time XSYNCERR is set.

24.5.4.10.6.2 Example of Unexpected Transmit Frame-Sync Pulse

Figure 24-150 shows an unexpected transmit frame-sync pulse during normal operation of the serial port with intervals between the data packets.

NOTE: The unexpected transmit frame-sync pulse does not influence the data transmit process, being ignored by the data transmit state-machine.

Figure 24-150. Unexpected Frame-Sync Pulse During a McBSP Transmission

mcbbsp-040

24.5.4.10.6.3 Preventing Unexpected Transmit Frame-Sync Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKX cycles, depending on the value in the McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY bit field. For each possible data delay, Figure 24-151 shows when a new frame-sync pulse on FSX can safely occur relative to the last bit of the current frame.

Figure 24-151. Proper Positioning of Transmit Frame-Sync Pulses**24.5.4.10.7 Overflow in the Transmitter**

The McBSP module indicates a transmitter overflow condition by setting the McBSPi.MCBSPLP_IRQSTATUS_REG[12] XOVLSTAT bit. This error occurs when the sDMA controller or MPU/DSP subsystem writes data to a full XB (this happens only if the MPU/DSP subsystem or sDMA controller does not respect the DMA length, does not wait for DMA request, or does not check the buffer status before writing data). According to the settings of the McBSPi.MCBSPLP_IRQENABLE_REG register, this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in the status register clears the interrupt.

24.5.4.11 McBSP DMA Configuration

The McBSP receive and transmit data DMA requests are active after the receive McBSPi.MCBSPLP_SPCR1_REG[0] RST and transmit McBSPi.MCBSPLP_SPCR2_REG[0] XRST bits are released. After reset the default DMA threshold (and length) is one.

The receive and transmit DMA requests can be individually disabled by setting the McBSPi.MCBSPLP_RCCR_REG[3] RDMAEN and McBSPi.MCBSPLP_XCCR_REG[3] XDMAEN bits to 0. When disabling the DMA, the DMA request line is deasserted even if a DMA transfer is pending and the DMA state-machine is not reset.

The DMA threshold and length configuration is done through the McBSPi.MCBSPLP_THRSH1_REG and McBSPi.MCBSPLP_THRSH2_REG registers as follows:

- (THRSH1_REG + 1) value represents the required receive DMA request length (the length of the transfer is the same as the threshold value plus 1). As long as the RB occupied locations level is greater than or equal to the THRSH1_REG value + 1, the DMA request is asserted. After transferring the configured (THRSH1_REG + 1) number of words, the receive DMA request is deasserted and reasserted as soon as the conditions are met again.
- (THRSH2_REG + 1) value represents the required transmit DMA request length (the length of the transfer is the same as the threshold value plus 1). As long as the XB free locations level is greater than or equal to the THRSH2_REG value + 1, the DMA request is asserted. After transferring the configured (THRSH2_REG + 1) number of words, the transmit DMA request is deasserted and reasserted as soon as the conditions are met.

NOTE: The MPU/DSP subsystem can decide not to use the DMA to transfer the data. In this case, the DMA must be disabled (or the DMA request can be ignored by MPU/DSP subsystem) and the common interrupt line (MCBSPi_IRQ) can be used. The MCBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit for receive and the MCBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit for transmit indicate when the threshold values are reached. Also, by reading the receive buffer status MCBSPi.MCBSPLP_RBUFFSTAT_REG register and transmit buffer status MCBSPi.MCBSPLP_XBUFFSTAT_REG register, the MPU/DSP subsystem can decide to transfer data even if the threshold is not reached. This mechanism is useful on the last transfer on the receive side when the threshold value is bigger than the occupied locations inside the receive buffer and the MPU/DSP subsystem needs to read this data. Because no interrupt or DMA request is asserted, the only option in this case is to read the value of the RB status register and to transfer the remaining data without using the DMA or interrupt indication.

24.5.4.12 Multichannel Selection Modes

24.5.4.12.1 Channels, Blocks and Partitions

A McBSP channel is a time slot for shifting in/out the bits of one serial word. The McBSP module supports up to 128 channels for reception and 128 channels for transmission. In the receiver and in the transmitter, the 128 available channels are divided into eight blocks that contain 16 contiguous channels each (see [Table 24-339](#)).

Table 24-339. McBSP Channels

| | |
|--------------------------------|----------------------------------|
| Block 0: Channels 0–15 | Block 4: Channels 64–79 |
| Block 1: Channels 16–31 | Block 5: Channels 80–95 |
| Block 2: Channels 32–47 | Block 6: Channels 96–111 |
| Block 3: Channels 48–63 | Block 6: Channels 112–127 |

The blocks are assigned to partitions according to the selected partition mode. In the 2-partition mode described in [Section 24.5.4.12.6, Using Two Partitions \(Legacy Only\)](#), assign one even-numbered block (0, 2, 4, or 6) to partition A and one odd-numbered block (1, 3, 5, or 7) block to partition B. In the 8-partition mode described in [Section 24.5.4.12.4, Using Eight Partitions](#), blocks 0 through 7 are automatically assigned to partitions A through H, respectively.

The number of partitions for reception and the number of partitions for transmission are independent of one another. For example, it is possible to use two receive partitions (A and B) and eight transmit partitions (A–H).

24.5.4.12.2 Multichannel Selection

When a McBSP module uses a time-division multiplexed (TDM) data stream while communicating with other McBSP modules or serial devices, the McBSP module may need to receive and/or transmit on only a few channels. To save memory and bus bandwidth, use a multichannel selection mode to prevent data flow in some of the channels.

Each channel partition has a dedicated channel enable register. If the appropriate multichannel selection mode is on, each bit in the register controls whether data flow is allowed or prevented in one of the channels that is assigned to that partition.

The McBSP module has one receive multichannel selection mode (see [Section 24.5.4.12.5, Receive Multichannel Selection Mode](#)) and three transmit multichannel selection modes (see [Section 24.5.4.12.7, Transmit Multichannel Selection Modes](#)).

24.5.4.12.3 Configuring a Frame for Multichannel Selection

Before enabling a multichannel selection mode, ensure that the data frame is properly configured:

- Select a single-phase frame (the McBSPi.MCBSPLP_RCR2_REG[15] RPHASE and McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bits are set to 0). Each frame represents a TDM data stream.
- Set a frame length (in the McBSPi.MCBSPLP_RCR1_REG[14:8] RFLEN1 and McBSPi.MCBSPLP_XCR1_REG[14:8] XFLEN1 bit fields) that includes the highest numbered channel to be used. For example, to use channels 0, 15, and 39 for reception, the receive frame length must be at least 40 (RFLEN1 = 39). In this case, if XFLEN1 = 39, the receiver creates 40 time slots per frame but receives data only during time slots 0, 15, and 39 of each frame.

24.5.4.12.4 Using Eight Partitions

For multichannel selection operation in the receiver and/or transmitter, eight partitions or two partitions (as previously described) can be used. If 8-partition mode (McBSPi.MCBSPLP_MCR1_REG[9] RMCME = 1 for reception, and McBSPi.MCBSPLP_MCR2_REG[9] XMCME = 1 for transmission) is selected, McBSP channels are activated in the following order: A, B, C, D, E, F, G, H.

In response to a frame-sync pulse, the receiver or transmitter begins with the channels in partition A and then continues with the other partitions, in order, until the complete frame is transferred. When the next frame-sync pulse occurs, the next frame is transferred, beginning with the channels in partition A.

In 8-partition mode, the McBSPi.MCBSPLP_MCR1_REG[6:5] RPABLK/McBSPi.MCBSPLP_MCR2_REG[6:5] XPABLK bit fields, and the McBSPi.MCBSPLP_MCR1_REG[8:7] RPBBLK/McBSPi.MCBSPLP_MCR2_REG[8:7] XPBBLK bit fields are ignored and the 16-channel blocks are assigned to the partitions as shown in Table 24-340 and Table 24-341. These assignments cannot be changed. The tables also show the registers used to control the channels in the partitions.

Table 24-340. Eight Partitions – Receive Channel Assignment and Control

| Receive Partition | Assigned Block of Receive Channels | Register Used for Channel Control |
|-------------------|------------------------------------|-----------------------------------|
| A | Block 0: Channels 0–15 | McBSPi.MCBSPLP_RCERA_REG |
| B | Block 1: Channels 16–31 | McBSPi.MCBSPLP_RCERB_REG |
| C | Block 2: Channels 32–47 | McBSPi.MCBSPLP_RCERC_REG |
| D | Block 3: Channels 48–63 | McBSPi.MCBSPLP_RCERD_REG |
| E | Block 4: Channels 64–79 | McBSPi.MCBSPLP_RCERE_REG |
| F | Block 5: Channels 80–95 | McBSPi.MCBSPLP_RCERF_REG |
| G | Block 6: Channels 96–111 | McBSPi.MCBSPLP_RCERG_REG |
| H | Block 7: Channels 112–127 | McBSPi.MCBSPLP_RCERH_REG |

Table 24-341. Eight Partitions – Transmit Channel Assignment and Control

| Transmit Partition | Assigned Block of Receive Channels | Register Used for Channel Control |
|--------------------|------------------------------------|-----------------------------------|
| A | Block 0: Channels 0–15 | McBSPi.MCBSPLP_XCERA_REG |
| B | Block 1: Channels 16–31 | McBSPi.MCBSPLP_XCERB_REG |
| C | Block 2: Channels 32–47 | McBSPi.MCBSPLP_XCERC_REG |
| D | Block 3: Channels 48–63 | McBSPi.MCBSPLP_XCERD_REG |
| E | Block 4: Channels 64–79 | McBSPi.MCBSPLP_XCERE_REG |
| F | Block 5: Channels 80–95 | McBSPi.MCBSPLP_XCERF_REG |
| G | Block 6: Channels 96–111 | McBSPi.MCBSPLP_XCERG_REG |
| H | Block 7: Channels 112–127 | McBSPi.MCBSPLP_XCERH_REG |

Figure 24-152 shows an example of the McBSP using 8-partition mode. In response to a frame-sync pulse, the McBSP module begins a frame transfer with partition A and then activates B, C, D, E, F, G, and H to complete a 128-word frame.

Figure 24-152. McBSP Data Transfer in 8-Partition Mode

24.5.4.12.5 Receive Multichannel Selection Mode

The McBSPi.MCBSPLP_MCR1_REG[0] RMCME bit determines whether all channels or only selected channels are enabled for reception.

- When RMCME = 0, all 128 receive channels are enabled and cannot be disabled.
- When RMCME = 1, the receive multichannel selection mode is enabled. In this mode:
 - Channels can be individually enabled or disabled. The enabled channels are those selected in the appropriate receive channel enable registers (McBSPi.MCBSPLP_RCERA_REG/McBSPi.MCBSPLP_RCERH_REG). The channels assigned to the McBSPi.MCBSPLP_RCERA_REG/McBSPi.MCBSPLP_RCERH_REG registers depend on the number of receive channel partitions (2 or 8), as defined by the McBSPi.MCBSPLP_MCR1_REG[9] RMCME bit.
 - If a receive channel is disabled, any bits received in that channel are not transferred to the RB, and as a result, the receiver ready bit (RRDY) is not set. Therefore, no DMA synchronization event is generated and, if the receiver interrupt mode depends on RRDY (McBSPi.MCBSPLP_SPCR1_REG[5:4] RINTM = 0b00), no interrupt is generated.

As an example of how the McBSP module behaves in the receive multichannel selection mode, suppose only channels 0, 15, and 39 are enabled and that the frame length is 40. The McBSP module:

1. Accepts bits shifted in from the mcbspi_dr pin in channel 0
2. Ignores bits received in channels 1–14
3. Accepts bits shifted in from the mcbspi_dr pin in channel 15
4. Ignores bits received in channels 16–38
5. Accepts bits shifted in from the mcbspi_dr pin in channel 39

24.5.4.12.6 Using Two Partitions (Legacy Only)

For multichannel selection operation in the receiver and/or the transmitter, two partitions or eight partitions can be used. If 2-partition mode (the McBSPi.MCBSPLP_MCR1_REG[9] RMCME bit is set to 0 for reception, and the McBSPi.MCBSPLP_MCR2_REG[9] XMCME bit is set to 0 for transmission) is selected, the McBSP channels are activated using an alternating scheme. In response to a frame-sync pulse, the receiver or transmitter begins with the channels in partition A and then alternates between partitions B and A until the complete frame is transferred. When the next frame-sync pulse occurs, the next frame is transferred beginning with the channels in partition A.

For reception, any two of the eight receive-channel blocks can be assigned to receive partitions A and B, which means up to 32 receive channels can be enabled at any given point. Similarly, any two of the eight transmit-channel blocks (up to 32 enabled transmit channels) can be assigned to transmit partitions A and B.

For reception:

- Assign an even-numbered channel block (0, 2, 4, or 6) to receive partition A by writing to the McBSPi.MCBSPLP_MCR1_REG[6:5] RPABLK bit field. In the receive multichannel selection mode, the channels in this partition are controlled by receive channel enable register A (McBSPi.MCBSPLP_RCERA_REG).
- Assign an odd-numbered block (1, 3, 5, or 7) to receive partition B with the McBSPi.MCBSPLP_MCR1_REG[8:7] RPBBLK bit field. In the receive multichannel selection mode, the channels in this partition are controlled by receive channel enable register B (McBSPi.MCBSPLP_RCERB_REG).

For transmission:

- Assign an even-numbered channel block (0, 2, 4, or 6) to transmit partition A by writing to the McBSPi.MCBSPLP_MCR2_REG[6:5] XPABLK bit field. In one of the transmit multichannel selection modes, the channels in this partition are controlled by transmit channel enable register A (McBSPi.MCBSPLP_XCERA_REG).
- Assign an odd-numbered block (1, 3, 5, or 7) to transmit partition B with the McBSPi.MCBSPLP_MCR1_REG[8:7] XPBBLK bit field. In one of the transmit multichannel selection modes, the channels in this partition are controlled by transmit channel enable register B (McBSPi.MCBSPLP_XCERB_REG).

Figure 24-153 shows an example of alternating between the channels of partition A and the channels of partition B. Channels 0–15 have been assigned to partition A, and channels 16–31 have been assigned to partition B. In response to a frame-sync pulse, the McBSP module begins a frame transfer with partition A and then alternates between partitions B and A until the complete frame is transferred.

Figure 24-153. Alternating Between Partitions A and B Channels

24.5.4.12.7 Transmit Multichannel Selection Modes

The McBSPi.MCBSPLP_MCR2_REG[1:0] XMCM bit field determines whether all channels or only selected channels are enabled and unmasked for transmission. The McBSP module has three transmit multichannel selection modes (XMCM = 0b01, XMCM = 0b10, and XMCM = 0b11), which are described in Table 24-342.

Table 24-342. Selecting a Transmit Multichannel Selection Mode With the XMCM Bit Field

| XMCM | Transmit Multichannel Selection Mode |
|------|---|
| 0b00 | No transmit multichannel selection mode is on. All channels are enabled and unmasked. No channels can be disabled or masked. |
| 0b01 | All channels are disabled unless they are selected in the appropriate transmit channel enable registers (McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG). If enabled, a channel in this mode is also unmasked. The McBSPi.MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 or 128 channels are selectable in the McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG registers. |
| 0b10 | All channels are enabled, but they are masked unless they are selected in the appropriate transmit channel enable registers (McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG). The McBSPi.MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 or 128 channels are selectable in the McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG registers. |
| 0b11 | This mode is used for symmetric transmission and reception. All channels are disabled for transmission unless they are enabled for reception in the appropriate receive channel enable registers (McBSPi.MCBSPLP_RCERA_REG/McBSPi.MCBSPLP_RCERH_REG). Once enabled, they are masked unless they are also selected in the appropriate transmit channel enable registers (McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG). The McBSPi.MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 or 128 channels are selectable in the McBSPi.MCBSPLP_RCERA_REG/McBSPi.MCBSPLP_RCERH_REG registers and the McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG registers. |

As an example of how the McBSP module behaves in a transmit multichannel selection mode, suppose that XMCM = 0b01 (all channels disabled unless individually enabled) and that only channels 0, 15, and 39 are enabled. Suppose also that the frame length is 40. The McBSP module:

1. Shifts data to the mcbspi_dx pin in channel 0
2. Places the mcbspi_dx pin in the high-impedance state in channels 1–14
3. Shifts data to the mcbspi_dx pin in channel 15
4. Places the mcbspi_dx pin in the high-impedance state in channels 16–38
5. Shifts data to the mcbspi_dx pin in channel 39

24.5.4.12.7.1 Disabling/Enabling Versus Masking/Unmasking

For transmission, a channel can be:

- Enabled and unmasked (transmission can begin and can be completed)
- Enabled but masked (transmission can begin but cannot be completed)
- Disabled (transmission cannot occur)

The definitions in [Table 24-343](#) explain the channel control options:

Table 24-343. McBSP Channel Control Options

| | |
|-------------------------|--|
| Enabled channel | A channel that can begin transmission by passing data from the data transmit register (McBSPi.MCBSPLP_DXR_REG) to the XSR through the XB. |
| Masked channel | A channel that cannot complete transmission. The mcbspi_dx pin is held in high-impedance state; data cannot be shifted out on the mcbspi_dx pin. In systems where symmetric transmit and receive provide software benefits, this feature allows transmit channels to be disabled on a shared serial bus. A similar feature is not needed for reception because multiple receptions cannot cause serial bus contention. |
| Disabled channel | A channel that is not enabled. A disabled channel is also masked. Because no DXR-to-XB copy occurs, the McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit is not set. Therefore, no DMA synchronization event is generated, and if the transmit interrupt mode depends on XRDY (McBSPi.MCBSPLP_SPCR2_REG[5:4] XINTM = 00b), no interrupt is generated. The McBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY bit is not affected. |
| Unmasked channel | A channel that is not masked. Data in the XSR(s) is shifted out on the mcbspi_dx pin. |

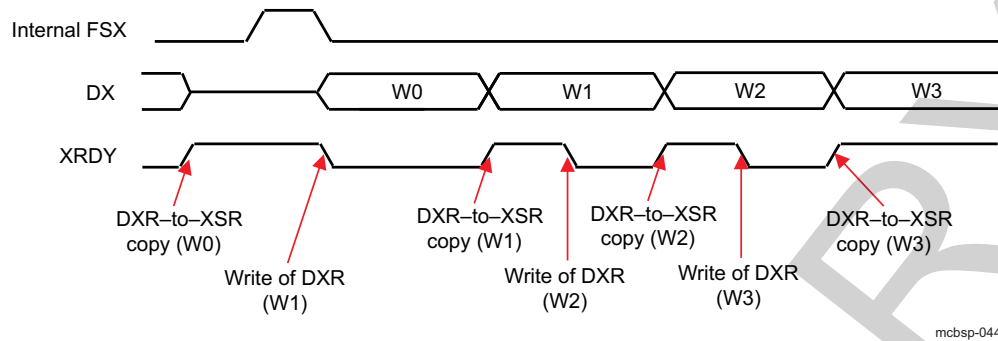

24.5.4.12.7.2 Activity on McBSP Pins for Different Values of XMCM

[Figure 24-154](#) shows the activity on the McBSP pins for the various values of the McBSPi.MCBSPLP_MCR2_REG[1:0] XMCM bit field. In all cases, the transmit frame is configured as follows:

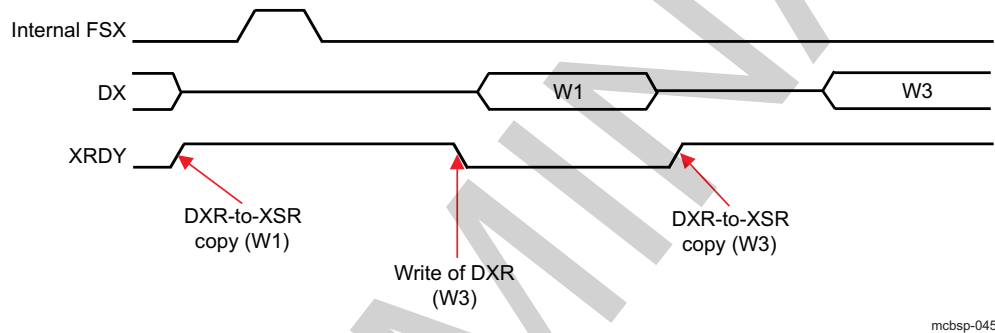

- XPHASE = 0: Single-phase frame (required for multichannel selection modes)
- XFRLN1 = 0b0000011: 4 words per frame
- XWDLEN1 = 0b000: 8 bits per word
- XMCME = 0: 2-partition mode (only partitions A and B are used)

In the case where McBSPi.MCBSPLP_MCR2_REG[1:0] XMCM = 0b11, transmission and reception are symmetric, which means the corresponding bits for the receiver (RPHASE, RFRLN1, RWDLEN1, and RMCME) must have the same values as XPHASE, XFRLN1, and XWDLEN1, respectively.

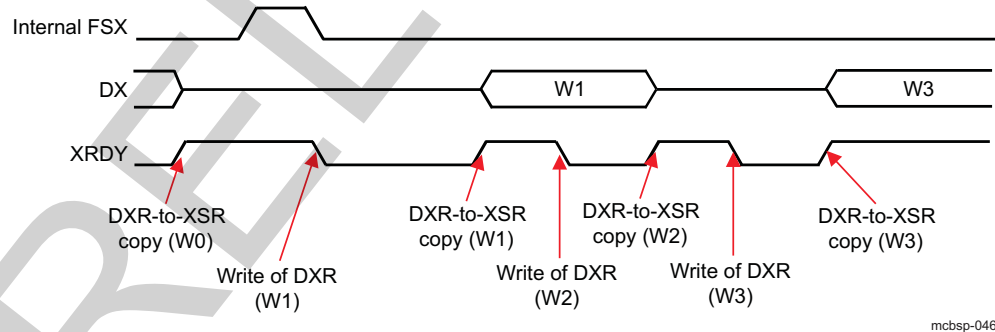

In [Figure 24-154](#), the arrows showing where the various events occur are only sample indications. Wherever possible, there is a time window in which these events can occur.

Figure 24-154. Activity on McBSP Pins When XMCM = 0b00

If XMCM = 0b00, all channels are enabled and unmasked. Words W0, W1, W2, and W3 are written to the XB, and then, from the XB, they are transferred by mcbspi_dx.

Figure 24-155. Activity on McBSP Pins When XMCM = 0b01

In [Figure 24-155](#) if XMCM = 0b01, XPABLK = 0b00, and XCERA = 0b1010, only channels 1 and 3 are enabled and unmasked. Words W1 and W3 are written to the XB, and then, from the XB, they are transferred by mcbspi_dx.

Figure 24-156. Activity on McBSP Pins When XMCM = 0b10

In [Figure 24-156](#) if XMCM = 0b10, XPABLK = 0b00, and XCERA = 0b1010, all channels are enabled, and only 1 and 3 are unmasked. Words W0, W1, W2, and W3 are written to the XB, but only W1 and W3, from the XB, are transferred by mcbspi_dx.

Figure 24-157. Activity on McBSP Pins When XMCM = 0b11

mcbsp-047

In [Figure 24-157](#) if XMCM = 0b11, RPABLK = 0b00, XPABLK = 0bX, RCERA = 0b1010, and XCERA = 0b1000, channels 1 and 3 are enabled in receive and transmit mode, but only 3 is unmasked. Words W1 and W3 are written to the XB, but only W3, from the XB, is transferred by mcbspi_dx.

24.5.5 McBSP Basic Programming Model

This section describes the programming model of a typical McBSP module.

CAUTION

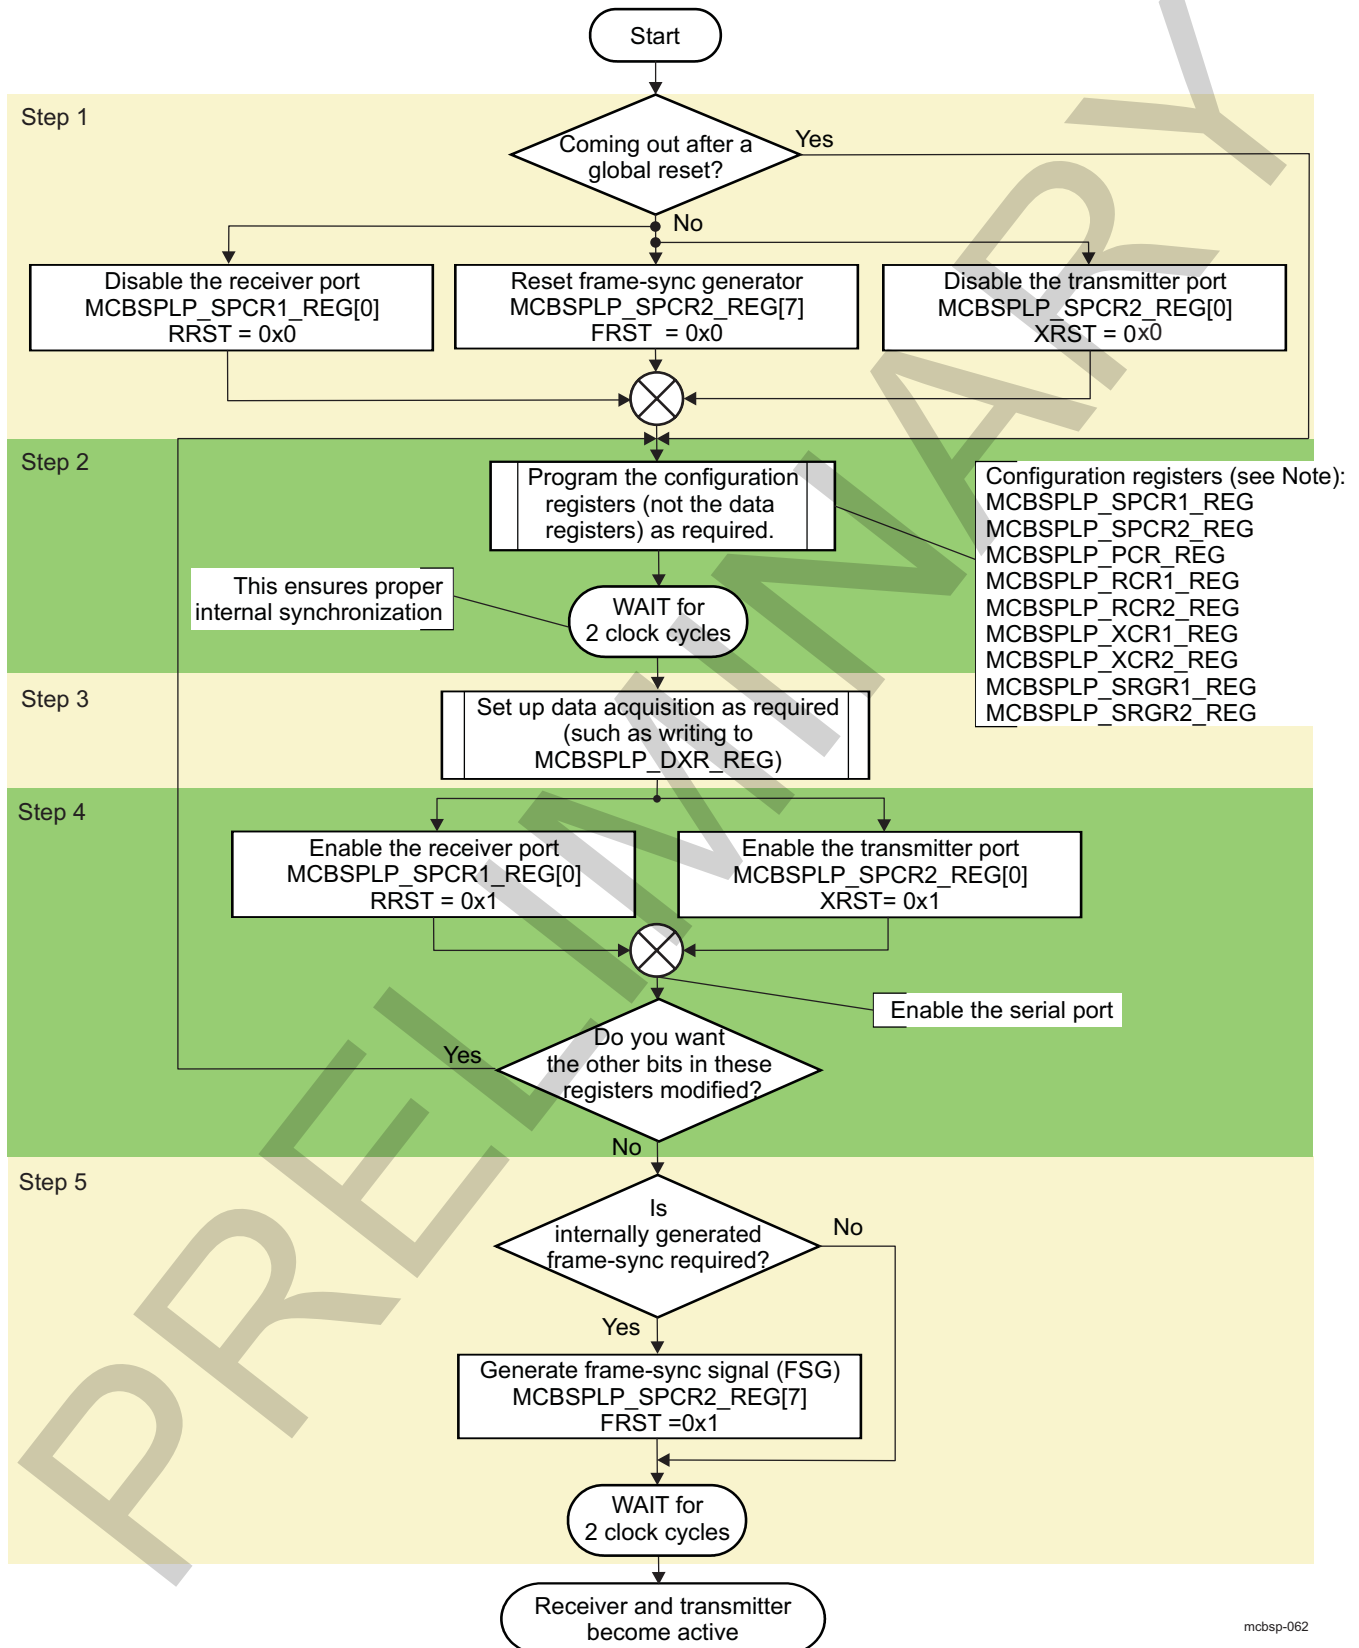

For all descriptions in this section, the McBSPi.MCBSPLP_XCCR_REG[11] XFULL_CYCLE and McBSPi.MCBSPLP_RCCR_REG[11] RFULL_CYCLE bits are their reset value (XFULL_CYCLE is set to 0 and RFULL_CYCLE is set to 1).

24.5.5.1 McBSP Initialization Procedure

This procedure for reset/initialization can be applied in general when the receiver or transmitter must be reset during its normal operation, and also when the SRG is not used for either operation.

[Figure 24-158](#) shows the serial port initialization procedure for master mode.

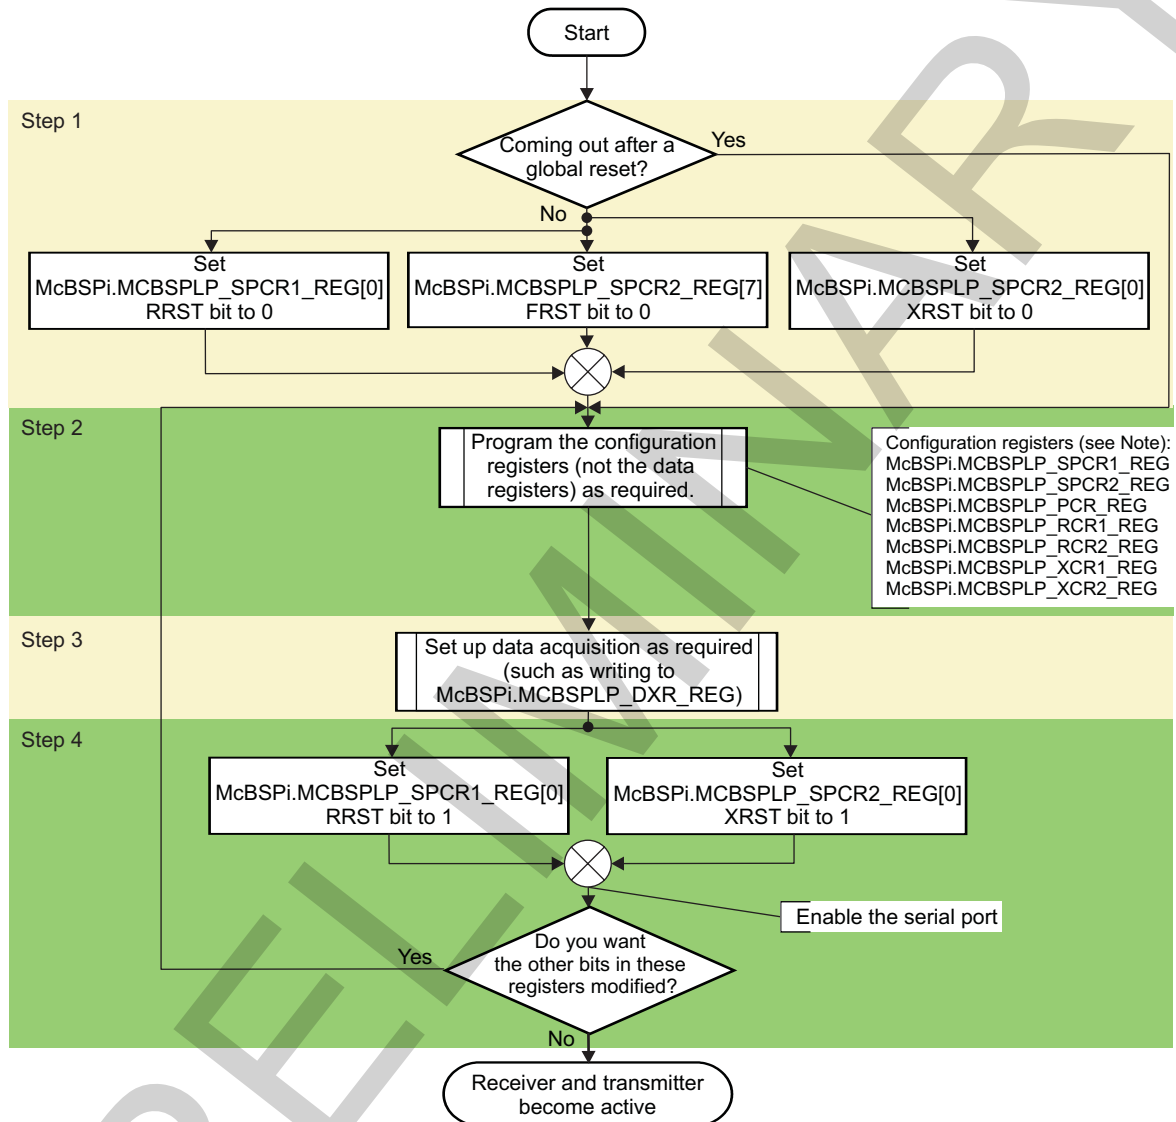

Figure 24-158. Flow Diagram of McBSP Initialization Procedure for Master Mode

Alternatively, on write (Step 1 or Step 4), the transmitter and receiver can be placed in or taken out of reset by modifying the McBSPi.MCBSPLP_SPCR2_REG[0] XRST and McBSPi.MCBSPLP_SPCR1_REG[0] RRST bits, respectively.

Figure 24-159 shows the flow diagram of the McBSP initialization procedure for slave mode.

Figure 24-159. Flow Diagram of McBSP Initialization Procedure for Slave Mode

mcbasp-075

NOTE:

- Alternatively, on write (Step 1 or Step 4), the transmitter and receiver can be placed in or taken out of reset by modifying the McBSPi.MCBSPLP_SPCR2_REG[0] XRST and McBSPi.MCBSPLP_SPCR1_REG[0] RRST bits, respectively.
- The necessary duration of the active-low period of XRST or RRST is at least two CLKR/CLKX cycles.
- The appropriate bits in serial port configuration registers (McBSPi.MCBSPLP_SPCR1_REG, McBSPi.MCBSPLP_SPCR2_REG, McBSPi.MCBSPLP_PCR_REG, McBSPi.MCBSPLP_RCR1_REG, McBSPi.MCBSPLP_RCR2_REG, McBSPi.MCBSPLP_XCR1_REG, McBSPi.MCBSPLP_XCR2_REG, McBSPi.MCBSPLP_THRSH2_REG, McBSPi.MCBSPLP_XCCR_REG, McBSPi.MCBSPLP_SYSCONFIG_REG, McBSPi.MCBSPLP_SRGR1_REG and McBSPi.MCBSPLP_SRGR2_REG) should be modified only when the affected portion of the serial port is in its reset state.
- In most cases, the data transmit register (McBSPi.MCBSPLP_DXR_REG) should be loaded by the MPU/DSP subsystem or the sDMA controller only when the transmitter is enabled (McBSPi.MCBSPLP_SPCR2_REG[0] XRST = 1). An exception to this rule is when these registers are used for loopback internal data.
- The bits of the channel control registers (McBSPi.MCBSPLP_MCR1_REG, McBSPi.MCBSPLP_MCR2_REG, McBSPi.MCBSPLP_RCER{A-H}_REG and McBSPi.MCBSPLP_XCER{A-H}_REG) can be modified at any time as long as they are not being used by the current reception/transmission in a multichannel selection mode.
- The SRG is reset by setting the McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit to 0.
- It is not necessary to wait if SRG is not used.
- The necessary duration of the active-low period of XRST or RRST is at least two
- Modification on-the-fly has no effect if a reset is not performed first.

Table 24-344. Register Call Summary for Flow Diagram of McBSP Initialization Procedure

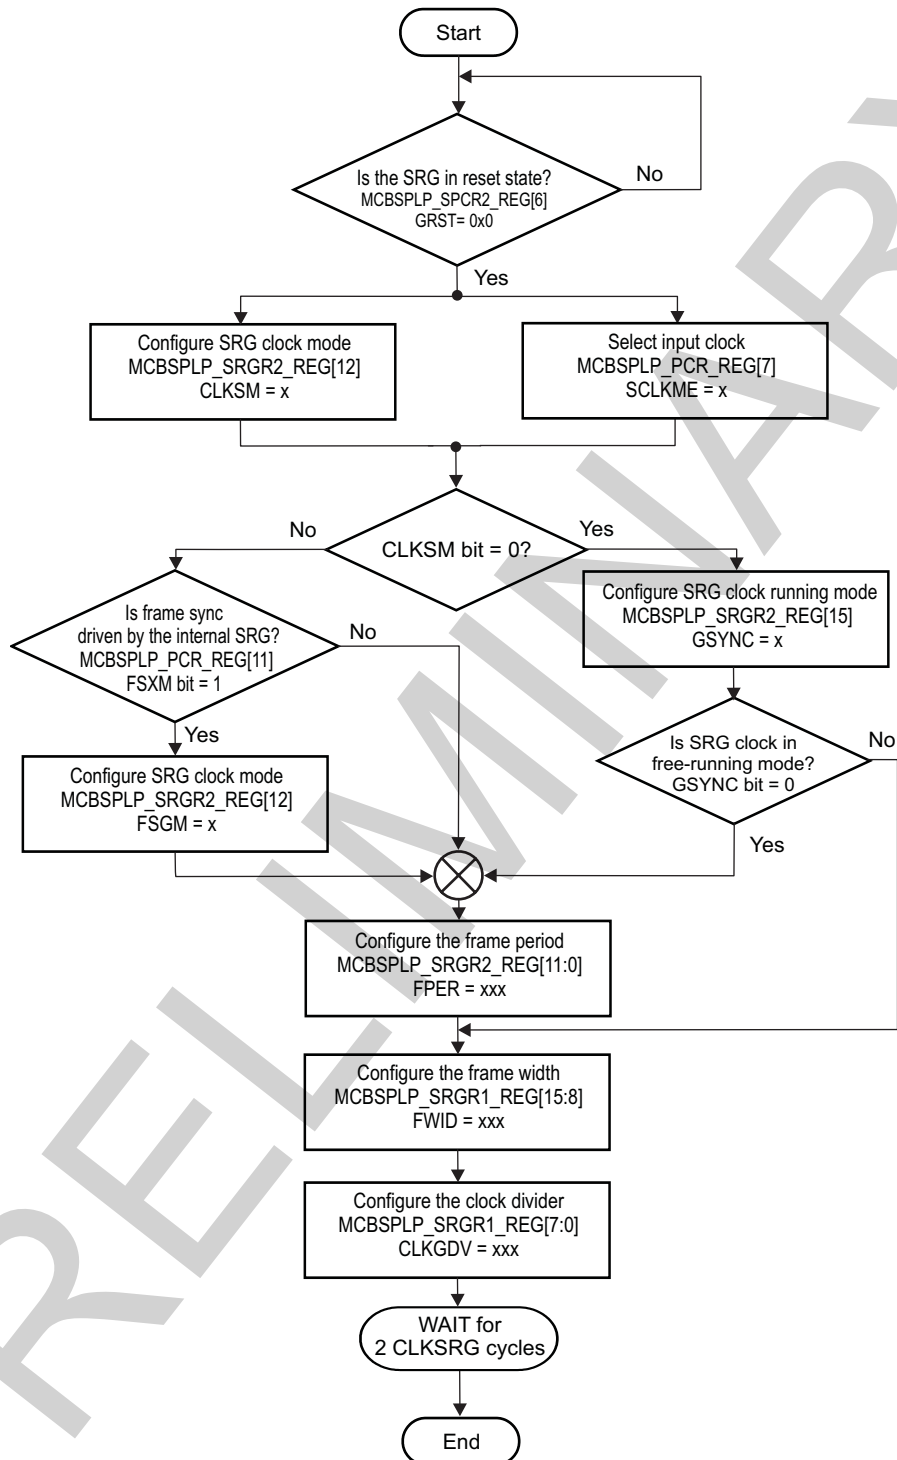

| Register Name | Register Name | Register Name |
|-------------------|------------------|-------------------|
| MCBSPLP_SPCR1_REG | MCBSPLP_RCR1_REG | MCBSPLP_XCR2_REG |
| MCBSPLP_SPCR2_REG | MCBSPLP_RCR2_REG | MCBSPLP_SRGR1_REG |
| MCBSPLP_PCR_REG | MCBSPLP_XCR1_REG | MCBSPLP_SRGR2_REG |

24.5.5.2 Reset and Initialization Procedure for the SRG

To reset and initialize the SRG:

1. Place the McBSP SRG in reset.
2. Program the registers that affect the SRG.
3. Enable the SRG (take it out of reset).
4. If necessary, enable the receiver and/or the transmitter.
5. If necessary, remove the receiver and/or transmitter from reset

Figure 24-160 shows the flow diagram for programming the SRG registers.

Figure 24-160. Flow Diagram for the SRG Registers Programming

mcbasp-073

Table 24-345. Register Call Summary for Flow Diagram for the SRG Registers Programming

| Register Name | Register Name |
|-------------------|-------------------|
| MCBSPLP_SPCR2_REG | MCBSPLP_PCR_REG |
| MCBSPLP_SRGR2_REG | MCBSPLP_SRGR1_REG |

24.5.5.3 Data Transfer DMA Request Configuration

This procedure configures the McBSP receive/transmit data DMA requests (MCBSPi_DMA_RX and MCBSPi_DMA_TX) (see [Table 24-346](#)).

Table 24-346. Data Transfer DMA Request Configuration

| Step | Register/Bit Field/Programming Model | Value |
|---|---------------------------------------|-------|
| Write the required receive DMA request length. | MCBSPLP_THRSH1_REG[6:0] RTHRESHOLD | x..x |
| Write the required transmit DMA request length. | MCBSPLP_THRSH2_REG[6:0] RTHRESHOLD | x..x |

NOTE:

- The length of the transfer is the same as the threshold value + 1
- In case of a number of transfers that exceed the number of the programmed DMA length, the McBSP module will respond to the command and will perform the transfer regardless of the receive buffer empty condition.
- In case of a number of transfers that exceed the number of the programmed DMA length, the McBSP module will respond to the command and will perform the transfer regardless of the transmit buffer full condition.

24.5.5.4 Interrupt Configuration

This procedure configures the common receive/transmit interrupt request line (see [Table 24-347](#)).

Table 24-347. Interruption Configuration

| Step | Register/Bit Field/Programming Model | Value |
|---------------------------------|--------------------------------------|-------|
| Enable the required IRQ events. | MCBSPLP_IRQENABLE_REG | x..x |

24.5.5.5 Receiver Configuration

To configure the McBSP receiver, perform the following steps:

- Step 1. Place the McBSP receiver in reset.
- Step 2. Program the McBSP registers for the desired receiver operation.
- Step 3. Take the receiver out of reset.

24.5.5.5.1 Place the Receiver in Reset (Step 1)

Table 24-348. Receiver Reset

| Step | Register/Bit Field/Programming Model | Value |
|------------------------------|--------------------------------------|-------|
| Place the receiver in reset. | MCBSPLP_SPCR1_REG[0] RST | 0x0 |

24.5.5.5.2 Programming the McBSP Registers for the Desired Receiver Configuration (Step 2)

This section describes the steps to be performed when software configures the McBSP receiver.

Global Configuration

Table 24-349 describes the steps to perform the global configuration.

Table 24-349. Global Configuration

| Step | Register/Bit Field/Programming Model | Value |
|---|--------------------------------------|------------|
| Set the receiver pins to operate as McBSP pins. | MCBSPLP_PCR_REG[12] RIOEN | 0x0 |
| Enable/disable DLB mode ⁽¹⁾ . | MCBSPLP_XCCR_REG[5] DLB | 0x0 or 0x1 |
| Enable/disable ALB mode ⁽¹⁾ . | MCBSPLP_SPCR1_REG[5] ALB | 0x0 or 0x1 |
| Select the clock used in synchronous transmit-receive mode (McBSP4 only) ⁽¹⁾ . | CONTROL_MCBSPLP[30] ALBCTRLRX_CLKX | 0x0 or 0x1 |
| Select frame synchronization used in the synchronous transmit-receive mode (McBSP4 only) ⁽¹⁾ . | CONTROL_MCBSPLP[31] ALBCTRLRX_FSX | 0x0 or 0x1 |
| Enable/disable the receive multichannel selection Mode ⁽¹⁾ . | MCBSPLP_MCR1_REG[0] RCMCM | 0x0 or 0x1 |

⁽¹⁾ Software decision

NOTE: In DLB mode the SRG and frame-sync generator must be enabled to generate the CLKX and FSX signals.

Data Configuration

Table 24-350 describes the steps to perform the data configuration.

Table 24-350. Data Configuration

| Step | Register/Bit Field/Programming Model | Value |
|--|--|------------|
| Select single/dual-phase frame ⁽¹⁾ . | MCBSPLP_RCR2_REG[15] RPHASE | 0x0 or 0x1 |
| Set the receive word length(s) for phase 1 ⁽¹⁾ . | MCBSPLP_RCR1_REG[7:5] RWDLEN1 | xxx |
| Set the receive word length(s) for phase 2 ⁽¹⁾ . | MCBSPLP_RCR2_REG[7:5] XWDLEN2 | xxx |
| Set the receive frame length*. | MCBSPLP_RCR1_REG[14:8] RFRLEN1 MCBSPLP_RCR2_REG[14:8] RFRLEN2 | xxx |
| Set the receive reverse mode ⁽¹⁾ . | MCBSPLP_RCR2_REG[4:3] RREVERSE | xx |
| Set the receive data delay ⁽¹⁾ . | MCBSPLP_RCR2_REG[1:0] RDATLY | xx |
| Set the receive sign-extension and justification mode ⁽¹⁾ . | MCBSPLP_SPCR1_REG[14:13] RJUST | xx |
| Enable the serial receiver port. | MCBSPLP_SPCR1_REG[0] RRST | 0x1 |
| Configure the receive buffer threshold value ⁽¹⁾ . | MCBSPLP_THRSH1_REG[6:0] RTHRESHOLD | x..x |

⁽¹⁾ Software decision

NOTE:

- When dual-phase frame is selected, the number of words per phase must be set to 1.
- If a single-phase frame is selected, RWDLEN1 selects the length for every serial word received in the frame. If a dual-phase frame is selected, RWDLEN1 and RWDLEN2 must be set to select both lengths. These bits can have different values.
- If a dual-phase frame is selected, the frame length must be two words.

Frame-Sync Configuration

Table 24-351 describes the steps to perform the frame-sync configuration.

Table 24-351. Frame-Sync Configuration

| Step | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|------------|
| Set the receive frame-sync mode ⁽¹⁾ . | MCBSPLP_PCR_REG[10] FSRM | 0x0 or 0x1 |
| Select SRG synchronization ⁽¹⁾ . | MCBSPLP_SRGR2_REG[15] GSYNC | 0x0 or 0x1 |
| Set the receive frame-sync polarity ⁽¹⁾ . | MCBSPLP_PCR_REG[2] FSRP | 0x0 or 0x1 |
| Set the SRG frame-sync period ⁽¹⁾ . | MCBSPLP_SRGR2_REG[11:0] FPER | x..x |
| Set the SRG frame-sync pulse width ⁽¹⁾ . | MCBSPLP_SRGR1_REG[15:8] FWID | x..x |

⁽¹⁾ Software decision

Clock Configuration

Table 24-352 describes the steps to perform clock configuration.

Table 24-352. Clock Configuration

| Step | Register/Bit Field/Programming Model | Value |
|---|---|------------|
| Set the receive clock mode ⁽¹⁾ . | MCBSPLP_PCR_REG[8] CLKRM | 0x0 or 0x1 |
| Set the receive clock polarity ⁽¹⁾ . | MCBSPLP_PCR_REG[0] CLKRP | 0x0 or 0x1 |
| Set the SRG clock divide-down value ⁽¹⁾ . | MCBSPLP_SRGR1_REG[7:0] CLKGDV | x..x |
| Set the SRG clock synchronization mode ⁽¹⁾ . | MCBSPLP_SRGR2_REG[15] GSYNC | 0x0 or 0x1 |
| Set the SRG input clock mode ⁽¹⁾ . | MCBSPLP_PCR_REG[7] SCKLME MCBSPLP_SRGR2_REG[13] CLKSM | 0x0 or 0x1 |
| Set the SRG input clock polarity ⁽¹⁾ . | MCBSPLP_SRGR2_REG[14] CLKSP MCBSPLP_PCR_REG[1] CLKXP MCBSPLP_PCR_REG[0] CLKRP | 0x0 or 0x1 |

⁽¹⁾ Software decision

NOTE: CLKRP = CLKXP in a system in which the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

24.5.5.5.3 Take the Receiver Out of Reset (Step 3)

Table 24-353. Take the Receiver Out of Reset

| Step | Register/Bit Field/Programming Model | Value |
|----------------------|--------------------------------------|-------|
| Enable the receiver. | MCBSPLP_SPCR1_REG[0] RST | 0x1 |

24.5.5.6 Transmitter Configuration

To configure the McBSP transmitter, perform the following steps:

- Step 1. Place the McBSP transmitter in reset.
- Step 2. Program the McBSP registers for the desired transmitter operation.
- Step 3. Take the transmitter out of reset.

24.5.5.6.1 Place the Transmitter in Reset (Step 1)

Table 24-354. Transmitter Reset

| Step | Register/Bit Field/Programming Model | Value |
|---------------------------------|--------------------------------------|-------|
| Place the transmitter in reset. | MCBSPLP_SPCR2_REG[0] RST | 0x0 |

24.5.5.6.2 Programming the McBSP Registers for the Desired Transmitter Operation (Step 2)

This section describes the steps to be performed when software configures the McBSP transmitter.

Global Configuration

Table 24-355 describes the steps to perform the global configuration.

Table 24-355. Global Configuration

| Step | Register/Bit Field/Programming Model | Value |
|---|--------------------------------------|------------|
| Set the transmitter pins to operate as McBSP pins. | MCBSPLP_PCR_REG[13] XIOEN | 0x0 |
| Enable/disable DLB mode ⁽¹⁾ . | MCBSPLP_XCCR_REG[5] DLB | 0x0 or 0x1 |
| Enable/disable ALB mode ⁽¹⁾ . | MCBSPLP_SPCR1_REG[5] ALB | 0x0 or 0x1 |
| Select clock used in the synchronous transmit-receive mode (McBSP4 only) ⁽¹⁾ . | CONTROL_MCBSPLP[30] ALBCTRLRX_CLKX | 0x0 or 0x1 |
| Select frame synchronization used in the synchronous transmit-receive mode (McBSP4 only) ⁽¹⁾ . | CONTROL_MCBSPLP[31] ALBCTRLRX_FSX | 0x0 or 0x1 |
| Enable/disable the transmit multichannel selection mode ⁽¹⁾ . | MCBSPLP_MCR1_REG[0] RCMCM | 0x0 or 0x1 |

⁽¹⁾ Software decision

Data Configuration

Table 24-356 describes the steps to perform the data configuration.

Table 24-356. Data Configuration

| Step | Register/Bit Field/Programming Model | Value |
|--|--|------------|
| Select single/dual-phase frame ⁽¹⁾ . | MCBSPLP_RCR2_REG[15] XPHASE | 0x0 or 0x1 |
| Set the transmit word length(s) for phase 1 ⁽¹⁾ . | MCBSPLP_XCR1_REG[7:5] XWDLEN1 | xxx |
| Set the transmit word length(s) for phase 2 ⁽¹⁾ . | MCBSPLP_XCR2_REG[7:5] XWDLEN2 | xxx |
| Set the transmit frame length ⁽¹⁾ . | MCBSPLP_XCR1_REG[14:8] XFRLEN1 MCBSPLP_XCR2_REG[14:8] XFRLEN2 | xxx |
| Set the transmit reverse mode ⁽¹⁾ . | MCBSPLP_XCR2_REG[4:3] XREVERSE | xx |
| Set the transmit data delay ⁽¹⁾ . | MCBSPLP_XCR2_REG[1:0] XDATLY | xx |
| Set the extra delay (DX delay) mode ⁽¹⁾ . | MCBSPLP_SPCR1_REG[7] DXENA | xx |
| Select the inserted delay value ⁽¹⁾ . | MCBSPLP_XCCR_REG[13:12] DXENDLY | xx |
| Set the interrupt line. | MCBSPLP_IRQENABLE_REG | x..x |
| Configure the transmit buffer threshold value ⁽¹⁾ . | MCBSPLP_THRSH2_REG[6:0] XTHRESHOLD | x..x |

⁽¹⁾ Software decision

NOTE:

- When dual-phase frame is selected, the number of words per phase must be set to 1.
- If a single-phase frame is selected, XWDLEN1 selects the length for every serial word transmit in the frame. If a dual-phase frame is selected, XWDLEN1 and XWDLEN2 must be set to select both lengths. These bits can have different values.
- If a dual-phase frame is selected, the frame length must be two words.

The DXENA bit controls the delay enabler on the mcbasp_dx pin. Set DXENA to enable an extra delay for turn-on time. Because this bit does not control the data itself, only the first bit is delayed (the delay is given by a combinatorial delay buffer). The inserted delay, 80 ps, 160 ps (default), 240 ps, or 320 ps, can be set using the McBSPi.MCBSPLP_XCCR_REG[13:12] DXENDLY bit field. If the mcbasp_dx pins of multiple McBSP modules are tied together, ensure that DXENA is set to 1 to avoid having more than one McBSP at a time transmitting on the data line.

Frame-Sync Configuration

Table 24-357 describes the steps to perform the frame-sync configuration.

Table 24-357. Frame-Sync Configuration

| Step | Register / Bit Field / Programming Model | Value |
|---|--|------------|
| Set the transmit frame-sync mode ⁽¹⁾ . | MCBSPLP_PCR_REG[11] FSXM MCBSPLP_SRGR2_REG[12] FSGM | 0x0 or 0x1 |
| Set the transmit frame-sync polarity ⁽¹⁾ . | MCBSPLP_PCR_REG[3] FSXP | 0x0 or 0x1 |
| Set the SRG frame-sync period ⁽¹⁾ . | MCBSPLP_SRGR2_REG[11:0] FPER | x..x |
| Set the SRG frame-sync pulse width ⁽¹⁾ . | MCBSPLP_SRGR1_REG[15:8] FWID | x..x |

⁽¹⁾ Software decision

Clock Configuration

Table 24-358 describes the steps to perform the clock configuration.

Table 24-358. Clock Configuration

| Step | Register / Bit Field / Programming Model | Value |
|---|---|------------|
| Set the transmit clock mode ⁽¹⁾ . | MCBSPLP_PCR_REG[9] CLKXM | 0x0 or 0x1 |
| Set the transmit clock polarity ⁽¹⁾ . | MCBSPLP_PCR_REG[1] CLKXP | 0x0 or 0x1 |
| Set the SRG clock divide-down value ⁽¹⁾ . | MCBSPLP_SRGR1_REG[7:0] CLKGDV | x..x |
| Set the SRG clock synchronization mode ⁽¹⁾ . | MCBSPLP_SRGR2_REG[15] GSYNC | 0x0 or 0x1 |
| Set the SRG input clock mode ⁽¹⁾ . | MCBSPLP_PCR_REG[7] SCKLME MCBSPLP_SRGR2_REG[13] CLKSM | 0x0 or 0x1 |
| Set the SRG input clock polarity ⁽¹⁾ . | MCBSPLP_SRGR2_REG[14] CLKSP MCBSPLP_PCR_REG[1] CLKXP MCBSPLP_PCR_REG[0] CLKRP | 0x0 or 0x1 |

⁽¹⁾ Software decision

NOTE: CLKRP = CLKXP in a system in which the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

24.5.5.6.3 Take the Receiver Out of Reset (Step 3)

Table 24-359. Take the Receiver Out of Reset

| Step | Register/Bit Field/Programming Model | Value |
|-------------------------|--------------------------------------|-------|
| Enable the transmitter. | MCBSPLP_SPCR2_REG[0] RST | 0x1 |

24.5.5.7 GPIO on the McBSP Pins (Legacy Only)

To use McBSP pins as GPIO pins rather than as serial port pins, follow these steps:

- For the receive pins (mcbssp_clkr, mcbssp_fsr, and mcbssp_dr as)

Table 24-360. Use Serial Receive Pins as GPIO Pins

| Step | Register/Bit Field/Programming Model | Value |
|---|--------------------------------------|-------|
| Place the receiver in reset. | MCBSPLP_SPCR1_REG[0] RRST | 0x0 |
| Enable GPIO for the serial port receiver. | MCBSPLP_PCR_REG[12] RIOEN | 0x1 |

- For the transmitter pins (mcbssp_clkx, mcbssp_fsx, and mcbssp_dx)

Table 24-361. Use Serial Transmit Pins as GPIO Pins

| Step | Register/Bit Field/ Programming Model | Value |
|--|---|-------|
| Place the transmit in reset. | MCBSPLP_SPCR2_REG[0] XRST | 0x0 |
| Enable GPIO for the serial port transmitter. | MCBSPLP_PCR_REG[12] XIOEN | 0x1 |

- **For the external clock pins (abe_clks)**

For the abe_clks pin (common to all McBSP modules), all of the reset and I/O conditions must be met as follows:

Table 24-362. Use External Clock Pin as GPIO Pin

| Step | Register/Bit Field/Programming Model | Value |
|--|---|-------|
| Place the receiver in reset. | MCBSPLP_SPCR1_REG[0] RRST | 0x0 |
| Place the transmit in reset. | MCBSPLP_SPCR2_REG[0] XRST | 0x0 |
| Enable GPIO for the serial port receiver. | MCBSPLP_PCR_REG[12] RIOEN | 0x1 |
| Enable GPIO for the serial port transmitter. | MCBSPLP_PCR_REG[12] XIOEN | 0x1 |

24.5.6 MCBSP Register Manual

Table 24-363 shows the base address and address space for the device module instances.

24.5.6.1 MCBSP Instance Summary

Table 24-363. MCBSP Instance Summary

| Module Name | Base Address L3 Interconnect | Base Address Cortex-A9 Private Access | Base Address DSP Private Access | Base Address L4-PER Interconnect | Size |
|-------------|---------------------------------|---|---------------------------------------|--|------|
| MCBSP1 | 0x4902 2000 | 0x4012 2000 | 0x2 2000 | N/A | 4KB |
| MCBSP2 | 0x4902 4000 | 0x4012 4000 | 0x2 4000 | N/A | 4KB |
| MCBSP3 | 0x4902 6000 | 0x4012 6000 | 0x2 6000 | N/A | 4KB |
| MCBSP4 | N/A | N/A | N/A | 0x4809 6000 | 4KB |

NOTE: Private access is an access that does not use the L3/L4 interconnects.

24.5.6.2 MCBSP Registers

CAUTION

The McBSP registers are limited to 32-bit data accesses; 16- and 8-bit accesses are not allowed and can corrupt register content.

24.5.6.2.1 MCBSP Register Summary

Table 24-364 through Table 24-367 summarize the MCBSP1, MCBSP2, MCBSP3, and MCBSP4 registers, respectively.

Table 24-364. MCBSP1 Register Summary

| Register Name | Type | Register Width (Bits) | Address Offset | Physical Address L3 Interconnect | Physical Address Cortex-A9 Private Access | Physical Address DSP Private Access |
|-------------------|------|--------------------------|----------------|-------------------------------------|---|---|
| MCBSPLP_DRR_REG | R | 32 | 0x0000 0000 | 0x4902 2000 | 0x4012 2000 | 0x2 2000 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|----------|
| 31:15 | RESERVED | Reserved | R | 0x000000 |
| 14 | IDLE_EN | Idle enable. This bit allows stopping all the clocks in the MCBSP1P. (legacy) 0x0: The McBSP is running 0x1: The clocks in the McBSP are shut off when both IDLE_EN=1 and peripheral domain is in idle mode | RW | 0 |
| 13 | XIOEN | Transmit General Purpose I/O Mode only when XRST=0 in SPCR[1,2] (legacy) 0x0: DX, FSX and CLKX are configured as serial port pins and do not function as general-purpose I/Os. 0x1: DX pin is a general purpose output. FSX and CLKX are general purpose I/Os. These serial port pins do not perform serial port operation. | RW | 0 |
| 12 | RIOEN | Receive General Purpose I/O Mode when RRST=0 in SPCR[1,2] (legacy) 0x0: DR, FSR, CLKR and CLKS are configured as serial port pins and do not function as general-purpose I/Os. 0x1: DR and CLKS pins are general purpose inputs; FSR and CLKR are general purpose I/Os. These serial port pins do not perform serial port operation. The CLKS pin is affected by a combination of RRST and RIOEN signals of the receiver. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 11 | FSXM | Transmit Frame-Synchronization Mode 0x0: Frame-sync signal derived from an external source 0x1: Frame synchronization is determined by the SRG frame-sync mode bit FSGM in SRGR2. | RW | 0 |
| 10 | FSRM | Receive Frame-Synchronization Mode 0x0: Frame-sync pulses generated by an external device. FSR is an input pin. 0x1: Frame synchronization generated internally by SRG. FSR is an output pin except when GSYNC=1 in SRGR. | RW | 0 |
| 9 | CLKXM | Transmitter Clock Mode 0x0: Transmitter clock is driven by an external clock with CLKX as an input pin. 0x1: CLKX is an output pin and is driven by the internal sample rate generator. | RW | 0 |
| 8 | CLKRM | Receiver Clock Mode 0x0: Case 1: Digital loopback mode not set (DLB=0) in SPCR1: Receive clock (CLKR) is an input driven by an external clock. Case 2: Digital loopback mode set (DLB=1) in SPCR1: Receive clock (not the CLKR pin) is driven by transmit clock (CLKX) which is based on the CLKXM bit in the PCR. CLKR pin is in high-impedance. 0x1: Case 1: Digital loopback mode not set (DLB=0) in SPCR1: CLKR is an output pin and is driven by the internal SRG. Case 2: Digital loopback mode set (DLB=1) in SPCR1: CLKR is an output pin and is driven by the transmit clock. The transmit clock is derived based on the CLKRM bit in the PCR. | RW | 0 |
| 7 | SCLKME | The frequency of CLKG is: $\text{CLKG frequency} = (\text{Input clock frequency}) / (\text{CLKGDV} + 1)$ SCLKME is used in conjunction with the CLKSM bit to select the input clock: 0x0: CLKSM = 0: Signal on CLKS pin CLKSM = 1: CPU clock 0x1: CLKSM = 0: Signal on CLKR pin CLKSM = 1: Signal on CLKX pin | RW | 0 |
| 6 | CLKS_STAT | CLKS pin status. Reflects value on CLKS pin when selected as a general purpose input. (legacy) Read 0x0: The signal on the CLKS pin is low Read 0x1: The signal on the CLKS pin is high | R | 0 |
| 5 | DX_STAT | DX pin status. Reflects value driven on to DX pin when selected as a general purpose output. (legacy) 0x0: Drive the signal on the DX pin low 0x1: Drive the signal on the DX pin high | RW | 0 |
| 4 | DR_STAT | DR pin status. Reflects value on DR pin when selected as a general purpose input. (legacy) Read 0x0: The signal on DR pin is low Read 0x1: The signal on DR pin is high | R | 0 |
| 3 | FSXP | Transmit Frame-Synchronization Polarity 0x0: Frame-sync pulse FSX is active high 0x1: Frame-sync pulse FSX is active low | RW | 0 |
| 2 | FSRP | Receive Frame-Synchronization Polarity 0x0: Frame-sync pulse FSR is active high 0x1: Frame-sync pulse FSR is active low | RW | 0 |
| 1 | CLKXP | Transmit Clock Polarity 0x0: Transmit data driven on rising edge of CLKX 0x1: Transmit data driven on falling edge of CLKX | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 0 | CLKRP | Receive Clock Polarity 0x0: Receive data sampled on falling edge of CLKR 0x1: Receive data sampled on rising edge of CLKR | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--|------|--------|
| 31:16 | RESERVED | Reserved | R | 0x0000 |
| 15 | EXTCLKGATE | External clock gating enable (CLKX and FSX master only). When this bit is set and the transmit clock and FSX are set as output, the CLKX is enabled when FSX is active plus 3 clock cycles after (clock is provided for FWID + 4 clock cycles, assuming that the FSX width, active, is FWID + 1 clock cycles); outside this window the external transmit clock is gated. The receive use the same gated transmit clock and transmit frame synchronization signals regardless of the CLKRM/FSRM settings. When using this mode the frame synchronization signal must be active during reception of the entire frame (FWID must be programmed accordingly) to ensure the proper receive process, which requires at least 3 cycles after the frame complete to transfer the data into the receive buffer. 0x0: External clock gating disabled. 0x1: External clock gating enable. | RW | 0 |
| 14 | PPCONNECT | Pair to pair connection. When set the DXENO pin is always set to 0 regardless of the frame boundary, setting the tree state buffer as output 0x0: Pair to pair connection. When set the DXENO pin is always set to 0 regardless of the frame boundary, setting the tree state buffer as output 0x1: Pair to pair connection. When set the DXENO pin is always set to 0 regardless of the frame boundary, setting the tree state buffer as output | RW | 0 |
| 13:12 | DXENDLY | When DXENA bit in SPCR1 is set to 1 this field selects the added delay as follow: 0x0: 80 ps 0x1: 160 ps (default) 0x2: 240 ps 0x3: 320 ps | RW | 0x1 |

| Bits | Field Name | Description | Type | Reset |
|------|-------------|--|------|-------|
| 11 | XFULL_CYCLE | Transmit full-cycle mode select. 0x0: McBSP operates in transmit half-cycle mode (transmit frame synchronization is sampled by the opposite edge of the clock used to drive transmit data). 0x1: McBSP operates in transmit full-cycle mode (transmit frame synchronization is sampled by the same edge of the clock used to drive transmit data). | RW | 0 |

24.6 Multichannel PDM Controller

24.6.1 McPDM Overview

The multichannel pulse density modulation (McPDM) module consists in a proprietary audio module dedicated to mobile phone terminals. It is composed of audio uplink and downlink paths communicating with an external audio companion chip through a dedicated interface.

Figure 24-161 is an overview of the McPDM module.

Figure 24-161. McPDM Overview

The McPDM module can support the following features:

- Full-duplex communication:
 - Five audio downlink channels with up to 3.84 Mbps each
 - Three audio uplink channels with up to 3.84 Mbps each
 - One command channel with up to 3.84 Mbps
 - One status channel with up to 3.84 Mbps
- Uplink and downlink FIFO operations:
 - 16 × 96-bit words for FIFO uplink, where a 96-bit word contains three 24-bit words for the audio uplink channels (one 24-bit word per audio uplink channel) and one 16-bit word for status information
 - 16 × 144-bit words for FIFO downlink, where a 144-bit word contains five 24-bit words for the audio downlink channels (one 24-bit word per audio downlink channel) and one 16-bit word for the command data.
- Interrupt request to MPU and DSP subsystems
- DMA requests with programmable FIFO thresholds:
 - One DMA request for downlink path
 - One DMA request for uplink path
- Upsampling and pulse-density modulators for each audio downlink channel (five channels)
- Offset cancellation feature for audio downlink channels 1 and 2
- Decimation filter and downsampling for each audio uplink channel (three channels)

- IDLE state hardware handshake
- Wake-up request

24.6.2 McPDM Environment

This section describes the McPDM application fields from an environment point of view (external connections). It describes McPDM connectivity options, lists all possible interfaces, and describes the protocol and data format used in each case.

24.6.2.1 McPDM Modes

Table 24-454 describes the modes and application fields of the McPDM module.

Table 24-454. Modes

| Mode | Description |
|--------------|---|
| Normal mode | Up to five audio channels are transmitted to, and up to three audio channels are received from, the audio companion chip. |
| Command mode | In addition to the audio channels, commands are transmitted to the audio companion chip. |
| Status mode | In addition to the audio channels, status information is received from the audio companion chip. |

24.6.2.2 McPDM Signals

Table 24-455 describes the McPDM module signals and specifies their links to modes.

Table 24-455. I/O

| Signal | I/O (1) | Description | Reset Value | Normal Mode | Command Mode | Status Mode |
|-----------------|------------|---|----------------|----------------|-----------------|----------------|
| abe_clks | I | Clock received from the audio companion chip. The clock frequency is: <ul style="list-style-type: none"> • 17.64 MHz for a sampling frequency of 88.2/176.4 kHz • 19.2 MHz for a sampling frequency of 96/192 kHz | 0 | x | x | x |
| abe_pdm_lb_clk | O | Clock loopback to the audio companion chip from the abe_clks clock signal. The frequency is the same as abe_clks frequency. (2) | 0 | x | x | x |
| abe_pdm_frame | I/O | Frame synchronization and command/status data | Z | x | x | x |
| abe_pdm_ul_data | I | Audio uplink path data | Z | x | x | x |
| abe_pdm_dl_data | O | Audio downlink path data | 0 | x | x | x |

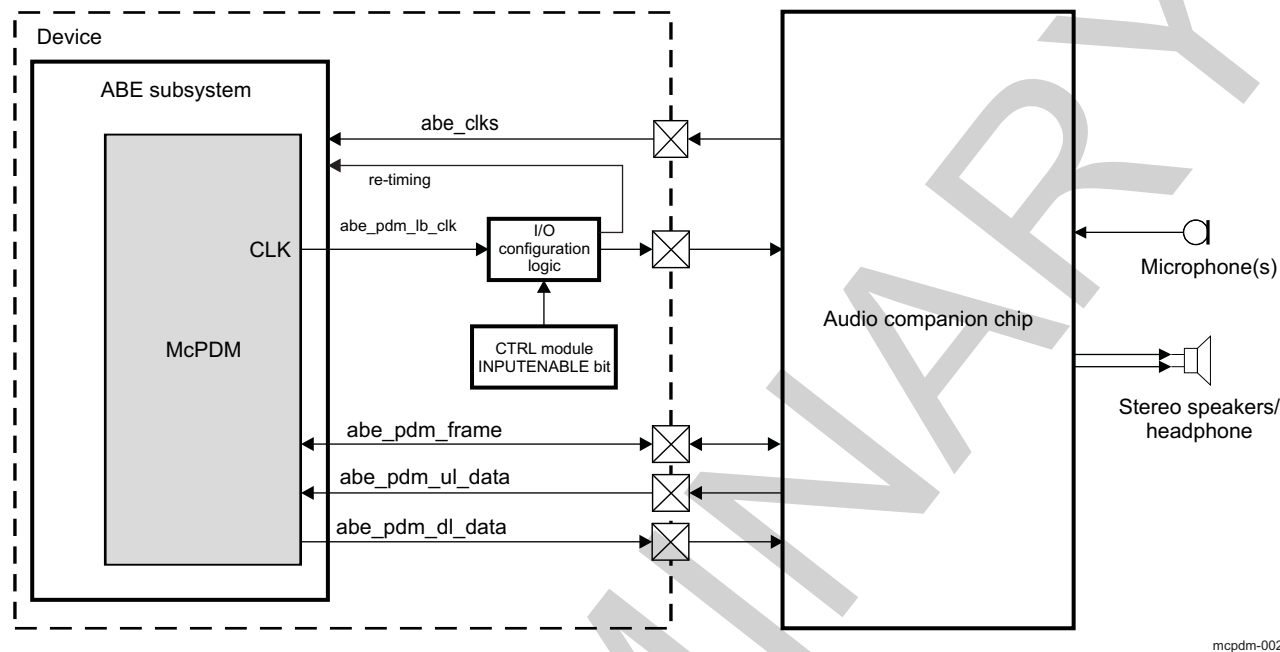

(1) I = Input; O = Output; I/O = Bidirectional

(2) This output signal is also used as retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).

24.6.2.3 McPDM Configurations

Figure 24-162 shows the McPDM generic configuration.

Figure 24-162. McPDM Generic Configuration

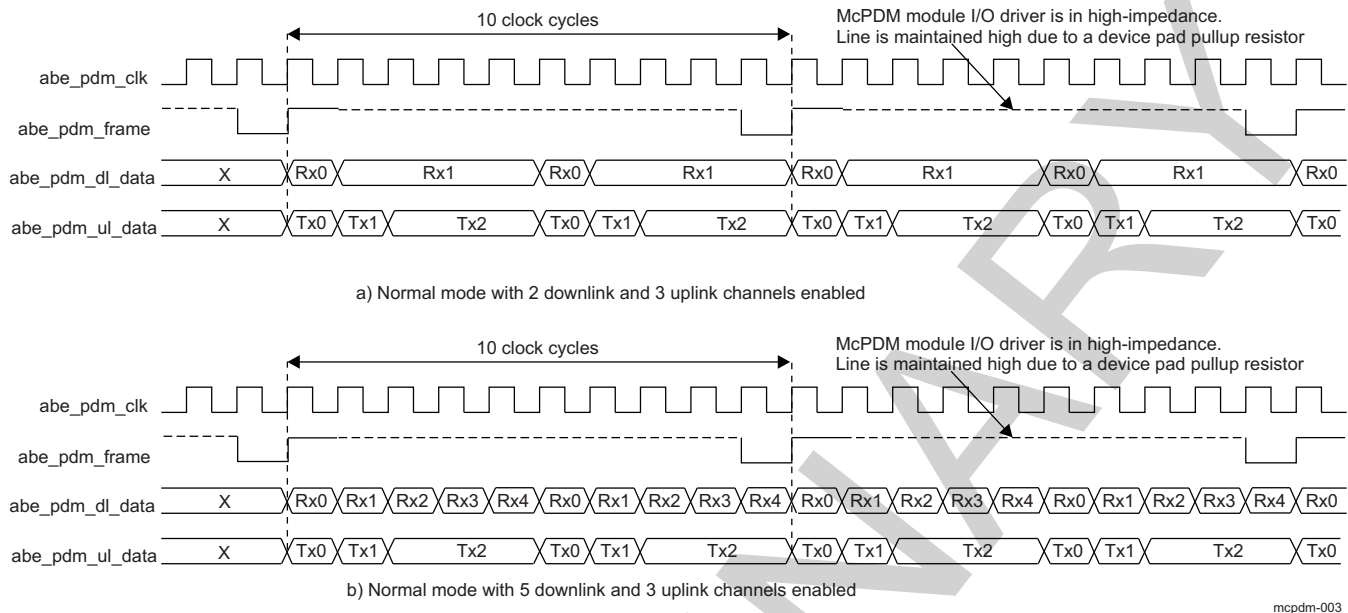

24.6.2.4 Protocols and Data Formats

24.6.2.4.1 Protocols and Data Formats in Normal Mode

This section describes data transfer on the interface in normal mode. In this mode, the `abe_pdm_frame` signal is used only for frame synchronization purposes. Figure 24-163 shows the protocols and data formats in normal mode for two examples:

- (a) With two downlink and three uplink channels enabled
- (b) With five downlink and three uplink channels enabled

Figure 24-163. Protocols and Data Formats in Normal Mode

In normal mode, the frequency ratio between the `abe_pdm_frame` and `abe_pdm_lb_clk` signals is 10. This ratio is static and the `abe_pdm_frame` signal low-pulse width is one clock period longer than the `abe_pdm_lb_clk` signal.

The `abe_pdm_frame` signal is driven by the McPDM module in the device to the external audio companion chip. The McPDM module drives the `abe_pdm_frame` signal low during one clock period of the `abe_pdm_lb_clk` signal, then it drives it high during one clock period of the `abe_pdm_lb_clk` signal before releasing the `abe_pdm_frame` I/O driver in high-impedance state. The McPDM module pad internal pullup resistor allows keeping a high-level state on the `abe_pdm_frame` line when the `abe_pdm_frame` I/O driver is in high-impedance state.

A maximum of two samples × five downlink channels (10 samples) can be transmitted by the McPDM module to the external audio companion chip during a frame period.

A maximum of two samples × three uplink channels (six samples) can be received by the McPDM module from the external audio companion chip during a frame period.

Each downlink and uplink channel can be independently enabled or disabled by setting to 1 or clearing to 0 the corresponding bit in the `MCPDM_CTRL` register.

24.6.2.4.2 Protocols and Data Formats in Command Mode

This section describes data transfer on the interface in command mode. In this mode, the `abe_pdm_frame` signal is used to transmit command words to the external audio companion chip. It allows configuring audio registers in the external audio companion chip (that is, amplifier gains) without using the legacy I²C interface, which may be busy and add latency to gain correction.

NOTE: In command mode, uplink channel samples are transmitted to and downlink channel samples are received from the external audio companion chip as in normal mode.

Figure 24-164 shows the protocols and data formats in command mode.

Figure 24-164. Protocols and Data Formats in Command Mode

24.6.2.4.2.1 Entering Command Mode

Command mode can be entered when command data are pending and no status mode is ongoing or detected.

If both of these conditions are met and the `MCPDM_CTRL[9]` `CMD_INT` bit is set to 1, the McPDM module automatically enters command mode.

To enter command mode, the McPDM module must drive the `abe_pdm_frame` signal low during two periods of the `abe_pdm_lb_clk` clock signal.

The external audio companion chip detects a command mode request from the McPDM module when a low state is detected during two periods of the `abe_pdm_lb_clk` clock signal. Once a command mode request is detected, the external audio companion chip enters command mode. In this mode, the status mode cannot be entered during at least four frame cycles.

If a status mode is detected or ongoing while a command is ready to be sent, the command data are stored in an internal register.

If one or more command data are written before the previous one is sent, the previous one is overwritten with the new one and only the last stored 16-bit command data are sent.

If new command data are available while the system is already in command mode, the current command completes normally and exits before re-entering command mode and transmitting the new command data a frame period later.

24.6.2.4.2.2 Command Data Transmission

The 16-bit command data are transmitted directly after the `abe_pdm_frame` signal is driven low during two periods of the `abe_pdm_lb_clk` clock signal.

When the `MCPDM_CTRL[9]` `CMD_INT` bit is set to 1, 16-bit command data must be written to the `MCPDM_DN_DATA` register. Only the 16 lower bits are significant. When no command must be transmitted on the `abe_pdm_frame` line, a null word (0x00000000) must be written as the command data.

When the `MCPDM_CTRL[9]` `CMD_INT` bit is cleared to 0, no 16-bit command data has to be written to the `MCPDM_DN_DATA` register.

24.6.2.4.2.3 Exiting Command Mode

After the 16-bit command data is sent, the McPDM module drives the `abe_pdm_frame` signal high during one period of the `abe_pdm_lb_clk` clock signal before releasing the `abe_pdm_frame` I/O driver in high-impedance state. The McPDM module pad internal pullup resistor allows keeping a high-level state on the `abe_pdm_frame` line when the `abe_pdm_frame` I/O driver is in high-impedance state.

The McPDM module exits automatically from command mode one period of the `abe_pdm_lb_clk` clock signal after the last bit of the command data has been transmitted on the `abe_pdm_frame` line.

NOTE: Due to this protocol mechanism, frame synchronization is lost (replaced by the ninth bit of the command data) during one frame period. The external audio companion chip must internally emulate a frame synchronization to send uplink channel samples and received downlink channel samples as in normal mode while receiving command data on the `abe_pdm_frame` line.

24.6.2.4.2.4 Multiple Command Data Access

As shown in [Figure 24-164](#), two consecutive command data can be sent every three frames. If no status mode is entered after a command data has been sent, the next command data is sent three frames after starting to send the current command data.

24.6.2.4.3 Protocols and Data Formats in Status Mode

This section describes data transfer on the interface in status mode. In this mode, the `abe_pdm_frame` signal is used to receive status information from the external audio companion chip.

NOTE: In status mode, uplink channel samples are transmitted to and downlink channel samples are received from the external audio companion chip as in normal mode.

Figure 24-165 shows the protocols and data formats in status mode.

Figure 24-165. Protocols and Data Formats in Status Mode

24.6.2.4.3.1 Entering Status Mode

Status mode can be entered when no command mode is detected during the last frame low pulse and no command mode is ongoing.

If both of these conditions are met and the [MCPDM_CTRL](#)[10] STATUS_INT bit is set to 1, the McPDM module automatically enters status mode when the command mode is complete.

In status mode, the status information data are sent by the external audio companion chip to the McPDM module. The status information is stored in an internal register.

If one or more status information packages are received before the previous status information is read, the status information stored in the internal register is overwritten with the new one.

In status mode, the external audio companion chip drives the `abe_pdm_frame` line low until the next frame synchronization low pulse. Then, it sends the 16-bit status information data on the `abe_pdm_frame` line. During the transmission of the status information, the McPDM module does not generate any frame-sync low pulse on the `abe_pdm_frame` line for one frame period.

24.6.2.4.3.2 Status Information Data Reception

The 16-bit status information data are received directly after the second frame-sync low pulse on the `abe_pdm_frame` line.

When the [MCPDM_CTRL](#)[10] STATUS_INT bit is set to 1, 16 bits of status information data must be read from the [MCPDM_UP_DATA](#) register. Only the 16 lower bits are significant. When the value of the status information is a null word (0x00000000), it means that no status information has been sent by the external audio companion chip.

When the [MCPDM_CTRL](#)[10] STATUS_INT bit is cleared to 0, no status information data has to be read from the [MCPDM_UP_DATA](#) register.

24.6.2.4.3.3 Exiting Status Mode

After the 16-bit status information data is sent, the external audio companion chip drives the `abe_pdm_frame` line high during one period of the `abe_pdm_lb_clk` clock signal before releasing its I/O driver in high-impedance state.

The McPDM module automatically exits the status mode one period of the `abe_pdm_lb_clk` clock signal after the last bit of the status information data has been transmitted on the `abe_pdm_frame` line. After exiting status mode, the McPDM module generates frame-sync low pulses.

NOTE: Due to the protocol mechanism, frame synchronization is lost during three frame periods. The external audio companion chip must internally emulate a frame synchronization to send uplink channel samples and received downlink channel samples as in normal mode while transmitting status information data on the `abe_pdm_frame` line.

24.6.2.4.3.4 Multiple Status Information Data Access

Multiple status information data can be sent by the external audio companion chip to the McPDM module every four frames.

Table 24-458. Hardware Requests

| Interrupt Requests | | | | |
|--------------------|--------------------|-------------------------|-------------|---|
| Module Instance | Source Signal Name | Destination Signal Name | Destination | Description |
| McPDM | MCPDM_IRQ | D_IRQ_63 | DSP | McPDM interrupt request to the DSP INTC |

24.6.4 McPDM Functional Description

24.6.4.1 McPDM Block Diagram

Figure 24-167 shows the McPDM block diagram.

Figure 24-167. McPDM Block Diagram

24.6.4.2 McPDM Clock Configuration

The functional clock MCPDM_FCLK is provided by the external audio companion chip. Its frequency can be either 17.64 MHz for a sampling frequency of 88.2/176.4 kHz, or 19.2 MHz for a sampling frequency of 96/192 kHz.

The functional clock is also looped-back to the audio companion chip through ABE_PDM_LB_CLK for resynchronization purposes.

24.6.4.3 McPDM Software Reset

To perform a software reset of the McPDM module, the MCPDM_SYSCONFIG[0] SOFTRESET bit must be set to 1. Reading the MCPDM_SYSCONFIG[0] SOFTRESET bit gives the status of the software reset:

- Read 1: The software reset is ongoing.
- Read 0: The software reset is complete.

Software must ensure that the software reset completes before doing McPDM operations. Moreover, uplink and downlink paths can be independently software reset by setting the MCPDM_CTRL[11] SW_UP_RST bit for the uplink path, and the MCPDM_CTRL[12] SW_DN_RST bit for the downlink path to 1. The software reset is stopped by clearing the MCPDM_CTRL[11] SW_UP_RST bit for the uplink path, and the MCPDM_CTRL[12] SW_DN_RST bit for the downlink path to 0.

The software reset of the McPDM module, after completion, puts all McPDM registers in their default state. The downlink/uplink reset, resets only the downlink/uplink hardware logic (no registers are affected).

24.6.4.4 McPDM Power Management

Table 24-459 describes the power-management features available to the McPDM module.

Table 24-459. Local Power-Management Features

| Feature | Registers | Description |
|------------------------|--|---|
| Clock autogating | N/A | Feature not available |
| Slave idle modes | MCPDM_SYSCONFIG [3:2] IDLEMODE bit field | Force-idle, no-idle, smart-idle, and smart-idle wake-up capable modes are available for the interface clock |
| Clock activity | N/A | Feature not available |
| Master standby modes | N/A | Feature not available |
| Global wake-up enable | N/A | Feature not available |
| Wake-up sources enable | MCPDM_IRQWAKEEN and MCPDM_DMAWAKEEN registers | Each register holds one active-high enable bit per event source able to generate wake-up signal |
| Audio channel enable | MCPDM_CTRL [0] PDM_UP1_EN to MCPDM_CTRL [2] PDM_UP3_EN bits for audio uplink channels MCPDM_CTRL [3] PDM_DN1_EN to MCPDM_CTRL [7] PDM_DN5_EN bits for audio downlink channels | Each of these bits allows enabling (set to 1) or disabling (clear to 0) the corresponding audio channel. |
| Status channel enable | MCPDM_CTRL [10] STATUS_INT bit for the status channel | This bit allows enabling (set to 1) or disabling (clear to 0) the status channel |
| Command channel enable | MCPDM_CTRL [9] CMD_INT bit for the command channel | This bit allows enabling (set to 1) or disabling (clear to 0) the command channel |

The MCPDM_ICLK interface clock is controlled through the PRCM module by using IDLE request and acknowledge signals. The [MCPDM_SYSCONFIG](#)[3:2] IDLEMODE bit field allows controlling the interface clock gating in idle mode.

For the uplink path, the interface clock can be put in idle after the uplink path is enabled. Wakeup is available according to the settings of the [MCPDM_IRQWAKEEN](#) and [MCPDM_DMAWAKEEN](#) registers and the FIFO uplink threshold configured in the [MCPDM_FIFO_CTRL_UP](#)[3:0] UP_TRESH bit field. The wake-up signal is asserted when the FIFO uplink level is equal to or greater than the FIFO uplink threshold value.

For the downlink path, the interface clock can be put in idle after the FIFO downlink level reaches the FIFO downlink threshold at least once. Wakeup is available according to the settings of the [MCPDM_IRQWAKEEN](#) and [MCPDM_DMAWAKEEN](#) registers and the FIFO downlink threshold configured in the [MCPDM_FIFO_CTRL_DN](#)[3:0] DN_TRESH bit field. The wake-up signal is asserted when the FIFO downlink level is below the FIFO downlink threshold value.

24.6.4.5 McPDM Interrupt Requests

The McPDM can generate interrupt requests to the Cortex-A9 MPU and DSP INTCs through the MCPDM_IRQ signal.

Table 24-460 lists the nonmaskable and maskable event flags and their mask that can cause the McPDM module to generate interrupts.

Table 24-460. Interrupt Events

| Nonmaskable Event Flag ⁽¹⁾ | Maskable Event Flag | Event Mask Bit | Event Unmask Bit | Description |
|--|--|---|---|--|
| MCPDM_IRQSTATUS_RAW [11] UP_IRQ_FULL | MCPDM_IRQSTATUS [11] UP_IRQ_FULL | MCPDM_IRQENABLE_CLR [11] UP_IRQ_FULL_MASK | MCPDM_IRQENABLE_SET [11] UP_IRQ_FULL_MASK | FIFO-uplink-full event. This event occurs when FIFO uplink is already full and a new word is written to the FIFO uplink by the uplink part of the McPDM module. |
| MCPDM_IRQSTATUS_RAW [10] UP_IRQ_ALST_FULL | MCPDM_IRQSTATUS [10] UP_IRQ_ALST_FULL | MCPDM_IRQENABLE_CLR [10] UP_IRQ_ALST_FULL_MASK | MCPDM_IRQENABLE_SET [10] UP_IRQ_ALST_FULL_MASK | FIFO-uplink-almost-full event. This event occurs when FIFO uplink contains (FIFO uplink size – 1) words and a new word is written to the FIFO uplink by the uplink part of the McPDM module. |
| MCPDM_IRQSTATUS_RAW [9] UP_IRQ_EMPTY | MCPDM_IRQSTATUS [9] UP_IRQ_EMPTY | MCPDM_IRQENABLE_CLR [9] UP_IRQ_EMPTY_MASK | MCPDM_IRQENABLE_SET [9] UP_IRQ_EMPTY_MASK | FIFO-uplink-empty event. This event occurs when FIFO uplink is already empty and a new word is read from the FIFO uplink by software. |
| MCPDM_IRQSTATUS_RAW [8] UP_IRQ | MCPDM_IRQSTATUS [8] UP_IRQ | MCPDM_IRQENABLE_CLR [8] UP_IRQ_MASK | MCPDM_IRQENABLE_SET [8] UP_IRQ_MASK | FIFO-uplink-read-request event. This event occurs when the number of words stored in the FIFO uplink is equal to or greater than the FIFO uplink threshold. |
| MCPDM_IRQSTATUS_RAW [3] DN_IRQ_FULL | MCPDM_IRQSTATUS [3] DN_IRQ_FULL | MCPDM_IRQENABLE_CLR [3] DN_IRQ_FULL_MASK | MCPDM_IRQENABLE_SET [3] DN_IRQ_FULL_MASK | FIFO-downlink-full event. This event occurs when FIFO downlink is already full and a new word is written to the FIFO downlink by software. |
| MCPDM_IRQSTATUS_RAW [2] DN_IRQ_ALST_EMPTY | MCPDM_IRQSTATUS [2] DN_IRQ_ALST_EMPTY | MCPDM_IRQENABLE_CLR [2] DN_IRQ_ALST_EMPTY_MASK | MCPDM_IRQENABLE_SET [2] DN_IRQ_ALST_EMPTY_MASK | FIFO-downlink-almost-empty event. This event occurs when FIFO downlink contains one word and a new word is read from the FIFO downlink by the downlink part of the McPDM module. |
| MCPDM_IRQSTATUS_RAW [1] DN_IRQ_EMPTY | MCPDM_IRQSTATUS [1] DN_IRQ_EMPTY | MCPDM_IRQENABLE_CLR [1] DN_IRQ_EMPTY_MASK | MCPDM_IRQENABLE_SET [1] DN_IRQ_EMPTY_MASK | FIFO-downlink-empty event. This event occurs when FIFO downlink is empty and a new word is read from the FIFO downlink by the downlink part of the McPDM module. |
| MCPDM_IRQSTATUS_RAW [0] DN_IRQ | MCPDM_IRQSTATUS [0] DN_IRQ | MCPDM_IRQENABLE_CLR [0] DN_IRQ_MASK | MCPDM_IRQENABLE_SET [0] DN_IRQ_MASK | FIFO-downlink-write-request event. This event occurs when the number of words stored in the FIFO downlink is less than the FIFO downlink threshold. |

⁽¹⁾ The MCPDM_IRQSTATUS_RAW register is mainly used for debug purposes.

CAUTION

Once an event generating the interrupt request has been processed by software, this event must be cleared by writing a logical 1 to the corresponding bit of the [MCPDM_IRQSTATUS](#) register.

Writing a logical 1 in a bit of the [MCPDM_IRQSTATUS](#) register also clears the corresponding bit in the [MCPDM_IRQSTATUS_RAW](#) register to 0.

An event can generate an interrupt request when a logical 1 is written to the corresponding mask bit in the [MCPDM_IRQENABLE_SET](#) register. Events are reported in the [MCPDM_IRQSTATUS](#) and [MCPDM_IRQSTATUS_RAW](#) registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the [MCPDM_IRQENABLE_CLR](#) register. Events are reported only in the [MCPDM_IRQSTATUS_RAW](#) register.

In case of the [MCPDM_IRQSTATUS_RAW](#) register, the event is reported in the corresponding bit, even if the interrupt request generation is disabled for this event.

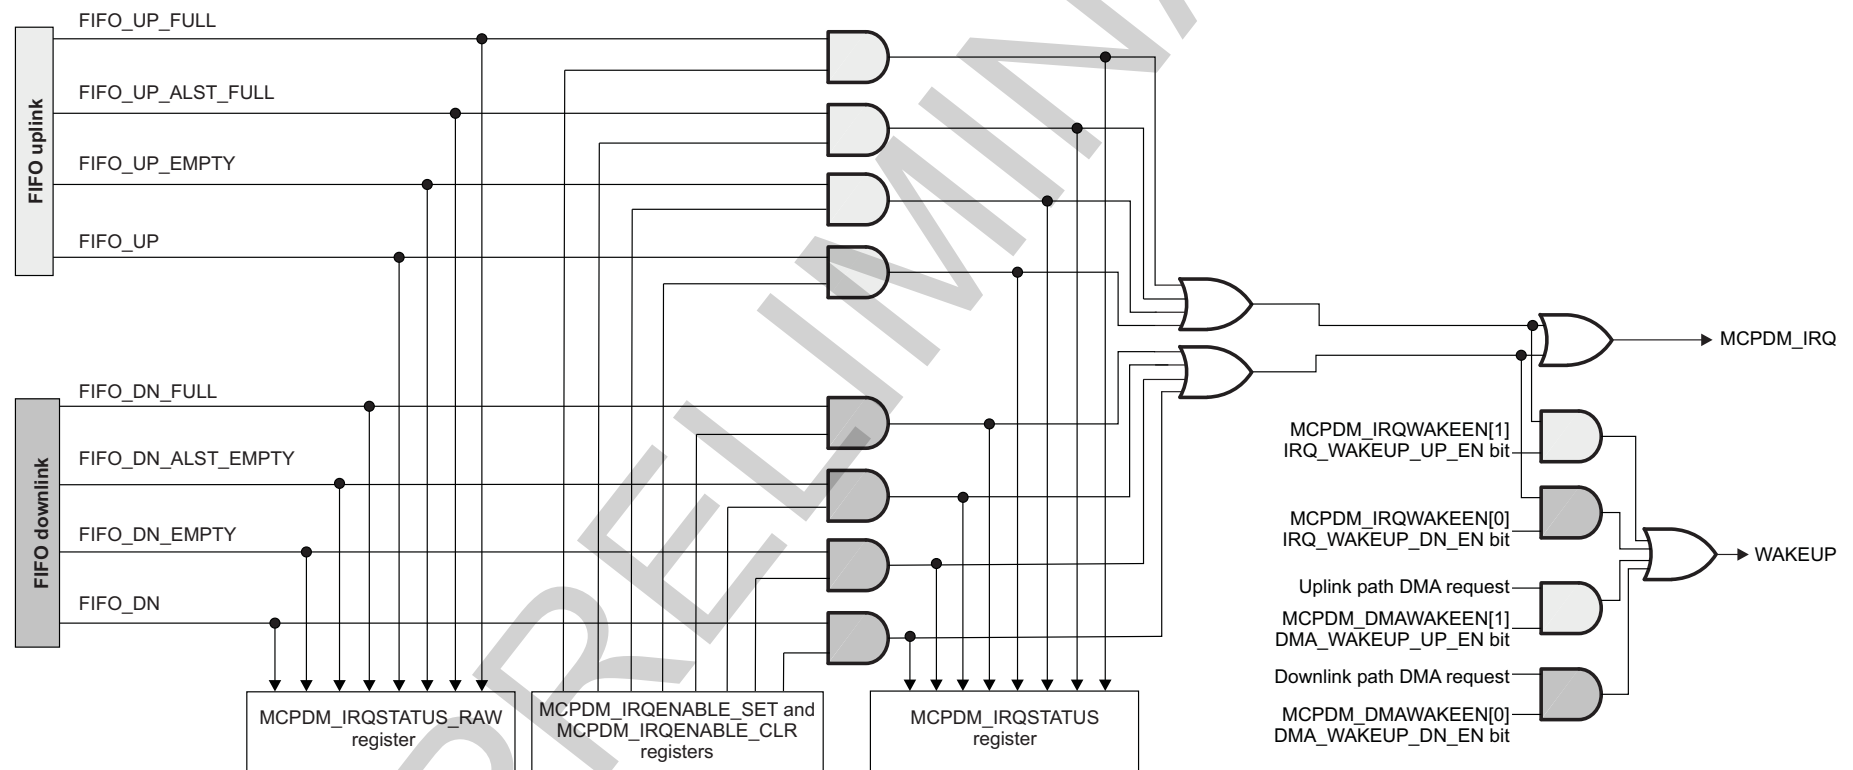

Writing a logical 1 in a bit of the [MCPDM_IRQSTATUS_RAW](#) register sets the corresponding bit in the [MCPDM_IRQSTATUS](#) register to 1.

The [MCPDM_IRQSTATUS_RAW](#) register is used primarily for debug purposes.

For more information about interrupt request signal mapping, see [Table 24-458](#).

[Figure 24-168](#) shows the interrupt tree of the McPDM module.

Figure 24-168. Interrupt Tree

mcpdm-008

24.6.4.6 McPDM DMA Requests

The McPDM module can generate two DMA requests to the sDMA, aDMA, and eDMA controllers:

- The uplink path can generate a DMA request through the MCPDM_DMA_UP signal.
- The downlink path can generate a DMA request through the MCPDM_DMA_DOWN signal.

Table 24-461 lists the DMA requests of the McPDM module.

Table 24-461. McPDM DMA Requests

| DMA Request Signal | DMA Request Generation Enabling Bit | DMA Request Generation Disabling Bit | Description |
|--------------------|---|---|--|
| MCPDM_DMA_UP | MCPDM_DMAENABLE_SET [1] DMA_UP_ENABLE | MCPDM_DMAENABLE_CLR [1] DMA_UP_ENABLE | Uplink path DMA request. This request is generated when the number of words in the FIFO uplink is equal to or above the FIFO uplink threshold. |
| MCPDM_DMA_DOWN | MCPDM_DMAENABLE_SET [0] DMA_DN_ENABLE | MCPDM_DMAENABLE_CLR [0] DMA_DN_ENABLE | Downlink path DMA request. This request is generated when the number of words in the FIFO downlink is below the FIFO downlink threshold. |

To enable or disable the DMA request generation on the MCPDM_DMA_UP signal, one of the following actions must be performed:

- Write a logical 1 to the [MCPDM_DMAENABLE_SET](#)[1] DMA_UP_ENABLE bit to enable the DMA request generation on the MCPDM_DMA_UP signal.
- Write a logical 1 to the [MCPDM_DMAENABLE_CLR](#)[1] DMA_UP_ENABLE bit to disable the DMA request generation on the MCPDM_DMA_UP signal.

To enable or disable the DMA request generation on the MCPDM_DMA_DOWN signal, one of the following actions must be performed:

- Write a logical 1 to the [MCPDM_DMAENABLE_SET](#)[0] DMA_DN_ENABLE bit to enable the DMA request generation on the MCPDM_DMA_DOWN signal.
- Write a logical 1 to the [MCPDM_DMAENABLE_CLR](#)[0] DMA_DN_ENABLE bit to disable the DMA request generation on the MCPDM_DMA_DOWN signal.

For more information about DMA request signals mapping, see [Table 24-458](#).

24.6.4.7 Uplink Path

[Figure 24-169](#) is a detailed block diagram of the uplink path in the McPDM module.

Figure 24-169. Uplink Path Detailed Block Diagram

24.6.4.7.1 Uplink Path Features

The uplink path has the following features:

- Three audio uplink channels
- One status channel
- Decimation filter for each audio uplink channel
- 16-word FIFO uplink with threshold setting
- Audio channel data formatting
- High-frequency sampling feature

24.6.4.7.2 Uplink Path Description

24.6.4.7.2.1 Uplink Data Received From the External Audio Companion Chip

The McPDM interface receives audio uplink channel data and status information data from the external audio companion chip at a clock rate of 17.64 MHz for a sampling frequency of 88.2 kHz, or 19.2 MHz for a sampling frequency of 96 kHz. This low-frequency sampling feature is enabled by default. The uplink path supports a high-frequency sampling feature to work with an ultrasonic external microphone. This feature is enabled by setting the [MCPDM_CTRL\[13\] DIV_SEL](#) bit to 1. Thus, the McPDM interface receives audio uplink channel data and status information data from the external audio companion chip at a clock rate of 17.64 MHz for a sampling frequency of 176.4 kHz, or 19.2 MHz for a sampling frequency of 192 kHz.

The McPDM interface extracts each data bit related to audio and sends it to the decimation filter of the corresponding channel. Therefore, for each audio uplink channel, the McPDM interface generates one bit data flow to the corresponding decimation filter at a rate of 3.528 Mbps for a sampling frequency of 88.2 kHz, or 3.84 Mbps for a sampling frequency of 96 kHz.

Moreover, when status information data are detected on the frame-sync signal ([ABE_PDM_FRAME](#)), the status information data are recovered and sent to the status channel. When no status information data are detected on the frame-sync signal, a null word (0x0000) is sent on the status channel.

For more information about protocols and data formats in normal mode, see [Section 24.6.2.4.1, Protocols and Data Formats in Normal Mode](#). For more information about protocols and data formats in status mode, see [Section 24.6.2.4.3, Protocols and Data Formats in Status Mode](#).

24.6.4.7.2.2 Decimation Filter

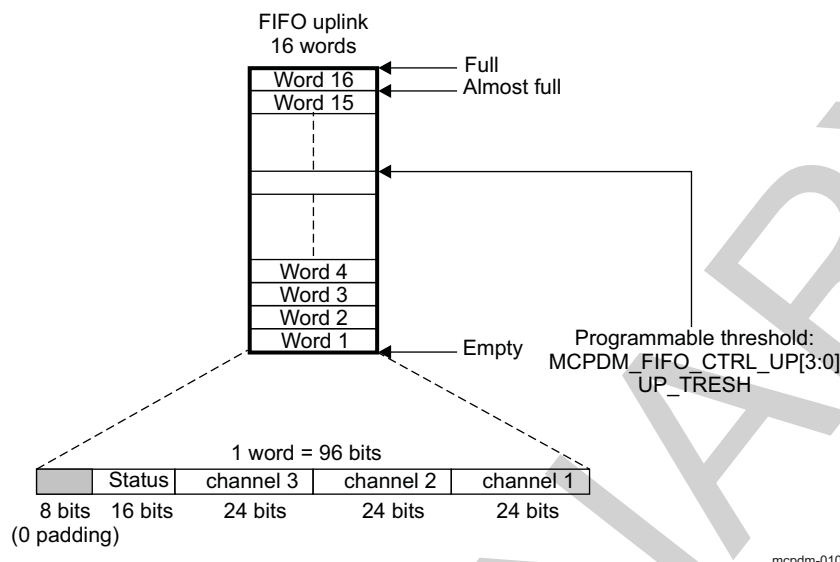

Each bit data flow is related to an audio uplink channel and is provided by the McPDM interface is processed by a decimation filter. The purpose of this filter is to band-limit the noise and downsample the incoming bit data flow to generate a 24-bit-wide signed data flow at a rate of 88.2 kbps for a sampling frequency of 88.2 kHz, or 96 kbps for a sampling frequency of 96 kHz.

24.6.4.7.2.3 FIFO Uplink Management

24.6.4.7.2.3.1 General Description

The McPDM module implements a FIFO for the uplink path for communication with the host processor in the device. The FIFO uplink can store up to 16 words. Each word is 96 bits wide and is a combination of 24-bit-wide signed audio uplink channel data coming from decimation filters and 16-bit-wide status information data coming from the McPDM interface.

[Figure 24-170](#) shows the FIFO uplink overview.

Figure 24-170. FIFO Uplink Overview

24.6.4.7.2.3.2 FIFO Operations

The FIFO uplink is filled with audio uplink channel data coming from decimation filters and status information data from the McPDM interface. Once the FIFO uplink threshold ([MCPDM_FIFO_CTRL_UP\[3:0\] UP_TRESH](#) bit field) is reached and, depending on conditions, an event occurs and generates an interrupt or DMA request.

NOTE: For more information about events generating an interrupt request, see [Section 24.6.4.5, McPDM Interrupt Requests](#).

For more information about conditions for DMA request generation, see [Section 24.6.4.6, McPDM DMA Requests](#).

When an interrupt request upon a FIFO uplink read-request event or an MCPDM_DMA_UP request occurs, the host processor or the DMA controller must read the words from the FIFO uplink ([MCPDM_UP_DATA](#) register). The number of read accesses from the host/DMA is determined by the following equation:

$$\text{Num_read_access} = (\text{PDM_UP1_EN} + \text{PDM_UP2_EN} + \text{PDM_UP3_EN} + \text{STAT_INT}) * (\text{UP_THRESH}),$$
 where the PDM_UP_THRESHOLD is programmed through the [MCPDM_FIFO_CTRL_UP\[3:0\] UP_TRESH](#) bit field.

PDM_UP1_EN, PDM_UP2_EN, PDM_UP3_EN, and STAT_INT are boolean values representing whether or not the corresponding channel is enabled.

For example, if audio uplink channels 1 and 3 are enabled, audio uplink channel 2 is disabled, the status channel is enabled, and the uplink threshold is programmed for one line only ([MCPDM_FIFO_CTRL_UP\[3:0\] UP_TRESH](#) = 0x0):

- Num_read_access = 3 because two audio uplink and the status channels are enabled.
- The first reading of the [MCPDM_UP_DATA](#) register should correspond to the audio uplink channel 1 data.
- The second reading of the [MCPDM_UP_DATA](#) register should correspond to the audio uplink channel 3 data.
- The third reading of the [MCPDM_UP_DATA](#) register should correspond to the status information data.

NOTE: No status information has been sent by the external audio companion chip if the status channel is enabled and the 16 lower bits of the corresponding data read from the [MCPDM_UP_DATA](#) register is 0x0000 .

The audio uplink and status channels cannot be enabled or disabled on the fly during uplink signaling. The uplink path must first be forced to reset by setting the [MCPDM_CTRL](#)[11] SW_UP_RST bit to 1 before enabling or disabling any channels.

Because the audio uplink channel data are 24 bits wide and the [MCPDM_UP_DATA](#) register is 32 bits wide, the [MCPDM_CTRL](#)[8] PDMOUTFORMAT bit allows selecting the justification of the 24-bit audio uplink channel data in the [MCPDM_UP_DATA](#) register:

- When the [MCPDM_CTRL](#)[8] PDMOUTFORMAT bit is cleared to 0, the 24-bit-wide signed audio uplink channel data are left-justified with eight 0 padding bits for the lower bits.
- When the [MCPDM_CTRL](#)[8] PDMOUT FORMAT is set to 1, the 24-bit-wide signed audio uplink channel data are right-justified and sign-extended.

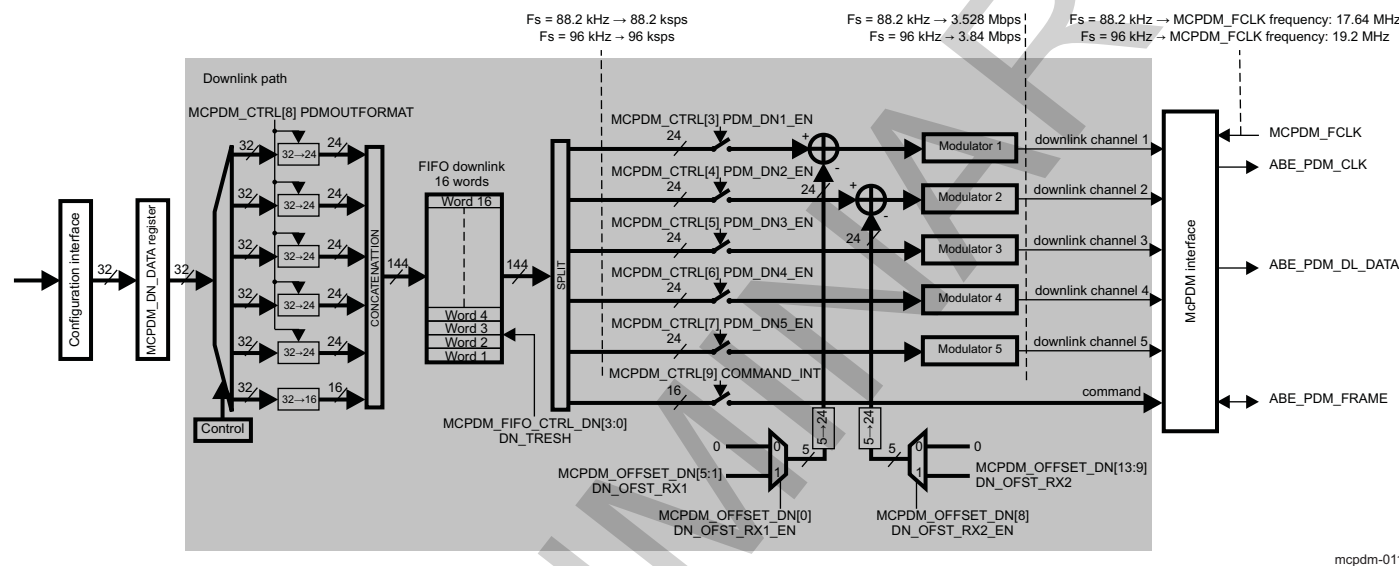

NOTE: The [MCPDM_CTRL](#)[8] PDMOUTFORMAT bit does not affect the status information format. When the status information data are read from the [MCPDM_UP_DATA](#) register, only the 16 lower bits are significant.

The setting of the [MCPDM_CTRL](#)[8] PDMOUTFORMAT bit also affects the audio downlink channel data format.

24.6.4.8 Downlink Path

Figure 24-171 is a detailed block diagram of the downlink path in the McPDM module.

Figure 24-171. Downlink Path Detailed Block Diagram

24.6.4.8.1 Downlink Path Features

The downlink path has the following features:

- Five audio downlink channels
- Offset cancellation for audio downlink channels 1 and 2
- One command channel
- Delta-sigma modulator for each audio downlink channel
- 16-word FIFO downlink with threshold setting
- Audio channel data formatting

24.6.4.8.2 Downlink Path Description

24.6.4.8.2.1 FIFO Downlink Management

24.6.4.8.2.1.1 General Description

The McPDM module implements a FIFO for the downlink path for communication with the host processor in the device. The FIFO downlink can store up to 16 words. Each word is 144 bits wide and is a combination of 24-bit-wide signed audio downlink channels data and 16-bit-wide command information data.

Figure 24-172 shows the FIFO downlink overview.

Figure 24-172. FIFO Downlink Overview

24.6.4.8.2.1.2 FIFO Operations

The FIFO downlink is read by the McPDM module and data related to the audio downlink channels are sent to the delta-sigma modulators, while the data related to the command information is sent to the McPDM interface. Once the FIFO pointer goes below the programmed threshold (the `MCPDM_FIFO_CTRL_DN[3:0] DN_TRESH` bit field), a DMA or interrupt request is sent to the DMA or interrupt handler and, depending on conditions, an event occurs and generates an interrupt or DMA request.

NOTE: For more information about events generating an interrupt request, see [Section 24.6.4.5, McPDM Interrupt Requests](#).

For more information about conditions for DMA request generation, see [Section 24.6.4.6, McPDM DMA Requests](#).

When an interrupt request upon a FIFO downlink write-request event or a MCPDM_DMA_DOWN request occurs, it indicates that the next words are available to be written to the [MCPDM_DN_DATA](#) register. The minimum number of write accesses from the host/DMA is determined by the following equation:

$$\text{Num_min_write_access} = \text{PDM_DN1_EN} + \text{PDM_DN2_EN} + \text{PDM_DN3_EN} + \text{PDM_DN4_EN} + \text{PDM_DN5_EN} + \text{CMD_INT}$$

PDM_DN1_EN, PDM_DN2_EN, PDM_DN3_EN, PDM_DN4_EN, PDM_DN5_EN and CMD_INT are boolean values representing whether the corresponding channel is enable or not.

The maximum number of write accesses (before overwriting the data in the FIFO still to be transmitted) from the host/DMA is determined by the following equation:

$$\text{Num_max_write_access} = (\text{FIFO_SIZE} - \text{DN_THRESH} + 1) * (\text{PDM_DN1_EN} + \text{PDM_DN2_EN} + \text{PDM_DN3_EN} + \text{PDM_DN4_EN} + \text{PDM_DN5_EN} + \text{CMD_INT})$$

FIFO_SIZE is the size of the downlink FIFO, and DN_THRESH is the downlink FIFO threshold, programmed through the [MCPDM_FIFO_CTRL_DN\[3:0\] DN_THRESHOLD](#) bit field.

For example, if audio downlink channels 1, 2, and 3 are enabled, audio downlink channels 4 and 5 are disabled, and the command channel is enabled:

- Num_min_write_access = 4, because three audio downlinks and the command channels are enabled.
- The first writing to the [MCPDM_DN_DATA](#) register should correspond to the audio downlink channel 1 data.
- The second writing to the [MCPDM_DN_DATA](#) register should correspond to the audio downlink channel 2 data.
- The third writing to the [MCPDM_DN_DATA](#) register should correspond to the audio downlink channel 3 data.
- The fourth writing to the [MCPDM_DN_DATA](#) register should correspond to the command information data.

NOTE: When the command channel is enabled and no command data need to be sent to the external audio companion chip, 0x0000 must be written to the 16 lower bits of the [MCPDM_DN_DATA](#) register as command data.

The audio downlink and command channels cannot be enabled or disabled on the fly during downlink signaling. The downlink path must first be forced to reset by setting the [MCPDM_CTRL\[12\] SW_DN_RST](#) bit to 1 before enabling or disabling any channels.

Because the audio downlink channel data are 24 bits wide and the [MCPDM_DN_DATA](#) register is 32 bits wide, the [MCPDM_CTRL\[8\] PDMOUTFORMAT](#) bit indicates the justification of the 24-bit audio downlink channel data in the [MCPDM_DN_DATA](#) register:

- When the [MCPDM_CTRL\[8\] PDMOUTFORMAT](#) is cleared to 0, the 24-bit-wide signed audio downlink channel data are left-justified with eight 0 padding bits for the lower bits.
- When [MCPDM_CTRL\[8\] PDMOUTFORMAT](#) is set to 1, the 24-bit-wide signed audio downlink channel data are right-justified and sign-extended.

NOTE: The [MCPDM_CTRL\[8\] PDMOUTFORMAT](#) bit does not affect the command information format. When the command information data are written to the [MCPDM_DN_DATA](#) register, only the 16 lower bits are significant.

The setting of the [MCPDM_CTRL\[8\] PDMOUTFORMAT](#) bit also affects the audio uplink channel data format.

24.6.4.8.2.1.3 Offset Cancellation

Because audio downlink channels 1 and 2 are related to the analog headset downlink path within the external audio companion chip, an offset cancellation feature is available for these channels to eliminate the offset of the analog headset downlink path.

When the offset cancellation feature is enabled, an offset value is subtracted from the audio data before being sent to the pulse-density modulator. The offset values are read from registers within the external audio companion chip and configured in the [MCPDM_DN_OFFSET\[5:1\] DN_OFST_RX1](#) bit field for the audio downlink channel 1, and in the [MCPDM_DN_OFFSET\[13:9\] DN_OFST_RX2](#) bit field for the audio downlink channel 2.

The offset cancellation feature is enabled or disabled by configuring the [MCPDM_DN_OFFSET\[0\] DN_OFST_RX1_EN](#) bit for the audio downlink channel 1, and the [MCPDM_DN_OFFSET\[8\] DN_OFST_RX2_EN](#) bit for the audio downlink channel 2 (00: Disabled, 10: Enabled).

24.6.4.8.2.1.4 Pulse-Density Modulators

Each 24-bit-wide data related to an audio downlink channel is processed by a pulse-density modulator. The purpose of this modulator is to upsample the incoming audio data and then perform a 1-bit pulse-density modulation to generate a 1-bit data flow at a rate of 3.528 Mbps for a sampling frequency of 88.2 kHz, or 3.84 Mbps for a sampling frequency of 96 kHz. The 1-bit pulse-density modulation allows using a 1-bit analog-to-digital converter (ADC) implemented in the external audio companion chip to convert the audio digital data into an audio analog signal.

24.6.4.8.2.1.4.1 Pulse-Density Modulators Watchdog Logic

If the 1-bit data flow coming out of the pulse-density modulator has 12 or more consecutive 1s or 0s, the pulse-density modulator had entered into an unstable or saturated condition. An unstable or saturated condition leads to unpredictable behavior of the pulse-density modulator, thereby producing random noise. To prevent this unstable or saturated condition from occurring, a watchdog logic is used to monitor the 1-bit output of the pulse-density modulator for 12 consecutive 1s or 12 consecutive 0s. If entry to an unstable condition is detected, the watchdog logic asserts the reset of the McPDM downlink paths for one clock pulse to put the McPDM hardware logic, related to the downlink mechanism, to initial state.

The watchdog logic is disabled by default. To enable it, the [MCPDM_CTRL\[14\] WD_EN](#) bit must be set to 0x1. If the watchdog logic is disabled, only the assertion of the downlink path reset [MCPDM_CTRL\[12\] SW_DN_RST](#) bit is allowed to reset the McPDM hardware logic, which is related to the downlink mechanism. If the watchdog logic is enabled, the downlink mechanism logic is reset when the downlink path reset or the watchdog reset is asserted.

[Figure 24-173](#) shows the McPDM watchdog logic mechanism.

Figure 24-173. McPDM Watchdog Logic

24.6.4.8.2.1.5 Downlink Data Sent to the External Audio Companion Chip

The McPDM interface transmits the audio downlink channel data and command data to the external audio companion chip at a clock rate of 17.64 MHz for a sampling frequency of 88.2 kHz, or 19.2 MHz for a sampling frequency of 96 kHz.

The command data are sent on the frame-sync signal (ABE_PDM_FRAME) when the command channel is enabled. When the command channel is disabled or the command data is 0x0000, no command data is sent on the frame-sync signal.

NOTE: For more information about protocols and data formats in normal mode, see [Section 24.6.2.4.1, Protocols and Data Formats in Normal Mode](#).

For more information about protocols and data formats in command mode, see [Section 24.6.2.4.2, Protocols and Data Formats in Command Mode](#).

24.6.4.9 Error Reporting

During normal operation, when interrupt and DMA requests are properly served, no FIFO-uplink-full and no FIFO-downlink-empty events should occur.

Nevertheless, if one of these events occurs, the corresponding path must be forced to reset by software before being reconfigured. For more information about events servicing, see [Section 24.6.5.1.2, McPDM Events Servicing](#).

Moreover, a FIFO-uplink-empty or FIFO-downlink-full event occurs only when all the channels of the corresponding path have been disabled during normal operation.

NOTE: Channels must not be enabled or disabled during normal operation.

Channels can be enabled or disabled when the corresponding path is forced to reset. For more information about McPDM software reset, see [Section 24.6.4.3, McPDM Software Reset](#).

24.6.5 McPDM Programming Guide

24.6.5.1 McPDM Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

24.6.5.1.1 Global Initialization

24.6.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules in the device when the McPDM module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the environment and the integration of the McPDM. For more information, see [Section 24.6.2, McPDM Environment](#), and [Section 24.6.3, McPDM Integration](#).

[Table 24-462](#) describes the global initialization of surrounding modules.

Table 24-462. Global Initialization of Surrounding Modules

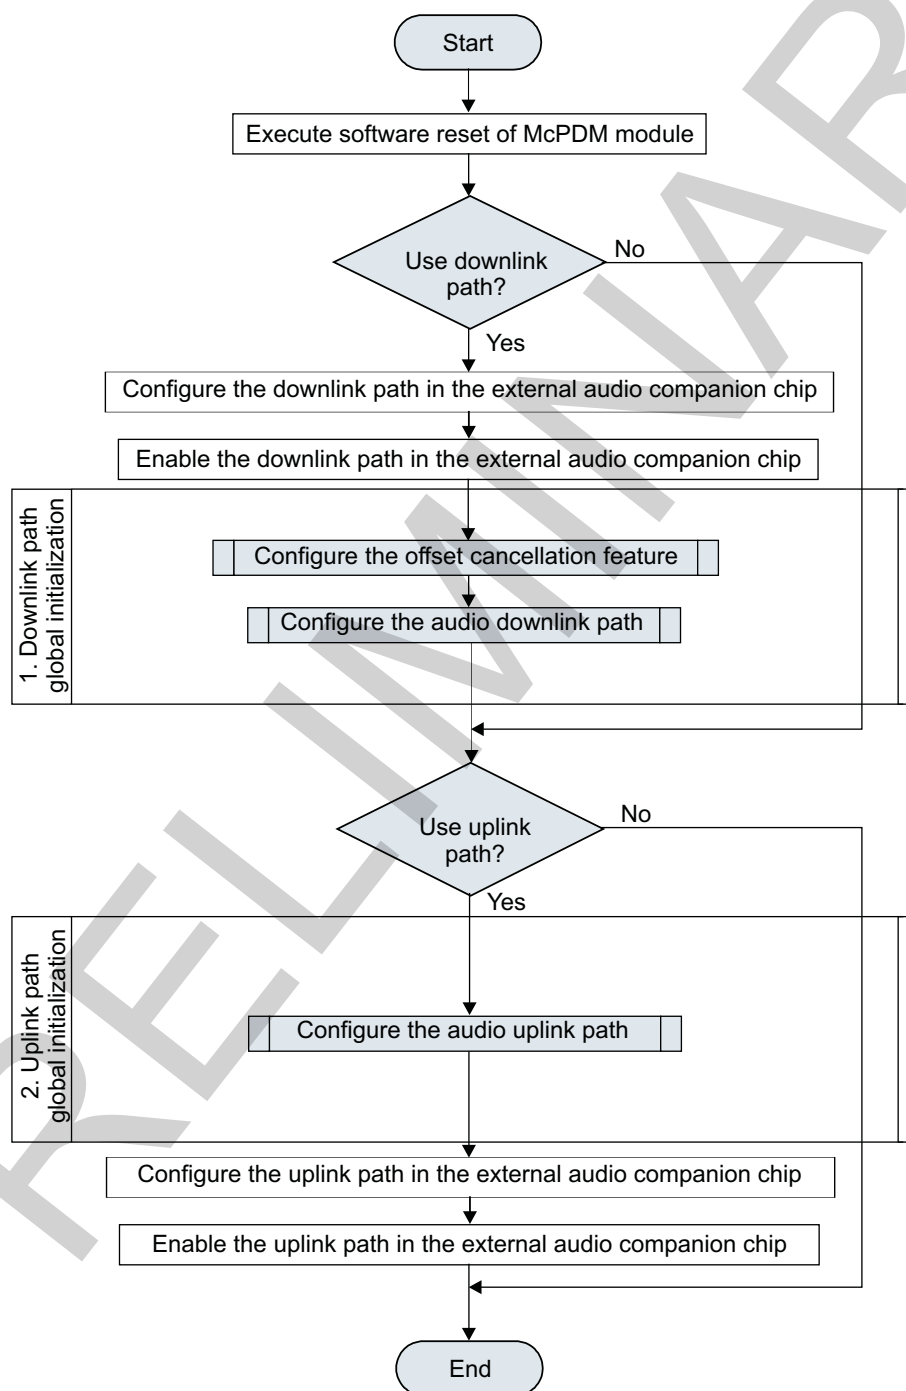

| Surrounding Modules | Comments |
|---|--|
| PRCM module | The McPDM interface clock must be enabled and the functional clock must not be gated. |
| Control module | The McPDM-specific pad muxing must be configured in the device control module. |
| (Optional) Cortex-A9 MPU INTC (or DSP INTC) | The Cortex-A9 MPU (or DSP) INTC must be configured to enable the interrupt request generation to the Cortex-A9 MPU (or DSP) subsystem when interrupt requests are generated by the McPDM module. |
| (Optional) sDMA (or eDMA or aDMA) | The sDMA (or eDMA or aDMA) controller must be configured to account for the DMA requests generated by the McPDM module in the case of autonomous data transfers from/to memory. |
| (Optional) Interconnect | For more information about the interconnect configuration, see Chapter 14, Interconnect . |
| External audio chip | Initialize the external audio chip according to the specific needs. |

24.6.5.1.1.2 McPDM Global Initialization

24.6.5.1.1.2.1 Main Sequence – McPDM Global Initialization

This procedure initializes the McPDM after a power-on reset (POR) or software reset. [Figure 24-174](#) shows a flow chart for the global initialization of the McPDM module.

Figure 24-174. McPDM Global Initialization Flow Chart

mcpdm-013

The McPDM software reset is executed by setting the [MCPDM_SYSCONFIG\[0\]](#) SOFTRESET bit to 0x1. To detect the reset done event, user software must check this bit until it is cleared to 0x0 by the hardware.

Configuration of the offset cancellation feature is optional. The use of that feature depends on the characteristics of the external audio chip attached to the McPDM interface. If the external chip adds some DC offset on its output, then the offset cancellation feature of the McPDM must be used.

Table 24-463 describes the steps of the downlink path global initialization.

Table 24-463. McPDM Downlink Path Global Initialization

| Procedure | Step | Access Type | Register/Bit Field/Programming Model | Value |
|--|--|-------------|---|--|
| Configure the offset cancellation feature. Only downlink path 1 and downlink path 2 can use the offset cancellation feature. | 1. Read the offset value for the audio downlink path 1 from the external audio companion chip through the I ² C interface. | R | Offset register 1 in the external audio companion chip | OFFSET1 |
| | 2. Configure the offset of the audio downlink path 1. | W | MCPDM_DN_OFFSET [5:1] DN_OFST_RX1 | OFFSET1 |
| | 3. Enable the offset cancellation feature for the audio downlink path 1. | W | MCPDM_DN_OFFSET [0] DN_OFST_RX1_EN | 0x1 |
| | 4. Read the offset value for the audio downlink path 2 from the external audio companion chip through the I ² C interface. | R | Offset register 2 in the external audio companion chip | OFFSET2 |
| | 5. Configure the offset of the audio downlink path 2. | W | MCPDM_DN_OFFSET [13:9] DN_OFST_RX2 | OFFSET2 |
| | 6. Enable the offset cancellation feature for the audio downlink path 2. | W | MCPDM_DN_OFFSET [8] DN_OFST_RX2_EN | 0x1 |
| Configure the audio downlink path. | 1. Enable the interrupt request generation for the downlink path. | W | a. MCPDM_IRQENABLE_SET [3] DN_IRQ_FULL_MASK b. MCPDM_IRQENABLE_SET [2] DN_IRQ_ALMST_EMPTY_MASK c. MCPDM_IRQENABLE_SET [1] DN_IRQ_EMPTY_MASK d. MCPDM_IRQENABLE_SET [0] DN_IRQ_MASK | When downlink DMA request not used: 0xF When downlink DMA request used: 0xE |
| | 2. Configure the FIFO downlink threshold. | W | MCPDM_FIFO_CTRL_DN [3:0] DN_TRESH | FIFO downlink threshold |
| | 3. Enable the DMA request generation for the downlink path (optional: only if DMA request generation for the downlink path is required). | W | MCPDM_DMAENABLE_SET [0] DMA_DN_ENABLE | 0x1 |
| | 4. Enable the downlink channels. | W | MCPDM_CTRL | See Table 24-459 . |

Table 24-464 describes the steps of the uplink path global initialization.

Table 24-464. McPDM Uplink Path Global Initialization

| Step | Access Type | Register/Bit Field/Programming Model | Value |
|--|-------------|--|--|
| 1. Enable the interrupt request generation for the uplink path. | W | a. MCPDM_IRQENABLE_SET [11] UP_IRQ_FULL_MASK b. MCPDM_IRQENABLE_SET [10] UP_IRQ_ALMST_FULL_MASK c. MCPDM_IRQENABLE_SET [9] UP_IRQ_EMPTY_MASK d. MCPDM_IRQENABLE_SET [8] UP_IRQ_MASK | When uplink DMA request not used: 0xF When uplink DMA request used: 0xE |
| 2. Configure the FIFO uplink threshold. | W | MCPDM_FIFO_CTRL_UP [3:0] UP_TRESH | FIFO uplink threshold |
| 3. Enable the DMA request generation for the uplink path (optional: only if DMA request generation for the uplink path is required). | W | MCPDM_DMAENABLE_SET [1] DMA_UP_ENABLE | 0x1 |

Table 24-464. McPDM Uplink Path Global Initialization (continued)

| Step | Access Type | Register/Bit Field/Programming Model | Value |
|--|-------------|---|------------------------------------|
| 4. Configure the FIFO uplink sampling frequency. | W | MCPDM_CTRL [13] DIV_SEL | 0x- |
| 5. Enable the uplink channels. | W | MCPDM_CTRL | See Table 24-459 . |

24.6.5.1.2 McPDM Events Servicing

24.6.5.1.2.1 Downlink Path Event Servicing

[Table 24-465](#) to [Table 24-468](#) describe the downlink path event servicing.

When the four downlink interrupts are enabled and then the downlink channel(s) is enabled, the FIFO-downlink-write request ([MCPDM_IRQSTATUS](#) = 0x1), instead of the FIFO-downlink-empty request ([MCPDM_IRQSTATUS](#) = 0x2), is generated. The first audio data to be sent is written from the interrupt handler. The McPDM module can work in two ways:

- Enable the desired downlink channels, and then write in the downlink FIFO the audio data that is going to be sent.
- Write the audio data in the downlink FIFO, and then enable the desired downlink channels to send this audio data.

In either way, the FIFO-downlink-write request is generated.

Table 24-465. FIFO-Downlink-Full Event Servicing

| Step | Access Type | Register/Bit Field/Programming Model | Value |
|--|-------------|---|-------|
| TEST TA: Is FIFO downlink full? | R | MCPDM_IRQSTATUS [3] DN_IRQ_FULL | |

| Bits | Field Name | Description | Type | Reset |
|-------|-------------------|---|------|---------|
| 31:12 | RESERVED | | R | 0x00000 |
| 11 | UP_IRQ_FULL | FIFO-uplink-full signal appears when a write access is performed and the FIFO uplink is already full. Read 0x0: No event pending Write 0x0: No action Write 0x1: Clear pending event Read 0x1: Event pending | RW | 0 |
| 10 | UP_IRQ_ALST_FULL | FIFO uplink almost-full signal appears when the FIFO uplink contains (FIFO uplink size – 1) elements. Read 0x0: No event pending Write 0x0: No action Write 0x1: Clear pending event Read 0x1: Event pending | RW | 0 |
| 9 | UP_IRQ_EMPTY | FIFO uplink empty signal appears when a read access is done and FIFO uplink already empty. Read 0x0: No event pending Write 0x0: No action Write 0x1: Clear pending event Read 0x1: Event pending | RW | 0 |
| 8 | UP_IRQ | FIFO uplink interrupt appears when the number of data present in the FIFO uplink has reached the value of the FIFO uplink threshold. Read 0x0: No event pending Write 0x0: No action Write 0x1: Clear pending event Read 0x1: Event pending | RW | 0 |
| 7:4 | RESERVED | | R | 0x0 |
| 3 | DN_IRQ_FULL | FIFO downlink full signal appears when the FIFO uplink is full and another a write access is performed. Read 0x0: No event pending Write 0x0: No action Write 0x1: Clear pending event Read 0x1: Event pending | RW | 0 |
| 2 | DN_IRQ_ALST_EMPTY | FIFO downlink almost empty signal appears when the FIFO downlink contains only one element. Read 0x0: No event pending Write 0x0: No action Write 0x1: Clear pending event Read 0x1: Event pending | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|--------------|---|---------------|-------|
| 1 | DN_IRQ_EMPTY | FIFO-downlink-empty signal appears when read access is performed and FIFO downlink is already empty. Read 0x0: No event pending Write 0x0: No action Write 0x1: Clear pending event Read 0x1: Event pending | RW W1toSet | 0 |
| 0 | DN_IRQ | FIFO downlink status is set when the number of data is below the FIFO downlink threshold value. Read 0x0: No event pending Write 0x0: No action Write 0x1: Clear pending event Read 0x1: Event pending | RW | 0 |

24.7 Digital Microphone Module

This section describes the digital microphone (DMIC) module.

24.7.1 DMIC Overview

The digital microphone (DMIC) module consists of an audio module dedicated to a mobile telephone terminal. The DMIC allows the support of up to six digital microphones. It provides an interface between the audio backend (ABE) module and microphones connected through the 6-wire DMIC serial interface.

The DMIC supports six paths. Because each path is composed of two digital microphone channels, the DMIC can be used with three stereo or six mono microphones. Each path is enabled or disabled independently.

The DMIC generates a pulse-density modulated (PDM) stream of bits and transfers it in one period or one half-period of the clock provided by the DMIC (oversampling clock).

Each microphone is directly connected to a filter decimator to extract the audio samples at the desired accuracy and sample rate. Data are stored in the first in first out (FIFO), which is controlled by interrupt request (IRQ) and direct memory access (DMA) request.

The DMIC pads are supplied with 1.8 V. These pads assure the transition to the host supply.

[Figure 24-175](#) shows the DMIC in the device.

Figure 24-175. DMIC

The main features of the DMIC are:

- Six external pin connections (three data lines and three clock lines)
- Using the three clock lines, the DMIC delivers three clock signals (same frequency, individually gateable) for all digital microphones.
- Using the three data lines, the DMIC receives audio data from external microphones.
- Supports stereo (up to three) and mono (up to six) digital microphones
- Each line can support two microphones working in clock phase opposition.
- Selectable functional clock source
- Programmable output clock frequency ($32 \times FS$, $50 \times FS$, $64 \times FS$, or $80 \times FS$, where $FS = 48 \text{ kHz}$)
- Programmable data sampling sensibility (rising or falling edge)
- One RX FIFO (16 words of 144 bits)
- Supports idle request/acknowledge power, reset, and clock management (PRCM) module protocol
- Interconnect sample format: 32 bits (only 24 are significant)
- One IRQ to the microprocessor unit (Cortex™-A9 microprocessor unit [MPU]) and digital signal processor (DSP) subsystems
- One DMA request capability on programmable FIFO threshold

24.7.2 DMIC Environment

This section describes the DMIC application fields from an environment point of view (that is, external connections). It presents the DMIC connectivity options, lists possible interfaces, and details the protocol and data format used in each case.

24.7.2.1 DMIC Interface With External MIC

24.7.2.1.1 DMIC Interface Overview

The DMIC interface is a 6-wire interface. The DMIC module can support up to three external stereo and six mono digital microphones. A DMIC is an external module that can deliver data. A clock is sent from the host to the microphone.

Figure 24-176 and Figure 24-177 show two cases of use of the DMIC, but all configurations are possible with stereo and mono digital microphones. The output of the DMIC is in 32-bit format.

Figure 24-176 shows the DMIC used with three stereo DMICs.

Figure 24-176. DMIC With Three Stereo DMICs

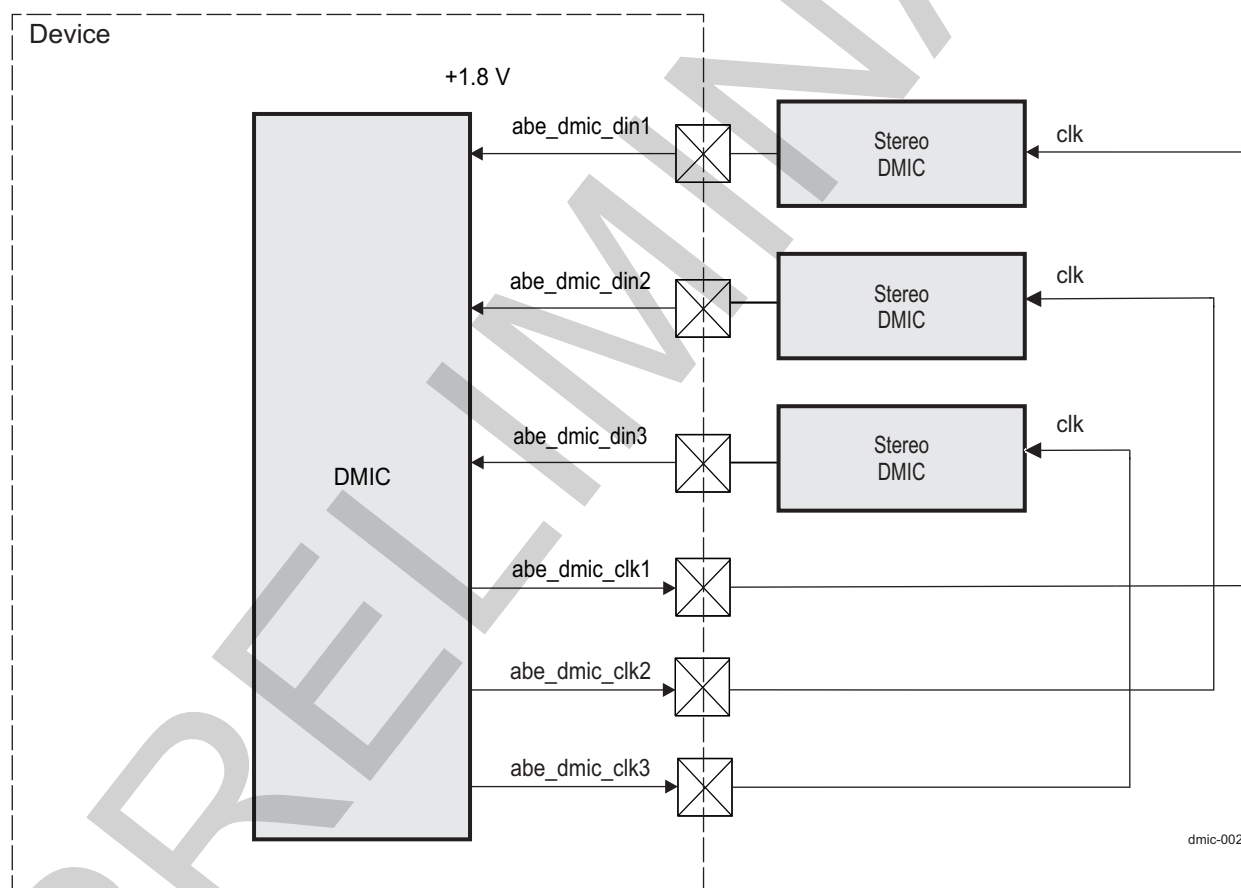

Figure 24-177 shows the DMIC used with six mono DMICs.

dmic-002

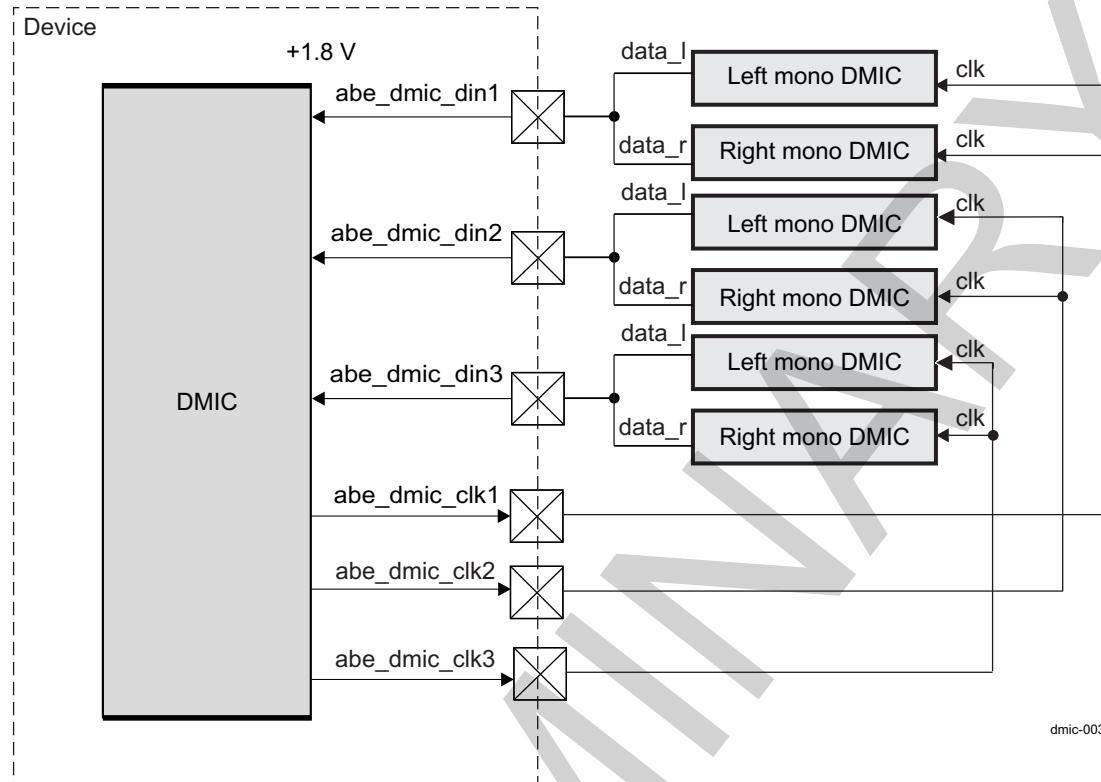

Figure 24-177. DMIC With Six Mono DMICs**24.7.2.1.2 DMIC Signals**

Table 24-507 describes the signals in the DMIC module.

Table 24-507. Input/Output

| Signal Name | I/O ⁽¹⁾ | Description | Reset Value ⁽¹⁾ |
|---------------|--------------------|--|----------------------------|
| abe_dmic_clk1 | O | Digital (stereo) microphone clock output 1 | 0 |
| abe_dmic_clk2 | O | Digital (stereo) microphone clock output 2 | 0 |
| abe_dmic_clk3 | O | Digital (stereo) microphone clock output 3 | 0 |
| abe_dmic_din1 | I | Digital (stereo) microphone data input 1 | Hi-Z |
| abe_dmic_din2 | I | Digital (stereo) microphone data input 2 | Hi-Z |
| abe_dmic_din3 | I | Digital (stereo) microphone data input 3 | Hi-Z |

⁽¹⁾ I = Input; O = Output; Hi-Z = High impedance

All DMIC external connections have pullup or pulldown resistors, selected and configured in the control module registers.

24.7.2.1.3 Serial Data Format

The DMIC generates a PDM stream of bits and transfers it in one period or one half-period of the clock. Then, the filter decimator extracts the 24-bit audio samples.

24.7.2.1.3.1 DMIC Clock Generation and Synchronization

When DMIC_POLAR is set to 0, the microphone left data is generated on the abe_dmic_clk low level. When DMIC_POLAR is set to 1, the microphone left data is generated on the abe_dmic_clk high level. There are three DMIC_POLARx bits (where x = 1, 2, or 3) corresponding to the three stereo paths:

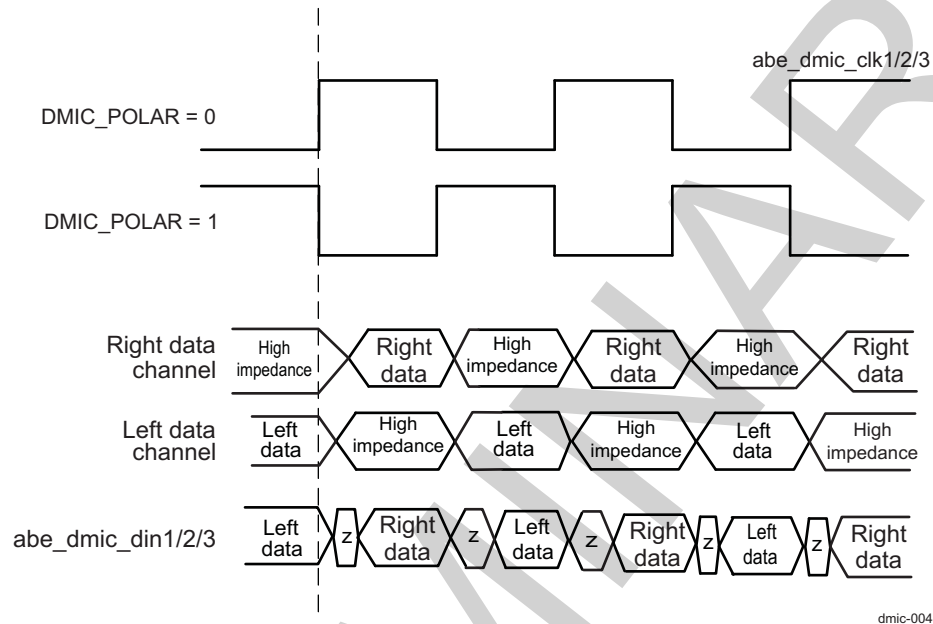

- **DMIC_CTRL[4]** for path 1

- [DMIC_CTRL\[5\]](#) for path 2
- [DMIC_CTRL\[6\]](#) for path 3

The DMIC_POLARx bits are set depending on the configuration of the external digital microphone.

[Figure 24-178](#) is a diagram of the DMIC interface with a DMIC.

Figure 24-178. DMIC Interface Diagram With External DMICs

24.7.2.2 DMIC Functional Path

The DMIC path processes, decimates, and filters the data from the DMIC interface, and stores the processed data in the FIFO. The FIFO is controlled by IRQ and DMA requests and is fed outside of the DMIC.

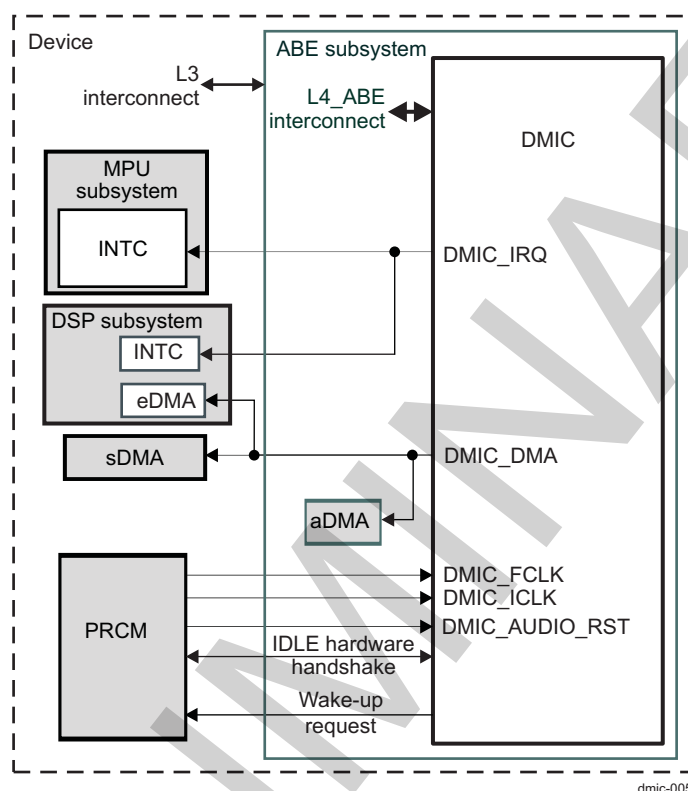

For more information about microphone data processing, see [Section 24.7.4.7, Audio Data Processing](#).

24.7.3 DMIC Integration

This section describes the integration of the DMIC in the device, and includes information about clocks, resets, and hardware requests.

Figure 24-179 shows the DMIC integration.

Figure 24-179. DMIC Integration

NOTE: For more information about the IDLE hardware handshake and the wake-up request, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

The DMIC integration includes:

- One functional clock
- One interface clock
- One IRQ
- One sDMA/aDMA/eDMA request
- IDLE hardware handshake
- Wake-up request

[Table 24-508](#) through [Table 24-510](#) summarize the integration of the module in the device.

Table 24-508. Integration Attributes

| Module Instance | Attributes | | |
|-----------------|--------------|--------------------|--------------|

| | DMIC_DMA | D_DMA_44 | eDMA | DMA request to the DSP DMA (eDMA) |

NOTE:

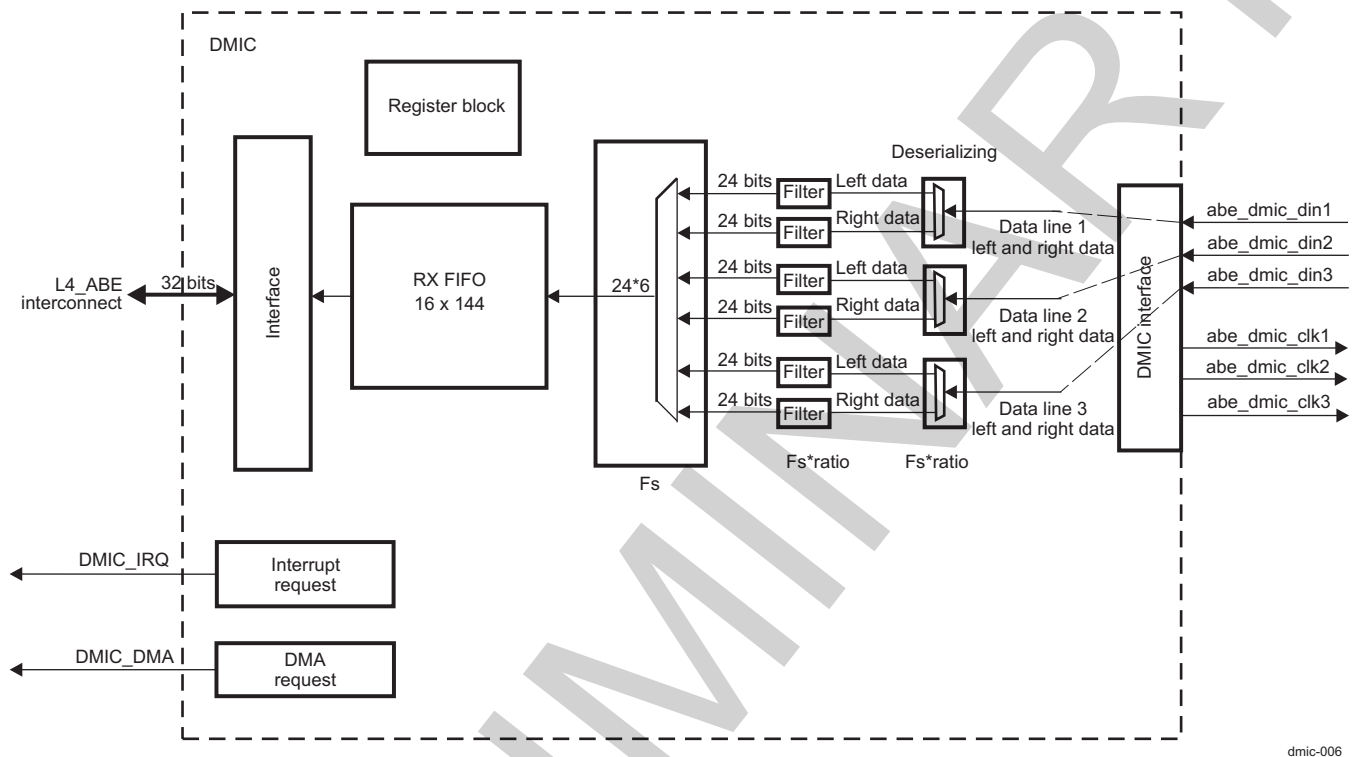

- For a description of the interrupt source, see [Section 24.7.4.5, Interrupt Requests](#).
- For a description of the DMA source, see [Section 24.7.4.6, DMA Requests](#).
- For information about PRCM clock gating and management and PRCM reset sources and distribution, see , *Power Domain*, in [Chapter 3, Power, Reset, and Clock Management](#).

24.7.4 DMIC Functional Description

24.7.4.1 Block Diagram

Figure 24-180 is the DMIC block diagram.

Figure 24-180. DMIC Block Diagram

24.7.4.2 DMIC Clock Configuration

The DMIC operates from one interface clock to interface with the L4-ABE interconnect and one selectable (among three) functional clock. These clocks are provided by the PRCM module. For the interface clock, request and acknowledge are set up between the PRCM module and the DMIC.

Figure 24-181 shows the DMIC clock selection.

Figure 24-181. DMIC Clock Selection

DMIC_FCLK is the source clock signal. Several source clocks are available and are selected according to the configuration of the [DMIC_CTRL\[9:7\]](#) DMIC_CLK_DIV bit field. For more information about

DMIC_FCLK selection, see [Figure 24-181](#). `abe_dmic_clkx` are the output clocks generated in the DMIC and are fed to the external microphones. They are also the internal clocks of the external microphones. The performance in terms of signal-to-noise ratio (SNR) depends on these clocks. Users must take care about the value of `abe_dmic_clkx` (the analog-to-digital converter [ADC] clock) when selecting the source clock (DMIC_FCLK). [Table 24-511](#) describes the `abe_dmic_clkx` generation.

Table 24-511. `abe_dmic_clkx` Generation

| DMIC_FCLK | DMIC_CLK_DIV | DMIC_FCLK/ <code>abe_dmic_clk</code> | <code>abe_dmic_clk</code> = ADC Clock | Ratio = <code>abe_dmic_clk</code> /FS = 48 kHz |
|------------|--------------|---|--|---|
| 19.2 MHz | 000 | 8 | 2.4 MHz | 50 |
| | 001 | 5 | 3.84 MHz | 80 |
| 24 MHz | 010 | 10 | 2.4 MHz | 50 |
| 24.576 MHz | 011 | 8 | 3.072 MHz | 64 |
| | 100 | 16 | 1.536 MHz | 32 |
| 12 MHz | 101 | 5 | 2.4 MHz | 50 |

The maximum clock on the interface is 3.84 MHz, with a source clock of 19.2 MHz.

24.7.4.3 DMIC Software Reset

[Table 24-512](#) lists the different types of software reset available at the module level.

Table 24-512. Reset Description

| Type | Name | Source | Description |
|----------|---|--------|--------------------------|
| Software | DMIC_SYSCONFIG[1] SOFTRESET | — | Module software reset |
| Software | DMIC_CTRL[10] SW_DMIC_RST | — | Reset-enabled DMIC paths |

The software path reset is gated by:

- [DMIC_CTRL\[0\]](#) DMIC_UP1_EN for path 1
- [DMIC_CTRL\[1\]](#) DMIC_UP2_EN for path 2
- [DMIC_CTRL\[2\]](#) DMIC_UP3_EN for path 3
- [DMIC_CTRL\[10\]](#) SW_DMIC_RST

When the [DMIC_CTRL\[10\]](#) SW_DMIC_RST bit is set to 1, the corresponding enabled DMIC paths are reset. Resets are cleared by writing 0.

NOTE: A software reset is required to change the configuration of enabled paths; for example, to disable path 3, a software reset of path 3 is mandatory for the change to be considered.

A module software reset can be performed by setting the [DMIC_SYSCONFIG\[1\]](#) SOFTRESET bit. This action starts a soft reset sequence.

The software reset status of the module can be checked by reading the [DMIC_SYSCONFIG\[0\]](#) SOFTRESET bit (0: reset is done; 1: reset is ongoing).

24.7.4.4 DMIC Power Management

[Table 24-513](#) describes the power-management features available for the DMIC.

Table 24-513. Local Power-Management Features

| Feature | Registers | Description |
|------------------|---|---|
| Clock autogating | N/A | Feature not available |
| Slave idle modes | DMIC_SYSCONFIG[3:2] SIDLEMODE | Force-idle, no-idle, smart-idle, and smart-idle wakeup capable modes are available. |
| Clock activity | N/A | Feature not available |

Table 24-513. Local Power-Management Features (continued)

| Feature | Registers | Description |
|------------------------|--|---|
| Master standby modes | N/A | Feature not available |
| Global wake-up enable | N/A | Feature not available |
| Wake-up sources enable | DMIC_IRQWAKEEN [0] IRQ_WAKEUP_EN DMIC_DMAWAKEEN [0] DMA_WAKEUP_EN | This register holds one active-high enable bit per event source that can generate a wake-up signal. |

24.7.4.5 DMIC Interrupt Requests

[Table 24-514](#) lists the event flags, and their mask, that can cause module interrupts.

Table 24-514. Interrupt Events

| Nonmaskable Event Flag ⁽¹⁾ | Maskable Event Flag | Event Mask Bit | Event Unmask Bit | Description |
|---|---|--|--|--|
| DMIC_IRQSTATUS_RAW[3] DMIC_IRQ_EMPTY | DMIC_IRQSTATUS[3] DMIC_IRQ_EMPTY | DMIC_IRQENABLE_CLR[3] DMIC_IRQ_EMPTY_MASK | DMIC_IRQENABLE_SET[3] DMIC_IRQ_EMPTY_MASK | FIFO empty event. This event occurs when the FIFO is already empty and a new word is read from the FIFO by software. |
| DMIC_IRQSTATUS_RAW[2] DMIC_IRQ_ALST_FULL | DMIC_IRQSTATUS[2] DMIC_IRQ_ALST_FULL | DMIC_IRQENABLE_CLR[2] DMIC_IRQ_ALST_FULL_MASK | DMIC_IRQENABLE_SET[2] DMIC_IRQ_ALST_FULL_MASK | FIFO almost-full event. This event occurs when the FIFO contains (FIFO size – 1) words and a new word is written to the FIFO. |
| DMIC_IRQSTATUS_RAW[1] DMIC_IRQ_FULL | DMIC_IRQSTATUS[1] DMIC_IRQ_FULL | DMIC_IRQENABLE_CLR[1] DMIC_IRQ_FULL_MASK | DMIC_IRQENABLE_SET[1] DMIC_IRQ_FULL_MASK | FIFO full event. This event occurs when the FIFO is already full and a new word is written to the FIFO. |
| DMIC_IRQSTATUS_RAW[0] DMIC_IRQ | DMIC_IRQSTATUS[0] DMIC_IRQ | DMIC_IRQENABLE_CLR[0] DMIC_IRQ_MASK | DMIC_IRQENABLE_SET[0] DMIC_IRQ_MASK | FIFO read request event. This event occurs when the number of words stored in the FIFO is equal to or greater than the FIFO threshold. |

⁽¹⁾ The DMIC_IRQSTATUS_RAW register is used primarily for debug purposes.

The interrupt line is asserted (active high) when one of the following signals appears:

- DMIC_IRQ_EMPTY
- DMIC_IRQ_ALST_FULL
- DMIC_IRQ_FULL
- DMIC_IRQ

Read the [DMIC_IRQSTATUS](#) register to determine which event occurs.

CAUTION

Interrupt lines must be cleared by software. Write 1 in the [DMIC_IRQSTATUS](#) register to clear the corresponding event.

An event can generate an IRQ when the corresponding mask bit in the [DMIC_IRQENABLE_SET](#) register is set to 1. Events are register bits that belong to the [DMIC_IRQSTATUS](#) and [DMIC_IRQSTATUS_RAW](#) registers (the same register accessed by two interconnect addresses). In the case of the [DMIC_IRQSTATUS_RAW](#) register, status event is set even if it is not enabled (used primarily for debug purposes). The [DMIC_IRQSTATUS](#) register is set by writing 1 to the [DMIC_IRQSTATUS_RAW](#) register.

Each internal interrupt signal can be masked by enabling the corresponding mask in the [DMIC_IRQENABLE_SET](#) register or disabling it in the [DMIC_IRQENABLE_CLR](#) register. This mechanism is defined in [Section 24.7.6, DMIC Register Manual](#).

[Figure 24-182](#) shows the interrupt tree with the event generated and the mask that enables or disables the event. All events are summarized to give the single interrupt generation.

Figure 24-182. Interrupt Tree

dmic-008

24.7.4.6 DMIC DMA Requests

The DMIC can generate one DMA request to the sDMA, aDMA, and eDMA controllers (see [Table 24-515](#)).

Table 24-515. DMIC DMA Request

| Name | Description | Enable DMA Bit | Disable DMA Bit |
|-----------------|---|--|--|
| DMIC_DMA_ENABLE | Data ready in FIFO (threshold is reached) | DMIC_DMAENABLE_SET [0] DMA_ENABLE | DMIC_DMAENABLE_CLR [0] DMA_ENABLE |

The DMA lines can be enabled or disabled depending on the value of the bits in the [DMIC_DMAENABLE_SET](#) and [DMIC_DMAENABLE_CLR](#) registers.

A DMA request is sent when data is ready in the FIFO. This request is used only to notify the host that data are ready in the FIFO.

24.7.4.7 Audio Data Processing

The DMIC supports six audio paths and can be used with three stereo or six mono microphones. Each path is independent and is enabled or disabled by using the following bits:

- [DMIC_CTRL](#)[0] DMIC_UP1_EN
- [DMIC_CTRL](#)[1] DMIC_UP2_EN
- [DMIC_CTRL](#)[2] DMIC_UP3_EN

24.7.4.7.1 Filtering

The external DMIC generates a PDM stream of bits and transfers it in one period or one half-period of the clock provided by the DMIC inside the device. The aim of the DMIC audio path is to process data from the DMIC interface, decimate and filter the data, and store the processed data in the FIFO.

The format of the DMIC data is 24 bits (the transfer format is 32 bits long). The following bits allow switching the polarity of the interface:

- [DMIC_CTRL](#)[4] DMIC_POLAR1
- [DMIC_CTRL](#)[5] DMIC_POLAR2
- [DMIC_CTRL](#)[6] DMIC_POLAR3

For more information, see [Section 24.7.2.1.3.1, DMIC Clock Generation and Synchronization](#).

Processed data from the DMIC interface are stored in the FIFO. The FIFO is controlled by the IRQ and DMA request and externally fed by the DMIC using the following interconnect format.

The three uplink paths are identical. Each uplink path is composed of a left and a right channel. The DMIC interface delivers six parallel data of 1 bit (3×2 paths of stereo data that can be used at six mono paths). Each bit goes to a filter. The aim of the filter is to limit the noise and perform decimation by factor D. Factor D depends on the DMIC_CLK_DIV register bits, as described in the ratio defined in [Table 24-511](#). The filters are sinc filter order 4. They are chosen with regard to the nature of the analog converter.

The format of the filter output is 24 bits.

24.7.4.8 FIFO Management

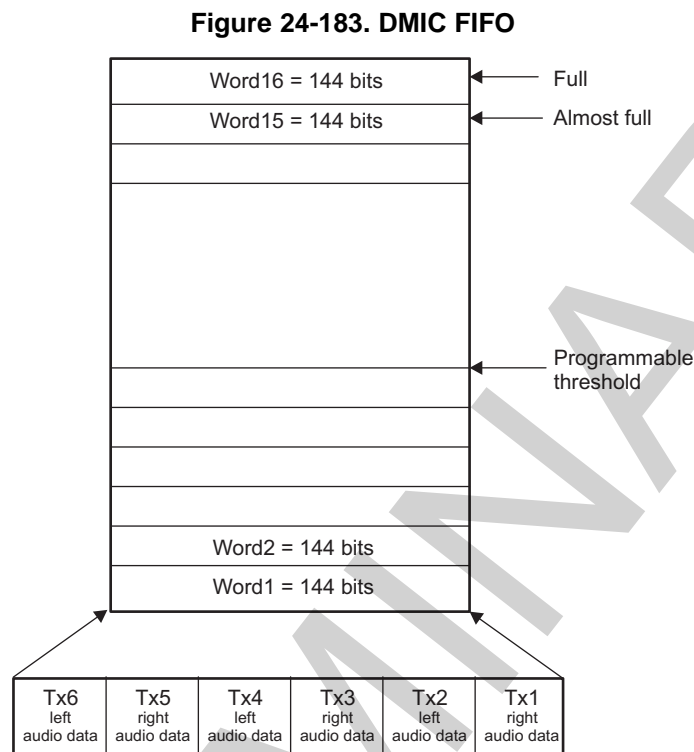

The DMIC implements an internal FIFO controlled by IRQ and DMA request. The host must read words in the FIFO. The interrupt line is used not only to inform the host that data are ready in the FIFO, but also to warn the host about events that can occur, such as FIFO full, almost full, or empty. A DMA request is used only to inform the host that data are ready in the FIFO.

24.7.4.8.1 FIFO General Description

The DMIC communicates with the host through L4-ABE interconnect access. DMIC audio data coming from external microphones are stored in the FIFO. The DMIC FIFO allows the exchange of information between the DMIC and the host. Each audio data is 24 bits long. The DMIC FIFO contains 16 words. Each word is the combination of six audio data ($24 \times 6 = 144$ bits) coming from the interface. The FIFO is controlled by interrupt lines and DMA requests. For more information about IRQs and DMA controls, see [Section 24.7.4.5, DMIC Interrupt Requests](#), and [Section 24.7.4.6, DMIC DMA Requests](#).

FIFO write access is done in the functional clock domain, and read access is done in the interface clock domain.

Figure 24-183 is an overview of the DMIC FIFO.

dmic-009

24.7.4.8.2 FIFO Operations

Audio data are filled in the FIFO from DMIC internal filters. The host must read words in the FIFO. The number of reads depends on the application that is configured by the following bits:

- [DMIC_CTRL\[0\]](#) DMIC_UP1_EN
- [DMIC_CTRL\[2\]](#) DMIC_UP3_EN
- [DMIC_CTRL\[1\]](#) DMIC_UP2_EN
- [DMIC_FIFO_CTRL\[3:0\]](#) DMIC_TRESH (FIFO threshold)

If only uplink path 2 and path 3 are enabled, for example, the Tx1 and Tx2 words are left and right data for path 2, and Tx3 and Tx4 are left and right data for path 3.

When the FIFO threshold is reached, and depending on conditions, an event is sent to the DMA handler. The host must read the exact number of words in the FIFO.

Two accesses are required to read a complete stereo audio path.

The number of read accesses from the host is determined by the following equation:

$$\text{Num_rd_access} = (\text{DMIC_UP1_EN} + \text{DMIC_UP2_EN} + \text{DMIC_UP3_EN}) \times 2 \times (\text{DMIC_TRESH})$$

The FIFO threshold is programmed through the [DMIC_FIFO_CTRL\[3:0\]](#) DMIC_TRESH bit field.

NOTE: If DMIC_TRESH = 1, the host is expected to perform $1 \times (\text{DMIC_UP1_EN} + \text{DMIC_UP2_EN} + \text{DMIC_UP3_EN}) \times 2$ read access every 96 kHz ($2 \times \text{FS}$).

If DMIC_TRESH = 2, the host is expected to perform $(\text{DMIC_UP1_EN} + \text{DMIC_UP2_EN} + \text{DMIC_UP3_EN}) \times 4$ read access every 48 kHz (FS).

If DMIC_TRESH = 12, the host is expected to perform $(\text{DMIC_UP1_EN} + \text{DMIC_UP2_EN} + \text{DMIC_UP3_EN}) \times 12$ access every 8 kHz (FS/6).

24.7.4.8.3 FIFO Output Range Definition

The [DMIC_CTRL\[3\]](#) DMICOUTFORMAT bit allows determining the format of the output of the DMIC uplink module.

When DMICOUTFORMAT = 0, the data going from the FIFO are left-shifted by 8 bits. When DMICOUTFORMAT = 1, the data are signed-extended on 32 bits.

The DMIC uplink modules process audio data based on twos complement format.

NOTE: When DMICOUTFORMAT = 0, the maximum positive swing analog voltage corresponds to a final DMIC output of 0x7FFF FF00. The maximum negative swing analog voltage corresponds to a final DMIC output of 0x8000 0000.

When DMICOUTFORMAT = 1, the sign is extended: The maximum positive swing analog voltage corresponds to a final DMIC output of 0x007F FFFF. The maximum negative swing analog voltage corresponds to a final DMIC output of 0xFF80 0000.

Reading the value of the corresponding audio data in the FIFO requires access to the [DMIC_DATA_REG](#) register. The first access gives the value of Tx1 right data, the second gives the value of Tx2 left data, up to Tx6 (the left audio data of the last audio path). If the path is disabled, 0x0 is read. All data are duplicated (for debug purposes) in their corresponding left or right data registers. [Table 24-516](#) describes the audio data path registers.

Table 24-516. Audio Data Path Registers

| Stereo Audio Path | Mono Audio Path | Data Register |
|-------------------|-----------------|---|
| Right path 1 | Mono path 1 | DMIC_FIFO_DMIC1R_DATA[23:0] |
| Left path 1 | Mono path 2 | DMIC_FIFO_DMIC1L_DATA[23:0] |
| Right path 2 | Mono path 3 | DMIC_FIFO_DMIC2R_DATA[23:0] |
| Left path 2 | Mono path 4 | DMIC_FIFO_DMIC2L_DATA[23:0] |
| Right path 3 | Mono path 5 | DMIC_FIFO_DMIC3R_DATA[23:0] |
| Left path 3 | Mono path 6 | DMIC_FIFO_DMIC3L_DATA[23:0] |

The output of the DMIC path for interconnect access is in 32-bit format.

24.7.5 DMIC Programming Guide

24.7.5.1 DMIC Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

24.7.5.1.1 Global Initialization

24.7.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the DMIC is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the DMIC. For more information, see [Section 24.7.3, DMIC Integration](#) and [Section 24.7.2, DMIC Environment](#).

[Table 24-517](#) describes the global initialization of surrounding modules.

Table 24-517. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|--|---|
| PRCM | Module interface and functional clocks must be enabled. See Chapter 3, Power, Reset, and Clock Management . |
| Control module | Module-specific pad muxing must be set in the control module. See Chapter 19, Control Module . |
| (optional) Cortex-A9 MPU interrupt controller (INTC) (or DSP INTC) | INTC configuration must be done to enable the interrupts from the DMIC. See Chapter 18, Interrupt Controllers . |
| (optional) sDMA (or eDMA or aDMA) | DMA configuration must be done to enable the DMIC DMA channel requests. |
| (optional) Interconnect | For more information about the interconnect configuration, see Chapter 14, Interconnect . |

NOTE: The INTC and DMA configurations are necessary if the interrupt and DMA-based communication modes are used.

24.7.5.1.1.2 DMIC Global Initialization

24.7.5.1.1.2.1 Main Sequence – DMIC Global Initialization

The procedure in [Table 24-518](#) initializes the DMIC after a power-on reset (POR).

Table 24-518. DMIC Global Initialization

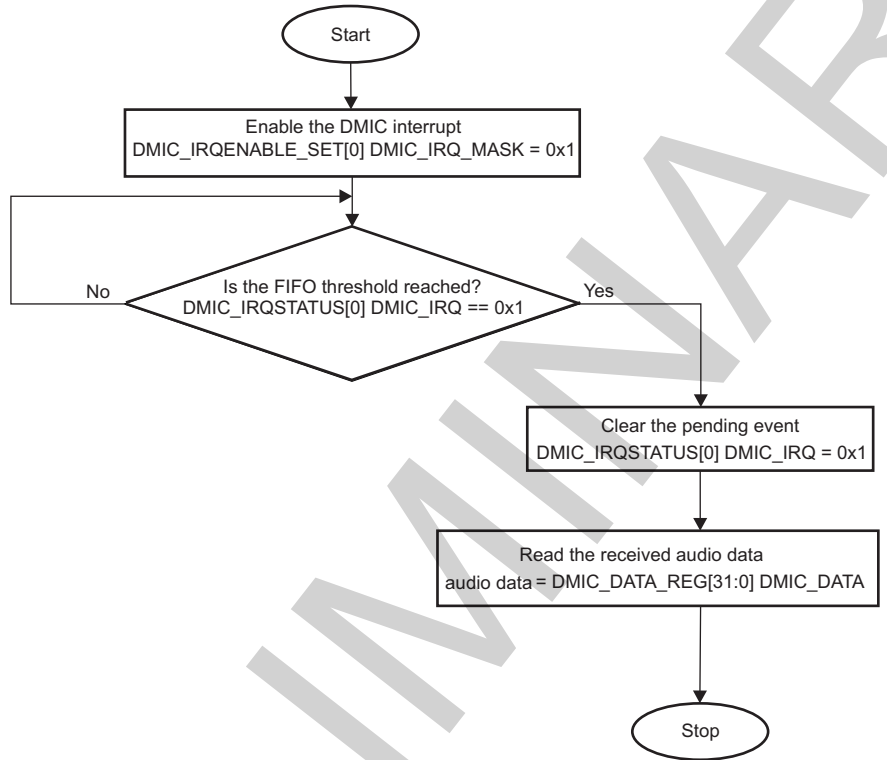

| Step | Register/Bit Field/Programming Model | Value |
|--|---|-------|
| Execute a software reset. | DMIC_SYSCONFIG[0] SOFTRESET | 0x1 |
| Wait for the software reset completion by polling. | DMIC_SYSCONFIG[0] SOFTRESET | ==0x0 |
| Configure the local power management. | DMIC_SYSCONFIG[3:2] SIDLEMODE | 0x- |
| Select the DMIC FIFO threshold. | DMIC_FIFO_CTRL[3:0] DMIC_TRESH | 0x- |
| Select the DMIC output clock frequency. | DMIC_CTRL[9:7] DMIC_CLK_DIV | 0x- |
| Select the DMIC FIFO data output format. | DMIC_CTRL[3] DMICOUTFORMAT | 0x- |
| Select the level (high or low) of the clock signal <code>abe_dmic_clki</code> when the left data is to be generated (extracted) from the external microphone <code>i</code> (where <code>i</code> = 1 to 3). | DMIC_CTRL[j] DMIC_POLAR _i (where <code>j</code> = 4 to 6, and <code>i</code> = 1 to 3) | 0x- |
| Enable audio path <code>i</code> (where <code>i</code> = 1 to 3). | DMIC_CTRL[k] DMIC_POLAR _i (where <code>k</code> = 0 to 2, and <code>i</code> = 1 to 3) | 0x1 |

24.7.5.1.2 Operational Mode Configuration

24.7.5.1.2.1 DMIC Polling Mode

Figure 24-184 shows the polling mode. Table 24-519 summarizes the register call for the polling mode. For the number of read accesses used while reading the received audio data, see Section 24.7.4.8, *FIFO Management*.

Figure 24-184. Polling Mode

dmic-010

Table 24-519. Register Call Summary for Polling Mode

| Register Name | Register Name | Register Name |
|--------------------|----------------|---------------|
| DMIC_IRQENABLE_SET | DMIC_IRQSTATUS | DMIC_DATA_REG |

24.7.5.1.2.2 DMIC Interrupt Mode

Table 24-520 lists the procedure to initialize interrupt mode.

Table 24-520. Interrupt Mode

| Step | Register/Bit Field/Programming Model | Value |
|-----------------------------|--------------------------------------|-------|
| Enable the DMIC interrupts. | DMIC_IRQENABLE_SET[3:0] | 0xF |

24.7.5.1.2.3 DMIC DMA Mode

Table 24-521 lists the procedure to initialize DMA mode.

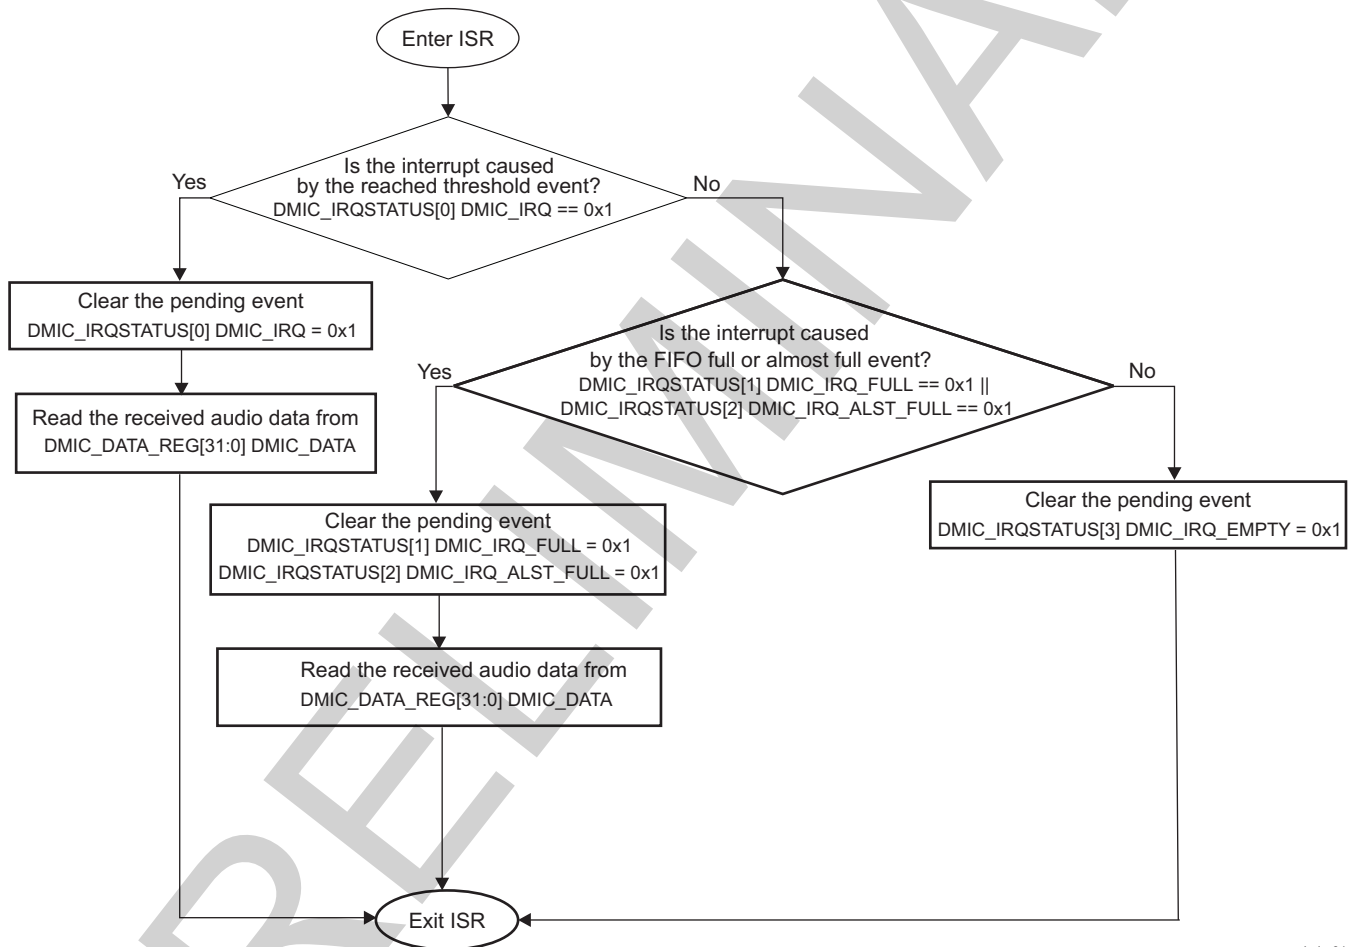

Table 24-521. DMA Mode

| Step | Register/Bit Field/Programming Model | Value |
|--------------------------------------|--|-------|
| Enable the DMIC DMA interrupt event. | DMIC_DMAENABLE_SET [0] DMA_ENABLE | 0x1 |

24.7.5.1.3 DMIC Events Servicing

24.7.5.1.3.1 DMIC Interrupt Servicing

This section describes the interrupt event servicing of the module. [Figure 24-185](#) shows the interrupt handler.

Figure 24-185. Interrupt Handler

dmic-011

When the interrupt is caused by the reached threshold event, for the number of read accesses used while reading the received audio data, see [Section 24.7.4.8, FIFO Management](#).

When the interrupt is caused by a FIFO full or almost-full event, software must read all the available data in the FIFO. If a FIFO full event occurred, the number of read accesses must be the maximum:

$$\text{Num_rd_access} = (\text{DMIC_UP1_EN} + \text{DMIC_UP2_EN} + \text{DMIC_UP3_EN}) \times 2 \times 15$$

If a FIFO almost-full event occurred, the number of read accesses must be:

$$\text{Num_rd_access} = (\text{DMIC_UP1_EN} + \text{DMIC_UP2_EN} + \text{DMIC_UP3_EN}) \times 2 \times 14$$

[Table 24-522](#) summarizes the register call for the interrupt handler.

Table 24-522. Register Call Summary for the Interrupt Handler

| Register Name | Register Name |
|--------------------------------|-------------------------------|
| DMIC_IRQSTATUS | DMIC_DATA_REG |

24.7.6 DMIC Register Manual

24.7.6.1 DMIC Instance Summary

Table 24-523 is the DMIC instance summary.

Table 24-523. DMIC Instance Summary

| Module Name | Base Address L3 Interconnect | Base Address Cortex-A9 Private Access | Base Address DSP Private Access | Size |
|-------------|---------------------------------|---|------------------------------------|------|
| DMIC | 0x4902 E000 | 0x4012 E000 | 0x2 E000 | 4KB |

NOTE: Private access is an access that does not use the L3/L4 interconnects.

24.7.6.2 DMIC Registers

24.7.6.2.1 DMIC Register Summary

Table 24-524 summarizes the DMIC register mapping.

Table 24-524. DMIC Register Mapping Summary

24.8 Multichannel Audio Serial Port

This section describes the multichannel audio serial port (McASP).

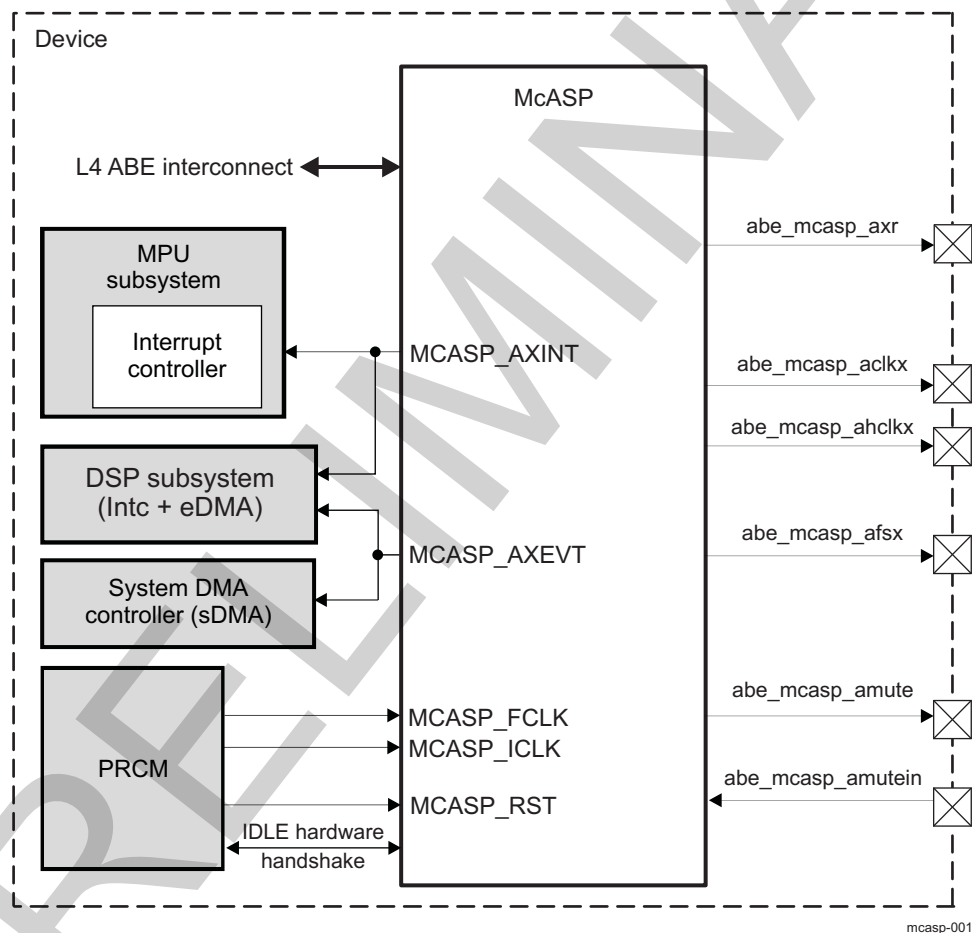

24.8.1 McASP Overview

This section introduces the multichannel audio serial port (McASP) module and describes its main functions and connections in the device.

The McASP functions as a general-purpose audio serial port optimized to the requirements of various audio applications. The McASP is useful for intercomponent digital audio interface transmission (DIT). The McASP has the flexibility to gluelessly connect to a Sony/Philips digital interface (S/PDIF) transmit physical layer component. The McASP module operates in transmit mode only; it has no receive capabilities.

Figure 24-186 shows the McASP module in the device.

Figure 24-186. McASP Module

The McASP module includes the following main features:

- Support of the idle request/acknowledge protocol
- Buffer for transmit operations
- One transmit direct memory access (DMA) request linked with a 32-bit register, and one transmit interrupt request
- One transmit channel
- One serializer

24.8.2 McASP Environment

This section describes the McASP application fields from an environment point of view (external connections), along with the McASP connectivity options. This section also lists all of the possible interfaces and describes the protocol and data format used in each case.

24.8.2.1 McASP Signals

Table 24-563 describes the McASP signals and specifies their links to functions.

Table 24-563. I/O

| Signal | I/O ⁽¹⁾ | Description |
|-------------------|--------------------|--------------------------------------|
| abe_mcasp_axr | O | Audio transmit data |
| abe_mcasp_aclkx | O | Transmit bit clock |
| abe_mcasp_ahclkx | O | Transmit high-frequency master clock |
| abe_mcasp_afsx | O | Transmit frame synchronization |
| abe_mcasp_amute | O | Mute out to external |
| abe_mcasp_amutein | I | Mute in from external |

⁽¹⁾ I = Input; O = Output

All McASP pins on the device can be individually programmed as general-purpose input/output (GPIO) if they are not used for serial port functions.

The McASP includes the following pins:

- Serializer:
 - Data pin abe_mcasp_axr
- Transmit clock generator:
 - abe_mcasp_aclkx: McASP transmit bit clock
 - abe_mcasp_ahclkx: McASP transmit high-frequency master clock
- Transmit frame-sync generator:
 - abe_mcasp_afsx: McASP transmit frame sync
- Mute in/out:
 - abe_mcasp_amutein: McASP mute input (from external device)
 - abe_mcasp_amute: McASP mute output

24.8.2.2 Protocols and Data Formats

24.8.2.2.1 Protocols Supported

The McASP transmit section uses the S/PDIF industry format, which is supported by the DIT transfer mode of the module.

Each transmit section can be programmed to support the following options on the basic serial protocol:

- Programmable clock and frame-sync polarity (rising or falling edge): abe_mcasp_aclkx, abe_mcasp_ahclkx, and abe_mcasp_afsx
- Slot length (number of bits per time slot): 8, 12, 16, 20, 24, 28, 32 bits supported
- Word length (bits per word): 8, 12, 16, 20, 24, 28, 32 bits; always less than or equal to the time slot length
- First-bit data delay: 0-, 1-, 2-bit clocks
- Left/right alignment of word inside slot
- Bit order: Most-significant bit (MSB) first or least-significant bit (LSB) first
- Bit mask/pad/rotate function
- Automatically aligns data in Q31 or integer format

- Automatically masks nonsignificant bits (sets to 0, 1, or extends value of another bit)

The DIT transfer mode includes the following additional transmitter features:

- Transmit-only mode: 384 time slots (subframe) per frame
- Biphase encoded LVCMOS output
- Channel status RAM (384 bits)
- User data RAM (384 bits)
- Separate valid bit (V) for subframes A and B

NOTE: An external transceiver must be connected to the McASP port in the device to translate the electrical signals delivered by the McASP (1.2 V or 1.8 V LVCMOS levels) to the electrical levels of the S/PDIF standard.

24.8.2.2.2 Definition of Terms

The serial bitstream transmitted by the McASP is a long sequence of 1s and 0s on an audio transmit pin (abe_mcasp_axr). However, the sequence has a hierarchical organization that can be described in terms of frames of data, slots, words, and bits.

A basic synchronous serial interface consists of three important components: clock, frame sync, and data. [Figure 24-187](#) shows two of the three basic components: the clock (abe_mcasp_aclx) and the data (abe_mcasp_axr). In operation, the transmitter uses abe_mcasp_aclx as serial clock.

- Bit:

A bit is the smallest entity in the serial data stream. The beginning and end of each bit is marked by an edge of the serial clock. The duration of a bit is a serial clock period. A 1 is represented by a logic high on the abe_mcasp_axr pin for the entire duration of the bit. A 0 is represented by a logic low on the abe_mcasp_axr pin for the entire duration of the bit.

- Word:

A word is a group of bits that make up the data being transferred between the McASP and the external device. [Figure 24-187](#) shows an 8-bit word.

- Slot:

A slot consists of the bits that make up the word and can consist of additional bits used to pad the word to a convenient number of bits for the interface between the McASP and the external device. In [Figure 24-187](#), the audio data consists of only 8 bits of useful data (8-bit word), but it is padded with four 0s (12-bit slot) to satisfy the desired protocol in interfacing to an external device. Within a slot, the bits can be shifted out of the McASP on the abe_mcasp_axr pin with either MSB or LSB first.

When the word size is smaller than the slot size, the word can be aligned to the left of the slot (beginning) or to the right of the slot (end). The additional bits in the slot not belonging to the word can be padded with 0, 1, or with one of the bits (typically, the MSB or LSB) from the data word.

[Figure 24-188](#) shows these options.

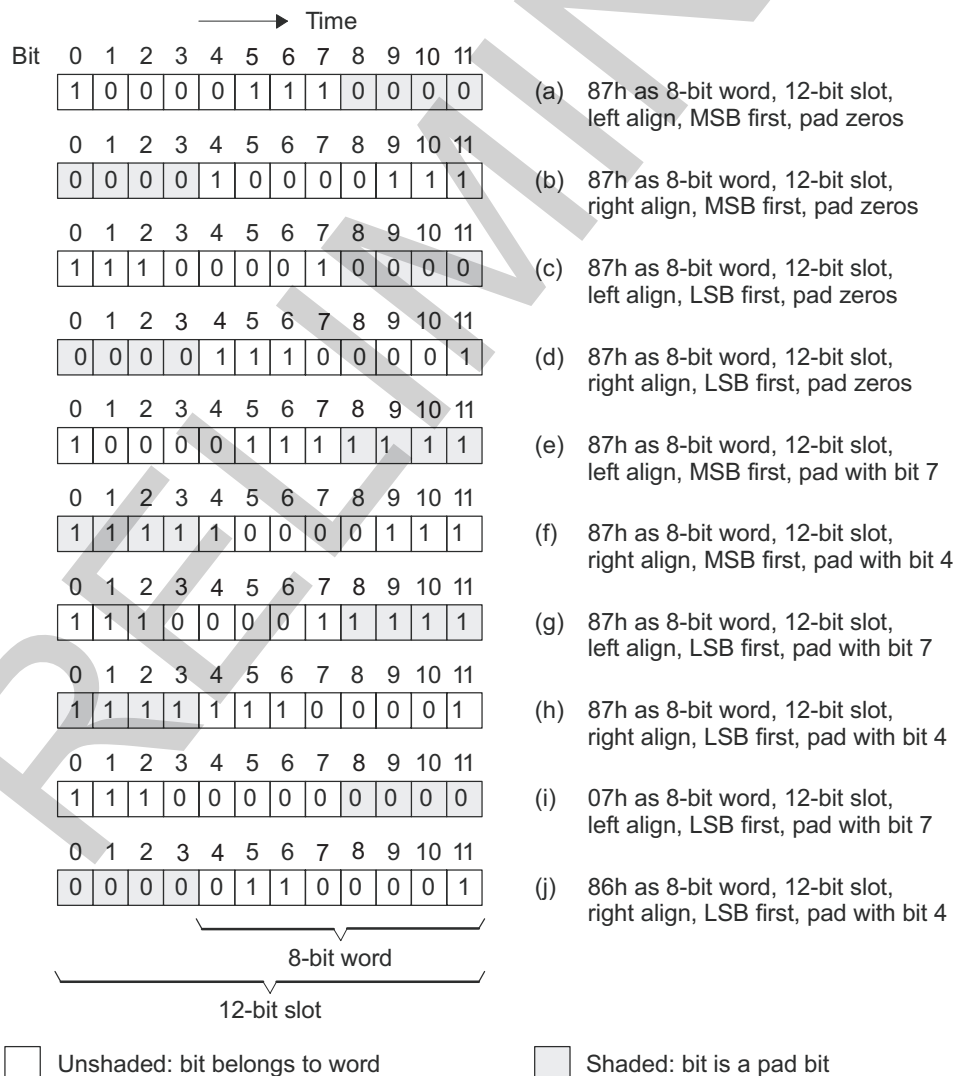

Figure 24-187. Definition of Bit, Word, and Slot

- (1) b7:b0 - bits. Bits b7 to b0 form a word.
- (2) P - pad bits. Bits b7 to b0, together with the 4 pad bits, form a slot.
- (3) In this example, the data is transmitted MSB first, left-aligned.

mcas-p-010

Figure 24-188. Bit Order and Word Alignment Within a Slot Examples

mcas-p-008

- Frame

The third basic element of a synchronous serial interface is the frame synchronization signal, also referred to as frame sync in this document. A frame contains one or multiple slots, as determined by the desired protocol. [Figure 24-189](#) shows an example frame of data and the frame definitions. In operation, the transmitter uses `abe_mcaspx_afx`. This example shows two slots in a frame and the frame-sync (FS) duration of the slot length.

This section shows only the generic definition of the frame sync. For more information about the frame-sync formats required for the transfer modes and protocols (DIT mode and S/PDIF format), see [Section 24.8.2.2.3, Frame Format](#).

Figure 24-189. Definition of Frame and Frame-Sync Width

The following terms are used throughout this chapter:

- DIT: Digital audio interface transmit. The McASP supports transmitting in S/PDIF format on the `abe_mcaspx_axr` data pin.
- Slot or time slot: For DIT format, a McASP time slot corresponds to a DIT subframe.

24.8.2.2.3 S/PDIF Coding Format

The McASP transmitter supports the S/PDIF format with 3.3-V biphase-mark encoded output. The S/PDIF format is supported by the DIT transfer mode of the McASP. This section briefly discusses the S/PDIF coding format.

24.8.2.2.3.1 Biphase-Mark Code

In S/PDIF format, the digital signal is coded using the biphase-mark code (BMC). The clock, frame, and data are embedded in only one signal: data pin `abe_mcaspx_axr`. In the BMC system, each data bit is encoded into two logical states (00, 01, 10, or 11) at the pin. These two logical states form a cell. The duration of the cell, which equals the duration of the data bit, is called a time interval. A logical 1 is represented by two transitions of the signal within a time interval, which corresponds to a cell with logical states 01 or 10. A logical 0 is represented by one transition within a time interval, which corresponds to a cell with logical states 00 or 11. In addition, the logical level at the start of a cell is inverted from the level at the end of the previous cell. [Figure 24-190](#) and [Table 24-564](#) show how data is encoded to the BMC format.

As shown in [Figure 24-190](#), the clock frequency is twice the unencoded data bit rate. In addition, the clock is always programmed to $128 \times f_s$, where f_s is the sample rate (see [Section 24.8.2.2.3.3, Frame Format](#), for details on how this clock rate is derived based on the S/PDIF format).

Table 24-564. Biphase-Mark Encoder

| Data (Unencoded) | Previous State at Pin abe_mcasep_axr | BMC-Encoded Cell Output at abe_mcasep_axr |
|------------------|---|--|
| 0 | 0 | 11 |
| 0 | 1 | 00 |
| 1 | 0 | 10 |
| 1 | 1 | 01 |

24.8.2.2.3.2 Subframe Format

Every audio sample transmitted in a subframe consists of 32 S/PDIF time intervals (or cells), numbered 0 to 31. [Figure 24-191](#) shows a subframe.

- Time intervals 0–3 carry one of the three permitted preambles to signify the type of audio sample in the current subframe. The preamble is not encoded in BMC format, and therefore the preamble code can contain more than two consecutive 0 or 1 logical states in a row. See [Table 24-565](#).
- Time intervals 4–27 carry the audio sample word in linear 2s-complement representation. The MSB is carried by time interval 27. When a 24-bit coding range is used, the LSB is in time interval 4. When a 20-bit coding range is used, time intervals 8–27 carry the audio sample word with the LSB in time interval 8. Time intervals 4–7 may be used for other applications and are designated auxiliary sample bits.
- If the source provides fewer bits than the interface allows (20 or 24), the unused LSBs are set to logical 0. For a nonlinear PCM audio application or a data application, the main data field can carry any other information.
- Time interval 28 carries the validity bit (V) associated with the main data field in the subframe.
- Time interval 29 carries the user data channel (U) associated with the main data field in the subframe.
- Time interval 30 carries the channel status information (C) associated with the main data field in the subframe. The channel status indicates if the data in the subframe is digital audio or some other type of data.
- Time interval 31 carries a parity bit (P) such that time intervals 4–31 carry an even number of 1s and an even number of 0s (even parity). As listed in [Table 24-565](#), the preambles (time intervals 0–3) are also defined with even parity.

Figure 24-191. S/PDIF Subframe Format

As listed in [Table 24-565](#), the McASP DIT generates only one polarity of preambles, and it assumes the previous logical state is 0. This is because the McASP assures an even-polarity encoding scheme when transmitting in DIT mode. If an underrun condition occurs, the DIT resynchronizes to the correct logic level on the `abe_mcasp_axr` pin before continuing with the next transmission.

Table 24-565. Preamble Codes

| Preamble Code ⁽¹⁾ | Previous Logical State | Logical States on pin <code>abe_mcasp_axr</code> ⁽²⁾ | Description |
|------------------------------|------------------------|---|---------------------------------|
| B (or Z) | 0 | 1110 1000 | Start of a block and subframe 1 |
| M (or X) | 0 | 1110 0010 | Subframe 1 |
| W (or Y) | 0 | 1110 0100 | Subframe 2 |

⁽¹⁾ Historically, preamble codes are referred to as B, M, and W. For use in professional applications, preambles are referred to as Z, X, and Y, respectively.

⁽²⁾ The preamble is not BMC-encoded. Each logical state is synchronized to the serial clock. These eight logical states make up time slots (cells) 0 to 3 in the S/PDIF stream.

24.8.2.2.3.3 Frame Format

An S/PDIF frame is composed of two subframes (see [Figure 24-192](#)). For linear coded audio applications, the rate of frame transmission normally corresponds exactly to the source sampling frequency f_s . The S/PDIF format clock rate is therefore $128 \times f_s$ ($128 = 32$ cells per subframe $\times 2$ clocks per cell $\times 2$ subframes per sample). For example, for an S/PDIF stream at a 192-kHz sampling frequency, the serial clock is 128×192 kHz = 24.58 MHz.

In 2-channel operation mode, the samples taken from both channels are transmitted by time multiplexing in consecutive subframes. Both subframes contain valid data. The first subframe (left or A channel in stereophonic operation and primary channel in monophonic operation) normally starts with preamble M. However, the preamble of the first subframe changes to preamble B once every 192 frames to identify the start of the block structure used to organize the channel status information. The second subframe (right or B channel in stereophonic operation and secondary channel in monophonic operation) always starts with preamble W.

In single-channel operation mode in a professional application, the frame format is the same as in the 2-channel mode. Data is carried in the first subframe and may be duplicated in the second subframe. If the second subframe is not carrying duplicate data, cell 28 (validity bit) is set to logical 1.

Figure 24-192. S/PDIF Frame Format

24.8.3 McASP Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

The McASP includes the following features:

- IDLE hardware handshake
- One DMA request
- One interrupt request (IRQ)

Figure 24-193 shows McASP integration.

Figure 24-193. McASP Integration

NOTE: For more information about the IDLE hardware handshake, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 24-566 through Table 24-568 summarize the integration of the module in the device.

Table 24-566. Integration Attributes

| Module Instance | Attributes | | |
|-----------------|--------------|--------------------|--------------|

- For the description of the DMA source, see [Section 24.8.4.12, DMA Requests](#).

24.8.4 McASP Functional Description

24.8.4.1 Block Diagram

Figure 24-194 shows the major blocks of the McASP. The McASP has a transmit clock generator and a frame-sync generator, serializer, format unit, and error-checking logic.

Figure 24-194. McASP Block Diagram

NOTE: The AUXCLK clock is sourced directly from MCASP_FCLK.

24.8.4.2 McASP Clock and Frame-Sync Configuration

The transmit serial clock (clock at the bit rate) can be sourced internally by passing through two clock dividers off the internal clock source (AUXCLK). The bit rate clock is generated internally and is driven out on the `abe_mcasp_aclkx` pin. An internally generated high-frequency clock can be driven out onto the `abe_mcasp_ahclkx` pin to serve as a reference clock for other components in the system.

24.8.4.2.1 Transmit Clock

The transmit bit clock, `abe_mcasp_aclkx`, is generated internally. For this purpose, the `MCASP_ACLKXCTL[5]` `CLKXM` bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the `MCASP_ACLKXCTL[4:0]` `CLKXDIV` bit field) from the source signal.

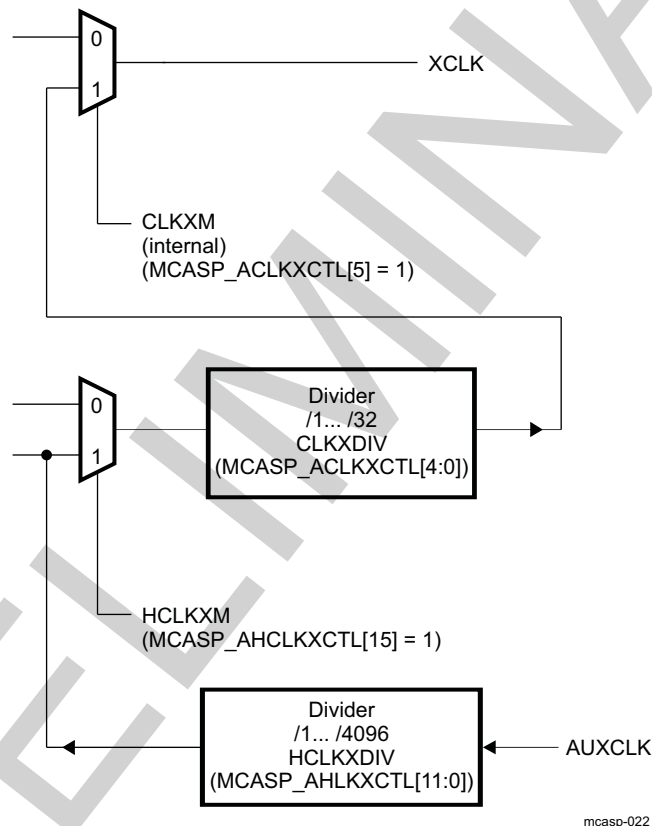

The transmit high-frequency master clock, `abe_mcasp_ahclkx`, is also generated internally. For this purpose, the `MCASP_AHCLKXCTL[15]` `HCLKXM` bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the `MCASP_AHCLKXCTL[11:0]` `HCLKXDIV` bit field) from the McASP internal clock source `AUXCLK`.

The transmit clock configuration is controlled by the following registers:

- `MCASP_ACLKXCTL`
- `MCASP_AHCLKXCTL`

Figure 24-195 is the block diagram of the transmit clock generator.

Figure 24-195. Transmit Clock Generator Block Diagram

24.8.4.2.2 Frame-Sync Generator

The transmit frame-sync pin is `abe_mcasp_afsx`. The frame-sync generator must be configured through the control register (`MCASP_TXFMCTL`) as:

- Internally generated `MCASP_TXFMCTL[1]` `FSXM` = 1
- Frame-sync polarity: Rising edge `MCASP_TXFMCTL[0]` `FSXP` = 0
- Frame-sync width: Single bit `MCASP_TXFMCTL[4]` `FXWID` = 0
- 384-slot, `MCASP_TXFMCTL[15:7]` `XMOD` = 1 1000 0000b

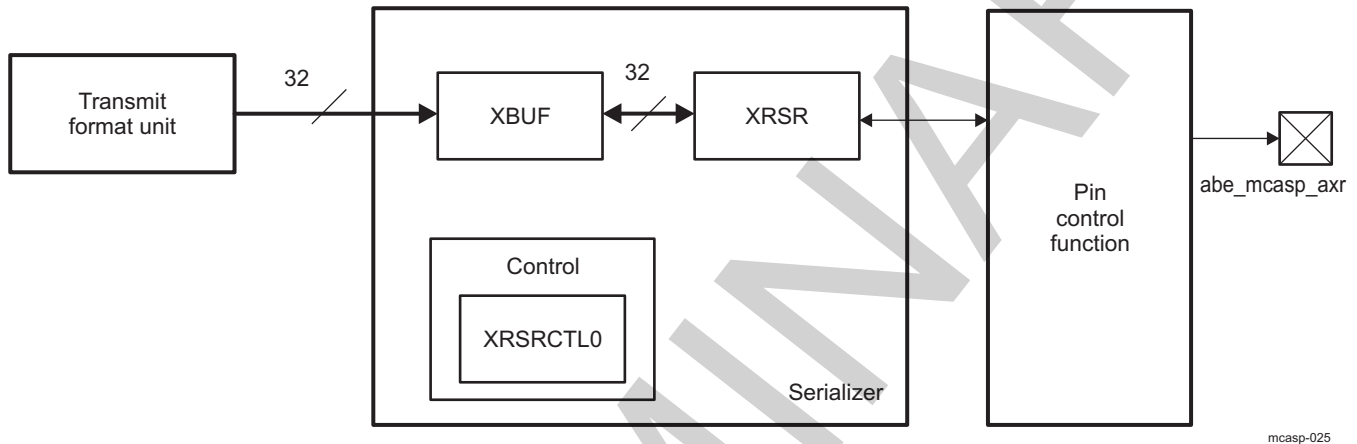

24.8.4.3 Serializers

The serializer shifts serial data out of the McASP. It consists of a shift register (XRSR), a data buffer (XBUF), a control register ([MCASP_XRSRCTL0](#)), a serial data pin ([abe_mcasp_axr](#)), and logic to support the data alignment options of the McASP.

The serializer must be configured to transmit through the control register, thus shifting out data to [abe_mcasp_axr](#). The serializer is clocked from the transmit section clock ([abe_mcasp_aclkx](#)) if configured to transmit. A serializer configured to transmit operates in lockstep.

[Figure 24-196](#) is the serializer block diagram.

Figure 24-196. Individual Serializer and Connections Within McASP

For transmit, the microprocessor unit (MPU) services the McASP by writing data into the XBUF register, which is an alias of the [MCASP_TXBUF0](#) register. The data automatically passes through the transmit format unit before reaching the XBUF register in the serializer. The data is then copied from XBUF to XRSR and shifted out from [abe_mcasp_axr](#) synchronously to the serial clock.

In addition to the data, the serializer shifts out other DIT-specific information accordingly (preamble, user data, etc.). The serializer configuration is controlled by [MCASP_XRSRCTL0\[1:0\]](#) SRMOD = 0x1. Thus, the serializer is configured to operate in transmit mode.

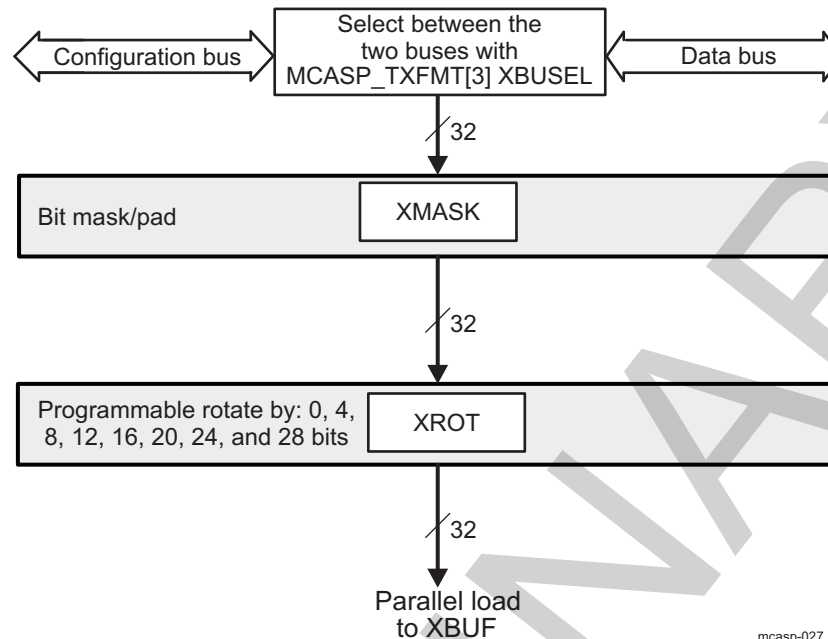

24.8.4.4 Format Unit

The McASP has one transmit data formatting unit. This unit automatically remaps the data bits within the transmitted words between a natural format for the MPU (such as a Q31 representation) and the required format for the external serial device. During the remapping process, the format unit can also mask off certain bits.

This formatting unit consists of two stages:

- Bit mask (masks off bits)
- Rotate right (aligns data within word)

[Figure 24-197](#) shows the transmit formatting unit.

Figure 24-197. Transmit Format Unit

As shown in [Figure 24-197](#), the data to the transmit format unit can come from the configuration bus or the data bus. The selection is made through the [MCASP_TXFMT\[3\] XBUSEL](#) bit.

The bit mask stage includes a full 32-bit mask register, allowing selected individual bits to pass through the stage unchanged or be masked off.

The rotate-right stage performs bitwise rotation by 0 bits for right-aligned Q31 data and bitwise rotation by 8 bits for left-aligned Q31 data, programmable by the [MCASP_TXFMT\[2:0\] XROT](#) bit field. This is a rotation process, not a shifting process, so bit 0 gets shifted back into bit 31 during the process.

The [MCASP_TXFMT\[17:16\] XDATLY](#) bit field must be set to a 0-bit delay (0x0 value).

For left-aligned Q31 data, the following transmit format unit settings process the data into right-aligned 24-bit audio data, ready for transmission:

- [MCASP_TXFMT\[2:0\] XROT](#) = 0x2 (rotate right by 8 bits)
- [MCASP_TXFMT\[15\] XRVRS](#) = 0x0 – Bit reversal is not enabled; the McASP naturally transmits and receives in an LSB-first order.
- [MCASP_TXMASK\[32\] XMASK](#) = 0xFFFFFFF0 – 0xFFFFF000
- [MCASP_TXFMT\[14:13\] XPAD](#) = 0x0 (Pad extra bits with 0s.)

For right-aligned data, the following transmit format unit settings process the data into right-aligned 24-bit audio data ready for transmission:

- [MCASP_TXFMT\[2:0\] XROT](#) = 0x0 (rotate right by 0 bits)
- [MCASP_TXFMT\[15\] XRVRS](#) = 0x0 – Bit reversal is not enabled; the McASP naturally transmits and receives in an LSB-first order.
- [MCASP_TXMASK\[32\] XMASK](#) = 0x00FFFFFF – 0x0000FFFF
- [MCASP_TXFMT\[14:13\] XPAD](#) = 0x0 (Pad extra bits with 0s.)

[Table 24-589](#) provides more details and specific examples. The examples use internal representation in integer and Q31 notation, but other fractional notations are also possible.

24.8.4.5 Transmit State-Machine

The transmit state-machine controls the interactions between the various units in the transmit section. In addition, the state-machine keeps track of error conditions and serial port status. No serial transfers can occur until the transmit state-machine is released from reset.

The transmit state-machine is controlled by the transmit bitstream format register ([MCASP_TXFMT](#)) and it reports the McASP status and error conditions in the transmitter status register ([MCASP_TXSTAT](#)).

24.8.4.6 Transmit TDM Sequencer

The time division multiplexing (TDM) sequencer is used to count the 384 subframes (slots) in the DIT block. If currently transmitting slot 1, slot 2 (next value of the TDM slot counter) should be used during the encode phase to select the appropriate C, V, and U bit, because the data encoded and written to the [MCASP_TXBUF0](#) register during the current time slot (slot 1) is actually shifted out on the next time slot.

The transmit TDM sequencer is controlled by the [MCASP_TXTDM](#) register and reports the current transmit slot to the [MCASP_TXTDMSLOT\[9:0\]](#) XSLOT CNT bit field.

24.8.4.7 McASP Software Reset

The McASP can be put into reset through the global transmit control register ([MCASP_GBLCTL](#)). A valid serial clock must be supplied to the McASP to assert the software reset bits in the [MCASP_GBLCTL](#) register.

24.8.4.8 McASP Power Management

[Table 24-569](#) describes power-management features available to the McASP.

Table 24-569. Local Power-Management Features

| Feature | Registers | Description |
|------------------|---|--|
| Slave idle modes | MCASP_SYSCONFIG[1:0] IDLE_MODE | Force-idle, no-idle, and smart-idle modes are available. |

24.8.4.9 Transfer Modes

24.8.4.9.1 DIT Transfer Mode

The DIT transfer mode of the McASP also supports transmission of audio data in S/PDIF, AES-3, and IEC-60958 formats. These formats are designed to carry audio data between different systems through an optical or coaxial cable. The DIT mode applies only to a serializer configured as transmitter, not receiver. For a description of the S/PDIF format, see [Section 24.8.2.2.3, S/PDIF Coding Format](#).

24.8.4.9.1.1 Transmit DIT Encoding

When the McASP operates in DIT mode, the data transmitted is output as a biphasic-mark encoded bitstream, with preamble, channel status, user data, validity, and parity automatically stuffed into the bitstream by the McASP. The McASP includes separate validity bits for even/odd subframes and two 384-bit RAM modules to hold channel status and user data bits.

The transmit TDM time slot register ([MCASP_TXTDM](#)) should be programmed to all 1s during DIT mode. TDM functionality is not supported in DIT mode, except that the TDM slot counter counts the DIT subframes.

To transmit data in DIT mode, the following pins are typically required:

- `abe_mcasp_ahclkx` – transmit high-frequency master clock (The internal clock source can be used instead.)
- One serial data pin, `abe_mcasp_axr`, with serializer configured to transmit

The actual 24-bit audio data must always be in bit positions 23–0 after passing through the first three stages of the transmit format unit.

24.8.4.9.1.2 Transmit DIT Clock and Frame-Sync Generation

The DIT transmitter works only in the following configuration:

- In the transmit frame control register ([MCASP_TXFMCTL](#)):
 - Internally generated transmit frame sync, FSXM = 1
 - Rising-edge frame sync, FSXP = 0
 - Bit-width frame sync, FXWID = 0
 - 384-slot TDM, XMOD = 1 1000 0000b
- In the transmit clock control register ([MCASP_ACLKXCTL](#)), ASYNC = 1
- In the transmit bitstream format register ([MCASP_TXFMT](#)), XSSZ = 1111 (32-bit slot size)

All combinations of `abe_mcasp_ahclkx` and `abe_mcasp_aclkx` are supported.

The following summarizes the register configurations required for DIT mode. DIT mode-specific bit fields are in bold face:

- [MCASP_PFUNC](#): The data pin must be configured for McASP function. If `abe_mcasp_ahclkx` is used, it must also be configured for McASP function. Other pins can be configured to function as GPIOs, if desired.
- [MCASP_PDIR](#): The data pin must be configured as output. If internal clock source AUXCLK is used as the reference clock, it may be output on the `abe_mcasp_ahclkx` pin by configuring `abe_mcasp_ahclkx` as an output.
- [MCASP_GBLCTL](#): Global initialization
- [MCASP_AMUTE](#): Program all fields according to the mute control desired.
- [MCASP_TXDITCTL](#): The **DITEN** bit must be set to 1 to enable DIT mode. Configure other bits as desired.
- [MCASP_TXMASK](#): Mask the desired bits, depending upon left-aligned or right-aligned internal data.
- [MCASP_TXFMT](#): **XDATDLY** = 0. **XRVR** = 0. **XPAD** = 0. **XSSZ** = Fh (32-bit slot). **XBUSEL** = configured as desired. The **XROT** bit is configured either 0 or 8-bit rotate.
- [MCASP_TXFMCTL](#): Configure the bits according to former discussions.
- [MCASP_ACLKXCTL](#): **ASYNC** = 1. Program the CLKXDIV bits to obtain the bit clock rate desired. CLKXM = 1.
- [MCASP_AHCLKXCTL](#): Program the HCLKXDIV bits to obtain the high-frequency bit clock rate desired.
- [MCASP_TXTDM](#): Set to FFFF FFFFh for all active slots for DIT transfers.
- [MCASP_TXEVTCTL](#): Program all fields according to the interrupts desired.
- [MCASP_TXCLKCHK](#): Program all fields according to the clock checking desired.
- [MCASP_XRSRCTL0](#): Set **SRMOD** = 1 (transmitter) for the DIT pins.
- [MCASP_DITCSRAi](#) and [MCASP_DITCSRBi](#): Program the channel status bits as desired.
- [MCASP_DITUDRAi](#) and [MCASP_DITUDRBi](#): Program the user data bits as desired.

24.8.4.9.1.3 DIT Channel Status and User Data Register Files

The channel status registers ([MCASP_DITCSRAi](#) and [MCASP_DITCSRBi](#)) and user data registers ([MCASP_DITUDRAi](#) and [MCASP_DITUDRBi](#)) are not double-buffered. Typically, programmers use one of the synchronizing interrupts, such as the last slot, to create an event at a safe time so the register may be updated. In addition, the MPU reads the transmit TDM slot counter to determine which word of the register is being used.

It is a software requirement to avoid writing to the word of user data and channel status that are being used to encode the current time slot; otherwise, it is undetermined whether old or new data is used to encode the bitstream.

The DIT subframe format is defined in [Section 24.8.2.2.3.2, Subframe Format](#). The channel status information (C) and user data (U) are defined in the following DIT control registers:

- MCASP_DITCSRA0 to MCASP_DITCSRA5: The 192 bits in these six registers contain the channel status information for the left channel within each frame.
- MCASP_DITCSRB0 to MCASP_DITCSRB5: The 192 bits in these six registers contain the channel status information for the right channel within each frame.
- MCASP_DITUDRA0 to MCASP_DITUDRA5: The 192 bits in these six registers contain the user data information for the left channel within each frame.
- MCASP_DITUDRB0 to MCASP_DITUDRB5: The 192 bits in these six registers contain the user data information for the right channel within each frame.
- The S/PDIF block format is shown in [Figure 24-192](#). There are 192 frames within a block (frame 0 to frame 191). There are two subframes within each frame (subframes 1 and 2 for the left and right channels, respectively).

The channel status and user data information sent on each subframe is summarized in [Table 24-570](#).

Table 24-570. Channel Status and User Data for Each DIT Block

| Frame | Subframe | Preamble | Channel Status Defined in: | User Data Defined in: |

24.8.4.10 Data Transmission

The MPU services the McASP by writing data to the [MCASP_TXBUF0](#) register for transmit operations. The McASP sets status flags and notifies the MPU whenever data is ready to be transmitted.

[Section 24.8.4.10.1](#), *Data Ready Status and Event/Interrupt Generation*, discusses data-ready status in detail.

The [MCASP_TXBUF0](#) register can be accessed through one of the two peripheral ports of the device:

- Data port (DAT): This port is dedicated to data transfers on the device.
- Configuration bus (CFG): This port is used for data transfers and peripheral configuration control on the device.

[Section 24.8.4.10.1.2](#), *Transfers Through the Data Port (DAT)*, and [Section 24.8.4.10.1.3](#), *Transfers Through the Configuration Bus (CFG)*, discuss how to perform transfers through the data port and the configuration bus, respectively.

The MPU or the DMA can be used to service the McASP through either of these peripheral ports. The MPU and DMA usages are discussed in [Section 24.8.4.10.1.4](#), *Using the MPU for McASP Servicing*, and [Section 24.8.4.10.1.5](#), *Using the DMA for McASP Servicing*, respectively.

24.8.4.10.1 Data Ready Status and Event/Interrupt Generation

24.8.4.10.1.1 Transmit Data Ready

The transmit data ready flag XDATA bit in the [MCASP_TXSTAT](#) register reflects the status of the [MCASP_TXBUF0](#) register. The XDATA flag is set when data is transferred from the [MCASP_TXBUF0\[n\]](#) buffer to the XRSR[n] shift register, thus indicating that the [MCASP_TXBUF0](#) is empty and ready to accept new data from the MPU. This flag is cleared when the XDATA bit is written with 1, or when the serializer configured as transmitter is written by the MPU.

Whenever XDATA is set, the DMA AXEVT event is automatically generated to notify the DMA of the [MCASP_TXBUF0](#) empty status. An AXINTn interrupt is also generated if the XDATA interrupt is enabled in the [MCASP_EVTCTLX](#) register (for details, see [Section 24.8.4.11.1](#), *Transmit Data Ready Interrupt*).

For DMA requests, the McASP does not require that [MCASP_TXSTAT](#) be read between DMA events. This means that, even if [MCASP_TXSTAT](#) already has the XDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

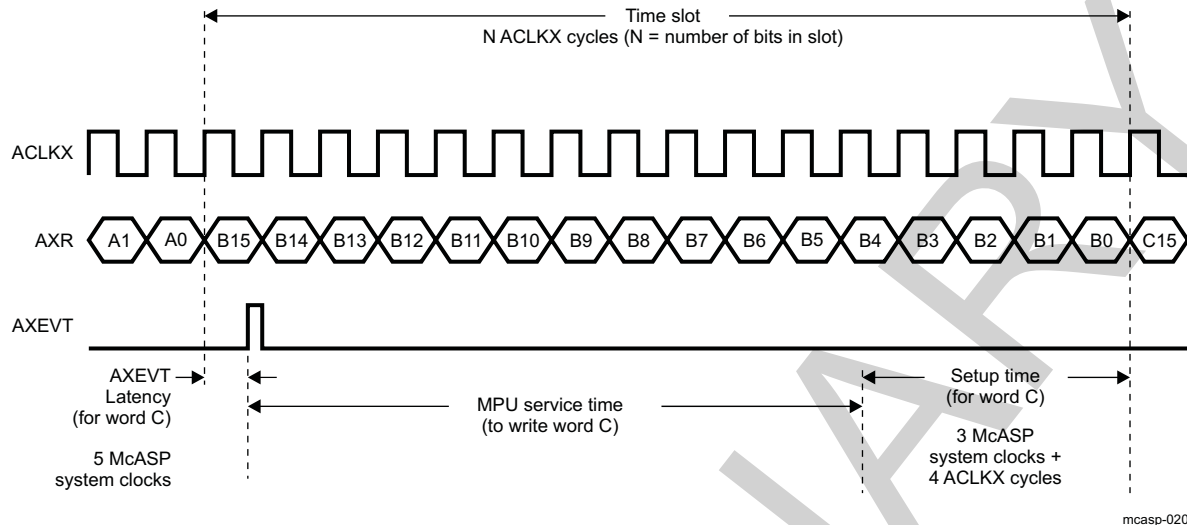

Because the serializer acts in lockstep, only one DMA event is generated to indicate that the transmit serializer is ready to be written to with new data.

[Figure 24-198](#) shows the timing details of when AXEVT is generated at the McASP boundary. In this example, as soon as the last bit (A0) of word A is transmitted, the McASP sets the XDATA flag and generates an AXEVT event. However, it takes up to five McASP system clocks (AXEVT latency) before AXEVT is active at the McASP boundary. Upon AXEVT, the MPU can begin servicing the McASP by writing word C into the [MCASP_TXBUF0](#) (service time). The MPU must write word C into the [MCASP_TXBUF0](#) within the setup time required by the McASP (setup time).

The maximum service time (see [Figure 24-198](#)) can be calculated as:

$$\text{Service Time} = \text{Time Slot} - \text{AXEVT Latency} - \text{Setup Time}$$

Figure 24-198. MPU Service Time Upon Transmit DMA Event (AXEVT)

24.8.4.10.1.2 Transfers Through the Data Port (DAT)

CAUTION

To perform internal transfers through the data port, clear the XBUSEL bit to 0 in the [MCASP_TXFMT](#) register. Failure to do so may result in software malfunction.

Typically, the [MCASP_TXBUF0](#) register is accessed through the data port. To access through the data port, simply have the MPU or DMA access [MCASP_TXBUF0](#) through its data port location.

NOTE: DAT allows the MPU, DSP subsystem, or DMA to access only the transmit buffer [MCASP_TXBUF0](#) register. There is no way to access the McASP configuration registers within the MPU/DSP subsystem/DMA DAT address ranges.

For transmit operations through the data port, the DMA/MPU must write to the [MCASP_TXBUF0](#) data port address to service the active transmit serializer.

When transmitting, the DMA/MPU must write data to the serializer and transmit within each time slot. Failure to do so may result in a buffer underrun condition (see [Section 24.8.4.14.1, Buffer Underrun Error – Transmitter](#)).

24.8.4.10.1.3 Transfers Through the Configuration Bus (CFG)

CAUTION

To perform internal transfers through the configuration bus, set the XBUSEL bit to 1 in the [MCASP_TXFMT](#) register. Failure to do so may result in software malfunction.

In this method, the DMA/MPU accesses the [MCASP_TXBUF0](#) register through the configuration bus address.

When transmitting, the DMA/MPU must write data to the serializer and transmit within each time slot. Failure to do so may result in a buffer underrun condition ([Section 24.8.4.14.1, Buffer Underrun Error – Transmitter](#)).

24.8.4.10.1.4 Using the MPU for McASP Servicing

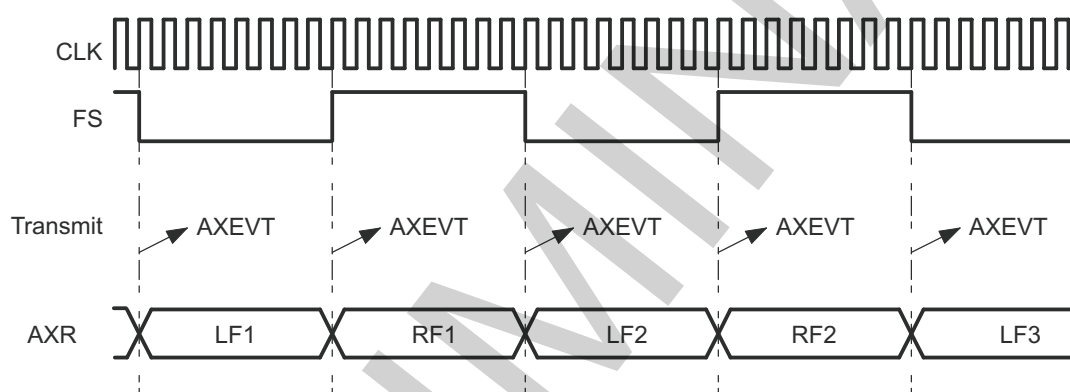

The MPU can be used to service the McASP through interrupts (upon MCASP_AXINT interrupt) or through polling the XDATA bit in the [MCASP_TXSTAT](#) register. As discussed in [Section 24.8.4.10.1.2, Transfers Through the Data Port \(DAT\)](#), and [Section 24.8.4.10.1.3, Transfers Through the Configuration Bus \(CFG\)](#), the MPU can access through the data port or the configuration bus.

To use the MPU to service the McASP through interrupts, the XSTAT bit must be enabled in the [MCASP_TXEVTCTL](#) register to generate the MCASP_AXINT interrupt to the MPU upon data ready.

24.8.4.10.1.5 Using the DMA for McASP Servicing

The typical scenario is to use the DMA to service the McASP through the data port, although the DMA can also service the McASP through the configuration bus.

Figure 24-199. DMA Transmit Event in an Audio Example – One Event

mcasep-013

The DMA event AXEVT, which is triggered upon each XDATA transition from 0 to 1, is used to service the McASP transmit buffer (XBUF). [Figure 24-199](#) is an example of an audio system with two audio channels (LF and RF) transmitted through the `abe_mcasp_axr` pin on the McASP. It shows the points at which event AXEVT is triggered.

The DMA AXEVT event is triggered on each time slot. In the example, AXEVT is triggered for each transmit audio channel time slot (time slot for channel LF, and time slot for channel RF). DMA events are generated automatically upon data ready, whereas MPU interrupt generation must be enabled in the [MCASP_EVTCTLX](#) register.

24.8.4.11 Interrupt Requests

[Table 24-571](#) lists the event flags that can cause module interrupts.

Table 24-571. TX Events

| Event Mask | Event Flag | Map to | Description |
|---|--|-------------|-----------------------------------|
| MCASP_EVTCTLX[0] XUNDRN | MCASP_TXSTAT[0] XUNDRN | MCASP_AXINT | Transmit underrun |
| MCASP_EVTCTLX[1] XSYNCERR | MCASP_TXSTAT[1] XSYNCERR | MCASP_AXINT | Unexpected transmit frame sync |
| MCASP_EVTCTLX[2] XCKFAIL | MCASP_TXSTAT[2] XCKFAIL | MCASP_AXINT | Transmit clock failure |
| MCASP_EVTCTLX[4] XLAST | MCASP_TXSTAT[4] XLAST | MCASP_AXINT | Transmit last slot interrupt |
| MCASP_EVTCTLX[5] XDATA | MCASP_TXSTAT[5] XDATA | MCASP_AXINT | Transmit data-ready interrupt |
| MCASP_EVTCTLX[7] XSTAFRM | MCASP_TXSTAT[7] XSTAFRM | MCASP_AXINT | Transmit start of frame interrupt |

An interrupt line is asserted (active high) when one of these events occurs. Read the [MCASP_TXSTAT](#) register to determine which event occurs.

24.8.4.11.1 Transmit Data Ready Interrupt

The transmit data-ready interrupt (XDATA) is generated if XDATA is 1 in the [MCASP_TXSTAT](#) register and XDATA is enabled in [MCASP_EVTCTLX](#). [Section 24.8.4.10.1, Data Ready Status and Event/Interrupt Generation](#), provides details on when XDATA is set in the [MCASP_TXSTAT](#) register.

A transmit-start-of-frame interrupt (XSTAFRM) is triggered by the recognition of a transmit frame sync.

A transmit-last-slot interrupt (XLAST) is a qualified version of the data-ready interrupt (XDATA). It has the same behavior as the data-ready interrupt, but is further qualified by having the data requested belonging to the last slot (the slot that just ended is the next-to-last TDM slot, the current slot is the last slot).

24.8.4.11.2 Error Interrupt

Upon detection, the following error conditions generate interrupt flags:

In the transmit status register ([MCASP_TXSTAT](#)):

- Transmit underrun (XUNDRN)
- Transmit DMA error (XDMAERR)

Each interrupt source also has a corresponding enable bit in the transmit interrupt control register ([MCASP_EVTCTLX](#)). If the enable bit is set, an interrupt is requested when the interrupt flag is set in [MCASP_TXSTAT](#). If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

24.8.4.12 DMA Requests

The McASP can generate one DMA request to the sDMA and eDMA controllers to transmit data ([MCASP_AXEVT](#)).

A DMA request to transmit data is generated if the XDATDMA bit in the [MCASP_TXEVTCTL](#) register is cleared.

24.8.4.13 Audio Mute (AMUTE) Function

The McASP includes an automatic audio mute function (see [Figure 24-200](#)) that asserts, in hardware, the AMUTE pin to a preprogrammed output state, as selected by the MUTEN bit in the audio mute control register ([MCASP_AMUTE](#)). The AMUTE pin is asserted when one of the interrupt flags is set or an external device issues an error signal on the `abe_mcasp_amutein` input. Typically, the `abe_mcasp_amutein` input is shared with a device interrupt pin.

The `abe_mcasp_amutein` input allows the on-chip logic to consider a mute input from other devices in the system so that all errors may be considered. The `abe_mcasp_amutein` input has a programmable polarity to allow it to adapt to different devices, as selected by the INPOL bit in the [MCASP_AMUTE](#) register, and it must be explicitly enabled.

In addition to the external `abe_mcasp_amutein` input, the `abe_mcasp_amute` pin output may be asserted when one of the error interrupt flags is set and its mute function is enabled in the [MCASP_AMUTE](#) register.

When one or more errors are detected and enabled, the `abe_mcasp_amute` pin is driven to an active state that is selected by MUTEN in the [MCASP_AMUTE](#) register. The active polarity of the AMUTE pin is programmable by the MUTEN bit (the inactive polarity is the opposite of the active polarity). The `abe_mcasp_amute` pin remains driven active until software clears all the error interrupt flags that are enabled to mute, and until the `abe_mcasp_amutein` is inactive.

Figure 24-200. Audio Mute (AMUTE) Block Diagram

mcasep-017

24.8.4.14 Error Reporting

The McASP includes error-checking capability for the serial protocol and data underrun. In addition, the McASP includes a timer that continually measures the high-frequency master clock every 32 AHCLKX clock cycles. The value of the timer can be read to get a measurement of the clock frequency and has a minimum and maximum range setting that can set an error flag if the master clock goes out of a specified range.

When one or more errors (software selectable) are detected or the `abe_mcasep_amutein` input pin is asserted, the `abe_mcasep_amute` output pin may be asserted to a high or low level to immediately mute the audio output. In addition, an interrupt can be generated if desired, based on one or more error sources.

24.8.4.14.1 Buffer Underrun Error – Transmitter

A buffer underrun occurs when the serializer is instructed by the transmit state-machine to transfer data from [MCASP_TXBUF0](#) to XRSR, but [MCASP_TXBUF0](#) has not yet been written with new data since the last time the transfer occurred. When this occurs, the transmit state-machine sets the XUNDRN flag.

An underrun is checked only once per time slot. The [MCASP_TXSTAT\[0\]](#) XUNDRN flag is set when an underrun condition occurs. Once set, the XUNDRN flag remains set until the host explicitly writes 1 to the XUNDRN bit to clear it.

A pair of BMC zeros is shifted out when an underrun occurs (four bit times at 128 bps). By shifting out a pair of zeros, a clock can be recovered on the receiver. To recover, reset the McASP and restart with the proper initialization.

24.8.4.14.2 DMA Error – Transmitter

A transmit DMA error, as indicated by the XDMAERR flag in the [MCASP_TXSTAT](#) register, occurs when the DMA (or MPU) writes more words to the data port of the McASP than it should.

XDMAERR indicates that the DMA (or MPU) wrote too many words to the McASP for a given transmit DMA event. Writing too few words results in a transmit underrun error setting XUNDRN in [MCASP_TXSTAT](#).

While XDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or MPU. The McASP transmitter and the DMA must be reinitialized to resynchronize them.

24.8.4.14.3 Clock Failure Detection

24.8.4.14.3.1 Clock Failure Check Startup

It is initially expected of the clock failure circuits to generate an error until at least one measurement is taken. Therefore, the clock failure interrupts, clock switch, and mute functions should not be enabled immediately, but only after a specific startup procedure.

The start the transmit clock failure check procedure:

1. Configure the transmit clock failure detect logic (XMIN, XMAX, XPS) in the transmit clock check control register ([MCASP_TXCLKCHK](#)).
2. Clear the transmit clock failure flag (XCKFAIL) in the transmit status register ([MCASP_TXSTAT](#)).
3. Wait until the first measurement is taken (32 AHCLKX clock periods).
4. Verify that no clock failure is detected.
5. Repeat Step 2 through Step 4 until the clock is running and is no longer issuing clock failure errors.
6. After the transmit clock is measured and falls within the acceptable range, the following can be enabled:
 - (a) The transmit clock failure interrupt enable bit (XCKFAIL) in the transmitter interrupt control register ([MCASP_EVTCTLX](#))
 - (b) The mute option (XCKFAIL) in the mute control register ([MCASP_AMUTE](#))

24.8.4.14.3.2 Transmit Clock Failure Check and Recovery

The transmit clock failure check circuit (see [Figure 24-201](#)) works off the internal McASP system clock and the external high-frequency serial clock ([abe_mcasp_ahclkx](#)). It continually counts the number of system clocks for every 32 high-rate serial clock ([abe_mcasp_ahclkx](#)) periods, and stores the count in XCNT of the transmit clock check control register ([MCASP_TXCLKCHK](#)) every 32 high-rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (XMIN), and automatically flags an interrupt (XCKFAIL in [MCASP_TXSTAT](#)) when an out-of-range condition occurs. An

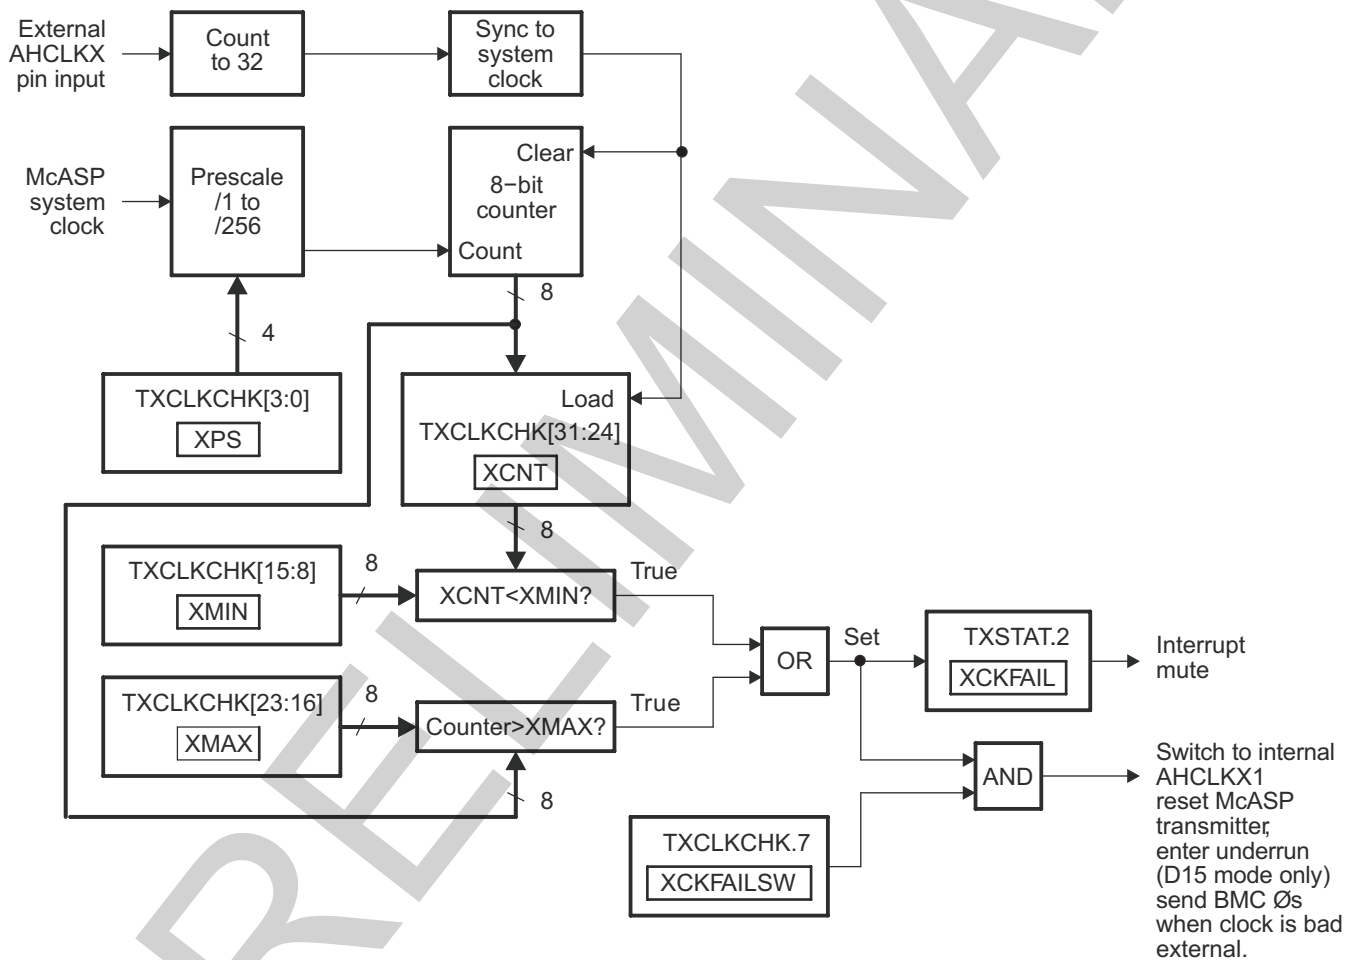

out-of-range minimum condition occurs when the count is less than XMIN. The logic continually compares the current count (from the running system clock counter) to the maximum allowable boundary (XMAX). This is so that if the external clock completely stops, the counter value is not copied to XCNT. An out-of-range maximum condition occurs when the count is greater than XMAX. The XMIN and XMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

For the transmit clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

If a clock failure is detected, the transmit clock failure flag (XCKFAIL) in `MCASP_TXSTAT` is set. This causes an interrupt if the transmit clock failure interrupt enable bit (XCKFAIL) in `MCASP_EVTCTLX` is set.

Figure 24-201. Transmit Clock Failure Detection Circuit Block Diagram

mcasp-014

24.8.5 McASP Low-Level Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the McASP module.

24.8.5.1 Global Initialization

24.8.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the McASP module is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the McASP (for more information, see the [Section 24.8.3](#), *McASP Integration*, and [Section 24.8.2](#), *McASP Environment*).

[Table 24-572](#), describes the global initialization of surrounding modules.

Table 24-572. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|---|---|
| PRCM | Module functional and interface clocks must be enabled. (See Chapter 3 , <i>Power, Reset, and Clock Management</i> .) |
| Control module | Module-specific pad muxing and other pad configurations must be set in the control module. (See Chapter 19 , <i>Control Module</i> .) |
| (Optional) Cortex-A9 MPU INTC or DSP INTC | INTC configuration must be done to enable the interrupts from the McASP. (See Chapter 18 , <i>Interrupt Controllers</i> .) |
| (Optional) sDMA (or eDMA or aDMA) | DMA configuration must be done to enable the McASP DMA data channel requests. |
| (Optional) ABE_L4 and L3 Interconnects | For more information about the interconnect configuration, see Chapter 14 , <i>Interconnect</i> . |

NOTE: The MPU/DSP INTC and the sDMA/eDMA/aDMA configurations are required when the interrupt and DMA-based communication modes are used.

24.8.5.1.2 McASP Global Initialization

24.8.5.1.2.1 Main Sequence – McASP Global Initialization

The procedure in [Table 24-573](#) initializes the McASP after a power-on reset (POR).

Table 24-573. McASP Global Initialization

| Step | Register/Bit Field/Programming Model | Value |
|--|---|-------------|
| Apply software reset to different McASP components. | MCASP_GBLCTL [12:8] | 0x00 |
| Poll the bits to ensure the active reset value (0x00) is successfully latched into the register. | MCASP_GBLCTL [12:8] | =0x00 |
| Configure the local power management. | MCASP_SYSCONFIG [1:0] IDLE_MODE | 0x- |
| Configure the transmit format unit. | See Section 24.8.5.1.2.2 . | |
| Configure the transmit frame sync generator. | See Section 24.8.5.1.2.3 . | |
| Configure the transmit clock generator. | See Section 24.8.5.1.2.4 . | |
| Configure the TDM sequencer—set all slots active. | MCASP_TXTDM [31:0] XTDMs | 0xFFFF FFFF |
| Configure the serializer for transmit mode operation. | MCASP_XRSRCTL0 [1:0] SRMOD | 0x1 |
| Configure the McASP pins functionality. | See Section 24.8.5.1.2.5 . | |
| Configure the McASP mute input/output conditions. | See Table 24-578 . | |
| Enable the McASP DIT-transmission mode. | MCASP_TXDITCTL [0] DITEN | 0x1 |
| Configure DIT-specific subframe fields. | See Table 24-579 . | |

Table 24-573. McASP Global Initialization (continued)

| Step | Register/Bit Field/Programming Model | Value |
|--|--|-------|
| Release from reset state the divider that outputs the <code>abe_mcaspl_ahclkx</code> clock. ⁽¹⁾ | <code>MCASP_GBLCTL</code> [9] XHCLKRST | 0x1 |
| Poll the bit to ensure that it is successfully latched in the register. | <code>MCASP_GBLCTL</code> [9] XHCLKRST | =0x1 |
| Release from reset state the divider that outputs the <code>abe_mcaspl_aclkx</code> clock. ⁽¹⁾ | <code>MCASP_GBLCTL</code> [8] XCLKRST | 0x1 |
| Poll the bit to ensure that it is successfully latched in the register. | <code>MCASP_GBLCTL</code> [8] XCLKRST | =0x1 |

⁽¹⁾ During reset state the local McASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the `MCASP_AHCLKX` and `MCASP_ACLKX` registers are ignored; hence, the transmission clock does not stop during the reset state of the dividers.

24.8.5.1.2.2 Subsequence – Transmit Format Unit Configuration

The procedure in [Table 24-574](#) configures the transmit frame format unit of the McASP module.

NOTE:

- The first transmit data bit always has a 0-bit delay.
- The bitstream is always transmitted in least-significant-bit (LSB)-first order.
- Pad value for extra bits in a certain slot is always 0.

Table 24-574. Transmit Format Unit Configuration

| Step | Register/Bit Field/Programming Model | Value |
|---|--|-------|
| Configure the slot size to 32 bits. | <code>MCASP_TXFMT</code> [7:4] XSSZ | 0xF |
| IF: the MPU or DMA data to transmit is left- aligned | Software test condition | |
| Set data mask in the range 0xFFFF FF00 – 0xFFFF 0000. | <code>MCASP_TXMASK</code> [31:0] XMASK | 0x- |
| Rotate data right by 8-bit positions. | <code>MCASP_TXFMT</code> [2:0] XROT | 0x2 |
| ELSE | | |
| Set data mask in the range 0x00FF FFFF– 0x0000 FFFF. | <code>MCASP_TXMASK</code> [31:0] XMASK | 0x- |
| Rotate data right by 0-bit positions. | <code>MCASP_TXFMT</code> [2:0] XROT | 0x0 |
| ENDIF | | |

24.8.5.1.2.3 Subsequence – Transmit Frame Synchronization Generator Configuration

The procedure in [Table 24-575](#) configures the transmit frame synchronization generator of the McASP module.

NOTE: The frame synchronization signal is always rising-edge active and always has a single-bit width.

Table 24-575. Transmit Frame-Synchronization Generator Configuration

| Step | Register/Bit Field/Programming Model | Value |
|--|--|-------|
| Select 384-slot size block. | <code>MCASP_TXFMCTL</code> [15:7] XMOD | 0x180 |
| Select internally-generated transmit frame sync. | <code>MCASP_TXFMCTL</code> [1] FSXM | 0x1 |

24.8.5.1.2.4 Subsequence – Transmit Clock Generator Configuration

NOTE: By default, the ACLKX and AHCLKX clocks are generated only from the McASP internal clock source.

The procedure in [Table 24-576](#) configures the transmit clock generator of the McASP module.

Table 24-576. Transmit Clock Generator Configuration

| Step | Register/Bit Field/Programming Model | Value |
|--|--|-------|
| Set the divisor for the internally generated high frequency clock– <code>abe_mcasp_ahclkx</code> . | MCASP_AHCLKXCTL [11:0] HCLKXDIV | 0x- |
| Set the divisor for the internally generated transmission clock– <code>abe_mcasp_aclkx</code> . | MCASP_ACLKXCTL [4:0] CLKXDIV | 0x- |
| Configure the transmit clock failure detect logic. | See Section 24.8.4.14.3.1 , <i>Clock Failure Check Startup</i> . | |

24.8.5.1.2.5 Subsequence—McASP Pins Functional Configuration

The procedure in [Table 24-577](#) configures the McASP pins for McASP functionality.

Table 24-577. McASP Pins Functional Configuration

| Step | Register/Bit Field/Programming Model | Value |
|--|---|-------|
| Configure module different pins to have McASP functionality. | MCASP_PFUNC [31:0] | 0x0 |
| Configure the McASP pins as outputs: | | |
| <code>abe_mcasp_afsx</code> | MCASP_PDIR [28] AFSX; | 0x1 |
| <code>abe_mcasp_ahclkx</code> | MCASP_PDIR [27] AHCLKX; | 0x1 |
| <code>abe_mcasp_aclkx</code> | MCASP_PDIR [26] ACLKX; | 0x1 |
| <code>abe_mcasp_amute</code> | MCASP_PDIR [25] AMUTE; | 0x1 |
| <code>abe_mcasp_axr</code> | MCASP_PDIR [0] AXR0; | 0x1 |

24.8.5.1.2.6 Subsequence – McASP Mute Input/Output Trigger Condition Settings

The procedure in [Table 24-578](#) configures the behavior of the mute associated I/Os and different trigger conditions for the McASP mute output functionality.

Table 24-578. McASP Mute Input/Output Trigger Condition Settings

| Step | Register/Bit Field/Programming Model | Value |
|---|--|-------|
| Optional: Select to drive AMUTE active enable bit on transmit DMA error. | MCASP_AMUTE [12] XDMAERR | 0x1 |
| Optional: Select to drive AMUTE active enable bit on transmit clock failure. | MCASP_AMUTE [10] XCKFAIL | 0x1 |
| Optional: Select to drive AMUTE active enable bit on transmit frame synchronization error. | MCASP_AMUTE [8] XSYNCERR | 0x1 |
| Optional: Select to drive AMUTE active enable bit on transmit underrun error. | MCASP_AMUTE [6] XUNDRN | 0x1 |
| Optional: Enable sensitivity of the <code>abe_mcasp_amute</code> output to <code>abe_mcasp_amutein</code> error source. | MCASP_AMUTE [3] INEN | 0x1 |
| Optional: Select the <code>abe_mcasp_amutein</code> input polarity. | MCASP_AMUTE [2] INPOL | 0x1 |
| Optional: Configure the behavior of the <code>abe_mcasp_amute</code> output. | MCASP_AMUTE [1:0] MUTEN | 0x1 |

24.8.5.1.2.7 Subsequence – DIT-Specific Subframe Fields Configuration

NOTE: The McASP integrated in the device supports only the DIT transmission mode that uses the S/PDIF protocol.

The procedure in [Table 24-579](#) configures the DIT-specific subframe fields as part of the S/PDIF format data.

Table 24-579. DIT-Specific Subframe Fields Configuration

| Step | Register/Bit Field/Programming Model | Value |
|--|---|-------|
| Configure the valid bit value for odd time slots. | MCASP_TXDITCTL[3] VB | 0x- |
| Configure the valid bit value for even time slots. | MCASP_TXDITCTL[2] VA | 0x- |
| Configure the user data bit for each subframe A and B in a 384-slot S/PDIF block. | MCASP_DITUDRAi[31:0] DITUDRAi, where i = 0 to 5 | 0x- |
| | MCASP_DITUDRBi[31:0] DITUDRBi, where i = 0 to 5 | 0x- |
| Configure the channel status bit for each subframe A and B in a 384-slot S/PDIF block. | MCASP_DITCSRAi[31:0], where i = 0 to 5 | 0x- |
| | MCASP_DITCSRBi[31:0], where i = 0 to 5 | 0x- |

24.8.5.2 Operational Modes Configuration

24.8.5.2.1 McASP DIT Transmission Mode

24.8.5.2.1.1 Main Sequence – McASP DIT Polling Transmission Method

[Figure 24-202](#) shows the McASP DIT polling method.

NOTE:

- The McASP polling transmission model considers the MPU/DSP as the source of audio data for the McASP transmission buffer.
- The DMA request is disabled and the XDMAERR event is not analyzed.
- The flow chart shown in [Figure 24-202](#) shows the sequence for transmitting one DIT frame.

Figure 24-202. McASP DIT Transmission Polling Method

mcasp-028

Table 24-580 summarizes the register call for the polling mode.

Table 24-580. Register Call Summary for Main Sequence – McASP DIT Transmission Polling Method

| Register Name | Register Name | Register Name | Register Name | Register Name |
|---------------|---------------|---------------|---------------|----------------|
| MCASP_TXSTAT | MCASP_GBLCTL | MCASP_TXBUF0 | MCASP_TXFMT | MCASP_TXEVTCTL |

Table 24-581 summarizes the subprocess call for the polling mode.

Table 24-581. Subprocess Call Summary for Main Sequence – McASP DIT Transmission Polling Method

| Subprocess Name | Cross-Reference |
|-----------------|-----------------|
| Error handling | Figure 24-206 |

24.8.5.2.1.2 Main Sequence – McASP DIT Interrupt Transmission Method

Figure 24-203 shows the initial setup for interrupt-based transmission.

Figure 24-203. Subsequence – DIT Transmission Startup Procedure

mcasep-029

Table 24-582 shows the configuration of the McASP using the McASP DIT interrupt method for transmission.

Table 24-582. McASP Interrupt Transmission Model

| Step | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|-------|
| Select the CFG or DATA port to access the transmit buffer. | MCASP_TXFMT[3] XBUSEL | 0x- |
| Disable DMA requests generation. | MCASP_TXEVTCTL[0] XDATDMA | 0x1 |
| Clear the transmitter status logic. | MCASP_TXSTAT[8:0] | 0xFF |
| Enable the data ready event transmit interrupt. | MCASP_EVTCTLX[5] XDATA | 0x1 |
| Optional: Enable the transmit error event interrupts. | MCASP_EVTCTLX[2] XCKFAIL | 0x1 |
| | MCASP_EVTCTLX[1] XSYNCERR | 0x1 |
| | MCASP_EVTCTLX[0] XUNDRN | 0x1 |
| Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt. | MCASP_EVTCTLX [7] XSTAFRM | 0x1 |
| | MCASP_EVTCTLX[4] XLAST | 0x1 |
| Disable the DMA error event. | MCASP_EVTCTLX[7] XDMAERR | 0x0 |
| DIT transmission startup procedure | See Figure 24-203. | |

Table 24-583 summarizes the register call to initialize the McASP to transmit using interrupt events.

Table 24-583. Register Call Summary for Subsequence – McASP DIT Transmission Startup Procedure

| Register Name | Register Name |
|---------------|---------------|
| MCASP_GBLCTL | MCASP_TXBUF0 |

24.8.5.2.1.3 Main Sequence –McASP DIT DMA Transmission Method

Table 24-584 shows the configuration of the McASP using the DMA method for transmission. Possible interrupt error event servicing is also considered. Table 24-583 shows the initial setup for DMA-based transmission.

NOTE: Because of the DATA port burst access capability with the DMA method, It is preferable for transfers to be initiated through the DATA port rather than through the CFG port.

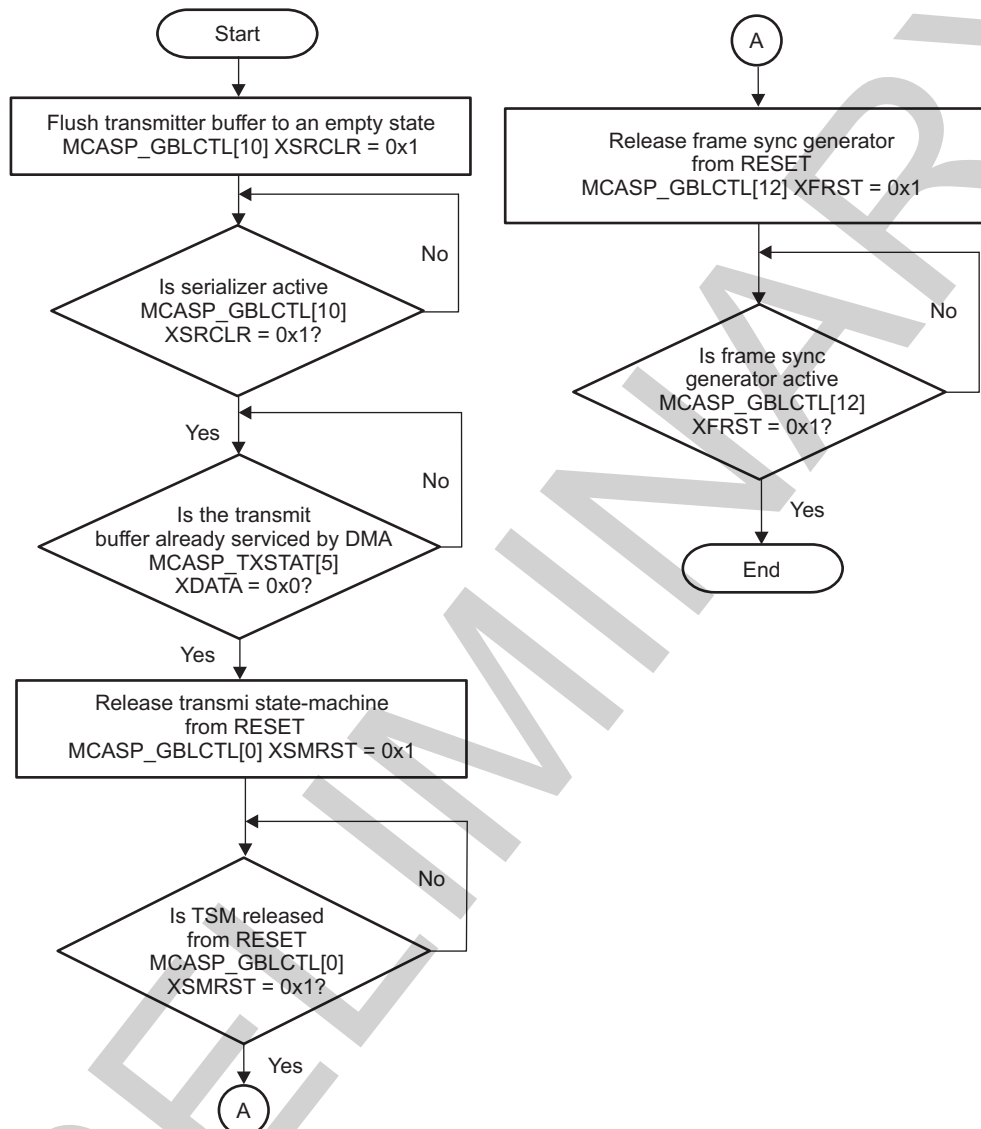

Table 24-584. McASP DMA Transmission Model with Interrupt Events Servicing

| Step | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|-------|
| Select DATA port to access the transmit buffer. | MCASP_TXFMT[3] XBUSEL | 0x0 |
| Enable the DMA requests generation. | MCASP_TXEVTCTL[0] XDATDMA | 0x0 |
| Clear the transmitter status logic. | MCASP_TXSTAT[8:0] | 0xFF |
| Enable the DMA error event. | MCASP_EVTCTLX[7] XDMAERR | 0x1 |
| Optional: Enable the transmit error event interrupts. | MCASP_EVTCTLX[2] XCKFAIL | 0x1 |
| | MCASP_EVTCTLX[1] XSYNCERR | 0x1 |
| | MCASP_EVTCTLX[0] XUNDRN | 0x1 |
| Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt. | MCASP_EVTCTLX [7] XSTAFRM | 0x1 |
| | MCASP_EVTCTLX[4] XLAST | 0x1 |
| Disable the data ready event transmit interrupt. | MCASP_EVTCTLX[5] XDATA | 0x0 |
| DMA transmission procedure | See Section 24.8.5.2.1.4. | |

24.8.5.2.1.4 Subsequence – DIT DMA Transmission Procedure

Figure 24-204 shows the McASP initial setup when the DMA method is used for transmission.

Figure 24-204. Subsequence – DIT DMA Transmission Procedure

mcas-030

Table 24-585 shows the register call summary for the McASP DMA transmission procedure subsequence.

Table 24-585. Register Call Summary for Subsequence – McASP DMA Transmission Procedure

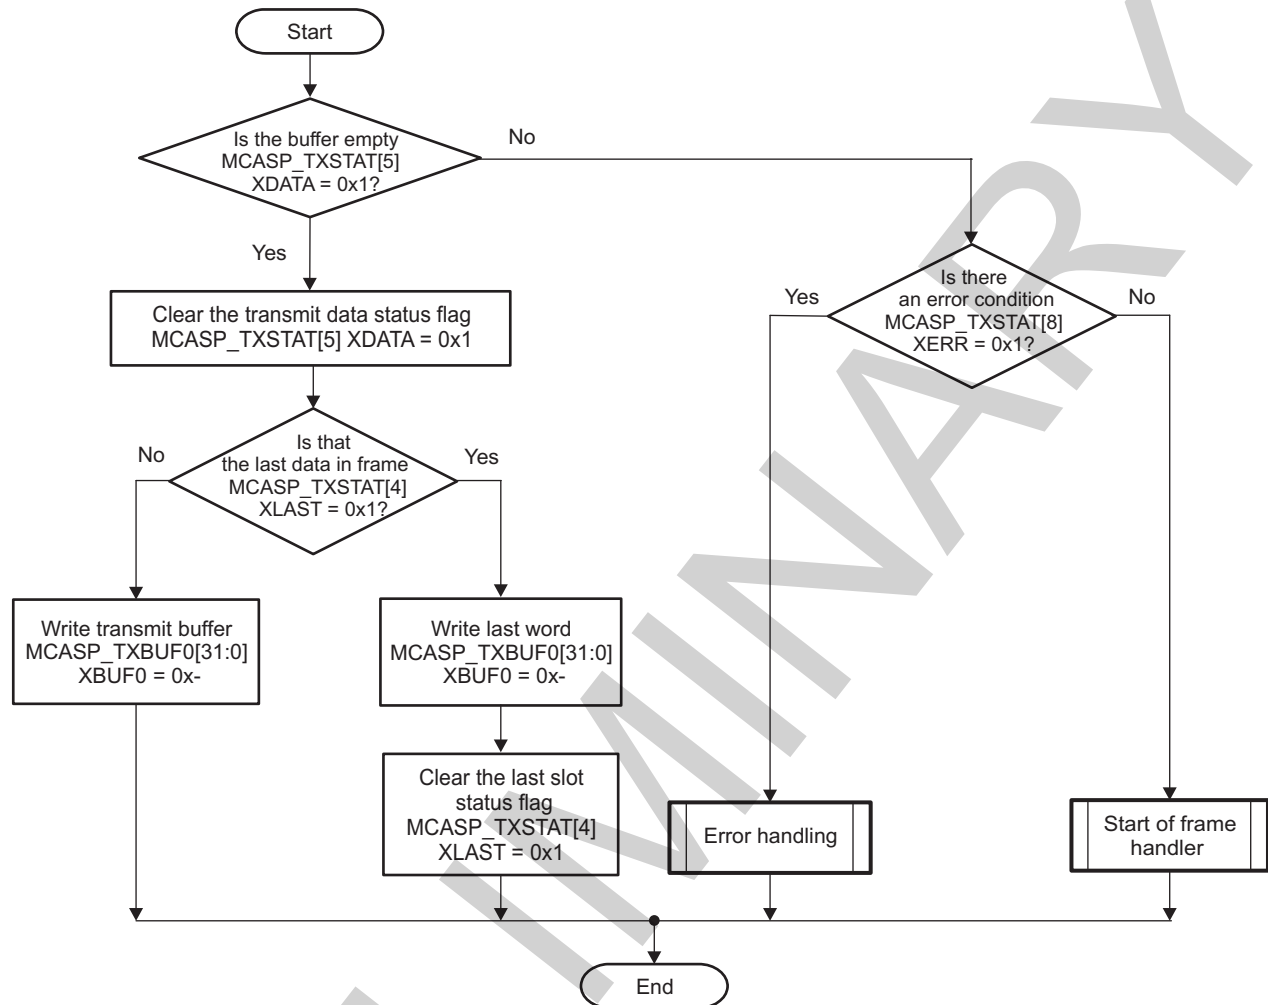

| Register Name | Register Name |
|---------------|---------------|
| MCASP_TXSTAT | MCASP_GBLCTL |

24.8.5.2.2 McASP Event Servicing

24.8.5.2.2.1 McASP Interrupt Events Servicing

Figure 24-205 shows the flow of interrupt events servicing for the McASP module.

Figure 24-205. McASP Interrupt Events Servicing

mcasp-031

Table 24-586 lists the register call summary for the interrupt event servicing.

Table 24-586. Register Call Summary for McASP Interrupt Events Servicing

| Register Name | Register Name |
|---------------|---------------|
| MCASP_TXSTAT | MCASP_TXBUF0 |

Table 24-587 lists the subprocess call summary for interrupt events servicing.

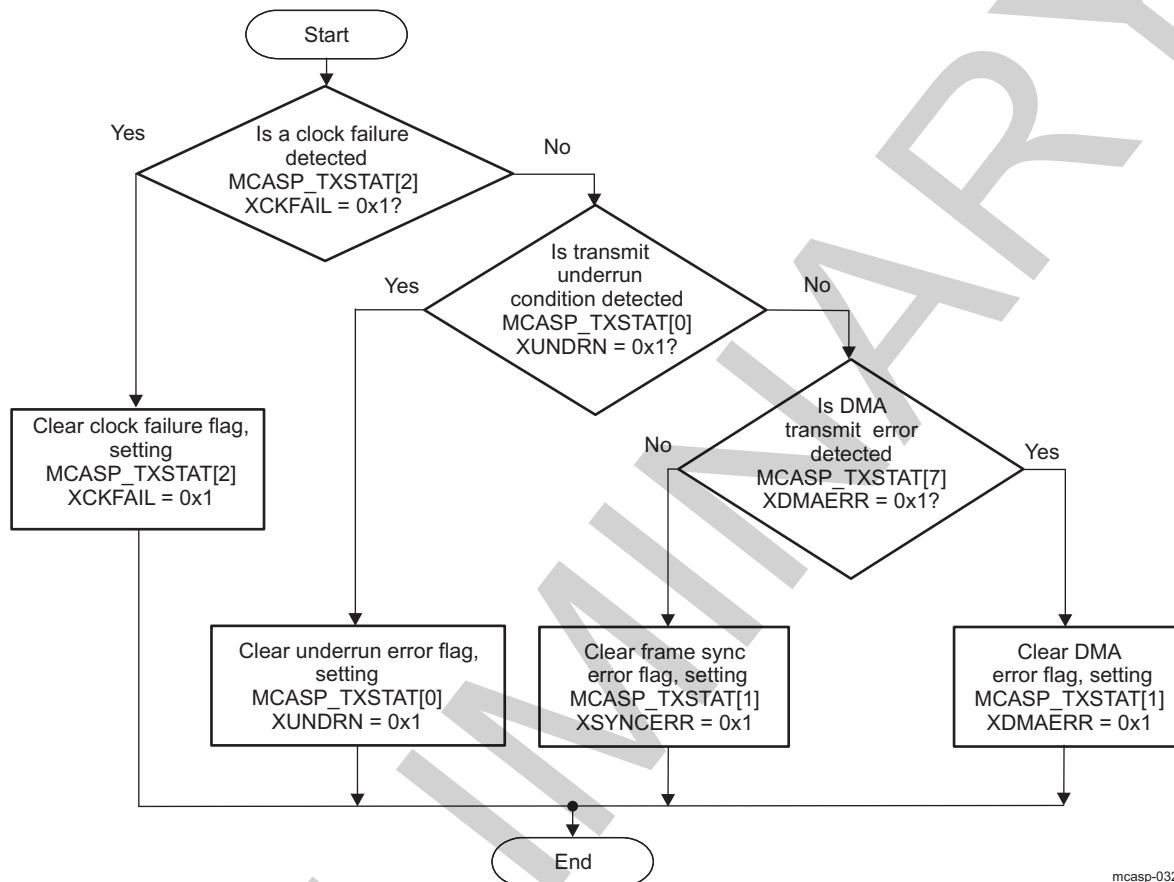

Table 24-587. Subprocess Call Summary for Interrupt Events Servicing

|-------------------------|---------------------|
| Error handling | Figure 24-206 |
| Start of frame handling | Section 24.8.4.11.1 |

24.8.5.2.2 Subsequence – Error Handling

Figure 24-206 shows the error handling schema for the McASP, which can be implemented as part of the interrupt service routine or as part of polling sequence.

Figure 24-206. McASP Error Handling

mcasp-032

Table 24-588 lists the register call summary for the McASP error handling.

Table 24-588. Register Call Summary for McASP Error Handling

| Register Name |
|---------------|
| MCASP_TXSTAT |

NOTE:

- For more information about clock failure handling, see [Section 24.8.4.14.3](#).
- For more information about transmit buffer underrun handling, see [Section 24.8.4.14.1](#).
- For more information about DMA error handling, see [Section 24.8.4.14.2](#).

24.8.6 McASP Register Manual

24.8.6.1 McASP Instance Summary

Table 24-589 summarizes the McASP instances.

Table 24-589. McASP Instance Summary

| Module Name | Base Address L3 Interconnect | Base Address Cortex-A9 Private Access | Base Address DSP Private Access | Size |
|-------------|------------------------------|---------------------------------------|---------------------------------|------|
| McASP | 0x4902 8000 | 0x4012 8000 | 0x01D2 8000 | 4KB |

NOTE: Private access is an access that does not use the L3 / L4 interconnects.

24.8.6.2 McASP Registers

24.8.6.2.1 McASP Register Summary

Table 24-590 summarizes the McASP register mapping.

Table 24-590. McASP Register Mapping Summary

| Register Name | Type | Register Width (Bits) | Address Offset | Physical Address L3 Interconnect | Physical Address Cortex-A9 Private Access | Physical Address DSP Private Access |

⁽¹⁾ i = 0 to 5 for McASP_L3Interconnect
i = 0 to 5 for McASP_Cortex-A9
i = 0 to 5 for McASP_DSP

⁽²⁾ j = 0 to 14

⁽³⁾ k = 0 to 30

NOTE: The address locations listed in [Table 24-590, McASP Register Mapping Summary](#), are relevant for accessing all McASP configuration registers and McASP_TXBUF0 registers through the McASP peripheral configuration (CFG) port.

McASP DAT allows the L3-interconnect, DSP subsystem, and MPU to access the McASP_TXBUF0 register at locations 0x4902 A200, 0x01D2 A200, and 0x4012 A200, respectively.

24.8.6.2.2 McASP Register Description

[Table 24-591](#) through [Table 24-645](#) describe the individual register bits.

Table 24-607. MCASP_GBLCTL

| | | | |
|-------------------------|---|-----------------|--|
| Address Offset | 0x0000 0044 | Instance | MCASP_L3 MCASP_CORTEX-A9 MCASP_DSP |
| Physical Address | 0x4902 8044 0x4012 8044 0x01D2 8044 | | |
| Description | Global transmit control register - provides initialization of the transmit section. The bit fields in MCASP_GBLCTL are synchronized and latched by the <code>abe_mcasp_aclkx</code> clock. Before programming MCASP_GBLCTL , ensure that the serial clocks are running. If the corresponding external serial clock, <code>abe_mcasp_clkx</code> , is not yet running, select the internal serial clock source in AHCLKXCTL and ACLKXCTL before programming MCASP_GBLCTL . Also, after programming any bits in MCASP_GBLCTL , do not proceed until reading back from MCASP_GBLCTL and verifying that the bits in MCASP_GBLCTL are latched. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|--------|--------|----------|---------|----------|---|---|---|---|---|---|---|--|--|--|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | | | |
| RESERVED | | | | | | | | | | | | | | | | | | | XFRST | XSMRST | XSRCLR | XHCLKRST | XCLKRST | RESERVED | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--|------|---------|
| 31:13 | RESERVED | Reserved | RW | 0x00000 |
| 12 | XFRST | Transmit frame-sync generator reset enable bit 0x0: The transmit frame-sync generator is reset. 0x1: The transmit frame-sync generator is active. When released from reset, the transmit frame-sync generator begins counting serial clocks and generating frame sync as programmed. | RW | 0 |
| 11 | XSMRST | Transmit state-machine reset enable bit 0x0: The transmit state-machine is held in reset. <code>abe_mcasp_axr</code> pin state: If MCASP_PFUNC [0] = 0 and MCASP_PDIR [0] = 1, the serializer drives the <code>abe_mcasp_axr</code> pin to the state specified for inactive time slot 0x1: The transmit state-machine is released from reset. When released from reset, the transmit state-machine immediately transfers data from <code>XBUF[n]</code> to <code>XRSR[n]</code> . The transmit state-machine sets the underrun flag (<code>XUNDRN</code>) in MCASP_TXSTAT , if <code>XBUF[n]</code> have not been preloaded with data before reset is released. The transmit state-machine also immediately begins detecting frame sync and is ready to transmit. Transmission of TDM time slot begins at slot 0 after reset is released. | RW | 0 |
| 10 | XSRCLR | Transmit serializer clear enable bit. By clearing and then setting this bit, the transmit buffer is flushed to an empty state (<code>XDATA</code> = 1). If <code>XSMRST</code> = 1, <code>XSRCLR</code> = 1, <code>XDATA</code> = 1, and <code>XBUF</code> is not loaded with new data before the start of the next active time slot, an underrun occurs. 0x0: The transmit serializer is cleared. 0x1: The transmit serializer is active. When the transmit serializer is first taken out of reset (<code>XSRCLR</code> changes from 0 to 1), the transmit data ready bit (<code>XDATA</code>) in MCASP_TXSTAT is set to indicate <code>XBUF</code> is ready to be written. | RW | 0 |
| 9 | XHCLKRST | Transmit high-frequency clock divider reset enable bit 0x0: The transmitter high-frequency clock divider is held in reset. 0x1: The transmitter high-frequency clock divider is running. | RW | 0 |
| 8 | XCLKRST | Transmit clock divider reset enable bit 0x0: The transmit clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input. 0x1: The transmit clock divider is running. | RW | 0 |
| 7:0 | RESERVED | Reserved | RW | 0x0 |

| RESERVED | | | | | | | | | | | | | | | | | | | XDMAERR | RESERVED | XCKFAIL | RESERVED | XSYNCERR | RESERVED | XUNDRN | RESERVED | INSTAT | INEN | INPOL | MUTEN | |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--|------|---------|
| 31:13 | RESERVED | Reserved | RW | 0x00000 |
| 12 | XDMAERR | Drives AMUTE active enable bit on transmit DMA error (XDMAERR). 0x0: Drive is disabled. Detection of transmit DMA error is ignored by abe_mcasp_amute. 0x1: Drive is enabled (active). Upon detection of transmit DMA error, abe_mcasp_amute is active and is driven according to MUTEN bits. | RW | 0 |
| 11 | RESERVED | Reserved | RW | 0 |
| 10 | XCKFAIL | XMT bad clock. Drives AMUTE active enable bit on transmit clock failure (XCKFAIL). 0x0: Drive is disabled. Detection of transmit clock failure is ignored by abe_mcasp_amute. 0x1: Drive is enabled (active). Upon detection of transmit clock failure, abe_mcasp_amute is active and is driven according to MUTEN bits. | RW | 0 |
| 9 | RESERVED | Reserved | RW | 0 |
| 8 | XSYNCERR | XMT unexpected FS. Drives AMUTE active enable bit on unexpected transmit frame-sync error (XSYNCERR). 0x0: Drive is disabled. Detection of unexpected transmit frame-sync error is ignored by abe_mcasp_amute. 0x1: Drive is enabled (active). Upon detection of unexpected transmit frame-sync error, abe_mcasp_amute is active and is driven according to MUTEN bit. | RW | 0 |
| 7 | RESERVED | Reserved | RW | 0 |
| 6 | XUNDRN | XMT underrun occurs. Drives AMUTE active enable bit on transmit underrun error (XUNDRN). 0x0: Drive is disabled. Detection of transmit underrun error is ignored by abe_mcasp_amute. 0x1: Drive is enabled (active). Upon detection of transmit underrun error, abe_mcasp_amute is active and is driven according to MUTEN bit. | RW | 0 |
| 5 | RESERVED | Reserved | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 4 | INSTAT | Status of mute in pin, determines drive on abe_mcasp_axr pin when the MCASP_PFUNC[0] and MCASP_PDIR[0] bits are set to 1. Read 0x0: Inactive Read 0x1: Active. Audio mute in error is detected. | R | 0 |
| 3 | INEN | Drive abe_mcasp_amute active when abe_mcasp_amutein error is active. 0x0: Drive is disabled. abe_mcasp_amutein is ignored by abe_mcasp_amute. 0x1: Drive is enabled (active). INSTAT = 1 drives abe_mcasp_amute active. | RW | 0 |
| 2 | INPOL | Audio mute in (abe_mcasp_amutein) polarity select bit 0x0: Polarity is active high. A high on abe_mcasp_amutein sets INSTAT to 1. 0x1: Polarity is active low. A low on abe_mcasp_amutein sets INSTAT to 1. | RW | 0 |
| 1:0 | MUTEN | abe_mcasp_amute pin enable bit field (unless overridden by GPIO registers) 0x0: Disabled, pin goes to 3-state condition. 0x1: Pin is driven high if error is detected. 0x2: Pin is driven low if error is detected. | RW | 0x0 |

| RESERVED | | | | | | | | | | | | | | | | | | | | | | | | XERR | XDMAERR | XSTAFRM | XDATA | XLAST | XTDMSLOT | XCKFAIL | XSYNCERR | XUNDRN |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-----------|
| 31:9 | RESERVED | Reserved | RW | 0x0000000 |
| 8 | XERR | XERR bit always returns a logic-OR of: XUNDRN XSYNCERR XCKFAIL XDMAERR. Allows a single bit to be checked to determine if a transmitter error interrupt has occurred. 0x0: No errors have occurred. 0x1: An error has occurred. | RW | 0 |
| 7 | XDMAERR | Transmit DMA error flag. XDMAERR is set when the CPU or DMA writes more words to the data port of the McASP in a given time slot than it should. Causes a transmit interrupt (XINT) if this bit and XDMAERR in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: Transmit DMA error did not occur. 0x1: Transmit DMA error occurred. | RW | 0 |
| 6 | XSTAFRM | Transmit start of frame flag. Causes a transmit interrupt (XINT) if this bit and XSTAFRM in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: No new transmit frame sync (AFSX) is detected. 0x1: A new transmit frame sync (AFSX) is detected. | RW | 0 |
| 5 | XDATA | Transmit data ready flag. Causes a transmit interrupt (XINT) if this bit and XDATA in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect 0x0: XBUF is written and is full 0x1: Data is copied from XBUF to XRSR. XBUF is empty and ready to be written. XDATA is also set when the transmit serializers are taken out of reset. When XDATA is set, it always causes a DMA event (AXEVT). | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-------|
| 4 | XLAST | Transmit last slot flag. XLAST, along with XDATA, are set if the current slot is the last slot in a frame. Causes a transmit interrupt (XINT) if this bit and XLAST in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: Current slot is not the last slot in a frame. 0x1: Current slot is the last slot in a frame. XDATA is also set. | RW | 0 |
| 3 | XTDMSLOT | Returns the LSB of XSLOT. Allows a single read of XSTAT to determine whether the current TDM time slot is even or odd. read 0x0: Current TDM time slot is odd. read 0x1: Current TDM time slot is even. | R | 0 |
| 2 | XCKFAIL | Transmit clock failure flag. XCKFAIL is set when the transmit clock failure detection circuit reports an error. Causes a transmit interrupt (XINT) if this bit and XCKFAIL in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: Transmit clock failure did not occur. 0x1: Transmit clock failure occurred | RW | 0 |
| 1 | XSYNCERR | Unexpected transmit frame-sync flag. XSYNCERR is set when a new transmit frame sync (AFSX) occurs before it is expected. Causes a transmit interrupt (XINT) if this bit and XSYNCERR in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: Unexpected transmit frame sync did not occur 0x1: Unexpected transmit frame sync occurred. | RW | 0 |
| 0 | XUNDRN | Transmitter underrun flag. XUNDRN is set when the transmit serializer is instructed to transfer data from XBUF to XRSR, but XBUF has not yet been serviced with new data since the last transfer. Causes a transmit interrupt (XINT) if this bit and XUNDRN in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: Transmitter underrun did not occur 0x1: Transmitter underrun occurred. | RW | 0 |

24.9 Serial Low-Power Inter-Chip Media Bus Controller

This section describes the features and functions of the serial low-power inter-chip media bus (SLIMbus®) controller.

24.9.1 SLIMbus Overview

There are two SLIMbus module instantiations, SLIMBUS1 and SLIMBUS2, in the device. SLIMbus1 is implemented in the audio backend (ABE) subsystem and is intended for the connection of external audio peripherals. SLIMBUS2 is at the top-level of the device and is intended for the connection of other types of peripherals.

The SLIMbus controller provides a bidirectional, multidrop, multichannel two-line serial interface between the device and other SLIMbus components in a system, such as audio codecs, Bluetooth® modules, and FM radio receivers/transmitters. Because of its versatility, the SLIMbus controller can play the role of a wide range of peripherals and clocked frame-oriented protocols (I2S™, PCM, and TDM).

Figure 24-207 shows the SLIMbus1 controller highlight.

Figure 24-207. SLIMbus1 Highlight

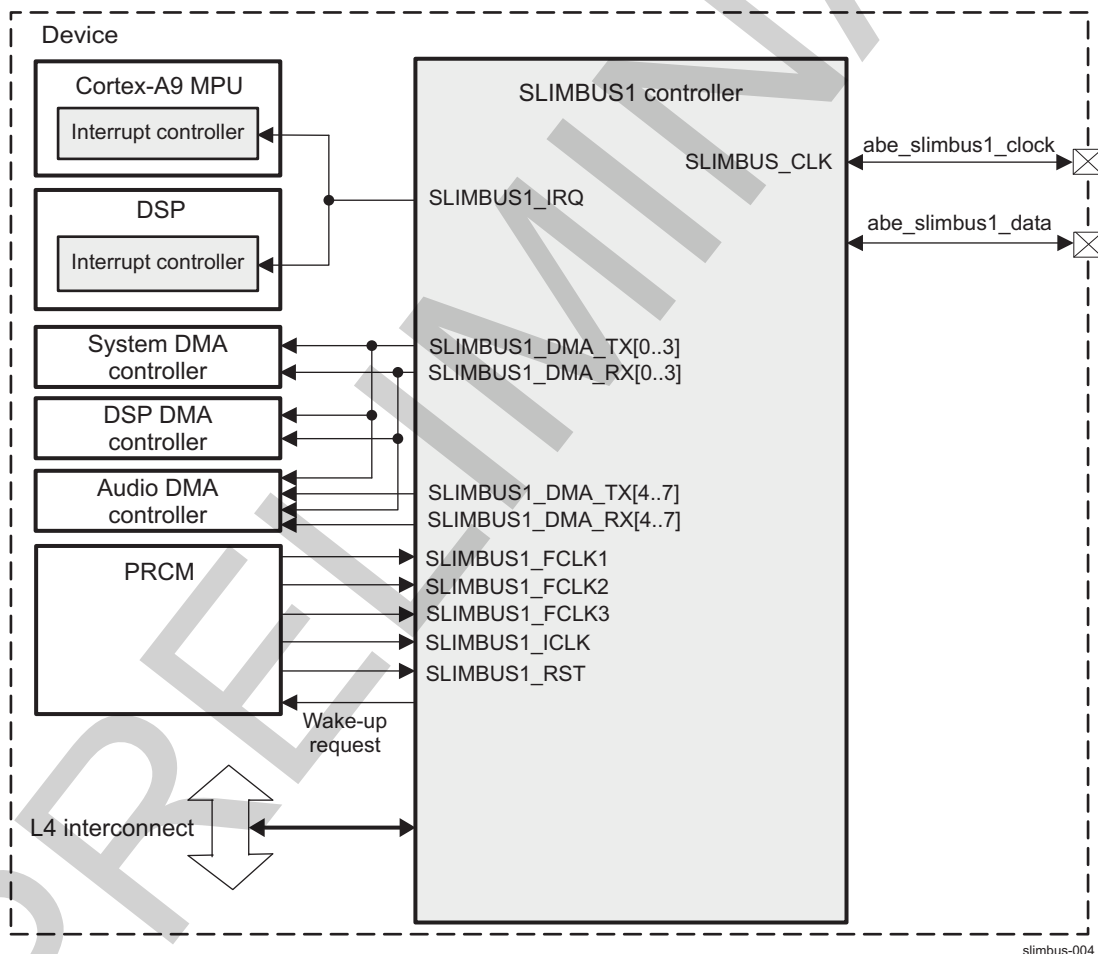

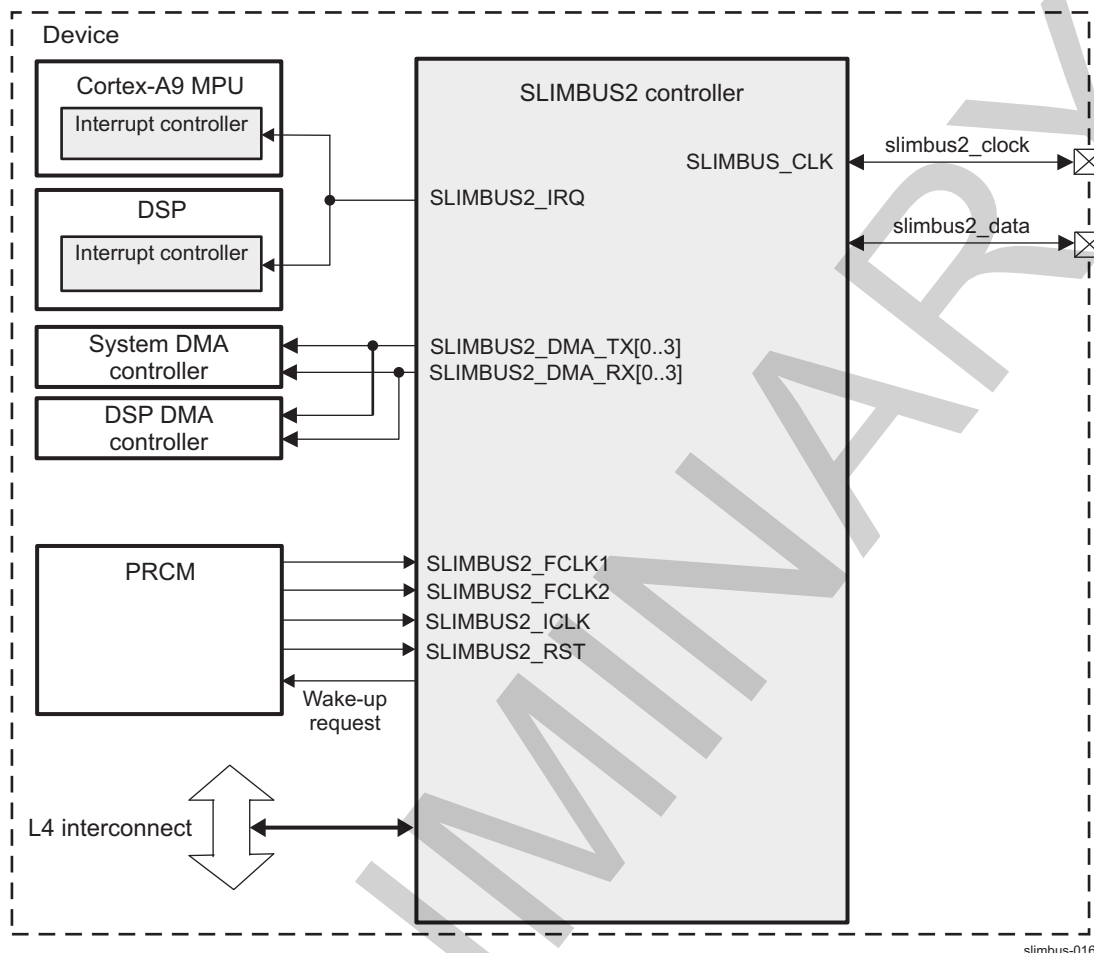

Figure 24-208 shows the SLIMbus2 controller highlight.

Figure 24-208. SLIMbus2 Highlight

24.9.1.1 Terminology

The SLIMbus module is by default the SLIMbus controller IP. The module implements a SLIMbus component by integrating together several submodules: a SLIMbus component contains a set of devices and the necessary logic needed to provide bus access to these devices.

Every component contains one Interface device and can contain additional devices belonging to other device classes (framer, manager, or generic devices).

- An interface device is the central status and control location of the component. All components have only one interface device.
- A framer device can generate the clock and synchronization information for the entire SLIMbus. Consequently, only one framer device (for all SLIMbus components) at a time can be active on the bus.
- A manager device controls the bus scheduling at high level: It assigns logical addresses to any device that is authorized to communicate using the bus, gives the bandwidth allocation, and so on. Only one manager device at a time can be active on the bus.
- A generic device implements the "useful" functionality of the component by sourcing/sinking the payload data. A component may include several generic devices so that each appears as a separate, standardized entity to the software driver.

NOTE: Typically, generic devices are used to transport data (rather than the specialized manager, framer, or interface devices, which typically do not feature data ports).

A device is a separately addressable entity within a SLIMbus component. Each device belongs to a single device class. After enumeration each device is addressed with a single logical address. A device (and especially a generic device) contains data ports to transmit and/or receive data. Each port is identified within the device by its port number (PN). A port is identified within the SLIMbus by its device address (logical address or enumeration address) and PN.

An enumeration address (EA) is a 48-bit value (composed of the manufacturer ID, product code, device ID, and instance value) that allows a device to receive messages.

A logical address (LA) is an 8-bit number used to uniquely identify an enumerated device on the bus.

24.9.1.2 Main Features

Each SLIMbus module includes the following main features:

- SLIMbus controller compliant with the MIPI SLIMbus standard version 1.01.00
- Support of seven SLIMbus devices:
 - One Interface device
 - One framer device
 - One manager device
 - Four generic devices
- SLIMBUS1: Eight TX and eight RX independent ports (data channels)
- SLIMBUS2: Four TX and four RX independent ports (data channels)
- FIFO access (one FIFO for transmit and one for receive), with DMA request (one line for transmit port and one line for receive port)
- SLIMBUS1: Message FIFO size is 32 bytes for transmit and 32 bytes for receive.
- SLIMBUS2: Message FIFO size is 32 bytes for transmit and 32 bytes for receive, by default. The message FIFO size can be reprogrammed to 64 (or 16 or 48) bytes if needed. However, typical use never exceeds 32 bytes.
- Data channel FIFO size is programmable for both modules.
- Programmable data length (sample size) from 4 to 32 bits
- Programmable port assignment to either of the four generic devices
- Supported transport protocols: Isochronous, pulled, pushed, asynchronous, and extended asynchronous transport protocols (the latter two in simplex and one-half duplex mode)
- No support for locked protocol
- SLIMbus clock rate: From 0 to 24.576 MHz

Each SLIMbus module has the following characteristics:

- The component is implemented by a digital controller (the current module), plus a physical layer (a set of CLK + DATA bidirectional input/output [I/O] drivers).
- Devices are logical entities implemented by a combination of hardware (automatic address decoding for message reception) and software (message decode, encode, etc.).
- Ports (and their mapping to data channels) are supported by the module hardware-implemented data channel agents. Each agent features a unidirectional FIFO, a DMA request, support for a number of transfer protocols, etc. One agent is used per port and per data direction: Transfer protocols are unidirectional and require only one data channel agent per data channel.

24.9.2 SLIMbus Environment

24.9.2.1 SLIMbus Component Connection Example

Figure 24-209 shows an example of a system with the SLIMbus1 controller connected to an audio peripheral component.

Figure 24-209. SLIMbus1 Typical Application System Overview

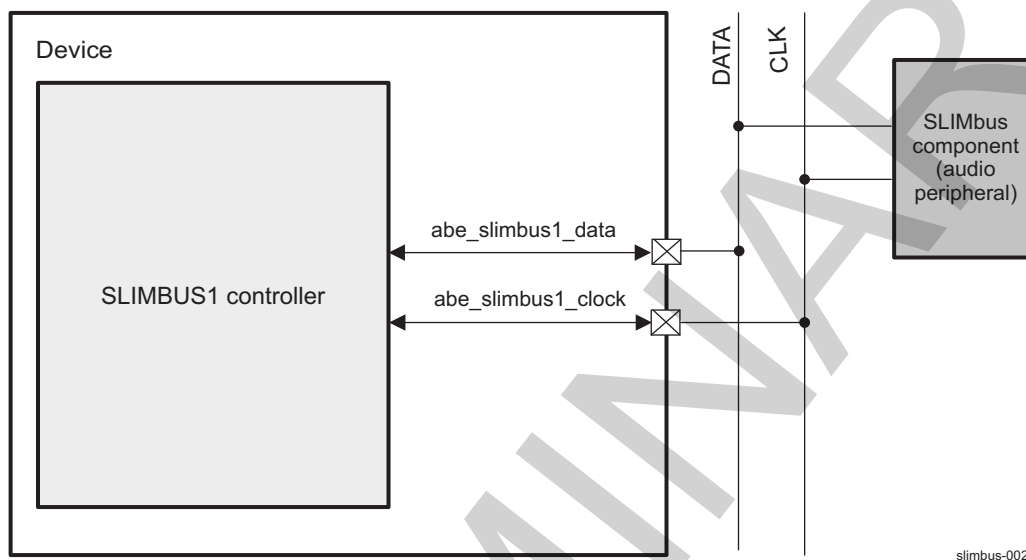

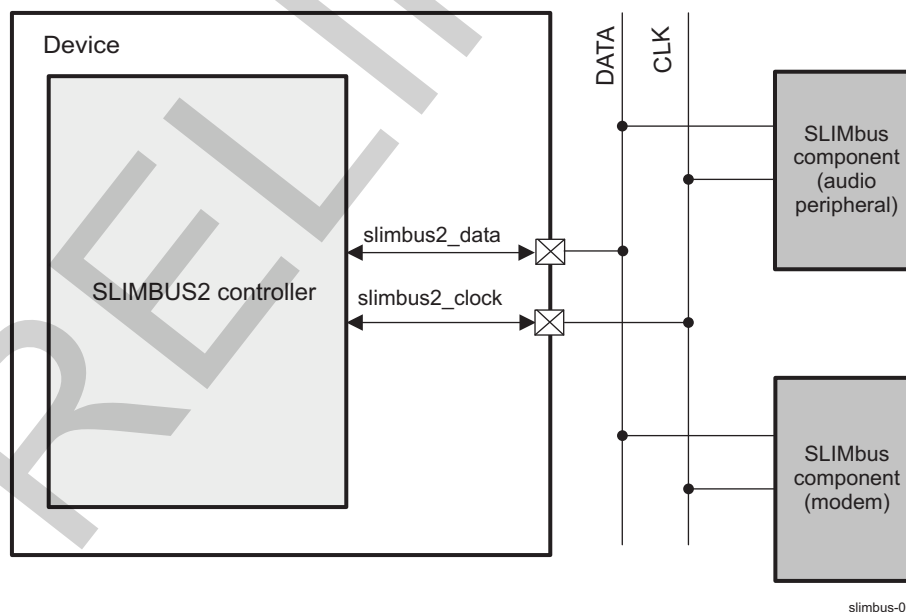

Figure 24-210 shows an example of a system with the SLIMbus2 controller connected to one audio peripheral component and one modem component.

Figure 24-210. SLIMbus2 Typical Application System Overview

The physical medium of SLIMbus is composed of two lines: CLK and DATA. All components of the bus are attached to both lines. The clock line (CLK) is driven by the (component containing the) active framer, and received (and used) by all other components on the bus. The data line (DATA) is driven alternately by all components, following the SLIMbus protocol.

The SLIMbus uses non-return-to-zero inverted (NRZI) signalling:

- A logical 1 is represented by a transition (a change) in the physical level.
- A logical 0 is represented by the same physical level as the previous bit.

24.9.2.2 SLIMbus Functional Interface

Table 24-647 describes the SLIMbus1 interface.

Table 24-647. SLIMbus1 Signals Description

| Signal | I/O | Description | Value at Reset |
|--------------------|-----|--------------------|----------------|
| abe_slimbus1_data | I/O | SLIMbus1 DATA pad | 1 |
| abe_slimbus1_clock | I/O | SLIMbus1 CLOCK pad | 1 |

Table 24-648 describes the SLIMbus2 interface.

Table 24-648. SLIMbus2 Signals Description

| Signal | I/O | Description | Value at Reset |
|----------------|-----|--------------------|----------------|
| slimbus2_data | I/O | SLIMbus2 DATA pad | 1 |
| slimbus2_clock | I/O | SLIMbus2 CLOCK pad | 1 |

24.9.2.3 SLIMbus Protocols and Data Formats

24.9.2.3.1 Frame Structure

The SLIMbus bitstream is transferred in time-division multiplexing (TDM) organization. TDM is a type of multiplexing in which two or more bitstreams are transferred apparently simultaneously as subchannels in one communication channel, but are physically taking turns on the channel. This organization allows SLIMbus to transfer control, data, and configuration information through only one DATA signal. The organization of information on the bus is called a frame structure. The frame structure is composed of five building blocks: cells, slots, subframes, frames and superframes.

- A cell is the smallest division of the SLIMbus data stream. A cell is defined as the region of the DATA line signal that lies between two consecutive positive edges of the CLK signal.
- A slot is a group of four contiguous cells. It is at the slot level that the SLIMbus DATA signal is time division-multiplexed between different channels.
- A frame is a group of 192 contiguous slots (768 cells). The first slot of each frame carries the frame-sync symbol.
- A subframe is the division of the frame structure at which control space and, if present, data space are interleaved. The subframe length can be 6, 8, 24, or 32 slots (24, 32, 96, and 128 cells).
- A superframe is composed of eight consecutive frames and contains a complete set of Framing Information.

Figure 24-211 shows the organization of the frame structure.

Figure 24-211. SLIMbus Frame Structure Overview

24.9.2.3.2 Control and Data Channels

A frame is divided into two parts: the control space and the data space. The control space contains the information needed for a device to discover the bus state, to track messages, and for the messages themselves. The control space size is programmable by setting the control space width (number of control space slots per subframe) and the subframe length. Data space is interleaved with control space at the subframe level. Slots not explicitly allocated to control space are considered data space. The active manager can organize these slots into data channels to transport application-specific data streams between devices on the bus. Data space can contain up to 256 data channels.

A data channel is a stream of one or more contiguous slots organized in a consistent data structure that repeats at a fixed interval. The largest possible group of contiguous slots within a data channel is known as a segment.

A data channel connects one data source port and one or several data sink ports, depending on the protocol used. A port can be connected only to a single data channel at a time.

A segment is composed of three fields: TAG, auxiliary information (AUX), and data fields. These fields are organized within the segment, as shown in [Figure 24-212](#). The exact composition of the segment depends on the transport protocol.

Figure 24-212. Segment Organization

24.9.2.3.2.1 Control Space Scheduling

The control space is a periodic allocation of blocks of contiguous slots with the following properties:

- Although the control space is composed of periodic blocks of 4-bit slots, it functions as a continuous stream of bits, and the interruptions for noncontrol space (that is, data space) sequences have no effect on its operation.
- The control space contains all synchronization references for the SLIMbus TDM structure; that is, it is not referenced to anything else because it is the reference.
- The control space scheduling changes only on reconfiguration boundaries.
- The subframe mode (SM) parameters unambiguously determine which slots belong to the control space.

The control space scheduling, encoded inside the SM, has the following structure:

- Each (fixed-length) frame is divided into a (whole) number of variable-sized subframes.
- The subframe length (SFL, encoded in the SM) is defined as the number of slots in a subframe.
- The control space is allocated in each subframe: The control-space width (CSW, also encoded in SM) is the number of control slots at the beginning of each subframe.

The control space is composed of $192/\text{SFL}$ blocks of CSW slots each, starting at intervals of SFL slots (knowing that there are 192 slots per frame). If the frame slots from $j = 0$ to $j = (192-1)$ and the blocks from $k = 0$ to $k = (192/\text{SFL})-1$ are indexed, the control space occupies in each frame, for the whole range of k :

- from slot $j = (k \times \text{SFL})$ included
- to slot $j = (k \times \text{SFL}) + \text{CSW} - 1$ included

The control space is further subdivided into a framing channel, guide channel, and shared message channel (SMC).

- The framing channel is composed of:
 - A 1-slot frame sync symbol (FSS), at the beginning (slot 0) of each frame. The FSS is the reference for the position of the frame in the bitstream. The fixed scheduling means that it can be retrieved and tracked regardless of the SM.
 - A framing information slot, at mid-frame (slot 96). This fixed offset means that it can also be retrieved independently of the SM. The framing information contains (among others) the value of SM, which allows all devices to determine the structure of the control space.
 - For all legal control space structures (encoded in the SM), the framing channel (slot 0 and slot 96) is inside the control space.
- The guide channel is composed of a periodic transmission of the guide byte. It is sent in the first two control space slots of each superframe (a fixed block of eight frames), after the FSS, in slot 0. The guide channel provides a sync point for the SMC (defined as follows). The two guide channel slots are not necessarily contiguous, depending on the SM, which determines the control space length and the subframe length:
 - Guide channel = slot 1 and slot 32 for $\text{SM} = 11$

- Guide channel = slot 6 and slot 12 for SM = 4
- Guide channel = slot 1 and slot 2 for SM > 12
- Etc.
- The SMC is by definition the rest of the control space; that is, not already allocated to the framing or guide channel. All devices may concurrently try to access the SMC following an arbitration process. The SMC contains an even number of slots (whole number of bytes) per frame and per superframe.

24.9.2.3.2.2 Data Channel Allocation, Segments

The bandwidth allocated for a given data channel is determined by the segment distribution (SD) and segment length (SL) of the channel. This allocation is fixed, periodic, reserved exclusively for the channel, and changes only on reconfiguration boundaries.

- Each data channel is allocated periodic blocks of contiguous slots, called data segments.
- Segments are all of equal length (SL) (in slots).
- Segment scheduling is periodic (with true, cycle-accurate periodicity).
 - The segment period is called the segment interval (SI), in slots, encoded in the SD).
 - There is always a whole number of data segments per superframe, called the channel rate multiplier (CRM), encoded in SD). The CRM is another way to express the period, because $CRM = 1536/SI$ (there are 1536 slots per superframe).
 - The segment window is another way to express the period: Each superframe can be divided into CRM segment windows, of length SI. For each data channel, each segment window contains one entire contiguous segment. Segments cannot cross segment window boundaries because some of the segments would then collide with the control space.
- The constant phase of a segment is the segment offset (SO), which is the distance between the start of the segment window and the start of the segment, in slots. SO is also encoded in SD, and its value is bounded as follows:
 - Because scheduling is periodic, offsets are defined modulo SI (that is, the segment must start inside the current window, not the next. SD encoding ensures that $SO < SI$).
 - Segment must not overlap with control space. The consequences of that vary with SM (encoded in SM), but the following is true for all SMs:
 - $SO > CSW \geq 1$: By definition, each superframe boundary is both the start of a frame (starting with CSW slots of control space; that is, at least one slot: the frame sync symbol) and the start of a segment window (the first window of the superframe, for all SD). To prevent overlap in that window, the segment must start (slot number = SO) after the control space end (slot number = $CSW-1$). Although it can be encoded in SD, the value $SO = 0$ is therefore illegal.
 - $SO+SL \leq SI$: By definition, each superframe boundary is both the start of a frame (starting at the FSS slot) and the end of a segment window (the last window of the superframe, for all SD). To prevent overlap in that window, the segment must end (slot number = $192-SI+SO+SL-1$) before the control space (frame sync symbol in slot 0 of following frame).

Notes on scheduling

- Data segments cannot cross a superframe/frame/subframe boundary, because the first slot (at least) of each subframe is allocated to the control space. This means that a data channel can be safely redefined (new SD, SL) at a reconfiguration boundary (which is also a superframe boundary), because that point cannot be in the middle of a segment.
- The composition of the segment, as defined by the transfer protocol (TP), and the contents of the channel have no affect on the allocation of the channel, although they must be compatible: the segment must be long enough (SL) to contain the TAG, AUX, and DATA fields. Some slots and some segments may remain unused.

24.9.2.3.2.3 Data Channel Presence

Data may or may not be present in each segment of the fixed, periodic series allocated to a data channel.

- The channel rate (CR) is defined as the number of data segments available per second. It depends on the channel rate multiplier (number of segments per superframe, encoded in SD[11:0]), and of the SLIMbus clock frequency. It does not depend on the total length of the segment, data length, or other.
- The presence rate (PR) is defined as the number of data segments used (that is, that contain actual data) per second, and is encoded in PR[6:0]. It depends on the selected application.

Data channel presence properties:

- The data presence determination depends on the TP:
 - Pushed: TAG presence bit (P) driven by the data source
 - Pulled: TAG presence bit (P) driven by the data source upon request driven by the data sink (SRQ)
 - Asynchronous: TAG presence bit (P) driven by the segment owner (either side)
 - Isochronous: All segments contain data, no presence indication required (because it would always be asserted).
- The presence rate is necessarily smaller than the channel rate: $PR \leq CR$. At best they are equal, which is always the case for isochronous protocol.
- The difference between channel rate and presence rate (CR-PR) is unused bandwidth and must be kept as small as possible in most cases. In other words, the CR must be kept as small as possible for a given PR requirement. The unused bandwidth has multiple uses:
 - Padding: Adjust the required PR to a nonmultiple bus speed.
 - PR jitter margin: Allow the PR to fluctuate around an average, with enough margin to allow faster-than-average periods, that compensate for slower-than-average periods.
 - Wasted bandwidth

When data presence is not fully determined by the properties of the data channel or by the other side of the interface (pulled data source, pushed data sink), it must be controlled based on the capacity of the local system to generate data (for sources) and absorb data (for sinks).

- Pushed or asynchronous source: The data source (transmitter) asserts the presence bit ($P = 1$) and transmits data when some data is available (in a transmit buffer).
- Pulled sink: The data sink (receiver) asserts the sample request ($SRQ = 1$) when it can accept more data (in a receive buffer).

24.9.2.3.2.4 Data Channel Segment Composition

The allocated size of a data channel segment is set by the SL parameter. The segment can be broken down into:

- TAG slots
- AUX slots
- DATA slots
- Unused slots

The parameters listed in [Table 24-649](#) configure the different lengths.

Table 24-649. Segment Composition

| Parameter | Register Field | Segment Field | Size Range (Slots) | Comments |
|--------------------|---|---------------|--------------------|---------------------------|
| Segment length | SLIMBUS_DCR_CONF1 G1_j[9:5] / SLIMBUS_DCT_CONF1 G1_j[9:5] SL | Segment | 1 to 31 | Encoding 0x0 is reserved. |
| Transport protocol | SLIMBUS_DCR_CONF1 G1_j[3:0] / SLIMBUS_DCT_CONF1 G1_j[3:0] TP | TAG | 0, 1, 2 | N/A |
| AUX format | SLIMBUS_DCR_CONF1 G1_j[19:16] / SLIMBUS_DCT_CONF1 G1_j[19:16] AF | AUX | 0, 1, 2 | N/A |

Table 24-649. Segment Composition (continued)

| Parameter | Register Field | Segment Field | Size Range (Slots) | Comments |
|-----------------------|---|---------------|--------------------|--|
| Data length | SLIMBUS_DCR_CONF1 G1_j[14:10] / SLIMBUS_DCT_CONF1 G1_j[14:10] DL | DATA | 0 to 31 | Encoding 0x0 is "all remaining slots," don't care if NVB is present. |
| Number of valid bytes | NVB (not in a register field, sent in the message) | DATA | 0 to 28, even only | Encoded in AUX field, overrides DL, exists only for TP = extended asynchronous |

NOTE:

- Explicit data length (DL) range is 1 to 31 slots. When encoding 0x0 is used, the DATA field occupies all remaining slots of the segment; that is, those not occupied by TAG and AUX. This allows the encoding of a 0-slot data length.
- NVB is available only in the extended asynchronous TP, which uses two TAG slots. The maximum remaining length is 31 (SL max) – 2 = 29 slots; that is, the maximum NVB is 14 bytes = 28 slots ≤ 29 (because NVB is byte-granular and cannot encode odd slot counts).
- Not all combinations are legal. For example, the DATA field of a pushed channel (TP = 0x1: 1 TAG slot) with no AUX information (AF = 0x0) and a 5-slot overall segment length (SL = 0x5) can have only one to four slots, encoded respectively as DL = 0x1, 0x2, 0x3, and 0x4/0x0.

In the current SLIMbus module:

- The SL, TP, AF, and DL setup parameters are received from the appropriate control messages (inside or outside reconfiguration sequences), and programmed into appropriate control registers. They are typically static over long periods.
- The TAG slots are generated (driven) and decoded (received) on the fly by the hardware:
 - The first TAG slot (if present, for all but isochronous TP) negotiates the value of the presence bit (P).
 - The second TAG slot (for extended asynchronous TP) contains the NVB field, which indicates the number of valid bytes contained in the segment. When the presence bit (P) is not asserted, the NVB is then not driven and implicitly = 0. There is no separate NVB setup register, as for SL, TP, AF, etc.
- AUX slots (if present) go through the same data path as the DATA slots. The decoding/encoding of the AUX information is assumed to be done outside the SLIMbus controller. Their value has no effect on the protocol.
- DATA slots (if present) go through the same data path as the AUX slots. Their value has no effect on the protocol.
- The encoding/decoding, merging/splitting between the different FIFO-stored slots is assumed to be done outside the SLIMbus controller; that is, before writing to the FIFO (in transmit) and after reading from the FIFO (in receive). No support logic is provided for those functions.
- When no data is transmitted during a given segment (presence bit P/VP = 0), only the first TAG slot (if any) is actively driven and the AUX/DATA slots are not used.

Table 24-650 gives the three cases of size calculation formulas for the TAG, AUX, and DATA fields, plus the FIFO-stored section of a segment, in slots with:

- SL, DL, NVB, TP, AF, and DL, the standard SLIMbus fields, as their integer value
- Size(TP), the TAG field size in slots, as a function of the TP (see *MIPI Alliance Specification for SLIMbus Version 1.01.00*)
- Size(AF), the AUX field size in slots, as a function of the AUX format ID AF (see *MIPI Alliance Specification for SLIMbus Version 1.01.00*)

Table 24-650. Data Segment Field Size Calculations

| Case | TAG Size = Size (TP) | AUX Size = Size (AF) | DATA Field Size | FIFO-Stored Size |
|--|----------------------|----------------------|--------------------------|--------------------------|
| Extended asynchronous protocol (TP = 0x6 or 0x7) | 2 | 0, 1, 2 | 1 + size(AF) + (2 x NVB) | 1 + size(AF) + (2 x NVB) |
| Other TP, DL > 0 | 0, 1 | 0, 1, 2 | DL | DL + size(AF) |
| Other TP, DL = 0 | 0, 1 | 0, 1, 2 | SL – size(TP) – size(AF) | SL – size(TP) |

24.9.2.3.3 SLIMbus Transfer Protocols

The SLIMbus module supports seven the following protocols:

- Isochronous
- Pushed
- Pulled
- Asynchronous
 - Simplex
 - Half-duplex
- Extended asynchronous
 - Simplex
 - Half-duplex

Table 24-651. SLIMbus Transfer Protocols

| Transfer Protocol | Multicast Capability | Data Length | AUX Length | LPCM (DT) | CTS Forcing | Pairing |
|------------------------------------|----------------------|-------------|------------|-----------|-------------|---------|
| Isochronous | Yes | 1–8 slots | 0–2 | Yes | N/A | Yes |
| Pushed | Yes | 1–8 slots | 0–2 | Yes | N/A | Yes |
| Pulled | No | 1–8 slots | 0–2 | Yes | N/A | Yes |
| Asynchronous, simplex | No | 1–8 slots | 0–2 | Yes | Yes | No |
| Asynchronous, half-duplex | No | 1–8 slots | 0–2 | Yes | Yes | No |
| Extended asynchronous, simplex | No | Any (NVB) | 0 | N/A | Yes | N/A |
| Extended asynchronous, half-duplex | No | Any (NVB) | 0 | N/A | Yes | N/A |

24.9.2.3.3.1 Isochronous Transfer Protocol

The isochronous transfer protocol is a unidirectional, streaming, multicast communication mode. Data is to be present in all allocated segments (this transfer protocol has no TAG field).

- 100 percent of the bandwidth is usable for AUX + DATA slots (no control TAG overhead).
- Because no flow control exists, multiple data sinks may be connected to the same data source (multicast capability).
- The range of possible presence rates (number of segments per second) is limited to simple ratios of the SLIMbus clock. If several data streams with incompatible presence rates must be multiplexed over the same bus, no combination of isochronous-based schedulings works. In those cases, the pushed or pulled transfer protocol must be used.

24.9.2.3.3.2 Pushed Transfer Protocol

The pushed transfer protocol is unidirectional, multicast, and controlled by the data source (transmitter), which pushes data toward the data sink (receiver). The presence of valid data in a segment is indicated by the presence (P) bit in the TAG field, driven by the source. The TAG field is composed of four bits: one reserved, one strobe (STR) bit, one reserved, and one presence (P) bit.

- The pushed data source is the master of the data flow through the presence (P) bit.
- The pushed data sink is slaved to the presence (P) bit.
- The TAG control field creates a 1-slot overhead per segment. The rest of the segment is usable for AUX + DATA slots.
- Because the flow control is generated by the source with no feedback from the sink, multiple data sinks may be connected to that source (multicast capability).
- The presence rate can be modulated at will from 0 (no data at all) to the full segment rate (data present in all segments) according to the requirement. Intermediate settings allow several streams with incompatible presence rates to be multiplexed over the same bus, at the cost of less than 100 percent bandwidth utilization (for example, a 44.1-kHz sample flow transmitted over a reserved 48-kHz data channel).

24.9.2.3.3.3 Pulled Transfer Protocol

The pulled transfer protocol is unidirectional, unicast, and controlled by the data sink (receiver), which pulls data from the data transmitter (source). The presence of valid data in a segment is indicated by the presence bit (P) in the TAG field, driven by the source. The TAG field is composed of four bits: one reserved, one sample request (SRQ) bit, one reserved, and one presence (P) bit.

- The pulled data sink is the master of the data flow through the (SRQ bit, itself determining the value of the presence bit (P), driven by the data source.
- The pulled data source is slaved to the SRQ bit.
- The TAG control field creates a 1-slot overhead per segment. The rest of the segment is usable for AUX + DATA slots.
- Because the flow control is generated by the sink with feedback from the source, only a single data sink may be connected to that source (unicast-only, no multicast capability).
- The presence rate can be modulated at will from 0 (no data at all) to the full segment rate (data present in all segments) according to the requirement. Intermediate settings allow several streams with incompatible presence rates to be multiplexed over the same bus, at the cost of less than 100 percent bandwidth utilization (for example, a 44.1-kHz sample flow transmitted over a reserved 48-kHz data channel).

24.9.2.3.3.4 Asynchronous Transfer Protocols

The asynchronous transfer protocols are typically used for on-demand, packet-based data transfers (that is, nonstreaming). Because the SLIMbus protocol and architecture are optimized for data streaming scenarios, asynchronous protocols are considered a useful extension rather than a central feature of the SLIMbus. An asynchronous data channel gets the same periodic, reserved, fixed-bandwidth slot allocation as a streaming (for example, isochronous) data channel.

An asynchronous data channel is a point-to-point (unicast) communication link between a primary owner device and a secondary owner device.

A half-duplex asynchronous channel is a bidirectional data channel.

- A handshake protocol is used to determine the direction of the channel through its ownership. The channel owner is the data source, and the other is the sink.
- Once the ownership (data direction) is determined, both source and sink can regulate the flow of data, depending on data availability (source) and free buffer availability (sink).
- Half-duplex ports can be used when bandwidth is sparse (compare simplex and full duplex).
- However, each half-duplex port requires two data channel agents (with FIFO and control logic) inside the controller, one in each direction, contrary to all other asynchronous modes and transfer protocols. Those two associated agents must be configured coherently.

A simplex asynchronous channel is a unidirectional data channel, a simplified version of the half-duplex channel defined perviously. The ownership is never given to the secondary owner.

- Secondary owner never requests the channel. As a consequence, the roles are never exchanged: the primary owner is always data source, and the secondary owner always data sink.
- Simplex ports are used in pairs of opposite directions to implement full-duplex communication, where each direction has its own reserved bandwidth. As far as the controller is concerned, the two simplex links are treated as fully independent data channels, with independent configurations; only the higher layers (software) associate the two.
- Two simplex ports use the same number of data channel agents (that is, FIFOs and control logic) as a single half-duplex port (two per controller in each case; the only difference is in the bandwidth management).

24.9.2.3.3.5 Extended Asynchronous Transfer Protocols

The extended asynchronous transfer protocols are extensions of the plain asynchronous transfer protocol. The main features are retained: point-to-point (unicast) between a primary and a secondary owner, simplex (unidirectional) or half-duplex (bidirectional), and so on.

The difference lies in a more flexible management of the DATA slots: In the plain asynchronous TP, each segment contains no data (presence [P] bit = 0) or a fixed amount of data (P = 1), preconfigured for all segments. In the extended asynchronous mode, a number of valid bytes (NVB) 4-bit field is added before each segment, in a second TAG slot, to indicate a variable number of significant DATA slots (the granularity is 1 byte = 2 slots).

NOTE: AUX slots (when present; not in the current implementation) are not counted in NVB, just as they are not counted in DL in the plain asynchronous TP.

24.9.2.3.4 Half-Duplex Versus Full-Duplex Asynchronous Configurations

Half-duplex and full-duplex modes are similar in their operation, in that they use two data channel agents (FIFOs and associated control hardware) in opposite directions (one TX, one RX) to transmit and receive data over a bidirectional, unicast (point-to-point) asynchronous link. However, there are differences:

- The half-duplex setup uses a single data channel (in the SLIMbus sense); that is, a single reserved data space segment allocation, used alternately in both directions, according to the dynamic ownership negotiated in the TAG slots.
- The full-duplex setup uses two data channels (in the SLIMbus sense); that is, two separate reserved data space segment allocations, each used in a fixed direction (opposite of the other) (that is, with no ownership change).

24.9.3 SLIMbus Integration

Figure 24-213 and Figure 24-214 show the integration of the two SLIMbus module instantiations in the device. The SLIMBUS1 module is part of the ABE module

Figure 24-213. SLIMBUS1 Integration

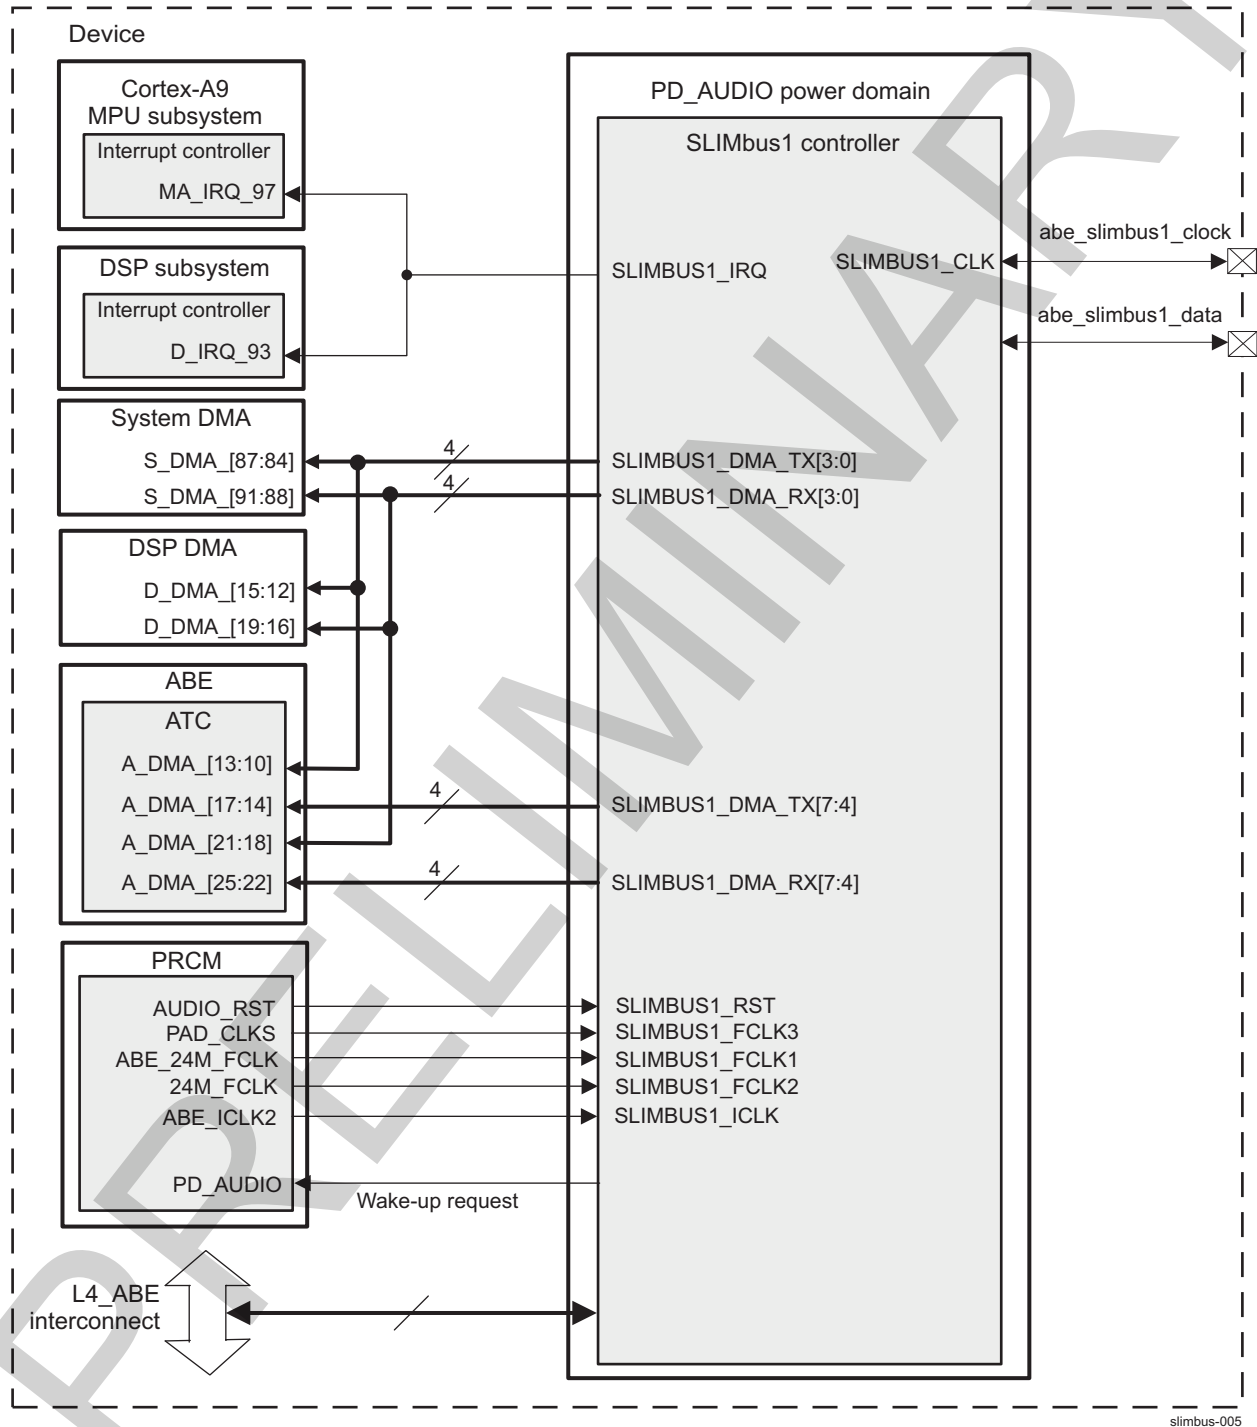

Figure 24-214. SLIMBUS2 Integration

Table 24-652 through Table 24-654 summarize the integration of the modules in the device.

Table 24-652. Integration Attributes

| Module Instance | Attributes | | |
|-----------------|--------------|--------------------|--------------|
| | Power Domain | Wake-Up Capability | Interconnect |
| SLIMBUS1 | PD_AUDIO | Yes | L4_ABE |
| SLIMBUS2 | PD_L4_PER | Yes | L4_PER |

Table 24-653. Clocks and Resets

| Clocks | | | | |
|-----------------|-------------------------|--------------------|-------------------------------------|---|
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| SLIMBUS1 | SLIMBUS1_FCLK3 | PAD_CLKS | PRCM | Functional clock, divided by 4 or more inside SLIMbus module. The source is the <code>abe_clks</code> pin gated by the PRCM module. |
| | SLIMBUS1_FCLK1 | ABE_24M_FCLK | PRCM | Functional clock, divided by 4 or more inside SLIMbus module |
| | SLIMBUS1_ICLK | ABE_ICLK2 | PRCM | Interface clock |
| | SLIMBUS1_FCLK2 | 24M_FCLK | PRCM | Functional clock, divided by 4 or more inside SLIMbus module |
| | SLIMBUS1_CLK | SLIMBUS_UCLKS | <code>abe_slimbus1_clock</code> pin | SLIMBUS clock, may or may not be locally generated |
| SLIMBUS2 | SLIMBUS2_ICLK | PER_L4_ICLK | PRCM | Interface clock |
| | SLIMBUS2_CLK | PAD_SLIMBUS_CLKS | <code>slimbus2_clock</code> pin | SLIMBUS clock, may or may not be locally generated |
| | SLIMBUS2_FCLK2 | PER_24MC_FCLK | PRCM | Functional clock, divided by 4 or more inside SLIMbus module |
| | SLIMBUS2_FCLK1 | PER_ABE_24M_FCLK | PRCM | Functional clock, divided by 4 or more inside SLIMbus module |
| Resets | | | | |
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| SLIMBUS1 | SLIMBUS1_RST | AUDIO_RST | PRCM | Reset to SLIMbus1 module |
| SLIMBUS2 | SLIMBUS2_RST | L4_PER_RST | PRCM | Reset to SLIMbus2 module |

Table 24-654. Hardware Requests

| Interrupt Requests | | | | |
|--------------------|--------------------|-------------------------|------------------|---|
| Module Instance | Source Signal Name | Destination Signal Name | Destination | Description |
| SLIMBUS1 | SLIMBUS1_IRQ | MA_IRQ_97 | Cortex-A9 INTC | SLIMBUS1 interrupt to Cortex-A9 MPU |
| | SLIMBUS1_IRQ | D_IRQ_93 | DSP INTC | SLIMBUS1 interrupt to DSP |
| SLIMBUS2 | SLIMBUS2_IRQ | MA_IRQ_98 | Cortex-A9 INTC | SLIMBUS2 interrupt to Cortex-A9 MPU |
| | SLIMBUS2_IRQ | D_IRQ_94 | DSP INTC | SLIMBUS2 interrupt to DSP |
| DMA Requests | | | | |
| Module Instance | Source Signal Name | Destination Signal Name | Destination | Description |
| SLIMBUS1 | SLIMBUS1_DMA_TX0 | A_DMA_10 | aDMA (Audio DMA) | SLIMbus module 1 – transmit request channel 0 |
| | SLIMBUS1_DMA_TX1 | A_DMA_11 | aDMA | SLIMbus module 1 – transmit request channel 1 |
| | SLIMBUS1_DMA_TX2 | A_DMA_12 | aDMA | SLIMbus module 1 – transmit request channel 2 |
| | SLIMBUS1_DMA_TX3 | A_DMA_13 | aDMA | SLIMbus module 1 – transmit request channel 3 |
| | SLIMBUS1_DMA_TX4 | A_DMA_14 | aDMA | SLIMbus module 1 – transmit request channel 4 |
| | SLIMBUS1_DMA_TX5 | A_DMA_15 | aDMA | SLIMbus module 1 – transmit request channel 5 |
| | SLIMBUS1_DMA_TX6 | A_DMA_16 | aDMA | SLIMbus module 1 – transmit request channel 6 |
| | SLIMBUS1_DMA_TX7 | A_DMA_17 | aDMA | SLIMbus module 1 – transmit request channel 7 |
| | SLIMBUS1_DMA_RX0 | A_DMA_18 | aDMA | SLIMbus module 1 – receive request channel 0 |

Table 24-654. Hardware Requests (continued)

| | | | | |
|----------|----------------------|----------|----------------------|---|
| | SLIMBUS1_DM A_RX1 | A_DMA_19 | aDMA | SLIMbus module 1 – receive request channel 1 |
| | SLIMBUS1_DM A_RX2 | A_DMA_20 | aDMA | SLIMbus module 1 – receive request channel 2 |
| | SLIMBUS1_DM A_RX3 | A_DMA_21 | aDMA | SLIMbus module 1 – receive request channel 3 |
| | SLIMBUS1_DM A_RX4 | A_DMA_22 | aDMA | SLIMbus module 1 – receive request channel 4 |
| | SLIMBUS1_DM A_RX5 | A_DMA_23 | aDMA | SLIMbus module 1 – receive request channel 5 |
| | SLIMBUS1_DM A_RX6 | A_DMA_24 | aDMA | SLIMbus module 1 – receive request channel 6 |
| | SLIMBUS1_DM A_RX7 | A_DMA_25 | aDMA | SLIMbus module 1 – receive request channel 7 |
| | SLIMBUS1_DM A_TX0 | S_DMA_84 | sDMA (System DMA) | SLIMbus module 1 – transmit request channel 0 |
| | SLIMBUS1_DM A_TX1 | S_DMA_85 | sDMA | SLIMbus module 1 – transmit request channel 1 |
| | SLIMBUS1_DM A_TX2 | S_DMA_86 | sDMA | SLIMbus module 1 – transmit request channel 2 |
| | SLIMBUS1_DM A_TX3 | S_DMA_87 | sDMA | SLIMbus module 1 – transmit request channel 3 |
| | SLIMBUS1_DM A_RX0 | S_DMA_88 | sDMA | SLIMbus module 1 – receive request channel 0 |
| | SLIMBUS1_DM A_RX1 | S_DMA_89 | sDMA | SLIMbus module 1 – receive request channel 1 |
| | SLIMBUS1_DM A_RX2 | S_DMA_90 | sDMA | SLIMbus module 1 – receive request channel 2 |
| | SLIMBUS1_DM A_RX3 | S_DMA_91 | sDMA | SLIMbus module 1 – receive request channel 3 |
| | SLIMBUS1_DM A_TX0 | D_DMA_12 | dDMA (DSP DMA) | SLIMbus module 1 – transmit request channel 0 |
| | SLIMBUS1_DM A_TX1 | D_DMA_13 | dDMA | SLIMbus module 1 – transmit request channel 1 |
| | SLIMBUS1_DM A_TX2 | D_DMA_14 | dDMA | SLIMbus module 1 – transmit request channel 2 |
| | SLIMBUS1_DM A_TX3 | D_DMA_15 | dDMA | SLIMbus module 1 – transmit request channel 3 |
| | SLIMBUS1_DM A_RX0 | D_DMA_16 | dDMA | SLIMbus module 1 – receive request channel 0 |
| | SLIMBUS1_DM A_RX1 | D_DMA_17 | dDMA | SLIMbus module 1 – receive request channel 1 |
| | SLIMBUS1_DM A_RX2 | D_DMA_18 | dDMA | SLIMbus module 1 – receive request channel 2 |
| | SLIMBUS1_DM A_RX3 | D_DMA_19 | dDMA | SLIMbus module 1 – receive request channel 3 |
| SLIMBUS2 | SLIMBUS2_DM A_TX0 | D_DMA_20 | dDMA | SLIMbus module 2 – transmit request channel 0 |
| | SLIMBUS2_DM A_TX1 | D_DMA_21 | dDMA | SLIMbus module 2 – transmit request channel 1 |
| | SLIMBUS2_DM A_TX2 | D_DMA_22 | dDMA | SLIMbus module 2 – transmit request channel 2 |
| | SLIMBUS2_DM A_TX3 | D_DMA_23 | dDMA | SLIMbus module 2 – transmit request channel 3 |
| | SLIMBUS2_DM A_RX0 | D_DMA_24 | dDMA | SLIMbus module 2 – receive request channel 0 |

Table 24-654. Hardware Requests (continued)

| | | | |
|----------------------|----------|------|---|
| SLIMBUS2_DM A_RX1 | D_DMA_25 | dDMA | SLIMbus module 2 – receive request channel 1 |
| SLIMBUS2_DM A_RX2 | D_DMA_26 | dDMA | SLIMbus module 2 – receive request channel 2 |
| SLIMBUS2_DM A_RX3 | D_DMA_27 | dDMA | SLIMbus module 2 – receive request channel 3 |
| SLIMBUS2_DM A_TX0 | S_DMA_92 | sDMA | SLIMbus module 2 – transmit request channel 0 |
| SLIMBUS2_DM A_TX1 | S_DMA_93 | sDMA | SLIMbus module 2 – transmit request channel 1 |
| SLIMBUS2_DM A_TX2 | S_DMA_94 | sDMA | SLIMbus module 2 – transmit request channel 2 |
| SLIMBUS2_DM A_TX3 | S_DMA_95 | sDMA | SLIMbus module 2 – transmit request channel 3 |
| SLIMBUS2_DM A_RX0 | S_DMA_96 | sDMA | SLIMbus module 2 – receive request channel 0 |
| SLIMBUS2_DM A_RX1 | S_DMA_97 | sDMA | SLIMbus module 2 – receive request channel 1 |
| SLIMBUS2_DM A_RX2 | S_DMA_98 | sDMA | SLIMbus module 2 – receive request channel 2 |
| SLIMBUS2_DM A_RX3 | S_DMA_99 | sDMA | SLIMbus module 2 – receive request channel 3 |

NOTE:

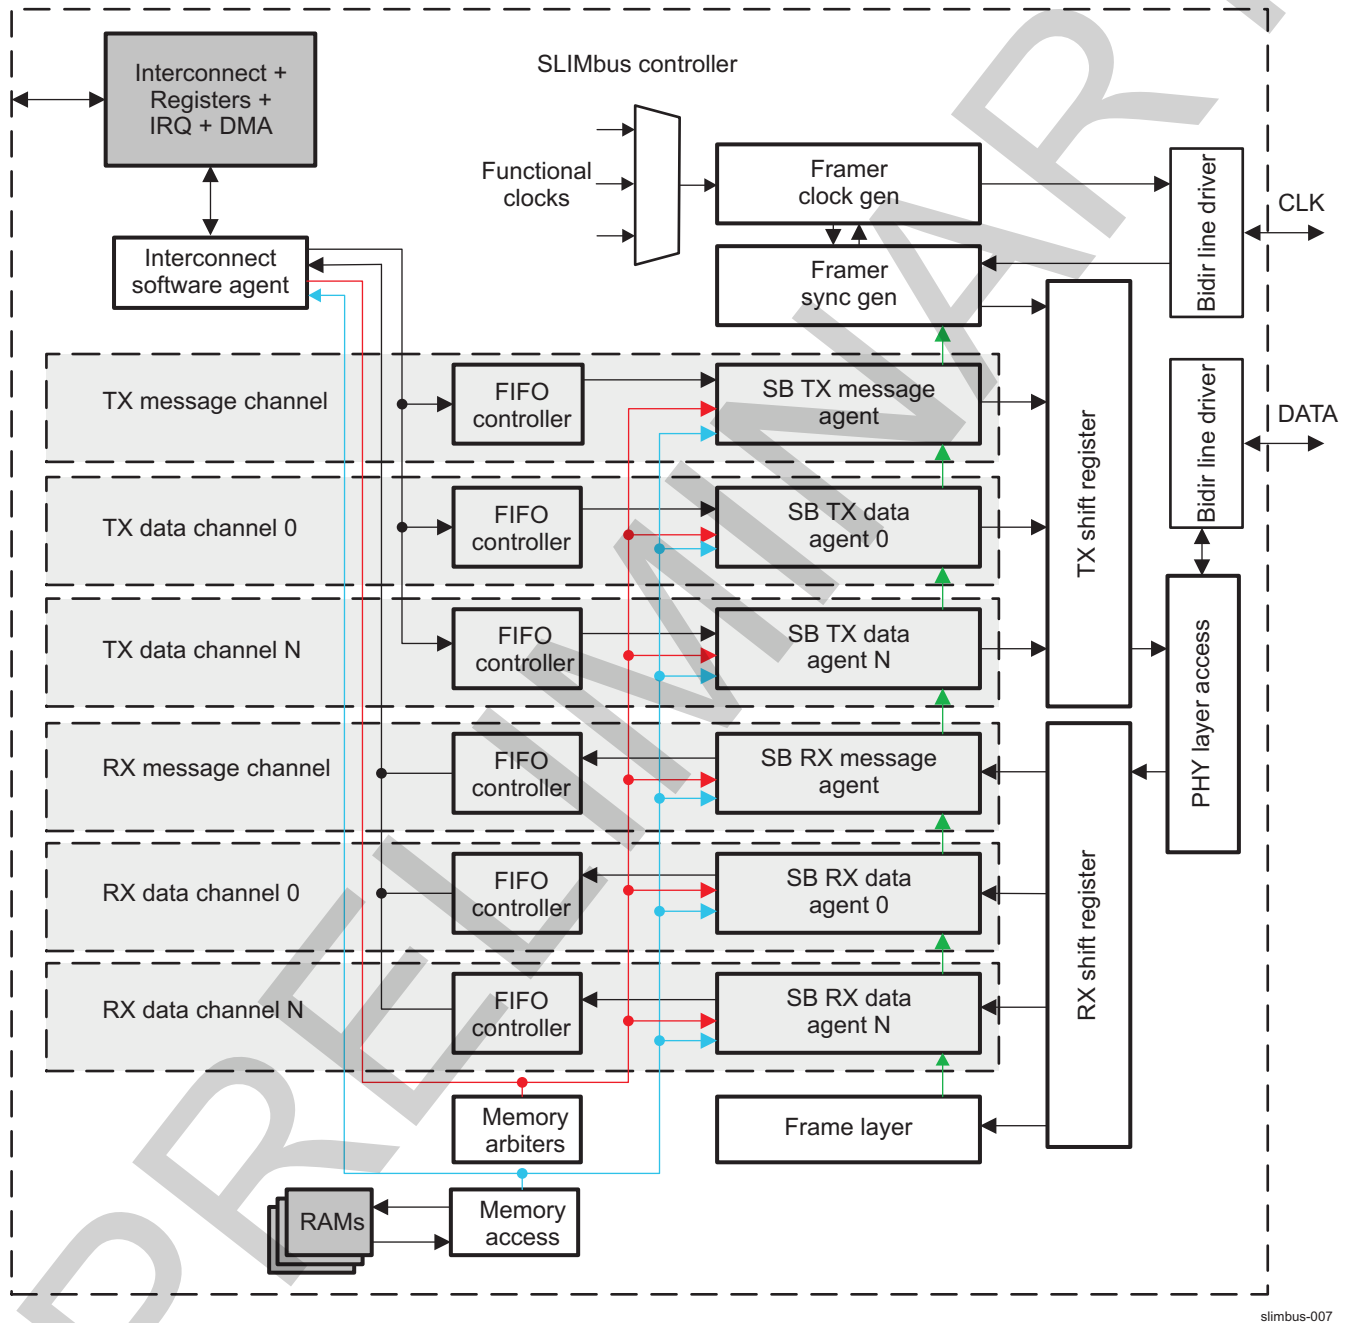

- For the description of the interrupt, see [Section 24.9.4.11](#), *Interrupt Service Routines*, and [Chapter 18](#), *Interrupt Controllers*.
- For the description of the DMA, see [Section 24.9.4.5.2](#), *Data Input/Output: DMA Request Mode*, and [Chapter 17](#), *SDMA*.

24.9.4 SLIMbus Functional Description

24.9.4.1 SLIMbus Block Description

Figure 24-215 shows the the overall architecture of a SLIMbus module.

Figure 24-215. SLIMbus Block Diagram

slimbus-007

- The red arrows represent the shared memory arbitration interface, from the arbiter to each agent.
- The blue arrows represent the shared memory access interface, from the memory access module to each agent.
- The green arrows represent the frame layer sync information broadcasted to all SB-side agents.

24.9.4.2 SLIMbus Clock Configuration

Most of the SLIMbus module runs off two main clocks: the L4 interface clock for the data input and output registers, and the control and status control registers; and the SLIMbus clock, taken from the serial interface (CLK line) for the SLIMbus-side logic.

The SLIMbus controller operates as clock source component (active framer), which drives the SLIMbus clock line CLK, or as clock receiver component, which gets its clock from the same CLK line.

- As a clock receiver, the module has by definition no control over the clock activity and can perform required operations based on that. Even clock pause is mostly transparent as far as the receiver logic is concerned (that is, everything happens as if time had stopped at the clock pause, and activity resumes seamlessly upon clock restart).
- As a clock source (also called active framer), the module relies on a local functional clock to drive the SLIMbus clock line. Such a functional clock is selected out of the available clock inputs. The appropriate input is expected to be active whenever it is needed (that is, when selected and used to run the SLIMbus clock and/or the module internal logic). In this case, the SLIMbus clock output is generated by selecting and dividing one functional clock input provided to the controller. Internal logic selects and divides the appropriate one depending on the SLIMbus configuration.

24.9.4.3 Software Reset

The [SLIMBUS_CMP_SYSCONFIG\[1\] SOFTRESET](#) bit controls the software reset; writing 1 to this bit starts a soft reset sequence.

24.9.4.4 System Power Management and Wakeup

24.9.4.4.1 Wake-Up Request

Both SLIMbus controllers are wake-up capable.

There are several levels of wake-up capability:

- Most IRQ events are potential wake-up sources, because they can occur while the external interface is idle, assuming the external and SLIMbus clocks are still running.
- The clock restart IRQ event (the [SLIMBUS_FR_INFO\[5\] CLOCK_RESTART](#) bit) following a clock pause is the only one that can take place when all module clocks are stopped.

24.9.4.4.2 Power Management

[Table 24-655](#) describes power-management features available for the SLIMbus module.

NOTE: For the description of the IdleMode feature, see [Chapter 3, Power, Reset, and Clock Management](#).

Table 24-655. Local Power-Management Features

| Feature | Registers | Description |
|------------------------|--|--|
| Clock auto gating | SLIMBUS_CMP_SYSCONFIG[8] AUTOGATINGDISABLE | Internal clock autogating is intended to conserve power when the module is not in use. |
| Slave idle modes | SLIMBUS_CMP_SYSCONFIG[3:2] IDLEMODE | Force-idle, no-idle, smart-idle, and smart-idle wake-up-capable modes are available. |
| Wake-up sources enable | SLIMBUS_FR_INFO[5] CLOCK_RESTART and most IRQ events | See Section 24.9.4.4.1 |

24.9.4.4.3 SLIMbus Boot and Reset Procedures

The SLIMbus standard defines different levels of resets and default states from which to boot. They are implemented by a mix of software and hardware.

NOTE: This does not include the module-wide software or hardware resets of the controller, which simply wipe off the entire logic with no consideration for any potentially ongoing SLIMbus operation.

Table 24-656 summarizes the control bit fields to set in the various reset and/or boot sequences. Any combination other than the ones described here may yield unpredictable results.

Table 24-656. Reset and Boot Control Summary

| Register / Field | SLIMBUS_FR_CONTROL | | SLIMBUS_FL_CONTROL | | |
|---|--------------------|-----------|--------------------|--------------|----------------------------------|
| | Boot | bus_reset | Boot | bus_shutdown | force_reconfigure ⁽¹⁾ |
| Clock receiver boot ⁽²⁾ | | | 1 | | 1 |
| Clock source boot | 1 | | | | 1 |
| Clock receiver component reset ^{(2) (3)} | | | 1 | | 1 |
| Clock source component reset | | 1 | | | 1 |
| Bus reset ^{(4) (5)} | | 1 | | | |
| Bus shutdown ⁽⁴⁾ | | | | 1 | |

⁽¹⁾ When used, the SLIMBUS_FL_CONTROL[2] FORCE_RECONFIGURE bit must be set (written to 1) last, because its action can be immediate. Other control bits can be set in any order.

⁽²⁾ The controls for boot and component reset look identical for the clock receiver. The difference is in the initial state of the component: in the first case, the component is in the undefined state (not started), in the second case it is operational.

⁽³⁾ The clock receiver component reset case shown here corresponds to the reception by the component interface of the RESET_DEVICE. In the two other cases, a bus reset is detected and the hardware automatically goes to the correct state.

⁽⁴⁾ The bus reset and shutdown belong to a reconfiguration (message) sequence and take place on the reconfiguration boundary: the SLIMBUS_FL_CONTROL[2] FORCE_RECONFIGURE is therefore not used.

⁽⁵⁾ The bus reset is executed only by the clock source (active framer).

24.9.4.4.3.1 Clock Receiver Component Boot

A clock receiver boot sequence is initiated when a component that is not the default active framer decides to join the SLIMbus. Provided the clock line is driven (that is, a framer is active), the clock receiver must eventually acquire the synchronization.

Clock receiver boot sequence:

- Initial state: Out of hardware module reset or following a SLIMbus shutdown
- Write 1 to the SLIMBUS_FL_CONTROL[0] BOOT bit to start the clock receiver.
- Write 1 to the SLIMBUS_FL_CONTROL[2] FORCE_RECONFIGURE bit.

24.9.4.4.3.2 Clock Source Component Boot

Source component is, by definition, the component including the active framer (that is, the clock driver). A clock source boot sequence is initiated when a component that is the default active framer joins the SLIMbus. The clock source drives the clock line and runs the SLIMbus boot sequence, allowing the connected clock receivers to synchronize to it.

NOTE: The component knows in advance that it is the only default active framer, in charge of booting the bus: That information must be available for the component, as well as the default SM, CG, and RF configuration parameters.

Clock source boot sequence:

- Initial state: The component is the designated default active framer and is out of hardware module reset or follows a SLIMbus shutdown.
- Write 1 to the SLIMBUS_FR_CONTROL[0] BOOT bit.
- Write the basic bus configuration, to be used by the active framer device to generate the clock and the framing channel contents:
 - Subframe mode (M) in the SLIMBUS_FL_SM[4:0] SM bit field: Sets the control space width and

- subframe length
- Clock gear (G) in the [SLIMBUS_FL.CG](#)[3:0] CG bit field: The root/SLIMbus frequency ratio is defined as $2^{(10-CG)}$
- Root frequency (F) in the [SLIMBUS_FL.RF](#)[3:0] RF bit field: Sets the root frequency
- Clock source selection, in the [SLIMBUS_FR.CLOCK_SOURCE](#)[5:3] CLKSEL and [SLIMBUS_FR.CLOCK_SOURCE](#)[2:0] CLKDIV bit fields
- The relationships (and limitations) between CG, RF, and the clock source selection also apply here.
- Write 1 to the [SLIMBUS_FL.CONTROL](#)[2] FORCE_RECONFIGURE bit to trigger the sequence execution
- The clock source starts immediately and eventually drives the CLK line and allows other components (clock receivers) to join the bus.

24.9.4.4.3.3 Bus Reset

A bus reset is a specific DATA and CLK sequence run by the active framer, scheduled after the bus has already booted, and which causes all components of the bus to reset. For more information about the bus reset detection mechanism, see [Section 24.9.4.4.3.4, Component Reset](#).

The bus reset is requested by the manager device through a reconfiguration sequence, and is run by the active framer starting at the following reconfiguration boundary.

Bus reset sequence, to be executed by all components:

- Write 1 to the [SLIMBUS_FR.CONTROL](#)[1] BUS_RESET bit.
- Wait for the end of the reconfiguration sequence to execute:
 - On the clock source (active framer), this must trigger a bus reset sequence.
 - On any other device (that is, a clock receiver), this must have no direct effect (other than clearing the [SLIMBUS_FR.CONTROL](#)[1] BUS_RESET bit).
 - Because all bus devices are being reset (bus is rebooted, almost from the beginning), the configuration (M, G, F parameters) can change (because those parameters must be reacquired by all attached devices as part of the resynchronization sequence, this is not a problem).

24.9.4.4.3.4 Component Reset

A component reset implies the (device) reset of all devices within that component. When a component reset condition is detected, software must therefore run the device reset sequence defined in [Section 24.9.4.4.3.5, Device Reset](#), as many times as necessary. Additional operations are also required.

A component reset has two possible causes:

- Bus reset sequence detected
- Interface device of the local component receives a reset order. (This is not a reconfiguration message; that is, the reset is effective immediately upon reception. Nevertheless, a specific action is needed to perform the device reset:)
 - Use the [SLIMBUS_FL.CONTROL](#)[1] COMPONENT_RESET bit.
 - If the component is a clock receiver (clock receiver FSM), the sequence is :
 - Write 1 to the [SLIMBUS_FL.CONTROL](#)[0] BOOT bit.
 - Write 1 to the [SLIMBUS_FL.CONTROL](#)[2] FORCE_RECONFIGURE bit to trigger the reset execution.
 - If the component is the active framer (clock source FSM), the sequence is :
 - Write 1 to the [SLIMBUS_FR.CONTROL](#)[1] BUS_RESET bit.
 - Write 1 to the [SLIMBUS_FL.CONTROL](#)[2] FORCE_RECONFIGURE bit to trigger the reset execution.
 - The effect of a clock source component reset is the same as a bus reset, except it takes place immediately instead of waiting for a reconfiguration boundary.

24.9.4.4.3.5 Device Reset

A device reset can have several causes:

- Component reset of the receiver component containing that device, caused by a bus reset reconfiguration message. If the cause of the device reset is a component reset, the sequence defined in [Section 24.9.4.4.3.4, Component Reset](#), is applied.
- A reset order targeted at the device itself. (This is not a reconfiguration message; that is, it is effective immediately upon reception. In this case, no additional action is required.)

The following sequence must be executed for all devices:

- Release the logical address (LA) of the device by clearing (writing 0 to) the [SLIMBUS_DEV_LA_i\[8\]](#) LA_ENABLE bit. It is assumed that the [SLIMBUS_DEV_LA_i\[9\]](#) EA_ENABLE bit remains set (1). The device returns to the default, nonenumerated state where it is identified by its hard-coded enumeration address (EA). The [SLIMBUS_DEV_LA_i\[7:0\]](#) LA bit may be assigned to another device by the bus manager (that is, keeping track of all device resets).
- The following hardware bits must also be cleared (by writing 1) when the device to which they belong (identified by the message target LA) is being reset:
 - The [SLIMBUS_FR_INFO\[2\]](#) FS, [SLIMBUS_FR_INFO\[1\]](#) FI, and [SLIMBUS_FR_INFO\[0\]](#) GC_TX_COL bits (framer device-specific IEs)
 - The [SLIMBUS_FL_INFO\[2\]](#) LOST_FS, [SLIMBUS_FL_INFO\[1\]](#) LOST_SFS, and [SLIMBUS_FL_INFO\[0\]](#) LOST_MS bits (interface device-specific IEs)
 - The [SLIMBUS_SMR_INFO\[0\]](#) MC_TX_COL, [SLIMBUS_SMT_INFO\[0\]](#) MC_TX_COL bit (primitives of interface device-specific IE)
 - The [SLIMBUS_DCT_INFO_i\[0\]](#)/[SLIMBUS_DCR_INFO_i\[0\]](#) DATA_TX_COL bit (generic device IEs)
- Reset all pending reconfiguration parameters by writing 1 to the [SLIMBUS_FL_CONTROL\[7\]](#) CLEAR_RECONFIGURATION bit (see [Section 24.9.4.4.4](#)).
- Reset all device ports (if any), as explained in [Section 24.9.4.4.3.6, Port Reset](#).

24.9.4.4.3.6 Port Reset

A port reset can have several causes:

- Device reset of the device to which the port belongs, which may be part of a wider component of the bus reset
- Synchronization loss. Although all ports are reset, this is not equivalent to a device reset, because logical addresses are not cleared.
- Specific software messages reception

24.9.4.4.3.7 Bus Shutdown

A bus shutdown stops definitively all SLIMbus activity (CLK and DATA) and brings the bus back to its original (preboot) state. When the shutdown is executed, the system must reboot from scratch.

The bus shutdown is requested by the manager device through a reconfiguration sequence.

Bus shutdown sequence:

- Write 1 to the [SLIMBUS_FL_CONTROL\[6\]](#) BUS_SHUTDOWN bit. This is valid for an active framer (clock source) or a clock receiver.
- Wait for the end of the reconfiguration sequence to execute.
- Beyond that point, the bus is down and can be restarted only by a boot sequence.

24.9.4.4.4 SLIMbus Reconfigure Parameters

During a reconfiguration message sequence, the controller accumulates parameter changes to be applied at the following reconfiguration boundary. If the sequence does not complete correctly, all changes are discarded. In specific boot and reset cases, the parameters are also set or reset automatically.

This section provides an overview of all the configuration register fields and their use.

Writing 1 to the [SLIMBUS_FL_CONTROL\[7\]](#) CLEAR_RECONFIGURATION bit has an immediate effect on the configuration registers.

- The following registers fields revert to their current value; that is, the value currently used for SLIMbus operations. The value previously written in is discarded.
 - The [SLIMBUS_FL_SM\[4:0\]](#) SM bit field: Sets the control space width and subframe length.
 - The [SLIMBUS_FL_CG\[3:0\]](#) CG bit field: The root/SLIMbus frequency ratio is defined as $2^{(10-G)}$.
 - The [SLIMBUS_FL_RF\[3:0\]](#) RF bit field: Sets the root frequency
 - The [SLIMBUS_FR_CLOCK_SOURCE\[5:3\]](#) CLKSEL: Clock input source selection
 - [SLIMBUS_FR_CLOCK_SOURCE\[2:0\]](#) CLKDIV bit field: Root divider ratio, applied on clock input to obtain root clock, to be used at next reconfiguration boundary. Input/ root frequency ratio is defined as $2^{(CLKDIV-1)}$.
 - The [SLIMBUS_DCT_CONFIG1_j\[31\]/SLIMBUS_DCR_CONFIG1_j\[31\]](#) ENABLE bit (this field is also cleared when the superframe or frame sync is lost): Data channel agent enabling control
 - The [SLIMBUS_DCT_CONFIG1_j\[15\]/SLIMBUS_DCR_CONFIG1_j\[15\]](#) CL bit: Channel link configuration mode selection
 - The [SLIMBUS_DCT_CONFIG1_j\[26:20\]/SLIMBUS_DCR_CONFIG1_j\[26:20\]](#) PR bit field: Presence rate configuration
 - The [SLIMBUS_DCT_CONFIG1_j\[3:0\]/SLIMBUS_DCR_CONFIG1_j\[3:0\]](#) TP bit field: Transfer protocol selection
 - The [SLIMBUS_DCT_CONFIG2_j\[11:0\]/SLIMBUS_DCR_CONFIG2_j\[11:0\]](#) SD bit field: Segment distribution
- The following register bits are cleared to 0. They correspond to features enabled for the upcoming reconfiguration boundary, and that are discarded here.
 - The [SLIMBUS_FR_CONTROL\[1\]](#) BUS_RESET bit: Bus reset request control
 - The [SLIMBUS_FR_CONTROL\[0\]](#) BOOT bit: Initiate an active framer (clock source) boot sequence for the component when the component is default active framer.
 - The [SLIMBUS_FL_CONTROL\[6\]](#) BUS_SHUTDOWN
 - [SLIMBUS_FL_CONTROL\[0\]](#) BOOT bit: Boot the component when not in active framer mode.
 - The [SLIMBUS_FL_CONTROL\[4\]](#) KILL_SFS bit is set when the reconfiguration sequence terminates incorrectly (in that case the bit must be set after the clear-up). Forces immediate frame synchronization loss.
 - The [SLIMBUS_FL_CONTROL\[7\]](#) CLEAR_RECONFIGURATION bit itself; that is, the bit never reads out 1.
 - The [SLIMBUS_FR_FRAMER_HANDBOVER\[12\]](#) HANDBOVER_ENABLE bit: Enable framer handover, upon NEXT_ACTIVE_FRAMER(NCO,NCI) reception.
 - The [SLIMBUS_FR_CLOCK_PAUSE\[0\]](#) CLOCK_PAUSE bit: Controls clock pause/restart
- The following bit fields do not change, although they are updated as part of the reconfiguration message sequence:
 - The [SLIMBUS_FR_FRAMER_HANDBOVER\[11:0\]](#) NCO_NCI bit field: The value is don't care as long as [SLIMBUS_FR_FRAMER_HANDBOVER\[12\]](#) HANDBOVER_ENABLE = 0, and is overwritten if a new handover is scheduled.
 - The [SLIMBUS_FR_CLOCK_PAUSE\[2:1\]](#) TRT bit field: The value is don't care as long as [SLIMBUS_FR_CLOCK_PAUSE\[0\]](#) CLOCK_PAUSE = 0, and is overwritten if a new pause is scheduled.

24.9.4.5 Data Channels (Ports) Management

Ports (contained in devices) are associated with data channels that connect several ports, typically one output port on a data source device and one or more inputs ports on a data sink device, over periodically scheduled data segments and using a given transfer protocol (TP).

24.9.4.5.1 Data input/output: manual mode

A data channel agent FIFO stores a whole number of FIFO words. A FIFO word is a chunk of data that contains the AUX and DATA information of one SLIMbus data segment, with the following properties:

- The FIFO word size minimum is 4 bits (one slot) in the current implementation, as defined in the MIPI SLIMbus standard 1.01.00; they are of little practical use.
- The FIFO word size maximum is 32 bits (eight slots) in the current implementation, equal to one physical FIFO RAM word and to one read/write access. Larger segment sizes (up to 31 slots = 124 bits) segments are defined in the MIPI SLIMbus standard version 1.01.00, but they are not implemented here.
- Between the minimum and maximum values, the FIFO word size is programmable, with a slot (that is, 4 bits) granularity.
- The AUX information is a field of 0, 1, or 2 slots (that is, 0, 4, or 8 bits) transmitted immediately before the DATA slots. All sizes are supported by current implementation. It is stored and managed along with the DATA by the module FIFOs.
- The DATA information is a field of 0 to 31 slots in the MIPI SLIMbus standard version 1.01.00, with slot granularity. This is implemented within the limits of the FIFO word size given previously, with AUX size + DATA size = FIFO word size; therefore, the DATA information is a field of 0 to 8 slots.
- The extended asynchronous transfer protocols (TP; that is, simplex and half-duplex) are exceptions to the previously discussed rules. In that case, the source device fills each segment with as many bytes as it deems necessary (provided it fits in the segment), and lets the sink device know how many through the TAG NVB field:
 - The source transmits as many whole FIFO words as it deems necessary. This implies that the FIFO word is a byte multiple (that is, an even number of 4-bit slots).
 - The sink receives a whole number of bytes, which it stores in byte-size FIFO words.
 - AUX is not applicable and is not supported in these modes.

Each read (or write) access to the appropriate [SLIMBUS_DCR_DATA_j](#) (respectively, [SLIMBUS_DCT_DATA_j](#)) removes (respectively, adds) one FIFO word from RX (TX) FIFO #N. [Table 24-657](#) lists examples of possible FIFO word mappings (with the AUX and DATA slots indicated as A() and D()) inside 32-bit read and write accesses.

NOTE: The transmission over the SLIMbus serial interface is always A(0) to A(N1), and then D(0) to D(N2); that is, MSB to LSB.

Table 24-657. Examples of AUX + DATA Mapping in 32-bit Read/Write Accesses

| FIFO Format | Word | FIFO Word Size (in Slots) | 32-bit Access Read/Write Data (Bit Range) | | | | | | | |
|----------------|------|---------------------------|---|--------|--------|--------|--------|-------|------|------|
| | | | 31..28 | 27..24 | 23..20 | 19..16 | 15..12 | 11..8 | 7..4 | 3..0 |
| 4-bit + 0 aux | | 1 (min) | | | | | | | | D(0) |
| 8-bit + 0 aux | | 2 | | | | | | | D(0) | D(1) |
| 12-bit + 0 aux | | 3 | | | | | | D(0) | D(1) | D(2) |
| 16-bit + 0 aux | | 4 | | | | | D(0) | D(1) | D(2) | D(3) |
| 24-bit + 0 aux | | 6 | | | D(0) | D(1) | D(2) | D(3) | D(4) | D(5) |
| 32-bit + 0 aux | | 8 (max) | D(0) | D(1) | D(2) | D(3) | D(4) | D(5) | D(6) | D(7) |
| 4-bit + 4 aux | | 2 | | | | | | | A(0) | D(0) |
| 24-bit + 4 aux | | 7 | | A(0) | D(0) | D(1) | D(2) | D(3) | D(4) | D(5) |
| 28-bit + 4 aux | | 8 (max) | A(0) | D(0) | D(1) | D(2) | D(3) | D(4) | D(5) | D(6) |
| 4-bit + 8 aux | | 3 | | | | | | A(0) | A(1) | D(0) |
| 24-bit + 8 aux | | 8 (max) | A(0) | A(1) | D(0) | D(1) | D(2) | D(3) | D(4) | D(5) |

24.9.4.5.2 Data Input/Output: DMA Request Mode

The DMA mode reuses all the features of the manual mode defined in [Section 24.9.4.5.1](#), but adds a DMA request generation mechanism to offload the data manipulation task to an external (off-module) DMA controller. As far as the FIFOs themselves are concerned, the accesses are unchanged. For more information about the DMA controller configuration see [Chapter 17](#), *SDMA*.

DMA data channels can be enabled by the [SLIMBUS_CMP_DMAENABLE_SET](#) register and disabled by the [SLIMBUS_CMP_DMAENABLE_CLR](#) register.

24.9.4.5.3 Data Channel Agent FIFO Control and Status

Each data channel agent is associated with a FIFO, fixed in either TX or RX direction. All TX FIFOs are mapped to a shared buffer space, all RX FIFOs to another shared buffer space. FIFO sizes are software-programmable.

A FIFO must be configured before the data channel is enabled, depending on system-related parameters. For instance, more or less FIFO depth may be required. More FIFO is desirable to prevent underflow/overflow errors in a jittery transmission, but may also carry an unacceptable latency penalty in a voice stream. In any case, FIFO depth is beyond the SLIMbus protocol.

24.9.4.6 FIFO Management

The SLIMbus controller includes two FIFOs, used to buffer transmit/receive data/messages. The SLIMBUS1 FIFO is 32 bytes for TX and 32 bytes for RX. The SLIMBUS2 FIFO is 64 bytes for TX and 64 bytes for RX. FIFO size information is given by the [SLIMBUS_CMP_HWINFO](#)[19:12] RRSZ and [11:4] TRSZ bit fields.

FIFOs are connected to SLIMbus-side agents, which transmit and receive data on the serial SLIMbus DATA line. All ports are synchronous to the SLIMbus clock. The numbers of data channel agents are given by [SLIMBUS_CMP_HWINFO](#)[27:24] TDC and [23:20] RDC bit fields.

A segment (see [Section 24.9.2.3.2](#)) passes through the internal RX and TX FIFOs, where it is stored in FIFO words. The size of the FIFO word, expressed in 4-bit slots, is configurable by software. The FIFO word size is hardware-calculated with the following parameters:

- The [SLIMBUS_DCR_CONFIG1_j](#)[9:5]/[SLIMBUS_DCT_CONFIG1_j](#)[9:5] SL bit field: Channel segment length, in slots
- The [SLIMBUS_DCR_CONFIG1_j](#)[14:10]/[SLIMBUS_DCT_CONFIG1_j](#)[14:10] DL bit field: Channel data length, integer
- The [SLIMBUS_DCR_CONFIG1_j](#)[3:0]/[SLIMBUS_DCT_CONFIG1_j](#)[3:0] TP (tag_length) bit field: Length of segment TAG field, function of the channel transfer protocol, in slots.
- The [SLIMBUS_DCR_CONFIG1_j](#)[19:16]/[SLIMBUS_DCT_CONFIG1_j](#)[19:16] AF (aux_length) bit field: Length of segment AUX field, function of the channel auxiliary format, in slots.

The FIFO word size is computed as follows by the module hardware:

- if DL is equal to 0, FIFO word size = SL tag_length(TP)
- if DL is not equal to 0, FIFO word size = aux_length(AF) + DL

24.9.4.6.1 FIFO Mapping

Each FIFO must be mapped in a free zone of the shared buffer before enabling, as follows:

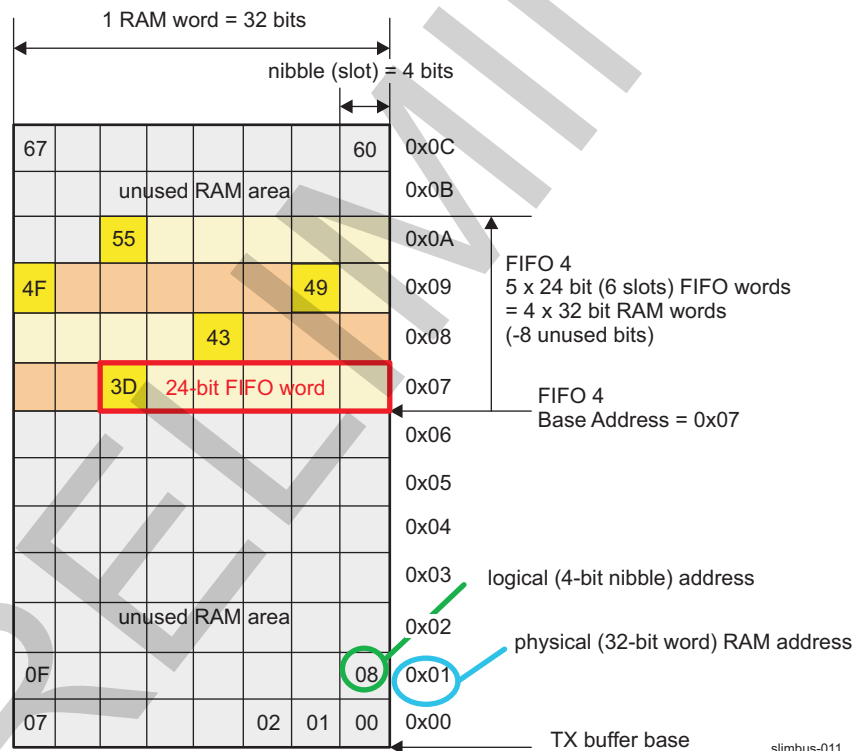

- The [SLIMBUS_DCR_FIFO_SETUP2_j](#)[7:0] SIZE and/or [SLIMBUS_DCT_FIFO_SETUP2_j](#)[7:0] SIZE + 1: Capacity of FIFO in FIFO words. (The minimum setting recommended by the SLIMbus protocol is 4-word deep.)
- The [SLIMBUS_SMT_FIFO_SETUP](#)[6:5] SIZE_HI/[SLIMBUS_SMR_FIFO_SETUP](#)[6:5] SIZE_HI and [SLIMBUS_SMT_FIFO_SETUP](#)[4:1] SIZE_LO/[SLIMBUS_SMR_FIFO_SETUP](#)[4:1] SIZE_LO bit fields: Capacity of shared TX/RX FIFOs, in bytes, minus 1.
- The [SLIMBUS_DCR_FIFO_SETUP1_j](#)[11:5] BASE_ADDR and/or [SLIMBUS_DCT_FIFO_SETUP1_j](#)[11:5] BASE_ADDR bit fields: RX and/or TX data channel agent FIFO base address within shared RX/TX RAM

- FIFO base nibble address = FIFO base physical add * 8
- FIFO top nibble address = FIFO base nibble add + (FIFO size * FIFO word size) – 1
- FIFO top physical address = FIFO top nibble add / 8
- The next base physical address available to map another FIFO is the current FIFO top physical address + 1.
- The shared RX and TX buffers are independent; that is, the RX and TX FIFOs are mapped to separate address spaces.

Figure 24-216 is an example mapping, with the following numerical configuration:

- Isochronous (SLIMBUS_DCT_CONFIG1_4[3:0] TP = 0x0) TX FIFO using TX data channel agent 4
- FIFO word size: 6 slots = 24 bits, 20 DATA + 4 AUX (AF = 0xB, DL = 0x5)
- FIFO size: SLIMBUS_DCT_FIFO_SETUP2_4[7:0] SIZE = 4 (4 + 1 = 5 FIFO words stored in FIFO)
- FIFO base physical address: SLIMBUS_DCT_FIFO_SETUP1_4[11:5] BASE_ADDR = 0x7 (= 7)
- FIFO base nibble address = 0x7 * 8 = 0x38 (56)
- FIFO top nibble address = 0x38 + (0x5 * 0x6) - 1 = 0x55 (= 85)
- FIFO top physical address = 0x55 / 0x8 = 0xA (= 10, this is a integer division)
- Next base physical address available to map another FIFO: 0xA + 1 = 0xB (= 11)

Figure 24-216. Example of FIFO Mapping in Shared Buffer

24.9.4.6.2 FIFO Status

The following receive-side status is available from the register fields:

- The [SLIMBUS_DCR_FIFO_STATUS_j\[11:2\]](#) RD_LEVEL bit field: Number of FIFO words stored in RX FIFO #n. (This field is 1 bit longer than the size and threshold fields, because it ranges from 0 to the FIFO size, whereas the other fields range only from 0 to the FIFO size minus 1.
- The [SLIMBUS_DCR_FIFO_STATUS_j\[0\]](#) EMPTYbit: Active (1) status when RX FIFO #n contains 0 words (rd_level = 0); otherwise, low (0). A read may cause an underflow.
- The [SLIMBUS_DCR_FIFO_STATUS_j\[1\]](#) HILEVEL bit: Active (1) status when FIFO (read) level is

(strictly) above the high threshold (that is, when there is more than a certain maximum of FIFO words stored in the FIFO). Equivalent to full in case `dma_hi_threshold = FIFO size - 1` (the maximum allowed value).

Table 24-658 shows numerical examples for all valid DMA threshold values and all levels in an RX FIFO of FIFO size = 4 FIFO words ([SLIMBUS_DCR_FIFO_SETUP2_j\[7:0\] SIZE = 0x3](#)).

NOTE: The valid threshold range is from 0 to FIFO size - 1: the case threshold = FIFO size is functionally useless and impossible to program for maximum-sized FIFOs (because the `rd_level` field is 1 bit wider than the threshold fields).

Table 24-658. HILEVEL/Empty Status of a 4-Word Receive FIFO, for all DMA Threshold Values

| rd_level (FIFO Words) | Empty | HILEVEL | | | |
|-----------------------|-------|---------|---------|---------|---------|
| | | thr = 0 | thr = 1 | thr = 2 | thr = 3 |
| 0 (empty FIFO) | 1 | 0 | 0 | 0 | 0 |
| 1 | 0 | 1 | 0 | 0 | 0 |
| 2 | 0 | 1 | 1 | 0 | 0 |
| 3 | 0 | 1 | 1 | 1 | 0 |
| 4 (full FIFO) | 0 | 1 | 1 | 1 | 1 |

The following transmit-side status is available from the following bit fields:

- [SLIMBUS_DCT_FIFO_STATUS_j\[11:2\]](#) WR_LEVEL: Number of free FIFO words in TX FIFO #n. (This field is 1 bit longer than the size and threshold fields, because it ranges from 0 to the FIFO size, whereas the other fields range only from 0 to the FIFO size minus 1).
- [SLIMBUS_DCT_FIFO_STATUS_j\[0\]](#) FULL: Active (1) status when TX FIFO #n contains FIFO size words (wr_level = 0); otherwise, low (0). A write may cause an overflow.
- [SLIMBUS_DCT_FIFO_STATUS_j\[1\]](#) LOLEVEL: Active (1) status when FIFO (write) level is under (or equal to) the low threshold; that is, when there is less than a certain minimum of free FIFO words in the FIFO. Equivalent to full in case dma_lo_threshold = 0.

Table 24-659 shows numerical examples for all valid DMA threshold values and all levels in a TX FIFO of FIFO size = 4 FIFO words ([SLIMBUS_DCT_FIFO_SETUP2_j\[7:0\]](#) SIZE = 0x3).

NOTE: The valid threshold range is from 0 to FIFO size – 1: the case threshold = FIFO size is functionally useless and impossible to program for maximum-sized FIFOs (because the wr_level field is 1 bit wider than the threshold fields).

Table 24-659. LOLEVEL/Full Status of a 4-Word Transmit FIFO, for all DMA Threshold Values

| wr_level (FIFO Words) | Full | LOLEVEL | | | |
|-----------------------|------|---------|---------|---------|---------|
| | | thr = 3 | thr = 2 | thr = 1 | thr = 0 |
| 4 (empty FIFO) | 1 | 1 | 1 | 1 | 0 |
| 3 | 0 | 1 | 1 | 1 | 0 |
| 2 | 0 | 0 | 1 | 1 | 0 |
| 1 | 0 | 0 | 0 | 1 | 0 |
| 0 (full FIFO) | 0 | 0 | 0 | 0 | 1 |

24.9.4.6.3 FIFO Configuration

The bit fields used to configure the FIFOs are:

- [SLIMBUS_DCR_FIFO_SETUP1_j\[11:5\]](#) BASE_ADDR and/or [SLIMBUS_DCT_FIFO_SETUP1_j\[11:5\]](#) BASE_ADDR: RX and/or TX data channel agent FIFO base address within shared RX/TX RAM
- [SLIMBUS_DCR_FIFO_SETUP1_j\[4:1\]](#) DMA_REQ_SIZE and/or [SLIMBUS_DCT_FIFO_SETUP1_j\[4:1\]](#) DMA_REQ_SIZE: DMA request size minus 1, in accesses
- [SLIMBUS_DCR_FIFO_SETUP2_j\[7:0\]](#) SIZE and/or [SLIMBUS_DCT_FIFO_SETUP2_j\[7:0\]](#) SIZE: Capacity of FIFO in FIFO words. (The FIFO can be 1-word deep [the minimum possible value], but it is not recommended. The minimum setting recommended by the SLIMbus protocol is 4-word deep).
- [SLIMBUS_DCR_FIFO_SETUP2_j\[15:8\]](#) SB_TRESHOLD: SLIMbus-side RX data channel agent FIFO threshold, used for SLIMbus reception.
- [SLIMBUS_DCT_FIFO_SETUP2_j\[15:8\]](#) SB_TRESHOLD: SLIMbus-side TX data channel agent FIFO threshold, used for SLIMbus transmission.
- [SLIMBUS_DCR_FIFO_SETUP2_j\[23:16\]](#) DMA_TRESHOLD: Software-side RX data channel agent FIFO low threshold. DMA write requests stop when [SLIMBUS_DCR_FIFO_STATUS_j\[11:2\]](#) RD_LEVEL goes under threshold.

- [SLIMBUS_DCT_FIFO_SETUP2_j\[23:16\]](#) DMA_TRESHOLD: Software-side TX data channel agent FIFO low threshold. DMA write requests stop when [SLIMBUS_DCT_FIFO_STATUS_j\[11:2\]](#) WR_LEVEL goes under threshold.
- [SLIMBUS_DCR_FIFO_SETUP2_j\[23:16\]](#) DMA_TRESHOLD: Software-side RX data channel agent FIFO high threshold. DMA read requests start when [SLIMBUS_DCR_FIFO_STATUS_j\[11:2\]](#) RD_LEVEL goes above threshold.
- [SLIMBUS_DCT_FIFO_SETUP2_j\[23:16\]](#) DMA_TRESHOLD: Software-side TX data channel agent FIFO high threshold. DMA read requests start when [SLIMBUS_DCT_FIFO_STATUS_j\[11:2\]](#) WR_LEVEL goes above threshold.
- [SLIMBUS_DCR_FIFO_STATUS_j\[0\]](#) EMPTY: Active (1) status when RX FIFO #n contains 0 words (rd_level = 0), else low (0). A read may cause an underflow.
- [SLIMBUS_DCT_FIFO_STATUS_j\[0\]](#) FULL: Active (1) status when TX FIFO #n contains FIFO size words (wr_level = 0), else low (0). A write may cause an overflow.
- [SLIMBUS_DCT_FIFO_STATUS_j\[1\]](#) LOLEVEL: Active (1) status when FIFO (write) level is under (or equal to) the low threshold, that is, when there is less than a certain minimum of free FIFO words in the FIFO. Equivalent to full in case dma_lo_threshold = 0.
- [SLIMBUS_DCR_FIFO_STATUS_j\[1\]](#) HILEVEL: Active (1) status when FIFO (read) level is (strictly) above the high threshold, that is, when there is more than a certain maximum of FIFO words stored in the FIFO. Equivalent to full in case dma_hi_threshold = FIFO size - 1 (the maximum allowed value).
- [SLIMBUS_DCR_FIFO_STATUS_j\[11:2\]](#) RD_LEVEL: Number of FIFO words stored in RX FIFO #n. (This field is 1 bit longer than the size and threshold fields, because it ranges from 0 to the FIFO size, whereas the other fields only range from 0 to the FIFO size minus 1).
- [SLIMBUS_DCT_FIFO_STATUS_j\[11:2\]](#) WR_LEVEL: Number of free FIFO words in TX FIFO #n. (This field is 1 bit longer than the size and threshold fields, because it ranges from 0 to the FIFO size, whereas the other fields only range from 0 to the FIFO size minus 1).

24.9.4.7 SLIMbus Transfer Protocols

Several registers are used to configure each Transfer Protocol. [Table 24-660](#) shows a description of these registers and fields.

Table 24-660. Register Fields Used to Configure Transfer Protocols

| Register | Field | Description |
|---|--------------|---|
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j [3:0] | TP | Transfer protocol choice |
| SLIMBUS_DCR_CONFIG1_j [4] | TP_QUALIFIER | Used only for asynchronous TPs (qualifier for plain/extended half-duplex asynchronous TPs) |
| SLIMBUS_DCT_CONFIG1_j [4] | TP_QUALIFIER | Used only for asynchronous TPs (qualifier for plain/extended half-duplex asynchronous TPs) |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j [9:5] | SL | Total segment length (SL), in 4-bit slots, SL = TAG length + AUX length + DATA length |
| SLIMBUS_DCR_CONFIG1_j [26:23] | PR_HI | 4-MSB presence rate (PR). Selects the base frequency and the calculation mode of N, with: $PR = 2^N \times \text{base frequency}$. |
| SLIMBUS_DCR_CONFIG1_j [22:20] | PR_LO | 3-LSB presence rate (PR). Sets the multiple of the base frequency for the presence frequency. |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j [14:10] | DL | Segment data length, in 4-bits slots. AUX+DATA length must fit in a FIFO word. |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j [15] | CL | N/A |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j [31] | ENABLE | Enable/disable data channel |
| SLIMBUS_DCR_CONFIG2_j / SLIMBUS_DCT_CONFIG2_j [11:0] | SD | Segment periodicity and offset (segment distribution) |

24.9.4.7.1 Isochronous Transfer Protocol

[Table 24-661](#) lists the register fields to program isochronous data transfer protocol.

Table 24-661. Register Fields Used for Isochronous Transfer Protocol

| Register | Field | Value |
|---|--------------|-------------------------------------|
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j [3:0] | TP | 0x0 (isochronous transfer protocol) |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j [4] | TP_QUALIFIER | Unused in this mode |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j [9:5] | SL | 2 to 8, see |
| SLIMBUS_DCR_CONFIG1_j [26:23] | PR_HI | N/A, only for information |
| SLIMBUS_DCR_CONFIG1_j [22:20] | PR_LO | N/A |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j [14:10] | DL | 2 to 8, see |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j [15] | CL | N/A |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j [31] | ENABLE | 1 (enabled) |
| SLIMBUS_DCR_CONFIG2_j / SLIMBUS_DCT_CONFIG2_j [11:0] | SD | Segment periodicity and offset |

24.9.4.7.1.1 Isochronous Segment Composition

Like for all other TPs, the TDM allocation of a pushed data channel is composed of periodic segments of equal length, with the 5-bit segment length (SL) defining the reserved length, in slots (1 to 31), and the segment distribution (SD) defining the segmen offset and periodicity.

Isochronous has no explicit presence bit because data is always assumed to be present. The SL-slots segment is therefore always composed of the following elements:

- 0, 1, or 2 AUX slots, as defined by the 4-bit auxiliary format (AF) configuration field
- 2 to 8 DATA slots, as defined by the 5-bit data length (DL) configuration field. Full range defined by standard is 1 to 31.
- 0 or more unused slots (should be 0, because this is wasted bandwidth)

NOTE:

- Maximum supported SL and DL are limited by the maximum FIFO word size (the actual implementation of the agent), because each segment (with data present) contains one FIFO word of DATA + AUX. In the current case, FIFO word size is 2 to 8 slots (8 to 32 bits):
 - DL range is 2 to 8 (assuming no AUX slot, or AUX slots stored with the DATA in the FIFO)
 - SL range is 2 to 8 (= DL, since there is no TAG in isochronous protocol).
 - DL = 0 is a special encoding where all slots after the AUX are considered to be DATA slots. In that case, there are by definition no unused slots.
- DL = 0 is a special encoding where all slots after the AUX are considered to be DATA slots. In that case, there are by definition no unused slots.
- Not all combinations of legal field values are legal. The condition is that AUX and DATA slots must fit within the allocated segment, that is, the sum must not be (strictly) greater than SL.
 - DL = 31 cannot be used with 1-slot AUX contents because 1 AUX slot + 31 DATA slots (DL) 31 segment slots (SL max) (assuming no more FIFO word size limit)
 - DL = 30 cannot be used with 2-slot AUX contents (assuming no more FIFO word size limit)
 - ...

24.9.4.7.2 Pushed Transfer Protocol

Table 24-662 lists the register fields to program to have a pushed data transfer protocol.

Table 24-662. Register Fields Used for Pushed Transfer Protocol

| Register | Field | Value |
|---|--------------|--------------------------------|
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[3:0] | TP | 0x1 (pushed Transfer Protocol) |
| SLIMBUS_DCR_CONFIG1_j[4] | TP_QUALIFIER | unused in this mode |
| SLIMBUS_DCT_CONFIG1_j[4] | TP_QUALIFIER | unused in this mode |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[9:5] | SL | 3 to 9, see |
| SLIMBUS_DCR_CONFIG1_j[26:23] | PR_HI | N/A, only for information |
| SLIMBUS_DCR_CONFIG1_j[22:20] | PR_LO | N/A, only for information |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[14:10] | DL | 2 to 8, see |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[15] | CL | N/A |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[31] | ENABLE | 1 (enabled) |
| SLIMBUS_DCR_CONFIG2_j / SLIMBUS_DCT_CONFIG2_j[11:0] | SD | segment periodicity and offset |

24.9.4.7.2.1 Pushed Segment Composition

Like for all other TPs, the TDM allocation of a pushed data channel is composed of periodic segments of equal length, with the 5-bit segment length (SL) defining the reserved length, in slots (1 to 31), and the segment distribution (SD) defining the segment's offset and periodicity.

When data is present (P=1), the SL-slots segment is composed of the following elements:

- 1 TAG slot for STR, P control bits (Sample TRAnsmit, Presence)
- 0, 1 or 2 AUX slots, as defined by the 4-bit auxiliary format (AF) configuration field
- 2 to 8 DATA slots, as defined by the 5-bit data length (DL) configuration field. Full range defined by standard is 1 to 30
- 0 or more unused slots. (should be 0, as this is wasted bandwidth)

When no data is present (P=0), all slots except the TAG are unused and undriven.

NOTE:

- Maximum supported SL and DL are limited by the maximum FIFO word size (that is, the agent's actual implementation), as each segment (with data present) contains one FIFO word of DATA + AUX. In the current case, FIFO word size is 2 to 8 slots (8 to 32 bits), that is,
 - DL range is 2 to 8 (assuming no AUX slot, or AUX slots stored with the DATA in the FIFO)
 - SL range is 3 to 9 (= DL + 1 TAG)
- DL=0 is a special encoding where all slots after the AUX are considered to be DATA slots. In that case, there are by definition no unused slots.
- Not all combinations of legal field values are legal. The condition is that AUX and DATA slots must fit within the allocated segment, that is, the sum must not be (strictly) greater than SL.
 - DL=31 cannot be used at all for pushed (although it is legal for other TPs) because 1 TAG slot + 31 DATA slots (DL) 31 segment slots (SL max).
 - DL=30 cannot be used with 1-slot AUX contents (assuming no more FIFO word size limit)
 - DL=29 cannot be used with 2-slot AUX contents (assuming no more FIFO word size limit)
 - ...

24.9.4.7.3 Pulled Transfer Protocol

Table 24-663 lists the register fields to program to have a pulled data transfer protocol.

Table 24-663. Register fields used for Pulled Transfer Protocol

| Register | Field | Value |
|---|--------------|--------------------------------|
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j [3:0] | TP | 0x2 (pulled Transfer Protocol) |
| SLIMBUS_DCR_CONFIG1_j [4] | TP_QUALIFIER | unused in this mode |
| SLIMBUS_DCT_CONFIG1_j [4] | TP_QUALIFIER | unused in this mode |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j [9:5] | SL | 3 to 9, see |
| SLIMBUS_DCR_CONFIG1_j [26:23] | PR_HI | N/A, only for information |
| SLIMBUS_DCR_CONFIG1_j [22:20] | PR_LO | N/A, only for information |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j [14:10] | DL | 2 to 8, see |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j [15] | CL | N/A |

Table 24-663. Register fields used for Pulled Transfer Protocol (continued)

| Register | Field | Value |
|--|--------|--------------------------------|
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j [31] | ENABLE | 1 (enabled) |
| SLIMBUS_DCR_CONFIG2_j / SLIMBUS_DCT_CONFIG2_j [11:0] | SD | segment periodicity and offset |

24.9.4.7.3.1 Pulled Segment Composition

Like for all other TPs, the TDM allocation of a pushed data channel is composed of periodic segments of equal length, with the 5-bit segment length (SL) defining the reserved length, in slots (1 to 31), and the segment distribution (SD) defining the segment's offset and periodicity.

When data is present (P=1), the SL-slots segment is composed of the following elements:

- 1 TAG slot for SRQ, P control bits (Sample ReQuest, Presence)
- 0, 1 or 2 AUX slots, as defined by the 4-bit auxiliary format (AF) configuration field
- 2 to 8 DATA slots, as defined by the 5-bit data length (DL) configuration field. Full range defined by standard is 1 to 30.
- 0 or more unused slots. (should be 0, as this is wasted bandwidth)

When no data is present (P=0), all slots except the TAG are unused and undriven.

NOTE:

- Maximum supported SL and DL are limited by the maximum FIFO word size (that is, the agent's actual implementation), as each segment (with data present) contains one FIFO word of DATA + AUX. In the current case, FIFO word size is 2 to 8 slots (8 to 32 bits), that is,
 - DL range is 2 to 8 (assuming no AUX slot, or AUX slots stored with the DATA in the FIFO)
 - SL range is 3 to 9 (= DL + 1 TAG)
- DL=0 is a special encoding where all slots after the AUX are considered to be DATA slots. In that case, there are by definition no unused slots.
- Not all combinations of legal field values are legal. The condition is that AUX and DATA slots must fit within the allocated segment, that is, the sum must not be (strictly) greater than SL.
 - DL=31 cannot be used at all for pushed (although it is legal for other TPs) because 1 TAG slot + 31 DATA slots (DL) 31 segment slots (SL max).
 - DL=30 cannot be used with 1-slot AUX contents (assuming no more FIFO word size limit)
 - DL=29 cannot be used with 2-slot AUX contents (assuming no more FIFO word size limit)
 - ...

24.9.4.7.4 Asynchronous Transfer Protocol

[Table 24-666](#) shows the configuration required for a (plain) asynchronous data channel agent, whether in simplex or in half-duplex mode.

One data channel requires one agent, except for 1/2 duplex where 2 agents are required (one in each direction).

Table 24-664. "Plain" Asynchronous Endpoint Configurations

| Agent Setup | Type | TP | TP_qualifier | SD, SL, DL, ENABLE | Notes |
|--------------------------|------|--|-----------------------|---|--------------------------|
| TX simplex | TX | 0x4 = "plain" asynchronous, simplex | 0b0 = primary owner | independent | always primary owner |
| TX 1/2 duplex, primary | TX | 0x5 = "plain" asynchronous, 1/2 duplex | 0b0 = primary owner | same than RX (programming identical in both associated agent) | associated with RX agent |
| TX 1/2 duplex, secondary | TX | 0x5 = "plain" asynchronous, 1/2 duplex | 0b1 = secondary owner | same than RX (programming identical in both associated agent) | associated with RX agent |
| RX simplex | RX | 0x4 = "plain" asynchronous, simplex | 0b1 = secondary owner | independent | always secondary owner |
| RX 1/2 duplex, primary | RX | 0x5 = "plain" asynchronous, 1/2 duplex | 0b0 = primary owner | same than TX (programming identical in both associated agent) | associated with TX agent |
| RX 1/2 duplex secondary | RX | 0x5 = "plain" asynchronous, 1/2 duplex | 0b1 = secondary owner | same than TX (programming identical in both associated agent) | associated with TX agent |

Table 24-667 lists the register fields to program to have a "plain" asynchronous transfer protocol.

Table 24-665. Register fields used for "Plain" Asynchronous Transfer Protocol

| Register (for a given data channel agent) | Field | Value |
|---|--------------|--|
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[3:0] | TP | 0x4 (simplex) or 0x5 (half duplex) |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[4] | TP_QUALIFIER | primary or secondary ownership setup |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[9:5] | SL | 3 to 9, see |
| SLIMBUS_DCR_CONFIG1_j[26:23] | PR_HI | Presence Rate, only for information |
| SLIMBUS_DCR_CONFIG1_j[22:20] | PR_LO | N/A, only for information |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[14:10] | DL | 2 to 8, see |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[15] | CL | 0 (disabled: makes no sense in asynchronous context) |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[31] | ENABLE | 1 (enabled) |
| SLIMBUS_DCR_CONFIG2_j / SLIMBUS_DCT_CONFIG2_j[11:0] | SD | segment periodicity and offset |

24.9.4.7.4.1 Asynchronous Segment Composition

Like for all other TPs, the TDM allocation of an asynchronous data channel is composed of periodic segments of equal length, with the 5-bit segment length (SL) defining the reserved length, in slots (2 to 31), and the segment distribution (SD) defining the segment's offset and periodicity.

When data is present (P=1), the SL-slots segment is composed of the following elements:

- 1 TAG slot for T1, T2, CTS, P control bits
- 0, 1 or 2 AUX slots, as defined by the 4-bit auxiliary format (AF) configuration field
- 2 to 8 DATA slots, as defined by the 5-bit data length (DL) configuration field. Full range defined by standard is 1 to 30.
- 0 or more unused slots. (should be 0, as this is wasted bandwidth)

When no data is present ($P=0$), only the TAG slot is (partially) driven, depending on the ownership control and data flow control protocol phases. All other slots are unused and undriven.

NOTE:

- Maximum supported SL and DL are limited by the maximum FIFO word size (that is, the agent's actual implementation), as each segment (with data present) contains one FIFO word of DATA + AUX. In the current case, FIFO word size is 2 to 8 slots (8 to 32 bits), that is,
 - DL range is 2 to 8 (assuming no AUX slot, or AUX slots stored with the DATA in the FIFO)
 - SL range is 3 to 9 (= DL + 1 TAG)
- DL=0 is a special encoding where all slots after the AUX are considered to be DATA slots. In that case, there are by definition no unused slots. When used, the actual length of the segment data (in slots) is determined by hardware, by subtracting the TAG and AUX slots from the total segment length (SL). This case is strictly equivalent to the "direct" encoding, that is, where DL is a non-zero figure.
- Not all combinations of legal field values are legal, even in an ideal implementation. The condition is that TAG, AUX and DATA slots must fit within the allocated segment, that is, the sum must not be (strictly) greater than SL.
 - DL=31 cannot be used at all for asynchronous (although it is legal for other TPs) because 1 TAG slot + 31 DATA slots (DL) 31 segment slots (SL max).
 - DL=30 cannot be used with 1-slot AUX contents (assuming no more FIFO word size limit)
 - DL=29 cannot be used with 2-slot AUX contents (assuming no more FIFO word size limit)
 - SL = 1 is forbidden, since the smallest asynchronous segment is 1 TAG slots + 1 DATA slot = 2 slots long.
 - ...

24.9.4.7.4.2 Programming Specificities for Half-Duplex Protocol

Contrary to all other standard transfer protocols (TP), the half-duplex asynchronous ones (plain or extended) are bidirectional, that is, DATA slots can go in both directions. This means that 1 half-duplex asynchronous port (mapped on 1 half-duplex asynchronous data channel) uses 2 unidirectional data channel agents (FIFOs and logic) in the same controller.

The two agents are of opposite directions (1 TX + 1 RX), and the configuration register fields must always be programmed simultaneously and with matching values for both, so that both own the exact same slots (the data channel's allocated distribution).

24.9.4.7.5 Extended Asynchronous Transfer Protocol

Table 24-666 shows the configuration required for an extended asynchronous data channel agent, whether in simplex or in half-duplex mode.

One data channel requires one agent, except for 1/2 duplex where 2 agents are required (one in each direction).

Table 24-666. Extended Asynchronous Endpoint Configurations

| Agent Setup | Type | TP | TP_qualifier | SD, SL, DL, ENABLE | Notes |
|-------------|------|--------------------------------------|---------------------|--------------------|----------------------|
| TX simplex | TX | 0x6 = extended asynchronous, simplex | 0b0 = primary owner | independent | always primary owner |

Table 24-666. Extended Asynchronous Endpoint Configurations (continued)

| Agent Setup | Type | TP | TP_qualifier | SD, SL, DL, ENABLE | Notes |
|--------------------------|------|---|-----------------------|---|--------------------------|
| TX 1/2 duplex, primary | TX | 0x7 = extended asynchronous, 1/2 duplex | 0b0 = primary owner | same than RX (programming identical in both associated agent) | associated with RX agent |
| TX 1/2 duplex, secondary | TX | 0x7 = extended asynchronous, 1/2 duplex | 0b1 = secondary owner | same than RX (programming identical in both associated agent) | associated with RX agent |
| RX simplex | RX | 0x6 = extended asynchronous, simplex | 0b1 = secondary owner | independent | always secondary owner |
| RX 1/2 duplex, primary | RX | 0x7 = extended asynchronous, 1/2 duplex | 0b0 = primary owner | same than TX (programming identical in both associated agent) | associated with TX agent |
| RX 1/2 duplex secondary | RX | 0x7 = extended asynchronous, 1/2 duplex | 0b1 = secondary owner | same than TX (programming identical in both associated agent) | associated with TX agent |

The data length within the segment is now determined in the TAG NVB field, so that the SLIMbus data length (DL) parameter is not needed in the SLIMbus definition. The corresponding configuration register field [SLIMBUS_DCR_CONFIG1_j](#) / [SLIMBUS_DCT_CONFIG1_j](#)[14:10] DL is still needed to set the FIFO word size: it must always be programmed to 0x2 (slots) = 1 byte, in both the data sinks and sources, which corresponds to the NVB granularity unit.

[Table 24-667](#) lists the register fields to program to have a "plain" asynchronous transfer protocol.

Table 24-667. Register fields used for Extended Asynchronous Transfer Protocol

| Register (for a given data channel agent) | Field | Value |
|---|--------------|---|
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j [3:0] | TP | 0x6 (simplex) or 0x7 (half duplex) |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j [4] | TP_QUALIFIER | primary or secondary ownership setup |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j [9:5] | SL | 4 to 31, see |
| SLIMBUS_DCR_CONFIG1_j [26:23] | PR_HI | Presence Rate, only for information |
| SLIMBUS_DCR_CONFIG1_j [22:20] | PR_LO | N/A, only for information |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j [14:10] | DL | 2: NVB data granularity (not the Slimbus "data length") |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j [15] | CL | 0 (disabled: makes no sense in asynchronous context) |
| SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j [31] | ENABLE | 1 (enabled) |
| SLIMBUS_DCR_CONFIG2_j / SLIMBUS_DCT_CONFIG2_j [11:0] | SD | segment periodicity and offset |

24.9.4.7.5.1 Extended Asynchronous Segment Composition

Like for all other TPs, the TDM allocation of an extended asynchronous data channel is composed of periodic segments of equal length, with the 5-bit segment length (SL) defining the reserved length, in slots (1 to 31), and the segment distribution (SD) defining the segment's offset and periodicity.

When data is present (P=1), the segment is composed of the following elements:

- 2 TAG slots for T1, T2, CTS, P control bits + 4-bit NVB field

- no (0) AUX slots. The current implementation does not support auxiliary fields in the extended asynchronous TP, that is, the only legal value in the 4-bit auxiliary format (AF) is 0b0000. Other values are theoretically allowed by the SLIMbus standard, but for this TP they have little functional use.
- 0 to 28 DATA slots, as defined by the 4-bit number of valid bytes (NVB) field
- 0 or more unused slots. (this is wasted bandwidth, but as NVB can change for each segment this is normal)

When no data is present (P=0):

- 1st TAG slot is (partially) driven, depending on the ownership / data flow control protocol phases.
- 2nd TAG slot is either driven to all-zero, or undriven, that is, it always reads out as all-zero.
- All other slots are unused and undriven

NOTE:

- SL should be configured so that the maximum number of DATA slots is even, otherwise there will always be at least one unused slot.
 - Largest supported SL is not limited by the maximum FIFO word size (that is, the agent's actual implementation), unlike all other transfer protocols, as several FIFO words can be concatenated inside the same data segment.
 - Not all combinations of legal field values are legal. The condition is that TAG, AUX and DATA slots must fit within the allocated segment, that is, the sum must not be (strictly) greater than SL.
 - NVB = 15 (15 valid data bytes = 30 slots) cannot be used, because 2 TAG slots + 30 DATA slots (NVB x 2) = 32 > 31 segment slots (SL max).
 - SL = 1,2,3 are forbidden, since the smallest extended asynchronous segment is 2 TAG slots + 1 DATA byte (NVB = 1) = 4 slots long.
 - ...
-

24.9.4.7.5.2 Programming Specificities for Half-Duplex Protocol

Contrary to all other standard transfer protocols (TP), the half-duplex asynchronous ones (plain or extended) are bidirectional, that is, DATA slots can go in both directions. This means that 1 half-duplex asynchronous port (mapped on 1 half-duplex asynchronous data channel) uses 2 unidirectional data channel agents (FIFOs and logic) in the same controller.

The two agents are of opposite directions (1 TX + 1 RX), and the configuration register fields must always be programmed simultaneously and with matching values for both, so that both own the exact same slots (the data channel's allocated distribution).

24.9.4.8 Paired-up channels

Two (or more) data channels with common properties can be paired up to operate in lockstep, for example, the left and right channels of a stereo audio flow: paired up data samples are generated together by a data source and need to arrive together at the data sink after going over the SLIMbus interface.

Assuming that pairing up has been implemented in both the sink and the source SLIMbus controllers of the data channel, it is enabled by configuring the channel as follows:

- Same segment windows: same channel rate, also expressed as segment interval (expressed in slots). This is encoded in the channel's Segment Distribution ([SLIMBUS_DCT_CONFIG2_j](#) / [SLIMBUS_DCR_CONFIG2_j](#)[11:0] SD).
- Same Segment Length ([SLIMBUS_DCT_CONFIG1_j](#) / [SLIMBUS_DCR_CONFIG1_j](#)[9:5] SL)
- Segment offset (also encoded in SD) is necessarily different, otherwise the two channels would be scheduled in the same slots. SD is therefore different.
- Sequential Channel Numbers (CN) are assigned to the channels to be paired up
- Data channel numbering and scheduling are defined by the active manager device, through the broadcasts of the NEXT_DEFINE_CHANNEL() message.

Contents must be aligned, as follows:

- Same Transfer Protocol ([SLIMBUS_DCT_CONFIG1_j](#) / [SLIMBUS_DCR_CONFIG1_j](#)[3:0] TP). Asynchronous protocols (extended or not) do not support pairing.
- Same Aux Format ([SLIMBUS_DCT_CONFIG1_j](#) / [SLIMBUS_DCR_CONFIG1_j](#)[19:16] AF)
- Same Data Length ([SLIMBUS_DCT_CONFIG1_j](#) / [SLIMBUS_DCR_CONFIG1_j](#)[14:10] DL)
- Pairing can be enabled through the Channel Link ([SLIMBUS_DCT_CONFIG1_j](#) / [SLIMBUS_DCR_CONFIG1_j](#)[15] CL) data channel content bit. Pairing between channel #N-1 and channel #N is enabled by setting the Channel Link (CL) content bit to 1 on channel #N. For example, to pair up channels #1 and #2, CL = 1 in channel #2 (thus linking it to #1) and CL = 0 in channel #1 (thus keeping it separate from channel #0).
- Data channel contents are defined by active manager device, through the broadcasting of the `NEXT_DEFINE_CONTENT()` and `CHANGE_CONTENT()` messages.

24.9.4.8.1 Paired-up behaviour for Isochronous TP

Data is by definition present in all segments, so that isochronous data channels with the same channel rate (as extracted from SD) are naturally paired up in normal operation. However, pairing also ensures that transmit underflows are also coupled:

- On the source side, if one of the channels has no data to transmit (TX underflow error, reported by IRQ) the other channels won't transmit any data either (even if they have some). This prevents the transmitter from getting out of sync.
- On the sink side, the underflow error will not be detected since no presence indication is transmitted, but the channels will remain in sync when the correct data flow resumes.

24.9.4.8.2 Paired-up behaviour for Pushed TP

Data presence in each segment is flagged by the STR/P bits (strobe/presence) driven by the data source in the TAG slot. On the source side, paired up channels must have the same P value in a given segment window, that is, data must only be transmitted (STR=P=1) when both channels have data to send. No requirements on the sink side.

24.9.4.8.3 Paired-up behaviour for Pulled TP

Data presence in a segment is requested by the SRQ TAG bit (sample request), driven by the sink, and confirmed by the P TAG bit (presence), driven by the source, so that SRQ and P are always equal in normal operation. The main pairing up requirement is therefore that the SRQ are aligned for all channel sinks, that is, that data is requested on all channels only if all sinks are ready to receive it, otherwise it is requested on none.

Pairing also ensures that transmit underflows are also coupled between channels: if for some reason a source cannot fulfill a request to drive data (SRQ=1, P=0: transmit underflow error, reported by IRQ), none of the other channels must drive data either, and all must flag P=0. The source side can only implement correct pairing if the sink side is correct in the first place; indeed, unless an underflow occurs, it is sufficient that the sink side implements pairing for the channels to be paired.

24.9.4.9 Device and Addressing Management

One of the manager device tasks is to keep track of devices present on the bus and to enumerate them, that is, assign a (different) Logical Address (LA) to each.

The manager device itself is implicitly enumerated by default, to Logical Address (LA) 0xFF. This is the only case where a device enumerates without `ASSIGN_LOGICAL_ADDRESS` message transmitted over the bus. Therefore for the manager device the following default configuration must be applied :

- [SLIMBUS_DEV_LA_i](#)[7:0] LA = 0xFF
- [SLIMBUS_DEV_LA_i](#)[8] LA_ENABLE = 1
- [SLIMBUS_DEV_LA_i](#)[9] EA_ENABLE = 1 (although manager is never addressed by Enumeration Address, EA)

The SLIMbus controller implements several devices, each of which is identified by its address. Addresses are used to exchange control messages over the shared message channel (SMC). The controller will recognize, store and respond (that is, acknowledge) to any message on the SMC targeted at one of the component's devices in the RX message FIFO.

The Enumeration Addresses (EA) composition is described in [Table 24-668](#), with:

- MI, PC and IV are Software-programmable and have the same value for all devices of the component with [SLIMBUS_CMP_MI_PC\[15:0\]](#) MI, [SLIMBUS_CMP_MI_PC\[31:16\]](#) PC and [SLIMBUS_CMP_IV\[7:0\]](#) IV.
- DI is hardwired and unique for each device within the component. It is given by [SLIMBUS_DCT_MAP_j / SLIMBUS_DCR_MAP_j\[7:0\]](#) DI bit field.
- Each device individual EA is Software-accessible, for reference, in read-only registers ([SLIMBUS_DEV_EA_LO_i](#) and [SLIMBUS_DEV_EA_HI_i](#) registers)

Table 24-668. Enumeration Address (EA) makeup

| EA Subfield | Size (bits) | Top Bit | Bottom Bit | Source |
|---------------------|-------------|---------|------------|---|
| MI: Manufacturer ID | 16 | 47 | 32 | SLIMBUS_CMP_MI_PC[15:0] MI |
| PC: Product Code | 16 | 31 | 16 | SLIMBUS_CMP_MI_PC[31:16] PC |
| DI: Device Index | 8 | 15 | 8 | hardwired |
| IV: Instance Value | 8 | 7 | 0 | SLIMBUS_CMP_IV[7:0] IV |
| Total: EA | 48 | 47 | 0 | SLIMBUS_DEV_EA_HI_i / SLIMBUS_DEV_EA_LO_i |

The Logical Address (LA) assigned by the manager range from 0x00 to 0xEF, with the exception of the active manager located by definition at LA = 0xFF. It is configured through [SLIMBUS_DEV_LA_i\[7:0\]](#) LA for device m.

By default, a device uses a unique, static 48-bit Enumeration Address (EA). The EA is used only for enumeration, that is, the acquisition a dynamic Logical Address (LA) assigned by the active manager device.

NOTE: The port number is given by [SLIMBUS_DCT_MAP_j / SLIMBUS_DCR_MAP_j\[13:8\]](#) PN bit field.

24.9.4.10 Message Management

24.9.4.10.1 Transmission

24.9.4.10.1.1 TX Message Sequence

The message transmission software sequence is the following:

- Initial state:
 - [SLIMBUS_SMT_CONTROL\[0\]](#) MESSAGE_ENABLE = 0: No ongoing TX message. This also implies that TX message FIFO can receive another message.
 - [SLIMBUS_SMT_INFO\[5:0\]](#) = 0 : TX message event flags must be cleared (to 0) by Software by writing 1 to the corresponding bit(s). Failing to meet this condition will not prevent the message transmission, but will prevent a proper readout of the message transmission's outcome
 - Optional: If the IRQ method is to be used (instead of polling), it must be cleared and enabled, that is, [SLIMBUS_CMP_IRQENABLE_SET\[2\]](#) SMT_INFO_EN = 1 and [SLIMBUS_CMP_IRQSTATUS\[2\]](#) SMT_INFO = 0. For more information about interrupts see [Section 24.9.4.11](#).
- FIFO loading:
 - The message is written byte by byte to register [SLIMBUS_SMT_MESSAGE\[7:0\]](#). SLIMbus endianness is retained (big-endian) that is, serial message starts with the MSB (bit 7) of the first byte written into the FIFO and ends with the LSB (bit 0) of the last written byte.

- The minimum message size is 6 bytes (5 entered to the FIFO), for a short-arbitration (that is, logical source address LA = 1 byte), broadcast (that is, no destination address), no-payload message.
- The maximum theoretical message size is 39 bytes (38 entered to the FIFO), for a long-arbitration (that is, enumeration source address EA = 6 bytes), maximum remaining length (RL = 5b11111 = 31 bytes) message. The TX message FIFO can hold 32 bytes, that is, most messages (of 33 bytes or less).
- An overflow event is flagged ([SLIMBUS_SMT_INFO\[1\] OVERFLOW](#) is set) if too many bytes are written in. The TX message FIFO is then cleared before another TX message sequence attempt is made.
- Transmission enabling:
 - Once the message has been loaded into the TX message FIFO, software must write 1 on field [SLIMBUS_SMT_CONTROL\[0\] MESSAGE_ENABLE](#).
- Transmission:
 - From that point on, the device will attempt to transmit the message stored in the FIFO. Actual transmission may be delayed because of Message Sync acquisition time (if not already operational), Ongoing message on the SMC, and Arbitration(s) lost to higher-priority messages.
- Transmission completion and reporting:
 - Transmission is considered complete if one of the following -mutually exclusive- conditions is met, and the corresponding bit of [SLIMBUS_SMT_INFO](#) is set : Negative response [SLIMBUS_SMT_INFO\[3\] NACK = 1](#), or Positive response : [SLIMBUS_SMT_INFO\[2\] PACK = 1](#), or No response: [SLIMBUS_SMT_INFO\[4\] NORE = 1](#), or Illegal response: [SLIMBUS_SMT_INFO\[5\] UDEF = 1](#), or Transmit collision: [SLIMBUS_SMT_INFO\[0\] MC_TX_COL = 1](#).
 - If enabled ([SLIMBUS_CMP_IRQENABLE_SET\[2\] SMT_INFO_EN = 1](#)), an interrupt request flag is set ([SLIMBUS_CMP_IRQSTATUS\[2\] SMT_INFO = 1](#)) and the IRQ line asserted.
 - Additionally, bit [SLIMBUS_SMT_CONTROL\[0\] MESSAGE_ENABLE](#) must auto-clear. Polling this bit will also work as an alternative to waiting for the IRQ.
 - Following the transmission, all message bytes have been removed from the TX message FIFO.

24.9.4.10.1.2 TX Message FIFO Clearing

The TX message FIFO must not be cleared as part of the normal message transmission operation, between messages. However, the clearing becomes necessary in case of error:

- FIFO overflow: the bit [SLIMBUS_SMT_INFO\[1\] OVERFLOW](#) is set
- FIFO underflow: the bit [SLIMBUS_SMR_INFO\[1\] UNDERFLOW](#) is set
- TX collision: the bit [SLIMBUS_SMT_INFO\[0\] MC_TX_COL](#) or the bit [SLIMBUS_SMR_INFO\[0\] MC_TX_COL](#) is set
- Undefined error condition, unknown FIFO content

Clearing is done by writing 0 to bit field [SLIMBUS_SMT_CONTROL\[0\] MESSAGE_ENABLE](#).

24.9.4.10.2 Message reception

24.9.4.10.2.1 Message Responding

The message responding and message receiving are separate but intertwined processes. Message responding starts as soon as a message is received, and consists in sending back information, including PACK or NACK.

24.9.4.10.2.2 RX Message Sequence

The message reception software sequence is the following:

- Initial state
 - [SLIMBUS_SMR_INFO](#) = 0x0: Pending (at 1) RX message event flags must be cleared (to 0) by Software by writing 1 to the corresponding bit(s).
 - Optional: If the IRQ method is to be used (instead of polling), it must be cleared and enabled, that

is, [SLIMBUS_CMP_IRQENABLE_SET](#)[3] SMR_INFO_EN = 1 and [SLIMBUS_CMP_IRQSTATUS](#)[3] SMR_INFO = 0. For more information about interrupts see [Section 24.9.4.11](#)

- Message reception
 - Message reception requires no intervention: Messages with target addresses enabled in [SLIMBUS_DEV_LA_i](#) registers are automatically loaded into the RX message FIFO.
- FIFO unloading
 - The message is read byte by byte off the FIFO and put into register [SLIMBUS_SMR_MESSAGE](#)[7:0]. SLIMbus endianness is used (big-endian) that is, serial message starts with the MSB (bit 7) of the first byte written into the FIFO and ends with the LSB (bit 0) of the last written byte.
 - The minimum message size is 6 bytes, for a short-arbitration (that is, logical source address LA = 1 byte), broadcast (that is, no destination address), no-payload message.
 - The maximum theoretical message size is 39 bytes, for a long-arbitration (that is, enumeration source address EA = 6 bytes), maximum remaining length (RL = 5b11111 = 31 bytes) message. The RX message FIFO can hold 32 bytes, that is, most message types.
 - An overflow event is flagged ([SLIMBUS_SMR_INFO](#)[1] OVERFLOW bit is set) if too many bytes are received, which will overwrite previous bytes.
 - An underflow event is flagged ([SLIMBUS_SMR_INFO](#)[1] UNDERFLOW bit is set) if too many bytes are read out. The RX message FIFO is cleared before another RX message sequence attempt is made.
- Message decoding and servicing
 - This phase takes place in parallel with the unloading phase above. In some cases, a partial decoding can lead the software to skip the end of the unloading and flush the FIFO. The software will check Device Association (thanks to the [SLIMBUS_SMR_INFO](#)[2] RECEIVED_MESSAGE bit) and Message Support.

24.9.4.10.2.3 RX Message FIFO Clearing

- While the software is reading the message off the FIFO, the receive message agent unconditionally answers NACK, forcing remote side to retransmit any new incoming message.
- Only once the message has been read out of the FIFO, the software writes 1 on [SLIMBUS_SMR_INFO](#)[2] RECEIVED_MESSAGE bit. This will automatically clear the FIFO.

The RX message FIFO is cleared as part of the normal message reception operation, between messages, although it is not strictly necessary. However, the clearing becomes compulsory in case of error:

- FIFO overflow: the bit [SLIMBUS_SMT_INFO](#)[1] OVERFLOW is set
- FIFO underflow: the bit [SLIMBUS_SMR_INFO](#)[1] UNDERFLOW is set
- Undefined error condition, unknown FIFO content

Clearing is done by writing 1 to register bit field [SLIMBUS_SMR_INFO](#)[2] RECEIVED_MESSAGE bit.

24.9.4.11 Interrupt Service Routines

This section lists specific software programming sequences, to be applied at specific phases of the SLIMbus protocol. This section covers the low-level software service of IRQs. More information about interrupts in the device can be found in [Chapter 18, Interrupt Controllers](#).

The SLIMbus controller has a single IRQ output line, controlled through 9-bit registers [SLIMBUS_CMP_IRQSTATUS](#), [SLIMBUS_CMP_IRQENABLE_SET](#) and [SLIMBUS_CMP_IRQENABLE_CLR](#). Each bit of this 1st level IRQ management points to a 2nd level information register. There are thus 9 such information registers, each connected with a specific submodule (framer device, interface device, message receiver, message transmitter, and one per generic data device).

2nd level information register and status register are written independently each other. When an event occurs, both bits are set to 1, and when the software writes 1 on either register the corresponding bit is cleared to 0. IRQ line is the status register output.

- When an event takes place, the corresponding 2nd level information bit must be set to 1 (if already 1: no change)
- When an event takes place, the corresponding 1st level IRQ status bit must be set to 1 (if enabled and if not already 1) and trigger an interrupt (if not already active). Note that this does not depend on the information bit's value: if the information bit is already high, the event must still potentially set the IRQ status bit.
- Writing 1 to a set IRQ status bit clears the bit and deasserts the IRQ line (if another status bit is set, the IRQ line will reassert immediately). Note that the clearing of the IRQ status does not depend on the information bit, that is, it will work even if the information bit has not been cleared.
- Writing 1 to a set information bit will clear the bit, but have no impact on the IRQ status

CAUTION

The software sequence should always be as follows:

1. Clear the status bit
2. Read the relative information register
3. When needed and allowed, clear the information register

24.9.4.11.1 Interrupt Requests

Table 24-669 lists the event flags, and their mask, that can cause module interrupts.

Table 24-669. Interrupts

| Interrupt Line | Event Flag | Event Mask |
|--------------------------------|--|--|
| SLIMBUS1_IRQ / SLIMBUS2_IRQ | SLIMBUS_CMP_IRQSTATUS_RAW[11:0] and SLIMBUS_CMP_IRQSTATUS[11:0] | SLIMBUS_CMP_IRQENABLE_SET[11:0] and SLIMBUS_CMP_IRQENABLE_CLR[11:0] |

24.9.4.11.2 Possible Interrupts

Table 24-670 lists all the interrupts that can occur and the related registers.

Table 24-670. Event Summary

| Register | Field Name | Wake-Up Source | IE | Description |
|-----------------------------|--------------------|----------------|-----|--|
| Frame layer events | | | | |
| SLIMBUS_FL_INFO[6] | RECONFIGURED | Yes | No | Reconfiguration boundary crossed |
| SLIMBUS_FL_INFO[5] | SAW_BUS_RESET | Yes | No | Bus reset sequence detected on the bus |
| SLIMBUS_FL_INFO[3] | FOUND_MS | Yes | No | Message synchronization acquired |
| SLIMBUS_FL_INFO[2] | LOST_MS | Yes | Yes | Message synchronization lost |
| SLIMBUS_FL_INFO[1] | LOST_SFS | Yes | Yes | Superframe synchronization lost |
| SLIMBUS_FL_INFO[0] | LOST_FS | Yes | Yes | Frame synchronization lost |
| Framer device events | | | | |
| SLIMBUS_FR_INFO[5] | CLOCK_RESTART | Yes | No | Clock restart request event detected |
| SLIMBUS_FR_INFO[4] | FRAMER_UNACTIVATED | Yes | Yes | Framer has left clock source operational state. |
| SLIMBUS_FR_INFO[3] | FRAMER_ACTIVATED | Yes | Yes | Framer has reached clock source operational state. |
| SLIMBUS_FR_INFO[2] | GC_TX_COL | Yes | Yes | Collision during guide byte transmit |
| SLIMBUS_FR_INFO[1] | FI_TX_COL | Yes | Yes | Collision during framing information transmit |

Table 24-670. Event Summary (continued)

| Register | Field Name | Wake-Up Source | IE | Description |
|---|----------------------|----------------|-----|--|
| SLIMBUS_FR_INFO[0] | FS_TX_COL | Yes | Yes | Collision during frame synchronization symbol transmit |
| Shared message transmit channel events | | | | |
| SLIMBUS_SMT_INFO[7] | ABORT | Yes | No | TX message was aborted before completion because of message synchronization loss. |
| SLIMBUS_SMT_INFO[5] | UDEF | Yes | No | TX message has UDEF response: Undefined response, protocol error. |
| SLIMBUS_SMT_INFO[4] | NORE | Yes | No | TX message has NORE response: No or all-zero message response. |
| SLIMBUS_SMT_INFO[3] | NACK | Yes | No | TX message has NACK response: At least one of the recipient components requested message retransmission. |
| SLIMBUS_SMT_INFO[2] | PACK | Yes | No | TX message has PACK response: All recipient devices accepted the message. |
| SLIMBUS_SMT_INFO[1] | OVERFLOW | No | No | Overflow in TX message FIFO |
| SLIMBUS_SMT_INFO[0] | MC_TX_COL | Yes | Yes | Transmit collision in message channel during message transmission |
| Shared message receive channel events | | | | |
| SLIMBUS_SMR_INFO[4] | OVERFLOW | Yes | No | Overflow in RX message FIFO. Message is larger than the FIFO. |
| SLIMBUS_SMR_INFO[3] | RECEIVED_RECONFIGURE | Yes | No | RECONFIGURE_NOW() message received |
| SLIMBUS_SMR_INFO[2] | RECEIVED_MESSAGE | Yes | No | Message is available in the RX message FIFO. |
| SLIMBUS_SMR_INFO[1] | UNDERFLOW | No | No | Underflow in RX message FIFO. Software tried to read more bytes than available. |
| SLIMBUS_SMR_INFO[0] | MC_TX_COL | Yes | Yes | Transmit collision in message channel during message reception |
| Data channel events | | | | |
| SLIMBUS_DCT_INFO_j[3] | LOLEVEL | Yes | No | Write level of TX data agent FIFO has gone above the threshold. |
| SLIMBUS_DCR_INFO_j[3] | HILEVEL | Yes | No | Read level of RX data agent FIFO has gone above the threshold. |
| SLIMBUS_DCT_INFO_j[2], SLIMBUS_DCR_INFO_j[2] | UNDERFLOW | Yes | No | Underflow in TX/RX data agent FIFO |
| SLIMBUS_DCT_INFO_j[1], SLIMBUS_DCR_INFO_j[1] | OVERFLOW | Yes | No | Overflow in TX/RX data agent FIFO |
| SLIMBUS_DCT_INFO_j[0], SLIMBUS_DCR_INFO_j[0] | DATA_TX_COL | Yes | Yes | TX collision in TX/RX data agent |

24.9.4.11.3 Interface Device ISRs

The Interface Device ISRs are applied when a bit of status register [SLIMBUS_FL_INFO](#) is set, which also triggers the assertion of bit field [SLIMBUS_CMP_IRQSTATUS\[0\] FL_INFO](#) and of the IRQ line, when enabled in bit field [SLIMBUS_CMP_IRQENABLE_SET\[0\] FL_INFO_EN](#). Service routines must be applied and the FL_INFO bit field cleared (by writing 1 to it).

24.9.4.11.3.1 Lost Frame Synchronization (LOST_FS)

24.9.4.11.3.1.1 Root Event

This interrupt occurs when a loss of frame synchronization happens. All data channels automatically stop, that is, all active [SLIMBUS_DCT_CONFIG1_j](#) / [SLIMBUS_DCR_CONFIG1_j](#)[31] ENABLE bits are cleared. Component automatically reacquires frame, superframe and message synchronization.

24.9.4.11.3.1.2 Interrupt Service Routine

Frame synchronization (FS) loss implies the loss of higher-level superframe and message synchronizations:

- Messages cannot be expected to be transmitted / received until the component is operational again. Additionally, any ongoing reconfiguration sequence must be interrupted and made invalid by MS loss. No action required if no reconfiguration sequence is ongoing.
- Implicit superframe synchronization loss triggers a reset of all component ports: see [Section 24.9.4.4.3.6](#).

This field, [SLIMBUS_FL_INFO](#)[0] LOST_FS, is not cleared by software into the ISR. Instead, it stays set until the component receives a REQUEST_CLEAR_INFORMATION message by the remote manager (Receiving a message implies of course that message synchronization has been restored in the mean time). Only at this point, software can apply the message and clear the designated field.

24.9.4.11.3.2 Lost Superframe Synchronization (LOST_SFS)

24.9.4.11.3.2.1 Root Event

This interrupt occurs when a loss of superframe synchronization happens. The loss of lower-level frame synchronization also implies the loss of superframe synchronization, if already acquired, but does not trigger the assertion of LOST_SFS Information Element. All data channels automatically stop, that is, all active [SLIMBUS_DCT_CONFIG1_j](#) / [SLIMBUS_DCR_CONFIG1_j](#)[31] ENABLE bits must be cleared. Component automatically reacquires superframe and message synchronization.

24.9.4.11.3.2.2 Interrupt Service Routine

Superframe synchronization (SFS) loss will trigger the reset of all ports of the component: see [Section 24.9.4.4.3.6](#).

Superframe synchronization loss implies the loss of message synchronization, that is, messages cannot be expected to be transmitted / received until the component is operational again. Additionally, any ongoing reconfiguration sequence must be interrupted and made invalid by MS loss. No action required if no reconfiguration sequence is ongoing.

This field, [SLIMBUS_FL_INFO](#)[1] LOST_SFS, is not cleared by software into the ISR. Instead, it stays set until the component receives a REQUEST_CLEAR_INFORMATION message by the remote manager (Receiving a message implies of course that message synchronization has been restored in the mean time). Only at this point, software can apply the message and clear the designated field.

24.9.4.11.3.3 Lost Message Synchronization (LOST_MS)

24.9.4.11.3.3.1 Root Event

This interrupt occurs when a loss of message synchronization happens. The loss of either lower-level frame or superframe synchronization also implies the loss of message synchronization, if already acquired, but does not trigger the assertion of LOST_MS Information Element. Component automatically reacquires message synchronization, by seeking for Guide Channel information.

24.9.4.11.3.3.2 Interrupt Service Routine

Any ongoing reconfiguration sequence must be interrupted and made invalid by the Message Synchronisation (MS) loss. No action required here if no reconfiguration sequence is ongoing.

This field, [SLIMBUS_FL_INFO\[2\]](#) LOST_MS, is not cleared by software into the ISR. Instead, it stays set until the component receives a REQUEST_CLEAR_INFORMATION message by the remote manager, requiring to clear it (Receiving a message implies of course that message synchronization has been restored in the mean time). Only at this point, software can apply the message and clear the designated field.

24.9.4.11.3.4 Found Message Synchronization (FOUND_MS)

24.9.4.11.3.4.1 Root Event

This interrupt occurs when acquisition of message synchronization. In that state, messages may be transmitted and received over the SMC.

24.9.4.11.3.4.2 Interrupt Service Routine

If MS is reacquired, following a previous LOST_MS event, then a REPORT_INFORMATION message must be transmitted, as follows:

- Source: interface device
- Destination: SLIMbus manager device (LA = 0xFF)
- Information Element: LOST_MS

If MS is reacquired, following a previous LOST_FS event, then a REPORT_INFORMATION message must be transmitted, as follows:

- Source: interface device
- Destination: SLIMbus manager device (LA = 0xFF)
- Information Element: LOST_FS

If MS is reacquired, following a previous LOST_SFS event, then a REPORT_INFORMATION message must be transmitted, as follows:

- Source: interface device
- Destination: SLIMbus manager device (LA = 0xFF)
- Information Element: LOST_SFS

If MS is reacquired, following a previous MC_TX_COL event, then a REPORT_INFORMATION message must be transmitted, as follows:

- Source: interface device
- Destination: SLIMbus manager device (LA = 0xFF)
- Information Element: MC_TX_COL

If MS is reacquired, following a previous UDEF (Received undefined message response) event, the message that caused UDEF must be retransmitted until it succeeds or until the retransmit maximum (fully managed by software) is reached.

In any case, software must clear the field [SLIMBUS_FL_INFO\[3\]](#) FOUND_MS. From that point on, any pending messages in the TX FIFO will be sent.

24.9.4.11.3.5 Reconfigured (RECONFIGURED)

24.9.4.11.3.5.1 Root Event

This interrupt occurs when crossing of a reconfiguration boundary. In case of clock pause, where the SLIMbus clock stops at the boundary (1st rising edge of the new superframe), the bit (and therefore the IRQ) is asserted at the clock pause, not at the clock restart.

24.9.4.11.3.5.2 Interrupt Service Routine

Completes the software-controller reconfiguration sequence. No reconfiguration must be applied to the control registers between the RECONFIGURE_NOW reception and the reconfiguration boundary. A attempt by the manager to start a new reconfiguration sequence during that interval is an error.

In the case of framer release handover and/or root frequency change, the active framer must start using a new clock input selection at the reconfiguration boundary (as per register field [SLIMBUS_FR_CLOCK_SOURCE\[5:3\] CLKSEL](#)). All non-selected SLIMbus clock inputs of active framer components and all SLIMbus clock inputs for clock receiver components (inactive framers), and that may have been used until the boundary, can be turned off at that point.

Field [SLIMBUS_FL_INFO\[6\] RECONFIGURED](#) must be software cleared (by writing 1 to it).

24.9.4.11.4 Framer Device ISRs

The Framer Device ISRs are applied when a bit of status register [FR_INFO](#) is set, which also triggers the assertion of bit field [SLIMBUS_CMP_IRQSTATUS\[1\] FR_INFO](#) and of the IRQ line, when enabled in bit field [SLIMBUS_CMP_IRQENABLE_SET\[1\] FR_INFO_EN](#). Service routines must be applied, and the [fr_info](#) bit field cleared (by writing 1 to it). Some interrupt generating events are collisions, which occur when the framer detects on DATA line a different value than it's actively driving.

24.9.4.11.4.1 Transmit Collision in Frame Sync Symbol (FS_TX_COL)

24.9.4.11.4.1.1 Root Event

Transmit collision detected while driving the frame sync symbol (as active framer) of the framing channel.

24.9.4.11.4.1.2 Interrupt Service Routine

A REPORT_INFORMATION message must be transmitted, as follows:

- Sender: framer device
- Destination: SLIMbus manager device (LA = 0xFF)
- Information Element: FS_TX_COL

This field is not cleared by software into the ISR. Instead, it stays set until the component receives a REQUEST_CLEAR_INFORMATION message by the remote manager (Receiving a message implies of course that message synchronization has been restored in the mean time). Only at this point, software can apply the message and clear the designated field.

24.9.4.11.4.2 Transmit Collision in Frame Sync Symbol (FI_TX_COL)

24.9.4.11.4.2.1 Root Event

Transmit collision detected while driving the framing information (as active framer) of the framing channel.

24.9.4.11.4.2.2 Interrupt Service Routine

A REPORT_INFORMATION message must be transmitted, as follows:

- Sender: framer device
- Destination: SLIMbus manager device (LA = 0xFF)
- Information Element: FI_TX_COL

This field is not cleared by software into the ISR. Instead, it stays set until the component receives a REQUEST_CLEAR_INFORMATION message by the remote manager (Receiving a message implies of course that message synchronization has been restored in the mean time). Only at this point, software can apply the message and clear the designated field.

24.9.4.11.4.3 Transmit Collision in Guide Channel (GC_TX_COL)

24.9.4.11.4.3.1 Root Event

Transmit collision detected while driving the guide byte (as active framer), that is, during the guide channel.

24.9.4.11.4.3.2 Interrupt Service Routine

A REPORT_INFORMATION message must be transmitted, as follows:

- Sender: framer device
- Destination: SLIMbus manager device (LA = 0xFF)
- Information Element: GC_TX_COL

This field is not cleared by software into the ISR. Instead, it stays set until the component receives a REQUEST_CLEAR_INFORMATION message by the remote manager (Receiving a message implies of course that message synchronization has been restored in the mean time). Only at this point, software can apply the message and clear the designated field.

24.9.4.11.4.4 Framer Device Activated (FRAMER_ACTIVATED)

24.9.4.11.4.4.1 Root Event

Acquisition of active framer role by the component. This event is only possible on bus boot (when default active framer) and incoming framer handover (when inactive framer).

24.9.4.11.4.4.2 Interrupt Service Routine

Assert software implemented ACTIVE_FRAMER information element.

Field [SLIMBUS_FR_INFO](#)[4] FRAMER_UNACTIVATED must be software cleared (by writing 1 to it).

The ACTIVE_FRAMER information element's assertion does not trigger the transmission by the framer device of a REPORT_INFORMATION message, since the information is already "publicized" by the framer handover process.

24.9.4.11.4.5 Framer Device Unactivated (FRAMER_UNACTIVATED)

24.9.4.11.4.5.1 Root Event

Loss of active framer role by the component. This event is only possible on bus shutdown and outgoing framer handover (when active framer).

24.9.4.11.4.5.2 Interrupt Service Routine

Deassert software-implemented ACTIVE_FRAMER information element.

Field [SLIMBUS_FR_INFO](#)[3] FRAMER_ACTIVATED must be software cleared (by writing 1 to it).

The ACTIVE_FRAMER information element's deassertion does not trigger the transmission by the framer device of a REPORT_INFORMATION message, since the information is already "publicized" by the framer handover process.

24.9.4.11.4.6 Restart After Clock Pause (CLOCK_RESTART)

24.9.4.11.4.6.1 Root Event

Transition detected on the DATA line during a clock pause, driven by any of the connected components and seen by the clock source (active framer) as a restart request. Note that this field is set for all clock restarts, even if the local framer is inactive.

24.9.4.11.4.6.2 Interrupt Service Routine

Field [SLIMBUS_FR_INFO](#)[5] CLOCK_RESTART must be software cleared (by writing 1 to it).

NOTE: Restart event is a source of asynchronous wakeup.

24.9.4.11.5 Shared Message Channel Transmit ISRs

These ISRs are applied when a bit of status register SMT_INFO is set, which also triggers the assertion of bit field [SLIMBUS_CMP_IRQSTATUS](#)[2] SMT_INFO and of the IRQ line, when enabled in bit field [SLIMBUS_CMP_IRQENABLE_SET](#)[2] SMT_INFO_EN. Service routines must be applied, and the fr_info bit field cleared (by writing 1 to it)

24.9.4.11.5.1 Transmit Collision in Message Body (MC_TX_COL)

24.9.4.11.5.1.1 Root Event

Transmit collision detected while transmitting a message, that is, writing any subfield except message response (arbitration, header, payload, or message integrity). The device immediately (before next cell) stop transmission and the component automatically lose message synchronization. The message has to be sent again, once message synchronization has been regained.

24.9.4.11.5.1.2 Interrupt Service Routine

This field, [SLIMBUS_SMT_INFO](#)[0] MC_TX_COL, is not cleared by software into the ISR. Instead, it stays set until the component receives a REQUEST_CLEAR_INFORMATION message by the remote manager (Receiving a message implies of course that message synchronization has been restored in the mean time). Only at this point, software can apply the message and clear the designated field.

24.9.4.11.5.2 TX Message FIFO Overflow (OVERFLOW)

24.9.4.11.5.2.1 Root Event

Overflow occurs when too many bytes are written into the TX message FIFO by the software, either because the entered message is too long or because the FIFO still contains bytes from previous messages. The state of the FIFO after an overflow event is undetermined, but the other FIFOs are unaffected.

24.9.4.11.5.2.2 Interrupt Service Routine

TX message FIFO must be cleared as explained in [Section 24.9.4.10.1.2](#).

Field [SLIMBUS_SMT_INFO](#)[1] OVERFLOW must be software cleared (by writing 1 to it).

Message transmission must resume normally.

24.9.4.11.5.3 Received Positive Acknowledge Message Response (PACK)

24.9.4.11.5.3.1 Root Event

Message written in the TX message FIFO was transmitted after unlimited, automatic arbitration retries, and removed from the FIFO. Received message response (MR) is PACK.

24.9.4.11.5.3.2 Interrupt Service Routine

No action required for this field: [SLIMBUS_SMT_INFO](#)[2] PACK. FIFO is now available for another message.

24.9.4.11.5.4 Received Negative Acknowledge Message Response (NACK)

24.9.4.11.5.4.1 Root Event

Message written in the TX message FIFO was transmitted after unlimited, automatic arbitration retries, and removed from the FIFO. Received message response (MR) is NACK.

24.9.4.11.5.4.2 Interrupt Service Routine

Current message must be eventually retransmitted until it succeeds or until the retransmit maximum (fully managed by software) is reached.

Field [SLIMBUS_SMT_INFO](#)[3] NACK must be software cleared (by writing 1 to it).

FIFO is available for another message, which can be the same or another one.

24.9.4.11.5.5 Received No Message Response (NORE)

24.9.4.11.5.5.1 Root Event

Message written in the TX message FIFO was transmitted after unlimited, automatic arbitration retries, and removed from the FIFO. Received message response (MR) is NORE.

24.9.4.11.5.5.2 Interrupt Service Routine

Current message must be eventually retransmitted until it succeeds or until the retransmit maximum (fully managed by software) is reached.

Field [SLIMBUS_SMT_INFO](#)[4] NORE must be software cleared (by writing 1 to it).

FIFO is available for another message, which can be the same or another one.

24.9.4.11.5.6 Received Undefined Message Response (UDEF)

24.9.4.11.5.6.1 Root Event

Message written in the TX message FIFO was transmitted after unlimited, automatic arbitration retries, and removed from the FIFO. Received message response (MR) is UDEF, that is, one of several undefined MR codes that are not combinations of legal responses, implying that an error has taken place. Component loses message synchronization, and reacquires it automatically.

24.9.4.11.5.6.2 Interrupt Service Routine

Field [SLIMBUS_SMT_INFO](#)[5] UDEF must be software cleared (by writing 1 to it).

FIFO is available for another message, which can be the same or another one.

24.9.4.11.5.7 TX Message FIFO Underflow (UNDERFLOW)

24.9.4.11.5.7.1 Root Event

Underflow takes place when the message transmission logic attempts to read more bytes than the FIFO contains. The state of the FIFO after an underflow event is undetermined, but the other FIFOs are unaffected.

24.9.4.11.5.7.2 Interrupt Service Routine

TX message FIFO must be cleared as explained in [Section 24.9.4.10.1.2](#).

Field must be software-cleared (by writing 1 to it).

Message transmission must resume normally, making sure the error is not repeated.

24.9.4.11.6 Shared Message Channel Receive ISRs

These ISRs are applied when a bit of status register SMR_INFO is set, which also triggers the assertion of bit field [SLIMBUS_CMP_IRQSTATUS\[3\]](#) SMR_INFO and of the IRQ line, when enabled in bit field [SLIMBUS_CMP_IRQENABLE_SET\[3\]](#) SMR_INFO_EN. Service routines must be applied, and the FR_INFO bit field cleared (by writing 1 to it)

24.9.4.11.6.1 Transmit Collision in Message Response (MC_TX_COL)

24.9.4.11.6.1.1 Root Event

Transmit collision detected while receiving a message, that is, writing the message response subfield. The component automatically loses message synchronization, and eventually reacquires it.

24.9.4.11.6.1.2 Interrupt Service Routine

The field [SLIMBUS_SMR_INFO\[0\]](#) MC_TX_COL must not be unconditionally software cleared, as it implements a Boolean IE that can only be cleared under specific conditions (and together with the [SLIMBUS_SMT_INFO\[0\]](#) MC_TX_COL).

24.9.4.11.6.2 RX Message FIFO Underflow (UNDERFLOW)

24.9.4.11.6.2.1 Root Event

Underflow takes place when too many bytes are read out of the RX message FIFO by the software, because of an error when estimating the message length, as defined in [Section 24.9.4.10.2.2](#). The state of the FIFO after an underflow event is undetermined, but the other FIFOs are unaffected.

24.9.4.11.6.2.2 Interrupt Service Routine

RX message FIFO must be cleared as explained in [Section 24.9.4.10.2.3](#).

Field [SLIMBUS_SMR_INFO\[1\]](#) UNDERFLOW must be software-cleared (by writing 1 to it).

NOTE: This software error is not supposed to take place, since the message itself is assumed to be correct and could affect the correct running of the SLIMbus protocol, if the received message cannot be recovered.

24.9.4.11.6.3 RX Message FIFO Overflow (OVERFLOW)

24.9.4.11.6.3.1 Root Event

Overflow occurs when too many bytes are received into the RX message FIFO because the entered message is too long. The state of the FIFO after an overflow event is undetermined, but the other FIFOs are unaffected.

24.9.4.11.6.3.2 Interrupt Service Routine

RX message FIFO must be cleared as explained in [Section 24.9.4.10.2.3](#).

Field must be software cleared (by writing 1 to it).

Message transmission must resume normally.

24.9.4.11.6.4 Message Received (RECEIVED_MESSAGE)

24.9.4.11.6.4.1 Root Event

A message has been received and checked by the hardware: target address matches a local device (LA or EA), message length is coherent with AT/RL fields, integrity is correct for both PI and MI, all target devices acknowledged the message (PACK MR transmitted and received).

24.9.4.11.6.4.2 Interrupt Service Routine

Received message must be unloaded from RX message FIFO, parsed, and the appropriate action taken, as explained in [Section 24.9.4.10.2.2](#).

Field [SLIMBUS_SMR_INFO\[2\]](#) RECEIVED_MESSAGE must be software cleared (by writing 1 to it). This will also clear the message FIFO and allow the local component to respond PACK to new incoming messages.

24.9.4.11.6.5 Reconfigure_now Message Received (RECEIVED_RECONFIGURE)

24.9.4.11.6.5.1 Root Event

A message has been received as in RECEIVED_MESSAGE event above, with the additional condition that it has been recognized by hardware as a RECONFIGURE_NOW() message. Note that by the time the ISR is executed, the reconfiguration may have already taken place.

24.9.4.11.6.5.2 Interrupt Service Routine

Field [SLIMBUS_SMR_INFO\[3\]](#) RECEIVED_CONFIGURE must be software cleared (by writing 1 to it).

24.9.4.11.7 Data Channel Port ISRs

These ISRs are applied when a bit of a status register [SLIMBUS_DCT_INFO_j](#) and/or [SLIMBUS_DCR_INFO_j](#) is set, which also triggers the assertion of bit field [SLIMBUS_CMP_IRQSTATUS\[11:4\]](#) DCT_INFO_j/DCR_INFO_j and of the IRQ line, when enabled in bit field [SLIMBUS_CMP_IRQENABLE_SET\[11:4\]](#) DCT/DCR_INFO_j. Service routines must be applied, and the [SLIMBUS_DCT_INFO_j](#) and/or [SLIMBUS_DCR_INFO_j](#) bit fields cleared (by writing 1 to it).

24.9.4.11.7.1 Transmit Collision in Data Channel Port (DATA_TX_COL)

24.9.4.11.7.1.1 Root Event

Transmit collision detected while writing to the considered data channel, in any of the TAG, AUX, or DATA fields. Note that transmit collisions are possible even for receive ports, as those port may also write some TAG cells (that is, for pulled TP), where transmit collisions are possible. The device must immediately (before next cell) stop writing to the bus, only resuming on next segment.

24.9.4.11.7.1.2 Interrupt Service Routine

The REPORT_INFORMATION message must be transmitted, from the port's stereo or voice device (that is, with that device's LA in source address of arbitration field), to the active manager (that is, with manager's target LA in header = 0xFF), and containing the information element (IE) of the same name (DATA_TX_COL).

The field [SLIMBUS_DCT_INFO_j\[0\]](#) DATA_TX_COL and/or [SLIMBUS_DCR_INFO_j\[0\]](#) DATA_TX_COL must not be unconditionally software cleared, as it implements a boolean IE that can only be cleared under specific conditions.

24.9.4.11.7.2 Data Channel FIFO Overflow (OVERFLOW)

24.9.4.11.7.2.1 Root Event

Overflow occurs when the data rate into the FIFO exceeds the data rate out of the FIFO for a sufficient amount of time, which can happen in both TX and RX ports. The state of the FIFO after an overflow event is undetermined, but the other FIFOs are unaffected.

24.9.4.11.7.2.2 Interrupt Service Routine

The SLIMbus protocol does not specify the handling of such an event. However, since data integrity cannot be guaranteed following an that event, stopping the channel is an option.

Field [SLIMBUS_DCT_INFO_j\[1\]](#) / [SLIMBUS_DCR_INFO_j\[1\]](#) OVERFLOW must be software cleared (by writing 1 to it).

24.9.4.11.7.3 Data Channel FIFO Underflow (UNDERFLOW)

24.9.4.11.7.3.1 Root Event

Underflow occurs when the data rate out of the FIFO exceeds the data rate into the FIFO for a sufficient amount of time, which can happen in both TX and RX ports. The state of the FIFO after an underflow event is undetermined, but the other FIFOs are unaffected.

24.9.4.11.7.3.2 Interrupt Service Routine

The SLIMbus protocol does not specify the handling of such an event. However, since data integrity cannot be guaranteed following an that event, stopping the channel is an option.

Field [SLIMBUS_DCT_INFO_j\[2\]](#) / [SLIMBUS_DCR_INFO_j\[2\]](#) UNDERFLOW must be software cleared (by writing 1 to it).

24.9.5 SLIMbus Programming Guide

24.9.5.1 SLIMbus Low-Level Programming Models

This section describes the low-level programming sequences for the configuration and use of the SLIMbus module. Because the SLIMbus protocol is implemented partly by hardware and partly by software in the current module, some higher-level procedures, such as sending and answering specific SLIMbus protocol messages, are mentioned for the sake of clarity.

24.9.5.1.1 Global Initialization

24.9.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the SLIMbus module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the SLIMbus module. See [Section 24.9.3, SLIMbus Integration](#), and [Section 24.9.2, SLIMbus Environment](#), for further information.

Table 24-671. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|-----------------------------|--|
| PRCM | The required SLIMbus clocks must be enabled. If the SLIMbus module does not contain the active frame, it receives its functional clock (SLIMbus clock) from the CLK pin. For a summary of the SLIMbus clocks, see Table 24-653 . See Chapter 3, Power, Reset, and Clock Management . |
| Control Module | Module specific pad multiplexing must be set in the control module. For more information about the module configuration, see Control Module . |
| (Optional) L4 Interconnect | For information about the L4-PER interconnect configuration, see Chapter 14, Interconnect . |
| (Optional) INTC | Cortex-A9 MPU and DSP subsystem INTCs must be configured to enable the interrupt requests to the Cortex-A9 MPU or to the DSP subsystem. |
| (Optional) sDMA and/or aDMA | sDMA (aDMA) configuration must be done to enable the module DMA channel requests. See sDMA . |

24.9.5.1.1.2 SLIMbus Global Initialization

24.9.5.1.1.2.1 SLIMbus Module Software Reset

This procedure brings the SLIMbus module to a known state.

Table 24-672. SLIMbus Module Software Reset

| Step | Register/Bit Field/Programming Model | Value |
|-------------------------------|--|-------|
| Initiate a software reset. | SLIMBUS_CMP_SYSCONFIG[0] SOFTRESET | 0x1 |
| Wait until reset is finished. | SLIMBUS_CMP_SYSCONFIG[0] SOFTRESET | =0x0 |

24.9.5.1.1.2.2 Power Management and Wake-Up Configuration

This procedure configures the idle mode for SLIMbus component. By definition, the target can handle read/write transactions as long as it is out of IDLE state.

Table 24-673. SLIMbus Power Management

| Step | Register/Bit Field/Programming Model | Value |
|--|--|-------|
| Configure the local power management. | SLIMBUS_CMP_SYSCONFIG[3:2] IDLEMODE | 0x- |
| Turn on/off internal clock autogating. | SLIMBUS_CMP_SYSCONFIG[8] AUTOGATINGDISABLE | 0x- |

24.9.5.1.2 SLIMbus Component Boot

The component boot sequence is initiated when the component decides to join the bus.

24.9.5.1.2.1 Clock Source Component Boot

This procedure performs component boot in clock source mode (the component contains the active framer of the given bus).

Table 24-674. Clock Source Component Boot

| Step | Register/Bit Field/Programming Model | Value |
|---|---|-------|
| Set the active-framer boot flag. | SLIMBUS_FR_CONTROL[0] BOOT | 0x1 |
