| Select the subframe length and the control space width: subframe mode (SM). | SLIMBUS_FL_SM[4:0] SM | 0x-- |
| Select root/SLIMbus frequency ratio: clock gear (CG). | SLIMBUS_FL_CG[3:0] CG | 0x- |
| Indicate the root frequency (RF) to the framer device. | SLIMBUS_FL_RF[3:0] RF | 0x- |
| Select a source of the functional (SLIMbus) clock (See also , <i>SLIMbus Integration</i>). | SLIMBUS_FR_CLOCK_SOURCE[5:3] CLKSEL | 0x- |
| Select a root divider ratio to obtain the desired root frequency (RF). | SLIMBUS_FR_CLOCK_SOURCE[2:0] CLKDIV | 0x- |
| Initiate reconfiguration. | SLIMBUS_FL_CONTROL[2] FORCE_RECONFIGURE | 0x1 |
| Wait for reconfiguration to finish. | SLIMBUS_FL_CONTROL[2] FORCE_RECONFIGURE | =0x0 |

24.9.5.1.2.2 Clock Receiver Component Boot

This procedure boots the SLIMbus when the component is in clock receiver mode (inactive framer).

Table 24-675. Clock Receiver Component Boot

| Step | Register/Bit Field/Programming Model | Value |
|-------------------------------------|---|-------|
| Set inactive-framer boot flag. | SLIMBUS_FL_CONTROL[0] BOOT | 0x1 |
| Initiate reconfiguration. | SLIMBUS_FL_CONTROL[2] FORCE_RECONFIGURE | 0x1 |
| Wait for reconfiguration to finish. | SLIMBUS_FL_CONTROL[2] FORCE_RECONFIGURE | =0x0 |

24.9.5.1.3 Data Agent Assignment

Before a SLIMbus device enumeration, it is assumed to have a given number of ports, and each port a given set of properties. Software must keep a data port table, updated by various events including SLIMbus resets, data channel config messages, and some reconfiguration messages.

At least one data agent (which implements the data ports in hardware) must be assigned to a SLIMbus device before it can receive/transmit actual payload data. The following settings must be done to configure the SLIMbus module.

Table 24-676. Data Agent Assignment

| Step | Register/Bit Field/ Programming Model | Value |
|---|--|-------|
| Set the port number (PN) for TX and/or RX data agent j. Must be unique within the device that it is mapped to.. | SLIMBUS_DCT_MAP_j[13:8] PN SLIMBUS_DCR_MAP_j[13:8] PN | 0x-- |
| Set the index of the device (DI) TX and or RX data agent j belongs to. | SLIMBUS_DCT_MAP_j[7:0] DI SLIMBUS_DCR_MAP_j[7:0] DI | 0x-- |
| Validate settings. | SLIMBUS_FL_CONTROL [8] VALIDATE_DCMAP | 0x1 |

24.9.5.1.4 Device Enumeration

Device enumeration is an acquisition of a dynamic logical address (LA) assigned by the active manager device. The LA ranges from 0x00 to 0xEF, with the exception of the active manager itself, located by definition at LA = 0xFF.

24.9.5.1.4.1 Manager Device Enumeration

This procedure performs an manager device enumeration when the local manager device is the bus active manager.

Table 24-677. Manager Device Enumeration

| Step | Register/Bit Field/Programming Model | Value |
|---|--|--------------------|
| Wait for message synchronization. | SLIMBUS_FL_INFO [3] FOUND_MS | =0x1 |
| Explicitly enumerate the device as active manager device. | SLIMBUS_DEV_LA_i[7:0] LA SLIMBUS_DEV_LA_i[8] LA_ENABLE SLIMBUS_DEV_LA_i[9] EA_ENABLE | 0xFF 0x1 0x1 |

24.9.5.1.4.2 Non-Manager Device Enumeration

This procedure is used when a non-manager device decides to participate on the bus. When the SLIMbus module contains the active manager, software must also perform the manager-side actions.

Table 24-678. Non-Manager Device Enumeration

| Step | Register/Bit Field/Programming Model | Value |
|--|--|-------------|
| Enable the device to receive broadcast messages. | SLIMBUS_DEV_LA_i[9] EA_ENABLE | 0x1 |
| Wait for message synchronization or for REQUEST_SELF_ANNOUNCEMENT() message from active manager. | SLIMBUS_FL_INFO [3] FOUND_MS or see Section 24.9.5.1.6 , <i>SLIMbus Transfer Procedures</i> . | =0x1 |
| Send REPORT_PRESENT() message to the active manager (LA = 0xFF). | See Section 24.9.5.1.6 , <i>SLIMbus Transfer Procedures</i> . | |
| Wait for ASSIGN_LOGICAL_ADDRESS(LA) message from the active manager. | See Section 24.9.5.1.6 , <i>SLIMbus Transfer Procedures</i> . | |
| Extract the LA from the message and set it in the hardware. | SLIMBUS_DEV_LA_i[7:0] LA SLIMBUS_DEV_LA_i[8] LA_ENABLE | 0x-- 0x1 |

24.9.5.1.5 Operational Modes Configuration

24.9.5.1.5.1 SLIMbus Transfer Protocol Configuration

This procedure configures the data channel(s) for a specific transfer protocol use. It is assumed that at this moment the required channels are connected by means of CONNECT_SOURCE(PN,CN) and CONNECT_SINK(PN,CN) messages. No action on hardware is required after receiving these messages, except for the standard checks and clearing of the message FIFO. The channel numbers (CN) are kept and handled by software. The steps listed are required from the configured side, but if the local component contains the active manager software must also perform the configuration steps. Changing the order of NEXT_* messages is allowed.

Table 24-679. SLIMbus Transfer Protocol Configuration

| Step | Register/Bit Field/Programming Model | Value |
|---|---|-------|
| Wait for BEGIN_RECONFIGURATION() message. | | |
| Clear reconfiguration parameters. | SLIMBUS_FL_CONTROL [7] CLEAR_RECONFIGURATION | 0x1 |
| Wait for NEXT_DEFINE_CHANNEL(CN, TP, SD, SL) message. | See Section 24.9.5.1.6 , <i>SLIMbus Transfer Procedures</i> . | |

Table 24-679. SLIMbus Transfer Protocol Configuration (continued)

| Step | Register/Bit Field/Programming Model | Value |
|--|--|--------------|
| Extract and set in hardware the transfer protocol (TP) for RX data agent j and/or for TX data agent j. | SLIMBUS_DCR_CONFIG1_j[3:0] TP SLIMBUS_DCT_CONFIG1_j[3:0] TP | 0x- |
| Extract and set in hardware the segment distribution (SD) for RX data agent j and/or for TX data agent j. | SLIMBUS_DCR_CONFIG2_j[11:0] SD SLIMBUS_DCT_CONFIG2_j[11:0] SD | 0x--- |
| Extract and set in hardware the segment length (SL) for RX data agent j and/or for TX data agent j. | SLIMBUS_DCR_CONFIG1_j[9:5] SL SLIMBUS_DCT_CONFIG1_j[9:5] SL | 0x-- |
| IF: Transfer protocol is asynchronous simplex | TP | =0x4 or =0x6 |
| Set secondary owner if data agent j is RX or set primary owner if data agent j is TX. | SLIMBUS_DCR_CONFIG1_j[4] TP_QUALIFIER SLIMBUS_DCT_CONFIG1_j[4] TP_QUALIFIER | 0x1 0x0 |
| ELSEIF: Asynchronous half-duplex | TP | =0x5 or =0x7 |
| Set ownership for data channel (combines one TX and one RX data agent). | SLIMBUS_DCR_CONFIG1_j[4] TP_QUALIFIER SLIMBUS_DCT_CONFIG1_j[4] TP_QUALIFIER | 0x- |
| ENDIF | | |
| Wait for NEXT_DEFINE_CONTENT(CN, FL, PR, AF, DT, CL, DL) message. | See Section 24.9.5.1.6, SLIMbus Transfer Procedures . | |
| Extract and set in hardware the number of AUX slots in a segment for RX data agent j and/or for TX data agent j. | SLIMBUS_DCR_CONFIG1_j[19:16] AF SLIMBUS_DCT_CONFIG1_j[19:16] AF | 0x-- |
| IF: Data type (DT) extracted from message is LPCM audio | DT | =0x1 |
| Enable unsigned-to-OSAM encoding for RX data agent j and/or for TX data agent j. | SLIMBUS_DCR_CONFIG1_j[28] DT_LPCM SLIMBUS_DCT_CONFIG1_j[28] DT_LPCM | 0x1 |
| ELSE | | |
| Disable unsigned-to-OSAM encoding for RX data agent j and/or for TX data agent j. | SLIMBUS_DCR_CONFIG1_j[28] DT_LPCM SLIMBUS_DCT_CONFIG1_j[28] DT_LPCM | 0x0 |
| ENDIF | | |
| Extract and set in hardware the channel link bit (CL) for RX data agent j and/or for TX data agent j. | SLIMBUS_DCR_CONFIG1_j[15] CL SLIMBUS_DCT_CONFIG1_j[15] CL | 0x- |
| Extract and set in hardware the AUX + data length (DL) for RX data agent j and/or for TX data agent j. | SLIMBUS_DCR_CONFIG1_j[14:10] DL SLIMBUS_DCT_CONFIG1_j[14:10] DL | 0x-- |
| Perform the data FIFO(s) setup for RX and/or TX data agent(s). | See Section 24.9.5.1.5.2, SLIMbus Data FIFO Mapping and Setup . | |
| Wait for NEXT_ACTIVATE_CHANNEL() message. | See Section 24.9.5.1.6, SLIMbus Transfer Procedures . | |
| Request enabling of RX data agent j and/or of TX data agent j. | SLIMBUS_DCR_CONFIG1_j[31] ENABLE SLIMBUS_DCT_CONFIG1_j[31] ENABLE | 0x1 |
| Wait for RECONFIGURE_NOW() message. | See Section 24.9.5.1.6, SLIMbus Transfer Procedures . | |
| This message is hardware-decoded and executed. No software action on the module is required except for emptying the FIFO to allow receiving of further messages. | SLIMBUS_SMR_INFO[2] RECEIVED_MESSAGE [3] RECEIVED_CONFIGURE | 0x1 |

24.9.5.1.5.2 SLIMbus Data FIFO Mapping and Setup

This procedure maps each used FIFO to a free zone of the shared buffer. It also sets the FIFO thresholds used to trigger loading and unloading the FIFOs. These settings depend on the available free space, segment word length, and required FIFO depth. Thus, at this moment, the protocol type must be known and the data agent must not be enabled.

Table 24-680. SLIMbus Data FIFO Mapping and Setup

| Step | Register/Bit Field/Programming Model | Value |
|--|--|-------|
| Set the capacity (in segment words) of data FIFO for RX agent j and/or for TX data agent j. | SLIMBUS_DCR_FIFO_SETUP2_j[7:0] SIZE SLIMBUS_DCT_FIFO_SETUP2_j[7:0] SIZE | 0x-- |
| Set the FIFO base address within shared RAM for RX agent j and/or for TX data agent j. | SLIMBUS_DCR_FIFO_SETUP1_j[11:5] BASE_ADDR SLIMBUS_DCT_FIFO_SETUP1_j[11:5] BASE_ADDR | 0x-- |
| Set SLIMbus-side FIFO threshold for RX data agent j and/or for TX data agent j. | SLIMBUS_DCR_FIFO_SETUP2_j[15:8] SB_THRESHOLD SLIMBUS_DCT_FIFO_SETUP2_j[15:8] SB_THRESHOLD | 0x-- |
| Set software-side FIFO threshold for RX data agent j and/or for TX data agent j. | SLIMBUS_DCR_FIFO_SETUP2_j[23:16] DMA_THRESHOLD SLIMBUS_DCT_FIFO_SETUP2_j[23:16] DMA_THRESHOLD | 0x-- |
| Bring the FIFO to empty state: RX data agent j and/or TX data agent j. | SLIMBUS_DCR_FIFO_SETUP1_j[0] FIFO_CLEAR SLIMBUS_DCT_FIFO_SETUP1_j[0] FIFO_CLEAR | 0x1 |
| Wait for clearing to complete. | SLIMBUS_DCR_FIFO_SETUP1_j[0] FIFO_CLEAR SLIMBUS_DCT_FIFO_SETUP1_j[0] FIFO_CLEAR | =0x0 |

24.9.5.1.6 SLIMbus Transfer Procedures

This section describes the low-level programming steps for message and data reception and transmission. For more information about message syntax, see the *MIPI Alliance Specification for SLIMbus Version 1.01.00*.

24.9.5.1.6.1 Transmitting Message, Polling Mode

This procedure transmits a message over the SLIMbus without the use of interrupts.

Table 24-681. Message Transmit Procedure, Polling Method

| Step | Register/Bit Field/Programming Model | Value |
|--|---|-------|
| Wait if an ongoing TX message is still in progress. | SLIMBUS_SMT_CONTROL[0] MESSAGE_ENABLE | =0x0 |
| Clear TX message event flags. | SLIMBUS_SMT_INFO[7:0] | 0xBF |
| Load the whole message byte-by-byte, except for the last one. That is, message integrity (MI) and response (MR), which are handled by hardware. The primary integrity (PI) field is computed and overwritten by hardware; thus, write any value for PI. The message cannot be larger than the FIFO size. | SLIMBUS_SMT_MESSAGE[7:0] | 0x-- |
| Initiate the transmit sequence. | SLIMBUS_SMT_CONTROL[0] MESSAGE_ENABLE | 0x1 |
| Check the message outcome by polling the information register bits. Process the event as described in Section 24.9.5.1.7, Event Handling . | SLIMBUS_SMT_INFO Negative response: [3] NACK Positive response: [2] PACK No response: [4] NORE Illegal response: [5] UDEF FIFO overflow: [1] OVERFLOW Transmit collision: [0] MC_TX_COL Message sync loss: [7] ABORT | =0x1 |

24.9.5.1.6.2 Transmitting Message, Interrupt Mode

This procedure transmits a message over the SLIMbus with interrupts enabled.

Table 24-682. Message Transmit Procedure, Interrupt Method

| Step | Register/Bit Field/Programming Model | Value |
|--|--|-------|
| Enable the shared-message-channel transmit interrupts. | SLIMBUS_CMP_IRQENABLE_SET[2] SMT_INFO_EN | 0x1 |
| Clear the interrupt status bit. | SLIMBUS_CMP_IRQSTATUS [2] SMT_INFO | 0x1 |
| The procedure continues without difference from polling mode. The exception is that if any info bit is set, it triggers an interrupt. The interrupt-service-routine then checks which info bit is set. | See Section 24.9.5.1.6.1, Transmitting Message, Polling Mode . | |

24.9.5.1.6.3 Receiving Message, Polling Mode

This procedure reads a received in FIFO message without using interrupts.

Table 24-683. Message Receive Procedure, Polling Method

| Step | Register/Bit Field/Programming Model | Value |
|---|--|-------|
| Check for a received message. | SLIMBUS_SMR_INFO[2] RECEIVED_MESSAGE | =0x1 |
| IF: Message is RECONFIGURE_NOW() | SLIMBUS_SMR_INFO[3] RECEIVED_RECONFIGURE | =0x1 |
| RECONFIGURE_NOW() is hardware-decoded and executed. Software is required only to allow further message reception. | SLIMBUS_SMR_INFO[2] RECEIVED_MESSAGE SLIMBUS_SMR_INFO[3] RECEIVED_RECONFIGURE | 0x1 |
| ELSE | | |

Table 24-683. Message Receive Procedure, Polling Method (continued)

| Step | Register/Bit Field/Programming Model | Value |
|---|--|-------------|
| Read the message byte-by-byte and decode it in parallel. The message size is determined from the message itself, from the arbitration type (AT) and remaining length (RL) fields. Read until message end is reached: (2 bytes if AT = 0xF, or 7 bytes if AT = 0x5) + 1 byte + RL bytes | SLIMBUS_SMR_MESSAGE[7:0] | 0x- |
| Optionally, software can check for FIFO underflow event after every read out. Last byte then must be ignored. The event flag must be cleared by writing 0x1 to it. | SLIMBUS_SMR_INFO[1] UNDERFLOW SLIMBUS_SMR_INFO[1] UNDERFLOW | =0x1 0x1 |
| Allow further message reception. | SLIMBUS_SMR_INFO[2] RECEIVED_MESSAGE | 0x1 |
| ENDIF | | |

24.9.5.1.6.4 Receiving Message, Interrupt Mode

This procedure reads the received in FIFO message by using interrupts.

Table 24-684. Message Receive, Interrupt Method

| Step | Register/Bit Field/Programming Model | Value |
|--|---|-------|
| Enable the shared-message-channel receive interrupts. | SLIMBUS_CMP_IRQENABLE_SET[3] SMR_INFO_EN | 0x1 |
| Clear the interrupt status bit. | SLIMBUS_CMP_IRQSTATUS [3] SMR_INFO | 0x1 |
| Wait for SMR_INFO interrupt. | | |
| Clear the interrupt status bit. | SLIMBUS_CMP_IRQSTATUS [3] SMR_INFO | 0x1 |
| The procedure continues without difference from polling mode. The exception is that any set info bit triggers an interrupt. The interrupt-service-routine then checks to determine which event occurred. | See Section 24.9.5.1.6.3, Receiving Message, Polling Mode . | |

24.9.5.1.6.5 Receiving Data

This procedure reads actual payload data off the FIFO. The data is read one data segment at a time (AUX + data) with no packing mode. Packing allows several small segments to be fit in a single FIFO access. Packing mode is selected through the SLIMBUS_DCR_FIFO_SETUP2_j[31] PACKING bit field.

Table 24-685. Receiving Data, Polling Method

| Step | Register/Bit Field/Programming Model | Value |
|--|---------------------------------------|----------------------|
| Wait for SLIMBUS_DCR_FIFO_SETUP2_j[23:16] DMA_THRESHOLD number of segment words to be available in FIFO. | SLIMBUS_DCR_FIFO_STATUS_j [1] HILEVEL | =0x1 |
| Read SLIMBUS_DCR_FIFO_SETUP2_j[23:16] DMA_THRESHOLD segment words from FIFO. | SLIMBUS_DCR_DATA_j | See ⁽¹⁾ . |
| Additionally, software can check whether no more segments are available to read. | SLIMBUS_DCR_FIFO_STATUS_j [0] EMPTY | =0x1 |

⁽¹⁾ Segment word size varies between 1 and 8 slots (4 and 32 bits). Segments can be in packed or nonpacked mode.

The following procedure uses an interrupt method to receive data.

Table 24-686. Receiving Data, Interrupt Method

| Step | Register/Bit Field/Programming Model | Value |
|---|---|--------------------|
| Enable the data receive interrupt. Write 0x1 for the required data agent. | SLIMBUS_CMP_IRQENABLE_SET | 0x1 |
| Clear the corresponding interrupt status bit. | SLIMBUS_CMP_IRQSTATUS | 0x1 |
| Wait for interrupt. | | |
| Check the high-level info bit. | SLIMBUS_DCR_INFO_j [3] HILEVEL | =0x1 |
| Clear the interrupt status bit of the data agent. | SLIMBUS_CMP_IRQSTATUS | 0x1 |
| Read SLIMBUS_DCR_FIFO_SETUP2_j [23:16] DMA_THRESHOLD segment words from FIFO. | SLIMBUS_DCR_DATA_j | See ⁽¹⁾ |
| Additionally, software can check whether no more segments are available to read. | SLIMBUS_DCR_FIFO_STATUS_j [0] EMPTY | =0x1 |
| Clear the high-level info bit. | SLIMBUS_DCR_INFO_j [3] HILEVEL | 0x1 |

⁽¹⁾ Segment word size varies between 1 and 8 slots (4 and 32 bits). Segments can be in packed or nonpacked mode.

This procedure enables DMA request generation to the sDMA or aDMA engine, which must be configured in advance. DMA request starts whenever the threshold condition is met. DMA request stops after a certain number of nonempty read accesses to the FIFO are complete. This size typically corresponds to a DMA burst and in the [SLIMBUS_DCR_FIFO_SETUP1_j](#)[4:1] DMA_REQ_SIZE bit field.

Table 24-687. Receiving Data, DMA Enable

| Step | Register/Bit Field/Programming Model | Value |
|---|--|-------|
| Set DMA request size (for precise DMA mode). | SLIMBUS_DCR_FIFO_SETUP1_j [4:1] DMA_REQ_SIZE | 0x- |
| Enable the data receive DMA requests. Write 0x1 for the required RX data agent. | SLIMBUS_CMP_DMAENABLE_SET | 0x1 |

24.9.5.1.6.6 Transmitting Data

This procedure loads actual payload data into the FIFO. The data is loaded one data segment at a time (AUX + data), when packing mode is not used. Packing allows several small segments to be fit into a single FIFO access. Packing mode is selected through the [SLIMBUS_DCT_FIFO_SETUP2_j](#)[31] PACKING bit field.

Table 24-688. Transmitting Data, Polling Method

| Step | Register/Bit Field/Programming Model | Value |
|--|---|--------------------|
| Wait for SLIMBUS_DCT_FIFO_SETUP2_j [23:16] DMA_THRESHOLD number of free segment words. | SLIMBUS_DCT_FIFO_STATUS_j [1] LOLEVEL | =0x1 |
| Write SLIMBUS_DCR_FIFO_SETUP2_j [23:16] DMA_THRESHOLD segment words to FIFO. | SLIMBUS_DCT_DATA_j | See ⁽¹⁾ |
| Additionally, software can check whether no more FIFO space is available to write. | SLIMBUS_DCT_FIFO_STATUS_j [0] FULL | =0x1 |

⁽¹⁾ Segment word size varies between 1 and 8 slots (4 and 32 bits). Segments can be in packed or nonpacked mode.

The following procedure uses an interrupt method to transmit data.

Table 24-689. Transmitting Data, Interrupt Method

| Step | Register/Bit Field/Programming Model | Value |
|--|---|-------|
| Enable the data transmit interrupt. Write 0x1 for the required data agent. | SLIMBUS_CMP_IRQENABLE_SET | 0x1 |
| Clear the corresponding interrupt status bit. | SLIMBUS_CMP_IRQSTATUS | 0x1 |
| Wait for interrupt. | | |

Table 24-689. Transmitting Data, Interrupt Method (continued)

| Step | Register/Bit Field/Programming Model | Value |
|---|--|--------------------|
| Check the low-level info bit. | SLIMBUS_DCT_INFO_j [3] LOLEVEL | =0x1 |
| Clear the interrupt status bit of the data agent. | SLIMBUS_CMP_IRQSTATUS | 0x1 |
| Read SLIMBUS_DCT_FIFO_SETUP2_j [23:16] DMA_THRESHOLD segment words from FIFO. | SLIMBUS_DCT_DATA_j | See ⁽¹⁾ |
| Additionally, software can check if no more space is available to write | SLIMBUS_DCT_FIFO_STATUS_j [0] FULL | =0x1 |
| Clear the low-level info bit. | SLIMBUS_DCT_INFO_j [3] LOLEVEL | 0x1 |

⁽¹⁾ Segment word size varies between 1 and 8 slots (4 and 32 bits). Segments can be in packed or nonpacked mode.

This procedure enables DMA request generation to the sDMA or aDMA engine, which must be configured in advance. DMA request starts whenever the threshold condition is met. DMA requests stops after a certain number of nonempty read accesses to the FIFO are complete. This size typically corresponds to a DMA burst and in the [SLIMBUS_DCT_FIFO_SETUP1_j](#)[4:1] DMA_REQ_SIZE bit field.

Table 24-690. Transmitting Data, DMA Enable

| Step | Register/Bit Field/Programming Model | Value |
|---|--|-------|
| Set DMA request size (for presize DMA mode). | SLIMBUS_DCT_FIFO_SETUP1_j [4:1] DMA_REQ_SIZE | 0x- |
| Enable the data receive DMA requests. Write 0x1 for the required TX data agent. | SLIMBUS_CMP_DMAENABLE_SET | 0x1 |

24.9.5.1.7 Event Handling

Events must be serviced in the following way:

1. Clear the interrupt status bit (if interrupts are enabled).
2. Read the relative information register to determine the event.
3. Process the event as required. See [Section 24.9.4.11.1, Interrupt Requests](#).
4. When needed and allowed, clear the information register bit(s). For example, it is not necessary to clear the [SLIMBUS_SMR_INFO](#)[2] RECEIVED_MESSAGE bit until the message is read, decoded, and executed, as it will allow the reception of other messages.

24.9.6 SLIMbus Register Manual

24.9.6.1 SLIMbus Register Overview

The registers described in this section are prefixed with one of the following:

- **CMP:** Component- (that is, module) level control and status.
- **SMT:** Shared Messages Transmit: All messages transmitted to the serial SLIMbus interface. This resource is shared by all devices within the component (all devices can transmit messages).
- **SMR:** Shared Messages Receive: All messages received from the serial SLIMbus interface. This resource is shared by all devices within the component (all devices can receive messages).
- **FL:** Frame Layer status and control. The frame layer is the hardware-implemented protocol layer located just above the physical layer, and shared by all devices of a component.
- **FR:** Framer device-specific status and control. The framer device is one of the component's devices (logical entities of the SLIMbus); exactly one framer device may optionally be implemented in each SLIMbus component. Note that the framer device is not always active (in which case the related registers aren't used either), and that some of the framer's control and status is shared with the (always-present, always-active) interface device.
- **DEV:** Device control and status. The same register structure is repeated as many times as there are devices supported by the component (that is, the module), including the (compulsory) interface device, the framer device (optional), the manager device (optional), and the generic devices (optional, one or several instances).
- **DCT:** Data Channel Transmit: The same register structure is repeated as many times as there are transmit data channels supported, that is, FIFOs and associated logic. Devices (typically generic devices) are associated to a data channel for the transmissions of data towards the SLIMbus serial interface.
- **DCR:** Data Channel Receive: The same register structure is repeated as many times as there are receive data channels supported, that is, FIFOs and associated logic. Devices (typically generic devices) are associated to a data channel for the reception of data from the SLIMbus serial interface.

24.9.6.2 SLIMbus Instance Summary

Table 24-691 shows the base address and address space for the SLIMbus module instances.

Table 24-691. SLIMbus Instance Summary

| Module Name | Base Address L3 Interconnect | Base Address Cortex-A9 Private Access | Base Address DSP Private Access | Size |
|-------------|---------------------------------|--|------------------------------------|------|
| SLIMBUS1 | 0x4902 C000 | 0x4012 C000 | 0x2 C000 | 4 KB |
| SLIMBUS2 | 0x4807 6000 | - | - | 4 KB |

NOTE: Private Access is an access which is not using the L3/L4 interconnects.

24.9.6.3 SLIMbus Registers

24.9.6.3.1 SLIMBUS1 Register Summary

Table 24-692. SLIMBUS1 Register Mapping Summary

| Register Name | Type | Register Width (Bits) | Address Offset | Physical Address L3 Interconnect | Physical Address Cortex-A9 Private Access | Physical Address DSP Private Access |
|---------------------------------------|------|-----------------------------|----------------|--|--|---|
| SLIMBUS_CMP_REVISION | R | 32 | 0x0000 0000 | 0x4902 C000 | 0x4012 C000 | 0x2 C000 |
| SLIMBUS_CMP_HWINFO | R | 32 | 0x0000 0004 | 0x4902 C004 | 0x4012 C004 | 0x2 C004 |

- [SLIMBUS2 Register Summary: \[1\]](#)

Table 24-696. SLIMBUS_CMP_HWINFO

| | | | |
|-------------------------|--|-----------------|--|
| Address Offset | 0x0000 0004 | | |
| Physical Address | 0x4902 C004 0x4012 C004 0x2 C004 0x4807 6004 | Instance | SLIMBUS1_L3 SLIMBUS1_CORTEX-A9 SLIMBUS1_DSP SLIMBUS2_L3 |
| Description | Those read-only, hardcoded fields display the values of the eponymous hardware configuration depending on module instantiation - SLIMBUS1 or SLIMBUS2. | | |
| Type | R | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|-----|----|----|----|-----|----|----|----|-----|----|----|----|------|----|----|----|------|----|----|----|-----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| DEV | | | | TDC | | | | RDC | | | | RRSZ | | | | TRSZ | | | | PSZ | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|----------------------------------|
| 31:28 | DEV | Device count: number of devices supported by the component, most notably through the automatic reception of the messages addressed to them. Sets the number of instances of the "DEV_XYZ" registers. | R | 0x7 |
| 27:24 | TDC | Transmit Data agent Count: Number of transmit hardware data agents (FIFO and associated logic) Sets the number of instances of the "DCT_XYZ" registers. | R | See Table 24-698 |
| 23:20 | RDC | Receive Data agent Count: Number of receive hardware data agents (FIFO and associated logic) Sets the number of instances of the "DCR_XYZ" registers. | R | See Table 24-698 |
| 19:12 | RRSZ | Size of receive FIFO RAM, in 32-bit words. RX message FIFO and all RX data FIFOs map to that shared RAM. | R | See Table 24-698 |
| 11:4 | TRSZ | Size of transmit FIFO RAM, in 32-bit words. TX message FIFO and all TX data FIFOs map to that shared RAM. | R | See Table 24-698 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-------|
| 3:0 | PSZ | Size of (both TX and RX) FIFO segment word pointers, in bits. Determines the maximum number of (variable-sized) segment words a data agent FIFO can contain. Sets the width of FIFO control and status fields: size, threshold, level. | R | 0x8 |

| Bits | Field Name | Description | Type | Reset |
|------|----------------|---|------|----------|
| 31:9 | RESERVED | | R | 0x000000 |
| 8 | VALIDATE_DCMAP | Validates the mapping of data channels on devices: to be used after modifying the DC*_MAP* fields (DI and PN). Write 0x0: No action Write 0x1: Validates all DCT_MAP / DCR_MAP values | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|-----------------------|--|------|-------|
| 7 | CLEAR_RECONFIGURATION | Clear all updates cumulated since the last reconfiguration, return reconfiguration fields to currently active value. Self-cleared immediately. Write 0x0: No action Write 0x1: Clear reconfiguration | RW | 0 |
| 6 | BUS_SHUTDOWN | Sets both the clock source or the clock receiver FSMs back to "Undefined" state at the next reconfiguration boundary. Executed (and bit self-cleared) on next reconfiguration (forced or not); also cleared by a "clear_reconfiguration". Write 0x0: Cancel pending request (not used in normal operation) if any, otherwise no action Write 0x1: Assert request for next reconfiguration Read 0x1: Request pending for next reconfiguration Read 0x0: No request pending for next reconfiguration | RW | 0 |
| 5 | KILL_FS | Force immediate Frame Synchronization loss (implying as well message and superframe sync) When in "Operational", "SeekingMessageSync" or "SeekingSuperFrameSync" states, component shall go to "SeekingFrameSync" and start reaquiring frame sync. No effect otherwise. For debug use. Write 0x0: No action Write 0x1: Force frame sync loss Read 0x0: Always reads 0 because of immediate action. | RW | 0 |
| 4 | KILL_SFS | Force SuperFrame Synchronization loss at next reconfiguration boundary (implying as well message sync loss). When in "Operational" or "SeekingMessageSync" states, component shall go to "SeekingSuperFrameSync" and start reaquiring superframe sync. No effect otherwise. Used by clock receiver component upon imcompletely received reconfiguration sequence. Write 0x0: No action Write 0x1: Schedule superframe sync loss Read 0x1: Superframe sync loss pending Read 0x0: No pending superframe sync loss | RW | 0 |
| 3 | KILL_MS | Force an immediate Message Synchronization loss. When in "Operational" state, component shall go to "SeekingMessageSync" and start reaquiring message sync. No effect otherwise. For debug use. Write 0x0: No action Write 0x1: Force message sync loss Read 0x0: Always reads 0 because of immediate action. | RW | 0 |
| 2 | FORCE_RECONFIGURE | Force a reconfiguration boundary at next superframe boundary, rather than wait for a RECONFIGURE_NOW() message. Write 0x0: Cancel pending request (not used in normal operation) if any, otherwise no action Write 0x1: Assert reconfiguration request for next superframe boundary Read 0x1: Reconfiguration request pending for next superframe boundary Read 0x0: No request pending | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|-----------------|--|------|-------|
| 1 | COMPONENT_RESET | Component reset request control: Transitions clock receiver FSM to state "Reset" (from any other state). Immediate action. Set upon reception of the RESET_DEVICE() message by the interface device, which requires a component-level reset. Note that a component-level reset is also required in case of bus reset, but the transition to "Reset" state happens automatically in that case and this bit is not used. Write 0x1: Assert request for next reconfiguration | RW | 0 |
| 0 | BOOT | Boot the component when not in active framer mode (don't care when in active framer mode). Transitions clock receiver FSM from state "Undefined" to "Reset". 0x0: No action 0x1: Enable clock receiver boot sequence | RW | 0 |

| 31:2 | RESERVED | | R | 0x0000 0000 |
| 1 | BUS_RESET | Bus reset request control, when framer is already active. Set upon reception of the NEXT_RESET_BUS() message. Transitions clock source FSM to state "StartingClock" (from "Operational"). Write 0x0: Cancel pending request (not used in normal operation) if any, otherwise no action Write 0x1: Assert request for next reconfiguration Read 0x1: Request pending for next reconfiguration Read 0x0: No request pending for next reconfiguration | RW | 0 |
| 0 | BOOT | Initiate an active framer (clock source) boot sequence for the component, that is, when component is default active framer. Transitions clock source FSM from state "Undefined" to "CheckingDataLine". Transitions clock receiver FSM from state "Undefined" to "Reset". No effect if bus has already booted. Write 0x0: Cancel pending request (not used in normal operation) if any, otherwise no action Write 0x1: Assert request for next reconfiguration Read 0x1: Request pending for next reconfiguration Read 0x0: No request pending for next reconfiguration | RW | 0 |

| ENABLE | | CTS_LAST_VALUE | | RESERVED | | DT_LPCM | | RESERVED | | | | | | | | AF | | | | CL | | DL | | | | | | SL | | | | | | TP_QUALIFIER | | TP | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|----------------|---|------|-------|
| 31 | ENABLE | Data agent enabling control. Auto-cleared upon frame or superframe sync loss. Read 0x1: Data agent is enabled Read 0x0: Data agent is disabled | RW | 0 |
| 30 | CTS_LAST_VALUE | Last received value of the CTS TAG bit. Only updated for asynchronous TP, when primary owner (that is, transmitter) of the channel. Read 0x1: Local sink signals TAG.CTS=1 that is, it can receive data (and remote source can transmit some) Read 0x0: Local sink signals TAG.CTS=0 that is, it cannot receive any data (and remote source shall not transmit any) | R | 0 |
| 29 | RESERVED | | R | 0 |
| 28 | DT_LPCM | Unsigned-to-OSAM encoding enable for Data Type (DT) = LPCM audio (0x1) 0x0: DT!=0x1: encoding disabled 0x1: DT=0x1: encoding enabled | RW | 0 |
| 27:20 | RESERVED | | R | 0x00 |
| 19:16 | AF | Auxilliary Format (AF) used in segment word size calculation. Non-zero values not supported in extended asynchronous TPs. 0xF: User-defined 8-bit AUX (2 AUX slot per segment) 0x0: No AUX information (0 AUX slots per segment) 0x1: ZCUV for tunneling IEC60958 (1 AUX slot per segment) 0xB: User-defined 4-bit AUX (1 AUX slot per segment) | RW | 0x0 |
| 15 | CL | Channel Link (CL) enable: Pairing up of current channel with previous one (that is, channel index below) Tied-0, read-only field for channel index 0, since there is no "previous" channel in that case. TP and segment interval (encoded in SD) must be equal between the linked channels. 0x0: Current channel independent from previous one. 0x1: Current channel paired up with previous one. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|--------------|---|------|-------|
| 14:10 | DL | <p>Segment Data Length (DL), in 4-bit slots (except when 0). AUX + DATA length shall fit in a segment word, that is, 1 to 32 bits.</p> <p>In extended async TPs, sets segment word size (0 and odd values illegal) instead.</p> <p>0x6: 6 slots (24 bits)</p> <p>0x1: 1 slot (4 bits)</p> <p>0x7: 7 slots (28 bits), requiring at most 1 AUX slot to fit in max-size 32-bit segment word</p> <p>0x0: Length not indicated: Segment slots that are not TAG or AUX are DATA (that is, no unused slot)</p> <p>0x2: 2 slots (8 bits)</p> <p>0x8: 8 slots (32 bits), requiring zero AUX slot, to fit in a max-size 32-bit segment word</p> <p>0x4: 4 slots (16 bits)</p> <p>0x5: 5 slots (20 bits)</p> <p>0x3: 3 slots (12 bits)</p> | RW | 0x00 |
| 9:5 | SL | <p>total Segment Length (SL), in 4-bit slots.</p> <p>SL = TAG length + AUX length + DATA length</p> <p>0x0: Reserved value</p> | RW | 0x00 |
| 4 | TP_QUALIFIER | <p>Qualifier for plain/extended half-duplex asynchronous TPs (owner ID).</p> <p>Unused and don't care for other TPs.</p> <p>0x0: 1/2 duplex TPs: Local device is primary channel owner, uses T1 token</p> <p>0x1: 1/2 duplex TPs: Local device is secondary channel owner, uses T2 token</p> | RW | 0 |
| 3:0 | TP | <p>Transport Protocol (TP)</p> <p>Determines also the TAG length (from 0 to 2 slots).</p> <p>0x6: Extended asynchronous-half-duplex (unicast, 2-slot TAG)</p> <p>0x1: Pushed (multicast, 1-slot TAG)</p> <p>0x7: Extended asynchronous-simplex (unicast, 2-slot TAG)</p> <p>0x0: Isochronous (multicast, no TAG)</p> <p>0x2: Pulled (unicast, 1-slot TAG)</p> <p>0x4: Asynchronous-simplex (unicast, 1-slot TAG)</p> <p>0x5: Asynchronous-half-duplex (unicast, 1-slot TAG)</p> <p>0xF: User-defined protocol 2 NOT SUPPORTED, RESERVED VALUE</p> <p>0x3: Locked (multicast, no TAG) NOT SUPPORTED, RESERVED VALUE</p> <p>0xE: User-defined protocol 1 NOT SUPPORTED, RESERVED VALUE</p> | RW | 0x0 |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|--------------|---|------|--------|
| 31 | COUNT_EN | <p>Down-counter mode control. Only applicable in precise DMA mode.</p> <p>Write 0x0: Disable down-counter mode. Should typically be used only when ACC_CNT = 0. If ACC_CNT 0, DMA request gets deasserted immediately.</p> <p>Write 0x1: Enable down-counter mode. ACC_CNT is typically set to the desired value in the same write access.</p> <p>Read 0x1: Down-counter mode is enabled: DMA request can only be active when ACC_CNT 0</p> <p>Read 0x0: Down-counter mode is disabled: DMA request follows FIFO level, and is active during no-transmission periods.</p> | RW | 0 |
| 30:16 | ACC_CNT | <p>"Packet mode" down-counter of segment words, decremented on DCR_DATA read accesses. In that mode, DMA request shall reassert when ACC_CNT = RD_LEVEL (that is, whole packet received).</p> <p>Write 0x0: Deasserts current DMA request by forcing the count to zero (not typical operation)</p> <p>Write 0x7F: Set largest packet size (in accesses) to transfer before DMA request deassertion. Any lower value is also valid to enter.</p> <p>Read 0x7F: Maximum number of accesses still to be transferred before DMA deassertion. Unless interrupted, counter shall go through all values down to zero.</p> <p>Read 0x0: No access left to transfer, DMA request currently inactive.</p> | RW | 0x0000 |
| 15 | IMPRECISE_EN | <p>Precise vs. Imprecise DMA requesting mode control. (A DMA request is a single assertion-deassertion cycle.)</p> <p>0x0: DMA request contains a defined number of accesses</p> <p>0x1: DMA request is not expected to trigger a fixed number of accesses</p> | RW | 0 |
| 14:11 | RESERVED | | R | 0x0 |
| 10:2 | RD_LEVEL | <p>Number of segment words stored in FIFO, that can be read out.</p> <p>Read 0x100: FIFO is full of readable words (assuming maximum size)</p> <p>Read 0x0: FIFO contains no readable word</p> | R | 0x000 |
| 1 | HILEVEL | <p>Indicator of read level (RD_LEVEL: number of readable segment words) with respect to (read) threshold (DMA_THRESHOLD). Activates DMA read requests when high.</p> <p>Read 0x1: RD_LEVEL DMA_THRESHOLD</p> <p>Read 0x0: RD_LEVEL = DMA_THRESHOLD</p> | R | 0 |
| 0 | EMPTY | <p>FIFO empty indicator</p> <p>Read 0x1: FIFO contains no readable word (RD_LEVEL = 0)</p> <p>Read 0x0: FIFO contains at least one readable word (RD_LEVEL 0)</p> | R | 1 |

24.10 MIPI-HSI

This section describes the MIPI high-speed synchronous serial interface (HSI).

24.10.1 HSI Overview

The MIPI HSI module is a multichannel and full-duplex serial communications interface, composed of two transmitters (HST) in charge of the transmitted information and two receivers (HSR) in charge of the received information, sharing a 16-channel DMA.

The HSI peripheral is typically used to enable the device to exchange information with an external cellular modem.

Figure 24-217 is an overview of the HSI module.

Figure 24-217. HSI Overview

HSI supports the following features:

- Full duplex
- No static clock matching
- Interface speed up to 192 Mbps on transmitter and up to 225 Mbps on receiver
- Transmission speed and operation mode dynamically configurable
- Logical channels:
 - Up to 16 logical channels on receiver
 - Up to 16 logical channels on transmitter
- One 32-request DMA engine:
 - 16 transmit + 16 receive requests from HSI port

- 16 logical DMA channels
- Interrupt requests:
 - Three to each processor subsystem (two from HSI port, one from DMA)

24.10.2 HSI Environment

This section describes the HSI application fields from an environment point of view (external connections).

24.10.2.1 HSI Signals

[Table 24-791](#) describes the HSI module I/O signals.

Table 24-791. HSI I/O Signals

| Pin Name | I/O ⁽¹⁾ | Description | Reset Value ⁽²⁾ |
|--------------|--------------------|---|----------------------------|
| hsi1_cawake | I | HSI port 1 wake-up signal from an external serial transmitter | hi-Z |
| hsi1_cadata | I | HSI port 1 receiver data from an external transmitter | hi-Z |
| hsi1_caflag | I | HSI port 1 receiver flag from an external transmitter | hi-Z |
| hsi1_acready | O | HSI port 1 synchronization signal to an external transmitter | 1 |
| hsi1_acwake | O | HSI port 1 wake-up signal to an external serial receiver | 0 |
| hsi1_acdata | O | HSI port 1 transmission data (level transmission signaling) to an external receiver | 0 |
| hsi1_acflag | O | HSI port 1 transmission flag (bit transition signaling) to an external receiver | 1 |
| hsi1_caready | I | HSI port 1 synchronization signal from an external receiver | hi-Z |
| hsi2_cawake | I | HSI port 2 wake-up signal from an external serial transmitter | hi-Z |
| hsi2_cadata | I | HSI port 2 receiver data from an external transmitter | hi-Z |
| hsi2_caflag | I | HSI port 2 receiver flag from an external transmitter | hi-Z |
| hsi2_acready | O | HSI port 2 synchronization signal to an external transmitter | hi-Z |
| hsi2_acwake | O | HSI port 2 wake-up signal to an external serial receiver | hi-Z |
| hsi2_acdata | O | HSI port 2 transmission data (level transmission signaling) to an external receiver | hi-Z |
| hsi2_acflag | O | HSI port 2 transmission flag (bit transition signaling) to an external receiver | hi-Z |
| hsi2_caready | I | HSI port 2 synchronization signal from an external receiver | hi-Z |

⁽¹⁾ I = input; O = output; I/O = Bidirectional

⁽²⁾ hi-Z = High impedance

24.10.2.2 HSI Typical Application

Figure 24-218 shows the HSI typical application.

Figure 24-218. HSI Typical Application

hsi-002

24.10.3 HSI Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 24-219 shows the HSI module integration.

Figure 24-219. HSI Integration

NOTE: For more information about the IDLE/STANDBY hardware handshake and the wake-up request, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Interrupt lines HSI_P1_MPU_IRQ and HSI_P2_MPU_IRQ are shared between the Cortex-A9 MPU and Cortex-M3 MPU INTCs. It is strongly recommended to unmask each interrupt source in only one INTC at a time.

[Table 24-792](#) through [Table 24-794](#) summarize the integration of the module in the device.

Table 24-792. Integration Attributes

| Module Instance | Attributes | | |
|-----------------|--------------|--------------------|--------------|
| | Power Domain | Wake-Up Capability | Interconnect |
| HSI | PD_L3_INIT | NA | L3 L4_CFG |

Table 24-793. Clocks and Resets

| | HSI_P2_MPU_IRQ ⁽¹⁾ | MA_IRQ_68 | Cortex-A9 | HSI MPU request – Port 2 |
| No DMA Requests | | | | |

⁽¹⁾ Interrupts shared between the Cortex-A9 MPU INTC and Cortex-M3 MPU INTC

NOTE: For a description of interrupt sources, see [Section 24.10.4.5, Interrupt Requests](#).

24.10.4 HSI Functional Description

NOTE: In the functional description section, the following common internal signal names are used for the corresponding external HSI signals (for simplification):

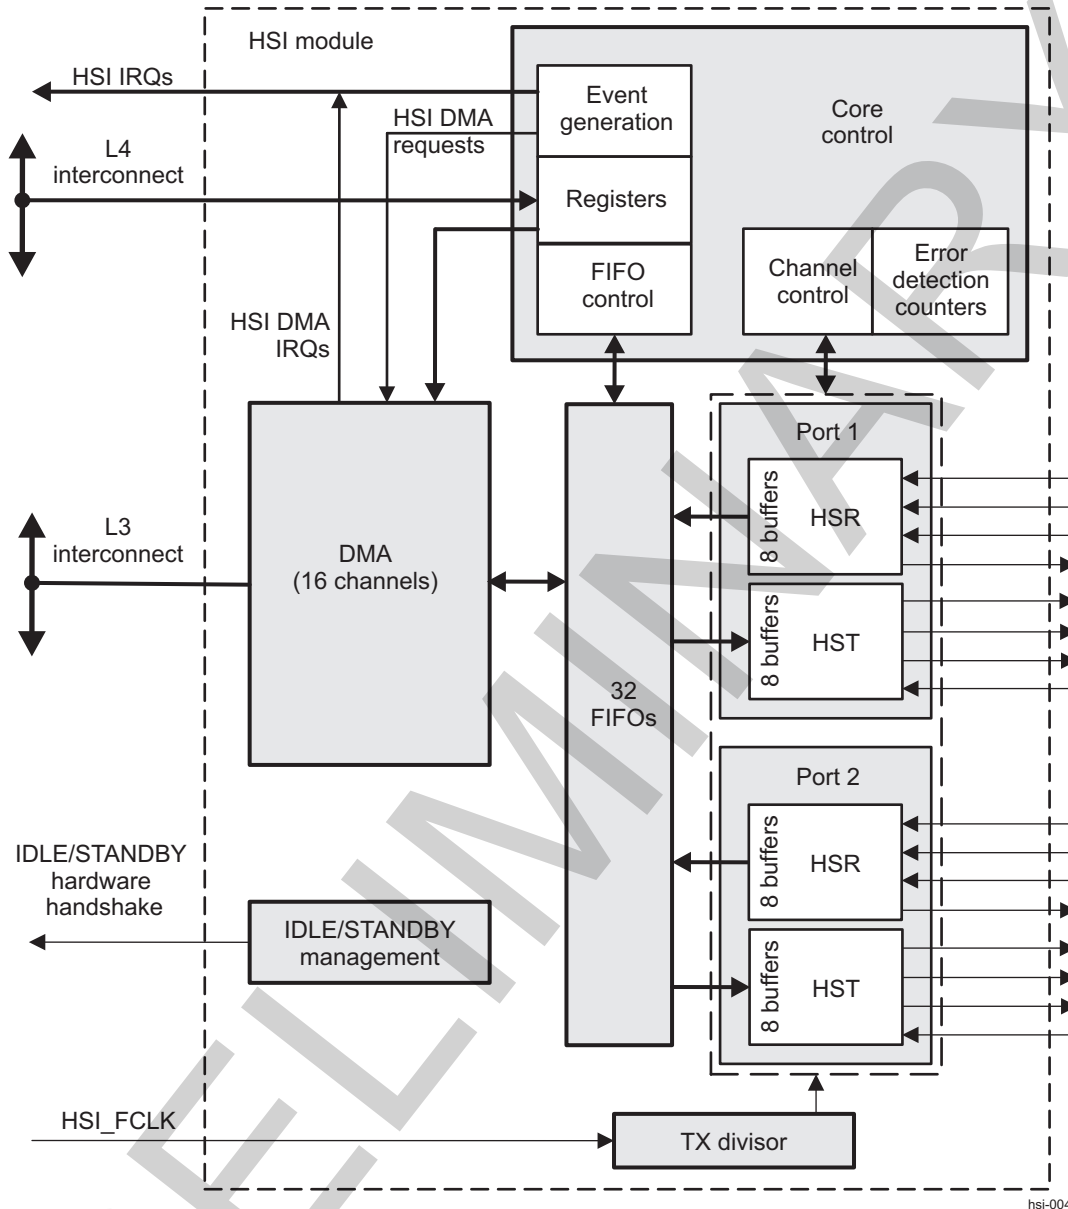

- WAKE: hsi1_cawake, hsi1_acwake, hsi2_cawake, and hsi2_acwake
 - DATA: hsi1_cadata, hsi1_acdata, hsi2_cadata, and hsi2_acdata
 - FLAG: hsi1_caflag, hsi1_acflag, hsi2_caflag, and hsi2_acflag
 - READY: hsi1_acready, hsi1_caready, hsi2_acready, and hsi2_caready
-

24.10.4.1 Block Diagram

The HSI controller is a subsystem built around two full-duplex multichannel synchronous serial interfaces. It contains a 16-bidirectional-logical-channel DMA in charge of handling data transfers between HSI modules and the L3 interconnect. Interrupt access to data is also available.

NOTE: Transmit data cannot be read back, and received data cannot be written in DMA and IRQ-based transfers.

[Figure 24-220](#) shows most HSI module features.

Figure 24-220. HSI Controller Architecture Overview

hsi-004

NOTE: A bypass path in the DMA allows a processor (MPU or DSP) to retrieve or provide data received or to be transmitted on an interrupt triggered access, when the DMA is not enabled.

24.10.4.2 Clock Configuration

The HSI module has four fully asynchronous clock domains:

- Interface clock domain
- Functional clock domain
- Receive clock domain on port 1
- Receive clock domain on port 2

24.10.4.2.1 Interface Clock Domain

The following clocks are part of the interface clock domain:

- HSI_DMA_ICLK runs the interface master port (L3). This clock is used for DMA master access to the L3 interconnect and also serves as the DMA functional clock.
- HSI_ICLK runs the interface slave port (L4). This clock is used to configure the module and to transmit and receive data through register access in an interrupt-based manner.

24.10.4.2.2 Functional Clock Domain

The functional clock (HSI_FCLK) runs the transmitter/receiver logic.

24.10.4.2.2.1 Transmit Clock

The transmit clock is obtained from the functional clock and is used to generate transmitter DATA and FLAG lines, according to the standard. Namely, the DATA line must always reflect the transmitted bit value, whereas the FLAG line must provide a transition (0 to 1, or 1 to 0) when the current DATA value is the same as the previous one.

The transmit data rate is programmable through the [HST_DIVISOR_Pp\[7:0\]](#) TX_RATE_DIV_VAL bit field.

Transmit clock = HSI_FCLK / (TX_RATE_DIV_VAL + 1).

24.10.4.2.2.2 Receive Error Detection Counters Clocks

The functional clock is also used to obtain clocks for receive error counters, which are independently divided versions of the functional clock. Division is set by software through the [HSR_DIVISOR_Pp\[7:0\]](#) RX_RATE_DIV_VAL bit field, which sets the bit rate clock for the frame time-out counter. This clock is further divided to generate an edge per frame to be sent to the frame burst counter.

24.10.4.2.3 Receive Clock Domain (Port 1 and Port 2)

The RX clock is retrieved from the DATA and FLAG signals available on the serial interface. A self-clocked source synchronous receiver implementation is done as follows: simple XOR of the DATA and FLAG signals recovers a signal displaying a transition on every bit time. From this signal, two clocks are generated with the appropriate phase, which can recover bit values, by sampling the DATA line, where the transmitted bit is always available.

24.10.4.3 Software Reset

The HSI module can be reset by software through the [HSI_SYSCONFIG\[1\]](#) SOFTRESET bit. Setting this bit to 1 enables an active global software reset that is functionally equivalent to a hardware reset. The [HSI_SYSSTATUS\[0\]](#) RESETDONE bit indicates that the software reset is complete when its value is set to 1. Software must ensure that the software reset completes before performing HSI operations.

The DMA engine can be independently reset by software through the [DMA_GRST\[0\]](#) SWRESET bit. Setting this bit to 1 resets the DMA registers and logic. This bit is automatically cleared when the DMA reset completes.

24.10.4.4 Power Management

[Table 24-795](#) describes power-management features available for the HSI module.

NOTE: For descriptions of IdleMode and StandbyMode features, see [Section 3.1.1.1.2](#), *Module-Level Clock Management*, in [Chapter 3](#), *Power, Reset, and Clock Management*.

Table 24-795. Local Power-Management Features

| Feature | Registers | Description |
|----------------------|--|--|
| Clock auto gating | HSI_SYSCONFIG [0] AUTOIDLE DMA_GCR [3] AUTOGATING | This bit allows a local power optimization inside the module by gating the HSI_ICLK clock upon the interface activity. This bit allows a local power optimization inside the module by gating the HSI_DMA_ICLK clock upon the interface activity. |
| Slave idle modes | HSI_SYSCONFIG [4:3] SIDLEMODE | Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available. |
| Master standby modes | HSI_SYSCONFIG [13:12] MIDLEMODE | Force-standby, no-standby, smart-standby, and smart-standby wake-up modes are available. |

24.10.4.4.1 HSI Module Power-Management Modes

24.10.4.4.1.1 Standby

When asserted, this signal informs the PRCM module that HSI is quiet and does not generate any traffic on the interconnect.

The HSI module supports four STANDBY handshake modes, selected through the [HSI_SYSCONFIG](#)[13:12] MIDLEMODE bit field:

- Force-standby (0x0): Selecting this mode asserts the standby signal unconditionally of the HSI activity. Software must ensure that HSI is disabled and does not generate any activity before activating this mode.
- No-standby (0x1): Standby signal is never asserted.
- Smart-standby (0x2): Standby signal is asserted when internal HSI DMA does not generate activity anymore (namely, upon DMA idle acknowledge signal assertion).
- Smart-standby wakeup (0x3): Standby signal is asserted when internal HSI DMA does not generate activity anymore (namely, upon DMA idle acknowledge signal assertion). It can also generate a wake-up request.

24.10.4.4.1.2 Idle

The PRCM module asserts an IDLE request signal when it requires the HSI slave port to be idled. Any access to this port after the IDLE request signal has been asserted generates an error.

The HSI module supports four IDLE handshake modes, selected through the [HSI_SYSCONFIG](#)[4:3] SIDLEMODE bit field:

- Force-idle (0x0): An IDLE request is acknowledged unconditionally.
- No-idle (0x1): An IDLE request is never acknowledged.
- Smart-idle (0x2): Acknowledgment to an IDLE request is given based on the internal HSI module activity.
- Smart-idle wakeup (0x3): Acknowledgment to an IDLE request is given based on the internal HSI module activity. Additionally, when in this mode, the HSI module is allowed to generate a wake-up request.

24.10.4.4.1.3 Auto-Idle

The HSI module provides an auto-idle option for the interface clock domain. Auto-idle mode is enabled by setting the [HSI_SYSCONFIG](#)[0] AUTOIDLE and/or [DMA_GCR](#)[3] AUTOGATING bits to 1. When this mode is enabled and there is no activity on the interconnect interface, the interface clock is disabled internally to the module to reduce power consumption. When there is new activity on the interconnect interface, the interface clock is restarted without any latency penalty.

24.10.4.4.1.4 DMA Engine Switch Off Mode

The DMA interface clock (HSI_DMA_ICLK) can be switched off by setting the [DMA_GCR\[0\] SWITCH_OFF](#) bit to 1. DMA clock activity is then cut off. Software must ensure that ongoing transitions are complete before cutting off clocks. Once the DMA is switched off, access to reset this bit is possible only through the configuration port.

24.10.4.5 Interrupt Requests

[Table 24-796](#) lists the event flags, and their mask, that can cause module interrupts.

Table 24-796. Events

| Event Flag | Event Mask | Map to | Description |
|---|---|----------------------------------|--|
| HSI_Pp_M_IRQrU_STATUS [26] HSR_WAKE | HSI_Pp_M_IRQrU_ENABLE [26] HSR_WAKE | HSI_P1_MPU_IRQ HSI_P2_MPU_IRQ | Wake detected on any channel 8–15. |
| HSI_Pp_D_IRQrU_STATUS [26] HSR_WAKE | HSI_Pp_D_IRQrU_ENABLE [26] HSR_WAKE | HSI_P1_DSP_IRQ HSI_P2_DSP_IRQ | |
| HSI_Pp_M_IRQrU_STATUS [25] HSR_BREAK | HSI_Pp_M_IRQrU_ENABLE [25] HSR_BREAK | HSI_P1_MPU_IRQ HSI_P2_MPU_IRQ | Break detected on any channel 8–15. |
| HSI_Pp_D_IRQrU_STATUS [25] HSR_BREAK | HSI_Pp_D_IRQrU_ENABLE [25] HSR_BREAK | HSI_P1_DSP_IRQ HSI_P2_DSP_IRQ | |
| HSI_Pp_M_IRQrU_STATUS [24] HSR_ERROR | HSI_Pp_M_IRQrU_ENABLE [24] HSR_ERROR | HSI_P1_MPU_IRQ HSI_P2_MPU_IRQ | Error detected on any channel 8–15 |
| HSI_Pp_D_IRQrU_STATUS [24] HSR_ERROR | HSI_Pp_D_IRQrU_ENABLE [24] HSR_ERROR | HSI_P1_DSP_IRQ HSI_P2_DSP_IRQ | |
| HSI_Pp_M_IRQrU_STATUS [23:16] HSR_OVERRUN_CHI | HSI_Pp_M_IRQrU_ENABLE [23:16] HSR_OVERRUN_ENI | HSI_P1_MPU_IRQ HSI_P2_MPU_IRQ | Data overrun in real time mode on any channel 8–15 |
| HSI_Pp_D_IRQrU_STATUS [23:16] HSR_OVERRUN_CHI | HSI_Pp_D_IRQrU_ENABLE [23:16] HSR_OVERRUN_ENI | HSI_P1_DSP_IRQ HSI_P2_DSP_IRQ | |
| HSI_Pp_M_IRQrU_STATUS [15:8] HSR_AVAILABLE_CHI | HSI_Pp_M_IRQrU_ENABLE [15:8] HSR_AVAILABLE_ENI | HSI_P1_MPU_IRQ HSI_P2_MPU_IRQ | Data received on any channel 8–15 |
| HSI_Pp_D_IRQrU_STATUS [15:8] HSR_AVAILABLE_CHI | HSI_Pp_D_IRQrU_ENABLE [15:8] HSR_AVAILABLE_ENI | HSI_P1_DSP_IRQ HSI_P2_DSP_IRQ | |
| HSI_Pp_M_IRQrU_STATUS [7:0] HST_ACCEPTED_CHI | HSI_Pp_M_IRQrU_ENABLE [7:0] HST_ACCEPTED_ENI | HSI_P1_MPU_IRQ HSI_P2_MPU_IRQ | Data transmitted on any channel 8–15 |
| HSI_Pp_D_IRQrU_STATUS [7:0] HST_ACCEPTED_CHI | HSI_Pp_D_IRQrU_ENABLE [7:0] HST_ACCEPTED_ENI | HSI_P1_DSP_IRQ HSI_P2_DSP_IRQ | |
| HSI_Pp_M_IRQr_STATUS [26] HSR_WAKE | HSI_Pp_M_IRQr_ENABLE [26] HSR_WAKE | HSI_P1_MPU_IRQ HSI_P2_MPU_IRQ | Wake detected on any channel 0–7 |
| HSI_Pp_D_IRQr_STATUS [26] HSR_WAKE | HSI_Pp_D_IRQr_ENABLE [26] HSR_WAKE | HSI_P1_DSP_IRQ HSI_P2_DSP_IRQ | |
| HSI_Pp_M_IRQr_STATUS [25] HSR_BREAK | HSI_Pp_M_IRQr_ENABLE [25] HSR_BREAK | HSI_P1_MPU_IRQ HSI_P2_MPU_IRQ | Break detected on any channel 0–7 |
| HSI_Pp_D_IRQr_STATUS [25] HSR_BREAK | HSI_Pp_D_IRQr_ENABLE [25] HSR_BREAK | HSI_P1_DSP_IRQ HSI_P2_DSP_IRQ | |
| HSI_Pp_M_IRQr_STATUS [24] HSR_ERROR | HSI_Pp_M_IRQr_ENABLE [24] HSR_ERROR | HSI_P1_MPU_IRQ HSI_P2_MPU_IRQ | Error detected on any channel 0–7 |
| HSI_Pp_D_IRQr_STATUS [24] HSR_ERROR | HSI_Pp_D_IRQr_ENABLE [24] HSR_ERROR | HSI_P1_DSP_IRQ HSI_P2_DSP_IRQ | |
| HSI_Pp_M_IRQr_STATUS [23:16] HSR_OVERRUN_CHI | HSI_Pp_M_IRQr_ENABLE [23:16] HSR_OVERRUN_ENI | HSI_P1_MPU_IRQ HSI_P2_MPU_IRQ | Data overrun in real time mode on any channel 0–7 |
| HSI_Pp_D_IRQr_STATUS [23:16] HSR_OVERRUN_CHI | HSI_Pp_D_IRQr_ENABLE [23:16] HSR_OVERRUN_ENI | HSI_P1_DSP_IRQ HSI_P2_DSP_IRQ | |
| HSI_Pp_M_IRQr_STATUS [15:8] HSR_AVAILABLE_CHI | HSI_Pp_M_IRQr_ENABLE [15:8] HSR_AVAILABLE_ENI | HSI_P1_MPU_IRQ HSI_P2_MPU_IRQ | Data received on any channel 0–7 |
| HSI_Pp_D_IRQr_STATUS [15:8] HSR_AVAILABLE_CHI | HSI_Pp_D_IRQr_ENABLE [15:8] HSR_AVAILABLE_ENI | HSI_P1_DSP_IRQ HSI_P2_DSP_IRQ | |

Table 24-796. Events (continued)

| Event Flag | Event Mask | Map to | Description |
|---|---|------------------------------------|-------------------------------------|
| HSI_Pp_M_IRQr_STATUS[7:0] HST_ACCEPTED_CHI | HSI_Pp_M_IRQr_ENABLE[7:0] HST_ACCEPTED_ENI | HSI_P1_MPU_IRQ HSI_P2_MPU_IRQ | Data transmitted on any channel 0–7 |
| HSI_Pp_D_IRQr_STATUS[7:0] HST_ACCEPTED_CHI | HSI_Pp_D_IRQr_ENABLE[7:0] HST_ACCEPTED_ENI | HSI_P1_DSP_IRQ HSI_P2_DSP_IRQ | |
| HSI_DMA_M_IRQSTATUS[15:0] DMA_CHI | HSI_DMA_M_IRQENABLE[15:0] DMA_EN_CHI | HSI_P1_MPU_IRQ HSI_P2_MPU_IRQ | Channel 0–15 status |

| DMA_CSR_CCIR_i[21] BLOCK_IS | DMA_CSR_CCIR_i[5] BLOCK_IE | HSI_DMA_DSP_IRQ HSI_DMA_MPU_IRQ | Block transferred |
| DMA_CSR_CCIR_i[18] HALF_IS | DMA_CSR_CCIR_i[2] HALF_IE | HSI_DMA_DSP_IRQ HSI_DMA_MPU_IRQ | Half block reached |
| DMA_CSR_CCIR_i[16] TOUT_IS | DMA_CSR_CCIR_i[0] TOUT_IE | HSI_DMA_DSP_IRQ HSI_DMA_MPU_IRQ | Time-out event |

24.10.4.5.1 Interrupts

By default, there are four interrupt output lines per HSI port (Mpuirq_0, Mpuirq_1, Dspirq_0, Dspirq_1), and two in the case of the DMA interrupt (MPU, DSP). The following registers are related to these interrupt outputs as follows:

- Status registers:
 - [HSI_Pp_M_IRQrU_STATUS](#) / [HSI_Pp_M_IRQr_STATUS](#) for Mpuirq_r (where r = 0 or 1)
 - [HSI_Pp_D_IRQrU_STATUS](#)/ [HSI_Pp_D_IRQr_STATUS](#) for Dspirq_r (where r = 0 or 1)
 - [HSI_DMA_M_IRQSTATUS](#) for DMA interrupt to MPU
 - [HSI_DMA_D_IRQSTATUS](#) for DMA interrupt to DSP
- Enable registers:
 - [HSI_Pp_M_IRQrU_ENABLE](#) / [HSI_Pp_M_IRQr_ENABLE](#) for Mpuirq_r (where r = 0 or 1)
 - [HSI_Pp_D_IRQrU_ENABLE](#)/ [HSI_Pp_D_IRQr_ENABLE](#) for Dspirq_r (where r = 0 or 1)
 - [HSI_DMA_M_IRQENABLE](#) for DMA interrupt to MPU
 - [HSI_DMA_D_IRQENABLE](#) for DMA interrupt to DSP

However, Mpuirq_0 and Mpuirq_1 are further combined (logical OR) into one common interrupt output per port (HSI_P1_MPU_IRQ for port 1, and HSI_P2_MPU_IRQ for port 2). The same goes for Dspirq_0 and Dspirq_1 (HSI_P1_DSP_IRQ for port 1, and HSI_P2_DSP_IRQ for port 2).

This means that it is enough to enable one of the FIFO/WAKE/BREAK/ERROR interrupt events per port (for example, in [HSI_Pp_M_IRQ0\(U\)_ENABLE](#)) to raise the corresponding interrupt request. Enabling both [HSI_Pp_M_IRQ0\(U\)_ENABLE](#) and [HSI_Pp_M_IRQ1\(U\)_ENABLE](#) would only mean extra checks and clears (in the corresponding IRQ status register). The same is true for the DSP-related IRQ enable/status registers.

The HSI module outputs six interrupt signals (for more information, see [Section 24.10.3, MIPI HSI Integration](#)). All the interrupts are active-high level-sensitive. Each interrupt line is activated by a set of individual sources. All interrupt sources can individually be enabled and disabled.

For each interrupt, 2 status bits and 2 mask bits are provided, allowing independent masking for the different processors (that is, 1 status bit and 1 mask bit for the MPU [Cortex-A9 or Cortex-M3] interrupts, and 1 status bit and 1 mask bit for the DSP interrupts).

Interrupts in the HSI module are intended to:

- Signal any error condition in reception
- Support the WAKE condition detection
- Support the BREAK condition detection
- Warn of DMA transfer status or problems

- Signal to processors when to read received data and to write data to transmit

Because DMA has only 16 channels, 16 RX FIFO and 16 TX FIFO are managed by a mix of DMA-driven and interrupt-driven read/write policies.

24.10.4.5.1.1 HSI Interrupt Generation

Five types of interrupt events can be generated by each HSI port:

- Transmit FIFO not full: Occurs when TX FIFO is not full, so data can be written for transmission
- Received data available: Occurs when one data frame has been received and is available on the RX FIFO for reading
- Overrun: Occurs when data overrun is detected on HSI port p channel i
- Error: Any error defined by the MIPI HSI protocol activates this source of interrupt if this source is enabled.
- Break condition detected: Occurs upon reception of a continuous string of 0s that exceed those possible in any FRAME mode frame (data + header). Because FRAME mode always put a 1 before any frame, the maximum number of 0s occurring during normal transmission is clearly 32 plus the base 2 logarithm of channels used. Hardware works out this number based on register information on channels and receive mode, sets the [HSR_BREAK_Pp\[0\]](#) BREAK_VAL bit to 1, and issues an interrupt if this source is enabled.

All the events are cleared by software, upon setting the corresponding register bit to 1. Setting the bit to 0 has no effect.

24.10.4.5.1.2 DMA Interrupt Generation

Three types of interrupt events can be generated by each DMA channel:

- End of Block: Enabled through the [DMA_CSR_CCIR_i\[5\]](#) BLOCK_IE bit, it occurs when the last element of the transfer has been written into destination. The [DMA_CEN_i\[15:0\]](#) SIZE bit field defines the number of elements in a block.
- Half Block: Enabled through the [DMA_CSR_CCIR_i\[2\]](#) HALF_IE bit, it occurs when a half of the elements have been written into destination.
- Time-out error: Enabled through the [DMA_CSR_CCIR_i\[0\]](#) TOU_IE bit, it occurs when destination slave answers by an error code.

All interrupt events are generated on the same logical channel dedicated interrupt line. When an interrupt is issued by a logical channel, its [DMA_CSR_CCIR_i](#) status register is set to record the interrupt cause, if the interrupt event bit is enabled in the relevant [DMA_CSR_CCIR_i](#) register. The processor interrupt service routine can read this channel status register to identify the sources of the interrupt. The status bits are automatically cleared after they are read by the processor, unless it is an emulation read.

There are two classes of DMA interrupt events:

- Error events: Errors during the transfer
- Status events: DMA transfer status, such as end of block or half-block

The DMA manages the two classes differently.

For an enabled error event, the following sequence occurs:

1. The appropriate bit in the [DMA_CSR_CCIR_i](#) register is set.
2. An interrupt is generated.
3. The ports are released.
4. The currently active logical channel is disabled and must be reprogrammed.
5. Other channels are not affected, and a new channel can get over, according to programmed priorities.

For an enabled status event, the following sequence occurs:

1. The appropriate bit in the [DMA_CSR_CCIR_i](#) register is set.
2. An interrupt is generated.
3. A new interrupt cannot be generated until the status register is read and thereby cleared.

All the events are cleared by software, upon setting the corresponding interrupt status register ([HSI_DMA_M_IRQSTATUS](#) or [HSI_DMA_D_IRQSTATUS](#)) to 1. Setting the interrupt status register to 0 has no effect.

24.10.4.6 DMA Module

24.10.4.6.1 DMA Overview

The DMA module transfers data between the HSI interfaces and the device on-chip memories. The DMA module supports 16 logical channels and is a dual-port initiator (peripheral port/memory port) with one slave port for configuration. The memory port provides an interface to the memory space and the peripheral port provides an interface to the HSI interfaces. In the HSI controller, the L4_CFG port accesses can be routed directly to the HSI interfaces. This is done by setting the DMA in bypass mode to route the DMA slave port to the DMA peripheral port.

DMA features:

- One target port, for configuration
- 16 logical channels: n for transmission and $16-n$ for reception
- One initiator port, for transfer to/from memory
- One port to/from LCH memory (this memory holds some registers)
- 32-bit data handling only
- Constant addressing mode on peripheral port/FIFO
- Post-increment addressing mode with burst support on memory port
- Software enabling
- Hardware activation of data transfer on peripheral port
- Logical channels interleaving with only few-cycles-latency
- Fixed allocation of memory and peripheral port to a logical channel
- LCH first-come-first-served + fixed priority arbitration
- Low-power operation (hardware control for clock domains activity)
- Software reset

24.10.4.6.2 DMA Memories

DMA channel register memory is managed by the DMA. Only the DMA interfaces this memory. A processor must program the DMA registers included in this memory.

The DMA has access to 16 dual-port FIFO 8×32 bits for reception and 16 dual-port FIFO 8×32 bits for transmission. They are provided in the form of two separate memories.

24.10.4.6.3 DMA Basic Operation Outline

DMA write and read operations are helped by tags, to manage possibly disorderly answers. Posted or nonposted operations are possible. In any case, the interconnect always manages them as nonposted. This is consistent with DMA operations that need to know (for example, if main memory write was successful). If not, the error response from L3 interconnect slave produces a DMA error and the corresponding interrupt. DMA addressing of FIFO memories is always on a constant address, corresponding to 1 of the 16 [HST_BUFFER_Pp_CHN_i](#) (or [HSR_BUFFER_Pp_CHN_i](#)) registers.

These registers are associated with the 16 FIFOs, and the naming reflects only the reset value of the association FIFO, HSI logical channel. Therefore, at reset, the FIFO addressed on the [HSR_BUFFER_P2_CHN_4](#) register is associated with the fourth logical channel of the second port. Nevertheless, software can change this mapping and associate the same FIFO (for example, to the seventh channel of the first port). This mapping is performed by software through the [HST_MAPPINGf\[4:1\]](#) CH_NUMBER or [HSR_MAPPINGf\[4:1\]](#) CH_NUMBER bit fields.

24.10.4.6.4 DMA Configuration

Before performing a DMA transfer, the following DMA registers must be configured:

- [DMA_CCR_CSDP_i](#): Sets source and destination parameters and channel control
 - [DMA_CCR_CSDP_i](#)[15:14] DST_BURST_EN: Destination burst enable (0x0 and 0x1: single access; 0x2: burst 4 × 32 bits; 0x3: burst 8 × 32 bits)
 - [DMA_CCR_CSDP_i](#)[12:9] DST: Transfer destination (0x8: transfer to memory port; 0x9: transfer to peripheral port)
 - [DMA_CCR_CSDP_i](#)[8:7] SRC_BURST_EN: Source burst enable (0x0 and 0x1: single access; 0x2: burst 4 × 32 bits; 0x3: burst 8 × 32 bits)
 - [DMA_CCR_CSDP_i](#)[5:2] SRC: Transfer source (0x8: transfer from memory port; 0x9: transfer from peripheral port)
 - [DMA_CCR_CSDP_i](#)[31:30] DST_ADD_MODE: Destination addressing mode (0x0: constant address mode; 0x1: post-incremented address mode)
 - [DMA_CCR_CSDP_i](#)[29:28] SRC_ADD_MODE: Source addressing mode (0x0: constant address mode; 0x1: post-incremented address mode)
- [DMA_CSR_CCIR_i](#): Enables DMA sources of interrupt events
- [DMA_CSSA_i](#)[31:0] ADDR: Stores 32 bits of the source address
- [DMA_CDSA_i](#)[31:0] ADDR: Stores 32 bits of the destination address
- [DMA_CEN_i](#)[31:0] SIZE: Defines the number of elements in a block. The maximum number of elements is 65535.

To start a DMA transfer, the DMA channel to be used must be enabled by setting the [DMA_CCR_CSDP_i](#)[23] ENABLE bit to 1. Once the DMA transfer is finished, the [DMA_CCR_CSDP_i](#)[23] ENABLE bit is automatically reset by hardware.

The [DMA_CDAC_CSAC_i](#)[15:0] ADDRESS_CSAC (or [DMA_CDAC_CSAC_i](#)[31:15] ADDRESS_CDAC) bit field can be used to monitor the progress of a DMA transfer on the channel source (or destination). It is a snapshot of the source (or destination) address generated by the channel counter. It is incremented on each access made on channels.

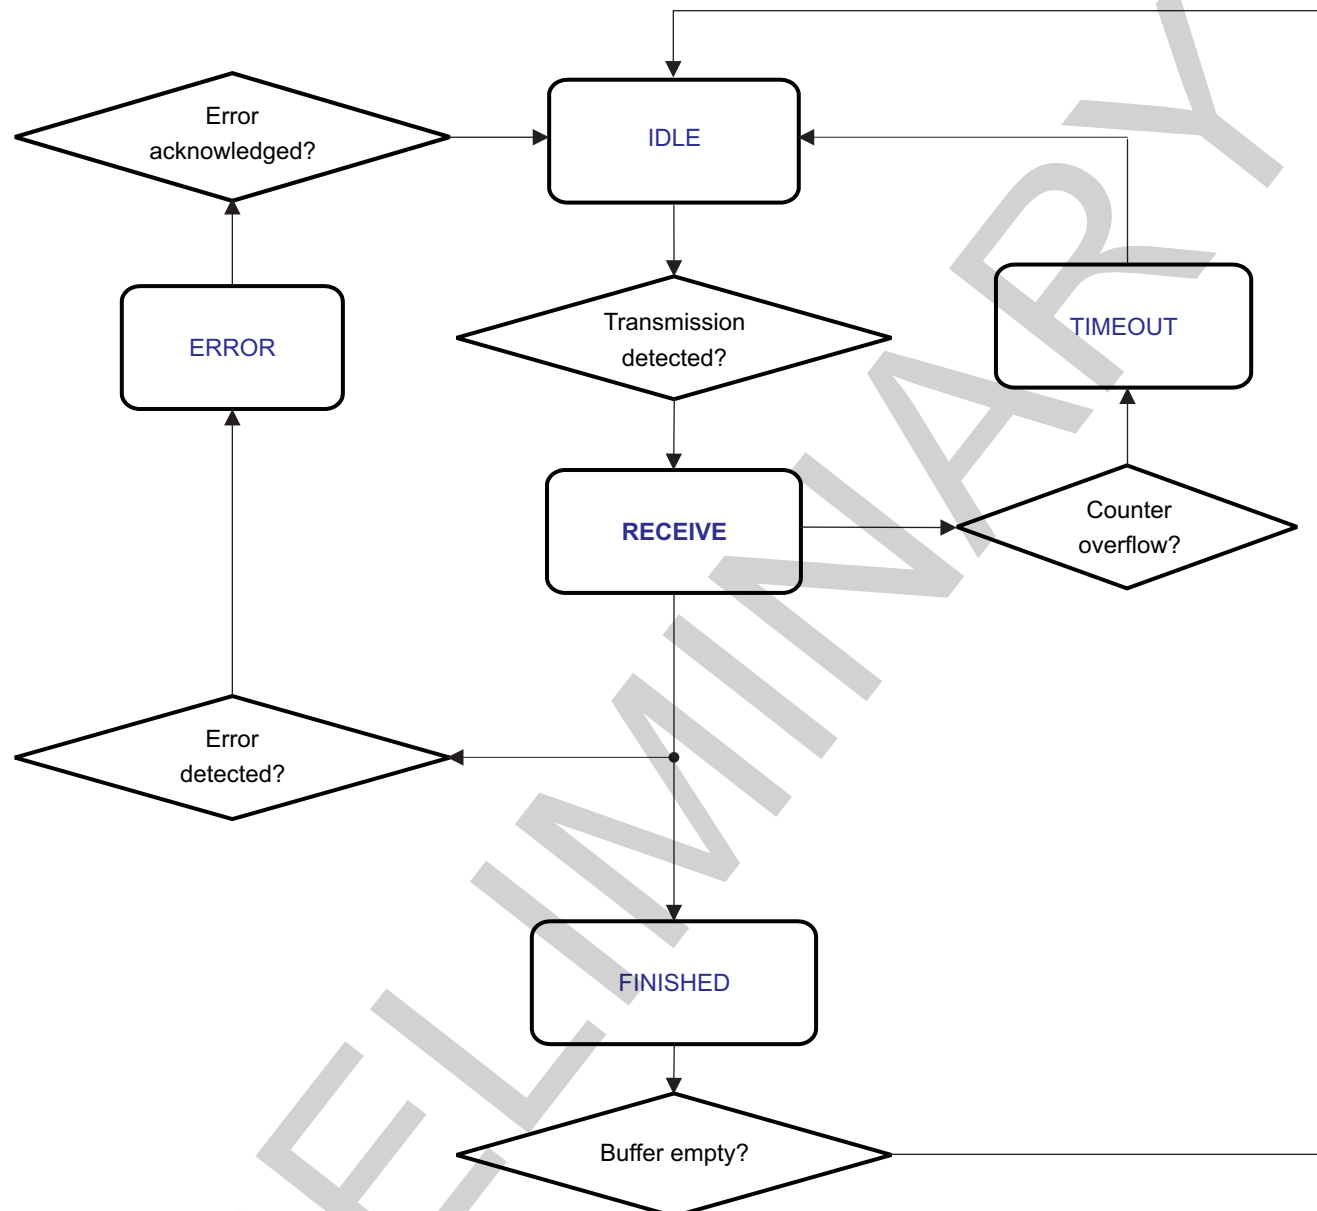

24.10.4.7 HSR Module

The HSR module is the receiver part of the HSI module. It features 16 channels.

24.10.4.7.1 Receive Data

The value on the DATA line is always the transmitted bit, when sampled by the clock recovered. The double level of buffering allows the data to be safely transferred to the FIFO, while a new frame is stored. Data headers do not belong in FIFO and must be decoded to load data on the correct FIFO (there is one logical FIFO per logical channel).

[Figure 24-221](#) shows the receive state-machine implemented in the HSI module.

Figure 24-221. Receive FSM

hsi-007

24.10.4.7.2 Transmission Detection

Reception starts upon two alternate conditions:

- The remote transmitter raises the WAKE line (in this case, it does not actually transmit until the local receiver raises the READY line).
- An activity (in the form of transitions) appears on the FLAG/DATA lines, in case the remote transmitter does not implement the WAKE signal. The receiver must then save and store the received data, at least one frame long, before preventing further transmission by setting READY to 0.

24.10.4.7.3 Receive Buffers

For each logical channel, the [HSR_BUFFER_Pp_CHN_i](#)[31:0] DATA bit field holds one frame. The appropriate bit in the [HSR_BUFSTATE_Pp](#) register is set to 1 by hardware when the corresponding [HSR_BUFFER_Pp_CHN_i](#) register holds one frame. Reading the [HSR_BUFFER_Pp_CHN_i](#)[31:0] DATA bit field automatically resets the appropriate bit in [HSR_BUFSTATE_Pp](#). This lets the receiver put another data frame in [HSR_BUFFER_Pp_CHN_i](#), setting again [HSR_BUFSTATE_Pp](#).

Some applications need reversed byte ordering of frames. This is supported by the [HSR_SWAPBUFFER_Pp_CHN_i](#) register (see [Figure 24-222](#)). By reading this register instead of the corresponding [HSR_BUFFER_Pp_CHN_i](#) register on the same channel, byte ordering of the 4 bytes in a frame is reversed.

Figure 24-222. HSR_SWAPBUFFER_Pp_CHN_i Register

hsi-008

Reading the MSB of the [HSR_SWAPBUFFER_Pp_CHN_i](#) register sets the corresponding bit of [HSR_BUFSTATE_Pp](#) to empty.

NOTE: Read access to the register with 0x3 and 0xF byte-enable removes the receive FIFO-related item. If only 16-bit accesses are used, the upper 2 bytes must be read first (byte-enable 0xC). Between two consecutive 16-bit FIFO-related accesses there cannot be any other FIFO-related OCP access.

24.10.4.7.4 Receive Operations

Logically, the receiver amounts to the receiver shift register, double-buffering and the FSM. The current state of the FSM can be observed and controlled through the [HSR_RXSTATE_Pp](#)[2:0] RXSTATEVAL bit field. For the receive FSM, a functional description is shown in [Figure 24-221](#).

The receiver FSM is in IDLE state when no transmission is detected, or the [HSR_MODE_Pp](#)[1:0] MODE_VAL bit field = FRAME and no synchronization bit is detected. Otherwise, it stores the first received bit and transitions to RECEIVING state, where it stops until a full frame is received.

Depending on the selected flow control, the READY line may have to go to 0 after the first bit is received.

Upon receiving a full frame, the FSM transitions to FINISHED state. Otherwise, the FSM transitions to TIMEOUT state as soon as a time-out value (if enabled and programmed in the [HSR_COUNTERS_Pp](#)[19:0] FT bit field) is reached. Then it moves to IDLE state.

After entering RECEIVED state, the FSM stays there until the received frame is correctly stored and there is room for another frame. At this point, READY is raised and the FSM goes to IDLE state. In pipelined flow, flow control by READY is not operating at each byte, and in real time flow it is never operating. In both cases, the FSM transitions immediately to IDLE, to receive more data. Illegal transitions or flags raised by error counters (see [Section 24.10.4.11, Error Reporting](#)), move the FSM to ERROR state, and then to HALT, to wait until the error is acknowledged by software, warned by an interrupt. Except for pipelined control flow, the READY output is always 1 in IDLE state and 0 anywhere else. In pipelined mode, the READY signal stays to 1, and is cleared by a condition on buffer full. The FSM state can be controlled by software by writing in the [HSR_RXSTATE_Pp](#)[2:0] RXSTATEVAL bit field. This can be useful to recover from an error condition.

24.10.4.7.5 Receive Exceptions

24.10.4.7.5.1 Break

Remote transmitter can force synchronization by a long enough string of 0s (equal to the number of header + data bits in the frame + 1). In frame mode, this sets the [HSR_BREAK_Pp\[0\]](#) BREAK_VAL bit to 1, which in turn sends an interrupt.

24.10.4.7.5.2 Overrun

An overrun condition is possible during real-time flow, if received data occur when the FSM is in FINISHED state. Whenever this happens, the [HSR_OVERRUN_Pp\[15:0\]](#) OVERRUN_VAL bit field is set for the corresponding logical channel, which in turn generates an interrupt.

An overrun exception is a legacy condition required in previous SSI hardware, where reception without the READY signal had to be supported. In HSI the READY signal always exists, but it cannot be used during real-time flow and the last 8 bits of a frame during pipelined flow. During real-time data flow, overrun can occur at any time. The main goal of using real-time flow is flushing FIFOs after an error. In that case, an overrun interrupt does not seem worth to be raised. Data does not have to be discarded. The real-time data are discarded if the receiver cannot follow the transmission rate, otherwise, the real-time data is kept in FIFO.

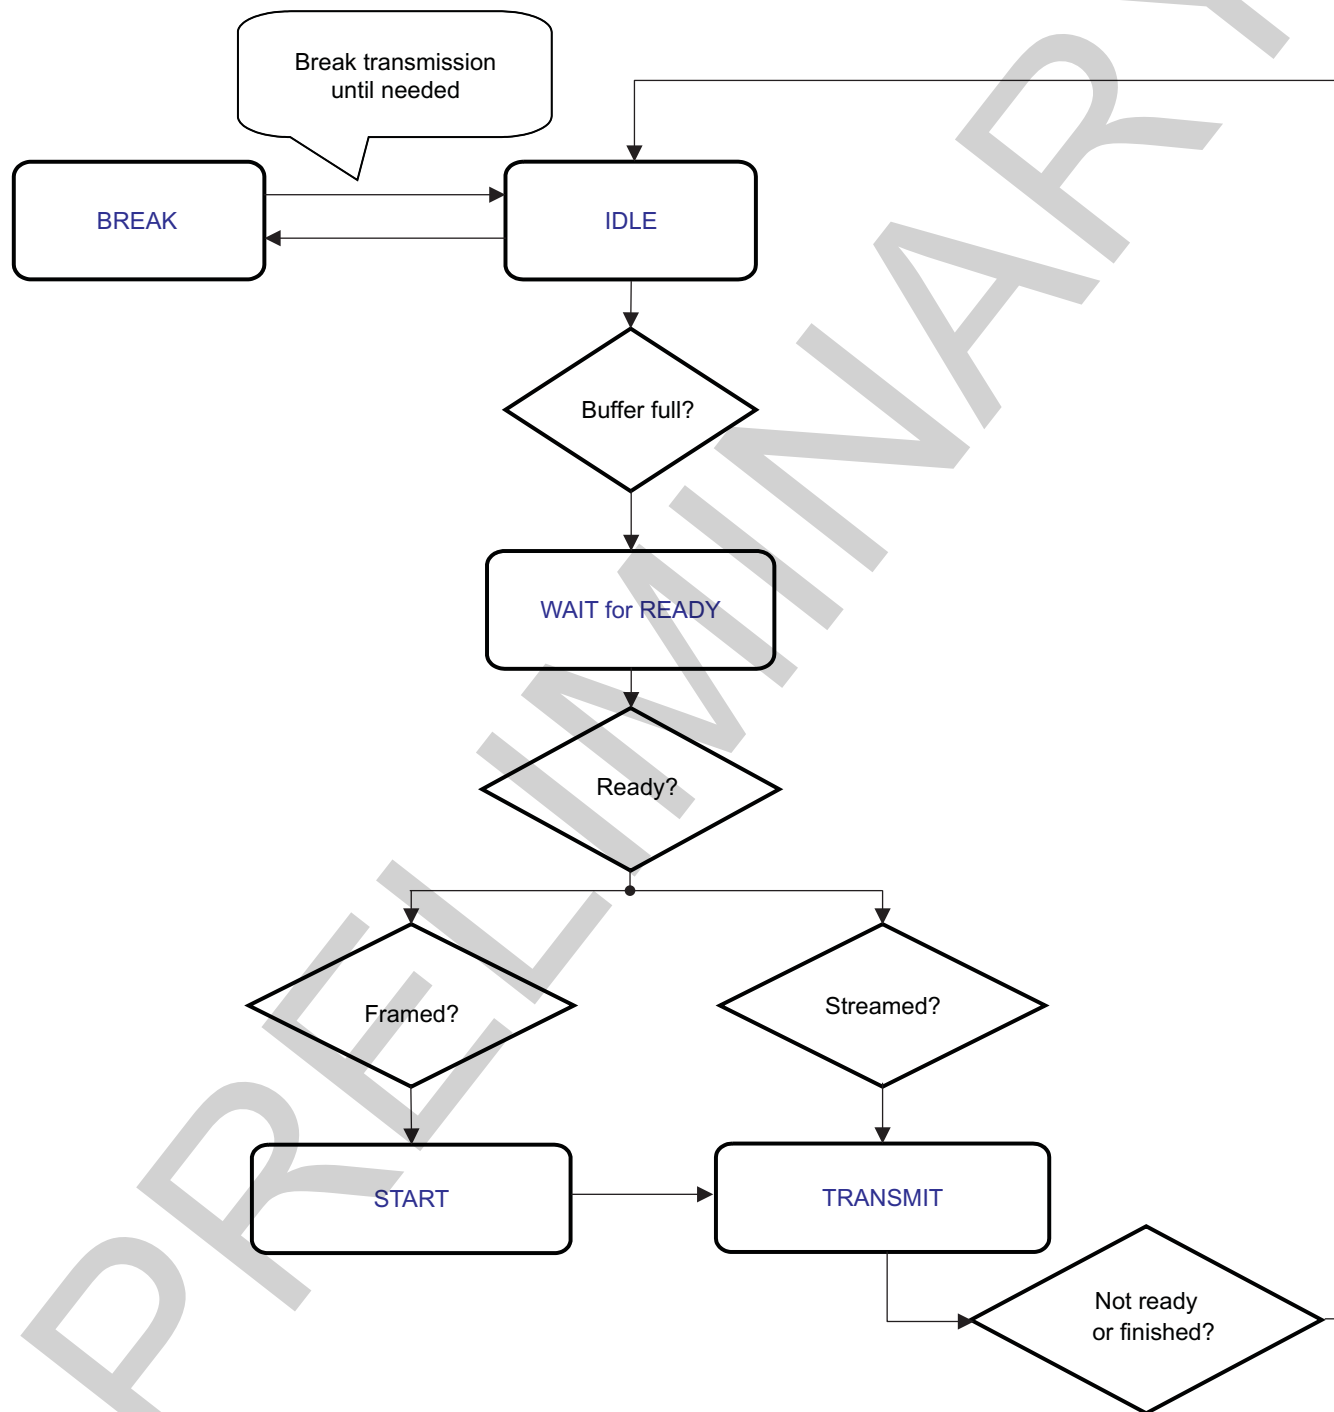

24.10.4.7.5.3 Errors

Several sources of errors are possible. In any of them, the receiver FSM stays in ERROR state until the error interrupt is acknowledged by writing the [HSR_ERRORACK_Pp](#) registers. Sources of errors include receive FRAME TIMEOUT, other receive errors flagged by error counters, and any other abnormal condition, as explained in [Section 24.10.4.11](#), *Error Reporting*.

24.10.4.8 HST Block

The HST block is the transmitter part of the HSI module. It features 16 channels. Figure 24-223 shows the receive state-machine implemented in the HSI module.

Figure 24-223. Transmit FSM

hsi-009

24.10.4.8.1 Configuration

Configuration of the component is expressed in terms of operation mode, number of logical channels, bit rate divisor, and arbitration mode.

24.10.4.8.1.1 Mode Register

The **HST_MODE_Pp** register cannot be changed without stopping the link.

There is one **HST_MODE_Pp**[3:2] FLOW_VAL bit field for each active transmit channel and another **HSR_MODE_Pp**[3:2] FLOW_VAL bit field for each active receive channel. The local transmitter (communicating with the remote receiver) uses the **HST_MODE_Pp**[3:2] FLOW_VAL bit field for interpretation of the received READY line, for example to signal errors.

The **HST_MODE_Pp** register has the following bit fields:

- WAKE_CTRL selects between software (when 0x0) or automatic (when 0x1) control for the WAKE line. The default is software control.
- MODE_VAL defines the following operation modes:
 - Sleep: Specifies whether internal clocks must run and port be operating
 - Stream: Receiver does not use start-bits.
 - Frame: Allows break transmission/reception defined as a longer-than-frame 0 sequence
- FLOW_VAL defines the following data flows:
 - Synchronized flow: The READY signal from the receiver drops after every first frame bit, rising when data are stored, and transmission of a new frame is possible.
 - Pipelined flow: The receiver cannot drop the READY line at some times.
 - Real-time flow: The receiver drops the READY line at the first received bit and raises it at the last one.

NOTE: READY is activated when the module is going into ACTIVE state (stream or frame mode). Receive mode must be selected at the end of the configuration of the module, because it activates the transfer from the remote side. This prevents the device from receiving incorrect data, losing data, and falsely starting communication.

24.10.4.8.1.2 Other Registers

- The **HST_FRAMESIZE_Pp** register is kept to offer legacy compatibility. It is a read-only register, returning 0x1F.
- The **HST_DIVISOR_Pp**[7:0] RX_RATE_DIV_VAL bit field sets the transmission bit rate, with 1 transmitted bit per clock cycle. Bit rate can be changed by software at any time.
- The **HST_CHANNELS_Pp**[4:0] CHAN_NUM_VAL bit field sets the number of logical channels. It must be a power of 2. The default value is 0x1. This corresponds to only one logical channel, always the same, and in that case, a header is not transmitted; It cannot be changed without stopping the link.
- **HST_MAPPINGf** contains important settings for each FIFO (one register per FIFO):
 - **HST_MAPPINGf**[0] ENABLE bit: FIFO is enabled or not.
 - **HST_MAPPINGf**[4:1] CH_NUMBER and **HSR_MAPPINGf**[7] PORT_NUMBER bit fields (channel number and port number): FIFO is assigned to an HSI logical channel on a physical port.
 - **HST_MAPPINGf**[13:10] THRESHOLD bit field is the number of empty TX FIFO locations that will activate interrupt automatically.
- The **HST_ARBMODE_Pp**[0] ARB_VAL bit allows choosing of the arbitration policy for time allocation to logical channels, when several channels have to transmit. Round-robin algorithm implements a circular scan: the same channel cannot transmit twice if another channel is ready to transmit. Scan proceeds in the same, unspecified direction (design choice). Fixed priority algorithm grants maximum priority to logical channel 0, minimum priority to channel 15. The right to transmit is assigned to the higher priority channel ready to transmit, independently of previous transmissions.

The choice between algorithms must consider that round-robin sets a maximum wait time for each channel, but it may require a long time to transmit long sequences of frames, on any channel. On the other hand, fixed priority allows limiting of transmission time for high priority channels, while low priority channel may wait for a long time.

It is important to understand that this register sets the allocation of one port resource (transmission lines) from 2 to 16 vying transmit FIFOs. Allocation of the 16 transmit FIFOs to 32 logical channels is

done by the [HST_MAPPINGf](#) register. For this second kind of allocation, no arbitration makes sense, because software is in charge to ensure against more than 16 logical channels transmitting at the same time.

24.10.4.8.2 Mapping

[Figure 24-224](#) shows an example of programming the [HST_MAPPINGf](#) register. No limitation is set on the choice of channel/FIFO/port association.

Each port has its [HST_ARBMODE_Pp](#) register so that it is also possible to program alternate algorithms on ports.

While the [HST_MAPPINGf](#) register cares only about FIFO, the [HST_ARBMODE_Pp](#) register is associated to a port and each port has its own one, which only selects a winner between ready-to-transmit channels of this port. For example, suppose that in [Figure 24-224](#) only the three represented channels need to transmit; then a yellow (Port 1) arbiter chooses between channel 11 and channel 2, while the cyan (Port 2) arbiter has no decision to take and lets channel 3 transmit.

Figure 24-224. MAPPING Register

24.10.4.8.3 Transmission Buffer

The transmission buffer holds a frame to be transmitted for each channel. The [HST_BUFSTATE_Pp\[7:0\]](#) BUFSTATE_VAL bit field indicates whether the [HST_BUFFER_Pp_CHN_i\[31:0\]](#) DATA bit field holds significant data, and it is not be cleared until transmit FSM is in IDLE state and arbitration indicates the channel is the next in line to transmit. The [HST_BUFSTATE_Pp](#) register is automatically written by hardware.

NOTE: Write access to the register with 0x3 and 0xF byte-enable loads its value into the transmit FIFO. If only 16-bit accesses are used, the upper 2 bytes must be written first (byte-enable 0xC). Between two consecutive 16-bit FIFO-related accesses there cannot be any other FIFO-related OCP access.

Some applications need reversed byte ordering of frames. This is supported by the [HST_SWAPBUFFER_Pp_CHN_i](#) register. By reading this register instead of the corresponding [HST_BUFFER_Pp_CHN_i](#) register on the same channel, byte ordering of the 4 bytes in a frame is reversed (see [Section 24.10.4.7.3, Receive Buffers](#)).

24.10.4.8.4 Break Pattern Transmission

Break pattern transmission is an alternative to normal transmission mode, and is used when trying to recover lost synchronization. It is started by software by setting the [HST_BREAK_Pp\[0\]](#) BREAK_VAL bit. As soon as transmit FSM is in IDLE state (ready to accept another frame for transmission), a nonzero value on the [HST_BREAK_Pp\[0\]](#) BREAK_VAL bit starts the BREAK sequence, and automatically clears the [HST_BREAK_Pp\[0\]](#) BREAK_VAL bit. A sequence of 0, longer than a frame, is transmitted.

24.10.4.8.5 Transmission Operations

The transmitter adds up to the transmit shift register, loaded from the transmission buffer, and the transmit FSM current state of the FSM can be observed and controlled through the [HST_TXSTATE_Pp\[2:0\]](#) TXSTATEVAL bit field. A functional description of the transmit FSM is shown in [Figure 24-223](#).

After reset, the transmitter is in IDLE state. It starts transmission when there is data in one of the transmission [HST_BUFFER_Pp_CHN_i](#) registers, depending on the value of [HST_BUFSTATE_Pp\[7:0\]](#) BUFSTATE_VAL bit field, or when the value of BREAK is not 0.

When transmitting a data frame (not a BREAK sequence), the frame to be transmitted is clocked from the [HST_BUFFER_Pp_CHN_i](#) register to the transmission shift register, and the FSM enters WAIT state until it receives READY = 1. At this point, it starts driving the DATA and FLAG lines with a preliminary start-bit at 1, if in STREAM mode, or with the frame, which amounts to header and payload data.

In case of synchronized data flow, the TRANSMIT state is left after one frame is transmitted, because READY always drops after the first transmitted bit. Transmit FSM transitions through IDLE and WAIT states before retransmitting, when READY rises.

In case of pipelined data flow, transmit FSM remains in TRANSMIT state as long as READY = 1, and transmission goes on, always clocking data from the appropriate [HST_BUFFER_Pp_CHN_i](#) register, as selected by arbitration. Transmission is stopped by the condition READY = 0, forcing FSM to go into IDLE state. READY must not switch during the last 8 nominal bit times.

24.10.4.8.6 Transmission Exceptions

There are no transmission errors. Reception of READY = 0 in the last 8 bits of frames is not flagged. The DATA ACCEPTED interrupt is used to inform software that the [HST_BUFFER_Pp_CHN_i\[31:0\]](#) DATA bit field is empty and to request more data.

24.10.4.9 HSI Wake Generator

The WAKE line is used to create a wake-up event for the external module that interfaces with HSI before a data transfer through the HSI serial interface.

The 16 bits (1 per HSI channel) of the [HSI_Pp_WAKE\[15:0\]](#) WAKE_CHI bit field are ORed together to drive the WAKE line, as shown in [Figure 24-225](#).

Figure 24-225. HSI_Pp_WAKE Control in Case of Managed Wake

hsi-011

The wake generator can be managed by software operations or automatically by hardware. If the wake generator is not managed, the WAKE signal is driven to 0 and the remote transmitter must wake itself upon activity detection on the DATA and FLAG lines.

24.10.4.9.1 Software Management of HSI Wake Generator

Software can get the responsibility to use and manage those bits to create and release wake-up events consistently with HSI use.

Because the [HSI_Pp_WAKE\[15:0\]](#) WAKE_CHI bit field can be managed by different threads/processors, this mechanism allows independent bit management by each thread. Without locking the [HSI_Pp_WAKE](#) register (as a read-modify-write does), it avoids one thread to overwrite the register change made by another thread. Each bit of the [HSI_Pp_SET_WAKE\[15:0\]](#) HSI_SET_WAKE_CHI bit field is owned by one thread at a time.

- The thread can set this bit by setting the corresponding bit of the [HSI_Pp_SET_WAKE\[15:0\]](#) HSI_SET_WAKE_CHI bit field to 1. This sets only this bit, thus leaving the other bits unchanged (no need of a read-modify-write).
- The thread can clear this bit by setting the corresponding bit of the [HSI_Pp_CLEAR_WAKE\[16:0\]](#) HSI_HSI_CLEAR_WAKE_CHI bit field to 1. This clears only this bit, thus leaving the other bits unchanged (no need of a read-modify-write).

24.10.4.9.2 Automatic Management of HSI Wake Generator

The wake generator is automatically managed when there is a transmission to be performed. When data are waiting for transmission in a FIFO TX, the hardware sets the corresponding bit of the [HSI_Pp_WAKE\[15:0\]](#) WAKE_CHI bit field, and this raises the WAKE signal on port p. Then WAKE is deasserted by the first occurrence of one event between a fixed time-out from the end of the last transfer, a transition to IDLE in idle-req protocol, a software clear of register.

24.10.4.10 FIFO Subsystem

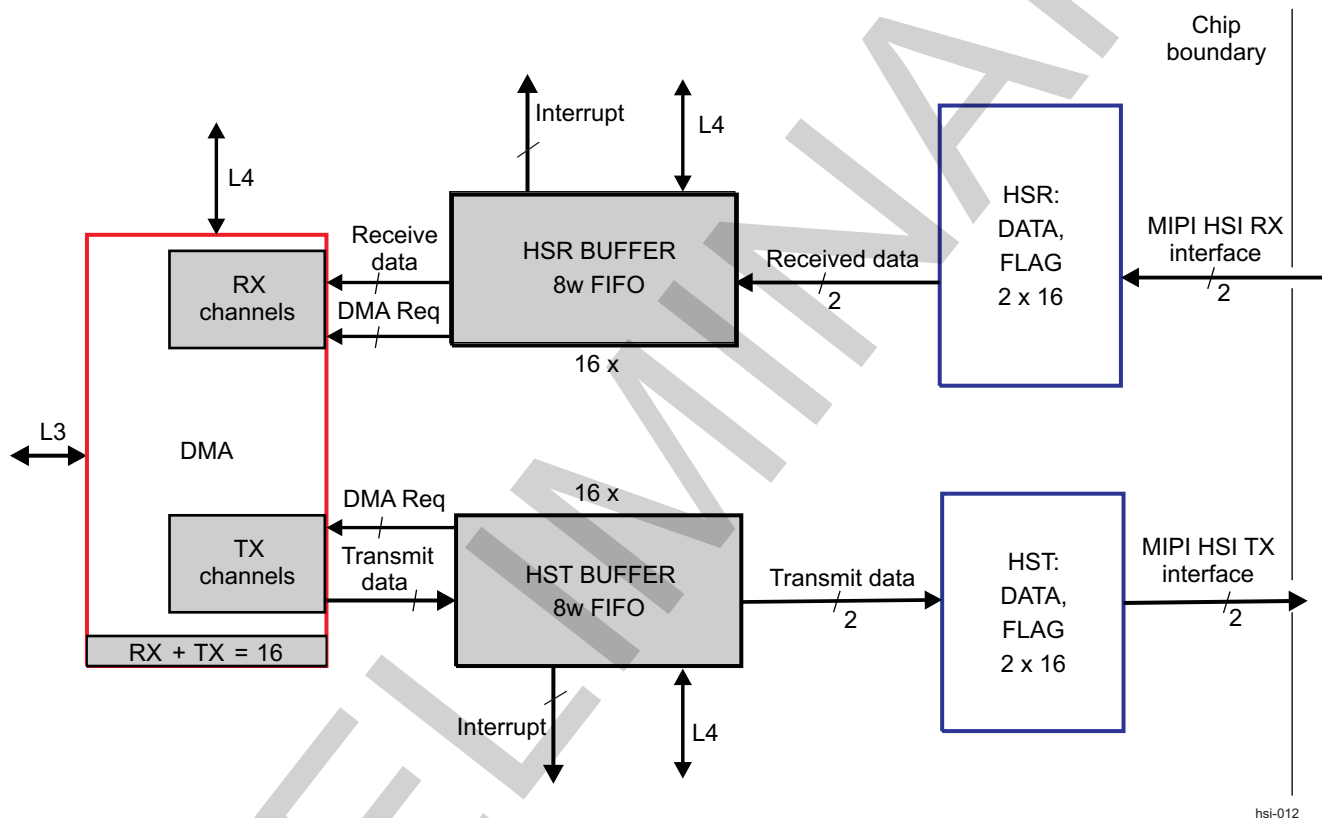

The FIFO subsystem allows temporary buffering while receive data is transferred from the receiver through DMA or the L4 interconnect to main memory, and the storing of transmit data read in main memory through DMA (or written by L4) before transmitting it. The FIFO depth is 8×32 -bit words for each channel, yielding a total size of 1KB with 16 bidirectional channels.

RX FIFOs are clocked by interconnect clock, TX FIFOs are clocked by undivided functional clock.

24.10.4.10.1 FIFO Subsystem Architecture

Figure 24-226 shows the overall FIFO architecture.

Figure 24-226. Overall FIFO Architecture

hsi-012

There are 16 DMA channels available. They can be used for RX or TX in any combination; direction is programmable.

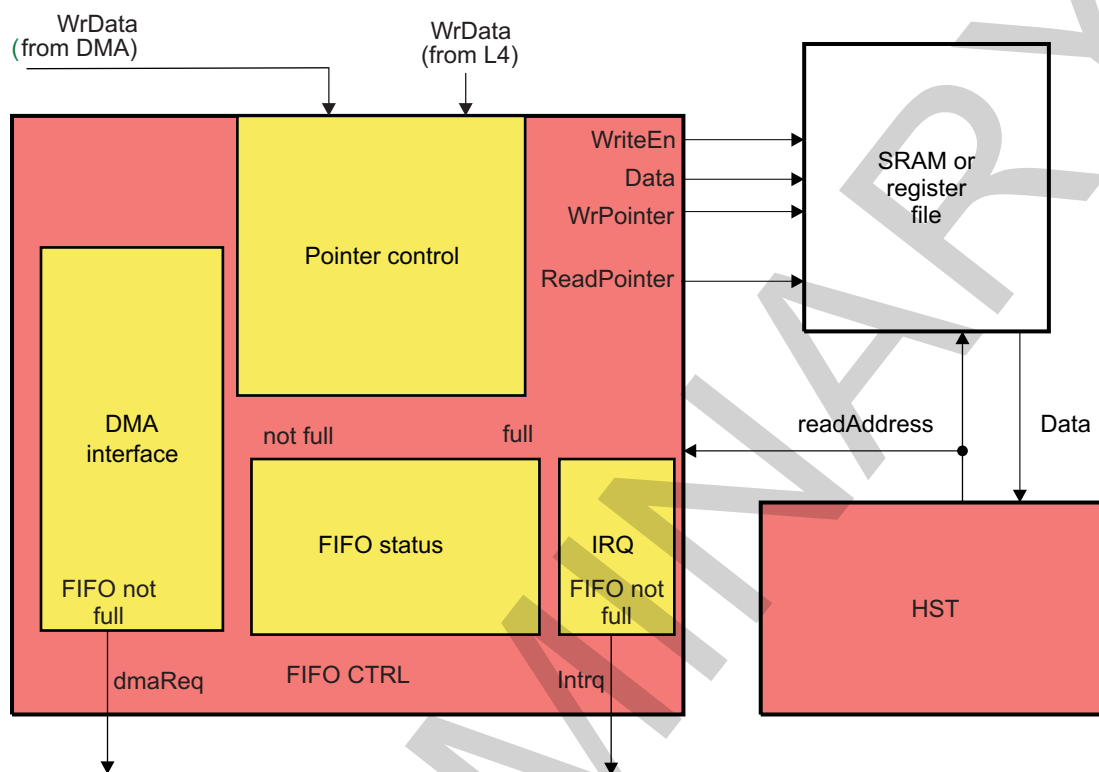

There are 16 RX FIFOs and 16 TX FIFOs. Not all FIFOs can be served by DMA, but all RX FIFOs (or else TX FIFOs) can be served by DMA, if needed. The other FIFOs, if used, must be read/written through the L4_CFG interconnect.

Both HSI ports provide up to 16×2 logical channels. This means that only one half of the HSI logical channels can be accommodated on the existing FIFOs. The others must not be used, and their use must flag an error. The 16 **HST_MAPPINGf** or **HSR_MAPPINGf** registers specify which HSI logical channel number is allowed to be received on RX FIFOs and/or fed for transmission by TX FIFOs. There is one mapping register for transmission and one for reception. Any attempt to transmit or process received data on HSI logical channels not previously mapped on mapping registers results in an error. In other words, some header values (bits 35 to 32) are not allowed at any given time, and generate an error when received. Software must ensure that the remote side sends payload on the allowed logical channels, specified by header values.

24.10.4.10.2 Transmit FIFO Architecture

Figure 24-227 shows the transmission FIFO architecture.

Figure 24-227. Transmission FIFO Architecture

hsi-013

The FIFO controller flags the condition of "room available in FIFO" or "FIFO not full" at any time when FIFO can host new data for transmission. This condition raises an interrupt request and a DMA request, if enabled. A programmable threshold in the corresponding [HST_MAPPING\[13:10\] THRESHOLD](#) bit field reduces the number of requests (they can be sent only when four words can be written in FIFO). The default value for the threshold is 0x0 (that is, a request rises as soon as one word can be written in FIFO). See [Table 24-797](#).

Table 24-797. Threshold for Transmit FIFO Interrupt/DMA Request

| HST_MAPPING[13:10] THRESHOLD | Number of Words in FIFO | Request |
|--|-------------------------|---------|
| 0 (legacy default) | Less than 8 | Yes |
| 1 | Less than 1 | Yes |
| 2 | Less than 2 | Yes |
| 3 | Less than 3 | Yes |
| 4 | Less than 4 | Yes |
| 5 | Less than 5 | Yes |
| 6 | Less than 6 | Yes |
| 7 | Less than 7 | Yes |
| 8 | Less than 8 | Yes |
| 9 to 15 | Any | No |

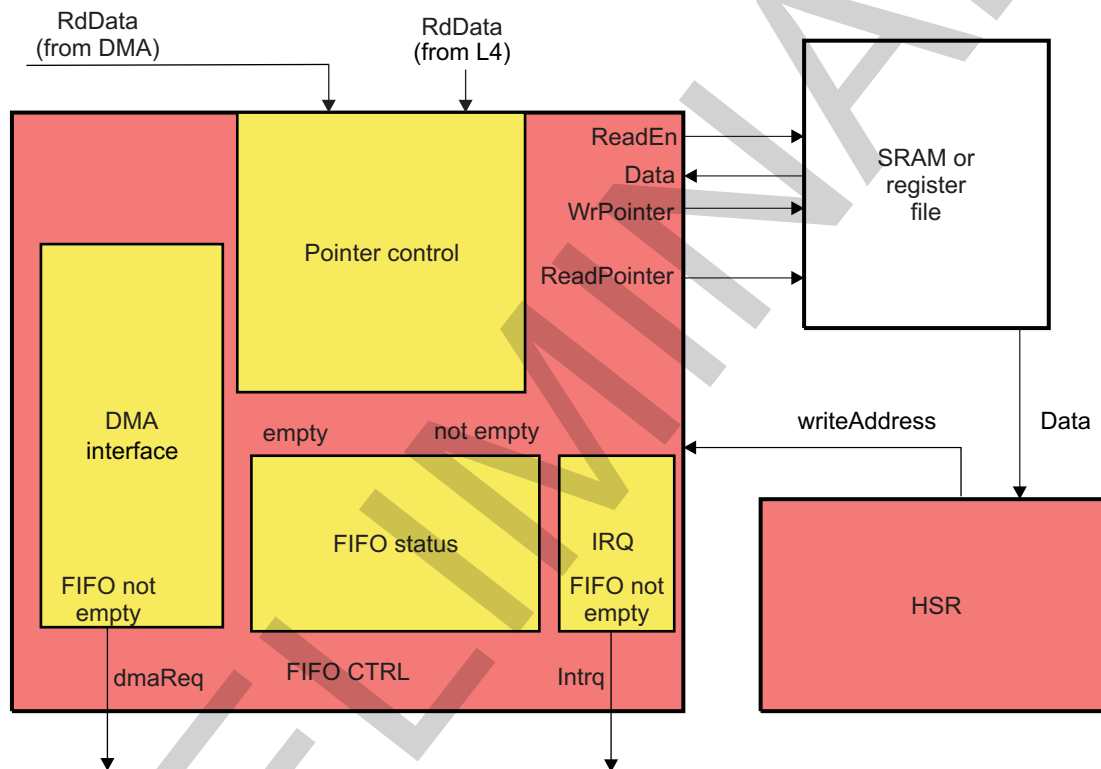

FIFO can be written by DMA and the L4 interconnect configuration port, but the L4 interconnect has fixed priority at any time. Software controls correct access. No hardware mechanism is provided to analyze and block concurrent operation, nor is any hardware control provided on reprogramming DMA registers during a transfer in which they are involved.

The address of FIFO is the corresponding [HST_BUFFER_Pp_CHN_i](#) register address. The FIFO controller generates the RAM addresses; namely, it manages the write pointer when DMA or the L4 interconnect access the [HST_BUFFER_Pp_CHN_i](#) address and it manages the read pointer when HST needs a data to transmit.

24.10.4.10.3 Receive FIFO Architecture

Figure 24-228 shows the reception FIFO architecture.

Figure 24-228. Reception FIFO Architecture

hsi-014

FIFO controller flags the condition of "unread data in FIFO" or "FIFO not empty" at any time when a FIFO hosts new data, received and not read. This condition can be simply the misalignment of the read pointer and write pointer. The condition raises an interrupt request and a DMA request, if enabled. The [HSR_MAPPING\[13:10\]](#) WORDS bit field informs software how many words must be read.

Unlike transmission, it is not possible here to filter requests through a threshold on the number of received words. If such a threshold is bigger than one, and a last single word is received after the last read, software is unaware that more data waits to be read.

The address of FIFO is the corresponding [HSR_BUFFER_Pp_CHN_i](#) register address. The FIFO controller generates the RAM addresses; namely, it manages the write pointer when HSR has received data, and it manages the read pointer when DMA or the L4 interconnect access the [HST_BUFFER_Pp_CHN_i](#) register.

24.10.4.10.4 FIFO Addressing

From a software point of view, a FIFO is seen at a single address, the corresponding [HST_BUFFER_Pp_CHN_i](#) or [HSR_BUFFER_Pp_CHN_i](#) register address. The [HST_SWAPBUFFER_Pp_CHN_i](#) or [HSR_SWAPBUFFER_Pp_CHN_i](#) register address is also provided to invert data endianness with byte granularity. FIFO overflow in RX is extremely unlikely, because of the large difference in HSI and L3 interconnect bit rate. However, if this occurs, the hardware prevents any loss of data by deasserting (setting to 0) the READY signal to the remote transmitter. FIFO overflow in TX is not flagged and must be avoided by software drivers.

24.10.4.11 Error Reporting

24.10.4.11.1 Detection of Errors

Error detection on the module is limited to the physical layer. No data corruption is checked, and no error is flagged as long as the receiver and transmitter agree on frame boundaries. Because clocking and data are recovered from alternate edges on the DATA and FLAG signals, three kinds of error can appear:

- Simultaneous edges
- Missing edges
- Additional edges

24.10.4.11.1.1 Simultaneous Edges

The transmitter is not supposed to produce simultaneous edges on the DATA and FLAG signals, but they can appear if the transmission rate is far higher than the receiver can handle. Given to the sampling protocol, this event may introduce errors in sampled data. Detecting this error is not easy, because the recovered clock is also affected, and in some configurations no other clock is available. One bit is available in the [HSR_ERROR_Pp](#) register, to report any hardware abnormal condition in data reception.

24.10.4.11.1.2 Missing Edges

Missing edges result in missing clock cycles, thus causing the receiver to get less data than expected on a given frame.

In synchronized flow, when the transmit side has completed transmission, the receiver side is still waiting for more data, and does not raise READY, thus stopping the transmitter from going on with more frames. A frame time-out counter (see [Section 24.10.4.11.2.1, Frame Time-Out Counter](#)) is used to escape this deadlock condition.

In pipelined flow, when the transmit side has completed transmission and has more data to transmit, the receiver accepts and processes this data as if they were part of the previous frame. Frame synchronization is then lost. It may randomly resume when in frame mode, as zeroes at the end of a frame are automatically discarded. But even in this case, a number of frames may be lost or corrupted. When in stream mode, no self-recovery is ever possible, and synchronization is lost forever. A frame burst counter (see [Section 24.10.4.11.2.3, Frame Burst Counter](#)) is used to limit the number of these potentially corrupted frames, simply by limiting the number of frames a transmitter can send back-to-back in a pipelined mode. A trailing bit counter (see [Section 24.10.4.11.2.2, Frame Tailing Bit Counter](#)) is used to check that the receiver and transmitter agree on being at the end of frame.

24.10.4.11.1.3 Additional Edges

Additional edges result in additional clock cycles, thus causing the receiver to get more data than expected on a given frame.

In synchronized flow, when the receive side thinks the frame is over, the transmitter keeps sending data until the end of frame is reached. In frame mode, if these additional bits are all 0s, they are discarded by the receiver, the transmission stops, and the receiver raises READY when it is available to receive a new frame. The transmit side starts a new frame and synchronization is recovered. But if at least one of the additional bits is set to 1, this can misguide the receiver that a new frame has already started and READY

stays at 0. The transmit side stops, waiting for $READY = 1$, a never occurring condition, because the receiver has lost synchronization. In this case, the link is stuck. This is also the case in stream mode, when the receiver wrongly thinks that a new frame is started, so it is not available to receive a full new frame, and it does not set $READY = 1$. A frame time-out counter (see [Section 24.10.4.11.2.1, Frame Time-out Counter](#)) is used to escape this deadlock condition.

24.10.4.11.2 Error Counters

Clocks for these three counters are provided through a division of the functional clock. These counters can be set to a value and can be stopped when some events occur. Events flag errors and set a corresponding bit in the [HSR_ERROR_Pp](#) register.

24.10.4.11.2.1 Frame Time-Out Counter

This counter is clocked by the functional clock, divided by the factor specified in the [HSR_DIVISOR_Pp\[7:0\]](#) RX_RATE_DIV_VAL bit field, to provide a clock at receive bit rate. Receive bit rate is always communicated by the remote transmitter through the protocol layer. This counter starts when the first bit of the frame is found and stops when 36 (or 37 depending on the mode) bits are correctly received by the receiver. If the counter overflows, an error is generated (the [HSR_ERROR_Pp\[1\]](#) FTE bit is set to 0). In OPP reduction of the functional clock only (receive side kept in fixed voltage domain), software can decide to reduce either the division factor for the clock, or the count, to use a clock consistent with receive rate, or a reduced count of a slower clock. This is transparent for hardware. This counter is not started when the receive rate is outside the full error detection rate range.

24.10.4.11.2.2 Frame Tailing Bit Counter

This counter can be clocked by the same clock as the frame time-out counter, which has the receiver bit rate frequency. It starts after the last bit of a frame is received, and $READY = 0$; in pipelined flow, this counter is started only after the end of the last frame received. No event stops the counter, except its own overflow. It counts up to 8. An error is logged (the [HSR_ERROR_Pp\[4\]](#) TBE bit is set to 0) if a 1 bit is received in frame mode before counter overflow, or any bit is received in stream mode before counter overflow. In OPP reduction of functional clock only (receive side kept in fixed voltage domain), software can decide to reduce either the division factor for the clock, or the count, to use a clock consistent with receive rate, or a reduced count of a slower clock. This is transparent for hardware. This counter is not started when receive rate is outside the full error detection rate range.

24.10.4.11.2.3 Frame Burst Counter

Differently from previous counters, this counter is clocked by a frame-sync signal obtained directly by received data. Its goal is to reduce the number of contiguous frames sent in pipelined flow. As explained in [Section 24.10.4.11.1, Detection of Errors](#), in some cases after missing/additional clock cycles, synchronization is lost and these pipelined frames can be corrupted. Software sets the count value, which can be as high as 256 (no higher values are supported by hardware). If $READY$ is dropped to 0, for reasons other than counter expiration, the counter is stopped and restarted as soon as transmission resumes. At the end of the count, $READY$ drops to 0. The tailing bit counter is started, and if it overflows without error detection and the receiver has enough room for another frame, $READY$ is reset to 1. No error and no interrupt are generated on this counter.

24.10.4.11.3 Error Registers

One error register per port is provided to check the error source that issued an interrupt, with more details than the error bit in the interrupt status register.

- The [HSR_ERROR_Pp\[0\]](#) SIG bit: Signal error bits are kept for legacy reasons, and they can be used for any abnormal situation the hardware wants to flag.
- The [HSR_ERROR_Pp\[1\]](#) FTE bit: Frame time-out error bits flag the situation when not even a frame has been received in the time corresponding to two or more frames, depending on the FTE counter software setting.
- The [HSR_ERROR_Pp\[4\]](#) FBE bit: Tailing bit error bits flag the situation when at least one spurious bit is received after the end of a frame, in the time corresponding to two or more bit times.

- The [HSR_ERROR_Pp\[7\]](#) RME bit: Receive mapping error bits flag the situation when data are received on a channel that is not mapped to any enabled FIFO.
- The [HSR_ERROR_Pp\[11\]](#) TME bit: Transmit mapping error bits flag the situation when DMA tries to access a FIFO that is not mapped to any logical channel, or is not enabled.

These two registers each have a companion [HSR_ERRORACK_Pp](#) register, where software must set the corresponding error bit to 1 to clear it.

24.10.5 HSI Programming Guide

24.10.5.1 HSI Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the HSI module.

24.10.5.1.1 Global Initialization

24.10.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the HSI module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the HSI.

For more information, see [Section 24.10.3, HSI Integration](#).

Table 24-798. Global Initialization of Surrounding Modules for HSI

| Surrounding Modules | Comments |
|---------------------------------|---|
| PRCM | HSI functional and interface clocks must be enabled. For more information, see Chapter 3 . |
| Control module | Module-specific pad muxing must be set in the control module. For more information, see Chapter 19 . |
| (Optional) Interrupt controller | The Cortex-A9 MPU, Cortex-M3 MPU, or DSP INTC must be configured to enable the interrupt request generation to the Cortex-A9 MPU, Cortex-M3 MPU, or DSP subsystem. For information about enabling interrupts, see Chapter 5 . |
| (Optional) Interconnect | For information about the L4 interconnect configuration, see Chapter 14, Interconnects . For information about L3 interconnect configuration, see Chapter 14, Interconnects . |

24.10.5.1.1.2 HSI Global Initialization

24.10.5.1.1.2.1 Main Sequence – HSI Global Initialization

This procedure initializes the HSI module after a power-on reset (POR) or software reset.

Table 24-799. HSI Global Initialization

| Step | Register/Bit Field/Programming Model | Value |
|--|--|-------|
| Perform an HSI software reset. | HSI_SYSCONFIG [1] SOFTRESET | 0x1 |
| WAIT UNTIL HSI reset is complete. | HSI_SYSSTATUS [0] RESETDONE | = 0x1 |
| Set standby mode configuration. | HSI_SYSCONFIG [13:12] MIDDLEMODE | 0x- |
| Set idle mode configuration. | HSI_SYSCONFIG [4:3] SIDLEMODE | 0x- |
| Clock auto gating. | HSI_SYSCONFIG [0] AUTOIDLE | 0x- |
| Set the transmit data rate. | HST_DIVISOR_Pp [7:0] TX_RATE_DIV_VAL | 0x- |
| (Optional) Enable DMA. | DMA_GCR [0] SWITCH_OFF | 0x0 |

24.10.5.1.2 HSI Operational Modes Configuration

24.10.5.1.2.1 HSI Transmit Mode/Receive Mode

24.10.5.1.2.1.1 Main Sequence – Configure HSI Transmitter

Table 24-800. HSI Configure HSI Transmitter

| Step | Register/Bit Field/Programming Model | Value |
|--|---|-------|
| Set the mode. | HST_MODE_Pp[1:0] MODE_VAL | 0x- |
| Set the data flow type. | HST_MODE_Pp[3:2] FLOW_VAL | 0x- |
| Set the hsi_wake line control. | HST_MODE_Pp[4] WAKE_CTRL | 0x- |
| Set the transmission bit rate | HST_DIVISOR_Pp[7:0] TX_RATE_DIV_VAL | 0x- |
| Set the arbitration mode. | HST_ARBMODE_Pp[0] ARB_VAL | 0x- |
| Set the number of active HSI logical channels. | HST_CHANNELS_Pp[4:0] CHAN_NUM_VAL | 0x- |
| Set the TX FIFO threshold. | HST_MAPPINGf[13:10] THRESHOLD | 0x- |
| Associate the TX FIFO to an HSI port. | HST_MAPPINGf[7] PORT_NUMBER | 0x- |
| Associate the TX FIFO to an HSI logical channel. | HST_MAPPINGf[4:1] CH_NUMBER | 0x- |
| Enable the TX FIFO. | HST_MAPPINGf[0] ENABLE | 0x- |

24.10.5.1.2.1.2 Main Sequence – Configure HSI Receiver

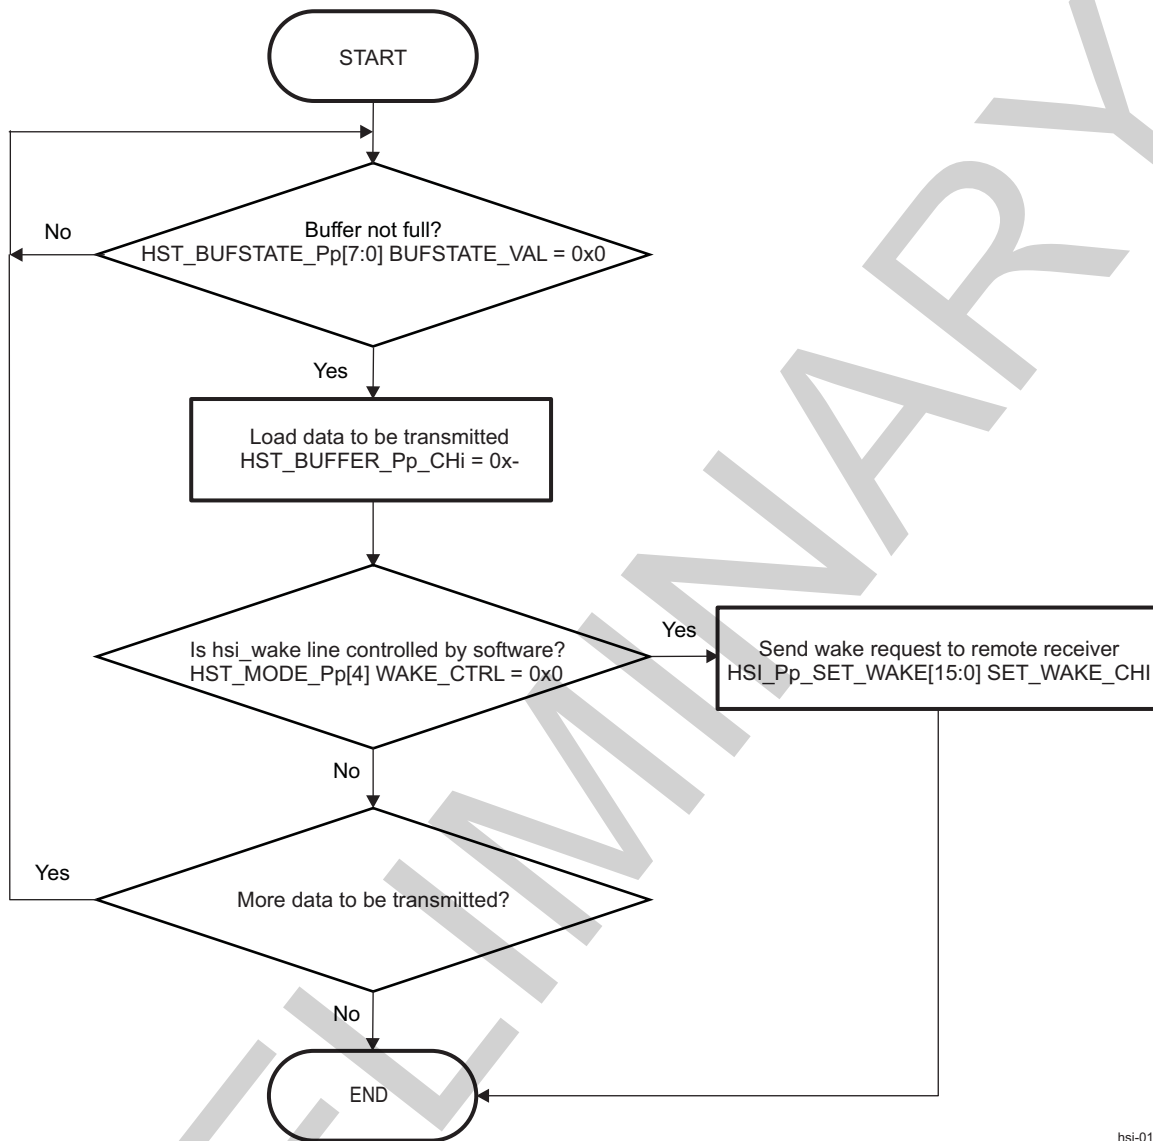

Table 24-801. HSI Configure HSI Receiver

| Step | Register/Bit Field/Programming Model | Value |
|---|---|-------|
| Set a clock frequency for the error detection counters. | HSR_DIVISOR_Pp[7:0] RX_RATE_DIV_VAL | 0x- |
| Set the number of active HSI logical channels. | HSR_CHANNELS_Pp[4:0] CHAN_NUM_VAL | 0x- |
| Set the frame timeout error counter. | HSR_COUNTERS_Pp[19:0] FT | 0x- |
| Set the tailing bit error counter. | HSR_COUNTERS_Pp[23:20] TB | 0x- |
| Set the frame burst error counter. | HSR_COUNTERS_Pp[31:24] FB | 0x- |
| Associate the RX FIFO to an HSI port. | HSR_MAPPINGf[7] PORT_NUMBER | 0x- |
| Associate the RX FIFO to an HSI logical channel. | HSR_MAPPINGf[4:1] CH_NUMBER | 0x- |
| Enable the RX FIFO. | HSR_MAPPINGf[0] ENABLE | 0x- |
| Set the mode in receive mode. | HSR_MODE_Pp[1:0] MODE_VAL | 0x- |
| Set the data flow type in receive mode. | HSR_MODE_Pp[3:2] FLOW_VAL | 0x- |

24.10.5.1.2.1.3 Main Sequence – HSI Polling Method

24.10.5.1.2.1.3.1 Sub-sequence – HSI Transmit in Polling Method

[Figure 24-229](#) is a procedure flow chart for HSI transmit in polling method.

Figure 24-229. HSI Transmit in Polling Method**Table 24-802. Register Call Summary for Subsequence – HSI Transmit in Polling Method**

| Register Name | Register Name | Register Name |
|---------------------------------|-------------------------------------|-----------------------------|
| HST_BUFSTATE_Pp | HST_BUFFER_Pp_CHN_i | HST_MODE_Pp |
| HSI_Pp_SET_WAKE | | |

24.10.5.1.2.1.3.2 Subsequence – HSI Receive in Polling Method

Table 24-803. Event Servicing in HSI Receive in Polling Method

| Step | Register/Bit Field/Programming Model | Value |
|--|---|-------|
| IF: Is there data frame to be read? | HSR_BUFSTATE_Pp[7:0] BUFSTATE_VAL | =0x1 |
| Identify number of words available in RX FIFO for reading. | HSR_MAPPING[13:10] WORDS | 0x- |
| Read data from RX FIFO. | HSR_BUFFER_Pp_CHN_i[31:0] DATA | 0x- |

24.10.5.1.2.1.5 Main Sequence – HSI DMA Mode

24.10.5.1.2.1.5.1 Sub-sequence – DMA Configuration

Table 24-809. HSI DMA Configuration

| Step | Register/Bit Field/Programming Model | Value |
|---|---|-------|
| Perform a DMA software reset. | DMA_GRST [0] SWRESET | 0x1 |
| WAIT UNTIL DMA reset is complete. | DMA_GRST [0] SWRESET | = 0x0 |
| Set autoidle mode configuration for DMA. | DMA_GCR [3] AUTOGATING | 0x1 |
| Configure HSI DMI receiver. | See Table 24-810 . | |
| Configure HSI DMI transmit. | See Table 24-811 . | |
| Enable DMA interrupts. | See Section 24.10.5.1.2.1.5.4 . | |
| Enable DMA channel to start DMA transfer. | DMA_CCR_CSDP_i [23] ENABLE | 0x1 |
| WHEN DMA INTERRUPT OCCURS | See Table 24-804 . | |

24.10.5.1.2.1.5.2 Subsequence – DMA Receive Mode

Table 24-810. Configure DMA Receive Mode

| Step | Register/Bit Field/Programming Model | Value |
|--|---|-------|
| Set the transfer source to peripheral port. | DMA_CCR_CSDP_i [5:2] SRC | 0x9 |
| (Optional) Set the source burst enable. | DMA_CCR_CSDP_i [8:7] SRC_BURST_EN | 0x1 |
| Set the transfer destination to memory port. | DMA_CCR_CSDP_i [12:9] DST | 0x8 |
| (Optional) Set the destination burst enable. | DMA_CCR_CSDP_i [15:14] DST_BURST_EN | 0x1 |
| Set the source addressing mode to constant address. | DMA_CCR_CSDP_i [29:28] SRC_ADD_MODE | 0x0 |
| Set the destination addressing mode to post-incremented address. | DMA_CCR_CSDP_i [31:30] DST_ADD_MODE | 0x1 |
| Set the source start address. | DMA_CSSA_i [31:0] ADDR | 0x- |
| Set the destination start address. | DMA_CDSA_i [31:0] ADDR | 0x- |
| Set the number of elements in a block. | DMA_CEN_i [15:0] SIZE | 0x- |

24.10.5.1.2.1.5.3 Subsequence – DMA Transmit Mode

Table 24-811. Configure DMA Transmit Mode

| Step | Register/Bit Field/Programming Model | Value |
|---|--|-------|
| Set the transfer source to memory port. | DMA_CCR_CSDP_i[5:2] SRC | 0x8 |
| (Optional) Set the source burst enable. | DMA_CCR_CSDP_i[8:7] SRC_BURST_EN | 0x1 |
| Set the transfer destination to peripheral port. | DMA_CCR_CSDP_i[12:9] DST | 0x9 |
| (Optional) Set the destination burst enable to single access. | DMA_CCR_CSDP_i[15:14] DST_BURST_EN | 0x1 |
| Set the source addressing mode to post-incremented address. | DMA_CCR_CSDP_i[29:28] SRC_ADD_MODE | 0x1 |
| Set the destination addressing mode to constant address. | DMA_CCR_CSDP_i[31:30] DST_ADD_MODE | 0x0 |
| Set the source start address. | DMA_CSSA_i[31:0] ADDR | 0x- |
| Set the destination start address. | DMA_CDSA_i[31:0] ADDR | 0x- |
| Set the number of elements in a block. | DMA_CEN_i[15:0] SIZE | 0x- |

24.10.5.1.2.1.5.4 Subsequence – Enable DMA Interrupts

Table 24-812. Enable DMA Interrupts

| Step | Register/Bit Field/Programming Model | Value |
|---|---|-------|
| Enable the DMA channels that shall generate an interrupt to a processor (MPU and/or DSP). | HSI_DMA_M_IRQENABLE[15:0] DMA_EN_CHI and/or HSI_DMA_D_IRQENABLE[15:0] DMA_EN_CHI | 0x- |
| Enable the DMA full-block interrupt event. | DMA_CSR_CCIR_i[5] BLOCK_IE | 0x1 |
| Enable the DMA half-block interrupt event. | DMA_CSR_CCIR_i[2] HALF_IE | 0x1 |
| Enable the DMA time-out overflow interrupt event. | DMA_CSR_CCIR_i[0] TOUT_IE | 0x1 |

24.10.5.1.2.1.5.5 Subsequence – DMA Interrupt Servicing

Table 24-813. Event Servicing in DMA Transmit/Receive Mode

| Step | Register/Bit Field /Programming Model | Value |
|--|---|-------|
| Identify which DMA channel has generated an interrupt. | HSI_DMA_M_IRQSTATUS[15:0] DMA_CHI and/or HSI_DMA_D_IRQSTATUS[15:0] DMA_CHI | 0x- |
| Identify the interrupt event type. | DMA_CSR_CCIR_i[21] BLOCK_IS and/or DMA_CSR_CCIR_i[18] HALF_IS and/or DMA_CSR_CCIR_i[16] TOUT_IS | 0x- |
| Acknowledge DMA global interrupt by setting the relevant bit to 1. | HSI_DMA_M_IRQSTATUS[15:0] DMA_CHI and/or HSI_DMA_D_IRQSTATUS[15:0] DMA_CHI | 0x- |

24.10.5.1.2.1.6 Main Sequence – HSI Error Reporting

Table 24-814. Enable HSI Error Interrupts

| Step | Register/Bit Field/Programming Model | Value |
|----------------------------------|---|-------|
| Enable error detected interrupt. | HSI_Pp_M_IRQrU_ENABLE[24] HSR_ERROR and/or HSI_Pp_D_IRQrU_ENABLE[24] HSR_ERROR and/or HSI_Pp_M_IRQr_ENABLE[24] HSR_ERROR and/or HSI_Pp_D_IRQr_ENABLE[24] HSR_ERROR | 0x1 |

Table 24-815. Event Servicing Error

| Step | Register/Bit Field/Programming Model | Value |
|---|---|-------|
| Read interrupt status register. | HSI_Pp_M_IRQrU_STATUS[24] HSR_ERROR and/or HSI_Pp_D_IRQrU_STATUS[24] HSR_ERROR and/or HSI_Pp_M_IRQr_STATUS[24] HSR_ERROR and/or HSI_Pp_D_IRQr_STATUS[24] HSR_ERROR | 0x- |
| Identify the interrupt event type. | HSR_ERROR_Pp[0] SIG HSR_ERROR_Pp[1] FTE HSR_ERROR_Pp[4] FBE HSR_ERROR_Pp[7] RME HSR_ERROR_Pp[11] TME | 0x- |
| Clear the event by writing 1 into the relevant bit. | HSR_ERRORACK_Pp[0] SIG HSR_ERRORACK_Pp[1] FTE HSR_ERRORACK_Pp[4] FBE HSR_ERRORACK_Pp[7] RME HSR_ERRORACK_Pp[11] TME | 0x1 |
| Acknowledge the interrupt by writing 1 into the relevant bit. | HSI_Pp_M_IRQrU_STATUS[24] HSR_ERROR and/or HSI_Pp_D_IRQrU_STATUS[24] HSR_ERROR and/or HSI_Pp_M_IRQr_STATUS[24] HSR_ERROR and/or HSI_Pp_D_IRQr_STATUS[24] HSR_ERROR | 0x1 |

24.10.6 HSI Register Manual

24.10.6.1 HSI Instance Summary

Table 24-816 summarizes the HSI instance.

Table 24-816. HSI Instance Summary

| Module Name | Module Base Address | Size |
|------------------|---------------------|------|
| HSI_TOP | 0x4A05 8000 | 5 KB |
| HSI_DMA_CHANNELS | 0x4A05 9800 | 1 KB |

24.11 High-Speed Multiport USB Host Subsystem

This section describes the HS universal serial bus (USB) host subsystem of the device.

24.11.1 High-Speed Multiport USB Host Subsystem Overview

NOTE: Copyright ©2004, 2005, 2006, 2007, 2008 Synopsys, Inc. All rights reserved. Used with permission.

The HS USB host subsystem is composed of:

- HS multiport USB host controller module
- USB TLL module
- Three HSIC digital front end (DFE) modules

The HS USB host subsystem consists of several ports delivered outside the device, with several modes per port. The modes are:

- UTMI+ low pin-count interface (ULPI) for external PHY
- ULPI transceiverless link (TLL)
- Serial TLL
- High-speed interchip (HSIC)

The HS USB host controller module contains two quasi-independent host controllers that operate in parallel:

- The EHCI controller, based on the *Enhanced Host Controller Interface (EHCI) Specification for USB Release 1.1*, is responsible for HS traffic (480 Mbps), over ULPI/USB 2.0 transceiver macrocell interface (UTMI).
- The OHCI controller, based on the *Open Host Controller Interface (OHCI) Specification for USB Release 1.0a*, is responsible for full-speed (FS)/low-speed (LS) traffic (12/1.5 Mbps, respectively), over a serial interface.

Each of the three external ports of the HS USB host controller module is owned by one of the controllers (EHCI or OHCI) at a given time. Each port can work in several modes:

- When the port is owned by the OHCI (FS) host, the 6-pin internal serial interface to the TLL is used.
- When the port is owned by the EHCI (HS) host, UTMI internal interface to the TLL, or ULPI to external PHY is used.

For more details on USB controller module internal architecture, see [Section 24.11.4.1, USB Host Controller Functionality](#).

The current subsystem does not support all dynamic USB speed negotiations, as expected from a standard USB host port at the same time. It supports:

- HS-only (with external HS physical layer [PHY]/HS TLL mode HSIC) on the EHCI
- FS-/LS-only (with external FS PHY/FS TLL mode) on the OHCI

The USB TLL module is the adapter on the host ports. It consists of two channels that are seen as emulating a pair of back-to-back PHYs and has:

- UTMI port, connected to the host controller module
- ULPI port, connected to a ULPI peripheral

The three HSIC DFEs plug into the UTMI port of the host controller module and control HSIC-capable bidirectional I/O drivers driving the HSIC lines (strobe/data).

[Figure 24-232](#) shows the HS USB host subsystem.

Figure 24-232. HS USB Host Controller

usb-006

NOTE: For more information about output pin names in different modes, see [Section 24.11.2.1, ULPIs](#); [Section 24.11.2.2, FS/LS Serial Interfaces](#); and [Section 24.11.2.3, HSIC Interface](#).

24.11.1.1 Main Features

The HS multiport USB host subsystem supports the following features:

- HS USB host controller:
 - One initiator on level 3 (L3)
 - One target on level 4 (L4)
 - Two IRQs

- No DMA request
- Implements a USB 2.0 HS host controller:
 - HS (480 Mbps) communication with HS USB peripherals or hubs
 - FS (12 Mbps) communication with FS USB peripherals or hubs
 - LS (1.5 Mbps) communication with LS USB peripherals
- Support for suspend, resume, remote wakeup
- Two downstream ports (2-port root hub, with each port supporting UTMI, ULPI, and serial interface)
- Heterogeneous port configuration (that is, different HS/FS PHYs with different clocking methods on different ports, supported simultaneously)
- Single FS host controller, compliant with OHCI software application programming interface (API), per-port power switching support
- Interface with UTMI PHYs (that is, the TLL module) on all ports
 - 8-bit data path
 - Synchronous (on-chip) interface, independent clock input per port (that is, the TLL module provides a clock to the host controller and to the remote USB controller).
 - HSIC front-end (after appropriate internal configuration)
- Interface with ULPI PHYs (transceivers) on all ports
 - 8-bit bidirectional data bus (SDR mode)
 - 12-pin interface
 - Independent clock input per port (ULPI PHY in output mode)
 - Supports only HS data transactions

CAUTION

The HS USB host subsystem can support only the external charge pump of PHY (no support of internal charge pump for ULPI PHY).

- Interconnect initiator for built-in DMA operation of EHCI/OHCI
- Interconnect target for configuration
- Link power management (LPM) support in OHCI and EHCI hosts
- Hardware save-and-restore (SAR) feature of the hardware context of the suspended host
- USBTLL module:
 - One interconnect target on L4
 - One IRQ
 - No DMA request
 - HS USB ports and each of them has four ports (A to D):
 - Port A: Host module UTMI+ port. Connects to the local link controller (host module). The UTMI "local" port is used in all configurations (that is, the entire channel can be seen as a protocol converted from that port to one of the other, "remote" ports. The port complies with UTMI+ version 1.0 and supports:
 - 8-data-bit, UTMI (HS/FS-capable)
 - UTMI+ L3 extensions
 - Vcontrol/Vstatus (from UTMI)
 - Serial FS 6-pin mode
 - Port B: Link-side UTMI+ port. Connects to HSIC front-end module.
 - Port C: PHY-side ULPI slave port. Connects to a remote (off-chip) ULPI link controller through I/O pads.
 - SDR ULPI mode (8-bit data width)

- Port D: Serial multimode port.
 - Supports 6-pin unidirectional and 4-/3-/2-pin bidirectional modes
 - All modes are supported for TLL or PHY interface configuration, except 2-pin mode (which is TLL-only).
 - Supports sideband signals (pullup/down control, speed/suspend enable, etc.)
- HSIC module: Converts UTMI into HSIC standard (2-wire TLL HS protocol)

24.11.2 HS Multiport USB Host Subsystem Environment

The HS USB host subsystem provides three kinds of interfaces for connection:

- ULPIs for HS data transactions (up to 480 Mbps) (see [Section 24.11.2.1, ULPIs](#))
- Serial interfaces, using the USBTLL module, for FS and LS data transactions (up to 12 Mbps) (see [Section 24.11.2.2, FS/LS Serial Interfaces](#))
- HSIC interface to two HSIC lines over HSIC-capable I/O drivers (see [Section 24.11.2.3, HSIC Interface](#))

Figure 24-233 is an overview of the environment of the HS USB host subsystem.

Figure 24-233. HS Multiport USB Host Subsystem Environment

usb_swpu140-072

NOTE: For more information about output pin names in different modes, see [Section 24.11.2.1, ULPIs](#); [Section 24.11.2.2, FS/LS Serial Interfaces](#); and [Section 24.11.2.3, HSIC Interface](#).

NOTE: The two ports are configured independently and can be in different modes.

For more information how the pins are multiplexed, see [Section 19.4.8, PAD Functional Multiplexing and Configuration](#).

24.11.2.1 ULPIs

The HS USB host subsystem supports the following configurations with the ULPIs:

- External USB transceiver:

- ULPIs: 12-pin/8-bit data SDR version
- TLL:
 - SDR ULPI mode (12-pin/8-bit data width)

The HS USB host subsystem supports USB ports that use the ULPI mode to connect to an off-chip HS ULPI transceiver (12-pin/8-bit data SDR mode) for data transactions (up to 480 Mbps). FS and LS are not supported over the ULPI.

The device supports TLL logic interfaces on its ports in ULPI TLL interface mode. TLL modes enable glueless interconnect to another USB device port.

The external USB transceiver ULPIs and ULPI TLL interfaces cannot be used together on the same port. It is possible for one port to use ULPI and the other port to use ULPI TLL.

Figure 24-234 and Figure 24-235 show typical applications using the HS USB host subsystem with ULPI and the ULPI TLL interface, respectively.

Figure 24-234. External USB Transceiver ULPIs

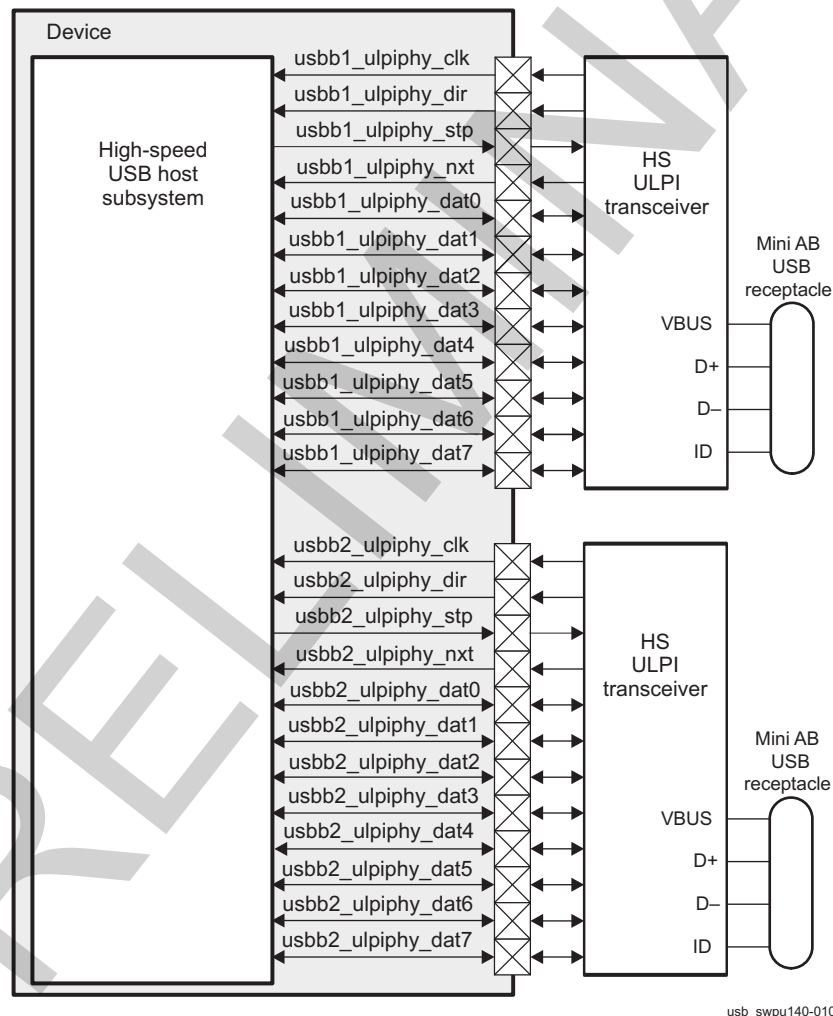

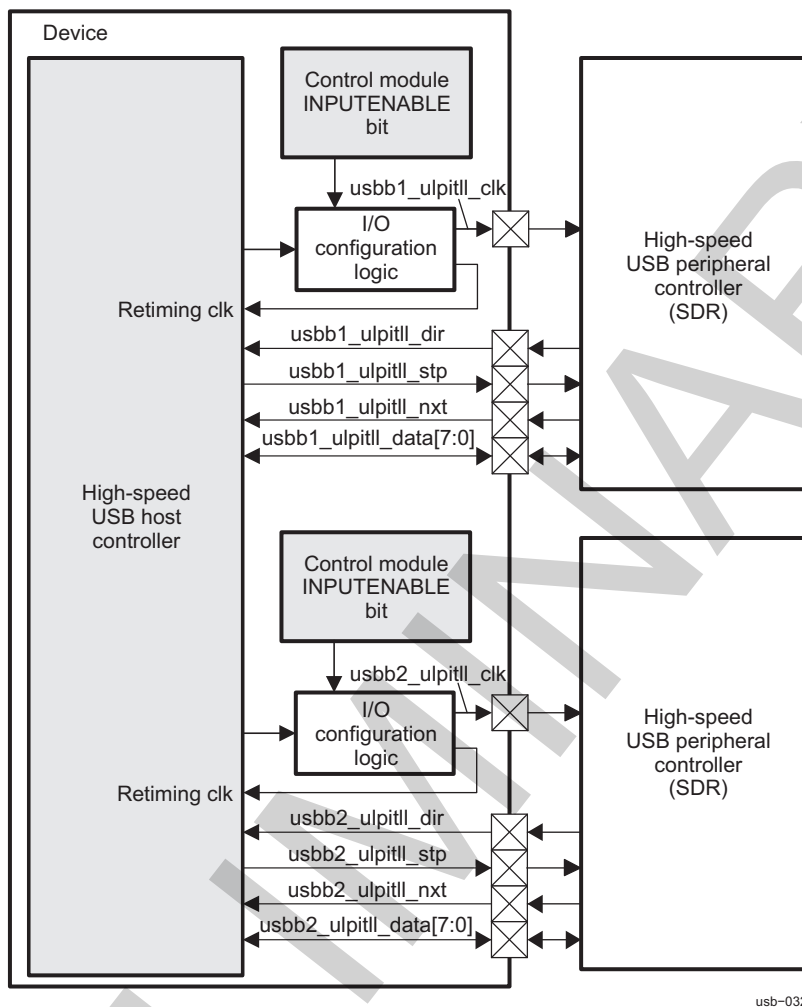

Figure 24-235. ULPI TLL Interfaces

The 12-pin ULPI uses an 8-bit data bus with data synchronous to the rising edge of the PHY (transceiver) clock (SDR mode).

24.11.2.1.1 Transceiver Interface Configuration in ULPI Mode

The HS USB host subsystem supports only the 12-pin/8-bit data SDR version of the ULPI mode.

Figure 24-236 shows USB ports using the 12-pin/8-bit data SDR version of the ULPI mode.

Figure 24-236. ULPIs – 12-Pin/8-Bit Data SDR Version

[Table 24-930](#) describes the I/O pins of the USB ports using the 12-pin/8-bit data SDR version of the ULPI mode.

Table 24-930. ULPI – 12-Pin/8-Bit Data SDR Version I/O Description

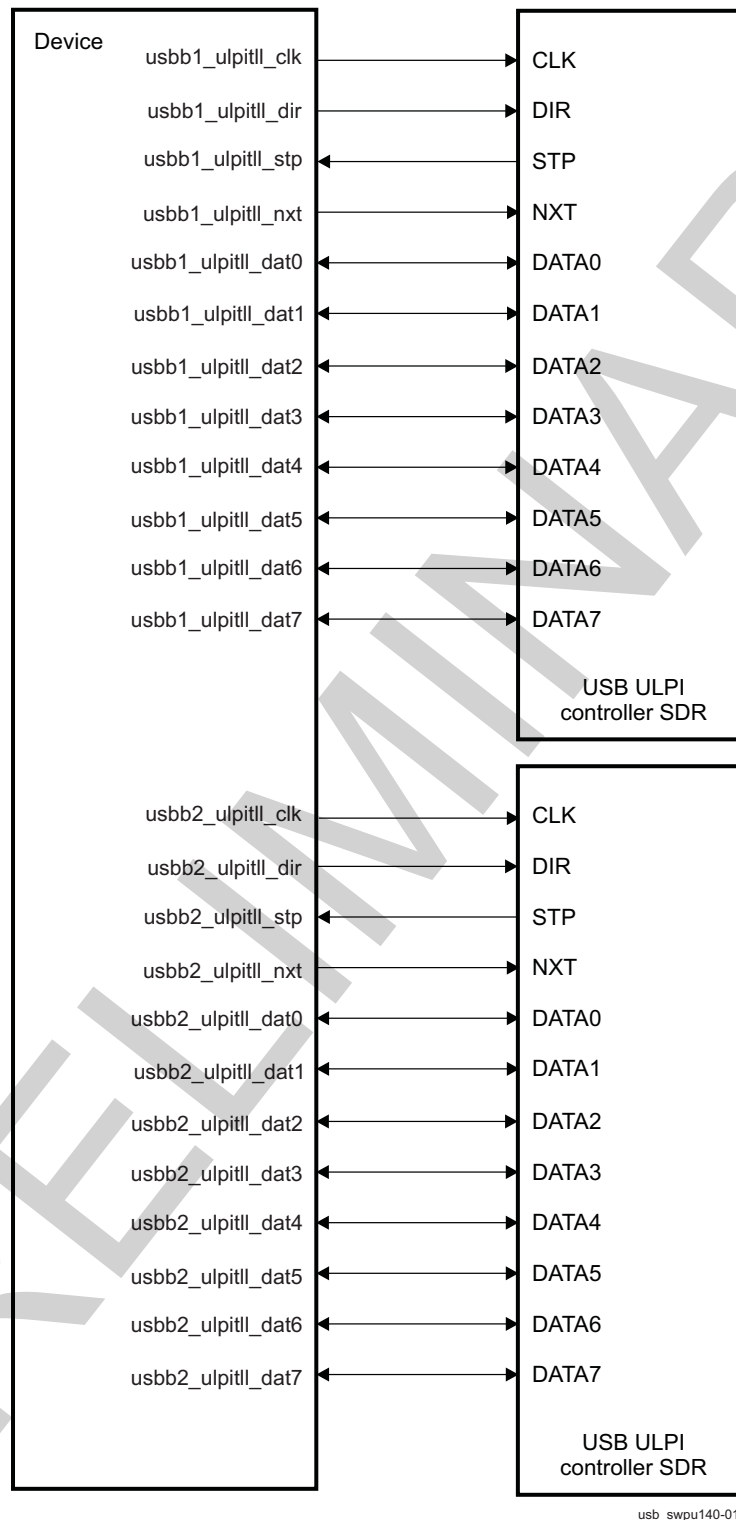

| Signal Name | I/O ⁽¹⁾ | Description | Reset Value |
|--------------------------------------|--------------------|---|-------------|
| HS USB Host Controller Port 1 | | | |
| usbb1_ulpiiphy_clk | I | Clock input from remote PHY IC | 0 |
| usbb1_ulpiiphy_dir | I | Data direction control from remote PHY IC | Unknown |
| usbb1_ulpiiphy_stp | O | Stop signal to remote PHY IC | 1 |
| usbb1_ulpiiphy_nxt | I | Next signal from remote PHY IC | Unknown |
| usbb1_ulpiiphy_dat0 | I/O | Bidirectional DATA0 | Unknown |
| usbb1_ulpiiphy_dat1 | I/O | Bidirectional DATA1 | Unknown |
| usbb1_ulpiiphy_dat2 | I/O | Bidirectional DATA2 | Unknown |
| usbb1_ulpiiphy_dat3 | I/O | Bidirectional DATA3 | Unknown |
| usbb1_ulpiiphy_dat4 | I/O | Bidirectional DATA4 | Unknown |
| usbb1_ulpiiphy_dat5 | I/O | Bidirectional DATA5 | Unknown |
| usbb1_ulpiiphy_dat6 | I/O | Bidirectional DATA6 | Unknown |
| usbb1_ulpiiphy_dat7 | I/O | Bidirectional DATA7 | Unknown |

| usbb2_ulpiiphy_dat7 | I/O | Bidirectional DATA7 | Unknown |

⁽¹⁾ I = Input; O = Output

24.11.2.1.2 TLL Interface Configuration in ULPI Mode

The HS USB host controller is coupled with the USBTLL module to compose the ULPI TLL interface modes.

Figure 24-237 shows USB ports using the 12-pin/8-bit data SDR version of the ULPI TLL interface mode.

Figure 24-237. ULPI TLL Interfaces – 12-Pin/8-Bit Data SDR Version

[Table 24-931](#) describes the I/O pins of the USB ports using the 12-pin/8-bit data SDR version of the ULPI TLL interface mode.

Table 24-931. ULPI TLL Interfaces – 12-Pin/8-Bit Data SDR Version I/O Description

| Signal Name | I/O ⁽¹⁾ | Description | Reset Value |
|--------------------------|--------------------|--|-------------|
| HS USB TLL Port 1 | | | |
| usbb1_ulpitll_clk | O | Clock output to remote ULPI link controller ⁽²⁾ | 0 |
| usbb1_ulpitll_dir | O | Data direction control from remote ULPI link controller | 0 |
| usbb1_ulpitll_stp | I | Stop signal to remote ULPI link controller | Unknown |
| usbb1_ulpitll_nxt | O | Next signal from remote ULPI link controller | 0 |
| usbb1_ulpitll_dat0 | I/O | Bidirectional DATA0 | 0 |
| usbb1_ulpitll_dat1 | I/O | Bidirectional DATA1 | 0 |
| usbb1_ulpitll_dat2 | I/O | Bidirectional DATA2 | 0 |
| usbb1_ulpitll_dat3 | I/O | Bidirectional DATA3 | 0 |
| usbb1_ulpitll_dat4 | I/O | Bidirectional DATA4 | 0 |
| usbb1_ulpitll_dat5 | I/O | Bidirectional DATA5 | 0 |
| usbb1_ulpitll_dat6 | I/O | Bidirectional DATA6 | 0 |
| usbb1_ulpitll_dat7 | I/O | Bidirectional DATA7 | 0 |
| HS USB TLL Port 2 | | | |
| usbb2_ulpitll_clk | O | Clock output to remote ULPI link controller ⁽²⁾ | 0 |
| usbb2_ulpitll_dir | O | Data direction control from remote ULPI link controller | 0 |
| usbb2_ulpitll_stp | I | Stop signal to remote ULPI link controller | Unknown |
| usbb2_ulpitll_nxt | O | Next signal from remote ULPI link controller | 0 |
| usbb2_ulpitll_dat0 | I/O | Bidirectional DATA0 | 0 |
| usbb2_ulpitll_dat1 | I/O | Bidirectional DATA1 | 0 |
| usbb2_ulpitll_dat2 | I/O | Bidirectional DATA2 | 0 |
| usbb2_ulpitll_dat3 | I/O | Bidirectional DATA3 | 0 |
| usbb2_ulpitll_dat4 | I/O | Bidirectional DATA4 | 0 |
| usbb2_ulpitll_dat5 | I/O | Bidirectional DATA5 | 0 |
| usbb2_ulpitll_dat6 | I/O | Bidirectional DATA6 | 0 |
| usbb2_ulpitll_dat7 | I/O | Bidirectional DATA7 | 0 |

⁽¹⁾ I = Input; O = Output

⁽²⁾ This signal is also used as retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).

24.11.2.2 FS/LS Serial Interfaces

The HS USB host subsystem supports the following configurations with the serial interfaces:

- External USB transceiver (see [Section 24.11.2.2.3, External USB Transceiver Interface Configurations in Serial Modes](#))
 - Serial 6-pin PHY (transceiver) interfaces: 6-pin mode (TX: DAT/SE0 or TX: DP/DM unidirectional mode), 4-pin mode (DP/DM bidirectional mode), and 3-pin mode (DAT/SE0 bidirectional mode)
- TLL (see [Section 24.11.2.2.4, TLL Interface Configurations in Serial Modes](#))
 - Serial 6-pin TLL interfaces: 6-pin mode (DAT/SE0 and DP/DM unidirectional modes), 4-pin mode (DP/DM bidirectional mode), 3-pin mode (DAT/SE0 bidirectional mode), and 2-pin mode (DAT/SE0 and DP/DM bidirectional modes)

CAUTION

Only FS and LS data transactions are possible in serial mode. Transceiver interface is serial (its frequency is that of the actual USB line) and combinatorial (no clock is passed).

Whether in TLL or external transceiver configuration, the serial interface follows the same principles: it is limited to FS/LS, and HS requires a parallel interface.

24.11.2.2.1 Encoding in Serial Mode

24.11.2.2.1.1 Unidirectional

When an external USB transceiver is connected to the device and is used in 6-pin unidirectional DAT/SE0 encoding mode, the encoding described in [Table 24-932](#) is used.

Table 24-932. Signaling Between HS USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DAT/SE0 Signaling)

| Logical Signal Name | Device Pin Direction | Transceiver Pin Direction | Description | | | | | | | | | | | | | | | | | | | | | | | | | |
|---------------------|----------------------|---------------------------|---|----------|-----|-----|----|----|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|----------|----------|
| TXEN | Output | Input | When low, the USB transceiver drives D+ and D–. | | | | | | | | | | | | | | | | | | | | | | | | | |
| DAT and SE0 | Output | Input | Controls the values output by the USB transceiver on D+ and D– when TXEN is low; ignored when TXEN is high. <table><tr><td>TXEN</td><td>DAT</td><td>SE0</td><td>D+</td><td>D–</td></tr><tr><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td></tr><tr><td>0</td><td>1</td><td>0</td><td>1</td><td>0</td></tr><tr><td>0</td><td>X</td><td>1</td><td>0</td><td>0</td></tr><tr><td>1</td><td>X</td><td>X</td><td>Undriven</td><td>Undriven</td></tr></table> | TXEN | DAT | SE0 | D+ | D– | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 0 | X | 1 | 0 | 0 | 1 | X | X | Undriven | Undriven |

| | | | D+ DP |
| | | | 0 0 |
| DM | Input | Output | Output from transceiver single-ended D-signal receiver |
| | | | D- DM |
| | | | 0 0 |
| | | | 1 1 |

24.11.2.2.1.2 Bidirectional

When an external USB or USB OTG transceiver is connected to the device and is used in 3-pin bidirectional DAT/SE0 encoding mode, the encoding described in [Table 24-934](#) is used.

Table 24-934. Signaling Between HS USB Host Subsystem and 3-Pin Bidirectional USB Transceiver Using DAT/SE0 Signaling

| Logical Signal Name | Device Pin Direction | Transceiver Pin Direction | Description |
|---------------------|----------------------|---------------------------|--|
| TXEN | Output | Input | When low, the USB transceiver drives D+ and D-. |
| DAT and SE0 | Output | Input | When TXEN is low, the device drives DAT and SE0 and the transceiver drives D+ and D- based on the values of DAT and SE0. |
| | | | TXEN DAT SE0 D+ D- |
| | | | 0 0 0 0 1 |
| | | | 1 0 0 1 0 |
| | | | X 1 0 0 0 |
| | Input | Output | TXEN D+ D- DAT SE0 |
| | | | 1 0 0 0 1 |
| | | | 0 1 0 0 0 |
| | | | 1 0 1 1 0 |
| | | | 1 1 Undefined 0 |

NOTE: The device does not support 3-wire bidirectional signaling using DP/DM signals.

When an external USB or USB OTG transceiver is connected to the device and is used in 4-pin bidirectional DP/DM encoding mode, the encoding described in [Table 24-935](#) is used.

Table 24-935. Signaling Between HS USB Host Subsystem and 4-Pin Bidirectional USB Transceiver Using DP/DM Signaling

| Logical Signal Name | Device Pin Direction | Transceiver Pin Direction | Description |
|---------------------|----------------------|---------------------------|---|
| TXEN | Output | Input | When low, the USB transceiver drives D+ and D-. |

Table 24-935. Signaling Between HS USB Host Subsystem and 4-Pin Bidirectional USB Transceiver Using DP/DM Signaling (continued)

| | | | 1 | 1 | 1 |
| RCV | Input | Output | Output from transceiver differential receiver | | |
| | | | D+ | D– | RCV |
| | | | 0 | 0 | X |
| | | | 0 | 1 | 0 |
| | | | 1 | 0 | 1 |
| | | | 1 | 1 | X |

24.11.2.2.2 Sideband Signals for Serial Modes

Serial interfaces carry only the USB data information. Sideband control and status (respectively, to/from the transceiver/TLL or to the bus lines themselves) require additional signals, which are usually implemented in a case-by-case, ad hoc way.

- Sideband control examples: FS/LS (slew rate control), transceiver suspend, connect (D+/D– pullup), pulldown enable, VBUS drive, etc.
- Sideband status example: VBUS level (VBUS valid, session valid, session end, etc.)
- Sideband signal implementations: Dedicated lines (one per sideband information bit), serial bus + interrupt line with register-mapped control/status (I²C) UART, etc.)

Figure 24-238 and Figure 24-239 show system integration for sideband signals for two logically identical USB connections: one in transceiver configuration and one in TLL configuration. Although the sideband (purple) arrows are oriented from the controller to the transceiver in the two figures, the sideband information flow is bidirectional (that is, it flows from the controller to the transceiver [control] and from the transceiver to the controller [status]).

Figure 24-238 shows the transceiver configuration, where each side connects the sideband signals to its own transceiver. On the device (containing the USBTLL module), the sideband is decoded/re-encoded. The sideband signals available at the device boundary (and the USBTLL module) are decoded from the standard UTMI+ interface.

- The software-driven VBUS reporting procedure is described in [Section 24.11.4.2.6.1.1, VBUS Management in Serial Transceiver Configurations](#).

Figure 24-238. Serial Interface Sideband Integration – Transceiver Configuration

Figure 24-239 shows the TLL configuration, where both transceivers are emulated inside the USBTLL module.

- The transceiver of the local controller (left side of the figure) is working with the sideband information to/from the UTMI+ port. This is internal to the USBTLL module.
- The transceiver of the remote controller (right side of the figure) must communicate with its controller, which is on another IC. This is done in two ways:
 - The sideband input signals at the TLL module boundary (tlpuen, tldrvvbus, tllvbusvalid, etc.)
 - The software-driven VBUS control procedure described in [Section 24.11.4.2.6.2.2, VBUS Emulation in Serial TLL Modes](#)

Figure 24-239. Serial Interface Sideband Integration – TLL Configuration

24.11.2.2.3 External USB Transceiver Interface Configurations in Serial Modes

An external USB transceiver is required for each USB port used in the system. It converts between appropriate signaling for the HS USB host subsystem and appropriate signaling for the USB wire.

The serial interface mode of the HS USB host subsystem includes support for several types of USB transceivers. It provides signaling to up to two external USB transceivers.

Several types of external transceiver signaling are supported. Signaling between the HS USB subsystem in serial interface mode and the external USB transceiver for monitoring and controlling the differential USB signal can be done through a 6-, 4-, or 3-wire signaling interface, with two or more control signals provided by additional signals or through an I²C link.

The following subsections describe the transceiver interface modes supported by the HS USB host subsystem in the serial interface mode. In each case, the subsystem is connected to external transceivers, on the other side of the USB lines (D+/D-).

24.11.2.2.3.1 Unidirectional Transceiver Interface Modes: 6-Pin

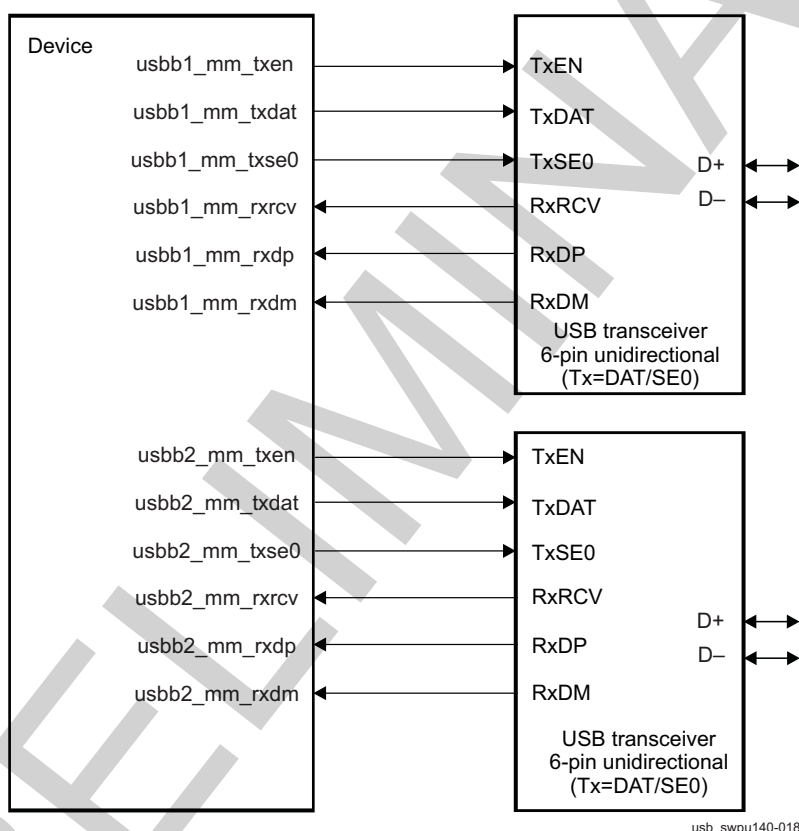

The 6-pin modes are the "natural" transceiver interface modes for the FS transceivers in the sense that they mirror the internal makeup of the transceivers.

Two encodings exist for TX: DAT/SE0 and DP/DM.

When an external USB is connected to the device and is used in 6-pin unidirectional DAT/SE0 signaling mode, the signaling described in [Table 24-932](#) is used.

[Figure 24-240](#) shows a USB port using DAT/SE0 encoding.

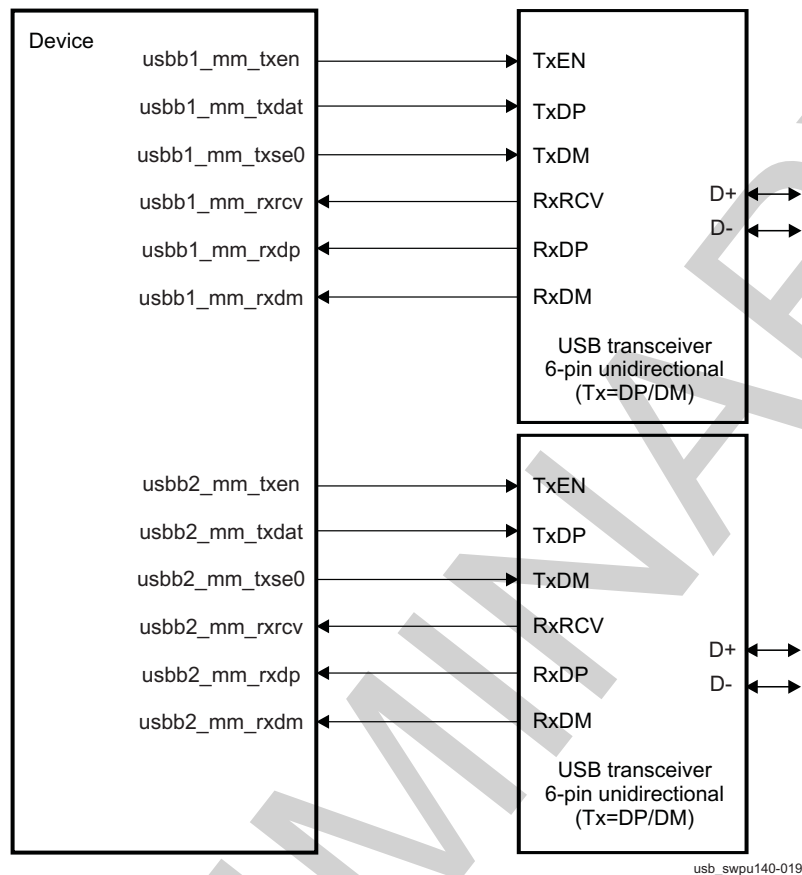

Figure 24-240. 6-Pin Unidirectional Using DAT/SE0 Signaling

When a USB is connected to the device and is used in 6-pin unidirectional DP/DM signaling mode, the signaling described in [Table 24-933](#) is used.

[Figure 24-241](#) shows a USB port using DP/DM encoding.

Figure 24-241. 6-Pin Unidirectional Using DP/DM Signaling

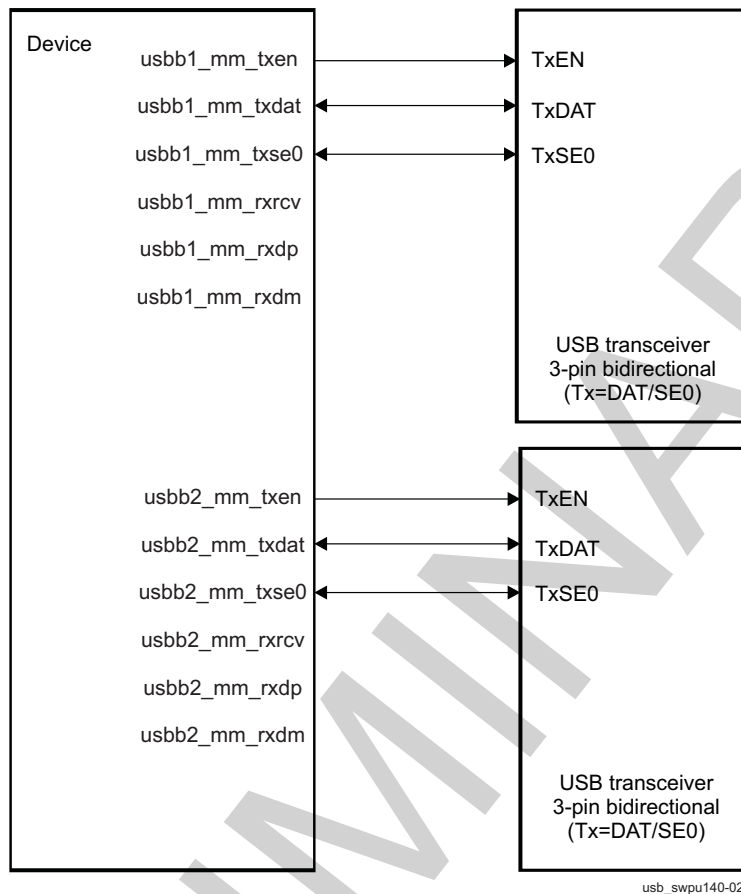

24.11.2.2.3.2 Bidirectional Transceiver Interface Modes: 3-Pin, 4-Pin

The bidirectional transceiver interface modes are pin-count optimizations of the unidirectional modes. They take advantage of the fact that a USB port is sending or receiving at any given time, but never both. The TX and RX paths of the unidirectional mode can be multiplexed on bidirectional lines. To prevent glitches at TX/RX turnaround, the same encoding is used for both directions (DAT/SE0 or DP/DM).

The signaling described in [Table 24-934](#) is used when a USB transceiver is connected to the device and is used in 3-pin bidirectional DAT/SE0 signaling mode.

NOTE: The device does not support 3-wire bidirectional signaling using DP/DM signals.

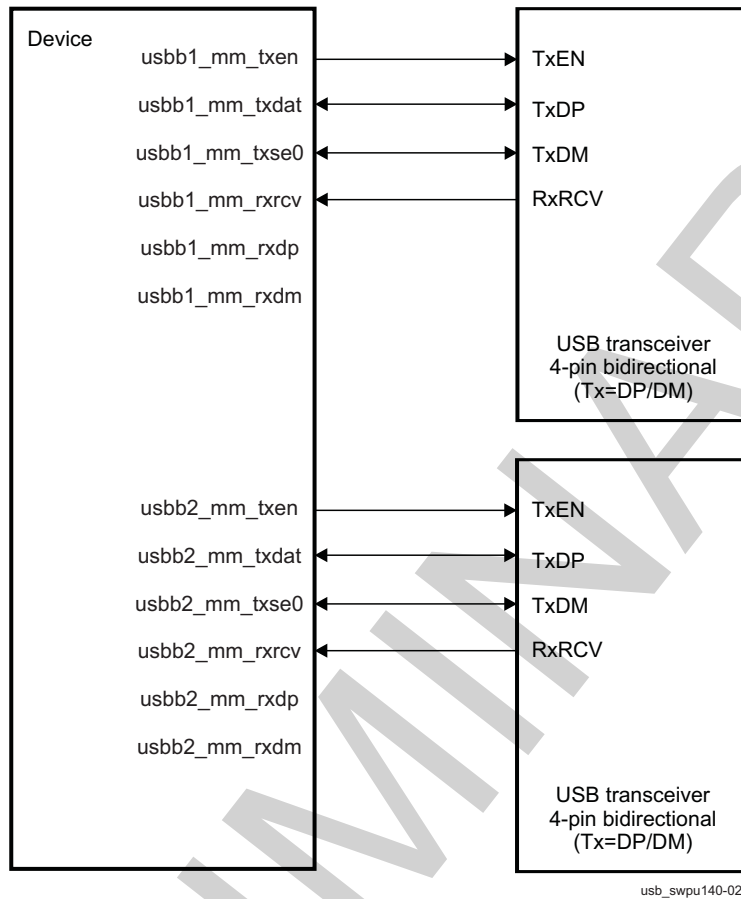

[Figure 24-242](#) shows a USB port using DAT/SE0 encoding.

Figure 24-242. 3-Pin Bidirectional Using DAT/SE0 Signaling

The signaling described in [Table 24-935](#) is used when a USB transceiver is connected to the device and is used in 4-pin bidirectional DP/DM signaling mode.

[Figure 24-243](#) shows a USB port using DP/DM encoding.

Figure 24-243. 4-Pin Bidirectional Using DP/DM Signaling

24.11.2.2.4 TLL Interface Configurations in Serial Modes

The HS USB host subsystem supports unidirectional and bidirectional TLL logic interfaces on its ports. The TLL modes enable glueless interconnect to the USB device port of another device without needing a costly transceiver.

Serial interface modes are FS or LS only. Transceiver interface is serial (its frequency is that of the actual USB line) and combinatorial (no clock is passed).

24.11.2.2.4.1 Unidirectional TLL Serial Modes

The 6-pin TLL configurations are mirror images of the 6-pin transceiver configurations previously discussed. The same signals are mapped on the same physical pins, but in opposite directions.

Two possible modes exist, depending on the TX data encoding used by the external device.

Figure 24-244 shows an external device using DAT/SE0 encoding.

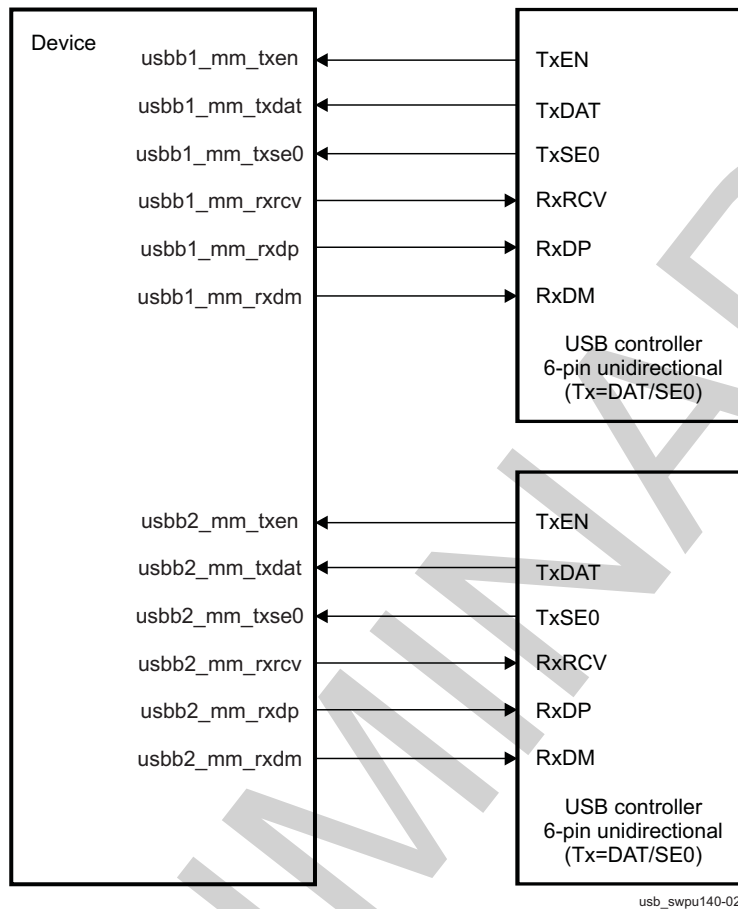

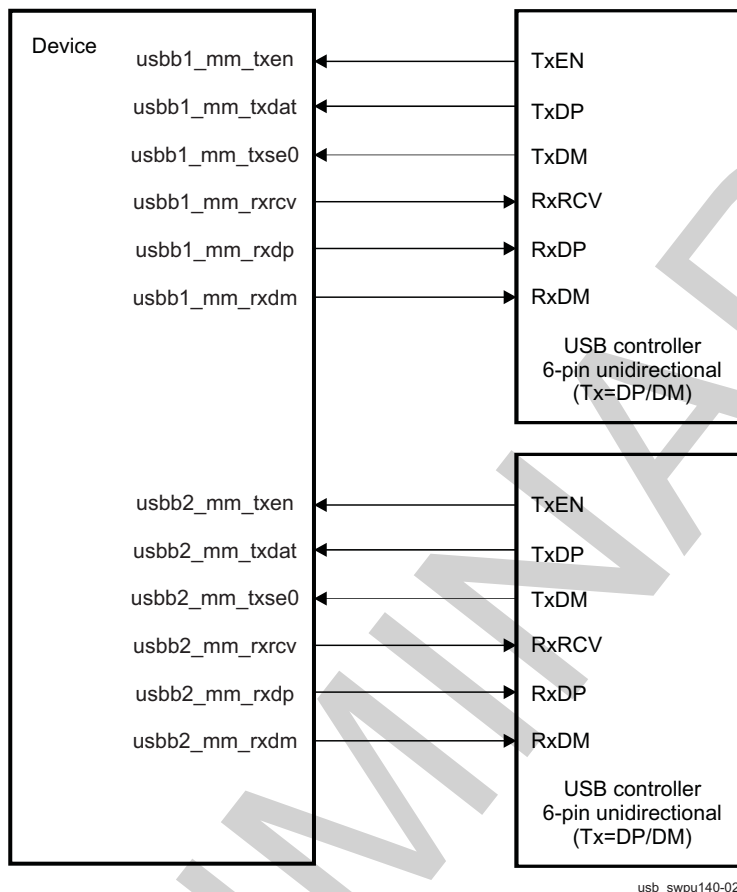

Figure 24-244. 6-Pin Unidirectional TLL Using DAT/SE0 Signaling

Figure 24-245 shows an external device using DP/DM encoding.

Figure 24-245. 6-Pin Unidirectional TLL Using DP/DM Signaling

24.11.2.2.4.2 Bidirectional TLL Serial Modes

The 3-pin/4-pin TLL configurations are mirror images of the 3-pin/4-pin transceiver configurations previously discussed. The same signals are mapped on the same physical pins, but in opposite directions (bidirectional lines remain bidirectional).

Two possible modes exist, depending on the TX data encoding used by the external device.

Figure 24-246 shows an external device using DAT/SE0 encoding.

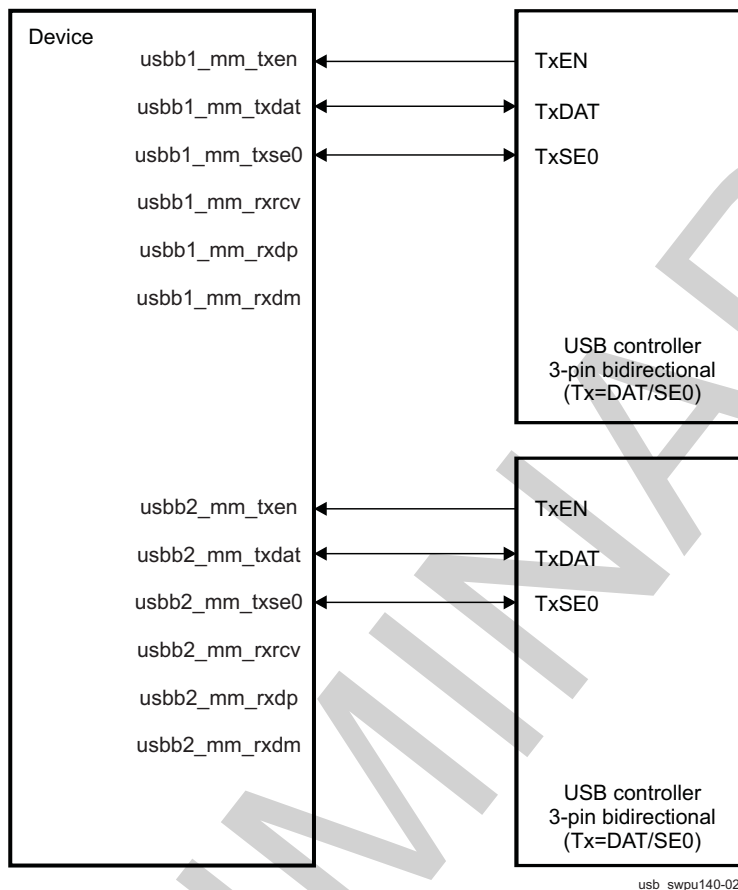

Figure 24-246. 3-Pin Bidirectional TLL Using DAT/SE0 Signaling

Figure 24-247 shows an external device using DP/DM encoding.

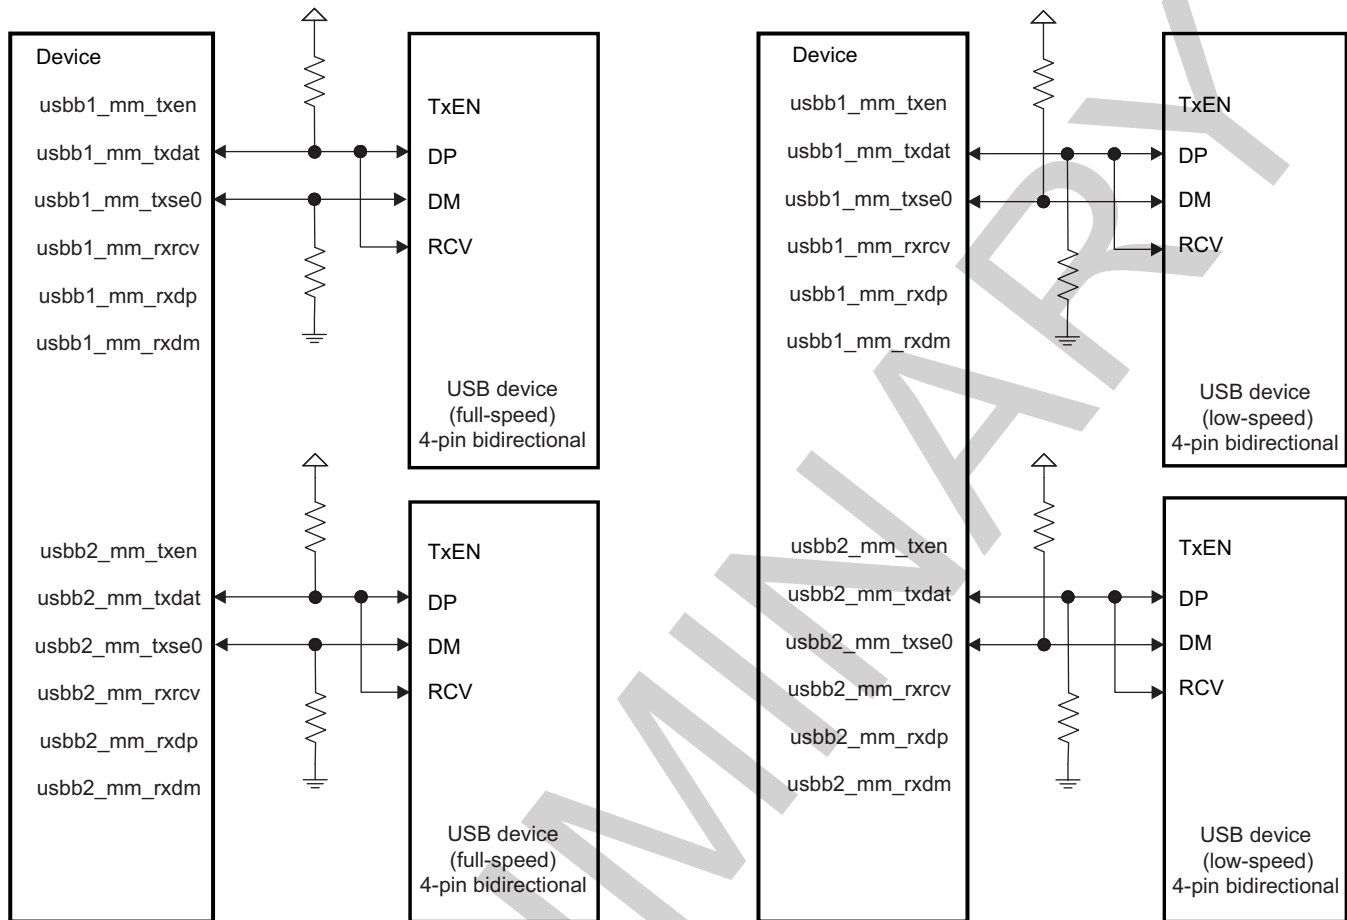

Figure 24-247. 4-Pin Bidirectional TLL Using DP/DM Signaling

The 2-pin TLL configurations have unique specifications:

- They require pullups/pulldowns to operate, because the bidirectional lines are not driven at all times like the other serial transceiver interfaces described previously. The connection of pull resistors depends on the speed of the controller.
- The module supports explicit 2-pin TLL modes, with DAT/SE0 or DP/DM encoding.
- Non-TLL modes (that is, transceiver configuration mode) can be used to implement the 2-pin functionality, using a specific connectivity.

Figure 24-248 shows a USB port using DP/DM encoding.

Figure 24-248. 2-Pin Bidirectional TLL Using DP/DM Encoding, With 4-Pin Bidirectional USB Device

usb_swpu140-026

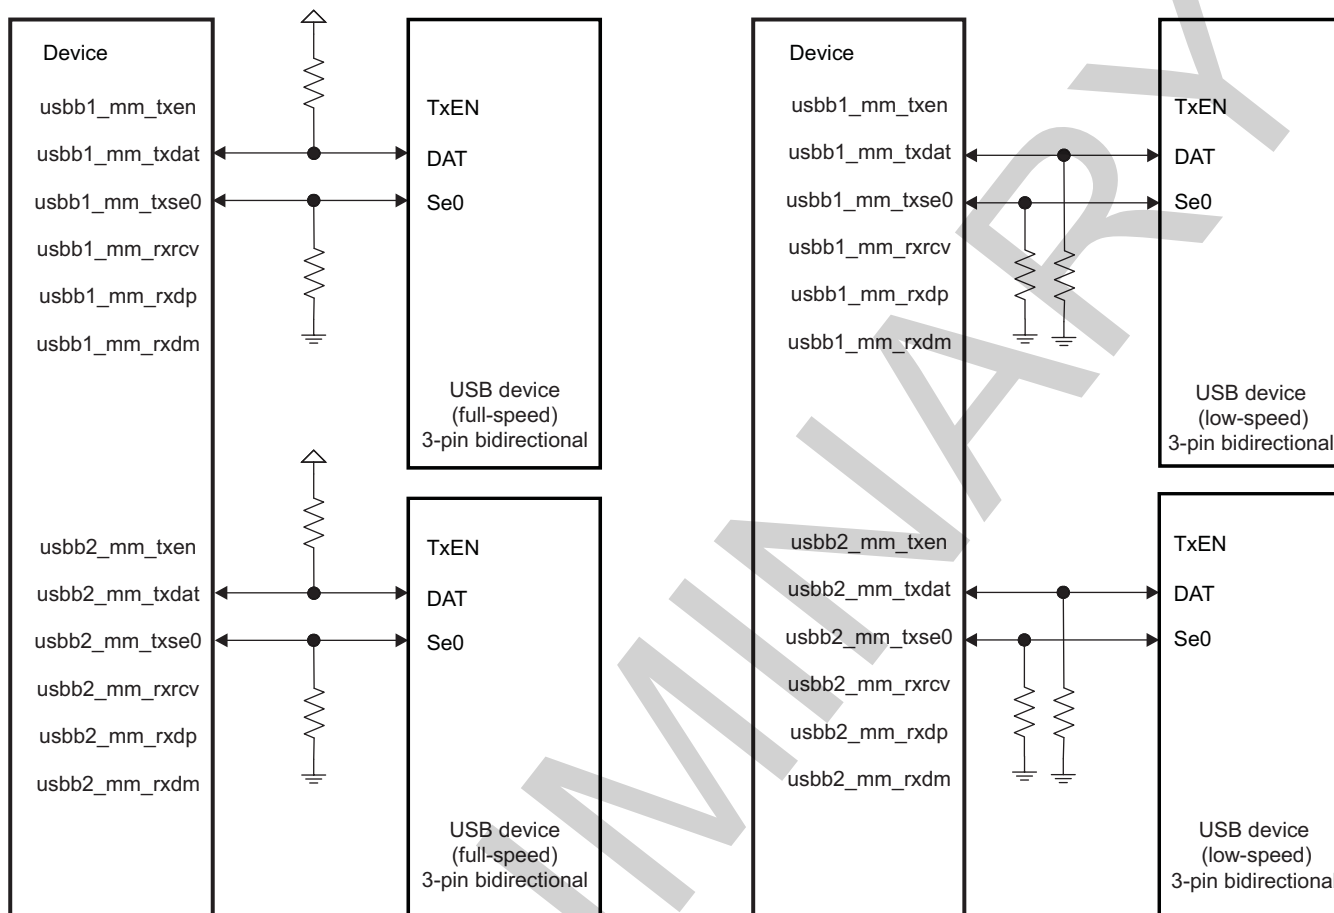

Table 24-936 shows the pullup/pulldown configuration for DP/DM encoding.

Table 24-936. Pullup/Pulldown Configuration for DP/DM Encoding

| | Nonconnected Device (Any Speed) | Connected LS Device | Connected FS Device |
|----|------------------------------------|------------------------|------------------------|
| DP | Pulldown | Pulldown | Pullup |
| DM | Pulldown | Pullup | Pulldown |

Figure 24-249 shows a USB port using DAT/SE0 encoding.

Figure 24-249. 2-Pin Bidirectional TLL Using DAT/SE0 Encoding, With 3-Pin Bidirectional USB Device

usb_swpu140-027

Table 24-937 shows the pullup/pulldown configuration for DAT/SE0 encoding.

Table 24-937. Pullup/Pulldown Configuration for DAT/SE0 Encoding

| | Nonconnected Device (Any Speed) | Connected LS Device | Connected FS Device |
|-----|------------------------------------|------------------------|------------------------|
| DAT | Pulldown | Pulldown | Pullup |
| SE0 | Pullup | Pulldown | Pulldown |

24.11.2.2.5 Interface Description in Serial Modes

Table 24-938 describes the I/O of the HS USB host subsystem serial interfaces.

Table 24-938. I/O Description

| Signal Name | I/O ⁽¹⁾ | Description | Value at Reset |
|--|--------------------|--|----------------|
| Multiple-Mode FS/LS Serial Interface: Port 1 | | | |
| usbb1_mm_txse0 | I/O | SE0 function in 3-pin bidirectional DAT/SE0 mode | 0 |
| | I/O | DM function in 4-pin bidirectional DP/DM mode | |
| | O | SE0 output in 6-pin unidirectional DAT/SE0 mode | |
| | O | DM output in 6-pin unidirectional DP/DM mode | |
| | I/O | SE0-TLL in 2-/3-pin bidirectional DAT/SE0 TLL mode | |
| | I/O | DM-TLL in 2-/4-pin bidirectional DP/DM TLL mode | |
| | I | SE0-TLL input in 6-pin unidirectional DAT/SE0 TLL mode | |
| | I | DM-TLL input in 6-pin unidirectional DP/DM TLL mode | |
| usbb1_mm_txdat | I/O | DAT function in 3-pin bidirectional DAT/SE0 mode | Unknown |
| | I/O | DP function in 4-pin bidirectional DP/DM mode | |
| | O | DAT output in 6-pin unidirectional DAT/SE0 mode | |
| | O | DP output in 6-pin unidirectional DAT/SE0 mode | |
| | I/O | DAT-TLL in 2-/3-pin bidirectional DAT/SE0 TLL mode | |
| | I/O | DP-TLL in 2-/4-pin bidirectional DP/DM TLL mode | |
| | I | DAT-TLL input in 6-pin unidirectional DAT/SE0 TLL mode | |
| | I | DP-TLL input in 6-pin unidirectional DP/DM TLL mode | |
| usbb1_mm_txen | O | Transmit enable in 3-pin bidirectional DAT/SE0 or 4-pin bidirectional DP/DM or 6-pin unidirectional modes | 1 |
| | I | Transmit enable in 3-pin bidirectional DAT/SE0 TLL or 4-pin bidirectional DP/DM TLL or 6-pin unidirectional TLL modes (not used in 2-pin bidirectional TLL modes) | |
| usbb1_mm_rxcv | I | Differential receiver signal input in 4-pin bidirectional DP/DM or 6-pin unidirectional modes (not used in 3-pin bidirectional DAT/SE0 mode) | Unknown |
| | O | Differential receiver signal output in 4-pin bidirectional DP/DM TLL or 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 TLL or 2-pin bidirectional TLL modes) | |
| usbb1_mm_rxdp | I | Single-ended DP receiver signal input in 6-pin unidirectional modes (not used in 3-pin bidirectional DAT/SE0 or 4-pin bidirectional DP/DM modes) | Unknown |
| | O | Single-ended DP receiver signal output in 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 TLL or 4-pin bidirectional DP/DM TLL or 2-pin bidirectional TLL modes) | |
| usbb1_mm_rxdm | I | Single-ended DM receiver signal input in 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 or 4-pin bidirectional DP/DM or 2-pin bidirectional TLL modes) | Unknown |
| | O | Single-ended DM receiver signal output in 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 TLL or 4-pin bidirectional DP/DM TLL or 2-pin bidirectional TLL modes) | |
| Multiple-Mode FS/LS Serial Interface: Port 2 | | | |
| usbb2_mm_txse0 | I/O | SE0 function in 3-pin bidirectional DAT/SE0 mode | 0 |
| | I/O | DM function in 4-pin bidirectional DP/DM mode | |
| | O | SE0 output in 6-pin unidirectional DAT/SE0 mode | |
| | O | DM output in 6-pin unidirectional DP/DM mode | |
| | I/O | SE0-TLL in 2-/3-pin bidirectional DAT/SE0 TLL mode | |
| | I/O | DM-TLL in 2-/4-pin bidirectional DP/DM TLL mode | |
| | I | SE0-TLL input in 6-pin unidirectional DAT/SE0 TLL mode | |
| | I | DM-TLL input in 6-pin unidirectional DP/DM TLL mode | |
| usbb2_mm_txdat | I/O | DAT function in 3-pin bidirectional DAT/SE0 mode | Unknown |
| | I/O | DP function in 4-pin bidirectional DP/DM mode | |
| | O | DAT output in 6-pin unidirectional DAT/SE0 mode | |
| | O | DP output in 6-pin unidirectional DAT/SE0 mode | |

⁽¹⁾ I = Input; O = Output

Table 24-938. I/O Description (continued)

| Signal Name | I/O ⁽¹⁾ | Description | Value at Reset |
|---|--------------------|---|----------------|
| Multiple-Mode FS/LS Serial Interface: Port 1 | | | |
| | I/O | DAT-TLL in 2-/3-pin bidirectional DAT/SE0 TLL mode | |
| | I/O | DP-TLL in 2-/4-pin bidirectional DP/DM TLL mode | |
| | I | DAT-TLL input in 6-pin unidirectional DAT/SE0 TLL mode | |
| | I | DP-TLL input in 6-pin unidirectional DP/DM TLL mode | |
| usbb2_mm_txen | O | Transmit enable in 3-pin bidirectional DAT/SE0 or 4-pin bidirectional DP/DM or 6-pin unidirectional modes | 1 |
| | I | Transmit enable in 3-pin bidirectional DAT/SE0 TLL or 4-pin bidirectional DP/DM TLL or 6-pin unidirectional TLL modes (not used in 2-pin bidirectional TLL modes) | |
| usbb2_mm_rxcv | I | Differential receiver signal input in 4-pin bidirectional DP/DM or 6-pin unidirectional modes (not used in 3-pin bidirectional DAT/SE0 mode) | Unknown |
| | O | Differential receiver signal output in the 4-pin bidirectional DP/DM TLL or 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 TLL or 2-pin bidirectional TLL modes) | |
| usbb2_mm_rxdp | I | Single-ended DP receiver signal input in 6-pin unidirectional modes (not used in 3-pin bidirectional DAT/SE0 or 4-pin bidirectional DP/DM modes) | Unknown |
| | O | Single-ended DP receiver signal output in 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 TLL or 4-pin bidirectional DP/DM TLL or 2-pin bidirectional TLL modes) | |
| usbb2_mm_rxdm | I | Single-ended DM receiver signal input in 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 or 4-pin bidirectional DP/DM or 2-pin bidirectional TLL modes) | Unknown |
| | O | Single-ended DM receiver signal output in 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 TLL or 4-pin bidirectional DP/DM TLL or 2-pin bidirectional TLL modes) | |

NOTE: ULPI (PHY) interfaces and ULPI TLL interfaces cannot be used together: either the ULPI (PHY) interfaces or the ULPI TLL interfaces are selected

24.11.2.3 HSIC Interface

The HS USB host subsystem supports the configurations with the HSIC interfaces shown in Figure 24-250.

Figure 24-250. HSIC Interface

Table 24-939 describes the I/O of the HSIC interface of the HS USB host subsystem.

Table 24-939. HSIC Interface

| Signal Name | I/O ⁽¹⁾ | Description | Reset Value |
|--------------------|--------------------|-------------------|-------------|
| HSUSB HSIC1 | | | |
| usbb1_hsic_data | I/O | HS interchip data | Unknown |

⁽¹⁾ I = Input; O = Output

Table 24-939. HSIC Interface (continued)

| Signal Name | I/O ⁽¹⁾ | Description | Reset Value |
|--------------------|--------------------|---------------------|-------------|
| usbb1_hsic_strobe | I/O | HS interchip strobe | Unknown |
| HSUSB HSIC2 | | | |
| usbb2_hsic_data | I/O | HS interchip data | Unknown |
| usbb2_hsic_strobe | I/O | HS interchip strobe | Unknown |

24.11.3 HS Multiport USB Host Subsystem Integration

This section describes the integration of the HS USB host subsystem, including information about clocks, resets, and hardware requests.

The USB host controller module includes other modules and additional logic attached to the UTMI/ULPI ports. The HS USB host controller is connected to the L3 interconnect master (initiator) and L4_CFG interconnect slave (target) interfaces.

The elements of the USB HS host subsystem are:

- The multiport USB host controller. Each port uses one of the following modes:
 - ULPI, to a ULPI PHY (typically, off-chip)
 - UTMI, to a local UTMI (typically, on-chip) PHY or emulation of a PHY
- A local phase-locked loop (PLL), able to provide the USB-grade 48-, 60-, 480-MHz clocks
- Two TLL channels, bundled inside a USBTLL module. Each HS TLL channel can be seen as emulating a pair of back-to-back PHYs, and has:
 - A UTMI port, connected to a controller port (the host, in this case)
 - A ULPI port, connected to a (typically, off-chip) ULPI controller (peripheral, in this case)
- Two HSIC DFEs. The DFE plugs into the UTMI port of an HSIC-capable controller (the host, in this case), and controls HSIC-capable bidirectional I/O drivers driving the HSIC lines (strobe/data).

Figure 24-251 shows the HS USB subsystem integration.

Figure 24-251. HS USB Subsystem Integration

usb_swpu140-028

Table 24-940 through Table 24-942 summarize the integration of the module in the device.

Table 24-940. Integration Attributes

| Module Instance | Attributes | |
|-----------------|--------------|--------------|
| | Power Domain | Interconnect |
| HSUSBHOST | PD_L3_INIT | L3 L4_CFG |
| HSUSBTLL | PD_L3_INIT | |

Table 24-941. Clocks and Resets

| Clocks | | | | |
|-----------------|-----------------------------|---------------------------------|----------------------|--|
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| HSUSBHOST | HS_USB_HOST_INIT_L4_ICLK | INIT_L4_ICLK | PRCM | L4 interconnect enable signal for the slave interface on L4 (see CD_L3_INIT Clock Source , in Chapter 3, Power, Reset, and Clock Management) |
| | HS_USB_HOST_INIT_L3_ICLK | INIT_L3_ICLK | PRCM | L3 interconnect clock for the L3 master port interface (see CD_L3_INIT Clock Domain , in Chapter 3, Power, Reset, and Clock Management) |
| | HSIC_P2_480 | HSIC_P2_480M_FCLK | PRCM | 480-MHz clock for the USB HSIC (see CD_L3_INIT Clock Domain in Chapter 3, Power, Reset, and Clock Management) |
| | HS_USB_HOST_UTMI_P1_FCLK | UTMI_P1_FCLK/usbb1_ulpi phy_clk | PRCM/external PHY IC | Port 1 UTMI interface functional clock (see CD_L3_INIT Clock Domain , and CM1_USB Clock Generator , in Chapter 3, Power, Reset, and Clock Management) |
| | HSIC_P1_60 | HSIC_P1_FCLK | PRCM | 60-MHz clock for the USB HSIC (see CD_L3_INIT Clock Domain , in Chapter 3, Power, Reset, and Clock Management) |
| | HSIC_P1_480 | HSIC_P1_480M_FCLK | PRCM | 480-MHz clock for the USB HSIC (see CD_L3_INIT Clock Domain in Chapter 3, Power, Reset, and Clock Management) |
| | HS_USB_HOST_INIT_48MC_FCLK | INIT_48MC_FCLK | PRCM | 48-MHz functional clock for OHCI and EHCI (see CD_L3_INIT Clock Domain , in Chapter 3, Power, Reset, and Clock Management) |
| | HSIC_P2_60 | HSIC_P2_FCLK | PRCM | 60-MHz clock for the USB HSIC (see CD_L3_INIT Clock Domain , in Chapter 3, Power, Reset, and Clock Management) |
| | HS_USB_HOST_UTMI_ROOT_GFCLK | UTMI_ROOT_GFCLK | PRCM | 60-MHz root hub clock (see CD_L3_INIT Clock Domain , in Chapter 3, Power, Reset, and Clock Management) |
| HSUSBTLL | HS_USB_HOST_UTMI_P2_FCLK | UTMI_P2_FCLK/usbb2_ulpi phy_clk | PRCM/external PHY IC | Port 2 UTMI interface functional clock (see CD_L3_INIT Clock Domain , and CM1_USB Clock Generator , in Chapter 3, Power, Reset, and Clock Management) |
| | HS_USB_HOST_INIT_L4_ICLK | INIT_L4_ICLK | PRCM | L4 interconnect enable signal for the slave interface on L4 (see CD_L3_INIT Clock Source , in Chapter 3, Power, Reset, and Clock Management) |
| | TLL_CH0_FCLK | TLL_CH0_FCLK | PRCM | Functional clock for channel 0 (see CD_L3_INIT Clock Domain , in Chapter 3, Power, Reset, and Clock Management) |
| | TLL_CH1_FCLK | TLL_CH1_FCLK | PRCM | Functional clock for channel 1 (see CD_L3_INIT Clock Domain , in Chapter 3, Power, Reset, and Clock Management) |

Table 24-941. Clocks and Resets (continued)

| Resets | | | | |
|-----------------|-------------------------|--------------------|--------|---|
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| HSUSBHOST | HSUSBHOST_RST | L3_INIT_RET_RST | PRCM | The signal resets the HSUSBHOST module. |
| HSUSBTLL | HSUSBTLL_RST | L3_INIT_RET_RST | PRCM | The signal resets the HSUSBTLL module. |

Table 24-942. Hardware Requests

| Interrupt Requests | | | | |
|--------------------|--------------------|-------------------------|----------------|---|
| Module Instance | Source Signal Name | Destination Signal Name | Destination | Description |
| HSUSBHOST | HSUSB_EHCI_IRQ | MA_IRQ_77 | Cortex-A9 INTC | Destination is Cortex-A9 interrupt controller (INTC). |
| | HSUSB_OHCI_IRQ | MA_IRQ_76 | Cortex-A9 INTC | Destination is Cortex-A9 INTC. |
| | HSUSB_EHCI_IRQ | MM_IRQ_57 | Cortex-M3 INTC | Destination is Cortex-M3 INTC. |
| | HSUSB_OHCI_IRQ | C2C_SSCM_GPI_19 | C2C SSCM | Destination is C2C SSCM. |
| | HSUSB_EHCI_IRQ | C2C_SSCM_GPI_20 | C2C SSCM | Destination is C2C SSCM. |
| HSUSBTLL | HSUSB_TLL_IRQ | MA_IRQ_78 | Cortex-A9 INTC | Destination is Cortex-A9 INTC. |
| | HSUSB_TLL_IRQ | MM_IRQ_58 | Cortex-M3 INTC | Destination is Cortex-M3 INTC. |
| | HSUSB_TLL_IRQ | C2C_SSCM_GPI_21 | C2C SSCM | Destination is C2C SSCM. |

The HS USB host controller and TLL module are attached to the L3_INIT_RET_RST reset domain. The L3_INIT_RET_RST signal resets the HS USB host controller and TLL module (see [Chapter 3, Power, Reset, and Clock Management](#)).

24.11.4 HS Multiport USB Host Subsystem Functional Description

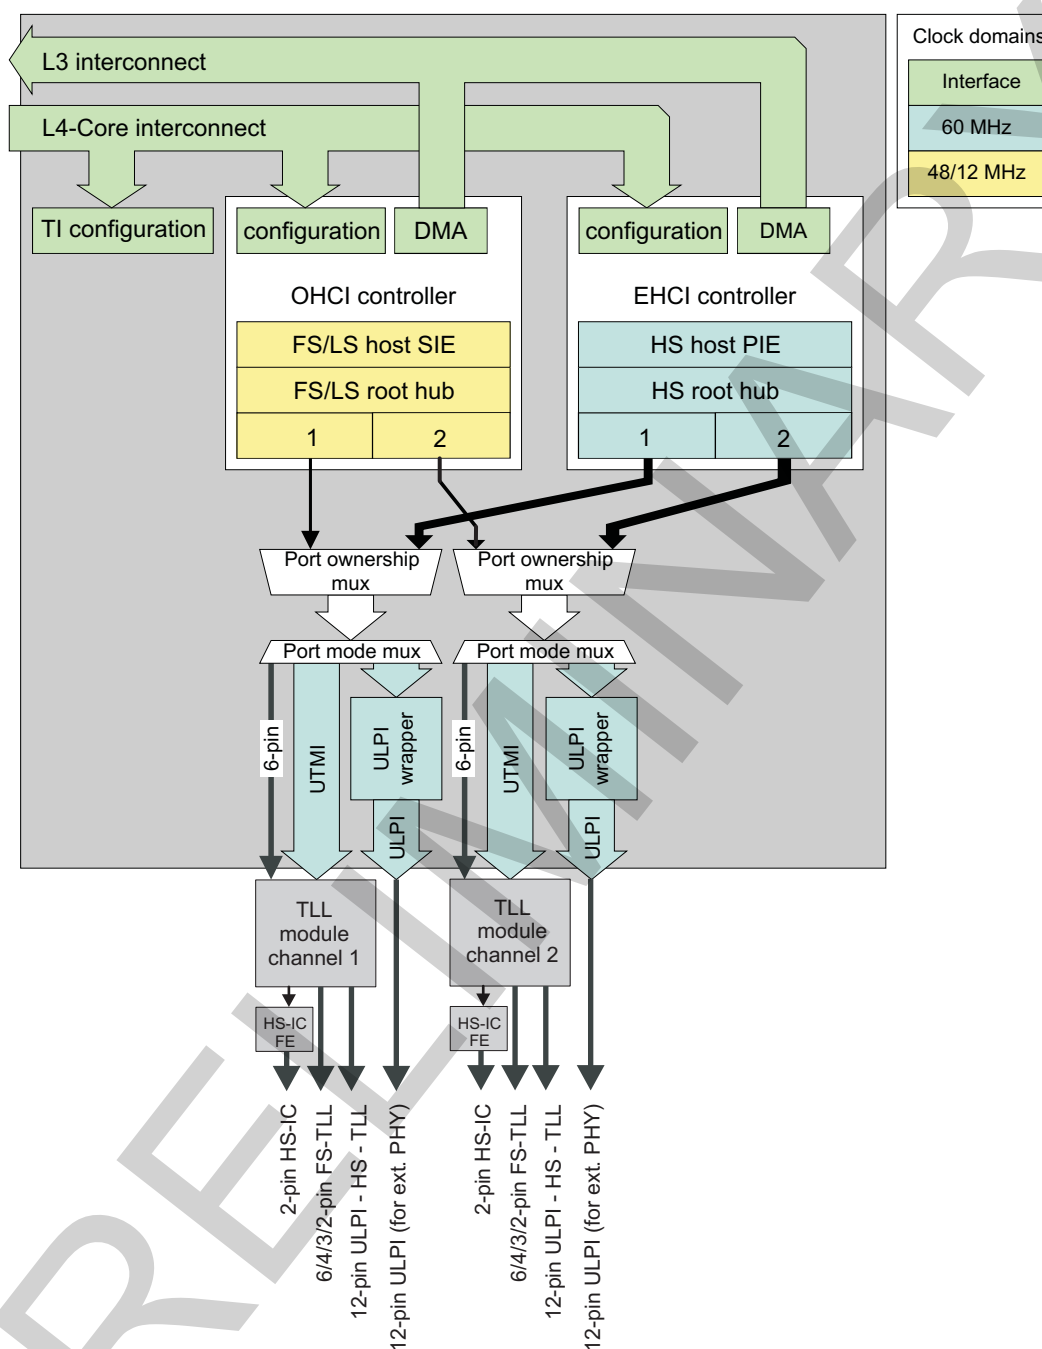

This section describes the functionality of the HS USB host subsystem by describing the HS USB host controller, USBTLL module.

24.11.4.1 USB Host Controller Functionality

The full details of the standard OHCI and EHCI host controller APIs (implemented by the current module) are not repeated here. For more information, see the following specifications:

- *Open Host Controller Interface (OHCI) Specification for USB Release 1.0a*
- *Enhanced Host Controller Interface (EHCI) Specification for USB Release 1.1*

[Figure 24-252](#) is an overview of the HS USB host controller internal architecture. It contains two independent, 3-port host controllers (OHCI and EHCI) that operate in parallel; however, only two physical ports are mapped in the device processor.

Figure 24-252. HS USB Host Controller Architecture

usb_swpu140-029

24.11.4.1.1 HS USB Host Controller Software Reset

The HS USB host controller has its own software-reset function through the [UHH_SYSCONFIG\[0\] SOFTRESET](#) bit. Setting this bit to 0x1 resets the HS USB host controller. The bit value of 0x1 remains until the reset completes. When the software reset completes, the SOFTRESET bit is automatically set to 0x0 and has the same effect as the hardware reset.

24.11.4.1.2 HS USB Host Controller Power Management

The USB protocol defines power-saving modes, where clocks can be shut down. The host asynchronously detects ULPI/UTMI events and asserts the wake-up output, which causes the clocks to restart.

To reduce dynamic power consumption, an efficient idle scheme in the device is based on:

- Efficient local autoclock gating for each module
- Implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated and deactivated safely without complex software intervention. In both cases, the HS USB host controller power management is applied only to the interface clock domain.

The HS USB host controller has master (initiator) and slave (target) interfaces:

- As an initiator, the HS USB host controller implements the standby handshake protocol to inform the PRCM module when it enters standby mode and does not generate traffic on the interconnect.
- As a target, the HS USB host controller implements the IDLE handshake protocol to allow the PRCM module requiring it to enter idle mode.

24.11.4.1.2.1 Standby Handshake Protocol

The HS USB host controller can go into standby mode, in which case it stops generating transactions on the interconnect. To save power, the module standby leads the PRCM module to disable the USB clocks.

The HS USB host controller has an Mstandby/Mwait handshake mechanism with the PRCM module (see [Chapter 3, Power, Reset, and Clock Management](#)).

The module is ready to enter standby mode (indicated by the Mstandby signal to the PRCM module asserted) when there is no USB activity and the module is idle. It means:

- The module is committed not to start any new transaction on its master interface.
- The whole module is idle and, therefore, the power manager can start the procedure to turn off the interface clock, if needed. This procedure must be implemented using the slave power-management protocol.

The handshake mechanism lets the module go into standby mode based on the [UHH_SYSCONFIG\[5:4\] STANDBYMODE](#) bit field.

[Table 24-943](#) lists the settings of standby mode.

Table 24-943. HS USB Host Controller Standby Mode Settings

| MIDLEMODE Value | Selected Mode | Description |
|-----------------|---------------|--|
| 0x0 | Force-standby | The HS USB host controller enters standby mode unconditionally (Mstandby is asserted unconditionally). |
| 0x1 | No-standby | The HS USB host controller never enters standby mode (Mstandby is never asserted). |
| 0x2 | Smart-standby | The HS USB host controller is ready to enter standby mode (Mstandby is asserted) when there is no more activity on the USB master interface of the interconnect. |

24.11.4.1.2.2 IDLE Handshake Protocol

The PRCM module handles an IDLE handshake protocol for the HS USB host controller. The IDLE handshake protocol lets the PRCM module requiring the HS USB host controller to enter idle mode. Although this handshake is completely hardware and out of any software control, the way in which the HS USB host controller acknowledges the PRCM IDLE request is configurable through the [UHH_SYSCONFIG\[3:2\] SIDLEMODE](#) bit field. [Table 24-944](#) lists the settings of SIDLEMODE and the related acknowledgment modes.

Table 24-944. HS USB Host Controller SIDLEMODE Settings

| SIDLEMODE Value | Selected Mode | Description |
|------------------------|----------------------|--|
| 0x0 | Force-idle | The HS USB host controller acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations. Because such a mode does not prevent the loss of data when the clock is switched off, the mode must be used carefully. |
| 0x1 | No-idle | The HS USB host controller never acknowledges any IDLE request from the PRCM module. This mode is safe from a module point of view because it ensures the clocks remain active; however, it is not efficient from a power-saving perspective because it does not allow the PRCM output clock to be shut off, and thus the power domain to be set to a lower power state. |
| 0x2 | Smart-idle | The HS USB host controller acknowledges the IDLE request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for an efficient system power management. |
| 0x3 | Smart-idle + wakeup | The HS USB host controller enters smart mode with asynchronous (master) wakeup enabled. |

24.11.4.1.2.3 Wake-Up Request

The wake-up request signal USBHOST_SWAKEUP is generated by the HS USB host controller to the PRCM module.

24.11.4.1.3 HS USB Host Controller Save and Restore

The hardware context of the USB HS host can be frozen, saved, and restored.

The SAR mechanism extracts the hardware context of the HS USB host controller (after all USB activity is suspended) before switching off (saving), saves it to an external always-on memory, and reinjects it later after the module is switched on again and reset (restored) seamlessly for the USB. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

24.11.4.1.4 HS USB Host Controller Port Status

The USB port status is given through the [UHH_HOSTCONFIG](#)[8] P1_CONNECT_STATUS and [UHH_HOSTCONFIG](#)[9] P2_CONNECT_STATUS bits. The default value of these bits is 0x0 indicating that peripheral is disconnected.

24.11.4.1.5 HS USB Host Controller Burst Control

To avoid buffer underflow, bursts must be enabled by setting the [UHH_HOSTCONFIG](#)[4:2] bit field to 0x7, and the [UHH_HOSTCONFIG](#)[5] ENA_INCR_ALIGN bit to 1.

24.11.4.1.6 OHCI Implementation Specifications

Some features of the OHCI API are optional and/or implementation-specific. The choices made in the current implementation, the HS USB host controller, are described in the following list and are reflected in the register descriptions (see [Section 24.11.6.5, OHCI Registers](#)). For all standard features, see the *Open Host Controller Interface (OHCI) Specification for USB Release 1.0a*.

- [HCFMINTERVAL](#)[30:16] FSMPS bit field (FullSpeedMaxPacketSize) = 0x0000: The host stops scheduling new packets 0 bit times before the end of the frame (that is, by default, there is no scheduling overrun protection). To be updated by the software driver.
- [HCRHDESCRIPTORA](#)[7:0] NDP bit field (NumberDownstreamPorts) = 0x03 = three ports
- [HCRHDESCRIPTORA](#)[9] NPS bit (NoPowerSwitching) = 0: Ports are power-switched by default.
- [HCRHDESCRIPTORA](#)[8] PSM bit (PowerSwitchingMode) = 1: Per-port power switching is supported, although PPCM default setup has all ports controlled globally.
- [HCRHDESCRIPTORA](#)[31:24] POTPG bit field (PowerOnToPowerGood) = 0x0A = 10: Power ramp-up time is 10 x 2 ms = 20 ms.
- [HCRHDESCRIPTORB](#)[15:0] DR bit field (DeviceRemovable) = 0x0000: By default, no nonremovable devices (that is, devices attached to any of the ports) are removable.

- [HCRHDESCRIPTORB](#)[31:16] PPCM bit field (PortPowerControlMask) = 0x0000: By default, all ports are affected only by global power control.

24.11.4.1.7 UTMI Interface

The host controller supports two ports. Each host controller port is configured to be in UTMI or ULPI mode (see the [UHH_HOSTCONFIG](#)[21:16] Px_MODE bit field).

In UTMI mode, a port has its UTMI signal set broadcasting the outgoing packets (from the host to the peripherals) and gathering the incoming ones (from the addressed peripheral to the host). ULPI signals for that port are undefined/don't care on all ports.

The UTMI ports between the HS USB host controller and the USBTLL module are on-chip and remain invisible.

UTMI transparent mode is used to connect with the HSIC, (see the [UHH_HOSTCONFIG](#)[17:16] P1_MODE or [UHH_HOSTCONFIG](#)[17:16] P2_MODE bit fields).

24.11.4.1.8 ULPI Interface

The host supports two ports. Each host controller port is configured to be either in UTMI or in ULPI mode (see the [UHH_HOSTCONFIG](#)[17:16] P1_MODE or [UHH_HOSTCONFIG](#)[17:16] P2_MODE bit fields).

In ULPI mode, a port has its ULPI signal set broadcasting the outgoing packets (that is, from the host to the peripherals) and gathering the incoming packets (that is, from the addressed peripheral to the host). UTMI signal sets are undefined/don't care on all ports.

NOTE: The ULPI clock (part of the 12-wire ULPI interface) is expected to be routed by the system from the ULPI CLK input I/O pad to the clock input used by all HS modes (ULPI and UTMI) for the current port.

24.11.4.2 USBTLL Module Functionality

24.11.4.2.1 USBTLL Software Reset

Writing 0x1 to the [USBTLL_SYSCONFIG](#)[1] SOFTRESET bit resets the USBTLL module. The bit value of 0x1 remains until the reset completes. When the software reset completes, the SOFTRESET bit is automatically set to 0x0 and has the same effect as the hardware reset.

24.11.4.2.2 USBTLL Power Management

The USB protocol defines power-saving modes, where clocks can be shut down.

24.11.4.2.2.1 IDLE Handshake Protocol

The PRCM module handles an IDLE handshake protocol for the USBTLL module. The IDLE handshake protocol lets the PRCM module require the HS USBTLL module to enter idle mode.

The way in which the HS USBTLL module acknowledges the PRCM IDLE request is configurable through the [USBTLL_SYSCONFIG](#)[4:3] SIDLEMODE bit field. [Table 24-945](#) lists related acknowledgment modes.

Table 24-945. HS USBTLL Module SIDLEMODE Settings

| SIDLEMODE Value | Selected Mode | Description |
|-----------------|---------------|---|
| 0x0 | Force-idle | The HS USB host controller acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations. |
| 0x1 | No-idle | The HS USB host controller never acknowledges any IDLE request from the PRCM module. |
| 0x2 | Smart-idle | The HS USB host controller acknowledges the IDLE request, basing its decision on its internal activity. |

24.11.4.2.3 USBTLL Save and Restore

The SAR mechanism extracts the hardware context of the USBTLL module (after all USB activity is suspended) before switching off (saving), saves it to an external always-on memory, and reinjects it later after the module is switched on again and reset (restored) seamlessly for the USB.

Hardware context of the USBTLL module is accessed through the USBTLL_SAR_CNTX_i[31:0] CNTX bit field.

The PRCM module enables the SAR mechanism for the USBTLL module. When set, the PRM module initiates the save and/or the restore sequences at the appropriate time. When not set, the USB host is treated as a standard module, and the save/restore sequences do not occur.

For more information, see [\[1\]](#).

[Table 24-946](#) lists the USBTLL registers affected by the SAR context.

NOTE: Because all addresses give access to the same physical register (that is, to the same piece of context), the ULPI registers with multiple accesses (write, set, clear) are listed only once in the table.

Table 24-946. USBTLL Registers Affected by the SAR Context

| Register Name | Comments on SAR Policy |
|------------------------------------|---------------------------------------|
| USBTLL_SYSCONFIG | Except the SOFTRESET bit (write-only) |
| USBTLL_IRQENABLE | — |
| TLL_SHARED_CONF | Except the FCLK_REQ bit |
| TLL_CHANNEL_CONF_i | Except the FLSLSTATE bit field |
| FUNCTION_CTRL_i | — |
| INTERFACE_CTRL_i | — |

24.11.4.2.4 USBTLL Channels and Ports

Following the same convention as UTMI and ULPI, the current specification is consistently PHY-centric (that is, directions are always given with respect to the transceiver emulated here by the TLL, and not with respect to the link controller): An input goes from the link controller to the TLL (transceiver emulator) (that is, it is an input for the USBTLL module). Reciprocally, an output goes from the TLL (transceiver) to the link controller (that is, it is an output for the USBTLL module).

By convention, the local link controller is the controller integrated on the same IC as the USBTLL module: This is the HS USB host controller in the device. The remote link controller is the other controller, located off-chip (that is, on another IC). One controller is always the USB host, the other is the USB peripheral, and they communicate through the USBTLL module.

A channel is defined as a independent USB path through the USBTLL module, which always converts the UTMI+ transceiver interface protocol coming from the local link controller (the HS USB host controller in the device). There are two channels of the USBTLL module in the device.

A USB port is a set of I/O signals that carry the data and control information from/to a USB line. Several port formats exist, with different capabilities. A channel has three ports. If the channel is active, two ports are active at the same time, depending on the configuration of the channel. The mode remains static throughout the USB operation.

24.11.4.2.5 USBTLL Channel Configuration

A channel configuration is a set of software settings that specifies the connection of two of the channel ports through the USBTLL module. USB data and control injected on one side (or port) comes out on the other side (or port) after a certain amount of processing, depending on the mode. [Table 24-947](#), lists the modes.

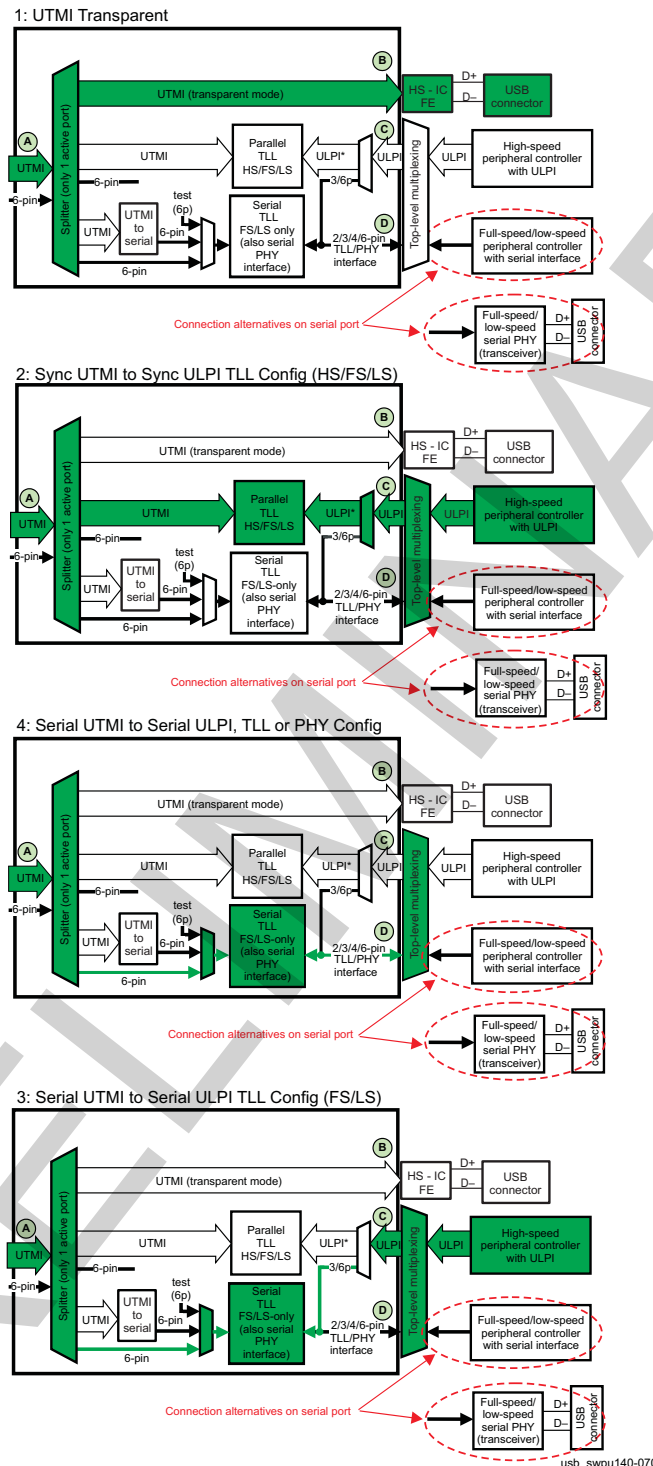

All configurations connect the PHY UTMI port (attached to the HS USB host controller) to one of the other two ports (attached to a variety of transceivers or controllers on the pad side).

[Table 24-947](#) describes the available modes and the software settings required for each. Channel *i* has the following settings:

- CHANMODE: [TLL_CHANNEL_CONF_i\[2:1\]](#) CHANMODE bit field
- FLSMODE: [TLL_CHANNEL_CONF_i\[27:24\]](#) FLSMODE bit field
- FLSSEIRIALMODE_3PIN/6PIN: Either the ULPI PHY-side [INTERFACE_CTRL_i\[1\]](#) FLSSEIRIALMODE_3PIN bit or the [INTERFACE_CTRL_i\[0\]](#) FLSSEIRIALMODE_6PIN bit (only one at a time can be set to 1)

Table 24-947. USBTLL Channel Configuration

| Configuration | Mode | CHANMODE | FLSMODE | Other Settings | Ports | Speed | Remote Port Connection |
|---------------|--------------------------------|----------|---------------------|------------------------------|-------|-------|--|
| 1 | UTMI transparent | 0 | N/A | – | A-B | – | UTMI transparent |
| 2 | ULPI synchronous TLL | 0 | N/A | FLSSEIRIALMODE_3PIN/6PIN = 0 | A-C | HFL | ULPI link (peripheral controller) |
| 3 | Serial UTMI to serial ULPI TLL | 0 | N/A | FLSSEIRIALMODE_3PIN/6PIN = 1 | A-C | FL | ULPI link (peripheral controller) supporting 3-/6-pin mode |
| 4 | Serial UTMI to serial TLL | 1 | 0x4-0x7; 0xA-0xB | – | A-D | FL | Serial link (2-/3-/4-/6-pin) |
| 4 | Serial UTMI to serial PHY | 1 | 0x0-0x3 | – | A-D | FL | Serial transceiver (2-/3-/4-/6-pin) |

Figure 24-253. Per-Configuration Data Path Through USBTLL

usb_swpu140-070

24.11.4.2.6 USBTLL VBUS Management and Emulations

In transceiver configurations, a USB cable is present, including a 5-V VBUS supply line. On the other hand, in TLL configurations, the physical USB lines are emulated and have no physical existence. This is especially true for the VBUS line, which distributes the 5-V power provided by the default host (or A-device) to the entire bus. VBUS is also used for signaling purposes, and those features must be emulated:

- A peripheral detects the presence of a host by detecting the presence of VBUS.
- USB OTG defines an elaborate voltage-sensing scheme to dynamically switch on and off VBUS (start and stop sessions). In the context of TLL, this brings no power savings compared to a simple suspend.
- In particular, USB OTG uses VBUS as a wake-up source (VBUS-pulsing SRP) for the default peripheral (or B-device).

For more information on how sideband controls are integrated, see [Figure 24-238](#) and [Figure 24-239](#) and the related explanations.

24.11.4.2.6.1 VBUS Control and Status for Transceiver (Non-TLL) Configurations

In non-TLL modes, VBUS exists, and the problem is to propagate control and status to and from the VBUS manager IC (typically, the transceiver).

Only serial transceiver configurations are concerned in the case of the HS USB host subsystem in the device.

24.11.4.2.6.1.1 VBUS Management in Serial Transceiver Configurations

VBUS management is not standardized in transceiver configurations. The chosen implementation is described in the following list (also see [Figure 24-238](#)).

- VBUS control required for host and OTG operation (VBUS drive, VBUS pullup "charge," VBUS pulldown "discharge") is assumed to be handled separately from the USBTLL module (that is, by software and straight to the power IC, which can be the transceiver, especially in OTG cases).
- The status of VBUS must be sampled by the appropriate hardware (again, most often the transceiver) and reported by software to the USBTLL module, using the [TLL_CHANNEL_CONF_i\[16\]](#) DRVVBUS and [TLL_CHANNEL_CONF_i\[15\]](#) CHRGVBUS bits, as indicated in [Table 24-948](#).

[Table 24-948](#) lists the values to write to the [TLL_CHANNEL_CONF_i](#) register depending on the status of VBUS observed by the transceiver on the VBUS line. The same register fields are also used in TLL configuration, and have been named according to that second configuration. In transceiver configurations, the signification of the fields is:

- DRVVBUS: Set to 1 to report a VBUS level greater than VBUS valid.
- CHRGVBUS: Set to 1 to report a VBUS level greater than session valid.

Table 24-948. VBUS Level Software Reporting for Serial Transceiver Configuration

| VBUS Status | TLL_CHANNEL_CONF_i[16] DRVVBUS | TLL_CHANNEL_CONF_i[15] CHRGVBUS |
|---------------------|--|---|
| VBUS valid | 1 | 1 |
| Session valid (A/B) | 0 | 1 |
| Session not valid | 0 | 0 |
| Session end | 0 | 0 |

24.11.4.2.6.2 VBUS Emulation for TLL Configurations

The TLL VBUS emulation sums up all actions on the VBUS line and obtains a voltage level, which is reported in the VBUS status bits following the protocol. The level depends on the immediate VBUS actions and has no memory of previous levels, whereas an actual VBUS line behaves like an RC circuit and takes time to charge and discharge. This causes the following differences:

- The TLL level always jumps abruptly from session valid to session end (and back) with no transient time in between (where session is neither valid nor ended) as in real life.
- The charge feature is used for VBUS-pulsing SRP and is enabled long enough to go over the session valid threshold, but without reaching VBUS valid. In the TLL, the transition to session valid is immediate, and VBUS valid is never reached even if the charge is intentionally kept active.
- The discharge feature is used in real life to accelerate the voltage drop of an undriven VBUS toward the session-end level. For TLL, therefore, this is useless (although the UTMI input/ULPI register bit does exist, for compatibility), and is always don't care.

24.11.4.2.6.2.1 VBUS Emulation in ULPI TLL Modes

Table 24-949 summarizes the VBUS emulation in ULPI TLL modes. VBUS controls are writable, static PHY-side registers on the ULPI side, and input signals on the ULPI ports (port A). VBUS status bits are read-only, volatile PHY-side registers on the ULPI, and output signals on the ULPI ports (port A).

Table 24-949. Emulation of VBUS Levels for UTMI-to-ULPI TLL Mode

| VBUS Controls (Actions) | | | VBUS Level | VBUS Status | | |
|--------------------------|---------------------------|------------------------------|-------------|---|--|--|
| OTG_CTRL_i[5] DRVVBUS | OTG_CTRL_i[4] CHRGVBUS | OTG_CTRL_i[3] DISCHRGVBUS | | USB_INT_STATU S_i[1] VBUSVALID bit | USB_INT_STATU S_i[2] SESSVALID bit | USB_INT_STATU S_i[3] SESEND bit |
| 1 | X | X | VBUS valid | 1 | 1 | 0 |
| 0 | 1 | X | VBUS valid | 0 | 1 | 0 |
| 0 | 0 | X | Session end | 0 | 0 | 1 |

24.11.4.2.6.2.2 VBUS Emulation in Serial TLL Modes

In serial TLL modes, VBUS status and control is implemented with ad hoc sideband signals (see Figure 24-239).

VBUS control can be done in software by writing to the following fields of the [TLL_CHANNEL_CONF_i](#) register:

- DRVVBUS: Set to 1 to drive VBUS to 5 V (for A-device or host)
- CHRGVBUS: Set to 1 to pull up VBUS (for SRP)
- There is no pulldown (discharge) control, because the emulated VBUS has no latency and VBUS level goes to the session-end level as soon as it is neither driven nor pulled up.

Alternatively, VBUS drive can also be hardware-controlled through a dedicated input. (The DRVVBUS bit and input signal are ORed internally.)

VBUS status is available on dedicated output signals. If those outputs are not available at the top level, a software alternative is to use the voltage status reported on the interface (through the standard UTMI+ sideband signals) of the local controller (the HS USB host controller in the device) and to pass it to the remote controller (a peripheral controller) by means of an ad hoc software-controller interface other than the USB. This is based on the fact that the level of VBUS is the same on both extremities of the bus (that is, it does not matter which side does the measurement).

24.11.4.2.7 USBTLL Multimode Serial Port

The multimode serial port requires six bidirectional I/O pads to support all eight defined modes (selected in the [TLL_CHANNEL_CONF_i](#)[27:24] FLSMODE bit field when field CHANMODE = 0x1 = UTMI-to-serial). Those modes are FS/LS only (that is, HS is not supported over a serial interface).

The pads are named TXEN, TXDAT, TXSE0, RXRCV, RXDP, and RXDM after their functionality in standard 6-pin mode (mode 0). Each pad has an input, output, and output-enable signal associated with it on the USBTLL entity.

Table 24-950 lists the function of each pad in each mode. USBTLL outputs are shown in yellow, inputs in blue, and bidirectional pads in green.

Table 24-950. Serial Mode Description, Signal Functionality

| Usual Name | 6-Pin Mode | 6-Pin Mode (Alt) | 3-Pin Mode | 4-Pin Mode | 6-Pin TLL Mode | 6-Pin TLL (Alt) Mode | 3-Pin TLL Mode | 4-Pin TLL Mode | 2-Pin TLL Mode | 2-Pin TLL (Alt) Mode |
|--|------------------|------------------|-----------------|---------------------|-----------------------|-----------------------|-----------------|-----------------------|-----------------|----------------------|
| TLL_CHANNEL_CONF_i [27:24] FLSMODE bit field | 0x0 | 0x1 | 0x2 | 0x3 | 0x4 | 0x5 | 0x6 | 0x7 | 0xA | 0xB |
| TX encoding | DAT/SE0 | DP/DM | DAT/SE0 | DP/DM | DAT/SE0 | DP/DM | DAT/SE0 | DP/DM | DAT/SE0 | DP/DM |
| RX encoding | DP/DM/RCV | DP/DM/RCV | DAT/SE0 | DP/DM/RCV | DP/DM/RCV | DP/DM/RCV | DAT/SE0 | DP/DM/RCV | DAT/SE0 | DP/DM |
| Pin use | Unidirectional | Unidirectional | Bidirectional | Bidirectional | Unidirectional | Unidirectional | Bidirectional | Bidirectional | Bidirectional | Bidirectional |
| Pin count | 6 | 6 | 3 | 4 | 6 or 5 ⁽¹⁾ | 6 or 5 ⁽¹⁾ | 3 | 4 or 3 ⁽²⁾ | 2 | 2 |
| I/O Pad Function Per Mode | | | | | | | | | | |
| TXEN | TX Enable | TX Enable | TX Enable | TX Enable | TX Enable | TX Enable | TX Enable | TX Enable | N/C | N/C |
| TXDAT | TX Diff Data | TX SE Plus Data | TX/RX Diff Data | TX/RX SE Plus Data | TX Diff Data | TX SE Plus Data | TX/RX Diff Data | TX/RX Diff Data | TX/RX Diff Data | TX/RX SE Plus Data |
| TXSE0 | TX force SE0 | TX SE Minus Data | TX/RX force SE0 | TX/RX SE Minus Data | TX force SE0 | TX SE Minus Data | TX/RX force SE0 | TX/RX force SE0 | TX/RX force SE0 | TX/RX SE Minus Data |
| RXRCV | RX Diff Data | RX Diff Data | N/C | RX Diff Data | RX Diff Data | RX Diff Data | N/C | RX Diff Data | N/C | N/C |
| RXDP | RX SE Plus Data | RX SE Plus Data | N/C | N/C | RX SE Plus Data | RX SE Plus Data | N/C | N/C | N/C | N/C |
| RXDP | RX SE Minus Data | RX SE Minus Data | N/C | N/C | RX SE Minus Data | RX SE Minus Data | N/C | N/C | N/C | N/C |

⁽¹⁾ RXRCV and RXDP carry the same information: RXDP can drive both inputs of the remote controller, and RXRCV can be kept unused.

⁽²⁾ Same remark for TXDAT (for outputs) and RXRCV: TXDAT only is enough.

24.11.4.2.8 USBTLL Attach/Connect Emulation for Serial Modes

This section applies to all serial TLL modes in the following circumstances:

- In UTMI-to-serial mode ([TLL_CHANNEL_CONF_i](#)[2:1] CHANMODE = 0x1) for all TLL values of the [TLL_CHANNEL_CONF_i](#)[27:24] FLSMODE bit field (0x4–0x7; 0xA–0xB)
- In UTMI-to-ULPI TLL mode ([TLL_CHANNEL_CONF_i](#)[2:1] CHANMODE = 0x0) when the ULPI bus is switched to 6-pin or 3-pin serial modes

In those modes, the USB bus lines are emulated by USBTLL internal logic and are never available on the outside. The pullup/pulldown actions described in the USB specification cannot be applied directly, and the USB cable cannot be physically attached.

Because serial modes do not specify a standard format for those sideband settings, a custom software-controlled one is implemented:

- The [TLL_CHANNEL_CONF_i](#)[4] TLLATTACH bit emulates the physical attachment of the two controllers through a TLL cable:
 - When this bit is cleared, the local controller RX path shows only the local controller (the HS USB host controller) actions on the bus: TX driving, pullups, pulldowns. The same applies for the remote controller RX path (except that test override is not available).
 - When the bit is set, the actions of both sides are applied to the same bus and are resolved, similar to a real bus. The RX path for both sides shows the same bus state.
- The [TLL_CHANNEL_CONF_i](#)[5] TLLCONNECT bit emulates the USB electrical connect (that is, the pullup by the USB peripheral of one of the two USB lines [by a 1.5-kΩ resistor]), which causes the line state to transition from SE0 to J, which is detected by the USB host. The register bit is ORed with a USBTLL module input signal; the connect control can be software (L4_CFG interconnect write access) or hardware (input level). The speed of the connection is determined by the TLLFULLSPEED bit.
- The [TLL_CHANNEL_CONF_i](#)[6] TLLFULLSPEED bit determines the speed (full or low) of the USB connect to be emulated. The connect enable (controlled as previously defined) results in the pulling up of D+ (1 = full speed) or D– (0 = low speed) (see [Table 24-951](#)).
- The 15-kΩ pulldowns are implicit: Because they are supposed to be turned on at least on the host side of the bus, they do not require additional control.

NOTE: Sideband control and status actions such as pullups are included in parallel (that is, nonserial) standards (UTMI, ULPI), and do not require custom additions.

Table 24-951. Pullup Enable Emulation in Serial TLL Modes

| TLL_CHANNEL_CONF_i Fields | | Input Signal | Resulting TLL Pullup Emulation | |
|---|------------|------------------------|--------------------------------|-----------|
| TLLFULLSPEED | TLLCONNECT | USB State | D+ Pullup | D– Pullup |
| 1 | 0 | Full-speed unconnected | Off | Off |
| 1 | 1 | Full-speed connected | On | Off |
| 0 | 0 | Low-speed unconnected | Off | Off |
| 0 | 1 | Low-speed connected | Off | On |

24.11.5 HS Multiport USB Host Subsystem Low-Level Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the HS USB host subsystem.

24.11.5.1 Global Initialization

24.11.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the HS USB host subsystem is used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the HS USB host subsystem.

[Table 24-952](#) describes the global initialization of surrounding modules.

Table 24-952. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|--|--|
| PRCM | All required clocks must be enabled. For ULPI PHY mode, mux the UTMI_P1_FCLK or UTMI_P2_FCLK to come from the external pad. See Section 3.6.3.2, CM Clock Source , in Chapter 3, Power, Reset, and Clock Management . |
| Cortex-A9 MPU INTC or Cortex-M3 MPU INTC | The Cortex-A9 MPU or Cortex-M3 MPU INTC must be configured to enable the interrupt request generation to the Cortex-A9 MPU or Cortex-M3 MPU subsystem when interrupt requests are generated by the HS multiport USB host subsystem. See the respective functional description in Chapter 18, Interrupt Controller , for the MPUs. |
| Interconnect (L3 and L4) | For more information, see Section 14.2, L3 Interconnect , and Section 14.3, L4 Interconnect . |

24.11.5.1.2 HS Multiport USB Host Subsystem Global Initialization

This procedure in [Table 24-953](#) initializes the HS multiport USB host subsystem after a power-on or software reset.

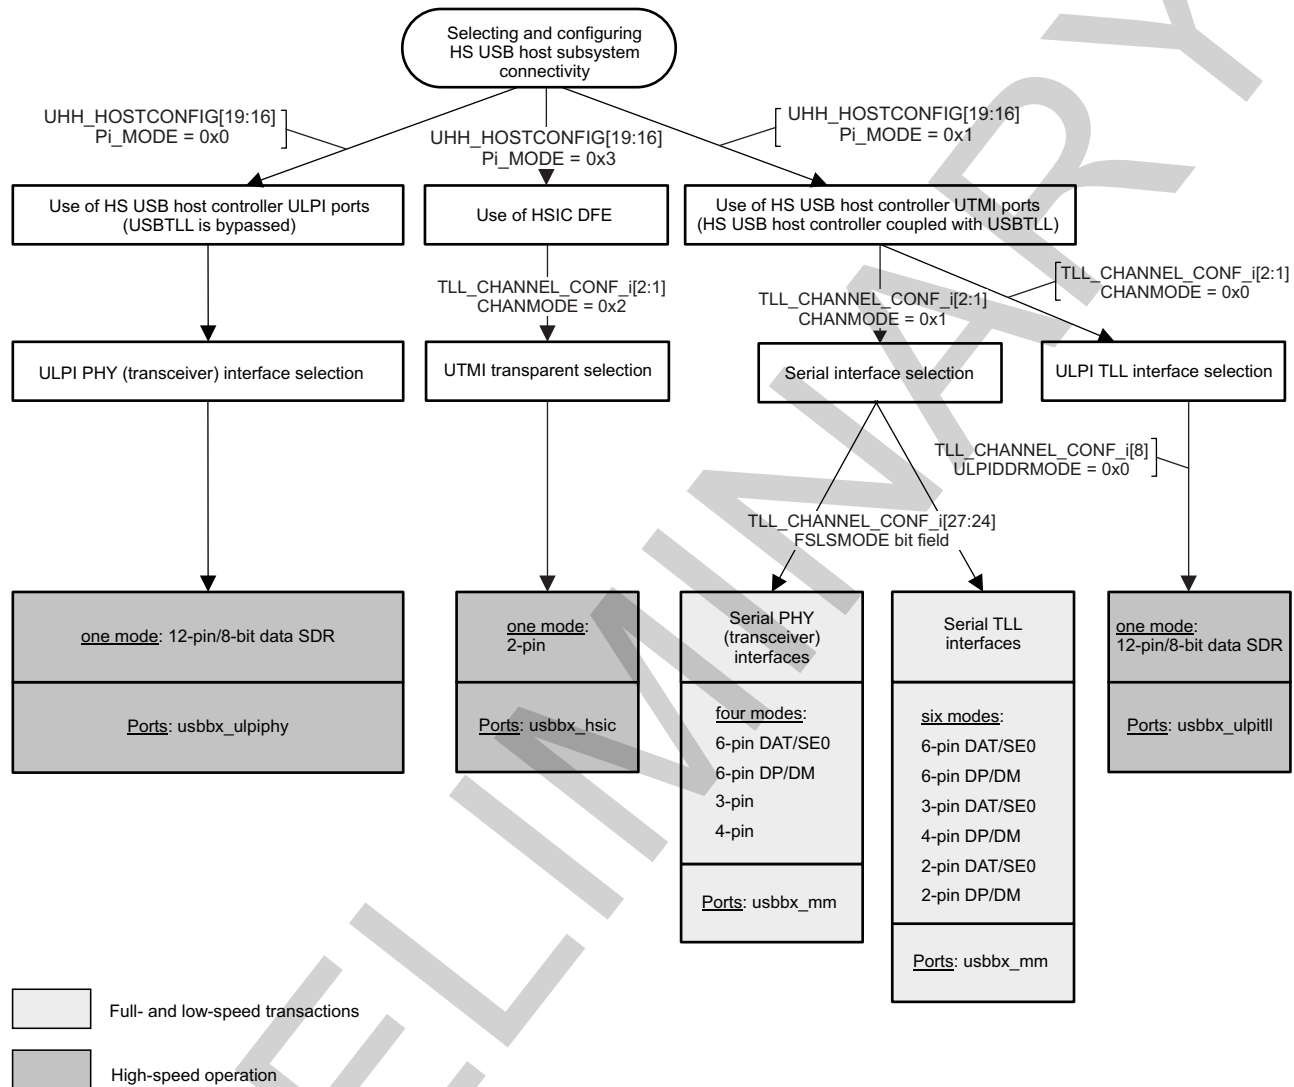

Table 24-953. HS Multiport USB Host Subsystem Global Initialization

| Step | Register/Bit Field/Programming Model | Value |
|--|---|-------|
| Perform a software reset on the TLL module. | USBTLL_SYSCONFIG[1] SOFTRESET | 0x1 |
| Wait until reset is finished. | USBTLL_SYSSTATUS[0] RESETDONE | =0x1 |
| Enable IRQ event for the TLL module. | USBTLL_IRQENABLE[1] FCLK_END_EN | 0x1 |
| Enable IRQ event for the TLL module. | USBTLL_IRQENABLE[0] FCLK_START_EN | =0x1 |
| Perform a software reset on the HS USB controller. | UHH_SYSCONFIG[0] SOFTRESET | 0x1 |
| Wait until the EHCI HS host is out of reset. | UHH_SYSSTATUS[2] EHCI_RESETDONE | =0x0 |
| Wait until the OHCI HS host is out of reset. | UHH_SYSSTATUS[1] OHCI_RESETDONE | =0x0 |
| Enable IRQ event for the OHCI HS host. | HCINTERRUPTENABLE[31] MIE | 0x1 |
| Enable IRQ event for the EHCI HS host. | USBINTR[0] USBIE | 0x1 |

24.11.5.2 Operational Modes Configuration (Selecting and Configuring USB Connectivity)

Figure 24-254 shows how to select and configure the HS USB host subsystem connectivity.

Figure 24-254. Selecting and Configuring HS USB Host Subsystem Connectivity

usb_swpu140-034

Table 24-954. Register Call Summary for Selecting and Configuring High-Speed USB Host Subsystem Connectivity

| Register Name | |
|----------------|--------------------|
| UHH_HOSTCONFIG | TLL_CHANNEL_CONF_i |

24.11.5.3 USBTLL Registers

The USBTLL module contains two types of software-programmable registers: TLL control and status registers and ULPI PHY-side registers.

24.11.5.3.1 TLL Control and Status Registers

These 32-bit registers configure the various channels. These registers are accessed by the MPU through the L4_CFG interconnect. They are used primarily before USB activity starts. The registers are:

- OCP-standard registers for revision number, IRQ, clocking management, etc.
- TLL-specific registers

24.11.5.3.2 ULPI PHY-Side Registers

Each TLL channel emulates a ULPI transceiver and therefore contains this set of 8-bit PHY-side registers, per ULPI specification. The registers are:

- All ULPI-mandatory standard registers and fields
- A selection of ULPI-optional standard registers and fields, when relevant to the TLL context
- Vendor-specific registers, mapped at the addresses specified for that purpose in the ULPI specification

These registers are accessed by the external (that is, off-chip) link controller over the ULPI port of each channel, in the 0x100-byte ULPI address space, using the ULPI register access protocol.

They are accessible by the L4_CFG interconnect: The ULPI register sets of all channels are mapped side by side in the upper part of the L4_CFG interconnect address space, where they can be accessed through byte accesses. If a conflict occurs between the two access modes, access over ULPI has priority, but both accesses eventually complete correctly. For normal USB activity, all register accesses are expected to go over ULPI, and register changes caused by L4_CFG interconnect accesses can compromise proper USB operation. The L4_CFG interconnect access port is intended for:

- Miscellaneous test and debug
- Nonintrusive observation of ongoing USB operations (test)
- Context restore: During USB suspend periods, the USBTLL module can be switched off to save power. When the module is switched on again, the ULPI register contents, which have been lost, can be restored over the L4_CFG interconnect before USB operations restart, provided they were saved elsewhere beforehand.

24.11.6 HS USB Host Subsystem Register Manual

This section provides the register description of the module.

24.11.6.1 USB_Host_HS Instance Summary

Table 24-955 summarizes the USB_Host_HS instance.

Table 24-955. USB_Host_HS Instance Summary

| Module Name | L4_CFG Base Address | Size |
|-----------------|---------------------|------|
| USBTLLHS_config | 0x4A06 2000 | 2KB |
| USBTLLHS_ULPI | 0x4A06 2800 | 2KB |
| HSUSBHOST | 0x4A06 4000 | 2KB |
| OHCI | 0x4A06 4800 | 1KB |
| EHCI | 0x4A06 4C00 | 1KB |

24.11.6.2 USBTLLHS_config Registers

24.11.6.2.1 USBTLLHS_config Register Summary

Table 24-956 summarizes the USBTLLHS_config register mapping.

Table 24-956. USBTLLHS_config Register Mapping Summary

| Register Name | Type | Register Width (Bits) | Address Offset | Physical Address |
|--|------|-----------------------|-------------------------|-------------------------|
| USBTLL_REVISION | R | 32 | 0x0000 0000 | 0x4A06 2000 |
| USBTLL_HWINFO | R | 32 | 0x0000 0004 | 0x4A06 2004 |
| USBTLL_SYSCONFIG | RW | 32 | 0x0000 0010 | 0x4A06 2010 |
| USBTLL_SYSSTATUS | R | 32 | 0x0000 0014 | 0x4A06 2014 |
| USBTLL_IRQSTATUS | RW | 32 | 0x0000 0018 | 0x4A06 2018 |

| 31:30 | RESERVED | | R | 0x0 |
| 29:28 | FSLSLINESTATE | Line state for Full/low speed serial modes Bit 1 = D- / Bit0 = D+ Read 0x0: Single-ended 0 Read 0x1: Full-Speed J = differential 1 Read 0x2: Full-Speed K = differential 0 Read 0x3: Single-ended 1 (illegal in USB) | R | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|-------|----------------|---|------|-------|
| 27:24 | FSLSMODE | Multiple-mode serial interface's mode select. Only when main channel mode is serial. No effect in other main modes. 0x0: 6-pin unidirectional PHY i/f mode. TX encoding is Dat/Se0 (default). 0x1: 6-pin unidirectional PHY i/f mode. TX encoding is Dp/Dm. 0x2: 3-pin bidirectional PHY i/f mode 0x3: 4-pin bidirectional PHY i/f mode 0x4: 6-pin unidirectional TLL mode. TX encoding is Dat/Se0. 0x5: 6-pin unidirectional TLL mode. TX encoding is Dp/Dm. 0x6: 3-pin bidirectional TLL mode 0x7: 4-pin bidirectional TLL mode 0xA: 2-pin bidirectional TLL mode. Encoding is Dat/Se0. 0xB: 2-pin bidirectional TLL mode. Encoding is Dp/Dm. | RW | 0x0 |
| 23:21 | RESERVED | | R | 0x0 |
| 20 | TESTTXSE0 | Force-Se0 transmit override value for serial mode test Don't care if TestEn = 0 (functional mode) or = TestTxen = 1 (TX = hiz) 0x0: drive differential value on TX according to TestTxDat 0x1: drive SE0 on TX | RW | 0 |
| 19 | TESTTXDAT | Differential data transmit override value for serial mode test Don't care if TestEn = 0 (functional mode) or = TestTxen = 1 (TX = hiz) or TestSe0 = 1 (TX = se0) 0x0: Drive full-speed K = differential 0 0x1: Drive full-speed J = differential 1 | RW | 0 |
| 18 | TESTTXEN | Differential data transmit override value for serial mode test Don't care if TestEn = 0 (functional mode) 0x0: Drive Tx according to TestTxDat/Se0 0x1: Drive Tx Hiz (no drive: pullups determine line state) | RW | 0 |
| 17 | TESTEN | Enable manual test override for serial mode TX path (from local controller UTMI port) 0x0: No override. Tx is from local link controller 0x1: Override enabled | RW | 0 |
| 16 | DRVVBUS | VBUS-drive for ChanMode = serial * In TLL config, write 1 to emulate serial-side VBUS drive * In PHY config, write 1 to report "VBUS valid" status (of actual VBUS) to UTMI controller 0x0: VBUS not driven 0x1: VBUS driven to 5 V | RW | 0 |
| 15 | CHRGVBUS | VBUS-drive for ChanMode = serial * In TLL config, write 1 to emulate serial-side VBUS charge/pullup (OTG) * In PHY config, write 1 to reports "session valid" status (of actual VBUS) to UTMI controller 0x0: VBUS not charged, session not valid 0x1: VBUS charged, session valid | RW | 0 |
| 14:12 | RESERVED | | R | 0x0 |
| 11 | ULPINOBITSTUFF | Disable bitstuff emulation in ULPI TLL for ULPI ChanMode 0x0: Bitstuff enabled, following USB standard 0x1: No bitstuff or associated delays (nonstandard) | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|----------------|---|-----------------|-------|
| 10 | ULPIAUTOIDLE | For ChanMode = ULPI TLL only. Allow the ULPI output clock to be stopped when ULPI goes into asynchronous mode (low-power, 3-pin serial, 6-pin serial). No effect in ULPI input clock mode. 0x0: ULPI output clock always-on 0x1: ULPI output clock stops during asynchronous ULPI modes | RW | 1 |
| 9 | UTMIAUTOIDLE | For ChanMode = ULPI TLL only. Allow the UTMI clock (output) to be stopped when UTMI goes to suspended mode (suspendm = 0) 0x0: UTMI clock output always on 0x1: UTMI clock output gated upon suspend | RW | 1 |
| 8 | RESERVED | | R | 0 |
| 7 | ULPIOUTCLKMODE | ULPI clocking mode select for ULPI TLL ChanMode. Hardcoded, for legacy only. Read 0x1: ULPI clock provided by PHY side (i.e. TLL, from functional clock). ULPI clock is output | R Returns 1s | 1 |
| 6 | TLLFULLSPEED | Sets PHY speed emulation in TLL (full/slow), which determines the line to pull up upon connect. The two connect source controls are: input m(N)_tlpuen, register field TllConnect. 0x0: Connect is Low-speed: D- pullup 0x1: Connect is Full-Speed: D+ pullup | RW | 1 |
| 5 | TLLCONNECT | Emulation of Full/Low-Speed connect (that is, D+ resp D- pullup) for serial TLL modes. Speed is determined by field TllSpeed. 0x0: Unconnected 0x1: Connected | RW | 0 |
| 4 | TLLATTACH | Emulates cable attach/detach for all serial TLL modes: * ChanMode = serial, in TLL mode (FsLsMode) * ChanMode = ULPI, in serial mode (6pin/3pin TLL) 0x0: Cable detach emulated on serial TLL 0x1: Cable attach emulated on serial TLL | RW | 1 |
| 3 | UTMIISADEV | Select the cable end "seen" by UTMI side of TLL, i.e. the emulated USB cable's orientation. The host must always be on A-side, peripheral on B-side. Reset value depends on generic DEFUTMIISHOST. 0x0: UTMI side is peripheral, ULPI side is host 0x1: UTMI side is host, ULPI side is peripheral | RW | 1 |
| 2:1 | CHANMODE | Main channel mode selection 0x0: UTMI-to-ULPI TLL mode (HS capable): to ULPI controller 0x1: UTMI-to-serial (FS/LS) mode: to serial controller (TLL) or serial PHY 0x2: Transparent UTMI mode: to UTMI PHY 0x3: No mode selected | RW | 0x0 |
| 0 | CHANEN | Active-high channel enable. A disabled channel is unclocked and kept under reset. 0x0: Channel i disabled 0x1: Channel i enabled | RW | 0 |

24.11.6.3.2 USBTLLHS_ULPI Register Description

Table 24-976 through Table 24-1054 describe the USBTLLHS_ULPI registers.

Table 24-976. VENDOR_ID_LO_i

| | | | |
|-------------------------|--|-----------------|---------------|
| Address Offset | 0x0000 0000 + (0x100 * i) | Index | i = 0 to 1 |
| Physical Address | 0x4A06 2800 + (0x100 * i) | Instance | USBTLLHS_ULPI |
| Description | Lower byte of USB-IF-supplied 16-bit vendor ID Value is set for all channels. Default is Texas Instruments Vendor ID = 0x0451. | | |
| Type | R | | |

| | | | | | | | |
|--------------|---|---|---|---|---|---|---|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| VENDOR_ID_LO | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|--------------|-------------|------|-------|
| 7:0 | VENDOR_ID_LO | | R | 0x51 |

CAUTION

The high-speed USB registers are limited to 32-bit data accesses; 16-bit and 8-bit accesses are not allowed and can corrupt register content.

OHCI register descriptions conform to the OHCI USB standard: *Open Host Controller Interface Specification for USB, Release 1.0a*. For more information about these registers or for new specification releases, search OHCI on www.usb.org.

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--|------|--------|
| 31:18 | RESERVED | Reserved | R | 0x0000 |
| 17:16 | SOC | Scheduling overrun count This is used to monitor any persistent scheduling problems. These bits are incremented on each scheduling overrun error. It is initialized to 0x0 and wraps around at 0x3. | R | 0x0 |
| 15:4 | RESERVED | Reserved | R | 0x000 |
| 3 | OCR | Ownership change request. This bit is set to request a change of control of the host controller. | RW | 0 |
| 2 | BLF | Bulk list filled This bit is used to indicate whether there are any TDs on the bulk list. It is set whenever it adds a TD to an ED in the bulk list. | RW | 0 |
| 1 | CLF | Control list filled This bit is used to indicate whether there are any TDs on the control list. It is set whenever it adds a TD to an ED in the control list. | RW | 0 |
| 0 | HCR | Host controller reset (software reset). Set this bit to initiate a USB host controller reset. This resets most USB host controller OHCI registers. OHCI register accesses must not be attempted until a read of this register returns a 0. 0x0: No effect 0x1: USB host controller is reset. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|-------|
| 18 | PSSC | Port 1 suspends status change. Set when the port leaves the suspend state; that is, after the full resume sequence has completed. Write 0x0: No effect Read 0x0: No resume completed (since either the last software clear, or the last port reset). Read 0x1: Resume completed on the port Write 0x1: Clears the bit | RW | 0 |
| 17 | PESC | Port 1 enable status change. This bit is set when the port 1 port enable status has changed. Write 0x0: No effect Write 0x1: Clears this bit | RW | 0 |
| 16 | CSC | Port 1 connect status change. This bit is set when the port1 port current connect status has changed due to a connect or disconnect event. If current connect status is 0 when a set port reset, set port enable, or set port suspend write occurs, this bit is set. Write 0x0: No effect Write 0x1: Clears this bit Note: If the HCRHDESCRIPTORB[1] DR bit is set, this bit is set only after a root hub reset to inform the system that the device is attached. | RW | 0 |
| 15:10 | RESERVED | Reserved | R | 0x00 |
| 9 | LSDA_CPP | Port 1 low-speed device attached/clear port power. This bit is valid only when port 1 current connect status is 1. Read 0x0: A full-speed device is attached to port 1. Read 0x1: A low-speed device is attached to port 1. Write 0x0: No effect Write 0x1: Clears the port 1 port power status | RW | 0 |
| 8 | PPS_SPP | Port 1 port power status/set port power Read 0x0: Port 1 power is enabled. Read 0x1: Port 1 power is not enabled. Write 0x0: No effect Write 0x1: Sets the port 1 port power status bit | RW | 0 |
| 7:5 | RESERVED | Reserved | R | 0x0 |
| 4 | PRS_SPR | Port 1 port reset status/set port reset Read 0x0: USB reset is not being sent to port 1. Read 0x1: Port 1 is signaling the USB reset. Write 0x0: No effect Write 0x1: Sets the port 1 port reset status bit and causes the USB host controller to begin signaling USB reset to port 1 | RW | 0 |
| 3 | RESERVED | | R | 0 |
| 2 | PSS_SPS | Port 1 port suspend status/set port suspend. This bit is cleared automatically at the end of the USB resume sequence and also at the end of the USB reset sequence. Write 0x0: No effect Read 0x0: Port 1 is not in the USB suspend state. Read 0x1: Port 1 is in the USB suspend state or is in the resume sequence. Write 0x1: If port 1 current connect status is 1, sets the port 1 port suspend status bit and places port 1 in USB suspend state. If current connect status is 0, sets instead connect status change to inform the USB host controller driver of an attempt to suspend a disconnected port. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 1 | PES_SPE | Port 1 port enable status/set port enable. This bit is automatically set at completion of port 1 USB reset if it was not already set before the USB reset completed, and is automatically set at the end of a USB suspend if the port was not enabled when the USB resume completed. Read 0x0: Port 1 is not enabled. Read 0x1: Port 1 is enabled. Write 0x0: No effect Write 0x1: When port 1 current connect status is 1 sets the port 1 port enable status bit. When port 1 current status is 0 has no effect. | RW | 0 |
| 0 | CCS_CPE | Port 1 current connection status/clear port enable Read 0x0: No USB device is attached to port 1. Read 0x1: A USB device is currently attached to port 1. Write 0x0: No effect Write 0x1: Clears the port 1 port enable bit Note: This bit is set to 1 if the HCRHDESCRIPTORB [1 DR bit] is set to indicate a nonremovable device on port 1. | RW | 0 |

| 9 | LSDA_CPP | Port 2 low-speed device attached/clear port power. This bit is valid only when port 2 current connect status is 1. Read 0x0: A full-speed device is attached to port 2. Read 0x1: A low-speed device is attached to port 2. Write 0x0: No effect Write 0x1: Clears the port 2 port power status | RW | 0 |
| 8 | PPS_SPP | Port 2 port power status/set port power Read 0x0: Port 2 power is enabled. Read 0x1: Port 2 power is not enabled. Write 0x0: No effect Write 0x1: Sets the port 2 port power status bit | RW | 0 |
| 7:5 | RESERVED | Reserved | R | 0x0 |
| 4 | PRS_SPR | Port 2 port reset status/set port reset Read 0x0: USB reset is not being sent to port 2. Read 0x1: Port 2 is signaling the USB reset. Write 0x0: No effect Write 0x1: Sets the port 2 port reset status bit and causes the USB host controller to begin signaling USB reset to port 2 | RW | 0 |
| 3 | RESERVED | | RW | 0 |
| 2 | PSS_SPS | Port 2 port suspend status/set port suspend. This bit is cleared automatically at the end of the USB resume sequence and also at the end of the USB reset sequence. Write 0x0: No effect Read 0x0: Port 2 is not in the USB suspend state. Read 0x1: Port 2 is in the USB suspend state or is in the resume sequence. Write 0x1: If port 2 current connect status is 1, sets the port 2 port suspend status bit and places port 2 in USB suspend state. If current connect status is 0, sets instead connect status change to inform the USB host controller driver of an attempt to suspend a disconnected port. | RW | 0 |
| 1 | PES_SPE | Port 2 port enable status/set port enable. This bit is automatically set at completion of port 2 USB reset if it was not already set before the USB reset completed, and is automatically set at the end of a USB suspend if the port was not enabled when the USB resume completed. Read 0x0: Port 2 is not enabled. Read 0x1: Port 2 is enabled. Write 0x0: No effect Write 0x1: When port 2 current connect status is 1 sets the port 2 port enable status bit. When port 2 current status is 0 has no effect. | RW | 0 |
| 0 | CCS_CPE | Port 2 current connection status/clear port enable Read 0x0: No USB device is attached to port 2. Read 0x1: A USB device is currently attached to port 2. Write 0x0: No effect Write 0x1: Clears the port 2 port enable bit Note: This bit is set to 1 if the HCRHDESCRIPTORB[1] DR bit is set to indicate a nonremovable device on port 2. | RW | 0 |

CAUTION

The high-speed USB registers are limited to 32-bit data accesses; 16-bit and 8-bit accesses are not allowed and can corrupt register content.

EHCI register descriptions conform to the EHCI USB standard: *Enhanced Host Controller Interface (EHCI) Specification for USB, Release 1.1*. For more information about these registers or for new specification releases, search EHCI on www.usb.org.

24.11.6.6.2 EHCI Register Description

Table 24-1119 through Table 24-1161 describe the EHCI registers.

| 31:20 | RESERVED | Reserved | R | 0x000 |
| 19:17 | RESERVED | Reserved | R | 0x0 |
| 16 | P_INDICATOR | Port indicator support indication This bit indicates whether the ports support port indicator control. 0x1: The port status and control registers include a read/write field for controlling the state of the port indicator. | R | 0 |
| 15:12 | N_CC | Number of companion controllers This field indicates the number of companion controllers associated with this USB 2.0 host controller. 0x0: There are no companion host controllers. Port-ownership hand-off is not supported. Only high-speed devices are supported on the host controller root ports. | R | 0x1 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| | | Others: There are companion USB 1.1 host controller(s). Port-ownership hand-off is supported. High-, full-, and low-speed devices are supported on the host controller root ports. | | |
| 11:8 | N_PCC | Number of ports per companion controller This field indicates the number of ports supported per companion host controller. It is used to indicate the port routing configuration to system software. For example, if N_PORTS has a value of 6 and N_CC has a value of 2, then N_PCC can have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. The number in this field must be consistent with N_PORTS and N_CC. | R | 0x3 |
| 7 | PRR | Port routing rules The first N_PCC ports are routed to the lowest-numbered function companion host controller, the next N_PCC ports are routed to the next lowest-function companion controller, and so on. | R | 0 |
| 6:5 | RESERVED | Reserved | R | 0x0 |
| 4 | PPC | Port power control This field indicates whether the host controller implementation includes port power control. 0x0: The ports do not have port power switches. 0x1: The ports have port power switches. | R | 1 |
| 3:0 | N_PORTS | Number of downstream ports This field specifies the number of physical downstream ports implemented on this host controller. | R | 0x3 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|-------|
| 31:28 | RESERVED | Reserved | R | 0x0 |
| 27:24 | HIRD | Host-initiated resume duration. If LPM is enabled, this field is RW; otherwise, it is R. The minimum for K-state during resume from LPM: 0x0: 50 μ s Each increment adds 75 μ s. | RW | 0x0 |
| 23:16 | ITC | Interrupt threshold control This field is used by the system software to select the maximum rate at which the host controller issues interrupts. The only valid values are defined below. If software writes an invalid value to this register, the results are undefined. 0x00: Reserved 0x01: 1 microframe 0x02: 2 microframes 0x04: 4 microframes 0x08: 8 microframes (default, equates to 1 ms) 0x10: 16 microframes (2 ms) 0x20: 32 microframes (4 ms) 0x40: 64 microframes (8 ms) Others: Undefined | RW | 0x08 |
| 15:12 | RESERVED | Reserved | R | 0x0 |
| 11 | ASPME | Asynchronous schedule park mode enable 0x0: Park mode is disabled. 0x1: Park mode is enabled. | RW | 1 |
| 10 | RESERVED | Reserved | R | 0 |
| 9:8 | ASPMC | Asynchronous schedule park mode count It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the asynchronous schedule before continuing traversal of the asynchronous schedule. Valid values are 0x1 to 0x3. Software must not write 0 to this bit when park mode enable is 1 because this may result in undefined behavior. | RW | 0x3 |
| 7 | LHCR | Light host controller reset It allows the driver to reset the EHCI controller without affecting the state of the ports or the relationship to the companion host controllers. Read 0x0: Light host controller reset is complete and it is safe for host software to reinitialize the host controller. Read 0x1: Light host controller reset is still ongoing. | RW | 0 |
| 6 | IAAD | Interrupt on async advance doorbell This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Write 0x1: Ring the doorbell. Software must not write 1 to this bit when the asynchronous schedule is disabled. Doing so may yield undefined results. | RW | 0 |
| 5 | ASE | Asynchronous schedule enable This bit controls whether the host controller skips processing the asynchronous schedule. 0x0: Do not process the asynchronous schedule | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-------|
| | | 0x1: Use the USBHOST.ASYNCLISTADDR register to access the asynchronous schedule. | | |
| 4 | PSE | Periodic schedule enable This bit controls whether the host controller skips processing the periodic schedule. 0x0: Do not process the periodic schedule 0x1: Use the USBHOST.PERIODICLISTBASE register to access the periodic schedule. | RW | 0 |
| 3:2 | FLS | Frame list size This field specifies the size of the frame list. The size of the frame list controls which bits in the frame index register should be used for the frame list current index. 0x0: 1024 elements (4096 bytes) 0x1: 512 elements (2048 bytes) 0x2: 256 elements (1024 bytes), for resource-constrained environments 0x3: Reserved | RW | 0 |
| 1 | HCR | Host controller reset This control bit is used by software to reset the host controller. Write 0x1: Reset the host controller, the PCI configuration registers are not affected by this reset and all operational registers are set to their initial values. This bit is set to 0 by the host controller when the reset process is complete. | W | 0 |
| 0 | RS | Run/stop 0x1: Run, the host controller proceeds with execution of the schedule. The host controller continues execution as long as this bit is set to 1. 0x0: Stop, the host controller completes the current and any actively pipelined transactions on the USB and then halts. | RW | 0 |

|-------|------------|---|------|--------|
| 31:16 | RESERVED | Reserved | R | 0x0000 |
| 15 | ASS | Asynchronous schedule status | R | 0 |
| | | The bit reports the current real status of the asynchronous schedule. | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| | | 0x0: The status of the asynchronous schedule is disabled. 0x1: The status of the asynchronous schedule is enabled. | | |
| 14 | PSS | Periodic schedule status The bit reports the current real status of the periodic schedule. 0x0: The status of the periodic schedule is disabled. 0x1: The status of the periodic schedule is enabled. | R | 0 |
| 13 | REC | Reclamation It is used to detect an empty asynchronous schedule. | R | 0 |
| 12 | HCH | Host controller halted This bit is a 0 whenever the USBHOST.USB_CMD[0] RS bit is a 1. The host controller sets this bit to 1 after it has stopped executing as a result of the RS bit being set to 0, either by software or by the host controller hardware. | R | 1 |
| 11:6 | RESERVED | Reserved | R | 0x00 |
| 5 | IAA | Interrupt on async advance System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by setting the USBHOST.USB_CMD[6] IAA bit to 1. This status bit indicates the assertion of that interrupt source. | RW | 0 |
| 4 | HSE | Host system error The host controller sets this bit to 1 when a serious error occurs during a host system access involving the host controller module. | RW | 0 |
| 3 | FLR | Frame list rollover The host controller sets this bit to 1 when the USBHOST.FRINDEX rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size. | RW | 0 |
| 2 | PCD | Port change detect The host controller sets this bit to 1 when any port for which the USBHOST.PORTSC_i[13] PO bit is set to 0 has a change bit transition from 0 to 1 or a USBHOST.PORTSC_i[6] FPR bit transition from 0 to 1. This bit is also set as a result of the USBHOST.PORTSC_i[1] CSC bit being set to 1 after system software has relinquished ownership of a connected port by setting the USBHOST.PORTSC_i[13] PO bit to 1. | RW | 0 |
| 1 | USBEI | USB error interrupt The host controller sets this bit to 1 when completion of a USB transaction results in an error condition. | RW | 0 |
| 0 | USBI | USB interrupt The host controller sets this bit to 1 on completion of a USB transaction, which results in the retirement of a transfer descriptor that had its IOC bit set. The host controller also sets this bit to 1 when a short packet is detected (actual number of bytes received was less than the expected number of bytes). | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|---------------|--|------|-------|
| 31:25 | DEVICEADDRESS | The USB device address for the device attached to and immediately downstream from the associated root port. R/W only if LPM is enabled; otherwise, R. | RW | 0x00 |
| 24:23 | SUSPENDSTATUS | Addition for LPM support. Indicates status of L1 suspend request: 0x0: Success 0x1: Not yet 0x2: Not supported 0x3: Time-out/error | R | 0x0 |
| 22 | RESERVED | Reserved | R | 0 |
| 21 | WDE | Wake on disconnect enable This field is 0 if the PP bit is 0. Write 0x1: Enables the port to be sensitive to device disconnects as wake-up events. | RW | 0 |
| 20 | WCE | Wake on connect enable This field is 0 if the PP bit is 0. Write 0x1: Enables the port to be sensitive to device connects as wake-up events. | RW | 0 |
| 19:16 | PTC | Port test control The port is operating in specific test modes as indicated by the specific value. The encoding of the test mode bits are: 0x0: Test mode not enabled 0x1: Test J_STATE 0x2: Test K_STATE 0x3: Test SE0_NAK 0x4: Test Packet 0x5: Test FORCE_ENABLE Others: Reserved | RW | 0x0 |
| 15:14 | PIC | Port indicator control (not implemented) | R | 0x0 |
| 13 | PO | Port owner | RW | 1 |

| Bits | Field Name | Description | Type | Reset | | | | | | | | | | | | | | | |
|-------------|------------|---|-------------|-----------|----------------|-----|-----|---|-----|---------|---|-----|---------|---|-----|-----------|--|----|-----|
| | | This bit unconditionally goes to 0x0 when the USBHOST.CONFIGFLAG[0] CF bit makes a transition from 0 to 1. This bit unconditionally goes to 0 whenever the USBHOST.CONFIGFLAG[0] CF bit is 0. 0x1: A companion host controller owns and controls the port. | | | | | | | | | | | | | | | | | |
| 12 | PP | Port power The function of this bit depends on the value of the USBHOST.HCSPARAMS[4] PPC bit. The behavior is as follows: <table><tr><th>PPC</th><th>PP</th><th>Operation</th></tr><tr><td>0x0</td><td>0x0</td><td>Forbidden</td></tr><tr><td>0x0</td><td>0x1</td><td>Host controller does not have port power control switches. Each port is hardwired to power.</td></tr><tr><td>0x1</td><td>0x0</td><td>Host controller has port power control switches. Current switch state is off.</td></tr><tr><td>0x1</td><td>0x1</td><td>Host controller has port power control switches. Current switch state is on.</td></tr></table> When an overcurrent condition is detected on a powered port and the USBHOST.HCSPARAMS[4] PPC bit is a 1, the PP bit in each affected port may be transitioned by the host controller from 1 to 0. | PPC | PP | Operation | 0x0 | 0x0 | Forbidden | 0x0 | 0x1 | Host controller does not have port power control switches. Each port is hardwired to power. | 0x1 | 0x0 | Host controller has port power control switches. Current switch state is off. | 0x1 | 0x1 | Host controller has port power control switches. Current switch state is on. | RW | 0 |
| PPC | PP | Operation | | | | | | | | | | | | | | | | | |
| 0x0 | 0x0 | Forbidden | | | | | | | | | | | | | | | | | |
| 0x0 | 0x1 | Host controller does not have port power control switches. Each port is hardwired to power. | | | | | | | | | | | | | | | | | |
| 0x1 | 0x0 | Host controller has port power control switches. Current switch state is off. | | | | | | | | | | | | | | | | | |
| 0x1 | 0x1 | Host controller has port power control switches. Current switch state is on. | | | | | | | | | | | | | | | | | |
| 11:10 | LS | Line status These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. This field is valid only when the port enable bit is 0 and the current connect status bit is set to 1. The encoding of the bits is: <table><tr><th>Bits[11:10]</th><th>USB State</th><th>Interpretation</th></tr><tr><td>0x0</td><td>SE0</td><td>Not low-speed device, perform EHCI reset.</td></tr><tr><td>0x2</td><td>J-state</td><td>Not low-speed device, perform EHCI reset.</td></tr><tr><td>0x1</td><td>K-state</td><td>Low-speed device, release ownership of port.</td></tr><tr><td>0x3</td><td>Undefined</td><td>Not low-speed device, perform EHCI reset.</td></tr></table> | Bits[11:10] | USB State | Interpretation | 0x0 | SE0 | Not low-speed device, perform EHCI reset. | 0x2 | J-state | Not low-speed device, perform EHCI reset. | 0x1 | K-state | Low-speed device, release ownership of port. | 0x3 | Undefined | Not low-speed device, perform EHCI reset. | R | 0x0 |
| Bits[11:10] | USB State | Interpretation | | | | | | | | | | | | | | | | | |
| 0x0 | SE0 | Not low-speed device, perform EHCI reset. | | | | | | | | | | | | | | | | | |
| 0x2 | J-state | Not low-speed device, perform EHCI reset. | | | | | | | | | | | | | | | | | |
| 0x1 | K-state | Low-speed device, release ownership of port. | | | | | | | | | | | | | | | | | |
| 0x3 | Undefined | Not low-speed device, perform EHCI reset. | | | | | | | | | | | | | | | | | |
| 9 | SUSPENDL1 | When this bit is set to 1, an LPM token is generated. 0: Suspend using L2 1: Suspend using L1 (LPM) | RW | 0 | | | | | | | | | | | | | | | |
| 8 | PR | Port reset This field is 0 if the PP bit is 0. 0x0: Port is not in reset. 0x1: Port is in reset. Write 0x0: Terminate the bus reset sequence. Write 0x1 when at 0x0: The bus reset sequence is started. | RW | 0 | | | | | | | | | | | | | | | |
| 7 | SUS | Suspend This field is 0 if the PP bit is 0. 0x0 when PED = 0x1: Port enabled 0x1 when PED = 0x1: Port in suspend state When PED = 0x0: Port disabled | RW | 0 | | | | | | | | | | | | | | | |
| 6 | FPR | Force port resume This field is 0 if the PP bit is 0. 0x0: No resume (K-state) detected/driven on port 0x1: Resume detected/driven on port | RW | 0 | | | | | | | | | | | | | | | |
| 5:4 | RESERVED | Reserved | R | 0 | | | | | | | | | | | | | | | |
| 3 | PEDC | Port enabled/disabled change This field is 0 if the PP bit is 0. Read 0x0: No change. | RW | 0 | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-------|
| | | Read 0x1: Port enabled/disabled status has changed. Write 0x1: Clears this bit to 0. | | |
| 2 | PED | Port enabled/disabled Software cannot enable a port by setting this bit to 1. The host controller only sets this to 1 when the reset sequence determines that the attached device is a high-speed device. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by host software. This field is 0 if the PP bit is 0. 0x0: Disable 0x1: Enable | RW | 0 |
| 1 | CSC | Connect status change Indicates a change has occurred in the port CCS bit. This field is 0 if the PP bit is 0. Read 0x0: No change Read 0x1: Change in current connect status Write 0x1: Clears this bit to 0 | RW | 0 |
| 0 | CCS | Current connect status This value reflects the current state of the port, and may not correspond directly to the event that caused the CSC bit to be set. This field is 0 if the PP bit is 0. 0x0: No device is present. 0x1: Device is present on port. | R | 0 |

24.12 High-Speed USB OTG Controller

This section describes the high-speed USB On-The-Go (OTG) controller of the device.

NOTE: The high-speed USB OTG controller is an instantiation of the MUSBMHDC from Mentor Graphics Corporation.

This document contains materials that are ©2003-2007 Mentor Graphics Corporation.

Mentor Graphics is a registered trademarks of Mentor Graphics Corporation or its affiliated companies in the United States and other countries.

24.12.1 High-Speed USB OTG Controller Overview

The High-Speed USB controller is a high-speed, USB OTG dual-role-device (DRD) link controller supporting the following modes:

- USB 2.0 peripheral (function controller) in high/full speed (480/12 Mbps, respectively)
- USB 2.0 host in high/full/low speed (480/12/1.5 Mbps, respectively), with one downstream port but multipoint capability when a hub is connected to it (split transaction support, etc.)
- USB 2.0 OTG DRD in high/full speed, with HNP (OTG1.3) and SRP support.

The high-speed USB OTG controller supports a single USB port, which uses the ULPI interface mode, to connect to an off-chip transceiver (12-pin/8-bit data SDR mode) and to connect on D+/D- (+ID) USB bus thanks to an embedded USB-HS OTG PHY.

It is connected to L3 master and L4 slave interfaces. It is clocked from independent functional clock from a PHY. This module operates either as the function controller of a high-/full-speed USB peripheral or as the host/peripheral in point-to-point or multi-point communications with other USB functions.

[Figure 24-255](#) highlights the high-speed USB controller.

Figure 24-255. High-Speed USB OTG Controller Highlight

24.12.1.1 Main Features

The high-speed USB controller features:

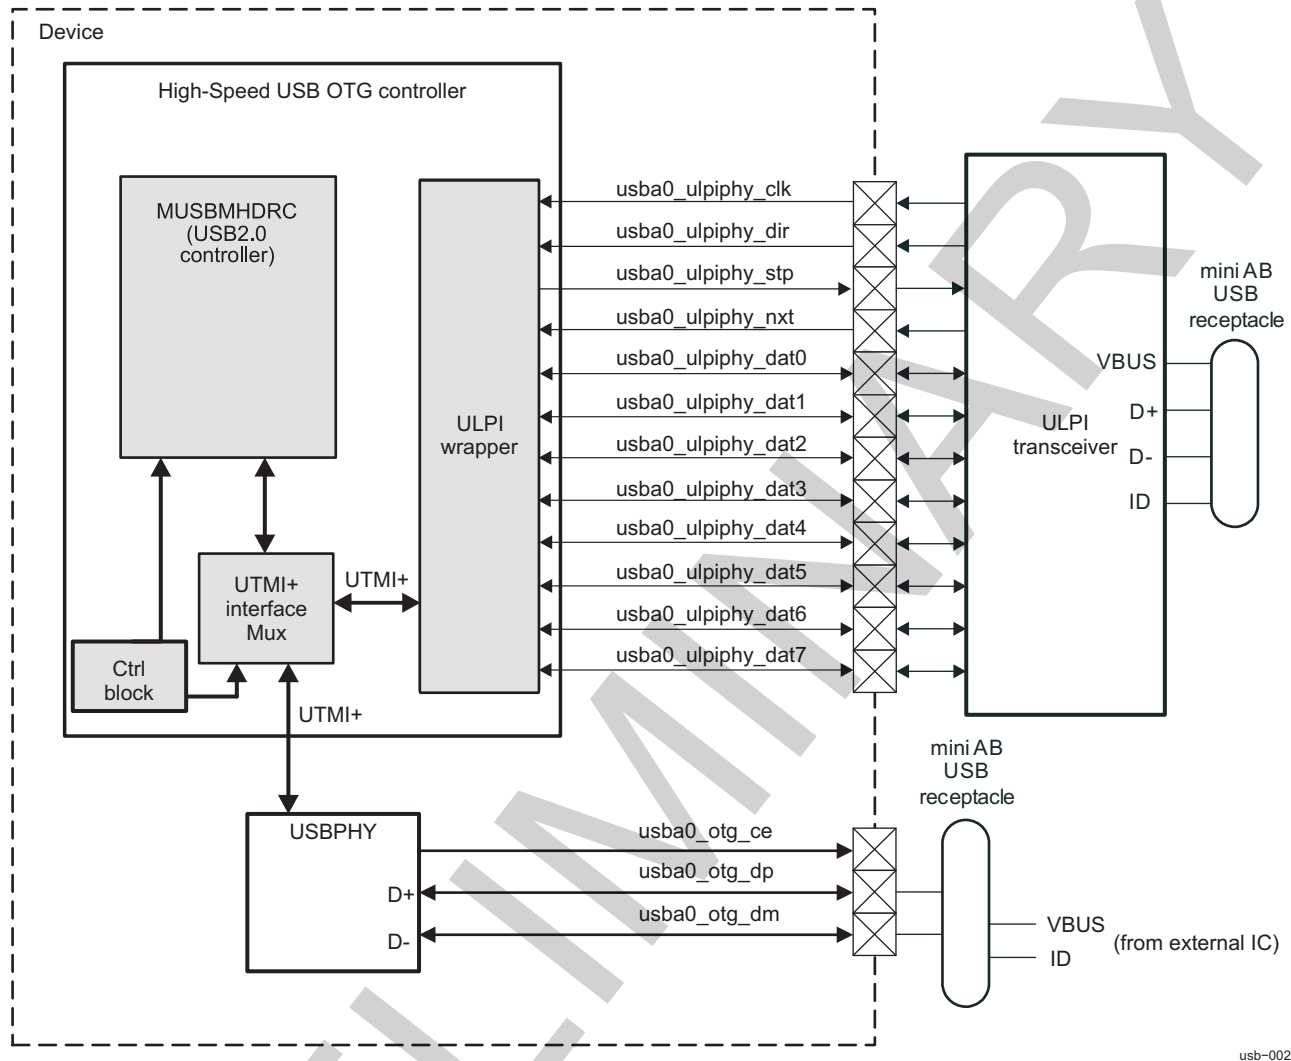

- L3 (master) interface supports:
 - 32-bit data bus width
 - 8/16/32 bit access supported
 - 32-bit address bus width
 - Burst supported
 - WNP not supported
- L4 (slave) interface supports:
 - 32-bit data bus width
 - 16/32 bit access supported
 - 12-bit address bus width
 - Burst not supported
 - WNP supported
- Complies with USB2.0 standard for high-speed (480 Mb/s) functions and with the OTG 1.3 (On-The-Go) supplement. Implement Link Power Management
- Contains embedded HS PHY with battery charger detection
- Contains PHY (physical layer) interface: ULPI interface (12-bit version)
- 15 transmit endpoints and 15 receive endpoints in addition to control endpoint 0
- Supports OTG communications with one or more high/full/low speed devices.
- Supports packet splitting / combining for bulk transfers
- Soft connect/disconnect option
- Performs all transaction scheduling in hardware
- Each endpoint can be configured for types (interrupt, bulk or isochronous), for size and double buffering operation within a limit of a 8KB of data and total RAM size of 16KB.
- Supports high-bandwidth isochronous and interrupt transfers.
- Supports suspend/resume and remote wake-up.
- Two interrupt lines.
- DMA access to endpoint FIFOs with internal DMA controller supporting 8 channels
- Supports host negotiation and session request protocols (HNP (OTG1.3) and SRP)
- CarKit feature implementation

USB-HS OTG PHY (USBPHY). This embedded PHY is composed of two modules:

- USB2PHYCORE contains the USB functions, drivers, receivers and pads for correct D+/D– signalling and the battery charger detection (supporting dead-battery mode). Delivers a 3.3-V output signal (charger enable) to control external battery charger.
- USB2PHYCM contains LDO and bandgap for providing voltage reference to USB2PHYCORE module.

24.12.2 High-Speed USB OTG Controller Environment

[Figure 24-256](#) shows a typical application using the high-speed USB controller.

Figure 24-256. High-Speed USB Controller Typical Application System

usb-002

NOTE: Only one interface can be active at a time.

The high-speed USB OTG controller supports a single USB port, which uses the ULPI interface mode, to connect to an off-chip transceiver (12-pin/8-bit data SDR mode). A mini A-B external receptacle allows the connection of an external device.

The 12-pin ULPI interface uses an 8-bit data bus with data synchronous to the rising edge of the PHY clock (SDR mode); the 8-pin ULPI uses a 4-bit data bus with data generated on both the rising and falling clock edge (DDR mode).

The current implementation of high-speed USB controller supports only the 12-pin, 8-bit version ULPI interface. The 12-pin/8-bit data SDR ULPI interface is selected through the [OTG_INTERFSEL\[2:0\]](#) PHYSEL field and must be set to 0x1.

Embedded PHY interface is 8-bit, UTMI+ and is selected through setting [OTG_INTERFSEL \[2:0\]](#) PHYSEL field to 0x0.

24.12.2.1 High-Speed USB OTG Controller Functional Interfaces

[Table 24-1163](#) describes the I/O signals of the high-speed USB controller interfaces shown in [Figure 24-256](#)

24.12.3 High-Speed USB OTG Controller Integration

The L3 (master) interconnect generates data traffic within the device. The L4(slave) interconnect is a configuration port for register setting.

[Figure 24-257](#) shows the high-speed USB controller integration in the device.

Figure 24-257. High-Speed USB Controller Integration

usb-003

Table 24-1164 through Table 24-1166 summarize the integration of the module in the device.

Table 24-1164. Integration Attributes

24.12.4 High-Speed USB OTG Controller Functional Description

24.12.4.1 Software Reset

The high-speed USB controller has a software reset through the [OTG_SYSCONFIG](#)[1] SOFTRESET bit. Writing 0x1 to this bit initiates reset of the module. The bit value 0x1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically cleared to 0x0 and has the same effect as the hardware reset. The status of the reset can be observed through the [OTG_SYSSTATUS](#)[0] RESETDONE bit.

24.12.4.2 Power Management

24.12.4.2.1 Overview

To save dynamic power consumption, an efficient idle scheme in the device is based on the following:

- An efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated/deactivated safely without complex software intervention. In both cases, the high-speed USB controller power management is applied only to the interface clock domain. The USB OTG functional clock, HSUSB_FCLK, is controlled by the transceiver and is responsible only for a very small percentage of the module overall power consumption.

The high-speed USB controller has both master (initiator) and slave (target) interfaces.

- As an initiator, the high-speed USB OTG controller implements the standby handshake protocol to inform the PRCM module when it enters standby mode and does not generate traffic on the interconnect.
- As a target, the high-speed USB OTG controller implements the IDLE handshake protocol to allow the PRCM module requiring it to enter idle mode.

24.12.4.2.2 System Power Management

24.12.4.2.2.1 Standby Handshake Protocol

The high-speed USB OTG controller can choose to go to standby mode, in which case it stops generating transactions on the interconnect. The module standby leads the PRCM to disable the USB clocks to save power.

The high-speed USB OTG controller has a MSTANDBY handshake mechanism with the PRCM module

The module is ready to enter standby mode (indicated by the MSTANDBY signal to the PRCM asserted) when the USB is in suspend mode and the module is idle. It means the following:

- The module is committed not to start any new transaction on its master interface.
- The module is idle and, therefore, the power manager can start the procedure to turn off the interface clock, if needed. This procedure must be implemented using the slave power-management protocol.

The handshake mechanism lets the module to go to standby state based on the [OTG_SYSCONFIG](#)[13:12] MIDDLEMODE field.

- Smart-standby

The high-speed USB controller is configured in smart-standby mode ([OTG_SYSCONFIG](#)[13:12] MIDDLEMODE field = 0x2). The module is ready to enter standby mode (MSTANDBY is asserted) when there is no more activity on the USB master interface of the interconnect. MSTANDBY is asserted when the module is idle and deasserted when the module is activated by either an external USB event or an appropriate register access. The module then waits for MWAIT deassertion before a DMA transfer is started.

- Force-standby

- When the high-speed USB controller operates as a host: The USBOTG.POWER[1] SUSPENDMODE bit is set to 0x1 to bring the module to low-power mode (suspend mode). After this setting, the high-speed USB controller waits for its idle state. Software must set

OTG_SYSCONFIG[13:12] MIDDLEMODE = 0x0. Hardware then asserts MSTANDBY. Similarly, to release the MSTANDBY signal, an appropriate register access must be applied, which can be either of the following two cases:

- Remote wakeup causes a RESUME interrupt
- Set the USBOTG.POWER[3] RESET bit to 0x1
- Write 0x2 to the **OTG_SYSCONFIG**[13:12] MIDDLEMODE.

OR

- Set the USBOTG.POWER[3] RESET bit to 0x1
- Write 0x2 to the **OTG_SYSCONFIG**[13:12] MIDDLEMODE.

- When the high-speed USB controller operates as a peripheral: When the USB bus is idle for 3 ms, a SUSPEND interrupt is generated by the high-speed USB controller. Software must set **OTG_SYSCONFIG**[13:12] MIDDLEMODE = 0x0. Hardware then asserts MSTANDBY. The high-speed USB controller then asserts MSTANDBY. Similarly, to release the MSTANDBY signal, an appropriate register access must be applied, which can be either of the following two cases:

- Set the USBOTG.POWER[2] RESUME bit to 0x1.
 - Write 0x2 to the **OTG_SYSCONFIG**[13:12] MIDDLEMODE.
- OR
- RESET interrupt is generated by the high-speed USB controller.
 - Write 0x2 to the **OTG_SYSCONFIG**[13:12] MIDDLEMODE.

When MSTANDBY is deasserted as a consequence of the previous register access, the module waits for MWAIT deassertion before a DMA transfer is started.

- No-standby

The high-speed USB controller is configured in no-standby mode (**OTG_SYSCONFIG**[13:12] MIDDLEMODE field = 0x1). The module never enters standby mode (that is, MSTANDBY is never asserted).

Table 24-1167 describes the high-speed USB standby mode settings.

Table 24-1167. HSUSBOTG Host Controller STANDBYMODE Settings

| OTG_SYSCONFIG [13:12] MIDDLEMODE Value | Selected Mode | Description |
|--|----------------------|---|
| 0x0 | Force-standby | The HSUSBOTG host controller enters standby mode unconditionally |
| 0x1 | No-standby | The HSUSBOTG host controller never enters standby mode |
| 0x2 | Smart-standby | The HSUSBOTG host controller is ready to enter standby mode when there is no more activity on the USB master interface of the interconnect. |

24.12.4.2.2 IDLE Handshake Protocol

The high-speed USB controller can be configured through the **OTG_SYSCONFIG**[4:3] SIDLEMODE field as one of the following acknowledgment modes:

- Smart-idle mode

When the high-speed USB controller receives an IDLE request from the PRCM module:

- The interface clock INIT_L3_ICLK is disabled, see [CD_L3_INIT Clock Domain](#)
- L4 interface clock idle transitions:

Configured in smart-idle mode (**OTG_SYSCONFIG**[4:3] SIDLEMODE field = 0x2), the high-speed USB controller checks for no ongoing activity. The idle acknowledge then is asserted and the module waits for active system clock gating by the PRCM module (this occurs only when all peripherals supplied by the same L3 clock domain are also ready for idle).

Once in smart idle mode (when the PRCM module gates the interface clock), the module has no activity, the interface clock paths are gated, no interrupt request can be generated, and the module is

ready to issue a wake-up request. If a wake-up condition occurs, the high-speed USB controller exits from smart idle mode if the [OTG_SYSCONFIG\[2\] ENABLEWAKEUP](#) bit is set to 0x1 (wake-up capability enabled).

- Smart-idle wake-up mode

The high-speed USB OTG controller is configured in smart-idle wake-up mode ([OTG_SYSCONFIG\[4:3\] Smart Idle Wkp](#) field = 0x3). The functionality of this mode is the same as smart-idle mode, additionally Wake up feature is enabled.

- Force-idle mode

When the high-speed USB controller receives an IDLE request from the PRCM module:

- The interface clock [INIT_L3_ICLK](#) is disabled, see [CD_L3_INIT Clock Domain](#)
- The L4 interface clock idle transitions:

Configured in force-idle mode ([OTG_SYSCONFIG\[4:3\] SIDLEMODE](#) field = 0x0), the high-speed USB controller waits unconditionally for active system clock gating by the PRCM module (this occurs only when all peripherals supplied by the same L3 clock domain are also ready for idle).

Once in idle mode (when the PRCM module gates the interface clock), the module has no activity, the interface clock paths are gated, no interrupt request can be generated, and the wake-up feature is totally inhibited.

- No-idle mode

When the high-speed USB controller receives an IDLE request from the PRCM module:

- The interface clock [INIT_L3_ICLK](#) is disabled [CD_L3_INIT Clock Domain](#)
- L4 interface clock idle transitions

Configured in no-idle mode ([OTG_SYSCONFIG\[4:3\] SIDLEMODE](#) bit field = 0x1), the high-speed USB controller module does not go to idle mode and the idle acknowledge is never sent.

[Table 24-1168](#) describes the high-speed USB sidle mode settings. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

Table 24-1168. HSUSBOTG Host Controller SIDLEMODE Settings

| OTG_SYSCONFIG[4:3] SIDLEMODE Value | Selected Mode | Description |
|--|--------------------|---|
| 0x0 | Force-idle | The HSUSBOTG host controller acknowledges unconditionally the IDLE request from the PRCM, regardless of its internal operations. |
| 0x1 | No-idle | The HSUSBOTG host controller never acknowledges any IDLE request from the PRCM. |
| 0x2 | Smart-idle | The HSUSBOTG host controller acknowledges the IDLE request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs or DMA requests are treated. |
| 0x3 | Smart-idle wake-up | The HSUSBOTG host controller enters smart mode with wakeup enabled. |

24.12.4.2.2.3 Wake-Up Request

Wake-up request is enabled by setting [OTG_SYSCONFIG\[2\] ENABLEWAKEUP](#) to 0x1. The enable wake-up feature works only when smart-idle wakeup is enabled.

24.12.4.2.3 Local Power Management

The high-speed USB OTG controller has local power management by internal clock gating features:

- Internal interface clock autogating: Clock for the L3 interconnect logic can be gated when the module is not accessed, if the [OTG_SYSCONFIG\[0\] AUTOIDLE](#) bit is set. Otherwise, this logic is free-running on the interface clock. This bit is used to save power when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

24.12.4.3 Inventra MUSBMHDC

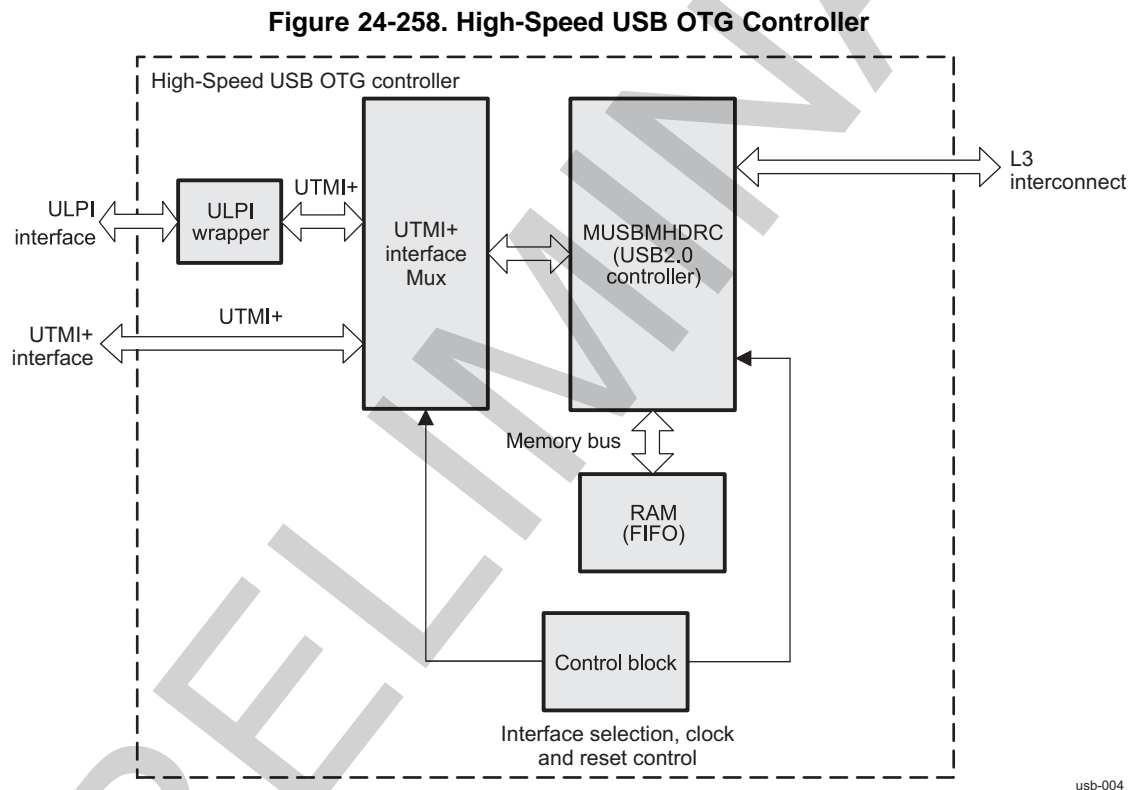

The core functionality of the module is provided by a third-party IP, the Inventra™ MUSBMHDC from Mentor Graphics® Corporation.

The high-speed USB OTG controller is basically the appropriate adaptation/integration of this IP to comply with TI requirements.

The high-speed USB OTG controller includes the following:

- MUSBMHDC (USB 2.0 controller)
- Master and slave bridges for conversion AHB to L3 interconnect and L3 interconnect to AHB
- Built-in self-test (BIST) controller
- Two memories (total of 16KB; available for various endpoints)
- Reset and clock generation
- DFT compliance with regards to latest specs

Figure 24-258 shows the high-speed USB controller.

24.12.4.4 Configuration

The following options are implemented in the TI high-speed USB OTG controller:

- 8-bit internal data path processing width (mandated by the use of ULPI)
- 32-bit vcontrol/vstatus support
- External charge pump: Hacked
- Software connect/disconnect supported
- Little-endian and big-endian byte ordering
- Eight DMA channels (with internal DMA initiator implemented)
- Dynamic FIFO sizing enabled
- 16-KB RAM buffer

- 15 IN/OUT endpoints in addition to control endpoint 0
- IN/OUT bulk packet splitting enabled
- High-bandwidth IN/OUT isochronous support enabled (see *Universal Serial Bus Specification Revision 2.0*)

24.12.4.5 Basic Operation

This section provides an overview of the module basic operation.

To implement the most time-critical functions in hardware, the module provides all of the encoding, decoding, and checking required to send and receive USB packets, interrupting the MPU only when endpoint data is successfully transferred. Generally, the following steps are performed.

24.12.4.5.1 Module Initialization

First, the firmware must do the overall initialization of the module by configuring the interrupts, DMA controller, and individual endpoints.

The specific items of a configuration for each endpoint are:

- Direction TX/RX
- Speed: High/full/low
- Special host settings when used in host mode (function address/hub parameters, etc.)
- Transaction protocol: Control/isochronous/bulk/interrupt
- Maximum packet size, that can be transferred through the endpoint
- Whether DMA is required (DMA enable)
- DMA mode
- Start address of the endpoint FIFO within the RAM block
- Maximum packet size allowed
- Whether double-buffering is required. This and the previous option define the amount of space that must be allocated to the FIFO. In the case of double-buffering, the FIFO size is doubled; therefore, the maximum supported size is 8196 bytes for the endpoint FIFOs.

NOTE: On the system level, it must be ensured that the reset and the interface are selected before the functional clock (OTG_60M_FCLK) is applied to the module. Correct functionality is not ensured if a reset deassertion or a change in the interface selection occurs when the functional clock OTG_60M_FCLK is already running.

24.12.4.5.2 Transaction Handling

Depending on whether the module is in the host or peripheral mode, an RX endpoint is assigned to IN or OUT transactions, respectively. Similarly, a TX endpoint is used for IN transactions in the peripheral mode and for OUT transactions in the host mode. When a transaction is complete, the appropriate endpoint interrupt is generated (if enabled).

When a transaction is handled through an RX endpoint, the received packet is placed in the RX FIFO, and the appropriate RX endpoint interrupt is generated. The packet can then be unloaded from the FIFO either manually (that is, by the MPU) or by the DMA. Although an RX endpoint is always active for a peripheral, in host mode the transaction must first be initiated by setting the appropriate request flag (REQPKT). This indicates to the transaction scheduler that there is an active transaction on this endpoint, which requires an IN token to be sent to the target function.

When a transaction is handled through a TX endpoint, the packet to send is loaded into the TX FIFO either manually (that is, by the MPU) or by the DMA. The transaction then must be initiated by setting the appropriate ready flag (TXPKTRDY) to indicate the availability of the new packet. When the packet is successfully sent (scheduled according to the protocol rules), the appropriate TX interrupt is generated.

24.12.4.6 Optional Features

This section gives a quick overview of the optional features that are available, depending on the endpoint configuration.

24.12.4.6.1 Double Packet Buffering

When double packet buffering is enabled (by setting the MSB of the FIFOSZ register two data packets can be stored in the FIFO. This option can be set for both the TX and RX endpoints in both the peripheral and host mode. For a TX endpoint, double-buffering means that up to two packets can be loaded into the FIFO awaiting transmission; for an RX endpoint, one packet can be received while another is being read. Double packet buffering is especially advisable for isochronous transactions to avoid underrun or overrun errors.

The high-speed USB controller provides dynamic FIFO sizing with an overall RAM size of 16KB, which can then be allocated to the different endpoints when the module is initialized. The maximum size of an endpoint FIFO is 4096 bytes for single packet buffering and 8192 bytes for double packet buffering. The firmware must ensure that a block of RAM is properly assigned to all TX and RX endpoints, considering the total RAM size and the maximum packet size set for the endpoint.

24.12.4.6.2 USBOTGHS Support for Big Endian

In the example in [Figure 24-259](#), the high-speed USB OTG controller module is configured as a USB device and is connected to a standard USB host. The two interconnect interfaces of the high-speed USB OTG controller connect it to the system bus. The register read/write is performed through the interconnect slave interface (control path). The data transfer to/from system memory takes place through the interconnect master interface (data path).

The data transfer on USB is always in little-endian mode, but on interconnect it can be in little- or big-endian mode, as shown in [Figure 24-259](#).

Figure 24-259. High-Speed USB OTG Controller Endianness

Big-endian support in the high-speed USB OTG controller may or may not require byte-swapping in the data path. Byte-swapping is performed based on the unit size of data. For example, if multiple bytes are packed into a single 32-bit word, these bytes must be swapped in a big-endian interconnect. On the other hand, if the data is simply a 32-bit word (for example, a 32-bit descriptor pointer in a memory buffer), the bytes in the word must not be swapped in big-endian mode.

In the high-speed USB OTG controller, the unit size of descriptors/descriptor pointers is 32 bits, and the unit size of USB data is 8 bits. Four 8-bit USB data are packed to form a 32-bit word. This 32-bit data requires byte-swapping, whereas the descriptors/descriptor pointers do not require byte-swapping.

NOTE: Byte-swapping is not required in the control path (slave interface).

The interconnect master interface (a submodule within the interconnect wrapper) supports big-endian conversion by setting the [OTG_BIGENDIAN\[0\]](#) BIG_ENDIAN bit to 0x1.

For interconnect write transactions, the data word is swapped, as shown in [Table 24-1169](#), before its output on the interconnect master interface. In case of an interconnect read transaction, the received data is swapped before its output on the AHB master interface of the MUSBMHDRC core. The interconnect MByteEn is swapped before the command is issued on the interconnect master interface. The interconnect MAddr is always aligned to the size of the interconnect data (32 bits). Hence, the interconnect MAddr is always word-aligned.

Table 24-1169. Interconnect Data and MByteEn in Little- and Big-Endian Modes

| Unit Size of Data | AHB Size (of Packed/Nonpacked Data) | AHB Start Address Offset (Always in Little-Endian Mode) | Interconnect MByteEn in Little-Endian Mode | Interconnect MByteEn in Big-Endian Mode | Interconnect Data in Little-Endian Mode | Interconnect Data in Big-Endian Mode |
|-------------------|-------------------------------------|---|--|---|---|--------------------------------------|
| Byte | Byte | 0 | 0001 | 1000 | xxxb0 | b0xxx |
| Byte | Byte | 1 | 0010 | 0100 | xxb0x | xb0xx |
| Byte | Byte | 2 | 0100 | 0010 | xb0xx | xxb0x |
| Byte | Byte | 3 | 1000 | 0001 | b0xxx | xxxb0 |
| Byte | Half-word | 0 | 0011 | 1100 | xxb1b0 | b0b1xx |
| Byte | Half-word | 2 | 1100 | 0011 | b1b0xx | xxb0b1 |
| Byte | Word | 0 | 1111 | 1111 | b3b2b1b0 | b0b1b2b3 |
| Half-word | Half-word ⁽¹⁾ | 0 | 0011 | 1100 | xxb1b0 | b1b0xx |
| Half-word | Half-word ⁽¹⁾ | 2 | 1100 | 0011 | b1b0xx | xxb1b0 |
| Half-word | Word ⁽¹⁾ | 0 | 1111 | 1111 | b3b2b1b0 | b1b0b3b2 |
| Word | Word ⁽²⁾ | 0 | 1111 | 1111 | b3b2b1b0 | b3b2b1b0 |

⁽¹⁾ Not a likely scenario for high-speed USB OTG controller

⁽²⁾ Corresponds to descriptor and descriptor pointer. No bytes are packed to form a word; hence, no byte-swapping is done in this case.

24.12.4.6.3 DMA

The high-speed USB controller has an internal DMA controller for efficient loading/unloading of the endpoint FIFOs. The DMA controller is configured for 8 channels and it has its own block of control registers and its own interrupt controller.

If the DMA is enabled for a TX endpoint, a DMA transfer occurs whenever the endpoint can accept another packet in its FIFO (that is, the DMA controller loads the packets into the FIFO without processor intervention).

If the DMA is enabled for an RX endpoint, a DMA transfer occurs whenever the endpoint has a packet in its FIFO (that is, the DMA CONTROLLER unloads the packets from the FIFO without processor intervention).

The high-speed USB controller supports two DMA request modes, which also affects the generation of endpoint interrupts.

- DMA request mode 0 is especially advisable for isochronous transfers but can also be used for bulk and interrupt transfers.
- DMA request mode 1 is mainly valuable for bulk transfers, where typically a large block of data is split into a series of packets of the maximum size.

24.12.4.6.3.1 DMA Request Mode 0

For RX endpoints, the DMA transfer is initiated when a data packet is available in the endpoint FIFO. The appropriate endpoint interrupt is also generated after the packets are received.

For TX endpoints, the DMA transfer is initiated when the endpoint FIFO can accept a data packet. The appropriate endpoint interrupt is also generated to prompt the loading of the packets.

24.12.4.6.3.2 DMA Request Mode 1

For RX endpoints the DMA transfer is initiated only when the received packet is the maximum packet size (as set in the RXMAXP register for the corresponding endpoint). The appropriate endpoint interrupt is generated only when the received packet is a short packet (that is, one less than the maximum packet size); otherwise, it is suppressed.

For TX endpoints, the DMA transfer is initiated when the endpoint FIFO can accept a data packet. The appropriate endpoint interrupt is suppressed.

24.12.4.6.3.3 Internal DMA Controller

The high-speed USB controller has an internal DMA controller to perform DMA transfers acting as host on the L3 interconnect. The DMA controller has eight channels, which can be independently programmed based on the following configuration options:

- DMA enable
- Direction (DMA write/DMA read)
- DMA mode (transfer one or more packets)
- Interrupt enable
- Endpoint number
- L3 interconnect memory address (32 bits)
- Byte count

The DMA controller can issue single accesses (8-bit, 16-bit, or 32-bit) and also bursts (4 × 32-bit, 8 × 32-bit, or 16 × 32-bit) on the L3 interconnect. The start address provided to the DMA controller must be 32-bit aligned.

24.12.4.7 Automatic Packet Splitting/Combining for Bulk Transfers

The high-speed USB controller offers the facility for bulk endpoints to store larger amounts of data in their FIFOs than can be transferred in a single USB operation. In other words, the module includes a configuration option that, if selected, allows larger data packets to be written to bulk TX endpoints, which are then split into packets of an appropriate size for transfer across the USB. A similar option exists for bulk RX endpoints, which, if selected, causes the module to combine the packet received across the USB into larger data packets before being read by the application software.

The firmware can enable these options by setting the corresponding bits (MPRXE and MPTXE) in the CONFIGDATA register. The necessary packet size information contains the payload size for one transaction and a multiplier defining the maximum number of USB packets. The payload is required to be either 8, 16, 32, 64, or (in case of high-speed transfers) 512 bytes; the multiplier can be any value up to 32.

24.12.4.8 High-Bandwidth Isochronous Endpoints

In the high-speed mode, isochronous endpoints can transfer up to three USB packets in any microframe with a payload of up to 1024 bytes in each packet, corresponding to a data transfer rate of up to 3072 bytes per microframe (see *Universal Serial Bus Specification Revision 2.0*).

For TX endpoints, the high-speed USB controller supports this by allowing loading data packets of up to 3072 bytes (that is, 3 × 1024 bytes) into the associated endpoint FIFO, which is then automatically split into USB packets of the maximum payload, or smaller to be transmitted in one microframe.

For RX endpoints, the module automatically combines all the USB packets received during a microframe into a single packet of up to 3072 bytes (that is, 3 × 1024 bytes) within the RX FIFO.

The number of USB packets transferred per microframe and the maximum payload in each packet is defined through the appropriate registers (RXMAXP and TXMAXP).

24.12.4.9 Carkit Implementation

Carkit feature implementation:

UART3 RX/TX muxing on the usba0_ulpihy_dat0 and usba0_ulpihy_dat1. To support carkit interrupt through USB0HS.DATA3, three different methods can be used:

- External PHY interrupt if provided: IRQ_SYS interrupt
- UART3 interrupt: CTS edge detection
- GPIO interrupt: Edge detection on GPIO associated to usba0_ulpihy_dat3 line

24.12.4.10 USB PHY

The device-embedded USB PHY is composed of the following modules:

- USB2PHYCORE: Contains the USB functions, drivers, receivers, and pads for correct D+/D- signaling, and the battery charger detection (supporting dead-battery mode). Delivers a 3.3-V output signal (charger enable [pin usba0_otg_ce]) to control an external battery charger.
- USB2PHYCM: Contains LDO and bandgap to provide voltage reference to the USB2PHYCORE module

The embedded PHY does not support the OTG features of USB-OTG standards (that is, ID pin detection and VBUS detection). This function is exported to an external companion chip (for example, the TWL6030). Software must retrieve the OTG HNP and SRP status from the TWL6030 (using the I2C1 interface) and configure the bits inside the control module that drive the related USBOTGHS UTMI+ interface signals. It must also read back the UTMI+ signals needed to configure the TWL6030 OTG module.

These signals are:

- Inputs of the USB controller driven by the control module:
 - Avalid: Indicates whether VBUS is above the A-Device session valid threshold
 - Bvalid (currently not used)
 - Vbusvalid: Indicates whether VBUS is above the threshold for normal operation
 - Sessend: Indicates whether VBUS is below the B-Device session end threshold
 - Iddig: Indicates the value of the ID pin of the USB connector
- Outputs of the USB controller readable in the control module:
 - Idpullup: Enables sampling of the ID pin of the USB connector
 - Drv vbus: Controls the driving of 5-V power on VBUS
 - Chrg vbus: Controls the charging of VBUS for initiating SRP
 - Dischrg vbus: Controls the discharging of VBUS for completing SRP

See the CONTROL_USBOTGHS_CONTROL register in [Chapter 19, Control Module](#), and the TWL6030 documentation.

The following UTMI signals are not connected:

- Txbitstufferable (no bit-stuffing out from the USB controller)
- Txbitstufferableh (because only 8 bits are used)

The following USBPHY signals are routed internally to the GPIO6 module pins to generate interrupts when any of the following events occur:

- CHGDETECTED: This signal indicates the output of the charger detection protocol.
 - 0: Charger not detected
 - 1: Charger detected

The value is latched until the charger protocol is reset.

- DPDM5VSHORT: This signal is asserted high if a short-circuit-to-VBUS condition is detected on the USB DP or DM pins. This signal is valid only if all power supplies are present. The short is detected if any or even none of the supplies are present.
 - 0: No short

1: VBUS short on DP or DM detected

For information about how to enable these interrupts, see [Chapter 26, General-Purpose Interface](#).

The USBPHY internal registers are listed in [Section 24.12.6.3, USBPHY Registers](#), for debug purposes.

CAUTION

For a correct read out of the USBPHY registers, the value of the [OCP2SCP_TIMING\[3:0\]](#) SYNC2 bit field must be set to 0x6 or more, and the [OCP2SCP_TIMING\[9:7\]](#) DIVISIONRATIO bit field must be left untouched.

24.12.5 High-Speed USB OTG Controller Basic Programming Model

This section describes the low-level hardware programming sequences for configuration and use of the high-speed USB OTG controller.

24.12.5.1 Global Initialization

24.12.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the high-speed USB OTG controller is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the high-speed USB OTG controller.

Table 24-1170. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|--|--|
| PRCM | All required clocks must be enabled, see Table 24-1165 . Do not apply OTG_60M_FCLK clock before the interface is selected. Refer to Section 3.6.3.2, CM Clock Source , in Chapter 3, Power, Reset, and Clock Management . |
| Cortex-A9 MPU INTC or Cortex-M3 MPU INTC | Cortex-A9 MPU or Cortex-M3 MPU interrupt controller must be configured to enable the interrupt request generation to the Cortex-A9 MPU or Cortex-M3 MPU subsystem when interrupt requests are generated by the High-Speed Multiport USB Host Subsystem. See the respective Functional Description in the Interrupt Controller chapter for the MPUs. |
| Interconnect (L3 and L4) | See Section 14.2, L3 Interconnect , and Section 14.3, L4 Interconnect , for more information. |

24.12.5.1.2 High-Speed USB OTG Controller Global Initialization

This procedure initializes the high-speed multiport USB host subsystem after a power-on or software reset. The module USBPHY is reset through boundary reset signal L3_INIT_RST coming from PRCM module.

Table 24-1171. High-Speed USB OTG Software Reset

| Step | Register/Bit Field/Programming Model | Value |
|--|--|-------|
| Perform a software reset on the USB OTG controller | OTG_SYSCONFIG[1] SOFTRESET | 0x1 |
| Wait until reset is finished | OTG_SYSSTATUS[0] RESETDONE | =0x1 |

Table 24-1172. Power Management Configuration

| Step | Register/Bit Field/Programming Model | Value |
|--------------------------------------|--|-------|
| Select master interface standby mode | OTG_SYSCONFIG[13:12] MIDLEMODE | 0x- |
| Select slave interface idle mode | OTG_SYSCONFIG[4:3] SIDLEMODE | 0x- |

Table 24-1172. Power Management Configuration (continued)

| Step | Register/Bit Field/Programming Model | Value |
|----------------------|--------------------------------------|-------|
| Set clock autogating | OTG_SYSCONFIG[0] AUTOIDLE | 0x- |

24.12.5.2 High-Speed USB OTG Controller Interface Modes

This procedure describes TI high-speed USB controller interface selection:

Table 24-1173. High-Speed USB Controller Interface Selection

| Step | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|-------|
| Select between embedded and external PHY interface | OTG_INTERFSEL[2:0] PHYSEL | 0x- |
| Enable functional PHY clock (OTG_60M_FCLK) | Refer to | - |

24.12.5.3 High-Speed USB OTG Controller Power Management Configuration

This section describes the settings for optimal high-speed USB controller power management, depending on the use of this module in the application.

24.12.5.3.1 No Application Mode

The optimal configuration when the high-speed USB controller is not used by the application is as follows:

Table 24-1174. Power Management Configuration - No Application Mode

| Step | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|-------|
| Switch master interface to force standby mode | OTG_SYSCONFIG[13:12] MIDDLEMODE | 0x0 |
| Switch slave interface to force-idle mode | OTG_SYSCONFIG[4:3] SIDLEMODE | 0x0 |
| Set the clock to smart mode - clock is cut-off if no activity on the interface | OTG_SYSCONFIG[0] AUTOIDLE | 0x1 |

24.12.5.3.2 Host or Peripheral Mode

When used as a host or in peripheral mode, the high-speed USB controller must be programmed as follows:

Table 24-1175. Power Management Configuration - Host or Peripheral Mode

| Step | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|-------|
| Switch Master interface to smart standby mode | OTG_SYSCONFIG[13:12] MIDDLEMODE | 0x2 |
| Switch Slave interface to smart-idle mode | OTG_SYSCONFIG[4:3] SIDLEMODE | 0x2 |
| Set the clock to smart mode - clock is cut-off if no activity on the interface | OTG_SYSCONFIG[0] AUTOIDLE | 0x1 |

24.12.5.3.3 Switching Between Host and Peripheral Mode

When used as a host/peripheral, the high-speed USB OTG controller must be programmed as follows:

Table 24-1176. Power Management Configuration - Switching Between Host and Peripheral Mode

| Step | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|-------|
| Switch Master interface to force standby mode | OTG_SYSCONFIG[13:12] MIDDLEMODE | 0x0 |
| Switch Slave interface to smart-idle mode | OTG_SYSCONFIG[4:3] SIDLEMODE | 0x2 |
| Set the clock to smart mode - clock is cut-off if no activity on the interface | OTG_SYSCONFIG[0] AUTOIDLE | 0x1 |

24.12.6 High-Speed USB OTG Controller Register Manual

This section presents only the TI-specific registers of the high-speed USB controller.

Table 24-1177 lists the base address and address space for the high-speed USB controller.

Table 24-1177. High-Speed USB OTG Controller Instance Summary

| Module Name | Base Address | Size |
|-------------|--------------|------------|
| HSUSBOTG | 0x4A0A B000 | 4KB |

PRELIMINARY

MMC/SD/SDIO

This chapter describes the features and functions of the multimedia card/SD card (MMC/SD/SDIO) interface of the device.

| Topic | Page |
|---|------|
| 25.1 MMC/SD/SDIO Overview | 5256 |
| 25.2 MMC/SD/SDIO Environment | 5263 |
| 25.3 MMC/SD/SDIO Integration | 5271 |
| 25.4 MMC/SD/SDIO Functional Description | 5274 |
| 25.5 MMC/SD/SDIO Programming Guide | 5303 |
| 25.6 MMC/SD/SDIO Register Manual | 5329 |

25.1 MMC/SD/SDIO Overview

The multimedia card high-speed/SD/SDIO (MMC/SD/SDIO) host controller provides an interface between a local host (LH) such as a microprocessor unit (MPU) or digital signal processor (DSP) and either MMC, SD memory cards, or SDIO cards and handles MMC/SD/SDIO transactions with minimal LH intervention.

Optionally, the controller is connected to the level 3 (L3) interconnect to have a direct access to system memory. It also supports two direct memory access (DMA) slave channels or a DMA master access (in this case, slave DMA channels are deactivated) depending on its integration. These controllers are embedded MMC/SD (eMMC/SD) controllers.

The application interface manages transaction semantics. The MMC/SD/SDIO host controller deals with MMC/SD/SDIO protocol at transmission level, data packing, adding cyclic redundancy checks (CRCs), start/end bit, and checking for syntactical correctness.

The application interface can send every MMC/SD/SDIO command and poll for the status of the adapter or wait for an interrupt request, which is sent back in case of exceptions or to warn of end of operation.

The application interface can read card responses or flag registers. It can also mask individual interrupt sources. All these operations can be performed by reading and writing control registers. The MMC/SD/SDIO host controller also supports two DMA channels.

There are five MMC/SD/SDIO host controllers inside the device:

[Figure 25-1](#) gives an overview of the MMC/SD/SDIO1 controller instance (eMMC/SD).

[Figure 25-2](#) gives an overview of the MMC/SD/SDIO2 controller instance (eMMC/SD).

[Figure 25-3](#) gives an overview of the MMC/SD/SDIO3 through MMC/SD/SDIO5 controller instances.

Figure 25-1. MMC/SD/SDIO1 Overview (where i = 1)

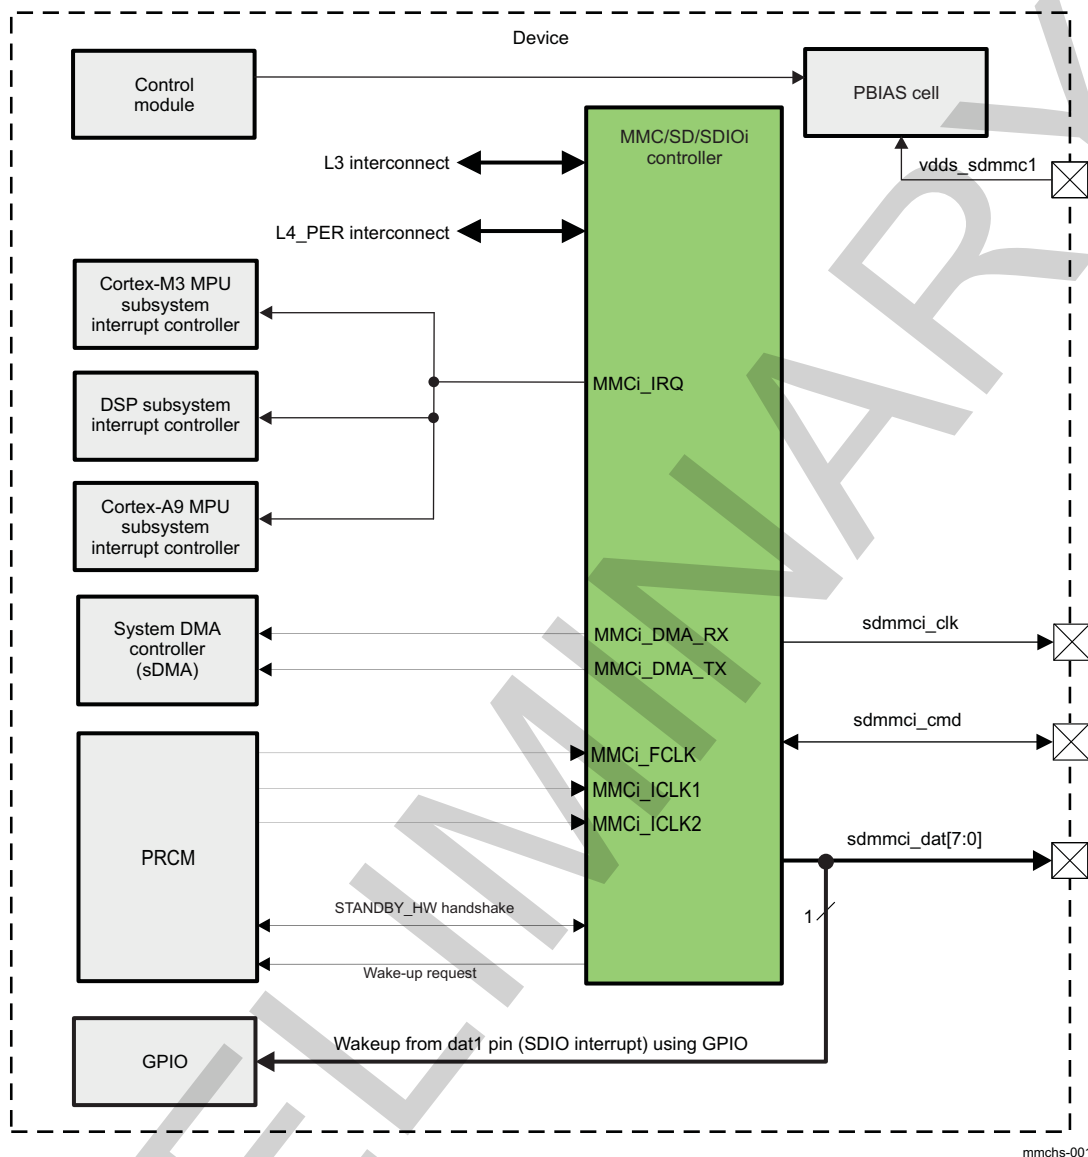

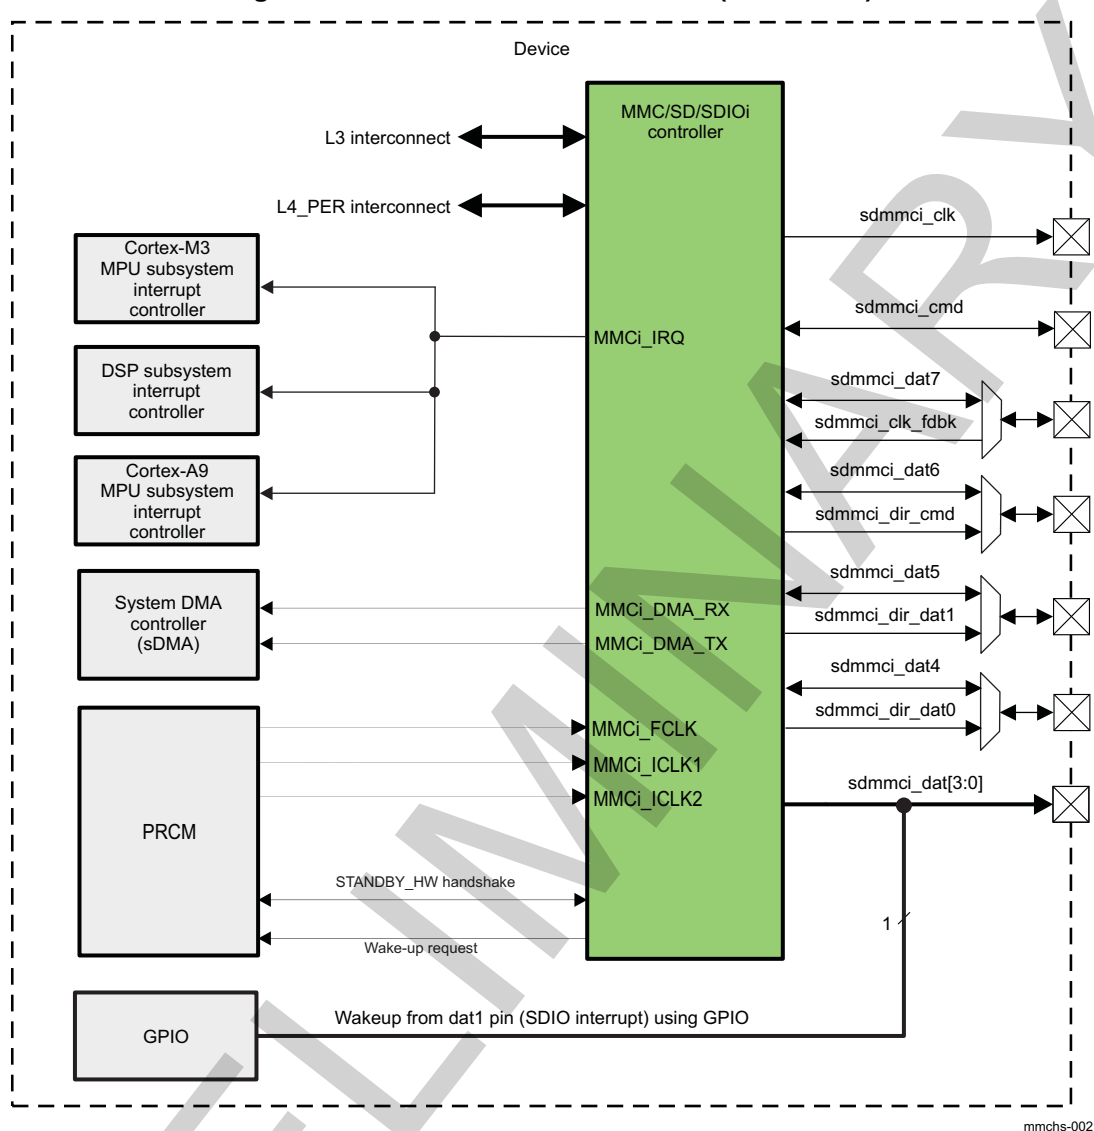

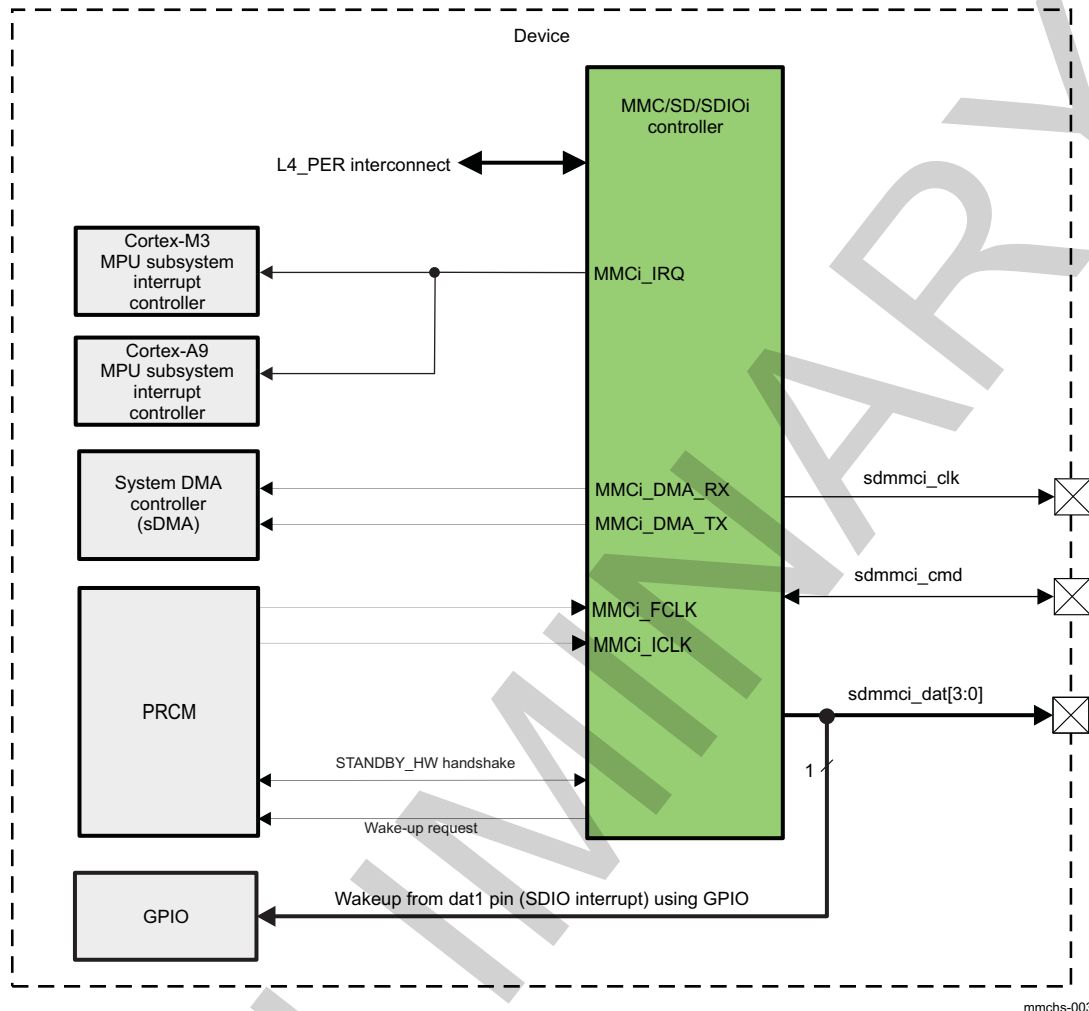

Figure 25-2. MMC/SD/SDIO2 Overview (where i = 2)

Figure 25-3. MMC/SD/SDIO3 Through MMC/SD/SDIO5 Overview (where i = 3, 4, or 5)

25.1.1 MMC/SD/SDIO Features

This section describes the features supplied by the MMC/SD/SDIO module.

Compliance with standards:

- Full compliance with MMC/eMMC command/response sets as defined in the *JC64 MMC/eMMC Standard Specification v4.41*, including high-capacity (size 2GB) cards HC MMC
- Full compliance with SD command/response sets as defined in the *SD Specifications Part 1 Physical Layer Simplified Specification*, v3.01, including high-capacity SDXC cards up to 2TB
- Full compliance with SDIO command/response sets and interrupt/read-wait suspend-resume operations, as defined in the *SDIO Card Specification, Part E1*, v2.00
- Full compliance with sets as defined in the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v2.00
- Full compliance with MMC bus testing procedure as defined in the *Multimedia Card System Specification*, v4.41
- Full compliance with CE-ATA command/response sets as defined in the *CE-ATA Standard Specification*
- Full compliance with ATA for MMCA specification
- Support command completion signal (CCS) and command completion signal disable (CCSD) management as specified in the *CE-ATA Standard Specification*

Main features of the MMC/SD/SDIO host controller:

- Flexible architecture allowing support for new command structure
- Support:
 - 1- or 4-bit transfer mode specifications for SD and SDIO cards
 - 1-, 4-, or 8-bit transfer mode specifications for MMC cards
- Built-in buffer for read or write (up to 2048 bytes in single-buffering, 1024 bytes in double-buffering)
- 32-bit-wide access bus to maximize bus throughput
- Single interrupt line for interrupt source events
- Two slave DMA channels (one for TX, one for RX)
- Designed for low power
- Programmable clock generation
- Support SDIO read wait and suspend/resume functions
- Support stop at block gap
- Support boot mode operations as specified in the *JEDEC JC 64 MMC/eMMC Standard Specification, v4.41*
- Support dual data rate transfers (DDR mode) as specified in *JEDEC JC64 MMC/eMMC Standard Specification, v4.41*
- Support SDA 2.0 Part A2 programming model

Optional features (depending on module integration):

- Master interface (L3 interconnect)
- One master DMA (32-bit ADMA2), replacing the two slave DMA channels
- Retention mode is supported
- Support SDA 2.0 Part A2 DMA feature (ADMA2)

Supported data rates:

- In MMC mode:
 - Up to 768 Mbps (96 MB/s), 8-bit DDR data transfer, with a clock running at 48 MHz
 - Up to 384 Mbps (48 MB/s), 8-bit SDR data transfer, with a clock running at 48 MHz
- In SD mode:
 - Up to 384 Mbps (48 MB/s), 4-bit DDR data transfer with a clock running at 48 MHz
 - Up to 384 Mbps (48 MB/s), 4-bit SDR data transfer with a clock running at 96 MHz
- In SDIO mode:
 - Up to 192 Mbps (24 MB/s) in high-speed mode, 4-bit data transfer with a clock running at 48 MHz
 - Up to 24 Mbps (3 MB/s) in default speed mode, 1-bit data transfer with a clock running at 24 MHz

Supported clock frequencies:

- MMC mode:
 - Up to 48 MHz in DDR and SDR modes
- SD mode:
 - Up to 48 MHz in DDR mode
 - Up to 96 MHz in SDR mode
- SDIO mode:
 - Up to 48 MHz in SDR mode

Known limitations:

- No built-in hardware support for error correction codes (ECCs). For information about ECC, see the *Multimedia Card System Specification, v4.4*, and the *SD Memory Card Specifications, v3.0*.

- The maximum block size defined in the *SD Memory Card Specifications*, v3.0, which the host driver can read and write to the buffer in the host controller, is 2048 bytes. The host controller supports a maximum block size of 1024 bytes. Up to 512 byte transfers, the buffer in the host controller is considered as a double-buffering with ping-pong management; half of the buffer can be written while the other half is read. For 512 to 1024 byte transfers, the entire buffer is dedicated to the transfer (read only or write only).
- SPI transfers are not supported.
- The module does not support card insertion and removal sensing with pullup resistor on the sdmmc_i_dat3 bus line, as specified in the *SD Memory Card Specifications – Part 1 Physical Layer Specification* (SD Group, May 2006).

The differences between the MMC/SD/SDIO host controllers and a standard SD host controller defined by the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v2.00 are:

- The MMC/SD/SDIO host controllers support MMC cards.
- The clock divider in the MMC/SD/SDIO host controller supports a wider range of frequency than specified in the *SD Memory Card Specifications*, v2.0. The MMC/SD/SDIO host controller supports odd and even clock ratio.
- The MMC/SD/SDIO host controller supports configurable busy time-out.
- sDMA and ADMA2 64-bit modes are not supported.
- There is no external LED control.

NOTE: Only even ratios are supported in DDR mode.

Table 25-1 lists the features supported in the 4.41 standard.

Table 25-1. Standard 4.41 Supported Features

| Feature | Support | Limitation | Comment |
|-----------------------------------|--|---|--|
| Bus width | 1-bit mode | | x 1, 4, 8 bits |
| | 4-bit mode | | |
| | 8-bit mode | | |
| Support density | No hardware limitation for density support | Limitation can come from file system (32GB) | |
| Simple boot (CMD, alternate boot) | No | | ROM code supports the following boot mode: In raw mode the booting image can be at one of the four consecutive locations in the main area: offset 0x0 0x20000 (128KB) 0x40000 (256KB) 0x60000 (384KB) (That is, it supports four boot partitions.) |
| Sleep mode | Yes | | |
| Reliable write | Yes | | |
| Secure write protection | Yes | | |
| Hardware reset | No | | Use the reset command instead of GPIO if hardware reset is needed. |
| Secure memory block (RPMB) | Yes | | |
| Partition feature | Yes | | |
| Secure erase | Yes | | |
| 1.2 V | Yes | | |

Table 25-1. Standard 4.41 Supported Features (continued)

| Feature | Support | Limitation | Comment |
|--|----------------------------------|------------|---------|
| DDR Interface (bandwidth) | Up to 96MBps in DDR mode – 8-bit | | |
| High-priority interrupt (read while write) | Yes | | |
| Background operation | Yes | | |
| Enhanced reliable write | Yes | | |

25.2 MMC/SD/SDIO Environment

One MMC/SD/SDIO host controller can support one MMC memory card, one SD memory card, or one SDIO card.

Other combinations (for example, two SD cards, one MMC card, and one SD card) are not supported through a single controller.

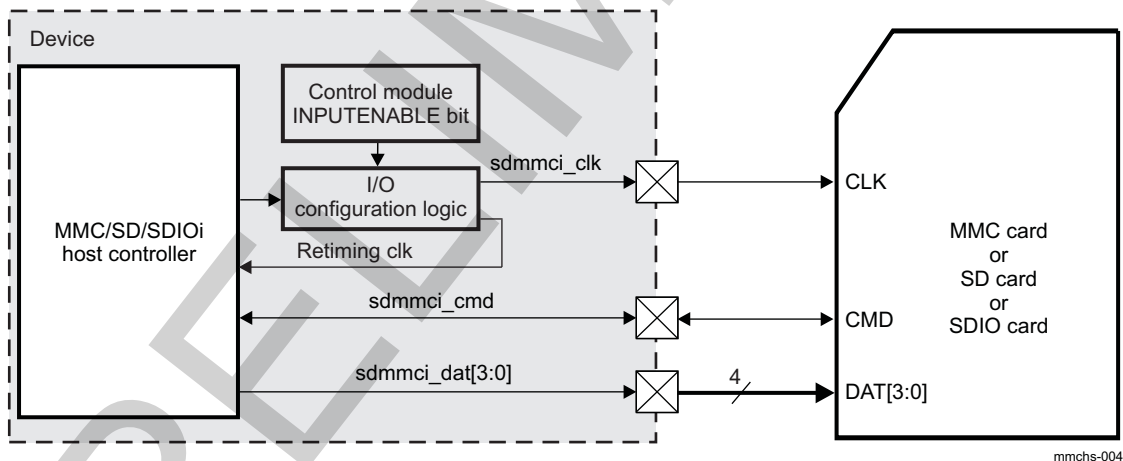

- The MMC/SD/SDIO1 controller integrates an internal transceiver that allows a direct connection to the MMC/SD/SDIO card (1.8 V and 3 V), without external transceiver. It is connected to the level 3 (L3) interconnect (internal DMA enabled) and supports 1-, 4-, and 8-bit data transfers.
- The MMC/SD/SDIO2 controller allows connecting MMC/SD/SDIO cards (only 1.8V cards) or an external device that uses the MMC/SD/SDIO interface (JC64, for example). The module is connected to the L3 interconnect (internal DMA enabled) and supports 1-, 4-, and 8-bit data transfers. The second instance also supports an external transceiver and provides direction signals for data and command.
- The MMC/SD/SDIO3, MMC/SD/SDIO4, and MMC/SD/SDIO5 controllers allow connecting MMC/SD/SDIO cards (only 1.8V cards) or an external device that uses the MMC/SD/SDIO interface (wireless LAN, for example). The modules are connected to the L4 interconnect and support 1-and 4-bit data transfers.

25.2.1 MMC/SD/SDIO Functional Modes

25.2.1.1 MMC/SD/SDIO Connected to an MMC, an SD, or an SDIO Card

Figure 25-4 shows the MMC/SD/SDIO_i host controller (where *i* = 1 through 5) connected to an MMC, an SD, or an SDIO card and its related external connections.

Figure 25-4. MMC/SD/SDIO_i Controller Connected to an MMC, an SD, or an SDIO Card Without External Transceiver (where *i* = 1 through 5)

NOTE: MMC/SD/SDIO1 and MMC/SD/SDIO2 support data transfers on 8 bits (and thus handle data on signals sdmmc_i_dat[7:0]).

Table 25-2 describes the MMC/SD/SDIO_i inputs and outputs.

Table 25-2. MMC/SD/SDIO_i I/O Description Without External Transceiver (where *i* = 1 through 5)

| Signal Name | I/O ⁽¹⁾ | Description | Reset Value ⁽²⁾ |
|-------------|--------------------|--|----------------------------|
| sdmmc_i_clk | O | External clock for MMC/SD/SDIO card ⁽³⁾ | 0 |

⁽¹⁾ I = Input; O = Output; I/O = Bidirectional

⁽²⁾ hi-Z = High impedance

⁽³⁾ This output signal is also used as retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).

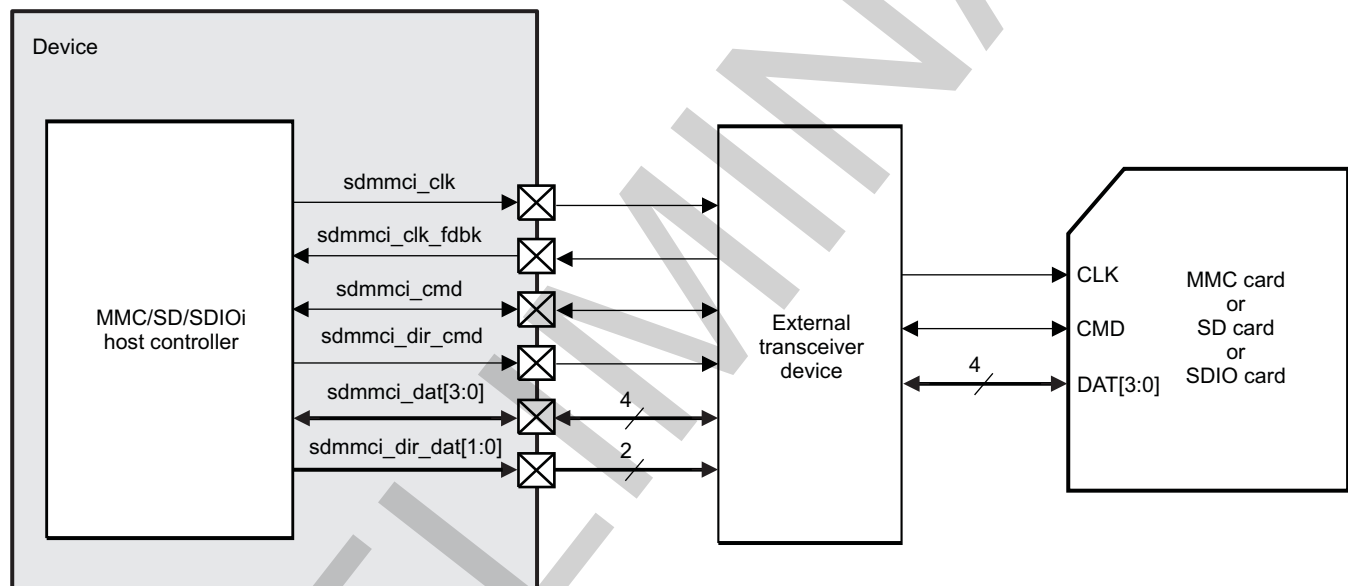

**Table 25-2. MMC/SD/SDIOi I/O Description Without External Transceiver (where i = 1 through 5)
(continued)**

| Signal Name | I/O ⁽¹⁾ | Description | Reset Value ⁽²⁾ |
|------------------|--------------------|---|----------------------------|
| sdmmc_i_cmd | I/O | Command signal | hi-Z ⁽⁴⁾ |
| sdmmc_i_dat[3:0] | I/O | Data signals | hi-Z ⁽⁴⁾ |
| sdmmc_i_dat[7:4] | I/O | Data signals (only for modules MMC/SD/SDIO1 and MMC/SD/SDIO2) | hi-Z ⁽⁴⁾ |

⁽⁴⁾ Initialized as input upon reset

25.2.1.2 MMC/SD/SDIO Connected to an MMC, an SD, or an SDIO Card Through an External Transceiver Device

Figure 25-5 shows the MMC/SD/SDIOi host controller (where i = 2) connected to an MMC, an SD, or an SDIO card and its related external connections.

Figure 25-5. MMC/SD/SDIOi Controller Connected to an MMC, an SD, or an SDIO Card With External Transceiver (where i = 2)

mmchs-005

Table 25-3 describes the MMC/SD/SDIOi inputs and outputs.

Table 25-3. MMC/SD/SDIOi I/O Description With External Transceiver (where i = 2)

| Signal Name | I/O ⁽¹⁾ | Description | Reset Value ⁽²⁾ |
|------------------|--------------------|--|----------------------------|
| sdmmc_i_clk | O | External clock for MMC/SD/SDIO card | 0 |
| sdmmc_i_clk_fdbk | I | Input clock from MMC/SD/SDIO card | 0 |
| sdmmc_i_cmd | I/O | Command signal | hi-Z ⁽³⁾ |
| sdmmc_i_dir_cmd | O | Direction control for mmc2_cmd signal when an external transceiver is used (high when transmit, low when receive) | 0 |
| sdmmc_i_dat[3:0] | I/O | Data signals | hi-Z ⁽³⁾ |
| sdmmc_i_dir_dat0 | O | Direction control for mmc2_dat0 signal when an external transceiver is used (high when transmit, low when receive) | 0 |

⁽¹⁾ I = Input; O = Output; I/O = Bidirectional

⁽²⁾ hi-Z = High impedance

⁽³⁾ Initialized as input upon reset

Table 25-3. MMC/SD/SDIOi I/O Description With External Transceiver (where i = 2) (continued)

| Signal Name | I/O ⁽¹⁾ | Description | Reset Value ⁽²⁾ |
|----------------|--------------------|--|----------------------------|
| sdmmc_dir_dat1 | O | Direction control for mmc2_dat1 signal when an external transceiver is used (high when transmit, low when receive) | 0 |

NOTE: There is no signal for individually controlling the sdmmc_dir_dat2 and sdmmc_dir_dat3 direction (sdmmc_dir_dat2 and sdmmc_dir_dat3 are not delivered). This may limit the use of this interface with the SDIO card requesting the wait feature on the sdmmc_dir_dat2 line.

25.2.2 Protocol and Data Format

The bus protocol between the MMC/SD/SDIOi host controller and the card is message-based. Each message is represented by one of the following parts:

Command: A command starts an operation. The command is transferred serially from the MMC/SD/SDIO host controller to the card on the sdmmc_cmd line.

Response: A response is an answer to a command. The response is sent from the card to the MMC/SD/SDIO host controller. It is transferred serially on the sdmmc_cmd line.

Data: Data are transferred from the MMC/SD/SDIOi host controller to the card or from a card to the MMC/SD/SDIO host controller using the data lines.

Busy: The sdmmc_dat0 signal is maintained low by the card as far as it is programming the data received.

CRC status: The CRC result is sent by the card through the sdmmc_dat0 line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on sdmmc_dat0. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on sdmmc_dat0 and starts the data programming procedure.

25.2.2.1 Protocol

There are two types of data transfer:

- Sequential operation
- Block-oriented operation

There are specific commands for each type of operation (sequential or block-oriented).

For information about commands and programming sequences supported by the MMC, SD, and SDIO cards, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification (Part E1)*.

[Figure 25-6](#) and [Figure 25-7](#) show how sequential operations are defined. Sequential operation is only for 1-bit transfer and initiates a continuous data stream. The transfer terminates when a stop command follows on the sdmmc_cmd line.

CAUTION

Stream commands are supported only by MMC cards.

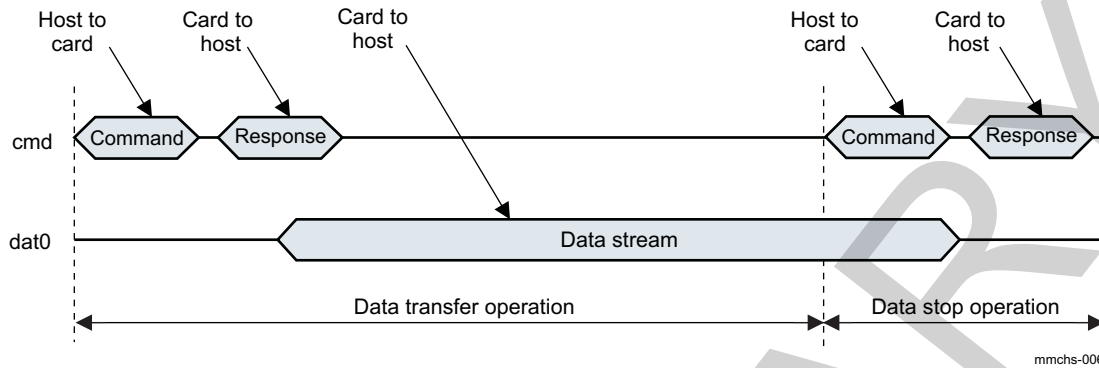

Figure 25-6. Sequential Read Operation (MMC Cards Only)**Figure 25-7. Sequential Write Operation (MMC Cards Only)**

Figure 25-8 and Figure 25-9 show how multiple block-oriented operations are defined. A multiple block-oriented operation sends a data block plus CRC bits. The transfer terminates when a stop command follows on the sdmmc_cmd line. These operations are available for all kinds of cards.

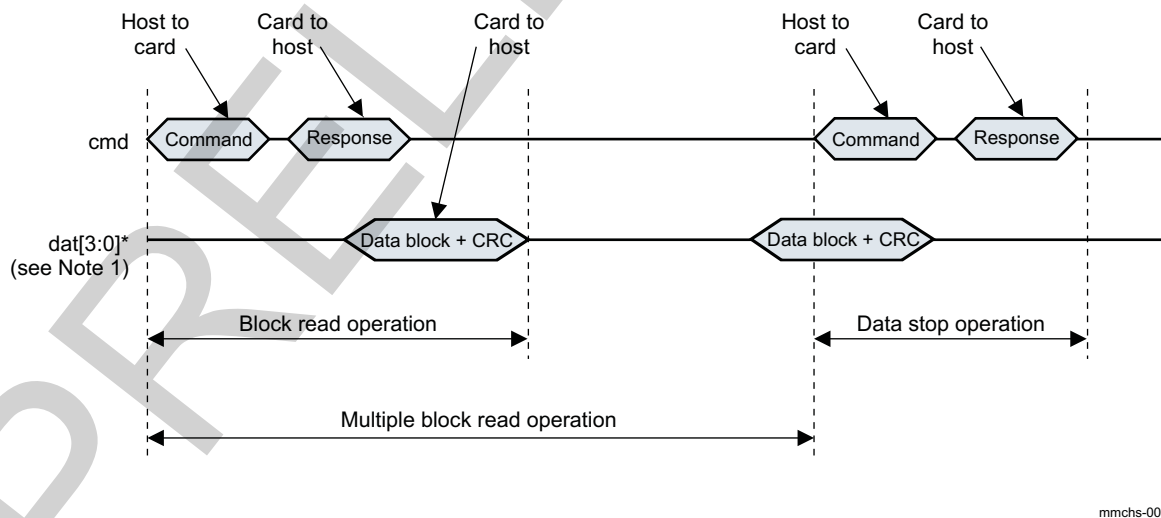

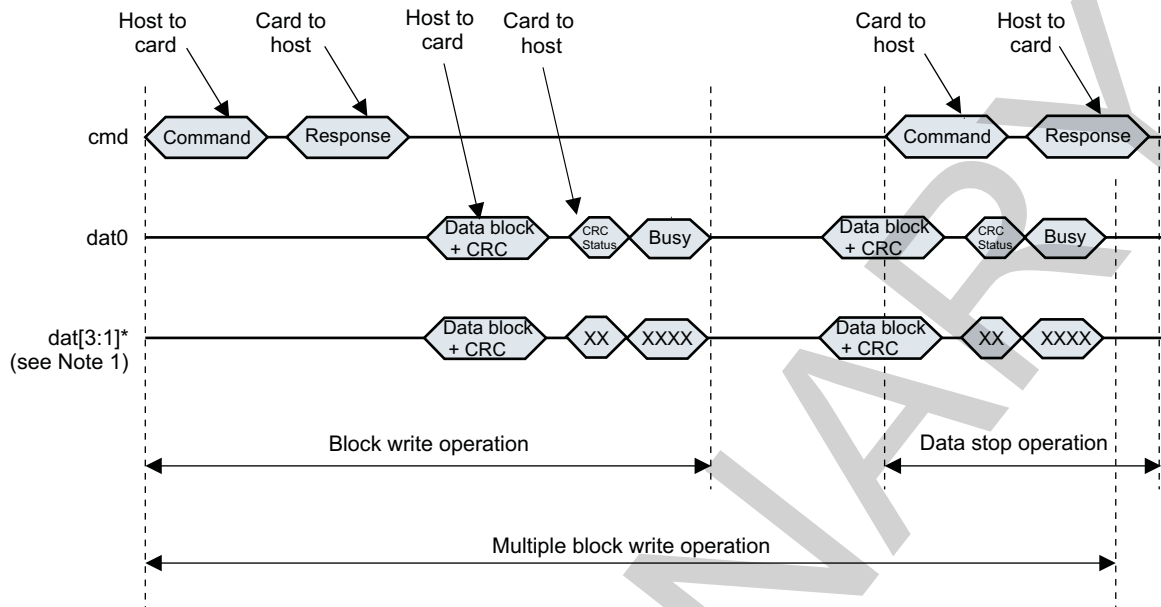

Figure 25-8. Multiple Block Read Operation

Figure 25-9. Multiple Block Write Operation With Card Busy Signal

mmchs-009

NOTE:

1. The card busy signal is not always generated by the card; the previous examples show a particular case.
2. Software must perform a software reset (set the MMCI.MMCHS_SYSCTL[26] SRD bit to 0x1) after a data time-out to ensure sdmmc_i_clk is stopped.
3. For multiblock transfer, and especially for MMC cards, a transfer can be aborted without using a stop command. If a CMD23 is used before data transfer to define the number of blocks that will be transferred, then the transfer stops automatically after the last block (if the MMC card supports this feature).

25.2.2.2 Data Format

Coding Scheme for Command Token

Command tokens always start with 0 and end with 1. The second bit is a transmitter bit: 1 for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see [Figure 25-10](#)).

Figure 25-10. Command Token Format

mmchs-010

Coding Scheme for Response Token

Response tokens always start with 0 and end with 1. The second bit is a transmitter bit: 0 for a card response. The content is different for each type of response (R1, R2, R3, R4, and R5, R6, R7 [for SDIO])

and the content is protected by 7-bit CRC checksum (see [Figure 25-11](#) and [Figure 25-12](#)). Depending on the type of commands sent to the card, the [MMCHS_CMD](#) register must be configured differently to avoid false CRC or index errors to be flagged on command response (see [Table 25-4](#)). For more information about response types, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification*.

Figure 25-11. Response Token Format (R1, R3, R4, R5, R6, R7)

Figure 25-12. Response Token Format (R2)

Table 25-4. Relationship Between Configuration and Name of Response Type

| Response Type MMCi.MMCHS_CMD[17:16] RSP_TYPE | Index Check Enable MMCi.MMCHS_CMD[20] CICE | CRC Check Enable MMCi.MMCHS_CMD[19] CCCE | Name of Response Type |
|--|--|--|-----------------------|
| 00 | 0 | 0 | No response |
| 01 | 0 | 1 | R2 |
| 10 | 0 | 0 | R3 (R4 for SD cards) |
| 10 | 1 | 1 | R1, R6, R5, R7 |
| 11 | 1 | 1 | R1b, R5b |

Coding Scheme for Data Token

Data tokens always start with 0 and end with 1 (see [Figure 25-13](#) through [Figure 25-15](#)).

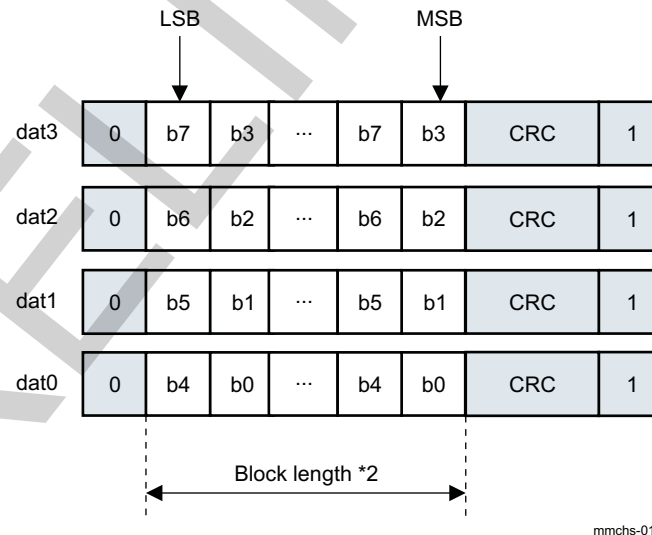

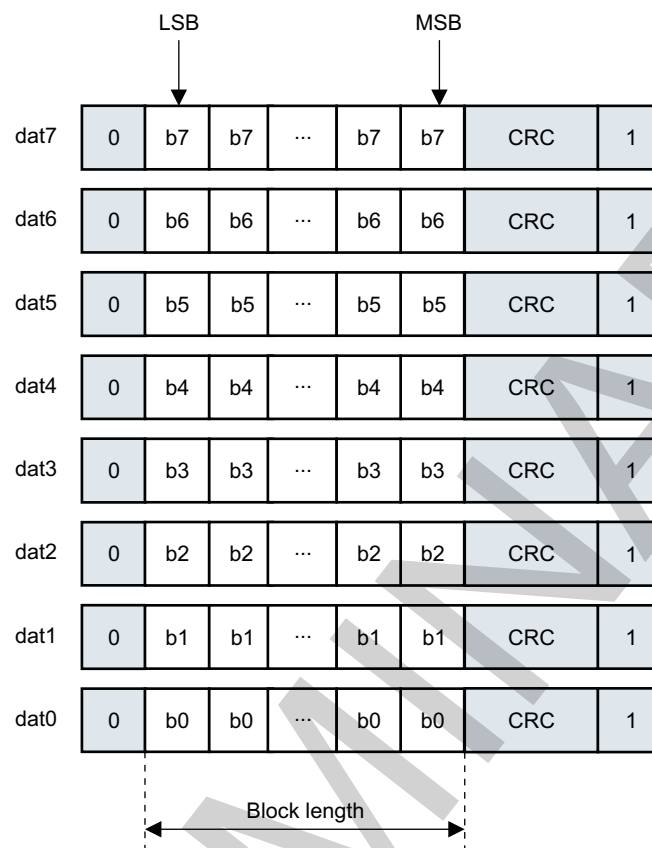

Figure 25-15. Data Token Format for 8-Bit Transfers

mmchs-015

25.3 MMC/SD/SDIO Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 25-16 shows the MMC/SD/SDIO integration.

Figure 25-16. MMC/SD/SDIO Controllers Integration

NOTE: For more information about the IDLE hardware handshake and the wake-up request, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 25-5 through Table 25-7 summarize the integration of the module in the device.

Table 25-5. Integration Attributes

| Module Instance | Attributes | |
|-----------------|--------------|--------------|
| | Power Domain | Interconnect |
| HSMMC1 | PD_L3_INIT | L3 L4_PER |
| HSMMC2 | PD_L3_INIT | L3 L4_PER |
| HSMMC3 | PD_L4_PER | L4_PER |
| HSMMC4 | PD_L4_PER | L4_PER |
| HSMMC5 | PD_L4_PER | L4_PER |

Table 25-6. Clocks and Resets

| Clocks | | | | |
|-----------------|-------------------------|--------------------|--------|----------------------|
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| HSMMC1 | MMC1_FCLK | MMC1_FCLK | PRCM | MMC1 function clock |
| | MMC1_ICLK2 | INIT_L4_ICLK | PRCM | MMC1 interface clock |
| | MMC1_ICLK1 | INIT_L3_ICLK | PRCM | MMC1 interface clock |
| HSMMC2 | MMC2_FCLK | MMC2_FCLK | PRCM | MMC2 function clock |

NOTE:

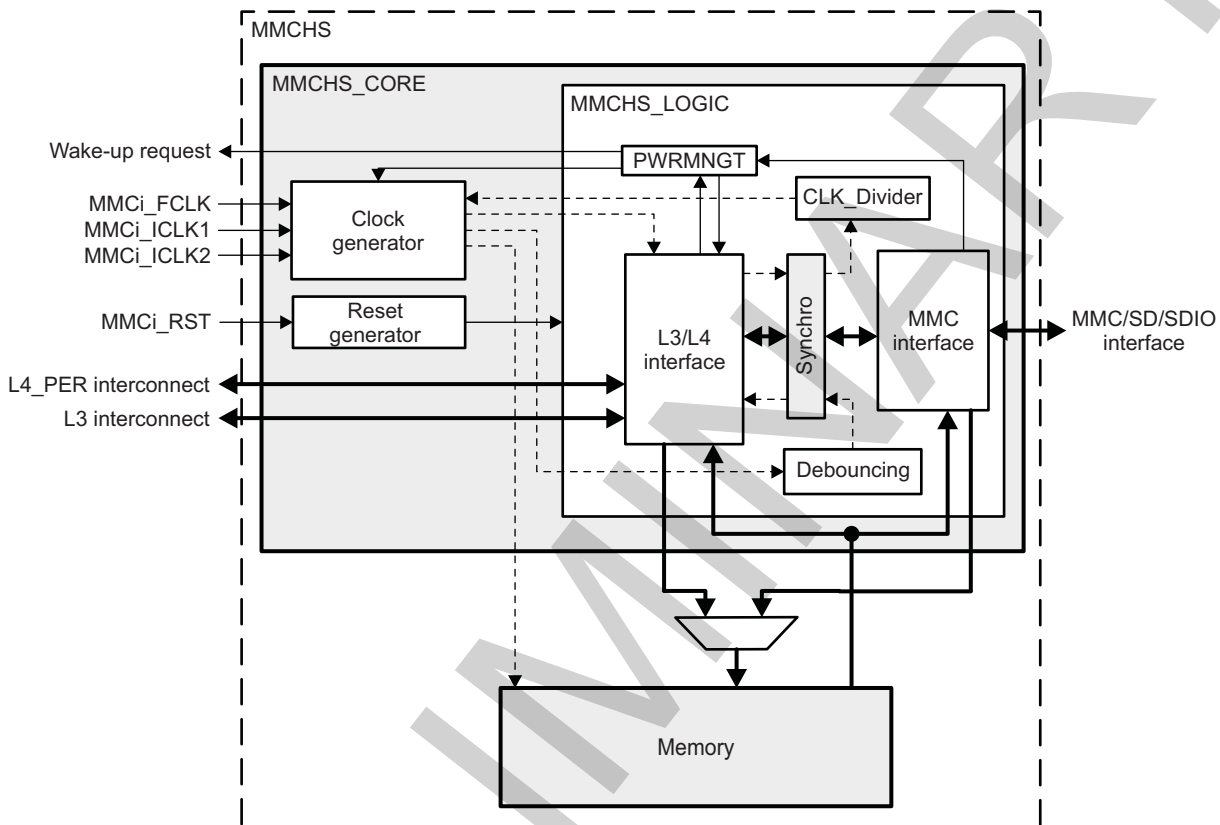

- For a description of the interrupt source, see [Section 25.4.4, Interrupt Requests](#).
- For a description of the DMA source, see [Section 25.4.5, DMA Modes](#).

25.4 MMC/SD/SDIO Functional Description

25.4.1 Block Diagram

Figure 25-17 is a block diagram of the MMC/SD/SDIOi host controller.

Figure 25-17. MMC/SD/SDIO Diagram

mmchs-017

25.4.2 Resets

25.4.2.1 Hardware Reset

The module is reinitialized by the hardware (see Table 25-6 for more information about reset signals).

The MMCHS.MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by software to check whether the module is ready to use after a hardware reset.

NOTE: The functional clock (MMCHS_FCLK) and interface clock (MMCHS_ICLK) must be provided to the module to allow the RESETDONE status bit to be set.

The debounce clock (MMCHS_32K) must be active to reset the module correctly.

This hardware reset signal has a global reset action on the module. All configuration registers and all state-machines are reset in all clock domains.

25.4.2.2 Software Reset

The module is reinitialized by software through the MMCHS.MMCHS_SYSCONFIG[1] SOFTRESET bit. This bit has the same action on the module logic as the hardware signal (MMCHS_RST), with the following exceptions:

- Debounce logic

- MMCI.MMCHS_PSTATE, MMCI.MMCHS_CAPA, and MMCI.MMCHS_CUR_CAPA registers (see the corresponding register description)

The SOFTRESET bit is active high. The bit is automatically reinitialized to 0 by hardware. The MMCI.MMCHS_SYSCTL[24] SRA bit has the same action on the design as the SOFTRESET bit.

The MMCI.MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by software to check whether the module is ready to use after a software reset.

Moreover, two partial software reset bits are provided:

- MMCI.MMCHS_SYSCTL[26] SRD
- MMCI.MMCHS_SYSCTL[25] SRC

These two reset bits are useful to reinitialize data or command processes, respectively, in case of line conflict. When these bits are set to 1, a reset process is automatically released when the reset completes:

- The MMCI.MMCHS_SYSCTL[26] SRD bit resets all finite state-machines (FSMs) and status management that handle data transfers on the interface and functional sides.
- The MMCI.MMCHS_SYSCTL[25] SRC bit resets all FSMs and status management that handle command transfers on the interface and functional sides.

25.4.3 Power Management

The MMC/SD/SDIO host controller can enter into different modes and save power:

- Normal mode
- Idle mode

The two modes are mutually exclusive (the module can be in normal mode or in idle mode). The MMC/SD/SDIO host controller is compliant with the handshake protocol of the PRCM module.

When the MMC/SD/SDIO power domain is off, the only way to wake up the power domain and different MMC/SD/SDIO clocks is to monitor the state of the sdmmc_i_dat1 input pin through a different GPIO line for each MMC/SD/SDIO interface (for more information, see [Section 26.1](#), *GPIO Overview*, in [Chapter 26](#), *GPIO*).

Normal Mode

The autogating of interface and functional clocks occurs when the following conditions are met:

- The MMCI.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1.
- There is no transaction on the MMC interface.

The autogating of interface and functional clocks stops when the following conditions are met:

- A register access occurs through the L4 interconnect.
- A wake-up event occurs (an interrupt from an SDIO card).
- A transaction on the MMC/SD/SIO interface starts.

Then the MMC/SD/SDIO host controller enters into LOW-POWER state (MMCI_ICLK clock autogated) even if the MMCI.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 0.

The functional clock is internally switched off and only interconnect read and write accesses are allowed.

Idle Mode

The MMCI_ICLK and MMCI_FCLK clocks provided to the MMC/SD/SDIO host controller are switched off upon a PRCM module request. They are switched back upon module request.

The MMC/SD/SDIO host controller complies with the handshaking protocol of the PRCM module:

- Idle request from the system power manager
- Idle acknowledgment from the MMC/SD/SDIO host controller
- Wake-up request from the MMC/SD/SDIO host controller

The idle acknowledgment varies according to the MMCI.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field:

- 0x0: Force-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request unconditionally.
- 0x1: No-idle mode. The MMC/SD/SDIO host controller ignores the system power manager request and behaves normally as if the request was not asserted.
- 0x2: Smart-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state.
- 0x3: Smart-idle wake-up-capable mode. The MMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state. However, the module may generate wake-up events when in IDLE state (related to IRQ or DMA requests)

During the smart-idle mode period, the MMC/SD/SDIO host controller acknowledges that the MMCi_ICLK and MMCi_FCLK clocks may be switched off, regardless of the value set in the MMCi.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY bit field.

Transition From Normal Mode to Smart-Idle Mode

Smart-idle mode is enabled when the MMCi.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x2 or 0x3.

The MMC/SD/SDIOi host controller goes into idle mode when the PRCM issues an idle request, according to its internal activity.

The MMC/SD/SDIO host controller acknowledges the idle request from the PRCM after ensuring the following:

- The current multi- or single-block transfer is complete.
- Any interrupt or DMA request is asserted.
- There is no card interrupt on the sdmmc_i_dat1 signal.

As long as the MMC/SD/SDIOi controller does not acknowledge the idle request, if an event occurs, the MMC/SD/SDIOi host controller can still generate an interrupt or a DMA request. In this case, the module ignores the idle request from the PRCM module.

As soon as the MMC/SD/SDIOi controller acknowledges the idle request from the PRCM module:

- If smart-idle mode: The module does not assert any new interrupt or DMA request.
- If smart-idle wake-up-capable mode: The module may generate wake-up events related to an interrupt or DMA request.

Wake-Up Event in Smart-Idle Mode

The wake-up feature is enabled when the following enable wake-up bits are set:

- The MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit is set to 0x1.
- The MMCi.MMCHS_HCTL[24] IWE bit is set to 0x1.
- The MMCi.MMCHS_IE[8] CIRQ_ENABLE bit is set to 0x1.

The wakeup is generated only in smart-idle mode, when the module is in idle mode.

Table 25-8 lists the supported cases in smart-idle mode.

Table 25-8. Smart-Idle Mode and Wake-Up Capabilities

| Mode | MMCi_ICLK Clock | MMCi_FCLK Clock | Wake-Up Event |
|----------------|------------------------------------|------------------------------------|--|
| Card interrupt | May be switched off ⁽¹⁾ | May be switched off ⁽¹⁾ | The module sends an asynchronous wake-up request when a card interrupt on sdmmc_i_dat1 signal is detected. |

⁽¹⁾ The MMC/SD/SDIOi host controller assumes that both clocks may be switched off, regardless of the value set in the MMCi.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY bit field.

Transition From Smart-Idle Mode to Normal Mode

The MMC/SD/SDIO host controller detects the end of the idle period when the PRCM module deasserts the idle request.

For the wake-up event, there is a corresponding interrupt status in the MMCi.MMCHS_STAT register. The MMC/SD/SDIOi host controller operates the conversion between the wake-up and interrupt (or DMA request) upon exit from smart-idle mode, if the associated enable bit is set in the MMCi.MMCHS_ISE register.

Interrupts and wake-up events have independent enable and disable controls, accessible through the MMCi.MMCHS_HCTL and MMCi.MMCHS_ISE registers. The overall consistency must be ensured by software.

The interrupt status register MMCi.MMCHS_STAT is updated in the CIRQ bit with the event that caused the wake-up when the MMCi.MMCHS_IE[8] CIRQ_ENABLE associated bit is enabled.

Then, the wake-up event at the origin of the transition from smart-idle mode to normal mode is converted into its corresponding interrupt or DMA request. (The MMCi.MMCHS_STAT register is updated and the status of the interrupt signal changes.)

When the idle request from the PRCM module is deasserted, the module switches back to normal mode. The module is fully operational.

Force-Idle Mode

Force-idle mode is enabled when the MMCi.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0.

Force-idle mode is an idle mode in which the MMC/SD/SDIOi host controller responds unconditionally to the idle request from the PRCM module. Moreover, in this mode, the MMC/SD/SDIOi host controller unconditionally deasserts interrupts and DMA request lines asserted.

The transition from normal mode to force-idle mode does not affect the bits of the MMCi.MMCHS_STAT register.

In force-idle mode, the interrupt and DMA request lines are deasserted. MMCi_ICLK and MMCi_FCLK can be switched off.

CAUTION

In force-idle mode, an idle request from the PRCM module during a command or a data transfer can lead to an unexpected and unpredictable result. When the module is idle, any access to the module generates an error as long as the MMCi_ICLK clock is alive.

The module exits force-idle mode when the PRCM module deasserts the idle request. Then the module switches back to normal mode. The module is fully operational. Interrupt and DMA request lines are optionally asserted one clock cycle later.

Local Power Management

Table 25-9 describes the power-management features available for the MMC/SD/SDIOi modules.

NOTE: For information about source clock gating and a description of the sleep/wake-up transitions, see Section 3.1.1.1, *Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 25-9. Local Power-Management Features

| Feature | Registers | Description |
|-------------------|--------------------------------|---|
| Clock auto gating | MMCHS_SYSCONFIG[0] AUTOIDLE | This bit allows a local power optimization inside the module by gating the MMCi_ICLK clock upon the interface activity, or gating the MMCi_FCLK clock upon the internal activity. |

Table 25-9. Local Power-Management Features (continued)

| Feature | Registers | Description |
|------------------------|--|--|
| Slave idle modes | MMCHS_SYSCONFIG [3:4] SIDLEMODE | Force-idle, no-idle, and smart-idle modes are available. |
| Clock activity | MMCHS_SYSCONFIG [8:9] CLOCKACTIVITY | For configuration details, see Table 25-10 . |
| Master standby modes | MMCHS_SYSCONFIG [12:13] STANDBYMODE | Force-idle, no-idle, and smart-idle modes are available. |
| Global wake-up enable | MMCHS_SYSCONFIG [2] ENAWAKEUP | This bit enables the wake-up feature at the module level. |
| Wake-up sources enable | MMCHS_HCTL register | This register holds one active-high enable bit per event source that is able to generate a wake-up signal. |

Table 25-10. Clock Activity Settings

| CLOCKACTIVITY Values | Clock State When Module is in IDLE State | | Features Available When Module is in IDLE State | Wake-Up Events |
|----------------------|--|-----------|---|----------------|
| | MMCi_ICLK | MMCi_FCLK | | |
| 00 | OFF | OFF | None | Card interrupt |
| 10 | OFF | ON | None | |
| 01 | ON | OFF | None | |
| 11 | ON | ON | All | |

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the CLOCKACTIVITY and MMCi clock PRCM control bits. For a description of the ClockActivity feature, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

25.4.4 Interrupt Requests

Several internal module events can generate an interrupt. Each interrupt has a status bit, an interrupt enable bit, and a signal status enable:

- The status of each type of interrupt is automatically updated in the MMCi.[MMCHS_STAT](#) register; it indicates which service is required.
- The interrupt status enable bits of the MMCi.[MMCHS_IE](#) register enable or disable the automatic update of the MMCi.[MMCHS_STAT](#) register on an event-by-event basis.
- The interrupt signal enable bits of the MMCi.[MMCHS_ISE](#) register enable or disable the transmission of an interrupt request on the interrupt line MMCi_IRQ (from the MMC/SD/SDIOi host controller to the MPU subsystem INTC) on an event-by-event basis.

If an interrupt status is disabled in the MMCi.[MMCHS_IE](#) register, then the corresponding interrupt request is not transmitted, and the value of the corresponding interrupt signal enable in the MMCi.[MMCHS_ISE](#) register is ignored.

When an interrupt event occurs, the corresponding status bit is automatically set to 0x1 (the MMC/SD/SDIOi host controller updates the status bit) in the MMCi.[MMCHS_STAT](#) register. If a mask is later applied on the interrupt in the MMCi.[MMCHS_ISE](#) register, the interrupt request is deactivated.

When the interrupt source has not been serviced, if the interrupt status is cleared in the MMCi.[MMCHS_STAT](#) register and the corresponding mask is removed from the MMCi.[MMCHS_ISE](#) register, the interrupt status is not asserted again in the MMCi.[MMCHS_STAT](#) register and the MMC/SD/SDIOi host controller does not transmit an interrupt request.

CAUTION

If the buffer write ready (BWR) interrupt or the buffer read ready (BRR) only interrupt are not serviced and are cleared in the MMCi.MMCHS_STAT register, and the corresponding mask is removed, then the MMC/SD/SDIOi host controller waits for the service of the interrupt without updating the status MMCi.MMCHS_STAT register or transmitting an interrupt request.

Table 25-11 lists the event flags, and their mask, that can cause module interrupts.

Table 25-11. Events

| Event Flag | Event Mask | Map to | Description |
|----------------------|------------------------------|----------|---|
| MMCHS_STAT[29] BADA | MMCHS_IE[29] BADA_ENABLE | MMCi_IRQ | <p>Bad access to data space. This bit is set automatically to indicate a bad access to buffer when not allowed:</p> <p>This bit is set during a read access to the data register (MMCHS_DATA) while buffer reads are not allowed (MMCHS_PSTATE[11] BRE = 0).</p> <p>This bit is set during a write access to the data register (MMCHS_DATA) while buffer writes are not allowed (MMCHS_STATE[10] BWE = 0).</p> |
| MMCHS_STAT[28] CERR | MMCHS_IE[28] CERR_ENABLE | MMCi_IRQ | Card error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5, or R5b. Only bits referenced as type E (error) in the status field in the response can set a card status error. An error bit in the response is flagged only if the corresponding bit in the card status response error MMCHS_CSRE is set. There is no card error detection for the auto CMD12 command. |
| MMCHS_STAT[25] ADMAE | MMCHS_IE[25] ADMAE_ENABLE | MMCi_IRQ | ADMA error. This bit is set when the host controller detects errors during an ADMA-based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA error status register. In addition, the host controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. |
| MMCHS_STAT[24] ACE | MMCHS_IE[24] ACE_ENABLE | MMCi_IRQ | Auto CMD12 error. This bit is set automatically when one bit in the auto CMD12 error status register changes from 0 to 1. |
| MMCHS_STAT[22] DEB | MMCHS_IE[22] DEB_ENABLE | MMCi_IRQ | Data end bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on the DAT line or at the end position of the CRC status in write mode. |
| MMCHS_STAT[21] DCRC | MMCHS_IE[21] DCRC_ENABLE | MMCi_IRQ | Data CRC error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status difference of a position 010 token during a block write command. |
| MMCHS_STAT[20] DTO | MMCHS_IE[20] DTO_ENABLE | MMCi_IRQ | <p>Data time-out error. This bit is set automatically according to the following conditions:</p> <ul style="list-style-type: none"> – Busy time-out for R1b, R5b response type – Busy time-out after write CRC status – Write CRC status time-out – Read data time-out |
| MMCHS_STAT[19] CIE | MMCHS_IE[19] CIE_ENABLE | MMCi_IRQ | Command index error. This bit is set automatically when the response index differs from the corresponding command index previously emitted. The check is enabled through the MMCHS_CMD[20] CICE bit. |

Table 25-11. Events (continued)

| Event Flag | Event Mask | Map to | Description |
|--------------------------------------|---|----------|--|
| MMCHS_STAT [18] CEB | MMCHS_IE [18] CEB_ENABLE | MMCi_IRQ | Command end bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response. |
| MMCHS_STAT [17] CCRC | MMCHS_IE [17] CCRC_ENABLE | MMCi_IRQ | Command CRC error. This bit is set automatically when there is a CRC7 error in the command response. CRC check is enabled through the MMCHS_CMD [19] CCCE bit. |
| MMCHS_STAT [16] CTO | MMCHS_IE [16] CTO_ENABLE | MMCi_IRQ | Command time-out error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within five clock cycles, the time-out is still detected at 64 clock cycles. |
| MMCHS_STAT [15] ERRI | MMCHS_IE [15] ERRI_ENABLE | MMCi_IRQ | Error interrupt. If any of the bits in the error interrupt status register (MMCHS_STAT [24:15]) are set, this bit is set to 1. |
| MMCHS_STAT [10] BSR | MMCHS_IE [10] BSR_ENABLE | MMCi_IRQ | Boot status received interrupt. This bit is set automatically when the MMCHS_CON [18] BOOT_CF0 bit is set to 0x1 or 0x2 and a boot status is received on the dat0 line. This interrupt is useful only for the MMC card. |
| MMCHS_STAT [8] CIRQ | MMCHS_IE [8] CIRQ_ENABLE | MMCi_IRQ | Card interrupt. This bit is used only for SD, SDIO, and CE-ATA cards. In 1-bit mode, the interrupt source is asynchronous (can be a source of asynchronous wakeup). In 4-bit mode, the interrupt source is sampled during the interrupt cycle. In CE-ATA mode, the interrupt source is detected when the card drives the CMD line to 0 during one cycle after data transmission end. |
| MMCHS_STAT [5] BRR | MMCHS_IE [5] BRR_ENABLE | MMCi_IRQ | Buffer read ready. This bit is set automatically during a read operation to the card (see class 2 block-oriented read commands) when one block specified by the MMCHS_BLK [10:0] BLEN bit field is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the LH needs to empty the buffer by reading it. |
| MMCHS_STAT [4] BWR | MMCHS_IE [4] BWR_ENABLE | MMCi_IRQ | Buffer write ready. This bit is set automatically during a write operation to the card (see class 4 block-oriented write command) when the host can write a complete block as specified by the MMCHS_BLK [10:0] BLEN bit field. It indicates that the memory card has emptied one block from the buffer and that the LH can write one block of data into the buffer. |
| MMCHS_STAT [3] DMA | MMCHS_IE [3] DMA_ENABLE | MMCi_IRQ | DMA interrupt. This status is set when an interrupt is required in the ADMA instruction and after the data transfer completes. |
| MMCHS_STAT [2] BGE | MMCHS_IE [2] BGE_ENABLE | MMCi_IRQ | Block gap event. When a stop at the block gap is requested (MMCHS_HCTL [16] SBGR), this bit is automatically set when transaction is stopped at the block gap during a read or write operation. |
| MMCHS_STAT [1] TC | MMCHS_IE [1] TC_ENABLE | MMCi_IRQ | Transfer completed. This bit is always set when a read/write transfer is complete or between two blocks when the transfer is stopped because of a stop at block gap request (MMCHS_HCTL [16] SBGR). – In read mode: This bit is automatically set on completion of a read transfer (MMCHS_PSTATE [9] RTA). |

Table 25-11. Events (continued)

| Event Flag | Event Mask | Map to | Description |
|----------------------------------|---------------------------------------|----------|--|
| | | | – In write mode: This bit is automatically set on completion of the DAT line use (MMCHS_PSTATE[2] DLA). |
| MMCHS_STAT[0] CC | MMCHS_IE[0] CC_ENABLE | MMCi_IRQ | Command complete. This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCHS_PSTATE[0] CMDI). If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command time-out error (MMCHS_STAT[16] CTO) has higher priority than command complete (MMCHS_STAT[0] CC). If a response is expected but none is received, then a command time-out error is detected and signaled, instead of the command complete interrupt. |

NOTE: To send an interrupt request to the MMCi_IRQ line, the mask/unmask bit must be set in the MMCi.[MMCHS_IE](#) and MMCi.[MMCHS_ISE](#) registers.

The MMC/SD/SDIOi host controller supports interrupt-driven operation and polling.

25.4.4.1 Interrupt-Driven Operation

An interrupt enable bit must be set in the MMCi.[MMCHS_IE](#) register to enable the module internal source of interrupt.

When an interrupt event occurs, the single interrupt line is asserted and the LH must:

1. Read the MMCi.[MMCHS_STAT](#) register to identify which event occurred.
2. Write 1 into the corresponding bit of the MMCi.[MMCHS_STAT](#) register to clear the interrupt status and release the interrupt line (if a read is done after this write, this returns 0).

NOTE: In the MMCi.[MMCHS_STAT](#) register, the card interrupt (CIRQ) and error interrupt (ERRI) bits cannot be cleared.

The MMCi.[MMCHS_STAT\[8\] CIRQ](#) status bit must be masked by disabling the MMCi.[MMCHS_IE\[8\] CIRQ_ENABLE](#) bit (set to 0x0), and then the interrupt routine must clear the SDIO interrupt source in the SDIO card common control register (CCCR).

The MMCi.[MMCHS_STAT\[15\] ERRI](#) bit is automatically cleared when all status bits in the MMCi.[MMCHS_STAT\[31:16\]](#) bit field are cleared.

25.4.4.2 Polling

When the interrupt capability of an event is disabled in the MMCi.[MMCHS_ISE](#) register, the interrupt line is not asserted:

- Software can poll the status bit in the MMCi.[MMCHS_STAT](#) register to detect when the corresponding event occurs.
- Writing 1 into the corresponding bit of the MMCi.[MMCHS_STAT](#) register clears the interrupt status and does not affect the interrupt line state.

NOTE: Refer to the previous note concerning clearing of the CIRQ and ERRI bits.

25.4.5 DMA Modes

Two DMA managements can be used to load data from memory to the internal buffer of the controller (or vice versa). These modes are exclusive and depend on the module integration.

- DMA master mode

DMA master mode is selected by setting the [MMCHS_CON\[20\]](#) DMA_MNS bit to 1. In this case, the controller has direct access to data using a specific algorithm called ADMA2 (prevents the system from being interrupted). Data are exchanged using the L3 master interface, which supports burst accesses to maximize throughput.

NOTE: This mode is supported only by modules connected to the L3 interconnect. See [Section 25.1, MMC/SD/SDIO Overview](#), for more information and/or check the value of the [MMCHS_HL_HWINFO\[0\]](#) MADMA_EN bit.

This mode is available for modules MMC1 and MMC2.

- DMA slave mode

DMA slave mode is selected by setting the [MMCHS_CON\[20\]](#) DMA_MNS bit to 0. In this case, the controller is slave on the DMA transaction managed by two separated requests (MMCi_DMA_TX and MMcI_DMA_RX).

NOTE: This mode is the only mode supported by modules that are not connected to the L3 interconnect (regardless of the value of the [MMCHS_CON\[20\]](#) DMA_MNS bit). See [Section 25.1, MMC/SD/SDIO Overview](#), for more information and/or to check the value of the [MMCHS_HL_HWINFO\[0\]](#) MADMA_EN bit.

This mode is available for all MMC modules.

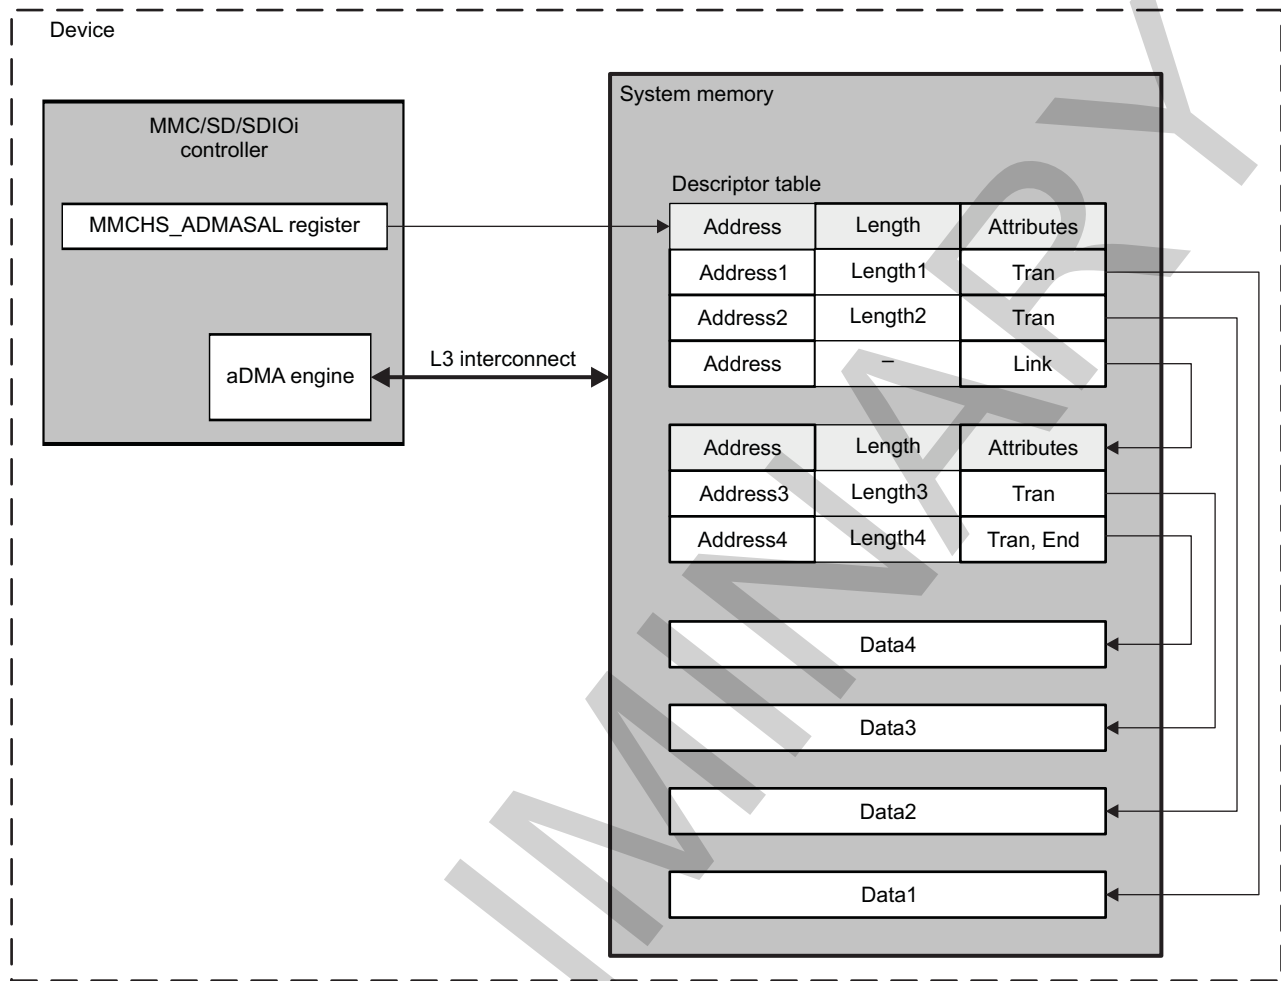

25.4.5.1 Master DMA Operations

The MMC/SD/SDIOi host controller has direct access to the internal data. This feature is called advanced DMA (ADMA). It follows a specific algorithm (ADMA2) defined by an instruction in memory that starts at an address previously loaded in the [MMCHS_ADMASAL](#) register before any data command issued to the MMC card. Only 32-bit address spacing is supported by the controller for data storage.

NOTE: This mode is supported only by modules connected to the L3 interconnect. See [Section 25.1, MMC/SD/SDIO Overview](#), for more information and/or to check the value of the [MMCHS_HL_HWINFO\[0\]](#) MADMA_EN bit.

These instructions must be loaded by software in a 32-bit-addressed descriptor table in system memory, as shown in [Figure 25-18](#). In this case the [MMCHS_ADMASAL](#) register is used as the program address pointer

Figure 25-18. ADMA Block Diagram Overview

mmchs-018

25.4.5.1.1 Descriptor Table Description

Each descriptor line contains an address, a length, and attributes fields. The attributes define which operation will be processed. Every descriptor line is a 64-bit-wide register that is fetched in the controller using the L3 master interface, and requires two 32-bit accesses to memory.

Table 25-12 shows the structure of a descriptor line.

Table 25-12. Descriptor Line Overview

| Address Field | | Length | | Reserved | | Attributes | | | | |
|----------------|----|---------------|----|----------|---|------------|------|---|-----|-----------|
| 63 | 32 | 31 | 16 | 15 | 6 | 5 | 4 | 3 | 2 | 1 0 |
| 32-bit Address | | 16-bit Length | | 0x0 | | Act2 | Act1 | 0 | Int | Ent Valid |

The attribute of the descriptor line is divided into two parts:

- Attributes[5:4]: The action to be processed by the ADMA engine
- Attributes[3:0]: Additional parameters characterizing the behavior of the ADMA engine

Table 25-13 describes the available actions of a descriptor line.

Table 25-13. Available Actions of a Descriptor Line

| Act2 | Act1 | Symbol | Comment | Operation |
|------|------|--------|-----------------|--|
| 0 | 0 | Nop | No operation | Do not execute the current line and go to the next line. |
| 0 | 1 | Rsv | Reserved | Reserved action. Behaves the same as the Nop command. |
| 1 | 0 | Tran | Transfer data | Transfer data of one descriptor line. |
| 1 | 1 | Link | Link descriptor | Link to another descriptor. |

Table 25-14 describes the additional parameters of a descriptor line.

Table 25-14. Additional Parameters of a Descriptor Line

| Bit | Description |
|-------|--|
| Valid | Valid = 1 indicates that this descriptor line is effective. If Valid = 0, an ADMA error interrupt is generated and the ADMA is stopped. This prevents runaways. |
| End | End = 1 indicates the end of a descriptor. The transfer-complete interrupt is generated when the operation of the descriptor line is complete. |
| Int | Int = 1 generates a DMA interrupt when the operation of the descriptor line is complete. |

25.4.5.1.2 Requirements for Descriptors

The following sections discuss restrictions and tips on how to correctly configure the descriptors to be used by the ADMA engine.

25.4.5.1.2.1 Data Length

There are three requirements to program descriptors:

- The minimum unit of address is 4 bytes.
- The maximum data length of each descriptor line is less than 64KB.
- Total length = Length₁ + Length₂ + Length₃ + ... + Length_n must be a multiple of the block size.

If the total length of a descriptor is not a multiple of the block size, data transfer with the ADMA engine may not have been terminated. In this case, the controller returns a data time-out event and the transfer is aborted.

The block count register (the [MMCHS_BLK\[31:16\]](#) NBLK bit field) is defined as 16 bits and limits data transfers to a maximum of 65,535 blocks. If the ADMA data transfer size is less than or equal to the 65,535-block transfer, the block count register can be used. In this case, the total length of the descriptor table must be equivalent to "block size" by "block count." If the ADMA data transfer is greater than 65,535 blocks, the block count register must be disabled by setting the block count enable bit (the [MMCHS_CMD\[1\]](#) BCE bit) to 0. In this case, the length of the data transfer is not designated by the block count but by the descriptor table.

NOTE: The timing for detecting the last block on the SD bus may differ, which affects control of the read transfer active ([MMCHS_PSTATE\[9\]](#) RTA), write transfer active ([MMCHS_PSTATE\[8\]](#) WTA), and DAT line active ([MMCHS_PSTATE\[2\]](#) DLA) bits. In case of a read operation, more blocks than required may be read from the card. The host driver must ignore an out-of-range error if the read operation is for the last block of the memory area.

25.4.5.1.2.2 Supported Features

The ADMA engine does not support the suspend/resume function. However, the stop and continue functions are available.

When the stop-at-block-gap-request (the [MMCHS_HCTL\[16\]](#) SBGR bit) is set during the ADMA operation, the block gap event interrupt is generated when the ADMA is stopped at block gap (the [MMCHS_STAT\[2\]](#) BGE bit). The host controller must stop the ADMA read operation by using read wait or by stopping the SD clock. While stopping ADMA, SD commands cannot be issued.

25.4.5.1.2.3 Error Generation

When an error occurs during an ADMA transfer, the ADMA operation is stopped and the ADMA error interrupt is generated. The ADMA error state field (the [MMCHS_ADMAES\[1:0\]](#) AES bit field) holds the state of the ADMA when it is stopped. Software can identify the erroneous descriptor line by using the following method:

- If ADMA stopped at ST_FDS state, the ADMA system address register ([MMCHS_ADMASAL](#)) points to the erroneous descriptor line.
- If ADMA stopped at ST_TFR or ST_STOP state, the ADMA system address register points to the descriptor line following the erroneous one.

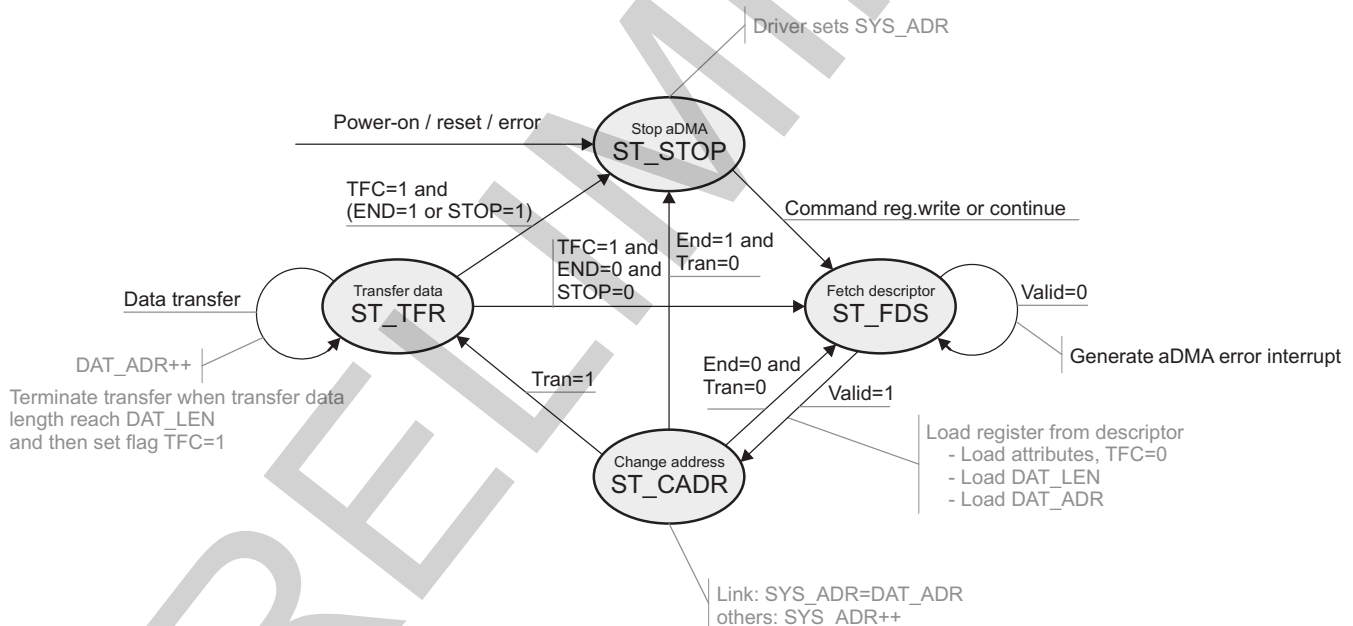

25.4.5.1.3 Advanced DMA Description

The ADMA is a DMA controller embedded in each eMMC controller. It can be seen as a small sequencer that fetches a descriptor line and executes the corresponding action. The base address of the descriptor table is stored in the [MMCHS_ADMASAL](#) register.

NOTE: Software must write the base address of the descriptor table in the [MMCHS_ADMASAL](#) register before the first use of the ADMA engine.

The ADMA program is executed according to descriptor attributes (see [Section 25.4.5.1.1, Descriptor Table Description](#)) and an FSM, as shown in [Figure 25-19](#).

Figure 25-19. ADMA Finite State-Machine

mmchs-019

[Table 25-15](#) describes each state of the ADMA FSM.

Table 25-15. ADMA2 States Description

| State Name | Operation |
|------------------------------|---|
| ST_FDS (fetch descriptor) | ADMA2 fetches a descriptor line and sets parameters in internal registers. It then goes to the ST_CADR state. |
| ST_CADR (change address) | Link operation loads another descriptor address to the ADMA system address register (MMCHS_ADMASAL). In other operations, the ADMA system address register is incremented to point to the next descriptor line. NOTE: ADMA2 does not stop at this state if some errors occur. |

Table 25-15. ADMA2 States Description (continued)

| State Name | Operation |
|---------------------------|--|
| ST_TFR (transfer data) | Data transfer of one descriptor line is executed between system memory and the SD card: <ul style="list-style-type: none"> • If data transfer continues (End = 0) go to ST_FDS state. • If data transfer completes, go to ST_STOP state. |
| ST_STOP (stop DMA) | ADMA2 stays in this state in the following cases: <ul style="list-style-type: none"> • After power on reset (POR) or software reset • All descriptor data transfers are complete. If a new ADMA operation is stated by writing the command register, go to ST_FDS state. |

Table 25-16 gives the description of each symbol used in the ADMA FSM state-machine (see Figure 25-19).

Table 25-16. ADMA FSM Symbol Definition

| Symbol | Definition |
|-----------|-----------------------------------|
| SYS_ADR | ADMA system address register |
| SYS_ADR++ | Point to next descriptor line |
| DAT_ADR | Data address register (internal) |
| DAT_LEN | Data length register (internal) |
| TFC | Transfer complete flag (internal) |
| STOP | Stop-at-block-gap request |

25.4.5.2 Slave DMA Operations

The MMC/SD/SDIOi host controller can be interfaced with a DMA controller. At the system level, the advantage is to discharge the LH of the data transfers. The module does not support wide DMA access (above 1024 bytes) for SD cards, as specified in the *SD Card Specification* and *SD Host Controller Standard Specification*.

NOTE: This mode is implied by modules that are not connected to the L3 interconnect (regardless of the value of the [MMCHS_CON\[20\]](#) DMA_MNS bit). See [Section 25.4.5.1, Master DMA Operations](#), for more information and/or to check the value of the [MMCHS_HL_HWINFO\[0\]](#) MADMA_EN bit.

The DMA request is issued if the following conditions are met:

- The MMCI.MMCHS_CMD[0] DE bit is set to 1 to trigger the initial DMA request (the write must be done when running the data transfer command).
- A command was emitted on the sdmmci_cmd line.
- There is enough space in the buffer of the MMC/SD/SDIOi host controller to write an entire block (BLEN writes).

25.4.5.2.1 DMA Receive Mode

In a DMA block read operation (single or multiple), the request signal MMCI_DMA_RX is asserted to its active level when a complete block is written in the buffer. The block size transfer is specified in the MMCI.MMCHS_BLK[10:0] BLEN bit field.

MMCI_DMA_RX is deasserted to its inactive level when the sDMA reads one word from the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot read access or several DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to the BLEN field block size.

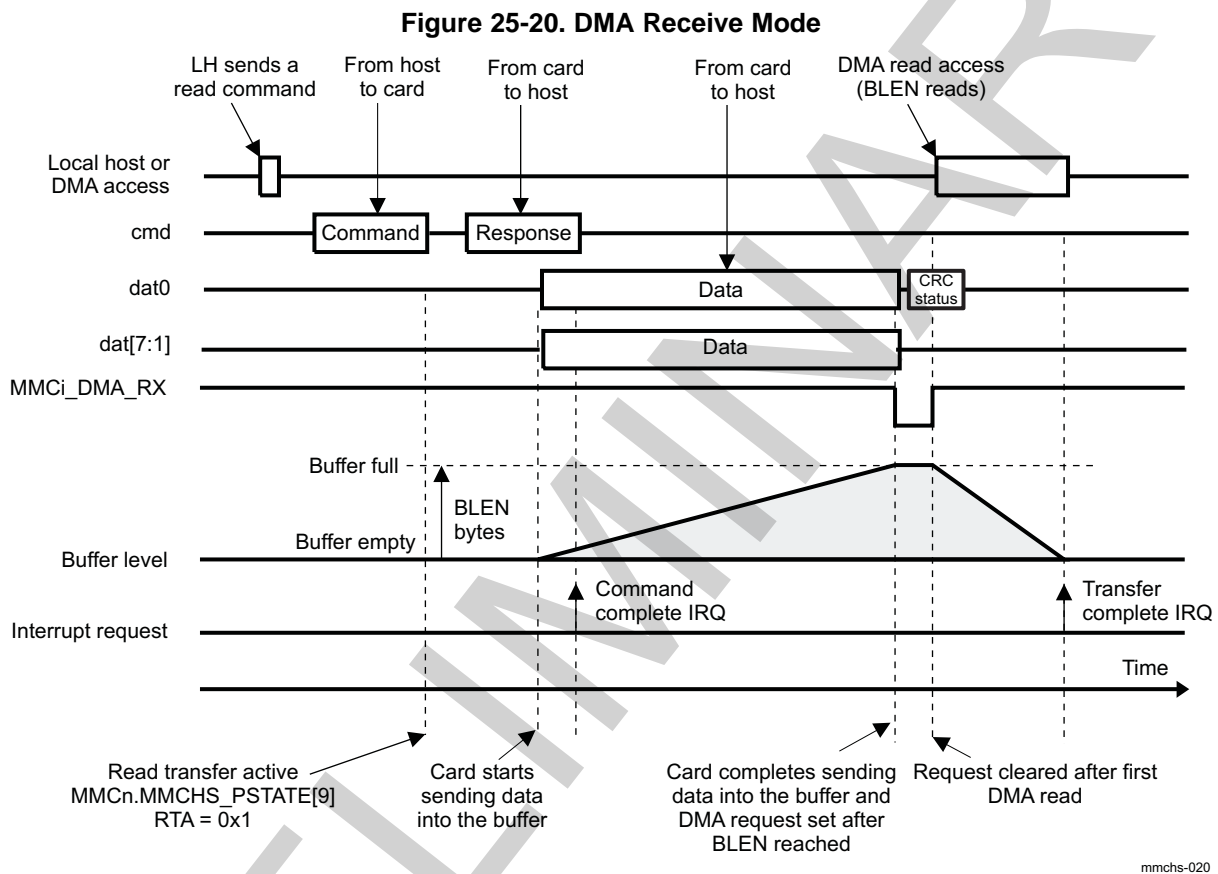

New DMA requests are internally masked if the sDMA has not read exactly BLEN bytes and a new complete block is not ready. Because DMA accesses are 32-bit accesses, the number of sDMA read is Integer(BLEN/4) + 1.

The receive buffer never overflows. In multiple block transfers for block sizes larger than 512 bytes, when the buffer becomes full, the `sdmhci_clk` clock signal (provided to the card) is momentarily stopped until the sDMA or the MPU performs a read access, which reads a complete block in the buffer.

To summarize:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 25-20 shows DMA receive mode.

25.4.5.2.2 DMA Transmit Mode

In a DMA block write operation (single or multiple), the request signal `MMCi_DMA_TX` is asserted to its active level when a complete block is to be written to the buffer. The block size transfer is specified in the `MMCi.MMCHS_BLK[10:0]` BLEN bit field.

`MMCi_DMA_TX` is deasserted to its inactive level when the sDMA writes one word to the buffer.

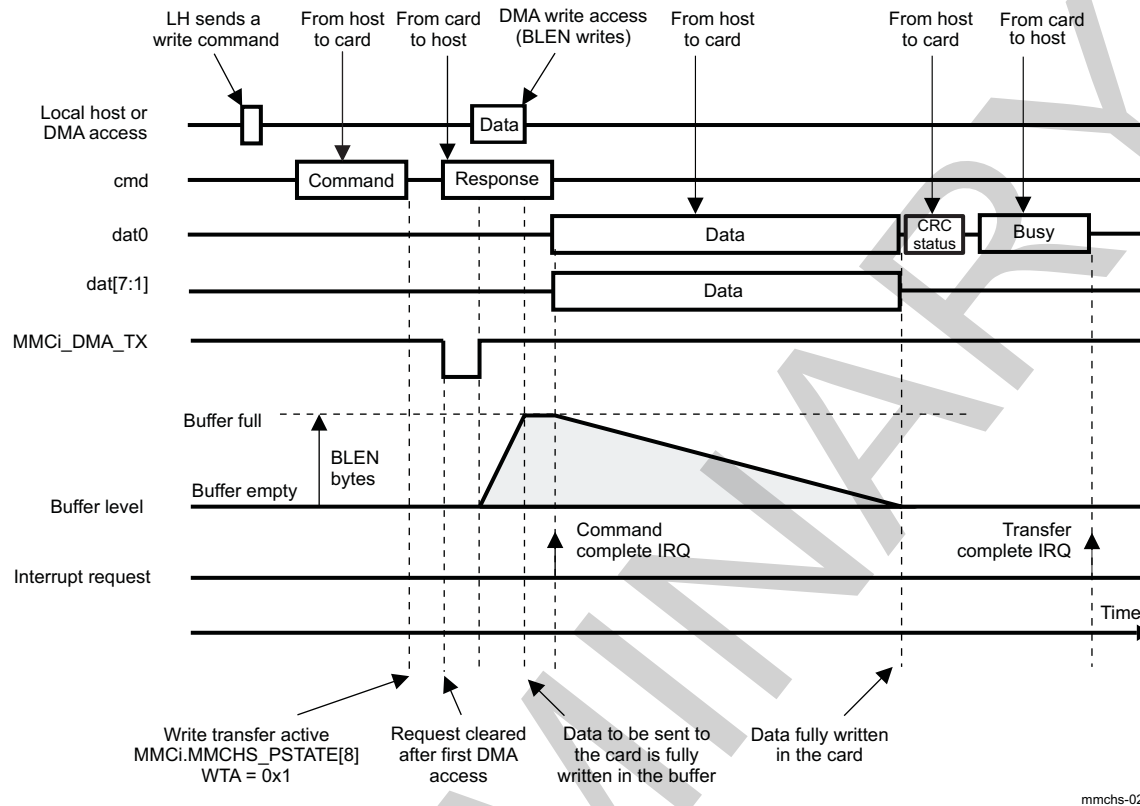

Only one request is sent per block; the DMA controller can make a 1-shot write access or multiple write DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to the BLEN field block size.

New DMA requests are internally masked if the sDMA has not written exactly BLEN bytes (because DMA accesses are 32-bit accesses, the number of sDMA reads is $\text{Integer}(\text{BLEN}/4) + 1$) and if there is not enough memory space to write a complete block in the buffer.

To summarize:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 25-21 shows DMA transmit mode.

Figure 25-21. DMA Transmit Mode

25.4.6 Mode Selection

The MMC/SD/SDIO host controller can be used in two modes: MMC and SD/SDIO. It has been designed to be the most transparent with the type of card.

The type of the card connected is differentiated by the software initialization procedure. Software identifies the type of card connected during software initialization. For each card type, there are corresponding commands. Some commands are not supported by all cards. For more information, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification, Part E1*.

The purpose of the module is to transfer commands and data to whatever card is connected, respecting the protocol of the connected card.

Writes and reads to the card must respect the appropriate protocol of that card.

25.4.7 Buffer Management

25.4.7.1 Data Buffer

The MMC/SD/SDIOi host controller uses a data buffer. This buffer transfers data from one data bus (interconnect) to another data bus (SD/SDIO or MMC card bus) and vice versa.

The buffer is the heart of the interface and ensures the transfer between the two interfaces (interconnect and the card).

To enhance performance, the data buffer is completed by a prefetch register and a post-write buffer that are not accessible by the host controller.

The read access time of the prefetch register is faster than that of the data buffer. The prefetch register allows data to be read from the data buffer at an increased speed by preloading data into the prefetch register.

The entry point of the data buffer, prefetch buffer, and post-write buffer is the 32-bit register MMCi.MMCHS_DATA register. A write access to the MMCi.MMCHS_DATA register followed by a read access from the MMCi.MMCHS_DATA register corresponds to a write access to the post-write buffer followed by a read access to the prefetch buffer. As a consequence, it is normal that the data of the write access to the MMCi.MMCHS_DATA register and the data of the read access to the MMCi.MMCHS_DATA register are different.

The number of 32-bit accesses to the MMCi.MMCHS_DATA register that are needed to read (or write) a data block with a size of the MMCi.MMCHS_BLK[10:0] BLEN bit field equals the rounded up result of BLEN divided by 4.

The maximum block size supported by the host controller is hard-coded in the MMCi.MMCHS_CAPA[17:16] MBL bit field and cannot be changed.

A read access to the MMCi.MMCHS_DATA register is allowed only when the buffer read-enable status is set to 1 (the MMCi.MMCHS_PSTATE[11] BRE bit); otherwise, a bad access (the MMCi.MMCHS_STAT[29] BADA bit) is signaled.

A write access to the MMCi.MMCHS_DATA register is allowed only when the buffer write-enable status is set to 1 (the MMCi.MMCHS_PSTATE[10] BWE bit); otherwise, a bad access (the MMCi.MMCHS_STAT[29] BADA bit) is signaled and the data are not written.

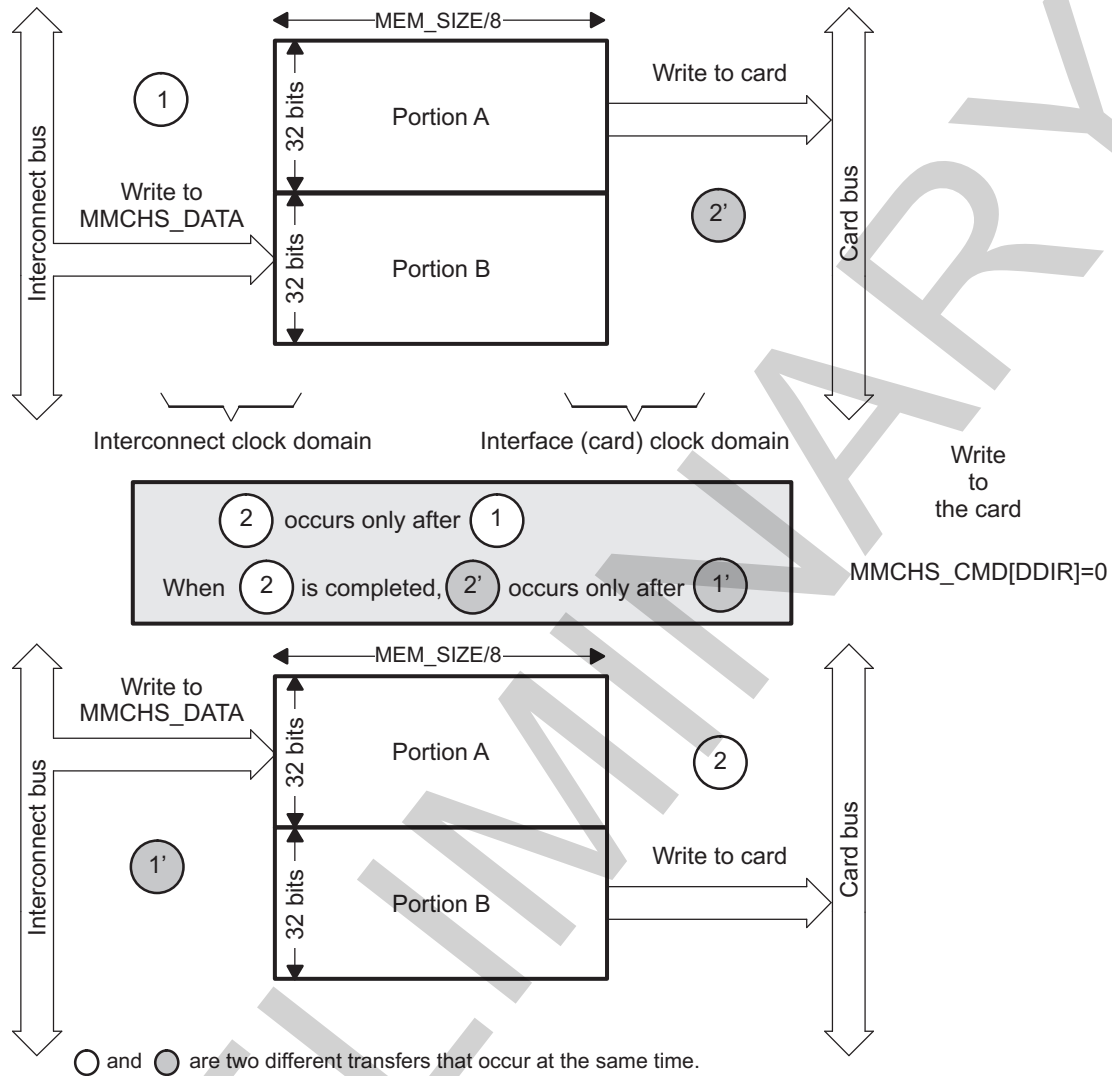

The data buffer has two modes of operation to store and read of the first and second portions of the data buffer:

- When the size of the data block to transfer is less than or equal to MEM_SIZE/2 (in double-buffering), two data transfers can occur at the same time from one data bus to the other data bus, and vice versa. The MMC/SD/SDIO host controller uses the two portions of the data buffer in a ping-pong manner so that storing and reading the first and second portions of the data buffer are automatically interchanged from time to time so that data may be read from one portion (for instance, through a DMA read access on the interconnect bus) while data (for instance, from the card) are being stored into the other portion, and vice versa. When BLEN is less than or equal to 0x200 (that is, less than or equal to 512 bytes), each of the two portions of the buffer that can be used have a size of BLEN (that is, 32 bits × BLEN divided by 4). No more than this total size of 2 × 32 bits × BLEN divided by 4 can be used.

CAUTION

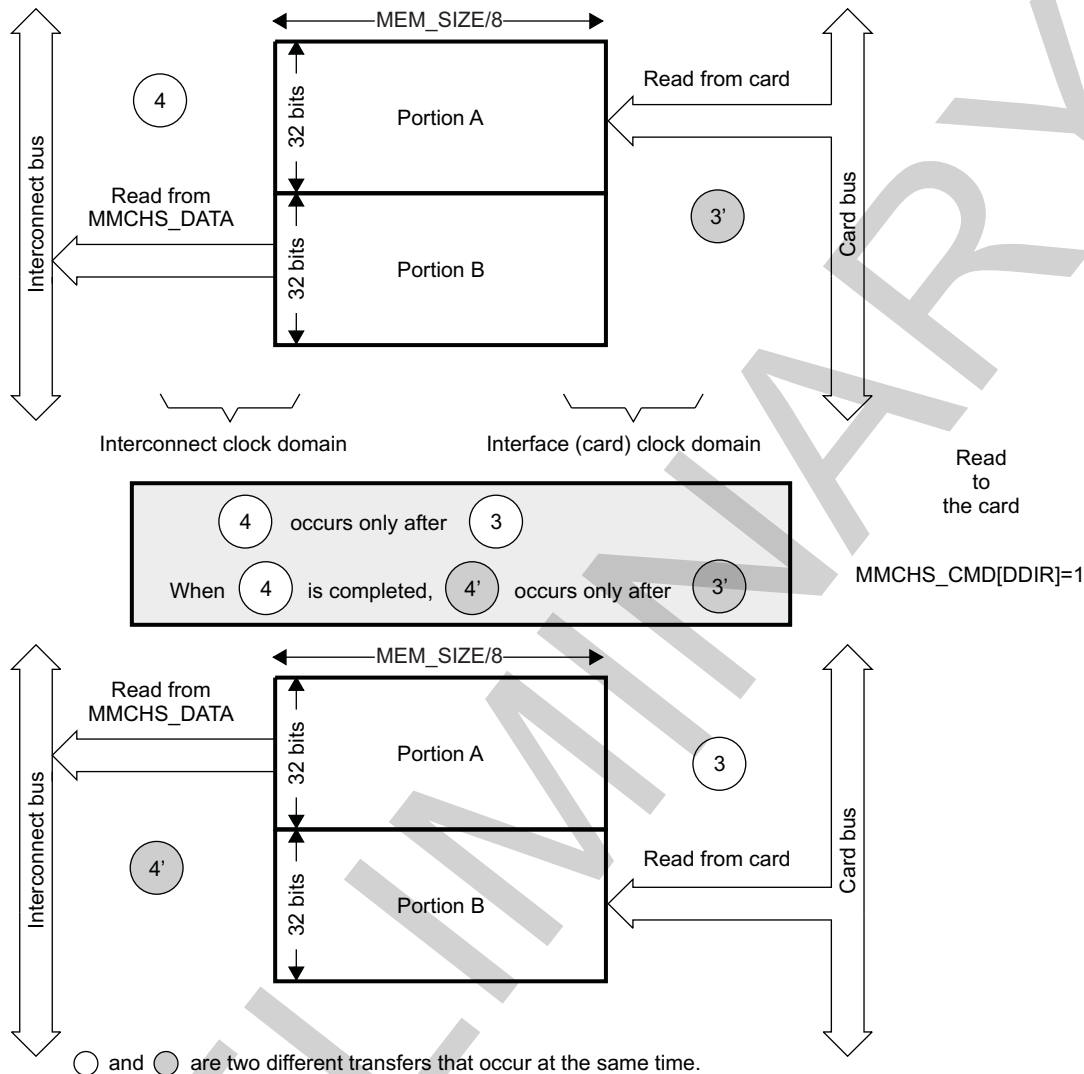

The MMCi.MMCHS_CMD[4] DDIR bit must be configured before a transfer to indicate the direction of the transfer.

Figure 25-22 and Figure 25-23 show the buffer management for a write and for a read, respectively.

Figure 25-22. Buffer Management for a Write

mmchs-022

Figure 25-23. Buffer Management for a Read

mmchs-023

- When the size of the data block to transfer is larger than $\text{MEM_SIZE}/2$, only one data transfer can occur at a time from one data bus to the other data bus. The MMC/SD/SDIOi host controller uses the entire data buffer as a single portion.

In this mode, a bad access (the MMCi.MMCHS_STAT[29] BADA bit) is signaled when two data transfers occur at the same time from one data bus to the other data bus, and vice versa.

25.4.7.1.1 Memory Size, Block Length, and Buffer-Management Relationship

The maximum block length and buffer management that can be targeted by the system depend on the memory depth setting (see Table 25-17).

NOTE: Double-buffering is always the buffer management for larger memory depth.

Table 25-17. Memory Size, BLLEN, and Buffer Relationship

| Memory Size (MMCHS_HL_HWINFO[5:2] MEM_SIZE in bytes) | 512 | 1024 |
|---|-----|------|
| Maximum block length supported | 512 | 1024 |

Table 25-17. Memory Size, BLEN, and Buffer Relationship (continued)

| Memory Size (MMCHS_HL_HWINFO [5:2] MEM_SIZE in bytes) | 512 | 1024 |
|---|----------|--------------|
| Double-buffering for maximum block length | N/A | BLEN=512 |
| Single-buffering for block length | BLEN=512 | 512BLEN=1024 |

NOTE: For single-buffering management, throughput on the MMC bus interface deteriorates in multiblock transfers, because the controller must wait for the filling or emptying of the buffer between each block transfer on the MMC bus. The clock is maintained on write MMC transfers (the [MMCHS_CMD](#)[3] DDIR bit is 0) and halted on read MMC transfers (the [MMCHS_CMD](#)[3] DDIR bit is 1).

25.4.7.1.2 Data Buffer Status

The data buffer status is defined in the following interrupt status register and status register:

- Interrupt status registers:
 - MMCi.[MMCHS_STAT](#)[29] BADA: Bad access to data space
 - MMCi.[MMCHS_STAT](#)[5] BRR: Buffer read ready
 - MMCi.[MMCHS_STAT](#)[4] BWR: Buffer write ready
- Status registers:
 - MMCi.[MMCHS_PSTATE](#)[11] BRE: Buffer read enable
 - MMCi.[MMCHS_PSTATE](#)[10] BWE: Buffer write enable

25.4.8 Transfer Process

The process of a transfer depends on the type of command. It can be with or without a response, and with or without data.

25.4.8.1 Different Types of Commands

Different types of commands are specific to the MMC, SD, and SDIO cards. For more information, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, *SDIO Card Specification, Part E1*, or *SD Card Specification, Part A2*, *SD Host Controller Standard Specification*.

25.4.8.2 Different Types of Responses

Different types of responses are specific to the MMC, SD, and SDIO cards. For more information, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, *SDIO Card Specification, Part E1*, or the *SD Card Specification, Part A2*, *SD Host Controller Standard Specification*.

[Table 25-18](#) describes how the MMC, SD, and SDIO responses are stored in the [MMCHS_RSPxx](#) registers.

Table 25-18. MMC, SD, SDIO Responses in the [MMCHS_RSPxx](#) Registers

| Kind of Response | Response Field | Response Register |
|--|---|--|
| R1, R1b (normal response), R3, R4, R5, R5b, R6, R7 | RESP [39:8] ⁽¹⁾ | MMCHS_RSP10 [31:0] |
| R1b (Auto CMD12 response) | RESP [39:8] ⁽¹⁾ | MMCHS_RSP76 [31:0] |
| R2 | RESP [127:0] ⁽¹⁾ | MMCHS_RSP76 [31:0] MMCHS_RSP54 [31:0] MMCHS_RSP32 [31:0] MMCHS_RSP10 [31:0] |

⁽¹⁾ RESP refers to the command response format described in the specifications mentioned.

When the host controller modifies part of the MMCHS_RSPxx registers, it preserves the unmodified bits.

The host controller stores the Auto CMD12 response in the [MMCHS_RSP76](#)[31:0] register because the host controller may have a multiple block data DAT line transfer executing concurrently with a command. This lets the host controller avoid overwriting the Auto CMD12 response with the command response stored in the [MMCHS_RSP10](#) register, and vice versa.

25.4.9 Transfer or Command Status and Errors Reporting

Flags in the MMC/SD/SDIOi host controller show the status of communication with the card:

- A time-out (of a command, data, or response)
- A CRC error

Error conditions generate interrupts. For more information, see [Table 25-19](#) and the register description.

Table 25-19. CC and TC Values Upon Error Detected

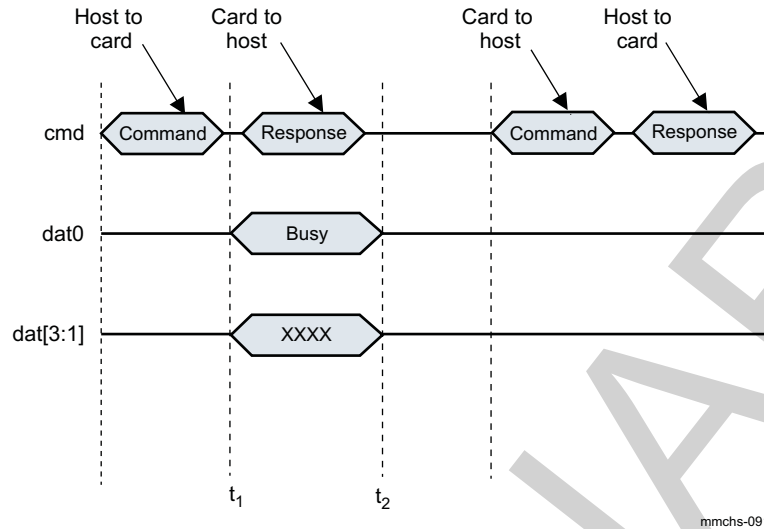

| Error Hold in MMCHS_STAT | CC | TC | Comments |
|--------------------------|----|----|--|
| 29 BADA | | | No dependency with CC or TC BADA is related to the MMCHS_DATA register accesses. Its assertion does not depend on the ongoing transfer. |
| 28 CERR | 1 | | CC is set upon CERR. |
| 22 DEB | | 1 | TC is set upon DEB. |
| 21 DCRC | | 1 | TC is set upon DCRC. |
| 20 DTO | | | DTO and TC are mutually exclusive. DCRC and DEB cannot occur with DTO. |
| 19 CIE | 1 | | CC is set upon CIE. |
| 18 CEB | 1 | | CC is set upon CEB. |
| 17 CCRC | 1 | | CC can be set upon CCRC. See CTO comment. |
| 16 CTO | | | CTO and CC are mutually exclusive. CIE, CEB, and CERR cannot occur with CTO. CTO can occur at the same time as CCRC: It indicates a command abort due to contention on the CMD line. In this case no CC appears. |

A [MMCHS_STAT](#)[21] DCRC event can be asserted in the following conditions:

- Busy time-out for R1b, R5b response type
- Busy time-out after write CRC status
- Write CRC status time-out
- Read data time-out
- Boot acknowledge time-out

25.4.9.1 Busy Time-Out for R1b, R5b Response Type

[Figure 25-24](#) shows the DCRC event condition asserted when there is busy time-out for Rb1, R5b response.

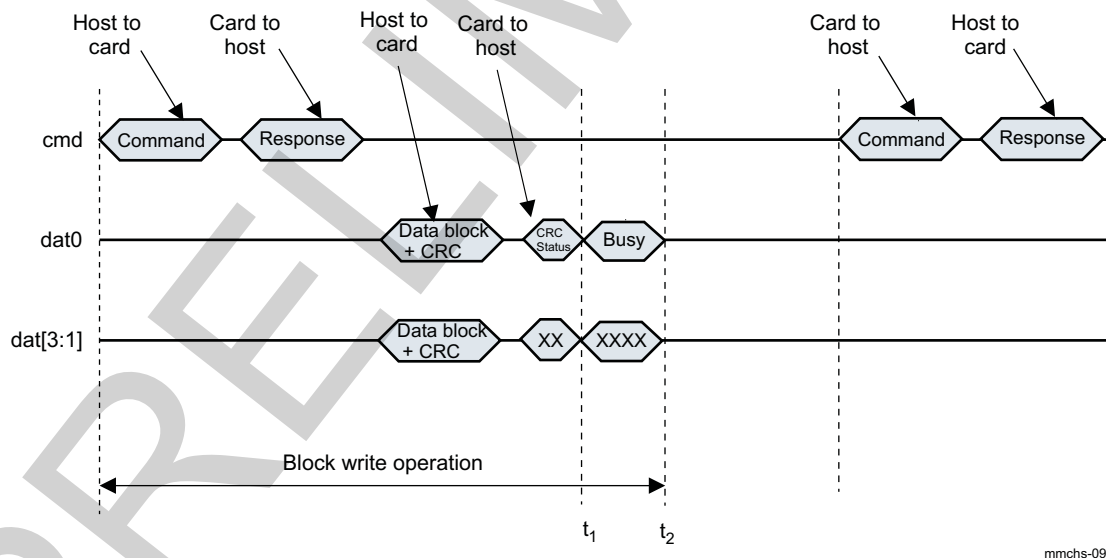

Figure 25-24. Busy Time-Out for R1b, R5b Response Type

t_1 – Data time-out counter is loaded and starts after R1b, R5b response type.

t_2 – Data time-out counter stops and if it is 0, the [MMCHS_STAT\[21\]](#) DCRC bit is generated.

25.4.9.2 Busy Time-Out After Write CRC Status

[Figure 25-25](#) shows the DCRC event condition asserted when there is busy time-out after write CRC status.

Figure 25-25. Busy Time-Out After Write CRC Status

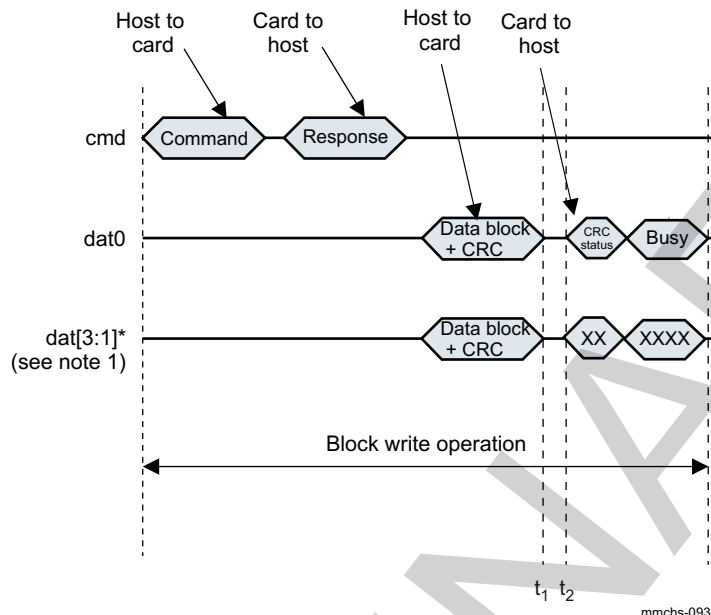

t_1 – Data time-out counter is loaded and starts after CRC status.

t_2 – Data time-out counter stops and if it is 0, the [MMCHS_STAT\[21\]](#) DCRC bit is generated.

25.4.9.3 Write CRC Status Time-Out

[Figure 25-26](#) shows the DCRC event condition asserted when there is write CRC status time-out.

Figure 25-26. Write CRC Status Time-Out

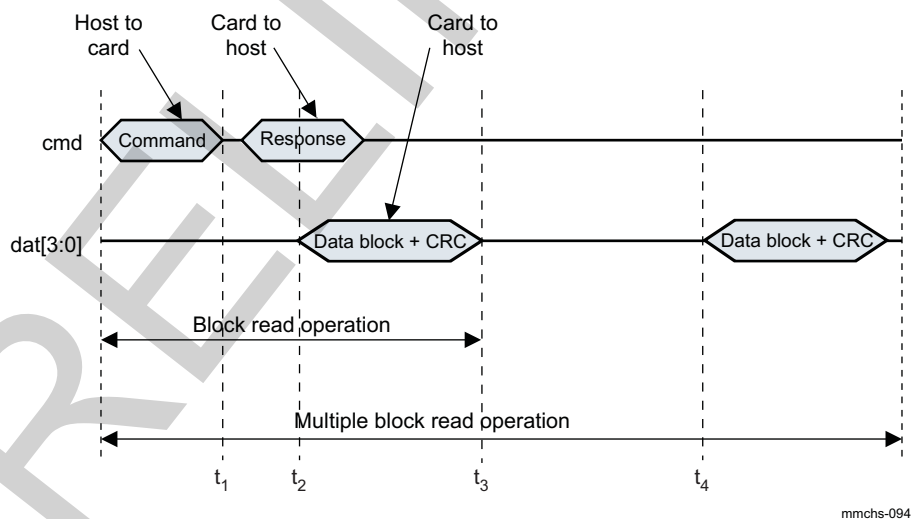

t_1 – Data time-out counter is loaded and starts after data block + CRC.

t_2 – Data time-out counter stops and if it is 0, the [MMCHS_STAT\[21\]](#) DCRC bit is generated.

25.4.9.4 Read Data Time-Out

[Figure 25-27](#) shows the DCRC event condition asserted when there is read data time-out.

Figure 25-27. Read Data Time-Out

t_1 – Data time-out counter is loaded and starts after command transmission.

t_2 – Data time-out counter stops and if it is 0, the [MMCHS_STAT\[21\]](#) DCRC bit is generated.

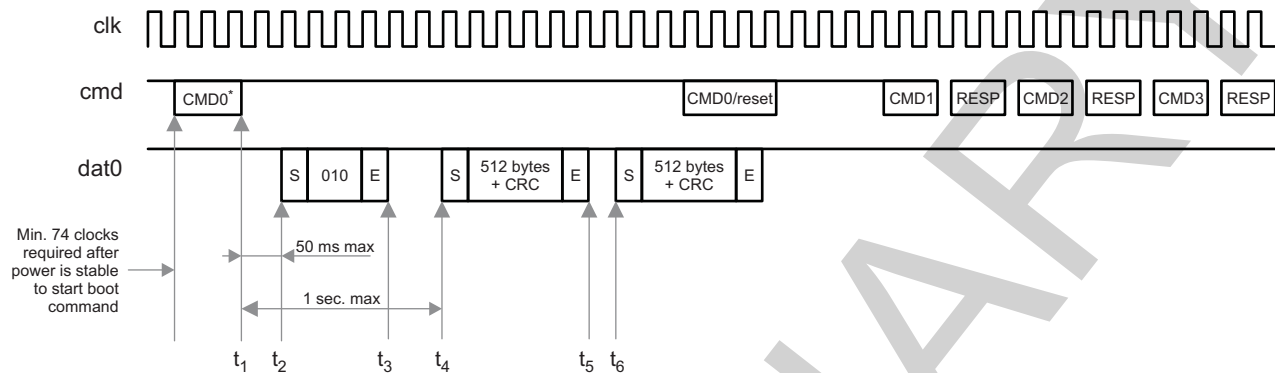

t_3 – Data time-out counter is loaded and starts after data block + CRC transmission.

t_4 – Data time-out counter stops and if it is 0, the [MMCHS_STAT\[21\]](#) DCRC bit is generated.

25.4.9.5 Boot Acknowledge Time-Out

Figure 25-28 shows the DCRC event condition asserted when there is a boot acknowledge time-out and CMD0 is used.

Figure 25-28. Boot Acknowledge Time-Out When Using CMD0

* Refer to MMC specification for correct Argument

mmchs-095

- t₁ – Data time-out counter is loaded and starts after CMD0.
- t₂ – Data time-out counter stops and if it is 0, the [MMCHS_STAT\[21\]](#) DCRC bit is generated.
- t₃ – Data time-out counter is loaded and starts.
- t₄ – Data time-out counter stops and if it is 0, the [MMCHS_STAT\[21\]](#) DCRC bit is generated.
- t₅ – Data time-out counter is loaded and starts after data + CRC transmission.
- t₆ – Data time-out counter stops and if it is 0, the [MMCHS_STAT\[21\]](#) DCRC bit is generated.

Figure 25-29 shows the DCRC event condition asserted when there is boot acknowledge time-out when the CMD line is tied to 0.

Figure 25-29. Boot Acknowledge Time-Out When CMD Line Tied to 0

mmchs-096

- t₁ – Data time-out counter is loaded and starts after the CMD line is tied to 0.
- t₂ – Data time-out counter stops and if it is 0, the [MMCHS_STAT\[21\]](#) DCRC bit is generated.
- t₃ – Data time-out counter is loaded and starts.
- t₄ – Data time-out counter stops and if it is 0, the [MMCHS_STAT\[21\]](#) DCRC bit is generated.
- t₅ – Data time-out counter is loaded and starts after data + CRC transmission.
- t₆ – Data time-out counter stops and if it is 0, the [MMCHS_STAT\[21\]](#) DCRC bit is generated.

25.4.10 Auto Command 12 Timings

With the UHS definition of SD cards with higher frequency for MMC clock up to 208, the SD standard imposes a specific timing for the arrival of the auto command 12 (ACMD12) end bit.

25.4.10.1 ACMD12 Timings During Write Transfer

A margin named Nrc in the range of two to eight cycles has been defined for SDR50 and SDR104 card components for write data transfers, because the ACMD12 end bit must arrive after the CRC status end bit.

Figure 25-30 shows the ACMD12 timings during write transfer.

The host controller has a margin of 18 clock cycles to ensure that the ACMD12 end bit arrives after the CRC status. This margin does not depend on the MMC bus configuration, DDR, or standard transfer, 1-, 4-, or 8-bit bus width.

25.4.10.2 ACMD12 Timings During Read Transfer

With UHS cards, the gap timing between two successive cards has been extended from two cycles to four cycles. It provides more flexibility for the host ACMD12 arrival to receive the last complete and reliable block. The MMCHS controller follows only the left border case defined by the SD UHS specification.

Figure 25-31 shows ACMD12 timings during read transfer.

The ACMD12 arrival sent by the host controller is not sensitive to the MMC bus configuration, whether it is a DDR or standard transfer and whether it is a 1-, 4-, or 8-bit bus width transfer.

25.4.11 Transfer Stop

Whenever a transfer is initiated, the transmission may be willed to stop while it is still not finished. Several cases are possible, depending on the transfer type:

- Multiple-block-oriented transfers (transfer length is known)

- Continuous stream transfers (transfer has an infinite length)

NOTE: Because the MMC/SD/SDIOi controller manages transfers based on a block granularity, the buffer accepts a block only if there is enough space to store it completely. Consequently, if a block is pending in the buffer, no command is sent to the card because the card clock will be shut off by the controller.

The MMC/SD/SDIOi controller includes two features that make a transfer stop more convenient and easier to manage:

- ACMD12 (for MMC and SD only):

This feature is enabled by setting the MMCI.MMCHS_CMD[2] ACEN bit to 0x1 (this setting is relevant for a MMC/SD transfer with a known number of blocks to transfer). When the ACMD12 feature is enabled, the MMC/SD/SDIOi controller automatically issues a CMD12 command when the expected number of blocks is exchanged.

- Stop at block gap:

This feature is enabled by setting the MMCI.MMCHS_HCTL[16] SBGR bit to 0x1. When enabled, this capability holds the transfer on until the end of a block boundary. If a stop transmission is needed, software can use this pause to send a CMD12 to the card.

- ADMA mode:

For ADMA-capable modules (MMC1 and MMC2) (for more information, see [Section 25.4.5, DMA Modes](#)), the last instruction can stop the transfer (the END bit is enabled in the descriptor line).

NOTE: For MMC and SD cards, the stop-at-block-gap feature is not supported in read mode.

For SDIO cards, this setting can be supported in read mode if the card has a read-wait capability.

[Table 25-20](#) shows the common way to stop a transfer, indicating the command to send and the features to enable.

Table 25-20. MMC/SD/SDIOi Controller Transfer Stop Command Summary

| | | Write Transfer | | Read Transfer | |
|-------------------------------------|---|---|---|---|---|
| | | SD/MMC | SDIO | SD/MMC | SDIO |
| Single block | | Transfer ends automatically. Wait TC. | Transfer ends automatically. Wait TC. | Transfer ends automatically. Wait TC. | Transfer ends automatically. Wait TC. |
| Multiblocks (finite or infinite) | Before the programmed block boundary | Send CMD12. Wait TC. | Send CMD52. Wait TC. | Send CMD12. Wait TC. | Send CMD52. Wait TC. |
| | Stop at the end of the transfer (finite transfer only) | ACMD12 active Transfer ends automatically. Wait TC. | Set MMCI.MMCHS_HCTL[16] SBGR bit to 0x1. Send CMD52. Wait TC. | ACMD12 active Transfer ends automatically. Wait TC. | If READ_WAIT supported Stop at block gap. Wait TC. <hr/> If READ_WAIT not supported Send CMD52. Wait TC. |

NOTE: The MMC/SD/SDIOi controller sends the stop command to the card on a block boundary, regardless of when the command was written to the controller registers.

25.4.12 Retention Mode

This mode is enabled if the generic parameter bit MMCHS_HL_HWINFO[6] RETMODE is set to 1 during module integration. The controller can enter into retention mode when the module was previously set in

idle mode. When the module goes into retention mode all clocks are left inactive at low level except for registers that are driven by a falling-edge clock, which are kept as free during retention mode. This also means that all divided functional clock subdomains are forced low when the module enters smart-idle mode. In force-idle mode, the system must ensure that all divided functional clocks are set inactive or are in bypass mode by configuring the [MMCHS_SYSCTL](#) register correctly before entering idle mode (under software responsibility).

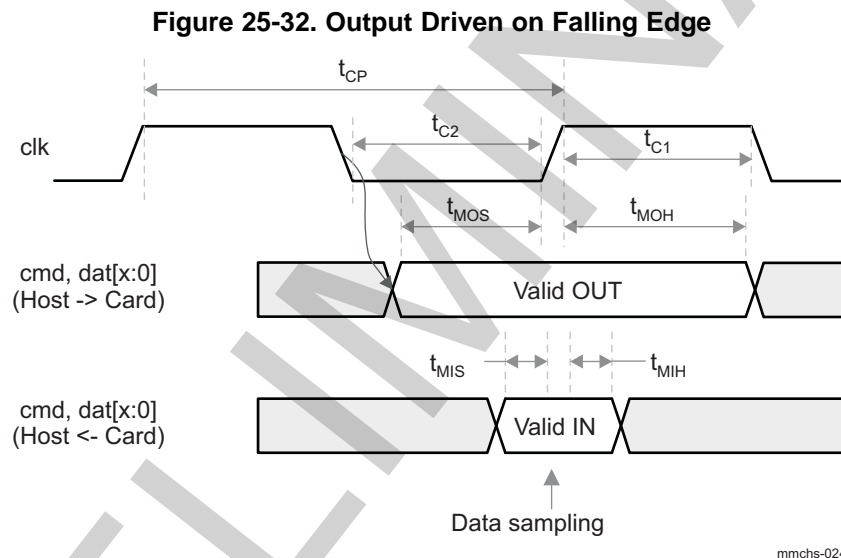

25.4.13 Output Signals Generation

The MMC/SD/SDIO output signals can be driven on the falling edge or rising edge, depending on the [MMCHS_HCTL\[2\]](#) HSPE bit. This feature allows reaching better timing performance, and thus increasing data transfer frequency.

25.4.13.1 Generation on Falling Edge of MMC Clock

The controller is by default in this mode to maximize hold timings. In this case, the [MMCHS_HCTL\[2\]](#) HSPE bit is set to 0.

[Figure 25-32](#) shows the output signals of the module when generating from the falling edge of the MMC clock.

25.4.13.2 Generation on Rising Edge of MMC Clock

This mode increases setup timings and allows reaching higher bus frequency. This feature is activated by setting the [MMCHS_HCTL\[2\]](#) HSPE bit to 1. The controller must be set in this mode to support SDR transfers.

NOTE: Do not use this feature in DDR mode (when the [MMCHS_CON\[19\]](#) DDR bit is set to 1).

[Figure 25-33](#) shows the output signals of the module when generating from the rising edge of the MMC clock.

Figure 25-33. Output Driven on Rising Edge

mmchs-025

25.4.14 Card Boot Mode Management

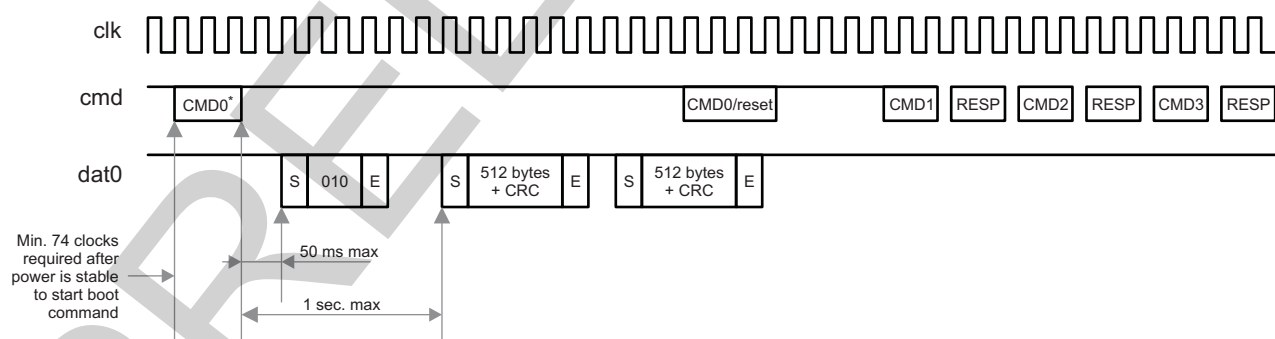

Boot operation mode allows the MMC/SD/SDIOi host controller to read boot data from the connected slave (MMC device) by keeping CMD line low after power on (or sending CMD0 with a specific argument) before issuing CMD1. The data can be read from the boot area or user area, depending on the register setting.

Power-on boot defines a way for the boot code to be accessed by the MMC/SD/SDIOi host controller without an upper-level software driver, speeding the time it takes for a controller to access the boot code.

The two possible ways to issue a boot command (issuing a CMD0 or driving the CMD line to 0 during the whole boot phase) are described in the following sections.

25.4.14.1 Boot Mode Using CMD0

Figure 25-34 shows the timing diagram of a boot sequence using CMD0.

Figure 25-34. Boot Mode Using the CMD0 Timing Diagram

* Refer to MMC specification for correct Argument

mmchs-026

For more information about how to configure the MMC/SD/SDIO host controller, see [Section 25.5.1.2.3.1, Boot Using the CMD0](#).

25.4.14.2 Boot Mode With CMD Line Tied to 0

Figure 25-35 shows the timing diagram of a boot sequence with CMD line tied to 0.

Figure 25-35. Boot Mode With CMD Line Tied to 0 Timing Diagram

For more information about how to configure the MMC/SD/SDIO host controller, see [Section 25.5.1.2.3.2, Boot With CMD Line Tied to 0](#).

25.4.15 MMC CE-ATA Command Completion Disable Management

The MMC/SD/SDIOi host controller supports CE-ATA features, in particular the detection of command completion token. When a command that requires a command completion signal (the [MMCHS_CON\[12\]](#) CEATA and [MMCHS_CMD\[2\]](#) ACEN bits set to 1) is launched, the host system is no longer allowed to emit a new command in parallel to the data transfer unless it is a command completion disable token.

The settings to emit a command completion disable token are:

- The [MMCHS_CON\[12\]](#) CEATA bit is set to 1.
- The [MMCHS_CON\[2\]](#) bit HR set to 1.
- Clear the [MMCHS_ARG](#) register.
- Write into the [MMCHS_CMD](#) register with the value 0x00000000.

When a command completion disable token was emitted (that is, the [MMCHS_STAT\[0\]](#) CC bit received), the host system is again allowed to emit another type of command (for example, a CMD12 to abort transfer).

A critical case can be encountered when command completion signal disable (CCSD) is emitted during the last data block transfer, and the sequence on the command line is sent close to the command completion signal (CCS) token sent by the card.

Three possible cases are:

- CCS is received immediately before CCSD is emitted:
An interrupt CIRQ is generated with CCS detection, CCSD is transmitted to the card, and then an interrupt CC is generated when CCSD ends. In this case, the card considers the CCSD sequence.
- CCS is not generated or is generated during the CCSD transfer:
The CCS bit cannot be detected (conflict is not possible because they drive the same level on the command line, and no CIRQ interrupt is generated; a CC interrupt is generated when CCSD ends).
- CCS is generated without CCSD token required:
Only the interrupt CIRQ is generated when CCS is detected.

25.4.16 Test Registers

Test registers are available to comply with the *SD Host Controller Specification*. This feature is useful to generate interrupts manually for driver debugging.

The force event register ([MMCHS_FE](#)) is used to control the error interrupt status and ACMD12 error status.

The system test register ([MMCHS_SYSTEST](#)) is used to control the signals that connect to I/O pins when the module is configured in the system test mode (the [MMCHS_CON](#)[4] MODE bit = 1) for boundary connectivity verification.

25.4.17 MMC/SD/SDIO Hardware Status Features

[Table 25-21](#) describes the MMC/SD/SDIO hardware status features.

Table 25-21. MMC/SD/SDIO Hardware Status Features

| Feature | Type | Register/Bit Field/Observability Control | Description |
|-----------------------------|--------|--|---|
| Interrupt flags | | See Section 25.4.4 , <i>Interrupt Requests</i> . | |
| CMD line signal level | Status | MMCHS_PSTATE [24] CLEV | Indicates the level of the command line |
| DAT lines signal level | Status | MMCHS_PSTATE [23:20] DLEV | Indicates the level of the data lines |
| Buffer read enable | Status | MMCHS_PSTATE [11] BRE | Readable data exists in the buffer. |
| Buffer write enable | Status | MMCHS_PSTATE [10] BWE | Indicates whether there is enough space in the buffer to write BLEN bytes of data |
| Read transfer active | Status | MMCHS_PSTATE [9] RTA | Used to detect completion of a read transfer. |
| Write transfer active | Status | MMCHS_PSTATE [8] WTA | Indicates a write transfer active |
| Data line active | Status | MMCHS_PSTATE [2] DLA | Indicates whether the data lines are active |
| Command Inhibit (DAT lines) | Status | MMCHS_PSTATE [1] DATI | Indicates whether issuing of command using data lines is allowed |
| Command inhibit (CMD line) | Status | MMCHS_PSTATE [0] CMDI | Indicates whether issuing of command using command line is allowed |

25.5 MMC/SD/SDIO Programming Guide

25.5.1 Low-Level Programming Models

25.5.1.1 Global Initialization

25.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the module must be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MMC/SD/SDIO modules. For more information, see [Section 25.3](#), *MMC/SD/SDIO Integration*, and [Section 25.2](#), *MMC/SD/SDIO Environment*.

Table 25-22. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|-----------------------------------|---|
| PRCM | Module interface and functional clocks must be enabled. See Chapter 3 , <i>Power, Reset, and Clock Management</i> . |
| Control module | Module-specific pad muxing and configuration must be set in the control module. See Chapter 19 , <i>Control Module</i> . |
| (optional) MPU INTC (or DSP INTC) | MPU INTC configuration must be done to enable the interrupts from the MMCHS module. See Chapter 18 , <i>Interrupt Controllers</i> . |
| (optional) sDMA (or dDMA) | DMA configuration must be done to enable the module DMA channel requests. See Chapter 17 , <i>sDMA</i> . |
| (optional) Interconnect | For more information about the interconnect configuration, see Chapter 14 , <i>Interconnect</i> . |

NOTE: The MPU/DSP INTC and the sDMA/dDMA configurations are necessary if the interrupt and DMA-based communication modes are used.

25.5.1.1.2 MMC/SD/SDIO Host Controller Initialization Flow

[Table 25-23](#) shows the general boot process.

Table 25-23. MMC/SD/SDIO Controller Meta Initialization Steps

| Step | Access Type | Register/Bit Field/Programming Model | Value |
|------------------------------------|-------------|--|-------|
| Initialize clocks. | | See Section 25.5.1.1.2.1 . | |
| Software reset of the controller. | | See Section 25.5.1.1.2.2 . | |
| Set module hardware capabilities. | | See Section 25.5.1.1.2.3 . | |
| Set module idle and wake-up modes. | | See Section 25.5.1.1.2.4 . | |

25.5.1.1.2.1 Enable Interface and Functional clock for MMC Controller

Before any MMCHS register access, the MMCHS interface clock and functional clock in the PRCM module registers must be enabled. See [Section 3.6.9.4](#), *Clock Domain Module Attributes*, in [Chapter 3](#), *Power, Reset, and Clock Management*.

25.5.1.1.2.2 MMCHS Soft Reset Flow

[Figure 25-36](#) shows the soft reset process of the MMCHS controller.

Figure 25-36. MMC/SD/SDIO Controller Software Reset Flow**Table 25-24. Register Call Summary for Main Sequence – Software Reset Flow**

| Register Name | Register Name |
|---------------------------------|---------------------------------|
| MMCHS_SYSCONFIG | MMCHS_SYSSTATUS |

25.5.1.1.2.3 Set MMCHS Default Capabilities

Software must read capabilities (in boot ROM, for example) and is allowed to set (write) the MMCi.[MMCHS_CAPA](#)[26:24] and MMCi.[MMCHS_CUR_CAPA](#)[23:0] bit fields before the MMC/SD/SDIO host driver is started.

25.5.1.1.2.4 Wake-Up Configuration

[Table 25-25](#) describes the MMCHS controller wake-up configuration.

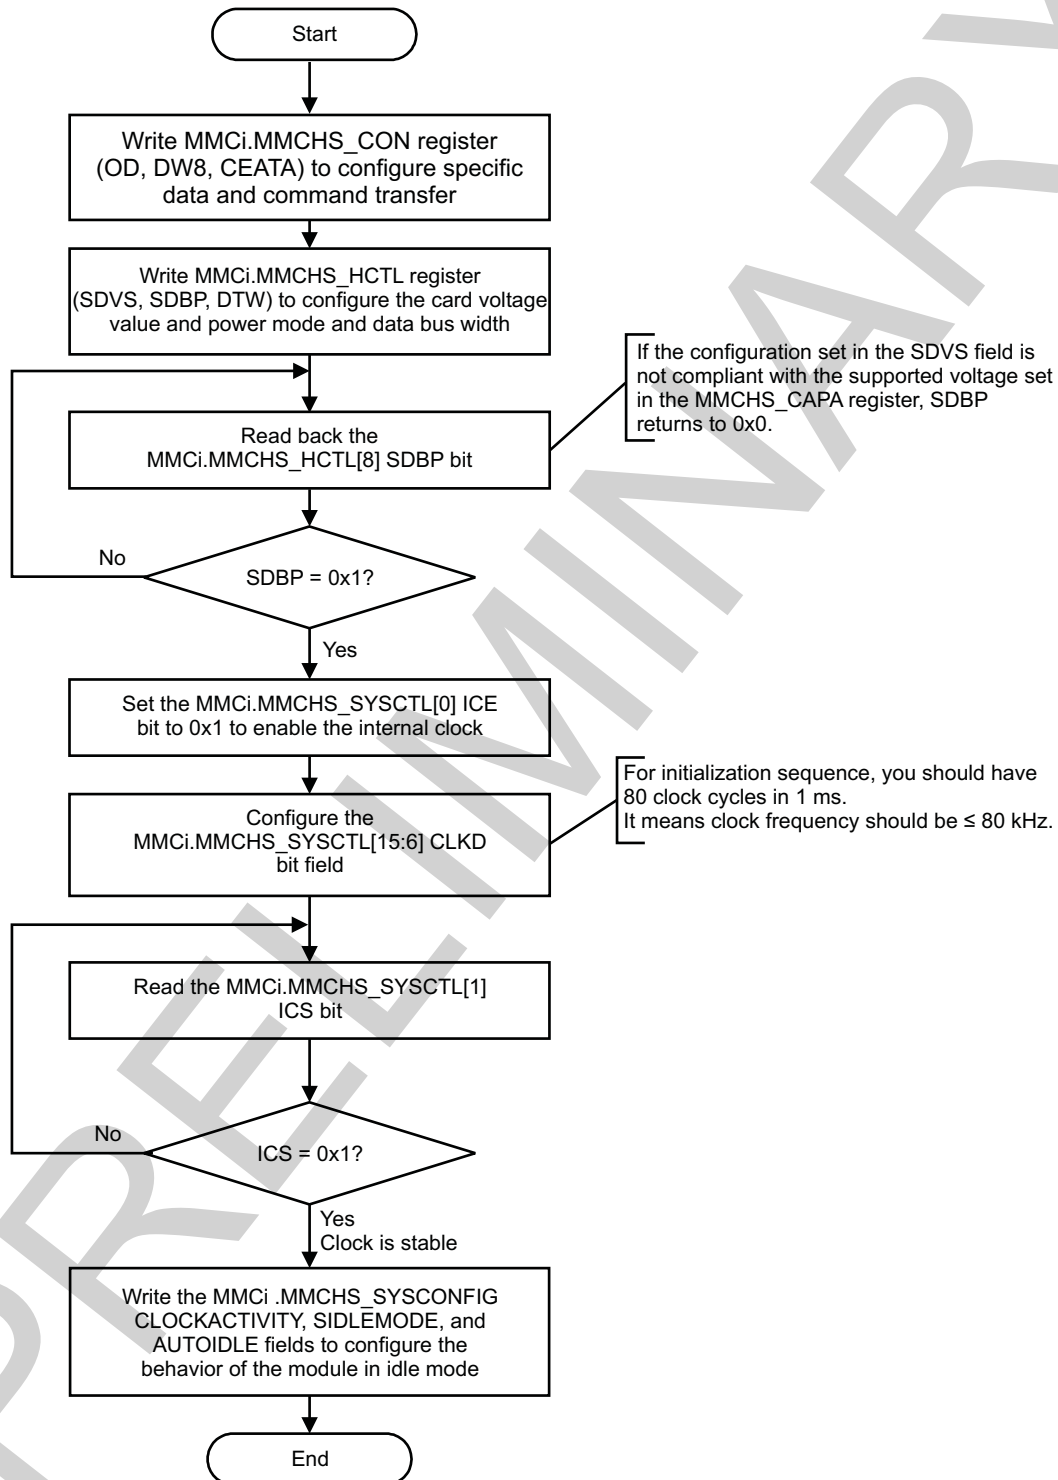

Table 25-25. MMC/SD/SDIO Controller Wake-Up Configuration

| Step | Access Type | Register/Bit Field/Programming Model | Value |
|--|-------------|---|-------|
| Configure wake-up bit (if necessary). | W | MMCi. MMCHS_SYSCONFIG [2] ENAWAKEUP | 0x1 |
| Enable wake-up events on SD card interrupt (if necessary). | W | MMCi. MMCHS_HCTL [24] IWE | 0x1 |
| SDIO card only: Enable card interrupt (if necessary). | W | MMCi. MMCHS_IE [8] CIRQ_ENABLE | 0x1 |

25.5.1.1.2.5 MMC Host and Bus Configuration

Figure 25-37 shows the MMC bus configuration process.

Figure 25-37. MMC/SD/SDIO Controller Bus Configuration

| MMCHS_SYSCONFIG | MMCHS_SYSCTL |

25.5.1.2 Operational Modes Configuration

25.5.1.2.1 Basic Operations for MMC/SD/SDIO Host Controller

The MMC/SD/SDIO host controller performs data transfers: data to card (referred to as write transfers) and data from card (referred to as read transfers).

The host controller requires transfers to run on a block-by-block basis rather than on a DMA burst size basis. A single DMA request (or block request interrupt) is signaled for each block. Pipelining is supported as long as the block size is less than one half of the memory buffer size.

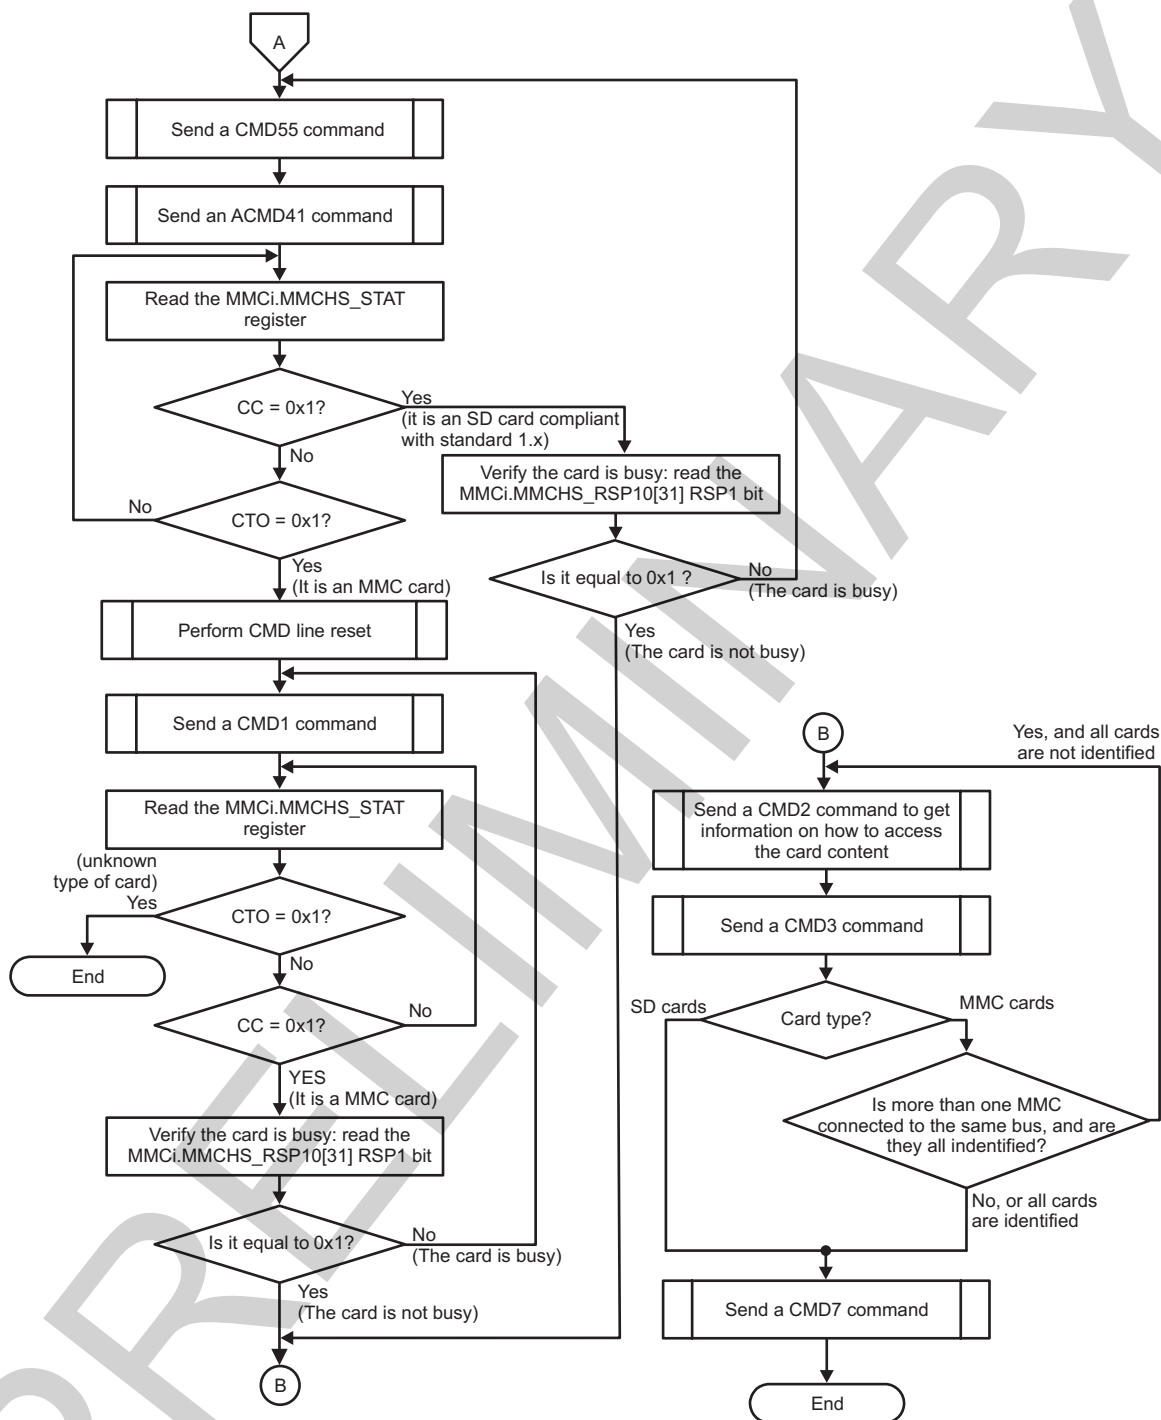

25.5.1.2.1.1 Card Detection, Identification, and Selection

[Figure 25-38](#) and [Figure 25-39](#) show the card identification and selection process.

Figure 25-38. MMC/SD/SDIO Controller Card Identification and Selection – Part 1

mmchs-030

CAUTION

CE-ATA protocol is supported only by MMC cards.

In CE-ATA mode, issuing a command during the transfer (except a CCSD command) is not allowed.

In CE-ATA mode, infinite transfers are not allowed; only finite transfers are permitted.

25.5.1.2.1.6 Suspend-Resume Flow

The suspend and resume feature is supported only by SDIO cards.

25.5.1.2.1.6.1 Suspend Flow

[Figure 25-44](#) shows the suspend flow for SDIO cards.

| Send SWITCH command (CMD6). | Section 25.5.1.2.1.7.1 |

25.5.1.2.2 Bus Voltage Selection

The MMC/SD/SDIO1 controller can operate with two types of card voltages: 1.8 V and 3.0 V. For this reason, dual voltage pads are implemented on this interface. For technological concerns, those pads must have an internal bias voltage reference to operate. The PBIAS module supplies this bias voltage, depending on the settings of the CONTROL.CONTROL_PBIASLITE register.

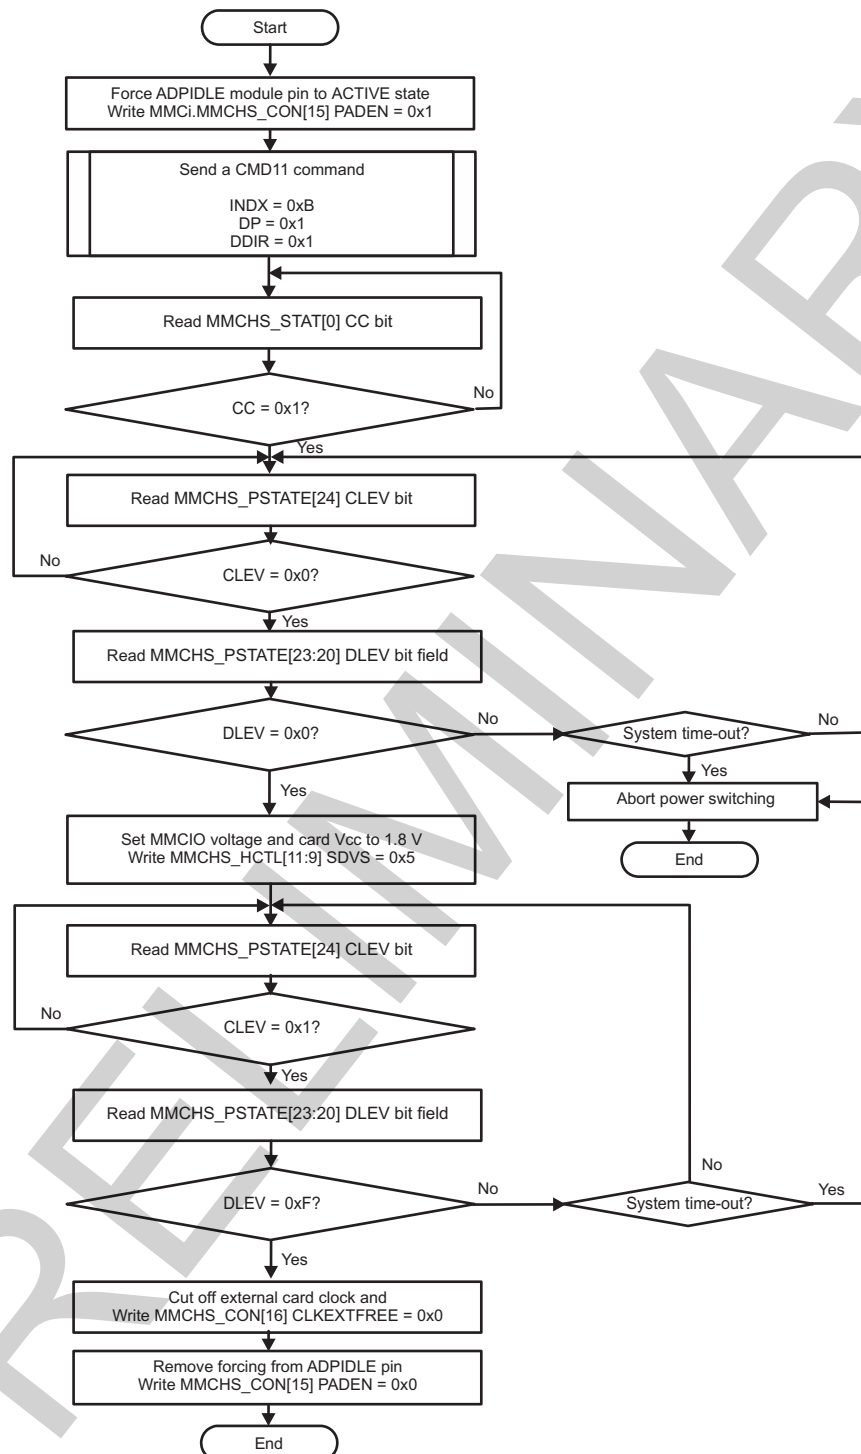

For more information about the MMC1_PBIAS cell, see [Section 19.4.9](#), *Extended-Drain I/O and PBIAS Cell*, in [Chapter 19](#), *Control Module*.

For the steps involved in transitioning from 1.8 V to 3.0 V and from 3.0 V to 1.8 V, applicable to the MMC/SD/SDIO1 controller, see [Section 19.5.1.2.1](#), *Extended-Drain I/Os and PBIAS Cell Programming Guide*, in [Chapter 19](#), *Control Module*.

CAUTION

The BIAS voltage must be set using the procedure described in [Section 19.5.1.2.1](#), *Extended-Drain I/Os and PBIAS Cell Programming Guide*, in [Chapter 19](#), *Control Module*. Failure to follow this procedure can damage the MMCHS interface.

[Figure 25-50](#) shows how to configure the MMCHS controller to fit with power switching sequence.

Figure 25-50. MMC/SD/SDIO Power Switching Procedure

mmchs-042

25.5.1.2.3 Boot Mode Configuration

The following sections describe the two possible ways to issue a boot command: issue a CMD0 or drive the CMD line to 0 during the whole boot phase.

25.5.1.2.3.1 Boot Using CMD0

[Figure 25-51](#) shows the necessary steps to configure the controller boot mode using CMD0.

Figure 25-51. MMC/SD/SDIO Controller Boot Using CMD0

mmchs-043

To abort a boot sequence, the system must issue a CMD0 with the [MMCHS_CMD](#)[23:22] CMD_TYPE bit field set to 0x3 (the [MMCHS_CON](#)[17] BOOT_ACK bit previously cleared to 0x0) during the transfer to abort the transfer and enable the card to exit from boot state.

Table 25-52. Register Call Summary for Main Sequence – Boot Using CMD0

| Register Name | Register Name | Register Name |

| RESERVED | | | | | | | | | | | | | | | | | | | | | | | RETMODE | MEM_SIZE | | | MERGE_MEM | MADMA_EN | | | |
| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-----------------------------------|
| 31:7 | RESERVED | Reserved | R | 0x00000000 |
| 6 | RETMODE | Retention mode generic parameter This bit field indicates whether the retention mode is supported using the pin PIRFFRET. 0x0: Retention mode disabled 0x1: Retention mode enabled | R | See Table 25-63 . |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|---|
| 5:2 | MEM_SIZE | Memory size for FIFO buffer: Read 0x1: Memory of 512 bytes, max block length is 512 bytes Read 0x2: Memory of 1024 bytes, max block length is 1024 bytes Read 0x4: Memory of 2048 bytes, max block length is 2048 bytes Read 0x8: Memory of 4096 bytes, max block length is 2048 bytes | R | 0x2 |
| 1 | MERGE_MEM | Memory merged for FIFO buffer: This register defines the configuration of FIFO buffer architecture. If the bit is set STA and DFT shall support clock multiplexing and balancing. Read 0x0: 2 memories instantiated, one per data transfer direction. Read 0x1: A single memory is used with multiplexed addresses, data and clocks. | R | 0 |
| 0 | MADMA_EN | Master DMA enabled generic parameter: This register defines the configuration of the controller to know if it supports the master DMA management called ADMA. Read 0x0: No Master DMA (ADMA) management supported Read 0x1: Controller supports ADMA | R | Please refer to Table 25-64 |

| Description | System Test register This register is used to control the signals that connect to I/O pins when the module is configured in system test (SYSTEST) mode for boundary connectivity verification. Note: In SYSTEST mode, a write into MMCHS_CMD register will not start a transfer. The buffer behaves as a stack accessible only by the local host (push and pop operations). In this mode, the Transfer Block Size (MMCHS_BLK [11:0] BLEN) and the Blocks count for current transfer (MMCHS_BLK [31:16] NBLK) are needed to generate a Buffer write ready interrupt (MMCHS_STAT [4] BWR) or a Buffer read ready interrupt (MMCHS_STAT [5] BRR) and DMA requests if enabled. | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-------|
| 21 | SDMA_LNE | <p>Slave DMA Level/Edge Request: The waveform of the DMA request can be configured either edge sensitive with early de-assertion on first access to MMCHS_DATA register or late de-assertion, request remains active until last allowed data written into MMCHS_DATA.</p> <p>0x0: Slave DMA edge sensitive, Early DMA de-assertion 0x1: Slave DMA level sensitive, Late DMA de-assertion</p> | RW | 0 |
| 20 | DMA_MNS | <p>DMA Master or Slave selection: When this bit is set and the controller is configured to use the DMA, Interconnect master interface is used to get datas from system using ADMA2 procedure (direct access to the memory). This option is only available if generic parameter MMCHS_HL_HWINFO[0] MADMA_EN is asserted to 1.</p> <p>0x0: The controller is slave on data transfers with system. 0x1: The controller is master on data exchange with system, controller must be configured as using DMA.</p> | RW | 0 |
| 19 | DDR | <p>Dual Data Rate mode: When this register is set, the controller uses both clock edge to emit or receive data. Odd bytes are transmitted on falling edges and even bytes are transmitted on rise edges. It only applies on Data bytes and CRC, Start, end bits and CRC status are kept full cycle. This bit field is only meaningful and active for even clock divider ratio of MMCHS_SYSCCTL[15:6] CLKD, it is insensitive to MMCHS_HCTL[2] HSPE setting.</p> <p>0x0: Standard mode : data are transmitted on a single edge depending on MMCHS_HCTL[2] HSPE. 0x1: Data Bytes and CRC are transmitted on both edge.</p> | RW | 0 |
| 18 | BOOT_CF0 | <p>Boot status supported: This register is set when the CMD line need to be forced to 0 for a boot sequence. CMD line is driven to 0 after writing in MMCHS_CMD. The line is released when this bit field is de-asserted and abort data transfer in case of a pending transaction.</p> <p>Write 0x0: CMD line is released when it was previously forced to 0 by a boot sequence. Read 0x0: CMD line not forced Read 0x1: CMD line forced to 0 is enabled Write 0x1: CMD line forced to 0 is enabled and will be active after writing into MMCHS_CMD</p> | RW | 0 |
| 17 | BOOT_ACK | <p>Book acknowledge received: When this bit is set the controller should receive a boot status on DAT0 line after next command issued. If no status is received a data timeout will be generated.</p> <p>0x0: No acknowledge to be received 0x1: A boot status will be received on DAT0 line after issuing a command.</p> | RW | 0 |
| 16 | CLKEXTFREE | <p>External clock free running: This register is used to maintain card clock out of transfer transaction to enable slave module for example to generate a synchronous interrupt on DAT[1]. The Clock will be maintain only if MMCHS_SYSCCTL[2] CEN is set.</p> <p>0x0: External card clock is cut off outside active transaction period. 0x1: External card clock is maintain even out of active transaction period only if MMCHS_SYSCCTL[2] CEN is set.</p> | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 15 | PADEN | Control Power for MMC Lines: This register is only useful when MMC PADs contain power saving mechanism to minimize its leakage power. It works as a GPIO that directly control the ACTIVE pin of PADs. Excepted for DAT[1], the signal is also combine outside the module with the dedicated power control MMCHS_CON[11] CTPL bit. 0x0: ADPIDLE module pin is not forced, it is automatically generated by the MMC fsms. 0x1: ADPIDLE module pin is forced to active state. | RW | 0 |
| 14 | OBIE | Out-of-Band Interrupt Enable MMC cards only: This bit enables the detection of Out-of-Band Interrupt on MMC_OBI input pin. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration. 0x0: Out-of-Band interrupt detection disabled 0x1: Out-of-Band interrupt detection enabled | RW | 0 |
| 13 | OBIP | Out-of-Band Interrupt Polarity MMC cards only: This bit selects the active level of the out-of-band interrupt coming from MMC cards. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration. 0x0: active high level 0x1: active low level | RW | 0 |
| 12 | CEATA | CE-ATA control mode MMC cards compliant with CE-ATA:By default, this bit is set to 0. It is use to indicate that next commands are considered as specific CE-ATA commands that potentially use 'command completion' features. 0x0: Standard MMC/SD/SDIO mode. 0x1: CE-ATA mode next commands are considered as CE-ATA commands. | RW | 0 |
| 11 | CTPL | Control Power for DAT[1] line MMC and SD cards: By default, this bit is set to 0 and the host controller automatically disables all the input buffers outside of a transaction to minimize the leakage current. SDIO cards: When this bit is set to 1, the host controller automatically disables all the input buffers except the buffer of DAT[1] outside of a transaction in order to detect asynchronous card interrupt on DAT[1] line and minimize the leakage current of the buffers. 0x0: Disable all the input buffers outside of a transaction. 0x1: Disable all the input buffers except the buffer of DAT[1] outside of a transaction. | RW | 0 |
| 10:9 | DVAL | Debounce filter value All cards This register is used to define a debounce period to filter the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: 33 us debounce period 0x1: 231 us debounce period 0x2: 1 ms debounce period 0x3: 8,4 ms debounce period | RW | 0x3 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 8 | WPP | <p>Write protect polarity For SD and SDIO cards only This bit selects the active level of the write protect input signal (SDWP). The usage of the write protect input signal (SDWP) is optional and depends on the system integration and the type of the connector housing that accommodates the card.</p> <p>0x0: active high level 0x1: active low level</p> | RW | 0 |
| 7 | CDP | <p>Card detect polarity All cards This bit selects the active level of the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card.</p> <p>0x0: active high level 0x1: active low level</p> | RW | 0 |
| 6 | MIT | <p>MMC interrupt command Only for MMC cards. This bit must be set to 1, when the next write access to the command register (MMCHS_CMD) is for writing a MMC interrupt command (CMD40) requiring the command timeout detection to be disabled for the command response.</p> <p>0x0: Command timeout enabled 0x1: Command timeout disabled</p> | RW | 0 |
| 5 | DW8 | <p>8-bit mode MMC select For SD/SDIO cards, this bit must be set to 0. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliancy with MMC standard specification 4.x (see section 3.6).</p> <p>0x0: 1-bit or 4-bit Data width (DAT[0] used, MMC, SD cards) 0x1: 8-bit Data width (DAT[7:0] used, MMC cards)</p> | RW | 0 |
| 4 | MODE | <p>Mode select All cards These bits select between Functional mode and SYSTEST mode.</p> <p>0x0: Functional mode. Transfers to the MMC/SD/SDIO cards follow the card protocol. MMC clock is enabled. MMC/SD transfers are operated under the control of the CMD register.</p> <p>0x1: SYSTEST mode The signal pins are configured as general-purpose input/output and the 1024-byte buffer is configured as a stack memory accessible only by the local host or system DMA. The pins retain their default type (input, output or in-out). SYSTEST mode is operated under the control of the SYSTEST register.</p> | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-------|
| 3 | STR | <p>Stream command Only for MMC cards. This bit must be set to 1 only for the stream data transfers (read or write) of the adtc commands. Stream read is a class 1 command (CMD11: READ_DAT_UNTIL_STOP). Stream write is a class 3 command (CMD20: WRITE_DAT_UNTIL_STOP). 0x0: Block oriented data transfer 0x1: Stream oriented data transfer</p> | RW | 0 |
| 2 | HR | <p>Broadcast host response Only for MMC cards. This register is used to force the host to generate a 48-bit response for bc command type. It can be used to terminate the interrupt mode by generating a CMD40 response by the core (see section 4.3, "Interrupt Mode", in the MMC [1] specification). In order to have the host response to be generated in open drain mode, the register MMCHS_CON[0] OD must be set to 1. When MMCHS_CON[12] CEATA is set to 1 and MMCHS_ARG set to 0x00000000 when writing 0x00000000 into MMCHS_CMD register, the host controller performs a 'command completion signal disable' token that is, CMD line held to 0 during 47 cycles followed by a 1. 0x0: The host does not generate a 48-bit response instead of a command. 0x1: The host generates a 48-bit response instead of a command or a command completion signal disable token.</p> | RW | 0 |
| 1 | INIT | <p>Send initialization stream All cards. When this bit is set to 1, and the card is idle, an initialization sequence is sent to the card. An initialization sequence consists of setting the CMD line to 1 during 80 clock cycles. The initialisation sequence is mandatory - but it is not required to do it through this bit - this bit makes it easier. Clock divider (MMCHS_SYSCTL[15:6] CLKD) should be set to ensure that 80 clock periods are greater than 1ms. (see section 9.3, "Power-Up", in the MMC card specification [1], or section 6.4 in the SD card specification [2]). Note: in this mode, there is no command sent to the card and no response is expected 0x0: The host does not send an initialization sequence. 0x1: The host sends an initialization sequence.</p> | RW | 0 |
| 0 | OD | <p>Card open drain mode. Only for MMC cards. This bit must be set to 1 for MMC card commands 1, 2, 3 and 40, and if the MMC card bus is operating in open-drain mode during the response phase to the command sent. Typically, during card identification mode when the card is either in idle, ready or ident state. It is also necessary to set this bit to 1, for a broadcast host response (see Broadcast host response register MMCHS_CON[2] HR) 0x0: No Open Drain 0x1: Open Drain or Broadcast host response</p> | RW | 0 |

| 23:22 | CMD_TYPE | <p>Command type This register specifies three types of special command: Suspend, Resume and Abort. These bits shall be set to 00b for all other commands.</p> <p>0x0: Others Commands 0x1: CMD52 for writing "Bus Suspend" in CCCR 0x2: CMD52 for writing "Function Select" in CCCR 0x3: Abort command CMD12, CMD52 for writing " I/O Abort" in CCCR</p> | RW | 0x0 |
| 21 | DP | <p>Data present select This register indicates that data is present and DAT line shall be used. It must be set to 0 in the following conditions: - command using only CMD line - command with no data transfer but using busy signal on DAT[0] - Resume command</p> <p>0x0: Command with no data transfer 0x1: Command with data transfer</p> | RW | 0 |
| 20 | CICE | <p>Command Index check enable This bit must be set to 1 to enable index check on command response to compare the index field in the response against the index of the command. If the index is not the same in the response as in the command, it is reported as a command index error (MMCHS_STAT[19] CIE set to 1) Note: The register CICE cannot be configured for an Auto CMD12, then index check is automatically checked when this command is issued.</p> <p>0x0: Index check disable 0x1: Index check enable</p> | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--|------|-------|
| 19 | CCCE | <p>Command CRC check enable</p> <p>This bit must be set to 1 to enable CRC7 check on command response to protect the response against transmission errors on the bus.</p> <p>If an error is detected, it is reported as a command CRC error (MMCHS_STAT[17] CCRC set to 1).</p> <p>Note: The register CCCE cannot be configured for an Auto CMD12, and then CRC check is automatically checked when this command is issued.</p> <p>0x0: CRC7 check disable</p> <p>0x1: CRC7 check enable</p> | RW | 0 |
| 18 | RESERVED | <p>Reserved.</p> <p>This bit is initialized to zero, and writes to it are ignored.</p> | R | 0 |
| 17:16 | RSP_TYPE | <p>Response type</p> <p>This bits defines the response type of the command</p> <p>0x0: No response</p> <p>0x1: Response Length 136 bits</p> <p>0x2: Response Length 48 bits</p> <p>0x3: Response Length 48 bits with busy after response</p> | RW | 0x0 |
| 15:6 | RESERVED | <p>Reserved.</p> <p>These bits are initialized to zero, and writes to them are ignored.</p> | R | 0x000 |
| 5 | MSBS | <p>Multi/Single block select</p> <p>This bit must be set to 1 for data transfer in case of multi block command.</p> <p>For any others command this bit shall be set to 0.</p> <p>0x0: Single block.</p> <p>If this bit is 0, it is not necessary to set the register MMCHS_BLK[31:16] NBLK.</p> <p>0x1: Multi block.</p> <p>When Block Count is disabled (MMCHS_CMD[1] BCE is set to 0) in Multiple block transfers (MMCHS_CMD[5] MSBS is set to 1), the module can perform infinite transfer.</p> | RW | 0 |
| 4 | DDIR | <p>Data transfer Direction Select</p> <p>This bit defines either data transfer will be a read or a write.</p> <p>0x0: Data Write (host to card)</p> <p>0x1: Data Read (card to host)</p> | RW | 0 |
| 3 | RESERVED | <p>Reserved.</p> <p>These bits are initialized to zero, and writes to them are ignored.</p> | R | 0 |
| 2 | ACEN | <p>Auto CMD12 Enable</p> <p>SDIO does not support this feature.</p> <p>When this bit is set to 1, the host controller issues a CMD12 automatically after the transfer completion of the last block.</p> <p>The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop data transfer. In particular, safe commands do not require CMD12.</p> <p>0x0: Auto CMD12 disable</p> <p>0x1: Auto CMD12 enable or CCS detection enabled.</p> | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 1 | BCE | Block Count Enable Multiple block transfers only. This bit is used to enable the block count register (MMCHS_BLK[31:16] NBLK). When Block Count is disabled (MMCHS_CMD[1] BCE is set to 0) in Multiple block transfers (MMCHS_CMD[5] MSBS is set to 1), the module can perform infinite transfer. 0x0: Block count disabled for infinite transfer. 0x1: Block count enabled for multiple block transfer with known number of blocks | RW | 0 |
| 0 | DE | DMA Enable This bit is used to enable DMA mode for host data access. 0x0: DMA mode disable 0x1: DMA mode enable | RW | 0 |

| Physical Address | 0x4809 C220 0x480B 4220 0x480A D220 0x480D 1220 0x480D 5220 | Instance | MMCHS1 MMCHS2 MMCHS3 MMCHS4 MMCHS5 |
| Description | <p>Data Register</p> <p>This register is the 32-bit entry point of the buffer for read or write data transfers. The buffer size is 32bits x256(1024 bytes). Bytes within a word are stored and read in little endian format. This buffer can be used as two 512 byte buffers to transfer data efficiently without reducing the throughput.</p> <p>Sequential and contiguous access is necessary to increment the pointer correctly. Random or skipped access is not allowed. In little endian, if the local host accesses this register byte-wise or 16bit-wise, the least significant byte (bits [7:0]) must always be written/read first. The update of the buffer address is done on the most significant byte write for full 32-bit DATA register or on the most significant byte of the last word of block transfer.</p> <p>Example 1: Byte or 16-bit access</p> <p>Mbyteen[3:0]=0001 (1-byte) = Mbyteen[3:0]=0010 (1-byte) = Mbyteen[3:0]=1100 (2-bytes) OK</p> <p>Mbyteen[3:0]=0001 (1-byte) = Mbyteen[3:0]=0010 (1-byte) = Mbyteen[3:0]=0100 (1-byte) OK</p> <p>Mbyteen[3:0]=0001 (1-byte) = Mbyteen[3:0]=0010 (1-byte) = Mbyteen[3:0]=1000 (1-byte) Bad</p> | | |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--|------|-------|
| 31:25 | RESERVED | Reserved. These bits are initialized to zero, and writes to them are ignored. | R | 0x00 |
| 24 | CLEV | CMD line signal level This status is used to check the CMD line level to recover from errors, and for debugging. The value of this register after reset depends on the CMD line level at that time. Read 0x0: The CMD line level is 0. Read 0x1: The CMD line level is 1. | R | - |
| 23:20 | DLEV | DAT[3:0] line signal level DAT[3] = bit 23 DAT[2] = bit 22 DAT[1] = bit 21 DAT[0] = bit 20 This status is used to check DAT line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DAT[0]. The value of these registers after reset depends on the DAT lines level at that time. | R | 0x- |
| 19 | WP | Write protect switch pin level For SDIO cards only. This bit reflects the write protect input pin (SDWP) level. The value of this register after reset depends on the protect input pin (SDWP) level at that time. Read 0x0: If MMCHS_CON[8] WPP is set to 0 (default), the card is write protected, otherwise the card is not protected. Read 0x1: If MMCHS_CON[8] WPP is set to 0 (default), the card is not write protected, otherwise the card is protected. | R | - |
| 18 | CDPL | Card detect pin level This bit reflects the inverse value of the card detect input pin (SDCD), debouncing is not performed on this bit and bit is valid only when Card State Stable (MMCHS_PSTATE[17] CSS) is set to 1. Use of this bit is limited to testing since it must be debounced by software. The value of this register after reset depends on the card detect input pin (SDCD) level at that time. Read 0x0: The value of the card detect input pin (SDCD) is 1 Read 0x1: The value of the card detect input pin (SDCD) is 0 | R | - |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|-------|
| 17 | CSS | <p>Card State Stable</p> <p>This bit is used for testing. It is set to 1 only when Card Detect Pin Level is stable (MMCHS_PSTATE[18] CDPL). Debouncing is performed on the card detect input pin (SDCD) to detect card stability.</p> <p>This bit is not affected by a software reset.</p> <p>Read 0x0: Reset or Debouncing</p> <p>Read 0x1: No card or card inserted</p> | R | 0 |
| 16 | CINS | <p>Card inserted</p> <p>This bit is the debounced value of the card detect input pin (SDCD).</p> <p>An inactive to active transition of the card detect input pin (SDCD) will generate a card insertion interrupt (MMCHS_STAT[6] CINS).</p> <p>A active to inactive transition of the card detect input pin (SDCD) will generate a card removal interrupt (MMCHS_STAT[7] CREM).</p> <p>This bit is not affected by a software reset.</p> <p>Read 0x0: If MMCHS_CON[7] CDP is set to 0 (default), no card is detected. The card may have been removed from the card slot.</p> <p>If MMCHS_CON[7] CDP is set to 1, the card has been inserted.</p> <p>Read 0x1: If MMCHS_CON[7] CDP is set to 0 (default), the card has been inserted from the card slot.</p> <p>If MMCHS_CON[7] CDP is set to 1, no card is detected. The card may have been removed from the card slot.</p> | R | 0 |
| 15:12 | RESERVED | <p>Reserved.</p> <p>These bits are initialized to zero, and writes to them are ignored.</p> | R | 0x0 |
| 11 | BRE | <p>Buffer read enable</p> <p>This bit is used for non-DMA read transfers.</p> <p>It indicates that a complete block specified by MMCHS_BLK[11:0] BLEN has been written in the buffer and is ready to be read.</p> <p>It is set to 0 when the entire block is read from the buffer.</p> <p>It is set to 1 when a block data is ready in the buffer and generates the Buffer read ready status of interrupt (MMCHS_STAT[5] BRR).</p> <p>Read 0x0: Read BLEN bytes disable</p> <p>Read 0x1: Read BLEN bytes enable. Readable data exists in the buffer.</p> | R | 0 |
| 10 | BWE | <p>Buffer Write enable</p> <p>This status is used for non-DMA write transfers.</p> <p>It indicates if space is available for write data.</p> <p>Read 0x0: There is no room left in the buffer to write BLEN bytes of data.</p> <p>Read 0x1: There is enough space in the buffer to write BLEN bytes of data.</p> | R | 0 |
| 9 | RTA | <p>Read transfer active</p> <p>This status is used for detecting completion of a read transfer. It is set to 1 after the end bit of read command or by activating a continue request (MMCHS_HCTL[17] CR) following a stop at block gap request. This bit is set to 0 when all data have been read by the local host after last block or after a stop at block gap request.</p> <p>Read 0x0: No valid data on the DAT lines.</p> <p>Read 0x1: read data transfer on going.</p> | R | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 8 | WTA | <p>Write transfer active</p> <p>This status indicates a write transfer active. It is set to 1 after the end bit of write command or by activating a continue request (MMCHS_HCTL[17] CR) following a stop at block gap request. This bit is set to 0 when CRC status has been received after last block or after a stop at block gap request.</p> <p>Read 0x0: No valid data on the DAT lines.</p> <p>Read 0x1: Write data transfer on going.</p> | R | 0 |
| 7:3 | RESERVED | <p>Reserved.</p> <p>These bits are initialized to zero, and writes to them are ignored.</p> | R | 0x00 |
| 2 | DLA | <p>DAT line active</p> <p>This status bit indicates whether one of the DAT line is in use.</p> <p>In the case of read transactions (card to host):</p> <p>This bit is set to 1 after the end bit of read command or by activating continue request MMCHS_HCTL[17] CR. This bit is set to 0 when the host controller received the end bit of the last data block or at the beginning of the read wait mode.</p> <p>In the case of write transactions (host to card):</p> <p>This bit is set to 1 after the end bit of write command or by activating continue request MMCHS_HCTL[17] CR. This bit is set to 0 on the end of busy event for the last block; host controller must wait 8 clock cycles with line not busy to really consider not "busy state" or after the busy block as a result of a stop at gap request.</p> <p>Read 0x0: DAT Line inactive</p> <p>Read 0x1: DAT Line active</p> | R | 0 |
| 1 | DATI | <p>Command inhibit(DAT)</p> <p>This status bit is generated if either DAT line is active (MMCHS_PSTATE[2] DLA) or Read transfer is active (MMCHS_PSTATE[9] RTA) or when a command with busy is issued. This bit prevents the local host to issue a command.</p> <p>A change of this bit from 1 to 0 generates a transfer complete interrupt (MMCHS_STAT[1] TC).</p> <p>Read 0x0: Issuing of command using the DAT lines is allowed</p> <p>Read 0x1: Issuing of command using DAT lines is not allowed</p> | R | 0 |
| 0 | CMDI | <p>Command inhibit(CMD)</p> <p>This status bit indicates that the CMD line is in use. This bit is set to 0 when the most significant byte is written into the command register. This bit is not set when Auto CMD12 is transmitted.</p> <p>This bit is set to 0 in either the following cases:</p> <ul style="list-style-type: none"> - After the end bit of the command response, excepted if there is a command conflict error (MMCHS_STAT[17] CCRC or MMCHS_STAT[18] CEB set to 1) or a Auto CMD12 is not executed (MMCHS_AC12[0] ACNE). - After the end bit of the command without response (MMCHS_CMD[17:16] RSP_TYPE set to "00") <p>In case of a command data error is detected (MMCHS_STAT[16] CTO set to 1), this register is not automatically cleared.</p> <p>Read 0x0: Issuing of command using CMD line is allowed</p> <p>Read 0x1: Issuing of command using CMD line is not allowed</p> | R | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--|------|-------|
| 31:28 | RESERVED | Reserved. These bits are initialized to zero, and writes to them are ignored. | R | 0x0 |
| 27 | OBWE | Wakeup event enable for 'Out-of-Band' Interrupt. This bit enables wakeup events for 'Out-of-Band' assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[2] ENAWAKEUP). The write to this register is ignored when MMCHS_CON[14] OBIE is not set. 0x0: Disable wakeup on 'Out-of-Band' Interrupt 0x1: Enable wakeup on 'Out-of-Band' Interrupt | RW | 0 |
| 26 | REM | Wakeup event enable on SD card removal This bit enables wakeup events for card removal assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[2] ENAWAKEUP). 0x0: Disable wakeup on card removal 0x1: Enable wakeup on card removal | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|-------|
| 25 | INS | Wakeup event enable on SD card insertion This bit enables wakeup events for card insertion assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[2] ENAWAKEUP). 0x0: Disable wakeup on card insertion 0x1: Enable wakeup on card insertion | RW | 0 |
| 24 | IWE | Wakeup event enable on SD card interrupt This bit enables wakeup events for card interrupt assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[2] ENAWAKEUP). 0x0: Disable wakeup on card interrupt 0x1: Enable wakeup on card interrupt | RW | 0 |
| 23:20 | RESERVED | Reserved. These bits are initialized to zero, and writes to them are ignored. | R | 0x0 |
| 19 | IBG | Interrupt block at gap This bit is valid only in 4-bit mode of SDIO card to enable interrupt detection in the interrupt cycle at block gap for a multiple block transfer. For MMC cards and for SD card this bit should be set to 0. 0x0: Disable interrupt detection at the block gap in 4-bit mode 0x1: Enable interrupt detection at the block gap in 4-bit mode | RW | 0 |
| 18 | RWC | Read wait control The read wait function is optional only for SDIO cards. If the card supports read wait, this bit must be enabled, then requesting a stop at block gap (MMCHS_HCTL[16] SBGR) generates a read wait period after the current end of block. Be careful, if read wait is not supported it may cause a conflict on DAT line. 0x0: Disable Read Wait Control. Suspend/Resume cannot be supported. 0x1: Enable Read Wait Control | RW | 0 |
| 17 | CR | Continue request This bit is used to restart a transaction that was stopped by requesting a stop at block gap (MMCHS_HCTL[16] SBGR). Set this bit to 1 restarts the transfer. The bit is automatically set to 0 by the host controller when transfer has restarted i.e DAT line is active (MMCHS_PSTATE[2] DLA) or transferring data (MMCHS_PSTATE[8] WTA). The Stop at block gap request must be disabled (MMCHS_HCTL[16] SBGR = 0) before setting this bit. 0x0: No affect 0x1: transfer restart | RW | 0 |
| 16 | SBGR | Stop at block gap request This bit is used to stop executing a transaction at the next block gap. The transfer can restart with a continue request (MMCHS_HCTL[17] CR) or during a suspend/resume sequence. In case of read transfer, the card must support read wait control. In case of write transfer, the host driver shall set this bit after all block data written. Until the transfer completion (MMCHS_STAT[1] TC set to 1), the host driver shall leave this bit set to 1. If this bit is set, the local host shall not write to the data register (MMCHS_DATA). 0x0: Transfer mode 0x1: Stop at block gap | RW | 0 |
| 15:12 | RESERVED | Reserved. These bits are initialized to zero, and writes to them are ignored. | R | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 11:9 | SDVS | SD bus voltage select All cards. The host driver should set to these bits to select the voltage level for the card according to the voltage supported by the system (MMCHS_CAPA[26:24]) before starting a transfer. 0x5: 1.8V (Typical) 0x6: 3.0V (Typical) 0x7: 3.3V (Typical) | RW | 0x0 |
| 8 | SDBP | SD bus power Before setting this bit, the host driver shall select the SD bus voltage (MMCHS_HCTL[11:9] SDVS). If the host controller detects the No card state, this bit is automatically set to 0. If the module is power off, a write in the command register (MMCHS_CMD) will not start the transfer. A write to this bit has no effect if the selected SD bus voltage is not supported according to capability register (MMCHS_CAPA[26:24]). 0x0: Power off 0x1: Power on | RW | 0 |
| 7 | CDSS | Card Detect Signal Selection This bit selects source for the card detection. When the source for the card detection is switched, the interrupt should be disabled during the switching period by clearing the Interrupt Status/Signal Enable register in order to mask unexpected interrupt being caused by the glitch. The Interrupt Status/Signal Enable should be disabled during over the period of debouncing. 0x0: SDCD# is selected (for normal use) 0x1: The Card Detect Test Level is selected (for test purpose) | RW | 0 |
| 6 | CDTL | Card Detect Test Level: This bit is enabled while the Card Detect Signal Selection is set to 1 and it indicates card inserted or not. 0x0: No Card 0x1: Card Inserted | RW | 0 |
| 5 | RESERVED | Reserved. These bits are initialized to zero, and writes to them are ignored. | R | 0 |
| 4:3 | DMAS | DMA Select Mode: One of supported DMA modes can be selected. The host driver shall check support of DMA modes by referring the Capabilities register. Use of selected DMA is determined by DMA Enable of the Transfer Mode register. This register is only meaningful when MMCHS_HL_HWINFO[0] MADMA_EN is set to 1. When MMCHS_HL_HWINFO[0] MADMA_EN is set to 0 the bit field is read only and returned value is 0. 0x0: Reserved 0x1: Reserved 0x2: 32-bit Address ADMA2 is selected 0x3: Reserved | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 2 | HSPE | <p>High Speed Enable: Before setting this bit, the Host Driver shall check the High Speed Support in the Capabilities register. If this bit is set to 0 (default), the Host Controller outputs CMD line and DAT lines at the falling edge of the SD Clock. If this bit is set to 1, the Host Controller outputs CMD line and DAT lines at the rising edge of the SD Clock. This bit shall not be set when dual data rate mode is activated in MMCHS_CON[19] DDR.</p> <p>0x0: Normal speed mode 0x1: High speed mode</p> | RW | 0 |
| 1 | DTW | <p>Data transfer width For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliance with MMC standard specification 4.x (see section 3.6). This register has no effect when the MMC 8-bit mode is selected (register MMCHS_CON[5] DW8 set to 1), For SD/SDIO cards, this bit must be set following a valid SET_BUS_WIDTH command (ACMD6) with the value written in bit 1 of the argument. Prior to this command, the SD card configuration register (SCR) must be verified for the supported bus width by the SD card.</p> <p>0x0: 1-bit Data width (DAT[0] used) 0x1: 4-bit Data width (DAT[3:0] used)</p> | RW | 0 |
| 0 | LED | <p>Reserved bit. LED control feature is not supported This bit is initialized to zero, and writes to it are ignored.</p> | R | 0 |

|-------|------------|---|------|-------|
| 31:27 | RESERVED | Reserved. These bits are initialized to zero, and writes to them are ignored. | R | 0x00 |
| 26 | SRD | Software reset for DAT line. This bit is set to 1 for reset and released to 0 when completed. For more information about SRD bit manipulation, see Section 25.5.1.2.1.1, DATA Lines Reset Procedure . DAT finite state machine in both clock domain are also reset. The following registers are cleared by MMCHS_SYSCCTL[26] SRD: - MMCHS_DATA - MMCHS_PSTATE[11] BRE, MMCHS_PSTATE[10] BWE, MMCHS_PSTATE[9] RTA, MMCHS_PSTATE[8] WTA, MMCHS_PSTATE[2] DLA, MMCHS_PSTATE[1] DATI - MMCHS_HCTL: SBGR and CR - MMCHS_STAT: MMCHS_STAT[5] BRR, MMCHS_STAT[4] BWR, MMCHS_STAT[2] BGE and MMCHS_STAT[1] TC Interconnect and MMC buffer data management is reinitialized. 0x0: Reset completed 0x1: Software reset for DAT line | RW | 0 |
| 25 | SRC | Software reset for CMD line For more information about SRC bit manipulation, see Section 25.5.1.2.1.1, CMD Line Reset Procedure . This bit is set to 1 for reset and released to 0 when completed. CMD finite state-machine in both clock domain are also reset. The following registers are cleared by MMCHS_SYSCCTL[25] SRC: - MMCHS_PSTATE[0] CMDI - MMCHS_STAT[0] CC Interconnect and MMC command status management is reinitialized. 0x0: Reset completed 0x1: Software reset for CMD line | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--|------|-------|
| 24 | SRA | Software reset for all This bit is set to 1 for reset, and released to 0 when completed. This reset affects the entire host controller except for the card detection circuit and capabilities registers. 0x0: Reset completed 0x1: Software reset for all the design | RW | 0 |
| 23:20 | RESERVED | Reserved. These bits are initialized to 0, and writes to them are ignored. | R | 0x0 |
| 19:16 | DTO | Data timeout counter value and busy timeout. This value determines the interval by which DAT lines timeouts are detected. The host driver needs to set this bit field based on - the maximum read access time (NAC) (Refer to the SD Specification Part1 Physical Layer), - the data read access time values (TAAC and NSAC) in the card specific data register (CSD) of the card, - the timeout clock base frequency (MMCHS_CAPA[5:0] TCF). If the card does not respond within the specified number of cycles, a data timeout error occurs (MMCHS_STAT[20] DTO). The MMCHS_SYSCTL[19:16] DTO register is also used to check busy duration, to generate busy timeout for commands with busy response or for busy programming during a write command. Timeout on CRC status is generated if no CRC token is present after a block write. 0x0: TCF x 2 ¹³ 0x1: TCF x 2 ¹⁴ 0xE: TCF x 2 ²⁷ 0xF: Reserved | RW | 0x0 |
| 15:6 | CLKD | Clock frequency select These bits define the ratio between MMCI_FCLK and the output clock frequency on the CLK pin of either the memory card (MMC, SD or SDIO). 0x0: MMCI_FCLK bypass 0x1: MMCI_FCLK bypass 0x2: MMCI_FCLK / 2 0x3: MMCI_FCLK / 3 0x3FF: MMCI_FCLK / 1023 | RW | 0x000 |
| 5:3 | RESERVED | Reserved. These bits are initialized to zero, and writes to them are ignored. | R | 0x0 |
| 2 | CEN | Clock enable This bit controls if the clock is provided to the card or not. 0x0: The clock is not provided to the card . Clock frequency can be changed . 0x1: The clock is provided to the card and can be automatically gated when MMCHS_SYSCONFIG[0] AUTOIDLE is set to 1 (default value) . The host driver shall wait to set this bit to 1 until the Internal clock is stable (MMCHS_SYSCTL[1] ICS). | RW | 0 |
| 1 | ICS | Internal clock stable (status) This bit indicates either the internal clock is stable or not. Read 0x0: The internal clock is not stable. Read 0x1: The internal clock is stable after enabling the clock (MMCHS_SYSCTL[1] ICE) or after changing the clock ratio (MMCHS_SYSCTL[15:6] CLKD). | R | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 0 | ICE | <p>Internal clock enable</p> <p>This register controls the internal clock activity. In very low power state, the internal clock is stopped. Note: The activity of the debounce clock (used for wakeup events) and the interface clock (used for reads and writes to the module register map) are not affected by this register.</p> <p>0x0: The internal clock is stopped (very low power state).</p> <p>0x1: The internal clock oscillates and can be automatically gated when MMCHS_SYSCONFIG[0] AUTOIDLE is set to 1 (default value) .</p> | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--|------|-------|
| 31:30 | RESERVED | Reserved. These bits are initialized to zero, and writes to them are ignored. | R | 0x0 |
| 29 | BADA | Bad access to data space This bit is set automatically to indicate a bad access to buffer when not allowed: -This bit is set during a read access to the data register (MMCHS_DATA) while buffer reads are not allowed (MMCHS_PSTATE [11] BRE = 0) -This bit is set during a write access to the data register (MMCHS_DATA) while buffer writes are not allowed (MMCHS_PSTATE [10] BWE = 0) Write 0x0: Status bit unchanged Read 0x0: No Interrupt. Read 0x1: Bad Access Write 0x1: Status is cleared | RW | 0 |
| 28 | CERR | Card error This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E(error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response error MMCHS_CSRE is set. There is no card error detection for autoCMD12 command. The host driver shall read MMCHS_RSP76 register to detect error bits in the command response. Write 0x0: Status bit unchanged Read 0x0: No Error Write 0x1: Status is cleared Read 0x1: Card error | RW | 0 |
| 27:26 | RESERVED | Reserved. These bits are initialized to zero, and writes to them are ignored. | R | 0x0 |
| 25 | ADMAE | ADMA Error: This bit is set when the Host Controller detects errors during ADMA based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA Error Status Register. In addition, the Host Controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. ADMA Error State in the ADMA Error Status indicates that an error occurs in ST_FDS state. The Host Driver may find that Valid bit is not set at the error descriptor. Write 0x0: Status bit unchanged Read 0x0: No Interrupt. Write 0x1: Status is cleared Read 0x1: ADMA error | RW | 0 |
| 24 | ACE | Auto CMD12 error This bit is set automatically when one of the bits in Auto CMD12 Error status register has changed from 0 to 1. Write 0x0: Status bit unchanged Read 0x0: No Error. Read 0x1: AutoCMD12 error Write 0x1: Status is cleared | RW | 0 |
| 23 | CLE | Reserved. Current limit error is not supported. These bits are initialized to zero, and writes to them are ignored. | R | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|-------|
| 16 | CTO | <p>Command Timeout Error</p> <p>This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within 5 clock cycles - the timeout is still detected at 64 clock cycles.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x0: No error</p> <p>Read 0x1: Time Out</p> <p>Write 0x1: Status is cleared</p> | RW | 0 |
| 15 | ERRI | <p>Error Interrupt</p> <p>If any of the bits in the Error Interrupt Status register (MMCHS_STAT[24:15]) are set, then this bit is set to 1. Therefore the host driver can efficiently test for an error by checking this bit first. Writes to this bit are ignored.</p> <p>Read 0x0: No Interrupt.</p> <p>Read 0x1: Error interrupt event(s) occurred</p> | R | 0 |
| 14:11 | RESERVED | <p>Reserved.</p> <p>These bits are initialized to zero, and writes to them are ignored.</p> | R | 0x0 |
| 10 | BSR | <p>Boot status received interrupt</p> <p>This bit is set automatically when MMCHS_CON[18] BOOT_CF0 is set 0x0 or 0x1 and a boot status is received on DAT[0] line. This interrupt is only useful for MMC card.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x0: No Interrupt.</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: Boot status received interrupt.</p> | RW | 0 |
| 9 | OBI | <p>Out-Of-Band interrupt</p> <p>This bit is set automatically when MMCHS_CON[14] OBIE is set and an Out-of-Band interrupt occurs on OBI pin.</p> <p>The interrupt detection depends on polarity controlled by MMCHS_CON[13] OBIP.</p> <p>This interrupt is only useful for MMC card.</p> <p>The Out-of-Band interrupt signal is a system specific feature for future use, this signal is not required for existing specification implementation.</p> <p>Read 0x0: No Out-Of-Band interrupt.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Interrupt Out-Of-Band occurs</p> <p>Write 0x1: Status is cleared</p> | RW | 0 |
| 8 | CIRQ | <p>Card interrupt</p> <p>This bit is only used for SD and SDIO and CE-ATA cards.</p> <p>In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wakeup).</p> <p>In 4-bit mode, interrupt source is sampled during the interrupt cycle.</p> <p>In CE-ATA mode, interrupt source is detected when the card drives CMD line to zero during one cycle after data transmission end. All modes above are fully exclusive.</p> <p>The controller interrupt must be clear by setting MMCHS_IE[8] CIRQ_ENABLE to 0, then the host driver must start the interrupt service with card (clearing card interrupt status) to remove card interrupt source. Otherwise the Controller interrupt will be reasserted as soon as MMCHS_IE[8] CIRQ_ENABLE is set to 1. Writes to this bit are ignored.</p> <p>Read 0x0: No card interrupt</p> <p>Read 0x1: Generate card interrupt</p> | R | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 7 | CREM | <p>Card removal</p> <p>This bit is set automatically when MMCHS_PSTATE[16] CINS changes from 1 to 0.</p> <p>A clear of this bit doesn't affect Card inserted present state (MMCHS_PSTATE[16] CINS).</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x0: Card state stable or Debouncing</p> <p>Read 0x1: Card removed</p> <p>Write 0x1: Status is cleared</p> | RW | 0 |
| 6 | CINS | <p>Card insertion</p> <p>This bit is set automatically when MMCHS_PSTATE[16] changes from 0 to 1.</p> <p>A clear of this bit doesn't affect Card inserted present state (MMCHS_PSTATE[16] CINS).</p> <p>Read 0x0: Card state stable or debouncing</p> <p>Write 0x0: Status bit unchanged</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: Card inserted</p> | RW | 0 |
| 5 | BRR | <p>Buffer read ready</p> <p>This bit is set automatically during a read operation to the card (see class 2 - block oriented read commands) when one block specified by MMCHS_BLK[11:0] BLEN is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the local host needs to empty the buffer by reading it. Note: If the DMA receive-mode is enabled, this bit is never set; instead a DMA receive request to the main DMA controller of the system is generated.</p> <p>Read 0x0: Not Ready to read buffer</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Ready to read buffer</p> <p>Write 0x1: Status is cleared</p> | RW | 0 |
| 4 | BWR | <p>Buffer write ready</p> <p>This bit is set automatically during a write operation to the card (see class 4 - block oriented write command) when the host can write a complete block as specified by MMCHS_BLK[11:0] BLEN. It indicates that the memory card has emptied one block from the buffer and that the local host is able to write one block of data into the buffer. Note: If the DMA transmit mode is enabled, this bit is never set; instead, a DMA transmit request to the main DMA controller of the system is generated.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x0: Not Ready to write buffer</p> <p>Read 0x1: Ready to write buffer</p> <p>Write 0x1: Status is cleared</p> | RW | 0 |
| 3 | DMA | <p>DMA interrupt :</p> <p>This status is set when an interrupt is required in the ADMA instruction and after the data transfer completion.</p> <p>Read 0x0: Dma interrupt detected</p> <p>Write 0x0: Status bit unchanged</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: No dma interrupt</p> | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-------|
| 2 | BGE | <p>Block gap event</p> <p>When a stop at block gap is requested (MMCHS_HCTL[16] SBGR), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.</p> <p>This event does not occur when the stop at block gap is requested on the last block.</p> <p>In read mode, a 1-to-0 transition of the DAT Line active status (MMCHS_PSTATE[2] DLA) between data blocks generates a Block gap event interrupt.</p> <p>Read 0x0: No block gap event</p> <p>Write 0x0: Status bit unchanged</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: Transaction stopped at block gap</p> | RW | 0 |
| 1 | TC | <p>Transfer completed</p> <p>This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap request (MMCHS_HCTL[16] SBGR).</p> <p>In Read mode:</p> <p>This bit is automatically set on completion of a read transfer (MMCHS_PSTATE[9] RTA).</p> <p>In write mode:</p> <p>This bit is set automatically on completion of the DAT line use (MMCHS_PSTATE[2] DLA).</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x0: No transfer complete</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: Data transfer complete</p> | RW | 0 |
| 0 | CC | <p>Command complete</p> <p>This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCHS_PSTATE[0] CMDI)</p> <p>If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command.</p> <p>A command timeout error (MMCHS_STAT[16] CTO) has higher priority than command complete (MMCHS_STAT[0] CC).</p> <p>If a response is expected but none is received, then a command timeout error is detected and signaled instead of the command complete interrupt.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x0: No Command complete</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: Command complete</p> | RW | 0 |

| Description | Auto CMD12 Error Status Register The host driver may determine which of the errors cases related to Auto CMD12 has occurred by checking this MMCHS_AC12 register when an Auto CMD12 Error interrupt occurs. This register is valid only when Auto CMD12 is enabled (MMCHS_CMD[2] ACEN) and Auto CMD12Error (MMCHS_STAT[24] ACE) is set to 1. Note: These bits are automatically reset when starting a new adtc command with data. | | |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|-------|
| 31:29 | RESERVED | Reserved. These bits are initialized to zero, and writes to them are ignored. | R | 0x0 |
| 28 | BIT64 | 64-bit system bus support: Setting 1 to this bit indicates that the Host Controller supports 64-bit address descriptor mode and is connected to 64-bit address system bus. Read 0x0: 32-bit system bus address Read 0x1: 64-bit system bus address | R | 0 |
| 27 | RESERVED | | R | 0 |
| 26 | VS18 | Voltage support 1.8 V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via RESETN signal) Write 0x0: 1.8 V not supported Read 0x0: 1.8 V not supported Read 0x1: 1.8 V supported Write 0x1: 1.8 V supported | RW | 0 |
| 25 | VS30 | Voltage support 3.0 V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via RESETN signal) Read 0x0: 3.0 V not supported Write 0x0: 3.0 V not supported Write 0x1: 3.0 V supported Read 0x1: 3.0 V supported | RW | 0 |
| 24 | VS33 | Voltage support 3.3 V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via RESETN signal) Read 0x0: 3.3 V not supported Write 0x0: 3.3 V not supported Write 0x1: 3.3 V supported Read 0x1: 3.3 V supported | RW | 0 |
| 23 | SRS | Suspend/Resume support (SDIO cards only) This bit indicates whether the host controller supports suspend/resume functionality. Read 0x0: The host controller does not suspend/resume functionality. Read 0x1: The host controller supports suspend/resume functionality. | R | 1 |
| 22 | DS | DMA support This bit indicates that the Host Controller is able to use DMA to transfer data between system memory and the Host Controller directly. Read 0x0: DMA not supported Read 0x1: DMA supported | R | 1 |
| 21 | HSS | High-speed support This bit indicates that the host controller supports high-speed operations and can supply an up-to maximum card frequency. Read 0x0: High speed not supported Read 0x1: High speed supported | R | 1 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--|------|-------|
| 20 | RESERVED | Reserved. This bit is initialized to zero, and writes to it are ignored. | R | 0 |
| 19 | AD2S | ADMA2 support: This bit indicates whether the host controller is capable of using ADMA2. It depends on setting of generic parameter MMCHS_HL_HWINFO[0] MADMA_EN Read 0x0: ADMA2 not supported Read 0x1: ADMA2 supported | R | 1 |
| 18 | RESERVED | Reserved. This bit is initialized to zero, and writes to it are ignored. | R | 0 |
| 17:16 | MBL | Maximum block length This value indicates the maximum block size that the host driver can read and write to the buffer in the host controller. This value depends on definition of generic parameter with a max value of 2048 bytes. The host controller supports 512- byte and 1024-byte block transfers. Read 0x0: 512 bytes Read 0x1: 1024 bytes Read 0x2: 2048 bytes | R | 0x1 |
| 15:14 | RESERVED | Reserved. These bits are initialized to zero, and writes to them are ignored. | R | 0x0 |
| 13:8 | BCF | Base clock frequency for clock provided to the card. Read 0x0: The value indicating the base (maximum) frequency for the output clock provided to the card is system dependent and is not available in this register. Get the information via another method. | R | 0x00 |
| 7 | TCU | Timeout clock unit This bit shows the unit of base clock frequency used to detect Data Timeout Error (MMCHS_STAT[20] DTO). Read 0x0: kHz Read 0x1: MHz | R | 1 |
| 6 | RESERVED | Reserved. This bit is initialized to zero, and writes to it are ignored. | R | 0 |
| 5:0 | TCF | Timeout clock frequency The timeout clock frequency is used to detect Data Timeout Error (MMCHS_STAT[20] DTO). Read 0x0: The timeout clock frequency depends on the frequency of the clock provided to the card. The value of the timeout clock frequency is not available in this register. | R | 0x00 |

| Description | ADMA Error Status Register When ADMA Error Interrupt is occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address Register holds the address around the error descriptor. For recovering the error, the Host Driver requires the ADMA state to identify the error descriptor address as follows: ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address ST_FDS: Current location set in the ADMA System Address register is the error descriptor address ST_CADR: This state is never set because do not generate ADMA error in this state. ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address In case of write operation, the Host Driver should use ACMD22 to get the number of written block rather than using this information, since unwritten data may exist in the Host Controller. The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. In this case, ADMA Error State indicates that an error occurs at ST_FDS state. The Host Driver may find that the Valid bit is not set in the error descriptor. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

PRELIMINARY

General-Purpose Interface

This chapter describes the general-purpose interface on the device.

| Topic | Page |
|---|------|
| 26.1 General-Purpose Interface Overview | 5390 |
| 26.2 General-Purpose Interface Environment | 5393 |
| 26.3 General-Purpose Interface Integration | 5399 |

| 26.5 General-Purpose Interface Programming Guide | 5417 |
| 26.6 General-Purpose Interface Register Manual | 5419 |

26.1 General-Purpose Interface Overview

The general-purpose interface combines six general-purpose input/output (GPIO) banks.

Each GPIO module provides 32 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 192 (6×32) pins.

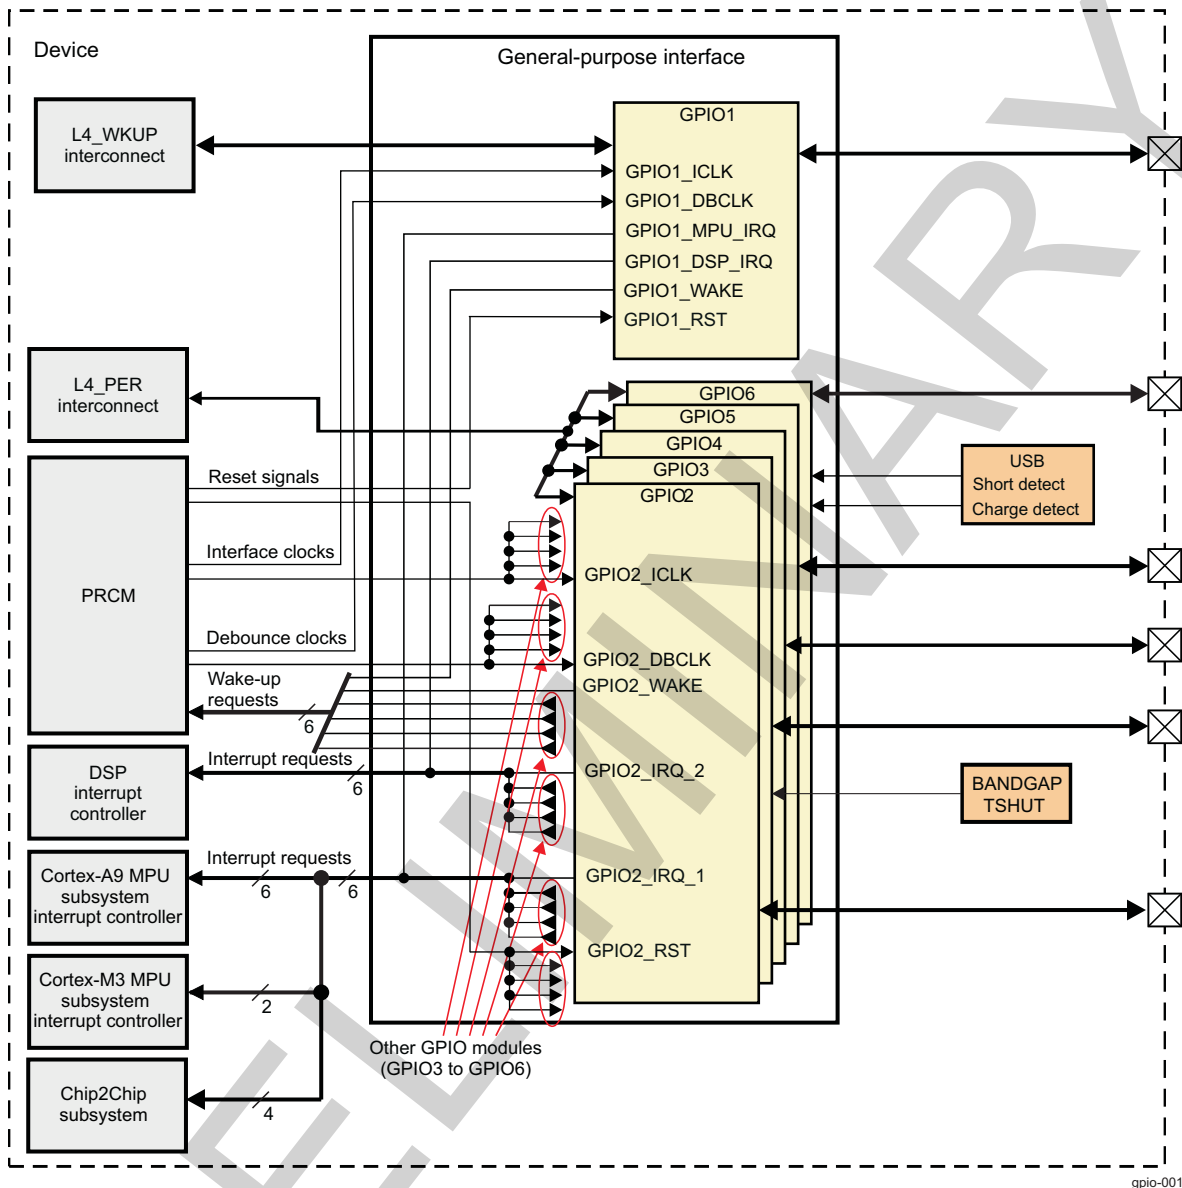

These pins can be configured for the following applications:

- Data input (capture)/output (drive)
- Keyboard interface with a debounce cell
- Interrupt generation in active mode upon the detection of external events. Detected events are processed by two parallel independent interrupt-generation submodules to support biprocessor operations.
- Wake-up request generation in idle mode upon the detection of external events

These modules do not include pad control (pullup/pulldown control, open-drain feature). For more information, see [Section 19.4.8](#), *Pad Functional Multiplexing and Configuration*, in [Chapter 19](#), *Control Module*.

[Figure 26-1](#) is an overview of the general-purpose interface.

Figure 26-1. General-Purpose Interface Overview

The GPIOs include the following global features:

- Synchronous interrupt requests in active mode from each channel are processed by two identical interrupt generation submodules used independently by the digital signal processor (DSP) and microprocessor unit (MPU) Cortex™-A9 and Cortex™-M3 subsystems. One of these interrupts is mapped on the DSP subsystem interrupt controller (INTC) and the other on the MPU Cortex-A9 and Cortex-M3 subsystem INTCs.
- Asynchronous wake-up requests in idle mode from input channels are merged together to issue one wake-up signal per GPIO.
- Data input (capture)/output (drive)
- Power management support

The general-purpose interface has 12 interrupt lines (two interrupt lines per GPIO instance).

Each GPIO produces a wake-up request signal to the power, reset, and clock management (PRCM) module.

Each channel in the GPIOs has the following features:

- The GPIOi.GPIO_OE register controls the output capability for each pin.
- The output line level reflects the value written in the GPIOi.GPIO_DATAOUT register through the level 4 (L4) interconnect.
- The input line can be fed to the GPIO through an optional and configurable debounce cell. (Because the debouncing time value is global for all ports of one GPIO, up to five different debouncing time values are possible.)
- The input line value is sampled into the GPIOi.GPIO_DATAIN register and can be read through the L4 interconnect.
- In active mode, the input line can be used through level and edge detectors to trigger synchronous interrupts. The edge (rising, falling, or both) or the level used (logical 0, logical 1, or both) can be configured.
- In idle mode, the input line can be used to activate the asynchronous wake-up request (on edge detection: rising edge, falling edge, or both).

The module provides an alternative to the atomic test and set operations for the following registers:

- GPIOi.GPIO_DATAOUT
- GPIOi.GPIO_IRQSTATUS_SET_0
- GPIOi.GPIO_IRQSTATUS_SET_1
- GPIOi.GPIO_IRQSTATUS_CLR_0
- GPIOi.GPIO_IRQSTATUS_CLR_1

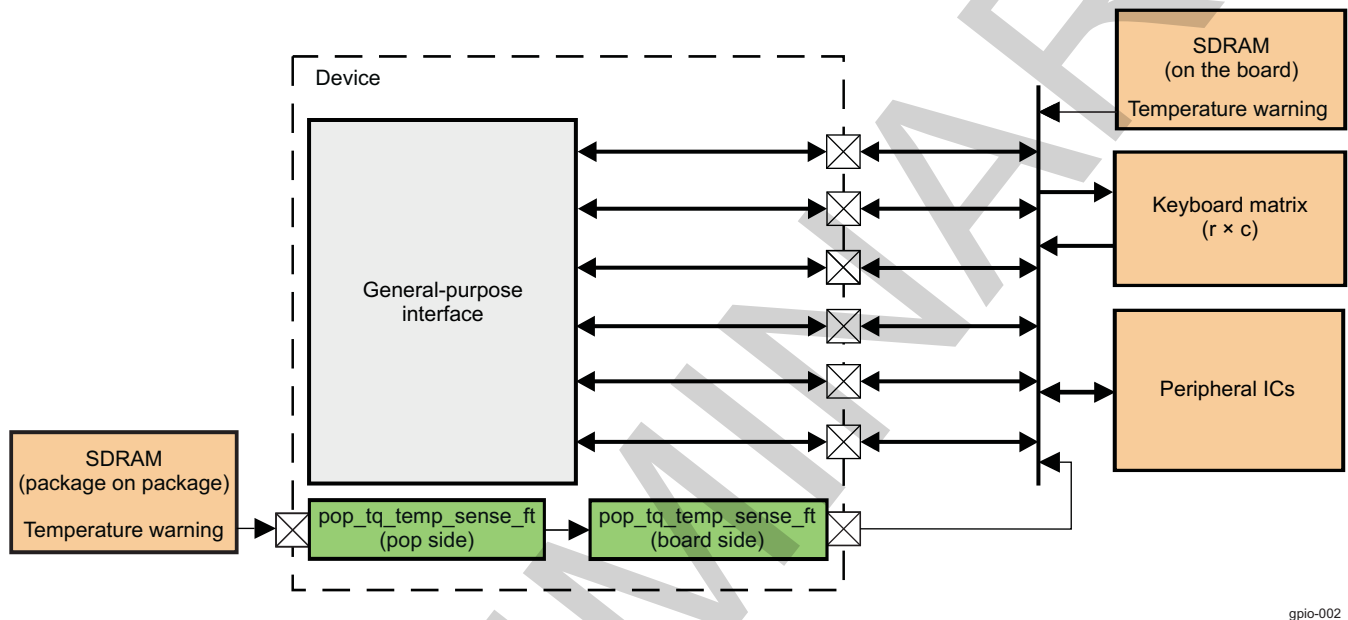

For these registers, the modules implement the set-and-clear protocol register update (see [Section 26.4.9, General-Purpose Interface Set-and-Clear Protocol](#)).

26.2 General-Purpose Interface Environment

The general-purpose interface combines six GPIO modules for a flexible, user-programmable, GPIO controller. The general-purpose interface implements functions that are not implemented with the dedicated controllers in the device and require simple input and/or output software-controlled signals. The general-purpose interface allows a variety of custom connections and expands the I/O capabilities of the system to the real world.

Figure 26-2 shows a typical application using the general-purpose interface.

Figure 26-2. General-Purpose Interface Typical Application

NOTE: Most memories provide a temperature sensor to control the autorefresh duty cycle. The device monitors the temperature of the external memory using the pop_tq_temp_sense_ft ball and a GPIO input. To do this, pop_tq_temp_sense_ft is connected to a GPIO through the customer board. This feature is application-dependent.

CAUTION

Because of buffer strength, an external serial resistor must be connected to the balls where gpio_106 through gpio_109 are muxed with MMC signals.

The general-purpose interface can physically connect the device to a keyboard matrix and peripheral integrated circuits (ICs).

26.2.1 General-Purpose Interface as a Keyboard Interface

The general-purpose interface can be used as a keyboard interface. Channels can be dedicated based on the keyboard matrix ($r \times c$). Figure 26-3 shows row channels configured as inputs with the input debounce feature enabled. The row channels are driven high with an external pullup. Column channels are configured as outputs and drive a low level.

Figure 26-3. General-Purpose Interface Used as a Keyboard Interface

When a keyboard matrix key is pressed, the corresponding row and column lines are shorted together and a low level is driven on the corresponding row channel. This generates an interrupt based on the proper configuration (see [Section 26.4.6, General-Purpose Interface Interrupt and Wake-Up Requests](#)).

When the keyboard interrupt is received, the processor (MPU and/or DSP subsystem) can disable the keyboard interrupt and scan the column channels for the key coordinates.

- The scanning sequence has as many states as column channels: For each step in the sequence, the processor drives one column channel low and the others high.
- The processor reads the values of the row channels and thus detects which keys in the column are pressed.

At the end of the scanning sequence, the processor establishes which keys are pressed. The keyboard interface can then be reconfigured in the interrupt waiting state.

26.2.2 General-Purpose Interface Signals

[Table 26-1](#) describes the module signals.

Table 26-1. I/O Description

| Signal | I/O ⁽¹⁾ | Description | Reset Value ⁽²⁾ |
|---------------|--------------------|----------------------------|----------------------------|
| gpio_[1:0] | I/O | GPIO | Hi-Z |
| gpio_wk[1:0] | I/O | GPIO (direct wake-up path) | Hi-Z |
| gpio_[3:2] | I/O | GPIO | Hi-Z |
| gpio_wk[3:2] | I/O | GPIO (direct wake-up path) | Hi-Z |
| gpio_wk[10:4] | I/O | GPIO (direct wake-up path) | Hi-Z |
| gpio_[28:11] | I/O | GPIO | Hi-Z |
| gpio_wk29 | I/O | GPIO (direct wake-up path) | Hi-Z |
| gpi_wk30 | I | GPIO (direct wake-up path) | Hi-Z |
| gpo_wk31 | O | GPIO (direct wake-up path) | Hi-Z |

⁽¹⁾ I = Input; O = Output; I/O = Bidirectional

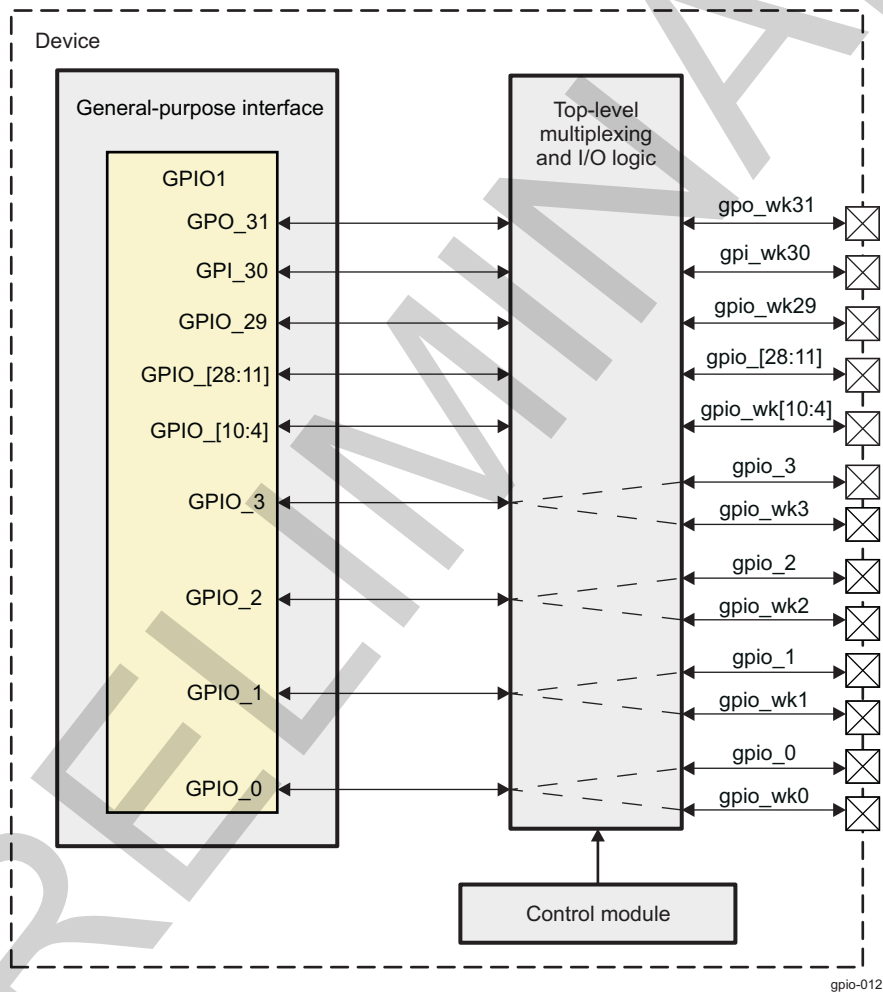

⁽²⁾ Hi-Z = High impedance

Table 26-1. I/O Description (continued)

| Signal | I/O ⁽¹⁾ | Description | Reset Value ⁽²⁾ |
|----------------|--------------------|------------------|----------------------------|
| gpio_[56:32] | I/O | GPIO | Hi-Z |
| gpio_[66:59] | I/O | GPIO | Hi-Z |
| gpi_[80:67] | I | GPIO inputs only | Hi-Z |
| gpio_[174:81] | I/O | GPIO | Hi-Z |
| gpi_[178:175] | I | GPIO | Hi-Z |
| gpio_[191:181] | I/O | GPIO | Hi-Z |

Figure 26-4 shows the signal connections of GPIO1.

Figure 26-4. GPIO1 Signal Connections

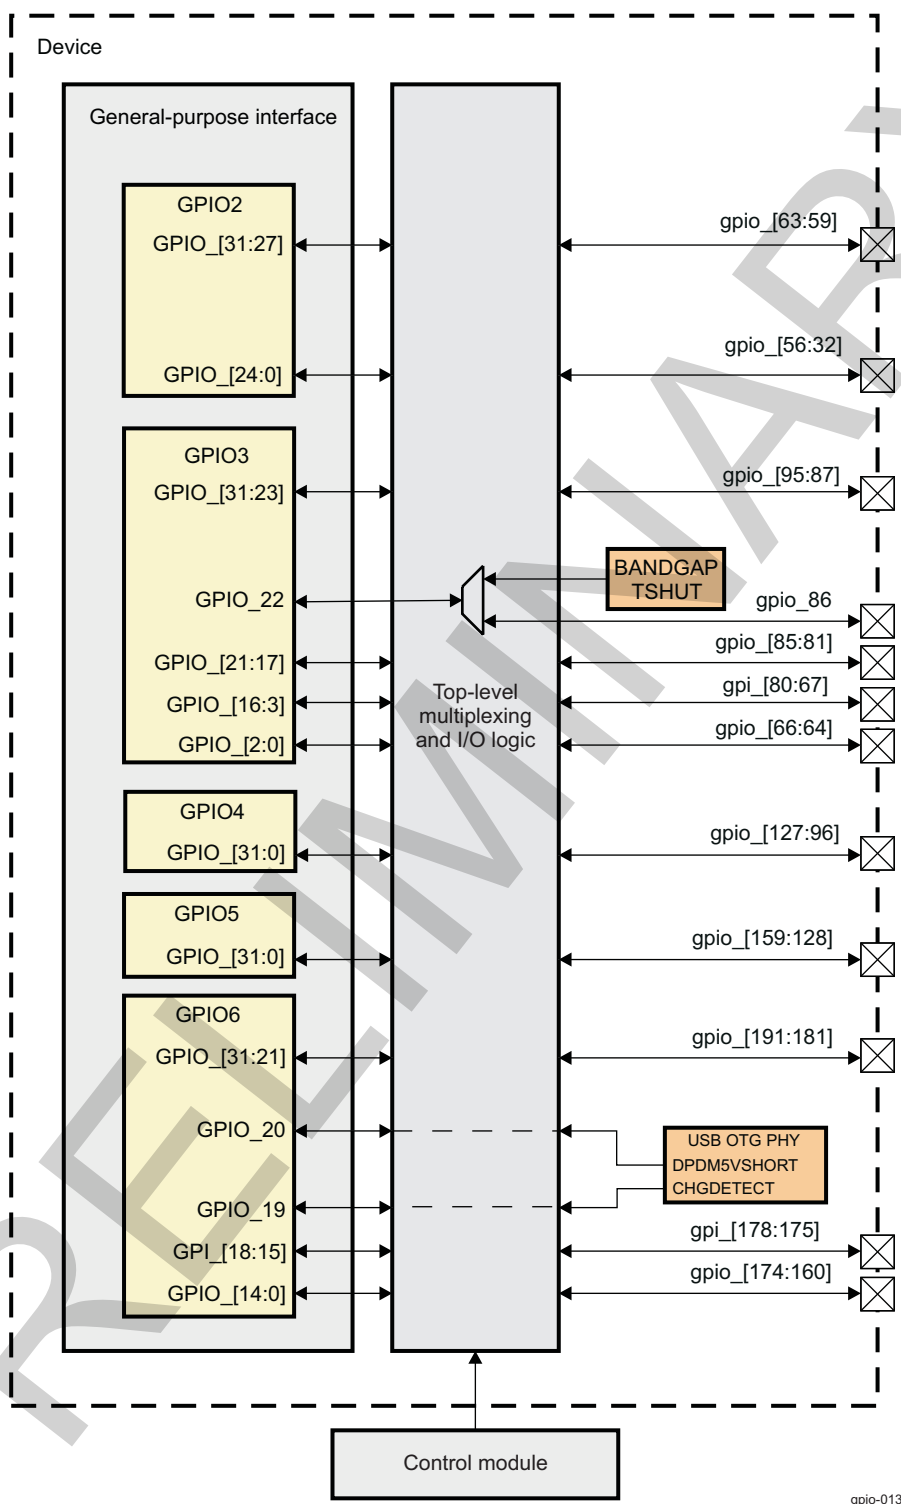

NOTE: Users must not use a GPIO channel through two device pads simultaneously. The following channels can be mapped on two different device pads:

- GPIO[3:2] of the GPIO1 module (signals gpio_[3:2] or gpio_wk[3:2]; each can be routed to a different device pad). See [Figure 26-4](#).
- GPIO[8:4] of the GPIO4 module (signals gpio_[104:100]; each can be routed to two different device pads)

Therefore, appropriate configuration must be done through the pad configuration registers. See [Section 19.4.8, Pad Functional Multiplexing and Configuration](#), in [Chapter 19, Control Module](#).

[Figure 26-5](#) shows the signal connections of GPIO2 through GPIO6.

Figure 26-5. GPIO2 Through GPIO6 Signal Connections

NOTE: The GPIO_22 channel of the GPIO3 module receives a thermal shutdown (TSHUT) signal from the BANDGAP module whenever pad mux mode is not set to 3 (gpio_86 signal selected). See [Section 19.4.8, Pad Functional Multiplexing and Configuration](#), in [Chapter 19, Control Module](#).

NOTE: For more information about the signals and channel descriptions of GPIO1 through GPIO6, see [Section 26.4.7](#), *General-Purpose Interface Channels Description*.

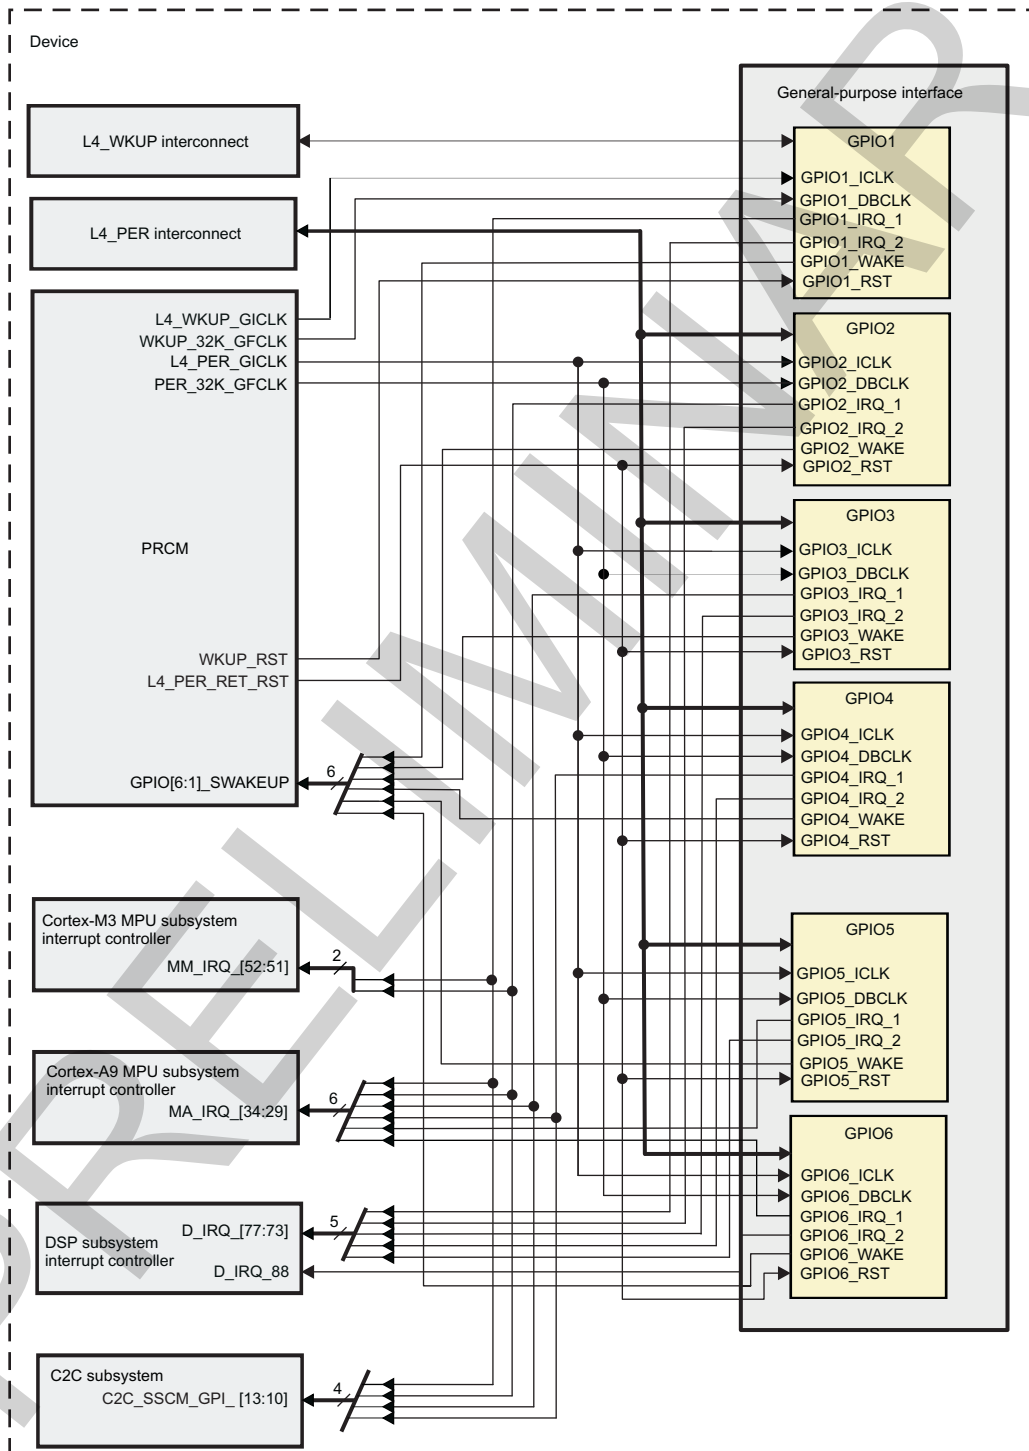

NOTE: For more information about GPIO signal multiplexing, see [Section 19.4.8](#), *Pad Functional Multiplexing and Configuration*, in [Chapter 19](#), *Control Module*.

26.3 General-Purpose Interface Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 26-6 shows this module integration.

Figure 26-6. GPIO Integration

gpio-004

NOTE: For more information about the IDLE hardware handshake and the wake-up request, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 26-2](#) through [Table 26-4](#) summarize the integration of the module in the device.

Table 26-2. Integration Attributes

| Module Instance | Attributes | |
|-------------------------|--------------|--------------|
| | Power Domain | Interconnect |
| GPIO1 | PD_WKUP | L4_WKUP |

| GPIO5 | GPIO5_DSP_IRQ | D_IRQ_77 | DSP | An interrupt to the DSP (second interrupt) |
| | GPIO5_MPU_IRQ | MA_IRQ_33 | Cortex-A9 | An interrupt to the MPU subsystem (first interrupt) |
| GPIO6 | GPIO6_DSP_IRQ | D_IRQ_88 | DSP | An interrupt to the DSP (second interrupt) |
| | GPIO6_MPU_IRQ | MA_IRQ_34 | Cortex-A9 | An interrupt to the MPU subsystem (first interrupt) |

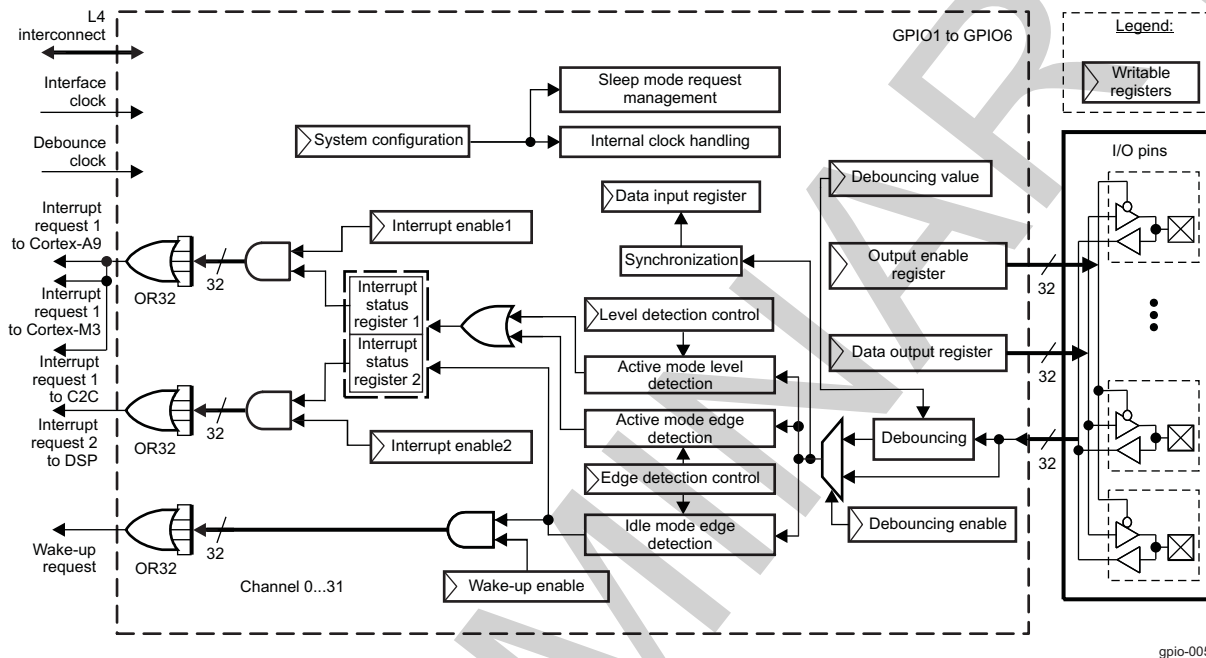

NOTE: For a description of interrupt source, see [Section 26.4.6, General-Purpose Interface Interrupt and Wake-Up Requests](#).

26.4 General-Purpose Interface Functional Description

26.4.1 General-Purpose Interface Description

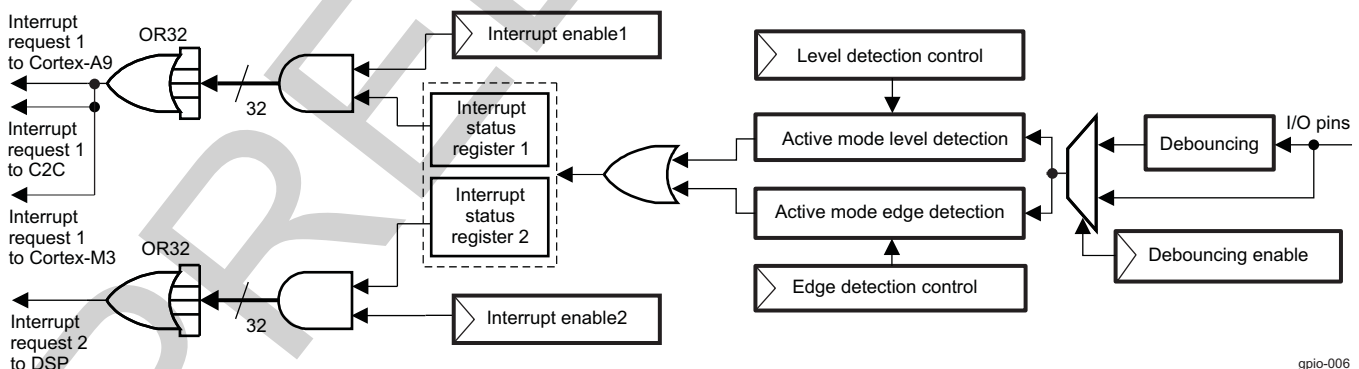

Figure 26-7 shows the details of the GPIOs in the general-purpose interface block diagram, including their configuration registers and main functional paths.

Figure 26-7. General-Purpose Interface Block Diagram

The synchronous path (for active mode operation) used to generate a synchronous interrupt request on expected event detection on any input GPIO. Synchronous interrupt request lines 1 and 2 are active based on their respective interrupt enable 1 and 2 registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_1, GPIOi.GPIO_IRQSTATUS_CLR_0, and GPIOi.GPIO_IRQSTATUS_CLR_1). See Figure 26-8.

Figure 26-8. Synchronous Path

The asynchronous path (for idle mode operation) used to generate an asynchronous wake-up request on the expected edge detection on any input GPIO. The asynchronous wake-up request line is active based on the wake-up-enable register. See Figure 26-9.

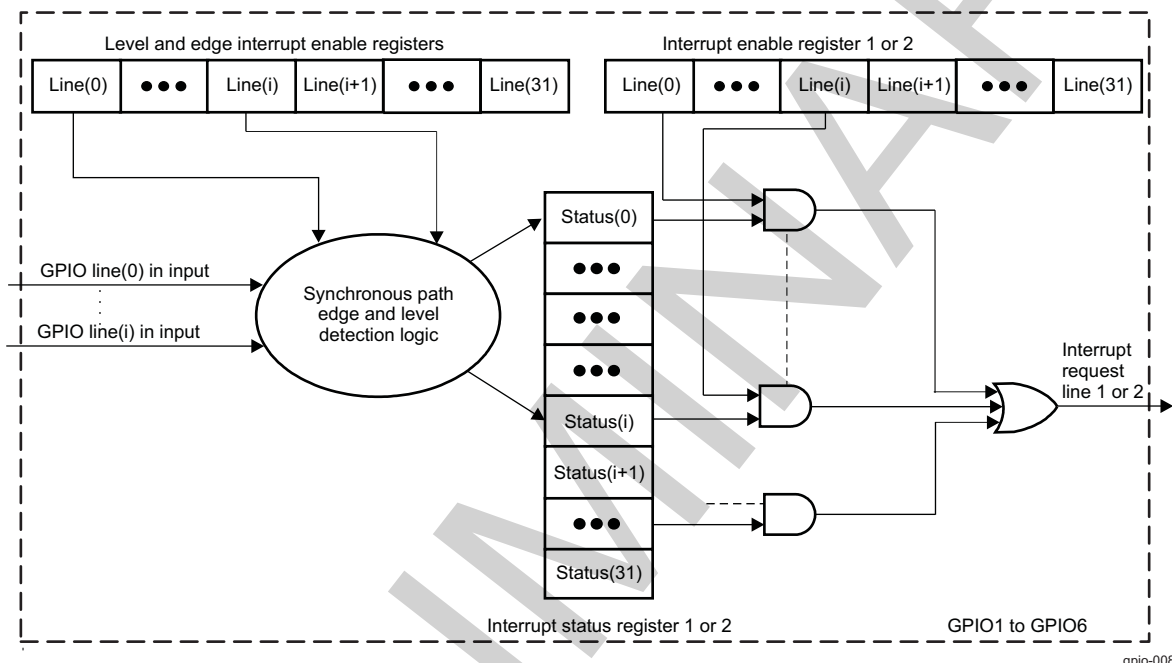

When the debounce feature is active, the latency depends on the value of the debouncing time register (GPIOi.GPIO_DEBOUNCINGTIME) (see [Section 26.4.3, General-Purpose Interface Clock Configuration](#)) and is less than three internally gated interface clock cycles plus two interface clock cycles plus GPIOi.GPIO_DEBOUNCINGTIME register value debounce clock cycles plus three debounce clock cycles.

Synchronous interrupt request line 1 is mapped on the Cortex-A9 MPU, Cortex-M3 MPU, and C2C subsystems.

Synchronous interrupt request line 2 is mapped on the DSP INTC.

Figure 26-10 is an overview of the interrupt request generation.

Figure 26-10. Interrupt Request Generation

26.4.2.2 Asynchronous Path: Wake-Up Request Generation

In the general-purpose interface, six wake-up lines (one wake-up line per GPIO module instance) connect to the PRCM module.

Asynchronous wake-up requests from input channels are merged to issue one wake-up signal to the system per each GPIO module. The wake-up-enable registers (GPIOi.GPIO_IRQWAKEN_0 and GPIOi.GPIO_IRQWAKEN_1) select the channel(s) considered for the wake-up request generation. The asynchronous wake-up request is reflected into the synchronous interrupt status registers (GPIOi.GPIO_IRQSTATUS_0 and GPIOi.GPIO_IRQSTATUS_1).

In idle mode (the interface clock is shut down and the GPIO configuration registers are programmed; see [Section 26.4.6, General-Purpose Interface Interrupt and Wake-Up Requests](#)), an asynchronous path detects the expected transition(s) on a GPIO input (based on register programming) and activates an asynchronous wake-up request by the sideband signal (GPIOi_SWAKEUP, where i = 1, 2, 3, 4, 5, or 6), if the wake-up-enable register is set.

When the system is awakened, the interface clock is restarted and synchronously set to 1 based on the input GPIO pin triggering the wake-up request and the corresponding bit in the interrupt status registers (GPIOi.GPIO_IRQSTATUS_0 and GPIOi.GPIO_IRQSTATUS_1). On the following internal clock cycle, interrupt lines 1 and/or 2 are active (active low) when the corresponding bits are set in the interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_1, GPIOi.GPIO_IRQSTATUS_CLR_0, and GPIOi.GPIO_IRQSTATUS_CLR_1).

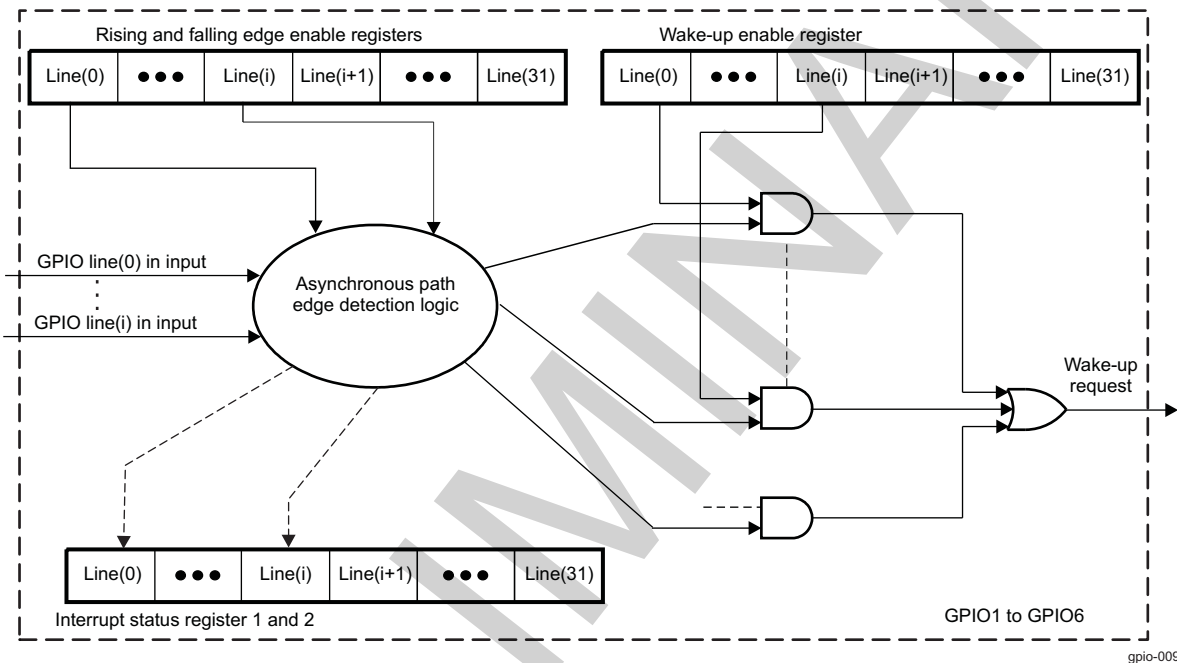

NOTE: When debouncing is not enabled, a minimum input pulse width does not trigger the wake-up request because there is no sampling operation.

When debouncing is enabled, the minimum pulse width is set by the specified debouncing time.

The GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP bit enables or disables the GPIO wake-up feature globally. If this bit is set to 0, the wake-up-enable registers (GPIOi.GPIO_IRQWAKEN_0 and GPIOi.GPIO_IRQWAKEN_1) have no effect.

Figure 26-11 is an overview of wake-up request generation.

Figure 26-11. Wake-Up Request Generation

26.4.2.3 Wake-Up Event Conditions During Transition To and From IDLE State

Figure 26-12 shows the wake-up event conditions.

In phase A, only the synchronous path is enabled. A synchronous interrupt request (see [Section 26.4.2.1, Synchronous Path: Interrupt Request Generation](#)) activates the interrupt line(s) and prevents the GPIO from transitioning into IDLE state until the interrupt is cleared.

In phase B, the asynchronous path and synchronous path are enabled during the first five functional clock cycles of the SLEEPTRANS state. During this period a synchronous interrupt request (see [Section 26.4.2.1, Synchronous Path: Interrupt Request Generation](#)) prevents the GPIO from transitioning into IDLE state. A shorter pulse puts the module into IDLE state but triggers a wakeup once in IDLE.

In phase C, only the asynchronous path is enabled. A wake-up request (see [Section 26.4.2.2, Asynchronous Path: Wake-Up Request Generation](#)) triggers a wake-up request from the GPIO and when the module is awakened an interrupt is generated. If debouncing is not enabled, there is no minimum input pulse width to trigger the wake-up request.

In phase D, eight OCP clock cycles occur until the module is in FUNCT state, the synchronous path is enabled, and an event that fulfills the pulse width requirements (see [Section 26.4.2.1, Synchronous Path: Interrupt Request Generation](#)) activates the interrupt line(s).

In phase E, only the synchronous path is enabled. A synchronous interrupt request (see [Section 26.4.2.1, Synchronous Path: Interrupt Request Generation](#)) activates the interrupt line(s).

Figure 26-12. Wake-Up Event Conditions

26.4.2.4 Interrupt (or Wake-Up) Line Release

When the host processor (the MPU and/or DSP subsystem in the device) receives an interrupt request issued by the GPIO, it reads the corresponding interrupt status register (GPIOi.GPIO_IRQSTATUS_0 or GPIOi.GPIO_IRQSTATUS_1) to determine which GPIO input triggered the interrupt (or the wake-up request).

After servicing the interrupt (or acknowledging the wake-up request), the processor resets the status bit and releases the interrupt line by setting the corresponding bit of the interrupt status register to 1. If there is still a pending interrupt request to serve (all bits in the interrupt status register that are not masked by the interrupt-enable register are not cleared), the interrupt line is reasserted.

NOTE: The status bit must be reset to re-enter idle mode.

26.4.3 General-Purpose Interface Clock Configuration

26.4.3.1 Clocking

Each GPIO uses two clocks:

- **Debounce clock:** The 32-kHz debounce clock, GPIOi_DBCLK (where i = 1, 2, 3, 4, 5, or 6, with one debounce clock per module), comes from the PRCM module and is used for the debounce cell logic (without the corresponding configuration registers). This cell can sample the input line and filters the input level using a programmed delay.

The debouncing value register (GPIOi.GPIO_DEBOUNCINGTIME) is used to set the debouncing time for all input lines in the GPIO module. The value is global for all the ports of one GPIO, so up to six different debouncing values are possible. The debounce cell runs with the debounce clock (32 kHz). This register represents the number of clock cycle(s) to be used (one cycle is 31 μs long).

The following formula describes the required input stable time to be propagated to the debounced output:

Required input line stable = (GPIOi.GPIO_DEBOUNCINGTIME[7:0] DEBOUNCVAL bit field value + 1) × 31,

where the value of the DEBOUNCVAL bit field is from 0 to 255.

For more information, see [CD_L4_PER_Clock Domain](#), and [CD_WKUP_Clock Domain](#), in [Chapter 3, Power, Reset, and Clock Management](#).

- **Interface clock:** The interface clock, GPIOi_ICLK (where i = 1, 2, 3, 4, 5, or 6), comes from the PRCM module and is used throughout the GPIO (except within the debounce cell logic). GPIOi_ICLK clocks the data exchanges between the L4 interconnect and the internal logic. The clock-gating features allow module power consumption to be adapted to the activity.

For more information, see [CD_L4_PER_Clock Domain](#), and [CD_WKUP_Clock Domain](#), in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 26-3](#) describes the GPIO clocks.

Table 26-5 summarizes the functional clock configuration.

Table 26-5. Functional Clock Configuration

| Interface Clock | GPIO_CTRL[2:1] GATINGRATIO | Functional Clock |
|------------------------------|----------------------------|----------------------------------|
| GPIOi_ICLK, where i = 1 to 6 | 00 | GPIOi_ICLK / 1, where i = 1 to 6 |
| GPIOi_ICLK, where i = 1 to 6 | 01 | GPIOi_ICLK / 2, where i = 1 to 6 |
| GPIOi_ICLK, where i = 1 to 6 | 10 | GPIOi_ICLK / 4, where i = 1 to 6 |
| GPIOi_ICLK, where i = 1 to 6 | 11 | GPIOi_ICLK / 8, where i = 1 to 6 |

26.4.4 General-Purpose Interface Hardware and Software Reset

The GPIO can be reset by using the domain reset (hardware reset) or by setting a dedicated configuration bit (software reset) in each GPIO.

- Hardware reset: GPIO2 to GPIO6 are attached to the PER_RST reset domain. GPIO1 is attached to the WKUP_RST reset domain.

The hardware reset has a global reset action on the GPIOs of the general-purpose interface. All configuration registers and internal logic are reset when it is active (low level). In each GPIO, the GPIOi.GPIO_SYSSTATUS[0] RESETDONE bit monitors the internal reset status; it is set when the reset completes. For more information, see [Reset Domains](#), in [Chapter 3, Power, Reset, and Clock Management](#).

- Software reset: Each GPIO has its own software reset using the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit (where i = 1, 2, 3, 4, 5, or 6). The software reset has the same effect as the hardware reset signal, but this reset can be applied on one or more modules.

Setting the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit to 1, (where i = 1, 2, 3, 4, 5, or 6) resets the module. A bit value of 1 remains until the reset completes. When the software reset completes, the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit is automatically reset to 0 and has the same effect as a hardware reset. The GPIOi.GPIO_SYSSTATUS[0] RESETDONE bit is cleared during a software reset. This bit is set to 1 when the software reset completes.

26.4.5 General-Purpose Interface Power Management

26.4.5.1 Power Domain

GPIO1 is attached to the WKUP power domain (see [Section 3.1.1.2, Power Management](#), in [Chapter 3, Power, Reset, and Clock Management](#)). This domain is composed of the logic permanently supplied to manage domain power state transitions and detect wake-up events. The WKUP power domain is continuously active. GPIO2 to GPIO6 are attached to the PER power domain (see [Section 3.1.1.2, Power Management](#), in [Chapter 3, Power, Reset, and Clock Management](#)). The PER power domain is not active continuously.

26.4.5.2 Power Management

26.4.5.2.1 Idle Scheme

To reduce dynamic consumption, an efficient idle scheme is based on the following:

- An efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated and deactivated safely without requiring complex software management.

The idle mode request, idle acknowledge, and wake-up request (GPIOi_WAKEUP, where i = 1, 2, 3, 4, 5, or 6) are sideband signals between the PRCM module and the general-purpose interface (see [Section 26.4.6.2, Wake-Up Request Generation](#)).

26.4.5.2.2 Operating Modes

The following four operating modes are defined for the modules:

- **Active mode:** The module runs synchronously on the interface clock; interrupts can be generated based on the configuration and external signals.
- **Idle mode:** Power-saving mode with the module in a waiting state. The interface clock can be stopped, an interrupt cannot be generated, and a wake-up signal can be generated based on the configuration and external signals.

If the debounce clock provided by the PRCM module is active, the debounce cell can sample and filter the input to generate a wake-up event. If the debounce clock is inactive, the debounce cell gates all input signals and thus cannot be used.

- **Inactive mode:** The module has no activity. The interface clock can be stopped, an interrupt cannot be generated, and the wake-up feature is inhibited.
- **Disabled mode:** The module is not used. The internal clock paths are gated, and an interrupt or wake-up request cannot be generated.

Idle and inactive modes are configured within the module and activated on request by the PRCM module (see [Section 3.1.1.2, Power Management](#), in [Chapter 3, Power, Reset, and Clock Management](#)) through sideband signals (see [Section 26.4.5.2.3, System Power Management and Wakeup](#)).

The disabled mode is set by software through a dedicated configuration bit, GPIOi.GPIO_CTRL[0] DISABLEMODULE (0: The module is enabled and clocks are not gated; 1: The module is disabled and clocks are gated). It unconditionally gates the internal clock paths that are not used for the L4 interconnect.

26.4.5.2.3 System Power Management and Wakeup

The PRCM module can require the GPIOs to be idled for power-saving purposes.

The general-purpose interface has six identical idle mode request/acknowledge (handshake) mechanisms with the PRCM module (see [Section 26.4.6.2, Wake-Up Request Generation](#)): one per GPIO. The general-purpose interface allows the GPIOs to enter idle mode based on the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field.

Idle acknowledge depends on the configuration and activity of each GPIO:

- **Smart-idle mode**

When the GPIO is configured in smart-idle mode, it checks for more activity (capture of the input GPIO pins in the GPIOi.GPIO_DATAIN register is complete with no pending interrupt; all interrupt status bits are cleared), and there is no access to the GPIO.GPIO_DEBOUNCINGTIME register, which is waiting to be synchronized.

Idle acknowledge is then asserted and the module enters into idle mode. It waits for active system clock gating by the PRCM module (when all peripherals supplied by the same L4 interface clock domain are also ready for idle).

In idle mode (that is, when the PRCM module gates the interface clock), no interrupt occurs and the module is ready to issue a wake-up request.

When the expected transition occurs on an enabled GPIO input pin, the GPIO exits from idle mode if the GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP bit is set to 1 (wake-up capability is enabled).

- **Smart-idle wake-up mode**

If the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field selects smart-idle or smart-idle wake-up mode, the GPIO module evaluates its internal capability to switch off the interface clock. When all internal activity ceases (the data input register captures the input GPIO pins, there is no pending interrupt, all interrupt status bits are cleared, and there is no write access to the GPIO.GPIO_DEBOUNCINGTIME register pending to be synchronized), the Idle acknowledge is asserted and the GPIO enters into idle mode, ready to issue a wake-up request when the expected transition occurs on an enabled GPIO input pin. This wake-up request is sent only if the GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP bit of the system configuration register enables the GPIO wake-up capability (see [Section 26.6.2.2, System Configuration Register](#)). When the system is awake, the idle request goes inactive, the idle acknowledge and wake-up request (if the GPIO triggered the systems wakeup) signals are immediately deasserted, and the asynchronous wake-up request (if

existing) is reflected into the synchronous interrupt status registers.

- Force-idle mode

When the GPIO is configured in force-idle mode (the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field = 2b00) and receives an idle request from the PRCM module, the GPIO waits unconditionally for active system clock gating by the PRCM module. (This occurs only when all peripherals supplied by the same L4 interface clock domain are also ready for idle.)

When in idle mode (that is, when the PRCM module gates the interface clock), the module (in inactive mode) has no activity, the interface clock paths are gated, an interrupt cannot be generated, and the wake-up feature is inhibited.

- No-idle mode

When the GPIO is configured in no-idle mode (the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field = 2b01) and receives an idle request from the PRCM module, the GPIO does not go into idle mode and the idle acknowledge is never sent.

NOTE: For more information about idle modes, see [Section 3.1.1.2, Power Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

26.4.5.2.4 Module Power Saving

The GPIO has local power management by internal clock-gating features:

- Internal interface clock gating: The clock for the L4 interconnect logic can be gated when the GPIO module is not accessed, if the GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit is set. Otherwise, this logic is free-running on the interface clock.
- Clock gating for the input data sample logic: Clock for the input data sample logic can be gated when the data in the GPIOi.GPIO_DATAIN register is not accessed.
- Clock gating for the event detection logic: Each GPIO implements four clock groups used for the logic in the synchronous event detection. Each group of eight input GPIO pins has a separate enable signal depending on the setting of the edge/level detection register (because the input is 32 bits, four groups of eight inputs are defined for each GPIO). If a group requires no detection, the corresponding clock is gated.

Grouping the edge/level enable can save the power consumption of the GPIO module.

If any of the following registers is set to 0x01 01 01 01, then all clocks are active (power consumption is high). If they are set to 0x00 00 00 FF, then a single clock is active (power saving).

- GPIOi.GPIO_LEVELDETECT0
- GPIOi.GPIO_LEVELDETECT1
- GPIOi.GPIO_RISINGDETECT
- GPIOi.GPIO_FALLINGDETECT

NOTE: When the clocks are enabled by writing to the following registers, the detection starts after five clock cycles. This period is required to clean the synchronization edge/level detection pipeline.

- GPIOi.GPIO_LEVELDETECT0
- GPIOi.GPIO_LEVELDETECT1
- GPIOi.GPIO_RISINGDETECT
- GPIOi.GPIO_FALLINGDETECT

The mechanism is independent of each clock group. If the clock has been started before and a new setting is performed, the following steps are recommended:

1. Set the new detection required.
2. Disable the previous setting (if necessary).

In this way, the corresponding clock is not gated and the detection starts immediately.

All channels are also gated using a one-out-of-N scheme. N is the GPIOi.GPIO_CTRL[2:1]

GATINGRATIO bit field and can take the values 1 (2b00), 2 (2b01), 4 (2b10), or 8 (2b11). The interface clock is enabled for this logic one cycle every N cycles. When N is equal to 1, there is no gating and this logic is free-running on the interface clock. When N is 2, 4, or 8, this logic runs at the equivalent frequency of interface clock frequency divided by N.

- Inactive mode: In inactive mode, all internal clock paths are gated.
- Disabled mode: All internal clock paths not used for the L4 interconnect are gated. The GPIOi.GPIO_CTRL[0] DISABLEMODULE bit controls a clock-gating feature at the module level. When set to 1, this bit forces clock gating for all internal clock paths. Internal activity in the module is suspended. The L4 interconnect is not affected by this bit.

The interface clock gating is controlled through the GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit, which is used to save power when the module is not used because of the multiplexing configuration selected at the device level. This bit takes precedence over all other internal configuration bits.

Table 26-6 describes the power-management features available for the general-purpose interface module.

NOTE: For information about source clock gating and a description of sleep/wake-up transitions, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

For descriptions of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 26-6. Local Power-Management Features

| Feature | Registers | Description |
|------------------------|--|---|
| Clock autogating | GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE | Sets the clock-gating strategy for the OCP interface block. |
| Slave idle modes | GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE | Force-idle, no-idle, and smart-idle wake-up-capable modes are available. |
| Clock activity | GPIOi.GPIO_CTRL[0] DISABLEMODULE | Enable and disable the module. |
| Debouncing enable | GPIOi.GPIO_DEBOUNCENABLE[31:0] DEBOUNCEENABLE | Debouncing mode is available. |
| Global wake-up enable | GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP | This bit enables the wake-up feature at module level. |
| Wake-up sources enable | GPIOi.GPIO_IRQWAKEN_0[31:0] INTLINE GPIOi.GPIO_IRQWAKEN_1[31:0] INTLINE | This register enables or disables a specific IRQ request source to generate a wake-up signal. |

Table 26-7 describes the clock activity settings.

Table 26-7. Clock Activity Settings

| GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE | Selected Mode | Description | Wake-Up Events |
|------------------------------------|--------------------|---|----------------|
| 00 | Force-idle | The GPIO goes into inactive mode independently of the internal module state, and the idle acknowledge is never sent. | No |
| 01 | No-idle | The GPIO does not go into the idle mode and the idle acknowledge is never sent. | No |
| 10 | Smart-idle | The GPIO evaluates its internal capability to switch off the interface clock. If there is no more internal activity, the idle acknowledge is asserted and the GPIO enters into idle mode. | No |
| 11 | Smart-idle wake-up | The GPIO evaluates its internal capability to have the interface clock switched off. If there is no more internal activity, the idle acknowledge is asserted and the GPIO enters into idle mode. | Yes |

26.4.6 General-Purpose Interface Interrupt and Wake-Up Requests

26.4.6.1 Interrupt Request Generation

All interrupt sources (the 32 GPIO input channels) are merged to issue two synchronous interrupt requests in each GPIO module. Thus, the general-purpose interface has 12 interrupt lines (two interrupt lines per each GPIO instance).

- Synchronous interrupt request line 1 is mapped on the Cortex-A9 and Cortex-M3 MPU INTCs, and on the C2C subsystem.
- Synchronous interrupt request line 2 is mapped on the DSP INTC.

Table 26-8 lists the event flags, and their mask, that can cause module interrupts.

Table 26-8. Events

| Event Flag | Event Mask | Synchronous | Sensitivity | Map to | Description |
|---------------------------------------|--|-------------|-------------|---|---|
| GPIOi.GPIO_IRQSTATUS_0[31:0] INTLINE | GPIOi.GPIO_IRQSTATUS_SET_0[31:0] INTLINE | Yes | Edge/level | MA_IRQ_n MM_IRQ_n ⁽¹⁾ C2C_IRQ_n ⁽²⁾ | Corresponds to the first line of interrupt |
| GPIOi.GPIO_IRQSTATUS_1[31:0] INTLINE | GPIOi.GPIO_IRQSTATUS_SET_1[31:0] INTLINE | Yes | Edge/level | D_IRQ_n | Corresponds to the second line of interrupt |
| GPIOi.GPIO_IRQSTATUS_0 [31:0] INTLINE | GPIOi.GPIO_IRQSTATUS_CLR_0[31:0] INTLINE | Yes | Edge/level | MA_IRQ_n MM_IRQ_n ⁽¹⁾ C2C_IRQ_n ⁽²⁾ | Corresponds to the first line of interrupt |
| GPIOi.GPIO_IRQSTATUS_1[31:0] INTLINE | GPIOi.GPIO_IRQSTATUS_CLR_1[31:0] INTLINE | Yes | Edge/level | D_IRQ_n | Corresponds to the second line of interrupt |
| GPIOi.GPIO_IRQSTATUS_0[31:0] INTLINE | GPIOi.GPIO_IRQWAKEN_0[31:0] INTLINE | No | Edge/level | MA_IRQ_n MM_IRQ_n ⁽¹⁾ C2C_IRQ_n ⁽²⁾ | Corresponds to the first line of interrupt |
| GPIOi.GPIO_IRQSTATUS_1[31:0] INTLINE | GPIOi.GPIO_IRQWAKEN_1[31:0] INTLINE | No | Edge/level | D_IRQ_n | Corresponds to the second line of interrupt |

⁽¹⁾ For GPIO1 and GPIO2 only

⁽²⁾ For GPIO1 to GPIO4 only

Synchronous interrupt request lines 1 and 2 are active depending on their respective interrupt-enable 1 and 2 registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_1, GPIOi.GPIO_IRQSTATUS_CLR_0, and GPIOi.GPIO_IRQSTATUS_CLR_1).

- Interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_1)

The interrupt-enable 1 (or interrupt-enable 2) register allows masking of the expected transition on input GPIO to prevent the generation of an interrupt request on line 1 (or line 2). The interrupt-enable registers are programmed synchronously with the interface clock.

These registers can be accessed with direct read/write operations or using the alternate set-and-clear protocol feature for register update. This feature allows the setting or clearing of explicit bits of these registers with a single write access (see Section 26.4.9, *General-Purpose Interface Set-and-Clear Protocol*).

- Interrupt status registers (GPIOi.GPIO_IRQSTATUS_0 and GPIOi.GPIO_IRQSTATUS_1)

The interrupt status 1 (or interrupt status 2) register determines which of the input GPIO pins triggered the interrupt line1 (or interrupt line 2) request (or the wake-up line).

When a bit in this register is set to 1, it indicates that the corresponding GPIO pin is requesting the interrupt (or the wakeup). To reset a bit in this register, set the appropriate bit to 1. However, an interrupt cannot be generated by setting the interrupt status 1 (or interrupt status 2) register to 1.

If 0 is written to a bit in this register, the value remains unchanged. The interrupt status 1 (or interrupt status 2) register is synchronous with the interface clock. In idle mode, the event is detected through an asynchronous path, and the corresponding bit in the interrupt status1 and interrupt status 2 registers are set when the GPIO is awakened.

CAUTION

After servicing the interrupt, the status bit in the interrupt status register (GPIOi.GPIO_IRQSTATUS_0 or GPIOi.GPIO_IRQSTATUS_1) must be reset and the interrupt line must be released (by setting the corresponding bit of the interrupt status register to 1) before enabling an interrupt for the GPIO channel in the interrupt-enable register (GPIOi.GPIO_IRQSTATUS_SET_0 or GPIOi.GPIO_IRQSTATUS_SET_1) to prevent the occurrence of unexpected interrupts when enabling an interrupt for the GPIO channel.

26.4.6.2 Wake-Up Request Generation

GPIO1 of the general-purpose interface is attached to the WKUP power domain (see [Section 3.1.1.2, Power Management](#), in [Chapter 3, Power, Reset, and Clock Management](#)) and can wake up the system.

NOTE: GPIO2 to GPIO6 belong to the PER power domain and thus their wake-up capabilities are operational only when the PER power domain is active.

All wake-up sources (the 32 input GPIO channels) are merged together to issue a single asynchronous wake-up request in each GPIO following the expected transition(s) (based on register programming). Each GPIO generates a wake-up signal to the PRCM module.

NOTE: Only gpio_wk[10:0] and gpio_wk[31:29] can be used to generate a direct wake-up event.

The asynchronous wake-up request line is active based on the GPIOi.GPIO_IRQWAKEN_0 and GPIOi.GPIO_IRQWAKEN_1 wake-up-enable registers (where i = 1, 2, 3, 4, 5, or 6).

The wake-up-enable register allows masking of the expected transition on input GPIO to prevent the generation of a wake-up request. The wake-up-enable register is programmed synchronously with the interface clock before any idle mode request coming from the host processor.

NOTE: There must be a correlation between the wake-up-enable and interrupt-enable registers. If a GPIO pin has a wakeup configured on it, it must also have the corresponding interrupt enabled (on one of the two interrupt lines). Otherwise, it is possible to have a wake-up event, but after exiting the IDLE state, no interrupt is generated; thus, the corresponding bit from the interrupt status register is not cleared, and the module does not acknowledge a future idle request.

[Table 26-9](#) lists the mapping of the wake-up signals.

Table 26-9. Wake-Up Signals

| Name | Mapping | Comments |
|------------|---------------|---|
| GPIOi_WAKE | GPIOi_SWAKEUP | Where i = 1, 2, 3, 4, 5, and 6. Destination is the PRCM module. |

26.4.7 General-Purpose Interface Channel Description

[Table 26-10](#) describes the GPIO channels.

Table 26-10. GPIO Channel Description

| Channel Number | Type ⁽¹⁾ | Mapping | Wake-Up Feature | Comments |
|----------------|---------------------|---------|-----------------|----------|
| GPIO1 | | | | |

⁽²⁾ Only when the PER power domain is active

⁽³⁾ The GPIO channel is not available on device pads. Reserved for internal use only (see the Comments column).

⁽⁴⁾ The GPIO channel is not available on device pads. Reserved for internal use only (see the Comments column).

⁽⁵⁾ Only when the PER power domain is active

⁽⁶⁾ The GPIO channel provides additional internal functionality (see the Comments column), besides its GPIO capabilities, when it is not connected to a pad of the device. That is, the corresponding pad is configured in a mode different from multiplexing mode 3. For more information about pad configuration and multiplexing, see [Section 19.4.8, Pad Functional Multiplexing and Configuration](#), in [Chapter 19, Control Module](#).

NOTE: The thermal shutdown comparator output signal (TSHUT) is an output from the BANDGAP module. This signal is low during normal operation and goes high during a thermal shutdown event. When channel 22 of GPIO3 is not connected to a ball of the device (the corresponding pin is configured in a mode different from configuration mode 4), TSHUT is connected to channel 22 of GPIO3. The channel has to be correctly configured so that it can generate an interrupt when a low-to-high transition occurs on TSHUT.

For more information about pin configuration, see [Section 19.4.8, Pad Functional Multiplexing and Configuration](#), in [Chapter 19, Control Module](#).

NOTE: Channels 20 and 19 of GPIO6 are internally connected inside the device to the short detection (DPDM5VSHORT) and charger detection (CHGDETECT) outputs, respectively, of the USB OTG PHY module. This allows interrupt generation on the corresponding GPIO channel, if either of the mentioned events occurs.

26.4.8 General-Purpose Interface Data Input/Output Capabilities

The output-enable register (GPIOi.GPIO_OE) controls the output/input capability of each pin. At reset, all the GPIO-related pins are configured as inputs, and their output capabilities are disabled. This register is not used within the module. Its only function is to carry the pad configuration.

When configured as an output (the desired bit is reset in the GPIOi.GPIO_OE register), the value of the corresponding bit in the GPIOi.GPIO_DATAOUT register is driven on the corresponding GPIO pin. Data is written to the data-output register synchronously with the interface clock. This register can be accessed with read/write operations or by using the alternate set-and-clear protocol register update feature. This feature gives the possibility to set or clear specific bits of this register with a single write access to the set-output data register (GPIOi.GPIO_SETDATAOUT) or to the clear-output data register (GPIOi.GPIO_CLEARDATAOUT) address (see [Section 26.4.9, General-Purpose Interface Set-and-Clear Protocol](#)). If the application uses a pin as an output and does not want interrupt/wake-up generation from this pin, the application must properly configure the wake-up-enable registers (GPIOi.GPIO_IRQWAKEN_0 and GPIOi.GPIO_IRQWAKEN_1) and the interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_1).

When configured as an input (the desired bit is set to 1 in the GPIOi.GPIO_OE register), the state of the input can be read from the corresponding bit in the GPIOi.GPIO_DATAIN register. The input data is sampled synchronously with the interface clock and then captured in the data input register synchronously with the interface clock. When the GPIO pin levels change, they are captured into this register after two interface clock cycles (the required cycles to synchronize and to write data). If the application uses a pin as an input, the application must properly configure the wake-up enable registers (GPIOi.GPIO_IRQWAKEN_0 and GPIOi.GPIO_IRQWAKEN_1) and the interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_0) to the interrupt and wake-up feature as needed.

For more information on the alternate set-and-clear protocol, see [Section 26.4.9, General-Purpose Interface Set-and-Clear Protocol](#).

26.4.9 General-Purpose Interface Set-and-Clear Protocol

26.4.9.1 Description

The GPIO module implements the set-and-clear protocol register update for the following registers:

- GPIOi.GPIO_DATAOUT
- GPIOi.GPIO_IRQSTATUS_CLR_0
- GPIOi.GPIO_IRQSTATUS_CLR_1
- GPIOi.GPIO_IRQSTATUS_SET_0
- GPIOi.GPIO_IRQSTATUS_SET_1

This protocol is an alternative to the atomic test and set operations and consists of writing operations at dedicated addresses (one address for setting bit[s] and one address for clearing bit[s]). The data to write is 1 at bit position(s) to clear (or to set) and 0 at unaffected bit(s). Registers can be accessed in two ways:

- Standard: Full register read and write operations at the primary register address
- Set and clear: Separate addresses are provided to set (and clear) bits in registers. Writing 1 at these addresses sets (or clears) the corresponding bit into the equivalent register; writing 0 has no effect.

Therefore, for these registers, three addresses are defined for one unique physical register. Reading these addresses has the same effect and returns the register value.

26.4.9.2 Clear Instruction

26.4.9.2.1 Clear Register Addresses

- Clear interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_CLR_0 and GPIOi.GPIO_IRQSTATUS_CLR_1).

A write operation in the GPIOi.GPIO_IRQSTATUS_CLR_0 (or GPIOi.GPIO_IRQSTATUS_CLR_1) register clears the corresponding bit in the same register when the written bit is 1; a written bit at 0 has no effect.

A read of the clear interrupt-enable 0 (or enable 1) register returns the value of the GPIOi.GPIO_IRQSTATUS_CLR_0 (or GPIOi.GPIO_IRQSTATUS_CLR_1) register.

- Clear data-output register (GPIOi.GPIO_CLEARDATAOUT).

A write operation in the clear data-output register clears the corresponding bit in the data-output register when the written bit is 1; a written bit at 0 has no effect.

A read of the clear data-output register returns the value of the data-output register.

26.4.9.2.2 Clear Instruction Example

Assume the data-output register (or one of the interrupt/wake-up-enable register) contains the binary value, 0b0000 0001 0000 0001, and bit 0 is to be clear.

With the clear instruction feature, write 0b0000 0000 0000 0001 at the address of the clear data-output register (or at the address of the clear interrupt/wake-up-enable register). After this write operation, a reading of the data-output register (or the interrupt/wake-up-enable register) returns 0b0000 0001 0000 0000; bit 0 is cleared.

NOTE: Although the general-purpose interface registers are 32 bits wide, only the least-significant 16 bits are represented in this example.

Figure 26-13 shows an example of a clear instruction.

Figure 26-13. GPIO_CLEARDATAOUT Register Example

26.4.9.3 Set Instruction

26.4.9.3.1 Set Register Addresses

- Set interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_1).

A write operation in the GPIOi.GPIO_IRQSTATUS_SET_0 (or GPIOi.GPIO_IRQSTATUS_SET_1)

register sets the corresponding bit in the same register when the written bit is 1; a written bit at 0 has no effect.

A read of the set interrupt-enable 0 (or enable 1) register returns the value of the interrupt GPIOi.GPIO_IRQSTATUS_SET_0 (or GPIOi.GPIO_IRQSTATUS_SET_1) register.

- Set data-output register (GPIOi.GPIO_SETDATAOUT).

A write operation in the set data-output register sets the corresponding bit in the data-output register when the written bit is 1; a written bit at 0 has no effect.

A read of the set data-output register returns the value of the data-output register.

26.4.9.3.2 Set Instruction Example

Assume the interrupt-enable 1 (or enable 2) register (or the data-output register) contains the binary value, 0b0000 0001 0000 0000, and bits 15, 3, 2, and 1 are to be set.

With the set instruction feature, write 0b1000 0000 0000 1110 at the address of the set interrupt enable 1 (or enable 2) register (or at the address of the set data-output register). After this write operation, a reading of the interrupt-enable 1 (or enable 2) register (or the data-output register) returns 0b1000 0001 0000 1110; bits 15, 3, 2, and 1 are set.

NOTE: Although the general-purpose interface registers are 32 bits wide, only the least-significant 16 bits are represented in this example.

Figure 26-14 shows an example of a set instruction.

Figure 26-14. Write in GPIO_IRQSTATUS_SET_0 Register Example

gpio-011

The set wake-up-enable register offers the same feature with the wake-up-enable register.

26.5 General-Purpose Interface Programming Guide

26.5.1 General-Purpose Interface Low-Level Programming Models

26.5.1.1 Global Initialization

26.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the general-purpose interface module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the general-purpose interface. For more information, see [Section 26.3, General-Purpose Interface Integration](#), and [Section 26.2, General-Purpose Interface Environment](#).

[Table 26-11](#) describes the global initialization of modules surrounding the general-purpose interface module.

Table 26-11. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|---------------------|--|
| PRCM | Module interface and functional clocks must be enabled. For more information about the module configuration, see Chapter 3, Power, Reset, and Clock Management . |
| Control module | Module-specific pad muxing must be set in the control module. For more information about the module configuration, see Chapter 19, Control Module . |
| MPU INTC | MPU INTC configuration must be done to enable the interrupts from the general-purpose interface module. See Chapter 18, Interrupt Controllers . |
| DSP INTC | DSP INTC configuration must be done to enable the interrupts from the general-purpose interface module. See Chapter 18, Interrupt Controllers . |

26.5.1.1.2 General-Purpose Interface Module Global Initialization

This procedure in [Table 26-12](#) initializes the general-purpose interface module after a POR or software reset.

Table 26-12. General-Purpose Interface Global Initialization

| Step | Register/Bit Field/Programming Model | Value |
|--|--|-------------|
| Execute software reset. | GPIO_SYSCONFIG[1] SOFTRESET | 0x1 |
| Wait until reset completed? | GPIO_SYSSTATUS[0] RESETDONE | = 0x1 |
| Configure idle mode. | GPIO_SYSCONFIG[4:3] IDLEMODE | 0x– |
| Configure interface clock gating. | GPIO_SYSCONFIG[0] AUTOIDLE | 0x– |
| Set clock gating power saving. | GPIO_LEVELDETECT0[31:0] LEVELDETECT0 and GPIO_LEVELDETECT1[31:0] LEVELDETECT1 and GPIO_RISINGDETECT[31:0] RISINGDETECT and GPIO_FALLINGDETECT[31:0] FALLINGDETECT | 0x0000 00FF |
| Set clock gating ratio. | GPIO_CTRL[2:1] GATINGRATIO | 0x– |
| Configure GPIO channels as input or output. | GPIO_OE[31:0] OUTPUTEN | 0x– |
| Set debounce time value. | GPIO_DEBOUNCINGTIME[7:0] DEBOUNCETIME | 0x– |
| Enable/disable debouncing for desired input line. | GPIO_DEBOUNCENABLE[7:0] DEBOUNCEENABLE | 0x– |
| Interrupt and Wake-Up Request Configuration | | |
| Enable/disable interrupts. | GPIO_IRQSTATUS_SET_0[31:0] INTLINE and/or GPIO_IRQSTATUS_SET_1[31:0] INTLINE | 0x– |
| Enable/disable wakeup for GPIO channels. | GPIO_IRQWAKEN_0[31:0] INTLINE and/or GPIO_IRQWAKEN_1[31:0] INTLINE | 0x– |
| Enable/disable wake-up generation. | GPIO_SYSCONFIG[2] ENAWAKEUP | 0x1 |

26.5.1.2 General-Purpose Interface Operational Modes Configuration

Table 26-13 through Table 26-16 list the configurations of the various steps of general-purpose interface operational modes.

26.5.1.2.1 General-Purpose Interface Read Input Register

Table 26-13. General-Purpose Interface Read Input Register

| Step | Register/Bit Field/Programming Model | Value |
|----------------------------|---|-------|
| Read input register value. | GPIO_DATAIN [31:0] DATAIN | 0x– |

26.5.1.2.2 General-Purpose Interface Write Output Register

Table 26-14. General-Purpose Interface Write Output Register

| Step | Register/Bit Field/Programming Model | Value |
|---------------------------------|---|-------|
| Write value to output register. | GPIO_DATAOUT [31:0] DATAOUT | 0x– |

26.5.1.2.3 General-Purpose Interface Set Bit Function

Table 26-15. General-Purpose Interface Set Bit Function

| Step | Register/Bit Field/Programming Model | Value |
|--|---|-------|
| Write 0x1 to set desired bit(s) in register. | GPIO_SETDATAOUT [31:0] INTLINE | 0x- |
| | GPIO_IRQSTATUS_SET_0 [31:0] INTLINE | |
| | GPIO_IRQSTATUS_SET_1 [31:0] INTLINE | |

26.5.1.2.4 General-Purpose Interface Clear Bit Function

Table 26-16. General-Purpose Interface Clear Bit Function

| Step | Register/Bit Field /Programming Model | Value |
|--|---|-------|
| Write 0x1 to clear desired bit(s) in register. | GPIO_CLEARDATAOUT [31:0] INTLINE | 0x1 |
| | GPIO_IRQSTATUS_CLR_0 [31:0] INTLINE | |
| | GPIO_IRQSTATUS_CLR_1 [31:0] INTLINE | |

26.6 General-Purpose Interface Register Manual

26.6.1 General-Purpose Interface Instance Summary

Table 26-17 summarizes the general-purpose interface instance.

Table 26-17. Instance Summary

| Module Name | Base Address | Size |
|-------------|--------------|------|
| GPIO1 | 0x4A31 0000 | 4KB |
| GPIO2 | 0x4805 5000 | 4KB |
| GPIO3 | 0x4805 7000 | 4KB |
| GPIO4 | 0x4805 9000 | 4KB |
| GPIO5 | 0x4805 B000 | 4KB |
| GPIO6 | 0x4805 D000 | 4KB |

26.6.2 General-Purpose Interface Registers

26.6.2.1 General-Purpose Interface Register Summary

Table 26-18 summarizes the general-purpose interface GPIO1 to GPIO3 registers.

Table 26-18. General-Purpose Interface GPIO1 to GPIO3 Registers Summary

| | | | |
|-------------------------|--|-----------------|--|
| Address Offset | 0x0000 0010 | | |
| Physical Address | 0x4A31 0010 0x4805 5010 0x4805 7010 0x4805 9010 0x4805 B010 0x4805 D010 | Instance | GPIO1 GPIO2 GPIO3 GPIO4 GPIO5 GPIO6 |
| Description | System configuration register | | |
| Type | R | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|----------|---|---|---|-----------|---|-----------|---|----------|--|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | | |
| RESERVED | | | | | | | | | | | | | | | | | | | | | | | | IDLEMODE | | | | ENAWAKEUP | | SOFTRESET | | AUTOIDLE | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|------------|
| 31:5 | RESERVED | Reserved | R | 0x00000000 |
| 4:3 | IDLEMODE | 0x0: Force-idle: An idle request is acknowledged unconditionally. 0x1: No-idle: An idle request is never acknowledged. 0x2: Smart-idle: The acknowledgment to an idle request is given based on the internal activity (see 4.1.2). 0x3: Smart-idle wakeup | RW | 0x0 |
| 2 | ENAWAKEUP | Wake-up control 0x0: Wake-up generation is disabled. 0x1: Wake-up capability is enabled upon expected transition on input GPIO pin. | RW | 0 |
| 1 | SOFTRESET | Software reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset. | RW | 0 |
| 0 | AUTOIDLE | OCF clock gating control. 0x0: Internal Interface OCF clock is free-running. 0x1: Automatic internal OCF clock gating, based on the OCF interface activity | RW | 0 |

Keyboard Controller

This chapter describes the keyboard module of the device.

| Topic | Page |
|---|------|
| 27.1 Keyboard Controller Overview | 5440 |
| 27.2 Keyboard Controller Environment | 5442 |
| 27.3 Keyboard Controller Integration | 5445 |
| 27.4 Keyboard Controller Functional Description | 5447 |
| 27.5 Keyboard Controller Programming Guide | 5457 |
| 27.6 Keyboard Controller Register Manual | 5461 |

27.1 Keyboard Controller Overview

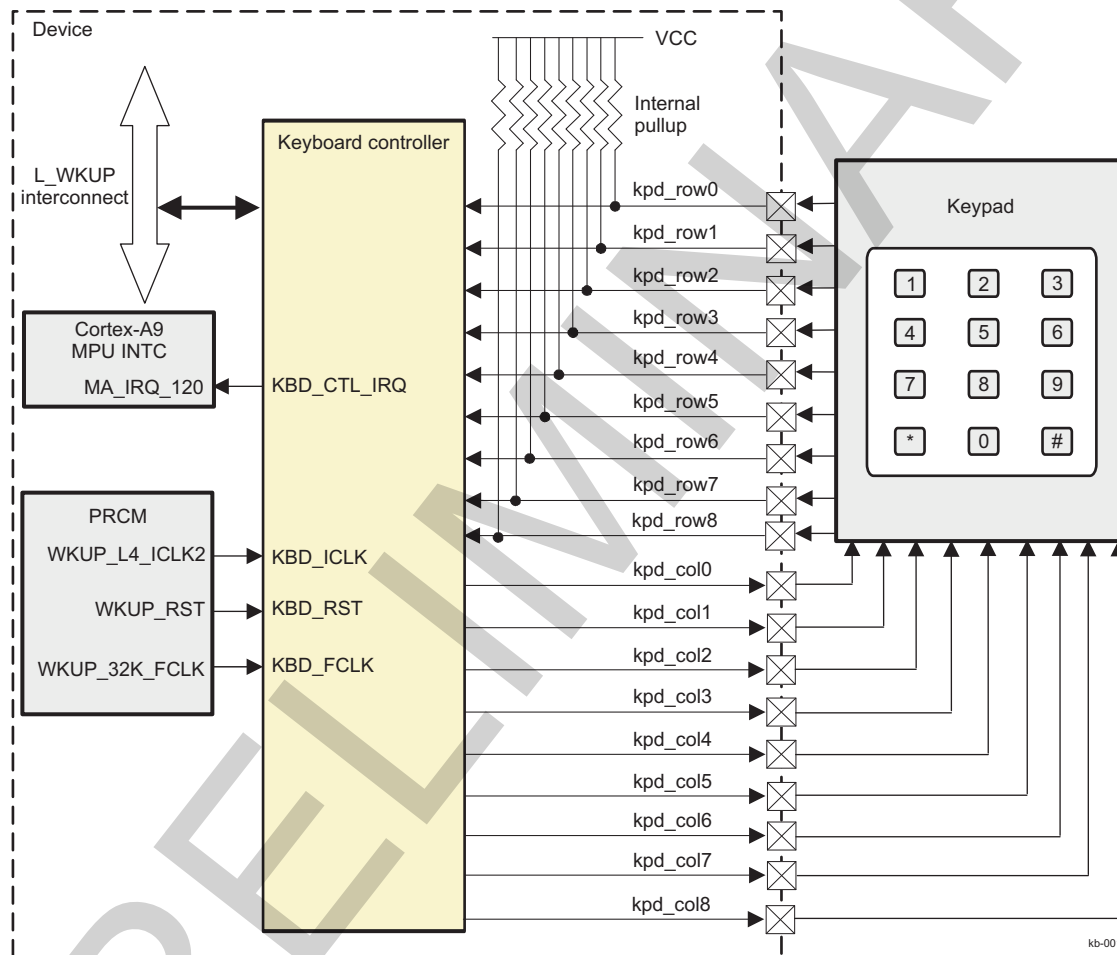

The keyboard controller implements a built-in scanning algorithm for hardware-based key-press decoding and reduces overhead in the microprocessor unit (MPU) software.

The keyboard controller includes a debouncing feature to ensure that only one key combination can be registered in the programmed time.

The keyboard controller can handle up to 9×9 keys, works on a 32-kHz clock, and can generate wake-up events when the chip is in sleep mode.

Figure 27-1 shows the keyboard controller.

Figure 27-1. Keyboard Controller Overview

The keyboard controller includes the following main features:

- Support of multiconfiguration keyboards up to 9 rows \times 9 columns
- Each key coded on 1 bit in two 32-bit registers
- Long-key value or repeat timing reconfigurable on the fly
- Event detection on key press and key release
- Multikey-press detection and decoding
- Long-key detection on prolonged key press
- Integrated timer with four programmable comparison values
- Programmable time-out on permanent key press or after keyboard release
- Programmable interrupt generation on key events
- Software reset capability

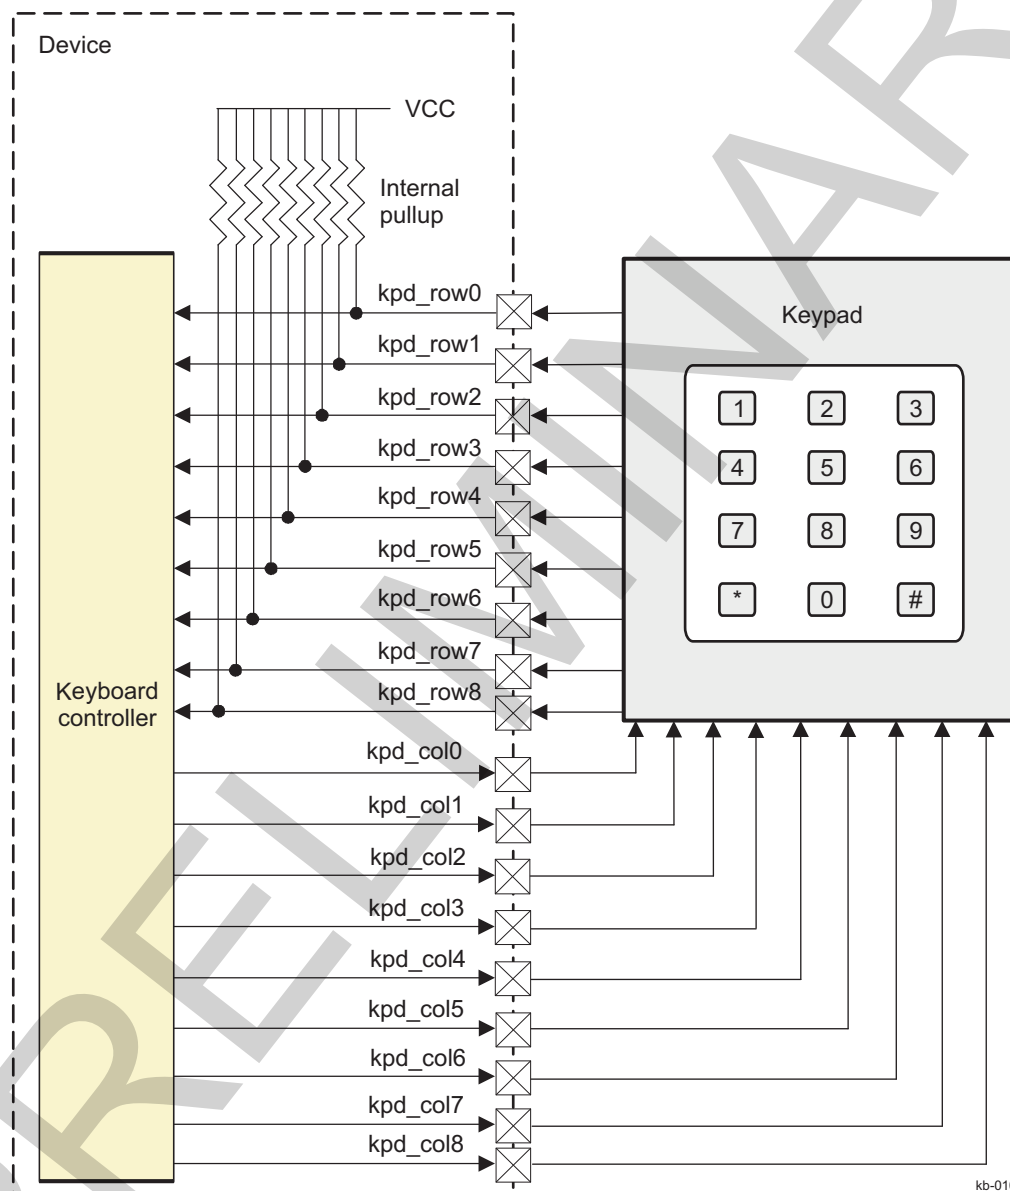

- Read/write-posted register access modes
- 8-/16-/32-bit access supported on the level 4 (L4) interface
- 32-bit data bus
- 7-bit address bus

27.2 Keyboard Controller Environment

The keyboard controller external interface pins map on the device pads when the device general-purpose input/output (GPIO) cells are configured and multiplexed for the keypad function by the control module. For more information, see [Section 19.4.8, Pad Functional Multiplexing and Configuration](#), and [Section 26.2.1, General-Purpose Interface as a Keyboard interface](#).

The external keypad typically connects directly to the keyboard controller of the device (see [Figure 27-2](#)).

Figure 27-2. Typical Keyboard Environment

27.2.1 Keyboard Controller Functions/Modes

The keyboard controller executes two functions:

- Keypad scanning and decoding for input of the external key presses. For more information, see [Section 27.4.5, Keyboard Controller Software Mode](#), and [Section 27.4.6, Keyboard Controller Hardware Decoding Modes](#).
- Device wake-up by interrupt request to the processor when a key is pressed and the device is in idle or sleep mode. For more information, see [Section 27.4.6.4, Keyboard Controller Interrupt Generation](#).

27.2.2 Keyboard Controller Signals

Table 27-1 describes the module signals and specifies their links to functions.

Table 27-1. I/O External Keyboard Signals

| Signal | I/O ⁽¹⁾ | Description | Reset Value ⁽²⁾ | Function | Wake-Up Capability |
|----------|--------------------|----------------------------------|----------------------------|-------------|--------------------|
| kpd_row0 | I | Keypad row 0 feed | hi-Z (pulled up) | Key reading | Yes |
| kpd_row1 | I | Keypad row 1 feed | hi-Z (pulled up) | Key reading | Yes |
| kpd_row2 | I | Keypad row 2 feed | hi-Z (pulled up) | Key reading | Yes |
| kpd_row3 | I | Keypad row 3 feed | hi-Z (pulled up) | Key reading | Yes |
| kpd_row4 | I | Keypad row 4 feed | hi-Z (pulled up) | Key reading | Yes |
| kpd_row5 | I | Keypad row 5 feed | hi-Z (pulled up) | Key reading | Yes |
| kpd_row6 | I | Keypad row 6 feed | hi-Z (pulled up) | Key reading | Yes |
| kpd_row7 | I | Keypad row 7 feed | hi-Z (pulled up) | Key reading | Yes |
| kpd_row8 | I | Keypad row 8 feed | hi-Z (pulled up) | Key reading | Yes |
| kpd_col0 | O | Keypad column 0 feed, active low | hi-Z | Key reading | No |
| kpd_col1 | O | Keypad column 1 feed, active low | hi-Z | Key reading | No |
| kpd_col2 | O | Keypad column 2 feed, active low | hi-Z | Key reading | No |
| kpd_col3 | O | Keypad column 3 feed, active low | hi-Z | Key reading | No |
| kpd_col4 | O | Keypad column 4 feed, active low | hi-Z | Key reading | No |
| kpd_col5 | O | Keypad column 5 feed, active low | hi-Z | Key reading | No |
| kpd_col6 | O | Keypad column 6 feed, active low | hi-Z | Key reading | No |
| kpd_col7 | O | Keypad column 7 feed, active low | hi-Z | Key reading | No |
| kpd_col8 | O | Keypad column 8 feed, active low | hi-Z | Key reading | No |

⁽¹⁾ I = Input; O = Output; I/O = Bidirectional

⁽²⁾ hi-Z = High impedance

27.2.3 Protocols and Data Formats

The keyboard controller detects and decodes multikey combinations using the following rules:

- Any 2-key combination is valid and can be decoded.
- Combinations using more than two keys are valid only if the rows and columns used do not cross over on another key to be detected. This is caused by equipotent propagation on a row/column (multikey limitations).

Figure 27-3 shows an example of multikey limitation.

Figure 27-3. Multikey Limitation Example

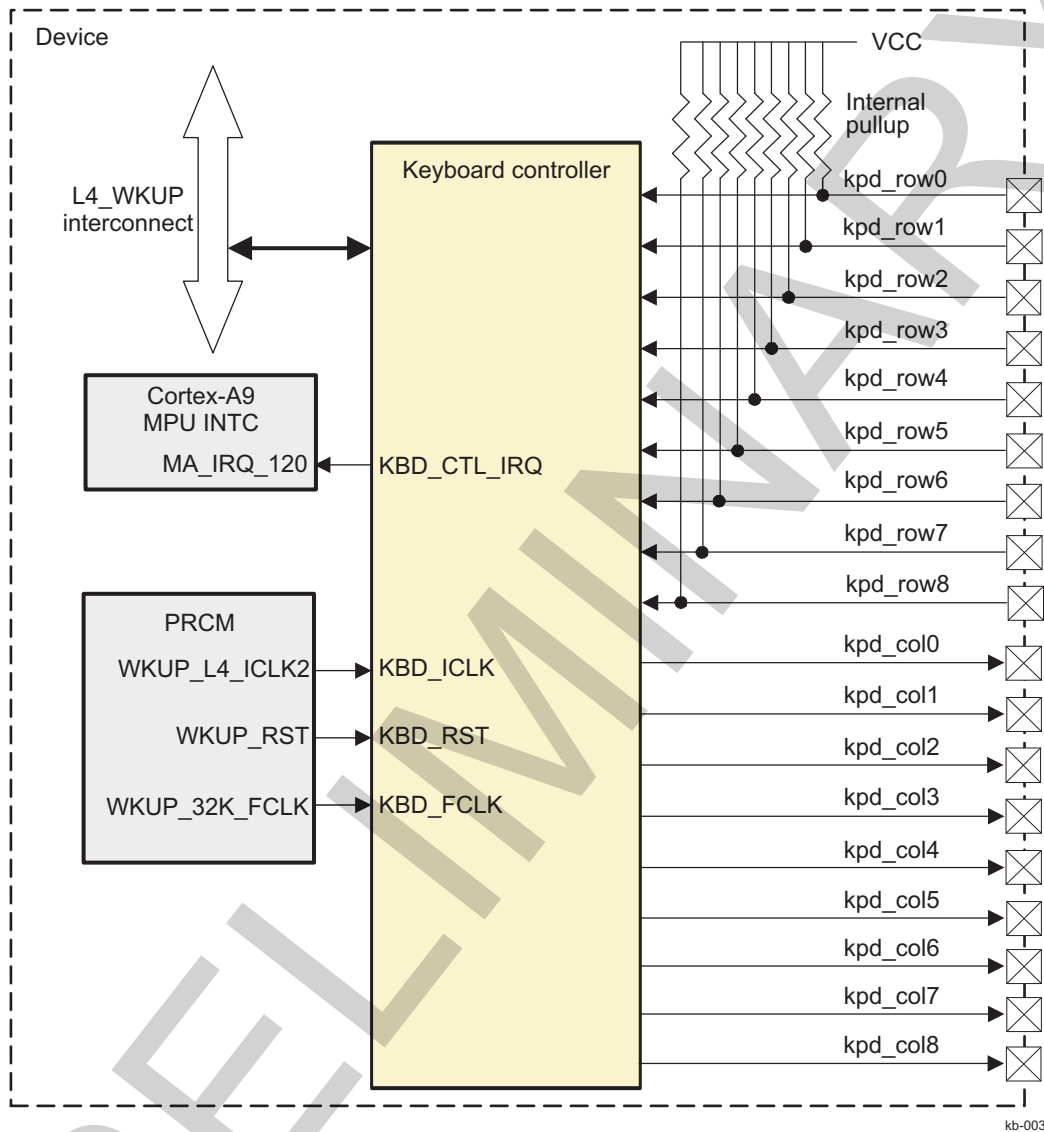

kb-007

NOTE: When using the keyboard controller with a smaller keypad (for example, 5×5), unused rows must be tied high to prevent disturbing the scanning process. Normally, all rows must be pulled up internally at the I/O cells of the device.

27.3 Keyboard Controller Integration

Figure 27-4 shows keyboard controller integration.

Figure 27-4. Keyboard Controller Integration

The control module must enable the internal pullups of the GPIO cells for all keypad rows (for more information about configuration, see [Chapter 19, Control Module](#)).

[Table 27-2](#) through [Table 27-4](#) summarize the integration of the module in the device.

Table 27-2. Integration Attributes

| Module Instance | Attributes | | |
|---------------------|--------------|--------------------|--------------|
| | Power Domain | Wake-Up Capability | Interconnect |
| KEYBOARD CONTROLLER | PD_WKUP | Yes | L4_WKUP |

Table 27-3. Clocks and Resets

| Clocks | | | | |
|-----------------|-------------------------|--------------------|--------|-------------|
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| | | | | |

Table 27-3. Clocks and Resets (continued)

| | | | | |

| KEYBOARD CONTROLLER | KBD_FCLK | WKUP_32K_FCLK | PRCM | 32-kHz functional clock. For information about power, reset, clock management (PRCM) clock gating and management, see Section 3.1.1.1.4, Clock Domain-Level Clock Management , in Chapter 3, Power, Reset, and Clock Management . |
| KEYBOARD CONTROLLER | KBD_ICLK | WKUP_L4_ICLK2 | PRCM | L4-interconnect interface clock. For information about PRCM clock gating and management, see Section 3.1.1.1.4, Clock Domain-Level Clock Management , in Chapter 3, Power, Reset, and Clock Management . |
| Resets | | | | |
| KEYBOARD CONTROLLER | KBD_RST | WKUP_RST | PRCM | Active low asynchronous general reset. For information about PRCM reset sources and distribution, see Section 3.1.1.1.4, Clock Domain-Level Clock Management , in Chapter 3, Power, Reset, and Clock Management . |

Table 27-4. Hardware Requests

| Interrupt Requests | | | | |
|---------------------------|---------------------------|--------------------------------|--------------------|---|
| Module Instance | Source Signal Name | Destination Signal Name | Destination | Description |
| KEYBOARD CONTROLLER | KBD_CTL_IRQ | MA_IRQ_120 | Cortex™-A9 INTC | Interrupt signal to the interrupt controller (INTC) of the MPU. For information about INTC interrupt control, see Chapter 18, Interrupt Controllers . |

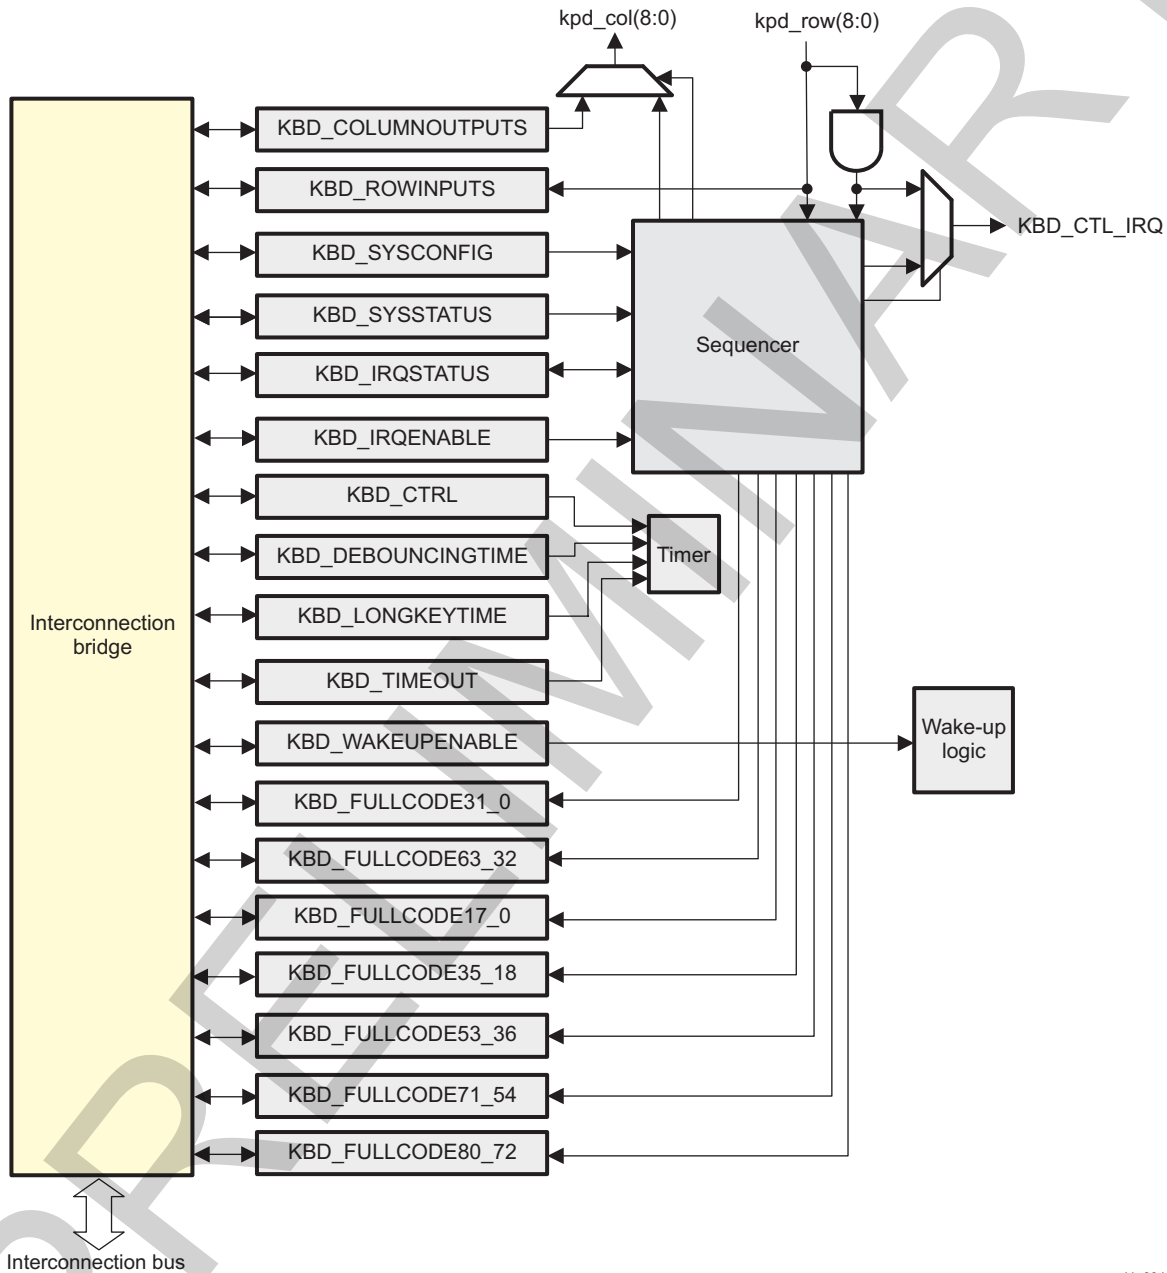

NOTE: For the description of the interrupt source, see [Section 27.4.4, Interrupt Requests](#).

27.4 Keyboard Controller Functional Description

27.4.1 Keyboard Controller Block Diagram

Figure 27-5 shows the functional specification block diagram of the keyboard controller.

Figure 27-5. Keyboard Controller Block Diagram

The keyboard controller detects events issued on any key of the connected keyboard and generates an interrupt to alert the host processor. The built-in hardware-scan algorithm decodes the pressed keys, including multikey combinations.

To reduce MPU software overhead, the hardware performs detecting and decoding in the keyboard controller state-machine. However, hardware decoding can be deactivated so that software handles the scanning algorithm.

The value of the columns output is determined in the [KBD_COLUMNOUTPUTS\[8:0\]](#) KBC_REG bit field. To activate a keypad row-column connection, the corresponding bit must be 0b0.

The following sections describe subfunctions and subfunction interactions (control, data paths).

27.4.2 Keyboard Controller Software Reset

To perform a software reset, set the [KBD_SYSCONFIG\[1\]](#) SOFTRESET bit to 1. The [KBD_SYSSTATUS\[0\]](#) RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the [KBD_SYSCONFIG\[1\]](#) SOFTRESET bit is automatically reset. Software must ensure that the software reset completes before performing mailbox operations.

27.4.3 Keyboard Controller Power Management

[Table 27-5](#) describes the power-management features available for the keyboard controller.

NOTE: For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1.4, Clock Domain-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 27-5. Local Power-Management Features

| Feature | Registers | Description |
|------------------------|---|--|
| Clock autogating | KBD_SYSCONFIG[0] AUTOGATING | This bit allows local power optimization in the module by gating the KBD_ICLK clock upon interface activity, or gating KBD_FCLK upon internal activity. |
| Slave idle modes | KBD_SYSCONFIG[4:3] IDLEMODE | Force-idle, no-idle, and smart-idle modes are available. |
| Clock activity | KBD_SYSCONFIG[9:8] CLOCKACTIVITY | For configuration details, see Table 27-6 . |
| Master standby modes | N/A | N/A |
| Global wake-up enable | KBD_SYSCONFIG[2] ENAWAKEUP | This bit enables the wake-up feature at the module level. If smart-idle mode is selected, this bit provides the option of smart-idle wake-up-capable mode. |
| Wake-up sources enable | KBD_WAKEUPENABLE | This register holds one active-high enable bit per event source able to generate a wake-up signal. |

[Table 27-6](#) lists the clock activity settings.

Table 27-6. Clock Activity Settings

| KBD_SYSCONFIG [9:8] CLOCKACTIVITY Values | Clock State When Module is in IDLE State | | Features Available When Module is in IDLE State | Wake-Up Events |
|---|---|----------|--|---|
| | KBD_ICLK | KBD_FCLK | | |
| 00 | OFF | OFF | None | The wake-up capability of the module is disabled. |
| 10 | OFF | ON | All | Asserting of wake-up signal |
| 01 | ON | OFF | None | The wake-up capability of the module is disabled. |
| 11 | ON | ON | All | Asserting of wake-up signal |

CAUTION

The PRCM module has no hardware means of reading the CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the keyboard controller CLOCKACTIVITY and keyboard controller clock PRCM control bits. For a description of the ClockActivity feature, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

27.4.4 Keyboard Controller Interrupt Requests

[Table 27-7](#) lists the event flags, and their mask, that can cause module interrupts.

Table 27-7. Events

| Event Flag | Event Mask | Description |
|---|--|-------------------------------|
| KBD_IRQSTATUS [3] MISS_EVENT | – | A miss event occurs. |
| KBD_IRQSTATUS [2] IT_TIMEOUT | KBD_IRQENABLE [2] IT_TIMEOUT_EN | A time-out event is detected. |
| KBD_IRQSTATUS [1] IT_LONG_KEY | KBD_IRQENABLE [1] IT_LONG_KEY_EN | A long-key event is detected. |
| KBD_IRQSTATUS [0] IT_EVENT | KBD_IRQENABLE [0] IT_EVENT_EN | An event is detected. |

27.4.5 Keyboard Controller Software Mode

The [KBD_CTRL](#)[1] NSOFTWARE_MODE bit selects software mode when it is set to 0.

In software mode, the keyboard controller internal sequencer, which performs automatic scanning and decoding, is disabled. Consequently, software must manually perform the scanning algorithm.

The scanning sequence is managed using the keyboard controller column outputs register ([KBD_COLUMNOUTPUTS](#)) and the keyboard controller row inputs register ([KBD_ROWINPUTS](#)). In this configuration, the keyboard interrupt is a logical ANDing of all bits of the [KBD_ROWINPUTS](#) register.

For more information about the software scan, see [Section 27.5.1, Keyboard Controller Low-Level Programming Model](#).

27.4.6 Keyboard Controller Hardware Decoding Modes

27.4.6.1 Functional Modes

When running in hardware (default) decoding mode (the [KBD_CTRL](#)[1] NSOFTWARE_MODE bit is set to 1), the keyboard controller offers several functional modes; these modes are summarized in [Table 27-8](#).

The keyboard interrupt depends on the configuration in the keyboard controller interrupt-enable register ([KBD_IRQENABLE](#)). If the event is enabled (bit 0 at 1), an interrupt is generated when the sequencer detects an event. Even if this interrupt is disabled, the flag status of the keyboard controller interrupt-status register ([KBD_IRQSTATUS](#)) is updated.

Table 27-8. Keyboard Controller Functional Modes

| Functional Mode | Associated Interrupt | Associated Timer Value | Description | Control |
|-----------------|----------------------|------------------------|---|---|
| Keyboard event | Event interrupt | Debouncing value | Occurs when a key is pressed or released Always enabled | KBD_CTRL [8:5] bits must be set to 0 to disable all the other features. |
| Long key | Long-key interrupt | Long-key value | Used to detect a key that is pressed for a long time Should be associated with the long-key time-out function or repeat mode | KBD_CTRL [5] LONG_KEY bit |

Table 27-8. Keyboard Controller Functional Modes (continued)

| Functional Mode | Associated Interrupt | Associated Timer Value | Description | Control |
|-------------------|----------------------|-------------------------|--|--|
| Repeat key | Long-key interrupt | Long-key value | Generates an interrupt every long-key delay No time-out can be associated. | KBD_CTRL [8] REPEAT_MODE bit |
| Empty time-out | Time-out interrupt | Empty time-out value | Interrupt generated if no key is pressed during an empty time-out period. | KBD_CTRL [6] TIMEOUT_EMPTY bit |
| Long-key time-out | Time-out interrupt | Long-key time-out value | Associated with the long-key function Generated after a long-key interrupt if no event occurs during a long-key time-out period | KBD_CTRL [7] TIMEOUT_LONG_KEY bit |

Each mode can be activated/deactivated by setting the corresponding bits (5, 6, 7, and 8) in the [KBD_CTRL](#) register with the appropriate values (for more information, see [Section 27.6, Keyboard Controller Register Manual](#)).

27.4.6.2 Keyboard Controller Timer

As described in the previous section, each functional mode is associated with a timer value. Depending on the selected mode, the keyboard controller timer is loaded with the corresponding value as set in the related registers:

- [KBD_DEBOUNCINGTIME](#)
- [KBD_KEYLONGTIME](#)
- [KBD_TIMEOUT](#)

[Table 27-9](#) summarizes the values of the keyboard controller timer.

Table 27-9. Keyboard Controller Timer Values

| Timer Value | Associated Register Field | Description |
|--------------------|--|---|
| Debouncing time | KBD_DEBOUNCINGTIME [5:0] DEBOUNCING_VALUE | To remove the effects of glitches when an event occurs on the keyboard, the controller waits for a debouncing period before taking a snapshot of the current state on the keyboard matrix. The timer is loaded with the debouncing time value after each detected event on the keyboard matrix. An event interrupt is generated after this delay. |
| Long-key time | KBD_KEYLONGTIME [11:0] LONG_KEY_VALUE | This is the delay before generating a long-key interrupt after an event interrupt. If the long-key mode is selected, the timer is loaded with the long-key time value after an event interrupt is generated. In repeat mode, the timer is reloaded with the same value after a long-key interrupt, and starts to count down again. |
| Long-key time-out | KBD_TIMEOUT [15:0] TIMEOUT_VALUE | The timer is loaded with the time-out value and then a long-key interrupt is generated and starts to count down. When it reaches 0, a time-out interrupt is generated and the keyboard controller returns to its IDLE state. This long-key time-out does not work in repeat mode. |
| Empty key time-out | KBD_TIMEOUT [15:0] TIMEOUT_VALUE | The time-out interrupt occurs if no key is pressed during this delay. The keyboard controller then returns to IDLE state. |

The timer countdown period depends on three factors:

- The loaded value as set in:
 - [KBD_DEBOUNCINGTIME](#)
 - [KBD_KEYLONGTIME](#)
 - [KBD_TIMEOUT](#)
- The value of the prescale clock timer as set in the [KBD_CTRL](#)[4:2] PTV bit field. This programmable clock divider allows the reduction of the clock frequency used by the timer.
- The frequency of the keyboard controller functional clock (32 kHz)

The period is calculated as follows:

$$T_{\text{period}} = (T_{\text{value}} + 1) \times 2^{\text{PTV} + 1} \times T_{\text{clk}}$$

Where:

T_{value} is the value stored in the [KBD_DEBOUNCINGTIME](#), [KBD_KEYLONGTIME](#), or [KBD_TIMEOUT](#) register.

PTV is the value of the [KBD_CTRL\[4:2\]](#) register PTV bit field.

T_{clk} is the period of the 32-kHz functional clock; that is, 31.25 μs .

The [KBD_CTRL\[4:2\]](#) PTV bit field determines the division factor of the timer clock. [Table 27-10](#) lists the divider rates.

Table 27-10. Timer Prescale Values

| KBD_CTRL[4:2] PTV Value | Divisor |
|---|---------|
| 0 | 2 |
| 1 | 4 |
| 2 | 8 |
| 3 | 16 |
| 4 | 32 |
| 5 | 64 |
| 6 | 128 |
| 7 | 256 |

NOTE: The timer minimum period is 62.5 μs ; its maximum period is 524.288 seconds.

CAUTION

To prevent undefined results, the [KBD_CTRL\[4:2\]](#) PTV bit field must not be changed when the timer is running.

The timer value registers ([KBD_DEBOUNCINGTIME](#), [KBD_KEYLONGTIME](#), and [KBD_TIMEOUT](#)) can be updated at any time, whether or not the timer is running. Nevertheless, the timer is updated only on the fly for the long-key time value. The new debouncing and time-out values are loaded only on the next load. Depending on the updated register, two cases can occur:

- The [KBD_KEYLONGTIME](#) register is updated; the new value stored in the [KBD_KEYLONGTIME](#) register is loaded into the timer when the register is written. If the timer is already counting down when [KBD_KEYLONGTIME](#) is updated, it counts down from the new value loaded in [KBD_KEYLONGTIME](#).
- The [KBD_DEBOUNCINGTIME](#) or [KBD_TIMEOUT](#) register is updated; the new value is considered only when the next timer loads. If the timer is counting down when the registers are updated, the timer continues counting down from the previous value and is loaded with the new one on the next load.

Regardless of the timer state (stopped, counting down any of the values previously described, etc.), when a new event occurs on the keyboard, the timer is stopped and loaded with the debouncing time value. It then starts counting down.

27.4.6.3 State-Machine Status

To facilitate debugging, each state of the state-machine is coded in a register that indicates the current state of the machine. [Table 27-11](#) lists the corresponding codes.

Table 27-11. State-Machine Values

| KBD_STATEMACHINE[3:0] Value | Description |
|------------------------------------|------------------------------|
| 0x0 | Idle |
| 0x1 | Scanning |
| 0x2 | Load timer debouncing |
| 0x3 | Test timer debouncing |
| 0x4 | Generated interrupt event |
| 0x6 | Load timer long key |
| 0x7 | Test timer long key |
| 0x8 | Generated interrupt long key |
| 0x9 | Load timer time-out |
| 0xA | Test timer time-out |
| 0xB | Generated interrupt time-out |
| 0xF | Other |

27.4.6.4 Keyboard Controller Interrupt Generation

27.4.6.4.1 Interrupt-Generation Scheme

The keyboard controller generates one interrupt signal to external INTC KBD_CTL_IRQ. Each functional mode generates dedicated interrupt events (logged in the [KBD_IRQSTATUS](#) register) that can be masked or unmasked using the [KBD_IRQENABLE](#) register.

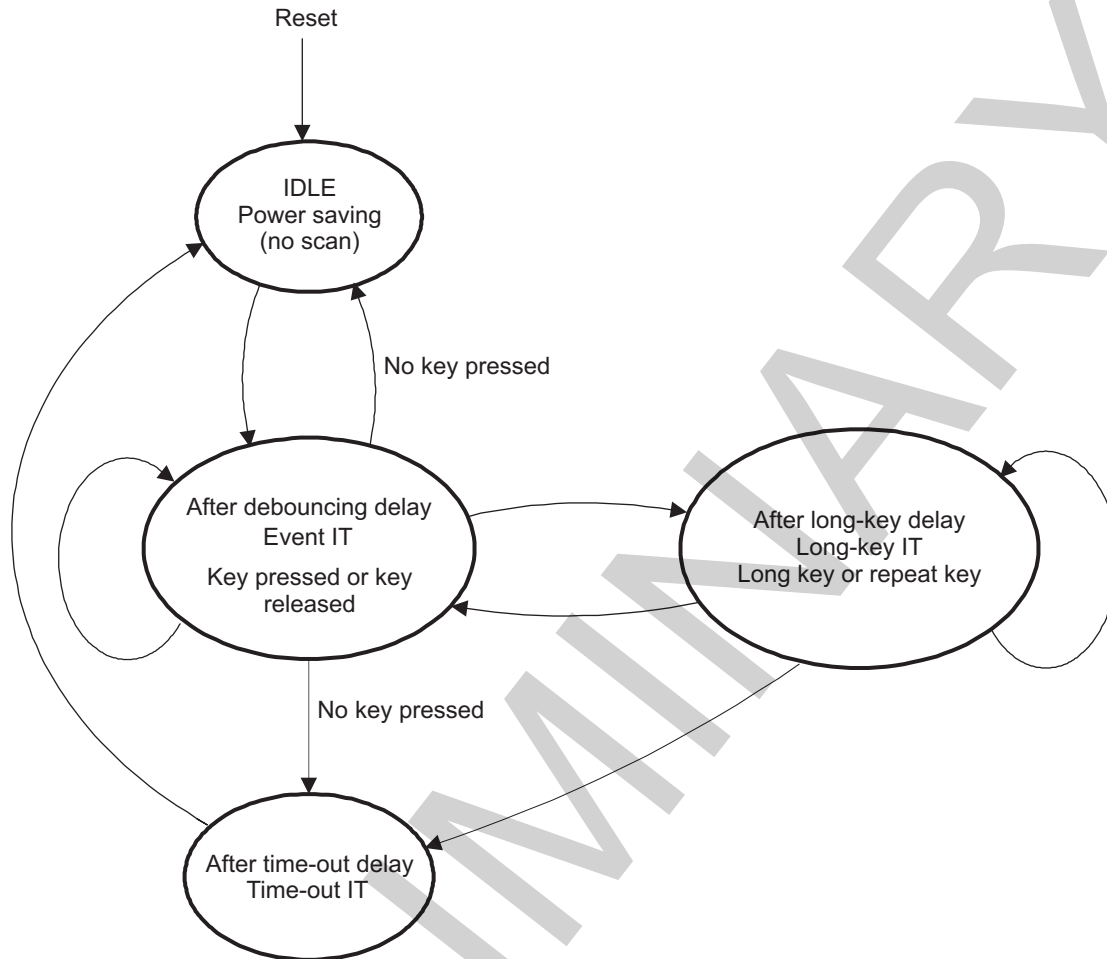

The [KBD_IRQSTATUS](#) register is updated when the selected functional mode generates an interrupt event. However, the KBD_CTL_IRQ signal is asserted on the related event only when the corresponding bit is set in the [KBD_IRQENABLE](#) register.

NOTE: To reset the interrupt status bit, 1 must be written to the appropriate bit of the [KBD_IRQSTATUS](#) read/write register.

[Figure 27-6](#) shows the different interrupt events generated in each keyboard controller functional mode and details the relationships between them.

NOTE: Depending on the selected mode, some interrupt events cannot be generated.

Figure 27-6. Functional Modes and Related Interrupt Events

kb-005

While running in hardware-decoding mode, the keyboard controller performs automatic scans when not in IDLE state. When a key-press event occurs on the keyboard matrix, the keyboard controller leaves IDLE state and an interrupt event (the [KBD_IRQSTATUS\[0\] IT_EVENT](#) bit) is set after the timer counts down the debouncing delay. An IT_EVENT is generated when a key is pressed or released.

NOTE: An IT_EVENT is generated regardless of the selected functional mode. If no time-out is set and no more keys are pressed, the keyboard controller returns to IDLE state.

If long-key detection mode is set when the timer counts down the long-key delay, an interrupt long key (the [KBD_IRQSTATUS\[1\] IT_LONG_KEY](#) bit) is generated. If the repeat mode is set, the IT_LONG_KEY interrupt is generated periodically every long-key delay.

A time-out can also be set in event detection or long-key detection mode. In this case, a time-out interrupt (the [KBD_IRQSTATUS\[2\] IT_TIMEOUT](#) bit) is generated after the time-out delay timer expires. After such an interrupt, the keyboard controller always returns to IDLE state.

NOTE: No time-out can be set in repeat mode. Only a keyboard event can stop the periodic interrupt generation.

27.4.6.4.2 Keyboard Buffer and Missed Events (Overflow Feature)

The keyboard controller has an overrun feature: A dedicated buffer allows the keyboard controller to memorize two successive events. If two successive events occur before a read is performed, the second event is stored and a second interrupt is generated when the first interrupt is cleared, allowing two consecutive key events to be received.

If a third event occurs before the first event is treated, a missed event interrupt (the [KBD_IRQSTATUS\[3\]](#) MISS_EVENT bit) is generated to report the lost event.

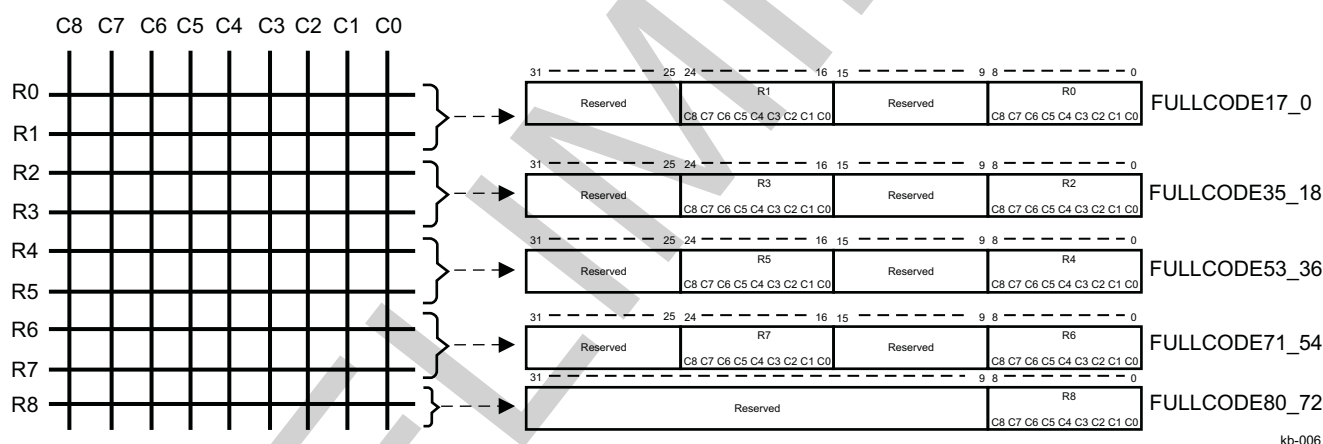

NOTE: The MISS_EVENT interrupt is not routed to the KBD_CTL_IRQ signal; software must check the [KBD_IRQSTATUS\[3\]](#) MISS_EVENT bit to detect any missed events.

27.4.7 Keyboard Controller Key Coding Registers

The keyboard controller matrix pressed keys state (indicating which columns/rows are connected) is reflected in the [KBD_FULLCODE17_0](#) to [KBD_FULLCODE80_72](#) registers, as shown in [Figure 27-7](#). These registers are updated only when interrupt event status is inactive to prevent a lost event.

NOTE: The [KBD_FULLCODE31_0](#) and [KBD_FULLCODE63_32](#) registers, which are limited to supporting keyboards of a maximum 8×8 array size, can be used for back-to-back software compatibility.

Figure 27-7. Key Coding Registers

kb-006

Each of the 9×9 keyboard size supporting registers ([KBD_FULLCODE17_0](#) up to [KBD_FULLCODE71_54](#)) stores the state of two keyboard rows. The [KBD_FULLCODE80_72](#) register stores the state of the last row, R8:

- The [KBD_FULLCODE17_0](#) register code rows 0, 1 (row 0 is coded between bits 0 and 8, row 1 is coded between bits 16 and 24)
- The [KBD_FULLCODE35_18](#) register code rows 2, 3 (row 2 is coded between bits 0 and 8, row 3 is coded between bits 16 and 24)
- The [KBD_FULLCODE53_36](#) register code rows 4, 5 (row 4 is coded between bits 0 and 8, row 5 is coded between bits 16 and 24)
- The [KBD_FULLCODE71_54](#) register code rows 6, 7 (row 6 is coded between bits 0 and 8, row 7 is coded between bits 16 and 24)
- The [KBD_FULLCODE80_72](#) register code row 8 (row 8 is coded between bits 0 and 8)

In each of these registers (excluding [KBD_FULLCODE80_72](#)):

- Bit 0 corresponds to column(0) – row (i) key, ... , bit 8 corresponds to column(8) – row (i) key.
- Bits from 9 to 15 are reserved.

- Bit 16 corresponds to column(0) – row (i+1) key, ... , bit 24 corresponds to column (8) – row (i+1) key.
- Bits 31 to 25 are reserved, where $i = 0, 2, 4, 6$.

In register [KBD_FULLCODE80_72](#) bit 0 corresponds to column (0) – row (8) key, ..., the bit 8 corresponds to column (8) – row (8) key, and the remaining bits (from 9 to 31) are reserved.

Each of the 8×8 -keyboard size supporting registers ([KBD_FULLCODE31_0](#) and [KBD_FULLCODE63_32](#)) stores the state of four keyboard rows:

- The [KBD_FULLCODE31_0](#) register code rows 0, 1, 2, and 3 (row 0 is coded between bits 0 and 7, row 1 is coded between bits 8 and 15, row 2 is coded between bits 16 and 23, and row 3 is coded between bits 24 and 31)
- The [KBD_FULLCODE63_32](#) register code rows 4, 5, 6, and 7 (row 4 is coded between bits 0 and 7, row 5 is coded between bits 8 and 15, row 6 is coded between bits 16 and 23, and row 7 is coded between bits 24 and 31)

In these registers:

- [KBD_FULLCODE31_0](#)[0] corresponds to column (0) – row (0) key,..., [KBD_FULLCODE31_0](#)[7] corresponds to column (7) – row (0).
- [KBD_FULLCODE31_0](#)[8] corresponds to column (0) – row (1) key,..., [KBD_FULLCODE31_0](#)[15] corresponds to column (7) – row (1).
- [KBD_FULLCODE31_0](#)[16] corresponds to column (0) – row (2) key,..., [KBD_FULLCODE31_0](#)[23] corresponds to column (7) – row (2).
- [KBD_FULLCODE31_0](#)[24] corresponds to column (0) – row (3) key,..., [KBD_FULLCODE31_0](#)[31] corresponds to column (7) – row (3).
- [KBD_FULLCODE63_32](#)[0] corresponds to column (0) – row (4) key,..., [KBD_FULLCODE63_32](#)[7] corresponds to column (7) – row (4).
- [KBD_FULLCODE63_32](#)[8] corresponds to column (0) – row (5) key,..., [KBD_FULLCODE63_32](#)[15] corresponds to column (7) – row (5).
- [KBD_FULLCODE63_32](#)[16] corresponds to column (0) – row (6) key,..., [KBD_FULLCODE63_32](#)[23] corresponds to column (7) – row (6).
- [KBD_FULLCODE63_32](#)[24] corresponds to column (0) – row (7) key,..., [KBD_FULLCODE63_32](#)[31] corresponds to column (7) – row (7).

NOTE: The keyboard fullcode registers are not updated in software mode.

NOTE: When using a smaller keyboard (for example, 5×5 or 4×4), the bits of the unused columns/rows are not used either.

27.4.8 Keyboard Controller Register Access

27.4.8.1 Write Registers Access

The keyboard module uses a posted-write scheme to update any internal registers. This means the write transaction is immediately acknowledged on the L4 interface, although the effective write operation occurs later due to a resynchronization in the functional clock domain. This has the advantage of not stalling the interconnect system or the CPU that requested the write transaction. For each functional register, a pending bit is provided that is set if there is a pending write access to this register. The pending bits are accessible in the keyboard pending write register ([KBD_PENDING](#)).

In this mode, it is mandatory that the CPU checks the pending bits before any write access in the functional registers. If a write is attempted to a register with a previous access pending, the previous access is discarded without notice (this can also lead to unexpected results).

A register read following a posted write (on the same register) may not read the previous write value if the write posted process is not complete. Software synchronization must be used to avoid noncoherent read.

This posted period is defined as the interval between the posted write access request and the reset of the pending bit in the [KBD_PENDING](#) register, and can be quantified:

$$T(\text{reset posted bit maximum}) = 3 \times T_{\text{iclk}} + 3 \times T_{\text{funcclk}}$$

The time it takes to accomplish the writing is:

$$T(\text{write accomplish maximum}) = 1 \times T_{\text{iclk}} + 3 \times T_{\text{funcclk}}$$

where:

T_{iclk} is the L4 interface clock period, and T_{funcclk} is the functional clock period.

27.4.8.2 Read Registers Access

The keyboard module uses a posted-read scheme for reading any internal register. The read transaction is immediately acknowledged on the L4 interface. The value of the functional register to be read must be previously synchronized. This has the advantage of not stalling the interconnect system or the CPU that requested the read transaction.

The posted-read scheme can be used only if $\text{Freq}(\text{KBD_FCLK}) < \text{Freq}(\text{KBD_ICLK})/4$.

27.5 Keyboard Controller Programming Guide

27.5.1 Keyboard Controller Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

27.5.1.1 Global Initialization

27.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the keyboard module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the keyboard. For more information, see [Section 27.2, Keyboard Controller Environment](#), and [Section 27.3, Keyboard Controller Integration](#).

[Table 27-12](#) describes the global initialization of surrounding modules.

Table 27-12. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|---------------------|---|
| PRCM | The module interface (WKUP_L4_ICLK2) and functional (WKUP_32K_FCLK) clocks must be enabled. See Section 3.10.2.1.2, Clock Management Global Initialization , in Chapter 3, Power, Reset, and Clock Management . |
| Cortex-A9 MPU INTC | Interrupt request KBD_CTL_IRQ from the keyboard must be unmasked. For more information, see Chapter 18, Interrupt Controllers . |
| Control module | The PAD CONFIG registers must be configured in to map the keyboard interface signals on the device pins through the multiplexers (mux mode 0 must be switched on) to determine the signal directions and to enable the internal pullups of the GPIO cells for all the keyboard rows. For more information about configuration, see Section 19.4.8, Pad Functional Multiplexing and Configuration , and Section 26.2.1, General-Purpose Interface as a Keyboard interface . |

27.5.1.1.2 Keyboard Controller Global Initialization

27.5.1.1.2.1 Main Sequence – Keyboard Controller Global Initialization

This procedure initializes the keyboard controller after a POR or software reset (see [Table 27-13](#)).

Table 27-13. Keyboard Controller Global Initialization

| Step | Register/Bit Field/Programming Model | Value |
|---|---|------------|
| Configure the parameters of the L4 interface and enable the clock activity. | KBD_SYSCONFIG | 0x00000– |
| Configure the debouncing time of filtering the glitches on pressing or releasing key. | KBD_DEBOUNCINGTIME [5:0] DEBOUNCING_VALUE | 0x– |
| Configure the duration of a key press to allow shortcut detection (desired value of the long-key interrupt or repeat mode value). | KBD_KEYLONGTIME [11:0] LONG_KEY_VALUE | 0x– |
| Configure the period of the long inactivity on the keyboard (desired value of the time-out interrupt). | KBD_TIMEOUT [15:0] TIMEOUT_VALUE | 0x– |
| Define the logical value of the column outputs (KEYPAD configuration) (logical 0 bit = active column-row). | KBD_COLUMNOUTPUTS [8:0] KBC_REG | 0x– |
| Perform the functional configuration of the keyboard module and the prescale clock timer value. | KBD_CTRL | 0x00000– |
| Clear the interrupt-status register. | KBD_IRQSTATUS | 0x0000000F |
| Enable (0b1)/disable (0b0) certain keyboard events for generating an interrupt request. | KBD_IRQENABLE [2:0] IT_..._EN | 0x– |

Table 27-13. Keyboard Controller Global Initialization (continued)

| Step | Register/Bit Field/Programming Model | Value |
|--|--|-------|
| Unmask (0b1)/mask (0b0) the expected source of wake-up event that generates a wake-up request. | KBD_WAKEUPENABLE [2:0] WUP_..._ENA | 0x– |

27.5.1.2 Operational Modes Configuration

27.5.1.2.1 Keyboard Controller in Hardware Decoding Mode (Default Mode)

27.5.1.2.1.1 Main Sequence – Keyboard Controller Hardware Mode

After reset, all available functional modes are disabled, except detect-event mode, which is always active. [Table 27-14](#) describes the keyboard controller hardware mode.

Table 27-14. Keyboard Controller Hardware Mode

| Step | Register/Bit Field/Programming Model | Value |
|--|--|------------|
| Activate the internal keyboard controller sequencer by setting the bit. | KBD_CTRL [1] NSOFTWARE_MODE | 0b1 |
| Select the functional mode by setting its corresponding bit to 1. | KBD_CTRL [8:5] | 0x– |
| Configure the duration of a key press to allow shortcut detection (desired value of the long-key interrupt or repeat mode value). | KBD_KEYLONGTIME [11:0] LONG_KEY_VALUE | 0x– |
| Configure the period of the long inactivity on the keyboard (desired value of the time-out interrupt). | KBD_TIMEOUT [15:0] TIMEOUT_VALUE | 0x– |
| Configure the debouncing time of filtering the glitches on pressing or releasing key. | KBD_DEBOUNCINGTIME [5:0] DEBOUNCING_VALUE | 0x– |
| Clear the interrupt-status register. | KBD_IRQSTATUS | 0x0000000F |
| Enable (by writing 1)/disable (by writing 0) certain keyboard event for generating an interrupt request | KBD_IRQENABLE [2:0] IT_..._EN | 0x– |
| Unmask (0b1)/mask (0b0) the expected source of wake-up event that generates a wake-up request. | KBD_WAKEUPENABLE [2:0] WUP_..._ENA | 0x– |
| Wait for the KBD_CTL_IRQ interrupt signal assertion. | | |
| Read the interrupt-status register to determine which event caused the interrupt. | KBD_IRQSTATUS | |
| Read the KBD_FULLCODE17_0 to KBD_FULLCODE80_72 registers (or 8 × 8 keyboard-size-supporting KBD_FULLCODE31_0 and KBD_FULLCODE63_32 registers) to determine which key matrix combination was pressed. | KBD_FULLCODE17_0 [ROWi bits] (where i = 0 to 1) up to KBD_FULLCODE71_54 [ROWi bits] (where i = 6 to 7); KBD_FULLCODE80_72 [ROWi bits] (where i = 8); (or KBD_FULLCODE31_0 [j] FULL_CODE_31_0 and KBD_FULLCODE63_32 [k] FULL_CODE_63_32 bits (where j = 0 to 31, k = 32 to 63) | |
| Clear the corresponding bit(s) in the interrupt-status register by writing logical 1. | KBD_IRQSTATUS | 0x1 |

NOTE: The long-key detection mode and the repeat mode cannot be used simultaneously, because they share the same interrupt status bit and are mutually exclusive. Software must ensure that only one of these modes at a time is selected.

NOTE: All interrupts are disabled on reset.

NOTE: When two events occur successively before the first event is read, the second interrupt is generated when the first interrupt is cleared. When more than two events in a row occur, the [KBD_IRQSTATUS\[3\] MISS_EVENT](#) bit is set. Software must check this bit, which is not reflected on the [KBD_CTL_IRQ](#) line.

NOTE: The keyboard controller uses a posted-write scheme to update any internal register. Software must read the pending write status bits to ensure that the next write access is not discarded because of ongoing write synchronization. For more information, see [Section 27.4.8.1, Write Registers Access](#).

27.5.1.2.2 Keyboard Controller Software Scanning Mode

27.5.1.2.2.1 Main Sequence – Keyboard Controller Software Mode

[Table 27-15](#) describes the keyboard controller software mode.

Table 27-15. Keyboard Controller Software Mode

| Step | Register/Bit Field/Programming Model | Value D |
|---|---|---------|
| Deactivate the internal keyboard controller sequencer by clearing the bit. | KBD_CTRL[1] NSOFTWARE_MODE | 0b0 |
| Enable the event interrupt by setting the bit. | KBD_IRQENABLE[0] IT_EVENT_EN | 0b1 |
| Wait for the KBD_CTL_IRQ interrupt signal assertion. Begin the software scan when the interrupt signal is asserted: | | |
| 1) Disable all columns to drive a logical 0 on the kpd_col[8:0] output by writing 0xFF. (logical 1 bit = inactive column-row) | KBD_COLUMNOUTPUTS[8:0] KBC_REG | 0xFF |
| 2) Drive kpd_col(i) output, (where i = 0 to 8), to 0 to capture a pressed-key-event, at the corresponding row input. | KBD_COLUMNOUTPUTS[i] KBC_REG (where i = 0 to 8) | 0b0 |
| 3) Read the KBR_LATCH bit field of the KBD_ROWINPUTS register to determine which is the pressed key. IF: KBR_LATCH k-bit = 0 , where k = 0 to 8 Then, the corresponding k-row is connected to the column being enabled. | KBD_ROWINPUTS[8:0] KBR_LATCH | |
| END IF | | |
| Repeat steps 2) and 3) for all existing columns. | KBD_WAKEUPENABLE[2:0] WUP_..._ENA | 0x– |

NOTE: In software mode, during the manual keyboard scan, an interrupt is generated when a pressed key is detected.

27.5.1.2.3 Using the Timer

For information about programming the keyboard controller timer, see [Section 27.4.6.2, Keyboard Controller Timer](#).

27.5.1.2.4 State-Machine Status Register

To see the state of the state-machine, see [Section 27.4.6.3, State-Machine Status](#).

27.5.1.3 Keyboard Controller Events Servicing

[Table 27-16](#) lists the keyboard controller event servicing.

Table 27-16. Keyboard Controller Event Servicing

| Step | Register/Bit Field/Programming Model | Value |
|--|---|-------------|
| Clear all eventual previous indications of treated interrupts; write the IRQSTATUS register: | KBD_IRQSTATUS | 0x0000000F |
| Enable the desired sources of interrupt by writing in: | KBD_IRQENABLE | 0x00000000– |
| Unmask (enable) the desired sources of interrupt by writing logical 1 in the desired bit fields. | KBD_WAKEUPENABLE | 0x00000000– |
| When event occurs: | | |
| Read the status register. | KBD_IRQSTATUS | |
| IF: KBD_IRQSTATUS [3] MISS_EVENT = 1 | Start the interrupt handler for missed event. | |
| ELSIF: KBD_IRQSTATUS [2] IT_TIMEOUT = 1 | Start the interrupt handler for timeout event. | |
| ELSIF: KBD_IRQSTATUS [1] IT_LONG_KEY = 1 | Start the interrupt handler for long key pressed event. | |
| ELSIF: KBD_IRQSTATUS [0] IT_EVENT = 1 | Start the interrupt handler for pressed key event. | |
| ENDIF | | |
| Wait for the execution of the corresponding interrupt handler. | Interrupt controller of the MPU | |
| Clear the corresponding IRQ status register bits by writing 1 there. | KBD_IRQSTATUS | 0x00000000– |
| Disable the corresponding sources of interrupt if needed by writing 0 at the corresponding bit fields. | KBD_IRQENABLE or KBD_WAKEUPENABLE | 0x00000000– |

PRELIMINARY

Initialization

This chapter introduces the steps in the general-purpose (GP) device initialization.

| Topic | Page |
|--|------|
| 28.1 Initialization Overview | 5478 |
| 28.2 Preinitialization | 5480 |
| 28.3 Reset Sequences | 5497 |
| 28.4 Device Initialization by ROM Code | 5498 |
| 28.5 Services for HLOS Support | 5564 |

28.1 Initialization Overview

This chapter provides an overview of the requirements for initializing the device from power on to OS/application execution. It provides an overview of the overall initialization process, including hardware- and software-related steps, a general overview of the ROM code operational requirements, and the behavior expectations.

28.1.1 Terminology

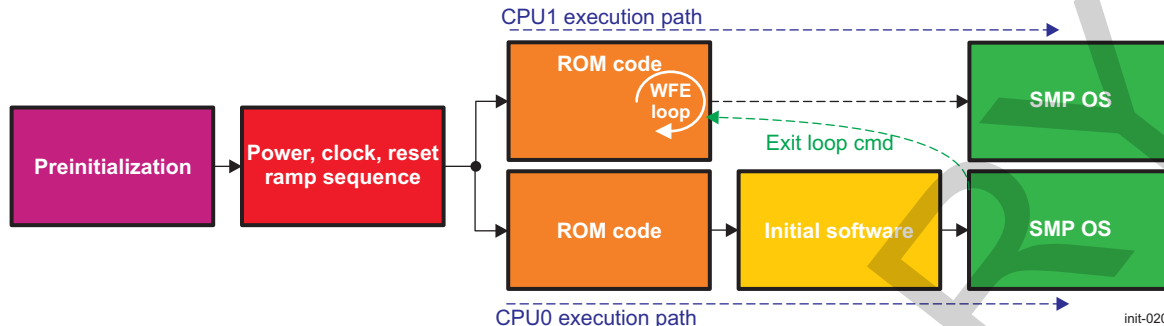

- **Bootstrap:** Initial software launched by the ROM code during the memory booting phase
- **Configuration Header (CH):** Optional structure, that precedes the initial software and allows the redefinition of the ROM code default settings
- **Downloaded software:** Initial software downloaded into the internal static RAM (SRAM) by the ROM code during the peripheral booting phase
- **eFuse:** A one-time programmable memory location usually set at the factory
- **Flash loader:** Downloaded software launched by the ROM code in preflashing. It also programs an image in external memories.
- **GP device:** General-purpose device
- **Initial software:** Software executed by any of the ROM code mechanisms (memory booting or peripheral booting). Initial software is a generic term for bootstrap and downloaded software.
- **Memory booting:** ROM code mechanism that consists of executing initial software from external memory
- **Master CPU:** The ARM® Cortex™-A9 MPCore™ CPU for which CPU-ID is 0. It configures the multicore platform and starts the ROM code to ensure device booting from a mass storage memory (memory booting) or a peripheral interface (peripheral booting).
- **Peripheral booting:** ROM code mechanism that consists of polling selected interfaces, downloading, and executing initial software (in this case, downloaded software) in the internal RAM
- **Permanent booting device:** Memory device containing, by default, the image to be executed during the booting sequence. It is the default memory booting device. The permanent booting device is used after warm reset if no software booting configuration is programmed.
- **Preflashing:** A specific case of peripheral booting where the ROM code mechanism is used to program the external flash memory
- **ROM Code:** The on-chip software in OMAP™ ROM that implements booting
- **Save-And-Restore (SAR RAM) memory:** On-chip RAM memory that is not cleared after warm resets or wakeups from low-power modes
- **Slave CPU:** The ARM Cortex-A9 MPCore CPU for which CPU-ID is 1. It is brought to the wait-for-event (WFE) state by the ROM code, waiting to be woken up by the master CPU.
- **Software booting configuration:** A logical structure stored in the SAR memory that allows the redefinition of the ROM code default settings when booting after a warm reset

28.1.2 Initialization Process

Figure 28-1 is an overview of the initialization process and its steps:

- **Preinitialization:** Power, clock, and control connections must be present, and the boot configuration pins must be held at the desired logical levels.
- **Power, clock, reset ramp sequence:** Specific sequence that is applied by the power-management chip
- **ROM code:** Responsible for finding/downloading and for executing the initial software by using the master CPU
- **Initial software:** Software that prepares and passes control to application software or to the high-level operating system (HLOS)
- **Symmetric multiprocessing (SMP)-capable HLOS** or application (primarily for diagnostics)

Figure 28-1. Initialization Process

The first two steps in the initialization process are hardware-oriented; however, they require understanding of the process of configuring these system interface pins (balls on the device), which have software-configurable functionality. This configuration is an essential part of the chip configuration and is application-dependent. This chapter discusses these pins and the associated configuration registers that are vital to the correct initialization of the device.

28.2 Preinitialization

To accomplish a successful boot-up operation with a general-purpose (GP) device, certain hardware configuration settings must be in place. Clock, reset, and power connections, as well as pins involved in setting the boot memory space for the master CPU, must be connected and driven correctly to successfully initialize the device. The following sections describe the specific requirements for the preinitialization stage.

28.2.1 Power Requirements

The device can be supplied by an external power-management integrated circuit (PMIC). TI provides a global solution with the device connected to the TWL6032 power-management/TWL6041 audio codec IC.

[Figure 28-2](#) shows the power connections between the OMAP device and the TWL6032 power IC.

Figure 28-2. Power Supply Connections

NOTE: Figure 28-2 is an example of power connections between the device and the TWL6032. These connections depend on the actual application.

Table 28-1 describes the device power balls.

Table 28-1. OMAP Power Balls ⁽¹⁾

| Voltage Ball Name | Domain |

| vdds_1p8_fref | Oscillator, slicer, fref_clk0_out, and fref_clk_ioreq |

For more information about power management, see *Power Management Functional Description*, in [Chapter 3, Power, Reset, and Clock Management](#).

The OMAP4470 power supply structure is based on the following constraints:

- Because most of the I/Os must be powered before the core, they are supplied on a specific rail (1.2 or 1.8 V).
- For OMAP4470-1800, the MPU is supplied with additional power resource. It is controlled by SmartReflex link and a GPIO pin.
- IVA, ABE, and Core are mapped on dedicated SMPS to allow independent SmartReflex dynamic frequency and voltage scaling for each of them.
- Because the DPLL, DSI, CSI, and USB OTG interfaces are noise-sensitive power domains, they are supplied by a dedicated rail to avoid other power sinks from affecting their power rail.
- Because bandgap, BodyBias LDOs, and SRAM LDOs must be supplied at 1.8 V from the beginning of the power-up sequence up to the end of power down, they are supplied by V1V8. This also applies to the WKUP LDO at 1.2 V.
- HDMI, eFuse VPP, SDMMC, and USB I/Os have specific requirements (sequencing, dual voltage, noise immunity, etc.) that require each of them be supplied by a dedicated power source.

28.2.2 Access to Power-Management IC

The ROM code accesses the power-management chip (PMIC) for the following purposes:

- SD/MMC1 powering:
 - The VMMC LDO is switched on by the ROM code when booting from the SD/MMC1 interface.

NOTE: The power supplies required for SD/MMC interface 2 are not controlled by the ROM code. It is assumed that the PMIC (or the system hardware) properly powers the SD/MMC module attached to this interface.

- USB peripheral booting (internal or external transceiver):
 - PrevStartOk mechanism

This mechanism provides the ability to bypass the USB connection if a specific flag is set in the TWL6032 RTC domain (retained when the system is switched off).

- USB transceiver powering

The TWL6032 LDOUSB is turned on by the ROM code.

NOTE: If TWL6032 is not present and the USB external transceiver boot is chosen, the TWL6032-related operations do not complete without blocking the USB boot procedure.

- USB peripheral booting (internal transceiver):

- VBUS detection

The VBUS power pad is localized on the TWL6032 power IC. As a result, the ROM code must read from a TWL6032 register to get the status reflecting the device attachment to the USB link.

- Gating the TWL6032 USB charging circuitry during a suspend scenario

If this event occurs, the ROM code should detect a suspend event and gate the charge circuitry inside the TWL6032.

NOTE: If TWL6032 and/or VBUS are not detected, the USB boot is blocked when booting from the internal transceiver, except if the USB(2) option is chosen.

28.2.2.1 PMIC Detection

When booting from an SD/MMC card or USB internal transceiver (and only for these two booting options) the ROM code tries to access the power device through the inter-integrated circuit (I²C™). The first access is a read transaction to obtain the TWL6032 version register. If this read access is successful (that is, the I²C transaction is acknowledged), the ROM code considers that a power-management device is attached, assuming it is TWL6032. The version value read is neither used in any computation nor compared to any hardcoded value.

If the first read transaction fails (that is, the I²C transaction times out or is not acknowledged), the ROM code logs it into a flag and does not try any further transaction until the next reset cycle. In this case, the nondetection of the companion chip does not block the SD/MMC1 boot process. However, the MMC card boot procedures do not work as defined in this document. In particular, The ROM code does not ensure that the SD/MMC1 interface is powered when accessing the memory contents.

The nondetection of the power-management IC blocks the USB internal transceiver boot, except when USB(2) booting mode is chosen.

An alternate way to boot from the USB internal transceiver without the TWL6032 and with the USB(1) booting option is to have the alternate power-management IC match (or emulate) at least read the P1, P2, and P8 commands (see [Section 28.2.2.2, Summary of the I²C Transactions](#)).

If TWL6032 is not present, but the USB(2) option is chosen, or registers are emulated, the following functions are not ensured to work:

- The PrevStartOk mechanism is not functional (the specific flag is not checked).
- The ROM code does not ensure that the VUSB power is applied to the USB transceiver.
- Peripheral booting from the internal USB transceiver is not ensured to be functional, because the VBUS state read transaction is not performed.
- The ROM code does not support the suspend scenario during USB peripheral boot from the internal transceiver.

From the ROM code perspective, nothing prevents the use of another power IC together with the OMAP4470. However, special care must be taken if considering the two previously mentioned booting options (SD/MMC1 or USB internal transceiver).

[Table 28-2](#) summarizes the USB booting options according to TWL6032 presence.

Table 28-2. USB Booting Options

| Booting Option | TWL6032 Detected | TWL6032 Emulated | Description |
|----------------|------------------|------------------|---|
| USB(1) | Yes | N/A | Full USB booting |
| USB(1) | No | Yes | ROM code does not ensure VUSB, VBUS, PrevStartOk, or suspend mode. |
| USB(1) | No | No | USB booting is not possible. |
| USB(2) | Yes | N/A | Full USB booting |
| USB(2) | No | Yes | ROM code does not ensure VUSB, VBUS, PrevStartOk, or suspend mode. |
| USB(2) | No | No | ROM code does not ensure VUSB or VBUS. PrevStartOk and suspend mode are not supported. |
| USB-ULPI | Yes | N/A | ROM code does not ensure VUSB or VBUS. PrevStartOk is supported. Suspend mode is not supported. |
| USB-ULPI | No | Yes | ROM code does not ensure VUSB, VBUS, or PrevStartOk. Suspend mode is not supported. |
| USB-ULPI | No | No | ROM does not ensure VUSB or VBUS. PrevStartOk and suspend mode are not supported. |

28.2.2.2 Summary of the I²C Transactions

The ROM code accesses the power-management chip through the I2C1 interface. [Table 28-3](#) summarizes the list of accesses.

Table 28-3. Register Accesses to PMIC

| ID | I ² C Address | Register Address | TWL6032 Register | Access Type | Value | Transaction Condition |
|----|--------------------------|------------------|------------------|-------------------------|----------|--------------------------------------|
| P1 | 0x4A | 0x87 | JTAGVERNUM | R | 0x- | Bootting from MMC1, USB, or USB-ULPI |
| P2 | 0x48 | 0x2B | PHOENIX_SEQ_CFG | R/W | 0x-/0x00 | Bootting from USB or USB-ULPI |
| P3 | 0x48 | 0x9B | VMMC_CFG_VOLTAGE | W (ORed) ⁽¹⁾ | 0x15 | Bootting from MMC1 |
| P4 | 0x48 | 0x9A | VMMC_CFG_STATE | W (ORed) ⁽¹⁾ | 0xE1 | Bootting from MMC1 |
| P5 | 0x48 | 0xA3 | VUSB_CFG_VOLTAGE | W (ORed) ⁽¹⁾ | 0x18 | Bootting from USB or USB-ULPI |
| P6 | 0x48 | 0xE5 | MISC2 | W | 0x08 | Bootting from USB or USB-ULPI |
| P7 | 0x48 | 0xA2 | VUSB_CFG_STATE | W | 0xE1 | Bootting from USB or USB-ULPI |
| P8 | 0x49 | 0xE3 | CONTROLLER_STAT1 | R | 0x- | Bootting from USB or USB-ULPI |
| P9 | 0x49 | 0xE8 | CHARGERUSB_CTRL1 | W | 0x80 | Bootting from USB |

⁽¹⁾ (1) The register is not blindly overwritten but is first read and then ORed with the specified value.

Transaction description

P1: JTAGVERNUM: PMIC detection. There must be a register at this location; however, its value is not used further by ROM code.

P2: PHOENIX_SEQ_CFG: The PrevStartOk flag is checked when performing USB peripheral boot (internal or external transceiver). If the flag is set, the USB peripheral booting procedure is skipped. In any case the full register is cleared (write 0x00) after the read transaction.

P3: VMMC_CFG_VOLTAGE: For the sake of powering the SDMMC1 card cage, the VMMC_CFG_VOLTAGE and VMMC_CFG_STATE registers are configured to set the VMMC LDO to 3 V. The value 0x15 is written to the VMMC_CFG_VOLTAGE register (selects 3-V output).

P4: VMMC_CFG_STATE: The value 0xE1 is written to the VMMC_CFG_STATE register (applies to all register groups, LDO state switched on).

P5: VUSB_CFG_VOLTAGE: The OMAP internal USB transceiver must be powered with a 3.3-V source to ensure its correct functionality. Three registers are used for this purpose. The VUSB_CFG_VOLTAGE register is written the value 0x18 for selecting 3.3 V.

P6: MISC2: The MISC2 register is written the value 0x08 for selecting the VBUS source.

P7: VUSB_CFG_STATE: The VUSB_CFG_STATE register is written the value 0xE1 for switching the VUSB LDO on for all register groups.

P8: CONTROLLER_STAT1: VBUS detection is performed by reading the VBUS_DET bit from the CONTROLLER_STAT1 register. If this bit is set, it reflects that a USB cable is plugged.

P9: CHARGERUSB_CTRL1: This register is written the value 0x80 (SUSPEND_BOOT = 1) for gating the charge circuitry when getting a USB SUSPEND event. If this bit is not set, the USB boot is aborted.

The complete description of the TWL6032 register map is in TWL6032 documentation.

NOTE: No specific action is performed regarding the TWL6032 primary watchdog feature. In particular, if it is active (configurable in EEPROM) in the companion device, a system reset may occur before ROM code completes. The elapse value for the reset must be appropriately tuned so that the ROM code is not interrupted before the full platform start up (that is, before the initial software can take a specific action).

- 12-, 16.8-, 19.2-, 26-, or 38.4-MHz reference clock input from external oscillator or clock supplied using internal crystal oscillator (up to 20 MHz)
- 32-kHz CMOS clock input
- Six configurable output clocks
- Eight input signals to define the boot mode and device system clock source
- Two reset sources
 - Power-on reset (POR) (cold reset)
 - Bidirectional warm reset

28.2.3.2 Clocking Scheme

28.2.3.2.1 Required System Input Clocks

The device operation requires external input clocks, as follows:

- 32k clock: A 32.768-kHz crystal is connected to the TWL6032 device that embeds the 32k-oscillator (a square CMOS clock can also be delivered on the 32k_xtalin pin if the 32k-crystal is connected on another device of the system). The resulting 32k clock is delivered to the entire system on three outputs:
 - CLK32KAO_is always on (meaning that when TWL6032 VIO is on; that is, it is in WAIT-ON or ACTIVE state). It is used to deliver a 32k clock to always-on features, such as the OMAP and modem.
 - CLK32KG is software-controlled and is delivered when requested by the OMAP (this input is on by default at platform boot).
 - CLK32KAUDIO is software-controlled and is delivered to the audio IC (not shown in [Figure 28-3](#)) when requested by the OMAP (this input is on by default at platform boot).
- High-speed clock: The platform high-speed (HS) low-jitter sine clock is provided by the clock driver (CDC3S04) to the audio IC, OMAP, and other peripherals requesting low-jitter sine clock (up to three outputs are available for peripherals). The OMAP device delivers digital clocks to other peripherals. The OMAP supports different flavors of clock sources at several frequencies:
 - Crystal source. An internal oscillator embedded in the OMAP is used. In this mode, the input clock is limited to 20 MHz by oscillator construction. The fref_clk_ioreq is then set as an input to be used by an external device to request the OMAP to deliver the clock on fref_clk0_out. The fref_slicer_in pin can then be used to input an auxiliary clock (mainly for debugging purposes).
 - External oscillator type source. The internal OMAP oscillator is disabled. The external source delivers a sine (slicer active) or square (slicer bypassed) single-ended clock on the fref_slicer_in pin. The external source is enabled by the fref_clk_ioreq output. fref_xtal_in can then be used to input an auxiliary clock (oscillator-bypass mode).
- Audio clock: The audio IC device builds its own clock, either from the 32k clock or the HS clock (depending on the audio scenario). This internal clock is delivered to the ABE subsystem (abe_clks input) for audio flow synchronization.

Clock input modes are selected by the sysboot pin (sys_boot[6:7]) to allow the system to wake up in the proper mode, even after a cold boot (selection of the relevant input pin [fref_slicer_in or fref_xtal_in/out] and slicer/oscillator mode setting [on or bypass]).

The OMAP provides the HS clock to other devices through six fref_clk[0:5]_out pins.

[Table 28-4](#) lists the mapping for the OMAP clock input sources. [Table 28-5](#) lists the TWL6032 clock requirements.

Table 28-4. Mapping for Input Sources

| Input Source | Mapping | Frequency Range/List | Type |
|---------------------|----------------------------|---------------------------------|-----------------------------|
| Internal oscillator | fref_xtal_in/fref_xtal_out | 12, 16.8, or 19.2 MHz | Crystal connection pins |
| External HS clock | fref_slicer_in | 12, 16.8, 19.2, 26, or 38.4 MHz | Sine or square single-ended |
| External 32k clock | sys_32k | 32.768 kHz (nom.) | Square |

Table 28-4. Mapping for Input Sources (continued)

| Input Source | Mapping | Frequency Range/List | Type |
|------------------|----------|----------------------|--------|
| TWL6041 audio IC | abe_clks | 19.2 MHz | Square |

Table 28-5. TWL6032 Clock Requirements

| Input Source | Mapping | Frequencies Range/List | Type |
|---------------------|--------------------|------------------------|-------------------------|
| Internal oscillator | OSC32KIN/OSC32KOUT | 32.768 kHz (nom.) | Crystal connection pins |

CAUTION

Clock configurations depend on core voltage, and maximum clock frequencies may not be applicable to production.

28.2.3.2.2 Optional System Output Clocks

The OMAP device can output six alternate clocks, `fref_clk[0:5]_out`. Output clocks 1 through 4 can be gated or enabled through associated clock-request signals, `fref_clk[1:4]_req`.

The clocks can be managed by software with the appropriate register in the power, reset, and clock management (PRCM) module. For more information, see [Section 3.3, PRCM Subsystem Environment](#).

28.2.3.3 Reset Configuration

28.2.3.3.1 ON/OFF Interconnect and Power-On-Reset

The entire system is typically awakened by an ON/OFF push button connected to the PMIC. This signal is active low (the PMIC has internal pullup). Power up is propagated to the OMAP through `NRESPWRON/sys_nrespwron` signals when the PMIC power-up sequence is achieved.

28.2.3.3.2 Warm Reset

A warm reset can be asserted by the OMAP, by an external button (typically for development platform), or by any other device connected to it. It is mainly used to propagate the OMAP internal reset to the whole platform to set it to a known state.

The OMAP releases `sys_nreswarm` after `NRESPWRON` is deasserted.

28.2.3.3.3 Peripheral Reset by `sys_pwron_reset_out`

`sys_pwron_reset_out` is provided to the system by the OMAP to power on and/or deactivate the reset of system peripherals. This signal is activated by SCRM during the power-up sequence a few milliseconds after the default-on clocks (OMAP – `fref_clk4_out` and CDC3S04 – `CLK[1:4]`) are stabilized. This allows switching on peripherals that require synchronous reset.

`ss_pwron_reset_out` is controllable by software when the system is on. It is not affected by a warm reset.

28.2.3.3.4 Peripheral Reset by GPIO

Most of the peripherals are reset/power on/off by GPIO. By default, under POR, most OMAP signals are in safe mode with a default value driven by the I/O cell. The value is driven by an internal pullup or pulldown. Depending on the peripheral reset active level, users must select one GPIO or another (according to the reset value).

Once POR is released, the value on the pad is driven by the default configuration of control module. Most of time, this configuration is aligned with the default value selected on the I/O cell.

The next step is application-dependent: Users must configure the OMAP registers to validate GPIO use and the default configuration of the control module.

28.2.3.3.5 Warm Reset Impact on GPIOs

When a warm reset event occurs:

- The GPIO controller is reset. Consequently, the GPIO is automatically turned in input mode.
- The control module, which is part of the wake-up domain, is not reset. Information related to signal multiplexing mode and pullup or pulldown configuration is still valid.

Therefore, when a warm reset event happens, the output buffer is disabled. Consequently, two different behaviors can be defined with regard to what is expected by the platform:

- GPIO sensitive to warm reset:

To avoid getting a floating signal during (and after) a warm reset event, users must select a pullup or pulldown (depending on the reset value of the peripheral) and enable the pull.

- GPIO not sensitive to warm reset:

To avoid getting a floating signal during (and after) a warm reset event and to keep the same value that was driven before the reset, users must align the pull value with the drive value each time there is an access to a dedicated GPIO register.

NOTE: To avoid unnecessary consumption, user software must ensure that the internal pull resistor is disabled when the GPIO buffer is driving.

NOTE:

- For more information about device reset management, see [Section 3.5, Reset Management Functional Description](#) in [Chapter 3, Power, Reset, and Clock Management](#).
 - To determine the cause of the last reset, see [Section 3.5.5, Reset Logging](#), in [Chapter 3, Power, Reset, and Clock Management](#).
-

28.2.3.4 PMIC and Audio IC Control

- I²C:

The PMIC and audio IC are controlled by the OMAP I2C1 (HS I²C) interface. Some internal pullup resistors are provided by the OMAP (different values can be selected to adapt the I/O buffer strength to the bus topology). The I²C links must first be started in fast-speed mode. Therefore, the buffer default pullup value must support this mode.

- SmartReflex control:

Some of the TWL6032 power resources are controlled through SmartReflex link (I²C-like). This control allows the host to drive the dynamic voltage frequency scaling (DVFS) and adaptive voltage scaling (AVS) operations of these resources. As with its I²C interfaces, some internal pullup resistors are provided on the OMAP SmartReflex I/Os.

- INT:

Both devices can activate the INT signal at any time when they require the host device to monitor their activity. When receiving such an interruption, the OMAP checks, through the I²C, to determine the source of the interrupt. These INT pins are active low.

- sys_pwr_req:

When exiting off mode, the OMAP ties up the sys_pwr_req pin to wake up the TWL6032 power application group.

28.2.3.5 TWL6032 Power Request Signals

The TWL6032 PMIC drives three external enable-output signals. This allows switching on some external resources at different stages of the power-up sequence:

- REGEN1/2 are driven high at the beginning of the power-up sequence, before any internal power source is turned on. They belong to the VBAT power domain. REGEN1 can typically be used for buck boost control.

- SYSEN is driven high immediately after the VCORE power output is turned on. It allows switching on the additional power regulator to supply the MPU subsystem. SYSEN belongs to the VIO power domain.

TWL6032 also receives five power resource requests: PREQ[1, 2A, 2B, 2C, 3]. These pins allow an external device to request TWL6032 power internal resources. TWL6032 power behavior when pins are activated must be programmed after the first boot (resources and PREQ pins allocated by group, resource behavior upon group activation, etc.). The typical PREQ allocation per group is:

- PREQ1: Application group. Connected to OMAP.
- PREQ2A, PREQ2B, and PREQ2C: Peripheral group. Connected to peripherals A, B, and C (for instance, Bluetooth®/FM/GPS/WLAN device, Wimax device, W-USB device).
- PREQ3: Modem group

NOTE: Powering the clock driver requires PREQ assertion. Therefore, it is advised to connect any peripheral receiving a clock from CDC3S04 to one PREQ.

The use of PREQ[1:3] is especially required when TWL6032 is in sleep mode, because it cannot handle an I²C command. Any device that requires the TWL6032 resource to wake up must first activate its associated PREQ. All TWL6032 power regulators are off or in sleep mode when TWL6032 is in sleep mode.

PREQ1 is used by OMAP when waking up from off mode to wake up the TWL6032.

28.2.4 Boot Configuration

Six external pads (sys_boot[5:0]) are used to select interfaces or devices for the booting list. The sys_boot[7:6] pads select the OMAP clock source configuration.

All eight pins are sampled and latched onto the SYSCTRL_GENERAL_CORE.CONTROL_STATUS[7:0] SYS_BOOT register bit field after POR. After booting, these pads can be used for other functions such as GPIOs, and the associated register bit field is not updated by the new functionality. For more information about pad multiplexing configuration, see [Section 19.4.8, Pad Functional Multiplexing and Configuration](#).

NOTE:

- If used as GPIOs, sys_boot[7:0] pads must be used only in output mode to ensure that the input values are selected by the pullups and pulldowns after POR.
 - Unlike sys_boot[5:0] pads, sys_boot[7:6] pads have no internal pullups or pulldowns automatically selected at POR. The sys_boot[5:0] pads have selected pulldowns at that moment. To avoid leakage, care must be taken to disable the pulldown in case the respective pad has external connection to VIO (= 1). See the appropriate register fields in [Chapter 19, Control Module](#).
-

28.2.4.1 System Clock Source Selection

[Figure 28-4](#) is an overview of the system clock selection. [Table 28-6](#) summarizes the selection.

Figure 28-4. System Clock Selection Diagram**Table 28-6. System Clock Selection Summary**

| sys_boot[7:6] | SYS_CLK Source | SYS_ALTCLK Source | Oscillator Mode | Slicer Mode | fref_clk_ioreq Mode |
|---------------|----------------|-------------------|-----------------|-------------|---------------------|
| 0b00 | fref_xtal_in | fref_slicer_in | Active | Power-down | Input |
| 0b01 | fref_xtal_in | fref_slicer_in | Bypass | Power-down | Output |
| 0b10 | fref_slicer_in | fref_xtal_in | Power-down | Active | Output |
| 0b11 | fref_slicer_in | fref_xtal_in | Power-down | Bypass | Output |

OMAP clock source settings description:

- sys_boot[7:6] = 0b00:
 - The system clock source is the on-chip oscillator.
 - The slicer is powered down and its input can be used to provide the OMAP with an alternate clock.
 - fref_clk_ioreq is a clock request input associated to fref_clk0_out by default.
- sys_boot[7:6] = 0b01:
 - The system clock source is external. The internal oscillator is bypassed to inject the system clock.
 - The slicer is powered down and the slicer input can be used to provide the chip with an alternate clock.
 - The fref_clk_ioreq signal is an output that requests the clock to the external clock supplier.
- sys_boot[7:6] = 0b10:
 - The system clock source is the on-chip slicer, supplied by an external oscillator. The internal

oscillator is powered down and the input can be configured to supply the alternate system clock to OMAP device.

- The slicer is active.
- The `fref_clk_ioreq` signal is an output that requests the clock from the external clock supplier.
- `sys_boot[7:6] = 0b11`:
 - The system clock source is external. The internal oscillator is powered down and the input can be configured to supply the alternate system clock to the OMAP device.
 - The slicer is bypassed to inject the system clock.
 - The `fref_clk_ioreq` signal is an output that requests the clock from the external clock supplier.

28.2.4.2 Booting Device Order Selection

The ROM code creates the device list (order) based on information gathered from two locations.

- The first location is the software booting configuration stored in the nonvolatile SAR memory, and used after warm resets.
- The second location is the `sys_boot[5:0]` external configuration pins sensed in the control module.

The SYSBOOT pins are used to index a booting device list from a table with possible booting scenarios. The order of examined booting devices is from the first to the fourth devices.

The following names are used in the tables:

- Memory types:
 - Execute in place (XIP): XIP memory without wait-signal monitoring enabled (NOR flash memory or other XIP device)
 - XIP wait: XIP memory with wait-signal monitoring
 - NAND: NAND flash memories (non-XIP)
 - OneNAND: OneNAND and Flex-OneNAND flash memories
 - MMC1: MMC/SD card or eMMC™/eSD™ device (SD/MMC port 1)
 - MMC2(1): eMMC or eSD memory device, first multiplexing option (SD/MMC port 2). See [Section 28.2.4.3, Boot Peripheral Pin Multiplexing](#).
 - MMC2_BOOT: eMMC on SD/MMC port 2 using boot partition. Pin multiplexing as in MMC2(1).
 - MMC2(2): eMMC or eSD memory device, second multiplexing option (SD/MMC port 2). See [Section 28.2.4.3, Boot Peripheral Pin Multiplexing](#).
- Peripheral interfaces:
 - USB(1): USB A0 from OMAP internal transceiver (USBPHY)
 - USB(2): USB A0 from OMAP internal transceiver (USBPHY). Allows USB booting even when no power-management IC is detected. See [Section 28.2.2.1, PMIC Detection](#).
 - USB-ULPI: USB A0 from external transceiver through ULPI interface
 - Universal asynchronous receiver/transmitter (UART): UART3 interface
- Permanent booting devices listed in [Table 28-7](#) are in **bold**.

NOTE: Only permanent booting devices (in bold) are put on in the list in case of a warm reset, and the device list is taken from the `sys_boot` pins. As a result, peripheral booting devices are skipped when the OMAP restarts from warm resets.

Users can force the execution of the peripheral booting procedure after warm reset by using the software booting configuration feature.

[Table 28-7](#) lists the booting device order when it is preferred to boot from a memory type device. This table is selected by ROM code when the `sys_boot5` pin is tied high (= 1) after reset and before booting completes. If fast XIP booting is selected, the `sys_boot5` pin controls the XIP wait-signal monitoring (that is, a logical high level enables wait-signal monitoring).

Table 28-7. Memory Preferred Booting

| sys_boot[5:0] | Bootting Devices Order | | | |
|----------------------------------|---|-----------------|-----------------|-----------------|
| | 1 st | 2 nd | 3 rd | 4 th |
| 0b100000 | MMC2(1) | USB(1) | | |
| 0b100001 | XIP | USB(1) | | |
| 0b100010 | XIPWAIT | USB(1) | | |
| 0b100011 | NAND | USB(1) | | |
| 0b100100 | MMC2_BOOT | USB(2) | | |
| 0b100101 | MMC1 | USB(1) | | |
| 0b100110 | OneNAND | USB(1) | | |
| 0b100111 | OneNAND | MMC2(1) | USB(1) | |
| 0b101000 | MMC2(1) | UART | | |
| 0b101001 | OneNAND | MMC2(1) | USB(2) | |
| 0b101010 | XIPWAIT | UART | | |
| 0b101011 | NAND | UART | | |
| 0b101100 | MMC2_BOOT | USB(1) | | |
| 0b101101 | MMC1 | UART | | |
| 0b101110 | OneNAND | UART | | |
| 0b101111 | MMC2(1) | USB-ULPI | | |
| 0b110000 | XIP | USB-ULPI | | |
| 0b110001 | XIPWAIT | USB-ULPI | | |
| 0b110010 | NAND | USB-ULPI | | |
| 0b110011 | MMC1 | USB(2) | | |
| 0b110100 | MMC1 | USB-ULPI | | |
| 0b110101 | OneNAND | USB-ULPI | | |
| 0b110110 | MMC2(1) | USB(1) | UART | MMC1 |
| 0b110111 | XIP | USB(1) | UART | MMC1 |
| 0b111000 | MMC2(2) | USB-ULPI | UART | |
| 0b111001 | NAND | USB(1) | UART | MMC1 |
| 0b111010 | MMC2(2) | UART | | |
| 0b111011 | MMC1 | USB(1) | UART | |
| 0b111100 | MMC2(2) | USB(1) | | |
| 0b111101 | MMC2(2) | USB(2) | | |
| 0b111110 | Reserved | | | |
| 0b111111 (Only on GP devices) | Fast XIP booting. Wait monitoring ON | USB(1) | UART | |

Table 28-8 lists the booting device order when it is preferred to boot from a peripheral-type device. This table is selected by ROM code when the sys_boot5 pin is tied low (= 0). If fast XIP booting is selected, the sys_boot5 pin controls the XIP wait-signal monitoring (that is, a logical low level disables wait-signal monitoring).

Table 28-8. Peripheral Preferred Booting

| sys_boot[5:0] | Booting Devices Order | | | |
|----------------------------------|--|-----------------|-----------------|-----------------|
| | 1 st | 2 nd | 3 rd | 4 th |
| 0b000000 | USB(1) | MMC2(1) | | |
| 0b000001 | USB(1) | XIP | | |
| 0b000010 | USB(1) | XIPWAIT | | |
| 0b000011 | USB(1) | NAND | | |
| 0b000100 | USB(2) | MMC2_BOOT | | |
| 0b000101 | USB(1) | MMC1 | | |
| 0b000110 | USB(1) | OneNAND | | |
| 0b000111 | USB(1) | OneNAND | MMC2(1) | |
| 0b001000 | UART | MMC2(1) | | |
| 0b001001 | USB(2) | OneNAND | MMC2(1) | |
| 0b001010 | UART | XIPWAIT | | |
| 0b001011 | UART | NAND | | |
| 0b001100 | USB(1) | MMC2_BOOT | | |
| 0b001101 | UART | MMC1 | | |
| 0b001110 | UART | OneNAND | | |
| 0b001111 | USB-ULPI | MMC2(1) | | |
| 0b010000 | USB-ULPI | XIP | | |
| 0b010001 | USB-ULPI | XIPWAIT | | |
| 0b010010 | USB-ULPI | NAND | | |
| 0b010011 | USB(2) | MMC1 | | |
| 0b010100 | USB-ULPI | MMC1 | | |
| 0b010101 | USB-ULPI | OneNAND | | |
| 0b010110 | USB(1) | UART | MMC1 | MMC2(1) |
| 0b010111 | USB(1) | UART | MMC1 | XIP |
| 0b011000 | USB-ULPI | UART | MMC2(2) | |
| 0b011001 | USB(1) | UART | MMC1 | NAND |
| 0b011010 | UART | MMC2(2) | | |
| 0b011011 | USB(1) | UART | MMC1 | |
| 0b011100 | USB(1) | MMC2(2) | | |
| 0b011101 | USB(2) | MMC2(2) | | |
| 0b011110 | | | Reserved | |
| 0b011111 (Only on GP devices) | Fast XIP booting. Wait monitoring OFF | USB(1) | UART | |

28.2.4.3 Boot Peripheral Pin Multiplexing

Table 28-9 lists the code pin multiplexing configuration supported by ROM according to boot peripheral.

Table 28-9. Pin Multiplexing According to Boot Peripheral

| Boot Device | Boot Interface | Pads |
|-----------------|--|--|
| NAND/OneNAND | GPMC | GPMC pads in mux mode 0, CS0, WAIT0 |
| XIP memory | GPMC | GPMC pads in mux mode 0, CS0, WAIT0 |
| MMC/SD/eMMC/eSD | SDMMC1 | SDMMC1 pads in mux mode 0 |
| eMMC/eSD | SDMMC2 (option 1) SDMMC2 (option 2) | GPMC pads in mux mode 1 SDMMC5 and FREF_CLK pads, all in mux mode 5 |
| UART | UART3 | UART3 pads in mux mode 0 |

Table 28-9. Pin Multiplexing According to Boot Peripheral (continued)

| Boot Device | Boot Interface | Pads |
|-------------------------------|-------------------------|----------------------------------|
| USB from internal transceiver | HSUSBOTG (USBA0-USBPHY) | USBA0_OTG pads in mux mode 0 |
| USB from external transceiver | HSUSBOTG (USBA0-ULPI) | DPM_EMU[2:13] pads in mux mode 1 |

NOTE: The ROM code examines the interfaces that are selected to be searched until a valid bootable interface/device is found. The activities on the pads of the searched interfaces must be considered in case they are connected to any other peripherals for any other purposes (for example, an LED connected to a GPMC pad muxed internally to a GPIO).

28.3 Reset Sequences

For the description of the reset sequences, see [Section 3.5.6, Reset Sequences](#), in [Section 3.5, Reset Management Functional Description](#).

28.4 Device Initialization by ROM Code

This section describes high-level booting concepts and provides basic knowledge for booting on the device.

28.4.1 Booting Overview

28.4.1.1 Booting Types

Bootting is the process of starting a bootstrap from one of the booting devices.

The ROM code has two functions for booting: Peripheral booting and memory booting.

- In peripheral booting, the ROM code polls a selected communication interface such as UART or USB, downloads the executable code over the interface, and executes it in internal RAM. Downloaded software from an external host can be used to program flash memories connected to the device. This special case of peripheral booting is called preflashing; software downloaded for preflashing is called the flash loader. The flash loader burns a new client application image in external flash memory. Initial software is a generic term for bootstrap, downloaded software, and flash loader. After the image is burnt, a software (warm) reset can be performed.
- In memory booting, the ROM code finds the bootstrap in permanent memories such as flash memory or memory cards and executes it. This process is normally performed after a cold or warm device reset.

The ROM code detects whether the device should download software from a peripheral interface (USB or UART) by using the `sys_boot[5:0]` pin configuration. This mechanism encompasses initial flashing in production (external memory is empty) and reflashing in service (external memory is already programmed).

28.4.1.2 ROM Code Architecture

Figure 28-5 shows the ROM code architecture. It is split into three main layers with a top-down approach: high-level, drivers, and hardware abstraction layer (HAL). One layer communicates with a lower-level layer through a unified interface.

- The high-level layer performs the main tasks of the public ROM code: multicore startup, watchdog and clock configurations, interrupt management, interaction with the power-management IC, and main booting routine.
- The driver layer implements the logical and communication protocols for any booting device in accordance with the interface specification.
- The HAL implements the lowest level code for interacting with the hardware infrastructure IPs. End booting devices are attached to the device I/O pads.

Figure 28-5 shows the three layers with their modules.

Figure 28-5. ROM Code Architecture

init-006

28.4.2 Memory Maps

28.4.2.1 ROM Memory Map

Figure 28-6 shows the 48-KB ROM memory map.

Figure 28-6. ROM Memory Map

- ROM exception vectors

Exceptions are redirected to ROM exception vectors (see [Table 28-10](#)). The reset exception is redirected to the public ROM code startup. Other exceptions are redirected to RAM handlers by loading appropriate addresses to the PC register.

Table 28-10. ROM Exception Vectors

| Address | Exception | Content |
|---------|--------------------------|--------------------------------|
| 0x30000 | Reset | Branch to the ROM code startup |
| 0x30004 | Undefined | PC = 0x4030 D004 |
| 0x30008 | Software interrupt (SWI) | PC = 0x4030 D008 |
| 0x3000C | Prefetch abort | PC = 0x4030 D00C |
| 0x30010 | Data abort | PC = 0x4030 D010 |
| 0x30014 | Unused | PC = 0x4030 D014 |
| 0x30018 | IRQ | PC = 0x4030 D018 |
| 0x3001C | FIQ | PC = 0x4030 D01C |

- ROM code cyclic redundancy check (CRC)

The ROM code CRC is calculated as 32-bit CRC code (CRC-32-IEEE 802.3) for the address range 0x30000–0x3BFFF. The 4-byte CRC code is stored at location 0x30020.

- Dead loops

Dead loops are branch instructions coded in ARM mode. They have multiple purposes (see [Table 28-11](#)).

Table 28-11. Dead Loops

| Address | Purpose |
|---------|--|
| 0x30080 | Undefined exception default handler |
| 0x30084 | SWI exception default handler |
| 0x30088 | Prefetch abort exception default handler |
| 0x3008C | Data abort exception default handler |
| 0x30090 | Unused exception default handler |
| 0x30094 | IRQ exception default handler |
| 0x30098 | FIQ exception default handler |

The fixed location of these dead loops facilitates debugging and testing. The first seven dead loops are default exception handlers linked to RAM exception vectors.

Dead loops can be called directly from code, but there is also a special function called from ROM code to execute a dead loop. This function is at address 0x300C0. The function is assembly code in ARM mode, which takes the dead loop address from the R0 register. The main purpose of the function is to issue a global software reset before going to a dead loop. In addition, the function clears the global cold reset status before issuing the global software reset.

- Code

This space is used to hold code and constant data.

- API table

The purpose of this table is to allow external code access to system maintenance, utility, and device driver functions which are used for ensuring the ROM code boot functionality. These functions can be reused at run time by calling a fixed address hardcoded in this table.

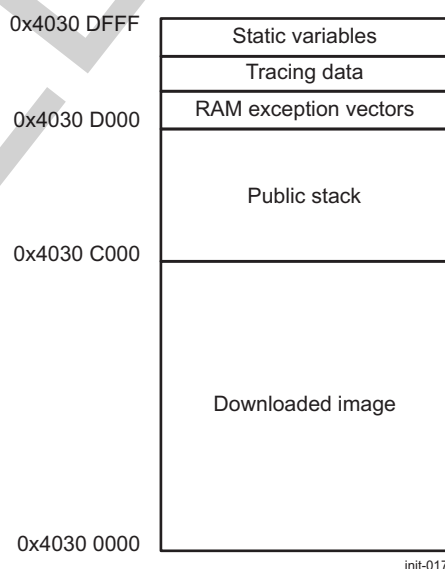

- ROM code version

The ROM code version consists of two decimal numbers: major and minor. It can be used to identify the ROM code release version burnt in a given IC (for example, useful during a debugging session). The ROM code version is a 32-bit hexadecimal value at address 0x3BFFC.

28.4.2.2 RAM Memory Map

The partitioning of the on-chip SRAM (L3 OCM RAM) shown in [Figure 28-7](#) is used during the booting process. Tracing and static variables areas can also be accessed when calling API functions.

Figure 28-7. RAM Memory Map

- Downloaded image

This space is used by the public ROM code to store a downloaded booting image. It can be up to

48KB.

- Public stack
This space is reserved for stack.
- RAM exception vectors

The RAM exception vectors provide an easy way to redirect exceptions to the custom handler. [Table 28-12](#) lists the contents of the RAM space reserved for RAM vectors. The first eight addresses are ARM instructions that load the value in the subsequent eight addresses into the PC. These instructions are executed when an exception occurs because they are called from ROM exception vectors. Undefined, SWI, unused, and FIQ exceptions are redirected to a hardcoded dead loop. Prefetch abort, data abort, and IRQ exception are redirected to predefined ROM handlers. Users can redirect an exception to another handler by writing its address to the appropriate location from 0x4030 D024 to 0x4030 D03C, or by overriding the branch (load into PC) instruction between addresses from 0x4030 D004 to 0x4030 D01C.

Table 28-12. RAM Exception Vectors

| Address | Exception | Content |
|-------------|------------------------------|--|
| 0x4030 D000 | Reserved | Reserved |
| 0x4030 D004 | Undefined | PC = [0x4030D024] |
| 0x4030 D008 | SWI | PC = [0x4030D028] |
| 0x4030 D00C | Prefetch abort | PC = [0x4030D02C] |
| 0x4030 D010 | Data abort | PC = [0x4030D030] |
| 0x4030 D014 | Unused | PC = [0x4030D034] |
| 0x4030 D018 | Interrupt request (IRQ) | PC = [0x4030D038] |
| 0x4030 D01C | Fast interrupt request (FIQ) | PC = [0x4030D03C] |
| 0x4030 D020 | Reserved | 0x30090 |
| 0x4030 D024 | Undefined | 0x30080 |
| 0x4030 D028 | SWI | 0x30084 |
| 0x4030 D02C | Prefetch abort | Address of default prefetch abort handler ⁽¹⁾ |
| 0x4030 D030 | Data abort | Address of default data abort handler ⁽¹⁾ |
| 0x4030 D034 | Unused | 0x30090 |
| 0x4030 D038 | IRQ | Address of default IRQ handler |
| 0x4030 D03C | FIQ | 0x30098 |

⁽¹⁾ The default handlers for prefetch and data abort perform reads from CP15 debug registers to retrieve the reason for the abort:

- In case of prefetch abort: the IFAR register is read from CP15 and stored into R0. The IFSR register is read and stored into the R1 register. Then the ROM code jumps to the prefetch abort dead loop (20088h).
- In case of data abort: the DFAR register is read from CP15 and stored into R0. The DFSR register is read and stored into the R1 register. Then the ROM code jumps to the data abort dead loop (2008Ch).

- Tracing data

This area contains trace vectors reflecting the execution path of the ROM code. The public ROM code tracing data is described in [Table 28-13](#). For more information about ROM code tracing, see [Section 28.4.9, Tracing](#).

Table 28-13. Tracing Data

| Address | Size (Bytes) | Description |
|-------------|--------------|---------------------------------------|
| 0x4030 D040 | 4 | Current tracing vector, word 1 |
| 0x4030 D044 | 4 | Current tracing vector, word 2 |
| 0x4030 D048 | 4 | Current tracing vector, word 3 |
| 0x4030 D04C | 4 | Cold reset run tracing vector, word 1 |
| 0x4030 D050 | 4 | Cold reset run tracing vector, word 2 |
| 0x4030 D054 | 4 | Cold reset run tracing vector, word 3 |

Table 28-13. Tracing Data (continued)

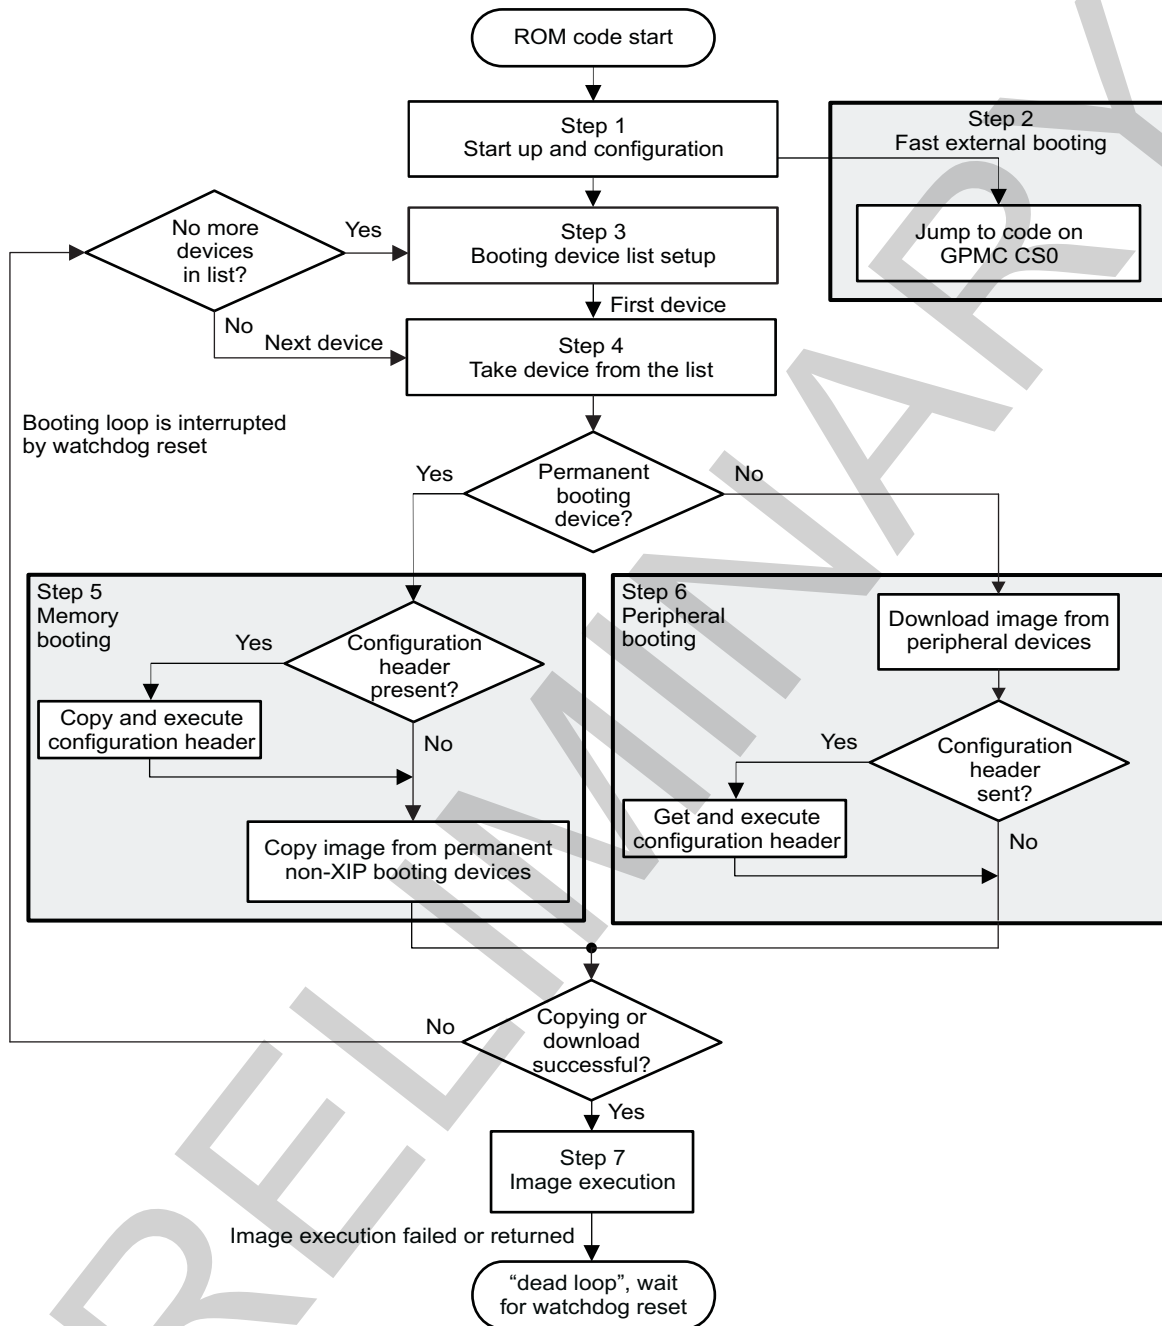

| Address | Size (Bytes) | Description |
|-------------|--------------|--|
| 0x4030 D058 | 4 | Current copy of the PRM_RSTST register (reset reasons) |
| 0x4030 D05C | 4 | Reserved |
| 0x4030 D060 | 4 | Reserved |
| 0x4030 D064 | 4 | Reserved |

- Static variables

ROM code static variables used at boot time (and possibly during run time if calling the ROM API functions).

28.4.3 Overall Booting Sequence

[Figure 28-8](#) shows the ROM code flow chart.

Figure 28-8. Overall Booting Sequence

init-007

The main loop of the booting module goes through the booting device list and tries to get an image from the currently selected booting device. The ROM code performs the following steps:

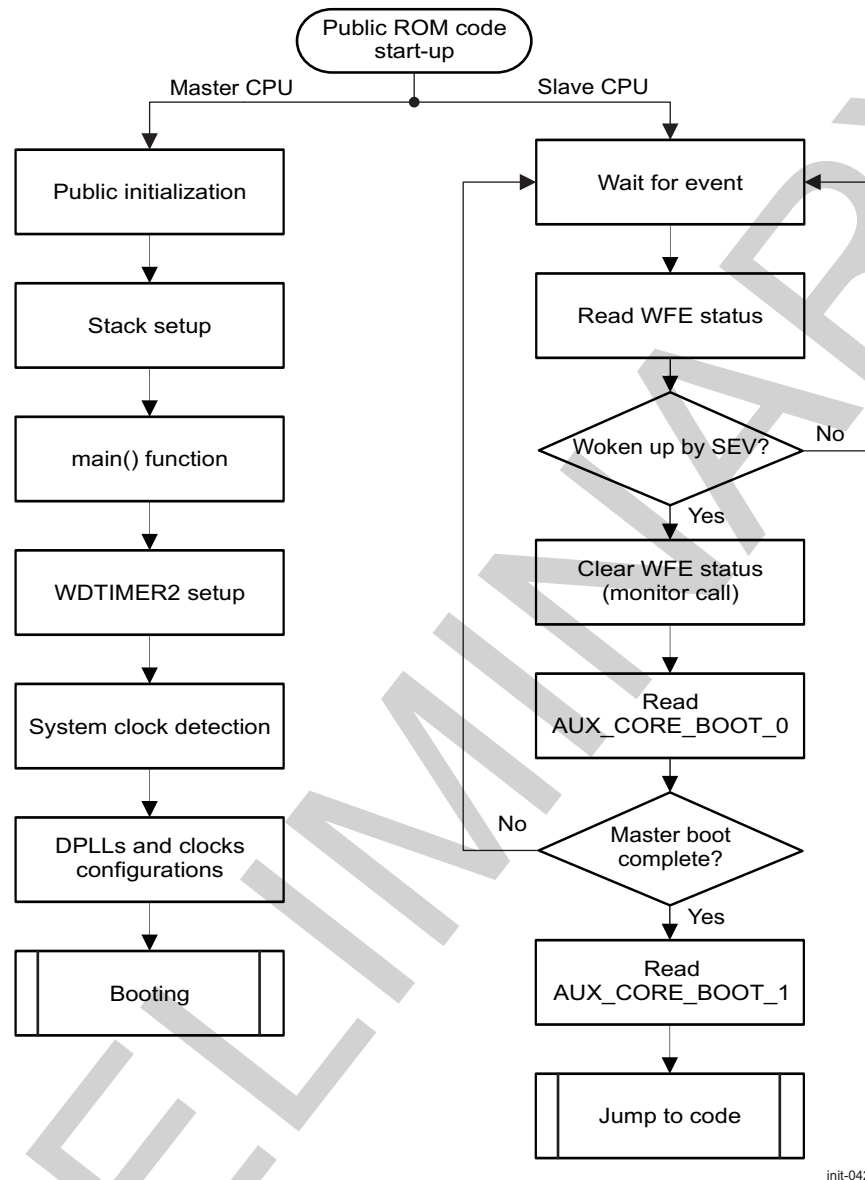

- Step 1. Basic configuration and initialization. Reading of SYSBOOT pins or software booting configuration
- Step 2. The path named fast external boot is a special low-latency boot mode. It consists of a blind jump to an external addressable memory. See [Section 28.4.6, Fast External Booting](#).
- Step 3. A booting device list is created (see [Section 28.4.4.3, Booting Device List Setup](#)). The list consists of all devices to be searched for a booting image. The list is created based on the sys_boot pins or the software booting configuration described in [Section 28.4.4.4, Software Booting Configuration](#). The software booting configuration structure is in the SAR memory and can be written by software before executing a software reset. After a software reset, the software booting configuration has priority over the sys_boot pin configuration.
- Step 4. The main loop of the booting procedure goes through the booting device list and tries to search for an image from the currently selected booting device. This loop is exited if a valid booting image is found and successfully executed or when the watchdog expires. If an image is found, ROM code executes memory booting or peripheral booting, depending on the type of the current booting device:
 - Memory booting is executed when the booting device is XIP memory, NAND, OneNAND/Flex-OneNAND, or eMMC/eSD/MMC/SD.
 - Peripheral booting is executed when the device is a UART or USB.
- Step 5. Memory booting reads data from memory-type devices. Memory booting is described in detail in [Section 28.4.7, Memory Booting](#).
- Step 6. Peripheral booting downloads data from communication interfaces. Peripheral booting is described in [Section 28.4.5, Peripheral Booting](#).
- Step 7. For the GP device, the image is automatically started.

An additional feature of the booting module is the execution of the CH. The CH configures the system for faster and more flexible booting from the selected permanent device. The CH, which is optional, is described in [Section 28.4.8.2, Configuration Header](#).

28.4.4 Startup and Configuration

28.4.4.1 Startup

[Figure 28-9](#) shows the ROM code start-up sequence.

Figure 28-9. ROM Code Multiprocessor Start-Up Sequence

The master CPU L1 instruction cache and branch prediction mechanisms are activated as part of the public boot process. The public vector base address is configured to the reset vector of ROM code (0x30000). The memory management unit (MMU) remains switched off during boot (thus, L1 data cache is off). The master CPU performs the public-side basic initialization and stack setup. Next, it configures WDTIMER2 (set to 3 minutes), performs system clock detection, and configures the system clock. Finally, it jumps to the booting routine.

No specific configuration is performed for the slave CPU, which keeps its default configuration after reset (L1 instruction and data caches off, branch prediction off, MMU off, no remap of public-vector-base address). The slave CPU is rapidly held in wait-for-event state. It stays in this state while the master CPU completes the public boot process and until jumping to the external software (for example, HLOS). At this stage, the external software can wake up the slave CPU by executing an SEV command.

Two internal memory-mapped registers are available to the OS for communicating start-up information. The AUX_CORE_BOOT_0 and AUX_CORE_BOOT_1 registers are in the MPU WakeupGen domain.

- AUX_CORE_BOOT_0 is used as a status register to signal the slave CPU that it must wake up after the send event operation initiated by the master CPU.

- AUX_CORE_BOOT_1 contains the address location to which the slave CPU must jump after wakeup. See the memory mapping of these registers in [Chapter 4, Dual Cortex-A9 Subsystem](#).

28.4.4.2 Clocking Configuration

The ROM code detects the system input clock frequency. The supported frequencies are:

- 12 MHz
- 16.8 MHz
- 19.2 MHz
- 26 MHz
- 38.4 MHz

After detecting the input clock, the ROM code configures the clocks and DPLLs required for ROM code execution.

The configured DPLLs are:

- Peripheral DPLL: Set to provide 192, 128, 96, 48, 24, and 12 MHz for peripheral blocks
- Core DPLL: Set to provide L3/L4 interconnect and MPU and EMIF clocks
- MPU DPLL: Left in bypass, and the MPU internal clock is derived from the core DPLL
- USB DPLL: Locked only in case of USB peripheral booting from internal transceiver. It is left unused in other cases (for example, memory boot or peripheral boot from UART or USB ULPI) to save power.

The multipliers and dividers of the DPLLs are set to values that depend on the input clock detected.

[Table 28-14](#) summarizes the ROM code default settings for key clocks.

Table 28-14. ROM Code Default Clock Settings

| Clock | Frequency [MHz] | Source |
|---------------------------------|-----------------|----------------------|
| FCORE_DPLL | 400 | Derived from SYS_CLK |
| CORE_X2_CLK | 200 | |
| CORE_CLK | 200 | CORE_X2_CLK/1 |
| L3_ICLK | 100 | CORE_CLK/2 |
| L4_ICLK | 50 | L3_ICLK/2 |
| FPER_DPLL | 384 | Derived from SYS_CLK |
| FUNC_192M_CLK | 192 | |
| FUNC_128M_CLK | 128 | |
| FUNC_96M_FCLK | 96 | |
| FUNC_48M_FCLK | 48 | |
| FMPU_DPLL (in bypass) | 200 | CORE_X2_CLK |
| MPU_DPLL_CLK | 200 | FMPU_DPLL/1 |
| FUSB_DPLL ⁽¹⁾ | 960 | Derived from SYS_CLK |
| INIT_960M | 960 | FUSB_DPLL/1 |
| INIT_480M | 480 | FUSB_DPLL/2 |
| INIT_60M | 60 | INIT_480M/8 |

⁽¹⁾ Locked only in case of USB peripheral booting from internal PHY

There are three ways to change DPLLs and all related clock divider, gating, and multiplexer configurations during the boot:

- ROM code default settings, described in [Table 28-14](#). They are always applied at any reset.
- Software booting configuration after a software reset, described in [Section 28.4.4.4, Software Booting Configuration](#)
- The CH, described in [Section 28.4.8.2, Configuration Header](#). The CH lets users have a known configuration (about GPMC and clock registers) after memory booting. This configuration can be blocked by the software booting configuration.

28.4.4.3 Booting Device List Setup

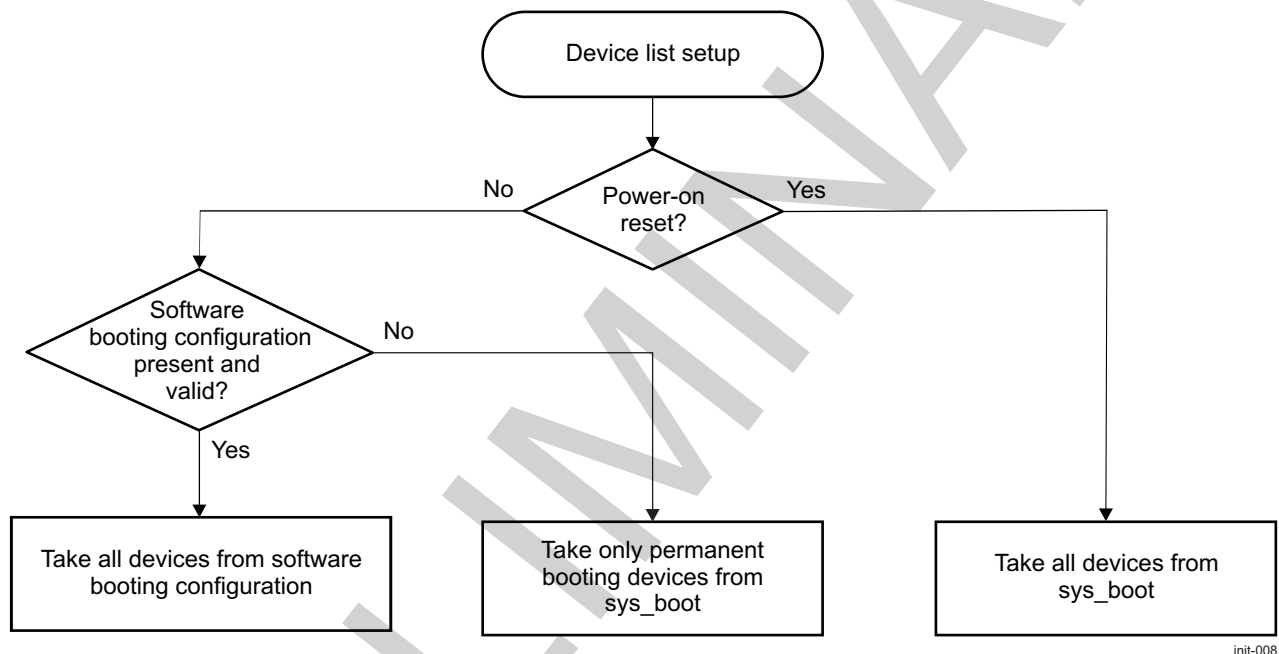

The ROM code creates a device list based on two sources:

- The software booting configuration is stored in nonvolatile RAM SAR memory.
- The sys_boot[5:0] pins sensed in the control module are used to index the device table from which the list of devices is extracted.

Figure 28-10 shows how the ROM code sets up the device list depending on the reset source.

NOTE: Only permanent booting devices are put on the list when reset is not power on and devices are taken from the sys_boot pins. Users can force peripheral booting after software reset using the software booting configuration.

Figure 28-10. Device List Setup

28.4.4.4 Software Booting Configuration

The software booting configuration is a logical structure stored in SAR RAM memory, which is not cleared after warm resets or wakeups from low-power modes.

28.4.4.4.1 Public Use of SAR RAM

At system level, the OMAP SAR RAM memory is divided into four banks. The public ROM code uses only the first bank, which is always public-accessible. More specifically, the software booting configuration structure must be in the upper 1.5 KB of the first bank.

The public ROM code offers some flexibility about the location of the software booting configuration structure. The PUBLIC_SW_BOOT_CFG_ADDR pointer defines the start address of the structure within the SAR RAM bank (see Table 28-15).

Table 28-15. Public Use of SAR RAM

| Logical name | Address | Size (Bytes) | Description |
|-------------------------|-------------|--------------|--|
| PUBLIC_SW_BOOT_CFG_ADDR | 0x4A32 6A00 | 4 | Public software booting configuration pointer. The word value at this location is: - Reset (zero) on a cold reset. - Read on a warm reset. |

Table 28-15. Public Use of SAR RAM (continued)

| Logical name | Address | Size (Bytes) | Description |
|------------------------|-------------|--------------|---|
| CPU0_WAKEUP_NS_PA_ADDR | 0x4A32 6A04 | 4 | CPU0 nonsecure wake-up restoration pointer ⁽¹⁾ |
| CPU1_WAKEUP_NS_PA_ADDR | 0x4A32 6A08 | 4 | CPU1 nonsecure wake-up restoration pointer ⁽¹⁾ |
| PUBLIC_SAR_RAM_1_FREE | 0x4A32 6A0C | ... | Recommended address for start of software booting configuration structure described in Section 28.4.4.2, Software Booting Configuration Structure . |

⁽¹⁾ This pointer is used as part of the restoration procedure from low-power modes.

As mentioned previously, the software booting configuration feature is optional. Hence, the public ROM code decides to use the feature based on the value read on a warm reset at the address pointed to by the PUBLIC_SW_BOOT_CFG_ADDR pointer. If the value matches the range 0x4A32 6A00–0x4A32 6FFF, the ROM code tries to extract the structure at that address. The value pointed to by PUBLIC_SW_BOOT_CFG_ADDR is always overwritten to 0 on a cold reset.

The recommended address for storing the software booting configuration structure described hereafter is defined as PUBLIC_SAR_RAM_1_FREE. It is, however, possible to locate the structure at any location within the 1.5-KB range.

It is moreover possible to use the public SAR RAM area for any other purpose, such as storing traces for HLOS use. Obviously, care must be taken not to overwrite the locations used for low-power modes and/or software booting configuration if used.

28.4.4.2 Software Booting Configuration Structure

[Table 28-16](#) describes the software booting configuration structure. It offers three levels of flexibility for redefining the ROM code defaults after a warm reset:

- Redefining the default device booting list (from ROM code defaults given by SYSBOOT pins configuration)
- Redefining the default clock settings
- Redefining time-outs linked to the peripheral booting mechanism

NOTE: The sections are provided as a linked list; therefore, the order and number of items is not relevant.

The ROM code searches for the next section at the location based on the size filled in the previous section. The clock configuration from software booting configuration overwrites the CH settings.

Table 28-16. Software Booting Configuration Structure

| Field | Size (Bytes) | Description |

28.4.5 Peripheral Booting

28.4.5.1 Description

The ROM code can boot from two different peripherals:

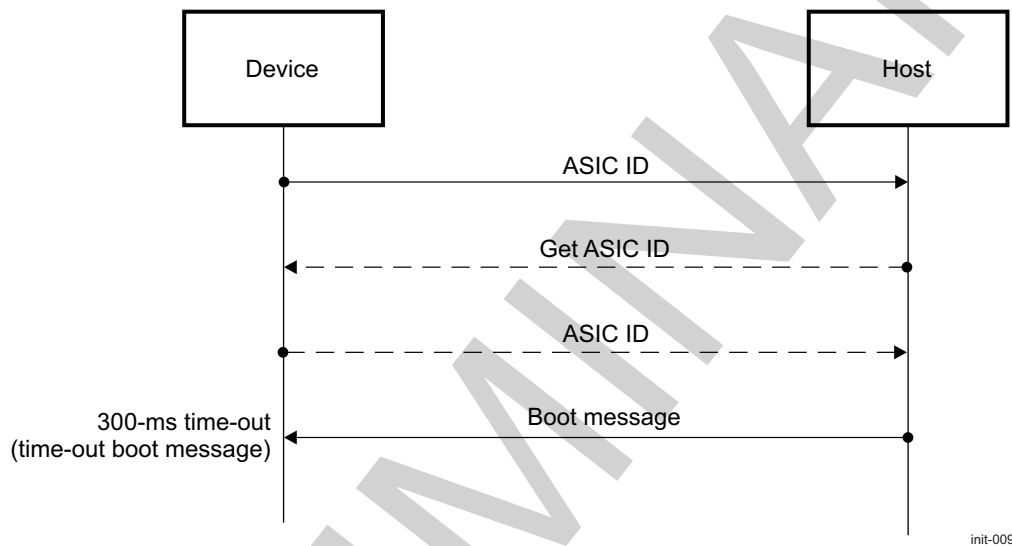

- USB: High-/full-speed USB from internal or external transceiver

- UART3: 115.2 Kbps, 8 bits, even parity, 1 stop-bit

The purpose of booting from a peripheral is to download a flash loader code from an external host. This booting method is used primarily for programming flash memories connected to the OMAP device (for example, in the case of initial flashing, firmware update or servicing). The overall peripheral booting procedure is shown in [Figure 28-13](#). It consists of a synchronization phase (handshake between host and OMAP device) and a transfer phase. The synchronization phase is similar for UART and USB boots. Both transfer phases use the same procedure.

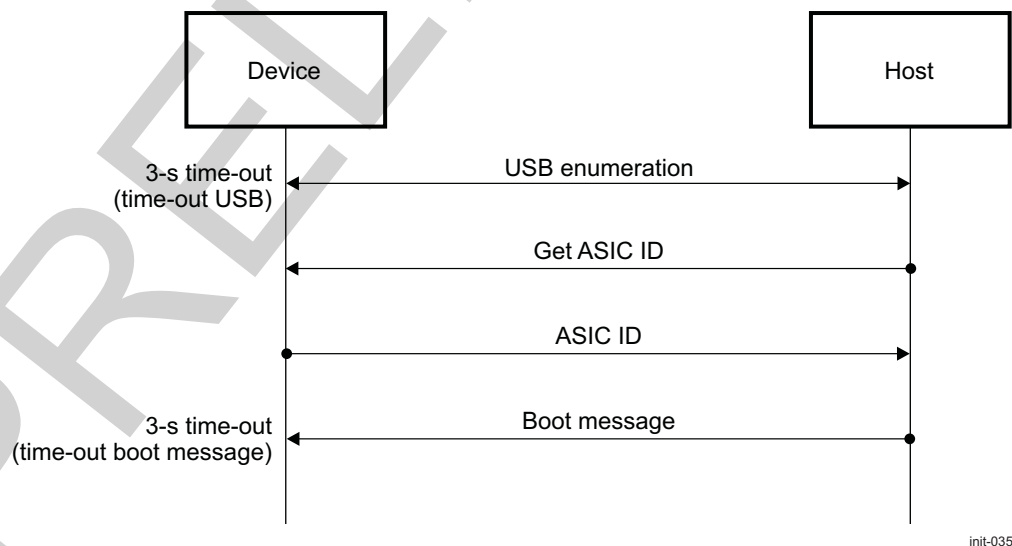

When booting from the UART, the ROM code first initializes the UART3 interface. Then the ROM code sends an ASIC ID block of data. From there, it expects to receive a boot message from the host within 300 ms, by default. [Figure 28-11](#) shows this procedure.

Figure 28-11. Synchronization Phase for UART

[Figure 28-12](#) shows the procedure when booting from the USB.

Figure 28-12. Synchronization Phase for USB

During the synchronization phase (see [Figure 28-11](#) and [Figure 28-12](#)), the OMAP device can provide a small packet of data called the ASIC ID (described in [Table 28-17](#)). It is a simple structure that contains different kinds of information, such as ROM version, checksums, and ID.

The default time-outs involved during the synchronization phase can be redefined after a warm reset by means of the software booting configuration (described in [Section 28.4.4.4, Software Booting Configuration](#)). The host can decide the desired operation by providing a booting message (see [Table 28-21](#)). This message can be: Get ASIC ID, peripheral boot, change device, or next device. If the OMAP device receives the Get ASIC ID boot message, it sends back the ASIC ID contents.

If the change device or next device message is received, the ROM code stops the current peripheral booting procedure and returns to the main booting, which decides about the next booting device according to the boot message received.

If the peripheral boot message is received without a time-out, the OMAP device is entering the transfer phase. From there, the flash loader image size (as a 32-bit word) and the flash loader image itself are expected to be received. The ROM code waits up to 1 minute for completion of image size reception, and up to 1 more minute to download the image. If the download procedure does not complete before this time, the peripheral booting returns with a TIMEOUT status. ROM code continues to examine the devices included in the booting device list. If the download procedure passes, the peripheral booting returns with a SUCCESS status and the image can be executed.

The USB or UART connection is left open at the end of the transfer phase and once exiting the ROM code for the initial software to take over. It means the initial software can reuse the currently established connection. In the case of a USB connection, the endpoints can be reused as such, without closing the connection and performing a full enumeration again.

Table 28-17. ASIC ID Structure

| ASIC ID Item | Size (Bytes) | Description |
|-------------------|--------------|---|
| Items | 1 | Number of subblocks |
| ID subblock | 7 | Device identification information |
| Reserved subblock | 4 | This subblock is transmitted, but does not contain useful information in case of GP device. |
| Reserved subblock | 23 | This subblock is transmitted, but does not contain useful information in case of GP device. |
| Reserved subblock | 35 | This subblock is transmitted, but does not contain useful information in case of GP device. |
| Checksum subblock | 11 | CRC (4 bytes) |

Table 28-18. Items

| Offset | Size (Bytes) | Description |
|--------|--------------|--|
| 0x00 | 1 | 0x05: Number of subblocks USB 0x04: Number of subblocks UART ⁽¹⁾ |

⁽¹⁾ The checksum subblock is not transmitted over the UART.

Table 28-19. ID Subblock

| Offset | Size (Bytes) | Description |
|--------|--------------|---|
| 0x01 | 1 | 0x01: Subblock ID |
| 0x02 | 1 | 0x05: Subblock size |
| 0x03 | 1 | 0x01: Fixed value |
| 0x04 | 2 | 0x44, 0x70: OMAP4470 device |
| 0x06 | 1 | 0x07: CH enabled (read from eFuse) 0x17: CH disabled (read from eFuse) |
| 0x07 | 1 | ROM revision |

| Offset | Size (Bytes) | Description |
|--------|--------------|-------------------|
| 0x46 | 1 | 0x15: Subblock ID |

⁽¹⁾ The checksum subblock is not transmitted over the UART.

Table 28-20. Checksum Subblock⁽¹⁾ (continued)

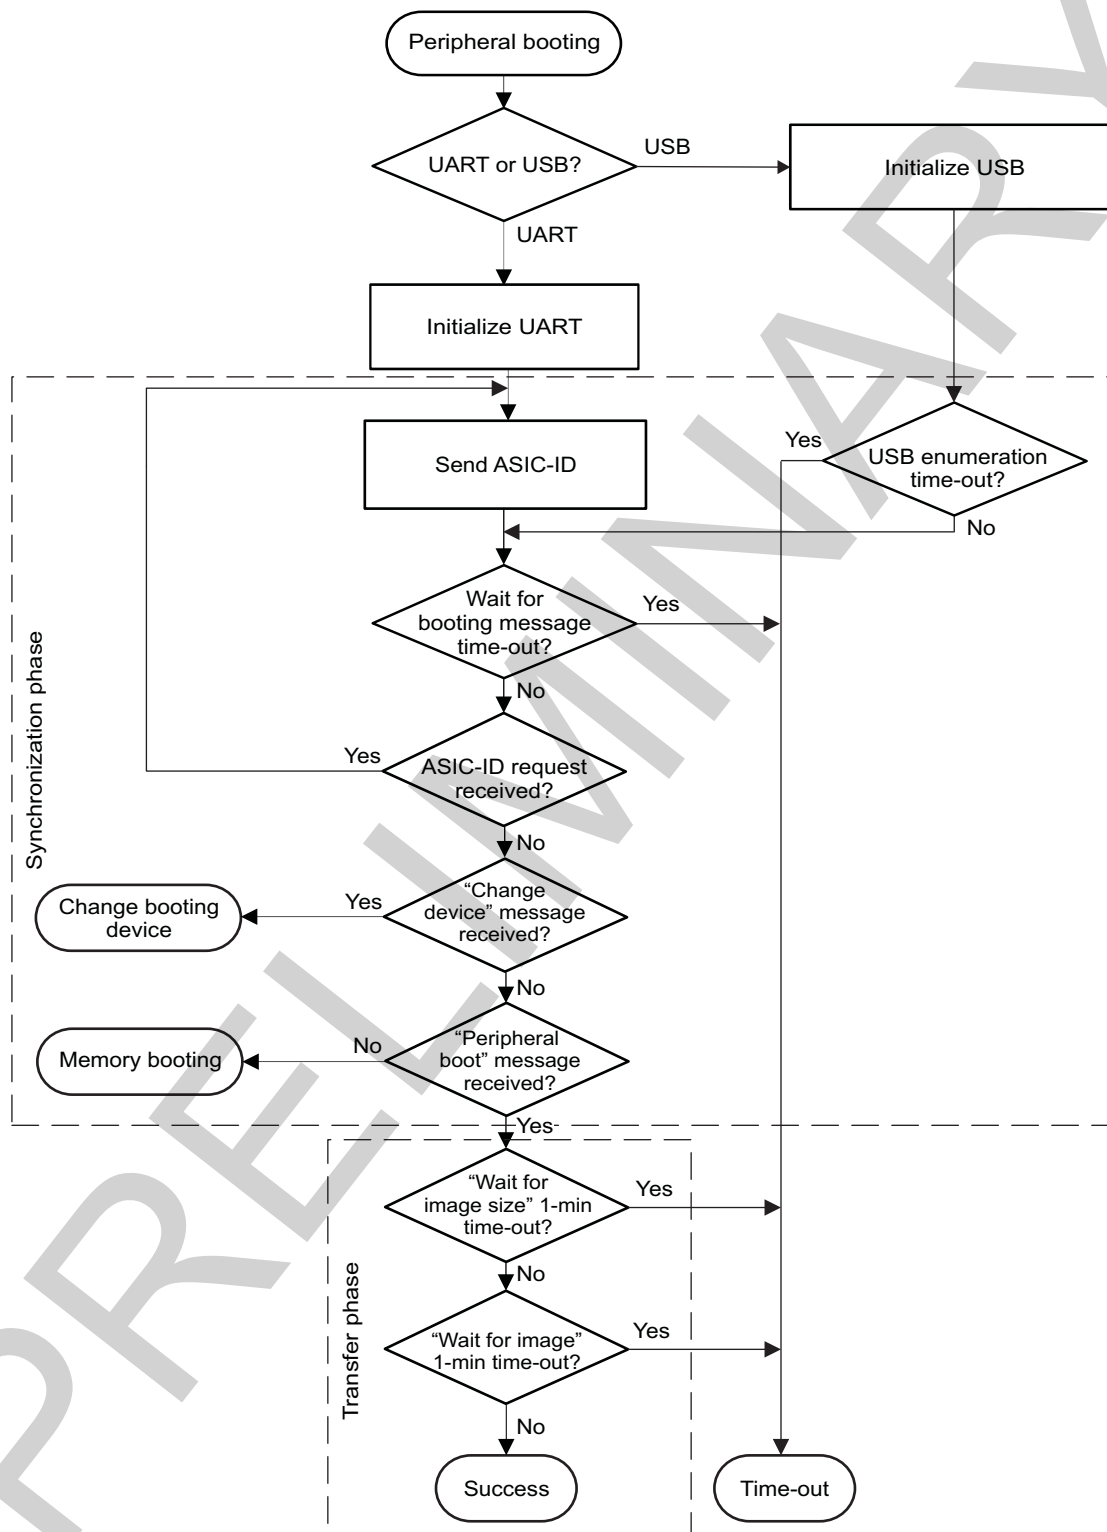

| Offset | Size (Bytes) | Description |
|--------|--------------|---------------------------|
| 0x47 | 1 | 0x09: Subblock size |
| 0x48 | 1 | 0x01: Fixed value |
| 0x49 | 4 | ROM CRC |
| 0x4D | 4 | 0x00000000: For GP device |

Table 28-21. Booting Messages

| Message Name | Value | Description |
|-----------------|-------------|--|
| Peripheral boot | 0xF003 0002 | Continue peripheral booting. |
| Get ASIC ID | 0xF003 0003 | ASIC ID request. The Get ASIC ID request message is optional. If received, the ROM code sends its ASIC ID data to the host in return. The host can issue the Get ASIC ID message multiple times if required. The structure of the ASIC ID is described in Table 28-17 . |
| Change device | 0xF003 xx06 | Skip current peripheral booting and continue booting from device type indicated by xx: <ul style="list-style-type: none"> 0x00: Void, no device 0x01: XIP memory 0x02: XIPWAIT memory (wait-signal monitoring on) 0x03: NAND 0x04: OneNAND 0x05: MMC1 0x06: MMC2(1) 0x07: MMC2(2) 0x08: MMC2_BOOT 0x43: UART 3 0x45: USB(1) (internal transceiver) 0x46: USB-ULPI 0x47: USB(2) (internal transceiver) Others: Reserved |
| Next device | 0xFFFF FFFF | Skip current device and move to the next device on the device list. |
| Memory booting | Others | Skip current peripheral booting and move to the first device for memory booting. |

Figure 28-13 shows the peripheral booting procedure.

Figure 28-13. Peripheral Booting Procedure

init-010

28.4.5.2 UART

The ROM code supports booting from a UART interface with the following characteristics:

- UART interface 3
- Communication parameters set to 115.2 Kbps, 8 bits, even parity, 1 stop-bit
- Two-pin interface: RX/TX
- The boot message default time-out is 300 ms (time-out boot message)

28.4.5.3 USB

The ROM code supports booting from a USB interface with the following characteristics:

- HSUSBOTG interface (USBA0)
- OMAP integrated transceiver (USBPHY) or external transceiver through the ULPI
- Enumeration default time-out is 3 s (time-out USB)
- The boot message default time-out is 3 s (time-out boot message).

NOTE: Even though using OTG-capable hardware, the ROM code does not handle any OTG-specific features.

28.4.5.3.1 Overview

[Figure 28-14](#) shows the USB initialization procedure.

Figure 28-14. USB Initialization Procedure

init-037

After internal USB module driver setup, the TWL6032 power IC is checked for presence. If found, the following actions are performed using I²C transactions through the I2C1 interface:

- PrevStartOk status flag check, as described in [Section 28.4.5.3.2](#).
- Get the VBUS status reflecting presence (or not) of the USB cable

- If VBUS was detected, then the VUSB regulator is enabled to power the internal OMAP transceiver.

In case of boot from external transceiver in accordance with the chosen SYSBOOT configuration:

- The HSUSBOTG hardware and PRCM clocks are configured for ULPI mode.
- The ROM code continues with the USB procedure only if the USB cable is detected (that is, VBUS is detected at external transceiver level and communicated as such through the ULPI traffic). If not, the initialization procedure is aborted.

NOTE: The OMAP USB DPLL is not set up in case of ULPI mode, for which the 60-MHz clock is driven by the external transceiver.

In case of boot from internal transceiver in accordance with the chosen SYSBOOT configuration:

- The USBOTGHS hardware and PRCM clocks are configured for UTMI mode and internal PHY clocks are enabled.
- For USB(1) only: The ROM code continues with the USB procedure only if the TWL6032 is detected and the USB cable is detected as present (that is, VBUS is detected at the TWL6032 level and read as such with a register read through I2C interface). If not, the initialization procedure is aborted.
- For USB(2) only: The ROM code continues with the USB procedure even if the TWL6032 is not detected and the USB cable is not detected as present at the TWL6032 level. This enables a USB boot with internal transceiver even without the TWL6032.
- The ROM code proceeds with charger detection, as described in [Section 28.4.5.3.2](#).
- It enables the USB DPLL for feeding the appropriate 60-MHz clock needed by the internal transceiver.

28.4.5.3.2 PrevStartOk Status Flag Check

The ROM code supports a mechanism for avoiding the boot time spent because of the enumeration time-out (default 3 s) in case the USB cable is attached and the USB option is present in the selected boot list but is not intended to initiate a peripheral booting procedure (for example, firmware update or flashing). This mechanism is jointly handled with the support of the TWL6032 device (not supported if TWL6032 is not detected). This mechanism is supported only for USB and not UART (see [Figure 28-15](#)).

Figure 28-15. PrevStartOk Mechanism

init-038

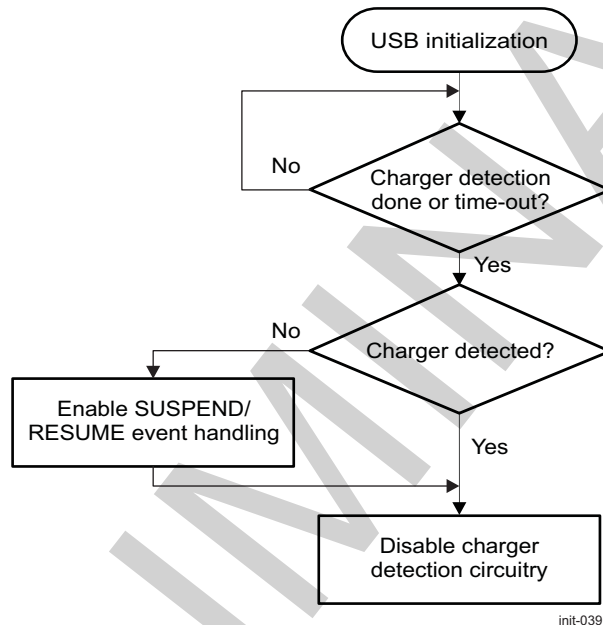

The ROM code first checks the value of a register in the TWL6032 RTC domain (hence, retained by the backup battery when the platform is switched off) by an I²C read access. If the PrevStartOk bit in this register is set, the USB peripheral booting is simply skipped. In any case, the bit is reset (zeroed) by the

ROM code, which means that the USB peripheral boot is re-enabled on the next cold reset (or warm reset if suitable software booting configuration is present). The initial software of the user must reset this bit by an I²C write access to disable USB peripheral booting on a subsequent reset. For more information about the accesses made toward the PrevStartOk bit in the PHOENIX_SEQ_CFG register, see TWL6032 documentation.

28.4.5.3.3 Charger Detection

The ROM code proceeds with charger detection as part of the USB peripheral booting procedure and in compliance with *Battery Charging Specification Revision 1.1*. It uses the specific charger detection hardware embedded in the OMAP device. Figure 28-16 shows the high-level procedure.

Figure 28-16. Charger Detection

The hardware charger detection mechanism should end up within the 500-ms time-out. The main goal of such detection is to gate the charger circuitry in TWL6032 in case a charger is not detected and a suspend event is detected on the OMAP side, for which the power consumption must be reduced.

28.4.5.3.4 SUSPEND and RESUME Handling

The SUSPEND event is detected by the HSUSBOTG module when activity on the bus stops for at least 3 ms. During peripheral booting time, a SUSPEND event is detected by the ROM code and processed by initiating a write into the TWL6032 to gate the charging circuitry. The ROM code releases the TWL6032 charger circuitry upon getting a RESUME event. During run time, SUSPEND and RESUME interrupts can be routed to the initial software to define custom handling.

28.4.5.3.5 USB Driver Descriptors

USB devices report their attributes using descriptors. A descriptor is a data structure with a defined format. Each descriptor begins with a byte-wide field that contains the total number of bytes in the descriptor followed by a byte-wide field that identifies the descriptor type. Using descriptors allows concise storage of the attributes of individual configurations so that each configuration can reuse descriptors or portions of descriptors from other configurations that have the same characteristics. Where appropriate, descriptors contain references to string descriptors. String descriptors contain displayable, human-readable description information. These descriptor details can be used for tool development or debugging:

- Device descriptor

A device descriptor contains general information about a USB device, including global information that applies to the device and all device configurations. A USB device has only one device descriptor. A device-qualifier descriptor is required because the ROM code uses the HS feature of the USB core. [Table 28-22](#) lists the device descriptors.

Table 28-22. Device Descriptor

| Field | Value | Description |
|--------------------|--|---|
| bLength | 0x12 | Size of this descriptor in bytes |
| bDescriptorType | 0x01 | Device descriptor type |
| bcdUSB | 0x0210 | USB specification release number in binary coded decimal (BCD) format |
| bDeviceClass | Vendor-specific (0xFF) | Class code |
| bDeviceSubClass | Vendor-specific (0xFF) | Subclass code |
| bDeviceProtocol | Vendor-specific (0xFF) | Protocol code |
| bMaxPacketSize0 | 0x40 | Maximum packet size for endpoint 0 |
| idVendor | 0x0451 | Vendor ID (Texas Instruments), TI default value |
| idProduct | 0x- | Product ID (OMAP4470), TI default value |
| bcdDevice | 0x0000 | Device release number |
| iManufacturer | See Section 28.4.5.3.6 . | Index of string descriptor describing manufacturer |
| iProduct | See Section 28.4.5.3.6 . | Index of string descriptor describing product |
| iSerialNumber | See Section 28.4.5.3.6 . | Index of string descriptor describing device serial number |
| bNumConfigurations | 0x01 | Number of possible configurations |

- Device-qualifier descriptor

The device-qualifier descriptor contains information about a HS-capable device that changes if the device operates at its other speed. This descriptor is retrieved by the host using the GetDescriptor() request (standard device request). [Table 28-23](#) describes a device-qualifier descriptor.

Table 28-23. Device-Qualifier Descriptor

| Field | Value | Description |
|--------------------|--------|---|
| bLength | 0x0a | Size of this descriptor in bytes |
| bDescriptorType | 0x06 | Device-qualifier descriptor type |
| bcdUSB | 0x0210 | USB specification release number in BCD |
| bDeviceClass | 0xFF | Class code |
| bDeviceSubClass | 0xFF | Subclass code |
| bDeviceProtocol | 0xFF | Protocol code |
| bMaxPacketSize0 | 0x40 | Maximum packet size for endpoint 0 |
| bNumConfigurations | 0x01 | Number of possible configurations |
| bReserved | 0x00 | Reserved for future use |

- Configuration descriptor

This descriptor gives information about a specific device configuration. It describes the number of interfaces supported by the configuration (see [Table 28-24](#)).

Table 28-24. Configuration Descriptor

| Field | Value | Description |
|---------------------|-------|--|
| bLength | 0x09 | Size of this descriptor in bytes |
| bDescriptorType | 0x02 | Configuration descriptor type |
| wTotalLength | – | Combined length of all descriptors |
| bNumInterfaces | 0x01 | Number of interfaces supported |
| bConfigurationValue | 0x01 | Value to use as an argument for the SetConfiguration() request |
| iConfiguration | Index | Index of string descriptor describing this configuration |

Table 28-24. Configuration Descriptor (continued)

| Field | Value | Description |
|--------------|-------|---|
| bmAttributes | 0xC0 | Power setting and remote wakeup |
| bMaxPower | 0x32 | Maximum power consumption of the USB device |

- Other speed configuration descriptor

This descriptor describes the configuration of a HS-capable device if it operates at its other possible speed (see [Table 28-25](#)).

Table 28-25. Other Speed Configuration Descriptor

| Field | Value | Description |
|---------------------|-------|--|
| bLength | 0x09 | Size of this descriptor in bytes |
| bDescriptorType | 0x07 | Other speed configuration descriptor type |
| wTotalLength | – | Combined length of all descriptors |
| bNumInterfaces | 0x01 | Number of interfaces supported |
| bConfigurationValue | 0x01 | Value to use as an argument for the SetConfiguration() request |
| iConfiguration | Index | Index of string descriptor describing this configuration |
| bmAttributes | 0xC0 | Power setting and remote wakeup |
| bMaxPower | 0x32 | Maximum power consumption of the USB device |

- Interface descriptor

This descriptor describes a specific interface in a configuration (see [Table 28-26](#)).

Table 28-26. Interface Descriptor

| Field | Value | Description |
|--------------------|-------|--|
| bLength | 0x09 | Size of this descriptor in bytes |
| bDescriptorType | 0x04 | Interface descriptor type |
| bInterfaceNumber | 0x00 | Number of this descriptor |
| bAlternateSetting | 0x00 | Value to select the alternate setting |
| bNumEndpoints | 0x02 | Number of endpoints used for this interface |
| bInterfaceClass | 0xFF | Class code |
| bInterfaceSubClass | 0xFF | Subclass code |
| bInterfaceProtocol | 0xFF | Protocol code |
| iInterface | Index | Index of string descriptor describing this interface |

- Endpoint descriptor

Each endpoint used for an interface has its own descriptor. This descriptor contains information required by the host to determine the bandwidth requirements of each endpoint. This descriptor is returned as part of the GetDescriptor(Configuration) request (see [Table 28-27](#) and [Table 28-28](#)).

Table 28-27. BULK IN Endpoint Descriptor

| Field | Value | Description |
|------------------|----------------------|---|
| bLength | 0x07 | Size of this descriptor in bytes |
| bDescriptorType | 0x05 | Endpoint descriptor type |
| bEndpointAddress | 0x81 (1 IN) | Address of the endpoint on the USB device |
| bmAttributes | 0x02 (Bulk) | Type of transfer |
| wMaxPacketSize | See ⁽¹⁾ . | Number of endpoints used for this interface |
| bInterval | 0x00 | Maximum NAK rate |

⁽¹⁾ The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

Table 28-28. BULK OUT Endpoint Descriptor

| Field | Value | Description |
|------------------|----------------------|---|
| bLength | 0x07 | Size of this descriptor in bytes |
| bDescriptorType | 0x05 | Endpoint descriptor type |
| bEndpointAddress | 0x01 (1 OUT) | Address of the endpoint on the USB device |
| bmAttributes | 0x02 (Bulk) | Type of transfer |
| wMaxPacketSize | See ⁽¹⁾ . | Number of endpoints used for this interface |
| bInterval | 0x00 | Maximum NAK rate |

⁽¹⁾ The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

- String descriptors

String descriptors use UNICODE encoding. The strings in a USB device can support multiple languages. When requesting a string descriptor, the requester specifies the desired language using a 16-bit language ID (LANGID) defined by the USB interface. String index 0 for all languages returns a string descriptor that contains an array of 2-byte LANGID codes supported by the device.

For the description of the different string descriptors, see:

- The language ID string descriptor ([Table 28-29](#))
- The manufacturer ID string descriptor ([Table 28-30](#))
- The product ID string descriptor ([Table 28-31](#))
- The configuration string descriptor ([Table 28-32](#))
- The interface string descriptor ([Table 28-33](#))

Table 28-29. Language ID String Descriptor

| Field | Value | Description |
|-----------------|---------------------|----------------------------------|
| bLength | 0x04 | Size of this descriptor in bytes |
| bDescriptorType | 0x03 | String descriptor type |
| wLangId | 0x0409 (US English) | Language ID code |

Table 28-30. Manufacturer ID String Descriptor

| Field | Value | Description |
|-----------------|-------------------|----------------------------------|
| bLength | 0x24 | Size of this descriptor in bytes |
| bDescriptorType | 0x03 | String descriptor type |
| bString | Texas Instruments | Manufacturer string |

Table 28-31. Product ID String Descriptor

| Field | Value | Description |
|-----------------|----------|----------------------------------|
| bLength | 0x12 | Size of this descriptor in bytes |
| bDescriptorType | 0x03 | String descriptor type |
| bString | OMAP4470 | Product string |

Table 28-32. Configuration String Descriptor

| Field | Value | Description |
|-----------------|-------|----------------------------------|
| bLength | 0x08 | Size of this descriptor in bytes |
| bDescriptorType | 0x03 | String descriptor type |
| bString | pbc | Configuration string |

Table 28-33. Interface String Descriptor

| Field | Value | Description |
|-----------------|-------|----------------------------------|
| bLength | 0x08 | Size of this descriptor in bytes |
| bDescriptorType | 0x03 | String descriptor type |
| bString | pbi | Interface string |

28.4.5.3.6 USB Customized Descriptors

There are two parameters in USB descriptors that customers can define after the chip is created: vendor ID (VID) and product ID (PID). The ROM code uses dedicated eFuses that hold VID and PID values. Other parameters can also be changed based on the VID value. The ROM code has an encoded set of parameters for customers who have defined their requirements before the ROM code has been done.

Table 28-34 lists the parameters that depend on the VID value.

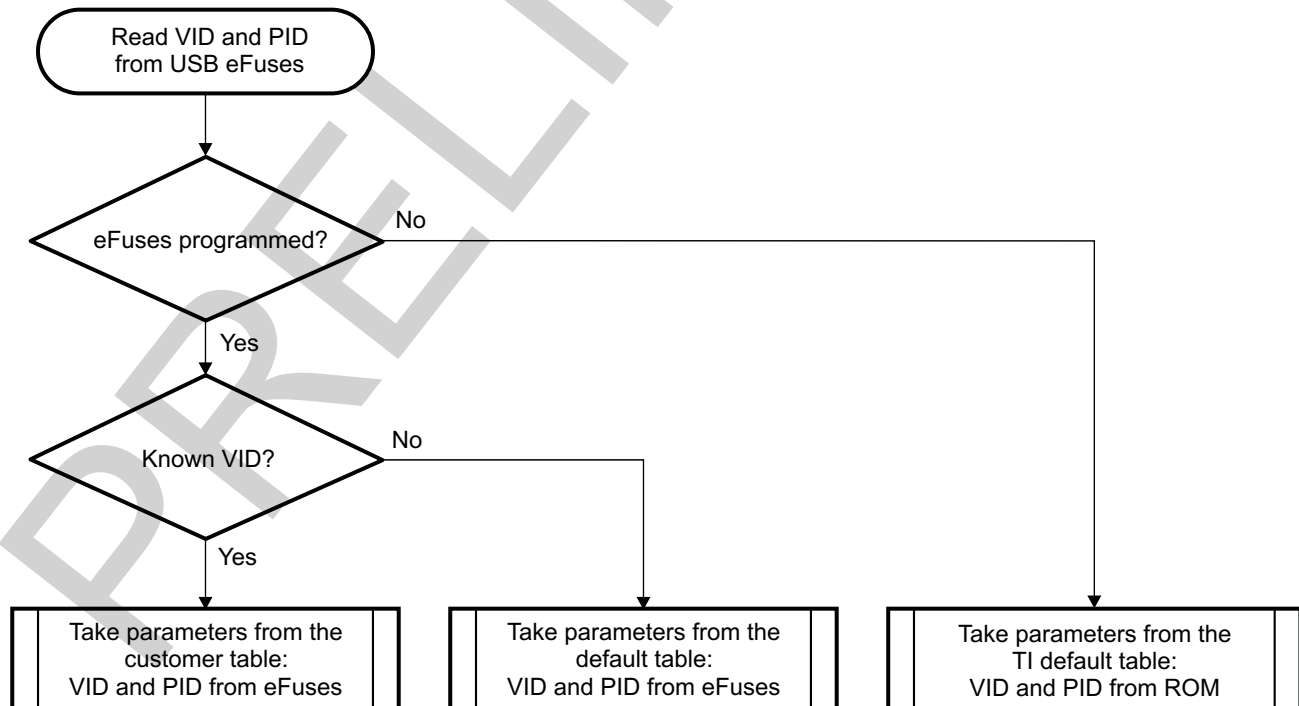

Table 28-34. Customized Descriptor Parameters

| Parameter | Size (Bytes) | Default Values (From eFuses) | TI Default Values (From ROM) |
|-----------------|--------------|------------------------------|------------------------------|
| Device ID code | 2 | 0x0000 | 0x0000 |
| Device class | 1 | 0xFF | 0xFF |
| Device subclass | 1 | 0xFF | 0xFF |
| Device protocol | 1 | 0xFF | 0xFF |
| Manufacturer | String | N/A | Texas Instruments |
| Product | String | OMAP4470 | OMAP4470 |
| Serial number | String | See ⁽¹⁾ . | See ⁽¹⁾ . |

⁽¹⁾ The standard device descriptor indicates that the device has no serial number.

Figure 28-17 shows an additional customer parameter selection method. It is based on the VID burned in the USB eFuses.

Figure 28-17. Customer USB Descriptor Selection

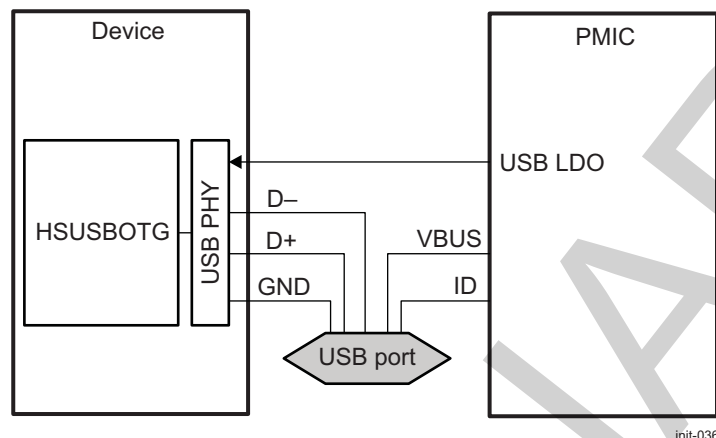

init-011

28.4.5.3.7 System Interconnection – Integrated Transceiver

When SYSBOOT selects the embedded PHY, the USB power/data path can be described as shown in Figure 28-18.

Figure 28-18. USB System Using Internal Transceiver

NOTE: USB(2) booting mode allows an alternate power-management IC to be used. In that case, the internal transceiver must be powered and configured upon startup and does not require any action from the ROM code for its configuration.

28.4.5.3.8 System Interconnection – External Transceiver

The USBOTGHS module uses the ultralow-pin-count interface (ULPI) to interconnect with an external USB transceiver. In this case, the ROM code does not interact with the transceiver. Thus, users must ensure that the transceiver power supply and clock are present and the transceiver is out of reset.

28.4.5.3.9 USB Driver Functionality

- Transactions supported:
 - Control transactions: Used for standard device requests
 - Bulk transactions: Used for data transfer in the image downloading stage. The ASIC ID is sent to the BULK IN endpoint and the image is transferred from the host over the BULK OUT endpoint.

The OMAP USB device first attaches to the host as an FS device. In the reset mechanism, the USB core requests HS operation. If the HS negotiation in the reset phase is successful, further transactions are at HS; otherwise, they are at FS. After reset, the USB driver checks for the speed of the device, whether it is FS or HS. Depending on the speed configured by the host, the standard USB device requests are answered with the corresponding descriptors.

- Standard device request restrictions:

Some standard device requests are not supported by the driver because the USB driver is dedicated for use by the ROM code for peripheral booting. Table 28-35 lists the standard device requests supported by the driver.

Table 28-35. Standard Device Requests Supported

| Request | Description | Support |
|-------------------|--|--|
| CLEAR_FEATURE | Sets/clears a specific feature | Supported only for ENDPOINT_HALT feature |
| GET_CONFIGURATION | Returns the current device configuration value | Yes |
| GET_DESCRIPTOR | Returns the specified descriptor | Yes |
| GET_INTERFACE | Returns the selected alternate setting for the specified interface | Yes |
| GET_STATUS | Returns the status for the specified recipient | Yes |

Table 28-35. Standard Device Requests Supported (continued)

| Request | Description | Support |
|-------------------|--|---|
| SET_ADDRESS | Sets the device address | Yes |
| SET_CONFIGURATION | Sets the device configuration | Yes |
| SET_DESCRIPTOR | Updates existing descriptors or adds new descriptors | Runtime updating of descriptors is not supported. |
| SET_FEATURE | Sets or enables a specific feature | Supported only for ENDPOINT_HALT feature |
| SET_INTERFACE | Selects an alternate setting in an interface | Runtime setting of alternate features is not supported. |
| SYNCH_FRAME | Sets and reports an endpoint synchronization frame | No, because isochronous transfers are not used |

28.4.6 Fast External Booting

28.4.6.1 Overview

The fast external boot is a special memory booting mode, possible only on GP devices. It consists of a blind jump to a code in an external XIP memory device connected to GPMC CS0. Fast external booting is set up by means of the SYSBOOT configuration pins and lets customers create their own booting code.

The jump is performed with minimum on-chip ROM code execution.

28.4.6.2 Fast External Booting Procedure

[Figure 28-19](#) shows the fast external boot procedure. The code is at the beginning and is written in Assembly Language. The code does not use any RAM and is designed for fast execution.

Figure 28-19. Fast External Boot Procedure

28.4.7 Memory Booting

28.4.7.1 Overview

The memory booting process starts an external code in memory devices. Only memory type of booting devices can be used by ROM code as permanent booting devices (that is, devices examined after both cold (POR) and warm resets). Temporary booting devices are examined only after cold resets. The supported permanent booting devices are:

- NOR flash devices
- NAND flash devices
- OneNAND/Flex-OneNAND devices
- eMMC/eSD embedded flash memories
- SD/MMC flash cards

Two main groups of permanent booting devices are distinguished by code shadowing. Code shadowing means copying code from a nondirectly addressable device (non-XIP) to RAM, where the code can be executed. Directly addressable devices are XIP devices.

[Figure 28-20](#) shows the general memory booting procedure common to all types of devices. First, CH is copied to internal RAM. It is copied even for XIP devices, because the OMAP device can temporarily lose a connection with XIP memory during CH execution. The second step is to shadow the image, if the device is not XIP. The last step is image execution and any return from image results in a dead loop.

If CH copying or shadowing fails, memory booting returns to the main booting procedure, which selects the next device for booting.

During the first read sector (512 bytes) call, sectors are copied to a temporary RAM buffer. Once the image is found and the destination address is known, the content of the temporary buffer is moved to the target RAM location so it is required to reread the first image sector. On a GP device, the GP header is discarded; therefore, only executable code is in RAM, with the first executable instruction at the destination address.

eMMC/eSD embedded memories, MMC/SD cards, NAND, and OneNAND/Flex-OneNAND devices can hold up to four copies of the booting image. Therefore, the ROM code searches for one valid image out of the four, if present, by walking over the first blocks of mass storage space. Other XIP devices (NOR) use only one copy of the booting image.

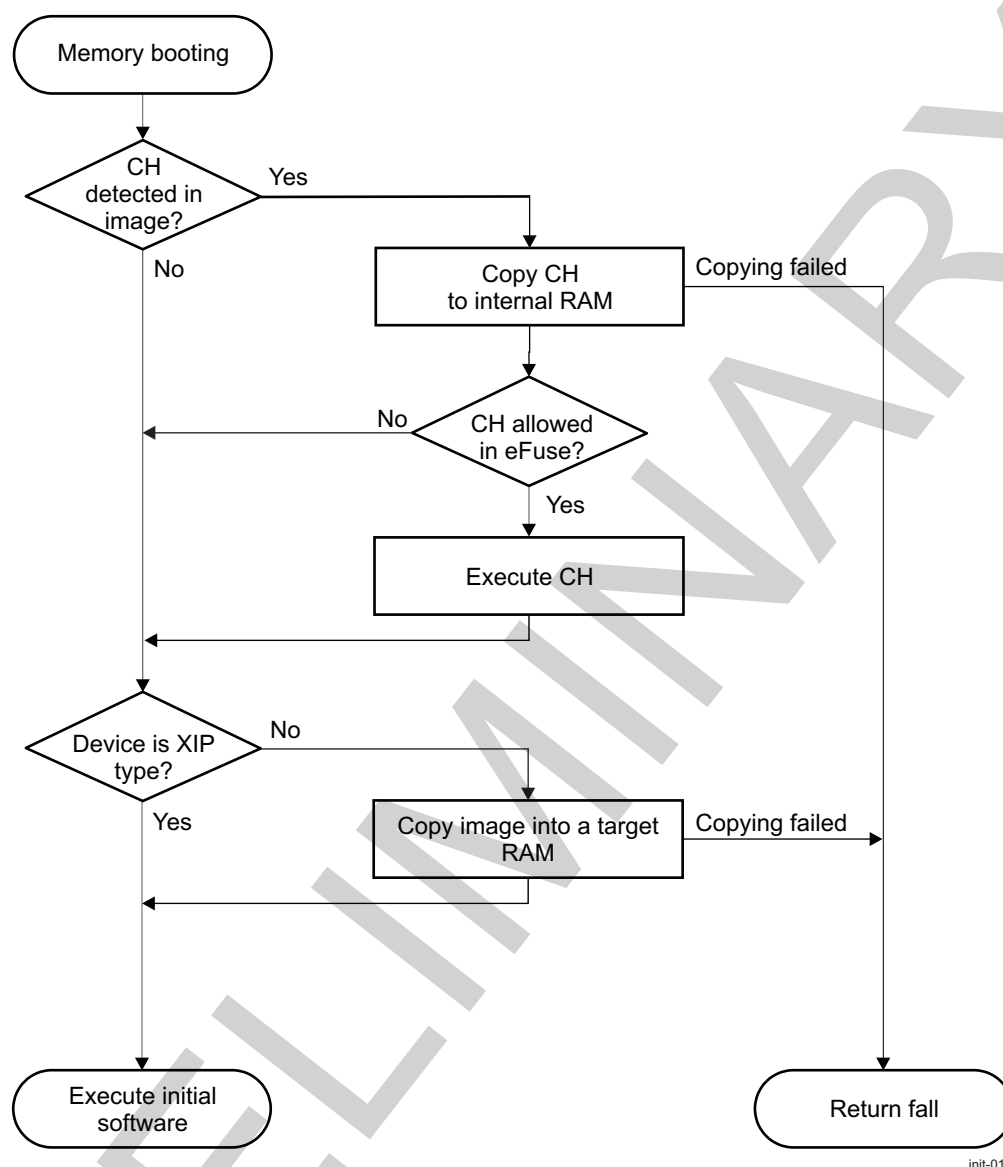

Figure 28-20. Memory Booting Procedure**28.4.7.2 Non-XIP Memory**

Figure 28-21 shows the procedure used when memory booting runs with non-XIP devices. The shaded procedures are specific to each device. NAND and OneNAND/Flex-OneNAND devices use up to four copies of the image in the first four physical blocks. Therefore, the ROM code searches for the image in the first four physical blocks of these devices. Other devices use only one copy of the image and the block loop runs only once.

During image shadowing on a GP device, the CH is expected to be in a separate sector before the initial software.

Figure 28-21. Image Shadowing on GP Device

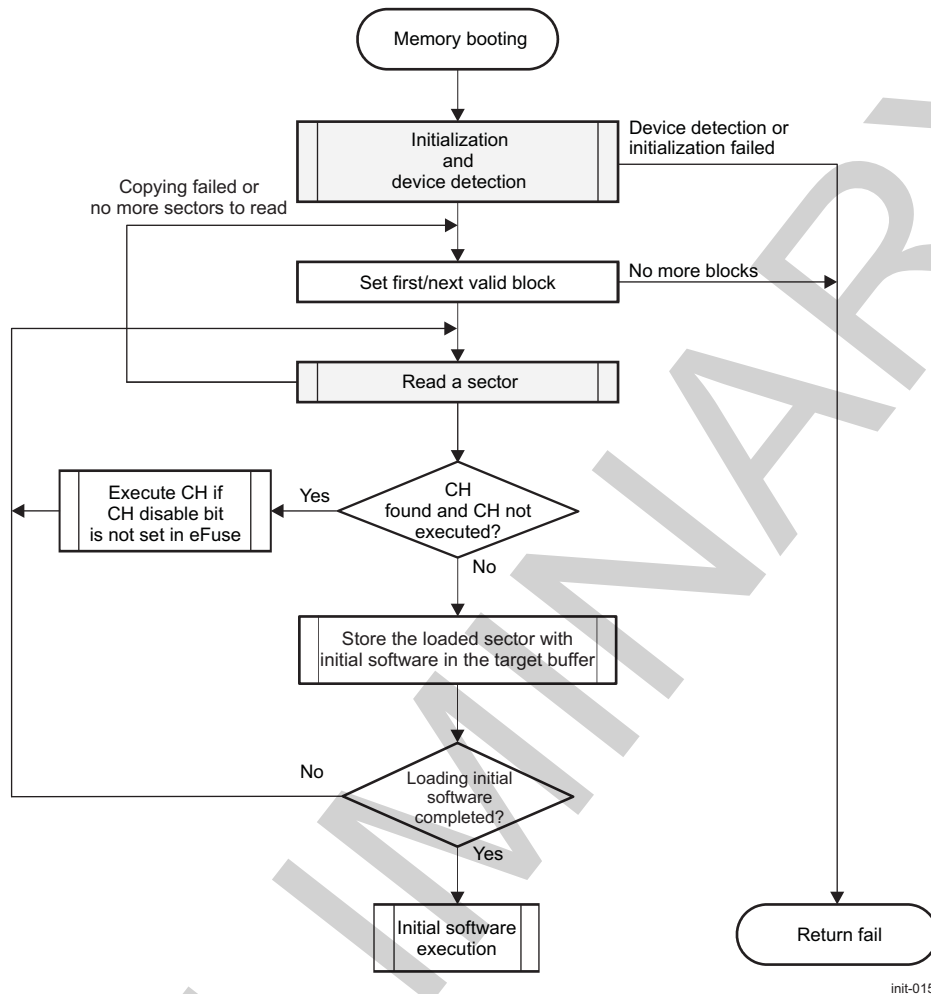

Table 28-36 summarizes the number of blocks and sectors searched during memory booting from devices requiring image shadowing. A sector is assumed to be 512 bytes long. NANDs and OneNAND/Flex-OneNAND are organized with blocks, which are erasable units. MMC/SD/eMMC/eSD + FAT12/16/32 booting consists of reading a file.

Table 28-36. Blocks and Sectors Searched on Non-XIP Memories

| Memory | Maximum Number of Checked Blocks | Number of Sectors Searched |
|-------------------------------|----------------------------------|---|
| NAND | First 4 | Number of sectors in a block ⁽¹⁾ |
| OneNAND/Flex-OneNAND | First 4 | 8 |
| eMMC/eSD raw | First 4 | 1 |
| MMC/SD raw | First 4 | 1 |
| MMC/SD/eMMC/eSD + FAT12/16/32 | 1 File | |

⁽¹⁾ Depends on NAND geometry

For more information about the GPMC module, see [Section 16.4, GPMC Overview](#).

The following sections describe the supported device types.

28.4.7.3 XIP Memory

The ROM code can boot directly from XIP devices, such as NOR flash memories, that have the following characteristics:

- The GPMC is the communication interface.
- Memories up to 1 Gb (128MB) can be connected.
- x16 data bus width only
- Asynchronous protocol and address/data multiplexed mode
- The GPMC clock is 50 MHz.
- The device is connected to CS0 mapped to address 0x0800 0000.
- The wait pin signal gpmc_wait0 is monitored according to the sys_boot configuration pins.

Depending on the SYSBOOT option, the GPMC can be configured to use the wait signal connected to the gpmc_wait0 pin. Wait pin polarity is set to stall accessing memory when gpmc_wait0 is low. Wait-signal monitoring is used with memories that require a long time for initialization after reset, or that must pause while reading data.

For an XIP memory booting, no user intervention is required; the following debugging steps are described. Only the CH, which is not mandatory, lets users change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device for booting.

Bootting from an XIP device consists of the following steps:

1. Configure the GPMC for XIP device access.
2. Verify that the CH is present at address 0x0800 0000. If it is, copy the entire sector (512 bytes) to internal RAM and execute the CH.
3. Set the image location:
 - 0x0800 0000 if the CH is not found
 - 0x0800 0200 if the CH is found
4. Verify that a bootable image is at the image location.
5. Execute the image if it is found.
6. If the image is not found, return from XIP booting to the main booting loop.

28.4.7.3.1 GPMC Initialization

[Table 28-37](#) lists the timing settings of the GPMC when set for XIP and other address-data accessible devices, such as OneNAND/Flex-OneNAND. [Table 28-37](#) is included for debug information.

Table 28-37. XIP Timing Parameters

| Parameter | Value [Clock Cycles] (1) | Register Initialization (where i = 0–7) | Reset Value |
|--------------------|--------------------------------|--|-------------|
| Write cycle period | 17 | The GPMC_CONFIG5_i[12:8] WRCYCLETIME bit field is set to 0x11. | 0x11 |
| Read cycle period | 17 | The GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field is set to 0x11. | 0x11 |
| CS low time | 1 | The GPMC_CONFIG2_i[3:0] CSONTIME bit field is set to 0x1. | 0x1 |
| CS high time | 16 | The GPMC_CONFIG2_i[12:8] CSRDOFFTIME bit field is set to 0x10. | 0x10 |
| ADV low time | 1 | The GPMC_CONFIG3_i[3:0] ADVONTIME bit field is set to 0x1. | 0x1 |
| ADV high time | 2 | The GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field is set to 0x2. | 0x2 |
| OE low time | 3 | The GPMC_CONFIG4_i[3:0] OEONTIME bit field is set to 0x3. | 0x6 |
| OE high time | 16 | The GPMC_CONFIG4_i[12:8] OEOFFTIME bit field is set to 0x10. | 0x10 |
| WE low time | 3 | The GPMC_CONFIG4_i[19:16] WEONTIME bit field is set to 0x3. | 0x05 |

(1) The one clock cycle is 20 ns, which corresponds to 50-MHz frequency.

Table 28-37. XIP Timing Parameters (continued)

| Parameter | Value [Clock Cycles] (1) | Register Initialization (where i = 0–7) | Reset Value |
|-----------------|--------------------------------|---|-------------|
| WE high time | 15 | The GPMC_CONFIG4_i[28:24] WEOFFTIME bit field is set to 0xF. | 0x10 |
| Data latch time | 15 | The GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field is set to 0xF. | 0x0F |

There is no specific identification routine executed before booting from an XIP device.

28.4.7.4 NAND

NAND flash memory is not an XIP device; it requires shadowing before the code can be executed. ROM code support for the NAND flash devices has the following characteristics:

- The GPMC is the communication interface.
- Device from 512 Mbit (64MB)
- x8 and x16 bus width
- Support for large page size (2048 bytes + 64 spare bytes) or very large page size 4096 bytes + 128/218 spare bytes)
- Chip enable (CE) don't care devices only
- Single-level cell (SLC) and multilevel cell (MLC) devices
- Device identification based on ONFI or ROM table
- ECC correction: 8 bits/sector for most devices (16 bits/sector for devices with large spare area)
- GPMC timings are adjusted for NAND access.
- The GPMC clock is 50 MHz.
- The device is connected to CS0.
- The wait pin signal gpmc_wait0 is connected to the NAND BUSY output.
- Four physical blocks are searched for an image. Block size depends on the device.

For NAND memory booting, no user intervention is needed; the information in the following subsections is included for debugging. Only the CH, which is not mandatory, lets the user change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device for booting.

28.4.7.4.1 Initialization and NAND Detection

The initialization routine for NAND consists of three parts: GPMC initialization, device detection with parameter determination, and bad block detection.

- GPMC initialization

The GPMC interface is configured so that it can access NAND. Because NAND memories do not need the address bus, it is released. The data bus width is initially set to 8 bits. If necessary, it is changed to 16 bits after the device parameters are determined. [Table 28-38](#) shows the GPMC configuration used during NAND boot. [Table 28-38](#) is included for debug information.

Table 28-38. NAND Timing Parameters

| Parameter | Value (Clock Cycles) | Register Initialization (where i = 0–7) | Reset Value |
|------------------------|----------------------|---|-------------|
| Write cycle time | 20 | GPMC_CONFIG5_i[12:8] WRCYCLETIME = 0x14 | 0x11 |
| Read cycle time | 20 | GPMC_CONFIG5_i[4:0] RDCYCLETIME = 0x14 | 0x11 |
| CS low time | 0 | GPMC_CONFIG2_i[3:0] CSONTIME = 0x0 | 0x1 |
| CS low to OE low time | 5 | GPMC_CONFIG4_i[3:0] OEONTIME = 0x5 | 0x6 |
| CS low to OE high time | 16 | GPMC_CONFIG4_i[12:8] OEOFFTIME = 0x10 | 0x10 |

Table 28-38. NAND Timing Parameters (continued)

| Parameter | Value (Clock Cycles) | Register Initialization (where i = 0–7) | Reset Value |
|---------------------------|----------------------|--|-------------|
| CS low to WE low time | 1 | GPMC_CONFIG4_i[19:16] WEONTIME = 0x1 | 0x5 |
| CS low to WE high time | 15 | GPMC_CONFIG4_i[28:24] WEOFFTIME = 0xF | 0x10 |
| CS low to data latch time | 14 | GPMC_CONFIG5_i[20:16] RDACCESSTIME = 0xE | 0xF |

- Device detection and parameters

The ROM code first performs an initial wait for device auto initialization (with 250-ms time-out) with polling of the ready information. Then, it must identify the NAND type connected to the GPMC interface. The GPMC is initialized using 8 bits, asynchronous mode. The NAND device is reset (command FFh) and its status is polled until ready for operation (with 100-ms time-out). The ONFI Read ID (command 90h/address 20h) is sent to the NAND device. If it replies with the ONFI signature (4 bytes) then a Read parameters page (command ECh) is sent. The information provided in [Table 28-39](#) is then extracted: page size, spare area size, number of pages per block, and the addressing mode. The remaining data bytes from the parameter page stream are ignored.

Table 28-39. ONFI Parameters Page Description

| Offset | Description | Size (Bytes) |
|--------|--------------------------------|--------------|
| 6 | Features supported | 2 |
| 80 | Number of data bytes per page | 4 |
| 84 | Number of spare bytes per page | 2 |
| 92 | Number of pages per block | 4 |
| 101 | Number of address cycles | 1 |

If the ONFI Read ID command fails (it will be the case with any device not supporting ONFI), then the device is reset again with polling for device to be ready (with 100-ms time-out). Then, the standard Read ID (command 90h/address 00h) is sent. If the Device ID (second byte of the ID byte stream) is recognized as being a supported device, then the device parameters are extracted from an internal ROM code table. [Table 28-40](#) lists the supported devices.

Table 28-40. Supported NAND Devices

| Capacity | Device ID | Bus Width | Page Size in Bytes |
|----------|-----------|-----------|--------------------|
| 512 Mb | F0h | 8 | 2048 |
| 512 Mb | C0h | 16 | 2048 |
| 512 Mb | A0h | 8 | 2048 |
| 512 Mb | B0h | 16 | 2048 |
| 512 Mb | F2h | 8 | 2048 |
| 512 Mb | C2h | 16 | 2048 |
| 512 Mb | A2h | 8 | 2048 |
| 512 Mb | B2h | 16 | 2048 |
| 1 Gb | F1h | 8 | 2048 |
| 1 Gb | C1h | 16 | 2048 |
| 1 Gb | A1h | 8 | 2048 |
| 1 Gb | B1h | 16 | 2048 |
| 2 Gb | DAh | 8 | 2048 (4096) |
| 2 Gb | CAh | 16 | 2048 (4096) |
| 2 Gb | AAh | 8 | 2048 (4096) |
| 2 Gb | BAh | 16 | 2048 (4096) |
| 2 Gb | 83h | 8 | 2048 (4096) |
| 2 Gb | 93h | 16 | 2048 (4096) |

Table 28-40. Supported NAND Devices (continued)

| Capacity | Device ID | Bus Width | Page Size in Bytes |
|----------|-----------|-----------|--------------------|
| 4 Gb | DCh | 8 | 2048 (4096) |
| 4 Gb | CCh | 16 | 2048 (4096) |
| 4 Gb | ACh | 8 | 2048 (4096) |
| 4 Gb | BCh | 16 | 2048 (4096) |
| 4 Gb | 84h | 8 | 2048 (4096) |
| 4 Gb | 94h | 16 | 2048 (4096) |
| 8 Gb | D3h | 8 | 2048 (4096) |
| 8 Gb | C3h | 16 | 2048 (4096) |
| 8 Gb | A3h | 8 | 2048 (4096) |
| 8 Gb | B3h | 16 | 2048 (4096) |
| 8 Gb | 85h | 8 | 2048 (4096) |
| 8 Gb | 95h | 16 | 2048 (4096) |
| 16 Gb | D5h | 8 | 2048 (4096) |
| 16 Gb | C5h | 16 | 2048 (4096) |
| 16 Gb | A5h | 8 | 2048 (4096) |
| 16 Gb | B5h | 16 | 2048 (4096) |
| 16 Gb | 86h | 8 | 2048 (4096) |
| 16 Gb | 96h | 16 | 2048 (4096) |
| 32 Gb | D7h | 8 | 2048 (4096) |
| 32 Gb | C7h | 16 | 2048 (4096) |
| 32 Gb | A7h | 8 | 2048 (4096) |
| 32 Gb | B7h | 16 | 2048 (4096) |
| 32 Gb | 87h | 8 | 2048 (4096) |
| 32 Gb | 97h | 16 | 2048 (4096) |
| 64 Gb | DEh | 8 | 2048 (4096) |
| 64 Gb | CEh | 16 | 2048 (4096) |
| 64 Gb | AEh | 8 | 2048 (4096) |
| 64 Gb | BEh | 16 | 2048 (4096) |

After retrieving parameters from the table, the page size and block size are updated based on the fourth byte of the NAND ID data. Because of inconsistency among manufacturers, only devices recognized to be at least 2Gb have these parameters updated. Therefore, the ROM code supports 4-KB page devices, but only if their size, according to the table, is at least 2Gb. Devices that are smaller than 2Gb have the block size parameter set to 128KB (when the page size is 2KB).

[Table 28-41](#) shows the fourth ID data byte encoding used in the ROM code.

Table 28-41. Fourth NAND ID Data Byte

| Item | Description | I/O Number | | | | | | | |
|--------------------------|-------------|------------|---|---|---|---|---|---|---|
| | | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Page size | 512 bytes | | | | | | | 0 | 0 |
| | 2048 bytes | | | | | | | 0 | 1 |
| | 4096 bytes | | | | | | | 1 | 0 |
| | 8192 bytes | | | | | | | 1 | 1 |
| Cell type ⁽¹⁾ | 2 levels | | | | | 0 | 0 | | |
| | 4 levels | | | | | 0 | 1 | | |
| | 8 levels | | | | | 1 | 0 | | |
| | 16 levels | | | | | 1 | 1 | | |

⁽¹⁾ Read by ROM code only when the manufacturer code (first ID byte) is 98h

Table 28-41. Fourth NAND ID Data Byte (continued)

| Item | Description | I/O Number | | | | | | | |
|-------------------|-------------|------------|---|---|---|---|---|---|---|
| | | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Block size | 64KB | | | 0 | 0 | | | | |
| | 128KB | | | 0 | 1 | | | | |
| | 256KB | | | 1 | 0 | | | | |
| | 512KB | | | 1 | 1 | | | | |

Figure 28-22 shows the detection procedure. Once the NAND device is successfully detected, the ROM code changes the GPMC to 16-bit bus width, if necessary.

Figure 28-22. NAND Device Detection

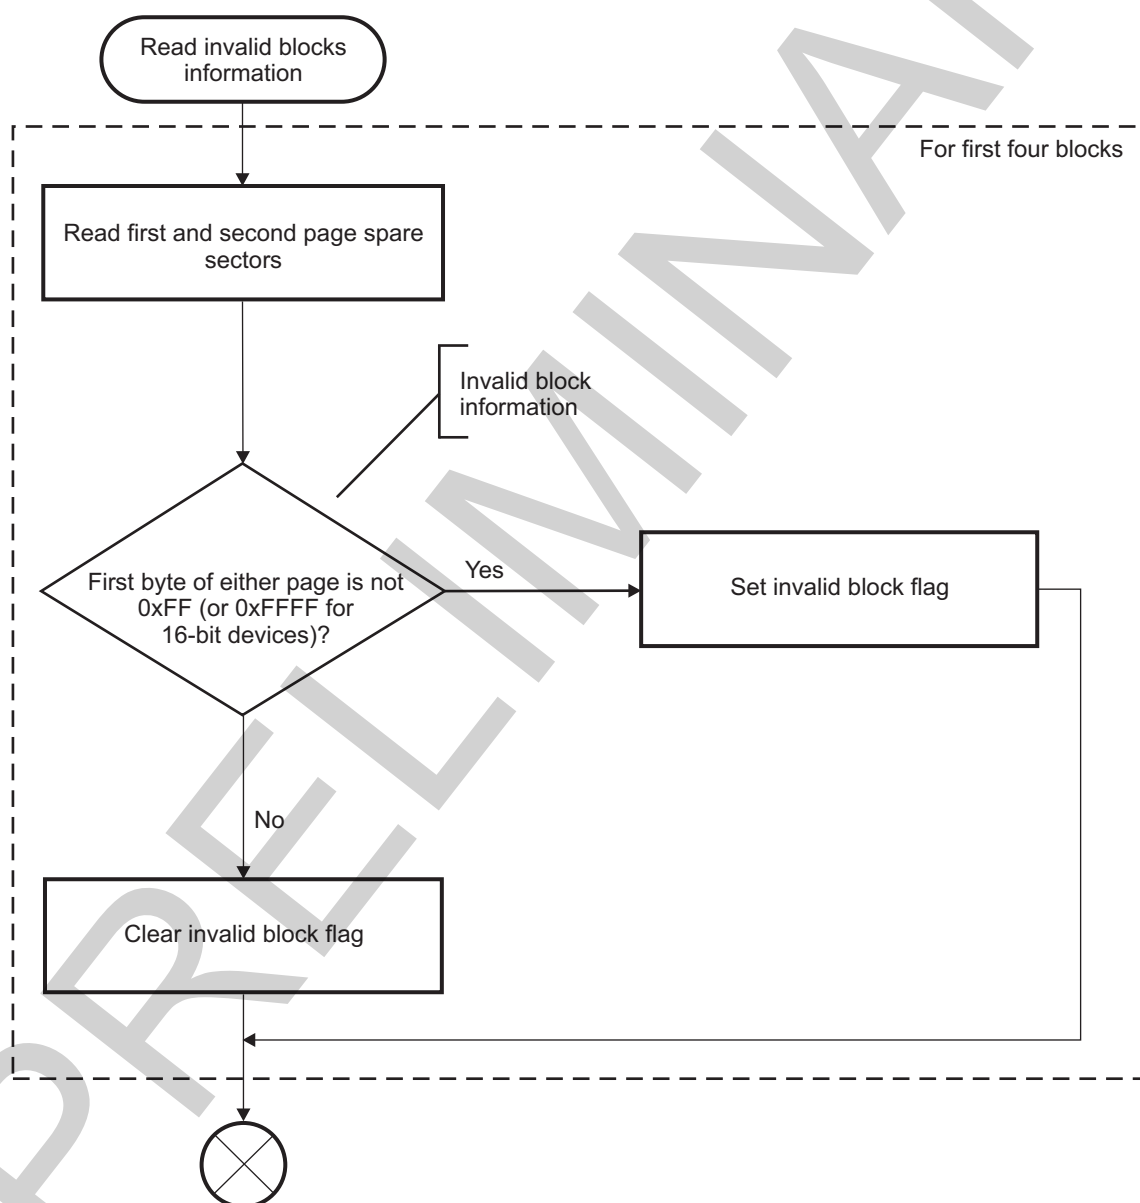

init-023

- Bad block verification

Invalid blocks contain invalid bits whose reliability cannot be ensured by the manufacturer. These bits are identified in the factory or during the programming and reported in the initial invalid block information in the spare area on the first and second page of each block. Because the ROM code looks for an image in the first four blocks, it detects the validity status of these blocks. Blocks detected as invalid are not accessed later. Block validity status is coded in the spare areas of the first two pages of a block (first byte equal to FFh in the first and second pages for an 8-bit device/first word equal to FFFFh in the first and second pages for a 16-bit device).

Figure 28-23 shows the invalid block detection routine. The routine consists in reading spare areas and checking the validity data pattern.

Figure 28-23. Bad NAND Invalid Block Detection

init-033

28.4.7.4.2 Read Sector Procedure

During the booting procedure, the ROM code reads 512-byte sectors from the NAND device. The reading fails in two cases:

- The accessed sector is in a block marked as invalid.
- The accessed sector contains an error that cannot be corrected with ECC.

The ROM code uses normal read (command 00h 30h) for reading NAND page data.

Page data can contain errors caused by memory alteration. The ROM code uses an ECC correction algorithm to detect and possibly correct those errors. The default ECC correction applied is BCH 8b/sector using the GPMC and ELM hardware.

For device ID codes D3h, C3h, D5h, C5h, D7h, C7h, DEh, and CEh when the manufacturer code (first ID byte) is 98h, the cell type information is checked in the fourth byte of ID data. If it is equal to 10b, the ECC correction applied is BCH 16b/sector.

The BCH data is automatically calculated by the GPMC on reading each 512-byte sector. The computed ECC is compared against the ECC stored in the spare area for the corresponding page. Depending on the page size, the amount of ECC data bytes stored in the corresponding spare area is different. Figure 28-24 and Figure 28-25 show the mapping of ECC data inside the spare area for 2KB-page and 4KB- page devices, respectively. If both ECC data are equal, the read sector function returns the read 512-byte sector without error. Otherwise, the ROM code tries to correct error(s) in the corresponding sector (this procedure is assisted by the ELM hardware) and returns the data if successful. If errors are uncorrectable, the function returns with FAIL.

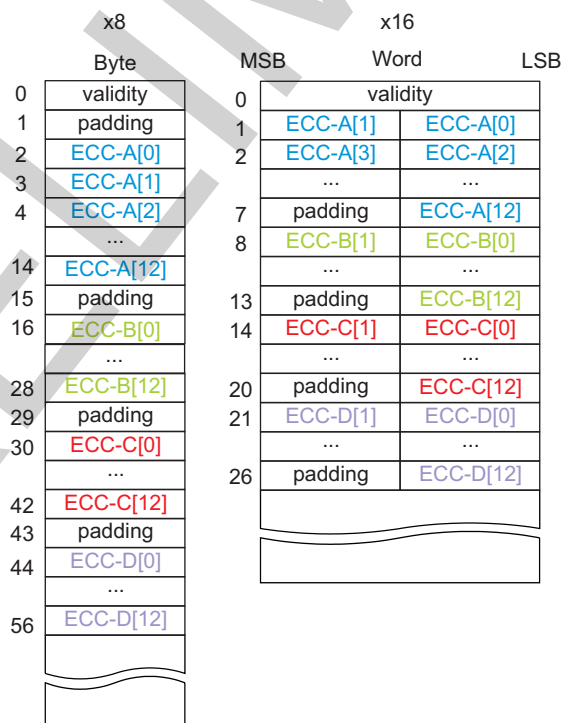

The first two bytes in the spare area are always reserved for block state information:

- First word equal to FFFFh for a 16-bit device to check block validity
- First byte equal to FFh for an 8-bit device to check block validity and the second byte is a padding

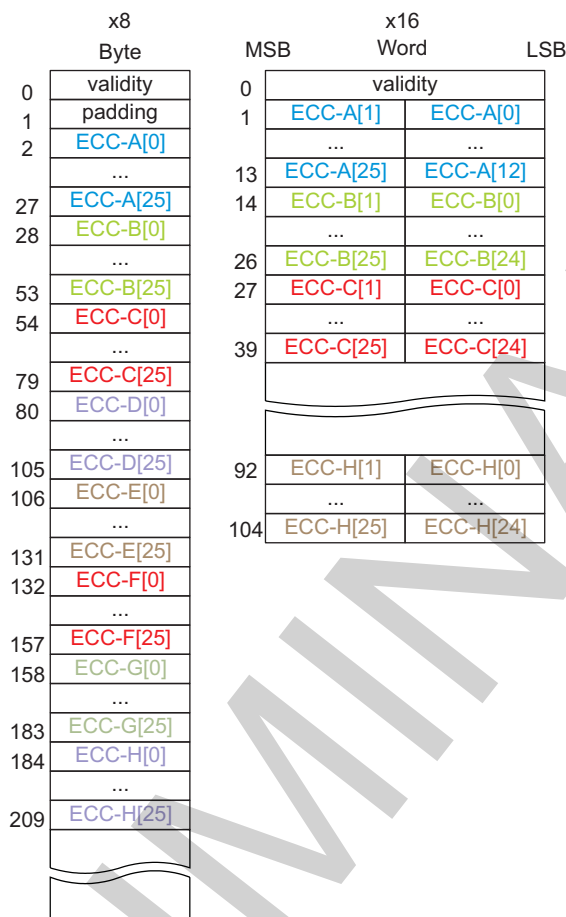

Concerning the length of ECC section in bytes, extra bytes can be added to make the access x16 compatible:

- For 8b BCH, there are 14 bytes ECC for each 512-byte sector (that is, 13 bytes ECC + 1 byte padding)
- For 16b BCH, there are 26 bytes ECC for each 512-byte sector (that is, no padding is needed)

Figure 28-24. ECC Data Mapping for 2-KB Page and 8b BCH Encoding

init-040

Figure 28-25. ECC Data Mapping for 4-KB Page and 16b BCH Encoding

init-041

28.4.7.5 OneNAND/Flex-OneNAND

The ROM code support for OneNAND/Flex-OneNAND devices has the following characteristics:

- Devices from 512 Mbits
- The GPMC is the communication interface.
- x16 data bus width only
- Asynchronous protocol and address/data multiplexed mode
- GPMC reset default timings are used.
- The GPMC clock is 50 MHz.
- The device is connected to GPMC CS0 mapped to address 0x0800 0000.
- The wait pin signal gpmc_wait0 is not monitored.
- Four physical blocks are searched for an image. The block size is 128KB (typically).
- Data correction is fully handled by the OneNAND/FlexOneNAND device

The OneNAND/Flex-OneNAND device is a NAND matrix coupled with RAM buffers and a NOR-type interface. ECC correction handling is done automatically by the internal state-machine. The page to be accessed is first loaded in the RAM buffer using memory-mapped registers. Then, the page is read directly from the buffer using a NOR-type interface.

For OneNAND/Flex-OneNAND memory booting, no user intervention is required. The information in the following sections is included for debugging. Only the CH, which is not mandatory, lets users change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device for booting.

28.4.7.5.1 Initialization and OneNAND/Flex-OneNAND Detection

The initialization routine for OneNAND/Flex-OneNAND consists of two parts: GPMC initialization and device detection with parameter determination.

- GPMC initialization

The ROM code first initializes the GPMC interface in XIP mode (that is, asynchronous 16-bit multiplexed mode). Wait signal monitoring is disabled.

- Device detection and parameters

The ROM code identifies a OneNAND/Flex-OneNAND device by reading the device identification data. There are two ways to read identification data: using serial commands and reading from fixed memory-mapped registers. The ROM code reads identification data using both methods and compares the results. When the comparison passes, the ROM code assumes that the OneNAND/Flex-OneNAND device is connected. If the device is successfully recognized, the ROM code reads the device configuration (number and size of data buffers) and configures it for asynchronous mode (default).

28.4.7.5.2 OneNAND/Flex-OneNAND Read Sector Procedure

When booting requests a sector from the OneNAND/Flex-OneNAND device, the ROM code performs the load operation, which transfers the content of the requested sector to the data buffer RAM. The ROM code waits until the operation completes, polling the OneNAND/Flex-OneNAND interrupt register. The status register is then checked and the ROM code returns FAIL if the operation completes with an error. Otherwise, the data buffer RAM is copied to the destination buffer. [Figure 28-26](#) shows this procedure.

Figure 28-26. OneNAND/Flex-OneNAND Read Sector

28.4.7.5.3 OneNAND/Flex-OneNAND Support Limitations

As described in [Section 28.4.7.5.1, Initialization and OneNAND/Flex-OneNAND Detection](#), the ROM code checks only the coherency of the device ID obtained by two different methods. There is no table of supported Flex-OneNANDs in ROM code. This removes any dependency of the ROM code on device IDs from different manufacturers. However, the driver works with the following assumption:

- Page size is assumed to be 2048 bytes, divided into four 512-byte sectors. In case of OneNAND/Flex-OneNAND, with 4096-byte pages, divided into eight sectors, users must program only the first sectors (sectors 0-3) of each page. Sectors 4-7 of each page are not considered by the driver.

28.4.7.6 eMMC/eSD Embedded Memories and MMC/SD Cards

The OMAP device allows booting from eMMC/eSD embedded memories or MMC/SD cards connected to SD/MMC1 or SD/MMC2. The booting interface is selected by configuration of the sys_boot pins.

The HS MMC/SD/SDIO host controllers (MMCHS) handle the physical layer, while the ROM code handles the simplified logical protocol layer (read-only protocol). A limited range of commands is implemented in the ROM code.

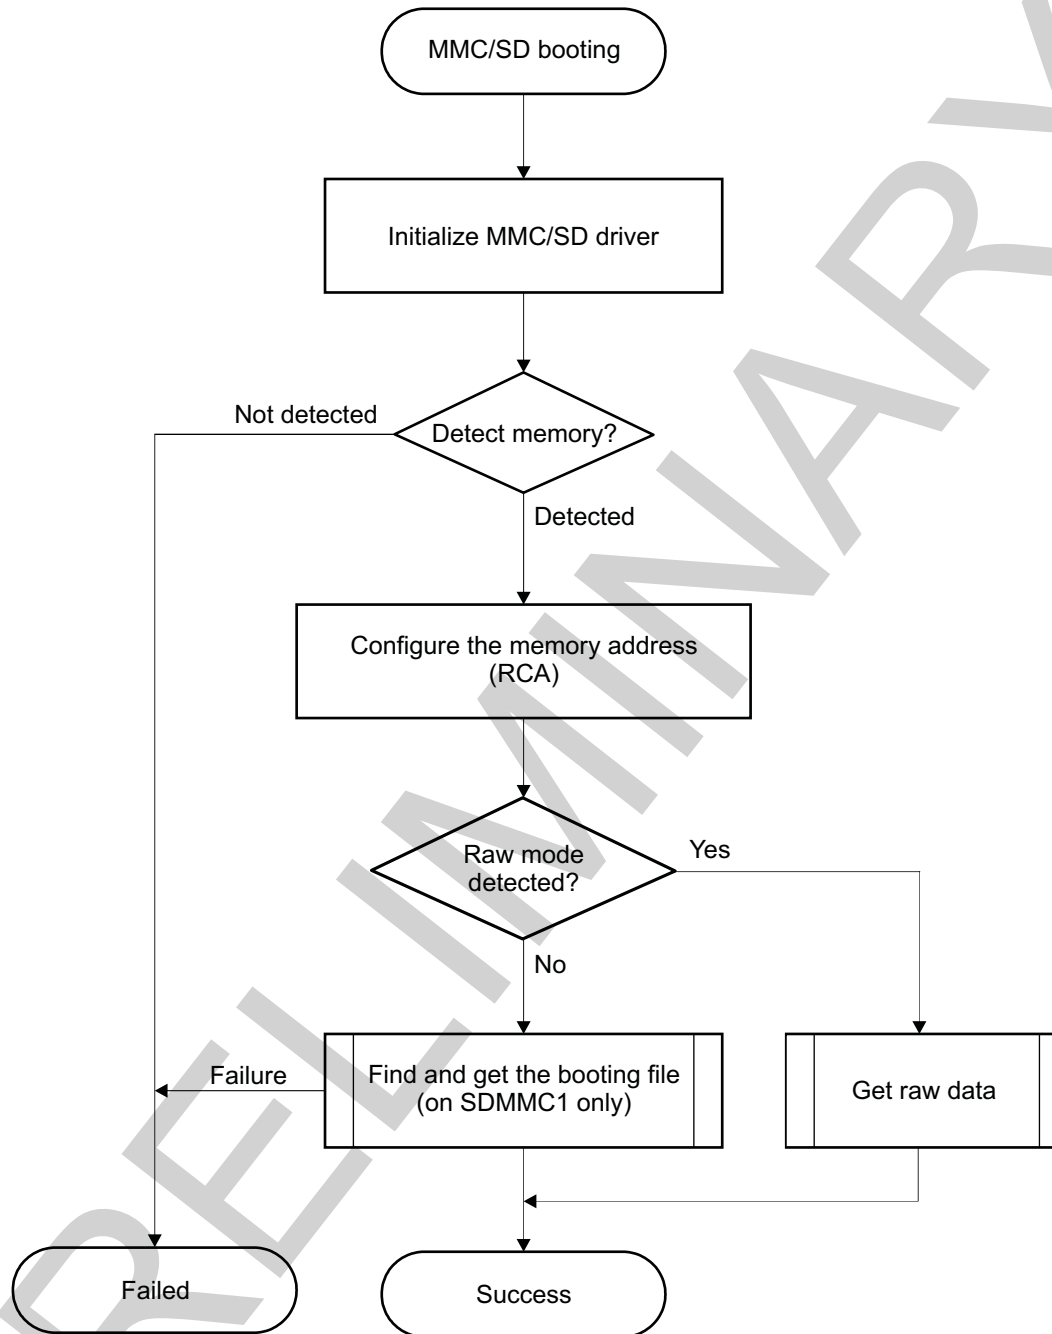

The MMC interface 1 supports 1.8-V/3-V digital I/Os. The selection on I/O voltage level is done using the PBIAS circuitry. The PBIAS reference level is sensed by the ROM code and PBIAS cell voltage setup appropriately before any communication with the device. The MMC interface 2 supports only 1.8-V digital I/Os.

The OMAP device supports two booting modes:

- Raw: The booting image data is read directly from sectors in the user area.
- File system (FAT12/16/32 supported with or without master boot record): The image data is read from a booting file.

When using the SDMMC1 interface, raw and file system modes are supported. When using the SDMMC2 interface, only raw mode is supported. The purpose of this approach is to avoid the boot time penalty of searching for a file system hierarchy when it is not always necessary.

[Figure 28-27](#) shows the complete procedure.

Figure 28-27. eMMC/eSD and MMC/SD Booting

init-016

28.4.7.6.1 eMMC/eSD Memories

The ROM code supports eMMC/eSD cards, with the following conditions:

- eMMC devices compliant with *Embedded MultiMediaCard (eMMC) eMMC/Card Product Standard, High Capacity, including Reliable Write Boot, and Sleep Modes, Dual Data Rate, Multiple Partitions Supports and Security Enhancement v4.41* from the MMCA Technical Committee. The exception is the hardware reset feature. If the user software requires MMC hardware reset, it can be accomplished with a GPIO.
- eSD devices compliant with *SD Specification Part 1 eSD (Embedded SD) Specification Addendum v2.1* from the SD Card Association

- The eMMC/eSD memory device is powered externally by a power-management IC or other power supply.
- Initial 1-bit MMC mode, optional 4-bit or 8-bit modes
- Clock frequency:
 - Identification mode: 400 kHz
 - Data transfer mode: Up to 10 MHz, optionally up to 19.2 MHz
- Only one memory connected to the bus
- TI mode and boot partition mode (eMMC)

28.4.7.6.1.1 System Conditions and Limitations

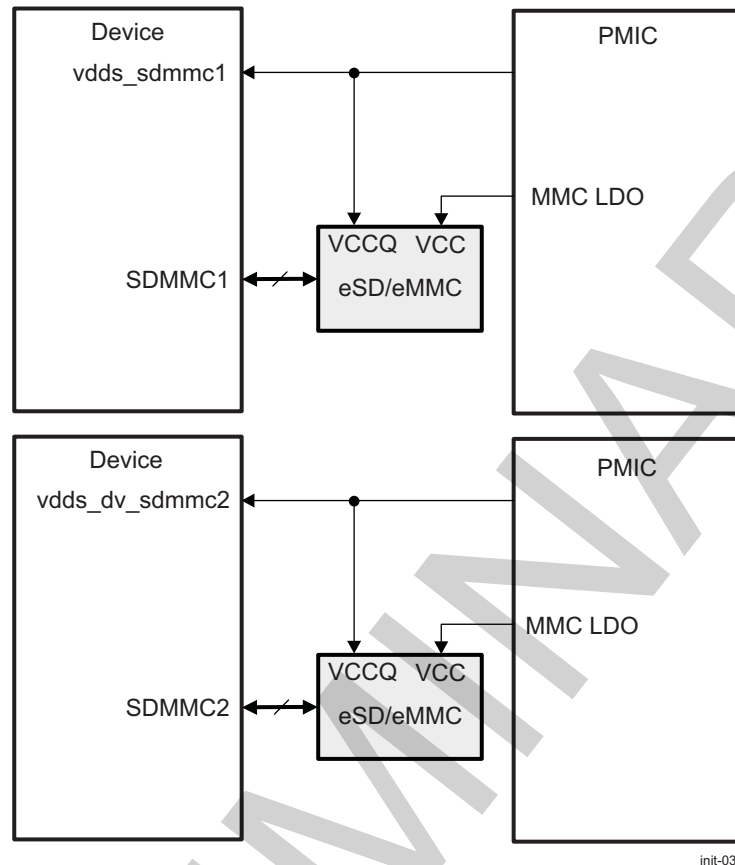

- When using TI mode, the booting image is assumed to be in the User Data Area (no use of boot and/or RPMB partitions). Customers must set up the eMMC device appropriately so that the booting image is in a reliable area within the User Data Area (possibly with the Enhanced User Data Area property).
- The ROM code does not provide a bus direction control signaling in case of using MMC interface 2 with level shifters.
- The ROM code expects that the eMMC device is powered externally and supplies are set and stable upon entering the booting procedure. The ROM code does not perform any software action to the companion device with respect to powering the eMMC/eSD device.

28.4.7.6.1.2 eMMC/eSD Memory Connection

An eMMC/eSD device typically requires two supplies: one for the core memory array (selectable 1.8/2.9 V at TWL6032 BOOT2 pin level) (see TWL6032 documentation), and one for the device interface I/Os and controller (typical VCCQ = 1.8 V). Both memory device supply pins can possibly be merged into one, thus requiring only one power supply.

The SD/MMC2 interface shares the same balls as the GPMC interface. Therefore, the ROM code performs the necessary pin mux configuration to route the MMC signal through the GPMC balls.

[Figure 28-28](#) shows an example of the system connection between the PMIC, memory device, and OMAP device.

Figure 28-28. eMMC/eSD Connection

The ROM code supports the muxing of MMC interface 2 through two paths:

- GPMC pins in configuration mode 1 (Mux1)
- SDMMC5/FREF_CLKx pins in Mux5

The ROM code performs the necessary I/O pin muxing configuration to route the MMC2 signals through the appropriate pins depending on the selected SYSBOOT configuration.

28.4.7.6.1.3 eMMC Boot Partitions

The ROM code supports the *Alternative Boot operation mode* specific to eMMC devices as described in the eMMC standard. It does not support the hardware *Boot operation mode* (CMD line held low for 74 clk cycles) described in the same document.

The Alternative Boot operation mode is selected through MMC2_BOOT option, as described in the , *Booting Device Order Selection*.

To trigger the Alternative Boot operation mode, the ROM code sends a specific CMD0 + Argument 0xFFFFFFFF. Then, the ROM Code waits for up to 50 ms for the eMMC device to send back a boot acknowledge signal. If the timeout elapses, then the ROM code skips the Alternative Boot mode. Booting from eMMC partitions is done in 1-bit mode at 19.2 MHz. This configuration is static and cannot be changed.

For correct handling of eMMC boot partitions, it is necessary to prepare the eMMC device at flashing time with the following settings applied in the device EXT_CSD register:

- The BOOT_ACK and BOOT_PARTITION_ENABLE fields must be updated accordingly (EXT_CSD[179], bit 6 and bits [5:3]) respectively to activate the boot acknowledge signal and select the boot partition from which to boot from.
- RST_N must be enabled for correct handling of the warm reset cases (EXT_CSD[162] bits [1:0] = 0x1).

- Optionally the BOOT_CONFIG_PROT (EXT_CSD[178]) may be updated for altering access permissions to the boot partition(s).

NOTE:

- It is highly recommended to refer to the eMMC standard for details on EXT_CSD handling.
 - The EXT_CSD is updated by using a SWITCH command as detailed in the eMMC standard.
 - The mentioned EXT_CSD fields are retained after a power cycle so only one flashing phase is required
-

If the Alternate Boot operation mode is successful and the booting image is properly retrieved, then the eMMC device state remains in the Boot state even after the execution has been passed to the initial software. It is the responsibility of the initial software to bring the device out of the Boot state.

Once the system has booted and upon triggering a warm reset at OMAP level (it can be triggered by the warm-reset push button, a timer, watchdog, etc.), it is important that the eMMC device is properly brought to its Pre-Idle state so that the next Alternate Boot operation succeeds. This is ensured by the RST_N pin to be connected to OMAP nRESWARM. Otherwise, the boot procedure will fail after a warm reset.

In Raw (Boot) mode, the size of the booting image is determined after the first sector read access. In case of GP device, the boot image size is contained within the GP header. This ensures that the ROM code is only retrieving the necessary size of data and not the full contents of the boot partition.

28.4.7.6.2 MMC/SD Cards

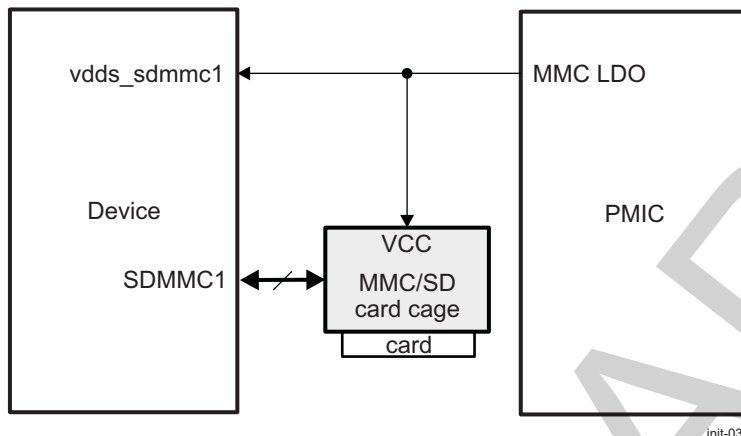

The ROM code supports booting from MMC/SD cards under the following conditions:

- MMC/SD cards compliant with *The MultiMediaCard System Specification* from the MMCA Technical Committee and the *SD Memory Card Specifications, File System Specification* from the SD Association. These include low- and high-capacity cards.
- MMC/SD cards connected to SDMMC interface 1
- 3-V VCC power supply, support for 3-V or 1.8-V I/O voltages
- Initial 1-bit MMC mode, optional 4-bit or 8-bit modes
- Clock frequency:
 - Identification mode: 400 kHz
 - Data transfer mode: Up to 10 MHz (optionally up to 19.2 MHz)
- Only one card connected to the bus

28.4.7.6.2.1 MMC/SD Card Connection

An SD/MMC card can be connected to the MMC1 interface, typically through a card cage. The ROM code sends the appropriate I²C sequence to the power-management IC (PMIC) to set the MMC LDO to 3 V and switch it on.

Figure 28-29 shows the typical connection between the PMIC, the card, and the OMAP device .

Figure 28-29. MMC/SD Card Connection

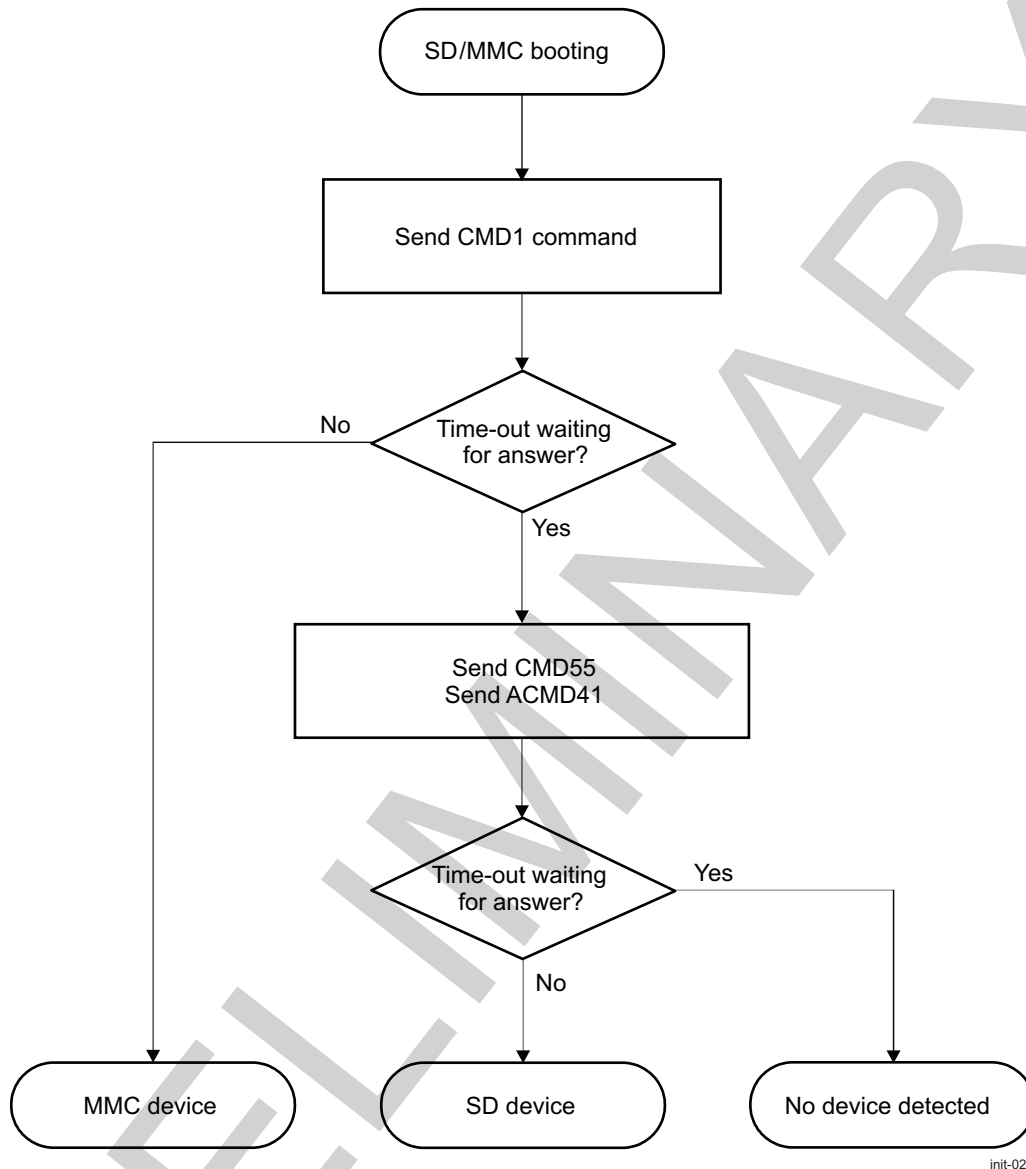

NOTE: The ROM code does not handle the card detection feature on the card cage.

28.4.7.6.3 Initialization and Detection

The ROM code initializes the memory device or card connected on the interface using the standard high-voltage range (3.0 V). If neither a card nor memory device is detected, the ROM code moves to the next booting device. The standard identification process and relative card address (RCA) assignment are used. However, the ROM code assumes that only one memory or card is connected on the bus. This is done using the CMD line common to the SD and MMC memory devices. The MMC and SD standards describe this phase as the initialization phase. They differ in the first commands involved, CMD1 and ACMD41. The ROM code uses this command difference to discriminate between MMC and SD cards; that is, CMD1 is supported only by the MMC standard and ACMD41 is only supported by the SD standard. The ROM code first sends a CMD1 to the device and gets an answer only if an MMC device is connected. If no response is received, ACMD41 (a combination of CMD55 and ACMD41) is sent, and an response is expected from an SD device. If no response is received, no devices are connected and the ROM code exits MMC/SD booting with FAIL.

Figure 28-30 shows the MMC/SD detection procedure.

Figure 28-30. MMC/SD Detection Procedure

init-026

28.4.7.6.4 Read Sector Procedure

- Raw mode

In raw mode, an image can be at one of the four consecutive locations in the main area: offset 0x0 (0KB)/0x20000 (128KB)/0x40000 (256KB)/0x60000 (384KB). For this reason, the size of a booting image must not exceed 128KB. However, a device with an image greater than 128KB can be flash starting at one of the aforementioned locations. Therefore, the ROM code does not check the image size. The only drawback is that the image crosses the subsequent image boundary. Raw mode is detected by reading sectors 0, 256, 512, and 768. The content of these sectors is verified for the presence of a TOC structure. For a GP device, a CH (if used) must be in the first sector followed by a GP header. The CH can be void (containing only a CHSETTINGS item for which the Valid field is 0), as described in [Section 28.4.8.2, Configuration Header](#). Image data is read directly from continuous sectors of a card. If raw mode is not detected, file system mode is assumed.

- File system handling

File system support is available only for the SDMMC1 interface. The sector read procedure uses the standard MMC/SD read data procedure. The sector address is generated based on the booting

memory file map collected during initialization. Thus, the ROM code can freely address sectors in the booting file space.

28.4.7.6.5 File System Handling

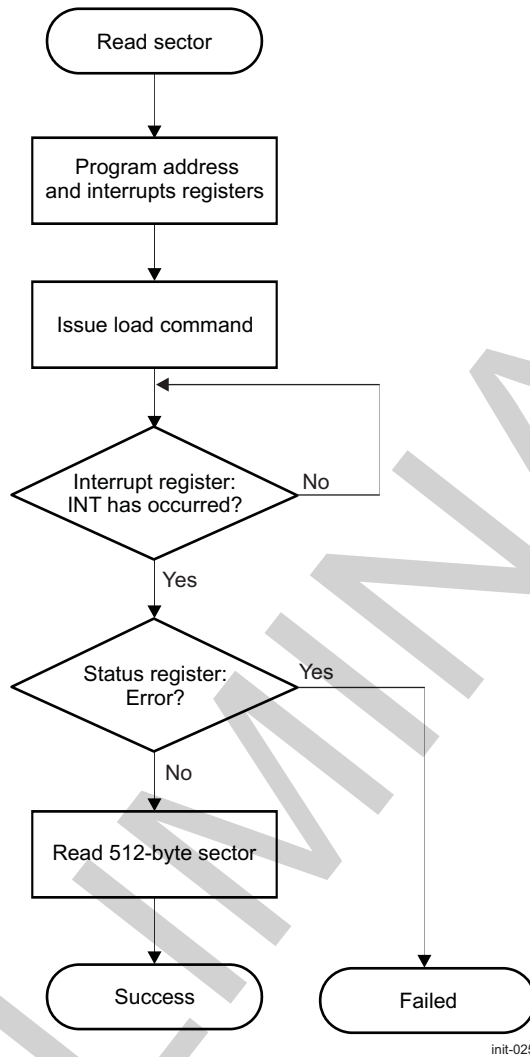

The MMC/SD cards can hold a file system that the ROM code reads. The image used by the booting procedure is taken from a booting file named MLO. This file must be in the root directory on an **active** primary partition of type FAT12/16 or FAT32.

An MMC/SD card can be configured as floppy-like or hard-drive-like:

- When acting like a floppy, the content of the card is a single FAT12/16/32 file system without an MBR holding a partition table.
- When acting like a hard drive, an MBR is present in the first sector of the card. This MBR holds a table of partitions, one of which must be FAT12/16/32, primary, and active.

According to the *MultiMediaCard FAT16 File System Specification* from the MMCA Technical Committee, the card must always hold an MBR, except for MMC cards using a floppy-like file system. However, depending on the operating system used, the MMC/SD card is formatted with or without partition(s) (using an MBR). The ROM code supports both types: floppy-like or hard-drive-like. The ROM code retrieves a map of the booting file from the FAT table. The booting file map is a collection of all FAT table entries related to the booting file (a FAT entry points to a cluster holding part of the file). The booting procedure uses this map to access any 512-byte sector in the booting file without involving the ROM code FAT module. [Figure 28-31](#) shows the complete process.

Figure 28-31. SD/MMC Get Booting File

28.4.7.6.5.1 MBR and FAT File System

This paragraph describes functions used by the ROM code to recognize whether an MBR with a FAT is used. It is not intended to fully describe the MBR and the FAT file system detection and reading procedure. The ROM code can detect FAT12/16/32 allocation table types. It cannot boot on devices with NTFS or Linux® FS partitions. Some memory devices that support file systems can be formatted with or without MBR; therefore, the first task of the ROM code is to detect whether the device is holding an MBR in the first sector.

The MBR is the first sector of a memory device. It consists of executable code, four partition entries, and one signature. The aim of such a structure is to divide the hard disk in partitions used primarily to boot different systems (for instance, Microsoft Windows™). This structure is described in [Table 28-42](#), and the partition table entry is described in [Table 28-43](#).

Table 28-42. Master Boot Record Structure

| Offset | Length (Bytes) | Entry Description |
|--------|----------------|-----------------------|
| 0000h | 446 | Optional code |
| 01BEh | 16 | Partition table entry |
| 01CEh | 16 | Partition table entry |
| 01DEh | 16 | Partition table entry |
| 01EEh | 16 | Partition table entry |
| 01FEh | 2 | Signature (0xAA55) |

Table 28-43. Partition Table Entry

| Offset | Length [Bytes] | Entry Description | Value |
|--------|----------------|--|--|
| 0000h | 1 | Partition state | 00h: Inactive 80h: Active |
| 0001h | 1 | Partition start head | Hs |
| 0002h | 2 | Partition start cylinder and sector | Cs[7:0]–Cs[9:8]–Ss[5:0] |
| 0004h | 1 | Partition type | 01h: FAT12 04h, 06h, 0Eh: FAT16 0Bh, 0Ch, 0Fh: FAT32 |
| 0005h | 16 | Partition end head | He |
| 0006h | 2 | Partition end cylinder and sector | Ce[7:0]–Ce[9:8]–Se[5:0] |
| 0008h | 4 | First sector position relative to the beginning of media | LBAs = Cs.H.S + Hs.S + Ss–1 |
| 000Ch | 4 | Number of sectors in partition | LBAe = Ce.H.S + He.S + Se–1 Nb s= LBAe–LBAs + 1 |

SD/MMC booting consists of the following steps:

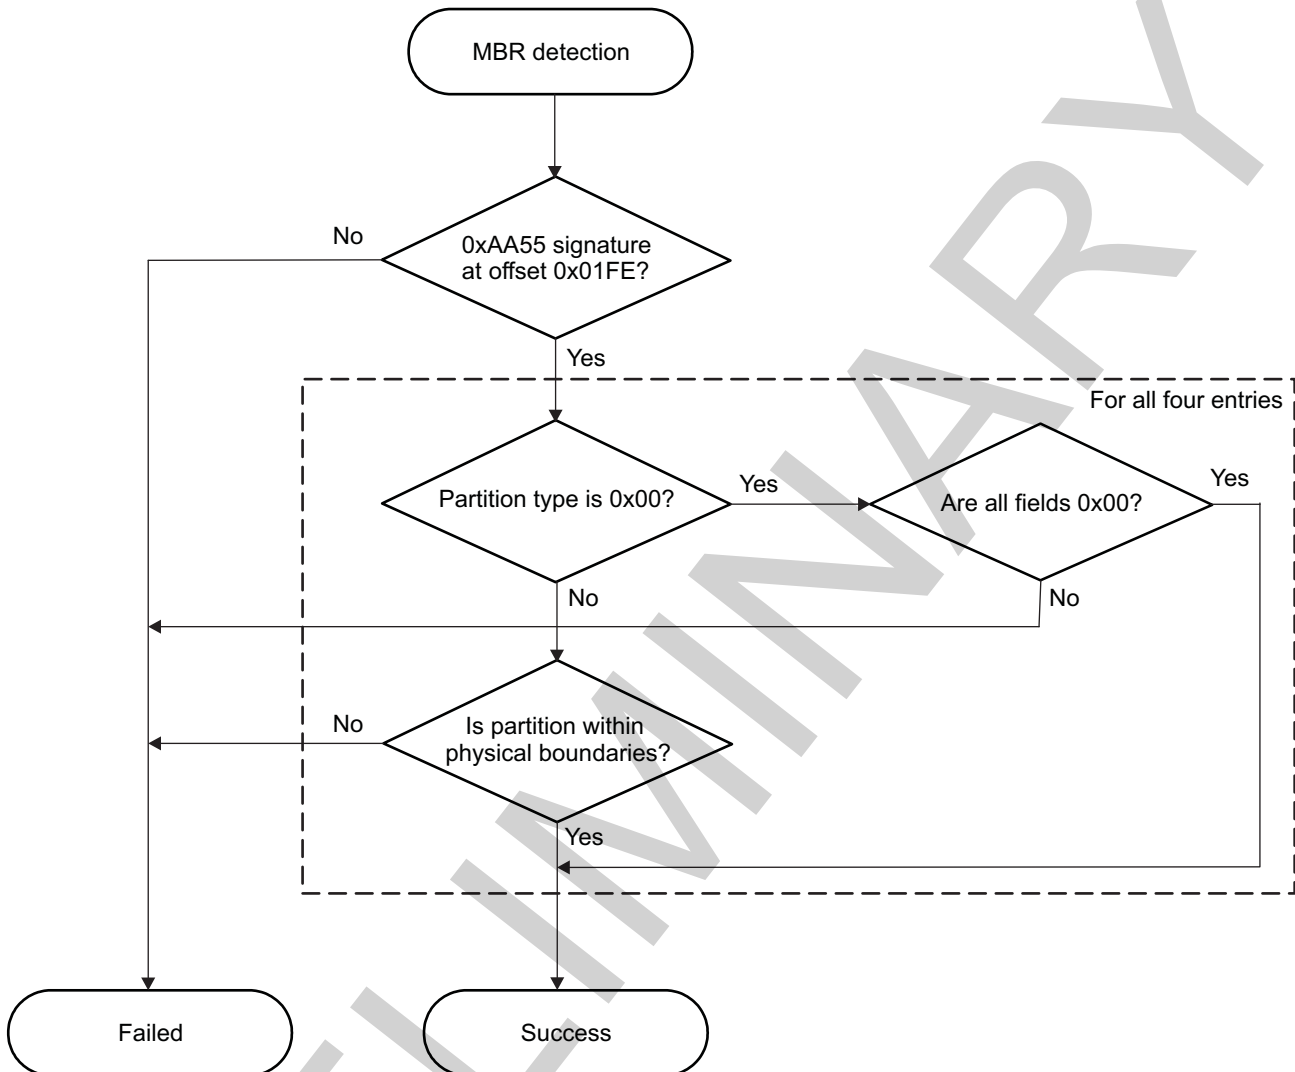

1. MBR detection

The ROM code first checks whether the MBR signature is present, and then it searches an active FAT12/16/32 partition in all four MBR partition entries, based on the Type field. If the MBR entries are not valid, or if no usable partition is found, the ROM code returns to the booting procedure with FAIL. The extended partitions are not checked; the booting file must reside in a primary partition. Each partition entry is checked:

- If its type is set to 00h, all fields in the entry must be 00h.
- The partition is checked to be within physical boundaries (that is, the partition is inside and it fits the total physical sectors).

See [Figure 28-32](#) for more information about MBR detection.

Figure 28-32. MBR Detection Procedure

init-028

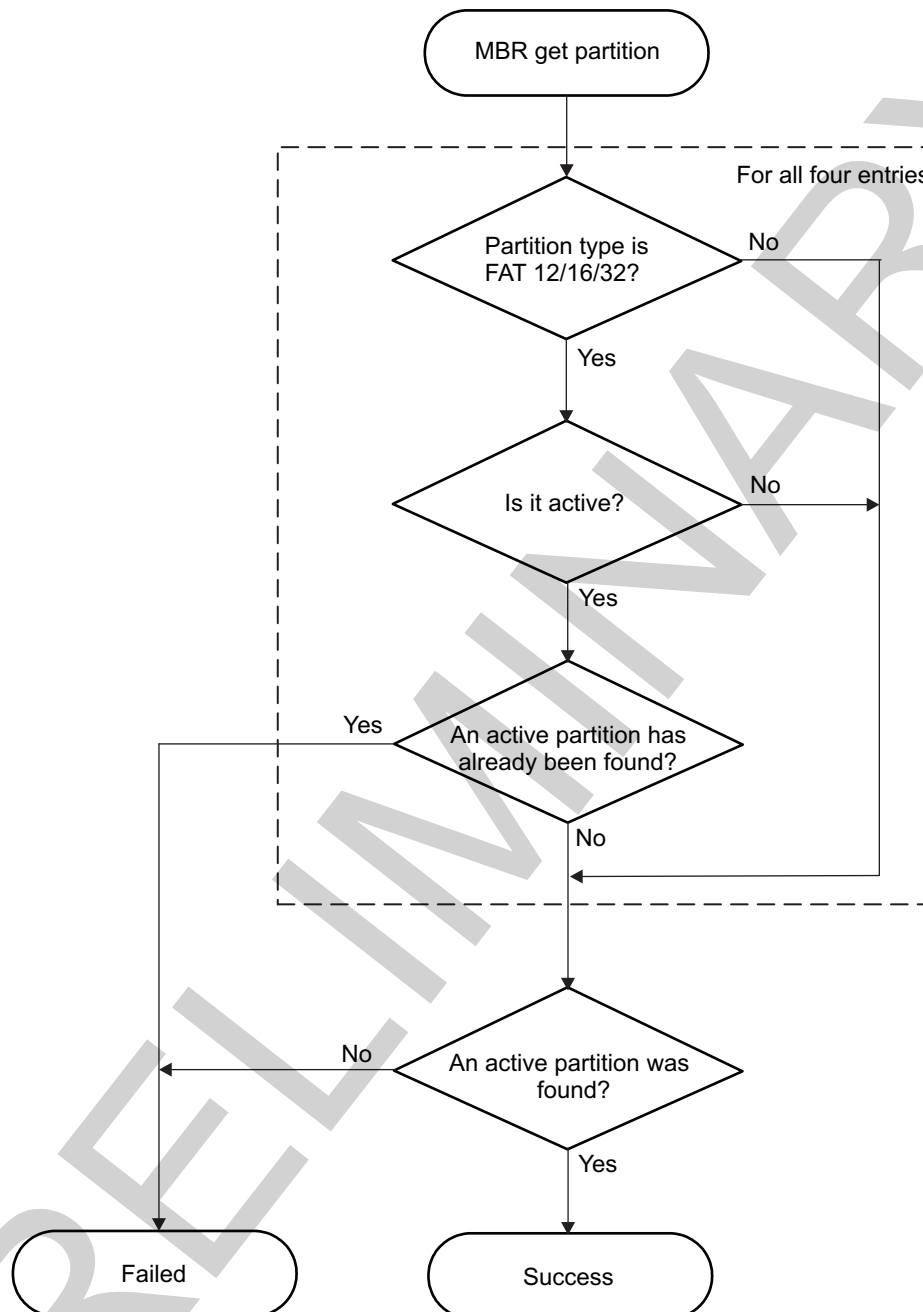

2. Get the MBR partition.

Once identified, the ROM code gets the partition using the procedure described in [Figure 28-32](#). The partition type is checked to be FAT12/16 or FAT32. Its state must be 00h (inactive) or 80h (active.) The ROM code returns with FAIL if no active primary FAT12/16/32 is found, or the test fails if there is more than one active partition. If an active partition is found, its first sector is read and used later. If no MBR is present (in case of a floppy-like system), the first sector of the device is read and used later. The read sector is checked to be a valid FAT12/16 or FAT32 partition. If this fails, the ROM code returns with FAIL if another partition type is used (for instance, Linux FS) or if the partition is not valid.

The FAT file system consists of several parts:

- Boot sector, which holds the BIOS parameter block (BPB). Not all are used by the ROM code.
- FAT, which describes the use of each cluster of the partition
- Data area, which holds the files, directories, and root directory (for FAT12/16, the root directory has a specific fixed location)

To check whether a sector holds a valid FAT12/16/32 partition, many fields of the boot sector (used by all FAT types) that must have specific values are checked. [Figure 28-33](#) shows more about getting the partition.

Figure 28-33. MBR, Get Partition

init-029

3. Find the booting file.

When a partition is found, the root directory entries are searched for a booting file named MLO in the root directory of the FAT12/16/32 file system. The file is not searched in any other location. For a FAT12/16 file system, the root directory has a fixed location, which is cluster 0. For a FAT32 file system, its cluster location is given by BPB_RootClus. The formula to find the sector number (relative to device sector 0, not partition sector 0) of a cluster is given by the following equation:

$$Cluster_{sector} = BPB_HiddSec + BPB_RsvdSecCnt + BPB_NumFATs \cdot BPB_FATSz + Cluster \cdot BPB_SecPerClus$$

init-E001

NOTE: BPB_FatSz is BPB_FatSz16 for FAT12/16, or BPB_FatSz32 for FAT32.

NOTE: The BPB_HiddSec field can contain 0, even though the FAT file system is somewhere other than on sector 0 (floppy-like). The ROM code uses the partition offset taken from the MBR instead of this field, which can be wrong. If no MBR is found (floppy-like), the value 0 is used.

Each entry in the root directory is 32 bytes and holds information about the file (the filename, date of creation, rights, cluster location, etc.). (See [Table 28-44](#).)

Table 28-44. FAT Directory Entry

| Offset | Length [Bytes] | Name | Description |
|--------|----------------|------------------|--|
| 0000h | 11 | DIR_Name | Short Name (8 + 3) |
| 000Bh | 1 | DIR_Attr | File Attributes: 01h – ATTR_READ_ONLY 02h – ATTR_HIDDEN 04h – ATTR_SYSTEM 08h – ATTR_VOLUME_ID 10h – ATTR_DIRECTORY 20h – ATTR_ARCHIVE 0Fh – ATTR_LONG_NAME |
| 000Ch | 1 | DIR_NTRes | Reserved. Set to 00h. |
| 000Dh | 1 | DIR_CrtTimeTenth | Millisecond stamp at file creation |
| 000Eh | 2 | DIR_CrtTime | Time file was created. |
| 0010h | 2 | DIR_CrtDate | Date file was created. |
| 0012h | 2 | DIR_LstAccDate | Last access date |
| 0014h | 2 | DIR_FstClusHi | High word of the first cluster number of this entry |
| 0016h | 2 | DIR_WrtTime | Time of last write |
| 0018h | 2 | DIR_WrtDate | Date of last write |
| 001Ah | 2 | DIR_FstClusLo | Low word of the first cluster number of this entry |
| 001Ch | 4 | DIR_FileSize | File size in bytes |

The ROM code checks each entry in the root directory until either the booting file is found or the entry is empty (first byte is 00h), or when the end of the root directory is reached. Entries with the ATTR_LONG_NAME attribute (LFN) and first byte at E5h (erased file) are ignored. When found, the first cluster offset of the file is read from the DIR_FstClusHi/DIR_FstClusLo fields. There is a slight difference between FAT12/16 and FAT32 when handling the root directory. On FAT12/16, this directory has a fixed location (see [Table 28-44](#)) and length fixed by BPB_RootEntCnt, which is the total of 32-byte entries. Therefore, handling this directory is straightforward. On FAT32, the root directory is like a standard file. The FAT must be used to retrieve each sector of the directory. The way in which the FAT is handled is described in Step 4.

4. Buffer FAT entries in the FAT buffer

When the booting file is found, the ROM code reads the FAT and buffers the singly-linked chain of clusters in a FAT buffer used by booting to access the file directly, sector by sector. For FAT12/16 and for FAT32, multiple copies of the FAT exist (ROM code supports only two copies), after the boot sector.

$$FATn_{sector} = BPB_HiddSec + BPB_RsvdSecCnt + BP_FatSz \cdot n$$

init-E002

The size of the FAT buffer is given by BPB_FATsSz16 or BPB_FATsSz32. The ROM code checks each copy of the FAT if they are identical. If the values are different, the ROM code uses the value from the last FAT copy. With the FAT32 file system, the copy system can be disabled according to a flag in BPB_ExtFlags[7]. If this flag is set, the FAT BPB_ExtFlags[3:0] bit field is used. In this case, no verification is made by the ROM code with other copies of FAT.

The FAT is a simple array of values, each referring to a cluster in the data area. One entry of the array is 12, 16, or 32 bits, depending on the file system in use. The value in an entry defines whether the

cluster is being used or not, and if another cluster must be considered. This creates a singly-linked chain of clusters defining the file. The meaning of an entry is described in [Table 28-45](#).

NOTE: For compatibility, cluster 0 and cluster 1 are not used for files, and these entries must contain:

- FF8h and FFFh (for FAT12)
- FFF8h and FFFFh (for FAT16)
- 0FFFFFFF8h and 0FFFFFFFh (for FAT32)

Table 28-45. FAT Entry Description

| FAT12 | FAT16 | FAT32 | Description |
|-----------|-----------------|---------------------------|--|
| 000h | 0000h | 00000000h | Free cluster |
| 001h | 0001h | 00000001h | Reserved cluster |
| 002h–FEFh | 0002h– FFEFh | 00000002h– 0FFFFFFEFh | Used cluster; value points to next cluster |
| FF0h–FF6h | FFF0h– FFF6h | 0FFFFFFF0h– 0FFFFFFF6h | Reserved values |
| FF7h | FFF7h | 0FFFFFFF7h | Bad cluster |
| FF8h–FFFh | FFF8h– FFFFh | 0FFFFFFF8h– 0FFFFFFFh | Last cluster in file |

NOTE: FAT32 uses only bits [27:0]; the upper 4 bits are usually 0 and must be left untouched.

When accessing the root directory for FAT32, the ROM code starts from the root directory cluster entry and follows the linked chain to retrieve the clusters.

When the booting file has been found, the ROM code buffers each FAT entry corresponding to the file in a sector way. This means each cluster is translated to one or several sectors, depending on how many sectors are in a cluster (BPB_SecPerClus). This buffer is used later by the booting procedure to access the file.

28.4.8 Image Format

28.4.8.1 Overview

An image has two major parts:

- AAn optional CH
- Software to execute

The CH can contain several parameters set by users to speed up booting. It is further described in [Section 28.4.8.2, Configuration Header](#).

The second part contains the software that is loaded into the memory and executed.

[Figure 28-34](#) is an overview of the boot image formats. There are two image types:

1. GP non-XIP memory booting: This image type is used for memories that require shadowing (for example, MMC). An image can contain a CH that includes at least a CHSETTINGS item entry. Next, there must be a small header (referred to as a GP header) that contains information about the size and the destination address.
2. When the memory device is of XIP type (for example, NOR), the GP header is not required, and the image can contain code for direct execution. Optionally, the first sector can contain a CH. The same image format is used for peripheral booting (where the code is transferred to internal RAM).

Figure 28-34. Image Formats

init-018

28.4.8.2 Configuration Header

The ROM code default settings (such as clock frequencies, EMIF, GPMC, or MMCHS interfaces) can be tuned by the user by using the CH.

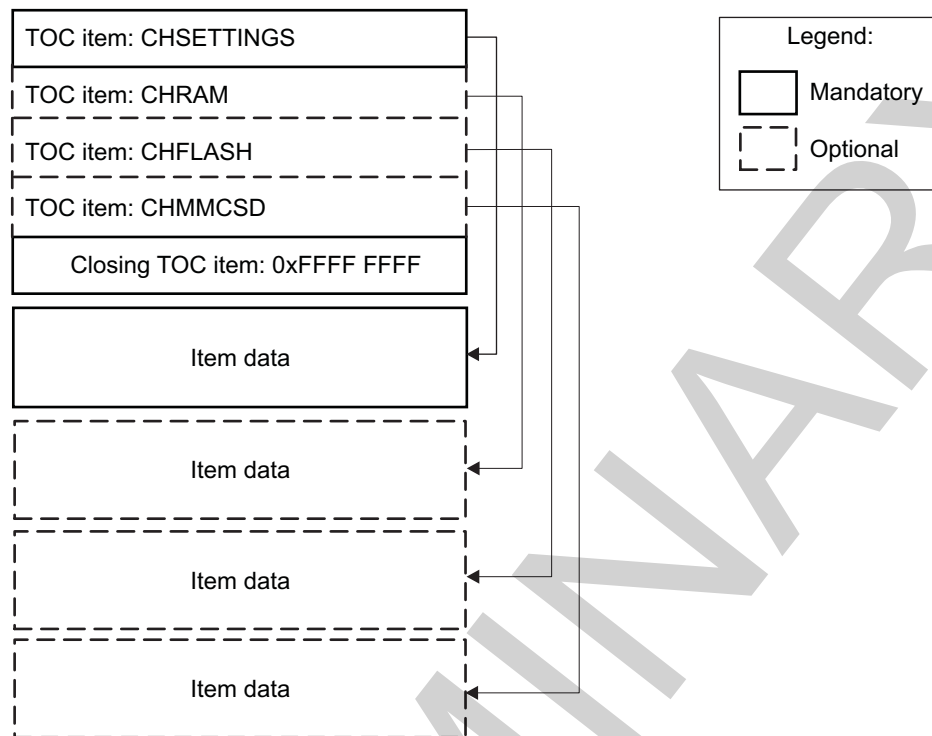

The CH can contain the following parts:

- Settings: Various clock settings (mandatory)
- RAM: EMIF settings
- FLASH: Flash interface (GPMC) settings
- MMC/SD: MMCHS interface settings

The beginning of the CH is a table of contents (TOC), which points to each item. This is described in [Figure 28-35](#). Each TOC item is a simple structure described in [Table 28-46](#). The complete CH (CH TOC and items) should fit in a 512-byte sector.

The ROM code identifies the presence of a CH by reading the first TOC item if it contains a known string (CHSETTINGS, CHRAM, etc.). Next, the TOC is identified and searched until a 0xFFFF FFFF offset is found. The CH is read and parameters are executed sequentially.

For the sake of simplicity, each field represents the content of a register to be modified. Only fields required for the configuration are used; fields for status, for instance, are not modified and therefore are not shown in the tables.

Figure 28-35. CH Format

init-019

Table 28-46. CH TOC Item

| Offset | Field | Size (Bytes) | Description |
|--------|----------|--------------|---|
| 0x0000 | Start | 4 | Offset from the start address of the TOC to the actual address of item contents |
| 0x0004 | Size | 4 | Size of item |
| 0x0008 | Reserved | 4 | Unused |
| 0x000C | Reserved | 4 | Unused |
| 0x0010 | Reserved | 4 | Unused |
| 0x0014 | Filename | 12 | 12-character name of a item, including the zero termination character(\0) |

28.4.8.2.1 CHSETTINGS Item

The CHSETTINGS configuration header contains settings specific to the clock system. The ROM code configures the OMAP clocking to some default settings as described in [Section 28.4.4.2, Clocking Configuration](#). The CH CHSETTINGS section contains a method to override the ROM code default clock settings.

[Table 28-47](#) describes the fields. The clocking procedure and the clocking setting structure are described in [Section 28.4.4.4, Software Booting Configuration](#).

Table 28-47. CHSETTINGS Item

| Offset | Field | Description |
|--------|-------------|---|
| 0000h | Section key | Key used for item verification: C0C0C0C1h |
| 0004h | Valid | Enables/disables the section: 00h: Disable |

Table 28-47. CHSETTINGS Item (continued)

| Offset | Field | Description |
|--------|-------------------|---|
| | | Others: Enable |
| 0005h | Version | Configuration header version 01h Others: Reserved |
| 0006h | Reserved | |
| 0008h | Clocking settings | Described in Table 28-16 starting from the FLAGS field. |

28.4.8.2.2 CHRAM Item

The CHRAM configuration header contains settings specific to the SDRAM memory controller (EMIF). [Table 28-48](#) describes the fields. The ROM code does not configure the EMIF by default, because it cannot assume any external SDRAM type. Therefore, if the ROM code is needed to configure the SDRAM access, the user must provide the appropriate timing details in the CHRAM structure. For more information, see [Section 16.3](#), *EMIF Controller*, and [Section 16.3.6](#), *EMIF Register Manual*.

Table 28-48. CHRAM Item

| Offset | Field | Description |
|--------|----------------------|--|
| 0000h | Section key | Key used for section verification: C0C0C0C2h. |
| 0004h | Valid | Enables/disables the section: 00h: Disable Other: Enable |
| 0005h | Reserved | |
| 0008h | SdramConfig (EMIF1) | SDRAM configuration register (EMIF1.EMIF_SDRAM_CONFIG) |
| 000Ch | SdramRefresh (EMIF1) | SDRAM Refresh control register (EMIF1.EMIF_SDRAM_REF_CTRL) |
| 0010h | SdramTim1 (EMIF1) | SDRAM timing 1 register (EMIF1.EMIF_SDRAM_TIM_1) |
| 0014h | SdramTim2 (EMIF1) | SDRAM timing 2 register (EMIF1.EMIF_SDRAM_TIM_2) |
| 0018h | SdramTim3 (EMIF1) | SDRAM timing 3 register (EMIF1.EMIF_SDRAM_TIM_3) |
| 001Ch | PwrMgtCtrl (EMIF1) | Power-management control register (EMIF1.EMIF_PWR_MGMT_CTRL) |
| 0020h | DdrPhyCtrl1 (EMIF1) | DDR PHY control 1 register (EMIF1.EMIF_DDR_PHY_CTRL_1) |
| 0024h | DdrPhyCtrl2 (EMIF1) | DDR PHY control 2 register (EMIF1.EMIF_DDR_PHY_CTRL_2) |
| 0028h | ModeReg1 (EMIF1) | Mode register MR1 (in the LPDDR2 device) |
| 0029h | ModeReg2 (EMIF1) | Mode register MR2 (in the LPDDR2 device) |
| 002Ah | ModeReg3 (EMIF1) | Mode register MR3 (in the LPDDR2 device) |
| 002Bh | Reserved | |
| 002Ch | SdramConfig (EMIF2) | SDRAM configuration register (EMIF2.EMIF_SDRAM_CONFIG) |
| 0030h | SdramRefresh (EMIF2) | SDRAM refresh control register (EMIF2.EMIF_SDRAM_REF_CTRL) |
| 0034h | SdramTim1 (EMIF2) | SDRAM timing 1 register (EMIF2.EMIF_SDRAM_TIM_1) |
| 0038h | SdramTim2 (EMIF2) | SDRAM timing 2 register (EMIF2.EMIF_SDRAM_TIM_2) |
| 003Ch | SdramTim3 (EMIF2) | SDRAM timing 3 register (EMIF2.EMIF_SDRAM_TIM_3) |
| 0040h | PwrMgtCtrl (EMIF2) | Power-management control register (EMIF2.EMIF_PWR_MGMT_CTRL) |
| 0044h | DdrPhyCtrl1 (EMIF2) | DDR PHY control 1 register (EMIF2.EMIF_DDR_PHY_CTRL_1) |
| 0048h | DdrPhyCtrl2 (EMIF2) | DDR PHY control 2 register (EMIF2.EMIF_DDR_PHY_CTRL_2) |
| 004Ch | ModeReg1 (EMIF2) | Mode register MR1 (in the LPDDR2 device) |
| 004Dh | ModeReg2 (EMIF2) | Mode register MR2 (in the LPDDR2 device) |
| 004Eh | ModeReg3 (EMIF2) | Mode register MR3 (in the LPDDR2 device) |
| 004Fh | Reserved | |
| 0050h | DMM LISA Map 0 | DMM LISA section 0 mapping (see Section 16.2 for more information about the DMM module architecture) |

Table 28-48. CHRAM Item (continued)

| Offset | Field | Description |
|--------|-------|--|
| 0054h | Flags | <p>Setting bits 0 to 3 requests ROM code to configure the appropriate channel/chip select:</p> <p>Bit[0]: Configure EMIF1 CS0</p> <p>Bit[1]: Configure EMIF1 CS1</p> <p>Bit[2]: Configure EMIF2 CS0</p> <p>Bit[3]: Configure EMIF2 CS1</p> <p>Bits[8:11]: EMIF temperature monitoring timeout. If the value is non-zero, the ROM code checks the MR4 register of the EMIF LPDDR2. As long as the SDRAM Refresh Rate field is not 0x3 (Temperature not $\leq 85^{\circ}\text{C}$) it indicates an abnormal EMIF temperature state and the ROM code loops. When the SDRAM Refresh Rate goes back to 0x3, the ROM Code resumes EMIF initialization. The waiting loop cannot exceed the timeout value indicated by this flag. When the timeout expires, the ROM code resumes EMIF initialization.</p> <p>0x0: no temperature monitoring</p> <p>0x1: timeout 1 second</p> <p>0x2: timeout 2 seconds</p> <p>0x3: timeout 3 seconds</p> <p>0x5: timeout 5 seconds</p> <p>0xA: timeout 10 seconds</p> <p>Other bits: Reserved</p> |

NOTE:

- The ROM code supports only the LPDDR2 memory type (as set in the SDRAM configuration register EMIF_SDRAM_CONFIG).
- It is assumed that the same kind of SDRAM (same type and timings) is attached to both CSs when requesting the configuration of both CSs for a given EMIF (for example, if bits 0 and 1 of the Flags field are set, it is assumed that both EMIF1 CSs are attached to the same kind of memory).

28.4.8.2.3 CHFLASH Item

The CHFLASH configuration header contains settings specific to the general-purpose memory controller (GPMC). For more information, see [Section 16.4, GPMC Overview](#). [Table 28-49](#) describes the fields.

Table 28-49. CHFLASH Item

| Offset | Field | Description |
|--------|----------------------------|--|
| 0000h | Section Key | Key used for section verification: C0C0C0C3h. |
| 0004h | Valid | <p>Enables/disables the section:</p> <p>00h: Disable</p> <p>Others: Enable</p> |
| 0005h | Reserved | |
| 0008h | GPMC_SYSCONFIG (LSB) | Register values |
| 000Ah | GPMC_IRQENABLE (LSB) | |
| 000Ch | GPMC_TIMEOUT_CONTROL (LSB) | |
| 000Eh | GPMC_CONFIG (LSB) | |
| 0010h | GPMC_CONFIG1_0 | |
| 0014h | GPMC_CONFIG2_0 | |
| 0018h | GPMC_CONFIG3_0 | |
| 001Ch | GPMC_CONFIG4_0 | |
| 0020h | GPMC_CONFIG5_0 | |
| 0024h | GPMC_CONFIG6_0 | |

Table 28-49. CHFLASH Item (continued)

| Offset | Field | Description |
|--------|-----------------------------|--|
| 0028h | GPMC_CONFIG7_0 | |
| 002Ch | GPMC_PREFETCH_CONFIG1 | |
| 0030h | GPMC_PREFETCH_CONFIG2 (LSB) | |
| 0032h | GPMC_PREFETCH_CONTROL (LSB) | |
| 0034h | GPMC_ECC_CONFIG | |
| 0036h | GPMC_ECC_CONTROL | |
| 0038h | GPMC_ECC_SIZE_CONFIG (LSB) | |
| 003Ch | Enable_A1_A10 | 0: Do not change A1– A10 pads Others: Enable A1– A10 pads |

28.4.8.2.4 CHMMCS D Item

The CHMMCS D configuration header contains settings specific to the high-speed MMC/SD/SDIO host controller (MMCHS). For more information, see [Chapter 25, MMC/SD/SDIO](#). [Table 28-50](#) describes the fields.

Table 28-50. CHMMCS D Item

| Offset | Register Modified | Description |
|--------|---------------------------|---|
| 0000h | Section key | Key used for section verification C0C0C0C4h |
| 0004h | Valid | Enables/disables the section: 00h: Disable Other: Enable |
| 0005h | Reserved | |
| 0008h | MMCHS_SYSCTRL(MSW) | Update MMCHS SYSCTRL interface register with the value specified in these fields. The register is not updated if the value is 0xFFFFFFFF. |
| 000Ah | MMCHS_SYSCTRL(LSW) | |
| 000Ch | MMCHS interface bus width | 1: 1 bit 2: 4 bits 4: 8 bits 0xFFFF FFFF: Do not update bus width. Others: Reserved |

The ROM code provides a booting parameter structure to the initial software (see [Section 28.4.8.4, Image Execution](#)). This structure contains a field that indicates whether the configuration header items have been correctly processed. For a CHMMCS D item, if the MMCHS_SYSCTRL and bus width fields are set to 0xFFFF FFFF, the booting parameters report that the CHMMCS D section has not been executed, regardless of the value of the Valid field.

28.4.8.3 GP Header

When the booting memory device is non-XIP (for example, MMC) the image must contain a small header, located before the executable code, and having the size of the software to load and the destination address of where to store it. [Table 28-51](#) describes the image format. The GP header is not required when booting from an XIP memory device (for example, NOR) or in case of peripheral booting. In this case, the peripheral or memory booting image starts directly with executable code.

Table 28-51. GP Header Format

| Field | Non-XIP Device Offset | XIP Device Offset | Size (Bytes) | Description |
|-------|-----------------------|-------------------|--------------|-------------------|
| Size | 0x0000 | – | 4 | Size of the image |

Table 28-51. GP Header Format (continued)

| Field | Non-XIP Device Offset | XIP Device Offset | Size (Bytes) | Description |
|-------------|-----------------------|-------------------|--------------|--|
| Destination | 0x0004 | – | 4 | Address where to store the image or code entry point |
| Image | 0x0008 | 0x0000 | x | Executable code |

NOTE: The Destination address field stands for:

- Target address for the image copy from the non-XIP storage to the target XIP location (for example, internal RAM or SDRAM)
- Entry point for image code

Users must take care to locate the code entry point to the target address for image copy.

28.4.8.4 Image Execution

The image is executed when the ROM code performs the branch to the first executable instruction in the initial software. For a GP device in non-XIP, the execution address is the first word after the GP header. The branch is performed in public ARM supervisor mode. The R0 register points to the booting parameter structure that contains information about booting execution. [Table 28-52](#) shows the booting parameter structure.

Table 28-52. Booting Parameter Structure

| Offset | Field | Size (Bytes) | Description |
|--------|----------------------------------|--------------|---|
| 0x00 | Booting message | 4 | Last received booting message |
| 0x04 | Memory booting device descriptor | 4 | Pointer to the memory device descriptor that has been used during the memory booting process |

28.4.9 Tracing

Tracing in the public ROM code consists in three 32-bit vectors for which each bit corresponds to a particular way point in the ROM code execution sequence. [Table 28-53](#) through [Table 28-55](#) list the organization of the tracing data in RAM. Tracing vectors are initialized at the beginning of the start-up phase and are updated all along the boot process.

There are two sets of tracing vectors ([Table 28-13](#)). The first set is the current trace information (after a cold or warm reset). The second set holds a copy of trace vectors collected at the first ROM code run after a cold reset. As a result, after a warm reset it is possible to have visibility on the boot scenario that occurred during a cold reset.

[Table 28-53](#) lists the organization of tracing vector 1.

Table 28-53. Tracing Vector 1

| Bit | Group | Meaning |
|-----|-----------------|--|
| 0 | General | Passed the public reset vector |
| 1 | General | Entered main function |
| 2 | General | Running after the cold reset |
| 3 | Boot | Main booting routine entered |
| 4 | Memory boot | Memory booting started |
| 5 | Peripheral boot | Peripheral booting started |
| 6 | Boot | Booting loop reached last device |
| 7 | Boot | GP header (non-XIP) found |

28.5 Services for HLOS Support

The ROM code provides different services that can be called on GP devices for L2 cache maintenance, wake up of slave CPU(s), etc. These services are implemented in monitor mode (the service must be called by writing the function ID into the R12 register and using the SMC instruction) and do not use any resources like RAM/stack or hardware outside the master CPU. The caller must ensure the save and restore of the processor registers before and after calling the monitor service.

The following code example shows how the monitor ROM code functions can be accessed by an application running in public mode:

```

;-----
; FUNCTION: PL310_SetDebugL2Cache
;
; DESCRIPTION: Function calls the Monitor Service to configure the debug
;               control register of the L2 cache.
;
; INPUTS: r0 Value to set in the debug control register
;
; RETURN:
;
;-----
PL310_SetDebugL2Cache FUNCTION
    PUSH {R1-R12, LR}
    LDR R12, =API_MONITOR_L2CACHE_SETDEBUG_INDEX
    SMC 0x1
    POP {R1-R12, PC}
ENDFUNC

```

28.5.1 L2 Cache Maintenance

Table 28-56. L2 Cache Write Debug Register

| Function ID | Description | |
|-------------|--|-----------------------------|
| R12 = 0x100 | This function sets the input parameter value in the L2 Cache Debug register. | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 | Debug register value to set |
| Output | | |
| Return | | |

Table 28-57. L2 Cache Clean and Invalidate Range of Physical Address

| Function ID | Description | |
|-------------|---|--|
| R12 = 0x101 | This function cleans and invalidates a range Physical Addresses. This is a workaround of the clean and invalidate L2 cache. | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 R1 | Physical Start Address of the range Size of the range to invalidate |
| Output | | |
| Return | | |

Table 28-58. Enable/Disable L2 Cache

| Function ID | Description |
|-------------|--|
| R12 = 0x102 | This function sets the given input value in the L2 Cache Control register (enable/disable) |

Table 28-58. Enable/Disable L2 Cache (continued)

| Function ID | Description | |
|-------------|-------------|-------------------------------|
| Parameters | | |
| Type | Location | Description |
| Input | R0 | Control register value to set |
| Output | | |
| Return | | |

Table 28-59. Write Auxiliary Control Register

| Function ID | Description | |
|-------------|---|------------------------------|
| R12 = 0x109 | This function writes the PL310 Auxiliary Control register with the input given value in R0. | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 | Value to set in the register |
| Output | | |
| Return | | |

Table 28-60. Write Tag and Data RAM Latency Control Register

| Function ID | Description | |
|-------------|---|---|
| R12 = 0x112 | This function writes the PL310 Tag and Data RAM Latency Control Register with the input given value in R0 and R1. | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 R1 | Tag RAM latency to set Data RAM latency to set |
| Output | | |
| Return | | |

Table 28-61. Write Prefetch Control Register

| Function ID | Description | |
|-------------|--|------------------------------|
| R12 = 0x113 | This function writes the PL310 prefetch control register with the input given value in R0. | |
| Parameters | | |
| Type | Location | Description |
| Input | RO | Value to set in the register |
| Output | | |
| Return | | |

28.5.2 Multicore Infrastructure Maintenance

Table 28-62. Read AUX_CORE_BOOT_0 and AUX_CORE_BOOT_1 Registers

| Function ID | Description |
|-------------|--|
| R12 = 0x103 | This function reads both AUX_CORE_BOOT_0/1 registers. The function is kept for compatibility with OMAP4430 ES1.0. AUX_CORE_BOOT_0 and AUX_CORE_BOOT_1 have memory-mapped access. See Chapter 4, Dual Cortex-A9 Subsystem . |
| Parameters | |

**Table 28-62. Read AUX_CORE_BOOT_0 and AUX_CORE_BOOT_1 Registers
(continued)**

| Function ID | Description | |
|-------------|-------------|--|
| Type | Location | Description |
| Input | | |
| Output | R0 R1 | AUX_CORE_BOOT_0 register value AUX_CORE_BOOT_1 register value |
| Return | | |

Table 28-63. Modify AUX_CORE_BOOT_0

| Function ID | Description | |
|-------------|--|--------------------------------------|
| R12 = 0x104 | This function modifies the AUX_CORE_BOOT_0 register used as a status bit. The function sets and clears the bit given in the parameter and returns the new register value after operation. This function is kept for compatibility with OMAP4430 ES1.0. AUX_CORE_BOOT_0 has memory-mapped access. See Chapter 4, Dual Cortex-A9 Subsystem . | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 R1 | Bit mask to set Bit mask to clear |
| Output | | |
| Return | R0 | AUX_CORE_BOOT_0 register new value |

Table 28-64. Write AUX_CORE_BOOT_1

| Function ID | Description | |
|-------------|--|------------------------------|
| R12 = 0x105 | This function sets the value of the AUX_CORE_BOOT_1 register value used to give the CPU1 boot address. The given address can be virtual or physical. CPU1 MMU must be enabled before jumping to this address. This function is kept for compatibility with OMAP4430 ES1.0. AUX_CORE_BOOT_1 has memory-mapped access. See Chapter 4, Dual Cortex-A9 Subsystem . | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 | Value to set in the register |
| Output | | |
| Return | | |

Table 28-65. Read WKG_CONTROL_0/1 Register

| Function ID | Description | |
|-------------|--|---------------------------------------|
| R12 = 0x106 | This function returns the value of the WKG_CONTROL_0/1 register (CPU0 or CPU1) depending on the input parameter value. The function is kept for compatibility with OMAP4430 ES1.0. See the memory mapping and description in Chapter 4, Dual Cortex-A9 Subsystem . | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 | CPU ID |
| Output | | |
| Return | R0 | Value of the WKG_CONTROL_0/1 register |

Table 28-66. Clear WKG_CONTROL_0/1 Register

| Function ID | Description | |
|-------------|--|-----------------------------|
| R12 = 0x107 | This function clears the given bit mask of the WKG_CONTROL_0/1 register depending on the CPU ID. | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 R1 | CPU ID Bit mask to clear |
| Output | | |
| Return | | |

28.5.3 Snoop Control Unit (SCU)

Table 28-67. Set Power Status Register

| Function ID | Description | |
|-------------|--|--|
| R12 = 0x108 | This function sets the power status register of the CPU and cleans the full CPU L1 data cache, if the cache will be switched off when CPU enters into low-power state. | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 R1 | CPU power state value to set (0x2: CSWRET, 0x3: OFF) L1 data cache state (0x00: RET, 0xFF: OFF) |
| Output | | |
| Return | | |

28.5.4 Lockdown Translation Lookaside Buffers (TLBs)

Table 28-68. Select the TLB Entry for Read

| Function ID | Description | |
|-------------|---|-------------|
| R12 = 0x10A | This function writes the Select Lockdown TLB Entry for Read register. | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 | TLB entry |
| Output | | |
| Return | | |

Table 28-69. Select the TLB Entry for Write

| Function ID | Description | |
|-------------|--|-------------|
| R12 = 0x10B | This function writes the Select Lockdown TLB Entry for Write register. | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 | TLB entry |
| Output | | |
| Return | | |

Table 28-70. Read the TLB VA Entry

| Function ID | Description | |
|-------------|---|-----------------------|
| R12 = 0x10C | This function reads the Lockdown TLB VA register (Selected TLB Entry for Read). | |
| Parameters | | |
| Type | Location | Description |
| Input | | |
| Output | | |
| Return | R0 | Value of the register |

Table 28-71. Write the TLB VA Entry

| Function ID | Description | |
|-------------|--|----------------|
| R12 = 0x10D | This function writes the Lockdown TLB VA register (Selected TLB Entry for Write). The NS bit is forced to 1. | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 | Value to write |
| Output | | |
| Return | | |

Table 28-72. Read the TLB PA Entry

| Function ID | Description | |
|-------------|---|-----------------------|
| R12 = 0x10E | This function reads the Lockdown TLB PA register (Selected TLB Entry for Read). | |
| Parameters | | |
| Type | Location | Description |
| Input | | |
| Output | | |
| Return | R0 | Value of the register |

Table 28-73. Write the TLB PA Entry

| Function ID | Description | |
|-------------|---|----------------|
| R12 = 0x10F | This function writes the Lockdown TLB PA register (Selected TLB Entry for Write). | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 | Value to write |
| Output | | |
| Return | | |

Table 28-74. Read the TLB Attributes Entry

| Function ID | Description | |
|-------------|---|-------------|
| R12 = 0x110 | This function reads the Lockdown TLB Attributes register (Selected TLB Entry for Read). | |
| Parameters | | |
| Type | Location | Description |
| Input | | |
| Output | | |

Table 28-74. Read the TLB Attributes Entry (continued)

| Function ID | Description | |
|-------------|-------------|-----------------------|
| Return | R0 | Value of the register |

Table 28-75. Write the TLB Attributes Entry

| Function ID | Description | |
|-------------|--|----------------|
| R12 = 0x111 | This function writes the Lockdown TLB Attributes register (Selected TLB Entry for Write). The NS bit is forced to 1. | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 | Value to write |
| Output | | |
| Return | | |

PRELIMINARY

On-Chip Debug Support

This chapter describes the on-chip debug support.

29.1 Introduction

Debugging a system containing an embedded processor involves an environment that connects high-level debugging software, executed on a host computer, to a low-level debug interface supported by the target device. In between these levels is a debug and trace controller (DTC) that facilitates communication between the host debugger and the debug support logic on the target chip.

The DTC, a combination of hardware and software that connects the host debugger to the target system, uses one or more hardware interfaces and/or protocols to convert actions dictated by the debugger to JTAG® commands and scans that execute the core hardware.

The debug software and hardware components let the user control multiple central processing unit (CPU) cores embedded in the device in a global or local manner. This environment provides:

- Synchronized global starting and stopping of multiple processors
- Starting and stopping of an individual processor
- Processor-generated triggers that can be used to alter the execution flow of other processors

System topics include but are not limited to:

- System clocking and power-down issues
- Interconnection of multiple devices
- Trigger channels

For easy integration into applications, a set of libraries (APIs) for debug-IP programming and a software message library are being provided. CToolsLib is a collection of embedded target APIs/library to enable easy programmatic access to the chip tools (CTools), which are system-level debug facilities included in the debug subsystem capabilities of TI devices. More information about the APIs, download files, and other useful links for available libraries can be found on the CToolsLib Wiki site:

<http://processors.wiki.ti.com/index.php/CToolsLib>

The previous link(s) connect to TI community resources. Linked contents are provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

29.2 Debug Ports

29.2.1 IEEE1149.1

The target debug interface has the following signals:

- Five standard IEEE1149.1 JTAG signals:
 - nTRST
 - TCK
 - TMS
 - TDI
 - TDO
- A return clock (RTCK) due to the clocking requirements of the ARM968™ processor
- Two EMU [1:0] or five EMU [4:0] TI extensions, depending on the pin count (14 pins or 20 pins) in the JTAG header of the device.

Table 29-1 describes the IEEE1149.1 signals.

Table 29-1. IEEE1149.1 Signals

| Pin Name | Internal Signal Name | Type (1) | Pull Type (3) | Function | Description |
|---------------|----------------------|----------|---------------|------------------------------------|---|
| jtag_nrst | nTRST | I | PD | Test reset | When asserted (active low), causes all test and debug logic in the device to be reset along with the IEEE1149.1 interface |
| jtag_tck | TCK | I | PD | Test clock | This is the test clock used to drive an IEEE1149.1 TAP state-machine and logic. This is a free-running clock or a gated clock, depending on the DTC attached to the device and the RTCK monitoring. |
| jtag_rtck | RTCK | O | N/A | Returned (synchronized) test clock | Depending on the DTC attached to the device, either the JTAG signals are clocked from RTCK or the RTCK is monitored by the DTC to the gate TCK. |
| jtag_tms_tmse | TMS | I | PU | Test mode select | Directs the next state of the IEEE1149.1 TAP state-machine |
| jtag_tdi | TDI | I | PU | Test data input | Scans data input to the device |
| jtag_tdo | TDO | O | PU | Test data output | Scans data output by the device |
| dpm_emu0 | EMU0 | I/O | PU | Emulation 0 | Channel 0 trigger, or boot mode, or trace port |
| dpm_emu1 | EMU1 | I/O | PU | Emulation 1 | Channel 1 trigger, or boot mode, or trace port |
| dpm_emu2(2) | EMU2(2) | O | PD | Emulation 2 | Trace port |
| dpm_emu3(2) | EMU3(2) | O | PD | Emulation 3 | Trace port |
| dpm_emu4(2) | EMU4(2) | O | PD | Emulation 4 | Trace port |

(1) I = Input; O = Output; I/O = Bidirectional

(2) 20-pin JTAG header only

(3) PU = internal pullup; PD = internal pulldown

For information about the JTAG ID code value, see [Chapter 1, Introduction](#).

29.2.2 IEEE1149.7

Besides the standard (legacy) JTAG mode of operation, the target debug interface can also be switched to a compressed JTAG mode of operation, commonly referred to as the IEEE1149.7 standard. An IEEE1149.7 adapter module runs a 2-pin communication protocol on top of an IEEE1149.1 JTAG TAP. The debug-IP logic serializes the IEEE1149.1 transactions, using a variety of compression formats, to reduce the number of pins needed to implement a JTAG debug port. The device implements only a subset of the IEEE1149.7 protocol (see [Table 29-3](#)).

NOTE: At power-on reset (POR), the default debug interface mode is IEEE1149.1. See the IEEE1149.7 specification for the scan sequence required to switch modes.

The IEEE1149.7 communication protocol can switch between serial and parallel formats. The parallel format consists of the IEEE1149.1 signals, TCK, TMS, TDI, TDO, nTRST, and RTCK return clock, if stalls are required. The serial format uses two signals, TCK and TMSC. The values of the TMS, TDI, TDO, and RTCK signals are multiplexed on the bidirectional pin, jtag_tms_tmisc, by the Debug-IP logic. Each TCK of the DTC is serialized into a packet, which is transmitted to the IEEE1149.7 adapter, where it is converted back to parallel. The TDO and RTCK information are returned during the packet transmission.

NOTE: Only MScan, Oscan0, and Oscan4 formats can be used if the device requires stalls.

Table 29-2 describes the IEEE1149.7 signals.

Table 29-2. IEEE1149.7 Signals

| Pin Name | Internal Signal Name | Type (1) | Pull Type (2) | Function | Description |
|----------------|----------------------|----------|---------------|---------------------------------|---|
| jtag_tck | TCK | I | PD | Test clock | This is the test clock used to drive an IEEE1149.1 TAP state-machine and logic. This is a free-running clock or a gated clock, depending on the DTC attached to the device and the TMSC RDY field monitoring. |
| jtag_tms_tmisc | TMSC | I/O | PU | Test mode control and data scan | Compressed JTAG packet. The TMSC signal is driven only when the TCK signal is low. The signal level must be maintained by a keeper while the TCK signal is high. |

(1) I = Input; O = Output; I/O = Bidirectional

(2) PU = internal pullup; PD = internal pulldown

Table 29-3 summarizes the IEEE1149.7 features subset supported by the device.

Table 29-3. IEEE1149.7 Features Subset

| | IEEE1149.7 Feature | Device Support | Comment |
|----------------------------|--------------------|----------------|-------------------------------------|
| Configuration | Class 4 TAP | ✓ | Supports 2-pin operation |
| | Class 5 TAP | – | No BDX or CDX channel |
| Optional Components | FRST | – | Functional reset (done via ICEPick) |
| | TRST | – | Test reset |
| | RDBK capability | ✓ | Read back of register data |
| | Aux Pin Functions | – | Reuse of TDI and TDO pins |
| | TCKWID | ✓ | Programmable TCK width |

Table 29-3. IEEE1149.7 Features Subset (continued)

| | IEEE1149.7 Feature | Device Support | Comment |
|----------------------|--------------------|----------------|-----------------------------------|
| Scan Formats | JScan0 | ✓ | Parallel mode |
| | JScan1 | ✓ | Parallel with firewall |
| | JScan2 | ✓ | Parallel with super-bypass select |
| | JScan3 | ✓ | Parallel with register select |
| | SScan0 | – | Segmented scan |
| | SScan1 | – | Segmented scan plus stalls |
| | SScan2 | – | Segmented scan |
| | SScan3 | – | Segmented scan plus stalls |
| | Oscan0 | ✓ | Support stalls |
| | Oscan1 | ✓ | Nonstall mode |
| | Oscan2 | ✓ | Bidirectional transfers |
| | Oscan3 | ✓ | Host to target only |
| | Oscan4 | ✓ | Support stalls |
| | Oscan5 | ✓ | Pipelined |
| | Oscan6 | ✓ | Bidirectional transfers |
| | Oscan7 | ✓ | Host to target only |
| | Mscan | ✓ | Multi devices mode plus stalls |
| Power Control | Power down logic | – | Handled by ICEMelter |

29.2.3 Trace Port

On-chip debug and trace events can be exported to external equipment through the trace port in the device. The following exportable debug events and trace sources are supported:

- Debug events
 - Triggers. For more information about triggers, see [Section 29.4.2, Cross-Triggering](#).
- Trace sources
 - Processor trace: Cortex-A9 MPU trace supported by program trace macrocell (PTM) and trace port interface unit (TPIU) modules. For more information about processor trace, see [Section 29.7, Processor Trace](#).
 - System trace: Trace coming from various system instrumentation modules and supported by system trace module (STM). For more information about system trace, see [Section 29.8, System Instrumentation](#).

Not all debug and trace features can be supported concurrently due to the limited number of pins allocated for debugging. Thus, multiplexing among debug and trace sources is implemented. The configuration and the debug/trace source selection are done through the DRM module embedded in the debug subsystem.

[Table 29-4](#) describes the trace port signals.

Table 29-4. Trace Port Signals

| Pin Name | Internal Signal Name | I/O ⁽¹⁾ | Pull Type ⁽²⁾ | Description |
|-----------|----------------------|--------------------|--------------------------|-------------------------------|
| dpm_emu19 | EMU19 | O | PD | Debug resource manager pin 19 |
| dpm_emu18 | EMU18 | O | PD | Debug resource manager pin 18 |
| dpm_emu17 | EMU17 | O | PD | Debug resource manager pin 17 |
| dpm_emu16 | EMU16 | O | PD | Debug resource manager pin 16 |
| dpm_emu15 | EMU15 | O | PD | Debug resource manager pin 15 |
| dpm_emu14 | EMU14 | O | PD | Debug resource manager pin 14 |

⁽¹⁾ I = Input; O = Output; I/O = Bidirectional

⁽²⁾ PU = internal pullup; PD = internal pulldown

Table 29-4. Trace Port Signals (continued)

| Pin Name | Internal Signal Name | I/O ⁽¹⁾ | Pull Type ⁽²⁾ | Description |
|-----------|----------------------|--------------------|--------------------------|-------------------------------|
| dpm_emu13 | EMU13 | O | PD | Debug resource manager pin 13 |
| dpm_emu12 | EMU12 | O | PD | Debug resource manager pin 12 |
| dpm_emu11 | EMU11 | O | PD | Debug resource manager pin 11 |
| dpm_emu10 | EMU10 | O | PD | Debug resource manager pin 10 |
| dpm_emu9 | EMU9 | O | PD | Debug resource manager pin 9 |
| dpm_emu8 | EMU8 | O | PD | Debug resource manager pin 8 |
| dpm_emu7 | EMU7 | O | PD | Debug resource manager pin 7 |
| dpm_emu6 | EMU6 | O | PD | Debug resource manager pin 6 |
| dpm_emu5 | EMU5 | O | PD | Debug resource manager pin 5 |
| dpm_emu4 | EMU4 | O | PD | Debug resource manager pin 4 |
| dpm_emu3 | EMU3 | O | PD | Debug resource manager pin 3 |
| dpm_emu2 | EMU2 | O | PD | Debug resource manager pin 2 |
| dpm_emu1 | EMU1 | I/O | PU | Debug resource manager pin 1 |
| dpm_emu0 | EMU0 | I/O | PU | Debug resource manager pin 0 |

NOTE: The dpm_emu[19:0] pins are shared with other functional (application) pins on the device boundary. To use the dpm_emu[19:0] pins, the user must program the device application pin manager (control module) appropriately. For more information, see [Chapter 19, Control Module](#).

For more information about DRM multiplexing and concurrent debug modes, see [Section 29.9, Concurrent Debug Modes](#).

29.2.4 End Product

For an end product phone, there are usually severe connectivity constraints and the standard debug ports may not be available at board level. This could make it difficult to trace and debug software.

To ease the process of tracing and debugging, a narrow interface for debug and test (NIDnT) concept defined by MIPI is used. NIDnT is based on IEEE1149.7 and STM interfaces and re-uses application interface pins. In the context of the device, the application interface that can serve as an NIDnT port is the MMC1 interface. To use the NIDnT port, the relevant MMC1 pins must be set to the appropriate MUX mode through the control module.

[Table 29-5](#) shows the NIDnT port reusing MMC interface pins along with the corresponding MUX modes.

Table 29-5. NIDnT Port Reusing MMC Interface Pins

| Module | Control Module Multiplexing | | |
|----------------------|-----------------------------|------------|-------------------|
| | MUX0 (MMC) | MUX2 (STM) | MUX4 (IEEE1149.7) |
| Extension card (MMC) | sdmmc1_clk | dpm_emu19 | — |
| | sdmmc1_cmd | uart1_rx | — |
| | sdmmc1_dat0 | dpm_emu18 | — |
| | sdmmc1_dat1 | dpm_emu17 | — |
| | sdmmc1_dat2 | dpm_emu16 | jtag_tms_tmisc |
| | sdmmc1_dat3 | dpm_emu15 | jtag_tck |

NOTE: The nTRST signal must be driven high for the MMC1 interface to be used for IEEE1149.7 protocol.

NOTE: uart1_rx is an optional return channel. Depending on the trace receiver, the return channel is implemented by IEEE1149.1/IEEE1149.7.

For more information about how to configure the proper MUX mode, see [Chapter 19](#), *Control Module*.

For more information about the NIDnT concept, see the *MIPI Alliance Test and Debug – NIDnT-Port* specification.

29.2.5 Trace Connector and Board Layout Considerations

Because the device supports processor trace and system trace export, a 60-pin header in place of the traditional TI 14-pin, or a TI 20-pin emulation header, may be required at board level. For more information about the trace connectors and board layout considerations for these high-speed signals, see *Emulation and Trace Headers* (TI literature number SPRU655).

29.3 Debugger Connection

29.3.1 ICEPick Module

The debugger connects to the device through its JTAG interface. The first level of debug interface seen by the debugger is the IEEE1149.7 adapter connected to the ICEPick module embedded in the debug subsystem.

NOTE: ICEPick version D (ICEPick-D) is used in the device.

System-on-chip (SoC) designs typically have multiple processors, each having a JTAG TAP embedded in the processor. The ICEPick module manages these TAPs and the power, reset, and clock controls for modules that have TAPs.

The ICEPick module is visible only from the debugger point of view, and thus cannot be programmed by application software. The debugger can configure ICEPick through its own TAP controller. The ICEPick TAP has an instruction length of 6 bits and is the primary TAP. It is always visible in the scan chain and is used to control and monitor the other secondary TAPs.

ICEPick provides the following debug capabilities:

- Debug connect logic for enabling or disabling most ICEPick instructions
- Dynamic TAP insertion:
 - Serially linking up to 16 TAP controllers
 - Individually selecting one or more of the TAPs for scan without disrupting the instruction register (IR) state of other TAPs
- Power, reset, and clock management:
 - Provides the power and clock states of each domain
 - Provides debugger control of the power domain of a processor. Can force the domain power and clocks on, and prohibit the domain from being clock-gated or powered down while a debugger is connected.
 - Applies system reset
 - Provides wait-in-reset (WIR) boot mode
 - Provides global and local WIR release
 - Provides global and local reset blocking

The ICEPick module implements a connect register, which must be configured with a predefined key to enable the full set of JTAG instructions. When the debug connect key is properly programmed, ICEPick signals and subsystems emulation logics should be turned on.

For more information about ICEPick dynamic TAP insertion, see [Section 29.3.3, Dynamic TAP Insertion](#).

For more information about ICEPick power, reset, and clock management features, see [Section 29.5, Power, Reset, and Clock Management Debug Support](#).

29.3.2 Boot Modes

The initial configuration of ICEPick is determined by the level of the dpm_emu0 and dpm_emu1 pins upon POR release. At POR, dpm_emu0 and dpm_emu1 are automatically configured as inputs. The dpm_emu0 and dpm_emu1 pins are free when POR is released.

[Table 29-6](#) summarizes the ICEPick boot modes.

Table 29-6. ICEPick Boot Modes Upon POR

| dpm_emu1 | dpm_emu0 | TAPs in the TDI → TDO Path | Other Effects/Comments |
|----------|----------|----------------------------|------------------------|
| 0 | 0 | None | Reserved (do not use) |
| 0 | 1 | None | Reserved (do not use) |
| 1 | 0 | ICEPick | TAP only + WIR mode |

Table 29-6. ICEPick Boot Modes Upon POR (continued)

| dpm_emu1 | dpm_emu0 | TAPs in the TDI → TDO Path | Other Effects/Comments |
|----------|----------|----------------------------|-------------------------|
| 1 | 1 | ICEPick | TAP only (default mode) |

29.3.2.1 Default Boot Mode

In ICEPick-only configuration, none of the secondary TAPs are selected. The ICEPick TAP is the only TAP between device-level TDI and TDO pins. This is the recommended boot mode.

29.3.2.2 Wait-In-Reset

The device can boot to invoke WIR mode. If the device is booted in this mode, all processors within the device that support a TAP through ICEPick are held in reset until released. Individual processors may be released from reset (local), or all processors held in the reset state may be released at the same time (global).

29.3.3 Dynamic TAP Insertion

29.3.3.1 ICEPick Secondary TAPs

To include more or fewer secondary TAPs in the scan chain, the debugger must use the ICEPick TAP router to program the TAPs. At its root, ICEPick is a scan-path linker that lets the DTC selectively choose which subsystem TAPs are accessible through the device-level debug interface. Each secondary TAP can be dynamically included in or excluded from the scan path. From external JTAG interface point of view, secondary TAPs that are not selected appear not to exist.

Figure 29-1 shows the TAPs in the ICEPick scan chain.

Figure 29-1. ICEPick Scan Chain

NOTE: RES = Reserved/not used
CM3 = Cortex™-M3
DAP = Debug access port

Table 29-7 shows the secondary debug TAPs connected to the ICEPick scan chain along with the modules that can be accessed. The TAP number indicates the position of the TAP in the scan chain.

Table 29-7. ICEPick Secondary Debug TAP Mapping

| Secondary JTAG Port | CoreSight | TAP Number | Modules Accessed Through That JTAG Port |

PRELIMINARY

29.4 Primary Debug Support

29.4.1 Processor Native Debug Support

29.4.1.1 Cortex-A9 MPU

The dual Cortex-A9 processor supports the following native debug features:

- Halt mode and monitor mode debugging
- Six breakpoints and four watch points
- Asynchronous aborts
- Performance monitoring
- Cross-triggering: Allows stopping one CPU upon debug event (for example, breakpoint) detection in the other CPU

For more information about Cortex-A9 native debug support features, see the *Cortex-A9* technical reference manual.

29.4.1.2 Cortex-M3 MPU

The Cortex-M3 processor supports the following native debug features:

- Program halt and stepping
- Hardware breakpoints, breakpoint instruction
- Data watch point on access to data add, add range, and data value
- Register value accesses
- Debug monitor exception
- Memories accesses

For more information about Cortex-M3 native debug support features, see the *Cortex-M3* technical reference manual.

29.4.1.3 DSP

This information is not available in the public domain.

29.4.1.4 IVA-HD ARM968

The ARM968E-S processor supports the following native debug features through its EmbeddedICE-RT logic:

- Two hardware watch points/breakpoints
- Halt mode and monitor mode debugging
- Debug control and status registers
- Debug communications channel

For more information about ARM968 native debug support features, see the *ARM968E-S* technical reference manual.

29.4.1.5 IVA-HD Hardware Accelerators

Hardware accelerators offer the following debug capabilities through their embedded SyncBox module:

- Manual halt: Halt occurs at the SYNCBOX task boundary, when requested by the debugger.
- Single-step execution at SYNCBOX task level (from 1 to n macroblocks depending on the user software)
- Cross-triggering: Hardware accelerator can halt, after the execution of current SYNCBOX task, based on trigger event detection.
- Global run

Table 29-9 summarizes the debug capabilities of the hardware accelerator SYNCBOX.

Table 29-9. Hardware Accelerator Debug Capability Options

| Feature | iME3 | iPE3 | MC3 | CALC3 | iLF3 | ECD3 |
|--------------------------------|------|------|-----|-------|------|------|
| Core reset | – | – | – | – | – | – |
| Execution request | – | – | – | – | – | – |
| Trigger output | – | – | – | – | – | – |
| Trigger input | ✓ | ✓ | ✓ | ✓ | ✓ | ✓ |
| Number of trigger channels | 1 | 1 | 1 | 1 | 1 | 1 |
| Number of counters | 0 | 0 | 0 | 0 | 0 | 0 |
| Number of watch points | 0 | 0 | 0 | 0 | 0 | 0 |
| Number of hardware breakpoints | 0 | 0 | 0 | 0 | 0 | 0 |

29.4.2 Cross-Triggering

The device supports a cross-triggering feature, which provides a way to propagate debug (trigger) events from one processor subsystem/module to another. For example, *Sample Subsystem A* can be programmed to generate a debug event, which can then be exported as a global trigger across the device. Another *Sample Subsystem B* can be programmed to be sensitive to the trigger line input and to generate an action upon trigger detection.

Examples of debug events are: processor entering debug state, watch point match, PTM trigger, ETB full, ETB acquisition complete, etc.

Examples of debug actions are: debug request generation, restart (Cortex-A9 synchronous run), interrupt request generation, start/stop trace, etc.

Subsystems cross-triggering is consolidated at the device level by the XTRIGGER module, which is embedded in the debug subsystem.

NOTE: XTRIGGER is not programmatically visible from the JTAG interface or any device processor. Thus, cross-triggering is programmed at the subsystem level.

29.4.2.1 SoC Level Cross-Triggering

Table 29-10 summarizes the device cross-triggering capabilities.

Table 29-10. XTRIGGER

| Subsystem | Module | | Cortex-A9 | PTM/ ETB | Cortex-M3 | Cortex-M3 | Target Core | IVA3- C64x | IVA-HD ARM968 | IVA-HD ARM968 | HWA | PMI | CMI | OCP-WP | EMU0/ EMU1 |

| Power manager | PMI | – | – | – | – | – | – | – | – | – | – | | – | – | – |
| Clock manager | CMI | – | – | – | – | – | – | – | – | – | – | – | | – | – |
| Device | OCP-WP | ✓ | ✓ | ✓ | ✓ | ✓ | – | ✓ | ✓ | ✓ | – | ✓ | ✓ | | ✓ |
| | EMU0, EMU1 | ✓ | ✓ | ✓ | ✓ | ✓ | – | ✓ | ✓ | ✓ | – | ✓ | ✓ | ✓ | |

NOTE: The following modules support only trigger inputs:

- IVA-HD hardware accelerators
- IVA-HD SMSET
- PMI
- CMI

29.4.3 Suspend

The device supports a suspend feature, which provides a way to stop a "closely coupled" hardware process running on a peripheral-IP when the host processor enters a debug state. The suspend mechanism is important for debug to ensure that peripheral-IPs operate in a lock-step manner with a host controller processor.

An entry is provided for each peripheral-IP that must consider the suspend signals from a number of processors (MPU or DSP). For each peripheral-IP, sensitivity to the suspend signals is defined within two possibilities (and therefore is coded using 1 bit):

- Peripheral-IP is sensitive to the suspend line request.
- Peripheral-IP ignores the suspend line request.

For more information about how to program the sensitivity, see the corresponding peripheral-IP TRM chapter.

29.4.3.1 Debug Aware Peripherals and Host Processors

Table 29-11 lists the mapping of the device processors to the suspend control input lines.

Table 29-11. Debug Subsystem Suspend Input Lines

| Suspend Input Line | Host Processor |
|--------------------|-------------------|
| 0 | Reserved |

29.5 Power, Reset, and Clock Management Debug Support

The global PRCM module implements facilities to support debug across power and clock domain cycles. The debugger can control or get the status of each power and clock domain associated with an ICEPick secondary TAP.

ICEPick provides a set of directives allowing the debugger to:

- Get visibility on the associated power and clock domains state. This includes:
 - Current power setting indicating whether the power domain is on or off
 - Loss of power detected since software last checked the status
 - Current clock setting indicating whether the clock domain is on or off
 - Sleep desired (PM and CM indicate that the debug settings in ICEPick are changing the application state. If it were not for the ICEPick controls, the power or clock would be turned off.)
 - Subsystem reset state
 - Subsystem has entered a debug state that requires the attention of the host debug software.
- Override power/clock control settings to wake up a power or clock domain or to prevent a power or clock domain from going to sleep once it is in ACTIVE state
- Assert/block/extend reset; release from extended reset (WIR)

ICEPick handles debug power management at the device level. In addition, the device implements a second level of debug power management through the DAP-PC module integrated in the Cortex-A9 MPU subsystem, which provides the same capabilities as ICEPick for the two Cortex-A9 CPUs. Each Cortex-A9 CPU core is in its own independent power domain, which DAP-PC manages. The hierarchical debug power-management approach provided by DAP-PC at the subsystem level and by ICEPick at the device level ensures a theoretically independent debug capability for each Cortex-A9 CPU core.

NOTE: The debugger must properly sequence global ICEPick and local DAP-PC commands:

- To force clocks/power:
 1. The debugger must first force it for the Cortex-A9 MPU subsystem at the ICEPick level.
 2. The debugger must then force it for a specific Cortex-A9 CPU at the DAP-PC level.
 - To release clocks/power:
 1. The debugger must first release it for a specific Cortex-A9 CPU at the DAP-PC level.
 2. The debugger must then release the Cortex-A9 MPU subsystem controls at the ICEPick level.
-

29.6 Performance Monitoring

29.6.1 Cortex-A9 MPU Subsystem Performance Monitoring

29.6.1.1 Performance Monitoring Unit

The Cortex-A9 processor includes a PMU that enables events, such as cache misses and instructions executed, to be counted over a period of time. The PMU provides six counters to gather statistics about the operation of the processor and memory system. Each counter can count any of the events available in Cortex-A9. Upon counter overflow, PMU can generate an interrupt on its PMUIRQ output. This interrupt signal is mapped to the CTI TRIGIN[1] input and routed to a Cortex-A9 MPU interrupt controller input (MA_IRQ_54 for Cortex-A9 CPU0 PMU; MA_IRQ_55 for Cortex-A9 CPU1 PMU).

The Cortex-A9 PMU outputs 52 events (PMUEVENT[51:0]) to PTM (see [Table 29-13](#)).

Table 29-13. PMU Events

| PMU Event | Description |
|-----------|---|
| 0 | Software increment |
| 1 | Instruction fetch that causes a refill |
| 2 | Instruction fetch that causes a TLB refill |
| 3 | Data read or write operation that causes a refill |
| 4 | Data read or write operation that causes a cache access |
| 5 | Data read or write operation that causes a TLB refill |
| 6 | Data read architecturally executed |
| 7 | Data write architecturally executed |
| 8, 9 | Number of instructions renamed: b00 = No instructions renamed b01 = One instruction renamed b10 = Two instructions renamed |
| 10 | Exception taken |
| 11 | Exception return architecturally executed |
| 12 | Change to context ID retired |
| 13 | Software change of PC |
| 14 | Immediate branch architecturally executed |
| 15 | Number of predictable function returns |
| 16 | Unaligned access architecturally executed |
| 17 | Branch mispredicted or not predicted |
| 18 | Branches or other change in program flow |
| 19 | Java byte code executed |
| 20 | Software Java byte code executed |
| 21 | Jazelle® backward branches executed |
| 22 | Coherent line fill request that misses in other uniprocessors |
| 23 | Request for coherent line fill that hits in other uniprocessors |
| 24 | Instruction cache dependent stalls |
| 25 | Data cache dependent stalls |
| 26 | TLB miss dependent stalls |
| 27 | STREX passed |
| 28 | STREX failed |
| 29 | Data eviction |
| 30 | Issue does not dispatch any instruction. |
| 31 | Issue is empty. |
| 32 | Main execution unit pipe |
| 33 | Second execution unit pipe |

Table 29-13. PMU Events (continued)

| PMU Event | Description |
|-----------|--|
| 34 | Load/store pipe |
| 35, 36 | Number of floating-point instructions renamed: b00 = No floating-point instruction renamed b01 = One floating-point instruction renamed b10 = Two floating-point instructions renamed |
| 37, 38 | Number of NEON™ instructions renamed: b00 = No NEON instruction renamed b01 = One NEON instruction renamed b10 = Two NEON instructions renamed |
| 39 | PLD stall |
| 40 | Write stall |
| 41 | Instruction main TLB miss stall |
| 42 | Data main TLB miss stall |
| 43 | Instruction micro TLB miss stall |
| 44 | Data micro TLB miss stall |
| 45 | DMB stall |
| 46 | Integer core clock enabled |
| 47 | Data engine clock enabled |
| 48 | ISB |
| 49 | DSB |
| 50 | DMB |
| 51 | External interrupt |

For more information about Cortex-A9 PMU, see the *ARM Cortex-A9* technical reference manual.

29.6.1.2 Snoop Control Unit

The individual CPU event monitors can be configured to gather statistics about the operation of the snoop control unit (SCU).

29.6.1.3 L2 Cache (PL310)

The Cortex-A9 MPU subsystem includes 512KB of L2 cache and uses PL310 as the L2 cache controller. The PL310 includes logic to support cache event monitoring.

[Table 29-14](#) summarizes the PL310 L2 cache events.

Table 29-14. PL310 L2 Cache Events

| Event | Event Description |
|-------|--|
| 0 | Eviction of a line from the L2 cache |
| 1 | Data read hit in the L2 cache |
| 2 | Data read lookup to the L2 cache. Subsequently results in a hit or miss. |
| 3 | Data write hit in the L2 cache |
| 4 | Data write lookup to the L2 cache. Subsequently results in a hit or miss. |
| 5 | Data write lookup to the L2 cache with Write-Through attribute. Subsequently results in a hit or miss. |
| 6 | Instruction read hit in the L2 cache |
| 7 | Instruction read lookup to the L2 cache. Subsequently results in a hit or miss. |
| 8 | Prefetch line-fill sent to L3 |
| 9 | Allocation into the L2 cache caused by a write (with Write-Allocate attribute) miss |

The PL310 implements two 32-bit event counters. The PL310 can be configured to generate interrupts on error conditions or event counter overflow or increment. The PL310 interrupt is routed to MA_IRQ_0. When an interrupt occurs, software can look at the relevant interrupt status register to determine the source of the interrupt.

For more information about PL310, see the *ARM PrimeCell Level 2 Cache Controller (PL310) Technical Reference Manual*.

29.6.2 Cortex-M3 MPU Subsystem Performance Monitoring

29.6.2.1 Subsystem Counter Timer Module

The dual Cortex-M3 MPU subsystem includes a subsystem counter timer module (SCTM), which is embedded in shared cache and provides additional data to the user timing or profiling capability. The SCTM integrates eight profiling counters that collect:

- Forty-four shared cache events
- Four sleep/deep-sleep events from Cortex-M3 cores (one sleep and one deep-sleep event per core)

[Table 29-15](#) describes the repartition of the Cortex-M3 SCTM counters.

Table 29-15. Cortex-M3 SCTM Counters Repartition

| Counters | Features |
|----------|-------------------------------|
| 0, 1 | Timer and event |
| 2, 3 | 64-bit chained plus shadowing |
| 4, 5 | 64-bit chained plus shadowing |
| 6, 7 | Event |

29.6.2.2 Cache Events

[Table 29-16](#) summarizes the SCTM events for the Cortex-M3 MPU subsystem.

Table 29-16. SCTM Events for Cortex-M3 MPU Subsystem

| Input Index | Event Description |

29.6.3 DSP Subsystem Performance Monitoring

29.6.3.1 Subsystem Counter Timer Module

The DSP subsystem includes an SCTM, which is embedded in the DSP megamodule and provides additional data to the user timing or profiling capability. The SCTM integrates eight profiling counters that collect L1 and L2 events.

Table 29-15 describes the repartition of the DSP SCTM counters.

Table 29-17. DSP SCTM Counters Repartition

| Counters | Features |
|----------|---------------------|
| 0, 1 | Timer and event |
| 2–7 | Event (no chaining) |

29.6.3.2 L1 and L2 Events

Table 29-18 summarizes the SCTM events for the DSP subsystem.

Table 29-18. SCTM Events for DSP Subsystem

| Event | Event Description |
|-------|---|
| 1 | L1 Slave0 (program) tag hit |
| 2 | L1 Slave1 (data) tag hit |
| 3 | L1 Slave0 (program) tag miss |
| 4 | L1 Slave1 (data) tag miss |
| 5 | L1 Slave0 (program) fill buffer hit |
| 6 | L1 Slave1 (data) fill buffer hit |
| 7 | L1 Slave1 (data) write buffer access |
| 8 | L1 allocation FIFO |
| 9 | L1 Slave0 (program) bank conflict |
| 10 | L1 Slave1 (data) bank conflict |
| 11 | L1 Slave0 (program) cached request |
| 12 | L1 Slave1 (data) cached request |
| 13 | L1 Slave0 (program) waiting for fill buffer |
| 14 | L1 Slave1 (data) waiting for fill buffer |
| 15 | L1 Slave0 (program) waiting for maintenance |
| 16 | L1 Slave1 (data) waiting for maintenance |
| 17 | L1 eviction occurred |
| 18 | L1 replacement occurred |
| 19 | L1 allocation failed due to locked lines occurred |
| 20 | L2 tag hit |
| 21 | L2 tag miss |
| 22 | L2 fill buffer hit |
| 23 | L2 write buffer access |
| 24 | L2 allocation FIFO |
| 25 | L2 cached request |
| 26 | L2 waiting for fill buffer |
| 27 | L2 waiting for maintenance |
| 28 | L2 eviction occurred |
| 29 | L2 replacement occurred |
| 30 | L2 allocation failed due to locked lines occurred |
| 31 | Tied-off to 0 |

NOTE: Input index [0] is reserved for the free-running subsystem clock (used for total cycle profiling).

29.7 Processor Trace

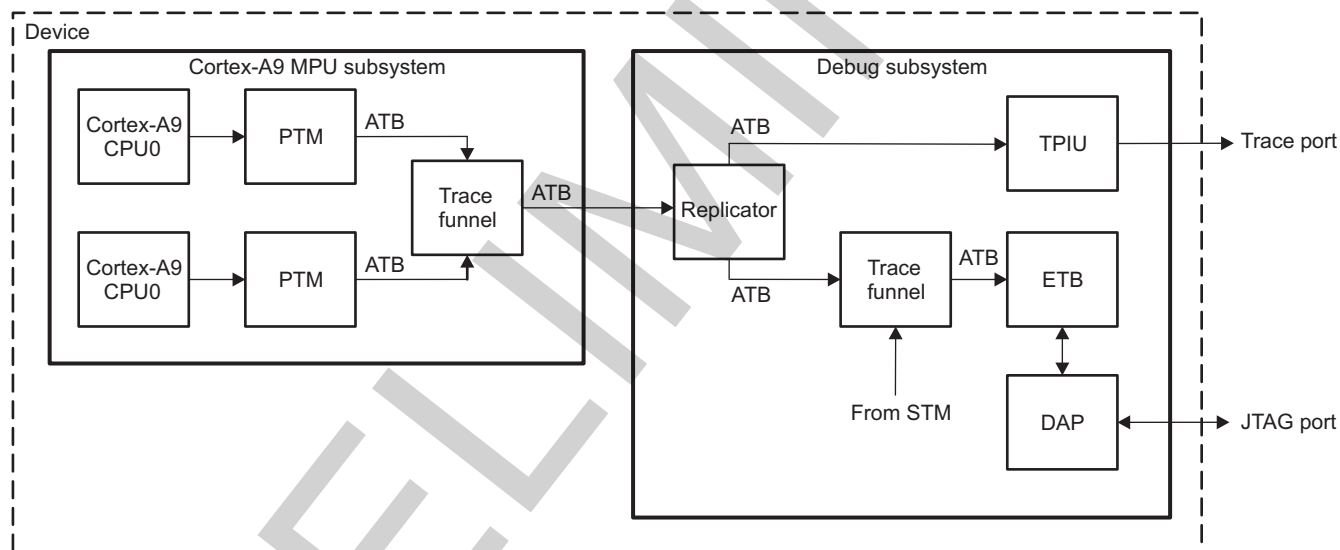

The device supports only Cortex-A9 processor trace. The main Cortex-A9 processor trace characteristics are:

- Program trace only (no data trace)
- Separate PTM for each Cortex-A9 CPU
- Trace can be:
 - Exported off-chip through TPIU in the debug subsystem (maximum number of trace data pins = 18)
 - Stored on-chip to ETB through CS-TF in the debug subsystem
- Trace can be optionally:
 - Cycle accurate useful for profiling sections of code
 - Interleaved dynamically between the two Cortex-A9 CPUs by a CS-TF embedded in the Cortex-A9 MPU subsystem

NOTE: Depending on use case, the device may not be able to interleave two cycle accurate traces without overflow (bandwidth restriction).

Figure 29-2 shows an overview of the processor trace flow.

Figure 29-2. Processor Trace Flow

debug-004

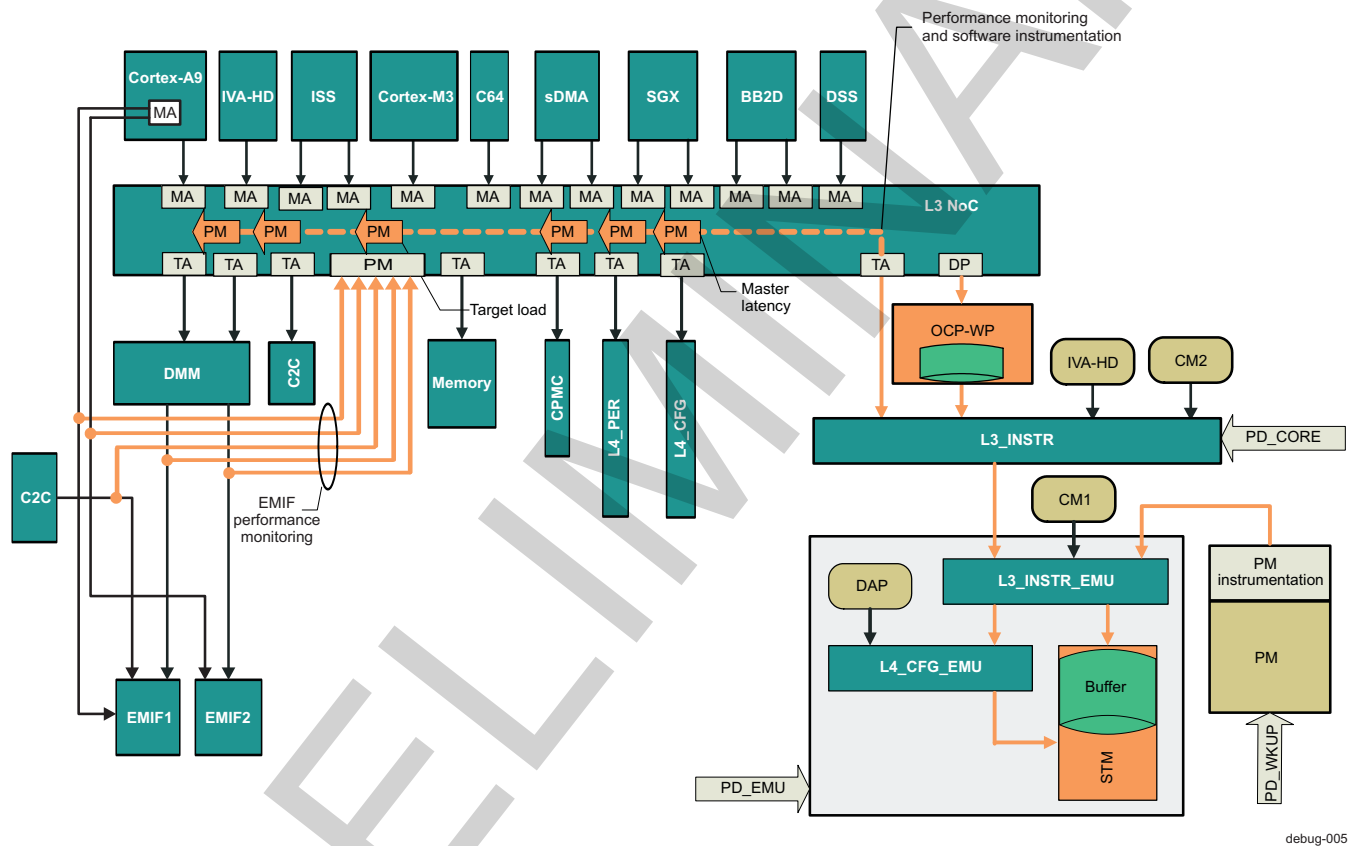

29.8 System Instrumentation

The device supports the following system instrumentation features:

- Real-time software trace (see [Section 29.8.2, Software Instrumentation](#))
- OCP target traffic monitoring (see [Section 29.8.3, OCP Watch-Point](#))
- OCP target load and master latency monitoring (see [Section 29.8.5, NoC Statistics Collector](#))
- HWA load monitoring (see [Section 29.8.4, IVA-HD Pipeline](#))
- PM events trace (see [Section 29.8.6, PM Instrumentation \[PMI\]](#))
- CM events trace (see [Section 29.8.7, CM Instrumentation \[CMI\]](#))

Figure 29-3 is an overview of the device system instrumentation framework.

Figure 29-3. System Instrumentation Framework

debug-005

29.8.1 MIPI STM

MIPI-STM is a trace module that aids in software debugging. The main features of this module are:

- Implements MIPI STP protocol (rev 1.0) with the following characteristics:
 - Highly optimized for software-generated traces
 - Automatic timestamping of messages
 - Support for 8-, 16-, and 32-bit data types
- Collects the following information:
 - Software messages
 - Hardware instrumentation trace from hardware agents:
 - OCP-WP
 - PMI

- CMI
- SMSET
- L3 NoC statistics collectors
- Exports trace data to:
 - External trace receiver
 - On-chip ETB buffer
- Available in 1-, 2-, or 4-pin mode with single- or dual-edge clock, depending on the trace bandwidth requirements and characteristics of the trace receiver
- Dedicated 128 × 32-bit FIFO buffer

A maximum of 255 different bus masters can be connected to the STM trace port through a bus arbiter. STP recognizes two distinct modes of tracing (software and hardware types), which use slightly different message combinations to output different types of data. The bus masters can be configured for either type to optimize the system for the different types of trace data.

29.8.2 Software Instrumentation

The device provides support for real-time software trace through user-defined message writes to specific memory mapped register (MMR) locations. Software masters can transmit trace data from the operating system (OS) processes or tasks on 256 different channels, with each channel being defined by the software protocol implemented. The different channels can be used to group different types of data logically so that it is easy to filter out the data irrelevant to the on-going debugging task. The message structures in STP are optimized to provide an efficient transport for software data through the STM module.

The software masters are:

- Cortex-A9 MPU subsystem
- DAP (for testing purpose)
- DSP subsystem
- Dual Cortex-M3 MPU subsystem
- sDMA controller write port (SDMA_WR)
- IVA-HD subsystem

Each software master has a master-ID assigned to it.

Software messages can be interleaved with other hardware messages.

Software messages are intrusive and use both processor cycles and memory.

29.8.3 OCP Watch-Point

The L3 interconnect provides five functional probes embedded and attached to the following L3 targets:

- GPMC
- L4-PER
- L4-CFG
- DMM1 (DMM target port 1)
- DMM2 (DMM target port 2)

The probes output are muxed together and then sent to the L3 interconnect debug port. A component called OCP-WP is used to collect data from functional probes and then transmit captured data to the STM module. The OCP-WP drives a Probe-ID signal to the L3 interconnect for probe selection. The probe selection is exclusive, meaning that interleaving is not possible.

The OCP-WP provides the following main features:

- Monitoring the OCP traffic originated by all initiators that can access the selected target where the probe is attached
- Filtering OCP monitored bus traffic by:

- Address range
- Initiator-ID (see [Table 29-20](#))
- Transaction type
- Transaction qualifier
- Generating a trigger upon watch-point match
- Starting and stopping OCP traffic monitoring upon:
 - WP address match
 - External trigger
- OCP-WP messages can be interleaved with software messages
- Programming from:
 - Debugger
 - Application

NOTE: The OCP-WP is restricted to monitor request flow.

[Table 29-19](#) summarizes the OCP targets that can be monitored by the OCP-WP and their respective probe-ID.

Table 29-19. L3 Interconnect Functional Probe Mapping

| Probe-ID | L3 OCP Target |
|----------|--------------------------|
| 000 | Reserved |
| 001 | GPMC |
| 010 | L4-PER |
| 011 | L4-CFG |
| 100 | DMM1 (DMM target port 1) |
| 101 | DMM2 (DMM target port 2) |
| 110 | Reserved |
| 111 | Reserved |

[Table 29-20](#) summarizes the ConnID (Initiator-ID) mapping from a debug point of view.

Table 29-20. ConnID Mapping (Debug View)

| ConnID | Initiator |
|--------|--|
| 0x0 | Cortex-A9 MPU subsystem |
| 0x4 | CS-DAP |
| 0x8 | DSP |
| 0xC | IVA-HD |
| 0xD | IVA-HD ICONT1 (software instrumentation) |
| 0xE | IVA-HD ICONT2 (software instrumentation) |
| 0x10 | ISS |
| 0x11 | Dual Cortex-M3 MPU subsystem |
| 0x12 | Face detect |
| 0x14 | sDMA_RD |
| 0x15 | sDMA_WR |
| 0x18 | SGX_M1 |
| 0x19 | SGX_M2 |
| 0x1A | BB2D_M1 |
| 0x1B | BB2D_M2 |
| 0x1C | Display subsystem |

Table 29-20. ConnID Mapping (Debug View) (continued)

| ConnID | Initiator |
|--------------|-----------|
| 0x20 | C2C |
| 0x24 | HSI |
| 0x28 | MMC1 |
| 0x29 | MMC2 |
| 0x30 | HSUSBHOST |
| 0x31 | HSUSBOTG |
| 0x32 | FSUSB |
| Other values | Reserved |

NOTE: For information about ConnID values from a protection/error logging point of view, see [Section 14.2.3.2.3](#), Master NIU Identification, in [Chapter 14](#), Interconnect,

29.8.4 IVA-HD Pipeline

The device takes advantage of the system trace infrastructure to provide visibility to the user regarding IVA-HD micro-task sequencing. This is supported through a SMSET module instantiated in the IVA-HD subsystem. The micro-task boundaries are handled as generic events and encapsulated in STP messages with an event-ID and local timestamp and exported through the MIPI-STM module.

The IVA-HD instrumentation scheme allows the user to understand micro-task dependencies, hardware accelerators load balancing, and potential bottlenecks. DMA transfer boundaries are reported as IVA-HD events. Software messages from ARM968 execution can be interleaved with IVA-HD events.

29.8.5 NoC Statistics Collector

The L3 interconnect supports a built-in performance monitoring feature by implementing a statistics collector (SC) component, which computes traffic statistics within a user-defined window and periodically reports to the user through the MIPI-STM interface. Three SC instances are instantiated in the device:

- One statistics collector dedicated to SDRAM load monitoring – SC_SDRAM (see [Section 29.8.5.1](#), *L3 Target Load Monitoring*, for more information)
- Two statistics collectors dedicated to master latency monitoring – SC_LAT0 and SC_LAT1 (see [Section 29.8.5.2](#), *L3 Master Latency Monitoring*, for more information)

Statistics collectors (SDRAM and LAT0/1) can report:

- Average burst length in bytes/packet per sampling window
- Average throughput in bytes/cycle
- % Link occupancy on the request link (for store transactions) during a sampling window
- % Link occupancy on the response link (for load transactions) during a sampling window
- % Arbitration conflict cycles on the request link
- % Initiator busy cycles on the response link
- Histogram of payload length in bytes (for example, 0–16, 16–32, 32–128) each sampling window.
- Histogram of quality of service (QoS) metric for IVA-HD initiator (for example, low priority, high priority) each sampling window.

The performance metrics are interleaved with software instrumentation data at the L3 interconnect level.

The performance monitoring probes implement three main functions:

- Events detection
- Transactions filtering
- Aggregation

The probes can be configured to detect the events summarized in [Table 29-21](#).

Table 29-21. Performance Monitoring Events Detection

| Event | Definition |
|----------|--|
| NONE | No event selected |
| ANY | Any clock cycles |
| TRANSFER | Word has been accepted by the receiver. |
| WAIT | Transfer has been initiated but the transmitter currently has no data to send. |
| BUSY | Receiver applies flow control |
| PKT | Transfer of a new packet header |
| DATA | Transfer of a payload word |
| IDLES | No communication over the link |
| LATENCY | Debug bit detection |

The probes can be configured to filter the traffic based on the criteria summarized in [Table 29-22](#).

Table 29-22. Performance Filtering Options

| Probe Filtering Options | Comment |
|------------------------------|----------------|
| Master address | Mask and match |
| Slave address ⁽¹⁾ | |
| UserInfo | |
| Read | |
| Write | |
| Error | |
| OCP address ⁽²⁾ | |

⁽¹⁾ SC_LAT0/1 only

⁽²⁾ SC_SDRAM only

The probes implement a user-defined set of counters that aggregate the events sampled by the detector and filtered according to the user setup.

NOTE: Statistics collectors counter values are not accessible by application software.

[Table 29-23](#) summarizes the performance probe aggregation modes.

Table 29-23. Aggregation Modes

| Aggregation Mode | Description |
|------------------|---|
| FILTER_HIT | The counter increments by 1 when the filter hits. |
| MIN_MAX_HIT | The counter increments by 1 when the filter hits and the selected event information is within range. - Payload length (bytes) - Pressure value - Request/response latency (clock cycles) |
| EVT_INFO | The selected event information is added to the counter value when the filter hits. Payload length (bytes) Pressure value Request/response latency (clock cycles) |
| AND_FILTER | The counter increments by 1 when all unit filters hit. |
| OR_FILTER | The counter increments by 1 when at least one unit filter hits. |
| SUM_REQ_EVT | The counter sums the events from any request port. |
| SUM_RSP_EVT | The counter sums the events from any response port. |
| SUM_ALL_EVT | The counter sums the events from any port. |
| EXT_EVT | The counter increments by 1 when selected external event input signal is sampled high. |

29.8.5.1 L3 Target Load Monitoring

The L3 interconnect implements five performance monitoring probes on LPDDR2 memory channels. The traffic statistics are computed within a user-defined window and periodically reported to the user through the MIPI-STM interface.

SC_SDRAM supports the following main features:

- Five probe inputs
 - Probe 0 – EMIF1 (DMM-EMIF1 128-bit port)
 - Probe 1 – EMIF2 (DMM-EMIF2 128-bit port)
 - Probe 2 – Memory Adapter 1 (MA-EMIF1 128-bit port)
 - Probe 3 – Memory Adapter 2 (MA-EMIF2 128-bit port)
 - Probe 4 – EMIF modem (C2C-EMIF1 64-bit port)
- Eight 32-bit counters shared concurrently
 - Counter 0 with two filters
 - Counter 1 with one filter
 - Counter 2 with two filters
 - Counter 3 with one filter
 - Counter 4 with one filter
 - Counter 5 with one filter
 - Counter 6 with one filter
 - Counter 7 with one filter
- Simple (with one element) or complex (with several elements) filters available
- Filtering according to:
 - Initiator of traffic
 - Access priorities
 - OCP address
- No latency counter. Only bandwidth measurement on this collector
- 32-bit collecting window counter
- Dump Identifier is 0x0 (tie-off value)
- Dumps frames at L3 interconnect slave address 0x19 (debug subsystem)

[Table 29-24](#) summarizes the SC_SDRAM configuration.

Table 29-24. SC_SDRAM Configuration

| Counters | Min Max | Filter Elements | L3 Target | | | | |
|-----------|------------|-----------------|-----------|-------|-----|-----|------------|
| Counter 0 | Yes | 2 | EMIF1 | EMIF2 | MA1 | MA2 | EMIF modem |
| Counter 1 | Yes | 1 | EMIF1 | EMIF2 | MA1 | MA2 | EMIF modem |
| Counter 2 | Yes | 2 | EMIF1 | EMIF2 | MA1 | MA2 | EMIF modem |
| Counter 3 | Yes | 1 | EMIF1 | EMIF2 | MA1 | MA2 | EMIF modem |
| Counter 4 | Yes | 1 | EMIF1 | EMIF2 | MA1 | MA2 | EMIF modem |
| Counter 5 | Yes | 1 | EMIF1 | EMIF2 | MA1 | MA2 | EMIF modem |
| Counter 6 | Yes | 1 | No | No | MA1 | MA2 | EMIF modem |
| Counter 7 | Yes | 1 | No | No | MA1 | MA2 | EMIF modem |

29.8.5.2 L3 Master Latency Monitoring

The device L3 interconnect implements twelve performance monitoring probes on the main L3 initiators:

- Cortex-A9 MPU subsystem

- DSP
- sDMA controller read port (SDMA_RD)
- sDMA controller write port (SDMA_WR)
- IVA-HD
- DSS
- ISS
- SGX master port 1 (SGX_M1)
- SGX master port 2 (SGX_M2)
- BB2D master port 1 (BB2D_M1)
- BB2D master port 2 (BB2D_M2)
- Dual Cortex-M3 MPU subsystem

The master latency statistics are computed within a user-defined window and periodically reported to the user through the MIPI-STM interface.

The probes can be configured to filter latencies in four classes and report to the user a latency distribution along execution.

Because the performance metrics and the software events are exported through a unified export channel, it is possible to correlate latency trends with on-going execution and system context.

Because computing latency requires maintaining the state between request and response ports, the probe cannot compute latency statistics on 100 percent of the initiator traffic. Hence, latency histograms must be extracted on large execution windows to be accurate.

29.8.5.2.1 SC_LAT0 Configuration

SC_LAT0 supports the following main features:

- Eight probe inputs:
 - Probe 0: Cortex-A9 MPU subsystem
 - Probe 1: DSP subsystem
 - Probe 2: SDMA_RD
 - Probe 3: SDMA_WR
 - Probe 4: DSS
 - Probe 5: ISS
 - Probe 6: SGX_M1
 - Probe 7: BB2D_M1
- Four 32-bit counters shared concurrently:
 - Counter 0 with one filter
 - Counter 1 with one filter
 - Counter 2 with one filter
 - Counter 3 with one filter
- Filtering according to:
 - L3 target
 - Access priorities
- 10-bit counter for latency measurement
- 32-bit collecting window counter
- Identifier is 0x1 (tie-off value)
- Dumps frames at slave address 0x19 (DEBUGSS)

Table 29-25 summarizes the SC_LAT0 configuration.

Table 29-25. SC_LAT0 Configuration

| Counters | Min Max | Filter Elements | L3 Master | | | | | | | |
|-----------|------------|--------------------|-------------------------------|-----|---------|---------|-----|-----|--------|---------|
| | | | Cortex-A9 MPU subsystem | DSP | SDMA_RD | SDMA_WR | DSS | ISS | SGX_M1 | BB2D_M1 |
| Counter 0 | Yes | 1 | Cortex-A9 MPU subsystem | DSP | SDMA_RD | SDMA_WR | DSS | ISS | SGX_M1 | BB2D_M1 |
| Counter 1 | Yes | 1 | Cortex-A9 MPU subsystem | DSP | SDMA_RD | SDMA_WR | DSS | ISS | SGX_M1 | BB2D_M1 |
| Counter 2 | Yes | 1 | Cortex-A9 MPU subsystem | DSP | SDMA_RD | SDMA_WR | DSS | ISS | SGX_M1 | BB2D_M1 |
| Counter 3 | Yes | 1 | Cortex-A9 MPU subsystem | DSP | SDMA_RD | SDMA_WR | DSS | ISS | SGX_M1 | BB2D_M1 |

29.8.5.2.2 SC_LAT1 Configuration

SC_LAT1 supports the following main features:

- Six probe inputs:
 - Probe 0: IVA-HD
 - Probe 1: Cortex-A9 MPU subsystem
 - Probe 2: SDMA_WR
 - Probe 3: SGX_M2
 - Probe 4: Dual Cortex-M3 MPU subsystem
 - Probe 5: BB2D_M2
- Four 32-bit counters shared concurrently:
 - Counter 0 with one filter
 - Counter 1 with one filter
 - Counter 2 with one filter
 - Counter 3 with one filter
- Filtering according to:
 - L3 target
 - Access priorities
- 10-bit counter for latency measurement
- 32-bit collecting window counter
- Identifier is 0x2 (tie-off value)
- Dumps frames at slave address 0x19 (DEBUGSS)

Table 29-26 summarizes the SC_LAT1 configuration.

Table 29-26. SC_LAT1 Configuration

| Counters | Min Max | Filter Elements | L3 Master | | | | | | | |
|-----------|------------|--------------------|-----------|----------------------------|---------|--------|---------------------------------|---------|--|--|
| | | | IVA-HD | Cortex-A9 MPU subsystem | SDMA_WR | SGX_M2 | Dual Cortex-M3 MPU subsystem | BB2D_M2 | | |
| Counter 0 | Yes | 1 | IVA-HD | Cortex-A9 MPU subsystem | SDMA_WR | SGX_M2 | Dual Cortex-M3 MPU subsystem | BB2D_M2 | | |
| Counter 1 | Yes | 1 | IVA-HD | Cortex-A9 MPU subsystem | SDMA_WR | SGX_M2 | Dual Cortex-M3 MPU subsystem | BB2D_M2 | | |
| Counter 2 | Yes | 1 | IVA-HD | Cortex-A9 MPU subsystem | SDMA_WR | SGX_M2 | Dual Cortex-M3 MPU subsystem | BB2D_M2 | | |
| Counter 3 | Yes | 1 | IVA-HD | Cortex-A9 MPU subsystem | SDMA_WR | SGX_M2 | Dual Cortex-M3 MPU subsystem | BB2D_M2 | | |

29.8.5.3 Statistics Collector Alarm Mode

Statistic collectors can be used to provide the application software with information about the NoC or SDRAM reaching corner cases (for example, too much traffic for a given OPP) while in application mode where for an end product use case the debug subsystem (which is normally exporting the statistic frames) is off. An interrupt-based scheme using a dedicated signal (L3_STAT_ALARM_IRQ) is implemented to avoid CPU polling periodically statistic registers. This interrupt alert is mapped to the MPU_IRQ_16 interrupt line and is fired when a given metric is out of specified range (below the programmed MIN threshold or above the programmed MAX threshold).

NOTE: NTPP statistic collectors (SC_LAT0/1) support latency measurement. However, comparison cannot be done on the latency counter. In case of latency measurement the comparison has to be done on number of latencies in user defined range, not on the latency value itself.

29.8.5.4 Statistics Collector Suspend Mode

The statistics collector module implements a suspend input that is used to avoid statistics collector counters to be updated while the processor has entered the debug state. This avoids triggering false alerts upon execution resume. When the statistics collector is asserted to 1, it freezes the monitoring process. When it goes back to 0, the monitoring resumes.

NOTE: If a frame is being dumped, it will not be stopped by suspend.

Each statistic collector has an ignore suspend register, which can be used to disable the suspend feature.

29.8.6 PM Instrumentation (PMI)

The device takes advantage of the system trace infrastructure to provide visibility to the user about the major power management events. This is supported through a PMI module (PM profiler) instantiated in the PRM module. The PRM state changes are handled as generic events and encapsulated in STP hardware messages and exported through the MIPI-STM module. The nature of the PM events does not require accurate timestamping and thus, timestamping is handled at STM or trace receiver level.

The PM events are organized by class. Any PM state change from a specific class refreshes the entire instrumentation frame associated with that class. The STP message structure includes a PM event-ID indicating the class of the PM events.

The PM event classes supported are:

- Logic voltage domain OPP change
- Memory voltage domain OPP change
- Logic power domain state change
- Memory power domain state change

The PMI has a unique hardware master-ID assigned to it.

The PMI supports the possibility to report on activity in different event classes in the same sampling window. The user has the flexibility to size the capture sampling window.

Software events from the PM routines instrumentation can be interleaved with the PM hardware events. The user can take advantage of that feature to understand latencies for a specific power-management scenario or strategy.

29.8.7 CM Instrumentation (CMI)

The device instantiates two CMI modules (CM profilers), one in CM1 (CMI1), and one in CM2 (CMI2). The CMI1 and CMI2 modules are instantiations of the same debug-IP and can operate concurrently. Each of them has a separate unique hardware master-ID assigned to it.

The CM events profiling is similar to the PM instrumentation. Two exclusive instrumentation modes are supported:

- Clock activity:
 - Exposes to the user a snapshot of the state of all the clock domains derived from the same DPLL when CM detects a state change in the clock domain
 - Exposes to the user a snapshot of the DPLL settings when the CM signals a DPLL programming
- Module activity:
 - Exposes to the user periodically the active cycles count of the target modules
 - Exposes to the user periodically the active cycles count of the initiator modules

It provides visibility to the user about the state of the major clock domains along the application code execution. The STP message reports the effective state of the clock domain and therefore can highlight scenarios where a particular dependency is preventing the clock domain from being switched off.

The CM event classes supported are:

- Events capture mode – four classes:
 - Clock domain state
 - DPLL settings update
 - Clock frequency divider ratio
 - Clock source selection update
- Module activity collection mode – two classes:
 - Target module activity
 - Initiator module activity

When in events capture mode, the CMI supports the possibility of reporting on activity in different event classes in the same sampling window. The user has the flexibility to size the capture sampling window.

29.9 Concurrent Debug Modes

The debugger or application software can program the DRM to route a specific debug function to each device debug port pin.

Because of the limited number of pins allocated to debug, debug and trace source signals are multiplexed.

Table 29-27 summarizes the trace port configuration.

Table 29-27. Trace Port Configuration

| Pin Name | Internal Signal Name | I/O | Trigger | JTAG 20-Pin Header | TPIU PTM (ARM Trace) | | STM (System Trace) | | |
|-----------|----------------------|-----|-----------|--------------------|----------------------|---------------|--------------------|-------------|-------------|
| | | | | | 16-Bit Mode | 18-Bit Mode | Option 1 | Option 2 | Option 3 |
| dpm_emu19 | EMU19 | O | | EMU4 | TRACEDATA[15] | TRACEDATA[17] | | STM_CLK | |
| dpm_emu18 | EMU18 | O | | EMU3 | TRACEDATA[14] | TRACEDATA[16] | | STM_DATA[0] | |
| dpm_emu17 | EMU17 | O | | EMU2 | TRACEDATA[13] | TRACEDATA[15] | | STM_DATA[1] | |
| dpm_emu16 | EMU16 | O | | | TRACEDATA[12] | TRACEDATA[14] | | STM_DATA[2] | |
| dpm_emu15 | EMU15 | O | | | TRACEDATA[11] | TRACEDATA[13] | | STM_DATA[3] | |
| dpm_emu14 | EMU14 | O | | | TRACEDATA[10] | TRACEDATA[12] | | UART1_RX | |
| dpm_emu13 | EMU13 | O | | | TRACEDATA[9] | TRACEDATA[11] | | | |
| dpm_emu12 | EMU12 | O | | | TRACEDATA[8] | TRACEDATA[10] | | | |
| dpm_emu11 | EMU11 | O | | | TRACEDATA[7] | TRACEDATA[9] | | | |
| dpm_emu10 | EMU10 | O | | | TRACEDATA[6] | TRACEDATA[8] | | | |
| dpm_emu9 | EMU9 | O | | | TRACEDATA[5] | TRACEDATA[7] | | | |
| dpm_emu8 | EMU8 | O | | | TRACEDATA[4] | TRACEDATA[6] | | | |
| dpm_emu7 | EMU7 | O | | | TRACEDATA[3] | TRACEDATA[5] | | | |
| dpm_emu6 | EMU6 | O | | | TRACEDATA[2] | TRACEDATA[4] | | | |
| dpm_emu5 | EMU5 | O | | | TRACEDATA[1] | TRACEDATA[3] | | | |
| dpm_emu4 | EMU4 | O | | | TRACEDATA[0] | TRACEDATA[2] | STM_DATA[3] | | |
| dpm_emu3 | EMU3 | O | | | TRACECTL | TRACECTL | STM_DATA[2] | | |
| dpm_emu2 | EMU2 | O | | | TRACECLK | TRACECLK | STM_CLK | | |
| dpm_emu1 | EMU1 | I/O | Trigger 1 | EMU1 | | TRACEDATA[1] | STM_DATA[1] | | STM_CLK |
| dpm_emu0 | EMU0 | I/O | Trigger 0 | EMU0 | | TRACEDATA[0] | STM_DATA[0] | | STM_DATA[0] |

NOTE: The configuration of the trace port must comply with Table 29-27; otherwise, it will be ignored by DRM hardware. For example, if Trigger0 is programmed on EMU10 and Trigger1 is programmed on EMU11, this configuration will be ignored.

Table 29-28 summarizes the concurrent debug and trace in the device.

Table 29-28. Concurrent Debug and Trace

| Debug Use Case | Concurrent Debug Flows | Debug Pins | Trace Pins | | |
|----------------|------------------------|------------|------------|---------|-------|
| | | Triggers | Data | Control | Clock |
| 0 | PTM | | 18 | 1 | 1 |
| | STM | | | | |
| | Triggers | | | | |
| 1 | PTM | | 16 | 1 | 1 |
| | STM | | | | |
| | Triggers | 2 | | | |
| 2 | PTM | | 16 | 1 | 1 |
| | STM | | 1 | – | 1 |
| | Triggers | | | | |
| 3 | PTM | | 8 | 1 | 1 |
| | STM | | 4 | – | 1 |
| | Triggers | 2 | | | |
| 4 | PTM | | 11 | 1 | 1 |
| | STM | | 4 | – | 1 |
| | Triggers | 2 | | | |

29.10 Memory Mapping

Table 29-29 summarizes the memory mapping of the debug modules.

Table 29-29. Debug Modules Memory Mapping

| Memory Space | Module Name | Start Address (hex) | End Address (hex) | Size |
|---------------------------------------|---|---------------------|-------------------|-------|
| L3_EMU | MIPI-STIM (256 × 4K channels) (address space 0) | 0x5400 0000 | 0x540F FFFF | 1MB |
| | MIPI-STIM (256 × 1K channels) (address space 1) | 0x5410 0000 | 0x5413 FFFF | 256KB |
| | Cortex-A9 CPU0 debug/PMU | 0x5414 0000 | 0x5414 1FFF | 8KB |
| | Cortex-A9 CPU1 debug/PMU | 0x5414 2000 | 0x5414 3FFF | 8KB |
| | CTI0 component | 0x5414 8000 | 0x5414 8FFF | 4KB |
| | CTI1 component | 0x5414 9000 | 0x5414 9FFF | 4KB |
| | PTM0 component | 0x5414 C000 | 0x5414 CFFF | 4KB |
| | PTM1 component | 0x5414 D000 | 0x5414 DFFF | 4KB |
| | CS-TF ⁽¹⁾ | 0x5415 8000 | 0x5415 8FFF | 4KB |
| | DAP-PC | 0x5415 9000 | 0x5415 9FFF | 4KB |
| | DRM | 0x5416 0000 | 0x5416 0FFF | 4KB |
| | MIPI-STIM | 0x5416 1000 | 0x5416 1FFF | 4KB |
| | CS-ETB | 0x5416 2000 | 0x5416 2FFF | 4KB |
| | CS-TPIU | 0x5416 3000 | 0x5416 3FFF | 4KB |
| | CS-TF ⁽²⁾ | 0x5416 4000 | 0x5416 4FFF | 4KB |
| L4_CFG | CMI1 | 0x4A00 4F00 | 0x4A00 4FFF | 256B |
| | CMI2 | 0x4A00 9F00 | 0x4A00 9FFF | 256B |
| | OCP-WP | 0x4A10 2000 | 0x4A10 2FFF | 4KB |
| L4_WKUP | PMI | 0x4A30 7F00 | 0x4A30 7FFF | 256B |
| IVA-HD configuration | ICECrusher-9 (ICONT1) | 0x5A04 0000 | 0x5A04 07FF | 2KB |
| | ICECrusher-9 (ICONT2) | 0x5A04 0800 | 0x5A04 0FFF | 2KB |
| | SMSET | 0x5A04 1000 | 0x5A04 1FFF | 4KB |
| L3 configuration | SC_SDRAM | 0x4500 0400 | 0x4500 05FF | 512B |
| | SC_LAT0 | 0x4500 0600 | 0x4500 07FF | 512B |
| | SC_LAT1 | 0x4500 0800 | 0x4500 09FF | 512B |
| DSP configuration | SCTM | 0x01C3 0400 | 0x01C3 05FF | 512B |
| Cortex-M3 MPU subsystem configuration | SCTM | 0x5508 0400 | 0x5508 07FF | 1KB |
| | ICECrusher-CS x 2 ⁽³⁾ | 0xE004 2000 | 0xE004 2FFF | 4KB |

(1) Embedded in Cortex-A9 MPU subsystem

(2) Embedded in debug subsystem

(3) Private memory access per Cortex-M3 core

Glossary

3

3D— Three Dimensional

3G— 3rd Generation of mobile communication systems

A

A/D— Analog to Digital Converter

ABB— Adaptive Body Bias

ABE— Audio Back End

ABEFW— Audio Back End Firewall

ACB— ac-bias frequency

ACBI— ac-bias line transitions per interrupt

ACE— ASIC Compiler Environment.

ACK— Acknowledge

ADC— Analog-to-Digital Converter/Conversion.

ADMA— Audio DMA

ADPLL— All Digital Phase Locked Loop. A closed loop frequency control system whose function is based on the phase-sensitive detection of the phase difference between the input signal and the output signal of the controlled oscillator (CO).

AE— Audio Engine. The AEES own processor.

AES— Advanced Encryption Standard

AEES— Audio Engine Subsystem

AEW— Auto Exposure and Auto White Balance

AF— Auto Focus

AFE— Analog Front End

AHB— Advanced High-performance Bus

ALE— Address Latch Enable

AMMU— Attribute Memory Management Unit

ANSI— American National Standards Institute

AP— Address Protection

APB— Advanced Peripheral Bus

APE— Application Engine

API— Application Programming Interface

AR— Automatic Reload

ARGB— Alpha Red Green Blue

ARM— Advanced RISC Machine

ASCII— American Standard Code for Information Interchange

ASIC— Application-Specific Integrated Circuit. A chip built for a particular application. In the context of this document, this refers to the FPGA that resides on the EVM board.

ASP— Application-Specific Peripheral

ATA— Interface standard for the connection of storage devices

ATB— AMBA Advanced Trace Bus

ATC— Audio Traffic Controller

AVDAC— Audio-Video DAC

AVS— Adaptive Voltage Scaling

AWB— Auto White Balance

B

B— Byte, 8 bits

BAYER— Bayer Filter mosaic. A color filter array (CFA) for arranging RGB color filters on a square grid of photosensors.

BB— Bus Busy

BCD— Binary-Coded Decimal.

BCH— Bose-Chaudhuri-Hocquenghem

BE— Big Endian.

BGA— Ball Grid Array

BGAP— Band Gap

BIOS— Built-In Operating System

BIST— Built-In Self-Test

BL— Buffer Logic

BOF— Beginning of Frame

BPP— Bits Per Pixel

BS— Block Synchronization

BSC— Boundary Scan Chain

BSMEM— Bit Stream Memory

BTA— Bus Turn Around

BTE— Burst Translation Engine

BW— Band Width

Bluetooth— A short-range radio technology aimed at simplifying communications among network devices and between devices and the Internet. It also aims to simplify data synchronization between network devices and other computers.

C

C2C— Chip-to-Chip

CABAC— Context-Adaptive Binary Arithmetic Coding

CALC3— Transform and Quantization Calculation Engine

CAS— Column Address Strobe

CAVLC— Context-Adaptive Variable Length Coder

CB— Copy Back

CBP— Coded Block Pattern

CBUFF— Circular Buffer

CCCR— Card Common Control Registers (SDIO)

CCP— Compact Camera Port

CDP— Coprocessor Data Operation

CDR— Clock Data Recovery

CE— Chip Enable

CEA-861-D— HDMI 1.3 video standard. It defines the video timing requirements, discovery structures, and data transfer structure.

CEC— Consumer Electronics Control

CFA— Color Filter Array

CH— Configuration Header. To use different settings than ROM Code defaults, that is, clock frequencies, SDRAM/DDRAM settings, GPMC settings if the customer wants.

CID— Card Identification Number

CIR— Consumer Infra Red

CLE— Command Latch Enable

CLK— Clock

CLUT— Color Look-Up Table

CM— Clock Management

CMEM— Coefficient Memory

CMOS— Complimentary Metal Oxide Semiconductor

CODEC— Coder/Decoder or Compression/Decompression. A device that codes in one direction of transmission and decodes in another direction of transmission.

CP15— Coprocessor 15. This coprocessor controls the operation and configuration of the TI925T.

CPR— Clock, Power, Reset

CPU— Central Processing Unit.

CRC— Cyclic Redundancy Check

CS— Chip-Select

CS-ETB— CoreSight Embedded Trace Buffer

CS-ETM— CoreSight Embedded Trace Macrocell

CS-TPIU— CoreSight Trace Port Interface Unit

CSI— Camera Serial Interface

CSW— Control Space Width

CSWR— Closed switch retention

CTM— Counter-Timer Module

CTRL— Control

CTS— Clear to Send

CVBS— Composite Video Broadcast Signal

ConnID— Connection Identifier. An Initiator Module Identifier. A ConnID is transmitted in-band with the request and is used for protection and error logging mechanism.

D

D2D— Die-to-Die

DAC— Digital to Analog Converter

DBB— Digital Baseband

DBI— Display Buffer Interface

DCD— Data Carrier Detect

DCO— Digitally Controlled Oscillator

DCS— Display Command Set

DCT— Discrete Cosine Transform.

DDC— Display Data Channel

DDMA— DSP Subsystem Direct Memory Access module

DDR— Double Data Rate

DE— Data Enable

DFF— Digital Flip-Flop

DFT— Design For Test

DI— Data In

DISPC— Display Controller

DL— Data Length

DLB— Data Loopback.

DLL— Delay-Locked Loop

DMA— Direct Memory Access.
DMC— Data Memory Controller
DMEM— Data Memory
DMIC— Digital Microphone Controller
DMM— Dynamic Memory Management
DNL— Differential nonlinearity. It describes the deviation between two analog values corresponding to adjacent input digital values for a DAC.
DO— Data Out
DPC— Defect Pixel Correction
DPCM— Differential Pulse Code Modulation
DPI— Display Parallel Interface
DPLL— Digital Phase-Locked Loop. Digital implementation of PLL.
DPS— Digital Power Switching
DRD— Dual-Role Device (a type of OTG USB device)
DRDY— Data Ready
DRM— Digital Rights Management
DRP— Digital Radio Processor
DSI— Display Serial Interface
DSP— Digital Signal Processor.
DSR— Data Set Ready
DSS— Display Sub-System. Also DISS
DT— Data Type
DTBC— Data Buffer Controller
DTCM— Data Tightly Coupled Memory
DTR— Data Transmit Ready
DVFS— Dynamic Voltage and Frequency Scaling
DVI— Digital Video Interface

E

EA— Enumeration Address
EAV— End of Active Video
ECC— Error Checking and Correction. Also Error Correction Code.
ECD3— Entropy Coder/Decoder
ED— Endpoint Descriptor
EFUSE— Electrical Fuse. A one-time programmable memory location usually set at the factory
EHCI— Enhanced Host Controller Interface

EMC— External Memory Controller
EMI— Electromagnetic interference
EMIF— External Memory Interface
EOB— End of Block
EOF— End of Frame
EOL— End of Line
EOT— End of Transfer
EPM— Emulation Pin Manager
ES— Erase Status
ETB— Embedded Trace Bus
ETM— Embedded Trace Macrocell

F

FAT— File Allocation Table
FCLK— Functional Clock
FCS— Frame Check Sequence
FD— Face Detect
FE— Framing Error.
FEC— Frame End Code
FF— Flip-Flop
FIFO— First In First Out.
FIQ— Fast Interrupt Request. See ISR.
FIR— Fast Infrared
FM— Frequency Modulate
FPS— Frame per Second
FROM— eFuse ROM
FS— Full-Speed
FSC— Frame Start Code. Also Frame Start Count.
FSM— Finite State Machine.
FSR— Fault Status Register
FV— Focus Value
FW— Firewall

G

GBC— Green Balance Correction
GDP— Generic Dot Product

GHB— Global History Buffer
GPIO— Genreal Purpose Input Output
GPMC— General Purpose Memory Controller

H

H.263— Video Codec Standart
H.264— Video Codec Standart
H/W— Hardware
HAL— Hardware Abstraction Layer
HBP— Horizontal Back Porch
HC— Host Controller
HD— High Definition
HDCP— High-bandwidth Digital Content Protection
HDMI— High-Definition Multimedia Interface
HDQ— Single-wire communication interface
HDTV— High-Definition Television
HFP— Horizontal Front Porch
HLOS— High-Level Operating System
HNP— Host Negotiation Protocol (OTG feature)
HPF— High-Pass Filter
HPI— Host Port Interface
HS— High-Speed
HSEC— Horizontal Sync End Code
HSI— High Speed Synchronous Serial Interface
HSSC— Horizontal Sync Start Code
HSSCLL— High-Speed Serial Control Channel
HSW— Horizontal Synchronization Pulse Width
HSYNC— Horizontal Synchronization.
HW— Hardware
HWA— Hardware Accelerators.
HWOBS— Hardware Observability
HWSEQ— Hardware Sequencer

I

I/F— Interface
I/O— Input/Output

I2C— Inter-Integrated Circuit.

I2S— Inter-IC Sound.

IA— Identifier Address

ICE— In-Circuit Emulation

ICEPICK— Generic TAP for emulation control

ICLK— Interface Clock

ICONT— Imaging Controller

ICR— Intersystem Communication Registers

ID— Identification

IDCT— Inverse Discrete Cosine Transform. See DCT.

ILF3— Improved Loop Filter engine

IM— Initiator Module. A module is an initiator whenever it is able to initiate read and write requests to the chip interconnect (typically: processors , DMA...).

IME3— Improved Motion Estimation engine

IMX— Image Extension coprocessor

INL— Integral Nonlinearity. It describes the maximum deviation between the ideal output of a DAC and the actual output level.

INT— Interrupt .

INTC— Interrupt Controller

IP— Intellectual Property

IPC— Interprocessor Communication. (also referred to as mailbox on occasion)

IPE3— Intra Prediction Estimation engine

IPIPE— Image Pipe

IPIPEIF— Image Pipe Interface

IQ— Inverse Quantization

IR— Incremental Redundancy Buffer

IRQ— Interrupt Request.

ISA— Instruction Set Architecture

ISIF— Image Sensor Interface

ISP— Image Signal Processor

ISR— Interrupt Service Routine.

ISS— Image SubSystem

IST— Interrupt Service Thread.

ITCM— Instruction Tightly Coupled Memory

IV— Initialization Vector

IVA— Image and Video Accelerator

IVA-HD— High Definition Image and Video Accelerator

IrDA— Infrared Data Association.

J

JEDEC— Joint Electronic Devices Engineering Council

JPEG— Joint Photographics Experts Group

JTAG— Joint Test Action Group.

K

KB— Kilobyte, 1024 B

KBD— Keyboard

Kbps— Kilobits per second

L

L1— Level 1 cache/memory

L2— Level 2 cache/memory

L3— First level of interconnect

L4— Second level of interconnect

LA— Logical Address

LAN— Local Area Network

LC— Logical Channel

LCD— Liquid Crystal Display.

LCM— Logical Channel to Memory

LCh— Logical DMA Channel. Also LCH

LDC— Load (from memory) to Coprocessor

LDC2— Lens Distortion Correction

LDM— Load Multiple

LDO— Low Dropout

LE— Little Endian.

LEC— Line End Code

LED— Light Emitting Diode.

LF— Loop Filter

LFB— Line-Fill-Buffer

LFN— Long File Name

LH— Local Host

LINK— Link Layer Device

LLP— Low-Level Protocol
LP— Low-Power, operation mode for PHY
LPCM— Linear Pulse Code Modulation
LPDDR— Low Power Double Data Rate
LPF— Loop Filter
LPM— Low-Power Mode
LPP— Lines Per Panel
LRB— Line-Read-Buffer
LS— Low-Speed
LSB— Least Significant Bit
LSC— Line Start Code
LSR— Linear Shift Register
LSW— Least Significant Word
LUT— Look-up Table

M

M2— Micro Memory
MAC— Message Authentication Code
MB— Megabyte, 1024 KB
MBAFF— MB-Level Adaptive Frame/Field
MBR— Master Boot Record
MC3— Motion Compensation Engine
MCSPi— Multichannel Serial Port Interface
MCU— Microcontroller Unit. Refers to the MPU.
ME— Motion Estimation
MEMIF— Memory Interface
MIF— Memory InterFace
MIPI— Mobile Industry Processor Interface
MIR— Medium Infrared
MJPEG— Motion JPEG
MMC— Multimedia Card
MMC/SD— Multimedia Card/SD
MMU— Memory Management Unit.
MP3— MPEG Layer 3.
MPEG— Motion Pictures Expert Group.

MPEG1— The first MPEG compression scheme specification.

MPU— Microprocessor Unit.

MS— Memory Stick

MSB— Most Significant Bit

MSGIF— Message Interface

Mb— Megabit

Mbps— Mega bits per second

McBSP— Multichannel Buffered Serial Port.

Modem— Modulator Demodulator

N

N/A— Not Applicable

NAC— Network Access Control

NAK— Not Acknowledged

NAND— NAND Flash memory.

NC— Not Connected

NIU— Network Interface Unit

NMI— Nonmaskable Interrupt. An interrupt that can be neither masked nor disabled.

NOP— No OPERATION (DSP/CPU instruction)

NOR— A type of flash memory

NRZI— Non-Return-to-Zero Inverted

NSF— Noise Filter

NTSC— National Television System Committee. Television broadcast system.

NVB— Number of Valid Bytes

NVIC— Nested Vectored Interrupt Controller

NVM— Non-volatile Memory

O

OCM— On-chip Memory

OCMC— On-chip Memory Controller

OCP— Open-Core Protocol

OCPI— Open-Core Protocol Interface

OE— Output Enable

OHCI— Open Host Controller Interface. This is an industry standard USB Host Controller Interface.

OMAP— Open Multimedia Application Platform

ON2— Video Codec Standart

OPP— Operating Performance Point
OS— Operating System
OSI— (OSI model) Open Systems Interconnection Basic Reference Model
OTG— On-The-Go (USB 2.0 specification)

P

PA— Program Address
PBIAS— PMOS Bias transistor to provide the bias voltage to extended drain IOs
PC— Program Counter
PCB— Printed Circuit Board
PCI— Peripheral Component Interconnect.
PCLK— Pixel Clock
PCM— Pulse Code Modulation.
PD— Program Data
PDA— Personal Digital Assistant
PDC— Power-down Controller
PDM— Pulse Density Modulation
PDU— Protocol Data Unit
PE— Parity Error
PF— Packet Footer
PFPW— Prefetch and Prewrite posting engine
PH— Packet Header
PHY— Physical Layer Device
PI— Pixel Interpolation
PID— Protocol Identifier. The PID register is used in Windows CE mode only.
PLL— Phase-Locked Loop.
PM— Programming Model
PMC— Program Memory Controller
PMEM— Program Memory
PMP— Power Management Port
POR— Power-On Reset
PPA— Primary Protected Application.
PPC— Palm-size PC
PPI— Physical Layer Protocol Interface
PPL— Pixels per Line

PRCM— Power, Reset, Clock Management module

PRM— Power and Reset manager

PS— Packet Start

PSC— Prescaler Counter

PSS— Program Suspend Status

PT— Packet Type

PTM— Program Trace Macrocell

PTV— Prescale Clock Timer Value. Sets the value of the divisor used in scaling the clock.

PU/PD— Pull-Up / Pull-Down

PWL— Pulse Width Light (modulator). A 4096-bit randomsequence generator that provides control of the LCD backlighting and keypad.

PWM— Pulse Width Modulation

PWR— Power

Q

QIQ— Quantization and Inverse Quantization

QMEM— Quantizer Memory

QMR— Quantizer Matrix

QVGA— Quarter Video Graphics Array. One-fourth the resolution of VGA.

R

R/W— Read/Write. Also RW.

R5— Release 5 of 3GPP specifications on IMS and HSDPA standards

R6— Release 6 of 3GPP specifications on Wireless LAN networks, HSUPA, MBMS and enhancements to IMS standards

RAM— Random Access Memory. A memory element that can be written to, as well as read.

RCA— Relative Card Address

RDR— Receive Data Register

RE— Read Enable

REQ— Request

RF— Radio Frequency

RFB— Remote Frame Buffer

RFBI— Remote Frame Buffer Interface

RFF— Retention Flip-Flop

RGB— Red Green Blue

RGBA— Red Green Blue Alpha

RI— Ring Indicator

RM— Reed-Muller code

RO— Read Only

ROM— Read Only Memory. A semiconductor storage element containing permanent data that cannot be changed.

RST— Reset

RT— Real-Time

RTA— Retention Till Access

RTC— Real-Time Clock. A clock that keeps track of the time even when the device is turned off.

RTL— Register Transfert Level

RTOS— Real-Time Operating System

RTS— Request to Send

RVLC— Reversible Variable Length Coder

RX— Receive/Receiver

RXD— Receive Data

S

S/PDIF— Sony/Philips Digital Interface

S/W— Software

SAM— Signal Amplitude Modulation

SAR— Save and Restore. Hardware context saving for power saving.

SAV— Start of Active Video

SB— Silicon Backplane (Trade Mark)

SBC— Stream Buffer Controller

SCCB— Serial Camera Control Interface. 3-wire and 2-wire serial bus defined and deployed by Omnivision Technologies, Inc.

SCL— Serial Clock. Programmable serial clock used in the I2C interface. Also SCLK.

SCM— System Control Module

SCP— Serial Configuration Port

SCR— SDIO Configuration Registers

SCRM— System Clock and Reset Manager

SCTM— System Counter Timer Module

SCU— Snoop Control Unit

SD— SD card. A non-volatile memory card.

SDA— Serial Data. Serial data bus in the I2C interface.

SDHC— SD High Capacity card

SDIO— SD Input/Output

SDMA— System Direct Memory Access module

SDP— Software Development Platform

SDR— Single Data Rate

SDRAM— Synchronous Dynamic Random Access Memory

SDRC— SDRAM Controller.

SE— Safe Environment. Execution environment inside a device, which is protected against tampering

SFL— Subframe Length

SGX— Accronym for Grafics Accelerator

SIM— Subscriber Identity Module

SIMCOP— Still image coprocessor

SIMD— Single Instruction-Stream, Multiple Data-Stream

SIR— Slow Infrared

SL2— Shared Level 2 (memory/interface)

SLM— Static Leakage Management

SLVS— Scalable Low Voltage Signaling

SMC— Shared Message Channel

SMEM— Sample Memory

SMI— Safe Monitor Interrupt

SMP— Symmetric Multiprocessor Platform

SMPS— Switch Mode Power Supply

SMSET— Software Message and System Event Trace module

SNR— Signal-to-Noise Ratio

SOC— System-On-a-Chip

SOF— Start Of Frame

SP— Serial Port or Small Page

SPI— Serial Port Interface. A signaling protocol for exchanging serial data.

SR— SmartReflex

SRAM— Static Random Access Memory

SRC— Sample Rate Conversion

SRG— Sample Rate Generator

SRP— Session Request Protocol (OTG feature)

SS— Subsystem

SSC— Spread Spectrum Clocking

SSI— Serial Synchronous Interface

ST— Start Timer

STC— Store from Coprocessor (to memory) or System Time Clock, which is the master clock in an MPEG-2 encoder or decoder system.

STM— Synchronous Transfer Mode or Store Multiple.

STN— Super-Twist Nematic. A technique for improving LCD display screens by twisting light rays.

SW— Software

SWI— Software Interrupt

SXGA— Super eXtended Graphics Array

SYSC— System Control Module

SmartReflex— Dynamic voltage sensing module that generates the voltage error signal proportional to the difference in desired voltage and the current voltage

T

TA— Target Agent

TAP— Test Access Port

TC— Traffic Controller. Allows asynchronous operation among the external memory interface, the MPU, and the DSP.

TCK— Test Clock

TCM— Tightly Coupled Memory

TD— Transfer Descriptor

TDI— Test Data Input

TDM— Time Division Multiplex/Multiplexing

TDO— Test Data Output

TFT— Thin Film Transistor. A type of LCD flat panel display screen in which each pixel is controlled by one to four transistors.

TI— Texas Instruments

TL— Transmission Line

TLB— Translation Lookaside Buffer. A cache that contains entries for virtual-to-physical address translation and access permission checking.

TLL— Transceiver Less Link. This is logic which allows the user to connect two USB transceiver interfaces together directly without the use of differential transceivers.

TM— Target Module. A target module cannot generate read/write requests to the chip interconnects, but respond to these requests. However it may generate interrupts or DMA request to the system (typically: peripherals, memory controllers).

TMDS— Transition Minimized Differential Signaling. A technology for transmitting high-speed serial data and is used by the DVI and HDMI video interfaces.

TMS— Test Mode Select

TOC— Table of Contents

TP— Tiny Page

TRM— Technical Reference Manual

TRST— Test Reset

TRX— USB Transceiver. The USB analog driver/receiver.

TSHUT— Temperature Shutdown.

TTB— Translation Table Base. It points to the base of a table in physical memory that contains section and page table descriptors.

TTH— Translation Table Hierarchy

TTL— Transistor Transistor Logic

TWL— Table Walking Logic

TX— Transmit/Transmitter

U

UART— Universal Asynchronous Receiver/Transmitter. Another name for the asynchronous serial port.

UE— Unrecoverable Error

UHS— Definition of SD cards with higher frequency

ULPI— UTMI+ Low Pin Interface (12-pin interface standard for connecting USB core logic to a USB transceiver)

ULPM— Ultralow-Power Mode

ULPS— Ultralow-Power State

UMC— Unified Memory Controller

USB— Universal Serial Bus. An external bus standard that supports data transfer rates of 12M bps (12 million bits per second). A single USB port can be used to connect up to 127 peripheral devices.

USSE— Universal Scalable Shader Engine

UTMI— USB 2.0 Transceiver Macrocell Interface

V

VA— Volt-Amps. A form of power management. A VA rating is the volts rating multiplied by the amps (current) rating, used to indicate the output capacity of an uninterruptible power supply (UPS) or other power source.

VBP— Vertical Back Porch

VC— Virtual Channel

VC-1— Video Codec Standart

VDMA— Video Direct Memory Access module

VENC— Video Encoder

VESA— Video Electronics Standards Association

VFP— Vertical Front Porch

VGA— Video Graphics Array. An industry standard for video cards.

VLC— Variable Length Decoder

VLCD— Variable Length Coding and Decoding coprocessor

VLCDJ— Variable-Length Coder/Decoder for JPEG

VLD— Variable Length Coder

VLIW— Very Long Instruction Word

VMODE— Bi-level voltage control interface

VP— Video Port

VRFB— Virtual Rotation Fixed Buffer

VS— Vertical Synchronization

VSEC— Vertical Sync End Code

VSSC— Vertical Sync Start Code

VSW— Vertical Synchronization Pulse Width

VSYN— Vertical Synchronization. A bidirectional vertical timing signal occurring once per frame with a pulse-width defined as an integral number of lines (half-lines for interlaced mode). Also VS.

W

WB— Write Buffer

WC— Word Count

WD— Watchdog. A timer that requires the user program or OS periodically write to the count register before the counter underflows.

WDT— Watchdog Timer

WE— Write Enable

WFI— Wait For Interrupt

WNP— Write Non-Posted

WP— Write Protect

WSS— Wide-Screen Signaling

WT— Write Through

WTBU— Wireless Terminal Business Unit

WUGEN— Wake-Up Generator

Word16— 16 bits word

X

XGA— eXtended Graphics Array. Also XVGA.

XIP— eXecution In Place

Y

YUV— Luminance-Bandwidth-Chrominance

e

eMMC— Embedded Multimedia Card

eSD— Embedded SD

PRELIMINARY

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
