### 8.10.2.59 GPDPUD Register (Offset = CCh) [Reset = FFFFFFFFh]

GPDPUD is shown in Figure 8-62 and described in Table 8-72.

Return to the Summary Table.

GPIO D Pull Up Disable Register (GPIO96 to 127)
Disables the Pull-Up on GPIO.
0: Enables the Pull-Up.
1: Disables the Pull-Up.
Reading the register returns the current value of the register setting.

### 8.10.2.60 GPDINV Register (Offset = D0h) [Reset = 00000000h]

GPDINV is shown in Figure 8-63 and described in Table 8-73.

Return to the Summary Table.

GPIO D Input Polarity Invert Registers (GPIO96 to 127)
Selects between non-inverted and inverted GPIO input to the device.
0: selects non-inverted GPIO input
1: selects inverted GPIO input
Reading the register returns the current value of the register setting.

**Figure 8-63. GPDINV Register**

### 8.10.2.61 GPDODR Register (Offset = D2h) [Reset = 00000000h]

GPDODR is shown in Figure 8-64 and described in Table 8-74.

Return to the Summary Table.

GPIO D Open Drain Output Register (GPIO96 to GPIO127)
Selects between normal and open-drain output for the GPIO pin.
0: Normal Output
1: Open Drain Output
Reading the register returns the current value of the register setting.
Note:
[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

### 8.10.2.62 GPDGMUX1 Register (Offset = E0h) [Reset = 00000000h]

GPDGMUX1 is shown in Figure 8-65 and described in Table 8-75.

Return to the Summary Table.

GPIO D Peripheral Group Mux (GPIO96 to 111)
Defines pin-muxing selection for GPIO.
Note: For complete pin-mux selection on GPIOx, GPAMUXy.GPIOx configuration is also required.

**Figure 8-65. GPDGMUX1 Register**

### 8.10.2.63 GPDGMUX2 Register (Offset = E2h) [Reset = 00000000h]

GPDGMUX2 is shown in Figure 8-66 and described in Table 8-76.

Return to the Summary Table.

GPIO D Peripheral Group Mux (GPIO112 to 127)
Defines pin-muxing selection for GPIO.
Note: For complete pin-mux selection on GPIOx, GPAMUXy.GPIOx configuration is also required.

**Figure 8-66. GPDGMUX2 Register**

### 8.10.2.66 GPDCSEL3 Register (Offset = ECh) [Reset = 00000000h]

GPDCSEL3 is shown in Figure 8-69 and described in Table 8-79.

Return to the Summary Table.

GPIO D Core Select Register (GPIO112 to 119)
Selects which master's GPIODAT/SET/CLEAR/TOGGLE registers control this GPIO pin
xx00: CPU1 selected
xx01: CPU1.CLA1 selected
xx10: CPU2 selected
xx11: CPU2.CLA1 selected

**Figure 8-69. GPDCSEL3 Register**

### 8.10.2.67 GPDCSEL4 Register (Offset = EEh) [Reset = 00000000h]

GPDCSEL4 is shown in Figure 8-70 and described in Table 8-80.

Return to the Summary Table.

GPIO D Core Select Register (GPIO120 to 127)
Selects which master's GPIODAT/SET/CLEAR/TOGGLE registers control this GPIO pin
xx00: CPU1 selected
xx01: CPU1.CLA1 selected
xx10: CPU2 selected
xx11: CPU2.CLA1 selected

**Figure 8-70. GPDCSEL4 Register**

### 8.10.2.68 GPDLOCK Register (Offset = FCh) [Reset = 00000000h]

GPDLOCK is shown in Figure 8-71 and described in Table 8-81.

Return to the Summary Table.

GPIO D Lock Configuration Register (GPIO96 to 127)
GPIO Configuration Lock for GPIO.
0: Bits in GPyMUX1, GPyMUX2, GPyDIR, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx register which control the same pin can be changed
1: Locks changes to the bits in GPyMUX1, GPyMUX2, GPyDIR, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx registers which control the same pin

**Figure 8-71. GPDLOCK Register**

### 8.10.2.69 GPDCR Register (Offset = FEh) [Reset = 00000000h]

GPDCR is shown in Figure 8-72 and described in Table 8-82.

Return to the Summary Table.

GPIO D Lock Commit Register (GPIO96 to 127)
GPIO Configuration Lock Commit for GPIO:
1: Locks changes to the bit in GPyLOCK register which controls the same pin
0: Bit in the GPyLOCK register which controls the same pin can be changed

**Figure 8-72. GPDCR Register**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 |

### 8.10.2.73 GPEMUX1 Register (Offset = 106h) [Reset = 00000000h]

GPEMUX1 is shown in Figure 8-76 and described in Table 8-86.

Return to the Summary Table.

GPIO E Mux 1 Register (GPIO128 to 143)
Defines pin-muxing selection for GPIO.
Notes:
The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO.

**Figure 8-76. GPEMUX1 Register**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 |

### 8.10.2.75 GPEDIR Register (Offset = 10Ah) [Reset = 00000000h]

GPEDIR is shown in Figure 8-78 and described in Table 8-88.

Return to the Summary Table.

GPIO E Direction Register (GPIO128 to 159)
Controls direction of GPIO pins when the specified pin is configured in GPIO mode.
0: Configures pin as input.
1: Configures pin as output.
Reading the register returns the current value of the register setting.

**Figure 8-78. GPEDIR Register**

### 8.10.2.76 GPEPUD Register (Offset = 10Ch) [Reset = FFFFFFFFh]

GPEPUD is shown in Figure 8-79 and described in Table 8-89.

Return to the Summary Table.

GPIO E Pull Up Disable Register (GPIO128 to 159)
Disables the Pull-Up on GPIO.
0: Enables the Pull-Up.
1: Disables the Pull-Up.
Reading the register returns the current value of the register setting.

### 8.10.2.77 GPEINV Register (Offset = 110h) [Reset = 00000000h]

GPEINV is shown in Figure 8-80 and described in Table 8-90.

Return to the Summary Table.

GPIO E Input Polarity Invert Registers (GPIO128 to 159)
Selects between non-inverted and inverted GPIO input to the device.
0: selects non-inverted GPIO input
1: selects inverted GPIO input
Reading the register returns the current value of the register setting.

**Figure 8-80. GPEINV Register**

### 8.10.2.78 GPEODR Register (Offset = 112h) [Reset = 00000000h]

GPEODR is shown in Figure 8-81 and described in Table 8-91.

Return to the Summary Table.

GPIO E Open Drain Output Register (GPIO128 to GPIO159)
Selects between normal and open-drain output for the GPIO pin.
0: Normal Output
1: Open Drain Output
Reading the register returns the current value of the register setting.
Note:
[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

### 8.10.2.79 GPEGMUX1 Register (Offset = 120h) [Reset = 00000000h]

GPEGMUX1 is shown in Figure 8-82 and described in Table 8-92.

Return to the Summary Table.

GPIO E Peripheral Group Mux (GPIO128 to 143)
Defines pin-muxing selection for GPIO.
Note: For complete pin-mux selection on GPIOx, GPAMUXy.GPIOx configuration is also required.

**Figure 8-82. GPEGMUX1 Register**

### 8.10.2.80 GPEGMUX2 Register (Offset = 122h) [Reset = 00000000h]

GPEGMUX2 is shown in Figure 8-83 and described in Table 8-93.

Return to the Summary Table.

GPIO E Peripheral Group Mux (GPIO144 to 159)
Defines pin-muxing selection for GPIO.
Note: For complete pin-mux selection on GPIOx, GPAMUXy.GPIOx configuration is also required.

**Figure 8-83. GPEGMUX2 Register**

### 8.10.2.85 GPELOCK Register (Offset = 13Ch) [Reset = 00000000h]

GPELOCK is shown in Figure 8-88 and described in Table 8-98.

Return to the Summary Table.

GPIO E Lock Configuration Register (GPIO128 to 159)
GPIO Configuration Lock for GPIO.
0: Bits in GPyMUX1, GPyMUX2, GPyDIR, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx register which control the same pin can be changed
1: Locks changes to the bits in GPyMUX1, GPyMUX2, GPyDIR, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx registers which control the same pin

**Figure 8-88. GPELOCK Register**

### 8.10.2.86 GPECR Register (Offset = 13Eh) [Reset = 00000000h]

GPECR is shown in Figure 8-89 and described in Table 8-99.

Return to the Summary Table.

GPIO E Lock Commit Register (GPIO128 to 159)
GPIO Configuration Lock Commit for GPIO:
1: Locks changes to the bit in GPyLOCK register which controls the same pin
0: Bit in the GPyLOCK register which controls the same pin can be changed

**Figure 8-89. GPECR Register**

### 8.10.2.89 GPFMUX1 Register (Offset = 146h) [Reset = 00000000h]

GPFMUX1 is shown in Figure 8-92 and described in Table 8-102.

Return to the Summary Table.

GPIO F Mux 1 Register (GPIO160 to 168)
Defines pin-muxing selection for GPIO.
Notes:
The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO.

### 8.10.2.90 GPFDIR Register (Offset = 14Ah) [Reset = 00000000h]

GPFDIR is shown in Figure 8-93 and described in Table 8-103.

Return to the Summary Table.

GPIO F Direction Register (GPIO160 to 168)
Controls direction of GPIO pins when the specified pin is configured in GPIO mode.
0: Configures pin as input.
1: Configures pin as output.
Reading the register returns the current value of the register setting.

### 8.10.2.91 GPFPUD Register (Offset = 14Ch) [Reset = FFFFFFFFh]

GPFPUD is shown in Figure 8-94 and described in Table 8-104.

Return to the Summary Table.

GPIO F Pull Up Disable Register (GPIO160 to 168)
Disables the Pull-Up on GPIO.
0: Enables the Pull-Up.
1: Disables the Pull-Up.
Reading the register returns the current value of the register setting.

### 8.10.2.92 GPFINV Register (Offset = 150h) [Reset = 00000000h]

GPFINV is shown in Figure 8-95 and described in Table 8-105.

Return to the Summary Table.

GPIO F Input Polarity Invert Registers (GPIO160 to 168)
Selects between non-inverted and inverted GPIO input to the device.
0: selects non-inverted GPIO input
1: selects inverted GPIO input
Reading the register returns the current value of the register setting.

### 8.10.2.93 GPFODR Register (Offset = 152h) [Reset = 00000000h]

GPFODR is shown in Figure 8-96 and described in Table 8-106.

Return to the Summary Table.

GPIO F Open Drain Output Register (GPIO160 to GPIO168)
Selects between normal and open-drain output for the GPIO pin.
0: Normal Output
1: Open Drain Output
Reading the register returns the current value of the register setting.
Note:
[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

### 8.10.2.94 GPFGMUX1 Register (Offset = 160h) [Reset = 00000000h]

GPFGMUX1 is shown in Figure 8-97 and described in Table 8-107.

Return to the Summary Table.

GPIO F Peripheral Group Mux (GPIO160 to 168)
Defines pin-muxing selection for GPIO.
Note: For complete pin-mux selection on GPIOx, GPAMUXy.GPIOx configuration is also required.

### 8.10.2.97 GPFLOCK Register (Offset = 17Ch) [Reset = 00000000h]

GPFLOCK is shown in Figure 8-100 and described in Table 8-110.

Return to the Summary Table.

GPIO F Lock Configuration Register (GPIO160 to 168)
GPIO Configuration Lock for GPIO.
0: Bits in GPyMUX1, GPyMUX2, GPyDIR, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx register which control the same pin can be changed
1: Locks changes to the bits in GPyMUX1, GPyMUX2, GPyDIR, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx registers which control the same pin

### 8.10.3 GPIO_DATA_REGS Registers

Table 8-112 lists the memory-mapped registers for the GPIO_DATA_REGS registers. All register offset addresses not listed in Table 8-112 should be considered as reserved locations and the register contents should not be modified.

**Table 8-112. GPIO_DATA_REGS Registers**

| Offset | Acronym | Register Name | Write Protection | Section |
|---|---|---|---|---|
| 0h | GPADAT | GPIO A Data Register (GPIO0 to 31) | | Go |
| 2h | GPASET | GPIO A Data Set Register (GPIO0 to 31) | | Go |
| 4h | GPACLEAR | GPIO A Data Clear Register (GPIO0 to 31) | | Go |
| 6h | GPATOGGLE | GPIO A Data Toggle Register (GPIO0 to 31) | | Go |
| 8h | GPBDAT | GPIO B Data Register (GPIO32 to 63) | | Go |
| Ah | GPBSET | GPIO B Data Set Register (GPIO32 to 63) | | Go |
| Ch | GPBCLEAR | GPIO B Data Clear Register (GPIO32 to 63) | | Go |
| Eh | GPBTOGGLE | GPIO B Data Toggle Register (GPIO32 to 63) | | Go |
| 10h | GPCDAT | GPIO C Data Register (GPIO64 to 95) | | Go |
| 12h | GPCSET | GPIO C Data Set Register (GPIO64 to 95) | | Go |
| 14h | GPCCLEAR | GPIO C Data Clear Register (GPIO64 to 95) | | Go |
| 16h | GPCTOGGLE | GPIO C Data Toggle Register (GPIO64 to 95) | | Go |
| 18h | GPDDAT | GPIO D Data Register (GPIO96 to 127) | | Go |
| 1Ah | GPDSET | GPIO D Data Set Register (GPIO96 to 127) | | Go |
| 1Ch | GPDCLEAR | GPIO D Data Clear Register (GPIO96 to 127) | | Go |
| 1Eh | GPDTOGGLE | GPIO D Data Toggle Register (GPIO96 to 127) | | Go |
| 20h | GPEDAT | GPIO E Data Register (GPIO128 to 159) | | Go |
| 22h | GPESET | GPIO E Data Set Register (GPIO128 to 159) | | Go |
| 24h | GPECLEAR | GPIO E Data Clear Register (GPIO128 to 159) | | Go |
| 26h | GPETOGGLE | GPIO E Data Toggle Register (GPIO128 to 159) | | Go |
| 28h | GPFDAT | GPIO F Data Register (GPIO160 to 168) | | Go |
| 2Ah | GPFSET | GPIO F Data Set Register (GPIO160 to 168) | | Go |
| 2Ch | GPFCLEAR | GPIO F Data Clear Register (GPIO160 to 168) | | Go |
| 2Eh | GPFTOGGLE | GPIO F Data Toggle Register (GPIO160 to 168) | | Go |

Complex bit access types are encoded to fit into small table cells. Table 8-113 shows the codes that are used for access types in this section.

**Table 8-113. GPIO_DATA_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| Write Type | | |
| W | W | Write |
| Reset or Default Value | | |
| *-n* | | Value after reset or the default value |
| Register Array Variables | | |
| i,j,k,l,m,n | | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |

### 8.10.3.1 GPADAT Register (Offset = 0h) [Reset = 00000000h]

GPADAT is shown in Figure 8-102 and described in Table 8-114.

Return to the Summary Table.

GPIO A Data Register (GPIO0 to 31)
Reading this register reflects the current state of the GPIO pin regardless of which mode the GPIO is in.
Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode. If the GPIO is not in output mode the value written is latched but will not be reflected on the GPIO pin or reads of the GPxDAT register. The written value latched will become active when the GPIO is put into GPIO Output mode
A system reset will clear all bits and latched values to zero.
NOTE: Bit-wise read-modify-write operations should not be performed on this register. For bit-wise operations the GPxSET, GPxCLEAR, or GPxTOGGLE registers should be used instead. If direct writes to GPxDAT are necessary, the entire register should be written at one time.

### 8.10.3.2 GPASET Register (Offset = 2h) [Reset = 00000000h]

GPASET is shown in Figure 8-103 and described in Table 8-115.

Return to the Summary Table.

GPIO A Data Set Register (GPIO0 to 31)
Writing a 1 will force GPIO output data latch to 1.
Writes of 0 are ignored.
Always reads back a 0.

**Figure 8-103. GPASET Register**

### 8.10.3.3 GPACLEAR Register (Offset = 4h) [Reset = 00000000h]

GPACLEAR is shown in Figure 8-104 and described in Table 8-116.

Return to the Summary Table.

GPIO A Data Clear Register (GPIO0 to 31)
Writing a 1 will force GPIO0 output data latch to 0.
Writes of 0 are ignored.
Always reads back a 0.

**Figure 8-104. GPACLEAR Register**

### 8.10.3.4 GPATOGGLE Register (Offset = 6h) [Reset = 00000000h]

GPATOGGLE is shown in Figure 8-105 and described in Table 8-117.

Return to the Summary Table.

GPIO A Data Toggle Register (GPIO0 to 31)
Writing a 1 will toggle GPIO0 output data latch 1 to 0 or 0 to 1.
Writes of 0 are ignored.
Always reads back a 0.

**Figure 8-105. GPATOGGLE Register**

### 8.10.3.5 GPBDAT Register (Offset = 8h) [Reset = 00000000h]

GPBDAT is shown in Figure 8-106 and described in Table 8-118.

Return to the Summary Table.

GPIO B Data Register (GPIO32 to 63)
Reading this register reflects the current state of the GPIO pin regardless of which mode the GPIO is in.
Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode. If the GPIO is not in output mode the value written is latched but will not be reflected on the GPIO pin or reads of the GPxDAT register. The written value latched will become active when the GPIO is put into GPIO Output mode
A system reset will clear all bits and latched values to zero.
NOTE: Bit-wise read-modify-write operations should not be performed on this register. For bit-wise operations the GPxSET, GPxCLEAR, or GPxTOGGLE registers should be used instead. If direct writes to GPxDAT are necessary, the entire register should be written at one time.

### 8.10.3.8 GPBTOGGLE Register (Offset = Eh) [Reset = 00000000h]

GPBTOGGLE is shown in Figure 8-109 and described in Table 8-121.

Return to the Summary Table.

GPIO B Data Toggle Register (GPIO32 to 63)
Writing a 1 will toggle GPIO0 output data latch 1 to 0 or 0 to 1.
Writes of 0 are ignored.
Always reads back a 0.

**Figure 8-109. GPBTOGGLE Register**

### 8.10.3.9 GPCDAT Register (Offset = 10h) [Reset = 00000000h]

GPCDAT is shown in Figure 8-110 and described in Table 8-122.

Return to the Summary Table.

GPIO C Data Register (GPIO64 to 95)
Reading this register reflects the current state of the GPIO pin regardless of which mode the GPIO is in.
Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode. If the GPIO is not in output mode the value written is latched but will not be reflected on the GPIO pin or reads of the GPxDAT register. The written value latched will become active when the GPIO is put into GPIO Output mode
A system reset will clear all bits and latched values to zero.
NOTE: Bit-wise read-modify-write operations should not be performed on this register. For bit-wise operations the GPxSET, GPxCLEAR, or GPxTOGGLE registers should be used instead. If direct writes to GPxDAT are necessary, the entire register should be written at one time.

### 8.10.3.10 GPCSET Register (Offset = 12h) [Reset = 00000000h]

GPCSET is shown in Figure 8-111 and described in Table 8-123.

Return to the Summary Table.

GPIO C Data Set Register (GPIO64 to 95)
Writing a 1 will force GPIO output data latch to 1.
Writes of 0 are ignored.
Always reads back a 0.

### 8.10.3.12 GPCTOGGLE Register (Offset = 16h) [Reset = 00000000h]

GPCTOGGLE is shown in Figure 8-113 and described in Table 8-125.

Return to the Summary Table.

GPIO C Data Toggle Register (GPIO64 to 95)
Writing a 1 will toggle GPIO0 output data latch 1 to 0 or 0 to 1.
Writes of 0 are ignored.
Always reads back a 0.

**Figure 8-113. GPCTOGGLE Register**

### 8.10.3.13 GPDDAT Register (Offset = 18h) [Reset = 00000000h]

GPDDAT is shown in Figure 8-114 and described in Table 8-126.

Return to the Summary Table.

GPIO D Data Register (GPIO96 to 127)
Reading this register reflects the current state of the GPIO pin regardless of which mode the GPIO is in.
Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode. If the GPIO is not in output mode the value written is latched but will not be reflected on the GPIO pin or reads of the GPxDAT register. The written value latched will become active when the GPIO is put into GPIO Output mode
A system reset will clear all bits and latched values to zero.
NOTE: Bit-wise read-modify-write operations should not be performed on this register. For bit-wise operations the GPxSET, GPxCLEAR, or GPxTOGGLE registers should be used instead. If direct writes to GPxDAT are necessary, the entire register should be written at one time.

### 8.10.3.14 GPDSET Register (Offset = 1Ah) [Reset = 00000000h]

GPDSET is shown in Figure 8-115 and described in Table 8-127.

Return to the Summary Table.

GPIO D Data Set Register (GPIO96 to 127)
Writing a 1 will force GPIO output data latch to 1.
Writes of 0 are ignored.
Always reads back a 0.

### 8.10.3.16 GPDTOGGLE Register (Offset = 1Eh) [Reset = 00000000h]

GPDTOGGLE is shown in Figure 8-117 and described in Table 8-129.

Return to the Summary Table.

GPIO D Data Toggle Register (GPIO96 to 127)
Writing a 1 will toggle GPIO0 output data latch 1 to 0 or 0 to 1.
Writes of 0 are ignored.
Always reads back a 0.

**Figure 8-117. GPDTOGGLE Register**

### 8.10.3.17 GPEDAT Register (Offset = 20h) [Reset = 00000000h]

GPEDAT is shown in Figure 8-118 and described in Table 8-130.

Return to the Summary Table.

GPIO E Data Register (GPIO128 to 159)
Reading this register reflects the current state of the GPIO pin regardless of which mode the GPIO is in.
Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode. If the GPIO is not in output mode the value written is latched but will not be reflected on the GPIO pin or reads of the GPxDAT register. The written value latched will become active when the GPIO is put into GPIO Output mode
A system reset will clear all bits and latched values to zero.
NOTE: Bit-wise read-modify-write operations should not be performed on this register. For bit-wise operations the GPxSET, GPxCLEAR, or GPxTOGGLE registers should be used instead. If direct writes to GPxDAT are necessary, the entire register should be written at one time.

### 8.10.3.18 GPESET Register (Offset = 22h) [Reset = 00000000h]

GPESET is shown in Figure 8-119 and described in Table 8-131.

Return to the Summary Table.

GPIO E Data Set Register (GPIO128 to 159)
Writing a 1 will force GPIO output data latch to 1.
Writes of 0 are ignored.
Always reads back a 0.

### 8.10.3.21 GPFDAT Register (Offset = 28h) [Reset = 00000000h]

GPFDAT is shown in Figure 8-122 and described in Table 8-134.

Return to the Summary Table.

GPIO F Data Register (GPIO160 to 168)
Reading this register reflects the current state of the GPIO pin regardless of which mode the GPIO is in.
Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode. If the GPIO is not in output mode the value written is latched but will not be reflected on the GPIO pin or reads of the GPxDAT register. The written value latched will become active when the GPIO is put into GPIO Output mode
A system reset will clear all bits and latched values to zero.
NOTE: Bit-wise read-modify-write operations should not be performed on this register. For bit-wise operations the GPxSET, GPxCLEAR, or GPxTOGGLE registers should be used instead. If direct writes to GPxDAT are necessary, the entire register should be written at one time.

### 8.10.3.22 GPFSET Register (Offset = 2Ah) [Reset = 00000000h]

GPFSET is shown in Figure 8-123 and described in Table 8-135.

Return to the Summary Table.

GPIO F Data Set Register (GPIO160 to 168)
Writing a 1 will force GPIO output data latch to 1.
Writes of 0 are ignored.
Always reads back a 0.

### 8.10.3.24 GPFTOGGLE Register (Offset = 2Eh) [Reset = 00000000h]

GPFTOGGLE is shown in Figure 8-125 and described in Table 8-137.

Return to the Summary Table.

GPIO F Data Toggle Register (GPIO160 to 168)
Writing a 1 will toggle GPIO0 output data latch 1 to 0 or 0 to 1.
Writes of 0 are ignored.
Always reads back a 0.

Chapter 9

# Crossbar (X-BAR)

The crossbars (referred to as X-BAR throughout this chapter) provide flexibility to connect device inputs, outputs, and internal resources in a variety of configurations.

The device contains a total of four X-BARs:

- Input X-BAR
- Output X-BAR
- CLB X-BAR
- ePWM X-BAR

Each of the X-BARs is named according to where the X-BAR takes signals. For example, the Input X-BAR brings external signals “in” to the device. The Output X-BAR takes internal signals “out” of the device to a GPIO. The CLB X-BAR and ePWM X-BAR take signals to the CLB and ePWM modules, respectively.

**9.1 Input X-BAR** ..... 1230
**9.2 ePWM, CLB, and GPIO Output X-BAR** ..... 1233
**9.3 XBAR Registers** ..... 1241

Copyright © 2024 Texas Instruments Incorporated

## 9.1 Input X-BAR

On this device, the Input X-BAR is used to route signals from a GPIO to many different IP blocks such as the ADC, eCAP, ePWM, and external interrupts. The input of each Input X-BAR instance (INPUTx) can be any GPIO, while the output of each instance connects to various IP blocks in the device. The digital input of AIOs are also available as inputs to the Input X-BAR. This flexibility relieves some of the constraints on peripheral muxing by allowing the user to connect any GPIO to the specified outputs of each Input X-BAR instance. Note that the GPIO selected by the Input X-BAR can be configured as either an input or an output. The Input X-BAR simply connects the signal on the input buffer to the output of the selected Input X-BAR instance. Therefore, you can do things such as route the output of an ePWM to the eCAP module for a frequency test).

The Input X-BAR is configured by way of the INPUTxSELECT registers. The destinations for each INPUTx are shown in Figure 9-1 and Table 9-1. For additional details on how each Input X-BAR connects to other IP blocks throughout the device, look for references to Input X-BAR in the chapter associated with that IP. Note that the destinations of each INPUTx are fixed and are not user-configurable. For more information on configuring the Input X-BAR, see the INPUT_XBAR_REGS register definitions in the *XBAR Registers* section.

## 9.2 ePWM, CLB, and GPIO Output X-BAR

This section describes the ePWM, CLB, and GPIO Output X-BAR. .

### *9.2.1 ePWM X-BAR*

The ePWM X-BAR brings signals to the ePWM modules. Specifically, the ePWM X-BAR is connected to the Digital Compare (DC) submodule of each ePWM module for actions such as tripzones and syncing. Refer to the *Enhanced Pulse Width Modulator (ePWM)* chapter for more information on additional ways the DC submodule can be used. Figure 9-2 shows the architecture of the ePWM X-BAR. Note that the architecture of the ePWM X-BAR is identical to the architecture of the GPIO Output X-BAR (with the exception of the output latch).

#### 9.2.1.1 ePWM X-BAR Architecture

The ePWM X-BAR has eight outputs that are routed to each ePWM module. Figure 9-2 represents the architecture of a single output, but this output is identical to the architecture of all of the other outputs.

First, determine the signals that can be passed to the ePWM by referencing Table 9-2. Select up to one signal per mux for each TRIPx output. Select the inputs to ePWM X-BAR using the TRIPxMUX0TO15CFG and TRIPxMUX16TO31CFG registers. To pass any signal through to the ePWM, enable the signal using the TRIPxMUXENABLE register. All signals that are enabled are logically ORed before being passed on to the respective TRIPx signal on the ePWM. To optionally invert the signal, use the TRIPOUTINV register.

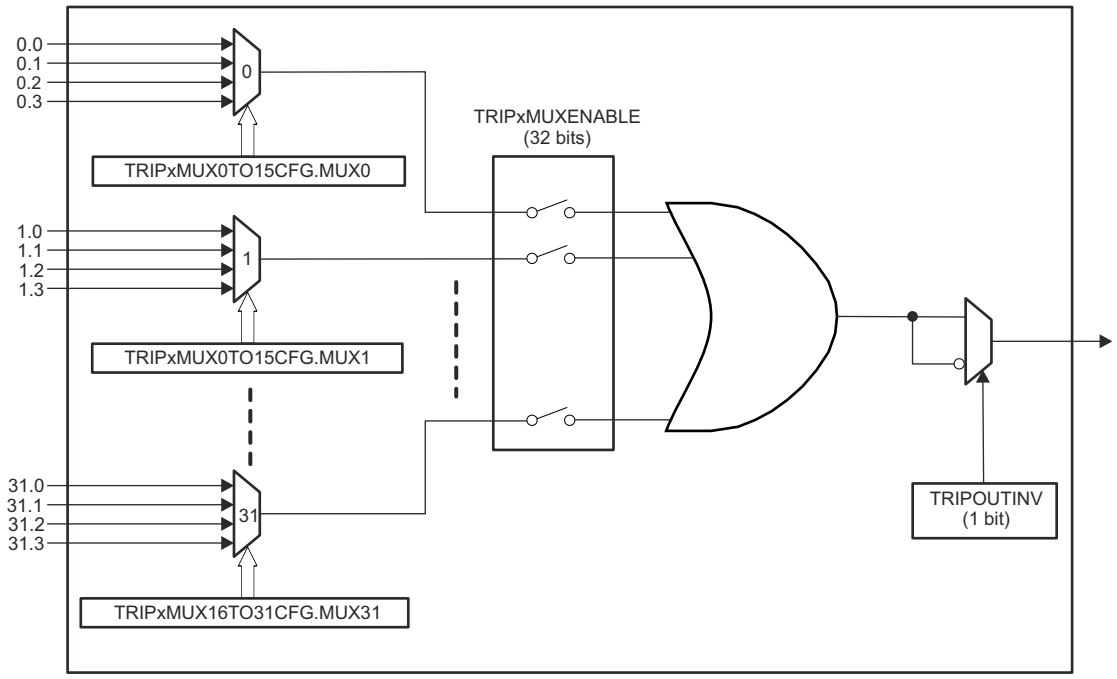

**Figure 9-2. ePWM X-BAR Architecture - Single Output**

Copyright © 2024 Texas Instruments Incorporated

**Note**

Do not use "Reserved" signals in your application.

### 9.2.2 CLB X-BAR

The CLB X-BAR brings signals to the CLB modules. Figure 9-3 shows the architecture of the CLB X-BAR. Note that the architecture of the CLB X-BAR is identical to the architecture of the GPIO Output X-BAR (with the exception of the output latch).

#### 9.2.2.1 CLB X-BAR Architecture

The CLB X-BAR has eight outputs that are routed to each CLB module. Figure 9-3 represents the architecture of a single output, but the output is identical to the architecture of all of the other outputs.

First, determine the signals that can be passed to the CLB by referencing Table 9-3. Select up to one signal per mux (31 total muxes) for each AUXSIGx output. Select the inputs to each mux using the AUXSIGxMUX0TO15CFG and AUXSIGxMUX16TO31CFG registers. To pass any signal through to the CLB, enable the mux in the AUXSIGxMUXENABLE register. All muxes that are enabled are logically ORed before being passed on to the respective AUXSIGx signal on the CLB. To optionally invert the signal, use the AUXSIGOUTINV register.

### 9.2.3 GPIO Output X-BAR

The GPIO Output X-BAR takes signals from inside the device and brings them out to a GPIO. Figure 9-5 shows the architecture of the GPIO Output X-BAR. The X-BAR contains eight outputs and each contains at least one position on the GPIO mux, denoted as OUTPUTXBARx. The X-BAR allows the selection of a single input or a logical-OR of many inputs.

#### 9.2.3.1 GPIO Output X-BAR Architecture

The GPIO Output X-BAR has eight outputs that are routed to the GPIO module. Figure 9-5 represents the architecture of a single output, but this output is identical to the architecture of all of the other outputs. Note that the architecture of the Output X-BAR (with the exception of the output latch) is similar to the architecture of the ePWM X-BAR.

First, determine the signals that can be passed to the GPIO by referencing Table 9-4. Select up to one signal per mux (32 total muxes) for each OUTPUTXBARx output. Select the inputs to each mux using the OUTPUTxMUX0TO15CFG and OUTPUTxMUX16TO31CFG registers. To pass any signal through to the GPIO, enable the mux in the OUTPUTxMUXENABLE register. All muxes that are enabled are logically ORed before being passed on to the respective OUTPUTx signal on the GPIO module. To optionally invert the signal, use the OUTPUTINV register. The final output is only recognized on the GPIO if the proper OUTPUTx muxing options are selected using the GPIO registers.

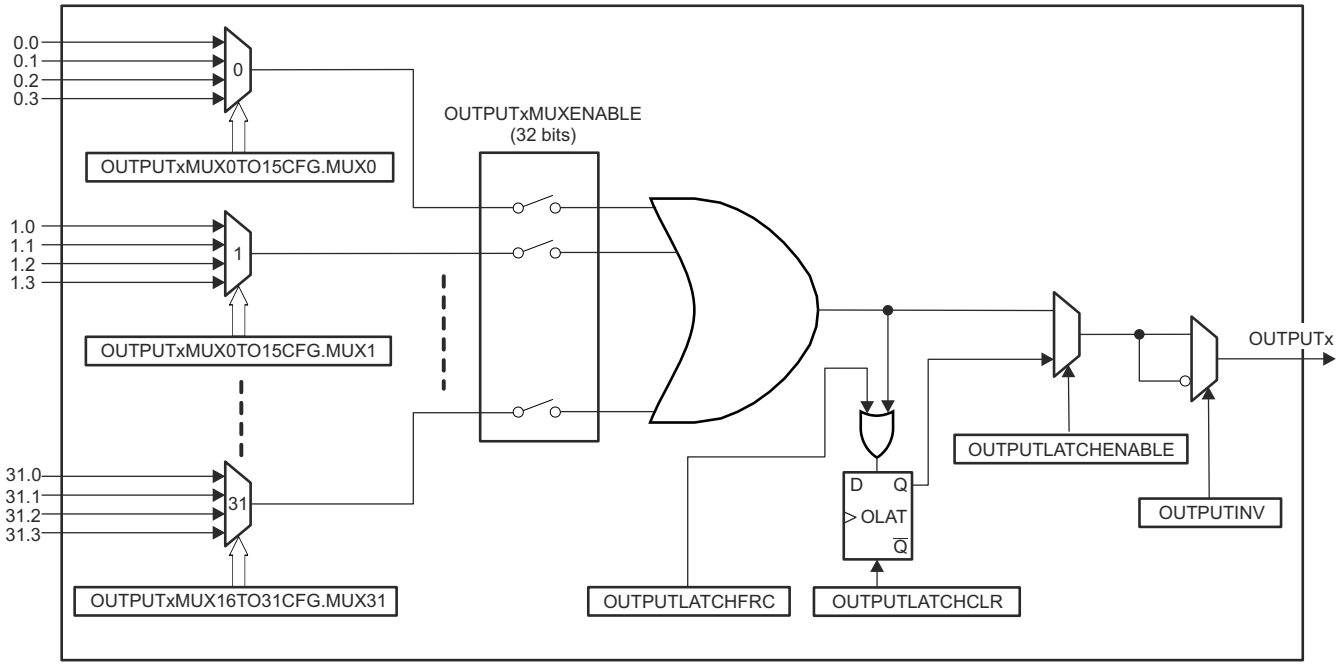

**Figure 9-5. GPIO Output X-BAR Architecture**

**Note**

Do not use "Reserved" signals in your application.

The ADCSOCAO and ADCSOCBO signals are active-high when routed through the X-BAR. The signal can be inverted by the respective OUTPUTINV bit depending on the application.

### 9.2.4 X-BAR Flags

With the exception of the CMPSS signals, the ePWM X-BAR and the Output X-BAR have all of the same input signals. Due to the inputs being similar between the ePWM X-BAR, CLB X-BAR, and Output X-BAR, all X-BAR modules leverage a single set of input flags to indicate which input signals have been triggered. This allows software to check the input flags when an event occurs. See Figure 9-6 for more information. There is a bit allocated for each input signal in one of the XBARFLGx registers. The flag remains set until cleared through the appropriate XBARCLRx register.

**Note**

Not all input sources are routed to all X-BAR modules. Refer to the X-BAR specific configuration tables for exact connections.

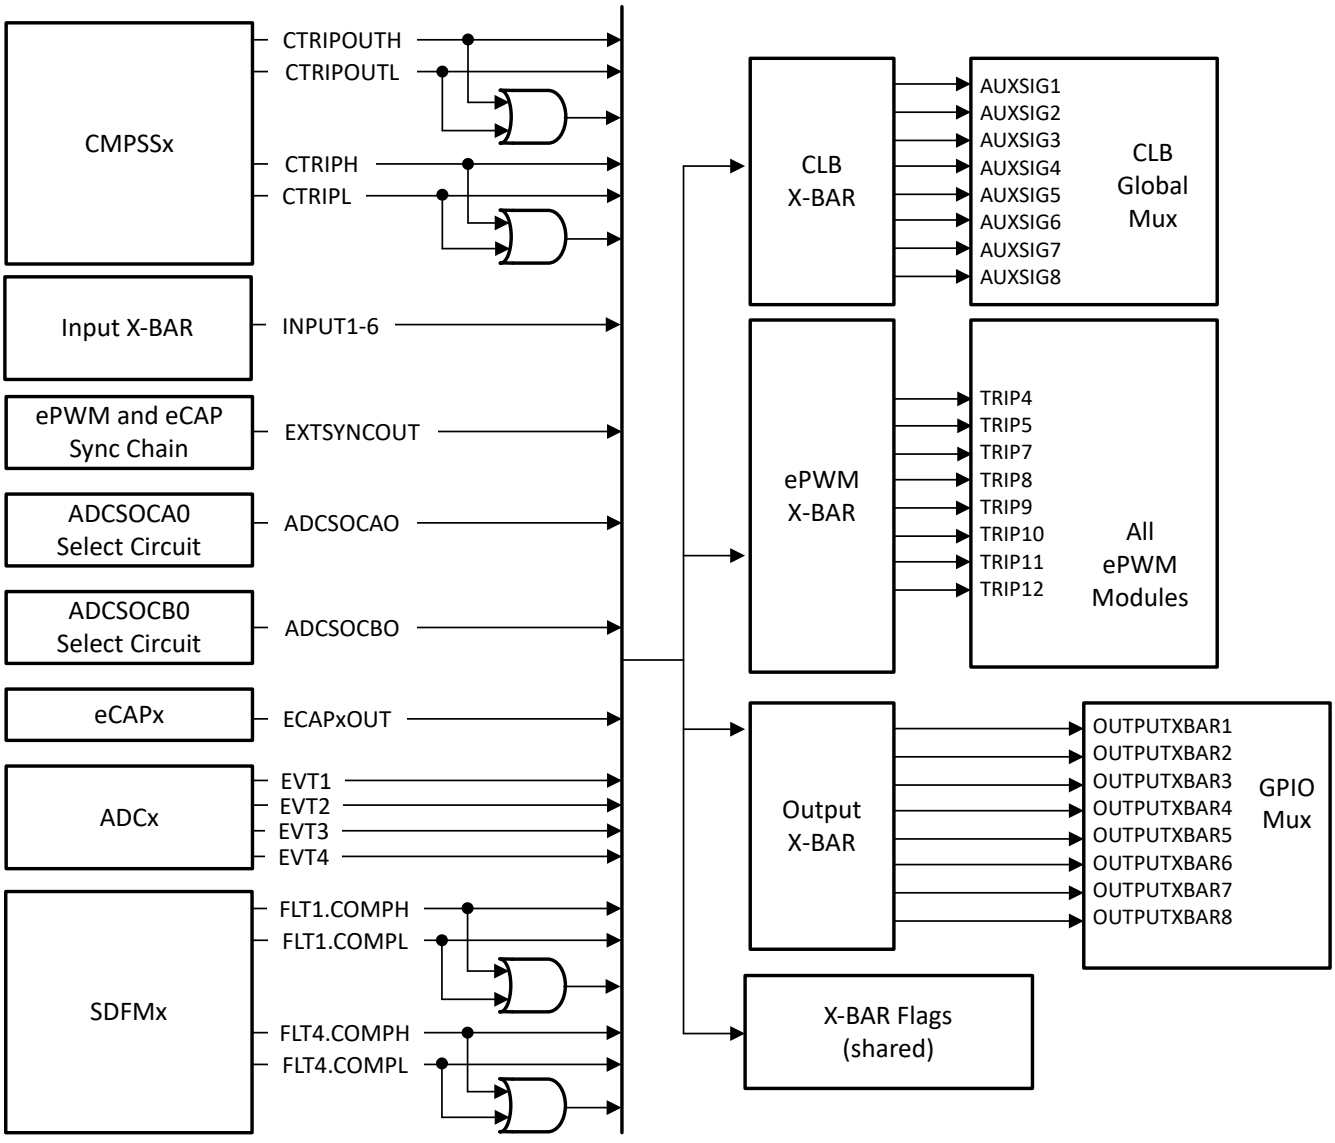

**Figure 9-6. X-BAR Input Sources**

### 9.3.2 INPUT_XBAR_REGS Registers

Table 9-6 lists the memory-mapped registers for the INPUT_XBAR_REGS registers. All register offset addresses not listed in Table 9-6 should be considered as reserved locations and the register contents should not be modified.

**Table 9-6. INPUT_XBAR_REGS Registers**

| Offset | Acronym | Register Name | Write Protection | Section |
|---|---|---|---|---|
| 0h | INPUT1SELECT | INPUT1 Input Select Register (GPIO0 to x) | EALLOW | Go |
| 1h | INPUT2SELECT | INPUT2 Input Select Register (GPIO0 to x) | EALLOW | Go |
| 2h | INPUT3SELECT | INPUT3 Input Select Register (GPIO0 to x) | EALLOW | Go |
| 3h | INPUT4SELECT | INPUT4 Input Select Register (GPIO0 to x) | EALLOW | Go |
| 4h | INPUT5SELECT | INPUT5 Input Select Register (GPIO0 to x) | EALLOW | Go |
| 5h | INPUT6SELECT | INPUT6 Input Select Register (GPIO0 to x) | EALLOW | Go |
| 6h | INPUT7SELECT | INPUT7 Input Select Register (GPIO0 to x) | EALLOW | Go |
| 7h | INPUT8SELECT | INPUT8 Input Select Register (GPIO0 to x) | EALLOW | Go |
| 8h | INPUT9SELECT | INPUT9 Input Select Register (GPIO0 to x) | EALLOW | Go |
| 9h | INPUT10SELECT | INPUT10 Input Select Register (GPIO0 to x) | EALLOW | Go |
| Ah | INPUT11SELECT | INPUT11 Input Select Register (GPIO0 to x) | EALLOW | Go |
| Bh | INPUT12SELECT | INPUT12 Input Select Register (GPIO0 to x) | EALLOW | Go |
| Ch | INPUT13SELECT | INPUT13 Input Select Register (GPIO0 to x) | EALLOW | Go |
| Dh | INPUT14SELECT | INPUT14 Input Select Register (GPIO0 to x) | EALLOW | Go |
| 1Eh | INPUTSELECTLOCK | Input Select Lock Register | EALLOW | Go |

Complex bit access types are encoded to fit into small table cells. Table 9-7 shows the codes that are used for access types in this section.

**Table 9-7. INPUT_XBAR_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| R-0 | R<br>-0 | Read<br>Returns 0s |
| Write Type | | |
| W | W | Write |
| WSonce | W<br>Sonce | Write<br>Set once |
| Reset or Default Value | | |
| *-n* | | Value after reset or the default value |
| Register Array Variables | | |
| i,j,k,l,m,n | | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y | | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

### 9.3.2.15 INPUTSELECTLOCK Register (Offset = 1Eh) [Reset = 00000000h]

INPUTSELECTLOCK is shown in Figure 9-21 and described in Table 9-22.

Return to the Summary Table.

Input Select Lock Register.
Any bit in this register, once set can only be cleared through SYSRSn. Write of 0 to any bit of this register has no effect. Reads to the registers which have LOCK protection are always allowed.

### 9.3.3 XBAR_REGS Registers

Table 9-23 lists the memory-mapped registers for the XBAR_REGS registers. All register offset addresses not listed in Table 9-23 should be considered as reserved locations and the register contents should not be modified.

**Table 9-23. XBAR_REGS Registers**

| Offset | Acronym | Register Name | Write Protection | Section |
|---|---|---|---|---|
| 0h | XBARFLG1 | X-Bar Input Flag Register 1 | | Go |
| 2h | XBARFLG2 | X-Bar Input Flag Register 2 | | Go |
| 4h | XBARFLG3 | X-Bar Input Flag Register 3 | | Go |
| 8h | XBARCLR1 | X-Bar Input Flag Clear Register 1 | | Go |
| Ah | XBARCLR2 | X-Bar Input Flag Clear Register 2 | | Go |
| Ch | XBARCLR3 | X-Bar Input Flag Clear Register 3 | | Go |

Complex bit access types are encoded to fit into small table cells. Table 9-24 shows the codes that are used for access types in this section.

**Table 9-24. XBAR_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| R-0 | R<br>-0 | Read<br>Returns 0s |
| Write Type | | |
| W1S | W<br>1S | Write<br>1 to set |
| Reset or Default Value | | |
| *-n* | | Value after reset or the default value |
| Register Array Variables | | |
| i,j,k,l,m,n | | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y | | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

### 9.3.3.1 XBARFLG1 Register (Offset = 0h) [Reset = 00000000h]

XBARFLG1 is shown in Figure 9-22 and described in Table 9-25.

Return to the Summary Table.

This register is used to flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered.
1: Corresponding Input was triggered
0: Corresponding Input was not triggered

**Figure 9-22. XBARFLG1 Register**

### 9.3.3.3 XBARFLG3 Register (Offset = 4h) [Reset = 00000000h]

XBARFLG3 is shown in Figure 9-24 and described in Table 9-27.

Return to the Summary Table.

This register is used to flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered.
1: Corresponding Input was triggered
0: Corresponding Input was not triggered

### 9.3.3.4 XBARCLR1 Register (Offset = 8h) [Reset = 00000000h]

XBARCLR1 is shown in Figure 9-25 and described in Table 9-28.

Return to the Summary Table.

This register is used to clear the flag(s) in the XBARFLG1 register.
1: Clears the corresponding bit in the XBARFLG1 register.
0: Writing 0 has no effect

### 9.3.3.6 XBARCLR3 Register (Offset = Ch) [Reset = 00000000h]

XBARCLR3 is shown in Figure 9-27 and described in Table 9-30.

Return to the Summary Table.

This register is used to clear the flag(s) in the XBARFLG3 register.
1: Clears the corresponding bit in the XBARFLG3 register.
0: Writing 0 has no effect

### 9.3.4 EPWM_XBAR_REGS Registers

Table 9-31 lists the memory-mapped registers for the EPWM_XBAR_REGS registers. All register offset addresses not listed in Table 9-31 should be considered as reserved locations and the register contents should not be modified.

**Table 9-31. EPWM_XBAR_REGS Registers**

| Offset | Acronym | Register Name | Write Protection | Section |
|---|---|---|---|---|
| 0h | TRIP4MUX0TO15CFG | ePWM XBAR Mux Configuration for TRIP4 | EALLOW | Go |
| 2h | TRIP4MUX16TO31CFG | ePWM XBAR Mux Configuration for TRIP4 | EALLOW | Go |
| 4h | TRIP5MUX0TO15CFG | ePWM XBAR Mux Configuration for TRIP5 | EALLOW | Go |
| 6h | TRIP5MUX16TO31CFG | ePWM XBAR Mux Configuration for TRIP5 | EALLOW | Go |
| 8h | TRIP7MUX0TO15CFG | ePWM XBAR Mux Configuration for TRIP7 | EALLOW | Go |
| Ah | TRIP7MUX16TO31CFG | ePWM XBAR Mux Configuration for TRIP7 | EALLOW | Go |
| Ch | TRIP8MUX0TO15CFG | ePWM XBAR Mux Configuration for TRIP8 | EALLOW | Go |
| Eh | TRIP8MUX16TO31CFG | ePWM XBAR Mux Configuration for TRIP8 | EALLOW | Go |
| 10h | TRIP9MUX0TO15CFG | ePWM XBAR Mux Configuration for TRIP9 | EALLOW | Go |
| 12h | TRIP9MUX16TO31CFG | ePWM XBAR Mux Configuration for TRIP9 | EALLOW | Go |
| 14h | TRIP10MUX0TO15CFG | ePWM XBAR Mux Configuration for TRIP10 | EALLOW | Go |
| 16h | TRIP10MUX16TO31CFG | ePWM XBAR Mux Configuration for TRIP10 | EALLOW | Go |
| 18h | TRIP11MUX0TO15CFG | ePWM XBAR Mux Configuration for TRIP11 | EALLOW | Go |
| 1Ah | TRIP11MUX16TO31CFG | ePWM XBAR Mux Configuration for TRIP11 | EALLOW | Go |
| 1Ch | TRIP12MUX0TO15CFG | ePWM XBAR Mux Configuration for TRIP12 | EALLOW | Go |
| 1Eh | TRIP12MUX16TO31CFG | ePWM XBAR Mux Configuration for TRIP12 | EALLOW | Go |
| 20h | TRIP4MUXENABLE | ePWM XBAR Mux Enable for TRIP4 | EALLOW | Go |
| 22h | TRIP5MUXENABLE | ePWM XBAR Mux Enable for TRIP5 | EALLOW | Go |
| 24h | TRIP7MUXENABLE | ePWM XBAR Mux Enable for TRIP7 | EALLOW | Go |
| 26h | TRIP8MUXENABLE | ePWM XBAR Mux Enable for TRIP8 | EALLOW | Go |
| 28h | TRIP9MUXENABLE | ePWM XBAR Mux Enable for TRIP9 | EALLOW | Go |
| 2Ah | TRIP10MUXENABLE | ePWM XBAR Mux Enable for TRIP10 | EALLOW | Go |
| 2Ch | TRIP11MUXENABLE | ePWM XBAR Mux Enable for TRIP11 | EALLOW | Go |
| 2Eh | TRIP12MUXENABLE | ePWM XBAR Mux Enable for TRIP12 | EALLOW | Go |
| 38h | TRIPOUTINV | ePWM XBAR Output Inversion Register | EALLOW | Go |
| 3Eh | TRIPLOCK | ePWM XBAR Configuration Lock register | EALLOW | Go |

Complex bit access types are encoded to fit into small table cells. Table 9-32 shows the codes that are used for access types in this section.

**Table 9-32. EPWM_XBAR_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| R-0 | R<br>-0 | Read<br>Returns 0s |
| Write Type | | |
| W | W | Write |
| WSonce | W<br>Sonce | Write<br>Set once |
| Reset or Default Value | | |
| *-n* | | Value after reset or the default value |

Copyright © 2024 Texas Instruments Incorporated

**Table 9-32. EPWM_XBAR_REGS Access Type Codes (continued)**

| Access Type | Code | Description |
|---|---|---|
| Register Array Variables | | |
| i,j,k,l,m,n | | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y | | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

### 9.3.4.18 TRIP5MUXENABLE Register (Offset = 22h) [Reset = 00000000h]

TRIP5MUXENABLE is shown in Figure 9-45 and described in Table 9-50.

Return to the Summary Table.

ePWM XBAR Mux Enable for TRIP5

### 9.3.4.23 TRIP11MUXENABLE Register (Offset = 2Ch) [Reset = 00000000h]

TRIP11MUXENABLE is shown in Figure 9-50 and described in Table 9-55.

Return to the Summary Table.

ePWM XBAR Mux Enable for TRIP11

| 3Eh | AUXSIGLOCK | ClbXbar Configuration Lock register | EALLOW | Go |

Complex bit access types are encoded to fit into small table cells. Table 9-60 shows the codes that are used for access types in this section.

**Table 9-60. CLB_XBAR_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| R-0 | R<br>-0 | Read<br>Returns 0s |
| Write Type | | |
| W | W | Write |
| WSonce | W<br>Sonce | Write<br>Set once |
| Reset or Default Value | | |
| *-n* | | Value after reset or the default value |

**Table 9-60. CLB_XBAR_REGS Access Type Codes (continued)**

| Access Type | Code | Description |
|---|---|---|
| Register Array Variables | | |
| i,j,k,l,m,n | | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y | | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

### 9.3.5.23 AUXSIG6MUXENABLE Register (Offset = 2Ch) [Reset = 00000000h]

AUXSIG6MUXENABLE is shown in Figure 9-76 and described in Table 9-83.

Return to the Summary Table.

CLB XBAR Mux Enable Register for Output-6

### 9.3.6 OUTPUT_XBAR_REGS Registers

Table 9-87 lists the memory-mapped registers for the OUTPUT_XBAR_REGS registers. All register offset addresses not listed in Table 9-87 should be considered as reserved locations and the register contents should not be modified.

**Table 9-87. OUTPUT_XBAR_REGS Registers**

| Offset | Acronym | Register Name | Write Protection | Section |
|---|---|---|---|---|
| 0h | OUTPUT1MUX0TO15CFG | Output X-BAR Mux Configuration for Output 1 | EALLOW | Go |
| 2h | OUTPUT1MUX16TO31CFG | Output X-BAR Mux Configuration for Output 1 | EALLOW | Go |
| 4h | OUTPUT2MUX0TO15CFG | Output X-BAR Mux Configuration for Output 2 | EALLOW | Go |
| 6h | OUTPUT2MUX16TO31CFG | Output X-BAR Mux Configuration for Output 2 | EALLOW | Go |
| 8h | OUTPUT3MUX0TO15CFG | Output X-BAR Mux Configuration for Output 3 | EALLOW | Go |
| Ah | OUTPUT3MUX16TO31CFG | Output X-BAR Mux Configuration for Output 3 | EALLOW | Go |

**Table 9-88. OUTPUT_XBAR_REGS Access Type Codes (continued)**

| Access Type | Code | Description |
|---|---|---|
| W1S | W<br>1S | Write<br>1 to set |
| WSonce | W<br>Sonce | Write<br>Set once |
| Reset or Default Value | | |
| *-n* | | Value after reset or the default value |
| Register Array Variables | | |
| i,j,k,l,m,n | | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y | | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

### 9.3.6.21 OUTPUT5MUXENABLE Register (Offset = 28h) [Reset = 00000000h]

OUTPUT5MUXENABLE is shown in Figure 9-100 and described in Table 9-109.

Return to the Summary Table.

Output X-BAR Mux Enable for Output 5

# *Analog Subsystem*

The analog subsystem module is described in this chapter.

**10.1 Introduction**.....1566
**10.2 Optimizing Power-Up Time**.....1570
**10.3 Analog Subsystem Registers**.....1571

Copyright © 2024 Texas Instruments Incorporated

## 10.1 Introduction

The analog modules on this device include the Analog-to-Digital Converter (ADC), Temperature Sensor, Buffered Digital-to-Analog Converter (DAC), and Comparator Subsystem (CMPSS).

### *10.1.1 Features*

The analog subsystem has the following features:

- Flexible voltage references
  - The ADCs are referenced to VREFHIx and VREFLOx pins
    - VREFHIx pin voltage must be driven in externally
- The buffered DACs are referenced to VREFHIx and VSSA
  - Alternately, these DACs can be referenced to the VDAC pin and VSSA
- The comparator DACs are referenced to VDDA and VSSA
  - Alternately, these DACs can be referenced to the VDAC pin and VSSA
- Flexible pin usage
  - Buffered DAC and comparator subsystem functions multiplexed with ADC inputs
- Internal connection to VREFLO on all ADCs for offset self-calibration

### *10.1.2 Block Diagram*

The following analog subsystem block diagrams show the connections between the different integrated analog modules to the device pins. These pins fall into two categories: analog module inputs/outputs and reference pins.

The reference pins, VREFHIA to VREFHID and VREFLOA to VREFLOD, can be used to externally supply the reference to the ADC. VREFHIA can also be used to supply the reference voltage to DAC A and DAC B and VREFHIB can be used to supply the reference to DAC C.

The analog module input and outputs are all ADC inputs by default. The pins that connect to CMPSS inputs can be used for the CMPSS without further action and without preventing use as an ADC input simultaneously. DAC outputs must be enabled; this prevents the channel from simultaneously being used as an ADC input (but the ADC can be used to sample the DAC output voltage, if desired).

The VDAC reference pin can be used to set an alternate range for DAC A, DAC B, and DAC C and for the DACs inside the CMPSS modules (the CMPSS DACs are referenced to VDDA and VSSA by default). Using this pin as a reference prevents the channel from being used as an ADC input (but the ADC can be used to sample the VDAC voltage, if desired). The choice of reference is configurable per-module for each CMPSS or buffered DAC, and the selection is made using the module's configuration registers.

The following notes apply to all packages:

- Not all analog pins are available on all devices. See the device data sheet to determine which pins are available.
- See the device data sheet to determine the allowable voltage range for VREFHI and VREFLO.
- An external capacitor is required on the VREFHI pins. See the device data sheet for the specific value required.
- For buffered DAC modules, VSSA is the low reference whether VREFHIx or VDAC is selected as the high reference.
- For CMPSS modules, VSSA is the low reference whether VDAC or VDDA is selected as the high reference.

**Table 10-1. Analog Signal Descriptions**

| Signal Name | Description |
|---|---|
| ADCINAx | ADC A Input |
| ADCINBx | ADC B Input |
| ADCINCx | ADC C Input |
| ADCINDx | ADC D Input |
| CMPINxP | Comparator subsystem positive input |
| CMPINxN | Comparator subsystem negative input |
| DACOUTx | Buffered DAC Output |
| TEMP SENSOR | Internal temperature sensor |
| VDAC | Optional external reference voltage for on-chip DACs. There is a 100pF capacitor to VSSA on this pin whether used for ADC input or DAC reference that cannot be disabled. If this pin is being used as a reference for the on-chip DACs, place at least a 1µF capacitor on this pin. |

**Table 10-2. Reference Summary**

| Module | Reference Option | Configured Where? | Register | Driverlib Function | Notes |
|---|---|---|---|---|---|
| ADC | External or Internal | Not Configurable | N/A | N/A | VREFHI must always be driven externally on this device. |
| Buffered DAC | VREFHI or VDAC | DAC Module | DacxRegs. DACCTL.bit.DACREFSEL | DAC_CTL_DACREFSEL | |
| | External or Internal | Not Configurable | N/A | N/A | VREFHI must always be driven externally on this device. |
| CMPSS DACs | VDDA or VDAC | CMPSS Module | CmpssxRegs. COMPDACCTL.bit.SELREF | CMPSS_COMPDACCTL_SELREF | |

## 10.2 Optimizing Power-Up Time

The analog-to-digital converters (ADC) and buffered digital-to-analog converters (DAC) share a common reference circuit. If needed, an application using one or more of these modules can optimize power-up time by taking advantage of the shared reference. Once one of the modules using the shared reference has been initialized in internal reference mode, the power-up time for subsequent modules can be optimized by subtracting the reference power-up time from the minimum power-up time requirement.

For instance, if ADCA requires $t_{ADCPUINT}$ to power up in internal reference mode, and $t_{ADCPUEXT}$ to power up in external reference mode, the application does not need to wait $t_{ADCPUINT}$ to power up a second ADC instance such as ADCC in internal reference mode. In this case, the application can simply wait for $t_{ADCPUEXT}$ after powering up ADCC, even though both ADCs are used in internal reference mode. In the same scenario, if the application wished to use DACA in internal reference mode, the required wait time after power-up is $t_{DACPUEXT}$, not the longer $t_{DACPUINT}$.

There is also a wait time associated with power-up in internal reference mode when switching between 2.5V and 3.3V range. See the device data sheet for wait time values.

## 10.3 Analog Subsystem Registers

This section describes the Analog Subsystem Registers.

### *10.3.1 Analog Subsystem Base Addresses*

**Table 10-3. Analog Subsystem Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|---|---|---|---|
| AnalogSubsysRegs | ANALOG_SUBSYS_REGS | 0x0005_D180 | 0x0005_D1FF |

Copyright © 2024 Texas Instruments Incorporated

### 10.3.2 ANALOG_SUBSYS_REGS Registers

Table 10-4 lists the memory-mapped registers for the ANALOG_SUBSYS_REGS registers. All register offset addresses not listed in Table 10-4 should be considered as reserved locations and the register contents should not be modified.

**Table 10-4. ANALOG_SUBSYS_REGS Registers**

| Offset | Acronym | Register Name | Write Protection | Section |
|---|---|---|---|---|
| 20h | INTOSC1TRIM | Internal Oscillator 1 Trim Register | EALLOW | Go |
| 22h | INTOSC2TRIM | Internal Oscillator 2 Trim Register | EALLOW | Go |
| 26h | TSNSCTL | Temperature Sensor Control Register | EALLOW | Go |
| 2Eh | LOCK | Lock Register | EALLOW | Go |
| 36h | ANAREFTRIMA | Analog Reference Trim A Register | EALLOW | Go |
| 38h | ANAREFTRIMB | Analog Reference Trim B Register | EALLOW | Go |
| 3Ah | ANAREFTRIMC | Analog Reference Trim C Register | EALLOW | Go |
| 3Ch | ANAREFTRIMD | Analog Reference Trim D Register | EALLOW | Go |

Complex bit access types are encoded to fit into small table cells. Table 10-5 shows the codes that are used for access types in this section.

**Table 10-5. ANALOG_SUBSYS_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| R-0 | R<br>-0 | Read<br>Returns 0s |
| Write Type | | |
| W | W | Write |
| WOnce | W<br>Once | Write<br>Write once |
| Reset or Default Value | | |
| *-n* | | Value after reset or the default value |
| Register Array Variables | | |
| i,j,k,l,m,n | | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y | | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

Chapter 11

# Analog-to-Digital Converter (ADC)

The analog-to-digital converter (ADC) module described in this chapter is a Type 4 ADC. See the *C2000 Real-Time Control Peripheral Reference Guide* for a list of all devices with modules of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

## 11.1 Introduction

The ADC module is a successive approximation (SAR) style ADC with selectable resolution of either 16 bits or 12 bits. The ADC is composed of a core and a wrapper. The core is composed of the analog circuits which include the channel select MUX, the sample-and-hold (S/H) circuit, the successive approximation circuits, voltage reference circuits, and other analog support circuits. The wrapper is composed of the digital circuits that configure and control the ADC. These circuits include the logic for programmable conversions, result registers, interfaces to analog circuits, interfaces to the peripheral buses, post-processing circuits, and interfaces to other on-chip modules.

Each ADC module consists of a single sample-and-hold (S/H) circuit. The ADC module is designed to be duplicated multiple times on the same chip, allowing simultaneous sampling or independent operation of multiple ADCs. The ADC wrapper is start-of-conversion (SOC) based (see Section 11.3).

### *11.1.2 Features*

Each ADC has the following features:

- Selectable resolution of 12 bits or 16 bits
- Ratiometric external reference set by VREFHI and VREFLO pins
- Differential signal conversions (16-bit mode only)
- Single-ended signal conversions (12-bit mode only)
- Input multiplexer with up to 16 channels (single-ended) or 8 channels (differential)
- 16 configurable SOCs
- 16 individually addressable result registers
- Multiple trigger sources
  - S/W - software immediate start
  - All ePWMs - ADCSOC A or B
  - GPIO XINT2
  - CPU Timers 0/1/2 (from each C28x core present)
  - ADCINT1/2
- Four flexible PIE interrupts
- Configurable interrupt placement
- Burst mode
- Four post-processing blocks, each with:
  - Saturating offset calibration
  - Error from set-point calculation
  - High, low, and zero-crossing compare, with interrupt and ePWM trip capability
  - Trigger-to-sample delay capture

**Note**

Not every channel is pinned out from all ADCs. Check the device data sheet to determine which channels are available.

## 11.2 ADC Configurability

Some ADC configurations are individually controlled by the SOCs, while others are globally controlled per ADC module. Table 11-1 summarizes the basic ADC options and the level of configurability. The subsequent sections discuss these configurations.

**Table 11-1. ADC Options and Configuration Levels**

| Options | Configurability |
|---|---|
| Clock | Per module(1) |
| Resolution | Per module(1) |
| Signal mode | Per module |
| Reference voltage source | Not configurable (external reference only) |
| Trigger source | Per SOC(1) |
| Converted channel | Per SOC |
| Acquisition window duration | Per SOC(1) |
| EOC location | Per module (early or late) |
| Burst Mode | Per module(1) |

(1) Writing these values differently to different ADC modules can cause the ADCs to operate asynchronously. See Section 11.13.1 for guidance on when the ADCs are operating synchronously or asynchronously.

### *11.2.1 Clock Configuration*

The base ADC clock is provided directly by the system clock (SYSCLK). SYSCLK is used to generate the ADC acquisition window. The register ADCCTL2 has a PRESCALE field that determines the ADCCLK. ADCCLK is used to clock the converter, and is only active during the conversion phase. At all other times, including during the sample-and-hold window, the ADCCLK signal is gated off.

In 16-bit mode, the core requires approximately 29.5 ADCCLK cycles to process a voltage into a conversion result, while in 12-bit mode, this process requires approximately 10.5 ADCCLK cycles. The choice of resolution also determines the necessary duration of the acquisition window, see Section 11.13.2.

**Note**

To determine an appropriate value for ADCCTL2.PRESCALE, see the device data sheet to determine the maximum SYSCLK and ADCCLK frequency.

### *11.2.2 Resolution*

The resolution of the ADC determines how finely the analog range is quantized into digital values. Each ADC module supports a configurable resolution of 16 bits or 12 bits.

The resolution must be configured by using either the AdcSetMode() or ADC_setMode() functions, depending on the header files used, provided in C2000ware in F2837xD_Adc.c. These functions make sure that the correct trim is loaded into the ADC trim registers, and must be called at least once after a device reset. Do not configure the resolution by directly writing to the ADCCTL2 register.

The resolution can be changed at any time when the ADC is idle (no active or pending SOCs). No wait time is necessary after changing the resolution before conversions can be initiated. If SOCs are active or pending when the resolution is changed, those SOCs can produce incorrect conversion results.

Copyright © 2024 Texas Instruments Incorporated

### 11.2.3 Voltage Reference

#### 11.2.3.1 External Reference Mode

Each ADC has a VREFHI input and a VREFLO input. In external reference mode, these pins are used as a ratiometric reference to determine the ADC conversion input range.

See Section 11.13.6 for information on how to supply the reference voltage.

**Note**

- On devices with no external VREFLO pin, VREFLO is internally connected to the device analog ground, VSSA.
- See the device data sheet to determine the allowable voltage range for VREFHI and VREFLO.
- The external reference mode requires an external capacitor on the VREFHI pin. See the device data sheet for the specific value required.

### 11.2.4 Signal Mode

The ADC supports two signal modes: single-ended and differential.

In single-ended mode, the input voltage to the converter is sampled through a single pin (ADCINx), referenced to VREFLO.

In differential signaling mode, the input voltage to the converter is sampled through a pair of input pins, one of which is the positive input (ADCINxP) and the other is the negative input (ADCINxN). The actual input voltage is the difference between the two (ADCINxP – ADCINxN).

**Note**

- In differential signal mode, VREFLO must be connected to VSSA.
- In differential signal mode, the common mode voltage is $V_{CM}$ = (ADCINxP + ADCINxN)/2

  The data sheet for a particular device places some requirements on how close this voltage needs to be to: (VREFHI + VREFLO)/2

  **Note**: The above condition is not met by connecting the negative input to VSSA or VREFLO.
- Differential signaling mode is advantageous because noise encountered on both inputs is largely canceled. The effect can be maximized by routing the positive and negative traces for the same differential input as close together as possible and keeping them symmetrical with respect to the signal reference.

The signal mode must be configured by using either the ADC_setMode() or AdcSetMode() functions, depending on the header files used, provided in C2000warein F2837xD_Adc.c. These functions make sure that the correct trim is loaded into the ADC trim registers. These functions must be called at least once after a device reset. The signal mode must not be configured by writing to the ADCCTL2 register directly.

### 11.2.5 Expected Conversion Results

Based on a given analog input voltage, the expected digital conversion is given in Table 11-2 and Table 11-3. Fractional values are truncated.

**Table 11-2. Analog to 12-bit Digital Formulas**

| | Analog Input | Digital Result |
|---|---|---|
| **Single-Ended** | when ADCINy ≤ VREFLO | ADCRESULTx = 0 |
| | when VREFLO < ADCINy < VREFHI | $ADCRESULTx = 4096\left(\frac{ADCINy - VREFLO}{VREFHI - VREFLO}\right)$ |
| | when ADCINy ≥ VREFHI | ADCRESULTx = 4095 |
| **Differential** | when ADCINyP - ADCINyN ≤ -(VREFHI-VREFLO) | ADCRESULTx = 0 |
| | when -(VREFHI-VREFLO) < ADCINyP - ADCINyN ≤ (VREFHI-VREFLO) | $ADCRESULTx = 4096\left(\frac{ADCINyP - ADCINyN + VREFHI - VREFLO}{2(VREFHI - VREFLO)}\right)$ |
| | when ADCINyP - ADCINyN ≥ (VREFHI-VREFLO) | ADCRESULTx = 4095 |

**Table 11-3. Analog to 16-bit Digital Formulas**

| | Analog Input | Digital Result |
|---|---|---|
| **Single-Ended** | Invalid Mode | Invalid Mode |
| **Differential** | when ADCINyP - ADCINyN ≤ -(VREFHI-VREFLO) | ADCRESULTx = 0 |
| | when -(VREFHI-VREFLO) < ADCINyP - ADCINyN ≤ (VREFHI-VREFLO) | $ADCRESULTx = 65536\left(\frac{ADCINy - VREFLO}{VREFHI - VREFLO}\right)$ |
| | when ADCINyP - ADCINyN ≥ (VREFHI-VREFLO) | ADCRESULTx = 65535 |

### 11.2.6 Interpreting Conversion Results

Based on a given ADC conversion result, the corresponding analog input is given in Table 11-4 and Table 11-5. This corresponds to the center of the possible range of analog voltages that can produce this conversion result.

**Table 11-4. 12-Bit Digital-to-Analog Formulas**

| | Digital Value | Analog Equivalent |
|---|---|---|
| **Single-Ended** | when ADCRESULTy = 0 | $\text{ADCINx} \leq \text{VREFLO}$ (1) |
| | when 0 < ADCRESULTy < 4095 | $\text{ADCINx} = (\text{VREFHI} - \text{VREFLO})\left(\frac{\text{ADCRESULTy}}{4096}\right) + \text{VREFLO}$ (2) |
| | when ADCRESULTy = 4095 | $\text{ADCINx} \geq \text{VREFHI}$ (3) |
| **Differential** | when ADCRESULTy = 0 | $ADCINxP - ADCINxN \leq (VREFHI - VREFLO)$ (4) |
| | when 0 < ADCRESULTy < 4095 | $ADCINxP - ADCINxN = (VREFHI - VREFLO)\left(\frac{ADCRESULTy}{2048} - 1\right)$ (5) |
| | when ADCRESULTy = 4095 | $ADCINxP - ADCINxN \geq (VREFHI - VREFLO)$ (6) |

**Table 11-5. 16-Bit Digital-to-Analog Formulas**

| | Digital Value | Analog Equivalent |
|---|---|---|
| **Single-Ended** | Invalid Mode | Invalid Mode |
| **Differential** | when ADCRESULTy = 0 | $ADCINxP - ADCINxN \leq (VREFHI - VREFLO)$ (7) |
| | when 0 < ADCRESULTy < 65535 | $ADCINxP - ADCINxN = (VREFHI - VREFLO)\left(\frac{ADCRESULTy}{2048} - 1\right)$ (8) |
| | when ADCRESULTy = 65535 | $ADCINxP - ADCINxN \geq (VREFHI - VREFLO)$ (9) |

## 11.3 SOC Principle of Operation

The ADC triggering and conversion sequencing is accomplished through configurable start-of-conversions (SOCs). Each SOC is a configuration set defining the single conversion of a single channel. In that set, there are three configurations: the trigger source that starts the conversion, the channel to convert, and the acquisition (sample) window duration. Upon receiving the trigger configured for a SOC, the wrapper makes sure that the specified channel is captured using the specified acquisition window duration.

Multiple SOCs can be configured for the same trigger, channel, and acquisition window as desired. Configuring multiple SOCs to use the same trigger allows the trigger to generate a sequence of conversions. Configuring multiple SOCs to use the same trigger and channel allows for oversampling.

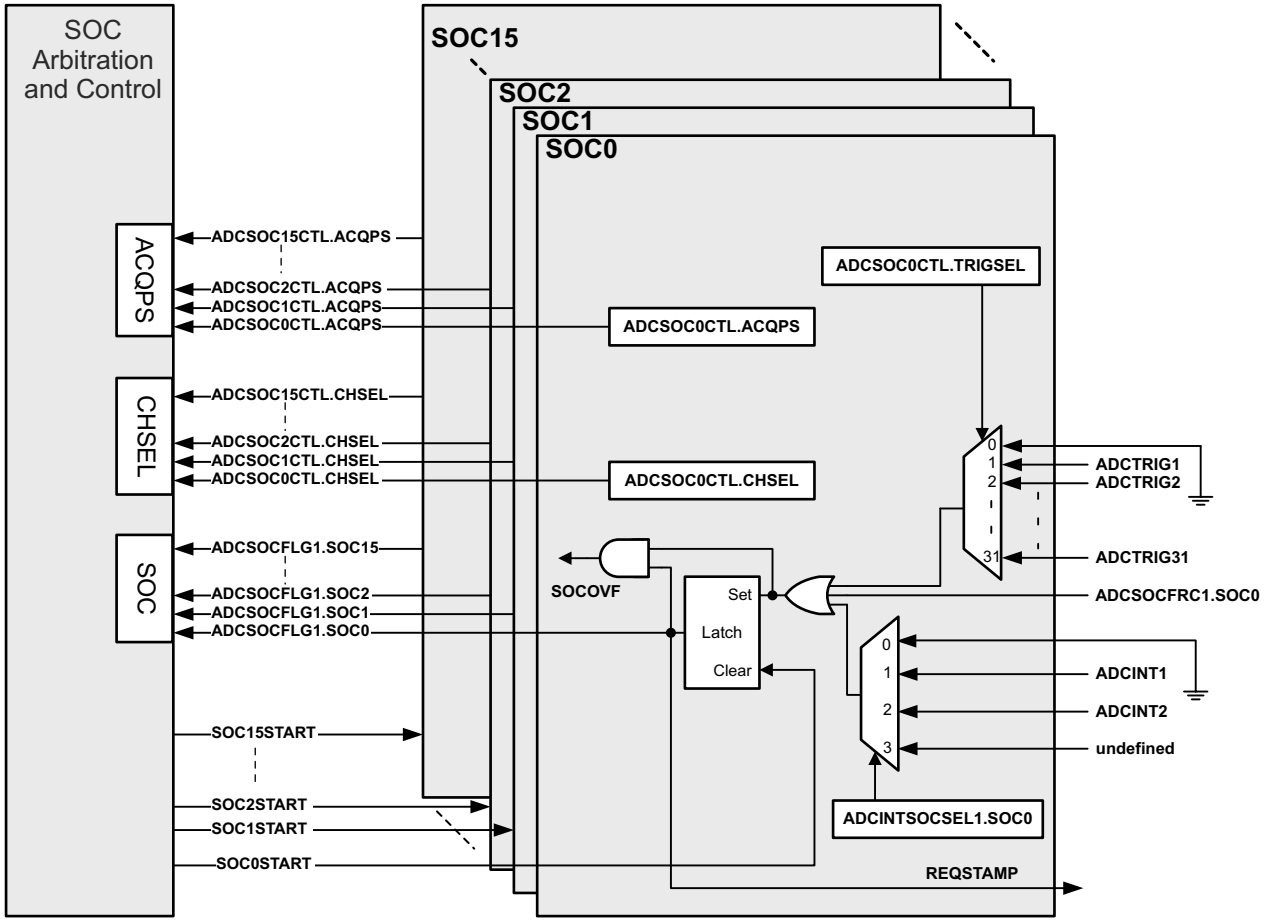

**Figure 11-2. SOC Block Diagram**

Copyright © 2024 Texas Instruments Incorporated

### 11.3.1 SOC Configuration

Each SOC has a configuration register, ADCSOCxCTL. Within this register, SOCx can be configured for trigger source, channel to convert, and acquisition (sample) window duration.

### 11.3.2 Trigger Operation

Each SOC can be configured to start on one of many input triggers. The primary trigger select for SOCx is in the ADCSOCxCTL.TRIGSEL register, which can select between:

- Disabled (software only)
- CPU Timers 0/1/2 (from each C28x core present)
- GPIO: Input X-Bar INPUT5
- ADCSOCA or ADCSOCB from each ePWM module

In addition, each SOC can also be triggered when the ADCINT1 flag or ADCINT2 flag is set. This is achieved by configuring the ADCINTSOCSEL1 register (for SOC0 to SOC7) or the ADCINTSOCSEL2 register (for SOC8 to SOC15). This is useful for creating continuous conversions.

### 11.3.3 ADC Acquisition (Sample and Hold) Window

External signal sources vary in the ability to drive an analog signal quickly and effectively. To achieve rated resolution, the signal source needs to charge the sampling capacitor in the ADC core to within 0.5 LSBs of the signal voltage. The acquisition window is the amount of time the sampling capacitor is allowed to charge and is configurable for SOCx by the ADCSOCxCTL.ACQPS register.

ACQPS is a 9-bit register that can be set to a value between 0 and 511, resulting in an acquisition window duration of:

Acquisition window = (ACQPS + 1) * (System Clock (SYSCLK) cycle time)

- The acquisition window duration is based on the System Clock (SYSCLK), not the ADC clock (ADCCLK).
- The selected acquisition window duration must be at least as long as one ADCCLK cycle.
- The data sheet specifies a minimum acquisition window duration (in nanoseconds). The user is responsible for selecting an acquisition window duration that meets this requirement.

Copyright © 2024 Texas Instruments Incorporated

### 11.3.4 ADC Input Models

For single-ended operation, the ADC input characteristics for values in the single-ended input model (see Figure 11-3) can be found in the device data sheet.

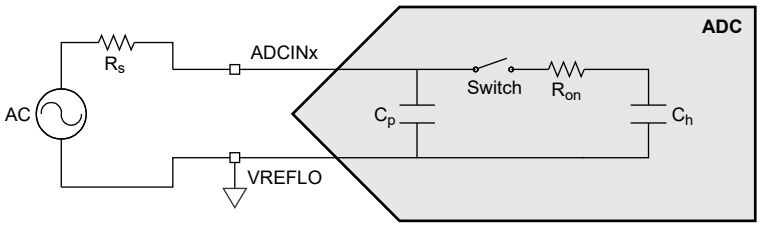

**Figure 11-3. Single-Ended Input Model**

For differential operation, the ADC input characteristics for values in the differential input model (see Figure 11-4 ) can be found in the device data sheet.

These input models must be used along with actual signal source impedance to determine the acquisition window duration. See Section 11.13.2 for more information.

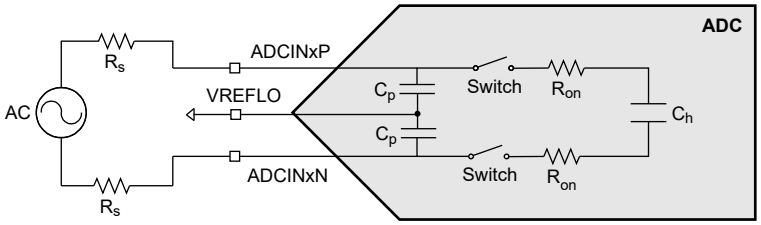

**Figure 11-4. Differential Input Model**

Copyright © 2024 Texas Instruments Incorporated

### 11.3.5 Channel Selection

Each SOC can be configured to convert any of the ADC channels. This behavior is selected for SOCx by the ADCSOCxCTL.CHSEL register. Depending on the signal mode, the selection is different. For single-ended signal mode, the value in CHSEL selects a single pin as the input. For differential signal mode, the value in CHSEL selects an even-odd pin pair to be the positive and negative inputs. This is summarized in Table 11-6.

**Note**

Regardless of configured resolution and signal mode, channel 13 on ADC-A (temperature sensor) and channel 12 on all ADCs are sampled in 12-bit single-ended mode.

**Table 11-6. Channel Selection of Input Pins**

| Input Mode | CHSEL | Input | |
|---|---|---|---|
| Single-Ended | 0 | ADCIN0 | |
| | 1 | ADCIN1 | |
| | 2 | ADCIN2 | |
| | 3 | ADCIN3 | |
| | 4 | ADCIN4 | |
| | 5 | ADCIN5 | |
| | 6 | ADCIN6 | |
| | 7 | ADCIN7 | |
| | 8 | ADCIN8 | |
| | 9 | ADCIN9 | |
| | 10 | ADCIN10 | |
| | 11 | ADCIN11 | |
| | 12 | ADCIN12 | |
| | 13 | ADCIN13 | |
| | 14 | ADCIN14 | |
| | 15 | ADCIN15 | |
| | **CHSEL** | **Positive Input** | **Negative Input** |
| Differential | 0 or 1 | ADCIN0 | ADCIN1 |
| | 2 or 3 | ADCIN2 | ADCIN3 |
| | 4 or 5 | ADCIN4 | ADCIN5 |
| | 6 or 7 | ADCIN6 | ADCIN7 |
| | 8 or 9 | ADCIN8 | ADCIN9 |
| | 10 or 11 | ADCIN10 | ADCIN11 |
| | 12 or 13 | ADCIN12 | ADCIN13 |
| | 14 or 15 | ADCIN14 | ADCIN15 |

## 11.4 SOC Configuration Examples

The following sections provide some specific examples of how to configure the SOCs to produce some conversions.

### *11.4.1 Single Conversion from ePWM Trigger*

To configure ADCA to perform a single conversion on channel ADCIN1 when the ePWM timer reaches the period match, a few things are necessary. First, ePWM3 must be configured to generate an SOCA or SOCB signal (in this statement, SOC refers to a signal in the ePWM module). See the *Enhanced Pulse Width Modulator Module (ePWM)* chapter on how to do this. Assume that SOCB was chosen.

SOC5 is chosen arbitrarily. Any of the 16 SOCs can be used.

Assuming a 100ns sample window is desired with a SYSCLK frequency of 200MHz, then the acquisition window duration must be 100ns/5ns = 20 SYSCLK cycles. The ACQPS field must be set to 20 - 1 = 19.

```
AdcaRegs.ADCSOC5CTL.bit.CHSEL = 1;      //SOC5 converts ADCINA1
AdcaRegs.ADCSOC5CTL.bit.ACQPS = 19;     //SOC5 uses a sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC5CTL.bit.TRIGSEL = 10;   //SOC5 begins conversion on ePWM3 SOCB
```

As configured, when ePWM3 matches the period and generates the SOCB signal, the ADC begins sampling channel ADCINA1 (SOC5) immediately if the ADC is idle. If the ADC is busy, ADCINA1 begins sampling when SOC5 gains priority (see Section 11.5). The ADC control logic samples ADCINA1 with the specified acquisition window width of 100ns. Immediately after the acquisition is complete, the ADC begins converting the sampled voltage to a digital value. When the ADC conversion is complete, the results are available in the ADCRESULT5 register (see Section 11.12 for exact sample, conversion, and result latch timings).

### *11.4.2 Oversampled Conversion from ePWM Trigger*

To configure the ADC to oversample ADCINA1 4 times, we use the same configurations as the previous example, but apply them to SOC5, SOC6, SOC7, and SOC8.

```
AdcaRegs.ADCSOC5CTL.bit.CHSEL = 1;        //SOC5 converts ADCINA1
AdcaRegs.ADCSOC5CTL.bit.ACQPS = 19;       //SOC5 uses a sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC5CTL.bit.TRIGSEL = 10;     //SOC5 begins conversion on ePWM3 SOCB
AdcaRegs.ADCSOC6CTL.bit.CHSEL = 1;        //SOC6 converts ADCINA1
AdcaRegs.ADCSOC6CTL.bit.ACQPS = 19;       //SOC6 uses a sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC6CTL.bit.TRIGSEL = 10;     //SOC6 begins conversion on ePWM3 SOCB
AdcaRegs.ADCSOC7CTL.bit.CHSEL = 1;        //SOC7 converts ADCINA1
AdcaRegs.ADCSOC7CTL.bit.ACQPS = 19;       //SOC7 uses a sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC7CTL.bit.TRIGSEL = 10;     //SOC7 begins conversion on ePWM3 SOCB
AdcaRegs.ADCSOC8CTL.bit.CHSEL = 1;        //SOC8 converts ADCINA1
AdcaRegs.ADCSOC8CTL.bit.ACQPS = 19;       //SOC8 uses a sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC8CTL.bit.TRIGSEL = 10;     //SOC8 begins conversion on ePWM3 SOCB
```

As configured, when ePWM3 matches the period and generates the SOCB signal, the ADC begins sampling channel ADCINA1 (SOC5) immediately if the ADC is idle. If the ADC is busy, ADCINA1 begins sampling when SOC5 gains priority (see Section 11.5). Once the conversion is complete for SOC5, SOC6 begins converting ADCINA1 and the results for SOC5 are placed in the ADCRESULT5 register. All four conversions eventually are completed sequentially, with the results in ADCRESULT5, ADCRESULT6, ADCRESULT7, and ADCRESULT8 for SOC5, SOC6, SOC7, and SOC8, respectively.

**Note**

It is possible, but unlikely, that the ADC can begin converting SOC6, SOC7, or SOC8 before SOC5 depending on the position of the round-robin pointer when the ePWM trigger is received. See Section 11.5 to understand how the next SOC to be converted is chosen.

Copyright © 2024 Texas Instruments Incorporated

### 11.4.3 Multiple Conversions from CPU Timer Trigger

This example shows how to sample multiple signals with different acquisition window requirements. CPU1 Timer 2 is used to generate the trigger. To see how to configure the CPU timer, see the *System Control and Interrupts* chapter.

A good first step when designing a sampling scheme with many signals is to list out the signals and the required acquisition window. From this, calculate the necessary number of SYSCLK cycles for each signal, then the ACQPS register setting. This is shown in Table 11-7, where a SYCLK of 200MHz is assumed (5ns cycle time).

**Table 11-7. Example Requirements for Multiple Signal Sampling**

| Signal Name | Acquisition Window Requirement | Acquisition Window (SYSCLK Cycles) | ACQPS Register Value |
|---|---|---|---|
| Signal 1 | >120ns | 120ns/5ns = 24 | 24 – 1 = 23 |
| Signal 2 | >444ns | 444ns/5ns = 89 (round up) | 89 – 1 = 88 |
| Signal 3 | >110ns | 110ns/5ns = 22 | 22 – 1 = 21 |
| Signal 4 | >291ns | 291ns/5ns = 59 (round up) | 59 – 1 = 58 |

Next decide which ADC pins to connect to each signal. This is highly dependent on the application board layout. Once the pins are selected, determining the value of CHSEL is straightforward (see Table 11-8).

**Table 11-8. Example Connections for Multiple Signal Sampling**

| Signal Name | ADC Pin | CHSEL Register Value |
|---|---|---|
| Signal 1 | ADCINA5 | 5 |
| Signal 2 | ADCINA0 | 0 |
| Signal 3 | ADCINA3 | 3 |
| Signal 4 | ADCINA2 | 2 |

With the information tabulated, generate the SOC configurations:

```
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 5;        //SOC0 converts ADCINA5
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 23;       //SOC0 uses a sample duration of 24 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 3;      //SOC0 begins conversion on CPU1 Timer 2
AdcaRegs.ADCSOC1CTL.bit.CHSEL = 0;        //SOC1 converts ADCINA0
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 88;       //SOC1 uses a sample duration of 89 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 3;      //SOC1 begins conversion on CPU1 Timer 2
AdcaRegs.ADCSOC2CTL.bit.CHSEL = 3;        //SOC2 converts ADCINA3
AdcaRegs.ADCSOC2CTL.bit.ACQPS = 21;       //SOC2 uses a sample duration of 22 SYSCLK cycles
AdcaRegs.ADCSOC2CTL.bit.TRIGSEL = 3;      //SOC2 begins conversion on CPU1 Timer 2
AdcaRegs.ADCSOC3CTL.bit.CHSEL = 2;        //SOC3 converts ADCINA2
AdcaRegs.ADCSOC3CTL.bit.ACQPS = 58;       //SOC3 uses a sample duration of 59 SYSCLK cycles
AdcaRegs.ADCSOC3CTL.bit.TRIGSEL = 3;      //SOC3 begins conversion on CPU1 Timer 2
```

As configured, when CPU1 Timer 2 generates an event, SOC0, SOC1, SOC2, and SOC3 eventually is sampled and converted, in that order. The conversion results for ACINA5 (Signal 1) are in ADCRESULT0. Similarly, The results for ADCINA0 (Signal 2), ADCINA3 (Signal 3), and ADCINA2 (Signal 4) are in ADCRESULT1, ADCRESULT2, and ADCRESULT3, respectively.

**Note**

There is a possibility, but unlikely, that the ADC can begin converting SOC1, SOC2, or SOC3 before SOC0 depending on the position of the round-robin pointer when the CPU Timer trigger is received. See Section 11.5 to understand how the next SOC to be converted is chosen.

Copyright © 2024 Texas Instruments Incorporated

### 11.4.4 Software Triggering of SOCs

At any point, whether or not the SOCs have been configured to accept a specific trigger, a software trigger can set the SOCs to be converted. This is accomplished by writing bits in the ADCSOCFRC1 register.

Software triggering of the previous example without waiting for the CPU1 Timer 2 to generate the trigger can be accomplished by the statement:

```
AdcaRegs.ADCSOCFRC1.all = 0x000F;        //set SOC flags for SOC0 to SOC3
```

## 11.5 ADC Conversion Priority

When multiple SOC flags are set at the same time, one of two forms of priority determines the converted order. The default priority method is round-robin. In this scheme, no SOC has an inherent higher priority than another. Priority depends on the round-robin pointer (RRPOINTER). The RRPOINTER reflected in the ADCSOCPRIORITYCTL register points to the last SOC converted. The highest priority SOC is given to the next value greater than the RRPOINTER value, wrapping around back to SOC0 after SOC15. At reset the value is 16 since 0 indicates a conversion has already occurred. When RRPOINTER equals 16 the highest priority is given to SOC0. The RRPOINTER is reset when the ADC module is reset or when the reset value is written to the SOCPRICTL register. The ADC module is reset by writing and clearing the SOFTPRES bit corresponding to the ADC instance.

An example of the round-robin priority method is given in Figure 11-5.

The SOCPRIORITY field in the ADCSOCPRIORITYCTL register can be used to assign high priority from a single to all of the SOCs. When configured as high priority, an SOC interrupts the round-robin wheel after any current conversion completes and inserts in as the next conversion. After the conversion completes, the round-robin wheel continues where the conversion was interrupted. If two high priority SOCs are triggered at the same time, the SOC with the lower number takes precedence.

High priority mode is assigned first to SOC0, then in increasing numerical order. The value written in the SOCPRIORITY field defines the first SOC that is not high priority. In other words, if a value of 4 is written into SOCPRIORITY, then SOC0, SOC1, SOC2, and SOC3 are defined as high priority, with SOC0 the highest.

An example using high priority SOC's is given in Figure 11-6.

## 11.6 Burst Mode

Burst mode allows a single trigger to walk through the round-robin SOCs one or more at a time. Setting the bit BURSTEN in the ADCBURSTCTL register configures the ADC wrapper for burst mode. This causes the TRIGSEL field to be ignored, but only for SOCs that are configured for round-robin operation (not high priority). Instead of the TRIGSEL field, all round-robin SOCs are triggered based on the BURSTTRIG field in the ADCBURSTCTL register. Upon reception of the burst trigger, the ADC wrapper does not set all round-robin SOCs to be converted, but only (ADCBURSTCTL.BURSTSIZE + 1) SOCs. The first SOC to be set is the SOC with the highest priority based on the round-robin pointer, and subsequent SOCs are set until BURSTSIZE SOCs have been set.

**Note**

When configuring the ADC for burst mode, the user is responsible for ensuring that each burst of conversions is allowed to complete before the next burst trigger is received. The value of (ADCBURSTCTL.BURSTSIZE + 1) must be less than or equal to the number of SOCs configured for round-robin priority.

For example, if SOCPRIORITY = 12, that is, SOC12, SOC13, SOC14, and SOC15 are in round-robin, ADCBURSTCTL.BURSTSIZE setting must be ≤3 for burst mode to operate correctly.

### *11.6.1 Burst Mode Example*

Burst mode can be used to sample a different set of signals on every other trigger. In the following example, ADCIN7 and ADCIN5 are converted on the first trigger from CPU1 Timer 2 and every other trigger thereafter. ADCIN2 and ACIN3 are converted on the second trigger from CPU1 Timer 2 and every other trigger thereafter. All signals are converted with 20 SYSCLK cycle wide acquisition windows, but different durations can be configured for each SOC as desired.

```
AdcaRegs.BURSTCTL.BURSTEN = 1;              //Enable ADC burst mode
AdcaRegs.BURSTCTL.BURSTTRIG = 3;            //CPU1 Timer 2 triggers burst of conversions
AdcaRegs.BURSTCTL.BURSTSIZE = 1;            //conversion bursts are 1 + 1 = 2 conversions long
AdcaRegs.SOCPRICTL.bit.SOCPRIORITY = 12;    //SOC0 to SOC11 are high priority
AdcaRegs.ADCSOC12CTL.bit.CHSEL = 7;         //SOC12 converts ADCINA7
AdcaRegs.ADCSOC12CTL.bit.ACQPS = 19;        //SOC12 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC13CTL.bit.CHSEL = 5;         //SOC13 converts ADCINA5
AdcaRegs.ADCSOC13CTL.bit.ACQPS = 19;        //SOC13 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC14CTL.bit.CHSEL = 2;         //SOC14 converts ADCINA2
AdcaRegs.ADCSOC14CTL.bit.ACQPS = 19;        //SOC14 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC15CTL.bit.CHSEL = 3;         //SOC15 converts ADCINA3
AdcaRegs.ADCSOC15CTL.bit.ACQPS = 19;        //SOC15 uses sample duration of 20 SYSCLK cycles
```

When the first CPU1 Timer 2 trigger is received, SOC12 and SOC13 are converted immediately if the ADC is idle. If the ADC is busy, SOC12 and SOC13 are converted once the SOCs gain priority. The results for SOC12 and SOC13 are in ADCRESULT12 and ADCRESULT13, respectively. After SOC13 completes, the round-robin pointer gives the highest priority to SOC14. Because of this, when the next CPU1 Timer 2 trigger is received, SOC14 and SOC15 is set as pending and eventually converted. The results for SOC14 and SOC15 are in ADCRESULT14 and ADCRESULT15, respectively. Subsequent triggers continue to toggle between converting SOC12 and SOC13, and converting SOC14 and SOC15.

While the above example toggles between two sets of conversions, three or more different sets of conversions can be achieved using a similar approach.

### 11.6.2 Burst Mode Priority Example

An example of priority resolution using burst mode and high-priority SOCs is presented in Figure 11-7.

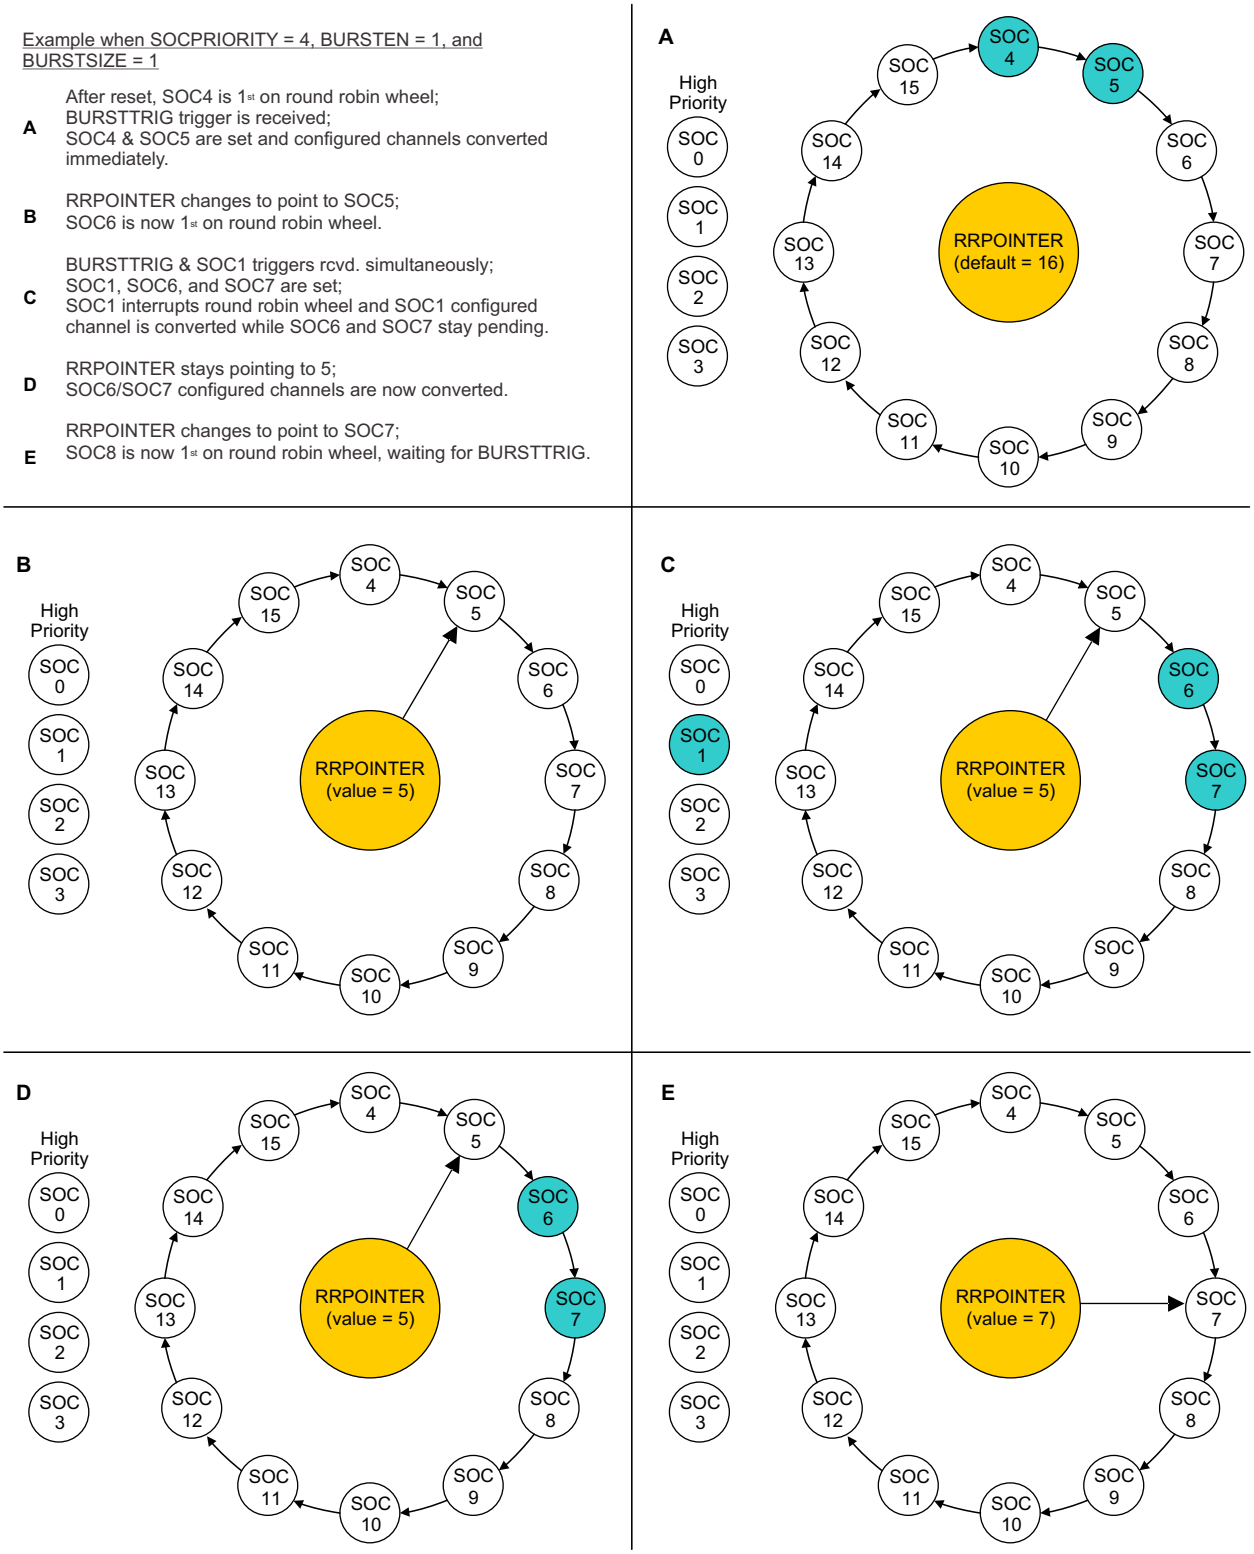

**Figure 11-7. Burst Priority Example**

## 11.7 EOC and Interrupt Operation

Each SOC has a corresponding end-of-conversion (EOC) signal. This EOC signal can be used to trigger an ADC interrupt. The ADC can be configured to generate the EOC pulse at either the end of the acquisition window or at the end of the voltage conversion. This is configured using the bit INTPULSEPOS in the ADCCTL1 register. See Section 11.12 for exact EOC pulse location.

Each ADC module has 4 configurable ADC interrupts. These interrupts can be triggered by any of the 16 EOC signals. The flag bit for each ADCINT can be read directly to determine if the associated SOC is complete or the interrupt can be passed on to the PIE.

**Note**

The ADCCTL1.ADCBSY bit being clear does not indicate that all conversions in a set of SOCs have completed, only that the ADC is ready to process the next conversion. To determine if a sequence of SOCs is complete, link an ADCINT flag to the last SOC in the sequence and monitor that ADCINT flag.

Figure 11-8 shows a block diagram of the ADC interrupt structure.

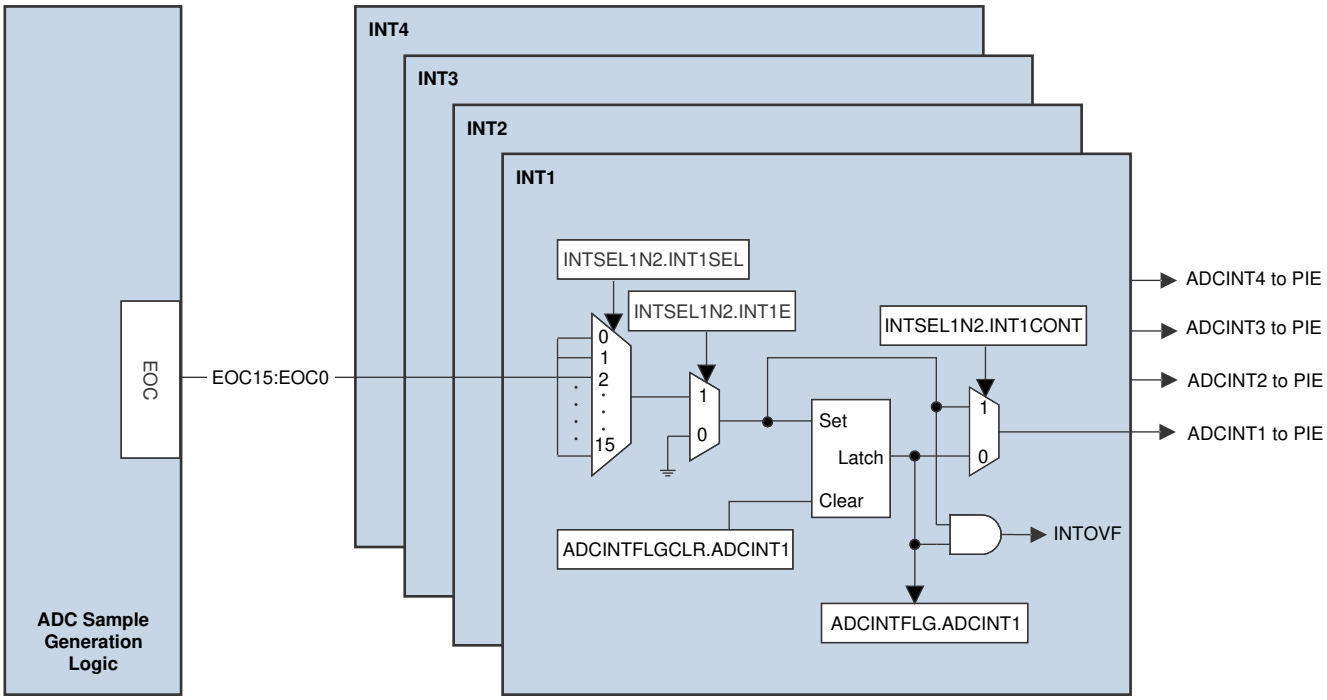

**Figure 11-8. ADC EOC Interrupts**

Copyright © 2024 Texas Instruments Incorporated

### 11.7.1 Interrupt Overflow

If the EOC signal sets a flag in the ADCINTFLG register, but that flag is already set, an interrupt overflow occurs. By default, overflow interrupts are not passed on to the PIE module. When an overflow occurs on a given flag in the ADCINTFLG register, the corresponding flag in the ADCINOVF register is set. This overflow flag is only used to detect that an overflow has occurred; the flag does not block further interrupts from propagating to the PIE module.

When an ADC interrupt overflow occurs, the application must check the appropriate ADCINTOVF flag inside the ISR or in the background loop and take appropriate action when an overflow is detected. The following code snippets demonstrate how to check the ADCINTOVF flag inside the ISR after attempting to clear the ADCINT flag.

```
// Clear the interrupt flag
AdcaRegs.ADCINTFLGCLR.bit.ADCINT1 = 1;      //clear INT1 flag for ADC-A

// Check if an overflow has occurred
if(1 == AdcaRegs.ADCINTOVF.bit.ADCINT1)     //ADCINT overflow occurred
{
    AdcaRegs.ADCINTOVFCLR.bit.ADCINT1 = 1   //Clear overflow flag
    AdcaRegs.ADCINTFLGCLR.bit.ADCINT1 = 1   //Re-clear ADCINT flag
}
```

```
//
// Clear the interrupt flag
//
ADC_clearInterruptStatus(ADCA_BASE, ADC_INT_NUMBER1);

//
// Check if an overflow has occurred
//
if(true == ADC_getInterruptOverflowStatus(ADCA_BASE, ADC_INT_NUMBER1))
{
    ADC_clearInterruptOverflowStatus(ADCA_BASE, ADC_INT_NUMBER1);
    ADC_clearInterruptStatus(ADCA_BASE, ADC_INT_NUMBER1);
}
```

### 11.7.2 Continue to Interrupt Mode

The INTxCONT bits in the ADCINTSEL1N2 and ADCINTSEL3N4 registers configure how interrupts are handled when an ADCINTFLG has not yet been cleared from a prior interrupt. This mode is disabled by default and additional overlapping interrupts are not issued to the PIE. By activating this mode, ADC interrupts always reach the PIE. If interrupts occur while ADCINTFLG is set, the ADCINTOVF register remains set regardless of the configuration of the INTxCONT bits.

### 11.7.3 Early Interrupt Configuration Mode

Enabling early interrupt mode can allow the application to enter the ADC interrupt service routine before the ADC results are ready. This allows the application to do any necessary pre-work so that the application can act on the ADC results immediately when the ADC results become available. If the timing of the early interrupt is too early, then the application needs to waste time until the updated ADC results become available. To prevent this situation, the time the ADC interrupt is entered in early interrupt mode is configurable by way of the DELAY field in the ADCINTCYCLE register.

- To use the configurable interrupt time, the ADC must be in early interrupt mode. To achieve this, clear the bit INTPULSEPOS to 0 in ADCCTL1.
- The DELAY value in the ADCINTCYCLE register sets the number of additional SYSCLK cycles after the falling edge of the SOC pulse before the ADCINT flag is set.
- If the value of DELAY goes beyond EOC, the ADC interrupt is generated along with EOC.
- Writing values to DELAY when INTPULSEPOS is set to 1 does not have any effect on the interrupt generation.

## 11.8 Post-Processing Blocks

Each ADC module contains four post-processing blocks (PPB). These blocks can be associated with any of the 16 RESULT registers using the ADCPPBxCONFIG.CONFIG bit field. The post-processing blocks have the ability to:

- Remove an offset associated with the ADCIN channel
- Subtract out a reference value
- Flag a zero-crossing point, with the option to trip a PWM and generate an interrupt
- Flag a high or low compare limit, with the option to trip a PWM and generate an interrupt
- Record the delay between the associated SOC trigger and when sampling actually begins

Figure 11-9 presents the structure of each PPB. Subsequent sections explain the use of each submodule.

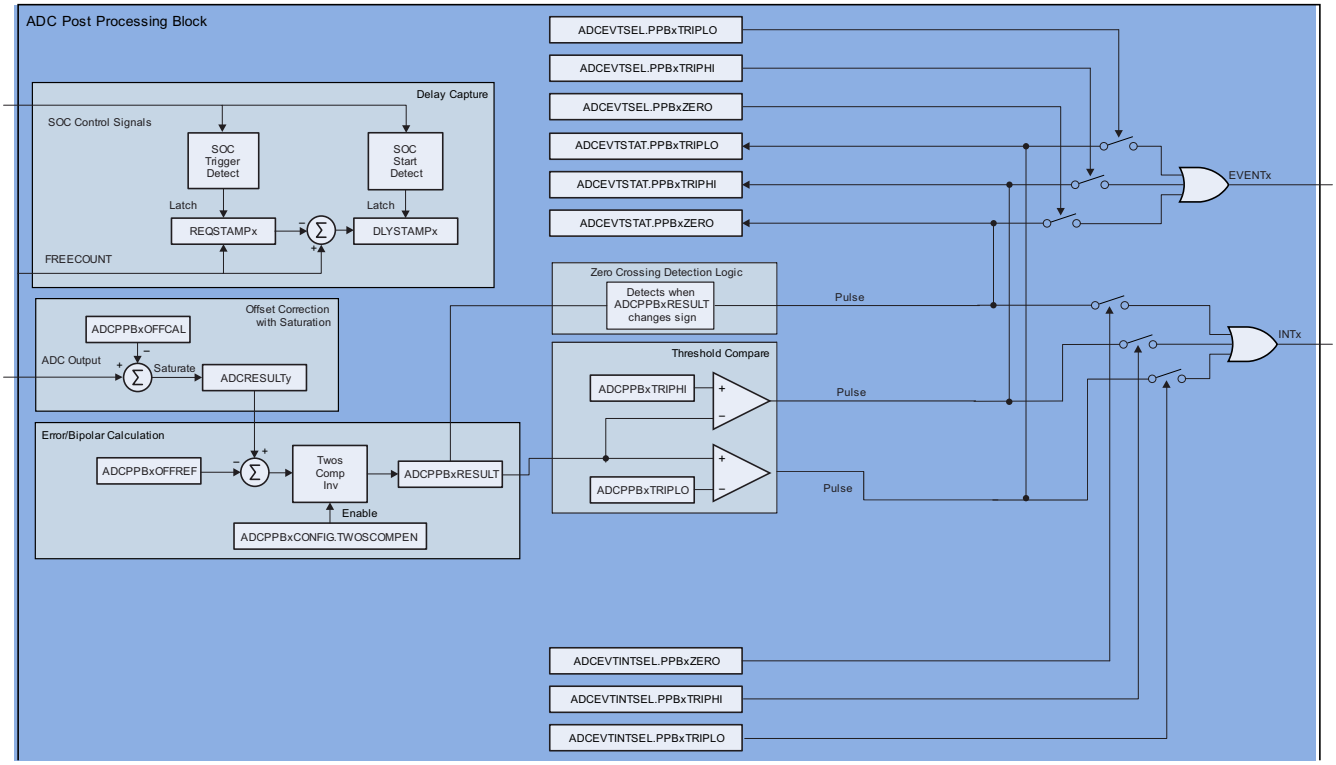

**Figure 11-9. ADC PPB Block Diagram**

Copyright © 2024 Texas Instruments Incorporated

### 11.8.1 PPB Offset Correction

In many applications, external sensors and signal sources produce an offset. A global trimming of the ADC offset is not enough to compensate for these offsets, which vary from channel to channel. The post-processing block can remove these offsets with zero overhead, saving numerous cycles in tight control loops.

Offset correction is accomplished by first pointing the ADCPPBxCONFIG.CONFIG to the desired SOC, then writing an offset correction value to the ADCPPBxOFFCAL.OFFCAL register. The post-processing block automatically adds or subtracts the value in the OFFCAL register from the raw conversion result and stores the value in the ADCRESULT register. This addition/subtraction saturates at 0 on the low end and either 4095 or 65535 on the high end for 12-bit or 16-bit mode, respectively.

**Note**

- Writing a 0 to the OFFCAL register effectively disables the offset correction feature, passing the raw result unchanged to the ADCRESULT register.
- To point multiple PPBs to the same SOC is possible. In this case, the OFFCAL value that is actually applied comes from the PPB with the highest number.
- In particular, care needs to be taken when using the PPB on SOC0, as all PPBs point to this SOC by default. This can cause unintentional overwriting of offset correction of a lower numbered PPB by a higher numbered PPB.

### 11.8.2 PPB Error Calculation

In many applications, an error from a set point or expected value must be computed from the digital output of an ADC conversion. In other cases, a bipolar signal is necessary or convenient for control calculations. The PPB can perform these functions automatically, reducing the sample to output latency and reducing software overhead.

Error calculation is accomplished by first pointing the ADCPPBxCONFIG.CONFIG to the desired SOC, then writing a value to the ADCPPBxOFFCAL.OFFREF register. The post-processing block automatically subtracts the value in the OFFREF register from the ADCRESULT value and stores the value in the ADCPPBxRESULT register. This subtraction produces a sign-extended 32-bit result. It is also possible to selectively invert the calculated value before storing in the ADCPPBxRESULT register by setting the TWOSCOMPEN bit in the ADCPPBxCONFIG register.

**Note**

- In 12-bit mode, do not write a value larger than 12 bits to the ADCPPBxOFFREF register.
- Since the ADCPPBxRESULT register is unique for each PPB, to point multiple PPBs to the same SOC and get different results for each PPB is possible.
- Writing a 0 to the ADCPPBxOFFREF register effectively disables the error calculation feature, passing the ADCRESULT value unchanged to the ADCPPBxRESULT register.
- Writing a new value to ADCPPBxOFFREF causes an immediate update to the ADCPPBxRESULT register. However, the flags coming out of the PPB do not change until the next end-of-conversion (EOC). For instance, if changing the ADCPPBxOFFREF register causes ADCPPBxRESULT to change signs, but the next conversion brings the result back to the same sign as before the OFFREF change, no ADCPPBxZERO flag is set.

### 11.8.3 PPB Limit Detection and Zero-Crossing Detection

Many applications perform a limit check against the ADC conversion results. The PPB can automatically perform a check against high and low limits, or whenever ADCPPBxRESULT changes sign. Based on these comparisons, the PPB can generate a trip to the PWM and an interrupt automatically, lowering the sample to

Copyright © 2024 Texas Instruments Incorporated

ePWM latency and reducing software overhead. This functionality also enables safety-conscious applications to trip the ePWM based on an out-of-range ADC conversion without any CPU intervention.

To enable this functionality, first point the ADCPPBxCONFIG.CONFIG to the desired SOC, then write a value to one or both of the registers ADCPPBxTRIPHI.LIMITHI and ADCPPBxTRIPLO.LIMITLO (zero-crossing detection does not require further configuration). Whenever these limits are exceeded, the PPBxTRIPHI bit or PPBxTRIPLO bit is set in the ADCEVTSTAT register. Note that the PPBxZERO bit in the ADCEVTSTAT register is gated by end-of-conversion (EOC), not by the sign change in the ADCPPBxRESULT register. The ADCEVTCLR register has corresponding bits to clear these event flags. The ADCEVTSEL register has corresponding bits which allow the events to propagate through to the PWM. The ADCEVTINTSEL register has corresponding bits that allow the events to propagate through to the PIE.

One PIE interrupt is shared between all the PPBs for a given ADC module as shown in Figure 11-10.

**Note**

- Zero-crossing and limit compare reference the ADCPPBxRESULT register. This includes any correction applied by the OFFCAL and OFFREF registers. TRIPHI and TRIPLO do not perform a signed comparison. It is recommended to leave OFFREF as 0 when using limit compare functionality.
- If different actions need to be taken for different PPB events from the same ADC module, then the ADCEVTINT ISR has to read the PPB event flags in the ADCEVTSTAT register to determine which event caused the interrupt.
- If different ePWM trips need to be generated separately for high compare, low compare, and zero-crossing, this can be achieved by pointing multiple PPBs to the same SOC.
- The zero-crossing detect circuit considers a result of zero to be positive.

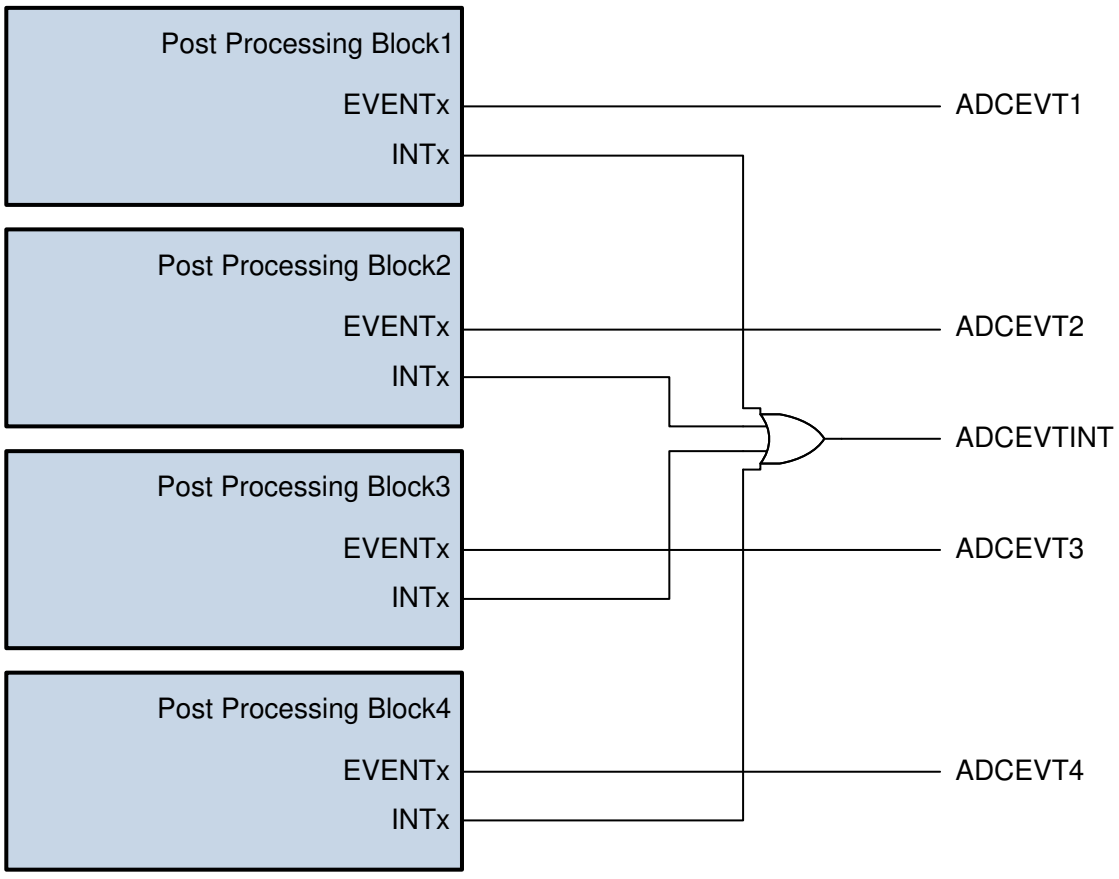

**Figure 11-10. ADC PPB Interrupt Event**

### 11.8.4 PPB Sample Delay Capture

When multiple control loops are running asynchronously on the same ADC, there is a chance that an ADC request from two or more loops collide, causing one of the samples to be delayed. This shows up as a measurement error in the system. By knowing when this delay occurs and the amount of delay that has occurred, software can employ extrapolation techniques to reduce the error.

To this effect, each PPB has the field DLYSTAMP in the ADCPPBxSTAMP register. This field contains the number of SYSCLK cycles between when the associate SOC was triggered and when the SOC began converting.

This is achieved by having a global 12-bit free running counter based off of SYSCLK, which is in the field FREECOUNT in the ADCCOUNTER register. When the trigger for the associated SOC arrives, the value of this counter is loaded into the bit field ADCPPBxTRIPLO.REQSTAMP. When the actual sample window for that SOC begins, the value in REQSTAMP is subtracted from the current FREECOUNT value and stored in DLYSTAMP.

**Note**

If more than 4096 SYSCLK cycles elapse between the SOC trigger and the actual start of the SOC acquisition, the FREECOUNT register can overflow more than once, leading to incorrect DLYSTAMP value. Be cautious when using very slow conversions to prevent this from happening.

The sample delay capture does not function, if the associated SOC is triggered using software. The sample delay capture, however, correctly records the delay, if the software triggering of a different SOC causes the SOC associated with the PPB to be delayed

## 11.9 Opens/Shorts Detection Circuit (OSDETECT)

The opens/shorts detection circuit (OSDETECT) can be used to detect pin faults in the system. The circuit connects to the ADC input after the channel select multiplexer but before the S+H circuit as shown in Figure 11-11.

**Note**

- The divider resistance tolerances can vary widely; hence, this feature must not be used to check for conversion accuracy.
- See the data sheet for implementation and availability of analog input channels.
- Due to high drive impedance, a S+H duration much longer than the ADC minimum is needed.

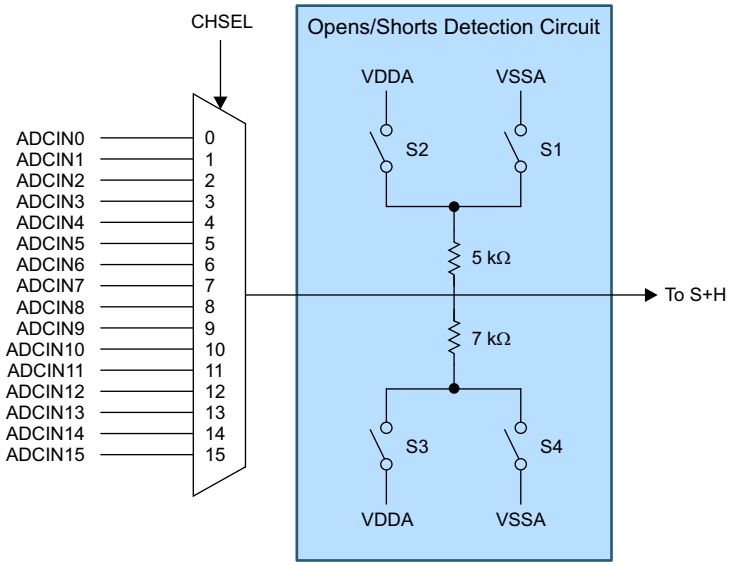

**Figure 11-11. Opens/Shorts Detection Circuit**

The circuit can be operated by writing a value to the DETECTCFG field in the ADCOSDETECT register. This causes the circuit to source a voltage onto the input during the S+H phase of any conversion. The voltage and drive strength of the OSDETECT circuit for different DETECTCFG settings is given in Table 11-9.

**Table 11-9. DETECTCFG Settings**

| ADCOSDETECT. DETECTCFG | Source Voltage | S4 | S3 | S2 | S1 | Drive Impedance |
|---|---|---|---|---|---|---|
| 0 | Off | Open | Open | Open | Open | Open |
| 1 | Zero Scale | Closed | Open | Open | Closed | 5K \|\| 7K |
| 2 | Full Scale | Open | Closed | Closed | Open | 5K \|\| 7K |

### 11.9.1 Implementation

A representative circuit with the OSDETECT implementation consists of the signal source with series resistance $R_S$, shunt capacitor $C_P$, the equivalent OSDETECT resistance $R_{OSDETECT}$ and voltage $V_{OSDETECT}$ is shown in Figure 11-12 and can be used as a basis to calculate the signal level going in to the sampling capacitor. $R_{OSDETECT}$ and $V_{OSDETECT}$ are the equivalent input resistance and voltage source contributed by the OSDETECT circuit with values shown in Table 11-9 for the different configuration settings. Refer to Figure 11-12 when deriving the input signal to S/H if signal source $V_S$ is driving while the OSDETECT feature is enabled.

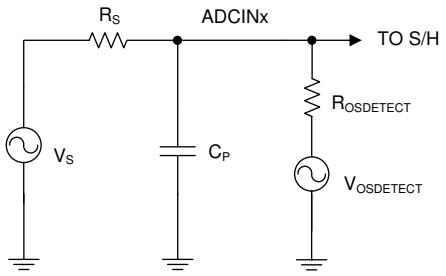

**Figure 11-12. Input Circuit Equivalent with OSDETECT Enabled**

The input impedance $R_S$ and $C_P$ are integral parts of the signal source or can have been implemented in the design to precondition the signal or to control signal settling time to meet S/H requirements. The input path has to be considered when using the OSDETECT feature, as this affects the conversion results. For instance, driving an input signal when this feature is enabled connects signal $V_S$ to the OSDETECT circuit through $R_S$ and affects the ADC results. Larger $C_P$ values (in the order greater than hundreds of pF) require using higher ACQPS to make sure the signal at the input has settled prior to conversion.

To enable the circuit:

1. Configure the ADC for conversion (for example, channel, SOC, ACQPS, prescaler, trigger, and so on).
2. Set up the ADCOSDETECT register for the desired voltage divider connection as shown in Table 11-9.
3. Initiate a conversion and inspect the conversion result.

Interpret the results based on what is driving on the input side and what are the values of $R_S$ and $C_P$. If the $V_S$ signal can be disconnected from the input pin, the circuit can be used to detect open and shorted input pins as described in the following sections.

### 11.9.2 Detecting an Open Input Pin

By cycling through the various OSDETECT settings, the input signal is pulled towards the sourced voltages. An input with good drive strength (pin not open) is minimally affected. However, if the pin is open, the sampled voltages is close to the source voltages specified in Table 11-9.

### 11.9.3 Detecting a Shorted Input Pin

By cycling through the various OSDETECT settings, the input signal is pulled towards the sourced voltages. An input with finite drive strength (pin not shorted) is pulled toward each sourced voltage. However, if the pin is shorted, the signal remains at the same voltage.

## 11.10 Power-Up Sequence

Upon device power-up or system level reset, the ADC is powered down and disabled. When powering up the ADC, use the following sequence:

1. Set the bit to enable the desired ADC clock in the PCLKCR13 register.
2. Set the desired ADC clock divider in the PRESCALE field of ADCCTL2.
3. Power up the ADC by setting the ADCPWDNZ bit in ADCCTL1.
4. Allow a delay before sampling. See the data sheet for the necessary time.

If multiple ADCs are powered up simultaneously, steps 1 and step 3 can each be done for all ADCs in one write instruction. Also, only one delay is necessary as long as the delay occurs after all the ADCs have begun powering up.

## 11.11 ADC Calibration

During the fabrication and test process, Texas Instruments calibrates the gain, offset, and linearity of the ADCs and the offset of the buffered DACs. These trim settings are stored in TI reserved OTP memory, and can be loaded using C-callable functions.

- The Device_cal() function copies the trim values for ADC and DAC offset from OTP memory to the respective trim registers.
- The CalAdcINL() function copies the trim values for linearity from OTP memory to the respective trim registers for the specified ADC.
- A different offset trim is required for each possible combination of resolution and signal mode. The GetAdcOffsetTrimOTP(Uint16) function takes an input value corresponding to the ADC, resolution, and signal mode and returns the corresponding offset trim value from OTP memory, which the user then moves into the ADC offset trim register.
- The trim functions in Device_cal() are callable in C2000ware as ADC_setOFFSETTRIM(), ADC_setINLTRIM(), and DAC_setDACTRIM(). These functions fetch production test trim values from TI reserved OTP memory locations, and write the values to the corresponding analog module register destinations. Because these values are stored in the CPU1 Flash subsystem, the functions must be executed from CPU1 to fetch the correct values.

Until the appropriate factory trim is loaded, the ADC and other analog modules are not specified to operate within the data sheet specifications. Similarly, if trim values other than the factory settings are placed into the trim registers, the ADC (and other modules) is not specified to operate within the data sheet specifications.

The boot ROM calls the calibration functions, so trim values are initially populated without user intervention. However, if the trims are cleared due to a module reset or modified for some other reason, then the user must call the calibration functions (defined in the C2000Ware header files).

**Note**

Trim and calibration values are stored in the OTP region of CPU1 Flash, and cannot be accessed by CPU2. When calling user calibration functions to update ADC, DAC or temperature sensor values, the function must be called from CPU1 code.

Refer to Section 11.11.2 for a tabulated description of associated function calls and ADC registers being populated during ADC calibration.

Copyright © 2024 Texas Instruments Incorporated

### 11.11.1 ADC Zero Offset Calibration

ADC offset error is determined and calibrated during factory testing. However, the user still has the option to perform offset calibration if the end application specifically requires this. This section describes how to perform offset calibration using internal VREFLO connection for single-ended operation, and external channels for differential operation.

Zero offset error is defined as the difference from 0 that occurs when converting a voltage at VREFLO (for single-ended operation), or the difference from MAX_CODE/2 when converting ADCINxP = ADCINxN (for differential mode). The zero offset error can be positive or negative. To correct this error, an adjustment of equal magnitude and opposite polarity is written into the ADCOFFTRIM register. The value contained in this register is applied before the results are available in the ADC result registers. This operation is fully contained within the ADC core, so the timing of the results is not affected, and the full dynamic range of the ADC is maintained for any trim value.

Using the GetAdcOffsetTrimOTP(Uint16) function, the ADCOFFTRIM register can be loaded with the factory calibrated offset error correction. The user can modify the ADCOFFTRIM register to compensate for additional offset error induced by the application environment if desired, but this is not typically necessary to achieve data manual specified performance.

**Note**

Regardless of the converter resolution, the size of each ADCOFFTRIM step is (VREFHI-VREFLO)/ 65536.

Use the following procedure to re-calibrate the ADC offset in 12-bit single-ended mode:

1. Set ADCOFFTRIM to +112 steps (0x70). This adds an artificial offset to account for negative offset that can reside in the ADC core.
2. Perform some multiple of 16 conversions on VREFLO (internal connection), accumulating the results (for example, 32*16 conversions = 512 conversions). Use the maximum value of ACQPS to make sure longer settling time to account for parasitic impedance of internal VREFLO connections.
3. Divide the accumulated result by the multiple of 16 (for example, for 512 conversions, divide by 32).
4. Set ADCOFFTRIM to 112 – result from step 3.

Use the following procedure to recalibrate the ADC offset in 16-bit differential mode:

1. Set ADCOFFTRIM to no adjustment (0x00).
2. Short ADCINxP and ADCINyN together (external connection) to a voltage near Vrefcm and accumulate some multiple of 16 conversions (for example, 32*16 conversions = 512 conversions).
3. Divide the accumulated result by the number of conversions (for example, for 512 conversions, divide by 512 ).
4. Set ADCOFFTRIM to 0 – result from step 3).

Copyright © 2024 Texas Instruments Incorporated

### 11.11.2 ADC Calibration Routines in OTP Memory

During factory testing, the calibration values for ADC offset (ADCOFFTRIM register) and ADC linearity correction (ADCINLTRIM1-6 registers) are measured per device. The resulting correction values for ADC offset and linearity and the associated functions to populate these into the corresponding ADC registers are stored in the OTP memory.Table 11-10 describes the function call, address pointer locations for the functions, and ADC registers being populated during device boot up sequence call to Device_cal() or any time the function call ADC_setMode() in C2000Ware is invoked. These functions generally must be called before using the ADC peripheral, and must be executed on CPU1. Following is an example of calibrating the ADC using C2000Ware driverlib functions. The ADC base macros used here come from within driverlib and are available for all ADC module instances.

```
//
// Calibrates the ADC reference, DAC offset, and internal oscillators
//
Device_cal();
//
// Calibrates the ADC A linearity; it is recommended to call the ADC_setMode function to
// properly calibrate the ADC linearity. The ADC_setINLTrim function will determine which
// linearity calibration function to call based on the ADC base that is passed in
//
ADC_setINLTrim(ADCA_BASE);
//
// Calibrates the offset trim for ADC A; it is recommended to call the ADC_setMode
// function to properly calibrate the ADC offset trim
//
ADC_setOffsetTrim(ADCA_BASE);
```

**Table 11-10. ADC Calibration Functions in OTP**

| Function Name | Pointer Address (OTP) | Description | Registers Populated |
|---|---|---|---|
| Device_cal() | 0x070282 | Calibration function for ADC reference, DAC offset, and internal oscillators | ANAREFTRIMA, ANAREFTRIMB, ANAREFTRIMC, ANAREFTRIMD, DACA OFFTRIM, DACB OFFTRIM, DACC OFFTRIM |
| ADC_calADCAINL() | 0x0703B4 | Calibration function for ADCA linearity; previously called by: `CalAdcaINL` | ADCA INLTRIM1-6 |

## 11.12 ADC Timings

The process of converting an analog voltage to a digital value is broken down into an S+H phase and a conversion phase. The ADC sample and hold circuits (S+H) are clocked by SYSCLK while the ADC conversion process is clocked by ADCCLK. ADCCLK is generated by dividing down SYSCLK based on the PRESCALE field in the ADCCTL2 register.

The S+H duration is the value of the ACQPS field of the SOC being converted, plus one, times the SYSCLK period. The user must make sure that this duration exceeds both 1 ADCCLK period and the minimum S+H duration specified in the data sheet. The conversion time is approximately 10.5 ADCCLK cycles in 12-bit mode and 29.5 ADCCLK cycles in 16-bit mode. The exact conversion time is always a whole number of SYSCLK cycles. See the timing diagrams and tables in Section 11.12.1 for exact timings.

### *11.12.1 ADC Timing Diagrams*

The following diagrams show the ADC conversion timings for two SOCs given the following assumptions:

- SOC0 and SOC1 are configured to use the same trigger.
- No other SOCs are converting or pending when the trigger occurs.
- The round robin pointer is in a state that causes SOC0 to convert first.
- ADCINTSEL is configured to set an ADCINT flag upon end of conversion for SOC0 (whether this flag propagates through to the CPU to cause an interrupt is determined by the configurations in the PIE module).

Table 11-11 describes the parameters in the following timing diagrams. Table 11-12 and Table 11-13 list the ADC timings..

**Table 11-11. ADC Timing Parameter Descriptions**

| Parameter | Description |
|---|---|
| $t_{SH}$ | The duration of the S+H window.<br>At the end of this window, the value on the S+H capacitor becomes the voltage to be converted into a digital value. The duration is given by (ACQPS + 1) SYSCLK cycles. ACQPS can be configured individually for each SOC, so $t_{SH}$ is not necessarily the same for different SOCs.<br>**Note:** The value on the S+H capacitor is captured approximately 5ns before the end of the S+H window regardless of device clock settings. |
| $t_{LAT}$ | The time from the end of the S+H window until the ADC results latch in the ADCRESULTx register.<br>If the ADCRESULTx register is read before this time, the previous conversion results are returned. |
| $t_{EOC}$ | The time from the end of the S+H window until the S+H window for the next ADC conversion can begin. In 16-bit mode, this coincides with the latching of the conversion results, while in 12-bit mode, the subsequent sample can start before the conversion results are latched. |
| $t_{INT}$ | The time from the end of the S+H window until an ADCINT flag is set (if configured).<br>If the INTPULSEPOS bit in the ADCCTL1 register is set, $t_{INT}$ coincides with the end of conversion (EOC) signal.<br>If the INTPULSEPOS bit is 0, and the OFFSET field in the ADCINTCYCLE register is not 0, then there is a delay of OFFSET SYSCLK cycles before the ADCINT flag is set. This delay can be used to enter the ISR exactly when the sample is ready.<br>If the INTPULSEPOS bit is 0, $t_{INT}$ coincides with the end of the S+H window. If $t_{INT}$ triggers a read of the ADC result register (directly through DMA or indirectly by triggering an ISR that reads the result), care must be taken to make sure the read occurs after the results latch (otherwise, the previous results are read). |

## 11.13 Additional Information

The following sections contain additional practical information.

### *11.13.1 Ensuring Synchronous Operation*

For best performance, all ADCs on the device must be operated synchronously. The device data sheet specifies the performance in both synchronous and asynchronous mode for those parameters which differ between the modes of operation.

To make sure synchronous operation, all ADCs on the device must operate in lockstep. This is accomplished by writing configurations to all ADCs that cause the sampling and conversion phases of all ADCs to be exactly aligned. The easiest way to accomplish this is to write identical values to the SOC configurations for each ADC for trigger select and ACQPS (S+H duration). In addition, synchronous ADCs must also configure identical values for the SOC priority control, burst mode, burst trigger, and burst size.

#### 11.13.1.1 Basic Synchronous Operation

The following example configures two SOCs each on ADCA and ADCB with identical trigger select and ACQPS values. This results in synchronous operation between ADCA and ADCB. For devices with more than two ADCs, the same principles can be used to synchronize all the ADCs.

```
Example: Basic Synchronous Operation
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4;      //SOC0 converts ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 0;      //SOC0 converts ADCINB0
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB

AdcaRegs.ADCSOC1CTL.bit.CHSEL = 4;      //SOC1 converts ADCINA4
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 30;     //SOC1 uses sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 10;   //SOC1 begins conversion on ePWM3 SOCB
AdcbRegs.ADCSOC1CTL.bit.CHSEL = 1;      //SOC1 converts ADCINB1
AdcbRegs.ADCSOC1CTL.bit.ACQPS = 30;     //SOC1 uses sample duration of 31 SYSCLK cycles
AdcbRegs.ADCSOC1CTL.bit.TRIGSEL = 10;   //SOC1 begins conversion on ePWM3 SOCB
```

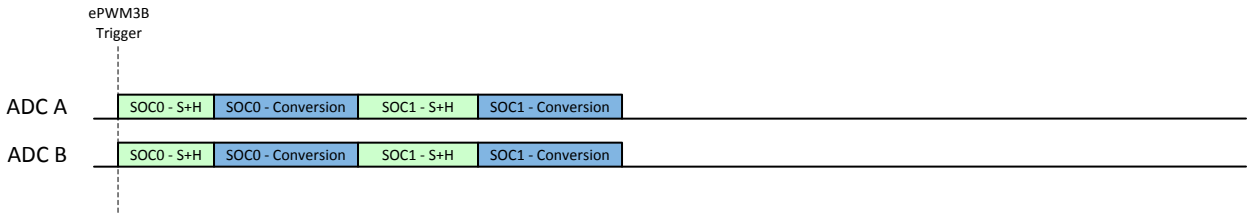

**Figure 11-17. Example: Basic Synchronous Operation**

Several things can be noted from Figure 11-17. First, while the ACQPS values must be the same for SOCs with the same number, different ACQPS values can be used for SOCs with different numbers. Because of this, synchronous operation does not require a single global S+H time, but instead only channels sampled simultaneously require identical S+H durations. Another important point from this example is that any channel select value can be used for any SOC. Finally, this example assumes round-robin operation. If high-priority SOCs are to be used, the priority must be configured the same on all ADCs.

Copyright © 2024 Texas Instruments Incorporated

#### 11.13.1.2 Synchronous Operation with Multiple Trigger Sources

As long as each set of SOCs has identical trigger select and ACQPS settings, multiple trigger sources can be used while still achieving synchronous operation.

The following example demonstrates synchronous operation between ADCA and ADCB while using three SOCs and two trigger sources. Figure 11-18 demonstrates that any combination of relative trigger timings still results in synchronous operation.

```
Example: Synchronous Operation With Multiple Trigger Sources
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4;      //SOC0 converts ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 0;      //SOC0 converts ADCINB0
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB

AdcaRegs.ADCSOC1CTL.bit.CHSEL = 4;      //SOC1 converts ADCINA4
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 30;     //SOC1 uses sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 10;   //SOC1 begins conversion on ePWM3 SOCB
AdcbRegs.ADCSOC1CTL.bit.CHSEL = 1;      //SOC1 converts ADCINB1
AdcbRegs.ADCSOC1CTL.bit.ACQPS = 30;     //SOC1 uses sample duration of 31 SYSCLK cycles
AdcbRegs.ADCSOC1CTL.bit.TRIGSEL = 10;   //SOC1 begins conversion on ePWM3 SOCB

AdcaRegs.ADCSOC2CTL.bit.CHSEL = 0;      //SOC2 converts ADCINA0
AdcaRegs.ADCSOC2CTL.bit.ACQPS = 19;     //SOC2 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC2CTL.bit.TRIGSEL = 2;    //SOC2 begins conversion on CPU Timer1
AdcbRegs.ADCSOC2CTL.bit.CHSEL = 2;      //SOC2 converts ADCINB2
AdcbRegs.ADCSOC2CTL.bit.ACQPS = 19;     //SOC2 uses sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC2CTL.bit.TRIGSEL = 2;    //SOC2 begins conversion on CPU Timer1
```

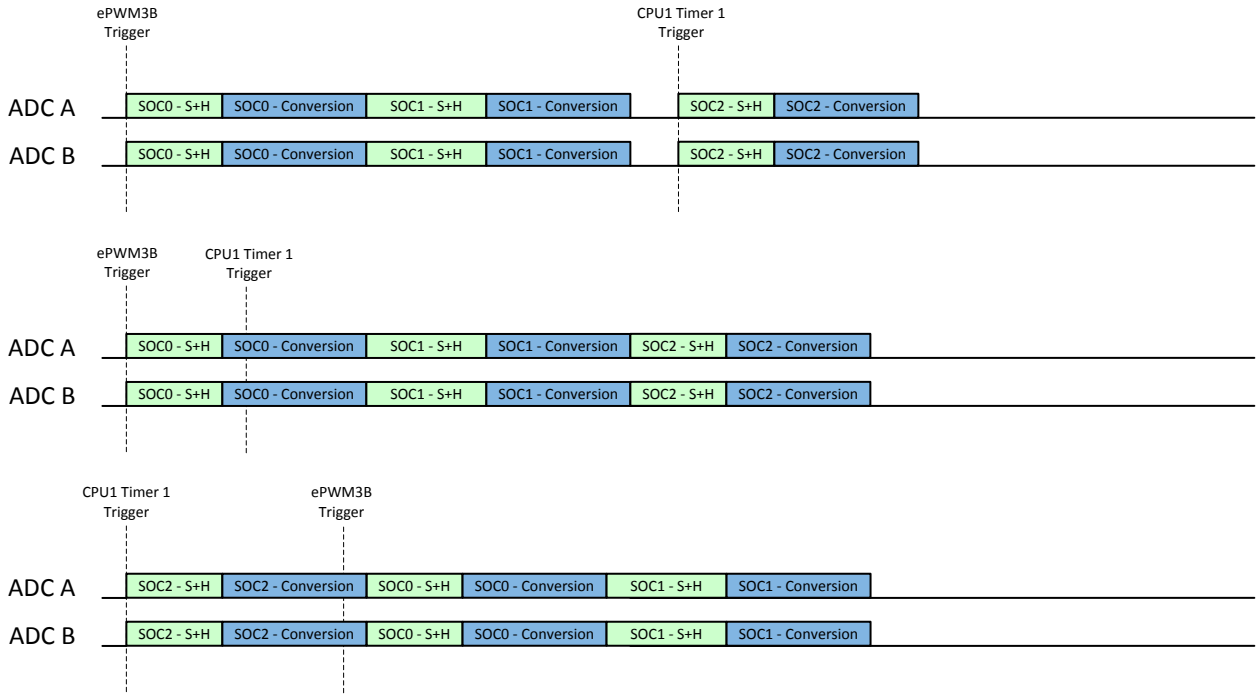

**Figure 11-18. Example: Synchronous Operation with Multiple Trigger Sources**

Note that any trigger source that can be selected in the TRIGSEL field can be used except for software triggering. There is no way to issue the software triggers for all ADCs simultaneously, so likely results in asynchronous operation. ADCINT1 or ADCINT2 can also be used as a trigger as long as the ADCINTSOCSEL1 and ADCINTSOCSEL2 registers are configured identically for all ADCs and software triggering is not used to start the chain of conversions.

Copyright © 2024 Texas Instruments Incorporated

#### 11.13.1.3 Synchronous Operation with Uneven SOC Numbers

If only one trigger source is used, one ADC can use more SOCs than the other ADCs while still operating synchronously.

```
Example: Synchronous Operation With Uneven SOC Numbers
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4;      //SOC0 converts ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 0;      //SOC0 converts ADCINB0
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB

AdcaRegs.ADCSOC1CTL.bit.CHSEL = 4;      //SOC1 converts ADCINA4
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 30;     //SOC1 uses sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 10;   //SOC1 begins conversion on ePWM3 SOCB
AdcbRegs.ADCSOC1CTL.bit.CHSEL = 1;      //SOC1 converts ADCINB1
AdcbRegs.ADCSOC1CTL.bit.ACQPS = 30;     //SOC1 uses sample duration of 31 SYSCLK cycles
AdcbRegs.ADCSOC1CTL.bit.TRIGSEL = 10;   //SOC1 begins conversion on ePWM3 SOCB

AdcaRegs.ADCSOC2CTL.bit.CHSEL = 0;      //SOC2 converts ADCINA0
AdcaRegs.ADCSOC2CTL.bit.ACQPS = 19;     //SOC2 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC2CTL.bit.TRIGSEL = 10;   //SOC2 begins conversion on ePWM3 SOCB
```

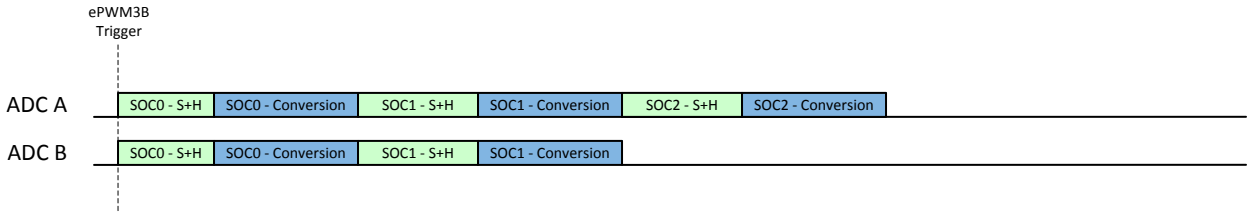

**Figure 11-19. Example: Synchronous Operation with Uneven SOC Numbers**

Note that if the trigger comes again before all SOCs have completed the conversions, ADCB begins converting immediately on SOC0 while ADCA does not start converting SOC0 again until SOC2 is complete. This results in asynchronous operation, so care must be taken to not overflow the trigger.

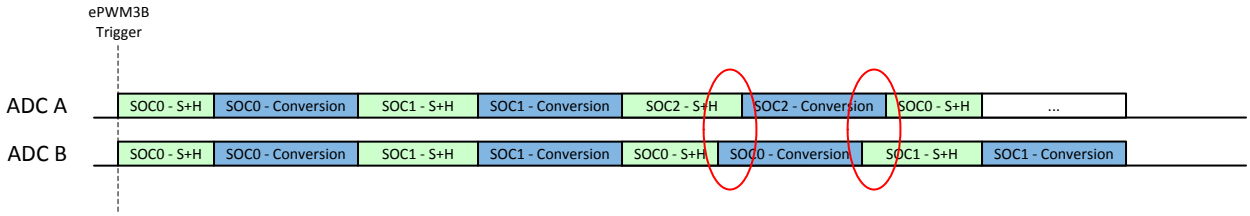

**Figure 11-20. Example: Asynchronous Operation with Uneven SOC Numbers – Trigger Overflow**

Copyright © 2024 Texas Instruments Incorporated

#### 11.13.1.4 Synchronous Operation with Different Resolutions

Configuring different ADCs to use different resolutions results in asynchronous operation. This occurs because the conversion time for 12-bit mode and 16-bit mode are different. Synchronous operation requires both the start and end of the conversion phase to be aligned, so even using the same S+H window duration does not result in synchronous operation.

```
Example: Asynchronous Operation with Different Resolutions
//ADCA = 12-bit mode
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4;      //SOC0 converts ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 50;     //SOC0 uses sample duration of 51 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB

//ADCB = 16-bit mode
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 0;      //SOC0 converts ADCINB0/B1
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 50;     //SOC0 uses sample duration of 51 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB
```

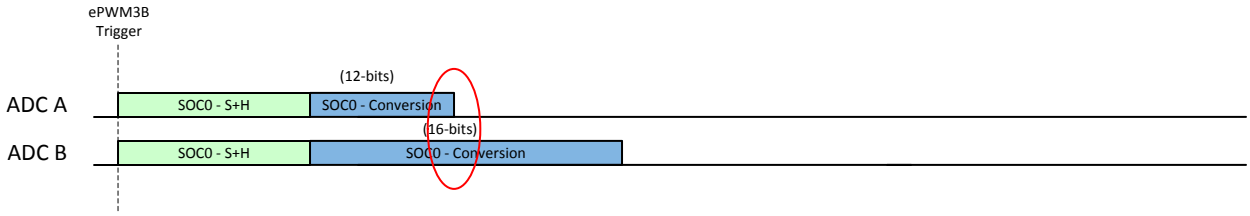

**Figure 11-21. Example: Asynchronous Operation with Different Resolutions**

To achieve synchronous operation while using both 12-bit and 16-bit resolution, conversions must be done in parallel at one resolution. Once conversions are complete at one resolution, the CPU must switch the resolution on all ADCs and then cause another trigger (this trigger must not be a software SOC force, as all ADCs cannot be started simultaneously using this method).

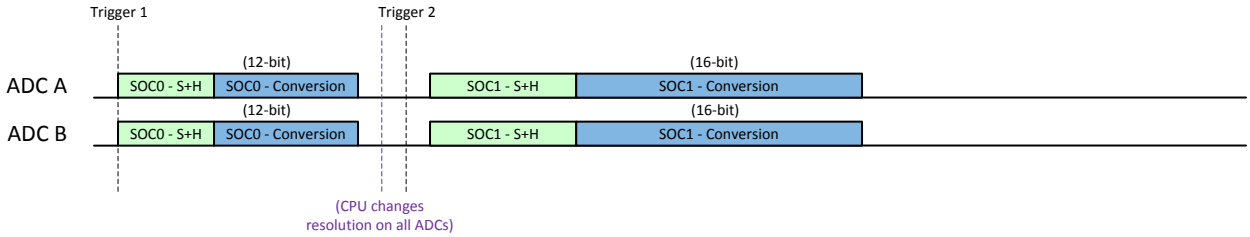

**Figure 11-22. Example: Synchronous Operation with Different Resolutions**

Copyright © 2024 Texas Instruments Incorporated

#### 11.13.1.5 Non-overlapping Conversions

If conversion timings can be made sure to not overlap by the user, then it is not necessary to configure all SOCs identically on all ADCs to achieve performance equivalent to synchronous operation. For example, if the two ADC triggers in a system come from two ePWM sources that are always 180-degrees out-of-phase, then SOC0 can be used for both ADCA and ADCB with different trigger sources and different ACQPS values.

```
Example: Operation with Non-overlapping Conversions
//ePWM3 SOCA and SOCB are 180 degrees out of phase
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4;      //SOC0 converts ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 0;      //SOC0 converts ADCINB0
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 9;    //SOC0 begins conversion on ePWM3 SOCA
```

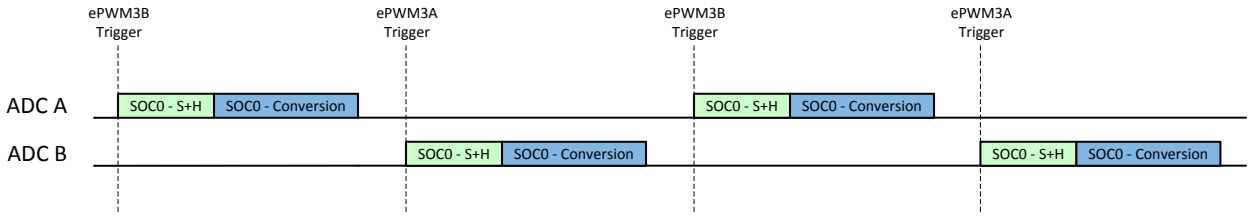

**Figure 11-23. Example: Synchronous Equivalent Operation with Non-Overlapping Conversions**

### *11.13.2 Choosing an Acquisition Window Duration*

For correct operation, the input signal to the ADC must be allowed adequate time to charge the sample and hold capacitor, Ch. Typically, the S+H duration is chosen such that the sampling capacitor is charged to within ½ LSB or ¼ LSB of the final value, depending on the tolerable settling error.

The best methodology to determine the required settling time is to simulate the ADC and ADC driving circuits to make sure adequate settling performance. See *ADC Input Circuit Evaluation for C2000 MCUs* and *Charge-Sharing Driving Circuits for C2000 ADCs* for additional guidance on ADC signal conditioning circuit design and evaluation.

An approximation of the required settling time can also be determined using an RC settling model. The time constant for the model is given by the equation:

$$\tau = (R_S + R_{on}) \times C_h + R_S \times \left(C_S + C_p\right) \tag{10}$$

And the number of time constants needed is given by the equation:

$$k = ln\left(\frac{2^n}{settling\ error}\right) - ln\left(\frac{C_S + C_P}{CH}\right) \tag{11}$$

So the total S+H time must be set to at least:

$$t = k \cdot \tau \tag{12}$$

Copyright © 2024 Texas Instruments Incorporated

Where the following parameters are provided by the ADC input model in the device data sheet:

- n = ADC resolution (in bits)
- $R_{ON}$ = ADC sampling switch resistance (provided in Ω)
- $C_H$ = ADC sampling capacitor (provided in pF)
- $C_p$ = ADC channel parasitic input capacitance (provided in pF)

And the following parameters are dependent on the application design:

- settling error = tolerable settling error (in LSBs)
- $R_s$ = ADC driving circuit source impedance (typically in Ω or kΩ)
- $C_S$ = capacitance on ADC input pin (typically in pF or nF)

For example, assuming the following parameters:

- n = 12-bits
- $R_{ON}$ = 500Ω
- $C_H$ = 12.5pF
- $C_p$ = 12.7pF
- settling error = ¼ LSB
- $R_s$ = 180Ω
- $C_s$ = 150pF

The time constant is calculated as:

$$\tau = (180\Omega + 500\Omega) \times 12.5pF + 180\Omega \times (150pF + 12.7pF) = 37.8ns \quad (13)$$

And the number of required time constants is:

$$k = ln\left(\frac{2^{12}}{0.25}\right) - ln\left(\frac{150pF + 12.7pF}{12.5pF}\right) = 9.70 - 2.57 = 7.13 \quad (14)$$

So the S+H time must be set to at least: 37.8ns × 7.13 = 270ns

If SYSCLK = 200MHz , then each SYSCLK cycle is 5ns. S+H duration is 270ns/5ns = 54 SYSCLK cycles, so ACQPS for this input is set to at least CEILING(54.0) – 1 = 53.

While this gives a rough estimate of the required acquisition window, a better method is to setup a circuit with the ADC input model, a model of the source impedance/capacitance, and any board parasitics in SPICE (or similar software) and simulate to verify that the sampling capacitor settles to the desired accuracy.

**Note**

The device data sheet specifies a minimum ADC S+H window duration. Do not use an ACQPS value that gives a duration less than this specification.

Copyright © 2024 Texas Instruments Incorporated

### 11.13.3 Achieving Simultaneous Sampling

While each ADC does not have dual S+H circuits, achieving simultaneous sampling is accomplished by setting the SOC triggers on two or more ADC modules to use the same trigger source. The following example demonstrates simultaneous sampling on 4 ADCs based on an ePWM3 event. ADCINA3, ADCINB5, ADCINC5, and ADCIND2 are sampled. An acquisition window of 20 SYSCLK cycles is used, but different durations are possible.

```
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 3;        //SOC0 convert ADCINA3
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;       //SOC0 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;     //SOC0 begins conversion on ePWM3 SOCB
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 5;        //SOC0 convert ADCINB5
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 19;       //SOC0 uses sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 10;     //SOC0 begins conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 5;        //SOC0 convert ADCINC5
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19;       //SOC0 uses sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 10;     //SOC0 begins conversion on ePWM3 SOCB
AdcdRegs.ADCSOC0CTL.bit.CHSEL = 2;        //SOC0 convert ADCIND2
AdcdRegs.ADCSOC0CTL.bit.ACQPS = 19;       //SOC0 uses sample duration of 20 SYSCLK cycles
AdcdRegs.ADCSOC0CTL.bit.TRIGSEL = 10;     //SOC0 begins conversion on ePWM3 SOCB
```

When the ePWM3 trigger is received, all four ADCs begin converting in parallel immediately. All results are stored in the ADCRESULT0 register for each ADC. Note that this assumes that all ADCs are idle when the trigger is received. If one or more ADCs is busy, the samples do not happen at exactly the same time.

### 11.13.4 Result Register Mapping

The ADC results and the ADC PPB results are duplicated for each memory bus controller in the system. Bus controllers include all CPUs, DMAs, and CLAs present on the specific part family and part number. For each bus controller, no access configuration is needed to allow read access to the result registers, and no contention occurs in cases where multiple bus controllers try to read the ADC results simultaneously.

### 11.13.5 Internal Temperature Sensor

The internal temperature sensor measures the junction temperature of the device. The output of the sensor can be sampled with the ADC through an internal connection. This can be enabled on channel ADCIN13 on ADCA by setting the ENABLE bit in the TSNSCTL register.

To convert the temperature sensor reading into a temperature, pass the temperature sensor reading to the GetTemperatureC() function in F2837xD_TempSensorConv.c .

Note that this function assumes that the temperature reading is taken with VREFHI = 2.5V. If a different reference voltage is used, the sample can be scaled appropriately before passing the sample to the function by using the following formula:

adjusted sensor reading = raw sensor reading * (VREFHI / 2.5V)

**Note**

To sample the temperature sensor, the ADC must be in single-ended 12-bit mode.

If the temperature sensor is sampled in 16-bit mode, the internal temperature sensor is sampled with a 12-bit resolution, regardless of the ADC mode currently configured. This does not change the resolution of results obtained on other SOCs for the given ADC.

Copyright © 2024 Texas Instruments Incorporated

### 11.13.6 Designing an External Reference Circuit

Figure 11-24 shows the basic organization of the external voltage reference generation circuitry. TI recommends that a single reference voltage generation source is shared by all ADC modules. This minimizes reference voltage mismatch between ADC modules. For best performance, the externally generated reference voltage must be buffered by a precision op-amp with good bandwidth and low output impedance before being driven into the ADC reference pin. A capacitor between the high and low reference pins must be placed on the PCB as close to the pins as practical to help absorb high-frequency currents. A series resistor (typically <1Ω) in series with this capacitor is sometimes necessary to maintain op-amp stability.

To share two reference pins between one op-amp driver is possible. This organization is shown in Figure 11-25. This can give slightly reduced performance compared to the case where each reference pin has a dedicated op-amp buffer, but can still be possible to achieve all ADC specifications in the data sheet.

### *11.14.1 ADC Examples*

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/adc

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

#### 11.14.1.1 ADC Software Triggering

FILE: adc_ex1_soc_software.c

This example converts some voltages on ADCA and ADCC based on a software trigger.

The ADCC will not convert until ADCA is complete, so the ADCs will not run asynchronously. However, this is much less efficient than allowing the ADCs to convert synchronously in parallel (for example, by using an ePWM trigger).

*External Connections*

*Watch Variables*
- *myADC0Result0* - Digital representation of the voltage on pin A0
- *myADC0Result1* - Digital representation of the voltage on pin A1

#### 11.14.1.2 ADC ePWM Triggering

FILE: adc_ex2_soc_epwm.c

This example sets up ePWM1 to periodically trigger a conversion on ADCA.

*External Connections*
- A0 should be connected to a signal to convert

*Watch Variables*
- *myADC0Results* - A sequence of analog-to-digital conversion samples from pin A0. The time between samples is determined based on the period of the ePWM timer.

#### 11.14.1.3 ADC Temperature Sensor Conversion

FILE: adc_ex3_temp_sensor.c

This example sets up the ePWM to periodically trigger the ADC. The ADC converts the internal connection to the temperature sensor, which is then interpreted as a temperature by calling the ADC_getTemperatureC() function.

*Watch Variables*
- *sensorSample* - The raw reading from the temperature sensor
- *sensorTemp* - The interpretation of the sensor sample as a temperature in degrees Celsius.

#### 11.14.1.4 ADC Synchronous SOC Software Force (adc_soc_software_sync)

FILE: adc_ex4_soc_software_sync.c

This example converts some voltages on ADCA and ADCC using input 5 of the input X-BAR as a software force. Input 5 is triggered by toggling GPIO0, but any spare GPIO could be used. This method will ensure that both ADCs start converting at exactly the same time.

*External Connections*

*Watch Variables*
- *myADC0Result0* : a digital representation of the voltage on pin A2
- *myADC0Result1* : a digital representation of the voltage on pin A3

#### 11.14.1.5 ADC Continuous Triggering (adc_soc_continuous)

FILE: adc_ex5_soc_continuous.c

Copyright © 2024 Texas Instruments Incorporated

This example sets up the ADC to convert continuously, achieving maximum sampling rate.
*External Connections*

- A0 pin should be connected to signal to convert

*Watch Variables*

- *adcAResults* - A sequence of analog-to-digital conversion samples from pin A0. The time between samples is the minimum possible based on the ADC speed.

#### 11.14.1.6 ADC PPB Offset (adc_ppb_offset)

FILE: adc_ex7_ppb_offset.c

This example software triggers the ADC. Some SOCs have automatic offset adjustment applied by the post-processing block. After the program runs, the memory will contain ADC & post-processing block(PPB) results.

*External Connections*

*Watch Variables*

- *myADC0Result* : a digital representation of the voltage on pin A2
- *myADC0PPBResult* : a digital representation of the voltage on pin A2, minus 100 LSBs of automatically added offset

#### 11.14.1.7 ADC PPB Limits (adc_ppb_limits)

FILE: adc_ex8_ppb_limits.c

This example sets up the ePWM to periodically trigger the ADC. If the results are outside of the defined range, the post-processing block will generate an interrupt.

The default limits are 1000LSBs and 3000LSBs. With VREFHI set to 3.3V, the PPB will generate an interrupt if the input voltage goes above about 2.4V or below about 0.8V.

*External Connections*

- A0 should be connected to a signal to convert

*Watch Variables*

- None

#### 11.14.1.8 ADC PPB Delay Capture (adc_ppb_delay)

FILE: adc_ex9_ppb_delay.c

This example demonstrates delay capture using the post-processing block.

Two asynchronous ADC triggers are setup:

- ePWM1, with period 2048, triggering SOC0 to convert on pin A0
- ePWM2, with period 9999, triggering SOC1 to convert on pin A2
  Each conversion generates an ISR at the end of the conversion. In the ISR for SOC0, a conversion counter is incremented and the PPB is checked to determine if the sample was delayed.
  After the program runs, the memory will contain:

*conversion* : the sequence of conversions using SOC0 that were delayed

- *delay* : the corresponding delay of each of the delayed conversions

#### 11.14.1.9 ADC ePWM Triggering Multiple SOC

FILE: adc_ex10_multiple_soc_epwm.c

This example sets up ePWM1 to periodically trigger a set of conversions on ADCA and ADCC. This example demonstrates multiple ADCs working together to process of a batch of conversions using the available parallelism across multiple ADCs.

ADCA Interrupt ISRs are used to read results of both ADCA and ADCC.

Copyright © 2024 Texas Instruments Incorporated

*External Connections*

*Watch Variables*

- *adcAResult0* - Digital representation of the voltage on pin A0
- *adcAResult1* - Digital representation of the voltage on pin A1
- *adcAResult2* - Digital representation of the voltage on pin A2
- *adcCResult1* - Digital representation of the voltage on pin C3
- *adcCResult2* - Digital representation of the voltage on pin C4

#### 11.14.1.10 ADC Burst Mode

FILE: adc_ex11_burst_mode_epwm.c

This example sets up ePWM1 to periodically trigger ADCA using burst mode. This allows for different channels to be sampled with each burst.

Each burst triggers 3 conversions. A0 and A1 are part of every burst while the third conversion rotates between A2, A3, and A4. This allows high importance signals to be sampled at high speed while lower priority signals can be sampled at a lower rate.

ADCA Interrupt ISRs are used to read results for ADCA.

*External Connections*

- A0, A1, A2, A3, A4

*Watch Variables*

- *adcAResult0* - Digital representation of the voltage on pin A0
- *adcAResult1* - Digital representation of the voltage on pin A1
- *adcAResult2* - Digital representation of the voltage on pin A2
- *adcAResult3* - Digital representation of the voltage on pin A3
- *adcAResult4* - Digital representation of the voltage on pin A4

#### 11.14.1.11 ADC Burst Mode Oversampling

FILE: adc_ex12_burst_mode_oversampling.c

This example is an ADC oversampling example implemented with software. The ADC SOCs are configured in burst mode, triggered by the ePWM SOC A event trigger.

*External Connection*

- A2

*Watch Variables*

- *Iv_results* - Array of digital values measured on pin A2 (oversampling is configured by Oversampling_Amount)

#### 11.14.1.12 ADC SOC Oversampling

FILE: adc_ex13_soc_oversampling.c

This example sets up ePWM1 to periodically trigger a set of conversions on ADCA including multiple SOCs that all convert A2 to achieve oversampling on A2.

ADCA Interrupt ISRs are used to read results of ADCA.

*External Connections*

- A0, A1, A2 should be connected to signals to be converted.

*Watch Variables*

- *adcAResult0* - Digital representation of the voltage on pin A0
- *adcAResult1* - Digital representation of the voltage on pin A1
- *adcAResult2* - Digital representation of the voltage on pin A2

Copyright © 2024 Texas Instruments Incorporated

#### 11.14.1.13 ADC PPB PWM trip (adc_ppb_pwm_trip)

FILE: adc_ex14_ppb_pwm_trip.c

This example demonstrates EPWM tripping through ADC limit detection PPB block. ADCAINT1 is configured to periodically trigger the ADCA channel 2 post initial software forced trigger. The limit detection post-processing block(PPB) is configured and if the ADC results are outside of the defined range, the post-processing block will generate an ADCxEVTy event. This event is configured as EPWM trip source through configuring EPWM XBAR and corresponding EPWM's trip zone and digital compare sub-modules. The example showcases

- one-shot
- and direct tripping of PWMs through ADCAEVT1 source via Digital compare submodule.

The default limits are 0LSBs and 3600LSBs. With VREFHI set to 3.3V, the PPB will generate a trip event if the input voltage goes above about 2.9V.

*External Connections*

- A2 should be connected to a signal to convert
- Observe the following signals on an oscilloscope
  - ePWM1(GPIO0 - GPIO1)
  - ePWM2(GPIO2 - GPIO3)
  - ePWM3(GPIO4 - GPIO5)

*Watch Variables*

- adcA2Results - digital representation of the voltage on pin A2

## 11.15 ADC Registers

This section describes the Analog-to-Digital Converter Registers.

### *11.15.1 ADC Base Addresses*

**Table 11-14. ADC Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|---|---|---|---|
| AdcaResultRegs | ADC_RESULT_REGS | 0x0000_0B00 | 0x0000_0B1F |
| AdcbResultRegs | ADC_RESULT_REGS | 0x0000_0B20 | 0x0000_0B3F |
| AdccResultRegs | ADC_RESULT_REGS | 0x0000_0B40 | 0x0000_0B5F |
| AdcdResultRegs | ADC_RESULT_REGS | 0x0000_0B60 | 0x0000_0B7F |
| AdcaRegs | ADC_REGS | 0x0000_7400 | 0x0000_747F |
| AdcbRegs | ADC_REGS | 0x0000_7480 | 0x0000_74FF |
| AdccRegs | ADC_REGS | 0x0000_7500 | 0x0000_757F |
| AdcdRegs | ADC_REGS | 0x0000_7580 | 0x0000_75FF |

### 11.15.2 ADC_RESULT_REGS Registers

Table 11-15 lists the memory-mapped registers for the ADC_RESULT_REGS registers. All register offset addresses not listed in Table 11-15 should be considered as reserved locations and the register contents should not be modified.

**Table 11-15. ADC_RESULT_REGS Registers**

| Offset | Acronym | Register Name | Write Protection | Section |
|---|---|---|---|---|
| 0h | ADCRESULT0 | ADC Result 0 Register | | Go |
| 1h | ADCRESULT1 | ADC Result 1 Register | | Go |
| 2h | ADCRESULT2 | ADC Result 2 Register | | Go |
| 3h | ADCRESULT3 | ADC Result 3 Register | | Go |
| 4h | ADCRESULT4 | ADC Result 4 Register | | Go |
| 5h | ADCRESULT5 | ADC Result 5 Register | | Go |
| 6h | ADCRESULT6 | ADC Result 6 Register | | Go |
| 7h | ADCRESULT7 | ADC Result 7 Register | | Go |
| 8h | ADCRESULT8 | ADC Result 8 Register | | Go |
| 9h | ADCRESULT9 | ADC Result 9 Register | | Go |
| Ah | ADCRESULT10 | ADC Result 10 Register | | Go |
| Bh | ADCRESULT11 | ADC Result 11 Register | | Go |
| Ch | ADCRESULT12 | ADC Result 12 Register | | Go |
| Dh | ADCRESULT13 | ADC Result 13 Register | | Go |
| Eh | ADCRESULT14 | ADC Result 14 Register | | Go |
| Fh | ADCRESULT15 | ADC Result 15 Register | | Go |
| 10h | ADCPPB1RESULT | ADC Post Processing Block 1 Result Register | | Go |
| 12h | ADCPPB2RESULT | ADC Post Processing Block 2 Result Register | | Go |
| 14h | ADCPPB3RESULT | ADC Post Processing Block 3 Result Register | | Go |
| 16h | ADCPPB4RESULT | ADC Post Processing Block 4 Result Register | | Go |

Complex bit access types are encoded to fit into small table cells. Table 11-16 shows the codes that are used for access types in this section.

**Table 11-16. ADC_RESULT_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| Reset or Default Value | | |
| *-n* | | Value after reset or the default value |
| Register Array Variables | | |
| i,j,k,l,m,n | | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y | | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

Complex bit access types are encoded to fit into small table cells. Table 11-38 shows the codes that are used for access types in this section.

**Table 11-38. ADC_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| R-0 | R<br>-0 | Read<br>Returns 0s |
| Write Type | | |
| W | W | Write |
| W1C | W<br>1C | Write<br>1 to clear |
| W1S | W<br>1S | Write<br>1 to set |
| Reset or Default Value | | |

Copyright © 2024 Texas Instruments Incorporated

**Table 11-38. ADC_REGS Access Type Codes (continued)**

| Access Type | Code | Description |
|---|---|---|
| *-n* | | Value after reset or the default value |
| Register Array Variables | | |
| i,j,k,l,m,n | | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y | | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 15-14 | SOC7 | R/W | 0h | SOC7 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC7. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register.<br>00 No ADCINT will trigger SOC7. TRIGSEL field alone determines SOC0 trigger.<br>01 ADCINT1 will trigger SOC7.<br>10 ADCINT2 will trigger SOC7.<br>11 Invalid selection.<br>Reset type: SYSRSn |
| 13-12 | SOC6 | R/W | 0h | SOC6 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC6. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register.<br>00 No ADCINT will trigger SOC6. TRIGSEL field alone determines SOC0 trigger.<br>01 ADCINT1 will trigger SOC6.<br>10 ADCINT2 will trigger SOC6.<br>11 Invalid selection.<br>Reset type: SYSRSn |
| 11-10 | SOC5 | R/W | 0h | SOC5 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC5. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register.<br>00 No ADCINT will trigger SOC5. TRIGSEL field alone determines SOC0 trigger.<br>01 ADCINT1 will trigger SOC5.<br>10 ADCINT2 will trigger SOC5.<br>11 Invalid selection.<br>Reset type: SYSRSn |
| 9-8 | SOC4 | R/W | 0h | SOC4 ADC Interrupt Trigger Select. Selects which, if any, ADCINT triggers SOC4. The trigger selected in this field is in addition to the TRIGSEL field in the ADCSOCxCTL register.<br>00 No ADCINT will trigger SOC4. TRIGSEL field alone determines SOC0 trigger.<br>01 ADCINT1 will trigger SOC4.<br>10 ADCINT2 will trigger SOC4.<br>11 Invalid selection.<br>Reset type: SYSRSn |

**Table 11-51. ADCSOCFLG1 Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 12 | SOC12 | R | 0h | SOC12 Start of Conversion Flag. Indicates the state of SOC12 conversions.<br>0 No sample pending for SOC12.<br>1 Trigger has been received and sample is pending for SOC12. This bit will be automatically cleared when the SOC12 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not.<br>Reset type: SYSRSn |
| 11 | SOC11 | R | 0h | SOC11 Start of Conversion Flag. Indicates the state of SOC11 conversions.<br>0 No sample pending for SOC11.<br>1 Trigger has been received and sample is pending for SOC11. This bit will be automatically cleared when the SOC11 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not.<br>Reset type: SYSRSn |
| 10 | SOC10 | R | 0h | SOC10 Start of Conversion Flag. Indicates the state of SOC10 conversions.<br>0 No sample pending for SOC10.<br>1 Trigger has been received and sample is pending for SOC10. This bit will be automatically cleared when the SOC10 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not.<br>Reset type: SYSRSn |
| 9 | SOC9 | R | 0h | SOC9 Start of Conversion Flag. Indicates the state of SOC9 conversions.<br>0 No sample pending for SOC9.<br>1 Trigger has been received and sample is pending for SOC9. This bit will be automatically cleared when the SOC9 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not.<br>Reset type: SYSRSn |
| 8 | SOC8 | R | 0h | SOC8 Start of Conversion Flag. Indicates the state of SOC8 conversions.<br>0 No sample pending for SOC8.<br>1 Trigger has been received and sample is pending for SOC8. This bit will be automatically cleared when the SOC8 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not.<br>Reset type: SYSRSn |

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 4 | SOC4 | R-0/W1S | 0h | SOC4 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC4 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.<br>0 No action.<br>1 Force SOC4 flag bit to 1. This will cause a conversion to start once priority is given to SOC4.<br>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC4 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.<br>Reset type: SYSRSn |
| 3 | SOC3 | R-0/W1S | 0h | SOC3 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC3 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.<br>0 No action.<br>1 Force SOC3 flag bit to 1. This will cause a conversion to start once priority is given to SOC3.<br>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC3 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.<br>Reset type: SYSRSn |
| 2 | SOC2 | R-0/W1S | 0h | SOC2 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC2 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.<br>0 No action.<br>1 Force SOC2 flag bit to 1. This will cause a conversion to start once priority is given to SOC2.<br>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC2 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.<br>Reset type: SYSRSn |
| 1 | SOC1 | R-0/W1S | 0h | SOC1 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC1 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0.<br>0 No action.<br>1 Force SOC1 flag bit to 1. This will cause a conversion to start once priority is given to SOC1.<br>If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC1 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not.<br>Reset type: SYSRSn |

Chapter 12

# Buffered Digital-to-Analog Converter (DAC)

The buffered digital-to-analog converter (DAC) is an analog module that can output a programmable, arbitrary reference voltage.

**12.1 Introduction**....1790
**12.2 Using the DAC**....1791
**12.3 Lock Registers**....1792
**12.4 Software**....1793
**12.5 DAC Registers**....1793

Copyright © 2024 Texas Instruments Incorporated

## 12.1 Introduction

The buffered DAC module consists of an internal 12-bit DAC and an analog output buffer that is capable of driving an external load. An integrated pull-down resistor on the DAC output helps to provide a known pin voltage when the output buffer is disabled. This pull-down resistor cannot be disabled and remains as a passive component on the pin, even for other shared pinmux functions. The buffered DAC is a general-purpose DAC that can be used to generate a DC voltage in addition to AC waveforms such as sine waves, square waves, triangle waves and so forth. Software writes to the DAC value register can take effect immediately or can be synchronized with EPWMSYNCPER events.

### *12.1.1 DAC Related Collateral*

**Foundational Materials**

- C2000 Academy - DAC
- *High Speed, Digital to Analog Converters Basics Application Report*
- *Real-Time Control Reference Guide*
  - Refer to the DAC section
- *Understanding Data Converters Application Report*

**Getting Started Materials**

- MathWorks F2807x/F2837xD/F2837xS/F28004x/F2838x DAC
  - NOTE: This is a non-TI (third party) site.

### *12.1.2 Features*

Each buffered DAC has the following features:

- 12-bit programmable internal DAC
- Selectable reference voltage source
- Pull-down resistor on output
- Ability to synchronize with EPWMSYNCPER

### *12.1.3 Block Diagram*

The block diagram for the buffered DAC is shown in Figure 12-1.

Copyright © 2024 Texas Instruments Incorporated

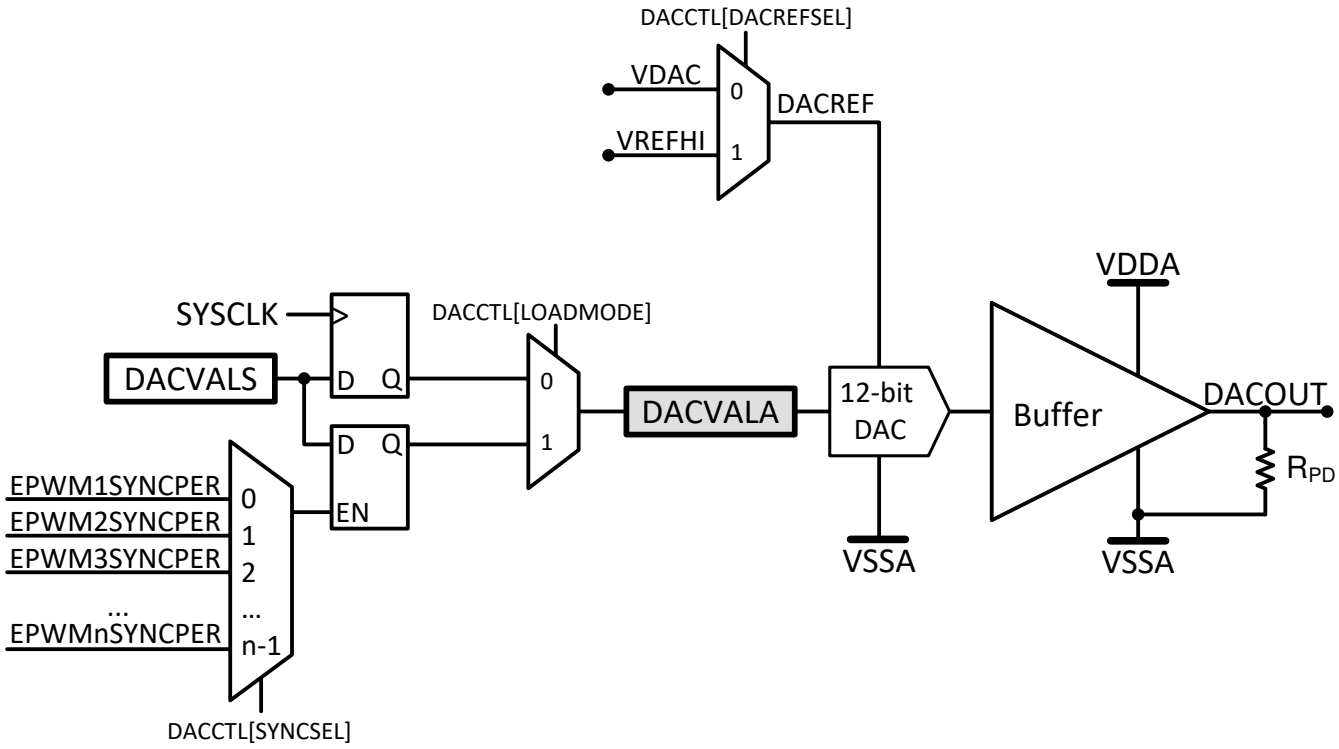

**Figure 12-1. DAC Module Block Diagram**

## 12.2 Using the DAC

The internal DAC's reference voltage source, DACREF, is selectable between VDAC and VREFHI.

Two sets of DACVAL registers, DACVALA and DACVALS, are present in the buffered DAC module. DACVALA is a read-only register that actively controls the buffered DAC value. DACVALS is a writable shadow register that loads into DACVALA either immediately or synchronized with the next EPWMSYNCPER event. If the clock to the buffered DAC is disabled while the buffered DAC is outputting a voltage, the output voltage remains unaffected, but DACVALA and DACVALS is no longer updated with register writes. Enabling the clock to the buffered DAC restores the DAC to the state before the clock was disabled.

The output of the internal DAC is calculated with the following equation:

$$DACOUT = \frac{DACVALA * DACREF}{4096} \quad (15)$$

The output buffer of the buffered DAC can exhibit non-linear behavior near the supply rails (VDDA/VSSA). To determine the linear range of the buffered DAC, see the device-specific data sheet.

### *12.2.1 Initialization Sequence*

1. Enable the buffered DAC clock.
2. Set DACREF with DACREFSEL.
3. Power up the buffered DAC with DACOUTEN.
4. Wait for the power-up time to elapse before outputting a voltage. To determine the power-up time of the buffered DAC, see the device data sheet.
5. For predictable behavior of the buffered DAC, consecutive writes to DACVALS must be spaced apart according to the settling time of the buffered DAC. To determine the settling time of the buffered DAC, see the device data sheet.

Copyright © 2024 Texas Instruments Incorporated

### 12.2.2 DAC Offset Adjustment

Zero offset error is defined as the difference between the voltage at midcode (2048) and 1.25V (for 2.5V reference voltage). DAC offset error is calibrated at 2.5V reference voltage and loaded into the DAC offset trim register as part of the Device_cal() function. If the DAC is used at any reference voltage other than 2.5V, the offset trim must be adjusted to make sure the offset error performance stays within the device-specific data sheet limits. The DAC offset register is a 16-bit register that contains the 8-bit signed offset trim in the lower half of the register. Use the function call DAC_tuneOffsetTrim() found in C2000Ware to adjust the offset.

### 12.2.3 EPWMSYNCPER Signal

EPWMSYNCPER comes from the Time-Base submodule of the EPWM. For a detailed description of how this signal is generated, refer to the *Time-Base Submodule* section of the *Enhanced Pulse Width Modulator (ePWM)* chapter.

The EPWMSYNCPER signal that loads DACVALA when DACCTL [LOADMODE] = 1 is a level trigger load. If TBCTR and TBPRD of the EPWM are both 0, EPWMSYNCPER is held at a high level and DACVALA is immediately loaded from DACVALS irrespective of the value of DACCTL [LOADMODE]. Due to this, configure the EPWM first before setting DACCTL [LOADMODE] to 1.

**Note**

The name of the sync signal that the GPDAC receives from the EPWM has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCI and EPWMSYNCO. For a description of these signals, see the *Enhanced Pulse Width Modulator (ePWM)* chapter.

## 12.3 Lock Registers

A DACLOCK register is provided to prevent spurious writes from modifying the DACCTL, DACVALS, and DACOUTEN registers. Once a register is protected through DACLOCK, write access are locked out until the device is reset.

## 12.4 Software

### *12.4.1 DAC Examples*

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/dac

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

#### 12.4.1.1 Buffered DAC Enable

FILE: buffdac_ex1_enable.c

This example generates a voltage on the buffered DAC output, DACOUTA/ADCINA0 and uses the default DAC reference setting of VDAC.

*ExternalConnections*

- When the DAC reference is set to VDAC, an external reference voltage must be applied to the VDAC pin. This can be accomplished by connecting a jumper wire from 3.3V to ADCINB0.

#### 12.4.1.2 Buffered DAC Random

FILE: buffdac_ex2_random.c

This example generates random voltages on the buffered DAC output, DACOUTA/ADCINA0 and uses the default DAC reference setting of VDAC.

*ExternalConnections*

- When the DAC reference is set to VDAC, an external reference voltage must be applied to the VDAC pin. This can accomplished by connecting a jumper wire from 3.3V to ADCINB0.

#### 12.4.1.3 Buffered DAC Sine (buffdac_sine)

FILE: buffdac_ex3_waveform.c

This example generates a sine wave on the buffered DAC output, DACOUTA/ADCINA0 (HSEC Pin 9) and uses the default DAC reference setting of VDAC.

When the DAC reference is set to VDAC, an external reference voltage must be applied to the VDAC pin. This can accomplished by connecting a jumper wire from 3.3V to ADCINB0.

## 12.5 DAC Registers

This section describes the Buffered Digital to Analog Converter registers.

### *12.5.1 DAC Base Addresses*

**Table 12-1. DAC Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|---|---|---|---|
| DacaRegs | DAC_REGS | 0x0000_5C00 | 0x0000_5C0F |
| DacbRegs | DAC_REGS | 0x0000_5C10 | 0x0000_5C1F |
| DaccRegs | DAC_REGS | 0x0000_5C20 | 0x0000_5C2F |

### 12.5.2 DAC_REGS Registers

Table 12-2 lists the memory-mapped registers for the DAC_REGS registers. All register offset addresses not listed in Table 12-2 should be considered as reserved locations and the register contents should not be modified.

**Table 12-2. DAC_REGS Registers**

| Offset | Acronym | Register Name | Write Protection | Section |
|---|---|---|---|---|
| 0h | DACREV | DAC Revision Register | | Go |
| 1h | DACCTL | DAC Control Register | EALLOW | Go |
| 2h | DACVALA | DAC Value Register - Active | | Go |
| 3h | DACVALS | DAC Value Register - Shadow | | Go |
| 4h | DACOUTEN | DAC Output Enable Register | EALLOW | Go |
| 5h | DACLOCK | DAC Lock Register | EALLOW | Go |
| 6h | DACTRIM | DAC Trim Register | EALLOW | Go |

Complex bit access types are encoded to fit into small table cells. Table 12-3 shows the codes that are used for access types in this section.

**Table 12-3. DAC_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| R-0 | R<br>-0 | Read<br>Returns 0s |

Chapter 13

# Comparator Subsystem (CMPSS)

The Comparator Subsystem (CMPSS) consists of analog comparators and supporting circuits that are useful for power applications such as peak current mode control, switched-mode power, power factor correction, voltage trip monitoring, and so forth.

See the *C2000 Real-Time Control Peripheral Reference Guide* for a list of all devices with modules of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

## 13.1 Introduction

The comparator subsystem is built around a number of modules. Each subsystem contains two comparators, two reference 12-bit DACs, and two digital filters. The subsystem also includes one ramp generator. The ramp generator ramps down only.Comparators are denoted "H" or "L" within each module where “H” and “L” represent high and low, respectively. Each comparator generates a digital output which indicates whether the voltage on the positive input is greater than the voltage on the negative input. The positive input of the comparator is driven from an external pin. The negative input can be driven by an external pin or by the programmable reference 12-bit DAC . Each comparator output passes through a programmable digital filter that can remove spurious trip signals. An unfiltered output is also available if filtering is not required.

A ramp generator circuit is optionally available to control the reference 12-bit DAC value for the high comparator in the subsystem.

### *13.1.1 CMPSS Related Collateral*

**Foundational Materials**

- C2000 Academy - CMPSS
- *Real-Time Control Reference Guide*
  - Refer to the Comparator section

**Expert Materials**

- *Peak Current Control Realization for Boost Circuit Based On C2000™ MCU Application Report*
- *Peak Current Mode Controlled PSFB Converter Reference Design Using C2000™ Real-time MCU*
- *Understanding and Applying Current-Mode Control Theory Application Report*

### *13.1.2 Features*

Each CMPSS includes:

- Two analog comparators
- Two programmable reference 12-bit DACs
- One decrementing ramp generator
- Two digital filters, max filter clock prescale = $2^{10}$
- Ability to synchronize submodules with EPWMSYNCPER
- Ability to synchronize output with SYSCLK
- Ability to latch output
- Ability to invert output
- Option to use hysteresis on the input
- Option for negative input of comparator to be driven by an external signal or by the reference DAC
- The DAC reference voltage can be set to VDDA or VDAC

Copyright © 2024 Texas Instruments Incorporated

### 13.1.3 Block Diagram

The block diagram for the CMPSS is shown in Figure 13-1.

- CTRIPx(x= "H" or "L") signals are connected to the ePWM X-BAR for ePWM trip response. See the *Enhanced Pulse Width Modulator (ePWM)* chapter for more details on the ePWM X-BAR mux configuration.
- CTRIPxOUTx(x= "H" or "L") signals are connected to the Output X-BAR for external signaling. See the *General-Purpose Input/Output (GPIO)* chapter for more details on the Output X-BAR mux configuration.

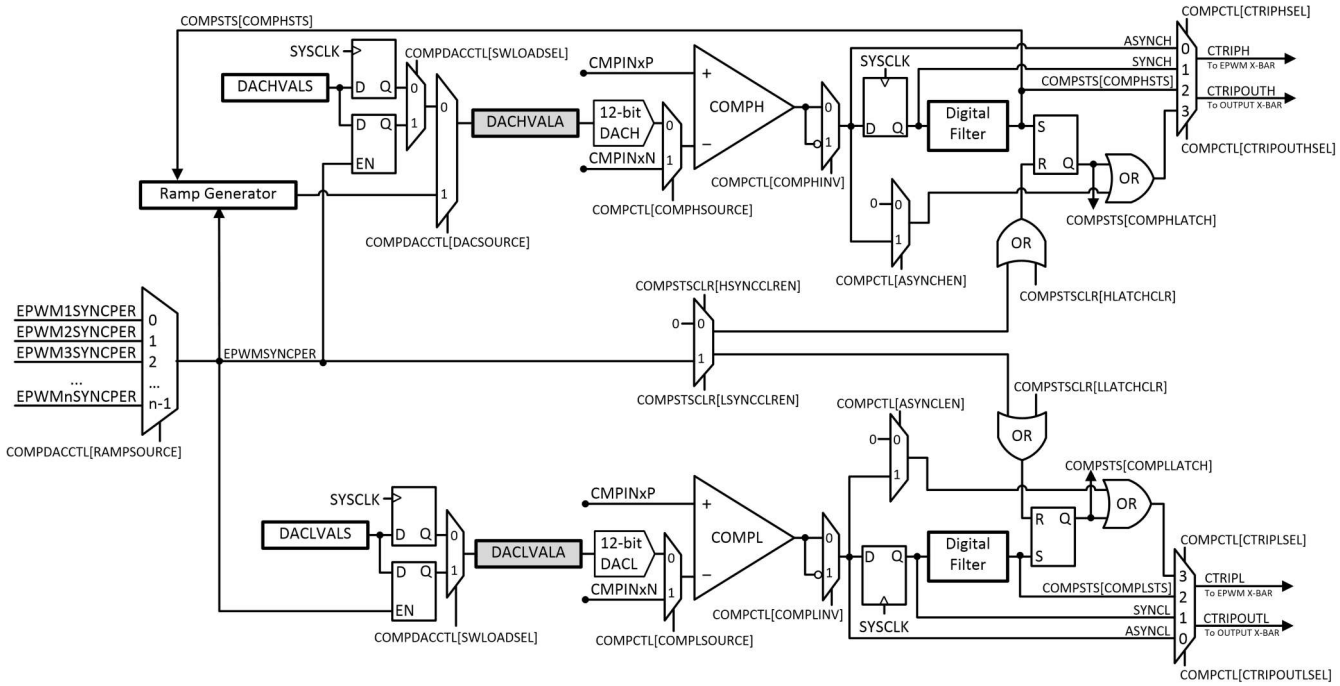

**Figure 13-1. CMPSS Module Block Diagram**

## 13.2 Comparator

The comparator generates a high digital output when the voltage on the positive input is greater than the voltage on the negative input, and a low digital output when the voltage on the positive input is less than the voltage on the negative input. The comparator is illustrated in Figure 13-2.

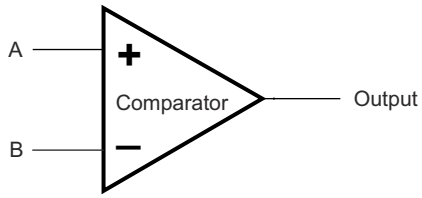

**Figure 13-2. Comparator Block Diagram**

| Voltages | Output |
|---|---|
| Voltage A > Voltage B | 1 |
| Voltage A < Voltage B | 0 |

Copyright © 2024 Texas Instruments Incorporated

## 13.3 Reference DAC

Each reference 12-bit DAC can be configured to drive a reference voltage into the negative input of the respective comparator. The reference 12-bit DAC output is internal only and cannot be observed externally.

Two sets of DACxVAL registers, DACxVALA and DACxVALS, are present for each reference 12-bit DAC. DACxVALA is a read-only register that actively controls the reference 12-bit DAC value. DACxVALS is a writable shadow register that loads into DACxVALA either immediately or synchronized with the next EPWMSYNCPER event. The high and low reference 12-bit DAC (DACx) can optionally source the register DACxVALA value from the ramp generator instead of the register DACxVALS.

The operating range of the reference 12-bit DAC is bounded by DACREF and VSSA. The high-voltage reference is VDDA by default, but the high voltage reference can be configured to be VDAC using the COMPDACCTL register. The reference 12-bit DAC is illustrated in Figure 13-3.

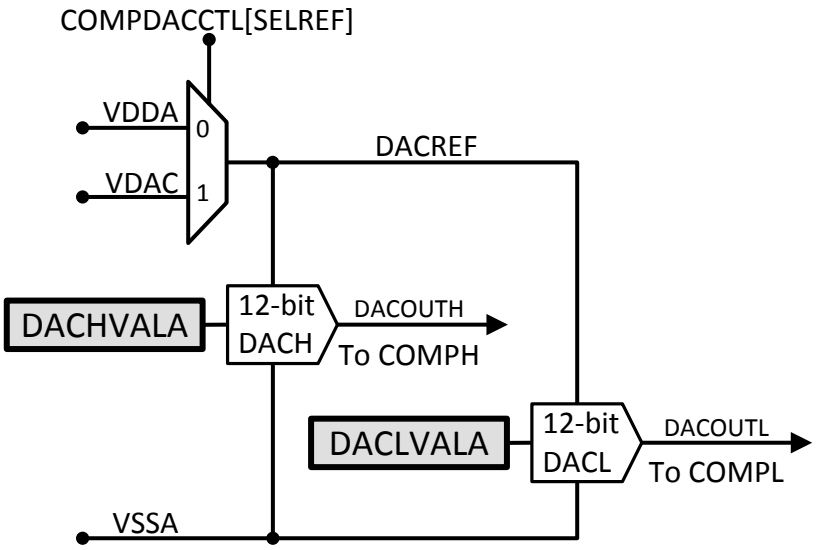

**Figure 13-3. Reference DAC Block Diagram**

The output of the reference 12-bit DAC can be calculated as:

$$DACOUT = \frac{(1 + DACVALA)*DACREF}{4096} \quad (16)$$

**Note**

- In the situations where both the DACH and DACL are driving the high and low comparators, a trip on one comparator can temporarily disturb the DAC output of the other comparator. The amount and length of time of this disturbance is specified in the device data sheet as “CMPSS DAC output disturbance” and “CMPSS DAC disturbance time”, respectively.

  Users must design the system carefully so that if the input signal crosses either DACH or DACL and trips the associated comparator, the input signal stays more than a “CMPSS DAC output disturbance” away from the other comparator trip point for “CMPSS DAC disturbance time”.
- The DACH setting must always be higher than the DACL setting. If the user is not using the DACL, the DACLVALS register must be set to 0 to avoid the comparator COMPL from tripping and affecting the DACH. In this case, there is no limitation on the DACHVALS setting. Accordingly, when not using the DACH, the user must set the DACHVALS register to the maximum.
- The CMPSS instance can be enabled before programming the reference DAC values.

## 13.4 Ramp Generator

This section discusses the characteristics and behavior of the ramp generator.

### *13.4.1 Ramp Generator Overview*

The ramp generator produces a falling ramp input for the high-reference 12-bit DAC when selected. In this mode, the reference 12-bit DAC uses the most-significant 12 bits of the RAMPSTS countdown register as the input. The low 4 bits of the RAMPSTS countdown register effectively act as a prescale for the falling ramp rate configurable with RAMPDECVALA.

The ramp generator is enabled by setting DACSOURCE = 1. When DACSOURCE = 1 is selected, the value of RAMPSTS is loaded from RAMPMAXREFS and the register remains static until the selected EPWMSYNCPER signal is received. After receiving the selected EPWMSYNCPER signal, the value of RAMPDECVALA is subtracted from RAMPSTS on every subsequent SYSCLK cycle.

To prevent the subtraction from commencing a SYSCLK cycle after a EPWMSYNCPER event, the RAMPDLYA register that serves as a delay counter can be used to hold off the RAMPSTS subtraction. On receiving a EPWMSYNCPER event, the value of RAMPDLYA is decremented by one on every SYSCLK cycle until the register reaches zero. So, the RAMPSTS subtraction only begins when RAMPDLYA is zero.

Copyright © 2024 Texas Instruments Incorporated

### 13.4.2 Ramp Generator Behavior

The ramp generator makes state changes on every rising edge of DACSOURCE, EPWMSYNCPER, and COMPHSTS.

On the rising edge of DACSOURCE: RAMPMAXREFA, RAMPDECVALA, and RAMPDLYA are loaded with the shadow registers. RAMPSTS is loaded with RAMPMAXREFS.

On the rising edge of the selected EPWMSYNCPER: RAMPMAXREFA, RAMPDECVALA, and RAMPDLYA are loaded with the shadow registers. RAMPSTS is loaded with RAMPMAXREFS and starts decrementing when RAMPDLYA counter reaches zero.

On the rising edge of COMPHSTS with RAMPLOADSEL = 1: RAMPMAXREFA, RAMPDECVALA, and RAMPDLYA are loaded with the shadow registers. RAMPSTS is loaded with RAMPMAXREFS and stops decrementing.

On the rising edge of COMPHSTS with RAMPLOADSEL = 0: RAMPSTS is loaded with RAMPMAXREFA and stops decrementing.

Additionally, if the value of RAMPSTS reaches zero, the RAMPSTS register remains static at zero until the next EPWMSYNCPER is received. These state changes are illustrated in the ramp generator block diagram in Figure 13-4.

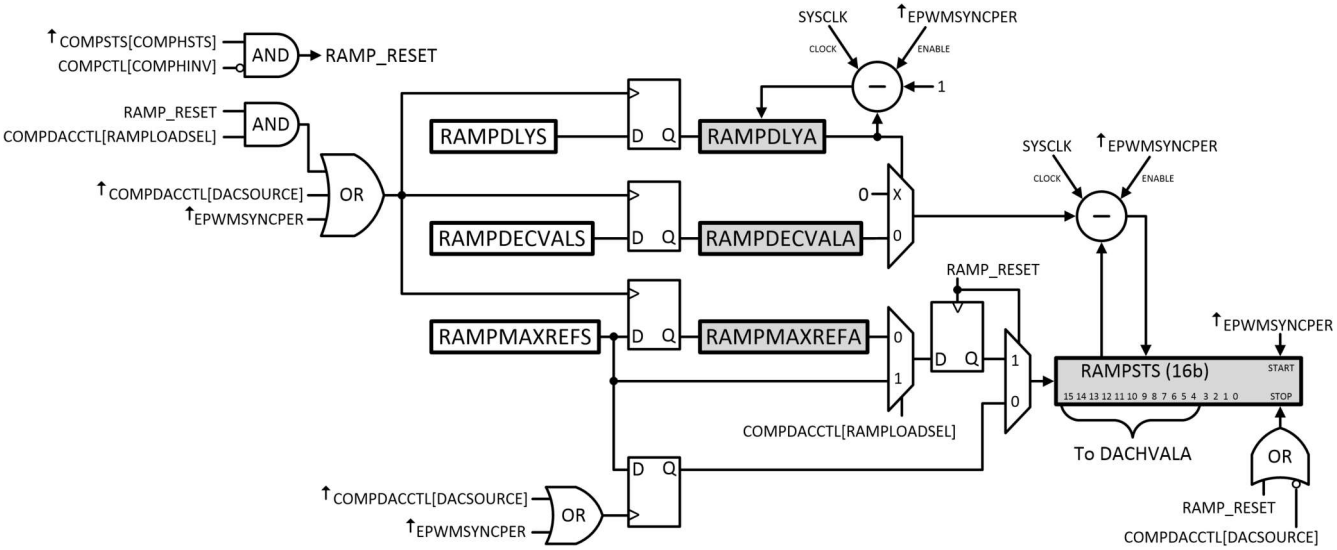

**Figure 13-4. Ramp Generator Block Diagram**

Copyright © 2024 Texas Instruments Incorporated

### 13.4.3 Ramp Generator Behavior at Corner Cases

Since the ramp generator makes state changes on every rising edge of EPWMSYNCPER and COMPHSTS, the following behavior can be expected on instances when these two events occur simultaneously or very close together.

Case 1: COMPHSTS rising edge occurs one or more cycles before EPWMSYNCPER rising edge.
RAMPSTS stops decrementing on COMPHSTS rising edge event. RAMPSTS starts decrementing on EPWMSYNCPER rising edge event when RAMPDLYA reaches 0.

Case 2: COMPHSTS rising edge occurs simultaneously as EPWMSYNCPER rising edge.
EPWMSYNCPER rising edge event takes precedence and RAMPSTS starts decrementing when RAMPDLYA reaches 0. COMPHSTS rising edge event is ignored and does not halt RAMPSTS.

Case 2: COMPHSTS rising edge occurs simultaneously as EPWMSYNCPER rising edge.
COMPHSTS rising edge event takes precedence and RAMPSTS stops decrementing. EPWMSYNCPER rising edge event is ignored and does not start decrementing RAMPSTS when RAMPDLYA reaches 0.

Case 3: COMPHSTS rising edge occurs one or more cycles after EPWMSYNCPER rising edge but before RAMPDLYA reaches 0.
RAMPSTS does not decrement when RAMPDLYA reaches 0.

Case 4: COMPHSTS rising edge occurs simultaneously as RAMPDLYA reaches 0 from EPWMSYNCPER rising edge.
RAMPSTS does not decrement.

This behavior is also illustrated in Figure 13-5.

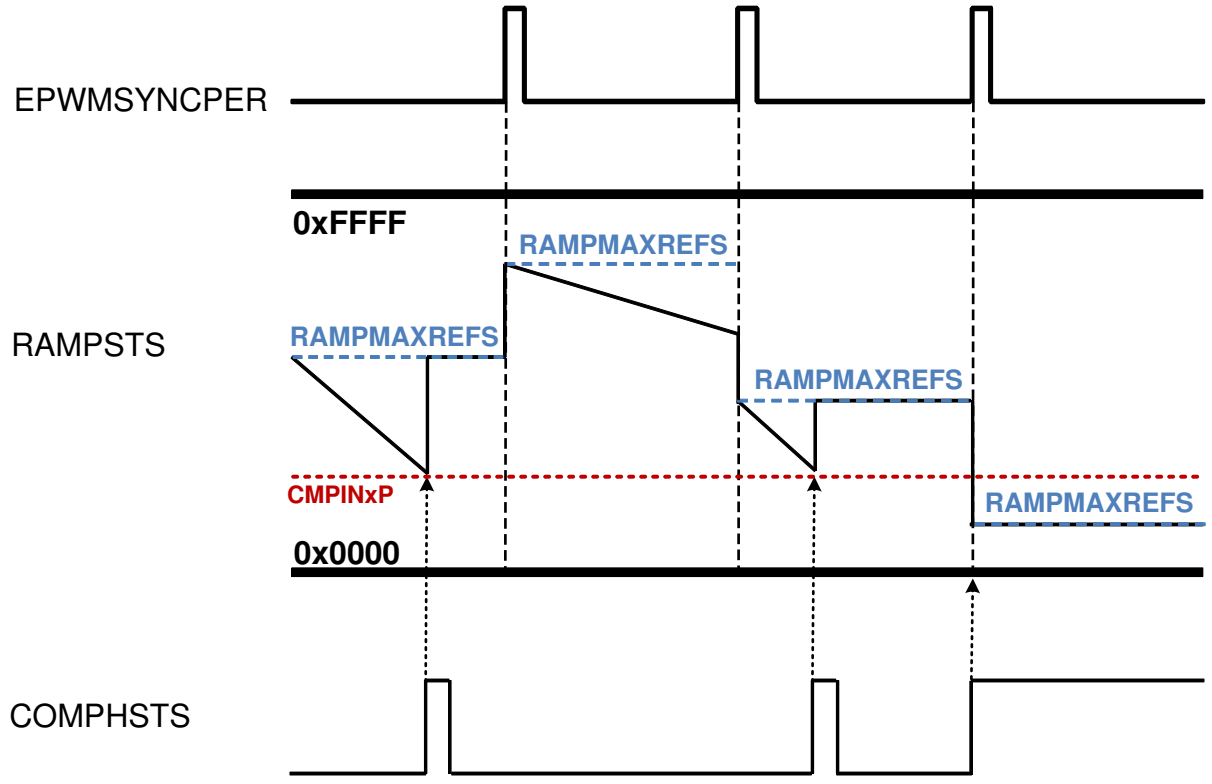

**Figure 13-5. Ramp Generator Behavior**

Copyright © 2024 Texas Instruments Incorporated

## 13.5 Digital Filter

The digital filter works on a window of FIFO samples (SAMPWIN) taken from the input. The filter output resolves to the majority value of the sample window, where majority is defined by the threshold (THRESH) value. If the majority threshold is not satisfied, the filter output remains unchanged.

For proper operation, the value of THRESH must be greater than SAMPWIN / 2 and less than or equal to SAMPWIN.

A prescale function (CLKPRESCALE) determines the filter sampling rate, where the filter FIFO captures one sample every prescale system clocks. Old data from the FIFO is discarded.

Note that for SAMPWIN, THRESH and CLKPRESCALE, the internal number used by the digital filter is + 1 in all cases. In essence, samples = SAMPWIN + 1, threshold = THRESH + 1 and prescale = CLKPRESCALE + 1.

A conceptual model of the digital filter is shown in Figure 13-6.

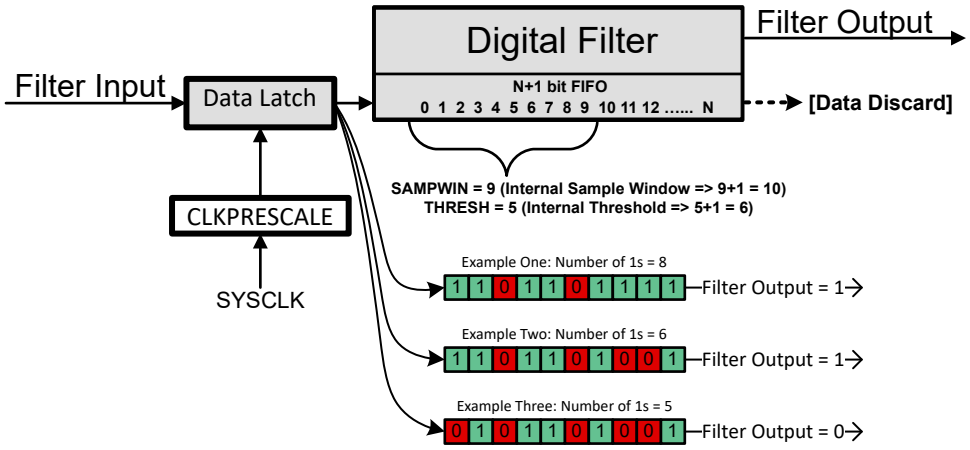

**Figure 13-6. Digital Filter Behavior**

Equivalent C code of the filter implementation is:

```
if (FILTER_OUTPUT == 0) {
    if (Num_1s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 1;
    }
}
else {
    if (Num_0s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 0;
    }
}
```

Copyright © 2024 Texas Instruments Incorporated

#### 13.5.1 Filter Initialization Sequence

For proper operation of the digital filter, the following initialization sequence is recommended:

1. Configure and enable the comparator for operation.
2. Configure the digital filter parameters for operation:
   - Set SAMPWIN for the number of samples to monitor in the FIFO window.
   - Set THRESH for the threshold required for majority qualification.
   - Set CLKPRESCALE for the digital filter clock prescale value.
3. Initialize the sample values in the digital FIFO window by setting FILINIT.
4. Clear COMPSTS latch using COMPSTSCLR, if the latched path is desired.
5. Configure the CTRIP and CTRIPOUT signal paths.
6. If desired, configure the destination module, for example, ePWM, GPIO, and so on to accept the filtered signals.

### 13.6 Using the CMPSS

#### 13.6.1 LATCHCLR and EPWMSYNCPER Signals

The LATCHCLR signal holds the latch output in reset (0) after the required delays. The LATCHCLR signal is activated in software using xLATCHCLR (x = H or L). The LATCHCLR signal can also be activated by EPWMSYNCPER when xSYNCCLREN (x = H or L) is set.

EPWMSYNCPER comes from the Time-Base submodule of the EPWM. For a detailed description of how this signal is generated, refer to the Time-Base submodule section in the *Enhanced Pulse Width Modulator (ePWM)* chapter.

The EPWMSYNCPER signal that loads DACxVALA when COMPDACCTL[SWLOADSEL] = 1 is a level trigger load. If TBCTR and TBPRD of the EPWM are both 0, EPWMSYNCPER is held at level high and DACxVALA is loaded immediately from DACxVALS irrespective of the value of COMPDACCTL[SWLOADSEL]. Due to this, configure the EPWM first before setting COMPDACCTL[SWLOADSEL] to 1.

**Note**

The name of the sync signal that the CMPSS receives from the EPWM has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCI and EPWMSYNCO. For a description of what are these signals, see the *Enhanced Pulse Width Modulator (ePWM)* chapter.

#### 13.6.2 Synchronizer, Digital Filter, and Latch Delays

The synchronization block adds a delay of 1-2 sysclks. If the digital filter is bypassed (all filter settings are 0), the digital filter adds a delay of 2 sysclks. The latch adds 1 sysclk delay.

Copyright © 2024 Texas Instruments Incorporated

### 13.6.3 Calibrating the CMPSS

The CMPSS has two sources of offset errors: comparator offset error and compdac offset error. In the data sheet, the comparator offset error is referred to as ***Input referred offset error*** and compdac offset error is referred to as ***Static offset error***. See the device data sheet for the values.

If both inputs of the comparator are driven from a pin, only the comparator offset error applies. However if the inverting input of the comparator is driven from the compdac, then only the compdac offset error applies. This is because the compdac offset error includes comparator offset error.

Due to the offset errors, the CMPSS must be calibrated to make sure trips happen at the expected levels. The following flow outlines how the calibration can be performed if the inverting input of the comparator is driven from the compdac.

Notes before calibration:

1. A static DC signal is required on the non-inverting input of the comparator.
2. Hysteresis can be disabled for calibration and can be re-enabled after calibration is complete.
3. A noisy input can make calibration difficult, so use the latch with non-zero filter settings depending on how noisy is the signal on the non-inverting input.

This approach sweeps down the compdac:

1. Set the starting compdac value to max, 0xFFF.
   - Optional: Instead of setting the starting compdac value to maximum, set to ***Vtarget*** + ***Static offset error*** + ***Margin***. Where ***Vtarget*** is the approximate DC voltage on the non-inverting input, ***Static offset error*** is the compdac offset error specification and ***Margin*** is some amount of guard band. This can lead to a faster calibration but only works if ***Vtarget*** is known. Alternatively, if ***Vtarget*** is unknown, the ADC can be used to convert ***Vtarget***.
2. Decrement compdac value by 1.
3. Wait for compdac to settle.
4. Clear latch.
5. Wait for possible latch set.
6. If latch is set, trip code is found exit.
   - Optional: The trip code can be double checked by:
     a. Increasing compdac value by 1.
     b. Clear latch.
     c. Wait for possible latch set.
     d. Latch can be unset.
7. If latch is unset, go back to step 2 and repeat.

It is also possible to calibrate the CMPSS, if both inputs of the comparator are driven from a pin. For this case, the flow stays the same but the voltage on the inverting pin of the comparator is swept externally.

### 13.6.4 Enabling and Disabling the CMPSS Clock

If the clock to the CMPSS module is disabled while the comparator is active, the following behavior can be expected:

- The comparator remains unaffected and continues to trip from voltages on the inputs.
- If the reference 12-bit DAC is driving the negative input of the comparator, the voltage on the negative input remains static and unaffected but DACVALA can no longer be updated from the ramp generator or DACVALS.
- The ramp generator, synchronize block and digital filter freeze on the current states.

Enabling the clock to the CMPSS restores the clock to the state before the clock was disabled.

## 13.7 Software

### *13.7.1 CMPSS Examples*

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/cmpss

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

#### 13.7.1.1 CMPSS Asynchronous Trip

FILE: cmpss_ex1_asynch.c

This example enables the CMPSS1 COMPH comparator and feeds the asynchronous CTRIPOUTH signal to the GPIO14/OUTPUTXBAR3 pin and CTRIPH to GPIO15/EPWM8B.

CMPSS is configured to generate trip signals to trip the EPWM signals. CMPIN1P is used to give positive input and internal DAC is configured to provide the negative input. Internal DAC is configured to provide a signal at VDD/2. An EPWM signal is generated at GPIO15 and is configured to be tripped by CTRIPOUTH.

When a low input(VSS) is provided to CMPIN1P,
- Trip signal(GPIO14) output is low
- PWM8B(GPIO15) gives a PWM signal

When a high input(higher than VDD/2) is provided to CMPIN1P,
- Trip signal(GPIO14) output turns high
- PWM8B(GPIO15) gets tripped and outputs as high

*External Connections*
- Outputs can be observed on GPIO14 and GPIO15
- Comparator input pin is on ADCINA2

*Watch Variables*
- None

#### 13.7.1.2 CMPSS Digital Filter Configuration

FILE: cmpss_ex2_digital_filter.c

This example enables the CMPSS1 COMPH comparator and feeds the output through the digital filter to the GPIO14/OUTPUTXBAR3 pin.

CMPIN1P is used to give positive input and internal DAC is configured to provide the negative input. Internal DAC is configured to provide a signal at VDD/2.

When a low input(VSS) is provided to CMPIN1P,
- GPIO14 output is low

When a high input(higher than VDD/2) is provided to CMPIN1P,
- GPIO14 output turns high

| 1Ah | COMPLOCK | CMPSS Lock Register | EALLOW | Go |

Complex bit access types are encoded to fit into small table cells. Table 13-3 shows the codes that are used for access types in this section.

**Table 13-3. CMPSS_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| R-0 | R<br>-0 | Read<br>Returns 0s |
| Write Type | | |
| W | W | Write |
| W1S | W<br>1S | Write<br>1 to set |
| WSonce | W<br>Sonce | Write<br>Set once |
| Reset or Default Value | | |
| *-n* | | Value after reset or the default value |
| Register Array Variables | | |

Copyright © 2024 Texas Instruments Incorporated

**Table 13-3. CMPSS_REGS Access Type Codes (continued)**

| Access Type | Code | Description |
|---|---|---|
| i,j,k,l,m,n | | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y | | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

Chapter 14

# Sigma Delta Filter Module (SDFM)

The sigma delta filter module (SDFM) is a four-channel digital filter designed specifically for current measurement and resolver position decoding in motor control applications. Each input channel can receive an independent delta-sigma (ΔΣ) modulator bit stream. The bit streams are processed by four individually-programmable digital decimation filters. The filter set includes a fast comparator (secondary filter) for immediate digital threshold comparisons for over-current and under-current monitoring, and zeros crossing detection.

### 14.1.2 Features

SDFM features include:

- Eight external pins per SDFM module
  - Four sigma-delta data input pins per SDFM module (SD-Dx, where x = 1 to 4)
  - Four sigma-delta clock input pins per SDFM module (SD-Cx, where x = 1 to 4)
- Different configurable modulator clock modes supported:
  - Mode 0: Modulator clock rate equals the modulator data rate.
  - Mode 1: Modulator clock rate running at half the modulator data rate.
  - Mode 2: Modulator data is Manchester-encoded. Modulator clock is not required.
  - Mode 3: Modulator clock rate is double that of the modulator data rate
- Four independent, configurable secondary filter (comparator) units per SDFM module:
  - Four different filter type selection (Sinc1/Sinc2/SincFast/Sinc3) options available
  - Ability to detect over-value condition, under-value condition, and Threshold-crossing conditions
  - OSR value for comparator filter unit (COSR) programmable from 1 to 32
- Four independent configurable primary filter (data filter) units per SDFM module:
  - Four different filter type selection (Sinc1/Sinc2/SincFast/Sinc3) options available
  - OSR value for data filter unit (DOSR) programmable from 1 to 256
  - Ability to enable or disable (or both) individual filter module
  - Ability to synchronize all four independent filters of an SDFM module by using the Master Filter Enable (MFE) bit or by using PWM signals
- Data filter output can be represented in either 16 bits or 32 bits.
- PWMs can be used to generate a modulator clock for sigma-delta modulators.

Copyright © 2024 Texas Instruments Incorporated

### 14.1.3 Block Diagram

Each SDFM module has four independent filter modules. These filter modules are identical and can be configured independently. Each individual filter module has the following units:

- Input control unit
- Primary filter (data filter) unit
- Secondary filter (comparator filter) unit with 4 independent comparators

Figure 14-2 shows the SDFM module block diagram. The SDFM port operation is configured and controlled by the registers listed in Section 14.11.

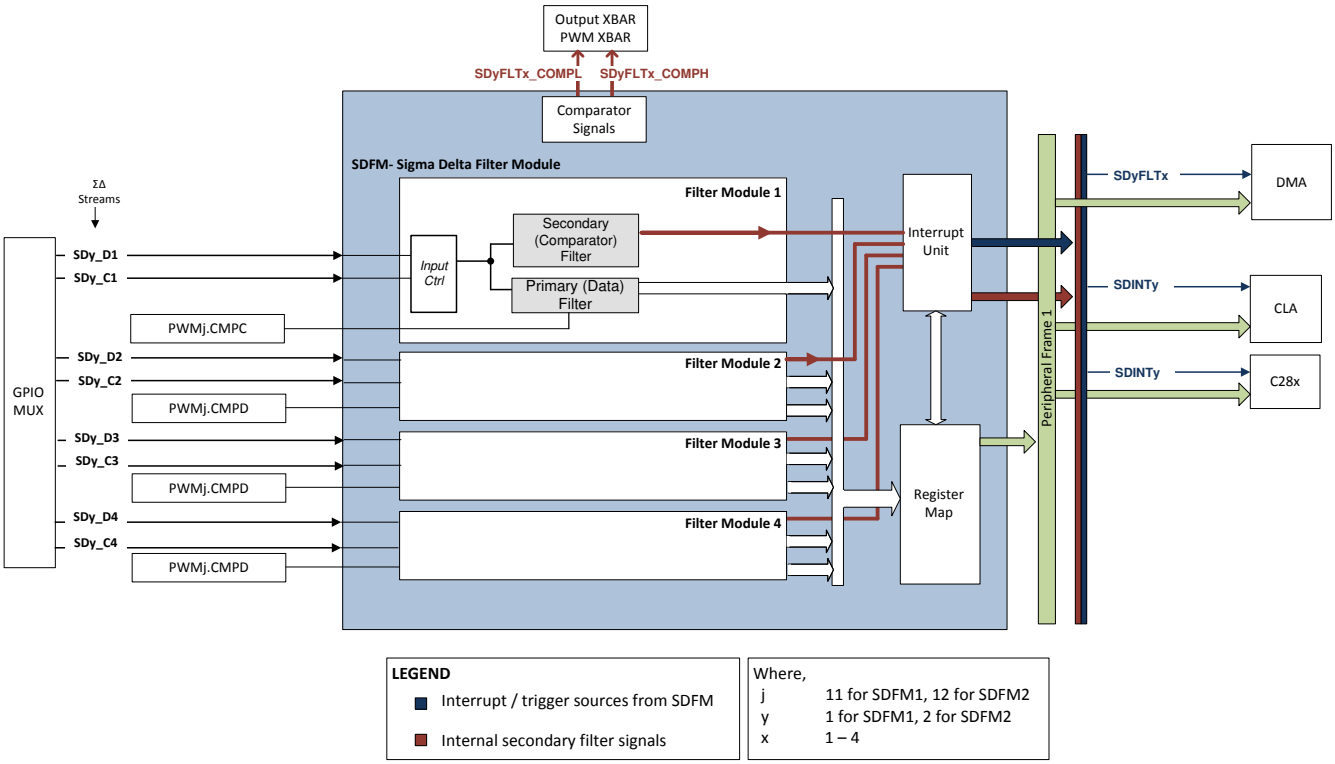

**Figure 14-2. Sigma Delta Filter Module (SDFM) Block Diagram**

**Note**

When using PWM11 or PWM12 for SDFM data filter synchronization, you must make sure that only one CMPC or CMPD event is generated per PWM timer period. Using PWM in up-count or down-count mode automatically makes sure that you get only one PWMC or PWMD event. But, if you want to use up-down count mode, then you need to make sure that only one CMPC or CMPD event per PWM cycle is generated; otherwise, the filter synchronizer corrupts the SDFM timing by providing two pulses per PWM cycle.

Each filter module shown in Figure 14-3 has a primary (data) filter and a secondary (comparator) filter pair that receives the same bit stream. Except for the input bit stream, both the primary and secondary filter are completely independent of each other. Each of these filter modules can be independently configured. So, in a SDFM module, there is a total of four primary filters and four secondary filters.

## 14.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

For proper SDFM operation, use the following GPIO input qualification. Other GPIO qualifications are not supported.

- **Recommended option:** GPIO Input qualification = 3-sample GPIO Input Qualification. This option provides additional hardware protection against occasional random noise glitches. When GPIO Input qualification is a 3-sample window, make sure to check that the SDFM Electrical Data and Timing (Using 3-Sample GPIO Input Qualification) requirement is met and be aware of the following caution message and note.
- If GPIO Input qualification is ASYNC, make sure to check that the SDFM Electrical Data and Timing (Using ASYNC) requirement is met and be aware that this option is susceptible to random noise glitches.

**CAUTION**

The SDFM clock inputs (SDx_Cy pins) directly clock the SDFM module. Any glitches or ringing noise on these inputs can corrupt the SDFM module operation. Special precautions must be taken on these signals to make sure of a clean and noise-free signal that meets SDFM timing requirements. Precautions such as series termination for ringing due to any impedance mismatch of the clock driver and spacing of traces from other noisy signals are recommended.

**Note**

The SDFM module expects SD-Dx to change on the falling edge of SD-Cx and strobes for SD-Dx on the rising edge. But some SD-modulators in the market change SD-Dx on the rising edge and expect SDFM to strobe for data on the falling edge. In such cases, the GPIO inversion feature (GPxINV) is used on SD-Cx pin to change polarity and make it compatible with the SDFM.

The SDFM Qualified GPIO (3-sample) option provides protection against SDFM module corruption due to occasional random noise glitches on the SDx_Cy pin that can result in a false comparator trip and filter output.

The SDFM Qualified GPIO (3-sample) option does not provide protection against persistent violations of the above timing requirements. Timing violations results in data corruption proportional to the number of bits that violate the requirements.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

Copyright © 2024 Texas Instruments Incorporated

## 14.3 Input Control Unit

The input control unit receives sigma delta modulated data and a sigma delta modulated clock. The modulated data received is captured and passed on to the data filter unit and comparator unit. This unit can be configured to receive the modulated data in four different modes. Table 14-1 and Figure 14-4 show how SDCTLPARMx.MOD bits can be configured in these four different modes.

**Table 14-1. Modulator Clock Modes**

| Modulator Mode [MOD] | Description |
|---|---|
| 0 | The modulator clock is running with the modulator data rate. The modulator data is strobed at every rising edge of the modulator clock. |
| 1 | The modulator clock is running with half of the modulator data rate. The modulator data is strobed at every edge of the modulator clock. |
| 2 | The modulator clock is off and the modulator data is Manchester-encoded. |
| 3 | The modulator clock is running with double the modulator data rate. The modulator data is strobed at every other positive modulator clock edge. |

**Note**

To achieve the maximum value, the sigma-delta modulator has to be operated at absolute maximum positive or negative full scale, which is outside of the recommended full scale range of 80% of most sigma-delta modulators.

When MOD=2, data and modulated clock signals are encoded into modulated data as shown in Mode 2 of Figure 14-4. In this mode, the clock input SD-Cx pin can be left floating. The input control unit performs continuous automatic calibration to achieve optimum decoding performance.

Copyright © 2024 Texas Instruments Incorporated

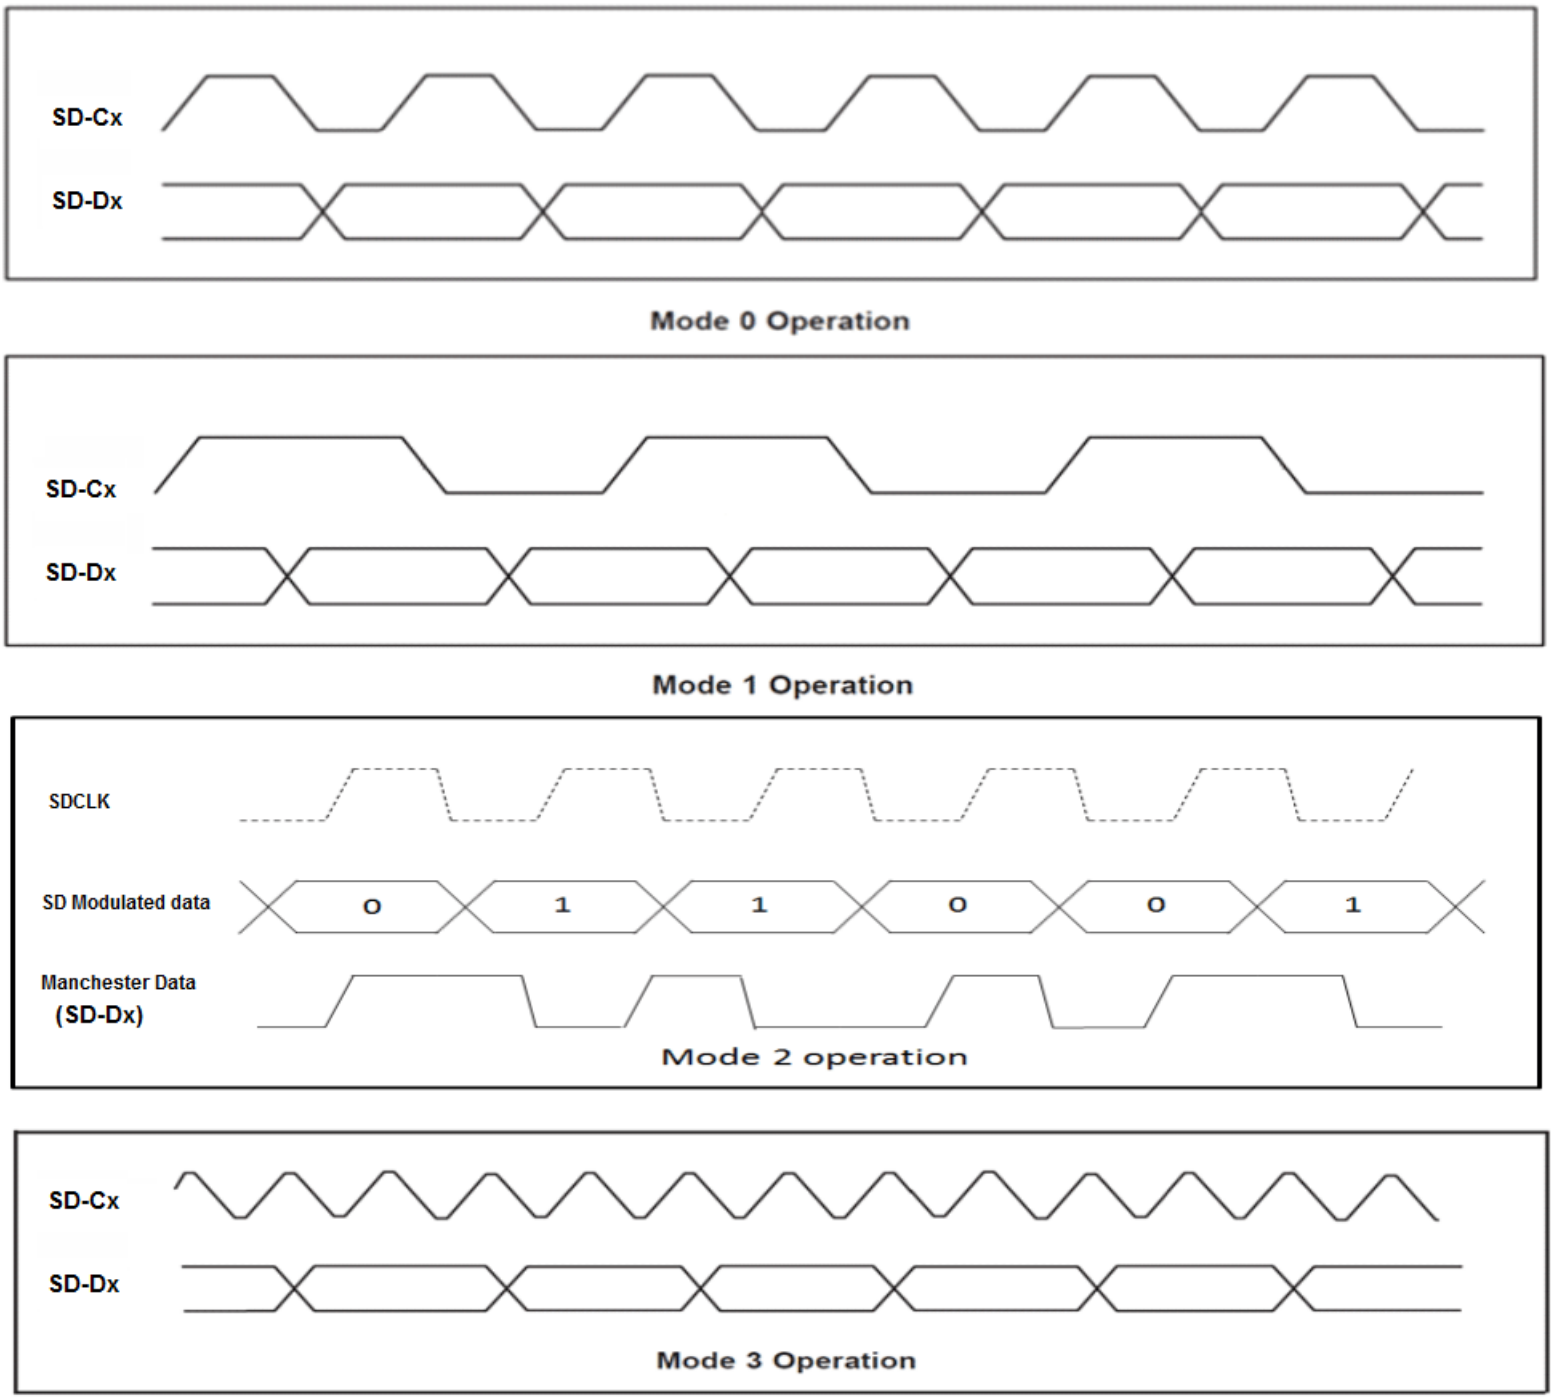

**Figure 14-4. Different Modulator Modes Supported**

## 14.4 Sinc Filter

Both the comparator filter and data filter available in SDFM have the Sinc$^N$ filter as the core. The Sinc$^N$ filter is essentially a low-pass filter that converts the input bit stream into digital data by digital filtering and decimation. This filtered digital data represents analog input given to the sigma delta modulator. Simplified Sinc$^N$ architecture

Copyright © 2024 Texas Instruments Incorporated

consists of cascaded integrators and differentiators separated by a down-sampler as shown in Figure 14-5. The Z-transfer function of the Sinc filter of order N is shown in Figure 14-6.

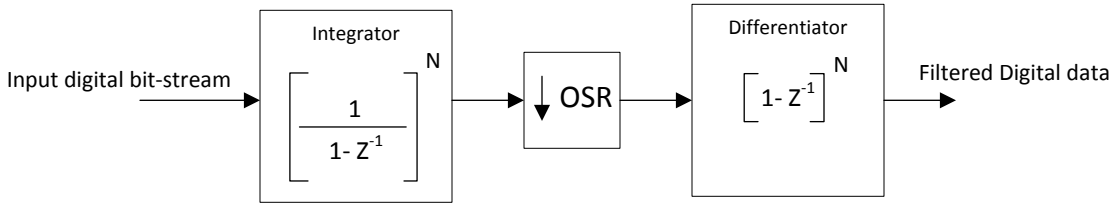

**Figure 14-5. Simplified Sinc Filter Architecture**

$$H(Z) = \left[ \frac{1 - Z^{-OSR}}{1 - Z^{-1}} \right]^{N}$$

N = Order of Sinc filter
OSR = Over Sampling Ratio

**Figure 14-6. Z-Transform of Sinc Filter of Order N**

Effective resolution of the Sinc filter (ENOB) depends upon filter type, OSR and sigma-delta modulator frequency. Typically, higher resolution or ENOB can be achieved by higher OSR for a given filter type; however, the tradeoff is increased filter delay. It is important to choose the right sigma delta modulator by studying the optimal speed versus resolution tradeoff. Refer to the corresponding sigma delta modulator data sheet to determine the effective resolution for a given Sinc filter configuration. Figure 14-7 shows the frequency response of different filter structures when OSR = 32 and when the sigma delta modulator frequency is 10MHz.

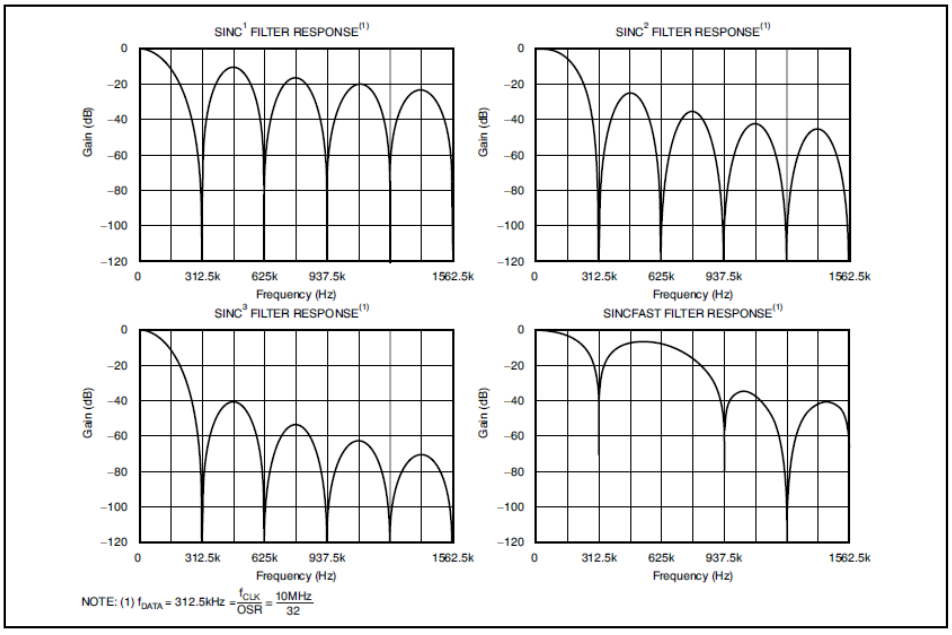

**Figure 14-7. Frequency Response of Different Sinc Filters**

Copyright © 2024 Texas Instruments Incorporated

The order of different sinc filter is shown in Table 14-2.

**Table 14-2. Order of Sinc Filter**

| Filter Type | Order of Sinc Filter |
|---|---|
| Sinc1 | 1 |
| Sinc2 | 2 |
| Sinc3 | 3 |
| SincFast | 3 |

### *14.4.1 Data Rate and Latency of the Sinc Filter*

The data rate of the sinc filter (filter throughput) represented in samples/sec is calculated by the following formula:

$$Data\ rate\ of\ Sinc\ filter = \frac{Modulator\ data\ rate}{OSR} \tag{17}$$

The latency of the sinc filter represented in secs is defined as the amount of time taken by a sinc filter type to deliver the correct filtered output upon initiation. For a given filter type, latency is calculated by the following formula:

$$Latency\ of\ Sinc\ filter = \frac{Order\ of\ Sinc\ filter}{Data\ rate\ of\ Sinc\ filter} \tag{18}$$

***Example configuration:***

| | |
|---|---|
| Sinc filter type | = sinc3 |
| Modulator data rate | = 10MHz |
| OSR | = 256 |
| Data rate of Sinc Filter | = 10MHz/256 = 39.1K samples/second |
| Sinc filter latency | = 76.8µs |
| Sinc filter type | = sinc2 |
| Modulator data rate | = 10MHz |
| OSR | = 256 |
| Data rate of Sinc Filter | = 10MHz/256 = 39.1K samples/second |
| Sinc filter latency | =51.2µs |

Copyright © 2024 Texas Instruments Incorporated

## 14.5 Data (Primary) Filter Unit

The data filter is a configurable Sinc filter which supports the following filter types: Sinc1, Sinc2, Sinc3, and SincFast. The data filter OSR (DOSR) settings can be configured from 1 to 256 and is independent of the comparator filter. Effective resolution of the data filter (ENOB) depends upon Data filter type, DOSR, and sigma-delta modulator frequency. By default, the data filter is disabled and setting of SDDFPARMx.FEN = 1 enables the data filter. The data filter output is represented in 25-bit signed integer in two's complement format. This filter unit translates a low input signal as '-1' and a high input signal as '1'. The resulting calculation gives both positive and negative values for the output of the data filter. Table 14-3 shows the different full scale values that the data filter can store using different OSRs.

See Section 14.4.1 to understand how to calculate data rate and latency of data filter.

**Table 14-3. Peak Data Values for Different DOSR/Filter Combinations**

| DOSR | Sinc1 | Sinc2 | Sinc3 | SincFast |
|---|---|---|---|---|
| x | x | $x^2$ | $x^3$ | $2x^2$ |
| 4 | –4 to 4 | –16 to 16 | –64 to 64 | –32 to 32 |
| 8 | –8 to 8 | –64 to 64 | –512 to 512 | –128 to 128 |
| 16 | –16 to 16 | –256 to 256 | –4096 to 4096 | –512 to 512 |
| 32 | –32 to 32 | –1024 to 1024 | –32,768 to 32,768 | –2048 to 2048 |
| 64 | –64 to 64 | –4096 to 4096 | –262,144 to 262,144 | –8192 to 8192 |

### 14.5.1 32-bit or 16-bit Data Filter Output Representation

The data filter output can be represented in either 32-bit or 16-bit format.

**32-bit data filter representation:**

- When SDDPARMx.DR = 1, data filter output is represented in 32-bit format. Writes to shift control bits do not have any bearing on the output of the data filter in this configuration.

**16-bit data filter representation:**

- By default, data filter output is represented in 16-bit format
- When SDDPARMx.DR = 0, data filter output is represented in 16-bit format. But it is the responsibility of the user to configure the corresponding shift control bits in the SDDPARMx register to control which 16-bit part of the 32-bit word is sent to the register map.

  For example, for the data filter configuration below:
  - Filter type = Sinc3
  - OSR = 128
  - SDDPARMx.DR = 0

  The data filter with a 25-bit signed output value can be in the range of –2,097,152 to 2,097,152. But, 16-bit signed output supports values only from –32,768 to 32,767. Therefore, it is required to configure shift control bits (SDDPARMx.SH) to 7 to represent the data filter output correctly in 16-bit format. Table 14-4 shows the configuration settings of shift control bits for different OSR and filter types.

**Table 14-4. Shift Control Bit Configuration Settings**

| OSR | Sinc1 | Sinc2 | SincFast | Sinc3 |
|---|---|---|---|---|
| 1 to 31 | 0 | 0 | 0 | 0 |
| 32 to 40 | 0 | 0 | 0 | 1 |
| 41 to 50 | 0 | 0 | 0 | 2 |
| 51 to 63 | 0 | 0 | 0 | 3 |
| 64 to 80 | 0 | 0 | 0 | 4 |
| 81 to 101 | 0 | 0 | 0 | 5 |
| 102 to 127 | 0 | 0 | 0 | 6 |
| 128 to 161 | 0 | 0 | 1 | 7 |
| 162 to 181 | 0 | 0 | 1 | 8 |
| 182 to 203 | 0 | 1 | 2 | 8 |
| 204 to 255 | 0 | 1 | 2 | 9 |
| 256 | 0 | 2 | 3 | 9 |

**CAUTION**

Configuring shift control bits incorrectly results in getting an incorrect 16-bit data filter output.

Copyright © 2024 Texas Instruments Incorporated

### 14.5.2 SDSYNC Event

Primary (data) filters can be synchronized with respect to the PWM event (called SDSYNC event). The SDSYNC signal from the PWM module is used to reset the DOSR counter. This feature is by default disabled and can be enabled by setting SDDFPARMx.SDSYNCEN = 1. Figure 14-8 shows how the PWM signals are connected to the sigma delta module. In this device, PWM11 can be used to reset SDFM1 filter modules and PWM12 can be used to reset SDFM2 modules.

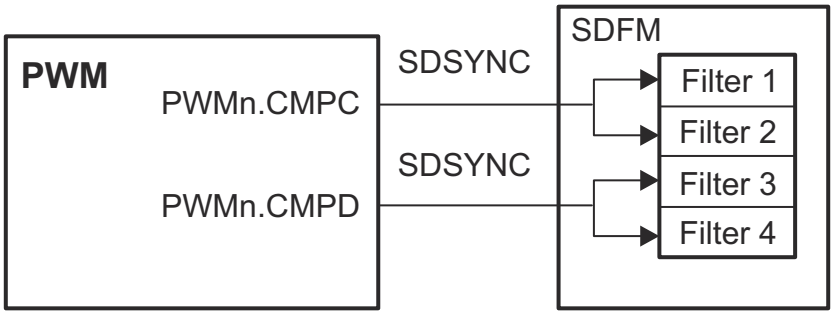

**Figure 14-8. SDSYNC Event**

Because of the inherent architecture of the Sinc filter (Sinc1, Sinc2, Sinc3, SincFast), the first few samples, depending upon filter type, are incorrect. Table 14-5 shows the number of incorrect samples on the following conditions:

- When Sinc filter is enabled and configured for first time.
- When Sinc filter is disabled and re-enabled or reconfigured in the middle of operation.
- When data filter receives SDSYNC event from PWM.

**Table 14-5. Number of Incorrect Samples Tabulated**

| Filter Type | Number of Incorrect Samples After the Filter is Enabled and Configured |
|---|---|
| Sinc1 | No incorrect sample. |
| Sinc2 | The first sample of the Sinc2 filter is incorrect. |
| SincFast | The first two samples of the SincFast filter are incorrect. |
| Sinc3 | The first two samples of the Sinc3 filter are incorrect. |

**CAUTION**

SDFM comparator interrupts can be enabled only after providing sufficient settling time to make sure the comparator filter does not trip on these incorrect samples. Therefore, SDFM comparator interrupts (IELx and IEHx) can be enabled only after a sufficient delay is provided after the comparator filter is configured. This sufficient delay is calculated by adding the latency of the comparator filter and 5 SD-Cx clock cycles.

## 14.6 Comparator (Secondary) Filter Unit

Most control systems require protection of the system by tripping the PWM in case the current or voltage goes out of bounds. The primary purpose of the secondary (comparator) filter is to allow the user to monitor input conditions with a fast settling time. This allows the user to trip PWMs to protect the system from potential damage.

**Note**

The secondary (comparator) filter cannot be synchronized with respect to the PWM event (SDSYNC event).

The comparator filter is a configurable Sinc filter that supports the following filter types: Sinc1, Sinc2, Sinc3, and SincFast. The comparator OSR (COSR) settings can be configured from 1 to 32 and is independent of the data filter. Effective resolution of the comparator filter (ENOB) depends upon the comparator filter type, COSR, and sigma-delta modulator frequency. By default, the comparator filter is enabled. The comparator filter output is represented in 16-bit unsigned format. This filter unit translates a low input signal as 0 and a high input signal as 1. The resulting calculations give only positive values for the output of the comparator filter. Table 14-6 shows the different full-scale values that the comparator filter can store using different OSRs.

**Table 14-6. Peak Data Values for Different OSR/Filter Combinations**

| OSR | Sinc1 | Sinc2 | Sinc3 | SincFast |
|---|---|---|---|---|
| x | 0 to x | 0 to x2 | 0 to x3 | 0 to 2x2 |
| 4 | 0 to 4 | 0 to 16 | 0 to 64 | 0 to 32 |
| 8 | 0 to 8 | 0 to 64 | 0 to 512 | 0 to 128 |
| 16 | 0 to 16 | 0 to 256 | 0 to 4096 | 0 to 512 |
| 32 | 0 to 32 | 0 to 1024 | 0 to 32,768 | 0 to 2048 |

See Section 14.4.1 to understand how to calculate data rate and latency of comparator filter.

The output of the comparator filter is not memory-mapped; instead the output is connected to digital comparators explained below.

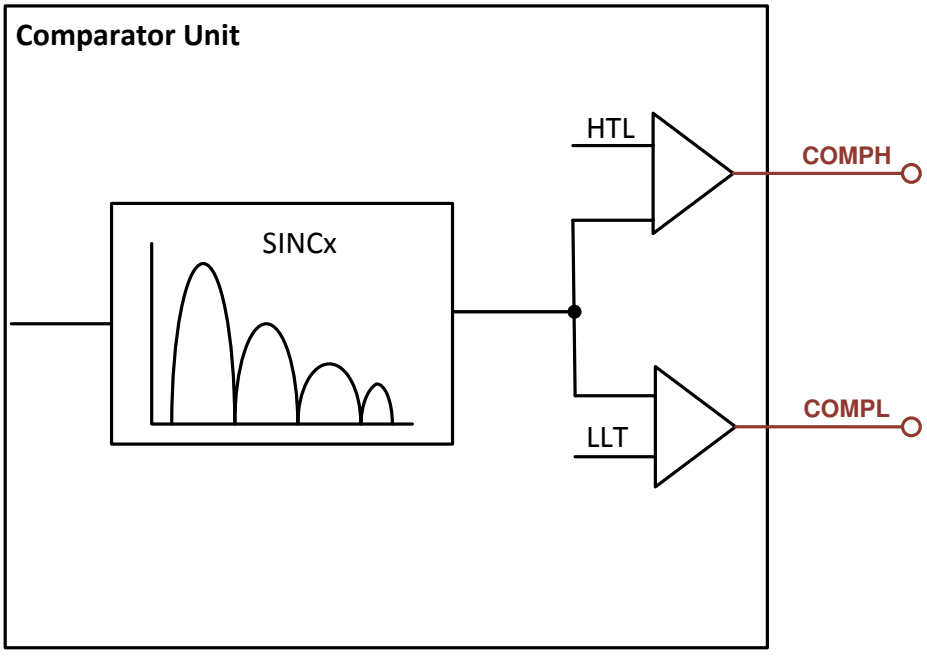

**Figure 14-9. Comparator Unit Structure**

### 14.6.1 Higher Threshold (HLT) Comparator

- High threshold comparator can be used to detect over-value condition.
- When comparator data > = higher threshold register, a high threshold event is generated.
- Higher threshold comparator events can be configured to trigger following events: CPU interrupt, CLA task, PWM trip.
- This device has one high threshold comparator:
  - **Higher Threshold (HLT) Comparator**: When SDCTL.MIE = 1 and SDCPARMx.IEH = 1, the high threshold event triggers an SDFM interrupt (SDINT) and sets the SDIFLG.IEHx flag showing the over-value condition is triggered. This SDIFLG.IEHx flag can be reset if the corresponding bit in the SDIFLGCLR register is set and if the interrupt source is no longer active.

### 14.6.2 Lower Threshold (LLT) Comparator

- The low threshold comparator can be used to detect under-value condition.
- When comparator data < = Lower Threshold register, a low threshold event is generated.
- Lower threshold comparator events can be configured to trigger following events: CPU interrupt, CLA task, PWM trip.
- This device has one low threshold comparator..
  - **Lower Threshold (LLT) Comparator** : When SDCTL.MIE = 1 and SDCPARMx.IEL = 1, the low threshold event triggers an SDFM interrupt (SDINT) and sets the SDIFLG.IELx flag showing an under-value condition is triggered. This SDIFLG.IELx flag can be reset, if the corresponding bit in the SDIFLGCLR register is set and if the interrupt source is no longer active.

## 14.7 Theoretical SDFM Filter Output

The following equations can be used to derive a theoretical filter output of an SDFM filter output for both a comparator filter and a data filter.

$$\text{Density of ones in bitstream} = \frac{\text{Input Voltage} + \text{Vclipping}}{2 \times \text{Vclipping}} \tag{19}$$

Where:

- Vclipping = maximum differential voltage input range of modulator
- Input voltage = Differential input voltage applied to the modulator

$$\text{Comparator Filter Output (Theoretical)} = \text{Density of ones in bitstream} \times \text{Maximum Filter Output (FilterType, COSR)} \tag{20}$$

$$\text{FilterOutput} = \left\{\frac{\text{absolute(Input voltage)}}{\text{Vclipping}}\right\} \times \text{Maximum Filter Output (FilterType, DOSR)} \tag{21}$$

$$\text{Data Filter Output_32bit(Theoretical)} = \begin{cases} \text{FilterOutput} & \text{if Input Voltage is +ve voltage} \\ \text{2's complement of FilterOutput} & \text{if input voltage is -ve voltage} \end{cases} \tag{22}$$

$$\text{Data Filter Output_16bit(Theoretical)} = \text{Data Filter Output_32bit(Theoretical)} >> \text{Shift value(FilterType, OSR)} \tag{23}$$

Copyright © 2024 Texas Instruments Incorporated

For example, when using the AMC1306x25 modulator:

| | | |
|---|---|---|
| AMC1306x25 | Vclipping =<br>Input voltage (AINP - AINN) = | 320mV<br>100mV |
| SDFM filter settings | Filter type =<br>Comparator OSR (COSR) =<br>Data filter OSR (DOSR) = | 3<br>32<br>100 |

| | | |
|---|---|---|
| Density of 1s in bit stream | Using Equation 19 | 0.65625 |
| Comparator filter output<br>Filter type = Sinc3<br>COSR = 32 | Using Equation 20 | 21504 |
| Data filter output (32-bit)<br>Filter type = Sinc3<br>DOSR = 100 | Using Equation 21 and Equation 22 | 312500 |
| Data filter output (32-bit)<br>Filter type = Sinc3<br>DOSR = 100<br>(Right shift by 5) | Using Equation 23 | 9765 |

## 14.8 Interrupt Unit

Each SDFM can generate one CPU interrupt (SDINT).

### *14.8.1 SDFM (SDINT) Interrupt Sources*

Figure 14-10 shows the structure of the interrupt unit. Each SDFM module can generate a CPU interrupt. An SDFM interrupt can be triggered by any of these 16 events.

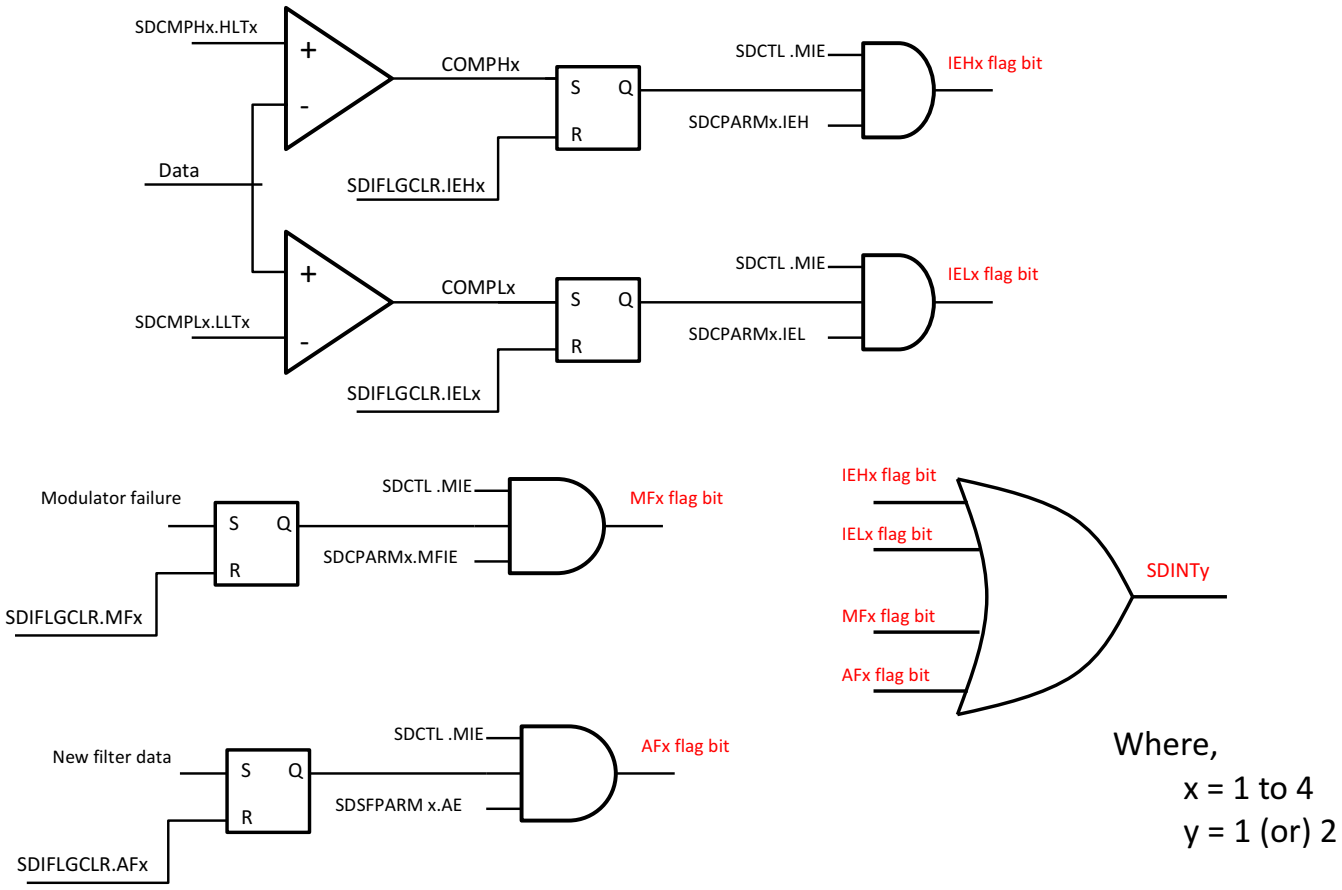

**Figure 14-10. SDFM Error (SD_ERR) Interrupt Sources**

Copyright © 2024 Texas Instruments Incorporated

**1. Comparator Lower Threshold events (COMPLx)**

COMPL events from any of the four comparator filter module can trigger CPU interrupt. This event can be configured to trigger SDINT interrupt only if below configurations are made:

- Enable Main interrupt enable (SDCTL.MIE = 1)
- Enable comparator filter lower threshold interrupt (SDCPARMx.IEL = 1)

On a COMPL event, SDIFLG.IELx flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

**2. Comparator High Threshold events (COMPHx)**

COMPH events from any of the four comparator filter module can trigger CPU interrupt. This event can be configured to trigger SDINT interrupt only if below configurations are made:

- Enable Main interrupt enable (SDCTL.MIE = 1)
- Enable comparator filter lower threshold interrupt (SDCPARMx.IEH = 1)

On a COMPH event, SDIFLG.IELx flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

**3. Modulator Failure (MFx) event**

Modulator failures (MFx) are generated when SD-Cx goes missing. The modulator clock is considered missing if SD-Cx does not toggle for 64-SYSCLKs. MFx events from any of the four filter modules can trigger CPU interrupt. This event can be configured to trigger SDINT interrupt only if below configurations are made:

- Enable Main Interrupt Enable (SDCTL.MIE = 1)
- Enable modulator clock failure interrupt source (SDCPARMx.MFIE = 1)

On a MFx event, SDIFLG.MFx flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

**4. New Filter Data Ready (AFx) event**

When the primary filter is ready with a new filter data, the AFx event is generated. AFx events from any of the four primary filter modules can be configured to trigger a CPU interrupt. This event can be configured to trigger SDINT interrupt only if below configurations are made:

- Enable Main interrupt enable (SDCTL.MIE = 1)
- Enable data filter acknowledge (SDDFPARMx.AE = 1)

On an AFx event, the SDIFLG.AFx flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

## 14.9 Register Descriptions

The register descriptions are shown in the following table and subsections.

**Table 14-7. General Registers**

| Name | SDFM1 address | SDFM2 address | Size (x16) | Description | EALLOW? |
|---|---|---|---|---|---|
| SDIFLG | 0x5E00 | 0x5E80 | 2 | Interrupt Flag Register | |
| SDIFLGCLR | 0x5E02 | 0x5E82 | 2 | Interrupt Flag Clear Register | |
| SDCTL | 0x5E04 | 0x5E84 | 1 | SD Control Register | YES |
| SDMFILEN | 0x5E06 | 0x5E86 | 1 | SD Master Filter Enable | YES |
| Reserved | 0x5E07 | 0x5E87 | 1 | Reserved | |

**Table 14-8. Filter 1 Registers**

| Name | SDFM1 address | SDFM2 address | Size (x16) | Description | EALLOW? |
|---|---|---|---|---|---|
| SDCTLPARM1 | 0x5E10 | 0x5E90 | 1 | Control Parameter Register for Ch1 | YES |
| SDDFPARM1 | 0x5E11 | 0x5E91 | 1 | Data Filter Parameter Register for Ch1 | YES |
| SDDPARM1 | 0x5E12 | 0x5E92 | 1 | Integer Parameter Register for Ch1 | YES |
| SDCMPH1 | 0x5E13 | 0x5E93 | 1 | High-level Threshold Register for Ch1 | YES |
| SDCMPL1 | 0x5E14 | 0x5E94 | 1 | Low-level Threshold Register for Ch1 | YES |
| SDCPARM1 | 0x5E15 | 0x5E95 | 1 | Comparator Parameter Register for Ch1 | YES |

## 14.10 Software

### 14.10.1 SDFM Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/sdfm

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

## 14.11 SDFM Registers

This section describes the Sigma Delta Filter Module registers.

### 14.11.1 SDFM Base Addresses

**Table 14-12. SDFM Base Address Table**

| Device Registers | Register Name | Start Address | End Address |
|---|---|---|---|
| Sdfm1Regs | SDFM_REGS | 0x0000_5E00 | 0x0000_5E7F |
| Sdfm2Regs | SDFM_REGS | 0x0000_5E80 | 0x0000_5EFF |

Copyright © 2024 Texas Instruments Incorporated

### 14.11.2 SDFM_REGS Registers

Table 14-13 lists the memory-mapped registers for the SDFM_REGS registers. All register offset addresses not listed in Table 14-13 should be considered as reserved locations and the register contents should not be modified.

**Table 14-13. SDFM_REGS Registers**

| Offset | Acronym | Register Name | Write Protection | Section |
|---|---|---|---|---|
| 0h | SDIFLG | Interrupt Flag Register | | Go |
| 2h | SDIFLGCLR | Interrupt Flag Clear Register | | Go |
| 4h | SDCTL | SD Control Register | EALLOW | Go |
| 6h | SDMFILEN | SD Master Filter Enable | EALLOW | Go |
| 10h | SDCTLPARM1 | Control Parameter Register for Ch1 | EALLOW | Go |
| 11h | SDDFPARM1 | Data Filter Parameter Register for Ch1 | EALLOW | Go |
| 12h | SDDPARM1 | Integer Parameter Register for Ch1 | EALLOW | Go |
| 13h | SDCMPH1 | High-level Threshold Register for Ch1 | EALLOW | Go |
| 14h | SDCMPL1 | Low-level Threshold Register for Ch1 | EALLOW | Go |
| 15h | SDCPARM1 | Comparator Parameter Register for Ch1 | EALLOW | Go |
| 16h | SDDATA1 | Filter Data Register (16 or 32bit) for Ch1 | | Go |
| 20h | SDCTLPARM2 | Control Parameter Register for Ch2 | EALLOW | Go |
| 21h | SDDFPARM2 | Data Filter Parameter Register for Ch2 | EALLOW | Go |
| 22h | SDDPARM2 | Integer Parameter Register for Ch2 | EALLOW | Go |
| 23h | SDCMPH2 | High-level Threshold Register for Ch2 | EALLOW | Go |
| 24h | SDCMPL2 | Low-level Threshold Register for Ch2 | EALLOW | Go |
| 25h | SDCPARM2 | Comparator Parameter Register for Ch2 | EALLOW | Go |
| 26h | SDDATA2 | Filter Data Register (16 or 32bit) for Ch2 | | Go |
| 30h | SDCTLPARM3 | Control Parameter Register for Ch3 | EALLOW | Go |
| 31h | SDDFPARM3 | Data Filter Parameter Register for Ch3 | EALLOW | Go |
| 32h | SDDPARM3 | Integer Parameter Register for Ch3 | EALLOW | Go |
| 33h | SDCMPH3 | High-level Threshold Register for Ch3 | EALLOW | Go |
| 34h | SDCMPL3 | Low-level Threshold Register for Ch3 | EALLOW | Go |
| 35h | SDCPARM3 | Comparator Parameter Register for Ch3 | EALLOW | Go |
| 36h | SDDATA3 | Filter Data Register (16 or 32bit) for Ch3 | | Go |
| 40h | SDCTLPARM4 | Control Parameter Register for Ch4 | EALLOW | Go |
| 41h | SDDFPARM4 | Data Filter Parameter Register for Ch4 | EALLOW | Go |
| 42h | SDDPARM4 | Integer Parameter Register for Ch4 | EALLOW | Go |
| 43h | SDCMPH4 | High-level Threshold Register for Ch4 | EALLOW | Go |
| 44h | SDCMPL4 | Low-level Threshold Register for Ch4 | EALLOW | Go |
| 45h | SDCPARM4 | Comparator Parameter Register for Ch4 | EALLOW | Go |
| 46h | SDDATA4 | Filter Data Register (16 or 32bit) for Ch4 | | Go |

Complex bit access types are encoded to fit into small table cells. Table 14-14 shows the codes that are used for access types in this section.

**Table 14-14. SDFM_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| R-0 | R<br>-0 | Read<br>Returns 0s |

Copyright © 2024 Texas Instruments Incorporated

**Table 14-14. SDFM_REGS Access Type Codes (continued)**

| Access Type | Code | Description |
|---|---|---|
| Write Type | | |
| W | W | Write |
| W1S | W<br>1S | Write<br>1 to set |
| Reset or Default Value | | |
| *-n* | | Value after reset or the default value |
| Register Array Variables | | |
| i,j,k,l,m,n | | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y | | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

Chapter 15

# Enhanced Pulse Width Modulator (ePWM)

The enhanced pulse width modulator (ePWM) peripheral is a key element in controlling many of the power electronic systems found in both commercial and industrial equipment. These systems include digital motor control, switch mode power supply control, uninterruptible power supplies (UPS), and other forms of power conversion. The ePWM peripheral can also perform a digital-to-analog (DAC) function, where the duty cycle is equivalent to a DAC analog value; it is sometimes referred to as a power DAC.

This chapter is applicable for ePWM type 4 with added register protection capability. See the *C2000 Real-Time Control Peripheral Reference Guide* for a list of all devices with an ePWM module of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

Further information can be found in the *Flexible PWMs Enable Multi-Axis Drives, Multi-Level Inverters Technical Brief*.

## 15.1 Introduction

This chapter includes an overview and information about each submodule:

- Time Base (TB) Submodule
- Counter Compare (CC) Submodule
- Action Qualifier (AQ) Submodule
- Dead-Band Generator (DB) Submodule
- PWM Chopper (PC) Submodule
- Trip Zone (TZ) Submodule
- Event Trigger (ET) Submodule
- Digital Compare (DC) Submodule

The ePWM Type 4 is functionally compatible to Type 2 (a Type 3 does not exist). Type 4 has the following enhancements in addition to the Type 2 features:

- **Register Address Map:** Additional registers are required for new features on ePWM Type 4. The ePWM register address space has been remapped for better alignment and easy usage.
- **Delayed Trip Functionality:** Changes have been added to achieve deadband insertion capabilities to support, for example, delayed trip functionality needed for peak current mode control type application scenarios. This has been accomplished by allowing comparator events to go into the Action Qualifier as a trigger event (Events T1 and T2). If comparator T1 / T2 events are used to edit the PWM, changes to the PWM waveform do not take place immediately. Instead, the waveform synchronizes to the next TBCLK.
- **Dead-Band Generator Submodule Enhancements:** Shadowing of the DBCTL register to allow dynamic configuration changes.
- **One Shot and Global Load of Registers:** The ePWM Type 4 allows one shot and global load capability from shadow to active registers to avoid partial loads in, for example, multiphase applications. ePWM Type 4 also allows a programmable prescale of shadow to active load events. ePWM Type 4 Global Load can simplify ePWM software by removing interrupts and making sure that all registers are loaded at the same time.
- **Trip-Zone Submodule Enhancements:** Independent flags have been added to reflect the trip status for each of the TZ sources. Changes have been made to the trip-zone submodule to support certain power converter switching techniques like valley switching.
- **Digital Compare Submodule Enhancements:** Blanking window filter register width has been increased from 8 to 16 bits. DCCAP functionality has been enhanced to provide more programmability.
- **PWM SYNC Related Enhancements:** The ePWM Type 4 allows PWM SYNCOUT generation based on CMPC and CMPD events. These events can also be used for PWMSYNC pulse selection.

The ePWM Type 2 is fully compatible to Type 1. Type 2 has the following enhancements in addition to the Type 1 features:

- **High-Resolution Dead-Band Capability:** High-resolution capability is added to dead-band RED and FED in half-cycle clocking mode.
- **Dead-Band Generator Submodule Enhancements:** The ePWM Type 2 has features to enable both RED and FED on either PWM outputs. Provides increased dead band with 14-bit counters and dead-band / dead-band high-resolution registers are shadowed
- **High-Resolution Extension available on ePWMxB outputs:** Provides the ability to enable high-resolution period and duty cycle control on ePWMxB outputs. This is discussed in more detail in Section 15.14.
- **Counter Compare Submodule Enhancements:** The ePWM Type 2 allows interrupts and SOC events to be generated by additional counter compares CMPC and CMPD.
- **Event Trigger Submodule Enhancements:** Prescaling logic to issue interrupt requests and ADC start of conversion expanded up to every 15 events. This submodule allows software initialization of event counters on SYNC event.
- **Digital Compare Submodule Enhancements:** Digital Compare Trip Select logic [DCTRIPSEL] has up to 12 external trip sources selected by the Input X-BAR logic in addition to an ability to OR all of them (up to 14 [external and internal sources]) to create the respective DCxEVTs.

Copyright © 2024 Texas Instruments Incorporated

- **Simultaneous Writes to TBPRD and CMPx Registers:** This feature allows writes to TBPRD, CMPA:CMPAHR, CMPB:CMPBHR, CMPC and CMPD of any ePWM module to be tied to any other ePWM module, and also allows all ePWM modules to be tied to a particular ePWM module if desired.
- **Shadow to Active Load on SYNC of TBPRD and CMP Registers:** This feature supports simultaneous writes of TBPRD and CMPA/B/C/D registers.

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention and must be highly programmable and very flexible while being easy to understand and use. The ePWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the ePWM is built up from smaller single channel submodules with separate resources that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand the operation quickly.

In this document, the letter x within a signal or submodule name is used to indicate a generic ePWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the ePWMx instance. Thus, EPWM1A and EPWM1B belong to ePWM1 and likewise EPWM4A and EPWM4B belong to ePWM4.

**Type0 to Type1 Enhancements**

- **Increased Dead-Band Resolution:** Dead-band clocking has been enhanced to allow half-cycle clocking to double resolution.
- **Enhanced Interrupt and SOC Generation:** Interrupts and ADC start-of-conversion can now be generated on both the TBCTR == zero and TBCTR == period events. This feature enables dual edge PWM control. Additionally, the ADC start-of-conversion can be generated from an event defined in the digital compare submodule.
- **High-Resolution Period Capability:** Provides the ability to enable high-resolution period. This is discussed in more detail in Section 15.14.
- **Digital Compare Submodule:** The digital compare submodule enhances the event triggering and trip zone submodules by providing filtering, blanking and improved trip functionality to digital compare signals. Such features are essential for peak current mode control and for support of analog comparators.

**Note**

The name of the sync signal that goes to the CMPSS and GPDAC has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCI and EPWMSYNCO. For a description of these signals, see Table 15-2.

### *15.1.2 Submodule Overview*

The ePWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. Multiple ePWM modules are instanced within a device as shown in Figure 15-1. Each ePWM instance is identical with one exception. Some instances include a hardware extension that allows more precise control of the PWM outputs. This extension is the high-resolution pulse width modulator (HRPWM) and is described in Section 15.14. See the device data sheet to determine which ePWM instances include this feature. Each ePWM module is indicated by a numerical value starting with 1. For example, ePWM1 is the first instance and ePWM3 is the third instance in the system and ePWMx indicates any instance.

The ePWM modules are chained together by way of a clock synchronization scheme that allows them to operate as a single system when required. Additionally, this synchronization scheme can be extended to the capture peripheral submodules (eCAP). The number of submodules is device-dependent and based on target application needs. Submodules can also operate standalone.

Each ePWM module supports the following features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations:
  - Two independent PWM outputs with single-edge operation
  - Two independent PWM outputs with dual-edge symmetric operation
  - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software.
- Programmable phase-control support for lag or lead operation relative to other ePWM modules.
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis.
- Dead-band generation with independent rising and falling edge delay control.
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions.
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs.
- All events can trigger both CPU interrupts and ADC start of conversion (SOC)
- Programmable event prescaling minimizes CPU overhead on interrupts.
- PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives.

Each ePWM module is connected to the input/output signals shown in Figure 15-1. The signals are described in detail in subsequent sections.

The order in which the ePWM modules are connected can differ from what is shown in Figure 15-1. See Section 15.4.3.3 for the synchronization scheme for a particular device. Each ePWM module consists of eight submodules and is connected within a system by way of the signals shown in Figure 15-2.

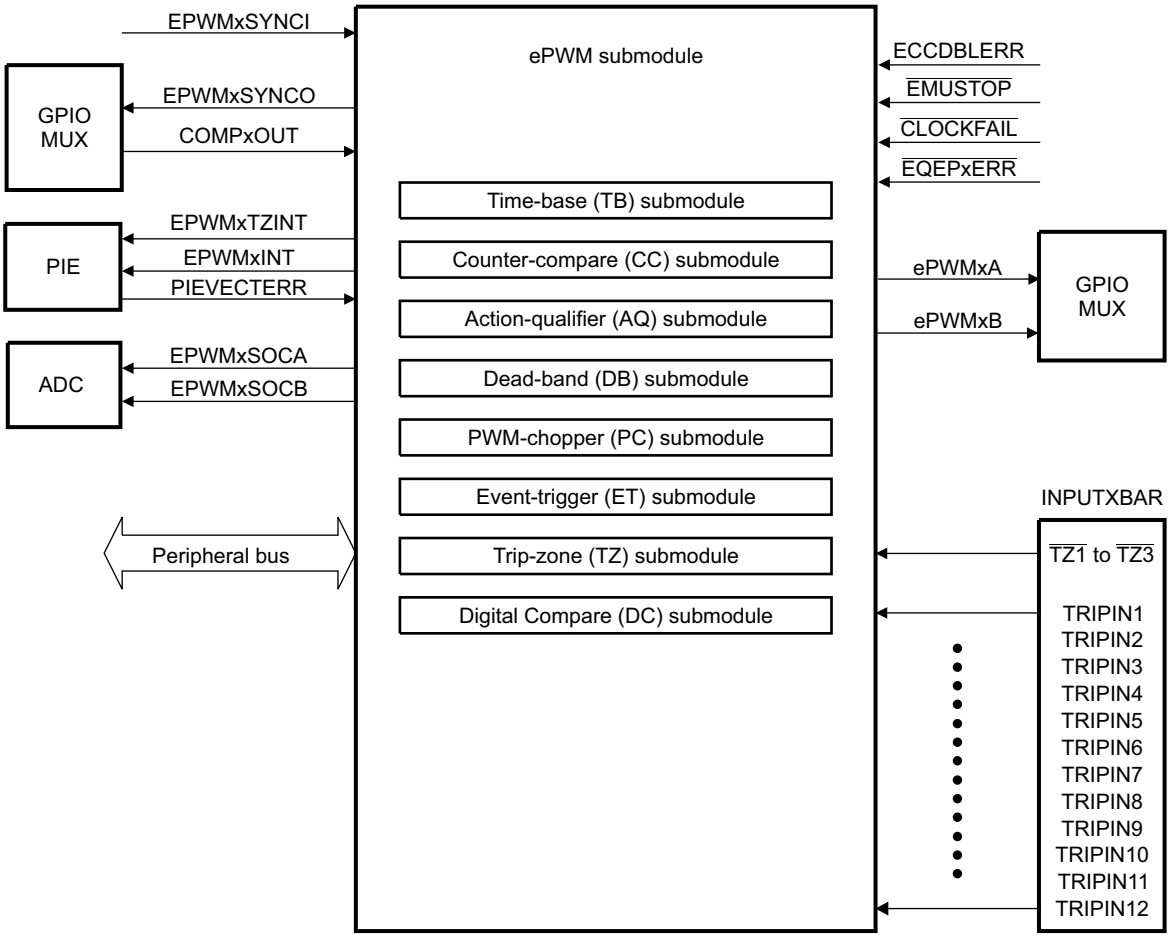

**Figure 15-2. Submodules and Signal Connections for an ePWM Module**

Copyright © 2024 Texas Instruments Incorporated

Figure 15-3 shows more internal details of a single ePWM module. The main signals used by the ePWM module are:

- **PWM output signals (EPWMxA and EPWMxB)**

  The PWM output signals are made available external to the device.

- **Trip-zone signals ($\overline{TZ1}$ to $\overline{TZ6}$)**

  These input signals alert the ePWM module of fault conditions external to the ePWM module. Each submodule on a device can be configured to either use or ignore any of the trip-zone signals. The $\overline{TZ1}$ to $\overline{TZ3}$ trip-zone signals can be configured as asynchronous inputs through the GPIO peripheral using the Input X-BAR logic, refer to Figure 15-50. $\overline{TZ4}$ is connected to an inverted EQEPx error signal (EQEPxERR), which can be generated from any one of the EQEP submodule (for those devices with an EQEP module). $\overline{TZ5}$ is connected to the system clock fail logic, and $\overline{TZ6}$ is connected to the $\overline{EMUSTOP}$ output from the CPU. This allows configuring a trip action when the clock fails or the CPU halts.

- **Time-base synchronization input (EPWMxSYNCI), output (EPWMxSYNCO), and peripheral (EPWMxSYNCPER) signals**

  The synchronization signals daisy chain the ePWM modules together. Each module can be configured to either use or ignore the synchronization input. The clock synchronization input and output signal are brought out to pins only for ePWM1 (ePWM module #1). The ePWM modules are separated into groups of three for syncing purposes. An external sync signal (EXTSYNCIN1 or EXTSYNCIN2) can be used to issue a sync signal to the first ePWM module in each chain. These same modules can also send the EPWMxSYNCOUT signal to a GPIO. For more information, see Section 15.4.3.3.

  Each ePWM module also generates another PWMSYNC signal called EPWMxSYNCPER. EPWMxSYNCPER goes to the GPDAC and CMPSS for synchronization purposes. Functionality is configured using the HRPCTL register, but has no relation with the HRPWM. For more information on how EPWMxSYNCPER is used by the GPDAC and CMPSS, see the respective chapters.

- **ADC start-of-conversion signals (EPWMxSOCA and EPWMxSOCB)**

  Each ePWM module has two ADC start of conversion signals. Any ePWM module can trigger a start of conversion. Whichever event triggers the start of conversion is configured in the event-trigger submodule of the ePWM.

- **Comparator output signals (COMPxOUT)**

  Output signals from the comparator module can be fed through the Input X-BAR and EPWM X-BAR to one or all of the 12 trip inputs [TRIPIN1 - TRIPIN12] and in conjunction with the trip zone signals can generate digital compare events.

- **Peripheral bus**

  The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the ePWM register file.

## 15.2 Configuring Device Pins

To connect the device input pins to the module, the Input X-BAR and EPWM X-BAR must be used. Some examples of when an external signal can be needed are TZx, TRIPx, and EXTSYNCIN. Any GPIO on the device can be configured as an input. The GPIO input qualification can be set to asynchronous mode by setting the appropriate GPxQSEL register bits to 11b. The internal pullups can be configured in the GPyPUD register. Since the GPIO mode is used, the GPyINV register can invert the signals. Additionally, some TRIPx (TRIP4-12 excluding TRIP6) signals must be routed through the ePWM X-Bar in addition to the Input X-Bar.

The GPIO mux registers must be configured for this peripheral. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux, GPIO settings, and XBAR configuration.

## 15.3 ePWM Modules Overview

Eight submodules are included in every ePWM peripheral. Each of these submodules performs specific tasks that can be configured by software.

Table 15-1 lists the key submodules together with a list of the main configuration parameters. For example, if you need to adjust or control the duty cycle of a PWM waveform, see the counter-compare submodule in Section 15.5 for relevant details.

**Table 15-1. Submodule Configuration Parameters**

| Submodule | Configuration Parameter or Option |
|---|---|
| Time Base (TB) | • Scale the time-base clock (TBCLK) relative to the ePWM clock (EPWMCLK).<br>• Configure the PWM time-base counter (TBCTR) frequency or period.<br>• Set the mode for the time-base counter:<br>– count-up mode: used for asymmetric PWM<br>– count-down mode: used for asymmetric PWM<br>– count-up-and-down mode: used for symmetric PWM<br>• Configure the time-base phase relative to another ePWM module.<br>• Synchronize the time-base counter between modules through hardware or software.<br>• Configure the direction (up or down) of the time-base counter after a synchronization event.<br>• Simultaneous writes to the TBPRD registers on all PWM's corresponding to the configuration on EPWMXLINK.<br>• Configure how the time-base counter behaves when the device is halted by an emulator.<br>• Specify the source for the synchronization output of the ePWM module<br>– Synchronization input signal<br>– Time-base counter equal to zero<br>– Time-base counter equal to counter-compare B (CMPB)<br>– No output synchronization signal generated.<br>• Configure one shot and global load of registers in this module. |
| Counter Compare (CC) | • Specify the PWM duty cycle for output EPWMxA and output EPWMxB<br>• Specify the time at which switching events occur on the EPWMxA or EPWMxB output<br>• Specify the programmable delay for interrupt and SOC generation with additional comparators<br>• Simultaneous writes to the CMPA, CMPB, CMPC, CMPD registers on all PWM's corresponding to the configuration on EPWMXLINK.<br>• Configure one shot and global load of registers in this module. |

Copyright © 2024 Texas Instruments Incorporated

**Table 15-1. Submodule Configuration Parameters (continued)**

| Submodule | Configuration Parameter or Option |
|---|---|
| Action Qualifier (AQ) | • Specify the type of action taken when a time-base counter-compare, trip-zone submodule, or comparator event occurs:<br>– No action taken<br>– Output EPWMxA and EPWMxB switched high<br>– Output EPWMxA and EPWMxB switched low<br>– Output EPWMxA and EPWMxB toggled<br>• Force the PWM output state through software control<br>• Configure and control the PWM dead band through software<br>• Configure one shot and global load of registers in this module. |
| Dead-Band Generator (DB) | • Control of traditional complementary dead-band relationship between upper and lower switches<br>• Specify the output rising-edge-delay value<br>• Specify the output falling-edge delay value<br>• Bypass the dead-band module entirely. In this case the PWM waveform is passed through without modification.<br>• Option to enable half-cycle clocking for double resolution.<br>• Allow ePWMxB phase shifting with respect to the ePWMxA output.<br>• Configure one shot and global load of registers in this module. |
| PWM Chopper (PC) | • Create a chopping (carrier) frequency.<br>• Pulse width of the first pulse in the chopped pulse train.<br>• Duty cycle of the second and subsequent pulses.<br>• Bypass the PWM chopper module entirely. In this case the PWM waveform is passed through without modification. |
| Trip Zone (TZ) | • Configure the ePWM module to react to one, all, or none of the trip-zone signals or digital compare events.<br>• Specify the trip action taken when a fault occurs:<br>– Force EPWMxA and EPWMxB high<br>– Force EPWMxA and EPWMxB low<br>– Force EPWMxA and EPWMxB to a high-impedance state<br>– Configure EPWMxA and EPWMxB to ignore any trip condition.<br>• Configure how often the ePWM reacts to each trip-zone signal:<br>– One-shot<br>– Cycle-by-cycle<br>• Enable the trip-zone to initiate an interrupt.<br>• Bypass the trip-zone module entirely.<br>• Programmable option for cycle-by-cycle trip clear<br>• If desired, independently configure trip actions taken when time-base counter is counting down. |
| Event Trigger (ET) | • Enable the ePWM events that trigger an interrupt.<br>• Enable ePWM events that trigger an ADC start-of-conversion event.<br>• Specify the rate at which events cause triggers (every occurrence or every 2nd or up to 15th occurrence)<br>• Poll, set, or clear event flags |
| Digital Compare (DC) | • Enables comparator (COMP) module outputs and trip zone signals which are configured using the Input X-BAR to create events and filtered events<br>• Specify event-filtering options to capture TBCTR counter, generate blanking window, or insert delay in PWM output or time-base counter based on captured value. |

Copyright © 2024 Texas Instruments Incorporated

## 15.4 Time-Base (TB) Submodule

Each ePWM module has a time-base submodule that determines all of the event timing for the ePWM module. Built-in synchronization logic allows the time-base of multiple ePWM modules to work together as a single system.

Figure 15-4 illustrates the time-base submodule within the ePWM.

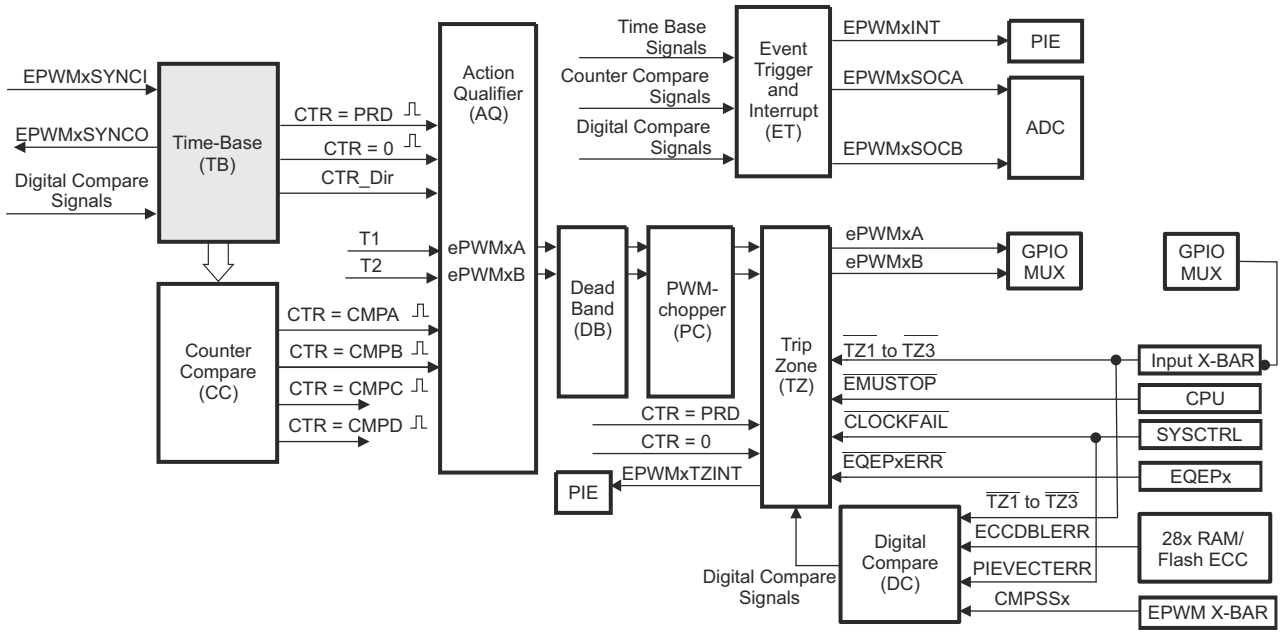

**Figure 15-4. Time-Base Submodule**

### *15.4.1 Purpose of the Time-Base Submodule*

The time-base submodule can be configured for the following:

- Specify the ePWM time-base counter (TBCTR) frequency or period to control how often events occur.
- Manage time-base synchronization with other ePWM modules.
- Maintain a phase relationship with other ePWM modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
  - CTR = PRD: Time-base counter equal to the specified period (TBCTR = TBPRD).
  - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00).
- Configure the rate of the time-base clock; a prescaled version of the ePWM clock (EPWMCLK). This allows the time-base counter to increment/decrement at a slower rate.

**Note**

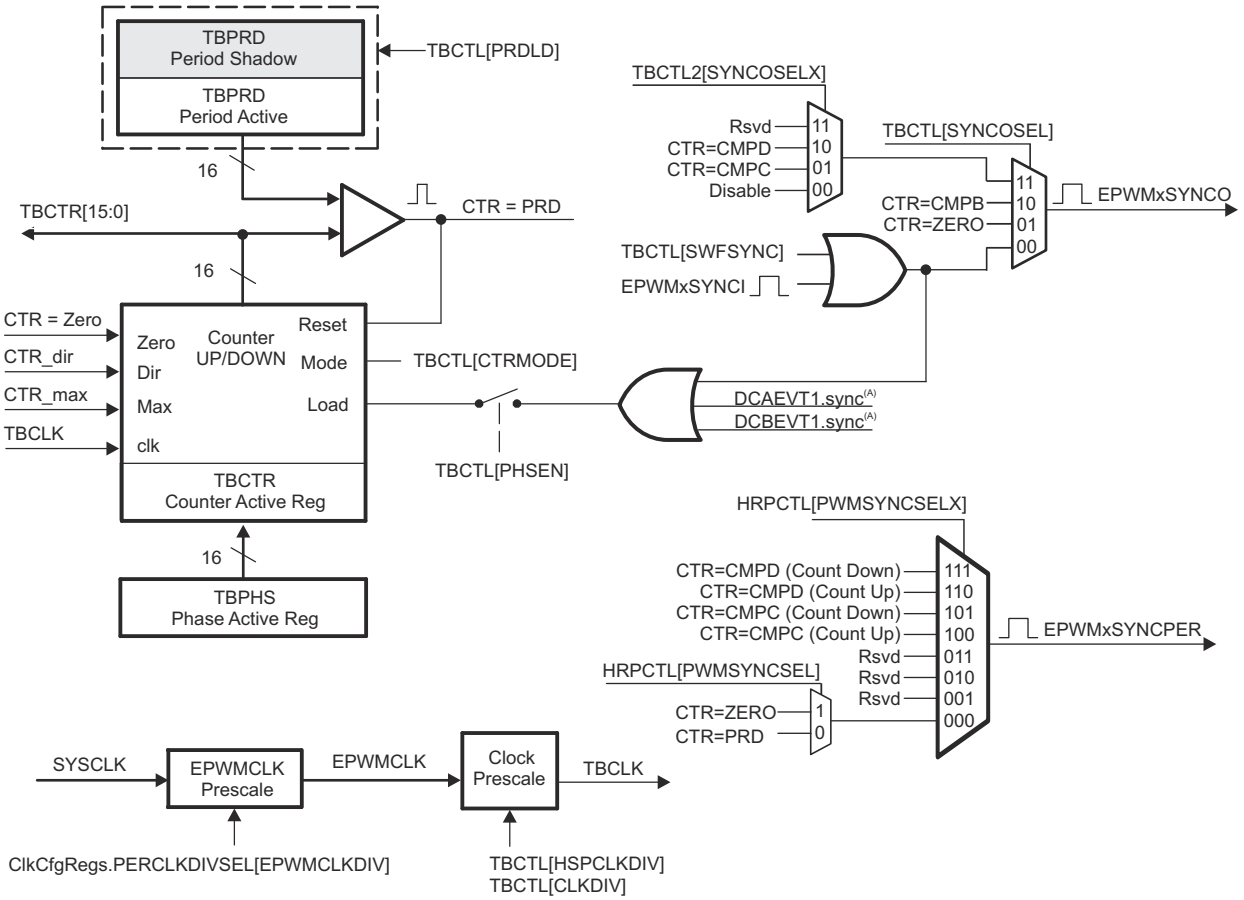
The Type 4 ePWM clocking varies from previous ePWM types. Prior to the Type 4 ePWM, the time-base submodule is clocked directly by the system clock (SYSCLKOUT). On this version of the ePWM, there is a divider (EPWMCLKDIV) of the system clock that defaults to EPWMCLK = SYSCLKOUT/2.

If required by the application code to update the TBCTR value through software while the TBCTR is counting, note that the time-base module needs at least 1 TBCLK cycle for the time-base related events to be realized. Hence, the TBCTR can be written with TBCTR = PRD-1 instead of TBCTR = PRD (in case the counter is counting up) and can be written as TBCTR = 1 instead of TBCTR = 0 (in case the counter is counting down) for the events to be realized.

Copyright © 2024 Texas Instruments Incorporated

### 15.4.2 Controlling and Monitoring the Time-Base Submodule

The block diagram in Figure 15-5 shows the critical signals and registers of the time-base submodule. Table 15-2 provides descriptions of the key signals associated with the time-base submodule.



A. These signals are generated by the digital compare (DC) submodule.

**Figure 15-5. Time-Base Submodule Signals and Registers**

Copyright © 2024 Texas Instruments Incorporated

**Table 15-2. Key Time-Base Signals**

| Signal | Description |
|---|---|
| EPWMxSYNCI | Time-base synchronization input.<br>Input pulse used to synchronize the time-base counter with the counter of ePWM module earlier in the synchronization chain. An ePWM peripheral can be configured to use or ignore this signal. For the first ePWM module in each synchronization chain, this signal can come from a device pin using INPUT5 or INPUT6 of the Input X-BAR or from a previous ePWM module. For subsequent ePWM modules in each chain, this signal is passed from another ePWM peripheral. For example, EPWM2SYNCI is generated by the ePWM1 peripheral, EPWM3SYNCI is generated by ePWM2 and so forth. For information on the synchronization order of a particular device, see Section 15.4.3.3. |
| EPWMxSYNCO | Time-base synchronization output.<br>This output pulse is used to synchronize the counter of an ePWM module later in the synchronization chain. The ePWM module generates this signal from one of three event sources:<br>1. EPWMxSYNCI (Synchronization input pulse)<br>2. CTR = Zero: The time-base counter equal to zero (TBCTR = 0x00).<br>3. CTR = CMPB: The time-base counter equal to the counter-compare B (TBCTR = CMPB) register. |
| EPWMxSYNCPER | Time-base peripheral synchronization output.<br>This output signal is used to synchronize the GPDAC and CMPSS to the EPWM. The output signal can be configured using the HRPCTL register. Note that this signal has no relation with the HRPWM. |
| CTR = PRD | Time-base counter equal to the specified period.<br>This signal is generated whenever the counter value is equal to the active period register value. That is when TBCTR = TBPRD. |
| CTR = Zero | Time-base counter equal to zero<br>This signal is generated whenever the counter value is zero. That is when TBCTR equals 0x00. |
| CTR = CMPB | Time-base counter equal to active counter-compare B register (TBCTR = CMPB).<br>This event is generated by the counter-compare submodule and used by the synchronization out logic |
| CTR_dir | Time-base counter direction.<br>Indicates the current direction of the ePWM's time-base counter. The signal is high when the counter is increasing and the signal is low when the counter is decreasing. |
| CTR_max | Time-base counter equal max value. (TBCTR = 0xFFFF)<br>Generated event when the TBCTR value reaches the maximum value. This signal is only used only as a status bit |
| TBCLK | Time-base clock.<br>This is a prescaled version of the ePWM clock (EPWMCLK) and is used by all submodules within the ePWM. This clock determines the rate at which time-base counter increments or decrements. |

Copyright © 2024 Texas Instruments Incorporated

### 15.4.3 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period (TBPRD) register and the mode of the time-base counter. Figure 15-6 shows the period ($T_{pwm}$) and frequency ($F_{pwm}$) relationships for the up-count, down-count, and up-down-count time-base counter modes when the period is set to 4 (TBPRD = 4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the ePWM clock (EPWMCLK).

The time-base counter has three modes of operation selected by the time-base control register (TBCTL):

- **Up-Down Count Mode:** In up-down count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until the counter reaches zero. At this point, the counter repeats the pattern and begins to increment.
- **Up-Count Mode:** In up-count mode, the time-base counter starts from zero and increments until the counter reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.
- **Down-Count Mode:** In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until the counter reaches zero. When the counter reaches zero, the time-base counter is reset to the period value and begins to decrement once again.

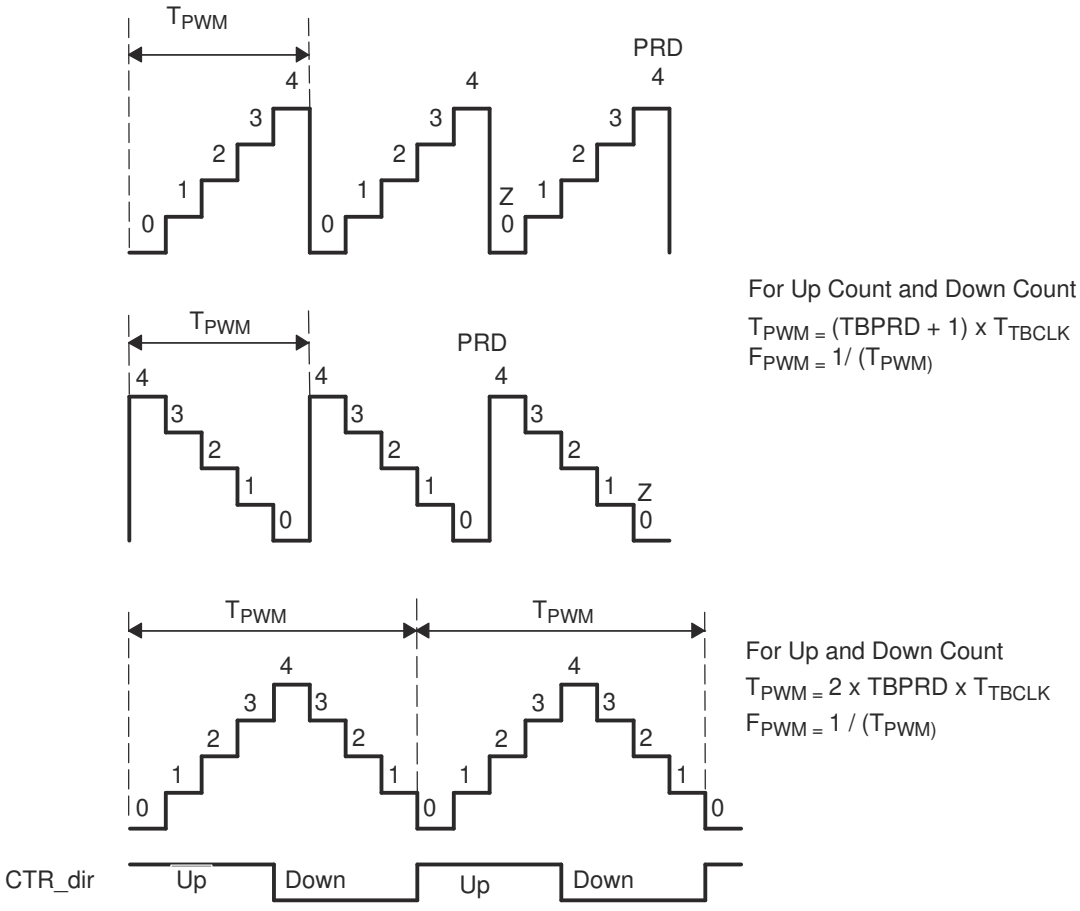


**Figure 15-6. Time-Base Frequency and Period**

Copyright © 2024 Texas Instruments Incorporated

#### 15.4.3.1 Time-Base Period Shadow Register

The time-base period register (TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the ePWM module:

- **Active Register:** The active register controls the hardware and is responsible for actions that the hardware causes or invokes.
- **Shadow Register:** The shadow register buffers provide a temporary holding location for the active register and have no direct effect on any control hardware. At a strategic point in time, the shadow register content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the TBCTL[PRDLD] bit. This bit enables and disables the TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:** The TBPRD shadow register is enabled when TBCTL[PRDLD] = 0. Reads from and writes to the TBPRD memory address go to the shadow register. The shadow register contents are transferred to the active register (TBPRD (Active) ← TBPRD (shadow)) when the time-base counter equals zero (TBCTR = 0x00) and/or a sync event as determined by the TBCTL2[PRDLDSYNC] bit. The PRDLDSYNC bit is valid only if TBCTL[PRDLD] = 0. By default the TBPRD shadow register is enabled. The sources for the SYNC input is explained in Section 15.4.3.3.

  The global load control mechanism can also be used with the time-base period register by configuring the appropriate bits in the global load configuration register (GLDCFG). When global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in Global Shadow to Active Load Control Register (GLDCTL). Global load control mechanism is explained in Section 15.4.7.
- **Time-Base Period Immediate Load Mode:** If immediate load mode is selected (TBCTL[PRDLD] = 1), then a read from or a write to the TBPRD memory address goes directly to the active register.

#### 15.4.3.2 Time-Base Clock Synchronization

The TBCLKSYNC bit in the peripheral clock enable registers allows all users to globally synchronize all enabled ePWM modules to the time-base clock (TBCLK). When set, all enabled ePWM module clocks are started with the first rising edge of TBCLK aligned. For synchronized TBCLKs, the prescalers for each ePWM module must be set identically.

The proper procedure for enabling ePWM clocks is as follows:

1. Enable ePWM module clocks in the PCLKCRx register
2. Set TBCLKSYNC= 0
3. Configure ePWM modules
4. Set TBCLKSYNC= 1

In a multicore environment, GTBCLKSYNC can be used to override the core-specific TBCLKSYNC. When GTBCLKSYNC is set, TBCLKSYNC is ignored in all cores and therefore clearing or setting the TBCLKSYNC has no affect. If this feature is not required, GTBCLKSYNC must be cleared. In a multicore environment where different ePWM modules are assigned to different cores, the GTBCLKSYNC bit can be used to enable and disable the Time-Base clock of all ePWM modules simultaneously.

Copyright © 2024 Texas Instruments Incorporated

#### 15.4.3.3 Time-Base Counter Synchronization

The ePWM synchronization scheme allows for increased flexibility of synchronization of the ePWM modules. Each ePWM module has a synchronization input (SYNCI), a synchronization output (SYNCO) and a peripheral synchronization output (SYNCPER). In Figure 15-7, EXTSYNCIN1 is sourced from INPUTXBAR5 and EXTSYNCIN2 is sourced from INPUTXBAR6, which can be configured to select any GPIO as the synchronization input. When configuring the sync chain propagation path using the SYNCSEL registers, make sure that the longest path does not exceed four ePWM/eCAP modules.

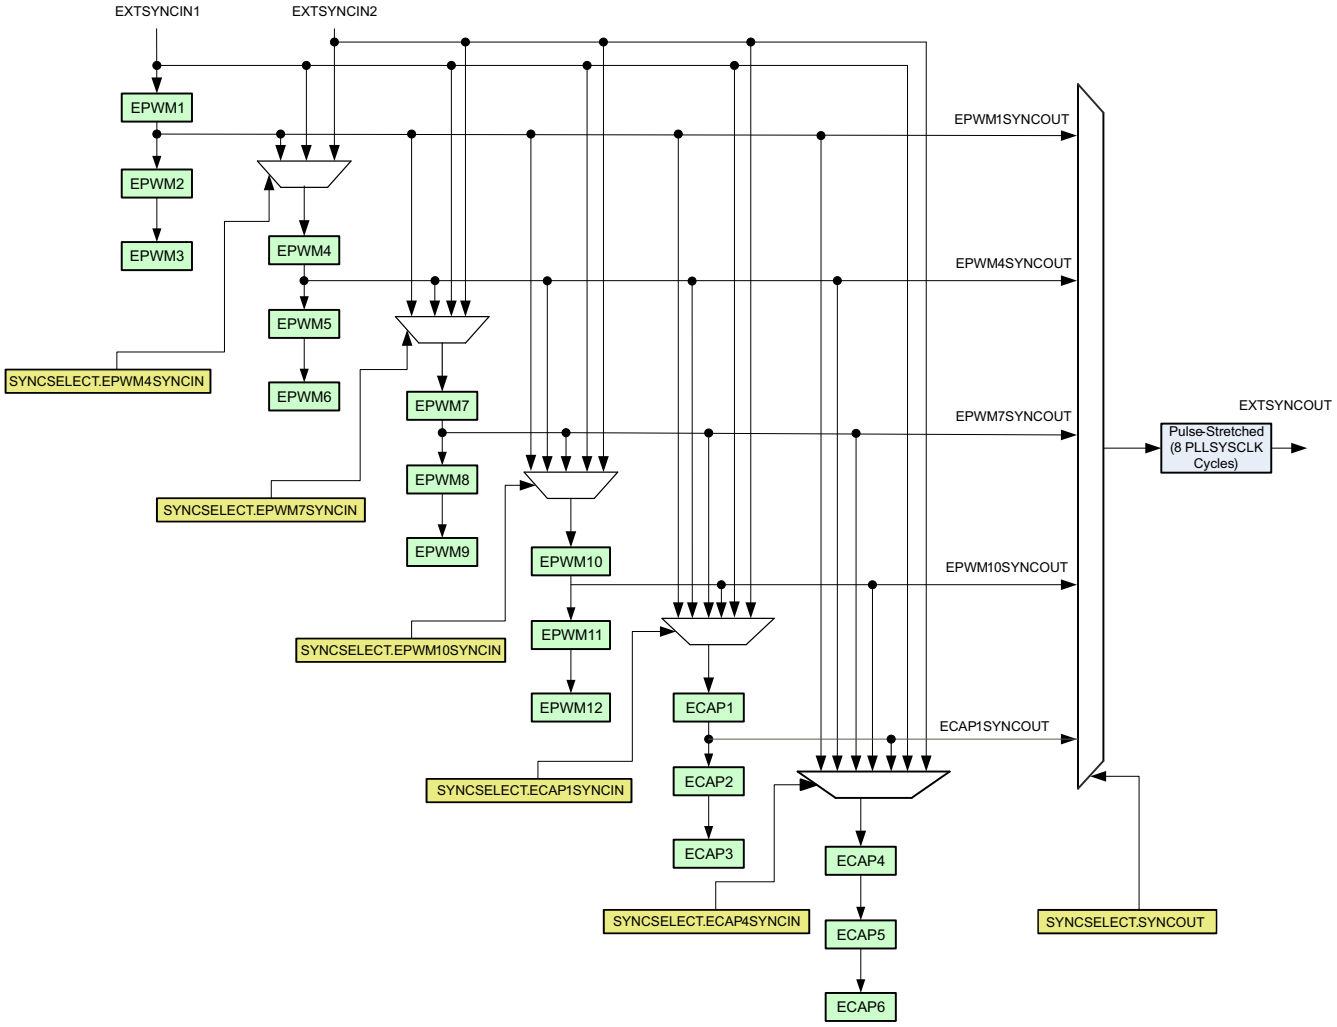

**Figure 15-7. Time-Base Counter Synchronization Scheme**

**Note**

See the data sheet for the number of ePWM and eCAP modules available on your specific device.

Each ePWM module can be configured to use or ignore the synchronization input. If the TBCTL[PHSEN] bit is set, then the time-base counter (TBCTR) of the ePWM module is automatically loaded with the phase register (TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCI: Synchronization Input Pulse:** The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (TBPHS → TBCTR). This operation occurs on the next valid time-base clock (TBCLK) edge.

Copyright © 2024 Texas Instruments Incorporated

The delay from internal control module to target modules is given by:
  – if (TBCLK = EPWMCLK): 2 x EPWMCLK
  – if (TBCLK < EPWMCLK): 1 x TBCLK
- **Software Forced Synchronization Pulse:** Writing a 1 to the TBCTL[SWFSYNC] control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCI.
- **Digital Compare Event Synchronization Pulse:** DCAEVT1 and DCBEVT1 digital compare events can be configured to generate synchronization pulses which have the same affect as EPWMxSYNCI.

**Note**

If the EPWMxSYNCI signal is held high, the sync does not continuously occur. The EPWMxSYNCI is rising edge activated.

This feature enables the ePWM module to be automatically synchronized to the time base of another ePWM module. Lead or lag phase control can be added to the waveforms generated by different ePWM modules to synchronize them. In up-down-count mode, the TBCTL[PHSDIR] bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The PHSDIR bit is ignored in count-up or count-down modes. See Figure 15-8 through Figure 15-11 for examples.

Clearing the TBCTL[PHSEN] bit configures the ePWM to ignore the synchronization input pulse. The synchronization pulse can still be allowed to flow-through to the EPWMxSYNCO and be used to synchronize other ePWM modules. In this way, a controller time-base (for example, ePWM1) can be set up and downstream modules (ePWM2 - ePWMx) can run in synchronization with the controller. See Section 15.13 for more details on synchronization strategies.

### *15.4.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules*

The TBCLKSYNC bit can be used to globally synchronize the time-base clocks of all enabled ePWM modules on a device. This bit is part of the device's clock enable registers and is described in the *System Control and Interrupts* section of this manual. When TBCLKSYNC = 0, the time-base clock of all ePWM modules is stopped (default). When TBCLKSYNC = 1, all ePWM time-base clocks are started with the rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescaler bits in the TBCTL register of each ePWM module must be set identically. The proper procedure for enabling the ePWM clocks is:

1. Enable the individual ePWM module clocks. This is described in the *System Control and Interrupts* chapter.
2. Set TBCLKSYNC= 0. This stops the time-base clock within any enabled ePWM module.
3. Configure the prescaler values and desired ePWM modes.
4. Set TBCLKSYNC = 1.

### *15.4.5 Simultaneous Writes to TBPRD and CMPx Registers Between ePWM Modules*

For variable frequency applications, there is a need for simultaneous writes of TBPRD and CMPx registers between ePWM modules. This prevents situations where a CTR = 0 or CTR = PRD pulse forces a shadow to active load of these registers before all registers are updated between ePWM modules (resulting in some registers being loaded from new shadow values while others are loaded from old shadow values). To support this, an ePWM register linking scheme for TBPRD:TBPRDHR, CMPA:CMPAHR, CMPB:CMPBHR, CMPC, and CMPD registers between PWM modules has been added.

Refer to the register description for EPWMXLINK to see the linked register bit-field values for corresponding ePWM. An example of using the EPWMXLINK is linking ePWM2 CMPA with CMPA of ePWM1 through ePWM2's EPWMXLINK[CMPALINK] register bit-field. In this case, a write to CMPA of ePWM1 also changes the CMPA value for ePWM2.

### 15.4.6 Time-Base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode that is asymmetrical
- Down-count mode that is asymmetrical
- Up-down-count that is symmetrical
- Frozen where the time-base counter is held constant at the current value

To illustrate the operation of the first three modes, the following timing diagrams show when events are generated and how the time-base responds to an EPWMxSYNCI signal.

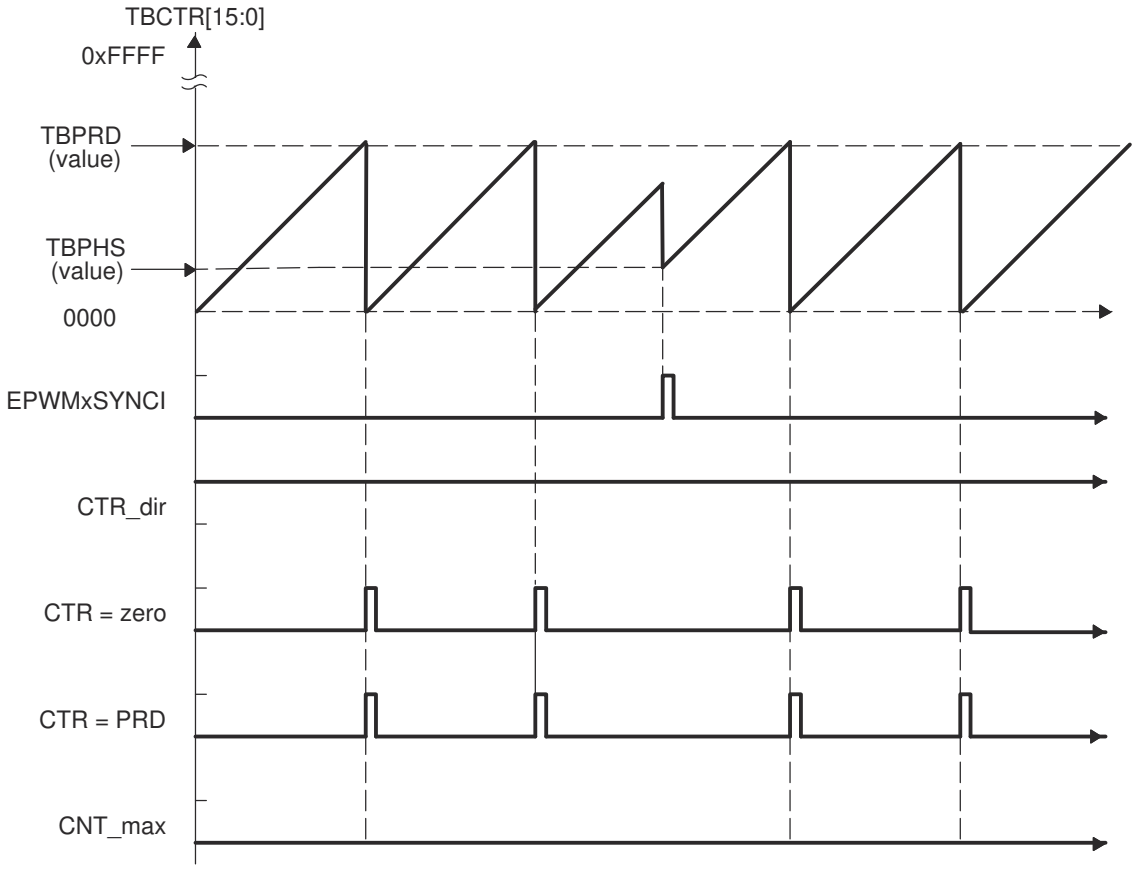

**Figure 15-8. Time-Base Up-Count Mode Waveforms**

### 15.4.7 Global Load

Figure 15-12 shows the signals and registers associated with the global load feature.

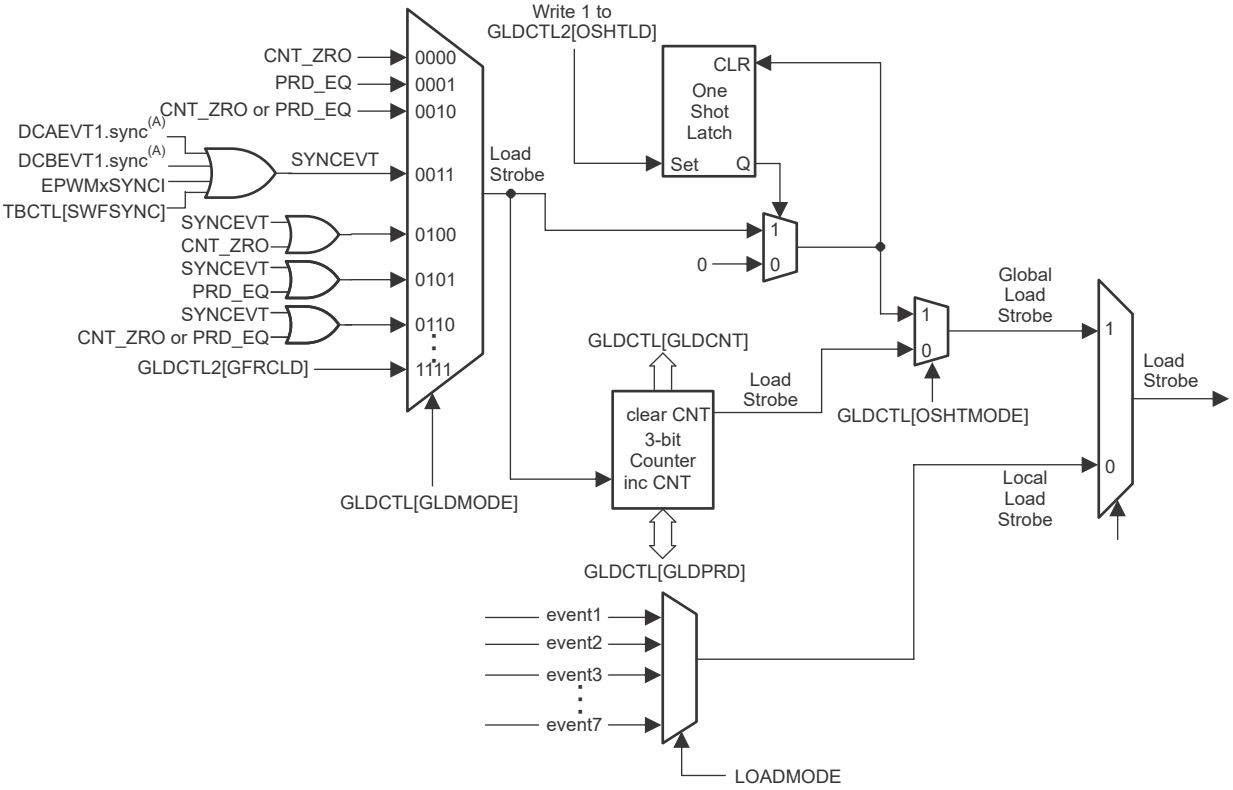

**Figure 15-12. Global Load: Signals and Registers**

**Note**

The SYNCEVT signal is only propagated through when PHSEN is SET.

When this feature is enabled, the transfer of contents from the shadow register to the active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in Global Shadow to Active Load Control Register (GLDCTL[GLDMODE]). When GLDCTL[GLD] = 1, shadow to active load event selection bits for individual shadowed registers are ignored and global load mode takes effect for the corresponding registers enabled by GLDCFG[REGx].

When GLDCTL[GLD] = 1 and GLDCFG[REGx] = 0, global load mode does not affect the corresponding register (REGx). Shadow to active load event selection bits for individual shadowed registers decide how the transfer of contents from shadow register to active register takes place.

#### 15.4.7.1 Global Load Pulse Pre-Scalar

This feature provides the capability to choose shadow to active transfers to happen once in 'N' occurrences of selected global load pulse (GLDCTL[GLDMODE]). This pre-scale functionality is not available for registers that cannot or are not configured to use the global load mechanism (that is, GLDCTL[GLD] = 0 or GLDCFG[REGx] = 0).

Copyright © 2024 Texas Instruments Incorporated

#### 15.4.7.2 One-Shot Load Mode

This feature allows users to cause the shadow register to active register transfers to occur once. When GLDCTL2[OSHTLD] = 1 the shadow to active register transfer, for registers that are configured to use the global load mechanism, takes place on the event selected by GLDCTL[GLDMODE].

Software force loading of contents from shadow register to active register is possible by using GLDCTL2[GFRCLD]. The GLDCTL2 register can also be linked across multiple PWM modules by using EPWMXLINK[GLDCTL2LINK]. This, along with the one-shot load mode feature discussed above, provides a method to correctly update multiple PWM registers in one or more PWM modules at certain PWM events or, if desired, in the same clock cycle. This is very useful in variable frequency applications and/or multi-phase interleaved applications.

**Note**

One-shot load mode must not be used when high-resolution mode is enabled.

#### 15.4.7.3 One-Shot Sync Mode

To enable the one-shot sync mode to generate a SYNCOUT pulse, configure the TBCTL2[OSHTSYNCMODE] bit and set the TBCTL2[OSHTSYNC] bit as shown in Figure 15-13.

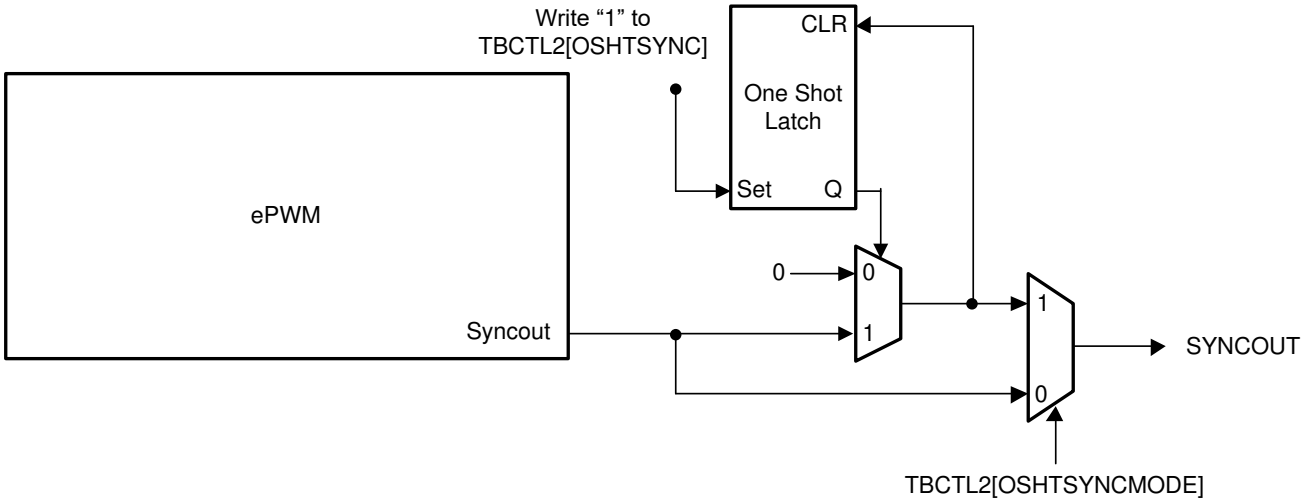

**Figure 15-13. One-Shot Sync Mode**

## 15.5 Counter-Compare (CC) Submodule

Figure 15-14 illustrates the counter-compare submodule within the ePWM.

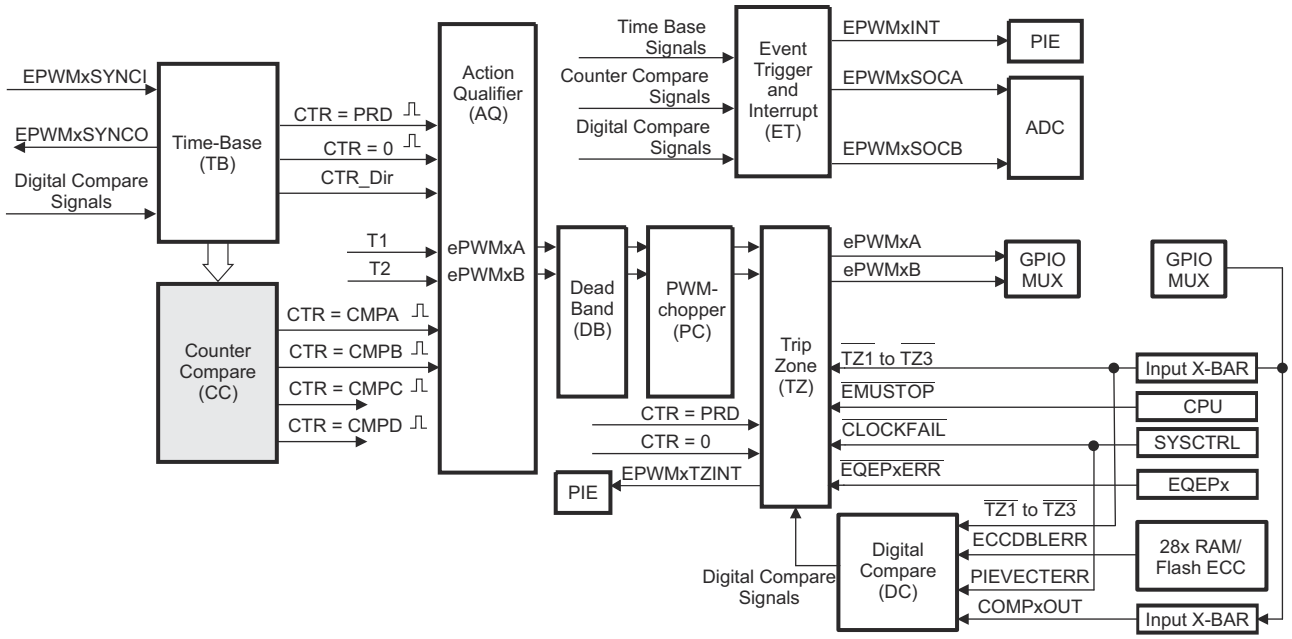

**Figure 15-14. Counter-Compare Submodule**

### *15.5.1 Purpose of the Counter-Compare Submodule*

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (CMPA), counter-compare B (CMPB), counter-compare C (CMPC), and counter-compare D (CMPD) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

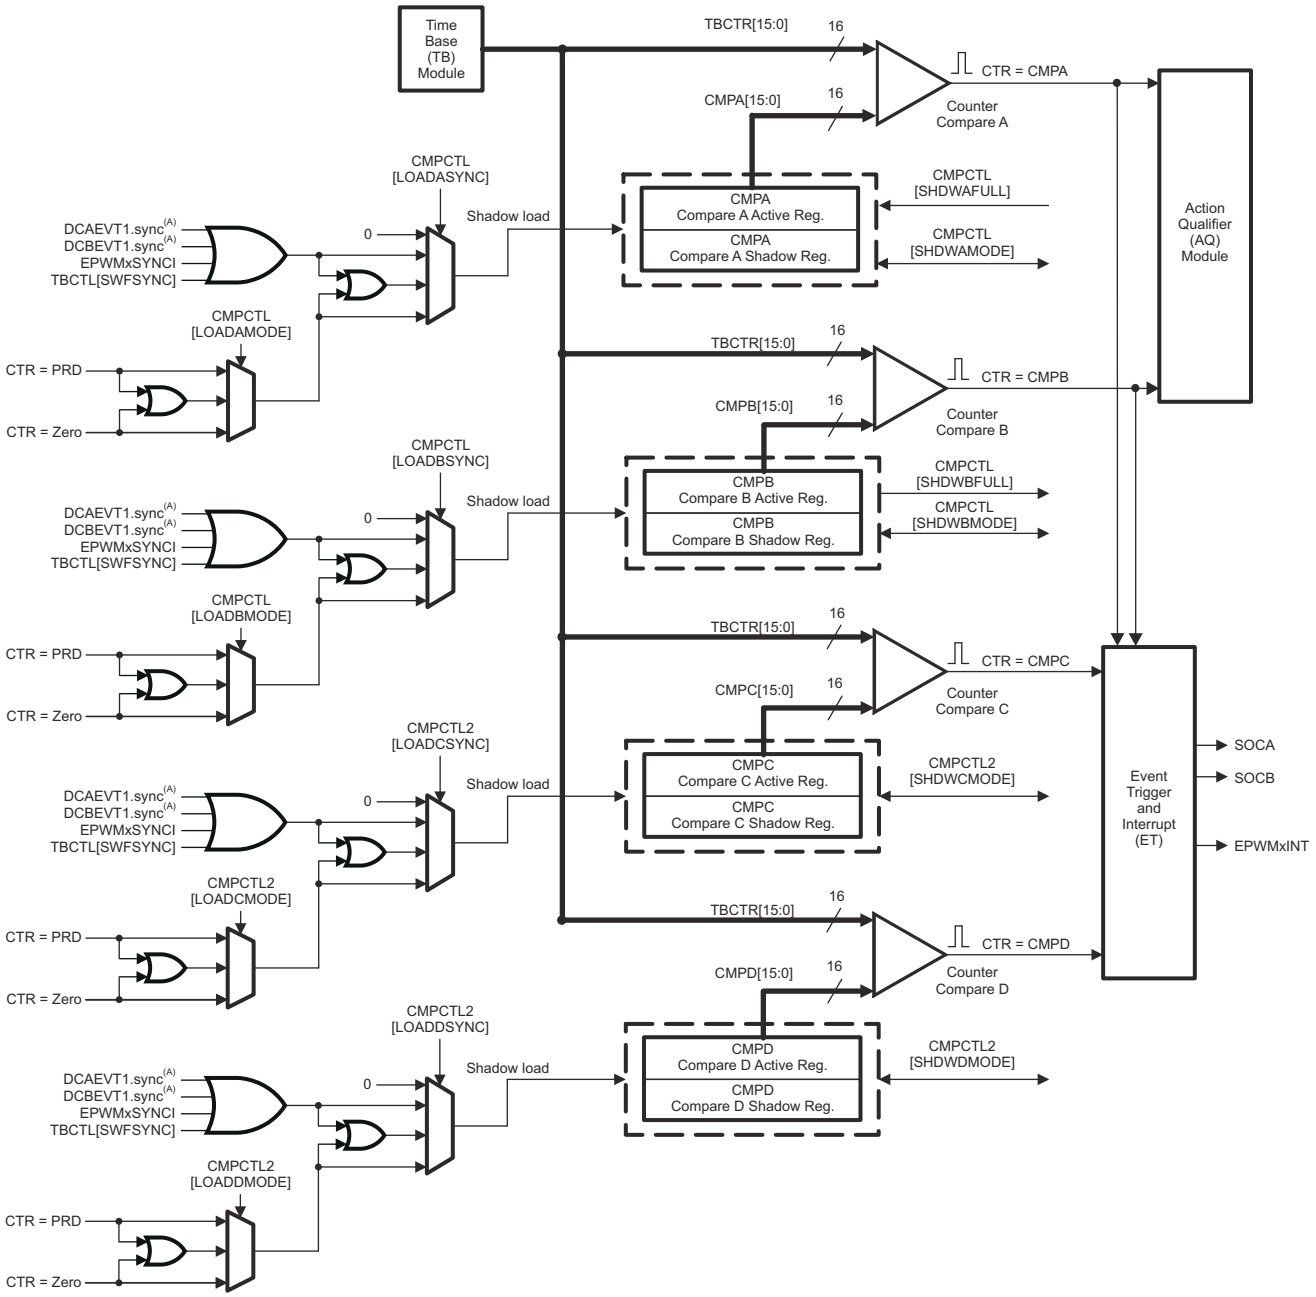
The counter-compare:

- Generates events based on programmable time stamps using the CMPA, CMPB, CMPC, and CMPD registers:
  - CTR = CMPA: Time-base counter equals counter-compare A register (TBCTR = CMPA)
  - CTR = CMPB: Time-base counter equals counter-compare B register (TBCTR = CMPB)
  - CTR = CMPC: Time-base counter equals counter-compare C register (TBCTR = CMPC)
  - CTR = CMPD: Time-base counter equals counter-compare D register (TBCTR = CMPD)
- Controls the PWM duty cycle, if the action-qualifier submodule is configured appropriately using counter-compare A (CMPA) and counter-compare B (CMPB)
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle

Copyright © 2024 Texas Instruments Incorporated

### 15.5.2 Controlling and Monitoring the Counter-Compare Submodule

The counter-compare submodule operation is shown in Figure 15-15.



A. These events are generated by the ePWM digital compare (DC) submodule based on the levels of the TRIPIN inputs (for example, CMPSSx and $\overline{TZ}$ signals).

**Figure 15-15. Detailed View of the Counter-Compare Submodule**

Copyright © 2024 Texas Instruments Incorporated

### 15.5.3 Operational Highlights for the Counter-Compare Submodule

The counter-compare submodule is responsible for generating events that can be used in the action-qualifier and event-trigger submodules. There are four independent compare events:

1. CTR = CMPA: Time-base counter equal to counter-compare A register (TBCTR = CMPA).
2. CTR = CMPB: Time-base counter equal to counter-compare B register (TBCTR = CMPB).
3. CTR = CMPC: Time-base counter equal to counter-compare C register (TBCTR = CMPC). This event can be used to generate an event in the event trigger submodule only.
4. CTR = CMPD: Time-base counter equal to counter-compare D register (TBCTR = CMPD). This event can be used to generate an event in the event trigger submodule only

For up-count or down-count mode, each event occurs only once per cycle. For up-down count mode, each event occurs twice per cycle if the compare value is between 0x00-TBPRD; and once per cycle if the compare value is equal to 0x00 or equal to TBPRD. These events are applies to the action-qualifier submodule where the events are qualified by the counter direction and converted into actions if enabled. Refer to Section 15.6.1 for more details.

The counter-compare registers CMPA and CMPB each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occur at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. The register that is written to or read from is determined by the CMPCTL[SHDWAMODE] and CMPCTL[SHDWBMODE] bits. These bits enable and disable the CMPC shadow register and CMPD shadow register, respectively. The behavior of the two load modes is:

**Shadow Mode:**

The shadow mode for the CMPA is enabled by clearing the CMPCTL[SHDWAMODE] bit and the shadow register for CMPB is enabled by clearing the CMPCTL[SHDWBMODE] bit. Shadow mode is enabled by default for both CMPA and CMPB.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the CMPCTL[LOADAMODE], CMPCTL[LOADBMODE], CMPCTL[LOADASYNC], and CMPCTL[LOADBSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCI or TBCTL[SWFSYNC]
- Both SYNC event or a selection made by LOADAMODE/LOADBMODE

Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

**Note**

Refer to Section 15.6.5 for valid configurations of CMPA/CMPB and LOADAMODE/LOADBMODE.

**Immediate Load Mode:**

If the immediate load mode is selected (that is, CMPCTL[SHDWAMODE] = 1 or CMPCTL[SHDWBMODE] = 1), then a read from or a write to the register goes directly to the active register.

Copyright © 2024 Texas Instruments Incorporated

**Additional Comparators**

The counter-compare submodule on ePWMs type 2 and later are responsible for generating two additional independent compare events based on two compare registers, which is fed to Event Trigger submodule:

1. CTR = CMPC: Time-base counter equal to counter-compare C register (TBCTR = CMPC).
2. CTR = CMPD: Time-base counter equal to counter-compare D register (TBCTR = CMPD).

The counter-compare registers CMPC and CMPD each have an associated shadow register. By default this register is shadowed. The memory address of the active register and the shadow register is identical. The value in the active CMPC and CMPD register is compared to the time-base counter (TBCTR). When the values are equal, the counter compare module generates a “time-base counter equal to counter compare C or counter compare D ” event respectively. Shadowing of this register is enabled and disabled by the CMPCTL2[SHDWCMODE] and CMPCTL2[SHDWDMODE] bit. These bits enable and disable the CMPC shadow register and CMPD shadow register respectively. The behavior of the two load modes is described below:

**Shadow Mode:**

The shadow mode for the CMPC is enabled by clearing the CMPCTL2[SHDWCMODE] bit and the shadow register for CMPD is enabled by clearing the CMPCTL2[SHDWDMODE] bit. Shadow mode is enabled by default for both CMPC and CMPD.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the CMPCTL2[LOADCMODE], CMPCTL2[LOADDMODE], CMPCTL2[LOADCSYNC], and CMPCTL2[LOADDSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCI or TBCTL[SWFSYNC]
- Both SYNC event or a selection made by LOADCMODE/LOADDMODE

Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

**Immediate Load Mode:**

If the immediate load mode is selected (that is, CMPCTL2[SHDWCMODE] = 1 or CMPCTL2[SHDWDMODE] = 1), then a read from or a write to the register goes directly to the active register.

**Global Load Support**

The global load control mechanism can also be used for all counter-compare registers by configuring the appropriate bits in the global load configuration register (GLDCFG). When the global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in the Global Shadow to Active Load Control Register (GLDCTL). The global load control mechanism is explained in Section 15.4.7.

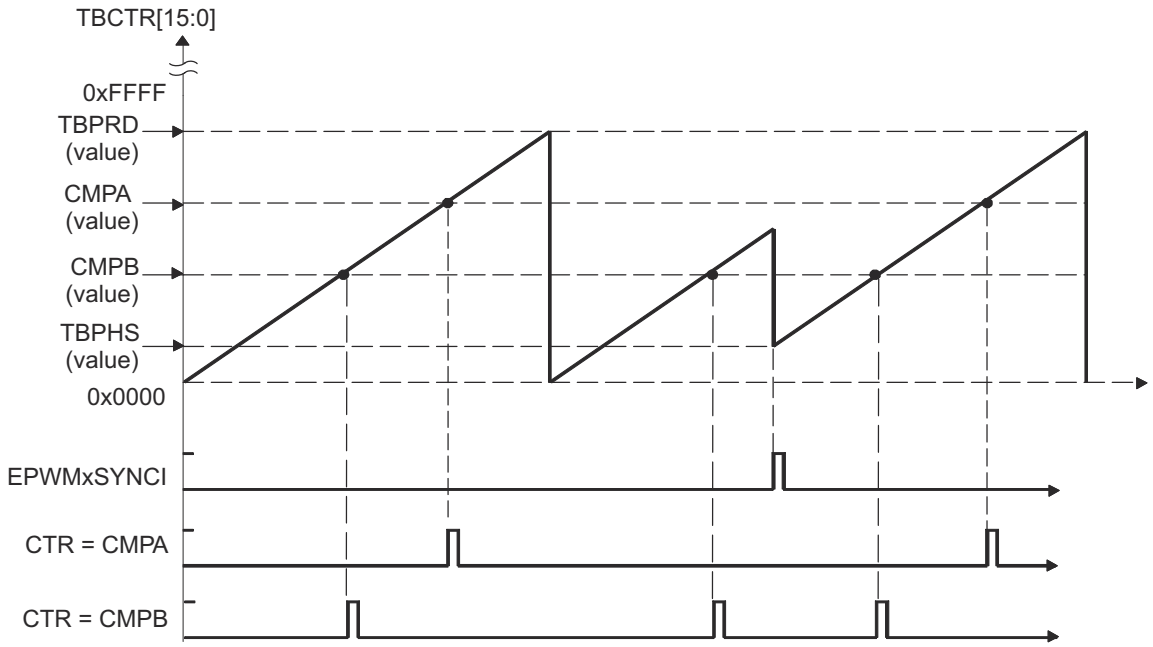
### *15.5.4 Count Mode Timing Waveforms*

The counter-compare module can generate compare events in all three count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.
- Up-down-count mode: used to generate a symmetrical PWM waveform.

To best illustrate the operation of the first three modes, the timing diagrams in Figure 15-16 through Figure 15-19 show when events are generated and how the EPWMxSYNCI signal interacts.

Copyright © 2024 Texas Instruments Incorporated



An EPWMxSYNCI external synchronization event can cause a discontinuity in the TBCTR count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

## 15.6 Action-Qualifier (AQ) Submodule

The action-qualifier submodule has the most important role in waveform construction and PWM generation. The action-qualifier submodule decides which events are converted into various action types, thereby, producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

Figure 15-20 illustrates the action-qualifier submodule within the ePWM.

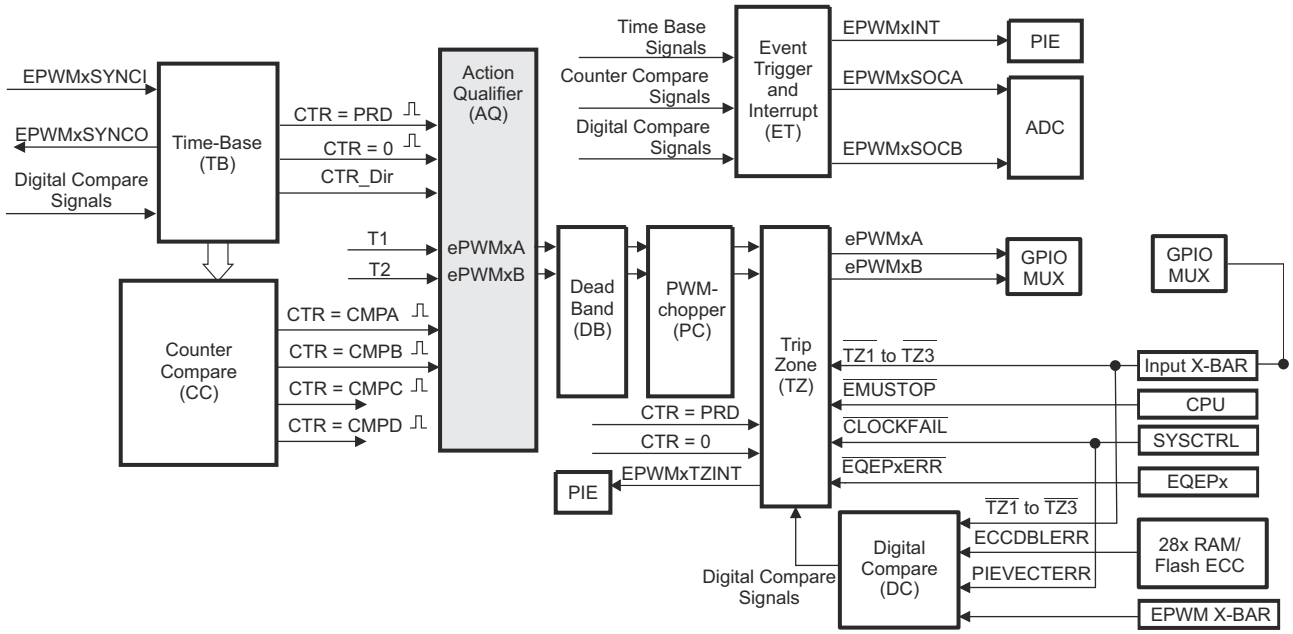

**Figure 15-20. Action-Qualifier Submodule**

### *15.6.1 Purpose of the Action-Qualifier Submodule*

The action-qualifier submodule is responsible for the following:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
  - CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
  - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
  - CTR = CMPA: Time-base counter equal to the counter-compare A register (TBCTR = CMPA)
  - CTR = CMPB: Time-base counter equal to the counter-compare B register (TBCTR = CMPB)
- T1, T2 events: Trigger events based on comparator, trip or syncin events
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when it is decreasing

Copyright © 2024 Texas Instruments Incorporated

### 15.6.2 Action-Qualifier Submodule Control and Status Register Definitions

The action-qualifier submodule operation is shown in Figure 15-21 and monitored by way of the registers in Section 15.15.

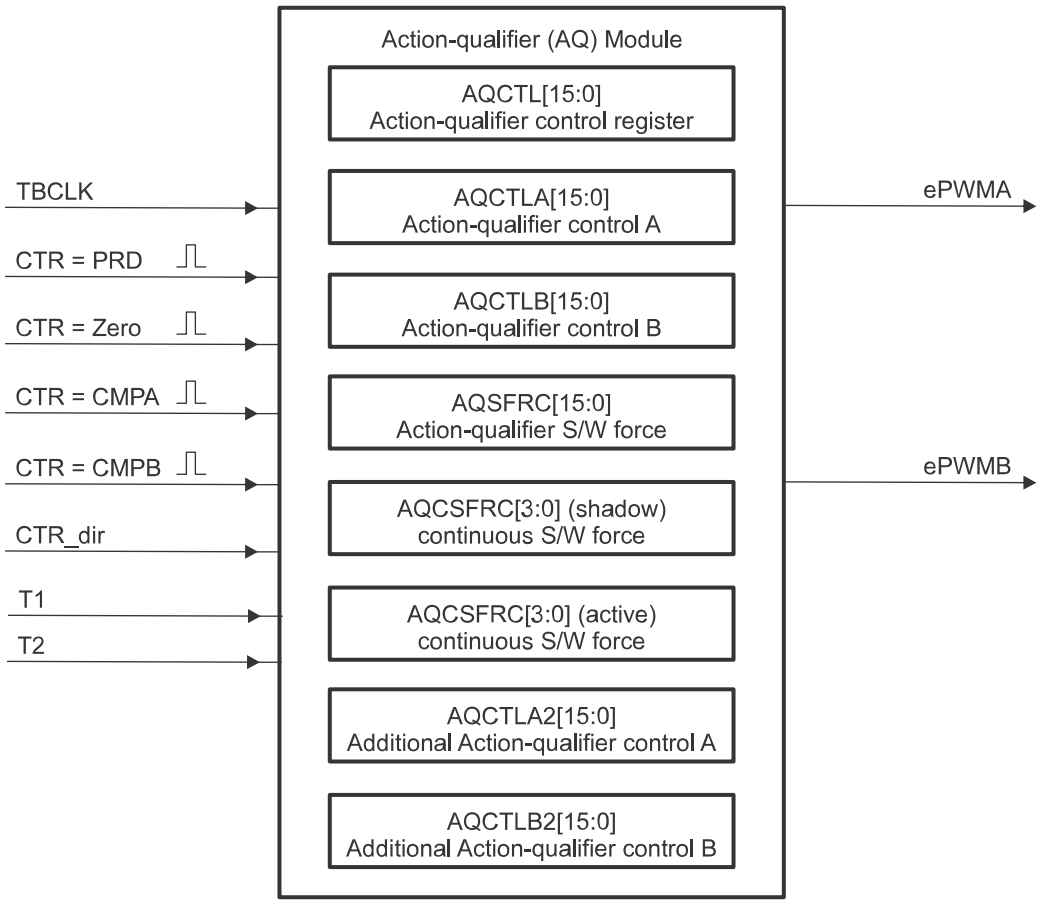

**Figure 15-21. Action-Qualifier Submodule Inputs and Outputs**

For convenience, the possible input events are summarized again in Table 15-3.

**Table 15-3. Action-Qualifier Submodule Possible Input Events**

| Signal | Description | Registers Compared |
|---|---|---|
| CTR = PRD | Time-base counter equal to the period value | TBCTR = TBPRD |
| CTR = Zero | Time-base counter equal to 0 | TBCTR = 0x00 |
| CTR = CMPA | Time-base counter equal to the counter-compare A | TBCTR = CMPA |
| CTR = CMPB | Time-base counter equal to the counter-compare B | TBCTR = CMPB |
| T1 event | Based on comparator, trip, or syncin events | None |
| T2 event | Based on comparator, trip, or syncin events | None |
| Software forced event | Asynchronous event initiated by software | |

The software forced action is a useful asynchronous event. This control is handled by the AQSFRC and AQCSFRC registers.

Copyright © 2024 Texas Instruments Incorporated

**Note**

If the CSFA is not used in shadow mode, the RLDCSF bit must be configured to disable shadow mode.

The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:** Set output EPWMxA or EPWMxB to a high level.
- **Clear Low:** Set output EPWMxA or EPWMxB to a low level.
- **Toggle:** If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.
- **Do Nothing:** Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts and ADC start of conversion. See the description in Section 15.10 for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. For example, both CTR = CMPA and CTR = CMPB can operate on output EPWMxA. All qualifier actions are configured using the control registers found in the *ePWM Registers* section.

For clarity, the illustrations in this chapter use a set of symbolic actions. These symbols are summarized in Figure 15-22. Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and the time positions are programmed by way of the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"(the default at reset).

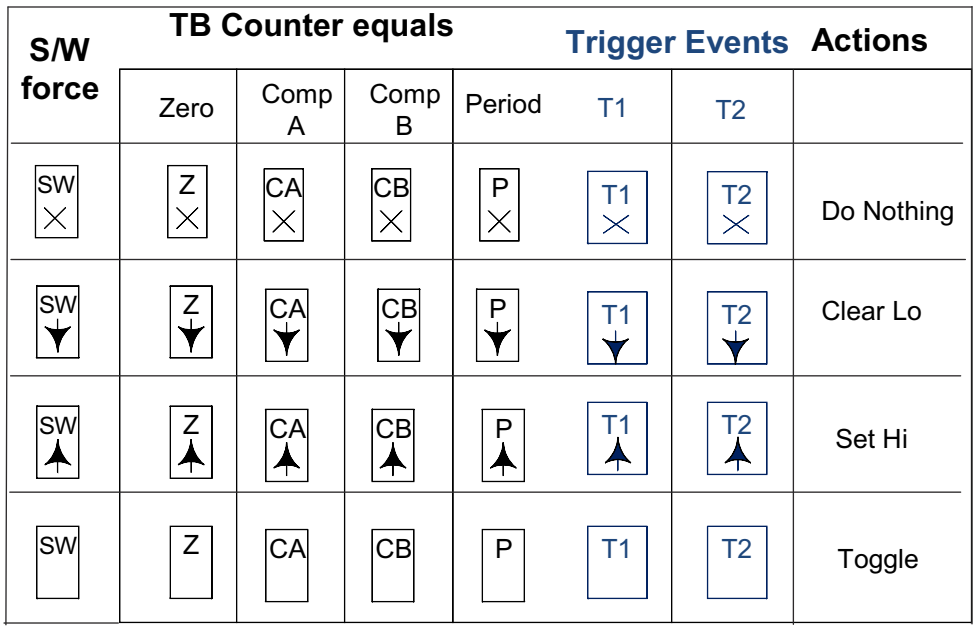

**Figure 15-22. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs**

The Action Qualifier Trigger Event Source Selection register (AQTSRCSEL) is used to select the source for T1 and T2 events. T1/T2 selection and configuration of a trip/digital-compare event in Action Qualifier submodule is independent of the configuration of that event in the Trip-Zone submodule. A particular trip event can or cannot

Copyright © 2024 Texas Instruments Incorporated

be configured to cause trip action in the Trip Zone submodule, but the same event can be used by the Action Qualifier to generate T1/T2 for controlling PWM generation.

### 15.6.3 Action-Qualifier Event Priority

It is possible for the ePWM action qualifier to receive more than one event at the same time. In this case, events are assigned a priority by the hardware. The general rule is events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down count mode are shown in Table 15-4. A priority level of 1 is the highest priority and level 10 is the lowest. The priority changes slightly depending on the direction of TBCTR.

**Table 15-4. Action-Qualifier Event Priority for Up-Down-Count Mode**

| Priority Level | Event If TBCTR is Incrementing TBCTR = Zero up to TBCTR = TBPRD | Event If TBCTR is Decrementing TBCTR = TBPRD down to TBCTR = 1 |
|---|---|---|
| 1 (Highest) | Software forced event | Software forced event |
| 2 | T1 on up-count (T1U) | T1 on down-count (T1D) |
| 3 | T2 on up-count (T2U) | T2 on down-count (T2D) |
| 4 | Counter equals CMPB on up-count (CBU) | Counter equals CMPB on down-count (CBD) |
| 5 | Counter equals CMPA on up-count (CAU) | Counter equals CMPA on down-count (CAD) |
| 6 (Lowest) | Counter equals zero | Counter equals period (TBPRD) |

Table 15-5 shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up; therefore, down-count events never are taken.

**Table 15-5. Action-Qualifier Event Priority for Up-Count Mode**

| Priority Level | Event |
|---|---|
| 1 (Highest) | Software forced event |
| 2 | Counter equal to period (TBPRD) |
| 3 | T1 on up-count (T1U) |
| 4 | T2 on up-count (T2U) |
| 5 | Counter equal to CMPB on up-count (CBU) |
| 6 | Counter equal to CMPA on up-count (CAU) |
| 7 (Lowest) | Counter equal to Zero |

Table 15-6 shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down; therefore, up-count events never are taken.

**Table 15-6. Action-Qualifier Event Priority for Down-Count Mode**

| Priority Level | Event |
|---|---|
| 1 (Highest) | Software forced event |
| 2 | Counter equal to Zero |
| 3 | T1 on down-count (T1D) |
| 4 | T2 on down-count (T2D) |
| 5 | Counter equal to CMPB on down-count (CBD) |
| 6 | Counter equal to CMPA on down-count (CAD) |
| 7 (Lowest) | Counter equal to period (TBPRD) |

Copyright © 2024 Texas Instruments Incorporated

It is possible to set the compare value greater than the period. In this case, the action takes place as shown in Table 15-7.

**Table 15-7. Behavior if CMPA/CMPB is Greater than the Period**

| Counter Mode | Compare on Up-Count Event CAD/CBD | Compare on Down-Count Event CAD/CBD |
|---|---|---|
| Up-Count Mode | If CMPA/CMPB ≤ TBPRD period, then the event occurs on a compare match (TBCTR=CMPA or CMPB). | Never occurs. |
| | If CMPA/CMPB > TBPRD, then the event does not occur. | |
| Down-Count Mode | Never occurs. | If CMPA/CMPB < TBPRD, the event occurs on a compare match (TBCTR=CMPA or CMPB). |
| | | If CMPA/CMPB ≥ TBPRD, the event occurs on a period match (TBCTR=TBPRD). |
| Up-Down Count Mode | If CMPA/CMPB < TBPRD and the counter is incrementing, the event occurs on a compare match (TBCTR=CMPA or CMPB). | If CMPA/CMPB < TBPRD and the counter is decrementing, the event occurs on a compare match (TBCTR=CMPA or CMPB). |
| | If CMPA/CMPB is ≥ TBPRD, the event occurs on a period match (TBCTR = TBPRD). | If CMPA/CMPB ≥ TBPRD, the event occurs on a period match (TBCTR=TBPRD). |

### *15.6.4 AQCTLA and AQCTLB Shadow Mode Operations*

To enable Action Qualifier mode changes which must occur at the end of a period even when the phase changes, shadowing of the AQCTLA and AQCTLB registers has been added on ePWMs type 2 and later. Additionally, shadow to active load on SYNC of these registers is supported as well. Shadowing of this register is enabled and disabled by the AQCTL[SHDWAQAMODE] and AQCTL[SHDWAQBMODE] bits. These bits enable and disable the AQCTLA shadow register and AQCTLB shadow register, respectively. The behavior of the two load modes is:

**Shadow Mode:**

The shadow mode for the AQCTLA is enabled by setting the AQCTL[SHDWAQAMODE] bit, and the shadow register for AQCTLB is enabled by setting the AQCTL[SHDWAQBMODE] bit. Shadow mode is disabled by default for both AQCTLA and AQCTLB

If the shadow register is enabled, then the content of the shadow register is transferred to the active register on one of the following events as specified by the AQCTL[LDAQAMODE], AQCTL[LDAQBMODE], AQCTL[LDAQASYNC], and AQCTL[LDAQBSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCI or TBCTL[SWFSYNC]
- Both SYNC event or a selection made by LDAQAMODE/LDAQBMODE

**Global Load Support**

Global load control mechanism can also be used for AQCTLA:AQCTLA2, AQCTLB:AQCTLB2, and AQCSFRC registers by configuring the appropriate bits in the global load configuration register (GLDCFG). When global load mode is selected, the transfer of contents from shadow register to active register for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in the Global Shadow to Active Load Control Register (GLDCTL). The global load control mechanism is explained in Section 15.4.7.

**Immediate Load Mode:**

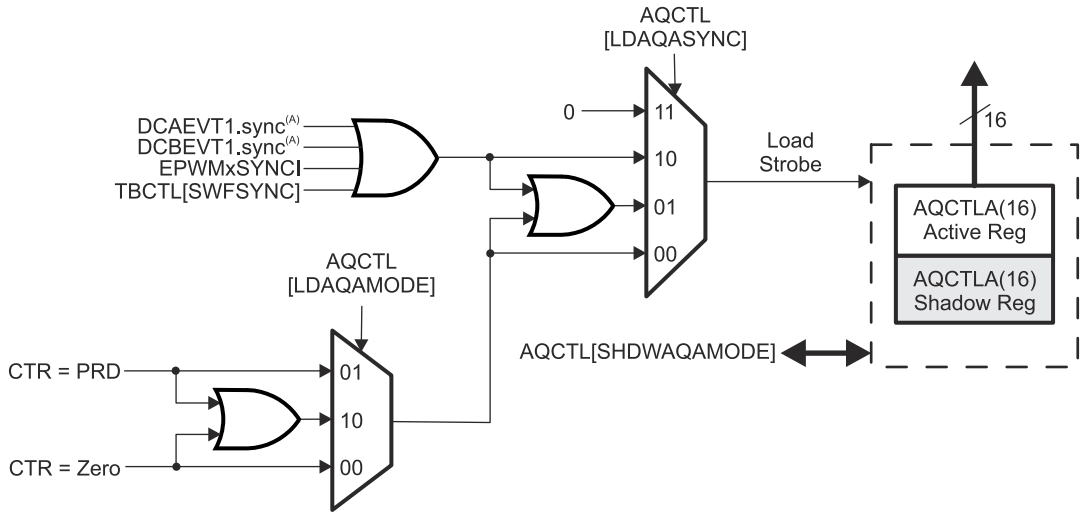
If the immediate load mode is selected (that is, AQCTL[SHDWAQAMODE] = 0 or AQCTL[SHDWAQBMODE] = 0), then a read from or a write to the register goes directly to the active register. See Figure 15-23 and Figure 15-24.

Copyright © 2024 Texas Instruments Incorporated

**Note**

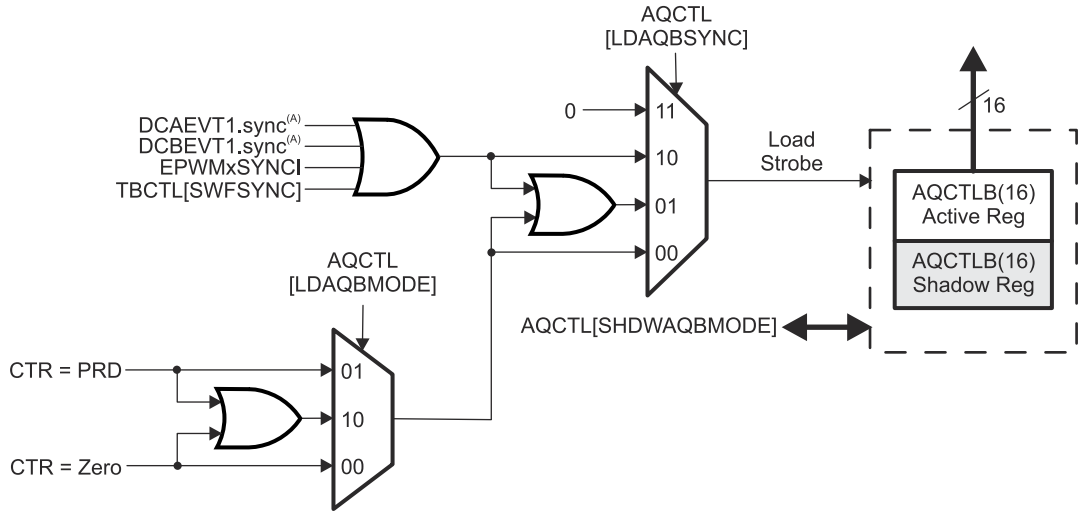
Shadow to Active Load of Action Qualifier Output A/B Control Register [AQCTLA and AQCTLB] on CMPA = 0 or CMPB = 0 boundary

If the Counter-Compare A Register (CMPA) or Counter-Compare B Register (CMPB) is set to a value of 0 and the action qualifier action on AQCTLA and AQCTLB is configured to occur in the same instant as a shadow to active load (that is, CMPA=0 and AQCTLA shadow to active load on TBCTR=0 using AQCTL register LDAQAMODE and LDAQAMODE bits), then both events enter contention. It is recommended to use a Non-Zero Counter-Compare when using Shadow to Active Load of Action Qualifier Output A/B Control Register on TBCTR = 0 boundary.



A. These events are generated by the ePWM digital compare (DC) submodule based on the levels of the TRIPIN inputs (for example, CMPSSx and $\overline{TZ}$ signals).

**Figure 15-23. AQCTL[SHDWAQAMODE]**



A. These events are generated by the ePWM digital compare (DC) submodule based on the levels of the TRIPIN inputs (for example, CMPSSx and $\overline{TZ}$ signals).

### 15.6.5 Configuration Requirements for Common Waveforms

**Note**

The waveforms in this chapter show the behavior of the ePWMs for a static compare register value. In a running system, the active compare registers (CMPA and CMPB) are typically updated from the respective shadow registers once every period. Specify when the update takes place: either when the time-base counter reaches zero or when the time-base counter reaches the period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

**Use up-down count mode to generate a symmetric PWM:**

- If loading CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1.
- If loading CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD-1.

  This means there is always a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

**Use up-down count mode to generate an asymmetric PWM:**

- To achieve 50%-0% asymmetric PWM use the following configuration: Load CMPA/CMPB on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to TBPRD to achieve 50%-0% PWM duty.

**When using up-count mode to generate an asymmetric PWM:**

- To achieve 0-100% asymmetric PWM, you **must** load CMPA/CMPB on TBPRD. When CMPA/CMPB is not loaded on TBCTR=PRD, boundary conditions can occur depending on the timing of the write and the value written to CMPA/CMPB. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to TBPRD+1 to achieve 0-100% PWM duty.

**When using up-count mode to generate an asymmetric PWM with deadband enabled:**

- To achieve 0%-100% PWM use the following configuration: When the CMPA value is too close to 0 or PRD such that the following conditions are met (CMPX < Deadband) or (CMPX > PRD – Deadband), the actions specified by the AQCTL register for CMPX do not take effect. To avoid this, the AQCTL settings must be altered under these conditions only to generate either high or low pulses for both CAU or CAD events (both set or both clear). Make sure that this software update is occurring synchronous to the PWM carrier cycle, and shadow mode is enabled.

**When using up-down count mode to generate an asymmetric PWM with deadband enabled:**

- To achieve 0%-100% PWM use the following configuration: When the CMPA value is too close to 0 or PRD such that the following conditions are met (CMPX < Deadband/2) or (CMPX > PRD – (Deadband)/2), the actions specified by the AQCTL register for CMPX do not take effect. To avoid this, the AQCTL settings must be altered under these conditions only to generate either high or low pulses for both CAU or CAD events (both set or both clear). Make sure that this software update is occurring synchronous to the PWM carrier cycle, and shadow mode is enabled.

See *Using Enhanced Pulse Width Modulator (ePWM) Module for 0-100% Duty Cycle Control*.

Figure 15-25 shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCTR. In this mode, 0%-100% DC modulation is achieved by using equal compare matches on the up count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing, the CMPA match pulls the PWM output high. Likewise when the counter is decrementing, the compare match pulls the PWM signal low. When CMPA = 0, the PWM signal is high for the entire period giving a 100% duty waveform. When CMPA = TBPRD, the PWM signal is low achieving 0% duty.

Copyright © 2024 Texas Instruments Incorporated

When using this configuration in practice, if loading CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1. If loading CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD-1. This means there is always a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

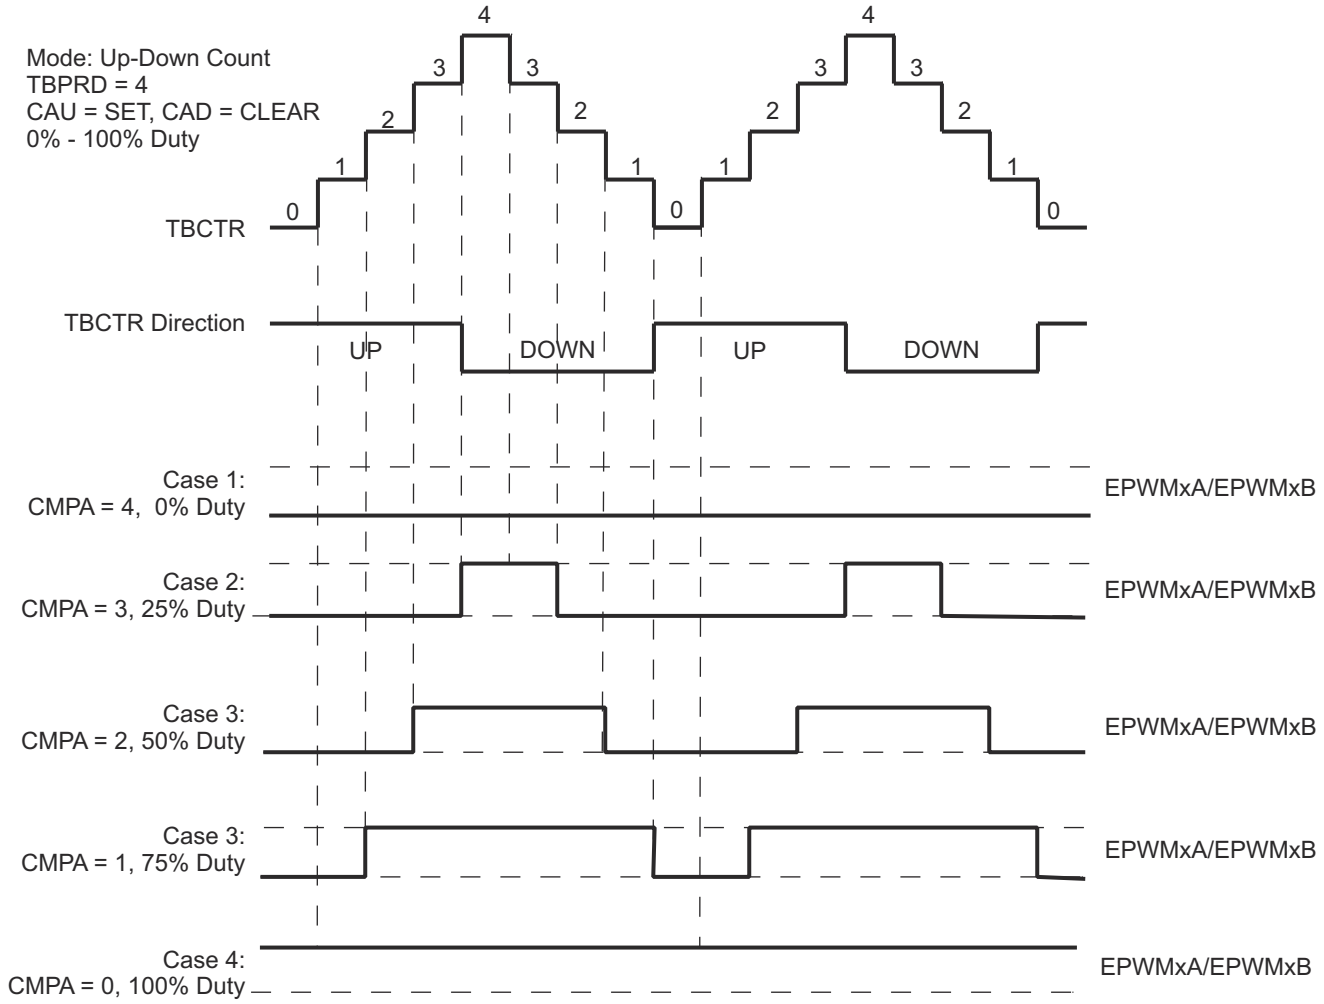

**Figure 15-25. Up-Down Count Mode Symmetrical Waveform**

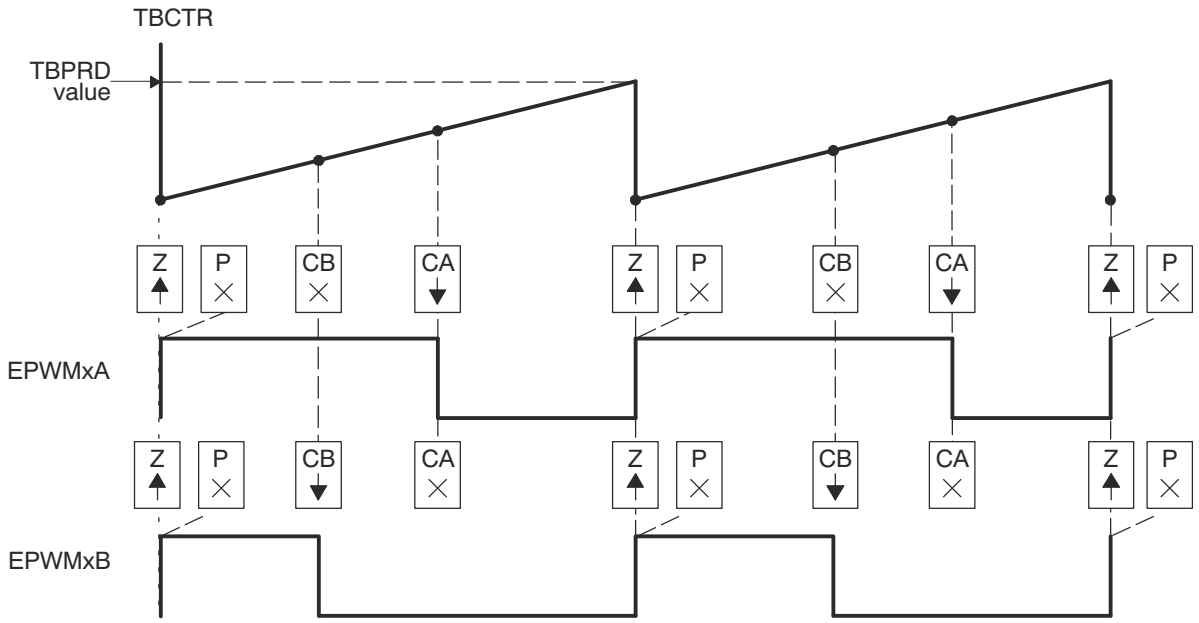
The PWM waveforms in Figure 15-26 through Figure 15-31 show some common action-qualifier configurations. Some conventions used in the figures and examples are as follows:

- TBPRD, CMPA, and CMPB refer to the value written in the respective registers. The active register, not the shadow register, is used by the hardware.
- CMPx, refers to either CMPA or CMPB.
- EPWMxA and EPWMxB refer to the output signals from ePWMx
- Up-Down means count-up-and count-down mode, Up means up-count mode and Down means down-count mode
- Sym = Symmetric, Asym = Asymmetric

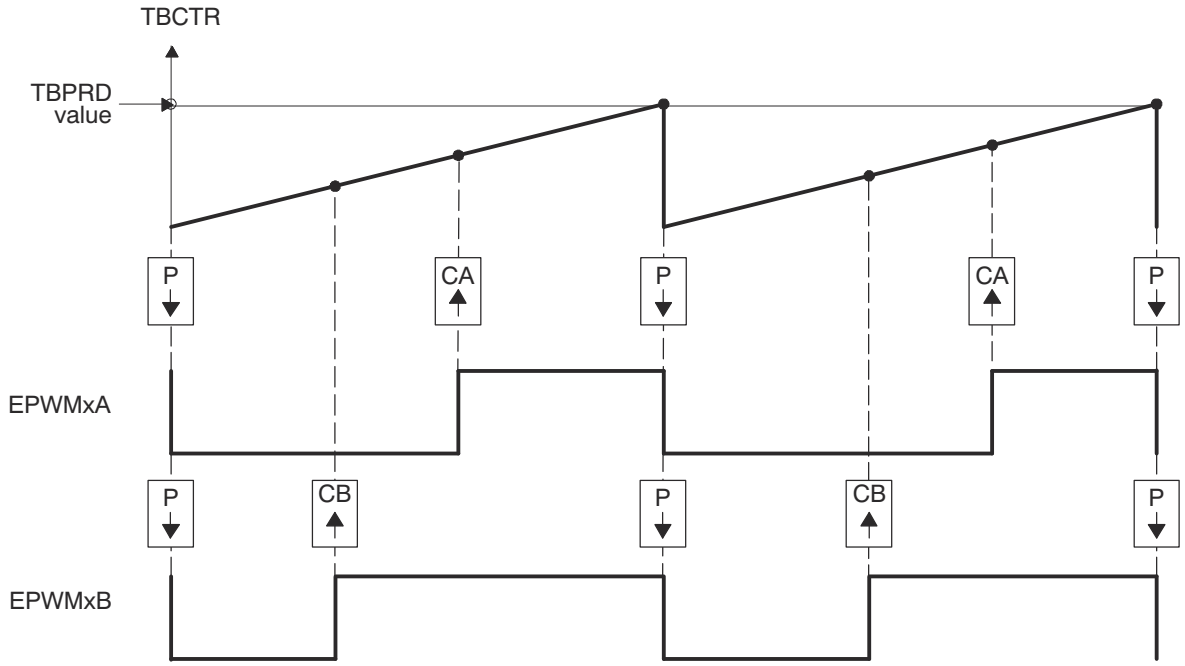
Copyright © 2024 Texas Instruments Incorporated



A. PWM period = (TBPRD + 1) × $T_{TBCLK}$
B. Duty modulation for EPWMxA is set by CMPA, and is active high (that is, high time duty proportional to CMPA).
C. Duty modulation for EPWMxB is set by CMPB and is active high (that is, high time duty proportional to CMPB).
D. The "Do Nothing" actions (X) are shown for completeness, but are not shown on subsequent diagrams.
E. Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

**Figure 15-26. Up, Single Edge Asymmetric Waveform, with Independent Modulation on EPWMxA and EPWMxB—Active High**

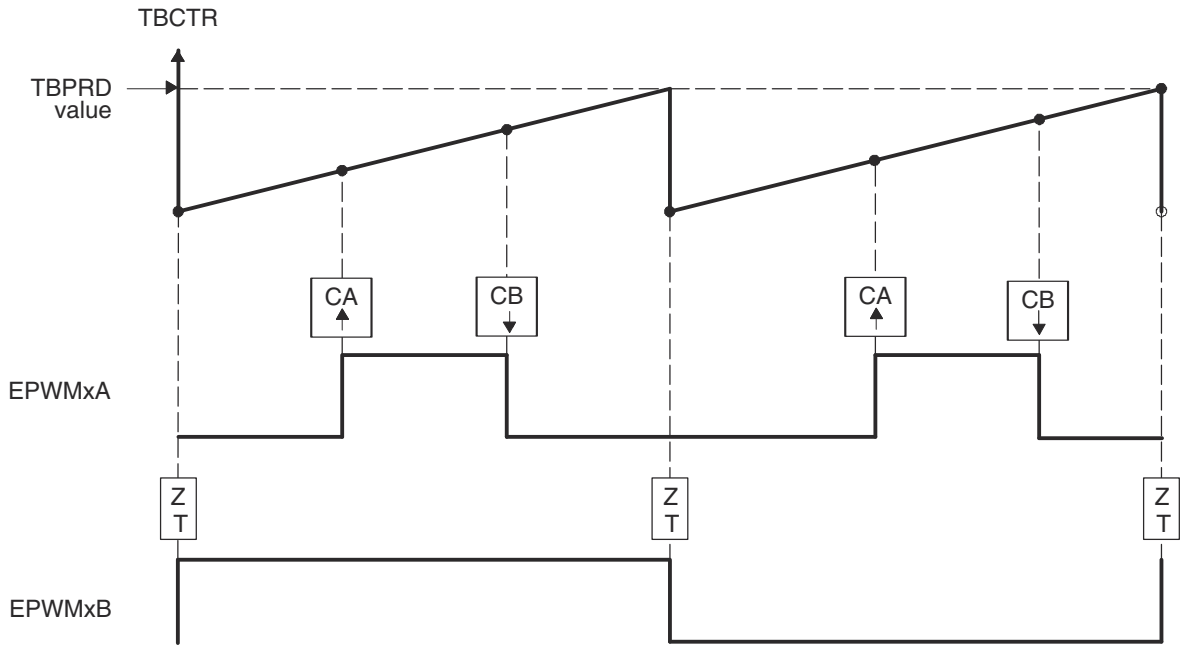
Copyright © 2024 Texas Instruments Incorporated



A. PWM period = (TBPRD + 1) × $T_{TBCLK}$
B. Duty modulation for EPWMxA is set by CMPA, and is active low (that is, the low time duty is proportional to CMPA).
C. Duty modulation for EPWMxB is set by CMPB and is active low (that is, the low time duty is proportional to CMPB).
D. Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

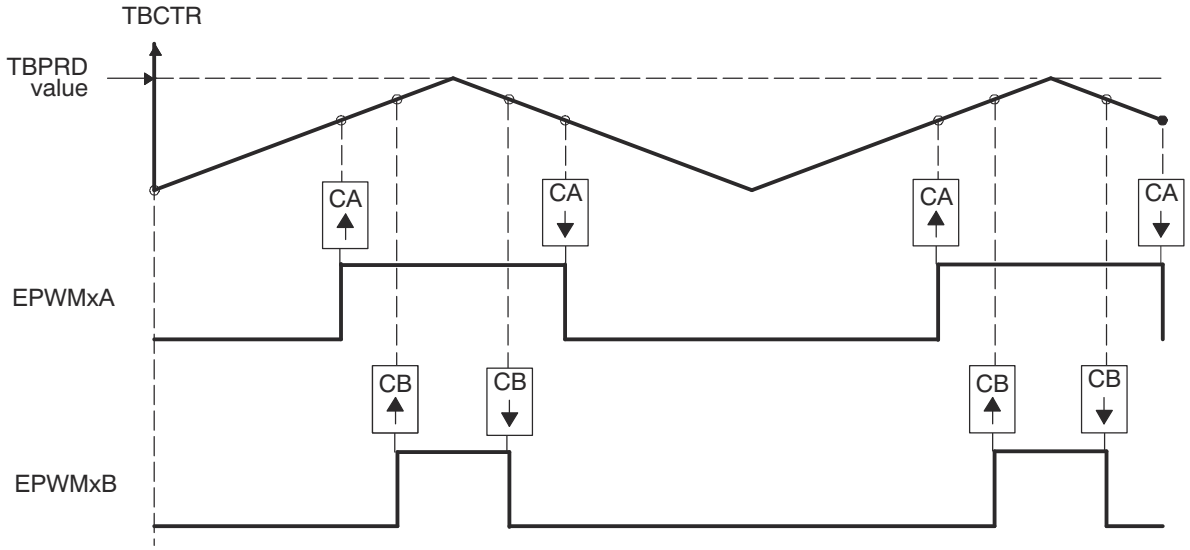
**Figure 15-27. Up, Single Edge Asymmetric Waveform with Independent Modulation on EPWMxA and EPWMxB—Active Low**

Copyright © 2024 Texas Instruments Incorporated



A. PWM frequency = 1/((TBPRD + 1) × $T_{TBCLK}$)
B. Pulse can be placed anywhere within the PWM cycle (0000 - TBPRD)
C. High time duty proportional to (CMPB - CMPA)

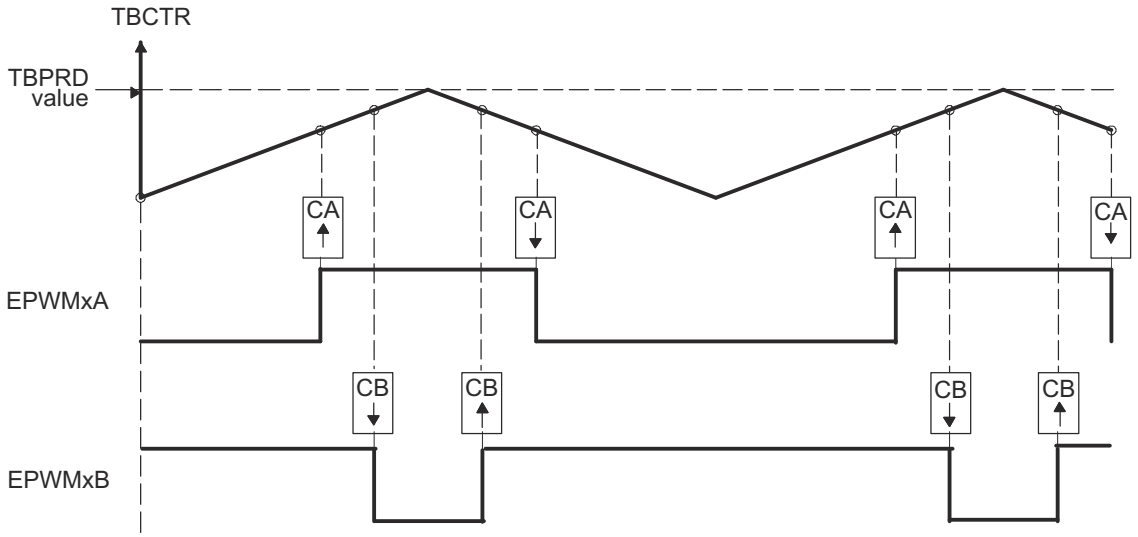
**Figure 15-28. Up-Count, Pulse Placement Asymmetric Waveform With Independent Modulation on EPWMxA**



A. PWM period = 2 x TBPRD × $T_{TBCLK}$
B. Duty modulation for EPWMxA is set by CMPA, and is active low (that is, the low time duty is proportional to CMPA).
C. Duty modulation for EPWMxB is set by CMPB and is active low (that is, the low time duty is proportional to CMPB).
D. Outputs EPWMxA and EPWMxB can drive independent power switches.

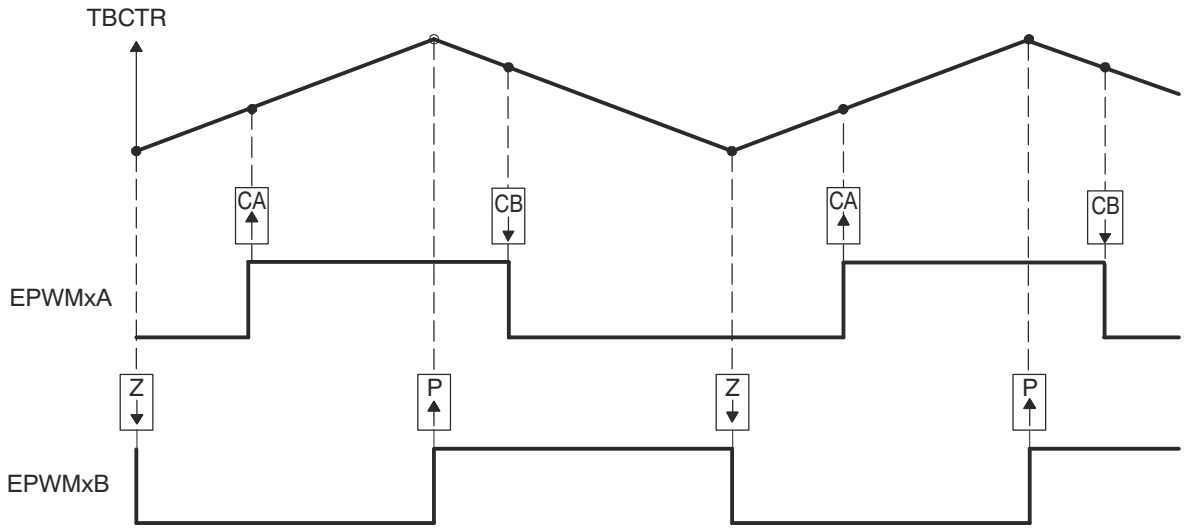
**Figure 15-29. Up-Down Count, Dual-Edge Symmetric Waveform, with Independent Modulation on EPWMxA and EPWMxB — Active Low**

Copyright © 2024 Texas Instruments Incorporated



A. PWM period = 2 × TBPRD × $T_{TBCLK}$
B. Duty modulation for EPWMxA is set by CMPA, and is active low, that is, low time duty proportional to CMPA.
C. Duty modulation for EPWMxB is set by CMPB and is active high, that is, high time duty proportional to CMPB.
D. Outputs EPWMx can drive upper/lower (complementary) power switches.
E. Dead-band = CMPB - CMPA (fully programmable edge placement by software). Note the dead-band module is also available if the more classical edge delay method is required.

**Figure 15-30. Up-Down Count, Dual-Edge Symmetric Waveform, with Independent Modulation on EPWMxA and EPWMxB — Complementary**



A. PWM period = 2 × TBPRD × TBCLK
B. Rising edge and falling edge can be asymmetrically positioned within a PWM cycle. This allows for pulse placement techniques.
C. Duty modulation for EPWMxA is set by CMPA and CMPB.
D. Low time duty for EPWMxA is proportional to (CMPA + CMPB).
E. To change this example to active high, CMPA and CMPB actions need to be inverted (that is, Clear on CMPA, Set on CMPB).
F. Duty modulation for EPWMxB is fixed at 50% (utilizes spare action resources for EPWMxB).

**Figure 15-31. Up-Down Count, Dual-Edge Asymmetric Waveform, with Independent Modulation on EPWMxA—Active Low**

## 15.7 Dead-Band Generator (DB) Submodule

Figure 15-33 illustrates the dead-band submodule within the ePWM.

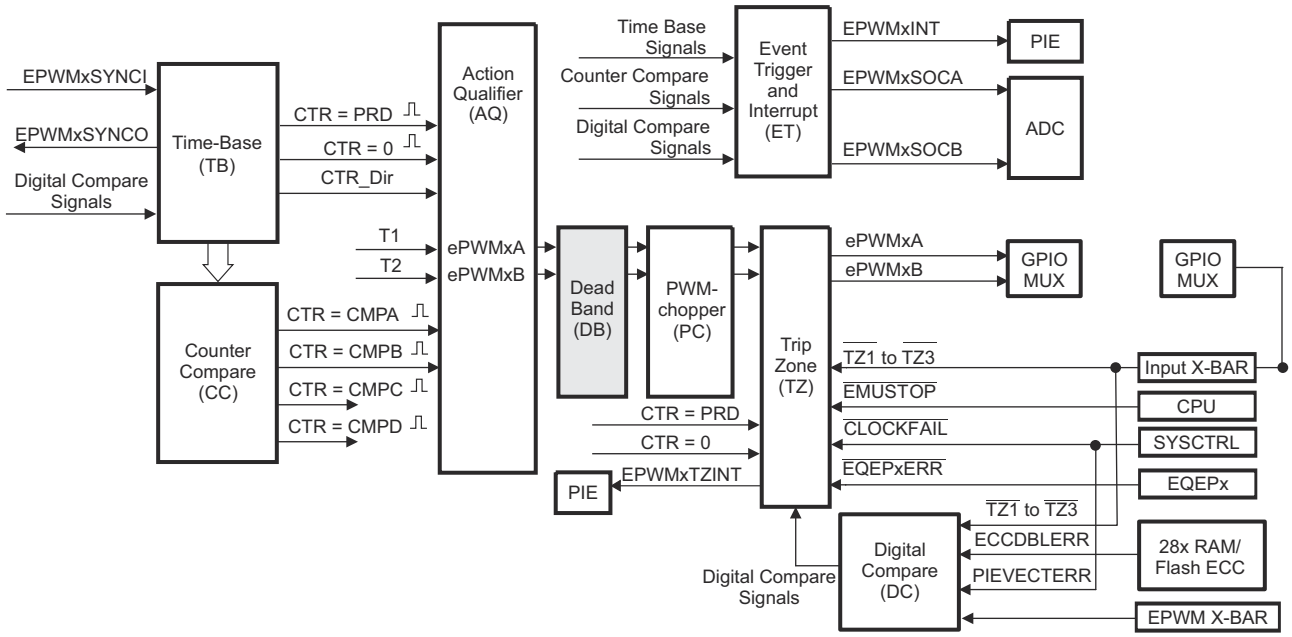

**Figure 15-33. Dead_Band Submodule**

### *15.7.1 Purpose of the Dead-Band Submodule*

The action-qualifier (AQ) module section discussed how the AQ module can generate the required dead band by having full control over edge placement using both the CMPA and CMPB resources of the ePWM module. However, if the more classical edge delay-based dead band with polarity control is required, then the dead-band submodule described here must be used.

The key functions of the dead-band module are:

- Generating appropriate signal pairs (EPWMxA and EPWMxB) with dead-band relationship from a single EPWMxA input
- Programming signal pairs for:
  - Active high (AH)
  - Active low (AL)
  - Active high complementary (AHC)
  - Active low complementary (ALC)
- Adding programmable delay to rising edges (RED)
- Adding programmable delay to falling edges (FED)
- Can be totally bypassed from the signal path (note dotted lines in diagram)

Copyright © 2024 Texas Instruments Incorporated

### 15.7.2 Dead-band Submodule Additional Operating Modes

On type 1 ePWM RED can appear on one channel output and FED can appear on the other channel output.

The following list shows the distinct difference between type 1 and type 4 modules with respect to dead-band operating modes:

- By adding S6, S7, and S8 in Figure 15-34, RED and FED can appear on both the A-channel and B-channel outputs. Additionally, both RED and FED together can be applied to either the A-channel or B-channel outputs to allow B-channel phase shifting with respect to the A-channel.

**Note**

Phase shifting B-channel with respect to the A-channel using the dead-band submodule additional operating modes has limitations with respect to the choice of RED and FED delay with respect to the operating duty cycle of the ePWMxA and ePWMxB outputs.

- The dead-band counters have also been increased to 14 bits
- Deadband and deadband high-resolution registers are now shadowed
- High-resolution deadband RED and FED have been enabled using the DBREDHR and DBFEDHR registers

**Note**

The PWM chopper is not enabled when high-resolution deadband is enabled.

High-resolution deadband RED and FED requires half-cycle clocking mode (DBCTL[HALFCYCLE] = 1).

Cannot have both RED and FED together applied to both ePWMxA and ePWMxB. RED and FED together can be applied only to either OutA OR OutB.

Phase shifting B-channel with respect to the A-channel: When PWMxB is derived from PWMxA using the DEDB_MODE bit and by delaying rising edge and falling edge by the phase shift amount. When the duty cycle value on PWMxA is less than this phase shift amount, PWMxA's falling edge has precedence over the delayed rising edge for PWMxB. Make sure the duty cycle value of the current waveform applied to the dead-band module is greater than the required phase shift amount.

The Type 4 action qualifier and dead-band outputs of the ePWM module are delayed by one TBCLK cycle in comparison to the Type 2 ePWM module, although the Type 4 behavior is the same as the Type 3 PWM. Both PWMA and PWMB signals are delayed under all circumstances.

Copyright © 2024 Texas Instruments Incorporated

**Shadow Mode:**

The shadow mode for the DBRED is enabled by setting the DBCTL[SHDWDBREDMODE] bit and the shadow register for DBFED is enabled by setting the DBCTL [SHDWDBFEDMODE] bit. Shadow mode is disabled by default for both DBRED and DBFED

If the shadow register is enabled, then the content of the shadow register is transferred to the active register on one of the following events as specified by the DBCTL [LOADREDMODE] and DBCTL [LOADFEDMODE] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero

The DBCTL register can be shadowed. The shadow mode for DBCTL is enabled by setting the DBCTL2[SHDWDBCTLMODE] bit. If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the DBCTL2[LOADDBCTLMODE] register bit:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD)
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero

**Note**

The application software must enable shadow load mode in the DBCTL[SHDWDBREDMODE] and DBCTL[SHDWDBFEDMODE] **before** programming values for the DBRED and DBFED registers. If the shadow register is enabled **after** programming the DBRED and DBFED registers, the DBRED and DBFED registers are loaded with a value of 0.

**Global Load Support**

Global load control mechanism can also be used for DBRED:DBREDHR, DBFED:DBFEDHR, and DBCTL registers by configuring the appropriate bits in the global load configuration register (GLDCFG). When global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in the Global Shadow to Active Load Control Register (GLDCTL). The Global load control mechanism is explained in Section 15.4.7.

**Note**

When DBRED/DBFED active is loaded with a new shadow value while DB counters are counting, the new DBRED/DBFED value only affects the NEXT PWMx edge and not the current edge.

A Deadband value of zero cannot be used when the Global Shadow to Active Load is set to occur at CTR=ZERO. Similarly, a Deadband value of PRD cannot be used when the Global Shadow to Active Load is set to occur at CTR=PRD.

TBPRDHR cannot be used with Global load. If high-resolution period must be changed in the application, users must write to the individual period registers from an ePWM ISR (The ISR must be synchronous with the PWM switching period), where the Global Load One-Shot bit is also written to.

### 15.7.3 Operational Highlights for the Dead-Band Submodule

The configuration options for the dead-band submodule are shown in Figure 15-34.

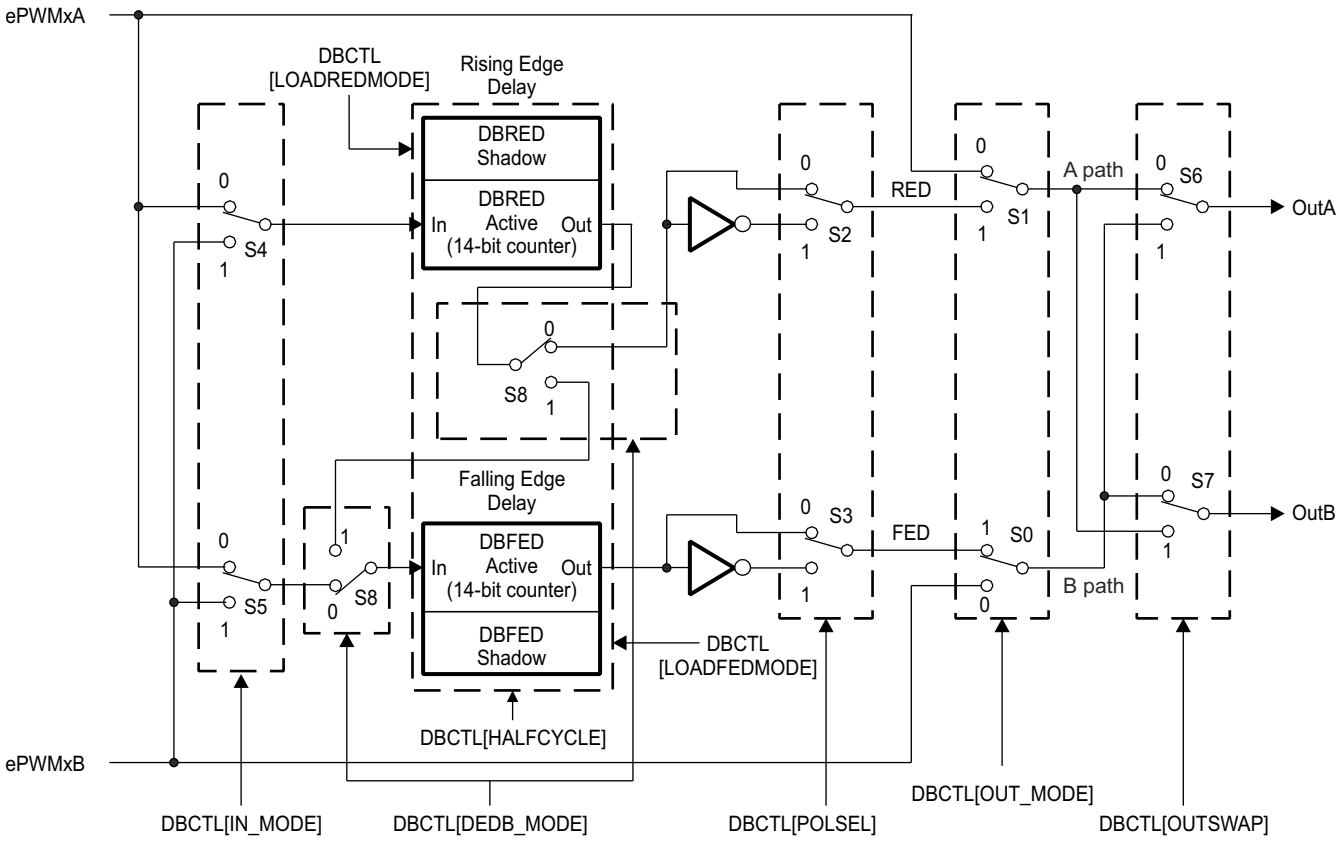

**Figure 15-34. Configuration Options for the Dead-Band Submodule**

Although all combinations are supported, not all are typical usage modes. Table 15-8 documents some classical dead-band configurations. These modes assume that the DBCTL[IN_MODE] is configured such that EPWMxA In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in Table 15-8 fall into the following categories:

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED):** Allows the user to fully disable the dead-band submodule from the PWM signal path.
- **Mode 2-5: Classical Dead-Band Polarity Settings:** These represent typical polarity configurations that can address all the active-high and active-low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in Figure 15-35. Note that to generate equivalent waveforms to Figure 15-35, configure the action-qualifier submodule to generate the signal as shown for EPWMxA.
- **Mode 6: Bypass rising-edge delay (RED) and Mode 7: Bypass falling-edge delay (FED):** Finally the last two entries in Table 15-8 show combinations where either the falling-edge delay (FED) or rising-edge delay (RED) blocks are bypassed.

Figure 15-35 shows waveforms for typical cases where 0% < duty < 100%.

**Table 15-8. Classical Dead-Band Operating Modes**

| Mode | Mode Description | DBCTL[POLSEL] | | DBCTL[OUT_MODE] | |
|---|---|---|---|---|---|
| | | S3 | S2 | S1 | S0 |
| 1 | EPWMxA and EPWMxB Passed Through (No Delay) | X | X | 0 | 0 |
| 2 | Active High Complementary (AHC) | 1 | 0 | 1 | 1 |
| 3 | Active Low Complementary (ALC) | 0 | 1 | 1 | 1 |
| 4 | Active High (AH) | 0 | 0 | 1 | 1 |
| 5 | Active Low (AL) | 1 | 1 | 1 | 1 |
| 6 | EPWMxA Out = EPWMxA In (No Delay)<br>EPWMxB Out = EPWMxA In with Falling-Edge Delay | 0 or 1 | 0 or 1 | 0 | 1 |
| 7 | EPWMxA Out = EPWMxA In with Rising-Edge Delay<br>EPWMxB Out = EPWMxB In with No Delay | 0 or 1 | 0 or 1 | 1 | 0 |

**Table 15-9. Additional Dead-Band Operating Modes**

| Mode Description | DBCTL[DEDB-MODE] | DBCTL[OUTSWAP] | |
|---|---|---|---|
| | S8 | S6 | S7 |
| EPWMxA and EPWMxB signals are as defined by OUT-MODE bits. | 0 | 0 | 0 |
| EPWMxA = A-path as defined by OUT-MODE bits.<br>EPWMxB = A-path as defined by OUT-MODE bits (rising-edge delay or delay-bypassed A-signal path) | 0 | 0 | 1 |
| EPWMxA = B-path as defined by OUT-MODE bits (falling-edge delay or delay-bypassed B-signal path)<br>EPWMxB = B-path as defined by OUT-MODE bits | 0 | 1 | 0 |
| EPWMxA = B-path as defined by OUT-MODE bits (falling-edge delay or delay-bypassed B-signal path)<br>EPWMxB = A-path as defined by OUT-MODE bits (rising-edge delay or delay-bypassed A-signal path) | 0 | 1 | 1 |
| Rising-edge delay applied to EPWMxA / EPWMxB as selected by S4 switch (IN-MODE bits) on A signal path only.<br>Falling-edge delay applied to EPWMxA / EPWMxB as selected by S5 switch (IN-MODE bits) on B signal path only. | 0 | X | X |
| Rising-edge delay and falling-edge delay applied to source selected by S4 switch (IN-MODE bits) and output to B signal path only.(1) | 1 | X | X |

(1) When this bit is set to 1, the user can always either set OUT_MODE bits such that Apath = InA or set OUTSWAP bits such that EPWMxA=Bpath. Otherwise, EPWMxA is invalid.

Copyright © 2024 Texas Instruments Incorporated

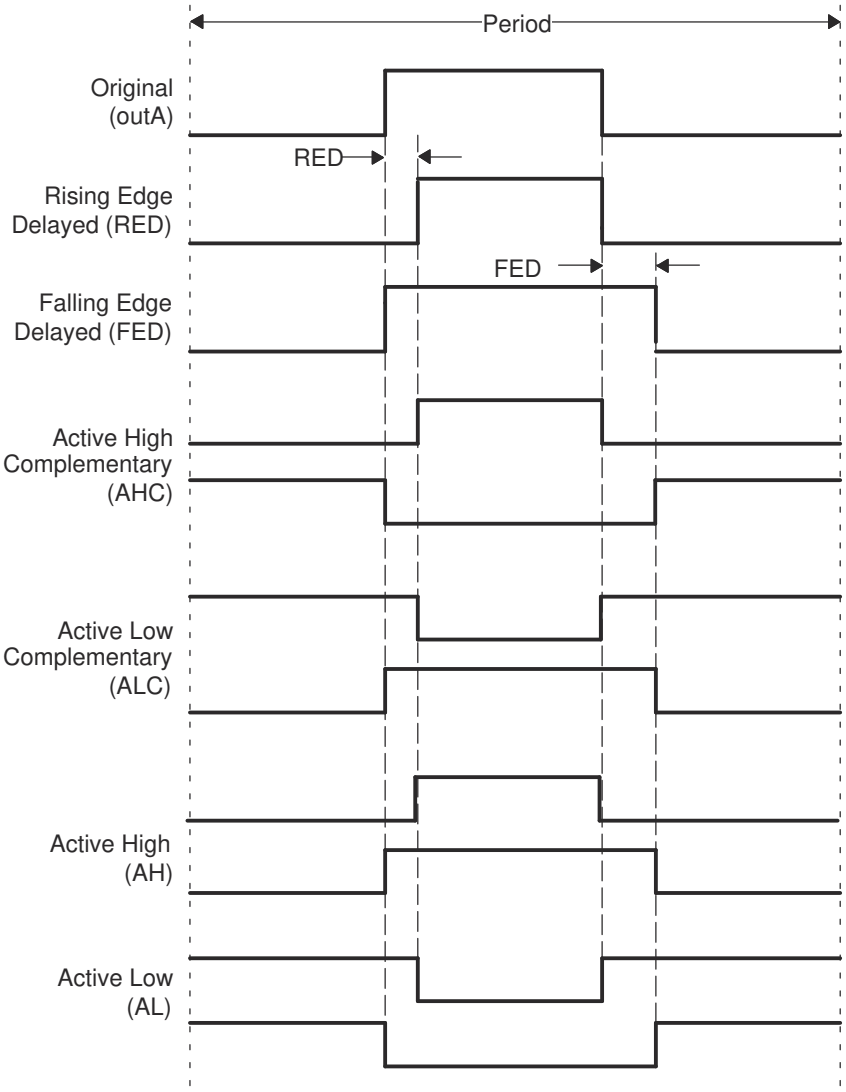

**Figure 15-35. Dead-Band Waveforms for Typical Cases (0% < Duty < 100%)**

The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the DBRED and DBFED registers. These are 10-bit registers and the value represents the number of TBCLK (time-base clock) pulses by which a signal edge is delayed. For example, the formula to calculate falling-edge-delay and rising-edge-delay is:

$FED = DBFED \times T_{TBCLK}$

$RED = DBRED \times T_{TBCLK}$

Where $T_{TBCLK}$ is the period of TBCLK, the prescaled version of EPWMCLK.

Copyright © 2024 Texas Instruments Incorporated

For convenience, delay values for various TBCLK options are shown in Table 15-10. The ePWM input clock frequency that these delay values been computed by is 100MHz.

**Table 15-10. Dead-Band Delay Values in µs as a Function of DBFED and DBRED**

| Dead-Band Value | Dead-Band Delay (µs) | | |
|---|---|---|---|
| DBFED, DBRED | TBCLK = EPWMCLK/1 | TBCLK = EPWMCLK /2 | TBCLK = EPWMCLK/4 |
| 1 | 0.01 | 0.02 | 0.04 |
| 5 | 0.05 | 0.10 | 0.20 |
| 10 | 0.10 | 0.20 | 0.40 |
| 100 | 1.00 | 2.00 | 4.00 |
| 200 | 2.00 | 4.00 | 8.00 |
| 400 | 4.00 | 8.00 | 16.00 |
| 500 | 5.00 | 10.00 | 20.00 |
| 600 | 6.00 | 12.00 | 24.00 |
| 700 | 7.00 | 14.00 | 28.00 |
| 800 | 8.00 | 16.00 | 32.00 |
| 900 | 9.00 | 18.00 | 36.00 |
| 1000 | 10.00 | 20.00 | 40.00 |

When half-cycle clocking is enabled, the formula to calculate the falling-edge-delay and rising-edge-delay becomes:

$FED = DBFED \times T_{TBCLK}/2$

$RED = DBRED \times T_{TBCLK}/2$

## 15.8 PWM Chopper (PC) Submodule

The PWM chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if pulse transformer-based gate drivers to control the power switching elements are needed.

Figure 15-36 illustrates the PWM chopper submodule within the ePWM.

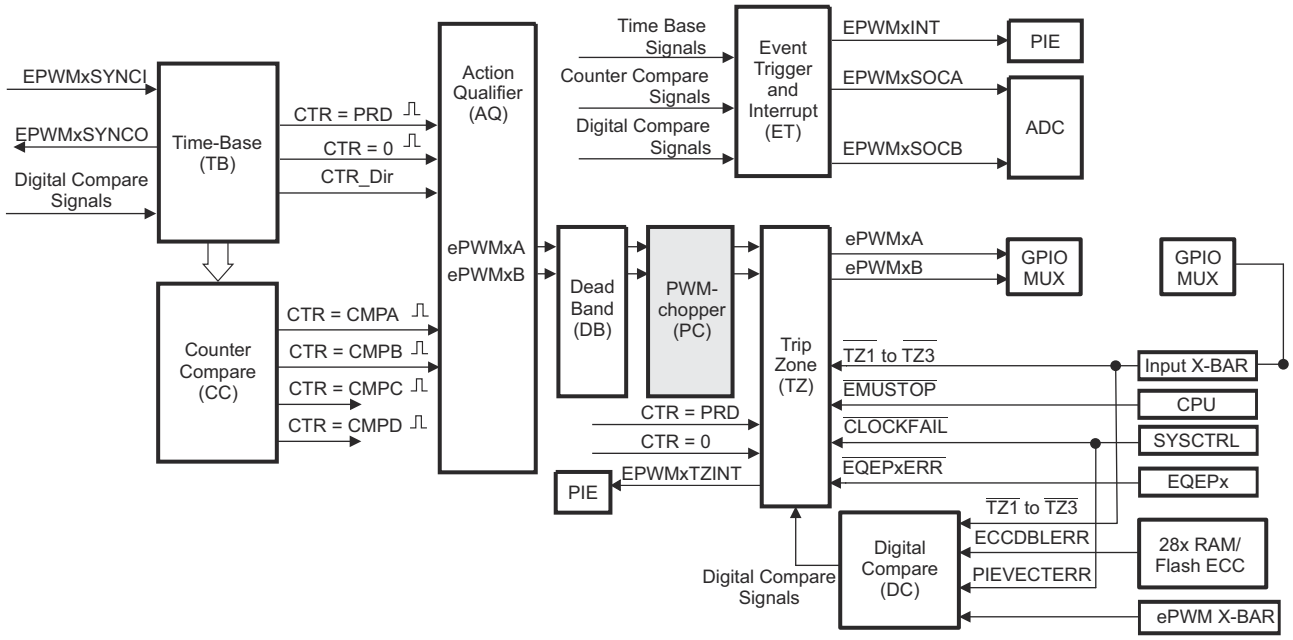

**Figure 15-36. PWM Chopper Submodule**

### *15.8.1 Purpose of the PWM Chopper Submodule*

The key functions of the PWM chopper submodule are:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

### *15.8.2 Operational Highlights for the PWM Chopper Submodule*

Figure 15-37 shows the operational details of the PWM chopper submodule. The carrier clock is derived from EPWMCLK. The clock frequency and duty cycle are controlled using the CHPFREQ and CHPDUTY bits in the PCCTL register. The one-shot block is a feature that provides a high energy first pulse to make sure hard and fast power switch turn on, while the subsequent pulses sustain pulses, making sure the power switch remains on. The one-shot width is programmed using the OSHTWTH bits. The PWM chopper submodule can be fully disabled (bypassed) using the CHPEN bit.

Copyright © 2024 Texas Instruments Incorporated

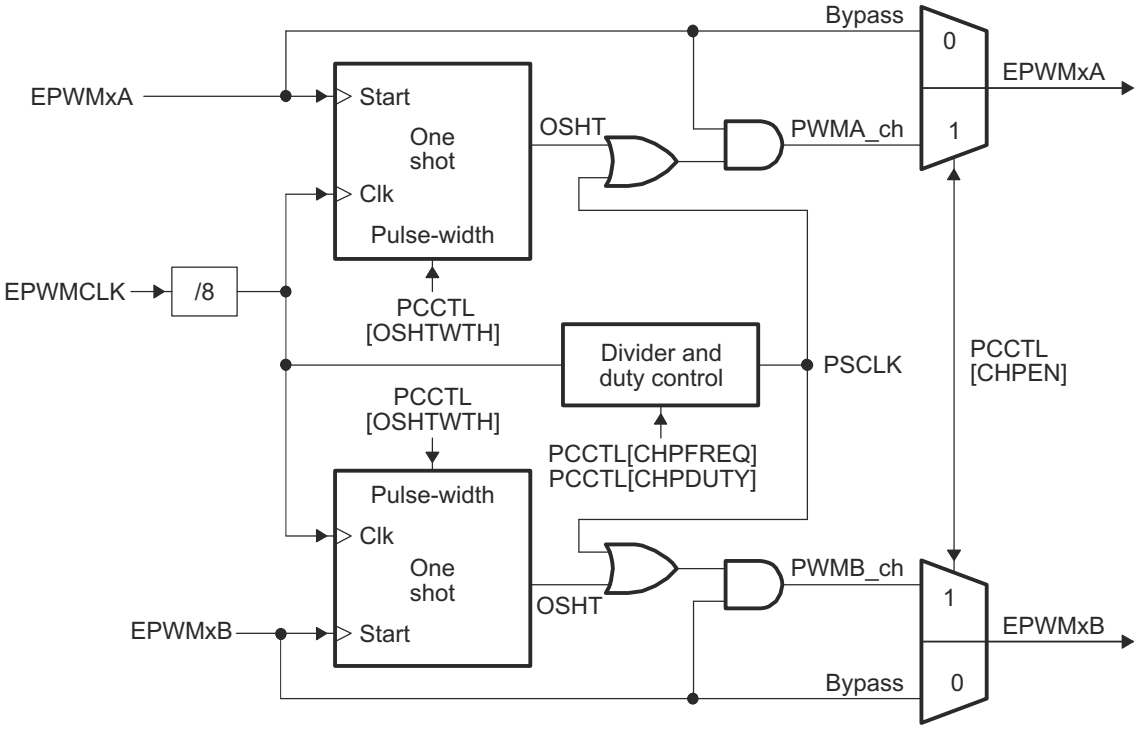

**Figure 15-37. PWM Chopper Submodule Operational Details**

### *15.8.3 Waveforms*

Figure 15-38 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

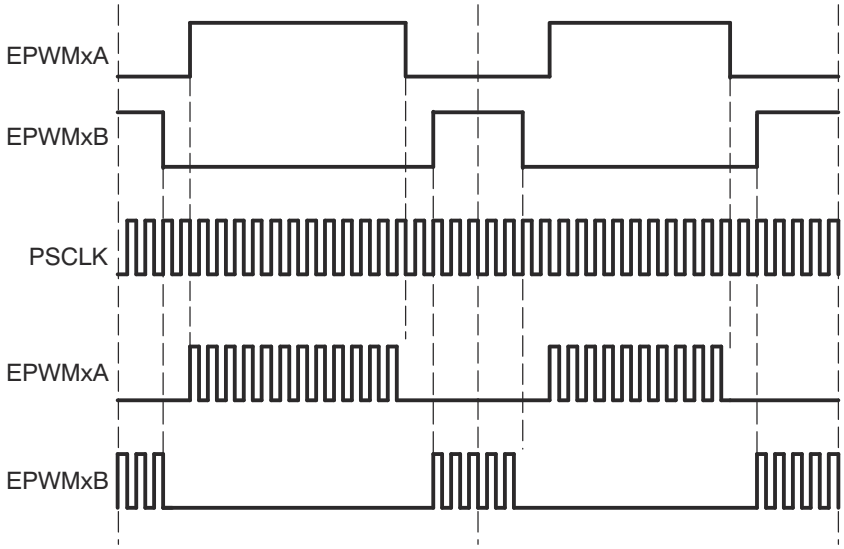

**Figure 15-38. Simple PWM Chopper Submodule Waveforms Showing Chopping Action Only**

Copyright © 2024 Texas Instruments Incorporated

#### 15.8.3.1 One-Shot Pulse

The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$$T_{1stpulse} = T_{EPWMCLK} \times 8 \times OSHTWTH$$

Where $T_{EPWMCLK}$ is the period of the system clock (EPWMCLK) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 15-39 shows the first and subsequent sustaining pulses and Table 15-11 gives the possible pulse width values for a EPWMCLK = 80MHz.

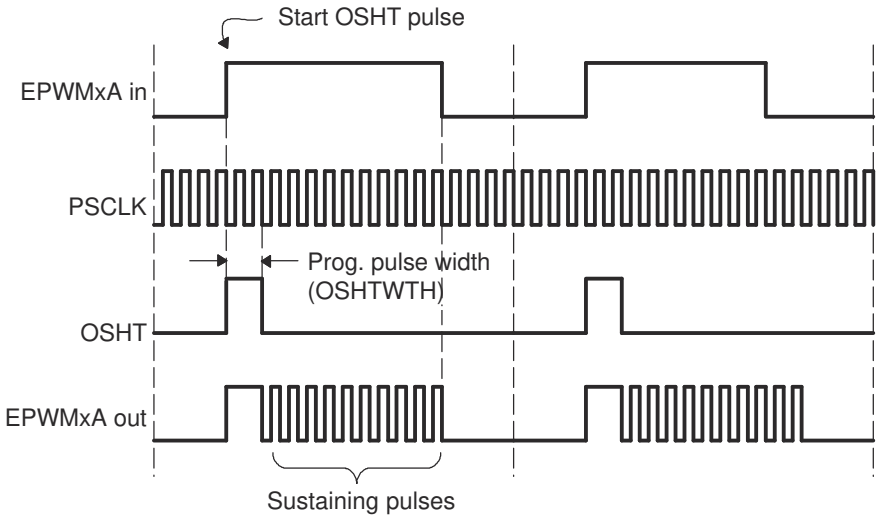

**Figure 15-39. PWM Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses**

**Table 15-11. Possible Pulse Width Values for EPWMCLK = 80MHz**

| OSHTWTH (hex) | Pulse Width (ns) |
|---|---|
| 0 | 100 |
| 1 | 200 |
| 2 | 300 |
| 3 | 400 |
| 4 | 500 |
| 5 | 600 |
| 6 | 700 |
| 7 | 800 |
| 8 | 900 |
| 9 | 1000 |
| A | 1100 |
| B | 1200 |
| C | 1300 |
| D | 1400 |
| E | 1500 |
| F | 1600 |

### 15.8.3.2 Duty Cycle Control

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses make sure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized using software control.

Figure 15-40 shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5% to 87.5%.

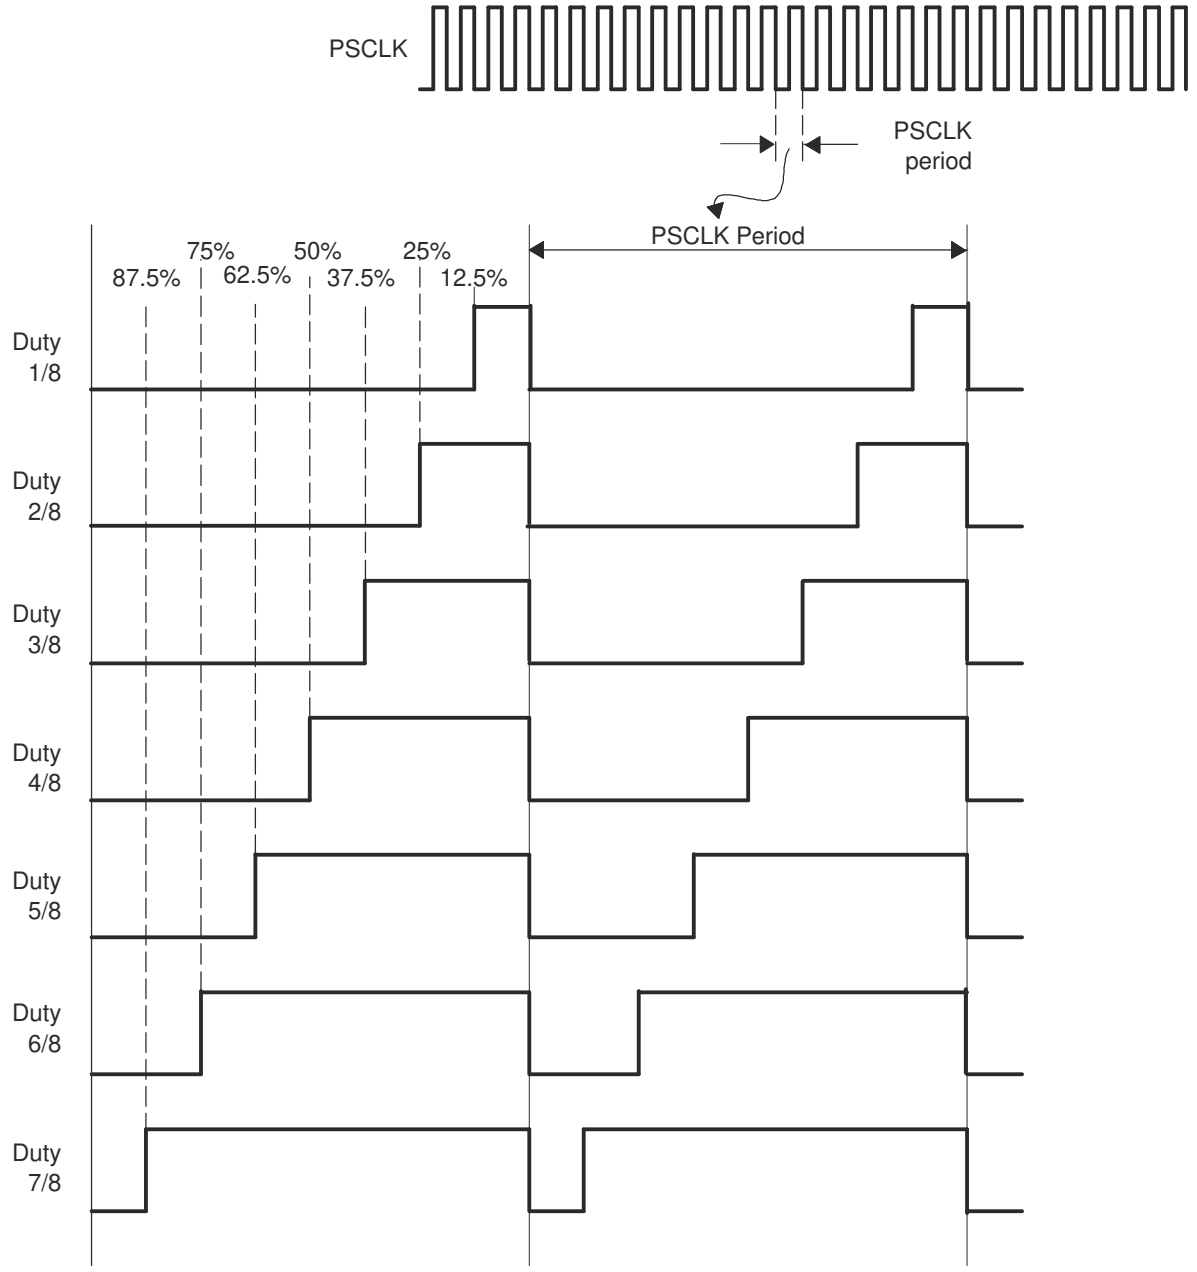

**Figure 15-40. PWM Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses**

Copyright © 2024 Texas Instruments Incorporated

## 15.9 Trip-Zone (TZ) Submodule

Each ePWM module is connected to six $\overline{TZn}$ signals ($\overline{TZ1}$ to $\overline{TZ6}$). $\overline{TZ1}$ to $\overline{TZ3}$ are sourced from the GPIO mux. $\overline{TZ4}$ is sourced from an inverted EQEPxERR signal on those devices with an EQEP module. $\overline{TZ5}$ is connected to the system clock fail logic, and $\overline{TZ6}$ is sourced from the EMUSTOP output from the CPU. These signals indicate external fault or trip conditions, and the ePWM outputs can be programmed to respond accordingly when faults occur.

Figure 15-41 illustrates the trip-zone submodule within the ePWM.

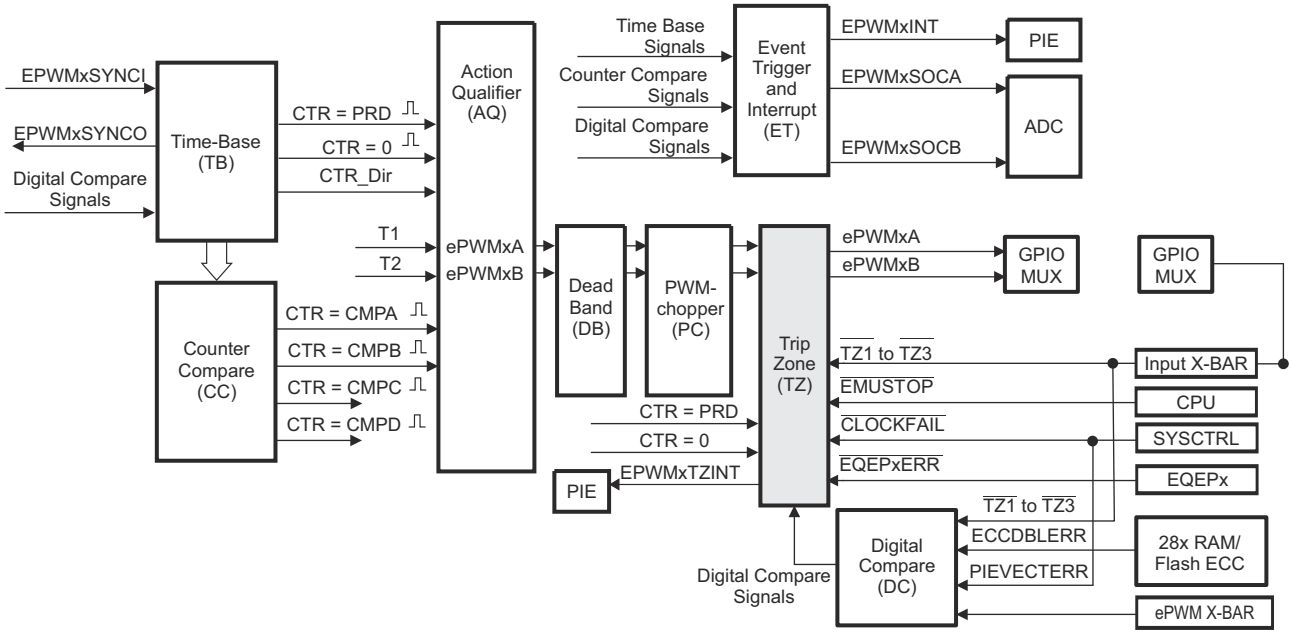

**Figure 15-41. Trip-Zone Submodule**

### *15.9.1 Purpose of the Trip-Zone Submodule*

The key functions of the trip-zone submodule are:

- Trip inputs $\overline{TZ1}$ to $\overline{TZ6}$ can be flexibly mapped to any ePWM module.
- Upon a fault condition, outputs EPWMxA and EPWMxB can be forced to one of the following:
  - High
  - Low
  - High-impedance
  - No action taken
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Support for digital compare tripping (DC) based on state of on-chip analog comparator module outputs and $\overline{TZ1}$ to $\overline{TZ3}$ signals.
- Each trip-zone input and digital compare (DC) submodule DCAEVT1/2 or DCBEVT1/2 force event can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone input.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if the trip-zone submodule is not required.

Copyright © 2024 Texas Instruments Incorporated

### 15.9.2 Operational Highlights for the Trip-Zone Submodule

The following sections describe the operational highlights and configuration options for the trip-zone submodule.

The trip-zone signals $\overline{TZ1}$ to $\overline{TZ6}$ (also collectively referred to as $\overline{TZn}$) are active-low input signals. When one of these signals goes low, or when a DCAEVT1/2 or DCBEVT1/2 force happens based on the TZDCSEL register event selection, the indication is that a trip event has occurred. Each ePWM module can be individually configured to ignore or use each of the trip-zone signals or DC events. Which trip-zone signals or DC events are used by a particular ePWM module is determined by the TZSEL register for that specific ePWM module. The trip-zone signals can or cannot be synchronized to the ePWMclock (EPWMCLK) and digitally filtered within the GPIO MUX block. A minimum of 3*TBCLK low pulse width on $\overline{TZn}$ inputs is sufficient to trigger a fault condition on the ePWM module. If the pulse width is less than this, the trip condition cannot be latched by CBC or OST latches. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on $\overline{TZn}$ inputs. The GPIOs or peripherals must be appropriately configured. For more information, see the *System Control and Interrupts* chapter.

Each $\overline{TZn}$ input can be individually configured to provide either a cycle-by-cycle or one-shot trip event for an ePWM module. DCAEVT1 and DCBEVT1 events can be configured to directly trip an ePWM module or provide a one-shot trip event to the module. Likewise, DCAEVT2 and DCBEVT2 events can also be configured to directly trip an ePWM module or provide a cycle-by-cycle trip event to the module. This configuration is determined by the TZSEL[DCAEVT1/2], TZSEL[DCBEVT1/2], TZSEL[CBCn], and TZSEL[OSHTn] control bits (where n corresponds to the trip input), respectively.

- **Cycle-by-Cycle (CBC):**

  When a cycle-by-cycle trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and EPWMxB outputs. Table 15-12 lists some of the possible actions. Independent actions can be specified based on the occurrence of the event while the counter is counting up or while the counter is counting down by appropriately configuring bits in the TZCTL2 register. Actions specified in the TZCTL2 register take effect only when the ETZE bit in TZCTL2 is set.

  Additionally, when a cycle-by-cycle trip event occurs, the cycle-by-cycle trip event flag (TZFLG[CBC]) is set and a EPWMx_TZINT interrupt is generated when enabled in the TZEINT register and interrupt controller. A corresponding flag for the event that caused the CBC event is also set in register TZCBCFLG.

  If the CBC interrupt is enabled using the TZEINT register and DCAEVT2 or DCBEVT2 are selected as CBC trip sources using the TZSEL register, it is not necessary to also enable the DCAEVT2 or DCBEVT2 interrupts in the TZEINT register, as the DC events trigger interrupts through the CBC mechanism.

  The specified condition on the inputs is automatically cleared based on the selection made with TZCLR[CBCPULSE] if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset every PWM cycle. The TZFLG[CBC] and TZCBCFLG flag bits remain set until the flag bits are manually cleared by writing to the TZCLR[CBC] and TZCBCCLR flag bits. If the cycle-by-cycle trip event is still present when the TZFLG[CBC] and TZCBCFLG register bits are cleared, then these bits are again immediately set.

- **One-Shot (OSHT):**

  When a one-shot trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and EPWMxB output. Table 15-12 lists some of the possible actions. Independent actions can be specified based on the occurrence of the event while the counter is counting up and while the counter is counting down by appropriately configuring bits in TZCTL2 register. Actions specified in TZCTL2 register take effect only when ETZE bit in TZCTL2 is set.

  Additionally, when a one-shot trip event occurs, the one-shot trip event flag (TZFLG[OST]) is set and a EPWMx_TZINT interrupt is generated when enabled in the TZEINT register and interrupt controller. A corresponding flag for the event that caused the OST event is also set in register TZOSTFLG. The one-shot trip condition must be cleared manually by writing to the TZCLR[OST] bit. If desired, the TZOSTFLG register bit can be cleared by manually writing to the corresponding bit in the TZOSTCLR register.

Copyright © 2024 Texas Instruments Incorporated

If the one-shot interrupt is enabled using the TZEINT register and DCAEVT1 or DCBEVT1 are selected as OSHT trip sources using the TZSEL register, it is not necessary to also enable the DCAEVT1 or DCBEVT1 interrupts in the TZEINT register, as the DC events trigger interrupts through the OSHT mechanism.

**Note**

Clear the TZFLG and TZOSTFLG flags after making sure that the TRIPIN source of the OST has become inactive. Otherwise, if interrupts are enabled, depending on when the flags are cleared, an OST interrupt can occur and the OST flags are zero.

- **Digital Compare Events (DCAEVT1/2 and DCBEVT1/2):**

  A digital compare DCAEVT1/2 or DCBEVT1/2 event is generated based on a combination of the DCAH/DCAL and DCBH/DCBL signals as selected by the TZDCSEL register. The signals which source the DCAH/DCAL and DCBH/DCBL signals are selected using the DCTRIPSEL register and can be either trip zone input pins or analog comparator CMPSSx signals. For more information on the digital compare submodule signals, see Section 15.11.

  When a digital compare event occurs, the action specified in the TZCTL[DCAEVT1/2] and TZCTL[DCBEVT1/2] bits is carried out immediately on the EPWMxA and EPWMxB output. Table 15-12 lists the possible actions. Independent actions can be specified based on the occurrence of the event while the counter is counting up and while the counter is counting down by appropriately configuring bits in TZCTLDCA and TZCTLDCB register. Actions specified in TZCTLDCA and TZCTLDCB registers take effect only when ETZE bit in TZCTL2 is set.

  In addition, the relevant DC trip event flag (TZFLG[DCAEVT1/2] / TZFLG[DCBEVT1/2]) is set and a EPWMx_TZINT interrupt is generated when enabled in the TZEINT register and interrupt controller.

  The specified condition on the pins is automatically cleared when the DC trip event is no longer present. The TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag bit remains set until the flag is manually cleared by writing to the TZCLR[DCAEVT1/2] or TZCLR[DCBEVT1/2] bit. If the DC trip event is still present when the TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag is cleared, then the flag is again immediately set.

The action taken when a trip event occurs can be configured individually for each of the ePWM output pins by way of the TZCTL, TZCTL2, TZCTLDCA, and TZCTLDCB register bit fields. Some of the possible actions, shown in Table 15-12, can be taken on a trip event.

**Table 15-12. Possible Actions On a Trip Event**

| TZCTL Register Bitfield Settings | EPWMxA and EPWMxB | Comment |
|---|---|---|
| 0,0 | High-Impedance | Tripped |
| 0,1 | Force to High State | Tripped |
| 1,0 | Force to Low State | Tripped |
| 1,1 | No Change | Do Nothing.<br>No change is made to the output. |

***Example 15-1. Trip-Zone Configurations***

**Scenario A:**
A one-shot trip event on $\overline{TZ1}$ pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

- Configure the ePWM1 registers as follows:
  - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A is forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B is forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM2
  - TZCTL[TZA] = 1: EPWM2A is forced high on a trip event.
  - TZCTL[TZB] = 1: EPWM2B is forced high on a trip event.

**Scenario B:**
A cycle-by-cycle event on $\overline{TZ5}$ pulls both EPWM1A, EPWM1B low.
A one-shot event on $\overline{TZ1}$ or $\overline{TZ6}$ puts EPWM2A into a high impedance state.

- Configure the ePWM1 registers as follows:
  - TZSEL[CBC5] = 1: enables $\overline{TZ5}$ as a cycle-by-cycle event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A is forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B is forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM2
  - TZSEL[OSHT6] = 1: enables $\overline{TZ6}$ as a one-shot event source for ePWM2
  - TZCTL[TZA] = 0: EPWM2A is put into a high-impedance state on a trip event.
  - TZCTL[TZB] = 3: EPWM2B ignores the trip event.

**Note**

When configuring the GPIOs and INPUT X-BAR/EPWM X-BAR options, be aware that a change in the X-BAR input selections can cause an unwanted event. Therefore, set up the GPIO and X-BAR input configurations before enabling the ePWM Trip-Zone. If a requirement is to change the GPIO/X-BAR configurations while the ePWM Trip-Zone is enabled, the user can turn off the TRIPs by clearing the TZSEL register and reconfiguring the TRIP selection (TZSEL) after the INPUT XBAR selection is changed.

### *15.9.3 Generating Trip Event Interrupts*

Figure 15-42 and Figure 15-43 illustrate the trip-zone submodule control and interrupt logic, respectively. DCAEVT1/2 and DCBEVT1/2 signals are described in further detail in Section 15.11.

## 15.10 Event-Trigger (ET) Submodule

The key functions of the event-trigger submodule are:

- Receives event inputs generated by the time-base, counter-compare, and digital-compare submodules
- Uses the time-base direction information for up/down event qualification
- Uses prescaling logic to issue interrupt requests and ADC start of conversion at:
  - Every event
  - Every second event
  - Up to every fifteenth event
- Provides full visibility of event generation using event counters and flags
- Allows software forcing of Interrupts and ADC start of conversion

The event-trigger submodule manages the events generated by the time-base submodule, the counter-compare submodule, and the digital-compare submodule to generate an interrupt to the CPU and a start of conversion pulse to the ADC when a selected event occurs.

Figure 15-44 illustrates the event-trigger submodule within the ePWM.

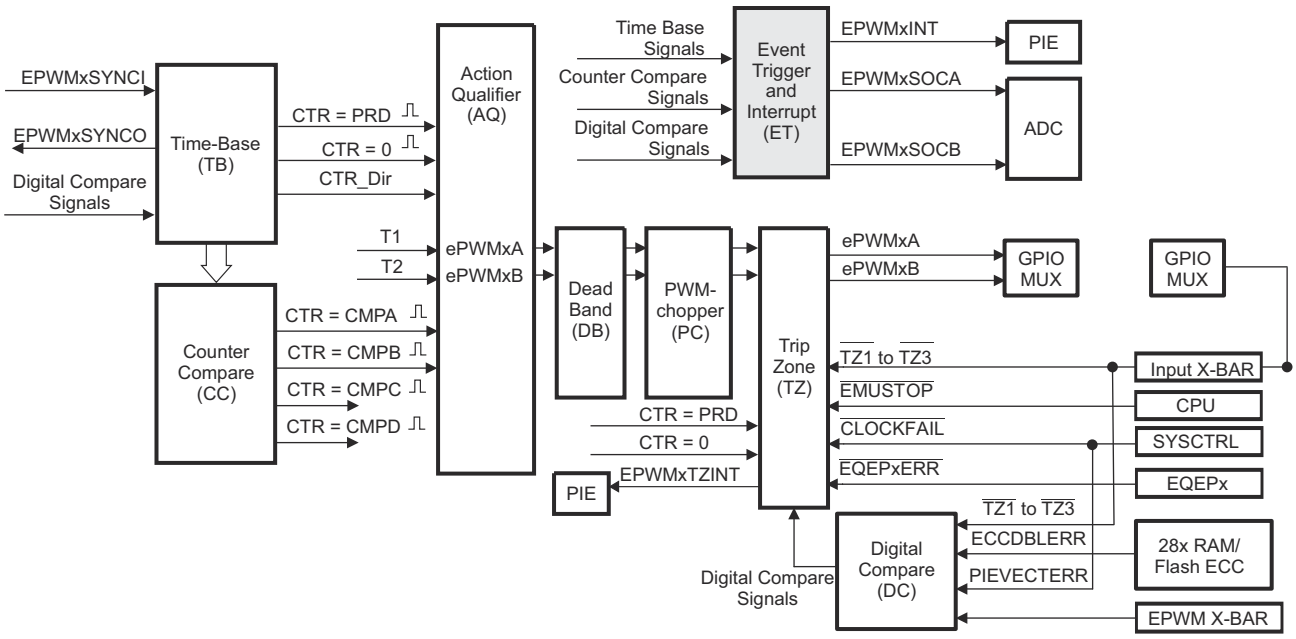

**Figure 15-44. Event-Trigger Submodule**

### 15.10.1 Operational Overview of the ePWM Event-Trigger Submodule

The event-trigger submodule monitors various event conditions (shown as inputs on the left side of Figure 15-45) and can be configured to prescale these events before issuing an Interrupt request or an ADC start of conversion. The event-trigger prescaling logic can issue Interrupt requests and ADC start of conversion at:

- Every event
- Every second event
- Up to every fifteenth event

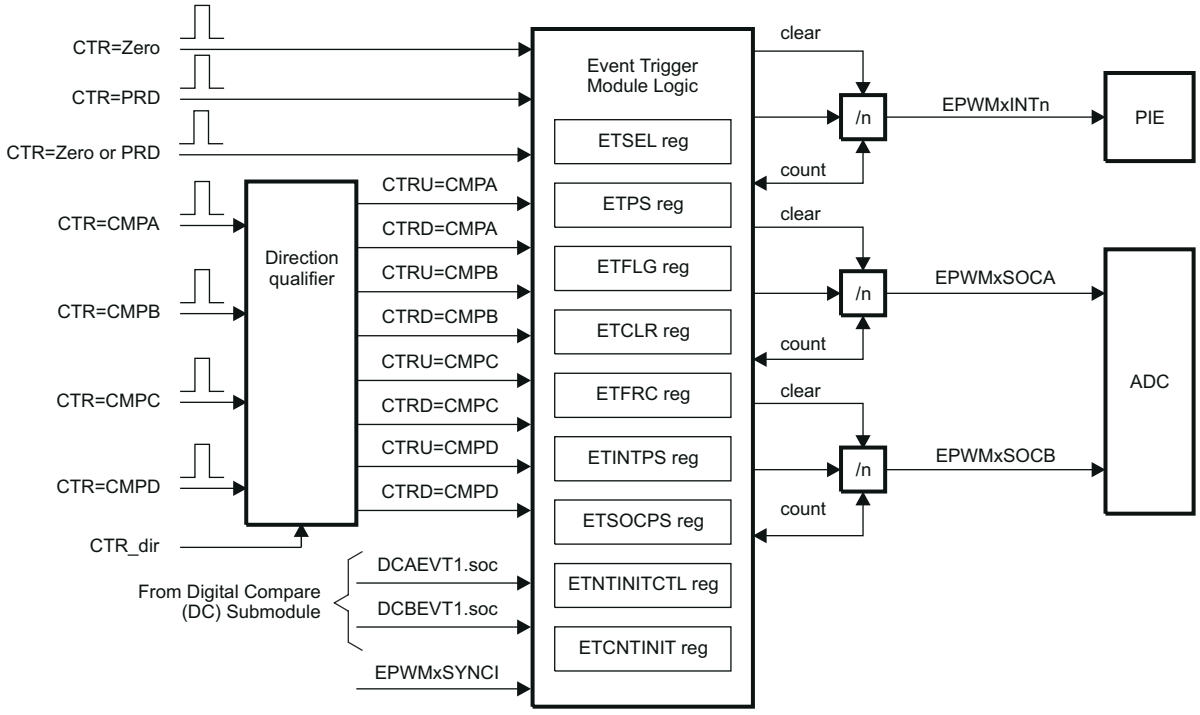

**Figure 15-45. Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs**

- ETSEL - This selects which of the possible events trigger an interrupt or start an ADC conversion.
- ETPS - This programs the event prescaling options mentioned above.
- ETFLG - These are flag bits indicating status of the selected and prescaled events.
- ETCLR - These bits allow clearing the flag bits in the ETFLG register using software.
- ETFRC - These bits allow software forcing of an event. Useful for debugging or software intervention.
- ETINTPS - This programs the interrupt event prescaling options, supporting count and period up to 15 events.
- ETSOCPS - This programs the SOC event prescaling options, supporting count and period up to 15 events.
- ETCNTINITCTL - These bits enable ETCNTINIT initialization using SYNC event or using software force.
- ETCNTINIT - These bits allow initializing INT/SOCA/SOCB counters on SYNC events (or software force) with user programmed value.

A more detailed look at how the various register bits interact with the Interrupt and ADC start of conversion logic are shown in Figure 15-46, Figure 15-47, and Figure 15-48.

Figure 15-46 shows the event-trigger's interrupt generation logic. The interrupt-period (ETPS[INTPRD]) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt.
- Generate an interrupt on every event.
- Generate an interrupt on every second event.
- Generate an interrupt on every third event.

Copyright © 2024 Texas Instruments Incorporated

The selection made on ETPS[INTPSSEL] bit determines whether ETINTPS register, INTCNT2 and INTPRD2 bit fields determine frequency of events (interrupt once every 0-15 events).

The event that can cause an interrupt is configured by the interrupt selection (ETSEL[INTSEL]) and (ETSEL[INTSELCMP]) bits. The event can be one of the following:

- Time-base counter equal to zero (TBCTR = 0x00).
- Time-base counter equal to period (TBCTR = TBPRD).
- Time-base counter equal to zero or period (TBCTR = 0x00 || TBCTR = TBPRD).
- Time-base counter equal to the compare A register (CMPA) when the timer is incrementing.
- Time-base counter equal to the compare A register (CMPA) when the timer is decrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is incrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is decrementing.
- Time-base counter equal to the compare C register (CMPC) when the timer is incrementing.
- Time-base counter equal to the compare C register (CMPC) when the timer is decrementing.
- Time-base counter equal to the compare D register (CMPD) when the timer is incrementing.
- Time-base counter equal to the compare D register (CMPD) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter ETPS[INTCNT] or ETINTPS[INTCNT2] register bits based off of the selection made using ETPS[INTPSSEL]. That is, when the specified event occurs the ETPS[INTCNT] or ETINTPS[INTCNT2] bits are incremented until the bits reach the value specified by ETPS[INTPRD] or ETINTPS[INTPRD2] determined again by the selection made in ETPS[INTPSSEL]. When ETPS[INTCNT] = ETPS[INTPRD], the counter stops counting and the counter output is set. The counter is only cleared when an interrupt is sent to the interrupt controller.

When ETPS[INTCNT] reaches ETPS[INTPRD], the following behavior occurs. [The following behavior is also applicable to ETINTPS[INTCNT2] and ETINTPS[INTPRD2]:

- If interrupts are enabled, ETSEL[INTEN] = 1 and the interrupt flag is clear, ETFLG[INT] = 0, then an interrupt pulse is generated and the interrupt flag is set, ETFLG[INT] = 1, and the event counter is cleared ETPS[INTCNT] = 0. The counter begins counting events again.
- If interrupts are disabled, ETSEL[INTEN] = 0, or the interrupt flag is set, ETFLG[INT] = 1, the counter stops counting events when the counter reaches the period value ETPS[INTCNT] = ETPS[INTPRD].
- If interrupts are enabled, but the interrupt flag is already set, then the counter holds the output high until the ENTFLG[INT] flag is cleared. This allows for one interrupt to be pending while one is serviced.

Writing a 0 to the INTPRD bits automatically clears the counter (INTCNT = 0) and the counter output resets (so no interrupts are generated). For all other writes to INTPRD, INTCNT retains the previous value. INTCNT resets when INTCNT overflows. Writing a 1 to the ETFRC[INT] bit increments the event counter INTCNT. The counter behaves as previously described when INTCNT = INTPRD. When INTPRD = 0, the counter is disabled and hence no events are detected and the ETFRC[INT] bit is also ignored. The same applies to ETINTPS[INTCNT2] and ETINTPS[INTPRD2].

The previous definition means that an interrupt on every event, on every second event, or on every third event if using the INTCNT and INTPRD can be generated. An interrupt on every event up to 15 events if using the INTCNT2 and INTPRD2 can be generated.

The INTCNT2 value can be initialized with the value from ETCNTINIT[INTINIT] based on the selection made in ETCNTINITCTL[INTINITEN]. When ETCNTINITCTL[INTINITEN] is set, then initialization of INTCNT2 counter with contents of ETCNTINIT[INTINIT] on a SYNC event or software force is determined by ETCNTINITCTL[INTINITFRC].

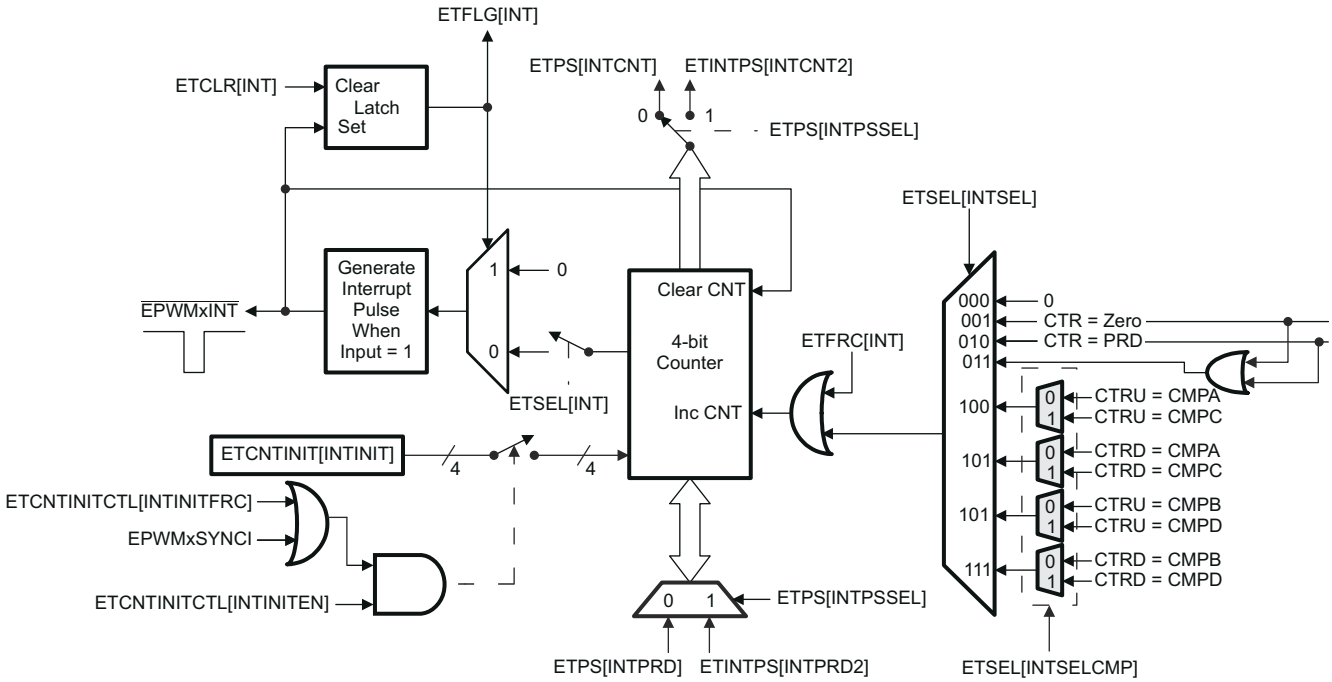

**Figure 15-46. Event-Trigger Interrupt Generator**

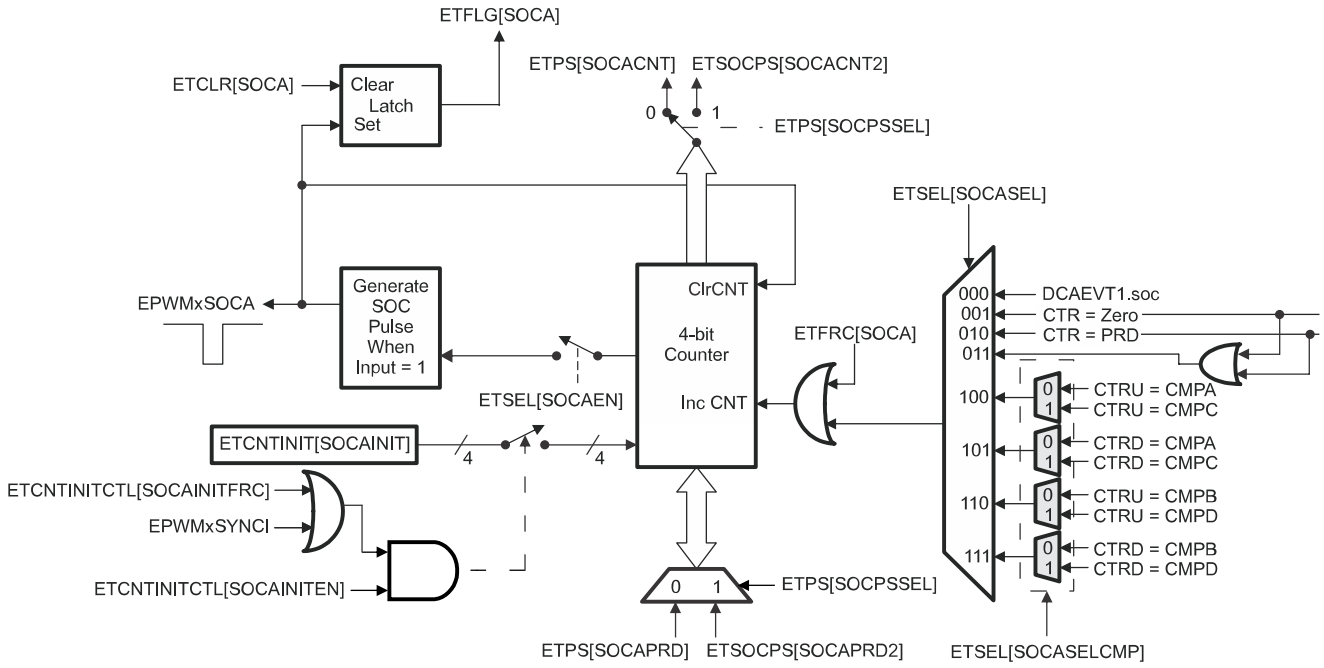
Figure 15-47 shows the operation of the event-trigger's start-of-conversion-A (SOCA) pulse generator. The enhancements include SOCASELCMP and SOCBSELCMP bit fields defined in the ETSEL register enable CMPC and CMPD events respectively to cause a start of conversion. The ETPS[SOCPSSEL] bit field determines whether SOCACNT2 and SOCAPRD2 take control or not. The ETPS[SOCACNT] counter and ETPS[SOCAPRD] period values behave similarly to the interrupt generator except that the pulses are continuously generated. That is, the pulse flag ETFLG[SOCA] is latched when a pulse is generated, but the interrupt generator does not stop further pulse generation. The enable and disable bit ETSEL[SOCAEN] stops pulse generation, but input events can still be counted until the period value is reached as with the interrupt generation logic. The event that triggers an SOCA and SOCB pulse can be configured separately in the ETSEL[SOCASEL] and ETSEL[SOCBSEL] bits. The possible events are the same events that can be specified for the interrupt generation logic with the addition of the DCAEVT1.soc and DCBEVT1.soc event signals from the digital compare (DC) submodule. The SOCACNT2 initialization scheme is very similar to the interrupt generator with respective enable, value initialize and SYNC or software force options.

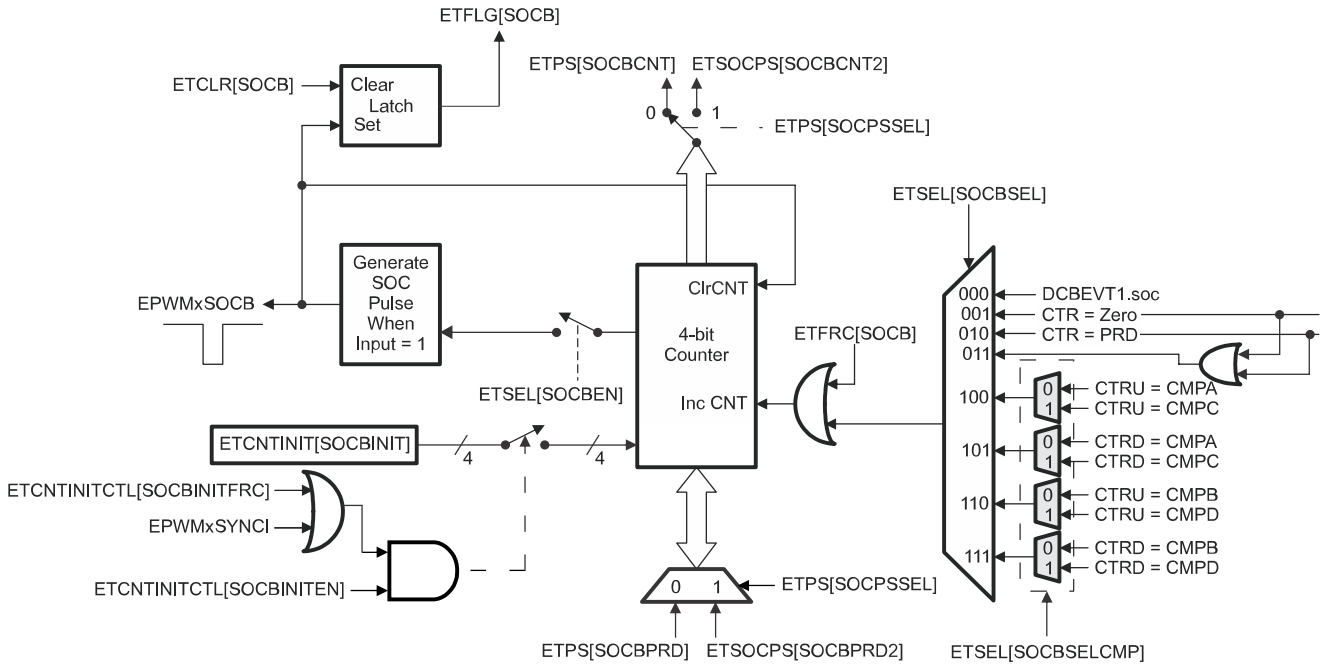
Copyright © 2024 Texas Instruments Incorporated



NOTE: The DCAEVT1.soc signals are generated by the Digital Compare (DC) submodule in Section 15.11.

**Figure 15-47. Event-Trigger SOCA Pulse Generator**

Figure 15-48 shows the operation of the event-trigger's start-of-conversion-B (SOCB) pulse generator. The event-trigger's SOCB pulse generator operates the same way as the SOCA.



NOTE: The DCBEVT1.soc signals are generated by the Digital Compare (DC) submodule in Section 15.11.

## 15.11 Digital Compare (DC) Submodule

Figure 15-49 illustrates where the digital compare (DC) submodule signals interface to other submodules in the ePWM system.

The eCAP input signals are sourced from the Input X-BAR signals as shown in Figure 15-50.

On this device, any of the GPIO pins can be flexibly mapped to be the trip-zone input and trip inputs to the trip-zone submodule and digital compare submodule. The Input X-BAR Input Select (INPUTxSELECT) register defines which GPIO pins gets assigned to be the trip-zone inputs / trip inputs.

The digital compare (DC) submodule compares signals external to the ePWM module (for instance, CMPSSx signals from the analog comparators) to directly generate PWM events/actions which then feed to the event-trigger, trip-zone, and time-base submodules. Additionally, blanking window functionality is supported to filter noise or unwanted pulses from the DC event signals.

**Note**

The user is responsible for driving the correct state on the selected pin before enabling the clock and configuring the trip input for the respective ePWM peripheral to avoid spurious latch of the TRIP signal.

### 15.11.1 Purpose of the Digital Compare Submodule

The key functions of the digital compare submodule are:

- Analog comparator (COMP) module outputs fed though the Input X-BAR, EPWM X-BAR, externally using the GPIO peripheral, interrupt controller signals, ECC error signals, TZ1, $\overline{TZ2}$, and $\overline{TZ3}$ inputs generate Digital Compare A High/Low (DCAH, DCAL) and Digital Compare B High/Low (DCBH, DCBL) signals.
- DCAH/L and DCBH/L signals trigger events that can then either be filtered or applied directly to the trip-zone, event-trigger, and time-base submodules to:
  - generate a trip zone interrupt
  - generate an ADC start of conversion
  - force an event
  - generate a synchronization event for synchronizing the ePWM module TBCTR.
- Event filtering (blanking window logic) can optionally blank the input signal to remove noise.

### 15.11.2 Enhanced Trip Action Using CMPSS

To allow multiple CMPSS at a time to affect DCA/BEVTx events and trip actions, there is a OR logic to bring together ALL trip inputs (up to 15) from sources external to the ePWM module and feed into DCAH, DCAL, DCBH, and DCBL as a “combinational input” using the DCTRIPSEL register. This is configured by selecting “Trip combination input” (value of 0xF) in the DCTRIPSEL register.

There is a discrete choice of which trip inputs to put through the combinational logic for generating the DCAH, DCAL, DCBH, and DCBL signals. This is achieved using the DCAHTRIPSEL, DCALTRIPSEL, DCBHTRIPSEL, and DCBLTRIPSEL register selections. Inputs selected for combinational input are passed through to the DCTRIPSEL register.

### 15.11.3 Using CMPSS to Trip the ePWM on a Cycle-by-Cycle Basis

When using the CMPSS to trip the ePWM on a cycle-by-cycle basis, steps can be taken to prevent an asserted comparator trip state in one PWM cycle from extending into the following cycle. The CMPSS can be used to signal a trip condition to the downstream ePWM modules. For applications like peak current mode control, only one trip event per PWM cycle is expected. Under certain conditions, it is possible for a sustained or late trip event (arriving near the end of a PWM cycle) to carry over into the next PWM cycle if precautions are not taken. If either the CMPSS Digital Filter or the ePWM Digital Compare (DC) submodule is configured to qualify the comparator trip signal, “N” number of clock cycles of qualification are introduced before the ePWM trip logic can respond to logic changes of the trip signal. Once an ePWM trip condition is qualified, the trip condition remains active for N clock cycles after the comparator trip signal has de-asserted. If a qualified comparator trip signal remains asserted within N clock cycles prior to the end of a PWM cycle, the trip condition is not cleared until after the following PWM cycle has started. Thus, the new PWM cycle detects a trip condition as soon as the cycle begins.

To avoid this undesired trip condition, the application can take steps to make sure that the qualified trip signal seen by the ePWM trip logic is deasserted prior to the end of each PWM cycle. This can be accomplished through various methods:

- Design the system such that a comparator trip is not asserted within N clock cycles prior to the end of the PWM cycle.
- Activate blanking of the comparator trip signal using the ePWM event filter at least two clock cycles prior to the PWMSYNCPER signal and continue blanking for at least N clock cycles into the next PWM cycle.
- If the CMPSS COMPxLATCH path is used, clear the COMPxLATCH at least N clock cycles prior to the end of the PWM cycle. The latch can be cleared by software (using COMPSTSCLR) or by generating an early PWMSYNCPER signal. The ePWM modules on this device include the ability to generate PWMSYNCPER upon a CMPC or CMPD match (using HRPCTL) for arbitrary PWMSYNCPER placement within the PWM cycle.

### 15.11.4 Operation Highlights of the Digital Compare Submodule

The following sections describe the operational highlights and configuration options for the digital compare submodule.

#### 15.11.4.1 Digital Compare Events

As described in Section 15.11.1, trip zone inputs ($\overline{TZ1}$, $\overline{TZ2}$, and $\overline{TZ3}$) and CMPSSx signals from the analog comparator (COMP) module can be selected using the DCTRIPSEL bits to generate the Digital Compare A High and Low (DCAH/L) and Digital Compare B High and Low (DCBH/L) signals. Then, the configuration of the TZDCSEL register qualifies the actions on the selected DCAH/L and DCBH/L signals, which generate the DCAEVT1/2 and DCBEVT1/2 events (Event Qualification A and B).

**Note**

The $\overline{TZn}$ signals, when used as a DCEVT tripping functions, are treated as a normal input signal and can be defined to be active-high or active-low inputs. ePWM outputs are asynchronously tripped when either the $\overline{TZn}$, DCAEVTx.force, or DCBEVTx.force signals are active. For the condition to remain latched, a minimum of 3 * TBCLK sync pulse width is required. If pulse width is < 3*TBCLK sync pulse width, the trip condition can or can not get latched by CBC or OST latches.

The DCAEVT1/2 and DCBEVT1/2 events can then be filtered to provide a filtered version of the event signals (DCEVTFILT) or the filtering can be bypassed. Filtering is discussed further in Event Filtering. Either the DCAEVT1/2 and DCBEVT1/2 event signals or the filtered DCEVTFILT event signals can generate a force to the trip zone module, a TZ interrupt, an ADC SOC, or a PWM sync signal.

- **force signal:** DCAEVT1/2.force signals force trip zone conditions which either directly influence the output on the EPWMxA pin (using TZCTL, TZCTLDCA, TZCTLDCB register configurations) or, if the DCAEVT1/2 signals are selected as one-shot or cycle-by-cycle trip sources (using the TZSEL register), the DCAEVT1/2.force signals can effect the trip action using the TZCTL or TZCTL2 register configurations. The DCBEVT1/2.force signals behaves similarly, but affect the EPWMxB output pin instead of the EPWMxA output pin.

  The priority of conflicting actions on the TZCTL, TZCTL2, TZCTLDCA and TZCTLDCB registers is as follows (highest priority overrides lower priority):

  Output EPWMxA:
  - TZA (highest) -> DCAEVT1 -> DCAEVT2 (lowest)
  - TZAU (highest) -> DCAEVT1U -> DCAEVT2U (lowest)
  - TZAD (highest) -> DCAEVT1D -> DCAEVT2D (lowest)

  Output EPWMxB:
  - TZB (highest) -> DCBEVT1 -> DCBEVT2 (lowest)
  - TZBU (highest) -> DCBEVT1U -> DCBEVT2U (lowest)
  - TZBD (highest) -> DCBEVT1D -> DCBEVT2D (lowest)
- **interrupt signal:** DCAEVT1/2.interrupt signals generate trip zone interrupts to the interrupt controller. To enable the interrupt, set the DCAEVT1, DCAEVT2, DCBEVT1, or DCBEVT2 bits in the TZEINT register. Once one of these events occurs, an EPWMxTZINT interrupt is triggered, and the corresponding bit in the TZCLR register must be set to clear the interrupt.
- **soc signal:** The DCAEVT1.soc signal interfaces with the event-trigger submodule and can be selected as an event which generates an ADC start-of-conversion-A (SOCA) pulse using the ETSEL[SOCASEL] bit. Likewise, the DCBEVT1.soc signal can be selected as an event which generates an ADC start-of-conversion-B (SOCB) pulse using the ETSEL[SOCBSEL] bit.
- **sync signal:** The DCAEVT1.sync and DCBEVT1.sync events are ORed with the EPWMxSYNCI input signal and the TBCTL[SWFSYNC] signal to generate a synchronization pulse to the time-base counter.

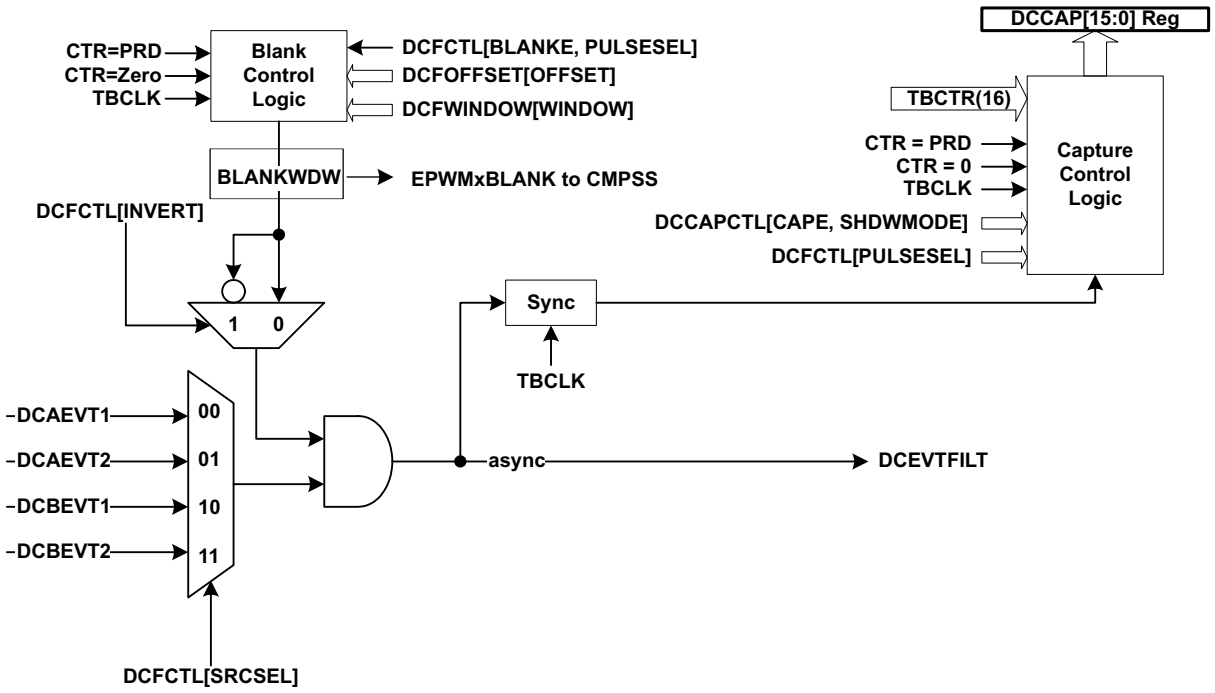
### 15.11.4.2 Event Filtering

**Blank Control Logic:** The DCAEVT1/2 and DCBEVT1/2 events can be filtered using event filtering logic to remove noise by optionally blanking events for a certain period of time. This is useful for cases where the analog comparator outputs can be selected to trigger DCAEVT1/2 and DCBEVT1/2 events, and the blank control logic is used to filter out potential noise on the signal prior to tripping the PWM outputs or generating an interrupt or ADC start-of-conversion. Blank control logic is used to define a blanking window, which ignores all event occurrences on the signal while the window is active. The blanking window is configured in the DCFCTL, DCFOFFSET, and DCFWINDOW registers. The DCFCTL register enables the blanking window and aligns the blanking window to either a CTR = PRD pulse or a CTR = 0 pulse or both CTR = PRD and CTR = 0 as specified by DCFCTL[PULSESEL]. DCFCTL[SRCSEL] selects the DCxEVTy event source for the DCEVTFILT signal. An offset value in TBCLK counts is programmed into the DCFOFFSET register, which determines at what point after the CTR = PRD or CTR = 0 pulse the blanking window starts. The duration of the blanking window, in number of TBCLK counts after the offset counter expires, is written to the DCFWINDOW register by the application. Before and after the blanking window ends, events can generate soc, sync, interrupt, and force signals as before. Figure 15-55 shows the details of the event filtering logic.



A. On the F2837x/F2807x family of devices, EPWMxBLANK does not go to the CMPSS

**Figure 15-55. Event Filtering**

**Capture Control Logic:** The event filtering can also capture the TBCTR value of the selected DCxEVTy event as configured in the DCCAPCTL register. When capture control logic is enabled, the selected DCxEVTy event triggers capture of the TBCTR to the active register. The CPU reads directly from the active register unless shadow mode is enabled by DCCAPCTL[SHDWMODE]. When shadow mode is enabled, the active register information is copied to shadow register on the event specified by DCFCCTL[PULSESEL], and the CPU reads from the shadow register. After the selected DCxEVTy event, no further capture events occur until the event specified by DCCAPCTL[CAPMODE]. The CAPMODE can be configured two ways: (1) no further capture events occur until the event defined by DCFCTL[PULSESEL] or (2) no further capture events occur until the compare-event flag at DCCAPCTL[CAPSTS] is cleared by DCCAPCTL[CAPCLR].

#### 15.11.4.3 Valley Switching

Event filtering depicts the valley switching function along with the event filtering logic described in Event Filtering. This function can be used to achieve programmable valley switching without any additional external circuitry. This module provides an on-chip hardware mechanism that can:

- Capture the oscillation period
- Accurately delay the PWM switching instant
- Allow a programmable number of edges before the delay takes effect
- Provide multiple choices of triggers and events
- Allow easy adaptability for optimum performance under changing system/operating conditions

The DCxEVTy signal needs further processing to support valley switching. Here is a brief description of how valley switching function is enabled:

1. Select one of the DCxEVTy events as input to the valley switching block (DCFCTL[SRCSEL]) with an option to add the blanking window (Blank Control Logic). This is where the comparator output (or external input) above is selected as an input to the valley switching block.
2. Configure the edge filter to capture ‘n’ rising, falling or both edges through the edge selection logic (DCFCTL[EDGEMODE, EDGECOUNT]).
3. Select the correct event to reset and restart the edge filter (VCAPCTL[TRIGSEL]). Edge capturing event is triggered or armed by this selected edge.
4. Enable valley capture logic (VCAPCTL[VCAPE]).
5. Select the start edge that indicates the start of capture for oscillation period measurement (VCNTCFG[STARTEDGE]). This is where the 16-bit counter starts counting.
6. Select the stop edge (VCNTCFG[STOPEDGE]) that indicates the edge at which the 16-bit counter stops counting. The captured counter value (CNTVAL) provides oscillation period information.
   - The STOPEDGE value must always be greater than STARTEDGE value.
7. Configure and apply the captured delay (CNTVAL) to the edge filtered DCxEVTy signal. The CNTVAL value can be applied as is or applied in conjunction with a software programmed value (useful for offset adjustment) (SWVDELVAL) or only a fraction of the delay can be applied with or without SWVDELVAL. This is useful to correctly apply a delay corresponding to the valley point. (VCAPCTL[VDELAYDIV])
8. Configure VCAPCTL[EDGEFILTDLYSEL] to apply hardware delay based on the captured value above.

Once the counter is stopped, counter value is copied into CNTVAL register and counter is reset to zero. No further captures are done until the logic is triggered again by occurrence of event selected by VCAPCTL[TRIGSEL]. In this implementation, the software trigger is used as the source for VCAPCTL[TRIGSEL]. Upon occurrence of the trigger event, irrespective of the current status of the counter, the counter is reset and starts counting from zero upon occurrence of the STARTEDGE. Similarly, upon occurrence of the trigger event, the edge filter is reset and starts counting from zero upon occurrence of the STARTEDGE.

Output from the valley switching block (DCEVTFILT) is then used to synchronize the PWM time-base. The process is shown in Figure 15-57.

**Note**

A specific application example showcasing the usage of valley switching hardware and software is available in C2000Ware.

## 15.13 Applications to Power Topologies

An ePWM module has all the local resources necessary to operate completely as a standalone module or to operate in synchronization with other identical ePWM modules.

### *15.13.1 Overview of Multiple Modules*

Previously in this chapter, all discussions have described the operation of a single module. To facilitate the understanding of multiple modules working together in a system, the ePWM module described in reference is represented by the more simplified block diagram shown in Figure 15-59. This simplified ePWM block shows only the key resources needed to explain how a multiswitch power topology is controlled with multiple ePWM modules working together.

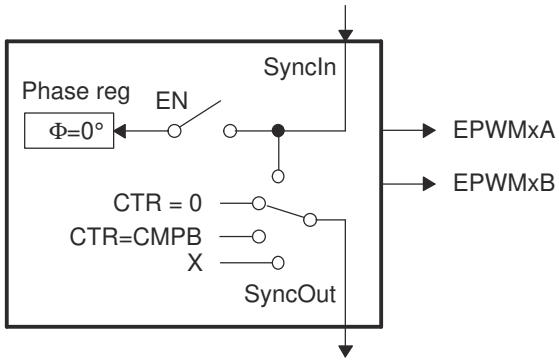

**Figure 15-59. Simplified ePWM Module**

Copyright © 2024 Texas Instruments Incorporated

### 15.13.2 Key Configuration Capabilities

The key configuration choices available to each module are as follows:

- Options for SyncIn
  - Load own counter with phase register on an incoming sync strobe—enable (EN) switch closed
  - Do nothing or ignore incoming sync strobe—enable switch open
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides no sync to other modules—SyncOut connected to X (disabled)
- Options for SyncOut
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides no sync to other modules—SyncOut connected to X (disabled)

For each choice of SyncOut, a module can also choose to load the counter with a new phase value on a SyncIn strobe input or choose to ignore the value (that is, by the enable switch). Although various combinations are possible, the two most common—Master module and Slave module modes—are shown in Figure 15-60.

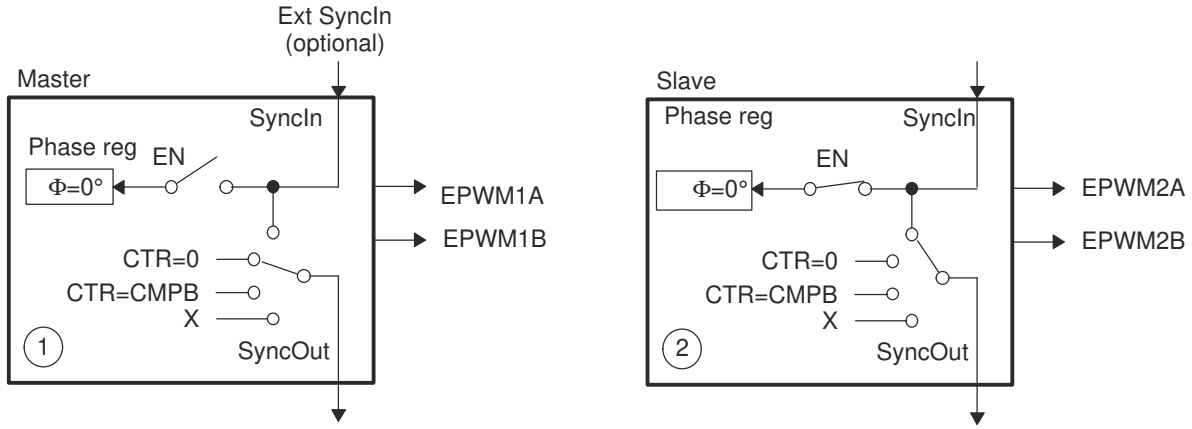

**Figure 15-60. EPWM1 Configured as a Typical Master, EPWM2 Configured as a Slave**

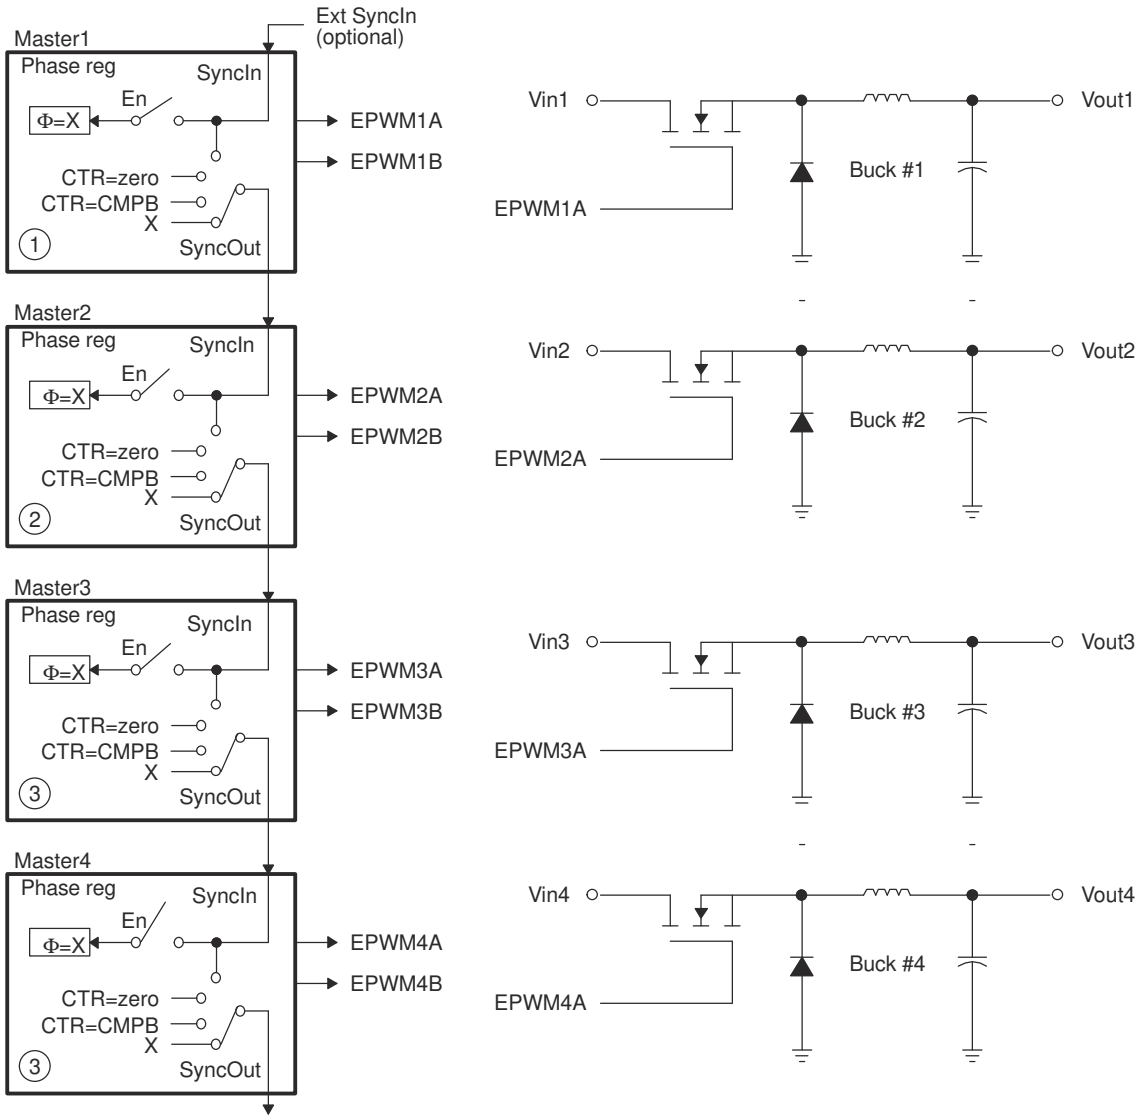
### 15.13.3 Controlling Multiple Buck Converters With Independent Frequencies

One of the simplest power converter topologies is the buck. A single ePWM module configured as a master can control two buck stages with the same PWM frequency. If independent frequency control is required for each buck converter, then one ePWM module must be allocated for each converter stage. Figure 15-61 shows four buck stages, each running at independent frequencies. In this case, all four ePWM modules are configured as Masters and no synchronization is used. Figure 15-62 shows the waveforms generated by the setup shown in Figure 15-61; note that only three waveforms are shown, although there are four stages.



A. φ = X indicates value in phase register is a "don't care"

**Figure 15-61. Control of Four Buck Stages. Here $F_{PWM1} \neq F_{PWM2} \neq F_{PWM3} \neq F_{PWM4}$**

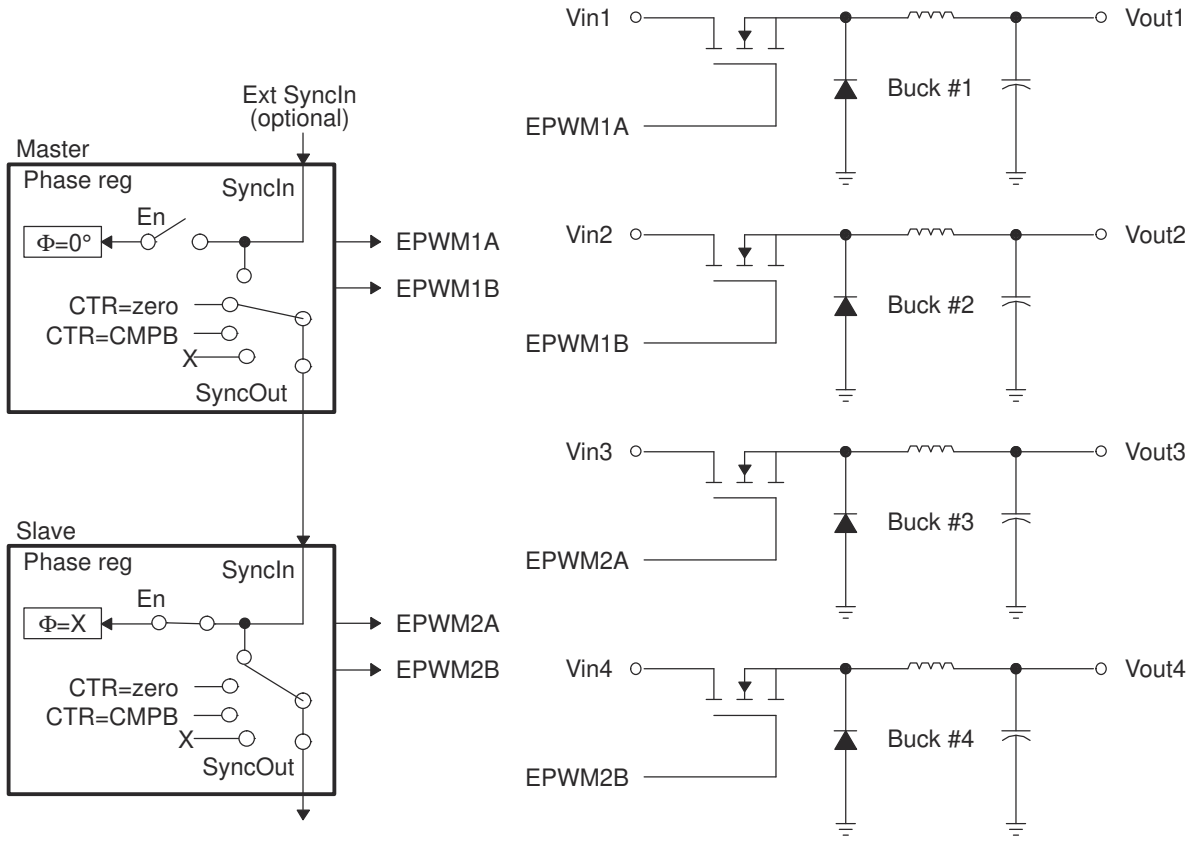
### 15.13.4 Controlling Multiple Buck Converters With Same Frequencies

If synchronization is a requirement, ePWM module 2 is configured as a slave and operates at integer multiple (N) frequencies of module 1. The sync signal from master to slave makes sure these modules remain locked. Figure 15-63 shows such a configuration; Figure 15-64 shows the waveforms generated by the configuration.



A. φ = X indicates value in phase register is a "don't care"

### 15.13.5 Controlling Multiple Half H-Bridge (HHB) Converters

Topologies that require control of multiple switching elements can also be addressed with these same ePWM modules. It is possible to control a Half-H bridge stage with a single ePWM module. This control can be extended to multiple stages. Figure 15-65 shows control of two synchronized Half-H bridge stages where stage 2 can operate at integer multiple (N) frequencies of stage 1. Figure 15-66 shows the waveforms generated by the configuration shown in Figure 15-65.

ePWM module 2 (slave) is configured for Sync flow-through; if required, this configuration allows for a third Half-H bridge to be controlled by ePWM module 3 and also, most importantly, to remain in synchronization with master ePWM module 1.

### 15.13.6 Controlling Dual 3-Phase Inverters for Motors (ACI and PMSM)

The idea of multiple modules controlling a single power stage can be extended to the 3-phase inverter case. In such a case, six switching elements are controlled using three PWM modules, one for each leg of the inverter. Each leg must switch at the same frequency and all legs must be synchronized. A master slaves configuration easily addresses this requirement. Figure 15-67 shows how six PWM modules control two independent 3-phase inverters; each running a motor.

As in the cases shown in the previous sections, we have a choice of running each inverter at a different frequency (module 1 and module 4 are masters as in Figure 15-67), or both inverters can be synchronized by using one master (module 1) and five slaves. In this case, the frequency of modules 4, 5, and 6 (all equal) can be integer multiples of the frequency for modules 1, 2, and 3 (also all equal).

### 15.13.7 Practical Applications Using Phase Control Between PWM Modules

So far, none of the examples have made use of the phase register (TBPHS). It has either been set to zero or a don't care. However, by programming appropriate values into TBPHS, multiple PWM modules can address another class of power topologies that rely on phase relationship between legs (or stages) for correct operation. As described in the time-base submodule section, a PWM module can be configured to allow a SyncIn pulse to cause the TBPHS register to be loaded into the TBCTR register. To illustrate this concept, Figure 15-69 shows a master and slave module with a phase relationship of 120° (that is, the slave leads the master).

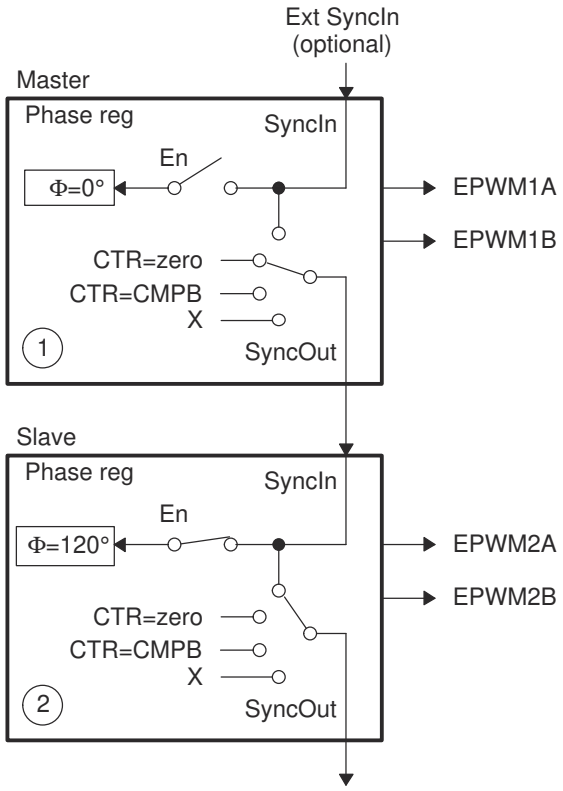

**Figure 15-69. Configuring Two PWM Modules for Phase Control**

Figure 15-70 shows the associated timing waveforms for this configuration. Here, TBPRD = 600 for both master and slave. For the slave, TBPHS = 200 (that is, 200/600 x 360° = 120°). Whenever the master generates a SyncIn pulse (CTR = PRD), the value of TBPHS = 200 is loaded into the slave TBCTR register so the slave time-base is always leading the master time-base by 120°.

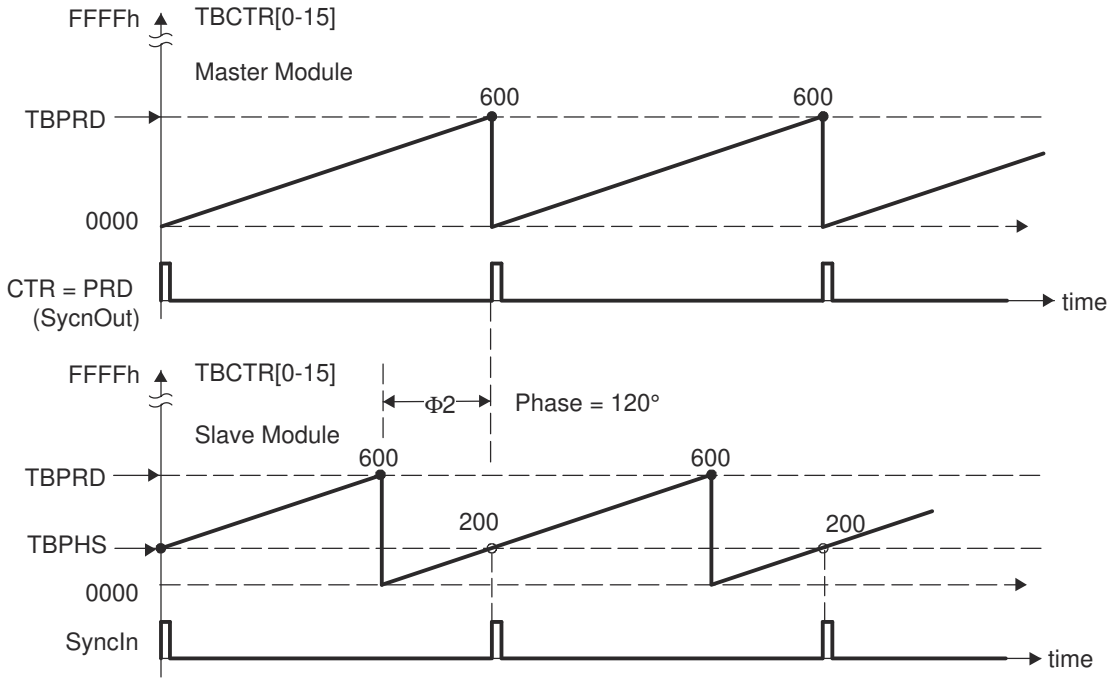

**Figure 15-70. Timing Waveforms Associated with Phase Control Between Two Modules**

### *15.13.8 Controlling a 3-Phase Interleaved DC/DC Converter*

A popular power topology that makes use of phase-offset between modules is shown in Figure 15-71. This system uses three PWM modules, with module 1 configured as the master. To work, the phase relationship between adjacent modules must be F = 120°. This is achieved by setting the slave TBPHS registers 2 and 3 with values of 1/3 and 2/3 of the period value, respectively. For example, if the period register is loaded with a value of 600 counts, then TBPHS (slave 2) = 200 and TBPHS (slave 3) = 400. Both slave modules are synchronized to the master module 1.

This concept can be extended to four or more phases, by setting the TBPHS values appropriately. The following formula gives the TBPHS values for N phases:

TBPHS(N,M) = (TBPRD/N) x (M-1)

Where:

N = number of phases

M = PWM module number

For example, for the 3-phase case (N=3), TBPRD = 600,

TBPHS(3,2) = (600/3) x (2-1) = 200 (that is, Phase value for Slave module 2)

TBPHS(3,3) = 400 (that is, Phase value for Slave module 3)

Figure 15-72 shows the waveforms for the configuration in Figure 15-71.

### 15.13.9 Controlling Zero Voltage Switched Full Bridge (ZVSFB) Converter

The example given in Figure 15-73 assumes a static or constant phase relationship between legs (modules). In such a case, control is achieved by modulating the duty cycle. It is also possible to dynamically change the phase value on a cycle-by-cycle basis. This feature lends to controlling a class of power topologies known as *phase-shifted full bridge*, or *zero voltage switched full bridge.* Here the controlled parameter is not duty cycle (this is kept constant at approximately 50 percent); instead it is the phase relationship between legs. Such a system can be implemented by allocating the resources of two PWM modules to control a single power stage, which in turn requires control of four switching elements. Figure 15-74 shows a master and slave module combination synchronized together to control a full H-bridge. In this case, both master and slave modules are required to switch at the same PWM frequency. The phase is controlled by using the slave phase register (TBPHS). The master phase register is not used and therefore can be initialized to zero.

### 15.13.10 Controlling a Peak Current Mode Controlled Buck Module

Peak current control techniques offer a number of benefits like automatic over current limiting, fast correction for input voltage variations and reducing magnetic saturation. Figure 15-75 shows the use of ePWM1A along with the on-chip analog comparator for buck converter topology. The output current is sensed through a current sense resistor and fed to the positive terminal of the on-chip comparator. The internal programmable 12-bit DAC can be used to provide a reference peak current at the negative terminal of the comparator. Alternatively, an external reference can be connected at this input. The comparator output is an input to the Digital compare sub-module. The ePWM module is configured in such a way so as to trip the ePWM1A output as soon as the sensed current reaches the peak reference value. A cycle-by-cycle trip mechanism is used. Figure 15-76 shows the waveforms generated by the configuration.

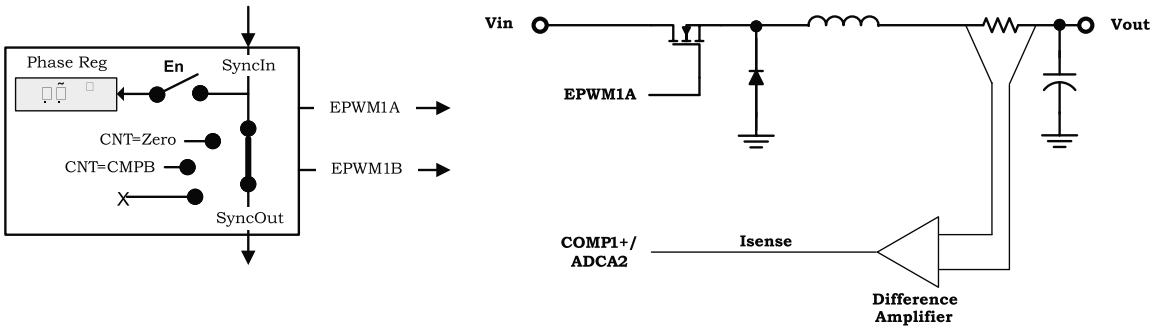

**Figure 15-75. Peak Current Mode Control of Buck Converter**

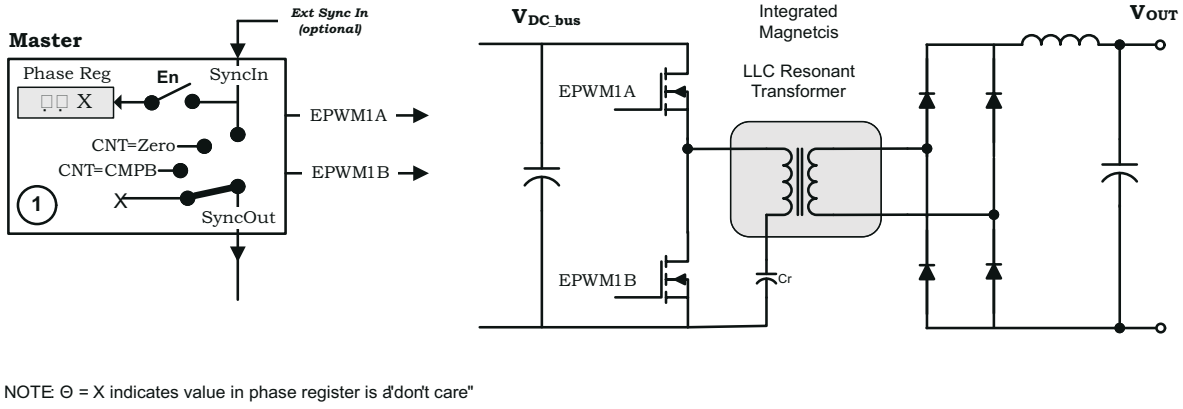
### 15.13.11 Controlling H-Bridge LLC Resonant Converter

Various topologies of resonant converters are well-known in the field of power electronics for many years. In addition to these, H-bridge LLC resonant converter topology has recently gained popularity in many consumer electronics applications where high efficiency and power density are required. In this example, single channel configuration of ePWM1 is detailed, yet the configuration can easily be extended to multichannel. Here the controlled parameter is not duty cycle (this is kept constant at approximately 50 percent); instead the parameter is frequency. Although the deadband is not controlled and kept constant as 300ns (that is, 30 at 100MHz TBCLK), the user can update the deadband in real time to enhance the efficiency by adjusting enough time delay for soft switching.



NOTE: Θ = X indicates value in phase register is a "don't care"

**Figure 15-77. Control of Two Resonant Converter Stages**

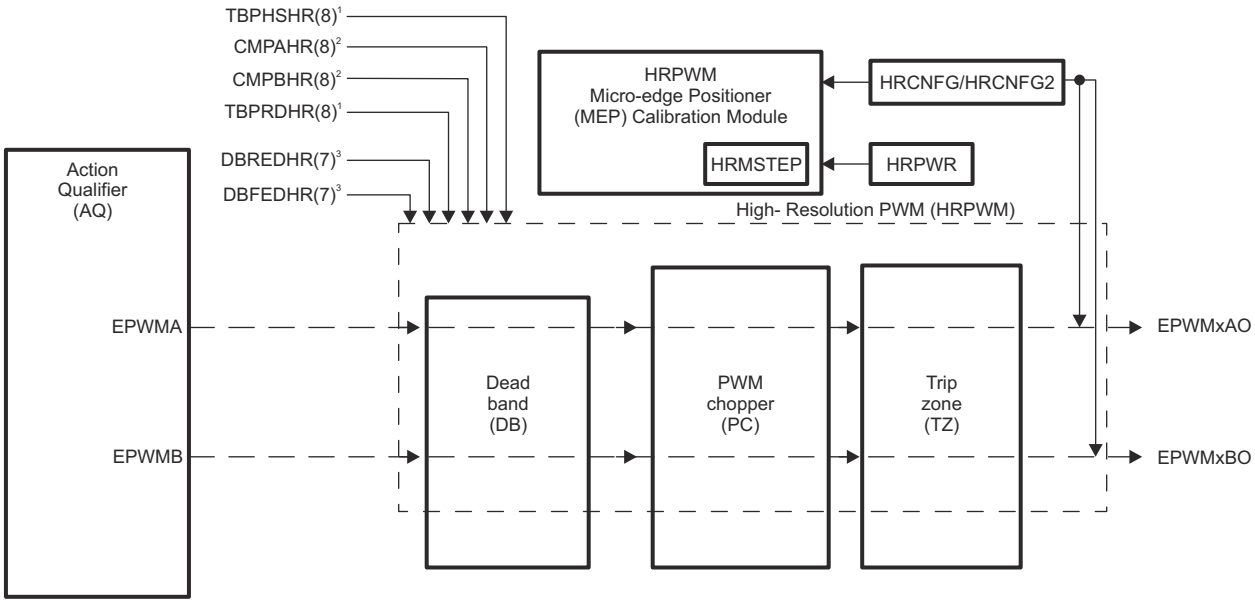
## 15.14 High-Resolution Pulse Width Modulator (HRPWM)

Figure 15-79 shows a block diagram of the HRPWM. This module extends the time resolution capabilities of the conventionally derived digital pulse width modulator (PWM). HRPWM is typically used when PWM resolution falls below approximately 9-10 bits. The key features of HRPWM are:

- Extended time resolution capability
- Used in both duty cycle and phase-shift control methods
- Finer time granularity control or edge positioning using extensions to the Compare A, Compare B and Phase registers
- Implemented using the A and B signal path of PWM, that is, on the EPWMxA and EPWMxB output
- Dead band high-resolution control for falling and rising edge delay in half cycle clocking operation
- Self-check diagnostics software mode to check if the micro edge positioner (MEP) logic is running how designed
- Enables high-resolution output swapping on the EPWMxA and EPWMxB output
- Enables high-resolution output on EPWMxB signal output using inversion of EPWMxA signal output
- Enables high-resolution period, duty and phase control on the EPWMxA and EPWMxB output on devices with an ePWM module

**Note**

See the device data sheet to determine if your device has an ePWM module with high-resolution period support.



A. From ePWM Time-base (TB) submodule
B. From ePWM counter-compare (CC) submodule
C. From ePWM Deadband (DB) submodule

**Figure 15-79. HRPWM Block Diagram**

Copyright © 2024 Texas Instruments Incorporated

The ePWM peripheral is used to perform a function mathematically equivalent to a digital-to-analog converter (DAC). As shown in Figure 15-80, the effective resolution for conventionally generated PWM is a function of PWM frequency (or period) and system clock frequency.

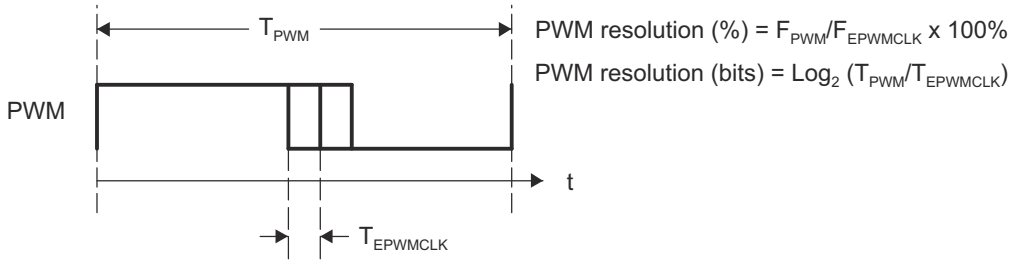


**Figure 15-80. Resolution Calculations for Conventionally Generated PWM**

If the required PWM operating frequency does not offer sufficient resolution in PWM mode, consider using HRPWM. As an example of improved performance offered by HRPWM, Table 15-13 shows resolution in bits for various PWM frequencies. These values assume a MEP step size of 180ps. See the device data sheet for typical and maximum performance specifications for the MEP.

**Table 15-13. Resolution for PWM and HRPWM**

| PWM Frequency (kHz) | Regular Resolution (PWM) 100MHz EPWMCLK | | High Resolution (HRPWM) | |
|---|---|---|---|---|
| | Bits | % | Bits | % |
| 20 | 12.3 | 0.02 | 18.1 | 0.000 |
| 50 | 11 | 0.05 | 16.8 | 0.001 |
| 100 | 10 | 0.1 | 15.8 | 0.002 |
| 150 | 9.4 | 0.15 | 15.2 | 0.003 |
| 200 | 9 | 0.2 | 14.8 | 0.004 |
| 250 | 8.6 | 0.25 | 14.4 | 0.005 |
| 500 | 7.6 | 0.5 | 13.4 | 0.009 |
| 1000 | 6.6 | 1 | 12.4 | 0.018 |
| 1500 | 6.1 | 1.5 | 11.9 | 0.027 |
| 2000 | 5.6 | 2 | 11.4 | 0.036 |

Although each application can differ, typical low-frequency PWM operation (below 250kHz) does not require HRPWM. HRPWM capability is most useful for high-frequency PWM requirements of power conversion topologies such as:

- Single-phase buck, boost, and flyback
- Multiphase buck, boost, and flyback
- Phase-shifted full bridge
- Direct modulation of D-Class power amplifiers

### 15.14.1 Operational Description of HRPWM

The HRPWM is based on micro-edge positioner (MEP) technology. MEP logic is capable of positioning an edge very finely by sub-dividing one coarse system clock of a conventional PWM generator. The time step accuracy is on the order of 150ps. See the device data sheet for the typical MEP step size on a particular device. The HRPWM also has a self-check software diagnostics mode to check if the MEP logic is running as designed under all operating conditions. Details on software diagnostics and functions are in Section 15.14.1.7.

Figure 15-81 shows the relationship between one coarse system clock and edge position in terms of MEP steps, which are controlled using an 8-bit field in the Compare A extension register (CMPAHR). The same operating logic applies to CMPBHR as well.

To generate an HRPWM waveform, configure the ePWM registers to generate a conventional PWM of a given frequency and polarity. The HRPWM works together with the ePWM registers to extend edge resolution. Although many programming combinations are possible, only a few are needed and practical. These methods are described in Section 15.14.1.8.

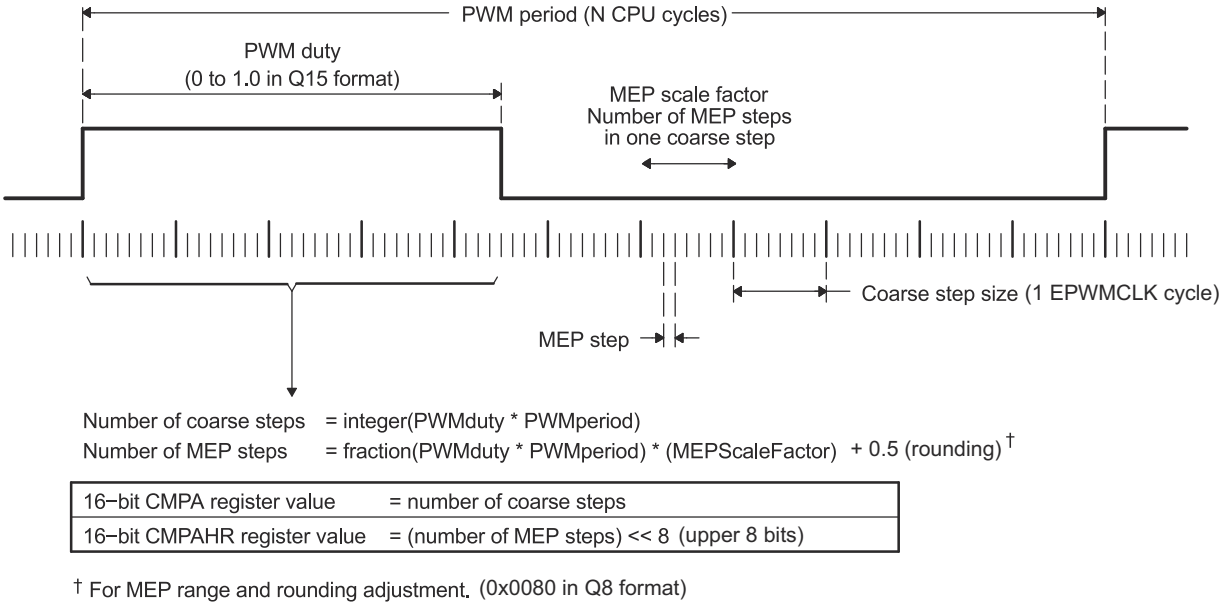

**Figure 15-81. Operating Logic Using MEP**

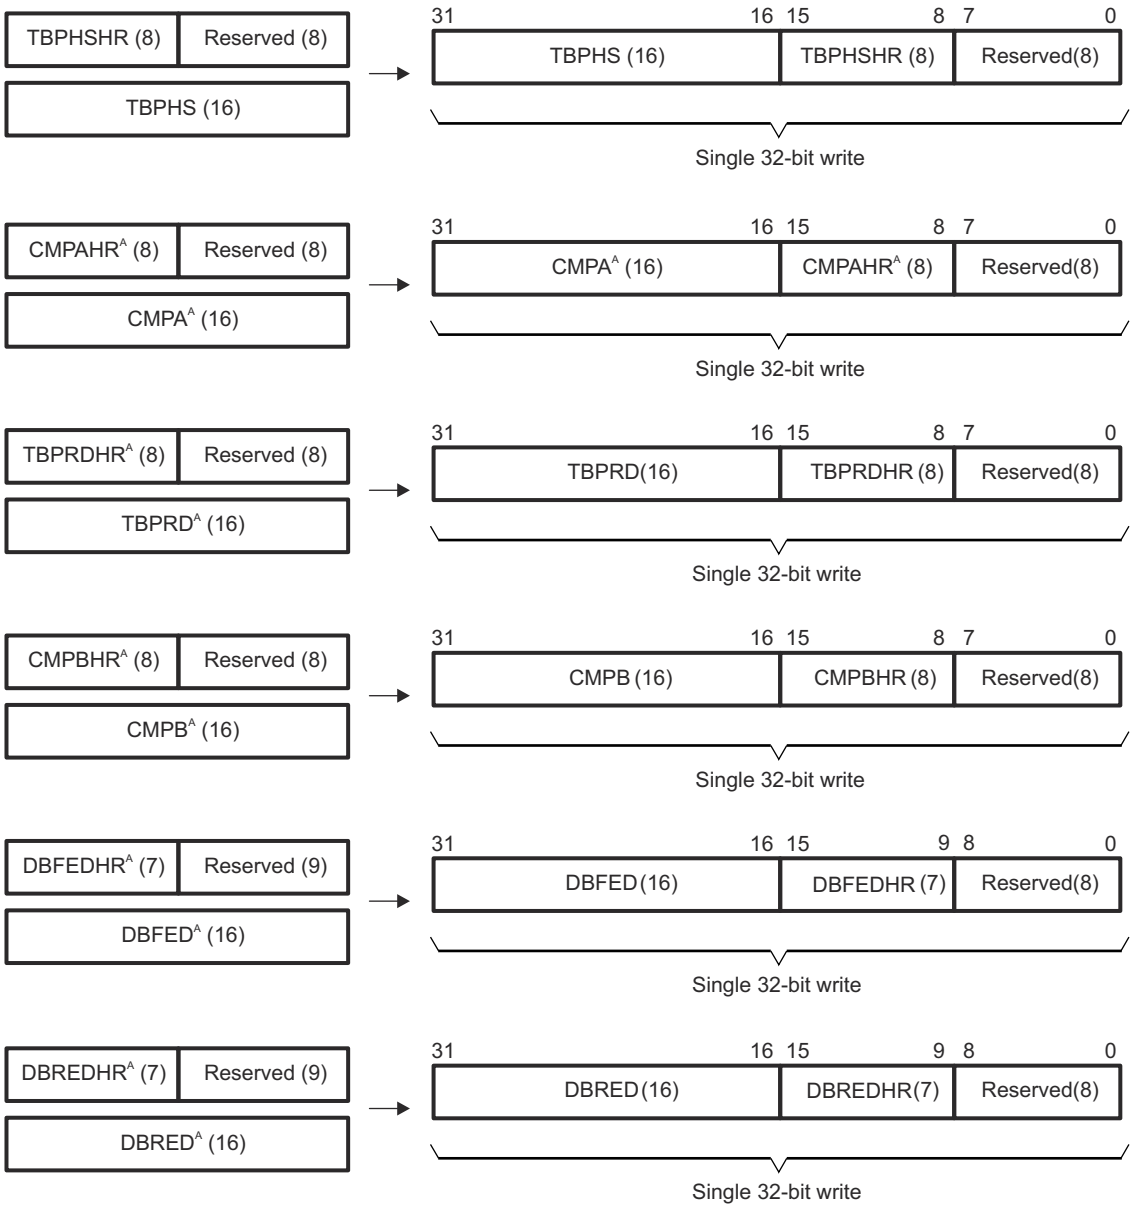
#### 15.14.1.1 Controlling the HRPWM Capabilities

The MEP of the HRPWM is controlled by six extension registers. These HRPWM registers are concatenated with the 16-bit TBPHS, TBPRD, CMPA, CMPBM, DBREDM, and DBFEDM registers used to control PWM operation.

- TBPHSHR - Time Base Phase High Resolution Register
- CMPAHR - Counter Compare A High Resolution Register; CMPAHR is for use with the AQ output of Channel A, and is not related to CMPA
- TBPRDHR - Time Base Period High Resolution Register. (available on some devices)
- CMPBHR - Counter Compare B High Resolution Register; CMPBHR is for use with the AQ output of Channel B, and is not related to CMPB
- DBREDHR - Dead-band Generator Rising Edge Delay High Resolution Register
- DBFEDHR - Dead-band Generator Falling Edge Delay High Resolution Register

Copyright © 2024 Texas Instruments Incorporated



A. Dependent upon your device, these registers can be mirrored and can be written to at two different memory locations.

**Figure 15-82. HRPWM Extension Registers and Memory Configuration**

**Note**

HRPWM capabilities on Deadband Rising Edge Delay and Falling Edge Delay is applicable only during dead band half cycle clocking Operation. The number of MEP steps is half in size [bits 15:9 ] than duty and phase high-resolution registers for the same reason.

HRPWM capabilities are controlled using the Channel A and B PWM signal path. HRPWM support on the Dead band signal path is available by properly configuring the HRCNFG2 register. Figure 15-83 shows how the HRPWM interfaces with the 8-bit extension registers.

A. These events are generated by the ePWM Digital Compare (DC) submodule based on the levels of the TRIPIN inputs.

**Figure 15-83. HRPWM System Interface**

Copyright © 2024 Texas Instruments Incorporated

#### 15.14.1.2 HRPWM Source Clock

The HRPWM module and HRCAL module are clocked from the EPWM1CLK. Therefore, EPWM1CLK must be enabled for the HRCAL or any of the HRPWM modules to be enabled. Figure 15-84 shows the HRCAL and HRPWM modules sourced from the ePWM1 clock source.

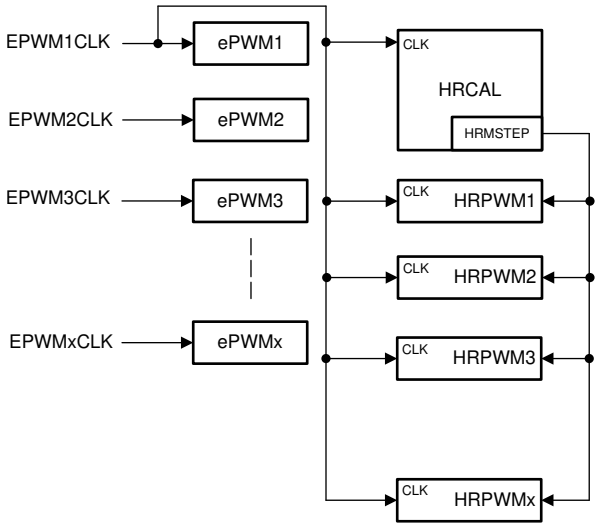

**Figure 15-84. HRPWM and HRCAL Source Clock**

#### 15.14.1.3 Configuring the HRPWM

Once the ePWM has been configured to provide conventional PWM of a given frequency and polarity, the HRPWM is configured by programming the HRCNFG register in that particular ePWM module's register space. This register provides the following configuration options:

| | |
|---|---|
| **Edge Mode** | The MEP can be programmed to provide precise position control on the rising edge (RE), falling edge (FE) or both edges (BE) at the same time. FE and RE are used for power topologies requiring duty cycle control (CMPA or CMPB high-resolution control), while BE is used for topologies requiring phase shifting, for example, phase shifted full bridge (TBPHS or TBPRD high-resolution control). |
| **Control Mode** | The MEP is programmed to be controlled either from the CMPAHR/CMPBHR register in case of duty cycle control or the TBPHSHR register (phase control). RE or FE control mode can be used with the CMPAHR or CMPBHR register. BE control mode can be used with the TBPHSHR register. When the MEP is controlled from the TBPRDHR register (period control), the duty cycle and phase can also be controlled using their respective high-resolution registers. |
| **Shadow Mode** | This mode provides the same shadowing (double buffering) option as in regular PWM mode. This option is valid only when operating from the CMPAHR, CMPBHR, and TBPRDHR registers and can be chosen to be the same as the regular load option for the CMPA/CMPB register. If TBPHSHR is used, then this option has no effect. |
| **High-Resolution B Signal Control** | The B signal path of an ePWM channel can generate a high-resolution output by outputting an inverted version of the high-resolution ePWMxA signal on the ePWMxB pin. A Type 2 or Type 4 HRPWM module can also enable high-resolution features on the B signal path independently of the A signal path as well. |
| **Swap ePWMxA and ePWMxB Outputs** | This mode enables the swapping of the high-resolution A and B outputs. The mode selection allows either A and B Outputs Unchanged or A Output Comes Out On B and B Output Comes Out On A. |

Copyright © 2024 Texas Instruments Incorporated

**Auto-conversion Mode**

This mode is used in conjunction with the scale factor optimization (SFO) software only. For a type 4 HRPWM module, below is a description of the Auto-conversion Mode taking CMPAHR as an example. If auto-conversion is enabled, CMPAHR = fraction(PWMduty*PWMperiod)<<8. The scale factor optimization software calculates the MEP scale factor in the background code and automatically updates the HRMSTEP register with the calculated number of MEP steps per coarse step. The MEP Calibration Module then uses the values in the HRMSTEP and CMPAHR registers to automatically calculate the appropriate number of MEP steps represented by the fractional duty cycle and moves the high-resolution ePWM signal edge accordingly. If auto-conversion is disabled, the CMPAHR register behaves like a type 0 HRPWM module and CMPAHR = (fraction(PWMduty * PWMperiod) * MEP Scale Factor + 0.5)<<8). All calculations need to be performed by your code in this mode, and the HRMSTEP register is ignored. Auto-conversion for high-resolution period has the same behavior as auto-conversion for high-resolution duty cycle. Auto-conversion must always be enabled for high-resolution period mode.

**Note**

If the HRPWM module is configured in UP-DOWN counter mode, the shadow mode for the HRPWM registers must be set to load on both ZERO AND PERIOD. New values from the user are loaded to the shadow registers only at CTR=ZERO, but the shadow mode of for the registers must be set to both ZERO AND PERIOD. The CTR=PRD event is used for specific internal logic inside the HRPWM module.

Auto-conversion Mode performs the calculation for CMPBHR , DBREDHR, and DBFEDHR. The scale factor optimization software calculates the MEP scale factor in the background code and automatically updates the HRMSTEP register with the calculated number of MEP steps per coarse step. The MEP Calibration Module then uses the values in the HRMSTEP and CMPBHR or DBREDHR/DBFEDHR register to automatically calculate the appropriate number of MEP steps represented by the fractional components and moves the high-resolution ePWM signal edge accordingly. If auto-conversion is disabled, CMPBHR behaves the same as CMPAHR. CMPBHR = (fraction(PWMduty * PWMperiod) * MEP Scale Factor + 0.5)<<8).

**Note**

HRPWM functionality is only available on CPU1.

Copyright © 2024 Texas Instruments Incorporated

#### 15.14.1.4 Configuring High-Resolution in Deadband Rising-Edge and Falling-Edge Delay

Once the ePWM has been configured to provide conventional PWM of a given frequency, polarity, and dead band enabled in half-cycle clocking mode, the high-resolution operation on dead band RED and FED lines are enabled by programming the HRCNFG2 register in that particular ePWM module register space. This register provides the following configuration options:

**Edge Mode** The MEP can be programmed to provide precise position control on the dead band rising edge (RED), dead band falling edge (FED), or both edges (rising edge of DBRED signal and falling edge of DBFED signal) at the same time.

**Control Mode** Selects the time event that loads the shadow value in the active register for DBRED and DBFED in high-resolution mode. Select the pulse to match the selection in the ePWM DBCTL[LOADREDMODE] and DBCTL[LOADFEDMODE] bits.

#### 15.14.1.5 Principle of Operation

The MEP logic is capable of placing an edge in one of 255 (8 bits) discrete time steps (see the device data sheet for typical MEP step size). The MEP works with the TBM and CCM registers to be certain that time steps are applied and that edge placement accuracy is maintained over a wide range of PWM frequencies, system clock frequencies, and other operating conditions. Table 15-14 shows the typical range of operating frequencies supported by the HRPWM.

**Table 15-14. Relationship Between MEP Steps, PWM Frequency, and Resolution**

| System (MHz) | MEP Steps Per EPWMCLK (1) (2) (3) | PWM Minimum (Hz) (4) | PWM Maximum (MHz) | Resolution at Maximum (Bits) (5) |
|---|---|---|---|---|
| 60.0 | 93 | 916 | 3.00 | 10.9 |
| 70.0 | 79 | 1068 | 3.50 | 10.6 |
| 80.0 | 69 | 1221 | 4.00 | 10.4 |
| 90.0 | 62 | 1373 | 4.50 | 10.3 |
| 100.0 | 56 | 1526 | 5.00 | 10.1 |

(1) TBCLK = EPWMCLK.
(2) Table data based on a MEP time resolution of 180ps (this is an example value. See the device data sheet for MEP limits)
(3) MEP steps applied = $T_{EPWMCLK}$/180ps in this example.
(4) PWM minimum frequency is based on a maximum period value,(TBPRD = 65535). PWM mode is asymmetrical up-count.
(5) Resolution in bits is given for the maximum PWM frequency stated.

#### 15.14.1.5.1 Edge Positioning

**Note**

The following example is presented using the [CMPA:CMPAHR] register combination. The theory of operation and equations are the same, if intending to use the [CMPBM:CMPBHRM] for duty cycle control.

In a typical power control loop, a digital controller issues a duty command, usually expressed in a per unit or percentage terms. Assume that for a particular operating point, the demanded duty cycle is 0.405 or 40.5% on time and the required converter PWM frequency is 1.25MHz. In conventional PWM generation with a system clock of 100MHz, the duty cycle choices are in the vicinity of 40.5%. As shown in Figure 15-85, a compare value of 32 counts (duty = 40%) is the closest to 40.5% that can be attained. This is equivalent to an edge position of 320ns instead of the desired 324ns. This data is shown in Table 15-15.

By utilizing the MEP, an edge position much closer to the desired point of 324ns can be achieved. Table 15-15 shows that in addition to the CMPA value, 22 steps of the MEP (CMPAHR register) positions the edge at 323.96ns, resulting in almost zero error. In this example, assume that the MEP has a step resolution of 180ps.

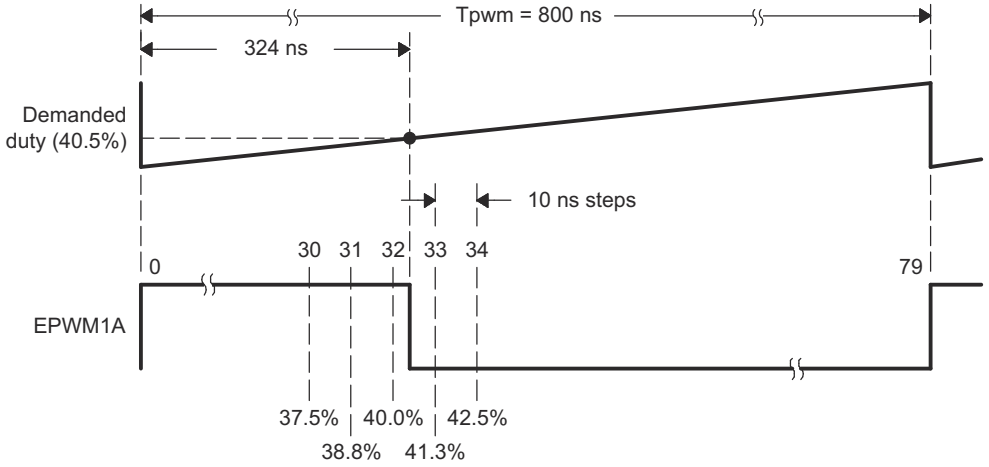

**Figure 15-85. Required PWM Waveform for a Requested Duty = 40.5%**

**Table 15-15. CMPA versus Duty (left), and [CMPA:CMPAHR] versus Duty (right)**

| CMPA (count)(1) (2) (3) | Duty (%) | High Time (ns) | CMPA (count) | CMPAHR (count) | Duty (%) | High Time (ns) |
|---|---|---|---|---|---|---|
| 28 | ***35.0*** | 280 | 32 | 18 | ***40.405*** | 323.24 |
| 29 | ***36.3*** | 290 | 32 | 19 | ***40.428*** | 323.42 |
| 30 | ***37.5*** | 300 | 32 | 20 | ***40.450*** | 323.60 |
| 31 | ***38.8*** | 310 | 32 | 21 | ***40.473*** | 323.78 |
| 32 | ***40.0*** | 320 | 32 | 22 | ***40.495*** | 323.96 |
| 33 | ***41.3*** | 330 | 32 | 23 | ***40.518*** | 324.14 |
| 34 | ***42.5*** | 340 | 32 | 24 | ***40.540*** | 324.32 |
| | | | 32 | 25 | ***40.563*** | 324.50 |
| Required | | | 32 | 26 | ***40.585*** | 324.68 |
| 32.40 | ***40.5*** | 324 | 32 | 27 | ***40.608*** | 324.86 |

(1) Assumed MEP step size for the above example = 180ps. See the device-specific data sheet for typical and maximum MEP values.
(2) TBCLK = 100MHz, 10ns
(3) For a PWM Period register value of 80 counts, PWM Period = 80 × 10ns = 800ns, PWM frequency = 1/800ns = 1.25MHz

#### 15.14.1.5.2 Scaling Considerations

The mechanics of how to position an edge precisely in time has been demonstrated using the resources of the standard CMPA and MEP (CMPAHR) registers. In a practical application, however, it is necessary to seamlessly provide the CPU a mapping function from a per-unit (fractional) duty cycle to a final integer (non-fractional) representation that is written to the [CMPA:CMPAHR] register combination.

To do this, first examine the scaling or mapping steps involved. It is common in control software to express duty cycle in a per-unit or percentage basis. This has the advantage of performing all needed math calculations without concern for the final absolute duty cycle, expressed in clock counts or high time in nanoseconds (ns). Furthermore, it makes the code more transportable across multiple converter types running different PWM frequencies.

To implement the mapping scheme, a two-step scaling procedure is required.

**Assumptions for this example:**

| | | |
|---|---|---|
| TBCLK | = | 10ns (100MHz) |
| PWM frequency | = | 1.25MHz (1/800ns) |
| Required PWM duty cycle, **PWMDuty** | = | 0.405 (40.5%) |
| PWM period in terms of coarse steps, **PWMPeriod** (800ns/10ns) | = | 80 |
| Number of MEP steps per coarse step at 180ps (10ns/180ps), **MEP_ScaleFactor** | = | 55 |
| Value to keep CMPAHR within the range of 1-255 and fractional rounding constant (default value) | = | 0.5 (0080h in Q8 format) |

**Step 1: Percentage Integer Duty value conversion for CMPA register**

| | | |
|---|---|---|
| CMPA register value | = | int(**PWMDuty***PWMPeriod**); int means integer part |
| | = | int(0.405 * 80) |
| | = | int(32.4) |
| CMPA register value | = | 32 (20h) |

**Step 2: Fractional value conversion for CMPAHR register**

| | | |
|---|---|---|
| CMPAHR | = | (frac(**PWMDuty***PWMPeriod**)*MEP_ScaleFactor** + 0.5) <<8); frac means fractional part |
| | = | (frac(32.4) * 55 + 0.5) <<8; Shifting is to move the value to the high byte of CMPAHR. |
| | = | (0.4 * 55 + 0.5) <<8 |
| | = | (22 + 0.5) <<8 |
| | = | 22.5 * 256; Shifting left by 8 is the same as multiplying by 256. |
| | = | 5760 (1680h) |
| CMPAHR | = | 1680h CMPAHR value = 1600h (lower 8 bits are ignored by hardware). |

Copyright © 2024 Texas Instruments Incorporated

**Note**

If the AUTOCONV bit (HRCNFG.6) is set and the MEP_ScaleFactor is in the HRMSTEP register, then CMPAHR / CMPBHR register value = frac (PWMDuty*PWMperiod<<8). The rest of the conversion calculations are performed automatically in hardware, and the correct MEP-scaled signal edge appears on the ePWM channel output. If AUTOCONV is not set, the above calculations must be performed by software.

The MEP scale factor (MEP_ScaleFactor) varies with the system clock and DSP operating conditions. TI provides an MEP scale factor optimizing (SFO) software C function, which uses the built in diagnostics in each HRPWM and returns the best scale factor for a given operating point.

The scale factor varies slowly over a limited range so the optimizing C function can be run very slowly in a background loop.

The CMPA, CMPB, CMPAHR and CMPBHR registers are configured in memory so that the 32-bit data capability of the CPU can write this as a single concatenated value, that is, [CMPA:CMPAHR], [CMPB:CMPBHR], and so on.

The mapping scheme has been implemented in both C and assembly, as shown in Section 15.14.1.8. The actual implementation takes advantage of the 32-bit CPU architecture and is somewhat different from the steps shown in Section 15.14.1.5.2.

For time-critical control loops where every cycle counts, the assembly version is recommended. This is a cycle optimized function (11 EPWMCLK cycles) that takes a Q15 duty value as input and writes a single [CMPA:CMPAHR] value.

#### *15.14.1.5.3 Duty Cycle Range Limitation*

In high-resolution mode, the MEP is not active for 100% of the PWM period and becomes operational:

- Three EPWMCLK cycles after the period starts when high-resolution period (TBPRDHR) control is not enabled.
- When high-resolution period (TBPRDHR) control is enabled using the HRPCTL register:
  - In up-count mode: three EPWMCLK cycles after the period starts until three EPWMCLK cycles before the period ends.
  - In up-down count mode: when counting up, three cycles after CTR = 0 until three cycles before CTR = PRD, and when counting down, three cycles after CTR = PRD until three cycles before CTR = 0.
- When using DBREDHR or DBFEDHR, DBRED or DBFED (the register corresponding to the edge with high-resolution displacement) must be greater than or equal to 7.

Duty cycle range limitations are illustrated in Figure 15-86 to Figure 15-89. This limitation imposes a duty cycle limit on the MEP. For example, precision edge control is not available all the way down to 0% duty cycle. When high-resolution period control is disabled, regular PWM duty control is fully operational down to 0% duty cycle despite the unavailability of HRPWM features in the first three cycles. In most applications, this cannot be an issue as the controller regulation point is usually not designed to be close to 0% duty cycle. To better understand the useable duty cycle range, see Table 15-16. When high-resolution period control is enabled (HRPCTL[HRPE] = 1), the duty cycle must not fall within the restricted range; otherwise, there can be undefined behavior on the ePWMxA output.

Copyright © 2024 Texas Instruments Incorporated

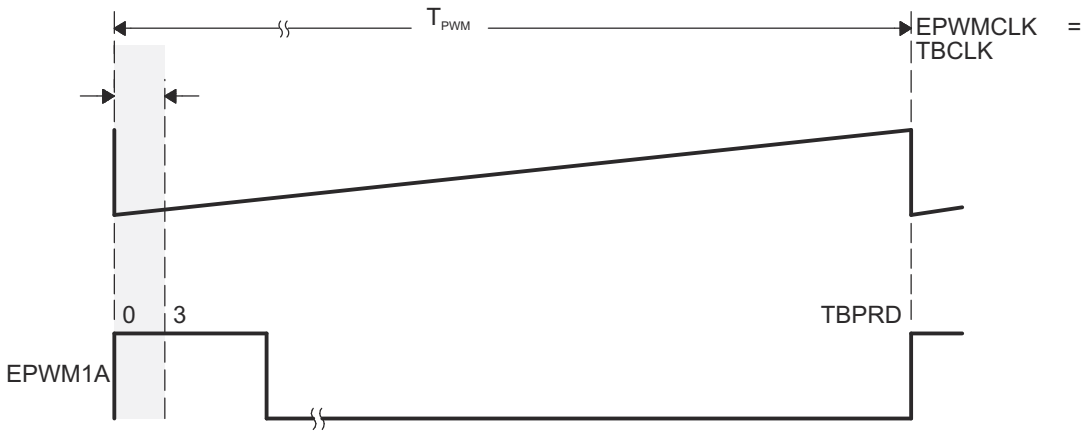

**Figure 15-86. Low % Duty Cycle Range Limitation Example (HRPCTL[HRPE] = 0)**

**Table 15-16. Duty Cycle Range Limitation for Three EPWMCLK/TBCLK Cycles**

| PWM Frequency(1) (kHz) | 3 Cycles Minimum Duty | 3 Cycles Maximum Duty(2) |
|---|---|---|
| 200 | 0.6% | 99.4% |
| 400 | 1.2% | 98.8% |
| 600 | 1.8% | 98.2% |
| 800 | 2.4% | 97.6% |
| 1000 | 3% | 97% |
| 1200 | 3.6% | 96.4% |
| 1400 | 4.2% | 95.8% |
| 1600 | 4.8% | 95.2% |
| 1800 | 5.4% | 94.6% |
| 2000 | 6% | 94% |

(1) EPWMCLK = TBCLK = 100MHz
(2) This limitation applies only if high-resolution period (TBPRDHR) control is enabled.

If the application demands HRPWM operation below the minimum duty cycle limitation, then the HRPWM can be configured to operate in count-down mode with the rising edge position (REP) controlled by the MEP when high-resolution period is disabled (HRPCTL[HRPE] = 0). This is illustrated in Figure 15-87. In this configuration, the minimum duty cycle limitation is no longer an issue. However, there is a maximum duty limitation with same percent numbers as given in Table 15-16.

**CAUTION**

If the application has enabled high-resolution period control (HRPCTL[HRPE] = 1), the duty cycle must not fall within the restricted range; otherwise, there can be undefined behavior on the ePWM output.

#### 15.14.1.5.4 High-Resolution Period

High-resolution period control using the MEP logic is supported on devices with a Type 1 ePWM module or greater.

**Note**

When high-resolution period control is enabled, on ePWMxA only, and not ePWMxB output and conversely, the non high-resolution output has ±1 TBCLK cycle jitter in up-count mode and ±2 TBCLK cycle jitter in up-down count mode.

The scaling procedure described for duty cycle in Section 15.14.1.5.2 applies for high-resolution period as well:

**Assumptions for this example:**

| | |
|---|---|
| TBCLK | = 10ns (100MHz) |
| Required PWM frequency | = 175kHz (period of 571.428) |
| Number of MEP steps per coarse step at 180ps (10ns/180ps), (MEP_ScaleFactor) | = 55 |
| Value to keep TBPRDHR within range of 1-255 and fractional rounding constant (default value) | = 0.5 (0080h in Q8 format) |

**Problem:**

In up-count mode:

- If TBPRD = 571, then PWM frequency = 174.82kHz (period = (571+1)* $T_{TBCLK}$).
- If TBPRD = 570, then PWM frequency = 175.13kHz (period = (570+1)* $T_{TBCLK}$).

In up-down count mode:

- If TBPRD = 286, then PWM frequency = 174.82kHz (period = (286*2)* $T_{TBCLK}$).
- If TBPRD = 285, then PWM frequency = 175.44kHz (period = (285*2)* $T_{TBCLK}$).

**Solution:**

With 55 MEP steps per coarse step at 180ps each:

**Step 1: Percentage Integer Period value conversion for TBPRD register**

| | |
|---|---|
| Integer period value | = 571 * $T_{TBCLK}$ |
| | = int (571.428) * $T_{TBCLK}$ |
| | = int (PWMperiod) * $T_{TBCLK}$ |
| In up-count mode: | |
| TBPRD | = 570 (TBPRD = period value - 1) |
| | = 023Ah |
| In up-down count mode: | = 285 (TBPRD = period value/2) |
| TBPRD | = 011Dh |

Copyright © 2024 Texas Instruments Incorporated

**Step 2: Fractional value conversion for TBPRDHR register**

In up-count mode:

| | |
|---|---|
| TBPRDHR register value | = (frac(PWMperiod) * MEP_ScaleFactor + 0.5) |
| If auto-conversion enabled and HRMSTEP = | |
| MEP_ScaleFactor value (55): | = frac (PWMperiod) << 8 (Shifting is to move the value to the high byte of TBPRDHR) |
| TBPRDHR register value | = frac (571.428) << 8 |
| | = 0.428 × 256 |
| | = 6D00h |
| The auto-conversion then automatically performs the calculation, such that TBPRDHR MEP delay is scaled by hardware to: | = ((TBPRDHR(15:0) >> 8) × HRMSTEP + 80h) << 8 |
| | = (006Dh × 55 + 80h) >> 8 |
| | = (17EBh) >> 8 |
| Period MEP delay | = 0017h MEP Steps |

In up-down count mode:

| | |
|---|---|
| TBPRDHR register value | = (frac(PWMperiod) * MEP_ScaleFactor + 0.5) |
| If auto-conversion enabled and HRMSTEP = | |
| MEP_ScaleFactor value (55): | = frac (PWMperiod / 2) << 8 (Shifting is to move the value to the high byte of TBPRDHR) |
| TBPRDHR register value | = frac (285.714) << 8 |
| | = 0.714 × 256 |
| | = B600h |
| The auto-conversion then automatically performs the calculation, such that TBPRDHR MEP delay is scaled by hardware to: | = ((TBPRDHR(15:0) >> 8) × HRMSTEP + 80h) << 8 |
| | = (00B6h × 55 + 80h) >> 8 |
| | = (279Ah) >> 8 |
| Period MEP delay | = 0027h MEP Steps |

#### 15.14.1.5.4.1 High-Resolution Period Configuration

To use high-resolution period, the ePWMx module must be initialized in the exact order presented.

The following steps use CMPA with shadow registers and the corresponding HRCNFG bits for high-resolution operation on EPWMxA. For high-resolution operation on EPWMxB, make the appropriate substitutions with the B channel fields.

1. Enable ePWMx clock
2. Enable HRPWM clock
3. Disable TBCLKSYNC
4. Configure ePWMx registers - AQ, TBPRD, CC, and so on.
   - ePWMx can only be configured for up-count or up-down count modes. High-resolution period is not compatible with down-count mode.
   - TBPRD and CC registers must be configured for shadow loads.
   - CMPCTL[LOADAMODE]
     - In up-count mode: CMPCTL[LOADAMODE] = 1 (load on CTR = PRD)
     - In up-down count mode: CMPCTL[LOADAMODE] = 2 (load on CTR=0 or CTR=PRD)
5. Configure the HRCNFG register such that:
   - HRCNFG[HRLOAD] = 2 (load on either CTR = 0 or CTR = PRD)
   - HRCNFG[AUTOCONV] = 1 (Enable auto-conversion)
   - HRCNFG[EDGMODE] = 3 (MEP control on both edges)
6. For TBPHS:TBPHSHR synchronization with high-resolution period, set both HRPCTL[TBPSHRLOADE] = 1 and TBCTL[PHSEN] = 1. In up-down count mode these bits must be set to 1 regardless of the contents of TBPHSHR.
7. Enable high-resolution period control (HRPCTL[HRPE] = 1)
8. Enable TBCLKSYNC
9. TBCTL[SWFSYNC] = 1
10. HRMSTEP must contain an accurate MEP scale factor (# of MEP steps per EPWMCLK coarse step) because auto-conversion is enabled. The MEP scale factor can be acquired using the SFO() function described in Section 15.14.2.
11. To control high-resolution period, write to the TBPRDHR(M) registers.

**Note**

When high-resolution period mode is enabled, an EPWMxSYNC pulse introduces ±1-2 cycle jitter to the PWM (±1 cycle in up-count mode and ±2 cycle in up-down count mode). For this reason, TBCTL[SYNCOSEL] cannot be set to 1 (CTR = 0 is EPWMxSYNCO source) or 2 (CTR = CMPB is EPWMxSYNCO source). Otherwise, the jitter occurs on every PWM cycle with the synchronization pulse.

When TBCTL[SYNCOSEL] = 0 (EPWMxSYNCI is EPWMxSYNCO source), a software synchronization pulse can be issued only once during high-resolution period initialization. If a software sync pulse is applied while the PWM is running, the jitter appears on the PWM output at the time of the sync pulse.

Copyright © 2024 Texas Instruments Incorporated

#### 15.14.1.6 Deadband High-Resolution Operation

**Note**

In up-count mode, the dead-band module is not available when any high-resolution mode is enabled.

**Assumptions for this example:**

| | |
|---|---|
| System clock | = 10ns (100MHz) |
| Deadband enabled in half-cycle mode, TBCLK = EPWMCLK | |
| Required PWM frequency | 1.33MHz (1/750ns) |
| Required PWM duty cycle | 0.5 (50%) |
| Required Deadband Rising-Edge Delay | 5% over duty |
| Required Deadband Rising-Edge Delay in ns | (0.05 * 375ns) = 18.75ns |

**Note**

Similar to the duty cycle restrictions when using HRPWM, the DBRED and DBFED values must be greater than 3 to use high-resolution deadband.

**Deadband delay values as a function of DBFED and DBRED:**

When half-cycle clocking is enabled, the formula to calculate the falling-edge delay (FED) and rising-edge delay (RED) becomes:

FED = DBFED * TBCLK / 2

RED = DBRED * TBCLK / 2

**DBRED and DBFED calculated values:**

Required Deadband Rising-Edge Delay in ns = 18.75ns

DBRED = RED / (TBCLK / 2)

DBRED = 18.75ns/5ns

DBRED Required = 3.75ns

With 55 MEP steps per coarse step at 180ps each:

Copyright © 2024 Texas Instruments Incorporated

**Step 1: Integer Deadband value conversion for DBREDM register**

| | |
|---|---|
| Integer DBRED value | = int (RED / (TBCLK / 2)) |
| | = int (3.75) |
| DBRED | = 3 |

**Step 2: Fractional value conversion for Deadband high-resolution register DBREDHR**

| | |
|---|---|
| DBREDHR register value | = (frac(DBRED Required) * MEP_ScaleFactor + 0.5) << 8 (Shifting is to move the value to the high byte of DBREDHR) |
| | = (frac (3.75) * 55 + 0.5) << 8 |
| | = (0.75 * 55 + 0.5) << 8 |
| | = (41.75) * 256 Shifting left by 8 is the same as multiplying by 256. |
| DBREDHR value | = 29C0h MEP Steps |
| | Hardware ignores lower 9 bits in the above calculated DBREDHR value |

**Note**

If the AUTOCONV bit (HRCNFG.6) is set and the MEP_ScaleFactor is in the HRMSTEP register, then DBREDHR:DBRED = frac((required DB value) < <8). The rest of the conversion calculations are performed automatically in hardware, and the correct MEP-scaled signal edge appears on the ePWM channel output. If AUTOCONV is not set, the above calculations must be performed by software.

#### 15.14.1.7 Scale Factor Optimizing Software (SFO)

The micro edge positioner (MEP) logic is capable of placing an edge in one of 255 discrete time steps. As previously mentioned, the size of these steps is on the order of 150ps (see the device data sheet for typical MEP step size on your device). The MEP step size varies based on worst-case process parameters, operating temperature, and voltage. MEP step size increases with decreasing voltage and increasing temperature and decreases with increasing voltage and decreasing temperature. Applications that use the HRPWM feature can use the TI-supplied MEP scale factor optimization (SFO) software function. The SFO function helps to dynamically determine the number of MEP steps per EPWMCLK period while the HRPWM is in operation.

To utilize the MEP capabilities effectively, the correct value for the MEP scaling factor needs to be known by the software. To accomplish this, the HRPWM module has built in self-check and diagnostic capabilities that can be used to determine the optimum MEP scale factor value for any operating condition. TI provides a C-callable library containing one SFO function that utilizes this hardware and determines the optimum MEP scale factor. As such, MEP control and diagnostics registers are reserved for TI use.

A detailed description of the SFO library - SFO_TI_Build_V8.lib software can be found in SFO Library Software - SFO TI_Build_V8.lib.

Copyright © 2024 Texas Instruments Incorporated

#### 15.14.1.8 HRPWM Examples Using Optimized Assembly Code

The best way to understand how to use the HRPWM capabilities is through two real examples:

1. Simple buck converter using asymmetrical PWM (count-up) with active high polarity.
2. DAC function using simple R+C reconstruction filter.

The following examples all have initialization and configuration code written in C. To make these easier to understand, the #defines shown below are used.

Example 15-2 assumes MEP step size of 150ps and does not use the SFO library.

***Example 15-2. #Defines for HRPWM Header Files***

```
// HRPWM (High Resolution PWM) //
================================
// HRCNFG
#define HR_Disable 0x0
#define HR_REP 0x1          // Rising Edge position
#define HR_FEP 0x2          // Falling Edge position
#define HR_BEP 0x3          // Both Edge position #define HR_CMP 0x0 // CMPAHR controlled
#define HR_PHS 0x1          // TBPHSHR controlled #define HR_CTR_ZERO 0x0 // CTR = Zero event
#define HR_CTR_PRD 0x1      // CTR = Period event
#define HR_CTR_ZERO_PRD 0x2 // CTR = ZERO or Period event
#define HR_NORM_B  0x0      // Normal ePWMxB output
#define HR_INVERT_B 0x1     // ePWMxB is inverted ePWMxA output
```

#### 15.14.1.8.1 Implementing a Simple Buck Converter

In this example, the PWM requirements are:

- PWM frequency = 1MHz (that is, TBPRD = 100)
- PWM mode = asymmetrical, up-count
- Resolution = 12.7 bits (with a MEP step size of 150ps)

Figure 15-90 and Figure 15-91 show the required PWM waveform. As explained previously, configuration for the ePWM1 module is almost identical to the normal case except that the appropriate MEP options need to be enabled/selected.

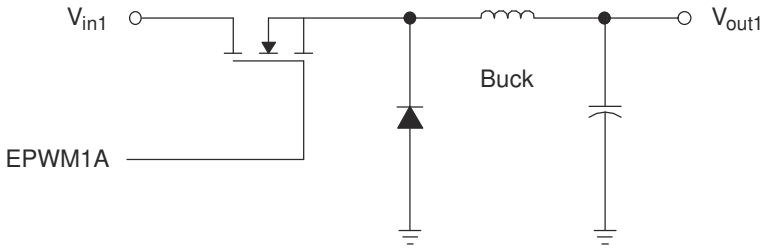

**Figure 15-90. Simple Buck Controlled Converter Using a Single PWM**

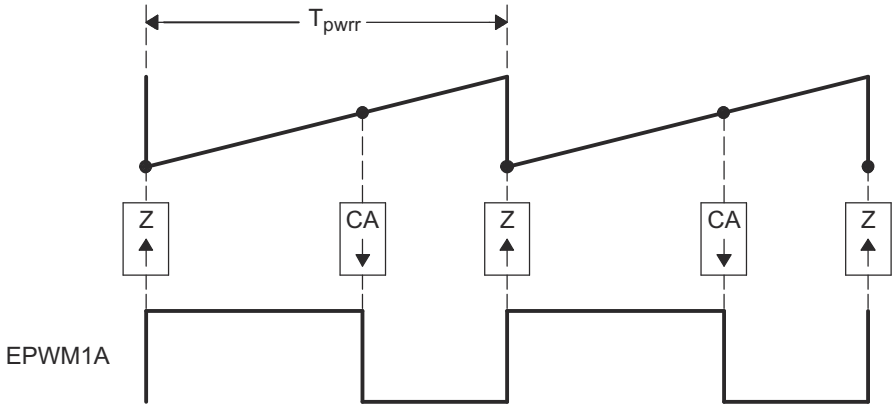

**Figure 15-91. PWM Waveform Generated for Simple Buck Controlled Converter**

The example code shown consists of two main parts:

- Initialization code (executed once)
- Run time code (typically executed within an ISR)

Example 15-3 shows the Initialization code. The first part is configured for conventional PWM. The second part sets up the HRPWM resources.

This example assumes MEP step size of 150ps and does not use the SFO library.

Example 15-4 shows an assembly example of run-time code for the HRPWM buck converter.

Copyright © 2024 Texas Instruments Incorporated

### Example 15-3. HRPWM Buck Converter Initialization Code

```
void HrBuckDrvCnf(void)
 {
// Config for conventional PWM first
EPwm1Regs.TBCTL.bit.PRDLD = TB_IMMEDIATE;         // set Immediate load
EPwm1Regs.TBPRD = 100;                            // Period set for 1000kHz PWM
hrbuck_period = 200;                              // Used for Q15 to Q0 scaling
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE;           // EPWM1 is the Master
EPwm1Regs.TBCTL.bit.SYNCOSEL = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1;
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
// Note: ChB is initialized here only for comparison purposes, it is not required

EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO;     // optional
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;       // optional
EPwm1Regs.AQCTLA.bit.ZRO = AQ_SET;
EPwm1Regs.AQCTLA.bit.CAU = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.ZRO = AQ_SET;                // optional
EPwm1Regs.AQCTLB.bit.CBU = AQ_CLEAR;              // optional
// Now configure the HRPWM resources
EALLOW;                                           // Note these registers are protected
                                                  // and act only on ChA
EPwm1Regs.HRCNFG.all = 0x0;                       // clear all bits first
EPwm1Regs.HRCNFG.bit.EDGMODE = HR_FEP;            // Control Falling Edge Position
EPwm1Regs.HRCNFG.bit.CTLMODE = HR_CMP;            // CMPAHR controls the MEP
EPwm1Regs.HRCNFG.bit.HRLOAD = HR_CTR_ZERO;        // Shadow load on CTR=Zero
EDIS;
MEP_ScaleFactor = 66*256;                         // Start with typical Scale Factor
                                                  // value for 100MHz
                                                  // Note: Use SFO functions to update
                                                     MEP_ScaleFactor dynamically
}
```

### Example 15-4. HRPWM Buck Converter Run-Time Code

```
EPWM1_BASE .set 0x6800
CMPAHR1 .set EPWM1_BASE+0x8
;=============================================
HRBUCK_DRV; (can execute within an ISR or loop)

#### 15.14.1.8.2 Implementing a DAC Function Using an R+C Reconstruction Filter

In this example, the PWM requirements are:

- PWM frequency = 400kHz (that is, TBPRD = 250)
- PWM mode = Asymmetrical, Up-count
- Resolution = 14 bits (MEP step size = 150ps)

Figure 15-92 and Figure 15-93 show the DAC function and the required PWM waveform. As explained previously, configuration for the ePWM1 module is almost identical to the normal case except that the appropriate MEP options need to be enabled/selected.

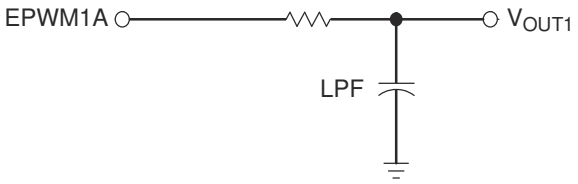

**Figure 15-92. Simple Reconstruction Filter for a PWM-based DAC**

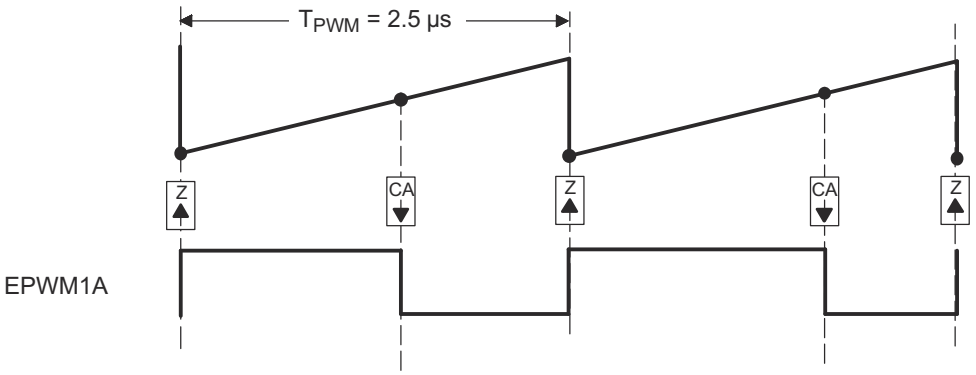

**Figure 15-93. PWM Waveform Generated for the PWM DAC Function**

The example code shown consists of two main parts:

- Initialization code (executed once)
- Run time code (typically executed within an ISR)

This example assumes a typical MEP_SP and does not use the SFO library.

Example 15-5 shows the Initialization code. The first part is configured for conventional PWM. The second part sets up the HRPWM resources.

Example 15-6 shows an assembly example of run-time code that can execute in a high-speed ISR loop.

Copyright © 2024 Texas Instruments Incorporated

### Example 15-5. PWM DAC Function Initialization Code

```
void HrPwmDacDrvCnf(void)
{
// Config for conventional PWM first
EPwm1Regs.TBCTL.bit.PRDLD = TB_IMMEDIATE;      // Set Immediate load
EPwm1Regs.TBPRD = 250;                         // Period set for 400kHz PWM
hrDAC_period = 250;                            // Used for Q15 to Q0 scaling
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE;        // EPWM1 is the Master
EPwm1Regs.TBCTL.bit.SYNCOSEL = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1;
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
// Note: ChB is initialized here only for comparison purposes, it is not required

EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO;  // optional
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;    // optional

EPwm1Regs.AQCTLA.bit.ZRO = AQ_SET;
EPwm1Regs.AQCTLA.bit.CAU = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.ZRO = AQ_SET;             // optional
EPwm1Regs.AQCTLB.bit.CBU = AQ_CLEAR;           // optional
// Now configure the HRPWM resources
EALLOW;                                        // Note these registers are protected
                                               // and act only on ChA.
EPwm1Regs.HRCNFG.all = 0x0;                    // Clear all bits first
EPwm1Regs.HRCNFG.bit.EDGMODE = HR_FEP;         // Control falling edge position
EPwm1Regs.HRCNFG.bit.CTLMODE = HR_CMP;         // CMPAHR controls the MEP.
EPwm1Regs.HRCNFG.bit.HRLOAD = HR_CTR_ZERO;     // Shadow load on CTR=Zero.
EDIS;
MEP_ScaleFactor = 66*256;                      // Start with typical Scale Factor
                                               // value for 100MHz.
                                               // Use SFO functions to update MEP_ScaleFactor
                                               // dynamically.
}
```

### Example 15-6. PWM DAC Function Run-Time Code

```
EPWM1_BASE .set 0x6800
CMPAHR1 .set EPWM1_BASE+0x8
;================================================
HRPWM_DAC_DRV; (can execute within an ISR or loop)
;================================================
      MOVW DP, #_HRDAC_In
      MOVL XAR2,@_HRDAC_In             ; Pointer to input Q15 duty (XAR2)
      MOVL XAR3,#CMPAHR1               ; Pointer to HRPWM CMPA reg (XAR3)

; Output for EPWM1A (HRPWM
      MOV T,*XAR2                      ; T <= duty
      MPY ACC,T,@_hrDAC_period         ; Q15 to Q0 scaling based on period
      ADD ACC,@_HrDAC_period<<15       ; Offset for bipolar operation
      MOV T,@_MEP_ScaleFactor          ; MEP scale factor (from optimizer s/w)
      MPYU P,T,@AL                     ; P <= T * AL, optimizer scaling
      MOVH @AL,P                       ; AL <= P, move result back to ACC
      ADD ACC, #0x080                  ; MEP range and rounding adjustment
      MOVL *XAR3,ACC                   ; CMPA:CMPAHR(31:8) <= ACC

; Output for EPWM1B (Regular Res) Optional - for comparison purpose only
      MOV *+XAR3[2],AH                 ; Store ACCH to regular CMPB
```

### 15.14.2 SFO Library Software - SFO_TI_Build_V8.lib

Table 15-17 lists several features of the SFO_TI_Build_V8.lib library.

**Table 15-17. SFO Library Features**

| | SFO_TI_Build_V8.lib | Unit |
|---|---|---|
| Completion-checking? | Yes | Function return value |
| Typical cycles required for SFO() to update MEP_ScaleFactor if called repetitively without interrupts | 130,000 | EPWMCLK cycles |

#### 15.14.2.1 Scale Factor Optimizer Function - int SFO()

This routine drives the micro-edge positioner (MEP) calibration module to run SFO diagnostics and determine the appropriate MEP scale factor (number of MEP steps per coarse EPWMCLK step) for a device at any given time.

If EPWMCLK = TBCLK = 100MHz and assuming the MEP step size is 150ps, the typical scale factor value at 100MHz = 66 MEP steps per TBCLK unit (10ns)

The function returns a MEP scale factor value:

MEP_ScaleFactor = Number of MEP steps per EPWMCLK

**Constraints when using this function:**

- SFO() can be used with a minimum EPWMCLK = TBCLK = 50MHz. MEP diagnostics logic uses EPWMCLK and not TBCLK, so the EPWMCLK restriction is an important constraint. Below 50MHz with device process variation, the MEP step size can decrease under cold temperature and high core voltage conditions to such a point that 255 MEP steps do not span an entire EPWMCLK cycle.
- At any time, SFO() can be called to run SFO diagnostics on the MEP calibration module.

**Usage:**

- SFO() can be called at any time in the background while the ePWM channels are running in HRPWM mode. The scale factor result obtained can be applied to all ePWM channels running in HRPWM mode because the function makes use of the diagnostics logic in the MEP calibration module (which runs independently of ePWM channels).
- This routine returns a 1 when calibration is finished and a new scale factor has been calculated or returns a 0 if calibration is still running. The routine returns a 2 if there is an error, and the MEP_ScaleFactor is greater than the maximum 255 fine steps per coarse EPWMCLK cycle. In this case, the HRMSTEP register maintains the last MEP scale factor value less than 256 for auto conversion.
- All ePWM modules operating in HRPWM incur only a 3 EPWMCLK cycle minimum duty cycle limitation when high-resolution period control is not used. If high-resolution period control is enabled, there is an additional duty cycle limitation 3-EPWMCLK cycles before the end of the PWM period (see Section 15.14.1.5.3).
- The SFO() function also updates the HRMSTEP register with the scale factor result. If the HRCNFG[AUTOCONV] bit is set, the application software is responsible only for setting CMPAHR = fraction(PWMduty*PWMperiod) << 8 or CMPBHR = fraction(PWMduty*PWMperiod) << 8 or TBPRDHR = fraction (PWMperiod) while running SFO() in the background. The MEP Calibration Module then uses the values in the HRMSTEP and CMPAHR/CMPBHR/TBPRDHR register to automatically calculate the appropriate number of MEP steps represented by the fractional duty cycle or period and move the high-resolution ePWM signal edge accordingly.
- If the HRCNFG[AUTOCONV] bit is clear, the HRMSTEP register is ignored. The application software needs to perform the necessary calculations manually so that:
  - CMPAHR = (fraction(PWMduty * PWMperiod) * MEP Scale Factor) << 8 + 0x080.
  - Similar behavior applies for TBPHSHR, CMPBHR, DBREDHR, and DBFEDHR. Auto-conversion must be enabled when using TBPRDHR.

Copyright © 2024 Texas Instruments Incorporated

The following code snippet shows how to use the HRPWM DUTY using driverlib functions.

```
float32_t dutyFine = 85.62;
float32_t count = (dutyFine * (float32_t)(EPWM_TIMER_TBPRD << 8))/100;
uint32_t compCount = (count);
HRPWM_setCounterCompareValue(EPWM1_BASE, HRPWM_COUNTER_COMPARE_A, compCount);
HRPWM_setCounterCompareValue(EPWM1_BASE, HRPWM_COUNTER_COMPARE_B, compCount);
```

The routine can be run as a background task in a slow loop requiring negligible CPU cycles. The repetition rate at which an SFO function needs to be executed depends on the application's operating environment. As with all digital CMOS devices, temperature and supply voltage variations have an effect on MEP operation. However, in most applications these parameters vary slowly and therefore is often sufficient to execute the SFO function once every 5 to 10 seconds. If more rapid variations are expected, then execution can be performed more frequently to match the application. Note there is no high limit restriction on the SFO function repetition rate; hence, the SFO function can execute as quickly as the background loop is capable.

While using the HRPWM feature, HRPWM logic is not active for the first 3 EPWMCLK cycles of the PWM period (and the last 3 EPWMCLK cycles of the PWM period if TBPRDHR is used). While running the application in this configuration, if high-resolution period control is disabled (HRPCTL[HRPE=0]) and the CMPA/CMPB register value is less than three cycles, then the CMPAHR/CMPBHR register must be cleared to zero. If high-resolution period control is enabled (HRPCTL[HRPE=1]), the CMPA register value must not fall below 3 or above TBPRD-3.This can avoid any unexpected transitions on the PWM signal.

#### 15.14.2.2 Software Usage

The software library function SFO(), calculates the MEP scale factor for the HRPWM-supported ePWM modules. The scale factor is an integer value in the range 1-255, and represents the number of micro step edge positions available for a system clock period. The scale factor value is returned in an integer variable called MEP_ScaleFactor. For example, see Table 15-18.

**Table 15-18. Factor Values**

| Software Function call | Functional Description | Updated Variables |
|---|---|---|
| SFO() | Returns MEP scale factor in the HRMSTEP register | MEP_ScaleFactor and HRMSTEP register. |

To use the HRPWM feature of the ePWMs, it is recommended that the SFO function be used as described here.

**Step 1. Add "Include" Files**

The SFO_V8.h file needs to be included as follows. This include file is mandatory while using the SFO library function. For the SFO() to operate, the appropriate (Device)_Device.h and (Device)_Epwm_defines.h must be included in the project. These include files are optional if customized header files are used in the end applications.

***Example 15-7. A Sample of How to Add "Include" Files***

```
#include "F28x7x_Device.h"         // F28x7x Headerfile
#include "F28x7x_EPwm_defines.h"   // init defines
#include "SFO_V8.h"                // SFO lib functions (needed for HRPWM)
```

Copyright © 2024 Texas Instruments Incorporated

### Step 2. Element Declaration

Declare an integer variable for the scale factor value as shown below.

***Example 15-8. Declaring an Element***

```
int MEP_ScaleFactor = 0;   //scale factor value
volatile struct EPWM_REGS *ePWM[] = {0, &EPwm1Regs, &EPwm2Regs, &EPwm3Regs,
&EPwm4Regs};
```

### Step 3. MEP_ScaleFactor Initialization

The SFO() function does not require a starting scale factor value in MEP_ScaleFactor. Prior to using the MEP_ScaleFactor variable in application code, SFO() can be called to drive the MEP calibration module to calculate an MEP_ScaleFactor value.

As part of the one-time initialization code prior to using MEP_ScaleFactor, include the following:

***Example 15-9. Initializing With a Scale Factor Value***

```
MEP_ScaleFactor initialized using function SFO ()
while (SFO() == 0) {} // MEP_ScaleFactor calculated by MEP Cal Module
```

### Step 4. Application Code

While the application is running, fluctuations in both device temperature and supply voltage can be expected. To be sure that good Scale Factors are used for each ePWM module, the SFO function can be re-run periodically as part of a slower back-ground loop. Some examples of this are shown here.

**Note**

See the HRPWM_SFO example in the device-specific C/C++ header files and peripheral examples available from the TI website.

***Example 15-10. SFO Function Calls***

```
main ()
 {
 int status;
    // User code
    // ePWM1, 2, 3, 4 are running in HRPWM mode
    // The status variable returns 1 once a new MEP_ScaleFactor has been
    // calculated by the MEP Calibration Module running SFO
    // diagnostics.
status = SFO();
if(status==2) {ESTOP0;}   // The function returns a 2 if MEP_ScaleFactor is greater
                          // than the maximum 255 allowed (error condition)
 }
```

Complex bit access types are encoded to fit into small table cells. Table 15-21 shows the codes that are used for access types in this section.

**Table 15-21. EPWM_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| R-0 | R<br>-0 | Read<br>Returns 0s |
| Write Type | | |
| W | W | Write |
| W1C | W<br>1C | Write<br>1 to clear |
| W1S | W<br>1S | Write<br>1 to set |
| Reset or Default Value | | |
| *-n* | | Value after reset or the default value |
| Register Array Variables | | |
| i,j,k,l,m,n | | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y | | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

### 15.15.2.1 TBCTL Register (Offset = 0h) [Reset = 0083h]

TBCTL is shown in Figure 15-94 and described in Table 15-22.

Return to the Summary Table.

Time Base Control Register

**Figure 15-94. TBCTL Register**

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|---|---|---|---|---|---|---|---|
| FREE_SOFT | | PHSDIR | CLKDIV | | | HSPCLKDIV | |
| R/W-0h | | R/W-0h | R/W-0h | | | R/W-1h | |
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| HSPCLKDIV | SWFSYNC | SYNCOSEL | | PRDLD | PHSEN | CTRMODE | |
| R/W-1h | R-0/W1S-0h | R/W-0h | | R/W-0h | R/W-0h | R/W-3h | |

**Table 15-22. TBCTL Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 15-14 | FREE_SOFT | R/W | 0h | Emulation Mode Bits. These bits select the behavior of the ePWM time-base counter during emulation events<br>00: Stop after the next time-base counter increment or decrement<br>01: Stop when counter completes a whole cycle:<br>- Up-count mode: stop when the time-base counter = period (TBCTR = TBPRD)<br>- Down-count mode: stop when the time-base counter = 0x00 (TBCTR = 0x00)<br>- Up-down-count mode: stop when the time-base counter = 0x00 (TBCTR = 0x00)<br>1x: Free run<br>Reset type: SYSRSn |
| 13 | PHSDIR | R/W | 0h | Phase Direction Bit<br>This bit is only used when the time-base counter is configured in the up-down-count mode. The<br>PHSDIR bit indicates the direction the time-base counter (TBCTR) will count after a synchronization<br>event occurs and a new phase value is loaded from the phase (TBPHS) register. This is<br>irrespective of the direction of the counter before the synchronization event..<br>In the up-count and down-count modes this bit is ignored.<br>0: Count down after the synchronization event.<br>1: Count up after the synchronization event.<br>Reset type: SYSRSn |
| 12-10 | CLKDIV | R/W | 0h | Time Base Clock Pre-Scale Bits<br>These bits select the time base clock pre-scale value (TBCLK = EPWMCLK/(HSPCLKDIV * CLKDIV):<br>000: /1 (default on reset)<br>001: /2<br>010: /4<br>011: /8<br>100: /16<br>101: /32<br>110: /64<br>111: /128<br>Reset type: SYSRSn |

**Table 15-22. TBCTL Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 9-7 | HSPCLKDIV | R/W | 1h | High Speed Time Base Clock Pre-Scale Bits<br>These bits determine part of the time-base clock prescale value. TBCLK = EPWMCLK / (HSPCLKDIV x CLKDIV). This divisor emulates the HSPCLK in the TMS320x281x system as used on the Event Manager (EV) peripheral.<br>000: /1<br>001: /2 (default on reset)<br>010: /4<br>011: /6<br>100: /8<br>101: /10<br>110: /12<br>111: /14<br>Reset type: SYSRSn |
| 6 | SWFSYNC | R-0/W1S | 0h | Software Forced Sync Pulse<br>0: Writing a 0 has no effect and reads always return a 0.<br>1: Writing a 1 forces a one-time synchronization pulse to be generated.<br>SWFSYNC affects EPWMxSYNCO only when SYNCOSEL = 00.<br>Reset type: SYSRSn |
| 5-4 | SYNCOSEL | R/W | 0h | Sync Output Select<br>00: EPWMxSYNCI / SWFSYNC<br>01: CTR = zero: Time-base counter equal to zero (TBCTR = 0x00)<br>10: CTR = CMPB : Time-base counter equal to counter-compare B (TBCTR = CMPB)<br>11: EPWMXSYNCO is defined by TBCTL2[SYNCOSELX]<br>Reset type: SYSRSn |
| 3 | PRDLD | R/W | 0h | Active Period Reg Load from Shadow Select<br>0: The period register (TBPRD) is loaded from its shadow register when the time-base counter, TBCTR, is equal to zero and/or a sync event as determined by the TBCTL2[PRDLDSYNC] bit.<br>A write/read to the TBPRD register accesses the shadow register.<br>1: Immediate Mode (Shadow register bypassed): A write or read to the TBPRD register accesses the active register.<br>Reset type: SYSRSn |
| 2 | PHSEN | R/W | 0h | Counter Reg Load from Phase Reg Enable<br>0: Do not load the time-base counter (TBCTR) from the time-base phase register (TBPHS).<br>1: Allow Counter to be loaded from the Phase register (TBPHS) and shadow to active load events when an EPWMxSYNCI input signal occurs or a software-forced sync signal, see bit 6.<br>Reset type: SYSRSn |
| 1-0 | CTRMODE | R/W | 3h | Counter Mode<br>The time-base counter mode is normally configured once and not changed during normal operation. If you change the mode of the counter, the change will take effect at the next TBCLK edge and the current counter value shall increment or decrement from the value before the mode change. These bits set the time-base counter mode of operation as follows:<br>00: Up-count mode<br>01: Down-count mode<br>10: Up-down count mode<br>11: Freeze counter operation (default on reset)<br>Reset type: SYSRSn |

**Table 15-28. DBCTL Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 15 | HALFCYCLE | R/W | 0h | Half Cycle Clocking Enable Bit<br>0: Full cycle clocking enabled. The dead-band counters are clocked at the TBCLK rate.<br>1: Half cycle clocking enabled. The dead-band counters are clocked at TBCLK*2.<br>Reset type: SYSRSn |
| 14 | DEDB_MODE | R/W | 0h | Dead Band Dual-Edge B Mode Control (S8 switch)<br>0: Rising edge delay applied to InA/InB as selected by S4 switch (IN-MODE bits) on A signal path only. Falling edge delay applied to InA/InB as selected by S5 switch (INMODE bits) on B signal path only.<br>1: Rising edge delay and falling edge delay applied to source selected by S4 switch (INMODE bits) and output to B signal path only. Note: When this bit is set to 1, user should always either set OUT_MODE bits such that Apath = InA OR OUTSWAP bits such that OutA=Bpath<br>otherwise, OutA will be invalid.<br>Reset type: SYSRSn |
| 13-12 | OUTSWAP | R/W | 0h | Dead Band Output Swap Control<br>Bit 13 controls the S6 switch and bit 12 controls the S7 switch.<br>00: OutA and OutB signals are as defined by OUT-MODE bits.<br>01: OutA = A-path as defined by OUT-MODE bits.<br>OutB = A-path as defined by OUT-MODE bits (rising edge delay or delay-bypassed A signal path).<br>10: OutA = B-path as defined by OUT-MODE bits (falling edge delay or delay-bypassed B signal path).<br>OutB = B-path as defined by OUT-MODE bits.<br>11: OutA = B-path as defined by OUT-MODE bits (falling edge delay or delay-bypassed B signal path).<br>OutB = A-path as defined by OUT-MODE bits (rising edge delay or delay-bypassed A signal path).<br>Reset type: SYSRSn |
| 11 | SHDWDBFEDMODE | R/W | 0h | FED Dead-Band Load Mode<br>0: Immediate mode. Only the active DBFED register is used. All writes/reads via the CPU directly access the active register for immediate 'FED dead-band action.'<br>1: Shadow mode. Operates as a double buffer. All writes via the CPU access Shadow register. Default at Reset is Immediate mode (for compatibility with legacy).<br>Reset type: SYSRSn |

Copyright © 2024 Texas Instruments Incorporated

**Table 15-28. DBCTL Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 10 | SHDWDBREDMODE | R/W | 0h | RED Dead-Band Load Mode<br>0: Immediate mode. Only the active DBRED register is used. All writes/reads via the CPU directly access the active register for immediate 'RED dead-band action.'<br>1: Shadow mode. Operates as a double buffer. All writes via the CPU access Shadow register. Default at Reset is Immediate mode (for compatibility with legacy).<br>Reset type: SYSRSn |
| 9-8 | LOADFEDMODE | R/W | 0h | Active DBFED Load from Shadow Select Mode<br>00: Load on Counter = 0 (CNT_eq)<br>01: Load on Counter = Period (PRD_eq)<br>10: Load on either Counter = 0, or Counter = Period<br>11: Freeze (no loads possible)<br>Note: has no effect in Immediate mode.<br>Reset type: SYSRSn |
| 7-6 | LOADREDMODE | R/W | 0h | Active DBRED Load from Shadow Select Mode<br>00: Load on Counter = 0 (CNT_eq)<br>01: Load on Counter = Period (PRD_eq)<br>10: Load on either Counter = 0, or Counter = Period<br>11: Freeze (no loads possible)<br>Note: has no effect in Immediate mode.<br>Reset type: SYSRSn |
| 5-4 | IN_MODE | R/W | 0h | Dead-Band Input Mode Control<br>Bit 5 controls the S5 switch and bit 4 controls the S4 switch shown. This allows you to select the input source to the falling-edge and rising-edge delay. To produce classical dead-band waveforms the default is EPWMxA In is the source for both falling and rising-edge delays.<br>00: EPWMxA In (from the action-qualifier) is the source for both falling-edge and rising-edge delay.<br>01: EPWMxB In (from the action-qualifier) is the source for rising-edge delayed signal.<br>EPWMxA In (from the action-qualifier) is the source for falling-edge delayed signal.<br>10: EPWMxA In (from the action-qualifier) is the source for rising-edge delayed signal.<br>EPWMxB In (from the action-qualifier) is the source for falling-edge delayed signal.<br>11: EPWMxB In (from the action-qualifier) is the source for both rising-edge delay and falling-edge delayed signal.<br>Reset type: SYSRSn |
| 3-2 | POLSEL | R/W | 0h | Polarity Select Control<br>Bit 3 controls the S3 switch and bit 2 controls the S2 switch.<br>This allows you to selectively invert one of the delayed signals before it is sent out of the dead-band submodule. The following descriptions correspond to classical upper/lower switch control as found in one leg of a digital motor control inverter. These assume that DBCTL[OUT_MODE] = 1,1 and DBCTL[IN_MODE] = 0x0. Other enhanced modes are also possible, but not regarded as typical usage modes.<br>00: Active high (AH) mode. Neither EPWMxA nor EPWMxB is inverted (default).<br>01: Active low complementary (ALC) mode. EPWMxA is inverted.<br>10: Active high complementary (AHC). EPWMxB is inverted.<br>11: Active low (AL) mode. Both EPWMxA and EPWMxB are inverted.<br>Reset type: SYSRSn |

| TBPRD | | | | | | | |
| R/W-0h | | | | | | | |

**Table 15-56. TBPRD Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 15-0 | TBPRD | R/W | 0h | Time Base Period Register<br>These bits determine the period of the time-base counter. This sets the PWM frequency. Shadowing of this register is enabled and disabled by the TBCTL[PRDLD] bit. By default this register is shadowed.<br>- If TBCTL[PRDLD] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the active register will be loaded from the shadow register when the time-base counter equals zero.<br>- If TBCTL[PRDLD] = 1, then the shadow is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware.<br>- The active and shadow registers share the same memory map address.<br>Reset type: SYSRSn |

Copyright © 2024 Texas Instruments Incorporated

### 15.15.2.36 CMPA Register (Offset = 6Ah) [Reset = 00000000h]

CMPA is shown in Figure 15-129 and described in Table 15-57.

Return to the Summary Table.

Counter Compare A Register

**Figure 15-129. CMPA Register**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| CMPA | | | | | | | | | | | | | | | | CMPAHR | | | | | | | | | | | | | | | |
| R/W-0h | | | | | | | | | | | | | | | | R/W-0h | | | | | | | | | | | | | | | |

**Table 15-57. CMPA Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-16 | CMPA | R/W | 0h | Compare A Register<br>The value in the active CMPA register is continuously compared to the time-base counter (TBCTR). When the values are equal, the counter-compare module generates a 'time-base counter equal to counter compare A' event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include:<br>- Do nothing<br>the event is ignored.<br>- Clear: Pull the EPWMxA and/or EPWMxB signal low<br>- Set: Pull the EPWMxA and/or EPWMxB signal high<br>- Toggle the EPWMxA and/or EPWMxB signal<br>Shadowing of this register is enabled and disabled by the CMPCTL[SHDWAMODE] bit. By default this register is shadowed.<br>- If CMPCTL[SHDWAMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADAMODE] bit field determines which event will load the active register from the shadow register.<br>- Before a write, the CMPCTL[SHDWAFULL] bit can be read to determine if the shadow register is currently full.<br>- If CMPCTL[SHDWAMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware.<br>- In either mode, the active and shadow registers share the same memory map address.<br>Reset type: SYSRSn |
| 15-0 | CMPAHR | R/W | 0h | Compare A HRPWM Extension Register<br>The UPPER 8-bits contain the high-resolution portion (most significant 8-bits) of the counter-compare A value. CMPA:CMPAHR can be accessed in a single 32-bit read/write. Shadowing is enabled and disabled by the CMPCTL[SHDWAMODE] bit as described for the CMPA register.<br>The lower 8 bits in this register are ignored<br>Reset type: SYSRSn |

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 31-16 | CMPB | R/W | 0h | Compare B Register<br>The value in the active CMPB register is continuously compared to the time-base counter (TBCTR). When the values are equal, the counter-compare module generates a 'time-base counter equal to counter compare B' event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include:<br>- Do nothing<br>the event is ignored.<br>- Clear: Pull the EPWMxA and/or EPWMxB signal low<br>- Set: Pull the EPWMxA and/or EPWMxB signal high<br>- Toggle the EPWMxA and/or EPWMxB signal<br>Shadowing of this register is enabled and disabled by the CMPCTL[SHDWBMODE] bit. By default this register is shadowed.<br>- If CMPCTL[SHDWBMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADBMODE] bit field determines which event will load the active register from the shadow register.<br>- Before a write, the CMPCTL[SHDWBFULL] bit can be read to determine if the shadow register is currently full.<br>- If CMPCTL[SHDWBMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware.<br>- In either mode, the active and shadow registers share the same memory map address.<br>Reset type: SYSRSn |
| 15-0 | CMPBHR | R/W | 0h | Compare B High Resolution Bits<br>The lower 8 bits in this register are ignored<br>Reset type: SYSRSn |

| 5 | DCBEVT1 | R | 0h | Latched Status Flag for Digital Compare Output B Event 1<br>0: Indicates no trip event has occurred on DCBEVT1<br>1: Indicates a trip event has occurred for the event defined for DCBEVT1<br>Reset type: SYSRSn |
| 4 | DCAEVT2 | R | 0h | Latched Status Flag for Digital Compare Output A Event 2<br>0: Indicates no trip event has occurred on DCAEVT2<br>1: Indicates a trip event has occurred for the event defined for DCAEVT2<br>Reset type: SYSRSn |
| 3 | DCAEVT1 | R | 0h | Latched Status Flag for Digital Compare Output A Event 1<br>0: Indicates no trip event has occurred on DCAEVT1<br>1: Indicates a trip event has occurred for the event defined for DCAEVT1<br>Reset type: SYSRSn |
| 2 | OST | R | 0h | Latched Status Flag for A One-Shot Trip Event<br>0: No one-shot trip event has occurred.<br>1: Indicates a trip event has occurred on a pin selected as a one-shot trip source.<br>This bit is cleared by writing the appropriate value to the TZCLR register.<br>Reset type: SYSRSn |

Copyright © 2024 Texas Instruments Incorporated

**Table 15-70. TZFLG Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 1 | CBC | R | 0h | Latched Status Flag for Cycle-By-Cycle Trip Event<br>0: No cycle-by-cycle trip event has occurred.<br>1: Indicates a trip event has occurred on a signal selected as a cycle-by-cycle trip source. The<br>TZFLG[CBC] bit will remain set until it is manually cleared by the user. If the cycle-by-cycle trip event is still present when the CBC bit is cleared, then CBC will be immediately set again. The specified condition on the signal is automatically cleared when the ePWM time-base counter reaches zero (TBCTR = 0x00) if the trip condition is no longer present. The condition on the signal is only cleared when the TBCTR = 0x00 no matter where in the cycle the CBC flag is cleared.<br>This bit is cleared by writing the appropriate value to the TZCLR register.<br>Reset type: SYSRSn |
| 0 | INT | R | 0h | Latched Trip Interrupt Status Flag<br>0: Indicates no interrupt has been generated.<br>1: Indicates an EPWMx_TZINT PIE interrupt was generated because of a trip condition.<br>No further EPWMx_TZINT PIE interrupts will be generated until this flag is cleared. If the interrupt flag is cleared when either CBC or OST is set, then another interrupt pulse will be generated. Clearing all flag bits will prevent further interrupts. This bit is cleared by writing the appropriate value to the TZCLR register.<br>Reset type: SYSRSn |

### 15.15.2.74 DCCAP Register (Offset = CFh) [Reset = 0000h]

DCCAP is shown in Figure 15-167 and described in Table 15-95.

Return to the Summary Table.

Digital Compare Counter Capture Register

**Figure 15-167. DCCAP Register**

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|---|---|---|---|---|---|---|---|
| DCCAP | | | | | | | |
| R-0h | | | | | | | |
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| DCCAP | | | | | | | |
| R-0h | | | | | | | |

**Table 15-95. DCCAP Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 15-0 | DCCAP | R | 0h | Digital Compare Time-Base Counter Capture<br>To enable time-base counter capture, set the DCCAPCLT[CAPE] bit to 1. If enabled, reflects the value of the time-base counter (TBCTR) on the low to high edge transition of a filtered (DCEVTFLT) event. Further capture events are ignored until the next period or zero as selected by the DCFCTL[PULSESEL] bit. Shadowing of DCCAP is enabled and disabled by the DCCAPCTL[SHDWMODE] bit. By default this register is shadowed.<br>- If DCCAPCTL[SHDWMODE] = 0, then the shadow is enabled. In this mode, the active register is copied to the shadow register on the TBCTR = TBPRD or TBCTR = zero as defined by the DCFCTL[PULSESEL] bit. CPU reads of this register will return the shadow register value.<br>- If DCCAPCTL[SHDWMODE] = 1, then the shadow register is disabled. In this mode, CPU reads will return the active register value. The active and shadow registers share the same memory map address.<br>Reset type: SYSRSn |

Chapter 16

# Enhanced Capture (eCAP)

This chapter describes the enhanced capture (eCAP) module, which is used in systems where accurate timing of external events is important.

The enhanced capture (eCAP) module is a Type 0 eCAP. See the *C2000 Real-Time Control Peripheral Reference Guide* for a list of all devices with an eCAP module of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

## 16.1 Introduction

### 16.1.1 Features

The features of the eCAP module include:

- Speed measurements of rotating machinery (for example, toothed sprockets sensed by way of Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors

The eCAP module features described in this chapter include:

- 4-event time-stamp registers (each 32 bits)
- Edge polarity selection for up to four sequenced time-stamp capture events
- Interrupt on either of the four events
- Single-shot capture of up to four event time-stamps
- Continuous mode capture of time stamps in a four-deep circular buffer
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- All above resources are dedicated to a single input pin
- When not used in capture mode, the eCAP module can be configured as a single-channel PWM output

### 16.1.2 ECAP Related Collateral

**Foundational Materials**

- C2000 Academy - ECAP

**Getting Started Materials**

- *Leveraging High Resolution Capture (HRCAP) for Single Wire Data Transfer Application Report*

## 16.2 Description

The eCAP module represents one complete capture channel that can be instantiated multiple times, depending on the target device. In the context of this guide, one eCAP channel has the following independent key resources:

- Dedicated input capture pin
- Output X-BAR is used to configure output in APWM mode
- 32-bit time base (counter)
- 4 x 32-bit time-stamp capture registers (CAP1-CAP4)
- Four-stage sequencer (modulo4 counter) that is synchronized to external events, eCAP pin rising/falling edges.
- Independent edge polarity (rising/falling edge) selection for all four events
- Input capture signal prescaling (from 2-62 or bypass)
- One-shot compare register (two bits) to freeze captures after 1-4 time-stamp events
- Control for continuous time-stamp captures using a four-deep circular buffer (CAP1-CAP4) scheme
- Interrupt capabilities on any of the four capture events

Copyright © 2024 Texas Instruments Incorporated

## 16.3 Configuring Device Pins for the eCAP

The Input X-BAR connects the device pins to the module as input. Any GPIO on the device can be configured as an input. The GPIO input qualification can be set to synchronous or asynchronous mode by setting the GPxQSELn register bits. Using synchronized inputs can help with noise immunity but affects the eCAP accuracy by ±2 cycles. The internal pull-ups can be configured in the GPyPUD register. Since the GPIO mode is used, the GPyINV register can invert the signals.

The Output X-BAR must be used to connect output signals to the OUTPUTXBARx output locations. The GPIO mux must then be configured to connect the OUTPUTXBARx lines to any of several IO pins with the GPIO mux. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux, GPIO settings, and XBAR configuration.

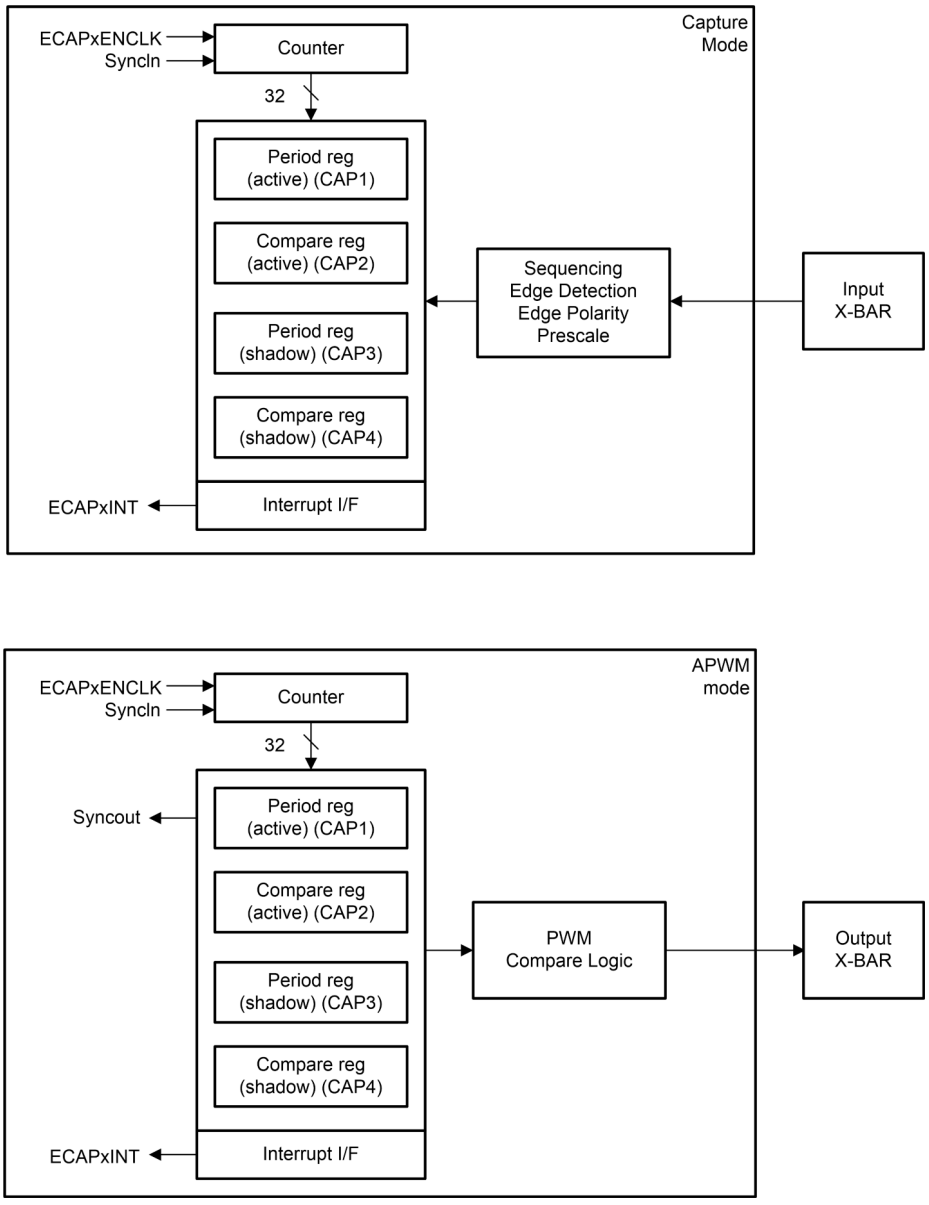
## 16.4 Capture and APWM Operating Mode

Use the eCAP module resources to implement a single-channel PWM generator (with 32-bit capabilities) when the eCAP module is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The CAP1 and CAP2 registers become the active period and compare registers, respectively, while CAP3 and CAP4 registers become the period and compare shadow registers, respectively. Figure 16-1 is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.

Figure 16-2 further descries the output of the eCAP in APWM mode based on the CMP and PRD values.



A. A single pin is shared between CAP and APWM functions. In capture mode, the pin is an input; in APWM mode, the pin is an output.

B. In APWM mode, writing any value to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.

**Figure 16-1. Capture and APWM Modes of Operation**

## 16.5 Capture Mode Description

Figure 16-3 shows the various components that implement the capture function.

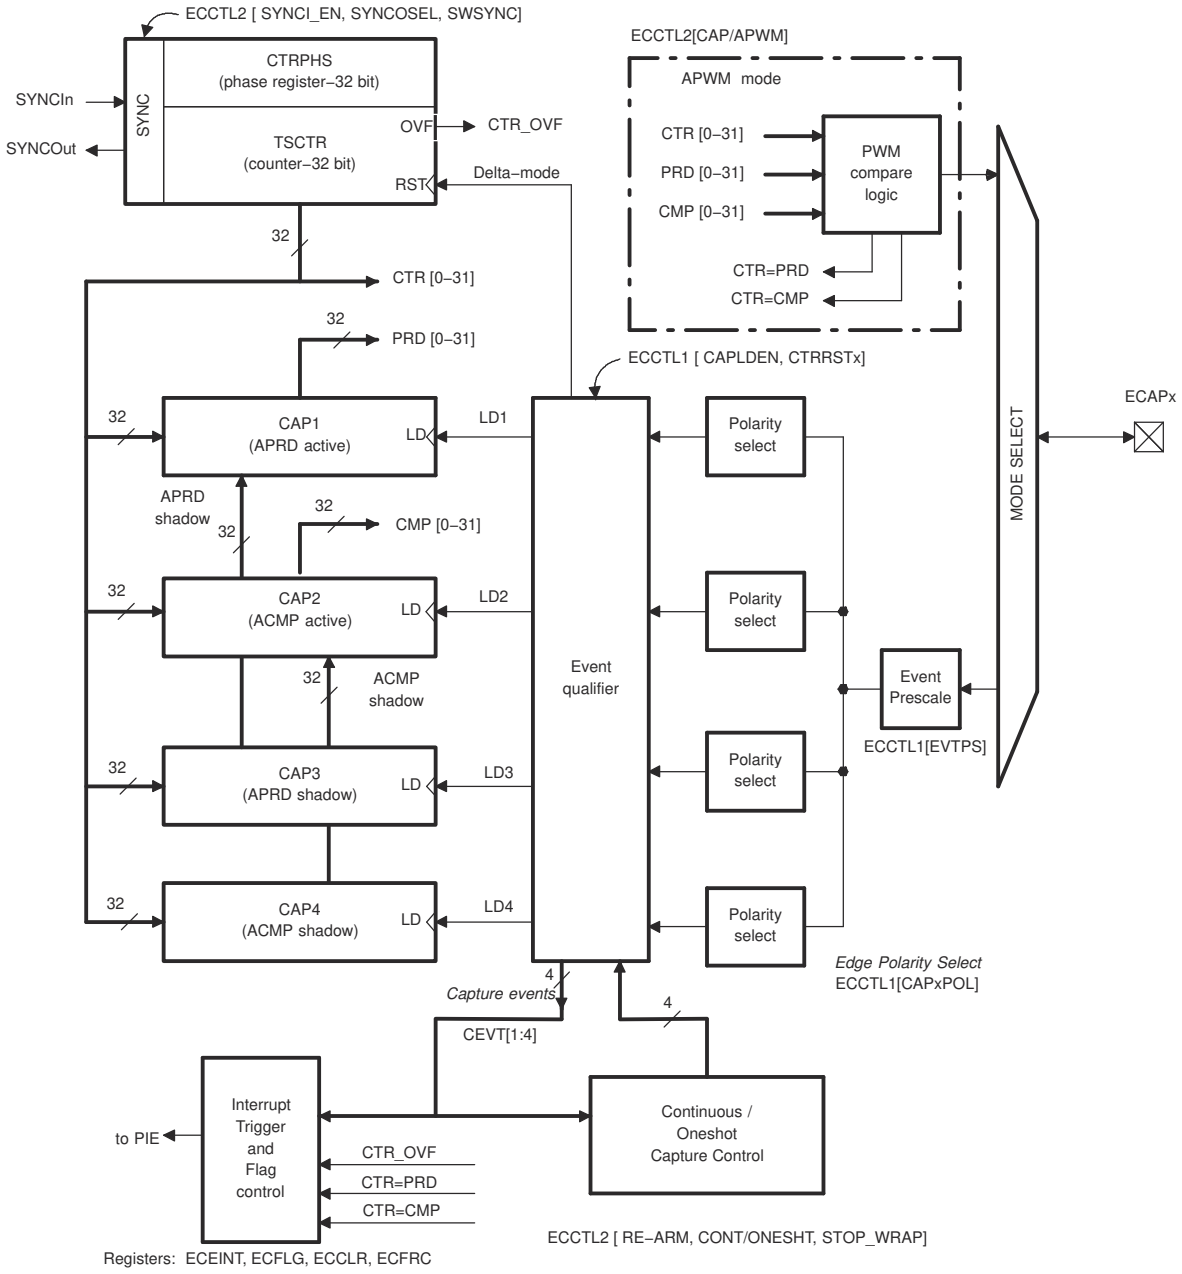

**Figure 16-3. eCAP Block Diagram**

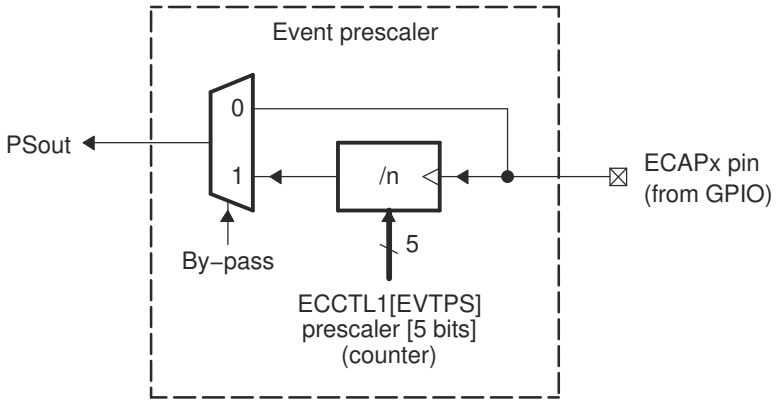
Copyright © 2024 Texas Instruments Incorporated

### 16.5.1 Event Prescaler

An input capture signal (pulse train) can be prescaled by N = 2-62 (in multiples of 2) or can bypass the prescaler. This is useful when very high frequency signals are used as inputs. Figure 16-4 shows a functional diagram and Figure 16-5 shows the operation of the prescale function.



A. When a prescale value of 1 is chosen (ECCTL1[13:9] = 0,0,0,0,0), the input capture signal bypasses the prescale logic completely.
B. The first Rise edge after Prescale configuration change is not passed to Capture logic, prescaler value takes into effect on the second rising edge after the configuration.

**Figure 16-4. Event Prescale Control**

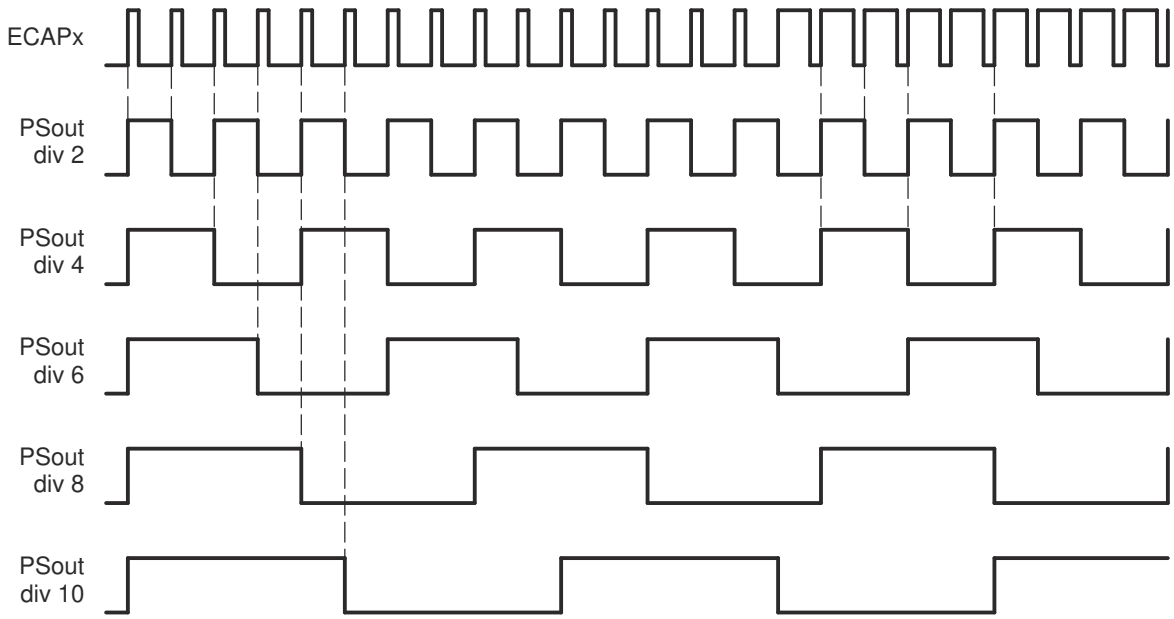


**Figure 16-5. Prescale Function Waveforms**

### 16.5.2 Edge Polarity Select and Qualifier

Functionality and features include:

- Four independent edge polarity (rising edge/falling edge) selection muxes are used, one for each capture event.
- Each edge (up to 4) is event qualified by the Modulo4 sequencer.

Copyright © 2024 Texas Instruments Incorporated

- The edge event is gated to the respective CAPx register by the Mod4 counter. The CAPx register is loaded on the falling edge.

### *16.5.3 Continuous/One-Shot Control*

Operation of eCAP in Continuous/One-Shot mode:

- The Mod4 (2-bit) counter is incremented using edge qualified events (CEVT1-CEVT4).
- The Mod4 counter continues counting (0->1->2->3->0) and wraps around unless stopped.
- During one-shot operation, a 2-bit stop register (STOP_WRAP) is used to compare the Mod4 counter output, and when equal, stops the Mod4 counter and inhibits further loads of the CAP1-CAP4 registers. In this mode, if TSCCTR counter is configured to reset on capture event (CEVTx) by configuring ECCTL1.CTRRSTx bit, the operation still keeps resetting the TSCCTR counter on capture event (CEVTx) after the STOP_WRAP value is reached and re-arm (REARM) has not occurred.

The continuous/one-shot block controls the start, stop and reset (zero) functions of the Mod4 counter, using a mono-shot type of action that can be triggered by the stop-value comparator and re-armed using software control.

Once armed, the eCAP module waits for 1-4 (defined by stop-value) capture events before freezing both the Mod4 counter and contents of CAP1-4 registers (time stamps).

Re-arming prepares the eCAP module for another capture sequence. Also, re-arming clears (to zero) the Mod4 counter and permits loading of CAP1-4 registers again, providing the CAPLDEN bit is set.

In continuous mode, the Mod4 counter continues to run (0->1->2->3->0, the one-shot action is ignored, and capture values continue to be written to CAP1-4 in a circular buffer sequence.

### 16.5.4 32-Bit Counter and Phase Control

This counter provides the time-base for event captures, and is clocked using the system clock.

A phase register is provided to achieve synchronization with other counters using a hardware and software forced sync. This is useful in APWM mode when a phase offset between modules is needed.

On any of the four event loads, an option to reset the 32-bit counter is given. This is useful for time difference capture. The 32-bit counter value is captured first, then the counter value is reset to 0 by any of the LD1-LD4 signals.

### 16.5.5 CAP1-CAP4 Registers

These 32-bit registers are supplied by the 32-bit counter timer bus, CTR[0-31], and are loaded (capture a time-stamp) when the respective LD inputs are strobed.

Control bit CAPLDEN can inhibit loading of the capture registers. During one-shot operation, this bit is cleared (loading is inhibited) automatically when a stop condition occurs, StopValue = Mod4.

CAP1 and CAP2 registers become the active period and compare registers, respectively, in APWM mode.

CAP3 and CAP4 registers become the respective shadow registers (APRD and ACMP) for CAP1 and CAP2 during APWM operation.

### 16.5.6 eCAP Synchronization

eCAP modules can be synchronized with each other by selecting a common SYNCIN source. SYNCIN source for eCAP can be either software sync-in or external sync-in. The external sync-in signal can come from EPWM, eCAP, or X-Bar. The SWSYNC of the eCAP module is logical ORed with the SYNC signal as shown in Figure 16-7. The SYNC signal is defined by the selection of SYNCSELECT[ECAPxSYNCIN] as shown in Figure 16-8.

**Note**

If SWSYNC is forced from ECAPx, then the Sync pulse is delayed by one clock cycle for sync pulse receiving ECAPs . This cycle delay/lag for the sync pulse receiving ECAPs can be corrected with the CTRPHS register. If there is an external SYNC signal, then all ECAPs see the signal at the same time.

Copyright © 2024 Texas Instruments Incorporated

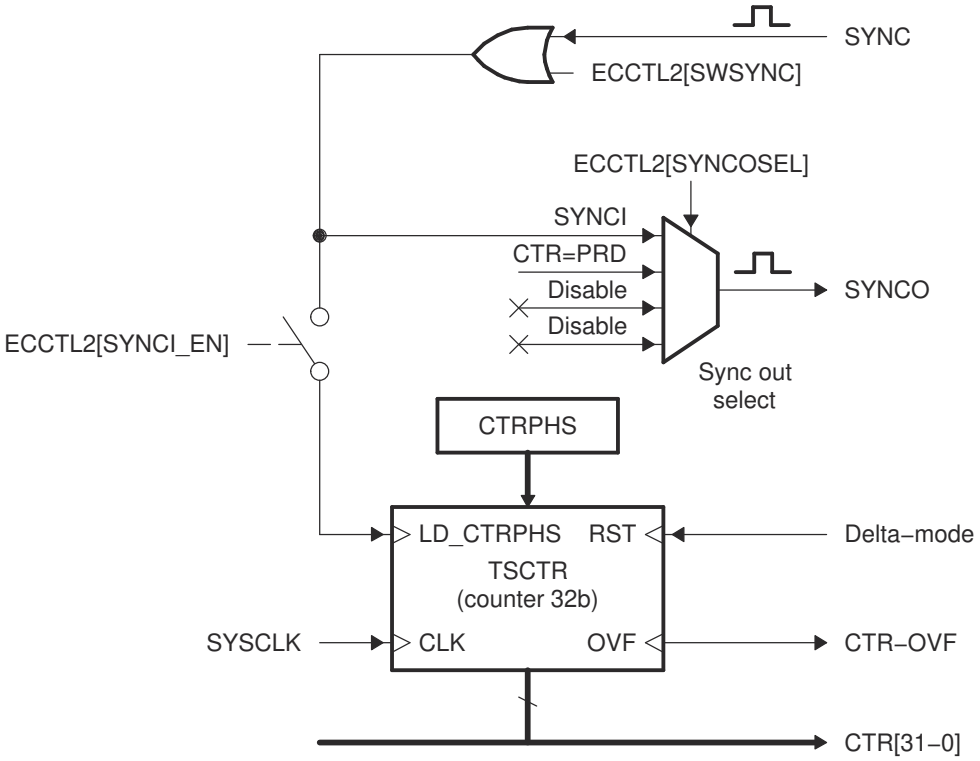

**Figure 16-7. Details of the Counter and Synchronization Block**

#### 16.5.6.1 Example 1 - Using SWSYNC with ECAP Module

Implement the following steps to use SWSYNC with ECAP1 and ECAP3.

- Configure ECAP[1..3].ECCTL2.SYNCO_SEL = 0x0, to allow the sync-in event to be the sync-out signal pass through.
- Configure ECAP[2..3].ECCTL2.SWSYNC = 0x0, to disable software synchronization for eCAP2 through eCAP3.
- The default sync signal comes from ePWM1, if TBCTL[SYNCOSEL] is not correctly configured this can cause undesired resets of the time-stamp register (TSCTR). Select an unused GPIO in InputXbarRegs.INPUT5SELECT. Configure this GPIO in output mode and write 0 to the GPIO DAT register. By default, this is programmed to GPIO0 so any activity on this pin can cause problems with the SWSYNC.
- Program SYNCSEL[ECAP1SYNCIN] = 0x5. This takes ECAPx.EXTSYNCIN to an inactive state.
- Configure ECAP1.ECCTL2.SWSYNC=0x1, this forces Software Synchronization of TSCTR counter

To use SWSYNC with other eCAP modules, make sure that the previous eCAP chain is not generating a SYNCOUT signal that interferes with the software synchronization.

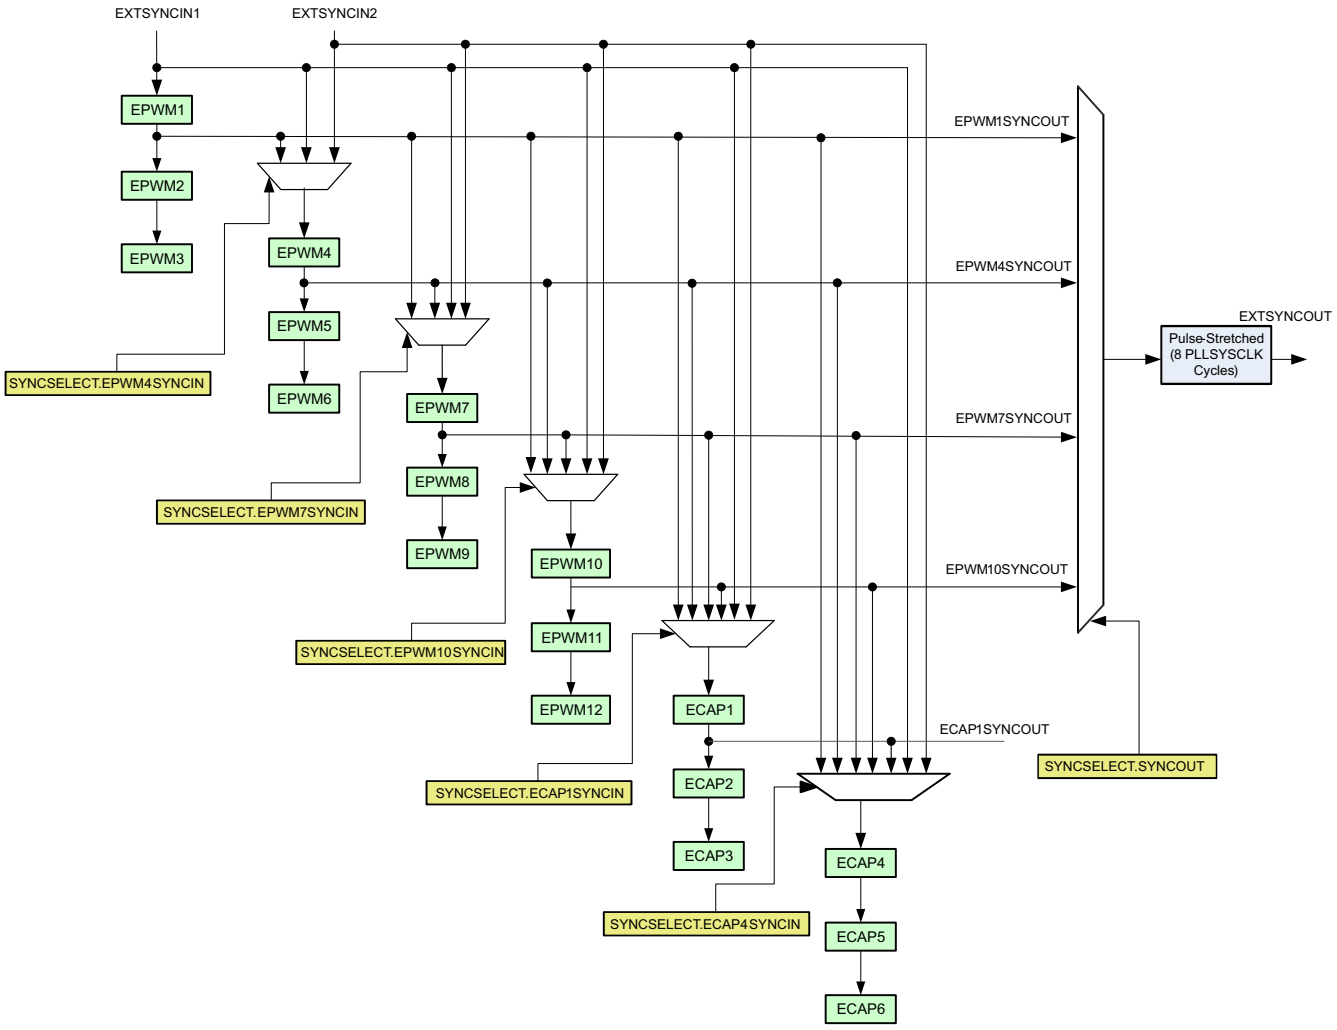

**Figure 16-8. Time-Base Counter Synchronization Scheme**

### *16.5.7 Interrupt Control*

Operation and features of the eCAP interrupt control include (see Figure 16-9):

- An interrupt can be generated on capture events (CEVT1-CEVT4, CTROVF) or APWM events (CTR = PRD, CTR = CMP).
- A counter overflow event (FFFFFFFF->00000000) is also provided as an interrupt source (CTROVF).
- The capture events are edge and sequencer-qualified (ordered in time) by the polarity select and Mod4 gating, respectively.
- One of these events can be selected as the interrupt source (from the eCAPx module) going to the PIE and CLA.
- Seven interrupt events (CEVT1, CEVT2, CEVT3, CEVT4, CNTOVF, CTR=PRD, CTR=CMP) can be generated.
- The interrupt enable register (ECEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (ECFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated to the PIE only if any of the interrupt events are enabled, the flag bit is 1, and the INT flag bit is 0. The interrupt service routine must clear the global interrupt flag bit and the serviced event using the interrupt clear register (ECCLR) before any other interrupt pulses are generated. To force an interrupt event, use the interrupt force register (ECFRC). This is useful for test purposes.

Copyright © 2024 Texas Instruments Incorporated

**Note**

The CEVT1, CEVT2, CEVT3, CEVT4 flags are only active in capture mode (ECCTL2[CAP/APWM == 0]). The CTR=PRD, CTR=CMP flags are only valid in APWM mode (ECCTL2[CAP/APWM == 1]). CNTOVF flag is valid in both modes.

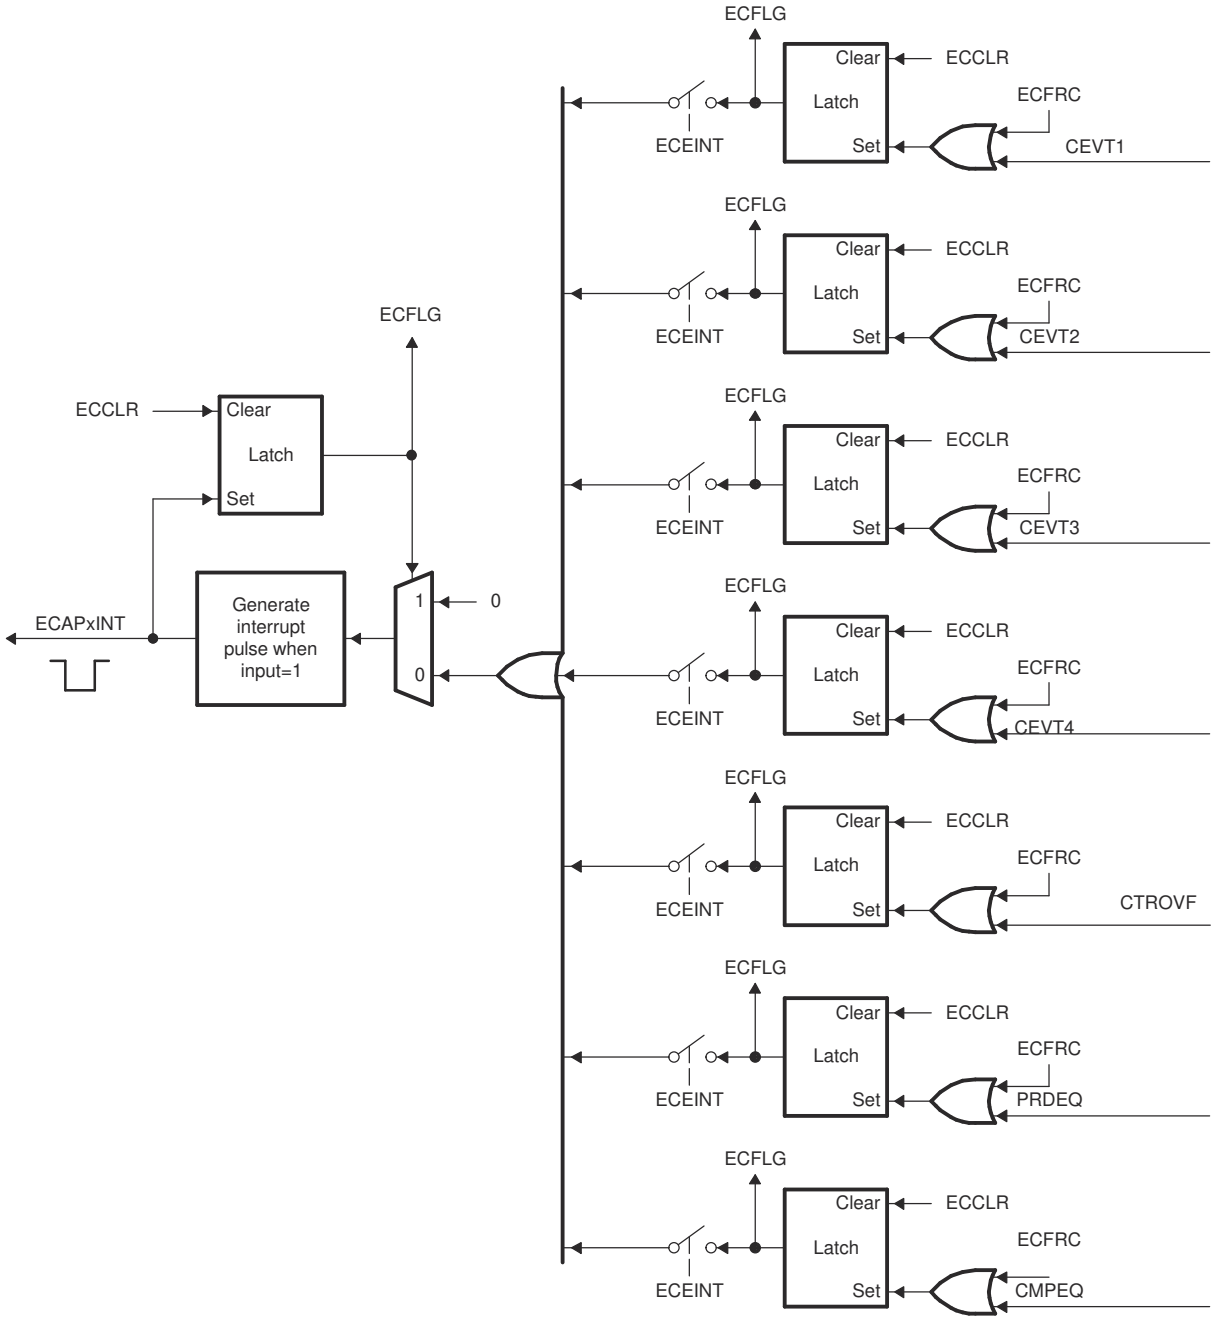

**Figure 16-9. Interrupts in eCAP Module**

Copyright © 2024 Texas Instruments Incorporated

### 16.5.8 DMA Interrupt

On Type 0 eCAP modules, the CPU was required to begin data transfers using DMA. New to the Type 1 eCAP, a separate DMA Trigger (ECAP_DMA_INT) enables continuous transfer of capture data from eCAP registers to on-chip memory using DMA. Any one of the four available interrupt events () can be selected as the trigger source for ECAP_DMA_INT using ECCTL2 [DMAEVTSEL].

### 16.5.9 Shadow Load and Lockout Control

In capture mode, this logic inhibits (locks out) any shadow loading of CAP1 or CAP2 from APRD and ACMP registers, respectively.

In APWM mode, shadow loading is active and two choices are permitted:

- Immediate - APRD or ACMP are transferred to CAP1 or CAP2 immediately upon writing a new value.
- On period equal, CTR[31:0] = PRD[31:0].

### 16.5.10 APWM Mode Operation

Main operating highlights of the APWM section:

- The time-stamp counter bus is made available for comparison by way of 2 digital (32-bit) comparators.
- When CAP1/2 registers are not used in capture mode, the contents can be used as Period and Compare values in APWM mode.
- Double buffering is achieved using shadow registers APRD and ACMP (CAP3/4). The shadow register contents are transferred over to CAP1/2 registers, either immediately upon a write, or on a CTR = PRD trigger.
- In APWM mode, writing to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.
- During initialization, write to the active registers for both period and compare. This automatically copies the initial values into the shadow values. For subsequent compare updates during run-time, use the shadow registers.

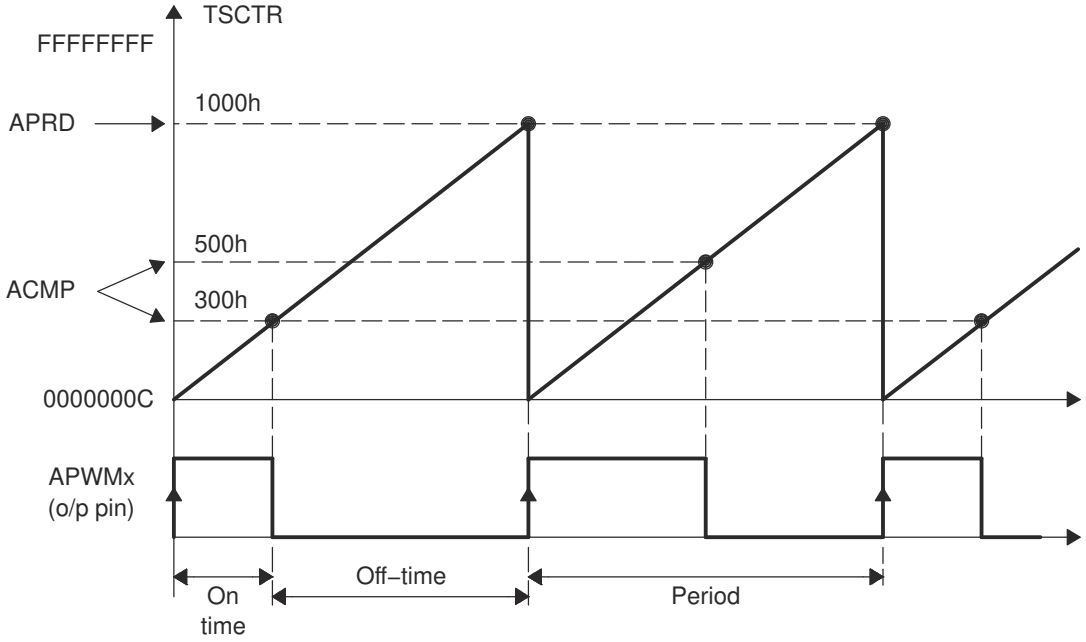

**Figure 16-10. PWM Waveform Details Of APWM Mode Operation**

Copyright © 2024 Texas Instruments Incorporated

The behavior of APWM active high mode (APWMPOL == 0) is as follows:

```
CMP = 0x00000000, output low for duration of period (0% duty)

CMP = 0x00000001, output high 1 cycle

CMP = 0x00000002, output high 2 cycles

CMP = PERIOD, output high except for 1 cycle (<100% duty)

CMP = PERIOD+1, output high for complete period (100% duty)

CMP > PERIOD+1, output high for complete period
```

The behavior of APWM active low mode (APWMPOL == 1) is as follows:

```
CMP = 0x00000000, output high for duration of period (0% duty)

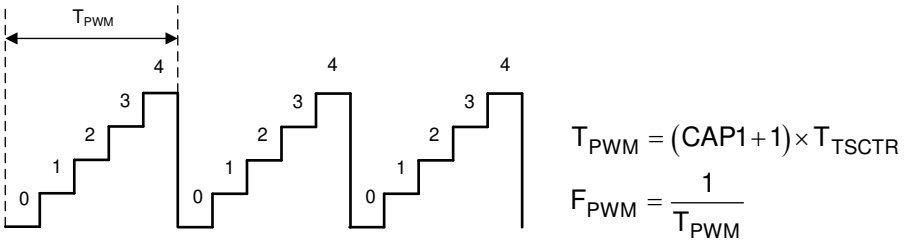
CMP = 0x00000001, output low 1 cycle

CMP = 0x00000002, output low 2 cycles

CMP = PERIOD, output low except for 1 cycle (<100% duty)

CMP = PERIOD+1, output low for complete period (100% duty)

CMP > PERIOD+1, output low for complete period
```



$$T_{PWM} = (CAP1 + 1) \times T_{TSCTR}$$

$$F_{PWM} = \frac{1}{T_{PWM}}$$

## 16.6 Application of the eCAP Module

The following sections provide applications examples to show how to operate the eCAP module.

### *16.6.1 Example 1 - Absolute Time-Stamp Operation Rising-Edge Trigger*

Figure 16-12 shows an example of continuous capture operation (Mod4 counter wraps around). In this figure, TSCTR counts-up without resetting and capture events are qualified on the rising edge only, this gives period (and frequency) information.

On an event, the TSCTR contents (time-stamp) is first captured, then Mod4 counter is incremented to the next state. When the TSCTR reaches FFFFFFFF (maximum value), the Mod4 counter wraps around to 00000000 (not shown in Figure 16-12), if this occurs, the CTROVF (counter overflow) flag is set, and an interrupt (if enabled) occurs. Captured Time-stamps are valid at the point indicated by the diagram (after the fourth event); hence, event CEVT4 can conveniently be used to trigger an interrupt and the CPU can read data from the CAPx registers.

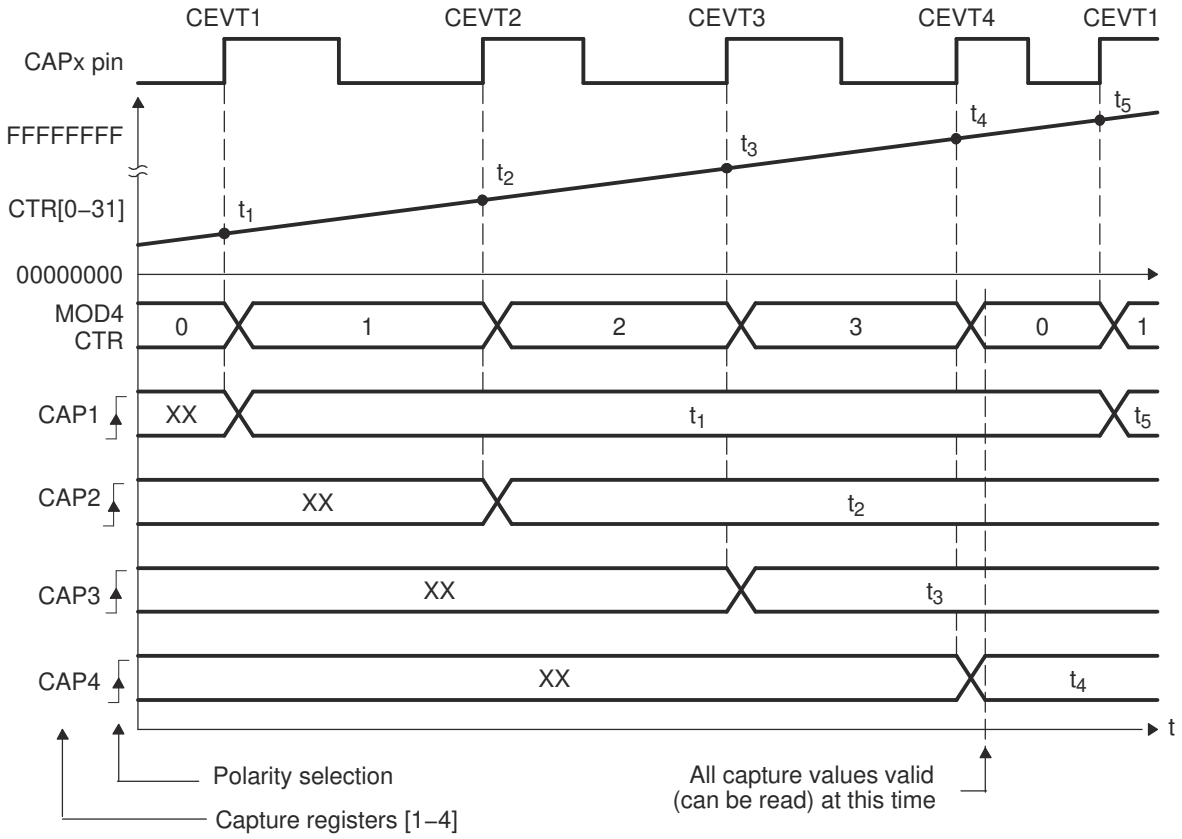

**Figure 16-12. Capture Sequence for Absolute Time-stamp and Rising-Edge Detect**

Copyright © 2024 Texas Instruments Incorporated

### 16.6.2 Example 2 - Absolute Time-Stamp Operation Rising- and Falling-Edge Trigger

In Figure 16-13, the eCAP operating mode is almost the same as in the previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information, that is: Period1 = $t_3 - t_1$, Period2 = $t_5 - t_3$, …and so on. Duty Cycle1 (on-time %) = $(t_2 - t_1)$ / Period1 x 100%, and so on. Duty Cycle1 (off-time %) = $(t_3 - t_2)$ / Period1 x 100%, and so on.

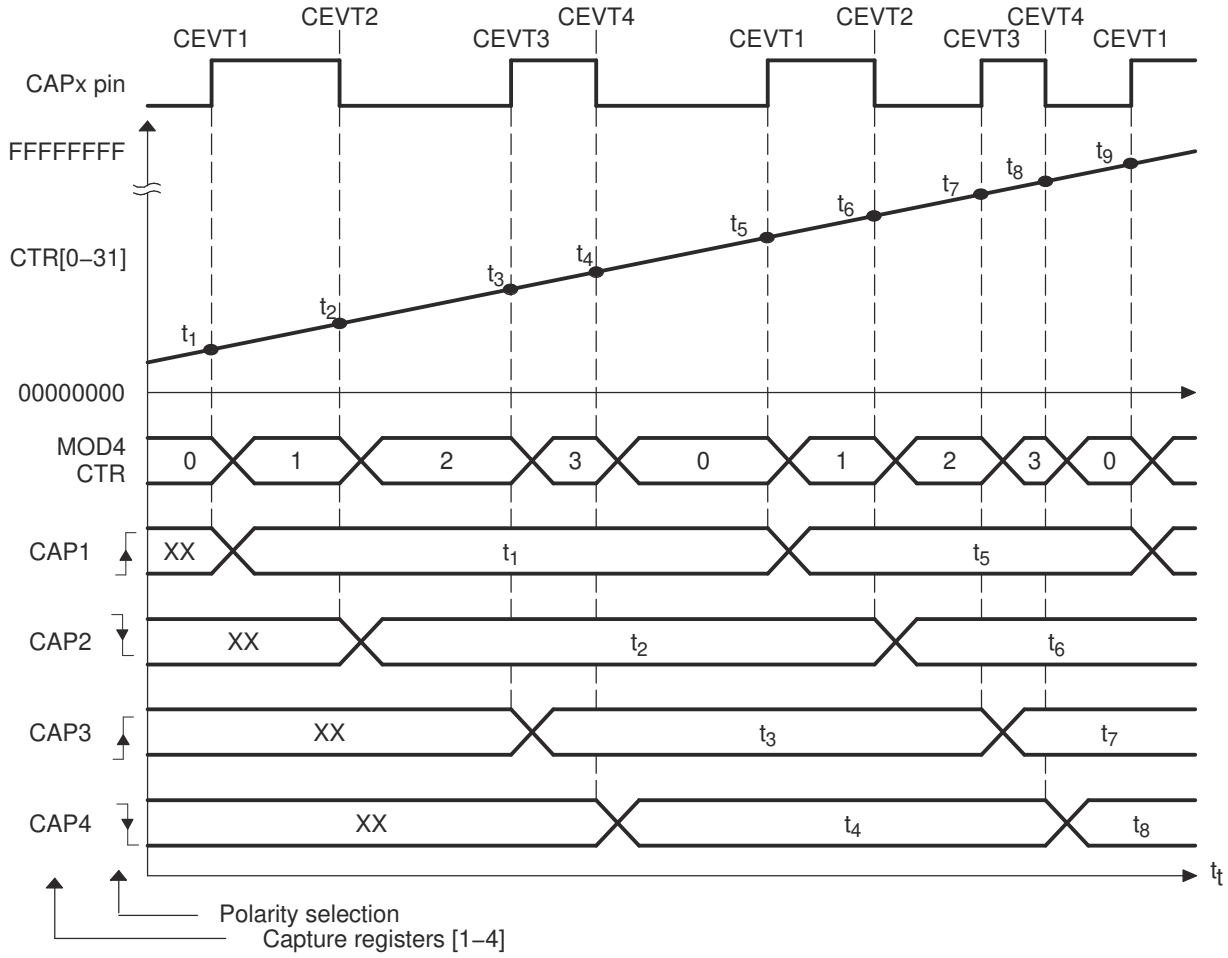

**Figure 16-13. Capture Sequence for Absolute Time-stamp with Rising- and Falling-Edge Detect**

Copyright © 2024 Texas Instruments Incorporated

### 16.6.3 Example 3 - Time Difference (Delta) Operation Rising-Edge Trigger

Figure 16-14 shows how the eCAP module can be used to collect delta timing data from pulse train waveforms. Here Continuous Capture mode (TSCTR counts-up without resetting, and Mod4 counter wraps around) is used. In Delta-time mode, TSCTR is reset back to zero on every valid event. Here capture events are qualified as rising edge only. On an event, TSCTR contents (Time-Stamp) is captured first, and then TSCTR is reset to zero. The Mod4 counter then increments to the next state. If TSCTR reaches FFFFFFFF (maximum value), before the next event, the Mod4 counter wraps around to 00000000 and continues, a CNTOVF (counter overflow) flag is set, and an interrupt (if enabled) occurs. The advantage of Delta-time mode is that the CAPx contents directly give timing data without the need for CPU calculations, that is, Period1 = $T_1$, Period2 = $T_2$, and so on. As shown in Figure 16-14, the CEVT1 event is a good trigger point to read the timing data, $T_1$, $T_2$, $T_3$, $T_4$ are all valid here.

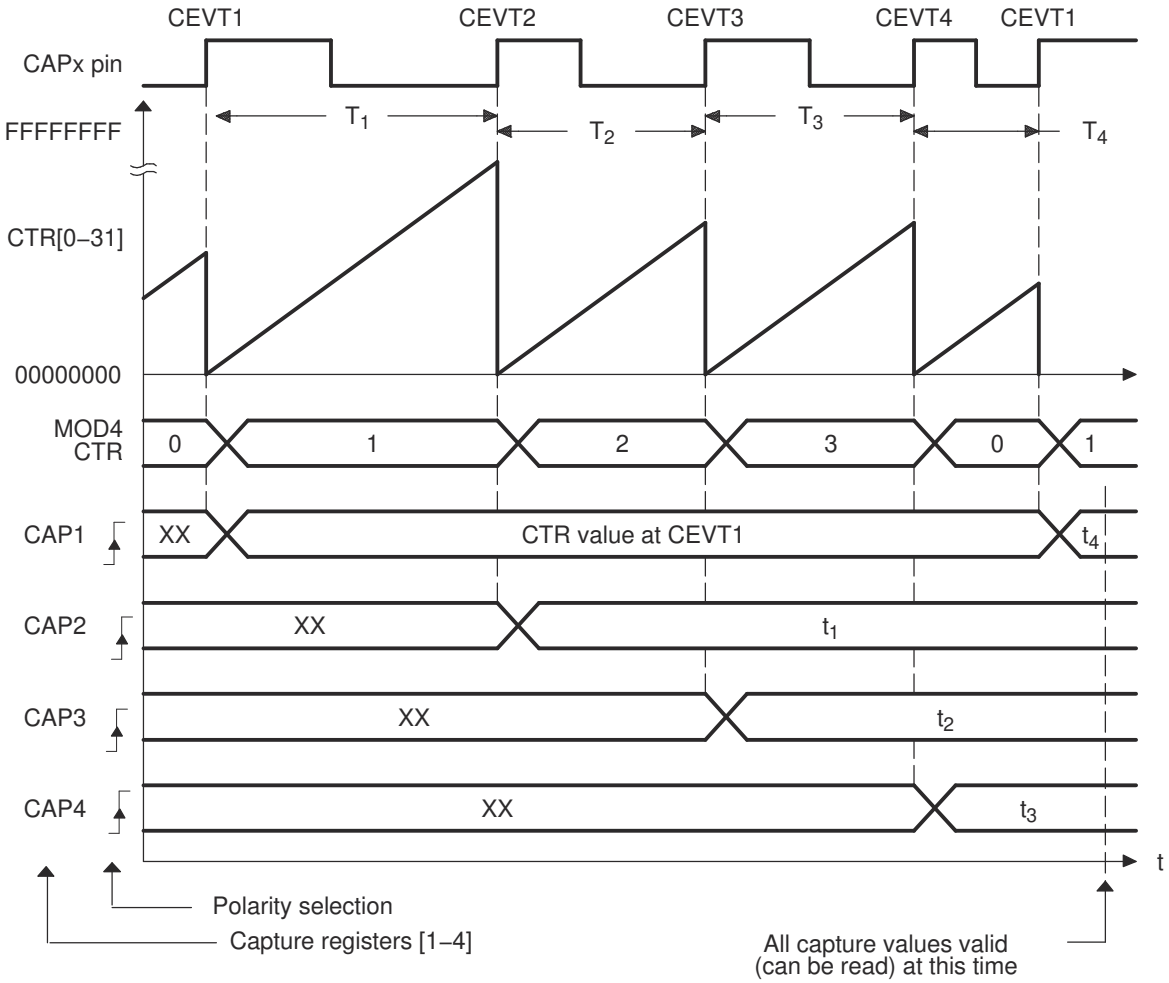

**Figure 16-14. Capture Sequence for Delta Mode Time-stamp and Rising Edge Detect**

Copyright © 2024 Texas Instruments Incorporated

### 16.6.4 Example 4 - Time Difference (Delta) Operation Rising- and Falling-Edge Trigger

In Figure 16-15, the eCAP operating mode is almost the same as in previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information, that is: Period1 = $T_1$+$T_2$, Period2 = $T_3$+$T_4$, and so on. Duty Cycle1 (on-time %) = $T_1$ / Period1 x 100%, Duty Cycle1 (off-time %) = $T_2$ / Period1 x 100%, and so on.

During initialization, write to the active registers for both period and compare. This action automatically copies the init values into the shadow values. For subsequent compare updates during run-time, the shadow registers must be used.

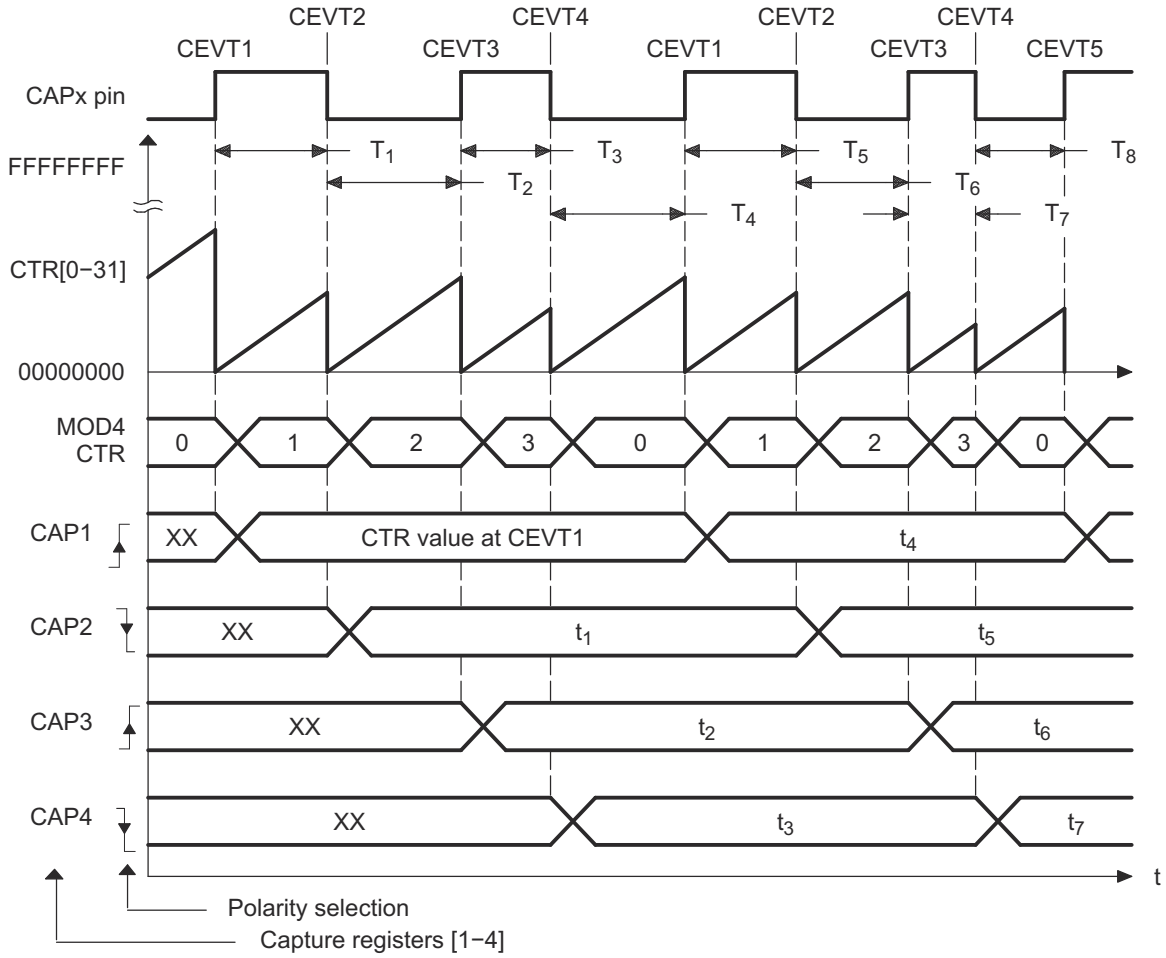

**Figure 16-15. Capture Sequence for Delta Mode Time-stamp with Rising- and Falling-Edge Detect**

## 16.7 Application of the APWM Mode

In this example, the eCAP module is configured to operate as a PWM generator. Here, a very simple single-channel PWM waveform is generated from the APWMx output pin. The PWM polarity is active high, which means that the compare value (CAP2 reg is now a compare register) represents the on-time (high level) of the period. Alternatively, if the APWMPOL bit is configured for active low, then the compare value represents the off-time.

### *16.7.1 Example 1 - Simple PWM Generation (Independent Channels)*

## 16.8 Software

### *16.8.1 ECAP Examples*

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/ecap

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

#### 16.8.1.1 eCAP APWM Example

FILE: ecap_ex1_apwm.c

This program sets up the eCAP module in APWM mode. The PWM waveform will come out on GPIO5. The frequency of PWM is configured to vary between 5Hz and 10Hz using the shadow registers to load the next period/compare values.

#### 16.8.1.2 eCAP Capture PWM Example

FILE: ecap_ex2_capture_pwm.c

This example configures ePWM3A for:
- Up count mode
- Period starts at 500 and goes up to 8000
- Toggle output on PRD

eCAP1 is configured to capture the time between rising and falling edge of the ePWM3A output.

*External Connections*
- eCAP1 is on GPIO16
- ePWM3A is on GPIO4
- Connect GPIO4 to GPIO16.

*Watch Variables*
- *ecap1PassCount* - Successful captures.
- *ecap1IntCount* - Interrupt counts.

#### 16.8.1.3 eCAP APWM Phase-shift Example

FILE: ecap_ex3_apwm_phase_shift.c

This program sets up the eCAP1 and eCAP2 modules in APWM mode to generate the two phase-shifted PWM outputs of same duty and frequency value The frequency, duty and phase values can be programmed of choice by updating the defined macros. By default 10 Khz frequency, 50% duty and 30% phase shift values are used. eCAP2 output leads the eCAP1 output by 30% GPIO5 and GPIO6 are used as eCAP1/2 outputs and can be probed using analyzer/CRO to observe the waveforms.

#### 16.8.1.4 eCAP Software Sync Example

FILE: ecap_ex4_sw_sync.c

This example configures ePWM3A for:
- Up count mode
- Period starts at 500 and goes up to 8000
- Toggle output on PRD

eCAP1, eCAP2 and eCAP3 are configured to capture the time between rising and falling edge of the ePWM3A output.

*External Connections*
- eCAP1, eCAP2, eCAP3 are on GPIO16
- ePWM3A is on GPIO4
- Connect GPIO4 to GPIO16.

Copyright © 2024 Texas Instruments Incorporated

*Watch Variables*

- *ecapPassCount* - Successful captures.
- *ecap3IntCount* - Interrupt counts.

## 16.9 eCAP Registers

This section describes the Enhanced Capture Registers.

### *16.9.1 eCAP Base Addresses*

**Table 16-1. eCAP Base Address Table**

| Device Register | Register Name | Start Address | End Address |
|---|---|---|---|
| ECap1Regs | ECAP_REGS | 0x0000_5000 | 0x0000_501F |
| ECap2Regs | ECAP_REGS | 0x0000_5020 | 0x0000_503F |
| ECap3Regs | ECAP_REGS | 0x0000_5040 | 0x0000_505F |
| ECap4Regs | ECAP_REGS | 0x0000_5060 | 0x0000_507F |
| ECap5Regs | ECAP_REGS | 0x0000_5080 | 0x0000_509F |
| ECap6Regs | ECAP_REGS | 0x0000_50A0 | 0x0000_50BF |

### 16.9.2 ECAP_REGS Registers

Table 16-2 lists the memory-mapped registers for the ECAP_REGS registers. All register offset addresses not listed in Table 16-2 should be considered as reserved locations and the register contents should not be modified.

**Table 16-2. ECAP_REGS Registers**

| Offset | Acronym | Register Name | Write Protection | Section |
|---|---|---|---|---|
| 0h | TSCTR | Time-Stamp Counter | | Go |
| 2h | CTRPHS | Counter Phase Offset Value Register | | Go |
| 4h | CAP1 | Capture 1 Register | | Go |
| 6h | CAP2 | Capture 2 Register | | Go |
| 8h | CAP3 | Capture 3 Register | | Go |
| Ah | CAP4 | Capture 4 Register | | Go |
| 14h | ECCTL1 | Capture Control Register 1 | | Go |
| 15h | ECCTL2 | Capture Control Register 2 | | Go |
| 16h | ECEINT | Capture Interrupt Enable Register | | Go |
| 17h | ECFLG | Capture Interrupt Flag Register | | Go |
| 18h | ECCLR | Capture Interrupt Clear Register | | Go |
| 19h | ECFRC | Capture Interrupt Force Register | | Go |

Complex bit access types are encoded to fit into small table cells. Table 16-3 shows the codes that are used for access types in this section.

**Table 16-3. ECAP_REGS Access Type Codes**

| Access Type | Code | Description |
|---|---|---|
| Read Type | | |
| R | R | Read |
| R-0 | R<br>-0 | Read<br>Returns 0s |
| Write Type | | |
| W | W | Write |
| W1C | W<br>1C | Write<br>1 to clear |
| W1S | W<br>1S | Write<br>1 to set |
| Reset or Default Value | | |
| *-n* | | Value after reset or the default value |
| Register Array Variables | | |
| i,j,k,l,m,n | | When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula. |
| y | | When this variable is used in a register name, an offset, or an address it refers to the value of a register array. |

### 16.9.2.8 ECCTL2 Register (Offset = 15h) [Reset = 0006h]

ECCTL2 is shown in Figure 16-24 and described in Table 16-11.

Return to the Summary Table.

Capture Control Register 2

**Figure 16-24. ECCTL2 Register**

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|---|---|---|---|---|---|---|---|
| RESERVED | | | | | APWMPOL | CAP_APWM | SWSYNC |
| R-0h | | | | | R/W-0h | R/W-0h | R-0/W1S-0h |
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| SYNCO_SEL | | SYNCI_EN | TSCTRSTOP | REARM | STOP_WRAP | | CONT_ONESHT |
| R/W-0h | | R/W-0h | R/W-0h | R-0/W1S-0h | R/W-3h | | R/W-0h |

**Table 16-11. ECCTL2 Register Field Descriptions**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 15-11 | RESERVED | R | 0h | Reserved |
| 10 | APWMPOL | R/W | 0h | APWM output polarity select. This is applicable only in APWM operating mode.<br>Reset type: SYSRSn<br>0h (R/W) = Output is active high (Compare value defines high time)<br>1h (R/W) = Output is active low (Compare value defines low time) |
| 9 | CAP_APWM | R/W | 0h | CAP/APWM operating mode select<br>Reset type: SYSRSn<br>0h (R/W) = ECAP module operates in capture mode. This mode forces the following configuration:<br>- Inhibits TSCTR resets via CTR = PRD event<br>- Inhibits shadow loads on CAP1 and 2 registers<br>- Permits user to enable CAP1-4 register load<br>- CAPx/APWMx pin operates as a capture input<br>1h (R/W) = ECAP module operates in APWM mode. This mode forces the following configuration:<br>- Resets TSCTR on CTR = PRD event (period boundary<br>- Permits shadow loading on CAP1 and 2 registers<br>- Disables loading of time-stamps into CAP1-4 registers<br>- CAPx/APWMx pin operates as a APWM output |
| 8 | SWSYNC | R-0/W1S | 0h | Software-forced Counter (TSCTR) Synchronizer. This provides the user a method to generate a synchronization pulse through software. In APWM mode, the synchronization pulse can also be sourced from the CTR = PRD event.<br>Reset type: SYSRSn<br>0h (R/W) = Writing a zero has no effect. Reading always returns a zero<br>1h (R/W) = Writing a one forces a TSCTR shadow load of current ECAP module and any ECAP modules down-stream providing the SYNCO_SEL bits are 0,0. After writing a 1, this bit returns to a zero. |
| 7-6 | SYNCO_SEL | R/W | 0h | Sync-Out Select<br>Reset type: SYSRSn<br>0h (R/W) = Select sync-in event to be the sync-out signal (pass through)<br>1h (R/W) = Select CTR = PRD event to be the sync-out signal. Note: Selection CTR = PRD is meaningful only in APWM mode<br>2h (R/W) = Disable sync out signal<br>3h (R/W) = Disable sync out signal |

Copyright © 2024 Texas Instruments Incorporated

**Table 16-11. ECCTL2 Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description |
|---|---|---|---|---|
| 5 | SYNCI_EN | R/W | 0h | Counter (TSCTR) Sync-In select mode<br>Reset type: SYSRSn<br>0h (R/W) = Disable sync-in option<br>1h (R/W) = Enable counter (TSCTR) to be loaded from CTRPHS register upon either a SYNCI signal or a S/W force event. |
| 4 | TSCTRSTOP | R/W | 0h | Time Stamp (TSCTR) Counter Stop (freeze) Control<br>Reset type: SYSRSn<br>0h (R/W) = TSCTR stopped<br>1h (R/W) = TSCTR free-running |
| 3 | REARM | R-0/W1S | 0h | Re-Arming Control. Note: The re-arm function is valid in one shot or continuous mode.<br>Reset type: SYSRSn<br>0h (R/W) = Has no effect (reading always returns a 0)<br>1h (R/W) = Arms the one-shot sequence as follows:<br>1) Resets the Mod4 counter to zero<br>2) Unfreezes the Mod4 counter<br>3) Enables capture register loads |
| 2-1 | STOP_WRAP | R/W | 3h | Stop value for one-shot mode. This is the number (between 1-4) of captures allowed to occur before the CAP(1-4) registers are frozen, that is, capture sequence is stopped.<br>Wrap value for continuous mode. This is the number (between 1-4) of the capture register in which the circular buffer wraps around and starts again.<br>Notes: STOP_WRAP is compared to Mod4 counter and, when equal, 2 actions occur:<br>- Mod4 counter is stopped (frozen)<br>- Capture register loads are inhibited<br>In one-shot mode, further interrupt events are blocked until re-armed.<br>Reset type: SYSRSn<br>0h (R/W) = Stop after Capture Event 1 in one-shot mode<br>Wrap after Capture Event 1 in continuous mode.<br>1h (R/W) = Stop after Capture Event 2 in one-shot mode<br>Wrap after Capture Event 2 in continuous mode.<br>2h (R/W) = Stop after Capture Event 3 in one-shot mode<br>Wrap after Capture Event 3 in continuous mode.<br>3h (R/W) = Stop after Capture Event 4 in one-shot mode<br>Wrap after Capture Event 4 in continuous mode. |
| 0 | CONT_ONESHT | R/W | 0h | Continuous or one-shot mode control (applicable only in capture mode)<br>Reset type: SYSRSn<br>0h (R/W) = Operate in continuous mode<br>1h (R/W) = Operate in one-Shot mode |

### 16.9.2.9 ECEINT Register (Offset = 16h) [Reset = 0000h]

ECEINT is shown in Figure 16-25 and described in Table 16-12.

Return to the Summary Table.

The interrupt enable bits (CEVT1, ...) block any of the selected events from generating an interrupt. Events will still be latched into the flag bit (ECFLG register) and can be forced/cleared via the ECFRC/ECCLR registers.
The proper procedure for configuring peripheral modes and interrupts is as follows:
- Disable global interrupts
- Stop eCAP counter
- Disable eCAP interrupts
- Configure peripheral registers
- Clear spurious eCAP interrupt flags
- Enable eCAP interrupts
- Start eCAP counter
- Enable global interrupts

**Figure 16-25. ECEINT Register**

Chapter 17

# Enhanced Quadrature Encoder Pulse (eQEP)

The enhanced Quadrature Encoder Pulse (eQEP) module described here is a Type 0 eQEP. See the *C2000 Real-Time Control Peripheral Reference Guide* for a list of all devices with a module of the same type to determine the differences between types and for a list of device-specific differences within a type.

The enhanced quadrature encoder pulse (eQEP) module is used for direct interface with a linear or rotary incremental encoder to get position, direction, and speed information from a rotating machine for use in a high-performance motion and position-control system.

## 17.1 Introduction

An incremental encoder disk is patterned with a track of slots along the periphery, as shown in Figure 17-1. These slots create an alternating pattern of dark and light lines. The disk count is defined as the number of dark and light line pairs that occur per revolution (lines per revolution). As a rule, a second track is added to generate a signal that occurs once per revolution (index signal: QEPI), which can be used to indicate an absolute position. Encoder manufacturers identify the index pulse using different terms such as index, marker, home position, and zero reference

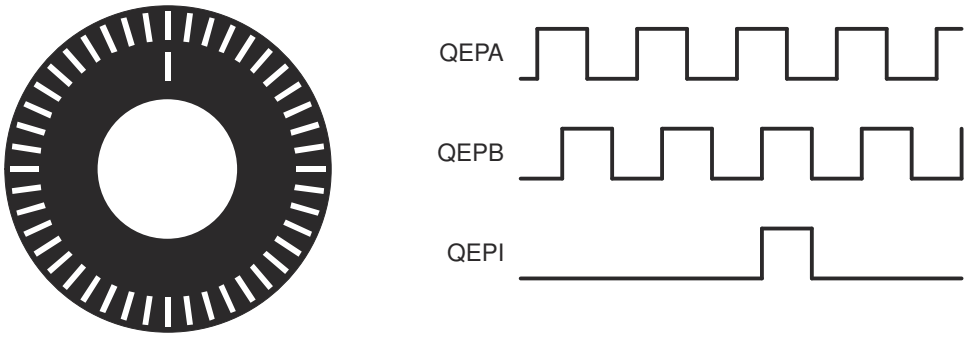

**Figure 17-1. Optical Encoder Disk**

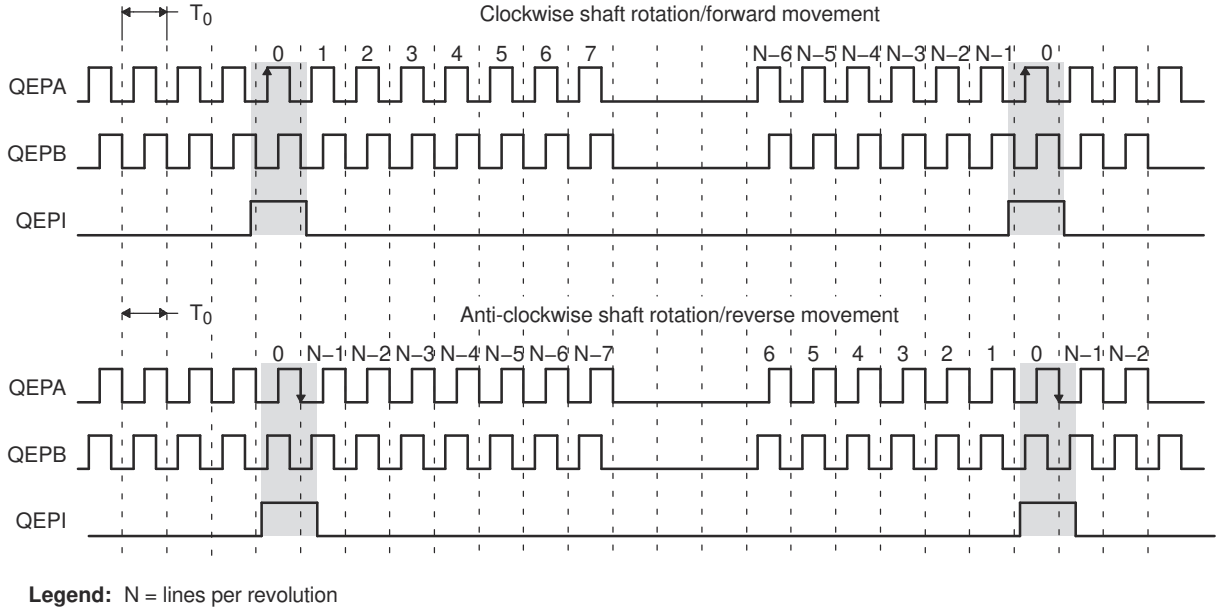
To derive direction information, the lines on the disk are read out by two different photo-elements that "look" at the disk pattern with a mechanical shift of 1/4 the pitch of a line pair between them. This shift is detected with a reticle or mask that restricts the view of the photo-element to the desired part of the disk lines. As the disk rotates, the two photo-elements generate signals that are shifted 90° out of phase from each other. These are commonly called the quadrature QEPA and QEPB signals. The clockwise direction for most encoders is defined as the QEPA channel going positive before the QEPB channel and conversely, as shown in Figure 17-2.



**Legend:** N = lines per revolution

**Figure 17-2. QEP Encoder Output Signal for Forward/Reverse Movement**

The encoder wheel typically makes one revolution for every revolution of the motor, or the wheel can be at a geared rotation ratio with respect to the motor. Therefore, the frequency of the digital signal coming from the QEPA and QEPB outputs varies proportionally with the velocity of the motor. For example, a 2000-line encoder

Copyright © 2024 Texas Instruments Incorporated

directly coupled to a motor running at 5000 revolutions-per-minute (rpm) results in a frequency of 166.6kHz, so by measuring the frequency of either the QEPA or QEPB output, the processor can determine the velocity of the motor.

Quadrature encoders from different manufacturers come with two forms of index pulse (gated index pulse or ungated index pulse) as shown in Figure 17-3. A nonstandard form of index pulse is ungated. In the ungated configuration, the index edges are not necessarily coincident with A and B signals. The gated index pulse is aligned to any of the four quadrature edges and width of the index pulse and can be equal to a quarter, half, or full period of the quadrature signal.

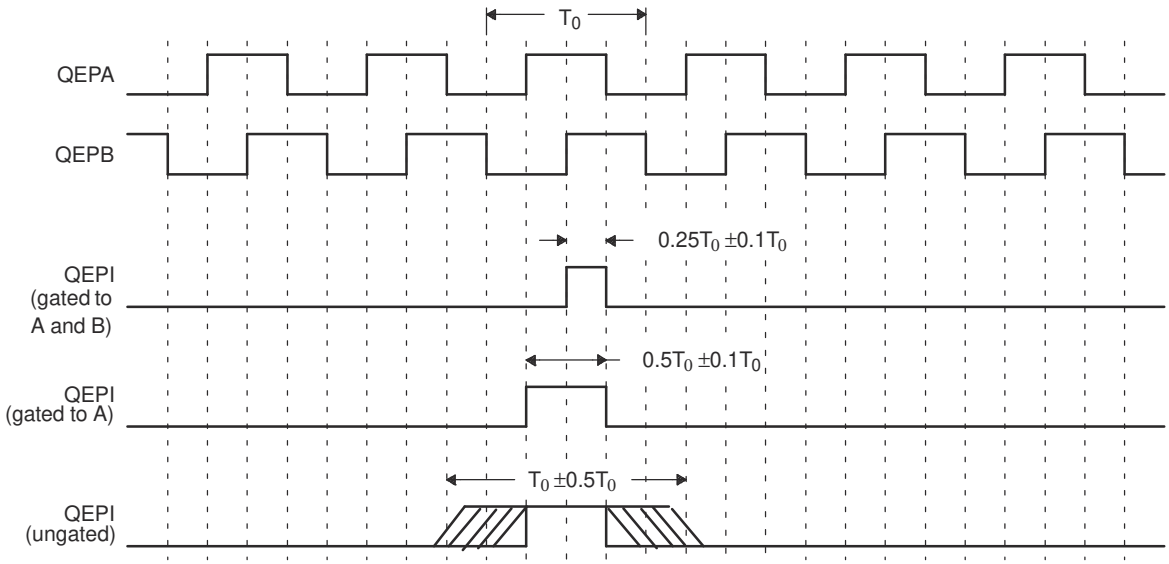


**Figure 17-3. Index Pulse Example**

Some typical applications of shaft encoders include robotics and computer input in the form of a mouse. Inside your mouse you can see where the mouse ball spins a pair of axles (a left/right, and an up/down axle). These axles are connected to optical shaft encoders that effectively tell the computer how fast and in what direction the mouse is moving.

**General Issues:** Estimating velocity from a digital position sensor is a cost-effective strategy in motor control. Two different first order approximations for velocity can be written as:

$$v(k) \approx \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad (24)$$

$$v(k) \approx \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad (25)$$

where:

- v(k) = Velocity at time instant k
- x(k) = Position at time instant k
- x(k-1) = Position at time instant k-1
- T = Fixed unit time or inverse of velocity calculation rate
- ΔX = Incremental position movement in unit time
- t(k) = Time instant "k"
- t(k-1) = Time instant "k-1"
- X = Fixed unit position
- ΔT = Incremental time elapsed for unit position movement

Copyright © 2024 Texas Instruments Incorporated

Equation 24 is the conventional approach to velocity estimation and requires a time base to provide a unit time event for velocity calculation. Unit time is basically the inverse of the velocity calculation rate.

The encoder count (position) is read once during each unit time event. The quantity [x(k) - x(k-1)] is formed by subtracting the previous reading from the current reading. Then the velocity estimate is computed by multiplying by the known constant 1/T (where T is the constant time between unit time events and is known in advance).

Estimation based on Equation 24 has an inherent accuracy limit directly related to the resolution of the position sensor and the unit time period T. For example, consider a 500 line-per-revolution quadrature encoder with a velocity calculation rate of 400Hz. When used for position, the quadrature encoder gives a four-fold increase in resolution; in this case, 2000 counts-per-revolution. The minimum rotation that can be detected is, therefore, 0.0005 revolutions, which gives a velocity resolution of 12rpm when sampled at 400Hz. While this resolution can be satisfactory at moderate or high speeds, for example 1% error at 1200rpm, this resolution clearly proves inadequate at low speeds. In fact, at speeds below 12rpm, the speed estimate is erroneously zero much of the time.

At low speed, Equation 25 provides a more accurate approach. It requires a position sensor that outputs a fixed interval pulse train, such as the aforementioned quadrature encoder. The width of each pulse is defined by motor speed for a given sensor resolution. Equation 25 can be used to calculate motor speed by measuring the elapsed time between successive quadrature pulse edges. However, this method suffers from the opposite limitation, as does Equation 24. A combination of relatively large motor speeds and high sensor resolution makes the time interval ΔT small, and thus more greatly influenced by the timer resolution. This can introduce considerable error into high-speed estimates.

For systems with a large speed range (that is, speed estimation is needed at both low and high speeds), one approach is to use Equation 25 at low speed and have the DSP software switch over to Equation 24 when the motor speed rises above some specified threshold.

## 17.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

For proper operation of the eQEP module, input GPIO pins must be configured using the GPxQSELn registers for synchronous input mode (with or without qualification). The asynchronous mode cannot be used for eQEP input pins. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

## 17.3 Description

This section provides the eQEP inputs, memory map, and functional description.

### *17.3.1 EQEP Inputs*

The eQEP inputs include two pins for quadrature-clock mode or direction-count mode, an index (or 0 marker), and a strobe input. The eQEP module requires that the QEPA, QEPB, and QEPI inputs are synchronized to SYSCLK prior to entering the module. The application code can enable the synchronous GPIO input feature on any eQEP-enabled GPIO pins (see the *General-Purpose Input/Output (GPIO)* chapter for more details).

- **QEPA/XCLK and QEPB/XDIR:** These two pins can be used in quadrature-clock mode or direction-count mode.
  - Quadrature-clock Mode: The eQEP encoders provide two square wave signals (A and B) 90 electrical degrees out of phase. This phase relationship is used to determine the direction of rotation of the input shaft and number of eQEP pulses from the index position to derive the relative position information. For forward or clockwise rotation, QEPA signal leads QEPB signal and conversely. The quadrature decoder uses these two inputs to generate quadrature-clock and direction signals.
  - Direction-count Mode: In direction-count mode, direction and clock signals are provided directly from the external source. Some position encoders have this type of output instead of quadrature output. The QEPA pin provides the clock input and the QEPB pin provides the direction input.
- **QEPI: Index or Zero Marker:** The eQEP encoder uses an index signal to assign an absolute start position from which position information is incrementally encoded using quadrature pulses. This pin is connected to the index output of the eQEP encoder to optionally reset the position counter for each revolution. This signal can be used to initialize or latch the position counter on the occurrence of a desired event on the index pin.
- **QEPS: Strobe Input:** This general-purpose strobe signal can initialize or latch the position counter on the occurrence of a desired event on the strobe pin. This signal is typically connected to a sensor or limit switch to notify that the motor has reached a defined position.

### 17.3.2 Functional Description

The eQEP peripheral contains the following major functional units (as shown in Figure 17-4):

- Programmable input qualification for each pin (part of the GPIO MUX)
- Quadrature decoder unit (QDU)
- Position counter and control unit for position measurement (PCCU)
- Quadrature edge-capture unit for low-speed measurement (QCAP)
- Unit time base for speed/frequency measurement (UTIME)
- Watchdog timer for detecting stalls (QWDOG)

## 17.4 Quadrature Decoder Unit (QDU)

Figure 17-5 shows a functional block diagram of the QDU.

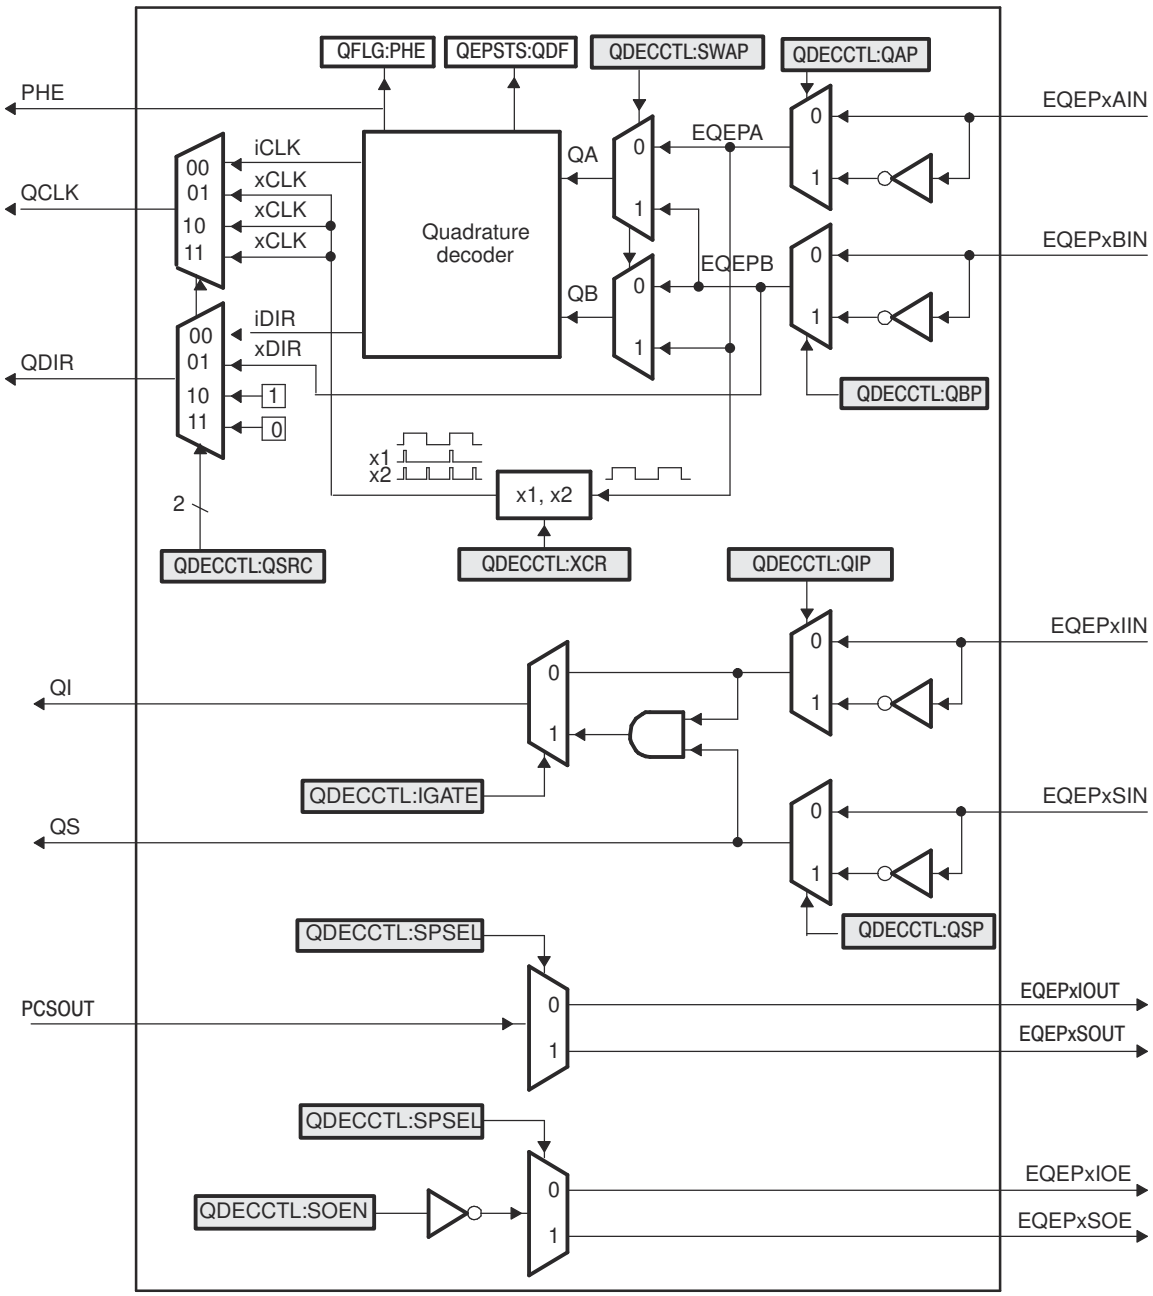

**Figure 17-5. Functional Block Diagram of Decoder Unit**

### *17.4.1 Position Counter Input Modes*

Clock and direction input to the position counter is selected using QDECCTL[QSRC] bits, based on interface input requirement as follows:

- Quadrature-count mode
- Direction-count mode
- UP-count mode
- DOWN-count mode

Copyright © 2024 Texas Instruments Incorporated

#### 17.4.1.1 Quadrature Count Mode

The quadrature decoder generates the direction and clock to the position counter in quadrature count mode.

**Direction Decoding**

The direction decoding logic of the eQEP circuit determines which one of the sequences (QEPA, QEPB) is the leading sequence and accordingly updates the direction information in the QEPSTS[QDF] bit. Table 17-2 and Figure 17-6 show the direction decoding logic in truth table and state machine form. Both edges of the QEPA and QEPB signals are sensed to generate count pulses for the position counter. Therefore, the frequency of the clock generated by the eQEP logic is four times that of each input sequence. Figure 17-7 shows the direction decoding and clock generation from the eQEP input signals.

**Table 17-2. Quadrature Decoder Truth Table**

| Previous Edge | Present Edge | QDIR | QPOSCNT |
|---|---|---|---|
| QA↑ | QB↑ | UP | Increment |
| | QB↓ | DOWN | Decrement |
| | QA↓ | TOGGLE | Increment or Decrement |
| QA↓ | QB↓ | UP | Increment |
| | QB↑ | DOWN | Decrement |
| | QA↑ | TOGGLE | Increment or Decrement |
| QB↑ | QA↑ | DOWN | Decrement |
| | QA↓ | UP | Increment |
| | QB↓ | TOGGLE | Increment or Decrement |
| QB↓ | QA↓ | DOWN | Decrement |
| | QA↑ | UP | Increment |
| | QB↑ | TOGGLE | Increment or Decrement |

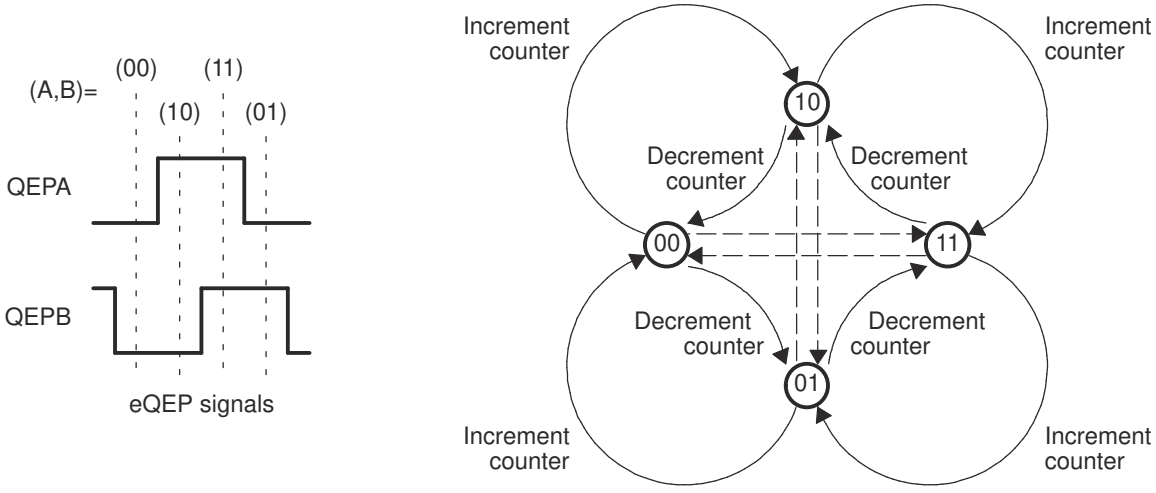

**Figure 17-6. Quadrature Decoder State Machine**

Copyright © 2024 Texas Instruments Incorporated

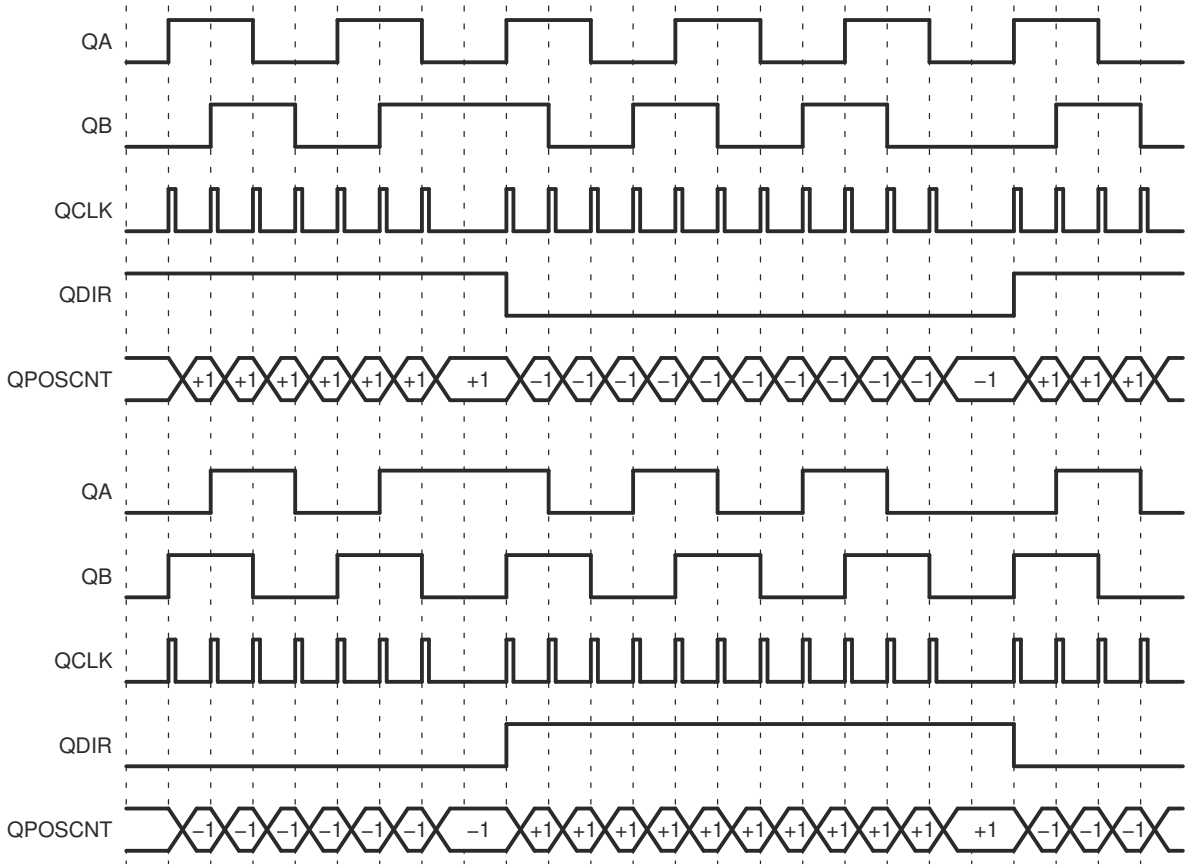

**Figure 17-7. Quadrature-clock and Direction Decoding**

**Phase Error Flag** In normal operating conditions, quadrature inputs QEPA and QEPB is 90 degrees out of phase. The phase error flag (PHE) is set in the QFLG register and the QPOSCNT value can be incorrect and offset by multiples of 1 or 3. That is, when edge transition is detected simultaneously on the QEPA and QEPB signals to optionally generate interrupts. State transitions marked by dashed lines in Figure 17-6 are invalid transitions that generate a phase error.

**Count Multiplication** The eQEP position counter provides 4x times the resolution of an input clock by generating a quadrature-clock (QCLK) on the rising/falling edges of both eQEP input clocks (QEPA and QEPB) as shown in Figure 17-7.

**Reverse Count** In normal quadrature count operation, QEPA input is applied to the QA input of the quadrature decoder and the QEPB input is applied to the QB input of the quadrature decoder. Reverse counting is enabled by setting the SWAP bit in the QDECCTL register. This swaps the input to the quadrature decoder; thereby, reversing the counting direction.

#### 17.4.1.2 Direction-Count Mode

Some position encoders provide direction and clock outputs, instead of quadrature outputs. In such cases, direction-count mode can be used. The QEPA input provides the clock for the position counter and the QEPB input has the direction information. The position counter is incremented on every rising edge of a QEPA input when the direction input is high, and decremented when the direction input is low.

Copyright © 2024 Texas Instruments Incorporated

#### 17.4.1.3 Up-Count Mode

The counter direction signal is hard-wired for up-count and the position counter is used to measure the frequency of the QEPA input. Clearing the QDECCTL[XCR] bit enables clock generation to the position counter on both edges of the QEPA input; thereby, increasing the measurement resolution by a factor of 2x. In up-count mode, we recommend that the application not configure QEPB as a GPIO mux option, or make sure that a signal edge is not generated on the QEPB input.

#### 17.4.1.4 Down-Count Mode

The counter direction signal is hardwired for a down-count and the position counter is used to measure the frequency of the QEPA input. Clearing the QDECCTL[XCR] bit enables clock generation to the position counter on both edges of a QEPA input, thereby increasing the measurement resolution by a factor of 2x. In down-count mode, the application must not configure QEPB as a GPIO mux option or make sure that a signal edge is not generated on the QEPB input.

### *17.4.2 eQEP Input Polarity Selection*

Each eQEP input can be inverted using QDECCTL[8:5] control bits. As an example, setting the QDECCTL[QIP] bit inverts the index input.

### *17.4.3 Position-Compare Sync Output*

The enhanced eQEP peripheral includes a position-compare unit that is used to generate the position-compare sync signal on compare match between the position-counter register (QPOSCNT) and the position- compare register (QPOSCMP). This sync signal can be output using an index pin or strobe pin of the EQEP peripheral.

Setting the QDECCTL[SOEN] bit enables the position-compare sync output and the QDECCTL[SPSEL] bit selects either an eQEP index pin or an eQEP strobe pin.

## 17.5 Position Counter and Control Unit (PCCU)

The position-counter and control unit provides two configuration registers (QEPCTL and QPOSCTL) for setting up position-counter operational modes, position-counter initialization/latch modes and position-compare logic for sync signal generation.

### *17.5.1 Position Counter Operating Modes*

Position-counter data can be captured in different manners. In some systems, the position counter is accumulated continuously for multiple revolutions and the position-counter value provides the position information with respect to the known reference. An example of this is the quadrature encoder mounted on the motor controlling the print head in the printer. Here the position counter is reset by moving the print head to the home position and then the position counter provides absolute position information with respect to home position.

In other systems, the position counter is reset on every revolution using index pulse, and the position counter provides a rotor angle with respect to the index pulse position.

The position counter can be configured to operate in following four modes

- Position-Counter Reset on Index Event
- Position-Counter Reset on Maximum Position
- Position-Counter Reset on the first Index Event
- Position-Counter Reset on Unit Time Out Event (Frequency Measurement)

In all the above operating modes, the position counter is reset to 0 on overflow and to the QPOSMAX register value on underflow. Overflow occurs when the position counter counts up after the QPOSMAX value. Underflow occurs when the position counter counts down after 0. The Interrupt flag is set to indicate overflow/underflow in QFLG register.
