(1) To ensure pad safe operation at 1.8 V or 3.0 V and desired signal performance, the corresponding extended-drain I/O cell and PBIAS cell must be appropriately configured by software prior to signal selection on the pad, regardless of the signal multiplexing mode. For more details on extended-drain I/O celsl and PBIAS cell descriptions and settings,see Section 19.4.9, *Extended-Drain I/O and PBIAS Cell*, and Section 19.5.1.2.1, *Extended-Drain I/Os and PBIAS Cells Programming Guide*.

3	SDMMC1_DAT5_ PULLUDENABLE	pullup/down enable for pad sdmmc1_dat5 0x0: pullup/down disabled 0x1: pullup/down enabled	RW	1

(1) To ensure pad safe operation at 1.8 V or 3.0 V and desired signal performance, the corresponding extended-drain I/O cell and PBIAS cell must be appropriately configured by software prior to signal selection on the pad, regardless of the signal multiplexing mode. For more details on extended-drain I/O celsl and PBIAS cell descriptions and settings,see Section 19.4.9, *Extended-Drain I/O and PBIAS Cell*, and Section 19.5.1.2.1, *Extended-Drain I/Os and PBIAS Cells Programming Guide*.

Mailbox

This chapter describes the Mailbox module in the device.

Topic **Page**

20.1 Mailbox Overview **4422**
20.2 Mailbox Integration **4424**
20.3 Mailbox Functional Description **4428**
20.4 Mailbox Programming Guide **4434**
20.5 Mailbox Register Manual **4437**

Copyright © 2011–2012, Texas Instruments Incorporated

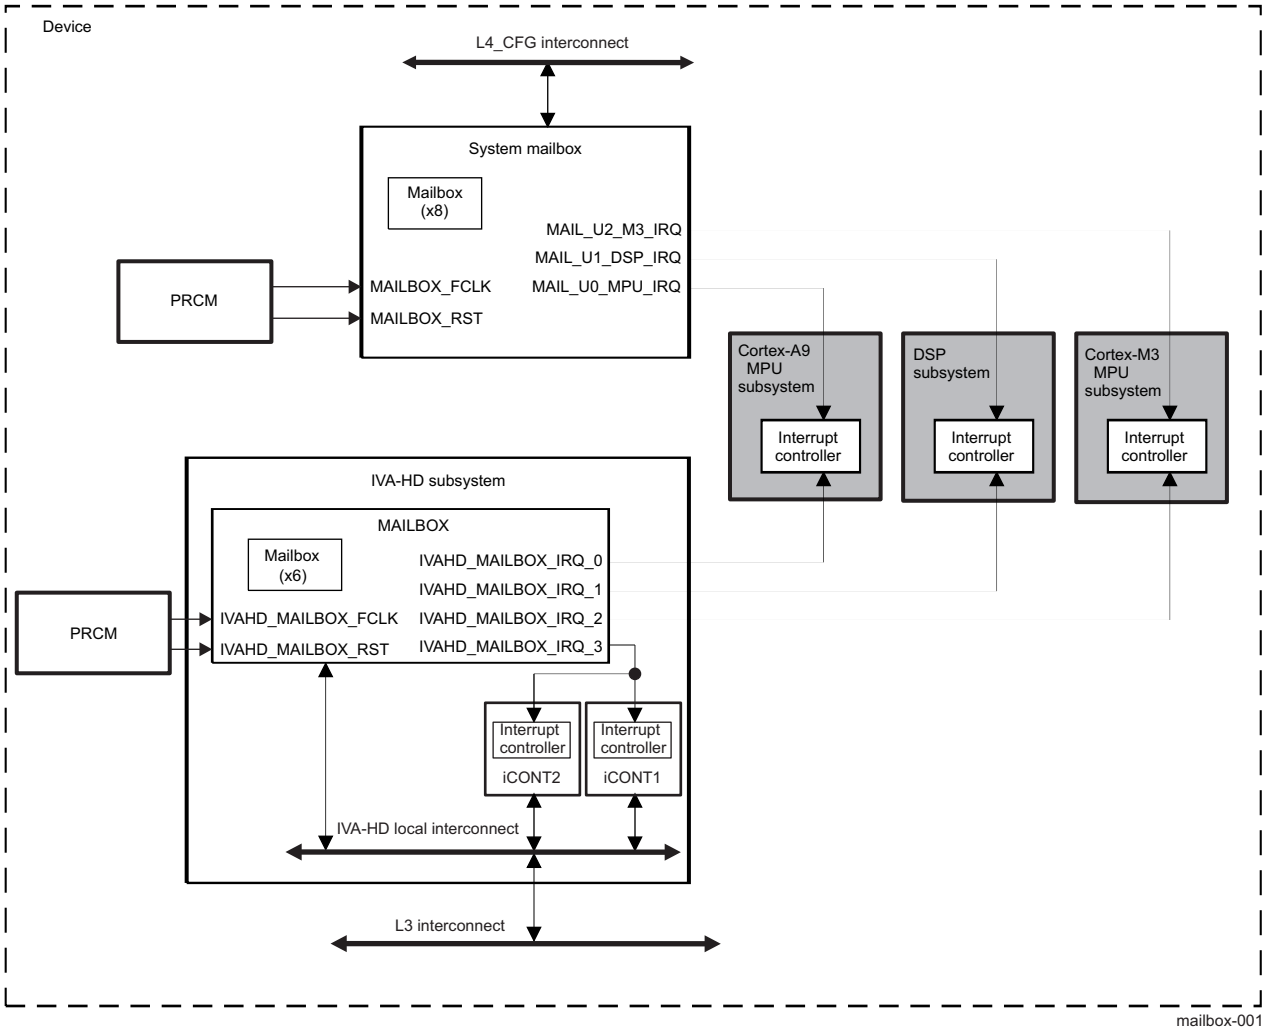
20.1 Mailbox Overview

Communication between the on-chip processors of the device uses a queued mailbox-interrupt mechanism.

The queued mailbox-interrupt mechanism allows the software to establish a communication channel between two processors through a set of registers and associated interrupt signals by sending and receiving messages (mailboxes).

Figure 20-1 shows an overview of the mailbox module.

Figure 20-1. Mailbox Overview



There are two mailbox module instances in the device:

- System mailbox - used for Cortex-A9 microprocessor unit (Cortex-A9 MPU), digital signal processor (DSP) and Cortex-M3 microprocessor unit (Cortex-M3 MPU) communications.
- IVA-HD mailbox - used for communication between one internal to the IVA-HD subsystem user (imaging controller 1 - iCONT1, or imaging controller 2 - iCONT2) and three external to the IVA-HD subsystem users (Cortex-A9 MPU, DSP and Cortex-M3 MPU). This communication is insured through three pairs of mailboxes.

The mailbox module includes the following features:

- Three users for the system mailbox instance (Cortex-A9 MPU, DSP and Cortex-M3 MPU)/four users for the IVA-HD mailbox instance (iCONT1/iCONT2, Cortex-A9 MPU, DSP and Cortex-M3 MPU)
- Eight mailbox message queues for the system mailbox instance/six mailbox message queues for the

Copyright © 2011–2012, Texas Instruments Incorporated

IVA-HD mailbox instance

- Flexible assignment of receiver and sender for each mailbox through interrupt configuration
- Three interrupts (one per user) for the system mailbox instance/four interrupts (one per user) for the IVA-HD mailbox instance
- 32-bit message width
- Four-message FIFO depth for each message queue
- Message reception and queue-not-full notification using interrupts
- Support of 16-/32-bit addressing scheme
- Power management support

Copyright © 2011–2012, Texas Instruments Incorporated

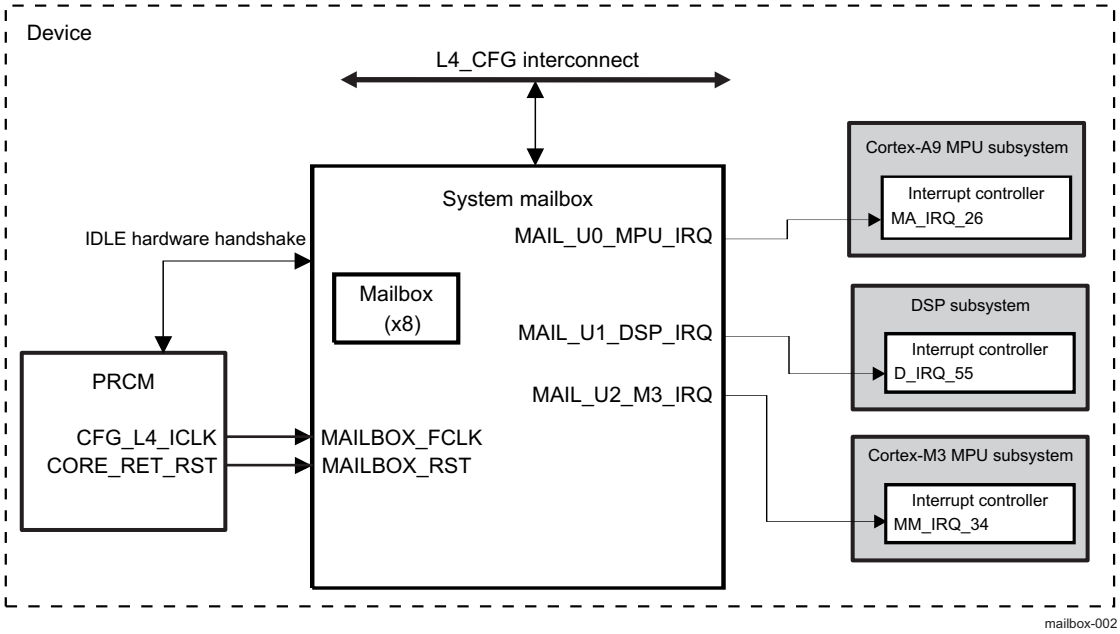
20.2 Mailbox Integration

This section describes the mailbox integration in the device, including information about clocks, resets, and hardware requests.

20.2.1 System Mailbox Integration

Figure 20-2 shows the system mailbox integration.

Figure 20-2. System Mailbox Integration



NOTE: For more information about the IDLE hardware handshake, see Section 3.1.1.1.2, *Module Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 20-1 through Table 20-3 summarize the system mailbox integration in the device.

SYSTEM_MAILBOX	MAILBOX_FCLK	CFG_L4_ICLK	PRCM	System mailbox functional/interface clock. For information about PRCM clock gating and management, see Section 3.6.15, *CD_L4_CFG Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
SYSTEM_MAILBOX	MAILBOX_RST	CORE_RET_RST	PRCM	System mailbox hardware reset. For information about PRCM reset sources and distribution, see Section 3.5.4, *Reset Domains*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 20-3. Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
SYSTEM_MAILBOX	MAIL_U0_MPU_IRQ	MA_IRQ_26	Cortex-A9	System mailbox user 0 interrupt request. For information about Cortex-A9 MPU interrupt mapping, see Section 18.3.2, *Interrupt Requests to the Cortex-A9 MPU Interrupt Controller*, in Chapter 18, *Interrupt Controllers*.
	MAIL_U1_DSP_IRQ	D_IRQ_55	DSP	System mailbox user 1 interrupt request. For information about DSP interrupt mapping, see Section 5.3.7, *Interrupt Requests*, in Chapter 5, *DSP Subsystem*.
	MAIL_U2_M3_IRQ	MM_IRQ_34	Cortex-M3	System mailbox user 2 interrupt request. For information about Cortex-M3 MPU interrupt mapping, see Section 18.3.3, *Interrupt Requests to the Cortex-M3 MPU Interrupt Controller*, in Chapter 18, *Interrupt Controllers*.
No DMA Requests				

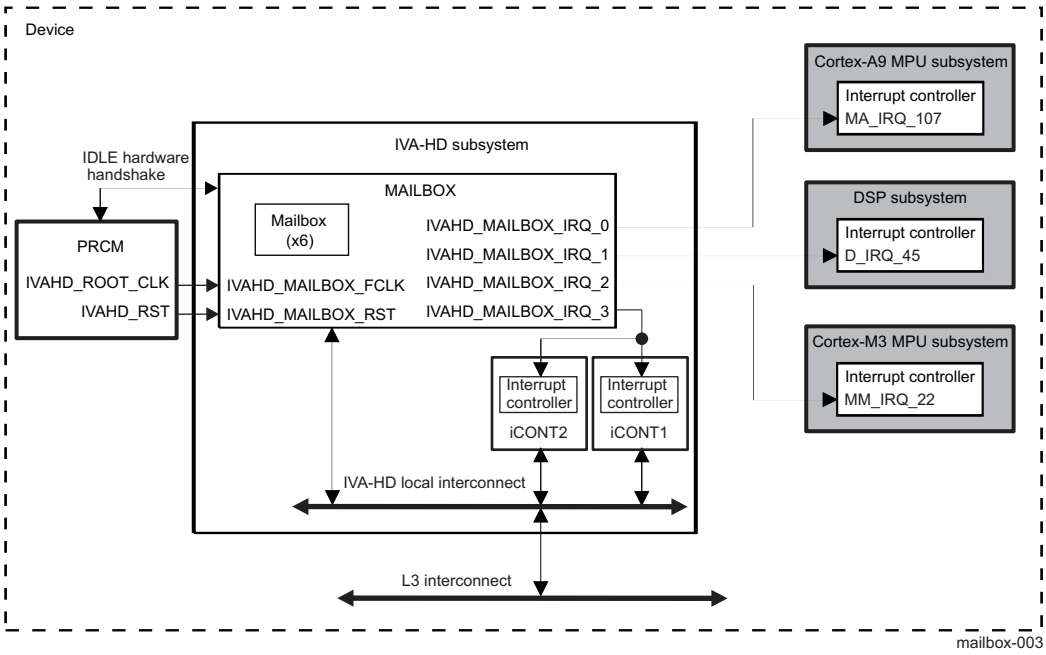
NOTE: For information about interrupt source description, see Section 20.3.4, *Interrupt Requests*.

20.2.2 IVA-HD Mailbox Integration

Figure 20-3 shows the IVA-HD mailbox integration.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 20-3. IVA-HD Mailbox Integration



NOTE: For more information about the IDLE hardware handshake, see Section 3.1.1.1.2, *Module Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

NOTE: The two imaging controllers - iCONT1 and iCONT2, are mapped on a shared interrupt line. The choice between them is done by masking mailbox interrupt on iCONT1 or iCONT2. For more information, see , *IVA-HD Imaging Controller* in Chapter 6, *IVA-HD Subsystem*.

Table 20-4 through Table 20-6 summarize the IVA-HD mailbox integration in the device.

Table 20-4. Integration Attributes

Module Instance	Attributes

20.3 Mailbox Functional Description

NOTE: In the mailbox functional description, *u* is the user number and *m* is the mailbox number as follows:

- for the system mailbox module instance, *u*=0 to 2 and *m*=0 to 7
- for the IVA-HD mailbox module instance, *u*=0 to 3 and *m*=0 to 5

The mailbox module provides a means of communication through message queues among the users (depending on the mailbox module instance). The individual mailbox modules (8 for the system mailbox instance, 6 for the IVA-HD mailbox instance), or FIFOs, can associate (or de-associate) with any of the processors using the MAILBOX_IRQENABLE_SET_u (or MAILBOX_IRQENABLE_CLR_u) register.

CAUTION

For the IVA-HD mailbox instance, communication is possible only if one of the users is iCONT1 or iCONT2.

The mailbox module includes the following user subsystems:

- User 0: Cortex-A9 MPU subsystem (u = 0)
- User 1: DSP subsystem (u = 1)
- User 2: Cortex-M3 MPU subsystem (u = 2)
- User 3: IVA-HD subsystem (u = 3) - only available to the IVA-HD mailbox instance

Each user has a dedicated interrupt signal from the corresponding mailbox module instance and dedicated interrupt enabling and status registers.
Each MAILBOX_IRQSTATUS_RAW_u/MAILBOX_IRQSTATUS_CLR_u interrupt status register corresponds to a particular user.

For the system mailbox instance, a user can query its interrupt status register through the L4_CFG interconnect.

For the IVA-HD mailbox instance, a user can query its interrupt status register as follows:

- Cortex-A9 MPU and Cortex-M3 MPU - through the L3 interconnect
- iCONT1/iCONT2 and DSP - private access (directly through the IVA-HD local interconnect)

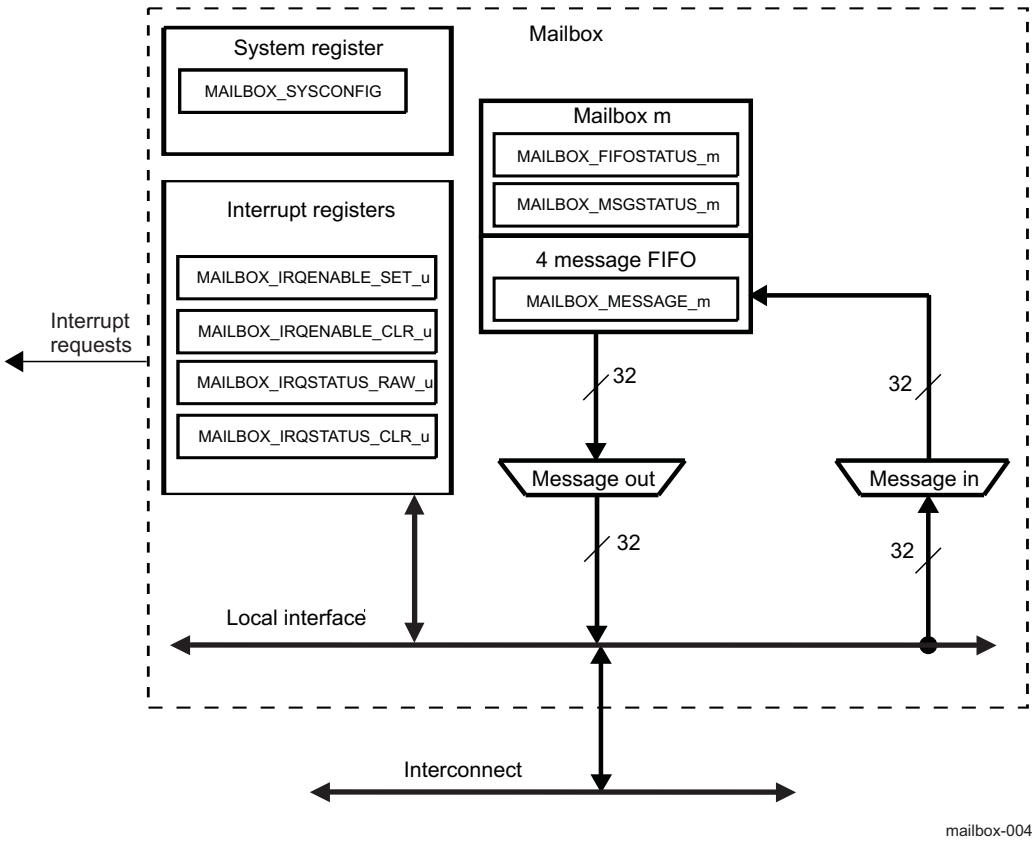
20.3.1 Mailbox Block Diagram

Figure 20-4 shows the mailbox block diagram.

Figure 20-4. Mailbox Block Diagram



NOTE: The interrupt requests and the interconnect depend on the mailbox module instance. For more information, see Section 20.2, *Mailbox Integration*.

20.3.2 Mailbox Software Reset

The mailbox module supports a software reset through the MAILBOX_SYSCONFIG[0] SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Reading the MAILBOX_SYSCONFIG[0] SOFTRESET bit gives the status of the software reset:

- Read 1: the software reset is on-going.
- Read 0: the software reset is complete.

The software must ensure that the software reset completes before doing mailbox operations.

20.3.3 Mailbox Power Management

Table 20-7 describes power-management features available for the mailbox module.

Copyright © 2011–2012, Texas Instruments Incorporated

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see Section 3.1.1.1.4, *Clock-Domain Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 20-7. Local Power Management Features

Feature	Registers	Description
Clock autogating	NA	Feature not available
Slave idle modes	MAILBOX_SYSCONFIG[3:2] SIDLEMODE bit field	Force-idle, no-idle and smart-idle modes are available
Clock activity	NA	Feature not available
Master standby modes	NA	Feature not available
Global wake-up enable	NA	Feature not available
Wake-up sources enable	NA	Feature not available

The mailbox module can be configured using the MAILBOX_SYSCONFIG[3:2] SIDLEMODE bit field to one of the following acknowledgment modes:

- Force-idle mode (SIDLEMODE = 0x0): The mailbox module immediately enters the idle state on receiving a low-power-mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state.
- No-idle mode (SIDLEMODE = 0x1): The mailbox module never enters the idle state.
- Smart-idle mode (SIDLEMODE = 0x2): After receiving a low-power-mode request from the PRCM module, the mailbox module enters the idle state only after all asserted output interrupts are acknowledged.

20.3.4 Mailbox Interrupt Requests

An interrupt request allows the user of the mailbox to be notified when a message is received or when the message queue is not full. There is one interrupt per user.

NOTE: For more information about interrupt requests, see Section 20.2, *Mailbox Integration*.

Table 20-8 lists the event flags, and their mask, that can cause module interrupts.

Table 20-8. Interrupt Events

Non-Maskable Event Flag [1]	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
MAILBOX_IRQSTATUS_RAW_u[0+m*2] NEWMSGSTATUSUUMBm	MAILBOX_IRQSTATUS_CLR_u[0+m*2] NEWMSGSTATUSUUMBm	MAILBOX_IRQENABLE_CLR_u[0+m*2] NEWMSGSTATUSUUMBm	MAILBOX_IRQENABLE_SET_u[0+m*2] NEWMSGSTATUSUUMBm	Mailbox *m* receives a new message.
MAILBOX_IRQSTATUS_RAW_u[1+m*2] NOTFULLSTATUSUUMBm	MAILBOX_IRQSTATUS_CLR_u[1+m*2] NOTFULLSTATUSUUMBm	MAILBOX_IRQENABLE_CLR_u[1+m*2] NOTFULLSTATUSUUMBm	MAILBOX_IRQENABLE_SET_u[1+m*2] NOTFULLSTATUSUUMBm	Mailbox *m* message queue is not full.

(1) MAILBOX.MAILBOX_IRQSTATUS_RAW_u register is mostly used for debug purposes.

Copyright © 2011–2012, Texas Instruments Incorporated

CAUTION

Once an event generating the interrupt request has been processed by the software, it must be cleared by writing a logical 1 in the corresponding bit of the MAILBOX_IRQSTATUS_CLR_u register.

Writing a logical 1 in a bit of the MAILBOX_IRQSTATUS_CLR_u register will also clear to 0 the corresponding bit in the appropriate MAILBOX_IRQSTATUS_RAW_u register.

An event can generate an interrupt request when a logical 1 is written to the corresponding unmask bit in the MAILBOX_IRQENABLE_SET_u register. Events are reported in the appropriate MAILBOX_IRQSTATUS_CLR_u and MAILBOX_IRQSTATUS_RAW_u registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the MAILBOX_IRQENABLE_CLR_u register. Events are only reported in the appropriate MAILBOX_IRQSTATUS_RAW_u register.

In case of the MAILBOX_IRQSTATUS_RAW_u register, the event is reported in the corresponding bit even if the interrupt request generation is disabled for this event.

20.3.5 Mailbox Assignment

20.3.5.1 Description

To assign a receiver to a mailbox, set the new message interrupt enable bit corresponding to the desired mailbox in the MAILBOX_IRQENABLE_SET_u register. The receiver reads the MAILBOX_MESSAGE_m register to retrieve a message from the mailbox.

An alternate method for the receiver that does not use the interrupts is to poll the MAILBOX_FIFOSTATUS_m and/or MAILBOX_MSGSTATUS_m registers to know when to send or retrieve a message to or from the mailbox. This method does not require assigning a receiver to a mailbox. Because this method does not include the explicit assignment of the mailbox, the software must avoid having multiple receivers use the same mailbox, which can result in incoherency.

To assign a sender to a mailbox, set the queue-not-full interrupt enable bit of the desired mailbox in the MAILBOX_IRQENABLE_SET_u register, where *u* is the number of the sending user. However, direct allocation of a mailbox to a sender is not recommended because it can cause the sending processor to be constantly interrupted.

It is recommended that register polling be used to:

- Check the status of either the MAILBOX_FIFOSTATUS_m or MAILBOX_MSGSTATUS_m registers
- Write the message to the corresponding MAILBOX_MESSAGE_m register, if space is available.

The sender might use the queue-not-full interrupt when the initial mailbox status check indicates the mailbox is full. In this case, the sender can enable the queue-not-full interrupt for its mailbox in the appropriate MAILBOX_IRQENABLE_SET_u register. This allows the sender to be notified by interrupt only when a FIFO queue has at least one available entry.

Reading the MAILBOX_IRQSTATUS_CLR_u register determines the status of the new message and the queue-not-full interrupts for a particular user. Writing 1 to the corresponding bit in the MAILBOX_IRQSTATUS_CLR_u register acknowledges, and subsequently clears, an interrupt.

CAUTION

Assigning multiple senders or multiple receivers to the same mailbox is not recommended.

Copyright © 2011–2012, Texas Instruments Incorporated

20.3.6 Sending and Receiving Messages

20.3.6.1 Description

When a 32-bit message is written to the MAILBOX_MESSAGE_m register, the message is appended into the FIFO queue. This queue holds four messages. If the queue is full, the message is discarded.

Queue overflow can be avoided by first reading the MAILBOX_FIFOSTATUS_m register to check that the mailbox message queue is not full before writing a new message to it.

Reading the MAILBOX_MESSAGE_m register returns the message at the beginning of the FIFO queue and removes it from the queue. If the FIFO queue is empty when the MAILBOX_MESSAGE_m register is read, the value 0 is returned.

The new message interrupt is asserted when at least one message is in the mailbox message FIFO queue. To determine the number of messages in the mailbox message FIFO queue, read the MAILBOX_MSGSTATUS_m register.

20.3.7 16-Bit Register Access

20.3.7.1 Description

So that 16-bit processors can access the mailbox module, the module allows 16-bit register read and write access, with restrictions for the MAILBOX_MESSAGE_m registers. The 16-bit half-words are organized in little endian fashion; that is, the least-significant 16 bits are at the low address and the most-significant 16 bits are at the high address (low address + 0x02).

All mailbox module registers can be read or written to directly using individual 16-bit accesses with no restriction on interleaving, except the MAILBOX_MESSAGE_m registers, which must always be accessed by either single 32-bit accesses or two consecutive 16-bit accesses.

CAUTION

When using 16-bit accesses, it is critical to ensure that the mailbox used has only one assigned receiver and only one assigned sender.

When using 16-bit accesses to the MAILBOX_MESSAGE_m registers, the order of access must be the least-significant half-word first (low address) and the most-significant half-word last (high address). This requirement is because of the update operation by the message FIFO of the MAILBOX_MSGSTATUS_m registers. The update of the FIFO queue contents and the associated status registers and possible interrupt generation occurs only when the most-significant 16 bits of a MAILBOX_MESSAGE_m are accessed.

20.4 Mailbox Programming Guide

20.4.1 Mailbox Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the mailbox module.

20.4.1.1 Global Initialization

20.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the mailbox module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the mailbox.

See Section 20.2, *Mailbox Integration*, for further information.

Table 20-9. Global Initialization of Surrounding Modules for System Mailbox

Surrounding Modules	Comments
PRCM	Mailbox functional/interface clock must be enabled. For more information, see Section 3.6.15 , *CD_L4_CFG Clock Domain*, in Chapter 3, *Power, Reset, and Clock Management*.
Interrupt Controllers	Cortex-A9 MPU, or Cortex-M3 MPU, or DSP interrupt controller must be configured to enable the interrupt request generation to the Cortex-A9 MPU, or Cortex-M3 MPU, or DSP subsystem. For information about enabling interrupts in Cortex-A9 MPU INTC, see the *ARM Cortex™-A9 MPCore Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp). For information about enabling interrupts in Cortex-M3 MPU INTC, see the *ARM Cortex™-M3 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp). For information about enabling interrupts in DSP INTC, see Chapter 5, *DSP Subsystem*.
Interconnect	For information about L4-CFG interconnect configuration, see Section 14.3, *L4 Interconnects,* in Chapter 14, *Interconnect*.

Table 20-10. Global Initialization of Surrounding Modules for IVA-HD Mailbox

Surrounding Modules	Comments
PRCM	Mailbox functional/interface clock must be enabled. For more information, see Chapter 3, *Power, Reset, and Clock Management*.
Interrupt Controllers	Cortex-A9 MPU, or Cortex-M3 MPU, or DSP, or iCONT1/iCONT2 interrupt controller must be configured to enable the interrupt request generation to the Cortex-A9 MPU, or Cortex-M3 MPU, or DSP, or IVA-HD subsystem. For information about enabling interrupts in Cortex-A9 MPU INTC, or Cortex-M3 MPU INTC, or DSP INTC, see Table 20-9, *Global Initialization of Surrounding Modules for System Mailbox*. For information about enabling interrupts in iCONT1/iCONT2, see , *iCONT* in Chapter 6, *IVA-HD Subsystem*.
Interconnect	For information about L3 interconnect configuration, see Section 14.2, *L3 Interconnects*, in Chapter 14, *Interconnect*.

20.4.1.1.2 Mailbox Global Initialization

20.4.1.1.2.1 Main Sequence - Mailbox Global Initialization

This procedure initializes the mailbox module after a power-on or software reset.

Table 20-11. Mailbox Global Initialization

Step	Register/ Bit Field / Programming Model	Value
Perform a software reset	MAILBOX_SYSCONFIG[0] SOFTRESET	0x1
Wait until reset is complete	MAILBOX_SYSCONFIG[0] SOFTRESET	= 0x0
Set idle mode configuration	MAILBOX_SYSCONFIG[3:2] SIDLEMODE	0x-

21.1 MMU Overview

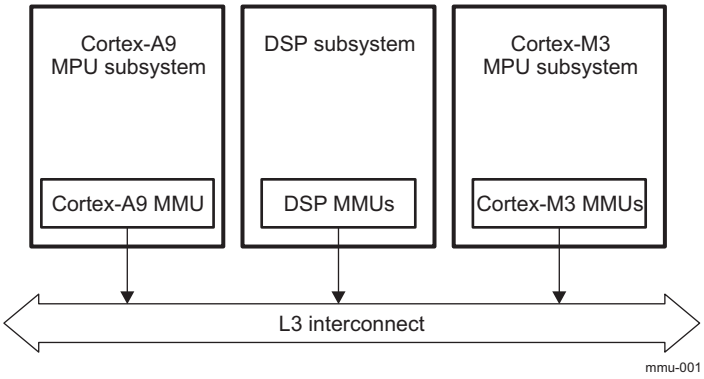
A memory management unit (MMU) is a hardware component responsible for handling accesses to memory requested by a processing unit. MMU functions include translation of virtual addresses to physical addresses (that is, virtual memory management) and cache control.

The device contains the following MMUs:

- In DSP - L1 Shared cache MMU and attribute MMU.
- In Dual Cortex-M3 MPU Subsystem - L1 Shared cache MMU and L2 MMU
- Cortex-A9 MMU

Figure 21-1 shows the MMU instances in the device.

Figure 21-1. Device MMU Instances



Copyright © 2011–2012, Texas Instruments Incorporated

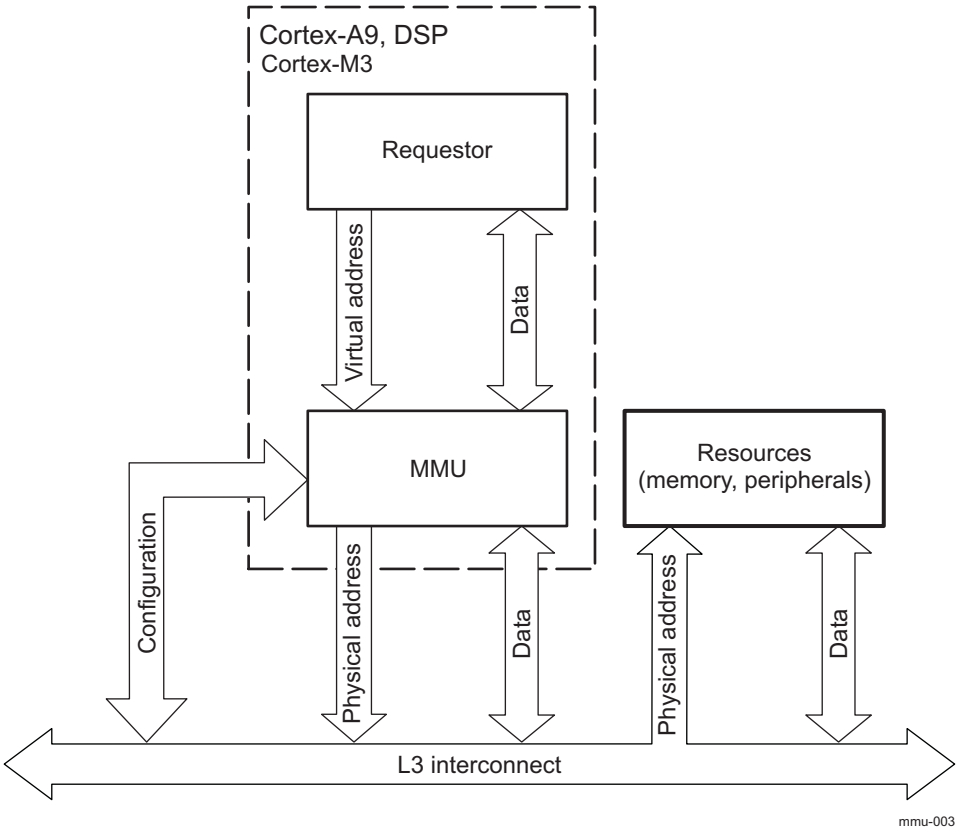
21.2 MMU Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

The MMU communicates accesses from the requestor (DSP, Cortex-M3 microprocessor unit (MPU), or Cortex-A9 MPU) to the L3 main interconnect, performing virtual to physical address translation. Although all MMUs are programmed (configured) through the L3 interconnect, the DSP MMU can be programmed both through the L3 interconnect or through the DSP local interconnect. DSP MMU and Cortex-M3 MMU error conditions are signaled as interrupts to the system main processor Cortex-A9 MPU.

Figure 21-2 shows typical MMU integration.

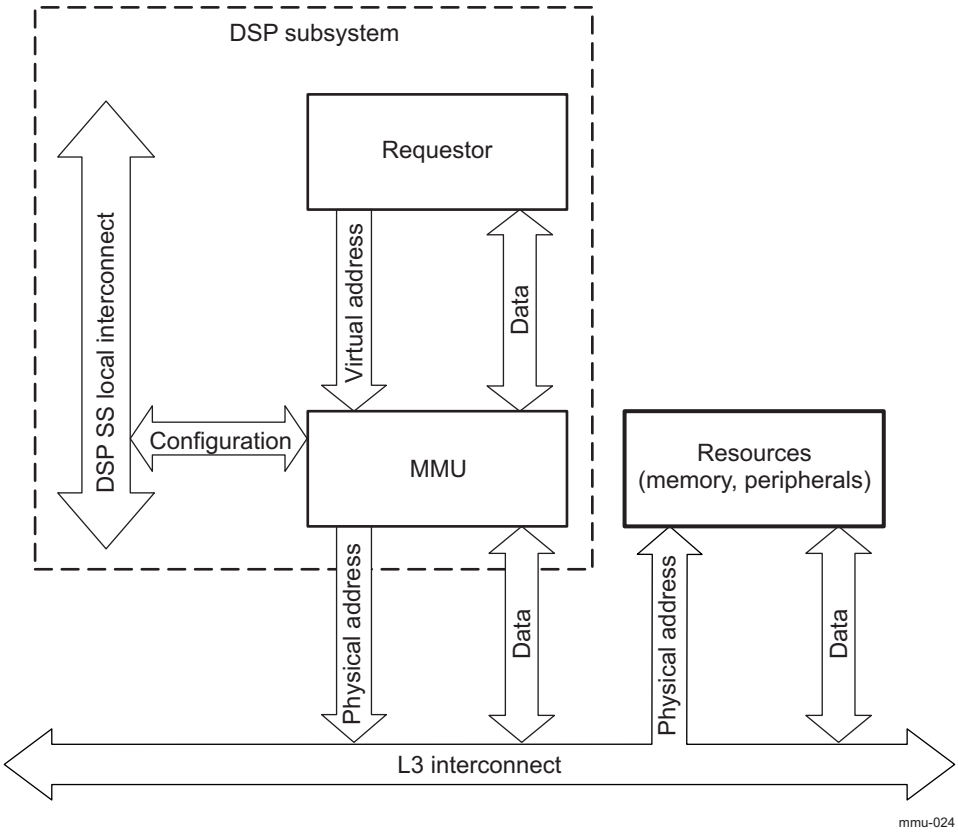
Figure 21-2. MMU Integration



NOTE: All MMUs are programmed through the L3 interconnect.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 21-3. DSP MMU Integration



NOTE: The DSP MMU can be programmed from both the DSP local interconnect and from the L3 interconnect.

Table 21-1 through Table 21-3 summarize the MMU integration in the various modules of the device.

Table 21-1. Integration Attributes

Module Instance	Power Domain
CORTEXM3_L2MMU and CORTEXM3_SCACHE_MMU	PD_CORE
CORTEXA9_MMU	PD_MPU

Table 21-2. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
CORTEXA9_MMU	ARM_FCLK	MPU_DPLL_CLK	MPU DPLL	Internal clock in the Cortex-A9 MPU subsystem; supplies the MMU in Cortex-A9.
CORTEXM3_L2MMU and CORTEXM3_SCACHE_MMU	MPU_M3_CLK	MPU_M3_CLK	PRCM	External clock from the power, reset, and clock management (PRCM) module; supplies the shared cache MMU and L2 MMU in Cortex-M3.
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
CORTEXM3_L2MMU	CORTEXM3_PWRON_RST	CORTEXM3_PWRON_RST	PRCM	Power-on reset signal for the Cortex-M3 MPU subsystem
	CORTEXM3_RST3	CORTEXM3_RST3	PRCM	Reset signal to the L2 MMU

Table 21-3. Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
CORTEXM3_L2MMU	CORTEXM3_MMU_IRQ	MA_IRQ_100	MPU_INTC	Cortex-M3 MPU L2MMU interrupt to the main MPU subsystem
	XLATE_MMU_FAULT	MM_IRQ_0	CortexM3_INTC	Internal interrupt from the L2MMU to the Cortex-M3 interrupt controller (INTC)
CORTEXM3_SCACHE_MMU	SHARED_CACHE_MMU_CPU_INT	MM_IRQ_1	CortexM3_INTC	Internal interrupt from the shared cache MMU to the CortexM3 INTC

NOTE:

- For a description of the interrupt source, see Section 21.3.5, *Interrupt Requests*.

There are 5 MMU modules in the device:

- Shared cache MMU – there are two Share cache MMUs, one in the Cortex-M3 MPU and other in DSP subsystem. Refer to the corresponding chapters for more information.
- L2 MMUs – there are two L2 MMUs, one in the Cortex-M3 MPU and other in DSP subsystem. The L2 MMUs are directly operating with the L3 interconnect (shared device memory space). These L2 MMUs are described in this chapter.
- Cortex-A9 MMU – this MMU is located in the ARM Cortex-A9 processor. For information about this MMU, see the *ARM® Cortex™-A9 MPCore Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

NOTE: There is PAT module in the Dynamic Memory Manager, which has similar to the MMU functionality. Refer to the DMM chapter, for more information.

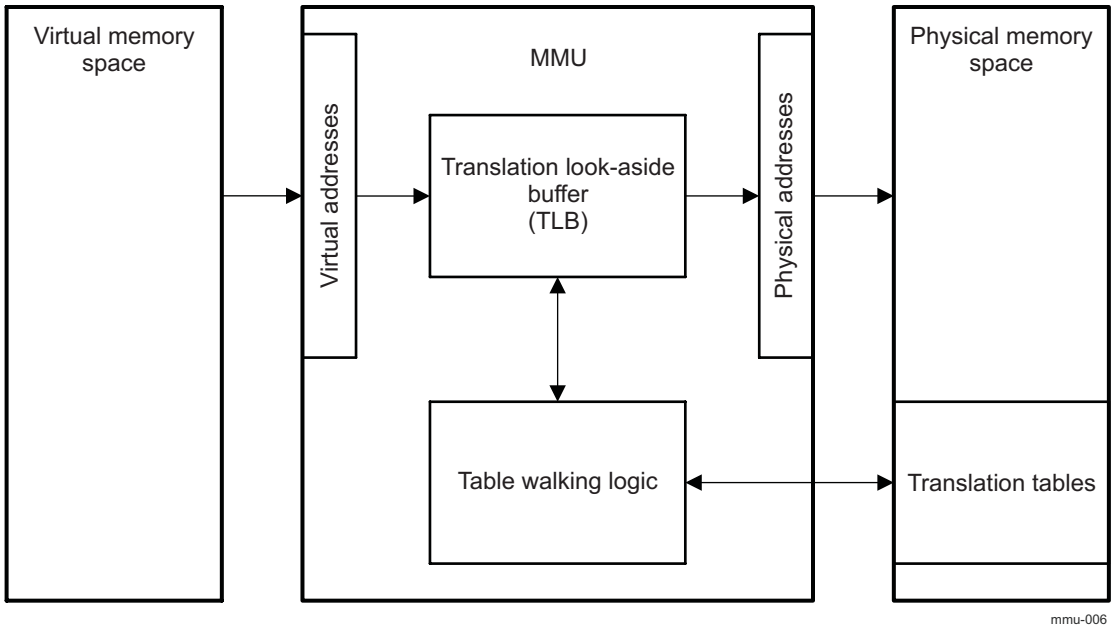
21.3 MMU Functional Description

21.3.1 MMU Block Diagram

The MMU manages the virtual to physical address translation for external addresses, as well as endianness conversion. The MMU can be programmed through the L3 interconnect. MMU programming is expected to be accomplished by the Cortex-A9 MPU, except for the DSP MMU, of which the configuration can be accomplished through the DSP local interconnect.

Figure 21-4 is the MMU block diagram.

Figure 21-4. MMU Block Diagram



Each table entry describes the translation of one contiguous memory region. For a description of the structure of these tables, see Section 21.3.1.2, *Translation Tables*.

Two major functional units exist in the MMU to provide address translation automatically based on the table entries:

- The table walker automatically retrieves the correct translation table entry for a requested translation. If two-level translation is used (for the translation of small memory pages), the table walker also automatically reads the required second-level translation table entry. The two-level translation is described later in the chapter.
- The translation look-aside buffer (TLB) stores recently used translation entries, acting like a cache of the translation table.

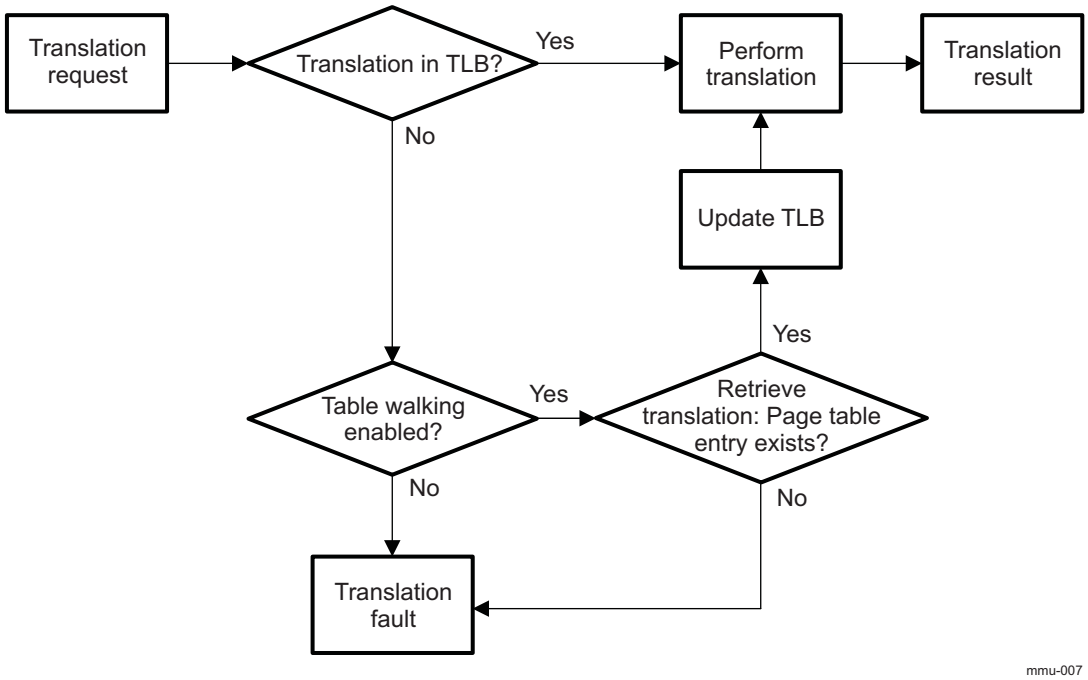
21.3.1.1 MMU Address Translation Process

Whenever an address translation is requested (that is, for every access with the MMU enabled), the MMU first checks whether the translation is contained in the TLB, which acts like a cache storing recent translations. The TLB can also be programmed manually to ensure that time-critical data can be translated without delay.

If the requested translation is not in the TLB, the table-walking logic retrieves this translation from the translation table(s), and then updates the TLB. The address translation is then performed. Figure 21-5 summarizes the process.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 21-5. Translation Process



21.3.1.2 Translation Tables

The translation of virtual to physical addresses is based on entries in translation tables that define the following properties:

- Address translation, that is, the correspondence between virtual and physical addresses
- Size of the memory region the entry translates
- Endianness, data access size, and the mixed property of this memory region

The virtual addresses index the translation tables. Each virtual address corresponds to exactly one entry in the translation table.

21.3.1.2.1 Translation Table Hierarchy

When developing a table-based address translation scheme, one of the most important design parameters is the memory page size described by each translation table entry. MMU instances support 4KB and 64KB pages, a 1MB section, and a 16MB supersection. Using bigger page sizes means a smaller translation table.

Using a smaller page size greatly increases the efficiency of dynamic memory allocation and defragmentation. That is why many operating systems (OSs) can operate on memory blocks as small as 4KB; however, the smaller size implies a more complex table structure.

A quick calculation shows that using 4KB memory pages with one translation table would require one million entries to span the entire 4GB address range. The table itself would be 32MB, a size that is not feasible.

However, using bigger pages greatly reduces the functionality of the OS memory management. Implementing a two-level hierarchy reconciles these two requirements. Within this hierarchy, one first-level translation table describes the translation properties based on 1MB memory regions.

Each of the entries in this first-level translation table can specify the following:

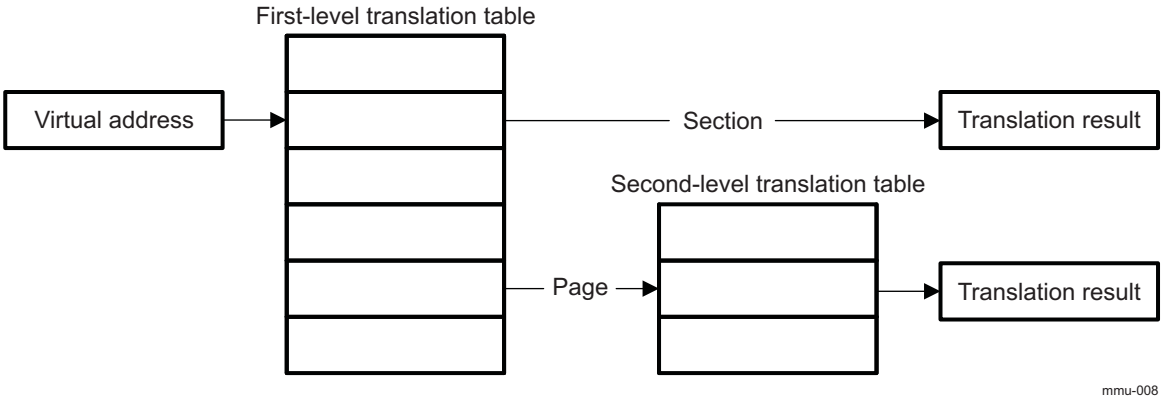
- The translation properties for a big memory section. This memory section can be either 1MB (section) or 16MB (supersection). In this case, all translation parameters are specified in the first-level translation table entry.

Copyright © 2011–2012, Texas Instruments Incorporated

- A pointer to a second-level translation table that specifies individual translation properties based on smaller pages within the 1MB page of memory. These pages can be either 64KB (large page) or 4KB (small page). In this case, the actual translation parameters are specified in the second-level translation table entry. The first-level translation table entry specifies only the base address of the second-level translation table.

This hierarchical approach means that additional translation information for smaller pages must be provided only when the pages are actually used. Figure 21-6 shows the hierarchy.

Figure 21-6. Translation Hierarchy



The structure of the first and second-level translation tables and their entries are described in more detail in Section 21.3.1.2.2, *First-Level Translation Table*, and Section 21.3.1.2.3, *Two-Level Translation*.

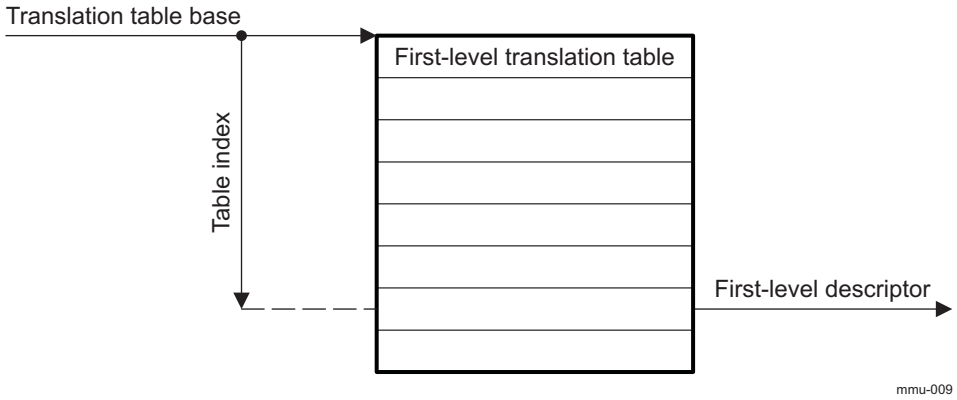
21.3.1.2.2 First-Level Translation Table

The first-level translation table describes the translation properties for 1MB sections. To describe a 4GB address range requires 4096 32-bit entries (so-called first-level descriptors).

The first-level translation table start address must be aligned on a multiple of the table size with a 128-byte minimum. Consequently, an alignment of at least 16K bytes is required for a complete 4096-entry table; that is, at least the last fourteen address bits must be zero.

The start address of the first-level translation table is specified by the so-called translation table base. The table is indexed by the upper 12-bits of the virtual address. Figure 21-7 shows this mechanism.

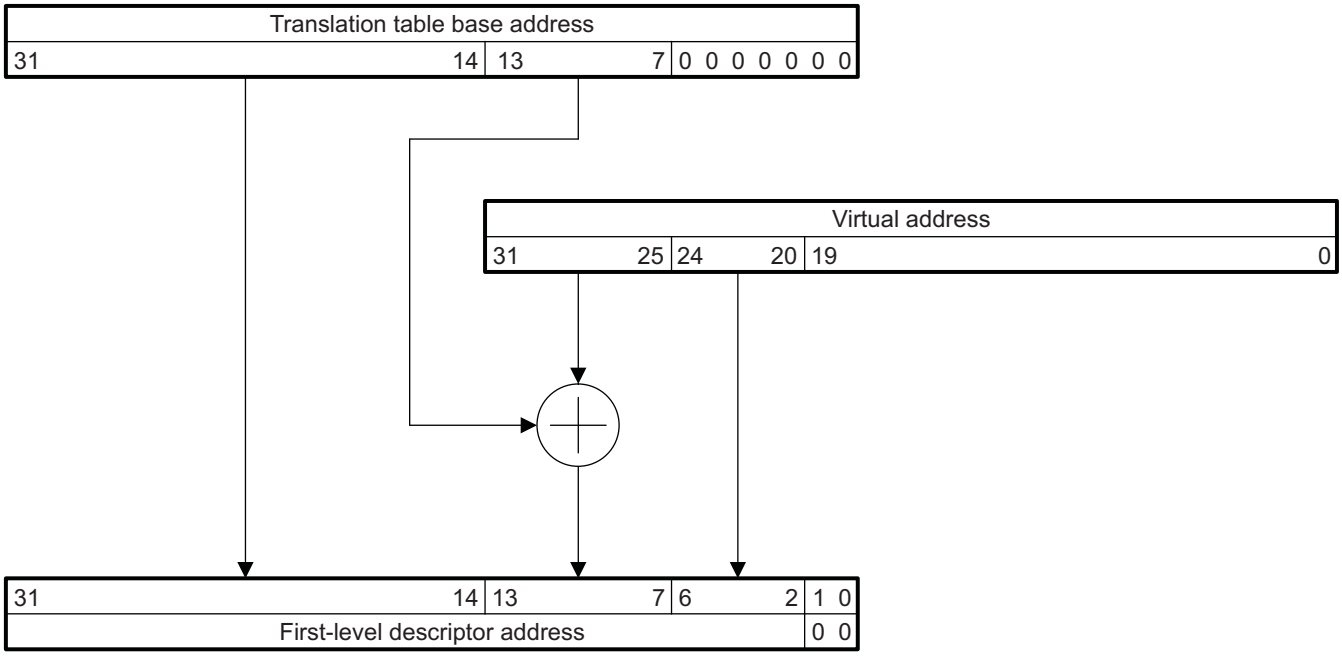
Figure 21-7. First-level Descriptor Address Calculation



To summarize, the translation table base and the translation table index together define the first-level descriptor address. Figure 21-8 outlines the precise mechanism used to calculate this address.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 21-8. Detailed First-Level Descriptor Address Calculation



As an example of this mechanism, consider a translation table base address of 0x8000:0000 and a virtual address of 0x1234:5678. In this case, the first-level descriptor address is 0x8000:0000 + (0x123 << 2) = 0x8000:048C.

21.3.1.2.2.1 First-Level Descriptor Format

Each first-level descriptor provides either the complete address translation for 1MB or 16MB sections or provides a pointer to a second-level translation table for 4KB or 64KB pages. Table 21-4 shows the first-level descriptor format.

Table 21-4. First-Level Descriptor Format

First-Level Descriptor Format												
31:24	23:20	19	18	17	16	15	14:12	11:10	9:2	1	0	
X										0	0	Fault
Second-Level Translation Table Base Address									X	0	1	Page
Section Base Address		X	0	M	X	E (1)	X	ES	X	1	0	Section
Supersection Base Address	X		1	M	X	E	X	ES	X	1	0	Supersection
X										1	1	Fault

(1) See for endianness limitations.

M = Mixed region: 0 = Page-based endianness, 1 = Access-based endianness

E = Endianness: 0 = Little endian, 1 = Big endian (endianness is locked on little endian)

ES = Element Size: 00 = 8-bit, 01= 16-bit, 10 = 32-bit, 11 = No endianness conversion

X = Don't care

21.3.1.2.2.2 First-Level Page Descriptor Format

If a translation granularity smaller than 1MB is required, a two-level translation process is used. In this case, the first-level block descriptor specifies only the start address of a second-level translation table. The second-level translation table entries specify the actual translation properties.

Copyright © 2011–2012, Texas Instruments Incorporated

21.3.1.2.2.3 First-Level Section Descriptor Format

Each section descriptor in the first-level translation table specifies the complete translation properties for a 1MB section or a 16MB supersection.

NOTE: Supersection descriptors must be repeated 16 times, because each descriptor in the first-level translation table describes 1MB of memory. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

In addition to the address translation itself, three parameters are specified in the section descriptors:

- Endianness

  The *endianness* parameter specifies whether the memory section uses a big- or little-endian data format. This parameter is locked to little endian. See for more information.

- Element size

  The *element size* parameter can optionally specify the data access size (8, 16, or 32 bits) for all data items in the defined section.

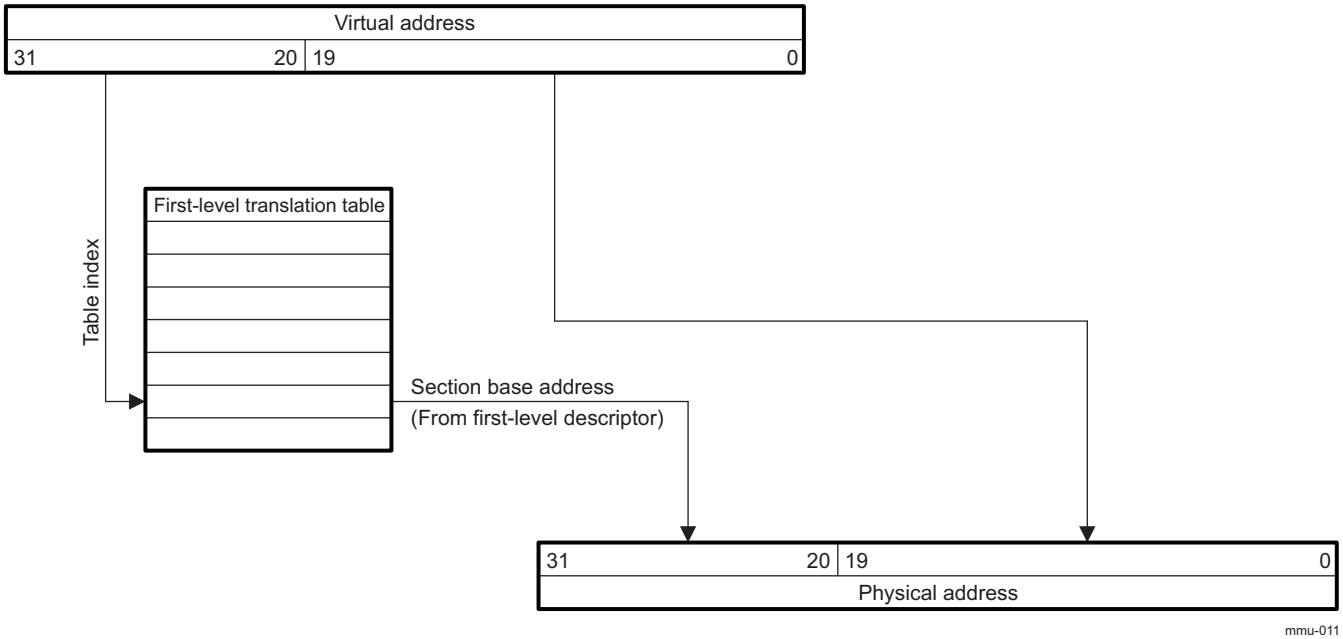
- Mixed region

  The *mixed region* parameter specifies whether the information about the data access size is detected from the access itself (access-based detection) or if the specified element size parameter is used (page-based detection). For example, the specified element size parameter can be used when several smaller sized accesses are packed into a bigger sized access, such as two 16-bit accesses packed into one 32-bit access. In this case, with no specified data access size, 32 bits would be the access size detected, leading to an incorrect result. To avoid this problem, specify the data access size for the memory section.

21.3.1.2.2.4 Section Translation Summary

Sections and supersections can be translated based solely on the information in the first-level translation table. Figure 21-9 summarizes the address translation process for a section.

Figure 21-9. Section Translation Summary



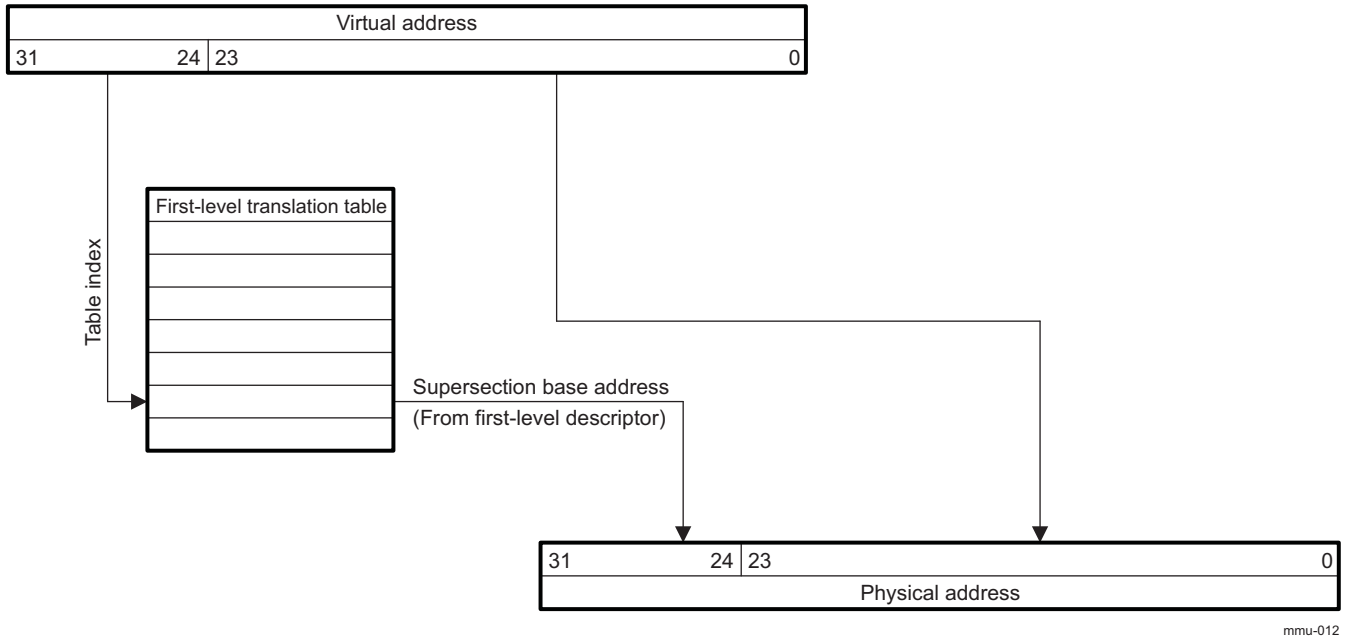
Copyright © 2011–2012, Texas Instruments Incorporated

21.3.1.2.2.5 Supersection Translation Summary

The translation of a supersection is similar to the translation of a section. The difference is that for a supersection only bits 31 to 24 index into the first-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a supersection.

Figure 21-10 shows the translation mechanism for a supersection.

Figure 21-10. Supersection Translation Summary

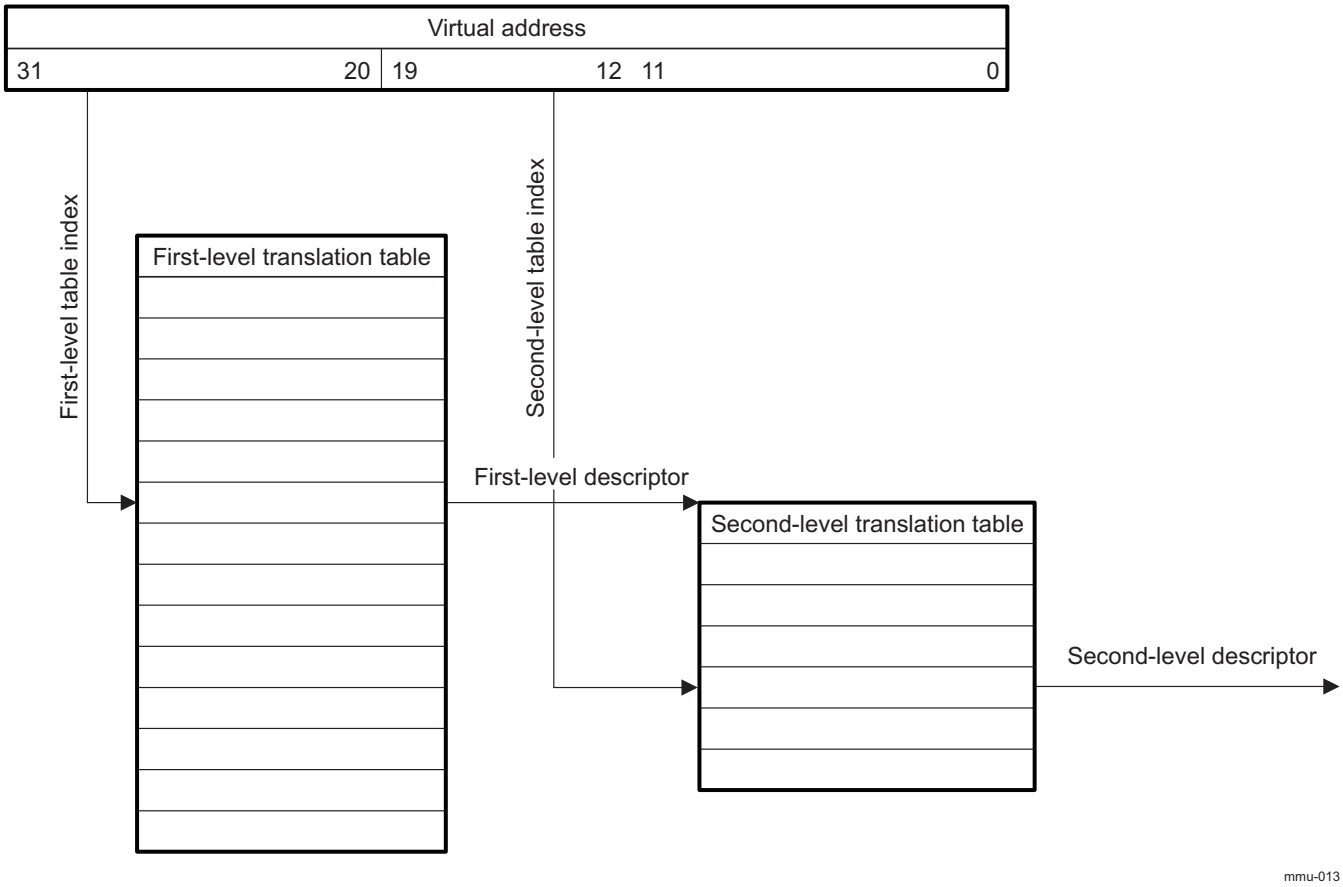


21.3.1.2.3 Two-Level Translation

Two-level translation is used when fine-grain granularity is required, that is, when memory sections smaller than 1MB are needed. In this case, the first-level descriptor provides a pointer to the base address of a second-level translation table. This second-level table is indexed by bits 19 to 12 of the virtual address. Figure 21-11 shows this indexing mechanism.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 21-11. Two-Level Translation



Each second-level translation table describes the translation of 1MB of address space in pages of 64KB (large page) or 4KB (small page). It consists of 256 second-level descriptors describing 4KB each.

NOTE: In the case of a large page, the same descriptor must be repeated 16 times. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

21.3.1.2.3.1 Second-Level Descriptor Format

Similar to first-level section descriptors, second-level descriptors provide all of the necessary information for the translation of a large or small page. Table 21-5 shows the format of second-level descriptors. The translation parameters (endianness, element size, and mixed region) have the same meaning as those for sections.

Table 21-5. Second-Level Descriptor Format

Second-Level Descriptor Format										
31:16	15:12	11	10	9	8:6	5:4	3:2	1	0	
X								0	0	Fault
Large Page Base Address	X	M	X	E (1)	X	ES	X	0	1	Large Page
Small Page Base Address		M	X	E	X	ES	X	1	X	Small Page

(1) See for endianness limitations.

Copyright © 2011–2012, Texas Instruments Incorporated

M = Mixed region: 0 = Page-based endianness, 1 = Access-based endianness

E = Endianness: 0 = Little-endian, 1 = Big-endian (endianness is locked on little endian)

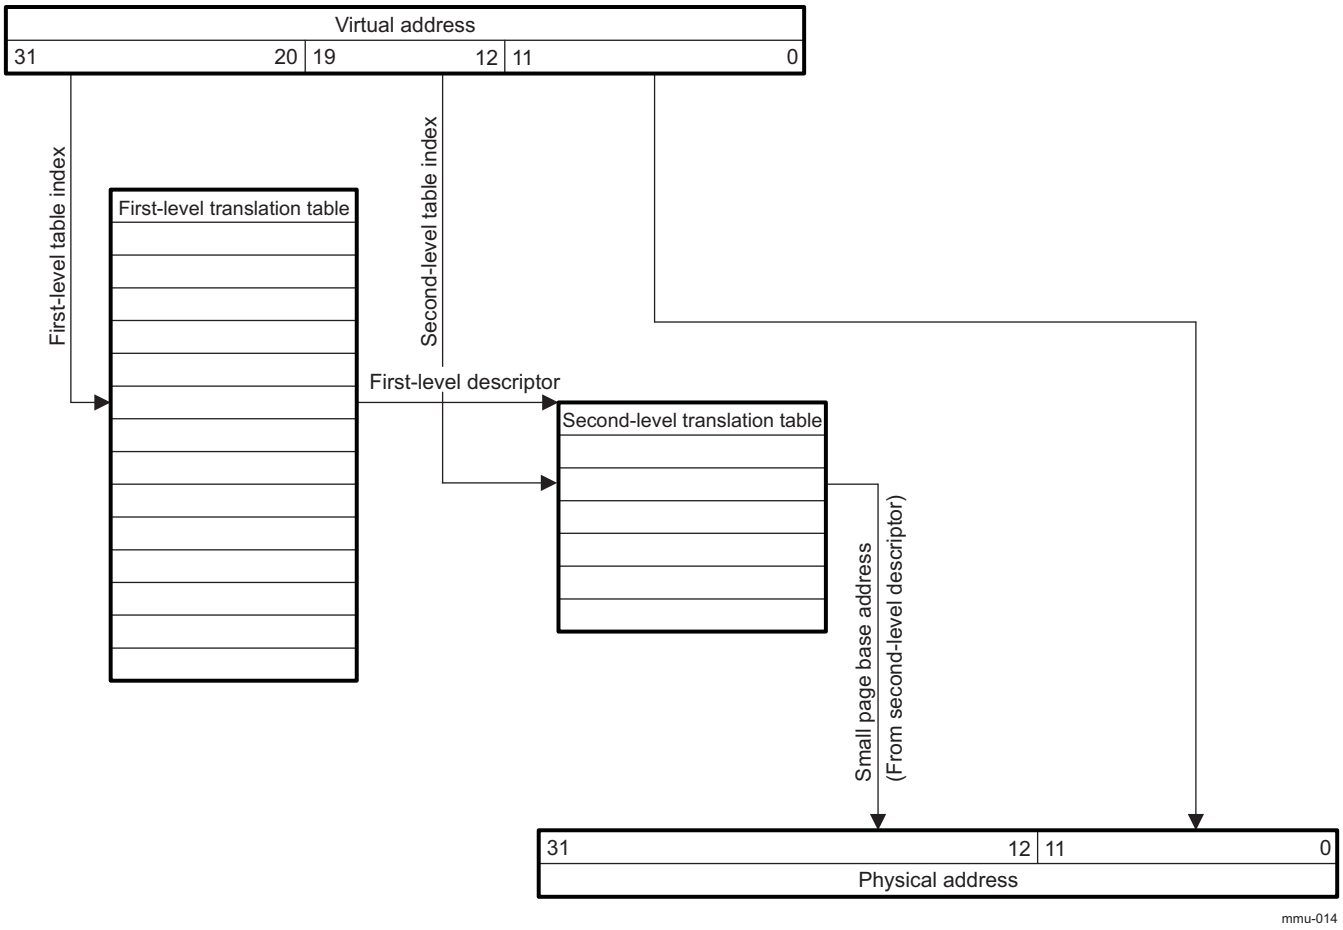
ES = Element Size: 00 = 8-bit, 01= 16-bit, 10 = 32-bit, 11 = No endianness conversion

X = Don't care

21.3.1.2.3.2 Small Page Translation Summary

Figure 21-12 summarizes the translation process for small pages.

Figure 21-12. Small Page Translation Summary



21.3.1.2.3.3 Large Page Translation Summary

The translation of a large page is similar to the translation of a small page. The difference is that, for a large page, only bits 19 to 16 index into the second-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a large page. This is shown in Figure 21-13.

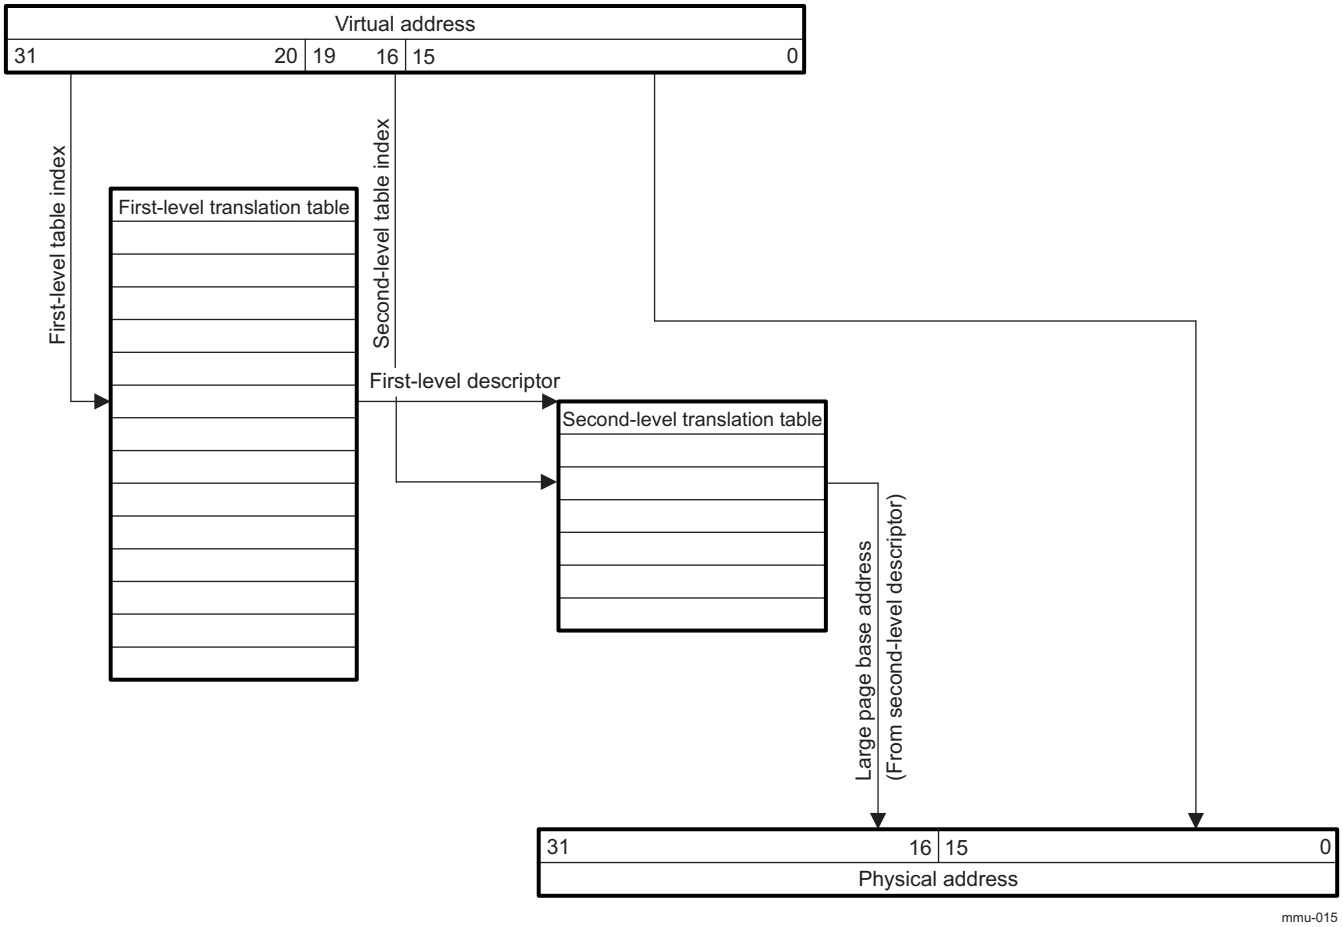
Figure 21-13. Large Page Translation Summary



21.3.1.3 Translation Lookaside Buffer

Translating virtual addresses to physical addresses is required for each memory access in systems using an MMU. To accelerate this translation process, a cache, or TLB, holds the result of recent translations.

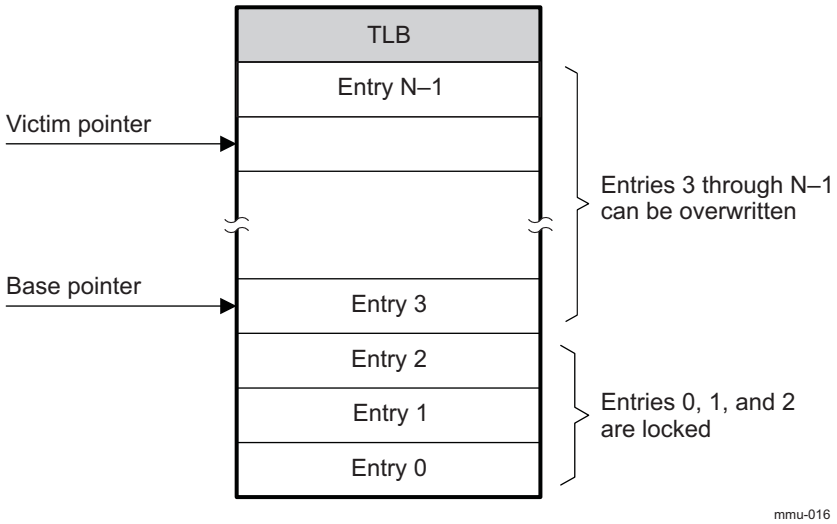
For every translation, the MMU internal logic first checks whether the requested translation is already cached in the TLB. If the translation is cached, this translation is used; otherwise the translation is retrieved from the translation tables and the TLB is updated. If the TLB is full, one of its entries must be replaced. This entry is selected on a random basis.

The first *n* TLB entries, where *n* < *Total Number N of TLB Entries*, can be protected (locked) against being overwritten by setting the TLB base pointer to *n*. When this mechanism is used, only unprotected entries can be overwritten. The victim pointer indicates the next TLB entry to be written. Figure 21-14 shows an example of the TLB with N TLB entries (ranging from 0 to N-1). The base pointer contains the value "3" protecting Entry 0, Entry 1, and Entry 2 and the victim pointer points to the next TLB entry to be updated.

NOTE: The last TLB entry (Entry N-1) always remains unprotected.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 21-14. TLB Entry Lock Mechanism



The table walking logic automatically writes the TLB entries. The entries can also be manually written, which is done typically to ensure that the translation of time-critical data accesses is already present in the TLB so that they execute as fast as possible. The entries must be locked to prevent them from being overwritten.

21.3.1.3.1 TLB Entry Format

TLB entries consist of two parts:

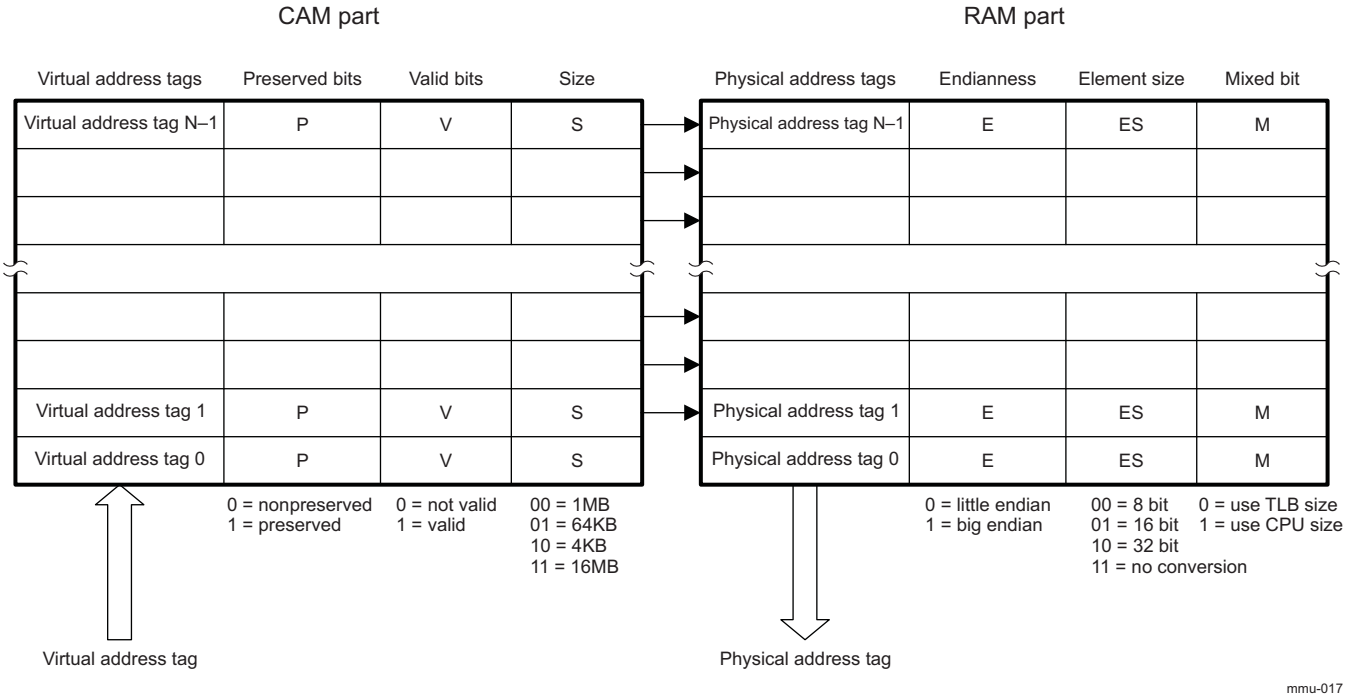
- The CAM part contains the virtual address tag used to determine if a virtual address translation is in the TLB. The TLB acts like a fully associative cache addressed by the virtual address tag. The CAM part also contains the section/page size, as well as the preserved and the valid parameters. See the MMU_CAM register table for more details.
- The RAM part contains the address translation that belongs to the virtual address tag as well as the endianness, element size, and mixed parameters described in Section 21.3.1.2.2, *First-Level Translation Table*. See the MMU_RAM register table for more details.

The valid parameter specifies whether an entry is valid or not. The preserved parameter determines the behavior of an entry in the event of a TLB flush. If an entry is set as preserved, it is not deleted when a TLB is flushed, that is, when MMU_GFLUSH[0] GLOBALFLUSH is set to 1. Preserved entries must be deleted manually. Section 21.3.1.2.2 describes the procedure to delete TLB entries.

Figure 21-16 shows the TLB entry structure.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 21-15. TLB Entry Structure



21.3.2 MMU Clock Configuration

There are two clock domains: The functional clock domain for the MMU, which is synchronous to the clock for the interconnect slave and master access ports; and the clock domain for the interconnect slave configuration port. As these clocks are matched, there is a single input clock with enables for each of the clock domains. If a clock domain should run at the same frequency as the input clock, that enable can be tied high.

Two clock enable signals exist, one to enable the interconnect data master and slave ports, and the other to enable the clock on the configuration L3 interconnect port. The clock signals are configured through the MMU_SYSCONFIG register. This is a system configuration register that controls the various parameters of the L3 interface.

21.3.3 MMU Software Reset

This section describes the software reset feature of the module. The MMU instances are reset together with their respective reset domains. See Table 21-2 for information about the reset domains of the different MMU instances.

To perform a software reset, write 1 in the MMU_SYSCONFIG[1] SOFTRESET bit. The MMU_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the MMU_SYSCONFIG[1] SOFTRESET bit is automatically reset. The software must ensure that the software reset completes before doing MMU operations. When an MMU instance is released from reset, its TLB is empty and the MMU is disabled.

21.3.4 MMU Power Management

As part of the device system-wide power management scheme, each MMU instance supports a communication protocol with the PRCM module that allows the PRCM module to request an MMU instance to enter a low-power state. When the MMU instance acknowledges a low-power mode request from the PRCM module, the clock to the instance is gated off at the PRCM clock generator. Because the clock is disabled at the source, the low-power mode offers lower power consumption than the internal clock gating method in the local power management.

Table 21-6 describes the power-management features available for the MMU modules.

Copyright © 2011–2012, Texas Instruments Incorporated

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see Section 3.1.1.1, *Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.1.1.1.2, *Module Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 21-6. MMU Local Power Management Features

Feature	Register
Idle modes	MMU_SYSCONFIG[4:3] IDLEMODE
Clock activity	MMU_SYSCONFIG[9:8] CLOCKACTIVITY
Clock autogating	MMU_SYSCONFIG[0] AUTOIDLE

NOTE: The MMU_SYSCONFIG[9:8] CLOCKACTIVITY bits are read only.

21.3.5 MMU Interrupt Requests

Table 21-7 lists the event flags and their masks that can cause module interrupts.

Table 21-7. Events

Event Flag	Event Mask	Synchronous	Sensitivity	Map to	Description
MMU_IRQSTATUS[4] MULTIHITFAULT	MMU_IRQENABLE[4] MULTIHITFAULT	Yes	Level	M3_IRQ_0	Error in the L2 MMU due to multiple matches in the TLB
MMU_IRQSTATUS[3] TABLEWALKFAULT	MMU_IRQENABLE[3] TABLEWALKFAULT	Yes	Level	M3_IRQ_0	Error in the L2 MMU due to error response received during a Table Walk
MMU_IRQSTATUS[2] EMUMISS	MMU_IRQENABLE[2] EMUMISS				For more information about emulation and debug features, see Chapter 29, *On-Chip Debug Support*.
MMU_IRQSTATUS[1] TRANSLATIONFAULT	MMU_IRQENABLE[1] TRANSLATIONFAULT	Yes	Level	M3_IRQ_0	Error in the L2 MMU due to invalid descriptor in the translation tables (translation fault)
MMU_IRQSTATUS[0] TLBMISS	MMU_IRQENABLE[0] TLBMISS	Yes	Level	M3_IRQ_0	Error in L2 MMU due to unrecoverable TLB miss (hardware TWL disabled)

21.3.6 MMU Error Handling

Table 21-8 summarizes the intended operation for real and potential error conditions.

Table 21-8. Error Handling

Item	Condition	Action
1	Table-walk read has an error response.	Treat generally the same as a translation fault, but set the TableWalkFault interrupt status bit to aid in diagnosis
2	MMU is disabled during table-walk.	Not permitted; can result in loss of the current transaction but must not deadlock the MMU.
		Avoid this condition by first disabling the table-walk logic and then polling the TWLRunning bit to ensure that no table walk is pending
3	MMU is disabled during an address translation.	Not permitted; can result in access to an unintended location, but must not deadlock MMU.
		This condition should be avoided by ensuring that no accesses are pending.

Copyright © 2011–2012, Texas Instruments Incorporated

Table 21-8. Error Handling (continued)

Item	Condition	Action
4	TLB is accessed during an address translation or a table walk.	Reading permitted; write should be done with care to ensure that the TLB is self-consistent at all times that a translation can occur.
5	TLB is flushed during address translation or a table walk.	Permitted; the flush is processed first, followed by the TWL update.
6	MMU is disabled while an interrupt is pending.	Not permitted; all pending interrupts should be processed before disabling the MMU.

L3 Interconnect configuration port: Accesses to undecoded register addresses must not give an error response.

To protect against changes to the address translation between a READEX and the corresponding write or during a burst the following configuration operations are protected against writes during these processes:

- TLB update
- Global flush
- Flush entry
- MMU disable

The protection is implemented by stalling the configuration interconnect transaction until the write can proceed safely.

Copyright © 2011–2012, Texas Instruments Incorporated

21.4 MMU Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

21.4.1 Global Initialization

21.4.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the MMU module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MMU. For more information, see Section Section 21.2, *MMU Module Integration* .

Table 21-9. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. For more information, see Chapter 3, *Power, Reset, and Clock Management*.
(optional) MPU INTC or DSP INTC or Cortex-M3 INTC	MPU, DSP, and Cortex-M3 interrupt controller configuration must be done to enable the interrupts from module.
Interconnect	For more information about the L3 interconnect configuration, see Section 14.2, *L3 Interconnect* .

NOTE: If the interrupt-based communication mode is used, the MPU, DSP, and Cortex-M3 interrupt controllers configurations are required.

21.4.1.2 MMU Global Initialization

21.4.1.2.1 Main Sequence—MMU Global Initialization

Figure 21-16 shows the procedure to initialize the MMU after a power-on or software reset.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 21-16. MMU Global Initialization

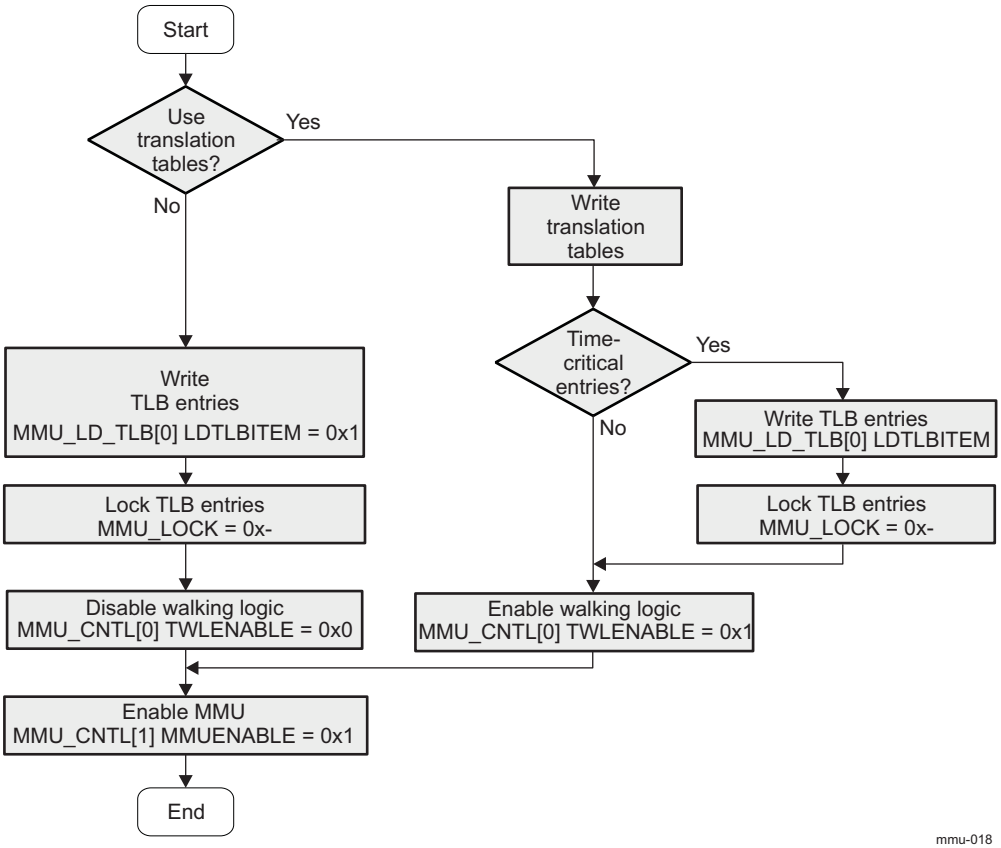


Table 21-10. Register Call Summary for Main Sequence—MMU Global Initialization

Register Name	Register Name	Register Name
MMU_LD_TLB	MMU_LOCK	MMU_CNTL

21.4.1.2.2 Subsequence—Configure a TLB entry

Table 21-11. Configure a TLB Entry

Step	Register / Bit Field / Programming Model	Value
Load the Virtual Address Tag	MMU_CAM[31:12] VATAG	0x-
Protect the TLB entry against flush	MMU_CAM[3] P	0x1
Validate the TLB entry	MMU_CAM[2] V	0x1
Define the page size	MMU_CAM[1:0] PAGESIZE	0x-

21.4.1.3 Operational Modes Configuration

21.4.1.3.1 Main Sequence—Writing TLB Entries Statically

Writing TLB entries statically avoids the need to write translation tables in memory and is commonly used for relatively small address spaces. This method ensures that the translation of time-critical data accesses execute as fast as possible with entries already present in the TLB. These entries must be locked to prevent them from being overwritten.

Copyright © 2011–2012, Texas Instruments Incorporated

Table 21-12. MMU Writing TLB Entries Statically

Step	Register/ Bit Field / Programming Model	Value
Execute software reset	MMU_SYSCONFIG[1] SOFTRESET	0x1
Wait for reset to complete	MMU_SYSSTATUS[0] RESETDONE	=0x1
Enable power saving via automatic interface clock gating	MMU_SYSCONFIG[0] AUTOIDLE	0x1
Configure TLB entries	See Table 21-11	
Load the physical Address of the page	MMU_RAM[31:12] PHYSICALADDRESS	0x-
Define the endianness of the page (little endian or big endian)	MMU_RAM[9] ENDIANNESS	0x-
Select the element size	MMU_RAM[8:7] ELEMENTSIZE	0x-
Define mixed page attribute	MMU_RAM[6] MIXED	0x-
Specify the TLB entry you want to write	MMU_LOCK[8:4] CURRENTVICTIM	0x-
Load the specified entry in the TLB	MMU_LD_TLB[0] LDTLBITEM	0x1
Enable multihit fault and TLB miss	MMU_IRQENABLE[4] MULTIHITFAULT	0x1
	MMU_IRQENABLE[0] TLBMISS	0x1
Enable memory translations	MMU_CNTL[1] MMUENABLE	0x1

21.4.1.3.2 Main Sequence—Protecting TLB Entries

The first *n* TLB entries (with *n* < total number of TLB entries) can be protected from being overwritten with new translations. This is useful to ensure that certain commonly used or time-critical translations are always in the TLB and do not require retrieval using the table walking process.

Table 21-13. Protecting TLB Entries

Step	Registe/Bit Field/Programming Model	Value
Locks the TLB entries	MMU_LOCK[14:10] BASEVALUE	0x-

21.4.1.3.3 Main Sequence—Deleting TLB Entries

Two mechanisms exist to delete TLB entries. All unpreserved TLB entries, that is, TLB entries written with the preserved bit set to zero, can be deleted by invoking a TLB flush. The preserved bit should only be used on protected TLB entries, as it does not prevent replacement by the table walking logic.

Table 21-14. Deleting TLB Entries

Step	Registet / Bit Field / Programming Model	Value
Flush all nonprotected TLB entries	MMU_GFLUSH[0] GLOBALFLUSH	0x1
Flush all TLB entries specified by the CAM register	MMU_FLUSH_ENTRY[0] FLUSHENTRY	0x1

21.4.1.3.4 Main Sequence—Read TLB Entries

TLB entries can be read by the programmer to determine the TLB content at runtime.

Table 21-15. Read TLB Entries

Step	Register / Bit Field / Programming Model	Value
Set the current victim pointer	MMU_LOCK[8:4] CURRENTVICTIM	0x-
Read RAM parts of the TLB entry	MMU_READ_RAM	
Read CAM parts of the TLB entry	MMU_READ_CAM

Spinlock

This chapter describes the Spinlock module of the device.

Topic **Page**

22.1 Spinlock Overview **4490**
22.2 Spinlock Integration **4491**
22.3 Spinlock Functional Description **4492**
22.4 Spinlock Programming Guide **4495**
22.5 Spinlock Register Manual **4498**

Copyright © 2011–2012, Texas Instruments Incorporated

22.1 Spinlock Overview

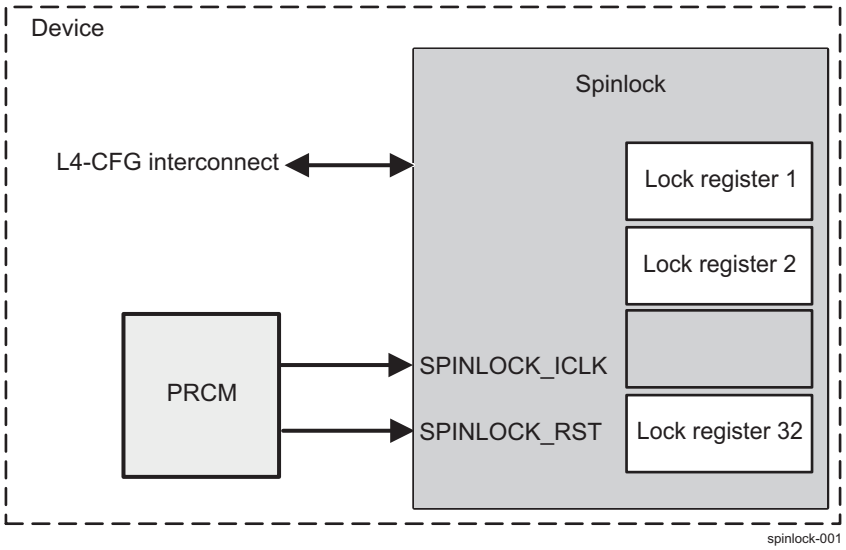
The Spinlock module provides hardware assistance for synchronizing the processes running on multiple processors in the device:

- Cortex-A9 microprocessor unit (MPU) subsystem
- Digital signal processor (DSP) subsystem
- Cortex-M3 MPU subsystem

The Spinlock module implements 32 spinlocks (or hardware semaphores), which provide an efficient way to perform a lock operation of a device resource using a single read-access, avoiding the need of a read-modify-write bus transfer that the programmable cores are not capable of.

Figure 22-1 shows the Spinlock module.

Figure 22-1. Spinlock Module



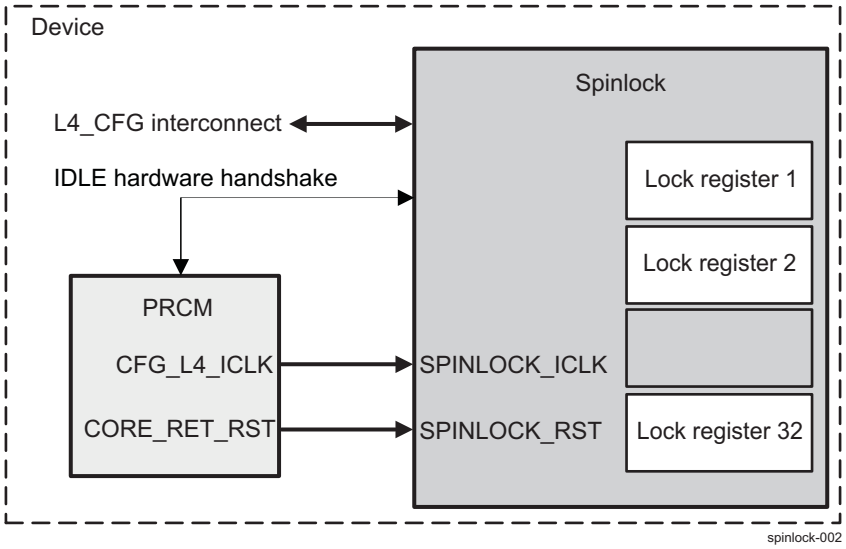
Copyright © 2011–2012, Texas Instruments Incorporated

22.2 Spinlock Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 22-2 shows the Spinlock integration.

Figure 22-2. Spinlock Integration



NOTE: For more information about the IDLE hardware handshake and the wake-up request, see Section 3.1.1.1.2, *Module Level Clock Management*, Chapter 3, *Power, Reset, and Clock Management*.

Table 22-1 and Table 22-2 summarize the integration of the module in the device.

Table 22-1. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
SPINLOCK	PD_CORE	L4_CFG

Table 22-2. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
SPINLOCK	SPINLOCK_ICLK	CFG_L4_ICLK	PRCM	Spinlock interface clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
SPINLOCK	SPINLOCK_RST	CORE_RET_RST	PRCM	Spinlock hardware reset. This reset is asynchronously applied to the Spinlock internal registers.

The Spinlock module does not support any interrupt and DMA requests.

Copyright © 2011–2012, Texas Instruments Incorporated

22.3 Spinlock Functional Description

22.3.1 Spinlock Software Reset

The Spinlock module can be reset by software through the SPINLOCK_SYSCONFIG[1] SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. The SPINLOCK_SYSTATUS[0] RESETDONE bit can be polled to check the reset status (reading 1 indicates that reset sequence is done; reading 0 indicates that reset sequence is in progress). The software must ensure that the software reset completes before doing Spinlock operations.

22.3.2 Spinlock Power Management

Table 22-3 describes power-management features available to the Spinlock module.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see Section 3.1.1.1.4, *Clock Domain Level Clock Management*, Chapter 3, *Power, Reset, and Clock Management*.
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.1.1.1.2, *Module Level Clock Management*, Chapter 3, *Power, Reset, and Clock Management*.

Table 22-3. Local Power Management Features

Feature	Registers	Description
Clock auto gating	SPINLOCK_SYSCONFIG[0] AUTOGATING bit	This bit indicates that the module uses an automatic internal interface clock gating strategy, based on interface activity.
Slave idle modes	SPINLOCK_SYSCONFIG[4:3] SIDLEMODE bit field	This bit field indicates that the module uses smart-idle mode.
Clock activity	SPINLOCK_SYSCONFIG[8] CLOCKACTIVITY bit	This bit indicates that the interface clock is not required by the module during idle mode and may be switched off.
Global wake-up enable	SPINLOCK_SYSCONFIG[2] ENAWAKEUP bit	This bit indicates that the wake-up generation feature (at module level) is disabled.

NOTE: All the local power management features are non-configurable (that is, their respective bits or bit fields are read-only).

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the CLOCKACTIVITY bit and Spinlock clock PRCM control bits.

The Spinlock module is normally idle, except when processing a request from its slave interface port. The smart-idle mode acknowledges idle requests from the PRCM only when the module is prepared to go idle. The Spinlock module is always ready to go idle if it does not have any request that it is processing.

The Spinlock module uses retention flops to retain state including the Taken state of each lock register. This means that the module can be placed in retention at any time when it is not processing a request and it is known that the system will not need to access the module.

Software must ensure to only power off the Spinlock module when no locks would be lost. In general, the steps to powering down the Spinlock module are:

- Check that all masters which might use the Spinlock module are either:

  (a) Already powered off, or

  (b) Notified that Spinlock is not available and the notification is acknowledged.

Copyright © 2011–2012, Texas Instruments Incorporated

- If desired, check that no locks are currently held in the Spinlock module. The status of each bank of 32 locks can be read from the SPINLOCK_SYSTATUS register. If any locks are held, they are orphaned because they are not held by any master that is still active. Alternatively, you may decide to wait a timeout period to allow any active master to clean up its locks before powering down.
- The Spinlock module can now be powered off by writing the appropriate status to the PRCM.

In the case of powering off the whole system, these steps are unnecessary.

22.3.3 About Spinlocks

Spinlocks are present to solve the need for synchronization and mutual exclusion between heterogeneous processors and those not operating under a single, shared operating system. There is no alternative mechanism to accomplish these operations between processors in separate subsystems.

Spinlocks are not the best way to synchronize between tasks or threads on one CPU. Instead, spinlocks are for use in synchronization between different subsystems in the device that don't have any other means of hardware-based synchronization.

Spinlocks do not solve all system synchronization issues. They have limited applicability and should be used with care to implement higher level synchronization protocols.

A spinlock is appropriate for mutual exclusion for access to a shared data structure. It should be used only when:

1. The time to hold the lock is predictable and small (for example, a maximum hold time of less than 200 CPU cycles may be acceptable).
2. The locking task cannot be preempted, suspended, or interrupted while holding the lock (this would make the hold time large and unpredictable).
3. The lock is lightly contended, that is the chance of any other process (or processor) trying to acquire the lock while it is held is small.

If these conditions are met, then the locking code can retry a failed attempt to acquire the lock until success.

If the conditions are not met, then a spinlock is not a good candidate. One alternative is to use a spinlock for critical section control (engineered to meet the conditions) to implement a higher level semaphore that can support preemption, notification, timeout or other higher level properties.

22.3.4 Spinlock Functional Operation

The Spinlock module supports 32 spinlocks. It accepts only a single command at a time and processes the command fully before accepting the next command. A lock is requested by reading the SPINLOCK_LOCK_REG_i[0] TAKEN bit. There are two states: Taken (SPINLOCK_LOCK_REG_i[0] TAKEN = 1) or Not Taken (SPINLOCK_LOCK_REG_i[0] TAKEN = 0).

When the status of lock *i* (where i = 0 to 31) is Not Taken (free), a read from the SPINLOCK_LOCK_REG_i register returns 0 and sets the lock to Taken (locked). When the status of lock *i* is Taken, a read returns 1 and does not change the state of the lock.

A write to the SPINLOCK_LOCK_REG_i register does not change the state of lock, unless when writing 0 when the lock is in Taken state. By doing this, the requester frees the lock.

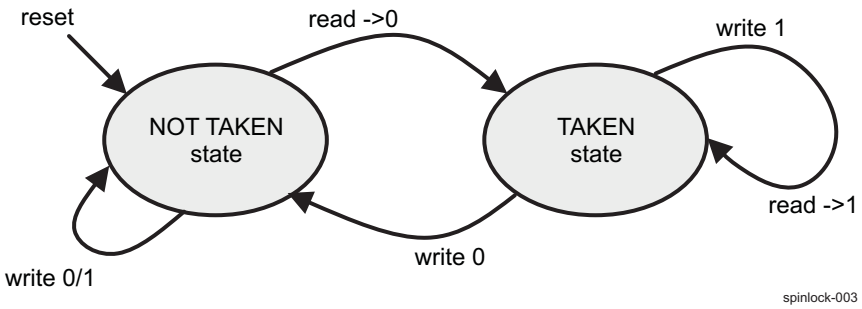
CAUTION

Only 32-bit reads and writes are supported.

Figure 22-3 shows the SPINLOCK_LOCK_REG_i register state diagram.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 22-3. Lock Register State Diagram



NOTE:

- There is no support to ensure that a lock register is locked and unlocked by the same process. This must be ensured in software.
- There is no support to check that the same initiator that acquired the lock is the one that is freeing the lock.

22.4 Spinlock Programming Guide

22.4.1 Spinlock Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

22.4.1.1 Surrounding Modules Global Initialization

This procedure initializes the surrounding modules when the Spinlock module is used for the first time after a device reset.

Table 22-4. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Spinlock interface clock must be enabled. For more information, see Section 3.6.15 , *CD_L4_CFG Clock Domain*, Chapter 3, *Power, Reset, and Clock Management*.
Interconnect	For more information about the L4-CFG interconnect configuration, see Section 14.3, *L4 Interconnects*.

22.4.1.2 Basic Spinlock Operations

The main spinlock operations are:

- Clear all the Taken spinlocks (only after a system bug recovery)
- Take a spinlock
- Release spinlock

22.4.1.2.1 Spinlocks Clearing After a System Bug Recovery

Module initialization (after reset) is not needed, except after system bug recovery. The following table presents the Spinlock initialization after a system bug recovery. Software should store 0 into each of the SPINLOCK_LOCK_REG_i registers at system startup to insure that all locks are initialized to Not Taken.

Table 22-5. Spinlock System Bug Recovery

Step	Register	Value
IF: SPINLOCK_SYSTATUS[0] IU0 = = 1?	SPINLOCK_SYSTATUS[0] IU0	
Free the 32 locks	SPINLOCK_LOCK_REG_i[0] TAKEN (i=0 to 31)	0x0
END		

22.4.1.2.2 Take and Release Spinlock

This procedure configures the take and release (free) operations for the Spinlock module. A spinlock should only be held with interrupts disabled. So, before attempting to obtain the spinlock, software should disable interrupts. Then it should read the SPINLOCK_LOCK_REG_i[0] TAKEN bit to attempt to obtain the lock. If it succeeds, it should proceed directly through the critical section then unlock and re-enable interrupts. If the acquisition attempt fails, the acquisition should be reattempted. To prevent unknown interrupt disabled time, interrupts should be re-enabled and then disabled before reattempting to acquire the lock. Figure 22-4 shows the described above procedure.

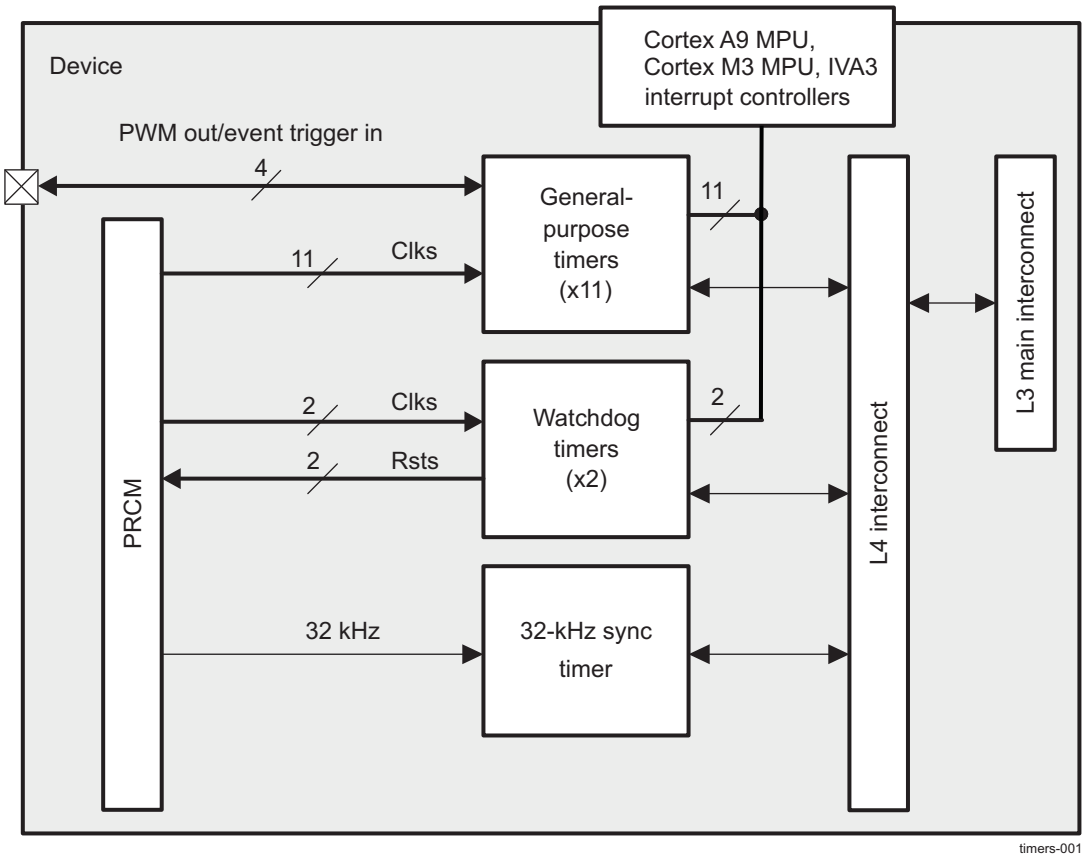
23.1 Timers Overview

The device includes several types of timers used by the system software, including 11 general-purpose (GP) timers , two watchdog timers, and a 32-kHz synchronized timer (sync timer). Figure 23-1 is a high-level block diagram of the device timers.

Figure 23-1. Timers



The two watchdog timers are clocked with 32-kHz clocks. The 32-kHz sync timer, which is reset only at power up, provides the operating system (OS) with a stable timing source that stores the relative time since the last power cycle of the product. Finally, 11 GP timers, which are useful simply as basic timers, are included to generate time-stamp-based interrupts to the system software or to use as a source of pulse-width modulation (PWM) signals.

23.2 General-Purpose Timers

23.2.1 General-Purpose Timers Overview

The device has 11 general-purpose (GP) timers: GPTIMER1 through GPTIMER11.

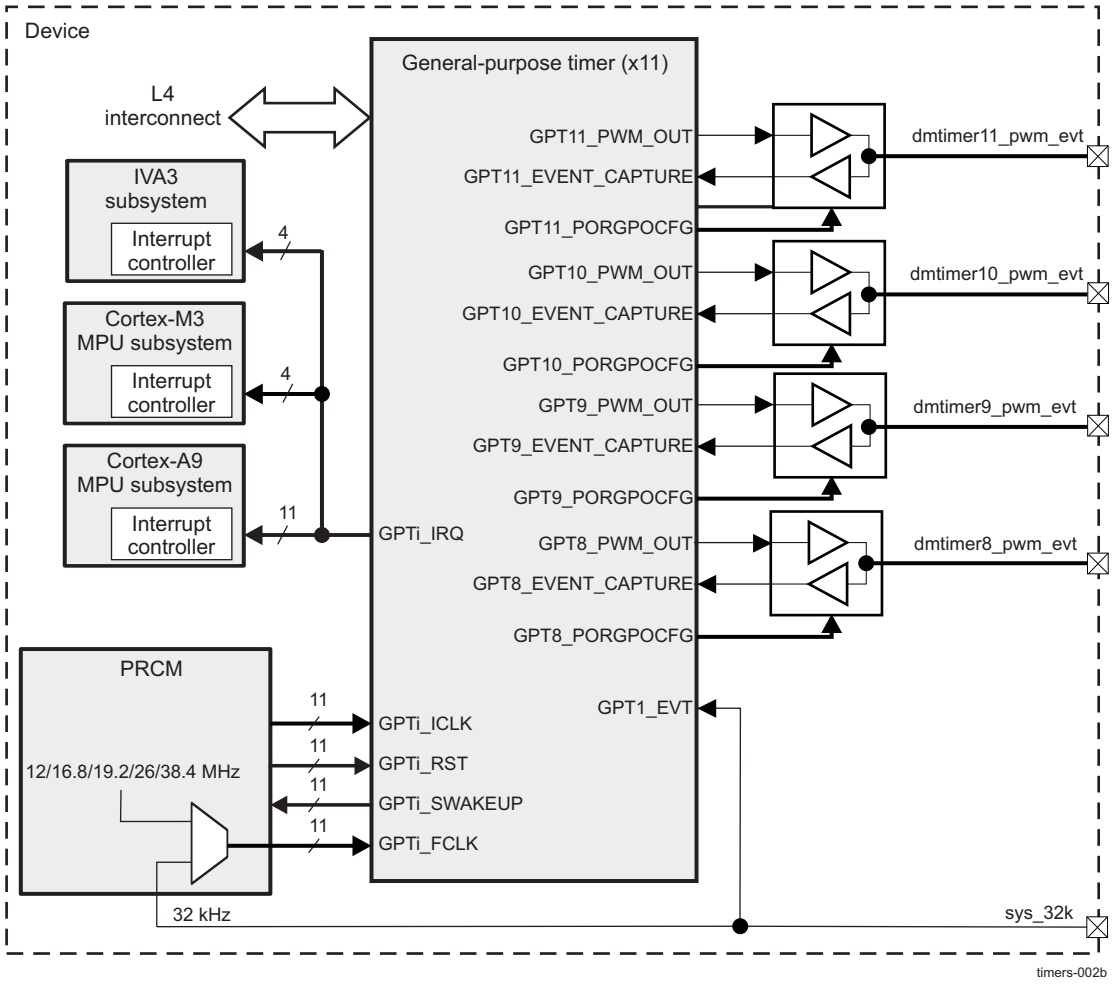
Each timer can be clocked from either the system clock (12, 16.8, 19.2, 26, or 38.4 MHz) or the 32-kHz clock. The selection of clock source is made at the power, reset, and clock management (PRCM) module level. For more information, see Section 3.6.3.1, *PRM Clock Source* in Chapter 3, *Power, Reset, and Clock Management*.

GPTIMER1 has its GPT1_EVENT_CAPTURE pin tied to the 32-kHz clock and can be used to gauge the system clock input; it detects its frequency among 12, 16.8, 19.2, 26, or 38.4 MHz.

Each timer can provide an interrupt to the microprocessor unit (MPU) subsystem. In addition, GPTIMER5 through GPTIMER8 also have interrupts connected to the IVA3 subsystem.

GPTIMER1, GPTIMER2, and GPTIMER10 include specific functions to generate accurate tick interrupts to the operating system. GPTIMER8 through GPTIMER11 are connected to external pins by their PWM output or their event capture input pin (for external timer triggering). Figure 23-2 is an overview of the GP timers.

Figure 23-2. GP Timers Overview



23.2.1.1 GP Timer Features

The following are the main features of the GP timer controllers:

- L4 slave interface support:

Copyright © 2011–2012, Texas Instruments Incorporated

  - 32-bit data bus width
  - 32-/16-bit access supported
  - 8-bit access not supported
  - 10-bit address bus width
  - Burst mode not supported
  - Software-selectable nonposted or posted write/read internal resynchronization modes
- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Compare and capture modes
- Autoreload mode
- Start/stop mode
- Programmable divider clock source (2^n where n = [0:8])
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- Dedicated GP output signal for using the GPTi_GPOCFG signal
- On-the-fly read/write register (while counting)
- 1-ms tick with 32,768-Hz functional clock generated (only GPTIMER1, GPTIMER2, and GPTIMER10)

Copyright © 2011–2012, Texas Instruments Incorporated

23.2.2 GP Timer Environment

23.2.2.1 GP Timer External System Interface

Four of the 11 GP timers can send or receive stimulus to/from the external (off-chip) system. In the device; however, only GPTIMER8 through GPTIMER11 are configured to output a pulse-width modulation (PWM) pulse or receive an external event signal used as a trigger to capture the current timer count. GPTIMER1 is also configured to receive an event trigger input (GPT1_EVENT_CAPTURE) tied to the internal 32-kHz clock. This event signal gauges the system clock input; detecting its frequency among 12, 16.8, 19.2, 26, or 38.4 MHz.

Figure 23-3 shows the external system interface for the GP timers, and Table 23-1 describes the GP timer inputs and outputs.

NOTE: Software control must ensure that MUX mode is configured to select the dmtimerx_pwm_evt (where x = 8 to 11) signal on only one pad. Other pads on which the same signal is multiplexed must be configured in safe mode or non-dmtimer mode to avoid two different pads driving the same signal.

For more information about the configuration of the dmtimer8_pwm_evt through dmtimer11_pwm_evt I/O pads, see Section 19.4.8, *PAD Functional Multiplexing and Configuration*.

Figure 23-3. GP Timers External System Interface

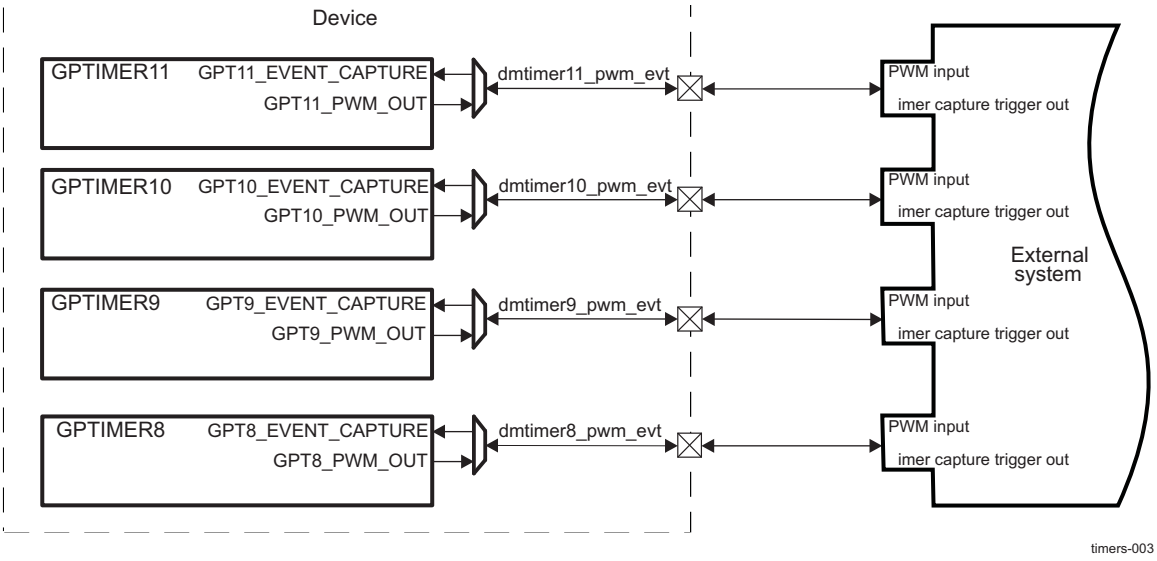


Table 23-1. Input/Output Description

Pin Name	Type [1]	Reset Value	Signal Name	Description
dmtimer8_pwm_evt	I/O	0	GPT8_EVENT_CAPTURE GPT8_PWM_OUT	GPTIMER8 trigger input/ PWM output
dmtimer9_pwm_evt	I/O	0	GPT9_EVENT_CAPTURE GPT9_PWM_OUT	GPTIMER9 trigger input/ PWM output
dmtimer10_pwm_evt	I/O	0	GPT10_EVENT_CAPTURE GPT10_PWM_OUT	GPTIMER10 trigger input/ PWM output
dmtimer11_pwm_evt	I/O	0	GPT11_EVENT_CAPTURE GPT11_PWM_OUT	GPTIMER11 trigger input/ PWM output

(1) When configured for that function; I = input, O = output

Copyright © 2011–2012, Texas Instruments Incorporated

NOTE: The event trigger input (GPTi_EVENT_CAPTURE) for GPTIMER2 through GPTIMER7 is internally tied low, and the PWM output (GPTi_PWM_OUT) is not connected.

NOTE: For GPTIMER8 through GPTIMER11, the GPTi_PORGPOCFG signal selects to connect the GPT pwm output or the GPT capture input to the dmtimerx_pwm_evt (where x = 8 to 11) pad at the top level. When the TCLR[14] GPO_CFG bit = 0b1 , the dmtimerx_pwm_evt functions as a capture input. When the TCLR[14] GPO_CFG bit = 0b0, the dmtimerx_pwm_evt functions as a pwm output (GPO_CFG = 0b0).

23.2.4 GP Timer Functional Description

Each GP timer contains a free-running upward counter with autoreload capability on overflow. The timer counter can be read and written on-the-fly (while counting). Each GP timer includes compare logic to allow an interrupt event on a programmable counter matching value. A dedicated output signal can be pulsed or toggled on either an overflow or a match event. This offers time-stamp trigger signaling or PWM signal sources. A dedicated input signal can be used to trigger an automatic timer counter capture or an interrupt event on a programmable input signal transition. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged into one module interrupt line and one wake-up line.

Each internal interrupt source can be independently enabled/disabled with a dedicated bit of the GPT_TIER register for the interrupt features, and a dedicated bit of the GPT_TWER register for the wake-up of GPTIMER1, GPTIMER2, and GPTIMER10. In addition, these timers have a mechanism implemented to generate an accurate tick interrupt.

For the other GP Timers, each internal interrupt source can be independently enabled/disabled through the GPT_IRQENABLE_SET and GPT_IRQENABLE_CLR register bit fields.

For each GP timer implemented in the device, there are two possible clock sources:

- 32-kHz clock
- System clock

Selection of the input clock source is done in the registers in the PRCM configuration (see Section 23.2.1, *GP Timer Overview*).

Each GP timer supports three functional modes:

- Timer mode
- Capture mode
- Compare mode

The capture and compare modes are disabled by default after core reset.

23.2.4.1 GP Timer Block Diagram

Figure 23-5 is a block diagram of the common GP timers, and Figure 23-6 is a block diagram of the GP timers with 1-ms tick generation module.

23.2.4.2 GPTIMER1, GPTIMER2, and GPTIMER10 Power Management

The GP timer modules have an internal bit, GPT1MS_TIOCP_CFG[0] AUTOIDLE, that is used to apply an internal interface clock gating strategy.

At the PRCM module level, when all conditions to shut off the PRCM module functional or interface output clocks are met (see Section 3.1.1.1.4, *Clock Domain-Level Clock Management*), the PRCM module automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the GPT1MS_TIOCP_CFG[4:3] IDLEMODE bit field.

Table 23-7 lists the IDLEMODE settings and the related acknowledgment modes.

Table 23-5. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The GP timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
10	Smart-idle	The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach to efficient system power management.
11	Reserved	

When configured in smart-idle mode, the GP timer also offers an additional granularity on GPTi_FCLK and GPTi_ICLK gating. The GPT1MS_TIOCP_CFG[9:8] CLOCKACTIVITY bit field is used to determine which clock is shut down (GPTi_FCLK, GPTi_ICLK, neither, or both clocks).

The CLOCKACTIVITY setting is used internally to the GP timer to determine the part of the module on which the conditions to acknowledge the PRCM IDLE request are tested. For example, if GPTi_FCLK is not to be shut down on a PRCM IDLE request, the GP timer considers only GPTi_ICLK and associated pending activities before acknowledging the request.

Some GP timer features are associated with GPTi_ICLK and others are associated with GPTi_FCLK. Using the CLOCKACTIVITY setting along with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if the GP timer acknowledges an IDLE request.

Table 23-6 lists the CLOCKACTIVITY settings and associated features.

Table 23-6. CLOCKACTIVITY Settings

CLOCKACTIVITY Value	GPTi_ICLK Effects	GPTi_FCLK Effects	Description	Associated Features
00	OFF	OFF	GPTi_ICLK and GPTi_FCLK are considered for generating the acknowledge. This setting also means GPTi_FCLK and GPTi_ICLK are likely to be shut down on PRCM IDLE request.	The idle acknowledge signal is asserted when there are no pending activities on the functional clock domain (improved latency in assertion of idle acknowledge). The wake-up capability of the GP timer is disabled.
01	ON	OFF	GPTi_ICLK is not shut down on PRCM IDLE request; only GPTi_FCLK is affected.	

Copyright © 2011–2012, Texas Instruments Incorporated

Table 23-6. CLOCKACTIVITY Settings (continued)

CLOCKACTIVITY Value	GPTi_ICLK Effects	GPTi_FCLK Effects	Description	Associated Features
10	OFF	ON	GPTi_FCLK is not shut down on PRCM IDLE request; only GPTi_ICLK is affected.	The idle acknowledge signal is asserted when there are no pending activities on the interface clock domain, without evaluating the pending activities on the functional clock domain (the GP timer enters into sleep mode, and if a pending interrupt event is completed during idle mode, the wake-up signal is asserted). The wake-up signal is enabled.
11	ON	ON	None of the clocks are shut down. Therefore, the GP timer can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clocks.	

CAUTION

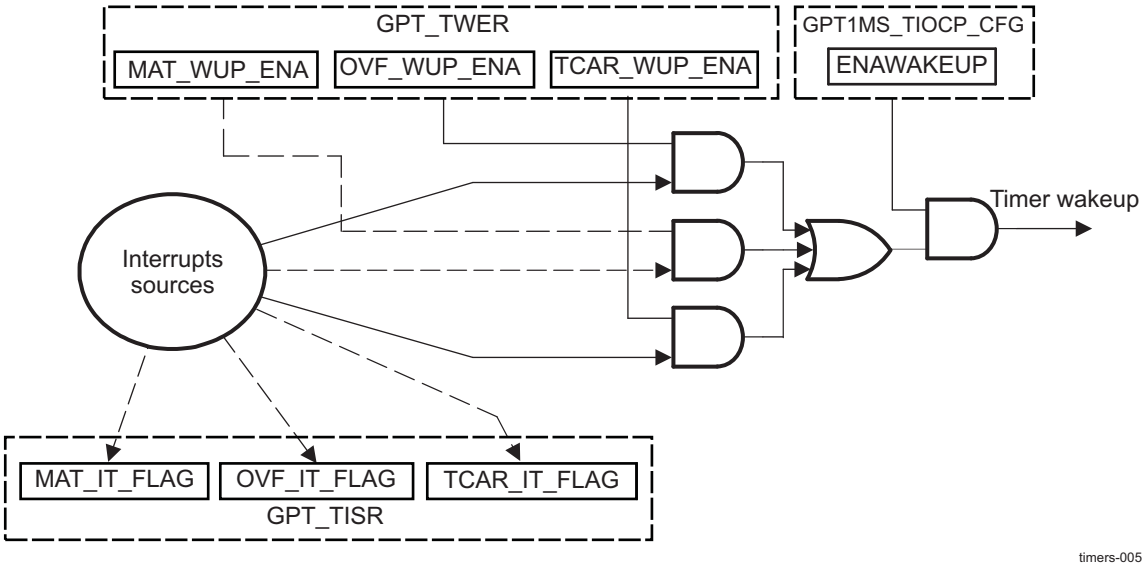
The PRCM module does not have any hardware means to read the CLOCKACTIVITY settings. The software must ensure consistent programming between the GP timer CLOCKACTIVITY and the PRCM module functional clock and interface clock control bits. If the GP timer is disabled in the CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the GP timer clocks. This can lead to unpredictable behavior.

23.2.4.2.1 Wake-Up Capability

If the GPT1MS_TIOCP_CFG[4:3] IDLEMODE bit field sets the smart-idle mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request. This wake-up request is sent only if the GPT1MS_TIOCP_CFG[2] ENAWAKEUP bit enables the timer wake-up capability.

Figure 23-7 shows the wake-up request generation. For more information on the GP timer clock control, see Section 3.6, *Clock Management Functional Description* in Chapter 3, *Power, Reset and Clock Management*.

Figure 23-7. Wake-Up Request Generation



Copyright © 2011–2012, Texas Instruments Incorporated

For GPTIMER1, GPTIMER2, and GPTIMER10, the timer wake-up enable-register (GPT_TWER) allows masking the expected source of the wake-up event that generates a wake-up request. The GPT_TWER register is synchronously programmed with the interface clock before the PRCM module sends an idle mode request. The expected source of the wake-up event is an overflow (GPT_TCRR), a timer match (the compare result of GPT_TCRR and GPT_TMAR matches the counter value), and a timer capture (detection of an external pulse transition of the correct polarity on the GPT_EVENT_CAPTURE).

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (GPT_TISR). The pending wake-up event is reset when the set status bit is overwritten with 1.

NOTE: The status bit must be reset to re-enter idle mode.

23.2.4.3 Power Management of Other GP Timers

At the PRCM module level, when all conditions to shut off the PRCM module functional or interface output clocks are met (see Section 3.1.1.1.4, *Clock Domain Level Clock Management*), the PRCM module automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the GPT_TIOCP_CFG[3:2] IDLEMODE bit field.

Table 23-7 lists the IDLEMODE settings and the related acknowledgment modes.

Table 23-7. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The GP timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, however, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
10	Smart-idle	The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach to efficient system power management.
11	Reserved	

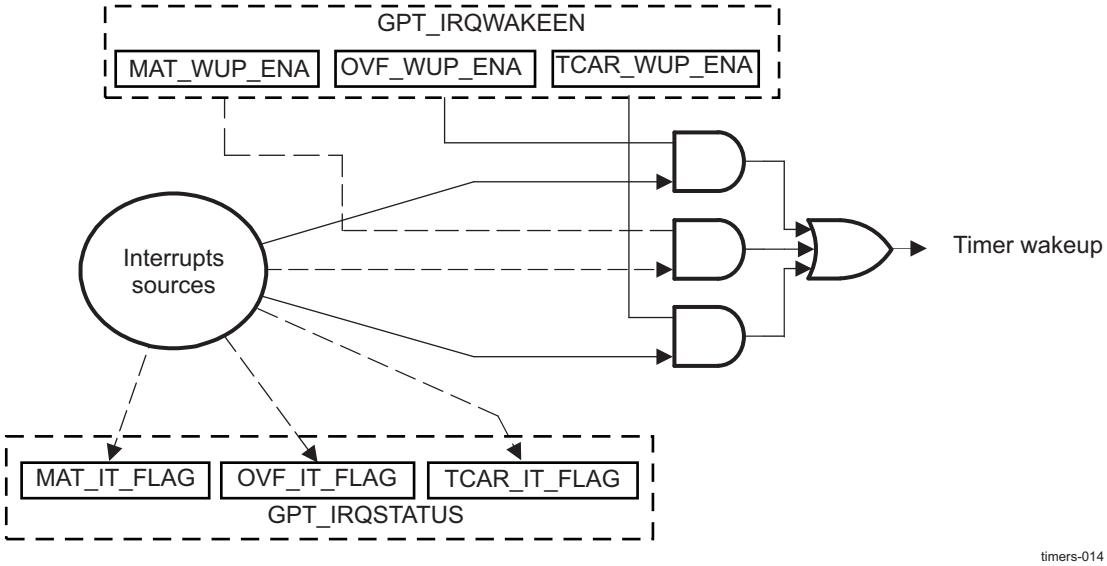
23.2.4.3.1 Wake-Up Capability

If the GPT_TIOCP_CFG[3:2] IDLEMODE bit field sets the smart-idle mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request. This wake-up request is sent only if the GPT_IRQWAKEEN[2:0] bit field enables the timer wake-up capability.

Figure 23-8 shows the wake-up request generation. For more information on the GP timer clock control, see Section 3.6, *Clock Management Functional Description* in Chapter 3, *Power, Reset and Clock Management*.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 23-8. Wake-Up Request Generation



When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (GPT_IRQSTATUS). The pending wake-up event is reset when the set status bit is overwritten with 1.

NOTE: The status bit must be reset to re-enter idle mode.

23.2.4.4 Software Reset

Two bit fields can generate a software reset of the GP timer:

- GPT1MS_TIOCP_CFG[1] SOFTRESET for GPTIMER1, GPTIMER2, and GPTIMER10, and GPT_TIOCP_CFG[0] SOFTRESET for other timers
- GPT_TSICR[1] SFT for all timers

For both bits, all read accesses return 0.

The GPT1MS_TIOCP_CFG[1] SOFTRESET/GPT_TIOCP_CFG[0] SOFTRESET bit allows resetting the functional and interface domains. The GPT_TSICR[1] SFT bit allows resetting the functional part of the GP timer.

Before accessing or using the GP timer, the local host must ensure that both internal resets are released by reading the GPT_TISTAT[0] RESETDONE (for GPTIMER1, GPTIMER2, and GPTIMER10), or the GPT_TIOCP_CFG[0] SOFTRESET bit (for other timers). This bit monitors the internal reset status.

23.2.4.5 GP Timer Interrupts

The timer can issue an overflow interrupt, a timer match interrupt, and a timer capture interrupt. Each internal interrupt source can be independently enabled/disabled in the interrupt-enable register (GPT_TIER for GPTIMER1, GPTIMER2, and GPTIMER10), or, for other timers, enable in the interrupt-enable register (GPT_IRQENABLE_SET) and disable in the interrupt disable register (GPT_IRQENABLE_CLR). When the interrupt event is issued, the associated interrupt status bit is set in the timer status register (GPT_TISR for GPTIMER1, GPTIMER2, and GPTIMER10, and GPT_IRQSTATUS for other timers).

Copyright © 2011–2012, Texas Instruments Incorporated

23.2.4.6 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the timer control register (GPT_TCLR[0] ST bit). The timer counter register (GPT_TCRR) can be loaded when stopped or on-the-fly (while counting). GPT_TCRR can be loaded directly by a GPT_TCRR write access with a new timer value. The GPT_TCRR register can also be loaded with the value held in the timer-load register GPT_TLDR by a trigger register (GPT_TTGR) write access. Loading of GPT_TCRR is done regardless of the GPT_TTGR written value. The timer counter register GPT_TCRR value can be read when stopped, or captured on-the-fly by a GPT_TCRR read access. The timer is stopped and the counter value is set to 0 when the module reset is asserted. The timer is maintained at stop after the reset is released.

In one-shot mode (the GPT_TCLR[1] AR bit set to 0), the counter is stopped after counting overflow occurs (the counter value remains at 0).

When the autoreload mode is enabled (the GPT_TCLR[1] AR bit set to 1), the GPT_TCRR register is reloaded with the timer-load register (GPT_TLDR) value after a counting overflow occurs.

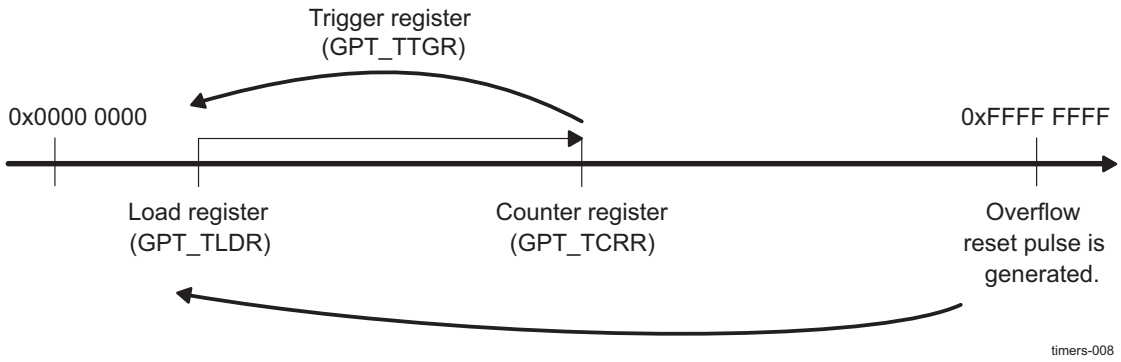
CAUTION

Do not put the overflow value (0xFFFF FFFF) in the GPT_TLDR register because it can lead to undesirable results.

An interrupt can be issued on overflow if the overflow interrupt-enable bit is set in the timer interrupt-enable register (GPT_TIER[1] OVF_IT_ENA bit set to 1 for GPTIMER1, GPTIMER2, and GPTIMER10, or GPT_IRQENABLE_SET[1] OVF_IT_FLAG bit set to 1 for other timers). A dedicated output pin (timer PWM) can be programmed in GPT_TCLR[12] through GPT_TCLR[11:10] (PT and TRG bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs. The GPT_TCLR[12] PT bit selects pulse/toggle modulation (GPT_TCLR[11:10] TRG bit field selects trigger mode).

Figure 23-9 shows the GPT_TCRR timing value.

Figure 23-9. GPT_TCRR Timing Value



23.2.4.6.1 1-ms Tick Generation (Only GPTIMER1, GPTIMER2, and GPTIMER10)

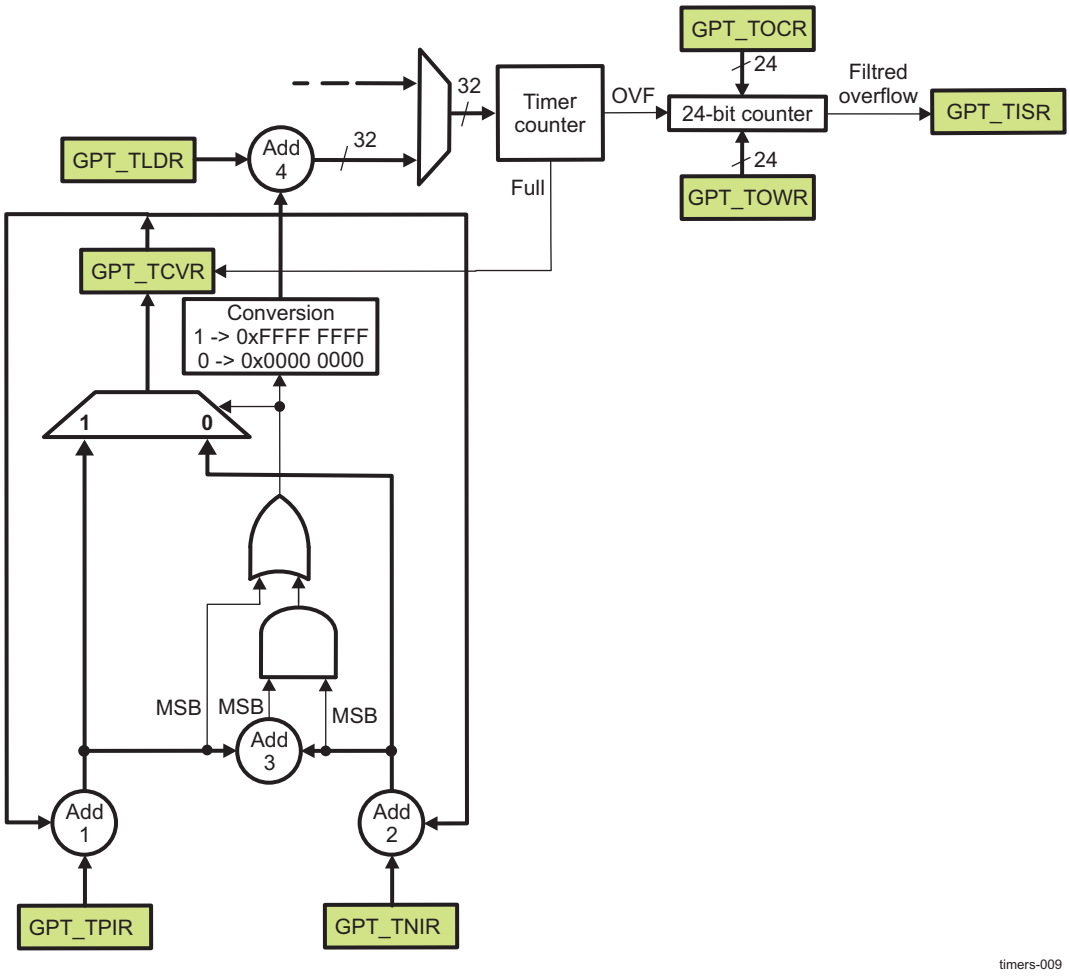
The interrupt period is not exactly 1 ms because the timer input clock is 32,768 Hz. If the clock counts up to 32, it obtains a 0.977-ms period; if it counts up to 33, it obtains a 1.007-ms period. For large granularity, the error is cumulative and can generate important deviations from the standard value.

To minimize the error between a true 1-ms tick and the tick generated by the 32,768 Hz timer, the sequencing of periods less than 1 ms and periods greater than 1 ms must be shuffled. An additional 1-ms block is used to correct this error. See Figure 23-10.

In this implementation, the increment sequencing is automatically managed by the timer to minimize the error. The user must define only the value of the timer positive increment register (GPT_TPIR[31:0] POSITIVE_INC_VALUE bit field) and the timer negative increment register (GPT_TNIR[31:0] NEGATIVE_INC_VALUE bit field). An automatic adaptation mechanism is used to simplify the programming model.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 23-10. Block Diagram of the 1-ms Tick Module



The GPT_TPIR, GPT_TNIR, and GPT_TCVR registers and adders Add1, Add2, and Add3 are used to define whether the next value loaded in the timer counter register (GPT_TCRR[31:0] TIMER_COUNTER bit field) is the value of the GPT_TLDR[31:0] LOAD_VALUE bit field (period less than 1 ms) or the value of GPT_TLDR[31:0] LOAD_VALUE –1 (period greater than 1 ms).

Table 23-8 lists the value loaded in the GPT_TCRR register according to the sign of the result of Add1, Add2, and Add3.

MSB = 0: Positive value, MSB = 1: Negative value

Table 23-8. Value Loaded in GPT_TCRR to Generate 1-ms Tick

0	1	0	GPT_TLDR[31:0] LOAD_VALUE bit field
0	1	1	GPT_TLDR[31:0] LOAD_VALUE –1
1	0	0	N/A
1	0	1	N/A
1	1	0	GPT_TLDR[31:0] LOAD_VALUE –1
1	1	1	GPT_TLDR[31:0] LOAD_VALUE –1

Copyright © 2011–2012, Texas Instruments Incorporated

The values of the GPT_TPIR and GPT_TNIR registers are calculated using the following formula:

- Positive increment value = ((INTEGER[F_{clk} * T_{tick}] + 1) * 1e6) - (F_{clk} * T_{tick} * 1e6)
- Negative increment value = (INTEGER[F_{clk} * T_{tick}] * 1e6) - (F_{clk} * T_{tick} * 1e6)

NOTE: Fclk clock frequency (kHz)

Ttick tick period (ms)

The timer overflow counter register (GPT_TOCR) and the timer overflow wrapping register GPT_TOWR) are used to filter interrupts. When the timer overflows, it increments the 24-bit GPT_TOCR register. When the 24-bit GPT_TOCR register values match the value in the 24-bit GPT_TOWR register and the timer overflow is asserted, the GPT_TOCR register is reset and an interrupt is generated to the GPT_TISR register.

With the conversion block in reset state (the positive increment register, negative increment register, and counter value register are zeroed), the programming model and the behavior of GPTIMER1, GPTIMER2, and GPTIMER10 remain unchanged.

For 1-ms tick with a 32,768-Hz clock:

- GPT_TPIR[31:0] POSITIVE_INC_VALUE = 232000
- GPT_TNIR[31:0] NEGATIVE_INC_VALUE = –768000
- GPT_TLDR[31:0] LOAD_VALUE = 0xFFFF FFE0

NOTE: Any value of the tick period can be generated with the appropriate value of the GPT_TPIR, GPT_TNIR, and GPT_TLDR registers.

By default, the GPT_TPIR, GPT_TNIR, GPT_TCVR, GPT_TOCR, and GPT_TOWR registers and the associated logic are in reset mode (all 0s) and have no action on the programming model.

23.2.4.7 Capture Mode Functionality

When a transition is detected on the module input pin (EVENT_CAPTURE), the timer value in the GPT_TCRR register can be captured and saved in the GPT_TCAR1 or TCAR2 register function of the mode selected in the GPT_TCLR[13] CAPT_MODE bit. The edge detection circuitry monitors transitions on the input pin (EVENT_CAPTURE).

The rising edge, falling edge, or both, can be selected in the GPT_TCLR[9:8] TCM bit field to trigger the timer counter capture. The module sets the GPT_TISR[2] TCAR_IT_FLAG bit for GPTIMER1, GPTIMER2, or GPTIMER10, and the GPT_IRQSTATUS[2] TCAR_IT_FLAG bit for other timers, when an active edge is detected, and at the same time, the counter value GPT_TCRR is stored in timer capture register GPT_TCAR1 or GPT_TCAR2, as follows:

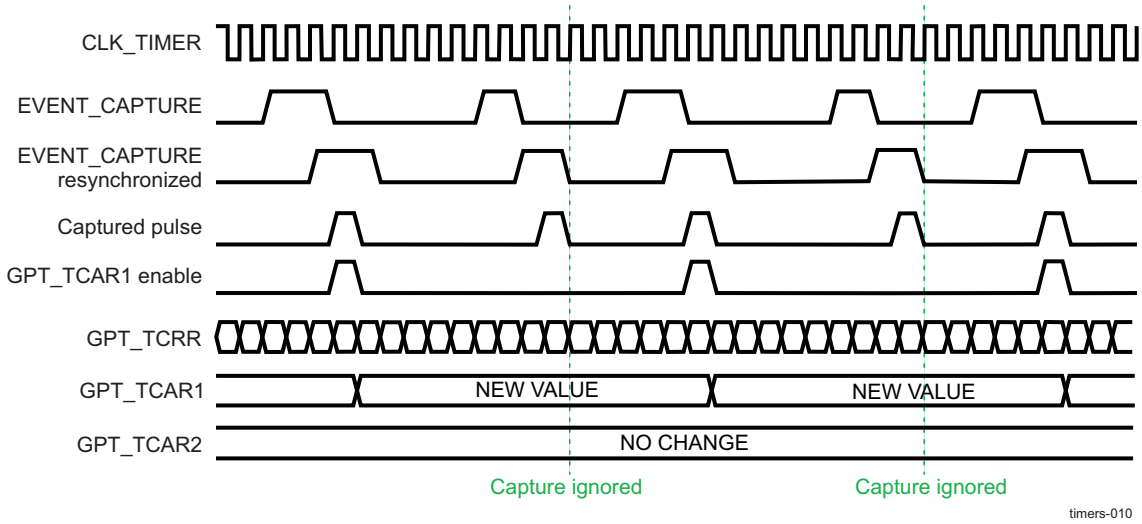
- If the GPT_TCLR[13] CAPT_MODE bit is 0, on the first enabled capture event, the value of the counter register is saved in the GPT_TCAR1 register, and all the next events are ignored (no update on the GPT_TCAR1 register and no interrupt triggering) until the detection logic is reset or the GPT_TISR[2] TCAR_IT_FLAG bit (or GPT_IRQSTATUS[2] TCAR_IT_FLAG, depending on the timer) is cleared by writing 1 to it.
- If the GPT_TCLR[13] CAPT_MODE bit is 1, on the first enabled capture event, the value of the counter register is saved in the GPT_TCAR1 register, and on the second enabled capture event, the value of the counter register is saved in the GPT_TCAR2 register. If a capture interrupt is enabled, the interrupt triggers on the second event capture. All other events are ignored (no update on GPT_TCAR1/GPT_TCAR2 and no interrupt triggering) until the detection logic is reset or GPT_TISR[2] TCAR_IT_FLAG bit (or GPT_IRQSTATUS[2] TCAR_IT_FLAG, depending on the timer) is cleared by writing 1 to it. This mechanism is useful for period calculation of a clock, if that clock is connected to the EVENT_CAPTURE input pin.

Copyright © 2011–2012, Texas Instruments Incorporated

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served. The GPT_TISR[2] TCAR_IT_FLAG bit or the GPT_IRQSTATUS[2] TCAR_IT_FLAG (previously 1) is cleared by writing 1 to it or when the edge detection mode bits (the GPT_TCLR[9:8] TCM bit field) are changed from no-capture mode detection to any other mode. The timer functional clock (input to prescaler) is used to sample the input pin (EVENT_CAPTURE). A negative or positive pulse input can be detected when the pulse time is greater than the functional clock period. An interrupt is issued on edge detection if the capture interrupt-enable bit is set in the GPT_TIER[2] TCAR_IT_ENA bit (for GPTIMER1, GPTIMER2, or GPTIMER10), or in the GPT_IRQENABLE_SET[2] TCAR_EN_FLAG bit (for other timers). See the examples in Figure 23-11 and Figure 23-12.

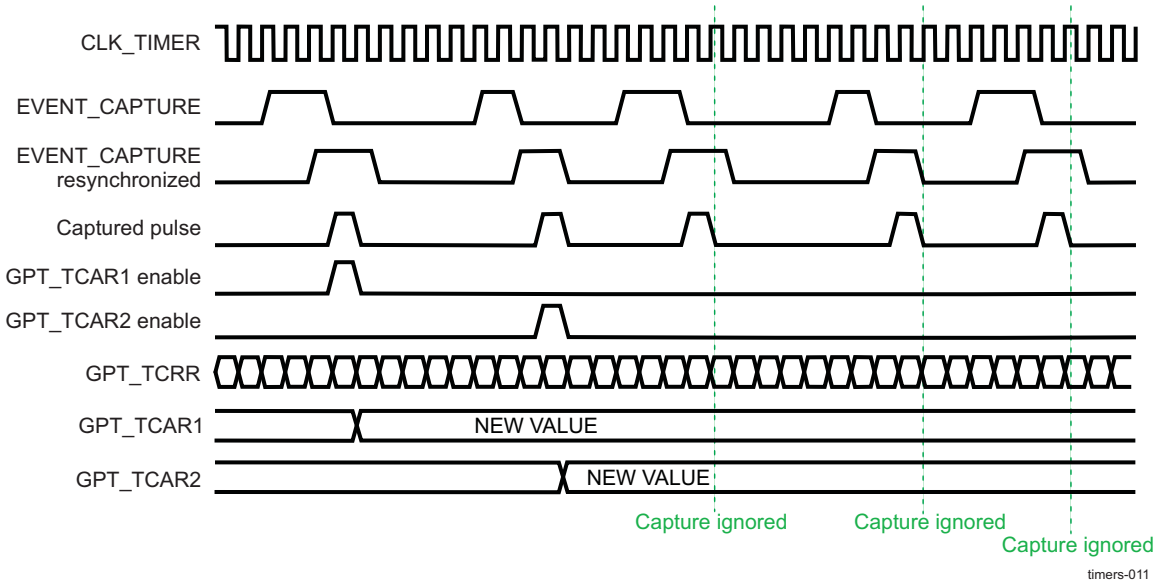
In Figure 23-11, the GPT_TCLR[9:8] TCM bit field value is 0b01, and GPT_TCLR[13] CAPT_MODE bit is 0. Only the rising edge of EVENT_CAPTURE triggers a capture in the GPT_TCAR1 and GPT_TCAR2 registers, and only the GPT_TCAR1 register updates.

Figure 23-11. Capture Wave Example for GPT_TCLR[13] CAPT_MODE = 0



In Figure 23-12, the value of the GPT_TCLR[9:8] TCM bit field is 0b01, and the GPT_TCLR[13] CAPT_MODE bit is 1. Only the rising edge of EVENT_CAPTURE triggers a capture in the GPT_TCAR1 register on the first enabled event, and the GPT_TCAR2 register updates on the second enabled event.

Figure 23-12. Capture Wave Example for GPT_TCLR[13] CAPT_MODE = 1



Copyright © 2011–2012, Texas Instruments Incorporated

23.2.4.8 Compare Mode Functionality

When compare enable-register GPT_TCLR[6] CE bit is set to 1, the timer value (GPT_TCRR[31:0] TIMER_COUNTER bit field) is continuously compared to the value held in the timer match register (GPT_TMAR). The GPT_TMAR[31:0] COMPARE_VALUE bit field value can be loaded at any time (timer counting or stopped). When the GPT_TCRR and the GPT_TMAR values match, an interrupt is issued, if the GPT_TIER[0] MAT_IT_ENA (for GPTIMER1, GPTIMER2, and GPTIMER10), or GPT_IRQSTATUS_SET[0] MAT_EN_FLAG bit (for other timers) is set.

The right programming way is to write a compare value to the GPT_TMAR register before setting the GPT_TCLR[6] CE bit to prevent any unwanted interrupts due to a reset value matching effect.

The dedicated output pin (timer PWM) can be programmed in the GPT_TCLR[12] PT bit through the GPT_TCLR[11:10] TRG bit field to generate one positive pulse (timer clock duration) or to invert the current value (toggle mode) when an overflow or a match occurs.

23.2.4.9 Prescaler Functionality

A prescaler can be used to divide the timer counter input clock frequency. The prescaler is enabled when the GPT_TCLR[5] PRE bit is set. The GPT_TCLR[4:2] PTV bit field sets the second prescaler ratio. The prescaler counter is reset when the timer counter is stopped or reloaded on-the-fly.

Table 23-9 lists the prescaler/timer reload values versus contexts.

Table 23-9. Prescaler/Timer Reload Values Versus Contexts

Context	Prescaler	Timer Counter
Overflow (when autoreload is on)	Reset	GPT_TLDR[31:0]
GPT_TCRR write	Reset	GPT_TCRR[31:0]
GPT_TTGR write	Reset	GPT_TLDR[31:0]
Stop	Reset	Frozen

23.2.4.10 Pulse-Width Modulation

The timer can be configured to provide a programmable PWM output. The timer PWM output pin can be configured to toggle on an event. The GPT_TCLR[11:10] TRG bit field determines on which register value the PWM pin toggles. Either overflow alone or both overflow and match can be selected to toggle the timer PWM pin when a compare condition occurs.

CAUTION

In toggle mode, when GPT_TCLR[11:10] TRG = 0x2 (overflow and match), the first event that toggles the PWM line is an overflow event. If a match event occurs first; it does not toggle the PWM line (see Figure 23-14).

The GPT_TCLR[7] SCPWM bit can be programmed to set or clear the timer PWM output signal only while the counter is stopped or the trigger is off. This allows setting the output pin to a known state before modulation starts. Modulation synchronously stops when the GPT_TCLR[11:10] TRG bit field is cleared and overflow occurs. This allows fixing a deterministic state of the output pin when modulation stops.

In Figure 23-13, the internal overflow pulse is set each time (0xFFFF FFFF - GPT_TLDR[31:0] LOAD_VALUE + 1) the value is reached, and the internal match pulse is set when the counter reaches the GPT_TMAR register value. Depending on the value of the GPT_TCLR[12] PT bit and GPT_TCLR[11:10] TRG bit field, the timer provides pulse or PWM event on the output pin (timer PWM).

The GPT_TLDR and GPT_TMAR registers must keep values below the overflow value (0xFFFF FFFF) by at least two units. In case the PWM trigger events are both overflow and match, the difference between the values kept in the GPT_TMAR register and the value in theGPT_TLDR register must be at least two units. When match event is used, the compare mode GPT_TCLR[6] CE bit must be set.

Copyright © 2011–2012, Texas Instruments Incorporated

In Figure 23-13, the GPT_TCLR[7] SCPWM bit is set to 0. In Figure 23-14, the GPT_TCLR[7] SCPWM bit is set to 1. To obtain the desired wave form, start the counter at 0xFFFF FFFE value (to ensure an overflow first) or adjust the line polarity (GPT_TCLR[7] SCPWM bit).

Figure 23-13. Timing Diagram of PWM With GPT_TCLR[7] SCPWM Bit = 0

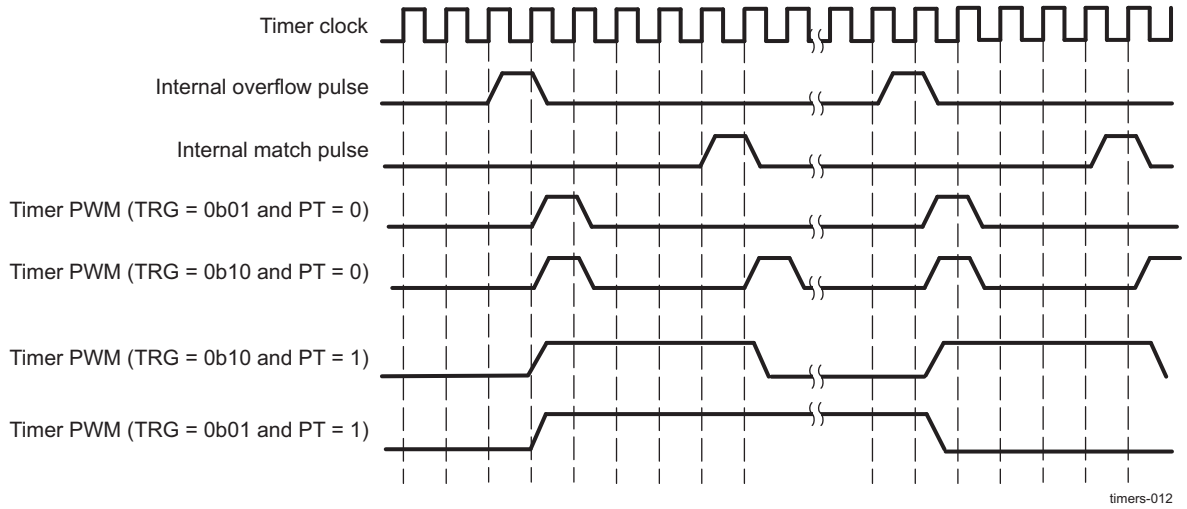


Figure 23-14. Timing Diagram of PWM With GPT_TCLR[7] SCPWM Bit = 1

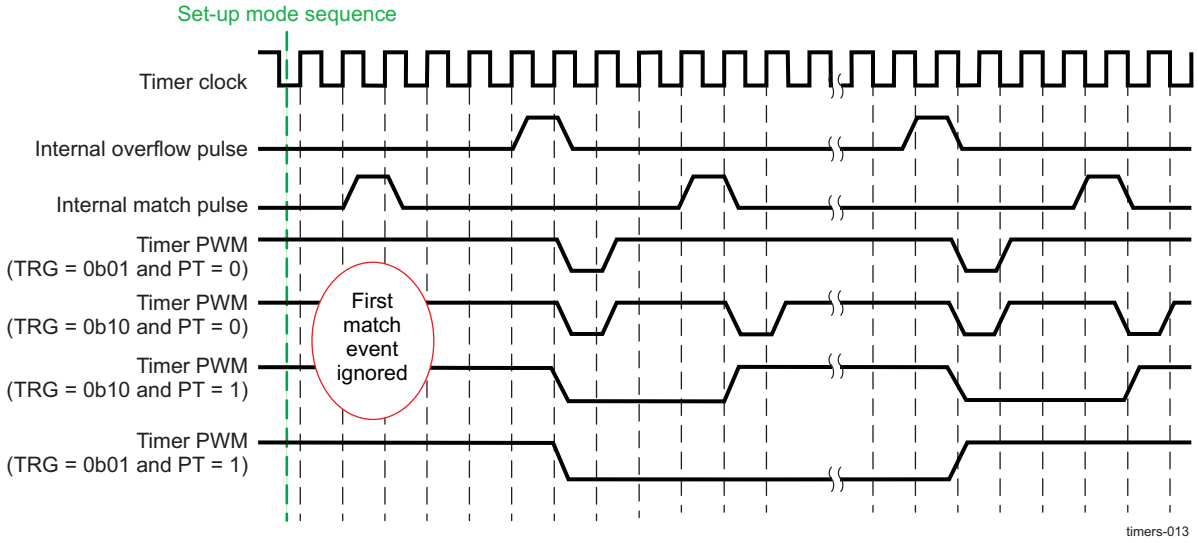

23.2.4.11 Timer Counting Rate

The timer rate is defined by the following values:

- Value of the prescaler fields (the GPT_TCLR[5] PRE bit and the GPT_TCLR[4:2] PTV bit field)
- Value loaded into the timer-load register (GPT_TLDR)

Table 23-10 lists the prescaler clock ratio values.

Table 23-10. Prescaler Clock Ratio Values

GPT_TCLR[5] PRE	GPT_TCLR[4:2] PTV	Divisor (PS)
0	X	1
1	0	2
1	1	4

Copyright © 2011–2012, Texas Instruments Incorporated

Table 23-10. Prescaler Clock Ratio Values (continued)

GPT_TCLR[5] PRE	GPT_TCLR[4:2] PTV	Divisor (PS)
1	2	8
1	3	16
1	4	32
1	5	64
1	6	128
1	7	256

Thus, the timer overflow rate is expressed as:

OVF_Rate = (0xFFFF FFFF – GPT_TLDR + 1) * (timer-functional clock period) * PS

With (timer-functional clock period) = 1/(timer-functional clock frequency) and PS = $2^{(PTV + 1)}$ if prescaler is enabled, or PS = 1 if prescaler is disabled.

CAUTION

Internal resynchronization causes any write to the GPT_TCLR[1] ST bit to have some latency before the register is updated:

2.5 * functional clock cycles write_GPT_TCLR_latency 3.5 * functional clock cycles

Remember to consider this latency whenever the timer must be started or stopped by a software change to the GPT_TCLR[1] ST bit.

CAUTION

- In the non-PWM mode, GPT_TLDR must be maintained at less than or equal to 0xFFFF FFFE.
- In the PWM mode, GPT_TLDR must be maintained at less than or equal to 0xFFFF FFFD.

For example, with a timer clock input of 32 kHz and the GPT_TCLR[5] PRE bit set to 0, the timer output period is as listed in Table 23-11.

Table 23-11. Value and Corresponding Interrupt Period

GPT_TLDR[31:0] LOAD_VALUE	Interrupt Period
0x0000 0000	39 h
0xFFFF 0000	2.1 s
0xFFFF FFF0	524 µs
0xFFFF FFFE	65.5 µs

23.2.4.12 Timer Under Emulation

During emulation mode, the timer continues to run according to the value of the GPT1MS_TIOCP_CFG[5]/GPT_TIOCP_CFG[1] EMUFREE bit.

If the GPT1MS_TIOCP_CFG[5]/GPT_TIOCP_CFG[1] EMUFREE bit is set to 1, timer execution is not stopped in emulation mode and the interrupt is still generated when overflow or match is reached.

If the GPT1MS_TIOCP_CFG[5]/GPT_TIOCP_CFG[1] EMUFREE bit is set to 0, the prescaler and timer are frozen and both resume on exit from emulation mode. The asynchronous external input pin (dmtimer_i_pwm_evt, with i=[8:11]) is internally synchronized on two timer-clock rising edges.

Copyright © 2011–2012, Texas Instruments Incorporated

23.2.4.13 Accessing GP Timer Registers

All accesses are nonposted until software reconfiguration. All registers are 32 bits wide, accessible through the L4 interface with 16-bit or 32-bit access (read/write).

Any 16-bit write access must be least-significant bit (LSB) first, and the second write access must be most-significant bit (MSB) first. Write operations to the following GP timer registers can skip the MSB access if it is not necessary to update the 16 MSBs of the register:

- GPT_TIDR
- GPT_TIOCP_CFG
- GPT1MS_TIOCP_CFG
- GPT_IRQSTATUS_RAW
- GPT_IRQSTATUS
- GPT_IRQENABLE_SET
- GPT_IRQENABLE_CLR
- GPT_IRQWAKEEN
- GPT_TISR
- GPT_TIER
- GPT_TWER
- GPT_TSICR

Write operations to the following functional registers must be complete (the MSB must be written even if the MSB data is not used):

- GPT_TCLR
- GPT_TCRR
- GPT_TLDR
- GPT_TTGR
- GPT_TMAR
- GPT_TPIR
- GPT_TNIR
- GPT_TCVR
- GPT_TOCR
- GPT_TOWR

The following L4 synchronous registers are not affected by the posted/nonposted mode selection; the write/read operation is effective and acknowledged (command accepted) after one L4 clock cycle from command assertion:

- GPT_TIDR
- GPT_TIOCP_CFG
- GPT1MS_TIOCP_CFG
- GPT_TISTAT
- GPT_IRQSTATUS
- GPT_IRQSTATUS_RAW
- GPT_IRQENABLE_SET
- GPT_IRQENABLE_CLR
- GPT_IRQWAKEEN
- GPT_TWPS
- GPT_TSICR

Copyright © 2011–2012, Texas Instruments Incorporated

23.2.4.13.1 Writing to Timer Registers

The host uses the L4 interface to write to the following registers synchronously with the timer interface clock:

- GPT_TLDR
- GPT_TCRR
- GPT_TCLR
- GPT_TIOCP_CFG
- GPT1MS_TIOCP_CFG
- GPT_IRQSTATUS
- GPT_IRQENABLE_SET
- GPT_IRQENABLE_CLR
- GPT_IRQWAKEEN
- GPT_TTGR
- GPT_TSICR
- GPT_TMAR

GPTIMER1, GPTIMER2, and GPTIMER10 also have the following registers:

- GPT_TPIR
- GPT_TNIR
- GPT_TCVR
- GPT_TOCR
- GPT_TOWR
- GPT_TIER
- GPT_TISR
- GPT_TWER

In 16-bit access mode, the 16 LSBs must be written before writing to the 16 MSBs.

23.2.4.13.1.1 Write Posting Synchronization Mode

This mode is used if the GPT_TSICR[2] POSTED bit is set to 1.

This mode uses a posted write scheme to update any internal register (GPT_TCLR, GPT_TCRR, GPT_TLDR, GPT_TTGR, GPT_TMAR, and GPT_TPIR, GPT_TNIR, GPT_TCVR, GPT_TOCR, and GPT_TOWR for GPTIMER1, GPTIMER2, and GPTIMER10). Therefore, the write transaction is immediately acknowledged on the L4 interface, although the effective write operation occurs later due to a resynchronization in the timer clock domain. The advantage is that neither the interconnect nor the device that requested the write transaction are stalled.

For each register, a status bit is provided in the timer write-posted status register GPT_TWPS. In this mode, it is mandatory that the software checks this status bit prior to any write access. In case a write is attempted to a register with a previous access pending, the previous access is discarded without notice.

The timer module updates the timer counter register value synchronously with the L4 clock. Consequently, any read access to the timer counter register GPT_TCRR does not add any resynchronization latency; the current value is always available.

NOTE: Since the overflow IRQ is generated, when the TCRR value reaches 0xFFFF FFFF, and not when it changes its value to the value after overflow, one must wait a delay of (1 * PS * timer-functional clock period) before any read access to the timer counter register GPT_TCRR to ensure a correct reading of its content.

If a write access is pending for a register, reading from this register does not yield a correct result. Software synchronization must be used to avoid incorrect results.

Copyright © 2011–2012, Texas Instruments Incorporated

The drawback of this automatic update mechanism is that it assumes a given relationship between the timer interface frequency and the timer clock frequency.

Functional frequency range: freq(timer clock) < freq(L4 interface clock)/4.

23.2.4.13.1.2 Write Nonposting Synchronization Mode

This mode is used if the GPT_TSICR[2] POSTED bit is set to 0. It uses a nonposted write scheme to update any internal register. Therefore, the write transaction is not acknowledged on the L4 interface until the effective write operation occurs after the resynchronization in the timer functional clock domain. The drawback is that both the interconnect and the device that requested the write transaction are stalled during this period.

The same full resynchronization scheme is used for a read transaction, and the same stall period applies. A register read following a write to the same register is always coherent.

This mode is functional regardless of the ratio between the L4 interface frequency and the timer clock frequency.

23.2.4.13.2 Reading From Timer Counter Registers

In 16-bit access mode, reading the 16 LSBs from the timer counter registers (GPT_TCRR, GPT_TCAR1, and GPT_TCAR2) captures the current timer counter value. This must be followed by reading the 16 MSBs.

IVA3 subsystem 16-bit accesses can be interleaved with MPU subsystem 32-bit accesses.

NOTE: LSB/MSB accesses cannot be interleaved (that is, the sequence LSB register 1, LSB register 2, MSB register 1, MSB register 2 is not supported).

23.2.5 GP Timer Low-Level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

23.2.5.1 Global Initialization

23.2.5.1.1 Global Initialization of Surrounding Modules

This section identifies the requirements for initializing the surrounding modules when the GP timer module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the GP timer. For more information, see Section 23.2.3 *GP Timers Integration* and Section 23.2.2, *GP Timers Environment*.

Table 23-12. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. For more information about the module configuration, see Section 3.1.1.1.2, *Module Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
Control Module	The module specific pad muxing must be set in the control module. For more information about the module configuration, see Section 19.4.8 *PAD Functional Multiplexing and Configuration,* in Chapter 19, *Control Module*.
MPU INTC	The MPU INTC configuration must be done to enable the interrupts from the GP timer module. See Section 4.4.3, *Interrupt Controller Registers*, in Chapter 4, *Cortex-A9 MPU Subsystem*.
DSP INTC	The DSP INTC configuration must be done to enable the interrupts from GP timer module. See Section 5.3.2.6, *INTC,* in Chapter 5, *DSP Subsystem*.

NOTE: Private Access is an access which is not using the L3/L4 interconnects.

23.2.6.2 GP Timer Registers

23.2.6.2.1 GP Timer Register Summary

CAUTION

The GP timer registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 23-21 through Table 23-27 provide the register summary and associated offset addresses for the 11 GP timer internal registers.

Description	This register controls the various parameters of the L4 interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												IDLEMODE		EMUFREE	SOFTRESET

Bits	Field Name	Description	Type	Reset
31:4	RESERVED	Reserved	R	0x0000000
3:2	IDLEMODE	Power management, req/ack control 0x0: Force-idle mode: local target idle state follows (acknowledges) the system idle requests unconditionally, that is, regardless of the IP module internal requirements. Back-up mode, for debug only. 0x1: No-idle mode: local target never enters idle state. Back-up mode, for debug only. 0x2: Smart-idle mode: local target idle state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module should not generate (IRQ- or DMA-request-related) wake-up events. 0x3: Smart-idle wake-up-capable mode: local target idle state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module may generate (IRQ- or DMA-request-related) wake-up events when in idle state. Mode is only relevant if the appropriate IP module *swake-up* output(s) is (are) implemented.	RW	0x0
1	EMUFREE	Emulation mode 0x0: The timer is frozen in emulation mode (PINSUSPENDN signal active). 0x1: The timer runs free, regardless of PINSUSPENDN value.	RW	0

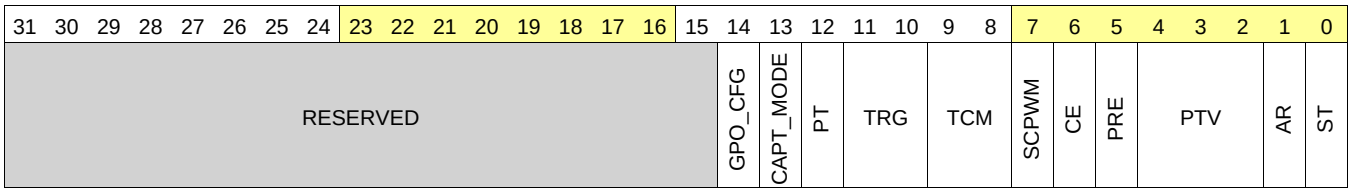
	0x4808 8038		GPTIMER11_L4
Description	This register controls optional features specific to the timer functionality.		
Type	RW		



Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Reserved	R	0x00000
14	GPO_CFG	General-purpose output - this register directly drives the GPTi_PORGPOCFG output pin. For specific use of the GPO_CFG bit, see Section 23.2.2.1, *GP Timer External System Interface*. 0x0: GPTi_PORGPOCFG drives 0. 0x1: GPTi_PORGPOCFG drives 1.	RW	0
13	CAPT_MODE	Capture mode select bit (first/second) 0x0: Single capture: Capture the first enabled capture event in TCAR1. 0x1: Capture on second event: Capture the second enabled capture event in TCAR2.	RW	0
12	PT	Pulse or toggle mode on GPTi_PWM_out output pin 0x0: Pulse modulation 0x1: Toggle modulation	RW	0
11:10	TRG	Trigger output mode on GPTi_PWM_out output pin 0x0: No trigger 0x1: Trigger on overflow. 0x2: Trigger on overflow and match. 0x3: Reserved	RW	0x0

Copyright © 2011–2012, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
9:8	TCM	Transition capture mode on GPTi_EVENT_CAPTURE input pin (When the TCM field passed from (00) to any other combination, the TCAR_IT_FLAG and the edge detection logic are cleared.) 0x0: No capture 0x1: Capture on rising edges of GPTi_EVENT_CAPTURE pin 0x2: Capture on falling edges of GPTi_EVENT_CAPTURE pin 0x3: Capture on both edges of GPTi_EVENT_CAPTURE pin	RW	0x0
7	SCPWM	Pulse width modulation output pin default setting This bit must be set or clear while the timer is stopped or the trigger is off. 0x0: Clear the GPTi_PWM_out output pin and select positive pulse for pulse mode. 0x1: Set the GPTi_PWM_out output pin and select negative pulse for pulse mode.	RW	0
6	CE	Compare enable 0x0: Compare mode is disable. 0x1: Compare mode is enable.	RW	0
5	PRE	Prescaler enable 0x0: The TIMER clock input pin clocks the counter. 0x1: The divided input pin clocks the counter.	RW	0
4:2	PTV	Prescale clock timer value The timer counter is prescaled with the value $2^{(PTV+1)}$. Example: PTV = 3, counter increases value (if started) after 16 functional clock periods.	RW	0x0
1	AR	Autoreload mode 0x0: One shot timer 0x1: Autoreload timer	RW	0
0	ST	Start/stop timer control 0x0: Stop timer: Only the counter is frozen. If one-shot mode selected (AR =0), this bit is automatically reset by internal logic when the counter is overflowed. 0x1: Start timer	RW	0

23.3 Watchdog Timers

23.3.1 Watchdog Timers Overview

The device includes two instances of the 32-bit watchdog timer: WDT2 and WDT3. Figure 23-15 shows how each timer is connected in the device.

NOTE: WDTi (where i is the watchdog timer instance: i = 2 or 3) stands for the following:

- WDT2: Watchdog timer 2, also called MPU watchdog timer
- WDT3: Watchdog timer 3, also called IVA3 watchdog timer

Each watchdog timer is an upward counter capable of generating a pulse on the reset pin and an interrupt to the device system modules following an overflow condition. The MPU watchdog timer serves a reset to the PRCM module and an interrupt to the MPU. The IVA3 watchdog timer serves a watchdog interrupt to the MPU, and its reset outputs are unused.

The watchdog timers can be accessed, loaded, and cleared by registers through the L4 interface. The MPU and IVA3 watchdog timers have the 32-kHz clock for their timer clock input.

The MPU watchdog timer directly generates a warm reset condition on overflow. The IVA3 watchdog timer generates an MPU interrupt condition on overflow, which can be used by the application software through the PRCM module to indirectly trigger a reset condition (that is, to the IVA3 subsystem).

The MPU watchdog timer connects to a single target agent port on the L4 interconnect.

Figure 23-15. Watchdog Timers Block Diagram

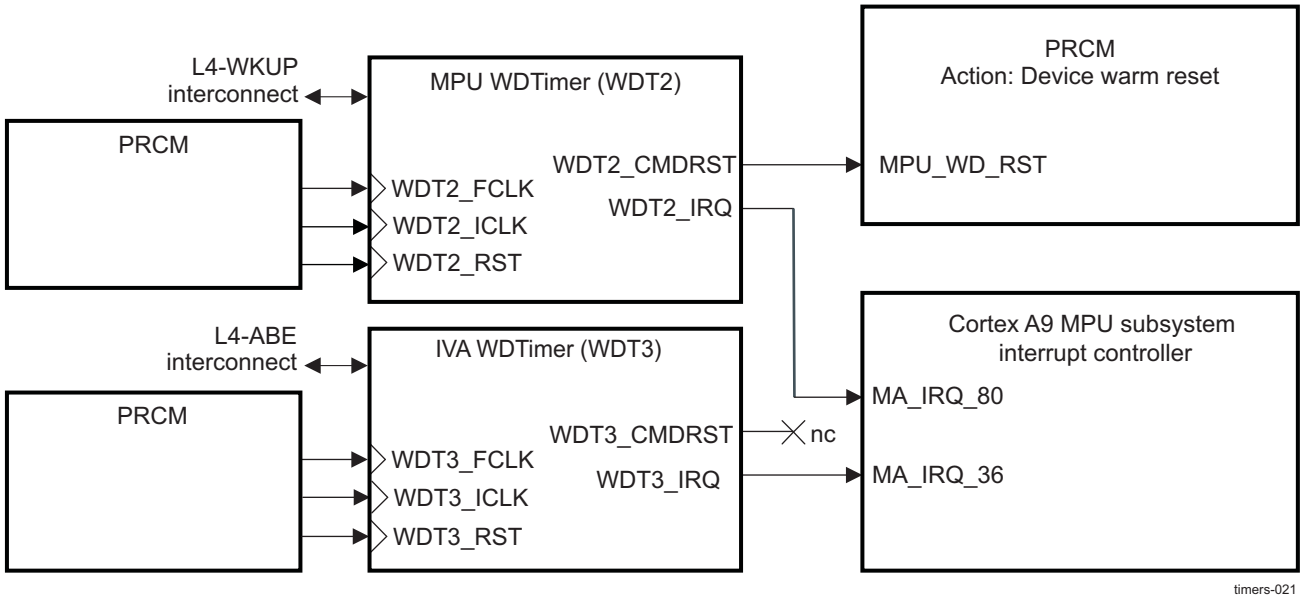

Table 23-80 lists the default state of the watchdog timers in the device.

Table 23-80. Watchdog Timers Default State

Timer	Default State	
MPU WDT2	Enabled	Not running
IVA3 WDT3	Enabled	Not running

Copyright © 2011–2012, Texas Instruments Incorporated

NOTE: The default state of the watchdog timers described in Table 23-80 is considered to be their state immediately after ROM code execution. For more information, see Chapter 28, *Initialization*.

23.3.1.1 Watchdog Timers Features

The main features of the watchdog timer controllers are:

- L4 slave interface support:
  - 32-bit data bus width
  - 32-/16-bit access supported
  - 8-bit access not supported
  - 11-bit address bus width
  - Burst mode not supported
  - Only posted write/read internal resynchronization mode supported
- Free-running 32-bit upward counter
- Programmable divider clock source (2^n where n = [0:7])
- On-the-fly read/write register (while counting)
- Subset programming model of the GP timer
- The watchdog timers are reset either on power-on or after a warm reset before they start counting.
- Reset or interrupt actions when a timer overflow condition occurs
- The watchdog timer generates a reset or an interrupt in its hardware integration (WDT2 or WDT3).

23.3.2 Watchdog Timer Environment

The watchdog timers are accessible through the L4 interface.

23.3.4 Watchdog Timers Functional Description

23.3.4.1 Power Management

There are two clock domains in the watchdog timers:

- Functional clock domain: WDTi_FCLK is the watchdog timer functional clock. It is used to clock the watchdog timer internal logic.
- Interface clock domain: WDTi_ICLK is the watchdog timer interface clock. It is used to synchronize the watchdog timer L4 port to the L4 interconnect. All accesses from the interconnect are synchronous to WDTi_ICLK.

Table 23-82 lists the source clocks for each watchdog timer in the device. For more information about clock control and domains, see Section 3.1.1.1, *Clock Management* in Chapter 3, *Power, Reset, and Clock Management*.

From a global system power-management perspective, when one or both of the watchdog timer clocks is no longer required, the watchdog timers can be deactivated at the PRCM module level in the corresponding registers.

At the PRCM module level, when the conditions to shut off the PRCM module functional or interface output clocks are met (for more information, see the , *Clock Domain Level Clock Management*), the PRCM module automatically launches a hardware handshake protocol to ensure the watchdog timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the watchdog timer.

Although this handshake is a hardware function and out of software control, the way the watchdog timer acknowledges the PRCM IDLE request is configurable through the WDT_WDSC[4:3] IDLEMODE bit field. Table 23-84 lists the settings and related acknowledgment modes of the IDLEMODE bit field.

Table 23-84. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The watchdog timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent loss of data when the clock is switched off.
01	No-idle	The watchdog timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, however, because it does not allow the PRCM module output clock to be shut off and thus the power domain to be set to a lower power state.
10	Smart-idle	The watchdog timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach for efficient system power management.
11	Smart-idle wakeup-capable mode	The watchdog timer acknowledges the IDLE request, basing its decision on its internal activity. The timer generates (IRQ-request-related) wake-up events when in IDLE state if the WDT_WIRQWAKEEN[1:0] bits are set to 1.

23.3.4.1.1 Wake-Up Capability

If the WDT_WDSC[4:3] IDLEMODE bit field sets smart-idle wakeup-capable mode (= 0 × 3), the timer evaluates its internal capability to have the interface clock switched off. When there is no more internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters into sleep mode, ready to issue a wake-up request. This wake-up request is sent only if the WDT_WIRQWAKEEN[0] OVF_WK_ENA and/or the WDT_WIRQWAKEEN[1] DLY_WK_ENA bits enable the overflow and/or the delay wake-up capability.

23.3.4.2 Interrupts

Table 23-85 list the event flags, and their masks, that cause module interrupts.

Copyright © 2011–2012, Texas Instruments Incorporated

Table 23-85. Watchdog Timer Events

Event Flag	Event Mask	Mapping	Comments
WDT_WIRQSTAT[0] EVENT_OVF	WDT_WIRQENSET/WDT_WIRQENCLR[0] OVF_IT_ENA	WDTi_IRQ	Watchdog timer overflow
WDT_WIRQSTAT[1] EVENT_DLY	WDT_WIRQENSET/WDT_WIRQENCLR[1] DLY_IT_ENA	WDTi_IRQ	Watchdog delay value reached

23.3.4.3 General Watchdog Timer Operation

The watchdog timers are based on an upward 32-bit counter coupled with a prescaler. The counter overflow is signaled through two independent signals: a simple reset signal and an interrupt signal, both active low. The use of these signals depends on whether they are connected or not. For this information, see Figure 23-15. The interrupt generation mechanism is controlled through the WDT_WIRQENSET/WDT_WIRQENCLR and WDT_WIRQSTAT registers.

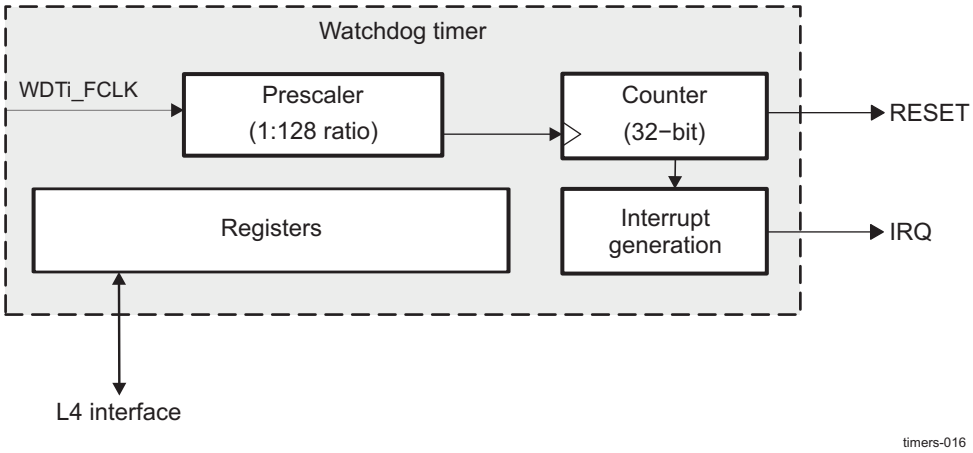
The prescaler ratio can be set from 1 to 128 by accessing the

WDT_WCLR[4:2] PTV bit field and the WDT_WCLR[5] PRE bit of the watchdog control register (WDT_WCLR).

The current timer value can be accessed on-the-fly by reading the watchdog timer counter register (WDT_WCRR), modified by accessing the watchdog timer load register (WDT_WLDR) (no on-the-fly update), or reloaded by following a specific reload sequence on the watchdog timer trigger register (WDT_WTGR). A start/stop sequence applied to the watchdog timer start/stop register (WDT_WSPR) can start and stop the watchdog timers.

Figure 23-17 is a functional block diagram of the watchdog timer.

Figure 23-17. 32-Bit Watchdog Timer Functional Block Diagram



23.3.4.4 Reset Context

The watchdog timers are enabled after reset. Table 23-86 lists the default reset values of the two watchdog timer load registers (the WDT_WLDR) and prescaler ratios (the WDT_WCLR[4:2] PTV bit field). To get these values, software must read the corresponding WDT_WCLR[4:2] PTV bit field and the 32-bit register to retrieve the static configuration of the module.

Table 23-86. Count and Prescaler Default Reset Values

Timer	WDT_WLDR Reset Value	PTV Reset Value
MPU WDT (WDT2)	0xFFFB 0000	0
IVA3 WDT (WDT3)	0xFFFB 0000	0

Copyright © 2011–2012, Texas Instruments Incorporated

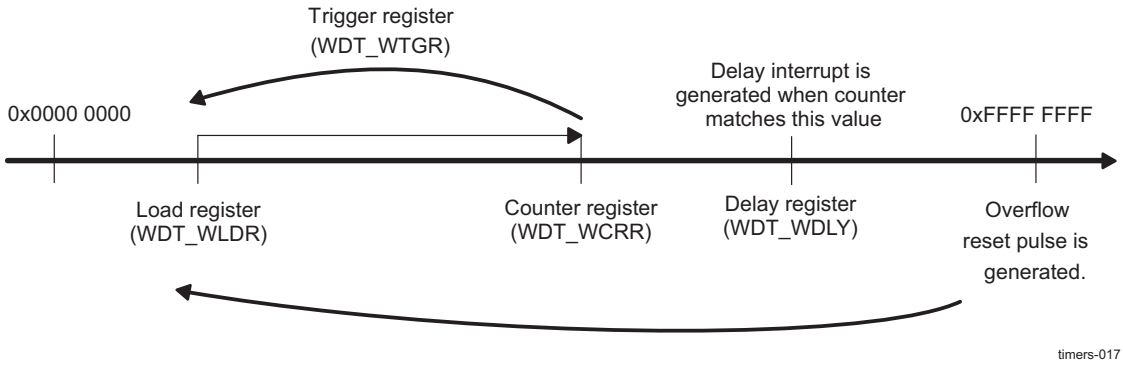
23.3.4.5 Overflow/Reset Generation

When the watchdog timer counter register (WDT_WCRR) overflows, an active-low reset pulse is generated to the PRCM module. This pulse is one prescaled timer clock cycle wide and occurs at the same time as the timer counter overflow.

After reset generation, the counter is automatically reloaded with the value stored in the watchdog load register (WDT_WLDR) and the prescaler is reset (the prescaler ratio remains unchanged). When the reset pulse output is generated, the timer counter begins incrementing again.

Figure 23-18 shows a general functional view of the watchdog timers.

Figure 23-18. Watchdog Timers General Functional View



23.3.4.6 Prescaler Value/Timer Reset Frequency

Each watchdog timer is composed of a prescaler stage and a timer counter.

The timer rate is defined by the following values:

- Value of the prescaler fields (the WDT_WCLR[5] PRE bit and the WDT_WCLR[4:2] PTV bit field)
- Value loaded into the timer load register (WDT_WLDR)

The prescaler stage is clocked with the timer clock and acts as a clock divider for the timer counter stage. The ratio is managed by accessing the ratio definition field (the WDT_WCLR[4:2] PTV bit field) and is enabled with the WDT_WCLR[5] PRE bit.

Table 23-87 lists the prescaler clock ratio values.

Table 23-87. Prescaler Clock Ratio Values

WDT_WCLR[5] PRE	WDT_WCLR[4:2] PTV	Clock Divider (PS)
0	X	1
1	0	1
1	1	2
1	2	4
1	3	8
1	4	16
1	5	32
1	6	64
1	7	128

Copyright © 2011–2012, Texas Instruments Incorporated

Thus the watchdog timer overflow rate is expressed as:

OVF_Rate = (0xFFFF FFFF – WDT_WLDR + 1) × (wd-functional clock period) × PS

where wd-functional clock period = 1/(wd-functional clock frequency) and PS = $2^{(PTV)}$

CAUTION

Internal resynchronization causes some latency in any software write to WDT_WSPR before WDT_WSPR is updated with the programmed value:

1.5 × functional clock cycles ≤ write_WDT_WSPR_latency ≤ 2.5 × functional clock cycles

Remember to consider this latency whenever the watchdog timer must be started or stopped.

For example, for a timer clock input of 32 kHz with a prescaler ratio value of 0x1 (clock divided by 2) and WDT_WCLR[5] PRE = 1 (clock divider enabled), the reset period is as listed in Table 23-88.

Table 23-88. Reset Period Examples

WDT_WLDR Value	Reset Period
0x0000 0000	74 h 56 min
0xFFFF 0000	4 s
0xFFFF FFF0	1 ms
0xFFFF FFFF	62.5 us

CAUTION

- Ensure that the reloaded value allows the correct operation of the application. When a watchdog timer is enabled, software must periodically trigger a reload before the counter overflows. Hence, the value of the WDT_WLDR[31:0] bit field must be chosen according to the ongoing activity preceding the watchdog reload.
- Due to design reasons, WDT_WLDR[31:0] = 0xFFFF FFFF is a special case, although such a value of WDT_WLDR is meaningless. When WDT_WLDR is programmed with the overflow value, a triggering event generates a reset/interrupt one functional clock cycle later, even if the watchdog timer is stopped.

Table 23-89 lists the default reset periods for the watchdog timers.

Table 23-89. Default Watchdog Timer Reset Periods

Watchdog Timers	Clock Source	Default Reset Period
MPU/IVA3 WDTs	32 kHz	10 s

23.3.4.7 Triggering a Timer Reload

To reload the timer counter and reset the prescaler before reaching overflow, a reload command is executed by accessing the watchdog timer trigger register (WDT_WTGR) using a specific reload sequence.

The specific reload sequence is performed whenever the written value on the WDT_WTGR register differs from its previous value. In this case, reload is executed in the same way as an overflow autoreload, but without the generation of a reset pulse.

Copyright © 2011–2012, Texas Instruments Incorporated

The timer counter is loaded with the value of the watchdog timer load register (the WDT_WLDR[31:0] TIMER_LOAD bit field), and the prescaler is reset.

23.3.4.8 Start/Stop Sequence for Watchdog Timers (Using the WDT_WSPR Register)

To start and stop a watchdog timer, access must be made through the start/stop register (WDT_WSPR) using a specific sequence.

To disable the timer, follow this sequence:

1. Write 0xXXXX AAAA in WDT_WSPR.
2. Write 0xXXXX 5555 in WDT_WSPR.

To enable the timer, follow this sequence:

1. Write 0xXXXX BBBB in WDT_WSPR.
2. Write 0xXXXX 4444 in WDT_WSPR.

All other write sequences on the WDT_WSPR register have no effect on the start/stop feature of the module.

23.3.4.9 Modifying Timer Count/Load Values and Prescaler Setting

To modify the timer counter value (the WDT_WCRR register), prescaler ratio (the WDT_WCLR[4:2] PTV bit field), delay configuration value (the WDT_WDLY[31:0] DLY_VALUE bit field), or the load value (the WDT_WLDR[31:0] TIMER_LOAD bit field), the watchdog timer must be disabled by using the start/stop sequence (the WDT_WSPR register).

After a write access, the load register value and prescaler ratio registers are updated immediately, but new values are considered only after the next consecutive counter overflow or after a new trigger command (the WDT_WTGR register).

23.3.4.10 Watchdog Counter Register Access Restriction (WDT_WCRR Register)

A 32-bit shadow register is implemented to read a coherent value of the WDT_WCRR register because the WDT_WCRR register is directly related to the timer counter value and is updated on the timer clock (WDT_FCLK). The shadow register is updated by a 16-bit LSB read command.

NOTE: Although the L4 clock (WDT_ICLK) is completely asynchronous with the timer clock (WDT_FCLK), some synchronization is performed to ensure that the value of the WDT_WCRR register is not read while it is being incremented.

When 32-bit read access is performed, the shadow register is not updated. Read access is performed directly from the accessed register.

To ensure that a coherent value is read inside WDT_WCRR, the first read access is to the lower 16 bits (offset = 0x08), followed by read access to the upper 16 bits (offset = 0x0A).

23.3.4.11 Watchdog Timer Interrupt Generation

When an interrupt source occurs, the interrupt status bit (the WDT_WIRQSTAT[0] EVENT_OVF or WDT_WIRQSTAT[1] EVENT_DLY bit) is set to 1. The output interrupt line (WDTi_IRQ) is asserted (active low) when status (the EVENT_xxx bit) and enable (the xxx_IT_ENA bit) flags are set to 1; the order is not relevant. Writing 1 to the enable bit (the status is already set at 1) also triggers the interrupt in the normal order (enable first, status next). The pending interrupt event is cleared when the set status bit is overwritten by a value of 1 by a write command in the WDT_WIRQSTAT register. Reading the WDT_WIRQSTAT register and writing the value back allows a fast interrupt acknowledge process.

The watchdog timer issues an overflow interrupt if this interrupt is enabled in the watchdog interrupt enable register (WDT_WIRQENSET[0] OVF_IT_ENA = 1). When the overflow occurs, the interrupt status bit (the WDT_WIRQSTAT[0] EVENT_OVF bit) is set to 1. The output interrupt line (WDT_IRQ) is asserted (active low) when status (EVENT_OVF) and enable (OVF_IT_ENA) flags are set to 1; the order is not relevant. This interrupt can be disabled by setting the WDT_WIRQENCLR[0] OVF_IT_ENA bit to 1.

Copyright © 2011–2012, Texas Instruments Incorporated

The watchdog can issue the delay interrupt if this interrupt is enabled in the interrupt enable register (WDT_WIRQENSET[1] DLY_IT_ENA = 1). When the counter is running and the counter value matches the value stored in the delay configuration register (WDT_WDLY), the corresponding interrupt status bit is set in the watchdog status register (WDT_WIRQSTAT) and the output interrupt line is asserted (active low) when the flag (EVENT_DLY) and enable (DLY_IT_ENA) bits are 1 in the WDT_WIRQSTAT and WDT_WIRQENSET registers, respectively; the order (normally enable, then flag), is not relevant. This interrupt can be disabled by setting the WDT_WIRQENCLR[1] DLY_IT_ENA bit to 1.

NOTE: Writing 0 to the WDT_WIRQSTAT[0] EVENT_OVF bit or the WDT_WIRQSTAT[1] EVENT_DLY bit has no effect.

The two clock domains are resynchronized because the interrupt event is generated on the functional clock domain (WDTi_FCLK) during the updating of the interrupt status register (WDT_WIRQSTAT).

The WDT_WDLY register is used to specify the value of the delay configuration register. The delay time to interrupt is the difference between the reload value stored in the counter load register (WDT_WLDR) and the programmed value in this register (WDT_WDLY).

Use the following formula to estimate the delay time:

Delay time period = (WDT_WDLY – WDT_WLDR + 1) × Timer clock period × Clock divider

Where:

- Timer clock period = 1/(Timer clock frequency)
- Clock divider = 2PTV

If the counter value (WDT_WCRR) reaches the programmed value (WDT_WDLY), the status bit (EVENT_DLY) gets set in the interrupt status register (WDT_WIRQSTAT), and an interrupt occurs if the corresponding enable bit is set in the interrupt enable register (WDT_WIRQENSET).

CAUTION

If the reload event occurs (after a triggering sequence or after a reset sequence) before reaching the programmed value (WDT_WDLY[31:0] WDLY_VALUE), no interrupt is generated.

Also, no interrupt is generated if the value programmed in the delay configuration register (WDT_WDLY) is less than the value stored in the counter load register (WDT_WLDR).

23.3.4.12 Watchdog Timers Under Emulation

During emulation mode, the watchdog timer can/cannot continue running, according to the value of the WDT_WDSC[5] EMUFREE bit of the system configuration register (WDT_WDSC).

- When EMUFREE is 1, watchdog timer execution is not stopped and a reset pulse is still generated when overflow is reached.
- When EMUFREE is 0, the counters (prescaler/timer) are frozen and incrementation restarts after exiting from emulation mode.

23.3.4.13 Accessing Watchdog Timer Registers

Posted/nonposted selection applies only to functional registers that require synchronization on/from the timer functional clock domain (WDTi_FCLK). For write/read operation, the following registers are affected:

- WDT_WCLR
- WDT_WCRR
- WDT_WLDR
- WDT_WTGR
- WDT_WDLY

Copyright © 2011–2012, Texas Instruments Incorporated

- WDT_WSPR

NOTE: To ensure completion of successive writes in a WDT2 or WDT3 functional clock domain register, user software must poll the appropriate WDT_WWPS status bit.

NOTE: To ensure coherent reading when a read transaction immediately follows a write access to a WDT2 or WDT3 functional clock domain register, user software must check the appropriate WDT_WWPS status bit.

The timer interface clock domain synchronous registers are not affected by the posted mode mechanism; the write/read operation is effective and acknowledged (command accepted) after one WDT_ICLK cycle from the command assertion. The timer interface clock domain synchronous registers are:

- WDT_WIDR
- WDT_WDSC
- WDT_WDST
- WDT_WIRQSTATRAW
- WDT_WIRQSTAT
- WDT_WIRQENSET
- WDT_WIRQENCLR
- WDT_WIRQWAKEEN
- WDT_WWPS

NOTE: Accesses to WDT2 and WDT3 functional clock domain synchronous registers are posted.

23.3.5 Watchdog Timer Low-Level Programming Model

This section covers the low-level hardware programming sequences for configuration and use of the module.

23.3.5.1 Global Initialization

23.3.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the watchdog timer is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the watchdog timer (see Table 23-90). For more information, see Section 23.3.2, *Watchdog Timer Environment*, and Section 23.3.3, *Watchdog Timer Integration.*

Table 23-90. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. for more information about the module configuration. For more information about the module configuration, see Section 3.1.1.1.2, *Module Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
Control module	Module-specific pad muxing must be set in the control module. For more information about the module configuration, see Section 19.4.8, *PAD Functional Multiplexing and Configuration* in Chapter 19, *Control Module*.
MPU INTC	The MPU INTC configuration must be performed to enable the interrupts from the watchdog timer. See Section 4.4.3, *Interrupt Controller Registers* in Chapter 4, *Cortex-A9 MPU Subsystem*.

23.3.5.1.2 Watchdog Timer Module Global Initialization

23.3.5.1.2.1 Main Sequence – Watchdog Timer Module Global Initialization

Table 23-91 lists the steps for initializing the watchdog timer module when the module is to be used for the first time.

Table 23-91. Watchdog Timer Module Global Initialization

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	WDT_WDSC[1] SOFTRESET	0x1
Wait until reset release?	WDT_WDSC[1] SOFTRESET	0x0
Configure idle mode.	WDT_WDSC[4:3] IDLEMODE	xx
Enable delay wakeup.	WDT_WIRQWAKEEN[1] DLY_WK_ENA	0x1
Enable overflow wakeup.	WDT_WIRQWAKEEN[0] OVF_WK_ENA	0x1
Enable delay interrupt.	WDT_WIRQENSET[1] ENABLE_DLY	0x1
Enable overflow interrupt.	WDT_WIRQENSET[0] ENABLE_OVF	0x1

23.3.5.2 Operational Mode Configuration

23.3.5.2.1 Watchdog Timer Basic Configuration

23.3.5.2.1.1 Main Sequence – Watchdog Timer Basic Configuration

Table 23-92 lists the steps for the basic configuration of the watchdog timer.

Table 23-92. Watchdog Timer Basic Configuration

Step	Register/Bit Field/Programming Model	Value
Disable the watchdog timer.	See Section 23.3.5.2.1.2.	
Set prescaler value.	WDT_WCLR[4:2] PTV	xxx
Enable prescaler.	WDT_WCLR[5] PRE	0x1
Load delay configuration value.	WDT_WDLY	xxx
Load timer counter value.	WDT_WCRR	xxx
Enable the watchdog timer.	See Section 23.3.5.2.1.3.	

23.3.5.2.1.2 Subsequence – Disable the Watchdog Timer

Table 23-93 lists the steps to disable the watchdog timer.

Table 23-93. Disable the Watchdog Timer

Step	Register/Bit Field/Programming Model	Value
Write disable sequence Data1.	WDT_WSPR	0xXXXX AAAA
Write disable sequence Data2.	WDT_WSPR	0xXXXX 5555

23.3.5.2.1.3 Subsequence – Enable the Watchdog Timer

Table 23-94 lists the steps to enable the watchdog timer.

Table 23-94. Enable the Watchdog Timer

Step	Register/Bit Field/Programming Model	Value
Write enable sequence Data1.	WDT_WSPR	0xXXXX BBBB
Write enable sequence Data2.	WDT_WSPR	0xXXXX 4444

23.3.6 Watchdog Timer Register Manual

23.3.6.1 Watchdog Timer Instance Summary

Table 23-95 lists the base address and address space for the watchdog timer module instances.

Table 23-95. Watchdog Timer Instance Summary

Module Name	Base Address L4 Interconnect	Base Address L3 Interconnect	Base Address Cortex-A9 Private Access	Base Address DSP Private Access	Size
WDTIMER2	0x4A31 4000	-	-	-	4KB
WDTIMER3	-	0x4903 0000	0x4013 0000	0x01D3 0000	4KB

NOTE: Private access is an access which is not using the L3/L4 interconnects.

23.3.6.2 Watchdog Timer Registers

23.3.6.2.1 Watchdog Timer Register Summary

CAUTION

The watchdog timers registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt register content.

Table 23-96 lists the WDTIMER2 registers.

Table 23-96. WDTIMER2 Register Mapping Summary

Bits	Field Name	Description	Type	Reset
4:3	IDLEMODE	Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state. 0x0: Force-idle mode: local target IDLE state follows (acknowledges) the system idle requests unconditionally, that is, regardless of the IP module internal requirements. Backup mode, for debug only. 0x1: No-idle mode: local target never enters IDLE state. Backup mode, for debug only. 0x2: Smart-idle mode: local target IDLE state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module should not generate (IRQ- or DMA-request-related) wake-up events. 0x3: Smart-idle wake-up-capable mode: local target IDLE state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module may generate (IRQ- or DMA-request-related) wake-up events when in IDLE state. Mode is relevant only if the appropriate IP module *swake-up* output(s) is (are) implemented.	RW	0x2
2	RESERVED	Write 0s for future compatibility. Reads return 0.	R	0
1	SOFTRESET	Software reset. (Optional) Read 0x0: Reset done, no pending action Write 0x0: No action Write 0x1: Initiate software reset. Read 0x1: Reset (software or other) ongoing	RW	0
0	RESERVED	Write os for future compatibility. Reads return 0.	R	0

23.4 32-kHz Synchronized Timer

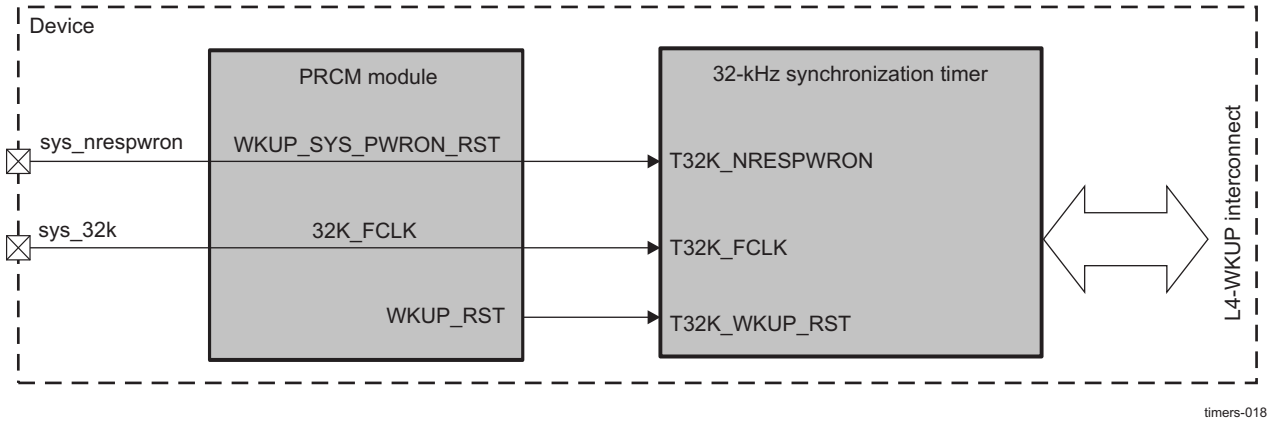
23.4.1 32-kHz Synchronized Timer Overview

The 32-kHz synchronized timer is a 32-bit counter clocked by the falling edge of the 32-kHz system clock. It is reset while the external asynchronous power-up reset (sys_nrespwron) primary input/output (I/O) is active (main device reset). When sys_nrespwron is released (on the rising edge of sys_nrespwron), after three 32-kHz clock periods, the counter starts counting up from the reset value of the counter register on the falling edge of the 32-kHz system clock. After reaching its highest value, the counter wraps back to 0 and starts counting again.

Figure 23-19 is the block diagram of the 32-kHz synchronized timer.

NOTE: sys_nrespwron is an active-low I/O.

Figure 23-19. 32-kHz Synchronized Timer Block Diagram



23.4.1.1 32-kHz Synchronized Timer Features

The main features of the 32-kHz synchronized timer controller are:

- L4 slave interface support:
  - 32-bit data bus width
  - 32-/16-bit access supported
  - 8-bit access not supported
  - 5-bit address bus width
  - Burst mode not supported
- Only read operations are supported on the module registers; no write operation is supported (no error/no action on write).
- Free-running 32-bit upward counter
- Start and keep counting after power-on reset
- Automatic roll over to 0; highest value reached: 0xFFFF FFFF
- On-the-fly read (while counting)

23.4.2 32-kHz Synchronized Timer Environment

The synchronized timer is accessible only through the L4 interface.

23.4.3 32-kHz Synchronized Timer Integration

Table 23-134 through Table 23-136 summarize the integration of the module in the device.

Copyright © 2011–2012, Texas Instruments Incorporated

23.4.4 32-kHz Synchronized Timer Functional Description

The synchronized timer is a counter that starts on the rising edge of an external asynchronous signal (sys_nrespwron). When sys_nrespwron is released (on the rising edge of sys_nrespwron), the counter starts counting up from the reset value of the counter register on the falling edge of the 32-kHz system clock after three inverted 32-kHz clock periods. After reaching its highest value, the counter wraps back to 0 and starts counting again with no additional delay. When sys_nrespwron is released (on the rising edge of sys_nrespwron), after three inverted 32-kHz clock periods, the counter starts counting up from the reset value of the counter register on the falling edge of the 32-kHz system clock.

Figure 23-20 shows the reset synchronization timing diagram. After reaching its highest value, the counter wraps back to 0 and starts counting again without any extra delay.

Figure 23-20. Reset Resynchronization Timing Diagram

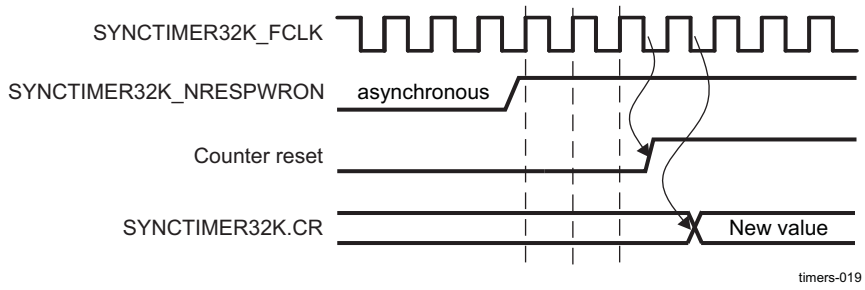

Figure 23-21 is the block diagram of the synchronized timer.

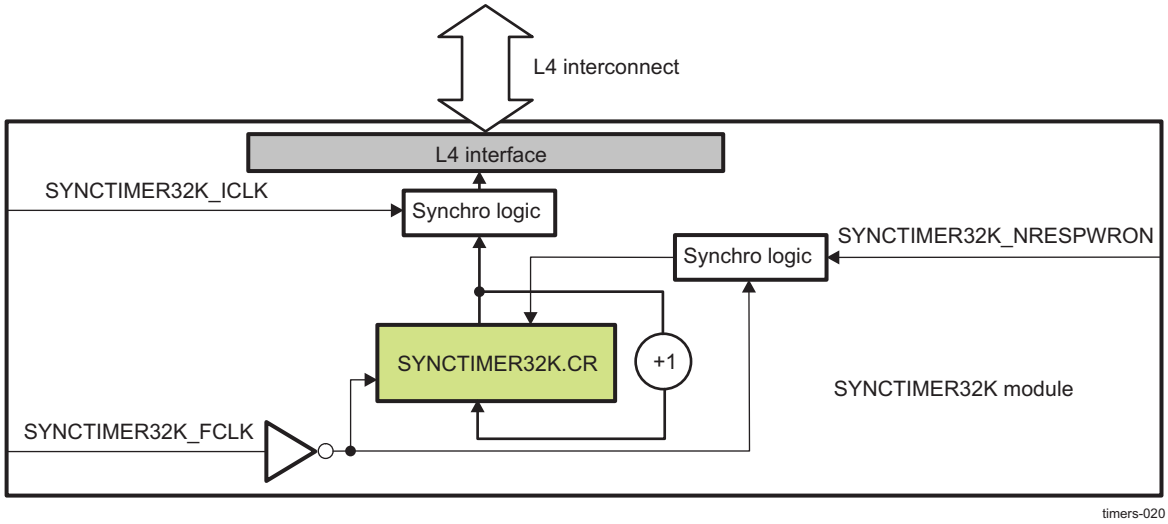
NOTE: sys_nrespwron is an active-low input.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 23-21. SYNCTIMER32K Block Diagram



The sync logic ensures the read transaction correctness by synchronizing the counter register read access on 32KSYNCNT_ICLK because the 32KSYNCNT_ICLK clock signal is completely asynchronous with S32KSYNCNT_FCLK. The sys_nrespwron input resets the counter register (32KSYNCNT_CR). The inverted 32KSYNCNT_FCLK clocks the sys_nrespwron reset signal.

23.4.4.1 Reading the 32-kHz Synchronized Timer

The counter register (32KSYNCNT_CR) is 32 bits wide and can be read using 32-bit and 16-bit access. For correct count capture using 16-bit access, it must be accessed as 16-bit LSB access first and 16-bit MSB access next. The internal logic ensures the integrity and correctness of the read data from 32KSYNCNT_CR when it is split into 16-bit data. The read data corresponds to the data when the read command is issued. Internal synchronization logic allows reading of the counter value with 32KSYNCNT_ICLK while the counter is running. There is a read latency, which is a synchronization delay and is one 32KSYNCNT_ICLK clock cycle. The time latency to read the synchronized counter register is minimum one read cycle for 32-bit access and two read cycles for 16-bit access, where each read cycle is equal to three 32KSYNCNT_ICLK clock cycles.

23.4.5 32KTimer Register Manual

Table 23-137 lists the base address and block size for the 32-kHz synchronized timer. It is memory mapped to the L4 peripheral bus memory space.

Table 23-137. 32KTimer Instance Summary

Module Name	Base Address L4 Interconnect	Size
32KTimer	0x4A30 4000	4KB

23.4.5.1 32KTimer Register Mapping Summary

CAUTION

The 32-kHz synchronized timer registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 23-138 lists the 32-kHz synchronized timer registers. through describe the register bits.

24.1 Multimaster High-Speed I²C Controller

24.1.1 HS I²C Overview

The device contains four multimaster high-speed (HS) inter-integrated circuit (I²C™) controllers (I2Ci modules, where i = 1, 2, 3, 4), each of which provides an interface between a local host (LH), such as a digital signal processor (DSP), and any I²C-bus-compatible device that connects through the I²C serial bus. External components attached to the I²C bus can serially transmit and receive up to 8 bits of data to and from the LH device through the 2-wire I²C interface.

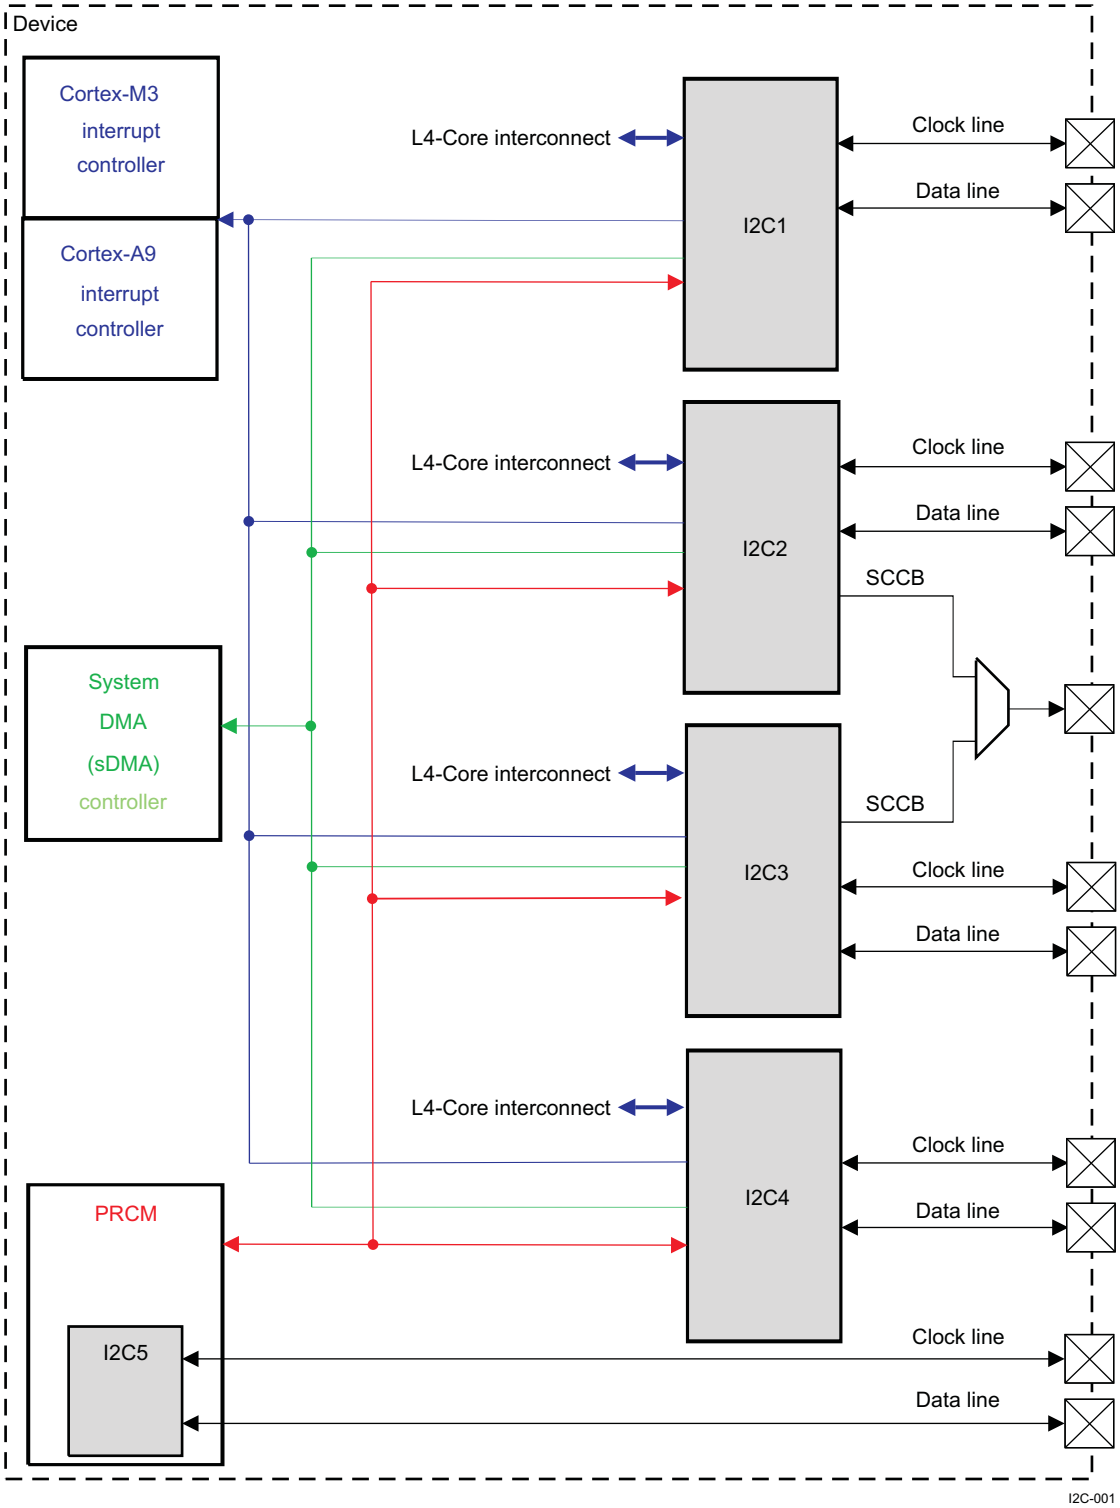
Each multimaster HS I²C controller can be configured to act like a slave or master I²C-compatible device. Moreover, each multimaster HS I²C controller can be configured in serial camera control bus (SCCB) mode (the SCCB is a serial bus developed by Omnivision Technologies, Inc.) to act as a master on a 2-wire SCCB bus. Only multimaster HS I²C controllers I2C2 and I2C3 can be configured in SCCB mode to act as a master device on a 3-wire SCCB bus.

The device contains a fifth master transmitter HS I²C interface (I2C5) in the power, reset, and clock management (PRCM) module to perform dynamic voltage control and power sequencing with an external power integrated circuit (IC).

Figure 24-1 shows the HS ***I²C*** controllers.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-1. HS I²C Controllers



The four multimaster HS I²C controllers have the following features:

- Compliant with Philips I²C specification version 2.1
- Supports standard mode (up to 100 Kbps) and fast mode (up to 400 Kbps)
- Supports HS mode for transfer up to 3.4 Mbps

Copyright © 2011–2012, Texas Instruments Incorporated

- Support for 3-wire/2-wire SCCB master mode for I2C2 and I2C3 modules, 2-wire SCCB master mode for I2C1 and I2C4 modules, up to 100 Kbps
- 7-bit and 10-bit device addressing modes
- General call
- Start/restart/stop
- Multimaster transmitter/slave receiver mode
- Multimaster receiver/slave transmitter mode
- Combined master transmit/receive and receive/transmit mode
- Built-in configurable FIFOs (8, 16, 32, 64 bytes) for buffered read or write
- Module enable/disable capability
- Programmable multislave channel (responds to four separate addresses)
- Programmable clock generation
- 8-bit-wide data access
- Open-core protocol (OCP) interface with LH application (OCP-IP 2.0 compliant)
- Designed for low power consumption
- Implement Auto Idle mechanism
- Implement Idle Request/Idle Acknowledge handshake mechanism
- Support for asynchronous wake-up mechanism
- Two direct memory access (DMA) channels
- Wide interrupt capability
- Supports OmniVision SCCB protocol
- Compliant with Highlander 0.8

The master transmitter HS I²C controller I2C5 has the following features:

- Support of HS and fast modes
- 7-bit addressing mode only
- Master transmitter mode only
- Start/restart/stop

NOTE: Before using HS I²C mode, determine that the target device supports this mode.

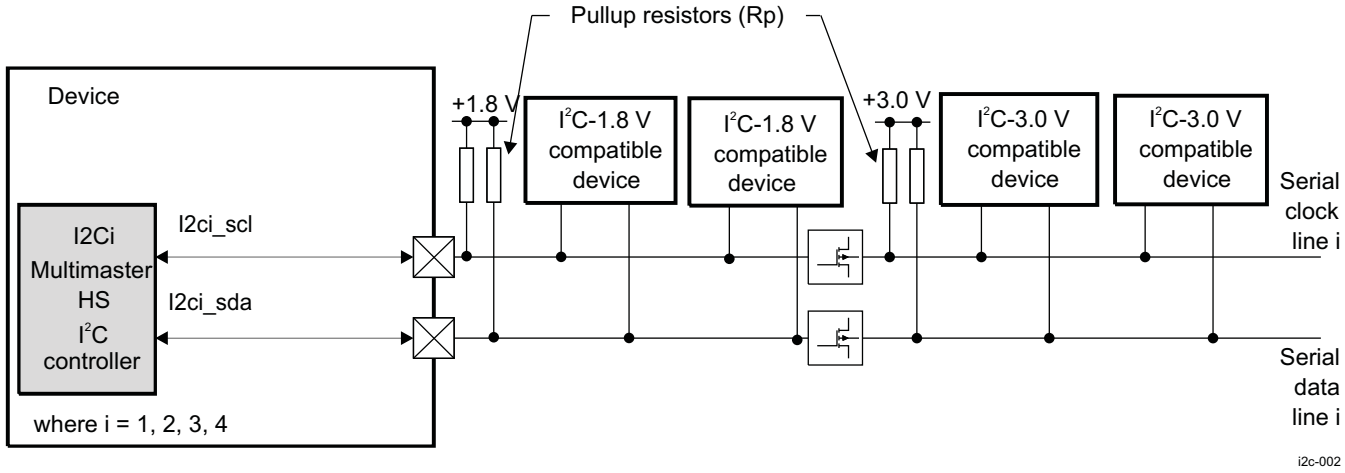
24.1.2 HS I²C Environment

This section describes the HS I²C application fields from an environment point of view (external connections). It describes HS I²C connectivity options, lists all possible interfaces, and describes the protocol and data format used in each case.

24.1.2.1 HS I²C in I²C Mode

Figure 24-2 shows the multimaster HS I²C controllers and their related connections with I²C-compliant devices in I²C mode.

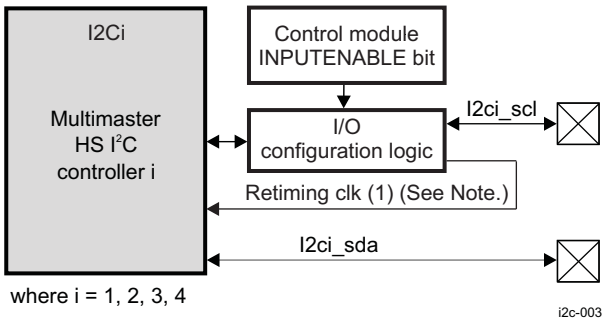
Figure 24-2. HS I²C and Typical Connections to I²C Devices



24.1.2.1.1 HS I²C Pins for Typical Connections in I²C Mode

Figure 24-3 shows the multimaster HS I²C controller pins used for typical connections with I²C devices.

Figure 24-3. HS I²C Interface Signals in I²C Mode



NOTE: In master mode, the clock signal (IP clk configured as output) is also used as retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).

24.1.2.1.2 HS I²C Interface Typical Connections

Table 24-1 lists the pins associated with the I²C interface.

Table 24-1. HS I²C Input/Output

Signal	I/O (1)	Description	Reset Value
i2ci_scl	I/O	I²C serial clock line(2). Open-drain output buffer. Requires external pullup resistor (Rp).	1

(1) I = Input; O = Output

(2) This output signal is also used as retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).

Table 24-1. HS I²C Input/Output (continued)

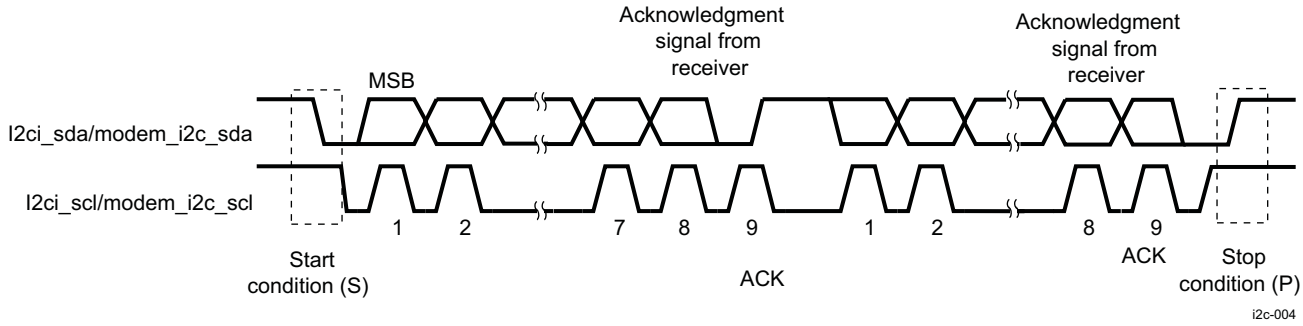
Signal	I/O [1]	Description	Reset Value
i2ci_sda	I/O	I²C serial data line. Open-drain output buffer. Requires external Rp.	1

24.1.2.1.3 HS I²C Typical Connection Protocol and Data Format

24.1.2.1.3.1 HS I²C Serial Data Format

The I²C controller operates in 8-bit word data format (byte write access supported for the last access). Each byte transmitted or received on the serial data line is 8 bits long. The number of bytes that can be transmitted or received is not restricted. The data is transferred with the most-significant bit (MSB) first. In receiver mode, each byte is followed by an acknowledge bit from the I²C. Figure 24-4 shows a typical I²C communication format.

Figure 24-4. HS I²C Data Transfer

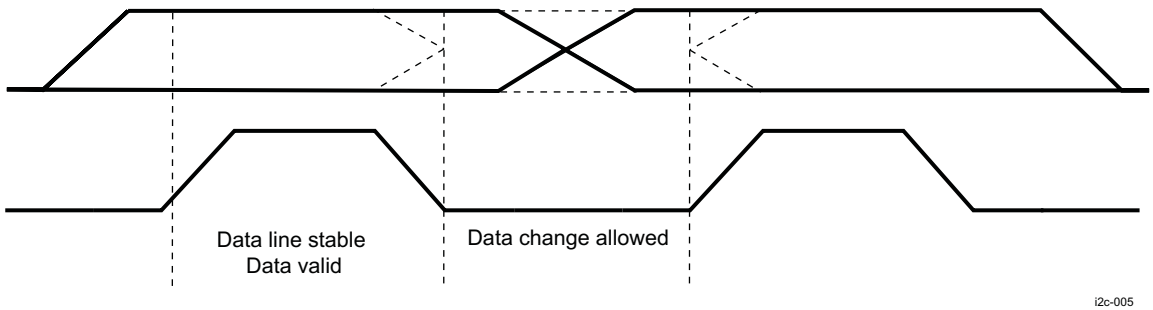


24.1.2.1.3.2 HS I²C Data Validity

The data on the serial data line (SDA) must be stable during the high period of the serial clock line. The high and low states of the data line can change only when the clock signal on the serial clock line (SCL) is low.

Figure 24-5 is an example of data validity requirements.

Figure 24-5. HS I²C Bit Transfer on the I²C Bus



24.1.2.1.3.3 HS I²C Start and Stop Conditions

The I²C module generates start (S) and stop (P) conditions when it is configured as a master.

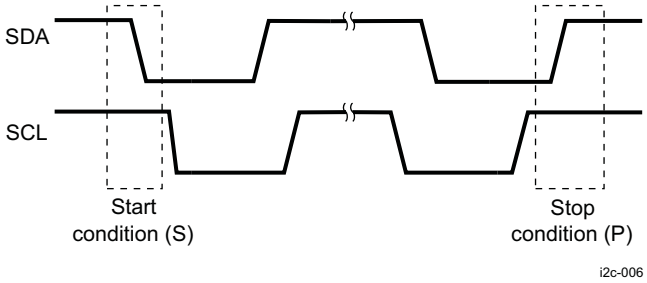
- An S condition is a high-to-low transition on the serial data line while serial clock line is high.
- A P condition is a low-to-high transition on the serial data line while serial clock line is high.

The bus is considered busy after the S condition (the I2Ci.I2C_STAT[12] BB bit is 1 to indicate that the bus is busy) and free after the P condition (the I2Ci.I2C_STAT[12] BB bit is 0 to indicate that the bus is free).

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-6 shows the waveforms that occur during an S and a P condition.

Figure 24-6. HS I²C S and P Condition Events



24.1.2.1.3.4 HS I²C Addressing

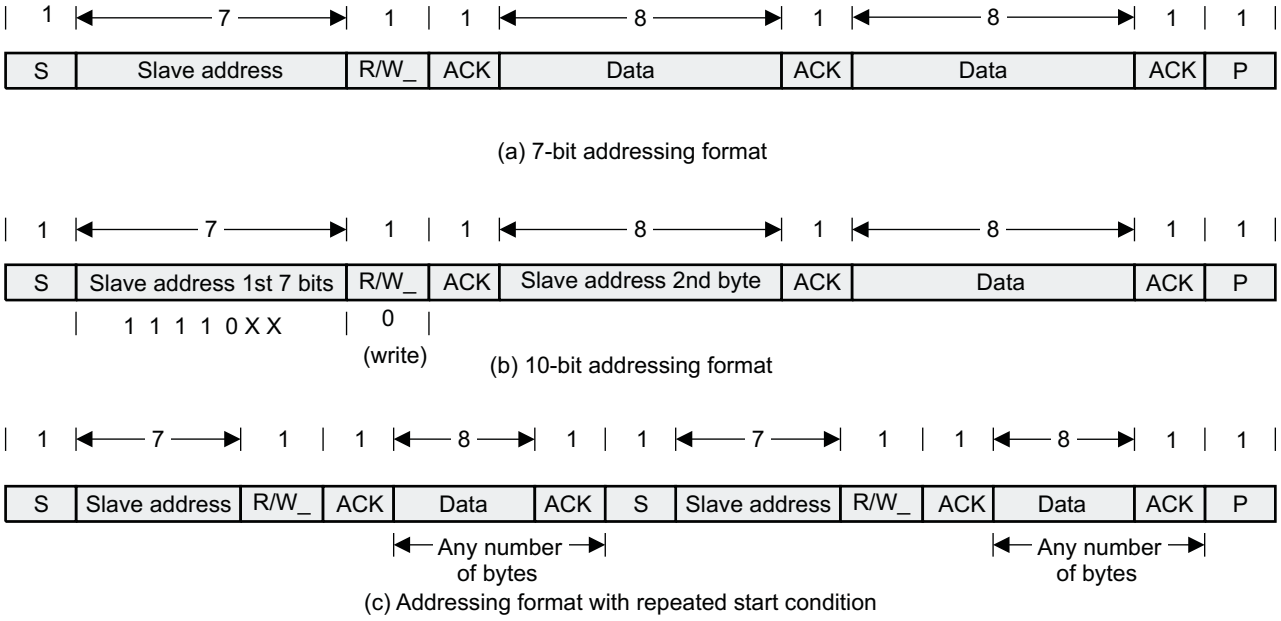
The I²C module supports two data formats in fast/standard (F/S) and HS modes:

- 7-bit/10-bit addressing format
- 7-bit/10-bit addressing format with repeated start (Sr) condition

24.1.2.1.3.4.1 Data Transfer Formats in F/S Mode

Figure 24-7 shows the I²C data transfer formats in F/S mode.

Figure 24-7. HS I²C Data Transfer Formats in F/S Mode



The first word after an S condition consists of 8 bits. In acknowledge mode, an extra dedicated acknowledgment bit is inserted after each byte.

In addressing formats with 7-bit addresses, the first byte is composed of 7 MSB slave address bits and 1 least-significant bit (LSB) R/W_ bit.

The LSB R/W_ bit of the address byte indicates the transmission direction of the data bytes that follow it. If R/W_ is 0, the master writes data to the selected slave; if it is 1, the master reads data from the slave.

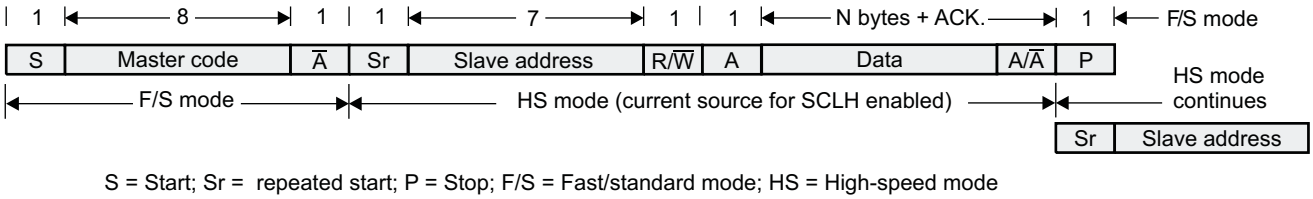
Copyright © 2011–2012, Texas Instruments Incorporated

In addressing formats with 10-bit addresses, the structure of the first byte is 11110XXY, where XX is the 2 MSBs of the 10-bit addresses, and Y is the R/W_ bit. If the R/W_ bit is 0, the next byte contains the last 8 bits of the slave address. If the R/W_ bit is 1, the next byte contains data transmitted from the slave to the master.

24.1.2.1.3.4.2 Data Transfer Format in HS Mode

Figure 24-8 shows the I²C data transfer format in HS mode.

Figure 24-8. HS I²C Data Transfer in HS Mode



S = Start; Sr = repeated start; P = Stop; F/S = Fast/standard mode; HS = High-speed mode

i2c-008

Each multimaster HS I²C controller can also operate in HS mode. In this case, after the S condition, the module, which is in F/S mode, writes the master code address (000001XXX, where XXX is the variable portion of the master code) on the bus. No device connected on the same bus acknowledges this address. The module switches the clock to the HS clock and after an Sr condition, and sends the slave address and the data, as shown in Figure 24-8.

24.1.2.1.3.5 HS I²C Master Transmitter

In master transmitter mode, data assembled in one of the previously described data formats is shifted out on the serial data line SDA in sync with the self-generated clock pulses on the serial clock line SCL. The clock pulses are inhibited and SCL is held low when the intervention of the processor is required (XUDF) after a byte is transmitted.

24.1.2.1.3.6 HS I²C Master Receiver

Master receiver mode can be entered only from master transmitter mode. With any of the address formats (a), (b), or (c) (see Figure 24-7), if R/W_ is high, the module enters master receiver mode after the slave address byte and bit R/W_ are transmitted. Serial data bits received on bus line SDAI are shifted in synchronization with the self-generated clock pulses on SCLI.

24.1.2.1.3.7 HS I²C Slave Transmitter

Slave transmitter mode can be entered only from slave receiver mode. With any of the address formats (a), (b), or (c) (see Figure 24-7), the slave transmitter is entered if the slave address byte is the same as its own address and bit R/W_ is transmitted, if R/W_ is high. The slave transmitter shifts the serial data out on the data line SDA in sync with the clock pulses that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (XUDF).

24.1.2.1.3.8 HS I²C Slave Receiver

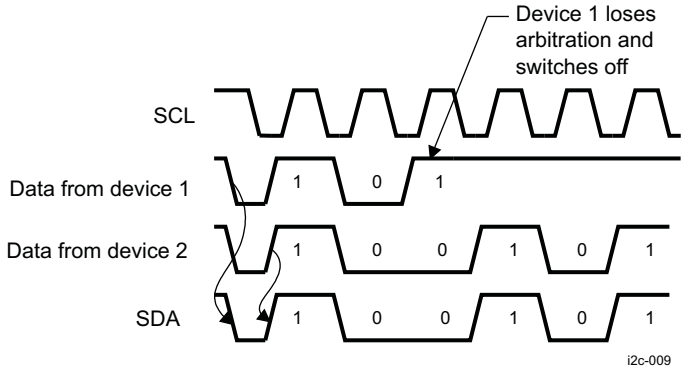
In this mode, serial data bits received on the bus line SDA are shifted-in in sync with the clock pulses on SCL that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (ROVR) after a byte is received.

Copyright © 2011–2012, Texas Instruments Incorporated

24.1.2.1.3.9 HS I²C Bus Arbitration

If two or more master transmitters start a transmission on the same bus almost simultaneously, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial bus by the competing transmitters. When a transmitter senses that a high signal it has presented on the bus has been overruled by a low signal, it switches to the slave receiver mode, sets the arbitration lost (AL) flag, and generates the arbitration lost interrupt. Figure 24-9 shows the arbitration procedure between two devices. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

Figure 24-9. HS I²C Arbitration Between Master Transmitters



24.1.2.1.3.10 HS I²C Clock Generation and Synchronization

Under normal conditions, only one master device generates the clock signal, SCL. During the arbitration procedure, however, there are two or more master devices and the clock must be synchronized so that the data output can be compared. The wired-AND property of the clock line means that a device that first generates a low period of the clock line overrules the other devices. At this high/low transition, the clock generators of the other devices are forced to start generating their own low period. The clock line is then held low by the device with the longest low period, while the other devices that finish their low periods must wait for the clock line to be released before starting their high periods. A synchronized signal on the clock line is thus obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period. If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the WAIT-state. In this way a slave can slow down a fast master and the slow device can create enough time to store a received byte or prepare a byte to be transmitted (Clock Stretching).

NOTE: In case the SCL or SDA lines are stuck low, the Bus Clear operation is supported.

If the clock line (SCL) is stuck low, the preferred procedure is to reset the bus using the hardware reset signal if your I²C devices have hardware reset inputs. If the I²C devices do not have hardware reset inputs, cycle power to the devices to activate the mandatory internal power-on reset (POR) circuit.

If the data line (SDA) is stuck low, the master should send nine clock pulses. The device that held the bus low should release it sometime within those nine clocks. If not, then use the hardware reset or cycle power to clear the bus.

Figure 24-10 shows clock synchronization.

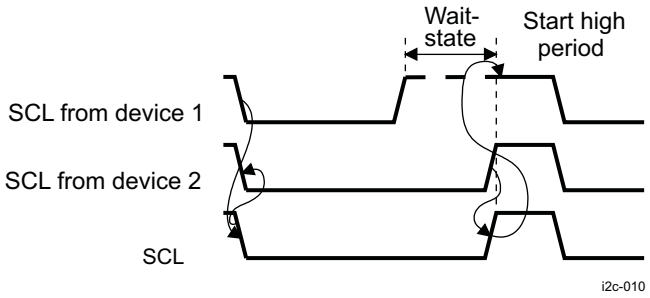
Figure 24-10. HS I²C Clock Generators Synchronization



24.1.2.1.3.11 HS I²C External Clock Configuration

Each multimaster HS I²C controller is clocked with an independent functional clock (I2Ci_FCLK) and an interface clock (I2Ci_ICLK) for interfacing with the L4_PER interconnect. These clocks are provided by the APE PRCM module for I2Ci (where i = 1, 2, 3, 4).

The SYS_CLK clock provided by the clock generator of the PRCM module is connected to the functional and interface clocks of the HS I²C controller I2C5. For detailed information about the module clocking, see Chapter 3, *Power, Reset, and Clock Management*.

The functional clock is processed by a prescaler block to produce the internal sampling clock. This clock is generated by the I²C prescaler block. The prescaler block consists of the I2Ci.I2C_PSC[7:0] PSC bit field (where i = 1, 2, 3, 4) that is used to divide down the functional clock to obtain an internal sampling clock with a frequency value of I2Ci_FCLK/(I2Ci.I2C_PSC[7:0] PSC bit field value + 1, where i = 1, 2, 3, 4).

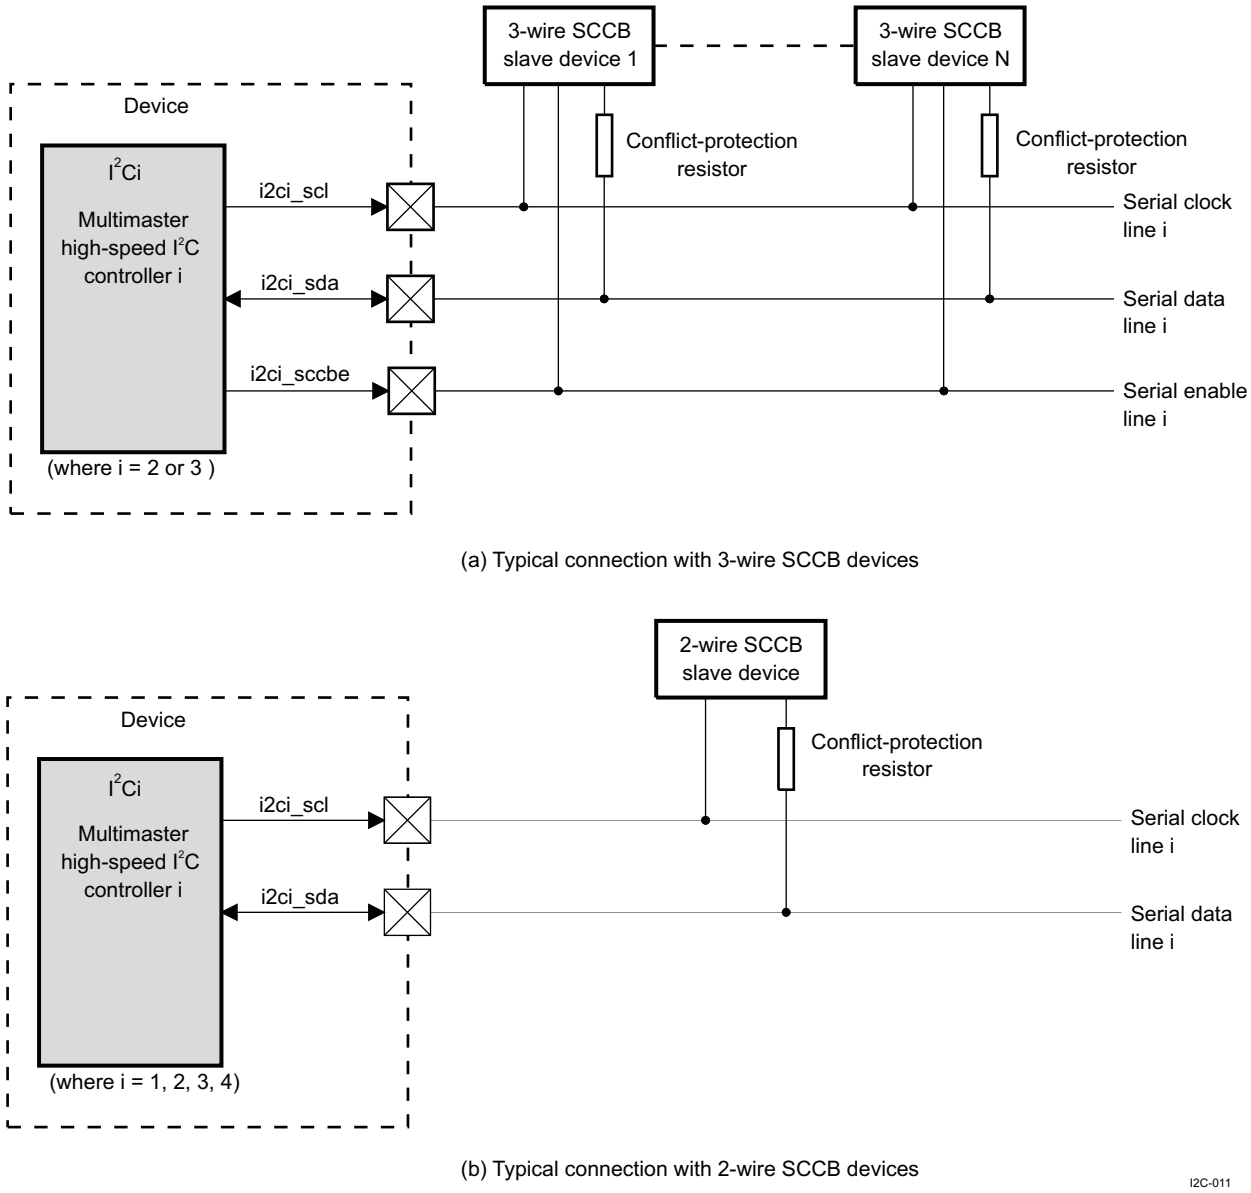
NOTE: The I2Ci.I2C_PSC[7:0] PSC bit field (where i = 5) of I2C5 is not accessible by software.

24.1.2.2 HS I²C in SCCB Mode

The multimaster HS I²C controllers support the 2-wire SCCB protocol in master mode as listed in Figure 24-11. Only I2C2 and I2C3 support the 3-wire SCCB protocol in master mode.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-11. HS I²C and Typical Connections to SCCB Devices



NOTE: Only one 2-wire SCCB slave device can be connected to the 2-wire SCCB bus.

24.1.2.2.1 HS I²C Pins for Typical Connections in SCCB Mode

Figure 24-12 shows the multimaster HS I²C controller pins used for typical connections with 3-wire or 2-wire SCCB devices.

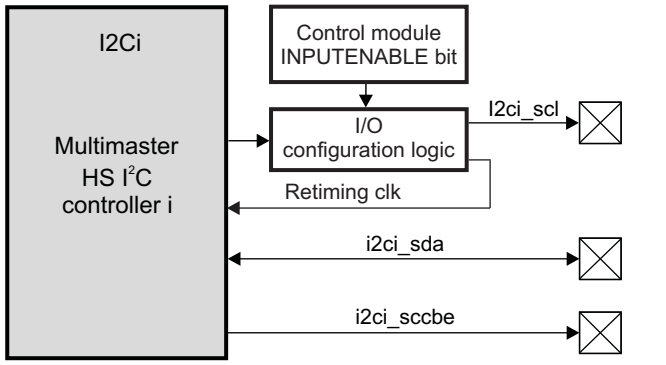
Figure 24-12. HS I²C Interface Signals in SCCB Mode



(where i = 1, 2, 3, 4 and i2ci_sccbe is not available for I2C1 and I2C4)

I2C-012

24.1.2.2.2 HS I²C SCCB Interface Typical Connections

Table 24-2 lists the pins associated with the SCCB interface.

Table 24-2. HS I²C Input/Output

Signal	I/O [1]	Description	Reset Value [2]	I2Ci.I2C_CON[15] I2C_EN bit = 0
i2ci_scl	O	SCCB serial clock line[3]. Standard CMOS output buffer.	Hi-Z	High
i2ci_sda	I/O(OD)	SCCB serial data line. Standard CMOS 3-state output buffer. Requires external conflict-protection resistor for each slave device connected to the bus.	Hi-Z	Hi-Z
i2ci_sccbe [4]	O	SCCB enable line. Standard CMOS output buffer.	High	High

(1) I = Input; O = Output; OD = Open Drain

(2) Hi-Z = High Impedance

(3) This output signal is also used as retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).

(4) This signal is used for the 3-wire SCCB protocol only.

NOTE: Because they share the same ball, the i2c2_sccbe and i2c3_sccbe signals are not available at the same time. For detailed information about pin configuration, see Chapter 19, *Control Module*.

I2C1 and I2C4 do not provide any i2c1_sccbe signal at the chip boundary of the device; thus, these modules do not support the 3-wire SCCB protocol.

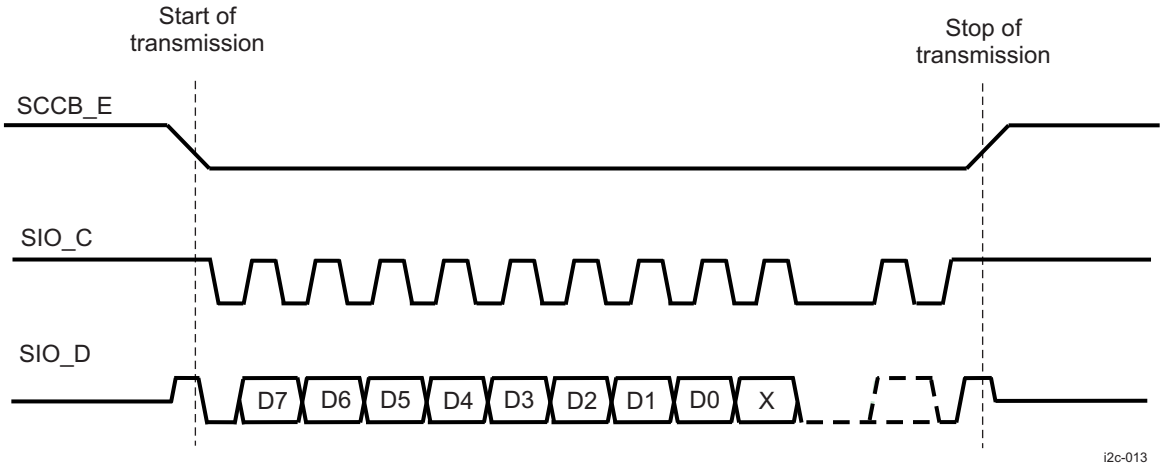
Copyright © 2011–2012, Texas Instruments Incorporated

24.1.2.2.3 HS I²C SCCB Typical Connection Protocol and Data Format

24.1.2.2.3.1 HS I²C SCCB Data Format

If the module is configured in SCCB mode of operation, the data format of transmissions appears as shown in Figure 24-13. For SCCB protocol compatibility I²C provides one more signal, SCCB_E, which acts like a transaction enable signal.

Figure 24-13. HS I²C 3-wire SCCB Transmission Timing Diagram

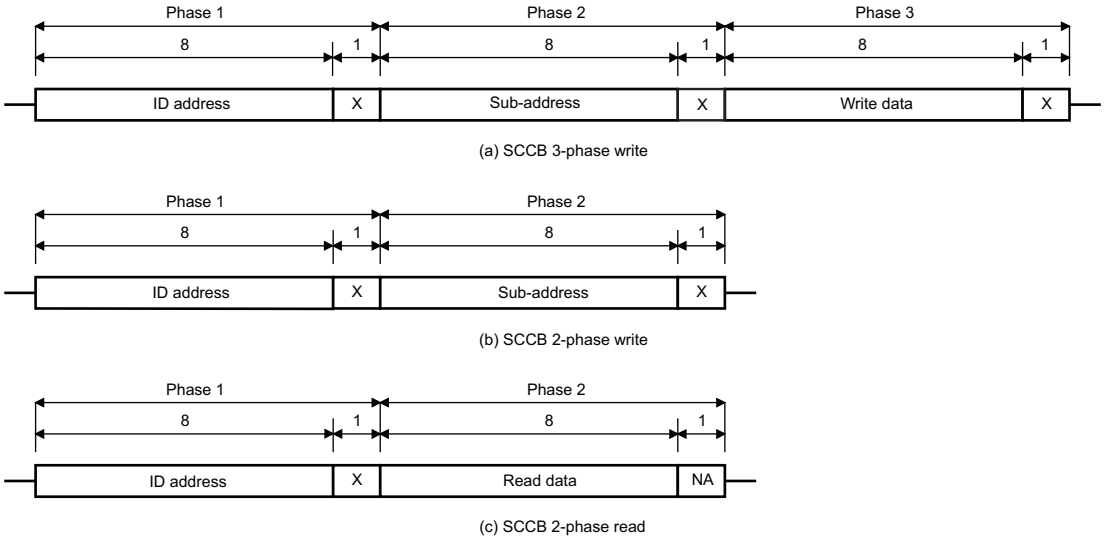


NOTE: When operating in 2-wire SCCB mode, the i2ci_sccbe signal is not used by the 2-wire SCCB-compliant slave device attached to the 2-wire SCCB bus.

24.1.2.2.3.2 HS I²C SCCB Transmission Data Formats

Figure 24-14 describes the data format of the three kinds of transmission.

Figure 24-14. HS I²C SCCB Transmission Data Formats



Copyright © 2011–2012, Texas Instruments Incorporated

The basic element of a data transmission is a phase. A phase contains 9 bits, which consist of an 8-bit sequential data transmission followed by a ninth bit. The ninth bit is a don't-care bit (X) or an NA bit, depending on whether the data transmission is a write or a read. The maximum number of phases that can be included in a transmission is three. The MSB is always asserted first for each phase.

A data transmission is one of three types:

- 3-phase write transmission:

  The 3-phase write transmission cycle (see (a) of Figure 24-14) is a full write operation in which the master can write 1 byte of data to a specific slave(s). The 7-bit slave address in the ID value identifies the specific slave that the master intends to access. The subaddress identifies the register location of the specified slave. The write data contains 8-bit data that the master intends to write over the content of this specific address. The ninth bit of each of the three phases is a don't-care bit (X bit).

- 2-phase write transmission:

  The 2-phase write transmission cycle is followed by a 2-phase read transmission cycle (see the following bullet). The purpose of issuing a 2-phase write transmission cycle (see (b) of Figure 24-14) is to identify the subaddress of some specific slave from which the master intends to read data for the following 2-phase read transmission cycle. The ninth bit of each phase is a don't-care bit (X bit).

- 2-phase read transmission:

  Either a 3-phase or a 2-phase write transmission cycle must be asserted ahead of a 2-phase read transmission cycle. The 2-phase read transmission cycle (see (c) of Figure 24-14) cannot identify the subaddress. The 2-phase write transmission cycle contains read data of 8 bits and a ninth don't-care bit or NA bit. The master must drive the NA bit at logical 1.

  In each transmission type, phase 1 (the 7-bit slave address of the ID value) is asserted by the master to identify the selected slave to which the data is read or written. Each slave has a unique 7-bit slave address. The 7-bit slave address of the ID value comprises 7 bits, from bit 7 to bit 1, that can identify up to 128 slaves. The eighth bit, bit 0, is the read/write selector bit that specifies the transmission direction of the current cycle. A logical 0 represents a write cycle and a logical 1 represents a read cycle. The ninth bit of phase 1 is a don't-care bit (X bit).

  Phase 2 (subaddress/read data) is asserted by the master (subaddress) or the slave(s) (read data). A phase 2 transmission asserted by the master identifies the subaddress of the slave(s) the master intends to access. A phase 2 transmission asserted by the slave(s) indicates the read data that the master will receive. The slave(s) recognize the subaddress of this read data according to the previous 3-phase or 2-phase write transmission cycle. The ninth bit is defined as a don't-care bit (X bit) when the master asserts phase 2. The ninth bit is defined as an NA bit when the slave(s) asserts the phase 2 transmission. The master is responsible for a logical 1 during the period of the NA bit.

  Phase 3 (write data) is asserted only by the master. This phase contains the data the master intends to write to the slave(s). Because the master asserts the transmission, the ninth bit of the phase 3 transmission is defined as a don't-care bit (X bit).

NOTE: A multimaster HS I²C controller configured in SCCB mode can perform two operations:

- Write a single byte to an SCCB slave device by using the 3-phase write transmission cycle
- Read a single byte from an SCCB slave device by using the 2-phase write transmission cycle followed by the 2-phase read transmission cycle

24.1.2.2.3.3 HS I²C Data Validity

The data validity is the same as described in Section 24.1.2.1.3.2, *HS I²C Data Validity*.

24.1.2.2.3.4 HS I²C S and P Conditions

The S and P conditions are the same as described in Section 24.1.2.1.3.3, *HS I²C Start and Stop Conditions*.

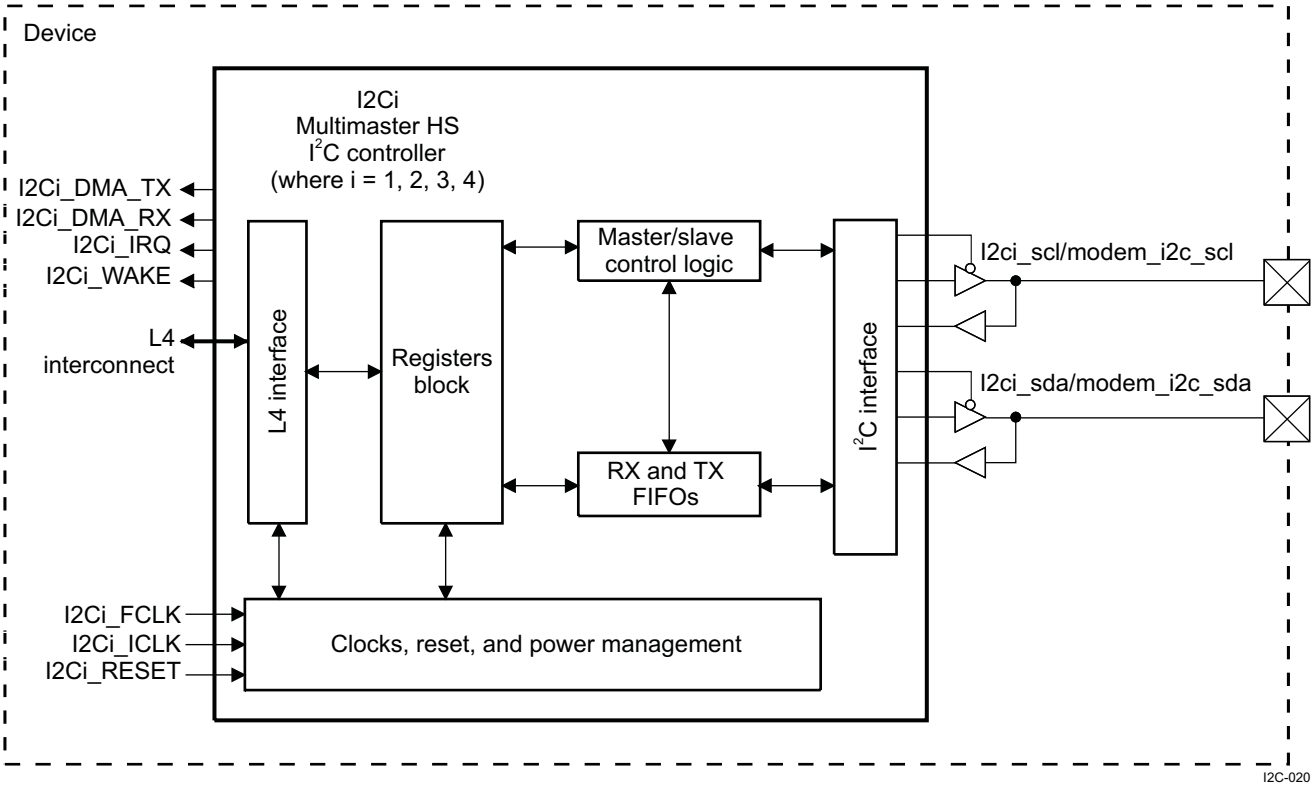
24.1.4 HS I²C Functional Description

24.1.4.1 HS I²C Block Diagram

Figure 24-21 is the multimaster I²C HS controller block diagram.

Figure 24-21. HS I²C Block Diagram



The five multimaster HS I²C controllers can be configured in F/S I²C mode, HS I²C mode, or SCCB mode. The operation mode is selected by configuring the I2Ci.I2C_CON[13:12] OPMODE bit field. Table 24-7 lists the available operation modes.

NOTE: The fifth master transmitter HS I²C interface (I2C5) in the PRCM module can also be configured in HS mode.

Table 24-7. HS I²C Operation Mode Selection

Operation Mode	Value of I2Ci.I2C_CON[13:12] OPMODE Bit Field
F/S I²C	0x0
HS I²C	0x1
SCCB	0x2
Reserved (not used)	0x3

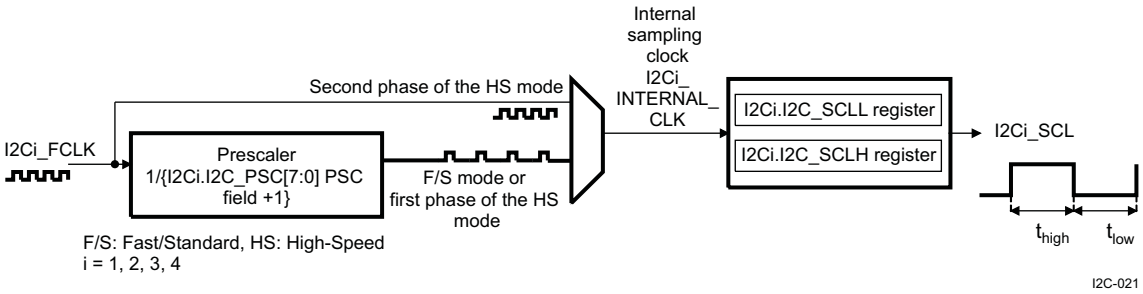
24.1.4.2 HS I²C Clocks

24.1.4.2.1 HS I²C Clocking

Figure 24-22 shows the I²C clock generation of the HS I²C controllers.

Figure 24-22. HS I²C Clock Generation



Each multimaster HS I²C controller uses the I2Ci_FCLK functional clock in the PRCM module. The internal sampling clock I2Ci_INTERNAL_CLK is generated by dividing the functional clock by the I2Ci.I2C_PSC[7:0] PSC bit field value + 1 in F/S mode, in SCCB mode, or in the first phase of HS mode; or by directly using the functional clock in the second phase of HS mode (prescaler is bypassed).

The low time of the I2Ci_SCL signal is determined by the I2Ci.I2C_SCLL[7:0] SCLL bit field in F/S mode, in SCCB mode, or in the first phase of HS mode; or by the I2Ci.I2C_SCLL[15:8] HSSCLL bit field in the second phase of HS mode.

The high time of the I2Ci_SCL signal is determined by the I2Ci.I2C_SCLH[7:0] SCLH bit field in F/S mode, in SCCB mode, or in the first phase of HS mode; or by the I2Ci.I2C_SCLH[15:8] HSSCLH bit field in the second phase of HS mode.

The low time of the I2C5 signal is determined by the PRM_VC_CFG_I2C_CLK[15:8] SCLL bit field in F/S mode or in the first phase of HS mode, or by the PRM_VC_CFG_I2C_CLK[31:24] HSSCLL bit field in the second phase of HS mode.

The high time of the I2C5 signal is determined by the PRM_VC_CFG_I2C_CLK[7:0] SCLH bit field in F/S mode or in the first phase of HS mode, or by the PRM_VC_CFG_I2C_CLK[23:16] HSSCLH bit field in the second phase of HS mode.

Table 24-8 lists the T_{LOW} and T_{HIGH} values in master mode only (in slave mode, the I²C controller does not generate the I²C clock).

Table 24-8. HS I²C T_{LOW} and T_{HIGH} Values of the I²C Clock

Mode	I²C Clock	t_{LOW}	t_{HIGH}	
			DFILTEREN bit = 0	DFILTEREN bit = 1
F/S, SCCB, or HS first phase	I2Ci_INTERNAL_CLK = I2Ci_FCLK / (I2Ci.I2C_PSC[7:0] PSC bit field + 1)	(I2Ci.I2C_SCLL[7:0] SCLL bit field value + 7) x I2Ci_INTERNAL_CLK period	(I2Ci.I2C_SCLH[7:0] SCLH bit field value + 5 + PROP_DELAY0) x I2Ci_INTERNAL_CLK period	(I2Ci.I2C_SCLH[7:0] SCLH bit field value + 5 + PROP_DELAY1) x I2Ci_INTERNAL_CLK period
HS second phase	I2Ci_FCLK	(I2Ci.I2C_SCLL[15:8] HSSCLL bit field value + 7) x I2Ci_FCLK period	(I2Ci.I2C_SCLH[15:8] HSSCLH bit field value + 5 + PROP_DELAY0) x I2Ci_FCLK period	(I2Ci.I2C_SCLH[15:8] HSSCLH bit field value + 5 + PROP_DELAY1) x I2Ci_FCLK period
F/S or HS first phase for I2C5	I2C5_FCLK	(PRM_VC_CFG_I2C_CLK[15:8] SCLL + 1) x I2C5_FCLK period	(PRM_VC_CFG_I2C_CLK[7:0] SCLH + 5 + PROP_DELAY0) x I2C5_FCLK period	(PRM_VC_CFG_I2C_CLK[7:0] SCLH + 5 + PROP_DELAY1) x I2C5_FCLK period

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-8. HS I²C T_{LOW} and T_{HIGH}Values of the I²C Clock (continued)

Mode	I²C Clock	t_{LOW}	t_{HIGH}	
			DFILTEREN bit = 0	DFILTEREN bit = 1
HS second phase for I2C5	I2C5_FCLK	(PRM_VC_CFG_I2C_CLK[31:24] HSSCLL + 1) x I2C5_FCLK period	(PRM_VC_CFG_I2C_CLK[23:16] HSSCLH + 5 + PROP_DELAY0) x I2C5_FCLK period	(PRM_VC_CFG_I2C_CLK[23:16] HSSCLH + 5 + PROP_DELAY1) x I2C5_FCLK period

NOTE: For HS mode, the I2Ci.I2C_SCLL[15:8] HSSCLL and I2Ci.I2C_SCLL[7:0] SCLL bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

For HS mode, the I2Ci.I2C_SCLH[15:8] HSSCLH and I2Ci.I2C_SCLH[7:0] SCLH bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

NOTE: The equations in Table 24-8 give the SCL timing values for SCLL/SCLH/HSSCLL/HSSCLH at HS I²C controller outputs. Actual T_{LOW} and T_{HIGH} periods may vary depending on the board (the load capacitance on the SCL signal). If necessary, any adjustments to the SCLL/SCLH/HSSCLL/HSSCLH values must be determined by measurements of actual SCL signal on the board

CAUTION

During active mode (the I2Ci.I2C_CON[15] I2C_EN bit is set to 1), make no changes to the I2Ci.I2C_SCLL and I2Ci.I2C_SCLH registers. Changes can result in unpredictable behavior.

NOTE: Each multimaster HS I²C controller can be used with an internal secondary pullup. This pullup is mandatory when the I²C controller is configured in HS mode for a bit rate of 3.4 Mbps, and the bus line capacitance exceeds 45 pF. Pullups can be programmed through:

- CONTROL_I2C_0[0] I2C1_SCL_PULLUPRESX bit or CONTROL_I2C_0[16] I2C1_SDA_PULLUPRESX bit for I2C1
- CONTROL_I2C_0[4] I2C2_SCL_PULLUPRESX bit or CONTROL_I2C_0[20] I2C2_SDA_PULLUPRESX bit for I2C2
- CONTROL_I2C_0[8] I2C3_SCL_PULLUPRESX bit or CONTROL_I2C_0[24] I2C3_SDA_PULLUPRESX bit for I2C3
- CONTROL_I2C_0[12] I2C4_SCL_PULLUPRESX bit or CONTROL_I2C_0[28] I2C4_SDA_PULLUPRESX bit for I2C4

The maximum bit rate specified by the SCCB specifications is 100 Kbps.

For more information see Section 19.4.12.9.8, *I2Cx I/Os Group Pullupresx Controls and Load Range Settings*.

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-9 lists the register values for obtaining the maximum I²C bit rates and the maximum period of the filtered spikes in F/S mode and HS mode.

Table 24-9. HS I²C Register Values for Maximum I²C Bit Rates in I²C F/S, I²C HS, and SCCB Modes[1]

	I²C Mode for I2Ci, where i = 1, 2, 3, 4			Description	SCCB Mode for I2Ci, where i = 2, 3		I²C Mode for I2C5 Fast and High-Speed Mode		
	Standard Mode	Fast Mode	High-Speed Mode						
I2Ci_FCLK frequency (MHz)	96				96		38.4		SYS_CLK clock frequency
I2Ci.I2C_PSC[7:0] PSC bit field value	**23**	**9**	**1**	Prescaler value for F/S and HS modes	**4**	Prescaler value for SCCB mode	Not accessible by software		
I2Ci_INTERNAL_CLK frequency (MHz)	4	9.6	96	19.2					
I2Ci.I2C_SCLL[7:0] SCLL bit field value	**13**	7	**113**	Value for F/S mode and first phase of HS mode	**89**	Value for SCCB mode	**PRM_VC_CFG_I2C_CLK[15:8] SCLL** (see Chapter 3, *Power, Reset, and Clock Management*)	43	Value for F/S mode and first phase of HS mode
I2Ci.I2C_SCLH[7:0] SCLH bit field value	**15**	**5**	**115**	Value for F/S mode and first phase of HS mode	**91**	Value for SCCB mode	**PRM_VC_CFG_I2C_CLK[7:0] SCLH** (see Chapter 3, *Power, Reset, and Clock Management*)	41	Value for F/S mode and first phase of HS mode
Maximum bit rate (Mbps)	0.1	0.4	0.4	F/S mode and first phase in HS mode maximum bit rate	0.1	SCCB mode maximum bit rate	Maximum bit rate (Mbps)	0.4	F/S mode and first phase in HS mode maximum bit rate
Maximum filter period (ns)	250	104	10		50		Maximum filter period (ns)	50	
I2Ci.I2C_SCLL[15:8] HSSCLL bit field value	**12**			Values for second phase of HS mode			**PRM_VC_CFG_I2C_CLK[31:24] HSSCLL** (see Chapter 3, *Power, Reset, and Clock Management*)	14	Values for second phase of HS mode
I2Ci.I2C_SCLH[15:8] HSSCLH bit field value	**5**			Values for second phase of HS mode			**PRM_VC_CFG_I2C_CLK[23:16] HSSCLH** (see Chapter 3, *Power, Reset, and Clock Management*)	0	Values for second phase of HS mode
HS mode maximum bit rate (Mbps)	3.31			HS mode maximum bit rate			HS mode maximum bit rate (Mbps)	3.2	HS mode maximum bit rate according to the corresponding SYS_CLK clock frequency
Maximum filter period (ns)	10							10	

(1) Programmable fields are in bold.

Copyright © 2011–2012, Texas Instruments Incorporated

NOTE: This table presents informative values only for the configuration parameters and the I²C bus performance obtained according to these values. The delays added by the analog pads are not considered in these figures.

NOTE: For I2Ci (where i = 1, 2, 3, 4)

I2Ci_INTERNAL_CLK freq = I2Ci_FCLK / (PSC + 1)

FS filter period = 1 / I2Ci_INTERNAL_CLK

HS filter period = 1 / I2Ci_FCLK freq

- If the DFILTEREN bit = 0:

HS bit rate = I2Ci_FCLK freq / (HSSCLL+ 7 + HSSCLH + 5 + PROP_DELAY0)

FS bit rate = I2Ci_INTERNAL_CLK / (SCLL + 7 + SCLH + 5 + PROP_DELAY0)

- If the DFILTEREN bit = 1:

HS bit rate = I2Ci_FCLK freq / (HSSCLL+ 7 + HSSCLH + 5 + PROP_DELAY1)

FS bit rate = I2Ci_INTERNAL_CLK / (SCLL + 7 + SCLH + 5 + PROP_DELAY1)

For I2C5 (SR):

I2C5_FCLK freq = SYS_CLK freq

HS/FS filter period = 1 / I2C5_FCLK freq

- If the DFILTEREN bit = 0:

HS bit rate = I2C5_FCLK freq / (HSSCLL + 1 + HSSCLH + 5 + PROP_DELAY0)

FS bit rate = I2C5_FCLK freq / (SCLL + 1 + SCLH + 5 + PROP_DELAY0)

- If the DFILTEREN bit = 1:

HS bit rate = I2C5_FCLK freq / (HSSCLL + 1 + HSSCLH + 5 + PROP_DELAY1)

FS bit rate = I2C5_FCLK freq / (SCLL + 1 + SCLH + 5 + PROP_DELAY1)

DFILTEREN refers to the VC_CFG_I2C_MODE[6] DFILTEREN bit. PROP_DELAYx (where x = 0 or 1) represents frequency-normalized I/O low-to-high propagation delay.

PROP_DELAY0 = 0 or 3 (values for bit rate maximum/minimum range)

PROP_DELAY1 = 1 or 4 (values for bit rate maximum/minimum range)

24.1.4.2.2 HS I²C Automatic Blocking of the I²C Clock Feature (I²C Mode Only)

This feature offers the possibility for the LH to command the blocking of the I²C clock after the slave addressing phase, when the I²C controller is addressed by an external master device using a certain Own Address.

The release of the I²C clock can be performed independently for each Own Address (I2Ci.I2C_OA , where i = 1, 2, 3, 4 and I2Ci.I2C_OAx registers, where x = 1, 2, 3) by deasserting the corresponding bit in the I2Ci.I2C_SBLOCK register.

24.1.4.3 HS I²C Software Reset

Each multimaster HS I²C controller supports the software reset by accessing the I2Ci.I2C_SYSC[1] SRST bit (1: reset; 0: normal mode).

The software reset status can be checked by accessing the I2Ci.I2C_SYSS[0] RDONE bit (1: reset is done; 0: reset is ongoing).

To perform a software reset:

1. Ensure that the module is disabled (clear the I2Ci.I2C_CON[15] I2C_EN bit to 0).
2. Set the I2Ci.I2C_SYSC[1] SRST bit to 1.
3. Enable the module by setting I2Ci.I2C_CON[15] I2C_EN bit to 1.
4. Check the I2Ci.I2C_SYSS[0] RDONE bit until it is set to 1 to indicate the software reset is complete.

NOTE: The I2Ci.I2C_CON[15] I2C_EN bit can hold the functional clock domain of the multimaster HS I²C controller in reset after the device reset has been released. When the system bus reset is removed, this bit remains cleared. The functional part of the I²C controller is held in reset state while this bit is 0, and all configuration registers can be accessed.

The I2Ci.I2C_CON[15] I2C_EN bit must be set to 1 to enable the functional part of the I²C controller.

The I2Ci.I2C_SYSS[0] RDONE bit is asserted only after the module is enabled by setting the I2Ci.I2C_CON[15] I2C_EN bit to 1.

24.1.4.4 HS I²C Power Management

Table 24-10 describes power-management features available for the multimaster HS I²C controllers.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see Section 3.1.1.1.2, *Module Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.1.1.1.2, *Module Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 24-10. HS I²C Local Power-Management Features

Feature	Registers	Description
Clock auto gating	I2Ci.I2C_SYSC[0] AUTOIDLE	This bit allows a local power optimization inside the module
Slave idle modes	I2Ci.I2C_SYSC[4:3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wake-up-capable modes are available.
Clock activity	I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY	For configuration details, see Table 24-11.
Global wake-up enable	I2Ci.I2C_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.

Copyright © 2011–2012, Texas Instruments Incorporated

NOTE: The voltage controllers, in which the HS I²C controller I2C5 are implemented, have no idle request/acknowledge mechanism. The idle modes for the voltage controllers are directly managed by the PRCM module.

Table 24-11. HS I²C Clock Activity Settings

I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY	Clock State When Module is in IDLE State		Features Available/Unavailable When Module is in IDLE State
	I2Ci_ICLK	I2C_ FCLK	
00	OFF	OFF	Both clocks are disabled
10	OFF	ON	Interface clock is disabled; functional clock is enabled
01	ON	OFF	Functional clock is disabled; interface clock is enabled
11	ON	ON	Both clocks are enabled

CAUTION

The PRCM module has no hardware means of reading the settings of CLOCKACTIVITY. Thus, software must ensure consistent programming between the I2C CLOCKACTIVITY and I2C clock PRCM control bits. For a description of the ClockActivity feature, see Section 3.1.1.1.2, *Module Level Clock Management* in Chapter 3, *Power, Reset, and Clock Management*.

24.1.4.5 HS I²C Interrupt Requests

Table 24-12 lists the event flags, and their mask, that can cause module interrupts.

Table 24-12. HS I²C Events

Event Flag	Event Mask	Event Unmask	Map to	Description
I2Ci.I2C_IRQSTATUS[0] AL	I2Ci.I2C_IRQENABLE_SET[0] AL_IE	I2Ci.I2C_IRQENABLE_CLR[0] AL_IE	I2Ci_IRQ	Arbitration lost IRQ enabled status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to the MPU subsystem. During reads, it always returns 0.
I2Ci.I2C_IRQSTATUS[1] NACK	I2Ci.I2C_IRQENABLE_SET[1] NACK_IE	I2Ci.I2C_IRQENABLE_CLR[1] NACK_IE	I2Ci_IRQ	No acknowledgment IRQ enabled status. Bit is set when No Acknowledge has been received, an interrupt is signaled to MPU subsystem. Write 1 to clear this bit.
I2Ci.I2C_IRQSTATUS[2] ARDY	I2Ci.I2C_IRQENABLE_SET[2] ARDY_IE	I2Ci.I2C_IRQENABLE_CLR[2] ARDY_IE	I2Ci_IRQ	Register access ready IRQ enabled status. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to MPU subsystem. Write 1 to clear.
I2Ci.I2C_IRQSTATUS[3] RRDY	I2Ci.I2C_IRQENABLE_SET[3] RRDY_IE	I2Ci.I2C_IRQENABLE_CLR[3] RRDY_IE	I2Ci_IRQ	Receive data ready IRQ enabled status. Set to 1 by core when receiver mode, a new data is able to be read. When set to 1 by core, an interrupt is signaled to MPU subsystem. Write 1 to clear.

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-12. HS I²C Events (continued)

Event Flag	Event Mask	Event Unmask	Map to	Description
I2Ci.I2C_IRQSTATUS[4] XRDY	I2Ci.I2C_IRQENABLE_SET[4] XRDY_IE	I2Ci.I2C_IRQENABLE_CLR[4] XRDY_IE	I2Ci_IRQ	Transmit data ready IRQ enabled status. Set to 1 by core when transmitter and when new data is requested. When set to 1 by core, an interrupt is signaled to MPU subsystem. Write 1 to clear.
I2Ci.I2C_IRQSTATUS[5] GC	I2Ci.I2C_IRQENABLE_SET[5] GC_IE	I2Ci.I2C_IRQENABLE_CLR[5] GC_IE	I2Ci_IRQ	General call IRQ enabled status. Set to 1 by core when General call address detected and interrupt signaled to MPU subsystem. Write 1 to clear.
I2Ci.I2C_IRQSTATUS[6] STC	I2Ci.I2C_IRQENABLE_SET[6] STC_IE	I2Ci.I2C_IRQENABLE_CLR[6] STC_IE	I2Ci_IRQ	Start Condition IRQ enabled status.
I2Ci.I2C_IRQSTATUS[7] AERR	I2Ci.I2C_IRQENABLE_SET[7] AERR_IE	I2Ci.I2C_IRQENABLE_CLR[7] AERR_IE	I2Ci_IRQ	Access Error IRQ enabled status.
I2Ci.I2C_IRQSTATUS[8] BF	I2Ci.I2C_IRQENABLE_SET[8] BF_IE	I2Ci.I2C_IRQENABLE_CLR[8] BF_IE	I2Ci_IRQ	Access Error IRQ enabled status.
I2Ci.I2C_IRQSTATUS[9] AAS	I2Ci.I2C_IRQENABLE_SET[9] AAS_IE	I2Ci.I2C_IRQENABLE_CLR[9] AAS_IE	I2Ci_IRQ	Address recognized as slave IRQ enabled status.
I2Ci.I2C_IRQSTATUS[10] XUDF	I2Ci.I2C_IRQENABLE_SET[10] XUDF_IE	I2Ci.I2C_IRQENABLE_CLR[10] XUDF_IE	I2Ci_IRQ	Transmit underflow enabled status. Writing into this bit has no effect.
I2Ci.I2C_IRQSTATUS[11] ROVR	I2Ci.I2C_IRQENABLE_SET[11] ROVR_IE	I2Ci.I2C_IRQENABLE_CLR[11] ROVR_IE	I2Ci_IRQ	Receive overrun enabled status. Writing into this bit has no effect.
I2Ci.I2C_IRQSTATUS[12] BB	-	-	I2Ci_IRQ	Bus busy status.
I2Ci.I2C_IRQSTATUS[13] RDR	I2Ci.I2C_IRQENABLE_SET[13] RDR_IE	I2Ci.I2C_IRQENABLE_CLR[13] RDR_IE	I2Ci_IRQ	Receive draining IRQ enabled status.
I2Ci.I2C_IRQSTATUS[14] XDR	I2Ci.I2C_IRQENABLE_SET[14] XDR_IE	I2Ci.I2C_IRQENABLE_CLR[14] XDR_IE	I2Ci_IRQ	Transmit draining IRQ enabled status.

24.1.4.6 HS I²C DMA Requests

Each multimaster HS I²C controller can generate two DMA requests to the system DMA (sDMA) controller. Table 24-13 lists the DMA requests with mapping on the sDMA controller. For information about DMA generation, see Section 24.1.4.8.3, *HS I²C FIFO DMA Mode (I²C Mode Only)*.

Table 24-13. HS I²C DMA Requests

Name	Source	Destination	Description
I2C1_DMA_TX	I2C1	S_DMA_26	I2C1 DMA write request to inform the sDMA to write new data in the I2C1.I2C_DATA[7:0] register
I2C1_DMA_RX	I2C1	S_DMA_27	I2C1 DMA read request to inform the sDMA to read the data in the I2C1.I2C_DATA[7:0] register
I2C2_DMA_TX	I2C2	S_DMA_28	I2C2 DMA write request to inform the sDMA to write new data in the I2C2.I2C_DATA[7:0] register
I2C2_DMA_RX	I2C2	S_DMA_29	I2C2 DMA read request to inform the sDMA to read the data in the I2C2.I2C_DATA[7:0] register
I2C3_DMA_TX	I2C3	S_DMA_24	I2C3 DMA write request to inform the sDMA to write new data in the I2C3.I2C_DATA[7:0] register
I2C3_DMA_RX	I2C3	S_DMA_25	I2C3 DMA read request to inform the sDMA to read the data in the I2C3.I2C_DATA[7:0] register

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-13. HS I²C DMA Requests (continued)

Name	Source	Destination	Description
I2C4_DMA_TX	I2C4	S_DMA_123	I2C4 DMA write request to inform the sDMA to write new data in the I2C4.I2C_DATA[7:0] register
I2C4_DMA_RX	I2C4	S_DMA_124	I2C4 DMA read request to inform the sDMA to read the data in the I2C4.I2C_DATA[7:0] register

NOTE: The HS I²C controller I2C5 does not generate any DMA requests.

24.1.4.7 HS I²C Programmable Multislave Channel Feature (I²C Mode Only)

This feature allows each multimaster HS I²C controller to be addressed using four separate Own Addresses configured in the I2Ci.I2C_OA and I2Ci.I2C_OAx registers (where x = 1, 2, 3). An additional register (I2Ci.I2C_ACTOA) is used to indicate to the LH which address is used by the external master to communicate with the I²C controller.

Each Own Address can be independently configured in 7-bit or 10-bit mode by setting the corresponding bit (I2Ci.I2C_CON[7] XOA, I2Ci.I2C_CON[6] XOA1, I2Ci.I2C_CON[5] XOA2, or I2Ci.I2C_CON[4] XOA3).

24.1.4.8 HS I²C FIFO Management

Each multimaster HS I²C controller implements two internal 8-bit FIFOs, the RX and TX FIFOs.

The depth of the RX and TX FIFOs is fixed at 16 bytes and can be checked by reading the I2Ci.I2C_BUFSTAT[15:14] FIFODEPTH bit field (0x0: 8 bytes, 0x1: 16 bytes, 0x2: 32 bytes, and 0x3: 64 bytes).

NOTE: FIFO depth is configured at design time and cannot be modified by software. FIFO thresholds must not exceed configured FIFO depth.

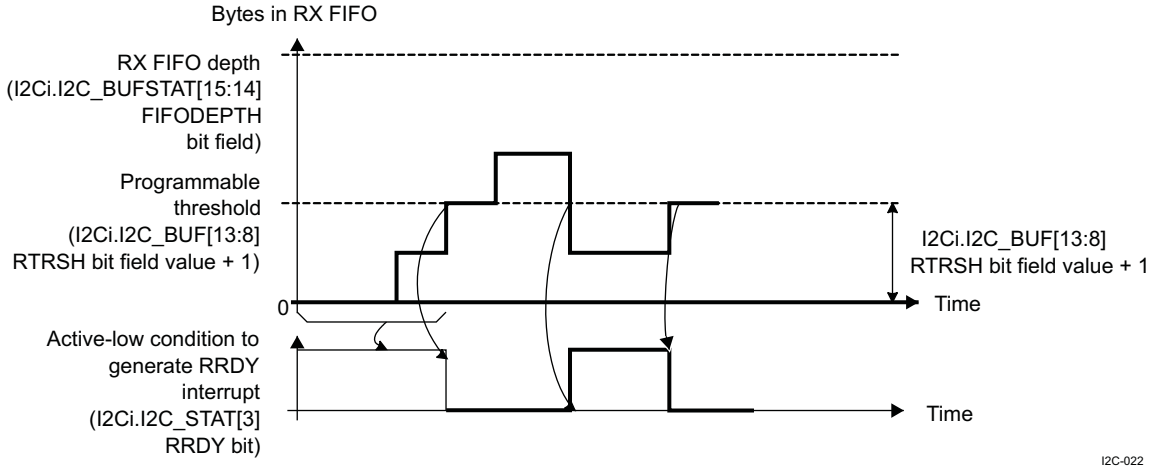
24.1.4.8.1 HS I²C FIFO Interrupt Mode

In first in first out (FIFO) interrupt mode (relevant interrupts enabled by the I2Ci.I2C_IE register), an interrupt signal informs the processor of the receiver and transmitter status. These interrupts are raised when the RX/TX FIFO thresholds (defined by the I2Ci.I2C_BUF[13:8] RTRSH bit field value + 1 for the RX FIFO or the I2Ci.I2C_BUF[5:0] TXTRSH bit field value + 1 for the TX FIFO) are reached; the interrupt signals instruct the LH to transfer data to the destination (from the I²C controller in receive mode and/or from any source to the I²C controller FIFO in transmit mode).

Figure 24-23 and Figure 24-24 show receive and transmit operations, respectively, from a FIFO management point of view.

Copyright © 2011–2012, Texas Instruments Incorporated

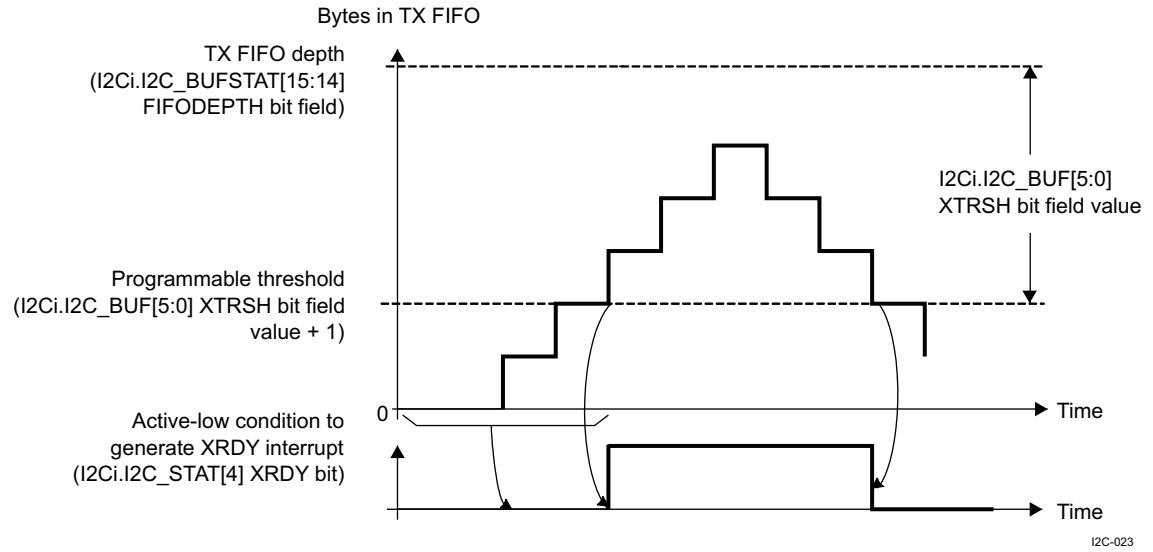
Figure 24-23. HS I²C Receive FIFO Interrupt Request Generation



In Figure 24-23, the RRDY interrupt condition shows that the condition for generating an RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the LH by writing 1 in the I2Ci.I2C_STAT[3] RRDY bit. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In receive mode, an RRDY interrupt is generated as soon as the FIFO reaches its receive threshold (I2Ci.I2C_BUF[13:8] RTRSH bit field value + 1). The interrupt can be deasserted only when the LH has handled enough bytes to make the number of bytes in the RX FIFO lower than the programmed threshold. For each interrupt, the LH can be configured to read a number of bytes equal to the value of the RX FIFO threshold.

Figure 24-24. HS I²C Transmit FIFO Interrupt Request Generation



In Figure 24-24, the XRDY interrupt condition shows that the condition for generating an XRDY interrupt is achieved. The interrupt request is generated when TX FIFO is empty or when the TX FIFO threshold is not reached, and the LH can clear the XRDY status bit by setting the I2Ci.I2C_STAT[4] XRDY bit to 1 after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In interrupt mode, the module offers two options for the LH application to handle the interrupts:

- When detecting an interrupt request (XRDY or RRDY type), the LH can write/read 1 data byte to/from the TX/RX FIFO and then clear the interrupt. The module reasserts the interrupt until the interrupt condition is not met.

Copyright © 2011–2012, Texas Instruments Incorporated

- When detecting an interrupt request (XRDY or RRDY type), the LH can be programmed to write/read the amount of data bytes specified by the corresponding FIFO threshold (I2C_BUF[5:0] TXTRSH + 1 or I2C_BUF[5:0] RXTRSH + 1). In this case, the interrupt condition is cleared and the next interrupt is asserted again when the XRDY or RRDY condition is met again.

If the second-interrupt-serving approach is used, an additional mechanism (draining feature) is implemented for cases where the transfer length is not a multiple of the FIFO threshold value (see Section 24.1.4.8.4, *Draining Feature [I²C Mode Only]*).

NOTE: In slave transmit mode (the I2Ci.I2C_CON[10] MST bit is cleared and the I2Ci.I2C_CON[9] TRX bit is set to 1), the draining feature must not be used, because the transfer length is not known at configuration time, and the external master can end the transfer at any point by not acknowledging 1 data byte. If the draining feature is used in slave transmit mode, data can remain in the TX FIFO without being transmitted over the I²C bus. In this case, the TX FIFO must be cleared by setting the I2Ci.I2C_BUF[6] TXFIFO_CLR bit.

NOTE: In SCCB mode, the RX and TX threshold values must be set to 1 by setting the I2Ci.I2C_BUF[13:8]RTRSH and I2Ci.I2C_BUF[5:0] TXTRSH fields to 0x0.

24.1.4.8.2 HS I²C FIFO Polling Mode

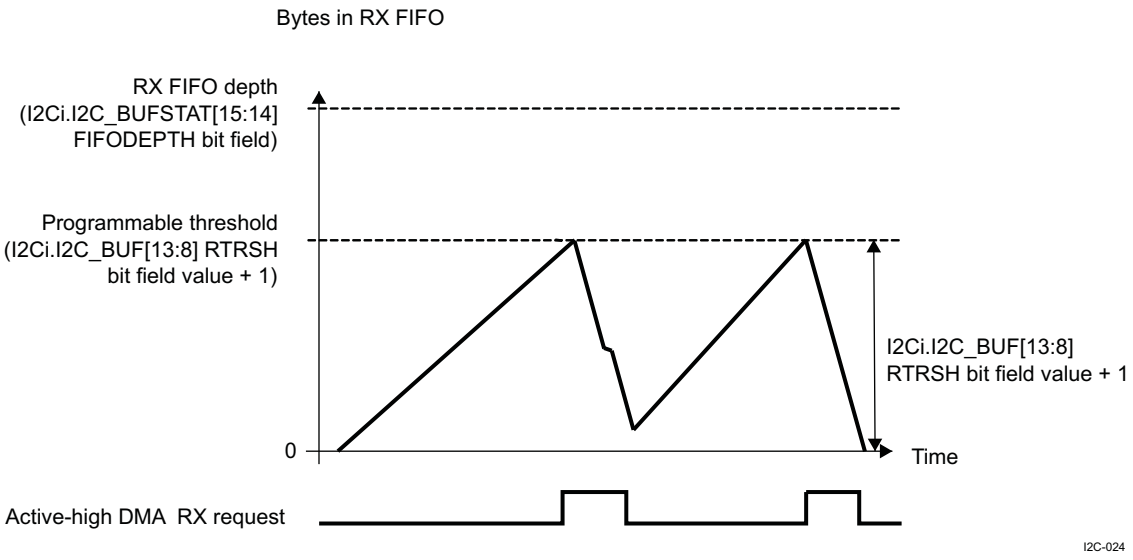
In FIFO polling mode (the I2Ci.I2C_IE[4] XRDY_IE and I2Ci.I2C_IE[3] RRDY_IE bits are disabled, and the I2Ci.I2C_BUF[15] RDMA_EN and I2Ci.I2C_BUF[7] XDMA_EN bits are disabled), the status of the module (receiver or transmitter) can be checked by polling the I2Ci.I2C_STAT[4] XRDY and the I2Ci.I2C_STAT[3] RRDY bits (the I2Ci.I2C_STAT[13] RDR and I2Ci.I2C_STAT[14] XDR bits can also be polled if the draining feature is enabled). The I2Ci.I2C_STAT[4] XRDY and I2Ci.I2C_STAT[3] RRDY bits accurately reflect the interrupt conditions described in the discussion of FIFO interrupt mode.

24.1.4.8.3 HS I²C FIFO DMA Mode (I²C Mode Only)

In receive mode, a DMA request is generated by the I2Ci_DMA_RX signal as soon as the RX FIFO exceeds its threshold level (the I2Ci.I2C_BUF[13:8] RTRSH bit field value + 1). This request is deasserted when the number of bytes defined by the threshold level is read by the DMA controller.

Figure 24-25 shows the DMA request generation in receive mode.

Figure 24-25. HS I²C Receive FIFO DMA Request Generation



Copyright © 2011–2012, Texas Instruments Incorporated

In transmit mode, a DMA request is automatically asserted by the I2Ci_DMA_TX signal when the TX FIFO is empty. This request is deasserted when the number of bytes (the 2Ci.I2C_BUF[5:0] TXTRSH bit field value + 1) is written in the FIFO by the DMA controller. If an insufficient number of bytes is written, the sDMA request remains active. Figure 24-26 and Figure 24-27 show the DMA TX transfers with different values for the I2Ci.I2C_BUF[5:0] TXTRSH bit field.

Figure 24-26. HS I²C Transmit FIFO Request Generation (High Threshold)

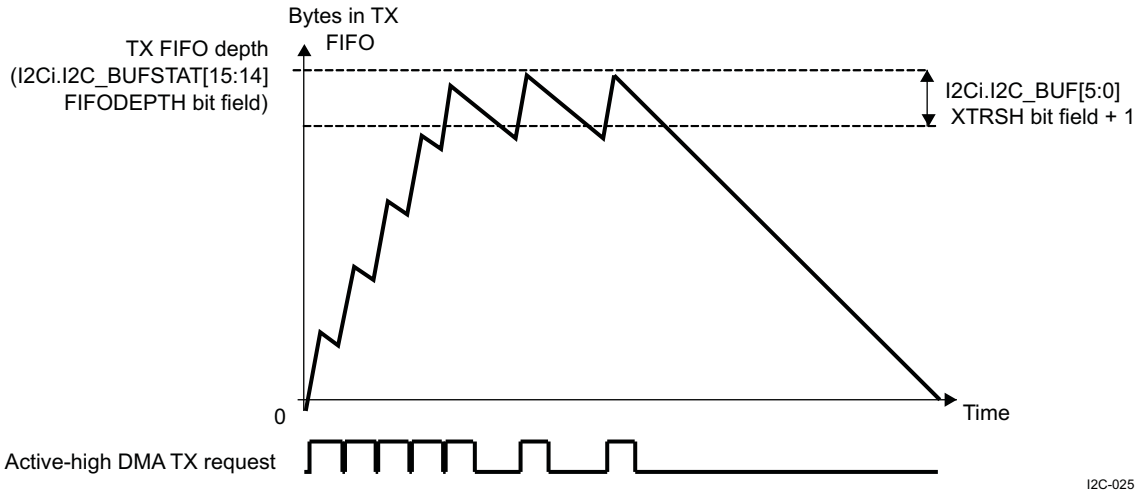


Figure 24-27. HS I²C Transmit FIFO Request Generation (Low Threshold)

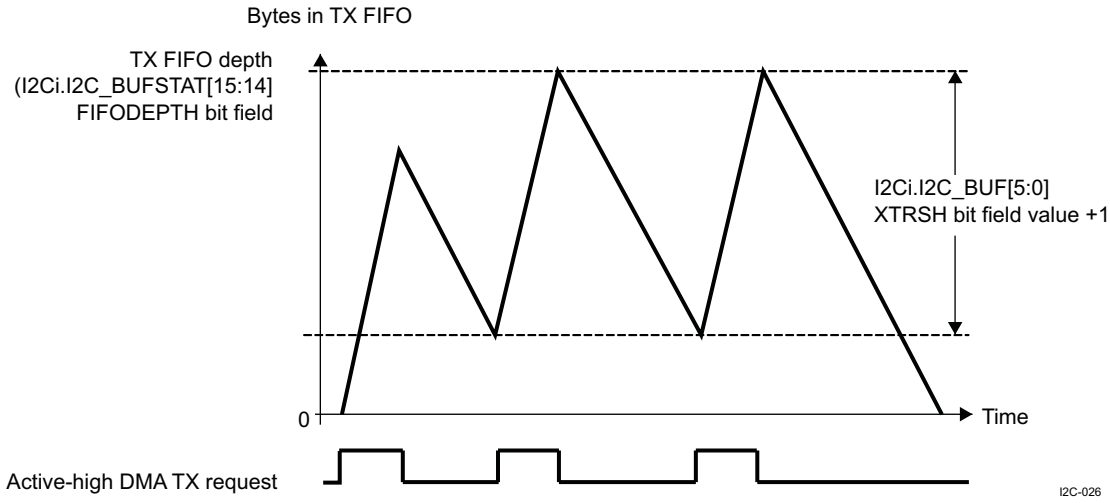

NOTE: In SCCB mode, the RX and TX threshold values must be set to 1 by setting the I2Ci.I2C_BUF[13:8] RTRSH and I2Ci.I2C_BUF[5:0] XTRSH bit fields to 0x0.

The I²C module allows the user to clear the RX or TX FIFO by setting the I2Ci.I2C_BUF[14] RXFIFO_CLR and I2Ci.I2C_BUF[6] TXFIFO_CLR registers, respectively, which act like software reset for the FIFOs. In DMA mode, these bits also reset the DMA state-machines. The FIFO clearing feature can be used when the following conditions are met:

- The module is configured as a transmitter.
- The external receiver responds with a NACK in the middle of the transfer.
- Data in the TX FIFO is waiting to be transferred.

Copyright © 2011–2012, Texas Instruments Incorporated

24.1.4.8.4 HS I²C Draining Feature (I²C Mode Only)

The draining feature is implemented to handle the end of a transfer whose length is not a multiple of the FIFO threshold values (the I2Ci.I2C_BUF[13:8] RTRSH bit field value + 1 for the RX threshold and I2Ci.I2C_BUF[5:0] TXTRSH field value + 1 for the TX threshold). It can also transfer the remaining number of bytes (because the threshold is not reached).

This feature prevents the LH or the DMA controller from trying more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having fewer bytes in the FIFO than the configured DMA transfer length). Otherwise, an AERR interrupt is generated by the I2Ci.I2C_STAT[7] AERR bit.

The draining mechanism generates an interrupt using the I2Ci.I2C_STAT[13] RDR or I2Ci.I2C_STAT[14] XDR bit at the end of the transfer, informing the LH that it must check the amount of data left to be transferred (the I2Ci.I2C_BUFSTAT[13:8] RXSTAT or I2Ci.I2C_BUFSTAT[5:0] TXSTAT bit fields) and enable the draining feature of the DMA controller by reconfiguring the DMA transfer length according to this value (when the DMA mode is enabled) or perform only the required number of data accesses (when the DMA mode is disabled).

In receive mode (master or slave), if the RX FIFO threshold (the I2Ci.I2C_BUF[13:8] RTRSH bit field value + 1) is not reached, but the transfer ends on the I²C bus and data remains in the RX FIFO (less than the threshold), the receive draining interrupt (the I2Ci.I2C_STAT[13] RDR bit) is asserted to inform the LH that it can read the amount of data in the RX FIFO (the I2Ci.I2C_BUFSTAT[13:8] RXSTAT bit field). The LH performs a number of data read accesses equal to the I2Ci.I2C_BUFSTAT[13:8] RXSTAT bit field (interrupt or polling mode), or reconfigures the sDMA controller with the required value to drain the FIFO.

In master transmit mode, if the TX FIFO threshold (I2Ci.I2C_BUF[5:0] TXTRSH bit field value + 1) is not reached, but the amount of data remaining to be written in the TX FIFO is less than the threshold, the transmit draining interrupt (the I2Ci.I2C_STAT[14] XDR bit) is asserted to inform the LH that it can read the amount of data remaining to be written in the TX FIFO (the I2Ci.I2C_BUFSTAT[5:0] TXSTAT bit field). The LH must write the required number of data bytes specified by the I2Ci.I2C_BUFSTAT[5:0] TXSTAT bit field value or reconfigure the sDMA controller with the value required to transfer the last bytes to the FIFO.

In master mode, the LH can alternately not check the values of the I2Ci.I2C_BUFSTAT[5:0] TXSTAT and I2Ci.I2C_BUFSTAT[13:8] RXSTAT bit fields, the LH can obtain this information internally (by computing the I2Ci.I2C_CNT[15:0] DATACOUNT bit field value modulo I2Ci.I2C_BUF[13:8] RTRSH or I2Ci.I2C_BUF[5:0] TXTRSH).

By default, the draining feature is disabled; it can be enabled using the I2Ci.I2C_IE[14] XDR_IE or I2Ci.I2C_IE[13] RDR_IE bits (default disabled) only for transfers with lengths not equal to the threshold values (I2Ci.I2C_BUF[5:0] TXTRSH bit field value + 1 for the TX threshold or I2Ci.I2C_BUF[13:8] RTRSH bit field value + 1 for the RX threshold).

24.1.4.9 HS I²C Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less in case of F/S operation modes and SCCB modes, and any noise that is 10 ns or less in case of HS mode operation. The noise filter is always one period of the I2Ci_INTERNAL_CLK clock. This way, for HS mode operation (prescaler bypassed), the filter suppresses spikes of less than 10.4 ns.

For SCCB modes (for example, I2Ci.I2C_PSC[7:0] PSC bit field = 4), the maximum width of suppressed spikes is 52 ns.

To ensure correct filtering, the prescaler must be programmed accordingly by the 2Ci.I2C_PSC[7:0] PSC bit field.

24.1.4.10 HS I²C Write and Read Operations in SCCB Mode

In SCCB mode, the multimaster HS I²C controller can write or read a single byte to or from the external SCCB device.

Copyright © 2011–2012, Texas Instruments Incorporated

To write a single byte to the external SCCB device, the multimaster HS I²C controller must be configured in multimaster transmitter mode by setting the I2Ci.I2C_CON[10] MST and I2Ci.I2C_CON[9] TRX bits to 1. The external device slave address (7-bit address of the ID value) is set in the I2Ci.I2C_SA register; the register address (8-bit subaddress in the external SCCB device) is set in the I2Ci.I2C_OA0 register. The 8-bit data to be transmitted is written by the LH in the I2Ci.I2C_DATA register.

To read a single byte from the external SCCB device, the multimaster HS I²C controller must be configured in multimaster receiver mode by setting the I2Ci.I2C_CON[10] MST bit to 1 and by clearing the I2Ci.I2C_CON[9] TRX bit to 0. The external device slave address (7-bit address of the ID value) is set in the I2Ci.I2C_SA register; the register address (8-bit subaddress in the external SCCB device) is set in the I2Ci.I2C_OA0 register. The 8-bit data received from the external SCCB device is read by the LH from the I2Ci.I2C_DATA register.

NOTE: In SCCB mode, the RX and TX thresholds must be set to 1 by configuring the I2Ci.I2C_BUF[13:8] RTRSH and I2Ci.I2C_BUF[5:0]XTRSH fields to 0x0.

24.1.4.11 HS I²C System Test Mode

A system test mode is available for multimaster HS I²C controller module testing. This mode is enabled by setting the I2Ci.I2C_SYSTEST[15] ST_EN bit to 1. When this bit is cleared to 0, the I²C controller is configured in normal operation mode.

In system test mode, the I2Ci_SYSTEST[13:12] TMODE bit field selects the type of test. Table 24-14 lists the tests available for the multimaster HS I²C controllers.

Table 24-14. HS I²C List of Tests

I2Ci.I2C_SYSTEST[13:12] TMODE	Test	Description
00	Functional mode	Normal operation mode
01	Reserved (not used)	
10	Test of i2ci_scl serial clock line	The i2ci_scl line is driven with a permanent clock as if mastered with the parameters set in the I2Ci.I2C_PSC, I2Ci.I2C_SCLL, and I2Ci.I2C_SCLH registers.
11	Loop-back mode + i2ci_scl/ i2ci_sda input/output	In master transmit mode only, data transmitted out of the I2Ci.I2C_DATA register (write action) is received in the same I2Ci.I2C_DATA register through an internal path through the FIFO buffers. The DMA and interrupt requests are normally generated if they are enabled. Moreover, the i2ci_scl, i2ci_sda, and i2ci_sccbe lines are controlled with the I2Ci.I2C_SYSTEST[4:0] bits..

NOTE: When the I2Ci.I2C_SYSTEST[13:12] TMODE bit field is set to 11, the I²C controller must be configured in I²C F/S (the I2Ci.I2C_CON[13:12] OPMODE set to 00) or I²C HS mode (the I2Ci.I2C_CON[13:12] OPMODE set to 01). The loop-back mode is not available in SCCB mode (the 2Ci.I2C_CON[13:12] OPMODE = b10).

NOTE: In normal operation mode (I2Ci.I2C_SYSTEST[15] ST_EN clear to 0), the I2Ci.I2C_SYSTEST[4:0] bits that control the i2ci_scl, i2ci_sda, and i2ci_sccbe lines in system test mode are read-only bits.

In system test mode (I2Ci.I2C_SYSTEST[15] ST_EN set to 1), the I2Ci.I2C_STAT[5:0] status bits can be set to 1 when the I2Ci.I2C_SYSTEST[11] SSB bit is set to 1. Clearing the I2Ci.I2C_SYSTEST[11] SSB bit to 0 does not clear the I2Ci.I2C_STAT[5:0] bits to 0. The I2Ci.I2C_STAT[5:0] bit field can be cleared to 0 only by writing 1 in the corresponding bits.

24.1.5 HS I²C Programming Guide

24.1.5.1 HS I²C Low-Level Programming Models

24.1.5.1.1 HS I²C Programming Model in I²C Mode

This section describes the programming model of the multimaster HS I²C controllers configured in I²C mode.

24.1.5.1.1.1 Main Program

24.1.5.1.1.1.1 Configure the Module Before Enabling the I²C Controller

Before enabling the I²C controller, perform the following:

1. Enable the functional and interface clocks.
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock by programming the corresponding value in the I2Ci.I2C_PSC[7:0] PSC field. This value depends on the frequency of the functional clock (I2Ci_FCLK).
3. Program the I2Ci.I2C_SCLL[7:0] SCLL and I2Ci.I2C_SCLH[7:0] SCLH bit fields to obtain a bit rate of 100 Kbps, 400 Kbps or 1Mbps. These values depend on the internal sampling clock frequency (see Table 24-8).
4. (Optional) Program the I2Ci.I2C_SCLL[15:8] HSSCLL and I2Ci.I2C_SCLH[15:8] HSSCLH bit fields to obtain a bit rate of 400 Kbps or 3.4 Mbps (for the second phase of HS mode). These values depend on the internal sampling clock frequency (see Table 24-8).
5. (Optional) If a bit rate of 3.4 Mbps is used and the bus line capacitance exceeds 45 pF, see Section 19.4.8, *PAD Functional Multiplexing and Configuration.*
6. Configure the Own Address of the I2C controller by storing it in the I2Ci.I2C_OA register. Up to four Own Addresses can be programmed in the I2Ci.I2C_OAx registers (where x = 0, 1, 2, 3) for each I²C controller.

   NOTE: For a 10-bit address, set the corresponding expand Own Address bit in the I2Ci.I2C_CON register.

7. Set the TX threshold (in transmitter mode) and the RX threshold (in receiver mode) by setting the I2Ci.I2C_BUF[5:0] TXTRSH bit field to (TX threshold to 1) and the I2Ci.I2C_BUF[13:8]RTRSH bit field to (RX threshold to 1), where the TX and RX thresholds are greater than or equal to 1.
8. Take the I²C controller out of reset by setting the I2Ci.I2C_CON[15] I2C_EN bit to 1.

24.1.5.1.1.1.2 Initialize the I²C Controller

To initialize the I²C controller, perform the following steps:

1. Configure the I2Ci.I2C_CON register:
   - For master or slave mode, set the I2Ci.I2C_CON[10] MST bit (0: slave; 1: master).
   - For transmitter or receiver mode, set the I2Ci.I2C_CON[9] TRX bit (0: receiver; 1: transmitter).
2. If using an interrupt to transmit and receive data, set the corresponding bit in the I2Ci.I2C_IE register to 1 (the I2Ci.I2C_IE[4] XRDY_IE bit for the transmit interrupt, the I2Ci.I2C_IE[3] RRDY bit for the receive interrupt).
3. If using DMA to receive and transmit data, set the corresponding bit in the I2Ci.I2C_BUF register to 1 (the I2Ci.I2C_BUF[15] RDMA_EN bit for the receive DMA channel, the I2Ci.I2C_BUF[7] XDMA_EN bit for the transmit DMA channel).

Copyright © 2011–2012, Texas Instruments Incorporated

24.1.5.1.1.1.3 Configure Slave Address and the Data Control Register

In master mode, configure the slave address register by programming the I2Ci.I2C_SA[9:0] SA bit field and the number of data bytes (I²C data payload) associated with the transfer by programming the I2Ci.I2C_CNT[15:0] DCOUNT bit field.

NOTE: For a 10-bit address, set the I2Ci.I2C_CON[8] XSA bit to 1.

24.1.5.1.1.1.4 Initiate a Transfer

Poll the I2Ci.I2C_STAT[12] BB bit. If it is cleared to 0 (bus not busy), configure the I2Ci.I2C_CON[0] STT and I2Ci.I2C_CON[1] STP bits. To initiate a transfer, the I2Ci.I2C_CON[0] STT bit must be set to 1, and it is not mandatory to set the I2Ci.I2C_CON[1] STP bit to 1.

24.1.5.1.1.1.5 Receive Data

Poll the I2Ci.I2C_STAT[3] RRDY bit, or use the RRDY interrupt (the I2Ci.I2C_IE[3] RRDY_IE bit must be set to 1) or the DMA RX channel (the I2Ci.I2C_BUF[15] RDMA_EN bit must be set to 1) to read the receive data in the I2Ci.I2C_DATA register.

If the transfer length does not equal the RX FIFO threshold (I2Ci.I2C_BUF[13:8] RTRSH field + 1), use the draining feature (enable the RDR interrupt by setting the I2Ci.I2C_IE[13] RDR_IE bit to 1).

NOTE: In receive mode only, the I2Ci.I2C_STAT[11] ROVR (receive overrun) bit indicates whether the receiver has experienced overrun. An overrun condition occurs when the shift register and the RX FIFO are full. An overrun condition does not result in data loss; the I²C controller simply holds i2ci_scl to low to prevent other bytes from being received.

The I2Ci.I2C_STAT[7] AERR bit is set to 1 when a read access is performed in the I2Ci.I2C_DATA register while the RX FIFO is empty. The corresponding interrupt can be enabled by setting the I2Ci.I2C_IE[7] AERR_IE bit to 1.

24.1.5.1.1.1.6 Transmit Data

Poll the I2Ci.I2C_STAT[4] XRDY bit, or use the XRDY interrupt (the I2Ci.I2C_IE[4] XRDY_IE bit must be set to 1) or the DMA TX channel (the I2Ci.I2C_BUF[7] XDMA_EN bit must be set to 1) to write data to the I2Ci.I2C_DATA register.

If the transfer length does not equal the TX FIFO threshold (I2Ci.I2C_BUF[5:0] TXTRSH field + 1), use the draining feature (enable the XDR interrupt by setting the I2Ci.I2C_IE[14] XDR_IE bit to 1).

NOTE: In transmit mode only, the I2Ci.I2C_STAT[10] XUDF bit indicates whether the transmitter has experienced underflow.

In master transmit mode, underflow occurs when the shift register and the TX FIFO are empty and there are still some bytes to transmit (the value of the I2Ci.I2C_CNT[15:0] DCOUNT bit field is not 0).

In slave transmit mode, underflow occurs when the shift register and the TX FIFO are empty and the external I²C master device still requests data bytes to be read.

The I2Ci.I2C_STAT[7] AERR bit is set to 1 when a write access is performed in the I2Ci.I2C_DATA register while the TX FIFO is full. The corresponding interrupt can be enabled by setting the I2Ci.I2C_IE[7] AERR_IE bit to 1.

24.1.5.1.1.2 Interrupt Subroutine Sequence

1. Test for arbitration lost (the I2Ci.I2C_STAT[0] AL it) and resolve accordingly.
2. Test for no acknowledgment (the I2Ci.I2C_STAT[1] NACK bit) and resolve accordingly.
3. Test for register access ready (the I2Ci.I2C_STAT[2] ARDY bit) and resolve accordingly.

Copyright © 2011–2012, Texas Instruments Incorporated

4. Test for receive data ready (the I2Ci.I2C_STAT[3] RRDY bit) and resolve accordingly.
5. Test for transmit data ready (the I2Ci.I2C_STAT[4] XRDY bit) and resolve accordingly.
6. Test for general call (the I2Ci.I2C_STAT[5] GC bit) and resolve accordingly.
7. Test for start (S) condition (the I2Ci.I2C_STAT[6] STC bit) and resolve accordingly. For this test, the functional clock must be inactive.
8. Test for access error (the I2Ci.I2C_STAT[7] AERR bit) and resolve accordingly.
9. Test for bus free (the I2Ci.I2C_STAT[8] BF bit) and resolve accordingly.

24.1.5.1.2 HS I²C (I2C5) Programming Model for Communication With Power Chips

This section describes the programming model of the master transmitter HS I²C controller (I2C5) for communication with one or more power chips. The HS I²C controller (I2C5) allowsthe two voltage Finite State Machines (FSMs) in the PRCM module of the device to be interfaced to external power chips through the I²C bus for dynamic voltage control of two power supplies and power sequencing. The primary programming tasks are to set up the configuration registers according to the external power supply chip(s) being used.

Copyright © 2011–2012, Texas Instruments Incorporated

24.1.5.1.2.1 Configure the Voltage Controller Registers

To use the voltage control function, the LH must configure the following registers in the voltage controller of the APE and 3G modem SS PRCM modules:

- The voltage configuration register address for each VDD channel in the PRCM.PRM_VC_VAL_SMPS_RA_VOL register
- The ON/ON-low-power-Retention/OFF command configuration register address for each VDD channel in the PRCM.PRM_VC_VAL_SMPS_RA_CMD register
- The set of ON/ON-low-power/Retention/OFF voltage/mode values in the APE PRCM.PRM_VC_VAL_CMD_VDD_CORE_L, APE PRCM.PRM_VC_VAL_CMD_VDD_IVA_L, and APE PRCM.PRM_VC_VAL_CMD_VDD_MPU_L registers, and 3G modem SS PRCM.PRM_VC_VAL_CMD_VDD_WGM_L register.
- The VDD channels configuration selection in the PRCM.PRM_VC_CFG_CHANNEL register

For more information about the voltage controller register configuration, see Chapter 3, *Power, Reset, and Clock Management*.

24.1.5.1.2.2 Configure the HS I²C Controller I2C5

At POR, the I2C5 is in HS mode (PRCM.PRM_VC_CFG_I2C_MODE[3] HSMODEEN bit). In HS mode, the LH must configure the master code value for the preamble I²C high-speed transmission by configuring the PRCM.PRM_VC_CFG_I2C_MODE[2:0] HSMCODE bit field. If the external power chips do not support the I²C HS mode, HS mode can be disabled and F/S mode enabled by clearing the PRCM.PRM_VC_CFG_I2C_MODE[3] HSMODEEN bit to 0.

By default, the Sr operation is enabled (PRCM.PRM_VC_CFG_I2C_MODE[4] SRMODEEN bit set to 1 at POR). In F/S mode, the Sr operation can be disabled by clearing the PRCM.PRM_VC_CFG_I2C_MODE[4] SRMODEEN bit to 0.

24.1.5.1.3 HS I²C Basic Programming Model in SCCB Mode

This section describes the programming model of the multimaster HS I²C controllers configured in SCCB mode.

24.1.5.1.3.1 Main Program

24.1.5.1.3.1.1 Configure the Module Before Enabling the I²C Controller

Before enabling the I²C controller, perform the following steps:

1. Enable the functional and interface clocks (see Table 24-7).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock (I2Ci_INTERNAL_CLK) by programming the corresponding value in the I2Ci.I2C_PSC[7:0] PSC field. This value depends on the frequency of the functional clock (I2Ci_FCLK). Because this frequency is 96MHz, the I2Ci.I2C_PSC[7:0] PSC field value is 0x7.
3. Program the I2Ci.I2C_SCLL[7:0] SCLL and I2Ci.I2C_SCLH[7:0] SCLH fields to obtain a bit rate of 100K bps (maximum authorized bit rate in SCCB mode). This value depends on the internal sampling clock frequency (see Table 24-8).
4. Configure the 7-bit slave address (ID value) by storing it in the I2Ci.I2C_SA register.
5. Configure the 8-bit register address (subaddress) by storing it in the I2Ci.I2C_OA0 register.
6. Configure the I2Ci.I2C_BUF[13:8]RTRSH field to 0x0 (RX threshold to 1) and the I2Ci.I2C_BUF[5:0]XTRSH field to 0x0 (TX threshold to 1).
7. Take the I²C controller out of reset by setting the I2Ci.I2C_CON[15] I2C_EN bit to 1.

24.1.5.1.3.1.2 Initialize the I²C Controller

To initialize the I²C controller, perform the following steps:

1. Configure the I2Ci.I2C_CON register:

Copyright © 2011–2012, Texas Instruments Incorporated

- In SCCB mode, only the master mode is supported; set the I2Ci.I2C_CON[10] MST bit to 1.
- For transmitter mode (write to the external SCCB device register) or receiver mode (read from the external SCCB device register), set the I2Ci.I2C_CON[9] TRX bit (0: receiver, 1: transmitter).

2. If using an interrupt to transmit/receive data, set to 1 the corresponding bit in the I2Ci.I2C_IE register (the I2Ci.I2C_IE[4] XRDY_IE bit for the transmit interrupt, the I2Ci.I2C_IE[3] RRDY bit for the receive interrupt).

24.1.5.1.3.1.3 Initiate a Transfer

Poll the I2Ci.I2C_STAT[12] BB bit. If it is cleared to 0 (bus not busy), set the I2Ci.I2C_CON[0] STT bit to 1. Because a transfer allows the LH to write or read only a single byte to or from the external SCCB device, the transmission automatically stops at the end of the transfer. When the transfer is complete, the I2Ci.I2C_STAT[2] ARDY bit is set to 1. In SCCB mode, the I2Ci.I2C_CON[1] STP bit is not used.

24.1.5.1.3.1.4 Receive Data

Poll the I2Ci.I2C_STAT[3] RRDY bit, or use the RRDY interrupt (the I2Ci.I2C_IE[3] RRDY_IE bit must be set to 1) to read the receive data in the I2Ci.I2C_DATA register.

NOTE: In SCCB mode, the I2Ci.I2C_BUF[13:8] RTRSH field (RX threshold) must be set to a value of 0x0 (RX threshold = 1).

24.1.5.1.3.1.5 Transmit Data

Poll the I2Ci.I2C_STAT[4] XRDY bit, or use the XRDY interrupt (the I2Ci.I2C_IE[4] XRDY_IE bit must be set to 1) to write the data to the I2Ci.I2C_DATA register.

NOTE: In SCCB mode, the I2Ci.I2C_BUF[5:0] TXTRSH field (TX threshold) must be set to a value of 0x0 (TX threshold = 1).

24.1.5.1.3.2 Interrupt Subroutine Sequence

1. Test for register access ready (I2Ci.I2C_STAT[2] ARDY status bit) and resolve accordingly.
2. Test for receive data ready (I2Ci.I2C_STAT[3] RRDY status bit) and resolve accordingly.
3. Test for transmit data ready (I2Ci.I2C_STAT[4] XRDY status bit) and resolve accordingly.

24.1.5.1.3.3 Programming Flow Diagrams

Figure 24-37 through Figure 24-41 are procedure flowcharts for programming the SCCB mode.

Bits	Field Name	Description	Type	Reset
15	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0
14	XDR	Transmit draining IRQ status. 0x0: Transmit draining inactive. 0x1: Transmit draining enabled.	RW	0
13	RDR	Receive draining IRQ status. 0x0: Receive draining inactive. 0x1: Receive draining enabled.	RW	0
12	BB	Bus busy status.Writing into this bit has no effect. Read 0x1: Bus is occupied. Read 0x0: Bus is free.	R	0
11	ROVR	Receive overrun status.Writing into this bit has no effect. Read 0x1: Receiver overrun. Read 0x0: Normal operation.	RW	0
10	XUDF	Transmit underflow status.Writing into this bit has no effect. Read 0x1: Transmit underflow. Read 0x0: Normal operation.	RW	0

Copyright © 2011–2012, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
9	AAS	Address recognized as slave IRQ status. 0x0: No action. 0x1: Address recognized.	RW	0
8	BF	Bus Free IRQ status. 0x0: No action. 0x1: Bus Free.	RW	0
7	AERR	Access Error IRQ status. 0x0: No action. 0x1: Access Error.	RW	0
6	STC	Start Condition IRQ status. 0x0: No action. 0x1: Start Condition detected.	RW	0
5	GC	General call IRQ status. Set to 1 by core when General call address detected and interrupt signaled to MPUSS. (1) 0x0: No general call detected. 0x1: General call address detected.	RW	0
4	XRDY	Transmit data ready IRQ status. Set to 1 by core when transmitter and when new data is requested. When set to 1 by core, an interrupt is signaled to MPUSS. (1) 0x0: Transmision ongoing. 0x1: Transmit data ready.	RW	0
3	RRDY	Receive data ready IRQ status. Set to 1 by core when receiver mode, a new data is able to be read. When set to 1 by core, an interrupt is signaled to MPUSS. (1) 0x0: No data available. 0x1: Receive data available.	RW	0
2	ARDY	Register access ready IRQ status. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to MPUSS. (1) 0x0: Module busy. 0x1: Access ready.	RW	0
1	NACK	No acknowledgement IRQ status. Bit is set when No Acknowledge has been received, an interrupt is signaled to MPUSS. (1) 0x0: Normal operation. 0x1: Not Acknowledge detected.	RW	0
0	AL	Arbitration lost IRQ status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to MPUSS. During reads, it always returns 0. 0x0: Normal operation. 0x1: Arbitration lost detected.	RW	0

Table 24-40. Register Call Summary for Register I2C_IRQSTATUS_RAW

Multimaster High-Speed I2C Controller

- HS I2C Register Summary: [0] [1]

1. Writing 1 in the bit field only sets the respective field to 1, used mainly for debug.

RESERVED	XDR	RDR	BB	ROVR	XUDF	AAS	BF	AERR	STC	GC	XRDY	RRDY	ARDY	NACK	AL

Bits	Field Name	Description	Type	Reset
15	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0
14	XDR	Transmit draining IRQ status. 0x0: Transmit draining inactive. 0x1: Transmit draining enabled.	RW W1toClr	0
13	RDR	Receive draining IRQ status. 0x0: Receive draining inactive. 0x1: Receive draining enabled.	RW W1toClr	0
12	BB	Bus busy status.Writing into this bit has no effect. Read 0x1: Bus is occupied. Read 0x0: Bus is free.	R	0
11	ROVR	Receive overrun status.Writing into this bit has no effect. Read 0x1: Receiver overrun. Read 0x0: Normal operation.	RW W1toClr	0
10	XUDF	Transmit underflow status.Writing into this bit has no effect. Read 0x1: Transmit underflow. Read 0x0: Normal operation.	RW W1toClr	0

Copyright © 2011–2012, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
9	AAS	Address recognized as slave IRQ status. 0x0: No action. 0x1: Address recognized.	RW W1toClr	0
8	BF	Bus Free IRQ status. 0x0: No action. 0x1: Bus Free.	RW W1toClr	0
7	AERR	Access Error IRQ status. 0x0: No action. 0x1: Access Error.	RW W1toClr	0
6	STC	Start Condition IRQ status. 0x0: No action. 0x1: Start Condition detected.	RW W1toClr	0
5	GC	General call IRQ status. Set to 1 by core when General call address detected and interrupt signaled to MPUSS. Write 1 to clear. 0x0: No general call detected. 0x1: General call address detected.	RW W1toClr	0
4	XRDY	Transmit data ready IRQ status. Set to 1 by core when transmitter and when new data is requested. When set to 1 by core, an interrupt is signaled to MPUSS. Write 1 to clear. 0x0: Transmision ongoing. 0x1: Transmit data ready.	RW W1toClr	0
3	RRDY	Receive data ready IRQ status. Set to 1 by core when receiver mode, a new data is able to be read. When set to 1 by core, an interrupt is signaled to MPUSS. Write 1 to clear. 0x0: No data available. 0x1: Receive data available.	RW W1toClr	0
2	ARDY	Register access ready IRQ status. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to MPUSS. Write 1 to clear. 0x0: Module busy. 0x1: Access ready.	RW W1toClr	0
1	NACK	No acknowledgement IRQ status. Bit is set when No Acknowledge has been received, an interrupt is signaled to MPUSS. Write 1 to clear this bit. 0x0: Normal operation. 0x1: Not Acknowledge detected.	RW W1toClr	0
0	AL	Arbitration lost IRQ status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to MPUSS. During reads, it always returns 0. 0x0: Normal operation. 0x1: Arbitration lost detected.	RW W1toClr	0

24.2 HDQ/1-Wire

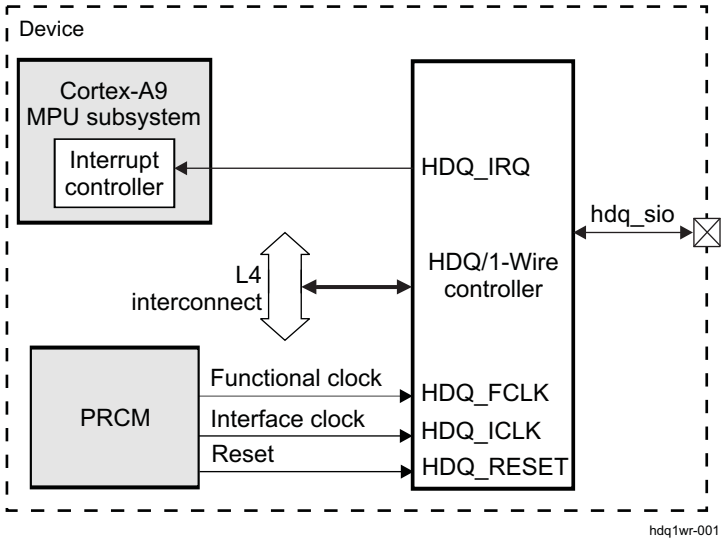
This section describes the HDQ™/ 1-Wire® interface for the device.

24.2.1 HDQ/1-Wire Overview

The HDQ/1-Wire module implements the hardware protocol of the master functions of the TI/Benchmarq HDQ and the Dallas Semiconductor 1-Wire® protocols. These protocols use a single wire for communication between the master (HDQ/1-Wire controller) and the slaves (HDQ/1-Wire external compliant devices).

Figure 24-42 shows the HDQ/1-Wire.

Figure 24-42. HDQ/1-Wire Overview



The HDQ/1-Wire has a generic L4 interface and is intended to be used in an interrupt-driven fashion. The 1-pin interface is implemented as an open-drain output at the device level.

The main features supported by the HDQ/1-Wire are the following:

- Benchmarq HDQ protocol
- Dallas Semiconductor 1-Wire protocol
- Power-down mode

The HDQ/1-Wire provides a communication rate of 5 Kbps over an address space of 128 bytes.

A typical application of the HDQ/1-Wire is the communication with battery monitor (gas gauge) integrated circuits.

Copyright © 2011–2012, Texas Instruments Incorporated

24.2.2 HDQ/1-Wire Environment

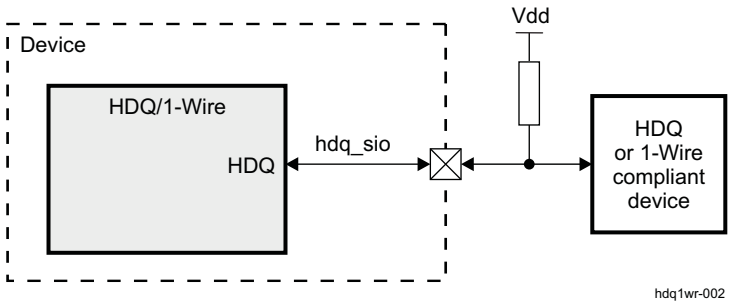
24.2.2.1 HDQ/1-Wire Functional Modes

The HDQ/1-Wire has two main modes: HDQ and 1-Wire. Each of these modes includes idle, active, and power-down submodes. Table 24-99 lists the HDQ/1-Wire functional modes, and Figure 24-43 shows an overview of a typical application.

Table 24-99. Functional Modes

Functions	Description
HDQ	Benchmarq HDQ protocol
1-Wire	Dallas Semiconductor 1-Wire protocol

Figure 24-43. HDQ/1-Wire Typical Application System Overview



An external pullup is required, because the two protocols use a return-to-1 mechanism (that is, after any command by any of the connected devices, the line is pulled to a logical high level).

The HDQ/1-Wire operates according to a command structure that is programmed into transmit command registers (as described in Section 24.2.5.1.2, *HDQ/1-Wire Low-level Programming Model*).

The 1-Wire mode runs at slower speeds than the capabilities of the mode.

Table 24-100 describes the external signal of the HDQ/1-Wire compliant module.

Table 24-100. I/O Description

Signal	I/O [1]	Description	Value at Reset
hdq_sio	I/O	Serial data input/output.Output is open drain type.	hi-Z (pulled to 1 by pullup)

(1) I = Input; O = Output; I/O = Bidirectional; hi-Z = High impedance

24.2.2.2 HDQ and 1-Wire (SDQ) Protocols

24.2.2.2.1 HDQ Protocol Initialization (Default)

In HDQ mode, the firmware does not require the host to create an initialization pulse to the slave. However, the slave can be reset by using an initialization pulse (also referred to as a break pulse). The initialization pulse is generated by setting the HDQ_CTRL_STATUS[2] INITIALIZATION bit and then setting the HDQ_CTRL_STATUS[4] GO bit. The slave does not respond with a presence pulse as it does in the 1-Wire protocol.

The HDQ is a command-based protocol in which the host sends a command byte to the slave. The command directs the slave either to store the next eight bits of data received to a register specified by the command byte (write operation) or to output the eight bits of data from a register specified by the command byte (read operation). The master implementation is a simple byte engine. Sending of the ID, command/address, and data is controlled by firmware. The master engine provides only a single HDQ.HDQ_TX_DATA register.

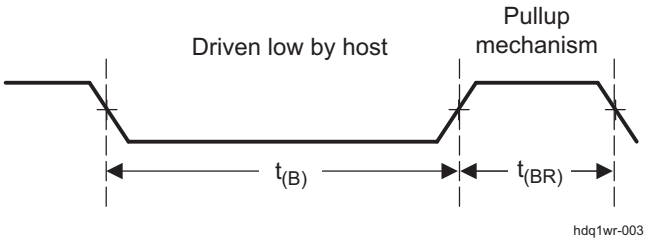
Copyright © 2011–2012, Texas Instruments Incorporated

The command and data bytes consist of a stream of eight bits with a maximum transmission rate of 5 Kbps. The least-significant bit (LSB) of a command or data byte is transmitted first. If a communication time-out occurs between the host and the slave (for example, if the host waits longer than the specified time for the slave to respond, or if this is the first access command), then the host must send an initialization pulse (BREAK) before sending the command again.

The slave detects a break when the HDQ pin is driven to a logic-low state for a specified break time t(B) or greater. The HDQ pin then returns to its normal ready-high logic state for a specified break-recovery time t(BR). The slave is then ready for a command from the host processor. Figure 24-44 shows this behavior.

An interrupt condition indicates a TX-complete, an RX-complete, or a time-out condition. Reading the interrupt status register clears all interrupt conditions. Only one interrupt signal is sent to the microcontroller, and only one overall mask bit can enable or disable the interrupt. The interrupt conditions cannot be individually masked.

Figure 24-44. HDQ Break-Pulse Timing Diagram

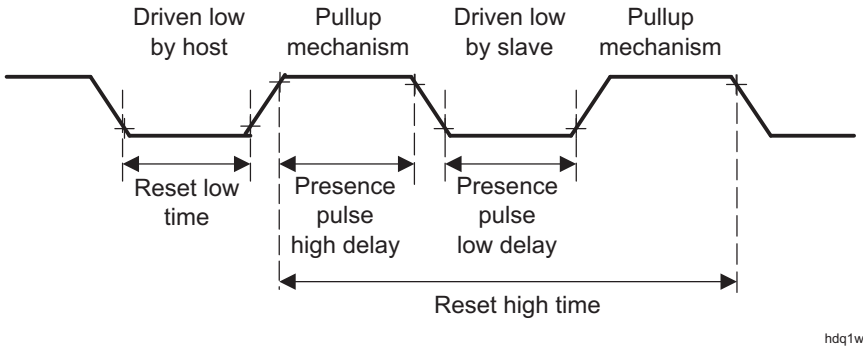


24.2.2.2.2 1-Wire (SDQ) Protocol Initialization

In 1-Wire (SDQ) protocol, the host first sends an initialization pulse (by pulling the line to a logic-low state) and then waits for the slave to respond with a presence pulse before enabling any communication sequence.

As for the initialization pulse, the presence pulse is a low-level pulse on the line initiated by the slave. The timing diagram in Figure 24-45 shows the 1-Wire (SDQ) reset sequence.

Figure 24-45. 1-Wire (SDQ) Reset Timing Diagram



The host drives the line to a logic-low state for a minimum of reset low time. Once the slave detects this pulse, it must drive the line to a logic-low state within the presence pulse high delay for a minimum period of presence pulse low time.

If the slave does not respond within this interval of time, a time-out event occurs and no transaction can be initiated. The host must initiate the reset sequence again before sending any command to the slave.

On the other hand, if the slave sends back its presence pulse within the specified time interval, the communication can be enabled after the reset high time.

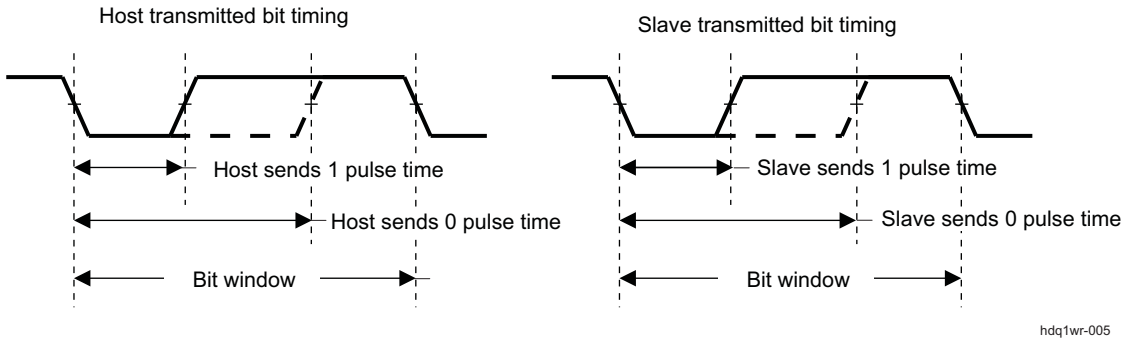
24.2.2.2.3 Communication Sequence (HDQ and 1-Wire Protocols)

The description in this section applies to both protocols.

Copyright © 2011–2012, Texas Instruments Incorporated

After a successful break pulse (HDQ mode) or initialization sequence (1-Wire protocol), the host and slave are ready for bit transmission. Each bit to transmit (either from the host to the slave or from the slave to the host) is preceded by a low-going edge on the line, as shown in Figure 24-46.

Figure 24-46. HDQ/1-Wire Transmitted Bit Timing



The return-to-1 data-bit frame consists of three distinct sections. The first section starts the transmission when either the slave or the host takes the line to a logic-low state. The next section is the actual data transmission in which the data must be valid during a specified period of time after the negative edge that starts the communication. The final section stops the transmission by returning the HDQ/1-Wire line to a logic-high state. Communication with an HDQ/1-Wire slave always occurs with the LSB being transmitted first.

The command byte of the HDQ/1-Wire protocols consists of eight contiguous valid command bits. The command byte contains two fields: R/W command and address. The R/W bit of the command byte determines whether the command is a read or a write, and the address field containing bits AD6-AD0 indicates the address to be read or written. Table 24-101 lists the command byte values.

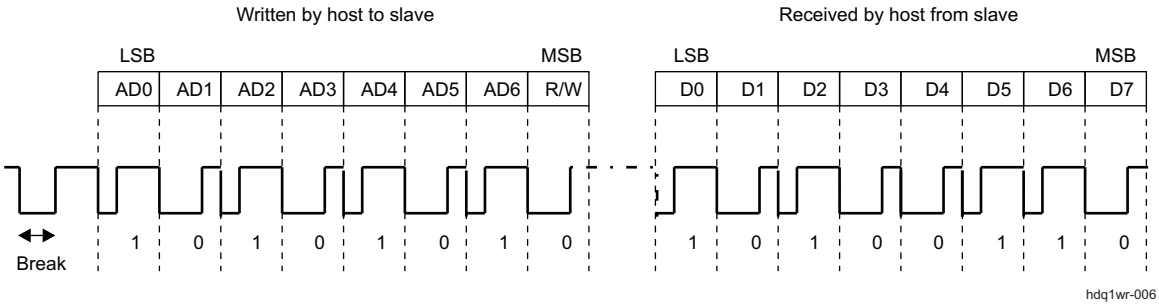
Table 24-101. HDQ/1-Wire Command Byte

7	6	5	4	3	2	1	0
R/W	AD6	AD5	AD4	AD3	AD2	AD1	AD0

R/W Indicates whether the command byte is a read or a write. A 1 indicates a write command; the following eight bits must be written to the register specified by the address field of the command byte. A 0 indicates that the command is a read. On a read command, the slave outputs the requested register contents.

AD6-AD0 Represent the seven bits labeled AD6-AD0 containing the address portion of the register to be accessed.
The communication sequence example in Figure 24-47 shows a read command at address 0x55; the received data is 0x65.

Figure 24-47. HDQ/1-Wire Communication Sequence



Copyright © 2011–2012, Texas Instruments Incorporated

24.2.3 HDQ/1-Wire Integration

Figure 24-48 shows HDQ/1-Wire integration in the device.

Figure 24-48. HDQ/1-Wire Integration

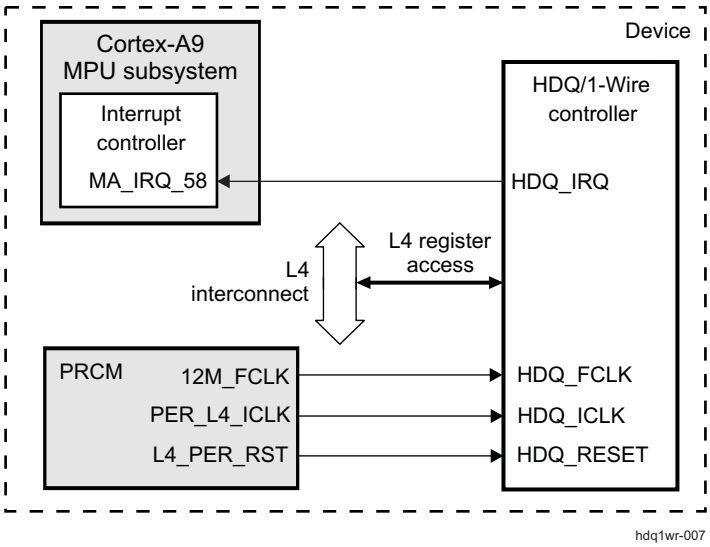


Table 24-102 through Table 24-104 summarize the integration of the module in the device.

Copyright © 2011–2012, Texas Instruments Incorporated

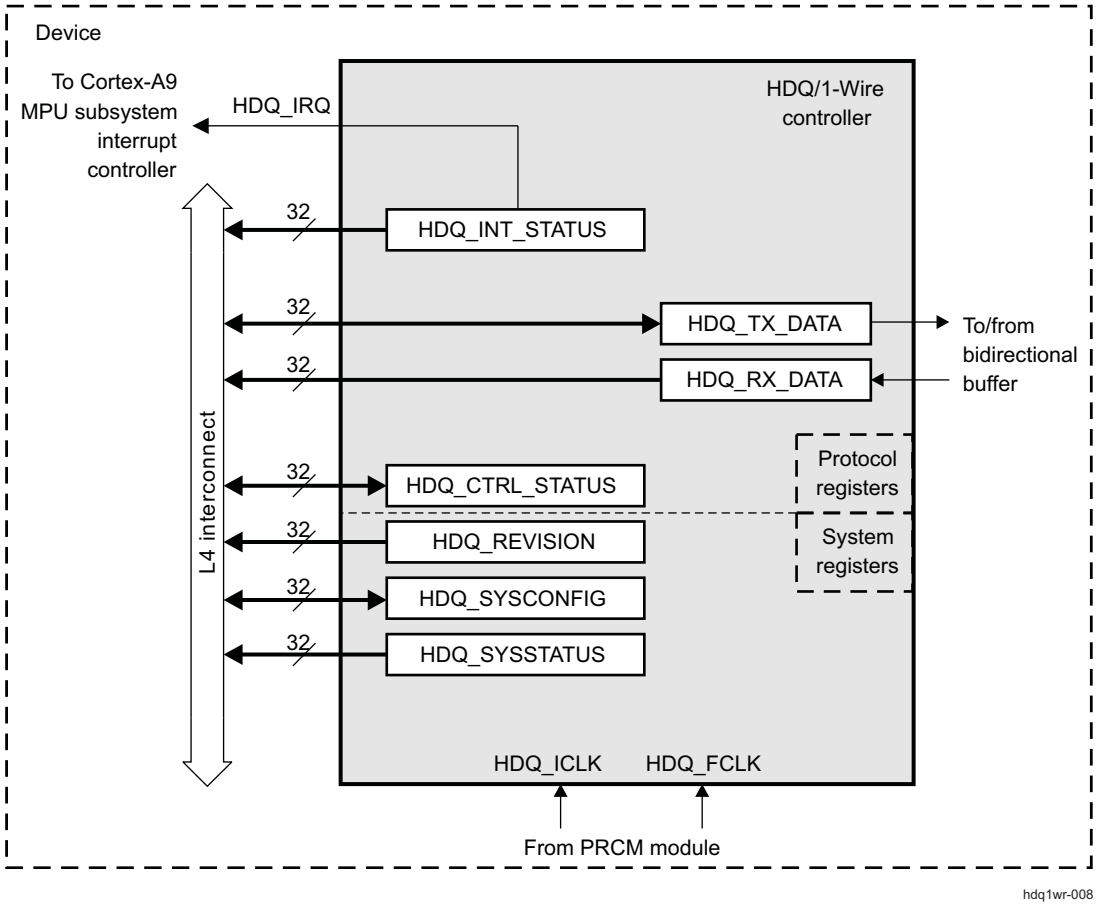
24.2.4 HDQ/1-Wire Functional Description

The HDQ/1-Wire works with HDQ and 1-Wire protocols. The protocols use a single wire to establish communication between the master and the slave. Both protocols use a return-to-1 mechanism; that is, after any command is driven, the line is pulled to a high level. This mechanism requires an external pullup.

24.2.4.1 HDQ/1-Wire Block Diagram

Figure 24-49 is the HDQ/1-Wire block diagram.

Figure 24-49. HDQ/1-Wire Block Diagram

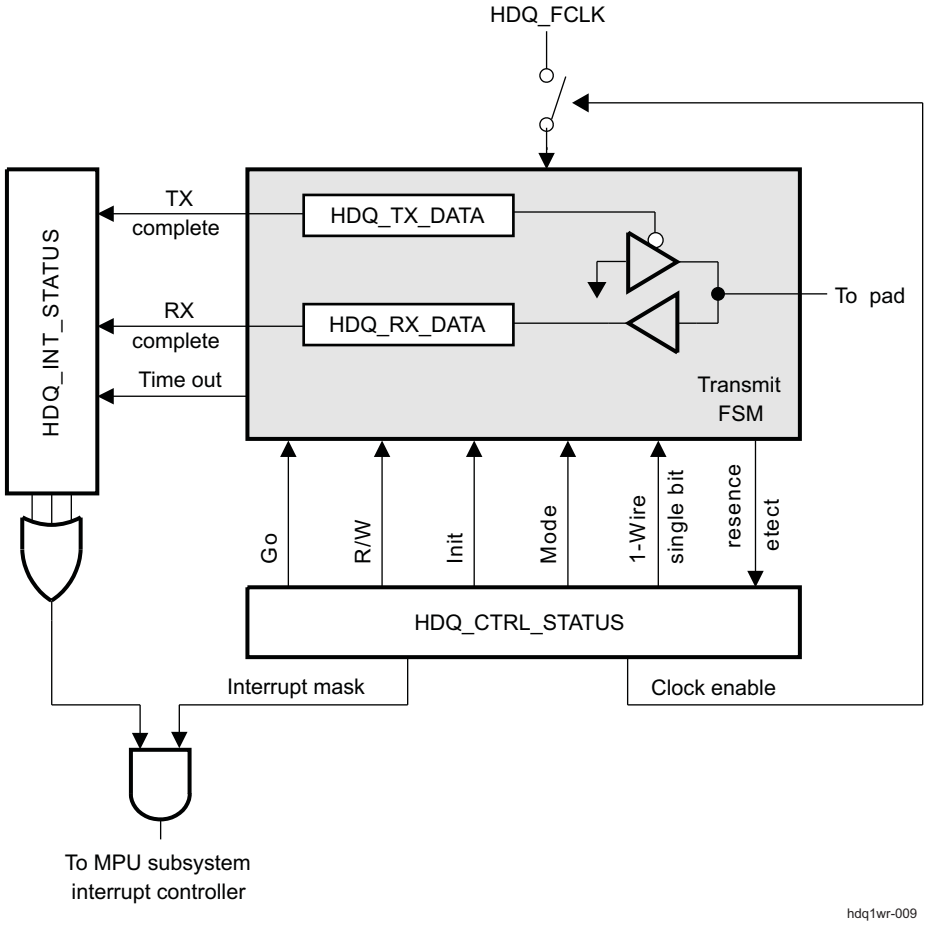


The HDQ.HDQ_CTRL_STATUS[0] MODE bit allows selection between the HDQ and 1-Wire protocols. This bit is assumed static for design purposes. The configuration is in HDQ mode by default.

Figure 24-50 shows the protocol-dedicated register scheme.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-50. Protocol Registers Description



The receive and transmit operations of the HDQ/1-Wire module are performed with respect to the timing of the slower HDQ protocol. When the 1-Wire protocol is used, it runs at lower speed than its full capabilities, but is still able to meet the timing requirements and practical considerations.

24.2.4.2 HDQ/1-Wire Clocking Configuration

24.2.4.2.1 HDQ/1-Wire Clocks

The HDQ/1-Wire subsystem operates from two clocks: a functional clock (HDQ_FCLK) and an interface clock (HDQ_ICLK). When these clocks are set in the PRCM module, the following rule must be observed: HDQ_ICLK ≥ HDQ_FCLK.

- The HDQ_FCLK functional clock is a fixed clock provided by the PRCM module. It is used to clock the internal module logic.

  For more information about the clock, see Section 3.6.8, *CD_L4_PER Clock Domain*, in Chapter 3, *Power, Reset, and Clock Management*.

  When the HDQ/1-Wire no longer requires the HDQ_FCLK, the software can disable it at the PRCM level. The clock is effectively cut, provided the other modules that receive it do not require it either.

  For details about the PRCM register settings and clock configuration, see Section 3.6.8, *CD_L4_PER Clock Domain*, in Chapter 3, *Power, Reset, and Clock Management*.

- The HDQ_ICLK interface clock runs at L4 interconnect clock speed and is used to trigger access to the HDQ/1-Wire L4 interface.

  When the HDQ/1-Wire no longer requires the HDQ_ICLK (no transfer is in progress), the software can disable it at the PRCM level. The clock is effectively cut, provided the other modules that receive it do

Copyright © 2011–2012, Texas Instruments Incorporated

not require it either.

For more information, see Section 3.6.8, *CD_L4_PER Clock Domain*.

24.2.4.3 HDQ/1-Wire Hardware and Software Reset

Global reset of the module is done at the power, reset, and clock management (PRCM) module level (for more information, see Section 3.6.8, *CD_L4_PER Clock Domain*) or by setting the HDQ.HDQ_SYSCONFIG[1] SOFTRESET bit to 1. Setting this bit enables an active software reset functionality equivalent to a hardware reset. The HDQ_FCLK functional clock must be enabled from the PRCM level and locally through the HDQ_CTRL_STATUS[5] CLOCKENABLE bit (set to 1) for the software reset to complete.

24.2.4.4 HDQ/1-Wire Power Management

Table 24-105 describes power-management features available to the HDQ/1-Wire.

Table 24-105. Local Power-Management Features

Feature	Registers	Description
Clock auto gating	HDQ_SYSCONFIG [0] AUTOIDLE bit	Auto-idle mode
Slave idle modes	N/A	N/A
Clock enable	HDQ.HDQ_CTRL_STATUS[5] CLOCKENABLE bit	Power-down mode
Master standby modes	N/A	N/A
Global wake-up enable	N/A	N/A
Wake-up sources enable	N/A	N/A

24.2.4.4.1 Auto-Idle Mode

The HDQ/1-Wire provides an auto-idle function in its interconnect clock domain.

The interconnect clock auto-idle power-saving mode is enabled or disabled through the HDQ.HDQ_SYSCONFIG[0] AUTOIDLE bit. When this mode is enabled and there is no activity on the interconnect interface, the interconnect clock (HDQ_ICLK) is disabled inside the module, thereby reducing power consumption. When there is new activity on the interconnect interface, the interconnect clock is restarted with no latency penalty. This mode is disabled by default after a reset.

The auto-idle mode can be enabled in order to reduce power consumption.

24.2.4.4.2 Power-Down Mode

The HDQ/1-Wire also provides a power-saving function in its functional clock domain.

Setting the CLOCKENABLE bit in the control and status register (HDQ.HDQ_CTRL_STATUS[5] CLOCKENABLE bit) to 0 shuts off the functional clock (HDQ_FCLK) to the state-machine. The state-machine is reset when the functional clock is disabled; if any transaction is ongoing, it is aborted into the reset state.

Before shutting off the functional clock, the software must wait for transaction-complete interrupt. In write operation the software must check whether the interrupt was generated after address/command byte was sent or after data byte was sent. The functional clock must not be shut off after address/command byte is sent; otherwise, the data is not written to the slave.

The register values are not affected by disabling the functional clock.

CAUTION

There is no hardware mechanism to prevent cutting off the HDQ/1-Wire clocks while the module is performing a transfer. This would result in loss of data being transferred.

Copyright © 2011–2012, Texas Instruments Incorporated

24.2.4.5 HDQ Interrupt Requests

The HDQ/1-Wire can generate one interrupt:

- HDQ_IRQ: This is an interrupt to the MPU subsystem INTC. It is mapped on MA_IRQ_58. Table 24-106 lists the events that can generate this interrupt.

Table 24-106. Events

Event Flag	Event Mask	Sync	Sensitivity	Map to	Description
HDQ_INT_STATUS[2] TXCOMPLETE	HDQ_CTRL_STATUS[31] INTERRUPTMASK	Yes	Level	HDQ_IRQ	A write operation of one byte was completed.
HDQ_INT_STATUS[1] RXCOMPLETE	HDQ_CTRL_STATUS[31] INTERRUPTMASK	Yes	Level	HDQ_IRQ	A byte has been successfully read.
HDQ_INT_STATUS[0] TIMEOUT	HDQ_CTRL_STATUS[31] INTERRUPTMASK	Yes	Level	HDQ_IRQ	After a read command initiated by the host, the slave did not pull the line low within the specified time.

24.2.4.6 HDQ Mode (Default)

24.2.4.6.1 HDQ Mode Features

The HDQ mode supports the following:

- Benchmarq HDQ protocol
- Power-down mode

24.2.4.6.2 Description

In the HDQ mode, there is no need for the host to create an initialization pulse to the slave. However, the host can reset the slave by using an initialization pulse (also known as a break pulse). Setting the HDQ.HDQ_CTRL_STATUS[2] INITIALIZATION bit and then setting the HDQ_CTRL_STATUS[4] GO bit creates this pulse by pulling the line down for a defined duration. When the slave receives the pulse, it is ready for communication but does not respond with a presence pulse.

In a typical write operation, two bytes are sent to the slave. The first byte corresponds to the command/address byte, and the second byte corresponds to the data to be written.

In a typical read operation, the host sends a command/address byte and the slave returns a byte of data.

The master is implemented to send and receive bytes. Sending the command/address and data is controlled by the firmware. The master provides only a single data TX register.

The HDQ protocol is a return-to-1 protocol. Consequently, after a byte is sent to the slave (either command/address + data for a write, or just command/address for a read), the host pulls the line up. The line is set to the high-impedance state in the device and an external pullup brings it to a logical high level.

In the case of a read operation, the slave also drives the line to a logic-low state before sending the requested data.

If the host initiates a read and does not receive data within a specified interval of time (that is, the slave does not drive the line low within this interval), the HDQ.HDQ_INT_STATUS[0] TIMEOUT bit is set, thereby indicating a read failure. The TIMEOUT bit remains set until the host reads the interrupt status register (HDQ.HDQ_INT_STATUS).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out on a transaction. The corresponding bit is set in the interrupt status register (HDQ.HDQ_INT_STATUS). This register is cleared as soon as it is read.

Only one interrupt signal is sent to the MPU, and only an overall mask can enable or disable the interrupts. These interrupts cannot be individually masked.

24.2.4.6.3 Single-Bit Mode

In HDQ mode, the single-bit mode (HDQ.HDQ_CTRL_STATUS[7] ONE_WIRE_SINGLE_BIT bit set to 1) has no effect because the HDQ protocol supports only byte transfers.

24.2.4.6.4 Interrupt Conditions

The HDQ/1-Wire provides the following interrupt status:

- Transmission complete:

  A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in HDQ protocol. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).
- Read complete:

  In HDQ mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).
- Presence detect/time-out:

  In HDQ mode, the interrupt status indicates that after a read command initiated by the host, the slave did not pull the line low within the specified time. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).

  In HDQ mode, a time-out condition is also used to indicate the successful completion of a break pulse. That is, if the master has sent the break pulse, it is indicated with a time-out instead of a TX-complete.

Only one interrupt is generated to the MPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all the interrupt status bits that were previously set.

24.2.4.7 1-Wire Mode

24.2.4.7.1 1-Wire Mode Features

The 1-Wire mode supports the following:

- Dallas Semiconductor 1-Wire protocol
- Power-down mode
- Single-bit mode

24.2.4.7.2 Description

The 1-Wire mode requires an initialization pulse to be sent to the slave(s) connected on the interface. If a slave is present, it responds with a presence pulse.

The initialization pulse is sent when the HDQ.HDQ_CTRL_STATUS[2] INITIALIZATION bit is set and the HDQ_CTRL_STATUS[4] GO bit is set afterwards.

When the slave receives the initialization pulse, it sends back its presence pulse by pulling down the line for a defined duration. The module detects this low-level pulse and sets the HDQ.HDQ_CTRL_STATUS[3] PRESENCEDETECT bit.

In a similar way, if a presence pulse is not received from the slave after an initialization pulse is sent, the PRESENCEDETECT bit remains cleared.

Whether or not a presence pulse is detected after an initialization pulse is sent, the HDQ.HDQ_INT_STATUS[0] TIMEOUT bit is set and an interrupt condition is generated.

In 1-Wire mode, the generated interrupt condition means the maximum time allowed for receiving the response has elapsed and the software must check the PRESENCEDETECT bit to determine whether or not there was a presence pulse.

The INITIALIZATION bit is cleared at the end of the initialization pulse at the same time as the TIMEOUT bit is set. The TIMEOUT bit is cleared when the interrupt status register (HDQ.HDQ_INT_STATUS) is read.

For read operations, 1-Wire is a bit-by-bit protocol, which means the slave must be clocked by the host for each bit of the byte to read.

The line is pulled up at the end of the command/address byte. On the first read, the host creates a low-going edge to initiate a bit read. The line is then pulled up (pulled to the high-impedance state by the host and set to a high logical level by the external pullup) and the slave either drives the line low to transmit a 0, or does not drive the line to transmit a 1. This sequence is repeated for each bit to read.

The first bit the host receives is the LSB, and the last bit is the most-significant bit (MSB) in the receive data register (HDQ.HDQ_RX_DATA).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out condition (that is, the time allowed for the slave to indicate its presence has elapsed). A read operation on the interrupt status register clears the interrupt conditions previously set. As in the HDQ mode, only one interrupt signal is sent to the MPU. Only an overall mask bit can enable or disable the interrupt (the interrupt conditions cannot be masked individually).

24.2.4.7.3 1-Wire Single-Bit Mode Operation

A single-bit mode can be entered by setting the appropriate bit in the control and status register (ONE_WIRE_SINGLE_BIT bit HDQ.HDQ_CTRL_STATUS[7]). In this mode, only one bit of data at a time is transferred between the master and the slave. After the bit is transferred, an interrupt is generated (that is, there is an RX-complete for a read operation and a TX-complete for a write operation). The ONE_WIRE_SINGLE_BIT bit is cleared by hardware after every single bit is received. Software must set this bit to re-enable reception in single-bit mode. Bit 0 of the RX register (HDQ.HDQ_RX_DATA) is updated each time a bit is received from the slave; bit 0 of the TX register (HDQ.HDQ_TX_DATA) contains the bit to be sent.

Copyright © 2011–2012, Texas Instruments Incorporated

24.2.4.7.4 Interrupt Conditions

The HDQ/1-Wire provides the following interrupt status:

- Transmission complete:

  A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in 1-Wire protocol. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).

- Read complete:

  In 1-Wire mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).

- Presence detect/time-out:

  In 1-Wire mode, the interrupt status indicates that it is now valid to check the PRESENCEDETECT bit. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).

Only one interrupt is generated to the MPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all interrupt status bits that were previously set.

24.2.4.7.5 Status Flags

The presence-condition-detected status flag is contained in the HDQ.HDQ_CTRL_STATUS[3] PRESENCEDETECT bit. This is valid only in 1-Wire mode. The flag is updated when the HDQ.HDQ_INT_STATUS[0] TIMEOUT bit is set. Therefore, its correct value shows only after the interrupt is generated. The firmware must wait for the time-out condition; otherwise, the flag keeps its previous value and is undefined.

24.2.5 HDQ/1-Wire Programming Models

This section describes the low-level hardware programming sequences for configuration and usage of the module. The basic protocol functions, such as slave initialization (reset), read-byte, and write-byte operations, are described. For a description of the functions, see the HDQ/1-Wire protocol documentation.

24.2.5.1 Global Initialization

24.2.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the HDQ/1-Wire module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the HDQ/1-Wire. Refer to the HDQ/1-Wire Module Integration and Environment Sections for further information.

Table 24-107. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. The interface clock must not be slower than the functional clock (HDQ_ICLK ≥ HDQ_FCLK). For more information about the module configuration, see Chapter 3, *Power, Reset, and Clock Management*.
Control Module	Module specific pad muxing and pullup must be set in the control module. For more information about the module configuration, see Chapter 19, *Control Module*.
MPU INTC	MPU INTC configuration must be done to enable the interrupts from HDQ/1-Wire module. See Section 18.4.1, *Cortex-A9 MPU INTC Functional Description,* in Chapter 18, *Interrupt Controllers*.

Table 24-117. HDQ/1-Wire Instance Summary

Module Name	Base Address	Size
HDQ/1-Wire	0x480B 2000	4KB

24.2.6.2 HDQ/1-Wire Registers

CAUTION

The following rules must be observed when accessing the module registers:

- A read from the HDQ_INT_STATUS register or the HDQ_RX_DATA register is not allowed unless the processor has been interrupted by the module.
- After the release of the GO bit in the HDQ_CTRL_STATUS register, no access to the HDQ_TX_DATA or HDQ_CTRL_STATUS register is allowed until the processor has been interrupted by the module.
- Polling of the HDQ_INT_STATUS register by software to determine whether an interrupt was generated is not allowed.

CAUTION

The HDQ/1-Wire registers are limited to 32-bit data accesses; 16-bit and 8-bit data accesses are not allowed and can corrupt register content.

24.3 UART/IrDA/CIR

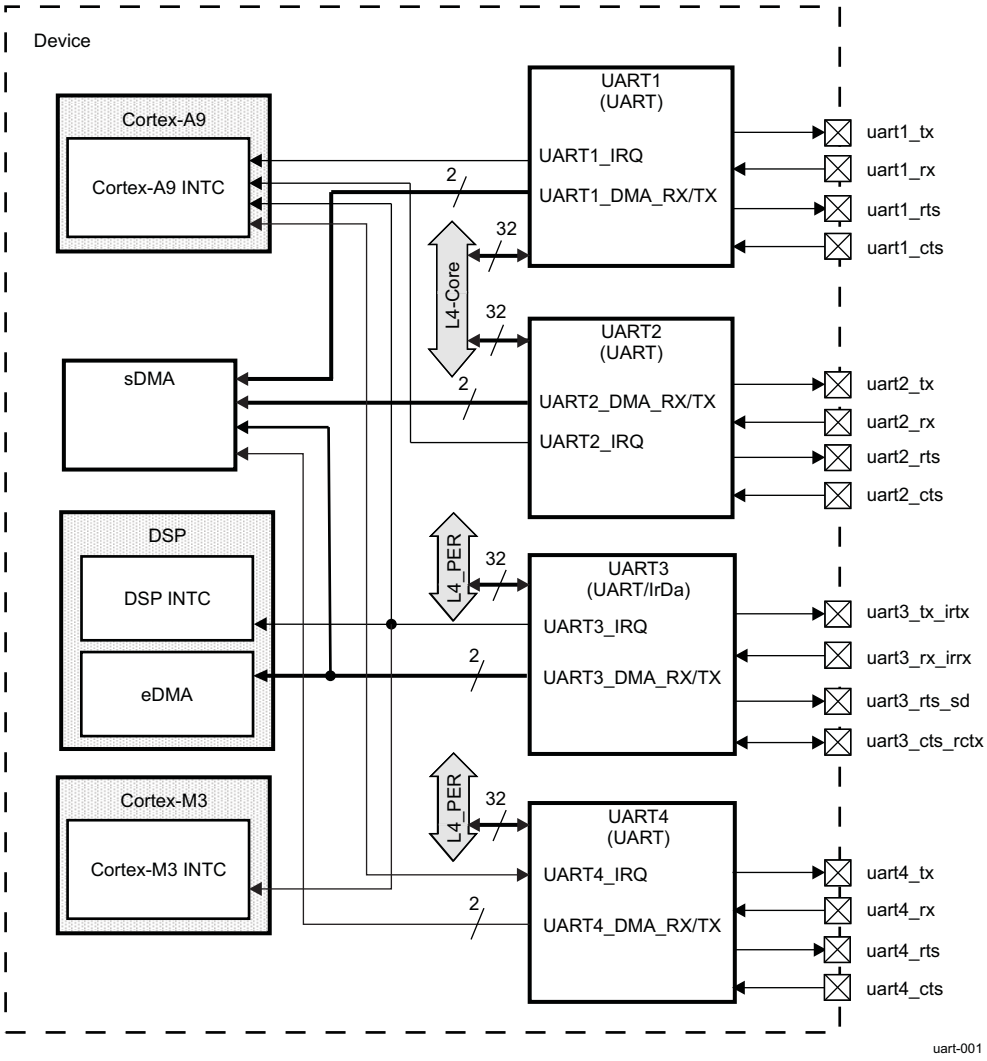
This chapter describes the function, operation, and configuration of the universal asynchronous receiver/transmitter (UART)/infrared data association (IrDA)/consumer infrared (CIR) module in the device.

24.3.1 UART/IrDA/CIR Overview

The device contains four UART devices controlled by the MPU (see Figure 24-51):

- Three UART-only modules (UART1, UART2, and UART4) are pinned out for use as UART devices only.
- UART3, which adds infrared communication support, is pinned out for use as a UART, IrDA, or CIR device, and can be programmed to any available operating mode.

Figure 24-51. UART Module



24.3.1.1 UART Features

The UARTs (UART1, UART2, UART3 when in UART mode, and UART4) include the following key features:

- 16C750 compatibility
- 64-byte FIFO buffer for receiver and 64-byte FIFO for transmitter
- Programmable interrupt trigger levels for FIFOs

Copyright © 2011–2012, Texas Instruments Incorporated

- Baud generation based on programmable divisors N (N = 1...16,384) operating from a fixed functional clock of 48 MHz

Oversampling is programmed by software as 16 or 13; thus, the baud rate computation is one of two options:

- Baud rate = (functional clock/16)/N
- Baud rate = (functional clock/13)/N

This software programming mode enables higher baud rates with the same error amount without changing the clock source:

- Break character detection and generation
- Configurable data format:
  - Data bit: 5, 6, 7, or 8 bits
  - Parity bit: Even, odd, none
  - Stop-bit: 1, 1.5, 2 bit(s)
- Flow control: Hardware (RTS/CTS) or software (XON/XOFF)

The UART clocks are connected to produce a baud rate of up to 3.6 Mbps. Table 24-133 lists the supported baud rates, the requested divisor, and the corresponding error versus the standard baud rate.

Table 24-133. UART Mode Baud Rates, Divisor Values, and Error Rates

Baud Rate	Oversampling	Divisor	Error (%)
300	16	10,000	0
600	16	5000	0
1200	16	2500	0
2400	16	1250	0
4800	16	625	0
9600	16	312	0.16
14,400	16	208	0.16
19,200	16	156	0.16
28,800	16	704	0.16
38,400	16	78	0.16
57,600	16	52	0.16
115,200	16	26	0.16
230,400	16	13	0.16
460,800	13	8	0.16
921,600	13	4	0.16
1,843,200	13	2	0.16
3,000,000	16	1	0
3,686,400	13	1	0.16

24.3.1.2 IrDA Features

The IrDA (UART3 only) includes the following key features:

- Support of IrDA 1.4 slow infrared (SIR), medium infrared (MIR), and fast infrared (FIR) communications:
  - Frame formatting: Addition of variable beginning-of-frame (xBOF) characters and end-of-frame (EOF) characters
  - Uplink/downlink cyclic redundancy check (CRC) generation/detection
  - Asynchronous transparency (automatic insertion of break character)
  - Eight-entry status FIFO (with selectable trigger levels) to monitor frame length and frame errors
  - Framing error, CRC error, illegal symbol (FIR), and abort pattern (SIR, MIR) detection

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-134 lists the supported baud rates, the requested divisor, and the corresponding error versus the standard baud rate.

Table 24-134. UART IrDA Mode Baud Rates, Divisor Values, and Error Rates

Baud Rate	IR Mode	Encoding	Divisor	Error (%)
2400	SIR	3/16	1250	0
9600	SIR	3/16	312	0.16
19,200	SIR	3/16	156	0.16
38,400	SIR	3/16	78	0.16
57,600	SIR	3/16	52	0.16
115,200	SIR	3/16	26	0.16
576,000	MIR	1/4	2	0
1,152,000	MIR	1/4	1	0
4,000,000	FIR	4 PPM(1)	1	0

(1) PPM = pulse-position modulation

24.3.1.3 CIR Features

The CIR mode uses a variable pulse-width modulation (PWM) technique (based on multiples of a programmable *t* period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on a user-definable frame structure and packet content.

The CIR (UART3 only) includes the following key features to provide CIR support for remote-control applications:

- Transmit mode only (Receive mode is not supported.)
- Free data format (supports any remote-control private standards)
- Selectable bit rate
- Configurable carrier frequency
- 1/2, 5/12, 1/3, or 1/4 carrier duty cycle

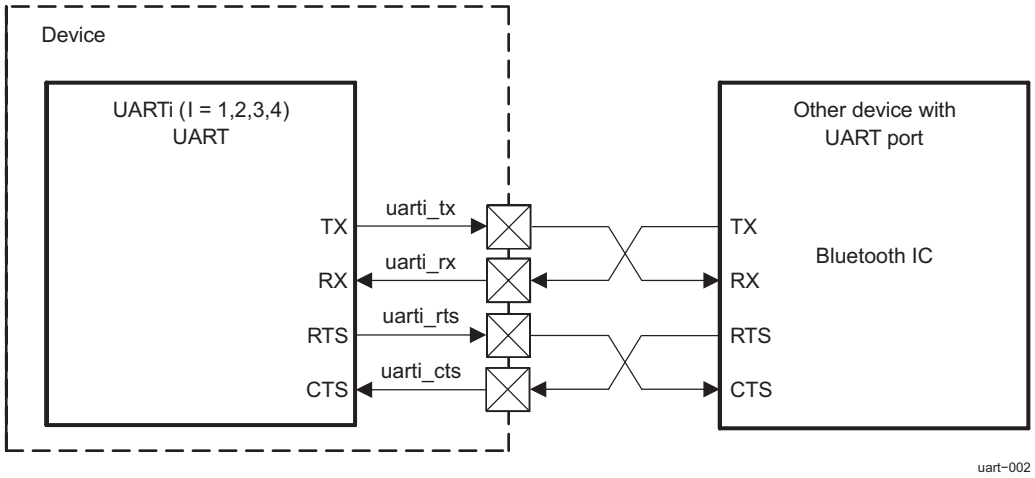
24.3.2 UART/IrDA/CIR Environment

This section describes the UART/IrDA/CIR connection with an external device.

24.3.2.1 System Using UART Communication With Hardware Handshake

Each UART instance can be easily connected to the UART port of an external IC (see Figure 24-52).

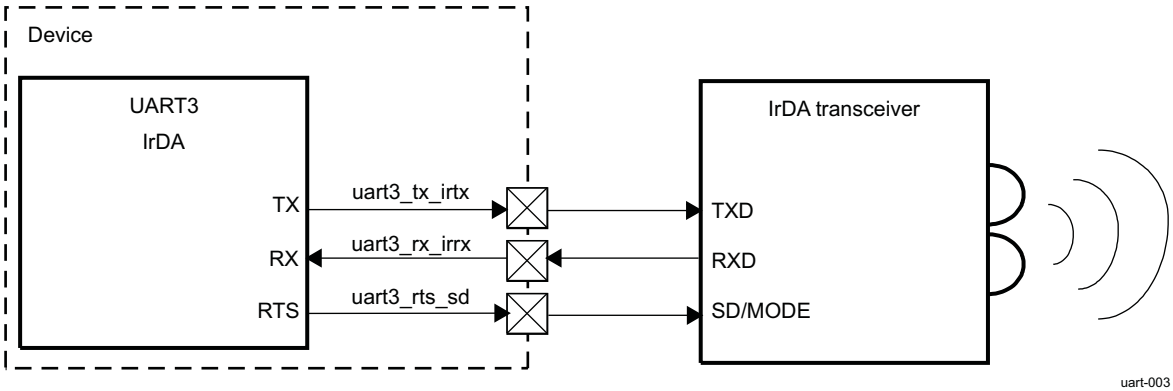
Figure 24-52. UART Mode Bus System Overview



24.3.2.2 System Using IrDA Communication Protocol

As Figure 24-53 shows, UART3 can be connected to an external infrared transceiver in the IrDA modes (FIR, SIR, and MIR).

Figure 24-53. IrDA System Overview



24.3.2.3 System Using CIR Communication Protocol With Remote Control

UART3 can be connected to an external infrared transceiver in CIR mode (see Figure 24-54).

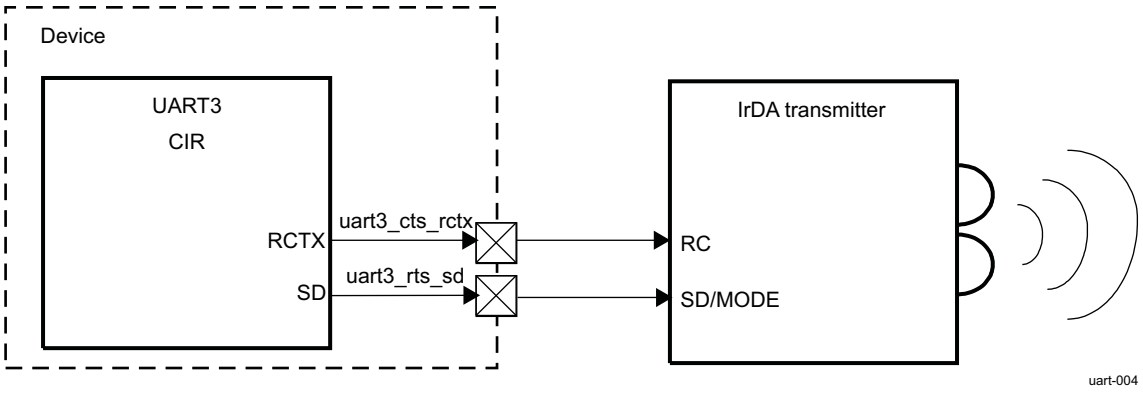
Figure 24-54. CIR System Overview



24.3.2.4 UART Interface

24.3.2.4.1 Description

Table 24-135 lists the UART interface input/output (I/O) signals.

Table 24-135. UART I/O Pins

Signal	I/O [1]	Description	Reset
UART Modem Signals			
uarti_rx	I	Serial data input	Unknown
uarti_tx	O	Serial data output Because this pin is active high in IrDA mode and the output is muxed, this pin is set to low on reset (when the UARTi.UART_MDR1[2:0] bit field is set to 0x7) and takes the defined inactive level of that signal corresponding to when and how the UARTi.UART_MDR1 register is programmed; that is, the output is 1 (inactive for UART modem modes) and 0 (inactive for IrDA modes).	1
uarti_cts	I	Clear to send Active-low modem status signal. Reading the UARTi.UART_MSR[4] NCTS_STS bit checks the condition of uarti_cts. Reading the UARTi.UART_MSR[0] CTS_STS bit checks a change of state of uarti_cts since the last read of the modem status register. The auto-nCTS mode uses uarti_cts to control the transmitter.	Unknown
uarti_rts	O	Request to send When active (low), the module is ready to receive data. Setting the UARTi.UART_MCR[1] RTS bit activates uarti_rts, which becomes inactive as the result of a module reset, loopback mode, or clearing the UARTi.UART_MCR[1] RTS bit. In auto-RTS mode, uarti_rts becomes inactive as a result of the receiver threshold logic.	1

(1) I = Input; O = Output

24.3.2.4.2 UART Protocol and Data Format

The UART device operates in three modes:

- UART 16x (<= 230.4 kbps)
- UART 16x with autobauding (>= 1200 bps and >= 115.2 kbps)
- UART 13x (>= 460.8 kbps)

Copyright © 2011–2012, Texas Instruments Incorporated

CAUTION

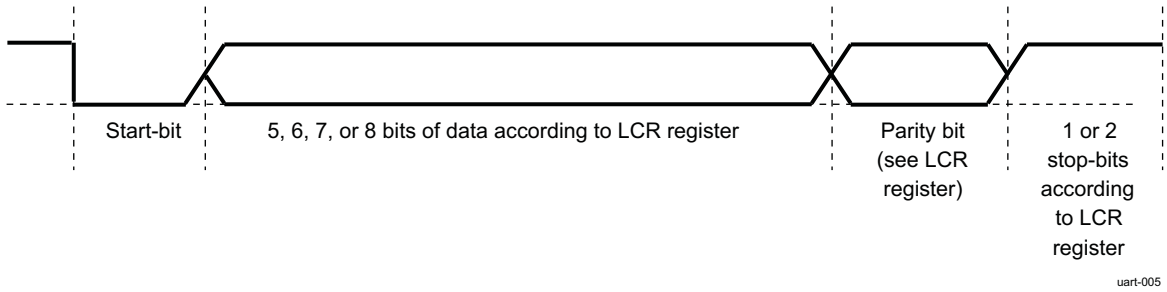
To be used as a UART, the operating mode must be programmed appropriately in the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to select UART, IrDA, or CIR mode.

The UART uses a wired interface for serial communication with a remote device.

The UART is functionally compatible with the TL16C750 UART and earlier designs such as the TL16C550.

Figure 24-55 shows the UART frame data format.

Figure 24-55. UART Frame Data Format



24.3.2.5 IrDA Functional Interfaces

24.3.2.5.1 UART3 Interface Description

Table 24-136 lists the UART3 interface I/O signals.

Table 24-136. UART3 I/O Signals

Signal	I/O [1]	Description	Reset
IrDA Signals			
uart3_rx_irrx	I	Serial data input	Unknown
uart3_tx_irtx	O	Serial data output in IrDA modes (SIR, MIR, and FIR). In other modes, this pin is set to the reset value (inactive state).	0
uart3_rts_sd	O	SD mode is used to configure the transceivers. The SD pinout is an inverted value of the UART3.UART_ACREG[6] SD_MOD bit.	1

(1) I = Input; O = Output

Copyright © 2011–2012, Texas Instruments Incorporated

24.3.2.5.2 IrDA Protocol and Data Format

24.3.2.5.2.1 SIR Mode

In SIR mode, data is transferred between the MPU and peripheral devices at speeds of up to 115,200 baud. A SIR transmit frame begins with start flags (a single 0xC0, a multiple 0xC0, or a single 0xC0 preceded by a number of 0xFF flags), is followed by frame data and a CRC-16, and ends with a stop flag (0xC1).

The bit format for a single word uses 1 start-bit, 8 data bits, and 1 stop-bit, and is unaffected by the use and settings of the UART3.UART_LCR register.

The UART3.UART_BLR[6] XBOF_TYPE bit selects whether the 0xC0 or 0xFF start patterns are used when multiple start flags are required.

The SIR transmit state-machine attaches start flags, CRC-16, and stop flags, and checks the outgoing data to establish whether data transparency is required.

SIR transparency is carried out if the outgoing data between the start and stop flags contains 0xC0, 0xC1, or 0x7D. If one of these start flags is about to be transmitted, the SIR state-machine first sends an escape character (0x7D), then inverts the fifth bit of the real data to be sent and sends this data immediately after the 0x7D character.

The SIR receive state-machine recovers the receive clock, removes the start flags and any transparency from the incoming data, and determines the frame boundary with reception of the stop flag. The SIR state-machine also checks for errors such as a frame abort (0x7D character followed immediately by a 0xC1 stop flag without transparency), a CRC error, or a frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.UART_LSR) to find possible errors of the received frame.

NOTE: The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. See the description of the UART3.UART_ACREG[5] DIS_IR_RX bit. This applies to all three modes: SIR, MIR, and FIR.

Infrared output in SIR mode can be 1.6-µs or 3/16 encoding, selected by the UART3.UART_ACREG[7] PULSE_TYPE bit. In 1.6-µs encoding, the infrared pulse width is 1.6 µs; and in 3/16th encoding, the infrared pulse width is 3/16th of a bit duration (1/baud rate).

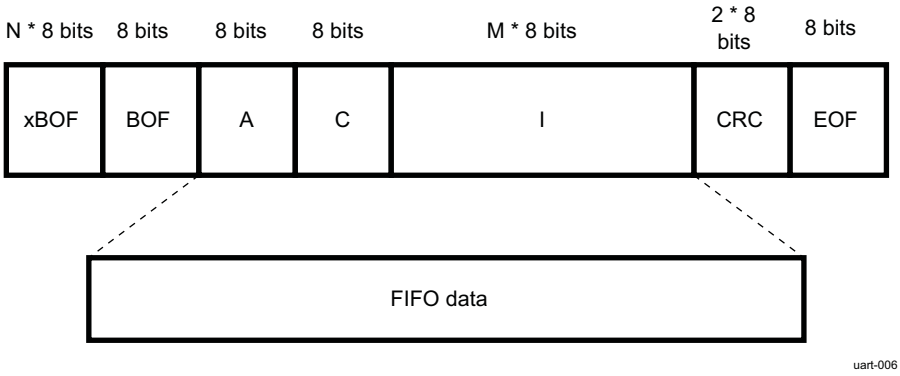
For back-to-back frames, the transmitting device must send at least two start flags at the start of each frame.

NOTE: Reception supports variable-length stop-bits.

24.3.2.5.2.1.1 Frame Format

Figure 24-56 shows the IrDA SIR frame format.

Figure 24-56. IrDA SIR Frame Format



Copyright © 2011–2012, Texas Instruments Incorporated

The CRC is applied on the address (A), control (C), and information (I) bytes.

NOTE: The two words of CRC are written to the FIFO in reception.

24.3.2.5.2.1.2 Asynchronous Transparency

Before transmitting a byte, the UART IrDA controller examines each byte of the payload and the CRC field (between BOF and EOF). For each byte equal to 0xC0 (BOF), 0xC1 (EOF), or 0x7D (control escape), the controller performs certain tasks:

- In transmission:
  - Inserts a control escape (CE) byte preceding the byte
  - Complements bit 5 of the byte (that is, exclusive ORs the byte with 0x20)

  The byte sent for the CRC computation is the initial byte written in the TX FIFO (before the XOR with 0x20).
- In reception:

  For the A, C, I, CRC field:
  - Compares the byte with the CE byte; if they are not equal, sends the byte to the CRC detector and stores it in the RX FIFO.
  - If the byte is equal to the CE byte, discards the CE byte
  - Complements bit 5 of the byte following the CE
  - Sends the complemented byte to the CRC detector and stores it in the RX FIFO

24.3.2.5.2.1.3 Abort Sequence

The transmitter can prematurely close a frame (abort) by sending the sequence 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

When a 0x7D character that is followed immediately by a 0xC1 character is received without transparency, the receiver treats the frame as an aborted frame.

24.3.2.5.2.1.4 Pulse Shaping

The SIR mode supports the 3/16 and the 1.6-us pulse duration methods in receive and transmit. The UART3.UART_ACREG[7] PULSE_TYPE bit selects the pulse-width method in transmit mode.

24.3.2.5.2.1.5 Encoder

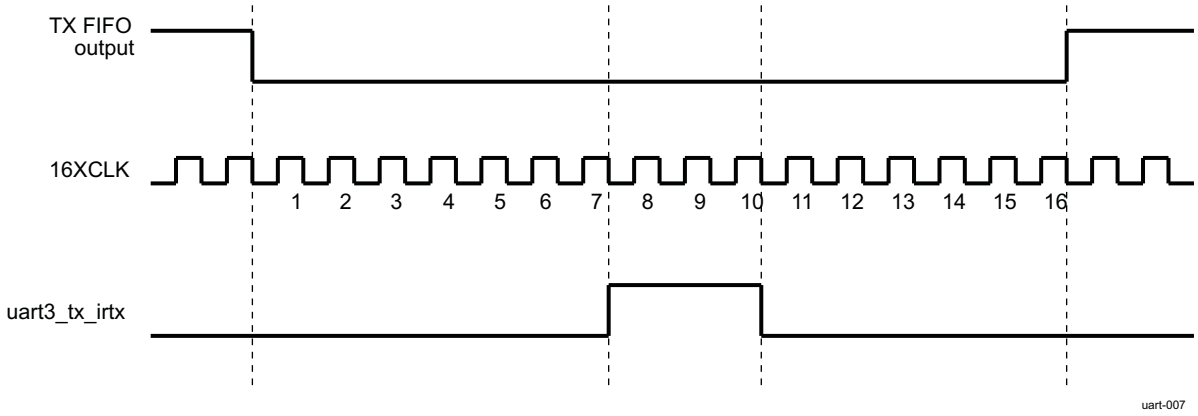
Serial data from the transmit state-machine are encoded to transmit data to the optoelectronics. While the TX FIFO output is high, the uart3_tx_irtx line is always low, and the counter used to form a pulse on uart3_tx_irtx is cleared continuously.

After the TX FIFO output resets to 0, uart3_tx_irtx rises on the falling edge of the seventh 16XCLK. On the falling edge of the tenth 16XCLK pulse, uart3_tx_irtx falls, creating a 3-clock-wide pulse. While the TX FIFO output stays low, a pulse is transmitted during the seventh to the tenth clock of each 16-clock bit cycle.

Figure 24-57 shows the IrDA SIR encoding mechanism.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-57. IrDA SIR Encoding Mechanism

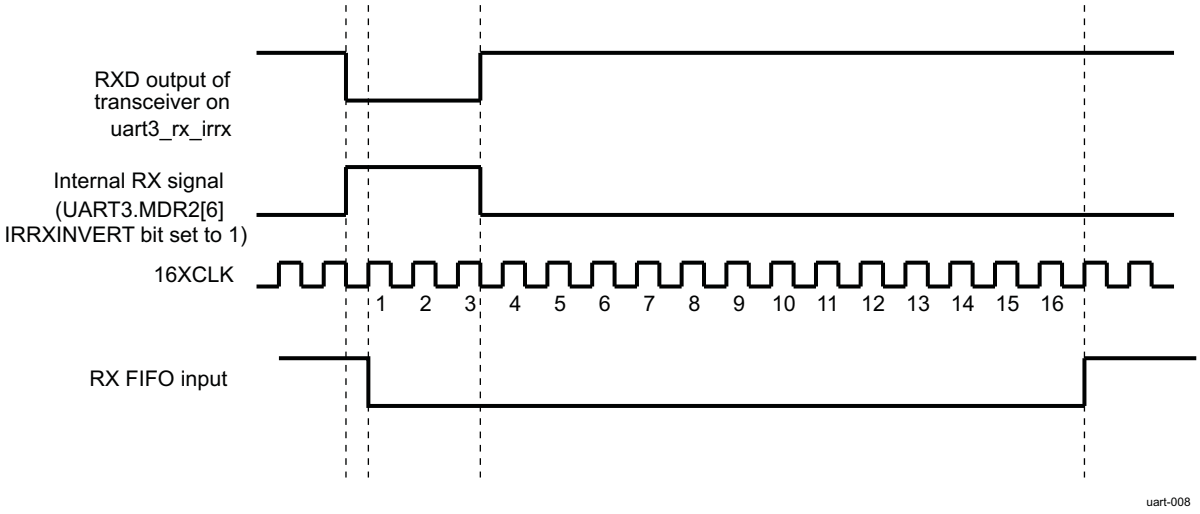


24.3.2.5.2.1.6 Decoder

After reset, the RX FIFO input is high and the 4-bit counter is cleared. When a rising edge is detected on RX, the RX FIFO input falls on the next rising edge of 16XCLK with sufficient setup time. The RX FIFO input stays low for 16 cycles (16XCLK) and then returns to high as required by the IrDA specification. As long as no pulses (rising edges) are detected on the RX, the RX FIFO input remains high.

Figure 24-58 shows the IrDA SIR decoding mechanism.

Figure 24-58. IrDA SIR Decoding Mechanism



The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. The operation of the uart3_rx_irrx input can be disabled using the UART3.UART_ACREG[5] DIS_IR_RX bit. The UART3.UART_MDR2[6] IRRXINVERT bit can invert the signal from the transceiver (RXD) pin to the IR RX logic in the UART. This inversion is performed by default.

24.3.2.5.2.1.7 IR Address Checking

In all IR modes, when address checking is enabled by setting the UART_EFR[1:0] bit field (see Table 24-137), only frames intended for the device are written to the RX FIFO. This is to avoid receiving frames not meant for this device in a multipoint infrared environment. To program two frame addresses that the UART3 receives in IrDA mode, use the UART3.UART_XON1_ADDR1[7:0] and UART3.UART_XON2_ADDR2[7:0] bit fields.

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-137. UART_EFR[1:0] IR Address Checking Options

UART_EFR[1]	UART_EFR[0]	IR Address Checking
0	0	All address-checking operations disabled
0	1	Only address 1 checking enabled
1	0	Only address 2 checking enabled
1	1	All address-checking operations enabled

24.3.2.5.2.2 SIR Free-Format Mode

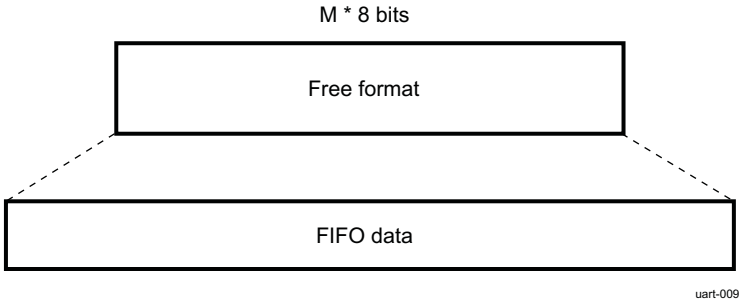
To allow complete software flexibility when transmitting and receiving infrared data packets, the SIR free-format (FF) mode is a subfunction of the existing SIR mode. In FF mode, all frames going to and from the FIFO buffers are untouched with respect to appending and removing control characters and CRC values.

The FF mode corresponds to a UART mode with a pulse modulation of 3/16 of baud rate pulse width.

For example, a normal SIR packet has BOF control and CRC error-checking data appended (transmitting) or removed (receiving) from the data going to and from the FIFOs.

Figure 24-59 shows SIR FF mode.

Figure 24-59. SIR FF Mode

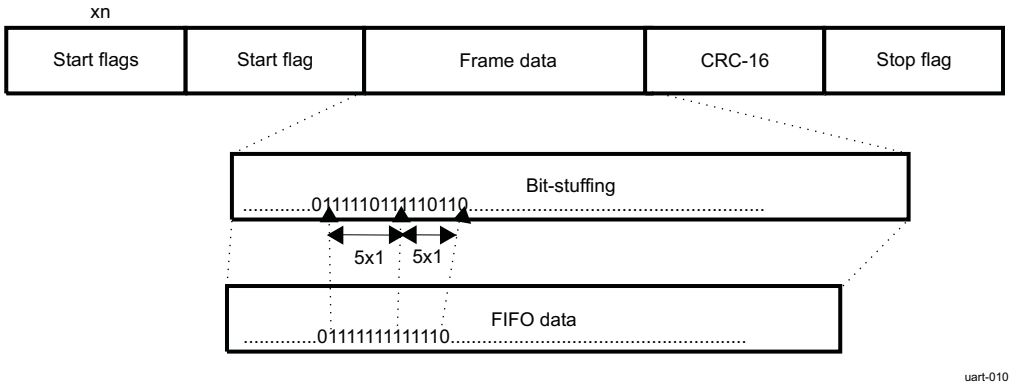


In SIR FF mode, the MPU software must construct (that is, encode and decode) the entire FIFO data packet.

24.3.2.5.2.3 MIR Mode

In MIR mode, data is transferred between the MPU and the peripheral devices at 0.576 or 1.152 Mbps speed. A MIR transmit frame starts with at least two start flags followed by a frame data and a CRC-16, and ends with a stop flag (see Figure 24-60).

Figure 24-60. MIR Transmit Frame Format



On transmit, the MIR state-machine attaches start flags, a CRC-16, and stop flags, as in SIR mode. All fields are transmitted LSB of each byte first.

Copyright © 2011–2012, Texas Instruments Incorporated

In MIR mode:

- The state-machine looks for consecutive 1s in the frame data and automatically inserts 0 after five consecutive 1s (this is called bit-stuffing).
- 0x7E is used for start and stop flags (unambiguously, not data, because of bit-stuffing).
- An abort sequence requires a minimum of seven consecutive 1s (unambiguously, not data, because of bit-stuffing).
- Back-to-back frames are allowed with three or more stop flags between them. If two consecutive frames are not back to back, the gap between the last stop flag of the first frame and the start flag of the second frame must be separated by at least seven bit durations.

On receive, the MIR receive state-machine recovers the receive clock, removes the start flags, destuffs the incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors such as frame abort, CRC error, and frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.UART_LSR) to detect errors of the received frame.

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

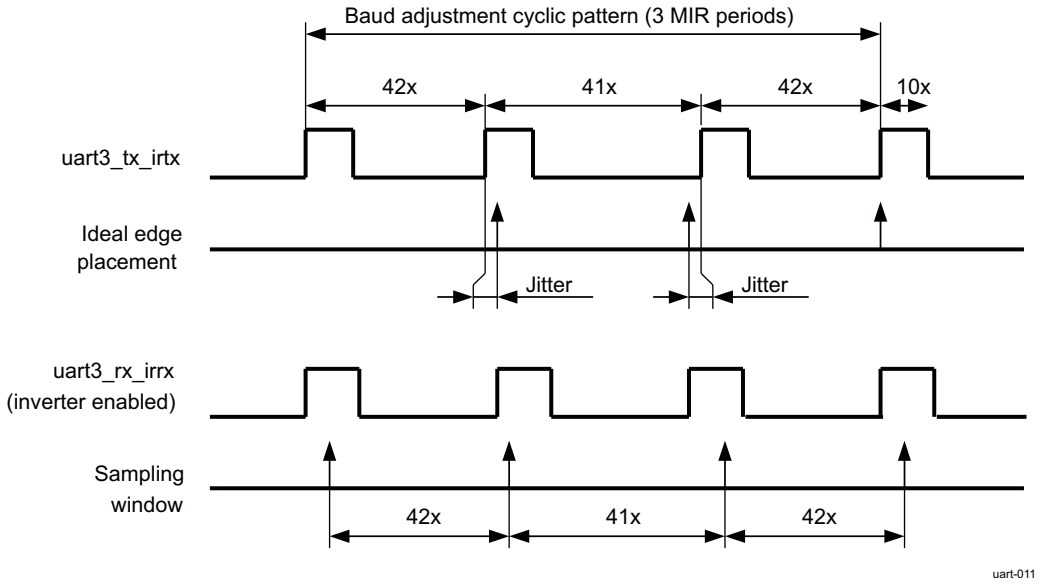
24.3.2.5.2.3.1 MIR Encoder/Decoder

To meet the MIR baud rate tolerance of 0.1 percent with a 48-MHz clock input, a 42-41-42 encoding/decoding adjustment is performed. The reference start point is the first start flag, and the 42-41-42 cyclic pattern is repeated until the stop flag is sent or detected.

The jitter created this way is within MIR tolerances. The pulse width is not exactly 1/4, but it is within the tolerances defined by IrDA specifications.

Figure 24-61 shows the MIR baud rate adjustment mechanism.

Figure 24-61. MIR Baud Rate Adjustment Mechanism



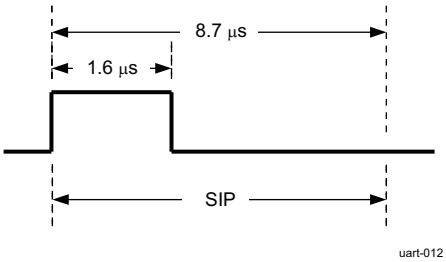
24.3.2.5.2.3.2 SIP Generation

In the MIR and FIR operation modes, the transmitter must send a serial infrared interaction pulse (SIP) at least once every 500 ms. The SIP informs slow devices (operating in SIR mode) that the medium is occupied.

Figure 24-62 shows the SIP.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-62. SIP



24.3.2.5.2.4 FIR Mode

In FIR mode, data is transferred between the MPU and the peripheral devices at 4 Mbps. A FIR transmit frame starts with a preamble that is followed by a start flag, frame data, CRC-32, and ends with a stop flag.

Figure 24-63 shows the FIR transmit frame format.

Figure 24-63. FIR Transmit Frame Format

Preamble (16x)	Start flag	Frame data	CRC-32	Stop flag

On transmit, the FIR transmit state-machine attaches the preamble, start flag, CRC-32, and stop flag. An abort sequence requires at least two transmissions of 0000. Back-to-back frames are allowed, but each frame must be complete.

The state-machine also encodes the transmit data into 4-PPM format (see Table 24-138) and generates the SIP (see Section 24.3.2.5.2.3.2, *SIP Generation*).

Table 24-138. 4-PPM Format

Data Bit Pair (Bin)	4-PPM Data Symbol (Bin)
00	1000
01	0100
10	0010
11	0001

The four symbols described in Table 24-138 are the legal, encoded data symbols. All other combinations are illegal for encoding data. Some of these illegal symbols are used in the definition of the preamble, start flag, and stop flag because they are unambiguously not data (see Table 24-139).

Table 24-139. FIR Preamble, Start Flag, and Stop Flag

Frame Part	Transmitted Frame (Bin)
Preamble	1000 0000 1010 1000 (16 repeated transmissions)
Start flag	0000 1100 0000 1100 0110 0000 0110 0000
Stop flag	0000 1100 0000 1100 0000 0110 0000 0110

All fields are transmitted the LSBs of each byte first (see Table 24-140).

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-140. FIR Data Byte Transmission Order Example

Data Byte (Hex)	Data Byte Pair (Bin)	4-PPM Data Symbol (Bin)	Transmission Order
0x0B	00	1000	4
	00	1000	3
	10	0010	2
	11	0001	1

On receive, the FIR receive state-machine recovers the receive clock, removes the preamble and the start flag, decodes the 4-PPM incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors such as illegal symbol, CRC error, and frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.UART_LSR) to detect errors of the received frame.

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

24.3.2.6 CIR Functional Interfaces

24.3.2.6.1 CIR Interface Description

Table 24-141 lists the CIR interface I/O signals.

Table 24-141. CIR I/O Signals

Signal	I/O [1]	Description	Reset
CIR Signals			
uart3_rx_irrx	I	Serial data input	Unknown
uart3_cts_rctx	O	Serial data output in CIR mode. In other modes, this pin is set to the reset value (inactive state).	0
uart3_rts_sd	O	SD mode is used to configure the transceivers. The SD pinout is an inverted value of the UART3.UART_ACREG[6] SD_MOD bit.	1

(1) I = Input; O = Output

24.3.2.6.2 CIR Protocol and Data Format

In CIR mode, the infrared operation functions as a programmable (universal) remote control.

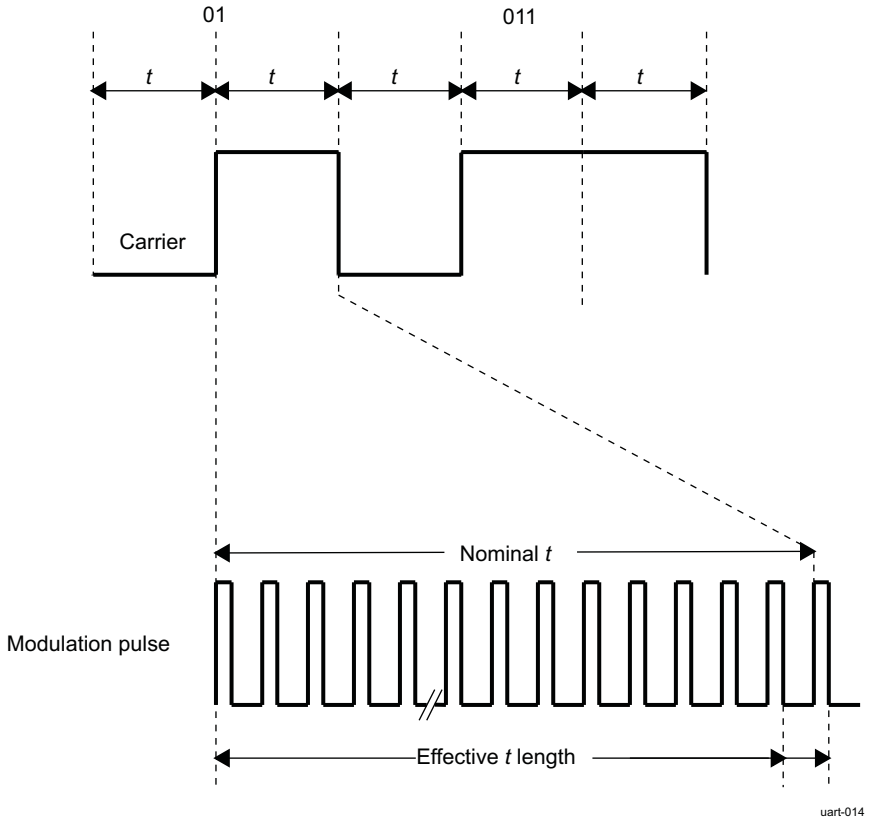
CIR mode uses a variable PWM technique (based on multiples of a programmable *t* period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on user-defined frame structure and packet content.

24.3.2.6.2.1 Carrier Modulation

Each modulated pulse that constitutes a digit is a train of on/off pulses (see Figure 24-64).

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-64. CIR Pulse Modulation

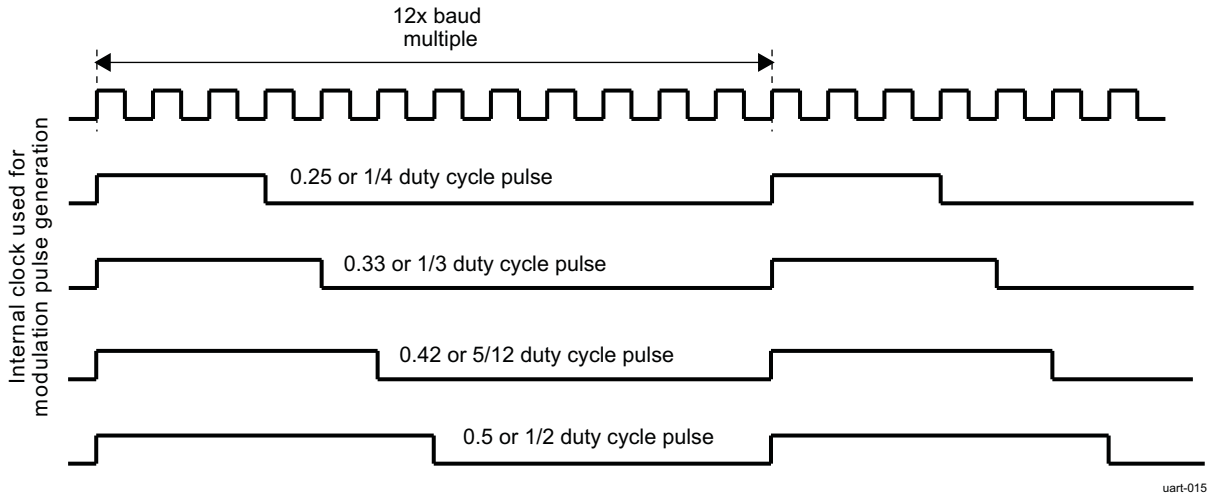


24.3.2.6.2.2 Pulse Duty Cycle

The programmer can choose one of four duty cycles for modulation pulses by setting the appropriate value in the UART3.UART_MDR2[5:4] CIR_PULSE_MODE bit field (1/4, 1/3, 5/12, or 1/2).

Figure 24-65 shows the CIR modulation duty cycles.

Figure 24-65. CIR Modulation Duty Cycle



The transmission logic ensures that all pulses are transmitted completely (no cutoff during transmission). While transmitting continuous bytes back-to-back, no delay is inserted between 2 transmitted bytes. Thus, software must handle the delay between consecutively transmitted bytes if the receiving end requires it.

Copyright © 2011–2012, Texas Instruments Incorporated

24.3.2.6.2.3 Consumer IR Encoding/Decoding

There are two methods of encoding for remote-control applications:

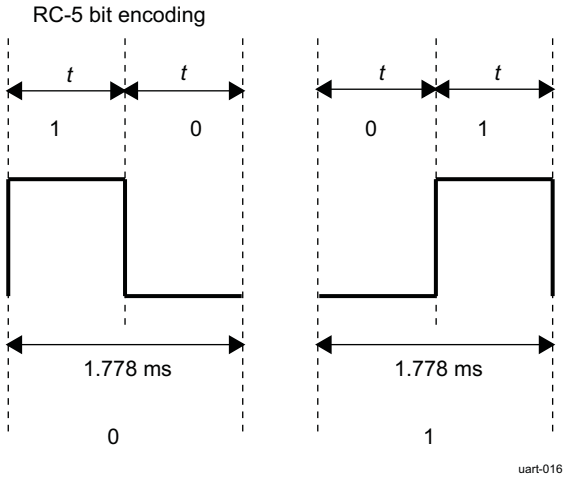
- Pulse duration encoding (time-extended bit forms): A variable pulse distance, or duration, in which the difference between logic 1 and logic 0 is the length of the pulse width
- Biphase encoding: The encoding of logic 0 and logic 1 is in the change of signal level from 1 to 0 or 0 to 1, respectively.

Japanese manufacturers favor pulse duration encoding; European manufacturers favor biphase encoding.

The CIR mode uses a completely flexible free-format encoding in which 1 is transmitted from the TX FIFO as a modulated pulse with duration *t*.

Similarly, 0 is transmitted as a blank duration T. The MPU constructs and deciphers the protocol of the data. For example, the RC-5 protocol using Manchester encoding can be emulated as using a 01 pair for 1 and a 10 pair for 0 (see Figure 24-66).

Figure 24-66. RC-5 Bit Encoding



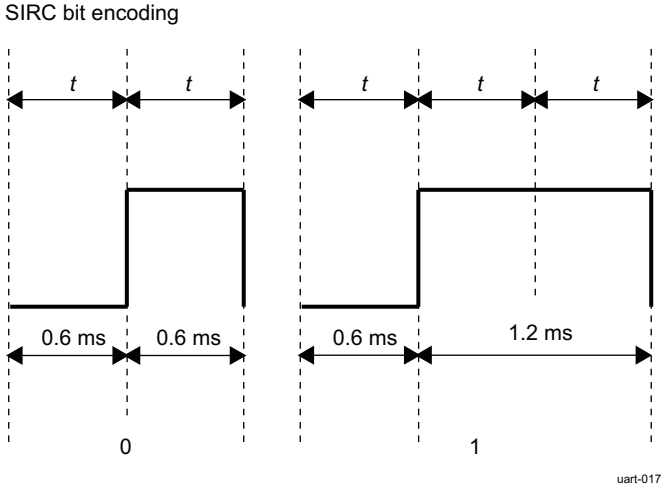
Because CIR mode logic does not impose a fixed format for infrared packets of data, the MPU software can define the format using simple data structures that are then modulated into an industry standard, such as RC-5 or SIRC. To send a sequence of 0101 in RC-5, the MPU software must write an 8-bit binary character of 10011001 to the data FIFO of the UART.

For SIRC, the modulation length (multiples of *t*) is used to distinguish between 1 and 0. The subsequent SIRC digits show the difference in encoding between this and, for example, RC-5. The pulse width is extended for one digit.

Figure 24-67 shows SIRC bit encoding.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-67. SIRC Bit Encoding



To construct comprehensive packets constituting remote-control commands, the MPU software must combine a number of 8-bit data characters in a sequence that follows one of the universally accepted formats.

Figure 24-68 shows a standard RC-5 frame as detected by UART3 in CIR mode (the SIRC format follows this). Each field in RC-5 can be considered as two *t* pulses (digital bits) from the TX FIFO.

Figure 24-68. RC-5 Standard Packet Format

S1	S2	T	A4	A3	A2	A1	A0	C5	C4	C3	C2	C1	C0

uart-018

Where:

S1, S2:	Start-bits (always 1)
T:	Toggle bit
A4..A0:	Address (or system) bits
C5..C0:	Command bits

The toggle bit T changes when a new command is transmitted to detect when the same key is pressed twice (effectively receiving the same data from the host consecutively). A brief delay in the transmission of the same command is detected by the use of the toggle bit because a code is sent while the MPU transmits characters to the UART for transmission. The address bits define the machine or device for which the infrared transmission is intended, and the command defines the operation.

To accommodate an extended RC-5 format, the S2 bit is replaced by an additional command bit (C6) that lets the command range increase to 7 bits. This format is known as the extended RC-5 format.

SIRC encoding uses the duration of modulation for mark and space; therefore, the duration of data bits in the standard frame length varies.

Figure 24-69 shows the packet format and bit encoding. As Figure 24-70 shows, 1 start-bit of 2.4 ms and control codes are followed by data that constitute the entire frame.

Figure 24-69. SIRC Packet Format

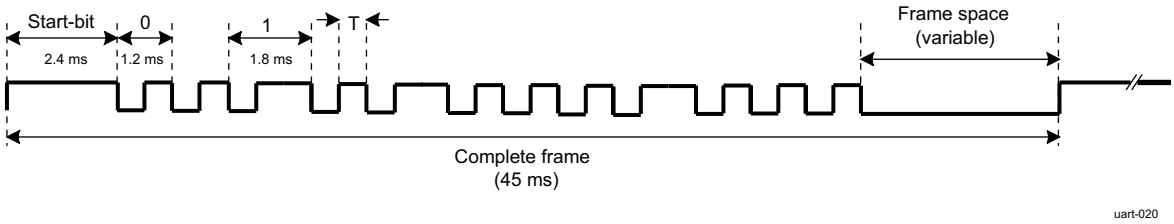
S	C0	C1	C2	C3	C4	C5	C6	D0	D1	D2	D3	D4

uart-019

Copyright © 2011–2012, Texas Instruments Incorporated

NOTE: The encoding must take a standard duration, but the contents of the data can vary. This implies that the control software for sending and receiving data packets must exercise a scheme of interpacket delay, where successive packets can be sent only after a real-time delay expires.

Figure 24-70. SIRC Bit Transmission Example



This document does not describe all encoding methods and techniques; the previous information discusses the considerations required to employ different encoding methods for different industry-standard protocols. See industry-standard documentation for specific methods of encoding and protocol use.

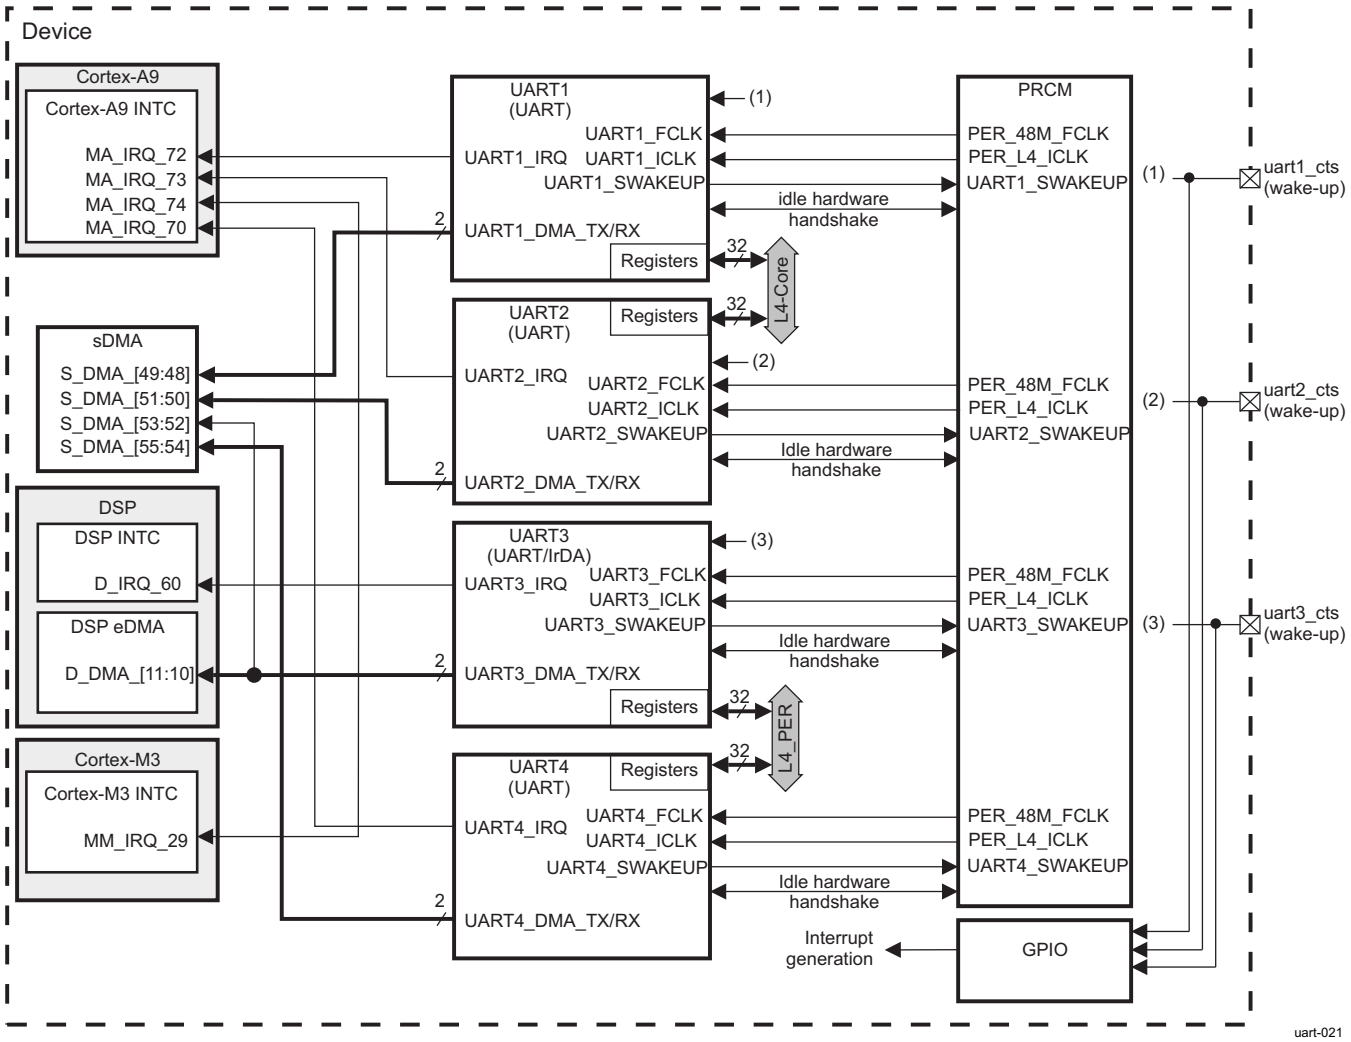
24.3.3 UART/IrDA/CIR Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 24-71 shows the device internal connections with related modules for UART functions.

Figure 24-71. UART/IrDA/CIR Integration



NOTE: For more information about the idle and standby hardware handshakes and the wake-up request, see , *Clock Domain-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 24-142 through Table 24-144 summarize the integration of the module in the device.

Table 24-142. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
UART1	PD_L4_PER	Yes	L4_PER
UART2	PD_L4_PER	Yes	L4_PER
UART3	PD_L4_PER	Yes	L4_PER
UART4	PD_L4_PER	Yes	L4_PER

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-143. Clocks and Resets

Clocks				
Module Instance	**Destination Signal**	**Source Signal**	**Source**	**Description**

24.3.4 UART/IrDA/CIR Functional Description

24.3.4.1 Block Diagram

The UART/IrDA/CIR module can be divided into three main blocks:

- FIFO management
- Mode selection
- Protocol formatting

FIFO management is common to all functions and enables the transmission and reception of data from the host processor point of view.

There are two modes:

- Function mode: Routes the data to the chosen function (UART, IrDA, or CIR) and enables the mechanism corresponding to the chosen function
- Register mode: Enables conditional access to registers

For more information about mode configuration, see Section 24.3.4.7, *Mode Selection*.

Protocol formatting has three subcategories:

- Clock generation: The 48-MHz input clock generates all necessary clocks.
- Data formatting: Each function uses its own state-machine that is responsible for the transition between FIFO data and frame data associated with it.
- Interrupt management: Different interrupt types are generated depending on the chosen function:
  - UART mode interrupts: Seven interrupts prioritized in six different levels
  - IrDA mode interrupts: Eight interrupts. The interrupt line is activated when any interrupt is generated (there is no priority).
  - CIR mode interrupts: A subset of existing IrDA mode interrupts is used.

  In each mode, when an interrupt is generated, the UART_IIR register indicates the interrupt type.

In parallel with these functional blocks, a power-saving strategy exists for each function.

Figure 24-72 is the UART/IrDA/CIR block diagram.

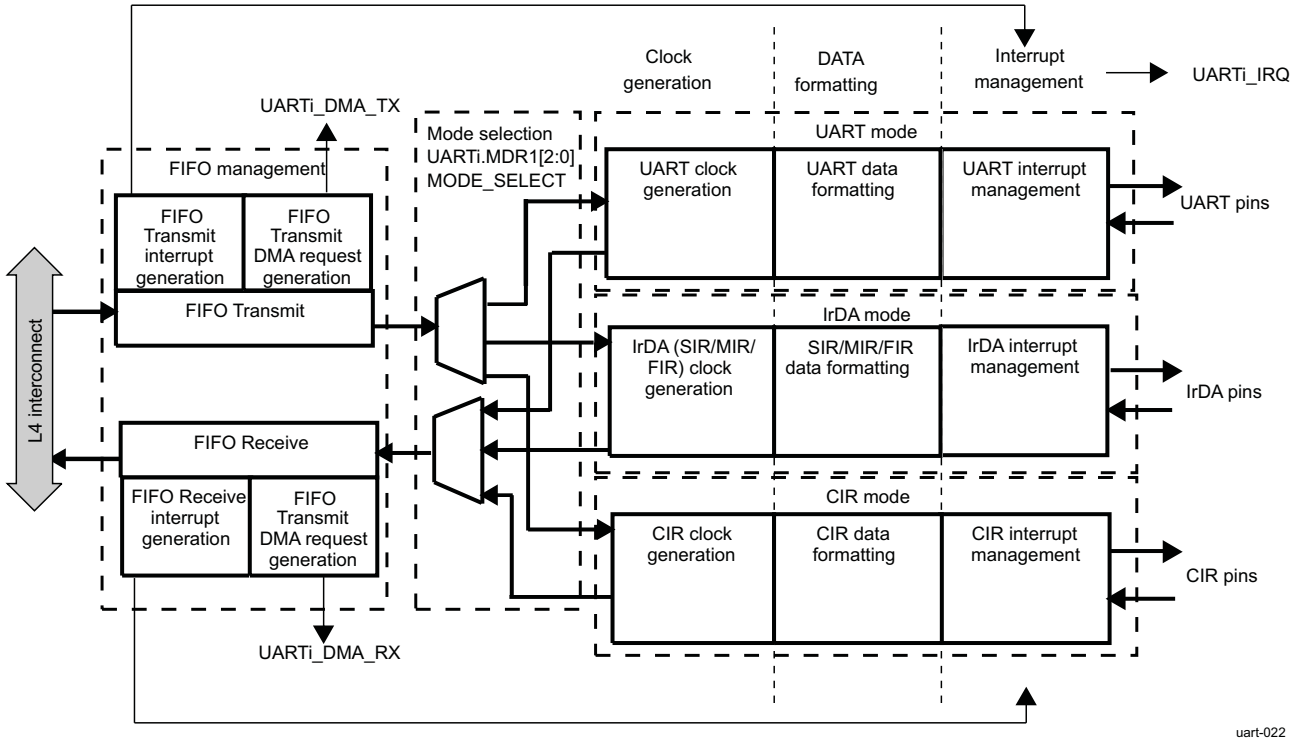
Figure 24-72. UART/IrDA/CIR Functional Specification Block Diagram



24.3.4.2 Clock Configuration

Each UART uses a 48-MHz functional clock for its logic and to generate external interface signals. Each UART uses an interface clock for register accesses. The PRCM module generates and controls all these clocks (for more information, see , *Clock Domain Module Attributes*, in Chapter 3, *Power, Reset, and Clock Management*).

The idle and wake-up processes use a handshake protocol between the PRCM and the UART (for a description of the protocol, see Section 3.1.1.1.2, *Module-Level Clock Managment*, in Chapter 3, *Power, Reset, and Clock Management*). The UARTi.UART_SYSC[4:3] IDLEMODE bit field controls UART idle mode.

24.3.4.3 Software Reset

The UARTi.UART_SYSC[1] SOFTRESET bit controls the software reset; setting this bit to 1 triggers a software reset functionally equivalent to hardware reset.

24.3.4.4 Power Management

24.3.4.4.1 UART Mode Power Management

24.3.4.4.1.1 Module Power Saving

In UART modes, sleep mode is enabled by setting the UARTi.UART_IER[4] SLEEP_MODE bit to 1 (when the UARTi.UART_EFR[4] ENHANCED_EN bit is set to 1).

Sleep mode is entered when all the following conditions exist:

- The serial data input line, uarti_rx, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- The only pending interrupts are THR interrupts.

Copyright © 2011–2012, Texas Instruments Incorporated

Sleep mode is a good way to lower UART power consumption, but this state can be achieved only when the UART is set to modem mode. Therefore, even if the UART has no key role functionally, it must be initialized in a functional mode to take advantage of sleep mode.

In sleep mode, the module clock and baud rate clock are stopped internally. Because most registers are clocked by these clocks, this greatly reduces power consumption. The module wakes up when a change is detected on the uarti_rx line, when data is written to the TX FIFO, and when there is a change in the state of the modem input pins.

An interrupt can be generated on a wake-up event by setting the UARTi.UART_SCR[4] RX_CTS_WU_EN bit to 1. To understand how to manage the interrupt, see Section 24.3.4.5.1.2, *Wake-Up Interrupt*.

NOTE: There must be no writing to the divisor latches, UARTi.UART_DLL and UARTi.UART_DLH, to set the baud clock (BCLK) while in sleep mode. It is advisable to disable sleep mode using the UARTi.UART_IER[4] SLEEP_MODE bit before writing to the UARTi.UART_DLL register or the UARTi.UART_DLH register.

24.3.4.4.1.2 System Power Saving

Sleep and auto-idle modes are embedded power-saving features. Power-reduction techniques can be applied at the system level by shutting down certain internal clock and power domains of the device.

The UART supports an idle req/idle ack handshaking protocol used at the system level to shut down the UART clocks in a clean and controlled manner and to switch the UART from interrupt-generation mode to wake-up generation mode for unmasked events (see the UARTi.UART_SYSC[2] ENAWAKEUP bit and the UARTi.UART_WER register).

For more information, see Section 3.1.1.1.2, *Module Level Clock Managment*, in Chapter 3, *Power, Reset, and Clock Management*.

24.3.4.4.2 IrDA Mode Power Management (UART3 Only)

24.3.4.4.2.1 Module Power Saving

In IrDA modes, sleep mode is enabled by setting the UART3.MDR[3] IR_SLEEP bit to 1.

Sleep mode is entered when all the following conditions exist:

- The serial data input line, uart3.rx_irrx, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

The module wakes up when a change is detected on the uart3_rx_irrx line or when data is written to the TX FIFO.

24.3.4.4.2.2 System Power Saving

System power saving for the IrDA mode has the same function as for the UART mode (see Section 24.3.4.4.1.2, *System Power Saving*).

24.3.4.4.3 CIR Mode Power Management (UART3 Only)

24.3.4.4.3.1 Module Power Saving

Module power saving for the CIR mode has the same function as for the IrDA mode (see Section 24.3.4.4.2.1, *Module Power Saving*).

Copyright © 2011–2012, Texas Instruments Incorporated

24.3.4.4.3.2 System Power Saving

System power saving for the CIR mode has the same function as for the UART mode (see Section 24.3.4.4.1.2, *System Power Saving*).

24.3.4.4.4 Local Power Management

Table 24-145 describes power-management features available for the UART.

NOTE: For information about source clock gating and sleep/wake-up transitions description, see Section 3.1.1.1.2, *Module-Level Clock Managment*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 24-145. Local Power-Management Features

Feature	Registers	Description
Clock autogating	UART_SYSC[0] AUTOIDLE	This bit allows local power optimization in the module by gating the UARTi_ICLK clock on interface activity or gating the UARTi_FCLK clock on internal activity.
Slave idle modes	UART_SYSC[4:3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	UART_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.
Wake-Up sources enable	N/A	Feature not available

24.3.4.5 Interrupt Requests

24.3.4.5.1 UART Mode Interrupt Management

24.3.4.5.1.1 UART Interrupts

UART mode includes seven possible interrupts prioritized to six levels.

When an interrupt is generated, the interrupt identification register (UARTi.UART_IIR) sets the UARTi.UART_IIR[0] IT_PENDING bit to 0 to indicate that an interrupt is pending, and indicates the type of interrupt through the UARTi.UART_IIR[5:1] bit field. Table 24-146 summarizes the interrupt control functions.

Table 24-146. UART Mode Interrupts

UART_IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000001	None	None	None	None
000110	1	Receiver line status	OE, FE, PE, or BI errors occur in characters in the RX FIFO.	FE, PE, BI: Read the UART_RHR register. OE: Read the UART_LSR register.
001100	2	RX time-out	Stale data in RX FIFO	Read the UART_RHR register.
000100	2	RHR interrupt	DRDY (data ready) (FIFO disable)	Read the UART_RHR register until the interrupt condition disappears.
			RX FIFO above trigger level (FIFO enable)	
000010	3	THR interrupt	TFE (UART_THR empty) (FIFO disable)	Write to the UART_THR until the interrupt condition disappears.
			TX FIFO below trigger level (FIFO enable)	

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-146. UART Mode Interrupts (continued)

UART_IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000000	4	Modem status	See the UART_MSR register.	Read the UART_MSR register.
010000	5	XOFF interrupt/special character interrupt	Receive XOFF characters/special character	Receive XON character(s), if XOFF interrupt/read of the UART_IIR register, if special character interrupt.
100000	6	CTS, RTS	RTS pin or CTS pin change state from active (low) to inactive (high).	Read the UART_IIR register.

For the receiver-line status interrupt, the RX_FIFO_STS bit (UARTi.UART_LSR[7]) generates the interrupt.

For the XOFF interrupt, if an XOFF flow character detection caused the interrupt, the interrupt is cleared by an XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the UARTi.UART_IIR register.

24.3.4.5.1.2 Wake-Up Interrupt

Wake-up interrupt is a special interrupt that works differently from other interrupts. This interrupt is enabled when the UARTi.UART_SCR[4] RX_CTS_WU_EN bit is set to 1. The UARTi.UART_IIR register is not modified when this occurs; the UART3.UART_SSR[1] RX_CTS_WU_STS bit must be checked to detect a wake-up event.

When a wake-up interrupt occurs, it can be cleared only by resetting the UARTi.UART_SCR[4] RX_CTS_WU_EN bit. This bit must be reenabled (set to 1) after the current wake-up interrupt event is processed to detect the next incoming wake-up event.

24.3.4.5.2 IrDA Mode Interrupt Management

24.3.4.5.2.1 IrDA Interrupts

The IrDA function generates interrupts. All interrupts can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UART3.UART_IER). The interrupt status of the device can be checked by reading the interrupt identification register (UART3.UART_IIR).

UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UART3.UART_IER and UART3.UART_IIR mappings, depending on the selected mode.

IrDA modes have eight possible interrupts (see Table 24-147). The interrupt line is activated when any interrupt is generated (there is no priority).

Table 24-147. IrDA Mode Interrupts

UART_IIR Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read the UART_RHR register until the interrupt condition disappears.
1	THR interrupt	TFE (UART_THR empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to the UART_THR until the interrupt condition disappears.
2	Last byte in RX FIFO	Last byte of frame in RX FIFO is available to be read at the RHR port.	Read the UART_RHR register.
3	RX overrun	Write to the UART_RHR register when the RX FIFO is full.	Read UART_RESUME register.

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-147. IrDA Mode Interrupts (continued)

UART_IIR Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
4	Status FIFO interrupt	Status FIFO triggers level reached.	Read STATUS FIFO.
5	TX status	1. UART_THR empty before EOF sent. Last bit of transmission of the IrDA frame occurred, but with an underrun error. OR 2. Transmission of the last bit of the IrDA frame completed successfully.	1. Read the UART_RESUME register. OR 2. Read the UART_IIR register.
6	Receiver line status interrupt	CRC, ABORT, or frame-length error is written into the STATUS FIFO.	Read the STATUS FIFO (read until empty - maximum of eight reads required).
7	Received EOF	Received end-of-frame	Read the UART_IIR register.

24.3.4.5.2.2 Wake-Up Interrupts

The wake-up interrupt for IrDA mode has the same function as that for UART mode (see Section 24.3.4.5.1.2, *Wake-Up Interrupt*).

CAUTION

Wake-Up interface implementation in this mode is based on the UARTi_SIDLEACK low-to-high transition instead of the UARTi_SIDLEACK state.

This does not ensure wake-up event generation as expected when configured in smart-idle mode, and the system wakes up for a short period.

24.3.4.5.3 CIR Mode Interrupt Management

24.3.4.5.3.1 CIR Interrupts

The CIR function generates interrupts that can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UART3.UART_IER). The interrupt status of the device can be checked by reading the interrupt identification register (UART3.UART_IIR).

UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UART3.UART_IER and UART3.UART_IIR mappings, depending on the selected mode.

Table 24-148 lists the interrupt modes to be maintained. In CIR mode, the sole purpose of the UART3.UART_IIR[5] bit is to indicate that the last bit of infrared data was passed to the uart3_cts_rctx pin.

Table 24-148. CIR Mode Interrupts

UART_IIR Bit Number	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
1	THR interrupt	TFE (UART_THR empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to the UART_THR register until the interrupt condition disappears.
2	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
3	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
4	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-148. CIR Mode Interrupts (continued)

UART_IIR Bit Number	Interrupt Type	Interrupt Source	Interrupt Reset Method
5	TX status	Transmission of the last bit of the frame is complete successfully.	Read the UART_IIR register.
6	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
7	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode

24.3.4.5.3.2 Wake-Up Interrupts

The wake-up interrupt for CIR mode has the same function as that for UART mode (see Section 24.3.4.5.1.2, *Wake-Up Interrupt*).

24.3.4.6 FIFO Management

The FIFO is accessed by reading and writing the UARTi.UART_RHR and UARTi.UART_THR registers. Parameters are controlled using the FIFO control register (UARTi.UART_FCR) and supplementary control register (UARTi.UART_SCR). Reading the UARTi.UART_SSR[0] TX_FIFO_FULL bit at 1 means the FIFO is full.

The UARTi.UART_TLR register controls the FIFO trigger level, which enables DMA and interrupt generation. After reset, transmit (TX) and receive (RX) FIFOs are disabled; thus, the trigger level is the default value of 1 byte. Figure 24-73 shows the FIFO management registers.

NOTE: Data in the UARTi.UART_RHR register is not overwritten when an overflow occurs.

NOTE: The UARTi.UART_SFLSR, UARTi.UART_SFREGL, and UARTi.UART_SFREGH status registers are used in IrDA mode only. For use, see Section 24.3.4.8.2.3, *IrDA Data Formatting*.

24.3.4.6.1 FIFO Trigger

24.3.4.6.1.1 Transmit FIFO Trigger

Table 24-149 lists the TX FIFO trigger level settings.

Table 24-149. TX FIFO Trigger Level Setting Summary

UART_SCR[6]	UART_TLR[3:0]	TX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit field (8,16, 32, or 56 spaces)
0	!= 0x0	Defined by the UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit field (from 4 to 60 spaces with a granularity of 4 spaces)
1	Value	Defined by the concatenated value of TX_FIFO_TRIG_DMA and TX_FIFO_TRIG (from 1 to 63 spaces with a granularity of 1 space) **Note:** The combination of TX_FIFO_TRIG_DMA = 0x0 and TX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of one space required). All zeros result in unpredictable behavior.

24.3.4.6.1.2 Receive FIFO Trigger

Table 24-150 lists the RX FIFO trigger level settings.

Table 24-150. RX FIFO Trigger Level Setting Summary

UART_SCR[7]	UART_TLR[7:4]	RX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.UART_FCR[7:6] RX_FIFO_TRIG bit field (8,16, 56, or 60 characters)
0	!= 0x0	Defined by the UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA bit field (from 4 to 60 characters with a granularity of 4 characters)
1	Value	Defined by the concatenated value of RX_FIFO_TRIG_DMA and RX_FIFO_TRIG (from 1 to 63 characters with a granularity of 1 character) **Note:** The combination of RX_FIFO_TRIG_DMA = 0x0 and RX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of one character required). All zeros result in unpredictable behavior.

The receive threshold is programmed using the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START and UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit fields:

- Trigger levels from 0 to 60 bytes are available with a granularity of 4 (trigger level = 4 x [4-bit register value]).
- To ensure correct device operation, ensure that RX_FIFO_TRIG_HALT > RX_FIFO_TRIG when auto-RTS is enabled.

  Delay = [4 + 16 x (1 + CHAR_LENGTH + Parity + Stop –0.5)] x Baud_rate + 4 x FCLK

  NOTE: The RTS signal is deasserted after the UART module receives the data over RX_FIFO_TRIG_HALT. Delay means how long the UART module takes to deassert the RTS signal after reaching RX_FIFO_TRIG_HALT.

- In FIFO interrupt mode with flow control, ensure that the trigger level to HALT transmission is greater than or equal to the RX FIFO trigger level (the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START bit field or the UARTi.UART_FCR[7:6] RX_FIFO_TRIG bit field); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist, because a DMA request is sent when a byte is received.

Copyright © 2011–2012, Texas Instruments Incorporated

24.3.4.6.2 FIFO Interrupt Mode

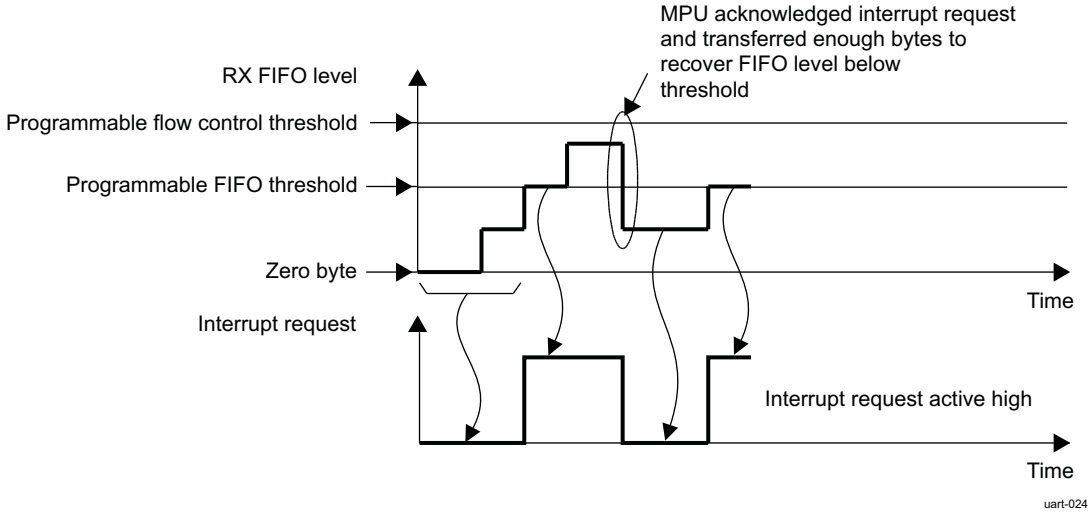
In FIFO interrupt mode (the FIFO control register UARTi.UART_FCR[0] FIFO_EN bit is set to 1 and relevant interrupts are enabled by the UARTi.UART_IER register), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the RX/TX FIFO threshold (the UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA and UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit fields or the UARTi.UART_FCR[7:6] RX_FIFO_TRIG and UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit fields, respectively) is reached.

The interrupt signals instruct the MPU to transfer data to the destination (from the UART in receive mode and/or from any source to the UART FIFO in transmit mode).

When UART flow control is enabled with interrupt capabilities, the UART flow control FIFO threshold (the UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit field) must be greater than or equal to the RX FIFO threshold.

Figure 24-74 shows the generation of the RX FIFO interrupt request.

Figure 24-74. RX FIFO Interrupt Request Generation

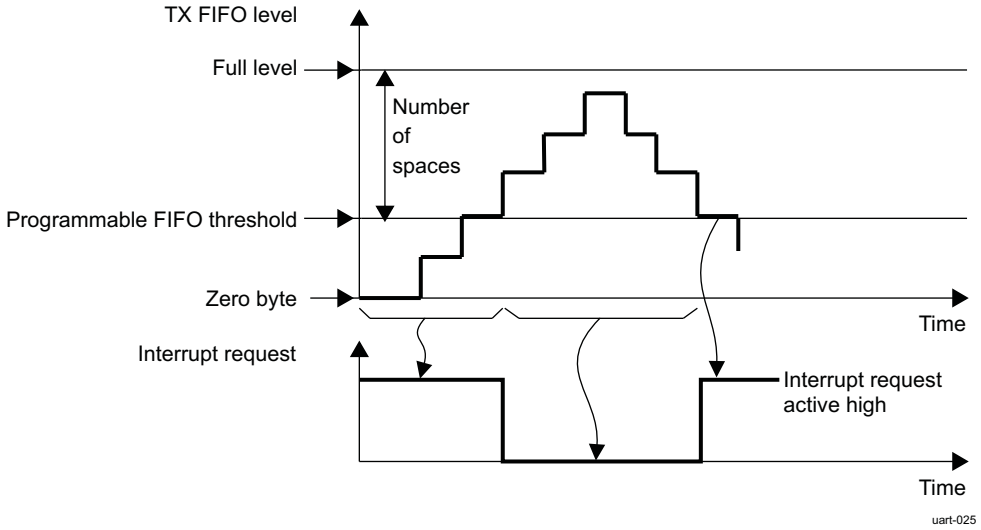


In receive mode, no interrupt is generated until the RX FIFO reaches its threshold. Once low, the interrupt can be deasserted only when the MPU has handled enough bytes to put the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

Figure 24-75 shows the generation of the TX FIFO interrupt request.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-75. TX FIFO Interrupt Request Generation



In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is deasserted when the TX FIFO crosses the threshold level. The interrupt line is deasserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

24.3.4.6.3 FIFO Polled Mode Operation

In FIFO polled mode (the UARTi.UART_FCR[0] FIFO_EN bit is set to 0 and the relevant interrupts are disabled by the UARTi.UART_IER register), the status of the receiver and transmitter can be checked by polling the line status register (UARTi.UART_LSR).

This mode is an alternative to the FIFO interrupt mode of operation in which the status of the receiver and transmitter is automatically determined by sending interrupts to the MPU.

24.3.4.6.4 FIFO DMA Mode Operation

Although DMA operation includes four modes (DMA modes 0 through 3), the information in Table 24-144 assumes that mode 1 is used. (Mode 2 and mode 3 are legacy modes that use only one DMA request for each module.)

In mode 2, the remaining DMA request is used for RX. In mode 3, the remaining DMA request is used for TX.

DMA requests in mode 2 and mode 3 use the following signals:

- S_DMA_48
- S_DMA_50
- S_DMA_52/D_DMA_10
- S_DMA_54

The following signals are not used by the module in mode 2 and mode 3:

- S_DMA_49
- S_DMA_51
- S_DMA_53/D_DMA_11
- S_DMA_55

These signals can be selected as follows:

- When the UARTi.UART_SCR[0] DMA_MODE_CTL bit is set to 0, setting the UARTi.UART_FCR[3] DMA_MODE_CTL bit to 0 enables DMA mode 0. Setting the DMA_MODE_CTL bit to 1 enables DMA mode 1.

Copyright © 2011–2012, Texas Instruments Incorporated

- When the DMA_MODE_CTL bit is set to 1, the UARTi.UART_FCR[2:1] DMA_MODE_2 bit field determines DMA mode 0 to mode 3 based on the supplementary control register (UART_SCR) description.

For example:

- If no DMA operation is desired, set the DMA_MODE_CTL bit to 1 and the DMA_MODE_2 bit field to 0x0. (The DMA_MODE bit is discarded.)
- If DMA mode 1 is desired, set the DMA_MODE_CTL bit to 0 and the DMA_MODE bit to 1, or set the DMA_MODE_CTL bit to 1 and the DMA_MODE_2 bit field to 01. (The DMA_MODE bit is discarded.)

If the FIFOs are disabled (the UARTi.UART_FCR[0] FIFO_EN bit is set to 0), the DMA occurs in single-character transfers.

When DMA mode 0 is programmed, the signals associated with DMA operation are not active.

Depending on UART_MDR3[2] SET_DMA_TX_THRESHOLD, the threshold can be programmed different ways:

- SET_TX_DMA_THRESHOLD = 1:

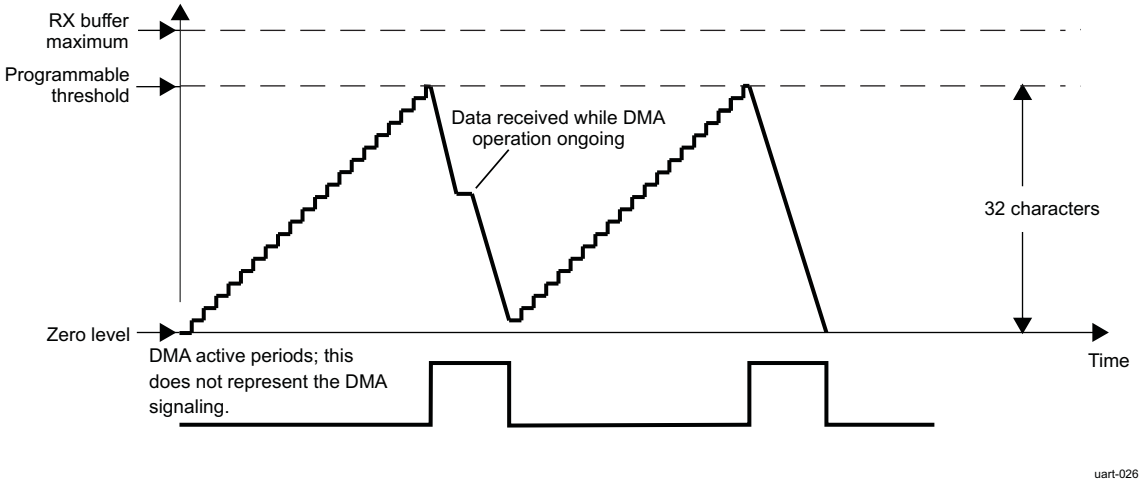
  The threshold value will be the value of the UART_TX_DMA_THRESHOLD register. If SET_TX_DMA_THRESHOLD + TX trigger spaces 64, then the default method of threshold is used: threshold value = TX FIFO size.
- SET_TX_DMA_THRESHOLD = 0:

  The threshold value = TX FIFO size TX trigger space. The TX DMA line is asserted if the TX FIFO level is lower then the threshold. It remains asserted until TX trigger spaces number of bytes are written into the FIFO. The DMA line is then deasserted and the FIFO level is compared with the threshold value.

24.3.4.6.4.1 DMA Transfers (DMA Mode 1, 2, or 3)

Figure 24-76 through Figure 24-79 show the supported DMA operations.

Figure 24-76. Receive FIFO DMA Request Generation (32 Characters)

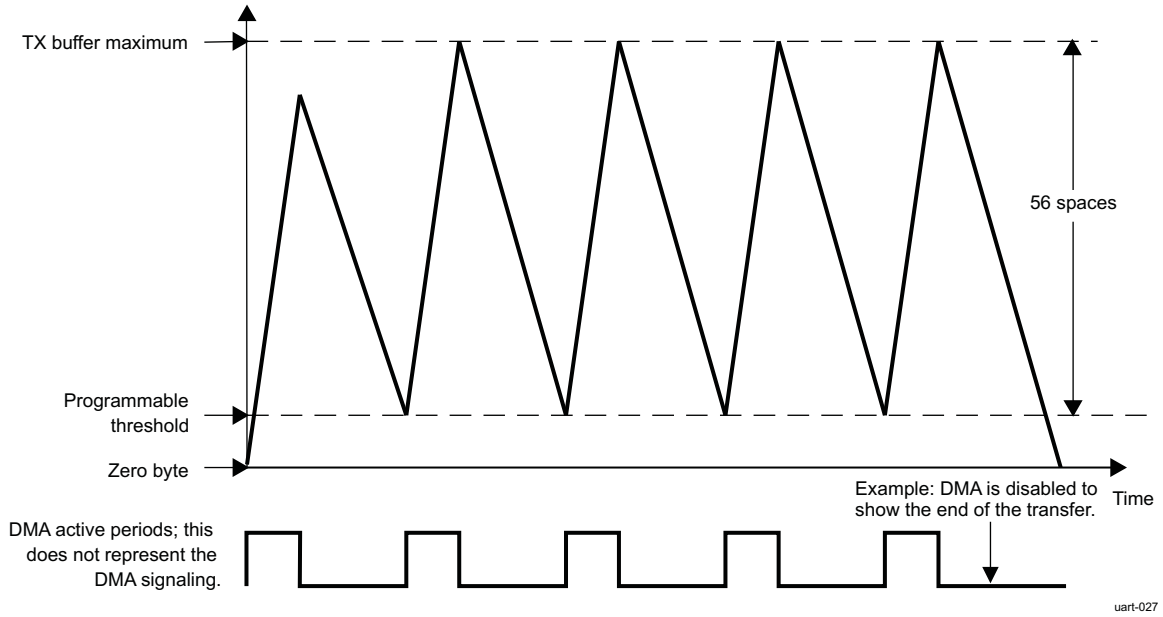


In receive mode, a DMA request is generated when the RX FIFO reaches its threshold level defined in the trigger level register (UARTi.UART_TLR). This request is deasserted when the number of bytes defined by the threshold level is read by the sDMA.

In transmit mode, a DMA request is automatically asserted when the TX FIFO is empty. This request is deasserted when the number of bytes defined by the number of spaces in the UARTi.UART_TLR register is written by the sDMA. If an insufficient number of characters is written, the DMA request stays active.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-77. Transmit FIFO DMA Request Generation (56 Spaces)



The DMA request is again asserted if the FIFO can receive the number of bytes defined by the UARTi.UART_TLR register.

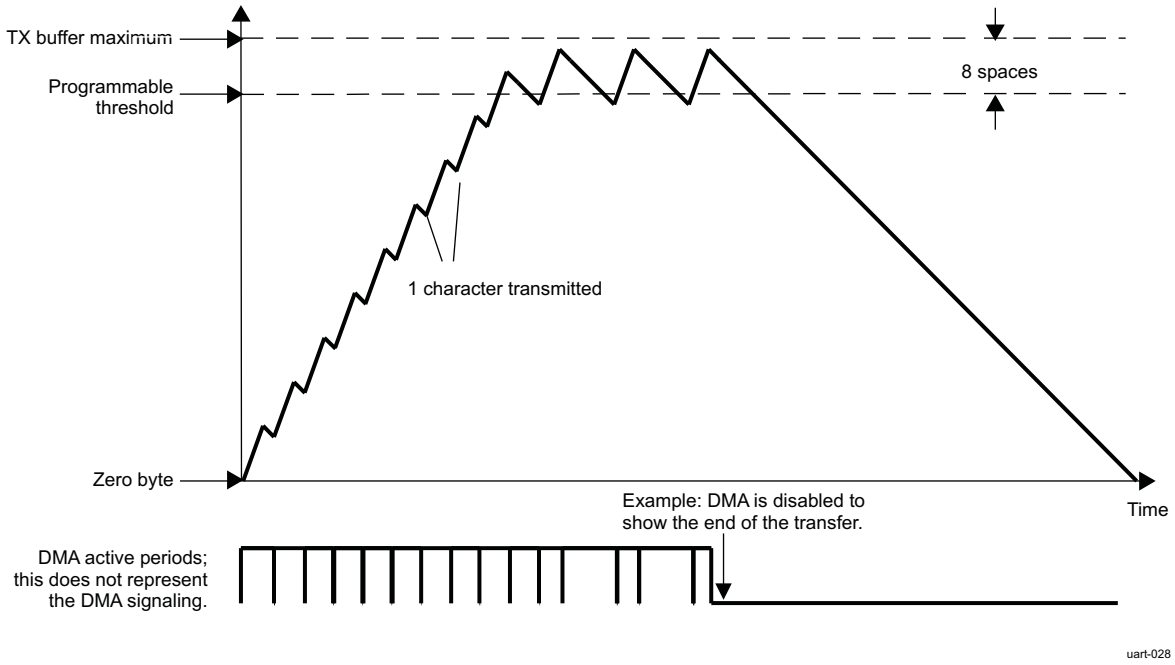
The threshold can be programmed in a number of ways. Figure 24-77 shows a DMA transfer operating with a space setting of 56 that can arise from using the auto settings in the UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit field or the UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit field concatenated with the TX_FIFO_TRIG bit field.

The setting of 56 spaces in the UART/IrDA/CIR module must correlate with the settings of the sDMA so that the buffer does not overflow (program the DMA request size of the LH controller to equal the number of spaces in the UART/IrDA/CIR module).

Figure 24-78 shows an example with eight spaces to show the buffer level crossing the space threshold. The LH DMA controller settings must correspond to those of the UART/IrDA/CIR module.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-78. Transmit FIFO DMA Request Generation (8 Spaces)

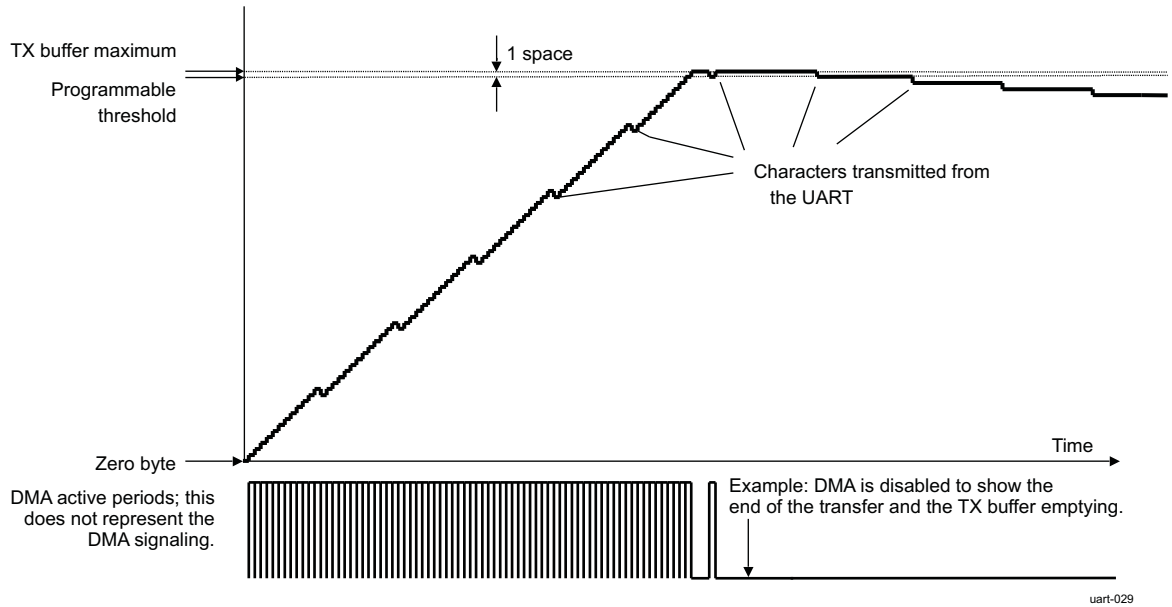


The next example shows the setting of one space that uses the DMA for each transfer of one character to the transmit buffer (see Figure 24-79). The buffer is filled faster than the baud rate at which data is transmitted to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer.

On two occasions, the buffer holds the maximum amount of data words; shortly after this, the DMA is disabled to show the slower transmission of the data words to the TX pin. Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UARTi.UART_DLL and UARTi.UART_DLH registers.

The DMA settings must correspond to the system LH DMA controller settings to ensure correct operation of this logic.

Figure 24-79. Transmit FIFO DMA Request Generation (1 Space)



Copyright © 2011–2012, Texas Instruments Incorporated

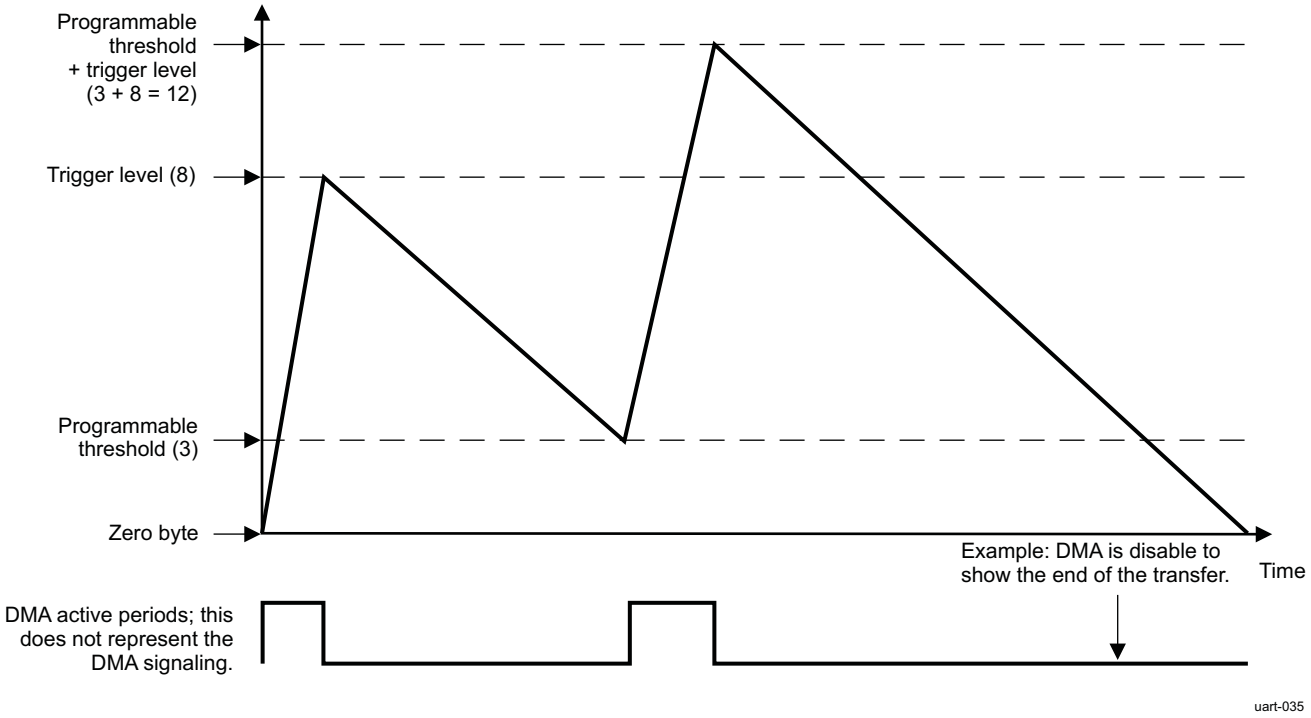
The final example shows the setting of eight spaces, but setting the TX DMA threshold directly by setting the UART_MDR3[1] NONDEFAULT_FREQ bit and the UART_TX_DMA_THRESHOLD register (see Figure 24-80). In the example, UART_TX_DMA_THRESHOLD[5:0] TX_DMA_THRESHOLD = 3 and the trigger level is 8. The buffer is filled at a faster rate than the baud rate transmits data to the TX pin. The buffer is filled with 8 bytes and the DMA operations stop transferring data to the transmit buffer. When the buffer is emptied to the threshold level by transmission, the DMA operation activates again to fill the buffer with 8 bytes.

Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UART_DLL and UART_DLH registers.

If the selected threshold level plus the trigger level exceed the maximum buffer size, the original TX DMA threshold method is used to prevent TX overrun, regardless of the value of the UART_MDR3[1] NONDEFAULT_FREQ bit.

The DMA settings must correspond to the settings of the system local host DMA controller to ensure the correct operation of this logic.

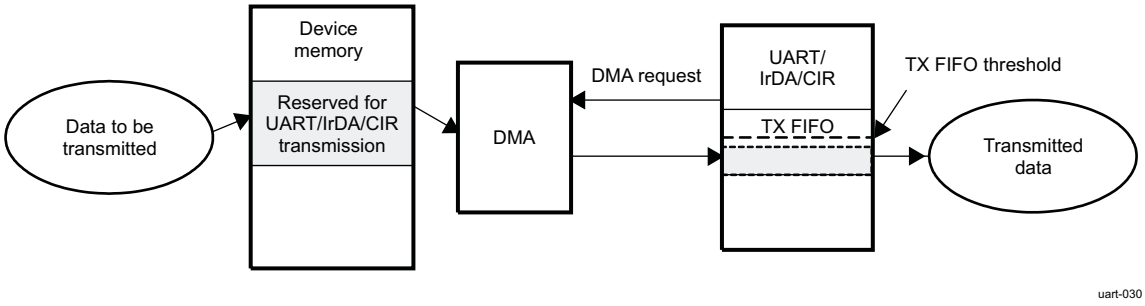
Figure 24-80. Transmit FIFO DMA Request Generation Using Direct TX DMA Threshold Programming. (Threshold = 3; Spaces = 8)



24.3.4.6.4.2 DMA Transmission

Figure 24-81 shows DMA transmission.

Figure 24-81. DMA Transmission



Copyright © 2011–2012, Texas Instruments Incorporated

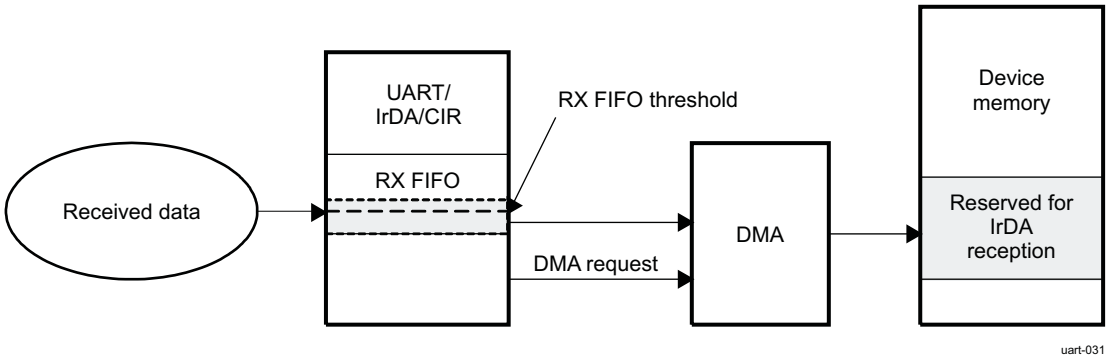
1. Data to be transmitted are put in the device memory reserved for UART/IrDA/CIR transmission by the DMA:
   (a) Until the TX FIFO trigger level is not reached, a DMA request is generated
   (b) An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).
2. Data in the TX FIFO are automatically transmitted.
3. The end of the transmission is signaled by the UARTi.UART_THR empty (TX FIFO empty).

NOTE: In IrDA mode, the transmission does not end immediately after the TX FIFO empties, at which point the last data byte, the CRC field, and the stop flag still must be transmitted; thus, the end of transmission occurs a few milliseconds after the UARTi.UART_THR register empties.

24.3.4.6.4.3 DMA Reception

Figure 24-82 shows DMA reception.

Figure 24-82. DMA Reception



1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA:
   (a) At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
   (b) An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

24.3.4.7 Mode Selection

24.3.4.7.1 Register Access Modes

24.3.4.7.1.1 Operational Mode and Configuration Modes

Register access depends on the register access mode, although register access modes are not correlated to functional mode selection. Three different modes are available:

- Operational mode
- Configuration mode A
- Configuration mode B

Operational mode is the selected mode when the function is active; serial data transfer can be performed in this mode.

Copyright © 2011–2012, Texas Instruments Incorporated

Configuration mode A and configuration mode B are used during module initialization steps. These modes enable access to configuration registers, which are hidden in the operational mode. The modes are used when the module is inactive (no serial data transfer processed) and only for initialization or reconfiguration of the module.

The value of the UARTi.UART_LCR register determines the register access mode (see Table 24-151).

Table 24-151. UART/IrDA/CIR Register Access Mode Programming (Using UART_LCR)

Mode	Condition
Configuration mode A	UART_LCR[7] = 0x1 and UART_LCR[7:0] != 0xBF
Configuration mode B	UART_LCR[7] = 0x1 and UART_LCR[7:0] = 0xBF
Operational mode	UART_LCR[7] = 0x0

24.3.4.7.1.2 Register Access Submode

In each access register mode (operational mode or configuration mode A/B), some register accesses are conditional on the programming of a submode (MSR_SPR, TCR_TLR, and XOFF). These registers are identified in Section 24.3.6, *UART/IrDA/CIR Register Manual*.

Table 24-152 through Table 24-154 summarize the register access submodes.

Table 24-152. Subconfiguration Mode A Summary

Mode	Condition
MSR_SPR	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

Table 24-153. Subconfiguration Mode B Summary

Mode	Condition
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1
XOFF	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)

Table 24-154. Suboperational Mode Summary

Mode	Condition
MSR_SPR	UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

24.3.4.7.1.3 Registers Available for the Register Access Modes

Table 24-155 lists the names of the register bits in each access register mode. Gray shading indicates that the register does not depend on the register access mode (available in all modes).

Table 24-155. UART/IrDA/CIR Register Access Mode Overview

Address Offset	Registers

(1) MSR_SPR mode is active (see Section 24.3.4.7.1.2, *Register Access Submode*)
(2) TCR_TLR mode is active (see Section 24.3.4.7.1.2, *Register Access Submode*)
(3) XOFF mode is active (see Section 24.3.4.7.1.2, *Register Access Submode*)

24.3.4.7.2 UART/IrDA (SIR, MIR, FIR)/CIR Mode Selection

To select a mode, set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field (see Table 24-156).

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-156. UART Mode Selection

Value	Mode
0x0:	UART 16x mode
0x1:	SIR mode (UART3 only)
0x2:	UART 16x auto-baud
0x3:	UART 13x mode
0x4:	MIR mode (UART3 only)
0x5:	FIR mode (UART3 only)
0x6:	CIR mode (UART3 only)

MODE_SELECT is effective when the module is in operational mode (see Section 24.3.4.7.1, *Register Access Modes*).

24.3.4.7.2.1 Registers Available for the UART Function

Only the registers listed in Table 24-157 are used for the UART function.

24.3.4.8 Protocol Formatting

24.3.4.8.1 UART Mode

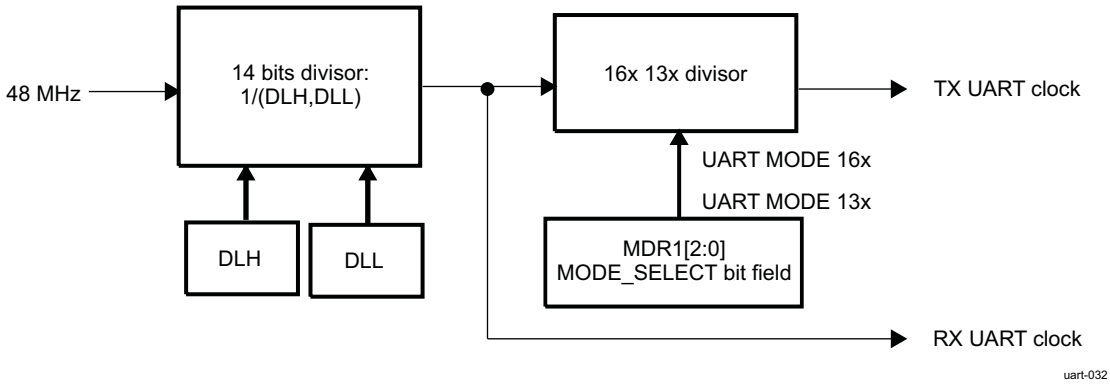
24.3.4.8.1.1 UART Clock Generation: Baud Rate Generation

The UART function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 24-83 shows the baud rate generator and associated controls.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-83. Baud Rate Generation



CAUTION

Before initializing or modifying clock parameter controls (UARTi.UART_DLH, UARTi.UART_DLL), MODE_SELECT = DISABLE (UARTi.UART_MDR1[2:0]) must be set to 0x7. Failure to observe this rule can result in unpredictable module behavior.

24.3.4.8.1.2 Choosing the Appropriate Divisor Value

Two divisor values are:

- UART 16x mode: Divisor value = Operating frequency/(16x baud rate)
- UART 13x mode: Divisor value = Operating frequency/(13x baud rate)

Table 24-160 describes the UART baud rate settings.

Table 24-160. UART Baud Rate Settings (48-MHz Clock)

Baud Rate	Baud Multiple	DLH,DLL (Decimal)	DLH,DLL (Hex)	Actual Baud Rate	Error (%)

24.3.4.8.1.3 UART Data Formatting

The UART can use hardware flow control to manage transmission and reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals.

The UART is enhanced with the autobauding function. In control mode, autobauding lets the speed, the number of bits per character, and the parity selected be set automatically.

24.3.4.8.1.3.1 Frame Formatting

When autobauding is not used, frame format attributes must be defined in the UARTi.UART_LCR register.

Character length is specified using the UARTi.UART_LCR[1:0] CHAR_LENGTH bit field.

The number of stop-bits is specified using the UARTi.UART_LCR[2] NB_STOP bit.

The parity bit is programmed using the UARTi.UART_LCR[5:3] PARITY_EN, PARITY_TYPE_1, and PARITY_TYPE_2 bit fields (see Table 24-161).

Table 24-161. UART Parity Bit Encoding

PARITY_EN	PARITY_TYPE_1	PARITY_TYPE_2	Parity
0	N/A	N/A	No parity
1	0	0	Odd parity
1	1	0	Even parity
1	0	1	Forced 1
1	1	1	Forced 0

24.3.4.8.1.3.2 Hardware Flow Control

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled and disabled independently by programming the UARTi.UART_EFR[7:6] AUTO_CTS_EN and AUTO_RTS_EN bit fields, respectively.

With auto-CTS, uarti_cts must be active before the module can transmit data.

Auto-RTS activates the uarti_rts output only when there is enough room in the RX FIFO to receive data. It deactivates the uarti_rts output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the UARTi.UART_TCR register determine the levels at which uarti_rts is activated and deactivated.

If auto-CTS and auto-RTS are enabled, data transmission does not occur unless the RX FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If auto-CTS and auto-RTS are not enabled, overrun errors occur if the transmit data rate exceeds the RX FIFO latency.

- Auto-RTS:

  Auto-RTS data flow control originates in the receiver block. The RX FIFO trigger levels used in auto-RTS are stored in the UARTi.UART_TCR register. uarti_rts is active if the RX FIFO level is below the HALT trigger level in the UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit field. When the RX FIFO HALT trigger level is reached, uarti_rts is deasserted. The sending device (for example, another UART) can send an additional byte after the trigger level is reached because it may not recognize the deassertion of RTS until it begins sending the additional byte.

  uarti_rts is automatically reasserted when the RX FIFO reaches the RESUME trigger level programmed by the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START bit field. This reassertion requests the sending device to resume transmission.

  In this case, uarti_rts is an active-low signal.

- Auto-CTS:

  The transmitter circuitry checks uarti_cts before sending the next data byte. When uarti_cts is active, the transmitter sends the next byte. To stop the transmitter from sending the next byte, uarti_cts must be deasserted before the middle of the last stop-bit currently sent.

Copyright © 2011–2012, Texas Instruments Incorporated

The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled, the uarti_cts state changes do not have to trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO, and a receiver overrun error can result.

In this case, uarti_cts is an active-low signal.

24.3.4.8.1.3.3 Software Flow Control

Software flow control is enabled through the enhanced feature register (UARTi.UART_EFR) and the modem control register (UARTi.UART_MCR). Different combinations of software flow control can be enabled by setting different combinations of the UARTi.UART_EFR[3:0] bit field (see Table 24-162).

Two other enhanced features relate to software flow control:

- XON any function (UARTi.UART_MCR[5]): Operation resumes after receiving any character after the XOFF character is recognized. If special character detect is enabled and special character is received after XOFF1, it does not resume transmission. The special character is stored in the RX FIFO.

NOTE: The XON-any character is written into the RX FIFO even if it is a software flow character.

- Special character (UARTi.UART_EFR[5]): Incoming data is compared to XOFF2. When the special character is detected, the XOFF interrupt (UARTi.UART_IIR[4]) is set, but it does not halt transmission. The XOFF interrupt is cleared by a read of UARTi.UART_IIR. The special character is transferred to the RX FIFO. Special character does not work with XON2, XOFF2, or sequential XOFFs.

Table 24-162. UART_EFR[3:0] Software Flow Control Options

Bit 3	Bit 2	Bit 1	Bit 0	TX, RX Software Flow Controls
0	0	X	X	No transmit flow control
1	0	X	X	Transmit XON1, XOFF1
0	1	X	X	Transmit XON2, XOFF2
1	1	X	X	Transmit XON1, XON2: XOFF1, XOFF2(1)
X	X	0	0	No receive flow control
X	X	1	0	Receiver compares XON1, XOFF1
X	X	0	1	Receiver compares XON2, XOFF2
X	X	1	1	Receiver compares XON1, XON2: XOFF1, XOFF2(1)

(1) In these cases, the XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2.
XON1 is defined in the UARTi.UART_XON1_ADDR1[7:0] XON_WORD1 bit field. XON2 is defined in the UARTi.UART_XON2_ADDR2[7:0] XON_WORD2 bit field.
XOFF1 is defined in the UARTi.UART_XOFF1[7:0] XOFF_WORD1 bit field. XOFF2 is defined in the UARTi.UART_XOFF2[7:0] XOFF_WORD2 bit field.

24.3.4.8.1.3.3.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases, XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission stops after transmission of the current character completes. Detection of XOFF also sets the UARTi.UART_IIR[4] bit (if enabled by UARTi.UART_IER[5]) and causes the interrupt line to go low.

To resume transmission, an XON1/2 character must be received (in certain cases, XON1 and XON2 must be received sequentially). When the correct XON characters are received, the UARTi.UART_IIR[4] bit is cleared and the XOFF interrupt disappears.

NOTE: When a parity, framing, or break error occurs while receiving a software flow control character, this character is treated as normal data and is written to the RX FIFO.

Copyright © 2011–2012, Texas Instruments Incorporated

When XON-any and special character detect are disabled and software flow control is enabled, no valid XON or XOFF characters are written to the RX FIFO. For example, when UARTi.UART_EFR[1:0] = 0x2, if XON1 and XOFF1 characters are received, they are not written to the RX FIFO.

When pairs of software flow characters are programmed to be received sequentially (UARTi.UART_EFR[1:0] = 0x3), the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

24.3.4.8.1.3.3.2 Transmit (TX)

Two XOFF1 characters are transmitted when the RX FIFO passes the trigger level programmed by UARTi.UART_TCR[3:0]. As soon as the RX FIFO reaches the trigger level programmed by UARTi.UART_TCR[7:4], two XON1 characters are sent, so the data transfer recovers.

NOTE: If software flow control is disabled after an XOFF character is sent, the module transmits XON characters automatically to enable normal transmission.

The transmission of XOFF(s)/XON(s) follows the same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is 5, 6, or 7 characters, the 5, 6, or 7 LSBs of XOFF1/2 and XON1/2 are transmitted. The 5, 6, or 7 bits of a character are seldom transmitted, but this function is included to maintain compatibility with earlier designs.

It is assumed that software flow control and hardware flow control are never enabled simultaneously.

24.3.4.8.1.3.4 Autobauding Modes

In autobauding mode, the UART can extract transfer characteristics (speed, length, and parity) from an "at" (AT) command (ASCII code). These characteristics are used to receive data after an AT and to send data.

The following AT commands are valid:

AT	DATA	<CR>
at	DATA	<CR>
A/		
a/		

A line break during the acquisition of the sequence AT is not recognized, and an echo function is not implemented in hardware.

A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final <CR> (0x0D), are saved to the RX FIFO. The autobaud state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved in the RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The UARTi.UART_UASR register reflects the correct settings for the baud rate detected. Interrupt activity can continue in this fashion when a subsequent character is received. Therefore, it is recommended that the software enable the RHR interrupt when using the autobaud mode.

The following settings are detected in autobaud mode with a module clock of 48 MHz:

- Speed:
  - 115.2K baud
  - 57.6K baud
  - 38.4K baud

Copyright © 2011–2012, Texas Instruments Incorporated

- 28.8K baud
- 19.2K baud
- 14.4K baud
- 9.6K baud
- 4.8K baud
- 2.4K baud
- 1.2K baud

- Length: 7 or 8 bits
- Parity: Odd, even, or space

NOTE: The combination of 7-bit character plus space parity is not supported.

Autobauding mode is selected when the UARTi.UART_MDR1[2:0] MODE_SELECT bit field is set to 0x2. In UART autobauding mode, UARTi.UART_DLL, UARTi.UART_DLH, and UARTi.UART_LCR[5:0] bit field settings are not used; instead, UART_UASR is updated with the configuration detected by the autobauding logic.

UART_UASR Autobauding Status Register Use

This register is used to set up transmission according to the characteristics of the previous reception instead of the UARTi.UART_LCR, UARTi.UART_DLL, and UARTi.UART_DLH registers when the UART is in autobauding mode.

To reset the autobauding hardware (to start a new AT detection) or to set the UART in standard mode (no autobaud), the UARTi.UART_MDR1[2:0] MODE_ SELECT bit field must be set to reset state (0x7) and then to the UART in autobauding mode (0x2) or to the UART in standard mode (0x0).

Use limitation:

- Only 7- and 8-bit characters (5- and 6-bit not supported)
- 7-bit character with space parity not supported
- Baud rate between 1200 and 115,200 bps (10 possibilities)

24.3.4.8.1.3.5 Error Detection

When the UARTi.UART_LSR register is read, the UARTi.UART_LSR[4:2] bit field reflects the error bits (BI: break condition, FE: framing error, PE: parity error) of the character at the top of the RX FIFO (the next character to be read). Therefore, reading the UARTi.UART_LSR register and then reading the UARTi.UART_RHR register identifies errors in a character.

Reading the UARTi.UART_RHR register updates the BI, FE, and PE bits (see Table 24-146 for the UART mode interrupts).

The UARTi.UART_LSR[7] RX_FIFO_STS bit is set when there is an error in the RX FIFO and is cleared only when no errors remain in the RX FIFO.

NOTE: Reading the UARTi.UART_LSR register does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading the UARTi.UART_RHR register.

Reading the UARTi.UART_LSR register clears the OE bit if it is set (see Table 24-146 for the UART mode interrupts).

24.3.4.8.1.3.6 Overrun During Receive

Overrun during receive occurs if the RX state-machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the MPU with the UARTi.UART_IIR[5:1] IT_TYPE bit field set to 0x3 (receiver line status error) and discards the remaining portion of the frame.

Copyright © 2011–2012, Texas Instruments Incorporated

Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received, the MPU must:

- Reset the RX FIFO.
- Read the UARTi.UART_RESUME register, which clears the internal flag.

24.3.4.8.1.3.7 Time-Out and Break Conditions

24.3.4.8.1.3.7.1 Time-Out Counter

An RX idle condition is detected when the receiver line (uarti_rx) is high for a time that equals 4x the programmed word length + 12 bits. uarti_rx is sampled midway through each bit.

For sleep mode, the counter is reset when there is activity on uarti_rx.

For the time-out interrupt, the counter counts only when there is data in the RX FIFO, and the count is reset when there is activity on uarti_rx or when the UARTi.UART_RHR register is read.

24.3.4.8.1.3.7.2 Break Condition

When a break condition occurs, uarti_tx is pulled low. A break condition is activated by setting the UARTi.UART_LCR[6] BREAK_EN bit. The break condition is not aligned on word stream (a break condition can occur in the middle of a character). The only way to send a break condition on a full character is:

1. Reset the TX FIFO (if enabled).
2. Wait for the transmit shift register to empty (the UARTi.UART_LSR[6] TX_SR_E bit is set to 1).
3. Take a guard time according to stop-bit definition.
4. Set the BREAK_EN bit to 1.

The break condition is asserted while the BREAK_EN bit is set to 1.

The time-out counter and break condition apply only to UART modem operation and not to IrDA/CIR mode operation.

24.3.4.8.2 IrDA Mode (UART3 Only)

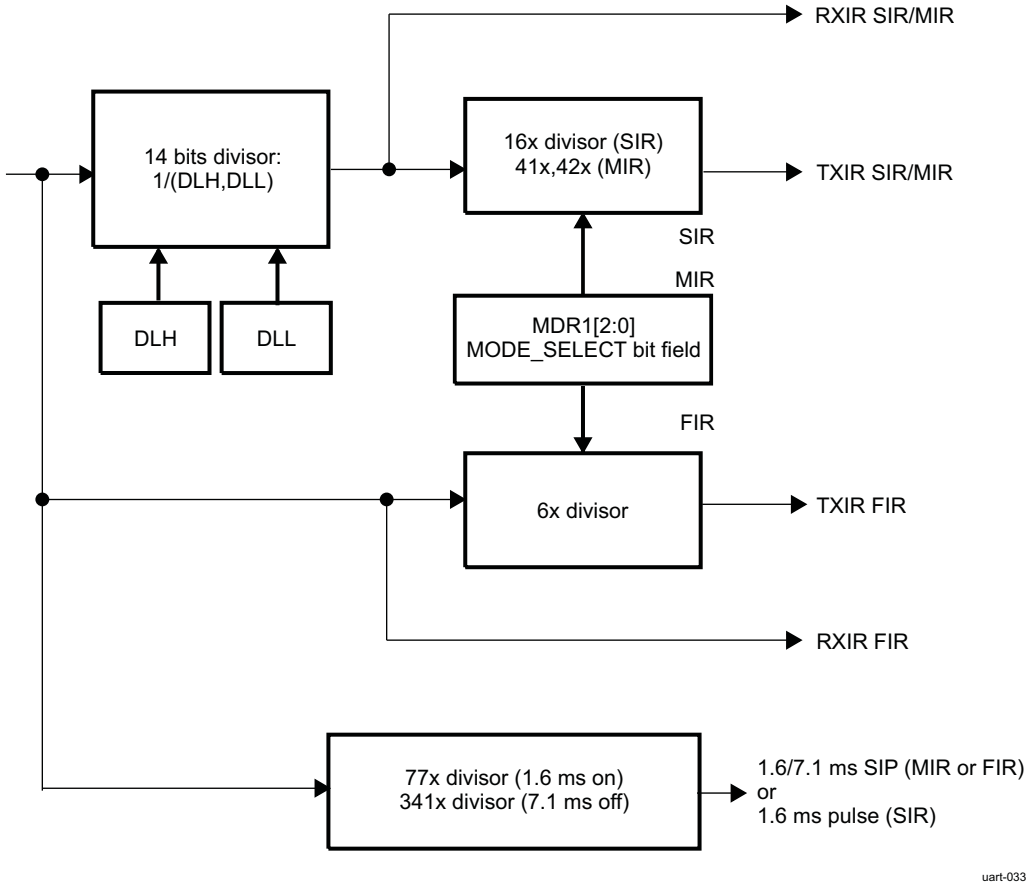
24.3.4.8.2.1 IrDA Clock Generation: Baud Generator

The IrDA function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 24-84 shows the baud rate generator and associated controls.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-84. Baud Rate Generator



CAUTION

Before initializing or modifying clock parameter controls (UARTi.UART_DLH, UARTi.UART_DLL), MODE_SELECT=DISABLE (UARTi.UART_MDR1[2:0]) must be set to 0x7). Failure to observe this rule can result in unpredictable module behavior.

24.3.4.8.2.2 Choosing the Appropriate Divisor Value

Three divisor values are:

- SIR mode: Divisor value = Operating frequency/(16x baud rate)
- MIR mode: Divisor value = Operating frequency/(41x/42x baud rate)
- FIR mode: Divisor value = None

Table 24-163 lists the IrDA baud rate settings.

Table 24-163. IrDA Baud Rate Settings

Baud Rate	IR Mode	Baud Multiple	Encoding	DLH, DLL (Decimal)	Actual Baud Rate	Error (%)	Source Jitter (%)	Pulse Duration
2.4 kbps	SIR	16x	3/16	1250	2.4 kbps	0	0	78.1 µs
9.6 kbps	SIR	16x	3/16	312	9.6153 kbps	+0.16	0	19.5 µs
19.2 kbps	SIR	16x	3/16	156	19.231 kbps	+0.16	0	9.75 µs

57.6 kbps	SIR	16x	3/16	52	57.692 kbps	+0.16	0	3.25 µs

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-163. IrDA Baud Rate Settings (continued)

Baud Rate	IR Mode	Baud Multiple	Encoding	DLH, DLL (Decimal)	Actual Baud Rate	Error (%)	Source Jitter (%)	Pulse Duration
115.2 kbps	SIR	16x	3/16	26	115.38 kbps	+0.16	0	1.62 µs
0.576 Mbps	MIR	41x/42x	1/4	2	0.5756 Mbps(1)	0	+1.63/–0.80	416 ns
1.152 Mbps	MIR	41x/42x	1/4	1	1.1511 Mbps(1)	0	+1.63/–0.80	208 ns
4 Mbps	FIR	6x	4 PPM	–	4 Mbps	0	0	125 ns

(1) Average value

NOTE: Baud rate error and source jitter table values do not include 48-MHz reference clock error and jitter.

24.3.4.8.2.3 IrDA Data Formatting

The methods described in this section apply to all IrDA modes (SIR, MIR, and FIR).

24.3.4.8.2.3.1 IR RX Polarity Control

The UART3.UART_MDR2[6] IRRXINVERT bit provides the flexibility to invert the uart3_rx_irrx pin in the UART to ensure that the protocol at the output of the transceiver has the same polarity at module level. By default, the uart3_rx_irrx pin is inverted because most transceivers invert the IR receive pin.

24.3.4.8.2.3.2 IrDA Reception Control

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

Operation of the uart3_rx_irrx input can be disabled by the UART3.UART_ACREG[5] DIS_IR_RX bit.

24.3.4.8.2.3.3 IR Address Checking

In all IR modes, when address checking is enabled, only frames intended for the device are written to the RX FIFO. This restriction avoids receiving frames not meant for this device in a multipoint infrared environment. It is possible to program two frame addresses that the UART IrDA receives, with the UART3.UART_XON1_ADDR1[7:0] XON_WORD1 and UART3.UART_XON2_ADDR2[7:0] XON_WORD2 bit fields.

Setting the UART_EFR[0] bit to 1 selects address1 checking. Setting the UART_EFR[1] bit to 1 selects address2 checking. Setting the UART_EFR[1:0] bit field to 0 disables all address checking operations. If both bits are set, the incoming frame is checked for private and public addresses.

If address checking is disabled, all received frames write to the RX FIFO.

24.3.4.8.2.3.4 Frame Closing

A transmission frame can be terminated in two ways:

- Frame-length method: Set the UART3.UART_MDR1[7] FRAME_END_MODE bit to 0. The MPU writes the value of the frame length to the UART3.UART_TXFLH and UART3.UART_TXFLL registers. The device automatically attaches end flags to the frame when the number of bytes transmitted equals the value of the frame length.
- Set-EOT bit method: Set the FRAME_END_MODE bit to 1. The MPU writes 1 to the UART3.UART_ACREG[0] EOT bit just before it writes the last byte to the TX FIFO. When the MPU writes the last byte to the TX FIFO, the device internally sets the tag bit for that character in the TX FIFO. As the TX state-machine reads data from the TX FIFO, it uses this tag-bit information to attach end flags and correctly terminate the frame.

Copyright © 2011–2012, Texas Instruments Incorporated

24.3.4.8.2.3.5 Store and Controlled Transmission

In store and controlled transmission (SCT) mode, the MPU starts writing data to the TX FIFO. Then, after writing a part of a frame (for a bigger frame) or an entire frame (a small frame; that is, a supervisory frame), the MPU writes 1 to the UART3.UART_ACREG[2] SCTX_EN bit (deferred TX start) to start transmission.

SCT mode is enabled by setting the UART3.UART_MDR1[5] SCT bit to 1. This transmission method differs from normal mode, in which data transmission starts immediately after data is written to the TX FIFO. SCT mode is useful for sending short frames without TX underrun.

24.3.4.8.2.3.6 Error Detection

When the UART3.UART_LSR register is read, the UART3.UART_LSR[4:2] bit field reflects the error bits [FL, CRC, ABORT] of the frame at the top of the STATUS FIFO (the next frame status to be read).

The error is triggered by an interrupt (for IrDA mode interrupts, see Table 24-147). The STATUS FIFO must be read until empty (a maximum of eight reads is required).

24.3.4.8.2.3.7 Underrun During Transmission

Underrun during transmission occurs when the TX FIFO is empty before the end of the frame is transmitted. When underrun occurs, the device closes the frame with end flags but attaches an incorrect CRC value. The receiving device detects a CRC error and discards the frame; it can then ask for a retransmission.

Underrun also causes an internal flag to be set, which disables additional transmissions. Before the next frame can be transmitted, the MPU must:

- Reset the TX FIFO.
- Read the UART3.UART_RESUME register, which clears the internal flag.

This function can be disabled by the UART3.UART_ACREG[4] DIS_TX_UNDERRUN bit, compensated by the extension of the stop-bit in transmission if the TX FIFO is empty.

24.3.4.8.2.3.8 Overrun During Receive

Overrun during receive for the IrDA mode has the same function as that for the UART mode (see Section 24.3.4.8.1.3.6, *Overrun During Receive*).

24.3.4.8.2.3.9 Status FIFO

In IrDA modes, a status FIFO records the received frame status. When a complete frame is received, the length of the frame and the error bits associated with the frame are written to the status FIFO.

Reading the UART3.UART_SFREGH[3:0] MSB and UART3.UART_SFREGL[3:0] (LSB) bit fields obtains the frame length. The frame error status is read in the UART3.UART_SFLSR register. Reading the UART3.UART_SFLSR register increments the status FIFO read pointer. Because the status FIFO is eight entries deep, it can hold the status of eight frames.

The MPU uses the frame-length information to locate the frame boundary in the received frame data. The MPU can screen bad frames using the error status information and can later request the sender to resend only the bad frames.

This status FIFO can be used effectively in DMA mode because the MPU must be interrupted only when the programmed status FIFO trigger level is reached, not each time a frame is received.

24.3.4.8.2.4 SIR Mode Data Formatting

This section provides specific instructions for SIR mode programming.

24.3.4.8.2.4.1 Abort Sequence

The transmitter can prematurely close a frame (abort) by sending the sequence 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

Copyright © 2011–2012, Texas Instruments Incorporated

A transmission frame can be aborted by setting the UART3.UART_ACREG[1] ABORT_EN bit to 1. When this bit is set to 1, 0x7D and 0xC1 are transmitted and the frame is not terminated with CRC or stop flags.

When a 0x7D character followed immediately by a 0xC1 character is received without transparency, the receiver treats a frame as an aborted frame.

CAUTION

When the TX FIFO is not empty and the UART3.UART_MDR1[5] SCT bit is set to 1, the UART IrDA starts a new transfer with data of a previous frame when the aborted frame is sent. Therefore, the TX FIFO must be reset before sending an aborted frame.

24.3.4.8.2.4.2 Pulse Shaping

SIR mode supports the 3/16 or the 1.6-µs pulse duration methods in receive and transmit. The UART3.UART_ACREG[7] PULSE_TYPE bit selects the pulse width method in the transmit mode.

24.3.4.8.2.4.3 SIR Free Format Programming

The SIR FF mode is selected by setting the module in the UART mode (UART3.UART_MDR1[2:0] MODE_SELECT = 0x0) and the UART3.UART_MDR2[3] UART_PULSE bit to 1 to allow pulse shaping.

Because the bit format stays the same, some UART mode configuration registers must be set at specific values:

- UART3.UART_LCR[1:0] CHAR_LENGTH bit field = 0x3 (8 data bits)
- UART3.UART_LCR[2] NB_STOP bit = 0x0 (1 stop-bit)
- UART3.UART_LCR[3] PARITY_EN bit = 0x0 (no parity)

The UART mode interrupts are used for the SIR FF mode, but many are not relevant (XOFF, RTS, CTS, modem status register, etc.).

24.3.4.8.2.5 MIR and FIR Mode Data Formatting

This section describes common instructions for FIR and MIR mode programming.

At the end of a frame reception, the MPU reads the line status register (UART3.UART_LSR) to detect errors in the received frame.

When the UART3.UART_MDR1[6] SIP_MODE bit is set to 1, the TX state-machine always sends one SIP at the end of a transmission frame. However, when the SIP_MODE bit is set to 0, SIP transmission depends on the UART3.UART_ACREG[3] SEND_SIP bit.

The MPU can set the SEND_SIP bit at least once every 500 ms. The advantage of this approach over the default approach is that the TX state-machine does not have to send the SIP at the end of each frame, thus reducing the overhead required.

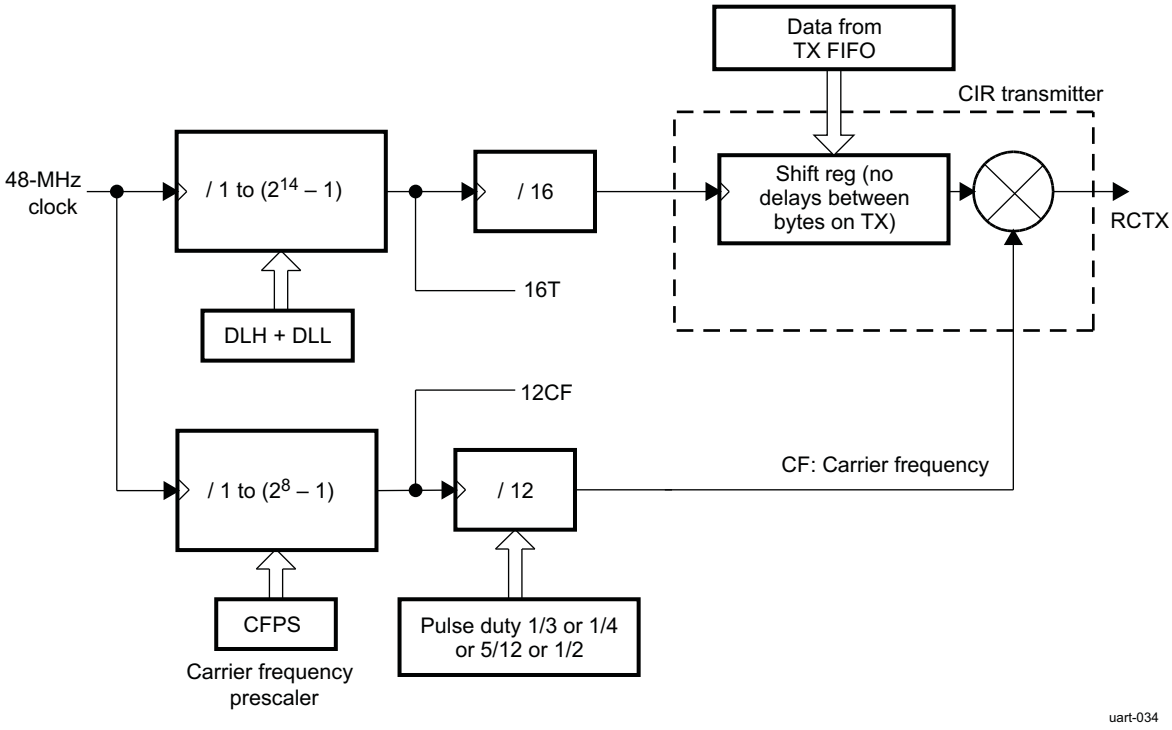
24.3.4.8.3 CIR Mode (UART3 Only)

24.3.4.8.3.1 CIR Mode Clock Generation

Depending on the encoding method (variable pulse distance/biphase), the MPU must develop a data structure that combines 1 and 0 with a *t* period to encode the complete frame to transmit. This can then be transmitted to the infrared output with a modulation method, as shown in Figure 24-85.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-85. CIR Mode Block Components



Based on the requested modulation frequency, the UART3.UART_CFPS register must be set with the correct dividing value to provide an accurate pulse frequency:

Dividing value = (FCLK/12)/MODfreq

Where:

FCLK = System clock frequency (48 MHz)

12 = Real value of baud multiple

MODfreq = Effective frequency of the modulation (MHz)

Example: For a targeted modulation frequency of 36 kHz, the value of UART_CFPS must be set to 0x7 (decimal), which provides a modulation frequency of 36.04 kHz.

NOTE: The UART3.UART_CFPS register starts with a reset value of 105 (decimal), which translates to a frequency of 38.1 kHz.

The duty cycle of these pulses is user-defined by the pulse duty register bits in the UART3.UART_MDR2 register. Table 24-164 shows the duty cycle.

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-164. Duty Cycle

UART_MDR2[5:4]	Duty Cycle (High-Level)
00	1/4
01	1/3
10	5/12
11	1/2

24.3.4.8.3.2 CIR Data Formatting

The methods described in this section apply to all CIR modes.

24.3.4.8.3.2.1 IR RX Polarity Control

The IR RX polarity control for CIR mode has the same function as that for IrDA mode (see Section 24.3.4.8.2.3.1, *IR RX Polarity Control*).

24.3.4.8.3.2.2 CIR Transmission

In transmission, the MPU software must exercise an element of real-time control to transmit data packets, each of which must be emitted at a constant delay from the start-bits of each individual packet. Thus, when sending a series of packets, the packet-to-packet delay must respect a specific delay. Two methods can be used to control this delay:

- Filling the TX FIFO with a number of zero bits that are transmitted with a *t* period
- Using an external system timer to control the delay between each start-of-frame or between the end of a frame and the start of the next one. This can be performed by:
  - Controlling the start of the frame using the UART3.UART_MDR1[5] SCT bit and the UART3.UART_ACREG[2] SCTX_EN bit, depending on the timer status
  - Using the UART3.UART_IIR[5] TX_STATUS_IT interrupt bit to preload the next frame in the TX FIFO and to control the start of the timer (in case of control delay between the end of a frame and the start of the next frame)

24.3.5 UART/IrDA/CIR Basic Programming Model

24.3.5.1 UART Programming Model

24.3.5.1.1 Quick Start

This section describes the procedure for operating the UART with FIFO and DMA or interrupts. This three-part procedure ensures the quick start of the UART. It does not cover every UART feature.

The first programming model covers software reset of the UART. The second programming model describes FIFO and DMA configuration. The last programming model describes protocol, baud rate, and interrupt configuration.

NOTE: Each programming model can be used independently of the other two; for instance, reconfiguring the FIFOs and DMA settings only.

Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see Section 24.3.4.7.1, *Register Access Modes*.

24.3.5.1.1.1 Software Reset

To clear the UART registers, perform the following steps:

Copyright © 2011–2012, Texas Instruments Incorporated

1. Initiate a software reset:
   Set the UARTi.UART_SYSC[1] SOFTRESET bit to 1.
2. Wait for the end of the reset operation:
   Poll the UARTi.UART_SYSS[0] RESETDONE bit until it equals 1.

24.3.5.1.1.2 FIFOs and DMA Settings

To enable and configure the receive and transmit FIFOs and program the DMA mode, perform the following steps:

1. Switch to register configuration mode B to access the UARTi.UART_EFR register:
   (a) Save the current UARTi.UART_LCR register value.
   (b) Set the UARTi.UART_LCR register value to 0x00BF.
2. Enable register submode TCR_TLR to access the UARTi.UART_TLR register (part 1 of 2):
   (a) Save the UARTi.UART_EFR[4] ENHANCED_EN value.
   (b) Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 1.
3. Switch to register configuration mode A to access the UARTi.UART_MCR register:
   Set the UARTi.UART_LCR register value to 0x0080.
4. Enable register submode TCR_TLR to access the UARTi.UART_TLR register (part 2 of 2):
   (a) Save the UARTi.UART_MCR[6] TCR_TLR value.
   (b) Set the UARTi.UART_MCR[6] TCR_TLR bit to 1.
5. Enable the FIFO; load the new FIFO triggers (part 1 of 3) and the new DMA mode (part 1 of 2):
   Set the following bits to the desired values:
   - UARTi.UART_FCR[7:6] RX_FIFO_TRIG
   - UARTi.UART_FCR[5:4] TX_FIFO_TRIG
   - UARTi.UART_FCR[3] DMA_MODE
   - UARTi.UART_FCR[0] FIFO_ENABLE (0: Disable the FIFO; 1: Enable the FIFO)

   NOTE: The UARTi.UART_FCR register is not readable.
6. Switch to register configuration mode B to access the UARTi.UART_EFR register:
   Set the UARTi.UART_LCR register value to 0x00BF.
7. Load the new FIFO triggers (part 2 of 3):
   Set the following bits to the desired values:
   - UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA
   - UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA
8. Load the new FIFO triggers (part 3 of 3) and the new DMA mode (part 2 of 2):
   Set the following bits to the desired values:
   - UARTi.UART_SCR[7] RX_TRIG_GRANU1
   - UARTi.UART_SCR[6] TX_TRIG_GRANU1
   - UARTi.UART_SCR[2:1] DMA_MODE_2
   - UARTi.UART_SCR[0] DMA_MODE_CTL
9. Restore the UARTi.UART_EFR[4] ENHANCED_EN value saved in Step 2a.
10. Switch to register configuration mode A to access the UARTi.UART_MCR register:
    Set the UARTi.UART_LCR register value to 0x0080.
11. Restore the UARTi.UART_MCR[6] TCR_TLR value saved in Step 4a.
12. Restore the UARTi.UART_LCR value saved in Step 1a.

Copyright © 2011–2012, Texas Instruments Incorporated

Triggers are used to generate interrupt and DMA requests. See Section 24.3.4.6.1.1, *Transmit FIFO Trigger,* to choose the following values:

- UARTi.UART_FCR[5:4] TX_FIFO_TRIG
- UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA
- UARTi.UART_SCR[6] TX_TRIG_GRANU1

Triggers are used to generate interrupt and DMA requests. See Section 24.3.4.6.1.2, *Receive FIFO Trigger*, to choose the following values:

- UARTi.UART_FCR[7:6] RX_FIFO_TRIG
- UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA
- UARTi.UART_SCR[7] RX_TRIG_GRANU1

DMA mode enables DMA requests. See Section 24.3.4.6.4, *FIFO DMA Mode Operation*, to choose the following values:

- UARTi.UART_FCR[3] DMA_MODE
- UARTi.UART_SCR[2:1] DMA_MODE_2
- UARTi.UART_SCR[0] DMA_MODE_CTL

24.3.5.1.1.3 Protocol, Baud Rate, and Interrupt Settings

To program the protocol, baud rate, and interrupt settings, perform the following steps:

1. Disable UART to access the UARTi.UART_DLL and UARTi.UART_DLH registers:

   Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Switch to register configuration mode B to access the UARTi.UART_EFR register:

   Set the UARTi.UART_LCR register value to 0x00BF.
3. Enable access to the UARTi.UART_IER[7:4] bit field:

   (a) Save the UARTi.UART_EFR[4] ENHANCED_EN value.

   (b) Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 1.
4. Switch to register operational mode to access the UARTi.UART_IER register:

   Set the UARTi.UART_LCR register value to 0x0000.
5. Clear the UARTi.UART_IER register (set the UARTi.UART_IER[4] SLEEP_MODE bit to 0 to change the UARTi.UART_DLL and UARTi.UART_DLH registers). Set the UARTi.UART_IER register value to 0x0000.
6. Switch to register configuration mode B to access the UARTi.UART_DLL and UARTi.UART_DLH registers:

   Set the UARTi.UART_LCR register value to 0x00BF.
7. Load the new divisor value:

   Set the UARTi.UART_DLL[7:0] CLOCK_LSB and UARTi.UART_DLH[5:0] CLOCK_MSB bit fields to the desired values.
8. Switch to register operational mode to access the UARTi.UART_IER register:

   Set the UARTi.UART_LCR register value to 0x0000.
9. Load the new interrupt configuration (0: Disable the interrupt; 1: Enable the interrupt):

   Set the following bits to the desired values:
   - UARTi.UART_IER[7] CTS_IT
   - UARTi.UART_IER[6] RTS_IT
   - UARTi.UART_IER[5] XOFF_IT
   - UARTi.UART_IER[4] SLEEP_MODE
   - UARTi.UART_IER[3] MODEM_STS_IT
   - UARTi.UART_IER[2] LINE_STS_IT
   - UARTi.UART_IER[1] THR_IT

Copyright © 2011–2012, Texas Instruments Incorporated

- UARTi.UART_IER[0] RHR_IT

10. Switch to register configuration mode B to access the UARTi.UART_EFR register:

    Set the UARTi.UART_LCR register value to 0x00BF.

11. Restore the UARTi.UART_EFR[4] ENHANCED_EN value saved in Step 3a.
12. Load the new protocol formatting (parity, stop-bit, character length) and switch to register operational mode:

    Set the UARTi.UART_LCR[7] DIV_EN bit to 0.

    Set the UARTi.UART_LCR[6] BREAK_EN bit to 0.

    Set the following bits to the desired values:

    - UARTi.UART_LCR[5] PARITY_TYPE_2
    - UARTi.UART_LCR[4] PARITY_TYPE_1
    - UARTi.UART_LCR[3] PARITY_EN
    - UARTi.UART_LCR[2] NB_STOP
    - UARTi.UART_LCR[1:0] CHAR_LENGTH

13. Load the new UART mode:

    Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to the desired value.

See Section 24.3.4.8.1.2, *Choosing the Appropriate Divisor Value*, to choose the following values:

- UARTi.UART_DLL[7:0] CLOCK_LSB
- UARTi.UART_DLH[5:0] CLOCK_MSB
- UARTi.UART_MDR1[2:0] MODE_SELECT

See Section 24.3.4.8.1.3.1, *Frame Formatting*, to choose the following values:

- UARTi.UART_LCR[5] PARITY_TYPE_2
- UARTi.UART_LCR[4] PARITY_TYPE_1
- UARTi.UART_LCR[3] PARITY_EN
- UARTi.UART_LCR[2] NB_STOP
- UARTi.UART_LCR[1:0] CHAR_LENGTH

24.3.5.1.2 Hardware and Software Flow Control Configuration

This section describes the programming steps to enable and configure hardware and software flow control. Hardware and software flow control cannot be used at the same time.

NOTE: Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see Section 24.3.4.7.1, *Register Access Modes*.

24.3.5.1.2.1 Hardware Flow Control Configuration

To enable and configure hardware flow control, perform the following steps:

1. Switch to register configuration mode A to access the UARTi.UART_MCR register:
   (a) Save the current UARTi.UART_LCR register value.
   (b) Set the UARTi.UART_LCR register value to 0x0080.
2. Enable register submode TCR_TLR to access the UARTi.UART_TCR register (part 1 of 2):
   (a) Save the UARTi.UART_MCR[6] TCR_TLR value.
   (b) Set the UARTi.UART_MCR[6] TCR_TLR bit to 1.
3. Switch to register configuration mode B to access the UARTi.UART_EFR register:

Copyright © 2011–2012, Texas Instruments Incorporated

Set the UARTi.UART_LCR register value to 0x00BF.

4. Enable register submode TCR_TLR to access the UARTi.UART_TCR register (part 2 of 2):
   (a) Save the UARTi.UART_EFR[4] ENHANCED_EN value.
   (b) Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 1.
5. Load the new start and halt trigger values for hardware flow control:
   Set the following bits to the desired values:
   - UARTi.UART_TCR[7:4] AUTO_RTS_START
   - UARTi.UART_TCR[3:0] AUTO_RTS_HALT
6. Enable or disable receive and transmit hardware flow control mode and restore the UARTi.UART_EFR[4] ENHANCED_EN value saved in Step 4a.
   Set the following bits to the desired values:
   - UARTi.UART_EFR[7] AUTO_CTS_EN (0: Disable; 1: Enable)
   - UARTi.UART_EFR[6] AUTO_RTS_EN (0: Disable; 1: Enable)

   Restore the UARTi.UART_EFR[4] ENHANCED_EN bit to the saved value.
7. Switch to register configuration mode A to access the UARTi.UART_MCR register:
   Set the UARTi.UART_LCR register value to 0x0080.
8. Restore the UARTi.UART_MCR[6] TCR_TLR value saved in Step 2a.
9. Restore the UARTi.UART_LCR value saved in Step 1a.

See Section 24.3.4.8.1.3.2, *Hardware Flow Control*, to choose the following values:

- UARTi.UART_EFR[7] AUTO_CTS_EN
- UARTi.UART_EFR[6] AUTO_RTS_EN
- UARTi.UART_TCR[7:4] AUTO_RTS_START
- UARTi.UART_TCR[3:0] AUTO_RTS_HALT

24.3.5.1.2.2 Software Flow Control Configuration

To enable and configure software flow control, perform the following steps:

1. Switch to register configuration mode B to access the UARTi.UART_EFR register.
   (a) Save the current UARTi.UART_LCR register value.
   (b) Set the UARTi.UART_LCR register value to 0x00BF.
2. Enable register submode XOFF to access the UARTi.UART_XOFF1 and UARTi.UART_XOFF2 registers:
   (a) Save the UARTi.UART_EFR[4] ENHANCED_EN value.
   (b) Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 0.
3. Load the new software flow control characters:
   Set the following bits to the desired values:
   - UARTi.UART_XON1_ADDR1[7:0] XON_WORD1
   - UARTi.UART_XON2_ADDR2[7:0] XON_WORD2
   - UARTi.UART_XOFF1[7:0] XOFF_WORD1
   - UARTi.UART_XOFF2[7:0] XOFF_WORD2
4. Enable access to the UARTi.UART_MCR[7:5] bit field and enable register submode TCR_TLR to access the UARTi.UART_TCR register (part 1 of 2):
   Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 1.
5. Switch to register configuration mode A to access the UARTi.UART_MCR register:
   Set the UARTi.UART_LCR register value to 0x0080.
6. Enable register submode TCR_TLR to access the UARTi.UART_TCR register (part 2 of 2) and enable or disable XON any function:

Copyright © 2011–2012, Texas Instruments Incorporated

(a) Save the UARTi.UART_MCR[6] TCR_TLR value.

(b) Set the UARTi.UART_MCR[6] TCR_TLR bit to 1.

(c) Set the UARTi.UART_MCR[5] XON_EN bit to the desired value (0: Disable; 1: Enable).

7. Switch to register configuration mode B to access the UARTi.UART_EFR register:

   Set the UARTi.UART_LCR register value to 0x00BF.

8. Load the new start and halt trigger values for software flow control:

   Set the following bits to the desired values:

   - UARTi.UART_TCR[7:4] AUTO_RTS_START
   - UARTi.UART_TCR[3:0] AUTO_RTS_HALT

9. Enable or disable special character function and load the new software flow control mode and restore the UARTi.UART_EFR[4] ENHANCED_EN value saved in Step 2a:

   Set the following bits to the desired values:

   - UARTi.UART_EFR[5] SPEC_CHAR (0: Disable; 1: Enable)
   - UARTi.UART_EFR[3:0] SW_FLOW_CONTROL

   Restore the UARTi.UART_EFR[4] ENHANCED_EN bit to the saved value.

10. Switch to register configuration mode A to access the UARTi.UART_MCR register:

    Set the UARTi.UART_LCR register value to 0x0080.

11. Restore the UARTi.UART_MCR[6] TCR_TLR bit value saved in Step 6a.
12. Restore the UARTi.UART_LCR value saved in Step 1a.

See Section 24.3.4.8.1.3.3, *Software Flow Control*, to choose the following values:

- UARTi.UART_EFR[5] SPEC_CHAR
- UARTi.UART_EFR[3:0] SW_FLOW_CONTROL
- UARTi.UART_TCR[7:4] AUTO_RTS_START
- UARTi.UART_TCR[3:0] AUTO_RTS_HALT
- UARTi.UART_XON1_ADDR1[7:0] XON_WORD1
- UARTi.UART_XON2_ADDR2[7:0] XON_WORD2
- UARTi.UART_XOFF1[7:0] XOFF_WORD1
- UARTi.UART_XOFF2[7:0] XOFF_WORD2

Copyright © 2011–2012, Texas Instruments Incorporated

24.3.5.2 IrDA Programming Model (UART3 Only)

24.3.5.2.1 SIR Mode

24.3.5.2.1.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with parity forced to 1, baud rate = 112.5KB, FIFOs disabled, 2 stop-bits, and 8-bit word length:

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers:
   Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_DLL and UART_DLH registers (the UART_LCR[7] DIV_EN bit = 1):
   UART3.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UART3.UART_LCR register in IrDA mode.)
3. Load the new baud rate (115.2 kbps):
   UART3.UART_DLL = 0x1A
   UART3.UART_DLH = 0x00
4. Set SIR mode:
   UART3.UART_MDR1[2:0] MODE_SELECT = 0x1
5. Disable access to the UART_DLL and UART_DLH registers and switch to register operational mode:
   UART3.UART_LCR = 0x00.
6. Optional: Enable the RHR interrupt:
   UART3.UART_IER[0] RHR_IT = 0x1

24.3.5.2.1.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 6-byte frame with no parity, baud rate = 112.5 kbps, FIFOs disabled, 3/16 encoding, 2 stop-bits, and 7-bit word length:

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers:
   Set the UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_EFR register:
   UART3.UART_LCR = 0xBF
3. Enable the enhanced features (the UART_EFR[4] ENAHNCED_EN bit = 1):
   Set the UART3.UART_EFR register value to 0x10.
4. Grant access to the UART_DLL and UART_DLH registers (the UART_LCR[7] DIV_EN bit = 1):
   UART3.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UART3.UART_LCR register in IrDA mode.)
5. Load the new baud rate (115.2 kbps):
   UART3.UART_DLL = 0x1A
   UART3.UART_DLH = 0x00
6. Set SIR mode (the UART_MDR1[2:0] MODE_SELECT bit field = 0x1):
   UART3.UART_MDR1 = 0x01
7. Disable access to the UART_DLL and UART_DLH registers and switch to register operational mode:
   UART3.UART_LCR = 0x00.
8. Force DTR output to active:
   UART3.UART_MCR[0] DTR = 1
9. Optional: Enable the THR interrupt:
   UART3.UART_IER[1] THR_IT = 1
10. Set transmit frame length to 6 bytes:
    UART3.UART_TXFLL = 0x06
11. Set 7 starts of frame transmission:
    UART3.UART_EBLR = 0x08
12. Optional: Set SIR pulse width to be 1.6 us:
    UART3.UART_ACREG[7] PULSE_TYPE = 1
13. Load the UART_THR register with the data to be transmitted.

Copyright © 2011–2012, Texas Instruments Incorporated

24.3.5.2.2 MIR Mode

24.3.5.2.2.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with no parity, baud rate = 1.152 Mpbs, and FIFOs disabled.

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers:
   Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_DLL and UART_DLH registers (UART_LCR[7] DIV_EN bit = 1):
   UART3.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UART3.UART_LCR register in IrDA mode.)
3. Load the new baud rate (1.152 Mpbs):
   UART3.UART_DLL = 0x01
   UART3.UART_DLH = 0x00
4. Set MIR mode:
   UART3.UART_MDR1[2:0] MODE_SELECT = 0x4
5. Disable access to the UART_DLL and UART_DLH registers and switch to register operational mode:
   UART3.UART_LCR = 0x00
6. Force DTR output to active (UART_MCR[0] DTR = 1):
   Force RTS output to active (UART_MCR[1] RTS = 1).
   UART3.UART_MCR = 0x3
7. Optional: Enable the RHR interrupt:
   UART3.UART_IER[0] RHR_IT = 1

24.3.5.2.2.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 60-byte frame with no parity, baud rate = 1.152 Mpbs, and FIFOs disabled:

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers:
   Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_DLL and UART_DLH registers (UART_LCR[7] DIV_EN bit = 1):
   UART3.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UART3.UART_LCR register in IrDA mode.)
3. Load the new baud rate (1.152 Mpbs):
   UART3.UART_DLL = 0x01
   UART3.UART_DLH = 0x00
4. Set MIR mode:
   UART3.UART_MDR1[2:0] MODE_SELECT = 0x4
5. Disable access to the UART_DLL and UART_DLH registers and switch to register operational mode:
   UART3.UART_LCR = 0x00
6. Force DTR output to active:
   UART3.UART_MCR[0] DTR = 1
7. Optional: Enable the THR interrupt:
   UART3.UART_IER[1] THR_IT = 1
8. Set the frame length to 60 bytes:
   UART3.UART_TXFLL = 0x3C
9. Optional: Transmit eight additional starts of frame (MIR mode requires two starts):
   UART3.UART_EBLR = 0x08
10. SIP is sent at the end of transmission:
    UART3.UART_ACREG[3] = 1
11. Load the UART_THR register with the data to be transmitted.

Copyright © 2011–2012, Texas Instruments Incorporated

24.3.5.2.3 FIR Mode

24.3.5.2.3.1 Receive

The following programming model explains how to program the module to receive the IrDA frame with no parity, baud rate = 4 Mbps, FIFOs enabled, 8-bit word length.

1. Disable the UART before accessing the UART3.UART_DLL and UART3.UART_DLH registers:
   Set the UART3.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_DLL and UART_DLH registers (UART_LCR[7] DIV_EN bit = 1):
   UART3.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UART3.UART_LCR register in IrDA mode.)
3. FIFO clear and enable:
   UART3.UART_FCR = 0x7 (TX/RX FIFO trigger: UART_FCR[7:6] and UART_FCR[5:4])
   UART3.UART_LCR[7] = 0
4. Set FIR mode:
   UART3.UART_MDR1[2:0] MODE_SELECT = 0x5
5. Set frame length:
   UART3.UART_RXFLL = 0xA (Data + CRC + STOP)
6. Disable access to the UART3.UART_DLL registers and UART3.UART_DLH and switch to register operational mode:
   UART3.UART_LCR[7] DIV_EN = 0x0
7. Optional: Enable the RHR interrupt:
   UART3.UART_IER[0] RHR_IT = 1

24.3.5.2.3.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 4-byte frame with no parity, baud rate = 4 Mbps, FIFOs enabled, and 8-bit word length.

1. Disable the UART before accessing the UART3.UART_DLL and UART3.UART_DLH registers:
   Set the UART3.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to EFR_REG:
   UART3.UART_LCR = 0xBF
3. Enable the enhanced features (EFR_REG[4] ENAHNCED_EN = 0x1):
   UART3.UART_EFR = 0x10
4. FIFO clear and enable:
   UART3.UART_FCR = 0x7 (TX/RX FIFO trigger: UART_FCR[7:6] and UART_FCR[5:4]).
   UART3.UART_LCR[7] = 0
5. Set FIR mode and enable auto-SIP mode:
   UART3.UART_MDR1 = 0x45
6. Set frame length:
   UART3.UART_TXFLL = 0x4
   UART3.UART_TXFLH = 0x0
   UART3.UART_RXFLL = 0xA (Data + CRC + STOP)
   UART3.UART_RXFLH = 0x0
7. Force DTR output to active:
   UART3.UART_MCR[0] DTR = 0x1
8. Optional: Enable the THR interrupt:
   UART3.UART_IER[1] THR_IT = 0x1
9. Optional: Transmit eight additional starts of frame (MIR mode requires two starts):
   UART3.UART_EBLR = 0x08
10. SIP is sent at the end of transmission:
    UART3.UART_ACREG[3] = 1
11. Load the UART_THR register with the data to be transmitted.

Copyright © 2011–2012, Texas Instruments Incorporated

24.3.6 UART/IrDA/CIR Register Manual

24.3.6.1 UART/IrDA/CIR Instance Summary

Table 24-165 shows the base address and address space for the UART/IrDA/CIR module instances.

Table 24-165. UART/IrDA/CIR Instance Summary

Module Name	Base Address	Size
UART1[1]	0x4806 A000	1KB
UART2[1]	0x4806 C000	1KB
UART3[2]	0x4802 0000	1KB
UART4[1]	0x4806 E000	1KB

(1) UART mode only
(2) UART, IrDA, or CIR mode

24.3.6.2.2 UART/IrDA/CIR Register Description

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-168. UART_THR

Address Offset	0x0000 0000		
Physical Address	0x4806 A000 0x4806 C000 0x4802 0000 0x4806 E000	**Instance**	UART1 UART2 UART3 UART4
Description	The transmitter section consists of the transmit holding register (THR) and the transmit shift register. The THR is a 64-byte FIFO. The local host (LH) writes data to the THR. The data is placed in the transmit shift register where it is shifted out serially on the TX output. If the FIFO is disabled, location 0 of the FIFO stores the data.		
Type	W		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 24-170. UART_RHR

Address Offset	0x0000 0000		
Physical Address	0x4806 A000 0x4806 C000 0x4802 0000 0x4806 E000	**Instance**	UART1 UART2 UART3 UART4
Description	The receiver section consists of the receiver holding register (RHR) and the receiver shift register. The RHR is a 64-byte FIFO. The receiver shift register receives serial data from RX input. The data is converted to parallel data and moved to the RHR. If the FIFO is disabled, location 0 of the FIFO stores the single data character. **Note:** If an overflow occurs, the data in the RHR is not overwritten.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 24-176. UART_IER_IRDA

Address Offset	0x0000 0004		
Physical Address	0x4806 A004 0x4806 C004 0x4802 0004 0x4806 E004	**Instance**	UART1 UART2 UART3 UART4
Description	There are 8 types of interrupt in these modes: received EOF, LSR interrupt, TX status, status FIFO interrupt, RX overrun, last byte in RX FIFO, THR interrupt, and RHR interrupt. These interrupts can be enabled and disabled individually. Note: The TX_STATUS_IT interrupt reflects two possible conditions. The MDR2[0] should be read to determine the status in the event of this interrupt.

Table 24-178. UART_IER_CIR

Address Offset	0x0000 0004		
Physical Address	0x4806 A004 0x4806 C004 0x4802 0004 0x4806 E004	**Instance**	UART1 UART2 UART3 UART4
Description	There are 6 types of interrupt in these modes: TX status, status FIFO interrupt, RX overrun, last byte in RX FIFO, THR interrupt, and RHR interrupt. These interrupts can be enabled and disabled individually. Note: The RX_STOP_IT interrupt is generated based on the value set in the BOF Length register (EBLR). In IR-CIR mode, contrary to the IR-IRDA mode, the TX_STATUS_IT has only one meaning that corresponds to the case MDR2[0] = 0.

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0.	R	0x000000
7	THR_EMPTY	Read 0x0: Transmit holding register (TX FIFO) is not empty. Read 0x1: Transmit hold register (TX FIFO) is empty. The transmission is not necessarily complete.	R	1
6	STS_FIFO_FULL	Read 0x0: Status FIFO not full Read 0x1: Status FIFO full	R	0
5	RX_LAST_BYTE	Read 0x0: The RX FIFO (RHR) does not contain the last byte of the frame to be read.	R	0

Copyright © 2011–2012, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
		Read 0x1: The RX FIFO (RHR) contains the last byte of the frame to be read. This bit is set only when the last byte of a frame is available to be read. It determines the frame boundary. It is cleared on a single read of the LSR register. See the note below.		
4	FRAME_TOO_LONG	Read 0x0: No frame-too-long error in frame Read 0x1: Frame-too-long error in the frame at the top of the STATUS FIFO, (next character to be read). This bit is set to 1 when a frame exceeding the maximum length (set by RXFLH and RXFLL registers) is received. When this error is detected, current frame reception is terminated. Reception is stopped until the next START flag is detected.	R	0
3	ABORT	Read 0x0: No abort pattern error in frame Read 0x1: Abort pattern is received. SIR and MIR: Abort pattern FIR: Illegal symbol	R	0
2	CRC	Read 0x0: No CRC error in frame Read 0x1: CRC error in the frame at the top of the STATUS FIFO (next character to be read)	R	0
1	STS_FIFO_E	Read 0x0: Status FIFO not empty Read 0x1: Status FIFO empty	R	1
0	RX_FIFO_E	Read 0x0: No data in the RX FIFO Read 0x1: At least one data character in the RX FIFO	R	1

Table 24-206. UART_TCR

Address Offset	0x0000 0018		
Physical Address	0x4806 A018 0x4806 C018 0x4802 0018 0x4806 E018	**Instance**	UART1 UART2 UART3 UART4
Description	Transmission control register This register stores the RX FIFO threshold levels to start/stop transmission during hardware/software flow control. Notes: Trigger levels from 0 to 60 bytes are available with a granularity of 4. (Trigger level = 4 x [4-bit register value]) The programmer must ensure that UART_TCR[3:0] > UART_TCR[7:4] when auto-RTS or software flow control is enabled to avoid a mis-operation of the device. In FIFO interrupt mode with flow control, the programmer must ensure that the trigger level to halt transmission is greater than or equal to the RX FIFO trigger level (UART_TLR[7:4] or UART_FCR[7:6]); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist because a DMA request is sent each time a byte is received.		
Type	RW

Table 24-218. UART_MDR1

Address Offset	0x0000 0020		
Physical Address	0x4806 A020 0x4806 C020 0x4802 0020 0x4806 E020	**Instance**	UART1 UART2 UART3 UART4
Description	Mode definition register 1 The mode of operation can be programmed by writing to MDR1[2:0] and therefore the MDR1 must be programmed on startup after configuration of the configuration registers (UART_DLL, UART_DLH, and UART_LCR). The value of MDR1[2:0] must not be changed again during normal operation. **Note:** If the module is disabled by setting the MODE_SELECT field to 111, interrupt requests can still be generated unless disabled through the interrupt enable register (IER). In this case, UART mode interrupts are visible. Reading the interrupt identification register (IIR) shows UART mode interrupt flags.

Table 24-220. UART_MDR2

Address Offset	0x0000 0024		
Physical Address	0x4806 A024	**Instance**	UART1
	0x4806 C024		UART2
	0x4802 0024		UART3
	0x4806 E024		UART4
Description	Mode definition register 2		
	IR-IrDA and IR-CIR modes only. UART_MDR2[0] describes the status of the interrupt in UART_IIR[5]. The IRTX_UNDERRUN bit should be read after an UART_IIR[5] TX_STATUS_IT interrupt. The bits [2:1] of this register set the trigger level for the frame status FIFO (8 entries) and must be programmed before the mode is programmed in UART_MDR1[2:0]. **Note:** The UART_MDR2[6] gives the flexibility to invert the RX pin in the UART to ensure that the protocol at the input of the transceiver module has the same polarity at module level. By default, the RX pin is inverted because most transceivers invert the IR receive pin.		
Type	RW

RESERVED																								SET_TXIR_ALT	IRRXINVERT	CIR_PULSE_MODE		UART_PULSE	STS_FIFO_TRIG		IRTX_UNDERRUN

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0. Write has no effect.	RW	0x000000
7	SET_TXIR_ALT	Provide alternate function for MDR1[4] (SET_TXIR). 0x0: Normal mode 0x1: Alternate mode for SET_TXIR	R	0
6	IRRXINVERT	IR mode only (IrDA and CIR). Invert RX pin in the module before the voting or sampling system logic of the infrared block. This does not affect the RX path in UART modem modes. 0x0: Inversion is performed. 0x1: No inversion is performed.	RW	0
5:4	CIR_PULSE_MODE	CIR pulse modulation definition. Defines high level of the pulse width associated with a digit: 0x0: Pulse width of 3 from 12 cycles 0x1: Pulse width of 4 from 12 cycles 0x2: Pulse width of 5 from 12 cycles 0x3: Pulse width of 6 from 12 cycles	RW	0x0
3	UART_PULSE	UART mode only. Allows pulse shaping in UART mode. 0x0: Normal UART mode 0x1: UART mode with a pulse shaping	RW	0
2:1	STS_FIFO_TRIG	IR-IrDA mode only. Frame status FIFO threshold select: 0x0: 1 entry 0x1: 4 entries 0x2: 7 entries 0x3: 8 entries	RW	0x0

Copyright © 2011–2012, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
0	IRTX_UNDERRUN	IrDA transmission status interrupt. When the UART_IIR[5] interrupt occurs, the meaning of the interrupt is: Read 0x0: The last bit of the frame transmitted successfully without error. Read 0x1: An underrun occurred. The last bit of the frame was transmitted but with an underrun error. The bit is reset to 0 when the UART_RESUME register is read.	R	0

Table 24-240. UART_UASR

Address Offset	0x0000 0038		
Physical Address	0x4806 A038 0x4806 C038 0x4802 0038 0x4806 E038	**Instance**	UART1 UART2 UART3 UART4
Description	UART autobauding status register UART autobauding mode only. This status register returns the speed, the number of bits by characters, and the type of the parity in UART autobauding mode. In autobauding mode, the input frequency of the UART modem must be fixed to 48 MHz. Any other module clock frequency results in incorrect baud rate recognition. **Note:** When the UART is in autobauding mode, this register, instead of the LCR, DLL, and DLH registers, is used to set up transmission according to the characteristics of the previous reception. To reset the autobauding hardware (to start a new AT detection), set MDR1[2:0] to 111 (reset value), then set MDR1[2:1] to 010 (UART in autobaud mode). To set the UART to standard mode (no autobaud), set MDR1[2:1] to 000.

Table 24-242. UART_ACREG

Address Offset	0x0000 003C		
Physical Address	0x4806 A03C 0x4806 C03C 0x4802 003C 0x4806 E03C	**Instance**	UART1 UART2 UART3 UART4
Description	Auxiliary control register. IR-IrDA and IR-CIR modes only.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								PULSE_TYPE	SD_MOD	DIS_IR_RX	DIS_TX_UNDERRUN	SEND_SIP	SCTX_EN	ABORT_EN	EOT_EN

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0. Write has no effect.	RW	0x000000
7	PULSE_TYPE	SIR pulse width select 0x0: 3/16 of baud-rate pulse width 0x1: 1.6 µs	RW	0
6	SD_MOD	Primary output used to configure transceivers. Connected to the SD/MODE input pin of IrDA transceivers. 0x0: SD pin is set to high. 0x1: SD pin is set to low.	RW	0
5	DIS_IR_RX	0x0: Normal operation (RX input automatically disabled during transmit but enabled outside of transmit operation) 0x1: Disables RX input (permanent state - independent of transmit)	RW	0
4	DIS_TX_UNDERRUN	It is recommended to disable TX FIFO underrun capability by masking corresponding underrun interrupt. When disabling underrun by setting ACREG[4] = 1, garbage data is sent over TX line. 0x0: Long stop-bits cannot be transmitted; TX underrun is enabled. 0x1: Long stop-bits can be transmitted; TX underrun is disabled.	RW	0
3	SEND_SIP	MIR/FIR modes only. Send serial infrared interaction pulse (SIP). If this bit is set during an MIR/FIR transmission, the SIP is sent at the end of it. This bit is cleared automatically at the end of the SIP transmission. 0x0: No action 0x1: Send SIP pulse.	RW	0
2	SCTX_EN	Store and controlled TX start. When MDR1[5] = 1 and the LH writes 1 to this bit, the TX state-machine starts frame transmission. This bit is self-clearing.	RW	0
1	ABORT_EN	Frame abort. The LH can intentionally abort transmission of a frame by writing 1 to this bit. Neither the end flag nor the CRC bits are appended to the frame. If TX FIFO is not empty and MDR1[5] = 1, UART IrDA starts a new transfer with data of the previous frame when the abort frame is sent. Therefore, TX FIFO must be reset before sending an abort frame.	RW	0

Copyright © 2011–2012, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
0	EOT_EN	EOT (end of transmission) bit. The LH writes 1 to this bit just before it writes the last byte to the TX FIFO in set-EOT bit frame closing method. This bit is cleared automatically when the LH writes to the THR (TX FIFO).	RW	0

Table 24-248. UART_EBLR

Address Offset	0x0000 0048		
Physical Address	0x4806 A048 0x4806 C048 0x4802 0048 0x4806 E048	**Instance**	UART1 UART2 UART3 UART4
Description	BOF length register IR-IrDA and IR-CIR modes only. In IR-IrDA SIR operation, this register specifies the number of BOF + xBOFs to transmit. Value set into this register must account for the BOF character; therefore, to send only one BOF with no XBOF, this register must be set to 1. To send one BOF with N XBOF, this register must be set to N + 1. The value 0 sends 1 BOF plus 255 XBOF. In IR-IrDA MIR mode, this register specifies the number of additional start flags (MIR protocol mandates a minimum of 2 start flags). In IR-CIR mode, this register specifies the number of consecutive 0s to be received before generating the RX_STOP interrupt (UART_IIR[2]). All received 0s are stored in the RX FIFO. When the register is set to 0, this feature is deactivated and always in reception state, which can be disabled by setting the ACREG[5] to 1. **Note:** If the RX_STOP interrupt occurs before a byte boundary, the remaining bits of the last byte are filled with 0s and passed into the RX FIFO.		
Type	RW

Physical Address	0x4806 A05C 0x4806 C05C 0x4802 005C 0x4806 E05C	**Instance**	UART1 UART2 UART3 UART4
Description	Wake-up enable register The UART wake-up enable register is used to mask and unmask a UART event that would subsequently notify the system. An event is any activity in the logic that could cause an interrupt and/or an activity that would require the system to wake up. Even if the wakeup is disabled for certain events, if these events are also an interrupt to the UART, the UART registers the interrupt.

Physical Address	0x4806 A060 0x4806 C060 0x4802 0060 0x4806 E060	**Instance**	UART1 UART2 UART3 UART4
Description	Carrier frequency prescaler Because the consumer IR works at modulation rates of 30 to 56.8 kHz, the 48-MHz clock must be prescaled before the clock can drive the IR logic. This register sets the divisor rate to give a range to accommodate the remote-control requirements in baud multiples of 12x. The value of the CFPS at reset is 0105 decimal, which equals 38.1 kHz output from starting conditions. The 48-MHz carrier is prescaled by the CFPS, which is then divided by the 12x baud multiple.

24.4 Multichannel Serial Port Interface

This section describes the four multichannel serial port interface (MCSPI) modules for the device.

24.4.1 MCSPI Overview

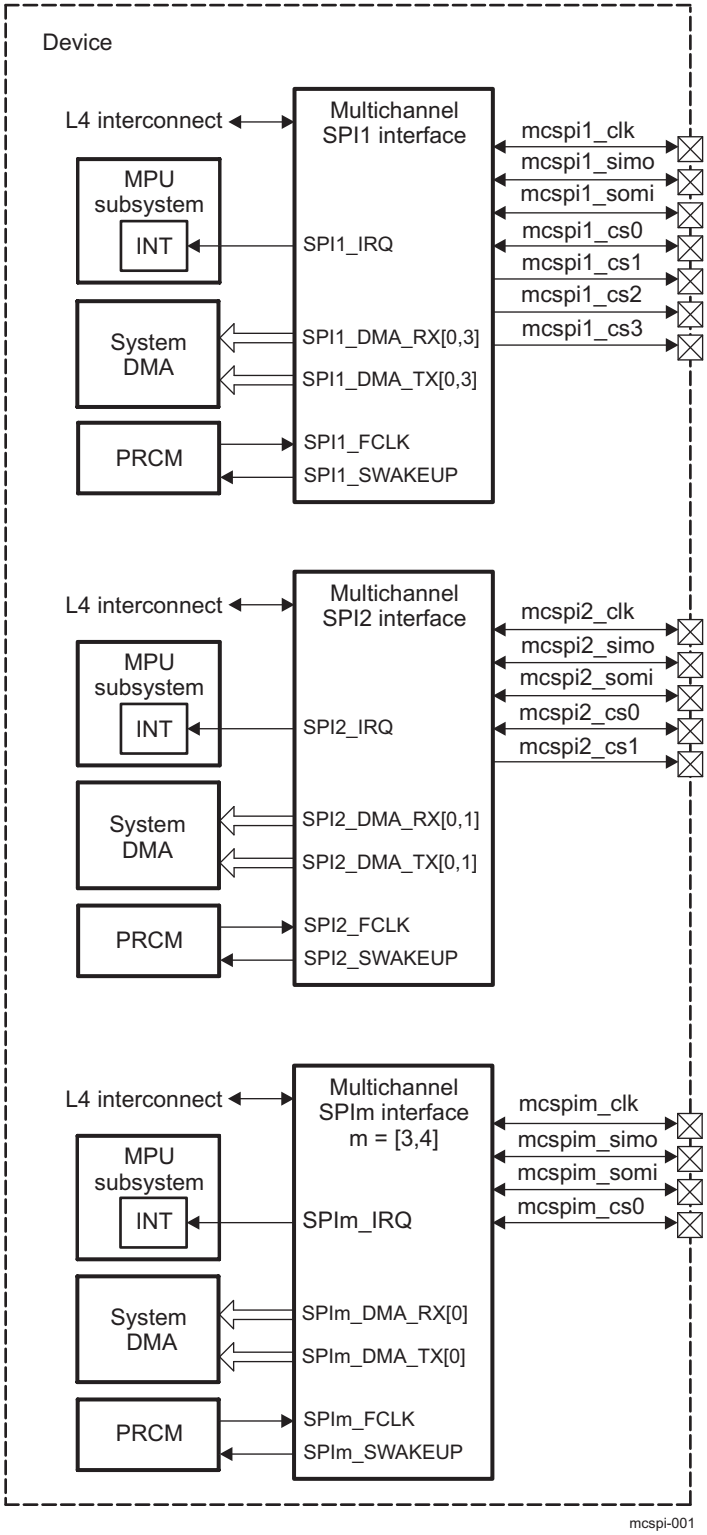
The MCSPI is a master/slave synchronous serial bus. The MCSPI has four separate modules (SPI1, SPI2, SPI3, and SPI4) in the device (see Figure 24-86). The MCSPI modules differ as follows: SPI1 supports up to four peripherals, SPI2 supports up to two peripherals, SPI3 and SPI4 support only one peripheral.

NOTE: In this chapter, *m = [1,4]* represents the module instance and *x* represents the channel in signal and register naming. The MCSPI has four instances, with each module instance having different channel numbers:

- SPI1: 4 channels (if *m = 1*, *x = 4*)
- SPI2: 2 channels (if *m = 2*, *x = 2*)
- SPI3: 1 channel (if *m = 3*, *x = 1*)
- SPI4: 1 channel (if *m = 4*, *x = 1*)

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-86. Multichannel Modules SPI1, SPI2, SPI3, and SPI4



The MCSPI instances include the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of SPI word lengths, ranging from 4 to 32 bits
- Up to four master channels, or single channel in slave mode

Copyright © 2011–2012, Texas Instruments Incorporated

- Master multichannel mode:
  - Full duplex/half duplex
  - Transmit-only/receive-only/transmit-and-receive modes
  - Flexible I/O port controls per channel
  - Two DMA requests (read/write) per channel
- Single interrupt line for multiple interrupt source events
- Power management through wake-up capabilities
- Enable the addition of a programmable start-bit for SPI transfer per channel (start-bit mode)
- Supports start-bit write command
- Supports start-bit pause and break sequence
- 64-byte built-in FIFO available for a single channel
- Force CS mode for continuous transfers

24.4.2 MCSPI Environment

Figure 24-87 shows a simplified overview of a typical application system using the MCSPI. This example is based on a TFS chip set, including a 2.2-inch color-active matrix thin-film transistor (TFT) liquid crystal display (LCD) with a light-emitting diode (LED) front light, a 4-wire resistive touch-screen panel, and LCD controllers. This chip set is associated with a touch-screen controller, powered by a power-management unit, and driven by the device. The MCSPI device interface is set to master mode; the touch-screen MCSPI controller interface operates in slave mode.

Table 24-275. MCSPI I/O Description (Slave Mode) (continued)

Signal Name	I/O	Description	Reset [1]
mcspim_simo	I	SPIm module serial data master out (slave input, master output)	Unknown
mcspim_somi	O	SPIm module serial data master input (slave output, master input)	–
mcspim_csx	I	SPIm module chip-select x output	Low

24.4.2.1.3 Multichannel SPI Protocol and Data Format

The synchronous SPI protocol allows a master device to initiate serial data transfers to a slave device. A slave select line (mcspim_csx) allows selection of an individual slave SPI device. Slave devices that are not selected do not interfere with SPI bus activities.

MCSPI offers the flexibility to modify the following parameters to adapt to the device features:

- Word length

  MCSPI supports any SPI word ranging from 4 bits to 32 bits long (the SPIm.MCSPI_CHxCONF[11:7] WL bit field).

  SPI word length can be changed between transmissions to allow the master device to communicate with peripheral slaves that have different requirements.
- SPI enable (mcspim_csx, for channel x of instance m)

  The polarity of the SPI enable signals is programmable (the SPIm.MCSPI_CHxCONF[6] EPOL bit). mcspim_csx signals can be active high or low.

  Assertion of the mcspim_csx signals is programmable and can be done manually or automatically. The manual assertion mode is available in single master mode only. mcspim_csx can be kept active between words with the SPIm.MCSPI_CHxCONF[20] FORCE bit.

  Two consecutive words for two different slave devices can go along with active mcspim_csx signals with different polarity.
- Programmable start-bit

  In start-bit mode a start-bit is added before the SPI word length to indicate how the next SPI word must be handled. The start-bit is enabled by setting the SPIm.MCSPI_CHxCONF[23] SBE bit to 1. The SPIm.MCSPI_CHxCONF[24] SBPOL bit defines the polarity of the start-bit.
- Programmable SPI clock
  - Bit rate

    In master mode, the baud rate of the SPI serial clock is programmable using the 48-MHz reference clock (from the PRCM module). Table 24-276 lists the spim_clk bit rates obtained for data transfer when programming the clock divider (the SPIm.MCSPI_CHxCONF[5:2] CLKD bit field).

Table 24-276. SPI Master Clock Rates

Divider	Clock Rate
1	48 MHz
2	24 MHz
4	12 MHz
8	6 MHz
16	3 MHz
32	1.5 MHz
64	750 kHz
128	375 kHz
256	~187 kHz
512	~93.7 kHz
1024	~46.8 kHz

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-276. SPI Master Clock Rates (continued)

Divider	Clock Rate
2048	~23.4 kHz
4096	~11.7 kHz

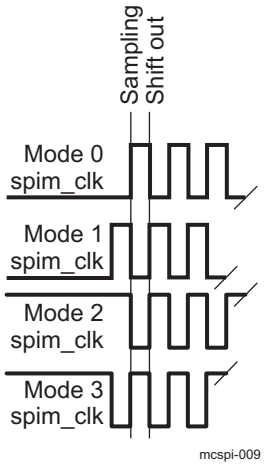
– Polarity and phase

The polarity (the SPIm.MCSPI_CHxCONF[1] POL bit) and the phase (the SPIm.MCSPI_CHxCONF[0] PHA bit) of the SPI serial clock (mcspim_clk) are configurable to offer four combinations. Software selects the right combination, depending on the device. See Table 24-277 and Figure 24-90.

Table 24-277. Phase and Polarity Combinations

Polarity (POL)	Phase (PHA)	SPI Mode	Comments
0	0	Mode 0	mcspim_clk is active high and sampling occurs on the rising edge.
0	1	Mode 1	mcspim_clk is active high and sampling occurs on the falling edge.
1	0	Mode 2	mcspim_clk is active low and sampling occurs on the falling edge.
1	1	Mode 3	mcspim_clk is active low and sampling occurs on the rising edge.

Figure 24-90. Phase and Polarity Combinations



24.4.2.1.3.1 Transfer Format

In master and slave modes, the MCSPI drives the data lines when spim_csx is asserted.

Each word is transmitted starting with the MSB.

This section explains the two cases of data transmission determined by the clock phase (PHA) and the type of data transmission using a start-bit (SBE) called the start-bit mode:

- Transmission in mode 0 and mode 2 (PHA = 0)

  When PHA = 0, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid one-half cycle of spim_clk after the assertion of spim_csx.

  Therefore, the first edge of the mcspim_clk line is used by the master to sample the first data bit sent by the slave. On the same edge, the first data bit sent by the master is sampled by the slave.

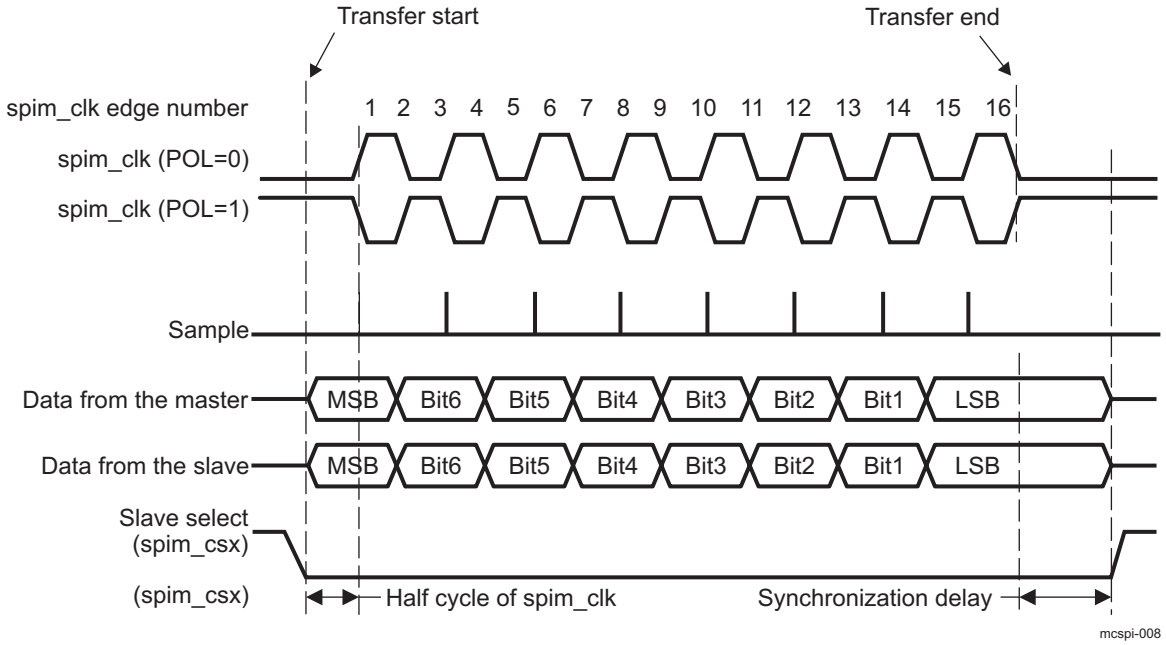
  On the next mcspim_clk edge, the received data bit is shifted into the receive shift register and a new data bit is transmitted on the serial data line.

  This process continues for a number of pulses on the spim_clk line defined by the SPI word length

Copyright © 2011–2012, Texas Instruments Incorporated

programmed in the master device, with data being latched on odd-numbered edges and shifted on even-numbered edges. See Figure 24-91.

Figure 24-91. Full-Duplex Transfer Format With PHA = 0



- Transmission in mode 1 and mode 3 (PHA = 1)

  When PHA = 1, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid on the following mcspim_clk edge (one-half cycle later). This is the sampling edge for the master and slave. A synchronization delay is added between the activation of mcspim_csx and the first mcspim_clk edge.

  The received data bit is shifted into the shift register on the third mcspim_clk edge.

  This process continues for a number of pulses on the mcspim_clk line defined by the SPI word length programmed in the master device, with data being latched on even-numbered edges and shifted on odd-numbered edges.

  NOTE: The minimum synchronization delay is one cycle of mcspim_clk, if the frequency of mcspim_clk equals the frequency of SPIm_FCLK (MCSPIm functional clock) in master mode. The minimum synchronization delay is one-half cycle of mcspim_clk, if the frequency of mcspim_clk is lower than the frequency of SPIm_FCLK in the master and slave modes.

- Transmission with a start-bit (SBE = 1)

  When the SPIm.MCSPI_CHxCONF[23] SBE bit is set to 1, a start-bit is added before the MSB to indicate whether the next SPI word must be handled as a command or as data.

  Figure 24-92 shows an example of a data transfer with an extra start-bit.

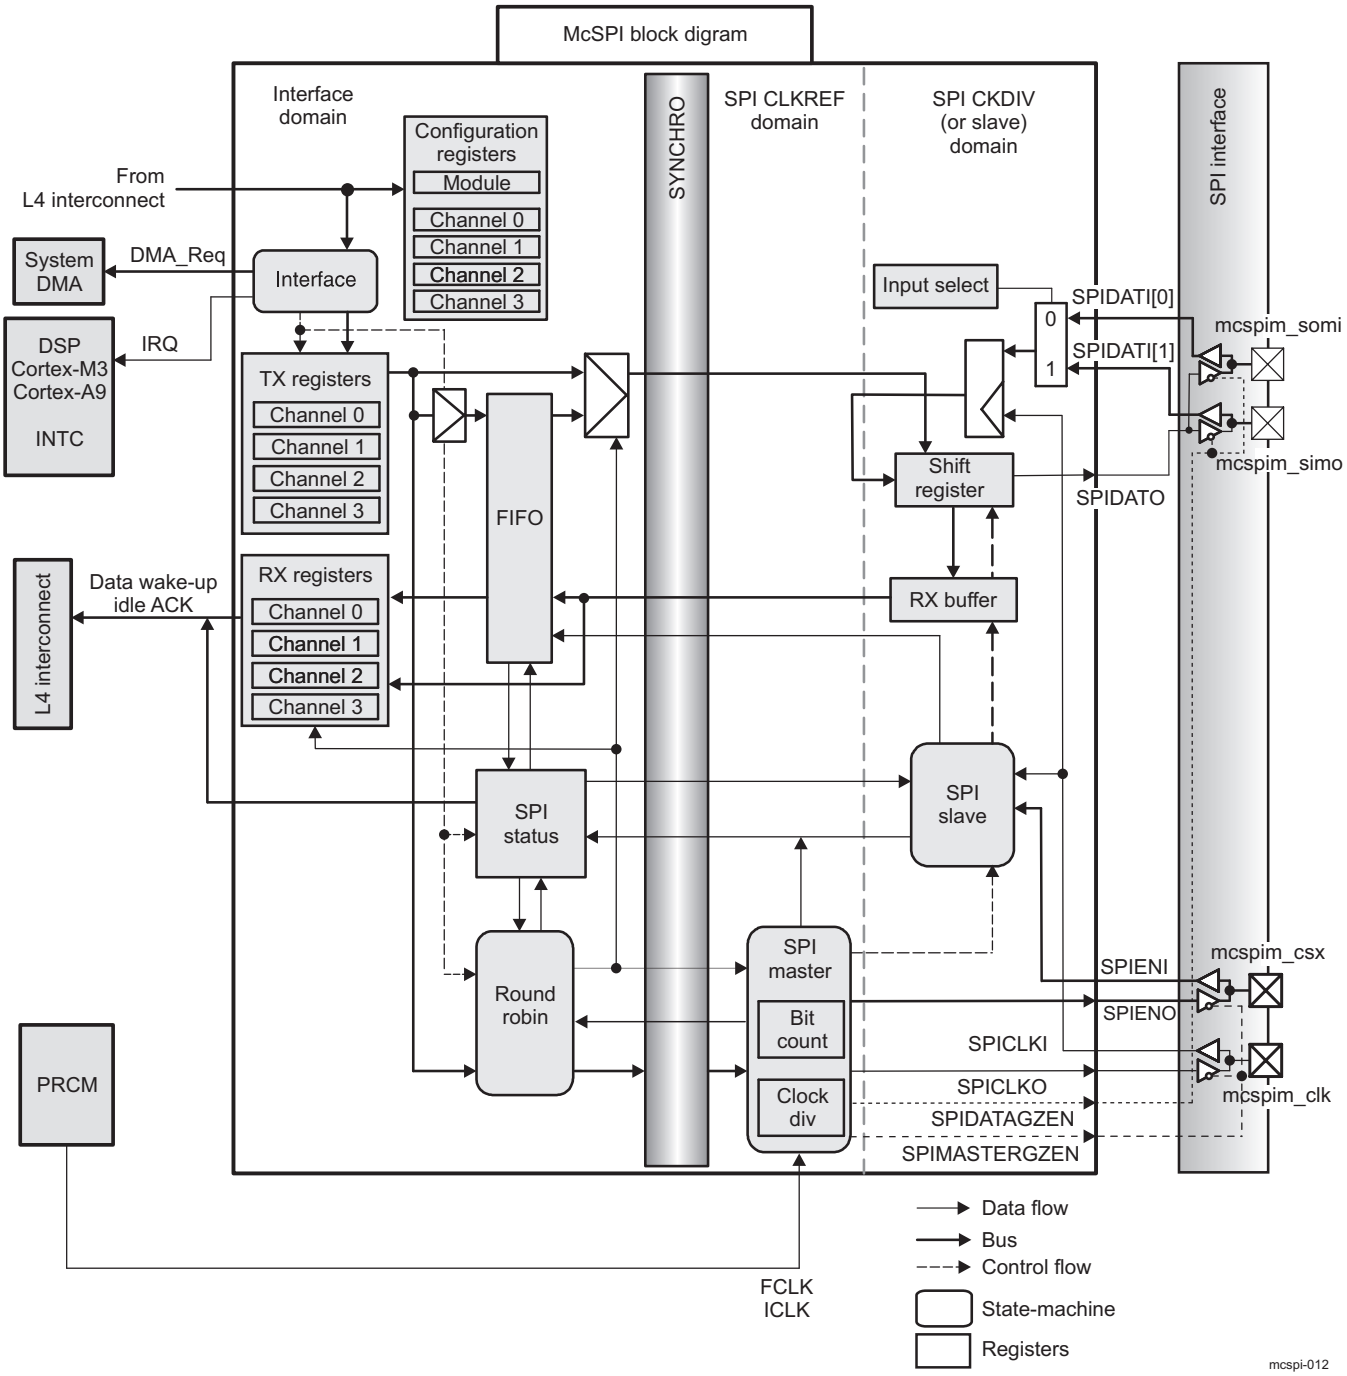
24.4.4 MCSPI Functional Description

24.4.4.1 MCSPI Block Diagram

Figure 24-98 shows the MCSPI module.

Figure 24-98. MCSPI Block Diagram



Copyright © 2011–2012, Texas Instruments Incorporated

24.4.4.2 Master Mode

24.4.4.2.1 Master Mode Features

The MCSPI master mode supports multichannel communication with up to four independent SPI communication channel contexts. The MCSPI initiates a data transfer on the data lines (mcspim_simo and mcspim_somi) and generates clock (mcspim_clk) and control (mcspim_csx) signals.

Connected to multiple external devices, the MCSPI exchanges data with one SPI device at a time through two main modes (available in slave mode):

- Two-data-pins interface mode (transmit-and-receive mode for full-duplex transmission)
- Single-data-pin interface mode (recommended for half-duplex transmission)

Two DMA request events (read and write) allow synchronized accesses of the DMA controller with the activity of MCSPI.

Three interrupt events can be used for data transmission and reception in master mode (for more information about interrupts, see Section 24.4.4.5.1, *Interrupt Events in Master Mode*).

24.4.4.2.2 Master Transmit-and-Receive Mode (Full Duplex)

In full-duplex transmission, data is transmitted (shifted out serially on mcspim_simo) and received (shifted in serially on mcspim_somi) simultaneously on separate data lines.

The master transmit-and-receive mode is programmable per channel (the SPIm.MCSPI_CHxCONF[13:12] TRM bit field).

Channel access to the shift registers for transmission/reception is based on the MCSPI_TXx transmitter register state, the MCSPI_RXx receiver register state, and round-robin arbitration.

Channels that meet the following rules are included in the round-robin list of active channels scheduled for transmission and/or reception. The arbiter skips channels that do not meet the rules and searches in the rotation for the next enabled channel.

- Rule 1: Only enabled channels (the SPIm.MCSPI_CHxCTRL[0] EN bit) can be scheduled for transmission and/or reception.
- Rule 2: If its MCSPI_TXx transmitter register is not empty (the SPIm.MCSPI_CHxSTAT[1] TXS bit), an enabled channel can be scheduled when the shift register is assigned. If the MCSPI_TXx register is empty when the shift register is assigned, the TXx_UNDERFLOW event is activated, and the next enabled channel with new data to transmit is scheduled (see also transmit-only mode).
- Rule 3: An enabled channel can be scheduled if its receive register is not full (the SPIm.MCSPI_CHxSTAT[0] RXS bit) when the shift register is assigned (see also receive-only mode). Therefore, the MCSPI_RXx register cannot be overwritten. The SPI1.MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set to this mode.

When SPI word transfer completes (the SPIm.MCSPI_CHxSTAT[2] EOT bit is set), the updated MCSPI_TXx register of the next scheduled channel is loaded into the shift register. The serialization (transmit-and-receive) starts depending on the channel communication configuration. When serialization completes, the received data transfers to the channel receive register.

The serial clock (mcspim_clk) synchronizes shifting and sampling of the information on the two serial data lines (mcspim_simo and mcspim_somi). Each time a bit transfers out from the master, 1 bit transfers in from the slave.

Figure 24-99 shows an example of a full-duplex system with a master device (MCSPI module *m*) on the left and a slave device on the right. After eight cycles of the serial clock mcspim_clk, WordA transfers from the master to the slave. At the same time, WordB transfers from the slave to the master.

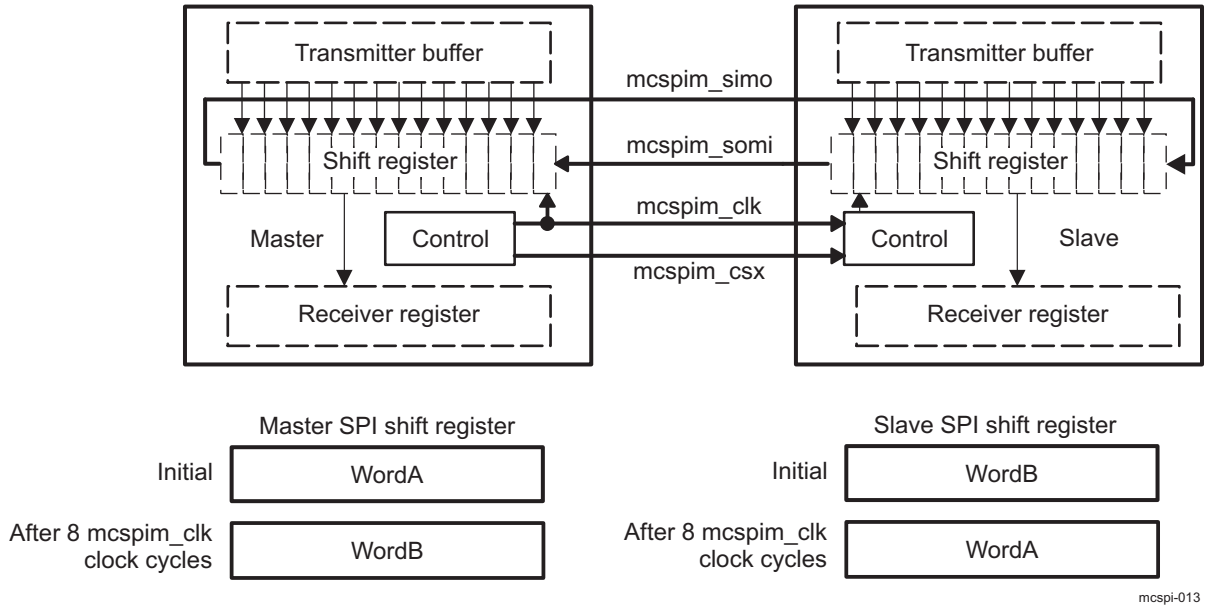
Figure 24-99. SPI Full-Duplex Transmission (Example)



24.4.4.2.3 Master Transmit-Only Mode (Half Duplex)

The master transmit-only mode prevents the MPU from reading the MCSPI_RXx register (minimizing data movement) when only transmission is meaningful.

The master transmit-only mode is programmable per channel (the SPIm.MCSPI_CHxCONF[13:12] TRM field). Transmission starts only after data is loaded into the MCSPI_TXx register.

Rule 1 and Rule 2, defined in Section 24.4.4.2.2, apply in this mode.

Rule 3, defined in Section 24.4.4.2.2, does not apply.

In master transmit-only mode, the MCSPI_RXx register state FULL does not prevent transmission and the MCSPI_RXx register is always overwritten with the new SPI word. This event is not significant when only transmission is meaningful. Thus, the RX0_OVERFLOW bit in the SPIm.MCSPI_IRQSTATUS register is never set in this mode.

The hardware automatically disables the RX_FULL interrupt and the DMA read requests.

The transfer status is given by the SPIm.MCSPI_CHxSTAT[2] EOT bit.

24.4.4.2.4 Master Receive-Only Mode (Half Duplex)

The master receive mode prevents the MPU from refilling the MCSPI_TXx register (minimizing data movement) when only reception is meaningful.

The master receive mode is programmable per channel (the SPIm.MCSPI_CHxCONF[13:12] TRM bit field).

The master receive-only mode enables channel scheduling only on the empty state of the MCSPI_RXx register.

Rule 1 and Rule 3, defined in Section 24.4.4.2.2, apply in this mode.

Rule 2, defined in Section 24.4.4.2.2, does not apply.

Copyright © 2011–2012, Texas Instruments Incorporated

In the master receive-only mode, software must write dummy data to the MCSPI_TXx register. Only one dummy write is enough to receive any number of words from the slave. Software should ensure that the MCSPI_TXx register is always full (the TXx_EMPTY bits of SPIm.MCSPI_IRQSTATUS) when receiving. The content of the MCSPI_TXx register is always loaded into the shift register when the shift register is assigned. After writing the dummy data to the MCSPI_TXx register, the TXx_EMPTY and TXx_UNDERFLOW bits in the SPIm.MCSPI_IRQSTATUS register are never set in receive-only mode.

The SPIm.MCSPI_CHxSTAT[2] EOT bit gives the status of serialization. The RXx_FULL bits of the SPIm.MCSPI_IRQSTATUS register are set when received data is loaded from the shift register to the corresponding MCSPI_RXx register. The SPIm.MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set in this mode.

24.4.4.2.5 Single-Channel Master Mode

When the MCSPI is configured as a master device with a single enabled channel, the assertion of the mcspim_csx signal can be controlled in two different ways:

- If the MCSPI_MODULCTRL[0] SINGLE bit is set to 0, mcspim_csx assertion and deassertion after each SPI word is automatically controlled by the MCSPI (see subsections of Section 24.4.4.2.1, *Master Mode Features*).
- If the MCSPI_MODULCTRL[0] SINGLE and MCSPI_CHxCONF[20] FORCE bits are set to ,: mcspim_csx assertion and deassertion is controlled by software (see Section 24.4.4.2.5.1, *Programming Tips When Switching to Another Channel*).

24.4.4.2.5.1 Programming Tips When Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for completion of the SPI word transfer (wait until the SPIm.MCSPI_CHxSTAT[2] EOT bit is set to 1) before disabling the current channel and enabling a different channel.
- Disable the current channel, and then enable the other channel.

24.4.4.2.5.2 Force mcspim_csx Mode

Continuous transfers are allowed manually by keeping the mcspim_csx signal active for successive SPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the mcspim_csx line. This mode is supported by all channels and any master sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the mcspim_csx active mode is supported when:

- A single channel is used (with the SPIm.MCSPI_MODULCTRL[0] SINGLE bit set to 1).
- Transfer parameters are loaded in the configuration register of the appropriate channel (SPIm.MCSPI_CHxCONF).

  The state of the mcspim_csx signal is programmable.

  – Writing 1 to the SPIm.MCSPI_CHxCONF[20] FORCE bit drives the mcspim_csx line high when the SPIm.MCSPI_CHxCONF[6] EPOL bit is set to 0. mcspim_csx is driven low when the SPIm.MCSPI_CHxCONF[6] EPOL bit is set to 1.

  – Writing 0 to the SPIm.MCSPI_CHxCONF[20] FORCE bit drives the mcspim_csx line low when the SPIm.MCSPI_CHxCONF[6] EPOL bit is set to 0. mcspim_csx is driven high when the SPIm.MCSPI_CHxCONF[6] EPOL bit is set to 1.
- A single channel is enabled (the SPIm.MCSPI_CHxCTRL[0] EN bit is set to 1). The first enabled channel activates the mcspim_csx line.

When the channel is enabled, the mcspim_csx signal activates with the programmed polarity. As in the multichannel master mode, the transfer start depends on the status of the MCSPI_TXx register (the SPIm.MCSPI_CHxSTAT[1] TXS bit), the status of the MCSPI_RXx register (the SPIm.MCSPI_CHxSTAT[1] RXS bit), and the defined mode (the SPIm.MCSPI_CHxCONF[13:12] TRM bit field) of the channel enabled.

Copyright © 2011–2012, Texas Instruments Incorporated

The SPIm.MCSPI_CHxSTAT[2] EOT bit gives the transfer status of each SPI word. The RXx_FULL bit in the SPIm.MCSPI_IRQSTATUS register is set when received data is loaded from the shift register to the MCSPI_RXx register.

A change in the configuration parameters is propagated directly on the SPI interface. If the mcspim_csx signal is activated, ensure that the configuration is changed only between SPI words to avoid corrupting the current transfer.

NOTE: To avoid data corruption, mcspim_csx polarity and mcspim_clk phase and mcspim_clk polarity must not be modified when the mcspim_csx signal is activated.

A delay between SPI words that requires the connected SPI slave device to switch from one configuration to another (for instance, from transmit-only to receive-only) must be handled by software.

At the end of the last SPI word, the channel must be deactivated (the SPIm.MCSPI_CHxCTRL[0] EN bit set to 0) and mcspim_csx can be forced to its INACTIVE state using the SPIm.MCSPI_CHxCONF[20] FORCE bit.

Figure 24-100 and Figure 24-101 show successive transfers with mcspim_csx maintained active low with a different configuration for each SPI word in single-data-pin and dual-data-pin interface modes, respectively.

Figure 24-100. Continuous Transfers With mcspim_csx Maintained Active (Single-Data-Pin Interface Mode)

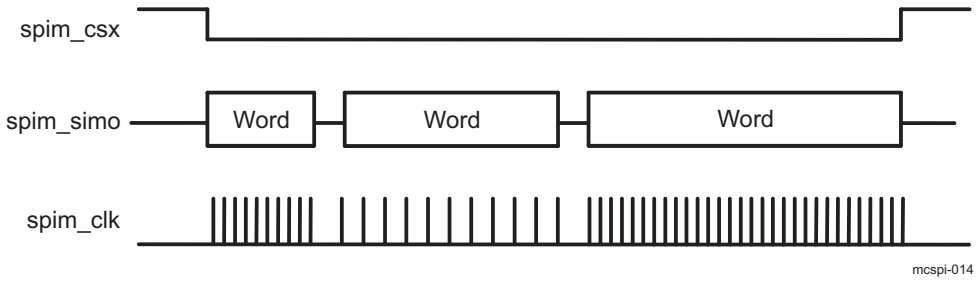


Figure 24-101. Continuous Transfers With mcspim_csx Maintained Active (Dual-Data-Pin Interface Mode)

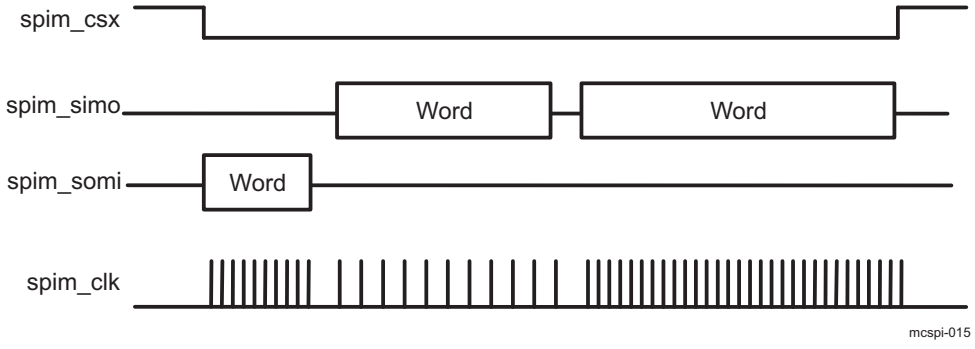


NOTE: Turbo mode described in Section 24.4.4.2.5.3, *Turbo Mode*, maintains mcspim_csx in active mode when the following conditions are met:

- A single channel is explicitly used (the SPIm.MCSPI_MODULCTRL[0] SINGLE bit is set to 1).
- Turbo mode is enabled in the configuration of the channel (the SPIm.MCSPI_CHxCONF[19] TURBO bit is set to 1).

Copyright © 2011–2012, Texas Instruments Incorporated

24.4.4.2.5.3 Turbo Mode

Turbo mode improves the throughput of the SPI interface when a single channel is enabled by allowing transfers until the shift register and the MCSPI_RXx register are full. Turbo mode is time saving when a transfer exceeds two words. This mode is programmable per channel (through the SPI1.MCSPI_CHxCONF[9] TURBO bit).

When several channels are enabled, the TURBO bit has no effect and the channel access to the shift registers remains as previously described.

In turbo mode, Rule 1 and Rule 2 apply, but Rule 3 does not (see Section 24.4.4.2.2). An enabled channel can be scheduled if its receive register is full (the SPIm.MCSPI_CHxSTAT[0] RXS bit) at the time of the shift-register assignment until the shift register is full.

The MCSPI_RXx register cannot be overwritten in turbo mode. Consequently, the SPIm.MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set in this mode.

24.4.4.2.6 Start-Bit Mode

In start-bit mode, an extended bit is added before the SPI word to indicate whether the next SPI word must be handled as a command or as data. This feature is available only in master mode. Start-bit mode cannot be used at the same time as turbo mode and/or force mcspim_csx mode. In this case, only one channel can be used; round-robin arbitration is not possible.

This mode is programmable per channel by setting the SPIm.MCSPI_CHxCONF[23] SBE bit to 1. The polarity of the extended bit is programmable per channel. When the SPIm.MCSPI_CHxCONF[24] SBPOL bit is set to 0, the SPI word must be handled as a command. When the SPIm.MCSPI_CHxCONF[24] SBPOL bit is set to 1, the SPI word must be handled as data. Moreover, start-bit polarity can be changed dynamically during start-bit transfer without disabling the channel for reconfiguration; in this case, users must configure the SPIm.MCSPI_CHxCONF[24] SBPOL bit before writing the SPI word to be transmitted to the TX register.

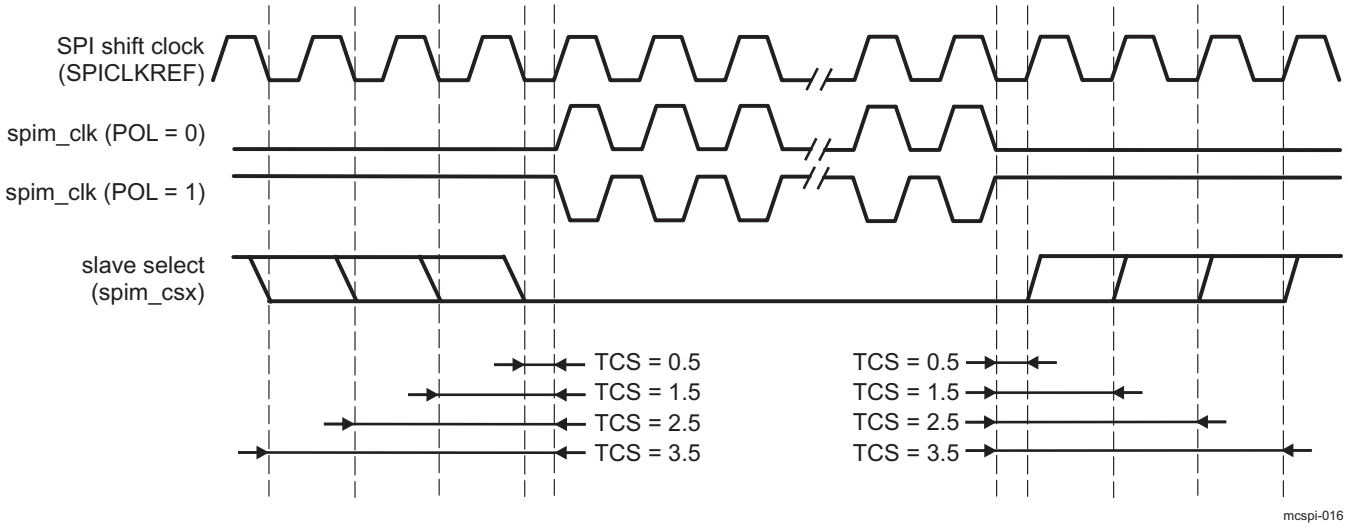
24.4.4.2.7 Chip-Select Timing Control

The chip-select (CS) timing control is available only in master mode with automatic CS generation (the MCSPI_MODULCTRL[0] SINGLE bit field set to 0) to add a programmable delay between CS assertion and first clock edge, or CS removal and last clock edge.

This mode is programmable per channel (the SPIm.MCSPI_CHxCONF TCS bit).

Figure 24-102 shows the CS SPIEN timing control.

Figure 24-102. CS SPIEN Timing Controls



Copyright © 2011–2012, Texas Instruments Incorporated

NOTE: Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between CS assertion and the first clock edge with PHA = 1 or between CS removal and the last clock edge with PHA = 0.

24.4.4.2.8 Programmable SPI Clock (mcspim_clk)

In master mode, the baud rate of the SPI serial clock is programmable.

An internal reference clock, SPIm_FCLK, is used as input of a programmable divider (the SPIm.MCSPI_CHxCONF[5:2] CLKD bit field) to generate the bit rate of the serial output clock mcspim_clk. Table 24-282 summarizes the supported divisor values.

Table 24-282. SPI Master Clock Rates

Divider	Clock Rate
1	48 MHz
2	24 MHz
4	12 MHz
8	6 MHz
16	3 MHz
32	1.5 MHz
64	750 kHz
128	375 kHz
256	~187 kHz
512	~93.7 kHz
1024	~46.8 kHz
2048	~23.4 kHz
4096	~11.7 kHz
8192 and higher: Division not supported	–

24.4.4.2.8.1 Clock Ratio Granularity

By default, the clock division ratio is defined by the SPIm.MCSPI_CHxCONF[5:2] CLKD bit field with power-of-2 granularity leading to a clock division in the range 1 to 4096; in this case, the duty cycle is always 50 percent. With the SPIm.MCSPI_CHxCONF[29] CLKG bit, clock division granularity can be changed to one clock cycle; in that case the SPIm.MCSPI_CHxCTRL[15:8] EXTCLK bit field is concatenated with the SPIm.MCSPI_CHxCONF[5:2] CLKD bit field to give a 12-bit-wide division ratio in the range 1 to 4096.

When granularity is one clock cycle (the CLKG bit set to 1), for the odd value of the clock ratio, the clock high level lasts one clock cycle more than the low level, depending on th SPIm.MCSPI_CHxCONF[1] POL and SPIm.MCSPI_CHxCONF[0] PHA bits (see Table 24-283).

Table 24-283. CLKSPIO High/Low Time Computation

Clock Ratio Fratio	CLKSPIO High Time	CLKSPIO Low Time
1	Thigh_ref	Tlow_ref
Even >= 2	T_ref * (Fratio/2)	T_ref * (Fratio/2)
Odd >= (POL = PHA)	T_ref * (Fratio – 1)/2	T_ref * (Fratio + 1)/2
Odd >= (POL =! PHA)	T_ref * (Fratio + 1)/2	T_ref * (Fratio – 1)/2

Copyright © 2011–2012, Texas Instruments Incorporated

NOTE: Fratio = spi1_clk frequency (Fout) division ratio
Thigh = spi1_clk high time period
Tlow = spi1_clk low time period
T_ref = SPI1_FCLK period
Thigh_ref = SPI1_FCLK high time period
Tlow_ref = SPI1_FCLK low time period

If the CLKG bit is set to 1; Fratio = EXTCLK concatenated with CLKD + 1.

Copyright © 2011–2012, Texas Instruments Incorporated

For odd ratio values, the duty cycle is calculated as follows:

Duty_cycle = (1 – 1/Fratio)/2

Table 24-284 shows examples of clock granularity with a clock source frequency of 48 MHz.

Table 24-284. Clock Granularity Examples

EXTCLK	CLKD	CLKG	Fratio	PHA	POL	Thigh (ns)	Tlow (ns)	Tperiod (ns)	Duty Cycle	Fout (MHz)
X	0	0	1	X	X	10.4	10.4	20.8	50–50	48
X	1	0	2	X	X	20.8	20.8	41.6	50–50	24
X	2	0	4	X	X	41.6	41.6	83.2	50–50	12
X	3	0	8	X	X	83.2	83.2	166.4	50–50	6
0	0	1	1	X	X	10.4	10.4	20.8	50–50	48
0	1	1	2	X	X	20.8	20.8	41.6	50–50	24
0	2	1	3	1	0	41.6	20.8	62.4	66–33	16
0	2	1	3	1	1	20.8	41.6	62.4	33–66	16
0	3	1	4	X	X	41.6	41.6	83.2	50–50	12
5	0	1	81	1	0	852.8	832	1684.8	50.6–49.4	0.592
5	7	1	88	X	X	915.2	915.2	1830.4	50–50	0.545

24.4.4.3 Slave Mode

To select the MCSPI slave mode, set the SPIm.MCSPI_MODULCTRL[2] MS bit.

A MCSPI slave device can be connected to up to four external SPI master devices but handles transactions with one SPI master device at a time.

In slave mode, the MCSPI initiates data transfer on the data lines (mcspim_simo and mcspim_somi) when it is selected by an active control signal (mcspim_csx) and receives an SPI clock (mcspim_clk) from the external SPI master device. Only channel 0 can be configured as a slave. In slave mode, the MCSPI uses the edge of mcspim_csx to detect word length. For this reason, mcspim_csx must become inactive between each word.

The MCSPI does not support mcspim_csx active between SPI words. It uses the edge to detect word length.

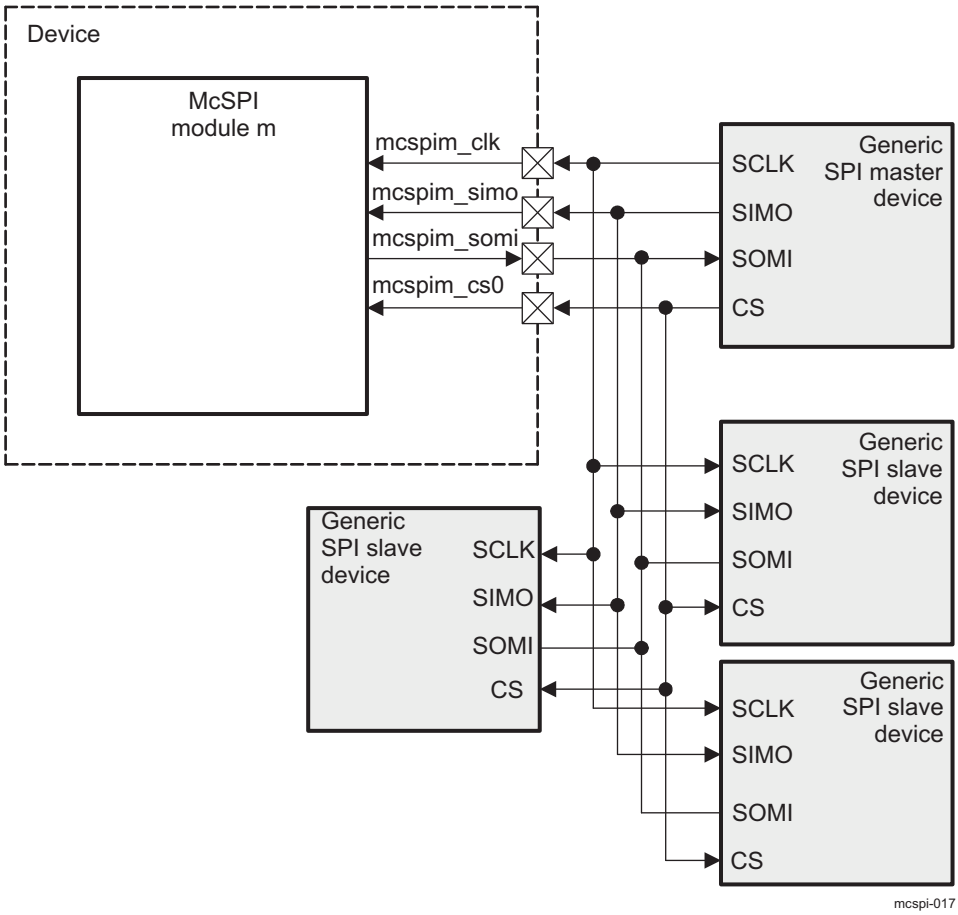
24.4.4.3.1 Dedicated Resources

Only channel 0 can be enabled in slave mode. In this section register names such as SPI1.MCSPI_CHxCTRL stand for SPI1.MCSPI_CH0CTRL, where x = 0 (channel 0 control register).

Figure 24-103 shows an example of four slaves wired on a single master device.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-103. Example of MCSPI Slave With One Master and Multiple Slave Devices on Channel 0



The channel 0 in slave mode has the following resources:

- Its own channel enable, programmable with the SPIm.MCSPI_CHxCTRL[0] EN bit (where x = 0). This channel must be enabled before transmission and reception.
- For this mode, the slave-select signal can be detected on any one of the mcspim_csx ports. This is programmable with the SPIm.MCSPI_CHxCONF[22:21] SPIENSLV bit field (where x = 0).
- Its own transmitter register, SPIm.MCSPI_TXx (where x = 0), on top of the common transmit shift register. If the MCSPI_TXx register is empty, the SPIm.MCSPI_CHxSTAT[1] TXS bit (where x = 0) is set. If MCSPI is selected by an external master (the active signal on the mcspim_csx port assigned to channel 0), the MCSPI_TXx register content of channel 0 is always loaded into the shift register, whether its content is updated or not. The MCSPI_TXx register must be loaded before MCSPI is selected by a master.
- Its own receiver register, SPIm.MCSPI_RXx (where x = 0), on top of the common receive shift register. If the MCSPI_RXx register is full, the SPIm.MCSPI_CHxSTAT[0] RXS bit (where x = 0) is set.

NOTE: The MCSPI_TXx register and MCSPI_RXx registers of the other channels are not used. Reading from or writing to a channel register other than channel 0 has no effect.

- Its own communication configuration with the following parameters through the SPIm. MCSPI_CHxCONF register (where x = 0):
  - Transmit and receive modes, programmable with the TRM field
  - Interface mode (two data pins or single data pin) and data pins assignment, both programmable with the IS and DPE bits. (The SPIm modules are in slave mode after reset and must be properly configured for the modules to act in master mode.)

Copyright © 2011–2012, Texas Instruments Incorporated

- SPI word length, programmable with the WL bit
- mcspim_csx polarity, programmable with the EPOL bit
- mcspim_clk polarity, programmable with the POL bit
- mcspim_clk phase, programmable with the PHA bit

The mcspim_clk frequency of a transfer is controlled by the external SPI master connected to the MCSPI slave device. The SPIm.MCSPI_CHxCONF[5:2] CLKD bit field (where x = 0) is not used in slave mode.

NOTE: The configuration of the channel can be loaded in the SPIm.MCSPI_CHxCONF register (where x = 0) only when the channel is disabled.

- Two DMA request events, read and write, synchronize read/write accesses of the DMA controller with the activity of MCSPI. DMA requests are asserted using the SPIm.MCSPI_CHxCONF[15] DMAR bit (where x = 0) for reading and the SPIm.MCSPI_CHxCONF[14] DMAW bit (where x = 0) for writing.
- Four interrupt events (see Section 24.4.4.5.2, *Interrupt Events in Slave Mode*)

24.4.4.3.2 Slave Transmit-and-Receive Mode

The slave receive mode is programmable (set the SPIm.MCSPI_CHxCONF[13:12] TRM bit field [where x = 0] to 0x0).

In slave transmit-and-receive mode, the MCSPI_TXx register must be loaded before MCSPI is selected by an external SPI master device.

After a channel is enabled, transmission and reception proceed with interrupt and DMA request events.

The MCSPI_TXx register content is always loaded in the shift register whether it is updated or not. The event TXx_UNDERFLOW is activated accordingly and does not prevent transmission.

When an SPI word transfer completes (the SPIm.MCSPI_CHxSTAT0[2] EOT bit [where x = 0] set to 1), the received data is transferred to the channel receive register.

To use MCSPI as a slave transmit-only device, the RXx_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled due to the MCSPI_RXx register state (see Section 24.4.4.5.2, *Interrupt Events in Slave Mode*).

24.4.4.3.3 Slave Transmit-Only Mode

The slave transmit-only mode is programmable (set the SPIm.MCSPI_CHxCONF[13:12] TRM bit field [where x = 0] to 0x2) and avoids the requirement for the MPU to read the MCSPI_RXx register (minimizing data movement) only when transmission is meaningful.

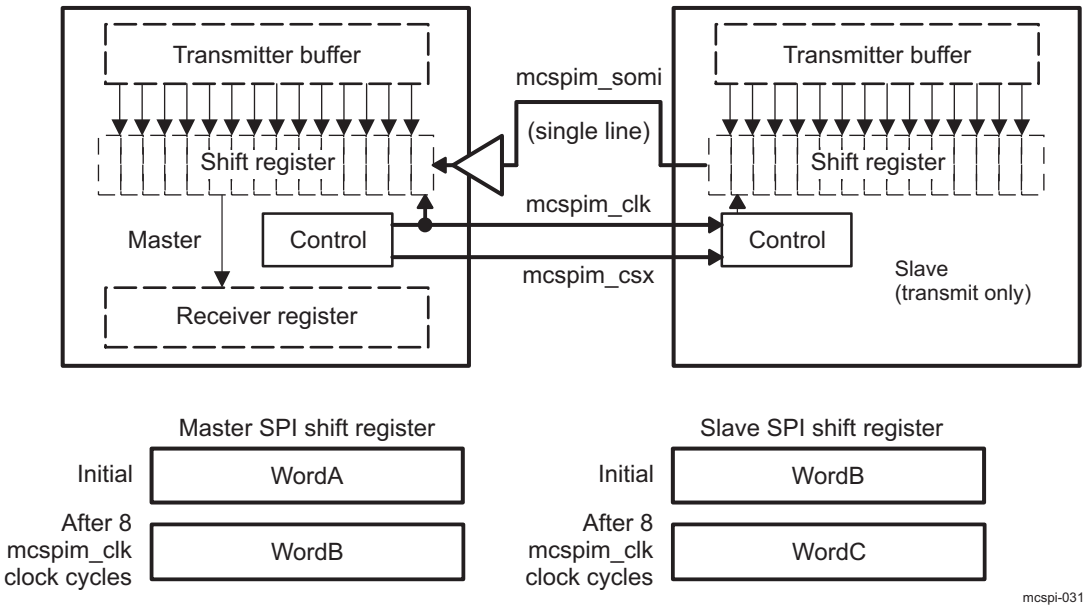
To use the MCSPI as a slave transmit-only device, the RXx_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled due to the MCSPI_RXx register state.

When the SPI word transfer completes, the SPIm.MCSPI_CHxSTAT[2] EOT bit is set (where x = 0).

Figure 24-104 shows a half-duplex system with a master device on the left and a transmit-only slave device on the right. Each time a bit transfers out from the slave device, 1 bit transfers in the master. After eight cycles of the serial clock mcspim_clk, WordB transfers from the slave to the master.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-104. SPI Half-Duplex Transmission (Transmit-Only Slave)



24.4.4.3.4 Slave Receive-Only Mode

The slave receive mode is programmable (set the SPIm.MCSPI_CHxCONF[13:12] TRM bit field [where x = 0] to 0x1).

In receive-only mode, the MCSPI_TXx register must be loaded before the MCSPI is selected by an external SPI master device. The MCSPI_TXx register content is always loaded into the shift register whether it is updated or not. The TXx_UNDERFLOW event is activated accordingly and does not prevent transmission.

When an SPI word transfer completes (the SPIm.MCSPI_CHxSTAT0[2] EOT bit [where x = 0] is set to 1), the received data is transferred to the channel receive register.

To use the MCSPI as a slave receive-only device, the TXx_EMPTY and TXx_UNDERFLOW interrupts and the DMA write requests must be disabled due to the MCSPI_TXx register state.

For a full-duplex transmission, the serial clock (mcspim_clk) synchronizes shifting and sampling of the information on the single serial data line. For full duplex, two data lines are required. If mcspim_clk synchronizes on a single serial data line, the data line should be half-duplex.

Figure 24-105 shows an example of a half-duplex system with a master device on the left and a receive-only slave device on the right. Each time a bit transfers out from the master, 1 bit transfers in from the slave. After eight cycles of the serial clock mcspim_clk, Word A transfers from the master to the slave.

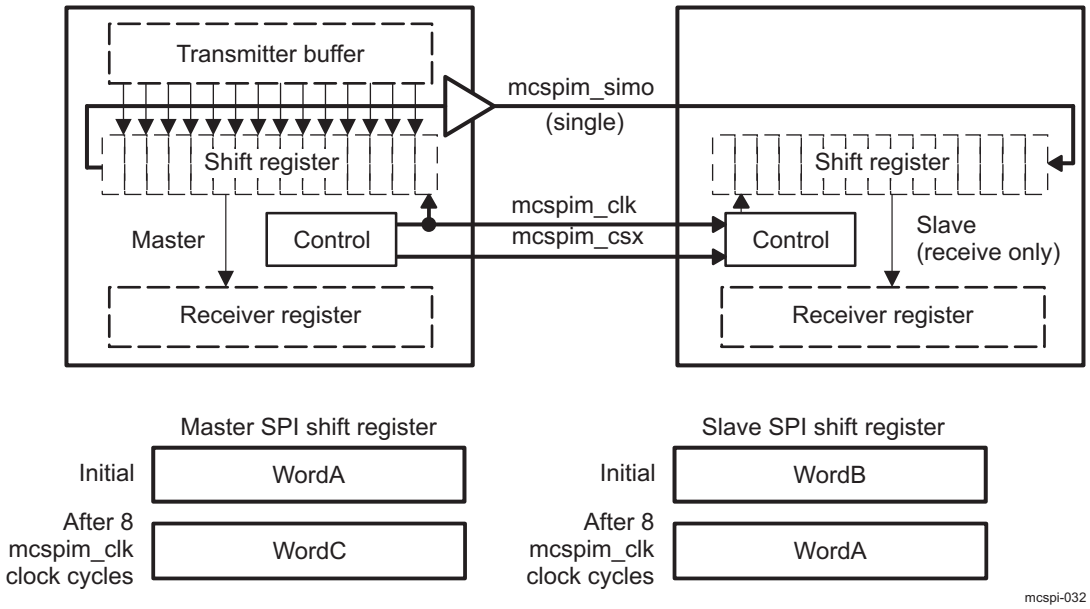
Figure 24-105. SPI Half-Duplex Transmission (Receive-Only Slave)



24.4.4.4 FIFO Buffer Management

The MCSPI controller has a built-in 64-byte buffer to unload the DMA or interrupt handler and improve data throughput.

This buffer can be used by only one channel at a time and is selected by setting the SPIm.MCSPI_CHxCONF[28] FFER or SPIm.MCSPI_CHxCONF[27] FFEW bits to 1. If several channels are selected and several FIFO enable bit fields are set to 1, the controller forces the buffer not to be used; the driver must set only one FIFO enable bit field.

The buffer can be used in the following modes:

- Master or slave mode
- Transmit-only, receive-only, or transmit-and-receive mode
- Single channel or turbo mode, or normal round-robin mode. In round-robin mode the buffer is used by only one channel.

  Every word length (SPIm.MCSPI_CHxCONF[11:7] WL) is supported.

In transmit-and-receive mode, the buffer can be used in transmit (see Figure 24-106) or receive (see Figure 24-107) directions, or in both directions. If only one direction is chosen in transmit-and-receive mode, the full buffer is used for this direction. In both directions, the buffer is split into two 32-byte buffers, one for each direction (see Figure 24-108).

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-106. Buffer Used in Transmit Direction Only

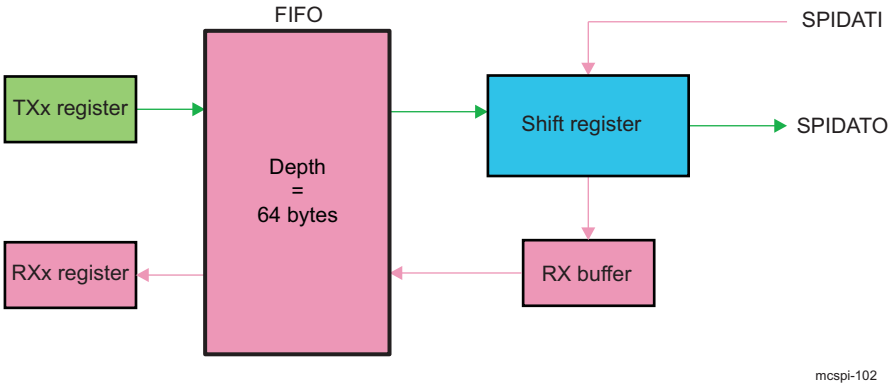


Figure 24-107. Buffer Used in Receive Direction Only

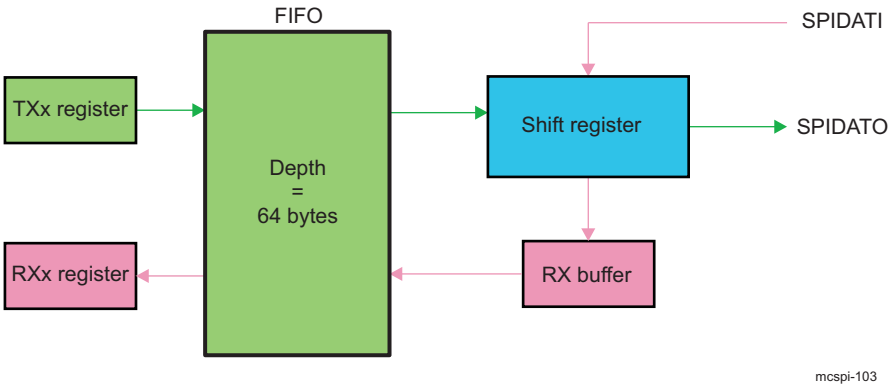

Figure 24-108. Buffer Used for Transmit and Receive Directions

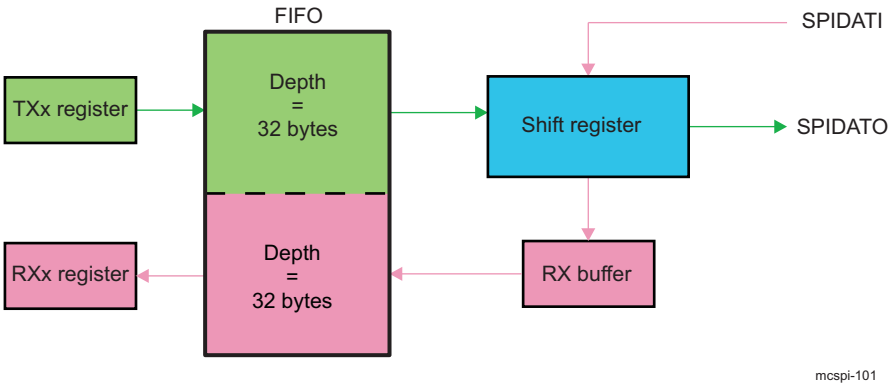


Two levels (SPIm.MCSPI_XFERLEVEL[5:0] AEL and SPIm.MCSPI_XFERLEVEL[13:8] AFL) rule the buffer management. The granularity of these levels is 1 byte; it is not aligned with the SPI word length. The driver must set these values as a multiple of the SPI word length defined in WL. Table 24-285 shows the number of bytes written in the FIFO, depending on the word length.

Table 24-285. FIFO Writes, Word Length Relationship

SPI Word Length WL	3 <= WL<= 7	8 <= WL <= 15	16 <= WL <= 31
Number of byted written in the FIFO	1 byte	2 bytes	4 bytes

Copyright © 2011–2012, Texas Instruments Incorporated

The FIFO buffer pointers are reset when the corresponding channel is enabled or the FIFO configuration changes.

24.4.4.4.1 Buffer Almost Full

The MCSPI_XFERLEVEL[15:8] AFL bit field is needed when the buffer is used to receive an SPI word from a slave (the MCSPI_CHxCONF[28] FFER bit must be set to 1). It defines the almost-full buffer status. See Figure 24-109.

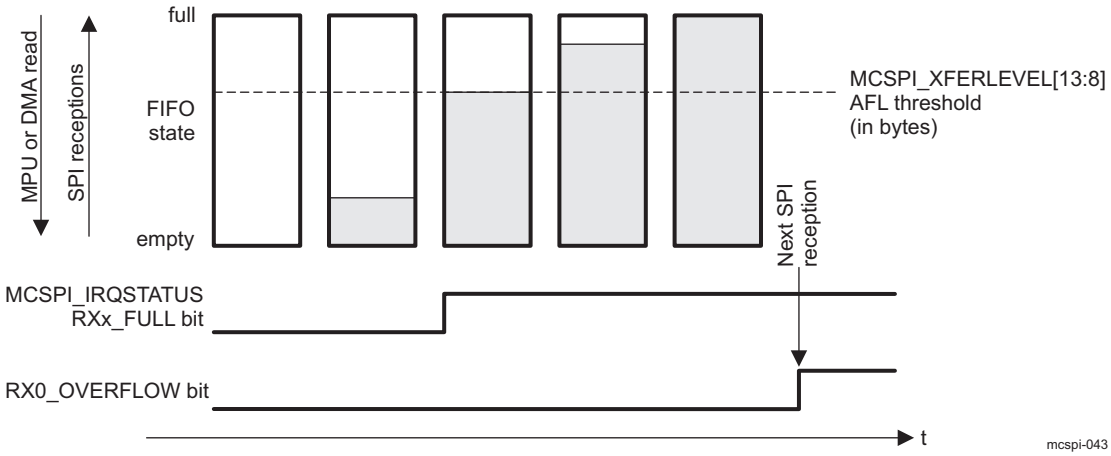
When the FIFO pointer reaches this level, an interrupt or a DMA request is sent to the MPU to enable the system to read AFL + 1 bytes from the receive register.

NOTE: AFL + 1 must correspond to a multiple value of the MCSPI_CHxCONF[11:7] WL bit field.

When DMA is used, the request is deasserted after the first receive register read.

No new request will be asserted again as long as the system has not performed the right number of read accesses.

Figure 24-109. Buffer Almost Full Level (AFL)



NOTE: The MCSPI_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the SPIm_DMA_RXx request is asserted on the same conditions as the MCSPI_IRQSTATUS RXx_FULL flag.

24.4.4.4.2 Buffer Almost Empty

The MCSPI_XFERLEVEL[7:0] AEL bit field is needed when the buffer is used to transmit an SPI word to a slave (the MCSPI_CHxCONF[27] FFEW bit must be set to 1). It defines the almost-empty buffer status. See Figure 24-110.

When the FIFO pointer has not reached this level, an interrupt or a DMA request is sent to the MPU to enable the system to write AEL + 1 bytes to the transmit register.

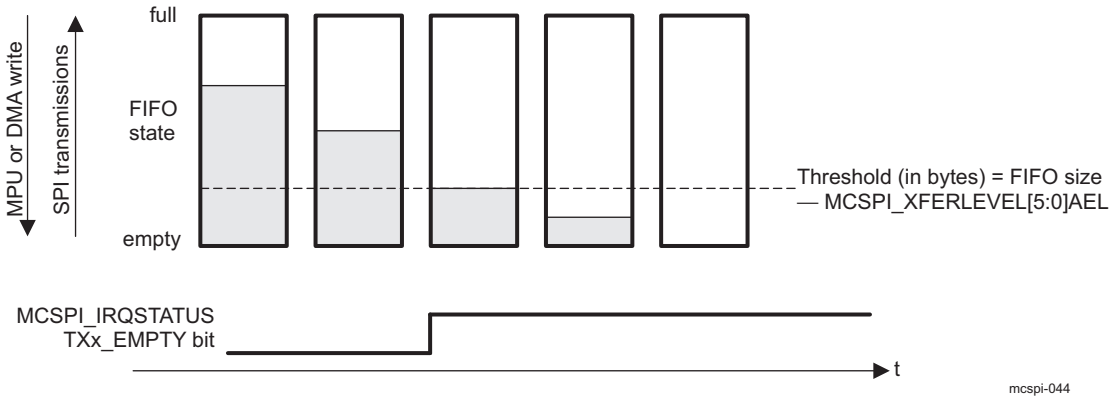
NOTE: AEL + 1 must correspond to a multiple value of the MCSPI_CHxCONF[11:7] WL bit field.

When DMA is used, the request is deasserted after the first transmit register write.

No new request will be asserted again as long as the system has not performed the right number of write accesses.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-110. Buffer Almost Empty Level (AEL)



NOTE: The MCSPI_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the SPIm_DMA_TXx request is asserted on the same conditions as the MCSPI_IRQSTATUS TXx_EMPTY flag.

24.4.4.4.3 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user must previously configure in the MCSPI_XFERLEVEL register the AEL and AFL levels and especially the MCSPI_XFERLEVEL[31:16] WCNT bit field to define the number of SPI words to be transferred using the FIFO before enabling the channel.

This counter allows the controller to stop the transfer correctly after a defined number of SPI word transfers. If WNCT is set to 0x0000, the counter is not used and the user must stop the transfer manually by disabling the channel; in this case, the user does not know how many SPI transfers have been done. For received words, software must poll the CHxSTAT[5] RXFFE bit and read the MCSPI_RXx receive register to empty the FIFO buffer.

When the end-of-word count interrupt is generated (the MCSPI_IRQSTATUS[17] EOW bit is set), the user can disable the channel and poll the MCSPI_CHxSTAT[5] RXFFE bit to know it lasts SPI words in the FIFO buffer and read them.

No new request is asserted as long as the system has not performed the correct number of write accesses.

24.4.4.5 Interrupts

Each channel can issue interrupt events.

Each interrupt event has status bits in the SPIm.MCSPI_IRQSTATUS register (RXx_FULL, TXx_UNDERFLOW, TXx_EMPTY, …) (where x = 0, 3) that indicate whether service is required. Each status bit has an interrupt enable bit (a mask) in the SPIm.MCSPI_IRQENABLE register (RXx_FULL_ENABLE, TXx_UNDERFLOW_ENABLE, TXx_EMPTY_ENABLE, ...).

When an interrupt occurs and a mask is later applied on it, the interrupt line is not asserted again, even if the interrupt source is not serviced.

The MCSPI supports interrupt-driven and polling operations.

24.4.4.5.1 Interrupt Events in Master Mode

In master mode, the interrupt events related to the MCSPI_TXx register state are TXx_EMPTY and TXx_UNDERFLOW. The interrupt event related to the MCSPI_RXx register state is RXx_FULL.

Copyright © 2011–2012, Texas Instruments Incorporated

24.4.4.5.1.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its MCSPI_TXx register is empty (transient event). Enabling a channel automatically triggers this event, except in master receive-only mode (see Section 24.4.4.2.4, *Master Receive-Only Mode*). When the FIFO buffer is enabled (the MCSPI_CHxCONF[27] FFEW bit is set to 1), the MCSPI_IRQSTATUS TXx_EMPTY bit is set as soon as there is enough space in the buffer to write a number of bytes defined by the MCSPI_XFERLEVEL[5:0] AEL bit field.

The MCSPI_TXx register must be loaded with data to remove the source of the interrupt; the SPIm.MCSPI_IRQSTATUS TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event will be asserted as soon as the MPU has not performed the number of writes into the MCSPI_TXx register defined by the MCSPI_XFERLEVEL[5:0] AEL bit field. The MPU must perform the right number of writes.

24.4.4.5.1.2 TXx_UNDERFLOW

The event TXx_UNDERFLOW is activated when the channel is enabled and if the MCSPI_TXx register or the FIFO is empty (not updated with new data) when an external master device starts a data transfer with the MCSPI (transmit and receive).

The TXx_UNDERFLOW is a harmless warning in master mode.

To avoid having a TXx_UNDERFLOW event at the beginning of a transmission, the event TXx_UNDERFLOW is not activated when no data has been loaded into the MCSPI_TXx register, because the channel has been enabled. To avoid having a TXx_UNDERFLOW event, the MCSPI_TXx register must seldom be loaded.

The SPIm.MCSPI_IRQSTATUS TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if event enabled as the interrupt source).

24.4.4.5.1.3 RXx_ FULL

The RXx_FULL event is activated when channel is enabled and MCSPI_RXx register becomes filled (transient event). When the FIFO buffer is enabled (the MCSPI_CHxCONF[28] FFER bit is set to 1), RXx_ FULL is asserted as soon as the number of bytes holds in the FIFO to be read reaches the MCSPI_XFERLEVEL[13:8] AFL threshold.

The MCSPI_RXx register must be read to remove the source of the interrupt; the MCSPI_IRQSTATUS RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event will be asserted as soon as the MPU has not performed AFL + 1 reads into MCSPI_RXx. The MPU must perform the right number of reads.

24.4.4.5.1.4 End Of Word Count

The MCSPI_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the MCSPI_XFERLEVEL[31:16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the SPI transfer is halted on the channel using the FIFO buffer as soon as MCSPI_XFERLEVEL[31:16] WCNT is not reloaded and the channel is not re-enabled.

The MCSPI_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event enabled as interrupt source).

Copyright © 2011–2012, Texas Instruments Incorporated

24.4.4.5.2 Interrupt Events in Slave Mode

In slave mode, the interrupt events related to the MCSPI_TXx register state are TXx_EMPTY and TXx_UNDERFLOW. The interrupt events related to the MCSPI_RXx register state are RXx_FULL and RX0_OVERFLOW (channels 1, 2, and 3 do not have a receiver overflow status bit). See the MCSPI_IRQSTATUS register.

24.4.4.5.2.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its MCSPI_TXx register is empty. Enabling the channel automatically raises this event. If the FIFO buffer is enabled (the MCSPI_CHxCONF[27] FFEW bit is set to 1), the TXx_EMPTY event will be asserted as soon as there is enough space in buffer to write a number of bytes defined by the MCSPI_XFERLEVEL[5:0] AEL bit field.

The MCSPI_TXx register must be loaded with data to remove the source of the interrupt; the SPIm.MCSPI_IRQSTATUS TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event will be asserted as soon as the MPU has not performed the number of write into the MCSPI_TXx register defined by MCSPI_XFERLEVEL[5:0] AEL bit field. The MPU must perform the right number of writes.

24.4.4.5.2.2 TXx_UNDERFLOW

The TXx_UNDERFLOW event is activated when a channel is enabled and if the MCSPI_TXx register is empty (not updated with new data) when an external master device starts a data transfer with the MCSPI (transmit and receive).

When FIFO is enabled, the data emitted while the underflow event is raised is not the last data written in the FIFO but the next data in the FIFO (an old transmitted value or a dummy data in the FIFO has been reset).

TXx_UNDERFLOW indicates an error (data loss) in slave mode.

To avoid having a TXx_UNDERFLOW event at the beginning of a transmission, the TXx_UNDERFLOW event is not activated when no data has been loaded into the MCSPI_TXx register because the channel is enabled.

The SPIm.MCSPI_IRQSTATUS TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

24.4.4.5.2.3 RXx_FULL

The RXx_FULL event is activated when a channel is enabled and the MCSPI_RXx register is being filled (transient event). When the FIFO buffer is enabled (the MCSPI_CHxCONF[28] FFER bit is set to 1), RXx_FULL is asserted as soon as the number of bytes holds in the buffer to read defined by the MCSPI_XFERLEVEL[13:8] AFL bit field.

The MCSPI_RXx register must be read to remove the source of the interrupt; the SPIm.MCSPI_IRQSTATUS RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event will be asserted as soon as the MPU has not performed AFL + 1 reads into MCSPI_RXx. The MPU must perform the correct number of reads.

24.4.4.5.2.4 RX0_OVERFLOW

The RX0_OVERFLOW event is activated in slave mode in either transmit-and-receive or receive-only mode, when a channel is enabled and the MCSPI_RXx register or FIFO is full when a new SPI word is received. The MCSPI_RXx register is always overwritten with the new SPI word. If the FIFO is enabled data within the FIFO are overwritten, it must be considered as corrupted. The RX0_OVERFLOW event should not appear in slave mode using the FIFO.

The RX0_OVERFLOW event indicates an error (data loss) in slave mode.

Copyright © 2011–2012, Texas Instruments Incorporated

The MCSPI_IRQSTATUS[3] RX0_OVERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

24.4.4.5.2.5 End Of Word Count

The MCSPI_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfer defined in the MCSPI_XFERLEVEL[31:16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the SPI transfer is halted on the channel using the FIFO buffer as soon as WCNT is not reloaded and the channel re-enabled.

The MCSPI_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if event enable as interrupt source).

24.4.4.5.3 Interrupt-Driven Operation

An interrupt enable bit in the SPIm.MCSPI_IRQENABLE register can be set to enable each event to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the MPU must:

1. Read the SPIm.MCSPI_IRQSTATUS register to identify which event occurred.
2. Read the MCSPI_RXx register that corresponds to the event to remove the source of an RXx_FULL event or write into the MCSPI_TXx register that corresponds to the event to remove the source of a TXx_EMPTY event. No action is required to remove the source of the WKS (wake-up), TXx_UNDERFLOW, and RX0_OVERFLOW events.
3. Set the corresponding bit of the SPIm.MCSPI_IRQSTATUS register to 1 to clear an interrupt status and then release the interrupt line.

The interrupt status bit must always be reset after channel enabling and before events are enabled as interrupt sources.

24.4.4.5.4 Polling

When the interrupt capability of an event is disabled in the SPIm.MCSPI_IRQENABLE register, the interrupt line is not asserted, but the status bits in the SPIm.MCSPI_IRQSTATUS register can be polled by software to detect when the corresponding event occurs.

Once the expected event occurs:

- RXx_FULL: To remove the source of the event, the MPU must read the corresponding MCSPI_RXx register.
- TXx_EMPTY: To remove the source of the event, the MPU must write into the corresponding MCSPI_TXx register.
- WKS (wake-up), TXx_UNDERFLOW, and RX0_OVERFLOW: No action is required to remove the source of the event.

To clear an interrupt, set the corresponding status bit of the SPIm.MCSPI_IRQSTATUS register to 1. This does not affect the interrupt line state.

24.4.4.6 DMA Requests

The sDMA controller module manages DMA accesses. The sDMA controller advantage is to reduce the MPU charge for data transfers.

Each MCSPI channel , if enabled, can issue DMA requests. There are two DMA request lines per MCSPI channel (one for read and one for write).

Copyright © 2011–2012, Texas Instruments Incorporated

The DMA read request line is asserted when the MCSPI channel is enabled and new data is available in the receive register of the MCSPI channel. A DMA read request can be individually masked with the SPI1.MCSPI_CHxCONF[15] DMAR bit. The DMA read request line is deasserted when reading of the MCSPI_RXx register of the MCSPI channel is complete.

The DMA write request line is asserted when the MCSPI channel is enabled and the MCSPI_TXx register of the MCSPI channel is empty. A DMA write request can be individually masked with the SPI1.MCSPI_CHxCONF[14] DMAW bit. The DMA write request line is deasserted when loading of the MCSPI_TXx register of the channel is complete.

24.4.4.7 Power Saving Management

Power consumption can be optimized by switching off internal clocks (interface and functional clock) when there is no activity. The MCSPI is compliant with the idle and wake-up system handshake protocol.

24.4.4.7.1 Normal Mode

In normal mode, internal SPI module clocks are automatically switched off (autogated) when there is no activity in slave or master mode.

Autogating of the module interface clock and functional clock occurs when the following conditions are met:

- The SPIm.MCSPI_SYSCONFIG[0] AUTOIDLE bit is set.
- In master mode, there is no data to transmit or receive in all channels.
- In slave mode, the MCSPI is not selected by the external master and there are no register accesses.

Autogating of the module interface clock and functional clock stops when the following conditions are met:

- In master mode, an internal access occurs.
- In slave mode, an internal access occurs or the MCSPI is selected by the external master.

24.4.4.7.2 Idle Mode

At the PRCM module level, when all conditions are met to shut off the CORE_48M_FCLK or CORE_L4_ICLK output clocks (for details, see Chapter 3, *Power, Reset, and Clock Management*), the PRCM module automatically launches a hardware handshake protocol to ensure that the MCSPI is ready to have its clocks switched off. Namely, the PRCM module asserts an idle request to the MCSPI.

Although this handshake is completely hardware-oriented and out of software control, the method in which the MCSPI module acknowledges the PRCM idle request is configurable through the MCSPI.SYSCONFIG[4:3] SIDLEMODE bit field.

The settings of the SIDLEMODE bit field and the related acknowledgment modes are:

- Force-idle mode (the SPIm.MCSPI_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0): The MCSPI module acknowledges unconditionally the idle request from the PRCM module, regardless of its internal operations. This mode must be used carefully in this case because it does not prevent the loss of data when the clock is switched off.
- No-idle mode (the SIDLEMODE bit is set to 0x1): The MCSPI never acknowledges an idle request from the PRCM module and is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient to save power because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
- Smart-idle mode (the SIDLEMODE bit is set to 0x2): The MCSPI acknowledges the idle request, basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for efficient system power management.

When configured in smart-idle mode, the MCSPI also offers an additional granularity on the CORE_48M_FCLK and CORE_L4_ICLK gating. The SPIm.SYSCONFIG[9:8] CLOCKACTIVITY bit field determines which clock shuts down (the CORE_48M_FCLK, CORE_L4_ICLK, neither clock, or both clocks).

Copyright © 2011–2012, Texas Instruments Incorporated

The CLOCKACTIVITY setting is used internally to the MCSPI to determine on which part of the module the conditions to acknowledge the PRCM idle request are tested. For example, if CORE_48M_FCLK is not shut down on a PRCM idle request, the MCSPI considers only CORE_L4_ICLK and the associated pending activities before acknowledging the request.

Some MCSPI features are associated with CORE_L4_ICLK and others with CORE_48M_FCLK. Using the CLOCKACTIVITY bit field with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if the MCSPI acknowledges an idle request.

The CLOCKACTIVITY settings and the associated features are:

- CLOCKACTIVITY set to 00: ICLK off and FCLK off, ICLK and FCLK are considered for generating the acknowledge. This setting also means that FCLK and ICLK are likely to be shut down on a PRCM idle request.
- CLOCKACTIVITY set to 01: ICLK on and FCLK off, ICLK is not shut down on a PRCM idle request; only FCLK is concerned.
- CLOCKACTIVITY set to 10: ICLK off and FCLK on, FCLK is not shut down on a PRCM idle request; only ICLK is concerned.
- CLOCKACTIVITY set to 11: ICLK on and FCLK on, none of the clocks are shut down. This means the MCSPI can potentially acknowledge the idle request without checking the internal functions linked to its clocks.

CAUTION

The PRCM module does not have a hardware means of reading the CLOCKACTIVITY settings. Therefore, software must ensure consistent programming between CLOCKACTIVITY and the CORE_48M_FCLK and CORE_L4_ICLK control bits in the PRCM module. If the MCSPI is disabled in the CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its idle request, which is acknowledged regardless of the features associated with the MCSPI clocks. This can lead to unpredictable behavior.

24.4.4.7.2.1 Wake-Up Event in Smart-Idle Mode

The module wake-up feature is enabled when the SPIm.MCSPI_SYSCONFIG[2] ENAWAKEUP and SPIm.MCSPI_WAKEUPENABLE[0] WKEN bits are set. Wake-up capability is relevant only when the module is configured in slave mode.

The module generates an asynchronous wakeup request to the system power manager to switch back the interface clock and the functional clock. A wake-up is requested when channel 0 is enabled and an asynchronous selection occurs on the mcspim.csx port associated with channel 0 (see the definition for the SPIm.MCSPI_CHxCONF[22:21] SPIENSLV bit field [where x = 0] in the register description table).

After the McSPI wake-up request, the system power manager must reactivate the interface clock:

- Before the beginning of the second SPI word serialization when the McSPI is in slave transmit-only mode or in slave transmit-and-receive mode
- Before the end of the second received SPI word in slave receive-only mode. To avoid data loss, the first received SPI word must be read from the SPIm.MCSPI_RXx register (where x = 0) before the completion of the second SPI word serialization.

Table 24-286 lists the supported cases in wake-up mode.

Table 24-286. Smart-Idle Mode and Wake-Up Capabilities

Mode	Interface Clock	SPI Clock Ref	Functionality	Wake-Up Event
Master	Must be maintained	Must be maintained	Full functionality, but the module does not generate a new interrupt or DMA request until the system exits wake-up mode	No wake-up event

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-286. Smart-Idle Mode and Wake-Up Capabilities (continued)

Mode	Interface Clock	SPI Clock Ref	Functionality	Wake-Up Event
Slave	Can be switched off	Can be switched off	An SPI word can be transmitted and/or received, but the module does not generate any new interrupts or DMA requests until the system exits wake-up mode.	The module asynchronously sends a wake-up request if an event on the mcspim_csx port associated with channel 0 is detected.

In wake-up mode, the interrupt and DMA request lines are no longer asserted.

Any access to the module in wake-up mode generates an error as long as the interface clock is alive.

24.4.4.7.2.2 Transitions From Smart-Idle Mode to Normal Mode

The MCSPI detects the end of the wake period through the idle and wake-up hardware handshake protocol.

The interrupt status register (the SPIm.MCSPI_IRQSTATUS[16] WKS bit) is updated with the event causing the wakeup; the wake-up event at the origin of the transition to the normal mode is converted to its corresponding interrupt when enabled by the SPIm.MCSPI_IRQENABLE[16] WKE bit or the DMA request.

Interrupts and wake-up events have independent enable and disable controls, accessible through the SPIm.MCSPI_IRQENABLE and SPIm.MCSPI_WAKEUPENABLE registers. Software must ensure the overall consistency.

The interrupt status register SPIm.MCSPI_IRQSTATUS is updated with the event causing the wake-up; the wake-up event at the origin of the transition to normal mode is converted to its corresponding interrupt request or DMA request. The module is fully operational.

24.4.4.7.2.3 Force-Idle Mode

Force-idle mode is enabled and exited as follows:

- Force-idle mode is enabled when the SPIm.MCSPI_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0.
  - In force-idle mode, the MCSPI responds unconditionally to the idle request by deasserting unconditionally the interrupt and DMA request lines, if asserted. In addition, the wake-up capability is totally inhibited even if the SPIm.MCSPI_SYSCONFIG[2] ENAWAKEUP and SPIm.MCSPI_WAKEUPENABLE[0] WKEN bits are set.
  - The transition from normal mode to idle mode does not affect the interrupt event bits of the SPIm.MCSPI_IRQSTATUS register.
  - In force-idle mode, because the module must be disabled, the interrupt and DMA request lines are likely deasserted. The interface clock and SPI clock provided to the MCSPI can be switched off.
  - An idle request during an SPI data transfer can lead to an unexpected and unpredictable result. Software must avoid such a request.
- The module exits force-idle mode through the idle and wake-up hardware handshake protocol.

  The module is fully operational. The interrupt and DMA request lines are optionally asserted one clock cycle later.

24.4.5 MCSPI Programming Guide

24.4.5.1 MCSPI Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the MCSPI module.

24.4.5.1.1 Global Initialization

24.4.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the I^2C module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the I^2C. For further information, see the *I^2C Module Integration* and *Environment* sections.

For more information, see Section 24.4.3.

Table 24-287 lists the information on the global initialization of the surrounding modules.

Table 24-287. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	MCSPI_FCLK functional clock must be enabled. See Section 3.1.1.1.2 , *Module Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
L4 Interconnect	For information about L4-PER interconnect configuration, see Section 14.3, *L4 Interconnects*, in Chapter 14, *Interconnect*.
sDMA	DMA configuration must be done to enable the module DMA channel requests. See Chapter 17, *SDMA*.
MPU INTC	Cortex-A9 MPU, Cortex-M3 MPU, or DSP INTC must be configured to enable the interrupt request generation to the Cortex-A9 MPU or Cortex-M3 MPU, or in Section 5.3.2.6, *INTC*, in Chapter 5, *DSP Subsystem*.

24.4.5.1.1.2 MCSPI Global Initialization

24.4.5.1.1.2.1 Main Sequence – MCSPI Global Initialization

This procedure initializes the MCSPI module after a POR or software reset.

Table 24-288. MCSPI Global Initialization

Step	Register/Bit Field/Programming Model	Value
Perform a software reset.	SPIm.MCSPI_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is finished?	SPIm.MCSPI_SYSSTATUS[0] RESETDONE	=0x1

24.4.5.1.2 Operational Mode Configuration

24.4.5.1.2.1 MCSPI Operational Modes

The selection of the working mode is done with the SPIm.MCSPI_CHxCONF register. Table 24-289 through Table 24-291 list the possible operating modes and their configurations.

Table 24-289. MCSPI Receive Mode Initialization

Step	Register/Bit Field/Programming Model	Value

Wait until end of transfer?	SPIm.MCSPI_CHxSTAT[2:1]	=0x2
Stop the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x0

24.4.5.1.2.1.1.4 Transmit-and-Receive Procedure – Polling Method

Table 24-294 lists the transmit-and-receive procedure using the polling method. The MCSPI is acting as master and slave.

Table 24-295. Transmit-and-Receive Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 24-291.	
Start the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x1
Wait until transmit/receive word?	SPIm.MCSPI_CHxSTAT[2:0]	=0x3
Stop the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x0

24.4.5.1.3 Common Transfer Procedures With FIFO – Polling Method

When using FIFO the MCSPI module can start the transfer only after the first write request is released by writing the MCSPI_TXx register. The first write request can be managed by the IRQ routine or DMA handler. The end of transfer is more complex and depends on the transfer type. See Table 24-294 through Table 24-301.

24.4.5.1.3.1 Receive-Only Procedure With Word Count – Polling Method

Table 24-296. Receive-Only Procedure With Word Count – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 24-289.	
Start the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x1
Wait until end of word count?	SPIm.MCSPI_IRQSTATUS[17] EOW	=0x1
Stop the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x0
Read from the receiver register.	SPIm.MCSPI_RXx	xxxx

24.4.5.1.3.2 Transmit-Only Procedure With and Without Word Count – Polling Method

Table 24-297. Transmit-Only Procedure Without Word Count – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 24-290.	
Start the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x1
Wait until end of word count?	SPIm.MCSPI_IRQSTATUS[17] EOW	=0x1
Wait until end of transfer?	SPIm.MCSPI_CHxSTAT[2] EOT SPIm.MCSPI_CHxSTAT[3] TXFFE	=0x1 =0x1
Stop the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x0

24.4.5.1.3.3 Transmit-Only Procedure With and Without Word Count – Interrupt Method

Table 24-298. Transmit-Only Procedure With Word Count – Interrupt Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 24-290.	
Start the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x1
Enable the interrupt for the transmit register.	SPIm.MCSPI_IRQENABLE[4] TX_EMPTY_ENABLE	0x1
End of word count.	SPIm.MCSPI_IRQSTATUS[17] EOW	=0x1
End of transfer	SPIm.MCSPI_CHxSTAT[2] EOT SPIm.MCSPI_CHxSTAT[3] TXFFE	=0x1 =0x1
Clear the interrupt.	SPIm.MCSPI_IRQENABLE[17] EOW_ENABLE	=0x0
Disable the interrupt for the transmit register.	SPIm.MCSPI_IRQENABLE[4] TX_EMPTY_ENABLE	0x0
Stop the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x0

24.4.5.1.3.4 Transmit-and-Receive Procedure With Word Count – Polling Method

Table 24-299. Transmit-and-Receive Procedure With Word Count – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 24-291.	
Start the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x1
Wait until end of word count?	SPIm.MCSPI_IRQSTATUS[17] EOW	=0x1
Stop the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x0
Read from the receiver register.	SPIm.MCSPI_RXx	xxxx

24.4.5.1.3.5 Transmit-and-Receive Procedure with Word Count – Interrupt Method

Table 24-300. Transmit-and-Receive Procedure With Word Count – Interrupt Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 24-291.	
Start the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x1
Enable the interrupt for the receiver register.	SPIm.MCSPI_IRQENABLE[2] RX_FULL_ENABLE	0x1
Enable the interrupt for the transmit register.	SPIm.MCSPI_IRQENABLE[4] TX_EMPTY_ENABLE	0x1
End of word count?	SPIm.MCSPI_IRQSTATUS[17] EOW	=0x1
Clear the interrupt.	SPIm.MCSPI_IRQENABLE[17] EOW_ENABLE	=0x0

24.4.6.2.2 MCSPI Register Description

Table 24-304 through Table 24-336 describe the individual MCSPI register bits.

Table 24-304. MCSPI_HL_REV

Address Offset	0x00		
Physical Address	See Table 24-303.	**Instance**	MCSPI1 MCSPI2 MCSPI3 MCSPI4
Description	IP Revision Identifier (X.Y.R) Used by software to track features, bugs, and compatibility		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REVISION																															

Bits	Field Name	Description	Type	Reset
31:0	REVISION	IP Revision	R	TI internal data

Table 24-305. Register Call Summary for Register MCSPI_HL_REV

Multichannel Serial Port Interface (MCSPI)

- MCSPI Register Summary: [0]

Table 24-306. MCSPI_HL_HWINFO

Address Offset	0x04		
Physical Address	See Table 24-303.	**Instance**	MCSPI1 MCSPI2 MCSPI3 MCSPI4
Description	Information about the IP module's hardware configuration, that is, typically the module's HDL generics (if any). Actual field format and encoding is up to the module's designer to decide.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVD																									RETMODE	FFNBYTE					USEFIFO

Bits	Field Name	Description	Type	Reset
31:7	RSVD	Reserved These bits are initialized to 0, and writes to them are ignored.	R	0x0000000
6	RETMODE	Retention Mode generic parameter. This bit field indicates whether the retention mode is supported using the pin PIRFFRET. 0x0: Retention mode disabled 0x1: Retention mode enabled	R	RETMODE

Copyright © 2011–2012, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
5:1	FFNBYTE	FIFO number of byte generic parameter This register defines the value of FFNBYTE generic parameter, only MSB bits from 8 down to 4 are taken into account. Read 0x1: FIFO 16 bytes depth Read 0x2: FIFO 32 bytes depth Read 0x4: FIFO 64 bytes depth Read 0x8: FIFO 128 bytes depth Read 0x10: FIFO 256 bytes depth	R	0x04
0	USEFIFO	Use of a FIFO enable: This bit indicates if a FIFO is integrated within controller design with its management. Read 0x0: FIFO not implemented in design Read 0x1: FIFO and its management implemented in design with depth defined by FFNBYTE generic	R	0

Physical Address	See Table 24-303.	**Instance**	MCSPI1 MCSPI2 MCSPI3 MCSPI4
Description	Clock management configuration		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVD																												IDLEMODE		FREEEMU	SOFTRESET

Copyright © 2011–2012, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
31:4	RSVD		R	0x0000000
3:2	IDLEMODE	Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state. 0x0: Force-idle mode: local target's IDLE state follows (acknowledges) the system's idle requests unconditionally, that is, regardless of the IP module's internal requirements. Backup mode, for debug only. 0x1: No-idle mode: local target never enters IDLE state. Backup mode, for debug only. 0x2: Smart-idle mode: local target's IDLE state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module shall not generate (IRQ- or DMA-request-related) wake-up events. 0x3: Smart-idle wake-up-capable mode: local target's IDLE state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module may generate (IRQ- or DMA-request-related) wake-up events when in IDLE state. Mode is relevant only if the appropriate IP module "swake-up" output(s) is (are) implemented.	RW	0x2
1	FREEEMU	Sensitivity to emulation (debug) suspend input signal. 0x0: IP module is sensitive to emulation suspend. 0x1: IP module is not sensitive to emulation suspend.	RW	0
0	SOFTRESET	Software reset. (Optional) Write 0x0: No action Read 0x0: Reset done, no pending action Read 0x1: Reset (software or other) ongoing Write 0x1: Initiate software reset	RW	0

Table 24-312. MCSPI_SYSCONFIG

Address Offset	0x110		
Physical Address	See Table 24-303	**Instance**	MCSPI1 MCSPI2 MCSPI3 MCSPI4
Description	This register allows controlling various parameters of the OCP interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																						CLOCKACTIVITY		RESERVED			SIDLEMODE		ENAWAKEUP	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Reads returns 0	RW	0x000000
9:8	CLOCKACTIVITY	Clocks activity during wake-up mode period 0x0: OCP and functional clocks may be switched off. 0x1: OCP clock is maintained. Functional clock may be switched off. 0x2: Functional clock is maintained. OCP clock may be switched off. 0x3: OCP and functional clocks are maintained.	RW	0x0
7:5	RESERVED	Reads returns 0	RW	0x0
4:3	SIDLEMODE	Power management 0x0: If an idle request is detected, the McSPI acknowledges it unconditionally and goes in inactive mode. Interrupt, DMA requests and wake-up lines are unconditionally deasserted and the module wake-up capability is deactivated even if the MCSPI_SYSCONFIG[EnaWakeUp] bit is set. 0x1: If an idle request is detected, the request is ignored and the module does not switch to wake-up mode, and keeps on behaving normally. 0x2: If an idle request is detected, the module will switch to wake-up mode based on its internal activity, and the wake-up capability can be used if the bit MCSPI_SYSCONFIG[EnaWakeUp] is set. 0x3: Reserved - do not use.	RW	0x2
2	ENAWAKEUP	Wake-up feature control 0x0: Wake-up capability is disabled. 0x1: Wake-up capability is enabled.	RW	1
1	SOFTRESET	Software reset. During reads it always returns 0. 0x0: (write) Normal mode 0x1: (write) Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware.	RW	0
0	AUTOIDLE	Internal OCP clock-gating strategy 0x0: OCP clock is free-running. 0x1: Automatic OCP clock gating strategy is applied, based on the OCP interface activity.	RW	1

Bits	Field Name	Description	Type	Reset
7	WAKD	SWAKEUP output (signal data value of internal signal to system). The signal is driven high or low according to the value written into this register bit. 0x0: The pin is driven low. 0x1: The pin is driven high.	RW	0
6	SPICLK	SPICLK line (signal data value) If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the CLKSPI line (high or low), and a write into this bit has no effect. If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the CLKSPI line is driven high or low according to the value written into this register.	RW	0
5	SPIDAT_1	SPIDAT[1] line (signal data value) If MCSPI_SYST[SPIDATDIR1] = 0 (output mode direction), the SPIDAT[1] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIDATDIR1] = 1 (input mode direction), this bit returns the value on the SPIDAT[1] line (high or low), and a write into this bit has no effect.	RW	0
4	SPIDAT_0	SPIDAT[0] line (signal data value) If MCSPI_SYST[SPIDATDIR0] = 0 (output mode direction), the SPIDAT[0] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIDATDIR0] = 1 (input mode direction), this bit returns the value on the SPIDAT[0] line (high or low), and a write into this bit has no effect.	RW	0
3	SPIEN_3	SPIEN[3] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the SPIENT[3] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the SPIEN[3] line (high or low), and a write into this bit has no effect.	RW	0
2	SPIEN_2	SPIEN[2] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the SPIENT[2] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the SPIEN[2] line (high or low), and a write into this bit has no effect.	RW	0
1	SPIEN_1	SPIEN[1] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the SPIENT[1] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the SPIEN[1] line (high or low), and a write into this bit has no effect.	RW	0
0	SPIEN_0	SPIEN[0] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the SPIENT[0] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the SPIEN[0] line (high or low), and a write into this bit has no effect.	RW	0

Table 24-324. MCSPI_MODULCTRL

Address Offset	0x128		
Physical Address	See Table 24-303.	**Instance**	MCSPI1 MCSPI2 MCSPI3 MCSPI4
Description	This register is dedicated to the configuration of the serial port interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							FDAA	MOA	INITDLY			SYSTEM_TEST	MS	PIN34	SINGLE

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reads returns 0.	RW	0x000000
8	FDAA	FIFO DMA address 256-bit aligned This register is used when a FIFO is managed by the module and DMA connected to the controller provides only 256-bit aligned address. If this bit is set the enabled channel which uses the FIFO has its data managed through MCSPI_DAFTX and MCSPI_DAFRX registers instead of MCSPI_TX(i) and MCSPI_RX(i) registers. 0x0: FIFO data managed by MCSPI_TX(i) and MCSPI_RX(i) registers. 0x1: FIFO data managed by MCSPI_DAFTX and MCSPI_DAFRX registers.	RW	0
7	MOA	Multiple word OCP access: This register can only be used when a channel is enabled using a FIFO. It allows the system to perform multiple SPI word access for a single 32-bit OCP word access. This is possible for WL < 16. 0x0: Multiple word access disabled 0x1: Multiple word access enabled with FIFO	RW	0
6:4	INITDLY	Initial SPI delay for first transfer: This register is an option only available in SINGLE master mode. The controller waits for a delay to transmit the first SPI word after channel enabled and corresponding TX register filled. This delay is based on SPI output frequency clock. No clock output provided to the boundary and chip select is not active in 4-pin mode within this period. 0x0: No delay for first spi transfer. 0x1: The controller wait 4 SPI bus clock 0x2: The controller wait 8 SPI bus clock 0x3: The controller wait 16 SPI bus clock 0x4: The controller wait 32 SPI bus clock	RW	0x0
3	SYSTEM_TEST	Enables the system test mode 0x0: Functional mode 0x1: System test mode (SYSTEST)	RW	0
2	MS	Master/slave 0x0: Master - The module generates the SPICLK and SPIEN[3:0]. 0x1: Slave - The module receives the SPICLK and SPIEN[3:0].	RW	1

Copyright © 2011–2012, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
1	PIN34	Pin mode selection: This register is used to configure the SPI pin mode, in master or slave mode. If asserted the controller only use SIMO, SOMI, and SPICLK clock pin for SPI transfers. 0x0: SPIEN is used as a chip-select. 0x1: SPIEN is not used. In this mode all related options to chip-select have no meaning.	RW	0
0	SINGLE	Single channel/Multi Channel (master mode only) 0x0: More than one channel will be used in master mode. 0x1: Only one channel will be used in master mode. This bit must be set in Force SPIEN mode.	RW	0

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Read returns 0.	R	0x0
29	CLKG	Clock divider granularity This register defines the granularity of channel clock divider: power of 2 or one clock cycle granularity. When this bit is set the register MCSPI_CHCTRL[EXTCLK] must be configured to reach a maximum of 4096 clock divider ratio. Then the clock divider ratio is a concatenation of MCSPI_CHCONF[CLKD] and MCSPI_CHCTRL[EXTCLK] values 0x0: Clock granularity of power of 2 0x1: One clock cycle granularity	RW	0

Copyright © 2011–2012, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
28	FFER	FIFO enabled for receive: Only one channel can have this bit field set. 0x0: The buffer is not used to receive data. 0x1: The buffer is used to receive data.	RW	0
27	FFEW	FIFO enabled for transmit: Only one channel can have this bit field set. 0x0: The buffer is not used to transmit data. 0x1: The buffer is used to transmit data.	RW	0
26:25	TCS0	Chip-select time control This 2-bit field defines the number of interface clock cycles between CS toggling and first or last edge of SPI clock. 0x0: 0.5 clock cycle 0x1: 1.5 clock cycles 0x2: 2.5 clock cycles 0x3: 3.5 clock cycles	RW	0x0
24	SBPOL	Start-bit polarity 0x0: Start-bit polarity is held to 0 during SPI transfer. 0x1: Start-bit polarity is held to 1 during SPI transfer.	RW	0
23	SBE	Start-bit enable for SPI transfer 0x0: Default SPI transfer length as specified by WL bit field 0x1: Start bit D/CX added before SPI transfer polarity is defined by MCSPI_CH0CONF[SBPOL]	RW	0
22:21	SPIENSLV	Channel 0 only and slave mode only: SPI slave select signal detection. Reserved bits for other cases. 0x0: Detection enabled only on SPIEN[0] 0x1: Detection enabled only on SPIEN[1] 0x2: Detection enabled only on SPIEN[2] 0x3: Detection enabled only on SPIEN[3]	RW	0x0
20	FORCE	Manual SPIEN assertion to keep SPIEN active between SPI words (single channel master mode only). 0x0: Writing 0 into this bit drives low the SPIEN line when MCSPI_CHCONF(i)[EPOL]=0, and drives it high when MCSPI_CHCONF(i)[EPOL]=1. 0x1: Writing 1 into this bit drives high the SPIEN line when MCSPI_CHCONF(i)[EPOL]=0, and drives it low when MCSPI_CHCONF(i)[EPOL]=1.	RW	0
19	TURBO	Turbo mode 0x0: Turbo is deactivated (recommended for single SPI word transfer). 0x1: Turbo is activated to maximize the throughput for multiple SPI words transfer.	RW	0
18	IS	Input Select 0x0: Data line 0 (SPIDAT[0]) selected for reception 0x1: Data line 1 (SPIDAT[1]) selected for reception	RW	1
17	DPE1	Transmission enable for data line 1 (SPIDATAGZEN[1]) 0x0: Data line 1 (SPIDAT[1]) selected for transmission 0x1: No transmission on Data Line1 (SPIDAT[1])	RW	1
16	DPE0	Transmission Enable for data line 0 (SPIDATAGZEN[0]) 0x0: Data Line0 (SPIDAT[0]) selected for transmission 0x1: No transmission on data line 0 (SPIDAT[0])	RW	0

Bits	Field Name	Description	Type	Reset
5:2	CLKD	Frequency divider for SPICLK (only when the module is a Master SPI device). A programmable clock divider divides the SPI reference clock (CLKSPIREF) with a 4-bit value, and results in a new clock SPICLK available to shift-in and shift-out data. By default the clock divider ratio has a power of 2 granularity when MCSPI_CHCONF[CLKG] is cleared. Otherwise this register is the 4-LSB bit of a 12-bit register concatenated with clock divider extension MCSPI_CHCTRL[EXTCLK] register. The value description below defines the clock ratio when MCSPI_CHCONF[CLKG] is set to 0. 0x0: 1 0x1: 2 0x2: 4 0x3: 8 0x4: 16 0x5: 32 0x6: 64 0x7: 128 0x8: 256 0x9: 512 0xA: 1024 0xB: 2048 0xC: 4096 0xD: 8192 0xE: 16384 0xF: 32768	RW	0x0
1	POL	SPICLK polarity 0x0: SPICLK is held high during the ACTIVE state 0x1: SPICLK is held low during the ACTIVE state	RW	0
0	PHA	SPICLK phase 0x0: Data are latched on odd-numbered edges of SPICLK. 0x1: Data are latched on even-numbered edges of SPICLK.	RW	0

24.5 Multichannel Buffered Serial Port (McBSP)

This section introduces the multichannel buffered serial port (McBSP)

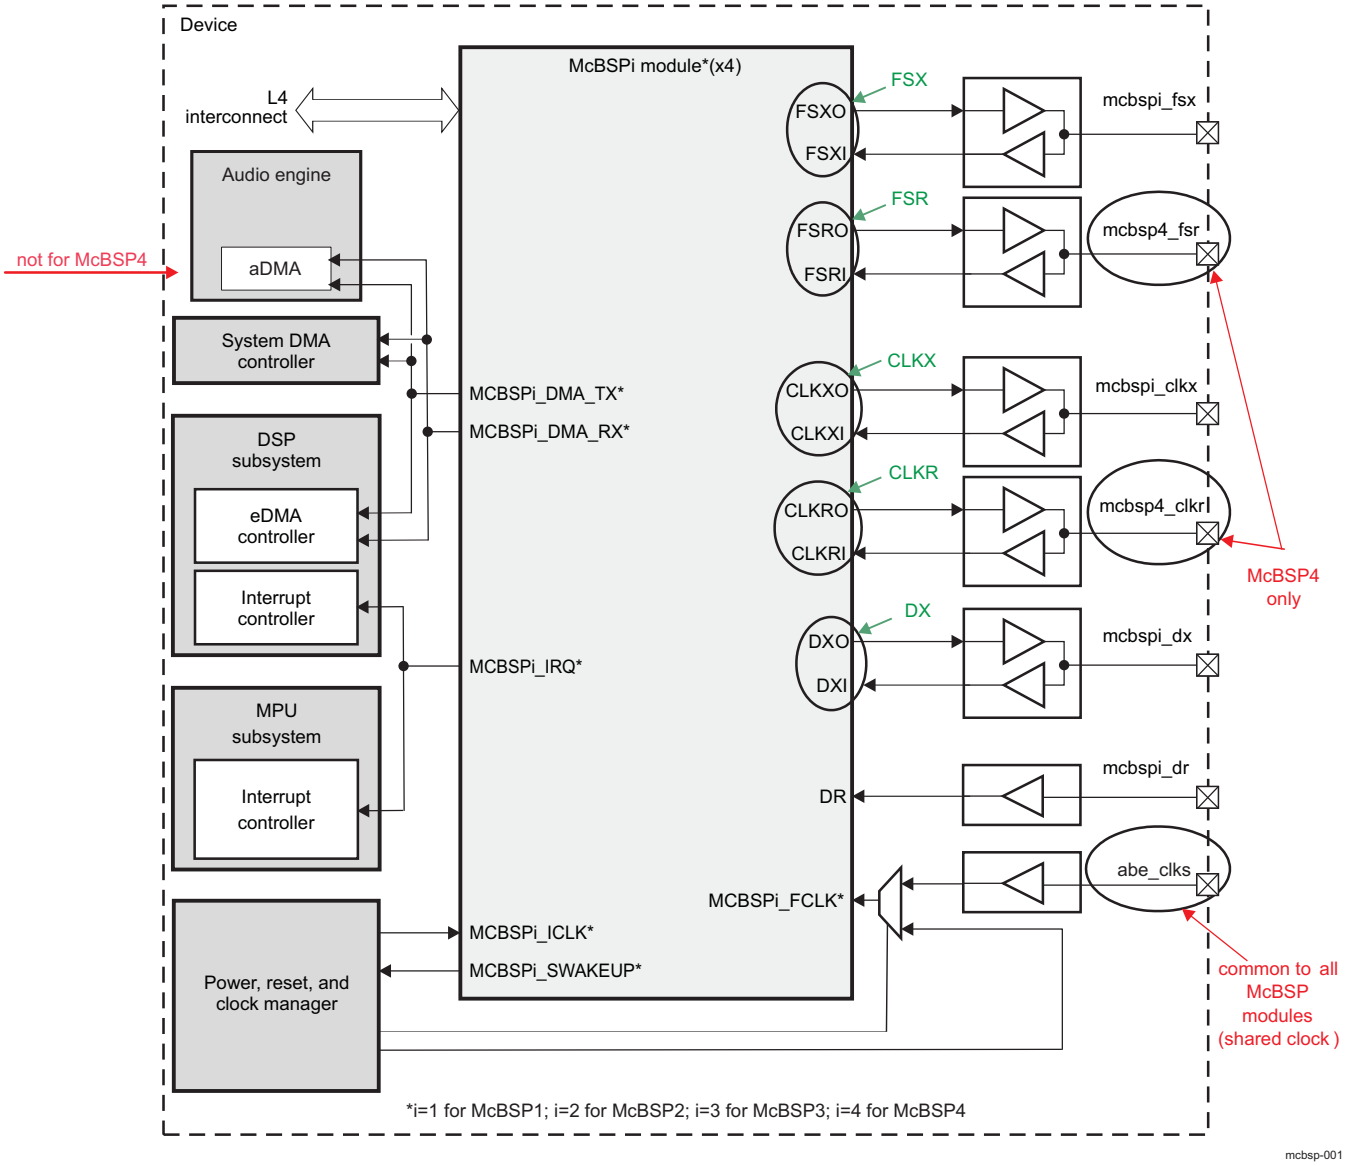
24.5.1 McBSP Overview

The McBSP provides a full-duplex direct serial interface between the device and other devices in a system such as other application devices (digital base band), audio and voice codec, etc. Because of its high level of versatility, it can accommodate a wide range of peripherals and clocked frame oriented protocols (for more information, see Section 24.5.1.1, *McBSP Features*).

The device provides four instances of the McBSP module.

Figure 24-111 is an overview of the McBSP in the device.

Figure 24-111. McBSP Highlight



24.5.1.1 McBSP Features

The main features of the McBSP modules are:

- L4 interconnect slave interface supports:

Copyright © 2011–2012, Texas Instruments Incorporated

  - 32-bit data bus width
  - 32-bit access supported
  - 16-/8-bit access not supported
  - 10-bit address bus width
  - Burst mode not supported
  - Write nonposted transaction mode supported
- 128 × 32-bit words (512 bytes) for each buffer for transmit/receive operations
- Transmit and receive direct memory access (DMA) requests triggered with programmable FIFO thresholds
- Serial interface description
  - 6-pin configuration (McBSP 4 only)
  - 4-pin configuration (McBSP1, 2, 3)
  - Full-duplex communication
  - Multichannel selection modes
    - Support to enable or block transfers in each channel
    - 128 channels for transmission and reception
  - Direct interface to industry-standard codecs, analog interface chips (AICs), and other serially connected A/D and D/A devices:
    - Inter-IC sound (I2S™) compliant devices
    - Pulse code modulation (PCM) devices
    - Time division multiplexed (TDM) bus devices

CAUTION

McBSP modules do not offer support for μ-law and A-law companding, two partitions mode dynamic reassignment, AC'97, and SPI protocol.

  - A wide selection of data sizes: 8, 12, 16, 20, 24, and 32 bits
  - Bit reordering (send/receive least-significant bit [LSB])
- Clock and frame-synchronization generation support:
  - Independent clocking and framing for reception and for transmission up to 48 MHz
  - Support for external generation of clock signals and frame-synchronization (frame-sync) signals
  - A programmable sample rate generator (SRG) for internal generation and control of clock signals and frame-sync signals
  - Programmable polarity for frame-sync pulses and clock signals

NOTE:

- McBSP modules do not support features such as retransmit or re-receive of an erroneous frame or word.
- McBSP modules support dual-phase frames to provide I2S fully compliant capabilities. This dual-phase mode, however, is limited to one channel (or word) for each phase instead of 128 channels maximum for single-phase mode.

Copyright © 2011–2012, Texas Instruments Incorporated

24.5.2 McBSP Environment

This section describes the intended functions for the McBSP module from an environment point of view (that is, external connections). It presents the McBSP connectivity options, lists the possible interfaces, and details the protocol and data format used in each case.

24.5.2.1 McBSP Functions

The device provides four instances of the McBSP module called McBSP1, McBSP2, McBSP3, and McBSP4.

The recommended use (nonexhaustive) for each McBSP module in the device is:

- McBSP1: Digital baseband (DBB) data
- McBSP2: Audio data
- McBSP3: Bluetooth® voice data
- McBSP4: Midi data

Table 24-338 describes the functions and the corresponding application fields.

Table 24-338. Functions Description

Function	Application Field	Recommended McBSP Module	Description
Control and data	DBB data	McBSP1	Serial interface to transfer data
Audio data	Audio data without audio buffer and sidetone feature	McBSP2	Audio interface to transfer audio data with I2S
	Midi data	McBSP4	
Voice data	Bluetooth voice data without sidetone feature	McBSP3	Voice interface to transfer voice data with PCM

24.5.2.2 McBSP Signals Descriptions

The four McBSP modules consist of a data-flow path and a control path connected to external devices by a serial interface with 6-pin configuration (McBSP 4 only) or 4-pin configuration (McBSP1, 2, 3).

For a McBSP module with 6-pin configuration, an internal loopback capability between transmitter and receiver clock signals, and both frame-sync signals, enables using the McBSP module with 4-pin configuration. The related internal multiplexers are controlled through the system control module on the device (see Section 24.5.3, *McBSP Integration*). Table 24-339 describes the inputs/outputs (I/Os).

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-339. I/O Description

Pin Name	I/O	Description	Internal Signal Name	Reset Value	Control and Data	Audio Data	Voice Data
abe_clks	I	External clock (shared by all McBSP modules)	CLKS	0	✓	✓	✓
abe_mcbspi_dr	I	Receive serial data	DR	Z	✓	✓	✓
abe_mcbspi_dx	(I)O[1]	Transmit serial data	DX	Z	✓	✓	✓
abe_mcbspi_clkx	I/O [2]	Transmit clock[3]	CLKX	Z	✓	✓	✓
abe_mcbspi_fsx	I/O [2]	Transmit frame synchronization [4]	FSX	Z	✓	✓	✓
mcbsp4_dr	I	Receive serial data	DR	Z	✓	✓	✓
mcbsp4_dx	(I)O [1]	Transmit serial data	DX	Z	✓	✓	✓
mcbsp4_clkx	I/O [2]	Transmit clock[3]	CLKX	Z	✓	✓	✓
mcbsp4_fsx	I/O [2]	Transmit frame synchronization [4]	FSX	Z	✓	✓	✓
mcbsp4_clkr	I/O [2]	Receive clock[5]	CLKR	Z	✓		
mcbsp4_fsr	I/O [2]	Receive frame synchronization [6]	FSR	Z	✓		

(1) i = 1 to 3; I = Input; O = Output; I/O = Bidirectional
(2) For details of the I/O selection, see Section 24.5.2.3.1, *McBSP Modes*.
(3) This signal is also used as CLKR when it is configured as output.
(4) This signal is also used as FSR when it is configured as output.
(5) This signal is also used as CLKX when it is configured as input.
(6) This signal is also used as FSX when it is configured as input.

- The abe_clks pin can be used to inject an external clock. This clock is used to generate control signals depending on the module internal configuration (see Section 24.5.4.9, *McBSP SRG*). The CLKS signal of the McBSP modules is linked to an external signal through the abe_clks pin, but the CLKS signal can also be linked to an internal clock provided by the power, reset, and clock management (PRCM) module of the device. For more information, see Section 24.5.3, *McBSP Integration*.
- Data are transmitted to external devices interfacing with McBSP modules through the mcbspi_dx pin. Data from those devices are received on the mcbspi_dr pin.

NOTE: The mcbspi_dx pin is an I/O signal to use the McBSP module in half-duplex mode.

- Control information is communicated by the following pins:
  - mcbspi_clkx (transmit clock)
  - mcbsp4_clkr (receive clock)
  - mcbspi_fsx (transmit frame-sync)
  - mcbsp4_fsr (receive frame-sync)

Copyright © 2011–2012, Texas Instruments Incorporated

CAUTION

External pins mcbsp4_clkr and mcbsp4_fsr are connected to pads only for McBSP4; other McBSP modules do not have these connections. For these modules, CLKR and FSR signals sources are mcbspi_clkx and mcbspi_fsx pins, respectively. Consequently, there is a light restriction on other McBSP modules when used in full-duplex mode. Reception and transmission use the same clock signal and the same frame-sync signal.

24.5.2.3 McBSP Functions Description

24.5.2.3.1 McBSP Modes

For all McBSP functions, McBSP modules can operate in master or slave mode. The difference between these modes is the definition of the source of McBSP clocks and McBSP frames synchronization:

- Master mode: McBSP module provides them to the external device
- Slave mode: McBSP module receives them from the external device

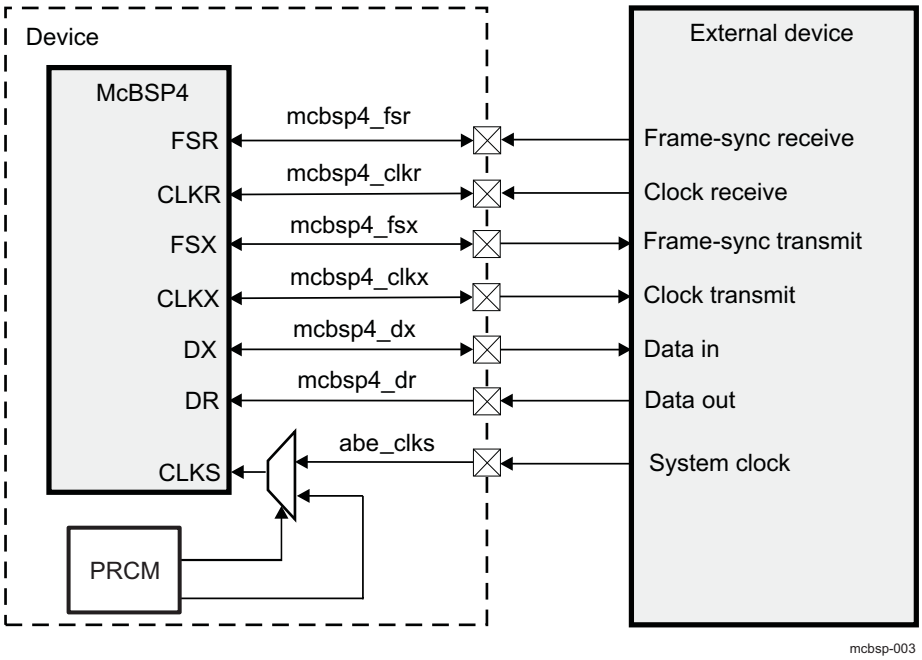
The choice between the two modes depends on technical data of the external device and the type of interface (protocols and data formats). For one McBSP module, there are four possible functions:

- Transmit-and-receive master mode
- Transmit-and-receive slave mode
- Transmit master mode and receive slave mode
- Transmit slave mode and receive master mode

NOTE: If the McBSP has a serial interface with 4-pin configuration (McBSP1, 2, 3), only modes 1 and 2 are possible.

Figure 24-112 shows the connection between McBSP4 (6-pin configuration) and an external device in transmit master mode and receive slave mode.

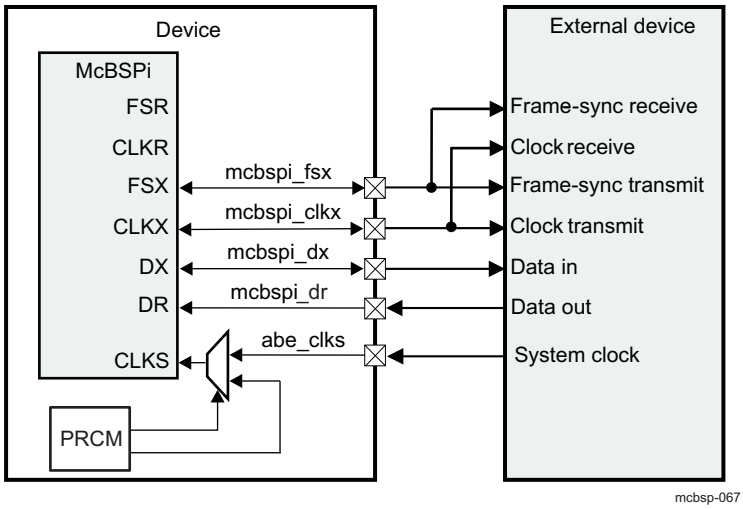
Figure 24-112. Mode Overview of McBSP4



Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-113 shows the connection between the McBSPi module, where i = 1, 2, or 3 (4-pin configuration) and an external device in transmit and receive master mode.

Figure 24-113. Mode Overview of McBSPi

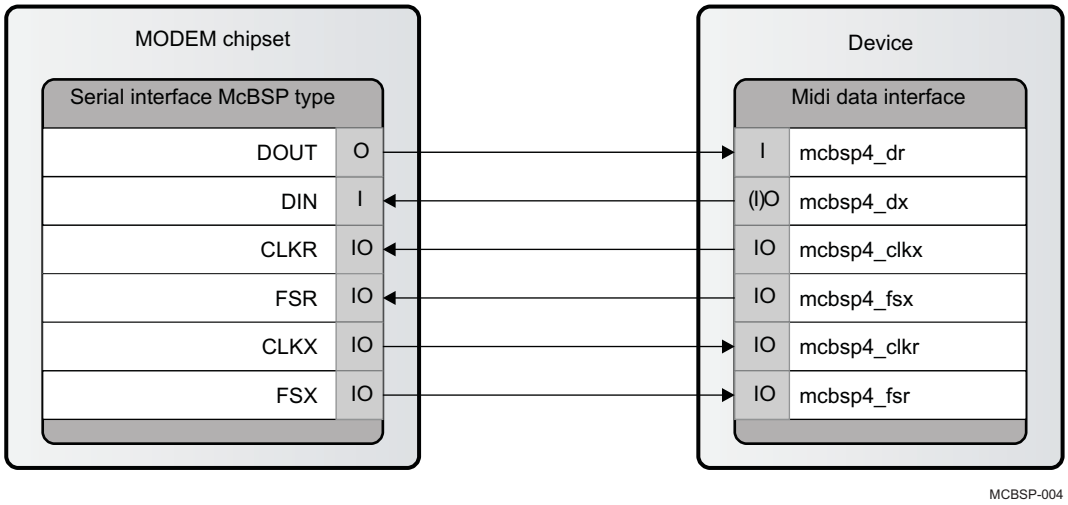


24.5.2.3.2 McBSP Functions

24.5.2.3.2.1 McBSP Function 1: Control and Data

In full-duplex mode (reception and transmission use independent clock signals and frame-sync signals), the McBSP module can be used to exchange control and data with an external chipset, allowing the device to be interfaced with a modem device. Figure 24-114 shows typical connections between device and modem chipset to show the Midi data application.

Figure 24-114. Midi Data Application



In Figure 24-114, McBSP4 is configured in transmit master mode and receive slave mode.

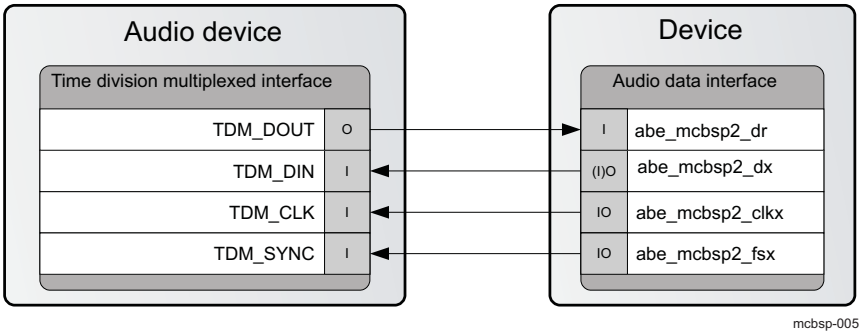
24.5.2.3.2.2 McBSP Function 2: Audio Data

The McBSP module is connected to audio devices through the I2S interface. The I2S link serial interface is a TDM slot-based serial interface that is used to transfer audio data. Those audio devices can be either AICs or other serially connected A/D and D/A devices.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-115 shows typical connections between a device and a typical device of analog audio interface to show the audio data application. The typical device contains several audio analog inputs and outputs and digital microphone inputs.

Figure 24-115. Audio Data Application



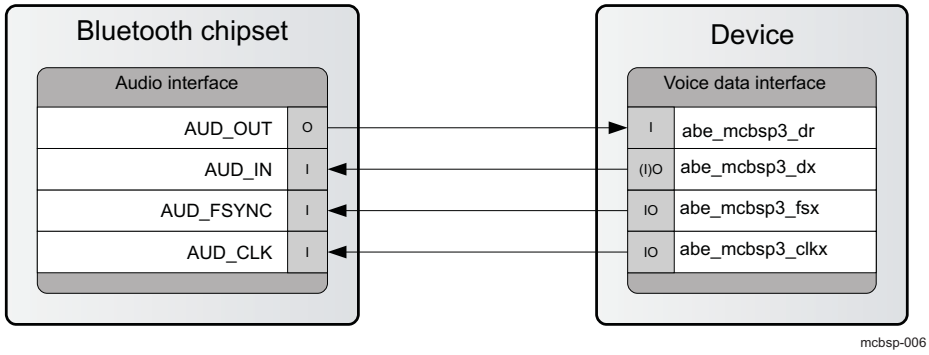
In Figure 24-115, McBSP2 is configured in transmit-and-receive master mode.

24.5.2.3.2.3 McBSP Function 3: Voice Data

The McBSP module is connected to a voice device through the PCM interface. The PCM link serial interface is a TDM slot-based serial interface that is used to transfer voice data. The voice devices can be modem chipsets, Bluetooth chipsets, or other devices with voice data interface.

Figure 24-116 shows typical connections between a device and a Bluetooth chipset (TI BRF6300 or TI BRF6350) to show voice data application.

Figure 24-116. Voice Data Application



In Figure 24-116, McBSP3 is configured in transmit-and-receive master mode.

24.5.2.4 McBSP Protocols and Data Formats

The McBSP module can use one of the three protocols with associated data formats:

- Serial protocol to exchange serial data
- Audio protocol to exchange the audio samples
- Voice protocol to exchange the voice samples

The McBSP modules offer the flexibility to modify the following parameters to adapt to the device features as described in the following subsections.

Copyright © 2011–2012, Texas Instruments Incorporated

24.5.2.4.1 Words, Frames, and Phases Definitions

24.5.2.4.1.1 Words or Channels

The data bits are transferred (transmission or reception) in a group called a serial word or channel. The number of bits in a word (length) is programmable through bit fields (McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 and McBSPi.MCBSPLP_RCR2_REG[7:5] RWDLEN2, McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 and McBSPi.MCBSPLP_XCR2_REG[7:5] XWDLEN2) and can be 8, 12, 16, 20, 24, or 32 bits (see Section 24.5.4.8.3, *Clocking and Framing Data*). The McBSP module uses clock signals to control the time for each bit transfer. Data are sampled/driven on the rising or falling edge of clock signals. This clock polarity is programmable through bit fields of the pin-control register (McBSPi.MCBSPLP_PCR_REG).

For more information, see Section 24.5.4.8.4, *Frame Phases (Dual-Phase Frame I2S Support)*.

24.5.2.4.1.2 Frames

One or more words (maximum 128) are transferred in a group called a frame. The McBSP module can transmit and receive a maximum of 128 words per frame, programmable through bit fields of transmit-and-receive control registers (McBSPi.MCBSPLP_XCR1_REG/McBSPi.MCBSPLP_XCR2_REG and McBSPi.MCBSPLP_RCR1_REG/McBSPi.MCBSPLP_RCR2_REG). For more details, see Section 24.5.4.8.3, *Clocking and Framing Data*.

All the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The McBSP module uses frame-sync signals to determine when each frame is received or transmitted. When a pulse occurs on a frame-sync signal, the McBSP module begins receiving or transmitting a frame of data. When the next pulse occurs, the McBSP module receives or transmits the next frame, and so on. The frame-sync pulse is active high or low. This pulse polarity is programmable through bit fields of the pin control register (McBSPi.MCBSPLP_PCR_REG).

Each frame transfer can be delayed by 0, 1, or 2 clock cycles, depending on the value of bits for transmit and receive control registers (McBSPi.MCBSPLP_XCR2_REG and McBSPi.MCBSPLP_RCR2_REG). For more information, see Section 24.5.4.10.6.3, *Preventing Unexpected Transmit Frame-sync Pulses* and Section 24.5.4.10.3.3, *Preventing Unexpected Receive Frame-sync Pulses*.

24.5.2.4.1.3 Phases

The McBSP module allows configuring of each frame to contain one or two phases. The McBSP module supports dual-phase frames to provide I2S fully compliant capabilities. These two phases represent left and right channels of audio stereo signals.

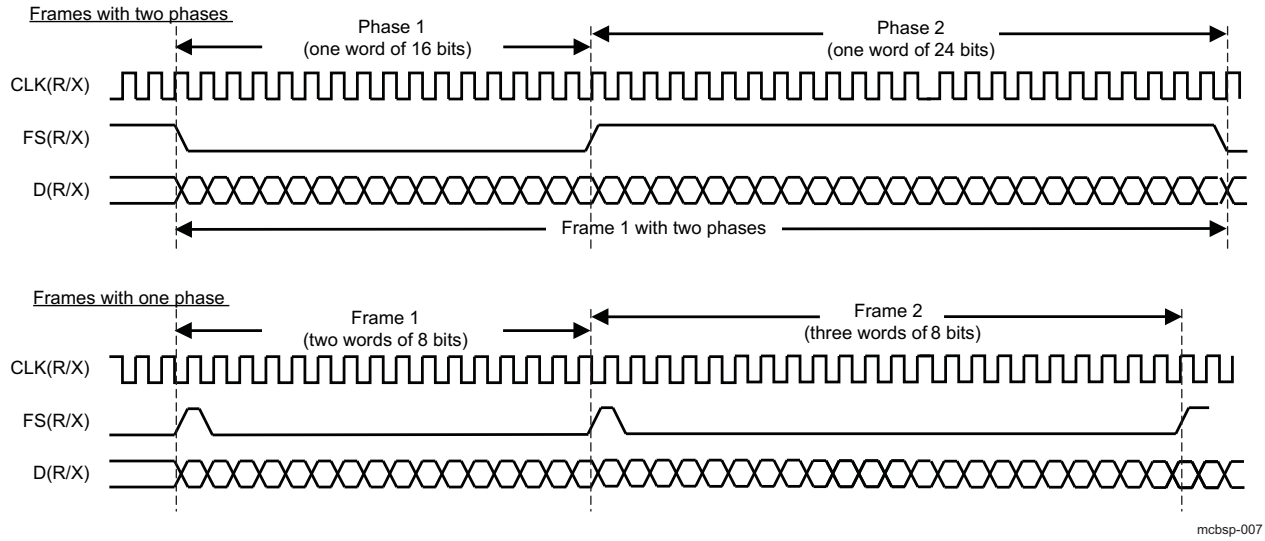
The limitation on dual-phase frame is that the number of words per phase must be set to 1 for both first and second phases. The number of bits per word, however, can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers.

For example, software may define a frame composed of a first phase with one 12-bit word and a second phase with one 16-bit word. This configuration allows the software to compose frames for custom applications. For more details, see Section 24.5.4.8.4, *Frame Phases (Dual-Phase Frame I2S Support)*.

Figure 24-117 shows signal activity for two possible reception/transmission scenarios.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-117. McBSP Reception/Transmission Signal Activity



24.5.2.4.2 Serial Protocol and Data Formats

24.5.2.4.2.1 Protocol

The serial protocol is used to send and receive control data without specific formats. This allows the McBSP module to accommodate all serial devices and their protocols.

24.5.2.4.2.2 Data Format

Figure 24-118 shows typical operation of the McBSP clock and frame-sync signals. Serial clocks CLKR and CLKX define the boundaries between bits for receive and transmit, respectively. Similarly, frame-sync signals FSR and FSX define the beginning of an element and/or frame transfer. The McBSP module allows the configuration of the following parameters for data and frame synchronization:

- Polarity of FSR, FSX, CLKX, and CLKR
- The number of words per frame
- The number of bits per word
- Whether subsequent frame synchronization restarts the serial data stream or is ignored
- The data delay from frame synchronization to first data bit which can be 0- , 1- , or 2-bit delays

The configuration is independent for receive and transmit parts. For more details and configuration examples, see Section 24.5.4, *McBSP Functional Description*, and Section 24.5.5, *McBSP Basic Programming Model*.

24.5.2.4.3 Audio Protocol and Data Formats

24.5.2.4.3.1 Protocol

The I2S protocol is used to send and receive audio data from 8-kHz to 48-kHz sampling rate (frame-sync frequency), with 16 bits or 32 bits per words (supported frequencies are 8, 11.025, 12, 16, 22.05, 24, 32, 44.1, and 48 kHz).

The frame-sync signal defines the frame length in the I2S protocol. Each frame consists of a fixed number of words. In dual-phase frame, the frame-sync signal is low for the left phase time slot and is high for the right phase time slot. In addition, the frame-sync signal is synchronous to the falling edge of the clock signal.

24.5.2.4.3.2 Data Formats

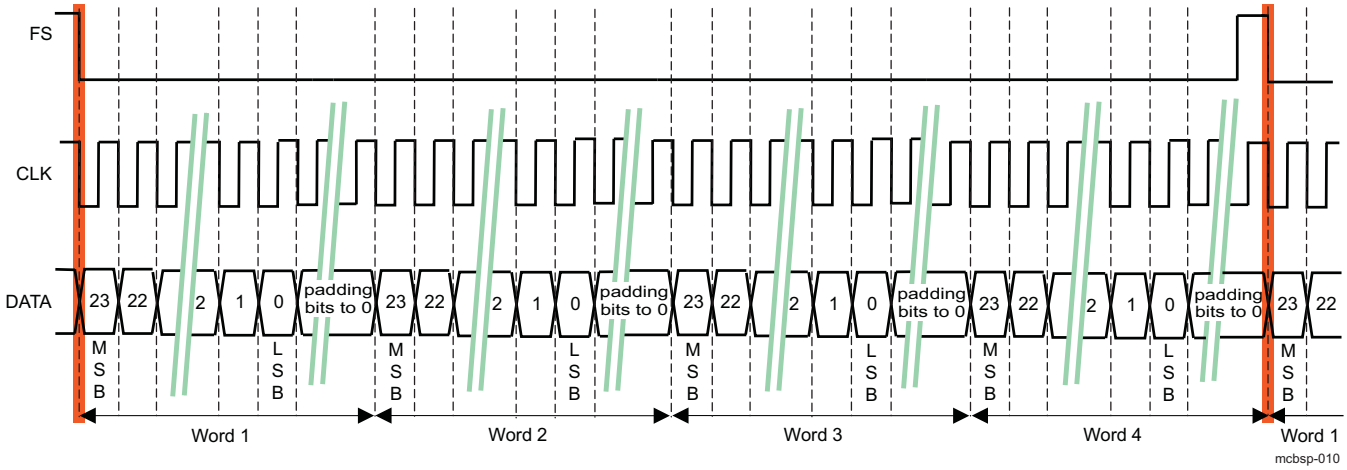
The I2S protocol supports TDM, I2S, left-justified, and right-justified data formats.

Bits of each word (sample) are clocked using the clock signal. For each word, the most-significant bit (MSB) is first. LSBs are padded to 0 when the data length (8, 12, 16, 20, or 24 bits) is less than the sample word width (16 or 32 bits).

24.5.2.4.3.2.1 TDM Data Format

Figure 24-119 shows that each frame of TDM data format is composed of four words (or channels).

Figure 24-119. TDM Data Format; Word Width: 32 Bits; Data Length: 24 Bits

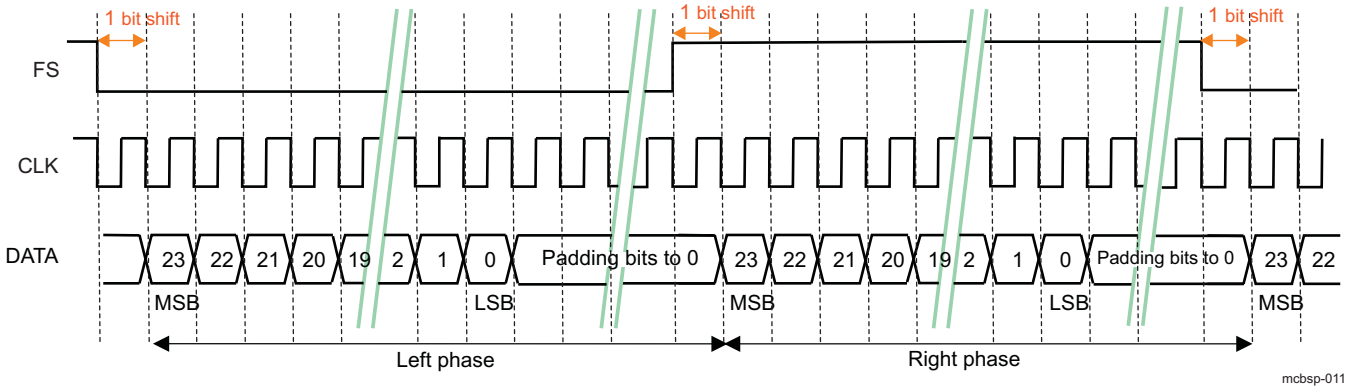


24.5.2.4.3.2.2 I2S Data Format

Figure 24-120 shows an example with 24-bit data (MSB first) and 8 padding bits at 0.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-120. I2S Data Format; Word Width: 32 Bits; Data Length: 24 Bits



24.5.2.4.3.2.3 Left-Justified Data Format

Figure 24-121 shows an example with 24-bit data (MSB first) and 8 padding bits at 0.

24.5.2.4.4 Voice Protocol and Data Formats

24.5.2.4.4.1 Protocol

The PCM protocol is intended to transfer voice data at 8-kHz (default narrowband mode) or 16-kHz (wideband mode) sample rate (frame-sync frequency). PCM protocol can act as a slave or master, and is used by the Bluetooth interface and the modem generic interface. The frame synchronization defines the frame length in the PCM protocol. Bits are clocked using the PCM clock signal, with the MSB first.

24.5.2.4.4.2 Data Formats

Two modes are available for the PCM protocol: mode 1 and mode 2. Both modes have two types of operations: mono or stereo channels. The difference between PCM mode 1 and PCM mode 2 is in the way in which they use the rising or the falling edge of the clock signal, and the frame-sync polarity.

- PCM mode 1: Input data is latched on the falling edge of the clock, and the transmitted data starts on the rising edge of the clock. The frame-sync pulse is active high.
- PCM mode 2: Input data is latched on the rising edge of the clock, and the transmitted data starts on the falling edge of the clock. The frame-sync pulse is active low.

Figure 24-123 and Figure 24-124 show an example of PCM protocol, mode 1 and mode 2, respectively, for a frame composed of one word (32 bits wide) with 16 bits of data.

Figure 24-123. PCM Protocol – Mode 1 Data Format

24.5.3 McBSP Integration

This section describes the integration of the McBSP module in the device, including information about clocks, resets, and hardware requests.

McBSP modules are divided into two families: McBSP modules that are gated in the AUDIO power domain (McBSP1, 2, and 3) and in the L4_PER power domain (McBSP4).

Figure 24-125 through Figure 24-128 show the integration of the McBSP modules in the device, including interrupt handlers, DMA requests, clock generators, and interconnections.

The features of the McBSP modules are:

- Wake-up request
- Two DMA requests
- One IRQ
- One functional clock
- One interface clock

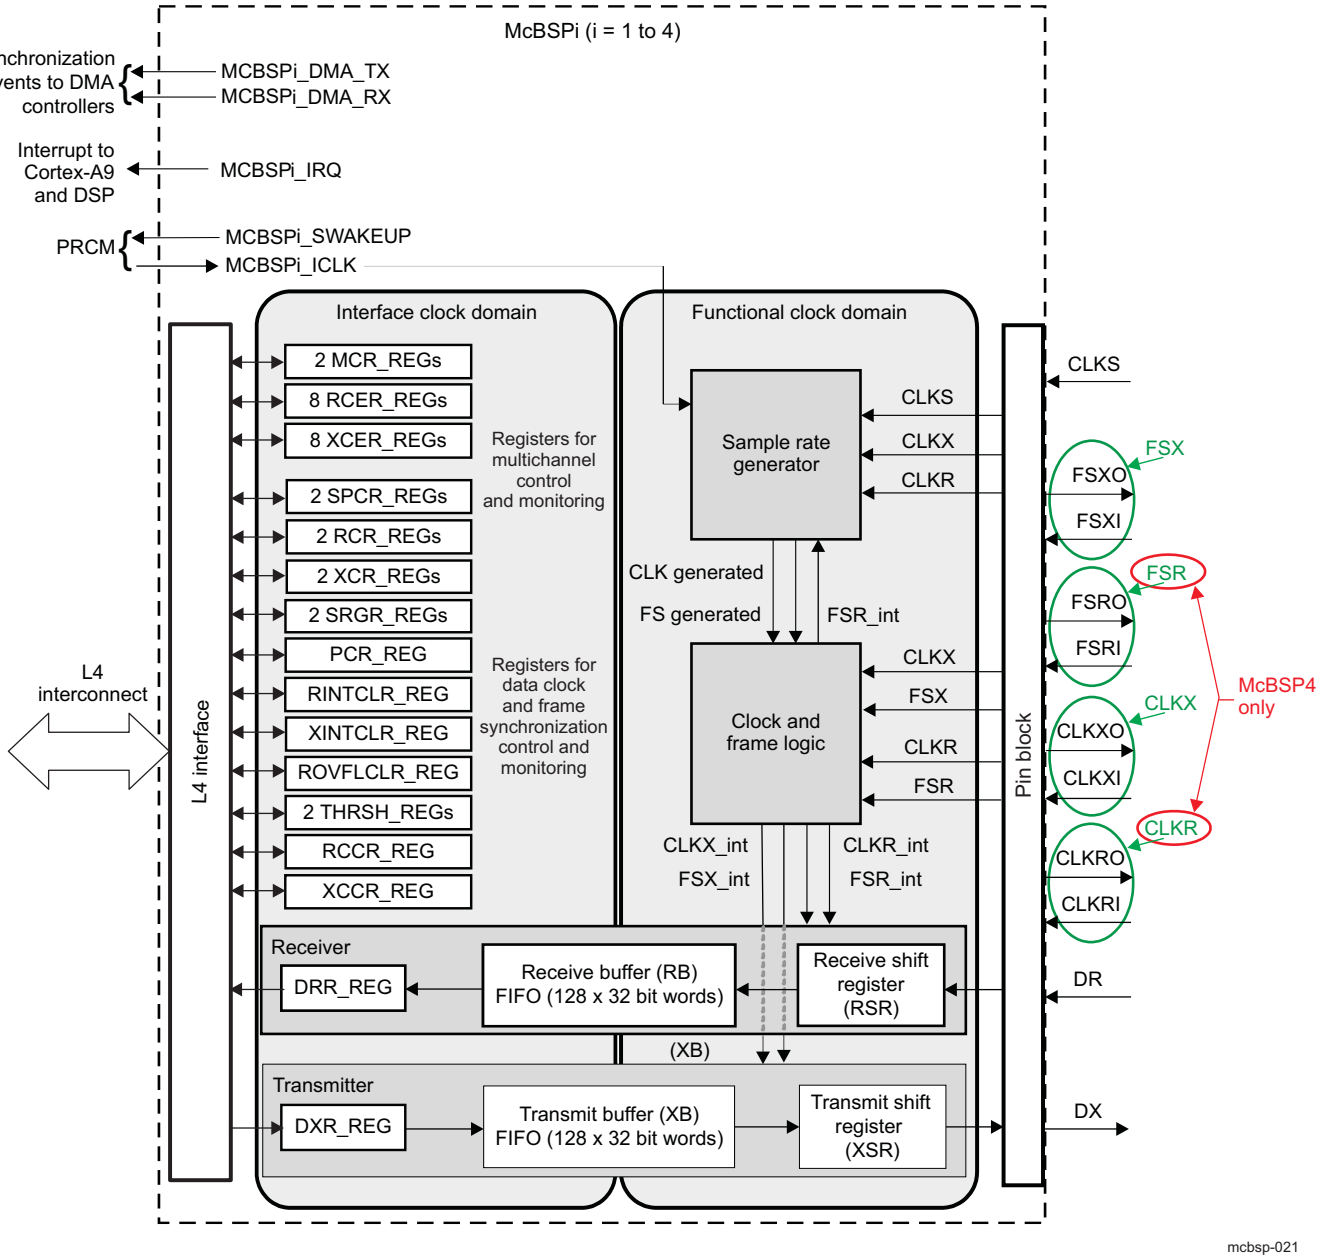
24.5.4 McBSP Functional Description

This section is a functional description of the McBSP module.

24.5.4.1 Block Diagram

Figure 24-129 shows the functional block diagram of the four instances of the McBSP modules.

Figure 24-129. McBSPi Block Diagram



24.5.4.2 Signal Source Control

The sources of the CLKX, DX, DR, FSX, FSR, and CLKR signals are defined by the system control module. The control registers of the system control module are used to select these signal sources. For more information, see Chapter 19, *Control Module*.

Copyright © 2011–2012, Texas Instruments Incorporated

24.5.4.3 McBSP Clock Configuration

24.5.4.3.1 McBSP1 Clocks

McBSP1 is clocked by a functional clock (CLKS and CLKX) and an interface clock (MCBSP1_ICLK).

- The functional clock is used to generate control signals depending on the internal configuration of the module (see Section 24.5.4, *McBSP Functional Description*). For McBSP1, the functional clock comes from the CLKS and CLKX signals. The choice between these two clocks is defined by the MCBSP1.MCBSPLP_PCR_REG[7] SCLKME bit and the MCBSP1.MCBSPLP_SRGR2_REG[13] CLKSM bit.

  The CLKS signal of McBSP1 is linked to an internal clock (MCBSP1_FCLK) provided by the PRCM module. The CLKS signal can also be linked to an external signal through the abe_clks pin of the device boundary.

  NOTE: When McBSP1 no longer requires the functional clock, software can disable it at the PRCM level by configuring the MODULEMODE bit field to 0x0 (PRCM.CM1_ABE_MCBSP1_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

  At the PRCM level, when all the conditions to shut off the MCBSP1_FCLK clock are met, the PRCM module automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the McBSP module. For more information, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

  Only the CLKX signal is connected by mcbsp4_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.
- The MCBSP1_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP1 L4 interface and McBSP1 configuration interface through the Cortex-A9 MPU/DSP shared bus. It can also be an input clock for the McBSP SRG (clock divider), depending on the module configuration (see Section 24.5.4.9, *McBSP SRG*). Its source is the ABE_ICLK2 signal.

  NOTE: When McBSP1 no longer requires the interface clock, software can disable it at the PRCM level by configuring the MODULEMODE bit field (PRCM.CM1_ABE_MCBSP1_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

  At the PRCM level, when all the conditions to shut off the ABE_ICLK2 clock are met the PRCM module automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the McBSP module. For more information, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset , and Clock Management*.

24.5.4.3.2 McBSP2 Clocks

McBSP2 is clocked by a functional clock (CLKS or CLKX) and an interface clock (MCBSP2_ICLK).

- The functional clock is used to generate control signals depending on the internal configuration of the module (see Section 24.5.4, *McBSP Functional Description*). For McBSP2, the functional clock comes from the CLKS and CLKX signals. The choice between these two clocks is defined by the MCBSP2.MCBSPLP_PCR_REG[7] SCLKME bit and the MCBSP2.MCBSPLP_SRGR2_REG[13] CLKSM bit.

Copyright © 2011–2012, Texas Instruments Incorporated

NOTE: When McBSP2 no longer requires the functional clock, software can disable it at the PRCM level by configuring the MODULEMODE bit field to 0x0 (PRCM.CM1_ABE_MCBSP2_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At the PRCM level, when all the conditions to shut off the MCBSP2_FCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the McBSP module. For more information, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Only the CLKX signal is connected by mcbsp2_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of the SRG.

- The MCBSP2_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP2 L4 interface and McBSP2 configuration interface through the Cortex-A9 MPU/DSP shared bus. It can also be an input clock for the McBSP SRG (clock divider), depending on the module configuration (see Section 24.5.4.9, *McBSP SRG*). Its source is the ABE_ICLK2 signal.

NOTE: When McBSP2 no longer requires the interface clock, software can disable it at the PRCM level by configuring the MODULEMODE bit field (PRCM.CM1_ABE_MCBSP2_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At the PRCM level, when all the conditions to shut off the ABE_ICLK2 clock are met the PRCM module automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the McBSP module. For more information, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

24.5.4.3.3 McBSP3 Clocks

McBSP3 is clocked by a functional clock (CLKS or CLKX) and an interface clock (MCBSP3_ICLK).

- The functional clock is used to generate control signals depending on the internal configuration of the module (see Section 24.5.4, *McBSP Functional Description*). For McBSP3, the functional clock comes from the CLKS and CLKX signals. The choice between these two clocks is defined by the MCBSP3.MCBSPLP_PCR_REG[7] SCLKME bit and the MCBSP3.MCBSPLP_SRGR2_REG[13] CLKSM bit.

NOTE: When McBSP3 no longer requires the functional clock, software can disable it at the PRCM level by configuring the MODULEMODE bit field to 0x0 (PRCM.CM1_ABE_MCBSP3_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At the PRCM level, when all the conditions to shut off the MCBSP3_FCLK clock are met the PRCM module automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the McBSP module. For more information, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Only, the CLKX signal is connected by mcbsp3_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.

- The MCBSP3_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP3 L4 interface and McBSP3 configuration interface via the Cortex-A9 MPU/DSP shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see Section 24.5.4.9, *McBSP SRG*). Its source is either the ABE_ICLK2 signal.

Copyright © 2011–2012, Texas Instruments Incorporated

NOTE: When the McBSP2 module does not require the interface clock anymore, the software can disable it at the PRCM level by configuring the MODULEMODE bit field (PRCM.CM1_ABE_MCBSP3_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At PRCM level, when all the conditions to shut-off ABE_ICLK2 clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to McBSP module. For more information, see Section 3.1.1.1.2, *Module Level Clock Management* in Chapter 3, *Power, Reset, and Clock Management*.

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE_PER[1] register AUTO_MCBSP3 bit set to 1). In this case, McBSP3_ICLK follows the AUDIO_L4 clock domain behavior on the device. For more information, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

24.5.4.3.4 McBSP4 Clocks

McBSP4 is clocked by a functional clock (CLKS, CLKX, or CLKR) and an interface clock (MCBSP4_ICLK).

- The functional clock is used to generate control signals depending on the internal configuration of the module (see Section 24.5.4, *McBSP Functional Description*). For McBSP4, the functional clock comes from the CLKS, CLKX, or CLKR signal. The choice between these three clocks is defined by the MCBSP4.MCBSPLP_PCR_REG[7] SCLKME bit and the MCBSP4.MCBSPLP_SRGR2_REG[13] CLKSM bit.

  NOTE: When McBSP4 no longer requires the PRCM functional clock, software can disable it at the PRCM level by setting the MODULEMODE bit (PRCM.CM_L4PER_MCBSP4_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

  At the PRCM level, when all the conditions to shut off the MCBSP4_FCLK clock are met the PRCM module automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to McBSP module. For more information, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

  The CLKX and CLKR signals are connected either by mcbsp4_clkx or mcbsp4_clkr pads. These signals are used like functional clocks by the intermediary of the SRG.
- The McBSP4_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP4 L4 interface and McBSP4 configuration interface via the Cortex-A9 MPU/DSP shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see Section 24.5.4.9, *McBSP SRG*). Its source is the PER_L4_ICLK signal.

  NOTE: When the McBSP4 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the MODULEMODE bit (PRCM.CM_L4PER_MCBSP4_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

  At PRCM level, when all the conditions to shut-off PER_L4_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP is ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the McBSP module. For more information, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Copyright © 2011–2012, Texas Instruments Incorporated

24.5.4.4 McBSP Software Reset

McBSP4 belongs to the L4_PER domain and its reset signal is L4_PER_RST from the PRCM module. The McBSP1, 2, and 3 modules belong to the AUDIO domain and their reset signal is AUDIO_RST from the PRCM module. Table 24-343 lists the software reset signals to all McBSP modules.

Table 24-343. Software Reset Signals to All McBSP Modules

Type	Bit Field	Register Source	Activation	Description
Software	SOFTRESET	MCBSPi.MCBSPLP_SYSCONFIG_REG[1]	Active high	McBSP global software reset
	RRST	MCBSPi.MCBSPLP_SPCR1_REG[0]	Active low	This resets and disables the receiver, including the RB.
	XRST	MCBSPi.MCBSPLP_SPCR2_REG[0]		This resets and disables the transmitter, including the XB.
	GRST	MCBSPi.MCBSPLP_SPCR2_REG[6]		SRG is reset.
	FRST	MCBSPi.MCBSPLP_SPCR2_REG[7]		Frame-sync logic is reset. Frame-sync generated signal is not generated by the SRG.

For a complete description of the McBSP initialization procedure, see Section 24.5.5.1, *McBSP Initialization Procedure*.

24.5.4.5 McBSP Power Management

24.5.4.5.1 McBSP Operating States

Two operating states are defined for all the McBSP modules:

- ACTIVE state: The module is running synchronously on the interface and functional clocks. Interrupts and DMA requests can be generated according to the configuration (register, master or slave mode, etc) and the external signals.
- IDLE state: As part of the system power management, the PRCM module can request the McBSP modules to enter IDLE state. Depending on the configured acknowledgment mode (force-idle, no-idle and smart-idle modes), a McBSP module effectively enters IDLE state or not. As soon as a McBSP module enters IDLE state, its only activities are those unrelated to clock activity (for example, wake-up features) and its clocks are likely to be switched off at the PRCM level.

NOTE: IDLE request and IDLE acknowledge are only internal signals, with no means to observe or to control. The generation and control of the signals is purely hardware (managed automatically by the PRCM module and the McBSP depending on the SIDLEMODE settings).

24.5.4.5.2 McBSP Acknowledgment Modes

During initialization or configuration of the McBSP module, software must configure how the McBSP module will answer an IDLE solicitation from the PRCM module (that is, the way IDLE acknowledge is asserted following assertion of an idle request).

Each McBSP module can be configured through the MCBSPi.MCBSPLP_SYSCONFIG_REG[4:3] SIDLEMODE bit field as one of the following acknowledgment modes:

- Force-idle mode (SIDLEMODE bit = 0x0): An IDLE request is acknowledged unconditionally, regardless of the internal state of the module. The McBSP module immediately enters IDLE state (no activity), interface and PRCM functional clocks can be stopped, and no interrupts and DMA requests can be generated. In this mode, the McBSP module freezes all the internal activity when the PRCM clocks are switched off by the PRCM module, leading to a potential loss of data.

Copyright © 2011–2012, Texas Instruments Incorporated

CAUTION

In force-idle mode, the wake-up feature is inhibited.

CAUTION

If the McBSP functional part, transmitter or receiver, is running within this period of time (the functional clock source is not the PRCM functional clock), the internal state of the McBSP module will not be idle (FSM states, processes, etc.), and when the McBSP module exits from the Force Idle state unexpected behavior may happen in both receiver and transmitter. To avoid this, both receive and transmit parts, must be disabled by software prior to idle request assertion (all functional clock external sources must be disabled).

- No-idle mode (SIDLEMODE bit = 0x1): An IDLE request is never acknowledged, meaning it prevents the PRCM module from switching off its related clocks and from putting in a lower power state than the power domain to which it belongs. The McBSP module never enters IDLE state (is active).
- Smart-idle mode (SIDLEMODE bit = 0x2): Acknowledgement to an IDLE request is given based on the internal activity of the McBSP module. The McBSP module is in a waiting state, interface and functional clocks can be stopped, no interrupts can be generated, and a wake-up signal can be generated according to the configuration (see Section 24.5.4.5.4, *Analysis of the Receiver Smart-Idle Behavior*) and external signals.

NOTE: The value MCBSPi.MCBSPLP_SYSCONFIG_REG[4:3] SIDLEMODE field = 0x3 must not be used.

When configured in smart-idle mode, the McBSP module also offers an additional granularity on MCBSPi_FCLK and MCBSPi_ICLK gating. The McBSPi.MCBSPLP_SYSCONFIG_REG[9:8] CLOCKACTIVITY bit field is used to determine which clock will be shut down (MCBSPi_FCLK, MCBSPi_ICLK, none of them, or both of them).

CLOCKACTIVITY setting is used in the McBSP module to determine on which part of the module the conditions to acknowledge the PRCM IDLE request will be tested. As an example, if MCBSPi_FCLK is said not to be shut down upon a PRCM IDLE request, this means the McBSP module will consider only MCBSPi_ICLK and the associated pending activities before acknowledging the request.

NOTE: Some McBSP features are associated with MCBSPi_ICLK and others with MCBSPi_FCLK. Using CLOCKACTIVITY along with the smart-idle mode ensures that the features associated with the clock that remain active are always enabled, even if the McBSP has acknowledged an IDLE request. For more information, see Section 24.5.4.5.4, *Analysis of the Receiver Smart-Idle Behavior*.

Table 24-344 lists the value of the bit field and indicates whether the interface (MCBSPi_ICLK) and PRCM functional (MCBSPi_FCLK) clocks can be switched off or not when an IDLE request is received by the McBSP module.

Table 24-344. State of Clocks When the Module is in Idle State

CLOCKACTIVITY Value	Interface Clock (MCBSPi_ICLK)	PRCM Functional Clock
0b00	Off	Off
0b01	Off	On
0b10	On	Off
0b11	On	On

Copyright © 2011–2012, Texas Instruments Incorporated

NOTE: Off means this clock can be switched off.

On means this clock must be maintained during the wake-up period.

CAUTION

The PRCM module does not have any hardware means to read CLOCKACTIVITY settings. Software must ensure a consistent programming between the McBSPi.MCBSPLP_SYSCONFIG_REG[9:8] CLOCKACTIVITY bit field and the PRCM MCBSPi_FCLK and L4_ICLK control bits (see notes in Section 24.5.4.3, *McBSP Clock Configuration*). If the McBSP module is disabled while CLOCKACTIVITY is set to 0x3, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the McBSP clocks. This may lead to unpredictable behaviors.

24.5.4.5.3 Wake-Up Capability

When configured in smart-idle mode, the sources for wake-up generation are a subset of the interrupt sources. The wake-up sources are enabled by setting the McBSPi.MCBSPLP_SYSCONFIG_REG[2] ENAWAKEUP bit (wake-up feature control):

- Set to 0, wake-up capability is disabled.
- Set to 1, wake-up capability is enabled.

The MCBSPi_SWAKEUP signal is the McBSP module asynchronous wake-up signal sent to the PRCM module when a wake-up generation is requested.

The wake-up configurations are defined by setting the corresponding bits in the McBSPi.MCBSPLP_WAKEUPEN_REG register.

24.5.4.5.3.1 Receive Wakeup

There are four receive possible wake-up configurations:

- McBSPi.MCBSPLP_WAKEUPEN_REG[3] RRDYEN bit: The McBSP module asserts the McBSPi_SWAKEUP request when the receive buffer reaches the high threshold value (RTHRESHOLD value + 1) of the McBSPi.MCBSPLP_THRSH1_REG register. If the McBSPi.MCBSPLP_IRQENABLE_REG[3] RRDYEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or DSP subsystems when exiting from idle mode (interrupt will be asserted once the McBSPi.MCBSPLP_IRQSTATUS_REG[3] RRDY bit changes from 0 to 1, indicating that received data is ready to be read).
- McBSPi.MCBSPLP_WAKEUPEN_REG[2] REOFEN bit: The McBSP module asserts the McBSPi_SWAKEUP request at the end of the frame. If the McBSPi.MCBSPLP_IRQENABLE_REG[2] REOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or DSP subsystems when exiting idle mode.
- McBSPi.MCBSPLP_WAKEUPEN_REG[1] RFSREN bit: The McBSP module sends a McBSPi_SWAKEUP request to the PRCM module when a receive frame-sync pulse is detected while the McBSP module is in idle mode. If the McBSPi.MCBSPLP_IRQENABLE_REG[1] RFSREN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or DSP subsystems when exiting idle mode.
- McBSPi.MCBSPLP_WAKEUPEN_REG[0] RSYNCERREN bit: The McBSP module asserts the McBSPi_SWAKEUP request when an unexpected receive frame-sync pulse is detected. If the McBSPi.MCBSPLP_IRQENABLE_REG[0] RSYNCERREN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or DSP subsystems when exiting from idle mode (interrupt is asserted once the McBSPi.MCBSPLP_IRQSTATUS_REG[0] RSYNCERR bit changes from 0 to 1, indicating that a receive error occurred).

Copyright © 2011–2012, Texas Instruments Incorporated

24.5.4.5.3.2 Transmit Wakeup

For transmit, there are five possible wake-up configuration scenarios:

- McBSPi.MCBSPLP_WAKEUPEN_REG[14] XEMPTYEOFEN bit: The McBSP module asserts the McBSPi_SWAKEUP request when a complete frame was transmitted and the transmit buffer is empty. If the McBSPi.MCBSPLP_IRQENABLE_REG[14] XEMPTYEOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or DSP subsystems when exiting idle mode.
- McBSPi.MCBSPLP_WAKEUPEN_REG[10] XRDYEN bit: The McBSP module asserts the McBSPi_SWAKEUP request when the transmit buffer reaches the high threshold value (XTHRESHOLD value + 1) of the McBSPi.MCBSPLP_THRSH2_REG register. If the McBSPi.MCBSPLP_IRQENABLE_REG[10] XRDYEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or DSP subsystems when exiting from idle mode (interrupt is asserted once the McBSPi.MCBSPLP_IRQSTATUS_REG[10] XRDY bit changes from 0 to 1, indicating that transmit buffer data is ready to accept new data).
- McBSPi.MCBSPLP_WAKEUPEN_REG[9] XEOFEN bit: The McBSP module asserts the McBSPi_SWAKEUP request at the end of the frame. If the McBSPi.MCBSPLP_IRQENABLE_REG[9] XEOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or DSP subsystems when exiting idle mode.
- McBSPi.MCBSPLP_WAKEUPEN_REG[8] XFSXEN bit: The McBSP module sends a McBSPi_SWAKEUP request when a transmit frame-sync pulse is detected while the module is in idle mode. If the McBSPi.MCBSPLP_IRQENABLE_REG[8] XFSXEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or DSP subsystems when exiting idle mode.
- McBSPi.MCBSPLP_WAKEUPEN_REG[7] XSYNCERREN bit: The McBSP module asserts the McBSPi_SWAKEUP request when an unexpected transmits frame-sync pulse is detected. If the McBSPi.MCBSPLP_IRQENABLE_REG[7] XSYNCERREN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or DSP subsystems when exiting idle mode (interrupt is asserted once the McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR bit changes from 0 to 1, indicating that a transmit error occurred).

24.5.4.5.3.3 Notes

When the mcbsp4_fsr/mcbspi_fsx pin is configured as an output, FSR/FSX wake-up generation makes no sense (the module cannot be in smart-idle mode).

Detection of RSYNCERR/XSYNCERR during idle mode can be used only when the mcbsp4_fsr/mcbspi_fsx pin is configured as an input and the remote system knows to assert such an error to trigger the wakeup of the McBSP module.

The module does not implement interrupt request (IRQ) assertion when configured as GPIO (pins that can be used to accept input signals and/or send output signals but are not linked to specific uses); also a wake-up capability in this mode is not available.

24.5.4.5.4 Analysis of the Receiver Smart-Idle Behavior

Table 24-345 provides an analysis of the power mode behavior.

In this table, the CLKRM bit is in the McBSPi.MCBSPLP_PCR_REG register on position 8, the CLKXM bit is in the McBSPi.MCBSPLP_PCR_REG[9] register, and the CLOCKACTIVITY bit is in the McBSPi.MCBSPLP_SYSCONFIG_REG[9:8] register.

The value X indicates that the bit value is not significant.

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-345. McBSP Smart-Idle Mode Configuration Behavior

CLKRM Bit	CLKXM Bit	McBSP Mode	Source of Functional Clock	CLOCKACTIVITY Bit	Behavior
0	0	Slave	Outside	0bXX	The module acknowledges the IDLE request as soon as there is no pending DMA, interrupt request, or transmit buffer threshold synchronization (only when wake-up event is set on transmit threshold reached), regardless of the CLOCKACTIVITY settings or receive and transmit activity.
0	1	Transmit master	MCBSPi_ICLK	0b0X	The McBSP does not acknowledge the IDLE request unless: • The transmit part is disabled (XDISABLE) or under software reset (XRST). • Transmit and receive parts are disabled (XDISABLE/RDISABLE) or under software reset (XRST/RRST). The IDLE acknowledge is asserted as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when the wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames were completed in case of transmit and/or receive disable.
			CLKS	0bX0	
			MCBSPi_ICLK	0b1X	The module acknowledges the IDLE request as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when the wake-up event is set on transmit/receive threshold reached).
			CLKS	0bX1	
			CLKR (outside)	0bXX	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when the wake-up event is set on transmit/receive threshold reached), regardless of the CLOCKACTIVITY settings.
1	0	Receive master	MCBSPi_ICLK	0b0X	The McBSP does not acknowledge the IDLE request unless the receive part is disabled (RDISABLE) or under software reset (RRST). The IDLE acknowledge is asserted as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when the wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames were completed in case of transmit and/or receive disable.
			CLKS	0bX0	
			MCBSPi_ICLK	0b1X	The module acknowledges the IDLE request as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached).
			CLKS	0bX1	
			CLKX	0bXX	When CLKX is used as source (the functional clock is provided from outside), the module acknowledges the IDLE request as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when the wake-up event is set on transmit/receive threshold reached), regardless of the CLOCKACTIVITY settings.

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-345. McBSP Smart-Idle Mode Configuration Behavior (continued)

CLKRM Bit	CLKXM Bit	McBSP Mode	Source of Functional Clock	CLOCKACTIVITY Bit	Behavior
1	1	Transmit and receive master	MCBSPi_ICLK	0b0X	The McBSP does not acknowledge the IDLE request unless transmit and receive parts are disabled (XDISABLE/RDISABLE) or under software reset (XRST/RRST). The IDLE acknowledge is asserted as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when the wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames were completed in case of transmit and/or receive disable. No wake-up event is available in this mode, because the entire McBSP and remote device activity is frozen.
			CLKS	0bX0	
			MCBSPi_ICLK	0b1X	The module acknowledges the IDLE request as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when the wake-up event is set on transmit/receive threshold reached).
			CLKS	0bX1	

NOTE: The RFSREN/XFSXEN mode is suitable for wake-up generation when both clocks (PRCM functional and interface) are switched off and the mcbsp4_fsr/mcbspi_fsx pin is configured as input. The frame-sync pulse is asynchronously detected during idle.

The RSYNCERREN/XSYNCERREN mode can be used to wake up the McBSP module only by a remote module implementing such a feature to trigger a wakeup. In this mode, the functional clock must be active.

24.5.4.6 McBSP Interrupt Requests

Each of the four McBSP modules can generate one common interrupt (MCBSPi_IRQ), shared between the Cortex-A9 MPU subsystem and DSP subsystem interrupt controllers (INTCs).

An event can generate an interrupt request when the corresponding mask bit in the McBSPi.MCBSPLP_IRQENABLE_REG register is set to 1.

Once an interrupt request is generated, software must read the McBSPi.MCBSPLP_IRQSTATUS_REG register to check which event has caused the interrupt request generation, and acknowledge each processed event by setting the corresponding bit in the McBSPi.MCBSPLP_IRQSTATUS_REG register to 1.

24.5.4.7 McBSP DMA Requests

The DMA requests are shared between the DSP subsystem DMA (eDMA) controller, system DMA (sDMA) controller, and audio engine DMA (aDMA) controller. Each of the four McBSP modules can generate two DMA events:

- MCBSPi_DMA_TX: McBSPi module transmit DMA request
- MCBSPi_DMA_RX: McBSPi module receive DMA request

Table 24-342 summaries the DMA events with the mapping on both DMA controllers.

The receive and transmit DMA requests can be individually disabled by setting the McBSPi.MCBSPLP_RCCR_REG[3] RDMAEN and McBSPi.MCBSPLP_XCCR_REG[3] XDMAEN bits to 0. When disabling the DMA, the DMA request line is deasserted even if a DMA transfer is pending and the DMA state-machine is not reset.

For more information, see Section 24.5.4.11, *McBSP DMA Configuration*.

24.5.4.8 McBSP Data Transfer Process

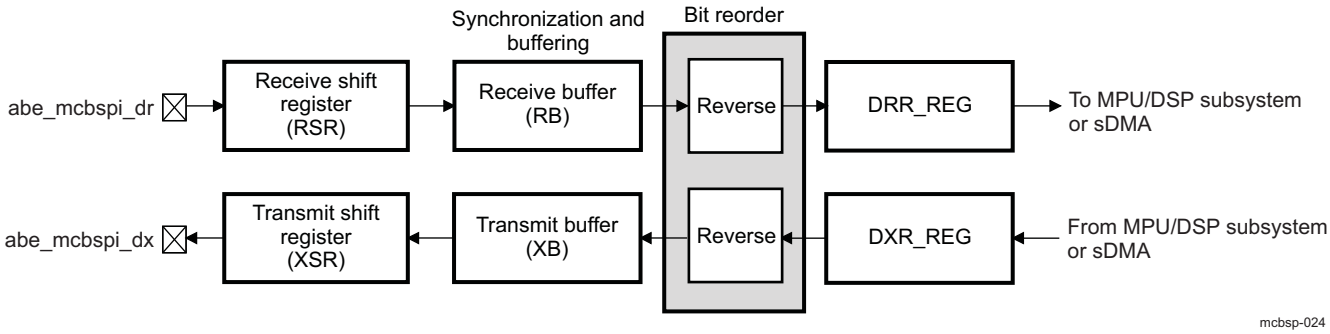
For McBSP modules, receive and transmit operations are triple-buffered (512 bytes buffers organized in 32-bit words are used).

All registers of McBSP data transfer paths are 32 bits wide. Figure 24-130 shows the McBSP data transfer paths.

CAUTION

The McBSP registers (DRR_REG and DXR_REG) are limited to 32-bit data accesses (L4 Interconnect); 16-and 8-bit accesses are not allowed and can corrupt register content.

Figure 24-130. McBSP Data Transfer Paths



24.5.4.8.1 Data Transfer Process for 8-/12-/16-/20-/24-/32-Bit-Long Words

NOTE: For each data word length, one data occupies one 32-bit buffer word.

Receive data arrives on the mcbspi_dr pin and is shifted into the receive shift register (RSR). When a full word (depending on the data length configuration) is received, the content of the shift register is copied into the receive buffer (RB) if it is not full. When the threshold of the RB is reached, the McBSP module asserts DMA or interrupt request and the content of the RB is then transferred (the sDMA or the eDMA controller reads the data receive register McBSPi.MCBSPLP_DRR_REG).

Transmit data is written by the MPU subsystem, DSP subsystem, or the DMA controller to the data transmit register (McBSPi.MCBSPLP_DXR_REG) using the McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit enable input (when a byte is not enabled, the byte value in the memory contains the previous written value). If there is no previous data in the transmit shift register (XSR), the value from the transmit buffer (XB) is copied to the XSR; otherwise, the content is copied to the XSR when the last bit of the previous data is shifted out on the mcbspi_dx pin.

24.5.4.8.2 Bit Reordering (Option to Transfer LSB First)

Generally, the McBSP module transmits or receives all data with the MSB first. However, some data protocols require the LSB to be transferred first.

If the McBSPi.MCBSPLP_XCR2_REG[4:3] XREVERSE bit field is set to 0b01, the bit ordering of the data words is reversed (LSB first) before being sent to the serial port. If McBSPi.MCBSPLP_RCR2_REG[4:3] RREVERSE bit field is set to 0b01, the bit ordering of the data words is reversed during reception (LSB first).

This feature is available for all the data formats from 8- to 32-bit data length.

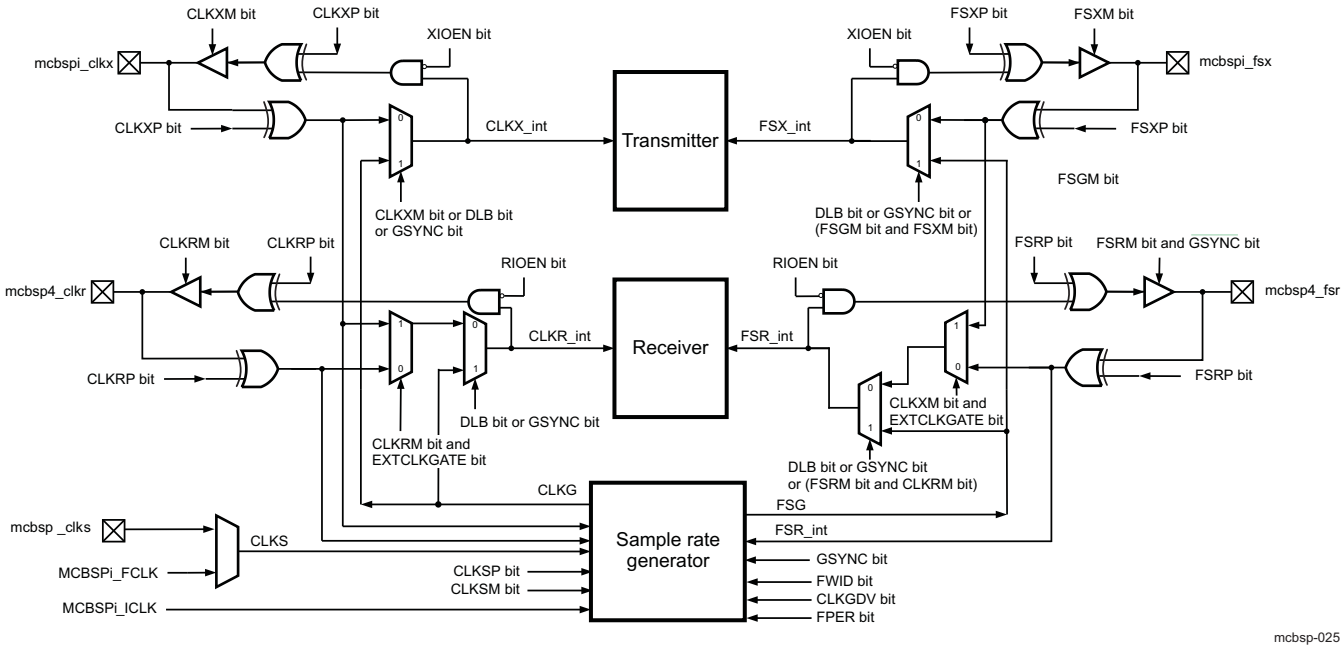
24.5.4.8.3 Clocking and Framing Data

This section explains basic concepts and terminology important for understanding how McBSP data transfers are timed and delimited.

Figure 24-131. Conceptual Block Diagram for Clock and Frame Generation When MCBSPLP_SPCR1_REG[15] ALB = 0



NOTE: For McBSP1, McBSP2, and McBSP3, the mcbspi_clkr pin is connected to the mcbspi_clkx pin, and the mcbspi_fsr pin is connected to the mcbspi_fsx pin.

The CLKR_int clock signal can be derived from three sources:

- The sample rate generator (CLKG): When MCBSPLP_XCCR_REG[5] DLB = 1 or MCBSPLP_SRGR2_REG[15] GSYNC = 1
- mcbsp4_clkr pin (CLKR): When MCBSPLP_PCR_REG[9] CLKXM = 0 and MCBSPLP_XCCR_REG[15] EXTCLKGATE = 0 and (MCBSPLP_XCCR_REG[5] DLB = 0 or MCBSPLP_SRGR2_REG[15] GSYNC = 0)
- mcbspi_clkx pin (CLKX) driven by sample rate generator (CLKG): When MCBSPLP_PCR_REG[9] CLKXM = 1 and MCBSPLP_XCCR_REG[15] EXTCLKGATE = 1 and (MCBSPLP_XCCR_REG[5] DLB = 0 or MCBSPLP_SRGR2_REG[15] GSYNC = 0)

The CLKX_int clock signal can be derived from two sources:

- The sample rate generator (CLKG): When MCBSPLP_PCR_REG[9] CLKXM = 1 or MCBSPLP_XCCR_REG[5] DLB = 1 or MCBSPLP_SRGR2_REG[15] GSYNC = 1
- mcbspi_clkx pin (CLKX): When MCBSPLP_PCR_REG[9] CLKXM = 0 or MCBSPLP_XCCR_REG[5] DLB = 0 or MCBSPLP_SRGR2_REG[15] GSYNC = 0

The FSR_int frame-sync signal can be derived from three sources:

- The sample rate generator (FSG): When MCBSPLP_XCCR_REG[5] DLB = 1 or MCBSPLP_SRGR2_REG[15] GSYNC = 1 or (MCBSPLP_PCR_REG[10] FSRM = 1 and MCBSPLP_PCR_REG[8] CLKRM = 1)
- mcbsp4_fsr pin (FSR): When MCBSPLP_PCR_REG[9] CLKXM = 0 and MCBSPLP_XCCR_REG[15] EXTCLKGATE = 0 and (MCBSPLP_XCCR_REG[5] DLB = 0 or MCBSPLP_SRGR2_REG[15] GSYNC = 0 or (MCBSPLP_PCR_REG[10] FSRM = 0 and MCBSPLP_PCR_REG[8] CLKRM = 0))
- mcbspi_fsx pin (FSX) driven by sample rate generator (FSG): When MCBSPLP_PCR_REG[9] CLKXM = 1 and MCBSPLP_XCCR_REG[15] EXTCLKGATE = 1 and (MCBSPLP_XCCR_REG[5] DLB = 0 or

Copyright © 2011–2012, Texas Instruments Incorporated

MCBSPLP_SRGR2_REG[15] GSYNC = 0 or (MCBSPLP_PCR_REG[10] FSRM = 0 and MCBSPLP_PCR_REG[8] CLKRM = 0))

The FSX_int frame-sync signal can be derived from two sources:

- The sample rate generator (FSG): When MCBSPLP_XCCR_REG[5] DLB = 1 or MCBSPLP_SRGR2_REG[15] GSYNC = 1 or (MCBSPLP_SRGR2_REG[12] FSGM = 1 and MCBSPLP_PCR_REG[11] FSXM = 1)
- mcbspi_fsx pin (FSX): When MCBSPLP_XCCR_REG[5] DLB = 0 or MCBSPLP_SRGR2_REG[15] GSYNC = 0 or (MCBSPLP_SRGR2_REG[12] FSGM = 0 and MCBSPLP_PCR_REG[11] FSXM = 0)

24.5.4.8.3.1 Clocking

Data is shifted 1 bit at a time from the mcbspi_dr pin to the RSRs or from the XSRs to the mcbspi_dx pin. The time for each bit transfer is controlled by the rising or falling edge of a clock signal.

The receive clock signal (CLKR_int) controls bit transfers from the mcbspi_dr pin to the RSRs. The transmit clock signal (CLKX_int) controls bit transfers from the XSRs to the mcbspi_dx pin. The CLKR_int and CLKX_int signals can be derived from a pin at the boundary of the McBSP module (mcbsp4_clkr and mcbspi_clkx, respectively) or derived from inside the McBSP module (see Figure 24-131). The clock source is selected by programming the McBSPi.MCBSPLP_PCR_REG[9] CLKXM and McBSPi.MCBSPLP_PCR_REG[8] CLKRM bits, respectively.

When the McBSPi.MCBSPLP_PCR_REG[9] CLKXM bit (transmitter clock mode) is set to:

- 0: CLKX_int is driven by an external clock and mcbspi_clkx is an input pin.
- 1: CLKX_int is driven by the internal SRG and mcbspi_clkx is an output pin.

For the McBSPi.MCBSPLP_PCR_REG[8] CLKRM bit (receiver clock mode), see Table 24-346.

Table 24-346. Receiver Clock Mode

Value	Digital Loopback Mode	mcbsp4_clkr Pin	Description
0x0	McBSPi.MCBSPLP_XCCR_REG[5] DLB = 0	Input	CLKR_int is driven by an external clock.
	McBSPi.MCBSPLP_XCCR_REG[5] DLB = 1	High -impedance	CLKR_int is driven by CLKX_int. The CLKX_int is derived based on the value of CLKXM.
0x1	McBSPi.MCBSPLP_XCCR_REG[5] DLB = 0	Output	CLKR_int is driven by the internal SRG.
	McBSPi.MCBSPLP_XCCR_REG[5] DLB = 1	Output	CLKR_int is driven by CLKX_int. The CLKX_int is derived based on the value of CLKXM.

The polarities of CLKR and CLKX signals are configured in McBSPi.MCBSPLP_PCR_REG register.

The McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit defines the transmit clock polarity:

- When set to 0, transmit data is driven on the rising edge of the CLKX signal.
- When set to 1, transmit data is driven on the falling edge of the CLKX signal.

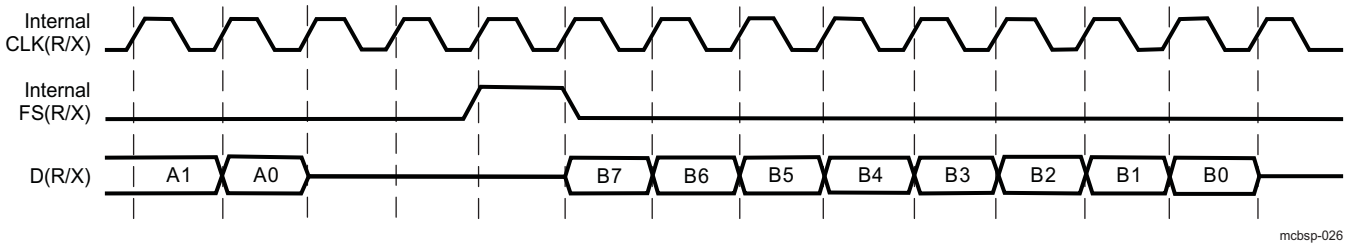
The McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit defines the receive clock polarity:

- When set to 0, receive data is sampled on the falling edge of the CLKX signal.
- When set to 1, transmit data sampled on the rising edge of the CLKX signal.

Figure 24-132 shows an example in which the clock signal controls the timing of each bit transfer on the pin.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-132. Clock Signal Control of Bit Transfer Timing



NOTE: The McBSP module is constrained to operate at an internal functional frequency of up to L4 interface frequency divided by 2. When driving CLKX or CLKR at the pin, choose an appropriate input clock frequency. When using the internal SRG for CLKX/CLKR/CLKS, choose an appropriate input clock frequency (up to L4 interface frequency) and divide down value by programming the McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV bit field.

24.5.4.8.3.2 Serial Words

Bits traveling between a shift register (RSR or XSR) and a data pin (mcbspi_dr or mcbspi_dx) are transferred in a group called a serial word. Software defines how many bits are in a word by programming:

- For the receiver: The McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 and McBSPi.MCBSPLP_RCR2_REG[7:5] RWDLEN2 bit fields
- For the transmitter: The McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 and McBSPi.MCBSPLP_XCR2_REG[7:5] XWDLEN2 bit fields

The difference of use is explained in Section 24.5.4.8.4.1, *Number of Phases, Words, and Bits per Frame*.

The various possibilities of word length are 8, 12, 16, 20, 24, and 32 bits (for field values, see Section 24.5.6, *MCBSP Register Manual*)

Bits coming from the mcbspi_dr pin are held in the RSR until it holds a full serial word, and then the word is passed to the RB and the McBSPi.MCBSPLP_DRR_REG register.

During transmission, the XSR accepts new data from the XB after a full serial word has been passed from the XSR to the mcbspi_dx pin.

In the example in Figure 24-135, an 8-bit word size was defined (see the transfer of the 8-bit word B).

24.5.4.8.3.3 Frames and Frame Synchronization

One or more words (up to 128) are transferred in a group called a frame. Software defines how many words are in a frame by programming:

- For the receiver: The McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1 and McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLEN2 bit fields
- For the transmitter: The McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 and McBSPi.MCBSPLP_XCR2_REG[14:8] XFRLEN2 bit fields

The difference between these registers is explained in Section 24.5.4.8.4.1, *Number of Phases, Words, and Bits per Frame*. For the corresponding field values and number of words, see Section 24.5.6, *MCBSP Register Manual*.

All the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The McBSP module uses frame-sync signals (FSG) to determine when each frame is received/transmitted. When a pulse occurs on a frame-sync signal, the McBSP module begins receiving/transmitting a frame of data. When the next pulse occurs, the McBSP module receives/transmits the next frame, and so on.

Copyright © 2011–2012, Texas Instruments Incorporated

Pulses on the receive frame-sync (FSR_int) signal initiate frame transfers on mcbspi_dr. Pulses on the transmit frame-sync (FSX_int) signal initiate frame transfers on mcbspi_dx. FSR_int or FSX_int signals can be derived from a pin at the boundary of the McBSP module (mcbsp4_fsr and mcbspi_fsx, respectively) or derived from inside the McBSP module (see Figure 24-130). The frame-sync source is selected by programming the McBSPi.MCBSPLP_PCR_REG[11] FSXM and McBSPi.MCBSPLP_PCR_REG[10] FSRM bits, respectively.

When the McBSPi.MCBSPLP_PCR_REG[11] FSXM bit (transmitter frame-sync mode) is set to:

- 0: FSX_int is derived from an external source and mcbspi_fsx is an input pin.
- 1: FSX_int is determined by the McBSPi.MCBSPLP_SRGR2_REG[12] FSGM bit and mcbspi_fsx is an output pin.

For the McBSPi.MCBSPLP_PCR_REG[10] FSRM bit (receiver frame-sync mode), is set to:

- 0: FSR_int is generated by an external source and mcbsp4_fsr is an input pin.
- 1: FSR_int is generated internally by the SRG. The mcbsp4_fsr is an output pin except when McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit is set to 0x1.

In the example in Figure 24-131, a one-word frame is transferred when a frame-sync pulse occurs. The polarities of FSR and FSX signals are programmable by bits in the McBSPi.MCBSPLP_PCR_REG register.

The McBSPi.MCBSPLP_PCR_REG[3] FSXP bit defines the transmit frame-sync polarity:

- When set to 0, frame-sync pulse FSX is active high.
- When set to 1, frame-sync pulse FSX is active low.

The McBSPi.MCBSPLP_PCR_REG[2] FSRP bit defines the receive frame-sync polarity:

- When set to 0, frame-sync pulse FSR is active high.
- When set to 1, frame-sync pulse FSR is active low.

In McBSP operation, the inactive-to-active transition of the frame-sync signal indicates the start of the next frame. For this reason, the frame-sync signal may be high for an arbitrary number of clock cycles. Only after the signal is recognized to have gone inactive, and then active again, does the next frame synchronization occur.

24.5.4.8.3.4 Detecting Frame-Sync Pulses, Even in Reset State

The McBSP module can generate receive and transmit interrupts to the Cortex-A9 MPU/DSP subsystems to indicate specific events in the McBSP module. To facilitate detection of frame synchronization, these interrupts can be sent in response to frame-sync pulses (see Section 24.5.5, *McBSP Basic Programming Model* for more information).

Unlike other serial port interrupt modes, this mode can operate while the associated portion of the serial port is in reset (such as activating receive interrupt when the receiver is in reset). In this case, the McBSPi.MCBSPLP_PCR_REG[0] FSRM/McBSPi.MCBSPLP_PCR_REG[1] FSXM bit and the McBSPi.MCBSPLP_PCR_REG[2] FSRP/McBSPi.MCBSPLP_PCR_REG[3] FSXP bit still selects the appropriate source and polarity of frame synchronization. Thus, even when the serial port is in reset state, these signals are synchronized to the interface clock (MCBSPi_ICLK) and then sent to the Cortex-A9 MPU/DSP subsystem in the form of receive interrupt and transmit interrupt at the point where they feed the receiver and transmitter of the serial port. Consequently, a new frame-sync pulse can be detected, and then the Cortex-A9 MPU/DSP subsystem can take the serial port out of reset safely.

24.5.4.8.3.5 Ignoring Frame-Sync Pulses

The McBSP module ignores transmit and/or receive frame-sync pulses if the frame transfer was started by a previous frame-sync pulse (unexpected frame-sync pulses). The McBSP module does not support features such as retransmit or re-receive of an erroneous frame or word. The receiver or transmitter ignores frame-sync pulses until the desired frame length or number of words is reached. For more information about unexpected frame-sync pulses, see Section 24.5.4.10.3, *Unexpected Receive Frame-Sync Pulse*, or Section 24.5.4.10.6, *Unexpected Transmit Frame-Sync Pulse*.

Copyright © 2011–2012, Texas Instruments Incorporated

24.5.4.8.3.6 Frame Frequency

The frame frequency is determined by the period between frame-sync pulses and is defined as shown in the following equation:

Frame frequency = Clock frequency/(number of clock cycles between two rising edges [or falling edges] of two consecutive frame-sync pulses)

The frame frequency can be increased by decreasing the time between frame-sync pulses (limited only by the number of bits per frame). As the frame transmit frequency increases, the inactivity period between the data packets for adjacent transfers decreases to zero.

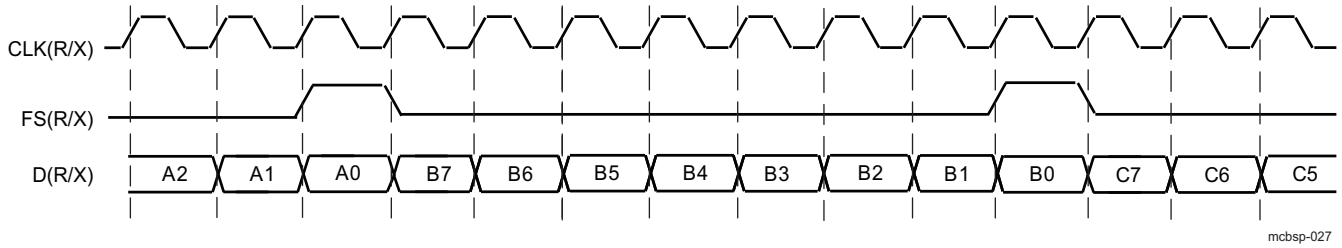
24.5.4.8.3.7 Maximum Frame Frequency

The minimum number of clock cycles between frame-sync pulses is equal to the number of bits transferred per frame. The maximum frame frequency is defined as shown in the following equation:

Maximum frame frequency = Clock frequency/number of bits per frame

Figure 24-133 shows the McBSP operating at maximum packet frequency. At maximum packet frequency, the data bits in consecutive packets are transmitted contiguously with no inactivity between bits.

Figure 24-133. McBSP Operating at Maximum Packet Frequency



If there is a 1-bit data delay as shown in Figure 24-133, the frame-sync pulse overlaps the last bit transmitted in the previous frame. Effectively, this permits a continuous stream of data, back-to-back transfers.

NOTE: When the McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY bit field is se to 0x0 (0-bit data delay), the first bit of data is transmitted asynchronously to the internal transmit clock signal (CLKX_int). For more information, see Table 24-396.

24.5.4.8.4 Frame Phases (Dual-Phase Frame I2S Support)

The McBSP module allows configuration of each frame to contain one or two phases. The support for dual-phase frames is required to provide I2S fully compliant capabilities (audio left and right channels—stereo audio stream).

CAUTION

The limitation on dual-phase frame support is that the number of words per phase must be set to 1 for both first and second phases. It is the only possible value for word per frame when using the dual-phase frame.

The number of bits per word can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers. For example, a user may define a frame as consisting of one phase containing one 16-bit word, followed by a second phase consisting of one 32-bit word. This configuration allows the user to compose frames for custom applications such as I2S protocol.

24.5.4.8.4.1 Number of Phases, Words, and Bits per Frame

Table 24-347 shows which bit fields in the receive control registers (McBSPi.MCBSPLP_RCR1_REG and McBSPi.MCBSPLP_RCR2_REG) and in the transmit control registers (McBSPi.MCBSPLP_XCR1_REG and McBSPi.MCBSPLP_XCR2_REG) determine the number of phases per frame, the number of words per frame, and the number of bits per word for each phase, for both receiver and transmitter. The maximum number of words per frame is limited to 2 when using dual-phase frames (one word for each phase), and to 128 for a single-phase frame. The number of bits per word can be 8, 12, 16, 20, 24, or 32 bits.

The following legend applies to Table 24-347:

- RPHASE => McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit
- XPHASE => McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit
- RFRLEN1 => McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1 bit field
- RFRLEN2 => McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLEN2 bit field
- XFRLEN1 => McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 bit field
- XFRLEN2 => McBSPi.MCBSPLP_XCR2_REG[14:8] XFRLEN2 bit field
- RWDLEN1 => McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 bit field
- RWDLEN2 => McBSPi.MCBSPLP_RCR2_REG[7:5] RWDLEN2 bit field
- XWDLEN1 => McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 bit field
- XWDLEN2 => McBSPi.MCBSPLP_XCR2_REG[7:5] XWDLEN2 bit field

Table 24-347. Phases, Words and Bits per Frame Control Bit

Operation	Number of Phases	Words per Frame Set With	Bits per Word Set With
Reception	1 (RPHASE = 0)	RFRLEN1	RWDLEN1
Reception	2 (RPHASE = 1)	RFRLEN1 = 0x0 and RFRLEN2 = 0x0	RWDLEN1 for phase 1 RWDLEN2 for phase 2
Transmission	1 (XPHASE = 0)	XFRLEN1	XWDLEN1
Transmission	2 (XPHASE = 1)	XFRLEN1 = 0x0 and XFRLEN2 = 0x0	XWDLEN1 for phase 1 XWDLEN2 for phase 2

24.5.4.8.4.2 Single-Phase Frame Example

Figure 24-134 shows an example of a single-phase data frame containing one 8-bit word. Because the transfer is configured for one data bit delay, the data on the mcbspi_dx and mcbspi_dr pins are available one clock cycle after FS(R/X) goes active. Table 24-348 lists the assumptions used in the example in Figure 24-134.

Table 24-348. Assumptions for the Single-Phase Frame Example

Assumption	Value	Bit or Field Name
Single-phase frame	0	McBSPi.MCBSPLP_RCR2_REG[15] RPHASE
		McBSPi.MCBSPLP_XCR2_REG[15] XPHASE
One word per frame	0x0	McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1
		McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1
8-bit word length	0x0	McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1
		McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1
Word length in register2	Ignored	McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLEN2
		McBSPi.MCBSPLP_XCR2_REG[14:8] XWDLEN2
Receive data clocked on falling edge	0	McBSPi.MCBSPLP_PCR_REG[0] CLKRP
Transmit data clocked on rising edge		McBSPi.MCBSPLP_PCR_REG[1] CLKXP
Active-high frame-sync signals	0	McBSPi.MCBSPLP_PCR_REG[2] FSRP
		McBSPi.MCBSPLP_PCR_REG[3] FSXP
1-bit data delay	01b	McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY

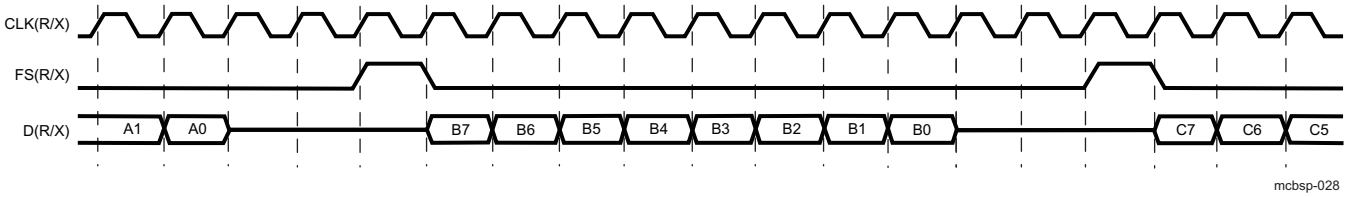
Figure 24-134. Single-Phase Frame for a McBSP Data Transfer



24.5.4.8.4.3 Dual-Phase Frame Example

Figure 24-135 shows an example of a frame. The first phase consists of one word of 16 bits, followed by a second phase of one word of 8 bits. The entire bitstream in the frame is contiguous. There are no gaps between words/phases. Table 24-349 lists the assumptions used in the example in Figure 24-135.

Table 24-349. Assumptions for the Dual-Phase Frame Example

Assumption	Value	Bit or Field Name
Single-phase frame	1	McBSPi.MCBSPLP_RCR2_REG[15] RPHASE
		McBSPi.MCBSPLP_XCR2_REG[15] XPHASE
One word per frame	0x0	McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1
		McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1
16-bit word length	0x0	McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1
		McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1
8-bit word length	0x2	McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLEN2
		McBSPi.MCBSPLP_XCR2_REG[14:8] XWDLEN2
Receive data clocked on falling edge	0	McBSPi.MCBSPLP_PCR_REG[0] CLKRP
Transmit data clocked on rising edge		McBSPi.MCBSPLP_PCR_REG[1] CLKXP
Active-high frame-sync signals	0	McBSPi.MCBSPLP_PCR_REG[2] FSRP
		McBSPi.MCBSPLP_PCR_REG[3] FSXP

24.5.4.8.5 McBSP Reception

This section explains the fundamental process of reception in the McBSP module. For information about how to program the McBSP receiver, see Section 24.5.5, *McBSP Basic Programming Model*, Section 24.5.5.4, *Interrupt Configuration*, and Section 24.5.5.5, *Receiver Configuration*.

Figure 24-136 and Figure 24-137 show how reception occurs in the McBSP module. A description of the process follows the figures. Figure 24-136 shows the physical path for the data.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-136. McBSP Reception Physical Data Path

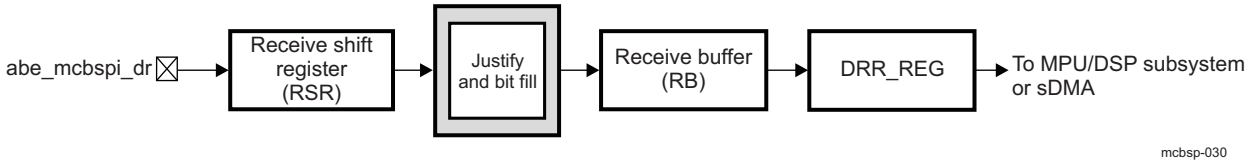

Figure 24-137 is a timing diagram showing signal activity for one possible reception scenario.

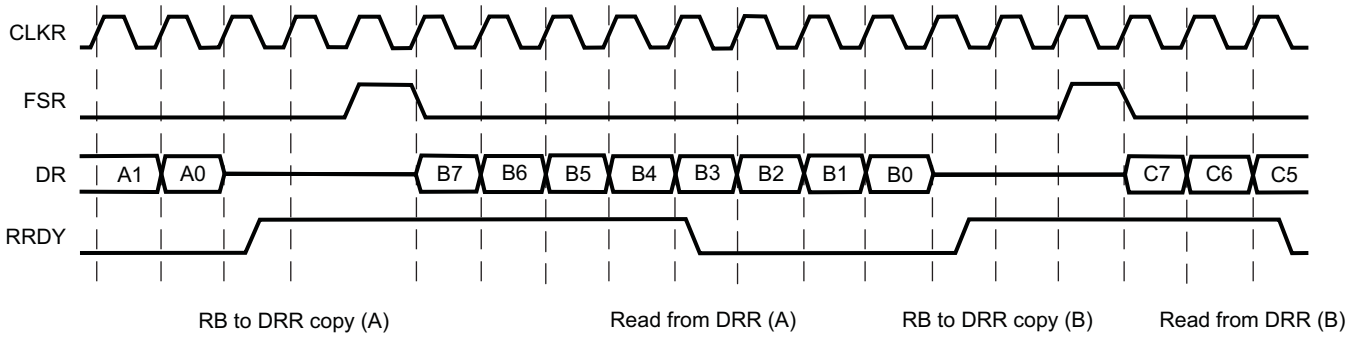
Figure 24-137. McBSP Reception Signal Activity



RRDY: Status of receiver ready bit (high is 1)

The following process describes how data travels from the mcbspi_dr pin to the MPU/DSP subsystem or to the sDMA controller:

1. The McBSP module waits for a receive frame-sync pulse on FSR_int.
2. When the pulse arrives, the McBSP module inserts the appropriate data delay that is selected with the McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY bit field. In the preceding timing diagram a 1-bit data delay is selected.
3. The McBSP module accepts data bits on the mcbspi_dr pin and shifts them into the RSR. For information about choosing a word length, see Section 24.5.5.6, *Transmitter Configuration*.
4. When a full word is received, the McBSP module copies the contents of the RSR to the RB, provided that RB is not full.
5. When the programmed receive threshold is reached (McBSPi.MCBSPLP_THRSH1_REG[6:0] RTHRESHOLD bit field), the McBSP module asserts the receiver ready bit (McBSPi.MCBSPLP_SPCR1_REG[1] RRDY). This indicates that receive data is ready to be read by the Cortex-A9 MPU/DSP subsystem or the sDMA controller by accessing the McBSPi.MCBSPLP_DRR_REG register.

   The data copied from RB to McBSPi.MCBSPLP_DRR_REG is justified and bit-filled according to the McBSPi.MCBSPLP_SPCR1_REG[14:13] RJUST bit field.
6. The Cortex-A9 MPU/DSP subsystem or the sDMA controller reads the data from the data receive register. When the RB is empty, the McBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit is cleared.

24.5.4.8.6 McBSP Transmission

This section explains the fundamental process of transmission in the McBSP module. For information about how to program the McBSP transmitter, see Section 24.5.5, *McBSP Basic Programming Model* and Section 24.5.5.6, *Transmitter Configuration*.

Figure 24-138 and Figure 24-139 show how transmission occurs in the McBSP module. A description of the process follows the figures. Figure 24-138 shows the physical path for the data.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-138. McBSP Transmission Physical Data Path

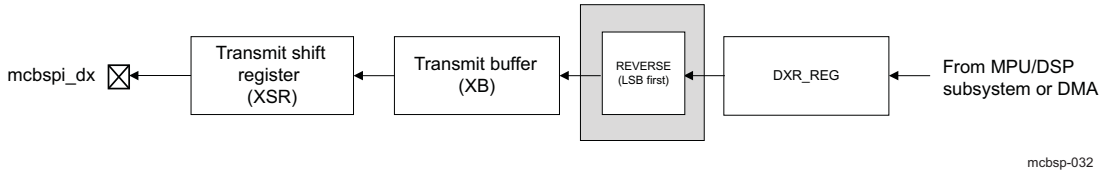


Figure 24-139 is a timing diagram showing signal activity for one possible transmission scenario.

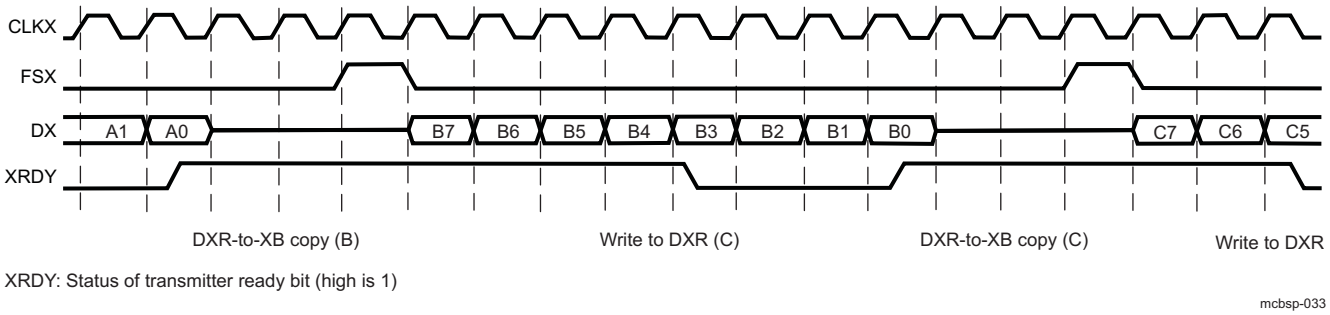
Figure 24-139. McBSP Transmission Signal Activity



XRDY: Status of transmitter ready bit (high is 1)

1. The Cortex-A9 MPU/DSP subsystem or the sDMA controller writes data to the data transmit register (McBSPi.MCBSPLP_DXR_REG). When the XB is reached the transmitter ready bit (McBSPi.MCBSPLP_SPCR2_REG[1] XRDY) is cleared to indicate that the transmitter is not ready for new data. For information about choosing a word length, see Table 24-392.
2. When new data arrives in the McBSPi.MCBSPLP_DXR_REG register, the McBSP module copies the content of the data transmit register to the XB. In addition, the transmit ready bit (McBSPi.MCBSPLP_SPCR2_REG[1] XRDY) is set as long as the buffer contains at least the transmit threshold number of free locations (the McBSPi.MCBSPLP_THRSH2_REG[6:0] XTHRESHOLD bit field). This indicates that the transmitter is ready to accept new data from the MPU/DSP subsystem or the sDMA controller.
3. The McBSP module waits for a transmit frame-sync pulse on FSX_int.
4. When the pulse arrives, the McBSP module inserts the appropriate data delay that is selected with the McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY bit field.

   In the preceding timing diagram, a 1-bit data delay is selected.
5. The McBSP module shifts data bits from the XSR to the mcbspi_dx pin.

24.5.4.8.7 Enable/Disable the Transmit and Receive Processes

The McBSP module has the option to stop and resume the transmit/receive process while the module is in functional mode (out of transmit/receive reset).

When the transmit/receive disable bit (McBSPi.MCBSPLP_XCCR_REG[0] XDISABLE/McBSPi.MCBSPLP_RCCR_REG[0] RDISABLE) is set, the McBSP module stops the transmit/receive operation at the next frame boundary (frame corruption avoided).

During the receive disable state, the frames that are sent (when the FSR signal is asserted while receive disable) by the remote device are lost, and the receive buffer overflow status bit (McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT) is not set. Also, the frames received by the remote device while the McBSPi.MCBSPLP_XCCR_REG[0] XDISABLE bit is set (when the FSX signal is asserted while transmit disable) are meaningless undefined data frames, and transmit buffer underflow status bit (McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT) is not set. The presence of the frame synchronization while transmit/receive process is disabled can be checked by reading the transmit/receive frame-sync interrupt status: McBSPi.MCBSPLP_IRQSTATUS_REG[8] XFSX/McBSPi.MCBSPLP_IRQSTATUS_REG[1] RFSR bits.

Copyright © 2011–2012, Texas Instruments Incorporated

As soon as the McBSPi.MCBSPLP_XCCR_REG[0] XDISABLE/McBSPi.MCBSPLP_RCCR_REG[0] RDISABLE bit is cleared, the transmit/receive process resumes at the next frame boundary.

NOTE: It is not recommended to use this mechanism together with the possibility to interrogate the transmit/receive buffer status register (McBSPi.MCBSPLP_XBUFFSTAT_REG[7:0] XBUFFSTAT/McBSPi.MCBSPLP_RBUFFSTAT_REG[7:0] RBUFFSTAT bit field indicating the occupied/available buffer locations), because this register is an interface clock (MCBSPi_ICLK) synchronous register and does not reflect the exact number of occupied/free locations available in the functional clock domain.

24.5.4.8.8 MCBSP Data Transfer Mode

NOTE: For all examples in this section, the configured CLKX edge is the rising edge (McBSPi.MCBSPLP_PCR_REG[1] CLKXP = 0x0) and the configured CLKR edge is the falling edge (McBSPi.MCBSPLP_PCR_REG[0] CLKRP = 0x0). These are the reset values.

In the following timing diagrams, a 1-bit data delay is selected (McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY = 0x01 and McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY = 0x01), because data often follows a 1-cycle active frame-synchronization.

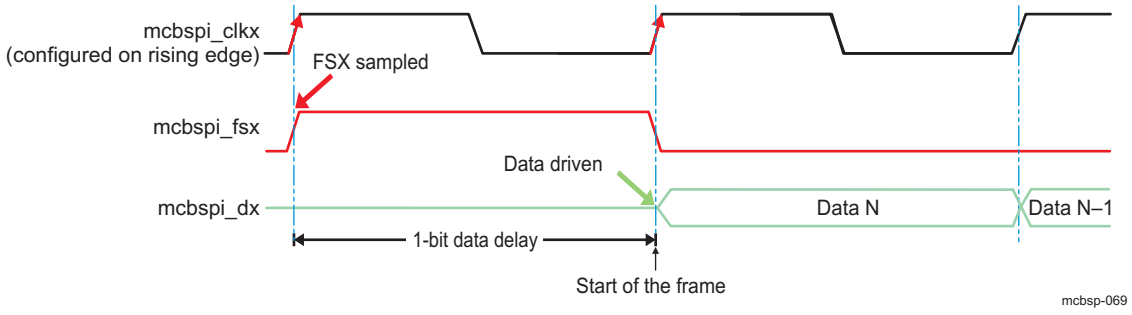
McBSP modules can support two edge selection modes for transmit and receive data transfer at the system level:

- The full-cycle mode, for which one clock period is used to transfer the data, generated on one edge and captured on the same edge (one clock period later)
- The half-cycle mode, for which one-half clock period is used to transfer the data, generated on one edge and captured on the opposite edge (one-half clock period later). New data are generated only every clock period, which ensures the required hold time.

24.5.4.8.8.1 Transmit Full-Cycle Mode

When configured in full-cycle mode (McBSPi.MCBSPLP_XCCR_REG[11] XFULL_CYCLE = 0x1), the FSX signal is sampled on the configured CLKX edge and the data is driven on the same configured edge. See Figure 24-140.

Figure 24-140. Transmit Full-Cycle Timing Diagram

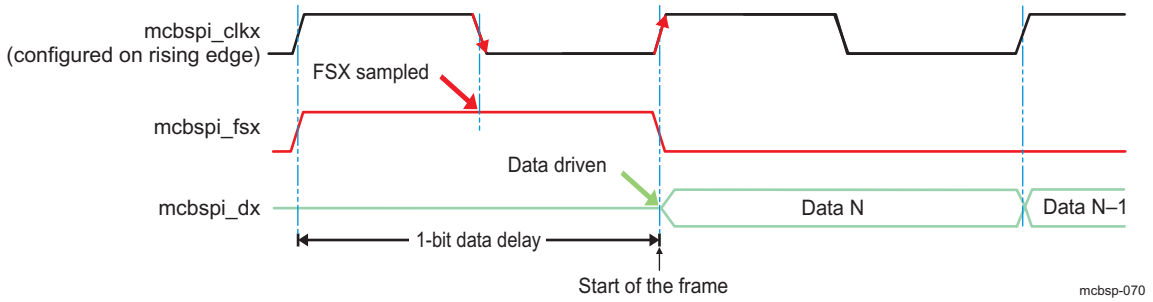


24.5.4.8.8.2 Transmit Half-Cycle Mode

When configured in half-cycle mode (McBSPi.MCBSPLP_XCCR_REG[11] XFULL_CYCLE = 0x0, reset value), the FSX signal is sampled on the opposite configured CLKX edge and the data is driven on the next configured edge. See Figure 24-141.

Copyright © 2011–2012, Texas Instruments Incorporated

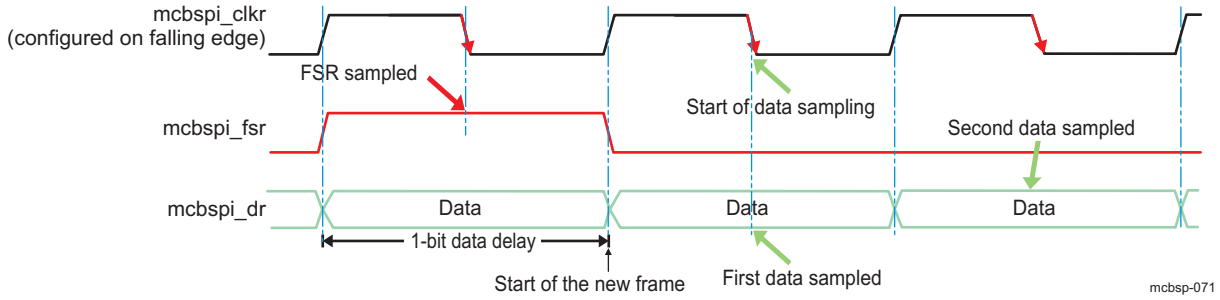
Figure 24-141. Transmit Half-Cycle Timing Diagram



24.5.4.8.8.3 Receive Full-Cycle Mode

When configured in full-cycle mode (McBSPi.MCBSPLP_RCCR_REG[11] RFULL_CYCLE = 0x1, reset value), the FSR signal is sampled on the configured CLKR edge and the data is driven on the same configured edge. See Figure 24-142.

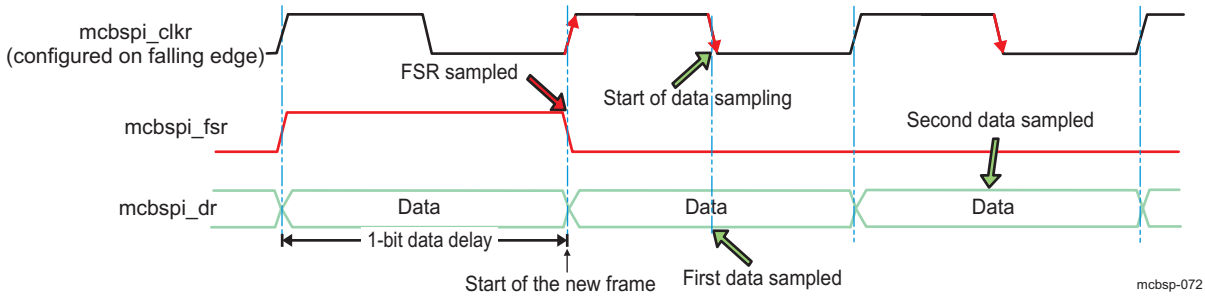
Figure 24-142. Receive Full-Cycle Timing Diagram



24.5.4.8.8.4 Receive Half-Cycle Mode

When configured in half-cycle mode (McBSPi.MCBSPLP_RCCR_REG[11] RFULL_CYCLE = 0x0), the FSR signal is sampled on the opposite configured CLKR edge and the data is driven on the next configured edge. See Figure 24-143.

Figure 24-143. Receive Half-Cycle Timing Diagram

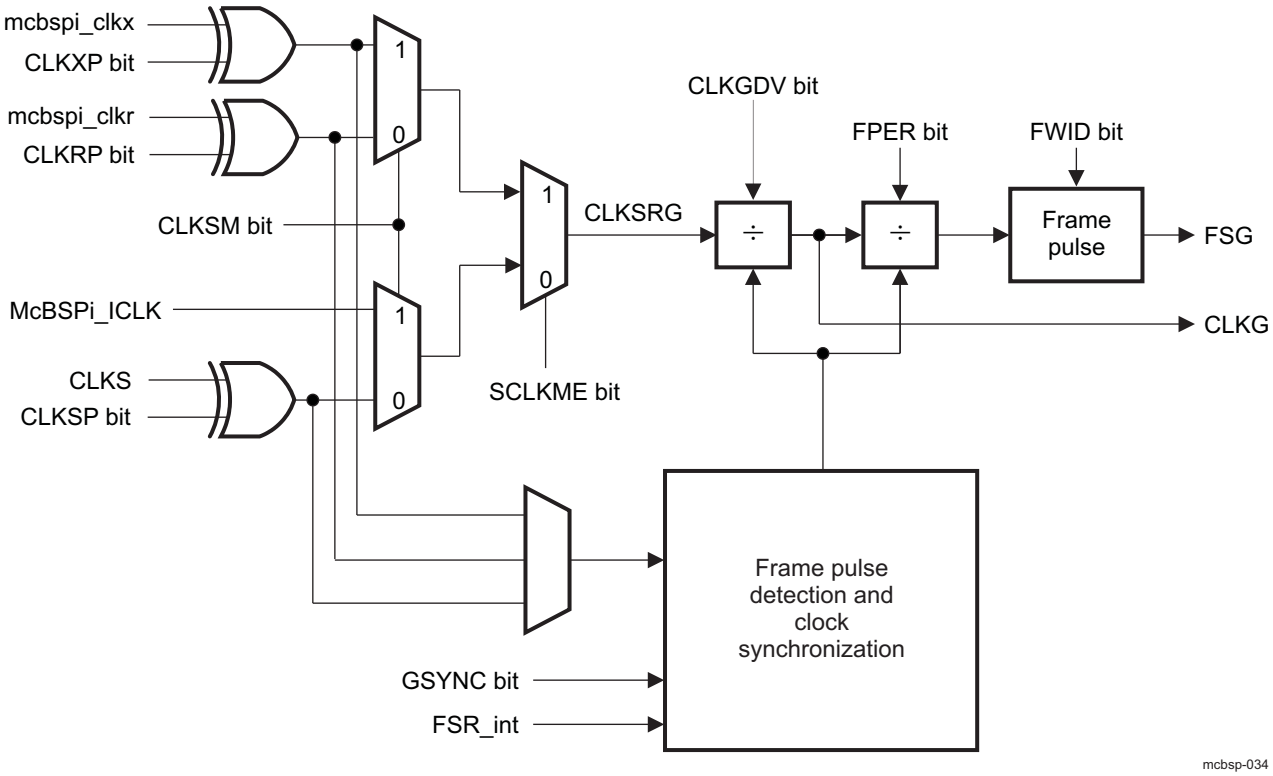


24.5.4.9 McBSP SRG

The McBSP module contains an internal SRG that can be used to generate an internal data clock (CLKG) and an internal frame-sync signal (FSG). CLKG can be used for bit shifting on the data receive pin (mcbspi_dr) and/or the data transmit pin (mcbspi_dx). FSG can be used to initiate frame transfers on the mcbspi_dr pin and/or mcbspi_dx pin. Figure 24-144 is a conceptual block diagram of the SRG.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-144. Conceptual Block Diagram of the SRG



The source clock for the SRG (labeled CLKSRG in the diagram) can be supplied by the interface clock (McBSPi_ICLK) or the functional clock (CLKS input), or by an external pin (mcbspi_clkx or mcbsp4_clkr). The source is selected with the McBSPi.MCBSPLP_PCR_REG[7] SCLKME bit and the McBSPi.MCBSPLP_SRGR2_REG[13] CLKSM bit.

If a pin or CLKS signal is used, the polarity of the incoming signal can be inverted with the appropriate polarity bit (McBSPi.MCBSPLP_SRGR2_REG[14] CLKSP, McBSPi.MCBSPLP_PCR_REG[1] CLKXP, or McBSPi.MCBSPLP_PCR_REG[0] CLKRP).

The SRG has a 3-stage clock divider that gives CLKG and FSG programmability.

The three stages provide:

- Clock divide-down: The source clock (CLKSRG) is divided according to the McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV bit field to produce the CLKG signal.
- Frame period divide-down: CLKG is divided according to the McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER bit field to control the period from the start of a frame-pulse to the start of the next pulse.
- Frame-sync pulse-width countdown: CLKG cycles are counted according to the McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID bit field to control the width of each frame-sync pulse.

NOTE: The McBSP module cannot operate at an internal functional frequency faster than L4 interface frequency divided by 2. Choose an input clock frequency and a McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV value such that CLKG is less than or equal to L4 interface frequency divided by 2.

In addition to the 3-stage clock divider, the SRG has a frame-sync pulse detection and clock synchronization module that allows synchronization of the clock divide-down with an incoming frame-sync pulse on the mcbsp4_fsr pin. This feature is enabled or disabled with the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit.

Copyright © 2011–2012, Texas Instruments Incorporated

CLKG is used as source to generate the output clocks CLKX and CLKR when the McBSPi.MCBSPLP_PCR_REG[9] CLKXM/McBSPi.MCBSPLP_PCR_REG[8] CLKRM bit indicates that the clock is an output. The output CLKX/CLKR is generated according to the clock polarity setting (see Figure 24-131).

For information about preparing the SRG for operation, see Section 24.5.5, *McBSP Basic Programming Model*.

24.5.4.9.1 Clock Generation in the SRG

The SRG can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both. Use of the SRG to drive clocking is controlled by the clock mode bits (McBSPi.MCBSPLP_PCR_REG[9] CLKXM and McBSPi.MCBSPLP_PCR_REG[8] CLKRM) and polarity mode bits (McBSPi.MCBSPLP_PCR_REG[1] CLKXP and McBSPi.MCBSPLP_PCR_REG[0] CLKRP).

When a clock mode bit is set to 1 (CLKRM = 1 for reception, CLKXM = 1 for transmission), the corresponding data clock (CLKR for reception, CLKX for transmission) is driven by the internal SRG output clock (CLKG) according to the polarity setting.

The effects of this setting on the McBSP module are partially affected by use of the digital loopback (DLB) mode, the analog loopback (ALB) mode, and by the synchronous receive/transmit setting, respectively, as described in Table 24-350. ALB mode is selected with the McBSPi.MCBSPLP_SPCR1_REG[15] ALB bit. DLB mode is selected with the McBSPi.MCBSPLP_XCCR_REG[5] DLB bit. The synchronous setting is controlled by input signals. These signals are defined by the control registers of the control module (for more information, see Chapter 19, *Control Module*).

When using the SRG as a clock source, ensure that the SRG is enabled (the McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit is set to1).

Table 24-350. Effects of DLB and ALB Bits on Clock Modes

Mode Bit Settings		Effect
CLKRM=1	DLB = 0 and ALB = 0 (Digital and analog loopback mode disabled)	mcbsp1_clkr is an output pin driven by the SRG output clock (CLKG).
	DLB = 0 and ALB = 1 (Digital loopback mode disabled and analog loopback mode enabled)	mcbsp1_clkr is an output pin driven by the SRG output clock (CLKG). The receiver functional part internal clock is driven by the CLKX input signal provided by the mcbspi_clkx pin. The source of CLKX depends on the CLKXM bit. The receive frame synchronization is driven by the FSX input signal provided by the mcbspi_fsx pin. The receive data is driven by the DX input loopback pin (mcbspi_dx).
	DLB = 1 and ALB = 0 (Digital loopback mode enabled and analog loopback mode disabled)	The SRG and the frame-sync generator must be enabled. The internal transmit and receive clocks are driven by the SRG (CLKG having the appropriate CLKXP polarity). The transmit and receive frame-sync signals are driven by the FSG (having the appropriate FSXP polarity). The transmit data is connected to the DR input data. In digital loopback mode, no serial link activity is seen by the remote device.
	DLB = 1 and ALB = 1 (Reserved mode)	Undefined functionality.

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-350. Effects of DLB and ALB Bits on Clock Modes (continued)

Mode Bit Settings		Effect
CLKXM=1	DLB = 0 and ALB = 0 (Digital and analog loopback mode disabled)	mcbspi_clkx is an output pin driven by the SRG output clock (CLKG).
	DLB = 0 and ALB = 1 (Digital loopback mode disabled and analog loopback mode enabled)	mcbspi_clkx is an output pin driven by the SRG output clock (CLKG).
	DLB = 1 and ALB = 0 (Digital loopback mode enabled and analog loopback mode disabled)	The SRG and the frame-sync generator must be enabled. The internal transmit and receive clocks are driven by the SRG (CLKG having the appropriate CLKXP polarity). The transmit and receive frame-sync signals are driven by the FSG (having the appropriate FSXP polarity). The transmit data is connected to the DR input data. In digital loopback mode, no serial link activity is seen by the remote device.
	DLB = 1 and ALB = 1 (Reserved mode)	Undefined functionality
	CONTROL_MCBSPLP[30] ALBCTRLRX_CLKX bit = 1 (synchronous setting and DLB = 0 and ALB = 0)	CLKX is an output pin driven by the SRG output clock (CLKG). CLKR is connected to the CLKX.

24.5.4.9.2 Frame-Sync Generation in the SRG

The SRG can produce a frame-sync signal (FSG) for use by the receiver, the transmitter, or both.

For the receiver to use FSG for frame synchronization, make sure the McBSPi.MCBSPLP_PCR_REG[10] FSRM bit is set to 1. (When FSRM is set to 0, receive frame synchronization is supplied through the mcbsp4_fsr pin.)

For the transmitter to use FSG for frame synchronization, the following bits must be set:

- McBSPi.MCBSPLP_PCR_REG[11] FSXM = 1: This indicates that transmit frame synchronization is supplied by the McBSP module rather than from the mcbspi_fsx pin.
- McBSPi.MCBSPLP_SRGR2_REG[12] FSGM = 1: This indicates that when FSXM is set to 1, transmit frame synchronization is supplied by the SRG.

NOTE: When FSGM = 0 and FSXM = 1, the transmit frame-sync signal (FSX) is generated when XB is not empty. When FSGM = 0, the McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER and McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID bit fields are used to determine the frame-sync period and width (external FSX is gated by the buffer empty condition).

In either case, the SRG must be enabled (the McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit is set to 1) and the frame-sync logic in the SRG must be enabled (the McBSPi.MCBSPLP_SPCR2_REG[7] FRST bit is set to 0).

24.5.4.9.2.1 Choosing the Width of the Frame-Sync Pulse

Each pulse on FSG has a programmable width. Program the McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID bit field, and the resulting pulse width is (FWID + 1) CLKG cycles, where CLKG is the output clock of the SRG. The range is from 1 to 256 clock periods.

24.5.4.9.2.2 Controlling the Period Between the Starting Edges of Frame-Sync Pulses

The user can control the amount of time from the starting edge of one FSG pulse to the starting edge of the next FSG pulse. This period is controlled in one of two ways, depending on the configuration of the SRG:

- If the SRG is using an external input clock and the cBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit is set to 1, FSG pulses in response to an inactive-to-active transition on the mcbsp4_fsr pin. Thus, an external device controls the frame-sync period.
- Otherwise, software programs the McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER bit field, and the resulting frame-sync period is (FPER + 1) CLKG cycles, where CLKG is the output clock of the SRG.

Copyright © 2011–2012, Texas Instruments Incorporated

The range is from 1 to 4096 clock periods.

24.5.4.9.2.3 Keeping FSG Synchronized to an External Clock

When an external signal is selected to drive the SRG, the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit and the mcbsp4_fsr pin can be used to configure the timing of FSG pulses.

Setting the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit to 1 ensures that the McBSP module and an external device are dividing down the input clock with the same phase relationship.

If the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit is set to 1, an inactive-to-active transition on the mcbsp4_fsr pin triggers a resynchronization of CLKG and generation of FSG.

24.5.4.9.3 Synchronizing SRG Outputs to an External Clock

The SRG can produce a clock signal (CLKG) and an FSG based on an input clock signal that is either:

- The interface clock signal (MCBSPi_ICLK)
- The CLKS signal (PRCM functional clock or abe_clks)
- A signal at the mcbsp4_clkr
- The mcbspi_clkx pin

When an external clock (abe_clks, mcbsp4_clkr, or mcbspi_clkx) is selected to drive the SRG, the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit and the mcbsp4_fsr pin can be used to control the timing of CLKG and the pulsing of FSG relative to the chosen input clock. Set the GSYNC bit to 1 so that the McBSP module and an external device divide-down the input clock with the same phase relationship.

If the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit is set to 1:

- An inactive-to-active transition on the mcbsp4_fsr pin triggers a resynchronization of the CLKG signal and a pulsing of the FSG signal.
- The CLKG signal always begins with a high state after synchronization.
- The FSR signal is always detected at the same edge of the input clock signal that generates the CLKG signal, no matter how long the FSR pulse is.
- The McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER bit field is ignored because the frame-sync period on FSG is determined by the arrival of the next frame-sync pulse on the mcbsp4_fsr pin.

If the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit is set to 0, the CLKG signal runs freely and is not resynchronized, and the frame-sync period on the FSG signal is determined by the McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER bit field.

24.5.4.9.3.1 Operating the Transmitter Synchronously With the Receiver

When the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit is set to 1, the transmitter can operate synchronously with the receiver, provided that the FSX signal is programmed to be driven by the FSG signal (McBSPi.MCBSPLP_SRGR2_REG[12] FSGM = 1 and McBSPi.MCBSPLP_PCR_REG[11] FSXM = 1). If the FSR input signal has appropriate timing so that it can be sampled by the falling edge of the CLKG signal, it can be used, instead, by setting the McBSPi.MCBSPLP_PCR_REG[11] FSXM bit to 0 and connecting the FSR signal to FSX externally.

The SRG clock drives the transmit and receive clocking (the McBSPi.MCBSPLP_PCR_REG[8] CLKRM and McBSPi.MCBSPLP_PCR_REG[9] CLKXM bits are set to 1). Therefore, the CLK(R/X) pin must not be driven by any other driving source.

24.5.4.9.3.2 Synchronization Examples

Figure 24-145 and Figure 24-146 show the clock and frame-sync operation with various polarities of CLKS (the chosen input clock) and FSR signals. These figures assume McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID = 0x0, for an FSG pulse that is one CLKG cycle wide. The McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER bit field is not programmed; the period from the start of a frame-sync pulse to the start of the next pulse is determined by the arrival of the next inactive-to-active transition on the mcbsp4_fsr pin.

Copyright © 2011–2012, Texas Instruments Incorporated

Both figures show what happens to the CLKG signal when the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit is set to 1 and if it is initially synchronized or not initially synchronized. Figure 24-146 has a slower CLKG frequency (it has a larger divide-down value in the McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV bit field).

Figure 24-145. CLKG Synchronization and FSG Generation (GSYNC = 1 and CLKGDV = 0x1)

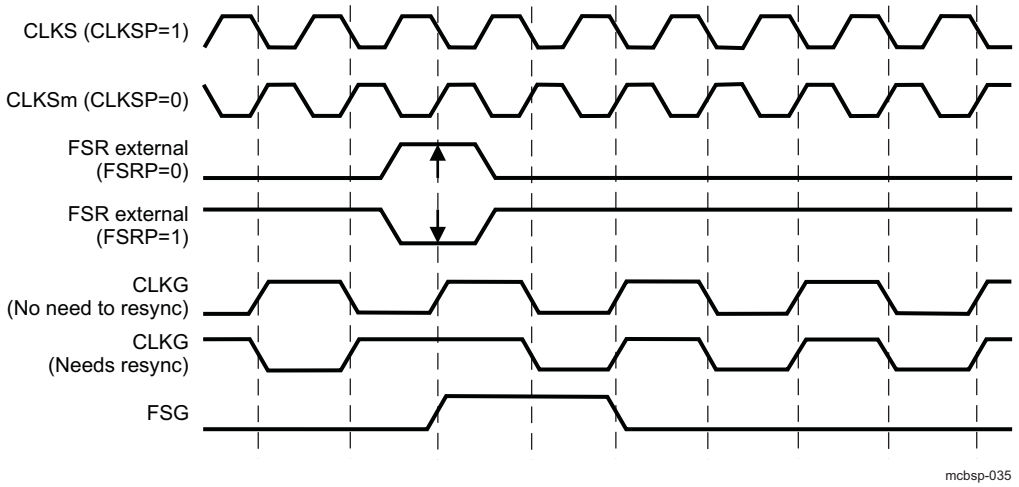


Figure 24-146. CLKG Synchronization and FSG Generation (GSYNC = 1 and CLKGDV = 0x3)

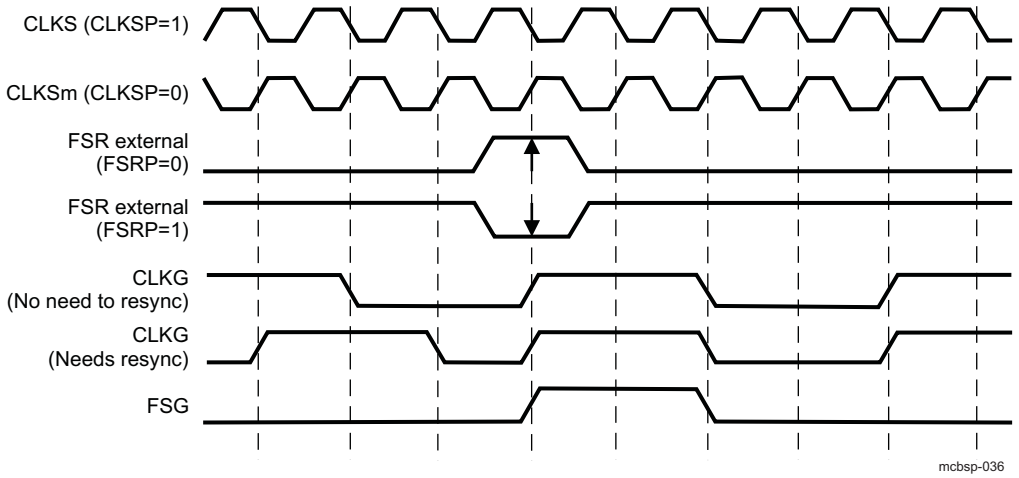

24.5.4.10 McBSP Exception/Error Conditions

24.5.4.10.1 Introduction

Several serial port events can constitute a system error. Any error condition can be a source of an interrupt:

- Receiver overrun (the McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT bit is set to 1, and the legacy mode McBSPi.MCBSPLP_SPCR1_REG[2] RFULL bit is set to 1)

  This occurs when the RB is full and the RSR is full with another new word shifted in from mcbspi_dr. Therefore, the McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT bit (McBSPi.MCBSPLP_SPCR1_REG[2] RFULL) indicates an error condition wherein any new data that can arrive at this time on mcbspi_dr replaces the contents of the RSR, and the previous word is lost. The RSR continues to be overwritten as long as new data arrives on mcbspi_dr and the McBSPi.MCBSPLP_DRR_REG register is not read. For more information about overrun in the receiver, see Section 24.5.4.10.2, *Overrun in the Receiver*.

Copyright © 2011–2012, Texas Instruments Incorporated

- Unexpected receive frame-sync pulse (the McBSPi.MCBSPLP_IRQSTATUS_REG[0] RSYNCERR bit is set to 1, and the legacy mode McBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR bit is set to 1)

  This occurs during reception when an unexpected frame-sync pulse arrives. An unexpected frame-sync pulse is one that is supposed to begin the next frame transfer before all the bits of the current frame are received. Such a pulse is ignored by the receiver, but sets the McBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR bit. For more information about receive frame-sync errors, see Section 24.5.4.10.3, *Unexpected Receive Frame-Sync Pulse*.
- Receiver underflow (the McBSPi.MCBSPLP_IRQSTATUS_REG[4] RUNDFLSTAT bit is set to 1)

  This occurs when the sDMA controller or MPU/DSP subsystem reads data from an empty receive buffer. For more information about underflow in the receiver, see Section 24.5.4.10.4, *Underflow in the Receiver*.
- Transmitter underflow (the McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT bit is set to 1, and the legacy mode McBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY bit is set to 0)

  If a new frame-sync signal arrives when the XB is empty, the previous data in the XSR is re-sent. This procedure continues for every new frame-sync pulse that arrives until the McBSPi.MCBSPLP_DXR_REG register is loaded with new data (and the XB is no longer empty). For more information about underflow in the transmitter, see Section 24.5.4.10.5, *Underflow in the Transmitter*.
- Unexpected transmit frame-sync pulse (the McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR bit is set to 1, and the legacy mode McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERRbit is set to 1)

  This occurs during transmission when an unexpected frame-sync pulse arrives. An unexpected frame-sync pulse is one that is supposed to begin the next frame transfer before all the bits of the current frame are transferred. Such a pulse is ignored by the transmitter, but sets the McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR bit. For more information, see Section 24.5.4.10.6, *Unexpected Transmit Frame-Sync Pulse*.
- Transmitter overflow (the McBSPi.MCBSPLP_IRQSTATUS_REG[12] XOVFLSTAT bit is set to 1)

  This occurs when the sDMA controller or MPU/DSP subsystem writes data to a full XB. For more information about underflow in the receiver, see Section 24.5.4.10.7, *Overflow in the Transmitter*.

24.5.4.10.2 Overrun in the Receiver

When the McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT bit is set to 1, and the McBSPi.MCBSPLP_SPCR1_REG[2] RFULL bit is set to 1 (legacy mode) indicates that the receiver has experienced overrun and is in an error condition. Receive overrun is set when all of the following conditions are met:

1. McBSPi.MCBSPLP_DRR_REG is not read even if the McBSPi.MCBSPLP_IRQSTATUS_REG[3] RRDY bit is set (legacy mode) and DMA or interrupt request has been asserted.
2. RB is full.
3. RSR is full.

As previously described, data arriving on mcbspi_dr is continuously shifted into the RSR. Once a complete word is shifted into the RSR, an RSR-to-RB copy can occur only if the RB is not full.

Either of the following events clears the legacy mode McBSPi.MCBSPLP_SPCR1_REG[2] RFULL bit and allows subsequent transfers to be read properly:

- The MPU/DSP subsystems or sDMA controller reads the McBSPi.MCBSPLP_DRR_REG register.
- The receiver is reset individually (the McBSPi.MCBSPLP_SPCR1_REG[0] RRST bit is set to 0) or as part of a global reset.

Another frame-sync pulse is required to restart the receiver.

According to the McBSPi.MCBSPLP_IRQENABLE_REG register setting, this condition can generate the MCBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in the McBSPi.MCBSPLP_IRQSTATUS_REG register clears the interrupt.

Figure 24-147 shows the receive overrun condition.

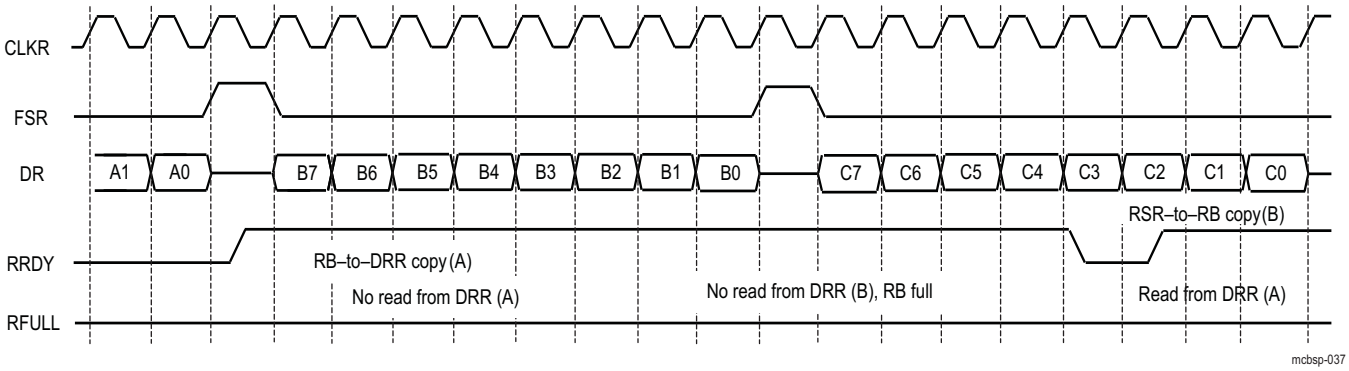
Figure 24-147. Overrun in the McBSP Receiver



24.5.4.10.3 Unexpected Receive Frame-Sync Pulse

24.5.4.10.3.1 Possible Responses to Receive Frame-Sync Pulses

If a frame-sync pulse starts the transfer of a new frame before the current frame is fully received, this pulse is treated as an unexpected frame-sync pulse, and the receiver sets the receive frame-sync error bit McBSPi.MCBSPLP_IRQSTATUS_REG[0] RSYNCERR (and the legacy McBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR bit).

According to the settings of the McBSPi.MCBSPLP_IRQENABLE_REG register, this condition can generate the MCBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in the McBSPi.MCBSPLP_IRQSTATUS_REG register clears the interrupt.

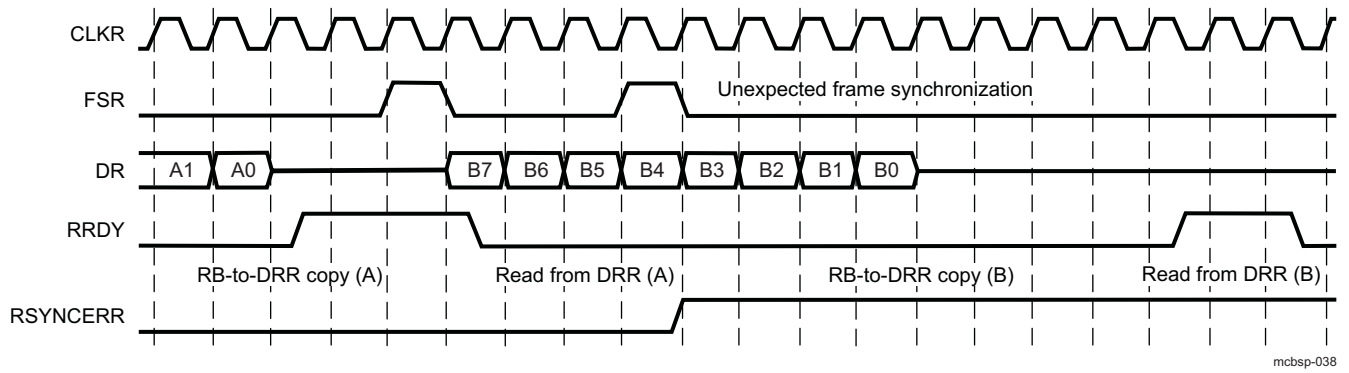
Using the legacy mode, the McBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR bit can be cleared only by a receiver reset or by setting this bit to 0. For the McBSP module to notify the MPU/DSP subsystem of receive frame-sync errors, set the legacy mode receive interrupt with the McBSPi.MCBSPLP_SPCR1_REG[5:4] RINTM bit field. When RINTM is set to 0b11, the McBSP module sends a receive interrupt (legacy mode) request to the MPU/DSP subsystems each time that RSYNCERR is set.

24.5.4.10.3.2 Example of an Unexpected Receive Frame-Sync Pulse

Figure 24-148 shows an unexpected receive frame-sync pulse during normal operation of the serial port with time intervals between data packets.

NOTE: The unexpected receive frame-sync pulse does not influence the data receive process, being ignored by the data receive state-machine.

Figure 24-148. Unexpected Frame-Sync Pulse During a McBSP Reception

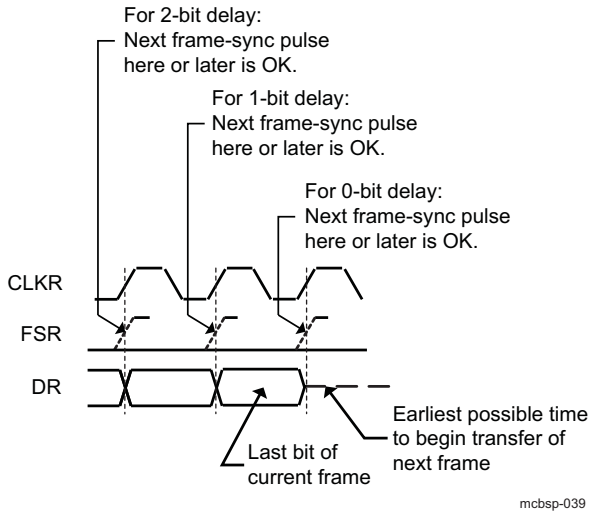


Copyright © 2011–2012, Texas Instruments Incorporated

24.5.4.10.3.3 Preventing Unexpected Receive Frame-Sync Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKR cycles, depending on the value of the McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY bit field. For each possible data delay, Figure 24-149 shows when a new frame-sync pulse on FSR can safely occur relative to the last bit of the current frame.

Figure 24-149. Proper Positioning of Receive Frame-Sync Pulses



24.5.4.10.4 Underflow in the Receiver

The McBSP module indicates a receiver underflow condition by setting the McBSPi.MCBSPLP_IRQSTATUS_REG[4] RUNDFLSTAT bit. This error occurs when sDMA controller or MPU/DSP subsystem reads data from an empty RB this happens only if the MPU/DSP subsystem or sDMA controller does not respect the DMA length, does not wait for DMA request, or does not check the buffer status before reading data. According to the McBSPi.MCBSPLP_IRQENABLE_REG register settings this condition can generate the MCBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.MCBSPLP_IRQSTATUS_REG register clears the interrupt.

24.5.4.10.5 Underflow in the Transmitter

The McBSP module indicates a transmitter empty (or underflow) condition by setting the McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT bit. The legacy mode McBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY bit is also cleared. Either of the following events activates the XEMPTY bit (XEMPTY = 0):

- The McBSPi.MCBSPLP_DXR_REG register has not been loaded and the XB is empty, and all bits of the data word in the XSR have been shifted out on the mcbspi_dx pin.
- The transmitter is reset (by forcing McBSPi.MCBSPLP_SPCR2_REG[0] XRST to 0, or by a global reset) and is then restarted.

The XEMPTY bit is deactivated (XEMPTY = 1) when a new word in the McBSPi.MCBSPLP_DXR_REG register is transferred to the XB. If the McBSPi.MCBSPLP_PCR_REG[11] FSXM bit is set to 1 and the McBSPi.MCBSPLP_SRGR2_REG[12] FSGM bit is set to 0, the FSX signal is generated when the XB is not empty. When the McBSPi.MCBSPLP_SRGR2_REG[12] FSGM bit is set to 0, the McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER and McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID bit fields are used to determine the frame-sync period and width (external FSX is gated by the buffer empty condition). Otherwise, the transmitter waits for the next frame-sync pulse before sending the next frame on the mcbspi_dx pin.

Copyright © 2011–2012, Texas Instruments Incorporated

When the transmitter is taken out of reset (the cBSPi.MCBSPLP_SPCR2_REG[0] XRST bit is set to 1), it is in a transmitter ready state (the McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit is set to 1) and transmitter empty (the McBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY bit is set to 0) state. If the McBSPi.MCBSPLP_DXR_REG register is loaded by the MPU/DSP subsystem or the sDMA controller before internal the FSX goes active high, a valid XB-to-XSR transfer occurs. This allows for the first word of the first frame to be valid even before the transmit frame-sync pulse is generated or detected. Alternatively, if a transmit frame-sync pulse is detected before McBSPi.MCBSPLP_DXR_REG is loaded, zeros are output on the mcbspi_dx pin.

The McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT bit indicates a real underflow condition, in which the frame is corrupted due to lack of data availability during the transmit process. According to the settings of the McBSPi.MCBSPLP_IRQENABLE_REG register, this condition can generate the MCBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.MCBSPLP_IRQSTATUS_REG register clears the interrupt.

24.5.4.10.6 Unexpected Transmit Frame-Sync Pulse

24.5.4.10.6.1 Possible Responses to Transmit Frame-Sync Pulses

If a frame-sync pulse starts the transfer of a new frame before the current frame is fully transmitted, this pulse is treated as an unexpected frame-sync pulse, and the transmitter sets the transmit frame-sync error bit McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR (and the legacy McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR bit).

According to the settings of the McBSPi.MCBSPLP_IRQENABLE_REG register, this condition can generate the MCBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in the status register clears the interrupt.

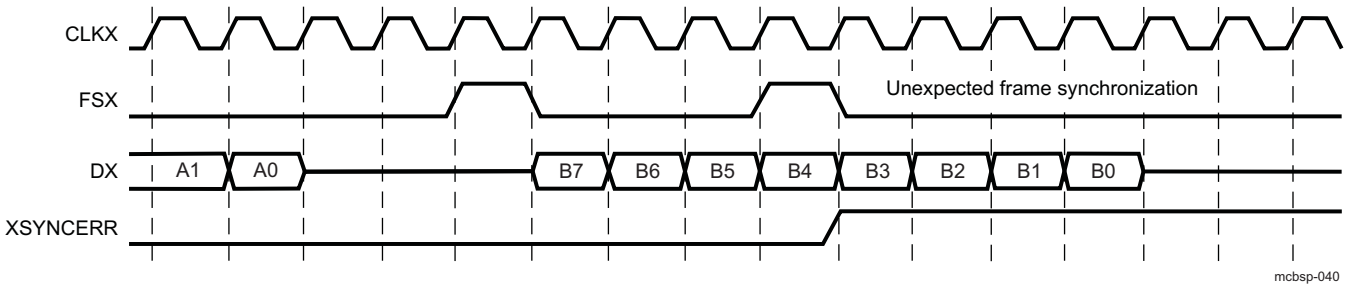
Using the legacy mode, the McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR bit can be cleared only by a transmitter reset or by setting this bit to 0. For the McBSP module to notify the MPU/DSP subsystem of frame-sync errors, set a special transmit interrupt mode with the McBSPi.MCBSPLP_SPCR2_REG[5:4] XINTM bit field. When XINTM is set to 0b11, the McBSP module sends a transmit interrupt request to the MPU/DSP subsystem each time XSYNCERR is set.

24.5.4.10.6.2 Example of Unexpected Transmit Frame-Sync Pulse

Figure 24-150 shows an unexpected transmit frame-sync pulse during normal operation of the serial port with intervals between the data packets.

NOTE: The unexpected transmit frame-sync pulse does not influence the data transmit process, being ignored by the data transmit state-machine.

Figure 24-150. Unexpected Frame-Sync Pulse During a McBSP Transmission

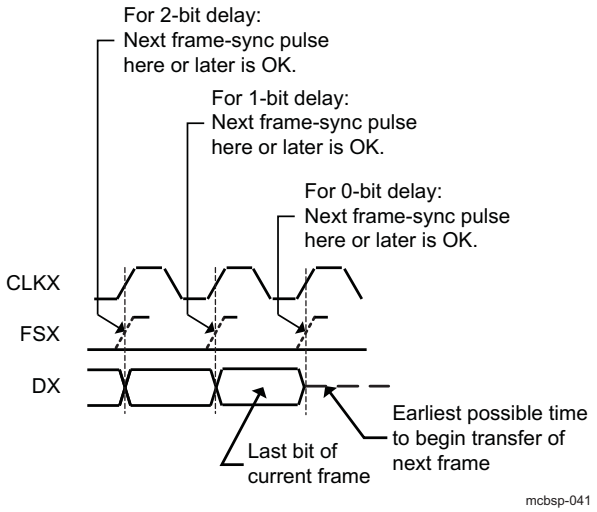


24.5.4.10.6.3 Preventing Unexpected Transmit Frame-Sync Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKX cycles, depending on the value in the McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY bit field. For each possible data delay, Figure 24-151 shows when a new frame-sync pulse on FSX can safely occur relative to the last bit of the current frame.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-151. Proper Positioning of Transmit Frame-Sync Pulses



24.5.4.10.7 Overflow in the Transmitter

The McBSP module indicates a transmitter overflow condition by setting the McBSPi.MCBSPLP_IRQSTATUS_REG[12] XOVFLSTAT bit. This error occurs when the sDMA controller or MPU/DSP subsystem writes data to a full XB (this happens only if the MPU/DSP subsystem or sDMA controller does not respect the DMA length, does not wait for DMA request, or does not check the buffer status before writing data). According to the settings of the McBSPi.MCBSPLP_IRQENABLE_REG register, this condition can generate the MCBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in the status register clears the interrupt.

24.5.4.11 McBSP DMA Configuration

The McBSP receive and transmit data DMA requests are active after the receive McBSPi.MCBSPLP_SPCR1_REG[0] RRST and transmit McBSPi.MCBSPLP_SPCR2_REG[0] XRST bits are released. After reset the default DMA threshold (and length) is one.

The receive and transmit DMA requests can be individually disabled by setting the McBSPi.MCBSPLP_RCCR_REG[3] RDMAEN and McBSPi.MCBSPLP_XCCR_REG[3] XDMAEN bits to 0. When disabling the DMA, the DMA request line is deasserted even if a DMA transfer is pending and the DMA state-machine is not reset.

The DMA threshold and length configuration is done through the McBSPi.MCBSPLP_THRSH1_REG and McBSPi.MCBSPLP_THRSH2_REG registers as follows:

- (THRSH1_REG + 1) value represents the required receive DMA request length (the length of the transfer is the same as the threshold value plus 1). As long as the RB occupied locations level is greater than or equal to the THRSH1_REG value + 1, the DMA request is asserted. After transferring the configured (THRSH1_REG + 1) number of words, the receive DMA request is de-asserted and reasserted as soon as the conditions are met again.
- (THRSH2_REG + 1) value represents the required transmit DMA request length (the length of the transfer is the same as the threshold value plus 1). As long as the XB free locations level is greater than or equal to the THRSH2_REG value + 1, the DMA request is asserted. After transferring the configured (THRSH2_REG + 1) number of words, the transmit DMA request is deasserted and reasserted as soon as the conditions are met.

Copyright © 2011–2012, Texas Instruments Incorporated

NOTE: The MPU/DSP subsystem can decide not to use the DMA to transfer the data. In this case, the DMA must be disabled (or the DMA request can be ignored by MPU/DSP subsystem) and the common interrupt line (MCBSPi_IRQ) can be used. The McBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit for receive and the McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit for transmit indicate when the threshold values are reached. Also, by reading the receive buffer status McBSPi.MCBSPLP_RBUFFSTAT_REG register and transmit buffer status McBSPi.MCBSPLP_XBUFFSTAT_REG register, the MPU/DSP subsystem can decide to transfer data even if the threshold is not reached. This mechanism is useful on the last transfer on the receive side when the threshold value is bigger than the occupied locations inside the receive buffer and the MPU/DSP subsystem needs to read this data. Because no interrupt or DMA request is asserted, the only option in this case is to read the value of the RB status register and to transfer the remaining data without using the DMA or interrupt indication.

24.5.4.12 Multichannel Selection Modes

24.5.4.12.1 Channels, Blocks and Partitions

A McBSP channel is a time slot for shifting in/out the bits of one serial word. The McBSP module supports up to 128 channels for reception and 128 channels for transmission. In the receiver and in the transmitter, the 128 available channels are divided into eight blocks that contain 16 contiguous channels each (see Table 24-351).

Table 24-351. McBSP Channels

Block 0: Channels 0–15	**Block 4: Channels 64–79**
Block 1: Channels 16–31	**Block 5: Channels 80–95**
Block 2: Channels 32–47	**Block 6: Channels 96–111**
Block 3: Channels 48–63	**Block 6: Channels 112–127**

The blocks are assigned to partitions according to the selected partition mode. In the 2-partition mode described in Section 24.5.4.12.6, *Using Two Partitions (Legacy Only)*, assign one even-numbered block (0, 2, 4, or 6) to partition A and one odd-numbered block (1, 3, 5, or 7) block to partition B. In the 8-partition mode described in Section 24.5.4.12.4, *Using Eight Partitions*, blocks 0 through 7 are automatically assigned to partitions A through H, respectively.

The number of partitions for reception and the number of partitions for transmission are independent of one another. For example, it is possible to use two receive partitions (A and B) and eight transmit partitions (A–H).

24.5.4.12.2 Multichannel Selection

When a McBSP module uses a time-division multiplexed (TDM) data stream while communicating with other McBSP modules or serial devices, the McBSP module may need to receive and/or transmit on only a few channels. To save memory and bus bandwidth, use a multichannel selection mode to prevent data flow in some of the channels.

Each channel partition has a dedicated channel enable register. If the appropriate multichannel selection mode is on, each bit in the register controls whether data flow is allowed or prevented in one of the channels that is assigned to that partition.

The McBSP module has one receive multichannel selection mode (see Section 24.5.4.12.5, *Receive Multichannel Selection Mode*) and three transmit multichannel selection modes (see Section 24.5.4.12.7, *Transmit Multichannel Selection Modes*).

24.5.4.12.3 Configuring a Frame for Multichannel Selection

Before enabling a multichannel selection mode, ensure that the data frame is properly configured:

Copyright © 2011–2012, Texas Instruments Incorporated

- Select a single-phase frame (the McBSPi.MCBSPLP_RCR2_REG[15] RPHASE and McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bits are set to 0). Each frame represents a TDM data stream.
- Set a frame length (in the McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1 and McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 bit fields) that includes the highest numbered channel to be used. For example, to use channels 0, 15, and 39 for reception, the receive frame length must be at least 40 (RFRLEN1 = 39). In this case, If XFRLEN1= 39, the receiver creates 40 time slots per frame but receives data only during time slots 0, 15, and 39 of each frame.

24.5.4.12.4 Using Eight Partitions

For multichannel selection operation in the receiver and/or transmitter, eight partitions or two partitions (as previously described) can be used. If 8-partition mode (McBSPi.MCBSPLP_MCR1_REG[9] RMCME = 1 for reception, and McBSPi.MCBSPLP_MCR2_REG[9] XMCME = 1 for transmission) is selected, McBSP channels are activated in the following order: A, B, C, D, E, F, G, H.

In response to a frame-sync pulse, the receiver or transmitter begins with the channels in partition A and then continues with the other partitions, in order, until the complete frame is transferred. When the next frame-sync pulse occurs, the next frame is transferred, beginning with the channels in partition A.

In 8-partition mode, the McBSPi.MCBSPLP_MCR1_REG[6:5] RPABLK/McBSPi.MCBSPLP_MCR2_REG[6:5] XPABLK bit fields, and the McBSPi.MCBSPLP_MCR1_REG[8:7] RPBBLK/McBSPi.MCBSPLP_MCR2_REG[8:7] XPBBLK bit fields are ignored and the 16-channel blocks are assigned to the partitions as shown in Table 24-352 and Table 24-353. These assignments cannot be changed. The tables also show the registers used to control the channels in the partitions.

Table 24-352. Eight Partitions – Receive Channel Assignment and Control

Receive Partition	Assigned Block of Receive Channels	Register Used for Channel Control
A	Block 0: Channels 0–15	McBSPi.MCBSPLP_RCERA_REG
B	Block 1: Channels 16–31	McBSPi.MCBSPLP_RCERB_REG
C	Block 2: Channels 32–47	McBSPi.MCBSPLP_RCERC_REG
D	Block 3: Channels 48–63	McBSPi.MCBSPLP_RCERD_REG
E	Block 4: Channels 64–79	McBSPi.MCBSPLP_RCERE_REG
F	Block 5: Channels 80–95	McBSPi.MCBSPLP_RCERF_REG
G	Block 6: Channels 96–111	McBSPi.MCBSPLP_RCERG_REG
H	Block 7: Channels 112–127	McBSPi.MCBSPLP_RCERH_REG

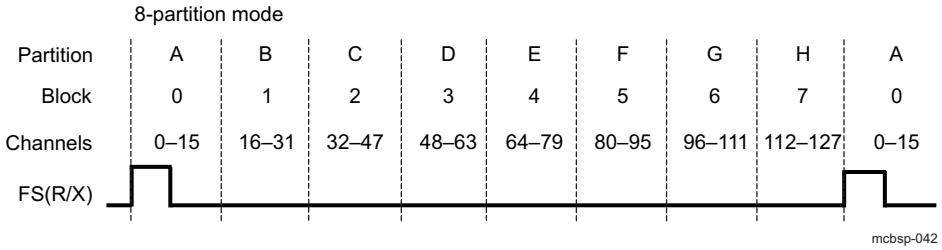
Table 24-353. Eight Partitions – Transmit Channel Assignment and Control

Transmit Partition	Assigned Block of Receive Channels	Register Used for Channel Control
A	Block 0: Channels 0–15	McBSPi.MCBSPLP_XCERA_REG
B	Block 1: Channels 16–31	McBSPi.MCBSPLP_XCERB_REG
C	Block 2: Channels 32–47	McBSPi.MCBSPLP_XCERC_REG
D	Block 3: Channels 48–63	McBSPi.MCBSPLP_XCERD_REG
E	Block 4: Channels 64–79	McBSPi.MCBSPLP_XCERE_REG
F	Block 5: Channels 80–95	McBSPi.MCBSPLP_XCERF_REG
G	Block 6: Channels 96–111	McBSPi.MCBSPLP_XCERG_REG
H	Block 7: Channels 112–127	McBSPi.MCBSPLP_XCERH_REG

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-152 shows an example of the McBSP using 8-partition mode. In response to a frame-sync pulse, the McBSP module begins a frame transfer with partition A and then activates B, C, D, E, F, G, and H to complete a 128-word frame.

Figure 24-152. McBSP Data Transfer in 8-Partition Mode



24.5.4.12.5 Receive Multichannel Selection Mode

The McBSPi.MCBSPLP_MCR1_REG[0] RMCM bit determines whether all channels or only selected channels are enabled for reception.

- When RMCM = 0, all 128 receive channels are enabled and cannot be disabled.
- When RMCM = 1, the receive multichannel selection mode is enabled. In this mode:
  - Channels can be individually enabled or disabled. The enabled channels are those selected in the appropriate receive channel enable registers (McBSPi.MCBSPLP_RCERA_REG/McBSPi.MCBSPLP_RCERH_REG). The channels assigned to the McBSPi.MCBSPLP_RCERA_REG/McBSPi.MCBSPLP_RCERH_REG registers depend on the number of receive channel partitions (2 or 8), as defined by the McBSPi.MCBSPLP_MCR1_REG[9] RMCME bit.
  - If a receive channel is disabled, any bits received in that channel are not transferred to the RB, and as a result, the receiver ready bit (RRDY) is not set. Therefore, no DMA synchronization event is generated and, if the receiver interrupt mode depends on RRDY (McBSPi.MCBSPLP_SPCR1_REG[5:4] RINTM = 0b00), no interrupt is generated.

As an example of how the McBSP module behaves in the receive multichannel selection mode, suppose only channels 0, 15, and 39 are enabled and that the frame length is 40. The McBSP module:

1. Accepts bits shifted in from the mcbspi_dr pin in channel 0
2. Ignores bits received in channels 1–14
3. Accepts bits shifted in from the mcbspi_dr pin in channel 15
4. Ignores bits received in channels 16–38
5. Accepts bits shifted in from the mcbspi_dr pin in channel 39

24.5.4.12.6 Using Two Partitions (Legacy Only)

For multichannel selection operation in the receiver and/or the transmitter, two partitions or eight partitions can be used. If 2-partition mode (the McBSPi.MCBSPLP_MCR1_REG[9] RMCME bit is set to 0 for reception, and the McBSPi.MCBSPLP_MCR2_REG[9] XMCME bit is set to 0 for transmission) is selected, the McBSP channels are activated using an alternating scheme. In response to a frame-sync pulse, the receiver or transmitter begins with the channels in partition A and then alternates between partitions B and A until the complete frame is transferred. When the next frame-sync pulse occurs, the next frame is transferred beginning with the channels in partition A.

For reception, any two of the eight receive-channel blocks can be assigned to receive partitions A and B, which means up to 32 receive channels can be enabled at any given point. Similarly, any two of the eight transmit-channel blocks (up to 32 enabled transmit channels) can be assigned to transmit partitions A and B.

For reception:

- Assign an even-numbered channel block (0, 2, 4, or 6) to receive partition A by writing to the McBSPi.MCBSPLP_MCR1_REG[6:5] RPABLK bit field. In the receive multichannel selection mode,

Copyright © 2011–2012, Texas Instruments Incorporated

the channels in this partition are controlled by receive channel enable register A (McBSPi.MCBSPLP_RCERA_REG).

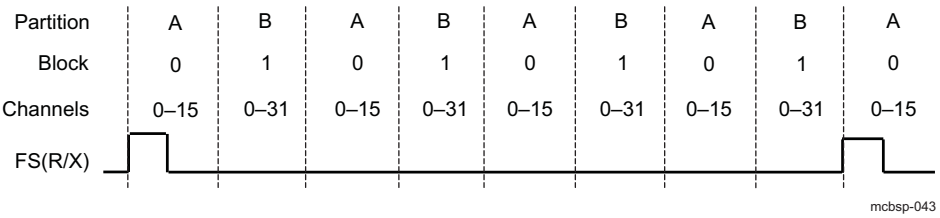
- Assign an odd-numbered block (1, 3, 5, or 7) to receive partition B with the McBSPi.MCBSPLP_MCR1_REG[8:7] RPBBLK bit field. In the receive multichannel selection mode, the channels in this partition are controlled by receive channel enable register B (McBSPi.MCBSPLP_RCERB_REG).

For transmission:

- Assign an even-numbered channel block (0, 2, 4, or 6) to transmit partition A by writing to the McBSPi.MCBSPLP_MCR2_REG[6:5] XPABLK bit field. In one of the transmit multichannel selection modes, the channels in this partition are controlled by transmit channel enable register A (McBSPi.MCBSPLP_XCERA_REG).
- Assign an odd-numbered block (1, 3, 5, or 7) to transmit partition B with the McBSPi.MCBSPLP_MCR1_REG[8:7] XPBBLK bit field. In one of the transmit multichannel selection modes, the channels in this partition are controlled by transmit channel enable register B (McBSPi.MCBSPLP_XCERB_REG).

Figure 24-153 shows an example of alternating between the channels of partition A and the channels of partition B. Channels 0–15 have been assigned to partition A, and channels 16–31 have been assigned to partition B. In response to a frame-sync pulse, the McBSP module begins a frame transfer with partition A and then alternates between partitions B and A until the complete frame is transferred.

Figure 24-153. Alternating Between Partitions A and B Channels



24.5.4.12.7 Transmit Multichannel Selection Modes

The McBSPi.MCBSPLP_MCR2_REG[1:0] XMCM bit field determines whether all channels or only selected channels are enabled and unmasked for transmission. The McBSP module has three transmit multichannel selection modes (XMCM = 0b01, XMCM = 0b10, and XMCM = 0b11), which are described in Table 24-354.

Table 24-354. Selecting a Transmit Multichannel Selection Mode With the XMCM Bit Field

XMCM	Transmit Multichannel Selection Mode
0b00	No transmit multichannel selection mode is on. All channels are enabled and unmasked. No channels can be disabled or masked.
0b01	All channels are disabled unless they are selected in the appropriate transmit channel enable registers (McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG). If enabled, a channel in this mode is also unmasked. The McBSPi.MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 or 128 channels are selectable in the McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG registers.
0b10	All channels are enabled, but they are masked unless they are selected in the appropriate transmit channel enable registers (McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG). The McBSPi.MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 or 128 channels are selectable in the McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG registers.
0b11	This mode is used for symmetric transmission and reception. All channels are disabled for transmission unless they are enabled for reception in the appropriate receive channel enable registers (McBSPi.MCBSPLP_RCERA_REG/McBSPi.MCBSPLP_RCERH_REG). Once enabled, they are masked unless they are also selected in the appropriate transmit channel enable registers (McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG). The McBSPi.MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 or 128 channels are selectable in the McBSPi.MCBSPLP_RCERA_REG/McBSPi.MCBSPLP_RCERH_REG registers and the McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG registers.

Copyright © 2011–2012, Texas Instruments Incorporated

As an example of how the McBSP module behaves in a transmit multichannel selection mode, suppose that XMCM = 0b01 (all channels disabled unless individually enabled) and that only channels 0, 15, and 39 are enabled. Suppose also that the frame length is 40. The McBSP module:

1. Shifts data to the mcbspi_dx pin in channel 0
2. Places the mcbspi_dx pin in the high-impedance state in channels 1–14
3. Shifts data to the mcbspi_dx pin in channel 15
4. Places the mcbspi_dx pin in the high-impedance state in channels 16–38
5. Shifts data to the mcbspi_dx pin in channel 39

24.5.4.12.7.1 Disabling/Enabling Versus Masking/Unmasking

For transmission, a channel can be:

- Enabled and unmasked (transmission can begin and can be completed)
- Enabled but masked (transmission can begin but cannot be completed)
- Disabled (transmission cannot occur)

The definitions in Table 24-355 explain the channel control options:

Table 24-355. McBSP Channel Control Options

Enabled channel	A channel that can begin transmission by passing data from the data transmit register (McBSPi.MCBSPLP_DXR_REG) to the XSR through the XB.
Masked channel	A channel that cannot complete transmission. The mcbspi_dx pin is held in high-impedance state; data cannot be shifted out on the mcbspi_dx pin. In systems where symmetric transmit and receive provide software benefits, this feature allows transmit channels to be disabled on a shared serial bus. A similar feature is not needed for reception because multiple receptions cannot cause serial bus contention.
Disabled channel	A channel that is not enabled. A disabled channel is also masked. Because no DXR-to-XB copy occurs, the McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit is not set. Therefore, no DMA synchronization event is generated, and if the transmit interrupt mode depends on XRDY (McBSPi.MCBSPLP_SPCR2_REG[5:4] XINTM = 00b), no interrupt is generated. The McBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY bit is not affected.
Unmasked channel	A channel that is not masked. Data in the XSR(s) is shifted out on the mcbspi_dx pin.

24.5.4.12.7.2 Activity on McBSP Pins for Different Values of XMCM

Figure 24-154 shows the activity on the McBSP pins for the various values of the McBSPi.MCBSPLP_MCR2_REG[1:0] XMCM bit field. In all cases, the transmit frame is configured as follows:

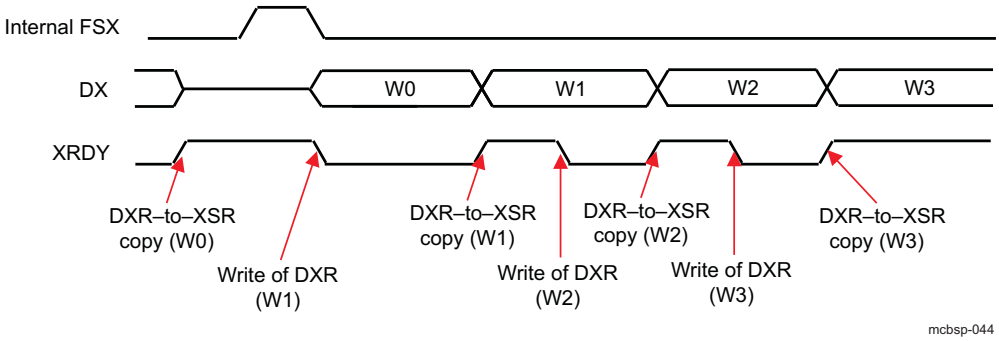
- XPHASE = 0: Single-phase frame (required for multichannel selection modes)
- XFRLEN1 = 0b0000011: 4 words per frame
- XWDLEN1 = 0b000: 8 bits per word
- XMCME = 0: 2-partition mode (only partitions A and B are used)

In the case where McBSPi.MCBSPLP_MCR2_REG[1:0] XMCM = 0b11, transmission and reception are symmetric, which means the corresponding bits for the receiver (RPHASE, RFRLEN1, RWDLEN1, and RMCME) must have the same values as XPHASE, XFRLEN1, and XWDLEN1, respectively.

In Figure 24-154, the arrows showing where the various events occur are only sample indications. Wherever possible, there is a time window in which these events can occur.

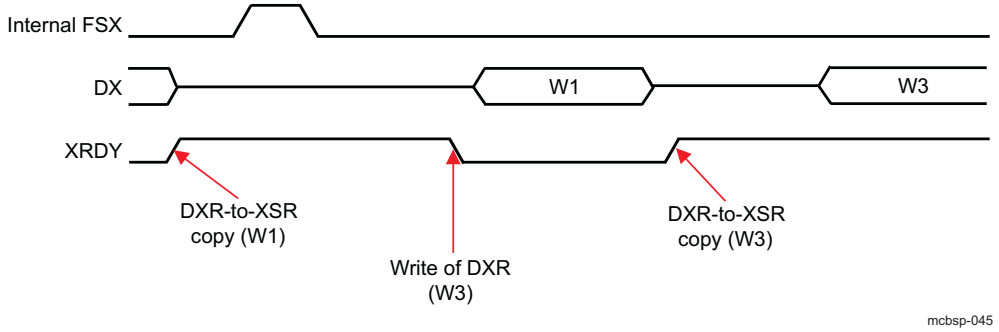
Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-154. Activity on McBSP Pins When XMCM = 0b00



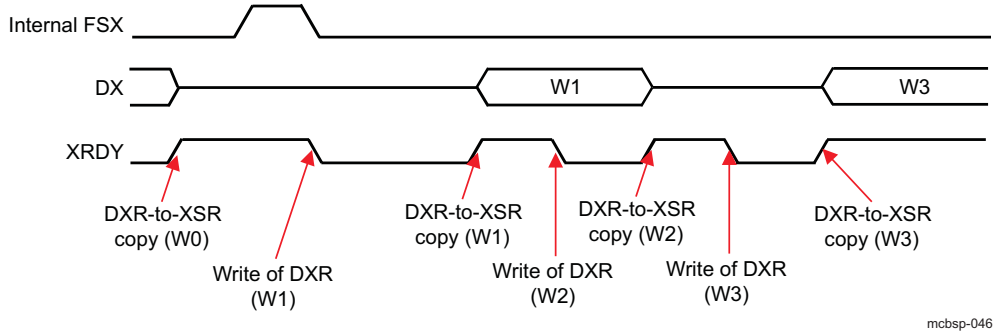
If XMCM = 0b00, all channels are enabled and unmasked. Words W0, W1, W2, and W3 are written to the XB, and then, from the XB, they are transferred by mcbspi_dx.

Figure 24-155. Activity on McBSP Pins When XMCM = 0b01



In Figure 24-155 if XMCM = 0b01, XPABLK = 0b00, and XCERA = 0b1010, only channels 1 and 3 are enabled and unmasked. Words W1 and W3 are written to the XB, and then, from the XB, they are transferred by mcbspi_dx.

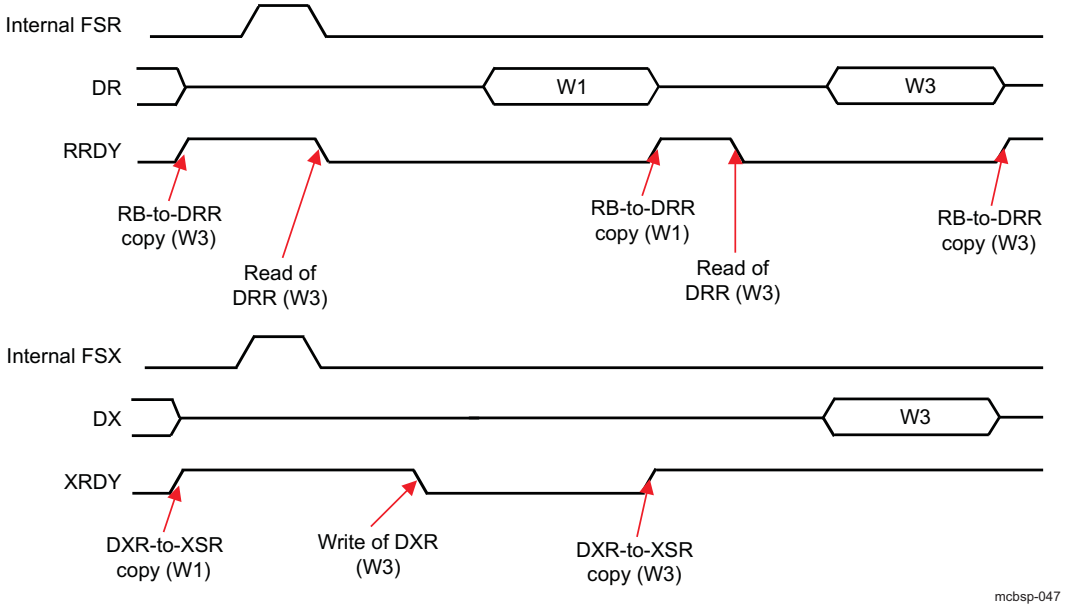
Figure 24-156. Activity on McBSP Pins When XMCM = 0b10



In Figure 24-156 if XMCM = 0b10, XPABLK = 0b00, and XCERA = 0b1010, all channels are enabled, and only 1 and 3 are unmasked. Words W0, W1, W2, and W3 are written to the XB, but only W1 and W3, from the XB, are transferred by mcbspi_dx.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-157. Activity on McBSP Pins When XMCM = 0b11



In Figure 24-157 if XMCM = 0b11, RPABLK = 0b00, XPABLK = 0bX, RCERA = 0b1010, and XCERA = 0b1000, channels 1 and 3 are enabled in receive and transmit mode, but only 3 is unmasked. Words W1 and W3 are written to the XB, but only W3, from the XB, is transferred by mcbspi_dx.

24.5.5 McBSP Basic Programming Model

This section describes the programming model of a typical McBSP module.

CAUTION

For all descriptions in this section, the McBSPi.MCBSPLP_XCCR_REG[11] XFULL_CYCLE and McBSPi.MCBSPLP_RCCR_REG[11] RFULL_CYCLE bits are their reset value (XFULL_CYCLE is set to 0 and RFULL_CYCLE is set to 1).

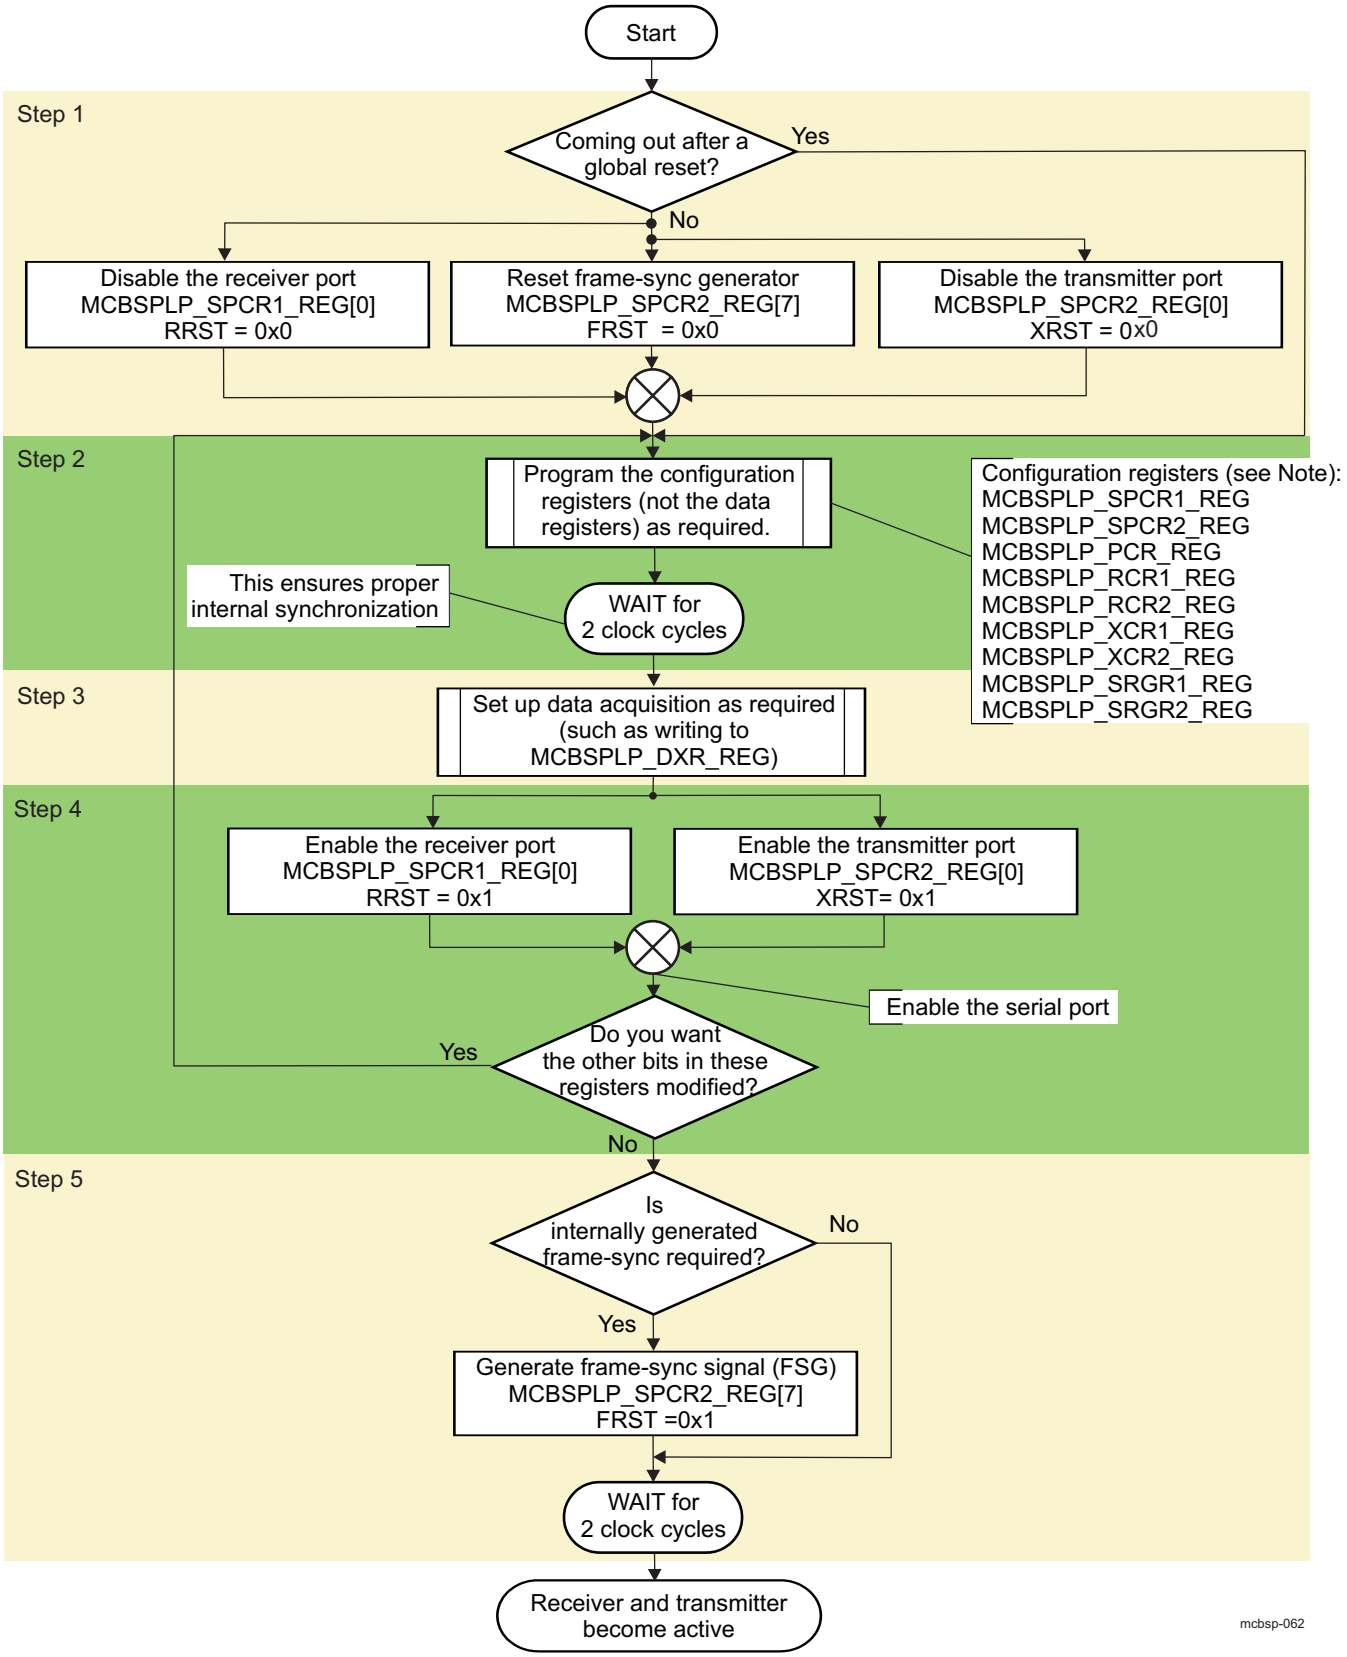
24.5.5.1 McBSP Initialization Procedure

This procedure for reset/initialization can be applied in general when the receiver or transmitter must be reset during its normal operation, and also when the SRG is not used for either operation.

Figure 24-158 shows the serial port initialization procedure for master mode.

Copyright © 2011–2012, Texas Instruments Incorporated

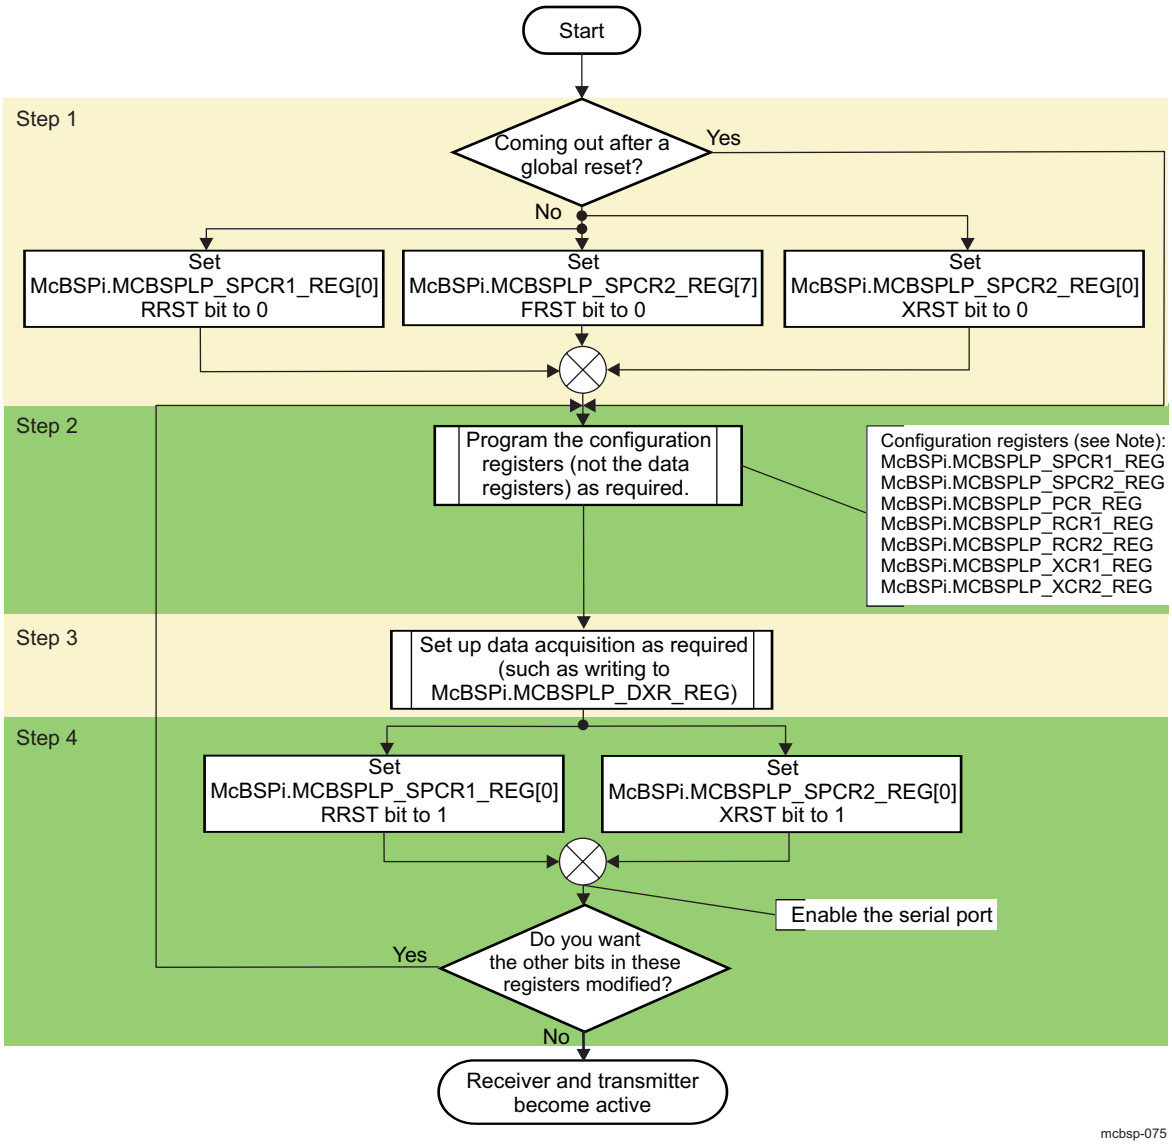
Figure 24-158. Flow Diagram of McBSP Initialization Procedure for Master Mode



Copyright © 2011–2012, Texas Instruments Incorporated

Alternatively, on write (Step 1 or Step 4), the transmitter and receiver can be placed in or taken out of reset by modifying the McBSPi.MCBSPLP_SPCR2_REG[0] XRST and McBSPi.MCBSPLP_SPCR1_REG[0] RRST bits, respectively.
Figure 24-159 shows the flow diagram of the McBSP initialization procedure for slave mode.

Figure 24-159. Flow Diagram of McBSP Initialization Procedure for Slave Mode



Copyright © 2011–2012, Texas Instruments Incorporated

NOTE:

- Alternatively, on write (Step 1 or Step 4), the transmitter and receiver can be placed in or taken out of reset by modifying the McBSPi.MCBSPLP_SPCR2_REG[0] XRST and McBSPi.MCBSPLP_SPCR1_REG[0] RRST bits, respectively.
- The necessary duration of the active-low period of XRST or RRST is at least two CLKR/CLKX cycles.
- The appropriate bits in serial port configuration registers (McBSPi.MCBSPLP_SPCR1_REG, McBSPi.MCBSPLP_SPCR2_REG, McBSPi.MCBSPLP_PCR_REG, McBSPi.MCBSPLP_RCR1_REG, McBSPi.MCBSPLP_RCR2_REG, McBSPi.MCBSPLP_XCR1_REG, McBSPi.MCBSPLP_XCR2_REG, McBSPi.MCBSPLP_THRSH2_REG, McBSPi.MCBSPLP_XCCR_REG, McBSPi.MCBSPLP_SYSCONFIG_REG, McBSPi.MCBSPLP_SRGR1_REG and McBSPi.MCBSPLP_SRGR2_REG) should be modified only when the affected portion of the serial port is in its reset state.
- In most cases, the data transmit register (McBSPi.MCBSPLP_DXR_REG) should be loaded by the MPU/DSP subsystem or the sDMA controller only when the transmitter is enabled (McBSPi.MCBSPLP_SPCR2_REG[0] XRST = 1). An exception to this rule is when these registers are used for loopback internal data.
- The bits of the channel control registers (McBSPi.MCBSPLP_MCR1_REG, McBSPi.MCBSPLP_MCR2_REG, McBSPi.MCBSPLP_RCER{A-H}_REG and McBSPi.MCBSPLP_XCER{A-H}_REG) can be modified at any time as long as they are not being used by the current reception/transmission in a multichannel selection mode.
- The SRG is reset by setting the McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit to 0.
- It is not necessary to wait if SRG is not used.
- The necessary duration of the active-low period of XRST or RRST is at least two
- Modification on-the-fly has no effect if a reset is not performed first.

Table 24-356. Register Call Summary for Flow Diagram of McBSP Initialization Procedure

Register Name	Register Name	Register Name
MCBSPLP_SPCR1_REG	MCBSPLP_RCR1_REG	MCBSPLP_XCR2_REG
MCBSPLP_SPCR2_REG	MCBSPLP_RCR2_REG	MCBSPLP_SRGR1_REG
MCBSPLP_PCR_REG	MCBSPLP_XCR1_REG	MCBSPLP_SRGR2_REG

24.5.5.2 Reset and Initialization Procedure for the SRG

To reset and initialize the SRG:

1. Place the McBSP SRG in reset.
2. Program the registers that affect the SRG.
3. Enable the SRG (take it out of reset).
4. If necessary, enable the receiver and/or the transmitter.
5. If necessary, remove the receiver and/or transmitter from reset

Figure 24-160 shows the flow diagram for programming the SRG registers.

24.5.5.3 Data Transfer DMA Request Configuration

This procedure configures the McBSP receive/transmit data DMA requests (MCBSPi_DMA_RX and MCBSPi_DMA_TX) (see Table 24-358).

Table 24-358. Data Transfer DMA Request Configuration

Step	Register/Bit Field/Programming Model	Value
Write the required receive DMA request length.	MCBSPLP_THRSH1_REG[6:0] RTHRESHOLD	x..x
Write the required transmit DMA request length.	MCBSPLP_THRSH2_REG[6:0] RTHRESHOLD	x..x

NOTE:

- The length of the transfer is the same as the threshold value + 1
- In case of a number of transfers that exceed the number of the programmed DMA length, the McBSP module will respond to the command and will perform the transfer regardless of the receive buffer empty condition.
- In case of a number of transfers that exceed the number of the programmed DMA length, the McBSP module will respond to the command and will perform the transfer regardless of the transmit buffer full condition.

24.5.5.4 Interrupt Configuration

This procedure configures the common receive/transmit interrupt request line (see Table 24-359).

Table 24-359. Interruption Configuration

Step	Register/Bit Field/Programming Model	Value
Enable the required IRQ events.	MCBSPLP_IRQENABLE_REG	x..x

24.5.5.5 Receiver Configuration

To configure the McBSP receiver, perform the following steps:

Step 1. Place the McBSP receiver in reset.

Step 2. Program the McBSP registers for the desired receiver operation.

Step 3. Take the receiver out of reset.

24.5.5.5.1 Place the Receiver in Reset (Step 1)

Table 24-360. Receiver Reset

Step	Register/Bit Field/Programming Model	Value
Place the receiver in reset.	MCBSPLP_SPCR1_REG[0] RST	0x0

Copyright © 2011–2012, Texas Instruments Incorporated

24.5.5.5.2 Programming the McBSP Registers for the Desired Receiver Configuration (Step 2)

This section describes the steps to be performed when software configures the McBSP receiver.

Global Configuration

Table 24-361 describes the steps to perform the global configuration.

Table 24-361. Global Configuration

Step	Register/Bit Field/Programming Model	Value
Set the receiver pins to operate as McBSP pins.	MCBSPLP_PCR_REG[12] RIOEN	0x0
Enable/disable DLB mode(1).	MCBSPLP_XCCR_REG[5] DLB	0x0 or 0x1
Enable/disable ALB mode(1).	MCBSPLP_SPCR1_REG[5] ALB	0x0 or 0x1
Select the clock used in synchronous transmit-receive mode (McBSP4 only)(1).	CONTROL_MCBSPLP[30] ALBCTRLRX_CLKX	0x0 or 0x1
Select frame synchronization used in the synchronous transmit-receive mode (McBSP4 only)(1).	CONTROL_MCBSPLP[31] ALBCTRLRX_FSX	0x0 or 0x1
Enable/disable the receive multichannel selection Mode(1).	MCBSPLP_MCR1_REG[0] RMCM	0x0 or 0x1

(1) Software decision

NOTE: In DLB mode the SRG and frame-sync generator must be enabled to generate the CLKX and FSX signals.

Data Configuration

Table 24-362 describes the steps to perform the data configuration.

Table 24-362. Data Configuration

Step	Register/Bit Field/Programming Model	Value
Select single/dual-phase frame (1).	MCBSPLP_RCR2_REG[15] RPHASE	0x0 or 0x1
Set the receive word length(s) for phase 1(1).	MCBSPLP_RCR1_REG[7:5] RWDLEN1	xxx
Set the receive word length(s) for phase 2(1).	MCBSPLP_RCR2_REG[7:5] XWDLEN2	xxx
Set the receive frame length*.	MCBSPLP_RCR1_REG[14:8] RFRLEN1 MCBSPLP_RCR2_REG[14:8] RFRLEN2	xxx
Set the receive reverse mode(1).	MCBSPLP_RCR2_REG[4:3] RREVERSE	xx
Set the receive data delay(1).	MCBSPLP_RCR2_REG[1:0] RDATLY	xx
Set the receive sign-extension and justification mode(1).	MCBSPLP_SPCR1_REG[14:13] RJUST	xx
Enable the serial receiver port.	MCBSPLP_SPCR1_REG[0] RRST	0x1
Configure the receive buffer threshold value(1).	MCBSPLP_THRSH1_REG[6:0] RTHRESHOLD	x..x

(1) Software decision

NOTE:

- When dual-phase frame is selected, the number of words per phase must be set to 1.
- If a single-phase frame is selected, RWDLEN1 selects the length for every serial word received in the frame. If a dual-phase frame is selected, RWDLEN1 and RWDLEN2 must be set to select both lengths. These bits can have different values.
- If a dual-phase frame is selected, the frame length must be two words.

Frame-Sync Configuration

Table 24-363 describes the steps to perform the frame-sync configuration.

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-363. Frame-Sync Configuration

Step	Register/Bit Field/Programming Model	Value
Set the receive frame-sync mode(1).	MCBSPLP_PCR_REG[10] FSRM	0x0 or 0x1
Select SRG synchronization(1).	MCBSPLP_SRGR2_REG[15] GSYNC	0x0 or 0x1
Set the receive frame-sync polarity (1).	MCBSPLP_PCR_REG[2] FSRP	0x0 or 0x1
Set the SRG frame-sync period(1).	MCBSPLP_SRGR2_REG[11:0] FPER	x..x
Set the SRG frame-sync pulse width(1).	MCBSPLP_SRGR1_REG[15:8] FWID	x..x

(1) Software decision

Clock Configuration

Table 24-364 describes the steps to perform clock configuration.

Table 24-364. Clock Configuration

Step	Register/Bit Field/Programming Model	Value
Set the receive clock mode(1).	MCBSPLP_PCR_REG[8] CLKRM	0x0 or 0x1
Set the receive clock polarity(1).	MCBSPLP_PCR_REG[0] CLKRP	0x0 or 0x1
Set the SRG clock divide-down value(1).	MCBSPLP_SRGR1_REG[7:0] CLKGDV	x..x
Set the SRG clock synchronization mode(1).	MCBSPLP_SRGR2_REG[15] GSYNC	0x0 or 0x1
Set the SRG input clock mode(1).	MCBSPLP_PCR_REG[7] SCKLME MCBSPLP_SRGR2_REG[13] CLKSM	0x0 or 0x1
Set the SRG input clock polarity(1).	MCBSPLP_SRGR2_REG[14] CLKSP MCBSPLP_PCR_REG[1] CLKXP MCBSPLP_PCR_REG[0] CLKRP	0x0 or 0x1

(1) Software decision

NOTE: CLKRP = CLKXP in a system in which the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

24.5.5.5.3 Take the Receiver Out of Reset (Step 3)

Table 24-365. Take the Receiver Out of Reset

Step	Register/Bit Field/Programming Model	Value
Enable the receiver.	MCBSPLP_SPCR1_REG[0] RST	0x1

24.5.5.6 Transmitter Configuration

To configure the McBSP transmitter, perform the following steps:

Step 1. Place the McBSP transmitter in reset.

Step 2. Program the McBSP registers for the desired transmitter operation.

Step 3. Take the transmitter out of reset.

24.5.5.6.1 Place the Transmitter in Reset (Step 1)

Table 24-366. Transmitter Reset

Step	Register/Bit Field/Programming Model	Value
Place the transmitter in reset.	MCBSPLP_SPCR2_REG[0] RST	0x0

Copyright © 2011–2012, Texas Instruments Incorporated

24.5.5.6.2 Programming the McBSP Registers for the Desired Transmitter Operation (Step 2)

This section describes the steps to be performed when software configures the McBSP transmitter.

Global Configuration

Table 24-367 describes the steps to perform the global configuration.

Table 24-367. Global Configuration

Step	Register/Bit Field/Programming Model	Value
Set the transmitter pins to operate as MCBSP pins.	MCBSPLP_PCR_REG[13] XIOEN	0x0
Enable/disable DLB mode(1).	MCBSPLP_XCCR_REG[5] DLB	0x0 or 0x1
Enable/disable ALB mode(1).	MCBSPLP_SPCR1_REG[5] ALB	0x0 or 0x1
Select clock used in the synchronous transmit-receive mode (McBSP4 only)(1).	CONTROL_MCBSPLP[30] ALBCTRLRX_CLKX	0x0 or 0x1
Select frame synchronization used in the synchronous transmit-receive mode (McBSP4 only)(1).	CONTROL_MCBSPLP[31] ALBCTRLRX_FSX	0x0 or 0x1
Enable/disable the transmit multichannel selection mode(1).	MCBSPLP_MCR1_REG[0] RMCM	0x0 or 0x1

(1) Software decision

Data Configuration

Table 24-368 describes the steps to perform the data configuration.

Table 24-368. Data Configuration

Step	Register/Bit Field/Programming Model	Value
Select single/dual-phase frame (1).	MCBSPLP_RCR2_REG[15] XPHASE	0x0 or 0x1
Set the transmit word length(s) for phase 1(1).	MCBSPLP_XCR1_REG[7:5] XWDLEN1	xxx
Set the transmit word length(s) for phase 2(1).	MCBSPLP_XCR2_REG[7:5] XWDLEN2	xxx
Set the transmit frame length(1).	MCBSPLP_XCR1_REG[14:8] XFRLEN1 MCBSPLP_XCR2_REG[14:8] XFRLEN2	xxx
Set the transmit reverse mode(1).	MCBSPLP_XCR2_REG[4:3] XREVERSE	xx
Set the transmit data delay(1).	MCBSPLP_XCR2_REG[1:0] XDATLY	xx
Set the extra delay (DX delay) mode(1).	MCBSPLP_SPCR1_REG[7] DXENA	xx
Select the inserted delay value(1).	MCBSPLP_XCCR_REG[13:12] DXENDLY	xx
Set the interrupt line.	MCBSPLP_IRQENABLE_REG	x..x
Configure the transmit buffer threshold value(1)	MCBSPLP_THRSH2_REG[6:0] XTHRESHOLD	x..x

(1) Software decision

NOTE:

- When dual-phase frame is selected, the number of words per phase must be set to 1.
- If a single-phase frame is selected, XWDLEN1 selects the length for every serial word transmit in the frame. If a dual–phase frame is selected, XWDLEN1 and XWDLEN2 must be set to select both lengths. These bits can have different values.
- If a dual-phase frame is selected, the frame length must be two words.

The DXENA bit controls the delay enabler on the mcbsp_dx pin. Set DXENA to enable an extra delay for turn-on time. Because this bit does not control the data itself, only the first bit is delayed (the delay is given by a combinatorial delay buffer). The inserted delay, 80 ps, 160 ps (default), 240 ps, or 320 ps, can be set using the McBSPi.MCBSPLP_XCCR_REG[13:12] DXENDLY bit field. If the mcbsp_dx pins of multiple McBSP modules are tied together, ensure that DXENA is set to 1 to avoid having more than one McBSP at a time transmitting on the data line.

Frame-Sync Configuration

Table 24-369 describes the steps to perform the frame-sync configuration.

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-369. Frame-Sync Configuration

Step	Register / Bit Field / Programming Model	Value
Set the transmit frame-sync mode(1).	MCBSPLP_PCR_REG[11] FSXM MCBSPLP_SRGR2_REG[12] FSGM	0x0 or 0x1
Set the transmit frame-sync polarity(1).	MCBSPLP_PCR_REG[3] FSXP	0x0 or 0x1
Set the SRG frame-sync period(1).	MCBSPLP_SRGR2_REG[11:0] FPER	x..x
Set the SRG frame-sync pulse width(1).	MCBSPLP_SRGR1_REG[15:8] FWID	x..x

(1) Software decision

Clock Configuration

Table 24-370 describes the steps to perform the clock configuration.

Table 24-370. Clock Configuration

Step	Register / Bit Field / Programming Model	Value
Set the transmit clock mode (1).	MCBSPLP_PCR_REG[9] CLKXM	0x0 or 0x1
Set the transmit clock polarity(1).	MCBSPLP_PCR_REG[1] CLKXP	0x0 or 0x1
Set the SRG clock divide-down value(1).	MCBSPLP_SRGR1_REG[7:0] CLKGDV	x..x
Set the SRG clock synchronization mode(1).	MCBSPLP_SRGR2_REG[15] GSYNC	0x0 or 0x1
Set the SRG input clock mode(1).	MCBSPLP_PCR_REG[7] SCKLME MCBSPLP_SRGR2_REG[13] CLKSM	0x0 or 0x1
Set the SRG input clock polarity(1)	MCBSPLP_SRGR2_REG[14] CLKSP MCBSPLP_PCR_REG[1] CLKXP MCBSPLP_PCR_REG[0] CLKRP	0x0 or 0x1

(1) Software decision

NOTE: CLKRP = CLKXP in a system in which the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

24.5.5.6.3 Take the Receiver Out of Reset (Step 3)

Table 24-371. Take the Receiver Out of Reset

Step	Register/Bit Field/Programming Model	Value
Enable the transmitter.	MCBSPLP_SPCR2_REG[0] RST	0x1

24.5.5.7 GPIO on the McBSP Pins (Legacy Only)

To use McBSP pins as GPIO pins rather than as serial port pins, follow these steps:

- **For the receive pins (mcbsp_clkr, mcbsp_fsr, and mcbsp_dr as)**

Table 24-372. Use Serial Receive Pins as GPIO Pins

Step	Register/Bit Field/Programming Model	Value
Place the receiver in reset.	MCBSPLP_SPCR1_REG[0] RRST	0x0
Enable GPIO for the serial port receiver.	MCBSPLP_PCR_REG[12] RIOEN	0x1

- **For the transmitter pins (mcbsp_clkx, mcbsp_fsx, and mcbsp_dx)**

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-373. Use Serial Transmit Pins as GPIO Pins

Step	Register/Bit Field/ Programming Model	Value
Place the transmit in reset.	MCBSPLP_SPCR2_REG[0] XRST	0x0
Enable GPIO for the serial port transmitter.	MCBSPLP_PCR_REG[12] XIOEN	0x1

- **For the external clock pins (abe_clks)**

  For the abe_clks pin (common to all McBSP modules), all of the reset and I/O conditions must be met as follows:

Table 24-374. Use External Clock Pin as GPIO Pin

Step	Register/Bit Field/Programming Model	Value
Place the receiver in reset.	MCBSPLP_SPCR1_REG[0] RRST	0x0
Place the transmit in reset.	MCBSPLP_SPCR2_REG[0] XRST	0x0
Enable GPIO for the serial port receiver.	MCBSPLP_PCR_REG[12] RIOEN	0x1
Enable GPIO for the serial port transmitter.	MCBSPLP_PCR_REG[12] XIOEN	0x1

24.5.6 MCBSP Register Manual

Table 24-375 shows the base address and address space for the device module instances.

24.5.6.1 MCBSP Instance Summary

Table 24-375. MCBSP Instance Summary

Module Name	Base Address L3 Interconnect	Base Address Cortex-A9 Private Access	Base Address DSP Private Access	Base Address L4-PER Interconnect	Size
MCBSP1	0x4902 2000	0x4012 2000	0x2 2000	N/A	4KB
MCBSP2	0x4902 4000	0x4012 4000	0x2 4000	N/A	4KB
MCBSP3	0x4902 6000	0x4012 6000	0x2 6000	N/A	4KB
MCBSP4	N/A	N/A	N/A	0x4809 6000	4KB

NOTE: Private access is an access that does not use the L3/L4 interconnects.

24.5.6.2 MCBSP Registers

CAUTION

The McBSP registers are limited to 32-bit data accesses; 16- and 8-bit accesses are not allowed and can corrupt register content.

24.5.6.2.1 MCBSP Register Summary

Table 24-376 through Table 24-379 summarize the MCBSP1, MCBSP2, MCBSP3, and MCBSP4 registers, respectively.

Table 24-376. MCBSP1 Register Summary

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address L3 Interconnect	Physical Address Cortex-A9 Private Access	Physical Address DSP Private Access

	0x4012 6010		MCBSP3_CORTEX-A9
	0x2 6010		MCBSP3_DSP
Description	McBSPLP serial port control register 2		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																						FREE	SOFT	FRST	GRST	XINTM		XSYNCERR	XEMPTY	XRDY	XRST

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Reserved	R	0x000000
9	FREE	Free Running Mode (When this bit is set, the module ignores the Msuspend input) 0x0: Free running mode is disabled 0x1: Free running mode is enabled	RW	0
8	SOFT	Soft Bit 0x0: SOFT mode is disabled: the module stops its activity immediately following MSuspend assertion 0x1: SOFT mode is enabled: the module freezes its state after completion of the current operation when MSuspend is asserted	RW	0
7	FRST	Frame-Sync Generator Reset 0x0: Frame-sync logic is reset. Frame-sync signal FSG is not generated by the sample-rate generator 0x1: Frame-sync signal FSG is generated after (FPER+1) number of CLKG clocks; that is, all frame counters are loaded with their programmed values	RW	0
6	GRST	Sample-Rate Generator Reset 0x0: SRG is reset 0x1: SRG is pulled out of reset. CLKG is driven as per programmed value in SRG registers (SRGR[1,2])	RW	0

Copyright © 2011–2012, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
5:4	XINTM	Transmit Interrupt Mode (legacy) 0x0: XINT is driven by XRDY 0x1: XINT generated by end-of-frame 0x2: XINT generated by a new frame synchronization 0x3: XINT generated by XSYNCERR	RW	0x0
3	XSYNCERR	Transmit Synchronization Error (writing 0 to this bit clear the legacy transmit interrupt if asserted due to XSYNCERR condition) 0x0: No synchronization error 0x1: Synchronization error detected by McBSP	RW	0
2	XEMPTY	Transmit Shift Register XSR Empty Read 0x0: XSR is empty Read 0x1: XSR is not empty	R	0
1	XRDY	Transmitter ready Read 0x0: Transmitter is not ready. Read 0x1: Transmitter is ready for new data in DXR	R	0
0	XRST	Transmitter reset. This resets and enables the transmitter. 0x0: The serial port transmitter is disabled and in reset state. 0x1: The serial port transmitter is enabled.	RW	0

RESERVED																GSYNC	CLKSP	CLKSM	FSGM	FPER											

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved	R	0x0000
15	GSYNC	0x0: The SRG clock (CLKG) is free running. 0x1: The SRG clock (CLKG) is running. But CLKG is resynchronized and frame-sync signal (FSG) is generated only after detecting the receive frame-sync signal (FSR). Also, frame period, FPER, is a don't care because the period is dictated by the external frame-sync pulse.	RW	0
14	CLKSP	CLKS Polarity Clock Edge Select Only used when the external clock CLKS drives the SRG clock (CLKSM=0). 0x0: Rising edge of CLKG and FSG. 0x1: Falling edge of CLKG and FSG.	RW	0
13	CLKSM	McBSPLP Sample Rate Generator Clock Mode 0x0: SCLKME=0: SRG clock derived from the CLKS pin. SCLKME=1: SRG clock derived from the CLKRI pin. 0x1: SCLKME=0: SRG clock derived from the CPU clock. SCLKME=1: SRG clock derived from the CLKXI clock.	RW	1
12	FSGM	Sample Rate Generator Transmit Frame-Synchronization Mode Used when FSXM=1 in the PCR. 0x0: Transmit frame-sync signal (FSX) is generated when transmit buffer is not empty When FSGM=0, FPER and FWID are used to determine the frame-sync period and width (external FSX is gated by the buffer empty condition). 0x1: Transmit frame-sync signal driven by the SRG frame-sync signal, FSG.	RW	0

Copyright © 2011–2012, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
11:0	FPER	Frame Period. This field plus 1 determines when the next frame-sync signal becomes active. Range: 1 to 4096 CLKG periods	RW	0x000

Description	McBSPLP pin control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																IDLE_EN	XIOEN	RIOEN	FSXM	FSRM	CLKXM	CLKRM	SCLKME	CLKS_STAT	DX_STAT	DR_STAT	FSXP	FSRP	CLKXP	CLKRP	

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Reserved	R	0x00000
14	IDLE_EN	Idle enable. This bit allows stopping all the clocks in the MCBSPLP. (legacy) 0x0: The McBSP is running 0x1: The clocks in the McBSP are shut off when both IDLE_EN=1 and peripheral domain is in idle mode	RW	0
13	XIOEN	Transmit General Purpose I/O Mode only when XRST=0 in SPCR[1,2] (legacy) 0x0: DX, FSX and CLKX are configured as serial port pins and do not function as general-purpose I/Os. 0x1: DX pin is a general purpose output. FSX and CLKX are general purpose I/Os. These serial port pins do not perform serial port operation.	RW	0
12	RIOEN	Receive General Purpose I/O Mode when RRST=0 in SPCR[1,2] (legacy) 0x0: DR, FSR, CLKR and CLKS are configured as serial port pins and do not function as general-purpose I/Os. 0x1: DR and CLKS pins are general purpose inputs; FSR and CLKR are general purpose I/Os. These serial port pins do not perform serial port operation. The CLKS pin is affected by a combination of RRST and RIOEN signals of the receiver.	RW	0

Copyright © 2011–2012, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
11	FSXM	Transmit Frame-Synchronization Mode 0x0: Frame-sync signal derived from an external source 0x1: Frame synchronization is determined by the SRG frame-sync mode bit FSGM in SRGR2.	RW	0
10	FSRM	Receive Frame-Synchronization Mode 0x0: Frame-sync pulses generated by an external device. FSR is an input pin. 0x1: Frame synchronization generated internally by SRG. FSR is an output pin except when GSYNC=1 in SRGR.	RW	0
9	CLKXM	Transmitter Clock Mode 0x0: Transmitter clock is driven by an external clock with CLKX as an input pin. 0x1: CLKX is an output pin and is driven by the internal sample rate generator.	RW	0
8	CLKRM	Receiver Clock Mode 0x0: Case 1: Digital loopback mode not set (DLB=0) in SPCR1: Receive clock (CLKR) is an input driven by an externaal clock. Case 2: Digital loopback mode set (DLB=1) in SPCR1: Receive clock (not the CLKR pin) is driven by transmit clock (CLKX) which is based on the CLKXM bit in the PCR. CLKR pin is in high-impedance. 0x1: Case 1: Digital loopback mode not set (DLB=0) in SPCR1: CLKR is an output pin and is driven by the internal SRG. Case 2: Digital loopback mode set (DLB=1) in SPCR1: CLKR is an output pin and is driven by the transmit clock. The transmit clock is derived based on the CLKRM bit in the PCR.	RW	0
7	SCLKME	The frequency of CLKG is: CLKG frequency = (Input clock frequency) / (CLKGDV + 1) SCLKME is used in conjunction with the CLKSM bit to select the input clock: 0x0: CLKSM = 0: Signal on CLKS pin CLKSM = 1: CPU clock 0x1: CLKSM = 0: Signal on CLKR pin CLKSM = 1: Signal on CLKX pin	RW	0
6	CLKS_STAT	CLKS pin status. Reflects value on CLKS pin when selected as a general purpose input. (legacy) Read 0x0: The signal on the CLKS pin is low Read 0x1: The signal on the CLKS pin is high	R	0
5	DX_STAT	DX pin status. Reflects value driven on to DX pin when selected as a general purpose output. (legacy) 0x0: Drive the signal on the DX pin low 0x1: Drive the signal on the DX pin high	RW	0
4	DR_STAT	DR pin status. Reflects value on DR pin when selected as a general purpose input. (legacy) Read 0x0: The signal on DR pin is low Read 0x1: The signal on DR pin is high	R	0
3	FSXP	Transmit Frame-Synchronization Polarity 0x0: Frame-sync pulse FSX is active high 0x1: Frame-sync pulse FSX is active low	RW	0
2	FSRP	Receive Frame-Synchronization Polarity 0x0: Frame-sync pulse FSR is active high 0x1: Frame-sync pulse FSR is active low	RW	0
1	CLKXP	Transmit Clock Polarity 0x0: Transmit data driven on rising edge of CLKX 0x1: Transmit data driven on falling edge of CLKX	RW	0

Copyright © 2011–2012, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
0	CLKRP	Receive Clock Polarity 0x0: Receive data sampled on falling edge of CLKR 0x1: Receive data sampled on rising edge of CLKR	RW	0

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved	R	0x0000
15	EXTCLKGATE	External clock gating enable (CLKX and FSX master only). When this bit is set and the transmit clock and FSX are set as output, the CLKX is enabled when FSX is active plus 3 clock cycles after (clock is provided for FWID + 4 clock cycles, assuming that the FSX width, active, is FWID + 1 clock cycles); outside this window the external transmit clock is gated. The receive use the same gated transmit clock and transmit frame synchronization signals regardless of the CLKRM/FSRM settings. When using this mode the frame synchronization signal must be active during reception of the entire frame (FWID must be programmed accordingly) to ensure the proper receive process, which requires at least 3 cycles after the frame complete to transfer the data into the receive buffer. 0x0: External clock gating disabled. 0x1: External clock gating enable.	RW	0
14	PPCONNECT	Pair to pair connection. When set the DXENO pin is always set to 0 regardless of the frame boundary, setting the tree state buffer as output 0x0: Pair to pair connection. 24.6 Multichannel PDM Controller

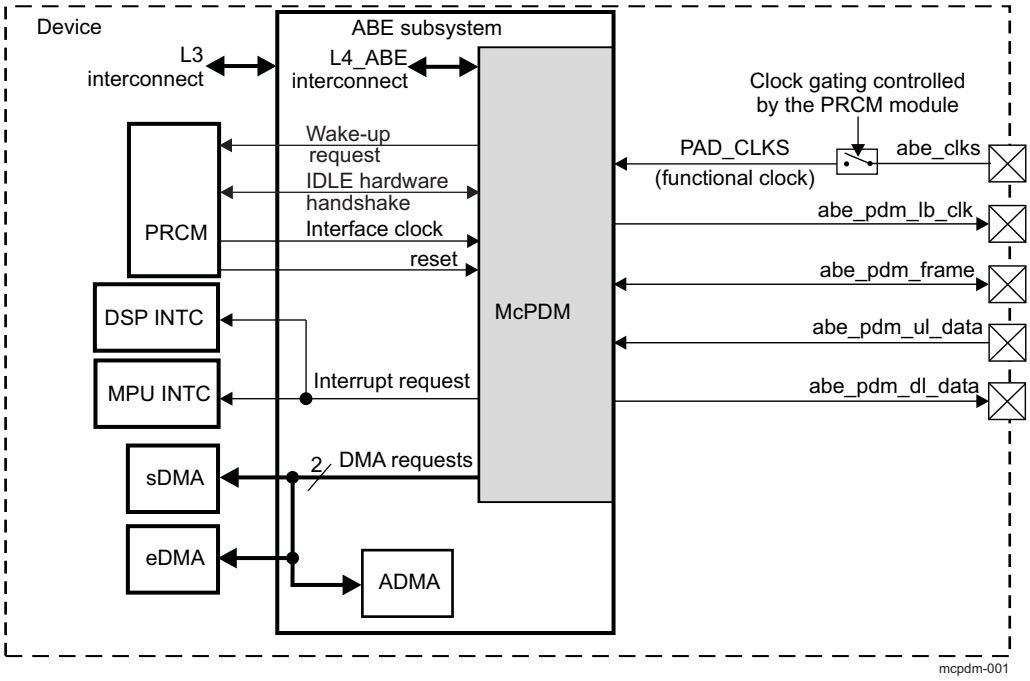
24.6.1 McPDM Overview

The multichannel pulse density modulation (McPDM) module consists in a proprietary audio module dedicated to mobile phone terminals. It is composed of audio uplink and downlink paths communicating with an external audio companion chip through a dedicated interface.

Figure 24-161 is an overview of the McPDM module.

Figure 24-161. McPDM Overview



The McPDM module can support the following features:

- Full-duplex communication:
  - Five audio downlink channels with up to 3.84 Mbps each
  - Three audio uplink channels with up to 3.84 Mbps each
  - One command channel with up to 3.84 Mbps
  - One status channel with up to 3.84 Mbps
- Uplink and downlink FIFO operations:
  - 16 × 96-bit words for FIFO uplink, where a 96-bit word contains three 24-bit words for the audio uplink channels (one 24-bit word per audio uplink channel) and one 16-bit word for status information
  - 16 × 144-bit words for FIFO downlink, where a 144-bit word contains five 24-bit words for the audio downlink channels (one 24-bit word per audio downlink channel) and one 16-bit word for the command data.
- Interrupt request to MPU and DSP subsystems
- DMA requests with programmable FIFO thresholds:
  - One DMA request for downlink path
  - One DMA request for uplink path
- Upsampling and pulse-density modulators for each audio downlink channel (five channels)
- Offset cancellation feature for audio downlink channels 1 and 2
- Decimation filter and downsampling for each audio uplink channel (three channels)

Copyright © 2011–2012, Texas Instruments Incorporated

- IDLE state hardware handshake
- Wake-up request

24.6.2 McPDM Environment

This section describes the McPDM application fields from an environment point of view (external connections). It describes McPDM connectivity options, lists all possible interfaces, and describes the protocol and data format used in each case.

24.6.2.1 McPDM Modes

Table 24-466 describes the modes and application fields of the McPDM module.

Table 24-466. Modes

Mode	Description
Normal mode	Up to five audio channels are transmitted to, and up to three audio channels are received from, the audio companion chip.
Command mode	In addition to the audio channels, commands are transmitted to the audio companion chip.
Status mode	In addition to the audio channels, status information is received from the audio companion chip.

24.6.2.2 McPDM Signals

Table 24-467 describes the McPDM module signals and specifies their links to modes.

Table 24-467. I/O

Signal	I/O (1)	Description	Reset Value	Normal Mode	Command Mode	Status Mode
abe_clks	I	Clock received from the audio companion chip. The clock frequency is: • 17.64 MHz for a sampling frequency of 88.2/176.4 kHz • 19.2 MHz for a sampling frequency of 96/192 kHz	0	x	x	x
abe_pdm_lb_clk	O	Clock loopback to the audio companion chip from the abe_clks clock signal. The frequency is the same as abe_clks frequency. (2)	0	x	x	x
abe_pdm_frame	I/O	Frame synchronization and command/status data	Z	x	x	x
abe_pdm_ul_data	I	Audio uplink path data	Z	x	x	x
abe_pdm_dl_data	O	Audio downlink path data	0	x	x	x

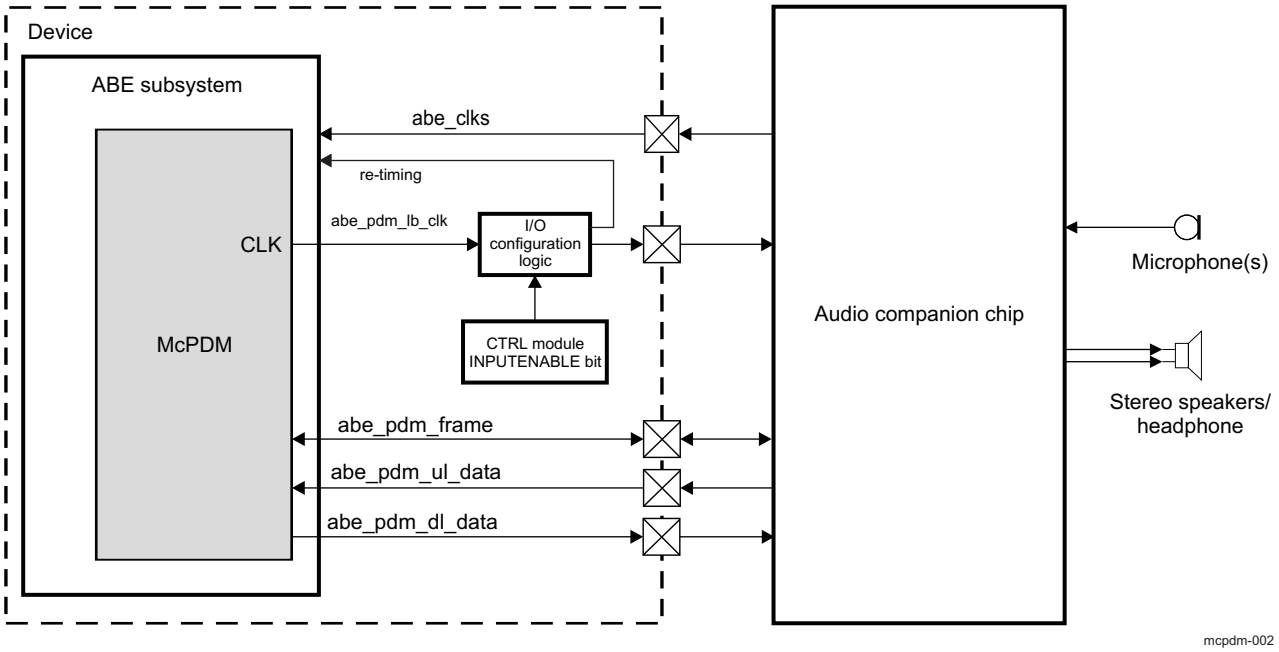
(1) I = Input; O = Output; I/O = Bidirectional
(2) This output signal is also used as retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).

Copyright © 2011–2012, Texas Instruments Incorporated

24.6.2.3 McPDM Configurations

Figure 24-162 shows the McPDM generic configuration.

Figure 24-162. McPDM Generic Configuration



24.6.2.4 Protocols and Data Formats

24.6.2.4.1 Protocols and Data Formats in Normal Mode

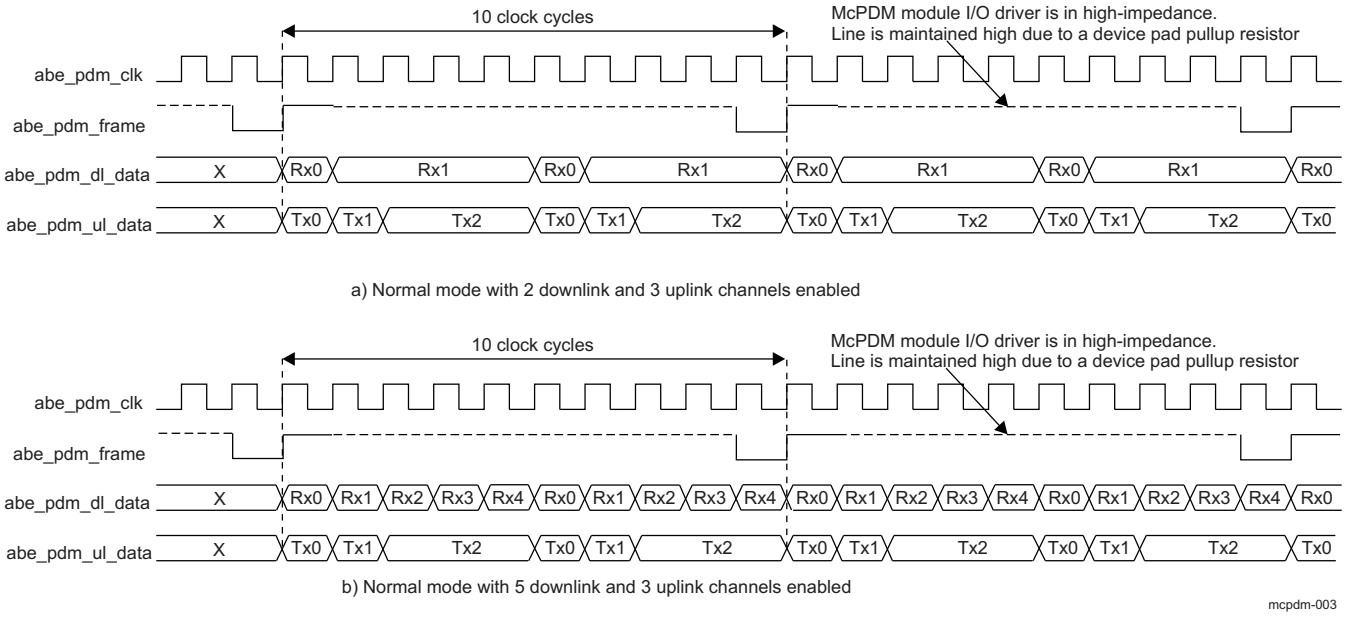
This section describes data transfer on the interface in normal mode. In this mode, the abe_pdm_frame signal is used only for frame synchronization purposes. Figure 24-163 shows the protocols and data formats in normal mode for two examples:

(a) With two downlink and three uplink channels enabled

(b) With five downlink and three uplink channels enabled

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-163. Protocols and Data Formats in Normal Mode



In normal mode, the frequency ratio between the abe_pdm_frame and abe_pdm_lb_clk signals is 10. This ratio is static and the abe_pdm_frame signal low-pulse width is one clock period longer than the abe_pdm_lb_clk signal.

The abe_pdm_frame signal is driven by the McPDM module in the device to the external audio companion chip. The McPDM module drives the abe_pdm_frame signal low during one clock period of the abe_pdm_lb_clk signal, then it drives it high during one clock period of the abe_pdm_lb_clk signal before releasing the abe_pdm_frame I/O driver in high-impedance state. The McPDM module pad internal pullup resistor allows keeping a high-level state on the abe_pdm_frame line when the abe_pdm_frame I/O driver is in high-impedance state.

A maximum of two samples × five downlink channels (10 samples) can be transmitted by the McPDM module to the external audio companion chip during a frame period.

A maximum of two samples × three uplink channels (six samples) can be received by the McPDM module from the external audio companion chip during a frame period.

Each downlink and uplink channel can be independently enabled or disabled by setting to 1 or clearing to 0 the corresponding bit in the MCPDM_CTRL register.

24.6.2.4.2 Protocols and Data Formats in Command Mode

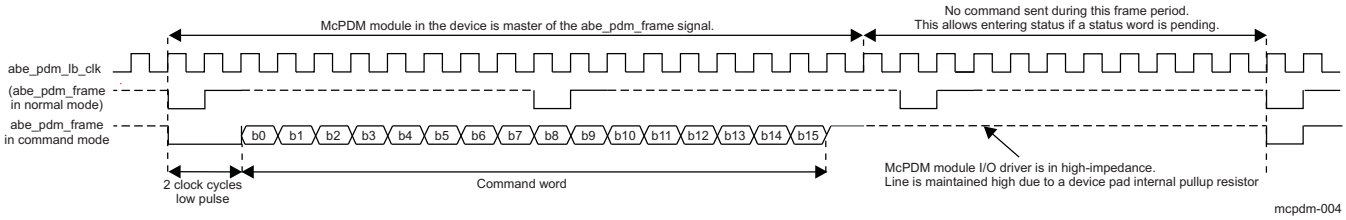
This section describes data transfer on the interface in command mode. In this mode, the abe_pdm_frame signal is used to transmit command words to the external audio companion chip. It allows configuring audio registers in the external audio companion chip (that is, amplifier gains) without using the legacy I^2C interface, which may be busy and add latency to gain correction.

NOTE: In command mode, uplink channel samples are transmitted to and downlink channel samples are received from the external audio companion chip as in normal mode.

Figure 24-164 shows the protocols and data formats in command mode.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-164. Protocols and Data Formats in Command Mode



24.6.2.4.2.1 Entering Command Mode

Command mode can be entered when command data are pending and no status mode is ongoing or detected.

If both of these conditions are met and the MCPDM_CTRL[9] CMD_INT bit is set to 1, the McPDM module automatically enters command mode.

To enter command mode, the McPDM module must drive the abe_pdm_frame signal low during two periods of the abe_pdm_lb_clk clock signal.

The external audio companion chip detects a command mode request from the McPDM module when a low state is detected during two periods of the abe_pdm_lb_clk clock signal. Once a command mode request is detected, the external audio companion chip enters command mode. In this mode, the status mode cannot be entered during at least four frame cycles.

If a status mode is detected or ongoing while a command is ready to be sent, the command data are stored in an internal register.

If one or more command data are written before the previous one is sent, the previous one is overwritten with the new one and only the last stored 16-bit command data are sent.

If new command data are available while the system is already in command mode, the current command completes normally and exits before re-entering command mode and transmitting the new command data a frame period later.

24.6.2.4.2.2 Command Data Transmission

The 16-bit command data are transmitted directly after the abe_pdm_frame signal is driven low during two periods of the abe_pdm_lb_clk clock signal.

When the MCPDM_CTRL[9] CMD_INT bit is set to 1, 16-bit command data must be written to the MCPDM_DN_DATA register. Only the 16 lower bits are significant. When no command must be transmitted on the abe_pdm_frame line, a null word (0x00000000) must be written as the command data.

When the MCPDM_CTRL[9] CMD_INT bit is cleared to 0, no 16-bit command data has to be written to the MCPDM_DN_DATA register.

24.6.2.4.2.3 Exiting Command Mode

After the 16-bit command data is sent, the McPDM module drives the abe_pdm_frame signal high during one period of the abe_pdm_lb_clk clock signal before releasing the abe_pdm_frame I/O driver in high-impedance state. The McPDM module pad internal pullup resistor allows keeping a high-level state on the abe_pdm_frame line when the abe_pdm_frame I/O driver is in high-impedance state.

The McPDM module exits automatically from command mode one period of the abe_pdm_lb_clk clock signal after the last bit of the command data has been transmitted on the abe_pdm_frame line.

Copyright © 2011–2012, Texas Instruments Incorporated

NOTE: Due to this protocol mechanism, frame synchronization is lost (replaced by the ninth bit of the command data) during one frame period. The external audio companion chip must internally emulate a frame synchronization to send uplink channel samples and received downlink channel samples as in normal mode while receiving command data on the abe_pdm_frame line.

24.6.2.4.2.4 Multiple Command Data Access

As shown in Figure 24-164, two consecutive command data can be sent every three frames. If no status mode is entered after a command data has been sent, the next command data is sent three frames after starting to send the current command data.

24.6.2.4.3 Protocols and Data Formats in Status Mode

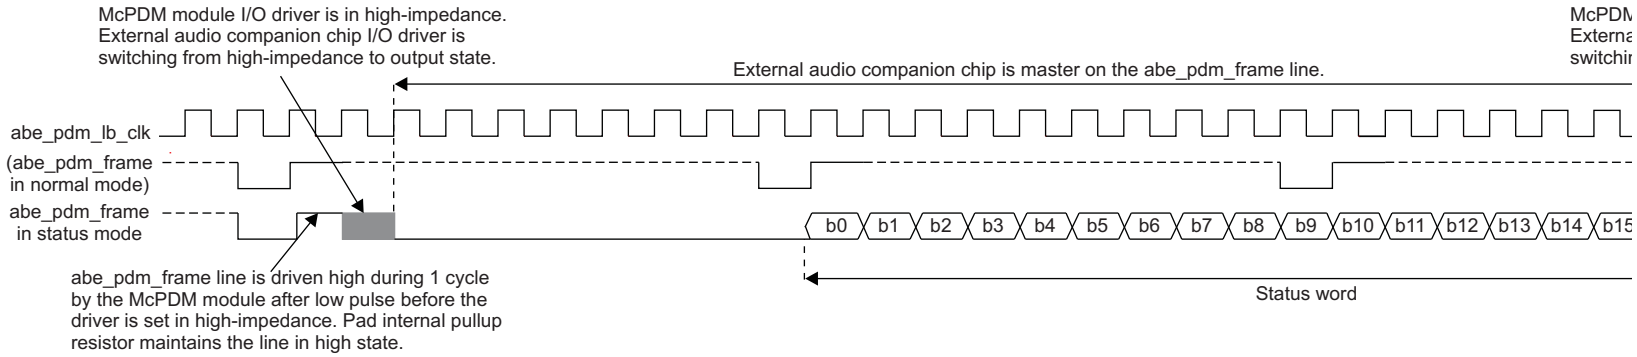
This section describes data transfer on the interface in status mode. In this mode, the abe_pdm_frame signal is used to receive status information from the external audio companion chip.

NOTE: In status mode, uplink channel samples are transmitted to and downlink channel samples are received from the external audio companion chip as in normal mode.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-165 shows the protocols and data formats in status mode.

Figure 24-165. Protocols and Data Formats in Status Mode



Copyright © 2011–2012, Texas Instruments Incorporated

24.6.2.4.3.1 Entering Status Mode

Status mode can be entered when no command mode is detected during the last frame low pulse and no command mode is ongoing.

If both of these conditions are met and the MCPDM_CTRL[10] STATUS_INT bit is set to 1, the McPDM module automatically enters status mode when the command mode is complete.

In status mode, the status information data are sent by the external audio companion chip to the McPDM module. The status information is stored in an internal register.

If one or more status information packages are received before the previous status information is read, the status information stored in the internal register is overwritten with the new one.

In status mode, the external audio companion chip drives the abe_pdm_frame line low until the next frame synchronization low pulse. Then, it sends the 16-bit status information data on the abe_pdm_frame line. During the transmission of the status information, the McPDM module does not generate any frame-sync low pulse on the abe_pdm_frame line for one frame period.

24.6.2.4.3.2 Status Information Data Reception

The 16-bit status information data are received directly after the second frame-sync low pulse on the abe_pdm_frame line.

When the MCPDM_CTRL[10] STATUS_INT bit is set to 1, 16 bits of status information data must be read from the MCPDM_UP_DATA register. Only the 16 lower bits are significant. When the value of the status information is a null word (0x00000000), it means that no status information has been sent by the external audio companion chip.

When the MCPDM_CTRL[10] STATUS_INT bit is cleared to 0, no status information data has to be read from the MCPDM_UP_DATA register.

24.6.2.4.3.3 Exiting Status Mode

After the 16-bit status information data is sent, the external audio companion chip drives the abe_pdm_frame line high during one period of the abe_pdm_lb_clk clock signal before releasing its I/O driver in high-impedance state.

The McPDM module automatically exits the status mode one period of the abe_pdm_lb_clk clock signal after the last bit of the status information data has been transmitted on the abe_pdm_frame line. After exiting status mode, the McPDM module generates frame-sync low pulses.

NOTE: Due to the protocol mechanism, frame synchronization is lost during three frame periods. The external audio companion chip must internally emulate a frame synchronization to send uplink channel samples and received downlink channel samples as in normal mode while transmitting status information data on the abe_pdm_frame line.

24.6.2.4.3.4 Multiple Status Information Data Access

Multiple status information data can be sent by the external audio companion chip to the McPDM module every four frames.

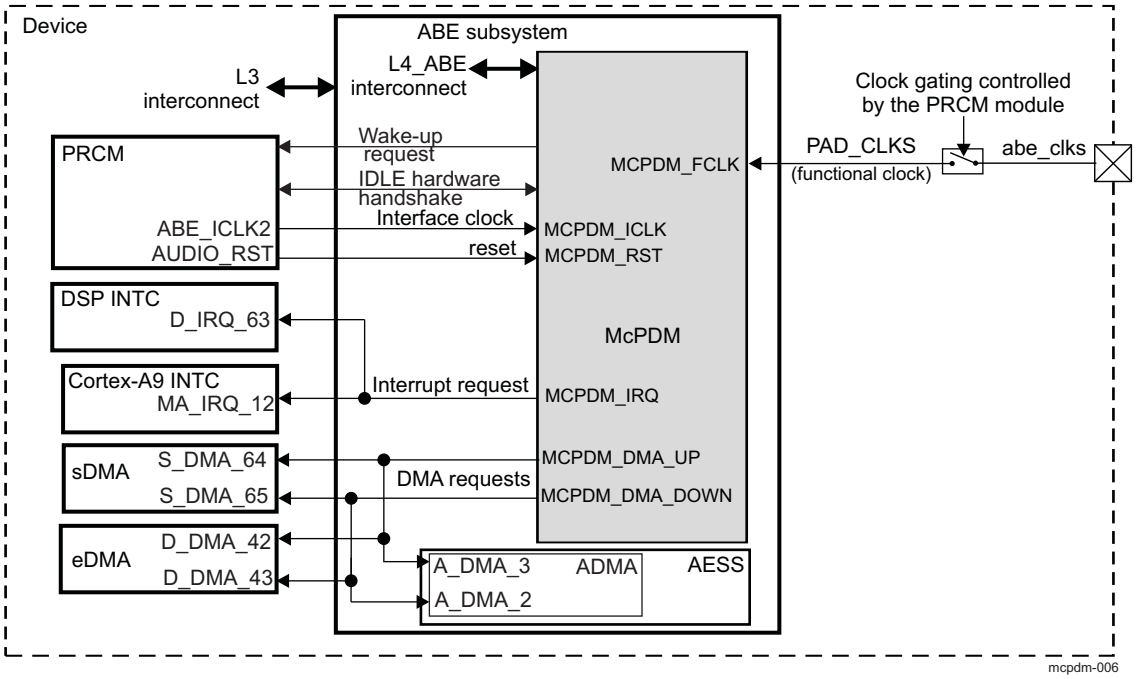
24.6.3 McPDM Integration

This section describes the McPDM module integration in the device, including information about clocks, resets, and hardware requests.

Figure 24-166 shows the McPDM integration.

Figure 24-166. McPDM Integration



NOTE: For more information about the IDLE hardware handshake and the wake-up request, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 24-468 through Table 24-470 summarize the integration of the module in the device.

Table 24-468. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
McPDM	PD_AUDIO	Yes	L4_ABE

Table 24-469. Clocks and Resets

Clocks

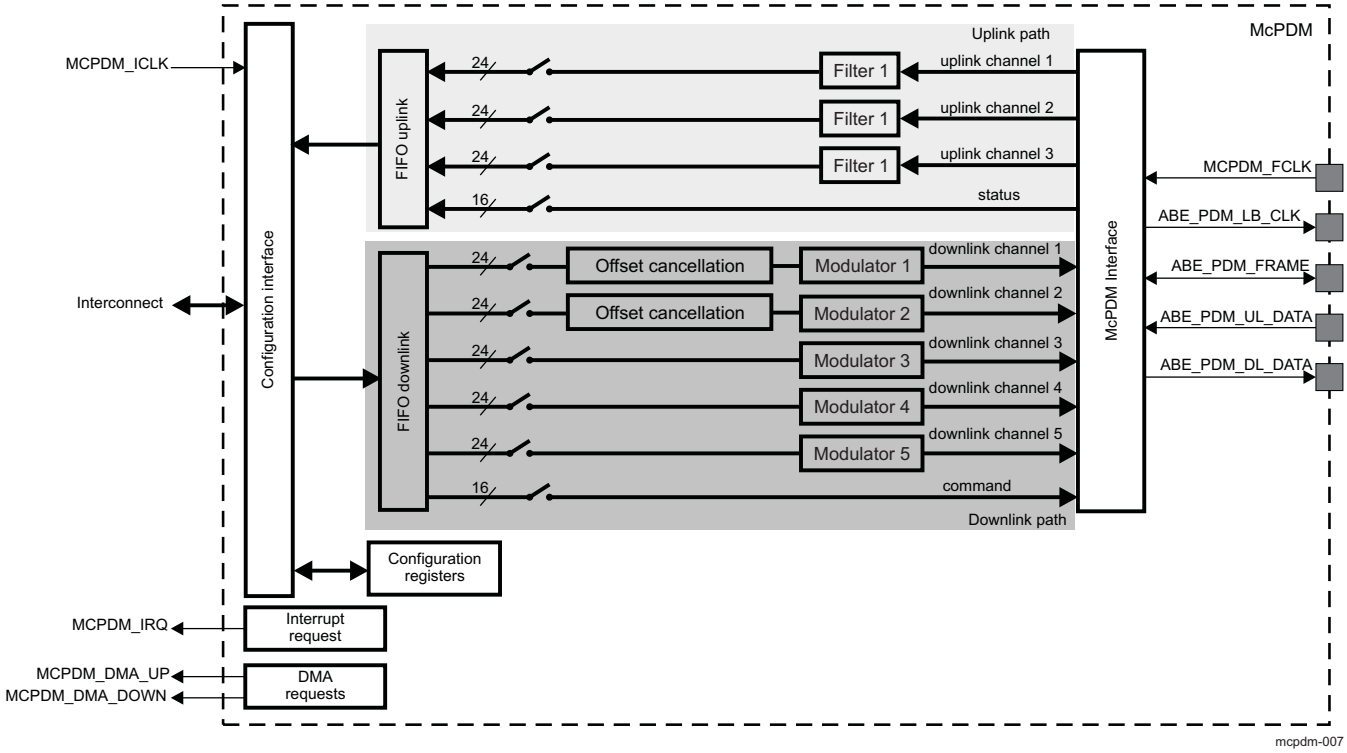
24.6.4 McPDM Functional Description

24.6.4.1 McPDM Block Diagram

Figure 24-167 shows the McPDM block diagram.

Figure 24-167. McPDM Block Diagram



24.6.4.2 McPDM Clock Configuration

The functional clock MCPDM_FCLK is provided by the external audio companion chip. Its frequency can be either 17.64 MHz for a sampling frequency of 88.2/176.4 kHz, or 19.2 MHz for a sampling frequency of 96/192 kHz.

The functional clock is also looped-back to the audio companion chip through ABE_PDM_LB_CLK for resynchronization purposes.

24.6.4.3 McPDM Software Reset

To perform a software reset of the McPDM module, the MCPDM_SYSCONFIG[0] SOFTRESET bit must be set to 1. Reading the MCPDM_SYSCONFIG[0] SOFTRESET bit gives the status of the software reset:

- Read 1: The software reset is ongoing.
- Read 0: The software reset is complete.

Software must ensure that the software reset completes before doing McPDM operations. Moreover, uplink and downlink paths can be independently software reset by setting the MCPDM_CTRL[11] SW_UP_RST bit for the uplink path, and the MCPDM_CTRL[12] SW_DN_RST bit for the downlink path to 1. The software reset is stopped by clearing the MCPDM_CTRL[11] SW_UP_RST bit for the uplink path, and the MCPDM_CTRL[12] SW_DN_RST bit for the downlink path to 0.

The software reset of the McPDM module, after completion, puts all McPDM registers in their default state. The downlink/uplink reset, resets only the downlink/uplink hardware logic (no registers are affected).

Copyright © 2011–2012, Texas Instruments Incorporated

24.6.4.4 McPDM Power Management

Table 24-471 describes the power-management features available to the McPDM module.

Table 24-471. Local Power-Management Features

Feature	Registers	Description
Clock autogating	N/A	Feature not available
Slave idle modes	MCPDM_SYSCONFIG[3:2] IDLEMODE bit field	Force-idle, no-idle, smart-idle, and smart-idle wake-up capable modes are available for the interface clock
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	MCPDM_IRQWAKEEN and MCPDM_DMAWAKEEN registers	Each register holds one active-high enable bit per event source able to generate wake-up signal
Audio channel enable	MCPDM_CTRL[0] PDM_UP1_EN to MCPDM_CTRL[2] PDM_UP3_EN bits for audio uplink channels MCPDM_CTRL[3] PDM_DN1_EN to MCPDM_CTRL[7] PDM_DN5_EN bits for audio downlink channels	Each of these bits allows enabling (set to 1) or disabling (clear to 0) the corresponding audio channel.
Status channel enable	MCPDM_CTRL[10] STATUS_INT bit for the status channel	This bit allows enabling (set to 1) or disabling (clear to 0) the status channel
Command channel enable	MCPDM_CTRL[9] CMD_INT bit for the command channel	This bit allows enabling (set to 1) or disabling (clear to 0) the command channel

The MCPDM_ICLK interface clock is controlled though the PRCM module by using IDLE request and acknowledge signals. The MCPDM_SYSCONFIG[3:2] IDLEMODE bit field allows controlling the interface clock gating in idle mode.

For the uplink path, the interface clock can be put in idle after the uplink path is enabled. Wakeup is available according to the settings of the MCPDM_IRQWAKEEN and MCPDM_DMAWAKEEN registers and the FIFO uplink threshold configured in the MCPDM_FIFO_CTRL_UP[3:0] UP_TRESH bit field. The wake-up signal is asserted when the FIFO uplink level is equal to or greater than the FIFO uplink threshold value.

For the downlink path, the interface clock can be put in idle after the FIFO downlink level reaches the FIFO downlink threshold at least once. Wakeup is available according to the settings of the MCPDM_IRQWAKEEN and MCPDM_DMAWAKEEN registers and the FIFO downlink threshold configured in the MCPDM_FIFO_CTRL_DN[3:0] DN_TRESH bit field. The wake-up signal is asserted when the FIFO downlink level is below the FIFO downlink threshold value.

24.6.4.5 McPDM Interrupt Requests

The McPDM can generate interrupt requests to the Cortex-A9 MPU and DSP INTCs through the MCPDM_IRQ signal.

Table 24-472 lists the nonmaskable and maskable event flags and their mask that can cause the McPDM module to generate interrupts.

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-472. Interrupt Events

Nonmaskable Event Flag [(1)]	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
MCPDM_IRQSTATUS_RAW[11] UP_IRQ_FULL	MCPDM_IRQSTATUS[11] UP_IRQ_FULL	MCPDM_IRQENABLE_CLR[11] UP_IRQ_FULL_MASK	MCPDM_IRQENABLE_SET[11] UP_IRQ_FULL_MASK	FIFO-uplink-full event. This event occurs when FIFO uplink is already full and a new word is written to the FIFO uplink by the uplink part of the McPDM module.
MCPDM_IRQSTATUS_RAW[10] UP_IRQ_ALST_FULL	MCPDM_IRQSTATUS[10] UP_IRQ_ALST_FULL	MCPDM_IRQENABLE_CLR[10] UP_IRQ_ALST_FULL_MASK	MCPDM_IRQENABLE_SET[10] UP_IRQ_ALST_FULL_MASK	FIFO-uplink-almost-full event. This event occurs when FIFO uplink contains (FIFO uplink size – 1) words and a new word is written to the FIFO uplink by the uplink part of the McPDM module.
MCPDM_IRQSTATUS_RAW[9] UP_IRQ_EMPTY	MCPDM_IRQSTATUS[9] UP_IRQ_EMPTY	MCPDM_IRQENABLE_CLR[9] UP_IRQ_EMPTY_MASK	MCPDM_IRQENABLE_SET[9] UP_IRQ_EMPTY_MASK	FIFO-uplink-empty event. This event occurs when FIFO uplink is already empty and a new word is read from the FIFO uplink by software.
MCPDM_IRQSTATUS_RAW[8] UP_IRQ	MCPDM_IRQSTATUS[8] UP_IRQ	MCPDM_IRQENABLE_CLR[8] UP_IRQ_MASK	MCPDM_IRQENABLE_SET[8] UP_IRQ_MASK	FIFO-uplink-read-request event. This event occurs when the number of words stored in the FIFO uplink is equal to or greater than the FIFO uplink threshold.
MCPDM_IRQSTATUS_RAW[3] DN_IRQ_FULL	MCPDM_IRQSTATUS[3] DN_IRQ_FULL	MCPDM_IRQENABLE_CLR[3] DN_IRQ_FULL_MASK	MCPDM_IRQENABLE_SET[3] DN_IRQ_FULL_MASK	FIFO-downlink-full event. This event occurs when FIFO downlink is already full and a new word is written to the FIFO downlink by software.
MCPDM_IRQSTATUS_RAW[2] DN_IRQ_ALST_EMPTY	MCPDM_IRQSTATUS[2] DN_IRQ_ALST_EMPTY	MCPDM_IRQENABLE_CLR[2] DN_IRQ_ALST_EMPTY_MASK	MCPDM_IRQENABLE_SET[2] DN_IRQ_ALST_EMPTY_MASK	FIFO-downlink-almost-empty event. This event occurs when FIFO downlink contains one word and a new word is read from the FIFO downlink by the downlink part of the McPDM module.
MCPDM_IRQSTATUS_RAW[1] DN_IRQ_EMPTY	MCPDM_IRQSTATUS[1] DN_IRQ_EMPTY	MCPDM_IRQENABLE_CLR[1] DN_IRQ_EMPTY_MASK	MCPDM_IRQENABLE_SET[1] DN_IRQ_EMPTY_MASK	FIFO-downlink-empty event. This event occurs when FIFO downlink is empty and a new word is read from the FIFO downlink by the downlink part of the McPDM module.
MCPDM_IRQSTATUS_RAW[0] DN_IRQ	MCPDM_IRQSTATUS[0] DN_IRQ	MCPDM_IRQENABLE_CLR[0] DN_IRQ_MASK	MCPDM_IRQENABLE_SET[0] DN_IRQ_MASK	FIFO-downlink-write-request event. This event occurs when the number of words stored in the FIFO downlink is less than the FIFO downlink threshold.

(1) The MCPDM_IRQSTATUS_RAW register is mainly used for debug purposes.

CAUTION

Once an event generating the interrupt request has been processed by software, this event must be cleared by writing a logical 1 to the corresponding bit of the MCPDM_IRQSTATUS register.

Writing a logical 1 in a bit of the MCPDM_IRQSTATUS register also clears the corresponding bit in the MCPDM_IRQSTATUS_RAW register to 0.

Copyright © 2011–2012, Texas Instruments Incorporated

An event can generate an interrupt request when a logical 1 is written to the corresponding mask bit in the MCPDM_IRQENABLE_SET register. Events are reported in the MCPDM_IRQSTATUS and MCPDM_IRQSTATUS_RAW registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the MCPDM_IRQENABLE_CLR register. Events are reported only in the MCPDM_IRQSTATUS_RAW register.

In case of the MCPDM_IRQSTATUS_RAW register, the event is reported in the corresponding bit, even if the interrupt request generation is disabled for this event.

Writing a logical 1 in a bit of the MCPDM_IRQSTATUS_RAW register sets the corresponding bit in the MCPDM_IRQSTATUS register to 1.

The MCPDM_IRQSTATUS_RAW register is used primarily for debug purposes.

For more information about interrupt request signal mapping, see Table 24-470.

Figure 24-168 shows the interrupt tree of the McPDM module.

Figure 24-168. Interrupt Tree

24.6.4.6 McPDM DMA Requests

The McPDM module can generate two DMA requests to the sDMA, aDMA, and eDMA controllers:

- The uplink path can generate a DMA request through the MCPDM_DMA_UP signal.
- The downlink path can generate a DMA request through the MCPDM_DMA_DOWN signal.

Table 24-473 lists the DMA requests of the McPDM module.

Table 24-473. McPDM DMA Requests

DMA Request Signal	DMA Request Generation Enabling Bit	DMA Request Generation Disabling Bit	Description
MCPDM_DMA_UP	MCPDM_DMAENABLE_SET [1] DMA_UP_ENABLE	MCPDM_DMAENABLE_CLR [1] DMA_UP_ENABLE	Uplink path DMA request. This request is generated when the number of words in the FIFO uplink is equal to or above the FIFO uplink threshold.
MCPDM_DMA_DOWN	MCPDM_DMAENABLE_SET [0] DMA_DN_ENABLE	MCPDM_DMAENABLE_CLR [0] DMA_DN_ENABLE	Downlink path DMA request. This request is generated when the number of words in the FIFO downlink is below the FIFO downlink threshold.

To enable or disable the DMA request generation on the MCPDM_DMA_UP signal, one of the following actions must be performed:

- Write a logical 1 to the MCPDM_DMAENABLE_SET[1] DMA_UP_ENABLE bit to enable the DMA request generation on the MCPDM_DMA_UP signal.
- Write a logical 1 to the MCPDM_DMAENABLE_CLR[1] DMA_UP_ENABLE bit to disable the DMA request generation on the MCPDM_DMA_UP signal.

To enable or disable the DMA request generation on the MCPDM_DMA_DOWN signal, one of the following actions must be performed:

- Write a logical 1 to the MCPDM_DMAENABLE_SET[0] DMA_DN_ENABLE bit to enable the DMA request generation on the MCPDM_DMA_DOWN signal.
- Write a logical 1 to the MCPDM_DMAENABLE_CLR[0] DMA_DN_ENABLE bit to disable the DMA request generation on the MCPDM_DMA_DOWN signal.

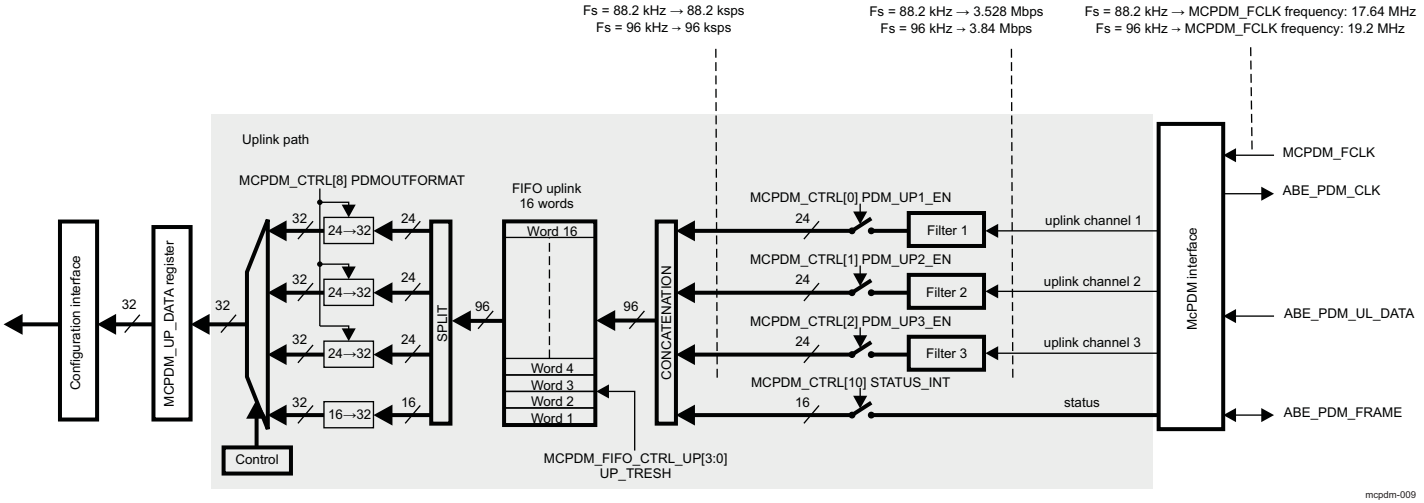
For more information about DMA request signals mapping, see Table 24-470.

24.6.4.7 Uplink Path

Figure 24-169 is a detailed block diagram of the uplink path in the McPDM module.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-169. Uplink Path Detailed Block Diagram



- The McPDM uplink input PDM data are provided by a 1 bit ADC Sigma-Delta (for each uplink channel).
- The McPDM uplink output PCM linear data format is equal to 24 bits signed format.
- It can be define 0dBpcm = maximum digital level allowed by the 24 bits data format is equal to amplitude peak ($2^{23} – 1$).
- McPDM uplink gain is product from filter decimation factor and filter gain → G = 40^4 × 4.89 = 12518400 (decimal).
- 0dB pdm at McPDM uplink input (all PDM bits at '1' state) is not allowed on real silicon because it will overload the McPDM uplink output:
  - For 0dBpdm McPDM input follows McPDM uplink theoretical decimal output should be: 12518400 = +3.48 dBpcm. The result is calculated by → 20log (12518400/($2^{23} – 1$)).
- –4dBpdm level at McPDM input will produce a McPDM uplink output equals to 7898610 = -0.52 dBpcm.

Copyright © 2011–2012, Texas Instruments Incorporated

24.6.4.7.1 Uplink Path Features

The uplink path has the following features:

- Three audio uplink channels
- One status channel
- Decimation filter for each audio uplink channel
- 16-word FIFO uplink with threshold setting
- Audio channel data formatting
- High-frequency sampling feature

24.6.4.7.2 Uplink Path Description

24.6.4.7.2.1 Uplink Data Received From the External Audio Companion Chip

The McPDM interface receives audio uplink channel data and status information data from the external audio companion chip at a clock rate of 17.64 MHz for a sampling frequency of 88.2 kHz, or 19.2 MHz for a sampling frequency of 96 kHz. This low-frequency sampling feature is enabled by default. The uplink path supports a high-frequency sampling feature to work with an ultrasonic external microphone. This feature is enabled by setting the MCPDM_CTRL[13] DIV_SEL bit to 1. Thus, the McPDM interface receives audio uplink channel data and status information data from the external audio companion chip at a clock rate of 17.64 MHz for a sampling frequency of 176.4 kHz, or 19.2 MHz for a sampling frequency of 192 kHz.

The McPDM interface extracts each data bit related to audio and sends it to the decimation filter of the corresponding channel. Therefore, for each audio uplink channel, the McPDM interface generates one bit data flow to the corresponding decimation filter at a rate of 3.528 Mbps for a sampling frequency of 88.2 kHz, or 3.84 Mbps for a sampling frequency of 96 kHz.

Moreover, when status information data are detected on the frame-sync signal (ABE_PDM_FRAME), the status information data are recovered and sent to the status channel. When no status information data are detected on the frame-sync signal, a null word (0x0000) is sent on the status channel.

For more information about protocols and data formats in normal mode, see Section 24.6.2.4.1, *Protocols and Data Formats in Normal Mode*. For more information about protocols and data formats in status mode, see Section 24.6.2.4.3, *Protocols and Data Formats in Status Mode*.

24.6.4.7.2.2 Decimation Filter

Each bit data flow is related to an audio uplink channel and is provided by the McPDM interface is processed by a decimation filter. The purpose of this filter is to band-limit the noise and downsample the incoming bit data flow to generate a 24-bit-wide signed data flow at a rate of 88.2 kbps for a sampling frequency of 88.2 kHz, or 96 kbps for a sampling frequency of 96 kHz.

24.6.4.7.2.3 FIFO Uplink Management

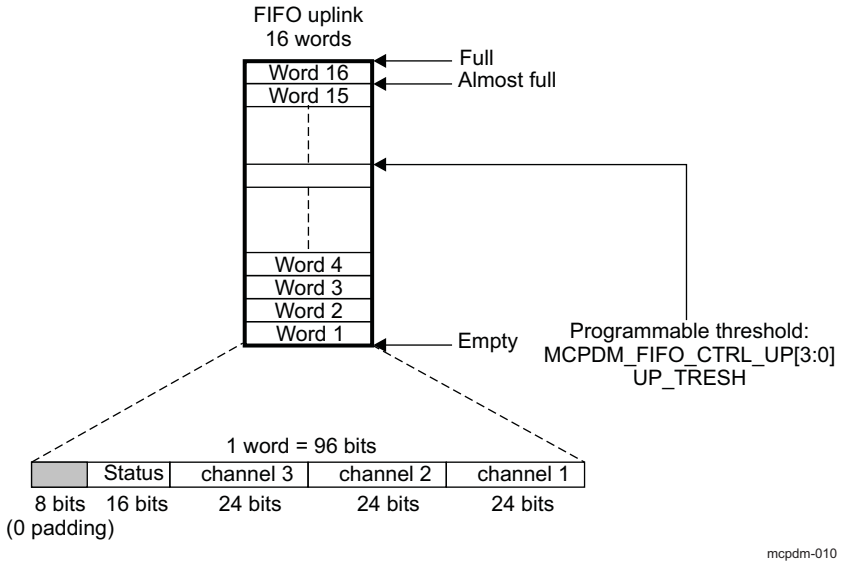
24.6.4.7.2.3.1 General Description

The McPDM module implements a FIFO for the uplink path for communication with the host processor in the device. The FIFO uplink can store up to 16 words. Each word is 96 bits wide and is a combination of 24-bit-wide signed audio uplink channel data coming from decimation filters and 16-bit-wide status information data coming from the McPDM interface.

Figure 24-170 shows the FIFO uplink overview.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-170. FIFO Uplink Overview



24.6.4.7.2.3.2 FIFO Operations

The FIFO uplink is filled with audio uplink channel data coming from decimation filters and status information data from the McPDM interface. Once the FIFO uplink threshold (MCPDM_FIFO_CTRL_UP[3:0] UP_TRESH bit field) is reached and, depending on conditions, an event occurs and generates an interrupt or DMA request.

NOTE: For more information about events generating an interrupt request, see Section 24.6.4.5, *McPDM Interrupt Requests*.

For more information about conditions for DMA request generation, see Section 24.6.4.6, *McPDM DMA Requests*.

When an interrupt request upon a FIFO uplink read-request event or an MCPDM_DMA_UP request occurs, the host processor or the DMA controller must read the words from the FIFO uplink (MCPDM_UP_DATA register). The number of read accesses from the host/DMA is determined by the following equation:

Num_read_access = (PDM_UP1_EN + PDM_UP2_EN + PDM_UP3_EN + STAT_INT) * (UP_THRESH), where the PDM_UP_THRESHOLD is programmed through the MCPDM_FIFO_CTRL_UP[3:0] UP_TRESH bit field.

PDM_UP1_EN, PDM_UP2_EN, PDM_UP3_EN, and STAT_INT are boolean values representing whether or not the corresponding channel is enabled.

For example, if audio uplink channels 1 and 3 are enabled, audio uplink channel 2 is disabled, the status channel is enabled, and the uplink threshold is programmed for one line only (MCPDM_FIFO_CTRL_UP[3:0] UP_THRESH = 0x0):

- Num_read_access = 3 because two audio uplink and the status channels are enabled.
- The first reading of the MCPDM_UP_DATA register should correspond to the audio uplink channel 1 data.
- The second reading of the MCPDM_UP_DATA register should correspond to the audio uplink channel 3 data.
- The third reading of the MCPDM_UP_DATA register should correspond to the status information data.

Copyright © 2011–2012, Texas Instruments Incorporated

NOTE: No status information has been sent by the external audio companion chip if the status channel is enabled and the 16 lower bits of the corresponding data read from the MCPDM_UP_DATA register is 0x0000 .

The audio uplink and status channels cannot be enabled or disabled on the fly during uplink signaling. The uplink path must first be forced to reset by setting the MCPDM_CTRL[11] SW_UP_RST bit to 1 before enabling or disabling any channels.

Because the audio uplink channel data are 24 bits wide and the MCPDM_UP_DATA register is 32 bits wide, the MCPDM_CTRL[8] PDMOUTFORMAT bit allows selecting the justification of the 24-bit audio uplink channel data in the MCPDM_UP_DATA register:

- When the MCPDM_CTRL[8] PDMOUTFORMAT bit is cleared to 0, the 24-bit-wide signed audio uplink channel data are left-justified with eight 0 padding bits for the lower bits (24 bits data Left Justified + 8 bits pad).
- When the MCPDM_CTRL[8] PDMOUT FORMAT is set to 1, the 24-bit-wide signed audio uplink channel data are right-justified and sign-extended (8 bits Pad + 24 bits data Right Justified). For both cases (right or left-justified), 24 bits data are MSB First format .

NOTE: The MCPDM_CTRL[8] PDMOUTFORMAT bit does not affect the status information format. When the status information data are read from the MCPDM_UP_DATA register, only the 16 lower bits are significant.

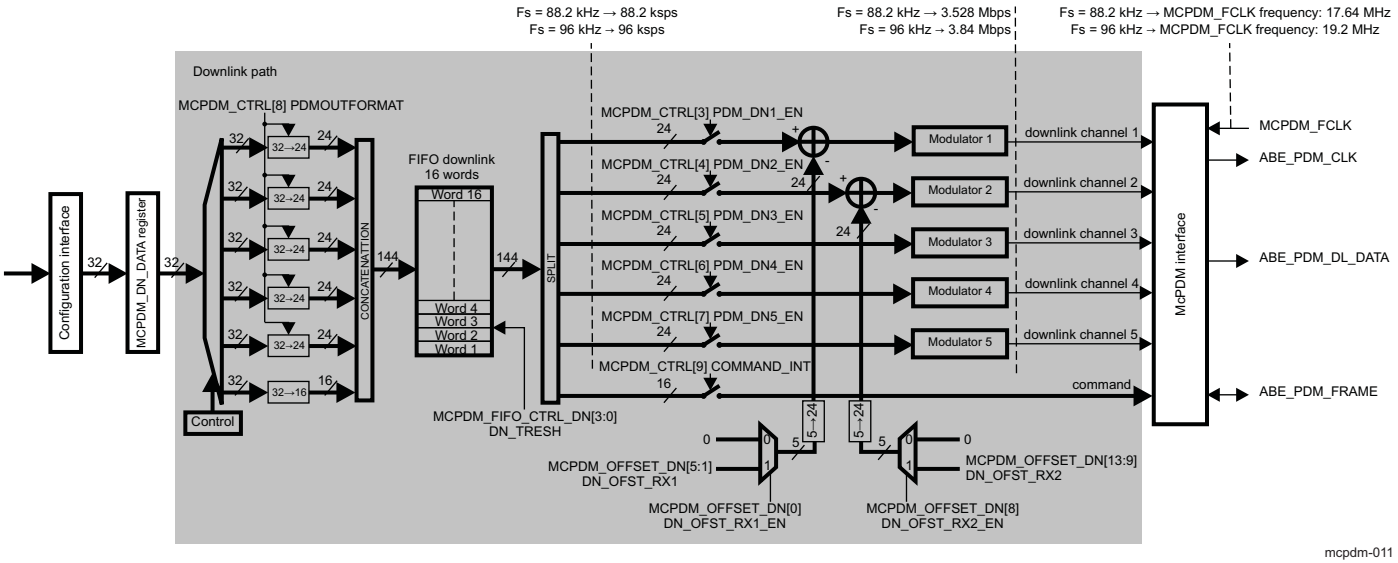
The setting of the MCPDM_CTRL[8] PDMOUTPUTFORMAT bit also affects the audio downlink channel data format.

Copyright © 2011–2012, Texas Instruments Incorporated

24.6.4.8 Downlink Path

Figure 24-171 is a detailed block diagram of the downlink path in the McPDM module.

Figure 24-171. Downlink Path Detailed Block Diagram



- The McPDM downlink and dBpcm is relative to the 24 bits signed format (ABE data format): 0dBpcm amplitude peak is equal to (2^{23} – 1)
- dBpdm is defined by the gain provided by the McPDM total gain is equal to –6.35dB
  - There is a –6dB attenuation at the input of the Sigma-Delta modulator
  - The Sigma-Delta has an intrinsic gain of –0.35dB

Then the gain between McPDM PDM output and McPDM PCM linear input is constant and equal to –6.35dB.

Copyright © 2011–2012, Texas Instruments Incorporated

24.6.4.8.1 Downlink Path Features

The downlink path has the following features:

- Five audio downlink channels
- Offset cancellation for audio downlink channels 1 and 2
- One command channel
- Delta-sigma modulator for each audio downlink channel
- 16-word FIFO downlink with threshold setting
- Audio channel data formatting

24.6.4.8.2 Downlink Path Description

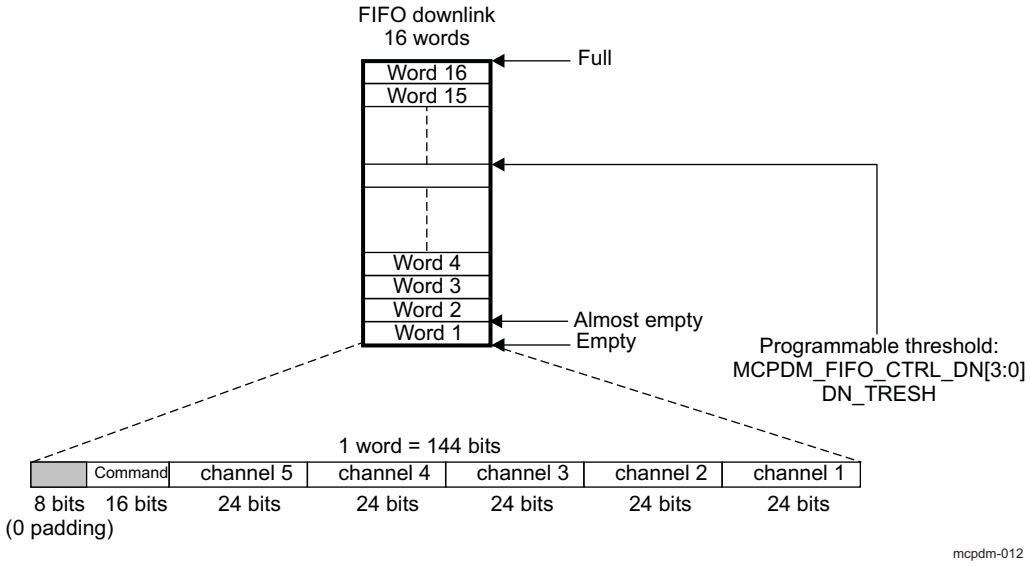
24.6.4.8.2.1 FIFO Downlink Management

24.6.4.8.2.1.1 General Description

The McPDM module implements a FIFO for the downlink path for communication with the host processor in the device. The FIFO downlink can store up to 16 words. Each word is 144 bits wide and is a combination of 24-bit-wide signed audio downlink channels data and 16-bit-wide command information data.

Figure 24-172 shows the FIFO downlink overview.

Figure 24-172. FIFO Downlink Overview



24.6.4.8.2.1.2 FIFO Operations

The FIFO downlink is read by the McPDM module and data related to the audio downlink channels are sent to the delta-sigma modulators, while the data related to the command information is sent to the McPDM interface. Once the FIFO pointer goes below the programmed threshold (the MCPDM_FIFO_CTRL_DN[3:0] DN_TRESH bit field), a DMA or interrupt request is sent to the DMA or interrupt handler and, depending on conditions, an event occurs and generates an interrupt or DMA request.

Copyright © 2011–2012, Texas Instruments Incorporated

NOTE: For more information about events generating an interrupt request, see Section 24.6.4.5, *McPDM Interrupt Requests*.

For more information about conditions for DMA request generation, see Section 24.6.4.6, *McPDM DMA Requests*.

When an interrupt request upon a FIFO downlink write-request event or a MCPDM_DMA_DOWN request occurs, it indicates that the next words are available to be written to the MCPDM_DN_DATA register. The minimum number of write accesses from the host/DMA is determined by the following equation:

Num_min_write_access = PDM_DN1_EN + PDM_DN2_EN + PDM_DN3_EN + PDM_DN4_EN + PDM_DN5_EN + CMD_INT

PDM_DN1_EN, PDM_DN2_EN, PDM_DN3_EN, PDM_DN4_EN, PDM_DN5_EN and CMD_INT are boolean values representing whether the corresponding channel is enable or not.

The maximum number of write accesses (before overwriting the data in the FIFO still to be transmitted) from the host/DMA is determined by the following equation:

Num_max_write_access = (FIFO_SIZE – DN_THRESH + 1) * (PDM_DN1_EN + PDM_DN2_EN + PDM_DN3_EN + PDM_DN4_EN + PDM_DN5_EN +CMD_INT)

FIFO_SIZE is the size of the downlink FIFO, and DN_THRESH is the downlink FIFO threshold, programmed through the MCPDM_FIFO_CTRL_DN[3:0] DN_THRESHOLD bit field.

For example, if audio downlink channels 1, 2, and 3 are enabled, audio downlink channels 4 and 5 are disabled, and the command channel is enabled:

- Num_min_write_access = 4, because three audio downlinks and the command channels are enabled.
- The first writing to the MCPDM_DN_DATA register should correspond to the audio downlink channel 1 data.
- The second writing to the MCPDM_DN_DATA register should correspond to the audio downlink channel 2 data.
- The third writing to the MCPDM_DN_DATA register should correspond to the audio downlink channel 3 data.
- The fourth writing to the MCPDM_DN_DATA register should correspond to the command information data.

NOTE: When the command channel is enabled and no command data need to be sent to the external audio companion chip, 0x0000 must be written to the 16 lower bits of the MCPDM_DN_DATA register as command data.

The audio downlink and command channels cannot be enabled or disabled on the fly during downlink signaling. The downlink path must first be forced to reset by setting the MCPDM_CTRL[12] SW_DN_RST bit to 1 before enabling or disabling any channels.

Because the audio downlink channel data are 24 bits wide and the MCPDM_DN_DATA register is 32 bits wide, the MCPDM_CTRL[8] PDMOUTFORMAT bit indicates the justification of the 24-bit audio downlink channel data in the MCPDM_DN_DATA register:

- When the MCPDM_CTRL[8] PDMOUTFORMAT is cleared to 0, the 24-bit-wide signed audio downlink channel data are left-justified with eight 0 padding bits for the lower bits (24 bits data Left Justified + 8 bits pad).
- When MCPDM_CTRL[8] PDMOUT FORMAT is set to 1, the 24-bit-wide signed audio downlink channel data are right-justified and sign-extended (8 bits Pad + 24 bits data Right Justified). For both cases (right or left-justified), 24 bits data transfer starts with MSB First format.

Copyright © 2011–2012, Texas Instruments Incorporated

NOTE: The MCPDM_CTRL[8] PDMOUTFORMAT bit does not affect the command information format. When the command information data are written to the MCPDM_DN_DATA register, only the 16 lower bits are significant.

The setting of the MCPDM_CTRL[8] PDMOUTPUTFORMAT bit also affects the audio uplink channel data format.

24.6.4.8.2.1.3 Offset Cancellation

Because audio downlink channels 1 and 2 are related to the analog headset downlink path within the external audio companion chip, an offset cancellation feature is available for these channels to eliminate the offset of the analog headset downlink path.

When the offset cancellation feature is enabled, an offset value is subtracted from the audio data before being sent to the pulse-density modulator. The offset values are read from registers within the external audio companion chip and configured in the MCPDM_DN_OFFSET[5:1] DN_OFST_RX1 bit field for the audio downlink channel 1, and in the MCPDM_DN_OFFSET[13:9] DN_OFST_RX2 bit field for the audio downlink channel 2.

The offset cancellation feature is enabled or disabled by configuring the MCPDM_DN_OFFSET[0] DN_OFST_RX1_EN bit for the audio downlink channel 1, and the MCPDM_DN_OFFSET[8] DN_OFST_RX2_EN bit for the audio downlink channel 2 (00: Disabled, 10: Enabled).

24.6.4.8.2.1.4 Pulse-Density Modulators

Each 24-bit-wide data related to an audio downlink channel is processed by a pulse-density modulator. The purpose of this modulator is to upsample the incoming audio data and then perform a 1-bit pulse-density modulation to generate a 1-bit data flow at a rate of 3.528 Mbps for a sampling frequency of 88.2 kHz, or 3.84 Mbps for a sampling frequency of 96 kHz. The 1-bit pulse-density modulation allows using a 1-bit analog-to-digital converter (ADC) implemented in the external audio companion chip to convert the audio digital data into an audio analog signal.

24.6.4.8.2.1.4.1 Pulse-Density Modulators Watchdog Logic

If the 1-bit data flow coming out of the pulse-density modulator has 12 or more consecutive 1s or 0s, the pulse-density modulator had entered into an unstable or saturated condition. An unstable or saturated condition leads to unpredictable behavior of the pulse-density modulator, thereby producing random noise. To prevent this unstable or saturated condition from occurring, a watchdog logic is used to monitor the 1-bit output of the pulse-density modulator for 12 consecutive 1s or 12 consecutive 0s. If entry to an unstable condition is detected, the watchdog logic asserts the reset of the McPDM downlink paths for one clock pulse to put the McPDM hardware logic, related to the downlink mechanism, to initial state.

The watchdog logic is disabled by default. To enable it, the MCPDM_CTRL[14] WD_EN bit must be set to 0x1. If the watchdog logic is disabled, only the assertion of the downlink path reset MCPDM_CTRL[12] SW_DN_RST bit is allowed to reset the McPDM hardware logic, which is related to the downlink mechanism. If the watchdog logic is enabled, the downlink mechanism logic is reset when the downlink path reset or the watchdog reset is asserted.

Figure 24-173 shows the McPDM watchdog logic mechanism.

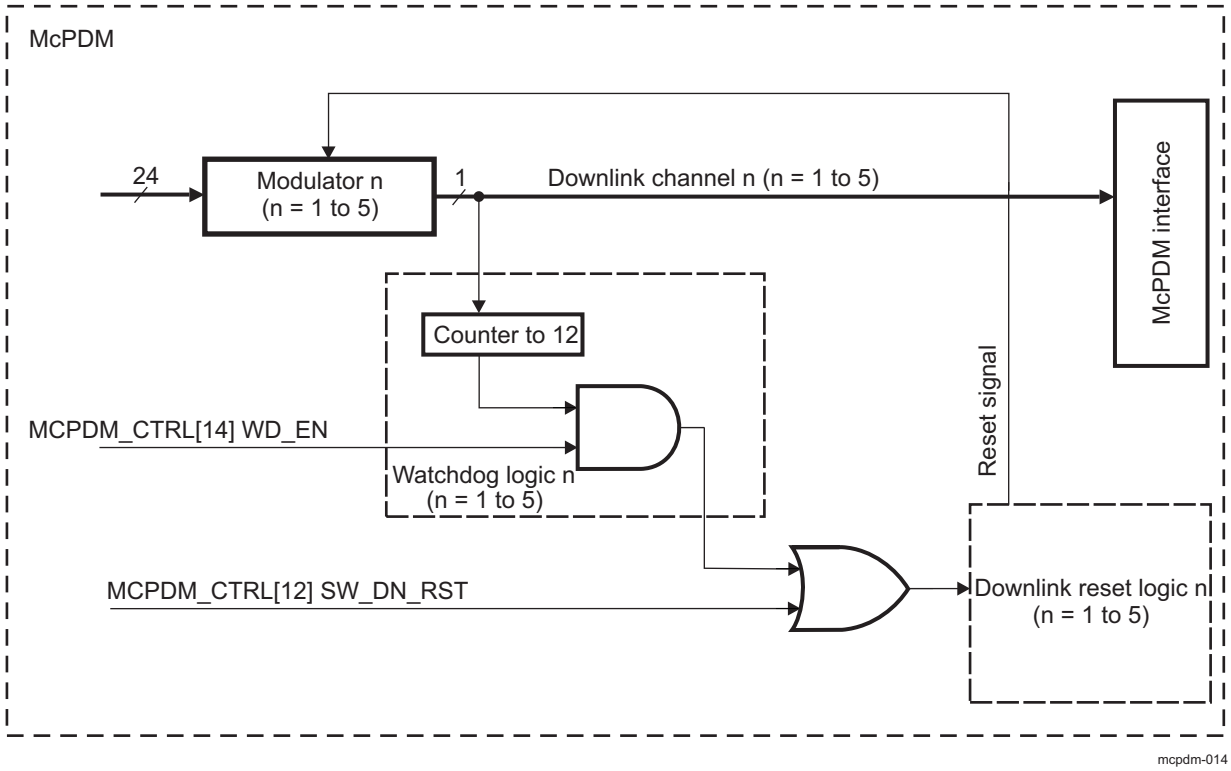
Figure 24-173. McPDM Watchdog Logic



24.6.4.8.2.1.5 Downlink Data Sent to the External Audio Companion Chip

The McPDM interface transmits the audio downlink channel data and command data to the external audio companion chip at a clock rate of 17.64 MHz for a sampling frequency of 88.2 kHz, or 19.2 MHz for a sampling frequency of 96 kHz.

The command data are sent on the frame-sync signal (ABE_PDM_FRAME) when the command channel is enabled. When the command channel is disabled or the command data is 0x0000, no command data is sent on the frame-sync signal.

NOTE: For more information about protocols and data formats in normal mode, see Section 24.6.2.4.1, *Protocols and Data Formats in Normal Mode*.

For more information about protocols and data formats in command mode, see Section 24.6.2.4.2, *Protocols and Data Formats in Command Mode*.

24.6.4.9 Error Reporting

During normal operation, when interrupt and DMA requests are properly served, no FIFO-uplink-full and no FIFO-downlink-empty events should occur.

Nevertheless, if one of these events occurs, the corresponding path must be forced to reset by software before being reconfigured. For more information about events servicing, see Section 24.6.5.1.2, *McPDM Events Servicing*.

Moreover, a FIFO-uplink-empty or FIFO-downlink-full event occurs only when all the channels of the corresponding path have been disabled during normal operation.

Copyright © 2011–2012, Texas Instruments Incorporated

NOTE: Channels must not be enabled or disabled during normal operation.

Channels can be enabled or disabled when the corresponding path is forced to reset. For more information about McPDM software reset, see Section 24.6.4.3, *McPDM Software Reset*.

24.6.5 McPDM Programming Guide

24.6.5.1 McPDM Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

24.6.5.1.1 Global Initialization

24.6.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules in the device when the McPDM module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the environment and the integration of the McPDM. For more information, see Section 24.6.2, *McPDM Environment*, and Section 24.6.3, *McPDM Integration*.

Table 24-474 describes the global initialization of surrounding modules.

Table 24-474. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM module	The McPDM interface clock must be enabled and the functional clock must not be gated.
Control module	The McPDM-specific pad muxing must be configured in the device control module.
(Optional) Cortex-A9 MPU INTC (or DSP INTC)	The Cortex-A9 MPU (or DSP) INTC must be configured to enable the interrupt request generation to the Cortex-A9 MPU (or DSP) subsystem when interrupt requests are generated by the McPDM module.
(Optional) sDMA (or eDMA or aDMA)	The sDMA (or eDMA or aDMA) controller must be configured to account for the DMA requests generated by the McPDM module in the case of autonomous data transfers from/to memory.
(Optional) Interconnect	For more information about the interconnect configuration, see Chapter 14, *Interconnect*.
External audio chip	Initialize the external audio chip according to the specific needs.
I^2C controller	For more information about the I^2C initialization, see Section 24.1, *Multimaster High-Speed I^2C Controller*.

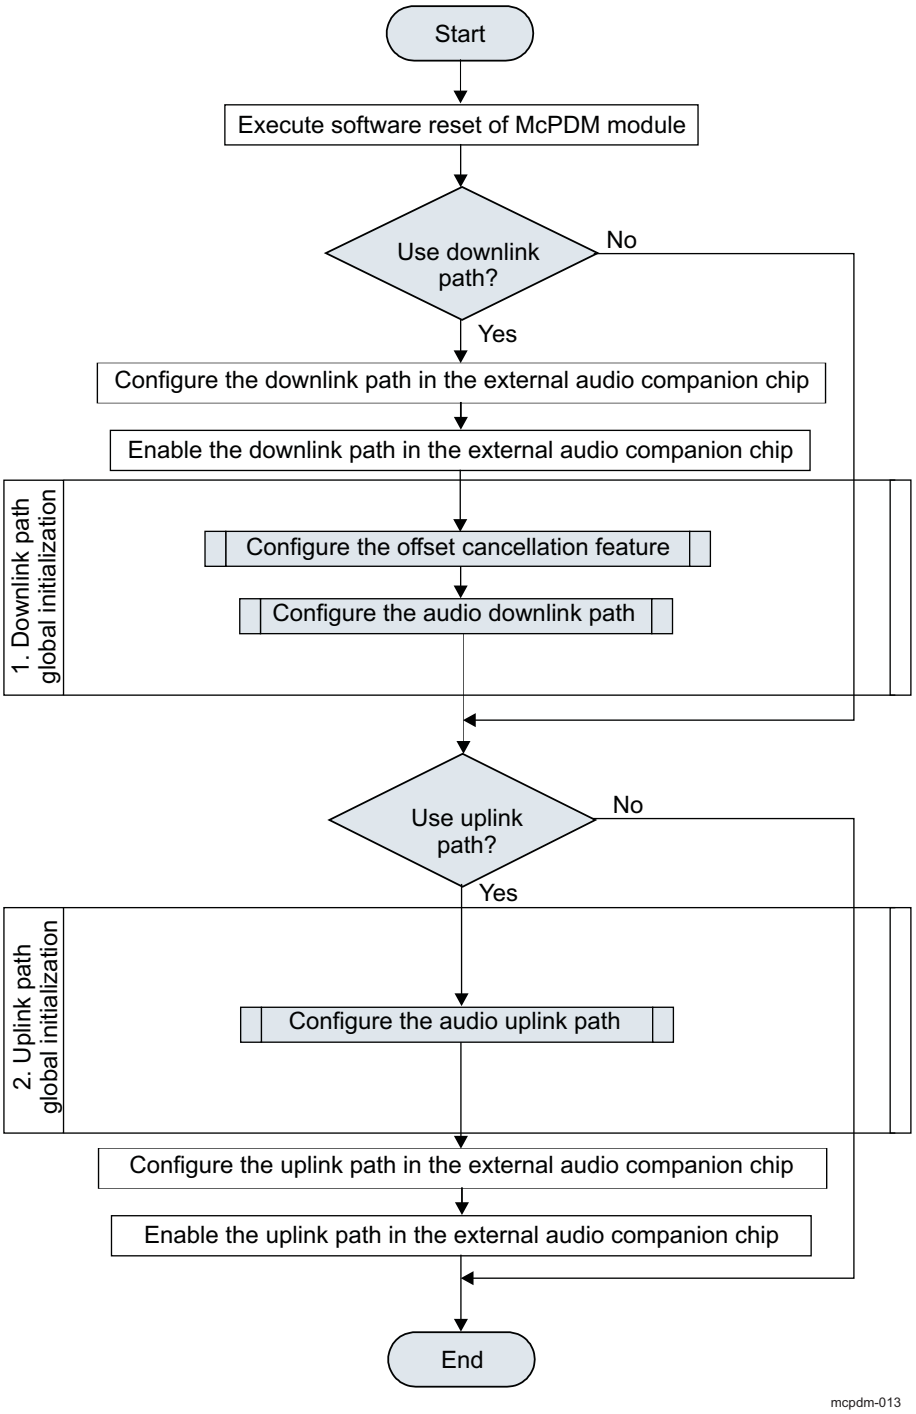
24.6.5.1.1.2 McPDM Global Initialization

24.6.5.1.1.2.1 Main Sequence – McPDM Global Initialization

This procedure initializes the McPDM after a power-on reset (POR) or software reset. Figure 24-174 shows a flow chart for the global initialization of the McPDM module.

Figure 24-174. McPDM Global Initialization Flow Chart



The McPDM software reset is executed by setting the MCPDM_SYSCONFIG[0] SOFTRESET bit to 0x1. To detect the reset done event, user software must check this bit until it is cleared to 0x0 by the hardware.

Configuration of the offset cancellation feature is optional. The use of that feature depends on the characteristics of the external audio chip attached to the McPDM interface. If the external chip adds some DC offset on its output, then the offset cancellation feature of the McPDM must be used.

Table 24-475 describes the steps of the downlink path global initialization.

Table 24-475. McPDM Downlink Path Global Initialization

Procedure	Step	Access Type	Register/Bit Field/Programming Model	Value
Configure the offset cancellation feature. Only downlink path 1 and downlink path 2 can use the offset cancellation feature.	1. Read the offset value for the audio downlink path 1 from the external audio companion chip through the I^2C interface.	R	Offset register 1 in the external audio companion chip	OFFSET1
	2. Configure the offset of the audio downlink path 1.	W	MCPDM_DN_OFFSET[5:1] DN_OFST_RX1	OFFSET1
	3. Enable the offset cancellation feature for the audio downlink path 1.	W	MCPDM_DN_OFFSET[0] DN_OFST_RX1_EN	0x1
	4. Read the offset value for the audio downlink path 2 from the external audio companion chip through the I^2C interface.	R	Offset register 2 in the external audio companion chip	OFFSET2
	5. Configure the offset of the audio downlink path 2.	W	MCPDM_DN_OFFSET[13:9] DN_OFST_RX2	OFFSET2
	6. Enable the offset cancellation feature for the audio downlink path 2.	W	MCPDM_DN_OFFSET[8] DN_OFST_RX2_EN	0x1
Configure the audio downlink path.	1. Enable the interrupt request generation for the downlink path.	W	a. MCPDM_IRQENABLE_SET[3] DN_IRQ_FULL_MASK b. MCPDM_IRQENABLE_SET[2] DN_IRQ_ALMST_EMPTY_MASK c. MCPDM_IRQENABLE_SET[1] DN_IRQ_EMPTY_MASK d. MCPDM_IRQENABLE_SET[0] DN_IRQ_MASK	When downlink DMA request not used: 0xF When downlink DMA request used: 0xE
	2. Configure the FIFO downlink threshold.	W	MCPDM_FIFO_CTRL_DN[3:0] DN_TRESH	FIFO downlink threshold
	3. Enable the DMA request generation for the downlink path (optional: only if DMA request generation for the downlink path is required).	W	MCPDM_DMAENABLE_SET[0] DMA_DN_ENABLE	0x1
	4. Enable the downlink channels.	W	MCPDM_CTRL	See Table 24-471.

Table 24-476 describes the steps of the uplink path global initialization.

Table 24-476. McPDM Uplink Path Global Initialization

Step	Access Type	Register/Bit Field/Programming Model	Value
1. Enable the interrupt request generation for the uplink path.	W	a. MCPDM_IRQENABLE_SET[11] UP_IRQ_FULL_MASK b. MCPDM_IRQENABLE_SET[10] UP_IRQ_ALMST_FULL_MASK c. MCPDM_IRQENABLE_SET[9] UP_IRQ_EMPTY_MASK d. MCPDM_IRQENABLE_SET[8] UP_IRQ_MASK	When uplink DMA request not used: 0xF When uplink DMA request used: 0xE
2. Configure the FIFO uplink threshold.	W	MCPDM_FIFO_CTRL_UP[3:0] UP_TRESH	FIFO uplink threshold
3. Enable the DMA request generation for the uplink path (optional: only if DMA request generation for the uplink path is required).	W	MCPDM_DMAENABLE_SET[1] DMA_UP_ENABLE	0x1

Table 24-476. McPDM Uplink Path Global Initialization (continued)

Step	Access Type	Register/Bit Field/Programming Model	Value
4. Configure the FIFO uplink sampling frequency.	W	MCPDM_CTRL[13] DIV_SEL	0x-
5. Enable the uplink channels.	W	MCPDM_CTRL	See Table 24-471.

24.6.5.1.2 McPDM Events Servicing

24.6.5.1.2.1 Downlink Path Event Servicing

Table 24-477 to Table 24-480 describe the downlink path event servicing.

When the four downlink interrupts are enabled and then the downlink channel(s) is enabled, the FIFO-downlink-write request (MCPDM_IRQSTATUS = 0x1), instead of the FIFO-downlink-empty request (MCPDM_IRQSTATUS = 0x2), is generated. The first audio data to be sent is written from the interrupt handler. The McPDM module can work in two ways:

- Enable the desired downlink channels, and then write in the downlink FIFO the audio data that is going to be sent.
- Write the audio data in the downlink FIFO, and then enable the desired downlink channels to send this audio data.

In either way, the FIFO-downlink-write request is generated.

Table 24-477. FIFO-Downlink-Full Event Servicing

Step	Access Type	Register/Bit Field/Programming Model	Value
TEST TA: Is FIFO downlink full?	R	MCPDM_IRQSTATUS[3] DN_IRQ_FULL

24.7 Digital Microphone Module

This section describes the digital microphone (DMIC) module.

24.7.1 DMIC Overview

The digital microphone (DMIC) module consists of an audio module dedicated to a mobile telephone terminal. The DMIC allows the support of up to six digital microphones. It provides an interface between the audio backend (ABE) module and microphones connected through the 6-wire DMIC serial interface.

The DMIC supports six paths. Because each path is composed of two digital microphone channels, the DMIC can be used with three stereo or six mono microphones. Each path is enabled or disabled independently.

The DMIC generates a pulse-density modulated (PDM) stream of bits and transfers it in one period or one half-period of the clock provided by the DMIC (oversampling clock).

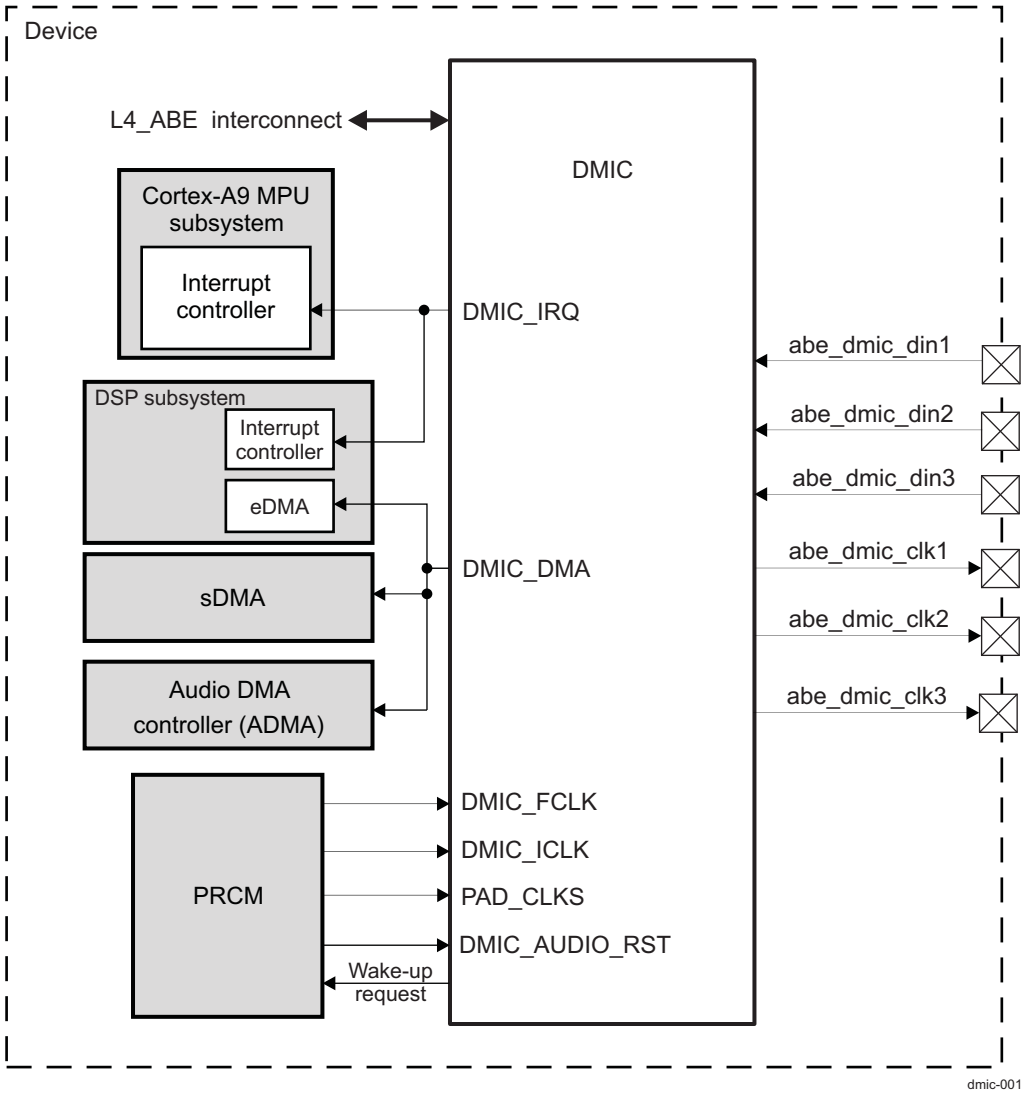
Each microphone is directly connected to a filter decimator to extract the audio samples at the desired accuracy and sample rate. Data are stored in the first in first out (FIFO), which is controlled by interrupt request (IRQ) and direct memory access (DMA) request.

The DMIC pads are supplied with 1.8 V. These pads assure the transition to the host supply.

Figure 24-175 shows the DMIC in the device.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-175. DMIC



The main features of the DMIC are:

- Six external pin connections (three data lines and three clock lines)
- Using the three clock lines, the DMIC delivers three clock signals (same frequency, individually gateable) for all digital microphones.
- Using the three data lines, the DMIC receives audio data from external microphones.
- Supports stereo (up to three) and mono (up to six) digital microphones
- Each line can support two microphones working in clock phase opposition.
- Selectable functional clock source
- Programmable output clock frequency (32 × FS, 50 × FS, 64 × FS, or 80 × FS, where FS = 48 kHz)
- Programmable data sampling sensibility (rising or falling edge)
- One RX FIFO (16 words of 144 bits)
- Supports idle request/acknowledge power, reset, and clock management (PRCM) module protocol
- Interconnect sample format: 32 bits (only 24 are significant)
- One IRQ to the microprocessor unit (Cortex ™-A9 microprocessor unit [MPU]) and digital signal processor (DSP) subsystems
- One DMA request capability on programmable FIFO threshold

24.7.2 DMIC Environment

This section describes the DMIC application fields from an environment point of view (that is, external connections). It presents the DMIC connectivity options, lists possible interfaces, and details the protocol and data format used in each case.

24.7.2.1 DMIC Interface With External MIC

24.7.2.1.1 DMIC Interface Overview

The DMIC interface is a 6-wire interface. The DMIC module can support up to three external stereo and six mono digital microphones. A DMIC is an external module that can deliver data. A clock is sent from the host to the microphone.

Figure 24-176 and Figure 24-177 show two cases of use of the DMIC, but all configurations are possible with stereo and mono digital microphones. The output of the DMIC is in 32-bit format.

Figure 24-176 shows the DMIC used with three stereo DMICs.

Figure 24-176. DMIC With Three Stereo DMICs

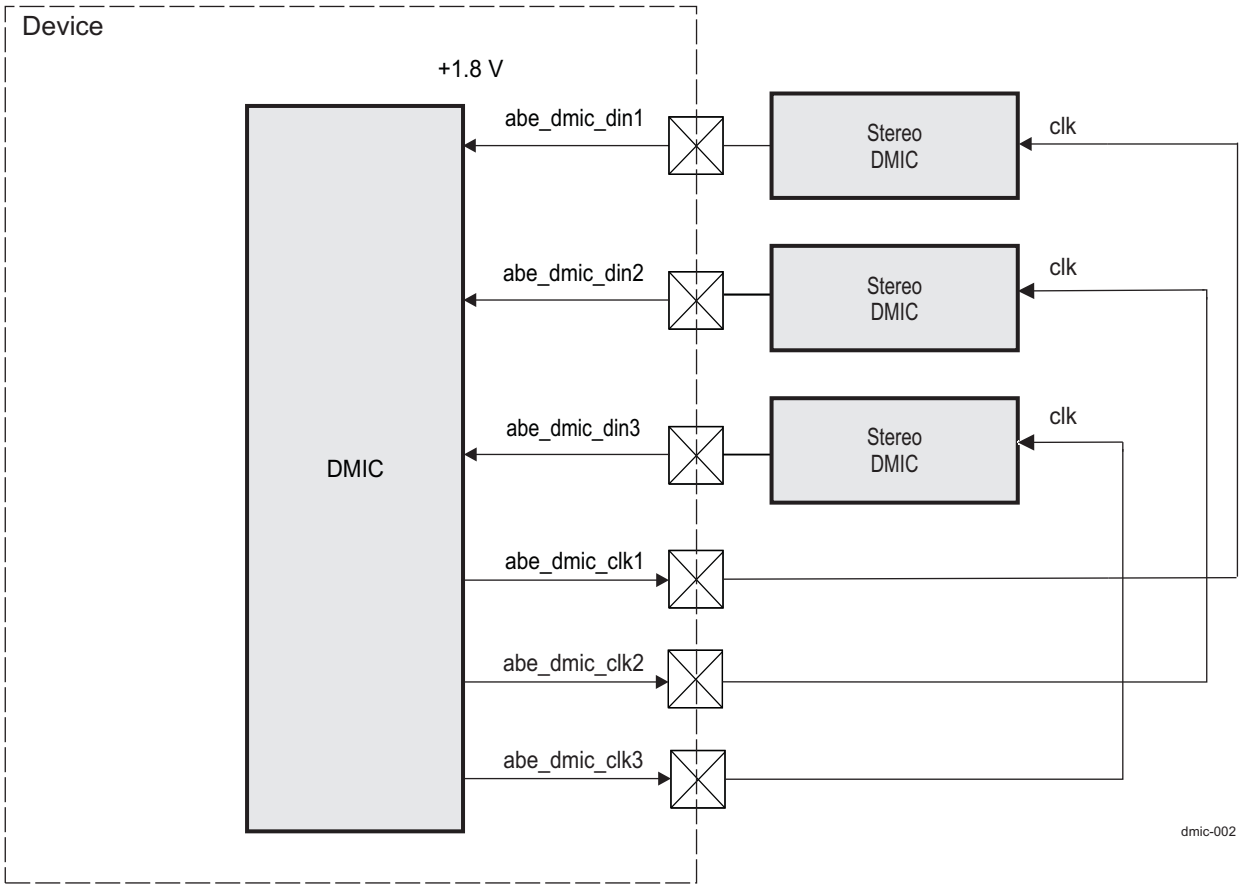

Figure 24-177 shows the DMIC used with six mono DMICs.

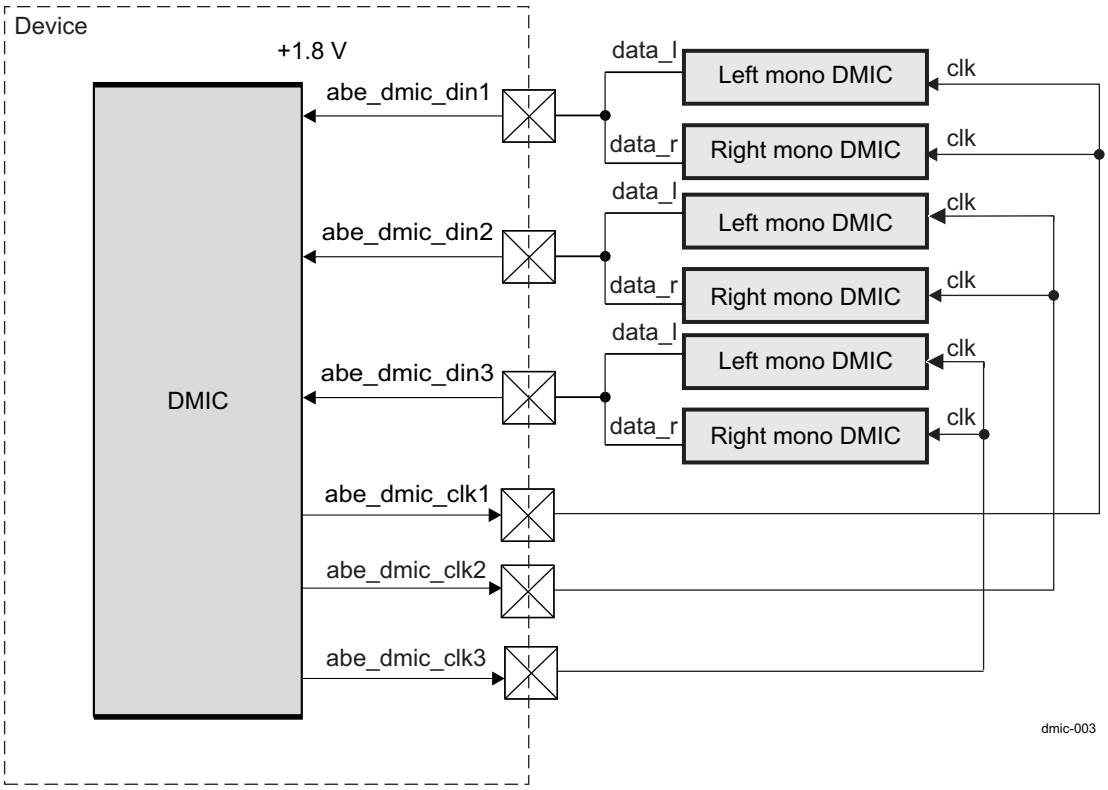
Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-177. DMIC With Six Mono DMICs



24.7.2.1.2 DMIC Signals

Table 24-519 describes the signals in the DMIC module.

Table 24-519. Input/Output

Signal Name	I/O [1]	Description	Reset Value [1]
abe_dmic_clk1	O	Digital (stereo) microphone clock output 1	0
abe_dmic_clk2	O	Digital (stereo) microphone clock output 2	0
abe_dmic_clk3	O	Digital (stereo) microphone clock output 3	0
abe_dmic_din1	I	Digital (stereo) microphone data input 1	Hi-Z
abe_dmic_din2	I	Digital (stereo) microphone data input 2	Hi-Z
abe_dmic_din3	I	Digital (stereo) microphone data input 3	Hi-Z

(1) I = Input; O = Output; Hi-Z = High impedance

All DMIC external connections have pullup or pulldown resistors, selected and configured in the control module registers.

24.7.2.1.3 Serial Data Format

The DMIC generates a PDM stream of bits and transfers it in one period or one half-period of the clock. Then, the filter decimator extracts the 24-bit audio samples.

24.7.2.1.3.1 DMIC Clock Generation and Synchronization

When DMIC_POLAR is set to 0, the microphone left data is generated on the abe_dmic_clk low level. When DMIC_POLAR is set to 1, the microphone left data is generated on the abe_dmic_clk high level. There are three DMIC_POLARx bits (where x = 1, 2, or 3) corresponding to the three stereo paths:

- DMIC_CTRL[4] for path 1

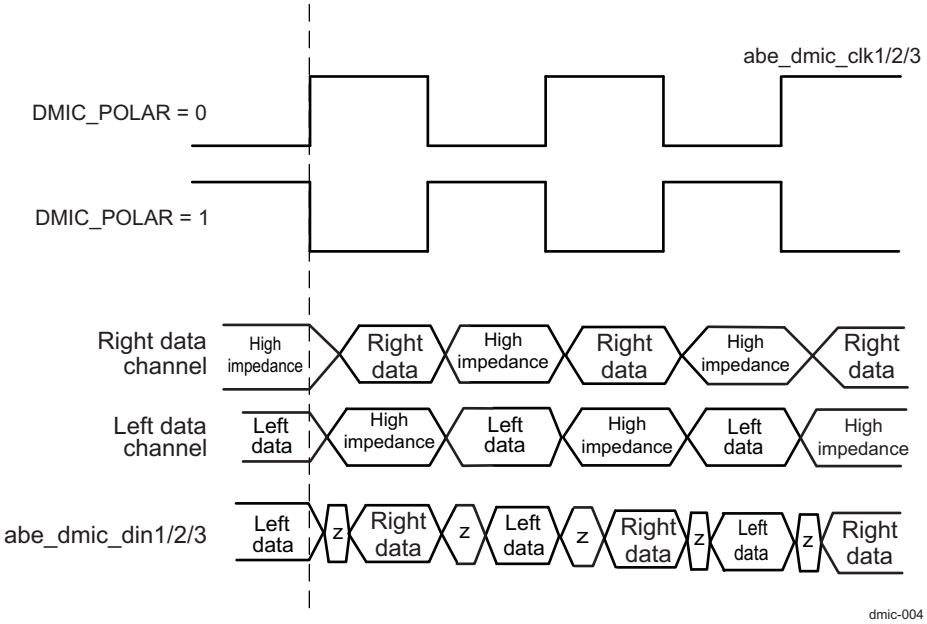
Copyright © 2011–2012, Texas Instruments Incorporated

- DMIC_CTRL[5] for path 2
- DMIC_CTRL[6] for path 3

The DMIC_POLARx bits are set depending on the configuration of the external digital microphone.

Figure 24-178 is a diagram of the DMIC interface with a DMIC.

Figure 24-178. DMIC Interface Diagram With External DMICs



24.7.2.2 DMIC Functional Path

The DMIC path processes, decimates, and filters the data from the DMIC interface, and stores the processed data in the FIFO. The FIFO is controlled by IRQ and DMA requests and is fed outside of the DMIC.

For more information about microphone data processing, see Section 24.7.4.7, *Audio Data Processing*.

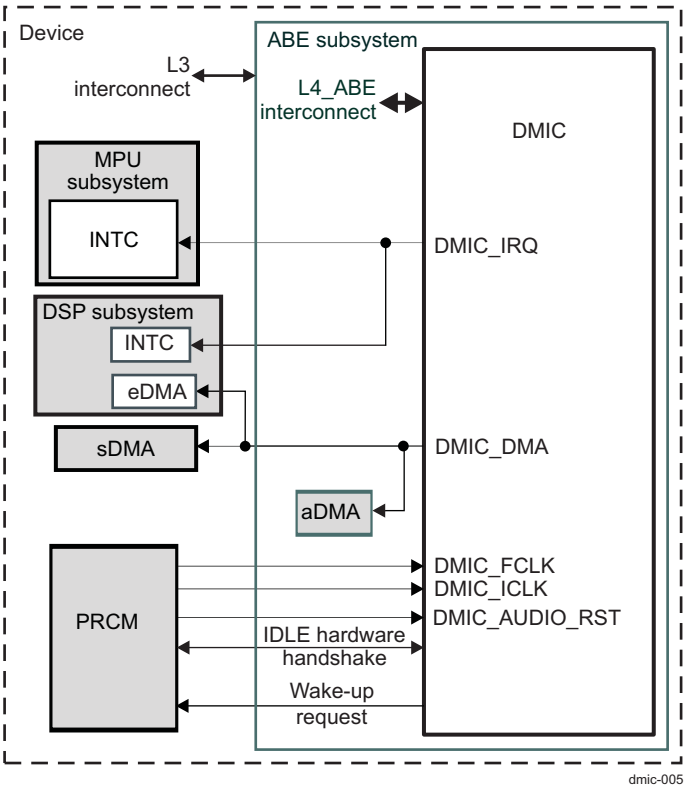
Copyright © 2011–2012, Texas Instruments Incorporated

24.7.3 DMIC Integration

This section describes the integration of the DMIC in the device, and includes information about clocks, resets, and hardware requests.

Figure 24-179 shows the DMIC integration.

Figure 24-179. DMIC Integration



NOTE: For more information about the IDLE hardware handshake and the wake-up request, see Section 3.1.1.1.2, *Module Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

The DMIC integration includes:

- One functional clock
- One interface clock
- One IRQ
- One sDMA/aDMA/eDMA request
- IDLE hardware handshake
- Wake-up request

Table 24-520 through Table 24-522 summarize the integration of the module in the device.

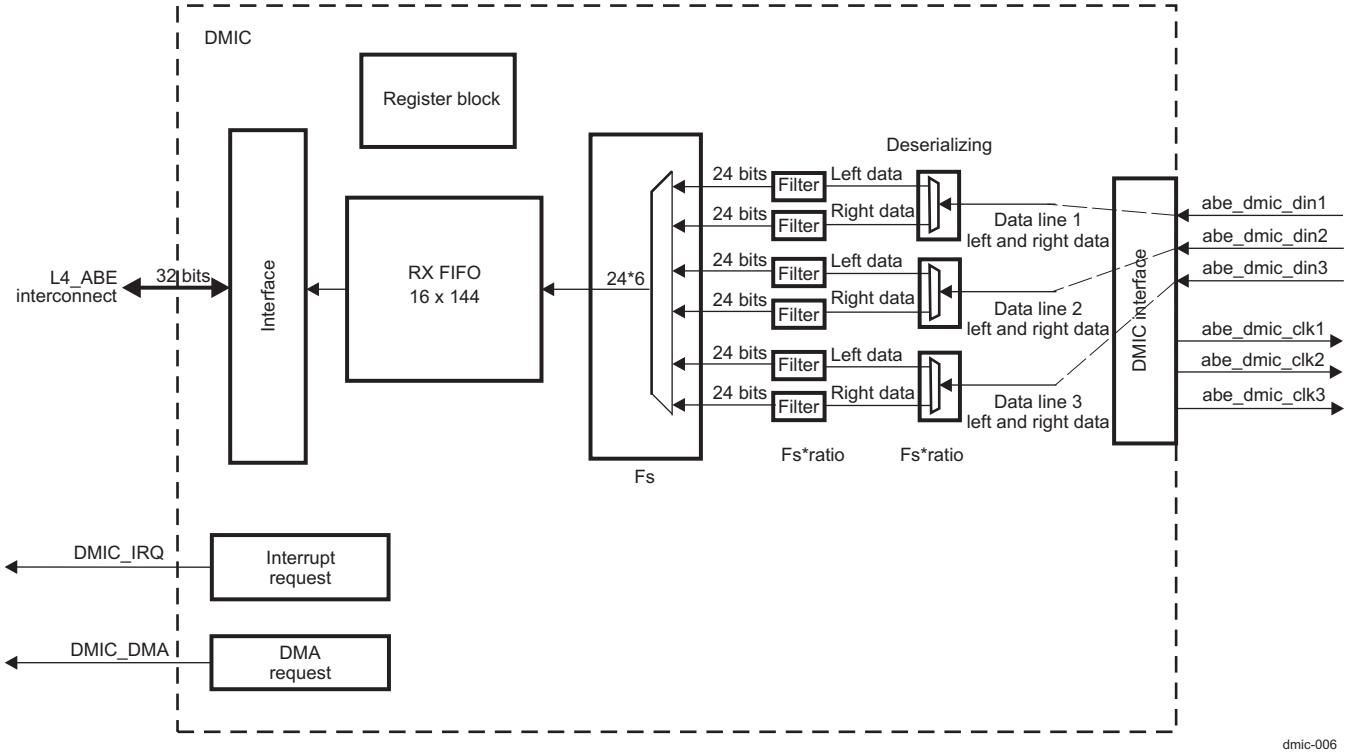
24.7.4 DMIC Functional Description

24.7.4.1 Block Diagram

Figure 24-180 is the DMIC block diagram.

Figure 24-180. DMIC Block Diagram

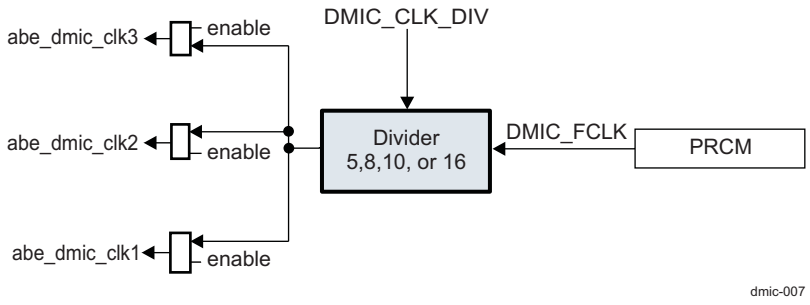


24.7.4.2 DMIC Clock Configuration

The DMIC operates from one interface clock to interface with the L4-ABE interconnect and one selectable (among three) functional clock. These clocks are provided by the PRCM module. For the interface clock, request and acknowledge are set up between the PRCM module and the DMIC.

Figure 24-181 shows the DMIC clock selection.

Figure 24-181. DMIC Clock Selection



Copyright © 2011–2012, Texas Instruments Incorporated

DMIC_FCLK is the source clock signal. Several source clocks are available and are selected according to the configuration of the DMIC_CTRL[9:7] DMIC_CLK_DIV bit field. For more information about DMIC_FCLK selection, see Figure 24-181. abe_dmic_clkx are the output clocks generated in the DMIC and are fed to the external microphones. They are also the internal clocks of the external microphones. The performance in terms of signal-to-noise ratio (SNR) depends on these clocks. Users must take care about the value of abe_dmic_clkx (the analog-to-digital converter [ADC] clock) when selecting the source clock (DMIC_FCLK). FS is the output sample rate from DMIC. For example, when DMIC_FCLK = 19.2 MHz and DMIC_CTRL[9:7] DMIC_CLK_DIV = 000, the Ratio is 25, DMIC is providing a 96 KHz sampling rate to the AESS or SDMA. Table 24-523 describes the abe_dmic_clkx generation.

Table 24-523. abe_dmic_clkx Generation

DMIC_FCLK	DMIC_ CLK_DIV	Ratio DMIC_FCLK/ abe_dmic_clk	abe_dmic_clk = ADC Clock	FS	Ratio = abe_dmic_clk/FS = 96 kHz
19.2/17.64 MHz	000	8	2.4/2.205 MHz	96/88.2 KHz	25
	001	5	3.84/3.528 MHz	96/88.2 KHz	40
19.2 MHz	110	5	3.84 MHz	192 KHz	20
24 MHz	010	10	2.4 MHz	96 KHz	25
24.576 MHz	011	8	3.072 MHz	96 KHz	32
	100	16	1.536 MHz	96 KHz	16
12 MHz	101	5	2.4 MHz	96 KHz	25

The maximum clock on the interface is 3.84 MHz, with a source clock of 19.2 MHz.

24.7.4.3 DMIC Software Reset

Table 24-524 lists the different types of software reset available at the module level.

Table 24-524. Reset Description

Type	Name	Source	Description
Software	DMIC_SYSCONFIG[1] SOFTRESET	–	Module software reset
Software	DMIC_CTRL[10] SW_DMIC_RST	–	Reset-enabled DMIC paths

The software path reset is gated by:

- DMIC_CTRL[0] DMIC_UP1_EN for path 1
- DMIC_CTRL[1] DMIC_UP2_EN for path 2
- DMIC_CTRL[2] DMIC_UP3_EN for path 3
- DMIC_CTRL[10] SW_DMIC_RST

When the DMIC_CTRL[10] SW_DMIC_RST bit is set to 1, the corresponding enabled DMIC paths are reset. Resets are cleared by writing 0.

NOTE: A software reset is required to change the configuration of enabled paths; for example, to disable path 3, a software reset of path 3 is mandatory for the change to be considered.

A module software reset can be performed by setting the DMIC_SYSCONFIG[1] SOFTRESET bit. This action starts a soft reset sequence.

The software reset status of the module can be checked by reading the DMIC_SYSCONFIG[0] SOFTRESET bit (0: reset is done; 1: reset is ongoing).

24.7.4.4 DMIC Power Management

Table 24-525 describes the power-management features available for the DMIC.

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-525. Local Power-Management Features

Feature	Registers	Description
Clock autogating	N/A	Feature not available
Slave idle modes	DMIC_SYSCONFIG[3:2] SIDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup capable modes are available.
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	DMIC_IRQWAKEEN[0] IRQ_WAKEUP_EN DMIC_DMAWAKEEN[0] DMA_WAKEUP_EN	This register holds one active-high enable bit per event source that can generate a wake-up signal.

24.7.4.5 DMIC Interrupt Requests

Table 24-526 lists the event flags, and their mask, that can cause module interrupts.

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-526. Interrupt Events

Nonmaskable Event Flag [1]	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
DMIC_IRQSTATUS_RAW[3] DMIC_IRQ_EMPTY	DMIC_IRQSTATUS[3] DMIC_IRQ_EMPTY	DMIC_IRQENABLE_CLR[3] DMIC_IRQ_EMPTY_MASK	DMIC_IRQENABLE_SET[3] DMIC_IRQ_EMPTY_MASK	FIFO empty event. This event occurs when the FIFO is already empty and a new word is read from the FIFO by software.
DMIC_IRQSTATUS_RAW[2] DMIC_IRQ_ALST_FULL	DMIC_IRQSTATUS[2] DMIC_IRQ_ALST_FULL	DMIC_IRQENABLE_CLR[2] DMIC_IRQ_ALST_FULL_MASK	DMIC_IRQENABLE_SET[2] DMIC_IRQ_ALST_FULL_MASK	FIFO almost-full event. This event occurs when the FIFO contains (FIFO size – 1) words and a new word is written to the FIFO.
DMIC_IRQSTATUS_RAW[1] DMIC_IRQ_FULL	DMIC_IRQSTATUS[1] DMIC_IRQ_FULL	DMIC_IRQENABLE_CLR[1] DMIC_IRQ_FULL_MASK	DMIC_IRQENABLE_SET[1] DMIC_IRQ_FULL_MASK	FIFO full event. This event occurs when the FIFO is already full and a new word is written to the FIFO.
DMIC_IRQSTATUS_RAW[0] DMIC_IRQ	DMIC_IRQSTATUS[0] DMIC_IRQ	DMIC_IRQENABLE_CLR[0] DMIC_IRQ_MASK	DMIC_IRQENABLE_SET[0] DMIC_IRQ_MASK	FIFO read request event. This event occurs when the number of words stored in the FIFO is equal to or greater than the FIFO threshold.

(1) The DMIC_IRQSTATUS_RAW register is used primarily for debug purposes.

The interrupt line is asserted (active high) when one of the following signals appears:

- DMIC_IRQ_EMPTY
- DMIC_IRQ_ALST_FULL
- DMIC_IRQ_FULL
- DMIC_IRQ

Read the DMIC_IRQSTATUS register to determine which event occurs.

CAUTION

Interrupt lines must be cleared by software. Write 1 in the DMIC_IRQSTATUS register to clear the corresponding event.

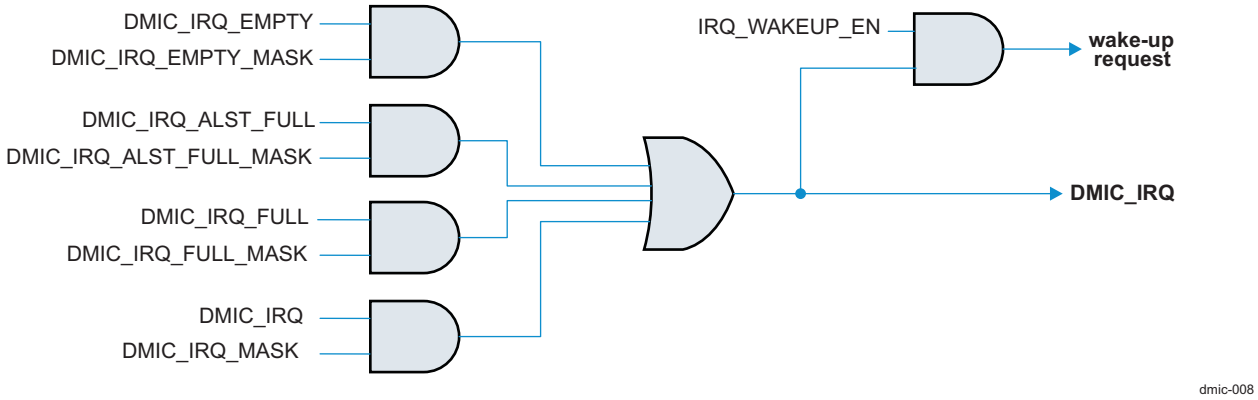
An event can generate an IRQ when the corresponding mask bit in the DMIC_IRQENABLE_SET register is set to 1. Events are register bits that belong to the DMIC_IRQSTATUS and DMIC_IRQSTATUS_RAW registers (the same register accessed by two interconnect addresses). In the case of the DMIC_IRQSTATUS_RAW register, status event is set even if it is not enabled (used primarily for debug purposes). The DMIC_IRQSTATUS register is set by writing 1 to the DMIC_IRQSTATUS_RAW register.

Each internal interrupt signal can be masked by enabling the corresponding mask in the DMIC_IRQENABLE_SET register or disabling it in the DMIC_IRQENABLE_CLR register. This mechanism is defined in Section 24.7.6, *DMIC Register Manual*.

Figure 24-182 shows the interrupt tree with the event generated and the mask that enables or disables the event. All events are summarized to give the single interrupt generation.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-182. Interrupt Tree



24.7.4.6 DMIC DMA Requests

The DMIC can generate one DMA request to the sDMA, aDMA, and eDMA controllers (see Table 24-527).

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-527. DMIC DMA Request

Name	Description	Enable DMA Bit	Disable DMA Bit
DMIC_DMA_ENABLE	Data ready in FIFO (threshold is reached)	DMIC_DMAENABLE_SET[0] DMA_ENABLE	DMIC_DMAENABLE_CLR[0] DMA_ENABLE

The DMA lines can be enabled or disabled depending on the value of the bits in the DMIC_DMAENABLE_SET and DMIC_DMAENABLE_CLR registers.

A DMA request is sent when data is ready in the FIFO. This request is used only to notify the host that data are ready in the FIFO.

24.7.4.7 Audio Data Processing

The DMIC supports six audio paths and can be used with three stereo or six mono microphones. Each path is independent and is enabled or disabled by using the following bits:

- DMIC_CTRL[0] DMIC_UP1_EN
- DMIC_CTRL[1] DMIC_UP2_EN
- DMIC_CTRL[2] DMIC_UP3_EN

24.7.4.7.1 Filtering

The external DMIC generates a PDM stream of bits and transfers it in one period or one half-period of the clock provided by the DMIC inside the device. The aim of the DMIC audio path is to process data from the DMIC interface, decimate and filter the data, and store the processed data in the FIFO.

The format of the DMIC data is 24 bits (the transfer format is 32 bits long). The following bits allow switching the polarity of the interface:

- DMIC_CTRL[4] DMIC_POLAR1
- DMIC_CTRL[5] DMIC_POLAR2
- DMIC_CTRL[6] DMIC_POLAR3

For more information, see Section 24.7.2.1.3.1, *DMIC Clock Generation and Synchronization*.

Processed data from the DMIC interface are stored in the FIFO. The FIFO is controlled by the IRQ and DMA request and externally fed by the DMIC using the following interconnect format.

The three uplink paths are identical. Each uplink path is composed of a left and a right channel. The DMIC interface delivers six parallel data of 1 bit (3 × 2 paths of stereo data that can be used at six mono paths). Each bit goes to a filter. The aim of the filter is to limit the noise and perform decimation by factor D. Factor D depends on the DMIC_CLK_DIV register bits, as described in the ratio defined in Table 24-523. The filters are sinc filter order 4. They are chosen with regard to the nature of the analog converter.

The format of the filter output is 24 bits.

24.7.4.8 FIFO Management

The DMIC implements an internal FIFO controlled by IRQ and DMA request. The host must read words in the FIFO. The interrupt line is used not only to inform the host that data are ready in the FIFO, but also to warn the host about events that can occur, such as FIFO full, almost full, or empty. A DMA request is used only to inform the host that data are ready in the FIFO.

24.7.4.8.1 FIFO General Description

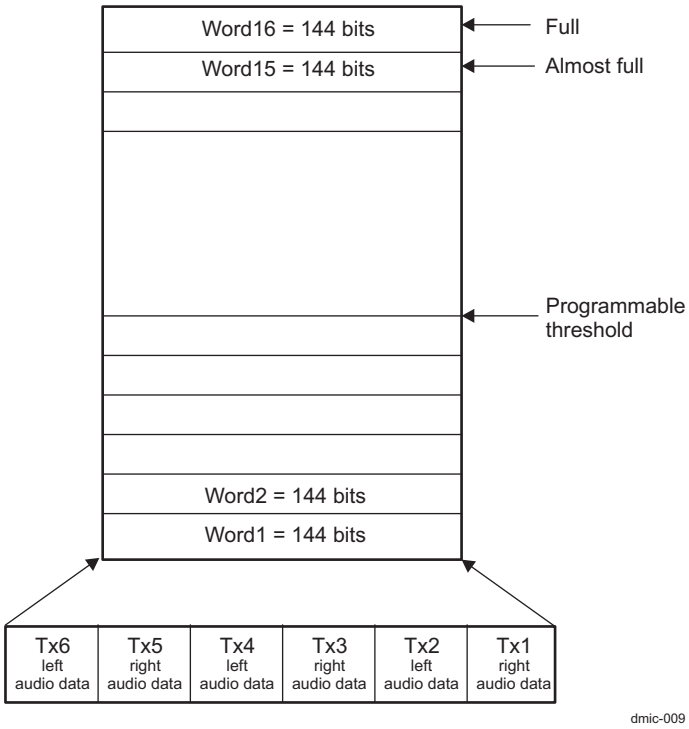
The DMIC communicates with the host through L4-ABE interconnect access. DMIC audio data coming from external microphones are stored in the FIFO. The DMIC FIFO allows the exchange of information between the DMIC and the host. Each audio data is 24 bits long. The DMIC FIFO contains 16 words. Each word is the combination of six audio data (24 × 6 = 144 bits) coming from the interface. The FIFO is controlled by interrupt lines and DMA requests. For more information about IRQs and DMA controls, see Section 24.7.4.5, *DMIC Interrupt Requests*, and Section 24.7.4.6, *DMIC DMA Requests*.

Copyright © 2011–2012, Texas Instruments Incorporated

FIFO write access is done in the functional clock domain, and read access is done in the interface clock domain.

Figure 24-183 is an overview of the DMIC FIFO.

Figure 24-183. DMIC FIFO



24.7.4.8.2 FIFO Operations

Audio data are filled in the FIFO from DMIC internal filters. The host must read words in the FIFO. The number of reads depends on the application that is configured by the following bits:

- DMIC_CTRL[0] DMIC_UP1_EN
- DMIC_CTRL[2] DMIC_UP3_EN
- DMIC_CTRL[1] DMIC_UP2_EN
- DMIC_FIFO_CTRL[3:0] DMIC_TRESH (FIFO threshold)

If only uplink path 2 and path 3 are enabled, for example, the Tx1 and Tx2 words are left and right data for path 2, and Tx3 and Tx4 are left and right data for path 3.

When the FIFO threshold is reached, and depending on conditions, an event is sent to the DMA handler. The host must read the exact number of words in the FIFO.

Two accesses are required to read a complete stereo audio path.

The number of read accesses from the host is determined by the following equation:

Num_rd_access = (DMIC_UP1_EN + DMIC_UP2_EN + DMIC_UP3_EN) × 2 × (DMIC_TRESH)

The FIFO threshold is programmed through the DMIC_FIFO_CTRL[3:0] DMIC_TRESH bit field.

Copyright © 2011–2012, Texas Instruments Incorporated

NOTE: If DMIC_TRESH = 1, the host is expected to perform 1 × (DMIC_UP1_EN + DMIC_UP2_EN + DMIC_UP3_EN) × 2 read access every 96 kHz (2 × FS).

If DMIC_TRESH = 2, the host is expected to perform (DMIC_UP1_EN + DMIC_UP2_EN + DMIC_UP3_EN) × 4 read access every 48 kHz (FS).

If DMIC_TRESH = 12, the host is expected to perform (DMIC_UP1_EN + DMIC_UP2_EN + DMIC_UP3_EN) × 12 access every 8 kHz (FS/6).

24.7.4.8.3 FIFO Output Range Definition

The DMIC_CTRL[3] DMICOUTFORMAT bit allows determining the format of the output of the DMIC uplink module.

When DMICOUTFORMAT = 0, the data going from the FIFO are left-shifted by 8 bits. When DMICOUTFORMAT = 1, the data are signed-extended on 32 bits.

The DMIC uplink modules process audio data based on twos complement format.

NOTE: When DMICOUTFORMAT = 0, the maximum positive swing analog voltage corresponds to a final DMIC output of 0x7FFF FF00. The maximum negative swing analog voltage corresponds to a final DMIC output of 0x8000 0000.

When DMICOUTFORMAT = 1, the sign is extended: The maximum positive swing analog voltage corresponds to a final DMIC output of 0x007F FFFF. The maximum negative swing analog voltage corresponds to a final DMIC output of 0xFF80 0000.

Reading the value of the corresponding audio data in the FIFO requires access to the DMIC_DATA_REG register. The first access gives the value of Tx1 right data, the second gives the value of Tx2 left data, up to Tx6 (the left audio data of the last audio path). If the path is disabled, 0x0 is read. All data are duplicated (for debug purposes) in their corresponding left or right data registers. Table 24-528 describes the audio data path registers.

Table 24-528. Audio Data Path Registers

Stereo Audio Path	Mono Audio Path	Data Register
Right path 1	Mono path 1	DMIC_FIFO_DMIC1R_DATA[23:0]
Left path 1	Mono path 2	DMIC_FIFO_DMIC1L_DATA[23:0]
Right path 2	Mono path 3	DMIC_FIFO_DMIC2R_DATA[23:0]
Left path 2	Mono path 4	DMIC_FIFO_DMIC2L_DATA[23:0]
Right path 3	Mono path 5	DMIC_FIFO_DMIC3R_DATA[23:0]
Left path 3	Mono path 6	DMIC_FIFO_DMIC3L_DATA[23:0]

The output of the DMIC path for interconnect access is in 32-bit format.

24.7.5 DMIC Programming Guide

24.7.5.1 DMIC Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

24.7.5.1.1 Global Initialization

24.7.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the DMIC is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the DMIC. For more information, see Section 24.7.3, *DMIC Integration* and Section 24.7.2, *DMIC Environment*.

Table 24-529 describes the global initialization of surrounding modules.

Table 24-529. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. See Chapter 3, *Power, Reset, and Clock Management*.
Control module	Module-specific pad muxing must be set in the control module. See Chapter 19, *Control Module*.
(optional) Cortex-A9 MPU interrupt controller (INTC) (or DSP INTC)	INTC configuration must be done to enable the interrupts from the DMIC. See Chapter 18, *Interrupt Controllers*.
(optional) sDMA (or eDMA or aDMA)	DMA configuration must be done to enable the DMIC DMA channel requests.
(optional) Interconnect	For more information about the interconnect configuration, see Chapter 14, *Interconnect*.

NOTE: The INTC and DMA configurations are necessary if the interrupt and DMA-based communication modes are used.

24.7.5.1.2 DMIC Global Initialization

24.7.5.1.2.1 Main Sequence – DMIC Global Initialization

The procedure in Table 24-530 initializes the DMIC after a power-on reset (POR).

Table 24-530. DMIC Global Initialization

Step	Register/Bit Field/Programming Model	Value
Execute a software reset.	DMIC_SYSCONFIG[0] SOFTRESET	0x1
Wait for the software reset completion by polling.	DMIC_SYSCONFIG[0] SOFTRESET	==0x0
Configure the local power management.	DMIC_SYSCONFIG[3:2] SIDLEMODE	0x-
Select the DMIC FIFO threshold.	DMIC_FIFO_CTRL[3:0] DMIC_TRESH	0x-
Select the DMIC output clock frequency.	DMIC_CTRL[9:7] DMIC_CLK_DIV	0x-
Select the DMIC FIFO data output format.	DMIC_CTRL[3] DMICOUTFORMAT	0x-
Select the level (high or low) of the clock signal abe_dmic_clki when the left data is to be generated (extracted) from the external microphone i (where i = 1 to 3).	DMIC_CTRL[j] DMIC_POLARi (where j = 4 to 6, and i = 1 to 3)	0x-
Enable audio path i (where i = 1 to 3).	DMIC_CTRL[k] DMIC_POLARi (where k = 0 to 2, and i = 1 to 3)	0x1

Table 24-533. DMA Mode

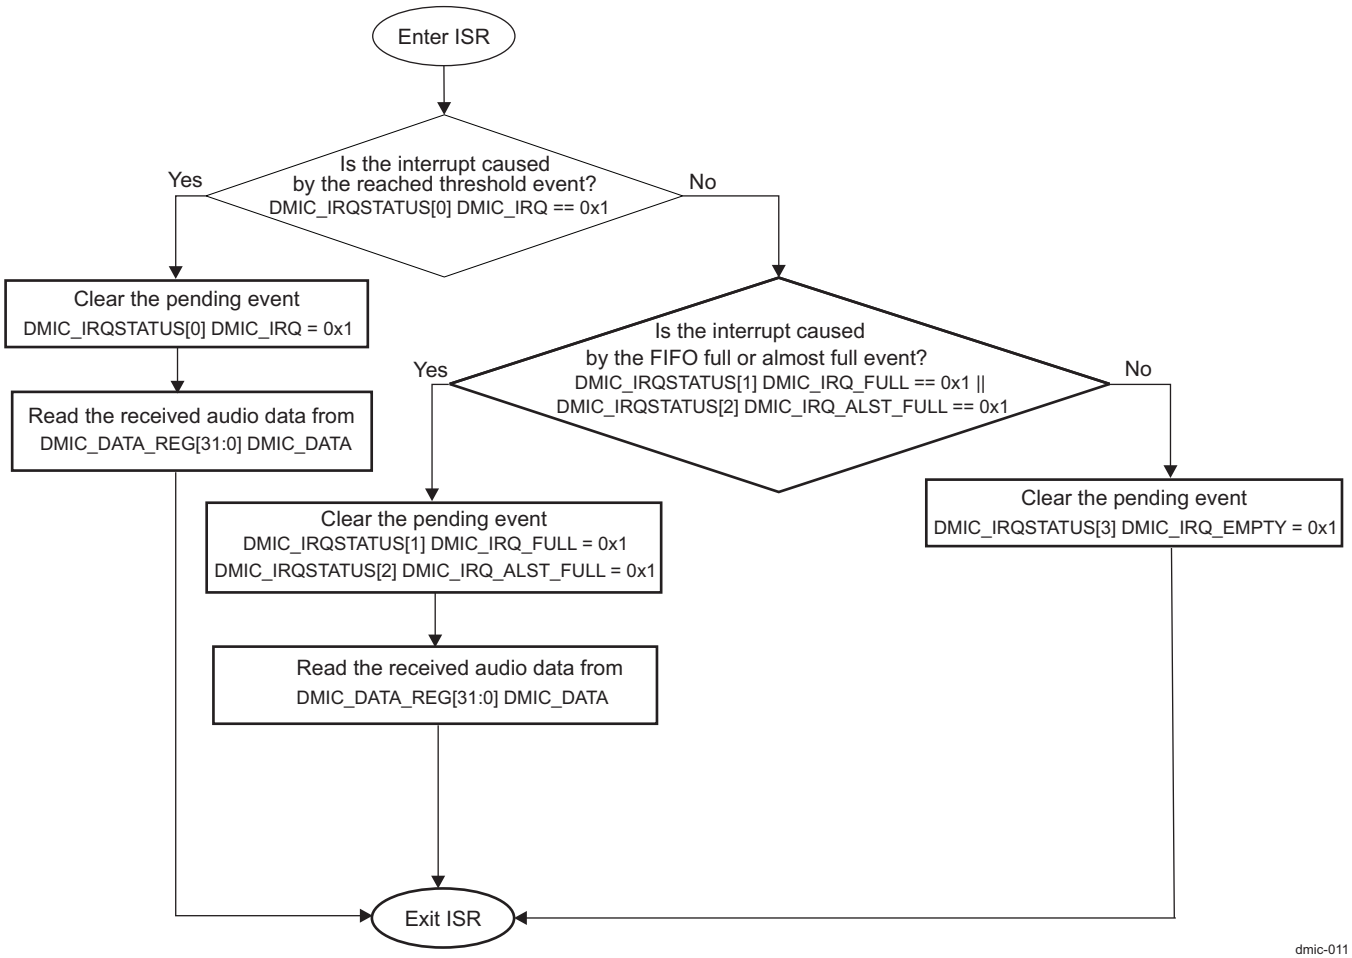
Step	Register/Bit Field/Programming Model	Value
Enable the DMIC DMA interrupt event.	DMIC_DMAENABLE_SET[0] DMA_ENABLE	0x1

24.7.5.1.3 DMIC Events Servicing

24.7.5.1.3.1 DMIC Interrupt Servicing

This section describes the interrupt event servicing of the module. Figure 24-185 shows the interrupt handler.

Figure 24-185. Interrupt Handler



When the interrupt is caused by the reached threshold event, for the number of read accesses used while reading the received audio data, see Section 24.7.4.8, *FIFO Management*.

When the interrupt is caused by a FIFO full or almost-full event, software must read all the available data in the FIFO. If a FIFO full event occurred, the number of read accesses must be the maximum:

Num_rd_access = (DMIC_UP1_EN + DMIC_UP2_EN + DMIC_UP3_EN) × 2 × 15

If a FIFO almost-full event occurred, the number of read accesses must be:

Num_rd_access = (DMIC_UP1_EN + DMIC_UP2_EN + DMIC_UP3_EN) × 2 × 14

Table 24-534 summarizes the register call for the interrupt handler.

24.7.6.2.2 DMIC Register Descriptions

through describe the DMIC registers.

Table 24-537. DMIC_REVISION

Address Offset	0x0000 0000		
Physical Address	0x4902 E000 0x4012 E000 0x2 E000	**Instance**	DMIC_L3 DMIC_CORTEX-A9 DMIC_DSP
Description	IP Revision Identifier (X.Y.R) used by software to track features, bugs, and compatibility		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REVISION																															

Bits	Field Name	Description	Type	Reset
31:0	REVISION	IP revision	R	See(1).

(1) TI internal data

Table 24-538. Register Call Summary for Register DMIC_REVISION

Digital Microphone Module

- DMIC Register Summary: [0]

Table 24-539. DMIC_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x4902 E010 0x4012 E010 0x2 E010	**Instance**	DMIC_L3 DMIC_CORTEX-A9 DMIC_DSP
Description	This register allows controlling various parameters of the DMIC interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												SIDLEMODE		FREEMU	SOFTRESET

Bits	Field Name	Description	Type	Reset
31:4	RESERVED	Reserved	R	0x0000000
3:2	SIDLEMODE	Configuration of the local target state management (idlereq/idleack control) 0x0: Force-idle. IDLE request is acknowledged unconditionally and immediately. 0x1: No-idle. IDLE request is never acknowledged. 0x2: Smart-idle. The acknowledgment to an IDLE request is given based on the internal activity. 0x3: Smart-idle wakeup capable mode	RW	0x2
1	FREEMU	Sensitivity to emulation (debug) suspend input signal 0x0: IP module is sensitive to emulation suspend. 0x1: IP module is not sensitive to emulation suspend.	RW	0

Copyright © 2011–2012, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
0	SOFTRESET	Module software reset. The bit is automatically reset by the hardware. It has same effect as the main hardware reset. Write 0x0: No action Read 0x0: Reset done, no pending action Read 0x1: Reset (software or other) ongoing Write 0x1: Initiate software reset.	RW	0

24.8 Multichannel Audio Serial Port

This section describes the multichannel audio serial port (McASP).

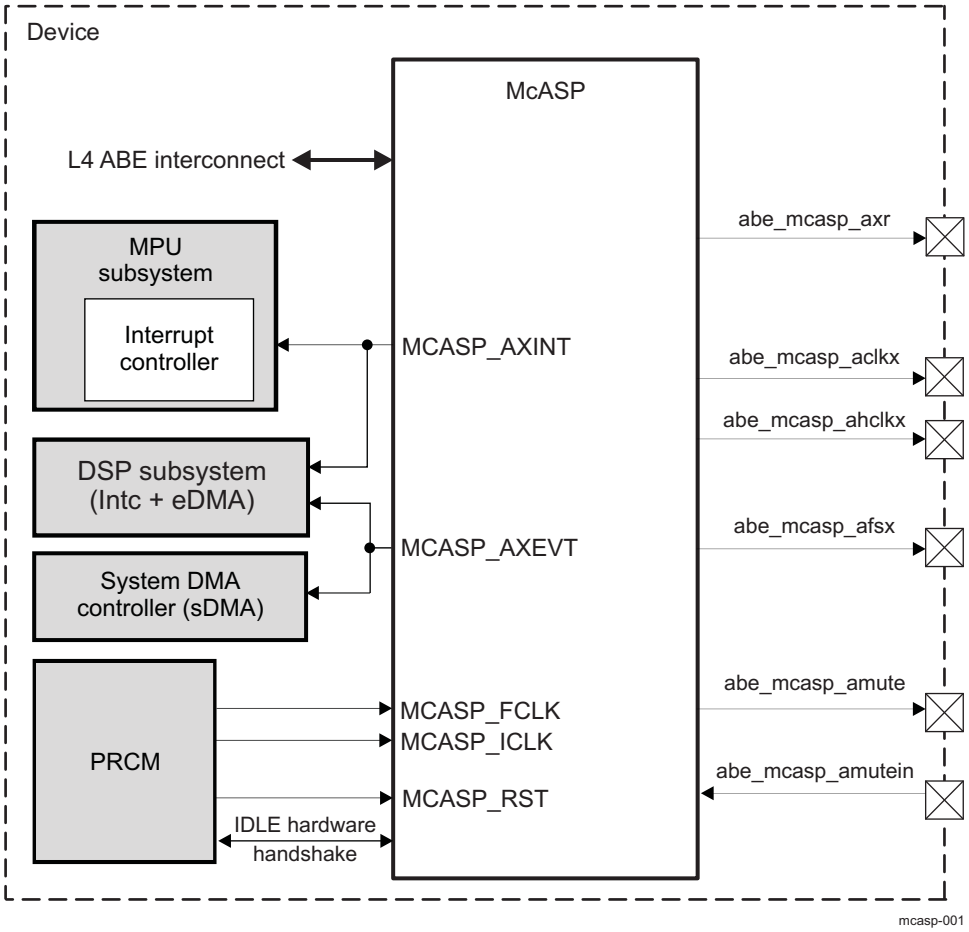
24.8.1 McASP Overview

This section introduces the multichannel audio serial port (McASP) module and describes its main functions and connections in the device.

The McASP functions as a general-purpose audio serial port optimized to the requirements of various audio applications. The McASP is useful for intercomponent digital audio interface transmission (DIT). The McASP has the flexibility to gluelessly connect to a Sony/Philips digital interface (S/PDIF) transmit physical layer component. The McASP module operates in transmit mode only; it has no receive capabilities.

Figure 24-186 shows the McASP module in the device.

Figure 24-186. McASP Module



The McASP module includes the following main features:

- Support of the idle request/acknowledge protocol
- One serializer implementing a single transmit channel
- A single 32-bit buffer in the serializer for transmit operations
- One transmit direct memory access (DMA) request linked with the serializer
- One transmit interrupt request linked with the serializer

Copyright © 2011–2012, Texas Instruments Incorporated

24.8.2 McASP Environment

This section describes the McASP application fields from an environment point of view (external connections), along with the McASP connectivity options. This section also lists all of the possible interfaces and describes the protocol and data format used in each case.

24.8.2.1 McASP Signals

Table 24-575 describes the McASP signals and specifies their links to functions.

Table 24-575. I/O

Signal	I/O (1)	Description
abe_mcasp_axr	O	Audio transmit data
abe_mcasp_aclkx	O	Transmit bit clock
abe_mcasp_ahclkx	O	Transmit high-frequency master clock
abe_mcasp_afsx	O	Transmit frame synchronization
abe_mcasp_amute	O	Mute out to external
abe_mcasp_amutein	I	Mute in from external

(1) I = Input; O = Output

All McASP pins on the device can be individually programmed as general-purpose input/output (GPIO) if they are not used for serial port functions.

The McASP includes the following pins:

- Serializer:
  - AXR0: serial data transmission pin. The corresponding McASP signal at device level is named abe_mcasp_axr.
- Transmit clock generator:
  - ACLKX: McASP transmit bit clock. The corresponding McASP signal at device level is named abe_mcasp_aclkx.
  - AHCLKX: McASP transmit high-frequency master clock. The corresponding McASP signal at device level is named abe_mcasp_ahclkx.
- Transmit frame-sync generator:
  - AFSX: McASP transmit frame sync. The corresponding McASP signal at device level is named abe_mcasp_afsx.
- Mute in/out:
  - AMUTEIN: McASP mute input (from external device). The corresponding McASP signal at device level is named abe_mcasp_amutein.
  - AMUTE: McASP mute output. The corresponding McASP signal at device level is named abe_mcasp_amute.

NOTE: For McASP transmission, it is necessary to set the output direction for the serializer AXR0 data pin (at the device level, the signal is named abe_mcasp_axr) in the MCASP_PDIR register. The transmit function has to be selected in the corresponding serializer control register (MCASP_XRSRCTL0).

24.8.2.2 Protocols and Data Formats

24.8.2.2.1 Protocols Supported

The McASP transmit section uses the S/PDIF industry format, which is supported by the DIT transfer mode of the module.

Each transmit section can be programmed to support the following options on the basic serial protocol:

Copyright © 2011–2012, Texas Instruments Incorporated

- Programmable clock and frame-sync polarity (rising or falling edge): abe_mcasp_aclkx, abe_mcasp_ahclkx, and abe_mcasp_afsx
- Slot length (number of bits per time slot): 8, 12, 16, 20, 24, 28, 32 bits supported
- Word length (bits per word): 8, 12, 16, 20, 24, 28, 32 bits; always less than or equal to the time slot length
- First-bit data delay: 0-, 1-, 2-bit clocks
- Left/right alignment of word inside slot
- Bit order: Most-significant bit (MSB) first or least-significant bit (LSB) first
- Bit mask/pad/rotate function
- Automatically aligns data in Q31 or integer format
- Automatically masks nonsignificant bits (sets to 0, 1, or extends value of another bit)

The DIT transfer mode includes the following additional transmitter features:

- Transmit-only mode: 384 time slots (subframe) per frame
- Biphase encoded LVCMOS output
- Channel status RAM (384 bits)
- User data RAM (384 bits)
- Separate valid bit (V) for subframes A and B

NOTE: An external transceiver must be connected to the McASP port in the device to translate the electrical signals delivered by the McASP (1.2 V or 1.8 V LVCMOS levels) to the electrical levels of the S/PDIF standard.

24.8.2.2.2 Definition of Terms

The serial bitstream transmitted by the McASP is a long sequence of 1s and 0s on an audio transmit pin (abe_mcasp_axr). However, the sequence has a hierarchical organization that can be described in terms of frames of data, slots, words, and bits.

A basic synchronous serial interface consists of three important components: clock, frame sync, and data. Figure 24-187 shows two of the three basic components: the clock (abe_mcasp_aclkx) and the data (abe_mcasp_axr). In operation, the transmitter uses abe_mcasp_aclkx as serial clock.

- Bit:

  A bit is the smallest entity in the serial data stream. The beginning and end of each bit is marked by an edge of the serial clock. The duration of a bit is a serial clock period. A 1 is represented by a logic high on the abe_mcasp_axr pin for the entire duration of the bit. A 0 is represented by a logic low on the abe_mcasp_axr pin for the entire duration of the bit.

- Word:

  A word is a group of bits that make up the data being transferred between the McASP and the external device. Figure 24-187 shows an 8-bit word.

- Slot:

  A slot consists of the bits that make up the word and can consist of additional bits used to pad the word to a convenient number of bits for the interface between the McASP and the external device. In Figure 24-187, the audio data consists of only 8 bits of useful data (8-bit word), but it is padded with four 0s (12-bit slot) to satisfy the desired protocol in interfacing to an external device. Within a slot, the bits can be shifted out of the McASP on the abe_mcasp_axr pin with either MSB or LSB first.

  When the word size is smaller than the slot size, the word can be aligned to the left of the slot (beginning) or to the right of the slot (end). The additional bits in the slot not belonging to the word can be padded with 0, 1, or with one of the bits (typically, the MSB or LSB) from the data word (that is, left-aligned words within a slot are terminated with padding bits and right-aligned words within a slot are preceded by padding bits to fit in the slot size). Figure 24-188 shows these options.

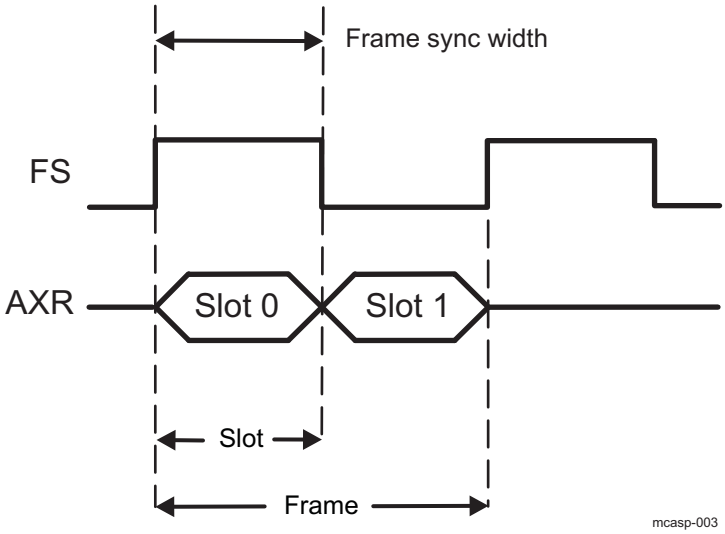
- Frame

  The third basic element of a synchronous serial interface is the frame synchronization signal, also referred to as frame sync in this document. A frame contains one or multiple slots, as determined by the desired protocol. Figure 24-189 shows an example frame of data and the frame definitions. In operation, the transmitter uses abe_mcasp_afsx. This example shows two slots in a frame and the frame-sync (FS) duration of the slot length.

  This section shows only the generic definition of the frame sync. For more information about the frame-sync formats required for the transfer modes and protocols (DIT mode and S/PDIF format), see Section 24.8.2.2.3, *Frame Format*.

Figure 24-189. Definition of Frame and Frame-Sync Width



The following terms are used throughout this chapter:

- DIT: Digital audio interface transmit. The McASP supports transmitting in S/PDIF format on the abe_mcasp_axr data pin.
- Slot or time slot: For DIT format, a McASP time slot corresponds to a DIT subframe.

24.8.2.2.3 S/PDIF Coding Format

The McASP transmitter supports the S/PDIF format with 1.8-V biphase-mark encoded output. The S/PDIF format is supported by the DIT transfer mode of the McASP. This section briefly discusses the S/PDIF coding format.

24.8.2.2.3.1 Biphase-Mark Code

In S/PDIF format, the digital signal is coded using the biphase-mark code (BMC). The clock, frame, and data are embedded in only one signal: data pin abe_mcasp_axr. In the BMC system, each data bit is encoded into two logical states (00, 01, 10, or 11) at the pin. These two logical states form a cell. The duration of the cell, which equals the duration of the data bit, is called a time interval. A logical 1 is represented by two transitions of the signal within a time interval, which corresponds to a cell with logical states 01 or 10. A logical 0 is represented by one transition within a time interval, which corresponds to a cell with logical states 00 or 11. In addition, the logical level at the start of a cell is inverted from the level at the end of the previous cell. Figure 24-190 and Table 24-576 show how data is encoded to the BMC format.

As shown in Figure 24-190, the clock frequency is twice the unencoded data bit rate. In addition, the clock is always programmed to 128 × f_s, where f_s is the sample rate (see Section 24.8.2.2.3.3, *Frame Format*, for details on how this clock rate is derived based on the S/PDIF format).

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-190. Biphase-Mark Code

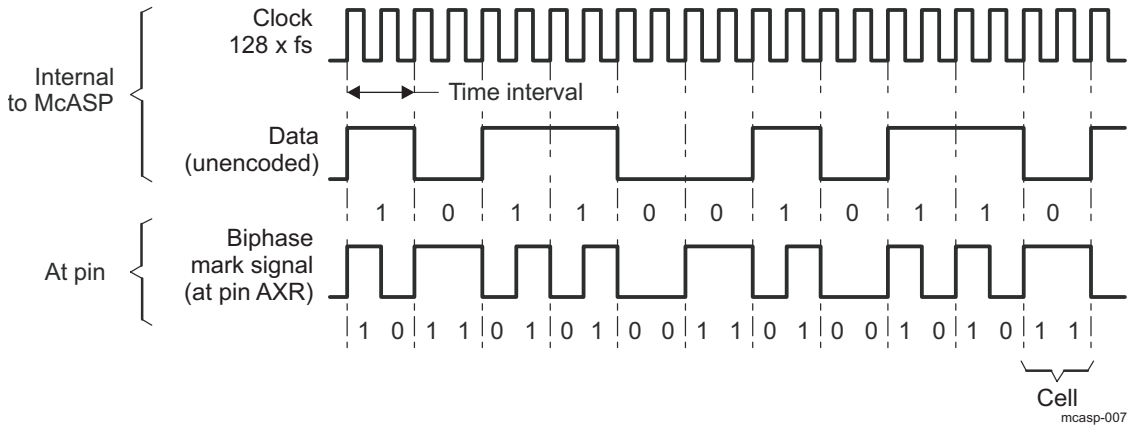


Table 24-576. Biphase-Mark Encoder

Data (Unencoded)	Previous State at Pin abe_mcasp_axr	BMC-Encoded Cell Output at abe_mcasp_axr
0	0	11
0	1	00
1	0	10
1	1	01

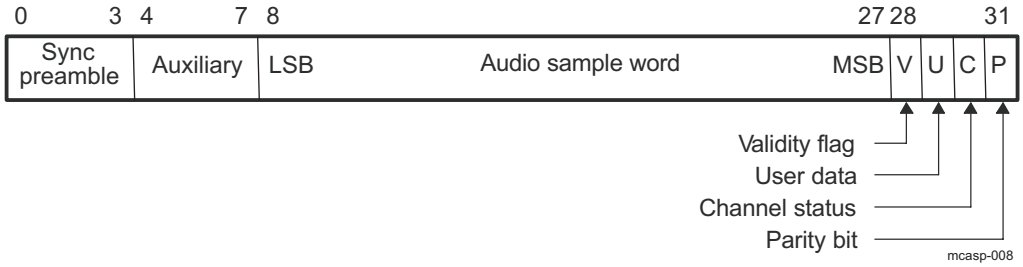
24.8.2.2.3.2 Subframe Format

Every audio sample transmitted in a subframe consists of 32 S/PDIF time intervals (or cells), numbered 0 to 31. Figure 24-191 shows a subframe.

- Time intervals 0–3 carry one of the three permitted preambles to signify the type of audio sample in the current subframe. The preamble is not encoded in BMC format, and therefore the preamble code can contain more than two consecutive 0 or 1 logical states in a row. See Table 24-577.
- Time intervals 4–27 carry the audio sample word in linear 2s-complement representation. The MSB is carried by time interval 27. When a 24-bit coding range is used, the LSB is in time interval 4. When a 20-bit coding range is used, time intervals 8-27 carry the audio sample word with the LSB in time interval 8. Time intervals 4–7 may be used for other applications and are designated auxiliary sample bits.
- If the source provides fewer bits than the interface allows (20 or 24), the unused LSBs are set to logical 0. For a nonlinear PCM audio application or a data application, the main data field can carry any other information.
- Time interval 28 carries the validity bit (V) associated with the main data field in the subframe.
- Time interval 29 carries the user data channel (U) associated with the main data field in the subframe.
- Time interval 30 carries the channel status information (C) associated with the main data field in the subframe. The channel status indicates if the data in the subframe is digital audio or some other type of data.
- Time interval 31 carries a parity bit (P) such that time intervals 4–31 carry an even number of 1s and an even number of 0s (even parity). As listed in Table 24-577, the preambles (time intervals 0–3) are also defined with even parity.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-191. S/PDIF Subframe Format



As listed in Table 24-577, the McASP DIT generates only one polarity of preambles, and it assumes the previous logical state is 0. This is because the McASP assures an even-polarity encoding scheme when transmitting in DIT mode. If an underrun condition occurs, the DIT resynchronizes to the correct logic level on the abe_mcasp_axr pin before continuing with the next transmission.

Table 24-577. Preamble Codes

Preamble Code [1]	Previous Logical State	Logical States on pin abe_mcasp_axr [2]	Description
B (or Z)	0	1110 1000	Start of a block and subframe 1
M (or X)	0	1110 0010	Subframe 1
W (or Y)	0	1110 0100	Subframe 2

(1) Historically, preamble codes are referred to as B, M, and W. For use in professional applications, preambles are referred to as Z, X, and Y, respectively.

(2) The preamble is not BMC-encoded. Each logical state is synchronized to the serial clock. These eight logical states make up time slots (cells) 0 to 3 in the S/PDIF stream.

24.8.2.2.3.3 Frame Format

An S/PDIF frame is composed of two subframes (see Figure 24-192). For linear coded audio applications, the rate of frame transmission normally corresponds exactly to the source sampling frequency f_s. The S/PDIF format clock rate is therefore 128 × f_s (128 = 32 cells per subframe × 2 clocks per cell × 2 subframes per sample). For example, for an S/PDIF stream at a 192-kHz sampling frequency, the serial clock is 128 × 192 kHz = 24.58 MHZ.

In 2-channel operation mode, the samples taken from both channels are transmitted by time multiplexing in consecutive subframes. Both subframes contain valid data (cell 28 validity bits for A- and B-channels, both set to 0).. The first subframe (left or A channel in stereophonic operation and primary channel in monophonic operation) normally starts with preamble M. However, the preamble of the first subframe changes to preamble B once every 192 frames to identify the start of the block structure used to organize the channel status information. The second subframe (right or B channel in stereophonic operation and secondary channel in monophonic operation) always starts with preamble W.

In single-channel operation mode in a professional application, the frame format is the same as in the 2-channel mode. Data is carried in the first subframe and may be duplicated in the second subframe. If the second subframe is not carrying duplicate data, cell 28 (validity bit) is set to logical 1.

24.8.3 McASP Integration

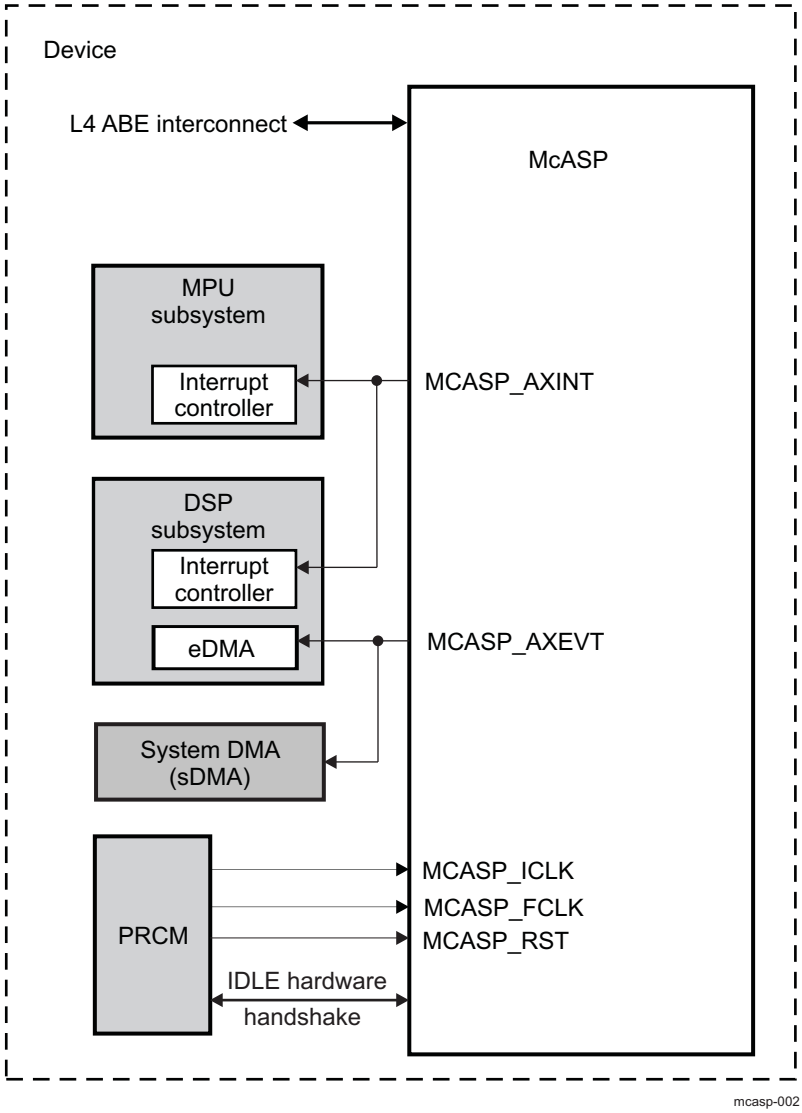
This section describes module integration in the device, including information about clocks, resets, and hardware requests.

The McASP includes the following features:

- IDLE hardware handshake
- One DMA request
- One interrupt request (IRQ)

Figure 24-193 shows McASP integration.

Figure 24-193. McASP Integration



NOTE: For more information about the IDLE hardware handshake, see Section 3.1.1.1.2, *Module Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 24-578 through Table 24-580 summarize the integration of the module in the device.

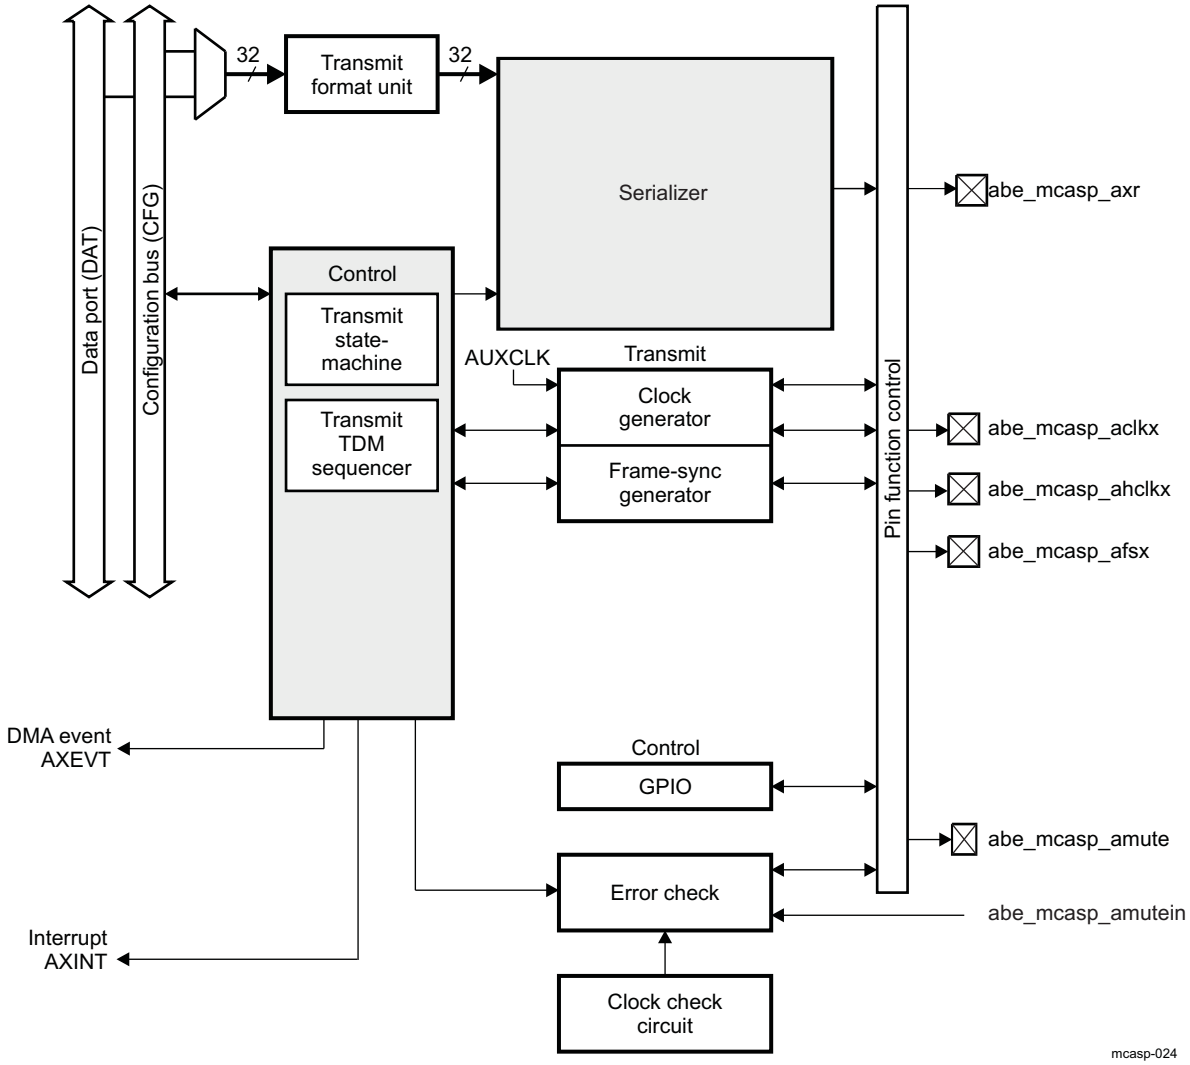
24.8.4 McASP Functional Description

24.8.4.1 Block Diagram

Figure 24-194 shows the major blocks of the McASP. The McASP has a transmit clock generator and a frame-sync generator, serializer, format unit, and error-checking logic.

Figure 24-194. McASP Block Diagram



NOTE: The AUXCLK clock is sourced directly from MCASP_FCLK.

24.8.4.2 McASP Clock and Frame-Sync Configuration

The transmit serial clock (clock at the bit rate) can be sourced internally by passing through two clock dividers off the internal clock source (AUXCLK). The bit rate clock is generated internally and is driven out on the abe_mcasp_aclkx pin. An internally generated high-frequency clock can be driven out onto the abe_mcasp_ahclkx pin to serve as a reference clock for other components in the system.

Copyright © 2011–2012, Texas Instruments Incorporated

24.8.4.2.1 Transmit Clock

The transmit bit clock, abe_mcasp_aclkx, is generated internally. For this purpose, the MCASP_ACLKXCTL[5] CLKXM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the MCASP_ACLKXCTL[4:0] CLKXDIV bit field) from the source signal.

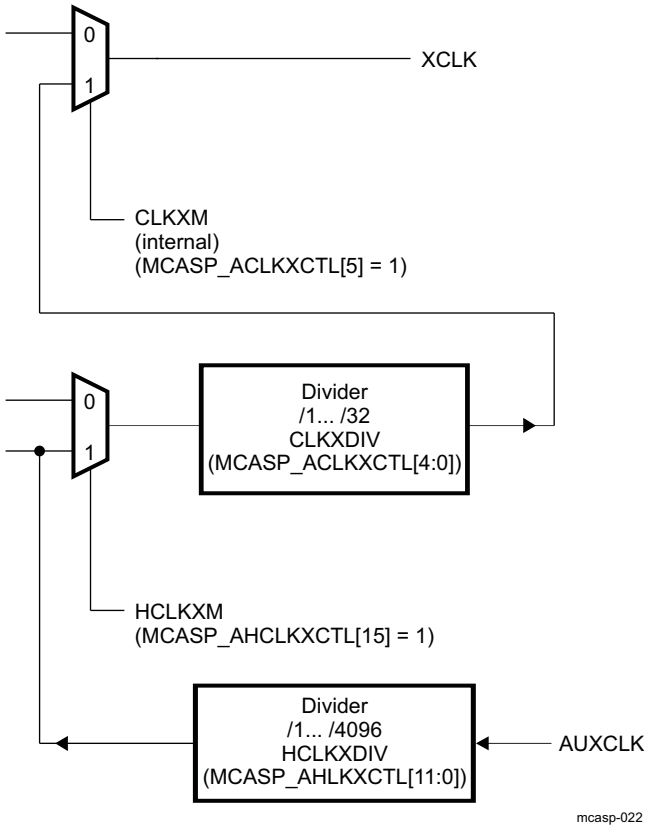
The transmit high-frequency master clock, abe_mcasp_ahclkx, is also generated internally. For this purpose, the MCASP_AHCLKXCTL[15] HCLKXM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the MCASP_AHCLKXCTL[11:0] HCLKXDIV bit field) from the McASP internal clock source AUXCLK.

The transmit clock configuration is controlled by the following registers:

- MCASP_ACLKXCTL
- MCASP_AHCLKXCTL

Figure 24-195 is the block diagram of the transmit clock generator.

Figure 24-195. Transmit Clock Generator Block Diagram



24.8.4.2.2 Frame-Sync Generator

The transmit frame-sync pin is abe_mcasp_afsx. The frame-sync generator must be configured through the control register (MCASP_TXFMCTL) as:

- Internally generated MCASP_TXFMCTL[1] FSXM = 1
- Frame-sync polarity: Rising edge MCASP_TXFMCTL[0] FSXP = 0
- Frame-sync width: Single bit MCASP_TXFMCTL[4] FXWID = 0
- 384-slot, MCASP_TXFMCTL[15:7] XMOD = 1 1000 0000b

Copyright © 2011–2012, Texas Instruments Incorporated

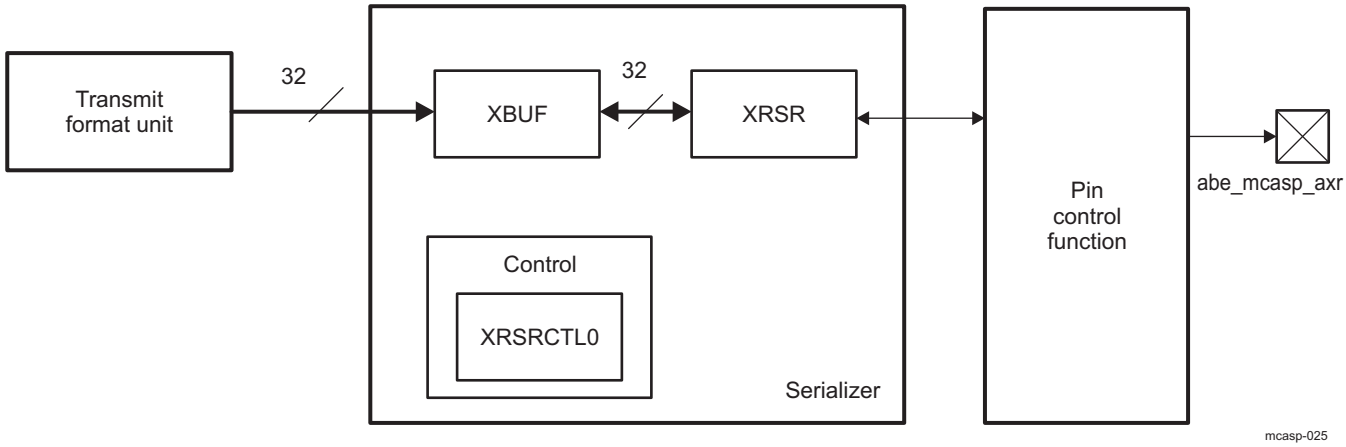
24.8.4.3 Serializers

The serializer shifts serial data out of the McASP. It consists of a shift register (XRSR), a data buffer (XBUF), a control register (MCASP_XRSRCTL0), a serial data pin (abe_mcasp_axr), and logic to support the data alignment options of the McASP.

The serializer must be configured to transmit through the control register, thus shifting out data to abe_mcasp_axr. The serializer is clocked from the transmit section clock (abe_mcasp_aclkx) if configured to transmit. A serializer configured to transmit operates in lockstep.

Figure 24-196 is the serializer block diagram.

Figure 24-196. Individual Serializer and Connections Within McASP



For transmit, the microprocessor unit (MPU) services the McASP by writing data into the MCASP_TXBUF0 register, which is an alias of the XBUF register for transmitting. The data automatically passes through the transmit format unit before reaching the XBUF register in the serializer. The data is then copied from XBUF to XRSR and shifted out from abe_mcasp_axr synchronously to the serial clock.

In addition to the data, the serializer shifts out other DIT-specific information accordingly (preamble, user data, etc.). The serializer configuration is controlled by MCASP_XRSRCTL0[1:0] SRMOD = 0x1. Thus, the serializer is configured to operate in transmit mode.

24.8.4.4 Format Unit

The McASP has one transmit formatting unit (TFU). This unit automatically remaps the data bits within the transmitted words between a natural format for the MPU (such as a Q31 representation) and the required format for the external serial device. During the remapping process, the format unit can also mask off certain bits.

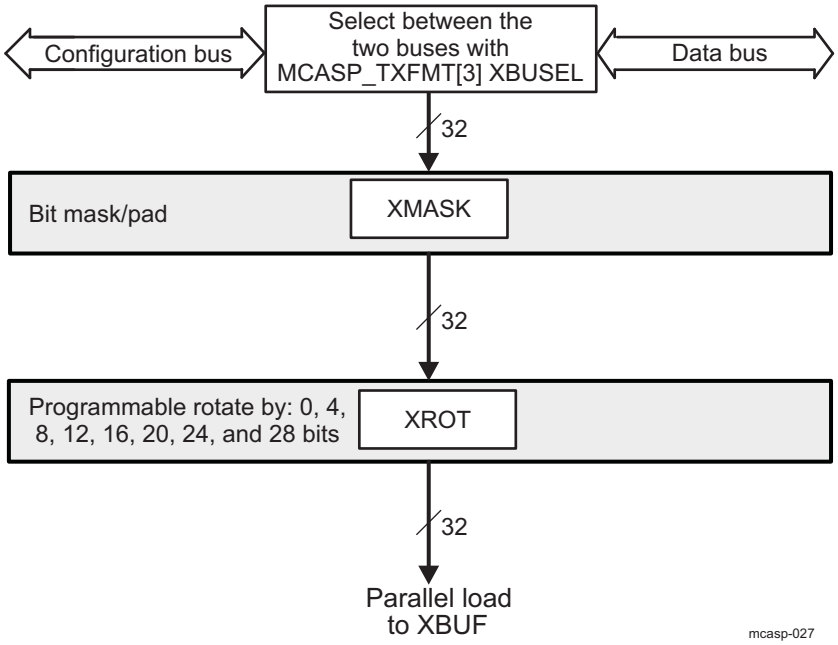
This formatting unit consists of two stages:

- Bit mask (masks off bits)
- Rotate right (aligns data within word)

Figure 24-197 shows the transmit formatting unit.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-197. Transmit Format Unit



As shown in Figure 24-197, the data to the transmit format unit can come from the configuration bus or the data bus. The selection is made through the MCASP_TXFMT[3] XBUSEL bit.

The bit mask stage includes a full 32-bit mask register, allowing selected individual bits to pass through the stage unchanged or be masked off.

In the transmit format unit (TFU), the input data bits are first masked-off with the MCASP_TXMASK[31:0] XMASK contents. The masked data is then right-rotated to MCASP_TXFMT[2:0] XROT positions, to produce the output word for a DIT transmission.

The bit mask stage includes a full 32-bit mask register, allowing selected individual bits to pass through the stage unchanged or be masked off.

While left-aligned Q31 data should be right-rotated by 4 positions, no right-rotation is required for right-aligned Q31 data. Because this is a rotation process, not a shifting process, bit 0 gets shifted back into bit 31 during the process.

The MCASP_TXFMT[17:16] XDATLY bit field must be set to a 0-bit delay (0x0 value).

For left-aligned Q31 data, the following transmit format unit settings process the data into right-aligned data, ready for transmission:

- MCASP_TXFMT[2:0] XROT = 0x2 (rotate right by 8 bits) - for 24-bit output audio data
- MCASP_TXFMT[2:0] XROT = 0x3 (rotate right by 12 bits) - for 20-bit output audio data
- MCASP_TXFMT[2:0] XROT = 0x4 (rotate right by 16 bits) - for 16-bit output audio data
- MCASP_TXFMT[15] XRVRS = 0x0 – Bit reversal is not enabled; the McASP naturally transmits and receives in an LSB-first order.
- MCASP_TXMASK[32] XMASK = 0xFFFFFF00 – 0xFFFF0000
- MCASP_TXFMT[14:13] XPAD = 0x0 (Pad extra bits with 0s.)

For right-aligned data, the following transmit format unit settings process the data into right-aligned audio data ready for transmission:

- MCASP_TXFMT[2:0] XROT = 0x0 (rotate right by 0 bits regardless of the audio word length)
- MCASP_TXFMT[15] XRVRS = 0x0 – Bit reversal is not enabled; the McASP naturally transmits and receives in an LSB-first order.
- MCASP_TXMASK[32] XMASK = 0x00FFFFFF – 0x0000FFFF

Copyright © 2011–2012, Texas Instruments Incorporated

- MCASP_TXFMT[14:13] XPAD = 0x0 (Pad extra bits with 0s.)

The example settings provided in Table 24-581 should be applied to McASP in cases when Q31 data is transmitted as a 24-, 20- and 16-bit left- or right-aligned audio word, respectively. Note that the listed settings allow the McASP TFU to preserve the most significant bits and cut only the LSBs of the original Q31 MPU data.

Table 24-581. McASP TFU Example Settings

Output audio word alignment	Audio Word Length	Right-rotation (multiple of 4-bit positions)	XMASK	XROT
LEFT	16	16	0xFFFF0000	0x4
LEFT	20	12	0xFFFFF000	0x3
LEFT	24	8	0xFFFFFF00	0x2
RIGHT	16	0	0x0000FFFF	0
RIGHT	20	0	0x000FFFFF	0
RIGHT	24	0	0x00FFFFFF	0

Assume the Q31 data word 0xFA5AFxxx (where x-marked nibbles of the data are applied as padding bits of the word) is generated by the MPU on the McASP CFG (peripheral) port. To transmit a left-aligned 20-bit version of the same word while preserving the MSBs in accordance with Table 24-581, the user sets XMASK=0xFFFFF000, and selects a right-rotation of 12 positions (XROT=0x3).

- After applying 0s (XPAD=0) as masking-off bits at the first TFU stage, the word is transformed to the word 0xFA5AF000.
- After a rotation by 12 positions to the right in TFU, the 20-bit output word obtained is 0x000FA5AF. The word gets ready for transmission being mapped with its LS-bit as bit 8 and its MS-bit as bit 27 within a S/PDIF bitstream. This word is shifted in a LSB-to-MSB order (XRVRS = 0x0) out of the XRSR register during a DIT transmission.

Assume that a right-aligned Q31 data word 0x yyyyE4B4 is generated by the MPU on the McASP CFG (peripheral) port (with the presumption that y-marked nibbles of the input data are applied as padding bits). To transmit a right-aligned 16-bit version of same word while preserving the MSBs in accordance with Table 24-581, the user sets XMASK=0x0000FFFF, and selects right-rotation to 0 positions (XROT=0x0).

- After masking-off with 0s at first TFU stage, the word is transformed to 0x0000E4B4.
- Since no rotation is applied, the 16-bit output word obtained is actually the one obtained in the masking stage: 0x0000E4B4.

The examples use internal representation in integer and Q31 notation, but other fractional notations are also possible.

24.8.4.5 Transmit State-Machine

The transmit state-machine controls the interactions between the various units in the transmit section. In addition, the state-machine keeps track of error conditions and serial port status. No serial transfers can occur until the transmit state-machine is released from reset.

The transmit state-machine is controlled by the transmit bitstream format register (MCASP_TXFMT) and it reports the McASP status and error conditions in the transmitter status register (MCASP_TXSTAT).

24.8.4.6 Transmit TDM Sequencer

The time division multiplexing (TDM) sequencer is used to count the 384 subframes (slots) in the DIT block. If currently transmitting slot 1, slot 2 (next value of the TDM slot counter) should be used during the encode phase to select the appropriate C, V, and U bit, because the data encoded and written to the MCASP_TXBUF0 register during the current time slot (slot 1) is actually shifted out on the next time slot.

The transmit TDM sequencer is controlled by the MCASP_TXTDM register and reports the current transmit slot to the MCASP_TXTDMSLOT[9:0] XSLOTCNT bit field.

Copyright © 2011–2012, Texas Instruments Incorporated

24.8.4.7 McASP Software Reset

The McASP can be put into reset through the global transmit control register (MCASP_GBLCTL). A valid serial clock must be supplied to the McASP to assert the software reset bits in the MCASP_GBLCTL register.

24.8.4.8 McASP Power Management

Table 24-582 describes power-management features available to the McASP.

Table 24-582. Local Power-Management Features

Feature	Registers	Description
Slave idle modes	MCASP_SYSCONFIG[1:0] IDLE_MODE	Force-idle, no-idle, and smart-idle modes are available.

24.8.4.9 Transfer Modes

24.8.4.9.1 DIT Transfer Mode

The DIT transfer mode of the McASP also supports transmission of audio data in S/PDIF, AES-3, and IEC-60958 formats. These formats are designed to carry audio data between different systems through an optical or coaxial cable. The DIT mode applies only to a serializer configured as transmitter, not receiver. For a description of the S/PDIF format, see Section 24.8.2.2.3, *S/PDIF Coding Format*.

24.8.4.9.1.1 Transmit DIT Encoding

When the McASP operates in DIT mode, the data transmitted is output as a biphase-mark encoded bitstream, with preamble, channel status, user data, validity, and parity automatically stuffed into the bitstream by the McASP. The McASP includes separate validity bits for even/odd subframes and two 384-bit RAM modules to hold channel status and user data bits.

The transmit TDM time slot register (MCASP_TXTDM) should be programmed to all 1s during DIT mode. TDM functionality is not supported in DIT mode, except that the TDM slot counter counts the DIT subframes.

To transmit data in DIT mode, the following pins are typically required:

- abe_mcasp_ahclkx – transmit high-frequency master clock (The internal clock source can be used instead.)
- One serial data pin, abe_mcasp_axr, with serializer configured to transmit

The actual 24-bit audio data must always be in bit positions 23–0 after passing through the first three stages of the transmit format unit.

24.8.4.9.1.2 Transmit DIT Clock and Frame-Sync Generation

The DIT transmitter works only in the following configuration:

- In the transmit frame control register (MCASP_TXFMCTL):
  - Internally generated transmit frame sync, FSXM = 1
  - Rising-edge frame sync, FSXP = 0
  - Bit-width frame sync, FXWID = 0
  - 384-slot TDM, XMOD = 1 1000 0000b
- In the transmit clock control register (MCASP_ACLKXCTL), ASYNC = 1
- In the transmit bitstream format register (MCASP_TXFMT), XSSZ = 1111 (32-bit slot size)

All combinations of abe_mcasp_ahclkx and abe_mcasp_aclkx are supported.

The following summarizes the register configurations required for DIT mode. DIT mode-specific bit fields are in bold face:

Copyright © 2011–2012, Texas Instruments Incorporated

- MCASP_PFUNC: The data pin must be configured for McASP function. If abe_mcasp_ahclkx is used, it must also be configured for McASP function. Other pins can be configured to function as GPIOs, if desired.
- MCASP_PDIR: The data pin must be configured as output. If internal clock source AUXCLK is used as the reference clock, it may be output on the abe_mcasp_ahclkx pin by configuring abe_mcasp_ahclkx as an output.
- MCASP_GBLCTL: Global initialization
- MCASP_AMUTE: Program all fields according to the mute control desired.
- MCASP_TXDITCTL: The **DITEN** bit must be set to 1 to enable DIT mode. Configure other bits as desired.
- **MCASP_TXMASK**: Mask the desired bits, depending upon left-aligned or right-aligned internal data.
- **MCASP_TXFMT: XDATDLY** = 0. **XRVRS** = 0. **XPAD** = 0. **XSSZ** = Fh (32-bit slot). XBUSEL = configured as desired. The **XROT** bit is configured either 0 or 8-bit rotate.
- **MCASP_TXFMCTL**: Configure the bits according to former discussions.
- **MCASP_ACLKXCTL**: **ASYNC** = 1. Program the CLKXDIV bits to obtain the bit clock rate desired. CLKXM = 1.
- **MCASP_AHCLKXCTL**: Program the HCLKXDIV bits to obtain the high-frequency bit clock rate desired.
- **MCASP_TXTDM**: Set to FFFF FFFFh for all active slots for DIT transfers.
- MCASP_TXEVTCTL: Program all fields according to the interrupts desired.
- MCASP_TXCLKCHK: Program all fields according to the clock checking desired.
- MCASP_XRSRCTL0: Set **SRMOD** = 1 (transmitter) for the DIT pins.
- **MCASP_DITCSRAi** and **MCASP_DITCSRBi**: Program the channel status bits as desired.
- **MCASP_DITUDRAi** and **MCASP_DITUDRBi**: Program the user data bits as desired.

24.8.4.9.1.3 DIT Channel Status and User Data Register Files

The channel status registers (MCASP_DITCSRAi and MCASP_DITCSRBi) and user data registers (MCASP_DITUDRAi and MCASP_DITUDRBi) are not double-buffered. Typically, programmers use one of the synchronizing interrupts, such as the last slot, to create an event at a safe time so the register may be updated. In addition, the MPU reads the transmit TDM slot counter to determine which word of the register is being used.

It is a software requirement to avoid writing to the word of user data and channel status that are being used to encode the current time slot; otherwise, it is undetermined whether old or new data is used to encode the bitstream.

The DIT subframe format is defined in Section 24.8.2.2.3.2, *Subframe Format*. The channel status information (C) and user data (U) are defined in the following DIT control registers:

- MCASP_DITCSRA0 to MCASP_DITCSRA5: The 192 bits in these six registers contain the channel status information for the left channel within each frame.
- MCASP_DITCSRB0 to MCASP_DITCSRB5: The 192 bits in these six registers contain the channel status information for the right channel within each frame.
- MCASP_DITUDRA0 to MCASP_DITUDRA5: The 192 bits in these six registers contain the user data information for the left channel within each frame.
- MCASP_DITUDRB0 to MCASP_DITUDRB5: The 192 bits in these six registers contain the user data information for the right channel within each frame.
- The S/PDIF block format is shown in Figure 24-192. There are 192 frames within a block (frame 0 to frame 191). There are two subframes within each frame (subframes 1 and 2 for the left and right channels, respectively).

The channel status and user data information sent on each subframe is summarized in Table 24-583.

24.8.4.10 Data Transmission

The MPU services the McASP by writing data to the MCASP_TXBUF0 register for transmit operations. The McASP sets status flags and notifies the MPU whenever data is ready to be transmitted. Section 24.8.4.10.1, *Data Ready Status and Event/Interrupt Generation*, discusses data-ready status in detail.

The MCASP_TXBUF0 register can be accessed through one of the two peripheral ports of the device:

Copyright © 2011–2012, Texas Instruments Incorporated

- Data port (DAT): This port is dedicated to DMA-initiated data transfers on the device.
- Configuration bus (CFG): This port is used for data transfers and peripheral configuration control on the device.

Section 24.8.4.10.1.2, *Transfers Through the Data Port (DAT)*, and Section 24.8.4.10.1.3, *Transfers Through the Configuration Bus (CFG),* discuss how to perform transfers through the data port and the configuration port, respectively.

The MPU and DMA usages are discussed in Section 24.8.4.10.1.4, *Using the MPU for McASP Servicing*, and Section 24.8.4.10.1.5, *Using the DMA for McASP Servicing*, respectively.

24.8.4.10.1 Data Ready Status and Event/Interrupt Generation

24.8.4.10.1.1 Transmit Data Ready

The transmit data ready flag XDATA bit in the MCASP_TXSTAT register reflects the status of the MCASP_TXBUF0 register. The XDATA flag is set when data is transferred from the MCASP_TXBUF0[n] buffer to the XRSR[n] shift register, thus indicating that the MCASP_TXBUF0 is empty and ready to accept new data from the MPU. This flag is cleared when the XDATA bit is written with 1, or when the serializer configured as transmitter is written by the MPU.

Whenever XDATA is set, the DMA AXEVT event is automatically generated to notify the DMA of the MCASP_TXBUF0 empty status. An AXINTn interrupt is also generated if the XDATA interrupt is enabled in the MCASP_EVTCTLX register (for details, see Section 24.8.4.11.1, *Transmit Data Ready Interrupt*).

For DMA requests, the McASP does not require that MCASP_TXSTAT be read between DMA events. This means that, even if MCASP_TXSTAT already has the XDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

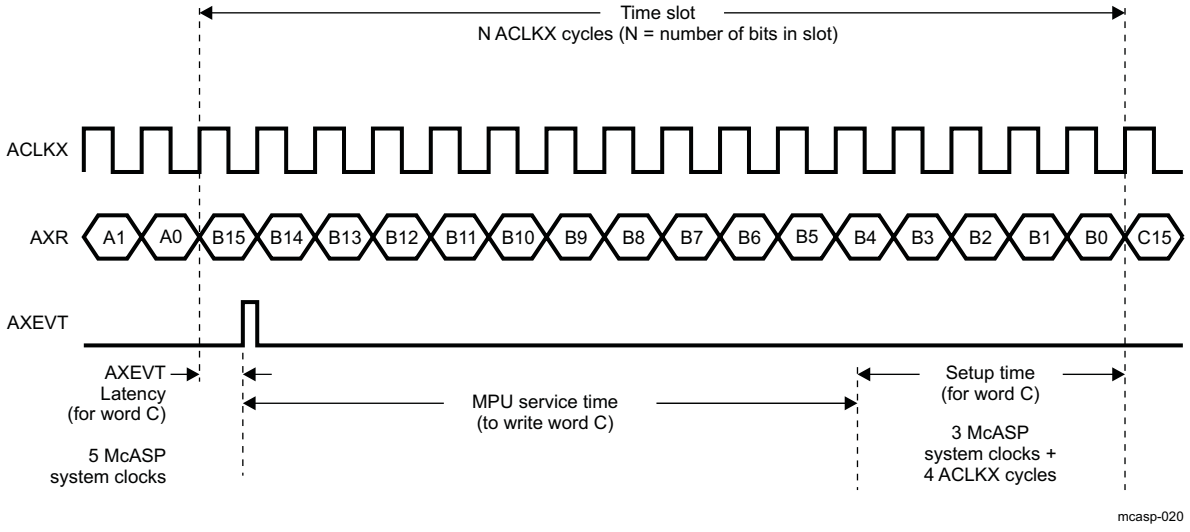
Because the serializer acts in lockstep, only one DMA event is generated to indicate that the transmit serializer is ready to be written to with new data.

Figure 24-198 shows the timing details of when AXEVT is generated at the McASP boundary. In this example, as soon as the last bit (A0) of word A is transmitted, the McASP sets the XDATA flag and generates an AXEVT event. However, it takes up to five McASP system clocks (AXEVT latency) before AXEVT is active at the McASP boundary. Upon AXEVT, the MPU can begin servicing the McASP by writing word C into the MCASP_TXBUF0 (service time). The MPU must write word C into the MCASP_TXBUF0 within the setup time required by the McASP (setup time).

The maximum service time (see Figure 24-198) can be calculated as:

Service Time = Time Slot – AXEVT Latency –Setup Time

Figure 24-198. MPU Service Time Upon Transmit DMA Event (AXEVT)



Copyright © 2011–2012, Texas Instruments Incorporated

24.8.4.10.1.2 Transfers Through the Data Port (DAT)

CAUTION

To perform internal transfers through the data port, clear the XBUSEL bit to 0 in the MCASP_TXFMT register. Failure to do so may result in software malfunction.

In a typical McASP transfer scenario, a DMA accesses the MCASP_TXBUF0 through the data port (DAT). To access through the data port, simply have the DMA access MCASP_TXBUF0 through its data port location.

NOTE: The DAT port allows the DMA to access only the transmit buffer MCASP_TXBUF0 register. There is no way to access the McASP configuration registers within the DMA DAT port address ranges.

NOTE: To service the transmit serializer, the DMA must write to the MCASP_TXBUF0 register using its L3 data port (DAT) address, while MPU/DSP must write to same register using its CFG (peripheral) port address. For more details about aaddressing MCASP_TXBUF0 through CFG and DAT ports, see Section 24.8.6.2.1, *McASP Register Summary*.

When transmitting, the DMA/MPU must write data to the serializer and transmit within each time slot. Failure to do so may result in a buffer underrun condition (see Section 24.8.4.14.1, *Buffer Underrun Error – Transmitter*).

24.8.4.10.1.3 Transfers Through the Configuration Bus (CFG)

CAUTION

To perform internal transfers through the configuration bus, set the XBUSEL bit to 1 in the MCASP_TXFMT register. Failure to do so may result in software malfunction.

In this method, the DMA/MPU accesses the MCASP_TXBUF0 register through the configuration bus address.

When transmitting, the DMA/MPU must write data to the serializer and transmit within each time slot. Failure to do so may result in a buffer underrun condition (Section 24.8.4.14.1, *Buffer Underrun Error – Transmitter*).

24.8.4.10.1.4 Using the MPU for McASP Servicing

The MPU can be used to service the McASP through interrupts (upon MCASP_AXINT interrupt) or through polling the XDATA bit in the MCASP_TXSTAT register. As discussed in Section 24.8.4.10.1.2, *Transfers Through the Data Port (DAT)*, and Section 24.8.4.10.1.3, *Transfers Through the Configuration Bus (CFG)*, the MPU can access the McASP XBUF serializer buffer through the CFG port.

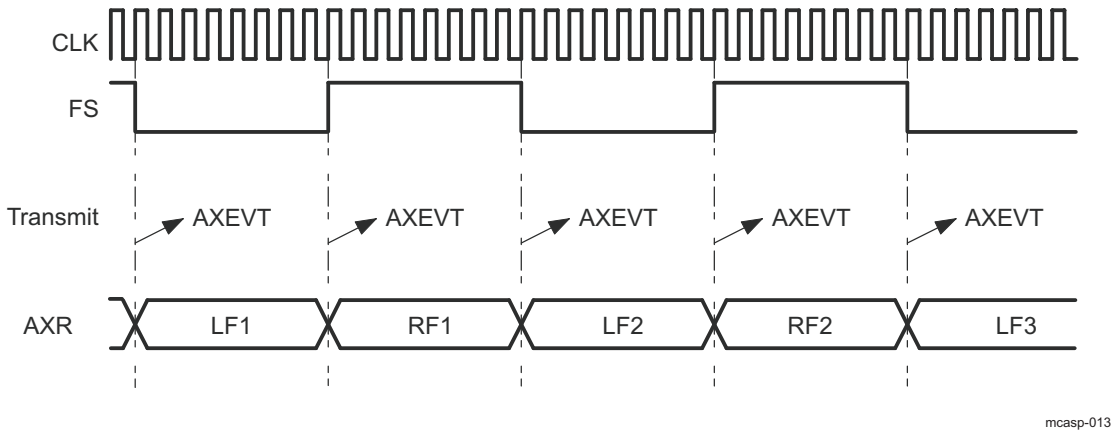
To use the MPU to service the McASP through interrupts, the XSTAT bit must be enabled in the MCASP_TXEVTCTL register to generate the MCASP_AXINT interrupt to the MPU upon data ready.

24.8.4.10.1.5 Using the DMA for McASP Servicing

The typical scenario is to use the DMA to service the McASP through the data port, although the DMA can also service the McASP through the configuration bus.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-199. DMA Transmit Event in an Audio Example – One Event



The DMA event AXEVT, which is triggered upon each XDATA transition from 0 to 1, is used to service the McASP transmit buffer (XBUF). Figure 24-199 is an example of an audio system with two audio channels (LF and RF) transmitted through the abe_mcasp_axr pin on the McASP. It shows the points at which event AXEVT is triggered.

The DMA AXEVT event is triggered on each time slot. In the example, AXEVT is triggered for each transmit audio channel time slot (time slot for channel LF, and time slot for channel RF). DMA events are generated automatically upon data ready, whereas MPU interrupt generation must be enabled in the MCASP_EVTCTLX register.

24.8.4.11 Interrupt Requests

Table 24-584 lists the event flags that can cause module interrupts.

Table 24-584. TX Events

Event Mask	Event Flag	Map to	Description
MCASP_EVTCTLX[0] XUNDRN	MCASP_TXSTAT[0] XUNDRN	MCASP_AXINT	Transmit underrun
MCASP_EVTCTLX[1] XSYNCERR	MCASP_TXSTAT[1] XSYNCERR	MCASP_AXINT	Unexpected transmit frame sync
MCASP_EVTCTLX[2] XCKFAIL	MCASP_TXSTAT[2] XCKFAIL	MCASP_AXINT	Transmit clock failure
MCASP_EVTCTLX[4] XLAST	MCASP_TXSTAT[4] XLAST	MCASP_AXINT	Transmit last slot interrupt
MCASP_EVTCTLX[5] XDATA	MCASP_TXSTAT[5] XDATA	MCASP_AXINT	Transmit data-ready interrupt
MCASP_EVTCTLX[7] XSTAFRM	MCASP_TXSTAT[7] XSTAFRM	MCASP_AXINT	Transmit start of frame interrupt

An interrupt line is asserted (active high) when one of these events occurs. Read the MCASP_TXSTAT register to determine which event occurs.

24.8.4.11.1 Transmit Data Ready Interrupt

The transmit data-ready interrupt (XDATA) is generated if XDATA is 1 in the MCASP_TXSTAT register and XDATA is enabled in MCASP_EVTCTLX. Section 24.8.4.10.1, *Data Ready Status and Event/Interrupt Generation*, provides details on when XDATA is set in the MCASP_TXSTAT register.

A transmit-start-of-frame interrupt (XSTAFRM) is triggered by the recognition of a transmit frame sync.

A transmit-last-slot interrupt (XLAST) is a qualified version of the data-ready interrupt (XDATA). It has the same behavior as the data-ready interrupt, but is further qualified by having the data requested belonging to the last slot (the slot that just ended is the next-to-last TDM slot, the current slot is the last slot).

24.8.4.11.2 Error Interrupt

Upon detection, the following error conditions generate interrupt flags:

Copyright © 2011–2012, Texas Instruments Incorporated

In the transmit status register (MCASP_TXSTAT):

- Transmit underrun (XUNDRN)
- Transmit DMA error (XDMAERR)

Each interrupt source also has a corresponding enable bit in the transmit interrupt control register (MCASP_EVTCTLX). If the enable bit is set, an interrupt is requested when the interrupt flag is set in MCASP_TXSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

24.8.4.12 DMA Requests

The McASP can generate one DMA request to the sDMA and eDMA controllers to transmit data (MCASP_AXEVT).

A DMA request to transmit data is generated if the XDATDMA bit in the MCASP_TXEVTCTL register is cleared.

24.8.4.13 Audio Mute (AMUTE) Function

The McASP includes an automatic audio mute function (see Figure 24-200) that asserts, in hardware, the AMUTE pin to a preprogrammed output state, as selected by the MUTEN bit in the audio mute control register (MCASP_AMUTE). The AMUTE pin is asserted when one of the interrupt flags is set or an external device issues an error signal on the abe_mcasp_amutein input. Typically, the abe_mcasp_amutein input is shared with a device interrupt pin.

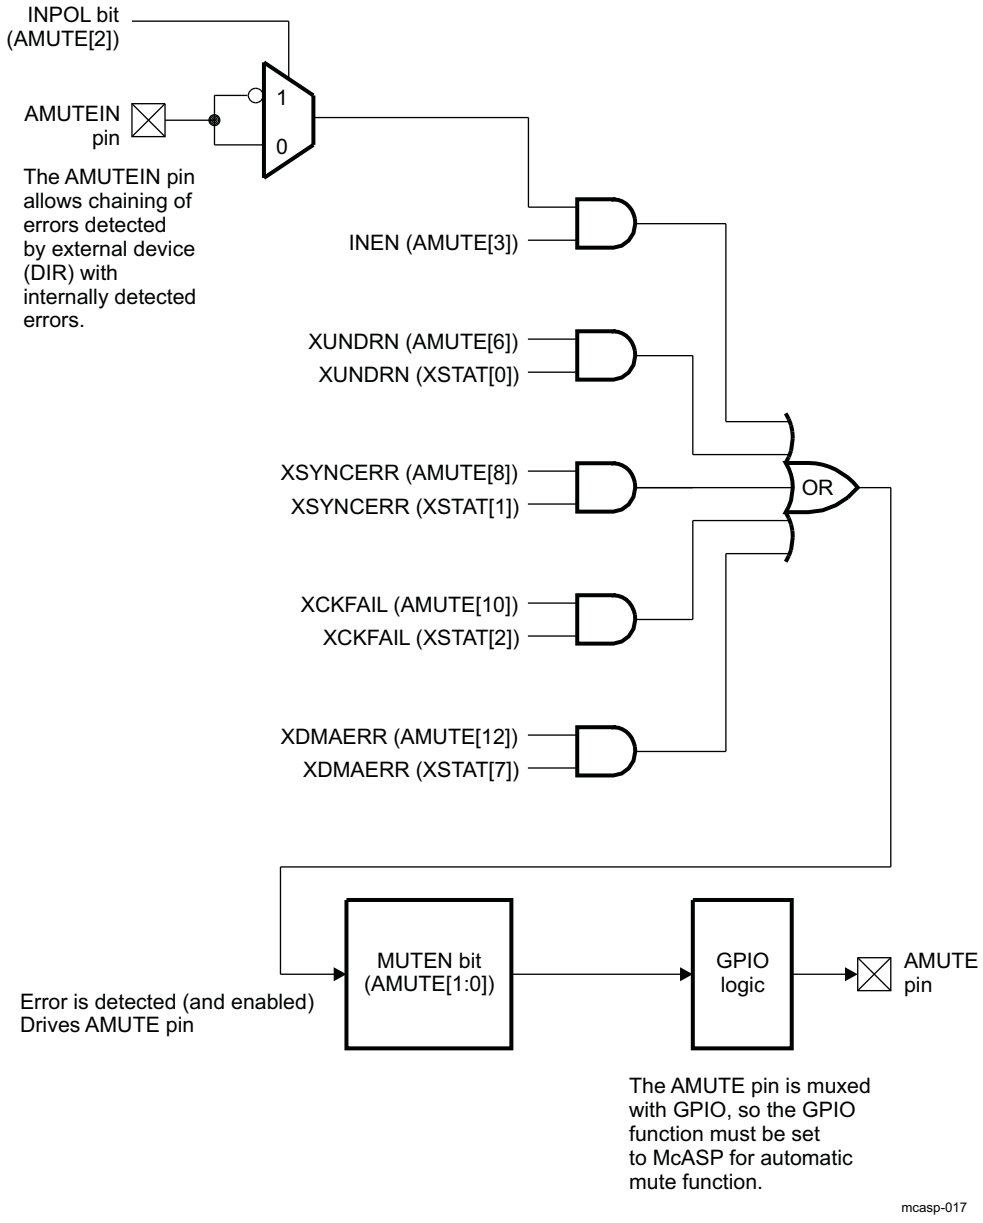
The abe_mcasp_amutein input allows the on-chip logic to consider a mute input from other devices in the system so that all errors may be considered. The abe_mcasp_amutein input has a programmable polarity to allow it to adapt to different devices, as selected by the INPOL bit in the MCASP_AMUTE register, and it must be explicitly enabled.

In addition to the external abe_mcasp_amutein input, the abe_mcasp_amute pin output may be asserted when one of the error interrupt flags is set and its mute function is enabled in the MCASP_AMUTE register.

When one or more errors are detected and enabled, the abe_mcasp_amute pin is driven to an active state that is selected by MUTEN in the MCASP_AMUTE register. The active polarity of the AMUTE pin is programmable by the MUTEN bit (the inactive polarity is the opposite of the active polarity). The abe_mcasp_amute pin remains driven active until software clears all the error interrupt flags that are enabled to mute, and until the abe_mcasp_amutein is inactive.

Copyright © 2011–2012, Texas Instruments Incorporated

Figure 24-200. Audio Mute (AMUTE) Block Diagram



24.8.4.14 Error Reporting

The McASP includes error-checking capability for the serial protocol and data underrun. In addition, the McASP includes a timer that continually measures the high-frequency master clock every 32 AHCLKX clock cycles. The value of the timer can be read to get a measurement of the clock frequency and has a minimum and maximum range setting that can set an error flag if the master clock goes out of a specified range.

When one or more errors (software selectable) are detected or the abe_mcasp_amutein input pin is asserted, the abe_mcasp_amute output pin may be asserted to a high or low level to immediately mute the audio output. In addition, an interrupt can be generated if desired, based on one or more error sources.

Copyright © 2011–2012, Texas Instruments Incorporated

24.8.4.14.1 Buffer Underrun Error –Transmitter

A buffer underrun occurs when the serializer is instructed by the transmit state-machine to transfer data from MCASP_TXBUF0 to XRSR, but MCASP_TXBUF0 has not yet been written with new data since the last time the transfer occurred. When this occurs, the transmit state-machine sets the XUNDRN flag.

An underrun is checked only once per time slot. The MCASP_TXSTAT[0] XUNDRN flag is set when an underrun condition occurs. Once set, the XUNDRN flag remains set until the host explicitly writes 1 to the XUNDRN bit to clear it.

A pair of BMC zeros is shifted out when an underrun occurs (four bit times at 128 bfs). By shifting out a pair of zeros, a clock can be recovered on the receiver. To recover, reset the McASP and restart with the proper initialization.

24.8.4.14.2 DMA Error –Transmitter

A transmit DMA error, as indicated by the XDMAERR flag in the MCASP_TXSTAT register, occurs when the DMA writes more words to the data port of the McASP than it should.

XDMAERR indicates that the DMA wrote too many words to the McASP for a given transmit DMA event. Writing too few words results in a transmit underrun error setting XUNDRN in MCASP_TXSTAT.

While XDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA. The McASP transmitter and the DMA must be reinitialized to resynchronize them.

24.8.4.14.3 Clock Failure Detection

24.8.4.14.3.1 Clock Failure Check Startup

It is initially expected of the clock failure circuits to generate an error until at least one measurement is taken. Therefore, the clock failure interrupts, clock switch, and mute functions should not be enabled immediately, but only after a specific startup procedure.

The start the transmit clock failure check procedure:

1. Configure the transmit clock failure detect logic (XMIN, XMAX, XPS) in the transmit clock check control register (MCASP_TXCLKCHK).
2. Clear the transmit clock failure flag (XCKFAIL) in the transmit status register (MCASP_TXSTAT).
3. Wait until the first measurement is taken (> 32 AHCLKX clock periods).
4. Verify that no clock failure is detected.
5. Repeat Step 2 through Step 4 until the clock is running and is no longer issuing clock failure errors.
6. After the transmit clock is measured and falls within the acceptable range, the following can be enabled:
   (a) The transmit clock failure interrupt enable bit (XCKFAIL) in the transmitter interrupt control register (MCASP_EVTCTLX)
   (b) The mute option (XCKFAIL) in the mute control register (MCASP_AMUTE)

24.8.4.14.3.2 Transmit Clock Failure Check and Recovery

The transmit clock failure check circuit (see Figure 24-201) works off the internal McASP system clock and the external high-frequency serial clock (abe_mcasp_ahclkx). It continually counts the number of system clocks for every 32 high-rate serial clock (abe_mcasp_ahclkx) periods, and stores the count in XCNT of the transmit clock check control register (MCASP_TXCLKCHK) every 32 high-rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (XMIN), and automatically flags an interrupt (XCKFAIL in MCASP_TXSTAT) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is less than XMIN. The logic continually compares the current count (from the running system clock counter) to the maximum allowable boundary (XMAX). This is so that if the external clock completely stops, the counter value is not copied to XCNT. An out-of-range maximum condition occurs when the count is greater than XMAX. The XMIN and XMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

Copyright © 2011–2012, Texas Instruments Incorporated

An out-of-range count may indicate that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

For the transmit clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

If a clock failure is detected, the transmit clock failure flag (XCKFAIL) in MCASP_TXSTAT is set. This causes an interrupt if the transmit clock failure interrupt enable bit (XCKFAIL) in MCASP_EVTCTLX is set.

24.8.5 McASP Low-Level Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the McASP module.

24.8.5.1 Global Initialization

24.8.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the McASP module is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the McASP (for more information, see the Section 24.8.3 , *McASP Integration*, and Section 24.8.2, *McASP Environment*).

Table 24-585, describes the global initialization of surrounding modules.

Table 24-585. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module functional and interface clocks must be enabled. (See Chapter 3, *Power, Reset, and Clock Management*.)
Control module	Module-specific pad muxing and other pad configurations must be set in the control module. (See Chapter 19, *Control Module*).
(Optional) Cortex-A9 MPU INTC or DSP INTC	INTC configuration must be done to enable the interrupts from the McASP. (See Chapter 18, *Interrupt Controllers*).
(Optional) sDMA (or eDMA or aDMA)	DMA configuration must be done to enable the McASP DMA data channel requests.
(Optional) ABE_L4 and L3 Interconnects	For more information about the interconnect configuration, see Chapter 14, *Interconnect*.

NOTE: The MPU/DSP INTC and the sDMA/eDMA/aDMA configurations are required when the interrupt and DMA-based communication modes are used.

24.8.5.1.2 McASP Global Initialization

24.8.5.1.2.1 Main Sequence – McASP Global Initialization

The procedure in Table 24-586 initializes the McASP after a power-on reset (POR).

Table 24-586. McASP Global Initialization

Step	Register/Bit Field/Programming Model	Value
Apply software reset to different McASP components.	MCASP_GBLCTL[12:8]	0x00
Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[12:8]	=0x00
Configure the local power management.	MCASP_SYSCONFIG[1:0] IDLE_MODE	0x-
Configure the transmit format unit.	See Section 24.8.5.1.2.2.	
Configure the transmit frame sync generator.	See Section 24.8.5.1.2.3.	
Configure the transmit clock generator.	See Section 24.8.5.1.2.4.	
Configure the TDM sequencer—set all slots active.	MCASP_TXTDM[31:0] XTDMS	0xFFFF FFFF
Configure the serializer for transmit mode operation.	MCASP_XRSRCTL0[1:0] SRMOD	0x1
Configure the McASP pins functionality.	See Section 24.8.5.1.2.5.	
Configure the McASP mute input/output conditions.	See Table 24-591.	
Enable the McASP DIT-transmission mode.	MCASP_TXDITCTL[0] DITEN	0x1
Configure DIT-specific subframe fields.	See Table 24-592.	

Copyright © 2011–2012, Texas Instruments Incorporated

Table 24-586. McASP Global Initialization (continued)

Step	Register/Bit Field/Programming Model	Value
Release from reset state the divider that outputs the abe_mcasp_ahclkx clock.(1)	MCASP_GBLCTL[9] XHCLKRST	0x1
Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[9] XHCLKRST	=0x1
Release from reset state the divider that outputs the abe_mcasp_aclkx clock. (1)	MCASP_GBLCTL[8] XCLKRST	0x1
Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[8] XCLKRST	=0x1

(1) During reset state the local McASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP_AHCLKX and MCASP_ ACLKX registers are ignored; hence, the transmission clock does not stop during the reset state of the dividers.

24.8.5.1.2.2 Subsequence – Transmit Format Unit Configuration

The procedure in Table 24-587 configures the transmit frame format unit of the McASP module.

NOTE:

- The first transmit data bit always has a 0-bit delay.
- The bitstream is always transmitted in least-significant-bit (LSB)-first order.
- Pad value for extra bits in a certain slot is always 0.

Table 24-587. Transmit Format Unit Configuration

Step	Register/Bit Field/Programming Model	Value
Configure the slot size to 32 bits.	MCASP_TXFMT[7:4] XSSZ	0xF
IF: the MPU or DMA data to transmit is left- aligned	Software test condition	
Set data mask in the range 0xFFFF FF00 – 0xFFFF 0000.	MCASP_TXMASK[31:0] XMASK	0x-(1)
Rotate data right by a multiple-of-4 bit positions.	MCASP_TXFMT[2:0] XROT	0x-(1)
ELSE		
Set data mask in the range 0x00FF FFFF– 0x0000 FFFF.	MCASP_TXMASK[31:0] XMASK	0x-(1)
Rotate data right by 0-bit positions.	MCASP_TXFMT[2:0] XROT	0x0
ENDIF		

(1) See Section 24.8.4.4, *Format Unit*.

24.8.5.1.2.3 Subsequence – Transmit Frame Synchronization Generator Configuration

The procedure in Table 24-588 configures the transmit frame synchronization generator of the McASP module.

NOTE: The frame synchronization signal is always rising-edge active and always has a single-bit width.

Table 24-588. Transmit Frame-Synchronization Generator Configuration

Step	Register/Bit Field/Programming Model	Value
Select 384-slot size block.	MCASP_TXFMCTL[15:7] XMOD	0x180
Select internally-generated transmit frame sync.	MCASP_TXFMCTL[1] FSXM	0x1

Copyright © 2011–2012, Texas Instruments Incorporated

24.8.5.1.2.4 Subsequence – Transmit Clock Generator Configuration

NOTE: By default, the ACLKX and AHCLKX clocks are generated only from the McASP internal clock source.

The procedure in Table 24-589 configures the transmit clock generator of the McASP module.

Table 24-589. Transmit Clock Generator Configuration

Step	Register/Bit Field/Programming Model	Value
Set the divisor for the internally generated high frequency clock– abe_mcasp_ahclkx.	MCASP_AHCLKXCTL[11:0] HCLKXDIV	0x-
Set he divisor for the internally generated transmission clock– abe_mcasp_aclkx.	MCASP_ACLKXCTL[4:0] CLKXDIV	0x-
Configure the transmit clock failure detect logic.	See Section 24.8.4.14.3.1, *Clock Failure Check Startup*.	

24.8.5.1.2.5 Subsequence—McASP Pins Functional Configuration

The procedure in Table 24-590 configures the McASP pins for McASP functionality.

Table 24-590. McASP Pins Functional Configuration

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have McASP functionality.	MCASP_PFUNC[31:0]	0x0
Configure the McASP pins as outputs: abe_mcasp_afsx abe_mcasp_ahclkx abe_mcasp_aclkx abe_mcasp_amute abe_mcasp_axr	MCASP_PDIR[28] AFSX; MCASP_PDIR[27] AHCLKX; MCASP_PDIR[26] ACLKX; MCASP_PDIR[25] AMUTE; MCASP_PDIR[0] AXR0;	0x1 0x1 0x1 0x1 0x1

24.8.5.1.2.6 Subsequence – McASP Mute Input/Output Trigger Condition Settings

The procedure in Table 24-591 configures the behavior of the mute associated I/Os and different trigger conditions for the McASP mute output functionality.

Table 24-591. McASP Mute Input/Output Trigger Condition Settings

Step	Register/Bit Field/Programming Model	Value
Optional: Select to drive AMUTE active enable bit on transmit DMA error.	MCASP_AMUTE[12] XDMAERR	0x1
Optional: Select to drive AMUTE active enable bit on transmit clock failure.	MCASP_AMUTE[10] XCKFAIL	0x1
Optional: Select to drive AMUTE active enable bit on transmit frame synchronization error.	MCASP_AMUTE[8] XSYNCERR	0x1
Optional: Select to drive AMUTE active enable bit on transmit underrun error.	MCASP_AMUTE[6] XUNDRN	0x1
Optional: Enable sensitivity of the abe_mcasp_amute output to abe_mcasp_amutein error source.	MCASP_AMUTE[3] INEN	0x1
Optional: Select the abe_mcasp_amutein input polarity.	MCASP_AMUTE[2] INPOL	0x1
Optional: Configure the behavior of the abe_mcasp_amute output.	MCASP_AMUTE[1:0] MUTEN	0x1

Copyright © 2011–2012, Texas Instruments Incorporated

24.8.5.1.2.7 Subsequence – DIT-Specific Subframe Fields Configuration

NOTE: The McASP integrated in the device supports only the DIT transmission mode that uses the S/PDIF protocol.

The procedure in Table 24-592 configures the DIT-specific subframe fields as part of the S/PDIF format data.

Table 24-592. DIT-Specific Subframe Fields Configuration

Step	Register/Bit Field/Programming Model	Value
Configure the valid bit value for odd time slots.	MCASP_TXDITCTL[3] VB	0x-
Configure the valid bit value for even time slots.	MCASP_TXDITCTL[2] VA	0x-
Configure the user data bit for each subframe A and B in a 384-slot S/PDIF block.	MCASP_DITUDRAi[31:0] DITUDRAi, where i = 0 to 5 MCASP_DITUDRBi[31:0] DITUDRBi, where i= 0 to 5	0x- 0x-
Configure the channel status bit for each subframe A and B in a 384-slot S/PDIF block.	MCASP_DITCSRAi[31:0] , where i = 0 to 5 MCASP_DITCSRBi[31:0] , where i = 0 to 5	0x- 0x-

24.8.5.2 Operational Modes Configuration

24.8.5.2.1 McASP DIT Transmission Mode

24.8.5.2.1.1 Main Sequence – McASP DIT Polling Transmission Method

Figure 24-202 shows the McASP DIT polling method.

NOTE:

- The McASP polling transmission model considers the MPU/DSP as the source of audio data for the McASP transmission buffer.
- The DMA request is disabled and the XDMAERR event is not analyzed.
- The flow chart shown in Figure 24-202 shows the sequence for transmitting one DIT frame.

Table 24-595. McASP Interrupt Transmission Model

Step	Register/Bit Field/Programming Model	Value
Select the CFG (peripheral) port to access the transmit buffer.	MCASP_TXFMT[3] XBUSEL	0x1
Disable DMA requests generation.	MCASP_TXEVTCTL[0] XDATDMA	0x1
Clear the transmitter status logic.	MCASP_TXSTAT[8:0]	0xFF
Enable the data ready event transmit interrupt.	MCASP_EVTCTLX[5] XDATA	0x1
Optional: Enable the transmit error event interrupts.	MCASP_EVTCTLX[2] XCKFAIL MCASP_EVTCTLX[1] XSYNCERR MCASP_EVTCTLX[0] XUNDRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt.	MCASP_EVTCTLX [7] XSTAFRM MCASP_EVTCTLX[4] XLAST	0x1 0x1
Disable the DMA error event.	MCASP_EVTCTLX[7] XDMAERR	0x0
DIT transmission startup procedure	See Figure 24-203.	

Table 24-596 summarizes the register call to initialize the McASP to transmit using interrupt events.

Table 24-596. Register Call Summary for Subsequence – McASP DIT Transmission Startup Procedure

Register Name	Register Name
MCASP_GBLCTL	MCASP_TXBUF0

24.8.5.2.1.3 Main Sequence –McASP DIT DMA Transmission Method

Table 24-597 shows the configuration of the McASP using the DMA method for transmission. Possible interrupt error event servicing is also considered. Table 24-596 shows the initial setup for DMA-based transmission.

NOTE: Because of the DATA port burst access capability with the DMA method, It is preferable for transfers to be initiated through the DATA port rather than through the CFG port.

Table 24-597. McASP DMA Transmission Model with Interrupt Events Servicing

Step	Register/Bit Field/Programming Model	Value
Select DATA port to access the transmit buffer.	MCASP_TXFMT[3] XBUSEL	0x0
Enable the DMA requests generation.	MCASP_TXEVTCTL[0] XDATDMA	0x0
Clear the transmitter status logic.	MCASP_TXSTAT[8:0]	0xFF
Enable the DMA error event.	MCASP_EVTCTLX[7] XDMAERR	0x1
Optional: Enable the transmit error event interrupts.	MCASP_EVTCTLX[2] XCKFAIL MCASP_EVTCTLX[1] XSYNCERR MCASP_EVTCTLX[0] XUNDRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt.	MCASP_EVTCTLX [7] XSTAFRM MCASP_EVTCTLX[4] XLAST	0x1 0x1
Disable the data ready event transmit interrupt.	MCASP_EVTCTLX[5] XDATA	0x0

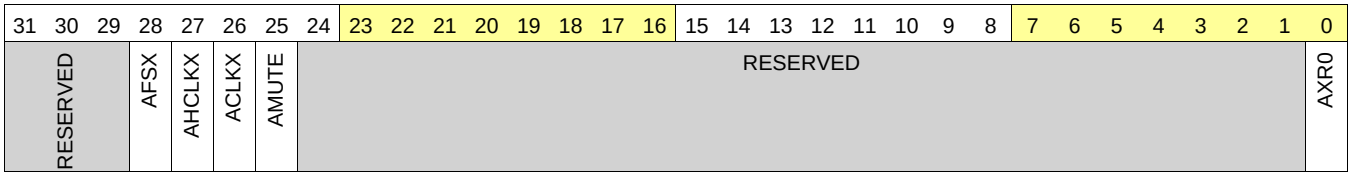
Table 24-612. MCASP_PDOUT

Address Offset	0x0000 0018
Physical Address	0x4902 8018 0x4012 8018 0x01D2 8018
Description	Pin data output register - holds a value for data out at all times, and may be read back at all times. The value held by MCASP_PDOUT is not affected by writing to MCASP_PDIR and MCASP_PFUNC. However, the data value in MCASP_PDOUT is driven out onto the McASP pin only if the corresponding bit in MCASP_PFUNC is set to 1 (GPIO function) and the corresponding bit in MCASP_PDIR is set to 1 (output). When reading data, it returns the corresponding bit value in MCASP_PDOUT[n]; it does not return the input from the I/O pin. When writing data, writes to the corresponding MCASP_PDOUT[n] bit. PDOUT has these aliases or alternate addresses: • MCASP_PDSET - when written to at this address, writing a 1 to a bit in MCASP_PDSET sets the corresponding bit in MCASP_PDOUT to 1; writing a 0 has no effect and keeps the bits in MCASP_PDOUT unchanged. • MCASP_PDCLR - when written to at this address, writing a 1 to a bit in MCASP_PDCLR clears the corresponding bit in MCASP_PDOUT to 0; writing a 0 has no effect and keeps the bits in MCASP_PDOUT unchanged There is only one set of data-out bits, MCASP_PDOUT[31:0]. The other registers, MCASP_PDSET and MCASP_PDCLR, are just different addresses for the same control bits, with different behaviors during writes.
Type	RW



Bits	Field Name	Description	Type	Reset
31:29	RESERVED	Reserved	RW	0
28	AFSX	Determines drive on AFSX output pin when the corresponding MCASP_PFUNC[28] and MCASP_PDIR[28] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
27	AHCLKX	Determines drive on AHCLKX output pin when the corresponding MCASP_PFUNC[27] and MCASP_PDIR[27] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
26	ACLKX	Determines drive on ACLKX output pin when the corresponding MCASP_PFUNC[26] and MCASP_PDIR[26] bits are set to 1 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
25	AMUTE	Determines drive on AMUTE output pin when the corresponding MCASP_PFUNC[25] and MCASP_PDIR[25] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
24:1	RESERVED	Reserved	RW	0x000
0	AXR0	Determines drive on abe_mcasp_axr output pin when the corresponding MCASP_PFUNC[0] and MCASP_PDIR[0] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0

Table 24-620. MCASP_GBLCTL

Address Offset	0x0000 0044		
Physical Address	0x4902 8044 0x4012 8044 0x01D2 8044	**Instance**	MCASP_L3 MCASP_CORTEX-A9 MCASP_DSP
Description	Global transmit control register - provides initialization of the transmit section. The bit fields in MCASP_GBLCTL are synchronized and latched by the abe_mcasp_aclkx clock. Before programming MCASP_GBLCTL, ensure that the serial clocks are running. If the corresponding external serial clock, abe_mcasp_clkx, is not yet running, select the internal serial clock source in AHCLKXCTL and ACLKXCTL before programming MCASP_GBLCTL. Also, after programming any bits in MCASP_GBLCTL, do not proceed until reading back from MCASP_GBLCTL and verifying that the bits in MCASP_GBLCTL are latched.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																			XFRST	XSMRST	XSRCLR	XHCLKRST	XCLKRST	RESERVED							

Bits	Field Name	Description	Type	Reset
31:13	RESERVED	Reserved	RW	0x00000
12	XFRST	Transmit frame-sync generator reset enable bit 0x0: The transmit frame-sync generator is reset. 0x1: The transmit frame-sync generator is active. When released from reset, the transmit frame-sync generator begins counting serial clocks and generating frame sync as programmed.	RW	0
11	XSMRST	Transmit state-machine reset enable bit 0x0: The transmit state-machine is held in reset. abe_mcasp_axr pin state: If MCASP_PFUNC[0] = 0 and MCASP_PDIR[0] = 1, the serializer drives the abe_mcasp_axr pin to the state specified for inactive time slot 0x1: The transmit state-machine is released from reset. When released from reset, the transmit state-machine immediately transfers data from XBUF[n] to XRSR[n]. The transmit state-machine sets the underrun flag (XUNDRN) in MCASP_TXSTAT, if XBUF[n] have not been preloaded with data before reset is released. The transmit state-machine also immediately begins detecting frame sync and is ready to transmit. Transmission of TDM time slot begins at slot 0 after reset is released.	RW	0
10	XSRCLR	Transmit serializer clear enable bit. By clearing and then setting this bit, the transmit buffer is flushed to an empty state (XDATA = 1). If XSMRST = 1, XSRCLR = 1, XDATA = 1, and XBUF is not loaded with new data before the start of the next active time slot, an underrun occurs. 0x0: The transmit serializer is cleared. 0x1: The transmit serializer is active. When the transmit serializer is first taken out of reset (XSRCLR changes from 0 to 1), the transmit data ready bit (XDATA) in MCASP_TXSTAT is set to indicate XBUF is ready to be written.	RW	0
9	XHCLKRST	Transmit high-frequency clock divider reset enable bit 0x0: The transmitter high-frequency clock divider is held in reset. 0x1: The transmitter high-frequency clock divider is running.	RW	0
8	XCLKRST	Transmit clock divider reset enable bit 0x0: The transmit clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input. 0x1: The transmit clock divider is running.	RW	0

Bits	Field Name	Description	Type	Reset
4	INSTAT	Status of mute in pin, determines drive on abe_mcasp_axr pin when the MCASP_PFUNC[0] and MCASP_PDIR[0] bits are set to 1. Read 0x0: Inactive Read 0x1: Active. Audio mute in error is detected.	R	0
3	INEN	Drive abe_mcasp_amute active when abe_mcasp_amutein error is active. 0x0: Drive is disabled. abe_mcasp_amutein is ignored by abe_mcasp_amute. 0x1: Drive is enabled (active). INSTAT = 1 drives abe_mcasp_amute active.	RW	0
2	INPOL	Audio mute in (abe_mcasp_amutein) polarity select bit 0x0: Polarity is active high. A high on abe_mcasp_amutein sets INSTAT to 1. 0x1: Polarity is active low. A low on abe_mcasp_amutein sets INSTAT to 1.	RW	0
1:0	MUTEN	abe_mcasp_amute pin enable bit field (unless overridden by GPIO registers) 0x0: Disabled, pin goes to 3-state condition. 0x1: Pin is driven high if error is detected. 0x2: Pin is driven low if error is detected.	RW	0x0

Address Offset	0x0000 00C0		
Physical Address	0x4902 80C0 0x4012 80C0 0x01D2 80C0	**Instance**	MCASP_L3 MCASP_CORTEX-A9 MCASP_DSP
Description	Transmitter status register - If the McASP logic attempts to set an interrupt flag in the same cycle that the CPU writes to the flag to clear it, the McASP logic has priority and the flag remains set. This also causes the generation of a new interrupt request.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							XERR	XDMAERR	XSTAFRM	XDATA	XLAST	XTDMSLOT	XCKFAIL	XSYNCERR	XUNDRN

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	RW	0x000000
8	XERR	XERR bit always returns a logic-OR of: XUNDRN | XSYNCERR | XCKFAIL | XDMAERR. Allows a single bit to be checked to determine if a transmitter error interrupt has occurred. 0x0: No errors have occurred. 0x1: An error has occurred.	RW	0
7	XDMAERR	Transmit DMA error flag. XDMAERR is set when the CPU or DMA writes more words to the data port of the McASPin a given time slot than it should. Causes a transmit interrupt (XINT) if this bit and XDMAERR in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: Transmit DMA error did not occur. 0x1: Transmit DMA error occurred.	RW	0
6	XSTAFRM	Transmit start of frame flag. Causes a transmit interrupt (XINT) if this bit and XSTAFRM in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: No new transmit frame sync (AFSX) is detected. 0x1: A new transmit frame sync (AFSX) is detected.	RW	0
5	XDATA	Transmit data ready flag. Causes a transmit interrupt (XINT) if this bit and XDATA in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect 0x0: XBUF is written and is full 0x1: Data is copied from XBUF to XRSR. XBUF is empty and ready to be written. XDATA is also set when the transmit serializers are taken out of reset. When XDATA is set, it always causes a DMA event (AXEVT).	RW	0

Copyright © 2011–2012, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
4	XLAST	Transmit last slot flag. XLAST, along with XDATA, are set if the current slot is the last slot in a frame. Causes a transmit interrupt (XINT) if this bit and XLAST in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect. 0x0: Current slot is not the last slot in a frame. 0x1: Current slot is the last slot in a frame. XDATA is also set.	RW	0
3	XTDMSLOT	Returns the LSB of XSLOT. Allows a single read of XSTAT to determine whether the current TDM time slot is even or odd. read 0x0: Current TDM time slot is odd. read 0x1: Current TDM time slot is even.	R	0
2	XCKFAIL	Transmit clock failure flag. XCKFAIL is set when the transmit clock failure detection circuit reports an error. Causes a transmit interrupt (XINT) if this bit and XCKFAIL in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect. 0x0: Transmit clock failure did not occur. 0x1: Transmit clock failure occurred	RW	0
1	XSYNCERR	Unexpected transmit frame-sync flag. XSYNCERR is set when a new transmit frame sync (AFSX) occurs before it is expected. Causes a transmit interrupt (XINT) if this bit and XSYNCERR in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect. 0x0: Unexpected transmit frame sync did not occur 0x1: Unexpected transmit frame sync occurred.	RW	0
0	XUNDRN	Transmitter underrun flag. XUNDRN is set when the transmit serializer is instructed to transfer data from XBUF to XRSR, but XBUF has not yet been serviced with new data since the last transfer. Causes a transmit interrupt (XINT) if this bit and XUNDRN in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect. 0x0: Transmitter underrun did not occur 0x1: Transmitter underrun occurred.	RW	0

Description	Transmit clock check control register - configures the transmit clock failure detection circuit.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
XCNT								XMAX								XMIN								RESERVED				XPS			

Bits	Field Name	Description	Type	Reset
31:24	XCNT	Transmit clock count value (from previous measurement). The clock circuit continually counts the number of system clocks for every 32 transmit high-frequency master clock (abe_mcasp_ahclkx) signals, and stores the count in XCNT until the next measurement is taken	R	0x00
23:16	XMAX	0x0 to 0xFF: Transmit clock maximum boundary. This 8-bit unsigned value sets the maximum allowed boundary for the clock check counter after 32 transmit high-frequency master clock (abe_mcasp_ahclkx) signals have been received. If the current counter value is greater than XMAX after counting 32 AHCLKX signals, XCKFAIL in XSTAT is set. The comparison is performed using unsigned arithmetic.	RW	0x00
15:8	XMIN	0x0 to 0xFF: Transmit clock minimum boundary. This 8-bit unsigned value sets the minimum allowed boundary for the clock check counter after 32 transmit high-frequency master clock (abe_mcasp_ahclkx) signals have been received. If XCNT is less than XMIN after counting 32 AHCLKX signals, XCKFAIL in XSTAT is set. The comparison is performed using unsigned arithmetic.	RW	0x00
7:4	RESERVED	Reserved	RW	0x0
